$$\mathcal{A}\begin{pmatrix} u^n_{i,j} \\ \\ \\ v^n_{i+1/2,j+1/2} \end{pmatrix} = \frac{1}{h}\begin{pmatrix} \{a(u^n_{i,j} + S^n_{i,j} - u^n_{i-1,j} - S^n_{i-1,j}) + b(v^n_{i+1/2,j-1/2} \\ \qquad + T^n_{i+1/2,j-1/2} - v^n_{i-1/2,j-1/2} - T^n_{i-1/2,j-1/2})\} \\ \\ \{a(u^n_{i,j+1} + S^n_{i,j+1} - u^n_{i,j} - S^n_{i,j}) + b(v^n_{i+1/2,j+1/2} \\ \qquad + T^n_{i+1/2,j+1/2} - v^n_{i+1/2,j-1/2} - T^n_{i+1/2,j-1/2})\} \end{pmatrix}, \tag{7.5}$$

where $S_{i,j}$ and $T_{i+1/2,j+1/2}$ are the second order corrections associated with the ENO reconstruction:

$$S_{i,j} = \begin{cases} \dfrac{u_{i+1,j} - u_{i,j}}{2} & \text{if } |u_{i+1,j} - u_{i,j}| \le |u_{i,j} - u_{i-1,j}|, \\ \dfrac{u_{i,j} - u_{i-1,j}}{2} & \text{otherwise,} \end{cases}$$

$$T_{i+1/2,j+1/2} = \begin{cases} \dfrac{v_{i+1/2,j+3/2} - v_{i+1/2,j+1/2}}{2} & \text{if } |v_{i+1/2,j+3/2} - v_{i+1/2,j+1/2}| \\ & \le |v_{i+1/2,j+1/2} - v_{i+1/2,j-1/2}|, \\ \dfrac{v_{i+1/2,j+1/2} - v_{i+1/2,j-1/2}}{2} & \text{otherwise.} \end{cases}$$

The expressions for the corrections $S_{i,j}$ and $T_{i+1/2,j+1/2}$ involve discretization stencils which are solution-dependent so that the discretization operator $\mathcal{A}$ corresponding to an ENO scheme has nonconstant coefficients. To gain insight into the behavior of the time integrator, "frozen-stencil" variations will be studied next. For such schemes, one of the two choices for the corrections S and T is systematically used for the entire domain, for all time-iterations, regardless of the computed solution. As a result, the corresponding operator $\mathcal{A}$ is linear with constant coefficients, and a standard Fourier analysis is feasible. It is clear that such frozen-stencil schemes would not converge numerically for a general nonlinear problem, unlike the original ENO scheme; the motivation for studying such an unpractical scheme is given at the end of the section. When the stencil is frozen, the discrete operator $\mathcal{A}$ is constant and (7.4) can be rewritten as

$$U^{n+1} = U^n - \Delta s \mathcal{A}(U^n) + (\Delta s)^2 \beta_2 \beta_0 \mathcal{A}^2(U^n). \tag{7.6}$$

Let G_2 be the amplification matrix associated with the operator $-\Delta s\mathcal{A}$ and I_d the identity matrix; then the amplification matrix $\mathcal{G}$ associated with (7.6) is given by

$$\mathcal{G} = I_d + G_2 + \beta_0 \beta_2 G_2 o G_2. \tag{7.7}$$

Note that μ is an eigenvalue for G_2 if and only if $1+\mu+\beta_0\beta_2\mu^2$ is an eigenvalue for $\mathcal{G}$. So one needs only to compute G_2 and its eigenvalues. Next, we analyze the spectral radius of G_2 for two particular choices of frozen stencils.

1. *Worst case scenario with frozen stencil: Downwind scheme.* Intuitively, the worst case scenario as far as stability is concerned corresponds to the case where the stencil in both directions includes systematically downwind information. With the advecting velocities $a, b > 0$, this corresponds to the choices

$$S_{i,j} = \frac{u_{i+1,j} - u_{i,j}}{2} \quad \text{and} \quad T_{i+1/2,j+1/2} = \frac{v_{i+1/2,j+3/2} - v_{i+1/2,j+1/2}}{2}.$$

Replacing $(u_{i,j}, v_{i+1/2,j+1/2})$ in (7.5) by a single Fourier harmonic leads to the amplification matrix

$$G_2 = \begin{bmatrix} -\lambda_1 I \sin(\phi_{k_1}) & -\lambda_2 I \left(\sin(\frac{\phi_{k_1}+\phi_{k_2}}{2}) + \sin(\frac{\phi_{k_1}-\phi_{k_2}}{2}) \right) \\ -\lambda_1 I \left(\sin(\frac{\phi_{k_1}+\phi_{k_2}}{2}) - \sin(\frac{\phi_{k_1}-\phi_{k_2}}{2}) \right) & -\lambda_2 I \sin(\phi_{k_2}) \end{bmatrix}$$

with $\phi_k = 2\pi k h$ and $I = \sqrt{-1}$. The eigenvalues of G_2 are $\mu_1 = 0$ and $\mu_2 = -(\lambda_1 \sin(\phi_{k_1}) + \lambda_2 \sin(\phi_{k_2}))I = -\Phi I$. Hence, the spectral radius of the matrix $\mathcal{G}$, given in (7.7), is less than or equal to one if and only if

$$|1 - \Phi I - \beta_0 \beta_2 \Phi^2| \le 1 \tag{7.8}$$

$$\iff \sqrt{1+\left(\beta_0\beta_2\Phi^2\right)^2-(2\beta_0\beta_2-1)\Phi^2}\le 1 \tag{7.9}$$

$$\implies (2\beta_0\beta_2-1)>0. \tag{7.10}$$

Taking into account that $|\phi|\le\lambda_1+\lambda_2$, if this last inequality is verified, then the stability condition for this case is given by the following CFL condition:

$$\lambda_1+\lambda_2\le\frac{\sqrt{2\beta_0\beta_2-1}}{\beta_0\beta_2}. \tag{7.11}$$

2. *Best case scenario with frozen stencil: Upwind scheme.*

$$S_{i,j}=\frac{u_{i,j}-u_{i-1,j}}{2}\quad\text{and}\quad T_{i+1/2,j+1/2}=\frac{v_{i+1/2,j+1/2}-v_{i+1/2,j-1/2}}{2}.$$

This case corresponds to a standard second order upwind scheme. A sufficient condition for stability is that each substep satisfies a classical CFL condition:

$$\begin{aligned}|\beta_0|(\lambda_1+\lambda_2)&\le 1,\\ (|\beta_1\alpha_2|+|\beta_2|)(\lambda_1+\lambda_2)&\le 1.\end{aligned} \tag{7.12}$$

A detailed analysis would lead to similar CFL conditions with less restrictive constants; however, the exact expressions will not be needed here. An interesting observation at this stage is that, as to be expected, the stability condition for the downwind scheme (7.10) and the CFL stability conditions (7.11)–(7.12) show opposite trends. For instance, one way to stabilize the downwind scheme is to pick β_0,β_2 large, which implies taking an intermediate time-step which is actually larger than the final time-step. Such a choice, however, would lead to a very severe final time-step restriction because of the CFL conditions, in particular those of the upwind scheme.

The motivation to study the frozen-stencil schemes is to get some insight on how to achieve a steady state as efficiently as possible. The heuristic in selecting coefficients for an efficient Runge–Kutta integrator is that a scheme that satisfies all the stability constraints from the two frozen-stencil limit schemes (in addition to at least the first order accuracy conditions (7.1)–(7.2)) must have excellent damping properties as it stabilizes even the particularly unstable downwind scheme. Therefore, it is expected that such an integrator would lead to an efficient pseudotime marching scheme to a steady state by damping numerically the oscillations faster than a time-accurate scheme would.

A first observation is that the condition in (7.10) for stability of the downwind frozen-stencil scheme is incompatible with the condition in (7.3) for second order accuracy in pseudotime. It is also trivial to verify that, as one should expect, the standard one-step forward Euler scheme (with $\beta_0=0$) cannot possibly satisfy the frozen-stencil stability condition for the downwind scheme.

Good damping per time-step is expected to be achieved by selecting a time integrator with coefficients that minimize the spectral radius in (7.9) (with a similar expression for the upwind scheme). One could attempt to find an optimal set of coefficients to minimize the spectral radii in a systematic search. However, such a procedure would be costly and probably not very useful because the results might not

be relevant to the actual ENO scheme with variable stencil as used for the nonlinear cell-problem. Instead, we limited the search to sampling a small number of combinations for the time-integrator coefficients and compared their performance (in conjunction with the second order variable-stencil ENO scheme) in numerical experiments for the actual cell-problem. Among the combinations we tested were the standard explicit Runge–Kutta integrators of order one and two mentioned earlier—that they were outperformed is consistent with the heuristic analysis above.

The best performance observed in our limited search was achieved by the following combination, whose coefficients satisfy all the frozen-stencil stability constraints:

$$\alpha_1 = \frac{1}{3}, \qquad \alpha_2 = \frac{2}{3}, \qquad \beta_0 = \frac{3}{2}, \qquad \beta_1 = -\frac{1}{2}, \qquad \beta_2 = \frac{1}{2}$$

with the following CFL condition:

$$\lambda_1 + \lambda_2 \leq \frac{2}{3}. \tag{7.13}$$

Even though this linearly stable scheme (in the frozen-stencil sense) is only first order accurate with respect to the pseudotime variable, numerical experiments such as the one reported in Figure 7.1 demonstrate that it significantly improves the convergence to a steady state compared to the second order time integrator. In that example, the eigenvalue oscillates rapidly in the pseudotime with the oscillation amplitude decaying to zero when the pseudotime grows, as predicted theoretically. The oscillations are rapidly damped with the first order scheme, (a), and with the hybrid second order in space and first order in time scheme, but are much less so with the overall second order scheme, (c). Because we are not interested in an accurate prediction of the time evolution but only in the steady state, the new scheme has the advantage of converging to a steady state almost as efficiently as the first order scheme, while at the same time achieving second order accuracy in space (at least in cases with smooth eigenfunctions) as will be demonstrated in the next section by analyzing the convergence of the results under systematic mesh refinement.

8. Validation.

8.1. Small-scale shears. To validate the method, we first consider the response of the flame to velocity fields generated with the Childress–Soward flow (see the stream function in (2.3)) with $\delta = 1$. Then, the velocity field is given by

$$v_1(x,y) = v_2(x,y) = \frac{\lambda}{\sqrt{2}} \left(-\sin(2\pi x)\cos(2\pi y) + \cos(2\pi x)\sin(2\pi y) \right).$$

This flow field actually represents a simple sine shear titled at 45 degrees. The problem can be reduced to a one-dimensional problem by aligning the coordinate system with the shearing direction, and the results in [5] and [17] can be applied directly to provide us with reference data. (Here, the stream function is scaled so that λ represents the maximum shear intensity.) We solve the problem numerically in the original coordinate system as a two-dimensional case using the gradient-preserving scheme. The combustion speed enhancement is then compared with the reference value.

The numerical procedure consists of minimizing $F(r)$ in (2.1) as a function of r, which requires solving the cell-problem corresponding to each trial value for r. The minimization is performed using a standard routine [3] to a specified tolerance; all our numerical experiments showed that there were no numerical difficulties associated

with the minimization routine itself, the key numerical issue being able to provide a sufficiently accurate value for the effective Hamiltonian $H(r)$.

The test cases reported below correspond to the front angle $\theta = \pi/4$ (i.e., the front normal is aligned with the shearing direction) and no mean flow $\overline{\lambda} = \overline{\theta} = 0$. With those parameters, it is particularly straightforward to predict analytically the burning speed enhancement as those set-ups are known theoretically to achieve the upper bound $F_e = \lambda$. Table 8.1 reports the computed values of F_e for three values of λ: small turbulence intensity $\lambda = 0.4$, medium intensity $\lambda = 1.6$, and large turbulence intensity $\lambda = 6.4$. (Recall that in all the test cases here, velocities are normalized with the laminar burning speed $S_L = 1$.) Figure 8.1 shows sequences of the corresponding wrinkled fronts: they represent a flame propagating from the right upper corner towards the left lower corner of the domain. Both the order 1 and the order 2 methods are seen in Table 8.1 to converge under mesh refinement, with the expected order of convergence: in particular, the gain in accuracy going from a first order to a second order method is significant at low resolutions—for practical purposes, it is possible, with the hybrid second order scheme, to predict F_e within one or two percent with the very coarse resolution of 16×16 ! Notice that the eigenfunctions computed here are not smooth (for instance, see the cusps in the flame fronts in Figure 8.1, corresponding to shocks in the gradients). As a consequence, one would expect a detailed numerical convergence study of the eigenfunction to show a reduction to first order convergence, even with the second order method. However, we are interested here only in the enhanced speed, obtained by processing the effective Hamiltonian, which itself is obtained by integration of the square of the norm of the eigenfunction gradient over the domain: this processing is sufficient to recover second order accuracy (see the last column of Table 8.1) even if the eigenfunction is locally first order accurate in the vicinity of the cusps.

8.2. Other flows. In the test cases with $\delta = 1$ just described, the small-scale flow is a simple shear aligned with the normal to the large-scale front so that the wrinkled flame front has a very simple topology, traveling without changing shape from the upper right corner into the unburnt mixture in the lower left corner, at a constant velocity. Such a simple flame pattern could have been computed using explicit formulas [5] and it was considered here only for the sake of validation. However, the gradient-preserving scheme is very robust and is designed to handle much more complex flame fronts behaviors. For instance, selecting $\delta < 1$ in (2.3) leads to more interesting turbulent-like flows. For $\delta = 0$ the flow corresponds to an array of eddies and for $\delta = 0.5$ we have a combination of eddies and shears; see Figure 2.1. Results for those two cases are reported in Tables 8.2 and 8.3 as well as in Figures 8.2 and

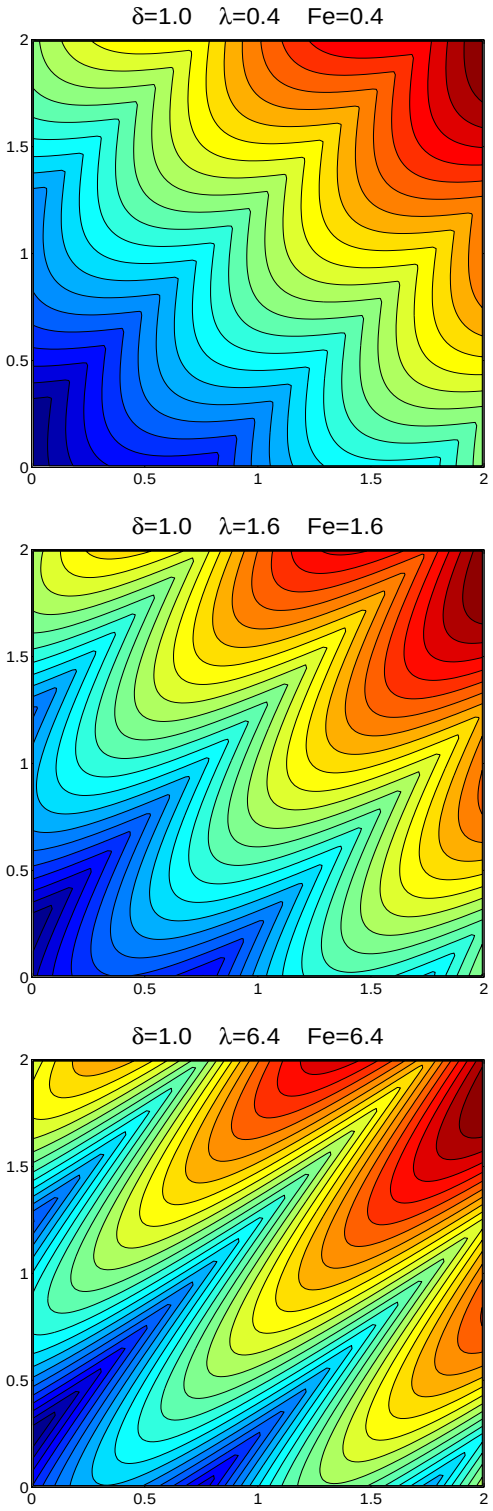

FIG. 8.1. *Instantaneous flame fronts with* $\delta = 1$*; same data as in Table* 8.1. *(Hybrid) second order method, resolution* 64×64 *(an array of* 2×2 *cells is shown).*

8.3. Again, the data are $\theta = \pi/4$, $\overline{\lambda} = \overline{\theta} = 0$. The results of the mesh refinement reported in the two tables for the intermediate turbulence intensity $\lambda = 1.6$ confirm the predicted order of accuracy and the significant gain in accuracy with the second order method. When $\delta \neq 1$, there are no analytical predictions available for F_e: instead, a reference value is obtained here by extrapolation of the data with the second order method—this should not affect the error analysis, except maybe for the estimation of the error on the finest grid. At low turbulence intensity $\lambda = 0.4$, the flame patterns at the top of Figures 8.2 and 8.3 appear to be very similar to the simple shear case from Figure 8.1. (Notice, however, that F_e decreases with δ.) At larger intensities, however, in particular when $\lambda = 6.4$, the flame patterns become much more complex, some portions of the front overlap other portions, and there are even topological changes associated with pockets of unburnt gas lagging behind the leading front. Many more computations of this type can be found in [14, 2], along with a more detailed analysis of the parameterization of F_e as a function of the characteristics of the flow.

9. Conclusion. A numerical method has been introduced to solve the nonlinear eigenvalue cell-problem arising in the homogenization theory of turbulent premixed flame fronts [17]. The scheme allows for the efficient second order accurate computation of both the effective Hamiltonian (i.e., the eigenvalue) and the eigenfunction (related to successive realizations of the wrinkled flame front). The eigenvalue problem is solved using pseudotime marching to the steady state of a system of conservation laws for the eigenfunction gradient. Theoretical arguments are presented regarding the importance of satisfying the constraint that the steady-state vector solution be effectively the gradient of a scalar function. Exploiting the symmetry of the problem, a novel staggered grid formulation is shown to automatically satisfy the gradient-structure constraint in some appropriate discrete sense if the initial data did. Numerical experiments with variations of the scheme confirm the theoretical predictions by demonstrating that (i) the gradient-preserving property is necessary to guarantee convergence to steady state (Figure 6.1), (ii) time integrators with good damping properties can be achieved by studying their behavior for frozen-stencil variations of the scheme (Figure 7.1), and (iii) the scheme does achieve the predicted second order accuracy, with a significant gain compared to the first order scheme at low resolution (Tables 8.1, 8.2, and 8.3).

The idea of converting a multidimensional Hamilton–Jacobi equation into a sys-

tem of conservation laws for the gradient of the solution w was also used by Jin and Xin [9]. Their scheme also enforces to some extent the gradient condition in a formulation that has many advantages for general cases. The scheme presented here is different in several respects: it exploits the specific structure of the Hamiltonian to enforce the gradient condition exactly, not in a relaxation sense as in [9]; the two components of the discrete vector solution are represented on staggered grids, whereas in [9] they are collocated, only w is staggered; the scheme presented here is geared toward the efficient computation of a steady-state solution for the effective Hamiltonian, a quantity that involves only $\mathbf{D}w$ and not w itself.

The scheme presented here was used successfully in [14, 2] to study systematically the parameterization of the turbulent enhancement of the flame speed for a variety of small-scale flows. The numerical data were used to identify two distinct scalings regimes, similar to those observed in experiments with real flames. The transition between the two regimes was shown to depend essentially on a nondimensional "flame residence time" that relates an intrinsic flame response time to a time scale related to the flame passage-time through a periodic cell; this qualitative analysis inspired by the numerical data was explained theoretically via a formal asymptotic analysis.

Ultimately, one objective is to use the asymptotic speed enhancement as a basis for a subgrid-scale model in large eddy simulations of turbulent flames, where the effect of the unresolved turbulent flow scales must be accounted for as a modelled enhanced burning speed. The feasibility of such a strategy is demonstrated in [15] for an idealized case: the scheme introduced in this paper is used to generate a complete database or "flamelet library" which can then be used repeatedly as an input to a level-set formulation for the flame front at large scales. Results of such computation are shown in [15] to be in excellent agreement with detailed direct simulation predictions for the wrinkled flames, with the large eddy simulations requiring only a small fraction of the computational cost of the detailed simulations.

Another potential application for the gradient-preserving scheme described in this paper would be to solve the quadratic nonlinear eigenvalue cell-problem arising in the homogenization of the stationary Schrödinger equation [7]. The method described in this paper exploits the specific structure of the quadratic flux in the cell-problem that splits very naturally into two distinct one-dimensional Riemann problems. One natural extension of the present scheme is to consider cases where such splitting is not possible.

CONSTRUCTION OF SMOOTH REFINABLE FUNCTION VECTORS BY CASCADE ALGORITHMS*

DI-RONG CHEN†

Abstract. This paper establishes an equivalent relation between the convergence of a cascade algorithm in Sobolev space and the convergence of an associated cascade algorithm in L_p space. It reduces the convergence in Sobolev space to that in L_p space. On the other hand, by the equivalence we present an algorithm for construction of refinement masks which generate convergent cascade algorithms in Sobolev space. It is very easy to implement the algorithm. Examples are given to illustrate the theory.

Key words. refinable function vector, Sobolev space, cascade algorithm, factorization of mask, joint spectral radius

1. Introduction.

Cascade algorithms give an iterative method for the generation of refinable function vectors which are the main building blocks for the construction of multiwavelets. The main purpose of this paper is to present an algorithm for constructing cascade algorithms that converge in Sobolev space.

Suppose that $a = (a(\alpha))_{\alpha\in\mathbb{Z}}$ is a sequence of $r \times r$ matrices and satisfies, for a positive integer $N, a(\alpha) = 0\ \forall\alpha \notin \{0, 1, \ldots, N\}$. A vector $\Phi = (\phi_1, \ldots, \phi_r)^T$ of compactly supported distributions is said to be *refinable associated with* a if it satisfies the following refinement equation:

$$\Phi = \sum_{\alpha=0}^{N} a(\alpha)\Phi(2\cdot -\alpha). \tag{1.1}$$

The sequence a is called the *refinement mask*. In terms of Fourier transform, we can rewrite (1.1) as

$$\widehat{\Phi}(2\omega) = H_a(\omega)\widehat{\Phi}(\omega), \qquad \omega \in \mathbb{R}, \tag{1.2}$$

where $H_a(\omega) := 1/2\sum_{\alpha=0}^{N} a(\alpha)e^{-i\alpha\omega}$.

It is known that if the matrix $H_a(0)$ has 1 as a simple eigenvalue and, for any positive integer $\beta, 2^\beta$ is not an eigenvalue of $H_a(0)$, then there exists a unique vector Φ of compactly supported distributions such that Φ satisfies (1.1) and the first nonzero component of $\widehat{\Phi}(0)$ is 1. This vector is referred as to the *normalized solution* of the refinement equation with mask a and denoted by Φ_a.

Let $W_p(\mathbb{R})$ denote $L_p(\mathbb{R}^s)$ for $1 \le p < \infty$ and the space $C_u(\mathbb{R})$ of uniformly continuous and bounded function on $\mathbb{R}$ for $p = \infty$. The Sobolev space $W_p^s(\mathbb{R})$ is defined as

$$W_p^s(\mathbb{R}) := \{\, f :\ D^\mu f \in W_p(\mathbb{R}),\ 0 \le \mu \le s\},$$

where $D^\mu = \frac{d^\mu}{dx^\mu}$ is the differential operator. Throughout, s is a nonnegative integer. The space $W_p^s(\mathbb{R})$ is a Banach space with the norm

$$||f||_{W_p^s(\mathbb{R})} := \max\{||D^\mu f||_p : 0 \le \mu \le s\}.$$

Let $(W_p^s(\mathbb{R}))^r$ be the Banach space consisting of all vectors $f := (f_1, \dots, f_r)^T$ with $f_j \in W_p^s(\mathbb{R})$ equipped with norm

$$\|f\|_{(W_p(\mathbb{R}))^r} := \max\{||f_j||_{W_p^s(\mathbb{R})} : 1 \le j \le r\}.$$

For a vector F_0 of compactly supported functions, we construct a sequence $(F_k)_{k\ge 0}$ by iteration $F_k = Q_a F_{k-1}, k = 1, 2, \dots$, where Q_a is the *cascade operator* associated with a defined as

$$Q_a F = \sum_{\alpha=0}^{N} a(\alpha) F(M \cdot -\alpha). \tag{1.3}$$

We say that the cascade algorithm associated with mask a (or generated by Q_a) converges on F_0 in $(W_p^s(\mathbb{R}))^r$ norm if

$$\lim_{n\to\infty} \|Q_a^n F_0 - \Phi_a\|_{(W_p^s(\mathbb{R}))^r} = 0. \tag{1.4}$$

Let $\mathbb{C}^{r\times m}$ be the space of $r \times m$ matrices with entries being complex numbers. Denote by $(\ell(\mathbb{Z}))^{r\times m}$ the set of all sequences $\lambda = (\lambda(\alpha))_{\alpha\in\mathbb{Z}}$ with $\lambda(\alpha) \in \mathbb{C}^{r\times m}$. Furthermore, let $(\ell_0(\mathbb{Z}))^{r\times m}$ denote the set of all sequences in $(\ell(\mathbb{Z}))^{r\times m}$ with finite supports. The *subdivision operator* S_a, associated with a mask $a \in (\ell_0(\mathbb{Z}))^{r\times r}$, is an operator defined on the space $(\ell(\mathbb{Z}^s))^{m\times r}$ as follows:

$$S_a c(\alpha) := \sum_{\beta\in\mathbb{Z}^s} c(\beta) a(\alpha - 2\beta), \qquad \alpha \in \mathbb{Z}^s. \tag{1.5}$$

For convenience, let

$$a_n = S_a^{n-1} a, \qquad n = 1, 2, \dots .$$

The iteration Q_a^n is related with S_a by the equality

$$Q_a^n F = \sum_{\alpha\in\mathbb{Z}} a_n(\alpha) F(2^n \cdot -\alpha).$$

The convergence of cascade algorithms is related intimately with the properties of refinable function vectors. There has been a comprehensive study of cascade algorithms. When $s = 0$ and $r = 1$, see [1] for $p = \infty$, [11] for $1 \le p \le \infty$ and [10] for $1 \le p \le \infty$, and the dilation matrix being an arbitrary isotropic matrix. For general r, see [14]. When $s > 0$, $p = 2$, and $r = 1$, see [9] and [12]. We studied this problem in the general setting in [3]. In [4], the effect of perturbation of refinement masks to the convergence was discussed.

While the papers mentioned above focused on the convergence in a fixed space, we clarify in this paper the relationship between the convergence of a cascade algorithm in Sobolev space and that of an associated cascade algorithm in L_p space. To this end we make use of the methods for factoring masks in [16] and [18]. An equivalence between the convergence in different spaces is established. By that equivalence we

present an algorithm for construction of masks which generate a convergent cascade algorithm in Sobolev space. It is somewhat like the construction of [18], of refinable function vectors with arbitrary approximation order and smoothness order. Roughly speaking, based on a convergent cascade algorithm in $(W_p^s(\mathbb{R}))^r$, we can construct a convergent cascade algorithm in $(W_p^{s+1}(\mathbb{R}))^r$ by one step of two scale similarity transform.

Although it is accepted that there is a direct relation between the smoothness of refinable function vectors and the factorization of masks, there has so far not been any equivalence without the stability condition. The present paper is related to [6], [15], and [17]. In [6] it was shown that the factorization of masks can lead to decay of the Fourier transform of the refinable function vectors. For a refinable function vector, which is a limit of a convergent cascade algorithm, its smoothness was characterized in terms of the factorization of mask [15, Theorem 4.2]. Under the stability condition, a relation between the spectral radius concerning the factorized masks and the smoothness of refinable function vectors is established in [15] by an approach different from ours. A specific factorization technique based on superfunction theory was presented in [17]. The importance of that technique for the study of the smoothness lies in determining *separately* the smoothness of each component of the refinable vectors. However, our aim is to provide a method for constructing smooth refinable function vectors by use of the factorization technique of masks in [16] and [18].

Here is a brief outline of the paper. In section 2, a formula for spectral radius of subdivision operators concerning factorization of masks is established. Moreover, we connect the formula with the notion of p-joint spectral radii. In section 3, an invariant subspace associated with p-joint spectral radius is characterized explicitly in terms of the factorization of the mask. The main results of the paper are presented in section 4. In this section we derive the equivalence between the convergence of a cascade algorithm Q_a in Sobolev norm and the convergence of another cascade algorithm generated by Q_{a_0} in L_p, where a_0 is determined by a. As a corollary, we give an algorithm for construction of masks which generate convergent cascade algorithms in Sobolev space. In section 5, we illustrate our theory by two examples.

2. Factorization of masks and spectral radii of subdivision operators. In this section we first give a formula, in terms of some limits, for spectral radii of subdivision operators concerning the factorization of masks. Then a relation between those limits and joint spectral radii is established.

Assume now that $\mathbb{C}^{r\times m}$ is equipped with a norm $||\cdot||$ on $\mathbb{C}^{r\times m}$. Here and elsewhere, all norms on a finite dimension space are denoted by $\|\cdot\|$. Let $(\ell_p(\mathbb{Z}))^{r\times m}$ be the normed linear space of sequences $\lambda = (\lambda(\alpha))_{\alpha\in\mathbb{Z}}, \lambda(\alpha) \in \mathbb{C}^{r\times m}$, such that $||\lambda||_p < \infty$, where

$$||\lambda||_p := \left(\sum_{\alpha\in\mathbb{Z}} \|\lambda(\alpha)\|^p\right)^{1/p}, \qquad 1 \le p < \infty,$$

and $\|\lambda\|_\infty := \sup_{\alpha\in\mathbb{Z}} ||\lambda(\alpha)||$. It is easily seen that, for any mask $b \in (\ell_0(\mathbb{Z}))^{r\times r}$, the subdivision operator S_b is a bounded operator on $(\ell_p(\mathbb{Z}))^{m\times r}$. Clearly, the set $(\ell_p(\mathbb{Z}))^{r\times m}$ is independent of the choice of norm $||\cdot||$ on $\mathbb{C}^{r\times m}$, and any two norms on $\mathbb{C}^{r\times m}$ induce two equivalent norms on $(\ell_p(\mathbb{Z}))^{r\times m}$. It is easily seen that, for any $b \in (\ell_0(\mathbb{Z}))^{r\times r}, S_b$ is a bounded operator on $(\ell_p(\mathbb{Z}))^{m\times r}$.

The convolution of $c * d = (c * d(\alpha))_{\alpha\in\mathbb{Z}} \in (\ell(\mathbb{Z}))^{l\times k}$, for two sequences $c \in$

$(\ell(\mathbb{Z}))^{l\times m}$ and $d\in(\ell(\mathbb{Z}))^{m\times k}$, is defined by

$$c*d(\alpha)=\sum_{\beta\in\mathbb{Z}}c(\alpha-\beta)d(\beta)\qquad\forall\alpha\in\mathbb{Z},$$

provided that the series converges for any entry and any $\alpha\in\mathbb{Z}$.

If $K\subseteq\mathbb{Z}$ is a finite set, we denote $(\ell(K))^{r\times m}$ the subspace consisting of all $c\in(\ell_0(\mathbb{Z}))^{r\times m}$ with supp$c\subseteq K$. Let

$$K_N:=\begin{cases}\{0,1\} & \text{for } N=1,\\ \{0,1,\dots,N-1\} & \text{for } N\geq 2.\end{cases}\tag{2.1}$$

The following interesting result concerning the spectral radius of S_b was established in [5].

THEOREM 2.1 (see [5]). *Let $b\in(\ell_0(\mathbb{Z}))^{r\times r}$. Suppose that $c\in(\ell_p(\mathbb{Z}))^{r\times r}$ satisfies*

$$c*t\neq 0\qquad\forall t\in(\ell(K_N))^{r\times 1}\backslash\{0\}.\tag{2.2}$$

We have

$$\rho_p(S_b)=\lim_{n\to\infty}||S_b^nc||_p^{\frac{1}{n}}.$$

We will extend the above result to the case when the mask a is factorable. This means that H_a satisfies

$$H_aC=C(2\cdot)H_b\tag{2.3}$$

for some mask $b\in(\ell_0(\mathbb{Z}))^{r\times r}$ and a 2π periodic $r\times r$ matrix $C(\omega)$.

For $\eta\in(\ell(\mathbb{Z}))^{m\times n}$, the Fourier transform $\widehat{\eta}$ of η is defined at least formally by

$$\widehat{\eta}(\omega)=\sum_{\alpha\in\mathbb{Z}}\eta(\alpha)e^{-i\alpha\omega}.$$

If there is $c\in(\ell(\mathbb{Z}))^{r\times r}$ such that $\widehat{c}=C$, then (2.3) is equivalent to

$$a*c=S_bc.\tag{2.4}$$

Theorem 2.1 is generalized as follows, which is the main result of this section and will be needed in section 4.

THEOREM 2.2. *Suppose that $a,b\in(\ell_0(\mathbb{Z}))^{r\times r}$ and $c\in(\ell_p(\mathbb{Z}))^{r\times r}$ satisfy* (2.4). *If c satisfies conditions of Theorem* 2.1*, then*

$$\rho_p(S_b)=\lim_{n\to\infty}||a_n*c||_p^{\frac{1}{n}}.$$

Proof. We claim that, for any positive integer n,

$$S_b^nc=a_n*c.\tag{2.5}$$

For $n=1$, (2.5) reduces to (2.4). Let us check (2.5) for $n=2$. In fact, it follows from (2.4) that

$$S_b^2c(\gamma)=\sum_{\alpha\in\mathbb{Z}}\sum_{\beta\in\mathbb{Z}}a(\beta)c(\alpha-\beta)b(\gamma-2\alpha)=\sum_{\beta\in\mathbb{Z}}a(\beta)S_bc(\gamma-2\beta)\qquad\forall\gamma\in\mathbb{Z}.$$

Using (2.4) again we obtain

$$S_b^2 c(\gamma) = \sum_{\beta\in\mathbb{Z}} a(\beta) a * c(\gamma - 2\beta) = \sum_{\beta\in\mathbb{Z}} a_2(\gamma-\beta)c(\beta) \qquad \forall \gamma \in \mathbb{Z},$$

as desired. The verification of (2.5) for general n may proceed inductively. The proof of our theorem is now complete by (2.5) and Theorem 2.1. □

While Theorem 2.2 connects the spectral radius of a subdivision operator with the limit $\lim_{n\to\infty} ||a_n * c||^{\frac{1}{n}}_p$, in the rest of this section we shall represent the limit in terms of the so-called p-joint spectral radius.

For $p = \infty$, the p-joint spectral radius, called the uniform joint spectral radius, was introduced in [19] and was employed to investigate regularity of refinable function in [7]. When $p = 1$, the p-joint spectral radius was introduced in [20] and was referred to as the mean joint spectral radius there. For $1 < p < \infty$, the p-joint spectral radius was introduced in [11] and applied to the study of L_p convergence of cascade algorithms. We recall from [11] the definition of p-joint spectral radius.

If V is a finite-dimensional space, let $\mathcal{B}(V)$ denote the collection of linear operators on V. Suppose that $\mathcal{A} \subseteq \mathcal{B}(V)$ is a finite set. For a positive integer n we denote by $\mathcal{A}^n$ the Cartesian power of $\mathcal{A}$:

$$\mathcal{A}^n = \big\{(A_1, \dots, A_n) : A_1, \dots, A_n \in \mathcal{A}\big\}.$$

Suppose that $\mathcal{B}(V)$ is equipped with the operator norm $||\cdot||$. For $1 \le p < \infty$, define a number $||\mathcal{A}^n||_p$ by

$$||\mathcal{A}^n||_p^p = \sum_{(A_1,\dots,A_n)\in\mathcal{A}^n} ||A_1 \cdots A_n||^p,$$

and, for $p = \infty$, define

$$||\mathcal{A}^n||_\infty = \max\big\{\, ||A_1 \cdots A_n|| : (A_1, \dots, A_n) \in \mathcal{A}^n \,\big\}.$$

The p-joint spectral radius of $\mathcal{A}$, for $1 \le p \le \infty$, is defined to be

$$\rho_p(\mathcal{A}) := \lim_{n\to\infty} ||\mathcal{A}^n||_p^{\frac{1}{n}}. \tag{2.6}$$

We know from [11] that this limit indeed exists and

$$\lim_{n\to\infty} ||\mathcal{A}^n||_p^{\frac{1}{n}} = \inf_{n\ge1} ||\mathcal{A}^n||_p^{\frac{1}{n}}.$$

For our purposes, we are mainly concerned with the operators A_ε, $\varepsilon = 0, 1$, on $(\ell_0(\mathbb{Z}))^{r\times m}$ defined as follows:

$$A_\varepsilon c(\alpha) = \sum_{\beta\in\mathbb{Z}} a(2\alpha + \varepsilon - \beta)c(\beta) \qquad \forall c \in (\ell_0(\mathbb{Z}))^{r\times m} \text{ and } \alpha \in \mathbb{Z}. \tag{2.7}$$

Let $\mathcal{A} := \{A_0, A_1\}$. A subspace $V \subseteq (\ell_0(\mathbb{Z}))^{r\times m}$ is called an $\mathcal{A}$ *invariant subspace* if

$$A_\varepsilon c \in V \qquad \forall \varepsilon = 0, 1 \text{ and } c \in V.$$

Suppose that M_1 and M_2 are two constants. It is easy to check that, for any $c \in (\ell_0(\mathbb{Z}))^{r\times m}$,

$$\operatorname{supp} c \subseteq [-M_1, M_2] \Longrightarrow \operatorname{supp} A_\varepsilon c \subseteq \left[\frac{-M_1 - 1}{2}, \frac{N + M_2}{2}\right], \qquad \varepsilon = 0, 1. \tag{2.8}$$

For any $c \in (\ell_0(\mathbb{Z}))^{r\times m}$, let $V(c)$ be the subspace spanned by

$$A_{\varepsilon_j}\cdots A_{\varepsilon_1}c,\ j=0,1,\ldots.$$

Clearly, $V(c)$ is an $\mathcal{A}$ invariant subspace, called the $\mathcal{A}$ invariant subspace *generated by c*. Moreover, we know by (2.8) that $V(c)$ is a finite-dimensional subspace. It follows from (2.8) that, for any $c \in (\ell_0(\mathbb{Z}))^{r\times m}$, there exists a finite set $K \subseteq \mathbb{Z}$ such that $V(c) \subseteq (\ell(K))^{r\times m}$. In particular, by (2.8), $(\ell(K_N))^{r\times m}$ is an invariant subspace of $\mathcal{A}$, where K_N is given as in (2.1).

For any $\alpha \in \mathbb{Z}$, there are unique $\varepsilon_1,\ldots,\varepsilon_n \in \{0,1\}$ and a $\gamma \in \mathbb{Z}$ such that $\alpha = 2^n\gamma+2^{n-1}\varepsilon_n\cdots+\varepsilon_1$. It is not difficult to check that (see, e.g., [3]), for $c \in (\ell_0(\mathbb{Z}))^{r\times m}$,

$$a_n * c(\alpha) = A_{\varepsilon_n}\cdots A_{\varepsilon_1}c(\gamma).$$

As is known, there is a finite set $K \subseteq \mathbb{Z}$ such that $V(c) \subseteq (\ell(K))^{r\times m}$. Then it follows from the last equality that

$$\|a_n * c\|_p = \sum_{\varepsilon_1,\ldots,\varepsilon_n=0,1} ||A_{\varepsilon_n}\cdots A_{\varepsilon_1}c||^p \qquad \forall c \in (\ell_0(\mathbb{Z}))^{r\times m}, \tag{2.9}$$

where $||\cdot||$ in the right-hand side is a norm on $(\ell(K))^{r\times m}$. With this equality we can derive for any $c \in (\ell_0(\mathbb{Z}))^{r\times m}$

$$\lim_{n\to\infty} ||a_n * c||_p^{\frac{1}{n}} = \rho_p\big(\{A_0|_{V(c)},\ A_1|_{V(c)}\}\big).$$

Consequently, for a finite dimension $\mathcal{A}$-invariant subspace $V \subseteq (\ell(K))^{r\times m}$ we have

$$\max\Big\{\lim_{n\to\infty} ||a_n * \lambda||_p^{\frac{1}{n}} :\ \lambda \in V\Big\} = \rho_p\big(\{A_0|_V,\ A_1|_V\}\big). \tag{2.10}$$

In fact, it was established in [10] for $m = r = 1$, and in [14] for $m = 1$ and general r. We refer to [10] and [14] for the details. By the same methods and (2.9), we can establish (2.10) for our setting.

For a sequence $c \in (\ell_0(\mathbb{Z}))^{r\times r}$, we define a subspace of $(\ell_0(\mathbb{Z}))^{r\times 1}$ as follows:

$$V(c*) := \big\{\lambda \in (\ell_0(\mathbb{Z}))^{r\times 1} : \lambda = c * \eta,\ \eta \in (\ell_0(\mathbb{Z}))^{r\times 1}\big\}. \tag{2.11}$$

With the help of (2.9) we can prove the following result.

THEOREM 2.3. *Recall that K_N is given as in* (2.1). *Let $c \in (\ell(K_N))^{r\times r}$. If $V(c*)$ is an $\mathcal{A}$ invariant subspace, we have*

$$\lim_{n\to\infty} ||a_n * c||_p^{\frac{1}{n}} = \rho_p\big(\{A_0|_{V(c*)\cap(\ell(K_N))^{r\times 1}}, A_1|_{V(c*)\cap(\ell(K_N))^{r\times 1}}\}\big).$$

Proof. Let $V := V(c*)\cap(\ell(K_N))^{r\times 1}$. As mentioned, $(\ell(K_N))^{r\times 1}$ is an $\mathcal{A}$ invariant subspace. Therefore, V is an $\mathcal{A}$ invariant subspace by the assumption.

For any $\lambda \in V(c*)$, there is an $\eta \in (\ell_0(\mathbb{Z}))^{r\times 1}$ such that $\lambda = c*\eta$. Thus, $||a_n*\lambda||_p \le \kappa_\lambda||a_n * c||_p, n = 1,2,\ldots,$ for some constant κ_λ. Thus,

$$\lim_{n\to\infty} ||a_n * \lambda||_p^{\frac{1}{n}} \le \lim_{n\to\infty} ||a_n * c||_p^{\frac{1}{n}} \qquad \forall \lambda \in V(c*).$$

On the other hand, we define η_j by setting $\eta_j(\alpha) = 0\ \forall\alpha \ne 0$ and $\eta_j(0)$ the jth-column of $r \times r$ identity matrix, $1 \le j \le r$. Moreover, let $\lambda_j = c * \eta_j, 1 \le j \le r$. Obviously, $a_n * \lambda_j$ is just the jth-column of $a_n * c, 1 \le j \le r$. It follows that

$$\lim_{n\to\infty} ||a_n * c||_p^{\frac{1}{n}} \le \max_{1\le j\le r} \lim_{n\to\infty} ||a_n * \lambda_j||_p^{\frac{1}{n}}.$$

Note that $\lambda_j \in V, 1 \le j \le r$. We have by the last two inequalities

$$\lim_{n\to\infty} ||a_n * c||_p^{\frac{1}{n}} = \max_{\lambda\in V} \lim_{n\to\infty} ||a_n * \lambda||_p^{\frac{1}{n}}.$$

The proof is complete by (2.10). □

Combining Theorems 2.2 and 2.3 we have the following result.

COROLLARY 2.4. *Suppose that a, b, and c are in $(\ell_0(\mathbb{Z}))^{r\times r}$ and satisfy the conditions of Theorem* 2.2. *In addition, suppose that $V(c*)$ is an invariant subspace of A_0 and A_1. Then*

$$\rho_p(S_b) = \rho_p\big(\{A_0|_{V(c*)\cap(\ell(K_N))^{r\times 1}}, A_1|_{V(c*)\cap(\ell(K_N))^{r\times 1}}\}\big).$$

3. Structures of some invariant subspaces. The main purpose of this section is to represent explicitly some invariant subspaces of both A_0 and A_1 in terms of convolution. These subspaces are important to the study of convergence of cascade algorithms.

In the study of convergence of cascade algorithms and regularities of function vectors, we usually restrict ourselves to a class of masks a satisfying some conditions on the modulii of eigenvalues of $H_a(0)$. The reason will soon be clear.

Suppose that s is a nonnegative integer. Recall that $H_a(\omega)$ is defined in section 1. Denote by E_{s+1} the set of all sequences $a \in (\ell_0(\mathbb{Z}))^{r\times r}$ satisfying the following conditions:

(1) 1 is a simple eigenvalue of $H_a(0)$.

(2) The other eigenvalues of $H_a(0)$ are of modulus less than 2^{-s}.

It was proved in [3] that $a \in E_{s+1}$ provided that the refinable function vector $\Phi_a \in (W_p^s(\mathbb{R}))^r$ satisfies $\widehat{\Phi}_a(0) \ne 0$ and the independence condition

$$\operatorname{span}\Big\{\widehat{\Phi}_a(2\alpha\pi) :\ \alpha \in \mathbb{Z}\Big\} = \mathbb{C}^r.$$

If $a \in E_{s+1}$, there exists a unique, up to a constant factor, $1 \times r$ vector $t_a(\omega)$ of trigonometric polynomials with spectrum contained in $\{\mu : 0 \le \mu \le s\}$ satisfying

$$D^\mu\big(t_a(2\cdot)H_a\big)(0) = D^\mu t_a(0), \qquad 0 \le \mu \le s. \tag{3.1}$$

We say a sequence $a \in (\ell_0(\mathbb{Z}))^{r\times r}$ satisfies *sum rules of order $s+1$ with t_a* if there is a vector t_a of trigonometric polynomials with $t_a(0) \ne 0$ such that (3.1) and the following equalities are true:

$$D^\mu\big(t_a(2\cdot)H_a\big)(\pi) = 0, \qquad 0 \le \mu \le s.$$

Let $\mathcal{S}_{s+1}$ denote the set of all sequences satisfying sum rules of order $s+1$. It is known that there is a close relation between the order of sum rules and the approximation order provided by the refinable function vector; see, for example, [16], [13], and [2].

For a mask $a \in E_{s+1}$, we define

$$V_a^s := \Big\{\lambda : \lambda \in (\ell_0(\mathbb{Z}))^{r\times 1}, D^\mu\big(t_a\widehat{\lambda}\big)(0) = 0,\ 0 \le \mu \le s\Big\}. \tag{3.2}$$

The importance of V_a^s lies in the following result.

LEMMA 3.1 (see [3]). *Let $\mathcal{A} = \{A_0, A_1\}$. Assume that $a \in E_{s+1}$ and V_a^s is given as above. Then V_a^s is an $\mathcal{A}$ invariant subspace if and only if a satisfies sum rules of order $s+1$ with t_a.*

For later use we will identify V_a^s with a subspace $V(c*)$ for some finitely supported sequence c determined by a. To this end, we need the results of [16] and [18] about factorizations of masks which satisfy sum rules of appropriate order.

Let $\mathcal{C}$ be the set of $r\times r$ matrices $C(\omega)$ with entries being 2π periodic trigonometric polynomials such that

(1) $C(0)$ has a simple eigenvalue 0;

(2) $\det C(\omega)=\kappa(1-e^{-i\omega})e^{-i\gamma\omega}$, where $\kappa\neq 0$ and $\gamma\in\mathbb{Z}$ are constants.

For any $x\in\mathbb{C}^r\backslash\{0\}$, we denote by C_x a matrix in $\mathcal{C}$ such that x is a left eigenvector of $C_x(0)$ with eigenvalue 0. We note that such a matrix is not unique. A special form of such matrices can be found in [16]. Furthermore, any two matrices C_x^1 and C_x^2 in $\mathcal{C}$ that have the same x as a left eigenvector with eigenvalue 0 are related by $C_x^1(\omega)M(\omega)=C_x^2(\omega)$, where the $r\times r$ matrix $M(\omega)$ is invertible for any ω and its entries are 2π periodic trigonometric polynomials.

By the definition of $\mathcal{C}$ we know there is a $r\times r$ matrix $G_x(\omega)$ with entries being 2π periodic trigonometric polynomials such that the following conditions are satisfied:

$$C_x(\omega)^{-1}=\frac{G_x(\omega)}{1-e^{-i\omega}}\qquad\forall\omega\notin 2\pi\mathbb{Z}. \tag{3.3}$$

The set $\mathcal{C}$ plays an important role in the factorization of refinement masks. The following result was established in [16] with special form of C_x and in [18] for the general case.

LEMMA 3.2 (see [16] and [18]). *Assume that $a\in E_{s+1}$. Then a satisfies sum rules of order $s+1$ with t_a if and only if there are nonzero vectors $x_0,x_1,\dots,x_s\in\mathbb{C}^r$ and a sequence $\tilde{a}\in(\ell_0(\mathbb{Z}))^{r\times r}$ such that the following conditions are satisfied:*

(1) *a can be factorized as follows:*

$$\widehat{a}C_{x_s}\cdots C_{x_0}=\frac{1}{2^{s+1}}C_{x_s}(2\cdot)\cdots C_{x_0}(2\cdot)\widehat{\tilde{a}}. \tag{3.4}$$

(2) *a^μ, $\mu=0,1,\dots,s-1$, satisfies sum rules of order $\mu+1$, where $a^\mu\in(\ell_0(\mathbb{Z}))^{r\times r}$ is defined by its Fourier transform*

$$\widehat{a^\mu}(\omega)=\frac{1}{2^{\mu+1}}C_{x_\mu}(2\omega)\cdots C_{x_0}(2\omega)\widehat{\tilde{a}(\omega)}C_{x_0}^{-1}(\omega)\cdots C_{x_\mu}^{-1}(\omega)\qquad\forall\omega\notin 2\pi\mathbb{Z}.$$

Suppose that $a\in E_{s+1}$ satisfies sum rules of order $s+1$. Then the factorization as in Lemma 3.2 holds. It was proved in [6] that 1 is a simple eigenvalue of $H_{a^j}(0), 0\le j\le s$, where $a^s=a$. Moreover, each $x_j, 0\le j\le s$, is a left eigenvector of $H_{a^j}(0)$ with the eigenvalue 1. In particular,

$$x_s=t_a(0)^T. \tag{3.5}$$

We recall that $a\in(\ell(K_N))^{r\times r}$. Suppose that a satisfies the conditions of Lemma 3.2. Without loss of generality we assume that $a^\mu, 0\le\mu\le s-1$, determined by condition (2) of Lemma 3.2, satisfy $a^\mu\in(\ell(K_N))^{r\times r}$ as well.

For our consideration we restate a result of Plonka and Strela in the following slightly different form. As in Lemma 3.2, it was proved in [16] with special C_x and in [18] for the general case.

LEMMA 3.3 (see [18, Theorem 2.4]). *Suppose that $a\in E_{s+1}$ and a satisfies sum rules of order $s+1$ with t_a. Let a^{s-1} and x_s be given as in condition (2) of Lemma 3.2. Then a^{s-1} satisfies sum rules of order s with $t_{a^{s-1}}$ verifying*

$$D^\mu t_{a^{s-1}}(0)=\frac{i}{\mu+1}D^{\mu+1}(t_aC_{x_s})(0),\qquad 0\le\mu\le s-1.$$

We are in a position to characterize the structure of V_a^s in terms of the factorization of mask which satisfies sum rules of order $s+1$.

THEOREM 3.4. *Suppose that a satisfies the hypotheses of Lemma 3.2 and, consequently, (3.4) is true for some $C_{x_s},\dots,C_{x_0}$. Let $C_s = C_{x_s}\cdots C_{x_0}$. Then a vector $\lambda \in (\ell_0(\mathbb{Z}))^{r\times 1}$ belongs to V_a^s if and only if there is a $\xi \in (\ell_0(\mathbb{Z}))^{r\times 1}$ such that*

$$\widehat{\lambda} = C_s\widehat{\xi}. \tag{3.6}$$

Proof. Let a satisfy sum rules of order $s+1$ with t_a. Recall that a^{s-1} is given as in (2) of Lemma 3.2. We first claim that

$$V_a^s = \left\{\lambda : \widehat{\lambda} = C_{x_s}\widehat{\eta},\ \eta \in V_{a^{s-1}}^{s-1}\right\}. \tag{3.7}$$

In fact, suppose first that $\lambda \in (\ell_0(\mathbb{Z}))^{r\times r}$ satisfies $\widehat{\lambda} = C_{x_s}\eta$ for some $\eta \in V_{a^{s-1}}^{s-1}$. By the definition of $C_{x_s}(\omega)$ and equality (3.5), it is easily seen that $t_a(0)C_{x_s}(0) = 0$ and, consequently,

$$t_a(0)\widehat{\lambda}(0) = 0.$$

Moreover, it follows from this equality and Lemma 3.3 that

$$\begin{aligned} D^{\mu+1}(t_a\widehat{\lambda})(0) &= \sum_{\nu\le\mu+1}\binom{\mu+1}{\nu}D^{\mu+1-\nu}(t_aC_{x_s})(0)D^\nu\widehat{\eta}(0)\\ &= \frac{\mu+1}{i}\sum_{\nu\le\mu}\binom{\mu}{\nu}D^{\mu-\nu}t_{a^{s-1}}(0)D^\nu\widehat{\eta}(0). \end{aligned}$$

We thus obtain

$$D^{\mu+1}(t_a\widehat{\lambda})(0) = \frac{\mu+1}{i}D^\mu(t_{a^{s-1}}\widehat{\eta})(0), \qquad 0\le\mu\le s-1. \tag{3.8}$$

Since $\eta \in V_{a^{s-1}}^{s-1}, D^{\mu+1}(t_a\widehat{\lambda})(0) = 0$ by (3.8), $0\le\mu\le s-1$. This proves $\lambda \in V_a^s$. Conversely, let $\lambda \in V_a^s$. Since $\operatorname{rank}C_{x_s}(0) = r-1$, it follows from (3.3) that $\operatorname{rank}G_{x_s}(0) = 1$. Furthermore, each row of $G_{x_s}(0)$ is a multiple of x_s^T due to the fact that x_s^T is a left eigenvector of $H_{x_s}(0)$ with the simple eigenvalue 1. Note that $t_a(0) = x_s^T$. Consequently, we have $G_{x_s}(0)\widehat{\lambda}(0) = 0$. This implies that there is an $\eta \in (\ell_0(\mathbb{Z}))^{r\times 1}$ such that $G_{x_s}(\omega)\widehat{\lambda}(\omega) = (1-e^{-i\omega})\widehat{\eta}(\omega)$, $\omega\in\mathbb{R}$. It follows from (3.3) that $\widehat{\eta}(\omega) = C_{x_s}(\omega)^{-1}\widehat{\lambda}(\omega)$, $\omega\in\mathbb{R}$. Substituting it into the right-hand side of (3.8) and appealing to Lemma 3.3 we conclude that (3.8) is true for any $0\le\mu\le s-1$. This together with $\lambda\in V_a^s$ tells us $\eta\in V_{a^{s-1}}^{s-1}$. Therefore we have proved (3.7), as claimed.

By replacing V_a^s with $V_{a^{s-1}}^{s-1},\dots,V_{a^1}^1$ recursively in (3.7), we know that $\lambda\in V_a^s$ if and only if there is an $\eta\in V_{a^0}^0$ such that

$$\widehat{\lambda} = C_{x_s}\cdots C_{x_1}\widehat{\eta}.$$

However, as is known, $a^0\in E_1$ and a^0 satisfies sum rules of order 1 with

$$t_{a^0}(\omega) = x_0^T \qquad \forall\omega\in\mathbb{R}.$$

Therefore, by the definitions of $V_{a^0}^0$ and $C_{x_0}(\omega)$, we have

$$V_{a^0}^0 = \left\{\eta\in(\ell_0(\mathbb{Z}))^{r\times 1} : \widehat{\eta} = C_{x_0}\widehat{\xi}, \xi\in(\ell_0(\mathbb{Z}))^{r\times 1}\right\}.$$

Thus (3.6) is true. The proof is complete. □

Let $c_s \in (\ell_0(\mathbb{Z}))^{r\times r}$ be given by its Fourier transform as follows:

$$\widehat{c}_s = C_{x_s} \cdots C_{x_0}. \tag{3.9}$$

Then we restate Theorem 3.4 in the following form.

COROLLARY 3.5. *Under the conditions of Theorem* 3.4 *and with the notations as above we have*

$$V_a^s = V(c_s *).$$

4. Convergence of cascade algorithms. In this section we establish the equivalence between the convergence of a cascade algorithm in Sobolev space and the convergence of an associated cascade algorithm in L_p space. Therefore, the problem of convergence of cascade algorithms in Sobolev norm may reduce to that in L_p space. On the other hand, an algorithm for construction of refinement masks which generate convergent cascade algorithms in Sobolev space is presented. The algorithm is easy to implement.

Assume as before that $a \in (\ell_0(\mathbb{Z}))^{r\times r}$ and $a \in E_{s+1}$. As mentioned in section 3, there is a unique vector t_a, up to a constant factor, such that (3.1) holds. Using $t_a(\omega)$, we define W_a^s to be the set of vectors F of compactly supported functions in $W_p^s(\mathbb{R})$ satisfying

$$t_a(0)\widehat{F}(0) = t_a(0)\widehat{\Phi}_a(0) \qquad \text{and} \qquad D^\mu(t_a\widehat{F})(2\alpha\pi) = 0 \ \ \forall \alpha \neq 0,\ 0 \le \mu \le s. \tag{4.1}$$

It had been proved in [3] that if

$$\lim_{n\to\infty} ||Q_a^n F_0 - \Phi_a||_{(W_p^s(\mathbb{R}))^r} = 0, \tag{4.2}$$

for some vector F_0 of compactly supported functions, then $F_0 \in W_a^s$. Therefore, the notion of convergence was defined in [3] as follows. Let $a \in E_{s+1}$. We say that the cascade algorithm generated by Q_a *converges in* $(W_p^s(\mathbb{R}))^r$ *norm* if (4.2) holds for any $F_0 \in W_a^s$.

The characterization of the convergence of cascade algorithm in terms of the p-joint spectral radius is given as follows.

THEOREM 4.1 (see [3]). *Assume that $a \in E_{s+1}$. Suppose that $H_a(\omega)$ and $t_a(\omega)$ satisfy* (3.1). *Let V_a^s be defined in* (3.2). *Then the cascade algorithm generated by Q_a converges in $(W_p^s(\mathbb{R}))^r$ norm if and only if the following conditions are satisfied:*

(1) *V_a^s is invariant under $A_\varepsilon, \varepsilon = 0, 1$.*

(2) *$\rho_p\left(\{A_0|_{V_N}, A_1|_{V_N}\}\right) < 2^{-s+1/p}$, where $V_N = V_a^s \cap (\ell(K_N))^{r\times 1}$.*

We are in a position to establish an equivalence between the convergence of a cascade algorithm in Sobolev space on one hand and the convergence of an associated cascade algorithm in L_p norm on the other hand.

THEOREM 4.2. *Assume that $a \in E_{s+1}$. Then the cascade algorithm generated by Q_a converges in $(W_p^s(\mathbb{R}))^r$ if and only if the following conditions are satisfied:*

(1) *There are $s+1$ nonzero vectors $x_0, x_1, \ldots, x_s \in \mathbb{C}^r$ and a sequence $\tilde{a} \in (\ell_0(\mathbb{Z}))^{r\times r}$ such that a satisfies conditions* (1) *and* (2) *of Lemma* 3.2.

(2) *The cascade algorithm corresponding to a^0 converges in $(W_p(\mathbb{R}))^r$, where a^0 is given in* (2) *of Lemma* 3.2.

If this is the case, then $\widehat{\Phi}_{a^0}(0) \neq 0$ and the refinable function vectors Φ_a and Φ_{a^0} are related by

$$(i\omega)^s\widehat{\Phi}_a = \kappa C_{x_s} \cdots C_{x_{s-1}}\widehat{\Phi}_{a^0}, \tag{4.3}$$

where κ is a constant.

Proof. Suppose that the cascade algorithm generated by Q_a converges in $(W_p^s(\mathbb{R}))^r$. Then $s+1 \le N$ and $a \in \mathcal{S}_{s+1}$ by [3]. Therefore, conditions (1) and (2) of Lemma 3.2 are true for some vectors $x_0, \dots, x_s$ and a sequence $\tilde{a} \in (\ell_0(\mathbb{Z}))^{r\times r}$.

Let $c_s \in (\ell_0(\mathbb{Z}))^{r\times r}$ be given as in (3.9). Then $V(c_s*) = V_a^s$ by Corollary 3.5 and, consequently, $V(c_s*)$ is invariant under $A_\varepsilon, \varepsilon = 0, 1$, by Theorem 4.1.

On the other hand, we may rewrite (3.4) as

$$a * c_s = 2^{-s-1} S_{\tilde{a}}.$$

By the requirements of $\mathcal{C}$, the Fourier transform $\widehat{c}_s$ of c_s is invertible for any $\omega \notin 2\pi\mathbb{Z}$. Consequently, c_s satisfies condition (2.2) on c. It follows from Corollary 2.4 that

$$\rho_p\big(\{A_0|_{V_a^s \cap (\ell(K_N))^{r\times 1}}, A_1|_{V_a^s \cap (\ell(K_N))^{r\times 1}}\}\big) = 2^{-s-1}\rho_p(S_{\tilde{a}}). \tag{4.4}$$

Let a^0 be defined in condition (2) of Lemma 3.2. As is known, $a^0 \in E_1$ and a^0 satisfies sum rules of order 1 with a constant vector $t_{a^0}(\omega) = x_0^T \ \forall \omega \in \mathbb{R}$. Let $A_\varepsilon^0, \varepsilon = 0, 1$, be defined in (2.7) by replacing a with a^0. Then $V_{a^0}^0$ is invariant under $A_\varepsilon^0, \varepsilon = 0, 1$, where $V_{a^0}^0$, corresponding to a^0, is given by (3.2). Similar to the proof of (4.4) we can establish

$$\rho_p\left(\left\{A_0^0|_{V_{a^0}^0 \cap (\ell(K_N))^{r\times 1}}, A_1^0|_{V_{a^0}^0 \cap (\ell(K_N))^{r\times 1}}\right\}\right) = 2^{-1}\rho_p(S_{\tilde{a}}). \tag{4.5}$$

Furthermore, by condition (2) of Theorem 4.1 and equality (4.4) we have

$$\rho_p(S_{\tilde{a}}) < 2^{1+1/p}. \tag{4.6}$$

It in turn implies by (4.5) that

$$\rho_p\left(\left\{A_0^0|_{V_{a^0}^0 \cap (\ell(K_N))^{r\times 1}}, A_1^0|_{V_{a^0}^0 \cap (\ell(K_N))^{r\times 1}}\right\}\right) < 2^{1/p}. \tag{4.7}$$

Therefore, the cascade algorithm associated with a^0 converges in $(W_p(\mathbb{R}))^r$ norm by Theorem 4.1. This proves the necessity of (1) and (2).

Assume now that conditions (1) and (2) are true. Then V_a^s as above is an invariant subspace of A_0 and A_1, thereby verifying condition (1) of Theorem 4.1. Moreover, by applying Theorem 4.1 to the cascade algorithm generated by Q_{a^0} and $s = 0$ we get (4.7). It is easy to deduce condition (2) of Theorem 4.1 from (4.4), (4.5), and (4.7). This proves the sufficiency of the theorem.

Finally, if the conditions of the theorem are satisfied, the relation (4.3) between Φ_a and Φ_{a^0} may be found, e.g., in [18]. Moreover, $\widehat{\Phi}_{a^0}(0) \neq 0$ since it is a right eigenvector of $H_{a^0}(0)$. The proof is complete. □

From the proof of Theorem 4.2 we know that, when a mask a is factorized as in condition (1) of Lemma 3.2, the cascade algorithm generated by Q_a converges in $(W_p^s(\mathbb{R}))^r$ norm if and only if the corresponding sequence $\tilde{a}$ satisfies (4.6).

While the matrices C_x are determined by a left eigenvector of $C_x(0)$ to the eigenvalue 0, it is convenient sometimes, as observed in [18], to identity the matrices with the help of right eigenvectors to the same eigenvalue. More precisely, we let y be a right eigenvector of $C_x(0)$ with eigenvalue 0, and we set $M_y(\omega) = C_x(\omega)$. Therefore, for any finitely supported sequence $a \in E_{s+1}$, $a \in \mathcal{S}_{s+1}$ is equivalent to the factorization

$$\widehat{a} M_{y_s} \cdots M_{y_0} = \frac{1}{2^{s+1}} M_{y_s}(2\cdot) \cdots M_{y_0}(2\cdot)\widehat{\tilde{a}}, \tag{4.8}$$

where y_j is a right eigenvector of $H_{a^{j-1}}(0)$, $0 \le j \le s$, to the eigenvalue 0, the sequences $a^j \in (\ell_0(\mathbb{Z}))^{r\times r}$ are given by

$$H_{a^j}(\omega) = \frac{1}{2} M_{y_j}(2\omega) H_{a^{j-1}}(\omega) M_{y_j}(\omega)^{-1}, \quad \omega \notin 2\pi\mathbb{Z}, \quad 0 \le j \le s-1,$$

and $a^{-1} = \tilde{a}$. We refer to Theorem 2.7 and Corollary 2.8 of [18] for the details.

At the end of this section we present an algorithm for construction of refinement masks which generate convergent cascade algorithms in Sobolev space.

ALGORITHM 4.3. *Start with a finitely supported sequence $\tilde{a}$ such that $H_{\tilde{a}}(0)$ has 1 as a simple eigenvalue and $\rho(H_{\tilde{a}}(0)) < 2$. Suppose that $\rho_p(S_{\tilde{a}}) < 2^{1+1/p}$. Let y_0 be a right eigenvector of $H_{\tilde{a}}(0)$ associated with eigenvalue 1. Choose a matrix $M_{y_0} \in \mathcal{C}$ satisfying $M_{y_0}(0)y_0 = 0$. Define a finitely supported sequence a^0 by*

$$H_{a^0}(\omega) = \frac{1}{2} M_{y_0}(2\omega) H_{\tilde{a}}(\omega) M_{y_0}(\omega)^{-1} \qquad \forall \omega \notin 2\pi\mathbb{Z}. \tag{4.9}$$

(1) *Find a right eigenvector y_{j+1} of $H_{a^j}(0)$ associated with eigenvalue 1.*
(2) *Construct a finitely supported sequence a^{j+1} by*

$$H_{a^{j+1}}(\omega) = \frac{1}{2} M_{y_{j+1}}(2\omega) H_{a^j}(\omega) M_{y_{j+1}}(\omega)^{-1} \qquad \forall \omega \notin 2\pi\mathbb{Z},$$

where $M_{y_{j+1}} \in \mathcal{C}$ satisfies $M_{y_{j+1}}(0)y_{j+1} = 0$.

(3) *Repeat steps 1 and 2 as many times as needed.*

s cycles of Algorithm (steps 1, 2, and 3) yield a refinement mask a^s generating a convergent cascade algorithm in Sobolev space $(W_p^s(\mathbb{R}))^r$ norm.

Let us justify our algorithm. By the assumptions on $\tilde{a}$ we know that the spectrum of $H_{\tilde{a}}(0)$ is $\{1, \mu_1, \dots, \mu_{r-1}\}$ with $|\mu_j| < 2, j = 1, \dots, r-1$. It follows from [6] that the spectrum of $H_{a^j}(0)$ is of form $\{1, 2^{-j-1}\mu_1, \dots, 2^{-j-1}\mu_{r-1}\}$. Consequently, 1 is a simple eigenvalue of $H_{a^j}(0)$. So step 3 is consistent. Clearly, $a^s \in E_{s+1}$. Moreover, $a^s \in \mathcal{S}_{s+1}$ by Theorem 2.7 and Corollary 2.8 in [18].

Finally, since $S_{\tilde{a}}$ satisfies (4.6), the cascade algorithm generated by Q_{a^s} converges in Sobolev space $(W_p^s(\mathbb{R}))^r$ norm by what is mentioned in the paragraph. ∎

5. Examples. The following examples will illustrate our theory.

EXAMPLE 5.1. *We consider a refinable function vector taken from* [8]. *Let $a \subseteq (\ell(\{0,1,2,3\}))^{2\times 2}$. Its Fourier transform $\widehat{a}$ is*

$$\begin{pmatrix} -\frac{(t^2-4t-3)(1+z)}{2(t+2)} & 1 \\ -\frac{3(t-1)(t+1)((t^2-3t-1)(1+z^3)+(t^2-t+3)(z+z^2))}{4(t+2)^2} & \frac{(3t^2+t-1)(1+z^2)}{2(t+2)} + z \end{pmatrix}, \qquad z = e^{-i\omega}.$$

Then, if $|t| < 1/2$, the cascade algorithm generated by Q_a converges in $(W_p^1(\mathbb{R}))^2$ norm for $1 \le p < \infty$. If $1/2 < |t| < 1$, it converges in $(W_p(\mathbb{R}))^2$ norm for $1 \le p \le \infty$.

Proof. It is known from [6] that (3.4) holds for $s = 1$ with $x_0 = (1,1)^T$, $x_1 = (-3(t^2-1)/(t+2), 1)^T$, and

$$\widehat{\tilde{a}}(\omega) = \begin{pmatrix} 2 & 0 \\ \frac{(t^2-3t-1)z^2+(-10t^2-8t+6)z+(t^2-3t-1)}{(t+2)} & 4t(1+z) \end{pmatrix}, \qquad z = e^{-i\omega}.$$

Let us first compute the spectral radius $\rho_p(S_{\tilde{a}})$ of $S_{\tilde{a}}$. To this end we cite the following formula of [14]:

$$\rho_p(S_{\tilde{a}}) = \rho_p\left(\left\{\tilde{A}_0|_{(\ell(\{0,1\}))^{2\times 1}}, \tilde{A}_1|_{(\ell(\{0,1\}))^{2\times 1}}\right\}\right), \tag{5.1}$$

where $\tilde{A}_\varepsilon$ is defined as in section 2 by replacing a with $\tilde{a}, \varepsilon = 0, 1$. Moreover, we identify any $\lambda \in (\ell(\{0,1\}))^{2\times 1}$ with a vector

$$\begin{pmatrix}\lambda(0)\\ \lambda(1)\end{pmatrix} \in \mathbb{C}^4$$

and, therefore, $\tilde{A}_\varepsilon|_{(\ell(\{0,1\}))^{2\times 1}}$, $\varepsilon = 0, 1$, with operators on $\mathbb{C}^4$. Choose a basis of $\mathbb{C}^4$ as follows. $e_1 = (0,0,1,0)^T$, $e_2 = (1,0,0,0)^T$, $e_3 = (0,0,0,1)^T$, $e_4 = (0,1,0,0)^T$. Denote by T_ε the representing matrix of $\tilde{A}_\varepsilon|_{(\ell(\{0,1\})^{2\times 1}}$ on this basis. Then by a simple computation we know

$$T_0 = \begin{pmatrix} 4t & 0 & \frac{-1-3t+t^2}{2+t} & 0\\ 0 & 4t & \frac{-1-3t+t^2}{2+t} & \frac{-2(-3+4t+5t^2)}{2+t}\\ 0 & 0 & 2 & 0\\ 0 & 0 & 0 & 0 \end{pmatrix}$$

and

$$T_1 = \begin{pmatrix} 4t & 4t & \frac{-2(-3+4t+5t^2)}{2+t} & \frac{-1-3t+t^2}{2+t}\\ 0 & 0 & 0 & \frac{-1-3t+t^2}{2+t}\\ 0 & 0 & 0 & 2\\ 0 & 0 & 0 & 0 \end{pmatrix}.$$

Appealing to (4.3) of [14] we have

$$\rho_p\left(\left\{\tilde{A}_0, \tilde{A}_1\right\}\right) = 4\max\{1/2, 2^{1/p}|t|\}, \qquad 1 \le p \le \infty.$$

It follows from (5.1) that $\rho_p(S_{\tilde{a}}) = 4\max\{1/2, 2^{1/p}|t|\}$.

As mentioned in the paragraph following Theorem 4.2, the cascade algorithm generated by Q_a converges in $(W_p^1(\mathbb{R}))^2$ norm if and only if (4.6) holds. Therefore, if $|t| < 1/2$, the cascade algorithm generated by Q_a converges in $(W_p^1(\mathbb{R}))^2$ norm for $1 \le p < \infty$ and *does not* converge in $(W_\infty^1(\mathbb{R}))^2$ norm.

For $1/2 < |t| < 1$ and $1 \le p \le \infty$, the cascade algorithm converges in $(W_p(\mathbb{R}))^2$ norm by Theorem 4.2. □

EXAMPLE 5.2. *Let* $y^1 = (\sqrt{2}, 1)^T$ *and* $a^0 \subseteq (\ell(\{0,1,2,3\}))^{2\times 2}$ *be given by*

$$H_{a^0}(\omega) = \frac{1}{20}\begin{pmatrix} 6+6e^{-i\omega} & 8\sqrt{2}\\ (-1+9e^{-i\omega}+9e^{-2i\omega}-e^{-3i\omega})/\sqrt{2} & -3+10e^{-i\omega}-3e^{-2i\omega}\end{pmatrix}.$$

If we define a^1 *by*

$$H_{a^1}(\omega) = \frac{1}{2}M_{y_1}(2\omega)H_{a^0}(\omega)M_{y_1}(\omega)^{-1}, \qquad \omega \notin 2\pi\mathbb{Z},$$

then the cascade algorithm generated by Q_{a^1} *converges in* $(W_\infty^1(\mathbb{R}))^2$ *norm.*

Proof. It is known (see [18]) that the normalized refinable function vector $\Phi_{a^0} = (\phi_1, \phi_2)^T$ has orthogonal shifts. Furthermore, ϕ_1 and ϕ_2 are continuous. It follows from [14] that the cascade algorithm generated by Q_{a^0} converges in $(W_\infty(\mathbb{R}))^2$ norm.

Therefore, by the proof of Theorem 4.2, a^0 can be factorized as in (4.9) for some $\tilde{a}$ and y_0, and $\tilde{a}$ satisfies the requirements of Algorithm 4.3. In order to construct a mask which generates a cascade algorithm converging in $(W_\infty^1(\mathbb{R}))^2$ norm, we need only to use one cycle of Algorithm 4.3.

In fact, it is easy to check that $y_1 = (\sqrt{2}, 1)^T$ is a right eigenvector of $H_{a^0}(0)$ with eigenvalue 1. Therefore, the conclusion is true by Algorithm 4.3.

In particular, if we set as in [18]

$$M_{y_1}(\omega) = \begin{pmatrix} 1 + e^{-i\omega} & -2\sqrt{2} \\ 1 - e^{-i\omega} & 0 \end{pmatrix},$$

then the mask a^1 is given by

$$H_{a^1}(\omega) = \frac{1}{40} \begin{pmatrix} -7 + 10e^{-i\omega} - 7e^{-2i\omega} & 15(1 - e^{-2i\omega} \\ -4(1 - e^{-2i\omega}) & 10(1 + e^{-i\omega})^2 \end{pmatrix}.$$

In this case, the components of Φ_{a^1} are symmetric [18]. □

Acknowledgments. The author thanks Prof. Rong-Qing Jia and Dr. Ding-Xuan Zhou for their very helpful comments and the anonymous referees for their valuable comments which helped to improve the presentation of the paper.

ENO-WAVELET TRANSFORMS FOR PIECEWISE SMOOTH FUNCTIONS*

TONY F. CHAN† AND H. M. ZHOU‡

Abstract. We have designed an adaptive essentially nonoscillatory (ENO)-wavelet transform for approximating discontinuous functions without oscillations near the discontinuities. Our approach is to apply the main idea from ENO schemes for numerical shock capturing to standard wavelet transforms. The crucial point is that the wavelet coefficients are computed without differencing function values across jumps. However, we accomplish this in a different way than in the standard ENO schemes. Whereas in the standard ENO schemes the stencils are adaptively chosen, in the ENO-wavelet transforms we adaptively change the function and use the same uniform stencils. The ENO-wavelet transform retains the essential properties and advantages of standard wavelet transforms such as concentrating the energy to the low frequencies, obtaining maximum accuracy, maintained up to the discontinuities, and having a multiresolution framework and fast algorithms, all without any edge artifacts. We have obtained a rigorous approximation error bound which shows that the error in the ENO-wavelet approximation depends only on the size of the derivative of the function away from the discontinuities. We will show some numerical examples to illustrate this error estimate.

1. Introduction.

In this paper, we develop new wavelet algorithms to approximate piecewise continuous functions, for instance piecewise smooth functions connected by large jumps. It is well known that wavelet linear approximation (i.e., truncating the high frequencies) can approximate smooth functions very efficiently: It can achieve high order accuracy by selecting appropriate wavelet basis; it can concentrate the large wavelet coefficients in the low frequencies; and it has a multiresolution framework and associated fast transform algorithms.

Standard wavelet linear approximation techniques cannot achieve similar results for functions which are not smooth, for example piecewise smooth functions with large jumps in function value or in its derivatives. Several problems arise near jumps, primarily caused by the well-known Gibbs phenomenon. The jumps generate large high frequency wavelet coefficients and thus linear approximation cannot get the same high accuracy near the points of discontinuity as in the smooth region. In fact, the jump points generate oscillations which cannot be removed by mesh refinement.

To overcome these problems within the standard wavelet transform framework, nonlinear data-dependent approximations, which selectively retain certain high frequency coefficients, are often used, e.g., hard and soft thresholding techniques; see [6], [15], [19], [18], [27], and corresponding references therein. The main idea of these thresholding approximations is to truncate both low and high frequency wavelet coefficients by their magnitudes, not frequencies. For instance, hard thresholding sets all coefficients whose magnitudes are less than a given tolerance to zero and retains the

other coefficients unchanged. It has been verified through many research efforts that such nonlinear processes can effectively reduce Gibbs oscillations, and therefore they have been widely used in many applications such as image compression and denoise, and even computation of partial differential equations. However, these techniques often require more complicated data structure to record the location of the retained wavelet coefficients and still cannot remove the effects of the Gibbs phenomenon completely unless all jump-related coefficients are preserved.

Another fundamental approach is to modify the wavelet transform to not generate large high frequency wavelet coefficients near jumps. A few papers in the literature have discussed this approach. Claypoole et al. [12] proposed an adaptive lifting scheme which lowers the order of approximation near jumps, thus minimizing the Gibbs effect. Consequently, this scheme suffers from reduced approximation accuracy near jumps, and some residual Gibbs phenomenon still exists. Another way due to Donoho is to construct orthonormal basis such as wedgelets [16] and ridgelets [7], [17] to represent the discontinuities.

In this paper, we develop a new wavelet algorithm by borrowing the well-developed essentially nonoscillatory (ENO) technique for shock capturing in computational fluid dynamics (e.g., see [23] and [29]) to modify the standard wavelet transform near discontinuities in order to overcome the above-mentioned difficulties. ENO schemes are systematic ways of adaptively defining piecewise polynomial approximations of the given functions according to their smoothness. There are two crucial points in designing ENO schemes. The first is to use one-sided information near jumps and never differencing across the discontinuities. The second is to adaptively form the divided difference table and select the smoothest *stencil* (the support of the basis) for every grid point. ENO schemes lead to uniform high accuracy approximations for each smooth piece of the function. We will use only the first point in our design of the ENO-wavelet transforms. Preliminary results of this work have been reported in [8].

Combining the ENO idea with the multiresolution data representation is a natural way to avoid oscillations in the approximations. In fact, it has been explored by Harten in his general framework of multiresolution in [20], [21], and [22]. (The lifting scheme of Sweldens [31] uses a similar idea.) Recent studies of his general framework and its application in data compression can be found in [2], [3], [4], and [9]. Harten's approach is to directly blend the two ideas and to fully implement the ENO schemes at every point. This consists of using the adaptive ENO finite difference table to select the stencil and then compute the decomposition as well as the reconstruction process. However, his method cannot be directly applied to the more generally used pyramidal filtering algorithms which the standard wavelet transforms are implemented in because in this context we have to work only with fixed size and fixed value filters, and these rigid filters cannot be directly used to compute the adaptive divided difference tables at each grid point.

Our goal is to design a more direct functional replacement of the standard wavelet transforms such that there are no oscillations at the discontinuities in the approximations. We want to stick with the classical pyramidal filtering framework because they are easy to use and have been successfully applied in many applications. Compared to Harten's multiresolution approach, which is more flexible and easier to adaptively implement than the ENO idea, the standard wavelet transforms are more regular and rigid in algorithmic structure; therefore, directly applying the ENO idea would lead to a more drastic perturbation of the underlying pyramidal filtering algorithms. This is the challenge we face.

Conceptually, the ENO-wavelet transforms that we will introduce in this paper are closely related to the ENO implementation of Harten's multiresolution framework. Both methods share the one-sided information idea, which computes the decomposition and reconstruction from smooth data. However, we achieve this in a different manner. The way we accomplish this is to not change the wavelet transforms or the filter coefficients, which most data-dependent multiresolution algorithms do, but instead locally change the function near the discontinuities in such a way that the standard filters are applied only to smooth data. By recording how the changes are made, the original discontinuous function can be exactly recovered by using the original inverse filters. Indeed, by applying the idea of using one-sided information near the discontinuities, we directly extend the functions from both sides of the discontinuities, thus we can apply the standard wavelet transforms on these extended values such that there are no large coefficients generated in the high frequencies and the low frequency approximations are essentially nonoscillatory, and therefore the Gibbs phenomenon can be completely avoided.

In addition, in this modified wavelet transform, the low frequency part preserves the piecewise smoothness of the original function. In particular, the jumps in the low frequency part is not spread widely as in the standard transform. Therefore, the same ENO idea can be recursively used for the coarser levels of the low pass coefficients. By doing so, the multiresolution framework also can be kept.

We show that the resulting wavelet transform retains all the desirable properties of the standard transform: It can have uniformly maximum accuracy, maintained up to the discontinuities (with a rigorous uniform order of the error bound); it concentrates the large coefficients to the low frequencies; it preserves the multiresolution framework and fast transform algorithms; and it is easy to implement. Furthermore, since we do not fully adopt the ENO schemes, in particular we do not build the divided difference table and compare the smoothness of all possible stencils at every point, the extra cost (in floating point operations) required by the modified ENO-wavelet transforms is insignificant. In fact, it is of the order $O(dl)$, where d is the number of discontinuities and $l+1$ the stencil length. Compared to the cost of the standard wavelet transform, which is of the order $O(nl)$, where n is the size of the data, the ratio of the extra cost over that of the standard transform is of the order $O(\frac{d}{n})$ which is independent of l and negligible when n is large.

Besides, since the designed ENO-wavelet transforms play the same role as the standard wavelet transforms in the applications, in principle, any of the numerous existing algorithms for postprocessing wavelet coefficients can also be used in conjunction with the ENO-wavelet coefficients. For example, ENO-wavelet transforms can be used in conjunction with the standard adaptive nonlinear techniques such as hard and soft thresholding, tree structured (e.g., Shapiro's EZW [28]) coders in image compression, and Coifman and Donoho's translation invariant algorithm [10] in denoising. However, in this paper we focus on the construction of ENO-wavelet transforms, and we will not discuss those applications in detail. Instead, we show a numerical example which illustrates the advantages of using the combination of ENO-wavelet transforms with hard thresholding in section 5.

The arrangement of the paper is as follows. In section 2 , we review the standard continuous and discrete wavelet transforms. In section 3, we give a general algorithm to implement the ENO-wavelet transform discretely. In section 4, we prove an error bound for the ENO-wavelet approximation which shows that the error in the ENO-wavelet approximation depends only on the size of the derivative of the function *away*

from the discontinuities. Finally, in section 5, we give some numerical examples to illustrate the main advantage of the ENO-wavelet transforms, including some two-dimensional (2-D) examples.

2. Wavelet transforms. Before we introduce the adaptive ENO-wavelet transforms, we briefly review the standard wavelet transforms; e.g., see [5], [11], [13], [14], [25], [26], [27], and [30]. We use Daubechies orthonormal wavelets as the framework in all discussion in this paper. We will go over both continuous and discrete wavelet transforms, because we will present our ENO-wavelet transforms in the discrete form and prove the approximation error bound by using the continuous form.

First, we review the standard wavelet transforms. To simplify the notation, we assume zeros have been padded to the data at the boundaries.

The standard wavelet transforms are based on translation and dilation. Suppose $\phi(x)$ and $\psi(x)$ are the scaling function and the corresponding wavelet, respectively, with finite support $[0, l]$, where l is a positive integer. It is well known that $\phi(x)$ satisfies the basic dilation equation

$$\phi(x) = \sqrt{2} \sum_{s=0}^{l} c_s \phi(2x - s) \tag{1}$$

and $\psi(x)$ satisfies the corresponding wavelet equation

$$\psi(x) = \sqrt{2} \sum_{s=0}^{l} h_s \phi(2x - s), \tag{2}$$

where the c_s's and h_s's are constants called low pass and high pass filter coefficients, respectively.

We assume that $\psi(x)$ has p vanishing moments

$$\int \psi(x) x^j dx = 0 \qquad \text{for} \quad j = 0, 1, \ldots, p-1. \tag{3}$$

We will use the following standard notations:

$$\phi_{j,i}(x) = 2^{\frac{j}{2}} \phi(2^j x - i) \tag{4}$$

and

$$\psi_{j,i}(x) = 2^{\frac{j}{2}} \phi(2^j x - i). \tag{5}$$

Consider the subspace V_j of L^2 defined by

$$V_j = Span\{\phi_{j,i}(x), i \in Z\}$$

and the subspace W_j of L^2 defined by

$$W_j = Span\{\psi_{j,i}(x), i \in Z\}.$$

The subspaces V_j's, $-\infty < j < \infty$, form a multiresolution of L^2 with the subspace W_j being the difference between V_j and V_{j+1}. In fact, the L^2 space has an orthonormal decomposition as

$$L^2 = V_J \oplus \sum_{j=J}^{\infty} W_j. \tag{6}$$

The projection of a L^2 function $f(x)$ onto the subspace V_j is defined by

$$f_j(x) = \sum_i \alpha_{j,i}\phi_{j,i}(x), \tag{7}$$

where

$$\alpha_{j,i} = \int f(x)\phi_{j,i}(x)dx, \qquad i = \cdots, -1, 0, 1, \ldots, \tag{8}$$

which we call low frequency wavelet coefficients. (They are often called scaling coefficients in many literatures.) Similarly, we can project $f(x)$ onto W_j by

$$w_j(x) = \sum_i \beta_{j,i}\psi_{j,i}(x), \tag{9}$$

where

$$\beta_{j,i} = \int f(x)\psi_{j,i}(x)dx, \quad i = \cdots, -1, 0, 1, \ldots, \tag{10}$$

which we call high frequency wavelet coefficients (often called wavelet coefficients in many literatures). In this paper, we refer to wavelet coefficients as both low and high frequency coefficients. Therefore, the function $f(x)$ can be decomposed by

$$f(x) = f_j(x) + \sum_{t=j}^{\infty} w_t(x). \tag{11}$$

The projection $f_j(x)$ is called the linear approximation of the function $f(x)$ in the subspace V_j.

From (4) and (5), the projection coefficients $\alpha_{j,i}$ and $\beta_{j,i}$ of $f(x)$ in the subspaces V_j and W_j can be easily computed by the so-called fast wavelet transform

$$\alpha_{j,i} = \sum_{s=0}^{l} c_s \alpha_{j+1,2i+s} \tag{12}$$

and

$$\beta_{j,i} = \sum_{s=0}^{l} h_s \alpha_{j+1,2i+s}. \tag{13}$$

In practice, discrete wavelet transforms are often directly used with a set of discrete numbers which are the low frequency coefficients of the L^2 function $f(x)$ at a fine level subspace V_{j+1}. In many applications, this set of numbers are sample values of the function $f(x)$ on a fine grid (although in [30] this is called a "wavelet crime").

Let us define the following matrices:

$$L = \begin{pmatrix} c_0 & c_1 & \cdots & c_l & & & & & \\ & & c_0 & c_1 & \cdots & c_l & & & \\ & & & & \cdots & \cdots & \cdots & & \\ & & & & & c_0 & c_1 & \cdots & c_l \end{pmatrix}$$

and

$$H = \begin{pmatrix} h_0 & h_1 & \cdots & h_l & & & & \\ & & h_0 & h_1 & \cdots & h_l & & \\ & & & & \cdots & \cdots & \cdots & \\ & & & & & h_0 & h_1 & \cdots & h_l \end{pmatrix}.$$

We also denote $\vec{\alpha}_j = (\ldots, \alpha_{j,i}, \alpha_{j,i+1}, \ldots)^T$ and $\vec{\beta}_j = (\ldots, \beta_{j,i}, \beta_{j,i+1}, \ldots)^T$.

By using matrix and vector forms, the fast wavelet transform equations (12) and (13) can be written as

$$\vec{\alpha}_j = L\vec{\alpha}_{j+1} \tag{14}$$

and

$$\vec{\beta}_j = H\vec{\alpha}_{j+1}. \tag{15}$$

It is well known that the wavelet transform matrices L and H are orthogonal:

$$L^*L + H^*H = I. \tag{16}$$

It follows that the inverse wavelet transform is simply

$$\vec{\alpha}_{j+1} = L^*\vec{\alpha}_j + H^*\vec{\beta}_j. \tag{17}$$

The standard linear wavelet approximation achieves maximum accuracy away from discontinuities, but it oscillates near the jumps. The reason for the oscillations is that some stencils cross jumps and cause the corresponding high frequency coefficients to becoming large and therefore more information is lost when the high frequency coefficients are discarded.

In Figure 1, we display a piecewise continuous function (left) and its DB4 wavelet coefficients (right) with low frequencies at the left end and high frequencies at the right end. From the right picture, we see that most of the high frequency coefficients are zero, except for a few large coefficients which are computed near jumps. Figure 2 displays the linear approximation (solid line) compared to the initial function (dotted line). The right picture is the zoom-in to show the approximation behavior near a jump. In this figure, we clearly see oscillations (people call them the Gibbs phenomenon) near discontinuities.

Since the oscillations are generated by discarding large high frequency coefficients which are computed on the stencils crossing discontinuities, to get rid of the oscillations, we want to avoid stencils crossing discontinuities. This motivates us to apply the ENO idea to avoid stencils crossing jumps.

Before we introduce the ENO-wavelet transforms, we give the following definition which we will use in the later sections. Given a function $f(x)$ which has discontinuous set D, then

$$D = \{x_i : f(x) \quad \text{is discontinuous at} \quad x_i\}.$$

Denote t as the closest distance between any two discontinuous points, i.e.,

$$t = \inf\{|x_i - x_j| : x_i, x_j \in D\}.$$

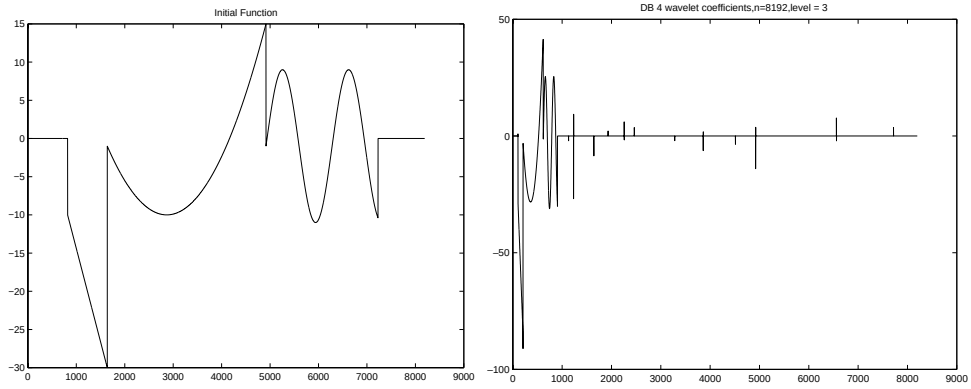

FIG. 1. *The initial function (left) and its DB4 coefficients (right). Most of the high frequency coefficients (right part) are zero except for a few large coefficients computed near the jumps.*

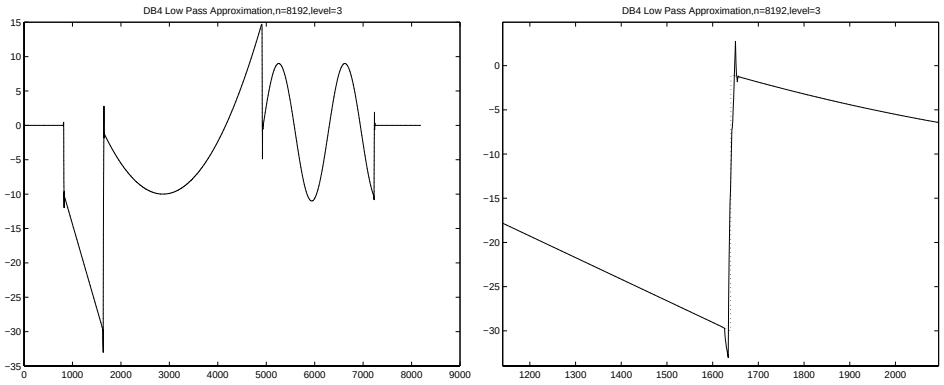

FIG. 2. *The approximation function (left) and its zoom-in (right). Oscillations are generated near the discontinuities in the linear approximation.*

DEFINITION 1. *For a given wavelet filter with stencil length $l+1$, we say a projection of $f(x)$ in space V_j with spatial step $\Delta x = 2^{-j}$ satisfies the* discontinuity separation property *(DSP) if $(l+2)\Delta x < t$.*

A projection satisfying the DSP implies that any one discontinuity is located at least one stencil and two data points away from other discontinuities. In other words, there are no two consecutive stencils containing two discontinuities. We assume that all projections we consider in this paper satisfy the DSP. Since our ENO-wavelet transform is essentially using ENO techniques to modify the standard wavelet transform near discontinuities, this property will avoid the modifications near one discontinuity interacting with the modifications near other discontinuities.

Remark. For any piecewise discontinuous function, a projection will satisfy this DSP if j is sufficiently large, i.e., if the discretization is fine enough. On the other hand, at the place where the DSP is invalid, the approximations produced by the ENO-wavelet transforms are comparable to that by the standard wavelet transforms. We will show numerical examples in section 5 illustrating this point.

3. ENO-wavelet transforms. In this section, we design the ENO-wavelet transforms. In addition to the standard wavelet transforms, our ENO-wavelet

transforms are composed of two phases: locating the jumps and forming the approximations at the discontinuities. First, assuming that the location of the jumps are known, we give the ENO-wavelet approximations at the discontinuities by using one-sided information to avoid oscillations. Then we give the methods to detect the exact subinterval on the next finer grid at which the discontinuity is located.

3.1. ENO-wavelet approximation at discontinuities. In this subsection, we assume that the exact subintervals on the next finer grid at which the discontinuities is located are known. We want to modify the standard wavelet transforms near the jumps such that oscillations can be avoided in the approximation. From ENO schemes, we borrow the idea of using one-sided information to form the approximation and avoid applying the wavelet filters crossing the discontinuities. Since we assume the DSP is satisfied by the given projection of the function $f(x)$, we can just consider the local modification near one jump. The main tool which we use to modify the standard wavelet transforms at the discontinuities is function extrapolation in the function spaces or in the wavelet spaces.

Direct function extrapolation. The first way is to extend the function directly at the discontinuity by extrapolation from both sides. Then we can apply the standard wavelet transforms on the extended functions and avoid computing wavelet coefficients using information from both sides.

To maintain the same approximation accuracy near the discontinuity as that for away from the discontinuity, the extrapolation has to be pth order accurate if the wavelet functions have p vanishing moments. For instance, we use constant extrapolation for Haar wavelets and $(p-1)$th order extrapolation for Daubechies-$2p$ orthogonal wavelets which have p vanishing moments.

We use the diagram in Figure 3 to show how to extend the function and compute the ENO-wavelet coefficients.

As shown in Figure 3, the discontinuity is located between $\{x(2i+l-2), x(2i+l-1)\}$. We extend the function from both sides of the discontinuity using $(p-1)$th order extrapolation; i.e., we use the information from the left side of the jump to extrapolate the function over $\hat{x}(2i+l-1), \ldots, \hat{x}(2i+2l-2)$ and use the information from the right side to extrapolate the function over $\bar{x}(2i), \ldots, \bar{x}(2i+l-2)$. And then for $i \le m \le i+k-2$, where $l = 2k-1$, we can compute the wavelet coefficients $\hat{\alpha}_{j,m}$ and $\hat{\beta}_{j,m}$ from the left side, and compute $\bar{\alpha}_{j,m}$ and $\bar{\beta}_{j,m}$ from the right side by using the standard wavelet transforms, respectively.

In general, we have the low frequency wavelet coefficients on the finer levels instead of knowing the function values themselves near the discontinuities. We extrapolate these finer level coefficients from both sides of the discontinuities to obtain the values of $\hat{\alpha}_{j+1,m}$ and $\bar{\alpha}_{j+1,m}$, and use the fast wavelet transforms (12) and (13) to compute the coarser level coefficients. For instance, we can compute $\hat{\alpha}_{j,i}$ and $\hat{\beta}_{j,i}$ by

$$\begin{aligned}\begin{pmatrix} \hat{\alpha}_{j,i} \\ \hat{\beta}_{j,i} \end{pmatrix} &= \begin{pmatrix} \sum_{s=0}^{l-2} c_s \alpha_{j+1,2i+s} + c_{l-1}\hat{\alpha}_{j+1,2i+l-1} + c_l \hat{\alpha}_{j+1,2i+l} \\ \sum_{s=0}^{l-2} h_s \alpha_{j+1,2i+s} + h_{l-1}\hat{\alpha}_{j+1,2i+l-1} + h_l \hat{\alpha}_{j+1,2i+l} \end{pmatrix} \\ &\equiv \begin{pmatrix} \delta_{j,i} \\ \gamma_{j,i} \end{pmatrix} + A \begin{pmatrix} \hat{\alpha}_{j+1,2i+l-1} \\ \hat{\alpha}_{j+1,2i+l} \end{pmatrix}, \end{aligned} \tag{18}$$

where $\delta_{j,i}$ and $\gamma_{j,i}$ are $\sum_{s=0}^{l-2} c_s \alpha_{j+1,2i+s}$ and $\sum_{s=0}^{l-2} h_s \alpha_{j+1,2i+s}$, respectively, and depend only on the unextrapolated values of $\alpha_{j+1,m}$, and A a 2×2 matrix defined by

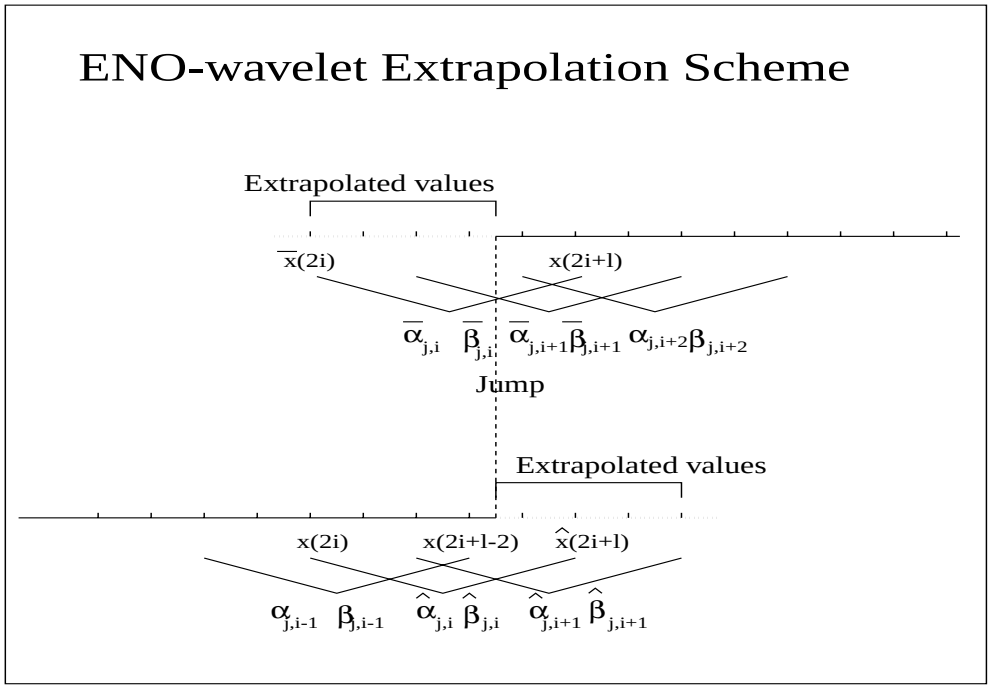

FIG. 3. *Coarse level extrapolation illustration. From the left side of the discontinuity, we extrapolate the low frequency coefficients $\hat{\alpha}_{j,m}$ to determine corresponding high frequency coefficients $\hat{\beta}_{j,m}$ and store them. From the right side of the discontinuity, we extend the high frequency coefficients $\bar{\beta}_{j,m}$ to determine and store the low frequency coefficients $\bar{\alpha}_{j,m}$.*

the filter coefficients as

$$A = \begin{pmatrix} c_{l-1} & c_l \\ h_{l-1} & h_l \end{pmatrix}.$$

In computing $\hat{\alpha}_{j,m}$ and $\hat{\beta}_{j,m}$ by the fast wavelet transforms, the number of extrapolated values we must use is 2 for $m = i$, 4 for $m = i + 1$, and so on. Those extrapolated values are determined from the smooth side of the discontinuity; then the high frequency coefficients $\hat{\beta}_{j,m}$ remain as small values as those of the smooth stencils.

By symmetry, we can compute $\bar{\alpha}_{j,m}$'s and $\bar{\beta}_{j,m}$'s from the right side in a similar way.

There are many methods to extrapolate the extended values. For example, a straightforward way is to use p-point polynomial extrapolation such as Lagrange polynomials or Taylor expansion polynomials. In our numerical experiments in this paper, we use Lagrange polynomial extrapolation. Least square extrapolation can be used too [33], especially for noisy data.

There is a storage problem for this direct function extrapolation. Indeed, it doubles the number of the wavelet coefficients near every discontinuity. To retain the perfect invertible property, we need to store the ENO-wavelet coefficients $\hat{\alpha}_{j,m}$ and $\hat{\beta}_{j,m}$ from the left side, also $\bar{\alpha}_{j,m}$ and $\bar{\beta}_{j,m}$ from the right side. Thus, the output sequences are no longer the same size as the input sequences. In many applications, such as image compression, this extra storage requirement definitely needs to be avoided.

Remark. In the least square extrapolation case, it is possible to reduce the demands of the extra storage because not all the wavelet coefficients $\hat{\alpha}_{j,m}$, $\hat{\beta}_{j,m}$, $\bar{\alpha}_{j,m}$, and $\bar{\beta}_{j,m}$ are linearly independent [33]. However, this requires complicated extra computation.

Our approach: Coarse level extrapolation. To avoid computing the wavelet coefficients using the information from both sides of the discontinuities, to maintain the same high order accuracy near the discontinuities as away from the discontinuities, and also to keep the size of the output sequences the same as that of the input sequences without significant extra computation, we introduce the coarse level extrapolation schemes. The idea is to extrapolate the coarser level wavelet coefficients near the discontinuities instead of the function values or the finer level wavelet coefficients.

We still use Figure 3 to illustrate these schemes. We consider the left side of the jump first.

In the direct function extrapolation case, the computation process is to directly extrapolate the finer level wavelet coefficients $\hat{\alpha}_{j+1,m}$, $(2i+l-1) \le m \le (2i+2l-2)$, and then compute the extended coarser level wavelet coefficients $\hat{\alpha}_{j,m}$ and $\hat{\beta}_{j,m}$, $i \le m \le (i+k-2)$ using the standard filters. We reverse the order of this process in our coarse level extrapolation. More precisely, we extrapolate the coarser level low frequency coefficients $\hat{\alpha}_{j,m}$ using the known low frequency coefficients from the left, and extend the coarser level high frequency coefficients $\hat{\beta}_{j,m}$ to zero (or some predefined values), and then determine the extended finer level wavelet coefficients. For example, in the direct function extrapolation, we extrapolate finer level values $\hat{\alpha}_{j+1,m}$ and then compute the coarser level coefficients $\hat{\alpha}_{j,i}$ and $\hat{\beta}_{j,i}$ by (18). On the contrary, we can first extend the coarser level coefficients $\hat{\alpha}_{j,i}$ and $\hat{\beta}_{j,i}$ and then determine the finer level values. Indeed, if the matrix A is nonsingular, we can uniquely determine the finer level values by solving (18). In this case, we can prescribe both the coarser level coefficients simultaneously. However, in Daubechies orthogonal wavelet transforms, the matrix A is singular, because

$$\frac{h_{l-1}}{c_{l-1}} = \frac{h_l}{c_l}. \tag{19}$$

Thus, in order to have a solution of (18), we must extend the coarser level coefficients $\hat{\alpha}_{j,i}$ and $\hat{\beta}_{j,i}$ in such a way that they satisfy

$$\begin{pmatrix} \hat{\alpha}_{j,i} \\ \hat{\beta}_{j,i} \end{pmatrix} - \begin{pmatrix} \delta_{j,i} \\ \gamma_{j,i} \end{pmatrix} \in R(A),$$

where $R(A)$ is the range space of A. This requirement implies that

$$\begin{pmatrix} -1 & \dfrac{c_l}{h_l} \end{pmatrix} \left[\begin{pmatrix} \hat{\alpha}_{j,i} \\ \hat{\beta}_{j,i} \end{pmatrix} - \begin{pmatrix} \delta_{j,i} \\ \gamma_{j,i} \end{pmatrix} \right] = 0,$$

which we can also rewrite as

$$\hat{\beta}_{j,i} = \gamma_{j,i} + \frac{h_l}{c_l}(\hat{\alpha}_{j,i} - \delta_{j,i}) \tag{20}$$

or

$$\hat{\alpha}_{j,i} = \delta_{j,i} + \frac{c_l}{h_l}(\hat{\beta}_{j,i} - \gamma_{j,i}). \tag{21}$$

Therefore, we cannot prescribe both $\hat{\alpha}_{j,i}$ and $\hat{\beta}_{j,i}$ simultaneously. Thus we have two choices:

(1) We can extrapolate the low frequency coefficients $\hat{\alpha}_{j,i}$ first and then determine the corresponding high frequency coefficients $\hat{\beta}_{j,i}$ by (20).
(2) Or we can extend $\hat{\beta}_{j,i}$ to zero first and then determine the corresponding $\hat{\alpha}_{j,i}$ by (21).

Once coefficients $\hat{\beta}_{j,i}$ and $\hat{\alpha}_{j,i}$ are obtained, we can determine the finer level coefficients $\hat{\alpha}_{j+1,2i+l-1}$ and $\hat{\alpha}_{j+1,2i+l}$. Since A is not invertible for Daubechies wavelets, $\hat{\alpha}_{j+1,2i+l-1}$ and $\hat{\alpha}_{j+1,2i+l}$ cannot be uniquely determined by $\hat{\beta}_{j,i}$ and $\hat{\alpha}_{j,i}$. There is one more freedom left to use. (In the case of the discontinuity being located between $\alpha_{j+1,2i+l-1}$ and $\alpha_{j+1,2i+l}$, $\hat{\alpha}_{j+1,2i+l}$ can be uniquely determined.) Indeed, there are many ways to completely determine the values of $\hat{\alpha}_{j+1,2i+l-1}$ and $\hat{\alpha}_{j+1,2i+l}$. For instance, one can simply extend $\hat{\alpha}_{j+1,2i+l-1}$ by any extrapolation technique, such as $(p-1)$th order polynomial extrapolation for smooth data or averaging extrapolation techniques for noisy data (we use them in our numerical experiments in section 5), and then determine $\hat{\alpha}_{j+1,2i+l}$ by $\hat{\beta}_{j,i}$ or $\hat{\alpha}_{j,i}$. Another possible way to uniquely extend the coefficients $\hat{\alpha}_{j+1,2i+l-1}$ and $\hat{\alpha}_{j+1,2i+l}$ on the finer level is to leave this extra freedom to be used in the next stencil by requiring some special desire properties in the next extended coarser level coefficients. This involves slightly more complicated formulation which we will not exploit further in this paper. Thereafter, the above procedure can be repeatedly used to the next stencil to compute $\hat{\beta}_{j,i+1}$ and $\hat{\alpha}_{j,i+1}$ by treating $\hat{\alpha}_{j+1,2i+l-1}$ and $\hat{\alpha}_{j+1,2i+l}$ as known values. By the same principle, all extended coefficients $\hat{\beta}_{j,m}$ and $\hat{\alpha}_{j,m}$ can be calculated.

Remark. We notice that in both cases (20) and (21) the coefficients are computed by applying the standard filters to the extended data which is smooth. This implies that there are no large coefficients generated by them.

Again by symmetry, we have two analogous choices for the right side of the jump.

Using this coarse level extrapolation technique, we can easily solve the storage problem which we have in the direct function extrapolation. In fact, we just need to store the high frequency coefficients $\hat{\beta}_{j,m}$ for choice (1) and the low frequency coefficients $\hat{\alpha}_{j,m}$ for choice (2). In our implementation, we use choice (1) for the left side of the jumps and choice (2) for the right side of the jumps; therefore we store $\hat{\beta}_{j,m}$ and $\bar{\alpha}_{j,m}$ for every m. This satisfies the standard wavelet storage scheme, i.e., storing one low frequency and one high frequency coefficient for every stencil.

Remark. We select choice (1) from the left side of the jumps and choice (2) from the right side because we want to keep half of the output sequence to be α's and half to be β's. It is possible to select choice (1) or choice (2) for both sides of the jumps, but that will not give equal number of α's and β's in the output sequence; also, it may destroy the data structure for the next level decomposition.

Since we know the way we extend the data at the discontinuities, we can easily extrapolate the low frequency coefficients $\hat{\alpha}_{j,m}$ from the left sides of the discontinuities. Using them together with the stored high frequency coefficients $\hat{\beta}_{j,m}$, we can exactly recover data at the left sides by applying the standard inverse filters. Similarly, the data at the right sides of the discontinuities can also be exactly restored.

For each stencil crossing a jump, an extra cost (in floating point operation) is required in the extrapolation of low frequency coefficients, which is of the order $O(1)$ per stencil, and in the computation of the corresponding high and low frequency coefficients by (20) and (21), which is of the order $O(l)$ per stencil. Overall, the extra cost over the standard wavelet transform is of the order $O(dl)$, where d is the number of discontinuities. Compared to the cost of the standard wavelet transform, which is

of the order $O(nl)$ where n is the size of data, the ratio of the extra cost over that of the standard transform is $O(\frac{d}{n})$, which is independent of l and negligible when n is large.

3.2. Locating the discontinuities. In the previous subsection, we showed how to modify the standard wavelet transforms at the discontinuities to avoid oscillations if we know the exact subinterval on the next finer grid at which the jumps are located. In this subsection, we introduce the methods to detect those exact subintervals for discontinuities for piecewise smooth functions with and without noise. First we give a method for smooth data.

Piecewise smooth functions. Our purpose is to avoid wavelet stencils crossing discontinuities. Theoretically, a discontinuity can be characterized by comparing the left and right limit of the derivatives $f^{(m)}(x)$ at the given point x; i.e., we call a point x a discontinuity if for some $m < p$ we have

$$f^{(m)}(x-) \neq f^{(m)}(x+).$$

We define the intensity of a jump in the mth derivative at x as

$$[f^{(m)}(x)] = |f^{(m)}(x+) - f^{(m)}(x-)|.$$

It is well known that the high pass filters in wavelet transforms measure the smoothness of functions: they produce smaller values at smoother regions and larger values at rougher regions. In fact, it has been shown in [1], [24], and [32] that if a function $f(x)$ is Lipschitz $\gamma \leq p$ at x, i.e., $|f(x+\delta) - f(x)| \leq \delta^\gamma$ for any small δ, the corresponding high frequency wavelet coefficients are of the order of $O(\Delta x^\gamma)$. From this, it is easy to obtain that at smooth regions the magnitudes of high frequency coefficients $|\beta_{j,i}|$ have the order of $|f^{(p)}(x)|O(\Delta x^p)$. On the other hand, if a stencil contains a discontinuity, no matter if it is a discontinuity in function value ($m = 0$) or in its mth derivative, the magnitude of the corresponding high frequency coefficient $|\beta_{j,i}|$ is of the order of $O(\Delta x^{(m)})$, which is at least one order lower than that at the smooth regions. Therefore, instead of fully adopting the ENO comparison idea which compares the magnitudes of divided differences on all possible stencils, we can use the magnitudes of the high frequency coefficients as our criterion to identify the discontinuities.

The obvious way, also the cheapest way, to identify the discontinuities is to compare the magnitudes of the high frequency coefficients on the current standard stencils $|\beta_{j,i}|$ with that on the previous standard stencils $|\beta_{j,i-1}|$. Since for smooth functions we have $|\beta_{j,i}| = |f^{(p)}(x)|O(\Delta x^p)$, this implies that at smooth regions, by Taylor expansion, we have

$$|\beta_{j,i}| = (1 + O(\Delta x))|\beta_{j,i-1}|, \tag{22}$$

where the constant in the term $O(\Delta x)$ depends on the size of higher order derivatives of $f(x)$ such as $\max_x |f^{(p+1)}(x)|$. In contrast, the magnitudes of high frequency coefficients $|\beta_{j,i}|$ based on the stencils containing the discontinuities are at least one order lower than that at the smooth regions. More precisely, if we assume function $f(x)$ has a jump in its mth derivatives at point $x_0 \in (i\Delta x, (i+l)\Delta x)$ for some integer i, using Taylor expansion, in a small neighborhood of x_0, we can write this function as

$$f(x) = g(x) + \begin{cases} f^{(m)}(x_0-)(x-x_0)^m + O(x-x_0)^{(m+1)}, & x \leq x_0, \\ f^{(m)}(x_0+)(x-x_0)^m + O(x-x_0)^{(m+1)}, & x_0 < x, \end{cases}$$

where $g(x)$ is its Taylor polynomial of order $m-1$ near x_0. Then the wavelet coefficients $\beta_{j,i}$ is estimated by using the vanishing moments property as

$$\begin{aligned}|\beta_{j,i}| &= \left|\int f(x)\psi_{j,i}(x)dx\right| \\ &= \left|\int_{i\Delta x}^{x_0}(f^{(m)}(x_0-)(x-x_0)^m + O(x-x_0)^{m+1})\psi_{j,i}(x)dx\right. \\ &\quad \left. + \int_{x_0}^{(i+l)\Delta x}(f^{(m)}(x_0+)(x-x_0)^m + O(x-x_0)^{m+1})\psi_{j,i}(x)dx\right| \\ &= |[f^{(m)}(x_0)]|O(\Delta x^m).\end{aligned}$$

It depends on the Δx^m and also on the intensity of the jump.

Thus, we can design a method to detect the discontinuities as follows: For each standard stencil, suppose we know that the previous standard stencil does not contain any discontinuities, if we have $|\beta_{j,i}| \le a|\beta_{j,i-1}|$, where $a > 1$ is a given constant, and then we treat the current stencil as a smooth stencil. Otherwise, we conclude that there are discontinuities contained in it.

The choice of constant a depends on the grid size Δx and also on the intensity of the jumps. In fact, the ratio between a high frequency coefficient at the rough regions and that at the smooth regions is of the order of $|[f^{(m)}(x)]|O(\Delta x^{(m-p)})$. When Δx becomes small, this ratio is large. We can choose a as any number such that

$$(1 + O(\Delta x)) \le a \le \min_x\{|[f^{(m)}(x)]|O(\Delta x^{(m-p)})\}, \tag{23}$$

provided the above minimal number is larger than $1+O(\Delta x)$. This is always true for piecewise smooth functions with small enough grid size Δx.

Remark. When a jump in the mth derivative has very small intensity less than $O(\Delta x^{(p-m)})$, this jump cannot be detected by the above-described method. However, the error caused by missing this jump is also very small, which is at the same order of the error bound we will give in section 4. In practice, especially when we care only about the jumps in function values, we have a large range to select a.

To completely avoid oscillations, we also need to know the exact locations of the discontinuities so that we can avoid computing the wavelet coefficients crossing them. In fact, the above comparison method based on the magnitudes of high frequency coefficients can also help us to locate the exact positions of the discontinuities. We will use the diagram in Figure 4 to explain how to find the exact jump positions.

Assume we consider the wavelet filters with length $(l+1)$. We compare the magnitude of the high frequency coefficient $|\beta_{j,i}|$ on the current stencil, which starts at $x(2i)$ with $|\beta_{j,i-1}|$ on the previous stencil. If we have $|\beta_{j,i}| > a|\beta_{j,i-1}|$, we identify the discontinuity lying in the current stencil. Since there are no discontinuities in the previous stencils, we know that this discontinuity must be located between $\{x(2i+l-2), x(2i+l)\}$, where it has only two possible positions: between $\{x(2i+l-2), x(2i+l-1)\}$ or between $\{x(2i+l-1), x(2i+l)\}$. In fact, we can determine the exact position of the jump by continuing to compare the subsequent values of $\beta_{j,m}$. As shown in Figure 4, we must have at least $(k-1)$ consecutive "large" $\beta_{j,m}$, $i \le m \le (i+k-2)$, because the subsequent $(k-1)$ stencils also include the discontinuity. We compute $\beta_{j,i+k-1}$ and $\beta_{j,i+k}$ on the corresponding standard stencils, if we have $|\beta_{j,i+k-1}| > a|\beta_{j,i+k}|$, and then we have k consecutive stencils containing the discontinuity, which implies that the discontinuity is located between $\{x(2i+l-1), x(2i+2l-1)\}$ (see Figure 4(a)).

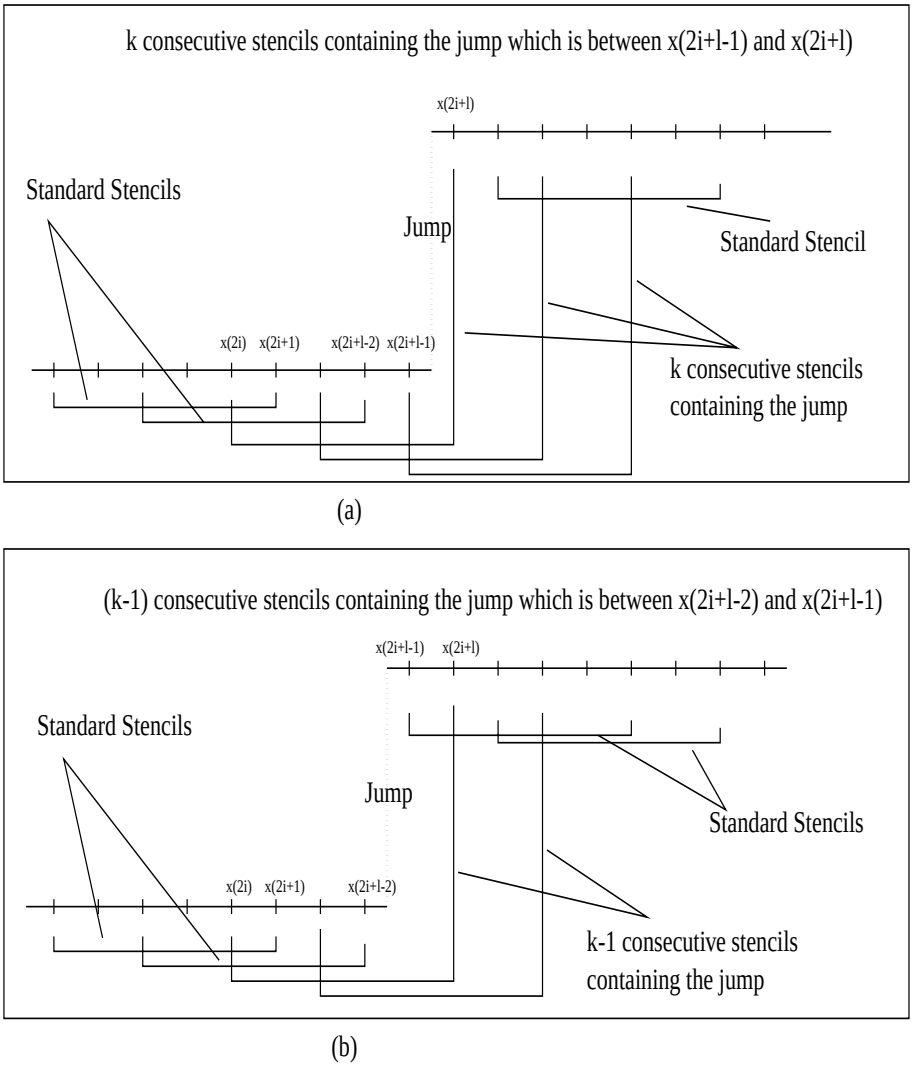

FIG. 4. *Locating the exact position of the jump by counting the number of consecutive stencils containing the jump.* (a) *If k stencils contain the jump, then the jump position is between $x(2i+l-1)$ and $x(2i+l)$.* (b) *If $(k-1)$ consecutive stencils contain the jump, then the jump is located between $x(2i+l-2)$ and $x(2i+l-1)$.*

If we have exactly $(k-1)$ consecutive standard stencils containing the discontinuity, then this implies that the jump must be located between $\{x(2i+l-2),\, x(2i+l-1)\}$ (see Figure 4(b)). We summarize the above arguments in the following proposition.

PROPOSITION 1. *Consider the wavelet filters with length $l+1$, where $l = 2k-1$. For a given index i, assume we have $|\beta_{j,i-1}| \le a|\beta_{j,i-2}|$ but $|\beta_{j,i}| > a|\beta_{j,i-1}|$. Then*

1. *if $|\beta_{j,i+k-1}| > a|\beta_{j,i+k}|$, which means there are k consecutive standard stencils containing the jump, then the discontinuity is located between $\{x(2i+l-1),\, x(2i+l)\}$;*
2. *or else we have $|\beta_{j,i+k-1}| \le a|\beta_{j,i+k}|$, which implies that there are $(k-1)$ consecutive standard stencils containing the jump, and then the discontinuity*

is located between $\{x(2i+l-2),\ x(2i+l-1)\}$.

The extra cost introduced by this comparison jump identification method over the standard wavelet transforms is just the comparison $|\beta_{j,i}| > a|\beta_{j,i-1}|$ for each stencil. In section 5, we use this detection method for all noise-free numerical examples.

Noisy data. The above-described detection method may not be reliable if the function is polluted by noise, especially when the noise is "large." This is because the high frequency coefficients β's may not be able to measure the correct order of smoothness of the functions. Indeed, the high frequency coefficients have the order $\|f^{(p)}(x)+\sigma n^{(p)}(x)\|O(\Delta x^p)$, where $n(x)$ is the random noise and σ a positive number indicating the noise level. In general, the derivatives of the noise $n^{(p)}(x)$ have large values. The noise term $\sigma n^{(p)}(x)$ can dominate the function term $f^{(p)}(x)$ if the noise level σ is large and thus the high frequency coefficients β's may not be able to detect certain discontinuities, e.g., if the jump is small or the discontinuity is in the higher derivatives. In this situation, we need to use heuristics to locate the exact position of the essential discontinuities. Here, we give a simple method to detect the significant large jumps in function values in noisy data.

In many applications, such as in image processing, large discontinuities in function value are the most significant features. Using the standard wavelet transforms, these large discontinuities will generate high frequency coefficients which can be much larger than those generated by the noise. (This is also the fundamental principle in the design of wavelet thresholding.) A simple way to detect these kinds of discontinuities is to look for these large magnitude high frequency coefficients and then compare the data values in the corresponding stencils to locate the exact jump positions. For example, we can look for the places which have the largest difference between two adjacent data values within the stencils. In our numerical experiments, we found that this simple way works very well in practice. In section 5, we will show an example using this method.

Remark. Other jump detection methods can be used for noisy data. As long as the exact subintervals of the discontinuities on the next finer grid are correctly determined, the coarse level ENO-wavelet approximations can be formed at the discontinuities, and our experience shows that it is not sensitive to the presence of noise.

In the ENO-wavelet transforms, to retain the perfect invertibility property, we need to store the adaptive information near every discontinuity, i.e., the exact location of the jump. The reason can also be illustrated by using Figure 4. If there is a jump in the low frequency coefficients (after down sampling) on the coarser level, one can predict a jump in the finer level coefficients. One can further identify the jump existing, for example, between $\{x(2i+l-2),\ x(2i+l)\}$ due to the down sampling. However, as shown in the diagram in Figure 4, for each identified jump, there are two possible locations, i.e., between $\{x(2i+l-2),\ x(2i+l-1)\}$ or between $\{x(2i+l-1),\ x(2i+l)\}$, in the finer level coefficients. Therefore, in order to achieve the perfect reconstruction, the exact locations of discontinuities have to be recorded. In our implementation, we just use one extra bit for each stencil near the discontinuities to indicate it contains a discontinuity. In the application of compression, which aims to reduce the total storage of representing an image, these extra bits need to be taken into account carefully. However, this is beyond the scope of this paper, and we will not discuss it here.

3.3. Forward and inverse transform algorithms. In this subsection, we explicitly present the complete one level forward and inverse ENO-wavelet transform algorithms for the noise-free piecewise smooth data.

We consider the forward transform algorithms first. We denote by $\{c_0, \ldots, c_l\}$ and $\{h_0, \ldots, h_l\}$ the standard wavelet filter coefficients, and by $\{r_0, \ldots, r_l\}$ and $\{d_0, \ldots, d_l\}$ the corresponding inverse filter coefficients. In this paper, since we consider Daubechies orthonormal wavelets, these inverse filter coefficients are defined as $r_s = (-1)^{s+1}h_s$, and $d_s = (-1)^s c_s$, for $s = 0, 1, \ldots, l$. We use a one-bit variable s_i to indicate whether a stencil contains a jump in our algorithms.

Forward Transform Algorithm.

For each i,

(i) compute $\beta_{j,i}$ by (13).

(ii) If $|\beta_{j,i}| \geq a|\beta_{j,i-1}|$ and $|\beta_{j,i}| \geq \epsilon$, then

- compute $\beta_{j,i+k-1}$ and $\beta_{j,i+k}$ by (13).
- Find the exact subinterval of the jump by Proposition 1. For $i \leq m \leq i+k$ or $i \leq m \leq i+k-1$,
  - for the left side of the jump, compute $\hat{\alpha}_{j,m}$ by extrapolation, compute $\hat{\beta}_{j,m}$ by (20), and then set
$$\beta_{j,m} = \hat{\beta}_{j,m}, s_i = 1;$$
  - for the right side of the jump, set $\bar{\beta}_{j,m} = 0$ and compute $\bar{\alpha}_{j,m}$ by (21), and set
$$\alpha_{j,m} = \bar{\alpha}_{j,m}.$$

(iii) Otherwise, compute $\alpha_{j,i}$ by (12). Set $s_i = 0$.

In the algorithm, ϵ is a predefined small positive number which is used to prevent the numerical instability caused by small $\beta_{j,i}$. More precisely, if both $\beta_{j,i}$ and $\beta_{j,i-1}$ are less than the given tolerance ϵ, we treat the current standard stencil as a smooth stencil.

In step (ii), it is possible to use any extrapolation techniques to handle the discontinuities.

Here, we just described the algorithm for one level ENO-wavelet transform with input data sequence $\alpha_{j+1,i}$, and output data $\alpha_{j,i}$ and $\beta_{j,i}$. The coefficient sequences $\alpha_{j,i}$ and $\beta_{j,i}$ have the same size, and their combined size is the same as the input data size at level $j+1$. The multiresolution transform algorithms can be constructed straightforwardly by recursively applying the one level transform to the low frequency coefficients $\alpha_{j,i}$. This is accomplished in the same way as that of the standard multiresolution algorithms. We do not explicitly include them in this paper. Similarly, we present the one level inverse transforms next.

Inverse Transform Algorithm.

For each i,

(i) if $s_i = 0$ and $s_j = 0$, $j = i-k, \ldots, i-1$, then the standard inverse wavelet transforms are applied:

$$\alpha_{j+1,2i} = \sum_{s=0}^{l} (r_{2s+1}\alpha_{j,i-s} + d_{2s+1}\beta_{j,i-s}) \tag{24}$$

and

$$\alpha_{j+1,2i+1} = \sum_{s=0}^{l} (r_{2s}\alpha_{j,i-s} + d_{2s}\beta_{j,i-s}). \tag{25}$$

(ii) If $s_j = 1$, $i-k \le j \le i$ or $i-k+1 \le j \le i$,
- use Proposition 1 to locate the position of the jump by counting the number of consecutive $s_i = 1$;
- extrapolate $\hat{\alpha}_{j,i}$ from the left side of the jump;
- set $\bar{\beta}_{j,i}$ as zero for the right side of the jump;
- use $\hat{\alpha}_{j,k}$ and $\beta_{j,k}$ to restore the left side by (24) and (25);
- use $\alpha_{j,k}$ and $\bar{\beta}_{j,k}$ to restore the right side of the jump by (24) and (25).

Two simple examples. We give two simple examples in the ENO-Haar and ENO-DB4 cases to illustrate the algorithms. First, we consider computing the transform coefficients of the following initial data:

$$\begin{pmatrix} 1 & 1 & 1 & 2 & 2 & 2 \end{pmatrix}.$$

The standard Haar produces the low and high frequency coefficients

$$\alpha = \begin{pmatrix} \frac{2}{\sqrt{2}} & \frac{3}{\sqrt{2}} & \frac{4}{\sqrt{2}} \end{pmatrix}, \qquad \beta = \begin{pmatrix} 0 & -\frac{1}{\sqrt{2}} & 0 \end{pmatrix}.$$

The corresponding linear approximation is

$$\begin{pmatrix} 1 & 1 & \frac{3}{2} & \frac{3}{2} & 2 & 2 \end{pmatrix},$$

which cannot recover the discontinuity correctly.

Using the ENO-Haar wavelet, we break the initial data sequence into two smooth pieces as shown in the following two rows:

$$\begin{pmatrix} & & y & 2 & 2 & 2 \\ 1 & 1 & 1 & x & & \end{pmatrix},$$

where x and y are some smooth extensions of the corresponding pieces. In fact, we extend x in a way such that the low frequency coefficient $\hat{\alpha}_2$ (boxed in (26)) based on the stencil $(1, x)$ is the same as the previous α_1, which is based on the stencil $(1, 1)$ giving $x = 1$. Similarly, we extend y in a way such that the high frequency coefficient $\bar{\beta}_2$ (boxed in (26)) is zero giving $y = 2$. Therefore we compute the high frequency coefficients $\hat{\beta}_2$ based on stencil $(1, x)$ and the low frequency coefficients $\bar{\alpha}_2$ based on stencil $(y, 2)$ by using the corresponding standard filters giving $\hat{\beta}_2 = 0$ and $\bar{\alpha}_2 = \frac{4}{\sqrt{2}}$. Thus we have the coefficients

$$\alpha = \begin{pmatrix} & \frac{4}{\sqrt{2}} & \frac{4}{\sqrt{2}} \\ \frac{2}{\sqrt{2}} & \boxed{\frac{2}{\sqrt{2}}} & \end{pmatrix}, \qquad \beta = \begin{pmatrix} & \boxed{0} & 0 \\ 0 & 0 & \end{pmatrix}. \tag{26}$$

Since we know how we extended $\hat{\alpha}_2$ and $\bar{\beta}_2$, we do not need to store them. In fact, we just need to store the low and high frequency coefficients as

$$\alpha = \begin{pmatrix} \frac{2}{\sqrt{2}} & \frac{4}{\sqrt{2}} & \frac{4}{\sqrt{2}} \end{pmatrix}, \qquad \beta = \begin{pmatrix} 0 & 0 & 0 \end{pmatrix},$$

which have the same storage schemes as the standard Haar wavelet transform.

When we reconstruct the linear approximation, we can first recover $\hat{\alpha}_2$ and $\bar{\beta}_2$ the same way as in the forward transform and then apply the standard inverse filters to the smooth data to build the approximation. In fact, in this case the linear approximation is exactly the initial data.

In the next example, we show a similar example in which the ENO-DB4 linear approximation is not exactly the same as the initial data, but it still preserves the jump well. The initial data is given as

$$a = \begin{pmatrix} 0 & 1 & 2 & 3 & 4.1 & 5 & 20 & 21 & 22 & 23 \end{pmatrix}.$$

To better demonstrate the coarse level extrapolation idea, we ignore the boundary extension at two ends of the array. We leave out the coefficients based on the boundary extension at the two ends and display only the coefficients corresponding to the middle part of the array. The DB4 filters are given by the low pass filter $(0.4830 \quad 0.8365 \quad 0.2241 \quad -0.1294)$ and the high pass filter $(-0.1294 \quad -0.2241 \quad 0.8365 \quad -0.4830)$. The standard DB4 low and high frequency coefficients (α_2 to α_5 and β_2 to β_5) are

$$\alpha = \begin{pmatrix} 0.8966 & 3.7474 & 7.9280 & 29.1808 \end{pmatrix}$$

and

$$\beta = \begin{pmatrix} -0.0000 & 0.0837 & 4.9368 & -0.0000 \end{pmatrix}.$$

Notice that in this case we have a large high frequency coefficient β_3 which corresponds to the discontinuity between $a_6 = 5$ and $a_7 = 20$ in the array. If we discard the high frequency part, the corresponding linear approximation for the central part of the array around the jump (from $a_3 = 2$ to $a_8 = 21$) is

$$\begin{pmatrix} 2.0108 & 3.0187 & 4.6689 & 6.1470 & 15.8703 & 23.3843 \end{pmatrix},$$

and the discontinuity cannot be preserved.

Using the ENO-DB4 wavelet, we break the initial data sequence into two smooth pieces as shown in the following two rows:

$$\begin{pmatrix} & & & & u & v & 20 & 21 & 22 & 23 \\ 0 & 1 & 2 & 3 & 4.1 & 5 & x & y & & \end{pmatrix},$$

where (x, y) and (u, v) are some smooth extensions of the corresponding pieces. In fact, we extend (x, y) in such a way that the low frequency coefficient $\hat{\alpha}_3 = 6.5983$ (boxed in (27)) based on the stencil $(4.1, 5, x, y)$ is the linear extension of the previous α_1 and α_2. Similarly, we extend (u, v) in such a way that the high frequency coefficient $\bar{\beta}_3$ (boxed in (28)) is zero. Therefore we compute the high frequency coefficients $\hat{\beta}_3$ based on stencil $(4.1, 5, x, y)$ by (20) giving $\hat{\beta}_3 = -0.0259$ and the low frequency coefficients $\bar{\alpha}_3$ based on stencil $(u, v, 20, 21)$ by the analogy of (20) at the right side of a jump giving $\bar{\alpha}_3 = 26.3524$. Thus we have the coefficients

$$\alpha = \begin{pmatrix} & & 26.3524 & 29.1808 \\ 0.8966 & 3.7474 & \boxed{6.5983} & \end{pmatrix} \tag{27}$$

and

$$\beta = \begin{pmatrix} & & \boxed{0} & 0 \\ 0 & 0.0837 & -0.0259 & \end{pmatrix}. \tag{28}$$

Since we know how we extended $\hat{\alpha}_3$ and $\bar{\beta}_3$, we do not need to store them. In fact, we just need to store the low and high frequency coefficients as

$$\alpha = \begin{pmatrix} 0.8966 & 3.7474 & 26.3524 & 29.1808 \end{pmatrix}, \qquad \beta = \begin{pmatrix} 0 & 0.0837 & -0.0259 & 0 \end{pmatrix},$$

which have the same storage schemes as the standard DB4 wavelet transform.

The recovered linear approximation for a_3 to a_8 is

$$\begin{pmatrix} 2.0108 & 3.0187 & 4.0267 & 5.0346 & 20.0000 & 21.0000 \end{pmatrix}.$$

In this case, although the linear approximation is not the same as the initial data, it forms a much more accurate approximation than that of the standard DB4 transform. More importantly, this approximation preserves the discontinuity sharply in contrast to the standard DB4 wavelet which smears the discontinuity.

Remarks.

(i) The ENO-wavelet transforms are just simple modifications of the standard wavelet transforms near discontinuities. The computational complexity of the algorithms remains $O(n)$, and they are relatively easy to implement.

(ii) In the transform algorithms and the corresponding inverse algorithms, the extended low frequency coefficients $\hat{\alpha}_{j,m}$ and the high frequency coefficients $\bar{\beta}_{j,m}$ can be computed by other extrapolation schemes such as least square extrapolation. This may be more robust, especially for noisy data.

(iii) The adaptive ENO-wavelet idea can also be used for other kind of wavelets. They do not necessarily have to be orthogonal wavelets. For instance, one can apply it to the biorthonormal wavelets.

(iv) Like other wavelet transforms, 2-D or even higher-dimensional transforms can be formed by tensor products. In the numerical example section, we will give a 2-D example.

(v) The adaptive ENO-wavelet idea can be recursively used even if the projections do not satisfy the DSP. In such a case, of course we will not get the nice error bound (see section 4), but the approximation errors are comparable to that of the standard wavelet transforms. Also, it is easy to modify the algorithms such that the standard wavelet transforms are applied at the place where the DSP is invalid.

4. Approximation error. In this section, we consider the ENO-wavelet approximation error for piecewise continuous functions.

Given a function $f(x)$ in L^2, in standard wavelet theory [27], [14], [30], it can be linearly approximated by its projection $f_j(x)$ in V_j as in (7) and (8). This linear approximation has a standard error estimate which we state in the following theorem; see also [30].

THEOREM 1. *Suppose the wavelet $\psi(x)$ generated by scaling function $\phi(x)$ has p vanishing moments and $f_j(x)$ is the approximation of $f(x)$, which has bounded pth order derivative, in V_j with basis $\phi_{j,k}(x)$; then,*

$$\|f(x) - f_j(x)\| \le C(\Delta x)^p \|f^{(p)}(x)\|, \tag{29}$$

where $\Delta x = 2^{-j}$ and C is a constant which is independent of j.

This theorem holds for the L^2 norm in general. Moreover, if the scaling function and its wavelet have finite support, then it also holds for the L^∞ norm.

In this theorem, we can see that the approximation error is controlled by two factors. One is the pth power of the spatial step Δx; the other is the norm of the pth derivative of the function. This error bound does not hold if the function does not have the finite pth derivative. This implies that the approximation could be poor for irregular functions even if the spatial step Δx is small. For piecewise continuous functions, especially functions with large jumps, the approximation error cannot be controlled as smooth functions. In fact, in the standard approximation function $f_j(x)$,

oscillations are generated near the discontinuous points, and they will not disappear even if the spatial step size is reduced (the Gibbs phenomenon).

In contrast, in our ENO-wavelet transforms, since no approximation coefficients are computed using information from both sides of the discontinuities, we can obtain a similar error estimate without taking derivatives across the jumps. In the next theorem, we state the estimation and prove it in the rest of this section.

THEOREM 2. *Suppose the scaling function $\phi(x)$ and its $\psi(x)$ have finite support in $[0, l]$, $\psi(x)$ has p vanishing moments, $f(x)$ is a piecewise continuous function in $[a, b]$ with bounded pth derivatives in each piece of smooth regions, and $f_j(x)$ is its jth level ENO-wavelet projection obtained by using any one of the three extrapolation methods given in section* 2.4 *with the choice of a satisfying* (23). *If the projection $f_{j+1}(x)$ satisfies the DSP, then*

$$\|f(x) - f_j(x)\| \le C(\Delta x)^p \|f^{(p)}(x)\|_{(a,b)\setminus D}, \tag{30}$$

where $\Delta x = 2^{-j}$ and D is the set where $f(x)$ has jumps in the function value or up to the pth derivatives. The norm $\|\cdot\|$ can be either the L^2 or the L^∞ norm.

Proof. We prove the inequality (30) under the L^∞ norm, and the L^2 result can be obtained in a similar way.

According to section 3.2, with the choice of a, all jumps in set D will be detected by the algorithms described for the piecewise smooth data unless the intensity of the jump is less than $O(\Delta x^{(p-m)})$, where the jump is in the mth derivative. In the latter case, the error caused by missing the jump is of the order of $O(\Delta x^p)$, which can be absorbed by the right-hand side of (30).

The DSP allows us to separate the discontinuities and individually consider a small neighborhood around each jump. Therefore, to simplify the discussion without loss of generality, we consider a piecewise function $f(x)$ with one jump at the origin. In other words,

$$f(x) = \begin{cases} f_1(x), & a \le x < 0, \\ f_2(x), & 0 \le x \le b, \end{cases}$$

where $f_1(x) \in C^p[a, 0]$ and $f_2(x) \in C^p[0, b]$. Because both $\phi_{j,i}(x)$ and $\psi_{j,i}(x)$ have support $[i, (l+i)\Delta x]$, the small neighborhood affected by the ENO decision is $[-l\Delta x, l\Delta x]$. In fact, the ENO-wavelet coefficients depend only on one-sided information and therefore, by symmetry, we just need to prove (30) in $[-l\Delta x, 0]$.

Before we prove that (30) holds for the three types of extrapolation methods, namely direct function extrapolation and the two choices of coarse level extension ((1) and (2) in section 3.1), we give some notations which we will frequently use in the proof.

Denote by $g_1(x)$ the $(p-1)$th order polynomial which is the first p term of the Taylor expansion of $f_1(x)$ at the origin, i.e.,

$$f_1(x) = g_1(x) + \frac{f_1^{(p)}(\xi)}{p!} x^p, \tag{31}$$

where ξ is in interval $[-l\Delta x, 0]$. Also denote by $\alpha_{j,m}$ and $\beta_{j,m}$ the ENO-wavelet low and high frequency coefficients, respectively, and $\bar{\alpha}_{j,m}$ the low frequency coefficients of the polynomial $g_1(x)$, i.e.,

$$\bar{\alpha}_{j,m} = \int g_1(x)\phi_{j,m}(x)dx$$

and

$$g_{1,j}(x) = \sum_m \bar{\alpha}_{j,m}\phi_{j,m}(x).$$

As we mentioned in section 3.1, different techniques can be used for extrapolation. Here we select the extrapolation by Taylor expansion as our starting point throughout the proof because of its simplicity. For other types of extrapolation techniques, the proof can be directly generalized by taking into account the difference between that type of extrapolation and the Taylor expansion extrapolation. For instance, the classical approximation result shows us that the difference between the Lagrange extrapolation that we use in the numerical experiments in this paper and Taylor expansion extrapolation is of the order of $O(\Delta x^p)$, which will be absorbed into the right-hand side of the estimate (30).

Now we are ready to prove that (30) holds for the three types of extrapolation methods. We first prove (30) for direct function extrapolation.

Direct function extrapolation. The direct function extrapolation extends $f_1(x)$ to interval $[0, l\Delta x]$ by defining

$$f_d(x) = \begin{cases} f_1(x), & -l\Delta x \le x < 0, \\ g_1(x), & 0 \le x \le l\Delta x. \end{cases}$$

The corresponding ENO-wavelet low frequency coefficients $\alpha_{j,m}$ are computed by

$$\alpha_{j,m} = \int f_d(x)\phi_{j,m}(x)dx, \tag{32}$$

and the approximation function is defined as

$$f_{d,j}(x) = \sum_m \alpha_{j,m}\phi_{j,m}(x), \qquad x \in [-l\Delta x, 0]. \tag{33}$$

For any point $x_0 \in [-l\Delta x, 0]$, by using (31) and the fact that since $g_1(x)$ is a $(p-1)$th order polynomial, $g_{1,j}(x) = g_1(x)$, we have

$$\begin{aligned} |f_1(x_0) - f_{d,j}(x_0)| &\le |f_1(x_0) - g_1(x_0)| + |g_{1,j}(x_0) - f_{d,j}(x_0)| \\ &\le C(\Delta x)^p \|f_1^{(p)}\| + |g_{1,j}(x_0) - f_{d,j}(x_0)|. \end{aligned} \tag{34}$$

Let q be an integer in $[-l, 0]$ such that $x_0 \in [q\Delta x, (q+1)\Delta x)$; then the last term of (34) can be bounded by

$$\begin{aligned} |g_{1,j}(x_0) - f_{d,j}(x_0)| &= \left| \sum_m (\bar{\alpha}_{j,m} - \alpha_{j,m})\phi_{j,m}(x_0) \right| \\ &\le \sum_{q-l \le m \le q} |\bar{\alpha}_{j,m} - \alpha_{j,m}||\phi_{j,m}(x_0)| \\ &= \sum_{q-l \le m \le q} |\bar{\alpha}_{j,m} - \alpha_{j,m}||(\Delta x)^{-\frac{1}{2}}\phi(2^j x_0 - m)|. \end{aligned} \tag{35}$$

To prove (30), we now need to estimate $|\bar{\alpha}_{j,m} - \alpha_{j,m}|$. Since when $m \le -l$ the coefficients are computed in the standard manner, i.e., $\bar{\alpha}_{j,m} = \alpha_{j,m}$, we just need to

consider all m with $-l+1 \le m \le 0$. In fact, we have

$$\begin{aligned}|\bar{\alpha}_{j,m} - \alpha_{j,m}| &= \left| \int (f_d(x) - g_1(x))\phi_{j,m}(x)dx \right| \\ &\le \left| \int_{m\Delta x}^{0} (f_d(x) - g_1(x))\phi_{j,m}(x)dx \right| \\ &\quad + \left| \int_{0}^{(m+l)\Delta x} (f_d(x) - g_1(x))\phi_{j,m}(x)dx \right|.\end{aligned}$$

Because $f_d(x)$ is the same as $g_1(x)$ in $[0, (m+l)\Delta x]$, using (31), we have

$$\begin{aligned}|\bar{\alpha}_{j,m} - \alpha_{j,m}| &= \left| \int_{m\Delta x}^{0} (f_1(x) - g_1(x))\phi_{j,m}(x)dx \right| \\ &\le \left(\int_{m\Delta x}^{0} |f_1(x) - g_1(x)|^2 dx \right)^{\frac{1}{2}} \left(\int_{m\Delta x}^{0} |\phi_{j,m}(x)|^2 dx \right)^{\frac{1}{2}} \\ &\le C(\Delta x)^p \|f^{(p)}\| (\Delta x)^{\frac{1}{2}} \\ &\le C(\Delta x)^{p+\frac{1}{2}} \|f^{(p)}\|.\end{aligned}$$

Therefore, combining this with (35), we have

$$|g_{1,j}(x_0) - f_{d,j}(x_0)| \le C(\Delta x)^p \|f^{(p)}\|.$$

This and (34) complete the proof of (30) for the case of direct function extrapolation.

Coarse level extrapolation. As described in section 3.1, there are two ways of extrapolating coefficients on the coarse level. One way is to set the extended high frequencies to zero. The other way is to extrapolate the low frequency coefficients by a $(p-1)$th order polynomial in wavelet space. In the following part of the proof, we consider them separately.

We consider the high frequency zero extension first.

Similar to the direct function extrapolation, we also extend $f_1(x)$ to the interval $[0, l\Delta x]$ and denote it by

$$f_h(x) = \begin{cases} f_1(x), & x \in [-l\Delta x, 0], \\ g_h(x), & x \in (0, l\Delta x], \end{cases}$$

where $g_h(x)$ is implicitly defined such that it makes $f_h(x)$ satisfy

$$\int f_h(x)\psi_{j,m}(x)dx = 0, \qquad -l+1 \le m \le 0, \tag{36}$$

and

$$\int f_h(x)\phi_{j,m}(x)dx = \alpha_{j,m}, \qquad -l+1 \le m \le 0. \tag{37}$$

The difference between $f_d(x)$ and $f_h(x)$ is that in the direct function extrapolation $f_d(x)$ we know that $g_1(x)$ is the $(p-1)$th order polynomial, but in this case $g_h(x)$ is unknown.

Formally following the proof of (30) for the direct function extrapolation, (34) and (35) also hold for this case. Therefore, we need only to estimate $|\bar{\alpha}_{j,m} - \alpha_{j,m}|, -l+1 \le$

$m \le 0$. We consider $m = -l+1$ first. Unlike in the direct function extrapolation, where $|\bar{\alpha}_{j,-l+1} - \alpha_{j,-l+1}|$ can be computed directly by the Taylor expansion, here we cannot bound $|\bar{\alpha}_{j,-l+1} - \alpha_{j,-l+1}|$ in the same way. Instead, we use the following trick to obtain the estimate we need.

From the dilation equation (1) and the wavelet equation (2), we have the following relationships:

$$\phi_{j,m}(x) = \sum_{s=0}^{l} c_s \phi_{j+1,s+2m}(x) \tag{38}$$

and

$$\psi_{j,m}(x) = \sum_{s=0}^{l} h_s \phi_{j+1,s+2m}(x). \tag{39}$$

Using (38), $\bar{\alpha}_{j,-l+1}$ and $\alpha_{j,-l+1}$ can be computed by

$$\alpha_{j,-l+1} = \int f_h(x)\phi_{j,-l+1}(x)dx = \sum_{s=0}^{l} c_s \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} f_h(x)\phi_{j+1,s-2l+2}(x)dx$$

and

$$\bar{\alpha}_{j,-l+1} = \int g_1(x)\phi_{j,-l+1}(x)dx = \sum_{s=0}^{l} c_s \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} g_1(x)\phi_{j+1,s-2l+2}(x)dx.$$

Therefore, we have

$$\begin{aligned} |\bar{\alpha}_{j,-l+1} - \alpha_{j,-l+1}| \le & \left| \sum_{s=0}^{l-2} c_s \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} (g_1(x) - f_h(x))\phi_{j+1,s-2l+2}(x)dx \right| \\ & + \left| c_{l-1} \int_{\frac{\Delta x}{2}(-l+1)}^{\frac{\Delta x}{2}} (g_1(x) - f_h(x))\phi_{j+1,1-l}(x)dx \right. \\ & \left. + c_l \int_{\frac{\Delta x}{2}(-l+2)}^{\Delta x} (g_1(x) - f_h(x))\phi_{j+1,2-l}(x)dx \right|. \end{aligned} \tag{40}$$

We know that only the last two terms involve the value of $f_h(x)$ in $[0, \Delta x]$. The other terms use $f_h(x)$ in $[-l\Delta x, 0]$, which is $f_1(x)$. Then, by Taylor expansion and Schwartz inequality,

$$\left| \sum_{s=0}^{l-2} c_s \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} (g_1(x) - f_h(x))\phi_{j+1,s-2l+2}(x)dx \right| \le C(\Delta x)^p \|f_1^{(p)}\| 2^{\frac{-(j+1)}{2}}. \tag{41}$$

Thus, to bound $|\bar{\alpha}_{j,-l+1} - \alpha_{j,-l+1}|$, the only remaining task is to estimate the last two terms in (40).

Considering that $g_1(x)$ is a $(p-1)$th order polynomial, we obtain

$$\int f_h(x)\psi_{j,-l+1}(x)dx = 0 = \int g_1(x)\psi_{j,-l+1}(x)dx.$$

Substituting the wavelet equation (39) into the above equation, we have

$$\sum_{s=0}^{l} h_s \int (f_h(x) - g_1(x))\phi_{j+1,s-2l+2}(x)dx = 0.$$

We can rewrite this equation in the following form:

$$\begin{aligned} & h_{l-1} \int_{\frac{\Delta x}{2}(-l+1)}^{\frac{\Delta x}{2}} (f_h(x) - g_1(x))\phi_{j+1,1-l}(x)dx \\ & + h_l \int_{\frac{\Delta x}{2}(-l+2)}^{\Delta x} (f_h(x) - g_1(x))\phi_{j+1,2-l}(x)dx \\ & \qquad = -\sum_{s=0}^{l-2} h_s \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} (f_h(x) - g_1(x))\phi_{j+1,s-2l+2}(x)dx. \end{aligned}$$

Notice that we have $\frac{h_{l-1}}{c_{l-1}} = \frac{h_l}{c_l}$. We find that the left-hand side contains the term we need to estimate, whereas the right-hand side uses only $f_h(x)$ at the left side of the origin and thus can be controlled again by Taylor expansion. This means that we have

$$\begin{aligned} & \left| c_{l-1} \int_{\frac{\Delta x}{2}(-l+1)}^{\frac{\Delta x}{2}} (f_h(x) - g_1(x))\phi_{j+1,1-l}(x)dx \right. \\ & \left. + c_l \int_{\frac{\Delta x}{2}(-l+2)}^{\Delta x} (f_h(x) - g_1(x))\phi_{j+1,2-l}(x)dx \right| \\ & \qquad \le \left| \frac{c_l}{h_l} \right| \sum_{s=0}^{l-2} |h_s| \int_{\frac{\Delta x}{2}(s-2l+2)}^{\frac{\Delta x}{2}(s-l+2)} |f_1(x) - g_1(x)||\phi_{j+1,s-2l+2}(x)|dx \\ & \qquad \le C(\Delta x)^p \|f_1^{(p)}\| 2^{\frac{-(j+1)}{2}}. \end{aligned} \tag{42}$$

Combining (40), (41), and (42), we have

$$|\bar{\alpha}_{j,-l+1} - \alpha_{j,-l+1}| \le C(\Delta x)^p \|f_1^{(p)}\| 2^{-\frac{(j+1)}{2}}.$$

Similarly, we can prove that, for all $m, -l+1 < m \le 0$,

$$|\bar{\alpha}_{j,m} - \alpha_{j,m}| \le C(\Delta x)^p \|f_1^{(p)}\| 2^{-\frac{(j+1)}{2}}.$$

Substituting them into (35), we prove that (30) holds for the high frequency extension case.

The last case we need to consider is the coarse level extrapolation of low frequency coefficients. To prove (30), we use the result obtained for the direct function extrapolation.

We denote by $\alpha_{j,m}^d$ the low frequency coefficients for $f_d(x)$. The jth level low frequency extrapolation approximation $f_{l,j}(x)$ is defined as

$$f_{l,j}(x) = \sum_m \alpha_{j,m}\phi_{j,m}(x).$$

For any point $x_0 \in [q\Delta x, (q+1)\Delta x) \subset [-l\Delta x, 0]$, we have

$$|f_1(x_0) - f_{l,j}(x_0)| \le |f_1(x_0) - f_{d,j}(x_0)| + |f_{d,j}(x_0) - f_{l,j}(x_0)|. \tag{43}$$

Using (30) for the direct function extrapolation case, we know that

$$|f_1(x_0) - f_{d,j}(x_0)| \le C(\Delta x)^p \|f_1^{(p)}\|. \tag{44}$$

And the remaining term can be bounded by

$$|f_{d,j}(x_0) - f_{l,j}(x_0)| \le \sum_{q-l\le m\le q} |\alpha_{j,m}^d - \alpha_{j,m}| |2^{\frac{j}{2}} \phi(2^j x_0 - m)|. \tag{45}$$

Again, we need to estimate $|\alpha_{j,m}^d - \alpha_{j,m}|$.

Unlike the previous two cases where the low frequency coefficients $\alpha_{j,m}$ are computed by integration (32) or (37), in this case $\alpha_{j,m}$ are determined by the low frequency extrapolation on the coarse level in wavelet space. So, to estimate $|\alpha_{j,m}^d - \alpha_{j,m}|$, we need to consider them in wavelet space. We introduce the following operator notations first.

Define the continuous wavelet transform (WT) of any function $f(x)$ in space V_j by

$$WT(f)(s) = \int f(x)\phi_{j,s}(x)dx = 2^{\frac{j}{2}} \int f(x)\phi(2^j x - s)dx.$$

Also define the following Taylor extrapolation operator (EX) of $f(x)$:

$$EX(f)(x) = \begin{cases} f(x), & x \le 0, \\ g(x), & x > 0, \end{cases}$$

where $g(x)$ is the $(p-1)$th order Taylor polynomial of $f(x)$. Using these notations, we can represent the low frequency wavelet coefficients

$$\alpha_{j,m} = EX_w(WT(f_1))(m), \quad \text{for} \quad -l+1 \le m \le 0,$$

and

$$\alpha_{j,m}^d = WT(EX_f(f_1))(m), \quad \text{for} \quad -l+1 \le m \le 0,$$

where EX_w and EX_f represent the extrapolation operator EX in the wavelet and physical space, respectively.

Instead of estimating $|\alpha_{j,m}^d - \alpha_{j,m}|$ directly, we prove the following more general result.

LEMMA 1. *Given a smooth function $g(x)$, let $g_{we}(s) = WT(EX_f(g))(s)$ and $g_{ew}(s) = EX_w(WT(g))(s)$; then*

$$|g_{we}(s) - g_{ew}(s)| \le C(\Delta x)^p \|g^{(p)}\| 2^{-\frac{j}{2}}.$$

Using this lemma, we obtain the desired bounds for $|\alpha_{j,m}^d - \alpha_{j,m}|$ easily by taking $s = m$. Combining them with (44) and (45), we prove that (30) holds for the low frequency coefficient extrapolation case.

Proof. Denote $\bar{g}(x) = EX_f(g)(x)$, and then

$$\begin{aligned} g_{we}(s) &= 2^{\frac{j}{2}} \int \bar{g}(x)\phi(2^j x - s)dx \\ &= 2^{-\frac{j}{2}} \int \bar{g}(2^{-j}(y-s))\phi(y)dy. \end{aligned}$$

By changing variable $z = 2^{-j}s$, and denoting

$$e_j(z) = \int \bar{g}(2^{-j}y - z)\phi(y)dy,$$

we have

$$g_{we}(s) = 2^{-\frac{j}{2}} e_j(2^{-j}s).$$

We also know that $e_j(z)$ is a smooth function and, by differentiating p times, we have

$$\|e_j^{(p)}\| = \left\| \int (-1)^p \bar{g}^{(p)}(2^{-j}y - z)\phi(y)dy \right\| \le C\|g^{(p)}\| \left\| \int \phi(y)dy \right\| \le C\|g^{(p)}\|. \tag{46}$$

Taking the $(p-1)$th order Taylor expansion of $e_j(z)$ at $z = -l\Delta x$, we have

$$e_j(z) = \hat{e}_j(z) + e_j^{(p)}(\xi)\frac{(z + l\Delta x)^p}{p!},$$

where $\hat{e}_j(z)$ is the $(p-1)$th order Taylor polynomial and $\xi \in [2l, 0]$. Since $g_{ew}(s)$ is the same as $g_{we}(s)$ if $s \le -l$, it is defined as the Taylor polynomial for $s > -l$ according to the definition of EX; i.e., we have

$$g_{ew}(s) = \begin{cases} 2^{-\frac{j}{2}} e_j(2^{-j}s), & s \le -l, \\ 2^{-\frac{j}{2}} \hat{e}_j(2^{-j}s), & s > -l. \end{cases}$$

Therefore,

$$\begin{aligned} |g_{we}(s) - g_{ew}(s)| &\le 2^{-\frac{j}{2}} |e_j(2^{-j}s) - \hat{e}_j(2^{-j}s)| \\ &\le C(\Delta x)^p \|g^{(p)}\| 2^{-\frac{j}{2}}. \end{aligned}$$

This completes the proof of Lemma 1 and also completes the proof of Theorem 2.

5. Numerical examples. In this section, we give some one-dimensional (1-D) and 2-D numerical examples by using the ENO-wavelet transforms. In particular, we show results of the ENO-Haar, ENO-DB4, and ENO-DB6 wavelet transforms.

In all examples, for simplicity, we just consider functions with zero values at the boundary. For nonzero boundary functions, we can easily extend the function by zero and treat the boundaries as discontinuities.

To illustrate the performance of ENO-wavelet transforms, we show picture comparisons of the standard wavelet approximations and corresponding ENO-wavelet approximations. In addition, we compare the L_∞ and L_2 errors of the standard wavelet approximations and the ENO-wavelet approximations at different levels by measuring $E_{\infty,j} = \inf_x \|f(x) - f_j(x)\|$, which is computed by finding the largest difference on the finest grid, and $E_{2,j} = \|f(x) - f_j(x)\|_2$. Using them, we compute the orders of accuracy defined by

$$Order_\infty = \log_2 \frac{E_{\infty,i}}{E_{\infty,i-1}}$$

and

$$Order_2 = \log_2 \frac{E_{2,i}}{E_{2,i-1}},$$

TABLE 1

Comparison of the maximum error of the standard Haar and the ENO-Haar wavelet approximation for the smooth function $\sin(x)$. *We see that they have the same approximation error for the smooth functions.*

3	0.0430	0.0430	1.070
2	0.0184	0.0184	1.202
1	0.0061	0.0061	1.585

TABLE 2

Comparison of the maximum error of the standard DB4 and the ENO-DB4 approximations for the smooth function $f(x) = \exp[-(\frac{1}{x} + \frac{1}{1-x})], 0 < x < 1$. *They have the same error and both achieve second order accuracy which agrees with the results in Theorem* 1 *for the smooth functions.*

Level	DB4 E_∞	ENO-DB4 E_∞	$Order_\infty$
4	3.316e-5	3.316e-5	
3	7.650e-6	7.650e-6	2.104
2	1.590e-6	1.590e-6	2.232
1	2.972e-7	2.973e-7	2.406

which indicates the order of accuracy of the approximation in the L_∞ norm and L_2 norm, respectively.

For all noise-free examples, we use the method described in section 3.2 to locate the exact positions of the discontinuities. And we select $a = 2$ and $\epsilon = 0.0001$ (as used in the algorithms in section 3.3) for all 1-D examples.

First, we compare the approximations for smooth functions. Table 1 is the comparison of Haar and ENO-Haar approximations for the smooth function $f(x) = \sin(x), 0 \le x \le 2\pi$ at different levels, and Table 2 is the comparison of DB4 and ENO-DB4 approximations for the function $f(x) = \exp[-(\frac{1}{x} + \frac{1}{1-x})], 0 < x < 1$.

We see from these tables that for smooth functions the ENO-wavelet transforms have exactly the same approximation error as the standard wavelet transforms. Both of them maintain the approximation order 1 and 2 for Haar and DB4, respectively, which agree with the results in Theorem 1. In fact, we notice that in this situation no singularity is detected, and the ENO-wavelet algorithms perform the standard transforms for completely smooth functions as we expected.

Next, we consider a piecewise smooth function defined by

$$f(x) = \begin{cases} 0, & 0 \le x < 0.2, \\ -50x - 5, & 0.2 \le x < 0.4, \\ 10\sin(4\pi x + 0.8\pi) - 1, & 0.4 \le x < 1.1, \\ 5e^{2x} - 100, & 1.1 \le x < 1.6, \\ 0, & 1.6 \le x \le 2. \end{cases}$$

We apply Haar and ENO-Haar, DB4 and ENO-DB4, and DB6 and ENO-DB6 transforms to this function and compare the approximation error. Figure 5 shows the comparison of the order of accuracy in the L_∞ and L_2 norm. It is clear that both L_∞ and L_2 order of accuracy for ENO-wavelet transforms are of the order 1, 2, and 3 for ENO-Haar, ENO-DB4, and ENO-DB6, respectively, and they agree with the results in Theorem 2. In contrast, standard wavelet transforms do not retain the corresponding order of accuracy for piecewise smooth functions.

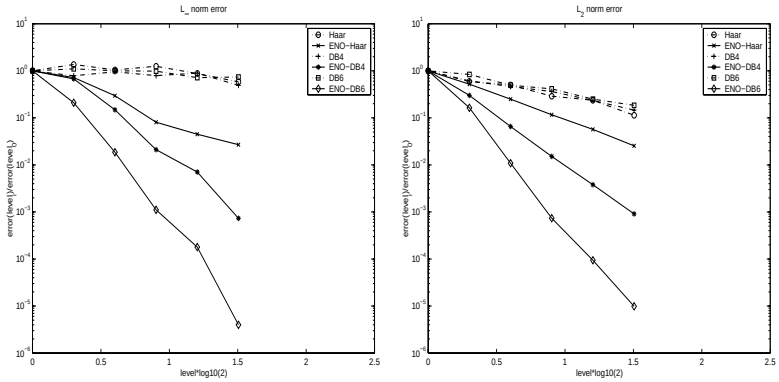

FIG. 5. *The approximation accuracy comparison of ENO-wavelet and wavelet transforms. Both L_∞ (left) and L_2 (right) order of accuracy show that ENO-wavelet transforms maintain the order* 1, 2, *and* 3 *for ENO-Haar, ENO-DB*4, *and ENO-DB*6, *respectively, and they agree with the results of Theorem* 2. *In contrast, standard wavelet transforms do not retain the order of accuracy for piecewise smooth functions.*

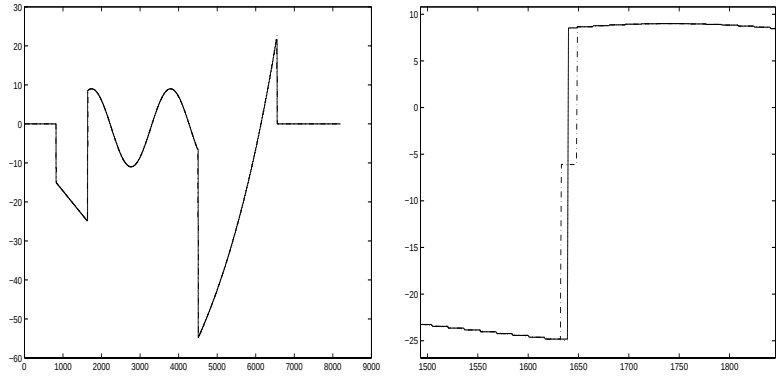

FIG. 6. *The* 4*-level ENO-Haar and Haar approximation. The left picture shows the original function (dotted line), the standard Haar approximation (dash-dotted line) and the ENO-Haar approximation (solid line). The right picture is a zoom-in near a discontinuity. We see the Gibbs phenomenon (staircase) in the standard Haar approximation but not in the ENO-Haar approximation.*

To see the Gibbs oscillations, we display the 4-level ENO-wavelet and standard wavelet approximations in Figures 6, 7, and 8 for ENO-Haar, ENO-DB4, and ENO-DB6 approximations, respectively. In the left column, we show the original function (dotted line), the standard wavelet linear approximations (dash-dotted), and the ENO-wavelet approximations (solid line). The right pictures are zoom-ins of the left pictures near a discontinuity. We clearly see the Gibbs oscillations in the standard approximations; in contrast, the ENO-wavelet approximations preserve the jump accurately.

In Figures 9, 10, and 11, we also present the standard Haar, DB4, and DB6 wavelet coefficients (dotted line) and the ENO-Haar, ENO-DB4, and ENO-DB6 wavelet coefficients (solid line), respectively. The left part corresponds to the low frequency coefficients and the right part to the high frequency coefficients. We notice that there are some large standard high frequency coefficients near the discontinuities. On the other hand, no large high frequency coefficients are present in the ENO-wavelet

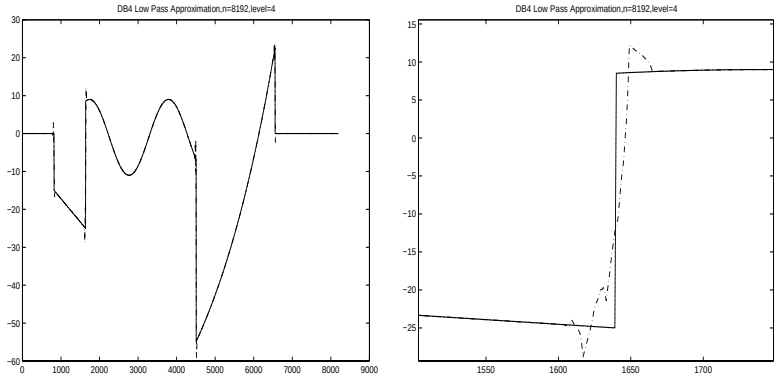

FIG. 7. *The 4-level ENO-DB4 and the standard DB4 approximations. The original discontinuous function (dotted line), the standard DB4 approximation (dash-dotted line), and the ENO-DB4 approximation (solid line) are displayed. The Gibbs phenomenon is clearly seen for the standard DB4 approximation but not for the ENO-DB4 approximation.*

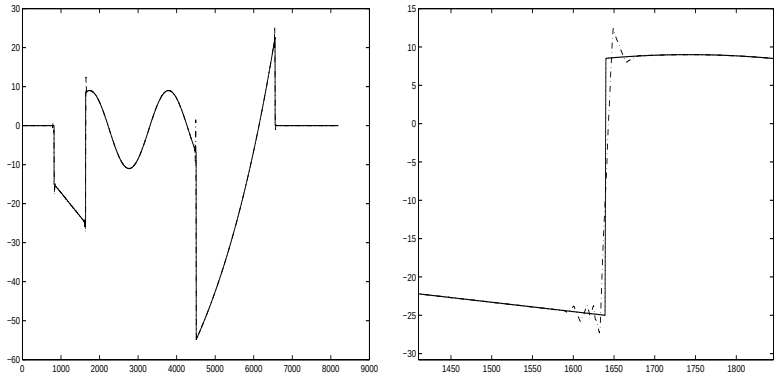

FIG. 8. *The 4-level ENO-DB6 (solid line) and the standard DB6 (dash-dotted line) approximation. The standard DB6 generates oscillations near discontinuities, but the ENO-DB6 does not.*

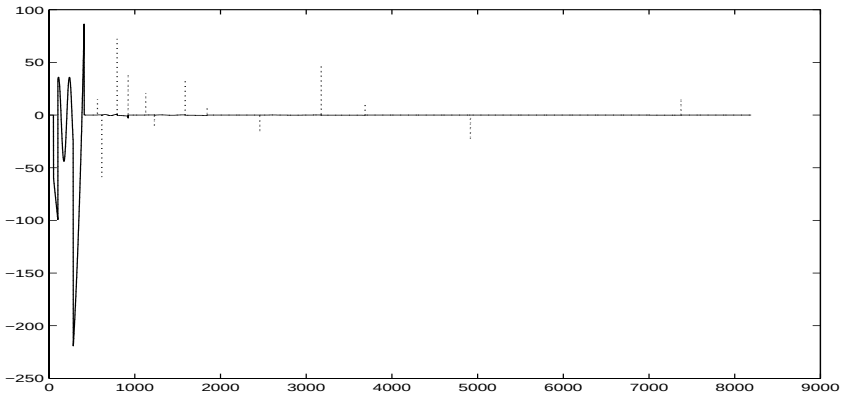

FIG. 9. *The 4-level ENO-Haar (solid line) and the standard Haar coefficients (dotted line). The left part corresponds to the low frequencies, the right part to the high frequencies. In the standard Haar coefficients, large high frequency coefficients present near discontinuities, while in the ENO-Haar case there are no large high frequency coefficients.*

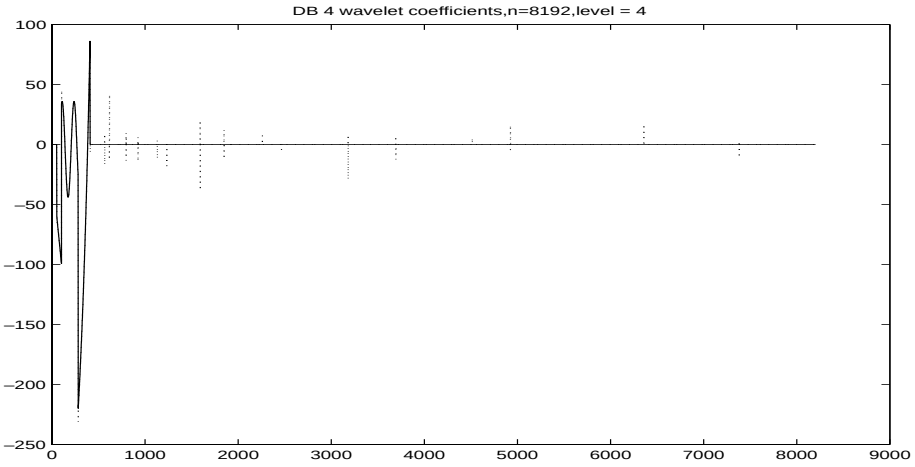

FIG. 10. *The* 4*-level ENO-DB*4 *coefficients (solid line) and the standard DB*4 *coefficients (dotted line). There are large high frequency coefficients (right part) near the discontinuities in the standard DB*4 *transform but not in the ENO-DB*4 *transform.*

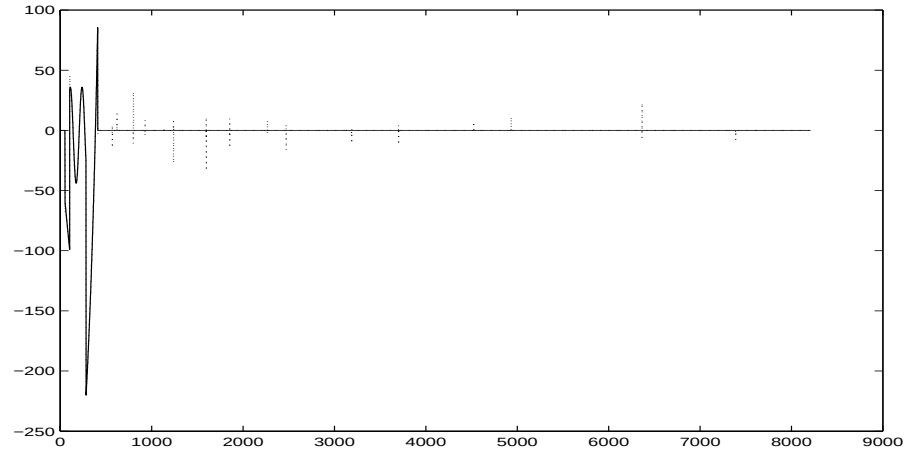

FIG. 11. *The* 4*-level ENO-DB*6 *coefficients (solid line) and the standard DB*6 *coefficients (dotted line). There are large high frequency coefficients near the discontinuities in the standard DB*6 *transform but not in the ENO-DB*6 *transform.*

coefficients. This illustrates that the ENO-wavelet coefficients have better distribution than standard wavelet coefficients; i.e., they have no large coefficients in the high frequencies, and the energy is concentrated in the low frequency end.

The next 1-D example we present here (Figure 12) is a comparison of the standard DB6 and the ENO-DB6 transforms to illustrate the performance at places where the DSP is not valid and also at jumps in the derivative. The original data (circles) has two discontinuities (the middle bump) which violate the DSP assumption, which requires that there are at least eight data points between any pair of discontinuities. Although the ENO-DB6 approximation (solid line) does not preserve this pair of discontinuities exactly, its approximation error is still comparable (actually better in this case) to that of the standard DB6 approximation (dotted line). At the left bump where the DSP holds, the ENO-DB6 does preserve the discontinuities exactly as we

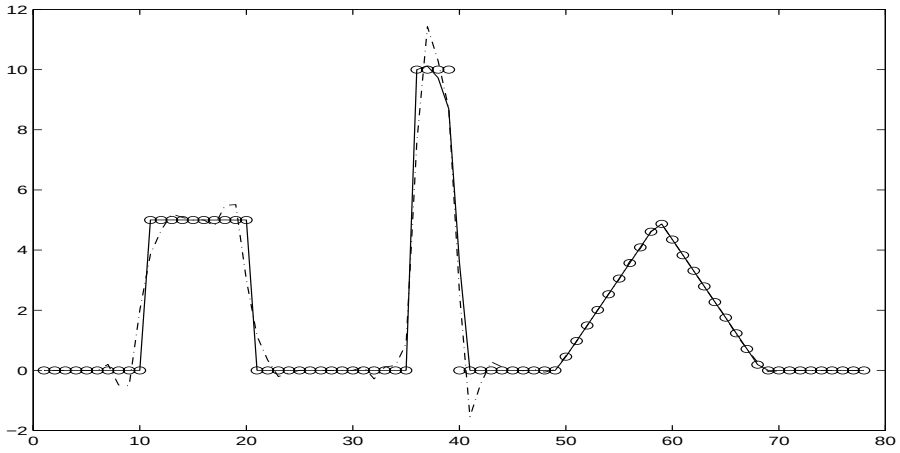

FIG. 12. *The level-*1 *approximation comparison of the ENO-DB*6 *and the standard DB*6 *wavelets at places where the DSP is invalid (the middle bump). The initial data (circles) has two close discontinuities. The ENO-DB*6 *approximation (solid line) error is comparable to that of the standard DB*6 *approximation (dotted line). The left bump satisfies the DSP and therefore the ENO-DB*6 *exactly recovers it. The right kink is a discontinuity in the first derivative, and the standard DB*6 *still generates oscillations although their magnitudes are not significant. The ENO-DB*6 *restores it perfectly, We display a zoom-in picture of this kink in Figure* 13.

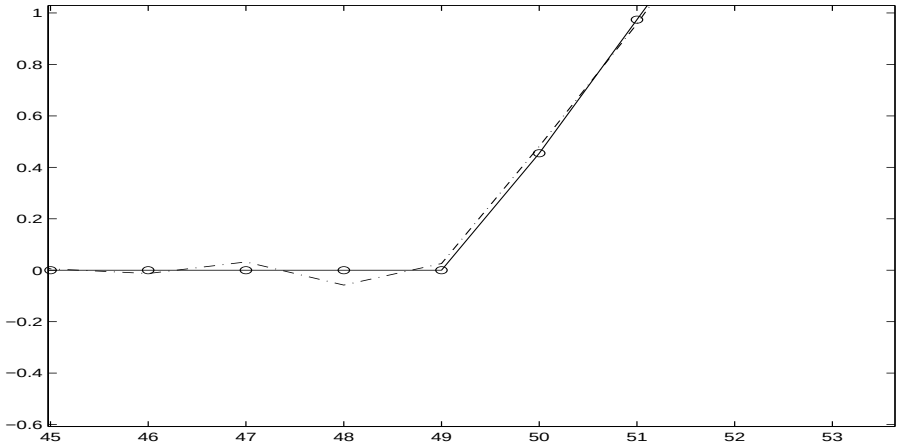

FIG. 13. *The zoom-in of Figure* 12 *at the kink where there is a discontinuity in its derivative. The ENO-DB*6 *(solid line) can recover it perfectly, but the standard DB*6 *(dash-dotted line) generates oscillations.*

expected. In the same example, we also display the comparison of the ENO-DB6 and the standard DB6 approximations at the right kink, which is not a discontinuity in function values but in its first order derivative. The standard DB6 approximation has oscillations, although their magnitudes are small, but the ENO-DB6 restores it exactly (see Figure 13).

The last 1-D example is applying the ENO-DB6 wavelet transform to a piecewise constant function polluted by Gaussian random noise (see Figure 14). For this example, the jump detection method corresponding to Lemma 1 does not work. Instead, we use the simple method given in section 3.2, which detects jumps by looking for

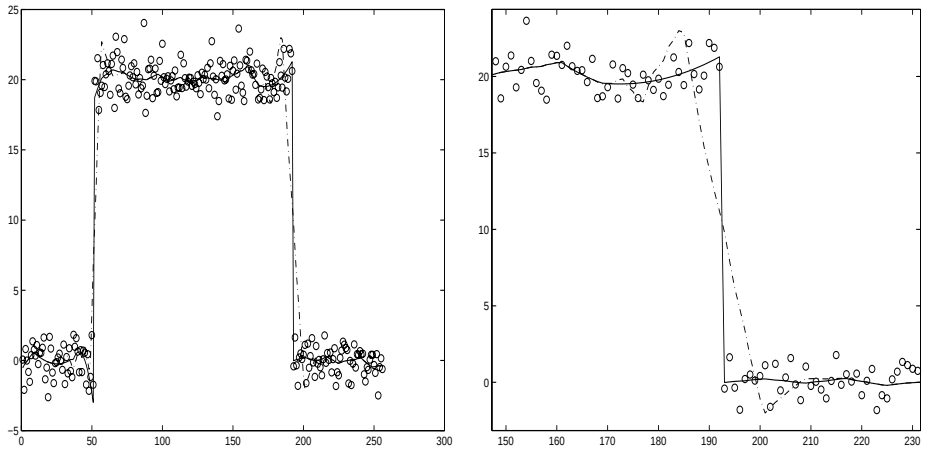

FIG. 14. *Left: The comparison of the* 3*-level ENO-DB*6 *approximation (solid line) with the standard DB*6 *approximation (dash-dotted line) for noisy initial data (circles). The ENO-DB*6 *approximation retains the sharp jumps, but the standard DB*6 *approximation does not (right picture). Right: A zoom-in of the left example at the discontinuities.*

stencils with significant larger high frequency coefficients than their neighbors and then locates the exact jump locations by directly comparing the differences between two adjacent function values within the stencil. Despite the presence of noise in the initial data (circles), the level-3 ENO-DB6 approximation (solid line) still retains the sharp edges (see zoom-in in the right picture in Figure 14) compared to the stan-

dard DB6 approximation (dash-dotted line) which not only has oscillations at the discontinuities but also smears them.

Finally, we give a 2-D testing image example to compare the standard Haar and the ENO-Haar approximations. Here we use tensor products of 1-D transforms. The original picture is shown in Figure 15. Figure 16 is the 3-level standard Haar approximation and Figure 17 is the 3-level ENO-Haar approximation. Both use low frequency approximations (the reconstructions are obtained from low frequency coefficients α_{J-3} only, where α_J is the original image) and store the same number of coefficients ($\frac{1}{64}$ of the original data). It is clear that in the standard Haar case the function becomes fuzzier than in the ENO-Haar case. This illustrates that the ENO-Haar approximation can reduce the edge oscillations for 2-D functions. In addition, as we mentioned in the introduction, we designed ENO-wavelet transforms not to replace the standard nonlinear adaptive wavelet techniques; rather we think it would be beneficial to use them in conjunction with the standard adaptive nonlinear techniques. For instance, we can combine ENO-wavelets with hard thresholding techniques as one can do it for the standard wavelet transforms. We show the standard hard thresholding approximation image by retaining the largest 64×64 coefficients in Figure 18, and we note that sharper edges are recovered comparing to the linear approximations. Similarly, we can apply the same thresholding techniques to the ENO-wavelet transforms. In Figure 19, we give the approximate image by using the ENO-Haar hard thresholding technique by keeping the largest 3506 ENO-Haar coefficients, which is 70% of number of coefficients retained in the previous image. In this image, edges are almost perfectly recovered.

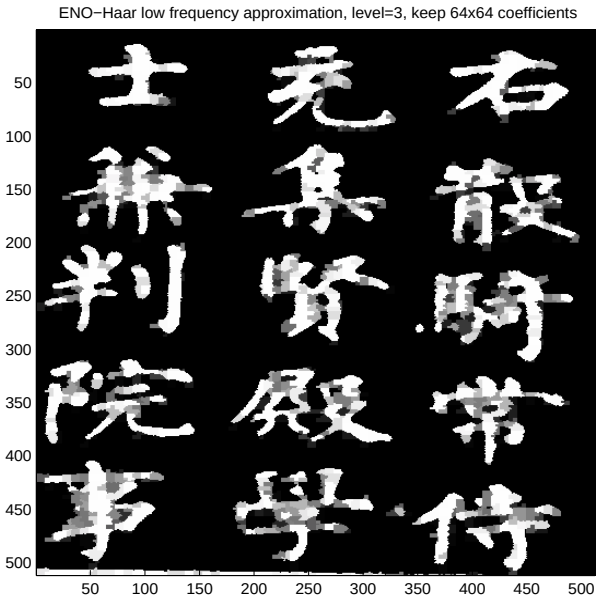

FIG. 17. *The* 3*-level ENO-Haar approximation: Similar to Figure* 16*, the reconstruction is obtained from low frequency coefficients* α_{J-3} *only. Both the edges and the interior of the characters are clearer than those in the standard Haar linear approximation.*

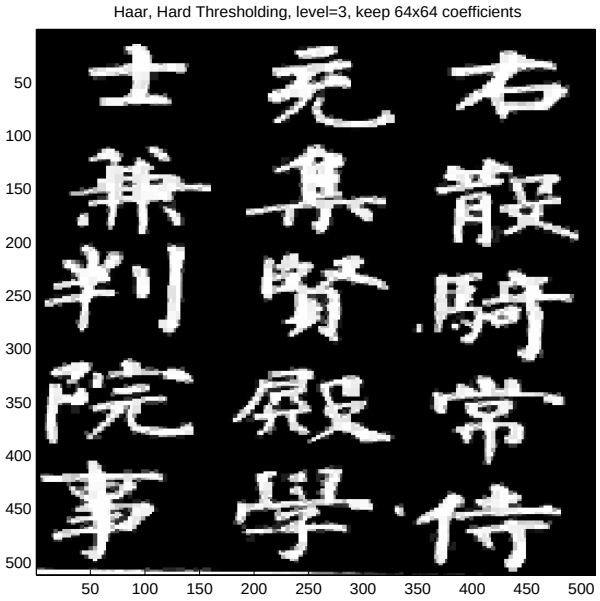

FIG. 18. *The* 3*-level standard Haar hard thresholding approximation: The image is reconstructed from the largest* 64×64 *wavelet coefficients (including* $\alpha_{J-3}, \beta_{J-3}, \beta_{J-2}, \beta_{J-1}$*). The edge artifacts are less severe than the standard linear approximation. On the other hard, the picture is comparable to the ENO-Haar low frequency approximation.*

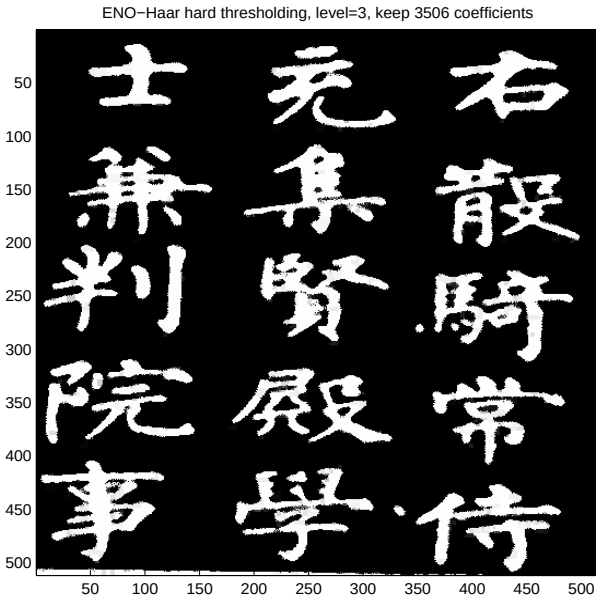

FIG. 19. *The 3-level ENO-Haar hard thresholding approximation: Similar to Figure 18, the image is reconstructed from the largest* 64×64 *ENO-wavelet coefficients (including* $\alpha_{J-3}, \beta_{J-3}, \beta_{J-2}, \beta_{J-1}$*). Less severe edge artifacts are generated compared to the previous images.*

A NEW NUMERICAL METHOD FOR BACKWARD PARABOLIC PROBLEMS IN THE MAXIMUM-NORM SETTING*

J. M. MARBÁN† AND C. PALENCIA‡

Abstract. A new method for solving numerically backward parabolic problems is proposed. As usual for this kind of ill posed problems, it is assumed that an a priori bound for the solution is available. The algorithm consists of two basic steps. First, a standard forward integration is performed, in order to approximate the solution at suitable future time levels. Second, a holomorphic recovery procedure is carried out, providing the required approximations for the preceding times. The analysis is valid in the maximum-norm setting, and rigorous estimates are derived. Among other advantages, the method can also be applied to nonlinear problems, and it produces a continuous output. Some numerical illustrations are presented.

Key words. ill posed problems, backward parabolic problems, maximum-norm, holomorphic recovery, harmonic measure, Chebyshev nodes, least squares method

1. Introduction.

The present paper is devoted to introducing and analyzing a new numerical method for backward parabolic problems. Our main estimate relies on an assumption (see (2.7) in section 2) that, for standard discretizations of classical parabolic problems, holds only in the maximum-norm setting. However, in order to outline the main difficulties associated with the kind of ill-posed problems we have in mind, let us start by adopting an abstract point of view. Thus, let X be a complex Banach space and let $A : D(A) \subset X \to X$ be the infinitesimal generator of a holomorphic semigroup $S(t)$, $t \geq 0$, of linear and bounded operators in X. We do not assume that A is densely defined so that $S(t)$ might fail to be continuous at $t = 0$ (see, e.g., [48]). In particular, this allows us to consider diffusion problems in the context of $X = L^\infty$. It is well known that the forward Cauchy problem

$$\begin{cases} w'(t) = Aw(t), & t \geq 0, \\ w(0) = w_0 \in X, \end{cases}$$

is well posed, being that its (generalized) solution is given by $w(t) = S(t)w_0$, $t \geq 0$. Moreover, there exists an angle $0 < \theta < \pi/2$ such that S admits a holomorphic extension, of exponential growth, to the sector

$$\Sigma_\theta = \{\, z \in \mathbb{C} \,:\, |\arg(z)| \leq \theta \,\}.$$

Without loss of generality, after performing an appropriate shift of A if necessary, we can assume that there exists $C_\theta > 0$ such that

$$\|S(z)\| \leq C_\theta, \qquad z \in \Sigma_\theta. \tag{1.1}$$

We are interested in the corresponding backward Cauchy problem (BCP)

$$\left\{ \begin{array}{l} w'(t) = Aw(t), \qquad 0 \le t \le T, \\ w(T) = w_T \in \mathcal{R}_T, \end{array} \right. \tag{1.2}$$

where $T > 0$ and w_T are given. Here $\mathcal{R}_T$ stands for the image of the operator $S(T)$. Problems of this nature arise in different contexts. Beyond their interest in connection with standard diffusion problems (then A is usually the laplacian operator Δ), they also appear, for instance, in some deconvolution problems, such as deblurring processes [10, 11, 12]. (Now $-A$ is often a fractional power of $-\Delta$.)

Fix $u_T \in \mathcal{R}_T$. Certainly, problem (1.2) with $w_T = u_T$ has got a unique solution [18] which hereon is denoted by $u : [0, +\infty) \to X$. However, in practice u_T is not available but rather some approximation $u_T + \delta\, u_T \in X$. This gives rise to two difficulties: (i) for unbounded A the available final datum $u_T + \delta\, u_T$ might not belong to $\mathcal{R}_T$, and (ii) the uncertainty due to $\delta\, u_T$ might propagate uncontrolled for $0 \le t < T$. Therefore, problems of this nature are typically ill posed. These difficulties can be partly overcome by incorporating some a priori information on the solution. In this paper we assume that a number $M_0 > 0$ is known in such a way that

$$\|u(t)\| \le M_0, \qquad 0 \le t \le T. \tag{1.3}$$

In the applications, the underlying physical problem usually provides reasonable values for M_0. However, what really matters for our method is an a priori bound

$$\|u(z)\| \le M, \qquad z \in \Sigma_\theta. \tag{1.4}$$

Notice that (1.1) and (1.3) give (1.4) with $M = C_\theta M_0$, though sharper estimates of M might be available in particular cases. This additional information renders problem (1.2) well posed, in the sense that the difference between two solutions satisfying (1.4) depends continuously on their difference at time T. Before stating this precisely, for the convenience of the reader, we recall the notion of harmonic measure [19, 21, 44]: Given a bounded, open domain $\Omega \subset \mathbb{C}$ whose boundary Γ consists of two disjoint, piecewise smooth arcs Γ_1 and Γ_2, the harmonic measure of Γ_1 with respect to Ω is the solution $\omega : \Omega \cup \Gamma \to \mathbb{R}$ of the Dirichlet problem

$$\left\{ \begin{array}{lll} \Delta\, \omega = 0 & \text{in} & \Omega, \\ \omega \ = 1 & \text{on} & \Gamma_1, \\ \omega \ = 0 & \text{on} & \Gamma_2. \end{array} \right.$$

Notice that, by virtue of the maximum principle, there holds $0 < \omega(z) < 1$ for $z \in \Omega$.

Now we are in a position to state the following theorem, whose proof, based on the *two-constants theorem* [44], is analogous to those of Theorem 6.2.1 in [18] and the main result in [36]. Recall that C_θ stands for a constant fulfilling (1.1).

THEOREM 1.1. *Let v_1, $v_2 : [0, T] \to X$ be two mappings satisfying the differential equation in* (1.2) *and assumption* (1.4) *for some $M > 0$. For $0 < \theta' \le \theta < \pi/2$, set*

$$\Omega = \{\, z \notin T + \Sigma_\theta \,:\, |\arg z| < \theta' \,\}$$

(see Figure 1*) and let Γ_1 be the part of the boundary of Ω lying in the sector $T + \Sigma_\theta$. Then*

$$\|v_2(t) - v_1(t)\| \le C_\theta^{\omega(t)} (2M)^{1-\omega(t)} \|v_2(T) - v_1(T)\|^{\omega(t)}, \qquad 0 \le t \le T, \tag{1.5}$$

where ω is the harmonic measure of Γ_1 with respect to Ω.

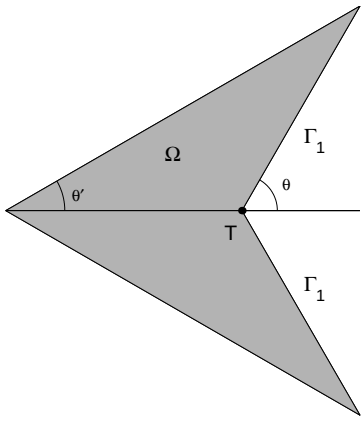

FIG. 1. *Domain* Ω *in Theorem* 1.1 *for* $\theta' < \theta$.

Thus, as we mentioned, problem (1.2) is well posed in a Hölder sense when restricted to solutions satisfying (1.4). Note that the Hölder exponent $\omega(t)$ degrades as t approaches $0+$ and that the sharper estimate of M yields the better bound in (1.5). It is also worth mentioning that the Hölder exponent $\omega(t)$, $0 < t < T$, depends on the ratio t/T rather than on t itself. Finally, notice that for a nonpositive self-adjoint generator A in a Hilbert space we can take the limits $\theta' \to \pi/2-$ and $\theta \to \pi/2-$ in (1.5). Then, since $C_{\pi/2}$ can be chosen equal to 1, we can take $M = M_0$, and (1.5) reads

$$\|v_2(t) - v_1(t)\| \le (2M_0)^{1-t/T} \|v_2(T) - v_1(T)\|^{t/T}, \qquad 0 \le t \le T,$$

a well-known result that can also be proved directly by using the logarithmic convexity of $\|v_2(t) - v_1(t)\|$ [18, 42].

A large variety of numerical methods have been proposed for (1.2). Some of them [13, 17, 30, 47] are based on the idea of quasi reversibility, while others use either some kind of regularization or filtering processes [1, 15, 16, 20, 46, 52]. Another interesting approach is presented in [8, 9], where (1.2) is transformed into a second order in time boundary value problem. In all these references X is assumed to be a Hilbert space and A a nonpositive self-adjoint operator. In [24] the backward heat equation, with constant coefficients, is dealt in L_p, $1 < p \le +\infty$, by considering an approach based on mollification and filtering. However, the numerical aspects are not developed, and this task does not seem to be straightforward. Pointwise estimates for this equation can also be found in [28]. More recently, a method relying on stochastic arguments, valid on Banach spaces, has been suggested in [7]. Nevertheless, the stochastic approach presents the drawback that the restriction on the step-size is too demanding.

Henceforth we restrict ourselves to classical parabolic problems in the maximum-norm setting. Thus, A is assumed to be a second order elliptic operator, $D(A)$ incorporates the boundary conditions, and X is taken to be the closure of $D(A)$ with respect to the maximum norm. It is known [49, 50] that A generates a holomorphic semigroup in X. Consideration of L^∞ spaces is also possible [48]. Our goal is to approximate the solution u of the problem

$$\begin{cases} u'(t) = Au(t), & 0 \le t \le T, \\ u(T) = u_T \in \mathcal{R}_T \end{cases} \tag{1.6}$$

from knowledge of a perturbed final datum $u_T + \delta\, u_T \in X$ with $\|\delta\, u_T\| \leq \delta$ and under assumption (1.4), where δ, $M > 0$ are given. Notice that $u_T + \delta\, u_T$ is not expected to belong to $\mathcal{R}_T$ so that, in general, this datum does not correspond to any solution of the equation in (1.2). Moreover, even in cases where $u_T + \delta\, u_T \in \mathcal{R}_T$, (1.4) is likely no longer satisfied by the solution v with final datum $u_T + \delta\, u_T$. Therefore, even though Theorem 1.1 provides the kind of estimates we can expect for the errors, in practice it cannot be applied.

Our algorithm is based on the realistic assumption that (1.6) can be integrated forward in time, i.e., for $t \geq T$, and it consists of two basic steps: (i) a standard forward integration in order to get fully discrete approximations $\hat{u}_h^n$ (belonging to discrete spaces X_h) to the values $u(t_n)$ of the solution at suitable future nodes $t_n \geq T$, $1 \leq n \leq N$, and (ii) the numerical holomorphic recovery of $u(t)$, $0 < t \leq T$, based on the previous approximations [33]. Let ε be the total uncertainty in the first step, i.e., the contributions of $\|\delta\, u_T\|$ and the error of the forward integration procedure. Our main result (see Theorem 3.1 below) essentially states that with a fairly moderate number of future nodes $N = O(|\ln \varepsilon|)$, the solution $u(t)$, $0 < t \leq T$, is approximated within an order $O\left((\varepsilon |\ln \varepsilon|)^{\omega^*(t)}\right)$, where ω^* is an appropriate harmonic measure. Among other advantages, let us point out that the method can also be applied to nonlinear problems and that it provides a continuous output $U_h(t)$ so that $u(t)$ can be readily approximated at any required time $0 < t \leq T$.

2. Notation and preliminaries. Recall that we are considering classical parabolic problems in the maximum norm, thus A is a second order elliptic operator and X is a Banach space formed by bounded mappings, endowed with the maximum norm. As we mentioned in the introduction, our numerical method is based on the realistic assumption that the forward parabolic problem

$$\left\{ \begin{array}{ll} v'(t) = Av(t), & t \geq 0, \\ v(0) = v_0 \in X & \end{array} \right. \tag{2.1}$$

can be fully discretized efficiently. Though the nature of this discretization is not essential to our algorithm, for the sake of convenience we adopt the standard approach of the method of lines. We introduce a well-known abstract setting (see, e.g., [27, 29, 40]) that covers either finite differences or finite elements, for the discretization in space, combined with a rational method for the discretization in time.

Let X_h, $0 < h \leq h_0$, be a family of finite dimensional normed spaces. All the norms used hereon, including operator norms, are denoted by $\|\cdot\|$. For $0 < h \leq h_0$, let $P_h : X \to X_h$ and $A_h : X_h \to X_h$ be linear operators, with P_h bounded. First, the solution of problem (2.1) is approximated by the solution $v_h : [0, +\infty) \to X_h$ of the semidiscrete problem

$$\left\{ \begin{array}{ll} v_h'(t) = A_h v_h(t), & t \geq 0, \\ v_h(0) = v_{h,0} := P_h v_0 \in X_h. & \end{array} \right. \tag{2.2}$$

Second, problem (2.2) is integrated in time by a rational method [6, 14, 23, 26, 37, 51] based on a rational approximation $r(z)$ to e^z of order $q \geq 1$. This approximation is assumed to be stable for variable step-sizes. This means the following:

(a) There exists $\bar{k} > 0$ (independent of h) such that the spectrum of kA_h, $0 < k \leq \bar{k}$, does not contain any pole of $r(z)$. Thus, for $0 < k \leq \bar{k}$, $r(kA_h)$ is a bounded operator in X_h, $0 < h \leq h_0$.

(b) For $\bar{t} > 0$ there exists C_s (independent of h) such that

$$\left\| \prod_{l=1}^{L} r(k_l A_h) \right\| \leq C_s, \tag{2.3}$$

for any finite sequence $\{k_l\}_{l=1}^{L}$ of step-sizes with $0 < k_l \leq \bar{k}$, $1 \leq l \leq L$, and with $\sum_{l=1}^{L} k_l \leq \bar{t}$.

It is known that the operators A_h arising when using either finite differences or finite elements are uniformly sectorial in h [3, 5]. Thus, by the abstract results in [4, 38], it turns out that (2.3) is satisfied in these important situations.

Given time levels $0 = \tau_0 < \tau_1 < \cdots < \tau_L = \bar{t}$, corresponding to step-sizes $k_{l+1} = \tau_{l+1} - \tau_l \leq \bar{k}$, the rational method applied to (2.2) provides the fully discrete approximations $v_h^l \simeq v_h(\tau_l)$ defined by

$$v_h^{l+1} = r(k_{l+1} A_h) v_h^l, \qquad 0 \leq l \leq L-1, \quad 0 < h \leq h_0.$$

The error is assumed to be of order $\varphi(h)$ in space, where $\varphi : (0, h_0] \to (0, +\infty)$ satisfies $\varphi(h) \to 0$ as $h \to 0+$, and of order q in time. To be precise, we assume that for given $\bar{t} > 0$ there exist $C_d > 0$ and $\nu > 0$ (independent of h) such that for a smooth enough initial datum $v_0 \in D((-A)^\nu)$ the error of the fully discrete scheme is governed by (see, e.g., [39, 51])

$$\|P_h v(\tau_l) - v_h^l\| \leq C_d \left(\|v_0\| + \|(-A)^\nu v_0\| \right) \cdot \left(\varphi(h) + k^q \right),$$

where $k = \max_{1 \leq l \leq L} k_l$.

Let us return to problem (1.6). For the analysis of our method it will be important to consider the forward problem

$$\begin{cases} u'(t) = Au(t), & t \geq T, \\ u(T) = u_T. \end{cases} \tag{2.4}$$

Since $u_T \in \mathcal{R}_T \subset D((-A)^\nu)$, given future nodes $\{T + \tau_l\}_{l=0}^{L}$, with $\{\tau_l\}_{l=0}^{L}$ as above, the fully discrete approximations to $u(T + \tau_l)$, denoted by u_h^l, satisfy

$$\|P_h u(T + \tau_l) - u_h^l\| \leq C_p(\varphi(h) + k^q), \qquad 1 \leq l \leq L, \quad 0 < h \leq h_0, \tag{2.5}$$

where $C_p = C_p(u_T)$.

For practical calculations, suitable bases $\{\chi_{h,j}\}_{j=1}^{J(h)}$ of X_h, $0 < h \leq h_0$, are required. Our hypothesis is that these bases are well conditioned in the following sense: there exist k_*, $k^* > 0$, independent of h, such that, for any $x_h \in X_h$,

$$x_h = \sum_{j=1}^{J(h)} x_{h,j} \chi_{h,j}, \tag{2.6}$$

there holds

$$k_* \cdot \max_{1 \leq j \leq J(h)} |x_{h,j}| \leq \|x_h\| \leq k^* \cdot \max_{1 \leq j \leq J(h)} |x_{h,j}|. \tag{2.7}$$

The coefficients in the expansion (2.6) will be denoted by

$$x_{h,j} =: \langle x_h, \chi_{h,j} \rangle, \qquad x_h \in X_h, \quad 1 \leq j \leq J(h).$$

To end this section we briefly describe the numerical algorithm in [33] for the recovery of holomorphic mappings.

Fix $0 < r < 1$ and set $I = [-r, r]$. For $N \geq 1$, let s_n, $1 \leq n \leq N$, be the Chebyshev nodes of first kind over I:

$$s_n = -r \cos\left(\frac{(2n-1)\pi}{2N}\right), \qquad 1 \leq n \leq N. \tag{2.8}$$

Let $D \subset \mathbb{C}$ be the unit disc and let $\tilde{f} : D \to \mathbb{C}$ be a holomorphic mapping. Set $\mathbf{w} = \{w_n\}_{n=1}^N := \{\tilde{f}(s_n)\}_{n=1}^N \in \mathbb{C}^N$ and assume that we are given perturbed nodal values $\mathbf{w} + \delta\,\mathbf{w} = \{w_n + \delta\, w_n\}_{n=1}^N \in \mathbb{C}^N$. The goal is to recover $\tilde{f}$ from knowledge of the approximate values $\mathbf{w}+\delta\,\mathbf{w}$ (see [33]). We also assume that $|\delta\, w_n| \leq \rho$, $1 \leq n \leq N$, and that $|\tilde{f}(s)| \leq H$, $s \in D$, where ρ and H are a priori known.

Let $\mathcal{S}_N$ be the linear space generated by the Cauchy kernels

$$K_n(s) = \frac{1}{1 - s_n s}, \qquad 1 \leq n \leq N.$$

The recovery of $\tilde{f}$ is provided by the least squares method (LSM) [33, 34] as $\tilde{F} \in \mathcal{S}_N$,

$$\tilde{F}(s) = \sum_{n=1}^{N} \gamma_n K_n(s),$$

by solving the constrained minimization problem

$$\begin{cases} \displaystyle\min_{G \in \mathcal{S}_N} \sum_{n=1}^{N} |G(s_n) - (w_n + \delta\, w_n)|^2 \\ \text{subject to} \\ \displaystyle\|G\|_2^2 := \sup_{0<\sigma<1} \frac{1}{2\pi} \int_0^{2\pi} |G(\sigma \mathrm{e}^{i\phi})|^2\, d\phi \leq H^2. \end{cases} \tag{2.9}$$

Set

$$\tau = \frac{r}{1 + \sqrt{1 - r^2}}, \qquad H^* = \frac{4H(1+r)}{1 - r^2}, \qquad \xi = 1 + \frac{\ln(\rho/H^*)}{\ln \tau}.$$

Corollary 2.1 in [33] shows that if $\rho < H^*$, then for $N = [\xi]$ and $s \in D$ we have

$$|\tilde{f}(s) - \tilde{F}(s)| \leq (2H\tilde{\gamma}(s))^{1-\tilde{\omega}(s)} \left(1 + \left(1 + \frac{2\ln \xi}{\pi}\right)\left(1 + \sqrt{\xi}\right)\right)^{\tilde{\omega}(s)} \rho^{\tilde{\omega}(s)}, \tag{2.10}$$

where

$$\tilde{\gamma}(s) = (1 + |s|)(1 - |s|)^{-1}(1 - \tilde{\omega}(s))^{-1} \tag{2.11}$$

and $\tilde{\omega} : \mathrm{cl}\,(D) \to [0, +\infty)$ is the harmonic measure of I with respect to $D \setminus I$ (see, e.g., [18, 44]), i.e., the continuous mapping in $\mathrm{cl}\,(D)$ that is harmonic in $D \setminus I$ and such that $\tilde{\omega}(s) = 1$ for $s \in I$, $\tilde{\omega}(s) = 0$ for $|s| = 1$.

In the present paper we rather use the simplified bound (easily derived from (2.10))

$$\left|\tilde{f}(s) - \tilde{F}(s)\right| \leq (2H\tilde{\gamma}(s))^{1-\tilde{\omega}(s)} (3N\rho)^{\tilde{\omega}(s)}, \qquad s \in D. \tag{2.12}$$

In practice, to solve the constrained minimization problem (2.9) an orthonormal basis $\{g_n\}_{n=1}^N$ of $\mathcal{S}_N$ is employed so that the matrix for the quadratic inequality constraint (see [22, section 12.1.1]) becomes the identity. We adopt the basis defined by (see [41])

$$g_1(s) = \frac{\sqrt{1-s_1^2}}{1-s_1 s}$$

and

$$g_n(s) = \frac{\sqrt{1-s_n^2}}{1-s_n s} \prod_{j=1}^{n-1} \frac{s-s_j}{1-s_j s}, \qquad 2 \le n \le N.$$

Working with this basis, problem (2.9) reduces to a matrix format which can be efficiently solved by means of the SVD (see [22, 33]). Finally, since

$$\max_{|s|\le 1} |g_n(s)| \le B_r := (1+r)^{1/2}(1-r)^{-1/2}, \qquad 1 \le n \le N,$$

Theorem 2.2 in [33] shows that we also have

$$|\tilde{f}(s) - \tilde{F}(s)| \le (H(1+B_r N^{1/2}))^{1-\tilde{\omega}(s)} (3N\rho)^{\tilde{\omega}(s)}, \qquad s \in D,$$

an estimate that can be advantageous when $|s| \to 1^-$.

3. The numerical algorithm for the BCP. For given integration parameters h and k (see section 2), set

$$\varepsilon = C_p\,(\varphi(h) + k^q) + C_s \|P_h\| \delta.$$

Fix R with $T < R < +\infty$ and set

$$\Sigma = \{\, z \in \Sigma_\theta \,:\, |z| \le R \,\}.$$

Let $\Psi : \Sigma \to \mathrm{cl}\,(D)$ be the conformal transformation (see Figure 2) with $\Psi(0) = -1$, $\Psi(R) = 1$, and $\Psi(T) = -r$ $(0 < r < 1)$, namely

$$\Psi(z) = \frac{a + \zeta - \zeta^{-1}}{a - \zeta + \zeta^{-1}},$$

where $\zeta = (z/R)^\sigma$, $a = b(1-r)/(1+r)$, $b = (T/R)^{-\sigma} - (T/R)^\sigma$, $\sigma = \pi/(2\theta)$.

Once M, r, and ε are fixed, set $\rho = \varepsilon/k_*$ and $H = M\|P_h\|/k_*$ and compute (see section 2)

$$N = [\xi], \qquad \xi = 1 + \frac{\ln(\rho/H^*)}{\ln \tau} = 1 + \frac{\ln(\varepsilon/(M^*\|P_h\|))}{\ln \tau}, \tag{3.1}$$

where $M^* = 4M(1+r)/(1-r^2)$. Let $-r < s_1 < \cdots < s_N < r$ be the corresponding Chebyshev nodes (2.8). Finally, set $T' = \Psi^{-1}(r)$ and $t_n = \Psi^{-1}(s_n)$, $1 \le n \le N$. Notice that the evaluation of $t = \Psi^{-1}(s)$, $-r \le s \le r$, reduces to solve the quadratic equation

$$(s+1)\zeta^2 + a(1-s)\zeta - (1+s) = 0, \qquad \zeta = (t/R)^\sigma.$$

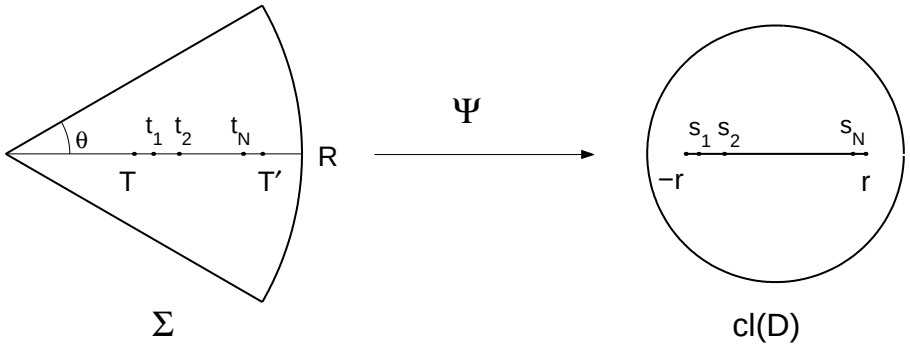

FIG. 2. *The conformal mapping* Ψ.

The numerical algorithm consists of two steps:

(1) Starting from the available approximate final datum $u_T + \delta\, u_T$, we integrate forward the problem

$$\begin{cases} \bar{u}'(t) = A\bar{u}(t), & T \le t \le T', \\ \bar{u}(T) = u_T + \delta\, u_T, \end{cases} \tag{3.2}$$

with the selected parameters h and k. The time levels τ_l, $1 \le l \le L$, must include the future nodes t_n, $1 \le n \le N$; i.e., $t_n = \tau_{l_n}$ for some $1 \le l_1 < l_2 < \cdots < l_N \le L$. For simplicity, the discrete values $\bar{u}_h^{l_n}$ are denoted by $\hat{u}_h^n$, $1 \le n \le N$. These vectors are stored.

(2) For each $1 \le j \le J(h)$, the holomorphic mapping

$$\tilde{f}_{h,j}(s) = \langle P_h u(\Psi^{-1}(s)), \chi_{h,j} \rangle, \qquad s \in D,$$

is recovered by the LSM algorithm from knowledge of the approximate values

$$\tilde{f}_{h,j}(s_n) \simeq \langle \hat{u}_h^n, \chi_{h,j} \rangle, \qquad 1 \le n \le N.$$

Let $\tilde{F}_{h,j} : D \to \mathbb{C}$ be the resulting recovery of $\tilde{f}_{h,j}$ provided by the LSM (2.9). Then the method adopts the approximations $U_h(t)$ to $P_h u(t)$, $0 \le t \le T$, defined by

$$P_h u(t) \simeq U_h(t) := \sum_{j=1}^{J(h)} F_{h,j}(t) \chi_{h,j},$$

where $F_{h,j} = \tilde{F}_{h,j} \circ \Psi$, $1 \le j \le J(h)$.

The following theorem provides a rigorous estimate for the error.

THEOREM 3.1. *Under the above conditions, for* $0 \le t \le T$ *there holds*

$$\|P_h u(t) - U_h(t)\| \le \left(\frac{k^*}{k_*}\right) (2\|P_h\| M\gamma(t))^{1-\omega(t)}\, (3N\varepsilon)^{\omega(t)}, \tag{3.3}$$

where $\gamma = \tilde{\gamma} \circ \Psi$ *(see* (2.11)*),* $\omega = \tilde{\omega} \circ \Psi$*, and* k_*, k^* *satisfy* (2.7).

Notice that ω is the harmonic measure of $[T, T']$ relative to $\Sigma \setminus [T, T']$. Thus, by the maximum principle, $\omega(t) < \omega_{\theta'}(t)$, $0 < t < T$, where now $\omega_{\theta'}$ stands for the harmonic measure used in Theorem 1.1. In fact, (3.3) with $\omega_{\theta'}$ instead of ω would

somehow be a quasi-optimal estimate. This suggests that a forward integration along the complex segments of Γ_1 in Figure 1 could provide such a quasi-optimal result, something left for future research. Notice also that the freedom in the choice of R and $T' = T'(R, r)$ results in different harmonic measures ω. Increasing R and T' provides better estimates (3.3) but requires a higher computational effort. On the other hand, T' very close to T requires less computation but leads to worse estimates (3.3). Let us also point out that the value $\omega(t)$ depends solely on the nondimensional quantities t/T, T'/T, and R/T (cf. Theorem 1.1). Finally, notice that, as for (1.5), estimate (3.3) becomes useless for times t with t/T close to 0.

Before proceeding with the proof of the theorem, several remarks are in order.

Remark 3.1. Notice that only the vectors $\hat{u}_h^n = \bar{u}_h^{l_n}$, corresponding to the future nodes t_n, $1 \le n \le N$, must be stored. Since typically $\|P_h\| = O(1)$ or $\|P_h\| = O(|\ln h|)$ (see, e.g., [45]), (3.1) shows that essentially $N = O(|\ln \varepsilon|)$. Thus, the algorithm requires a moderate amount of memory and accurately solving the required least square problems (see [33]) is rather cheap. Therefore, the efficiency of the new method relies on that of the numerical integration of the underlying forward problem.

Remark 3.2. Since constants C_p and C_s are unknown in most cases, it turns out that in general neither ε nor N could be determined. Set $\varepsilon_r = \varphi(h) + k^q + \delta$ (notice that this is the accessible part of the error) and $C_r = \max\{1, C_p, C_s\|P_h\|\}$ so that $\varepsilon \le C_r \cdot \varepsilon_r$. Then it is possible to prove that (3.3) remains valid by taking $N = [\xi_r]$, where ξ_r is the computable quantity

$$\xi_r := 1 + \frac{\ln(\varepsilon_r/(M^*\|P_h\|))}{\ln \tau}.$$

Remark 3.3. The algorithm provides the coefficients $F_{h,j}$ of the approximations

$$U_h(t) = \sum_{j=1}^{J(h)} F_{h,j}(t)\chi_{h,j}, \qquad 0 < t \le T,$$

where $F_{h,j}$ are continuous outputs; i.e., we are in a position to evaluate $U_h(t)$ at any $0 < t \le T$.

Remark 3.4. Notice that the different coefficients $F_{h,j}$ can be obtained in parallel from the future values $\hat{u}_h^n$. Moreover, when the basis $\chi_{h,j}$ is localized in space the recovery can be limited to indexes j affecting a given region of interest.

Remark 3.5. In some cases the aim could be the approximation of a certain functional of $u(t)$

$$\Lambda(u(t)), \qquad 0 < t \le T,$$

where $\Lambda \in X^*$, rather than $u(t)$ itself. Then, denoting by $\Lambda_h \in X_h^*$ a suitable approximation to Λ, the problem is reduced to compute

$$f_h(t) = \Lambda_h(P_h u(t)), \qquad 0 < t \le T.$$

Therefore, it is enough to recover the mapping f_h from knowledge of its nodal approximations

$$f_h(t_n) \simeq \Lambda_h(\hat{u}_h^n), \qquad 1 \le n \le N;$$

i.e., the recovery of all the individual coefficients $F_{h,j}$ of U_h is not required. Combining this idea with the previous remark, in practice we could first approximate u on a coarser grid and later refine up to the original grid where required.

Remark 3.6. Usually, an extension operator $E_h : X_h \to X$ such that $P_h E_h = I$ on X_h is available. In these cases we can adopt $E_h U_h(t)$ as the numerical aproximation to $u(t)$, rather than $U_h(t)$. We have

$$\|u(t) - E_h U_h(t)\| \leq \|(I - E_h P_h)u(t)\| + \|E_h\| \cdot \|P_h u(t) - U_h(t)\|.$$

The last term on the right-hand side has already been analyzed, while the first one depends on the approximation properties of X_h. Typically an estimate of the form (see, e.g., [39, 45, 51])

$$\|(I - E_h P_h)u(t)\| \leq C\varphi(h)\left(\|u(t)\| + \|(-A)^{\mu} u(t)\|\right)$$

for some $C, \mu > 0$ is known. Thus, when the above estimate holds, it turns out [43] that this term behaves like $O(\varphi(h)t^{-\mu})$ (or even like $O(\varphi(h))$ in cases where $u_0 \in D((-A)^{\mu})$). Hence, the bound (3.3) remains valid for $\|u(t) - E_h U_h(t)\|$.

Remark 3.7. Finally, it is worth mentioning that the linearity of problem (1.2) is not essential. In fact, as long as the solution $u(t)$ is holomorphic in a sector Σ, some a priori bound is available there, the errors in the forward integration behave like ε, and the full discretization is stable, our algorithm can be applied to backward, nonlinear evolution problems.

Usually, the infinitesimal generator of an abstract, parabolic nonlinear flux (see, e.g., [25, 31]) is the sum of a linear operator A and a dominated, nonlinear term $\mathcal{N}$. Then, the standard approach based on the variation-of-constants formula enables us to show that if $\mathcal{N}$ is holomorphic, then it is the nonlinear flux. This approach also yields estimates for the solution on sectors Σ where e^{zA} is holomorphic in terms of its initial datum. Thus, this kind of problems can be solved backward in time by means of the new method whenever a forward numerical integration can be performed.

Proof. Fix $1 \leq j \leq J(h)$. For $s \in D$ we have

$$|\tilde{f}_{h,j}(s)| = |\langle P_h u(\Psi^{-1}(s)), \chi_{h,j}\rangle| \leq k_*^{-1}\|P_h\| \cdot \|u(\Psi^{-1}(s))\| \leq k_*^{-1}\|P_h\| M.$$

Moreover, by (2.5), for $1 \leq n \leq N$

$$\|P_h u(t_n) - u_n^{l_n}\| \leq C_p\left(\varphi(h) + k^q\right)$$

and by (2.3)

$$\|u_h^{l_n} - \hat{u}_h^n\| = \|u_h^{l_n} - \bar{u}_h^{l_n}\| \leq C_s\|P_h\|\delta.$$

Therefore, by combining these inequalities, we get

$$\begin{aligned} |\tilde{f}_{h,j}(s_n) - \langle \hat{u}_h^n, \chi_{h,j}\rangle| &= |\langle P_h u(t_n) - \hat{u}_h^n, \chi_{h,j}\rangle| \\ &\leq k_*^{-1}\|P_h u(t_n) - \hat{u}_h^n\| \\ &\leq k_*^{-1} C_p\left(\varphi(h) + k^q\right) + k_*^{-1} C_s\|P_h\|\delta \\ &= k_*^{-1}\varepsilon. \end{aligned}$$

Now estimate (2.12) with $\rho = k_*^{-1}\varepsilon$ and $H = k_*^{-1}\|P_h\|M$ shows that for $s \in D$

$$|\tilde{f}_{h,j}(s) - \tilde{F}_{h,j}(s)| \leq k_*^{-1}\left(2\|P_h\|M\tilde{\gamma}(s)\right)^{1-\tilde{\omega}(s)}\left(3N\varepsilon\right)^{\tilde{\omega}(s)}.$$

Finally, for $t \in \Sigma$, setting $s = \Psi(t)$,

$$\|P_h u(t) - U_h(t)\| \leq k^* \sup_{1\leq j\leq J(h)} |\langle P_h u(t) - U_h(t), \chi_{h,j}\rangle| \leq k^* \sup_{1\leq j\leq J(h)} |\tilde{f}_{h,j}(s) - \tilde{F}_{h,j}(s)|,$$

and the theorem is proved since $\tilde{\omega}(s) = \omega(t)$. ∎

4. Numerical experiments. In this final section we present some numerical experiments in order to illustrate the new method and the theoretical results.

Experiment 1. Consider the backward problem

$$\left\{\begin{array}{ll} u_t(t,x) = u_{xx}(t,x), & 0 \le x \le 1, \quad t \ge 0, \\ u(t,0) = 0, & t \ge 0, \\ u(t,1) = 0, & t \ge 0, \\ u(T,x) = u_T(x) + \delta\, u_T(x) \in X = C_0[0,1], & \end{array}\right. \tag{4.1}$$

where $C_0[0,1]$ stands for the space formed by all the continuous mappings $f : [0,1] \to \mathbb{C}$ such that $f(0) = f(1) = 0$, endowed with the maximum norm.

We take $T = 1/8192$ and let $u_T \in C_0[0,1]$ be the value at time T of the exact solution of the forward heat equation with initial datum $u_0(x) = \sin(25\pi x^2)$ and homogeneous Dirichlet boundary conditions. Since no analytic expression for u_T is known we proceed as follows: First we integrate numerically the initial value problem, starting from u_0, in order to approximate u_T as well as $u(3T/4)$, $u(T/2)$, $u(T/4)$, $u(T/8)$ and $u(T/16)$. (These values are used for evaluating the errors shown in Table 1.) This is performed by combining central differences over a uniform mesh $x_j = jh$, $1 \le j \le J-1$, of size $h = 1/J$, for the discretization in space together with the well known MATLAB routine ODE23s, which is based on a modified Rosenbrock method [23], for the integration in time, in such a way that the total error is below 10^{-7}. Notice that in this situation $X_h = \mathbb{R}^{J-1}$, endowed with the maximum norm. The corresponding operator P_h brings each mapping f into the vector given by its grid values so that $k_* = k^* = \|P_h\| = 1$. Consideration of L^∞ spaces is also possible but requires the formalism introduced, for instance, in [2].

The final time T has been chosen so that the size of the oscillations in u_T close to the right endpoint is below 0.1, i.e., less than 10 percent of their initial size. Despite the fact that T is rather small, notice that it is the ratio t/T which is relevant to the experiment. Once we have accurately computed u_T, we introduce the perturbation $\delta\, u_T$ as a pseudorandom term, uniformly distributed on $[-\delta, \delta]$ with $\delta = 10^{-6}$ (see Figure 3) .

We take $\theta = \pi/2.2$, $R = 4.1T$, and $r = 0.3$. An easy calculation (based on the classical representation of the solution of the heat equation in terms of the Gaussian kernel) shows that $C_\theta = \sec^{1/2}\theta$ so that we can set $M = C_\theta \|u_0\|_\infty = \sec^{1/2}\theta$ in Theorem 3.1. Now we integrate forward (4.1) tuning h and the time step-sizes in such a way that $\varepsilon = 3\,\delta$. We are now in a position to calculate the number of nodes given by (3.1), which turns out to be $N = [9.75] = 9$. The resulting approximations at the required future nodes t_n, $1 \le n \le 9$, are displayed in Figure 4. From these approximations we construct the continuous outputs $U_h(t) \in \mathbb{R}^{J-1}$, $0 < t \le T$.

Table 1 shows the errors in the maximum norm at the past times $3T/4$, $T/2$, $T/4$, $T/8$, and $T/16$.

It is noteworthy how the solution is fairly well reproduced despite its severely oscillatory behavior and the loss of information at time T for points x close to 1. Note that even at $T/16$, i.e., about 95 percent of the way back, the relative error is only 7.8 percent. In fact, $U_h(t)$ and $P_h u(t)$, $t = T/2$, $T/4$, $T/8$, $T/16$, are hard to distinguish when plotted together (see Figure 5). A zoom corresponding to $t = T/16$ and the zone where the worst errors occur is displayed in Figure 6.

Finally, in order to compare errors in Table 1 with those predicted by Theorem 3.1, the corresponding harmonic measure ω must be numerically computed (for instance, by means of the D03EAF NAG FORTRAN library routine). It turns out that in this example the computed errors in Table 1 are smaller by a factor of 1/30 than those

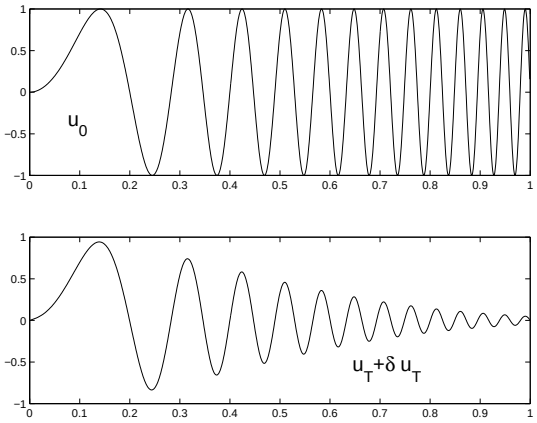

FIG. 3. *Initial datum u_0 and perturbed u_T.*

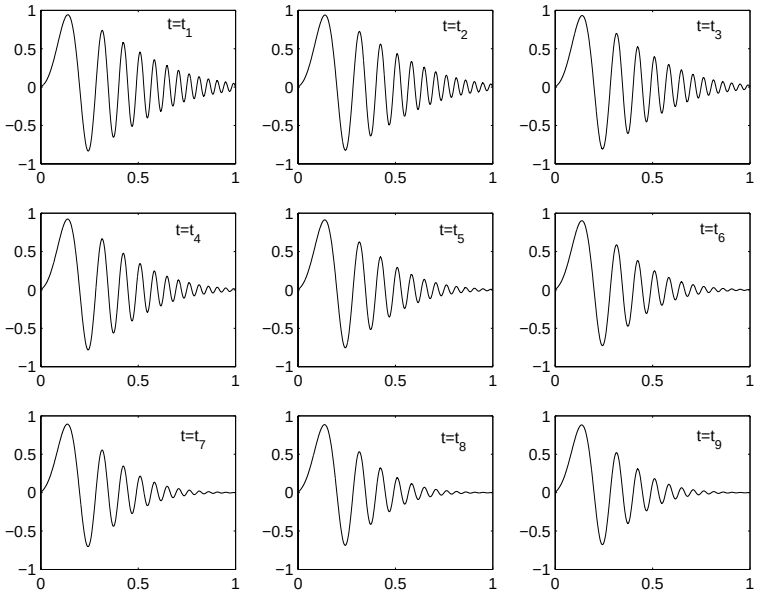

FIG. 4. *Numerical solution at future nodes.*

TABLE 1

Evaluation time	Absolute error
$t = T/16$	7.765457e-02
$t = T/8$	4.437583e-02
$t = T/4$	1.403523e-02
$t = T/2$	1.093864e-03
$t = 3T/4$	6.247916e-05

predicted by Theorem 3.1. (This factor is similar to the one found in the experiments in [33] when testing the LSM (2.9).)

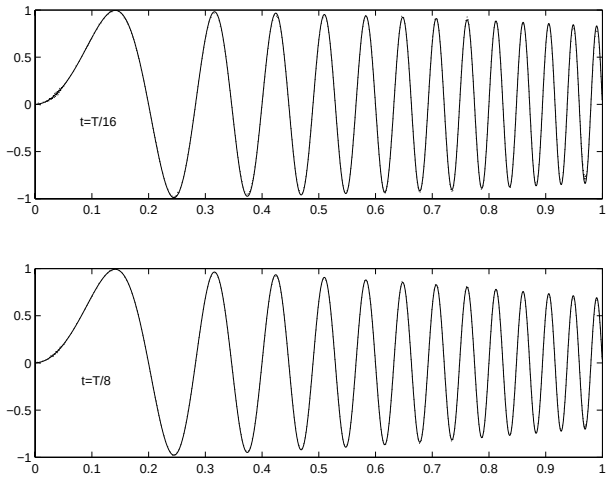

FIG. 5. *Numerical solution (dotted line) and exact solution (solid line) are hard to distinguish.*

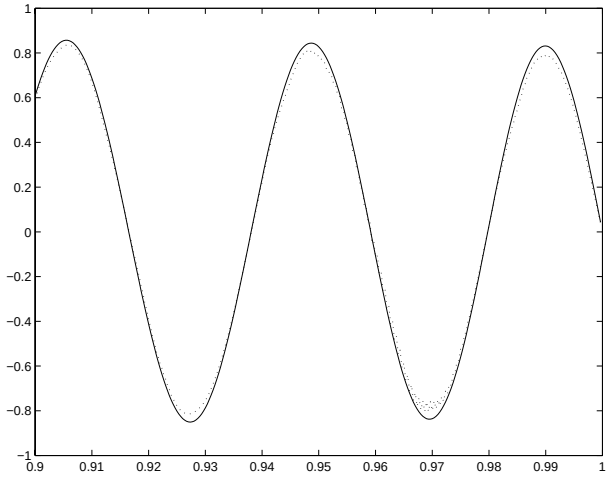

FIG. 6. *Zoom of the numerical solution (dotted line) and exact solution (solid line) at* $T/16$.

Experiment 2. Let us now consider the following nonlinear problem:

$$\begin{cases} u_t(t,x) = u_{xx}(t,x) + u(t,x)\,u_x(t,x) - \frac{1}{2}e^{-2t}\sin(2x), & 0 \le x \le \pi, \quad t \ge 0, \\ u(t,0) = 0 \qquad t \ge 0, \\ u(t,\pi) = 0 \qquad t \ge 0, \\ u(T,x) = u_T(x) + \delta\, u_T(x) \in X = C_0[0,\pi]. \end{cases}$$

The final time is taken to be $T = 1$ and $u_T(x) = e^{-1}\sin(x)$, $0 \le x \le \pi$. The source term is chosen in order for $u(t,x) = e^{-t}\sin(x)$ to be the solution, in the absence of perturbation. For the computations we take again $\delta\, u_T$ as a pseudorandom term of amplitude $\delta = 10^{-6}$. We maintain the values of r and θ. In this example, in the view of the solution, we take $M = 1$. The space and time discretizations are as in the

TABLE 2

Evaluation past times	Error for $M = 1$ ($N = 8$)	Error for $M = 7$ ($N = 9$)
$t = T/16$	1.324940e-02	6.238772e-02
$t = T/8$	8.925938e-03	3.698770e-02
$t = T/4$	3.251045e-03	1.220574e-02
$t = T/2$	2.424795e-04	9.937696e-04
$t = 3T/4$	7.889683e-06	3.986467e-05

TABLE 3

Evaluation past times	Absolute error
$t = T/16$	9.889366e-02
$t = T/8$	6.833551e-02
$t = T/4$	3.432584e-02
$t = T/2$	8.022480e-03
$t = 3T/4$	1.184737e-03

previous example. Now (3.1) provides $N = [8.71] = 8$. The errors in maximum norm are shown in Table 2. We repeat the experiment but now with $M = 7$. Then it turns out that $N = 9$. The corresponding errors are also shown in Table 2. This illustrates how a sharper a priori information yields better results.

Experiment 3. Finally we consider the two dimensional backward heat equation in the square $\Omega = [1, 1] \times [-1, 1]$:

$$\begin{cases} u_t(t,x,y) = (1/\pi)\Delta u(t,x,y), & (x,y) \in \Omega, \quad t \geq 0, \\ u(t,x,y) = 0, & (x,y) \in \partial\Omega, \quad t \geq 0, \\ u(T,x,y) = u_T(x,y) + \delta\, u_T(x,y) \in X = L_\infty([-1,1] \times [-1,1]), \end{cases}$$

with $T = 1/4$ and $u_T(x, y) = e^{-2\pi T} \sin(\pi x) \sin(\pi y)$. The solution for the unperturbed problem is clearly $u(t, x, y) = e^{-2\pi t} \sin(\pi x) \sin(\pi y)$. The term $\delta\, u_T$ is once more randomly generated but now with amplitude $\delta = 10^{-4}$. The discretization in space is performed by linear finite elements on a quasi-regular mesh of diameter $h = 10^{-2}$, while the time integration is carried out by the MATLAB ODE23S routine with $k = 10^{-2}$. Since $\varphi(h) = h^2 |\ln h|$ [45, 51], it turns out that $\varepsilon_r = 6.60517 \cdot 10^{-4}$. Moreover, M is assigned its exact value; i.e., $M = 1$. Now Remark 3.2 yields $N = [5.83] = 5$, and the errors at indicated times are collected in Table 3. Less accurate estimates of M lead to higher values of N and bigger errors.

Acknowledgment. The authors wish to express their gratitude to the anonymous referees for their helpful and valuable comments and suggestions.

NUMERICAL APPROXIMATION OF SOME LINEAR STOCHASTIC PARTIAL DIFFERENTIAL EQUATIONS DRIVEN BY SPECIAL ADDITIVE NOISES*

QIANG DU† AND TIANYU ZHANG‡

Abstract. This paper is concerned with the numerical approximation of some linear stochastic partial differential equations with additive noises. A special representation of the noise is considered, and it is compared with general representations of noises in the infinite dimensional setting. Convergence analysis and error estimates are presented for the numerical solution based on the standard finite difference and finite element methods. The effects of the noises on the accuracy of the approximations are illustrated. Results of the numerical experiments are provided.

Key words. stochastic partial differential equation, additive noise, finite difference method, finite element method, convergence, error estimate

1. Introduction.

In recent years, it has been increasingly acceptable to adopt SDE models as an essential component in the analysis of complex phenomena such as wave propagation [19], climate change [22], turbulence [21, 24], and phase transition [9, 16, 18]. The initial value and boundary value problems of stochastic partial differential equations (SPDEs) have been studied theoretically in, for example, [5, 6, 8, 10, 33]. Various numerical methods and approximation schemes for SDEs have also been developed, analyzed, and tested [1, 2, 4, 7, 12, 13, 14, 15, 20, 25, 27, 29, 28, 31, 34, 35].

For a given physical system, many different stochastic perturbations may be considered. Generically speaking, noise may enter the physical system either as temporal fluctuations of internal degrees of freedom or as random variations of some external control parameters; internal randomness often reflects itself in *additive* noise terms, while external fluctuations gives rise to *multiplicative* noise terms [18]. The main aim of this paper is to study the properties of some standard numerical approximations to the linear SPDEs for the random field $u = u(x,t)$ driven by an additive noise:

$$du = Au\,dt + dW, \quad x \in \Omega, \quad t > 0. \tag{1.1}$$

Here, Ω is a bounded spatial domain and A is a linear second order elliptic operator with deterministic coefficients, which is defined on a space of functions satisfying certain boundary conditions. W represents an infinite dimensional Brownian motion. We also consider the related time-independent equation

$$-Au = g + \dot{W}, \quad x \in \Omega, \tag{1.2}$$

where g is a given deterministic function and $\dot{W}$ denote a one-parameter family noise. The additive noises may appear in various forms, ranging from the space time white noise to colored noises generated by some infinite dimensional Brownian motion with a prescribed covariance operator [6, 28]. Once the equation is reformulated into a weak form [5], the usual Galerkin finite element methods can be constructed and also analyzed using standard techniques. A priori error estimates of the numerical solution depend on the regularity of the solutions of the original SPDE. Such regularity results are often much harder to establish than their deterministic counterpart [5, 33]. In fact, if dW corresponds to the Brownian white noise, then the regularity estimates are usually very weak, and they lead to very low order error estimates [1, 7, 13]. On the other hand, if the noise is more regular, then it becomes possible to get higher order of error estimates for the numerical solution. In recent years, studies of models with colored noises and their numerical approximation have started to receive more attention; see [28] for an example of physical application and the recent works [26, 14] for works related to stochastic ordinary differential equations (SODEs) and the time discretization. In the present work, we provide the connections between the discrete realizations of noises in different formulations of some SPDEs. Moreover, we illustrate how the error analysis of the standard finite element and finite difference approximations depends on the noises used in the model and the approximation. In order to present a simple analysis, in this paper we focus on the case $\Omega = (0, 1)$ and $Au = u_{xx} - bu$ with the homogeneous Dirichlet boundary condition and b being a deterministic coefficient, though much of our results can be readily extended to higher spatial dimensions and more general second order elliptic operators. For most of the discussion, we also try to present our results in simple finite element terminology that is familiar to people working on the numerical approximations of deterministic PDEs so that it is easy to be understood even for readers who are not necessarily experts on SDEs.

The paper is organized as follows. We first describe the various forms of the noises and their discrete representations. Next, we discuss some convergence results for standard finite element and finite difference approximations. The models used are one dimensional linear stochastic elliptic and parabolic equations, and the results are established for noises given in general forms, which include the spatial or space time white noises as special cases. Then numerical results are presented to support the theoretical analysis. Finally, some concluding remarks are given. The details of the proofs are provided in the appendix.

2. The representation of random noises. To study the accuracy of the discrete approximations, it is useful to first consider the properties of the noises which drive the stochastic equations and the discrete representations of the noises.

Following [1], we *regularize* the noise through discretization. Let $\{x_i = ih\}_0^n$ be a partition of $[0, 1]$ with $h = 1/n$. We begin with $\dot{W}(x)$ being the standard one-parameter family Brownian white noise that satisfies

$$E(\dot{W}(x) \cdot \dot{W}(x')) = \delta(x - x'), \tag{2.1}$$

where δ denote the usual Dirac δ-function and E the expectation. A piecewise constant approximation of the one-parameter white noise is given by [1]

$$\frac{d\widehat{W}_n(x)}{dx} = c_n \sum_{j=1}^{n} \eta_j \chi_j(x), \tag{2.2}$$

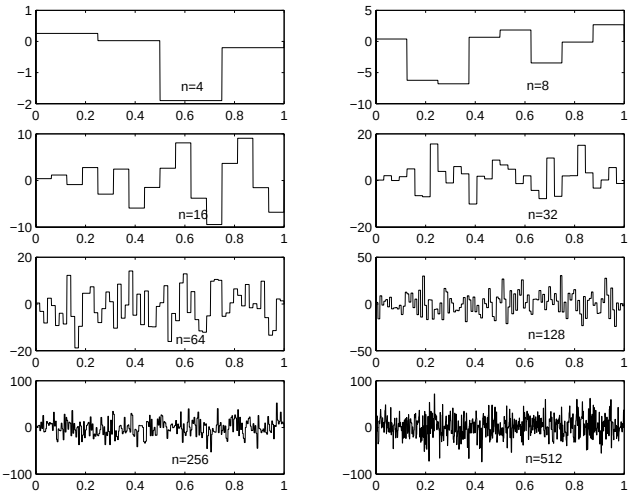

FIG. 2.1. *Piecewise constant approximation for the noise* $d\widehat{W}_n(x)/dx = (1/\sqrt{h})\sum_{j=1}^{n}\eta_j\chi_j(x)$.

where $c_n = h^{-1/2} = \sqrt{n}$ and, for $j = 1, 2, \ldots, N$, $\eta_j \in N(0,1)$ is independently and identically distributed (iid),

$$\sqrt{h}\eta_j = \int_{x_j}^{x_{j+1}} dW(x)\,, \quad \text{and} \quad \chi_j(x) = \begin{cases} 1, & x_j \le x < x_{j+1}, \\ 0 & \text{otherwise.} \end{cases}$$

The discrete analogue of (2.1) for the piecewise constant approximation is given by

$$E\left(\frac{d\widehat{W}_n(x)}{dx}\cdot\frac{d\widehat{W}_n(x')}{dx}\right) = \begin{cases} h^{-1} & \text{if } x_j \le x,\ x' < x_{j+1} \text{ for some } j, \\ 0 & \text{otherwise.} \end{cases}$$

Hence,

$$\lim_{n\to\infty} E\left(\frac{d\widehat{W}_n(x)}{dx}\cdot\frac{d\widehat{W}_n(x')}{dx}\right) = \delta(x - x').$$

In Figure 2.1, some sample realizations of the piecewise constant approximation of one-parameter white noise are illustrated for various values of n. (The random numbers are generated using MATLAB.) We note that similar discussions can be easily generalized to the space time two-parameter family white noises.

2.1. Noises in abstract forms. The SPDEs driven by the white noise often have poor regularity estimates. In the physical world, to take into account the short and long range correlations of the stochastic effects, both white noise and colored noises may be considered. There are many situations where colored noises model the reality more closely, and there are also instances where the important stochastic effects are the noises acting on a few selected frequencies.

In general, we may use an abstract formulation of the infinite dimensional noise:

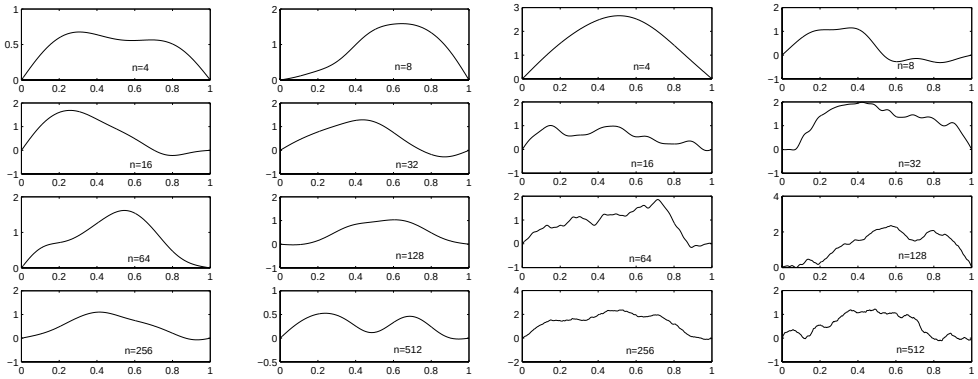

FIG. 2.2. *Noises by Fourier modes* $\sum_{k=1}^{n} \sigma_k \eta_k \sqrt{2} \sin k\pi x$ *with* $\sigma_k = \frac{1}{2^k}$ *(left) and* $\sigma_k = \frac{1}{k^{3/2}}$ *(right).*

$$\dot{W}(x) = \sum_{k=1}^{\infty} \sigma_k \eta_k \psi_k(x), \tag{2.3}$$

where the random variable $\eta_k \sim N(0,1)$ is iid for any k, the deterministic functions $\{\psi_k(x)\}$ form an orthonormal basis of $L_2(0,1)$ or its subspace, and the coefficients $\{\sigma_k\}$ are to be chosen to ascertain the convergence of the series in the mean square sense with respect to some suitable norms.

One of the examples is given by the Fourier modes $\psi_k(x) = \sqrt{2}\sin k\pi x$ which forms a basis of $H_0^1(0,1)$. According to the different decay rates of the coefficients, the noises may display quite different pictures. The pictures in Figure 2.2 and the left two columns of Figure 2.3 provide sample realizations of noises having forms (2.3) in the Fourier basis with coefficients $\sigma_k = 2^{-k}$, $k^{-3/2}$, and $k^{-1/2}$, respectively. Clearly, the realizations give trajectories that look smoother than the ones for the white noise. It can also be seen that the faster the coefficients σ_k decay, the smoother the noise trajectory dW_n/dx looks, which reflects stronger spatial correlation since the noises are heavily concentrated near a few low frequencies. On the other hand, if the coefficients decay sufficiently slowly, then the trajectory can clearly resemble that of a white noise away from the boundary. In fact, it is well known that for spatially uncorrelated white noises, their Fourier coefficients are independent of the frequencies, and they stay at a constant value.

In the analysis and numerical examples given in later sections, the noises given in terms of the Fourier modes are used. The Fourier modes provide one of many possible representations of noises where the smoothness of the noise trajectories are related to the decay of the coefficients in the representation. Another illustrative example is to define the noise in terms of the lowest order wavelet basis. We include the discussion here for comparison. Let ψ be the *wavelet function* and ϕ be the *scaling function* [32]. Let j denote the *dilation index* and k denote the *translation index*, and $\psi_{j,k}(x) = 2^{j/2}\psi(2^j x - k)$. The discrete noise formulated in the wavelet basis is given as

$$\dot{W}_J(x) = c\gamma\phi(x) + \sum_{j=0}^{J-1} \sum_{k=0}^{2^j-1} d_{j,k}\eta_{jk}\psi_{j,k}(x). \tag{2.4}$$

Here, J is the highest level to be considered, and $\gamma, \eta_{jk} \in N(0,1)$ are iid. In the

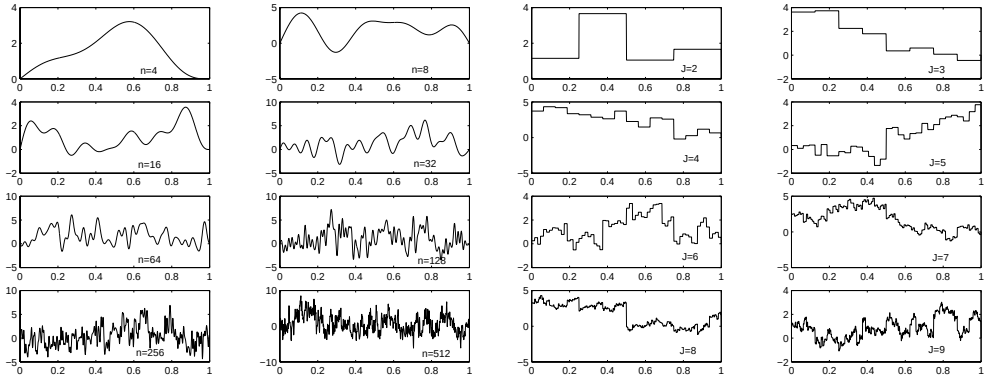

FIG. 2.3. *Noises by* $\sum_{k=1}^{n} \frac{1}{k^{1/2}} \eta_k \sqrt{2} \sin k\pi x$ *(left) and* $\gamma\phi(x) + \sum_{j=0}^{J-1} \sum_{k=0}^{2^j-1} \frac{1}{2^j} \eta_{jk} \psi_{j,k}(x)$ *(right).*

simplest case, we may take the *Haar* wavelet

$$\psi(x) = \begin{cases} 1, & 0 \le x < 1/2, \\ -1, & 1/2 \le x < 1, \\ 0 & \text{otherwise} \end{cases} \qquad \text{and} \qquad \phi(x) = \begin{cases} 1, & 0 \le x < 1, \\ 0 & \text{otherwise.} \end{cases}$$

The right two columns of Figure 2.3 show sample realizations of noises taking the form (2.4) with $c = 1$, $d_{j,k} = 2^{-j}$. The correlation of the noise (2.4) $E(\frac{dW_J(x)}{dx} \cdot \frac{dW_J(x')}{dx})$ is given by

$$E\left(\frac{dW_J(x)}{dx} \cdot \frac{dW_J(x')}{dx}\right) = c^2\phi(x)\phi(x') + \sum_{j=0}^{J-1} \sum_{k=0}^{2^j-1} d_{j,k}^2 \psi_{j,k}(x)\psi_{j,k}(x') \,. \tag{2.5}$$

If in (2.2) $n = 2^J$ and $h = 2^{-J}$, then the piecewise constant approximation of the white noise may also be represented using the wavelet Haar basis. In fact, let $\chi_k(x)$ be characteristic function of interval $[kh, (k+1)h]$; then

$$\frac{d\widehat{W}_n(x)}{dx} = \frac{1}{\sqrt{h}} \sum_{k=0}^{2^J-1} \eta_k \chi_k(x) = \gamma\phi(x) + \sum_{j=0}^{J-1} \sum_{l=0}^{2^j-1} \gamma_{j,l} \psi_{j,l}(x).$$

Here, $\gamma = 2^{-J/2} \sum_{k=0}^{2^J-1} \eta_k \sim N(0,1)$ and

$$\gamma_{j,l} = 2^{(j-J)/2} \left(\sum_{k=l2^{J-j}}^{(l+1)2^{J-j}-1} (-1)^{[k/2^{J-j-1}]} \eta_k \right) \sim N(0,1)$$

are iid. Corresponding to (2.5), $c = d_{j,k} = 1$ so that (2.5) leads again to (2.1). Naturally, when higher order wavelets are used [32, 30], we may expect to have discrete noises that are smoother spatially than the ones represented by the Haar basis when the high frequency coefficients enjoy fast decay properties. Comparing with Fourier modes, wavelet functions may also have compact support; thus, on the one hand, the noises in wavelet basis can closely resemble spatially uncorrelated white noises, while on the other hand they can also be used conveniently to simulate noise more concentrated on certain frequencies as well as certain spatial regions.

In summary, different forms to represent the various noises are discussed in this section. Similar discussion can be carried out in more than one space dimension and for noises parameterized by both time and space variables. Such discussions are relevant to the numerical study of SDEs as the solutions of the stochastic equations that use noises with better regularity become more regular themselves and thus may allow higher order numerical approximations.

3. Numerical method and error analysis. In [1], approximations of SPDEs with the additive space time white noise term discretized by the piecewise constant random process have been studied. Here, we follow roughly the same route, though more general types of noises are used. We show how the accuracy is affected by the correlation or the *smoothness* of the noises.

We divide the discussion into two parts, starting with the simplest one dimensional elliptic equation (boundary value problem of a SODE) and then moving to a parabolic equation in one space dimension and in time (initial boundary value problem of a SPDE). In the set-up of the problems, noises represented in general basis are used, but in the analysis we specialize in using the Fourier modes as the basis of choice to simplify the discussion.

3.1. One dimensional elliptic equation with noise. We now consider the SDE (1.2); that is,

$$\begin{cases} -\Delta u(x) + bu(x) = g(x) + \dot{W}(x), & 0 < x < 1, \\ u(0) = u(1) = 0, \end{cases} \tag{3.1}$$

where $\dot{W}(x)$ denotes the noise, $g(x)$ is a given deterministic term, and $b = b(x)$ is a given deterministic coefficient.

As in [1], we may first replace $\dot{W}(x)$ by a finite dimensional noise $\dot{W}_n(x)$ and let u_n denote the solution of the corresponding equation. We then numerically approximate the equation associated with $\dot{W}_n(x)$ and let u_n^h denote the numerical solution.

If the noise $\dot{W}(x)$ in (3.1) is the white noise, $\dot{W}_n(x)$ is the piecewise constant approximation (2.2), and the Galerkin finite element method with piecewise constant basis is applied to (3.1), the error estimate is given by [1]

$$\begin{aligned} &E\|u - u_n\|_{L_2} \le C\ h, \\ &E\|u_n - u_n^h\|_{L_2} \le C\ h^{3/2}, \\ &E\|u - u_n^h\|_{L_2} \le C\ h. \end{aligned}$$

Due to the poor regularity of the solution, it is seen that, even with higher order finite elements, the order of error estimates does not improve. With colored noises, the order of approximation may increase with better regularity on the solution and the use of higher order elements. As an illustration, we consider the following noise:

$$\dot{W}(x) = \sum_{k=1}^{\infty} \sigma_k \eta_k \psi_k(x), \tag{3.2}$$

where $\{\eta_k\}$ are random variables satisfying

$$\eta_k \sim N(0,1) \ \text{ and } \ cov(\eta_k, \eta_l) = E(\eta_k \eta_l) = q_{kl},$$

with $\{\sigma_k\}$ to be chosen.

Let $\{\sigma_k^n\}_{k=1}^{\infty}$ approach $\{\sigma_k\}_{k=1}^{\infty}$ as $n \to \infty$ in some appropriate sense; then an approximation of $\dot{W}(x)$ is

$$\dot{W}_n(x) = \sum_{k=1}^{\infty} \sqrt{2}\sigma_k^n \eta_k \psi_k(x) \sin k\pi x.$$

The definition of noise term leads to the following stochastic integral for $f \in L_2(0,1)$:

$$S = \int_0^1 f(x)dW(x) = \sum_{k=1}^{\infty} \sigma_k f_k \eta_k,$$

$$S_n = \int_0^1 f(x)dW_n(x) = \sum_{k=1}^{\infty} \sigma_k^n f_k \eta_k,$$

where $f_k = \int_0^1 f(x)\psi_k(x)dx$. That is, S and S_n are random variables having the distribution

$$S \sim N\left(0, \sum_{k=1}^{\infty}\sum_{l=1}^{\infty} \sigma_k \sigma_l f_k f_l q_{kl}\right),$$

$$S_n \sim N\left(0, \sum_{k=1}^{\infty}\sum_{l=1}^{\infty} \sigma_k^n \sigma_l^n f_k f_l q_{kl}\right),$$

provided the double sum is convergent.

For convenience, we introduce the following notation:

$$\overrightarrow{\sigma^n} = (\sigma_1^n, \sigma_2^n, \dots, \sigma_k^n, \dots)^T,$$
$$\vec{\sigma} = (\sigma_1, \sigma_2, \dots, \sigma_k, \dots)^T$$

are infinite column vectors. For two vectors $\overrightarrow{\sigma^n}$ and $\overrightarrow{f}$, we use $\overrightarrow{\sigma^n f}$ to denote the componentwise product

$$\overrightarrow{\sigma^n f} = (\sigma_1^n f_1, \sigma_2^n f_2, \dots, \sigma_k^n f_k, \dots)^T.$$

Let Q be the covariance matrix of random fields $\{\eta_k\}$, namely, Q is the infinite matrix (operator) with entries $Q = (q_{kl})_{k,l=1}^{\infty}$. For an integer s, let Q_s be the infinite matrix with entries $Q_s = ((kl)^s q_{kl})_{k,l=1}^{\infty}$. It is easy to see both Q and Q_s are positive semidefinite. Define the weighted semi-inner products of the vectors $\vec{\sigma}$ and $\vec{\delta}$ as

$$\langle \vec{\sigma}, \vec{\delta} \rangle_Q = \vec{\sigma}^T \cdot Q \cdot \vec{\delta} = \sum_{k=1}^{\infty}\sum_{l=1}^{\infty} \sigma_k \delta_l q_{kl},$$

$$\langle \vec{\sigma}, \vec{\delta} \rangle_{Q_s} = \vec{\sigma}^T \cdot Q_s \cdot \vec{\delta} = \sum_{k=1}^{\infty}\sum_{l=1}^{\infty} \sigma_k \delta_l (kl)^s q_{kl}.$$

The seminorms induced by the above semi-inner products are

$$\|\vec{\sigma}\|_Q^2 = \langle \vec{\sigma}, \vec{\sigma} \rangle_Q \quad \text{and} \quad \|\vec{\sigma}\|_{Q_s}^2 = \langle \vec{\sigma}, \vec{\sigma} \rangle_{Q_s}.$$

Note that $Q_0 = Q$. Using the above notation,

$$S \sim N\left(0, \|\overrightarrow{\sigma f}\|_Q^2\right), \qquad S_n \sim N\left(0, \|\overrightarrow{\sigma^n f}\|_Q^2\right).$$

The difference between S and S_n is given by

$$E|S - S_n|^2 = E|\sum_{k=1}^{\infty}(\sigma_k^n - \sigma_k) f_k \eta_k|^2 = \left\|\overrightarrow{\sigma f} - \overrightarrow{\sigma^n f}\right\|_Q^2.$$

Equation (3.1) can be written in a weak form or an integral form. Both forms are equivalent as shown in [3]. In fact, the solution of (3.1) is a stochastic process $u = u(x)$ which satisfies the weak formulation

$$-\int_0^1 u(x)\Delta\phi(x)dx + \int_0^1 bu(x)\phi(x)dx = \int_0^1 g(x)\phi(x)dx + \int_0^1 \phi(x)dW(x) \tag{3.3}$$

for $\phi \in C^2(0,1) \cap C_0(0,1)$. The integral form is

$$u(x) + \int_0^1 b\,k(x,y)\,u(y)dy = \int_0^1 k(x,y)g(y)dy + \int_0^1 k(x,y)dW(y). \tag{3.4}$$

Here, $k(x,y) = x \wedge y - xy$ is the Green's function associated with the elliptic equation $-\Delta v(x) = \phi(x), v(0) = v(1) = 0$ so that $v(x) = \int_0^1 k(x,y)\phi(y)dy$. ($x \wedge y$ means the smaller one of x and y.) In the present investigation, it is assumed the coefficient b is small enough so that $\lambda^2 = \int_0^1 \int_0^1 b^2 k^2(x,y)dxdy < 1$. We note that this condition is primarily needed in the case of $b < 0$; such a restriction can be lifted for $b > 0$, and the conclusions given later remain valid.

We now substitute $dW(y)$ by $dW_n(y)$ in (3.4) to obtain the following equation:

$$u_n(x) + \int_0^1 b\,k(x,y)\,u_n(y)dy = \int_0^1 k(x,y)g(y)dy + \int_0^1 k(x,y)dW_n(y). \tag{3.5}$$

Thus, $u_n(x)$ satisfy the two-point boundary value problem

$$-\Delta u_n(x) + bu_n(x) = g(x) + \dot{W}_n(x), \qquad u_n(0) = u_n(1) = 0. \tag{3.6}$$

The following theorem shows that u_n indeed approximates u, the solution of (3.4). In order to illustrate the higher order of convergence for more regular noises, we specialize our discussion to the choice of $\{\psi_k(x) = \sqrt{2}\sin k\pi x\}$, that is, noises represented by the Fourier modes.

THEOREM 3.1. *For $\dot{W}_n(x) = \sum_{k=1}^{\infty} \sigma_k^n \eta_k \psi_k(x)$ and $\psi_k(x) = \sqrt{2}\sin k\pi x$, if u_n and u are the solutions of* (3.5) *and* (3.4)*, respectively, then, for some constant $C > 0$,*

$$E\|u - u_n\|_{L_2} \le \frac{C}{1-\lambda}\left\|\overrightarrow{\sigma^n} - \vec{\sigma}\right\|_{Q_{-1}},$$

where $\lambda < 1$ is defined as before.

Proof. Let $e_n(x) = u(x) - u_n(x)$ and

$$F(x) = \int_0^1 k(x,y)dW(y) - \int_0^1 k(x,y)dW_n(y).$$

Subtracting (3.5) from (3.4), we have

$$e_n(x) = -\int_0^1 b\,k(x,y)\,e_n(y)dy + F(x).$$

By Hölder's inequality, it is easy to show that

$$\int_0^1 e_n^2(x)dx \le \lambda^2 \int_0^1 e_n^2(y)dy + 2\lambda \left(\int_0^1 F^2(x)dx\right)^{1/2} \left(\int_0^1 e_n^2(y)dy\right)^{1/2} + \int_0^1 F^2(x)dx,$$

where $\lambda^2 = \int_0^1 \int_0^1 b^2k^2(x,y)dxdy$ and it is assumed that $\lambda < 1$. Taking expectations on both sides, letting $\hat{e}_n = E(\int_0^1 e_n^2(x)dx)$ and $\hat{G}_n = E(\int_0^1 F^2(x)dx)$ and using the Burkholder–Gundy-type inequality $(EX)^2 \le E(X^2)$, we get

$$\hat{e}_n(1-\lambda^2) - 2\lambda\sqrt{\hat{e}_n}\sqrt{\hat{G}_n} - \hat{G}_n \le 0. \tag{3.7}$$

This implies

$$\sqrt{\hat{e}_n} \le \sqrt{\hat{G}_n}(1-\lambda). \tag{3.8}$$

Now let us estimate $\hat{G}_n$.

$$\begin{aligned}\hat{G}_n &= E\left(\int_0^1 F^2(x)dx\right) = \int_0^1 E\left(\sum_{k=1}^{\infty}(\sigma_k^n - \sigma_k)f_k(x)\eta_k\right)^2 dx \\ &= \int_0^1 \left\|\overrightarrow{\sigma f(x)} - \overrightarrow{\sigma^n f(x)}\right\|_Q^2 dx,\end{aligned}$$

where $\overrightarrow{f(x)} = (f_1(x), f_2(x), \dots, f_k(x), \dots)^T$ and $f_k(x) = \int_0^1 k(x,y)\psi_k(y)dy$. Since $k(x,y) = x \wedge y - xy$, direct calculation gives that, for any $x \in [0,1]$,

$$|f_k(x)| = \left|\int_0^1 k(x,y)\psi_k(y)dy\right| = \left|\int_0^1 k(x,y)\sqrt{2}\sin k\pi y dy\right| \le \frac{c}{k},$$

which implies that, for $x \in [0,1]$,

$$\left\|\overrightarrow{\sigma f(x)} - \overrightarrow{\sigma^n f(x)}\right\|_Q \le C\left\|\overrightarrow{\sigma} - \overrightarrow{\sigma^n}\right\|_{Q_{-1}}$$

for some constant $C > 0$. Hence,

$$\hat{G}_n \le C\left\|\vec{\sigma} - \overrightarrow{\sigma^n}\right\|_{Q_{-1}}^2.$$

Combining the above inequality with (3.8), we get

$$E\|u - u_n\|_{L_2} \le \sqrt{E\|u-u_n\|_{L_2}^2} = \sqrt{\hat{e}_n} \le \frac{C}{1-\lambda}\left\|\overrightarrow{\sigma^n} - \vec{\sigma}\right\|_{Q_{-1}}.$$

This proves the theorem. □

We now state a bound on $\dot{W}_n(x)$ in the following lemma.

LEMMA 3.1. *For* $\dot{W}_n(x) = \sum_{k=1}^{\infty} \sigma_k^n \eta_k \psi_k(x)$ *and* $\psi_k(x) = \sqrt{2}\sin k\pi x$, *if* $s \geq 0$ *is an integer, then*

$$E\|\dot{W}_n\|_{H^s} \leq C\left(\sum_{k=1}^{\infty}(\sigma_k^n k^s)^2\right)^{1/2},$$

provided that the right-hand side is convergent.

Proof. First,

$$\frac{d^s}{dx^s}\left(\frac{dW_n}{dx}\right) = \sum_{k=1}^{\infty}\sqrt{2}\sigma_k^n\eta_k(k\pi)^s \sin\left(s\frac{\pi}{2} + k\pi x\right).$$

Since $\{\sin(s\frac{\pi}{2} + k\pi x)\}$ are orthogonal on $[0,1]$, we have

$$\begin{aligned} E\left\|\frac{d^s}{dx^s}\left(\frac{dW_n}{dx}\right)\right\|_{L_2}^2 &= E\int_0^1\left(\sum_{k=1}^{\infty}\sqrt{2}\sigma_k^n\eta_k(k\pi)^s\sin\left(s\frac{\pi}{2}+k\pi x\right)\right)^2 dx \\ &= E\sum_{k=1}^{\infty}(\sigma_k^n)^2\eta_k^2(k\pi)^{2s} \leq c\sum_{k=1}^{\infty}(\sigma_k^n\cdot k^s)^2 \end{aligned}$$

for some constant $c > 0$. The above inequality also implies that, for any $r \leq s$,

$$E\left\|\frac{d^r}{dx^r}\left(\frac{dW_n}{dx}\right)\right\|_{L_2}^2 \leq E\left\|\frac{d^s}{dx^s}\left(\frac{dW_n}{dx}\right)\right\|_{L_2}^2.$$

Hence,

$$E\|\dot{W}_n\|_{H^s} \leq \sqrt{E\|\dot{W}_n\|_{H^s}^2} \leq C\left(\sum_{k=1}^{\infty}(\sigma_k^n k^s)^2\right)^{1/2}$$

for some constant $C > 0$. ∎

Concerning the above lemma, we note that similar lower bound can also be established. Moreover, the results may be established for the case $s < 0$ as well.

We now consider a standard finite element approximation of u_n. From the weak formulation (3.3), u_n satisfies

$$\int_0^1 u_n'\phi'(x)dx + b\int_0^1 u_n(x)\phi(x)dx = \int_0^1 g(x)\phi(x)dx + \int_0^1 \phi(x)dW_n(x) \tag{3.9}$$

for $\phi(x) \in H_0^1(0,1)$. By the Lax–Milgram theorem, there exists a unique solution $u_n \in H_0^1(0,1)$ to (3.9). For convenience, we consider the same partition of $[0,1]$: $0 = x_1 < x_2 < \cdots < x_{n+1} = 1$ with $x_i = (i-1)h$ and $h = 1/n$. If $V_0^h(0,1)$ denotes the finite element subspace of $H_0^1(0,1)$, and $\{\phi_j(x)\}_{j=1}^N$ forms a basis of $V_0^h(0,1)$, the finite element solution of (3.9) is $u_n^h \in V_0^h(0.1)$ that satisfies (3.9) for all $\phi(x) \in V_0^h(0,1)$. Thus, $u_n^h(x) = \sum_{l=1}^N u_l\phi_l(x)$ satisfies the following linear system for $j = 1, 2, \ldots, N$:

$$\begin{aligned} &\sum_{l=1}^N u_l\int_0^1 \phi_l'(x)\phi_j'(x) + b\sum_{l=1}^N u_l\int_0^1\phi_l(x)\phi_j(x)dx \\ &= \int_0^1 g(x)\phi_j(x)dx + \sum_{k=1}^{\infty}\sigma_k^n\eta_k\int_0^1\phi_j(x)\psi_k(x)dx, \end{aligned} \tag{3.10}$$

where $\eta_k \in N(0,1)$. The solution u_n^h is clearly well defined.

The following lemma gives the standard finite element error estimates of (3.9) in the pathwise sense.

LEMMA 3.2. *If $V_0^h(0,1)$ contain all piecewise polynomials of degree r in $H_0^1(0,1)$, and $u_n \in H_0^1(0,1) \cap H^{r+1}(0,1)$, then*

$$\|u_n - u_n^h\|_{L^2} + h|u_n - u_n^h|_{H^1} \le Ch^{r+1}\|u_n\|_{H^{r+1}} \le Ch^{r+1}\|g + \dot{W}_n\|_{H^{r-1}} \tag{3.11}$$

for some constant $C > 0$. □

Furthermore, combining Theorem 3.1 and Lemma 3.2, an estimate on $E(\|u - u_n^h\|_{L_2})$ follows from the triangle inequality.

THEOREM 3.2. *Let u and u_n^h be the solution of* (3.3) *and* (3.10)*, respectively; if the hypothesis in Lemma* 3.2 *is satisfied, then the error estimate is*

$$\begin{aligned} E\|u - u_n^h\|_{L_2} &\le C\left\{\left\|\overrightarrow{\sigma^n} - \vec{\sigma}\right\|_{Q_{-1}} + h^{r+1}\|g\|_{H^{r-1}} + h^{r+1}E\|\dot{W}_n\|_{H^{r-1}}\right\} \\ &\le C\left\{\left\|\overrightarrow{\sigma^n} - \vec{\sigma}\right\|_{Q_{-1}} + h^{r+1}\|g\|_{H^{r-1}} + h^{r+1}\left[\sum_{k=1}^{\infty}(\sigma_k^n k^{r-1})^2\right]^{1/2}\right\} \end{aligned} \tag{3.12}$$

for some generic constant $C > 0$. □

Numerical examples are given in a later section to provide an illustration of the specific order of error estimates one can get based on the above theorem.

Remark 3.1. The same idea can be applied to two dimensional elliptic equations in a rectangular domain, namely, by representing the two dimensional noise as the combinations of the tensor products of $\psi_k(x)$, similar to how Theorem 3.2 can be obtained.

3.2. Parabolic equation in one spatial dimension. Let $\frac{\partial^2 W}{\partial t \partial x}$ denote a space time noise term and g be a deterministic function; we now consider the linear stochastic equations of the form

$$\begin{cases} \frac{\partial u}{\partial t}(t,x) - \frac{\partial^2 u}{\partial x^2}(t,x) + bu(t,x) = \frac{\partial^2 W}{\partial t \partial x}(t,x) + g(t,x),\ t > 0, \\ u(0,x) = u_0(x),\ 0 \le x \le 1, \\ u(t,0) = u(t,1) = 0,\ t \ge 0, \end{cases} \tag{3.13}$$

where the coefficient b, for simplicity, is assumed to be a constant.

The weak formulation of (3.13) is

$$\begin{aligned} &\int_0^1 u(t,x)\phi(x)dx - \int_0^t\int_0^1 u(s,x)\frac{d^2\phi}{dx^2}dxds + \int_0^t\int_0^1 bu(s,x)\phi(x)dxds \\ &= \int_0^1 u_0(x)\phi(x)dx + \int_0^t\int_0^1 \phi(x)dW(s,x) + \int_0^t\int_0^1 g(s,x)\phi(x)dxds \end{aligned} \tag{3.14}$$

for $\phi \in C^2[0,1] \cap C_0[0,1]$. The integral formulation of (3.13) is

$$\begin{aligned} u(t,x) + \int_0^t\int_0^1 G_{t-s}(x,y)bu(x,y)dyds &= \int_0^1 G_t(x,y)u_0(y)dy \\ &+ \int_0^t\int_0^1 G_{t-s}(x,y)dW(s,y) + \int_0^t\int_0^1 G_{t-s}(x,y)g(s,y)dyds, \end{aligned} \tag{3.15}$$

where $G_t(x,y) = 2\sum_{m=1}^{\infty} \sin m\pi x \sin m\pi y e^{-(m\pi)^2 t}$ is the fundamental solution of

$$v_t(t,x) - v_{xx}(t,x) = 0, \quad v(0,x) = \phi(x), \quad v(t,0) = v(t,1) = 0,$$

so that $v(t,x) = \int_0^1 G_t(x,y)\phi(y)dy$.

Using the same idea as that in the previous section, we represent the noise as

$$\frac{\partial^2 W}{\partial t \partial x} = \sum_{k=1}^{\infty} \sigma_k(t)\dot{\eta_k}(t)\psi_k(x), \tag{3.16}$$

where $\sigma_k(t)$ is a continuous function, $\dot{\eta_k}(t)$ is the derivative of standard Wiener process, and $\psi_k(x) = \sqrt{2}\sin k\pi x$. Now define a partition of $[0,T] \times [0,1]$ by rectangles $[t_i, t_{i+1}] \times [x_j, x_{j+1}]$ for $i = 1, 2, \ldots, I$ and $j = 1, 2, \ldots, n$, where $t_i = (i-1)\Delta t$, $x_j = (j-1)h$, $\Delta t = T/I$, and $h = 1/n$. A sequence of noise which approximates the noise is defined as

$$\frac{\partial^2 W_n}{\partial t \partial x} = \sum_{k=1}^{\infty} \sigma_k^n(t)\psi_k(x) \sum_{i=1}^{I} \frac{1}{\sqrt{\Delta t}} \eta_{ki}\chi_i(t), \tag{3.17}$$

where $\chi_i(t)$ is the characteristic function for the ith time subinterval and

$$\eta_{ki} = \frac{1}{\sqrt{\Delta t}} \int_{t_i}^{t_{i+1}} d\eta_k(t) \ \sim \ N(0,1).$$

Replacing $\sigma_k(t)$ by $\sigma_k^n(t)$, we get the discretization in the x-direction, and replacing $\dot{\eta_k}(t)$ by $\sum_{i=1}^{I} \frac{1}{\sqrt{\Delta t}} \eta_{ki}\chi_i(t)$ we get the discretization in the t-direction. Then $\frac{\partial^2 W_n}{\partial t \partial x}$ is substituted for $\frac{\partial^2 W}{\partial t \partial x}$ in (3.15) to get the following equation:

$$\begin{aligned} u_n(t,x) + \int_0^t \int_0^1 G_{t-s}(x,y) b u_n(s,y) dy ds &= \int_0^1 G_t(x,y) u_0(y) dy \\ + \int_0^t \int_0^1 G_{t-s}(x,y) dW_n(s,y) &+ \int_0^t \int_0^1 G_{t-s}(x,y) g(s,y) dy ds; \end{aligned} \tag{3.18}$$

that is, u_n is the solution of the equation

$$\begin{cases} \frac{\partial u_n}{\partial t}(t,x) - \frac{\partial^2 u_n}{\partial x^2}(t,x) + b u_n(t,x) = \frac{\partial^2 W_n}{\partial t \partial x}(t,x) + g(t,x), \ t > 0, \\ u_n(0,x) = u_0(x), \ 0 \le x \le 1, \\ u_n(t,0) = u_n(t,1) = 0, \ t \ge 0. \end{cases} \tag{3.19}$$

Now we assume that

$$\int_0^T \int_0^1 \int_0^t \int_0^1 G_{t-s}^2(x,y) b^2 dy ds dx dt = \bar{\lambda}^2 < 1.$$

Then, under proper assumptions on $\{\sigma_k(t)\}$ and $\{\sigma_k^n(t)\}$, u_n approximates u, the solution of (3.15), as illustrated in the next theorem.

THEOREM 3.3. *Let* $\{\sigma_k(t)\}$ *and its derivative be uniformly bounded by*

$$|\sigma_k(t)| \le \beta_k, \ \ |\sigma_k'(t)| \le \gamma_k \ \ \forall t \in [0,T],$$

and the coefficients $\{\sigma_k^n(t)\}$ *are constructed such that*

$$|\sigma_k(t) - \sigma_k^n(t)| \le \alpha_k^n, \quad |\sigma_k^n(t)| \le \beta_k^n, \quad |\sigma_k^{n\prime}(t)| \le \gamma_k^n \quad \forall t \in [0,T]$$

with positive sequences $\{\alpha_k^n\}$ *being arbitrarily chosen,* $\{\beta_k^n\}$ *and* $\{\gamma_k^n\}$ *being related to* $\{\alpha_k^n\,\beta_k\}$ *and* $\{\gamma_k\}$. *Let* $u_n(t,x)$ *and* $u(t,x)$ *be the solution of* (3.18) *and* (3.15), *respectively; then, for some constants* $C > 0$, *independent of* Δt *and* h,

$$E\|u - u_n\|_{L_2}^2 \le \frac{C}{(1-\bar{\lambda})^2} \sum_{k=1}^{\infty} \left(\frac{(\alpha_k^n)^2}{2(k\pi)^2} + [k^4(\beta_k^n)^2 + (\gamma_k^n)^2](\Delta t)^2 \right), \tag{3.20}$$

provided that the infinite series are all convergent.

The proof of Theorem 3.3 is given in the appendix.

Remark 3.2. The assumption on $\bar{\lambda}$ being small is not crucial; some generalizations can be made without this assumption, for example when $b < 0$.

Now we consider the approximation of u_n. In particular, we use a finite element discretization with respect to the x variable and an implicit difference method in the t variable. Since u_n satisfies the weak formulation,

$$\begin{aligned} &\int_0^1 u_n(t,x)\phi(x)dx + \int_0^t \int_0^1 \frac{\partial u_n}{\partial x}(s,x)\frac{d\phi}{dx}(x)dxds + \int_0^t \int_0^1 bu_n(s,x)\phi(x)dxds \\ &= \int_0^1 u_0(x)\phi(x)dx + \int_0^t \int_0^1 \phi(x)dW_n(s,x) + \int_0^t \int_0^1 g(s,x)\phi(x)dxds \end{aligned} \tag{3.21}$$

for $\phi \in H_0^1(0,1)$. Meanwhile, the semidiscretization in space leads only to the following problem: find $u_n(t,\cdot) \in H_0^1(0,1)$, $t \in (0,T)$, such that

$$\int_0^1 \frac{\partial u_n}{\partial t}\phi dx + \int_0^1 \frac{\partial u_n}{\partial x}\frac{\partial \phi}{\partial x}dx + \int_0^1 bu_n\phi dx = \int_0^1 \left(g + \frac{\partial^2 W_n}{\partial t \partial x} \right)\phi dx \tag{3.22}$$

with

$$\int_0^1 u_n(0,x)\phi(x)dx = \int_0^1 u_0(x)\phi(x)dx$$

for all $\phi \in H_0^1(0,1), t \in (0,T)$.

The finite element discretization of (3.22) is to find $\bar{u}_n^h(t,\cdot) \in V_0^h(0,1)$, $t \in (0,T)$, such that

$$\int_0^1 \frac{\partial \bar{u}_n^h}{\partial t}\phi dx + \int_0^1 \frac{\partial \bar{u}_n^h}{\partial x}\frac{\partial \phi}{\partial x}dx + \int_0^1 b\bar{u}_n^h\phi dx = \int_0^1 \left(g + \frac{\partial^2 W_n}{\partial t \partial x} \right)\phi dx \tag{3.23}$$

with

$$\int_0^1 \bar{u}_n^h(0,x)\phi(x)dx = \int_0^1 u_0(x)\phi(x)dx$$

for all $\phi \in V_0^h(0,1)$, $t \in (0,T)$. Here, $V_0^h(0,1)$ denote the finite element subspace of $H_0^1(0,1)$. By using the expression

$$\bar{u}_n^h(t,x) = \sum_{l=1}^{n-1} u_l(t)\phi_l(x), \qquad t \in (0,T),$$

(3.23) leads to a system of ODEs for $u_l(t)$, $l = 1, \ldots, n-1$. Using the backward-Euler method to solve this ODE system yields the following numerical scheme:

$$\begin{aligned}
&\sum_{l=1}^{n-1}(u_{i+1,l} - u_{i,l}) \int_0^1 \phi_l(x)\phi_j(x)dx + \Delta t \sum_{l=1}^{n-1} u_{i+1,l} \int_0^1 \phi_l'(x)\phi_j'(x)dx \\
&\qquad + b\Delta t \sum_{l=1}^{n-1} u_{i+1,l} \int_0^1 \phi_l(x)\phi_j(x)dx \\
&= \int_{t_i}^{t_{i+1}} \int_0^1 g(s,x)\phi_j(x)dxds + \int_{t_i}^{t_{i+1}} \int_0^1 \phi_j(x)dW_n(s,x)
\end{aligned} \tag{3.24}$$

for $j = 1, 2, \ldots, n-1, i = 1, 2, \ldots, I$ where $u_{i,l} \approx u_l(t_i)$. Let

$$u_n^h(t_i, x) = \sum_{l=1}^{n-1} u_{i,l}\phi_l(x).$$

For simplicity, we now focus on the case of using the continuous piecewise linear finite element in the spatial discretization. The following pathwise error estimate can be found in Theorem 8.2 of [17]:

$$\begin{aligned}
&\|u_n(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2} \\
&\le C\sqrt{1 + \log\frac{t_m}{\Delta t}} \left(\max_{i\le m} \int_{t_{i-1}}^{t_i} \left\| \frac{\partial u_n}{\partial t}(\tau,\cdot) \right\|_{L_2} d\tau + \max_{t\le t_m} h^2 \|u_n(t,\cdot)\|_{H^2} \right).
\end{aligned} \tag{3.25}$$

The following lemma gives estimates of the terms on the right-hand side of (3.25).

LEMMA 3.3. *Let u_n be the solution of* (3.15) *with $g \in C^2([0,T]\times[0,1])$, $u_0 \in C^2[0,1]$, and $\sigma_k^n(t)$ has the bound given in Theorem* 3.3. *Let the constant b be suitably small. Then, if $\delta t \le 1/(2|b|)$, the following inequalities hold for some constant c, independent of Δt and h:*

$$E \int_{t_{i-1}}^{t_i} \left\| \frac{\partial u_n}{\partial t}(\tau,\cdot) \right\|_{L_2} d\tau \le c \left((\Delta t)^2 + \Delta t \sum_k k^2 (\beta_k^n)^2 + \sum_k (\Delta t \beta_k^n)^2 \right)^{1/2} \tag{3.26}$$

and

$$E\|u_n(t,\cdot)\|_{H^2} \le c \left(1 + \frac{1}{\Delta t} \sum_k k^2 (\beta_k^n)^2 \right)^{1/2}. \tag{3.27}$$

The proof of Lemma 3.3 is given in the appendix.

Combining Lemma 3.3 and inequality (3.25), we have the following theorem.

THEOREM 3.4. *Assume that the conditions in Lemma* 3.3 *hold; then*

$$\begin{aligned}
E\|u_n(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2} &\le c \left(1 + \log\frac{t_m}{\Delta t} \right)^{1/2} \\
&\times \left((\Delta t)^2 + \Delta t \sum_k k^2 (\beta_k^n)^2 + \sum_k (\Delta t \beta_k^n)^2 + \frac{h^4}{\Delta t} \sum_k k^2 (\beta_k^n)^2 \right)^{1/2}
\end{aligned}$$

for some constant c. ∎

The error $E\|u(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2}$ can be obtained by applying the triangle inequality to the results of Theorems 3.3 and 3.4.

Remark 3.3. Note that when applied to the case of white noise, that is, $\sigma_k(t) = 1$ for all k, we may take $\beta_k^n = \sigma_k^n = 1$, $\alpha_k^n = 0$ for $k \le N$, and $\beta_k^n = \sigma_k^n = 0$, $\alpha_k^n = 1$ for $k > N$, where $N \to \infty$ as $n \to \infty$; then, after simplification, the estimates in the above theorems give

$$E\|u(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2} \le c\left(1 + \log\frac{t_m}{\Delta t}\right)^{1/2}\left\{\frac{1}{N^{1/2}} + (\Delta t)^{1/2}N^{3/2} + \frac{h^2N^{3/2}}{(\Delta)^{1/2}}\right\}$$

so that $h = O(\Delta t)^{1/2}$ and $N = O(h^{-1/2}) = O((\Delta t)^{-1/4})$ give a best order of $(\Delta t)^{1/8}$ or $h^{1/4}$, up to a logarithmic factor, for $E\|u(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2}$. This is indeed a very low order convergence estimate as was expected [1]. In the next section, however, we present a few examples with colored noises for which the above theorems allow much better estimates on the order of the approximations.

Remark 3.4. The estimate on the order of convergence in the time step size is seen to be at best $O(\sqrt{\Delta t})$, which is largely due to the fact that we restricted our attention to the case where $\{\dot\eta_k(t)\}$ in (3.16) correspond to the derivatives of the Wiener process with t being the parameter. In many physical applications, other processes may also be used [11]. One may also naturally consider more general formulation for the noise terms $\{\dot\eta_k(t)\}$ like what is used for dW/dx in (3.2). In the case where $\{\dot\eta_k\}$ are more regular in time, better error estimates may be obtained using similar techniques.

Discussions and extensions to higher space dimensions can be found in [36].

4. Numerical results for some model equations.

4.1. One dimensional elliptic equation. We now study two cases of the one dimensional elliptic equation with noise described in the previous section. We demonstrate that for different forms of coefficient $\{\sigma_k^n\}$, different rates of convergence are to be obtained.

Case 1. Let the random variables $\{\eta_k\}$ be iid, namely,

$$q_{kl} = E(\eta_k\eta_l) = \delta_{kl} = \begin{cases} 1 & \text{if } k = l, \\ 0 & \text{if } k \ne l, \end{cases} \qquad \sigma_k = \frac{1}{k^{3/2}}, \quad \sigma_k^n = \begin{cases} \sigma_k, & k \le n, \\ 0, & k > n. \end{cases}$$

Then

$$\left\|\overrightarrow{\sigma^n} - \vec\sigma\right\|_{Q_{-1}} = \left(\sum_{k=n+1}^{\infty}\left(\frac{1}{k^{3/2}}\cdot\frac{1}{k}\right)^2\right)^{1/2} \le \frac{1}{n^2}.$$

From Lemma 3.1, we have, for some generic constant $C > 0$,

$$E\|\dot W_n\|_{L_2} \le C\left(\sum_{k=1}^{\infty}(\sigma_k^n)^2\right)^{1/2} \le C\left(\sum_{k=1}^{\infty}\frac{1}{k^3}\right)^{1/2} = C.$$

In other words, $\dot W_n \in L_2(0,1)$; this means that, in Theorem 3.2, $r = 1$. If the piecewise linear finite element basis is used, and $g \in L_2(0,1)$, the following error estimate yields

$$E(\|u - u_n^h\|_{L_2}) \le C(n^{-2} + h^2\|g + \dot W_n\|_{L_2}) \le C\,h^2\,.$$

Thus, asymptotically, we have a second order convergence rate in h for the expectation of the L^2 error.

Case 2. Now let us consider using different coefficients $\{\sigma_k^n\}$ which yield high order convergence results for high order finite element spaces. Still let

$$q_{kl} = E(\eta_k \eta_l) = \delta_{kl} = \begin{cases} 1 & \text{if } k = l, \\ 0 & \text{if } k \neq l, \end{cases} \qquad \sigma_k = \frac{1}{k^{7/2}}, \quad \sigma_k^n = \begin{cases} \sigma_k, & k \leq n, \\ 0, & k > n. \end{cases}$$

Then

$$\left\| \overrightarrow{\sigma^n} - \vec{\sigma} \right\|_{Q_{-1}} = \left(\sum_{k=n+1}^{\infty} \left(\frac{1}{k^{7/2}} \cdot \frac{1}{k} \right)^2 \right)^{1/2} \leq \frac{1}{n^4}.$$

From Lemma 3.1, we have

$$E\|\dot{W}_n\|_{H^2} \leq C \left(\sum_{k=1}^{\infty} (\sigma_k^n k^2)^2 \right)^{1/2} \leq C \left(\sum_{k=1}^{\infty} \left(\frac{1}{k^{7/2}} k^2 \right)^2 \right)^{1/2} = C.$$

In other words, $\dot{W}_n \in H^2(0,1)$; this means that, in Theorem 3.2, $r = 3$. If we use the cubic spline finite element basis, and assume that g is bounded in $H^2(0,1)$, the following error estimate yields

$$E(\|u - u_n^h\|_{L_2}) \leq C(n^{-4} + h^4 \|g + \dot{W}_n\|_{H^2}) \leq C\, h^4$$

for some constant C that depends only on g. Note that such a high order cannot be achieved if we have adopted a white noise [1].

The finite element method (3.10) is implemented for (3.1) with $g(x) = 2 + bx - bx^2$ and the noise $\dot{W}$ as defined in section 3. The exact solution of (3.1) is given by $u = u_d + u_s$, where u_d and u_s correspond to the deterministic and the stochastic parts. Moreover, $u_d(x) = x(1-x)$ and

$$u_s(x) = \sum_{k=1}^{\infty} \frac{\sqrt{2}\sigma_k}{b + (k\pi)^2} \eta_k \sin k\pi x \ .$$

The numerical solution is calculated for $n = 4, 8, 16, 32, 64, 128$ ($h = 1/n$ being the length of the subintervals). For each n, 10,000 runs are performed with different samples of the noise, $\|u - u_n^h\|_{L_2}$ is calculated for each sample, and the averaged value $E\|u - u_n^h\|_{L_2}$ is calculated.

For Case 1, we let $b = 0.5$, $\sigma_k = k^{-3/2}$, and we use the continuous piecewise linear finite element space. The left picture in Figure 4.1 gives the decay of error. The horizontal axis denotes $\log_{10} n$, and the vertical axis denotes $\log_{10} E\|u - u_n^h\|_{L_2}$. The slope of the error curve is nearly -2, in agreement with the theoretical result.

As for Case 2, we let $b = 0.5$, $\sigma_k = k^{-7/2}$, and we use the finite element space consisting of piecewise cubic splines. The right picture in Figure 4.1 gives the decay of error. The slope of the error curve is now nearly -4, also in agreement with the theoretical result.

4.2. Parabolic equation in one spatial dimension. Now consider a special case of parabolic equation described in the previous section. Let

$$\sigma_k(t) = \frac{\cos t}{k^3}, \qquad \sigma_k^n(t) = \begin{cases} \sigma_k(t), & k \leq n, \\ 0, & k > n, \end{cases}$$

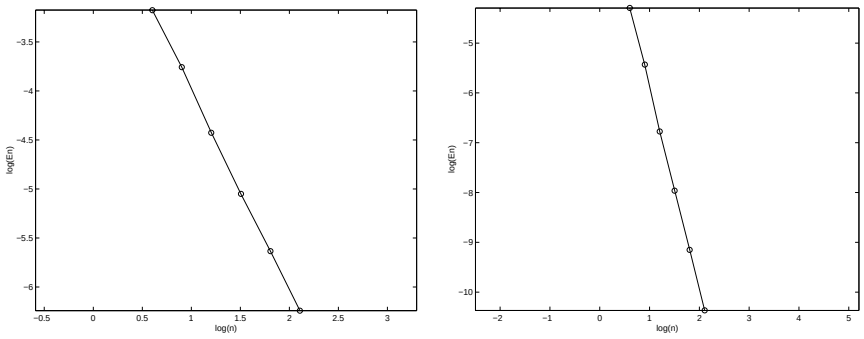

FIG. 4.1. *The error decay with* $\sigma_k = k^{-3/2}$ *and* $k^{-7/2}$.

and the upper bounds $\alpha_k^n, \beta_k^n, \gamma_k^n$ given in Theorem 3.3 can be chosen as

$$\alpha_k^n = \begin{cases} 0, & k \le n, \\ \frac{1}{k^3}, & k > n, \end{cases} \qquad \beta_k^n = \gamma_k^n = \frac{1}{k^3}.$$

Backward-Euler in time with the piecewise linear finite element in space approximation (3.24) was tested for the numerical solution of problem (3.14) with

$$g(t,x) = 10(1+b)x^2(1-x)^2e^t - 10(2-12x+12x^2)e^t \ .$$

We use $b = 0.5$ and $T = 1$. In the absence of noise term, the exact solution is

$$u(t,x) = u_d(t,x) = 10e^t x^2(1-x)^2 \ , \quad \text{with} \quad u_0(x) = 10x^2(1-x)^2 \ .$$

The exact value of $Eu(1, 0.5)$ is about 1.699.

In theory, using the above definitions, we have

$$\sum_{k=1}^{\infty} \frac{(\alpha_k^n)^2}{2(k\pi)^2} \le \sum_{k=n+1}^{\infty} \frac{1}{k^8} \le \frac{1}{n^7} = h^7, \tag{4.1}$$

$$\sum_{k=1}^{\infty} k^4(\beta_k^n)^2 + (\gamma_k^n)^2) \le \sum_{k=1}^{\infty} \left(\frac{1}{k^2} + \frac{1}{k^3} \right) \le C, \tag{4.2}$$

$$\sum_{k=1}^{\infty} (\beta_k^n)^2 \le \sum_{k=1}^{\infty} (k\beta_k^n)^2 \le C \ . \tag{4.3}$$

From Theorems 3.3 and 3.4, we have

$$E\|u - u_n\|_{L_2} \le c(h^7 + (\Delta t)^2)^{1/2},$$

$$E\|u_n(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2} \le c \left(1 + \log \frac{t_m}{\Delta t}\right)^{1/2} \left((\Delta t)^{1/2} + \frac{h^2}{(\Delta t)^{1/2}} \right).$$

Hence,

$$E\|u(t_m,\cdot) - u_n^h(t_m,\cdot)\|_{L_2} \le c \left(1 + \log \frac{t_m}{\Delta t}\right)^{1/2} \left((\Delta t)^{1/2} + \frac{h^2}{(\Delta t)^{1/2}} \right). \tag{4.4}$$

In the actual implementation, different values of Δt and h were used. For each pair $\{\Delta t, h\}$, 10,000 runs are performed with different sample of noise, and the ensemble averages are calculated. The numerical results of $E(u_n^h(1,0.5))$ and $E(u_n^h(1,0.5))^2$ are presented in Table 4.1.

The computational results converge as Δt and h approach to 0. From the table, it can be observed that, for fixed h, the results converge faster as Δt decreases, but for fixed Δt the convergence is less transparent as h decreases. This can be explained by the error estimate (4.4), which is bounded by $(\Delta t)^{1/2} + h^2(\Delta t)^{-1/2}$. If Δt and h are of the same order, the Δt term dominates in the estimate.

The numerical accuracy is also affected by the random number generators used in the different realizations. (The particular generator used in our implementation is obtained using MATLAB.) For comparison, the last two columns of Table 4.1 list the mean and variance of $\eta_{n/2,I}$. We see that, for the relatively larger magnitude of $E(\eta_{n/2,I})$, the error of $E(u_n^h(1,0.5))$ turns out to be larger as well.

Additional numerical examples can be found in [36].

5. Conclusion. In this paper, the numerical approximations of SDEs with different noise realizations are considered. In many instances of stochastic modeling, the noises may indeed be represented in various forms, with some emphasis on the correla-

tion in space and time, while others exhibit the correlation in frequency or spectrum. Our study indicates that the accuracy of the numerical approximation depends on the form of the underlying noise. Both rigorous error estimates and experimental results are provided in our paper.

Throughout our discussion, simple linear equations in one space dimension are used for the purpose of illustrations. We note that much of our consideration can be generalized to stochastic elliptic and parabolic equations in higher space dimensions. For the case of a simple two dimensional square domain, related discussions have been provided in [36]. By confining the theoretical analysis to the one space dimension here, some tedious technical details and complicated expressions are avoided.

Naturally, it will be very interesting to study the similar problems for nonlinear SDEs, which actually motivated the present investigation. It is hopeful that such studies may lead to a better understanding of the behaviors of the discretization error and the modeling error in conducting numerical simulations of nonlinear stochastic dynamics for practical problems [9, 18, 28].

Appendix.

Proof of Theorem 3.3.

Step 1. First, we verify the existence of such $\{\sigma_k^n(t)\}$. Since $\{\sigma_k'(t)\}$ are continuous on interval $[0,T]$, by the Weierstrass approximation theorem, for an arbitrary sequence α_k^n, where n is a fixed number, $k = 1, 2, \ldots$, there exists a sequence of polynomial $\{P_k^n(t)\}$ such that

$$|\sigma_k'(t) - P_k^n(t)| \le \frac{\alpha_k^n}{T} \ \forall t \in [0,T] \ .$$

Let

$$\sigma_k^n(t) = \int_0^t P_k^n(s)ds + \sigma_k(0),$$

and we have

$$|\sigma_k(t) - \sigma_k^n(t)| = \left| \int_0^t (\sigma_k'(s) - P_k^n(s))ds \right| \le \alpha_k^n.$$

By the triangle inequality,

$$|\sigma_k^n(t)| \le |\sigma_k(t)| + \alpha_k^n \le \beta_k + \alpha_k^n = \beta_k^n,$$

$$|\sigma_k^{n\prime}(t)| = |P_k^n(t)| \le |\sigma_k'(t)| + \frac{\alpha_k^n}{T} \le \gamma_k + \frac{\alpha_k^n}{T} = \gamma_k^n.$$

Step 2. Let $\bar{e}_n(t,x) = u(t,x) - u_n(t,x)$ and

$$F(t,x) = \int_0^t \int_0^1 G_{t-s}(x,y)dW(s,y) - \int_0^t \int_0^1 G_{t-s}(x,y)dW_n(s,y),$$

$$\bar{e}_n = E \int_0^T \int_0^1 \bar{e}_n^2(t,x)dxdt,$$

$$\bar{F}_n = E \int_0^T \int_0^1 F^2(t,x)dxdt.$$

Subtracting (3.18) from (3.15), and applying similar manipulation as that in section 3, we get

$$E\|u-u_n\|_{L_2}^2=\bar{e}_n\le\frac{\bar{F}_n}{(1-\bar{\lambda})^2}.$$

To estimate $\bar{F}_n$, we introduce an intermediate noise form

$$\frac{\partial^2\overline{W}_n}{\partial t\partial x}=\sum_{k=1}^{\infty}\sigma_k^n(t)\dot{\eta}_k(t)\psi_k(x),$$

that is, a noise discretized only in the x-direction. Let

$$F_1(t,x)=\int_0^t\int_0^1 G_{t-s}(x,y)dW(s,y)-\int_0^t\int_0^1 G_{t-s}(x,y)d\overline{W}_n(s,y),$$

$$F_2(t,x)=\int_0^t\int_0^1 G_{t-s}(x,y)d\overline{W}_n(s,y)-\int_0^t\int_0^1 G_{t-s}(x,y)dW_n(s,y);$$

then

$$F(t,x)=F_1(t,x)+F_2(t,x),$$

$$\bar{F}_n=E\int_0^T\int_0^1 F^2(t,x)dxdt\le 2\left(E\int_0^T\int_0^1 F_1^2(t,x)dxdt+E\int_0^T\int_0^1 F_2^2(t,x)dxdt\right).$$

Taking advantage of the orthogonality of $\{\sin k\pi x\}$ on the interval $[0,1]$, we have

$$F_1(t,x)=\sum_{k=1}^{\infty}\sqrt{2}\sin k\pi x e^{-(k\pi)^2t}\int_0^t(\sigma_k(s)-\sigma_k^n(s))e^{(k\pi)^2s}d\eta_k(s).$$

Since $\eta_k(t)$ is the standard Wiener process,

$$E\int_0^T\int_0^1 F_1^2(t,x)dxdt=\sum_{k=1}^{\infty}\int_0^T e^{-2(k\pi)^2t}\left(\int_0^t e^{2(k\pi)^2s}(\sigma_k(s)-\sigma_k^n(s))^2ds\right)dt$$

$$\le\sum_{k=1}^{\infty}(\alpha_k^n)^2\int_0^T e^{-2(k\pi)^2t}\left(\int_0^t e^{2(k\pi)^2s}ds\right)dt\le C_1\sum_{k=1}^{\infty}\frac{(\alpha_k^n)^2}{2(k\pi)^2}.$$

Using

$$\eta_{ki}=\frac{1}{\sqrt{\Delta t}}\int_{t_i}^{t_{i+1}}d\eta_k(t),$$

we have

$$F_2(t,x)=\sum_{k=1}^{\infty}\psi_k e^{-(k\pi)^2t}\left[\int_0^t e^{(k\pi)^2s}\sigma_k^n(s)d\eta_k(s)\right.$$

$$\left.-\int_0^t e^{(k\pi)^2s}\sigma_k^n(s)\sum_{i=1}^{I}\frac{1}{\sqrt{\Delta t}}\eta_{ki}\chi_i(s)ds\right]$$

$$=\sum_{k=1}^{\infty}\psi_k e^{-(k\pi)^2t}\left[\sum_{i=1}^{I_t-1}\int_{t_i}^{t_{i+1}}\left(e^{(k\pi)^2s}\sigma_k^n(s)-\frac{1}{\Delta t}\int_{t_i}^{t_{i+1}}e^{(k\pi)^2\tilde{s}}\sigma_k^n(\tilde{s})d\tilde{s}\right)d\eta_k(s)\right.$$

$$\left.+\int_{t_{I_t}}^{t}\left(e^{(k\pi)^2s}\sigma_k^n(s)-\frac{1}{t-t_{I_t}}\int_{t_{I_t}}^{t}e^{(k\pi)^2\tilde{s}}\sigma_k^n(\tilde{s})d\tilde{s}\right)d\eta_k(s)\right],$$

where I_t is the integer such that $t_{I_t} < t \le t_{I_t+1}$. Then

$$\begin{aligned}
&E\int_0^T\int_0^1 F_2^2(t,x)dxdt\\
&=\sum_{k=1}^{\infty}\int_0^T \frac{e^{-2(k\pi)^2t}}{(\Delta t)^2}\left(\sum_{i=1}^{I_t-1}\int_{t_i}^{t_{i+1}}\left(\int_{t_i}^{t_{i+1}}(e^{(k\pi)^2 s}\sigma_k^n(s)-e^{(k\pi)^2\tilde{s}}\sigma_k^n(\tilde{s}))d\tilde{s}\right)^2 ds\right.\\
&\quad\left.+\int_{t_{I_t}}^{t}(\frac{\Delta t}{t-t_{I_t}})^2\left(\int_{t_i}^{t_{i+1}}(e^{(k\pi)^2 s}\sigma_k^n(s)-e^{(k\pi)^2\tilde{s}}\sigma_k^n(\tilde{s}))d\tilde{s}\right)^2 ds\right)dt.
\end{aligned}$$

For s, $\tilde{s}\in[t_i,t_{i+1}]$, using the smoothness assumption on $\sigma_k(t)$, we get

$$\begin{aligned}
&|e^{(k\pi)^2 s}\sigma_k^n(s)-e^{(k\pi)^2\tilde{s}}\sigma_k^n(\tilde{s})|\\
&\le |e^{(k\pi)^2 s}-e^{(k\pi)^2\tilde{s}}|\sigma_k^n(s)+e^{(k\pi)^2\tilde{s}}|\sigma_k^n(s)-\sigma_k^n(\tilde{s})|\\
&\le (k\pi)^2 e^{(k\pi)^2 t_{i+1}}\sigma_k^n(s)\Delta t+e^{(k\pi)^2 t_{i+1}}\sigma_k^{n\prime}(\xi_i)\Delta t\\
&\le e^{(k\pi)^2 t_{i+1}}((k\pi)^2\beta_k^n+\gamma_k^n)\Delta t.
\end{aligned}$$

Here, $t_i\le\xi_i\le t_{i+1}$. Without loss of generality, we assume $t=t_{I_t+1}$; then

$$\begin{aligned}
&E\int_0^T\int_0^1 F_2^2(t,x)dxdt\\
&\le\sum_{k=1}^{\infty}\int_0^T e^{-2(k\pi)^2t}\left[\sum_{i=1}^{I_t}\int_{t_i}^{t_{i+1}}\frac{1}{(\Delta t)^2}(e^{(k\pi)^2 t_{i+1}}((k\pi)^2\beta_k^n+\gamma_k^n)(\Delta t)^2)^2 ds\right]dt\\
&\le C\sum_{k=1}^{\infty}\int_0^T e^{-2(k\pi)^2t}\left[\sum_{i=1}^{I_t}\int_{t_i}^{t_{i+1}}(e^{2(k\pi)^2 t_{i+1}}((k\pi)^4(\beta_k^n)^2+(\gamma_k^n)^2)(\Delta t)^2 ds\right]dt\\
&\le C\sum_{k=1}^{\infty}\sum_{i=1}^{I_t}\int_0^T e^{-2(k\pi)^2t}e^{2(k\pi)^2 t_{i+1}}dt(k^4(\beta_k^n)^2+(\gamma_k^n)^2)(\Delta t)^3\\
&\le C\sum_{k=1}^{\infty}\sum_{i=1}^{I_t}(k^4(\beta_k^n)^2+(\gamma_k^n)^2)(\Delta t)^3\\
&\le C\sum_{k=1}^{\infty}(k^4(\beta_k^n)^2+(\gamma_k^n)^2)(\Delta t)^2.
\end{aligned}$$

The last inequality comes from $\sum_{i=1}^{I_t},1\le I=1/\Delta t$. The theorem is now proved. □

Proof of Lemma 3.3. In general, by applying the same technique as in the proof of Theorem 3.1, we may first estimate

$$\begin{aligned}
E\int_0^t\int_0^1 u_n^2(t,x)dxdt&\le\frac{c}{1-\bar{\lambda}}E\int_0^t\int_0^1[(G_t(x,y)u_0(y))^2+(G_{t-s}(x,y)g(s,y))^2]dyds\\
&\quad+\frac{c}{1-\bar{\lambda}}E\int_0^t\int_0^1\left(\int_0^t\int_0^1 G_{t-s}(x,y)dW_n(s,y)\right)^2 dxdt.
\end{aligned}$$

Next, one may differentiate (3.18) to get

$$\frac{\partial u_n}{\partial t}(t,x) = -\int_0^t\int_0^1 \frac{\partial}{\partial t}G_{t-s}(x,y)bu_n(s,y)dyds + \int_0^1 \frac{\partial}{\partial t}G_t(x,y)u_0(y)dy + \int_0^t\int_0^1 \frac{\partial}{\partial t}G_{t-s}(x,y)g(s,y)dyds + \int_0^t\int_0^1 \frac{\partial}{\partial t}G_{t-s}(x,y)dW_n(s,y).$$

Then one may estimate $E\int_{t_{i-1}}^{t_i}\int_0^1(\frac{\partial u_n}{\partial t}(t,x))^2dxdt$ using the above equation. Similarly, one may estimate $E\int_0^1(\frac{\partial^2 u_n}{\partial x^2}(t,x))^2dxdt$.

Since we have assumed that b is a constant, we now provide a simpler estimate which, in spirit, is similar to the estimate derived from the integral formulation.

Let $g(t,x)=\sum_k g_k(t)\psi_k(x)$, $u_n(t,x)=\sum_k u_k^{(n)}(t)\psi_k(x)$, $u_0(x)=\sum_k u_k\psi_k(x)$; then

$$\frac{\partial}{\partial t}u_k^{(n)}(t) + (k^2\pi^2+b)u_k^{(n)}(t) = g_k(t) + \frac{\sigma_k^n(t)}{\sqrt{\Delta t}}\sum_i \eta_{ki}\chi_i(t).$$

Thus, for $t\in[t_{i-1},t_i)$,

$$u_k^{(n)}(t) = e^{-((k\pi)^2+b)t}u_k + \int_0^t e^{-((k\pi)^2+b)(t-s)}g_k(s)ds + \sum_{j=1}^{i}\int_0^t e^{-((k\pi)^2+b)(t-s)}\frac{\sigma_k^n(s)}{\sqrt{\Delta t}}\eta_{kj}\chi_j(s)ds.$$

This leads to

$$u_k^{(n)}(t) = e^{-((k\pi)^2+b)t}u_k + \int_0^t e^{-((k\pi)^2+b)(t-s)}g_k(s)ds + \sum_{j=1}^{i}\frac{\eta_{kj}}{\sqrt{\Delta t}}\int_{t_{j-1}}^{t_j^*} e^{-((k\pi)^2+b)(t-s)}\sigma_k^n(s)ds,$$

where $t_l^*=t_l$ for $l<i$ and $t_i^*=t$. It follows that

$$E\left[u_k^{(n)}(t)\right]^2 \le cu_k^2e^{-2((k\pi)^2+b)t} + cT\int_0^t e^{-2((k\pi)^2+b)(t-s)}g_k^2(s)ds + \frac{c}{\Delta t}\sum_{j=1}^{i}\left(\int_{t_{j-1}}^{t_j^*} e^{-((k\pi)^2+b)(t-s)}\sigma_k^n(s)ds\right)^2$$

for some constant c.

Since $u_0\in C^2[0,1]$ and $g\in C^2([0,T]\times[0,1])$, we have, for some constant $c>0$,

$$\sum_k (k\pi)^4\left\{u_k^2e^{-2((k\pi)^2+b)t} + \int_0^t e^{-2((k\pi)^2+b)(t-s)}g_k^2(s)ds\right\} \le c.$$

Using the bounds on σ_k^n and the fact that b is a small constant, we have

$$\begin{aligned}\sum_{l=1}^{i}\left(\int_{t_{l-1}}^{t_l^*} e^{-((k\pi)^2+b)(t-s)}\sigma_k^n(s)ds\right)^2 &\le c(\beta_k^n)^2\int_0^t e^{-2((k\pi)^2+b)(t-s)}ds\\ &\le \frac{c(\beta_k^n)^2}{(k\pi)^2+b}.\end{aligned}$$

Thus, for small b, we have

$$\begin{aligned}E\|u_n(\tau,\cdot)\|_{H^2} &\le (\,E\|u_n(\tau,\cdot)\|_{H^2}^2)^{1/2}\\ &\le c\left(1+\frac{1}{\Delta t}\sum_k\, k^2(\beta_k^n)^2\right)^{1/2}\end{aligned}$$

for some constant $c>0$. This proves the inequality (3.27).

For (3.26), we have

$$\frac{\partial}{\partial t}u_k^{(n)}(t) = -((k\pi)^2+b)u_k^{(n)}(t)+g_k(t)+\frac{\sigma_k^n(t)}{\sqrt{\Delta t}}\sum_i \eta_{ki}\chi_i(t).$$

So,

$$E\int_{t_{i-1}}^{t_i}\left(\frac{\partial}{\partial t}u_k^{(n)}(s)\right)^2 ds \le cE\int_{t_{i-1}}^{t_i}((k^2\pi^2+b)u_k^{(n)}(s))^2ds + c\int_{t_{i-1}}^{t_i}[g_k^2(s)+(\sigma_k^n(s))^2]ds.$$

Thus,

$$\begin{aligned}E\int_{t_{i-1}}^{t_i}\left\|\frac{\partial u_n}{\partial t}(\tau,\cdot)\right\|_{L_2} d\tau &\le \left(\Delta tE\int_{t_{i-1}}^{t_i}\left\|\frac{\partial u_n}{\partial t}(\tau,\cdot)\right\|_{L_2}^2 d\tau\right)^{1/2}\\ &\le c\left((\Delta t)^2+\Delta t\sum_k\, k^2(\beta_k^n)^2+\sum_k(\Delta t\beta_k^n)^2\right)^{1/2}.\end{aligned}$$

This proves (3.26). □

DYNAMIC ITERATION USING REDUCED ORDER MODELS: A METHOD FOR SIMULATION OF LARGE SCALE MODULAR SYSTEMS*

MURUHAN RATHINAM† AND LINDA R. PETZOLD†

Abstract. We describe a new iterative method, dynamic iteration using reduced order models (DIRM), for simulation of large scale modular systems using reduced order models that preserve the interconnection structure. This method may be compared to the waveform relaxation technique; however, unlike DIRM, waveform relaxation does not take advantage of model reduction techniques. The DIRM method involves simulating in turn each subsystem connected to model reduced versions of the other subsystems. The data from this simulation is then used to update the reduced model for that particular subsystem. We provide analytical results on convergence and accuracy of the DIRM method as well as numerical examples that demonstrate the success of DIRM and verify the analysis.

Key words. large scale systems, model reduction, dynamic iteration, proper orthogonal decomposition

1. Introduction.

Very large scale systems of differential and differential algebraic equations such as the U.S. power grid, very large scale integrated (VLSI) circuits, chemical reactors, and weather systems present challenges in computing. Usually such large scale systems consist of many interacting subsystems, which may in some problems be governed by very different physical laws. On such systems conventional methods of direct numerical integration of the full system may not be feasible without massive computing resources.

An iterative approach known as *waveform relaxation* (WR), where smaller subsystems are simulated separately and then the couplings are accounted for through iteration, was developed by researchers for the simulation of VLSI circuits. See Lelarasmee, Ruehli, and Sangiovanni-Vincentelli [7], Miekkala and Nevanlinna [9], and Miekkala [8] for details. The WR method is a form of *dynamic iteration* in the sense that the variable being iterated is a function (the entire solution waveform for a given time interval) and not a vector. This method has subsequently been applied by researchers to PDEs of parabolic and hyperbolic types [2]. Such a modular approach in principle has the advantage that it facilitates parallel computation, exploits the multirate nature of some problems, and offers the potential of using different numerical techniques for different subsystems. However, the WR technique has not become the mainstay in application areas. This is primarily due to the poor convergence properties of WR.

Another way to deal with models that are too complex is via model reduction. Several model reduction techniques have been studied by researchers in various fields. *Balanced truncation* has been studied by the control community (see Zhou and Doyle [15] and Lall, Marsden, and Glavaski [6], for instance), *proper orthogonal decomposition* (POD) has been applied in the study of turbulence (see Holmes, Lumley, and

Berkooz [5]), cascading failures in power grids (Parrilo et al. [11]), and control of compressors (Glavaski, Marsden, and Murray [3]), etc., and *selective modal analysis* has been developed by researchers in the electrical power field (Perèz-Arriaga et al. [12]), to name a few.

In this paper we present a method that combines the idea of dynamic iteration with the use of reduced order models. Our method also seeks to remedy some of the shortcomings of WR. Our approach, termed dynamic iteration using reduced order models (DIRM), involves simulation of each subsystem in turn while it is connected to reduced order models of the rest of the subsystems. The simulation results are then used to update the reduced order model for that particular subsystem. If the reduced order models are small enough, then the combination of an unreduced subsystem with the rest of the reduced subsystems results in a system small enough not to pose insurmountable computational difficulties. In principle any model reduction method that uses data from trajectories could be used in this iteration. In this paper we use POD (also known as *Karhunen–Loève decomposition*) for the model reduction.

Even though theoretically the WR method has good asymptotic convergence, in practice there may be large initial overheads. For example, consider a one-dimensional (1D) PDE with the spatial domain divided into 10 subsystems of adjacent regions. It will take nine iterations before the first subsystem "sees" the last subsystem. In the DIRM method, by contrast, every subsystem is connected to all other (reduced versions of) subsystems, and one may not expect such overheads. This is possible only because of the fact that DIRM incorporates reduced order models.

This paper is organized as follows. In section 2 we review the POD method of model reduction and comment on its application to modular systems. In section 3 we describe DIRM in detail and also provide a brief account of the WR technique. In section 4 we provide an analysis of the DIRM method as applied to a linear time invariant system consisting of two subsystems and present results on the accuracy and convergence behavior of DIRM. Section 5 describes several numerical examples. These include a nonlinear power grid simulation and some reaction diffusion problems described by PDEs, with comparison to WR. We also give some examples highlighting certain special cases, which include situations where DIRM has difficulty converging as predicted by the analysis, and show how to modify DIRM to fix this problem. Finally, in section 6 we present conclusions and discuss future research.

2. Model reduction using POD. The POD technique for model reduction consists of first finding a subspace in the full phase space of a given dynamical system and then constructing an approximating dynamical system in that subspace. The original dynamical system may be nonlinear, and in that case the resulting lower dimensional model will also typically be nonlinear.

2.1. POD. POD, also known as Karhunen–Loève decomposition or principal component analysis, provides a method for finding the best approximating subspace to a given set of data. Originally POD was used as a data representation technique. For model reduction of dynamical systems POD may be used on data points obtained from system trajectories obtained via experiments, numerical simulations, or analytical derivations. For more information see Rathinam and Petzold [13], Holmes, Lumley, and Berkooz [5], Moore [10], Lall, Marsden, and Glavaski [6], Glavaski, Marsden, and Murray [3], and references therein.

Given a set of data points $x^{(\alpha)} \in \mathbb{R}^n$, POD seeks a subspace $S \subset \mathbb{R}^n$ so that the total square distance

$$D = \sum_{\alpha=1}^{N} \left\| x^{(\alpha)} - \rho_S x^{(\alpha)} \right\|^2,$$

where ρ_S is the orthogonal projection onto the subspace S, is minimized. The norm considered is the 2-norm. (Thus we assume that the phase space comes equipped with a notion of inner product.) The solution to this problem may be stated in terms of the *correlation matrix* defined by

$$R = \sum_{\alpha=1}^{N} x^{(\alpha)} \left(x^{(\alpha)} \right)^T.$$

Note that R is $n \times n$ and symmetric positive semidefinite. Let $\lambda_1 \geq \lambda_2 \cdots \geq \lambda_n \geq 0$ be the ordered eigenvalues of R. Then the minimum value of D over all $k(\leq n)$ dimensional subspaces S is given by $\sum_{j=k+1}^{n} \lambda_j$ [5]. In addition, the S that minimizes D is the invariant subspace corresponding to the eigenvalues $\lambda_1, \ldots, \lambda_k$. In practice one need not compute R. Instead, it is efficient to use the $n \times N$ matrix X whose columns are $x^{(\alpha)}$. Then $\sqrt{\lambda_1}, \ldots, \sqrt{\lambda_n}$ are the singular values of X (assuming $n \leq N$), and S is the span of the left singular vectors of X corresponding to k the largest singular values. Note that $R = XX^T$.

Often it may be best to find an affine subspace as opposed to a linear subspace. This requires first to find the mean value of the data points

$$\bar{x} = \frac{1}{N} \sum_{\alpha=1}^{N} x^{(\alpha)}$$

and then construct the *covariance matrix* $\bar{R}$ given by

$$\bar{R} = \sum_{\alpha=1}^{N} \left(x^{(\alpha)} - \bar{x} \right) \left(x^{(\alpha)} - \bar{x} \right)^T.$$

Let S_0 be the invariant subspace of the k largest eigenvalues of $\bar{R}$. Then the best approximating affine subspace S passes through $\bar{x}$ and is obtained by shifting S_0 by $\bar{x}$. Algebraically the projection onto the subspace S is given by

$$z = \rho(x - \bar{x}), \tag{2.1}$$

where $z \in \mathbb{R}^k$ are coordinates in the subspace S, $x \in \mathbb{R}^n$ are coordinates in the original coordinate system in $\mathbb{R}^n$, and the matrix ρ of the projection consists of row vectors ϕ_i^T $(i = 1, \ldots, k)$, where ϕ_i are the unit eigenvectors corresponding to the largest k eigenvalues of $\bar{R}$. Note that given any point $p \in S$ with coordinates $z \in \mathbb{R}^k$ the coordinates $x \in \mathbb{R}^n$ of the same point in the original coordinate system are given by

$$x = \rho^T z + \bar{x}.$$

2.2. Galerkin projection. Having found the approximating subspace for our system data, our next task is to construct a vector-field on this subspace that represents the reduced order model. This procedure is known as Galerkin projection and has been widely used in reducing PDEs to ODEs by projecting onto appropriate basis functions that describe the spatial variations in the solution. The procedure is applicable to any subspace; the subspace need not be obtained from the POD method. See [5] for more details.

Suppose the original dynamical system in $\mathbb{R}^n$ is given by a vector-field f,

$$\dot{x} = f(x,t).$$

Let $S \subset \mathbb{R}^n$ be the best k dimensional approximating affine subspace with projection given by (2.1). A vector-field f_a in the subspace S is constructed by the following rule: for any point $p \in S$ compute the vector-field $f(p,t)$ and take the projection $\rho f(p,t)$ onto the subspace S to be the value of $f_a(p,t)$. If z are the subspace coordinates of p, then $f_a(z,t) = \rho f(\rho^T z + \bar{x}, t)$. Thus we obtain the following reduced model:

$$\dot{z} = f_a(z,t) = \rho f(\rho^T z + \bar{x}, t). \tag{2.2}$$

If we are solving an initial value problem with $x(0) = x_0$, then in the reduced model one has the initial condition $z(0) = z_0$, where

$$z_0 = \rho(x_0 - \bar{x}).$$

Hence the approximating solution $\hat{x}(t)$ in the original coordinates in $\mathbb{R}^n$ is given by

$$\hat{x}(t) = \rho^T z(t) + \bar{x}.$$

From the above it is easy to see that the approximating solution $\hat{x}(t)$ is the solution to the following initial value problem:

$$\dot{\hat{x}} = Pf(\hat{x},t), \qquad \hat{x}(0) = \hat{x}_0 = P(x_0 - \bar{x}) + \bar{x}, \tag{2.3}$$

where $P = \rho^T \rho \in \mathbb{R}^{n \times n}$ is the matrix of the projection expressed in the original coordinate system in $\mathbb{R}^n$. Also note that $\hat{x}_0$ is just the projection of x_0 onto the affine subspace S.

2.3. Modular model reduction. In this paper *modular system* shall mean any system expressed in the form

$$\dot{x}_i = f_i(x_1, \ldots, x_m, t), \qquad i = 1, \ldots, m. \tag{2.4}$$

Note that any system $\dot{x} = f(x,t)$ can be written in this form. All that is involved is a partitioning of the states $x = (x_1, \ldots, x_m)$, where $x_i \in \mathbb{R}^{n_i}$ are vectors. This partitioning may arise naturally from the physical interpretation of the system, as in the power grid example presented later, or may be introduced according to some optimal criteria for the simulation problem at hand. In this paper we consider situations where the overall system is very large; hence we modularize the system by breaking it into manageable smaller parts. The POD method can be made to "respect" the partitioning by forming separate covariance matrices for each of the subsystem states $x_i \in \mathbb{R}^{n_i}$,

$$\bar{R}_i = \sum_{\alpha=1}^{N} \left(x_i^{(\alpha)} - \bar{x}_i \right) \left(x_i^{(\alpha)} - \bar{x}_i \right)^T,$$

and computing separate projections $\rho_i \in \mathbb{R}^{k_i \times n_i}$ that operate within the state space of a subsystem. Thus the reduced model will be

$$\dot{z}_i = \rho_i f_i(\rho_1^T z_1 + \bar{x}_1, \ldots, \rho_m^T z_m + \bar{x}_m, t), \qquad i = 1, \ldots, m.$$

3. DIRM. In this section we describe the DIRM method of simulating a large scale modular system of the form (2.4). We first describe the WR method in order to put our method in context.

The basic idea behind WR as applied to system (2.4) may be explained as follows. Start with an initial approximation for solutions of each of the subsystem trajectories: $x_1^{(0)}(t), \ldots, x_m^{(0)}(t)$. At the kth iteration, simulate each subsystem separately:

$$\dot{x}_i^{(k)} = f_i(x_1^{(k-1)}(t), \ldots, x_{i-1}^{(k-1)}(t), x_i^{(k)}, x_{i+1}^{(k-1)}(t), \ldots, x_m^{(k-1)}(t), t), \quad i = 1, \ldots, m.$$

This is a simplified explanation of the method. For a detailed exposition and analysis we refer to [7], [9], and [8]. It has been shown that this iteration converges for ODE systems in finite interval simulations under some mild conditions. However, WR may suffer from slow convergence. Overlapping techniques are often used to speed up the convergence [8].

The DIRM method also simulates each subsystem in turn, but not in isolation. Instead, the unreduced model of the subsystem is connected to reduced order models of the other subsystems. If the reduced order models are small enough, then the overall size of the resulting system is still of manageable dimensions. Consider the modular system (2.4) with initial conditions $x_i(0) = x_{i,0}$ and suppose we are interested in a simulation interval $[0, T]$. The DIRM method is described as follows.

Start with some initial reduced model for each subsystem. In the POD approach a reduced model for subsystem i is characterized by the projection matrix ρ_i and the mean data value $\bar{x}_i$. Let the initial reduced models be $(\rho_i^{(0)}, \bar{x}_i^{(0)})$. One way to generate these is to simulate each subsystem in isolation (in the given interval), setting the states of the other subsystems to some constant values, for instance, the initial conditions. In other words, simulate the following equations:

$$\dot{x}_i = f_i(x_{1,0}, x_{2,0}, \ldots, x_{i-1,0}, x_i, x_{i+1,0}, \ldots, x_{m,0}, t), \qquad i = 1, \ldots, m,$$

with initial conditions $x_i = x_{i,0}$. The resulting solutions $x_i(t)$ may be used to compute the covariance matrices $\bar{R}_i$:

$$\begin{aligned} \bar{x}_i &= \frac{1}{T} \int_0^T x_i(t) dt, \\ \bar{R}_i &= \int_0^T (x_i(t) - \bar{x}_i)(x_i(t) - \bar{x}_i)^T dt. \end{aligned} \tag{3.1}$$

At the jth step in the iteration we have the reduced models from the previous step $(\rho_i^{(j-1)}, \bar{x}_i^{(j-1)})$. We also have the trajectories $x_i^{(j-1)}(t), t \in [0, T]$, which were used in constructing these reduced models. Now for $i = 1, \ldots, m$ connect the unreduced subsystem i with the reduced versions of all other subsystems and simulate the resulting system

$$\begin{aligned} \dot{x}_i &= f_i(X, t), \\ \dot{z}_l &= \rho_l^{(j-1)} f_l(X, t), \qquad l = 1, \ldots, i-1, i+1, \ldots, m, \end{aligned} \tag{3.2}$$

where X is the following list of vector arguments:

$$X = \left(\rho_1^{(j-1)}\right)^T z_1 + \bar{x}_1^{(j-1)}, \ldots, \left(\rho_{i-1}^{(j-1)}\right)^T z_{i-1} + \bar{x}_{i-1}^{(j-1)}, \\ x_i, \left(\rho_{i+1}^{(j-1)}\right)^T z_{i+1} + \bar{x}_{i+1}^{(j-1)}, \ldots, \left(\rho_m^{(j-1)}\right)^T z_m + \bar{x}_m^{(j-1)}.$$

Use the resulting trajectory for the ith subsystem $x_i^{(j)}(t)$ to compute an updated reduced order model for the ith subsystem $(\rho_i^{(j)}, \bar{x}_i^{(j)})$. The iteration is terminated when

$$\sup_{t\in[0,T]} \left\{ \|x_i^{(j)}(t) - x_i^{(j-1)}(t)\| \right\} \leq tol, \qquad i = 1, \ldots, m, \tag{3.3}$$

where *tol* is some specified tolerance.

Remark 3.1. In (3.2) the trajectories $z_l^{(j)}(t)$ correspond to reduced models, while the trajectory $x_i^{(j)}(t)$ corresponds to the full model. In situations when the coupling between subsystems is "weak," $x_i^{(j)}(t)$ will be more accurate than $z_l^{(j)}(t)$. Since the reduced models are computed directly from $x_i^{(j)}(t)$, the simulation for the next iteration $j+1$ is directly affected by $x_i^{(j)}(t)$ and only indirectly by $z_l^{(j)}(t)$. This helps keep the effect of errors due to model reduction small. Also note that the final solution comes directly from $x_i^{(j)}(t)$, and the $z_l^{(j)}(t)$ enter only indirectly.

For any technique involving reduced order models, accuracy is an important issue. Since reduced order models are computed from the trajectories obtained from the given initial value problem, when the coupling dynamics is not very strong the situation for DIRM is reasonably close to the circumstances under which the accuracy of the POD method could be expected to be as good as possible as indicated by the error analysis of POD in [13].

We have observed from various examples, linear and nonlinear, that the DIRM method generally converges. We have also found examples where it fails to converge, but on those occasions breaking up the time interval $[0, T]$ into smaller ones $[t_i, t_{i+1}]$, $i = 0, \ldots M-1$, where $t_0 = 0$ and $t_M = T$ and running the algorithm successively in each interval achieves convergence. It is known that WR also converges better when the interval length is smaller. However, of course there is an optimal length beyond which making the intervals smaller results in higher computational effort.

Remark 3.2. The method of model reduction we use in this paper is POD, but in the overall iteration of DIRM one could in principle replace POD with any model reduction scheme that depends on simulation data. (Methods such as balanced truncation in their original form cannot be used, since they depend only on the model and not on a given set of system trajectories.)

4. Analysis for linear time invariant systems with two subsystems. The iteration operator associated with DIRM is nonlinear even if the system of ODEs is linear. This significantly complicates the convergence analysis of DIRM. In this section we provide an analysis of the DIRM method for linear time invariant systems consisting of two subsystems. We also assume that in the model reduction via POD we fit the best approximating linear subspace instead of the more general method of fitting the best approximating affine subspace. Although these assumptions are somewhat restrictive, the purpose of the analysis is to provide qualitative results rather than sharp estimates of convergence rates.

4.1. Description of Jacobi DIRM iteration operator for two subsystems. Throughout the rest of section 4 we will be concerned with the case of two subsystems each of dimension n unless stated otherwise. Suppose that the system consists of states $x = (x_1, x_2)$ with $x_i \in \mathbb{R}^n$ for $i = 1, 2$, and that the system equations are given by

$$\begin{aligned} \dot{x}_1 &= A_1 x_1 + A_{12} x_2, \\ \dot{x}_2 &= A_{21} x_1 + A_2 x_2, \\ x_1(0) &= x_{10}, \qquad x_2(0) = x_{20}, \end{aligned} \tag{4.1}$$

and that we are interested in the finite simulation interval $[0, T]$. We shall also use the compact notation $\dot{x} = Ax,\ x(0) = x_0$ to denote the same system. We start with some approximate solution $x^{(0)}(t)$ of the system as the initial (zeroth) iterate. For instance we may use the solution of the decoupled systems given by $x^{(0)} = (x_1^{(0)}, x_2^{(0)})$ which satisfies $\dot{x}_1^{(0)} = A_1 x_1^{(0)},\ x_1^{(0)}(0) = x_{10}$ and $\dot{x}_2^{(0)} = A_2 x_2^{(0)},\ x_2^{(0)}(0) = x_{20}$. Another approach may be to use some reduced order model solution as $x^{(0)}$. Our analysis does not depend on this initial choice.

Suppose we have trajectory $x^{(\alpha)}$ at the αth iteration. Then we find best approximating $k(\leq n)$ dimensional subspaces in $\mathbb{R}^n$ (k is fixed throughout the iterations) and the corresponding orthogonal projections $P_1^{(\alpha)}$ and $P_2^{(\alpha)}$ (both are $n \times n$ matrices) for the trajectories $x_1^{(\alpha)}$ and $x_2^{(\alpha)}$, respectively. The next iterate $x^{(\alpha+1)}$ is obtained by forming partially reduced models. We combine unreduced system 1 with reduced system 2 to obtain $x_1^{(\alpha+1)}$ and similarly for $x_2^{(\alpha+1)}$. Then we find the projections $P_1^{(\alpha+1)}$ and $P_2^{(\alpha+1)}$ corresponding to $x_1^{(\alpha+1)}$ and $x_2^{(\alpha+1)}$. Thus if

$$P^{(\alpha)} = \begin{bmatrix} P_1^{(\alpha)} & 0_{n\times n} \\ 0_{n\times n} & P_2^{(\alpha)} \end{bmatrix}$$

is the combined projection at the α th iteration, then $x^{(\alpha+1)}$ is given by

$$\begin{aligned} \dot{x}_1^{(\alpha+1)} &= A_1 x_1^{(\alpha+1)} + A_{12} \hat{x}_2^{(\alpha+1)}, \\ \dot{\hat{x}}_2^{(\alpha+1)} &= P_2^{(\alpha)} A_{21} x_1^{(\alpha+1)} + P_2^{(\alpha)} A_2 \hat{x}_2^{(\alpha+1)}, \\ x_1^{(\alpha+1)}(0) &= x_{10}, \qquad \hat{x}_2^{(\alpha+1)}(0) = P_2^{(\alpha)} x_{20} \end{aligned} \tag{4.2}$$

and

$$\begin{aligned} \dot{\hat{x}}_1^{(\alpha+1)} &= P_1^{(\alpha)} A_1 \hat{x}_1^{(\alpha+1)} + P_1^{(\alpha)} A_{12} x_2^{(\alpha+1)}, \\ \dot{x}_2^{(\alpha+1)} &= A_{21} \hat{x}_1^{(\alpha+1)} + A_2 x_2^{(\alpha+1)}, \\ \hat{x}_1^{(\alpha+1)}(0) &= P_1^{(\alpha)} x_{10}, \qquad x_2^{(\alpha+1)}(0) = x_{20}. \end{aligned} \tag{4.3}$$

We can rewrite the above equations more compactly as

$$\begin{aligned} \dot{x}^{(\alpha+1)} &= A_d x^{(\alpha+1)} + A_o \hat{x}^{(\alpha+1)}, \\ \dot{\hat{x}}^{(\alpha+1)} &= P^{(\alpha)} A_o x^{(\alpha+1)} + P^{(\alpha)} A_d \hat{x}^{(\alpha+1)}, \\ x^{(\alpha+1)}(0) &= x_0, \qquad \hat{x}^{(\alpha+1)}(0) = P^{(\alpha)} x_0, \end{aligned} \tag{4.4}$$

where

$$P^{(\alpha)} = \begin{bmatrix} P_1^{(\alpha)} & 0_{n\times n} \\ 0_{n\times n} & P_2^{(\alpha)} \end{bmatrix}, \tag{4.5}$$

$$A_d = \begin{bmatrix} A_1 & 0_{n\times n} \\ 0_{n\times n} & A_2 \end{bmatrix}, \tag{4.6}$$

and

$$A_o = \begin{bmatrix} 0_{n\times n} & A_{12} \\ A_{21} & 0_{n\times n} \end{bmatrix}. \tag{4.7}$$

Thus $A = A_d + A_o$.

Define the iteration operator $\mathcal{I} : \mathcal{L}_2([0,T],\mathbb{R}^{2n}) \to \mathcal{L}_2([0,T],\mathbb{R}^{2n})$ as the one that maps $x^{(\alpha)}$ to $x^{(\alpha+1)}$. We are interested in the fixed points of this operator and their stability. It must be noted that $\mathcal{I}$ is essentially nonlinear and is the composition of two operators $\mathcal{I} = \mathcal{S} \circ \mathcal{R}$. Here $\mathcal{R} : \mathcal{L}_2([0,T],\mathbb{R}^{2n}) \to \mathcal{P}^2$ is the operator that maps $x^{(\alpha)}$ to $P^{(\alpha)} \in \mathcal{P}^2$, where $\mathcal{P} \subset \mathbb{R}^{n\times n}$ is the manifold of rank $k \le n$ orthogonal projections, and $\mathcal{S} : \mathcal{P}^2 \to \mathcal{L}_2([0,T],\mathbb{R}^{2n})$ maps $P^{(\alpha)}$ to $x^{(\alpha+1)}$ by (4.4). Let $X \in \mathcal{L}_2([0,T],\mathbb{R}^{2n})$ be the true solution of the original system of equations,

$$\dot{X} = AX, \qquad X(0) = x_0.$$

Let $x^* \in \mathcal{L}_2([0,T],\mathbb{R}^{2n})$ be any fixed point of $\mathcal{I}$, i.e., $\mathcal{I}x^* = x^*$. We would like x^* to be a good approximation for X. Our analysis will provide an upper bound on $\|x^* - X\|$. (All function norms are assumed to be 2-norms unless stated otherwise.) We shall show that the error depends on the norm of A_o (the off-diagonal part), the POD projection error $\|x^* - P^*x^*\|$, and the growth/decay properties of e^{At} in the time interval T.

Since $\mathcal{I}$ is nonlinear it is in general difficult to know if and how many fixed points exist. It is also difficult to determine whether $\mathcal{I}$ is globally contractive. In fact $\mathcal{I}$ is ill-defined for some trajectories x; this occurs when there are many k dimensional subspaces that best fit x in the least-square sense. However, it is clear that when A_o is the zero matrix, i.e., when the systems are decoupled, the iterations will converge after one step, and in addition there is only one fixed point. Under mild regularity conditions it can be shown that this fixed point will persist for nontrivial A_o, with $\|A_o\|$ small enough, and that this fixed point will be stable. We will provide an analysis that estimates the rate of convergence based on the linearization of $\mathcal{I}$ at a fixed point x^*. We will show that the convergence rate depends on $\|A_o\|$, norms of the exponentials of A and some related matrices, the interval length T, the error $\|x^* - P^*x^*\|$, as well as on the sensitivity of P to perturbations in x at the fixed point (x^*, P^*) which can be related to the eigenvalues of the correlation matrix of the fixed point trajectory x^*.

The rest of the subsections are organized as follows. In section 4.2 we summarize all the important results of our analysis up front. In section 4.3 we derive an estimate for the norm of the trajectory of a subsystem in a given finite time interval for a linear time invariant system with time varying inputs. In section 4.4 we show that under mild regularity conditions for sufficiently small values of $\|A_o\|$ a fixed point exists. In section 4.5 we derive an estimate for the error $\|x^* - X\|$, and in section 4.6 we provide an estimate for convergence rate of $\mathcal{I}$ and a discussion of the various factors that affect the convergence. Finally, in section 4.7 we study the behavior of DIRM for arbitrarily small time intervals.

4.2. Summary of the results of the analysis. Here we shall provide a summary of the results of the analysis from the rest of the subsections. The reader who is not interested in mathematical details and proofs may read this subsection and then skip to section 5 for numerical examples.

Result 1. For systems that are sufficiently diagonally dominant ($\|A_o\|$ small enough), under further mild regularity conditions a fixed point x^* of $\mathcal{I}$ exists. We do not provide a quantitative bound on $\|A_o\|$. This result is proven in section 4.4. See Proposition 4.5. This result holds for an arbitrary (finite) number of subsystems with possibly different dimensions.

Result 2. Assuming that a fixed point x^* of $\mathcal{I}$ exists we obtain an upper bound (4.21) for the error between the fixed point trajectory x^* and the true solution trajectory X of the system. This is shown in section 4.5. See Proposition 4.8.

Result 3. Assuming that a fixed point x^* of $\mathcal{I}$ exists we obtain an upper bound for $\|D\mathcal{I}(x^*)\|$ (the norm of the linearization of the iteration operator at the fixed point). If $\|D\mathcal{I}(x^*)\| < 1$, then DIRM will converge for all initial iterates $x^{(0)}$ that are sufficiently close to x^*. See section 4.6 and Proposition 4.9.

Result 4. We show that in the case of systems for which a fixed point x^* of DIRM exists for all small enough T, that DIRM converges to x^* for all sufficiently small T if our initial iterate $x^{(0)}$ is sufficiently close to x^*. See section 4.7 and Proposition 4.11.

Remark 4.1. The proof of Results 2 and 3 (and hence that of 4) use the equation (4.4) which holds for two subsystems. We expect "qualitatively" similar results to hold for arbitrary number of subsystems but cannot make any rigorous claims without further analysis. We have limited the analysis to two subsystems because an equation equivalent to (4.4) is combinatorially very cumbersome for the case of more than two subsystems.

The above results do not constitute a comprehensive convergence analysis. For instance we cannot make conclusions about global convergence of DIRM. But these results suggest that DIRM is likely to perform well if certain desirable conditions are met. This has been verified by numerical experiments.

4.3. Finite horizon response of a subsystem. In our analysis of errors and convergence rate we need to estimate the 2-norm of the trajectory of a subsystem in a given finite time interval in response to a forcing term (input) and nontrivial initial conditions for a linear time invariant system. In this section we introduce some relevant notation as well as estimates that will be employed in our later analysis.

Consider the system

$$\dot{x} = Ax + u$$

with input $u(t)$ and initial condition $x(0) = x_0$ in the interval $[0, T]$. We are only interested in $u \in \mathcal{L}_2([0,T], \mathbb{R}^n)$. The solution is

$$x(t) = \int_0^t e^{A(t-\tau)} u(\tau) d\tau + e^{At} x_0.$$

This may be written in the form

$$x = F(T; A)u + G(T; A)x_0, \tag{4.8}$$

where $F(T;A) : \mathcal{L}_2([0,T], \mathbb{R}^n) \to \mathcal{L}_2([0,T], \mathbb{R}^n)$ and $G(T;A) : \mathbb{R}^n \to \mathcal{L}_2([0,T], \mathbb{R}^n)$ are linear operators. It is in general very difficult to obtain sharp estimates for the

norms of $F(T;A)$ and $G(T;A)$, and in fact this basically reduces to the problem of estimating the norm of the matrix exponential. As such we shall not provide an estimate, but we will remark that these norms grow exponentially with T at a rate that is determined by the largest real part of any eigenvalue of A and in addition depend on the nonnormality of A. See [4] for an estimate of the matrix exponential. In our analysis we estimate $\|x\|$ as

$$\|x\| \le \|F(T;A)\|\|u\| + \|G(T;A)\|\|x_0\|, \tag{4.9}$$

expressing the results in terms of $\|F(T;A)\|$ and $\|G(T;A)\|$.

Remark 4.2. Note that the norms on $F(T;A)$ and $G(T;A)$ are the appropriate induced 2-norms.

We shall state and prove a simple lemma on $F(T;A)$ which will be used later.

LEMMA 4.3. $\lim_{T\to 0}\|F(T;A)\| = 0$.

Proof.

$$\begin{aligned}\|F(T;A)u\|^2 &= \int_0^T \left\| \int_0^t e^{A(t-\tau)}u(\tau)d\tau \right\|^2 dt \\ &\le \int_0^T \int_0^t \|e^{A(t-\tau)}\|^2\|u(\tau)\|^2 d\tau dt \\ &\le e^{2\|A\|T}\int_0^T \int_0^T \|u(\tau)\|^2 d\tau dt \\ &= Te^{2\|A\|T}\|u\|^2.\end{aligned}$$

So in fact, as $T \to 0$, $\|F(T;A)\| = \mathrm{O}(\sqrt{T})$. ∎

Now we will focus on a system that consists of two subsystems and obtain an estimate for one of the subsystems that relates the results with the norms of the coupling terms (the off-diagonal blocks) as well as the subsystem properties (diagonal blocks). Consider the coupled systems

$$\begin{aligned}\dot{x}_1 &= A_1x_1 + \kappa A_{12}x_2 + u_1, \\ \dot{x}_2 &= \kappa A_{21}x_1 + A_2x_2 + u_2, \\ x_1(0) = x_{10},\ x_2(0) &= x_{20}\end{aligned} \tag{4.10}$$

in the interval $[0,T]$. Here κ is a "coupling parameter" introduced to aid our analysis. The final results are all evaluated at $\kappa = 1$. We will obtain an estimate for $\|x_1\|$. Since $x_i(t)$ (for $i = 1,2$) is a (vector-valued) entire function of κ we may write it as

$$x_i(t;\kappa) = \sum_{\alpha=0}^{\infty} \kappa^\alpha \frac{\partial^\alpha x_i(t;0)}{\alpha!}, \qquad i = 1,2,$$

where $\partial = \frac{\partial}{\partial\kappa}$, and the series converges for all t and all κ. For $\alpha \ge 1$, $\partial^\alpha x_i(t;0)$ are given by the decoupled equations

$$\begin{aligned}\partial^\alpha \dot{x}_1(t;0) &= A_1\partial^\alpha x_1(t;0) + \alpha A_{12}\partial^{\alpha-1}x_2(t;0), \\ \partial^\alpha \dot{x}_2(t;0) &= A_2\partial^\alpha x_2(t;0) + \alpha A_{21}\partial^{\alpha-1}x_1(t;0), \\ \partial^\alpha x_1(0;0) = 0, &\qquad \partial^\alpha x_2(0;0) = 0.\end{aligned}$$

For the $\alpha = 0$ case we have

$$\begin{aligned}\dot{x}_1(t;0) &= A_1 x_1(t;0) + u_1(t),\\ \dot{x}_2(t;0) &= A_2 x_2(t;0) + u_2(t),\\ x_1(0;0) &= x_{10}, \qquad x_2(0;0) = x_{20}.\end{aligned}$$

Let $x_1(.\,;\kappa)$ denote the function, i.e., $x_1(.\,;\kappa) \in \mathcal{L}_2([0,T],\mathbb{R}^n)$. Setting $\kappa = 1$, from the above equations we can write $x_1(.\,;1)$ as

$$x_1(.\,;1) = \sum_{\alpha=0}^{\infty} F^\alpha x_1(.\,;0) + \sum_{\alpha=0}^{\infty} F^\alpha F_1 A_{12} x_2(.\,;0),$$

where the operators $F_1, F_2, F : \mathcal{L}_2([0,T],\mathbb{R}^n) \to \mathcal{L}_2([0,T],\mathbb{R}^n)$ are defined by $F_i = F(T;A_i)$, for $i = 1,2$, and

$$F = F_1 A_{12} F_2 A_{21}.$$

Assuming $\|F\| < 1$ (which is true for sufficiently small T by Lemma 4.3) we obtain an upper bound for $\|x_1\|$:

$$\|x_1\| \le \sum_{\alpha=0}^{\infty} \|F\|^\alpha \|x_{d1}\| + \sum_{\alpha=0}^{\infty} \|F\|^\alpha \|F_1\| \|A_{12}\| \|x_{d2}\|,$$

where we have dropped the parameter κ altogether and x_{di} for $i = 1,2$ denote the solutions of the decoupled systems: $\dot{x}_{di} = A_i x_{di} + u_i,\ x_{di}(0) = x_{i0}$. Finally, after simplifying the above bound, we obtain the result that, for sufficiently small T,

$$\|x_1\| \le \frac{(\|F_1\|\|u_1\| + \|G_1\|\|x_{10}\|)}{1 - \|F\|} + \frac{\|F_1\|\|A_{12}\|(\|F_2\|\|u_2\| + \|G_2\|\|x_{20}\|)}{1 - \|F\|}, \tag{4.11}$$

where we have used the estimates (4.9) for $\|x_{d1}\|$ and $\|x_{d2}\|$, and $G_i = G(T;A_i)$ for $i = 1,2$.

It is clear that the effect of subsystem 2 on subsystem 1 diminishes as the norm of A_{12} diminishes.

Remark 4.4. It is interesting to note that the κ series expansion mentioned here is intimately related to the Jacobi WR method. In fact the sequence of partial sums of the series for $\kappa = 1$ is the same as the sequence of iterates obtained by applying the Jacobi WR, i.e., WR with the splitting $A = A_d + A_o$, where A_d and A_o are defined by (4.6) and (4.7), respectively, starting with isolated subsystem (couplings assumed zero) solutions as the initial iterate.

4.4. Existence of fixed points of DIRM. In general it is hard to prove the existence of fixed points of the operator $\mathcal{I}$. However, under mild regularity conditions we can show that a fixed point exists for sufficiently small $\|A_o\|$. For this purpose we shall consider the iteration operator $\mathcal{J} : \mathcal{P}^2 \to \mathcal{P}^2$ that maps $P^{(\alpha)}$ to $P^{(\alpha+1)}$. Recalling that $\mathcal{I} = \mathcal{S} \circ \mathcal{R}$ from section 4.1 we see that $\mathcal{J} = \mathcal{R} \circ \mathcal{S}$. It is easy to see that x^* is a fixed point of $\mathcal{I}$ if and only if $P^* = \mathcal{R}x^*$ is a fixed point of $\mathcal{J}$ (provided $\mathcal{R}x^*$ is well defined) and similarly P^* is a fixed point of $\mathcal{J}$ if and only if $x^* = \mathcal{S}P^*$ is a fixed point of $\mathcal{I}$.

PROPOSITION 4.5. *Consider a system with a given diagonal part A_d as defined by* (4.6). *Let $x_d = (x_{d1}, x_{d2})$ be the solution of the decoupled systems; $\dot{x}_d = A_d x_d$, $x_d(0) = x_0$. Let $\nu_1^i \ge \nu_2^i \ge \cdots \ge \nu_n^i \ge 0$ be the eigenvalues of the correlation matrices*

of x_{di} for $i = 1, 2$, respectively. If $\nu_k^i > \nu_{k+1}^i$, for both $i = 1, 2$, then the operator $\mathcal{J}$ (and hence $\mathcal{I}$) has a fixed point for all off-diagonal parts A_o (as defined by (4.7)) in an open neighborhood of the origin in $\mathcal{O} \subset \mathbb{R}^{2n \times 2n}$. Here $\mathcal{O}$ is the $2n^2$ dimensional subspace of all possible off-diagonal parts.

Proof. Write the system $\dot{x} = Ax$ as

$$\dot{x} = A_d x + A_o x,$$

where A_d and A_o are defined according to (4.6) and (4.7), respectively. (Note that $A = A_d + A_o$.) We shall treat A_d as fixed and consider A_o as variable.

A fixed point

$$P^* = \begin{bmatrix} P_1^* & 0_{n\times n} \\ 0_{n\times n} & P_2^* \end{bmatrix}$$

of $\mathcal{J}$ must be such that $P_1 = P_1^*$ is a minimizer of $e_1(P_1, x_1)$ while holding x_1 fixed, and $P_2 = P_2^*$ is a minimizer of $e_2(P_2, x_2)$ while holding x_2 fixed, where $e_i(P_i, x_i)$ are defined by

$$e_i(P_i, x_i) = \int_0^T (P_i x_i(t) - x_i(t))^T (P_i x_i(t) - x_i(t)) dt, \qquad i = 1, 2.$$

Hence by applying the first order optimality conditions we see that $P = P^*$ must be a root of the following system of equations:

$$\begin{aligned} &\frac{\partial e_1}{\partial P_1}(P_1, S_1(P_2; A_o)) = 0, \\ &\frac{\partial e_2}{\partial P_2}(P_2, S_2(P_1; A_o)) = 0, \end{aligned} \tag{4.12}$$

where we have used the fact that $x_1 = x_1^*$ at the fixed point depends on P_2^* and similarly $x_2 = x_2^*$ depends on P_1^*. Here the "solution operator" S_1 maps $P_2^{(\alpha)}$ to $x_1^{(\alpha+1)}$ according to the equations (4.2). The operator S_2 is defined similarly. Note that the operators S_1 and S_2 in general both depend on A_o.

Because of the coupling, it is hard to decide if the system (4.12) has a root in general. However, when $A_o = 0 \in \mathcal{O}$, the original system of ODEs are decoupled and as such S_1 and S_2 are independent of P_2 and P_1, respectively. Hence the equations in (4.12) are decoupled. Furthermore, our assumption that $\nu_k^i > \nu_{k+1}^i$ for both $i = 1, 2$ implies that the two errors e_1 and e_2 can be minimized uniquely and independently according to the POD procedure. This proves the existence of a unique fixed point $P = P^*(A_o = 0)$ of the operator $\mathcal{J}$ for $A_o = 0$. The second order optimality conditions for unique minima imply that both $\frac{\partial^2 e_1}{\partial P_1^2}$ and $\frac{\partial^2 e_2}{\partial P_2^2}$ when evaluated at $A_o = 0$ and $P = P^*(A_o = 0)$ have full rank.

Therefore it also follows that the Jacobian

$$\begin{bmatrix} \frac{\partial^2 e_1}{\partial P_1^2} & \frac{\partial^2 e_1}{\partial P_1 \partial P_2} \\ \frac{\partial^2 e_2}{\partial P_1 \partial P_2} & \frac{\partial^2 e_2}{\partial P_2^2} \end{bmatrix}$$

is full rank for $A_o = 0$ and $P = P^*(A_o = 0)$. Hence, by the implicit function theorem, we conclude that a root $P = P^*(A_o)$ of (4.12) exists for all A_o in an open neighborhood of $0 \in \mathcal{O}$. Furthermore, by continuity it follows that $\frac{\partial^2 e_1}{\partial P_1^2}$ and $\frac{\partial^2 e_2}{\partial P_2^2}$ have

full rank for $(A_o, P = P^*(A_o))$ for all A_o in some open neighborhood of $0 \in \mathcal{O}$. This establishes $P = P^*(A_o)$ as a fixed point of $\mathcal{J}$ for all A_o in an open neighborhood of $0 \in \mathcal{O}$. ∎

COROLLARY 4.6. *Under similar assumptions Proposition* 4.5 *holds for an arbitrary number m of subsystems of possibly different dimensions.*

Proof. Follow the same line of reasoning with (4.12) replaced by

$$\frac{\partial e_i}{\partial P_i}(P_i, S_i(P_1, \ldots, P_{i-1}, P_{i+1}, \ldots, P_m; A_o)) = 0, \qquad i = 1, \ldots, m. \tag{4.13}$$

The key point is that the operator S_i does not depend on P_i. ∎

Remark 4.7. Ideally we would like to show that for any value of $\|A_o\|$ a fixed point exists for sufficiently small T. The intuition is that when T gets arbitrarily small, the trajectories are increasingly well approximated by straight lines. However, we do not have a proof yet.

4.5. Accuracy of DIRM. We will introduce a few new variables to facilitate our analysis. Given $P^{(\alpha)}, x^{(\alpha)}, \hat{x}^{(\alpha)}$, and X as defined in section 4.1, define $v^{(\alpha)}, w^{(\alpha)}$, and $\xi^{(\alpha)}$ as follows:

$$v^{(\alpha)} = P^{(\alpha-1)}x^{(\alpha)} - x^{(\alpha)}, \tag{4.14}$$

$$w^{(\alpha)} = \hat{x}^{(\alpha)} - P^{(\alpha-1)}x^{(\alpha)}, \tag{4.15}$$

and

$$\xi^{(\alpha)} = x^{(\alpha)} - X. \tag{4.16}$$

We may think of $v^{(\alpha)}$ as a "difference" trajectory that measures the gap between $x^{(\alpha)}$ and its projection $P^{(\alpha-1)}x^{(\alpha)}$ and $w^{(\alpha)}$ as a difference trajectory that measures the gap between the reduced trajectory $\hat{x}^{(\alpha)}$ and $P^{(\alpha-1)}x^{(\alpha)}$. The trajectory $\xi^{(\alpha)}$ is the error between the true solution and the DIRM iterate at step α.

Suppose x^* is a fixed point of $\mathcal{I}$. Assume $P^* = \mathcal{R}x^*$ is well defined. Let $\hat{x}^*, v^*, w^*$, and ξ^* be the corresponding fixed point trajectories. Note that the error in using DIRM is ξ^*. We will provide an estimate of $\|\xi^*\|$. Substituting $v^{(\alpha)} = v^*$, $P^{(\alpha-1)} = P^*$, and $x^{(\alpha)} = x^*$ in (4.14), we obtain

$$v^* = P^*x^* - x^*.$$

Similarly we obtain $w^* = \hat{x}^* - P^*x^*$ from (4.15). Note that these two relations imply that $\hat{x}^* - x^* = v^* + w^*$. Differentiating $w^* = \hat{x}^* - P^*x^*$ with respect to time, and using (4.4), we obtain

$$\begin{aligned} \dot{w}^* &= P^*A_d\hat{x}^* + P^*A_ox^* - P^*A_dx^* - P^*A_o\hat{x}^* \\ &= P^*(A_d - A_o)(\hat{x}^* - x^*). \end{aligned}$$

Hence we obtain the following differential equation for w^*:

$$\dot{w}^* = P^*(A_d - A_o)w^* + P^*(A_d - A_o)v^*, \qquad w^*(0) = 0. \tag{4.17}$$

Similarly (4.16) implies $\xi^* = x^* - X$. Differentiating and using (4.4), and $\dot{X} = AX = (A_d + A_o)X$, we obtain

$$\begin{aligned}\dot{\xi}^* &= A_d x^* + A_o \hat{x}^* - AX \\ &= A(x^* - X) + A_o(\hat{x}^* - x^*).\end{aligned}$$

Using $\hat{x}^* - x^* = v^* + w^*$ we write the equation for ξ^* as

$$\dot{\xi}^* = A\xi^* + A_o(v^* + w^*), \qquad \xi^*(0) = 0. \tag{4.18}$$

From the application of the estimate (4.9) to (4.17) we obtain that

$$\|w^*\| \leq \|F(T; P^*(A_d - A_o))\|\|A_d - A_o\|\|v^*\|. \tag{4.19}$$

Applying the estimate (4.9) to (4.18) and using the above equation we obtain

$$\|\xi^*\| \leq \|F(T; A)\|\|A_o\| \left\{1 + F(T; P^*(A_d - A_o))\|A_d - A_o\|\right\} \|v^*\|. \tag{4.20}$$

The quantity $\|v^*\|$ is the sum of the POD projection errors $\|P_i^* x_i - x_i\|$ of both the subsystems. This quantity is the same as the square root of the sum of the eigenvalues of the neglected modes summed over both the subsystems. Note that if the POD projection error of the fixed point trajectory is zero, then the error of the converged DIRM solution is zero. It is also clear that the error depends on the norm of the off-diagonal blocks A_o, on the norm of the exponentials of A and $P^*(A_d - A_o)$, as well as on the time interval T.

We have thus proved the following proposition.

PROPOSITION 4.8. *Let x^* be a fixed point of $\mathcal{I}$ and suppose that $P^* = \mathcal{R}x^*$ is well defined. Let X be the true solution: $\dot{X} = AX$; $X(0) = x_0$. Then the error $\|x^* - X\|$ (2-norm) satisfies*

$$\|x^* - X\| \leq \|F(T; A)\|\|A_o\| \left\{1 + F(T; P^*(A_d - A_o))\|A_d - A_o\|\right\} \|v^*\|, \tag{4.21}$$

where $\|v^*\| = \|P^* x^* - x^*\|$ is the projection error of the fixed point trajectory.

4.6. Rate of convergence. In this section, we will compute an upper bound for $\|D\mathcal{I}(x^*)\|$, the norm of the linearization of the iteration $\mathcal{I}$ at a fixed point x^*. First, we will compute $\delta x^{(\alpha+1)} = D\mathcal{I}(x^{(\alpha)})(\delta x^{(\alpha)})$, which is the variation in $x^{(\alpha+1)}$ due to a variation $\delta x^{(\alpha)}$ in $x^{(\alpha)}$. The notation $D\mathcal{I}(x)(\delta x)$ denotes the directional derivative of the operator $\mathcal{I}$ evaluated at $x \in \mathcal{L}_2([0,T], \mathbb{R}^{2n})$ in the direction $\delta x \in \mathcal{L}_2([0,T], \mathbb{R}^{2n})$. The variations of all quantities will be denoted by the prefix δ, except that the variation of $P^{(\alpha)}$ will be denoted by $E^{(\alpha)}$. In our analysis the norm used for the variations of trajectories will also be the 2-norm, and the norms of matrices will be the induced 2-norm.

Again we shall make use of the difference trajectories $v^{(\alpha)}$ and $w^{(\alpha)}$ as defined by (4.14) and (4.15). Taking variations of (4.14) (with α replaced by $\alpha + 1$) it follows that

$$\delta v^{(\alpha+1)} = E^{(\alpha)} x^{(\alpha+1)} + \left(P^{(\alpha)} - 1\right) \delta x^{(\alpha+1)}. \tag{4.22}$$

Following a procedure similar to the one that was used to obtain (4.18), we obtain from (4.16) the following equation for $\xi^{(\alpha+1)}$:

$$\dot{\xi}^{(\alpha+1)} = A\xi^{(\alpha+1)} + A_o\left(v^{(\alpha+1)} + w^{(\alpha+1)}\right), \qquad \xi^{(\alpha+1)}(0) = 0.$$

From (4.16) we also see that $\delta x^{(\alpha)} = \delta\xi^{(\alpha)}$. Therefore, taking variations of the above equation, we get

$$\delta\dot{x}^{(\alpha+1)} = A\delta x^{(\alpha+1)} + A_o\delta v^{(\alpha+1)} + A_o\delta w^{(\alpha+1)}, \qquad \delta x^{(\alpha+1)}(0) = 0. \tag{4.23}$$

Following a procedure similar to the one that was used to obtain (4.17), we obtain from (4.15) the following equation for $w^{(\alpha+1)}$:

$$\begin{aligned} \dot{w}^{(\alpha+1)} &= P^{(\alpha)}(A_d - A_o)w^{(\alpha+1)} + P^{(\alpha)}(A_d - A_o)v^{(\alpha+1)}, \\ w^{(\alpha+1)}(0) &= 0. \end{aligned} \tag{4.24}$$

Hence the variation $\delta w^{(\alpha+1)}$ is given by

$$\begin{aligned} \delta\dot{w}^{(\alpha+1)} &= P^{(\alpha)}(A_d - A_o)\delta w^{(\alpha+1)} + P^{(\alpha)}(A_d - A_o)\delta v^{(\alpha+1)} \\ &\quad + E^{(\alpha)}(A_d - A_o)\left(w^{(\alpha+1)} + v^{(\alpha+1)}\right), \quad \delta w^{(\alpha+1)}(0) = 0. \end{aligned} \tag{4.25}$$

Substituting for $\delta v^{(\alpha+1)}$ from (4.22) into (4.23) and (4.25) we get a coupled system of equations for $\delta x^{(\alpha+1)}$ and $\delta w^{(\alpha+1)}$:

$$\begin{aligned} \delta\dot{x}^{(\alpha+1)} &= (A + A_o(P^{(\alpha)} - 1))\delta x^{(\alpha+1)} + A_o\delta w^{(\alpha+1)} + A_oE^{(\alpha)}x^{(\alpha+1)}, \\ \delta\dot{w}^{(\alpha+1)} &= P^{(\alpha)}(A_d - A_o)\left(P^{(\alpha)} - 1\right)\delta x^{(\alpha+1)} + P^{(\alpha)}(A_d - A_o)\delta w^{(\alpha+1)} \\ &\quad + P^{(\alpha)}(A_d - A_o)E^{(\alpha)}x^{(\alpha+1)} + E^{(\alpha)}(A_d - A_o)\left(w^{(\alpha+1)} + v^{(\alpha+1)}\right), \\ \delta x^{(\alpha+1)}(0) &= 0, \qquad \delta w^{(\alpha+1)}(0) = 0. \end{aligned} \tag{4.26}$$

Note that the above system is driven by terms containing $x^{(\alpha+1)}$, $v^{(\alpha+1)}$, and $w^{(\alpha+1)}$. Since we are interested in perturbations about the fixed point x^*, we set

$$\begin{aligned} x^{(\alpha+1)} &= x^{(\alpha)} = x^*, \\ v^{(\alpha+1)} &= v^{(\alpha)} = v^*, \\ w^{(\alpha+1)} &= w^{(\alpha)} = w^*. \end{aligned}$$

Also we shall denote $\delta x^{(\alpha)} = \delta x$ and write $E^{(\alpha)}$ and $\delta x^{(\alpha+1)}$ as

$$\begin{aligned} E^{(\alpha)} &= \frac{dP}{dx}(x^*)(\delta x), \\ \delta x^{(\alpha+1)} &= D\mathcal{I}(x^*)(\delta x). \end{aligned}$$

Note that $\frac{dP}{dx}(x^*)(\delta x)$, which may also be written as $D\mathcal{R}(x^*)(\delta x)$, is the directional derivative of $P = \mathcal{R}(x)$ at $x = x^*$ in the direction δx. For sufficiently small T we apply the estimate (4.11) to (4.26) at a fixed point and obtain

$$\begin{aligned} \|D\mathcal{I}(x^*)(\delta x)\| &\le \frac{\|F_1\|}{(1 - \|F\|)}\left\|A_oP^*\frac{dP}{dx}(x^*)(\delta x)x^*\right\| \\ &+ \frac{\|F_1\|\|F_2\|\|A_o\|}{(1 - \|F\|)}\left\|P^*(A_d - A_o)\frac{dP}{dx}(x^*)(\delta x)x^* + \frac{dP}{dx}(x^*)(\delta x)(A_d - A_o)(w^* + v^*)\right\|, \end{aligned}$$

where

$$\begin{aligned} F_1 &= F(T; A + A_o(P^* - 1)), \\ F_2 &= F(T; P^*(A_d - A_o)), \\ F &= F_1A_oF_2P^*(A_d - A_o)(P^* - 1). \end{aligned} \tag{4.27}$$

We simplify further and write

$$\|D\mathcal{I}(x^*)(\delta x)\| \le \frac{\|F_1\|\|A_o\|}{(1-\|F\|)}H,$$

where the term H is given by

$$H = \left\|\frac{dP}{dx}(x^*)(\delta x)x^*\right\| + \|F_2\|\|A_d - A_o\|\left(\left\|\frac{dP}{dx}(x^*)(\delta x)x^*\right\| + \left\|\frac{dP}{dx}(x^*)(\delta x)\right\|\|v^* + w^*\|\right).$$

Using the estimate (4.19) one can obtain an upper bound for H which does not contain w^*. After rearranging some terms we obtain the upper bound

$$\|D\mathcal{I}(x^*)(\delta x)\| \le \frac{\|F_1\|\|A_o\|(1+\|F_2\|\|A_d - A_o\|)}{(1-\|F\|)} \times \left(\left\|\frac{dP}{dx}(x^*)(\delta x)x^*\right\| + \left\|\frac{dP}{dx}(x^*)(\delta x)\right\|\|F_2\|\|A_d - A_o\|\|v^*\|\right).$$

Taking the supremum over all unit norm variations δx, we obtain the bound

$$\|D\mathcal{I}(x^*)\| \le \frac{\|F_1\|\|A_o\|(1+\|F_2\|\|A_d - A_o\|)}{(1-\|F\|)} \times \left(\sup_{\|\delta x\|=1}\left\{\left\|\frac{dP}{dx}(x^*)(\delta x)x^*\right\|\right\} + \left\|\frac{dP}{dx}(x^*)\right\|\|F_2\|\|A_d - A_o\|\|v^*\|\right).$$

The sensitivity of the POD projection matrix $P(x)$ to perturbations in the trajectory x has been studied and quantified in [13]. It follows directly from the results in [13] that

$$\left\|\frac{dP}{dx}(x^*)\right\|_{\mathrm{F}} = \max_{i\le k,\, j\le n-k}\sqrt{2}\frac{\sqrt{\lambda_i^1+\lambda_{j+k}^1}}{\lambda_i^1-\lambda_{j+k}^1} + \max_{i\le k,\, j\le n-k}\sqrt{2}\frac{\sqrt{\lambda_i^2+\lambda_{j+k}^2}}{\lambda_i^2-\lambda_{j+k}^2}, \tag{4.28}$$

$$\sup_{\|\delta x\|=1}\left\{\left\|\frac{dP}{dx}(x^*)(\delta x)x^*\right\|\right\} = \left(\frac{\lambda_k^1+\lambda_{k+1}^1}{\lambda_k^1-\lambda_{k+1}^1}\right) + \left(\frac{\lambda_k^2+\lambda_{k+1}^2}{\lambda_k^2-\lambda_{k+1}^2}\right),$$

where $\lambda_1^i \ge \lambda_2^i \ge \cdots \ge \lambda_n^i$ are the ordered eigenvalues of the correlation matrix of the fixed point trajectories x_i^*, for $i = 1, 2$, and the subscript "F" denotes the Frobenius norm. Note that we have assumed that $\lambda_k^i > \lambda_{k+1}^i$, for $i = 1, 2$, in order for P^* to be well defined. Also note that $\|v^*\|$ is given by

$$\|v^*\| = \sqrt{\lambda_{k+1}^1 + \cdots + \lambda_n^1 + \lambda_{k+1}^2 + \cdots + \lambda_n^2}.$$

Since $\|\frac{dP}{dx}(x^*)\|_2 \le \|\frac{dP}{dx}(x^*)\|_{\mathrm{F}}$, using the expression for $\|v^*\|$ we may obtain an upper bound for $\|D\mathcal{I}(x^*)\|$ which we shall state as a proposition.

PROPOSITION 4.9. *Suppose $x^* = (x_1^*, x_2^*)$ is a fixed point of $\mathcal{I}$ and assume that $P^* = \mathcal{R}x^*$ is well defined. Then, for sufficiently small T, $\|D\mathcal{I}(x^*)\|$ satisfies*

$$\|D\mathcal{I}(x^*)\| \le \frac{\|F_1\|\|A_o\|}{(1-\|F\|)}(1+\|F_2\|\|A_d - A_o\|)\{\mathcal{C}_1(\lambda) + \mathcal{C}_2(\lambda)\|F_2\|\|A_d - A_o\|\}, \tag{4.29}$$

where $\mathcal{C}_1$ and $\mathcal{C}_2$ are functions of the eigenvalues λ of the correlation matrices of the fixed point trajectories x_1^* and x_2^* given by

$$\begin{aligned}
\mathcal{C}_1 &= \left(\frac{\lambda_k^1+\lambda_{k+1}^1}{\lambda_k^1-\lambda_{k+1}^1}\right)+\left(\frac{\lambda_k^2+\lambda_{k+1}^2}{\lambda_k^2-\lambda_{k+1}^2}\right),\\
\mathcal{C}_2 &= \left(\max_{i\le k,\, j\le n-k}\sqrt{2}\frac{\sqrt{\lambda_i^1+\lambda_{j+k}^1}}{\lambda_i^1-\lambda_{j+k}^1}+\max_{i\le k,\, j\le n-k}\sqrt{2}\frac{\sqrt{\lambda_i^2+\lambda_{j+k}^2}}{\lambda_i^2-\lambda_{j+k}^2}\right)\\
&\quad\times\sqrt{\lambda_{k+1}^1+\cdots+\lambda_n^1+\lambda_{k+1}^2+\cdots+\lambda_n^2},
\end{aligned}\tag{4.30}$$

and F_1, F_2, and F are as defined in (4.27).

It can be seen from the above results that the convergence rate becomes arbitrarily fast as $\|A_o\|$ becomes arbitrarily small, which agrees with intuition. We also see that the convergence is faster when the POD error is small. However, when the POD error is zero ($\lambda_{k+1}^1+\cdots+\lambda_n^1+\lambda_{k+1}^2+\cdots+\lambda_n^2=0$), the above expression does not predict arbitrarily fast convergence. This may seem counterintuitive. However, one needs to consider this more carefully. The quantity $\|v^*\|=\lambda_{k+1}^1+\cdots+\lambda_n^1+\lambda_{k+1}^2+\cdots+\lambda_n^2$ is the POD projection error of the fixed point trajectory. Even if this is zero, $\|v\|$ corresponding to a nearby trajectory x need not be. Convergence depends on the behavior of nearby trajectories as well. This is evident from the numerical example in section 5.4. If, however, all subsystem trajectories always lie in some k dimensional subspace, then it is clear that DIRM will converge after one iteration. In terms of the above analysis this corresponds to $P^{(\alpha)}$ being constant and $v^{(\alpha+1)}=0$ for all α. Hence $E^{(\alpha)}=0$ and $\delta v^{(\alpha+1)}=0$. Then from (4.24) we see that $w^{(\alpha+1)}=0$ as well. All these together and (4.26) imply that $\delta x^{(\alpha+1)}=0$, indicating immediate convergence.

The analysis also suggests that when the eigenvalues λ_k^1 and λ_{k+1}^1 (or λ_k^2 and λ_{k+1}^2) are very close to each other we may expect difficulties in convergence, since both $\mathcal{C}_1$ and $\mathcal{C}_2$ become very large. This is numerically evident from the example of section 5.3.

4.7. Small time interval case. In this section we consider the convergence behavior of DIRM as $T\to 0$. First let us state and prove the following lemma.

LEMMA 4.10. *Let $z:[0,T_0]\to\mathbb{R}^n$ be a C^n-smooth trajectory. Let $0<T<T_0$ and let $\lambda_1\ge\lambda_2\cdots\ge\lambda_n\ge 0$ be the eigenvalues of the correlation matrix of $z:[0,T]\to\mathbb{R}^n$. Hence λ_i are functions of T. Furthermore, suppose the values of z and its first $n-1$ derivatives at $t=0$ form a linearly independent set. Note that this assumption is generically true in the sense that it holds for an open and dense subset (in $\mathbb{R}^{n(n-1)}$) of possible values of $z(t)$ and its first $n-1$ derivatives at $t=0$. Then, as $T\to 0$, $\lambda_{j+1}/\lambda_j\to 0$ for any $1\le j\le n-1$.*

Proof. In order to keep the proof concise, we shall prove for the case when $z(t)$ is analytic. The proof for C^n is similar. By assumption the set

$$\{z(0), z^{(1)}(0),\ldots,z^{(n-1)}(0)\}$$

is linearly independent, where $z^{(j)}(t)$ denotes the jth derivative of $z(t)$. Since the correlation matrix $R=\int_0^T z(t)z^T(t)dt$ is analytic in T, using Taylor expansion we may write it as

$$R=\sum_{j=1}^{\infty} r_j T^j,$$

where after simplification

$$r_j = \frac{1}{j}\sum_{l=1}^{j} \frac{z^{(l-1)}(0)}{(l-1)!}\frac{(z^{(j-l)}(0))^T}{(j-l)!}, \qquad j = 1, 2, \ldots.$$

Note that when $z(t)$ is C^n, R is C^{n+1} smooth in T, and we should use Taylor's theorem with the remainder term which is $O(T^{n+1})$.

It is clear that $\text{Image}(r_j) = \text{span}\{z(0), z^{(1)}(0), \ldots, z^{(j-1)}(0)\}$ and that $\text{Null}(r_j) = \text{Image}(r_j)^{\perp}$. Hence by our assumption it follows that $\text{rank}\,(r_j) = j$ for $j = 1, \ldots, n$. Let $\mu_1^j \geq \mu_2^j \geq \cdots \geq \mu_n^j \geq 0$ be the eigenvalues of r_j for all j. Note that $\mu_j^j > 0$ and $\mu_l^j = 0$ for $l = j+1, \ldots, n$, and $j = 1, \ldots, n$.

Define partial sums

$$R_j = \sum_{l=1}^{j} r_l T^l$$

for $j = 1, \ldots, n$. Let $\nu_1^j \geq \nu_2^j \geq \cdots \geq \nu_n^j \geq 0$ be the eigenvalues of R_j. Since $\text{Image}(r_{j-1}) \subset \text{Image}(r_j)$, for $j = 1, \ldots, n$, it follows that $\text{rank}(R_j) = \text{rank}(r_j) = j$ for $j = 1, \ldots, n$. Hence $\nu_j^j > 0$ and $\nu_l^j = 0$ for $l = j+1, \ldots, n$ and $j = 1, \ldots, n$. Since $R_j = R_{j-1} + T^j r_j$, for $j = 1, \ldots, n$, using Theorem 8.1.5 of [4] on symmetric eigenvalue perturbations, we see that $\nu_j^j \leq \nu_j^{j-1} + T^j \mu_1^j$. The same theorem also yields $\nu_n^{j-1} + T^j \mu_j^j \leq \nu_j^j$. Since $\nu_n^{j-1} = \nu_j^{j-1} = 0$, we get

$$0 < T^j \mu_j^j \leq \nu_j^j \leq T^j \mu_1^j, \qquad j = 1, \ldots, n. \tag{4.31}$$

For $j = 1, \ldots, n$ we may write R as

$$R = R_j + T^{j+1} N_{j+1},$$

where $N_{j+1} = \sum_{l=1}^{\infty} r_{j+l} T^{l-1}$. Let $\tilde{\nu}_1^j \geq \tilde{\nu}_2^j \geq \cdots \geq \tilde{\nu}_n^j \geq 0$ be the eigenvalues of N_j for $j = 2, \ldots, n+1$. Application of Theorem 8.1.5 of [4] to $R = R_j + T^{j+1} N_{j+1}$ yields

$$\nu_j^j + T^{j+1}\tilde{\nu}_n^{j+1} \leq \lambda_j \leq \nu_j^j + T^{j+1}\tilde{\nu}_1^{j+1}, \qquad j = 1, \ldots, n.$$

This together with (4.31) implies

$$0 < T^j \mu_j^j \leq \lambda_j \leq T^j \mu_1^j + T^{j+1}\tilde{\nu}_1^{j+1}, \qquad j = 1, \ldots, n. \tag{4.32}$$

This yields

$$\frac{\lambda_{j+1}}{\lambda_j} \leq T\left(\frac{\mu_1^{j+1}}{\mu_j^j} + T\tilde{\nu}_1^{j+2}\right), \qquad j = 1, \ldots, n-1.$$

Since $\lim_{T\to 0} N_{j+2} = r_{j+2}$, by continuity $\lim_{T\to 0} \tilde{\nu}_1^{j+2} = \mu_1^{j+2}$ which is finite. Hence $\lim_{T\to 0} \frac{\lambda_{j+1}}{\lambda_j} = 0$ for $j = 1, \ldots, n-1$. ∎

Now we state the following proposition about convergence of DIRM in the limit $T \to 0$.

PROPOSITION 4.11. *Suppose there exists a T_1 such that for all $T < T_1$ a fixed point x^* of $\mathcal{I}$ exists and that $P^* = \mathcal{R}x^*$ is well defined. Further suppose x^* satisfies the*

conditions of Lemma 4.10. *Let* X *be the true solution. Then there exists a* $T_0 < T_1$ *such that DIRM converges to* x^**, for all* $T < T_0$*, for initial guesses* $x^{(0)}$ *that are sufficiently close to* x^*.

Proof. Application of Lemma 4.10 immediately yields that

$$\lim_{T\to 0} \mathcal{C}_1 = 2$$

and

$$\lim_{T\to 0} \mathcal{C}_2 = 0.$$

Also, as $T \to 0$, both $\|F_1\|$ and $\|F_2\| \to 0$ (Lemma 4.3), and hence $\|F\| \to 0$ as well. So $\|D\mathcal{I}(x^*)\| \to 0$ as $T \to 0$, and in particular $\|D\mathcal{I}(x^*)\| < 1$ for all small enough T. Hence DIRM will converge for all initial guesses $x^{(0)}$ that are sufficiently close to x^*. ∎

5. Examples.

5.1. Example: Nonlinear power grid. In this section we present a power grid model and apply the DIRM method to simulate the transient behavior. The model has been taken from the paper [11]. The model equations we use represent the coupling between power flows and frequency variations across power networks and are known as the *swing equations*. Swing dynamics potentially interact with protection mechanisms and may lead to cascading failures. See [11] for more details.

We used a power grid consisting of 36 nodes arranged in a 6×6 square grid. Each node is either a generator or a load. For general types of load situations we would need DAEs to represent the system. Here we assume that the loads are all synchronous motors. In that case the swing equations involve the variables δ_i, where indices $i = 1, \ldots, N$ denote the nodes ($N = 36$ in our example). Physically at node i, δ_i stands for the generator or motor rotor angle with respect to a synchronously rotating reference frame. The equations are then given by

$$M_i\ddot{\delta}_i + D_i\dot{\delta}_i = P_{mi} - P_{gi}, \qquad i = 1, \ldots, N, \tag{5.1}$$

where M_i and D_i are inertia and damping terms for the generator or motor at the ith node and P_{mi} is the mechanical power input to the generator or the mechanical power output (negative) of the motor at the ith node, and P_{gi} is the electrical power output from the ith node. It is assumed that the voltage magnitudes at the nodes are maintained fixed by regulators. The electrical power P_{gi} is given by

$$\begin{aligned} P_{gi} = Re(V_i^* I_i) &= Re\left(V_i^* \sum_{j=1}^{N} Y_{ij} V_j\right) \\ &= -\sum_{j=1}^{N} |V_i||V_j| b_{ij} \sin(\delta_i(t) - \delta_j(t)), \qquad i = 1, \ldots, N, \end{aligned} \tag{5.2}$$

where $V_i = |V_i|e^{i\delta_i}$, and $Y = G + iB$ is the admittance matrix for the network connections (with some of the i denoting $\sqrt{-1}$). We assume that the lines are lossless ($G = 0$). The b_{ij} are the terms of the *susceptance* matrix B. The diagonal entrees b_{ii} are all zero. If a line is not present between nodes i and j, then $b_{ij} = 0$. We chose $b_{ij} = 1$ for all connected lines.

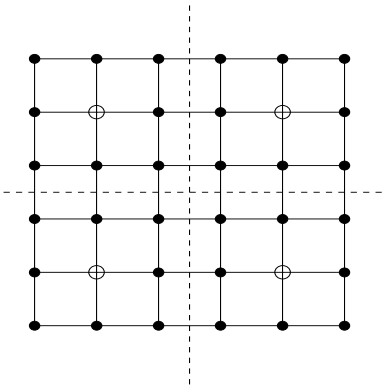

FIG. 5.1. *Power grid: generators—open circles; loads—filled circles.*

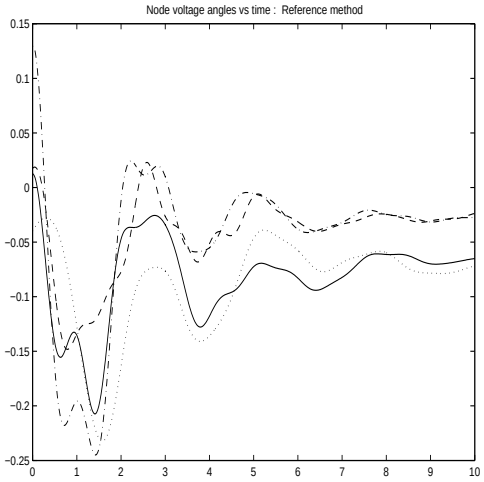

FIG. 5.2. δ_i *vs. time: reference method.*

The grid we chose is shown in Figure 5.1. The generators are marked by open circles, and all other nodes (filled circles) are motors. All physical parameters chosen were nondimensional. We chose all the voltage magnitudes to be the same (constant) value of 1. The mechanical powers P_{mi} were chosen to be -0.0880 for the motor nodes, and generator powers were all 0.7040 so that the total sums to zero. The parameter values $M_i = 2.0$ and $D_i = 0.8$ were chosen for the generators, while values $M_i = 0.1$ and $D_i = 0.1$ were chosen for all load motors. Given these parameters the swing equations have a nontrivial (not all δ_i are zero) steady state solution. We picked a random initial condition (Gaussian with zero mean and 0.1 standard deviation for both δ_i and $\dot{\delta}_i$ for all i). First, we used the MATLAB ODE solver `ode15s` to solve the equations in the interval $[0, 10]$, which indicated that the steady state was more or less reached in that time interval. A plot of the "reference solution" for δ_i for four of the nodes is shown in Figure 5.2. One motor node from each subsystem was chosen for this plot. In order to apply the DIRM method we modularized the system so that the square grid of 6×6 nodes was split into four subsystems, each consisting of a

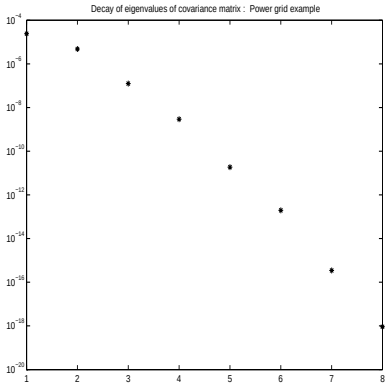

FIG. 5.3. *Decay of POD mode energies: power grid example.*

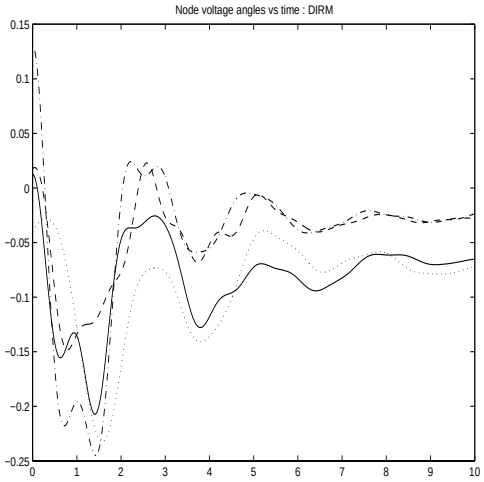

FIG. 5.4. δ_i *vs time: DIRM.*

square subgrid of 3×3 nodes. The broken lines in Figure 5.1 show this partitioning. DIRM did not converge when the simulation interval was $[0, 10]$. However, breaking the interval into smaller intervals achieved convergence. Using intervals of length 0.5 (i.e. $[0, 0.5]$, $[0.51]$, $\ldots$, $[9.5, 10]$) achieved convergence. We used the same MATLAB solver `ode15s` as the underlying solver. Within each interval at most seven iterations were required. The final value of the solution from one interval was used as the initial condition for the next interval. Initial reduced models were obtained by simulating each subsystem in isolation (all other subsystem states were assumed to remain zero) for the time interval under consideration. The reduced order models of all subsystems were chosen to be of dimension 3. (The full dimension of each subsystem is 18.) Figure 5.3 shows the largest eight eigenvalues of the DIRM solution for the first subsystem trajectory in the final simulation interval $[9.5, 10]$. The decay was similar for the other subsystems as well.

The solution obtained using DIRM is shown in Figure 5.4 for the same nodes as in Figure 5.2. The solutions of the reference method and DIRM are visually

indistinguishable and so we plotted them on separate figures. We also computed the maximum relative error e_r defined by

$$e_r = \sup_i \frac{\sup_{t\in[0,10]} |\hat{x}_i(t) - x_i(t)|}{\sup_{t\in[0,10]} |x_i(t)|}, \tag{5.3}$$

where i indexed over all states (node voltage phases and velocities). It was $e_r = 0.0037$; i.e., the relative error for any state variable was less than 0.37%.

An important point during swing dynamic transients is that large deviations of δ_i and $\dot{\delta}_i$ can trigger protection mechanisms that can shut down a line or a generator, and this changes the system parameters discontinuously (some b_{ij} change to 0, for instance) which in turn leads to further transients and so on (see [11]). Since our scheme predicts the solutions accurately, we expect it to predict the first failure (location and time) accurately. However, for accurate prediction beyond the first failure, we have to restart our iteration for a time interval beginning at the failure. Numerical simulations done by Cao and Petzold [1] revealed that the reduced model formed from trajectories obtained before a failure was not accurate after the failure and could not be used to predict further failures. If we include failures in our model, our iterative method may need to be modified. During the iterative simulations, if a subsystem indicates failure, then the time interval of simulation may be shortened so that the reduced models remain more accurate. We have not yet numerically investigated this type of scenario. This is a subject of future research.

5.2. PDE Example: Comparison with WR. We considered the reaction-convection-diffusion equation

$$x_t = \nu x_{ss} + a x_s + b x \tag{5.4}$$

in one spatial variable s in the interval $s \in [0, 6]$ with spatial discretization giving 100 equally spaced interior points. Both first and second spatial derivatives were approximated by centered differences. We used the triangular function

$$\begin{aligned} &x(0,s) = s/3, \qquad 0 \le s \le 3, \\ &x(0,s) = 1 - (s-3)/3, \qquad 3 \le s \le 6, \end{aligned} \tag{5.5}$$

as initial condition, and the boundary conditions were zero. This results in a tridiagonal linear system (ODE) of the form

$$\dot{x} = Ax,$$

where $x \in \mathbb{R}^{100}$.

For DIRM we divided the system into 10 subsystems each of size 10 consisting of adjacent grid points. For WR we used the splitting $A = A_d + A_o$, where A_d is block diagonal with 10×10 blocks and A_o the remaining off-diagonal coupling part. This corresponds to the Jacobi version of WR. We also used overlapping for WR in order to improve its convergence. It is known from the work of Miekkala that in the case of tridiagonal systems the order of convergence of WR is $\omega = 1$ (as defined by [8]), which is very slow. However, if we overlap by o variables, then $\omega = \frac{1}{o+1}$, and this should improve the asymptotic convergence [8].

Simulations of three different sets of parameter values are discussed here. In all cases we computed the solutions using the MATLAB ODE solver `ode15s` to provide a benchmark. The same solver was also used within DIRM and WR. In all simulations of DIRM and WR we used the convergence tolerance (see (3.3)) $tol = 0.001$ and a

TABLE 5.1

TABLE 5.3
Convergence and accuracy of DIRM and WR for the 1D PDE with pure diffusion. Parameter values $\nu = 0.1, a = 0, b = 0$. Simulation interval $[0, 10]$. Subsystem reduced model dimension $k = 3$.

	Number of iterations	Maximum error over subsystems
DIRM	2	0.4511×10^{-3}
WR overlap $o = 5$	21	1.9688×10^{-3}

maximum iteration count of 30. All the subsystem reduced models in DIRM were of dimension $k = 3$. The convergence and error results are summarized in Tables 5.1, 5.2, and 5.3. The error is measured by $\sup\{\|\hat{x}_i(t) - x_i(t)\|_2 : t \in [0, T],\ i = 1, \ldots, 10\}$, where $x_i(t)$ and $\hat{x}_i(t)$ are the benchmark solution and the iterative method (DIRM or WR) solution of the ith subsystem, respectively. The WR method in general needed some overlapping to achieve convergence. Especially the pure diffusion case required a greater overlap without which WR did not converge at all.

Note that couplings exist only between adjacent subsystems. This is essentially a property of 1D PDEs. Thus for the WR method we expect at least 10 iterations before the first subsystem "sees" the last subsystem. This is true even when overlapping is used. Hence we may expect at least 10 iterations (initial overhead) before we see convergence of WR. In DIRM, the entire system is always being simulated, albeit in a partially reduced form. Hence we do not expect this adverse effect. In order to test this hypothesis we considered the system with $\nu = 0.1, a = 1$, and $b = 0$. This gives rise to a system with diffusion as well as convection propagating towards the decreasing s direction ($a > 0$). This can be seen from Figure 5.5, where the initial condition as well as the solution (benchmark solver) at $t = 5$ are shown. This may be thought of as the initial triangle diffusing and propagating to the left at the same time. Thus there is more "information flow" from right to left than from left to right. In order to capture the waveform for the first subsystem (the leftmost 10 grid points) accurately we need to capture the information flow from the other subsystems. Hence we could expect that the WR method would take at least 10 iterations for convergence and also expect it to converge slower for the first (leftmost) subsystem than for the last (rightmost) subsystem. We picked a simulation interval $[0, 10]$ so that the entire system decayed to zero. We found that WR did not converge even after 30 iterations, and hence used overlapping by three variables, keeping the number of subsystems the

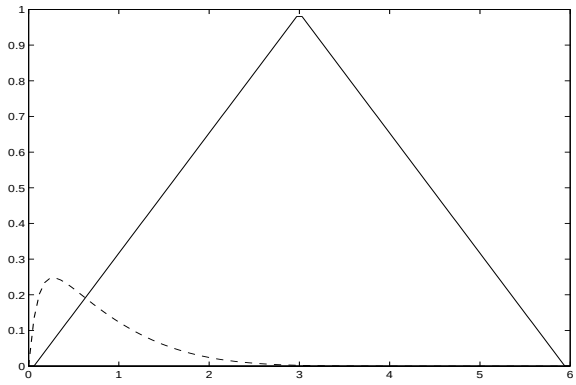

FIG. 5.5. *Plot of the benchmark solution $x(t,s)$ versus s at time $t=0$ (solid) and at time $t=5$ (dashed) for the convection-diffusion case with $\nu=0.1, a=1, b=0$.*

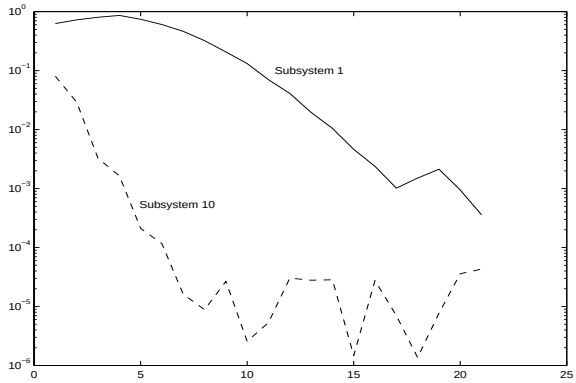

FIG. 5.6. *Convergence of subsystems 1 and 10 for WR with overlap $o=3$ for the convection-diffusion case with $\nu=0.1, a=1, b=0$. Plot of the difference $\sup\{\|x_i^{(j)}(t)-x_i^{(j-1)}(t)\|_2 : t\in[0,T]\}$ between successive iterates versus the iteration step j for subsystems $i=1$ and $i=10$.*

same. This resulted in the first nine subsystems being of size 13 and the last one being of size 10. The convergence plots for the overlapped WR for the first and last subsystems are shown in Figure 5.6, which confirms our intuition. The DIRM method did not experience this overhead and converged in three iterations. Figures 5.7 and 5.8 compare the convergence rates and Figure 5.9 compares the subsystem errors for DIRM and WR.

Second, we considered the system with $\nu=0.1, a=6$, and $b=6$. This system has a dominant reactive term. We picked the simulation interval $[0,1.2]$ in which the system had an explosive reaction after which it decayed to zero. The benchmark simulation showed that subsystem 1 (leftmost) underwent the most explosive change; see Figure 5.10. DIRM and WR with overlapping ($o=3$) performed comparably. Even though the maximum error (Table 5.2) seems large for both DIRM and WR with overlap, it occurred in subsystem 1 (which underwent the most explosive growth), and it is small compared to the peak value of the subsystem trajectory. In fact it was hard to visually distinguish the trajectory plots of subsystem 1 for DIRM and overlapped WR from those of the benchmark solution in Figure 5.10.

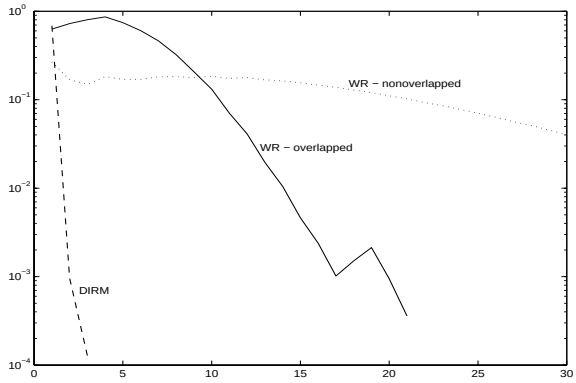

FIG. 5.7. *Convergence of subsystem* 1 *for WR with overlap* $o = 3$*, WR without overlap, and DIRM for the convection-diffusion case with* $\nu = 0.1, a = 1, b = 0$*. FIG. 5.10. *Plot of the benchmark solution of all* 10 *of the states of subsystem* 1 *for the reaction-convection-diffusion case with* $\nu = 0.1, a = 6, b = 6$.

Finally, we simulated the purely diffusive system with $\nu = 0.1, a = 0$, and $b = 0$. In this case WR performed worst, and DIRM performed best, showing a very clear advantage over WR. Overlapping by $o = 3$ was not sufficient to achieve convergence of WR. However, a bigger overlap of $o = 5$ achieved convergence.

In summary, DIRM seems to converge better than WR for both the convection-diffusion and pure diffusion cases, with the pure diffusion case being the strongest point for DIRM. For the reaction-convection-diffusion case there is no clear winner. Since the error in the POD method is large when system trajectories undergo explosive growth in the interval of interest ([13]), it is not surprising that DIRM performed worst for this type of equation. In contrast, WR seems to have performed best for the reaction-convection-diffusion case.

5.3. Example: Almost coincident eigenvalues $\lambda_k \approx \lambda_{k+1}$ and the modified DIRM method. The convergence analysis of DIRM in section 4.6 predicts difficulties in convergence if the eigenvalues λ_k and λ_{k+1} of the covariance matrix of the fixed point trajectory of any subsystem are very close. To generate such an example, we employ the equation

$$\dot{x} = A(x - f(t)) + f'(t), \tag{5.6}$$

which for any choice of A has $x = f(t)$ as the solution corresponding to the initial condition $x(0) = f(0)$.

Consider the following trajectory $g(t) \in \mathbb{R}^3$ such that the covariance matrix for the interval $[0, 1]$ has prescribed eigenvalues λ_1, λ_2, and λ_3:

$$g(t) = \left(\sqrt{2\lambda_1}\sin(2\pi t), \sqrt{2\lambda_2}\cos(2\pi t), \sqrt{2\lambda_3}\sin(4\pi t)\right).$$

Note that $g(0) = (0, \sqrt{2\lambda_2}, 0)$. We may construct a system of the form (5.6) which is six dimensional, and when split into two subsystems (each of dimension 3) the subsystem solution trajectories are both $g(t)$. According to the analysis of section 4.5, if A is diagonally dominant, and its fundamental modes do not grow substantially in the interval of simulation $[0, 1]$, and the POD projection error is small, then we

expect the fixed point trajectories of the subsystems to be close to the true solution $g(t)$. Thus for the system in (5.6), if we set $f(t) = (g(t), g(t))$, $\lambda_3 = \lambda_2$, and choose an A with the above properties and the initial condition $x(0) = (0, \sqrt{2\lambda_2}, 0, 0, \sqrt{2\lambda_2}, 0)$, then we can expect difficulties in convergence.

Numerical experiments were conducted with A obtained from discretizing the PDE in section 5.2 with $\nu = 1$, $a = b = 0$, and six interior points. The choice of $\lambda_1 = 0.5, \lambda_2 = \lambda_3 = 0.2$ lead to eight iterations for convergence; the choice of $\lambda_1 = 0.5, \lambda_2 = 0.2, \lambda_3 = 0.199$ required 12 iterations; and the choice $\lambda_1 = 0.5, \lambda_2, \lambda_3 = 0.19$ converged in four iterations. In other cases, where λ_2 and λ_3 were further separated, convergence took a similar number of (five or less) iterations.

Remark 5.1. Note that the $\lambda_2 = 0.2, \lambda_3 = 0.19$ case was worse than the $\lambda_2 = \lambda_3 = 0.2$ case because the fixed point trajectory is slightly different from the true solution trajectory. As a verification of our analysis we computed the quantities $\mathcal{C}_1$ and $\mathcal{C}_2$ of equations (4.30) for the fixed point trajectories of the above examples and observed that the larger they were the more the iterations needed for convergence.

In order to make DIRM robust against such situations we tried the following "modified DIRM" method. In modified DIRM, reduced models are computed from a covariance matrix and mean value that are a weighted combination of the covariance matrix and mean value of the current trajectory and some precomputed covariance matrix and mean which are typically obtained from an ensemble of trajectories such as those with initial conditions uniformly chosen from the unit sphere. Thus at the αth iteration, given trajectory $x^{(\alpha)}$ of a subsystem we compute the mean $\bar{x}^{(\alpha)}$ and the covariance matrix $R^{(\alpha)}$ of that trajectory as usual. However, instead of using $\bar{x}^{(\alpha)}$ and $R^{(\alpha)}$ to obtain the reduced model we compute

$$\tilde{R}^{(\alpha)} = \beta R^{(\alpha)} + (1-\beta) R_0,$$
$$\tilde{\bar{x}}^{(\alpha)} = \beta \bar{x}^{(\alpha)} + (1-\beta)\bar{x}_0,$$

where $0 < \beta \leq 1$, and then compute the projection $\tilde{P}^{(\alpha)}$ corresponding to $\tilde{R}^{(\alpha)}$. The new reduced model is given by $\tilde{\bar{x}}^{(\alpha)}$ and $\tilde{P}^{(\alpha)}$.

Here R_0 and $\bar{x}_0$ are precomputed from some ensemble of trajectories with various initial conditions and do not change from iteration to iteration. This method changes the fixed point of DIRM. Typically if β is small you would expect the method not to be so accurate.

When we applied the modified DIRM with $\beta = 0.9$, for the worst case above ($\lambda_1 = 0.5, \lambda_2 = 0.2, \lambda_3 = 0.199$), we converged in four iterations, with more or less the same accuracy as the unmodified DIRM. It is important to note that the precomputed covariance matrix R_0 should have reasonable separation between its kth and $k+1$st eigenvalues. Then for sufficiently small β we are guaranteed to have sufficient separation of λ_k and λ_{k+1}, the eigenvalues of $\tilde{R}$. This example confirms our analysis, and the modified DIRM method provides a safeguard against the situation of coincident eigenvalues.

Remark 5.2. In the modified DIRM method, it is easy to see that when $\beta = 0$ we have immediate convergence, since the reduced models do not change. However, its accuracy is not as good as that of the regular DIRM method. When $\beta = 1$ we have the regular DIRM method, which is more accurate, but does not always have good convergence behavior. So one may expect that by choosing an appropriate β we could achieve a good compromise between convergence and accuracy. However, the numerical experiments with the PDE example of section 5.2 showed that the convergence rate did not depend monotonically on β. For the parameter values

($\nu = 0.1, a = 6, b = 6$), subsystem reduced model dimension $k = 2$, and the time interval $[0, 0.5]$, convergence took 12 iterations for $\beta = 1$, 10 iterations for $\beta = 0.8$, 13 iterations for $\beta = 0.5$, and for the $\beta = 0$ case 1 iteration (as expected). This could be because there is an intermediate regime of β values where the loss of accuracy affects the convergence negatively. It should be noted that the WR method took more than 15 iterations.

5.4. Example: Fixed point trajectory with zero POD projection error. For the example in section 5.3, if we choose $\lambda_1 = 0.5, \lambda_2 = 0.2$, and $\lambda_3 = 0$, we have a solution trajectory which has zero POD projection error. The fixed point trajectory being close to the true solution also had almost zero POD projection error. Yet DIRM took four iterations to converge, in agreement with the convergence analysis (see section 4.6).

When trajectories of all the subsystems always lie in a k dimensional subspace (where k is the dimension of all the reduced order models), the POD projection error is always zero, and in this case convergence is immediate (in agreement with the convergence analysis). This can be numerically observed from an example $\dot{x} = Ax$, where rows of A corresponding to each subsystem are of rank k or less. When the row rank is strictly less than k we have zero POD projection error as well as coincident eigenvalues ($\lambda_k = \lambda_{k+1} = 0$). In this case DIRM still converges immediately, even though the projection matrices computed at each step may not converge.

6. Conclusions and future work. We have presented a new dynamic iteration called DIRM for simulation of large scale interconnected systems. DIRM uses reduced order models (obtained here via POD) of subsystems which are also refined during the iterations. We provided an analysis of the DIRM method as applied to linear time invariant systems of ODEs consisting of two subsystems, giving results on accuracy and convergence of DIRM. We also presented numerical examples, including some special cases chosen to test the validity of the analysis and to illustrate some special situations, and two realistic examples: a nonlinear power grid model and a discretized linear reaction-convection-diffusion type PDE in one dimension. Both the power grid and the PDE examples demonstrated the success of DIRM. In the PDE example we also provided comparisons with WR. This example showed that DIRM has clear advantages over WR for pure diffusion and convection-diffusion-type equations. DIRM performed worst for systems showing explosive reactions, for which WR performed best.

Future work will include DAEs as well as hybrid systems such as the power grid with failure models resulting in discontinuous changes in system parameters. The complementary nature of DIRM and WR seen in the PDE example suggests that the development of an approach that combines the two methods in an optimal manner might prove valuable in parallel computation of large scale systems. The framework of DIRM allows for the use of model reduction techniques other than POD provided that they are data driven. Since the POD reduced models may not achieve considerable savings for nonlinear banded Jacobian systems [13], it might be advantageous to explore the use of other model reduction methods.

Acknowledgments. We would like to thank John C. Doyle for suggesting the general notion of iterating reduced order models of subsystems. We would also like to thank Pablo Parrilo for providing us with the software for the power grid generation.

AN H^1-GALERKIN MIXED FINITE ELEMENT METHOD FOR AN EVOLUTION EQUATION WITH A POSITIVE-TYPE MEMORY TERM*

AMIYA K. PANI† AND GRAEME FAIRWEATHER‡

Abstract. An H^1-Galerkin mixed finite element method is analyzed for a class of evolution equations with memory. When a classical mixed method is applied to such problems, it has not been possible to obtain any estimate for the flux. However, the proposed approach yields optimal order convergence without the LBB consistency condition and quasi uniformity of the finite element mesh. Compared to the results proved for one space variable, the L^2 estimate of the flux is not optimal for problems in two and three space dimensions. Therefore, a modification of the method is proposed and analyzed. A maximum norm estimate is also derived in one and two space variables. A backward Euler approximation of the modified method is also analyzed.

Key words. evolution equation, positive-type memory, mixed finite element method, H^1-Galerkin, LBB condition, semidiscrete schemes, backward Euler method, optimal error estimates, flux estimates, several space variables

1. Introduction.

Consider the initial boundary value problem

$$\begin{aligned} u_t - \int_0^t \beta(t-s)\nabla\cdot(a(x)\nabla u(s))\,ds &= f(x,t), \quad (x,t)\in\Omega\times(0,T], \\ u(x,t) &= 0, \quad (x,t)\in\partial\Omega\times(0,T], \\ u(x,0) &= u_0(x), \quad x\in\Omega, \end{aligned} \tag{1.1}$$

where $u_t = \partial u/\partial t$, Ω is a bounded domain in R^d $(d = 1, 2, 3)$ with boundary $\partial\Omega$, and $a_1 \geq a(x) \geq a_0 > 0$, $x \in \Omega$, for positive constants a_1 and a_0. The kernel β is assumed to be positive definite, i.e., for each $t \in (0, T]$, $\beta \in L^1_{loc}(0,\infty)$, and

$$\int_0^t \left(\int_0^s \beta(s-\tau)v(\tau)\right) v(s)\,d\tau\,ds \geq 0, \quad v\in C[0,t]. \tag{1.2}$$

(Note that (1.2) holds if and only if

$$\Re\hat{\beta}(iy) = \int_0^\infty \beta(t)\cos(yt)\,dt \geq 0, \quad y\in R,$$

because, for any $\psi \in L^2(R_+)$,

$$\int_0^\infty \psi(t)\int_0^t \beta(t-s)\psi(s)\,ds\,dt = \frac{1}{2\pi}\int_{-\infty}^\infty \Re\hat{\beta}(iy)|\hat{\psi}(iy)|^2\,dy,$$

where $\hat{\psi}$ is the Laplace transform of ψ.) Problems of the type (1.1) and a nonlinear version thereof occur in viscoelasticity and heat conduction in materials with memory; see, for example, [8, 18].

Over the last decade, various numerical methods have been applied to (1.1) for both smooth and nonsmooth kernels. In [19], a spectral method is employed for the one dimensional form of (1.1) with a weakly singular kernel, while a finite difference scheme is used to discretize the spatial variable in [7]. Error estimates for methods based on an orthogonal spline collocation discretization in space combined with backward Euler or Crank–Nicolson-type time stepping schemes for (1.1) with $a = 1$ are derived in [3], where a modified spline collocation method for a one dimensional problem is also discussed. In [22], the Laplace transform is used in time with orthogonal spline collocation in space. In [9] and [10], finite element Galerkin methods are applied to discretize (1.1) in space, with finite difference schemes in time for both smooth and nonsmooth kernels. Convergence is discussed for smooth initial data and constant time step size in [9], and variable time stepping schemes are examined in [10]. In all of these papers, the positivity of the kernel plays a key role in the stability and convergence analyses.

To approximate both u and its flux $\boldsymbol{\sigma} := a\nabla u$ accurately, we reformulate (1.1) as the first order system

$$\boldsymbol{\sigma} = a\nabla u, \quad u_t - \int_0^t \beta(t-s)\nabla\cdot\boldsymbol{\sigma}(s)\,ds = f. \tag{1.3}$$

A standard procedure is to apply a classical mixed method to this system, but for this method it has not been possible to obtain an error estimate for the flux. The purpose of the present paper is to apply to (1.3) an H^1-Galerkin mixed method based on that proposed in [14] and to derive optimal error estimates for u in $L^\infty(L^2)$ and $L^\infty(H^1)$ and for $\boldsymbol{\sigma}$ in $L^\infty(L^2)$. It is observed that, compared to the results proved for problem (1.1) in one space variable, the $L^\infty(L^2)$-norm estimate of the flux is not optimal for the problem in two or three space variables. Therefore, a modification is considered in which a term containing the curl of the flux is added. This modification leads to a strong coercivity property of $\boldsymbol{\sigma}$ and facilitates the derivation of an optimal estimate in $L^\infty(L^2)$ for the flux.

As a consequence of our analysis, we obtain a maximum norm estimate for u in one and two space variables. We note that this has not been derived previously for the standard Galerkin method.

The proposed methods have several attractive features. First, they are not subject to the LBB consistency condition. The finite element spaces V_h (for approximating u) and $\mathbf{W_h}$ (for approximating the flux $\boldsymbol{\sigma}$) may be of differing polynomial degrees. Moreover, the L^2- and H^1-error estimates do not require the finite element mesh to be quasi-uniform. Related studies on least squares mixed methods for elliptic equations can be found in [4, 6, 11, 12, 13, 16] and references therein.

In the past, attempts have been made to circumvent the LBB-consistency condition by adding least square like terms, which are generally mesh dependent, to the classical mixed formulations for elliptic problems (see, for example, [1, 5]). These methods are known as stabilizing mixed finite element methods. In contrast to the stabilizing methods, the present formulation deals directly with the original equation and is not based on classical methods. In fact, it is not possible to apply even the classical mixed methods to derive any estimate of the flux for problem (1.1). The approach proposed in this article is not a stabilizing procedure and does not use mesh

dependent parameters. The reason for adding the curl term is simply to obtain a strong coercivity property.

A brief outline of this paper is as follows. In section 2, error estimates are derived for the semidiscrete case in one space variable, while in section 3 error bounds are obtained for (1.1) in two and three space variables, again for the semidiscrete case. Since the estimates are not sharp compared to the one dimensional case, in section 4, a modified H^1-Galerkin mixed finite element method is formulated, and error estimates are established for the semidiscrete case. In section 5, a discrete time backward Euler scheme is considered for the time discretization of the modified H^1-Galerkin mixed method, and error estimates are derived. Finally, in section 6, the key results of the paper are summarized and a possible extension of them indicated.

Throughout this paper, C denotes a generic positive constant which does not depend on the spatial and time discretization parameters h and Δt but may depend on T and $\|\beta\|_{L^1(0,T)}$. Also, we make use of the following: for a function $\phi \in H^1(0,T)$,

$$\phi(t) = \phi(0) + \int_0^t \phi_t(s)\, ds. \tag{1.4}$$

2. Error estimates for the semidiscrete case in one space variable. Consider the one dimensional form of (1.1),

$$\begin{aligned} u_t - \int_0^t \beta(t-s)(a(x)u_x(s))_x\, ds &= f(x,t), \quad (x,t) \in \Omega \times (0,T], \\ u(0,t) = u(1,t) &= 0, \quad t \in (0,T], \\ u(x,0) &= u_0(x), \quad x \in \Omega, \end{aligned} \tag{2.1}$$

where $\Omega = (0,1)$, $0 < T < \infty$, $a_1 \geq a(x) \geq a_0 > 0$, $x \in \Omega$, for positive constants a_1 and a_0. Setting $\sigma = au_x$, we rewrite (2.1) as the first order system

$$a(x)u_x = \sigma, \quad u_t - \int_0^t \beta(t-s)\sigma_x(s)\, ds = f. \tag{2.2}$$

We denote the natural inner product in $L^2(\Omega)$ by $(\cdot,\cdot)$ and the norm by $\|\cdot\|$, and let $H_0^1 = \{v \in H^1(\Omega) : v(0) = v(1) = 0\}$. Further, we use the classical Sobolev spaces $W^{m,p}(\Omega)$, $1 \leq p \leq \infty$, denoted by $W^{m,p}$, with norm $\|\cdot\|_{m,p}$. When $p = 2$, we simply write $W^{m,p}$ as H^m with norm $\|\cdot\|_m$. To derive the H^1-Galerkin mixed finite element method, we consider the following weak formulation of (2.2): find $\{u, \sigma\}$ satisfying

$$\begin{aligned} (au_x, v_x) &= (\sigma, v_x), \quad v \in H_0^1, \\ (\alpha\sigma_t, w) + \int_0^t \beta(t-s)\,(\sigma_x(s), w_x)\, ds &= -(f, w_x), \quad w \in H^1, \end{aligned} \tag{2.3}$$

where

$$\alpha = \frac{1}{a}. \tag{2.4}$$

Let V_h and W_h be finite dimensional subspaces of H_0^1 and H^1, respectively, with the following approximation properties: for $1 \leq p \leq \infty$ and positive integers k and r,

$$\inf_{v_h \in V_h} \{\|v - v_h\|_{L^p} + h\|v - v_h\|_{W^{1,p}}\} \leq Ch^{k+1}\|v\|_{W^{k+1,p}}, \quad v \in H_0^1 \cap W^{k+1,p},$$

and

$$\inf_{w_h \in W_h} \{\|w - w_h\|_{L^p} + h\|w - w_h\|_{W^{1,p}}\} \le Ch^{r+1}\|w\|_{W^{r+1,p}}, \quad w \in W^{r+1,p}.$$

With the finite element spaces V_h and W_h, we define the semidiscrete H^1-Galerkin mixed finite element approximation $\{u_h, \sigma_h\} : [0,T] \mapsto V_h \times W_h$ by

$$\begin{aligned} &(au_{hx}, v_{hx}) = (\sigma_h, v_{hx}), \quad v_h \in V_h, \\ &(\alpha\sigma_{ht}, w_h) + \int_0^t \beta(t-s)\,(\sigma_{hx}(s), w_{hx})\,ds = -(f, w_{hx}), \quad w_h \in W_h, \end{aligned} \tag{2.5}$$

with $u_h(0)$ and $\sigma_h(0)$ specified later. Since V_h and W_h are finite dimensional subspaces, the problem (2.5) leads to a linear system of integro-differential equations combined with algebraic equations of index one, as the stiffness matrix associated with $(\alpha u_{hx}, v_{hx})$ is invertible. Using Picard's iteration, it is easy to prove the existence of a unique pair of solutions to the system (2.5).

For use in the error analysis, we introduce the projections $\{\tilde{u}_h, \tilde{\sigma}_h\}$ defined by

$$\begin{aligned} &(a(u_x - \tilde{u}_{hx}), v_{hx}) = 0, \quad v_h \in V_h, \\ &A(\sigma - \tilde{\sigma}_h, w_h) = 0, \quad w_h \in W_h, \end{aligned} \tag{2.6}$$

where $A(\phi, \chi) = (\phi_x, \chi_x) + (\phi, \chi)$.

With $\eta = u - \tilde{u}_h$ and $\rho = \sigma - \tilde{\sigma}_h$, the following estimates are well known [20]: for $j = 0, 1$,

$$\|\eta\|_j \le Ch^{k+1-j}\|u\|_{k+1} \tag{2.7}$$

and

$$\|\rho\|_j + \|\rho_t\|_j \le Ch^{r+1-j}\left(\|\sigma\|_{r+1} + \|\sigma_t\|_{r+1}\right). \tag{2.8}$$

Moreover, for $j = 0, 1$, and $1 \le p \le \infty$, we have

$$\|\eta\|_{W^{j,p}} \le Ch^{k+1-j}\|u\|_{W^{k+1,p}}. \tag{2.9}$$

For the maximum norm estimate (i.e., when $p = \infty$), the finite element mesh is required to be quasi-uniform.

Using the projections $\{\tilde{u}_h, \tilde{\sigma}_h\}$, we write $u - u_h = (u - \tilde{u}_h) + (\tilde{u}_h - u_h) := \eta + \zeta$ and $\sigma - \sigma_h = (\sigma - \tilde{\sigma}_h) + (\tilde{\sigma}_h - \sigma_h) := \rho + \xi$. From (2.3), (2.5), and (2.6), we then obtain

$$(a\zeta_x, v_{hx}) = (\rho, v_{hx}) + (\xi, v_{hx}), \quad v_h \in V_h, \tag{2.10}$$

and

$$\begin{aligned} &(\alpha\xi_t, w_h) + \int_0^t \beta(t-s)\,(\xi_x(s), w_{hx})\,ds \\ &\qquad = -(\alpha\rho_t, w_h) + \int_0^t \beta(t-s)\,(\rho, w_h), \quad w_h \in W_h. \end{aligned} \tag{2.11}$$

THEOREM 2.1. *Assume that* $\sigma_0 = au_{0x}$ *and* $\sigma_h(0) = \tilde{\sigma}_h(0)$. *Then*

$$\|(\sigma - \sigma_h)(t)\| \le Ch^{r+1}\left[\|\sigma_0\|_{r+1} + \|\sigma_t\|_{L^1(H^{r+1})}\right], \quad t \in (0, T].$$

Moreover, for $1 < p \le \infty$,

$$\|(u - u_h)(t)\|_{L^p} \le Ch^{\min(k+1,r+1)}\left[\|\sigma_0\|_{r+1} + \|u\|_{L^\infty(W^{k+1,p})} + \|\sigma_t\|_{L^1(H^{r+1})}\right]$$

and

$$\|(u - u_h)(t)\|_1 \le Ch^{\min(k,r+1)}\left[\|\sigma_0\|_{r+1} + \|u\|_{L^\infty(H^{k+1})} + \|\sigma_t\|_{L^1(H^{r+1})}\right].$$

Proof. Since estimates of η and ρ are given by (2.7) and (2.8), respectively, it is sufficient to estimate ζ and ξ. To this end, set $v_h = \zeta$ in (2.10) and use $a \ge a_0 > 0$ to obtain

$$\|\zeta_x\| \le C(\|\rho\| + \|\xi\|). \tag{2.12}$$

Further, choose $w_h = \xi(t)$ in (2.11) and apply the Cauchy–Schwarz inequality with boundedness property of α to obtain

$$\begin{aligned} &\frac{d}{dt}\|\alpha^{\frac{1}{2}}\xi\|^2 + 2\int_0^t \beta(t-s)\,(\xi_x(s), \xi_x(t))\,ds \\ &\qquad \le C\left[\|\rho_t\| + \int_0^t \beta(t-s)\|\rho(s)\|\,ds\right]\|\xi(t)\|. \end{aligned} \tag{2.13}$$

On integrating (2.13) with respect to time, and using (1.2), the positive definiteness of β, and the fact that from (2.4) α is bounded below, we obtain

$$\|\xi(t)\|^2 \le C\left[\|\xi(0)\| + \int_0^t \|\rho_t(s)\|\,ds + \int_0^t\int_0^s \beta(s-\tau)\|\rho(\tau)\|\,d\tau\,ds\right]\max_{0\le s\le t}\|\xi(s)\|.$$

Since $\sigma_h(0) = \tilde{\sigma}_h(0)$, it follows that $\xi(0) = 0$. Then, taking the maximum of both sides over $[0, t]$, we have

$$\|\xi(t)\| \le \max_{0\le s\le t}\|\xi(s)\| \le C\left[\|\xi(0)\| + \int_0^t \|\rho_t(s)\|\,ds + \int_0^t B(t-s)\|\rho(s)\|\,ds\right].$$

Here

$$B(t) = \int_0^t \beta(s)\,ds, \tag{2.14}$$

and we have used

$$\int_0^t\int_0^s \beta(s-\tau)\|\rho(\tau)\|\,d\tau\,ds = \int_0^t B(t-s)\|\rho(s)\|\,ds.$$

From (2.8), the first estimate follows. Using the Sobolev embedding theorem and Poincaré inequality, it follows that $\|\zeta(t)\|_{L^p} \le C\|\zeta_x(t)\|$, $\zeta(t) \in H_0^1$. Finally, using (2.7)–(2.9), (2.12), and (1.4) appropriately, we apply the triangle inequality to complete the proof. ∎

Remark 2.1. (i) From the proof of Theorem 2.1, it is clear that we can choose $\sigma_h(0)$ as the L^2 projection of σ_0 into W_h instead of the elliptic projection $\tilde{\sigma}_h(0)$. Note

that the results presented in Theorem 2.1 are optimal with respect to the approximation property but not with respect to the regularity of the solution.

(ii) The estimates in Theorem 2.1 are also valid for a weakly singular kernel $\beta(t)$, i.e.,

$$\beta(t) = \frac{t^{\mu-1}}{\Gamma(\mu)}, \quad 0 < \mu < 1.$$

When $k = r$, the regularity results needed for optimal $L^\infty(L^2)$ estimates of u and $\boldsymbol{\sigma}$ are $u_0 \in H^{r+2}$, $u \in L^\infty(H^{r+1}) \cap W^{1,1}(H^{r+2})$, and these results can be easily derived under some compatibility conditions following the analysis of [9] (see Lemmas 5.1–5.6 of [9]).

3. Error estimates for problems in two and three space variables. Let $W = \left\{\mathbf{q} \in (L^2(\Omega))^d : \nabla \cdot \mathbf{q} \in L^2(\Omega)\right\}$ with norm

$$\|\mathbf{q}\|_{\mathbf{H}(\mathrm{div},\Omega)} = (\|\mathbf{q}\|^2 + \|\nabla \cdot \mathbf{q}\|^2)^{\frac{1}{2}}.$$

Then the weak formulation of (1.1) for $d = 2, 3$ is the following: find $\{u(t), \boldsymbol{\sigma}(t)\} \in H_0^1 \times \mathbf{W}$ satisfying

$$(a\nabla u, \nabla v) = (\boldsymbol{\sigma}, \nabla v), \quad v \in H_0^1,$$

$$(\alpha\boldsymbol{\sigma}_t, \mathbf{w}) + \int_0^t \beta(t-s)\,(\nabla\cdot\boldsymbol{\sigma}(s), \nabla\cdot\mathbf{w})\,ds = -(f, \nabla\cdot\mathbf{w}), \quad \mathbf{w} \in \mathbf{W}. \tag{3.1}$$

In the analysis of this problem, we employ the classical Hilbert Sobolev spaces $H^m(\Omega)$, denoted by H^m, with norm $\|\cdot\|_m$. Let $(H^m)^d = \mathbf{H}^m$ denote the corresponding product space with the usual product norm.

To define the semidiscrete H^1-Galerkin mixed finite element procedure, let $\mathcal{T}_h$ be a partition of Ω into a finite number of elements called simplices; i.e., $\Omega = \cup_{K\in\mathcal{T}_h} K$ with $h = \max\{\mathrm{diam}(K) : K \in \mathcal{T}_h\}$. Let V_h and $\mathbf{W}_h$ be finite dimensional subspaces of H_0^1 and $\mathbf{W}$, respectively, satisfying the following approximation properties: for nonnegative integers k and r,

$$\inf_{v_h\in V_h} \{\|v - v_h\| + h\|v - v_h\|_1\} \le Ch^{k+1}\|v\|_{k+1},\ v \in H^{k+1} \cap H_0^1 \tag{3.2}$$

and

$$\inf_{\mathbf{q}_h\in\mathbf{W}_h} \{\|\mathbf{q} - \mathbf{q}_h\| + h\|\mathbf{q} - \mathbf{q}_h\|_{\mathbf{H}(\mathrm{div};\Omega)}\} \le Ch^{r+1}\|\mathbf{q}\|_{r+1},\ \mathbf{q} \in \mathbf{H}^{r+1}. \tag{3.3}$$

Standard examples of such spaces are

$$V_h = \left\{v_h \in \mathcal{C}^0(\Omega) : v_h|_K \in P_k(K)\ \forall K \in \mathcal{T}_h, v_h = 0\ \text{ on }\ \partial\Omega\right\} \tag{3.4}$$

and

$$\mathbf{W}_h = \{\mathbf{q}_h \in \mathbf{W} : (\mathbf{q}_h)_i|_K \in P_r(K), i = 1, 2, \ldots, d\ \forall K \in \mathcal{T}_h\},$$

where $P_s(K)$ is the space of polynomials of degree $\le s$ on K. Other examples of approximating spaces can be found in [2] and [17]. Note that we also allow the use of isoparametric elements.

The semidiscrete H^1-Galerkin mixed finite element approximation $\{u_h, \boldsymbol{\sigma}_h\} : [0,T] \mapsto V_h \times \mathbf{W}_h$ for (3.1) is determined by

$$(a\nabla u_h, \nabla v_h) = (\boldsymbol{\sigma}_h, \nabla v_h), \quad v_h \in V_h, \tag{3.5}$$

and

$$(\alpha\boldsymbol{\sigma}_{ht}, \mathbf{w}_h) + \int_0^t \beta(t-s)\,(\nabla\cdot\boldsymbol{\sigma}_h(s), \nabla\cdot\mathbf{w}_h)\,ds = -(f, \nabla\cdot\mathbf{w}_h), \quad \mathbf{w}_h \in \mathbf{W}_h, \tag{3.6}$$

with $u_h(0)$ and $\boldsymbol{\sigma}_h(0)$ specified later.

Corresponding to (2.6), we define the projections $\tilde{u}_h \in V_h$ and $\tilde{\boldsymbol{\sigma}}_h \in \mathbf{W}_h$ by

$$(\nabla(u - \tilde{u}_h), \nabla v_h) = 0, \quad v_h \in V_h, \tag{3.7}$$

and

$$A(\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h, \mathbf{w}_h) = 0, \quad \mathbf{w}_h \in \mathbf{W}_h, \tag{3.8}$$

where $A(\mathbf{w}, \mathbf{w}_h) = (\nabla\cdot\mathbf{w}, \nabla\cdot\mathbf{w}_h) + (\mathbf{w}, \mathbf{w}_h)$.

With $\boldsymbol{\rho} = \boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h$ and $\eta = u - \tilde{u}_h$, the following estimates are easy to obtain (cf., [21]):

$$\|\eta(t)\| + h\|\nabla\eta(t)\| \le Ch^{k+1}\|u(t)\|_{k+1} \tag{3.9}$$

and

$$\|\boldsymbol{\rho}(t)\|_{\mathbf{H}(\mathrm{div},\Omega)} + \|\boldsymbol{\rho}_t(t)\|_{\mathbf{H}(\mathrm{div},\Omega)} \le Ch^r\left(\|\boldsymbol{\sigma}\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{r+1}\right). \tag{3.10}$$

To determine the desired error estimates, we write $u - u_h := (u - \tilde{u}_h) + (\tilde{u}_h - u_h) = \eta + \zeta$ and $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h := (\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h) + (\tilde{\boldsymbol{\sigma}}_h - \boldsymbol{\sigma}_h) = \boldsymbol{\rho} + \boldsymbol{\xi}$. From (3.1), (3.5)–(3.8), we obtain

$$(a\nabla\zeta, \nabla v_h) = ((\boldsymbol{\rho} + \boldsymbol{\xi}), \nabla v_h), \quad v_h \in V_h, \tag{3.11}$$

and

$$\begin{aligned}(\alpha\boldsymbol{\xi}_t, \mathbf{w}_h) + \int_0^t \beta(t-s)\,(\nabla\cdot\boldsymbol{\xi}(s), \nabla\cdot\mathbf{w}_h)\,ds \\ = -(\alpha\boldsymbol{\rho}_t, \mathbf{w}_h) + \int_0^t \beta(t-s)\,(\boldsymbol{\rho}(s), \mathbf{w}_h)\,ds, \quad \mathbf{w}_h \in \mathbf{W}_h.\end{aligned} \tag{3.12}$$

THEOREM 3.1. *With $\boldsymbol{\sigma}_0 = a\nabla u_0$, assume that*

$$\|\boldsymbol{\sigma}_0 - \boldsymbol{\sigma}_{0h}\|_{\mathbf{H}(\mathrm{div},\Omega)} \le Ch^r\|\boldsymbol{\sigma}_0\|_{r+1}.$$

Then

$$\|(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)(t)\| \le Ch^r\left[\|\boldsymbol{\sigma}_0\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right] \tag{3.13}$$

and

$$\begin{aligned}\|(u - u_h)(t)\| + h\|(u - u_h)\|_1 \\ \le Ch^{\min(k+1,r)}\left[\|\boldsymbol{\sigma}_0\|_{r+1} + \|u\|_{L^\infty(H^{k+1})} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right].\end{aligned}$$

Proof. Choose $v_h = \zeta$ in (3.11) to obtain

$$\|\nabla\zeta\| \le C(\|\boldsymbol{\rho}\| + \|\xi\|). \tag{3.14}$$

Next, set $\mathbf{w}_h = \boldsymbol{\xi}(t)$ in (3.12) and use the Cauchy–Schwarz inequality to obtain

$$\frac{1}{2}\frac{d}{dt}\|\alpha^{\frac{1}{2}}\boldsymbol{\xi}\|^2 + \int_0^t \beta(t-s)\,(\nabla\cdot\boldsymbol{\xi}(s), \nabla\cdot\boldsymbol{\xi}(t))\,ds \le \left[\|\boldsymbol{\rho}_t\| + \int_0^t \beta(t-s)\|\boldsymbol{\rho}(s)\|\,ds\right]\|\boldsymbol{\xi}(t)\|.$$

On integrating from 0 to t and using the positivity property (1.2) of β, the second term on the left-hand side of the resulting equation is nonnegative. As in the one dimensional case, on taking the maximum over $[0,t]$, we have

$$\|\boldsymbol{\xi}(t)\| \le C\left[\|\boldsymbol{\xi}(0)\| + \int_0^t \|\boldsymbol{\rho}_t(s)\|\,ds + \int_0^t B(t-s)\|\boldsymbol{\rho}(s)\|\,ds\right].$$

For the L^2-norm estimate of ζ, we use the Poincaré inequality, $\|\zeta\| \le C\|\nabla\zeta\|$. Since the $\mathbf{L}^2$ norm is dominated by the $\mathbf{H}(\mathrm{div},\Omega)$ norm, the use of the triangle inequality with (3.9)–(3.10) and (3.14) completes the proof. ∎

Remark 3.1. (i) In Theorem 3.1, the estimate (3.13) does not depend on the approximation properties of V_h, and hence the degree k of V_h does not influence the estimate of $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h$.

(ii) When $r = k+1$, we obtain the optimal order of convergence for $u - u_h$ in the L^2 norm, that is, optimality with respect to the approximation property, but not with respect to the regularity of the solution.

(iii) Estimate (3.13) indicates that the error estimate $\|(\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)(t)\|$ is not optimal in the L^2 norm. This is primarily due to the fact that the bounds in the L^2 norm for $\boldsymbol{\rho}$ and $\boldsymbol{\rho}_t$ are not of optimal order. Note that, for optimal L^2 estimates, the use of the Aubin–Nitsche trick requires an $\mathbf{H}^2$ regularity result for the adjoint operator

$$-\nabla(\nabla\cdot\boldsymbol{\Phi}) + \boldsymbol{\Phi}$$

associated with the bilinear form $A(\cdot,\cdot)$. In general, this is difficult to obtain as the operator is not coercive in the $\mathbf{H}^1$ norm. Since $-\Delta\boldsymbol{\Phi} = -\nabla(\nabla\cdot\boldsymbol{\Phi}) + \nabla\times\nabla\times\boldsymbol{\Phi}$, we therefore add a curl term to modify the formulation, and that is the theme of the next section.

4. Modified H^1-Galerkin mixed finite element method. Compared to the estimates obtained for the one dimensional case in section 2, the L^2 estimates derived in section 3 for $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h$ and $u - u_h$ are not optimal. Therefore, in this section, we propose a modification of the H^1-Galerkin mixed finite element method (3.5)–(3.6) so that optimal error estimates in the L^2 norm can be determined. In order to accomplish this, we use the fact that $\nabla\times\nabla v = \mathbf{0}$, and hence we add $\nabla\times(\alpha\boldsymbol{\sigma}) = \mathbf{0}$ to the first order system (1.3). More precisely, with $\alpha\boldsymbol{\sigma} = \nabla u$, we write (1.1) as

$$\begin{aligned} u_t - \int_0^t \beta(t-s)\nabla\cdot\boldsymbol{\sigma}(s)\,ds &= f(x,t), \quad x\in\Omega, \quad t\in(0,T], \\ \nabla\times(\alpha\boldsymbol{\sigma}) &= \mathbf{0}, \quad (x,t)\in\Omega\times(0,T], \\ \mathbf{n}\wedge\alpha\boldsymbol{\sigma} &= 0, \quad (x,t)\in\partial\Omega\times(0,T], \\ u(x,0) &= u_0(x), \quad x\in\Omega, \end{aligned}$$

where $\mathbf{n}$ is the outward normal and $\wedge$ denotes the exterior product. If

$$\mathbf{W} = \{\mathbf{w} \in (H^1(\Omega))^d : \mathbf{n} \wedge \alpha\mathbf{w} = 0 \text{ on } \partial\Omega\}, \quad d = 2, 3,$$

then the weak formulation of (1.1) is the following: find $\{u, \boldsymbol{\sigma}\} : [0, T] \mapsto H_0^1 \times \mathbf{W}$ such that

$$(\nabla u, \nabla v) = (\alpha\boldsymbol{\sigma}, \nabla v), \quad v \in H_0^1,$$

$$(\alpha\boldsymbol{\sigma}_t, \mathbf{w}) + \int_0^t \beta(t-s)\mathcal{A}(\boldsymbol{\sigma}(s), \mathbf{w})\, ds = (-f, \nabla \cdot \mathbf{w}), \ \mathbf{w} \in \mathbf{H}^1, \tag{4.1}$$

where

$$\mathcal{A}(\phi, \mathbf{w}) = (\nabla \cdot \phi, \nabla \cdot \mathbf{w}) + (\nabla \times \alpha\phi, \nabla \times \alpha\mathbf{w}).$$

For the modified H^1-Galerkin mixed finite element method, we take V_h as in (3.4) and define

$$\begin{aligned}\mathbf{W}_h = \{&\mathbf{w}_h \in C(\bar{\Omega})^d : (\mathbf{w}_h)_i \,|_K \in P_r(K),\ i = 1, \ldots, d\ \forall K \in \mathcal{T}_h,\\ &(\mathbf{n} \wedge \alpha\mathbf{w}_h) = 0 \text{ at the nodes on } \partial\Omega\}.\end{aligned}$$

Since $\mathbf{n} \wedge \alpha\mathbf{w}_h = 0$ only at the boundary nodes, the finite element space $\mathbf{W}_h$ is not a subspace of $\mathbf{W}$, and hence we have a mildly nonconforming method. Note that the finite dimensional spaces V_h and $\mathbf{W}_h$ have the approximation properties (3.2) and (3.3), respectively. The modified H^1-Galerkin mixed finite element method consists of determining the pair $\{u_h, \boldsymbol{\sigma}_h\} : [0, T] \mapsto V_h \times \mathbf{W}_h$ such that

$$(\nabla u_h, \nabla v_h) = (\alpha\boldsymbol{\sigma}_h, \nabla v_h), \quad v \in V_h,$$

$$(\alpha\boldsymbol{\sigma}_{ht}, \mathbf{w}_h) + \int_0^t \beta(t-s)\mathcal{A}(\boldsymbol{\sigma}_h, \mathbf{w}_h)\, ds = (-f, \nabla \cdot \mathbf{w}_h), \quad \mathbf{w}_h \in \mathbf{W}_h, \tag{4.2}$$

with $u_h(0)$ and $\boldsymbol{\sigma}_h(0)$ specified later.

For the error analysis, we define the projections $\{\tilde{u}_h, \tilde{\boldsymbol{\sigma}}_h\} : [0, T] \mapsto V_h \times \mathbf{W}_h$ by

$$\begin{aligned}&(\nabla(u - \tilde{u}_h), \nabla v_h) = 0, \quad v_h \in V_h,\\ &A_1(\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h, \mathbf{w}_h) = 0, \quad \mathbf{w}_h \in \mathbf{W}_h,\end{aligned} \tag{4.3}$$

where

$$A_1(\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h, \mathbf{w}_h) = \mathcal{A}(\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h, \mathbf{w}_h) + (\boldsymbol{\sigma} - \tilde{\boldsymbol{\sigma}}_h, \mathbf{w}_h).$$

When the domain Ω is convex or the boundary $\partial\Omega$ is of class $C^{1,1}$ or Ω is a curvilinear polygon (or polytope) of class $C^{1,1}$ with no concave angles, then there is a positive constant μ_0, independent of h, such that

$$\|\mathbf{q}_h\|^2_{\mathbf{H}(\mathrm{div},\Omega)} + \|\nabla \times (\alpha\mathbf{q}_h)\|^2 \geq \mu_0 \|\mathbf{q}_h\|^2_{\mathbf{H}^1(\Omega)} \tag{4.4}$$

for all $\mathbf{q}_h \in \mathbf{W}_h$ and for small h; see pp. 509–510 of [15]. Thus, $A_1(\cdot, \cdot)$ satisfies the coercivity condition

$$A_1(\boldsymbol{\phi}_h, \boldsymbol{\phi}_h) \geq \mu_0 \|\boldsymbol{\phi}_h\|_1^2, \quad \boldsymbol{\phi}_h \in \mathbf{W}_h.$$

Let $u-\tilde{u}_h=\eta$ and $\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}_h=\boldsymbol{\rho}$. With an appropriate modification of the analysis of [15] (see also [11, 12, 13]), it is easy to obtain the following estimates for $\boldsymbol{\rho}$ and $\boldsymbol{\rho}_t$:

$$\|\boldsymbol{\rho}\|_j+\|\boldsymbol{\rho}_t\|_j\le Ch^{r+1-j}[\|\boldsymbol{\sigma}\|_{r+1}+\|\boldsymbol{\sigma}_t\|_{r+1}],\quad j=0,1. \tag{4.5}$$

Note that the difficulties due to nonconformity enter the error analysis of $\boldsymbol{\rho}$ and $\boldsymbol{\rho}_t$. As before, we write $u-u_h:=(u-\tilde{u}_h)+(\tilde{u}_h-u_h)=\eta+\zeta$ and $\boldsymbol{\sigma}-\boldsymbol{\sigma}_h:=(\boldsymbol{\sigma}-\tilde{\boldsymbol{\sigma}}_h)+(\tilde{\boldsymbol{\sigma}}_h-\boldsymbol{\sigma}_h)=\boldsymbol{\rho}+\boldsymbol{\xi}$. From (4.1)–(4.3), we have

$$(\nabla\zeta,\nabla v_h)=(\alpha(\boldsymbol{\rho}+\boldsymbol{\xi}),\nabla v_h),\quad v_h\in V_h, \tag{4.6}$$

and

$$\begin{aligned}&(\alpha\boldsymbol{\xi}_t,\mathbf{w}_h)+\int_0^t\beta(t-s)\mathcal{A}(\boldsymbol{\xi},\mathbf{w}_h)\,ds\\&\quad=-(\alpha\boldsymbol{\rho}_t,\mathbf{w}_h)+\int_0^t\beta(t-s)(\boldsymbol{\rho}(s),\mathbf{w}_h)\,ds,\ \mathbf{w}_h\in\mathbf{W}_h.\end{aligned} \tag{4.7}$$

We now prove the main theorem in this section.

THEOREM 4.1. *Assume that* $\boldsymbol{\sigma}_h(0)=\tilde{\boldsymbol{\sigma}}_h(0)$ *with* $\boldsymbol{\sigma}_0=a\nabla u_0$. *Then*

$$\|(\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)(t)\|\le Ch^{r+1}\left[\|\boldsymbol{\sigma}_0\|_{r+1}+\|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right] \tag{4.8}$$

and

$$\begin{aligned}&\|(u-u_h)(t)\|+h\|(u-u_h)(t)\|_1\\&\quad\le Ch^{\min(k+1,r+1)}\left[\|u\|_{L^\infty(H^{k+1})}+\|\boldsymbol{\sigma}_0\|_{r+1}+\|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right].\end{aligned}$$

Proof. Choose $v_h=\zeta(t)$ in (4.6) to obtain

$$\|\nabla\zeta\|\le C\left(\|\boldsymbol{\rho}\|+\|\boldsymbol{\xi}\|\right). \tag{4.9}$$

Further, setting $\mathbf{w}_h=\boldsymbol{\xi}(t)$ in (4.7) gives

$$\frac{d}{dt}\|\alpha^{\frac{1}{2}}\boldsymbol{\xi}\|^2+2\int_0^t\beta(t-s)\mathcal{A}(\boldsymbol{\xi}(s),\boldsymbol{\xi}(t))\,ds\le\left(\|\boldsymbol{\rho}_t\|+\int_0^t\beta(t-s)\|\boldsymbol{\rho}(s)\|\,ds\right)\|\boldsymbol{\xi}\|.$$

Integrate from 0 to t and use (1.2) to obtain

$$\|\boldsymbol{\xi}(t)\|^2\le C[\|\boldsymbol{\xi}(0)\|+\int_0^t\|\boldsymbol{\rho}_t(s)\|\,ds+\int_0^t B(t-s)\|\boldsymbol{\rho}(s)\|\,ds]\max_{0\le s\le t}\|\boldsymbol{\xi}(s)\|,$$

where B is given by (2.14). Taking the maximum over $[0,t]$, it is easy to see that

$$\|\boldsymbol{\xi}(t)\|\le\max_{0\le s\le t}\|\boldsymbol{\xi}(s)\|\le C[\|\boldsymbol{\xi}(0)\|+\int_0^t\|\boldsymbol{\rho}_t(s)\|\,ds+\int_0^t B(t-s)\|\boldsymbol{\rho}(s)\|\,ds].$$

Since $\boldsymbol{\sigma}(0)=\tilde{\boldsymbol{\sigma}}_h(0)$, then $\boldsymbol{\xi}(0)=\mathbf{0}$. Using the triangle inequality and (4.5), we obtain (4.8). On substituting $\|\boldsymbol{\xi}(t)\|$ in (4.9), it follows that

$$\|\nabla\zeta(t)\|\le Ch^{r+1}\left(\|\boldsymbol{\sigma}\|_{L^\infty(\mathbf{H}^{r+1})}+\|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right). \tag{4.10}$$

Using (3.9), (1.4) with ϕ replaced by $\boldsymbol{\sigma}$ and the triangle inequality, we complete the proof. ∎

Remark 4.1. (i) With $r = k$, we have $\|u - u_h\|_{L^\infty(L^2)} = O(h^{k+1})$.

(ii) The present analysis yields better results than those of section 3 for the L^2 estimate of $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h$ but with additional regularity assumptions on the exact solution. Note that, from Theorem 4.1, $\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\| = O(h^{r+1})$ even if $k < r$, and hence the degree of V_h does not influence the estimate of $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h$.

COROLLARY 4.2. *Assume that $d = 2$, that is, $\Omega \subset R^2$, and $\boldsymbol{\sigma}_h(0) = \tilde{\boldsymbol{\sigma}}_h(0)$. Then*

$$\|(u - u_h)(t)\|_{L^\infty} \leq C \left(\log \frac{1}{h}\right) h^{\min(k+1,r+1)} [\|u\|_{L^\infty(H^{k+1})} + \|\boldsymbol{\sigma}_0\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}],$$

provided the finite element mesh is quasi-uniform.

Proof. Using the Sobolev imbedding theorem for $d = 2$, the inverse hypothesis, and the superconvergence estimate (4.10) for $\|\nabla\zeta\|$, we obtain

$$\|\zeta(t)\|_{L^\infty} \leq Ch^{\min(k+1,r+1)} \left(\log \frac{1}{h}\right)^{\frac{1}{2}} [\|u\|_{L^\infty(H^{k+1})} + \|\boldsymbol{\sigma}_0\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}].$$

From [2, 20], it follows that the error η in the elliptic projection satisfies

$$\|\eta(t)\|_{L^\infty} \leq \begin{cases} C \left(\log \dfrac{1}{h}\right) h^2 \|u\|_{L^\infty(W^{k+1,\infty})}, & k = 1, \\ Ch^{k+1} \|u\|_{L^\infty(W^{k+1,\infty})}, & k > 1. \end{cases}$$

The use of the triangle inequality completes the proof. ∎

5. The backward Euler method for the modified method. In this section, we briefly describe the backward Euler method for approximating $\{u, \boldsymbol{\sigma}\}$ of (4.1) and discuss the related error estimates. Since the error analysis for higher order time stepping schemes such as the Crank–Nicolson and second order backward difference methods is similar, we shall not pursue these methods further in this paper (see [9] for related results).

To describe the backward Euler method, let $\Delta t = T/M$, for some positive integer M, and set $t^n = n\Delta t$, $n = 0, \ldots, M$. For a smooth function ϕ on [0,T], define

$$\phi^n = \phi(t_n), \quad \partial_t \phi^n = \frac{\phi^n - \phi^{n-1}}{\Delta t}.$$

To approximate the integral, we introduce the right rectangle quadrature rule

$$q^n(\phi) = \Delta t \sum_{j=1}^{n} \beta_{n-j} \phi^j \approx \int_0^{t_n} \beta(t_n - s)\phi(s)\, ds,$$

where $\beta_{n-j} = \beta(t_n - t_j)$. This quadrature rule is positive [3, 9] in the sense that

$$\sum_{n=1}^{J} q^n(\phi)\phi^n = \Delta t \sum_{n=1}^{J} \sum_{j=1}^{n} \beta_{n-j} \phi^j \phi^n \geq 0, \ J = 1, \ldots, M.$$

The quadrature error

$$\epsilon^n(\phi) := q^n(\phi) - \int_0^{t_n} \beta(t_n - s)\phi(s)\, ds$$

satisfies

$$|\epsilon^n(\phi)| \le C\Delta t \int_0^{t_0} \left(|\phi(s)| + |\phi_t(s)|\right)\, ds,$$

provided $\beta,\ \phi \in C^1[0,T]$.

Let U^n and $\mathbf{Z}^n$ be approximations to u and $\boldsymbol{\sigma}$ at $t = t_n$, respectively, defined as follows. Given $\{U^{n-1}, \mathbf{Z}^{n-1}\} \in V_h \times \mathbf{W}_h$, determine $\{U^n, \mathbf{Z}^n\}$ in $V_h \times \mathbf{W}_h$ satisfying

$$\begin{aligned}(\nabla U^n, \nabla v_h) &= (\alpha \mathbf{Z}^n, \nabla v_h)\,, \quad v \in V_h,\\ (\alpha \partial_t \mathbf{Z}^n, \mathbf{w}_h) + q^n_{\mathcal{A}}(\mathbf{Z})(\mathbf{w}_h) &= (-f^n, \nabla\cdot \mathbf{w}_h)\,, \quad \mathbf{w}_h \in \mathbf{W}_h,\end{aligned}$$

with $U^0 = u_{0,h}$ specified later. Here,

$$q^n_{\mathcal{A}}(\mathbf{Z})(\mathbf{w}_h) = \Delta t \sum_{j=1}^{n} \beta_{n-j} \mathcal{A}\left(\mathbf{Z}^j, \mathbf{w}_h\right).$$

To determine the desired error estimates, we write $u^n - U^n := (u^n - \tilde{u}^n_h) + (\tilde{u}^n_h - U^n) = \eta^n + \zeta^n$ and $\boldsymbol{\sigma}^n - \mathbf{Z}^n := (\boldsymbol{\sigma}^n - \tilde{\boldsymbol{\sigma}}^n_h) + (\tilde{\boldsymbol{\sigma}}^n_h - \mathbf{Z}^n) = \boldsymbol{\rho}^n + \boldsymbol{\xi}^n$. Since estimates of η^n and $\boldsymbol{\rho}^n$ are given by (3.9) and (4.5) at $t = t_n$, it is sufficient to estimate ζ^n and $\boldsymbol{\xi}^n$. Note that the equations for ζ^n and $\boldsymbol{\xi}^n$ may be written as

$$(\nabla \zeta^n, \nabla v_h) = (\alpha(\boldsymbol{\rho}^n + \boldsymbol{\xi}^n), \nabla v_h)\,, \quad v_h \in V_h, \tag{5.1}$$

and

$$\begin{aligned}(\alpha \partial_t \boldsymbol{\xi}^n, \mathbf{w}_h) + q^n_{\mathcal{A}}(\boldsymbol{\xi})(\mathbf{w}_h) = &-(\alpha \partial_t \boldsymbol{\rho}^n + \alpha \boldsymbol{\tau}^n, \mathbf{w}_h)\\ &+\epsilon^n_{\mathcal{A}}(\boldsymbol{\sigma})(\mathbf{w}_h) + (q^n(\boldsymbol{\rho}), \mathbf{w}_h)\,,\ \mathbf{w}_h \in \mathbf{W}_h,\end{aligned} \tag{5.2}$$

where $\boldsymbol{\tau}^n = \boldsymbol{\sigma}_t(t_n) - \partial_t \boldsymbol{\sigma}(t_n)$ and

$$\epsilon^n_{\mathcal{A}}(\boldsymbol{\sigma})(\mathbf{w}_h) = q^n_{\mathcal{A}}(\boldsymbol{\sigma})(\mathbf{w}_h) - \int_0^{t_n} \beta(t_n - s)\mathcal{A}\left(\boldsymbol{\sigma}, \mathbf{w}_h\right) ds.$$

THEOREM 5.1. *Assume that* $\mathbf{Z}^0 = \tilde{\boldsymbol{\sigma}}_h(0)$ *with* $\boldsymbol{\sigma}_0 = a\nabla u_0$ *and* $\beta \in C^1[0,T]$. *Then*

$$\begin{aligned}\|\boldsymbol{\sigma}^J - \mathbf{Z}^J\| \le C \Big\{ & h^{r+1}\left[\|\boldsymbol{\sigma}_0\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right]\\ &+\Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2\right)\, ds\Big\}.\end{aligned}$$

Further,

$$\begin{aligned}\|u^J - U^J\| + h\|u^J - U^J\|_1 &\\ \le C \Big\{ & h^{\min(k+1,r+1)}\left[\|u\|_{L^\infty(H^{k+1})} + \|\boldsymbol{\sigma}_0\|_{r+1} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^{r+1})}\right]\\ &+ \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2\right)\, ds\Big\}.\end{aligned}$$

Proof. Choose $v_h = \zeta^n$ in (5.1) to obtain, for $n = 0, 1, \ldots, M$,

$$\|\nabla \zeta^n\| \le C(\|\boldsymbol{\rho}^n\| + \|\boldsymbol{\xi}^n\|). \tag{5.3}$$

Set $\mathbf{w}_h = \boldsymbol{\xi}^n$ in (5.2) and use the Cauchy–Schwarz inequality and Young's inequality to obtain

$$\frac{1}{2}\partial_t \|\alpha^{\frac{1}{2}} \boldsymbol{\xi}^n\|^2 + q_A^n(\boldsymbol{\xi})(\boldsymbol{\xi}^n) \le C\left[\|\partial_t \boldsymbol{\rho}^n\| + \|\epsilon_A^n(\boldsymbol{\sigma})\| + \|\boldsymbol{\tau}^n\| + \|q^n(\boldsymbol{\rho})\|\right] \|\boldsymbol{\xi}^n\|. \tag{5.4}$$

Note that

$$\begin{aligned}
\Delta t \sum_{n=1}^{J} \|\partial_t \boldsymbol{\rho}^n\| &\le C h^{r+1} \int_0^{t_J} \|\boldsymbol{\sigma}_t(s)\|_{r+1}\, ds, \\
\Delta t \sum_{n=1}^{J} \|\epsilon_A^n(\boldsymbol{\sigma})\| &\le C \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2\right)\, ds, \\
\Delta t \sum_{n=1}^{J} \|\boldsymbol{\tau}^n\| &\le C \Delta t \int_0^{t_J} \|\boldsymbol{\sigma}_{tt}(s)\|\, ds.
\end{aligned}$$

On substituting these estimates in (5.4) after summing from $n = 1, \ldots, J$, the second term on the left-hand side of the resulting inequality is nonnegative. Thus, we obtain

$$\begin{aligned}
\|\boldsymbol{\xi}^J\| \le \max_{1 \le n \le J} \|\boldsymbol{\xi}^n\| \le C \Bigg\{ &\|\boldsymbol{\xi}^0\| + h^{r+1} \left(\|\boldsymbol{\sigma}\|_{L^\infty(\mathbf{H}^{r+1})} + \int_0^{t_J} \|\boldsymbol{\sigma}_t(s)\|_{r+1}\, ds \right) \\
&+ \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2\right) ds \Bigg\}.
\end{aligned} \tag{5.5}$$

Note that $\boldsymbol{\xi}^0 = 0$. Using (5.5) in (5.3), we obtain the superconvergence result

$$\begin{aligned}
\|\nabla \zeta^J\| \le C \Bigg\{ &h^{r+1} [\|\boldsymbol{\sigma}\|_{L^\infty(\mathbf{H}^{r+1})} + \int_0^{t_J} \|\boldsymbol{\sigma}_t(s)\|_{r+1}\, ds] \\
&+ \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2\right) ds] \Bigg\}.
\end{aligned}$$

The use of the triangle inequality with the estimates of $\boldsymbol{\rho}^J$ and η^J completes the proof. ∎

In the remainder of the section, we relax the regularity assumptions on the kernel, requiring only $\beta \in L^1(0, T)$. We still assume that β is positive definite in the sense of (1.2). We now consider the backward Euler method using product integration [7, 9] to approximate the integral:

$$q^n(\phi) = \sum_{j=1}^{n} \int_{t_{j-1}}^{t_j} \beta(t_n - s)\phi^j\, ds = \sum_{j=1}^{n} \kappa_{n-j}\phi^j \approx \int_0^{t_n} \beta(t_n - s)\phi(s)\, ds, \tag{5.6}$$

where

$$\kappa_j = \int_{t_j}^{t_{j+1}} \beta(s)\, ds.$$

When

$$\beta \in L^1_{loc}(0,\infty) \cap C^2(0,\infty) \ \text{ and } \ (-1)^j \beta^{(j)}(t) \geq 0, \ \text{ for } \ t > 0, \ j = 0, 1, 2, \tag{5.7}$$

the product rule (5.6) is positive and the quadrature error satisfies [9]

$$|\epsilon^n(\phi)| \leq C\Delta t \int_0^{t_n} |\phi_t(s)|\, ds, \quad t_n \leq T. \tag{5.8}$$

For the commonly occurring kernel $\beta(t) = t^{\mu-1}/\Gamma(\mu), \quad 0 < \mu < 1$, (5.7) is satisfied, and the proof of the following theorem may be obtained by modifying the arguments used in the proof of Theorem 5.1 and by using (5.8).

THEOREM 5.2. *Assume that $\beta(t) = t^{\mu-1}/\Gamma(\mu)$, $0 < \mu < 1$, and that the quadrature q^n is the product rule of* (5.6). *Then, for $k = 1$, $r = 1$, and $J = 0, 1, \ldots, M$,*

$$\|\boldsymbol{\sigma}^J - \mathbf{Z}^J\| \leq C \left\{ h^2 \left[\|\boldsymbol{\sigma}\|_{L^\infty(\mathbf{H}^2)} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^2)} \right] + \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2 \right) ds \right\}.$$

Further,

$$\|u^J - U^J\| + h\|u^J - U^J\|_1 \leq C \left\{ h^2 \left[\|u\|_{L^\infty(H^2)} + \|\boldsymbol{\sigma}\|_{L^\infty(\mathbf{H}^2)} + \|\boldsymbol{\sigma}_t\|_{L^1(\mathbf{H}^2)} \right] + \Delta t \int_0^{t_J} \left(\|\boldsymbol{\sigma}_{tt}(s)\| + \|\boldsymbol{\sigma}(s)\|_2 + \|\boldsymbol{\sigma}_t(s)\|_2 \right) ds \right\}.$$

6. Concluding remarks. In this paper, a priori error estimates are derived for an H^1-Galerkin mixed finite element method without the LBB consistency condition and also without a quasi-uniformity assumption on the finite element mesh. Since the estimate for $\|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|$ derived in section 3 is not optimal in two and three space dimensions, a modification of the method is proposed and analyzed in section 4 to establish an optimal estimate in the L^2 norm as in the one dimensional case of section 2. Another notable advantage of the present method is that it allows the use of two different finite element spaces for approximating u and its flux $\boldsymbol{\sigma}$. In particular, use of piecewise linear polynomial spaces yields $O(h^2)$ of convergence in both $u - u_h$ and $\boldsymbol{\sigma} - \boldsymbol{\sigma}_h$ in the L^2 norm. Moreover, in two dimensions, we obtain a quasi-optimal maximum norm estimate for $u - u_h$.

The results presented in this paper can be easily extended to the initial and boundary value problem

$$\begin{aligned} u_t - \int_0^t \beta(t-s) \left[\nabla \cdot (a(x)\nabla u(s)) - b(x)u(s) \right] ds &= f(x,t), \quad (x,t) \in \Omega \times (0,T], \\ u(x,t) &= 0, \quad (x,t) \in \partial\Omega \times (0,T], \\ u(x,0) &= u_0(x), \quad x \in \Omega, \end{aligned}$$

where $b = b(x) \geq 0$, $x \in \Omega$. For the mixed formulation, this equation is rewritten as

$$\begin{aligned} \boldsymbol{\sigma} &= a\nabla u, \\ u_t - \int_0^t \beta(t-s) \left(\nabla \cdot \boldsymbol{\sigma}(s) - bu(s) \right) ds &= f. \end{aligned}$$

The corresponding H^1-Galerkin mixed finite element method is based on the weak formulation

$$
\begin{aligned}
&(a\nabla u, \nabla v) = (\boldsymbol{\sigma}, \nabla v), \quad v \in H_0^1, \\
&(\alpha \boldsymbol{\sigma}_t, \mathbf{w}) + \int_0^t \beta(t-s)\left[(\nabla\cdot\boldsymbol{\sigma}(s), \nabla\cdot\mathbf{w}) + (b\boldsymbol{\sigma}(s), \mathbf{w})\right] ds \\
&\qquad = -(f, \nabla\cdot\mathbf{w}) - \int_0^t \beta(t-s)\,(u(s)\nabla b, \mathbf{w}), \quad \mathbf{w} \in \mathbf{W}.
\end{aligned} \tag{6.1}
$$

Unlike (3.1), the system (6.1) is now strongly coupled with unknowns $(u, \boldsymbol{\sigma})$. Since the error estimates closely follow the proof techniques of the present paper, we shall not pursue these further.

ERROR ANALYSIS FOR CHARACTERISTICS-BASED METHODS FOR DEGENERATE PARABOLIC PROBLEMS*

ZHANGXIN CHEN†, RICHARD E. EWING‡, QIAOYUAN JIANG†, AND ANNA M. SPAGNUOLO‡

Abstract. We consider characteristics-based finite element methods for solving nonlinear, degenerate, advection-diffusion equations. These equations have applications in the simulation of petroleum reservoirs and groundwater aquifers and in the modeling of free boundary problems. Standard finite element Galerkin methods have been studied for these equations. In this paper, we analyze the characteristics-based finite element methods for them. The main difficulty in the analysis is that the equations are degenerate and the solution lacks regularity. Here we develop a technique that respects the degeneracy and the known minimal regularity. This technique is based on the Green operator for standard elliptic equations and is developed directly for the degenerate advection-diffusion equations. We concentrate our analysis on the modified method of characteristics (MMOC) and one of its variants, the modified method of characteristics with adjusted advection (MMOCAA), which conserves mass. We derive error estimates in various norms. The extension to other variants is discussed. The present technique is also applied to nondegenerate problems; error estimates previously obtained for the MMOC are derived under much weaker regularity assumptions on the solution, and the error estimates for the MMOCAA appear new even in the nondegenerate case. Finally, numerical results are presented to show the sharpness of the error estimates derived.

1. Introduction.

Let $\Omega \subset \Re^d$, $d \leq 3$, be a bounded domain and $J = (0, T]$, with $T > 0$. We consider and analyze characteristics-based finite element methods for the advection-diffusion equation in $u(x, t)$:

$$c\partial_t u + b \cdot \nabla u - \nabla \cdot (a(u)\nabla u) = f \qquad \text{in } \Omega \times J, \tag{1.1}$$

where $c = c(x, t)$, $b = b(x, t)$ (a vector), $a(u) = \alpha(x, t)\beta(u)$, and $f = f(x, t)$, with α being a $d \times d$ symmetric, positive-definite matrix and β a nonnegative function in u. Because β can be zero in u, (1.1) is generally degenerate in this variable.

Problem (1.1) arises in many applications. It appears in petroleum reservoir simulation that often requires the numerical solution for similar problems of multiphase fluid flow in porous media [6, 38], in groundwater aquifer modeling for the transport of a solute in porous media with an equilibrium adsorption reaction [26, 29, 31], and in the solution of parabolic free boundary problems [30, 35], for example. Standard finite element Galerkin methods have been studied for these applications with the degeneracy taken into account; see [11, 14, 15, 16, 17, 28, 34, 40, 43] in the reservoir

simulation, [5, 13, 19] for the groundwater modeling, and [32, 36] for the free boundary problems, for instance.

In the petroleum and groundwater areas, finite difference methods are most often used to solve equations analogous to (1.1). It is known [42] that certain finite difference methods are actually equivalent to mixed finite element methods of the lowest order on rectangles [7], combined with special quadrature rules. The mixed finite element methods for equations similar to (1.1) have been analyzed in [3].

It is well known that advection-diffusion equations often present serious numerical difficulties. Standard finite element and finite difference methods usually exhibit some combination of nonphysical oscillation and excessive numerical dispersion [27, 33]. Many numerical methods have been developed to overcome these difficulties. In this paper, we consider and analyze the modified method of characteristics (MMOC) (or the Eulerian–Lagrangian method) [25, 39] for (1.1). Because of the Lagrangian nature of the advection term, this method treats this term by a characteristic tracking scheme. It has many advantages and one fundamental flaw, the failure to preserve as an algebraic identity a desired conservation law associated with the underlying physical problem. Recently, a variant of the MMOC, called the modified method of characteristics with adjusted advection (MMOCAA) has been introduced [22]. The MMOCAA does preserve the desired conservation property and also the conceptual and computational advantages of the MMOC. For this reason, we also carry out a formal analysis for the MMOCAA procedure. The extension of the analysis to other recently developed characteristics-based methods, such as the Eulerian–Lagrangian localized adjoint method (ELLAM) [8] and the characteristic-mixed finite element method [2], is discussed.

The main difficulty in the error analysis is that problem (1.1) is degenerate and its solution lacks regularity. Here we develop a technique that respects the degeneracy and the known minimal regularity. This technique is based on the Green operator for standard elliptic equations and is developed directly for the degenerate advection-diffusion equation. We first establish sharp error estimates in various norms for the MMOC and MMOCAA in the degenerate case. We then use the present technique to obtain optimal error estimates for nondegenerate problems. The degenerate case is analyzed for the first time for these two characteristic methods, while the error estimates for the nondegenerate case are derived under much weaker regularity assumptions on the solution than those previously used.

The rest of the paper is outlined as follows. In the next section, we review the theoretical results available for (1.1). The MMOC and MMOCAA procedures are analyzed in the third and fourth sections, respectively. Numerical results are presented in the final section.

2. Preliminaries. The usual Sobolev spaces $W^{l,\pi}(\Omega)$ with the norm $\|\cdot\|_{W^{l,\pi}(\Omega)}$ will be used, where l is a nonnegative integer and $0 \le \pi \le \infty$. When $\pi = 2$, we simply write $H^l(\Omega) = W^{l,2}(\Omega)$. When $l = 0$, we have $L^2(\Omega) = H^0(\Omega)$. The spaces $L^2(J; W^{l,\pi}(\Omega))$ and $L^\infty(J; W^{l,\pi}(\Omega))$ will also be used, with the norms $\|\cdot\|_{L^2(J;W^{l,\pi}(\Omega))}$ and $\|\cdot\|_{L^\infty(J;W^{l,\pi}(\Omega))}$, respectively. Below $(\cdot,\cdot)_Q$ denotes the $L^2(Q)$ inner product (or sometimes the duality pairing); Q is omitted if $Q = \Omega$. Finally, set $\Omega_T = \Omega \times J$.

It follows from [1] that under appropriate boundary and initial conditions and reasonable assumptions on the data problem (1.1) has at least the regularity results

$$u \in L^\infty(J; L^1(\Omega)), \quad \partial_t u \in L^2(J; H^{-1}(\Omega)), \quad \beta(u)\nabla u \in L^2(J; (L^2(\Omega))^d), \tag{2.1}$$

where $H^{-1}(\Omega)$ is the dual to $H^1(\Omega)$. In general, we can only expect the above

regularity to hold for $\partial_t u$. Under the assumption that (1.1) is physically consistent so that a maximum principle holds, u can be shown to be bounded [1]:

$$u \in L^\infty(\Omega_T). \tag{2.2}$$

With (2.2), we introduce the Kirchhoff transformation

$$\theta = \int_{u_r}^{u} \beta(\xi)\mathrm{d}\xi,$$

where u_r is any reference element in a neighborhood of the solution u. For notational convenience later, take $u_r = 0$; i.e., θ is defined by

$$\theta = \int_{0}^{u} \beta(\xi)\mathrm{d}\xi. \tag{2.3}$$

A main assumption in the later analysis is that there is a constant β^*, independent of time, such that

$$\|\theta_1 - \theta_2\|^2_{L^2(\Omega)} \le \beta^*(\theta_1 - \theta_2, u_1 - u_2), \qquad u_1,\ u_2 \in L^2(\Omega), \tag{2.4}$$

where θ_i corresponds to u_i through (2.3), $i = 1, 2$. A sufficient condition for (2.4) to hold is

$$0 \le \beta(v) \le \beta^* < \infty \quad \text{ in a neighborhood of } u. \tag{2.5}$$

This assumption will be tacitly made later and is physically reasonable [14].

Also, we rewrite the advection-diffusion equation (1.1) in the form

$$c(x)\partial_t u + b(x)\cdot\nabla u - \nabla\cdot(\alpha(x)\nabla\theta) = f(x,t) \qquad \text{in } \Omega_T, \tag{2.6}$$

with θ given in (2.3). By lagging the coefficients in time in the first and second terms of (1.1), we easily obtain (2.6). Also, in physical applications (1.1) is often coupled with other equations that determine the coefficients c and b. In the petroleum application, for example, c is the porosity and b is a velocity field. These coefficients can be calculated independent of u, so (1.1) reduces to (2.6). Finally, the present analysis can be easily extended to the case where b and c explicitly depend on t. Note that (2.6) is still degenerate and nonlinear in u since $\nabla\theta = \beta(u)\nabla u$.

Next, to avoid the difficulty associated with the boundary conditions, we assume that (2.6) is Ω-periodic; i.e., all functions in (2.6) are spatially Ω-periodic. This is physically reasonable because no-flow boundaries are usually handled by reflection and interior flow behavior is often much more important than boundary effects.

Finally, we focus on the two space dimensions; i.e., $d = 2$. An analysis can be done in the same fashion for the three dimensions [41]. Therefore, we give an analysis of error estimates in the case where Ω is a rectangular domain.

3. Analysis for the MMOC.

3.1. The MMOC procedure.

We assume that the coefficients c and b satisfy

$$0 < c_* \le c(x) \le c^* < \infty, \quad \left|\frac{b(x)}{c(x)}\right| + \left|\nabla\cdot\left(\frac{b(x)}{c(x)}\right)\right| \le C, \quad x \in \Omega. \tag{3.1}$$

We also assume that $\alpha(x)$ is a 2×2 symmetric matrix that is uniformly positive definite with respect to $x \in \bar{\Omega}$; i.e., with $\alpha = (\alpha_{ij})$,

$$0 < \alpha_* \le |\xi|^{-2} \sum_{i,j=1}^{d} \alpha_{ij}(x)\xi_i\xi_j \le \alpha^* < \infty, \qquad x \in \bar{\Omega},\ \xi \neq 0 \in \Re^2. \tag{3.2}$$

Let

$$\psi(x) = \left(c^2(x) + |b(x)|^2\right)^{1/2},$$

and let the characteristic direction associated with the operator $c\partial_t u + b \cdot \nabla u$ be denoted by $\tau(x)$, where

$$\partial_\tau = \frac{c(x)}{\psi(x)}\partial_t + \frac{b(x)}{\psi(x)} \cdot \nabla.$$

Then (2.6) can be written as follows:

$$\psi(x)\partial_\tau u - \nabla \cdot (\alpha(x)\nabla\theta) = f(x,t) \qquad \text{in } \Omega_T, \tag{3.3}$$

where u is related to θ through (2.3): $u = \mathcal{U}(\theta)$, with $\mathcal{U}$ being the inverse of (2.3). The initial condition is given by

$$u(x,0) = u_0(x) \qquad \text{in } \Omega. \tag{3.4}$$

For $0 < h$, let $M_h \subset H^1(\Omega)$ be a standard C^0-finite element space such that the approximation property holds:

$$\inf_{v_h \in M_h} \|v - v_h\|_{H^1(\Omega)} \le Ch\|v\|_{H^2(\Omega)}, \tag{3.5}$$

where and below C (with or without a subscript) indicates a generic constant independent of h, which will probably take on different values in different occurrences. In this paper, we consider only lowest-order C^0-finite elements such that (3.5) is satisfied; due to lacking regularity on the true solution, no improvement in the asymptotic convergence rate results from taking higher-order finite element spaces. We denote by P_h the L^2-projection into M_h, which satisfies that

$$\|v - P_h v\|_{H^{-1}(\Omega)} \le Ch\|v\|_{L^2(\Omega)} \qquad \forall v \in L^2(\Omega). \tag{3.6}$$

For each positive integer N, let $0 = t^0 < t^1 < \cdots < t^N = T$ be a partition of J into subintervals $J^n = (t^{n-1}, t^n]$, with length $\Delta t^n = t^n - t^{n-1}$, $1 \le n \le N$, and let $\Delta t = \max_{1 \le n \le N} \Delta t^n$. Also, set $v^n = v(\cdot, t^n)$ and $\bar{v}^{n-1} = v(x - b(x)\Delta t^n/c(x), t^{n-1})$. The standard MMOC procedure is the determination of the map $\theta_h : \{t^1, \ldots, t^N\} \to M_h$ satisfying

$$\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, v\right) + (\alpha\nabla\theta_h^n, \nabla v) = (f^n, v) \qquad \forall v \in M_h,\ 1 \le n \le N, \tag{3.7}$$

where $u_h^n = \mathcal{U}(\theta_h^n)$, $1 \le n \le N$, and

$$u_h^0 = P_h u_0. \tag{3.8}$$

It can be shown that (3.7) determines $\{\theta_h\}$ and $\{u_h\}$ uniquely in terms of the data u_0 and f [12].

3.2. The Green operator. We introduce the bilinear form $a(\cdot,\cdot)$ on $H^1(\Omega)$,

$$a(v,w) = (\alpha\nabla v, \nabla w) + (v,w) \qquad \forall v,\ w \in H^1(\Omega),$$

and define the Green operator $G : H^{-1}(\Omega) \to H^1(\Omega)$ by

$$a(Gv,w) = (cv,w) \qquad \forall w \in H^1(\Omega),\ v \in H^{-1}(\Omega). \tag{3.9}$$

We assume that G is regular; i.e.,

$$\|Gv\|_{H^2(\Omega)} \le C\|v\|_{L^2(\Omega)} \qquad \forall v \in L^2(\Omega). \tag{3.10}$$

This assumption is satisfied with (the boundary of Ω) $\partial\Omega \in C^{1,1}$ (or, optionally, Ω being polygonal and convex). The norm in $H^{-1}(\Omega)$ can be represented in terms of G:

$$\|v\|_{H^{-1}(\Omega)} = a^{1/2}(Gv,Gv) = (cv,Gv)^{1/2} \qquad \forall v \in H^{-1}(\Omega). \tag{3.11}$$

The discrete Green operator $G_h : H^{-1}(\Omega) \to M_h$ is given by

$$a(G_h v,w) = (cv,w) \qquad \forall w \in M_h,\ v \in H^{-1}(\Omega). \tag{3.12}$$

By the regularity of G and (3.5), we have the approximation property [18]

$$\|(G-G_h)v\|_{H^l(\Omega)} \le Ch^{2-(l+\pi)}\|v\|_{B^{-\pi}(\Omega)}, \qquad 0 \le l,\pi \le 1, \tag{3.13}$$

where $B^{-\pi}(\Omega) = [L^2(\Omega), H^{-1}(\Omega)]_\pi$ is the interpolation space. Moreover, it follows from (3.12) that

$$a(G_h v, G_h v) \le C\|v\|^2_{H^{-1}(\Omega)} \qquad \forall v \in H^{-1}(\Omega). \tag{3.14}$$

3.3. Stability. In addition to assumptions (2.5), (3.1), and (3.2), we also assume that the norms

$$\|f\|_{L^\infty(J;H^{-1}(\Omega))} \text{ and } \|u_0\|_{L^2(\Omega)} \text{ are bounded.} \tag{3.15}$$

The proof of the next lemma can be found in [25] (see also Lemma 3.4 below).

LEMMA 3.1. *If $\eta \in L^2(\Omega)$ is Ω-periodic and $\bar\eta = \eta(x - g(x)\Delta t)$, where g and $\nabla\cdot g$ are bounded, then*

$$\|\eta - \bar\eta\|_{H^{-1}(\Omega)} \le C\Delta t\|\eta\|_{L^2(\Omega)}.$$

We now establish some stability results, which will be utilized in the subsequent error analysis. Note that inequality (2.5) needs to hold in the range of the numerical solution, so we extend β in some reasonable way [14].

LEMMA 3.2. *Under assumptions* (2.5), (3.1), (3.2), *and* (3.15), *we have*

$$\max_{1\le n\le N}\{\|u_h^n\|^2_{L^2(\Omega)} + \|\theta_h^n\|^2_{L^2(\Omega)}\} + \sum_{n=1}^N \|\nabla\theta_h^n\|^2_{L^2(\Omega)}\Delta t^n \le C.$$

Proof. Take $v = \theta_h^n$ in (3.7) to see that

$$\left(c\frac{u_h^n - \bar u_h^{n-1}}{\Delta t^n}, \theta_h^n\right) + (\alpha\nabla\theta_h^n, \nabla\theta_h^n) = (f^n, \theta_h^n);$$

after summing over n from 1 to N, this equation can be put in the form

$$\sum_{n=1}^{N}\left\{(c[u_h^n-u_h^{n-1}],\theta_h^n)+(\alpha\nabla\theta_h^n,\nabla\theta_h^n)\Delta t^n\right\} \tag{3.16}$$

$$=\sum_{n=1}^{N}\left\{(f^n,\theta_h^n)\Delta t^n+(c[\bar{u}_h^{n-1}-u_h^{n-1}],\theta_h^n)\right\}.$$

Define

$$\Phi(s)=\int_0^s\theta(\xi)\mathrm{d}\xi,$$

where

$$\theta(\xi)=\int_0^\xi\beta(\zeta)\mathrm{d}\zeta,$$

as defined in (2.3). Then we see that

$$(u_h^n-u_h^{n-1})\theta_h^n\geq\Phi(u_h^n)-\Phi(u_h^{n-1}),$$

so

$$\sum_{n=1}^{N}(c[u_h^n-u_h^{n-1}],\theta_h^n)\geq\sum_{n=1}^{N}\left(c[\Phi(u_h^n)-\Phi(u_h^{n-1})],1\right)=\left(c[\Phi(u_h^N)-\Phi(u_h^0)],1\right).$$

Using (2.5), we have

$$\Phi(u_h^N)\geq\frac{1}{2\beta^*}(\theta_h^N)^2\quad\text{ and }\quad\Phi(u_h^0)\leq\frac{\beta^*}{2}(u_h^0)^2.$$

Thus, by (3.1), we obtain

$$\sum_{n=1}^{N}(c[u_h^n-u_h^{n-1}],\theta_h^n)\geq\frac{c_*}{2\beta^*}\|\theta_h^N\|_{L^2(\Omega)}^2-\frac{c^*\beta^*}{2}\|u_h^0\|_{L^2(\Omega)}^2.$$

With this, (3.2), and the Schwarz inequality, (3.16) can be written as

$$\frac{c_*}{2\beta^*}\|\theta_h^N\|_{L^2(\Omega)}^2-\frac{c^*\beta^*}{2}\|u_h^0\|_{L^2(\Omega)}^2+\alpha_*\sum_{n=1}^{N}\|\nabla\theta_h^n\|_{L^2(\Omega)}^2\Delta t^n$$

$$\leq C\sum_{n=1}^{N}\left\{\|f^n\|_{H^{-1}(\Omega)}\Delta t^n+\|\bar{u}_h^{n-1}-u_h^{n-1}\|_{H^{-1}(\Omega)}\right\}\|\theta_h^n\|_{H^1(\Omega)},$$

which, together with Lemma 3.1, the discrete Gronwall inequality, the fact that $|\mathcal{U}(s)|\leq C_1|s|+C_2$, and a kick-back argument, yields the desired result. ∎

LEMMA 3.3. *With the same assumptions as in Lemma* 3.2, *if* $h=O(\Delta t)$, *we have*

$$\sum_{n=1}^{N}\left\|\frac{u_h^n-\bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}^2\Delta t^n\leq C.$$

Proof. Choose $v = G_h(u_h^n - \bar{u}_h^{n-1})/\Delta t^n$ in (3.7) to see that

$$\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) + \left(\alpha\nabla\theta_h^n, \nabla\frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) = \left(f^n, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right).$$

By the definition of G_h in (3.12), this equation becomes

$$\begin{aligned}\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) + \left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \theta_h^n\right) - \left(\frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}, \theta_h^n\right) \\ = \left(f^n, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right).\end{aligned} \tag{3.17}$$

Using (3.14), we have

$$\begin{aligned}&\left|\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \theta_h^n\right) - \left(\frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}, \theta_h^n\right)\right| \le C\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)} \|\theta_h^n\|_{H^1(\Omega)}, \\ &\left|\left(f^n, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right)\right| \le C\|f^n\|_{H^{-1}(\Omega)}\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}.\end{aligned} \tag{3.18}$$

Also, note that

$$\begin{aligned}&\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) \\ &\quad = \left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{G(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) + \left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{(G_h - G)(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right),\end{aligned}$$

so, by (3.13),

$$\begin{aligned}&\left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, \frac{G_h(u_h^n - \bar{u}_h^{n-1})}{\Delta t^n}\right) \\ &\quad \ge C\left(\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}^2 - \frac{1}{(\Delta t^n)^2}\|(G_h - G)(u_h^n - \bar{u}_h^{n-1})\|_{H^1(\Omega)}^2\right) \\ &\quad \ge C\left(\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}^2 - \frac{h^2}{(\Delta t^n)^2}\|u_h^n - \bar{u}_h^{n-1}\|_{L^2(\Omega)}^2\right).\end{aligned} \tag{3.19}$$

Substitute (3.18) and (3.19) into (3.17) and use Lemma 3.2 to obtain the desired result. ∎

3.4. Error analysis I. For the next lemma, we need the assumption

$$c \in W^{1,\infty}(\Omega) \quad \text{and} \quad \frac{b}{c} \in \left(W^{1,\infty}(\Omega)\right)^2. \tag{3.20}$$

The proof of the following lemma follows a similar treatment of Lemma 3.1 in [20]. However, the argument is simpler and the assumptions are weakened.

LEMMA 3.4. *With assumptions* (3.1) *and* (3.20)*, we have, for* Δt *sufficiently small,*

$$(c\bar{v}, G\bar{v}) - (cv, Gv) \le C\Delta t(cv, Gv) \qquad \forall v \in L^2(\Omega),$$

where $\bar{v} = v(x - b(x)\Delta t/c(x))$.

Proof. Let $y = x - b(x)\Delta t/c(x) \equiv H(x)$ for each $x \in \Omega$. The Jacobian of this transformation is

$$J(H(x)) = \begin{pmatrix} 1 - \partial_{x_1}\left(\frac{b_1}{c}\right)\Delta t & -\partial_{x_2}\left(\frac{b_1}{c}\right)\Delta t \\ -\partial_{x_1}\left(\frac{b_2}{c}\right)\Delta t & 1 - \partial_{x_2}\left(\frac{b_2}{c}\right)\Delta t \end{pmatrix},$$

so its determinant equals

$$|J(H(x))| = 1 - \nabla \cdot \left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right).$$

Note that, for Δt sufficiently small, $|J(H(x))| > 0$. Also, since H maps the periodic domain Ω onto itself, a change of variable leads to

$$\begin{aligned}(c\bar{v}, G\bar{v}) &= \int_\Omega c(x)v(y)Gv(y)\mathrm{d}x \\ &= \int_\Omega c(x)v(y)Gv(y)\frac{1}{|J(H(x))|}\mathrm{d}y \\ &= \int_\Omega c(x)v(y)Gv(y)\left(1 + \nabla \cdot \left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right)\right)\mathrm{d}y.\end{aligned}$$

Subtracting (cv, Gv) from both sides of this equation, we see that

$$\begin{aligned}(c\bar{v}, G\bar{v}) - (cv, Gv) &= \int_\Omega [c(x) - c(y)]v(y)Gv(y)\left(1 + \nabla \cdot \left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right)\right)\mathrm{d}y \\ &\quad + \int_\Omega c(y)v(y)Gv(y)\left(\nabla \cdot \left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right)\right)\mathrm{d}y \\ &\equiv A_1 + A_2.\end{aligned}$$

Note that

$$|c(x) - c(y)| \le \|\nabla c\|_{L^\infty(\Omega)}|x - y| \le \|\nabla c\|_{L^\infty(\Omega)}\left\|\frac{b}{c}\right\|_{L^\infty(\Omega)}\Delta t,$$

so that, by (3.1) and (3.20),

$$A_1 \le C\Delta t(cv, Gv).$$

Also, by (3.1), it is obvious that

$$A_2 \le C\Delta t(cv, Gv).$$

The bounds for A_1 and A_2 complete the proof. ∎

3.4.1. Case A: Under assumption (2.5). We first derive error estimates under assumption (2.5); i.e., (2.6) is degenerate. Note that, by the periodicity assumption, (3.3) (or (2.6)) can be written in the weak form

$$(\psi(x)\partial_\tau u, v) + (\alpha(x)\nabla\theta, \nabla v) = (f, v) \qquad \forall v \in H^1(\Omega). \tag{3.21}$$

Set

$$u_h(\cdot, t) = u_h^n(\cdot) \quad \text{and} \quad \theta_h(\cdot, t) = \theta_h^n(\cdot) \quad \text{for } t \in J^n, \quad n = 1, \dots, N.$$

Also, let

$$e_u(t) = u(t) - u_h(t), \quad e_\theta(t) = \theta(t) - \theta_h(t), \quad \text{and} \quad e_u^n = e_u(t^n).$$

Below ϵ is a positive constant independent of h and Δt, as small as we please. Also, whenever Lemma 3.4 is used, we will implicitly require that Δt be sufficiently small.

THEOREM 3.5. *Under assumptions* (2.1), (2.2), (2.5), (3.1), (3.2), (3.10), (3.15), (3.20), *and* $h = O(\Delta t)$, *we have the error estimate*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^N \|\theta^n - \theta_h^n\|^2_{L^2(\Omega)} \Delta t^n \le C\Delta t(1 + \Delta t \, \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}). \tag{3.22}$$

Proof. Take $v = Ge_u^n$ in (3.21) with $t = t^n$ and $v = G_h e_u^n$ in (3.7), subtract the resulting two equations, use (3.9) and (3.12), and sum over n from 1 to N to have the error equation

$$\begin{aligned}
&\sum_{n=1}^N \left(c[e_u^n - \bar{e}_u^{n-1}], Ge_u^n\right) + \sum_{n=1}^N (ce_\theta^n, e_u^n)\Delta t^n \\
&= \sum_{n=1}^N (f^n, Ge_u^n - G_h e_u^n)\Delta t^n + \sum_{n=1}^N \left\{(Ge_u^n, \theta^n) - (G_h e_u^n, \theta_h^n)\right\} \Delta t^n \\
&\quad - \sum_{n=1}^N \left(\psi\partial_\tau u^n - c\frac{u^n - \bar{u}^{n-1}}{\Delta t^n}, Ge_u^n\right) \Delta t^n - \sum_{n=1}^N \left(c\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}, Ge_u^n - G_h e_u^n\right) \Delta t^n.
\end{aligned} \tag{3.23}$$

With the obvious definition of I_i, $i = 1, \dots, 6$, we express (3.23) simply by

$$I_1 + I_2 = I_3 + I_4 + I_5 + I_6.$$

First, by (3.9) and (3.11), note that

$$\begin{aligned}
I_1 &= \sum_{n=1}^N a\left(G[e_u^n - \bar{e}_u^{n-1}], Ge_u^n\right) \\
&\ge \frac{1}{2}\sum_{n=1}^N \left\{a(Ge_u^n, Ge_u^n) - a(G\bar{e}_u^{n-1}, G\bar{e}_u^{n-1})\right\} \\
&= \frac{1}{2}\sum_{n=1}^N \{\|e_u^n\|^2_{H^{-1}(\Omega)} - \|e_u^{n-1}\|^2_{H^{-1}(\Omega)}\} + \frac{1}{2}\sum_{n=1}^N \{\|e_u^{n-1}\|^2_{H^{-1}(\Omega)} - \|\bar{e}_u^{n-1}\|^2_{H^{-1}(\Omega)}\},
\end{aligned}$$

so that, using Lemma 3.4,

$$I_1 \geq \frac{1}{2}\|e_u^N\|^2_{H^{-1}(\Omega)} - \frac{1}{2}\|e_u^0\|^2_{H^{-1}(\Omega)} - C\sum_{n=1}^{N}\|e_u^{n-1}\|^2_{H^{-1}(\Omega)}\Delta t^{n-1}.$$

Second, by (2.5) (i.e., (2.4)) and (3.1), we see that

$$I_2 \geq C\sum_{n=1}^{N}\|e_\theta^n\|^2_{L^2(\Omega)}\Delta t^n.$$

Third, apply (3.13) to have

$$\begin{aligned}|I_3| &\leq \sum_{n=1}^{N}\|f^n\|_{H^{-1}(\Omega)}\|Ge_u^n - G_he_u^n\|_{H^1(\Omega)}\Delta t^n\\ &\leq Ch\sum_{n=1}^{N}\|f^n\|_{H^{-1}(\Omega)}\|e_u^n\|_{L^2(\Omega)}\Delta t^n\\ &\leq Ch\left(\sum_{n=1}^{N}\|f^n\|^2_{H^{-1}(\Omega)}\Delta t^n + \sum_{n=1}^{N}\|e_u^n\|^2_{L^2(\Omega)}\Delta t^n\right).\end{aligned}$$

Fourth, it follows from (3.13) and (3.14) that

$$|I_4| \leq \epsilon\sum_{n=1}^{N}\|e_\theta^n\|^2_{L^2(\Omega)}\Delta t^n + C\sum_{n=1}^{N}(\|e_u^n\|^2_{H^{-1}(\Omega)} + h^2\|\theta^n\|^2_{L^2(\Omega)})\Delta t^n.$$

Fifth, exploit the standard backward (in the characteristic direction) difference analysis [25] and (3.11) to see that

$$\begin{aligned}|I_5| &\leq \sum_{n=1}^{N}\left\|\psi\partial_\tau u^n - c\frac{u^n - \bar{u}^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}\|Ge_u^n\|_{H^1(\Omega)}\Delta t^n\\ &\leq C\left((\Delta t)^2\left\|\partial_{\tau\tau}u\right\|^2_{L^2(J;H^{-1}(\Omega))} + \sum_{n=1}^{N}\|e_u^n\|^2_{H^{-1}(\Omega)}\Delta t^n\right).\end{aligned}$$

Sixth, by (3.13), we have

$$\begin{aligned}|I_6| &\leq \sum_{n=1}^{N}\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}\|Ge_u^n - G_he_u^n\|_{H^1(\Omega)}\Delta t^n\\ &\leq Ch\sum_{n=1}^{N}\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|_{H^{-1}(\Omega)}\|e_u^n\|_{L^2(\Omega)}\Delta t^n\\ &\leq Ch\left(\sum_{n=1}^{N}\left\|\frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n}\right\|^2_{H^{-1}(\Omega)}\Delta t^n + \sum_{n=1}^{N}\|e_u^n\|^2_{L^2(\Omega)}\Delta t^n\right).\end{aligned}$$

Finally, apply the bounds of I_i, $i = 1, \ldots, 6$, to (3.23) and use Lemmas 3.2 and 3.3, the discrete Gronwall lemma, (3.6), and (3.8) to obtain the desired result. ∎

Note that if the norm

$$\|\partial_{\tau\tau} u\|_{L^2(J;H^{-1}(\Omega))} \quad \text{is bounded,} \tag{3.24}$$

the left-hand side of (3.22) is bounded by $C\Delta t$. Assumption (3.24) appears physically reasonable, since the solution is much smoother along the characteristic direction. An error estimate without this assumption will be obtained in section 3.5. To check the optimality of the error estimate in Theorem 3.5, notice that we have utilized the whole regularity at our disposal. The estimate seems sharp under the present assumptions (2.5), (3.1), and (3.15) on the data; see the numerical example in section 5. Finally, we have derived an estimate for the error $u - u_h$ in the $H^{-1}(\Omega)$ norm. With the present assumption and technique, we are not able to obtain it in the $L^2(\Omega)$ norm due to the minimum regularity on the solution and the degeneracy of (1.1). For an estimate in this norm, see the next two subsections.

3.4.2. Case B: A nondegenerate case. For completeness, we also consider a nondegenerate case and derive error estimates under the minimal regularity on the solution. That is, instead of (2.5), (only) in this subsection we assume that

$$0 < \beta_* \le \beta(v) \le \beta^* < \infty \qquad \forall\, v \in \Re. \tag{3.25}$$

As mentioned before, (3.25) needs to hold only in a neighborhood of the solution. With this assumption, we now prove the next result.

THEOREM 3.6. *Under assumptions* (2.1), (2.2), (3.1), (3.2), (3.10), (3.15), (3.20), (3.25), *and* $h = O(\Delta t)$, *we have*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N} \{\|u^n - u_h^n\|^2_{L^2(\Omega)} + \|\theta^n - \theta_h^n\|^2_{L^2(\Omega)}\}\Delta t^n \le C(\Delta t)^2(1 + \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

Proof. The proof of Theorem 3.5 can be modified as follows. The error equation (3.23) and the estimate on I_1 and I_5 are the same as before. I_2, I_3, I_4, and I_6 are now estimated in a different manner:

$$\begin{aligned}
I_2 &\ge C \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)} \Delta t^n,\\
|I_3| &\le Ch^2 \sum_{n=1}^{N} \|f^n\|^2_{H^{-1}(\Omega)} \Delta t^n + \epsilon \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)} \Delta t^n,\\
|I_4| &\le \epsilon \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)} \Delta t^n + C \sum_{n=1}^{N} (\|e_u^n\|^2_{H^{-1}(\Omega)} + h^2 \|\theta^n\|^2_{L^2(\Omega)}) \Delta t^n,\\
|I_6| &\le Ch^2 \sum_{n=1}^{N} \left\| \frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n} \right\|^2_{H^{-1}(\Omega)} \Delta t^n + \epsilon \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)} \Delta t^n,
\end{aligned}$$

where (3.25) has been used. With these modifications, the desired result follows in the same fashion as for Theorem 3.5. ∎

The error estimate in the $L^2(\Omega)$ norm in this theorem in the nondegenerate case has been previously obtained in [25]; it is derived here, however, under much weaker regularity assumptions on the solution. Also, note that the estimate for $u - u_h$ in $L^2(J; H^1(\Omega))$ is optimal.

3.4.3. Case C: Another degenerate case. Note that assumption (2.5) implies that the diffusion coefficient in (2.6) (or in (3.3)) can be zero in the unknown u. We now consider another case where the following inequality holds:

$$0 \le \partial_\theta \mathcal{U}(\eta) \le \mathcal{U}^* < \infty \qquad \forall\, \eta \in \Re. \tag{3.26}$$

Recall that $\mathcal{U}$ is the inverse of (2.3). Again, (3.26) needs to hold only in a neighborhood of θ. This assumption says that the coefficient in the time differentiation term of (2.6) (or (3.3)) can be zero in θ. This case is sometimes referred to as the singular case [30, 35].

In this subsection we derive the error estimate under (3.26). Toward that end, we need another assumption. Let V be a subspace of $H^1(\Omega)$, and assume that

$$\|\nabla v\|_{L^2(\Omega)} \text{ is a norm in } V \text{ and is equivalent to } \|v\|_{H^1(\Omega)}. \tag{3.27}$$

In turn, this requires that the Poincare inequality holds in V. For example, if (2.6) is equipped with the Dirichlet boundary condition on the part of the boundary that has a positive Hausdorff measure, then we can define V in an appropriate way so that (3.27) holds. With (3.27), we can define the Green operator $G : H^{-1}(\Omega) \to V$ in terms of the bilinear form

$$a(v, w) = (\alpha \nabla v, \nabla w) \qquad \forall v,\ w \in V.$$

For future use (see the discussion on the extension of the present analysis for the characteristics-based methods to other boundary conditions later), we now state a result under assumptions (3.26) and (3.27).

THEOREM 3.7. *Under assumptions* (2.1), (2.2), (3.1), (3.2), (3.10), (3.15), (3.20), (3.26), (3.27), $h = O(\Delta t)$, *and* $M_h \subset V$, *we have*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N} \|u^n - u_h^n\|^2_{L^2(\Omega)} \Delta t^n \le C(\Delta t)^2 (1 + \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

Because of the definition of $a(\cdot,\cdot)$ in the present case, $I_4 \equiv 0$ in the error equation (3.23). Then the proof of Theorem 3.6 applies here.

3.5. Error analysis II. In this subsection, we derive error estimates without assumption (3.24).

LEMMA 3.8. *For* $v \in H^1(\Omega)$, *let* $\bar v(x) = v(\bar x)$, *where* $\bar x = x - b(x)\Delta t/c(x)$. *Then, under* (3.1) *and* (3.20), *we have*

$$\|v - \bar v\|_{L^2(\Omega)} \le C\Delta t \|\nabla v\|_{L^2(\Omega)}.$$

Proof. Let $z(x)$ be the unit vector in the direction of $x - \bar x$; i.e., $z(x) = x - \bar x/|x - \bar x|$. Then

$$v(x) - \bar v(x) = \int_0^1 |x - \bar x| \partial_z v(x + \zeta z) \mathrm{d}\zeta,$$

so

$$\int_\Omega |v(x) - \bar v(x)|^2 \mathrm{d}x = \int_\Omega |x - \bar x|^2 \left(\int_0^1 \partial_z v \mathrm{d}\zeta \right)^2 \mathrm{d}x.$$

Applying the facts that $|x-\bar{x}| \le C\Delta t$ and the determinant of the Jacobian of the transformation $x \to \bar{x}$ is $1+O(\Delta t)$ by (3.1) and (3.20), we see that

$$\int_\Omega |v(x)-\bar{v}(x)|^2 \mathrm{d}x \le C(\Delta t)^2 \|\nabla v\|^2_{L^2(\Omega)}.$$

Consequently, the desired result follows. □

In the present case, we need a slightly stronger assumption on the data:

$$b,\ \frac{b}{c} \in (H^2(\Omega))^2. \tag{3.28}$$

Also, whenever we use $1/|b(x)|$ below, we will assume that $|b(x)| \neq 0$ there.

LEMMA 3.9. *Under assumptions* (2.1), (2.2), (3.1), (3.10), (3.20), *and* (3.28), *we have*

$$\int_{J^n} \left(b\cdot\nabla u - c\frac{u^{n-1}-\bar{u}^{n-1}}{\Delta t^n}, Ge_u^n \right) dt \le C\Delta t^n (\|\partial_t u\|^2_{L^2(J^n;H^{-1}(\Omega))} + \Delta t^n), \quad 1 \le n \le N.$$

Proof. Let $z(x)$ be the unit vector in the direction of $b(x)$; i.e., $z(x) = b(x)/|b(x)|$. Then we see that

$$c(x)\frac{u^{n-1}-\bar{u}^{n-1}}{\Delta t^n} = \int_0^1 |b(x)| \partial_z u \left(x - \frac{b(x)}{c(x)}\Delta t^n \zeta, t^{n-1} \right) \mathrm{d}\zeta = \int_0^1 b(x)\cdot\nabla_y u^{n-1}(y)\mathrm{d}\zeta,$$

where $y = x - b(x)\Delta t^n \zeta / c(x)$. We denote this transformation by $y = H_\zeta(x)$ for each fixed $\zeta \in [0,1]$. Its Jacobian and determinant are, respectively,

$$J(H_\zeta(x)) = \begin{pmatrix} 1-\partial_{x_1}\left(\frac{b_1}{c}\right)\Delta t^n\zeta & -\partial_{x_2}\left(\frac{b_1}{c}\right)\Delta t^n\zeta \\ -\partial_{x_1}\left(\frac{b_2}{c}\right)\Delta t^n\zeta & 1-\partial_{x_2}\left(\frac{b_2}{c}\right)\Delta t^n\zeta \end{pmatrix}$$

and

$$|J(H_\zeta(x))| = 1 - \nabla\cdot\left(\frac{b}{c}(x)\right)\Delta t^n\zeta + O\left((\Delta t^n)^2\right).$$

Let

$$F_\zeta(x) = 1 + \nabla\cdot\left(\frac{b}{c}(x)\right)\Delta t^n\zeta + O\left((\Delta t^n)^2\right).$$

Then, as in the proof of Lemma 3.4, we have

$$\int_\Omega b(x)\cdot\nabla_y u^{n-1}(y) G e_u^n(x)\mathrm{d}x = \int_\Omega b(x)\cdot\nabla_y u^{n-1}(y) G e_u^n(x) F_\zeta(x)\mathrm{d}y,$$

so, by the periodicity assumption and the Green formula,

$$\begin{aligned}\int_\Omega b(x)\cdot\nabla_y u^{n-1}(y) G e_u^n(x)\mathrm{d}x = &-\int_\Omega \nabla_y\cdot b(x) u^{n-1}(y) G e_u^n(x) F_\zeta(x)\mathrm{d}y \\ &-\int_\Omega b(x)\cdot\nabla_y\left(G e_u^n(x)\right) u^{n-1}(y) F_\zeta(x)\mathrm{d}y \\ &-\int_\Omega u^{n-1}(y) G e_u^n(x) b(x)\cdot\nabla_y F_\zeta(x)\mathrm{d}y.\end{aligned}$$

Apply the periodicity assumption and the Green formula again to see that

$$\int_\Omega b(y)\cdot\nabla_y u(y)Ge_u^n(y)\mathrm{d}y = -\int_\Omega \nabla_y\cdot b(y)u(y)Ge_u^n(y)\mathrm{d}y - \int_\Omega b(y)\cdot\nabla_y\left(Ge_u^n(y)\right)u(y)\mathrm{d}y.$$

Subtract these two equations to obtain

$$\begin{aligned}
&\int_\Omega b(y)\cdot\nabla_y u(y)Ge_u^n(y)\mathrm{d}y - \int_\Omega b(x)\cdot\nabla_y u^{n-1}(y)Ge_u^n(x)\mathrm{d}x\\
&\quad= -\left\{\int_\Omega \nabla_y\cdot b(y)u(y)Ge_u^n(y)\mathrm{d}y - \int_\Omega \nabla_y\cdot b(x)u^{n-1}(y)Ge_u^n(x)F_\zeta(x)\mathrm{d}y\right\}\\
&\qquad-\left\{\int_\Omega b(y)\cdot\nabla_y\left(Ge_u^n(y)\right)u(y)\mathrm{d}y - \int_\Omega b(x)\cdot\nabla_y\left(Ge_u^n(x)\right)u^{n-1}(y)F_\zeta(x)\mathrm{d}y\right\}\\
&\qquad+\int_\Omega u^{n-1}(y)Ge_u^n(x)b(x)\cdot\nabla_y F_\zeta(x)\mathrm{d}y\\
&\quad\equiv II_1+II_2+II_3.
\end{aligned}$$

Observe that

$$\begin{aligned}
II_1 &= -\int_\Omega \nabla_y\cdot b(y)Ge_u^n(y)[u(y)-u^{n-1}(y)]\mathrm{d}y\\
&\quad-\left\{\int_\Omega \nabla_y\cdot b(y)u^{n-1}(y)Ge_u^n(y)\mathrm{d}y - \int_\Omega \nabla_y\cdot b(x)u^{n-1}(y)Ge_u^n(y)F_\zeta(x)\mathrm{d}y\right\}\\
&\quad-\left\{\int_\Omega \nabla_y\cdot b(x)u^{n-1}(y)Ge_u^n(y)F_\zeta(x)\mathrm{d}y - \int_\Omega \nabla_y\cdot b(x)u^{n-1}(y)Ge_u^n(x)F_\zeta(x)\mathrm{d}y\right\}\\
&\equiv II_{11}+II_{12}+II_{13}.
\end{aligned}$$

For $t\in J^n$, apply the Schwarz inequality, (2.1), (3.1), and (3.10) to have

$$\begin{aligned}
|II_{11}| &= \left|\int_\Omega\left\{\int_{t^{n-1}}^t \partial_t u(y,\xi)\mathrm{d}\xi\right\}\nabla_y\cdot b(y)Ge_u^n(y)\mathrm{d}y\right|\\
&\le C(\|\partial_t u\|^2_{L^2(J^n;H^{-1}(\Omega))}+\Delta t^n).
\end{aligned}$$

With a similar argument as in Lemma 3.4 and an application of Lemma 3.8 on $\nabla\cdot b$ and Ge_u^n, we can show that

$$|II_{12}|+|II_{13}|\le C\Delta t^n.$$

Analogously, with the expression

$$\begin{aligned}
II_2 &= -\int_\Omega b(y)\cdot\nabla_y Ge_u^n(y)[u(y)-u^{n-1}(y)]\mathrm{d}y\\
&\quad-\left\{\int_\Omega b(y)\cdot\nabla_y Ge_u^n(y)u^{n-1}(y)\mathrm{d}y - \int_\Omega b(x)\cdot\nabla_y Ge_u^n(y)u^{n-1}(y)F_\zeta(x)\mathrm{d}y\right\}\\
&\quad-\left\{\int_\Omega b(x)\cdot\nabla_y Ge_u^n(y)u^{n-1}(y)F_\zeta(x)\mathrm{d}y - \int_\Omega b(x)\cdot\nabla_y Ge_u^n(x)u^{n-1}(y)F_\zeta(x)\mathrm{d}y\right\},
\end{aligned}$$

we see that

$$|II_2|\le C(\|\partial_t u\|^2_{L^2(J^n;H^{-1}(\Omega))}+\Delta t^n).$$

Obviously, by (3.28), we have

$$|II_3| \le C\Delta t^n.$$

Finally, note that

$$\begin{aligned}&\int_{J^n}\left(b\cdot\nabla u - c\frac{u^{n-1}-\bar u^{n-1}}{\Delta t^n}, Ge_u^n\right)\mathrm{d}t\\ &\quad=\int_{J^n}\int_0^1\left\{\int_\Omega b(y)\cdot\nabla_y u(y)Ge_u^n(y)\mathrm{d}y - \int_\Omega b(x)\cdot\nabla_y u^{n-1}(y)Ge_u^n(x)\mathrm{d}x\right\}\mathrm{d}\zeta\mathrm{d}t.\end{aligned}$$

Consequently, the desired result comes from the bounds for II_i, $i=1,2,3$. ∎

We are now in a position to derive error estimates. As an example, we consider only Case A; i.e., we derive the error estimates under assumption (2.5). Cases B and C can be similarly handled.

For each $1\le n\le N$, we integrate (3.21) over J^n:

$$\int_{J^n}(\psi(x)\partial_\tau u, v)\mathrm{d}t + \int_{J^n}(\alpha(x)\nabla\theta,\nabla v)\mathrm{d}t = \int_{J^n}(f,v)\mathrm{d}t \qquad \forall v\in H^1(\Omega). \tag{3.29}$$

THEOREM 3.10. *Under assumptions* (2.1), (2.2), (2.5), (3.1), (3.2), (3.10), (3.15), (3.20), (3.28), *and* $h=O(\Delta t)$, *we have the error estimate*

$$\max_{1\le n\le N}\|u^n-u_h^n\|_{H^{-1}(\Omega)} + \|\theta-\theta_h\|_{L^2(\Omega_T)} \le C(\Delta t)^{1/2},$$

provided that $\|\partial_t f\|_{L^2(J;H^{-1}(\Omega))}$ *is bounded.*

Proof. Choose $v=Ge_u^n$ in (3.29) and $v=G_he_u^n$ in (3.7), subtract the resulting two equations, use (3.9) and (3.12), and sum over n from 1 to N to have the error equation

$$\begin{aligned}&\sum_{n=1}^N\left(c[e_u^n-\bar e_u^{n-1}], Ge_u^n\right) + \sum_{n=1}^N\int_{J^n}(c[\theta(t)-\theta_h^n], e_u^n)\,\mathrm{d}t\\ &=\sum_{n=1}^N\left\{\int_{J^n}(f-f^n, Ge_u^n)\mathrm{d}t + (f^n, Ge_u^n - G_he_u^n)\Delta t^n\right\}\\ &\quad+\sum_{n=1}^N\left\{\int_{J^n}(\theta, Ge_u^n)\mathrm{d}t - (\theta_h^n, G_he_u^n)\Delta t^n\right\}\\ &\quad-\sum_{n=1}^N\int_{J^n}\left(b\cdot\nabla u - c\frac{u^{n-1}-\bar u^{n-1}}{\Delta t^n}, Ge_u^n\right)\mathrm{d}t\\ &\quad-\sum_{n=1}^N\left(c\frac{u_h^n-\bar u_h^{n-1}}{\Delta t^n}, Ge_u^n - G_he_u^n\right)\Delta t^n.\end{aligned} \tag{3.30}$$

Again, with the obvious definition of I_i, $i=1,\dots,6$, we express (3.30) simply by

$$I_1+I_2 = I_3+I_4+I_5+I_6.$$

The term I_1 is estimated as in Theorem 3.5:

$$I_1 \ge \frac{1}{2}\|e_u^N\|^2_{H^{-1}(\Omega)} - \frac{1}{2}\|e_u^0\|^2_{H^{-1}(\Omega)} - C\sum_{n=1}^N\|e_u^{n-1}\|^2_{H^{-1}(\Omega)}\Delta t^{n-1}.$$

I_2 is written as

$$I_2 = \sum_{n=1}^{N} \int_{J^n} (c[\theta(t) - \theta_h^n], u(t) - u_h^n) \mathrm{d}t + \sum_{n=1}^{N} \int_{J^n} (c[\theta(t) - \theta_h^n], u^n - u(t)) \mathrm{d}t,$$

so, by (2.1), (2.5), (3.1), and Lemma 3.2,

$$I_2 \geq C\{\|\theta - \theta_h\|^2_{L^2(\Omega_T)} - \Delta t\}.$$

Next, by (3.13), we see that

$$\begin{aligned}
|I_3| &\leq \sum_{n=1}^{N} \{(\Delta t^n)^{1/2} \|\partial_t f\|_{L^2(J^n;H^{-1}(\Omega))} \|Ge_u^n\|_{H^1(\Omega)} + \|f^n\|_{H^{-1}(\Omega)} \|Ge_u^n - G_h e_u^n\|_{H^1(\Omega)}\} \Delta t^n \\
&\leq C \sum_{n=1}^{N} \{(\Delta t^n)^{1/2} \|\partial_t f\|_{L^2(J^n;H^{-1}(\Omega))} \|e_u^n\|_{H^{-1}(\Omega)} + h\|f^n\|_{H^{-1}(\Omega)} \|e_u^n\|_{L^2(\Omega)}\} \Delta t^n \\
&\leq C \left\{ (\Delta t)^2 \|\partial_t f\|^2_{L^2(J;H^{-1}(\Omega))} + \sum_{n=1}^{N} (\|e_u^n\|^2_{H^{-1}(\Omega)} + h\|f^n\|^2_{H^{-1}(\Omega)} + h\|e_u^n\|^2_{L^2(\Omega)}) \Delta t^n \right\}.
\end{aligned}$$

Also, it follows from (3.13) and (3.14) that

$$|I_4| \leq \epsilon \|e_\theta\|^2_{L^2(\Omega_T)} + C \left\{ \sum_{n=1}^{N} \|e_u^n\|^2_{H^{-1}(\Omega)} \Delta t^n + h^2 \|\theta\|^2_{L^2(\Omega_T)} \right\}.$$

Apply Lemma 3.9 to I_5 to see that

$$|I_5| \leq C\Delta t (1 + \|\partial_t u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

Finally, by (3.13), I_6 is bounded as follows:

$$\begin{aligned}
|I_6| &\leq \sum_{n=1}^{N} \left\| \frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n} \right\|_{H^{-1}(\Omega)} \|Ge_u^n - G_h e_u^n\|_{H^1(\Omega)} \Delta t^n \\
&\leq Ch \sum_{n=1}^{N} \left\| \frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n} \right\|_{H^{-1}(\Omega)} \|e_u^n\|_{L^2(\Omega)} \Delta t^n \\
&\leq Ch \left(\sum_{n=1}^{N} \left\| \frac{u_h^n - \bar{u}_h^{n-1}}{\Delta t^n} \right\|^2_{H^{-1}(\Omega)} \Delta t^n + \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)} \Delta t^n \right).
\end{aligned}$$

The rest of the proof is completed as in Theorem 3.5. ∎

We remark that the error estimate in Theorem 3.10 appears sharp under the present assumptions on the data, as mentioned before. Also, the present analysis can be extended to the more general nonlinear problem

$$c(u)\partial_t u + b(u) \cdot \nabla u - \nabla \cdot (a(u)\nabla u) = f(u) \qquad \text{in } \Omega \times J, \tag{3.31}$$

where $c(u) = c(x,t;u)$, $b(u) = b(x,t;u)$, and $f(u) = f(x,t;u)$. By linearizing b, c, and f, we can simply reduce (3.31) to (2.6). To be more accurate, we can use an extrapolation technique in the linearization of these coefficients [21].

4. Analysis for the MMOCAA. In this section, we carry out an analysis for the MMOCAA procedure.

4.1. The MMOCAA procedure. To introduce this procedure, we assume that

$$\nabla \cdot b = 0 \qquad \text{in } \Omega. \tag{4.1}$$

That is, b is divergence-free. This is physically reasonable, since b is typically a velocity field and (4.1) corresponds to the incompressibility condition. Note that, by (4.1), the periodicity assumption, and the divergence theorem, (2.6) with $f = 0$ yields the conservation law

$$\int_\Omega c(x)u(x,t)\mathrm{d}x = \int_\Omega c(x)u_0(x)\mathrm{d}x, \qquad t \in J. \tag{4.2}$$

In real applications, it is desirable to maintain at least a discrete form of this law in any numerical approximation of (2.6). However, in general, the MMOC procedure does not satisfy this property, and it creates an imbalance in mass [22].

Let M_h be defined as in the previous section, and let the initial approximation u_h^0 be defined as in (3.8). For $1 \le n \le N$, given $u_h^{n-1} \in M_h$, set

$$Q_h^{n-1} = \int_\Omega c(x)u_h^{n-1}(x)\mathrm{d}x, \qquad \bar{Q}_h^{n-1} = \int_\Omega c(x)\bar{u}_h^{n-1}(x)\mathrm{d}x.$$

As mentioned above, $Q_h^{n-1} \neq \bar{Q}_h^{n-1}$ in general. Define

$$\tilde{u}_h^{n-1}(x) = \begin{cases} \max\left\{ u_h^{n-1}\left(\bar{x} - \gamma\dfrac{b(x)}{c(x)}\left(\Delta t^n\right)^2\right), u_h^{n-1}\left(\bar{x} + \gamma\dfrac{b(x)}{c(x)}\left(\Delta t^n\right)^2\right)\right\} \\ \quad \text{if} \quad \bar{Q}_h^{n-1} < Q_h^{n-1}, \\ \min\left\{ u_h^{n-1}\left(\bar{x} - \gamma\dfrac{b(x)}{c(x)}\left(\Delta t^n\right)^2\right), u_h^{n-1}\left(\bar{x} + \gamma\dfrac{b(x)}{c(x)}\left(\Delta t^n\right)^2\right)\right\} \\ \quad \text{if} \quad \bar{Q}_h^{n-1} > Q_h^{n-1}, \end{cases}$$

and

$$\tilde{Q}_h^{n-1} = \int_\Omega c(x)\tilde{u}_h^{n-1}(x)\mathrm{d}x,$$

where γ is a fixed constant, normally chosen to be less than one [22], and $\bar{x} = x - b(x)\Delta t^n/c(x)$. If $\bar{Q}_h^{n-1} = \tilde{Q}_h^{n-1}$, we must accept that mass cannot be conserved; otherwise, find $\Lambda^{n-1} \in \Re$ such that

$$Q_h^{n-1} = \Lambda^{n-1}\bar{Q}_h^{n-1} + (1 - \Lambda^{n-1})\tilde{Q}_h^{n-1}. \tag{4.3}$$

Define

$$\hat{u}_h^{n-1} = \Lambda^{n-1}\bar{u}_h^{n-1} + (1 - \Lambda^{n-1})\tilde{u}_h^{n-1} \tag{4.4}$$

and

$$\hat{Q}_h^{n-1} = \int_\Omega c(x)\hat{u}_h^{n-1}(x)\mathrm{d}x. \tag{4.5}$$

Clearly, $\hat{Q}_h^{n-1} = Q_h^{n-1}$, so the conservation law is preserved. Now, continue in n with $\hat{u}_h^{n-1}$ in place of $\bar{u}_h^{n-1}$ in the original MMOC procedure (3.7); i.e.,

$$\left(c\frac{u_h^n - \hat{u}_h^{n-1}}{\Delta t^n}, v\right) + (\alpha\nabla\theta_h^n, \nabla v) = (f^n, v) \qquad \forall v \in M_h, \tag{4.6}$$

where $u_h^n = \mathcal{U}(\theta_h^n)$. Note that Λ^{n-1} is bounded; $0 \le \Lambda^{n-1} \le 1$ for small Δt^{n-1} [22].

4.2. Stability. The next lemma can be found in [44].

LEMMA 4.1. *Let $\eta \in L^2(\Omega)$ be Ω-periodic, and let $g_i \in (W^{1,\infty}(\Omega))^2$, $i = 1, 2$. For $\Lambda \in \Re$, define*

$$\hat{\eta}(x) = \Lambda\bar{\eta}(x) + (1-\Lambda)\tilde{\eta}(x) = \Lambda\eta(x - g_1(x)\Delta t) + (1-\Lambda)\eta(x - g_2(x)\Delta t),$$

where

$$\|g_1 - g_2\|_{L^\infty(\Omega)} \le C\Delta t.$$

Then

$$\|\eta - \hat{\eta}\|_{H^{-1}(\Omega)} \le C(\Lambda)\Delta t\|\eta\|_{L^2(\Omega)}.$$

LEMMA 4.2. *Under assumptions* (2.5), (3.1), (3.2), *and* (3.15), *the solution (u_h, θ_h) produced by the above MMOCAA procedure satisfies*

$$\max_{1\le n\le N}\{\|u_h^n\|^2_{L^2(\Omega)} + \|\theta_h^n\|^2_{L^2(\Omega)}\} + \sum_{n=1}^{N}\|\nabla\theta_h^n\|^2_{L^2(\Omega)}\Delta t^n \le C.$$

The proof of this lemma can be carried out as for Lemma 3.2. Namely, with $v = \theta_h^n$ in (4.6), we have

$$\begin{aligned}&\sum_{n=1}^{N}\left\{(c[u_h^n - u_h^{n-1}], \theta_h^n) + (\alpha\nabla\theta_h^n, \nabla\theta_h^n)\Delta t^n\right\}\\ &= \sum_{n=1}^{N}\left\{(f^n, \theta_h^n)\Delta t^n + (c[\hat{u}_h^{n-1} - u_h^{n-1}], \theta_h^n)\right\}.\end{aligned}$$

Now, applying Lemma 4.1 and the same argument as for Lemma 3.2, we can obtain the desired result.

LEMMA 4.3. *With the same assumptions as in Lemma* 4.2, *if $h = O(\Delta t)$, we have*

$$\sum_{n=1}^{N}\left\|\frac{u_h^n - \hat{u}_h^{n-1}}{\Delta t^n}\right\|^2_{H^{-1}(\Omega)}\Delta t^n \le C.$$

Note that, with $v = G_h(u_h^n - \hat{u}_h^{n-1})/\Delta t^n$ in (4.6), this equation becomes

$$\begin{aligned}&\left(c\frac{u_h^n - \hat{u}_h^{n-1}}{\Delta t^n}, \frac{G_h(u_h^n - \hat{u}_h^{n-1})}{\Delta t^n}\right) + \left(\alpha\nabla\theta_h^n, \nabla\frac{G_h(u_h^n - \hat{u}_h^{n-1})}{\Delta t^n}\right)\\ &\qquad = \left(f^n, \frac{G_h(u_h^n - \hat{u}_h^{n-1})}{\Delta t^n}\right),\end{aligned}$$

so the proof of this lemma can be completed as in Lemma 3.3.

4.3. Error analysis I. The next lemma is similar to Lemma 3.8.

LEMMA 4.4. *For $v \in H^1(\Omega)$, let $\bar{v}(x) = v(\bar{x})$ and $\tilde{v}(x) = v(\tilde{x})$, where $\bar{x} = x - b(x)\Delta t/c(x)$ and $\tilde{x} = \bar{x} - \gamma b(x)(\Delta t)^2/c(x)$ or $\tilde{x} = \bar{x} + \gamma b(x)(\Delta t)^2/c(x)$. Then, under* (3.1) *and* (3.20),

$$\|\bar{v} - \tilde{v}\|_{L^2(\Omega)} \le C(\Delta t)^2\|\nabla v\|_{L^2(\Omega)}.$$

Note that $|\bar{x} - \tilde{x}| \le C(\Delta t)^2$ by (3.1), so that this lemma can be shown as in Lemma 3.8.

LEMMA 4.5. *With assumptions* (3.1) *and* (3.20)*, we have*

$$(c\hat{v}, G\hat{v}) - (cv, Gv) \le C(\Lambda)\Delta t\{(cv, Gv) + \Delta t(v, v)^{1/2}(cv, Gv)^{1/2}\} \qquad \forall v \in L^2(\Omega),$$

where, for $\Lambda \in \Re$, $\hat{v}(x) = \Lambda\bar{v}(x) + (1-\Lambda)\tilde{v}(x)$*, with* $\bar{x}$ *and* $\tilde{x}$ *given as in Lemma* 4.4.

Proof. As in the proof of Lemma 3.4, we can show that, for $v \in L^2(\Omega)$,

$$(c\bar{v}, G\bar{v}) - (cv, Gv) \le C\Delta t(cv, Gv) \quad \text{and} \quad (c\tilde{v}, G\tilde{v}) - (cv, Gv) \le C\Delta t(cv, Gv).$$

By the definition of $\hat{v}$, we see that

$$\begin{aligned}(c\hat{v}, G\hat{v}) - (cv, Gv) = {} & \Lambda^2\left\{(c\bar{v}, G\bar{v}) - (cv, Gv)\right\} + (1-\Lambda)^2\left\{(c\tilde{v}, G\tilde{v}) - (cv, Gv)\right\} \\ & + \Lambda(1-\Lambda)\left\{(c\bar{v}, G\tilde{v}) + (c\tilde{v}, G\bar{v}) - 2(cv, Gv)\right\}.\end{aligned} \tag{4.7}$$

Consequently, it suffices to bound

$$\Lambda(1-\Lambda)\left\{(c\bar{v}, G\tilde{v}) + (c\tilde{v}, G\bar{v}) - 2(cv, Gv)\right\}.$$

Observe that

$$\begin{aligned}(c\tilde{v}, G\bar{v}) - (cv, Gv) &= \int_\Omega c(x)v(\tilde{x})Gv(\bar{x})\mathrm{d}x - \int_\Omega c(\tilde{x})v(\tilde{x})Gv(\tilde{x})\mathrm{d}\tilde{x} \\ &= \int_\Omega c(x)v(\tilde{x})[Gv(\bar{x}) - Gv(\tilde{x})]\mathrm{d}x \\ &\quad + \int_\Omega [c(x) - c(\tilde{x})]v(\tilde{x})Gv(\tilde{x})\left(1 + \nabla\cdot\left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right)\right)\mathrm{d}\tilde{x} \\ &\quad + \int_\Omega c(\tilde{x})v(\tilde{x})Gv(\tilde{x})\left(\nabla\cdot\left(\frac{b}{c}(x)\right)\Delta t + O\left((\Delta t)^2\right)\right)\mathrm{d}\tilde{x} \\ &\equiv T_1 + T_2 + T_3.\end{aligned}$$

By Lemma 4.4, (3.1), and (3.11), we see that

$$\begin{aligned}|T_1| &\le C\|v\|_{L^2(\Omega)}\|G\bar{v} - G\tilde{v}\|_{L^2(\Omega)} \\ &\le C(\Delta t)^2\|v\|_{L^2(\Omega)}\|\nabla Gv\|_{L^2(\Omega)} \\ &\le C(\Delta t)^2\|v\|_{L^2(\Omega)}\|v\|_{H^{-1}(\Omega)}.\end{aligned}$$

By (3.20), it is clear that

$$|T_2 + T_3| \le C\Delta t(cv, Gv).$$

Thus we have

$$(c\tilde{v}, G\bar{v}) - (cv, Gv) \le C\Delta t\{(cv, Gv) + \Delta t(v, v)^{1/2}(cv, Gv)^{1/2}\}. \tag{4.8}$$

In the same manner, we see that

$$(c\bar{v}, G\tilde{v}) - (cv, Gv) \le C\Delta t\{(cv, Gv) + \Delta t(v, v)^{1/2}(cv, Gv)^{1/2}\}. \tag{4.9}$$

Therefore, the lemma follows by combining (4.7)–(4.9). ∎

4.3.1. Case A: Under assumption (2.5). As in the last section, we first derive the error estimate under assumption (2.5).

THEOREM 4.6. *Under assumptions* (2.1), (2.2), (2.5), (3.1), (3.2), (3.10), (3.15), (3.20), *and* $h = O(\Delta t)$, *we have the error estimate for the MMOCAA procedure:*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N} \|\theta^n - \theta_h^n\|^2_{L^2(\Omega)} \Delta t^n \le C\Delta t(1 + \Delta t \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

Proof. Take $v = Ge_u^n$ in (3.21) with $t = t^n$ and $v = G_h e_u^n$ in (4.6), subtract the resulting two equations, use (3.9) and (3.12), and sum over n from 1 to N to have the error equation

$$\begin{aligned}
&\sum_{n=1}^{N} \left(c[e_u^n - \hat{e}_u^{n-1}], Ge_u^n\right) + \sum_{n=1}^{N} (ce_\theta^n, e_u^n)\Delta t^n \\
&= \sum_{n=1}^{N} (f^n, Ge_u^n - G_h e_u^n)\Delta t^n + \sum_{n=1}^{N} \{(Ge_u^n, \theta^n) - (G_h e_u^n, \theta_h^n)\}\, \Delta t^n \\
&\quad - \sum_{n=1}^{N} \left(\psi\partial_\tau u^n - c\frac{u^n - \hat{u}^{n-1}}{\Delta t^n}, Ge_u^n\right) \Delta t^n - \sum_{n=1}^{N} \left(c\frac{u_h^n - \hat{u}_h^{n-1}}{\Delta t^n}, Ge_u^n - G_h e_u^n\right) \Delta t^n.
\end{aligned}$$

As in Theorem 3.5, we express this equation by

$$I_1 + I_2 = I_3 + I_4 + I_5 + I_6.$$

The terms I_2–I_4 are estimated in the same way as in Theorem 3.5; I_1, I_5, and I_6 are bounded as follows. First,

$$I_1 \ge \frac{1}{2} \sum_{n=1}^{N} \{\|e_u^n\|^2_{H^{-1}(\Omega)} - \|e_u^{n-1}\|^2_{H^{-1}(\Omega)}\} + \frac{1}{2} \sum_{n=1}^{N} \{\|e_u^{n-1}\|^2_{H^{-1}(\Omega)} - \|\hat{e}_u^{n-1}\|^2_{H^{-1}(\Omega)}\},$$

so, by Lemma 4.5,

$$I_1 \ge \frac{1}{2}\|e_u^N\|^2_{H^{-1}(\Omega)} - \frac{1}{2}\|e_u^0\|^2_{H^{-1}(\Omega)} - C\sum_{n=1}^{N} (\|e_u^{n-1}\|^2_{H^{-1}(\Omega)} + \|e_u^{n-1}\|^2_{L^2(\Omega)}\Delta t^{n-1})\Delta t^{n-1}.$$

Second, note that

$$\begin{aligned}
&\psi\partial_\tau u^n - c\frac{u^n - \hat{u}^{n-1}}{\Delta t^n} \\
&\quad = \Lambda^{n-1}\psi\partial_\tau u^n - \Lambda^{n-1} c\frac{u^n - \bar{u}^{n-1}}{\Delta t^n} + (1 - \Lambda^{n-1})\psi\partial_\tau u^n - (1 - \Lambda^{n-1})c\frac{u^n - \tilde{u}^{n-1}}{\Delta t^n};
\end{aligned}$$

consequently, as in Theorem 3.5 and by the boundedness of Λ^{n-1},

$$|I_5| \le C\left((\Delta t)^2 \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))} + \sum_{n=1}^{N} \|e_u^n\|^2_{H^{-1}(\Omega)}\Delta t^n\right).$$

Finally, we see that

$$|I_6| \le Ch\left(\sum_{n=1}^{N} \left\|\frac{u_h^n - \hat{u}_h^{n-1}}{\Delta t^n}\right\|^2_{H^{-1}(\Omega)} \Delta t^n + \sum_{n=1}^{N} \|e_u^n\|^2_{L^2(\Omega)}\Delta t^n\right).$$

Apply the bounds of I_i, $i = 1, \ldots, 6$, Lemmas 4.2 and 4.3, the discrete Gronwall lemma, (3.6), and (3.8) to obtain the desired result. ∎

Again, the error estimate in Theorem 4.6 for the MMOCAA procedure seems sharp under the present assumptions on the data; see section 5.

4.3.2. Case B: A nondegenerate case. We now obtain the error estimate under assumption (3.25); i.e., we present the error analysis for the MMOCAA in the nondegenerate case. This case was analyzed in [23], but here a reduced regularity on solution is employed, as noted earlier.

THEOREM 4.7. *Under assumptions* (2.1), (2.2) (3.1), (3.2), (3.10), (3.15), (3.20), (3.25), *and* $h = O(\Delta t)$, *we have*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N} \{\|u^n - u_h^n\|^2_{L^2(\Omega)} + \|\theta^n - \theta_h^n\|^2_{L^2(\Omega)}\}\Delta t^n \le C(\Delta t)^2(1 + \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

This theorem can be shown as in Theorem 3.6 with an exception that I_1 is estimated by

$$I_1 \ge \frac{1}{2}\|e_u^N\|^2_{H^{-1}(\Omega)} - \frac{1}{2}\|e_u^0\|^2_{H^{-1}(\Omega)} - C\sum_{n=1}^{N} \|e_u^{n-1}\|^2_{H^{-1}(\Omega)}\Delta t^{n-1} - \epsilon \sum_{n=1}^{N} \|e_u^{n-1}\|^2_{L^2(\Omega)}\Delta t^{n-1}.$$

As for the MMOC, the estimate for $u - u_h$ in $L^2(J; H^1(\Omega))$ is optimal.

4.3.3. Case C: Another degenerate case. We finally state the error estimate under assumptions (3.26) and (3.27) for the MMOCAA procedure.

THEOREM 4.8. *Under assumptions* (2.1), (2.2), (3.1), (3.2), (3.10), (3.15), (3.20), (3.26), (3.27), $h = O(\Delta t)$, *and* $M_h \subset V$, *for the MMOCAA we have*

$$\max_{1\le n\le N} \|u^n - u_h^n\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N} \|u^n - u_h^n\|^2_{L^2(\Omega)}\Delta t^n \le C(\Delta t)^2(1 + \|\partial_{\tau\tau} u\|^2_{L^2(J;H^{-1}(\Omega))}).$$

The proof is given as in Theorem 3.7.

4.4. Error analysis II. We now treat the case without assumption (3.24). As an example, we state only the result corresponding to Case A; the other two cases can be handled in a similar fashion. Also, the proof of the next theorem can be completed as in Theorems 3.10 and 4.6.

THEOREM 4.9. *Under assumptions* (2.1), (2.2), (2.5), (3.1), (3.2), (3.10), (3.15), (3.20), (3.28), *and* $h = O(\Delta t)$, *we have the error estimate for the MMOCAA procedure*

$$\max_{1\le n\le N} \|u^n - u_h^n\|_{H^{-1}(\Omega)} + \|\theta - \theta_h\|_{L^2(\Omega_T)} \le C(\Delta t)^{1/2},$$

provided that $\|\partial f/\partial t\|_{L^2(J;H^{-1}(\Omega))}$ *is bounded.*

Remark. Another variant of the MMOC procedure has been recently introduced in [8]. It is referred to as the ELLAM there. This method globally conserves mass as well. The error analysis for the ELLAM (with the degeneracy taken into account) can be done similarly as in this section for the MMOCAA. We mention that the analysis for the ELLAM in a nondegenerate case has been given in [45].

A similar variant to the ELLAM scheme has been developed in [2]; it is called the characteristic-mixed finite element method (also see [24]). In this method, the diffusion term of (2.6) is treated using the classical mixed finite element method [7], where the diffusion coefficient is assumed to be positive. The present techniques have been developed primarily for degenerate problems. For the characteristic-mixed method to be able to treat the degenerate case, we can exploit the so-called expanded mixed finite element method [9, 10] for the discretization of the diffusion term. The development and analysis of the characteristic-expanded mixed finite element method will be our future work.

5. Numerical results. In this section, we present numerical results to show the sharpness of the error estimates derived in the earlier sections. We consider the so-called porous medium equation

$$\partial_t u - \Delta u^m = 0, \qquad m > 1.$$

This equation can be equivalently rewritten in form (1.1):

$$\partial_t u - \nabla \cdot (m u^{m-1} \nabla u) = 0, \qquad m > 1, \tag{5.1}$$

so we see that the diffusion coefficient $a(u)$ is mu^{m-1} and the variable θ equals u^m. Obviously, (5.1) is degenerate at zero. Equation (5.1) often arises in the flow of a gas in porous media. To see this, ignoring certain constants, the gas flow is governed by

$$\partial_t \rho + \nabla \cdot (\rho v) = 0, \quad v = -\nabla p, \quad \rho = p^\gamma, \tag{5.2}$$

where ρ is the density, p the pressure, v the velocity, and γ a (constant) ratio of specific heats. These equations are the mass conservation, Darcy's law, and equation of state [6, 27, 29, 38], respectively. Eliminating v and p in (5.2), we see that

$$\partial_t \rho - \frac{1}{1+\gamma} \Delta(\rho^{1+1/\gamma}) = 0.$$

Rescaling t by $1/(1+\gamma)$ leads to (5.1) with $u = \rho$.

Beginning from a delta function of integral Γ at the original, the exact solution to (5.1) is of the form [4, 37]

$$u(|x|, t) = \max\left\{0, t^{-\alpha}\left(\Gamma - \frac{\alpha(m-1)}{2dm}\frac{|x|^2}{t^{2\alpha/d}}\right)^{1/(m-1)}\right\},$$

where $\alpha = 1/(m - 1 + 2/d)$. This function is radially symmetric and has compact support. Figure 1 shows an example of this solution in two dimensions.

The finite element procedure (3.7) is utilized to solve (5.1). Since we are solely interested in checking the sharpness of the error estimates in Theorem 3.5, we concentrate on the one-dimensional case, $d = 1$. Also, we take $m = 2$ in (5.1). Note that $b = 0$ in the present case, so (3.7) reduces to the standard finite element method with a backward Euler procedure for $\partial_t u$. Further, with the present choice of the initial datum, (5.1) corresponds to the flow case with a point source. The approximate solutions with different mesh sizes and at different times are presented in Figure 2. This figure shows convergence of the approximate solutions. The error bounds and convergence rates in the $L^2(\Omega_T)$ norm for u and θ with $T = 0.01$, $\Gamma = 1.0$, and $m = 2$ are given in Table 1. From this table, we observe the sharpness of the error estimates in Theorem 3.5. Similar observations can be made for Theorems 3.10, 4.6, and 4.9.

PREDICTOR-CORRECTOR METHODS OF RUNGE–KUTTA TYPE FOR STOCHASTIC DIFFERENTIAL EQUATIONS*

KEVIN BURRAGE† AND TIANHAI TIAN†

Abstract. In this paper we construct predictor-corrector (PC) methods based on the trivial predictor and stochastic implicit Runge–Kutta (RK) correctors for solving stochastic differential equations. Using the colored rooted tree theory and stochastic B-series, the order condition theorem is derived for constructing stochastic RK methods based on PC implementations. We also present detailed order conditions of the PC methods using stochastic implicit RK correctors with strong global order 1.0 and 1.5. A two-stage implicit RK method with strong global order 1.0 and a four-stage implicit RK method with strong global order 1.5 used as the correctors are constructed in this paper. The mean-square stability properties and numerical results of the PC methods based on these two implicit RK correctors are reported.

Key words. stochastic differential equations, predictor-corrector methods, Runge–Kutta methods, numerical stability

1. Introduction.

Runge–Kutta (RK) methods are one of the most efficient classes of methods for solving ordinary differential equations (ODEs). Certain classes of implicit RK methods have excellent stability properties and are widely used to solve stiff ODEs. In the last decade, predictor-corrector (PC) methods have been one of the major classes of methods for solving nonstiff ODEs on parallel computers (see [2], [3], [4], [5], [6], [10], [15], [25], [27], and [28]).

By comparing the Taylor series expansion of the approximation solution to the Taylor series expansion of the exact solution over one step assuming exact initial values, Butcher [13] introduced the rooted tree theory that is the key to constructing RK methods for ODEs. As the RK-type PC methods can be represented as a special class of block explicit RK methods, the rooted tree theory has been applied to RK-type PC methods. Burrage [2], [6] has developed a comprehensive theory based on the use of Butcher series which allows the analysis of the local error of any RK-type PC method and has also applied this theory to an analysis of the local behavior of two classes of PC methods, including one which is based on the trivial predictor and an implicit RK corrector.

For solving stochastic differential equations (SDEs), stochastic RK methods are an important class of numerical methods. Rümelin [22] introduced the use of traditional RK methods for SDEs. These methods resemble in their structure deterministic RK methods for ODEs. Burrage and Burrage [7], [8] and Burrage [12] established the colored rooted tree theory and stochastic B-series which is generalized from the corresponding rooted tree theory and B-series for constructing numerical methods for ODEs. Based on these theories, Burrage and Burrage present order conditions for constructing a general class of stochastic RK methods for solving Stratonovich SDEs and also construct an explicit strong global order 1.0 two-stage RK method with

minimum principal error constants [17] and an explicit five-stage RK method with strong global order 1.5 [8]. Tian and Burrage [26] consider diagonally semi-implicit and implicit strong order 1.0 two-stage RK methods with good stability properties or good accuracy. In addition, in order to avoid the unboundedness of numerical solutions of the implicit stochastic RK methods, composite RK methods are constructed which are a combination of semi-implicit RK methods and implicit RK methods. Further research has been done by Komori, Mitsui, and Sugiura [18], in which they use the tree expansions of the true and numerical solutions to construct ROW-type schemes for SDEs.

For solving SDEs, the PC technique has been already applied to linear multistep implicit methods [1]. For weak solutions of SDEs, Kloeden and Platen [17] and Platen [21] consider families of PC methods with weak order 1.0 and 2.0. In this paper we consider PC methods using stochastic RK methods as correctors for strong solutions of SDEs. In section 2, we first give a brief review of the rooted tree theory for constructing RK methods and RK-type PC methods for ODEs and then give order conditions for constructing stochastic RK-type PC methods after a brief review of the colored rooted tree theory for constructing stochastic RK methods. In section 3, we give the detailed order conditions for two-stage RK-type PC methods with strong global order 1.0 and then construct a two-stage implicit RK method with strong global order 1.0. Similar work is done for four-stage RK-type PC methods with strong global order 1.5 in section 4. The mean-square stability properties of the RK-type PC methods using these two-stage and four-stage implicit RK correctors are considered in section 5. Numerical results are reported in section 6.

2. Order conditions for RK-type PC methods. In this section, a brief review is first given for the rooted tree theory and order conditions for constructing RK-type PC methods for ODEs. For solving the ODE

$$y'(t) = f(y(t)), \qquad y(t_0) = y_0, \qquad t \in [t_0, T], \quad y \in \mathbb{R}^m,$$

the class of s-stage RK methods is given by

$$\begin{aligned} Y_i &= y_n + h\sum_{j=1}^{s} a_{ij} f(Y_j), \qquad i = 1, 2, \dots, s, \\ y_{n+1} &= y_n + h\sum_{j=1}^{s} b_j f(Y_j), \end{aligned} \tag{2.1}$$

which can be represented by the so-called Butcher tableau

$$\begin{array}{c|c} \mathrm{c} & \mathrm{A} \\ \hline & \mathrm{b}^{\top} \end{array}, \qquad c = Ae, \qquad e = (1, \dots, 1)^{\top} \in \mathbb{R}^s. \tag{2.2}$$

In order to express derivatives of $f(y)$ systematically, Butcher [13] introduced the rooted tree theory which provides a general framework for studying order conditions of RK methods. Let T be the set of rooted trees and $t = [t_1, \dots, t_m]$ be the tree formed by joining subtrees $t_1, \dots, t_m$ each by a single branch to a common root. In addition, let ϕ denote the empty tree and τ the unique tree with one node. For each t, denote $\rho(t)$ as the number of nodes (vertices) of t, $h(t)$ as the height of t, with the height of the unique tree τ being 1, respectively. Then the elementary differential associated with $t = [t_1, \dots, t_m]$ is given by

$$F(t)y = f^{(m)}(F(t_1)y, \dots, F(t_m)y), \qquad F(\phi) = y.$$

With these definitions, the following order theorem holds for RK methods (see Burrage [6]).

THEOREM 2.1. *A RK method is of order w if and only if*

$$e(t) = 0 \qquad \forall \rho(t) \leq w,$$

where for any tree $t = [t_1, \ldots, t_m]$

$$e(\phi) = 0, \qquad e(t) = 1 - \rho(t) b^\top \prod_{j=1}^{m} k(t_j),$$

with

$$k(\phi) = e, \qquad k(t) = \rho(t) \prod_{j=1}^{m} \left(A k(t_j) \right).$$

Now consider a RK-type PC method which uses a RK corrector (2.1) and the trivial predictor based on the update value y_n, given by

$$\begin{aligned} Y^{(0)} &= (e \otimes I) y_n, \\ Y^{(k)} &= (e \otimes I) y_n + h(A \otimes I) f(Y^{(k-1)}), \qquad k = 1, 2, \ldots, l, \\ y_{n+1} &= y_n + h b^\top f(Y^{(l)}), \end{aligned}$$

where $Y = (Y_1^\top, \ldots, Y_s^\top)^\top$ and $f(Y) = (f(Y_1)^\top, \ldots, f(Y_s)^\top)^\top$. This method can be represented by a $(l+1)s$-stage explicit RK method, whose Butcher tableau is given by

$$\begin{array}{c|ccccc} 0 & 0 & & & & \\ \mathrm{c} & \mathrm{A} & 0 & & & \\ \mathrm{c} & 0 & \mathrm{A} & 0 & & \\ \vdots & \vdots & \ddots & \ddots & \ddots & \\ \mathrm{c} & 0 & \cdots & 0 & \mathrm{A} & 0 \\ \hline & 0 & \cdots & 0 & 0 & b^\top \end{array} .$$

Applying the order conditions for RK methods (Theorem 2.1) to this $(l+1)s$-stage explicit RK method, Burrage [2], [3], [6] presents a theoretical tool for measuring the error behavior of this RK-type PC method and gives the order conditions of this method.

THEOREM 2.2. *If a RK corrector is applied to the trivial predictor with l corrections, then the local error is given by*

$$l_{n+1} = \sum_{t \in T^*} e(t) \left[F(t) \right] y(t_n) \frac{h^{\rho(t)}}{\rho(t)!},$$

where for $t = [t_1, \ldots, t_m]$

$$e(t) = 1 - \rho(t) b^\top \prod_{i=1}^{m} k_l(t_i), \tag{2.3}$$

with

$$
\begin{aligned}
&k_0(\phi) = e, \quad k_0(t) = 0, \quad \rho(t) > 0,\\
&k_{j+1}(t) = \rho(t) \prod_{i=1}^{m} \left(A k_j(t_i)\right), \qquad j = 0, 1, \ldots, l-1.
\end{aligned} \tag{2.4}
$$

By studying the behavior of the local errors of a RK-type PC method, Burrage [2], [6] has shown that each application of a corrector increases the order of the overall method by one until the order of the corrector is reached. In addition, when the number of corrections is such that the order cannot increase further, then the effect of more corrections is to shift the errors due to the predictor further away from the principal error terms.

Now we consider the order conditions of stochastic RK-type PC methods for the Stratonovich SDE driven by d-dimensional Wiener processes

$$
dy(t) = g_0(y(t))dt + \sum_{j=1}^{d} g_j(y(t)) \circ dW_j(t), \qquad y(t_0) = y_0, \quad y \in \mathbb{R}^m, \tag{2.5}
$$

where the deterministic term $g_0(y(t))$ is the drift coefficient, the stochastic term $g_j(y(t))$ $(j = 1, \ldots, d)$ are the diffusion coefficients, and $W_j(t)$ is the Wiener process, whose increment $\Delta W_j(t) = W_j(t + \Delta t) - W_j(t)$ is a Gaussian random variable $N(0, \Delta t)$.

The solution of (2.5) can be written in integral form as

$$
y(t) = y(t_0) + \int_{t_0}^{t} g_0(y(t))dt + \sum_{j=1}^{d} \int_{t_0}^{t} g_j(y(t)) \circ d_j W(t),
$$

and can also be expressed as a stochastic Taylor series, given by

$$
\begin{aligned}
y(t) = y_0 &+ \sum_{j_1=0}^{d} g_{j_1}(y_0) J_{j_1,t} + \sum_{j_1,j_2=0}^{d} L^{j_1} g_{j_2}(y_0) J_{j_1 j_2, t}\\
&+ \sum_{j_1,j_2,j_3=0}^{d} L^{j_1} L^{j_2} g_{j_3}(y_0) J_{j_1 j_2 j_3, t} + \cdots,
\end{aligned} \tag{2.6}
$$

where the Stratonovich operator is defined by

$$
L^j = \sum_{k=1}^{m} g_j^k \frac{\partial}{\partial y^k}, \qquad j = 0, 1, \ldots, d
$$

and $J_{j_1,\ldots,j_k,t}$ represents the Stratonovich multiple integral which is defined recursively by (see [16] and [17])

$$
\begin{aligned}
J_{0,t} &= \int_{t_0}^{t} dt = t - t_0,\\
J_{j,t} &= \int_{t_0}^{t} \circ dW_j(t) = \Delta W_j(t),\\
J_{j_1 j_2 \cdots j_{k-1} j_k, t} &= \int_{t_0}^{t} J_{j_1 j_2 \cdots j_{k-1}, t} dt, \qquad j_k = 0,\\
J_{j_1 j_2 \cdots j_{k-1} j_k, t} &= \int_{t_0}^{t} J_{j_1 j_2 \cdots j_{k-1}, t} \circ dW_j(t), \qquad j_k = j, \quad j = 1, \ldots, d.
\end{aligned}
$$

In order to express the stochastic Taylor series more precisely, Burrage and Burrage present the colored rooted tree theory [7] and stochastic B-series [8] which have the same structure as the corresponding rooted tree theory and B-series.

DEFINITION 2.3. *The $(d+1)$-colored rooted trees can be defined recursively by*

(i) *the elementary rooted tree is τ_k which represent the deterministic elementary rooted tree τ_0 if $k=0$ and a stochastic one τ_k if $k \in \{1,2,\dots,d\}$;*

(ii) *if $t_1,\dots,t_m$ are $(d+1)$-colored rooted trees, then $[t_1,\dots,t_m]_k$ is the $(d+1)$-colored rooted tree in which $t_1,\dots,t_m$ are each joined by a single branch to τ_k ($k \in \{1,2,\dots,d\}$).*

Similar to the rooted tree theory for ODEs, denote T_1 as the set of all $(d+1)$-colored rooted trees, $\rho(t)$ as the number of vertices of t, $\alpha(t)$ as the number of ways of labelling the vertices of t so that the labels increase outwardly along the arcs, $h(t)$ as the height of t where the height of the elementary tree is 1, and $\gamma(t)$ as the density of $t=[t_1,\dots,t_m]_k$, defined by

$$\gamma(t) = \rho(t)\prod_{j=1}^{m}\gamma(t_j)$$

and where $J(t)$ represents the corresponding J-integral associated with tree t which is defined by

$$J(t)(h) = \int_0^h \prod_{j=1}^{m} J(t_j)(s)\circ dW_k(s), \qquad J(\tau_k)(h) = W_k(h).$$

In a similar manner to the deterministic case, an elementary differential can be associated with any $t \in T_1$ such that

$$\begin{aligned} F(\tau_k)(y) &= g_k(y),\\ F(t)(y) &= g_k^{(m)}(y)[F(t_1)(y),\dots,F(t_m)(y)], \qquad t=[t_1,\dots,t_m]_k. \end{aligned}$$

With the definitions of $(d+1)$-colored rooted trees, Burrage and Burrage [7] and Burrage [12] have given the Taylor series expansion of the exact solution of an SDE.

THEOREM 2.4. *The Stratonovich–Taylor series for the actual solution of the SDE given by* (2.5) *(together with initial value $y(t_0)=y_0$) is*

$$y(t_0+h) = \sum_{t\in T_1}\frac{\gamma(t)}{\rho(t)!}J(t)\alpha(t)F(t)(y(t_0)),$$

where $F(t)(y)$ is the elementary differential defined by the structure of tree t, and $J(t)$ represents the corresponding J-integral associated with tree t.

For solving the SDE (2.5), a general class of s-stage stochastic RK method derived by Burrage and Burrage [7] and Burrage [12] is given by

$$\begin{aligned} Y_i &= y_n + \sum_{k=0}^{d}\sum_{j=1}^{s} Z_{ij}^{(k)} g_k(Y_j), \qquad i=1,\dots,s,\\ y_{n+1} &= y_n + \sum_{k=0}^{d}\sum_{j=1}^{s} z_j^{(k)} g_k(Y_j), \end{aligned} \tag{2.7}$$

where $Z_{ij}^{(k)}$ and $z_j^{(k)}$ are random variables, which are functions of h, to be determined based on order and stability analysis. Note that in the case of the deterministic parameters $Z^{(0)}$ and $z^{(0)}$, h is included implicitly in these terms.

The numerical solution obtained by the stochastic RK method (2.7) can be written as a Taylor series expansion [7], given by

$$y(t_0 + h) = \sum_{t \in T} \frac{\gamma(t)}{\rho(t)!} a(t)\alpha(t)F(t)(y(t_0)),$$

where, for $t = [t_1, \ldots, t_m]_k$, $a(t)$ is defined by

$$a(t) = z^{(k)\top}\Phi(t),$$
$$\Phi(t) = \prod_{i=1}^{m} (Z^{(k)}\Phi(t_i)), \qquad \Phi(\tau_k) = e.$$

In designing numerical schemes for solving SDEs, some criteria are needed to measure the efficiency of a numerical scheme by means of its order of convergence. There are two criteria to measure the convergence order: strong convergence and weak convergence. For problems involving direct simulations of paths, it is required that the simulated sample paths be close to the exact solution of the original SDE. This consideration leads to the strong convergence criterion (for example, see Burrage [12]).

DEFINITION 2.5. *Let y_N be the numerical approximation to $y(t_N)$ at time $T = Nh + t_0$ after N steps with constant stepsize h; then y is said to converge strongly to y with order p if $\exists C > 0$ (independent of h but dependent on the length of the time interval $T - t_0$) and $\delta > 0$ such that*

$$E(|y_N - y(t_N)|) \le Ch^p, \qquad h \in (0, \delta).$$

The local truncation error at $t = t_{n+1}$ of the stochastic RK method (2.7) can be written as

$$L_n = \sum_{t \in T_1} \frac{\gamma(t)}{\rho(t)!} \alpha(t) \left(J(t) - a(t)\right) F(t)(y(t_n)).$$

Burrage and Burrage [8] have given the following definition to measure the accuracy of the RK methods

DEFINITION 2.6. *This stochastic RK method will have strong local order p if*

$$E[|L_n|] = O(h^{p+\frac{1}{2}})$$

and will have mean local order p if

$$E(L_n) = O(h^{p+1}).$$

In addition they have proven the following theorem concerning the relationship between the local error behavior and the global error behavior (see also Milstein [19]), given by the following theorem.

THEOREM 2.7. *Let the g_j possess all necessary partial derivatives for all $y \in \mathbb{R}^m$; then if*

$$\left(E\left[||l_n||^2\right]\right)^{1/2} = O(h^{p+1/2}) \quad \forall n$$

and

$$E[l_n] = O\left(h^{p+1}\right) \quad \forall n,$$

then

$$\left(E\left[||\epsilon_N||^2\right]\right)^{1/2} = O\left(h^p\right),$$

where ϵ_N is the global error at step point t_N with the assumption of the exact initial solution of $y_0 = y(t_0)$.

Thus the stochastic RK method (2.7) is of strong global order p if it has strong local order p and mean local order p.

For solving the SDE (2.5), the stochastic RK-type PC method, which is based on a stochastic RK corrector (2.7) and the trivial predictor, is given by

$$\begin{aligned} Y^{(0)} &= (e \otimes I) y_n, \\ Y^{(i)} &= (e \otimes I) y_n + \sum_{k=0}^{d} (Z^{(k)} \otimes I) g_k(Y^{(i-1)}), \qquad i = 1, 2, \ldots, l, \\ y_{n+1} &= y_n + \sum_{k=0}^{d} (z^{(k)} \otimes I) g_k(Y^{(l)}), \end{aligned} \tag{2.8}$$

where $Y^{(i)} = (Y_1^{(i)\top}, \ldots, Y_s^{(i)\top})^\top$, $Z^{(k)} = (Z_{ij}^{(k)})_{s\times s}$, and $z^{(k)} = (z_1^{(k)}, \ldots, z_s^{(k)})$, $(k = 0, 1, \ldots, d)$. This stochastic RK-type PC method can be represented by an $(l+1)s$-stage block explicit stochastic RK method characterized by the tableau

$$\begin{array}{c|ccccc|ccccc|c} 0 & & & & & & 0 & & & & & \\ Z^{(0)} & 0 & & & & \cdots\ \cdots & Z^{(d)} & 0 & & & & \\ 0 & Z^{(0)} & 0 & & & \cdots\ \cdots & 0 & Z^{(d)} & 0 & & & \\ \vdots & \ddots & \ddots & \ddots & & \cdots\ \cdots & \vdots & \ddots & \ddots & \ddots & & \\ 0 & \cdots & 0 & Z^{(0)} & 0 & \cdots\ \cdots & 0 & \cdots & 0 & Z^{(d)} & 0 & \\ \hline 0 & \cdots & 0 & 0 & z^{(0)} & \cdots\ \cdots & 0 & \cdots & 0 & 0 & z^{(d)} & \end{array}.$$

Applying the order theorem for stochastic RK methods to (2.8), we have the main theorem on order conditions for constructing stochastic RK-type PC methods (2.8) in this paper.

THEOREM 2.8. *If a stochastic RK corrector is applied to the trivial predictor with l corrections, then the strong local error of the stochastic RK-type PC method is given by*

$$l_{n+1} = \sum_{t\in T_1} \frac{\gamma(t)}{\rho(t)!} e(t)\alpha(t)[F(t)]y(t_n),$$

where for $t = [t_1, \ldots, t_m]_k$ $e(t) = J(t) - a_l(t)$ and $a_l(t)$ is given by

$$a_l(t) = z^{(k)}\Phi_l(t),$$

and

$$\begin{aligned} \Phi_0(\tau_k) &= e, \quad \Phi_0(t) = 0, \quad \rho(t) \geq 2, \\ \Phi_{j+1}(t) &= \prod_{i=1}^{m} (Z^{(k)}\Phi_j(t_i)). \end{aligned}$$

As a special case the expressions of $a_l(t)$ are considered with a different number of corrections. When no correction is performed ($l = 0$), then

$$\begin{aligned} t_1 &= \tau_j, & a_0(t_1) &= z^{(j)}e, \\ t_2 &= \tau_0, & a_0(t_2) &= z^{(0)}e, \\ h(t) &\geq 2, & a_0(t) &= 0. \end{aligned}$$

Here for t_1, $j = 1, 2, \ldots, d$. This notation is also valid for trees $t_3 \sim t_{18}$ in the following discussion.

If one correction is performed ($l = 1$), the expressions for $a_1(t)$ associated with trees t_1 and t_2 are the same as the corresponding $a_0(t)$, namely $a_1(t_i) = a_0(t_i)$ ($i = 1, 2$). For trees with more vertices, then, assuming that the j_i are nonzero,

$$\begin{aligned} t_3 &= [\tau_{j_1}]_{j_2}, & a_1(t_3) &= z^{(j_2)}Z^{(j_1)}e, \\ t_4 &= [\tau_0]_{j_1}, & a_1(t_4) &= z^{(j_1)}Z^{(0)}e, \\ t_5 &= [\tau_{j_1}]_0, & a_1(t_5) &= z^{(0)}Z^{(j_1)}e, \\ t_6 &= [\tau_0]_0, & a_1(t_6) &= z^{(0)}Z^{(0)}e, \\ t_7 &= [\tau_{j_1}, \tau_{j_2}]_{j_3}, & a_1(t_7) &= z^{(j_3)}(Z^{(j_1)}e)(Z^{(j_2)}e), \\ t_8 &= [\tau_{j_1}, \tau_{j_2}]_0, & a_1(t_8) &= z^{(0)}(Z^{(j_1)}e)(Z^{(j_2)}e), \\ t_9 &= [\tau_{j_1}, \tau_0]_{j_2}, & a_1(t_9) &= z^{(j_2)}(Z^{(j_1)}e)(Z^{(0)}e), \\ t_{10} &= [\tau_0, \tau_{j_1}]_{j_2}, & a_1(t_{10}) &= z^{(j_2)}(Z^{(0)}e)(Z^{(j_1)}e), \\ t_{11} &= [\tau_{j_1}, \tau_{j_2}, \tau_{j_3}]_{j_4}, & a_1(t_{11}) &= z^{(j_4)}(Z^{(j_1)}e)(Z^{(j_2)}e)(Z^{(j_3)}e), \\ h(t) &\geq 3, & a_1(t) &= 0. \end{aligned}$$

If two corrections are performed ($l = 2$), the expressions for $a_2(t)$ associated with trees $t_1, \ldots, t_{11}$ are the same as the corresponding $a_1(t)$, namely $a_2(t_i) = a_1(t_i)$ ($i = 1, \ldots, 11$). For trees with more vertices, then

$$\begin{aligned} t_{12} &= [[\tau_{j_1}]_{j_2}]_{j_3}, & a_2(t_{12}) &= z^{(j_3)}Z^{(j_2)}Z^{(j_1)}e, \\ t_{13} &= [[\tau_0]_{j_1}]_{j_2}, & a_2(t_{13}) &= z^{(j_2)}Z^{(j_1)}Z^{(0)}e, \\ t_{14} &= [[\tau_{j_1}]_0]_{j_2}, & a_2(t_{14}) &= z^{(j_2)}Z^{(0)}Z^{(j_1)}e, \\ t_{15} &= [[\tau_{j_1}]_{j_2}]_0, & a_2(t_{15}) &= z^{(0)}Z^{(j_2)}Z^{(j_1)}e, \\ t_{16} &= [[\tau_{j_1}]_{j_2}, \tau_{j_3}]_{j_4}, & a_2(t_{16}) &= z^{(j_4)}(Z^{(j_2)}Z^{(j_1)}e)(Z^{(j_3)}e), \\ t_{17} &= [[\tau_{j_1}, \tau_{j_2}]_{j_3}]_{j_4}, & a_2(t_{17}) &= z^{(j_4)}Z^{(j_3)}((Z^{(j_1)}e)(Z^{(j_2)}e)), \\ h(t) &\geq 4, & a_2(t) &= 0. \end{aligned}$$

When a stochastic RK-type PC method is corrected three times, the expressions for $a_3(t)$ associated with trees t_i ($i = 1, \ldots, 17$) are the same as the corresponding $a_2(t)$, namely

$$a_3(t_i) = a_2(t_i), \qquad i = 1, \ldots, 17.$$

For the analysis of the stochastic RK-type PC methods in this paper, we need only consider additionally the expression $a_3(t)$ for the tree $[[[\tau_{j_1}]_{j_2}]_{j_3}]_{j_4}$, where none of the j_i is zero, given by

$$t_{18} = [[[\tau_{j_1}]_{j_2}]_{j_3}]_{j_4}, \qquad a_3(t_{18}) = z^{(j_4)}Z^{(j_3)}Z^{(j_2)}Z^{(j_1)}e.$$

In the following sections the order conditions associated with trees $t_1, \ldots, t_{18}$ are used to construct stochastic RK-type PC methods.

3. Strong order 1.0 RK methods. The order theory developed in section 2 will apply to the very general class of problems (2.5) with $d > 1$. However, due to spatial constraints and the extreme difficulty in solving the order conditions for the arbitrary d case, we will focus on constructing effective PC methods for $d = 1$.

The s-stage RK methods with one stochastic variable $J_1 \sim N(0, h)$ are given by

$$\begin{aligned} Y =& (e \otimes I)y_n + h(A \otimes I)g_0(Y) + J_1(B \otimes I)g_1(Y), \\ y_{n+1} =& y_n + h(\alpha^\top \otimes I)g_0(Y) + J_1(\beta^\top \otimes I)g_1(Y), \end{aligned} \tag{3.1}$$

where A and B are $s \times s$ matrices, while α and β are s-dimensional vectors. According to the theorems given by Rümelin [22] and Burrage, Burrage, and Belward [9], the maximum strong global order of these stochastic RK methods is 1.0.

For the trivial predictor, the stochastic RK-type PC method using (3.1) as the corrector is given by

$$\begin{aligned} Y^{(0)} &= (e \otimes I)y_n, \\ Y^{(i)} &= (e \otimes I)y_n + h(A \otimes I)g_0(Y^{(i-1)}) + J_1(B \otimes I)g_1(Y^{(i-1)}), \quad i = 1, \cdots, l, \\ y_{n+1} &= y_n + h(\alpha^\top \otimes I)g_0(Y^{(l)}) + J_1(\beta^\top \otimes I)g_1(Y^{(l)}). \end{aligned} \tag{3.2}$$

Now consider the order conditions of the RK-type PC method (3.2). If no correction is performed, the local truncation error of this method is given by

$$l_{10} = h(1 - \alpha^\top e)F(\tau_0)(y(t_n)) + J_1(1 - \beta^\top e)F(\tau_1)(y(t_n)) + \sum_{\rho(t)\geq 2} J(t)F(t)(y(t_n)).$$

Assuming that

$$\alpha^\top e = 1, \qquad \beta^\top e = 1, \tag{3.3}$$

this method will have strong local order 0.5, namely $E(l_{10}^2) = O(h^2)$. In this case the PC method (3.2) is equivalent in strong order to the Euler–Maruyama method, given by

$$y_{n+1} = y_n + hg_0(y_n) + J_1 g_1(y_n).$$

It is well known that the numerical solution of the Euler–Maruyama method converges to the exact solution of the corresponding Itô SDE. Thus the numerical solution of method (3.2) without any correction may not converge to the exact solution of the Stratonovich SDE (2.5).

If one correction is performed ($l = 1$), method (3.2) will have strong local order 1.0 if, in addition to (3.3),

$$e(t_3) = J(t_3) - a(t_3) = \left(\frac{1}{2} - \beta^\top Be\right) J_1^2 = 0,$$

which is equivalent to

$$\beta^\top Be = \frac{1}{2}. \tag{3.4}$$

At the same time this method will have mean local error 1.0 as

$$E(e(t_i)) = 0, \qquad i = 4, 5, 7, 12,$$

where trees t_4, t_5, t_7, and t_{12} are those associated with terms corresponding to $h^{1.5}$. Thus the stochastic RK-type PC method (3.2) will have strong global order 1.0 if one correction is applied and the order conditions (3.3) and (3.4) are satisfied at the same time.

The order conditions (3.3) and (3.4) of the stochastic RK-type PC method with strong global order 1.0 are the same as those of the stochastic RK methods (3.1) with strong global order 1.0, given in [12]. Thus the strong global order of the RK-type PC method (3.2) is 1.0 if the strong global order of the original stochastic RK method (3.1) is 1.0 and one correction is applied.

Now we construct a two-stage implicit RK method. As there are only three order conditions in (3.3) and (3.4) and 12 coefficients in this method, additional conditions can be considered. For example, we can consider the stochastic order conditions on which the terms corresponding to $h^{1.5}$ have minimum coefficients, namely the stochastic order conditions for minimum principal error coefficients. The principal error coefficients are minimized if [12]

$$\alpha^\top Be = \frac{1}{2}, \quad \beta^\top Ae = \frac{1}{2}, \quad \beta^\top (Be)^2 = \frac{1}{3}, \quad \beta^\top B(Be) = \frac{1}{6}.$$

These four conditions are called the minimum principal error conditions.

Combining the order conditions (3.3) and (3.4) and the minimum principal error conditions together and assuming that $A = B$ and $\alpha = \beta$, we have the following two-stage implicit RK corrector method with strong global order 1.0, called IRK2, given by

$$\begin{array}{c|cccc} \frac{1}{3} & \frac{1}{4} & \frac{1-\sqrt{3}}{6} & \frac{1}{3} & \frac{1-\sqrt{3}}{6} \\ \frac{1+\sqrt{3}}{6} & \frac{1}{3} & \frac{1}{4} & \frac{1+\sqrt{3}}{6} & \frac{1}{3} \\ \hline & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{array} . \tag{3.5}$$

4. Strong order 1.5 RK methods. The second special class of the stochastic RK methods (2.7) that will be discussed is those with two stochastic variables J_1 and J_{10}/h, for solving problems of the form (2.5) with $d = 1$, given by

$$\begin{aligned} Y = \quad & (e \otimes I) y_n + h(A \otimes I) g_0(Y) + \left(J_1 (B_1 \otimes I) + \frac{J_{10}}{h} (B_2 \otimes I) \right) g_1(Y), \\ y_{n+1} = \quad & y_n + h(\alpha^\top \otimes I) g_0(Y) + \left(J_1 (\beta_1^\top \otimes I) + \frac{J_{10}}{h} (\beta_2^\top \otimes I) \right) g_1(Y), \end{aligned} \tag{4.1}$$

where A, B_1, and B_2 are $s \times s$ matrices and α, β_1, and β_2 are s-dimensional vectors. Here we remind readers that on the interval $[t_n, t_{n+1}]$, J_1 and J_{10}/h are closely related. In particular, if u and v are two independent $N(0, 1)$ random variables, then

$$J_1 = u\sqrt{h}, \qquad \frac{J_{10}}{h} = \frac{\sqrt{h}}{2} \left(u + \frac{v}{\sqrt{3}} \right).$$

Burrage and Burrage [7], [8] and Burrage [12] first present this class of stochastic RK methods and study the order conditions of these methods based on the colored

rooted tree theory and stochastic B-series. A five-stage explicit stochastic RK method with strong global order 1.5 is presented in [8].

For the trivial predictor, the stochastic RK-type PC method using (4.1) as a corrector is given by

(4.2)
$$\begin{aligned} Y^{(0)} =& (e \otimes I) y_n, \\ Y^{(i)} =& (e \otimes I) y_n + h(A \otimes I) g_0(Y^{(i-1)}) + \left(J_1 (B_1 \otimes I) + \frac{J_{10}}{h} (B_2 \otimes I) \right) g_1(Y^{(i-1)}), \\ & i = 1, \dots, l, \\ y_{n+1} =& y_n + h(\alpha^\top \otimes I) g_0(Y^{(l)}) + \left(J_1 (\beta_1^\top \otimes I) + \frac{J_{10}}{h} (\beta_2^\top \otimes I) \right) g_1(Y^{(l)}). \end{aligned}$$

Now consider the order conditions for this RK-type PC method. When one correction is performed, the order conditions necessary for strong order 1.5 associated with trees $t_1, \dots, t_{11}$ are given by

$$E\left(e^2(t_i)\right) = 0, \qquad i = 1, \dots, 11.$$

Let $c = Ae$, $b = B_1 e$, and $d = B_2 e$; the above order conditions are equivalent to (see [7] and [12])

(4.3)
$$\begin{aligned} \alpha^\top (e, c, d, b) &= \left(1, \frac{1}{2}, 1, 0 \right), \\ \beta_1^\top (e, c, b, d, b^2, d^2) &= \left(1, 1, \frac{1}{2}, -\beta_2^\top b, \frac{1}{3}, -2\beta_2^\top bd \right), \\ \beta_2^\top (e, c, d, b^2, d^2) &= (0, -1, 0, -2\beta_1^\top bd, 0). \end{aligned}$$

When method (4.2) is corrected twice, the order condition associated with tree t_{12} is $E(e^2(t_{12})) = 0$, which is equivalent to (see [7] and [12])

(4.4)
$$\begin{aligned} &\beta_1^\top B_1 b = \tfrac{1}{6}, \quad \beta_2^\top B_1 b + \beta_1^\top (B_2 b + B_1 d) = 0, \\ &\beta_2^\top B_2 d = 0, \quad \beta_1^\top B_2 d + \beta_2^\top (B_2 b + B_1 d) = 0. \end{aligned}$$

In order to get mean local order 1.5, it is necessary that the following mean order conditions should be satisfied:

$$E\left(e(t_i)\right) = 0, \qquad i = 8, 9, 11, 13, 14, 15, 16, 17,$$

which are equivalent to (see [8])

$$\begin{aligned} 0 &= \alpha^\top B_1 b + \frac{1}{2} \alpha^\top (B_1 d + B_2 b) + \frac{1}{3} \alpha^\top B_2 d, \\ 0 &= \alpha^\top \left(b^2 + bd + \frac{1}{3} d^2 \right), \\ 0 &= \beta_1^\top Ab + \frac{1}{2} \left(\beta_1^\top Ad + \beta_2^\top Ab \right) + \frac{1}{3} \beta_2^\top Ad, \\ 0 &= \beta_1^\top \left(cb + \frac{1}{2} cd \right) + \beta_2^\top \left(\frac{1}{2} cb + \frac{1}{3} cd \right), \end{aligned}$$

$$
\begin{aligned}
0 &= \beta_1^\top \left(B_1 c + \frac{1}{2} B_2 c \right) + \beta_2^\top \left(\frac{1}{2} B_1 c + \frac{1}{3} B_2 c \right), \\
\frac{3}{8} &= \beta_1^\top \mathrm{Diag}(b) \left(3B_1 b + \frac{3}{2} (B_1 d + B_2 b) + \frac{5}{6} B_2 d \right) \\
&\quad + \beta_2^\top \mathrm{Diag}(d) \left(\frac{5}{6} B_1 b + \frac{1}{2} (B_1 d + B_2 b) + \frac{1}{3} B_2 d \right) \\
&\quad + \left(\beta_1^\top \mathrm{Diag}(d) + \beta_2^\top \mathrm{Diag}(b) \right) \left(\frac{3}{2} B_1 b + \frac{5}{6} (B_1 d + B_2 b) + \frac{1}{2} B_2 d \right), \\
\frac{1}{4} &= \beta_1^\top \left(B_1 \left(3b^2 + 3bd + \frac{5}{6} d^2 \right) + B_2 \left(\frac{3}{2} b^2 + \frac{5}{3} bd + \frac{1}{2} d^2 \right) \right) \\
&\quad + \beta_2^\top \left(B_1 \left(\frac{3}{2} b^2 + \frac{5}{3} bd + \frac{1}{2} d^2 \right) + B_2 \left(\frac{5}{6} b^2 + bd + \frac{1}{3} d^2 \right) \right), \\
\frac{3}{4} &= \beta_1^\top \left(3b^3 + \frac{9}{2} b^2 d + \frac{5}{2} bd^2 + \frac{1}{2} d^3 \right) + \beta_2^\top \left(\frac{3}{2} b^3 + \frac{5}{2} b^2 d + \frac{3}{2} bd^2 + \frac{1}{3} d^3 \right).
\end{aligned} \tag{4.5}
$$

It should be noticed that, for expectation in the mean, trees t_9 and t_{10} are equivalent.

However, when two corrections are performed and all of the order conditions (4.3)∼(4.5) are satisfied, the strong local order of the RK-type PC method (4.2) is 1.5, but the mean local order of this method is still 1.0 as the mean order condition associated with tree t_{18} is not satisfied, since the height of t_{18} is 4 and so $a_2(t_{18}) = 0$. In order to get a RK-type PC method with strong global order 1.5, a third correction is needed. When a third correction is performed, the mean order condition associated with tree t_{18} is given by $E\left(e(t_{18})\right) = 0$, which is equivalent to [8]

$$
\begin{aligned}
\frac{1}{8} =& \beta_1^\top \left(B_1^2 \left(3b + \frac{3}{2} d \right) + B_2^2 \left(\frac{5}{6} b + \frac{1}{2} d \right) + (B_1 B_2 + B_2 B_1) \left(\frac{3}{2} b + \frac{5}{6} d \right) \right) \\
&+ \beta_2^\top \left(B_1^2 \left(\frac{3}{2} b + \frac{5}{6} d \right) + B_2^2 \left(\frac{1}{2} b + \frac{1}{3} d \right) + (B_1 B_2 + B_2 B_1) \left(\frac{5}{6} b + \frac{1}{2} d \right) \right).
\end{aligned} \tag{4.6}
$$

The order conditions (4.3)∼(4.6) of the stochastic RK-type PC method with strong global order 1.5 are the same as those of the stochastic RK method (4.1) with strong global order 1.5, given in [8]. Thus the strong global order of the RK-type PC method (4.2) with three corrections is 1.5 if the strong global order of the original RK method (4.1) is 1.5.

Now an implicit four-stage RK method with strong global order 1.5 is constructed. In order to have small error coefficients for the deterministic terms, the following additional order conditions are considered here, given by

$$
\alpha^\top A c = \frac{1}{6}, \quad \alpha^\top A c^2 = \frac{1}{12}, \quad \alpha^\top \mathrm{Diag}(c) A c = \frac{1}{8}, \quad \alpha^\top A^2 c = \frac{1}{24}. \tag{4.7}
$$

Using Maple to solve all of the order conditions (4.3)∼(4.7), we have the following strong global order 1.5 RK corrector method, which is called IRK4, with matrices A, B_1, and B_2:

$$
A = \begin{pmatrix}
1.00436335789 & -0.56006282797 & -0.41253045082 & -0.03177007950 \\
-0.04300768840 & -0.12902306500 & -0.04300768833 & -0.04300768833 \\
2.26132980150 & -2.30000000000 & 0.11987418760 & -0.33925011871 \\
3.51937593150 & -2.30000000000 & 0.11987418760 & -0.33925011871
\end{pmatrix},
$$

$$B^{(1)} = \begin{pmatrix} 0.10566243265 & 0.03522081088 & 0.03522081088 & 0.03522081088 \\ 0.19716878372 & 0.19716878372 & 0.19716878372 & 0.19716878372 \\ -0.19879713087 & 0.53213046420 & 0.50000000000 & 0.16666666667 \\ 0.16666666667 & 0.16666666667 & 0.16666666667 & 0.50000000000 \end{pmatrix},$$

$$B^{(2)} = \begin{pmatrix} 6.2322500476 & -3.7052829175 & -3.7979991039 & 1.2710319739 \\ -4.6564739362 & 2.8209539211 & 3.0265200151 & -1.1910000000 \\ -8.0122402257 & 3.2818190506 & 3.4496446680 & -1 \\ -9.7304211738 & 5 & 5 & -2.5503553321 \end{pmatrix},$$

and weight vectors $\alpha^\top$, $\gamma^{(1)\top}$, and $\gamma^{(2)\top}$:

$$\begin{array}{rcl} \alpha^\top & = & (1.205542599,\ 0.2329045687,\ -0.7937286771,\ 0.3552815092), \\ \gamma^{(1)\top} & = & (\ 0.5,\ 0.5,\ -0.8974417060,\ 0.8974417060), \\ \gamma^{(2)\top} & = & (\ 0,\ 0,\ 0.7948834118,\ -0.7948834118). \end{array}$$

Remark. This method requires only four parallel stages and three sequential stages (cf. the strong order 1.5 explicit stochastic RK method G5 of [8] which requires five sequential stages) and so is implemented efficiently on a four processor computer.

5. Stability properties of RK-type PC methods. In this paper the following linear test equation of Stratonovich type, given by

$$dy = aydt + by \circ dW(t), \qquad y(0) = y_0, \tag{5.1}$$

is used to discuss the stability properties of stochastic RK-type PC methods.

Applying a one-step numerical scheme to (5.1), this numerical scheme is represented by

$$y_{n+1} = R(h, a, b)y_n.$$

Saito and Mitsui [24] introduced the definition of mean-square (MS) stability.

DEFINITION 5.1. *A numerical scheme is said to be MS-stable for h, a, and b if*

$$\overline{R}(h, a, b) = E(|R(h, a, b)|^2) < 1.$$

$\overline{R}(h, a, b)$ is called the MS-stability function of the numerical scheme.

Another important stability definition is that of asymptotic stability. Saito and Mitsui [23] introduced the definition of T-stability to measure asymptotic stability and give two examples on the T-stability properties of numerical methods for weak solutions. Burrage and Tian [11] present a method to measure the T-stability for strong solutions and give the definition of T(A)-stability. Here we just consider the MS-stability properties of the stochastic RK-type PC methods presented in this paper.

Applying the stochastic RK-type PC methods (2.8) to (5.1) gives

$$\begin{aligned} Y^{(0)} &= ey_n, \\ Y^{(i)} &= ey_n + aZ^{(0)}Y^{(i-1)} + bZ^{(1)}Y^{(i-1)} \\ &= \left[I + \overline{Z} + \overline{Z}^2 + \cdots + \overline{Z}^i\right] ey_n, \quad i = 1, 2, \ldots, l, \\ y_{n+1} &= y_n + az^{(0)}Y^{(l)} + bz^{(1)}Y^{(l)} \\ &= \left(1 + \overline{z}\left[I + \overline{Z} + \overline{Z}^2 + \cdots + \overline{Z}^l\right] e\right) y_n, \end{aligned}$$

where

$$\overline{z} = az^{(0)} + bz^{(1)}, \qquad \overline{Z} = aZ^{(0)} + bZ^{(1)}.$$

Let

$$R^{(l)} = 1 + \overline{z}\left[I + \overline{Z} + \overline{Z}^2 + \cdots + \overline{Z}^l\right] e; \tag{5.2}$$

then the stochastic RK-type PC methods (2.8) are MS-stable for h, a, and b if

$$\overline{R}^{(l)} = E\left(\left|R^{(l)}\right|^2\right) < 1.$$

Now we consider the MS-stability properties of the stochastic RK-type PC methods (3.2) with strong global order 1.0. Applying these methods to (5.1) gives

$$R_1^{(l)}(p, q, \overline{J}_1) = 1 + (p\alpha^\top + q\overline{J}_1\beta^\top)\left(\sum_{i=0}^{l}(pA + q\overline{J}_1 B)^i\right) e,$$

where $p = ah$, $q = b\sqrt{h}$, and $\overline{J}_1 = \frac{J_1}{\sqrt{h}} \sim N(0,1)$. For the stochastic RK-type PC method based on the two-stage implicit RK corrector IRK2 (3.5), the expressions for $R_1^{(l)}$ are given by

$$\begin{aligned}
R_1^{(1)} &= 1 + p + q\overline{J}_1 + \frac{1}{2}(p + q\overline{J}_1)^2,\\
R_1^{(2)} &= 1 + p + q\overline{J}_1 + \frac{1}{2}(p + q\overline{J}_1)^2 + \frac{1}{6}(p + q\overline{J}_1)^3,\\
R_1^{(3)} &= 1 + p + q\overline{J}_1 + \frac{1}{2}(p + q\overline{J}_1)^2 + \frac{1}{6}(p + q\overline{J}_1)^3 + \frac{1}{36}(p + q\overline{J}_1)^4,
\end{aligned}$$

and the MS-stability functions are given by

$$\begin{aligned}
\overline{R}_1^{(1)} &= 1 + 2p + 2p^2 + p^3 + \frac{1}{4}p^4 + 2q^2 + 3pq^2 + \frac{3}{2}p^2q^2 + \frac{3}{4}q^4,\\
\overline{R}_1^{(2)} &= 1 + 2p + 2p^2 + \frac{4}{3}p^3 + \frac{7}{12}p^4 + \frac{1}{6}p^5 + \frac{1}{36}p^6 + 2q^2 + 4pq^2 + \frac{7}{2}p^2q^2\\
&\quad + \frac{5}{3}p^3q^2 + \frac{5}{12}p^4q^2 + \frac{7}{4}q^4 + \frac{5}{2}pq^4 + \frac{5}{4}p^2q^4 + \frac{5}{12}q^6,\\
\overline{R}_1^{(3)} &= 1 + 2p + 2p^2 + \frac{4}{3}p^3 + \frac{23}{36}p^4 + \frac{2}{9}p^5 + \frac{1}{18}p^6 + \frac{1}{108}p^7 + \frac{1}{1296}p^8\\
&\quad + 2q^2 + 4pq^2 + \frac{23}{6}p^2q^2 + \frac{20}{9}p^3q^2 + \frac{5}{6}p^4q^2 + \frac{7}{36}p^5q^2 + \frac{7}{324}p^6q^2\\
&\quad + \frac{23}{12}q^4 + \frac{10}{3}pq^4 + \frac{5}{2}p^2q^4 + \frac{35}{36}p^3q^4 + \frac{35}{216}p^4q^4\\
&\quad + \frac{5}{6}q^6 + \frac{35}{36}pq^6 + \frac{35}{108}p^2q^6 + \frac{35}{432}q^8.
\end{aligned}$$

Here denote $\overline{R}_1^{(0)}$ as the MS-stability function of this method without any correction, namely the explicit Euler method, given by

$$\overline{R}_1^{(0)} = (1 + p)^2 + q^2.$$

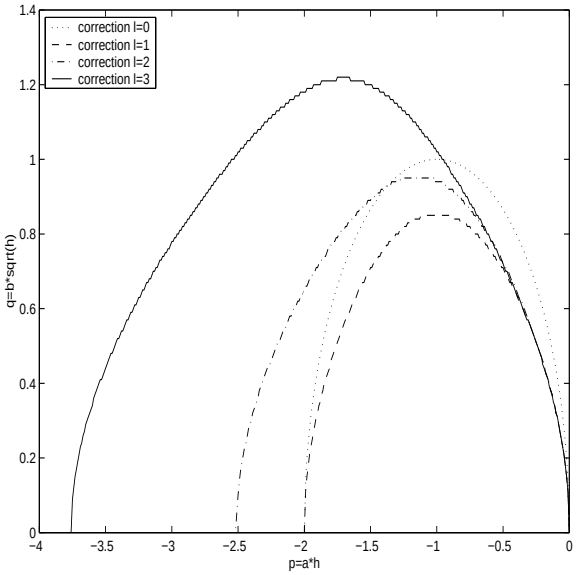

FIG. 1. *MS-stable regions of the two-stage stochastic RK-type PC method.*

Figure 1 gives the MS-stability regions of the stochastic RK-type PC method (3.2) based on IRK2 (3.5). The MS-stable regions are the areas under the plotted lines and are symmetric about the p-axis. The MS-stability properties of this method with two corrections are better than those with one correction. The MS-stability properties of this method are much improved when the third correction is performed.

6. Numerical results. Numerical results for solving SDEs driven by one Wiener process are reported in this section. Denoting $y_N^{(i)}$ as the numerical approximation to $y^{(i)}(t_N)$ at step point t_N in the ith simulation of all K simulations, we use means of MS errors MS, strong order 1 rate R_1 and strong order 1.5 rate $R_{1.5}$, defined by

$$MS = \sqrt{\frac{1}{K}\sum_{i=1}^{K}(y_N^{(i)} - y^{(i)}(t_N))^2}, \qquad R_1 = \frac{MS}{h}, \qquad R_{1.5} = \frac{MS}{h\sqrt{h}},$$

to measure the accuracy and the convergence properties of the stochastic RK-type PC methods. All of the data in this section are based on 1000 simulated trajectories.

The first test equation is a nonlinear problem, whose Stratonovich form is

$$dy = -\alpha(1-y^2)dt + \beta(1-y^2)\circ dW(t), \quad y(0) = 0.5, \quad t \in [0,1],$$

with $\alpha = -1$ and $\beta = 1$. The exact solution of this equation is [17]

$$y(t) = \frac{(1+y_0)\exp(-2\alpha t + 2\beta W(t)) + y_0 - 1}{(1+y_0)\exp(-2\alpha t + 2\beta W(t)) - y_0 + 1}.$$

Figure 2 gives the MS errors of the two stochastic RK-type PC methods based on IRK2 and IRK4, respectively, for solving the first test equation. For the two-stage PC method based on IRK2, the implicit corrector (3.5) is applied with a different number of corrections $l = 0, 1, 2, 3, 4$. From the left figure in Figure 2, the numerical

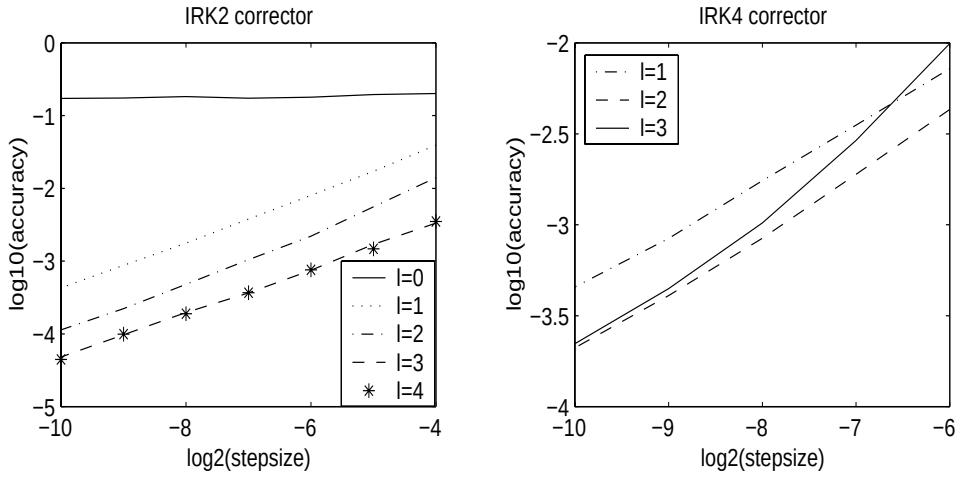

FIG. 2. *MS errors for solving the first test equation.*

solution when no correction is performed, denoted as $l = 0$, does not converge to the exact solution of the corresponding Stratonovich SDE. The strong convergence rates of this method with $l = 1$, 2, 3, or 4 are all equal to 1.0, as predicted by our theory. The averaged errors are smaller if more corrections are performed. The difference between the averaged errors of this method with three corrections and those with four corrections is small.

For the four-stage PC method based on IRK4, the implicit corrector is applied with a different number of corrections $l = 1, 2, 3$. From the right figure of Figure 2, the strong convergence rates of this method with $l = 1$ is equal to 1.0. When two corrections are performed, the strong convergence rate is between 1.0 and 1.5. The strong convergence rate of this method is 1.5 if three corrections are performed, which is again consistent with our theory.

It should be noticed that the accuracy of the stochastic RK-type PC method based on IRK4 with strong order 1.5 is not as good as that of the method based on IRK2 with strong order 1.0 when $2^{-10} \le h \le 2^{-6}$. The reason for this phenomenon is due to the eigenvalues of the method matrices. For IRK2, the eigenvalues of matrices A and B are

$$\lambda(A) = \lambda(B) = \frac{1}{3} \pm \frac{\sqrt{2}}{6} i,$$

while for IRK4 the eigenvalues of the method matrices are

$$\begin{aligned} \lambda(A) &= 0.400 \pm 0.622i, \ \ -0.072 \pm 0.253i, \\ \lambda(B_1) &= 0.096, \ 0.333, \ 0.878, \ -0.0053, \\ \lambda(B_2) &= 11.528, \ -0.335, \ -0.620 \pm 0.035i. \end{aligned}$$

The large eigenvalue of matrix B_2 causes amplifications in the errors of the PC method based on IRK4. This effect was well known in the deterministic case; see the work of Sommeijer [25].

In order to test out this supposition, we construct two methods, MIRK2 and MIRK4, which have strong order 1 and 1.5, respectively, and whose defining matrices

have smaller spectral radius. The MIRK2 method is given by

$$\begin{array}{c|cccc} \frac{1067}{3000} & \frac{933}{3000} & \frac{1067}{3000} & \frac{933}{3000} \\ -\frac{67}{1000} & \frac{67}{1000} & -\frac{67}{1000} & \frac{67}{1000} \\ \hline \frac{3}{4} & \frac{1}{4} & \frac{3}{4} & \frac{1}{4} \end{array} . \tag{6.1}$$

The eigenvalues of the defined method matrices are

$$\lambda(A) = \lambda(B) = \frac{317 \pm \sqrt{11}}{1500}.$$

The MIRK4 method is different from the IRK4 method just in the method matrices $B_M^{(1)}$ and $B_M^{(2)}$, given by

$$B_M^{(1)} = \begin{pmatrix} -0.4103843710 & 0.2113248635 & 0.2566537645 & 0.1537306083 \\ 1.1990595100 & 0 & -0.300000000 & -0.1103843746 \\ 0.2807539857 & 0.4849084469 & 0.3943375673 & -0.16000000 \\ 0.2807539819 & 0.4849084506 & 0.3943375673 & -0.160000000 \end{pmatrix},$$

$$B_M^{(2)} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -0.7602588353 & -0.7602588353 & -0.7602588353 & 0 \\ -0.7602588353 & -0.7602588353 & -0.7602588353 & 0 \end{pmatrix},$$

whose eigenvalues are

$$\lambda(B_M^{(1)}) = -0.36 \pm 0.038i, 0.55, 0, \qquad \lambda(B_M^{(2)}) = -0.76, 0, 0, 0.$$

Using the PC methods based on the correctors MIRK2 and MIRK4, we then repeated the calculations for solving the first test equation, and the numerical results are given in Figure 3. It is clear that the MIRK2 method is more effective than the IRK2 method, whose computational results are given by Figure 2. For four-stage correctors, the accuracy of the numerical results of MIRK4 is better than that of IRK4 with stepsize $h = 2^{-6}, 2^{-7}, 2^{-8}$. When $h = 2^{-9}$ and 2^{-10}, the accuracy of MIRK4 is just slightly better than that of IRK4.

The second test equation is also a nonlinear SDE, given by

$$dy = a(1 + y^2) \circ dt, \qquad y(0) = 1, \qquad t \in [0, 1],$$

with $a = 0.1$. The exact solution is given in [17], namely

$$y = \tan(aW(t) + \arctan y_0).$$

Figure 4 gives the MS errors of the four PC methods for the second test equation. In this case the implicit corrector is applied with a different number of corrections $l = 2, 3$. It is clear that the MIRK2 and MIRK4 methods with three corrections are much more effective than the IRK2 and IRK4 methods for the second test equation.

In order to discuss the relationship between the accuracy of the numerical methods and the computational cost, we use the following explicit two-stage RK methods to solve the first test equation:

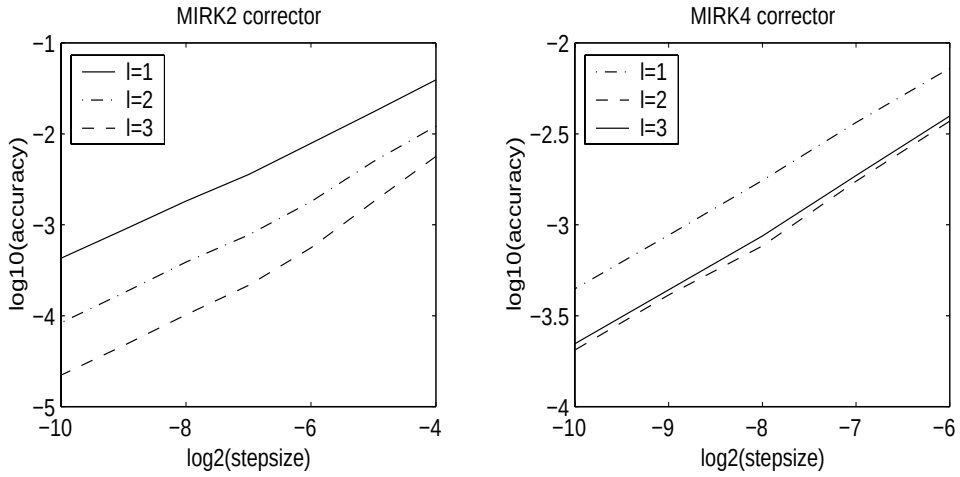

FIG. 3. *MS errors for solving the first test equation.*

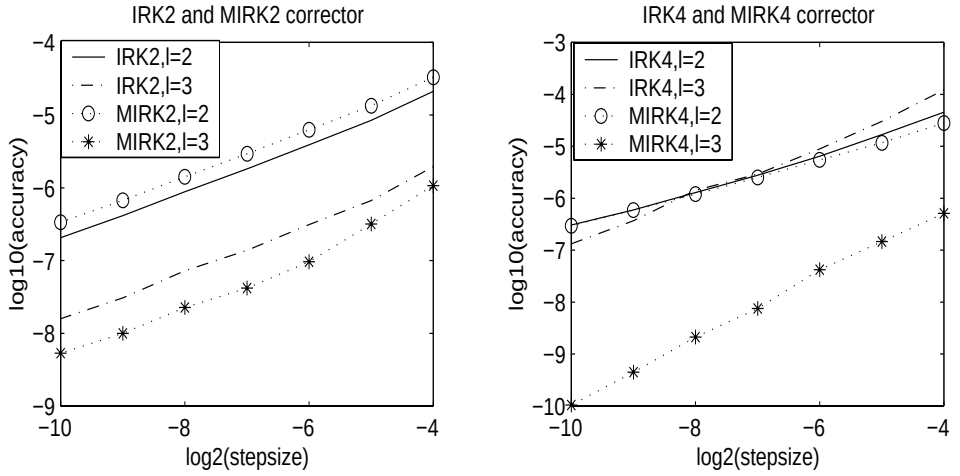

FIG. 4. *MS errors for solving the second test equation.*

(1) The Heun method [12].

$$
\begin{aligned}
Y &= y_n + hf(y_n) + \Delta W_n g(y_n),\\
y_{n+1} &= y_n + \frac{1}{2}h\left(f(y_n) + f(Y)\right) + \frac{1}{2}\Delta W_n\left(g(y_n) + g(Y)\right).
\end{aligned} \tag{6.2}
$$

(2) The Burrages scheme [12].

$$
\begin{aligned}
Y &= y_n + \frac{2}{3}hf(y_n) + \frac{2}{3}\Delta W_n g(y_n),\\
y_{n+1} &= y_n + h\left(\frac{1}{4}f(y_n) + \frac{3}{4}f(Y)\right) + \Delta W_n\left(\frac{1}{4}g(y_n) + \frac{3}{4}g(Y)\right).
\end{aligned} \tag{6.3}
$$

TABLE 1
Accuracy and computational cost of some stochastic RK methods.

	Heun	Burrages	Method 1	IRK2 ($l=3$)	MIRK2 ($l=3$)
Accuracy	4.9E-3	3.5E-3	4.7E-3	3.3E-3	5.6E-3
cost-flops	7.2E+6	7.9E+6	4.1E+6	3.0E+6	3.0E+6
Accuracy	5.9E-4	4.3E-4	5.2E-4	3.6E-4	2.2E-4
cost-flops	5.7E+7	6.4E+7	3.3E+7	2.4E+7	2.4E+7

(3) Method 1 in [26].

$$
\begin{aligned}
Y &= y_n + \frac{3}{10}hf(y_n) + \frac{58}{100}\Delta W_n g(y_n),\\
y_{n+1} &= y_n + h\left(\frac{56}{100}f(y_n) + \frac{44}{100}f(Y)\right) + \Delta W_n\left(\frac{4}{29}g(y_n) + \frac{25}{29}g(Y)\right).
\end{aligned}
\tag{6.4}
$$

Table 1 gives the accuracy and the computional cost, in terms of flops obtained by Matlab, of these explicit RK methods and those of the IRK2 and MIRK2 methods with three corrections. Clearly, both the IRK2 and MIRK2 methods with three corrections can achieve better accuracy than the other explicit methods with substantially reduced computation costs.

The third test equation is given by

$$
\begin{aligned}
dy_1 &= y_2 dt + \theta y_2 \circ dW(t),\\
dy_2 &= \mu\left((1-y_1^2)y_2 - y_1\right) + \theta\left((1-y_1^2)y_2 - y_1\right)\circ dW(t).
\end{aligned}
\tag{6.5}
$$

This equation is the ordinary Van der Pol equation [14] when $\theta = 0$. The Van der Pol equation is stiff when μ is large.

We use IRK2 with $l = 3$ to solve this equation. In Figure 5 we give four simulations of this equation. The top two simulations in Figure 5 are obtained with parameters $\mu = 1$, $\theta = 0.1$, and $\theta = 1$ and stepsize $h = 0.01$. The bottom two simulations are obtained with parameters $\mu = 10$, $\theta = 0.1$, and $\theta = 0.5$ and stepsize $h = 0.001$. The numerical simulations with $\theta = 0.1$ are similar to those of the deterministic Van der Pol equation with the same μ.

In order to discuss the efficiency of the two-stage PC methods, we use IRK2 ($l = 3$) with stepsize $h = 0.0001$ to get a numerical solution which is regarded as the "accurate" solution in the case of $\mu = 1$ and different θ. We compare this "accurate" solution with the numerical simulations obtained by the explicit RK methods (6.2), (6.3), and (6.4) and those obtained by IRK2 ($l = 3$) and MIRK2 ($l = 3$). Numerical results presented in Figure 6 are based on 100 simulations. The left figure of Figure 6 gives the accuracy of numerical solutions with $\mu = 1$ and $0.1 \le \theta \le 1.0$. The accuracy of numerical simulations of IRK2 ($l = 3$) and MIRK2 ($l = 3$) is considerably better than those of the other methods. In the right figure of Figure 6, we present the proportions of "acceptable" solutions with the standard that the averaged error is less than 1.0. It should be noticed that the proportions are dependent on the standard. We can get more "acceptable" simulations by IRK2 ($l = 3$) and MIRK2 ($l = 3$) than with the other explicit RK methods. The explicit RK methods are not suitable for solving this equation with values for $\theta > 1$.

Similar numerical results about the accuracy and the proportions of acceptable solutions can be also obtained for the case $\mu = 10$ and $\theta \in [0.1, 1.0]$. In this case a smaller stepsize, for example $h = 0.00001$, should be used for the "accurate solution."

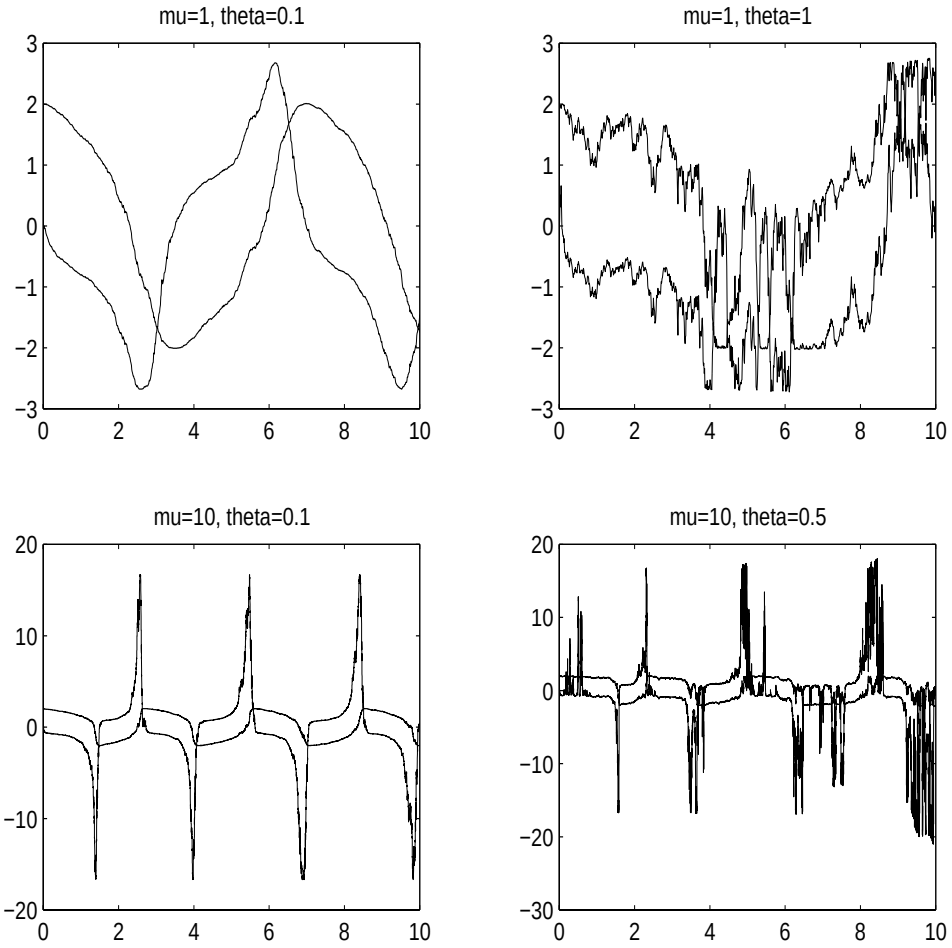

FIG. 5. *Numerical simulations of the stochastic Van der Pol equation with IRK*2 ($l = 3$).

7. Conclusions. In this paper we have constructed PC methods based on the trivial predictor and stochastic implicit RK correctors for solving SDEs. Using the colored rooted tree theory and stochastic B-series, we present an order condition theorem for constructing stochastic RK-type PC methods. We also present detailed order conditions of the stochastic RK-type PC methods with strong convergence order 1.0 and 1.5. Two two-stage implicit RK methods with strong global order 1.0 and two four-stage implicit RK methods with strong global order 1.5 are constructed in this paper. The following conclusions can be made from the stability analysis and numerical behavior of the RK-type PC methods presented in this paper.

(1) As the number of parameters is larger than the number of order conditions, additional conditions can be used to determine the coefficients of stochastic RK methods in order to get better stability properties and numerical behavior. For example, we may consider a two-stage implicit RK method which has good stability properties at infinity. Applying this method (3.1) to the linear test equation (5.1) gives

$$y_{n+1} = R(p, q)y_n,$$

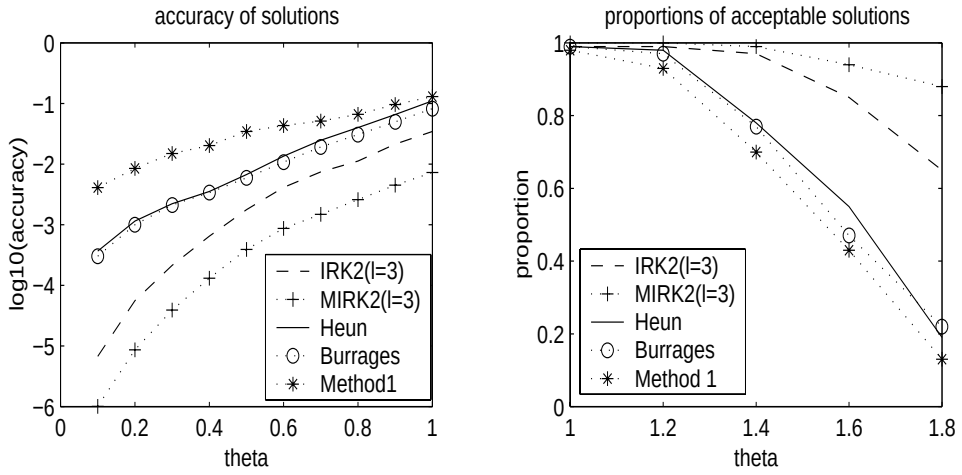

FIG. 6. *Proportions and MS accuracy of stable solutions for solving the Van der Pol problem with* $\mu = 1$ *and* θ *varying.*

where

$$R(p,q) = 1 + (p\alpha^\top + q\overline{J}_1\beta^\top)(I - pA - q\overline{J}_1 B)^{-1}e.$$

This method will have damping stability properties at infinity if

$$\alpha^\top A^{-1}e = 1, \qquad \beta^\top B^{-1}e = 1.$$

The implicit two-stage RK method (3.5) satisfies these conditions.

(2) Another possible way to improve the stability properties and the numerical behavior of stochastic RK-type PC methods is to reduce the magnitude of the eigenvalues of the matrices in the stochastic RK methods. The cue is in the expression of $R^{(l)}$ (5.2). In order to verify this supposition, we construct two methods, MIRK2 and MIRK4. Compared with IRK2 and IRK4, the eigenvalues of the method matrices in MIRK2 and MIRK4 are small in magnitude. Numerical results of the MIRK2 and MIRK4 methods are more accurate than those of IRK2 and IRK4. The effect has also been observed in the deterministic case.

(3) The stochastic RK-type PC methods are more effective than other explicit stochastic RK methods. For two-stage RK methods with strong order 1.0, the superiority of the PC method based on IRK2 or MIRK2 is due to the better stability properties (shown in Figures 1 and 6), the better accuracy, and the less computational cost (shown in Table 1 and Figure 6). For the RK methods with strong order 1.5, the PC method will be more effective than the explicit RK methods with the same order if it is implemented on a parallel computer.

Thus we may consider stochastic RK-type PC methods which have better stability properties and numerical behavior by adding additional conditions or by reducing the magnitude of the eigenvalues of the matrices in the stochastic RK methods. In addition, we can apply splitting techniques [20] to implicit RK methods to construct numerical schemes which are suitable for solving stiff SDEs. Finally, we note that these concepts can be applied to SDE problems driven by more then one Wiener process. However, spatial constraints for this work means that all of these are topics for future work.

SHARP L^2-ERROR ESTIMATES AND SUPERCONVERGENCE OF MIXED FINITE ELEMENT METHODS FOR NON-FICKIAN FLOWS IN POROUS MEDIA*

RICHARD E. EWING†, YANPING LIN‡, TONG SUN§, JUNPING WANG¶, AND SHUHUA ZHANG‖

Dedicated to Professor Zhichun Piao on the occasion of his 68th birthday

Abstract. A sharper L^2-error estimate is obtained for the non-Fickian flow of fluid in porous media by means of a mixed Ritz–Volterra projection instead of the mixed Ritz projection used in [R. E. Ewing, Y. Lin, and J. Wang, *Acta Math. Univ. Comenian.* (*N.S.*), 70 (2001), pp. 75–84]. Moreover, local L^2 superconvergence for the velocity along the Gauss lines and for the pressure at the Gauss points is derived for the mixed finite element method via the Ritz–Volterra projection, and global L^2 superconvergence for the velocity and the pressure is also investigated by virtue of an interpolation postprocessing technique. On the basis of the superconvergence estimates, some useful a posteriori error estimators are presented for this mixed finite element method.

Key words. non-Fickian flow, mixed finite element methods, mixed Ritz–Volterra projection, error estimates, superconvergence

1. Introduction.

As mentioned in [18, 19], the non-Fickian flow of fluid in porous media is complicated by the history effect which characterizes various mixing length growth of the flow and can be modeled by an integro-differential equation: Find $u = u(x,t)$ such that

$$
\begin{aligned}
u_t &= \nabla \cdot \sigma + cu + f && \text{in } \Omega \times J,\\
\sigma &= A(t) \cdot \nabla u - \int_0^t B(t,s) \cdot \nabla u(s) ds && \text{in } \Omega \times J,\\
u &= g && \text{on } \partial\Omega \times J,\\
u &= u_0(x) && x \in \Omega,\ t = 0,
\end{aligned}
\tag{1.1}
$$

where $\Omega \subset R^d$ $(d = 2, 3)$ is an open bounded domain with smooth boundary $\partial\Omega$, $J = (0, T)$ with $T > 0$, $A(t) = A(x, t)$ and $B(t, s) = B(x, t, s)$ are two 2×2 or 3×3 matrices, and A is positive definite, and c, f, g, and u_0 are known smooth functions. This kind of model can arise, e.g., from the transport of contaminants in the subsurface, which is of great interest for engineers, physicists, and mathematicians involved in porous media flows modeling. The evolution of a reactive chemical within a velocity field exhibits excitement on many scales, typically represented by using the classical Fickian dispersion theory. For instance, the evolution in such a velocity field, when modeled with Fickian-type constitutive laws, leads to a dispersion tensor dependent upon the timescales of observation. Hence, to avoid this difficulty, nonlocal Fickian models have been recently proposed, in which the dispersion term arising from integration with respect to time makes the flow non-Fickian, since it is not a pure diffusion term. For example, Chen, Ewing, and Lazarov [4, 5], Cushman [6], Cushman, Hu, and Deng [7], Cushman, Hu, and Ginn [8], and Hu, Deng, and Cushman [23] have developed a nonlocal theory and some applications for the flow of fluid in porous media. Furtado et al. [21], Glimm et al. [22], Neuman and Zhang [29], and Ewing [12, 13, 14] also studied the history effect of various mixing length growth for flow in heterogeneous porous media. In a recent laboratory experimental investigation of contaminant transport in heterogeneous porous media [32], some nonlocal behavior of dispersion tensors have been observed.

There is now sizeable literature on the numerical approximations of the problem (1.1). In [31], the method of backward Euler and Crank–Nicolson combined with a certain numerical quadrature rule is employed to deal with the time direction, which aims at reducing the computational cost and storage spaces due to the memory effect. Finite element methods have been also developed for the problem (1.1) during the past ten years [2, 3, 25, 26, 27, 28, 34], in which optimal and superconvergence can be found for the corresponding finite element approximations in various norms, such as L^p with $2 \le p \le \infty$. In particular, the method of using the Ritz–Volterra projection, discovered by Cannon and Lin [2], proved to be a powerful technique behind the analysis. In fact, in [28] the concept of Ritz–Volterra projection is proposed to unify much of the analysis of standard finite element methods for different types of problems, such as parabolic and hyperbolic integro-differential equations and Sobolev- and viscoelasticity-type equations. See [16, 17] for recent developments on finite volume element approximations, where the Ritz–Volterra projection is also employed.

However, to the best of our knowledge, there are few results except [18, 19, 24] available concerning the mathematical formulation and analysis of the mixed finite element method for (1.1). Unlike the standard finite element method, the mixed finite element method can give the numerical approximations of the velocity field and the pressure field at the same time, and also maintains the physical conservation, so that it is more favorable. Certainly, its theoretical analysis is more complicated than that of the standard finite element method. In [18, 19] the authors dealt with the general setting of the problem. However, the formulation and analysis given in [24] are valid for only a special case; i.e., the operator B is proportional to the operator A. The reader is referred to [24] for this special case. The mathematical difficulty associated with the analysis of numerical approximations to the solution of (1.1) lies on the integral term added to standard parabolic equations [33, 34]. In order to overcome this difficulty, the so-called mixed Ritz–Volterra projection will be proposed in section 2.

In the present paper we are concerned with the approximate solutions of (1.1) by mixed finite element methods. Sharper L^2-error estimates than those in [18, 19]

are obtained by employing a mixed Ritz–Volterra projection rather than the Ritz projection used in [18, 19]. In addition, local L^2 superconvergence for the velocity along the Gauss lines and for the pressure at the Gauss points is derived, and with the aid of an interpolation postprocessing method global L^2 superconvergence is also considered for the velocity and the pressure.

The paper is organized in the following way. In section 2, we give some necessary preparations, introduce the mixed Ritz–Volterra projection, and analyze its approximation properties. In section 3, we derive a sharper error estimate for the mixed finite element approximations in the L^2-norm. Sections 4 and 5 are devoted to the local and global superconvergence analysis of the mixed finite element method, respectively.

2. The mixed Ritz–Volterra-type projection. In this section, we give the mixed finite element approximate formula for the parabolic integro-differential equation (1.1) and the mixed Ritz–Volterra projection. For simplicity, the method will be presented on plane domains.

Let $W := L^2(\Omega)$ be the standard L^2 space on Ω with norm $\|\cdot\|_0$. Denote by

$$\mathbf{V} := H(\mathrm{div}, \Omega) = \left\{\sigma \in (L^2(\Omega))^2 : \ \nabla \cdot \sigma \in L^2(\Omega)\right\}$$

the Hilbert space equipped with the following norm:

$$\|\sigma\|_{\mathbf{V}} := \left(\|\sigma\|_0^2 + \|\nabla \cdot \sigma\|_0^2\right)^{\frac{1}{2}}.$$

There are several ways to discretize the problem (1.1) based on the variables σ and u; each method corresponds to a particular variational form of (1.1) [18, 19].

Let T_h be a finite element partition of Ω into triangles or quadrilaterals which is quasi-uniform. Let $\mathbf{V}_h \times W_h$ denote a pair of finite element spaces satisfying the Brezzi–Babuška condition. For example, the elements of Raviart and Thomas [30] would be a good choice for $\mathbf{V}_h$ and W_h. Although our results are based on the use of Raviart–Thomas elements of any order k, their extension to other stable elements can be discussed without any difficulty.

Let us recall from [18] that the weak mixed formulation of (1.1) is given by finding $(u, \sigma) \in W \times \mathbf{V}$ such that

$$\begin{aligned}
&(u_t, w) - (\nabla \cdot \sigma, w) - (cu, w) = (f, w) && \forall w \in W,\\
&(\alpha\sigma, \mathbf{v}) + \int_0^t (M(t,s)\sigma(s), \mathbf{v})ds + (\nabla \cdot \mathbf{v}, u) = \langle g, \mathbf{v} \cdot \mathbf{n}\rangle && \forall \mathbf{v} \in \mathbf{V},\\
&u(0,x) = u_0(x) \quad \text{in } L^2(\Omega),
\end{aligned} \tag{2.1}$$

where $\alpha = A^{-1}(t)$, $M(t,s) = R(t,s)A^{-1}(s)$, and $R(t,s)$ is the resolvent of the matrix $A^{-1}(t)B(t,s)$ and is given by

$$R(t,s) = A^{-1}(t)B(t,s) + \int_s^t A^{-1}(t)B(t,\tau)\ R(\tau,s)d\tau, \quad t > s \geq 0.$$

Here $\langle\cdot,\cdot\rangle$ indicates the L^2-inner product on $\partial\Omega$.

The corresponding semidiscrete version seeks a pair $(u_h, \sigma_h) \in W_h \times \mathbf{V}_h$ such that

$$\begin{aligned}
&(u_{h,t}, w_h) - (\nabla \cdot \sigma_h, w_h) - (cu_h, w_h) = (f, w_h) && \forall w_h \in W_h,\\
&(\alpha\sigma_h, \mathbf{v}_h) + \int_0^t (M(t,s)\sigma_h(s), \mathbf{v}_h)ds + (\nabla \cdot \mathbf{v}_h, u_h) = \langle g, \mathbf{n} \cdot \mathbf{v}_h\rangle && \forall \mathbf{v}_h \in \mathbf{V}_h.
\end{aligned} \tag{2.2}$$

The discrete initial condition $u_h(0,x) = u_{0,h}$, where $u_{0,h} \in W_h$ is some appropriately chosen approximation of the initial data $u_0(x)$, should be added to (2.2) for starting. The pair (u_h, σ_h) is a semidiscrete approximation of the true solution of (1.1) in the finite element space $W_h \times \mathbf{V}_h$ [1, 18, 19, 31], where $\sigma_h(0,x)$ is chosen to satisfy (2.2) with $t = 0$; namely, it is related to $u_{0,h}$ as follows:

$$(\alpha\sigma_h(0), \mathbf{v}_h) + (u_{0,h}, \nabla \cdot \mathbf{v}_h) = \langle g_0, \mathbf{n} \cdot \mathbf{v}_h \rangle, \tag{2.3}$$

where $g_0 = g(0,x)$ is the initial value of the boundary data.

In [18], utilizing the mixed Ritz projection we have obtained for the Raviart–Thomas element of the lowest order that

$$||u - u_h||_0^2 + ||\sigma - \sigma_h||_0^2 \le Ch^2 \left[||u_0||_1^2 + ||\sigma_0||_1^2 + \int_0^t (||u(s)||_2^2 + ||u_t(s)||_2^2) ds \right].$$

Also, we can extend easily the result to the case of any order k (≥ 1) to get

$$||u - u_h||_0^2 + ||\sigma - \sigma_h||_0^2 \le Ch^{2r} \left[||u_0||_r^2 + ||\sigma_0||_r^2 + \int_0^t (||u(s)||_{r+1}^2 + ||u_t(s)||_{r+1}^2) ds \right], \tag{2.4}$$

for $2 \le r \le k+1$. In fact, we can improve the error estimate by extending the idea from [2, 3] to introduce a new nonlocal projection incorporated with the memory effects, which allows us to obtain a sharper error estimate in regularity than that indicated in (2.4). This new projection is a natural extension of the standard Ritz–Volterra projection in the standard finite element method to the case of the mixed finite element approximations with memory. We refer the readers to [2, 3] and [28] for the analysis and applications of the Ritz–Volterra projection for standard finite element approximations to parabolic and hyperbolic integro-differential equations.

Before the mixed Ritz–Volterra projection is given, we need the following Raviart–Thomas projection [30]:

$$\Pi_h \times P_h : \mathbf{V} \times W \to \mathbf{V}_h \times W_h,$$

which has the following properties:

(i) P_h is the local $L^2(\Omega)$ projection.

(ii) Π_h and P_h satisfy

$$(\nabla \cdot (\sigma - \mathbf{\Pi}_h \sigma), w_h) = 0, \ w_h \in W_h \quad \text{and} \quad (\nabla \cdot \mathbf{v}_h, u - P_h u) = 0, \ \mathbf{v}_h \in \mathbf{V}_h. \tag{2.5}$$

(iii) The following approximation properties hold:

$$\begin{aligned} &||\sigma - \mathbf{\Pi}_h \sigma||_0 \le Ch^r ||\sigma||_r, && 1 \le r \le k+1, \\ &||\nabla \cdot (\sigma - \Pi_h \sigma)||_{-s} \le Ch^{r+s} ||\nabla \cdot \sigma||_r, && 0 \le r, \ s \le k+1, \\ &||u - P_h u||_{-s} \le Ch^{r+s} ||u||_r, && 0 \le r, \ s \le k+1. \end{aligned} \tag{2.6}$$

DEFINITION 2.1. *For $(u, \sigma) \in W \times \mathbf{V}$ we define a pair $(\bar{u}_h, \bar{\sigma}_h) : [0,T] \to W_h \times \mathbf{V}_h$ such that*

$$\begin{aligned} &\left(\alpha(\sigma - \bar{\sigma}_h) + \int_0^t M(t,s)(\sigma - \bar{\sigma}_h)(s) ds, \mathbf{v}_h \right) + (\nabla \cdot \mathbf{v}_h, u - \bar{u}_h) = 0, && \mathbf{v}_h \in \mathbf{V}_h, \\ &(\nabla \cdot (\sigma - \bar{\sigma}_h), w_h) + (c(u - \bar{u}_h), w_h) = 0, && w_h \in W_h, \end{aligned} \tag{2.7}$$

where $\alpha = A^{-1}$. The pair $(\bar{u}_h, \bar{\sigma}_h)$ is called the mixed Ritz–Volterra projection of (u, σ).

Let

$$\xi := \sigma - \bar{\sigma}_h,\ \eta := u - \bar{u}_h,\ \nu := \Pi_h\sigma - \bar{\sigma}_h,\ \tau := P_h u - \bar{u}_h,\ \rho := u - P_h u.$$

Then (2.7) becomes

$$\begin{aligned} &\left(\alpha\xi + \int_0^t M(t,s)\xi(s)ds, \mathbf{v}_h\right) + (\nabla\cdot\mathbf{v}_h, \eta) = 0, \qquad \mathbf{v}_h \in \mathbf{V}_h, \\ &(\nabla\cdot\xi, w_h) + (c\eta, w_h) = 0, \qquad w_h \in W_h, \end{aligned} \tag{2.8}$$

or, according to (2.5),

$$\begin{aligned} &(\alpha\xi, \mathbf{v}_h) + (\nabla\cdot\mathbf{v}_h, \tau) = f(\mathbf{v}_h), \qquad \mathbf{v}_h \in \mathbf{V}_h, \\ &(\nabla\cdot\xi, w_h) + (c\tau, w_h) = g(w_h), \qquad w_h \in W_h, \end{aligned} \tag{2.9}$$

where

$$f(\mathbf{v}_h) := -\left(\int_0^t M(t,s)\xi(s)ds, \mathbf{v}_h\right) \quad \text{and} \quad g(w_h) := -(c\rho, w_h).$$

In order to analyze (ξ, η), let us recall from [10] the following results.

LEMMA 2.2. *Let the index k of $\mathbf{V}_h \times W_h$ be at least one and let $0 \le s \le k-1$. Assume that Ω is $(s+2)$-regular* [10]. *Let $\xi \in \mathbf{V}$, $g \in W' = L^2(\Omega)$ and $f = \{\mathbf{f}_0, f_1\} \in \mathbf{V}'$ with $\mathbf{f}_0 \in (L^2(\Omega))^2$, $f_1 \in L^2(\Omega)$ and*

$$f(\mathbf{v}) = (\mathbf{f}_0, \mathbf{v}) + (f_1, \nabla\cdot\mathbf{v}), \quad \mathbf{v} \in \mathbf{V}.$$

If $z \in W_h$ satisfies the relations

$$\begin{aligned} &(\alpha\xi, \mathbf{v}_h) + (\nabla\cdot\mathbf{v}_h, z) = f(\mathbf{v}_h), \qquad \mathbf{v}_h \in \mathbf{V}_h, \\ &(\nabla\cdot\xi, w_h) + (cz, w_h) = g(w_h), \qquad w_h \in W_h, \end{aligned} \tag{2.10}$$

then there exists $h_0 > 0$ sufficiently small such that, for all $0 < h \le h_0$,

$$\begin{aligned} ||z||_{-s} \quad &\le C\left\{h^{s+1}||\xi||_0 + h^{s+2}||\nabla\cdot\xi||_0 + ||\mathbf{f}_0||_{-s-1} + h^{s+1}||\mathbf{f}_0||_0\right. \\ &\left. + ||f_1||_{-s} + h^s||f_1||_0 + ||g||_{-s-2} + h^{s+2}||g||_0\right\}. \end{aligned}$$

LEMMA 2.3. *Let the index k of $\mathbf{V}_h \times W_h$ be nonnegative, and let Ω be $(k+2)$-regular* [10]. *Let $\xi \in \mathbf{V}$, $g \in W' = L^2(\Omega)$ and $f = \{\mathbf{f}_0, 0\} \in \mathbf{V}'$. If $z \in W_h$ satisfies* (2.10), *then there exists $h_0 > 0$ sufficiently small such that, for all $0 < h \le h_0$,*

$$||z||_{-k} \le C\left\{h^{k+1}\left(||\xi||_0 + ||\nabla\cdot\xi||_0 + ||\mathbf{f}_0||_0 + ||g||_0\right) + ||\mathbf{f}_0||_{-k-1} + ||g||_{-k-2}\right\}.$$

Moreover, we also need the following lemma.

LEMMA 2.4. *Assume that the matrix $A(t)$ is positive definite. Then the norms $||\sigma||_0^2 := (\sigma, \sigma)$ and $||\sigma||_{A^{-1}}^2 := (A^{-1}\sigma, \sigma)$ are equivalent.*

We are now ready to state and prove our main result in this section.

THEOREM 2.5. *For $(u, \sigma) \in W \times \mathbf{V}$ its mixed Ritz–Volterra projection $(\bar{u}_h, \bar{\sigma}_h)$ defined by* (2.7) *exists and is unique. Moreover, there is a positive constant $C > 0$, independent of $h > 0$ small, such that the error $(u - \bar{u}_h, \sigma - \bar{\sigma}_h)$ can be estimated by*

$$\begin{aligned} &||u - \bar{u}_h||_0 \le C\begin{cases} h|||u(t)|||_2 & \text{if } k = 0, \\ h^r|||u(t)|||_r & \text{if } k \ge 1 \text{ and } 2 \le r \le k+1, \end{cases} \\ &||\sigma - \bar{\sigma}_h||_0 \le Ch^r|||u(t)|||_{r+1} \qquad \text{if } 1 \le r \le k+1, \\ &||\nabla\cdot(\sigma - \bar{\sigma}_h)||_0 \le Ch^r|||u(t)|||_{r+2} \quad \text{if } 0 \le r \le k+1, \end{aligned}$$

where

$$|||u(t)|||_r = ||u(t)||_r + \int_0^t ||u(s)||_r ds, \quad r \in R,\ t \geq 0.$$

Proof. We first prove the existence and uniqueness of the mixed Ritz–Volterra projection. If $M = 0$, then it follows from [1] that $(\bar{u}_h, \bar{\sigma}_h)$ exists uniquely. If M is nonzero, we see that (2.7) in fact can be written as a Volterra system for $(\bar{u}_h, \bar{\sigma}_h)$, i.e.,

$$A_h \begin{pmatrix} \bar{u}_h \\ \bar{\sigma}_h \end{pmatrix} = F_h + \int_0^t B_h(t,s) \begin{pmatrix} \bar{u}_h \\ \bar{\sigma}_h \end{pmatrix} ds,$$

where A_h and B_h are matrices with A_h nonsingular and F_h is a vector associated with the solution (u, σ). Hence, the theory of Volterra equations implies that $(\bar{u}_h, \bar{\sigma}_h)$ exists uniquely.

Next we turn our attention to error estimates. It follows from (2.6) and (2.9) that

$$\begin{aligned} &||f||_0 \leq C \int_0^t ||\xi||_0 ds, && ||f||_{-1} \leq C \int_0^t ||\xi||_{-1} ds, \\ &||g||_0 \leq C||\rho||_0, && ||g||_{-1} \leq C||\rho||_{-1}, \\ &||g||_{-2} \leq ||g||_{-1} \leq C||\rho||_{-1}, && ||\rho||_{-1} + h||\rho||_0 \leq Ch^{r+1}||u||_r. \end{aligned}$$

Now we apply either Lemma 2.2 with $s = 0$ or Lemma 2.3 with $k = 0$ to (2.9). Then, for h small and for Ω 2-regular we have for $0 \leq r \leq k+1$ that

$$\begin{aligned} ||\tau||_0 &\leq C\left\{h||\xi||_0 + h^{2-\delta_{k0}}||\nabla \cdot \xi||_0 + ||f||_{-1} + h||f||_0 + ||g||_{-2} + h||g||_0\right\} \\ &\leq C\left\{h||\xi||_0 + h^{2-\delta_{k0}}||\nabla \cdot \xi||_0 + \int_0^t (||\xi||_{-1} + h||\xi||_0) ds + (||\rho||_{-1} + h||\rho||_0)\right\} \\ &\leq C\left\{h|||\xi|||_0 + h^{2-\delta_{k0}}||\nabla \cdot \xi||_0 + \int_0^t ||\xi||_{-1} ds + h^{r+1}||u||_r\right\}, \end{aligned} \tag{2.11}$$

where

$$\delta_{k0} = \begin{cases} 1, & k = 0, \\ 0, & k \neq 0. \end{cases}$$

Letting $\varphi \in \left(H^1(\Omega)\right)^2$, then we derive from (2.5) and (2.8) that

$$\begin{aligned} &\left(\alpha\xi + \int_0^t M(t,s)\xi(s) ds, \varphi\right) + (\nabla \cdot \varphi, \eta) \\ &\quad = \left(\alpha\xi + \int_0^t M(t,s)\xi(s) ds, \varphi - \Pi_h\varphi\right) + (\nabla \cdot (\varphi - \Pi_h\varphi), \eta) \\ &\quad + \left(\alpha\xi + \int_0^t M(t,s)\xi(s) ds, \Pi_h\varphi\right) + (\nabla \cdot \Pi_h\varphi, \eta) \\ &\quad = \left(\alpha\xi + \int_0^t M(t,s)\xi(s) ds, \varphi - \Pi_h\varphi\right) + (\nabla \cdot (\varphi - \Pi_h\varphi), u) \end{aligned}$$

or

$$\begin{aligned} (\alpha\xi, \varphi) &= -\int_0^t (M(t,s)\xi(s), \varphi) ds - (\nabla \cdot \varphi, \eta) \\ &\quad + \left(\alpha\xi + \int_0^t M(t,s)\xi(s) ds, \varphi - \Pi_h\varphi\right) + (\nabla \cdot (\varphi - \Pi_h\varphi), u) \end{aligned}$$

which, together with (2.6), indicates that

$$\begin{aligned}|(\alpha\xi,\varphi)| &\le C\int_0^t ||\xi(s)||_{-1}ds||\varphi||_1 + ||\eta||_0||\varphi||_1 \\ &\quad + Ch|||\xi|||_0||\varphi||_1 + Ch||u||_1||\nabla\cdot(\varphi-\Pi_h\varphi)||_{-1} \\ &\le C\left(\int_0^t ||\varphi||_{-1}ds + ||\eta||_0 + Ch|||\xi|||_0 + Ch||u||_1\right)||\varphi||_1;\end{aligned}$$

that is,

$$||\xi||_{-1} \le C\left\{\int_0^t ||\xi(s)||_{-1}ds + ||\eta||_0 + Ch(|||\xi|||_0 + ||u||_1)\right\}.$$

This, together with Gronwall's lemma, implies that

$$||\xi||_{-1} \le C\left\{||\eta||_0 + Ch(|||\xi|||_0 + ||u||_1)\right\}. \tag{2.12}$$

Substitute (2.12) into (2.11) to obtain

$$||\tau||_0 \le C\left\{\int_0^t ||\eta(s)||_0 ds + h|||\xi|||_0 + h^{2-\delta_{k0}}||\nabla\cdot\xi||_0 + h^{r+1}||u||_r\right\}. \tag{2.13}$$

Therefore, for $0 \le r \le k+1$ we have

$$\begin{aligned}||\eta||_0 &\le ||\rho||_0 + ||\tau||_0 \\ &\le C\left\{\int_0^t ||\eta(s)||_0 ds + h|||\xi|||_0 + h^{2-\delta_{k0}}|||\nabla\cdot\xi|||_0 + h^r||u||_r\right\},\end{aligned}$$

and applying Gronwall's lemma leads to

$$||\eta||_0 \le C\left\{h|||\xi|||_0 + h^{2-\delta_{k0}}||\nabla\cdot\xi||_0 + h^r||u||_r\right\}. \tag{2.14}$$

Since, by (2.5), $(\nabla\cdot\nu, w_h) = (\nabla\cdot\xi, w_h)$ for $w_h \in W_h$, it follows from (2.8) and the choice $w_h = \nabla\cdot\nu \in W_h$ that

$$(\nabla\cdot\nu, \nabla\cdot\nu) = (\nabla\cdot\xi, \nabla\cdot\nu) = -(c\eta, \nabla\cdot\nu)$$

or

$$||\nabla\cdot\nu||_0 \le C||\eta||_0 \tag{2.15}$$

so that

$$||\nabla\cdot\xi||_0 \le ||\nabla\cdot\nu||_0 + ||\nabla\cdot(\sigma-\Pi_h\sigma)||_0 \le C(||\eta||_0 + h^q||\nabla\cdot\sigma||_q),\ 0 \le q \le k+1. \tag{2.16}$$

Also, according to (2.8) ν satisfies

$$\begin{aligned}&\left(\alpha\nu + \int_0^t M(t,s)\nu(s)ds, \nu\right) \\ &= \left(\alpha\xi + \int_0^t M(t,s)\xi(s)ds, \nu\right) + \left(\alpha(\Pi_h\sigma-\sigma) + \int_0^t M(t,s)(\Pi_h\sigma-\sigma)(s)ds, \nu\right) \\ &= -(\nabla\cdot\nu,\eta) + \left(\alpha(\Pi_h\sigma-\sigma) + \int_0^t M(t,s)(\Pi_h\sigma-\sigma)(s)ds, \nu\right) \\ &\le ||\nabla\cdot\nu||_0^2 + ||\eta||_0^2 + C|||\Pi_h\sigma-\sigma|||_0||\nu||_0.\end{aligned}$$

Then we find from Lemma 2.4, (2.15), and the ϵ-type inequality that

$$||\nu||_0^2 - C\int_0^t ||\nu(s)||_0^2 ds \le C(||\eta||_0 + |||\Pi_h\sigma - \sigma|||_0)$$

which, together with Gronwall's lemma and (2.6), implies

$$||\nu||_0 \le C(||\eta||_0 + |||\Pi_h\sigma - \sigma|||_0) \le C(||\eta||_0 + h^m|||\sigma|||_m),\ 1 \le m \le k+1, \tag{2.17}$$

and

$$||\xi||_0 \le ||\nu||_0 + ||\Pi_h\sigma - \sigma||_0 \le C(||\eta||_0 + h^m|||\sigma|||_m),\ 1 \le m \le k+1. \tag{2.18}$$

If (2.16) and (2.18) are substituted into (2.14), then for $0 \le r \le k+1$, $0 \le q \le k+1$, and $1 \le m \le k+1$ it follows that

$$||\eta||_0 \le C\left\{h|||\eta|||_0 + h^r||u||_r + h^{m+1}|||\sigma|||_m + h^{2-\delta_{k0}+q}||\nabla\cdot\sigma||_q\right\}.$$

Thus, for small h we obtain via Gronwall's inequality that

$$||\eta||_0 \le C\left\{h^r||u||_r + h^{m+1}|||\sigma|||_m + h^{2-\delta_{k0}+q}||\nabla\cdot\sigma||_q\right\},$$
$$0 \le r,\ q \le k+1,\ 1 \le m \le k+1.$$

Choose $r = m+1 = 2+q-\delta_{k0}$ to gain that

$$||\eta||_0 = \begin{cases} Ch|||u|||_2 & \text{if } k = 0, \\ Ch^r|||u|||_r & \text{if } k \ge 1 \text{ and } 2 \le r \le k+1, \end{cases}$$

since $||\sigma||_{r-1} + ||\nabla\cdot\sigma||_{r-2} \le C||u||_r$.

It then follows immediately that

$$||\xi||_0 \le Ch^r|||u|||_{r+1}, \qquad 1 \le r \le k+1,$$
$$||\nabla\cdot\xi||_0 \le Ch^r|||u|||_{r+2}, \qquad 0 \le r \le k+1.$$

Therefore, the proof of Theorem 2.5 is completed. □

THEOREM 2.6. *Let $(\bar{u}_h, \bar{\sigma}_h)$ be the mixed Ritz–Volterra projection of $(u,\sigma) \in W \times \mathbf{V}$ defined by (2.7). Then there is a positive constant $C > 0$, independent of $h > 0$ small, such that the error $(u - \bar{u}_h, \sigma - \bar{\sigma}_h)$ can be estimated for any positive integer m by*

$$||D_t^m(u - \bar{u}_h)||_0 \le C\begin{cases} h|||u(t)|||_{2,m} & \text{if } k = 0, \\ h^r|||u(t)|||_{r,m} & \text{if } k \ge 1 \text{ and } 2 \le r \le k+1, \end{cases}$$
$$||D_t^m(\sigma - \bar{\sigma}_h)||_0 \le Ch^r|||u(t)|||_{r+1,m} \quad \text{if } 1 \le r \le k+1,$$
$$||D_t^m(\nabla\cdot(\sigma - \bar{\sigma}_h))||_0 \le Ch^r|||u(t)|||_{r+2,m} \quad \text{if } 0 \le r \le k+1,$$

where

$$|||u(t)|||_{r,m} = \sum_{j=0}^m ||D_t^j u(t)||_r + \int_0^t \sum_{j=0}^m ||D_t^j u(s)||_r ds, \qquad r \in R,\ t \ge 0.$$

Proof. Differentiate (2.7), and then the result for $m = 1$ follows from the same arguments as those for Theorem 2.5.

The proof is completed by treating $m \geq 2$ inductively, using the further differentiation of (2.7). ∎

COROLLARY 2.7. *Let* $(\bar{u}_h, \bar{\sigma}_h)$ *be the mixed Ritz–Volterra projection of* $(u, \sigma) \in W \times \mathbf{V}$ *defined by* (2.7). *Then*

$$||u - \bar{u}_h||_\infty \leq Ch^r \left(||u||_{r,\infty} + |||u|||_{r+1} \right), \quad k \geq 1, \quad \textit{and} \quad 1 \leq r \leq k.$$

Proof. We easily see from (2.13) and Theorem 2.5 that

$$||\tau||_0 \leq Ch^{r+1} |||u|||_{r+1} \quad \text{for } k \geq 1 \quad \text{and} \quad 1 \leq r \leq k$$

and by the inverse inequality that

$$||\tau||_\infty \leq Ch^{-1} ||\tau||_0 \leq Ch^r |||u|||_{r+1}.$$

Thus, we have for $k \geq 1$ and $1 \leq r \leq k$ that

$$\begin{aligned} ||u - \bar{u}_h||_\infty &\leq ||u - P_h u||_\infty + ||\tau||_\infty \\ &\leq Ch^r (||u||_{r,\infty} + |||u|||_{r+1}). \end{aligned}$$ ∎

Remark 2.1. For $k = 0$ we do not have any estimate for the quantity $||u - \bar{u}_h||_\infty$. However, using the superconvergence analysis to be presented in Corollary 5.4, we have for the rectangular Raviart–Thomas elements of the lowest order,

$$||u - u_h||_\infty \leq Ch,$$

where (u, σ) and (u_h, σ_h) are the solutions of (2.1) and (2.2), respectively.

THEOREM 2.8. *Assume that* $(\bar{u}_h, \bar{\sigma}_h)$ *is the mixed Ritz–Volterra projection of* $(u, \sigma) \in W \times \mathbf{V}$ *defined by* (2.7). *Then there is a positive constant* $C_m > 0$, *independent of* $h > 0$ *small, such that for* $m \geq 0$

$$||D_t^m \bar{u}_h||_W + ||D_t^m \bar{\sigma}_h||_{\mathbf{V}} \leq C_m \left\{ \sum_{j=0}^{m} (||D_t^j \sigma||_{\mathbf{V}} + ||D_t^j u||_W) + \int_0^t (||\sigma||_{\mathbf{V}} + ||u||_W) ds \right\}. \tag{2.19}$$

Proof. Rewrite (2.7) as

$$\begin{aligned} &(\alpha \bar{\sigma}_h, \mathbf{v}_h) + (\nabla \cdot \mathbf{v}_h, \bar{u}_h) = F(\mathbf{v}_h), \qquad \mathbf{v}_h \in \mathbf{V}_h, \\ &(\nabla \cdot \bar{\sigma}_h, w_h) + (c\bar{u}_h, w_h) = G(w_h), \qquad w_h \in W_h, \end{aligned}$$

where

$$\begin{aligned} F(\mathbf{v}_h) &= \left(\alpha\sigma + \int_0^t M(t,s)(\sigma - \bar{\sigma}_h)(s) ds, \mathbf{v}_h \right) + (\nabla \cdot \mathbf{v}_h, u), \\ G(w_h) &= (\nabla \cdot \sigma, w_h) + (cu, w_h). \end{aligned}$$

$F(\mathbf{v}_h)$ and $G(w_h)$ can be considered as linear functionals of $\mathbf{v}_h$ and w_h defined on $\mathbf{V}_h$ and W_h, respectively. Thus, we have from the stability result of [1] that

$$\begin{aligned} ||\bar{\sigma}_h||_{\mathbf{V}} + ||\bar{u}_h||_W &\leq C \left\{ \sup_{\mathbf{v}_h \in \mathbf{V}_h} \frac{|F(\mathbf{v}_h)|}{||\mathbf{v}_h||_{\mathbf{V}}} + \sup_{w_h \in W_h} \frac{|G(w_h)|}{||w_h||_W} \right\} \\ &\leq C \left\{ ||\sigma||_{\mathbf{V}} + \int_0^t ||\sigma||_V ds + ||u||_W + \int_0^t ||\bar{\sigma}_h||_{\mathbf{V}} ds \right\}, \end{aligned}$$

or, by Gronwall's inequality,

$$||\bar{\sigma}_h||_{\mathbf{V}} + ||\bar{u}_h||_W \le C\left\{||\sigma||_{\mathbf{V}} + \int_0^t ||\sigma||_{\mathbf{V}} ds + ||u||_W\right\},$$

which demonstrates that (2.19) is true for $m = 0$.

We can also prove (2.19) for $m \ge 1$ by differentiating (2.7) with respect to time t and repeating the same arguments above with mathematical induction. ∎

Remark 2.2. This stability result (2.19) is needed in the analysis of the backward Euler time-discretization scheme. See [19] for details.

3. Sharp L^2-error estimates. In this section, we shall show a sharper L^2-error estimate than the one indicated in (2.4) for the time-continuous approximation scheme (2.2), where the regularity requirement is one order lower than in (2.4), by means of the mixed Ritz–Volterra-type projection instead of the mixed Ritz projection used in [18] to obtain (2.4). Here, let us consider the Raviart–Thomas elements of higher order $k \ge 1$ (see [18] for the lowest-order case).

THEOREM 3.1. *Assume that* (u, σ) *and* (u_h, σ_h) *are the solutions of* (2.1) *and* (2.2), *respectively,* $||P_h u_0 - u_h(0)|| \le Ch^r ||u_0||_r$ *and* $||\Pi_h \sigma(0) - \sigma_h(0)|| \le Ch^r ||u_0||_{r+1}$. *Then we have for* $k \ge 1$ *that*

$$\begin{aligned}
&||u(t) - u_h(t)||_0^2 \\
&\quad \le Ch^{2r}\left\{||u_0||_r^2 + \int_0^t [||u(s)||_r^2 + ||u_t(s)||_r^2] ds\right\}, \qquad 2 \le r \le k+1, \\
&||\sigma(t) - \sigma_h(t)||_0^2 \\
&\quad \le Ch^{2r}\left\{||u_0||_{r+1}^2 + \int_0^t [||u(s)||_{r+1}^2 + ||u_t(s)||_{r+1}^2] ds\right\}, \qquad 1 \le r \le k+1.
\end{aligned}$$

Proof. Let $(\bar{u}_h, \bar{\sigma}_h)$ be the mixed Ritz–Volterra projection of (u, σ) defined by (2.7), and we rewrite the errors as

$$\begin{aligned}
u - u_h &= (u - \bar{u}_h) + (\bar{u}_h - u_h) := \rho + \rho_h, \\
\sigma - \sigma_h &= (\sigma - \bar{\sigma}_h) + (\bar{\sigma}_h - \sigma_h) := \theta + \theta_h.
\end{aligned}$$

Then we know from Theorems 2.5 and 2.6 that

$$\begin{aligned}
&||\rho||_0 \le Ch^r |||u(t)|||_r, && k \ge 1, \quad \text{and} \quad 2 \le r \le k+1, \\
&||\rho_t||_0 \le Ch^r \left(|||u(t)|||_r + |||u_t(t)|||_r\right), && k \ge 1, \quad \text{and} \quad 2 \le r \le k+1
\end{aligned} \tag{3.1}$$

and

$$||\theta(t)||_0 \le Ch^r |||u|||_{r+1}, \quad 1 \le r \le k+1. \tag{3.2}$$

Thus, only $||\rho_h||_0$ and $||\theta_h||_0$ need to be estimated.

It follows from (2.1)–(2.2) and (2.7) that (ρ_h, θ_h) satisfies

$$\begin{aligned}
&\left(\alpha\theta_h + \int_0^t M(t,s)\theta_h(s) ds, \mathbf{v_h}\right) + (\nabla \cdot \mathbf{v}_h, \rho_h) = 0, && \mathbf{v}_h \in \mathbf{V}_h, \\
&(\rho_{h,t}, w_h) - (\nabla \cdot \theta_h, w_h) - (c\rho_h, w_h) = -(\rho_t, w_h), && w_h \in W_h.
\end{aligned} \tag{3.3}$$

Therefore, setting $w_h = \rho_h$ and $\mathbf{v}_h = \theta_h$ in (3.3) we obtain from their sum that

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}||\rho_h||_0^2 - (c\rho_h, \rho_h) + ||\theta_h||_{A^{-1}}^2 &= -\left(\int_0^t M(t,s)\theta_h(s)ds, \theta_h\right) - (\rho_t, \rho_h)\\ &\le C\int_0^t ||\theta_h(s)||_0 ds ||\theta_h||_0 + ||\rho_t||_0||\rho_h||_0\end{aligned}$$

and by means of Lemma 2.4 that

$$\frac{1}{2}\frac{d}{dt}||\rho_h||_0^2 + ||\theta_h||_{A^{-1}}^2 \le C\left(||\rho_h||_0^2 + \int_0^t ||\theta_h||_{A^{-1}}^2 ds\right) + \frac{1}{2}\left(||\theta_h||_{A^{-1}}^2 + ||\rho_t||_0^2\right).$$

Integrating from 0 to t leads to

$$||\rho_h||_0^2 + \int_0^t ||\theta_h||_{A^{-1}}^2 ds \le ||\rho_h(0)||_0^2 + \int_0^t \left[||\rho_h||_0^2 + \int_0^s ||\theta_h(s)||_{A^{-1}}^2 ds\right] + \int_0^t ||\rho_t||_0^2 ds$$

which, together with Gronwall's lemma, implies

$$||\rho_h||_0^2 + \int_0^t ||\theta_h(s)||_{A^{-1}}^2 ds \le C\left\{||\rho_h(0)||_0^2 + \int_0^t ||\rho_t||_0^2 ds\right\}. \tag{3.4}$$

It follows from (2.6), Theorem 2.5, and our initial approximation assumption that

$$\begin{aligned}||\rho_h(0)||_0^2 &= ||\bar{u}_h(0) - u_h(0)||_0^2 \le ||\bar{u}_h(0) - u_0||_0^2\\ &\quad + ||u_0 - P_h u_0||_0^2 + ||P_h u_0 - u_h(0)||_0^2\\ &\le Ch^{2r}||u_0||_r^2.\end{aligned} \tag{3.5}$$

Combining (3.1) and (3.5) with (3.4) we gain

$$||\rho_h||_0^2 \le Ch^{2r}\left\{||u_0||_r^2 + \int_0^t [||u(s)||_r^2 + ||u_t(s)||_r^2] ds\right\}. \tag{3.6}$$

In order to get the estimate for $\theta_h(t)$, we first differentiate (3.3) to obtain

$$\left(\alpha_t\theta_h + \alpha\theta_{h,t} + M(t,t)\theta_h + \int_0^t M_t(t,s)\theta_h(s)ds, \mathbf{v}_h\right) + (\nabla\cdot\mathbf{v}_h, \rho_{h,t}) = 0,\ \mathbf{v}_h \in \mathbf{V}_h,$$

and then by setting $\mathbf{v}_h = \theta_h$ in the above equation and $w_h = \rho_{h,t}$ in (3.3) we have that

$$\begin{aligned}||\rho_{h,t}||_0^2 + (\alpha\theta_{h,t}, \theta_h) + (\alpha_t\theta_h, \theta_h) &= -\left(M(t,t)\theta_h + \int_0^t M_t(t,s)\theta_h(s)ds, \theta_h\right)\\ &\quad + (c\rho_h, \rho_{h,t}) - (\rho_t, \rho_{h,t}).\end{aligned} \tag{3.7}$$

Since

$$\alpha(\theta_h^2)_t = (\alpha\theta_h^2)_t - \alpha_t\theta_h^2,$$

then

$$\begin{aligned}(\alpha\theta_{h,t},\theta_h) &= \int_\Omega \alpha\theta_{h,t}\theta_h = \frac{1}{2}\int_\Omega \alpha\frac{d}{dt}(\theta_h^2)\\ &= \frac{1}{2}\int_\Omega \frac{d}{dt}(\alpha\theta_h^2) - \frac{1}{2}\int_\Omega \alpha_t\theta_h^2\\ &= \frac{1}{2}\frac{d}{dt}||\theta_h||^2_{A^{-1}} - \frac{1}{2}(\alpha_t\theta_h,\theta_h).\end{aligned}$$

Hence, (3.7) can be rewritten as

$$\begin{aligned}||\rho_{h,t}||_0^2 + \frac{1}{2}\frac{d}{dt}||\theta_h||^2_{A^{-1}} + \frac{1}{2}(\alpha_t\theta_h,\theta_h) &= -\left(M(t,t)\theta_h + \int_0^t M_t(t,s)\theta_h(s)ds,\theta_h\right)\\ &\quad + (c\rho_h,\rho_{h,t}) - (\rho_t,\rho_{h,t}).\end{aligned}$$

Thus, from the ϵ-inequality we derive that

$$||\rho_{h,t}||_0^2 + \frac{d}{dt}||\theta_h||^2_{A^{-1}} \le C\left\{||\theta_h||_0^2 + \int_0^t ||\theta_h(s)||_0^2 ds + ||\rho_h||_0^2 + ||\rho_t||_0^2\right\}$$

and then via integrating from 0 to t, Lemma 2.4, and Gronwall's lemma that

$$||\theta_h||_0^2 \le C\left\{||\theta_h(0)||_0^2 + \int_0^t [||\rho_h(s)||_0^2 + ||\rho_t(s)||_0^2]\right\}. \tag{3.8}$$

It follows from (2.6), Theorem 2.5, and our initial approximation assumption that

$$\begin{aligned}||\theta_h(0)||_0^2 &= ||\bar\sigma_h(0) - \sigma_h(0)||_0^2 \le ||\bar\sigma_h(0) - \sigma(0)||_0^2\\ &\quad + ||\sigma(0) - \Pi_h\sigma(0)||_0^2 + ||\Pi_h\sigma(0) - \sigma_h(0)||_0^2\\ &\le Ch^{2r}||u_0||_{r+1}^2.\end{aligned} \tag{3.9}$$

If (3.1), (3.6), and (3.9) are substituted into (3.8), then we can obtain

$$||\theta_h||_0^2 \le Ch^{2r}\left\{||u_0||_{r+1}^2 + \int_0^t [||u(s)||_r^2 + ||u_t(s)||_r^2]ds\right\}.$$

Then the proofs of Theorem 3.1 are complete via the triangle inequality. ∎

Remark 3.1. The assumption in the above theorem $\|P_hu_0 - u_h(0)\|_0 \le Ch^r||u_0||_r$ and $||\Pi_h\sigma(0) - \sigma_h(0)||_0 \le Ch^r||u_0||_{r+1}$ is available. In fact, from (2.1) and (2.3) we know that

$$(\alpha(0)(\sigma - \sigma_h)(0),\mathbf{v}_h) + ((u - u_h)(0),\nabla\cdot\mathbf{v}_h) = 0, \qquad \mathbf{v}_h \in \mathbf{V}_h. \tag{3.10}$$

When we choose $u_h(0) = P_hu_0$, (3.10) becomes

$$(\alpha(0)(\sigma - \sigma_h)(0),\mathbf{v}_h) = 0, \qquad \mathbf{v}_h \in \mathbf{V}_h,$$

since $(u_0 - P_hu_0,\nabla\cdot\mathbf{v}_h) = 0$ according to (2.5). Thus, we have by virtue of (2.6) that

$$(\sigma(0)(\sigma_h(0) - \Pi_h\sigma(0)),\mathbf{v}_h) = (\alpha(0)(\sigma(0) - \Pi_h\sigma(0)),\mathbf{v}_h) \le Ch^r||u_0||_{r+1}||\mathbf{v}_h||_0$$

which, together with Lemma 2.4, indicates that

$$||\sigma_h(0) - \Pi_h\sigma(0)||_0 \le Ch^r||u_0||_{r+1}.$$

Remark 3.2. Compared with (2.4) the result presented in Theorem 3.1 is sharper, since the regularity requirement in Theorem 3.1 is one order lower for the pressure field than that in (2.4), which demonstrates that the mixed Ritz–Volterra projection is more favorable for the mixed finite element method of (2.1) than the mixed Ritz projection used to obtain (2.4).

4. Local L^2 superconvergence on rectangular elements. In the last decade considerable attention has been given to the analysis of superconvergence of mixed finite element approximations to elliptic [11, 15, 35, 36] and parabolic [4, 5] problems under various norms associated with the Gauss lines for the gradient and the Gauss points for the solution itself. In this section, we will extend these superconvergence results in mixed finite element approximations to our problem of parabolic integro-differential equations.

Following [15] we assume that $\Omega \subset R^2$ is a rectangle and define seminorms on $\mathbf{V}$ and W as follows. Letting $e = [a,b] \times [c,d] \in T_h$, we denote by $(g_1, g_2, \ldots, g_{k+1})$ the Gauss points in $[a,b]$ and $(\hat{g_1}, \hat{g_2}, \ldots, \hat{g}_{k+1})$ the Gauss points in $[c,d]$, and define

$$|||v_1|||_{1,e}^2 := \sum_{j=1}^{k+1} A_j \frac{d-c}{2} \int_a^b |v_1(s, \hat{g}_i)|^2 ds,$$
$$|||v_2|||_{2,e}^2 := \sum_{j=1}^{k+1} A_j \frac{b-a}{2} \int_c^d |v_2(s, g_i)|^2 ds,$$

where $A_j > 0$, $j = 1, 2, \ldots, k+1$, are the coefficients of the Gauss quadrature rule in $[-1, 1]$. Thus, for $\mathbf{v} = (v_1, v_2) \in \mathbf{V}$ and $w \in W$, we define

$$|||\mathbf{v}|||_*^2 := |||v_1|||_1^2 + |||v_2|||_2^2, \ |||v_i|||_i^2 := \sum_{e \in T_h} |||v_i|||_{i,e}^2, \ i = 1, 2,$$
$$|||w|||_*^2 := \frac{1}{4} \sum_{e \in T_h} \sum_{i,j=1}^{k+1} A_i A_j \ \text{area}(e) |w(g_i, \hat{g}_j)|^2.$$

Clearly, these two seminorms are equal to the L^2-norm of functions from $\mathbf{V}_h$ and W_h, respectively [11, 15], where $\mathbf{V}_h \times W_h$ is the Raviart–Thomas finite element space of index k (≥ 0). Moreover, let u^I represent the interpolation function of u of degree k with respect to x and y, respectively, on each element associated with the $(k+1)^2$ Gauss points. First of all, we need the following lemmas.

LEMMA 4.1. *Assume that $\sigma \in \left(H^{k+2}(\Omega)\right)^2 \cap \mathbf{V}$, $u \in H^{k+2}(\Omega)$, and u^I is the interpolation function of u defined by $(k+1)^2$ Gauss points. Then we have for some constant $C > 0$ that*

$$|||\sigma - \Pi_h \sigma|||_* \leq C h^{k+2} ||\sigma||_{k+2},$$
$$||P_h u - u^I||_0 \leq C h^{k+2} ||u||_{k+2}.$$

Proof. The proof can be found in [11, 15]. ∎

LEMMA 4.2. *Assume that $\sigma \in \left(H^{k+2}(\Omega)\right)^2 \cap \mathbf{V}$, $u \in H^{k+1}(\Omega)$, c and β are two $W^{1,\infty}(\Omega)$ functions. Then we have for some constant $C > 0$ that*

$$|(c(P_h u - u), w_h)| \leq C h^{k+2} ||u||_{k+1} ||w_h||_0, \qquad w_h \in W_h,$$
$$|(\beta(\Pi_h \sigma - \sigma), \mathbf{v}_h)| \leq C h^{k+2} ||\sigma||_{k+2} ||\mathbf{v}_h||_0, \qquad \mathbf{v}_h \in \mathbf{V}_h.$$

Proof. Let $\hat{c} := \displaystyle\int_\Omega c/|\Omega| dx$, where $|\Omega|$ is the measure of Ω. Then

$$|c(x,t) - \hat{c}(x,t)| \leq C h ||c||_{1,\infty}$$

which, together with the definition of the L^2-projection operator P_h, yields

$$\begin{aligned}|(c(P_hu-u),w_h)| &= |((c-\hat{c})(P_hu-u),w_h)|\\ &\le Ch||P_hu-u||_0||w_h||_0\\ &\le Ch^{k+2}||u||_{k+1}||w_h||_0.\end{aligned}$$

Thus, we obtain the first estimate in Lemma 4.2.

The proof for the second estimate is referred to in [11]. ∎

THEOREM 4.3. *Let $(\bar{u}_h,\bar{\sigma}_h)$ be the mixed Ritz–Volterra projection of (u,σ) defined by (2.7). Then there exists a positive constant $C>0$, independent of h, such that, for any $0\le t\le T$,*

$$|||u-\bar{u}_h|||_* + |||\sigma-\bar{\sigma}_h|||_* \le Ch^{k+2}\left(||u||_{k+2}+||\sigma||_{k+2}+\int_0^t||\sigma||_{k+2}ds\right).$$

Proof. We first observe by the equality of the norms $|||\cdot|||_*$ and $||\cdot||_0$ for the functions in the finite element spaces W_h and $\mathbf{V}_h$ that

$$\begin{aligned}|||u-\bar{u}_h|||_* &\le ||||u-P_hu|||_* + ||P_hu-\bar{u}_h||_0,\\ |||\sigma-\bar{\sigma}_h|||_* &\le |||\sigma-\Pi_h\sigma|||_* + ||\Pi_h\sigma-\bar{\sigma}_h||_0.\end{aligned}$$

Since $u-u^I=0$ at the $(k+1)^2$ Gauss points in each element e, we have according to Lemma 4.1 that

$$|||P_hu-u|||_* = |||P_hu-u^I|||_* = ||P_hu-u^I||_0 \le Ch^{k+2}||u||_{k+2}.$$

In addition, from Lemma 4.1 we also know

$$|||\sigma-\Pi_h\sigma|||_* \le Ch^{k+2}||\sigma||_{k+2}.$$

Hence, it is sufficient to bound $||P_hu-\bar{u}_h||_0$ and $||\Pi_h\sigma-\bar{\sigma}_h||_0$ to complete the proof of Theorem 4.3.

Let $\xi:=\Pi_h\sigma-\bar{\sigma}_h$ and $\tau:=P_hu-\bar{u}_h$. Then we see from (2.5) and (2.7) that

$$\begin{aligned}&(\alpha\xi,\mathbf{v}_h)+(\nabla\cdot\mathbf{v}_h,\tau)=F_0(\mathbf{v}_h)+F_1(\mathbf{v}_h), && \mathbf{v}_h\in\mathbf{V}_h,\\ &(\nabla\cdot\xi,w_h)+(c\tau,w_h)=G_0(w_h), && w_h\in W_h,\end{aligned}\tag{4.1}$$

where

$$\begin{aligned}F_0(\mathbf{v}_h) &= -\left(\alpha(\sigma-\Pi_h\sigma)+\int_0^t M(t,s)(\sigma-\Pi_h\sigma)(s)ds,\mathbf{v}_h\right), && \mathbf{v}_h\in\mathbf{V}_h,\\ F_1(\mathbf{v}_h) &= -\left(\int_0^t M(t,s)\xi(s)ds,\mathbf{v}_h\right), && \mathbf{v}_h\in\mathbf{V}_h,\\ G_0(w_h) &= -(c(u-P_hu),w_h), && w_h\in W_h.\end{aligned}$$

Since the terms F_0, F_1, and G_0 can be regarded as linear functionals of $\mathbf{v}_h$ and w_h defined on $\mathbf{V}_h$ and W_h, respectively, we then know from the stability result of [1] that for any fixed time $0\le t\le T$

$$||\xi||_{\mathbf{V}}+||\tau||_W \le C\left\{\sup_{\mathbf{v}_h\in\mathbf{V}_h}\frac{|F_0(\mathbf{v}_h)+F_1(\mathbf{v}_h)|}{||\mathbf{v}_h||_{\mathbf{V}}}+\sup_{w_h\in W_h}\frac{|G_0(w_h)|}{||w_h||_W}\right\}.\tag{4.2}$$

Let

$$F_0(t) = \sup_{\mathbf{v}_h \in \mathbf{V}_h} \frac{|F_0(\mathbf{v}_h)|}{||\mathbf{v}_h||_{\mathbf{V}}} \quad \text{and} \quad G_0(t) = \sup_{w_h \in W_h} \frac{|G_0(w_h)|}{||w_h||_W}$$

and notice that

$$\sup_{\mathbf{v}_h \in \mathbf{V}_h} \frac{|F_1(\mathbf{v}_h)|}{||\mathbf{v}_h||_{\mathbf{V}}} = \sup_{\mathbf{v}_h \in \mathbf{V}_h} \frac{\left|\left(\int_0^t M(t,s)\xi(s)ds, \mathbf{v}_h\right)\right|}{||\mathbf{v}_h||_{\mathbf{V}}} \le C \int_0^t ||\xi(s)||_{\mathbf{V}} ds.$$

Therefore, we find from (4.2) that

$$||\xi||_{\mathbf{V}} + ||\tau||_W \le C\left(F_0(t) + G_0(t) + C\int_0^t ||\xi(s)||_{\mathbf{V}} ds\right)$$

and by Gronwall's inequality that

$$||\xi||_{\mathbf{V}} + ||\tau||_W \le C(F_0(t) + G_0(t)). \tag{4.3}$$

Now we apply Lemma 4.2 to $F_0(t)$ and $G_0(t)$ to obtain

$$F_0(t) \le Ch^{k+2}\left(||\sigma||_{k+2} + \int_0^t ||\sigma(s)||_{k+2} ds\right) \quad \text{and} \quad G_0(t) \le Ch^{k+2}||u||_{k+1}$$

which, together with (4.3), indicates

$$||\xi||_{\mathbf{V}} + ||\tau||_W \le Ch^{k+2}(||u||_{k+1} + |||\sigma|||_{k+2}). \qquad \square$$

COROLLARY 4.4. *Let $(\bar{u}_h, \bar{\sigma}_h)$ be the mixed Ritz–Volterra projection of (u, σ). Then*

$$\begin{aligned}
&|||D_t(u - \bar{u}_h)|||_* + |||D_t(\sigma - \bar{\sigma}_h)|||_* \\
&\le Ch^{k+2}\left\{||u||_{k+1} + ||u_t||_{k+2} + ||\sigma||_{k+2} + ||\sigma_t||_{k+2} + \int_0^t [||u(s)||_{k+1} + ||\sigma(s)||_{k+2}] ds\right\}.
\end{aligned}$$

Proof. Differentiating (4.1) with respect to time t, then we see that ξ_t and τ_t satisfy the same equations with the right-hand sides replaced by

$$\begin{aligned}
F_0'(\mathbf{v}_h) &= -(\alpha(\sigma_t - \Pi_h\sigma_t) + (\alpha_t + M(t,t))(\sigma - \Pi_h\sigma), \mathbf{v}_h) \\
&\quad + \left(\int_0^t M_t(t,s)(\sigma - \Pi_h\sigma)(s)ds, \mathbf{v}_h\right), && \mathbf{v}_h \in \mathbf{V}_h, \\
F_1'(\mathbf{v}_h) &= -\left(M(t,t)\xi + \int_0^t M_t(t,s)\xi(s)ds, \mathbf{v}_h\right), && \mathbf{v}_h \in \mathbf{V}_h, \\
G_0'(w_h) &= -(c_t(u - P_h u + \tau), w_h) - (c(u - P_h u)_t, w_h), && w_h \in W_h.
\end{aligned}$$

Thus, Corollary 4.4 follows from the same argument above. $\square$

In order to obtain superconvergence results for mixed finite element approximations for our parabolic integro-differential equations we choose our initial data approximation $(u_h(0), \sigma_h(0)) \approx (u_0(x), A(0)\nabla u_0(x))$ as the mixed elliptic projection:

$$\begin{aligned}
&(\alpha(0)(\sigma_h(0) - \sigma(0)), \mathbf{v}_h) + (\nabla \cdot \mathbf{v}_h, u_h(0) - u_0) = 0, && \mathbf{v}_h \in \mathbf{V}_h, \\
&(\nabla \cdot (\sigma_h(0) - \sigma(0)), w_h) + (c(0)(u_h(0) - u_0), w_h) = 0, && w_h \in W_h.
\end{aligned} \tag{4.4}$$

THEOREM 4.5. *Let* (u,σ) *and* (u_h,σ_h) *be the solutions of* (2.1) *and* (2.2), *respectively, and* $(u_h(0),\sigma_h(0))$ *is chosen according to* (4.4). *Then there exists a positive constant* $C>0$ *such that, for any* $0\le t\le T$,

$$
\begin{aligned}
&|||u-u_h|||_* + |||\sigma-\sigma_h|||_* \\
&\le Ch^{k+2}\left\{||u||_{k+2}+||\sigma||_{k+2}+\left[\int_0^t (||u||_{k+1}^2+||\sigma||_{k+2}^2+||u_t||_{k+1}^2+||\sigma_t||_{k+2}^2)ds\right]^{1/2}\right\}.
\end{aligned}
$$

Proof. First, the errors are decomposed as

$$
\begin{aligned}
u-u_h &= (u-\bar{u}_h)+(\bar{u}_h-u_h) := \rho+\rho_h,\\
\sigma-\sigma_h &= (\sigma-\bar{\sigma}_h)+(\bar{\sigma}_h-\sigma_h) := \theta+\theta_h,
\end{aligned}
$$

and then by Theorem 4.3 we have that

$$
|||\rho|||_* + |||\theta|||_* \le Ch^{k+2}(||u||_{k+2}+|||\sigma|||_{k+2}).
$$

Moreover, from (2.7) and (4.4) we derive that

$$
\begin{aligned}
&(\alpha(0)\theta_h(0),\mathbf{v}_h)+(\nabla\cdot\mathbf{v}_h,\rho_h(0))=0, \qquad \mathbf{v}_h\in\mathbf{V}_h,\\
&(\nabla\cdot\theta_h(0),w_h)+(c(0)\rho_h(0),w_h)=0, \qquad w_h\in W_h,
\end{aligned}
$$

which, together with the uniqueness of the solution to (2.7), implies

$$
\theta_h(0)=\rho_h(0)=0. \tag{4.5}
$$

Furthermore, from the proof for Corollary 4.4 we know that

$$
||\tau_t||_0 \le Ch^{k+2}\left\{|||u|||_{k+1}+|||\sigma|||_{k+2}+||u_t||_{k+1}+||\sigma_t||_{k+2}\right\}
$$

which, together with the definition of the local L^2-projection operator P_h, demonstrates that

$$
\begin{aligned}
|(\rho_t,\rho_h)| &= |(\tau_t,\rho_h)|\\
&\le Ch^{k+2}\left\{|||u|||_{k+1}+|||\sigma|||_{k+2}+||u_t||_{k+1}+||\sigma_t||_{k+2}\right\}||\rho_h||_0.
\end{aligned}
$$

Noticing that $|||\rho_h|||_* = ||\rho_h||_0$ and $|||\theta_h|||_* = ||\theta_h||_0$ as well as (4.5), we can obtain the desired estimates for ρ_h and θ_h in L^2-norm through the same procedure as that in Theorem 3.1 for ρ_h and θ_h. ∎

5. Global L^2 superconvergence on quadrilaterals. In [20, 25] superconvergence has been obtained in mixed finite element methods on quadrilaterals for elliptic equations. Here we shall extend these results to our parabolic integro-differential equations. The strategy employed here is that we first examine the superclose accuracy between the interpolation function of the exact solution and the mixed finite element solution of (1.1) by means of integral identities, and then we use a suitable interpolation postprocessing method to obtain global superconvergence approximations [25, 26]. As by-products, these superconvergence results can be utilized to form a class of useful a posteriori error estimators to assess the accuracy of the mixed finite element solutions in applications.

Let $\hat{\mathbf{V}}_h(\hat{e}) \times \hat{W}_h(\hat{e})$ be the standard local Raviart–Thomas rectangular space on the reference element $\hat{e} := [-1,1] \times [-1,1]$ of order k (≥ 0); i.e.,

$$\begin{aligned} \hat{\mathbf{V}}_h(\hat{e}) &:= Q_{k+1,k}(\hat{e}) \times Q_{k,k+1}(\hat{e}), \\ \hat{W}_h(\hat{e}) &:= Q_{k,k}(\hat{e}), \end{aligned}$$

where $Q_{m,n}(\hat{e})$ indicates the space of polynomials of degree no more than m and n in x and y on $\hat{e}$, respectively. On arbitrary convex quadrilateral element $e \in T_h$, the local Raviart–Thomas space is defined by

$$\begin{aligned} \mathbf{V}_h(e) &:= \{\mathbf{q} = G\tilde{\mathbf{q}} \circ \hat{F}_e^{-1} : \ \tilde{\mathbf{q}} \in \hat{\mathbf{V}}_h(\hat{e})\}, \\ W_h(e) &:= \{w = \hat{w} \circ \hat{F}_e^{-1} : \ \hat{w} \in \hat{W}_h(\hat{e})\}, \end{aligned}$$

where $\hat{F}_e$ is the affine map which takes $\hat{e}$ onto e and $G := |\det(M_0)|^{-1} M_0$ with M_0 being the Jacobian matrix (derivative) of $\hat{F}_e$. Of course, $\mathbf{V}_h(e) \subset (C^\infty(e))^2$ and $W_h(e) \subset C^\infty(e)$ are no longer of polynomials on e unless e is a parallelogram.

The global Raviart–Thomas finite element space over the partition T_h is defined in the standard way as follows:

$$\begin{aligned} \mathbf{V}_h &:= \{\mathbf{v} \in H(\mathrm{div};\ \Omega) : \ \mathbf{v}|_e \in \mathbf{V}_h(e) \ \forall e \in T_h\}, \\ W_h &:= \{w \in L^2(\Omega) : \ w|_e \in W_h(e) \ \forall e \in T_h\}. \end{aligned}$$

Let $\tilde{\sigma}$ and $\tilde{u}$ be two vector-valued and scalar-valued functions, respectively, on the reference element $\hat{e}$. Recall that the interpolation functions (or the Raviart–Thomas projection) $\hat{\Pi}_h\tilde{\sigma}$ and $\hat{P}_h\tilde{u}$ over $\hat{e}$ are defined by the following linear systems:

$$\begin{aligned} &\int_{\hat{l}_i} (\tilde{\sigma} - \hat{\Pi}_h\tilde{\sigma}) \cdot \mathbf{n} q ds = 0 && \forall q \in P_k(\hat{l}_i), \qquad i = 1,2,3,4, \\ &\int_{\hat{e}} (\tilde{\sigma} - \hat{\Pi}_h\tilde{\sigma}) \cdot \phi = 0 && \forall \phi \in Q_{k-1,k}(\hat{e}) \times Q_{k,k-1}(\hat{e}), \quad \text{and} \\ &\int_{\hat{e}} (\tilde{u} - \hat{P}_h\tilde{u}) q = 0 && \forall q \in Q_{k,k}(\hat{e}), \quad \text{respectively,} \end{aligned} \tag{5.1}$$

where $\hat{l}_i$ ($i = 1,2,3,4$) is one of the four sides of $\hat{e}$, $\mathbf{n}$ is the outward normal vector to $\hat{e}$, and P_r denotes the set of polynomials of total degree no more than r. If $e \in T_h$ is an arbitrary quadrilateral element, and σ and u are two vector-valued and scalar-valued functions defined on e, then their interpolation functions $\Pi_h\sigma$ and P_hu on e are defined by

$$\Pi_h\sigma := G(\hat{\Pi}_h(G^{-1}\hat{\sigma})) \quad \text{and} \quad P_hu := \hat{P}_h\hat{u}, \quad \text{respectively,} \tag{5.2}$$

where $\hat{\sigma} := \sigma \circ \hat{F}_e$ and $\hat{u} := u \circ \hat{F}_e$. Then we have [20]

$$\begin{aligned} &(\nabla \cdot (\sigma - \Pi_h\sigma), w_h) = 0 && \forall w_h \in W_h, \\ &(\nabla \cdot \mathbf{v}_h, u - P_hu) = 0 && \forall \mathbf{v}_h \in \mathbf{V}_h. \end{aligned} \tag{5.3}$$

The semidiscrete mixed finite element method for (1.1) is now defined as follows: Find $(u_h, \sigma_h) \in W_h \times \mathbf{V}_h$ satisfying

$$\begin{aligned} &(u_{h,t}, w_h) - (\nabla \cdot \sigma_h, w_h) - (cu_h, w_h) = (f, w_h), && w_h \in W_h, \\ &(\alpha\sigma_h, \mathbf{v}_h) + \int_0^t (M(t,s)\sigma_h(s), \mathbf{v}_h) ds + (u_h, \nabla \cdot \mathbf{v}_h) = \langle g, \mathbf{n} \cdot \mathbf{v}_h \rangle, && \mathbf{v}_h \in \mathbf{V}_h, \\ &u_h(0) = P_hu_0, \quad \sigma_h(0) = \Pi_h\sigma(0). \end{aligned} \tag{5.4}$$

From (2.1) and (5.4) we derive the following error equation:

$$\begin{aligned}
&(u_t - u_{h,t}, w_h) - (\nabla\cdot(\sigma-\sigma_h), w_h) - (c(u-u_h), w_h) = 0, && w_h \in W_h,\\
&(\alpha(\sigma-\sigma_h), \mathbf{v}_h) + \int_0^t (M(t,s)(\sigma-\sigma_h)(s), \mathbf{v}_h)ds + (u-u_h, \nabla\cdot\mathbf{v}_h) = 0, && \mathbf{v}_h \in \mathbf{V}_h.
\end{aligned} \tag{5.5}$$

From [20, 25] we recall the following lemmas.

LEMMA 5.1. *If $P_h u$ is the interpolation function of u defined as in* (5.2), *and $c \in W^{1,\infty}(\Omega)$, then there exists a constant C such that*

$$|(c(u-P_h u), w_h)| \le Ch^{k+2}||u||_{k+1}||w_h||_0, \quad w_h \in W_h.$$

LEMMA 5.2. *If the finite element partition T_h is h^2-uniform* [20] *or a generalized rectangular mesh* [25], *and $\Pi_h\sigma$ is the interpolation function of σ defined as in* (5.2), *then there exists a constant C such that for sufficiently smooth β*

$$|(\beta(\sigma-\Pi_h\sigma), \mathbf{v}_h)| \le Ch^{k+2}||\sigma||_{k+2}||\mathbf{v}_h||_0, \quad \mathbf{v}_h \in \mathbf{V}_h.$$

We are now ready to get our main theorem in this section.

THEOREM 5.3. *Assume that the finite element partition T_h is h^2-uniform or generalized rectangular and (u_h, σ_h) is the approximate solution of* (1.1) *defined in* (5.4) *by using quadrilateral elements of Raviart–Thomas of order k. If the exact solution u and σ satisfies $u \in H^{k+1}(\Omega)$, and σ, $\sigma_t \in (H^{k+2}(\Omega))^2$, then we have*

$$||u_h - P_h u||_0 + ||\sigma_h - \Pi_h\sigma||_0 \le Ch^{k+2}\left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2 + ||\sigma_t||_{k+2}^2)ds\right]^{1/2}. \tag{5.6}$$

Proof. Let $\rho_h^* := u_h - P_h u$ and $\theta_h^* := \sigma_h - \Pi_h\sigma$. Then it follows from (5.3) and (5.5) that

$$\begin{aligned}
&(\alpha\theta_h^*, \mathbf{v}_h) + \int_0^t (M(t,s)\theta_h^*(s), \mathbf{v}_h)ds + (\rho_h^*, \nabla\cdot\mathbf{v}_h)\\
&\quad = \left(\alpha(\sigma-\Pi_h\sigma) + \int_0^t M(t,s)(\sigma-\Pi_h\sigma)(s)ds, \mathbf{v}_h\right), && \mathbf{v}_h \in \mathbf{V}_h,\\
&(\rho_{h,t}^*, w_h) - (\nabla\cdot\theta_h^*, w_h) - (c\rho_h^*, w_h) = -(c(u-P_h u), w_h), && w_h \in W_h.
\end{aligned} \tag{5.7}$$

Thus, letting $w_h = \rho_h^*$ and $\mathbf{v}_h = \theta_h^*$ in (5.7) we obtain from Lemmas 2.4, 5.1, and 5.2 as well as the ϵ-type inequality that

$$\frac{1}{2}\frac{d}{dt}||\rho_h^*||_0^2 + ||\theta_h^*||_0^2 \le C\left\{\int_0^t ||\theta_h^*||_0^2 ds + ||\rho_h^*||_0^2 + Ch^{2k+4}(||u||_{k+1}^2 + |||\sigma|||_{k+2}^2)\right\}.$$

Integrating from 0 to t and noticing $\rho_h^*(0) = 0$ yield according to Gronwall's lemma that

$$||\rho_h^*||_0^2 + \int_0^t ||\theta_h^*||_0^2 ds \le Ch^{2k+4}\int_0^t (||u||_{k+1}^2 + |||\sigma|||_{k+2}^2)ds$$

or

$$||\rho_h^*||_0 \le Ch^{k+2}\left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2)ds\right]^{1/2}. \tag{5.8}$$

Following the same steps to get the estimate for $\theta_h := \bar{\sigma}_h - \sigma_h$ in Theorem 3.1 we can also obtain

$$||\theta_h^*||_0 \le Ch^{k+2}\left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2 + ||\sigma_t||_{k+2}^2)ds\right]^{1/2}. \tag{5.9}$$

Combining (5.8) with (5.9) implies (5.6). □

As a by-product of (5.6), we immediately gain the following corollary from the inverse property of the finite element space and the approximation property of the local L^2-projection operator P_h.

COROLLARY 5.4. *Assume that T_h is h^2-uniform or a generalized rectangular mesh and the exact solution u and σ satisfies $u \in W^{k+1,\infty}(\Omega)$ and $\sigma \in (H^{k+2}(\Omega))^2$. Then we have for the mixed finite element solution u_h defined by* (5.4) *that*

$$||u - u_h||_\infty \le Ch^{k+1}\left\{||u||_{k+1,\infty} + \left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2)ds\right]^{1/2}\right\}.$$

In order to improve the accuracy of the finite element approximation to the exact solution on a global scale, a reasonable postprocessing method is proposed according to (5.1) and Theorem 5.3 [25, 26]. For this end, we need to define two postprocessing interpolation operators Π_{2h} and P_{2h} to satisfy

$$\begin{aligned}
&\Pi_{2h}\Pi_h = \Pi_{2h},\\
&||\Pi_{2h}\mathbf{v}_h||_0 \le C||\mathbf{v}_h||_0 && \forall \mathbf{v}_h \in \mathbf{V}_h,\\
&||\Pi_{2h}\sigma - \sigma||_0 \le Ch^{k+2}||\sigma||_{k+2} && \forall \sigma \in (H^{k+2}(\Omega))^2,\\
&P_{2h}P_h = P_{2h},\\
&||P_{2h}w_h||_0 \le C||w_h||_0 && \forall w_h \in W_h,\\
&||P_{2h}u - u||_0 \le Ch^{k+2}||u||_{k+2} && \forall u \in H^{k+2}(\Omega).
\end{aligned} \tag{5.10}$$

For easy exposition, we demonstrate our idea mainly for the case of $k = 2$. Thus, we assume that the standard rectangular partition $\hat{T}_h$ has been obtained from $\hat{T}_{2h} = \{\hat{\tau}\}$ with mesh size $2h$ by subdividing each element of $\hat{T}_{2h}$ into four small congruent rectangles. Let $\hat{\tau} := \bigcup_{i=1}^4 \hat{e}_i$ with $\hat{e}_i \in \hat{T}_h$. Thus, we can define two interpolation operators $\hat{\Pi}_{2h}$ and $\hat{P}_{2h}$ associated with $\hat{T}_{2h}$ of degree at most 3 in x and y on $\hat{\tau}$, respectively, according to the following conditions:

$$\begin{aligned}
&\hat{\Pi}_{2h}\tilde{\sigma}|_{\hat{\tau}} \in (Q_{3,3}(\hat{\tau}))^2, && \hat{P}_{2h}\tilde{u}|_{\hat{\tau}} \in Q_{3,3}(\hat{\tau}),\\
&\int_{\hat{l}_i} (\tilde{\sigma} - \hat{\Pi}_{2h}\tilde{\sigma}) \cdot \mathbf{n} q ds = 0 && \forall q \in P_1(\hat{l}_i),\ i = 1, 2, \ldots, 12,\\
&\int_{\hat{e}_i} (\tilde{\sigma} - \Pi_{2h}\tilde{\sigma}) = 0, && i = 1, 2, 3, 4, \quad \text{and}\\
&\int_{\hat{e}_i} (\tilde{u} - \hat{P}_{2h}\tilde{u})q = 0 && \forall q \in Q_{1,1}(\hat{e}_i),\ i = 1, 2, 3, 4, \quad \text{respectively,}
\end{aligned} \tag{5.11}$$

where $\hat{l}_i$ $(i = 1, 2, \ldots, 12)$ is one of the 12 sides of the four small elements $\hat{e}_i$ $(i = 1, 2, 3, 4)$.

Obviously, the following properties can be easily checked by (5.1) for $k = 2$ and (5.11):

$$
\begin{aligned}
&\hat{\Pi}_{2h}\hat{\Pi}_h = \hat{\Pi}_{2h},\\
&||\hat{\Pi}_{2h}\hat{\mathbf{v}}_h||_0 \le C||\hat{\mathbf{v}}_h||_0 \qquad \forall \hat{\mathbf{v}}_h \in \hat{\mathbf{V}}_h,\\
&||\hat{\Pi}_{2h}\tilde{\sigma} - \tilde{\sigma}||_0 \le Ch^4||\tilde{\sigma}||_4 \qquad \forall \tilde{\sigma} \in (H^4(\Omega))^2,\\
&\hat{P}_{2h}\hat{P}_h = \hat{P}_{2h},\\
&||\hat{P}_{2h}\hat{w}_h||_0 \le C||\hat{w}_h||_0 \qquad \forall \hat{w}_h \in \hat{W}_h,\\
&||\hat{P}_{2h}\tilde{u} - \tilde{u}||_0 \le Ch^4||\tilde{u}||_4 \qquad \forall \tilde{u} \in H^4(\Omega).
\end{aligned} \tag{5.12}
$$

Then we can define two interpolation operators Π_{2h} and P_{2h} associated with T_{2h} by

$$
\Pi_{2h}\sigma := G(\hat{\Pi}_{2h}(G^{-1}\sigma \circ \hat{F}_e)) \quad \text{and} \quad P_{2h}u := \hat{P}_{2h}(u \circ \hat{F}_e), \quad \text{respectively,} \tag{5.13}
$$

which satisfy (5.10) by (5.2) and (5.12). Similarly, we can also define Π_{2h} and P_{2h} for the case of $k \neq 2$.

By virtue of the two interpolation operators Π_{2h} and P_{2h} we immediately gain the following global superconvergence theorem.

THEOREM 5.5. *If there is, besides the conditions of Theorem* 5.3, $u \in H^{k+2}(\Omega)$, *then we have*

$$
\begin{aligned}
&||P_{2h}u_h - u||_0 + ||\Pi_{2h}\sigma_h - \sigma||_0\\
&\quad \le Ch^{k+2}\left\{||u||_{k+2} + ||\sigma||_{k+2} + \left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2 + ||\sigma_t||_{k+2}^2)ds\right]^{1/2}\right\}.
\end{aligned}
$$

Proof. From one of the properties of the operator P_{2h} in (5.10) we find that

$$
P_{2h}u_h - u = P_{2h}(u_h - P_h u) + (P_{2h}u - u).
$$

Therefore, it follows from Theorem 5.3 and (5.10) that

$$
\begin{aligned}
||P_{2h}u_h - u||_0 &\le C||u_h - P_h u||_0 + ||P_{2h}u - u||_0\\
&\le Ch^{k+2}\left\{||u||_{k+2} + \left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2)ds\right]^{1/2}\right\}.
\end{aligned}
$$

Analogously, we can obtain

$$
||\Pi_{2h}\sigma_h - \sigma||_0 \le Ch^{k+2}\left\{||\sigma||_{k+2} + \left[\int_0^t (||u||_{k+1}^2 + ||\sigma||_{k+2}^2 + ||\sigma_t||_{k+2}^2)ds\right]^{1/2}\right\}. \qquad \square
$$

It is of great importance for a mixed finite element method to have a computable a posteriori error estimator by which we can assess the accuracy of the mixed finite element solution in applications. One way to construct error estimators is to employ certain superconvergence properties of the finite element solutions. In fact, we have the following theorem.

THEOREM 5.6. *We have under the conditions of Theorem* 5.5 *that*

$$
||u - u_h||_0 = ||P_{2h}u_h - u_h||_0 + O(h^{k+2}), \tag{5.14}
$$

$$||\sigma - \sigma_h||_0 = ||\Pi_{2h}\sigma_h - \sigma_h||_0 + O(h^{k+2}). \tag{5.15}$$

In addition, if there exist positive constants C_1, C_2 *and small* ϵ_1, $\epsilon_2 \in (0,1)$ *such that*

$$||u - u_h||_0 \geq C_1 h^{k+2-\epsilon_1}, \tag{5.16}$$

$$||\sigma - \sigma_h||_0 \geq C_2 h^{k+2-\epsilon_2}, \tag{5.17}$$

then there hold

$$\lim_{h\to 0} \frac{||u - u_h||_0}{||P_{2h}u_h - u_h||_0} = 1, \tag{5.18}$$

$$\lim_{h\to 0} \frac{||\sigma - \sigma_h||_0}{||\Pi_{2h}\sigma_h - \sigma_h||_0} = 1. \tag{5.19}$$

Proof. It follows from Theorem 5.5 and

$$u - u_h = (P_{2h}u_h - u_h) + (u - P_{2h}u_h)$$

that

$$||u - u_h||_0 = ||P_{2h}u_h - u_h||_0 + O(h^{k+2}).$$

Thus, from (5.16) we know

$$\frac{||P_{2h}u_h - u_h||_0}{||u - u_h||_0} + Ch^{\epsilon_1} \geq 1$$

or

$$\lim_{h\to 0} \frac{||P_{2h}u_h - u_h||_0}{||u - u_h||_0} \geq 1. \tag{5.20}$$

Similarly, it follows from (5.16) and

$$||P_{2h}u_h - u_h||_0 = ||u - u_h||_0 + O(h^{k+2})$$

that

$$\overline{\lim_{h\to 0}} \frac{||P_{2h}u_h - u_h||_0}{||u - u_h||_0} \leq 1$$

which, together with (5.20), leads to (5.18).

Analogously, we can obtain (5.15) and (5.19). ∎

We know from (5.14) that the computable error quantity $||P_{2h}u_h - u_h||_0$ is the principal part of the mixed finite element error $||u - u_h||_0$ and can be used as a reliable a posteriori error indicator to assess the accuracy of the mixed finite element solution under the condition (5.16). Also, (5.16) seems to be a reasonable assumption, since $O(h^{k+1})$ is the optimal convergence rate of the mixed finite element solution in L^2-norm. The same comments are also valid for (5.15) and (5.17).

Acknowledgments. The authors express their thanks to the referees whose comments lead to improvements in the final version of the paper.

NEW LOCKING-FREE MIXED METHOD FOR THE REISSNER–MINDLIN THIN PLATE MODEL*

MOHAMED AMARA†, DANIELA CAPATINA-PAPAGHIUC†, AND AMNA CHATTI‡

Abstract. We are interested here in the Reissner–Mindlin model for a bending thin plate with physical boundary conditions. It is well known that this problem depends singularly upon the plate's thickness ε. By decomposing the bending moment and by dualizing its symmetry, we obtain an equivalent mixed formulation of the initial problem whose unknowns now belong to classical Sobolev spaces. We then propose a low-order conforming finite element method for which we obtain optimal error estimates independently upon the small parameter ε. Thus, the discrete method is unconditionally convergent and locking-free. It directly gives an approximation of the bending moment and allows us to recover the two other variables, which are the deflection and the rotation vector.

Key words. mixed formulation, finite element, error estimates, locking-free

1. Introduction and notations.

This paper is devoted to the study of the Reissner–Mindlin model for a bending thin plate satisfying physical boundary conditions.

We have already analyzed in [1] the simpler case of the Kirchhoff–Love problem for a bending plate with natural boundary conditions. We proposed there a conforming piecewise linear finite element method which is unconditionally convergent and which gives an optimal convergence rate whenever the exact solution is sufficiently smooth. One thus gets an approximation of the bending moment in the space $(L^2(\Omega))^4$, while the plate's deflection is approximated in the space $H^1(\Omega)$. To do that, the main idea consists of associating with the symmetric bending tensor a unique vector function, which is not a physical variable but which belongs to a classical Sobolev space $(H^1(\Omega))^2$, and then obtaining and discretizing an equivalent formulation in this new unknown.

The aim of the present work is to generalize to the Reissner–Mindlin case the approach that was used in [1] for the Kirchhoff–Love model.

The equations of the Reissner–Mindlin model depend upon a small parameter ε characterizing the plate's thickness. It is well known that this is a singular problem with respect to ε; in the limit case $\varepsilon = 0$ one obtains the Kirchhoff–Love model previously studied in [1]. One of the major difficulties in discretizing the Reissner–Mindlin problem consists of finding a finite element approximation which does not suffer from numerical locking as the plate's thickness becomes very small. For a general presentation of this phenomenon, one may see [3], for instance.

The physical boundary conditions imposed in this paper represent an additional difficulty from both the theoretical and the numerical point of view. Indeed, even if there are many papers in the literature dealing with the approximation of the Reissner–Mindlin model, the great majority of them consider simple Dirichlet bound-

ary conditions for the deflection and the rotation. That means that the plate is supposed to be clamped and in this case one usually eliminates the bending moment from the equations and computes only the deflection and the rotation. This approach is clearly no longer possible when dealing with complex boundary conditions like ours. Moreover, we are interested in obtaining a good approximation of the bending tensor, since in practice it usually represents the quantity of interest for the engineers. Thus, our formulation is new and explicitly takes into account the boundary conditions satisfied by the bending moment.

The approach developed here is based on the same idea as in [1], which is the decomposition of the bending moment by the means of Tartar's lemma (see, for instance, [8]). However, its symmetry is no longer imposed but is dualized by the means of a Lagrange multiplier. Therefore, we now associate with the bending tensor a couple of functions belonging to $(H^1(\Omega))^2 \times H^1(\Omega)$. This finally allows us to obtain an equivalent mixed formulation of the initial problem, whose operator can be written as follows:

$$\begin{pmatrix} A+\varepsilon^2 A_0 & B & C \\ B^T & O & O \\ C^T & O & O \end{pmatrix}, \tag{1.1}$$

where A and B are the same as in the Kirchhoff–Love case. The bilinear form B takes into account the boundary conditions imposed on the bending moment, A_0 takes into account the additional unknown of the Reissner–Mindlin model, that is, the rotation vector, and C dualizes the symmetry of the bending tensor.

Let us remark here that this kind of operator is not typical for such a singularly perturbed problem. Indeed, the mixed formulations usually employed (cf., for instance, [5], and references therein) are obtained by dualizing the constraint imposed in the limit case $\varepsilon = 0$ (that means, in our case, the constraint $\mathbf{r} = \nabla u$ imposed in the Kirchhoff-Love model). Their operator then writes as

$$\begin{pmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{B}^T & \varepsilon^2 \mathcal{C} \end{pmatrix},$$

so our approach in order to avoid the shear locking phenomenon is different.

Before proposing our approximation method, let us first point out the solutions generally proposed in the literature in order to get a locking-free discretization of the Reissner–Mindlin model. However, let us specify that all these methods are introduced for clamped plates and they do not apply to complex boundary conditions. For an exhaustive presentation of the existing results and for recent references on the Reissner–Mindlin model, the reader may see [7].

One of the most commonly used approach consists of writing a mixed formulation as above. But generally it is difficult to find simple and cheap finite element spaces for which the theory of Babuška–Brezzi holds. In practice, this leads to modifying certain operators by the means of reduced integration techniques, or to adding a stabilization term, or to using nonconforming finite elements (eventually enriched with bubble functions). Another solution is to write an equivalent formulation by the means of the Helmholtz decomposition and of two additional unknowns, as in [2] and in [5]. One may also work with the standard variational formulation and employ for the discretization more expensive continuous finite elements (see [11]) or nonconforming elements. Finally, one may employ p or hp methods (see, for instance, [11]), which are known to work well for problems concerned with locking, or use least squares methods, as in [4].

An outline of the paper is as follows. We begin by introducing the boundary value problem and by giving a mathematical framework in which it is well-posed. In section 3 we state a mixed variational formulation whose operator writes as in (1.1) and we show, thanks to the Babuška–Brezzi theory, that this problem is well-posed. Moreover, its main unknown is exactly the bending moment, while the dual unknowns are the displacement's trace and the rotation's normal trace (corresponding to the bilinear form B), respectively, an additional multiplier which dualizes the symmetry of the bending moment (corresponding to C). However, the test-functions corresponding to $A + \varepsilon^2 A_0$ have to satisfy the constraint $\mathrm{div}\mathbf{div}(\cdot) = 0$. In order to avoid its discretization, we associate with the bending moment a unique couple of functions now belonging to classical spaces, and we study an equivalent mixed formulation in these new variables. This is done in section 4, while in section 5 we rigorously establish the link between the two formulations of the problem. Finally, section 6 is devoted to the numerical approximation. We discretize the last saddle point problem by classical finite elements (continuous P_1 and P_2, discontinuous P_0), for which we prove a discrete inf-sup condition uniformly with respect to both h and ε. This insures the unconditional convergence of the method independently of the small parameter ε as well as optimal error estimates. Next, one gets uniform approximations of the initial physical variables in the following spaces: the bending moment in $(H(\mathrm{div};\Omega))^2$ endowed with the weighted-norm $\|\cdot\|_{0,\Omega} + \varepsilon \|\mathbf{div}(\cdot)\|_{0,\Omega}$, the transverse displacement in $H^1(\Omega)$, and the rotation $\mathbf{r}^\varepsilon$ in $L^2(\Omega)^2$, with also an approximation of $curl\mathbf{r}^\varepsilon$ in $L^2(\Omega)$. Let us also notice that the discrete bending moment and rotation are given by simple formulae, while the discrete deflection is obtained by solving a Laplace problem.

As a conclusion, we propose here a well-posed formulation which takes into account the physical boundary conditions imposed in the Reissner–Mindlin model. For any fixed ε, its discretization by simple low-order finite elements is shown to be unconditionally convergent and, moreover, locking-free. If the exact solution is sufficiently smooth, then an optimal convergence rate $O(h)$ is obtained.

2. Physical Reissner–Mindlin model. Let us begin this paragraph by introducing some notations which will be used in what follows. We note that $\mathbf{n} = (n_i)_{1\le i\le 2}$, the unit outward normal vector along Γ, and that $\mathbf{t} = (t_i)_{1\le i\le 2}$, the unit tangent vector to Γ oriented such that $t_1 = n_2$, $t_2 = -n_1$. We also employ in this paper the summation convention of Einstein, and we denote by the letter c any positive constant independent upon both the discretization parameter h and the plate's thickness ε. We agree to write the vectors in bold letters and the tensors in underlined letters. Let us also recall here some classical notation: for any vector function $\mathbf{v}$ and any scalar function v we note that

$$curl\,\mathbf{v} = \partial_1 v_2 - \partial_2 v_1, \qquad \mathrm{div}\,\mathbf{v} = \partial_i v_i,$$

$$\mathbf{curl}\,v = \begin{pmatrix} \partial_2 v \\ -\partial_1 v \end{pmatrix}, \quad \underline{curl}\,\mathbf{v} = \begin{pmatrix} \partial_2 v_1 & -\partial_1 v_1 \\ \partial_2 v_2 & -\partial_1 v_2 \end{pmatrix}, \quad \mathbf{div}\underline{\tau} = \begin{pmatrix} \partial_1\tau_{11} + \partial_2\tau_{12} \\ \partial_1\tau_{21} + \partial_2\tau_{22} \end{pmatrix},$$

and we equally put that

$$\underline{\nabla}\mathbf{v} = \begin{pmatrix} \partial_1 v_1 & \partial_2 v_1 \\ \partial_1 v_2 & \partial_2 v_2 \end{pmatrix}, \quad \underline{\varepsilon}(\mathbf{v}) = \frac{1}{2}(\underline{\nabla}\mathbf{v} + {}^T\underline{\nabla}\mathbf{v}), \quad \underline{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \underline{J} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

We denote the tangential and the normal derivative on the boundary of a scalar function v by, respectively,

$$\partial_t v = \nabla v \cdot \mathbf{t} \quad \text{and} \quad \partial_n v = \nabla v \cdot \mathbf{n}.$$

As usual, let us denote by Ω the medium surface of the plate and by 2ε the plate's thickness. In view of the finite element discretization, we suppose that Ω is a connected polygonal domain of $\mathbb{R}^2$. The hypothesis of connectivity is not essential but permits an easier presentation of the method. We also suppose that its boundary Γ is decomposed into three disjoint parts $\Gamma = \Gamma_0 \cup \Gamma_1 \cup \Gamma_2$, and on each one different boundary conditions are imposed. We consider here the case of linear elasticity and, for the sake of simplicity, the constitutive material is taken as homogeneous and isotropic. For technical reasons, we suppose that Ω has no cuts and that $m(\Gamma_0) > 0$, where $m(\Gamma_0)$ represents the measure of Γ_0.

Let us first recall the equations describing the Kirchhoff–Love problem analyzed in [1], which write as below:

$$\begin{cases} \operatorname{div}(\mathbf{div}\underline{\sigma}) = f & \text{in } \Omega, \\ u = \partial_n u = 0 & \text{on } \Gamma_0, \\ u = 0, \quad \underline{\sigma}\mathbf{n}\cdot\mathbf{n} = 0 & \text{on } \Gamma_1, \\ \underline{\sigma}\mathbf{n}\cdot\mathbf{n} = \partial_t(\underline{\sigma}\mathbf{n}\cdot\mathbf{t}) + \mathbf{div}\underline{\sigma}\cdot\mathbf{n} = 0 & \text{on } \Gamma_2, \\ \sigma_{ij} = (1-\nu)\partial_{ij}u + \nu\Delta u\delta_{ij} & \text{in } \Omega, \end{cases} \tag{2.1}$$

where ν is Poisson's coefficient. The function f represents the force density of the applied transverse loading and belongs to the space $L^2(\Omega)$. The boundary conditions mean that the plate is clamped on Γ_0, simply supported on Γ_1, while Γ_2 is a free boundary.

Then we consider, cf. [6], the following equations for the Reissner–Mindlin problem:

$$\begin{cases} -\dfrac{1}{1-\nu}\mathbf{div}\underline{\sigma}^\varepsilon + \dfrac{1}{\varepsilon^2}(\mathbf{r}^\varepsilon - \nabla u^\varepsilon) = 0 & \text{in } \Omega, \\ \dfrac{1-\nu}{\varepsilon^2}\operatorname{div}(\mathbf{r}^\varepsilon - \nabla u^\varepsilon) = f & \text{in } \Omega, \\ u^\varepsilon = 0, \quad \mathbf{r}^\varepsilon = 0 & \text{on } \Gamma_0, \\ u^\varepsilon = 0, \quad \mathbf{r}^\varepsilon\cdot\mathbf{t} = 0, \quad \underline{\sigma}^\varepsilon\mathbf{n}\cdot\mathbf{n} = 0 & \text{on } \Gamma_1, \\ \mathbf{r}^\varepsilon\cdot\mathbf{t} = \partial_t u^\varepsilon, \quad \underline{\sigma}^\varepsilon\mathbf{n}\cdot\mathbf{n} = \partial_t(\underline{\sigma}^\varepsilon\mathbf{n}\cdot\mathbf{t}) + \mathbf{div}\underline{\sigma}^\varepsilon\cdot\mathbf{n} = 0 & \text{on } \Gamma_2, \\ \sigma_{ij}^\varepsilon = (1-\nu)\,\varepsilon_{ij}(\mathbf{r}^\varepsilon) + \nu(\operatorname{div}\mathbf{r}^\varepsilon)\delta_{ij} & \text{in } \Omega. \end{cases} \tag{2.2}$$

The unknowns of the problem are the transverse displacement of the plate u^ε, the rotation $\mathbf{r}^\varepsilon$ of the unit normal to the medium surface, and the bending moment $\underline{\sigma}^\varepsilon$. Obviously, they depend upon the small parameter ε, which characterizes the plate's thickness.

Let us notice that (2.2) is a singular problem with respect to the small parameter ε. We remark here that, in the simpler case of a clamped plate (i.e., $\Gamma = \Gamma_0$) whose medium surface Ω is a convex domain, one has the following regularity result (see, for instance, [5]):

$$\mathbf{r}^\varepsilon \in (H^2(\Omega))^2, \quad u^\varepsilon \in H^2(\Omega),$$
$$\|\mathbf{r}^\varepsilon\|_{2,\Omega} + \|u^\varepsilon\|_{2,\Omega} + \varepsilon\,\|\mathbf{div}\underline{\sigma}^\varepsilon\|_{1,\Omega} \le c\,\|f\|_{0,\Omega}\,.$$

One cannot improve the above estimate for the term $\mathbf{div}\underline{\sigma}^\varepsilon$, even for a smoother domain and a smoother loading f: indeed, $\mathbf{div}\underline{\sigma}^\varepsilon$ is not uniformly bounded in $(H^1(\Omega))^2$ because of boundary layers in the Reissner–Mindlin model. This represents another source of difficulties in obtaining an approximation method uniformly convergent with respect to ε.

Let us now come back to the above two models of plate, and particularly to the boundary conditions considered in (2.2). With this choice, it is known (cf. Destuynder

and Salaun [6]) that as ε tends towards 0, the Reissner–Mindlin model (2.2) tends towards the Kirchhoff–Love model (2.1) in the following sense:

$$u^\varepsilon \overset{H^1(\Omega)}{\longrightarrow} u, \qquad \mathbf{r}^\varepsilon \overset{H^1(\Omega)}{\longrightarrow} \mathbf{r} = \nabla u,$$
$$\underline{\sigma}^\varepsilon \overset{L^2(\Omega)}{\longrightarrow} \underline{\sigma}, \qquad \mathbf{div}\underline{\sigma}^\varepsilon \overset{H^{-1}(\Omega)}{\longrightarrow} \mathbf{div}\underline{\sigma}.$$

Remark 2.1. One may consider other boundary conditions in the Reissner–Mindlin case, for instance, cf. [6]:

$$\begin{cases} u^\varepsilon = 0, \quad \mathbf{r}^\varepsilon = 0 & \text{on } \Gamma_0, \\ u^\varepsilon = 0, \quad \mathbf{r}^\varepsilon \cdot \mathbf{t} = 0, \quad \underline{\sigma}^\varepsilon \mathbf{n} \cdot \mathbf{n} = 0 & \text{on } \Gamma_1, \\ \underline{\sigma}^\varepsilon \mathbf{n} \cdot \mathbf{n} = \underline{\sigma}^\varepsilon \mathbf{n} \cdot \mathbf{t} = 0 & \text{on } \Gamma_2. \end{cases}$$

In this way, the Reissner–Mindlin model is obtained from the Kirchhoff–Love one by a penalty method. But then, due to the fact that the conditions on the free boundary Γ_2 are different in the two plate models, the convergence of the rotation vector $\mathbf{r}^\varepsilon$ towards ∇u will hold only with respect to the $L^2(\Omega)$-norm.

In order to write the variational formulation of (2.2), we introduce the Hilbert spaces

$$\underline{X} = \left\{ \underline{\tau} \in L^2(\Omega)^4 ;\ D(\underline{\tau}) \in L^2(\Omega) \right\},$$
$$\underline{X}^\varepsilon = \left\{ \underline{\tau} \in L^2(\Omega)^4 ;\ \varepsilon\, \mathbf{div}\underline{\tau} \in (L^2(\Omega))^2,\ D(\underline{\tau}) \in L^2(\Omega) \right\}$$

endowed with their natural norms

$$\| \underline{\tau} \|_{\underline{X}} = (\| \underline{\tau} \|_{0,\Omega}^2 + \| D(\underline{\tau}) \|_{0,\Omega}^2)^{1/2},$$
$$\| \underline{\tau} \|_{\underline{X}^\varepsilon} = (\| \underline{\tau} \|_{0,\Omega}^2 + \varepsilon^2 \| \mathbf{div}\underline{\tau} \|_{0,\Omega}^2 + \| D(\underline{\tau}) \|_{0,\Omega}^2)^{1/2}.$$

We recall that $\underline{X}$ is the space introduced in [1] for the analysis of the Kirchhoff–Love model, and the operator D is defined as follows: $D(\underline{\tau}) = \mathrm{div}(\mathbf{div}\underline{\tau}) = \partial_{ij}\tau_{ij}$. Then one can establish (see [1] for a complete proof) that $(\mathcal{D}(\overline{\Omega}))^4$ is a dense subspace of $\underline{X}$ and the trace operators

$$\gamma_0 : ((\mathcal{D}(\overline{\Omega}))^4, \|\cdot\|_{\underline{X}}) \longrightarrow H^{-1/2}(\Gamma), \qquad \gamma_0(\underline{\tau}) = \underline{\tau}\mathbf{n} \cdot \mathbf{n},$$
$$\gamma_1 : ((\mathcal{D}(\overline{\Omega}))^4, \|\cdot\|_{\underline{X}}) \longrightarrow H^{-3/2}(\Gamma), \qquad \gamma_1(\underline{\tau}) = \partial_t(\underline{\tau}\mathbf{n} \cdot \mathbf{t}) + \mathbf{div}\underline{\tau} \cdot \mathbf{n},$$

are linear and continuous, so they can be extended by continuity on $\underline{X}$. Moreover, for any $v \in H^2(\Omega)$ and any $\underline{\tau} \in \underline{X}$, one has the following Green's formula:

$$\int_\Omega D(\underline{\tau}) v \, d\Omega = \int_\Omega \tau_{ij}\partial_{ij} v \, d\Omega - \langle \gamma_0(\underline{\tau}), \partial_n v \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \gamma_1(\underline{\tau}), v \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}.$$

It is now obvious, since $\underline{X}^\varepsilon \subset \underline{X}$, that the operators γ_0 and γ_1 are well defined on $\underline{X}^\varepsilon$ by simply taking their restriction.

Remark 2.2. One clearly has $\underline{X}^\varepsilon = \underline{X}^{\varepsilon'}$ algebraically when $\varepsilon \neq 0$, $\varepsilon' \neq 0$. We choose this notation in order to preserve a parallelism between the formulations of the Reissner–Mindlin and Kirchhoff–Love models, respectively. We also have

$$\underline{X}^\varepsilon \subset (H(\mathrm{div};\Omega))^2, \qquad \mathbf{div}\underline{X}^\varepsilon \subset H(\mathrm{div};\Omega).$$

For any $f \in L^2(\Omega)$, we introduce

$$\underline{X}^{\varepsilon,f} = \{ \underline{\tau} \in \underline{X}^\varepsilon ;\ D(\underline{\tau}) = f \},$$

and we can easily show that $\underline{X}^{\varepsilon,f} \neq \emptyset$.

3. First formulation with respect to the bending moment. We derive in this section a mixed variational formulation of problem (2.2), whose main unknown will be the bending moment $\underline{\sigma}^\varepsilon$ which is a symmetric second-order tensor.

Let us put

$$M = \left\{ v \in H^{3/2}(\Gamma);\ v = 0 \text{ on } \Gamma_0 \cup \Gamma_1 \right\},$$
$$N = \left\{ v \in H^{1/2}(\Gamma);\ v = 0 \text{ on } \Gamma_0 \right\},$$

and let us introduce the bilinear forms $a^\varepsilon(\cdot,\cdot)$, $b(\cdot,\cdot)$, and $c(\cdot,\cdot)$, defined on $\underline{X}^\varepsilon \times \underline{X}^\varepsilon$, on $\underline{X}^\varepsilon \times (M \times N)$, and on $\underline{X}^\varepsilon \times L^2(\Omega)$, respectively, by the following relations:

$$a^\varepsilon(\underline{\sigma},\underline{\tau}) = a(\underline{\sigma},\underline{\tau}) + \varepsilon^2\, a_0(\underline{\sigma},\underline{\tau}),$$
$$b(\underline{\tau},(\zeta,\eta)) = \langle \gamma_1(\underline{\tau}),\zeta\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} - \langle \gamma_0(\underline{\tau}),\eta\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma},$$
$$c(\underline{\tau},\mu) = \int_\Omega (\tau_{12} - \tau_{21})\,\mu\, d\Omega,$$

where

$$a(\underline{\sigma},\underline{\tau}) = \frac{1}{1-\nu}\int_\Omega \underline{\sigma} : \underline{\tau}\, d\Omega - \frac{\nu}{1-\nu^2}\int_\Omega (tr\underline{\sigma})(tr\underline{\tau})\, d\Omega,$$
$$a_0(\underline{\sigma},\underline{\tau}) = \frac{1}{1-\nu}\int_\Omega \mathbf{div}\underline{\sigma}\cdot\mathbf{div}\underline{\tau}\, d\Omega.$$

The forms $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ as well as the spaces M, N are exactly the same as the ones employed in the Kirchhoff–Love formulation; see [1]. One can immediately notice that if $\underline{\sigma} \in \underline{X}^\varepsilon$ is symmetric, then

$$\forall \mu \in L^2(\Omega), \quad c(\underline{\sigma},\mu) = 0.$$

So, the role of the new term $c(\cdot,\cdot)$ is to dualize the symmetry of the bending tensor, while the bilinear form $\varepsilon^2\, a_0(\cdot,\cdot)$ takes into account the new variable which is the rotation vector.

We now propose the following variational formulation for the Reissner–Mindlin problem:

$$\text{(3.1)} \qquad \begin{cases} \text{find } \underline{\sigma}^\varepsilon \in \underline{X}^{\varepsilon,f},\ (u_0^\varepsilon, r_0^\varepsilon) \in M \times N,\ \lambda^\varepsilon \in L^2(\Omega) \text{ such that} & \\ \forall \underline{\tau} \in \underline{X}^{\varepsilon,0}, & a^\varepsilon(\underline{\sigma}^\varepsilon,\underline{\tau}) + b(\underline{\tau},(u_0^\varepsilon,r_0^\varepsilon)) + c(\underline{\tau},\lambda^\varepsilon) = 0, \\ \forall (\zeta,\eta) \in M \times N, & b(\underline{\sigma}^\varepsilon,(\zeta,\eta)) = 0, \\ \forall \mu \in L^2(\Omega), & c(\underline{\sigma}^\varepsilon,\mu) = 0, \end{cases}$$

which is a generalization of the one introduced in the Kirchhoff–Love case.

In a quite similar way, we show the following theorem.

THEOREM 3.1. *Problem* (3.1) *has a unique solution.*

Proof. It comes from the Babuška–Brezzi theory (see, for instance, [5]). Indeed, the bilinear form $a(\cdot,\cdot)$ is $(L^2(\Omega))^4$-elliptic since $(tr\underline{\tau})^2 \le 2\underline{\tau} : \underline{\tau}$. Therefore, for all $\underline{\tau} \in \underline{X}^{\varepsilon,0}$, one deduces the $\underline{X}^{\varepsilon,0}$-ellipticity of $a^\varepsilon(\cdot,\cdot)$:

$$a^\varepsilon(\underline{\tau},\underline{\tau}) \ge c(\| \underline{\tau} \|_{0,\Omega}^2 + \varepsilon^2 \| \mathbf{div}\underline{\tau} \|_{0,\Omega}^2) = c \| \underline{\tau} \|_{\underline{X}^\varepsilon}^2 .$$

It suffices now to establish the inf-sup condition for the bilinear form $d(\cdot,\cdot)$ obtained by adding the last two equations of (3.1):

$$\forall \underline{\tau} \in \underline{X}^{\varepsilon,0},\ \forall (\zeta,\eta,\mu) \in M \times N \times L^2(\Omega), \quad d(\underline{\tau},(\zeta,\eta,\mu)) = b(\underline{\tau},(\zeta,\eta)) + c(\underline{\tau},\mu).$$

We apply a classical idea, that is, we associate with any $(\zeta,\eta,\mu)\in M\times N\times L^2(\Omega)$ a tensor $\underline{\tau}\in\underline{X}^{\varepsilon,0}$ such that

$$\begin{cases} d(\underline{\tau},(\zeta,\eta,\mu))\geq c(\|\mu\|_{0,\Omega}+\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma})^2 \\ \|\,\underline{\tau}\,\|_{\underline{X}^\varepsilon}\leq c(\|\mu\|_{0,\Omega}+\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma}). \end{cases} \tag{3.2}$$

However, the construction of such a tensor $\underline{\tau}$ is quite technical.

We begin by finding $\underline{\tau}_1$ such that the inf-sup condition for $b(\cdot,\cdot)$ holds. For that, with any couple $(\zeta,\eta)\in M\times N$ we associate the function $\mathbf{q}=(\partial_t\zeta)\,\mathbf{t}+\eta\,\mathbf{n}$. Clearly, we have that $\mathbf{q}\in(H^{1/2}(\Gamma))^2$ and also, since $m(\Gamma_0)\neq 0$, that

$$\|\mathbf{q}\|_{1/2,\Gamma}\leq c(\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma}).$$

Indeed, this comes by noticing that $\mathbf{q}=\nabla w$ on Γ, where w is the unique solution of

$$\begin{cases} \Delta^2 w=0 & \text{in } \Omega,\\ w=\zeta & \text{on } \Gamma,\\ \partial_n w=\eta & \text{on } \Gamma. \end{cases}$$

Let us next consider the following auxiliary problem:

$$\begin{cases} \Delta\omega=0 & \text{in } \Omega,\\ \omega=\mathbf{q} & \text{on } \Gamma, \end{cases}$$

whose solution $\omega\in(H^1(\Omega))^2$ verifies $|\omega|_{1,\Omega}\leq c\,\|\mathbf{q}\|_{\frac12,\Gamma}$. By choosing $\underline{\tau}_1=-\underline{\nabla}\omega$, one obviously has $\mathbf{div}\underline{\tau}_1=0$ as well as $D(\underline{\tau}_1)=0$, so one can write, thanks to an integration by parts, that

$$\begin{aligned} b(\underline{\tau}_1,(\zeta,\eta)) &= \langle\partial_t(\underline{\tau}_1\mathbf{n}\cdot\mathbf{t}),\zeta\rangle_{-\frac32,\frac32,\Gamma}-\langle\underline{\tau}_1\mathbf{n}\cdot\mathbf{n},\eta\rangle_{-\frac12,\frac12,\Gamma}\\ &= -\langle\underline{\tau}_1\mathbf{n}\cdot\mathbf{t},\partial_t\zeta\rangle_{-\frac12,\frac12,\Gamma}-\langle\underline{\tau}_1\mathbf{n}\cdot\mathbf{n},\eta\rangle_{-\frac12,\frac12,\Gamma}\\ &= -\langle\underline{\tau}_1\mathbf{n},\omega\rangle_{-\frac12,\frac12,\Gamma}=|\omega|^2_{1,\Omega}. \end{aligned}$$

So we obtained, for this choice of the tensor $\underline{\tau}_1\in\underline{X}^{\varepsilon,0}$, that

$$b(\underline{\tau}_1,(\zeta,\eta))\geq c(\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma})^2 \quad\text{and}\quad \|\,\underline{\tau}_1\,\|_{\underline{X}^\varepsilon}=|\omega|_{1,\Omega}\leq c(\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma}).$$

Next, we define $\underline{\tau}_2\in\underline{X}^{\varepsilon,0}$ such that $\underline{\tau}=\underline{\tau}_1+\underline{\tau}_2$ satisfies the relations (3.2). The idea is to construct a tensor $\underline{\tau}_2$ with vanishing traces such that $b(\underline{\tau}_2,(\zeta,\eta))=0$, so we will only have to check the inf-sup condition for $c(\cdot,\cdot)$ now. For any $\mu\in L^2(\Omega)$, let us put

$$P(\mu)=\frac{1}{m(\Omega)}\int_\Omega\mu\,d\Omega$$

and consider $\lambda=\mu-P(\mu)-curl\omega$. The fact that

$$\int_\Omega curl\omega\,d\Omega=-\int_\Gamma\omega\cdot\mathbf{t}\,d\Gamma=-\int_\Gamma\partial_t\zeta\,d\Gamma=0$$

implies that λ belongs to $L^2_0(\Omega)=\left\{v\in L^2(\Omega);\ \int_\Omega v\,d\Omega=0\right\}$ and, moreover, that

$$\|\lambda\|_{0,\Omega}\leq c\,\|\mu\|_{0,\Omega}+|\omega|_{1,\Omega}\leq c(\|\mu\|_{0,\Omega}+\|\eta\|_{1/2,\Gamma}+\|\zeta\|_{3/2,\Gamma}).$$

Then there exists, cf. [8], a function $\mathbf{v} \in (H_0^1(\Omega))^2$ such that

$$\operatorname{div} \mathbf{v} = \lambda \text{ in } \Omega \qquad \text{and} \qquad |\mathbf{v}|_{1,\Omega} \leq c \, \|\lambda\|_{0,\Omega} .$$

Therefore, the new function

$$\varphi = \mathbf{v} + \frac{P(\mu)}{2} \begin{pmatrix} x \\ y \end{pmatrix}$$

satisfies the two conditions

$$\begin{aligned} &\operatorname{div} \varphi = \mu - curl\omega \qquad \text{in } \Omega, \\ &|\varphi|_{1,\Omega} \leq |\mathbf{v}|_{1,\Omega} + c \, \|\mu\|_{0,\Omega} \\ &\qquad \leq c(\|\mu\|_{0,\Omega} + \|\eta\|_{1/2,\Gamma} + \|\zeta\|_{3/2,\Gamma}). \end{aligned}$$

The boundary Γ being polygonal, one has that $\partial_t \varphi = c\mathbf{t}$, with $c = \frac{P(\mu)}{2}$, which implies that

$$\partial_t \varphi \cdot \mathbf{n} = 0, \qquad \partial_t(\partial_t \varphi \cdot \mathbf{t}) = 0 \qquad \text{on } \Gamma.$$

By next choosing that $\underline{\tau}_2 = -\underline{curl}\, \varphi \in \underline{X}^{\varepsilon,0}$, one gets

$$\begin{aligned} c(\underline{\tau}_2, \mu) &= \int_\Omega \operatorname{div} \varphi \, \mu \, d\Omega = \|\mu\|_{0,\Omega}^2 - c(\underline{\tau}_1, \mu) \, d\Omega, \\ \gamma_0(\underline{\tau}_2) &= -\partial_t \varphi \cdot \mathbf{n} = 0, \\ \gamma_1(\underline{\tau}_2) &= -\partial_t(\partial_t \varphi \cdot \mathbf{t}) = 0. \end{aligned}$$

Finally, for the tensor $\underline{\tau} = \underline{\tau}_1 + \underline{\tau}_2 \in \underline{X}^{\varepsilon,0}$ with $\mathbf{div}\underline{\tau} = 0$, we get (3.2), which means that the inf-sup condition for $d(\cdot,\cdot)$ uniformly holds with respect to ε. ∎

The next result gives the interpretation of the solution of (3.1) in terms of the Reissner–Mindlin boundary value problem (2.2).

THEOREM 3.2. *Let $(\underline{\sigma}^\varepsilon, (u_0^\varepsilon, r_0^\varepsilon), \lambda^\varepsilon)$ be the solution of* (3.1). *Then $\underline{\sigma}^\varepsilon$ represents the bending moment calculated by the Reissner–Mindlin model* (2.2), *and one equally has that*

$$\begin{cases} r_0^\varepsilon = \mathbf{r}^\varepsilon \cdot \mathbf{n} & \text{on } \Gamma, \\ u_0^\varepsilon = u^\varepsilon & \text{on } \Gamma, \\ \lambda^\varepsilon = -\frac{1}{2} curl \mathbf{r}^\varepsilon & \text{in } \Omega, \end{cases} \tag{3.3}$$

where $(\underline{\sigma}^\varepsilon, \mathbf{r}^\varepsilon, u^\varepsilon)$ satisfies the equations in (2.2).

Proof. The third equation of the variational problem (3.1) gives that $\underline{\sigma}^\varepsilon$ is symmetric, while the second equation implies that $\gamma_1(\underline{\sigma}^\varepsilon) = 0$ and $\gamma_1(\underline{\sigma}^\varepsilon) = 0$.

We introduce, as in the Kirchhoff–Love model, the symmetric tensor

$$\underline{\chi}^\varepsilon = \frac{1}{1-\nu} \left(\underline{\sigma}^\varepsilon - \frac{\nu}{1+\nu} (tr\underline{\sigma}^\varepsilon) \underline{I} \right).$$

We next show, by choosing $\underline{\tau} = \underline{curl}(\mathbf{curl}\, \varphi)$ with $\varphi \in \mathcal{D}(\Omega)$ as a test-function in the first equation of (3.1), that $\underline{\chi}^\varepsilon = \underline{\varepsilon}(\mathbf{r}^\varepsilon)$, which translates into the constitutive law of the plate according to (2.2):

$$\underline{\sigma}^\varepsilon = (1-\nu)\, \underline{\varepsilon}\, (\mathbf{r}^\varepsilon) + \nu (\operatorname{div} \mathbf{r}^\varepsilon) \underline{I}.$$

One clearly obtains, since $\underline{\tau}$ is symmetric, divergence-free, and with null traces, that

$$a(\underline{\sigma}^\varepsilon, \underline{\tau}) = 0 \quad \Leftrightarrow \quad \int_\Omega \underline{\chi}^\varepsilon : \underline{\tau}\, d\Omega = 0.$$

This leads to

$$curl \begin{pmatrix} \partial_1 \chi^\varepsilon_{12} - \partial_2 \chi^\varepsilon_{11} \\ \partial_1 \chi^\varepsilon_{22} - \partial_2 \chi^\varepsilon_{21} \end{pmatrix} = 0,$$

so there exists a function θ^ε such that

$$curl \begin{pmatrix} \chi^\varepsilon_{11} \\ \chi^\varepsilon_{12} - \theta^\varepsilon \end{pmatrix} = curl \begin{pmatrix} \chi^\varepsilon_{21} + \theta^\varepsilon \\ \chi^\varepsilon_{22} \end{pmatrix} = 0.$$

One can still write this as

$$\begin{pmatrix} \chi^\varepsilon_{11} \\ \chi^\varepsilon_{12} - \theta^\varepsilon \end{pmatrix} = \nabla r^\varepsilon_1, \ \begin{pmatrix} \chi^\varepsilon_{21} + \theta^\varepsilon \\ \chi^\varepsilon_{22} \end{pmatrix} = \nabla r^\varepsilon_2$$

or, equivalently,

$$\underline{\chi}^\varepsilon = \underline{\nabla} \mathbf{r}^\varepsilon + \theta^\varepsilon \underline{J}.$$

The symmetry of $\underline{\chi}^\varepsilon$ next gives that $\underline{\chi}^\varepsilon = \underline{\varepsilon}(\mathbf{r}^\varepsilon)$, where the vector $\mathbf{r}^\varepsilon \in (H^1(\Omega))^2$ is unique up to $\underline{\varepsilon}(\mathbf{r}^\varepsilon) = \underline{0}$, i.e., up to a polynomial $\left(\begin{smallmatrix} cy+a \\ -cx+b \end{smallmatrix}\right)$

Let us now take in (3.1) as test-function $\underline{\tau} = \underline{curl}\, \varphi + \frac{1}{2}(\mathrm{div}\varphi)\underline{J}$ with $\varphi \in (\mathcal{D}(\Omega))^2$. Obviously, $\underline{\tau}$ is symmetric and its traces vanish on Γ, so that

$$\begin{aligned} & a(\underline{\sigma}^\varepsilon, \underline{\tau}) + \varepsilon^2 a_0(\underline{\sigma}^\varepsilon, \underline{\tau}) = 0 \\ \Leftrightarrow & \int_\Omega \underline{\nabla} \mathbf{r}^\varepsilon : \underline{\tau}\, d\Omega + \frac{\varepsilon^2}{1-\nu} \int_\Omega \mathbf{div} \underline{\sigma}^\varepsilon \cdot \mathbf{div} \underline{\tau}\, d\Omega = 0 \\ \Leftrightarrow & \left\langle \frac{\varepsilon^2}{1-\nu} \mathbf{div} \underline{\sigma}^\varepsilon - \mathbf{r}^\varepsilon, \mathbf{curl}(\mathrm{div}\varphi) \right\rangle_{\mathcal{D}'(\Omega), \mathcal{D}(\Omega)} = 0 \\ \Leftrightarrow & \left\langle \nabla \left(curl \left(\frac{\varepsilon^2}{1-\nu} \mathbf{div} \underline{\sigma}^\varepsilon - \mathbf{r}^\varepsilon \right) \right), \varphi \right\rangle_{\mathcal{D}'(\Omega), \mathcal{D}(\Omega)} = 0 \quad \forall \varphi \in (\mathcal{D}(\Omega))^2. \end{aligned}$$

Since $curl \mathbf{r}^\varepsilon$ is unique up to a constant, we conclude that we can take

$$curl \left(\frac{\varepsilon^2}{1-\nu} \mathbf{div} \underline{\sigma}^\varepsilon - \mathbf{r}^\varepsilon \right) = 0,$$

where $\mathbf{r}^\varepsilon$ now belongs to $(H^1(\Omega)_{|\mathbb{R}})^2$. Thus, one finds a unique $u^\varepsilon \in H^1(\Omega)_{|\mathbb{R}}$ such that

$$\frac{\varepsilon^2}{1-\nu} \mathbf{div} \underline{\sigma}^\varepsilon - \mathbf{r}^\varepsilon = -\nabla u^\varepsilon.$$

We already know that $\underline{\sigma}^\varepsilon \in \underline{X}^{\varepsilon, f}$, which implies that $D(\underline{\sigma}^\varepsilon) = f$. So, we have actually shown that the functions $\underline{\sigma}^\varepsilon, \mathbf{r}^\varepsilon, u^\varepsilon$ satisfy the equations in Ω of the Reissner–Mindlin problem (2.2).

On the other hand, considering as a test-function $\underline{\tau} = \rho \underline{J}$ with $\rho \in \mathcal{D}(\Omega)$ arbitrary gives

$$\begin{aligned}
&\varepsilon^2 a_0(\underline{\sigma}^\varepsilon, \underline{\tau}) + c(\lambda^\varepsilon, \underline{\tau}) = 0 \\
\Leftrightarrow\ & \frac{\varepsilon^2}{1-\nu} \int_\Omega \mathbf{div}\underline{\sigma}^\varepsilon \cdot \mathbf{curl}\, \rho \, d\Omega + 2 \int_\Omega \lambda^\varepsilon \rho \, d\Omega = 0 \\
\Leftrightarrow\ & \left\langle curl \left(\frac{\varepsilon^2}{1-\nu} \mathbf{div}\underline{\sigma}^\varepsilon \right) + 2\lambda^\varepsilon, \rho \right\rangle_{\mathcal{D}'(\Omega), \mathcal{D}(\Omega)} = 0 \\
&\Leftrightarrow \lambda^\varepsilon = -\frac{1}{2} curl \mathbf{r}^\varepsilon.
\end{aligned}$$

We still have to check the boundary conditions for $\mathbf{r}^\varepsilon$ and u^ε. For that, let us consider an arbitrary tensor $\underline{\tau} \in \underline{X}^{\varepsilon,0}$. By Green's formula,

$$\begin{aligned}
&a^\varepsilon(\underline{\sigma}^\varepsilon, \underline{\tau}) + c(\lambda^\varepsilon, \underline{\tau}) \\
&= \int_\Omega \underline{\varepsilon}\,(\mathbf{r}^\varepsilon) : \underline{\tau} \, d\Omega + \frac{\varepsilon^2}{1-\nu} \int_\Omega \mathbf{div}\underline{\sigma}^\varepsilon \cdot \mathbf{div}\underline{\tau} \, d\Omega - \frac{1}{2} \int_\Omega curl \mathbf{r}^\varepsilon (\tau_{12} - \tau_{21}) \, d\Omega \\
&= \int_\Omega \underline{\nabla} \mathbf{r}^\varepsilon : \underline{\tau} \, d\Omega + \int_\Omega (\mathbf{r}^\varepsilon - \nabla u^\varepsilon) \cdot \mathbf{div}\underline{\tau} \, d\Omega = \langle \underline{\tau}\mathbf{n}, \mathbf{r}^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - \langle \mathbf{div}\underline{\tau} \cdot \mathbf{n}, u^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}.
\end{aligned}$$

In particular, for $\underline{\tau} = \rho \underline{J}$ with $\rho \in \mathcal{D}(\overline{\Omega})$, we have, since $b(\underline{\tau}, (u_0^\varepsilon, r_0^\varepsilon)) = 0$, that

$$\langle \underline{\tau}\mathbf{n}, \mathbf{r}^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - \langle \mathbf{div}\underline{\tau} \cdot \mathbf{n}, u^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0.$$

We decompose $\mathbf{r}^\varepsilon$ in the orthogonal basis $\{\mathbf{n}, \mathbf{t}\}$ and thus

$$\begin{aligned}
&\langle \underline{\tau}\mathbf{n} \cdot \mathbf{t}, \mathbf{r}^\varepsilon \cdot \mathbf{t} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \gamma_0(\underline{\tau}), \mathbf{r}^\varepsilon \cdot \mathbf{n} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} \\
&- \langle \gamma_1(\underline{\tau}), u^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t(\underline{\tau}\mathbf{n} \cdot \mathbf{t}), u^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0 \\
&\Leftrightarrow \langle \rho, \mathbf{r}^\varepsilon \cdot \mathbf{t} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - \langle \partial_t u^\varepsilon, \rho \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0 \\
&\Leftrightarrow \mathbf{r}^\varepsilon \cdot \mathbf{t} = \partial_t u^\varepsilon \quad \text{on } \Gamma.
\end{aligned}$$

The above equality holds in $H^{-1/2}(\Gamma)$, but the fact that $\mathbf{r}^\varepsilon$ belongs to the space $(H^{1/2}(\Gamma))^2$ implies an equality in $H^{1/2}(\Gamma)$; consequently, $u^\varepsilon \in H^{3/2}(\Gamma)$. Next taking $\underline{\tau} = \underline{curl}\, \varphi$ with an arbitrary $\varphi \in (\mathcal{D}(\overline{\Omega}))^2$, we obtain, according to the first equation of (3.1), that

$$\langle \underline{\tau}\mathbf{n}, \mathbf{r}^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - \langle \mathbf{div}\underline{\tau} \cdot \mathbf{n}, u^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \gamma_1(\underline{\tau}), u_0^\varepsilon \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} - \langle \gamma_0(\underline{\tau}), r_0^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0.$$

Since one has $\mathbf{div}\underline{\tau} = 0$ and

$$\begin{aligned}
\langle \underline{\tau}\mathbf{n}, \mathbf{r}^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} &= -\langle \partial_t \varphi \cdot \mathbf{n}, \mathbf{r}^\varepsilon \cdot \mathbf{n} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t(\partial_t \varphi \cdot \mathbf{t}), u^\varepsilon \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}, \\
\langle \gamma_1(\underline{\tau}), u_0^\varepsilon \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} &= -\langle \partial_t(\partial_t \varphi \cdot \mathbf{t}), u_0^\varepsilon \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}, \\
\langle \gamma_0(\underline{\tau}), r_0^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} &= -\langle \partial_t \varphi \cdot \mathbf{n}, r_0^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma},
\end{aligned}$$

one deduces the following relationship:

$$\forall \varphi \in (\mathcal{D}(\overline{\Omega}))^2, \quad -\langle \partial_t \varphi \cdot \mathbf{n}, \mathbf{r}^\varepsilon \cdot \mathbf{n} - r_0^\varepsilon \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t(\partial_t \varphi \cdot \mathbf{t}), u^\varepsilon - u_0^\varepsilon \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} = 0.$$

By a density argument of $\mathcal{D}(\overline{\Omega})$ into $H^1(\Omega)$, it actually turns out that

$$\forall \underline{\tau} \in \underline{X}^0, \quad b(\underline{\tau}, (\mathbf{r}^\varepsilon \cdot \mathbf{n} - r_0^\varepsilon, u^\varepsilon - u_0^\varepsilon)) = 0$$

with $(\mathbf{r}^\varepsilon \cdot \mathbf{n} - r_0^\varepsilon, u^\varepsilon - u_0^\varepsilon) \in H^{1/2}(\Gamma) \times H^{3/2}(\Gamma)$ by now. The same idea as in the Kirchhoff–Love case [1] leads us to $|w|_{2,\Omega} = 0$, where w satisfies the following biharmonic problem:

$$\begin{cases} \Delta^2 w = 0 & \text{in } \Omega, \\ w = u^\varepsilon - u_0^\varepsilon & \text{on } \Gamma, \\ \partial_n w = \mathbf{r}^\varepsilon \cdot \mathbf{n} - r_0^\varepsilon & \text{on } \Gamma. \end{cases}$$

So w is a first-order polynomial. Since $\partial_n w = \mathbf{c} \cdot \mathbf{n}$ with $\mathbf{c} \in \mathbb{R}^2$ and $\mathbf{r}^\varepsilon$ is unique up to a constant, we choose it such that $\mathbf{r}^\varepsilon \cdot \mathbf{n} = r_0^\varepsilon$ on Γ and $\nabla w = 0$. We finally obtain that $u^\varepsilon = u_0^\varepsilon$ on Γ, because u^ε is unique up to a constant, which we take equal to w.

We conclude that $\mathbf{r}^\varepsilon$ and u^ε satisfy the boundary conditions of the Reissner–Mindlin model, and, moreover, we have the equivalence stated in (3.3). ∎

From now on, we write $\underline{\sigma}^\varepsilon \in \underline{X}^{\varepsilon,f}$ as

$$\underline{\sigma}^\varepsilon = \underline{\sigma}^{\varepsilon,0} + \phi^f \underline{I},$$

where ϕ^f is the unique solution of

$$\begin{cases} \Delta\phi = f & \text{in } \Omega, \\ \phi = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ \partial_n \phi = 0 & \text{on } \Gamma_2 \end{cases} \tag{3.4}$$

and where $\underline{\sigma}^{\varepsilon,0} \in \underline{X}^{\varepsilon,0}$. By the means of this decomposition, we get a variational formulation in $\underline{\sigma}^{\varepsilon,0}$ equivalent to (3.1), which we will study in what follows:

$$\begin{cases} \text{find } \underline{\sigma}^{\varepsilon,0} \in \underline{X}^{\varepsilon,0},\ (u_0^\varepsilon, r_0^\varepsilon) \in M \times N,\ \lambda^\varepsilon \in L^2(\Omega) & \text{such that} \\ \forall \underline{\tau} \in \underline{X}^{\varepsilon,0}, & a^\varepsilon(\underline{\sigma}^{\varepsilon,0}, \underline{\tau}) + b(\underline{\tau}, (u_0^\varepsilon, r_0^\varepsilon)) + c(\underline{\tau}, \lambda^\varepsilon) = -a^\varepsilon(\phi^f \underline{I}, \underline{\tau}), \\ \forall (\zeta, \eta) \in M \times N, & b(\underline{\sigma}^{\varepsilon,0}, (\zeta, \eta)) = \langle \phi^f, \eta \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}, \\ \forall \mu \in L^2(\Omega), & c(\underline{\sigma}^{\varepsilon,0}, \mu) = 0. \end{cases} \tag{3.5}$$

Remark 3.1. In order to obtain the transverse displacement u^ε, one can now solve, thanks to (3.3), the second-order elliptic problem

$$\begin{cases} \Delta u^\varepsilon = \frac{1}{1+\nu} tr\underline{\sigma}^\varepsilon - \frac{\varepsilon^2}{1-\nu} f & \text{in } \Omega, \\ u^\varepsilon = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ u^\varepsilon = u_0^\varepsilon & \text{on } \Gamma_2, \end{cases} \tag{3.6}$$

while the rotation vector $\mathbf{r}^\varepsilon$ is given by the relation

$$\mathbf{r}^\varepsilon = \frac{\varepsilon^2}{1-\nu} \mathbf{div}\underline{\sigma}^\varepsilon + \nabla u^\varepsilon. \tag{3.7}$$

4. New mixed variational formulation. The previous formulation (3.5) of the problem is written on the space $\underline{X}^{\varepsilon,0}$, whose tensors satisfy the constraint $D(\underline{\tau}) = \mathrm{div}(\mathbf{div}\underline{\tau}) = 0$. In order to avoid its discretization, we introduce in this section an equivalent formulation, obtained by decomposing the elements of $\underline{X}^{\varepsilon,0}$. This new variational problem has the advantage of using only classical Sobolev spaces (like $H^1(\Omega)$, $H^{1/2}(\Gamma)$, $L^2(\Omega)$) which are easy to approximate by conforming finite elements.

In a similar manner as for the Kirchhoff–Love model [1], one can show (by applying Tartar's lemma twice) that for any $\underline{\tau} \in \underline{X}^{\varepsilon,0}$ there exist unique functions $\rho \in H^1(\Omega)_{|\mathbb{R}}$ and $\varphi \in (H^1(\Omega)_{|\mathbb{R}})^2$ such that $\underline{\tau}$ writes as

$$\underline{\tau} = \underline{curl}\,\varphi + \rho \underline{J}. \tag{4.1}$$

Let us consider the spaces

$$\mathbf{H} = \left\{ \varphi \in (H^1(\Omega))^2;\ \int_\Omega \varphi \, d\Omega = 0 \right\},$$
$$W^\varepsilon = \left\{ \rho \in L^2(\Omega);\ \int_\Omega \rho \, d\Omega = 0,\ \varepsilon\, \mathbf{curl}\rho \in L^2(\Omega)^2 \right\}$$

endowed, respectively, with the norms $|\cdot|_{1,\Omega}$ and $\|\cdot\|_{0,\Omega} + \varepsilon\,|\cdot|_{1,\Omega}$, and let us define the Hilbert space $\mathbf{Y}^\varepsilon = \mathbf{H} \times W^\varepsilon$.

We do not impose here, like in [1], the symmetry of the bending moment because this would lead us to consider a function φ too regular, difficult to approximate by continuous low-order finite elements. For this reason, with any $\underline{\sigma}$, $\underline{\tau} \in \underline{X}^{\varepsilon,0}$ we associate by means of (4.1) the corresponding couples (ψ, ξ), $(\varphi, \rho) \in \mathbf{Y}^\varepsilon$ and we introduce the following bilinear form on $\mathbf{Y}^\varepsilon \times \mathbf{Y}^\varepsilon$:

$$A^\varepsilon((\psi,\xi),(\varphi,\rho)) = A((\psi,\xi),(\varphi,\rho)) + \varepsilon^2 A_0((\psi,\xi),(\varphi,\rho)),$$

where

$$\begin{aligned} A((\psi,\xi),(\varphi,\rho)) = a(\underline{\sigma},\underline{\tau}) = \frac{1}{1-\nu}\int_\Omega &[(\xi - \partial_1\psi_1)(\rho - \partial_1\varphi_1) \\ &+ (\xi - \partial_2\psi_2)(\rho - \partial_2\varphi_2)]\, d\Omega \\ &+ \frac{1}{1-\nu}\int_\Omega (\partial_2\psi_1\partial_2\varphi_1 + \partial_1\psi_2\partial_1\varphi_2)\, d\Omega \\ &- \frac{\nu}{1-\nu^2}\int_\Omega (\partial_2\psi_1 - \partial_1\psi_2)(\partial_2\varphi_1 - \partial_1\varphi_2)\, d\Omega, \\ A_0((\psi,\xi),(\varphi,\rho)) = a_0(\underline{\sigma},\underline{\tau}) = \frac{1}{1-\nu}\int_\Omega &\mathbf{curl}\xi \cdot \mathbf{curl}\rho \, d\Omega. \end{aligned}$$

We also define the bilinear continuous forms $B(\cdot,\cdot)$, $C(\cdot,\cdot)$ on $\mathbf{Y}^\varepsilon \times \mathbf{Z}$ and on $\mathbf{Y}^\varepsilon \times L^2(\Omega)$, respectively, by putting

$$B((\varphi,\rho),\mathbf{q}) = -\langle \partial_t \mathbf{q}, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma},$$
$$C((\varphi,\rho),\lambda) = c(\underline{\tau},\lambda) = \int_\Omega \lambda\,(2\rho - \mathrm{div}\varphi)\, d\Omega,$$

where the space $\mathbf{Z}$ is given by

$$\mathbf{Z} = \left\{ \mathbf{q} \in H^{1/2}(\Gamma)^2;\ \mathbf{q} = 0 \text{ on } \Gamma_0,\ \mathbf{q}\cdot\mathbf{t} = 0 \text{ on } \Gamma_1,\ \int_\Gamma \mathbf{q}\cdot\mathbf{t}\, d\Gamma = 0 \right\}.$$

Remark 4.1. The forms $A(\cdot,\cdot)$ and $B(\cdot,\cdot)$ correspond to the equations of the Kirchhoff–Love model, while $C(\cdot,\cdot)$ dualizes the symmetry of the bending tensor and $A_0(\cdot,\cdot)$ takes into account the contribution of the rotation. The space $\mathbf{Z}$ is the same as the one employed in [1]. Let us also notice that with any $\mathbf{q} \in \mathbf{Z}$ one can associate a unique couple $(\zeta,\eta) \in M \times N$ such that $\mathbf{q} = (\partial_t\zeta)\mathbf{t} + \eta\mathbf{n}$; then $B((\varphi,\rho),\mathbf{q}) = b(\underline{\tau},(\zeta,\eta))$; see [1] for more details.

Finally, let us introduce the linear continuous forms $F^\varepsilon(\cdot)$ and $G(\cdot)$ defined on $\mathbf{Y}^\varepsilon$ and on $\mathbf{Z}$, respectively, by the relationship

$$F^\varepsilon((\varphi,\rho)) = -a^\varepsilon(\phi^f \underline{I},\underline{\tau}), \qquad G(\mathbf{q}) = \int_\Gamma \phi^f \mathbf{q}\cdot\mathbf{n}\, d\Gamma.$$

Then we state the following result.

THEOREM 4.1. *The variational problem*

$$\begin{cases} \text{find } (\psi^\varepsilon, \xi^\varepsilon) \in \mathbf{Y}^\varepsilon,\ \mathbf{p}^\varepsilon \in \mathbf{Z},\ \lambda^\varepsilon \in L^2(\Omega) \quad \text{such that} \\ \forall ((\varphi,\rho)) \in \mathbf{Y}^\varepsilon, \quad A^\varepsilon((\psi^\varepsilon,\xi^\varepsilon),(\varphi,\rho)) + B((\varphi,\rho),\mathbf{p}^\varepsilon) + C((\varphi,\rho),\lambda^\varepsilon) = F^\varepsilon((\varphi,\rho)), \\ \forall \mathbf{q} \in \mathbf{Z}, \qquad B((\psi^\varepsilon,\xi^\varepsilon),\mathbf{q}) = G(\mathbf{q}), \\ \forall \mu \in L^2(\Omega), \qquad C((\psi^\varepsilon,\xi^\varepsilon),\mu) = 0 \end{cases} \tag{4.2}$$

has a unique solution.

Proof. The existence and the uniqueness are obtained by the means of the Babuška–Brezzi theory. For that, it is sufficient to check the $\mathbf{Y}^\varepsilon$-ellipticity of the bilinear form $A^\varepsilon(\cdot,\cdot)$ and the inf-sup condition for $D(\cdot,\cdot) = B(\cdot,\cdot) + C(\cdot,\cdot)$.

Concerning the ellipticity, one has for any $(\varphi,\rho) \in \mathbf{Y}^\varepsilon$ that

$$A((\varphi,\rho),(\varphi,\rho)) = a(\underline{\tau},\underline{\tau}) \geq c \| \underline{\tau} \|^2_{0,\Omega},$$

where we have put $\underline{\tau} = \underline{curl}\,\varphi + \rho\underline{J}$. We show next that

$$|\varphi|^2_{1,\Omega} + \|\rho\|^2_{0,\Omega} \leq c \| \underline{\tau} \|^2_{0,\Omega}, \tag{4.3}$$

which leads to the $\mathbf{Y}^\varepsilon$-ellipticity of $A^\varepsilon(\cdot,\cdot)$ uniformly with respect to ε:

$$A^\varepsilon((\varphi,\rho),(\varphi,\rho)) \geq c(|\varphi|^2_{1,\Omega} + \|\rho\|^2_{0,\Omega} + \varepsilon^2 |\rho|^2_{1,\Omega}).$$

One has

$$\| \underline{\tau} \|^2_{0,\Omega} = |\varphi_1|^2_{1,\Omega} + |\varphi_2|^2_{1,\Omega} + 2\|\rho\|^2_{0,\Omega} - 2\int_\Omega \rho\,(\partial_1\varphi_1 + \partial_2\varphi_2)\ d\Omega.$$

According to Girault and Raviart [8], there exists a positive constant k such that the following statement holds, for any $\rho \in L^2_0(\Omega)$:

$$k\|\rho\|_{0,\Omega} \leq \|\nabla\rho\|_{-1,\Omega} = \| \mathbf{div}\underline{\tau} \|_{-1,\Omega} \leq k_1 \| \underline{\tau} \|_{0,\Omega}. \tag{4.4}$$

Next, let δ be a positive real number. Young's inequality implies that

$$2\int_\Omega \rho\,(\partial_1\varphi_1 + \partial_2\varphi_2)\ d\Omega \leq \delta^2 \|\rho\|^2_{0,\Omega} + \frac{1}{\delta^2}|\varphi|^2_{1,\Omega},$$

so

$$(2-\delta^2)\|\rho\|^2_{0,\Omega} + \left(1 - \frac{1}{\delta^2}\right)|\varphi|^2_{1,\Omega} \leq \| \underline{\tau} \|^2_{0,\Omega},$$

and, consequently, by means of (4.4), it holds for $\delta \geq 1$ that

$$|\varphi|^2_{1,\Omega} \leq c \| \underline{\tau} \|^2_{0,\Omega}.$$

So we obtain the estimate (4.3).

We still have to establish the inf-sup condition for the bilinear form $D(\cdot,\cdot)$ on $\mathbf{Y}^\varepsilon \times (\mathbf{Z} \times L^2(\Omega))$, where

$$D((\varphi,\rho),(\mathbf{q},\mu)) = B((\varphi,\rho),\mathbf{q}) + C((\varphi,\rho),\mu).$$

To do that, we fix an arbitrary couple $(\mathbf{q},\mu)\in\mathbf{Z}\times L^2(\Omega)$ and we construct $(\varphi,\rho)\in\mathbf{Y}^\varepsilon$ such that $D((\varphi,\rho),(\mathbf{q},\mu))\geq c(\|\mathbf{q}\|^2_{1/2,\Gamma}+\|\mu\|^2_{0,\Omega})$ and

$$|\varphi|_{1,\Omega}+\|\rho\|_{0,\Omega}+\varepsilon\,|\rho|_{1,\Omega}\leq c(\|\mathbf{q}\|_{1/2,\Gamma}+\|\mu\|_{0,\Omega}).$$

We will actually take $\rho=0$, so we have only to construct $\varphi\in\mathbf{H}$.

Exactly as in the Kirchhoff–Love case [1], with any $\mathbf{q}\in\mathbf{Z}$ we associate the solution $\mathbf{w}$ of the following boundary problem:

$$\begin{cases}\Delta\mathbf{w}=0 & \text{in }\Omega,\\ \mathbf{w}=\mathbf{q} & \text{on }\Gamma,\end{cases}$$

and we take $\varphi_1\in(H^1(\Omega)_{|\mathbb{R}})^2$ such that $\underline{\nabla}\varphi_1=\underline{curl}\,\mathbf{w}$. Then one has, for any $\rho\in W^\varepsilon$, that

$$B((\varphi_1,\rho),\mathbf{q})\geq c\,\|\mathbf{q}\|^2_{1/2,\Gamma}\quad\text{and}\quad|\varphi_1|_{1,\Omega}\leq c\,\|\mathbf{q}\|_{1/2,\Gamma}.$$

We equally have that $\mathrm{div}\varphi_1\in L^2_0(\Omega)$, since

$$\int_\Omega \mathrm{div}\varphi_1\,d\Omega=\int_\Gamma\mathbf{q}\cdot\mathbf{t}\,d\Gamma=0.$$

Next, let us consider an arbitrary $\mu\in L^2(\Omega)$ and put

$$\lambda=\mu-P(\mu)-\mathrm{div}\varphi_1\qquad\text{with }\lambda\in L^2_0(\Omega).$$

According to [8], one knows that there exists $\varphi_2\in(H^1_0(\Omega))^2$ such that

$$\mathrm{div}\varphi_2=\lambda\qquad\text{and}\qquad|\,\varphi_2\,|_{1,\Omega}\leq c\,\|\lambda\|_{0,\Omega}.$$

Finally, we set

$$\varphi=\varphi_1+\varphi_2+\frac{P(\mu)}{2}\begin{pmatrix}x\\ y\end{pmatrix}$$

and choose φ_1 (which is unique up to a constant) such that $\int_\Omega\varphi\,d\Omega=0$. Then we notice that $\varphi\in\mathbf{H}$ and, moreover,

$$\begin{cases}\mathrm{div}\,\varphi=\mu & \text{in }\Omega,\\ |\varphi|_{1,\Omega}\leq c(\|\mathbf{q}\|_{1/2,\Gamma}+\|\lambda\|_{0,\Omega}+\|P(\mu)\|_{0,\Omega})\leq c(\|\mathbf{q}\|_{1/2,\Gamma}+\|\mu\|_{0,\Omega}).\end{cases}$$

The boundary Γ being polygonal, one has that $\partial_t\varphi=\partial_t\varphi_1+c\mathbf{t}$, with $c=\frac{P(\mu)}{2}$, which implies that

$$\partial_t\varphi\cdot\mathbf{n}=\partial_t\varphi_1\cdot\mathbf{n},\qquad\partial_t(\partial_t\varphi\cdot\mathbf{t})=\partial_t(\partial_t\varphi_1\cdot\mathbf{t})\qquad\text{on }\Gamma,$$

so it turns out that

$$D((\varphi,0),\mathbf{q})=B((\varphi_1,0),\mathbf{q})+C((\varphi,0),\mu)\geq c(\|\mathbf{q}\|^2_{1/2,\Gamma}+\|\mu\|^2_{0,\Omega}).$$

Finally, this gives us the desired inf-sup condition, which obviously uniformly holds with respect to ε. □

5. Equivalence with the initial Reissner–Mindlin model. We establish in this paragraph the link between the solution of the previous variational formulation and the solution of (2.2). This is given by the following result.

THEOREM 5.1. *Let* $((\psi^\varepsilon, \xi^\varepsilon), \mathbf{p}^\varepsilon, \lambda^\varepsilon)$ *be the unique solution of* (4.2). *Then we have*

$$\begin{cases} \underline{\sigma}^\varepsilon = \underline{curl}\,\psi^\varepsilon + \xi^\varepsilon \underline{J} + \phi^f \underline{I} & \text{in } \Omega, \\ \mathbf{r}^\varepsilon = \mathbf{p}^\varepsilon & \text{on } \Gamma, \\ -\dfrac{1}{2} curl\, \mathbf{r}^\varepsilon = \lambda^\varepsilon & \text{in } \Omega, \end{cases} \tag{5.1}$$

where $(\underline{\sigma}^\varepsilon, u^\varepsilon, \mathbf{r}^\varepsilon)$ *is the solution of the initial Reissner–Mindlin problem* (2.2).

Proof. We present here the steps of the proof, since it is similar to the one given in [1].

We note $\widetilde{\underline{\sigma}}^\varepsilon = \underline{curl}\,\psi^\varepsilon + \xi^\varepsilon \underline{J} + \phi^f \underline{I}$, for which we obviously have $D(\widetilde{\underline{\sigma}}^\varepsilon) = f$. Moreover, the second equation of (4.2) implies that $\gamma_0(\widetilde{\underline{\sigma}}^\varepsilon) = \gamma_1(\widetilde{\underline{\sigma}}^\varepsilon) = 0$, while the third equation gives that $\widetilde{\underline{\sigma}}^\varepsilon$ is symmetric.

By taking as a test-function a couple $(\mathbf{curl}\,\varphi, 0) \in \mathbf{Y}^\varepsilon$ with an arbitrary $\varphi \in \mathcal{D}(\Omega)$, which corresponds to the tensor $\underline{\tau} = \underline{curl}\mathbf{curl}\,\varphi$, we get according to the proof of Theorem 3.2 the constitutive law of the plate. More precisely, we show that there exists a function $\widetilde{\mathbf{r}}^\varepsilon \in (H^1(\Omega))^2$ unique up to $\underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) = \underline{0}$ such that

$$\widetilde{\underline{\sigma}}^\varepsilon = (1-\nu)\,\underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) + \nu(\mathrm{div}\widetilde{\mathbf{r}}^\varepsilon)\underline{I}.$$

Another choice of the test-function, i.e., $(\varphi - P(\varphi), \frac{1}{2}\mathrm{div}\,\varphi) \in \mathbf{Y}^\varepsilon$ with $\varphi \in (\mathcal{D}(\Omega))^2$ (which means that the associated tensor is $\underline{\tau} = \underline{curl}\varphi + \frac{1}{2}\mathrm{div}\,\varphi$), allows us to obtain, exactly as in Theorem 3.2, the existence of a unique $\widetilde{u}^\varepsilon \in H^1(\Omega)_{|\mathbb{R}}$ satisfying

$$\frac{\varepsilon^2}{1-\nu}\mathbf{div}\widetilde{\underline{\sigma}}^\varepsilon = \widetilde{\mathbf{r}}^\varepsilon - \nabla\widetilde{u}^\varepsilon.$$

We next take as a test-function in (4.2) a couple $(0, \rho^0) \in \mathbf{Y}^\varepsilon$, with $\rho^0 = \rho - P(\rho)$ and $\rho \in \mathcal{D}(\overline{\Omega})$ arbitrary. This leads us to

$$\int_\Omega (curl\,\widetilde{\mathbf{r}}^\varepsilon + 2\lambda^\varepsilon)\rho^0\, d\Omega = 0 \quad \Leftrightarrow \quad curl\,\widetilde{\mathbf{r}}^\varepsilon + 2\lambda^\varepsilon = k, \quad k \in \mathbb{R}.$$

We have thus obtained that $\lambda^\varepsilon = -\frac{1}{2} curl\,\widetilde{\mathbf{r}}^\varepsilon + k$, and we shall next show that $k = 0$.

Let us study for the moment the boundary conditions satisfied by the functions $\widetilde{\mathbf{r}}^\varepsilon$ and $\widetilde{u}^\varepsilon$. The same choice as above, that is, $(0, \rho^0)$, gives us the following relationship, where $\underline{\tau} = \rho^0 \underline{J}$:

$$\int_\Omega \underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) : \underline{\tau}\, d\Omega + \frac{\varepsilon^2}{1-\nu}\int_\Omega \mathbf{div}\widetilde{\underline{\sigma}}^\varepsilon \cdot \mathbf{div}\underline{\tau}\, d\Omega + \int_\Omega \left(k - \frac{1}{2} curl\,\widetilde{\mathbf{r}}^\varepsilon\right)(\tau_{12} - \tau_{21})\, d\Omega = 0$$

$$\Leftrightarrow \int_\Omega (\widetilde{\mathbf{r}}^\varepsilon - \nabla\widetilde{u}^\varepsilon)\cdot\mathbf{curl}\rho^0\, d\Omega - \int_\Omega curl\,\widetilde{\mathbf{r}}^\varepsilon\,\rho^0\, d\Omega + 2k\int_\Omega \rho^0\, d\Omega = 0$$

$$\Leftrightarrow \langle \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} - \partial_t\widetilde{u}^\varepsilon, \rho^0\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0. \tag{5.2}$$

For $\rho \in \mathcal{D}(\Omega)$ with $\int_\Omega \rho\, d\Omega \neq 0$, the above equality implies $\langle \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} - \partial_t\widetilde{u}^\varepsilon, 1\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0$, so (5.2) now writes as

$$\forall \rho \in \mathcal{D}(\overline{\Omega}), \qquad \langle \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} - \partial_t\widetilde{u}^\varepsilon, \rho\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0,$$

which means $\widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} = \partial_t \widetilde{u}^\varepsilon$ on Γ. In order to obtain the other boundary conditions, we consider in the first equation of (4.2) the test-function $(\widehat{\varphi}, 0) \in \mathbf{Y}^\varepsilon$ with

$$\widehat{\varphi} = \varphi' - P(\varphi'), \quad \text{where} \quad \varphi' = \varphi - \frac{P(\mathrm{div}\varphi)}{2} \begin{pmatrix} x \\ y \end{pmatrix},$$

and where $\varphi \in (\mathcal{D}(\overline{\Omega}))^2$ is arbitrary. Then one has

$$\begin{aligned}
&\int_\Omega \underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) : \underline{curl}\, \varphi' \, d\Omega - \langle \partial_t \mathbf{p}^\varepsilon, \varphi' \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \int_\Omega \left(\frac{1}{2} curl\, \widetilde{\mathbf{r}}^\varepsilon - k \right) \mathrm{div}\varphi' \, d\Omega = 0 \\
&\quad \Leftrightarrow \int_\Omega \underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) : \underline{curl}\, \varphi \, d\Omega - \langle \partial_t \mathbf{p}^\varepsilon, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} \\
&\qquad + \frac{1}{2} \int_\Omega curl\, \widetilde{\mathbf{r}}^\varepsilon \, \mathrm{div}\varphi \, d\Omega + \left\langle \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t}, \frac{P(\mathrm{div}\varphi)}{2} \right\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0 \\
&\qquad \Leftrightarrow \int_\Omega \underline{\nabla} \widetilde{\mathbf{r}}^\varepsilon : \underline{curl}\, \varphi \, d\Omega - \langle \partial_t \mathbf{p}^\varepsilon, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0 \\
&\qquad\quad \Leftrightarrow \langle \partial_t (\widetilde{\mathbf{r}}^\varepsilon - \mathbf{p}^\varepsilon), \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0.
\end{aligned}$$

We used here the following relationships, which are true for any $\mathbf{c} \in \mathbb{R}^2$ and any $c \in \mathbb{R}$:

$$\langle \partial_t \mathbf{p}^\varepsilon, \mathbf{c} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0, \qquad \left\langle \partial_t \mathbf{p}^\varepsilon, c \begin{pmatrix} x \\ y \end{pmatrix} \right\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0, \qquad \langle \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t}, c \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0.$$

Since $\widetilde{\mathbf{r}}^\varepsilon$ is unique up to a constant, we first get that $\widetilde{\mathbf{r}}^\varepsilon = \mathbf{p}^\varepsilon$ on Γ. So we have that

$$\widetilde{\mathbf{r}}^\varepsilon = 0 \quad \text{on } \Gamma_0, \qquad \widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} = 0 \quad \text{on } \Gamma_0 \cup \Gamma_1,$$

and, since $\widetilde{\mathbf{r}}^\varepsilon \cdot \mathbf{t} = \partial_t \widetilde{u}^\varepsilon$ on Γ with $\widetilde{u}^\varepsilon$ unique up to a constant, we obtain $\widetilde{u}^\varepsilon = 0$ on $\Gamma_0 \cup \Gamma_1$.

Now, for the test-function $(\widehat{\varphi}, 0) \in \mathbf{Y}^\varepsilon$ with $\widehat{\varphi} = \varphi - P(\varphi)$ where $\varphi \in (\mathcal{D}(\overline{\Omega}))^2$ is arbitrary, it comes from (4.2) that

$$\begin{aligned}
&\int_\Omega \underline{\varepsilon}(\widetilde{\mathbf{r}}^\varepsilon) : \underline{curl}\, \varphi \, d\Omega - \langle \partial_t \mathbf{p}^\varepsilon, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \int_\Omega \left(\frac{1}{2} curl\, \widetilde{\mathbf{r}}^\varepsilon - k \right) \mathrm{div}\varphi \, d\Omega = 0 \\
&\quad \Leftrightarrow \int_\Omega \underline{\nabla} \widetilde{\mathbf{r}}^\varepsilon : \underline{curl}\, \varphi \, d\Omega - \langle \partial_t \widetilde{\mathbf{r}}^\varepsilon, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - k \int_\Omega \mathrm{div}\varphi \, d\Omega = 0 \\
&\quad\quad \Leftrightarrow k \int_\Omega \mathrm{div}\varphi \, d\Omega = 0 \quad \forall \varphi \in (\mathcal{D}(\overline{\Omega}))^2,
\end{aligned}$$

which means that $k = 0$. Therefore, $(\widetilde{\underline{\sigma}}^\varepsilon, \widetilde{u}^\varepsilon, \widetilde{\mathbf{r}}^\varepsilon)$ satisfies the relationships in (5.1) as well as the Reissner–Mindlin equations (2.2). The uniqueness of the solution of (2.2) ends our proof. ∎

Remark 5.1. We can now calculate the solution $(\underline{\sigma}^\varepsilon, u^\varepsilon, \mathbf{r}^\varepsilon)$ of the Reissner–Mindlin model by means of the solution $((\psi^\varepsilon, \xi^\varepsilon), \mathbf{p}^\varepsilon, \lambda^\varepsilon)$ of problem (4.2). Indeed, the bending moment is given by (5.1), the transverse displacement is obtained as solution of the elliptic problem

$$\begin{cases} \Delta u^\varepsilon = \dfrac{1}{1+\nu} tr \underline{\sigma}^\varepsilon - \dfrac{\varepsilon^2}{1-\nu} f & \text{in } \Omega, \\ u^\varepsilon = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ \partial_t u^\varepsilon = \mathbf{p}^\varepsilon \cdot \mathbf{t} & \text{on } \Gamma_2, \end{cases} \tag{5.3}$$

and the rotation is obtained thanks to the relationship (3.7).

6. Finite element approximation. We are interested here in the conforming discretization of the variational formulation (4.2) which describes the Reissner–Mindlin problem (2.2).

For that, let $(\mathcal{T}_h)_{h>0}$ be a regular family of triangulations of the polygonal domain $\overline{\Omega}$, each $\mathcal{T}_h$ consisting of triangles K—$\overline{\Omega} = \bigcup_{K\in\mathcal{T}_h} K$. We employ classical notations: for every triangle K of $\mathcal{T}_h$, we denote by h_K its diameter and by $h = \max_{K\in\mathcal{T}_h} h_K$ the discretization parameter. We also introduce the set $\partial\mathcal{T}_h$ of edges of the triangulation $\mathcal{T}_h$ situated on Γ.

6.1. Discrete variational formulation. In order to approximate $\mathbf{p}^\varepsilon$, we shall use the same finite elements as in the Kirchhoff–Love case, that is,

$$\mathbf{Z}_h = \left\{ \mathbf{q}_h \in \mathbf{Z};\ \ \mathbf{q}_h \in (\mathcal{C}^0(\Gamma))^2 \ \text{ and } \ \forall T \in \partial\mathcal{T}_h,\ \ \mathbf{q}_{h|T} \in (P_1(T))^2 \right\}.$$

The approximation of the additional unknowns $\xi^\varepsilon \in W^\varepsilon$ and $\lambda^\varepsilon \in L^2(\Omega)$ will be achieved in the following finite dimensional spaces:

$$W_h = \left\{ \rho_h \in H^1(\Omega);\ \ \forall K \in \mathcal{T}_h,\ \ \rho_{h|K} \in P_1(K) \right\},$$
$$L_h = \left\{ \lambda_h \in L^2(\Omega);\ \ \forall K \in \mathcal{T}_h,\ \ \lambda_{h|K} \in P_0(K) \right\},$$

while for ψ^ε we employ the finite element space $\mathbf{H}_h = \mathbf{H} \cap (H_h^1)^2$, where

$$H_h^1 = \left\{ \varphi_h \in H^1(\Omega);\ \ \forall K \in \mathcal{T}_h,\ \ \varphi_{h|K} \in P_2(K) \right\}.$$

Remark 6.1. For $\varepsilon \neq 0$, the space W^ε coincides algebraically with $H^1(\Omega)$ so W_h is a subspace of W^ε. The norm considered on W_h is obviously the weighted one previously defined on W^ε.

For the sake of simplicity, we denote

$$\mathbf{Y}_h = \mathbf{H}_h \times W_h \subset \mathbf{Y}^\varepsilon$$

and we put

$$\forall (\varphi_h, \rho_h) \in \mathbf{Y}_h, \quad F_h^\varepsilon((\varphi_h, \rho_h)) = -a^\varepsilon(\phi_h^f \underline{I}, \underline{curl}\,\varphi_h + \rho_h \underline{J})$$
$$\forall \mathbf{q}_h \in \mathbf{Z}_h, \qquad G_h(\mathbf{q}_h) = \int_\Gamma \phi_h^f\, \mathbf{q}_h \cdot \mathbf{n}\, d\Gamma.$$

The discrete function ϕ_h^f is a P_1-continuous finite element approximation of $\phi^f \in V$, the solution of the auxiliary problem (3.4). In order to calculate it explicitly, one can discretize the variational formulation of (3.4) and solve

$$\begin{cases} \text{find } \phi_h^f \in V_h \quad \text{such that} \\ \forall v_h \in V_h, \quad \displaystyle\int_\Omega \nabla\phi_h^f \cdot \nabla v_h\, d\Omega = \int_\Omega f v_h\, d\Omega, \end{cases} \tag{6.1}$$

where

$$V = \left\{ v \in H^1(\Omega);\ v = 0 \text{ on } \Gamma_0 \cup \Gamma_1 \right\}, \qquad V_h = W_h \cap V.$$

It is then obvious that

$$|\,\phi^f - \phi_h^f\,|_{1,\Omega} = \inf_{v_h \in V_h} |\,\phi^f - v_h\,|_{1,\Omega}\,.$$

Then we consider the discrete version of (4.2) written as below:

$$\begin{cases} \text{find } (\psi_h^\varepsilon, \xi_h^\varepsilon) \in \mathbf{Y}_h,\ \mathbf{p}_h^\varepsilon \in \mathbf{Z}_h,\ \lambda_h^\varepsilon \in L_h \quad \text{such that} \\ \forall (\varphi_h, \rho_h) \in \mathbf{Y}_h, \quad A^\varepsilon((\psi_h^\varepsilon, \xi_h^\varepsilon), (\varphi_h, \rho_h)) + B((\varphi_h, \rho_h), \mathbf{p}_h^\varepsilon) + C((\varphi_h, \rho_h), \lambda_h^\varepsilon) \\ \qquad\qquad = F_h^\varepsilon((\varphi_h, \rho_h)), \\ \forall \mathbf{q}_h \in \mathbf{Z}_h, \qquad B((\psi_h^\varepsilon, \xi_h^\varepsilon), \mathbf{q}_h) = G_h(\mathbf{q}_h), \\ \forall \mu_h \in L_h, \qquad C((\psi_h^\varepsilon, \xi_h^\varepsilon), \mu_h) = 0. \end{cases} \tag{6.2}$$

We prove in what follows that the discrete inf-sup condition of Babuška–Brezzi for the above mixed problem uniformly holds with respect to both the discretization parameter h and the plate's thickness ε.

THEOREM 6.1. *There exists a positive constant c, independent of h and ε, such that, for any $(\mathbf{q}_h, \mu_h) \in \mathbf{Z}_h \times L_h$,*

$$\sup_{(\varphi_h, \rho_h) \in \mathbf{Y}_h} \frac{B((\varphi_h, \rho_h), \mathbf{q}_h) + C((\varphi_h, \rho_h), \mu_h)}{|\varphi_h|_{1,\Omega} + \|\rho_h\|_{0,\Omega} + \varepsilon\, |\rho_h|_{1,\Omega}} \geq c(\|\mathbf{q}_h\|_{1/2,\Gamma} + \|\mu_h\|_{0,\Omega}).$$

Proof. We apply Fortin's trick. For that, we will use the continuous inf-sup condition established in Theorem 4.1 and the interpolation operator $P_h : (H^1(\Omega))^2 \cap (\mathcal{C}^0(\overline{\Omega}))^2 \to (H_h^1)^2$ defined hereafter.

Let us note by P_{1h} the classical Lagrange interpolation operator which satisfies, for any $\varphi \in (H^1(K))^2 \cap (\mathcal{C}^0(\overline{K}))^2$,

$$P_{1h}\varphi \in (\mathcal{P}_1(K))^2 \quad \text{and} \quad P_{1h}\varphi(S) = \varphi(S) \quad \forall S \text{ vertex of } K \in \mathcal{T}_h.$$

We introduce the operator P_{2h} defined by $P_{2h}\varphi \in (\mathcal{P}_2(K))^2$, and

$$\begin{aligned} P_{2h}\varphi(S) &= 0 \quad \text{for every vertex } S \text{ of } K, \\ \int_T (\varphi - P_{2h}\varphi)\, d\Gamma &= 0 \quad \text{for every edge } T \text{ of } K. \end{aligned}$$

Then we put on every triangle $K \in \mathcal{T}_h$

$$P_h\varphi = P_{1h}\varphi + P_{2h}(\varphi - P_{1h}\varphi),$$

which clearly satisfies the properties

$$\begin{aligned} &\forall T \in \partial\mathcal{T}_h, \quad \int_T P_h\varphi\, d\Gamma = \int_T \varphi\, d\Gamma, \\ &\forall K \in \mathcal{T}_h, \quad \int_K \operatorname{div}(P_h\varphi)\, d\Omega = \int_K \operatorname{div}\varphi\, d\Omega. \end{aligned} \tag{6.3}$$

If $\varphi \in \mathbf{H} \cap (\mathcal{C}^0(\overline{\Omega}))^2$, then we have only that $P_h\varphi$ belongs to $(H_h^1)^2$ and not to the space $\mathbf{H}$.

Let us now come back to the proof of the uniform inf-sup condition for problem (6.2).

With any $\mathbf{q}_h \in \mathbf{Z}_h$, we associate, exactly as in Theorem 4.1, a function $\varphi_1 \in (H^1(\Omega)_{|\mathbb{R}})^2$ such that

$$B((\varphi_1, 0), \mathbf{q}_h) \geq c\, \|\mathbf{q}_h\|_{1/2,\Gamma}^2 \quad \text{and} \quad |\varphi_1|_{1,\Omega} \leq c\, \|\mathbf{q}_h\|_{1/2,\Gamma}.$$

We recall that $\underline{\nabla}\varphi_1 = \underline{curl}\,\mathbf{w}$, where $\mathbf{w} \in (H^1(\Omega))^2$ is the unique function satisfying $\Delta\mathbf{w} = 0$ in Ω and $\mathbf{w} = \mathbf{q}_h$ on Γ. We also have, by construction, that $\mathrm{div}\varphi_1 \in L_0^2(\Omega)$. Since $\mathbf{q}_h \in (H^1(\Gamma))^2$, we obtain by classical results of regularity of the Laplace operator (see [9], [10]) that $\mathbf{w} \in (H^{1+a}(\Omega))^2$ with $a \in]0, \frac{1}{2}]$. We deduce that $\varphi_1 \in (H^{1+a}(\Omega))^2 \hookrightarrow (\mathcal{C}^0(\overline{\Omega}))^2$, so we can define $P_h\varphi_1$.

Then by considering the discrete function $\varphi_{1h} = P_h\varphi_1 \in (H_h^1)^2$, we have, thanks to (6.3), that

$$B((\varphi_1, 0), \mathbf{q}_h) = B((\varphi_{1h}, 0), \mathbf{q}_h).$$

On the other hand, we obtain, by passing to the reference finite element and using the Bramble–Hilbert lemma, that $|\varphi_1 - P_{2h}\varphi_1|_{1,K} \leq c\,|\varphi_1|_{1,K}$. This implies that

$$\forall K \in \mathcal{T}_h, \quad |\varphi_1 - \varphi_{1h}|_{1,K} \leq c\,|\varphi_1 - P_{1h}\varphi_1|_{1,K} \leq c\,|\varphi_1|_{1,K},$$

so by the triangle inequality, $|\varphi_{1h}|_{1,\Omega} \leq c\,|\varphi_1|_{1,\Omega}$. We now have that

$$\frac{B((\varphi_{1h}, 0), \mathbf{q}_h)}{|\,\varphi_{1h}\,|_{1,\Omega}} \geq c\frac{B((\varphi_1, 0), \mathbf{q}_h)}{|\varphi_1|_{1,\Omega}} \geq c\,\|\mathbf{q}_h\|_{1/2,\Gamma}.$$

Next, following the proof of Theorem 4.1, let us consider an arbitrary $\mu_h \in L_h$ and put

$$\lambda = \mu_h - P(\mu_h) - \mathrm{div}\varphi_{1h} \qquad \text{with } \lambda \in L_0^2(\Omega).$$

According to Girault and Raviart [8], one knows that there exists $\varphi_2 \in H_0^1(\Omega)^2$ such that

$$\mathrm{div}\varphi_2 = \lambda \qquad \text{with} \qquad |\,\varphi_2\,|_{1,\Omega} \leq c\,\|\lambda\|_{0,\Omega}.$$

Finally, we put $\varphi_h' = \varphi_{1h} + P_h\varphi_2 + \frac{P(\mu_h)}{2}\binom{x}{y}$, which belongs to $(H_h^1)^2$, and next consider

$$\varphi_h = \varphi_h' - P(\varphi_h').$$

This last function now belongs to $\mathbf{H}_h$, and it obviously satisfies

$$|\varphi_h|_{1,\Omega} \leq c(\|\mathbf{q}_h\|_{1/2,\Gamma} + \|\lambda\|_{0,\Omega} + \|\mu_h\|_{0,\Omega}) \leq c(\|\mathbf{q}_h\|_{1/2,\Gamma} + \|\mu_h\|_{0,\Omega}).$$

Then we notice that we have, thanks to (6.3),

$$C((\varphi_h, 0), \mu_h) = \|\mu_h\|_{0,\Omega}^2.$$

The boundary Γ being polygonal, one gets $\partial_t\varphi_h = \partial_t\varphi_{1h} + c\mathbf{t}$ with $c = \frac{P(\mu_h)}{2}$, which implies that

$$\partial_t\varphi_h \cdot \mathbf{n} = \partial_t\varphi_{1h} \cdot \mathbf{n}, \quad \partial_t(\partial_t\varphi_h \cdot \mathbf{t}) = \partial_t(\partial_t\varphi_{1h} \cdot \mathbf{t}) \quad \text{on } \Gamma,$$

so we have that

$$B((\varphi_h, 0), \mathbf{q}_h) = B((\varphi_{1h}, 0), \mathbf{q}_h).$$

Finally, this gives us

$$\sup_{(\psi_h,\rho_h)\in\mathbf{Y}_h} \frac{B((\psi_h,\rho_h),\mathbf{q}_h)+C((\psi_h,\rho_h),\mu_h)}{|\psi_h|_{1,\Omega}+\|\rho_h\|_{0,\Omega}+\varepsilon\,|\rho_h|_{1,\Omega}} \geq \frac{B((\varphi_h,0),\mathbf{q}_h)+C((\varphi_h,0),\mu_h)}{|\varphi_h|_{1,\Omega}} \geq c(\|\mathbf{q}_h\|_{1/2,\Gamma}+\|\mu_h\|_{0,\Omega}),$$

which ends the proof. □

Remark 6.2. It is equally possible to approximate ψ^ε by the same finite element as in the Kirchhoff–Love case (whose degrees of freedom are the values at the nodes of the triangulation, to which we add the values at the midpoints of the edges situated on $\Gamma_1\bigcup\Gamma_2$) and λ^ε by piecewise linear elements, and thus one will get a cheaper method. However, the discrete inf-sup condition will not be uniform with respect to h this time, and the convergence of the method will depend upon ε.

The previous result immediately gives, by using the Babuška–Brezzi theory, the following.

THEOREM 6.2. *Problem* (6.2) *admits a unique solution for any positive h and ε. Moreover, the following error bound holds:*

$$\begin{aligned}|\psi^\varepsilon-\psi_h^\varepsilon|_{1,\Omega}+\|\xi^\varepsilon-\xi_h^\varepsilon\|_{0,\Omega}+\varepsilon\,|\xi^\varepsilon-\xi_h^\varepsilon|_{1,\Omega}+\|\mathbf{p}^\varepsilon-\mathbf{p}_h^\varepsilon\|_{1/2,\Gamma}+\|\lambda^\varepsilon-\lambda_h^\varepsilon\|_{0,\Omega}\\ \leq c\{\inf_{\varphi_h\in\mathbf{H}_h}|\psi^\varepsilon-\varphi_h|_{1,\Omega}+\inf_{\rho_h\in W_h}(\|\xi^\varepsilon-\rho_h\|_{0,\Omega}+\varepsilon\,|\xi^\varepsilon-\rho_h|_{1,\Omega})\\ +\inf_{\mathbf{q}_h\in\mathbf{Z}_h}\|\mathbf{p}^\varepsilon-\mathbf{q}_h\|_{1/2,\Gamma}+\inf_{\mu_h\in L_h}\|\lambda^\varepsilon-\mu_h\|_{0,\Omega}+\inf_{v_h\in V_h}|\,\phi^f-v_h\,|_{1,\Omega}\}\end{aligned}$$

with a positive constant c independent of both h and ε. Therefore the proposed approximation method is unconditionally convergent for any fixed ε.

6.2. Approximation of the physical variables. In order to obtain the approximated bending moment, we set (according to Theorem 5.1)

$$\underline{\sigma}_h^\varepsilon=\underline{curl}\,\psi_h^\varepsilon+\xi_h^\varepsilon\underline{J}+\phi_h^f\underline{I}, \tag{6.4}$$

while a P_1-continuous finite element discretization of the boundary value problem (5.3) will give us an approximation u_h^ε of the transverse displacement u^ε. For that, we write that u^ε satisfies the variational formulation

$$\begin{cases}\text{find } u^\varepsilon\in H^1(\Omega) \text{ with } u^\varepsilon=g^\varepsilon \text{ on } \Gamma, \quad \text{such that}\\ \forall v\in H_0^1(\Omega), \quad \displaystyle\int_\Omega\nabla u^\varepsilon\cdot\nabla v\,d\Omega\\ \qquad\qquad =\dfrac{-1}{1+\nu}\displaystyle\int_\Omega(tr\underline{\sigma}^\varepsilon)v\,d\Omega+\dfrac{\varepsilon^2}{1-\nu}\displaystyle\int_\Omega fv\,d\Omega,\end{cases} \tag{6.5}$$

where the function $g^\varepsilon\in H^{3/2}(\Gamma)$ is defined on the boundary Γ by the relationships

$$g^\varepsilon=0 \quad \text{on } \Gamma_0\cup\Gamma_1, \qquad \partial_t g^\varepsilon=\mathbf{p}^\varepsilon\cdot\mathbf{t} \quad \text{on } \Gamma_2.$$

In order to calculate u_h^ε, we consider the next discrete version of (6.5):

$$\begin{cases}\text{find } u_h^\varepsilon\in W_h \text{ with } u_h^\varepsilon=I_h(g_h^\varepsilon) \text{ on } \Gamma, \quad \text{such that}\\ \forall v_h\in W_h^0, \quad \displaystyle\int_\Omega\nabla u_h^\varepsilon\cdot\nabla v_h\,d\Omega=\dfrac{-1}{1+\nu}\displaystyle\int_\Omega(tr\underline{\sigma}_h^\varepsilon)v_h\,d\Omega+\dfrac{\varepsilon^2}{1-\nu}\displaystyle\int_\Omega fv_h\,d\Omega,\end{cases}$$

where $\underline{\sigma}_h^\varepsilon$ is given by (6.4), of course, and where $W_h^0 = W_h \cap H_0^1(\Omega)$. Numerical integration has also been employed on the function g^ε, which has been replaced by an approximation $I_h(g_h^\varepsilon)$. The operator I_h denotes the P_1-continuous interpolation operator on the boundary Γ, and the function g_h^ε is taken as follows:

$$g_h^\varepsilon = 0 \quad \text{on } \Gamma_0 \cup \Gamma_1, \qquad \partial_t g_h^\varepsilon = \mathbf{p}_h^\varepsilon \cdot \mathbf{t} \quad \text{on } \Gamma_2.$$

Since $g_h^\varepsilon \in H^{3/2}(\Gamma) \hookrightarrow \mathcal{C}^0(\Gamma)$, one can clearly define $I_h(g_h^\varepsilon)$.

Then we get the following error bound:

$$|u^\varepsilon - u_h^\varepsilon|_{1,\Omega} \le c\{ \inf_{v_h \in W_h^0} | u^{\varepsilon,0} - v_h |_{1,\Omega} + \| \underline{\sigma}^\varepsilon - \underline{\sigma}_h^\varepsilon \|_{0,\Omega} + \|g^\varepsilon - I_h(g_h^\varepsilon)\|_{1/2,\Gamma}\},$$

where we have put $u^{\varepsilon,0} = u^\varepsilon - u^{\varepsilon,g} \in H_0^1(\Omega)$ and $u^{\varepsilon,g} \in H^1(\Omega)$, a continuous lifting satisfying $u^{\varepsilon,g} = g^\varepsilon$ on Γ and $\Delta u^{\varepsilon,g} = 0$ in Ω.

The discrete rotation vector $\mathbf{r}_h^\varepsilon$ will then be recovered by the means of (3.7):

$$\mathbf{r}_h^\varepsilon = \frac{\varepsilon^2}{1-\nu} \mathbf{div} \underline{\sigma}_h^\varepsilon + \nabla u_h^\varepsilon.$$

We used here the fact that $\mathbf{div}\underline{\sigma}_h^\varepsilon = \mathbf{curl}\xi_h^\varepsilon + \nabla\phi_h^f$ belongs to $L^2(\Omega)$, since $\xi_h^\varepsilon \in H^1(\Omega)$, $\phi_h^f \in H^1(\Omega)$, and $\psi_h^\varepsilon \in (H^1(\Omega))^2$, so the function $\underline{curl}\, \psi_h^\varepsilon$ belongs to $(H(\mathrm{div};\Omega))^2$.

Let us finally notice that the finite element method employed gives us low-order approximations of the physical quantities in the following spaces: $\underline{\sigma}_h^\varepsilon \in (H(\mathrm{div};\Omega))^2$, $u_h^\varepsilon \in H^1(\Omega)$, and $\mathbf{r}_h^\varepsilon \in L^2(\Omega)^2$, with also an approximation of $curl\mathbf{r}^\varepsilon$ in $L^2(\Omega)$ thanks to the multiplier λ^ε. Moreover, the described method uses classical finite element spaces (continuous P_1 and P_2, discontinuous P_0). The preprocessing of ϕ_h^f and post-processing of the displacement u_h^ε are very simple—one has to solve only twice, by P_1-continuous elements, a Laplacian problem. Let us remark that these two discrete problems have the same matrix, which is computed only once.

So, thanks to Theorem 6.2, we are now able to state the main result of the section.

THEOREM 6.3. *The above finite element method for the Reissner–Mindlin problem is unconditionally convergent. The next error estimate holds, with c independent of h and ε:*

$$\begin{aligned}
&\| \underline{\sigma}^\varepsilon - \underline{\sigma}_h^\varepsilon \|_{0,\Omega} \\
&\quad + \varepsilon \| \mathbf{div}(\underline{\sigma}^\varepsilon - \underline{\sigma}_h^\varepsilon) \|_{0,\Omega} + \| D(\underline{\sigma}^\varepsilon) - D(\underline{\sigma}_h^\varepsilon) \|_{-1,\Omega} + |u^\varepsilon - u_h^\varepsilon|_{1,\Omega} + \|\mathbf{r}^\varepsilon - \mathbf{r}_h^\varepsilon\|_{0,\Omega} \\
&\quad \le c\{ \inf_{\varphi_h \in \mathbf{H}_h} |\psi^\varepsilon - \varphi_h|_{1,\Omega} + \inf_{\rho_h \in W_h} (\|\xi^\varepsilon - \rho_h\|_{0,\Omega} + \varepsilon\, |\xi^\varepsilon - \rho_h|_{1,\Omega}) \\
&\quad + \inf_{\mathbf{q}_h \in \mathbf{Z}_h} \|\mathbf{p}^\varepsilon - \mathbf{q}_h\|_{1/2,\Gamma} + \inf_{\mu_h \in L_h} \|\lambda^\varepsilon - \mu_h\|_{0,\Omega} \\
&\quad + \inf_{v_h \in V_h} | \phi^f - v_h |_{1,\Omega} + \inf_{v_h \in W_h^0} | u^{\varepsilon,0} - v_h |_{1,\Omega} + \|g^\varepsilon - I_h(g_h^\varepsilon)\|_{1/2,\Gamma}\}.
\end{aligned}$$

6.3. Convergence rate. In what follows, we are looking for an upper bound of each right-hand side term of the previous inequality.

We first recall that the function $\phi^f \in H^1(\Omega)$ satisfies the boundary value problem (3.4). Then the regularity results for the Laplace operator ensure that there exists $b \in]\frac{1}{2}, 1]$ such that

$$\phi^f \in H^{1+b}(\Omega) \qquad \text{and} \qquad || \phi^f ||_{1+b,\Omega} \le c \|f\|_{0,\Omega},$$

with $b = 1$ if Ω is convex. Then we get

$$\inf_{v_h \in V_h} | \phi^f - v_h |_{1,\Omega} \leq ch^b \|f\|_{0,\Omega} .$$

Next, let us notice that we have by construction of g_h^ε that

$$\| g_h^\varepsilon - I_h(g_h^\varepsilon) \|_{\frac{1}{2},\Gamma} \leq ch \| g_h^\varepsilon \|_{\frac{3}{2},\Gamma} \leq ch \| \mathbf{p}_h^\varepsilon \|_{\frac{1}{2},\Gamma} \leq ch \|f\|_{0,\Omega} .$$

We equally know by classical results on the Laplace operator (see [9], [10]) that there exists $a \in]0,1]$ such that $u^{\varepsilon,g} \in H^{1+a}(\Omega)$. Moreover, we have that

$$\left\|u^{\varepsilon,0}\right\|_{1+a,\Omega} \leq \|u^\varepsilon\|_{1+a,\Omega} + c\|\mathbf{p}^\varepsilon\|_{-1/2+a,\Gamma} \leq c\|f\|_{0,\Omega} .$$

In order to obtain the convergence rate of the discretization method, let us assume the following regularity for the exact solution of (2.2):

$$\begin{gathered} \mathbf{r}^\varepsilon \in H^{1+a}(\Omega)^2, \quad u^\varepsilon \in H^{1+a}(\Omega), \\ \|\mathbf{r}^\varepsilon\|_{1+a,\Omega} + \|u^\varepsilon\|_{1+a,\Omega} + \varepsilon \| \mathbf{div}\underline{\sigma}^\varepsilon \|_{a,\Omega} \leq c\|f\|_{0,\Omega} . \end{gathered} \tag{6.6}$$

This hypothesis is verified in convex domains with $a = 1$, at least for clamped plates (cf., for instance, [5]). Now, the previous inequality implies that

$$|\psi^\varepsilon|_{1+a,\Omega} + \|\xi^\varepsilon\|_{a,\Omega} + \varepsilon\,|\xi^\varepsilon|_{1+a,\Omega} + \|\mathbf{p}^\varepsilon\|_{1/2+a,\Gamma} + \|\lambda^\varepsilon\|_{a,\Omega} \leq c\|f\|_{0,\Omega} ,$$

which, together with Theorem 6.3, allows us to deduce the following theorem.

THEOREM 6.4. *Under the regularity assumption* (6.6), *the discretization method for the Reissner–Mindlin model is convergent to order* $O(h^{min\{a,b\}})$*:*

$$\| \underline{\sigma}^\varepsilon - \underline{\sigma}_h^\varepsilon \|_{0,\Omega} + \varepsilon \| \mathbf{div}(\underline{\sigma}^\varepsilon - \underline{\sigma}_h^\varepsilon) \|_{0,\Omega} + |u^\varepsilon - u_h^\varepsilon|_{1,\Omega} + \|\mathbf{r}^\varepsilon - \mathbf{r}_h^\varepsilon\|_{0,\Omega} \leq ch^{min\{a,b\}} \|f\|_{0,\Omega}$$

independently of the plate's thickness ε*.*

Therefore, our method uses simple conforming finite elements of low degree, is unconditionally convergent and locking-free and, in the case of a convex polygon, for instance (when $a = b = 1$), it is also optimal of order $O(h)$.

NUMERICAL METHODS FOR STOCHASTIC SYSTEMS PRESERVING SYMPLECTIC STRUCTURE*

G. N. MILSTEIN†‡, YU. M. REPIN‡, AND M. V. TRETYAKOV§

Abstract. Stochastic Hamiltonian systems with multiplicative noise, phase flows of which preserve symplectic structure, are considered. To construct symplectic methods for such systems, sufficiently general fully implicit schemes, i.e., schemes with implicitness both in deterministic and stochastic terms, are needed. A new class of fully implicit methods for stochastic systems is proposed. Increments of Wiener processes in these fully implicit schemes are substituted by some truncated random variables. A number of symplectic integrators is constructed. Special attention is paid to systems with separable Hamiltonians. Some results of numerical experiments are presented. They demonstrate superiority of the proposed symplectic methods over very long times in comparison with nonsymplectic ones.

Key words. stochastic Hamiltonian systems, symplectic integration, implicit methods, mean-square convergence

1. Introduction.

Consider the following Cauchy problem for the system of stochastic differential equations (SDEs) in the sense of Stratonovich:

$$dP = f(t,P,Q)dt + \sum_{r=1}^{m} \sigma_r(t,P,Q) \circ dw_r(t), \qquad P(t_0) = p, \tag{1.1}$$

$$dQ = g(t,P,Q)dt + \sum_{r=1}^{m} \gamma_r(t,P,Q) \circ dw_r(t), \qquad Q(t_0) = q,$$

where P, Q, f, g, σ_r, γ_r are n-dimensional column vectors with the components P^i, Q^i, f^i, g^i, σ_r^i, γ_r^i, $i = 1,\dots,n$, and $w_r(t)$, $r = 1,\dots,m$, are independent standard Wiener processes. The diffusion coefficients σ_r, γ_r depend on P, Q (i.e., (1.1) is a system with multiplicative noise), in contrast to [3], where stochastic systems with additive noise are treated.

We suppose that all the coefficients of considered systems are sufficiently smooth functions defined for $(t,p,q) \in [t_0, t_0+T] \times R^d$, $d = 2n$, and they provide the property of extendability of solutions to the interval $[t_0, t_0+T]$. (Additional conditions in connection with considered methods consist of appropriate behavior of partial derivatives of the coefficients on infinity.)

We denote by $X(t;t_0,x) = (P^\top(t;t_0,p,q), Q^\top(t;t_0,p,q))^\top$, $t_0 \le t \le t_0+T$, the solution of problem (1.1). A more detailed notation is $X(t;t_0,x;\omega)$, where ω is an

elementary event. It is known that $X(t;t_0,x;\omega)$ is a phase flow (diffeomorphism) for almost every ω. See its properties in, e.g., [1, 2].

If there are functions $H_r(t,p,q)$, $r=0,\dots,m$, such that (see [1] and [3])

$$f^i(t,p,q)=-\partial H_0/\partial q^i,\qquad g^i(t,p,q)=\partial H_0/\partial p^i, \tag{1.2}$$
$$\sigma_r^i(t,p,q)=-\partial H_r/\partial q^i,\quad \gamma_r^i(t,p,q)=\partial H_r/\partial p^i,\quad i=1,\dots,n,\quad r=1,\dots,m,$$

then the phase flow of (1.1) preserves the following symplectic structure:

$$dP\wedge dQ=dp\wedge dq; \tag{1.3}$$

i.e., the sum of the oriented areas of projections onto the coordinate planes $(p^1,q^1),\dots,(p^n,q^n)$ is an integral invariant [4]. To avoid confusion, we note that the differentials in (1.1) and (1.3) have different meanings. In (1.1) P, Q are treated as functions of time and p, q are fixed parameters, while differentiation in (1.3) is made with respect to the initial data p, q.

Let P_k, Q_k, $k=0,\dots,N$, $t_{k+1}-t_k=h_{k+1}$, $t_N=t_0+T$, be a method for (1.1) based on the one-step approximation $\bar P=\bar P(t+h;t,p,q)$, $\bar Q=\bar Q(t+h;t,p,q)$. We say that the method preserves symplectic structure if

$$d\bar P\wedge d\bar Q=dp\wedge dq\,. \tag{1.4}$$

The present paper deals with symplectic integration of the Hamiltonian system with multiplicative noise (1.1), (1.3). It is a continuation of [3], where symplectic methods for Hamiltonian systems with additive noise were proposed. For symplectic integration of deterministic Hamiltonian systems see, e.g., [5, 6, 7, 8, 9] and references therein.

As is known [5], in the case of deterministic general Hamiltonian systems symplectic Runge–Kutta (RK) methods are all implicit. Hence it is natural to expect that to construct symplectic methods for general Hamiltonian systems with multiplicative noise fully implicit methods are needed. The known implicit methods for stochastic systems with multiplicative noise (see [10, 11]) contain implicitness in deterministic terms only. In [12] an implicitness is introduced in stochastic terms as well. However, the methods of [12] are of a very special form. In section 2 a new class of fully implicit methods for general stochastic systems is proposed. Increments of Wiener processes in these implicit schemes are substituted by some truncated random variables. They are important for both theory and practice of numerical integration of SDEs. We use these fully implicit methods in section 3 to construct symplectic methods for general Hamiltonian systems with multiplicative noise. Section 4 is devoted to a special case of separable Hamiltonians. Explicit symplectic integrators are constructed for such systems. In addition, symplectic methods for Hamiltonian systems with small multiplicative noise can be found in the preprint [13]. There one can also find some Liouvillian methods for stochastic systems preserving phase volume. Let us recall that the mean-square methods of higher order contain repeated Ito integrals which are difficult for simulation. In this paper, we prefer to derive methods which are efficient with respect to simulation of the used random variables. That is why orders of the methods derived are not too high. In the last section of the paper we present numerical tests. They clearly demonstrate superiority of the proposed symplectic methods over very long times in comparison with nonsymplectic ones.

2. Fully implicit methods. Construction of implicit methods for stochastic systems with additive noise does not cause any difficulties in principle. However, all

is much more intricate in the case of stochastic systems with multiplicative noise. The known implicit methods for such systems (see [10, 11]) contain implicitness restricted to deterministic terms, e.g., to the drift terms in the implicit Euler scheme. In [12], an implicitness is introduced in stochastic terms as well. However, methods of [12] are of a very special form. In particular, this form does not allow us to construct symplectic methods for stochastic Hamiltonian systems with multiplicative noise. In this section we construct a sufficiently large class of fully implicit methods of mean-square order 1/2 for general stochastic systems. These results are of independent and general interest. That is why in this section we consider SDEs in the Ito sense, following the traditional way of developing numerical methods. At the same time we should note that the Stratonovich form is preferable for SDEs preserving integral invariants.

2.1. The main idea and an example. Let us start with an example. Consider the Ito scalar equation

$$dX = \sigma X dw(t). \tag{2.1}$$

The one-step approximation of the Euler method $\hat{X}$ for (2.1) is

$$\hat{X} = x + \sigma x \Delta w(h). \tag{2.2}$$

We can represent this approximation in the form

$$\hat{X} = x + \sigma \hat{X} \Delta w + \sigma (x - \hat{X}) \Delta w = x - \sigma^2 x (\Delta w)^2 + \sigma \hat{X} \Delta w.$$

As h is small, $(\Delta w)^2 \sim h$, and we obtain the following "natural" implicit method:

$$\tilde{X} = x - \sigma^2 x h + \sigma \tilde{X} \Delta w(h). \tag{2.3}$$

However, this method cannot be realized since $1 - \sigma \Delta w(h)$ can vanish for any small h. Further, for the formal value of $\tilde{X}$ from (2.3)

$$\tilde{X} = \frac{x(1 - \sigma^2 h)}{1 - \sigma \Delta w(h)},$$

we have $E|\tilde{X}| = \infty$. (See [10].) Clearly, the method (2.3) is not suitable. The reason for this is the unboundedness of the random variable $\Delta w(h)$ for any arbitrarily small h.

Our basic idea consists of replacement of $\Delta w(h) = \xi \sqrt{h}$, where ξ is an $\mathcal{N}(0,1)$-distributed random variable, by another random variable $\zeta \sqrt{h} = \zeta_h \sqrt{h}$ such that $\zeta \sqrt{h}$ is bounded and the Euler type method

$$\check{X} = x + \sigma x \zeta \sqrt{h} \tag{2.4}$$

is of the mean-square order 1/2 as well. To achieve this, it is sufficient to require

$$E(\check{X} - \hat{X}) = O(h^{3/2}), \qquad E(\check{X} - \hat{X})^2 = O(h^2). \tag{2.5}$$

We take a symmetric ζ. Then $E(\check{X} - \hat{X}) = 0$. To satisfy the second equation in (2.5), the condition $E(\zeta_h - \xi)^2 = O(h)$ is sufficient.

We shall require a stronger inequality,

$$E(\zeta_h - \xi)^2 \le h^k, \qquad k \ge 1. \tag{2.6}$$

For $A_h > 0$ let

$$\zeta_h = \begin{cases} \xi, \ |\xi| \le A_h, \\ A_h, \ \xi > A_h, \\ -A_h, \ \xi < -A_h. \end{cases} \tag{2.7}$$

Since

$$\begin{aligned} E(\zeta_h - \xi)^2 &= \frac{2}{\sqrt{2\pi}} \int_{A_h}^{\infty} (x - A_h)^2 e^{-x^2/2} dx \\ &= \frac{2}{\sqrt{2\pi}} e^{-A_h^2/2} \int_{A_h}^{\infty} y^2 e^{-y^2/2} e^{-A_h y} dy < e^{-A_h^2/2}, \end{aligned}$$

the inequality (2.6) is fulfilled if $e^{-A_h^2/2} \le h^k$, i.e., $A_h^2 \ge 2k|\ln h|$. Thus, if

$$A_h = \sqrt{2k|\ln h|}, \qquad k \ge 1,$$

then the method based on the one-step approximation (2.4) has the mean-square order 1/2.

LEMMA 2.1. *Let* $A_h = \sqrt{2k|\ln h|}$, $k \ge 1$, *and* ζ_h *be defined by* (2.7). *Then the following inequality holds:*

$$0 \le E(\xi^2 - \zeta_h^2) = 1 - E\zeta_h^2 \le \left(1 + 2\sqrt{2k|\ln h|}\right) h^k. \tag{2.8}$$

Proof. We have

$$\begin{aligned} 1 - E\zeta_h^2 &= \frac{2}{\sqrt{2\pi}} \int_{A_h}^{\infty} (x^2 - A_h^2) e^{-x^2/2} dx \\ &= \frac{2}{\sqrt{2\pi}} \int_{A_h}^{\infty} \left[(x - A_h)^2 + 2A_h(x - A_h)\right] e^{-x^2/2} dx \\ &\le e^{-A_h^2/2} + \frac{4A_h}{\sqrt{2\pi}} \int_{A_h}^{\infty} x e^{-x^2/2} dx = e^{-A_h^2/2} \left(1 + \frac{4A_h}{\sqrt{2\pi}}\right) \le (1 + 2A_h) e^{-A_h^2/2}, \end{aligned}$$

whence (2.8) follows. □

Now consider the following implicit method (for definiteness we put $k = 1$ and $A_h = \sqrt{2|\ln h|}$):

$$\begin{aligned} \bar{X} &= x - \sigma^2 x h + \sigma \bar{X} \zeta_h \sqrt{h}, \\ \bar{X} &= \frac{x(1 - \sigma^2 h)}{1 - \sigma \zeta_h \sqrt{h}}. \end{aligned} \tag{2.9}$$

Since $|\zeta_h| \le \sqrt{2|\ln h|}$, this method is realizable for all h satisfying the inequality

$$2h|\ln h| < \frac{1}{\sigma^2}. \tag{2.10}$$

PROPOSITION 2.2. *The method* (2.9) *is of the mean-square order* 1/2.

Proof. Let us compare method (2.9) with the Euler method (2.2). We get

$$E\bar{X} = x(1 - \sigma^2 h) E \sum_{m=0}^{\infty} \sigma^m \zeta_h^m h^{m/2} = x(1 - \sigma^2 h) E \sum_{m=0}^{\infty} \sigma^{2m} \zeta_h^{2m} h^m.$$

It is obvious from here that the principal term in the expansion of $E(\bar{X}-\hat{X})$ is equal to $x\sigma^2 h(E\zeta_h^2-1)$. Due to Lemma 2.1, we obtain for all sufficiently small h

$$|E(\bar{X}-\hat{X})| \le C|x|\sigma^2\left(1+2\sqrt{2|\ln h|}\right)h^2, \tag{2.11}$$

where C is a positive constant.

Further,

$$\begin{aligned} E(\bar{X}-\hat{X})^2 &= E\left(-\sigma^2 xh+\sigma\bar{X}\zeta_h\sqrt{h}-\sigma x\xi\sqrt{h}\right)^2 \\ &\le 2\sigma^4x^2h^2+2E\left(\sigma\bar{X}\zeta_h\sqrt{h}-\sigma x\xi\sqrt{h}\right)^2 \\ &= 2\sigma^4x^2h^2+2E\left(\sigma\cdot\left(x-\sigma^2xh+\sigma\bar{X}\zeta_h\sqrt{h}\right)\zeta_h\sqrt{h}-\sigma x\xi\sqrt{h}\right)^2 \\ &\le 2\sigma^4x^2h^2+2\sigma^2x^2hE(\zeta_h-\xi)^2+C_1x^2h^2\le C_2x^2h^2 \end{aligned} \tag{2.12}$$

for all sufficiently small h and some positive constants C_1 and C_2. The inequalities (2.11) and (2.12) imply the mean-square convergence of implicit method (2.9) with order $1/2$. □

Introduction of implicitness in the stochastic term leads to the appearance of the compensating term $-\sigma^2xh$ in (2.9). This can be explained in the following way. Since $\bar{X}$ must be close to $x+\sigma x\zeta_h\sqrt{h}$, the expression $x+\sigma\bar{X}\zeta_h\sqrt{h}$ is close to $x+\sigma x\zeta_h\sqrt{h}+\sigma^2x\zeta_h^2h$. Consequently, making use of the compensating term results in $x+\sigma\bar{X}\zeta_h\sqrt{h}-\sigma^2xh=x+\sigma x\zeta_h\sqrt{h}+\sigma^2x(\zeta_h^2-1)h\approx x+\sigma x\zeta_h\sqrt{h}$; i.e., we get the correct result.

Now let us consider the expression $\sigma((1-\beta)x+\beta\bar{X})\zeta_h\sqrt{h}$ which introduces implicitness in the stochastic term with the parameter $0\le\beta\le1$. Clearly, the compensating term in this case is equal to $-\sigma^2\beta xh$. Thus, we derive the following method:

$$\bar{X}=x-\sigma^2\beta xh+\sigma((1-\beta)x+\beta\bar{X})\zeta_h\sqrt{h},\qquad 0\le\beta\le1. \tag{2.13}$$

The following proposition can be proved analogously to Proposition 2.2.

PROPOSITION 2.3. *The method* (2.13)*, as well as the methods*

$$\bar{X}=x-\sigma^2\beta x\zeta_h^2h+\sigma((1-\beta)x+\beta\bar{X})\zeta_h\sqrt{h},\qquad 0\le\beta\le1, \tag{2.14}$$

$$\bar{X}=x-\sigma^2\beta((1-\alpha)x+\alpha\bar{X})h+\sigma((1-\beta)x+\beta\bar{X})\zeta_h\sqrt{h},\qquad 0\le\alpha,\beta\le1, \tag{2.15}$$

are of the mean-square order $1/2$.

2.2. Convergence theorem. Now we are in position to introduce fully implicit methods for general systems of SDEs. For simplicity in writing we deal here with the following scalar Ito SDE:

$$dX=a(t,X)dt+b(t,X)dw(t). \tag{2.16}$$

We suppose that $a(t,x)$, $b(t,x)$, $\frac{\partial b}{\partial x}(t,x)$ are continuous for $t_0\le t\le T$, $x\in\mathbf{R}$, and there exists a positive constant L such that

$$|a(t,y)-a(t,x)|\le L|y-x|,\quad \left|\frac{\partial b}{\partial x}(t,x)\right|\le L,\quad t_0\le t\le T,\ x,y\in\mathbf{R}. \tag{2.17}$$

Note that below the same letter L (or K, or C) is used for various constants.

Consider the implicit one-step approximation (cf. (2.9))

$$\bar{X} = x + a(t,\bar{X})h - b(t,x)\frac{\partial b}{\partial x}(t,x)h + b(t,\bar{X})\zeta_h\sqrt{h}, \tag{2.18}$$

where ζ_h is defined by (2.7) with $A_h = \sqrt{2|\ln h|}$ for definiteness.

LEMMA 2.4. *There exist constants $K > 0$ and $h_0 > 0$ such that for any $h \le h_0$, $t_0 \le t \le T$, $x \in \mathbf{R}$ (2.18) has a unique solution $\bar{X}$ which satisfies the inequality*

$$|\bar{X} - x| \le K(1+|x|)\left(|\zeta_h|\sqrt{h} + h\right). \tag{2.19}$$

The solution $\bar{X}$ of (2.18) can be found by the method of simple iteration with x as the initial approximation.

Proof. For any fixed t, x, and h, let us introduce the function

$$\varphi(z) = x + a(t,z)h - b(t,x)\frac{\partial b}{\partial x}(t,x)h + b(t,z)\zeta_h\sqrt{h}.$$

Then (2.18) can be written as

$$\bar{X} = \varphi(\bar{X}).$$

There is a positive constant C such that for any $z \in \mathbf{R}$

$$|\varphi(z) - x| \le |a(t,x)|h + |a(t,z) - a(t,x)|h + |b(t,x)||\zeta_h|\sqrt{h} + |b(t,z) - b(t,x)||\zeta_h|\sqrt{h}$$
$$+ \left|b(t,x)\frac{\partial b}{\partial x}(t,x)\right| h \le C(1+|x|)\left(|\zeta_h|\sqrt{h} + h\right) + L|z-x|\left(|\zeta_h|\sqrt{h} + h\right).$$

Further, for any z_1, $z_2 \in \mathbf{R}$

$$|\varphi(z_2) - \varphi(z_1)| \le L|z_2 - z_1|\left(|\zeta_h|\sqrt{h} + h\right).$$

Clearly, there exist positive constants K and h_0 such that for any $h \le h_0$, $x \in \mathbf{R}$

$$L\left(|\zeta_h|\sqrt{h} + h\right) < 1,$$

and if

$$|z - x| \le K(1+|x|)\left(|\zeta_h|\sqrt{h} + h\right),$$

then

$$|\varphi(z) - x| \le K(1+|x|)\left(|\zeta_h|\sqrt{h} + h\right).$$

Let us note that the constants K in the last two inequalities are the same. Now the lemma follows from the contraction mapping principle. □

In addition to (2.17) suppose that there exist continuous $\partial a/\partial t$, $\partial b/\partial t$, and $\partial^2 b/\partial x^2$ and the inequalities

$$\left|\frac{\partial a}{\partial t}(t,x)\right| \le L(1+|x|), \quad \left|\frac{\partial b}{\partial t}(t,x)\right| \le L(1+|x|), \quad t_0 \le t \le T, \quad x \in \mathbf{R} \tag{2.20}$$

hold.

THEOREM 2.5. *Assume* (2.17) *and* (2.20). *Let there exist* $\delta > 0$ *such that if* $|y - x| \le \delta(1 + |x|)$, *then the inequality*

$$\left| b(t,x)\frac{\partial^2 b}{\partial x^2}(t,y) \right| \le L, \quad t_0 \le t \le T \tag{2.21}$$

holds.

Then the implicit method based on the one-step approximation (2.18) *converges in mean-square with the order* $1/2$.

Proof. Let $\hat{X}$ be the Euler approximation for (2.16):

$$\hat{X} = x + a(t,x)h + b(t,x)\Delta w(h).$$

Using the condition (2.17) only, we get

$$\begin{aligned} E|\bar{X} - \hat{X}|^2 &\le E\left| a(t,\bar{X})h - a(t,x)h + b(t,\bar{X})\zeta_h\sqrt{h} - b(t,x)\Delta w(h) - b(t,x)\frac{\partial b}{\partial x}(t,x)h \right|^2 \\ &\le LE|a(t,\bar{X}) - a(t,x)|^2h^2 + LE|b(t,\bar{X}) - b(t,x)|^2\zeta_h^2 h \\ &\quad + Lb^2(t,x)E(\zeta_h - \xi)^2 h + L\left| b(t,x)\frac{\partial b}{\partial x}(t,x) \right|^2 h^2 \\ &\le LE|\bar{X} - x|^2h^2 + LE|\bar{X} - x|^2\zeta_h^2 h + L(1 + |x|)^2E(\zeta_h - \xi)^2 h + L(1 + |x|)^2h^2. \end{aligned}$$

It follows from here, Lemma 2.4, the inequality $E\zeta^4 < E\xi^4 = 3$, and (2.6) that

$$E|\bar{X} - \hat{X}|^2 \le L(1 + |x|)^2h^2. \tag{2.22}$$

Now let us proceed to the evaluation of $E(\bar{X} - \hat{X})$. We have

(2.23)
$$|E(\bar{X} - \hat{X})| \le |Ea(t,\bar{X}) - a(t,x)|h + \left| E(b(t,\bar{X}) - b(t,x))\zeta_h\sqrt{h} - b(t,x)\frac{\partial b}{\partial x}(t,x)h \right|.$$

Due to Lemma 2.4, $E|\bar{X} - x| \le K(1 + |x|)(E|\zeta_h|\sqrt{h} + h)$. Then

$$|Ea(t,\bar{X}) - a(t,x)|h \le C(1 + |x|)h^{3/2}. \tag{2.24}$$

We have

$$\begin{aligned} &(b(t,\bar{X}) - b(t,x))\zeta_h\sqrt{h} - b(t,x)\frac{\partial b}{\partial x}(t,x)h \\ &\quad = \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot (\bar{X} - x)\zeta_h\sqrt{h} - b(t,x)\frac{\partial b}{\partial x}(t,x)h \\ &\quad = \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot \left(a(t,\bar{X})h + b(t,\bar{X})\zeta_h\sqrt{h} - b(t,x)\frac{\partial b}{\partial x}(t,x)h \right)\zeta_h\sqrt{h} \\ &\qquad - b(t,x)\frac{\partial b}{\partial x}(t,x)h \\ &\quad = \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot \left(a(t,\bar{X}) - b(t,x)\frac{\partial b}{\partial x}(t,x)h \right)\zeta_h h^{3/2} \\ &\qquad + \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot b(t,\bar{X})\zeta_h^2 h - b(t,x)\frac{\partial b}{\partial x}(t,x)h, \end{aligned} \tag{2.25}$$

where $0 \le \theta \le 1$.

Since $|\bar{X} - x| \le \rho(1 + |x|)$, where $\rho \to 0$ as $h \to 0$, we get $|\bar{X}| \le |x| + |\bar{X} - x| \le K(1 + |x|)$ for all sufficiently small h. Therefore

$$\left| E \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot a(t, \bar{X}) \zeta_h h^{3/2} \right| \le KE|a(t, \bar{X})\zeta_h| h^{3/2} \le KE(1 + |\bar{X}|)|\zeta_h| h^{3/2} \le K(1 + |x|)h^{3/2}. \tag{2.26}$$

Clearly,

$$\left| E \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot b(t, x) \frac{\partial b}{\partial x}(t, x) \zeta_h h^{3/2} \right| \le K(1 + |x|)h^{3/2}.$$

Let us estimate the last two terms in (2.25). We obtain

$$\begin{aligned} &\frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot b(t, \bar{X}) \zeta_h^2 h - b(t, x) \frac{\partial b}{\partial x}(t, x) h \\ &= \left(\frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) - \frac{\partial b}{\partial x}(t, x) \right) b(t, \bar{X}) \zeta_h^2 h \\ &+ \frac{\partial b}{\partial x}(t, x)(b(t, \bar{X}) - b(t, x)) \zeta_h^2 h + \frac{\partial b}{\partial x}(t, x) b(t, x)(\zeta_h^2 - 1) h \\ &= \frac{\partial^2 b}{\partial x^2}(t, x + \theta_1(\bar{X} - x)) \cdot \theta(\bar{X} - x) \cdot b(t, \bar{X}) \zeta_h^2 h \\ &+ \frac{\partial b}{\partial x}(t, x) \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot (\bar{X} - x) \zeta_h^2 h + \frac{\partial b}{\partial x}(t, x) b(t, x)(\zeta_h^2 - 1) h, \end{aligned}$$

where $0 \le \theta, \theta_1 \le 1$. Due to Lemma 2.4, we get $|x + \theta_1(\bar{X} - x) - \bar{X}| \le |\bar{X} - x| \le K(|\zeta_h|\sqrt{h} + h)(1 + |x|)$. For all sufficiently small h we have $K(|\zeta_h|\sqrt{h} + h) < \delta$ and consequently due to (2.21)

$$\left| \frac{\partial^2 b}{\partial x^2}(t, x + \theta_1(\bar{X} - x)) \cdot b(t, \bar{X}) \right| \le L. \tag{2.27}$$

Using (2.27), the conditions (2.17), and Lemmas 2.1 and 2.4, we obtain for the last two terms in (2.25)

$$\left| E \frac{\partial b}{\partial x}(t, x + \theta(\bar{X} - x)) \cdot b(t, \bar{X}) \zeta_h^2 h - b(t, x) \frac{\partial b}{\partial x}(t, x) h \right| \le K(1 + |x|)h^{3/2}. \tag{2.28}$$

Thus, (2.23)–(2.28) give

$$|E(\bar{X} - \hat{X})| \le K(1 + |x|)h^{3/2}. \tag{2.29}$$

It follows from (2.22) and (2.29) (see [10]) that the method based on (2.18) is of the mean-square order 1/2. □

REMARK 2.1. *The condition* (2.21) *is satisfied if, for instance,*

$$|b(t, x)| \le L, \quad \left| \frac{\partial^2 b}{\partial x^2}(t, x) \right| \le L, \quad t_0 \le t \le T, \quad x \in \mathbf{R} \tag{2.30}$$

or

$$\left| \frac{\partial^2 b}{\partial x^2}(t, x) \right| \le \frac{L}{1 + |x|}, \quad t_0 \le t \le T, \quad x \in \mathbf{R} \tag{2.31}$$

holds.

Let us underline that the conditions of Theorem 2.5 *are not necessary and the method is applicable more widely. This is true for other methods proposed in the paper as well.*

REMARK 2.2. *Let the function* $c(t,x) := b(t,x)\frac{\partial b}{\partial x}(t,x)$ *satisfy the condition*

$$|c(t,y) - c(t,x)| \le L|y-x|. \tag{2.32}$$

Consider the implicit one-step approximation

$$\bar{X} = x + a(t,\bar{X})h - b(t,\bar{X})\frac{\partial b}{\partial x}(t,\bar{X})h + b(t,\bar{X})\zeta_h\sqrt{h}. \tag{2.33}$$

It is not difficult to prove that Theorem 2.5 *is true for the implicit method based on* (2.33) *provided* (2.32) *is fulfilled.*

2.3. General construction. Let

$$dX^i = a^i(t,X)dt + \sum_{r=1}^{m} b_r^i(t,X)dw_r(t),\ i = 1,\dots,d. \tag{2.34}$$

Introduce the following one-step approximation:

(2.35)

$$\begin{aligned}\bar{X}^i = x^i &+ \sum_{k=1}^{l}\lambda_k^i a^i(t+\nu_k^i h, (1-\alpha_{k1}^i)x^1 + \alpha_{k1}^i\bar{X}^1,\dots,(1-\alpha_{kd}^i)x^d + \alpha_{kd}^i\bar{X}^d)h\\ &+ \sum_{r=1}^{m}\sum_{k=1}^{l}\mu_{rk}^i b_r^i(t+\nu_{rk}^i h, (1-\beta_{rk1}^i)x^1 + \beta_{rk1}^i\bar{X}^1,\dots,(1-\beta_{rkd}^i)x^d + \beta_{rkd}^i\bar{X}^d)\zeta_{rh}\sqrt{h}\\ &+ A^i,\end{aligned}$$

where $0 \le \nu,\alpha,\beta \le 1,\ \lambda,\mu \ge 0,\ \sum_{k=1}^{l}\lambda_k^i = 1,\ \sum_{k=1}^{l}\mu_{rk}^i = 1,\ i = 1,\dots,d,\ l$ is a positive integer, and A^i are some expressions to be found. Substituting the Euler-type approximation

$$\hat{X}^j = x^j + a^j(t,x)h + \sum_{s=1}^{m} b_s^j(t,x)\zeta_{sh}\sqrt{h}$$

instead of $\bar{X}^j,\ j = 1,\dots,d$, in b_r^i, we obtain

$$\begin{aligned}&b_r^i(t+\nu_{rk}^i h, (1-\beta_{rk1}^i)x^1 + \beta_{rk1}^i\bar{X}^1,\dots,(1-\beta_{rkd}^i)x^d + \beta_{rkd}^i\bar{X}^d)\\ &\quad\approx b_r^i(t,x) + \sum_{j=1}^{d}\frac{\partial b_r^i}{\partial x^j}(t,x)\beta_{rkj}^i\sum_{s=1}^{m} b_s^j(t,x)\zeta_{sh}\sqrt{h}.\end{aligned}$$

It is clear from here that either

$$A^i = -\sum_{r=1}^{m}\sum_{k=1}^{l}\mu_{rk}^i\sum_{j=1}^{d}\frac{\partial b_r^i}{\partial x^j}(t,x)\beta_{rkj}^i\sum_{s=1}^{m} b_s^j(t,x)\zeta_{sh}\sqrt{h}\zeta_{rh}\sqrt{h} \tag{2.36}$$

or

$$A^i = -\sum_{r=1}^{m}\sum_{k=1}^{l}\mu_{rk}^i\sum_{j=1}^{d}\frac{\partial b_r^i}{\partial x^j}(t,x)\beta_{rkj}^i b_r^j(t,x)h \tag{2.37}$$

can be put in (2.35).

Substituting one of these expressions in (2.35), we obtain a multiparameter family of implicit methods. It is also possible to introduce implicitness in A^i by changing t, x as it was done in the terms connecting with a^i. Moreover, the family can be extended if some a^i or b^i_r are represented as sums of terms. In this case the coefficients λ, ν, α, μ, β can differ for different terms.

It can be proved that under appropriate conditions of smoothness and boundedness on the coefficients of (2.34) the method based on the one-step approximation (2.35) with A^i as in (2.36) or (2.37) is of the mean-square order 1/2. The proof is analogous to the proof of Theorem 2.5.

Here and below we will not precisely indicate conditions on the coefficients a and b_r assuming that appropriate conditions on the coefficients hold. These conditions can be restored using the general theory [10] and Theorem 2.5. (See also Remarks 2.1 and 2.2.)

Let us give an example of fully implicit methods:

$$\bar{X} = x + a(t, \bar{X})h - \sum_{r=1}^{m}\sum_{j=1}^{d} \frac{\partial b_r}{\partial x^j}(t, \bar{X}) b_r^j(t, \bar{X})h + \sum_{r=1}^{m} b_r(t, \bar{X})\zeta_{rh}\sqrt{h}.$$

Further, in the case of SDEs in the sense of Stratonovich,

$$dX = a(t, X)dt + \sum_{r=1}^{m} b_r(t, X) \circ dw_r(t), \tag{2.38}$$

we construct the following derivative-free fully implicit method (midpoint method):

$$X_{k+1} = X_k + a\left(t_k + \frac{h}{2}, \frac{X_k + X_{k+1}}{2}\right)h + \sum_{r=1}^{m} b_r\left(t_k, \frac{X_k + X_{k+1}}{2}\right)(\zeta_{rh})_k\sqrt{h}. \tag{2.39}$$

For $b^i_r = 0$, this method coincides with the well-known deterministic midpoint scheme, which has the second order of convergence.

In the general case the method (2.39) is of the mean-square order 1/2. In the commutative case, i.e., when $\Lambda_i b_r = \Lambda_r b_i$ (here the operator $\Lambda_r := (b_r, \partial/\partial x)$), or in the case of a system with one noise (i.e., $m = 1$), the midpoint method (2.39) has the first mean-square order of convergence which is stated in the next theorem. (Its proof is available in the preprint [13].)

THEOREM 2.6. *Suppose that the commutative conditions* $\Lambda_i b_r = \Lambda_r b_i$, $i, r = 1, \dots, m$, *are fulfilled. Let* ζ_{rh} *be defined by* (2.7) *with* $A_h = \sqrt{4|\ln h|}$. *Then the method* (2.39) *for the system* (2.38) *has the first mean-square order of convergence.*

3. Symplectic methods for the general Hamiltonian system. Here, using the results of the previous section, we construct symplectic methods for the general Hamiltonian system with multiplicative noise (1.1), (1.3). Its Ito form reads

$$\begin{aligned} dP &= f dt + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n} \frac{\partial \sigma_r}{\partial p^j}\sigma_r^j dt + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n} \frac{\partial \sigma_r}{\partial q^j}\gamma_r^j dt + \sum_{r=1}^{m}\sigma_r dw_r(t), \\ dQ &= g dt + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n} \frac{\partial \gamma_r}{\partial p^j}\sigma_r^j dt + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n} \frac{\partial \gamma_r}{\partial q^j}\gamma_r^j dt + \sum_{r=1}^{m}\gamma_r dw_r(t). \end{aligned} \tag{3.1}$$

Introduce the following implicit method:

$$P_{k+1} = P_k + fh - \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\left(\frac{\partial\sigma_r}{\partial p^j}\sigma_r^j - \frac{\partial\sigma_r}{\partial q^j}\gamma_r^j\right)h + \sum_{r=1}^{m}\sigma_r\cdot(\zeta_{rh})_k\sqrt{h},$$
$$Q_{k+1} = Q_k + gh - \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\left(\frac{\partial\gamma_r}{\partial p^j}\sigma_r^j - \frac{\partial\gamma_r}{\partial q^j}\gamma_r^j\right)h + \sum_{r=1}^{m}\gamma_r\cdot(\zeta_{rh})_k\sqrt{h}, \tag{3.2}$$

where all the functions have t, P_{k+1}, Q_k as their arguments.

THEOREM 3.1. *The implicit method* (3.2) *for the system* (3.1), (1.3) (*or for system* (1.1), (1.3)) *is symplectic and of the mean-square order* 1/2.

Proof. The method (3.2) belongs to the family (2.35) and, consequently, the assertion about its order of convergence follows from the previous section. Let us prove symplecticness of the method. It is convenient to write the one-step approximation corresponding to (3.2) in the form

$$\bar{P}^i = p^i - \frac{\partial H_0}{\partial q^i}h - \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial^2 H_r}{\partial q^i\partial p^j}\frac{\partial H_r}{\partial q^j}h - \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial^2 H_r}{\partial q^i\partial q^j}\frac{\partial H_r}{\partial p^j}h - \sum_{r=1}^{m}\frac{\partial H_r}{\partial q^i}\zeta_{rh}\sqrt{h},$$
$$\bar{Q}^i = q^i + \frac{\partial H_0}{\partial p^i}h + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial^2 H_r}{\partial p^i\partial p^j}\frac{\partial H_r}{\partial q^j}h + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial^2 H_r}{\partial p^i\partial q^j}\frac{\partial H_r}{\partial p^j}h + \sum_{r=1}^{m}\frac{\partial H_r}{\partial p^i}\zeta_{rh}\sqrt{h}, \tag{3.3}$$

where $i = 1, \dots, n$ and all the functions have $t, \bar{P}, q$ as their arguments.

Introduce the following function $F(t,p,q)$ (h, ζ_{rh} are fixed here):

$$F(t,p,q) = H_0(t,p,q)h + \frac{1}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial H_r}{\partial q^j}(t,p,q)\frac{\partial H_r}{\partial p^j}(t,p,q)h + \sum_{r=1}^{m}H_r(t,p,q)\zeta_{rh}\sqrt{h}.$$

Then (3.3) can be written as

$$\bar{P}^i = p^i - \frac{\partial F}{\partial q^i}(t,\bar{P},q),$$
$$\bar{Q}^i = q^i + \frac{\partial F}{\partial p^i}(t,\bar{P},q). \tag{3.4}$$

We have (the arguments everywhere are t, $\bar{P}$, q)

$$\sum_{i=1}^{n}d\bar{P}^i\wedge d\bar{Q}^i = \sum_{i=1}^{n}d\bar{P}^i\wedge\left(dq^i + \sum_{j=1}^{n}F''_{p^ip^j}d\bar{P}^j + \sum_{j=1}^{n}F''_{p^iq^j}dq^j\right)$$
$$= \sum_{i=1}^{n}d\bar{P}^i\wedge dq^i + \sum_{i=1}^{n}\sum_{j=1}^{n}F''_{p^ip^j}d\bar{P}^i\wedge d\bar{P}^j + \sum_{i=1}^{n}\sum_{j=1}^{n}F''_{p^iq^j}d\bar{P}^i\wedge dq^j.$$

Since $d\bar{P}^i\wedge d\bar{P}^j = -d\bar{P}^j\wedge d\bar{P}^i$, we get

$$\sum_{i=1}^{n}d\bar{P}^i\wedge d\bar{Q}^i = \sum_{i=1}^{n}d\bar{P}^i\wedge dq^i + \sum_{i=1}^{n}\sum_{j=1}^{n}F''_{p^iq^j}d\bar{P}^i\wedge dq^j$$
$$= \sum_{i=1}^{n}d\bar{P}^i\wedge dq^i + \sum_{i=1}^{n}\sum_{j=1}^{n}F''_{q^ip^j}d\bar{P}^j\wedge dq^i. \tag{3.5}$$

Further,

$$d\bar{P}^i = dp^i - \sum_{j=1}^{n} F''_{q^i p^j} d\bar{P}^j - \sum_{j=1}^{n} F''_{q^i q^j} dq^j.$$

Substituting $\sum_{j=1}^{n} F''_{q^i p^j} d\bar{P}^j$ from here in (3.5), we obtain

$$\sum_{i=1}^{n} d\bar{P}^i \wedge d\bar{Q}^i = \sum_{i=1}^{n} d\bar{P}^i \wedge dq^i + \sum_{i=1}^{n} \left(dp^i - d\bar{P}^i - \sum_{j=1}^{n} F''_{q^i q^j} dq^j \right) \wedge dq^i$$
$$= \sum_{i=1}^{n} dp^i \wedge dq^i - \sum_{i=1}^{n} \sum_{j=1}^{n} F''_{q^i q^j} dq^j \wedge dq^i = \sum_{i=1}^{n} dp^i \wedge dq^i. \qquad \square$$

A more general symplectic method for the Hamiltonian system (1.1), (1.3) has the form

$$\begin{aligned} P_{k+1} &= P_k + f(t_k + \beta h, \alpha P_{k+1} + (1-\alpha)P_k, (1-\alpha)Q_{k+1} + \alpha Q_k)h \\ &\quad + \left(\frac{1}{2} - \alpha\right) \sum_{r=1}^{m} \sum_{j=1}^{n} \left(\frac{\partial \sigma_r}{\partial p^j} \sigma_r^j - \frac{\partial \sigma_r}{\partial q^j} \gamma_r^j \right) h + \sum_{r=1}^{m} \sigma_r \cdot (\zeta_{rh})_k \sqrt{h}, \\ Q_{k+1} &= Q_k + g(t_k + \beta h, \alpha P_{k+1} + (1-\alpha)P_k, (1-\alpha)Q_{k+1} + \alpha Q_k)h \\ &\quad + \left(\frac{1}{2} - \alpha\right) \sum_{r=1}^{m} \sum_{j=1}^{n} \left(\frac{\partial \gamma_r}{\partial p^j} \sigma_r^j - \frac{\partial \gamma_r}{\partial q^j} \gamma_r^j \right) h + \sum_{r=1}^{m} \gamma_r \cdot (\zeta_{rh})_k \sqrt{h}, \end{aligned} \tag{3.6}$$

where σ_r, γ_r, $r = 1, \dots, m$, and their derivatives are calculated at $(t_k, \alpha P_{k+1} + (1-\alpha)P_k, (1-\alpha)Q_{k+1} + \alpha Q_k)$, and α, $\beta \in [0,1]$ are parameters.

Using arguments similar to ones in the proof of Theorem 3.1, we obtain the following theorem.

THEOREM 3.2. *The implicit method* (3.6) *for the system* (1.1), (1.3) (*or for system* (3.1), (1.3)) *is symplectic and of the mean-square order* 1/2.

The method (3.2) is a particular case of (3.6) when $\alpha = 1$, $\beta = 0$. If $\alpha = \beta = 1/2$ the method (3.6) becomes the midpoint method (cf. (2.39)):

$$\begin{aligned} P_{k+1} &= P_k + f\left(t_k + \frac{h}{2}, \frac{P_k + P_{k+1}}{2}, \frac{Q_k + Q_{k+1}}{2}\right) h \\ &\quad + \sum_{r=1}^{m} \sigma_r \left(t_k, \frac{P_k + P_{k+1}}{2}, \frac{Q_k + Q_{k+1}}{2}\right) (\zeta_{rh})_k \sqrt{h}, \\ Q_{k+1} &= Q_k + g\left(t_k + \frac{h}{2}, \frac{P_k + P_{k+1}}{2}, \frac{Q_k + Q_{k+1}}{2}\right) h \\ &\quad + \sum_{r=1}^{m} \gamma_r \left(t_k, \frac{P_k + P_{k+1}}{2}, \frac{Q_k + Q_{k+1}}{2}\right) (\zeta_{rh})_k \sqrt{h}. \end{aligned} \tag{3.7}$$

REMARK 3.1. *In the commutative case, i.e., when* $\Lambda_i b_r = \Lambda_r b_i$, *or in the case of a system with one noise* (*i.e.*, $m = 1$), *the symplectic method* (3.7) *for* (1.1), (1.3) *has the first mean-square order of convergence.*

REMARK 3.2. *In the case of Hamiltonians that are separable in the noise part, i.e., when* $H_r(t,p,q) = U_r(t,q) + V_r(t,p)$, $r = 1, \dots, m$, *we can obtain symplectic*

methods for (1.1), (1.3) *which are explicit in stochastic terms and do not need truncated random variables. For instance,* (3.2) *acquires the form*

$$
\begin{aligned}
P_{k+1} &= P_k + f(t_k, P_{k+1}, Q_k)h \\
&\quad + \frac{h}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial \sigma_r}{\partial q^j}(t_k, Q_k)\cdot\gamma_r^j(P_{k+1}) + \sum_{r=1}^{m}\sigma_r(t_k, Q_k)\Delta_k w_r, \\
Q_{k+1} &= Q_k + g(t_k, P_{k+1}, Q_k)h \\
&\quad - \frac{h}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial \gamma_r}{\partial p^j}(P_{k+1})\cdot\sigma_r^j(t_k, Q_k) + \sum_{r=1}^{m}\gamma_r(t_k, P_{k+1})\Delta_k w_r.
\end{aligned} \tag{3.8}
$$

Of course, if it is necessary, fully implicit methods which require truncated random variables can be used in the case of separable Hamiltonians as well.

REMARK 3.3. *It is possible to construct fully explicit symplectic methods for the following partitioned system:*

$$
\begin{aligned}
dP &= f(t,Q)dt + \sum_{r=1}^{m}\sigma_r(t,Q)\circ dw_r(t),\ P(t_0) = p, \\
dQ &= g(P)dt + \sum_{r=1}^{m}\gamma_r(t)dw_r(t),\ Q(t_0) = q,
\end{aligned} \tag{3.9}
$$

with $f^i = -\partial U_0/\partial q^i$, $g^i = \partial V_0/\partial p^i$, $\sigma_r^i = -\partial U_r/\partial q^i$, $r = 1,\dots,m$, $i = 1,\dots,n$.

For instance, the explicit partitioned Runge–Kutta (*PRK*) *method* (*cf.* (4.5)–(4.6))

$$
\begin{aligned}
\mathcal{Q}_1 &= Q_k + \alpha h g(P_k), \\
\mathcal{P}_1 &= P_k + hf(t_k + \alpha h, \mathcal{Q}_1) + \frac{h}{2}\sum_{r=1}^{m}\sum_{j=1}^{n}\frac{\partial \sigma_r}{\partial q^j}(t_k, \mathcal{Q}_1)\cdot\gamma_r^j(t_k), \\
\mathcal{Q}_2 &= \mathcal{Q}_1 + (1-\alpha)hg(\mathcal{P}_1),
\end{aligned} \tag{3.10}
$$

$$
\begin{aligned}
P_{k+1} &= \mathcal{P}_1 + \sum_{r=1}^{m}\sigma_r(t_k, \mathcal{Q}_2)\Delta_k w_r, \\
Q_{k+1} &= \mathcal{Q}_2 + \sum_{r=1}^{m}\gamma_r(t_k)\Delta_k w_r,\ k = 0,\dots,N-1,
\end{aligned} \tag{3.11}
$$

with the parameter $0 \le \alpha \le 1$, *is symplectic and of the mean-square order* $1/2$.

A particular case of the system (3.9) *is considered in the next section, where explicit symplectic methods of a higher order are proposed.*

4. Explicit symplectic methods in the case of separable Hamiltonians. Consider a special case of the Hamiltonian system (1.1), (1.3) such that

$$
H_0(t,p,q) = V_0(p) + U_0(t,q), \quad H_r(t,p,q) = U_r(t,q), \quad r = 1,\dots,m. \tag{4.1}
$$

In this case we get the following system in the sense of Stratonovich:

$$
\begin{aligned}
dP &= f(t,Q)dt + \sum_{r=1}^{m}\sigma_r(t,Q)\circ dw_r(t), \qquad P(t_0) = p, \\
dQ &= g(P)dt,\ Q(t_0) = q,
\end{aligned} \tag{4.2}
$$

with

(4.3)

$$f^i = -\partial U_0/\partial q^i, \quad g^i = \partial V_0/\partial p^i, \quad \sigma_r^i = -\partial U_r/\partial q^i, \quad r = 1, \dots m, \quad i = 1, \dots, n.$$

We note that it is not difficult to consider a slightly more general separable Hamiltonian $H_0(t,p,q) = V_0(t,p) + U_0(t,q)$, but we restrict ourselves to H_0 from (4.1).

It is obvious that the system (4.2) has the same form in the sense of Ito.

For $V_0(p) = \frac{1}{2}(M^{-1}p, p)$ with M a constant, symmetric, invertible matrix, the system (4.2) takes the form

$$dP = f(t,Q)dt + \sum_{r=1}^{m} \sigma_r(t,Q)dw_r(t), \qquad P(t_0) = p, \tag{4.4}$$
$$dQ = M^{-1}Pdt, \qquad Q(t_0) = q.$$

This system can be written as a second-order differential equation with multiplicative noise. Some physical applications of stochastic symplectic integration for such systems are discussed in [14].

Due to specific features of the system (4.2), (4.3) we have succeeded in construction of explicit partitioned Runge-Kutta (PRK) methods of a higher order.

4.1. First-order methods. A PRK method for (4.2) has the form (cf. (3.10)–(3.11)):

$$\mathcal{Q}_1 = Q_k + \alpha h g(P_k), \qquad \mathcal{P}_1 = P_k + hf(t_k + \alpha h, \mathcal{Q}_1), \tag{4.5}$$
$$\mathcal{Q}_2 = \mathcal{Q}_1 + (1-\alpha)hg(\mathcal{P}_1),$$

$$P_{k+1} = \mathcal{P}_1 + \sum_{r=1}^{m} \sigma_r(t_k, \mathcal{Q}_2)\Delta_k w_r, \quad Q_{k+1} = \mathcal{Q}_2, \quad k = 0, \dots, N-1, \tag{4.6}$$

where $0 \le \alpha \le 1$ is a parameter.

THEOREM 4.1. *The explicit method* (4.5)–(4.6) *for the system* (4.2) *with* (4.3) *is symplectic and of the first mean-square order.*

Proof. In the case of the system (4.2) the operators Λ_r take the form $\Lambda_r = (\sigma_r, \partial/\partial p)$. Since σ_r do not depend on p, we get $\Lambda_i \sigma_j = 0$. It is known [10] that in such a case the Euler method has the first mean-square order of accuracy. Comparing the method (4.5)–(4.6) with the Euler method, it is not difficult to get that the method (4.5)–(4.6) is of the first mean-square order as well.

Due to (4.3), $\partial \sigma_r^i/\partial q^j = \partial \sigma_r^j/\partial q^i$. Using this, we obtain $dP_{k+1} \wedge dQ_{k+1} = d\mathcal{P}_1 \wedge d\mathcal{Q}_2$. It is easy to prove that $d\mathcal{P}_1 \wedge d\mathcal{Q}_2 = d\mathcal{P}_1 \wedge d\mathcal{Q}_1 = dP_k \wedge dQ_k$. Therefore the method (4.5)–(4.6) is symplectic. □

REMARK 4.1. *By swapping the roles of p and q, we can propose the following symplectic method of the first mean-square order for the system* (4.2) *with* (4.3)*:*

$$\mathcal{P} = P_k + \alpha h f(t_k, Q_k), \qquad \mathcal{Q} = Q_k + hg(\mathcal{P}), \tag{4.7}$$

$$P_{k+1} = \mathcal{P} + (1-\alpha)hf(t_{k+1}, \mathcal{Q}) + \sum_{r=1}^{m} \sigma_r(t_k, \mathcal{Q})\Delta_k w_r, \qquad Q_{k+1} = \mathcal{Q}. \tag{4.8}$$

4.2. Methods of order 3/2. Consider the relations

$$\mathcal{P}_i = p + h\sum_{j=1}^{s}\alpha_{ij}f(t+c_jh,\mathcal{Q}_j) + \sum_{j=1}^{s}\sum_{r=1}^{m}\sigma_r(t+d_jh,\mathcal{Q}_j)\left(\lambda_{ij}\varphi_r+\mu_{ij}\psi_r\right), \tag{4.9}$$

$$\mathcal{Q}_i = q + h\sum_{j=1}^{s}\hat{\alpha}_{ij}g(\mathcal{P}_j),\quad i=1,\dots,s,$$

$$\bar{P} = p + h\sum_{i=1}^{s}\beta_i f(t+c_ih,\mathcal{Q}_i) + \sum_{i=1}^{s}\sum_{r=1}^{m}\sigma_r(t+d_ih,\mathcal{Q}_i)\left(\nu_i\varphi_r+\varkappa_i\psi_r\right), \tag{4.10}$$

$$\bar{Q} = q + h\sum_{i=1}^{s}\hat{\beta}_i g(\mathcal{P}_i),$$

where φ_r, ψ_r do not depend on p and q, the parameters α_{ij}, $\hat{\alpha}_{ij}$, β_i, $\hat{\beta}_i$, λ_{ij}, μ_{ij}, ν_i, $\varkappa_i$ satisfy the conditions

$$\beta_i\hat{\alpha}_{ij} + \hat{\beta}_j\alpha_{ji} - \beta_i\hat{\beta}_j = 0, \tag{4.11}$$

$$\nu_i\hat{\alpha}_{ij} + \hat{\beta}_j\lambda_{ji} - \nu_i\hat{\beta}_j = 0,\quad \varkappa_i\hat{\alpha}_{ij} + \hat{\beta}_j\mu_{ji} - \varkappa_i\hat{\beta}_j = 0,\quad i,j=1,\dots,s,$$

and c_i, d_i are arbitrary parameters.

If $\sigma_r \equiv 0$ the relations (4.9)–(4.10) coincide with a general form of s-stage PRK methods for deterministic differential equations. (See, e.g., [5, p. 34].) It is known [9, 5] that the symplectic condition holds for $\bar{P}$, $\bar{Q}$ from (4.9)–(4.10) with (4.11) in the case of $\sigma_r \equiv 0$. By a generalization of the proof of Theorem 6.2 from [5], we prove the following lemma. (Another generalization is given in [3].)

LEMMA 4.2. *The relations* (4.9)–(4.10) *with conditions* (4.11) *preserve symplectic structure, i.e.,* $d\bar{P}\wedge d\bar{Q} = dp\wedge dq$.

Proof. Denote for awhile: $f_i = f(t+c_ih,\mathcal{Q}_i)$, $g_i = g(\mathcal{P}_i)$, $\sigma_{ri} = \sigma_r(t+d_ih,\mathcal{Q}_i)$. We get

$$\begin{aligned} d\bar{P}\wedge d\bar{Q} = dp\wedge dq + h\sum_{j=1}^{s}\hat{\beta}_j dp\wedge dg_j + h\sum_{i=1}^{s}\beta_i df_i\wedge dq + h^2\sum_{i=1}^{s}\sum_{j=1}^{s}\beta_i\hat{\beta}_j df_i\wedge dg_j \\ + \sum_{i=1}^{s}\sum_{r=1}^{m}\left(\nu_i\varphi_r+\varkappa_i\psi_r\right)d\sigma_{ri}\wedge dq + h\sum_{i=1}^{s}\sum_{j=1}^{s}\sum_{r=1}^{m}\left(\nu_i\varphi_r+\varkappa_i\psi_r\right)\hat{\beta}_j d\sigma_{ri}\wedge dg_j. \end{aligned} \tag{4.12}$$

Then we express $dp\wedge dg_j$ from

$$d\mathcal{P}_j\wedge dg_j = dp\wedge dg_j + h\sum_{i=1}^{s}\alpha_{ji}df_i\wedge dg_j + \sum_{i=1}^{s}\sum_{r=1}^{m}\left(\lambda_{ji}\varphi_r+\mu_{ji}\psi_r\right)d\sigma_{ri}\wedge dg_j$$

and substitute it in (4.12). Analogously, we act with $df_i\wedge dq$ and $d\sigma_{ri}\wedge dq$ finding them from the expressions for $df_i\wedge d\mathcal{Q}_i$ and $d\sigma_{ri}\wedge d\mathcal{Q}_i$. As a result, using (4.11), we obtain

$$\begin{aligned} d\bar{P}\wedge d\bar{Q} = dp\wedge dq + h\sum_{i=1}^{s}\hat{\beta}_i d\mathcal{P}_i\wedge dg_i + h\sum_{i=1}^{s}\beta_i df_i\wedge d\mathcal{Q}_i \\ + \sum_{i=1}^{s}\sum_{r=1}^{m}\left(\nu_i\varphi_r+\varkappa_i\psi_r\right)d\sigma_{ri}\wedge d\mathcal{Q}_i. \end{aligned}$$

Taking into account that the wedge product is skew-symmetric, the vector functions f, g, σ_r are gradients, f, σ_r do not depend on p, and g does not depend on q, it is not difficult to see that each of the terms $d\mathcal{P}_i \wedge dg_i$, $df_i \wedge d\mathcal{Q}_i$, $d\sigma_{ri} \wedge d\mathcal{Q}_i$ vanishes. Therefore $d\bar{P} \wedge d\bar{Q} = dp \wedge dq$. □

Introduce the following 2-stage explicit PRK method for the system (4.2), (4.3):

$$\mathcal{Q}_1 = Q_k, \qquad \mathcal{P}_1 = P_k + \frac{h}{4} f(t_k, \mathcal{Q}_1) + \frac{1}{2}\sum_{r=1}^{m} \sigma_r(t_k, \mathcal{Q}_1)\,(3(J_{r0})_k - \Delta_k w_r)\,, \tag{4.13}$$

$$\mathcal{Q}_2 = \mathcal{Q}_1 + \frac{2}{3} h g(\mathcal{P}_1),$$

$$\mathcal{P}_2 = \mathcal{P}_1 + \frac{3}{4} h f\left(t_k + \frac{2}{3}h, \mathcal{Q}_2\right) + \frac{3}{2}\sum_{r=1}^{m} \sigma_r\left(t_k + \frac{2}{3}h, \mathcal{Q}_2\right)(-(J_{r0})_k + \Delta_k w_r)\,,$$

$$P_{k+1} = \mathcal{P}_2, \quad Q_{k+1} = \mathcal{Q}_2 + \frac{h}{3} g(\mathcal{P}_2), \quad k = 0, \dots, N-1, \tag{4.14}$$

where

$$J_{r0} := \frac{1}{h}\int_t^{t+h} (w_r(\vartheta) - w_r(t))\, d\vartheta. \tag{4.15}$$

THEOREM 4.3. *The explicit PRK method* (4.13)–(4.14) *for system* (4.2), (4.3) *preserves symplectic structure and has the mean-square order* 3/2.

Proof. The method (4.13)–(4.14) has the form of (4.9)–(4.10), and its parameters satisfy the conditions (4.11). Then, Lemma 4.2 implies that this method preserves symplectic structure.

Now let us prove mean-square order of convergence of (4.13)–(4.14). To this end, introduce the one-step approximation for (4.2):

$$\tilde{P} = p + \sum_{r=1}^{m} \sigma_r \Delta w_r + hf + \sum_{r=1}^{m}\left[\frac{\partial \sigma_r}{\partial t} + \sum_{i=1}^{n} g^i \frac{\partial \sigma_r}{\partial q^i}\right] I_{0r} + \frac{h^2}{2}\left[\frac{\partial f}{\partial t} + \sum_{i=1}^{n} g^i \frac{\partial f}{\partial q^i}\right], \tag{4.16}$$

$$\tilde{Q} = q + hg + \sum_{r=1}^{m}\sum_{i=1}^{n} \sigma_r^i \frac{\partial g}{\partial p^i} I_{r0} + \frac{h^2}{2}\left[\sum_{i=1}^{n} f^i \frac{\partial g}{\partial p^i} + \frac{1}{2}\sum_{r=1}^{m}\sum_{i,j=1}^{n} \sigma_r^i \sigma_r^j \frac{\partial^2 g}{\partial p^i \partial p^j}\right],$$

where

$$I_{0r} = \int_t^{t+h} (\vartheta - t)\, dw_r(\vartheta), \qquad I_{r0} = \int_t^{t+h} (w_r(\vartheta) - w_r(t))\, d\vartheta = hJ_{r0}, \tag{4.17}$$

and all the coefficients are calculated at (t, p, q). We note that

$$(\Delta w_r - J_{r0})\, h = I_{0r}.$$

Using the general theory of numerical integration of SDEs [10], it is not difficult to show that the method based on (4.16) is of the mean-square order 3/2. Our nearest aim is to prove that the one-step approximation $\bar{P}$, $\bar{Q}$ corresponding to the method (4.13)–(4.14) is such that

$$\left| E\begin{bmatrix} \bar{P} - \tilde{P} \\ \bar{Q} - \tilde{Q} \end{bmatrix} \right| = O(h^3), \qquad \left(E\begin{bmatrix} \bar{P} - \tilde{P} \\ \bar{Q} - \tilde{Q} \end{bmatrix}^2 \right)^{1/2} = O(h^2). \tag{4.18}$$

Expanding the right-hand sides of the approximation $\bar{P}$, $\bar{Q}$ about (t,p,q), we obtain

$$\bar{P} = p + hf + \frac{h^2}{2}\frac{\partial f}{\partial t} + \frac{3}{4}h\sum_{i=1}^{n}\Delta\mathcal{Q}_2^i\frac{\partial f}{\partial q^i} + \sum_{r=1}^{m}\sigma_r\Delta w_r + \frac{3}{2}\sum_{r=1}^{m}\sum_{i=1}^{n}\Delta\mathcal{Q}_2^i\frac{\partial\sigma_r}{\partial q^i}\left(\Delta w_r - J_{r0}\right) + h\sum_{r=1}^{m}\frac{\partial\sigma_r}{\partial t}\left(\Delta w_r - J_{r0}\right) + \rho_1, \tag{4.19}$$

$$\bar{Q} = q + hg + \frac{h}{3}\sum_{i=1}^{n}\left(2\Delta\mathcal{P}_1^i + \Delta\mathcal{P}_2^i\right)\frac{\partial g}{\partial p^i} + \frac{h}{6}\sum_{i,j=1}^{n}(2\Delta\mathcal{P}_1^i\Delta\mathcal{P}_1^j + \Delta\mathcal{P}_2^i\Delta\mathcal{P}_2^j)\frac{\partial^2 g}{\partial p^i\partial p^j} + \rho_2,$$

$$\Delta\mathcal{P}_1 := \mathcal{P}_1 - p = \frac{h}{4}f + \frac{1}{2}\sum_{r=1}^{m}\sigma_r\left(3J_{r0} - \Delta w_r\right),$$

$$\Delta\mathcal{Q}_2 := \mathcal{Q}_2 - q = \frac{2}{3}hg + \frac{2}{3}h\sum_{i=1}^{n}\Delta\mathcal{P}_1^i\frac{\partial g}{\partial p^i} + \frac{h}{3}\sum_{i,j=1}^{n}\Delta\mathcal{P}_1^i\Delta\mathcal{P}_1^j\frac{\partial^2 g}{\partial p^i\partial p^j} + r_1,$$

$$\Delta\mathcal{P}_2 := \mathcal{P}_2 - p = hf + \sum_{r=1}^{m}\sigma_r\Delta w_r + r_2,$$

where all the coefficients are calculated at (t,p,q).

Due to properties of the Wiener process and Ito integrals, we have

$$E\Delta w_i = 0, \quad E\Delta w_i\Delta w_j = \delta_{ij}h, \quad E\Delta w_i\Delta w_j\Delta w_k = 0, \quad E\left(\Delta w_i\right)^4 = 3h^2,$$
$$EJ_{i0} = 0, \quad EJ_{i0}J_{j0} = \delta_{ij}\frac{h}{3}, \quad EJ_{i0}J_{j0}J_{k0} = 0, \quad E\left(J_{i0}\right)^4 = \frac{h^2}{3},$$
$$E\Delta w_iJ_{j0} = \delta_{ij}\frac{h}{2}, \quad E\Delta w_i\Delta w_jJ_{k0} = 0, \quad E\Delta w_iJ_{j0}J_{k0} = 0. \tag{4.20}$$

Then, under appropriate conditions on smoothness and boundedness of the coefficients of (4.2), we get

$$|E\rho_i| = O(h^3), \quad E\left(\rho_i\right)^2 = O(h^5), \quad i = 1,2,$$
$$|Er_1| = O(h^3), \quad E\left(r_1\right)^2 = O(h^5), \quad |Er_2| = O(h^2), \quad E\left(r_2\right)^2 = O(h^3). \tag{4.21}$$

In addition to (4.20) we note that

$$E\left(\Delta w_r - J_{r0}\right)\left(3J_{r0} - \Delta w_r\right) = 0, \quad E\left(3J_{r0} - \Delta w_r\right)^2 = h. \tag{4.22}$$

Using (4.20)–(4.22), we obtain from (4.19)

$$\bar{P} = p + \sum_{r=1}^{m}\sigma_r\Delta w_r + hf + \sum_{r=1}^{m}\left[\frac{\partial\sigma_r}{\partial t} + \sum_{i=1}^{n}g^i\frac{\partial\sigma_r}{\partial q^i}\right]I_{0r} + \frac{h^2}{2}\left[\frac{\partial f}{\partial t} + \sum_{i=1}^{n}g^i\frac{\partial f}{\partial q^i}\right] + R_1,$$

$$\bar{Q} = q + hg + \sum_{r=1}^{m}\sum_{i=1}^{n}\sigma_r^i\frac{\partial g}{\partial p^i}I_{r0} + \frac{h^2}{2}\left[\sum_{i=1}^{n}f^i\frac{\partial g}{\partial p^i} + \frac{1}{2}\sum_{r=1}^{m}\sum_{i,j=1}^{n}\sigma_r^i\sigma_r^j\frac{\partial^2 g}{\partial p^i\partial p^j}\right] + R_2$$

with R_i, $i = 1, 2$, such that

$$|ER_i| = O(h^3), \quad E\left(R_i\right)^2 = O(h^4), \quad i = 1, 2.$$

This implies (4.18). It follows from (4.18) that the method (4.13)–(4.14) is of the mean-square order 3/2. □

REMARK 4.2. *The random variables* $\Delta_k w_r(h)$, $(J_{r0})_k$ *have a Gaussian joint distribution, and they can be simulated at each step by* $2m$ *independent* $\mathcal{N}(0,1)$*-distributed random variables* ξ_{rk} *and* η_{rk}, $r = 0, \ldots, m$:

$$\Delta_k w_r(h) = \xi_{rk}\sqrt{h}, \qquad (J_{r0})_k = \left(\xi_{rk}/2 + \eta_{rk}/\sqrt{12}\right)\sqrt{h}\,.$$

As a result, the method (4.13)–(4.14) *takes the constructive form.*

REMARK 4.3. *It is very unusual that the direct expansion of* (4.13)–(4.14) *does not contain the habitual term* $\frac{h^2}{4}\sum_{r=1}^{m}\sum_{i,j=1}^{n}\frac{\partial^2 g}{\partial p^i \partial p^j}\sigma_r^i\sigma_r^j$. *The similar term in the expansion contains some combinations of* Δw_r *and* J_{r0} *instead of* h. (*See a similar remark in* [3].)

REMARK 4.4. *In the case of* $\sigma_r = 0$, $r = 1, \ldots, m$, *the method* (4.13)–(4.14) *coincides with the well-known deterministic symplectic PRK method of the second order. Adapting other explicit deterministic second-order PRK methods from* [5, 9], *it is possible to construct other explicit symplectic methods of the order* 3/2 *for the system* (4.2), (4.3).

REMARK 4.5. *In the case of a more general system than* (4.2) *methods of the order* 3/2 *require simulation of repeated Ito integrals which is a laborious problem from the computational point of view. We do not consider such methods in the paper.* (*See also the introduction.*)

Lemma 4.2 *can be generalized for the general separable case, i.e., for the system* (1.1), (1.3) *with* $H_r = V_r(p) + U_r(t,q)$, $r = 0, 1, \ldots, m$, *and it can also be generalized for the general stochastic Hamiltonian system* (1.1), (1.3). *In the case of systems with one noise repeated Ito integrals can effectively be simulated, and generalizations of Lemma* 4.2 *can be used for constructing high-order symplectic methods for Hamiltonian systems with one noise* (*i.e., when* $m = 1$).

5. Numerical tests.

5.1. Kubo oscillator. The system of SDEs in the sense of Stratonovich (Kubo oscillator)

$$\begin{aligned} dX^1 &= -aX^2 dt - \sigma X^2 \circ dw(t), \qquad X^1(0) = x^1, \\ dX^2 &= aX^1 dt + \sigma X^1 \circ dw(t), \qquad X^2(0) = x^2, \end{aligned} \tag{5.1}$$

is often used for testing numerical methods. (See, e.g., [15], where some nonsymplectic stochastic methods based on deterministic symplectic methods are used.) Here a and σ are constants, and $w(t)$ is a one-dimensional standard Wiener process.

The phase flow of this system preserves symplectic structure. Moreover, the quantity $\mathcal{H}(x^1, x^2) = \left(x^1\right)^2 + \left(x^2\right)^2$ is conservative for this system; i.e.,

$$\mathcal{H}(X^1(t), X^2(t)) = \mathcal{H}(x^1, x^2) \text{ for } t \geq 0.$$

This means that a phase trajectory of (5.1) belongs to the circle with the center at the origin and with the radius $\sqrt{\mathcal{H}(x^1, x^2)}$.

We test here three methods. In application to (5.1) the symplectic PRK method (3.8) takes the following form:

$$X^1_{k+1} = X^1_k - aX^2_k h - \frac{\sigma^2}{2} X^1_{k+1} h - \sigma X^2_k \Delta_k w, \tag{5.2}$$
$$X^2_{k+1} = X^2_k + aX^1_{k+1} h + \frac{\sigma^2}{2} X^2_k h + \sigma X^1_{k+1} \Delta_k w.$$

This method is implicit in the deterministic part only.

The midpoint method (3.7) applied to the system with one noise (5.1) reads

$$X^1_{k+1} = X^1_k - a\frac{X^2_k + X^2_{k+1}}{2} h - \sigma \frac{X^2_k + X^2_{k+1}}{2} (\zeta_h)_k \sqrt{h}, \tag{5.3}$$
$$X^2_{k+1} = X^2_k + a\frac{X^1_k + X^1_{k+1}}{2} h + \sigma \frac{X^1_k + X^1_{k+1}}{2} (\zeta_h)_k \sqrt{h}.$$

This is a fully implicit method. Note that due to specific features of the system (5.1), the formula (5.3) is valid (solvable) not only in the case of the truncated random variable ζ_h but also if we put $\Delta_k w$ instead of $(\zeta_h)_k \sqrt{h}$.

The method (5.3) is of the first mean-square order. The method (5.2) is of the mean-square order $1/2$ as well as the Euler method:

$$X^1_{k+1} = X^1_k - aX^2_k h - \frac{\sigma^2}{2} X^1_k h - \sigma X^2_k \Delta_k w, \tag{5.4}$$
$$X^2_{k+1} = X^2_k + aX^1_k h - \frac{\sigma^2}{2} X^2_k h + \sigma X^1_k \Delta_k w,$$

which, of course, is not symplectic.

Figure 1 gives approximations of a sample phase trajectory of (5.1) simulated by the symplectic methods (5.2) and (5.3) and by the Euler method (5.4). The initial condition is $x^1 = 1$, $x^2 = 0$. The corresponding exact phase trajectory belongs to the circle with the center at the origin and with the unit radius.

We see that the Euler method is not appropriate for simulation of the oscillator (5.1) on long time intervals, while the symplectic methods preserve conservative properties of the Kubo oscillator.

These experiments also demonstrate that the midpoint method is much more accurate than the other methods applied. It is not difficult to check that $\mathcal{H}(x^1, x^2)$ is conserved by the midpoint method (5.3), but it is not conserved by the symplectic PRK method (5.2). This is similar to the deterministic case. Indeed, it is known [8, 5] that symplectic deterministic RK methods (e.g., the midpoint scheme) conserve all quadratic functions that are conserved by the Hamiltonian system being integrated, while deterministic PRK methods do not possess this property.

5.2. A model for synchrotron oscillations of particles in storage rings. In [14] a model describing synchrotron oscillations of particles in storage rings under the influence of external fluctuating electromagnetic fields was considered. This model can be written in the following form:

$$dP = -\omega^2 \sin(Q) dt - \sigma_1 \cos(Q) dw_1 - \sigma_2 \sin(Q) dw_2, \tag{5.5}$$
$$dQ = P dt.$$

P and Q are scalars here. The system (5.5) is of the form (4.2), and therefore its phase flow preserves symplectic structure.

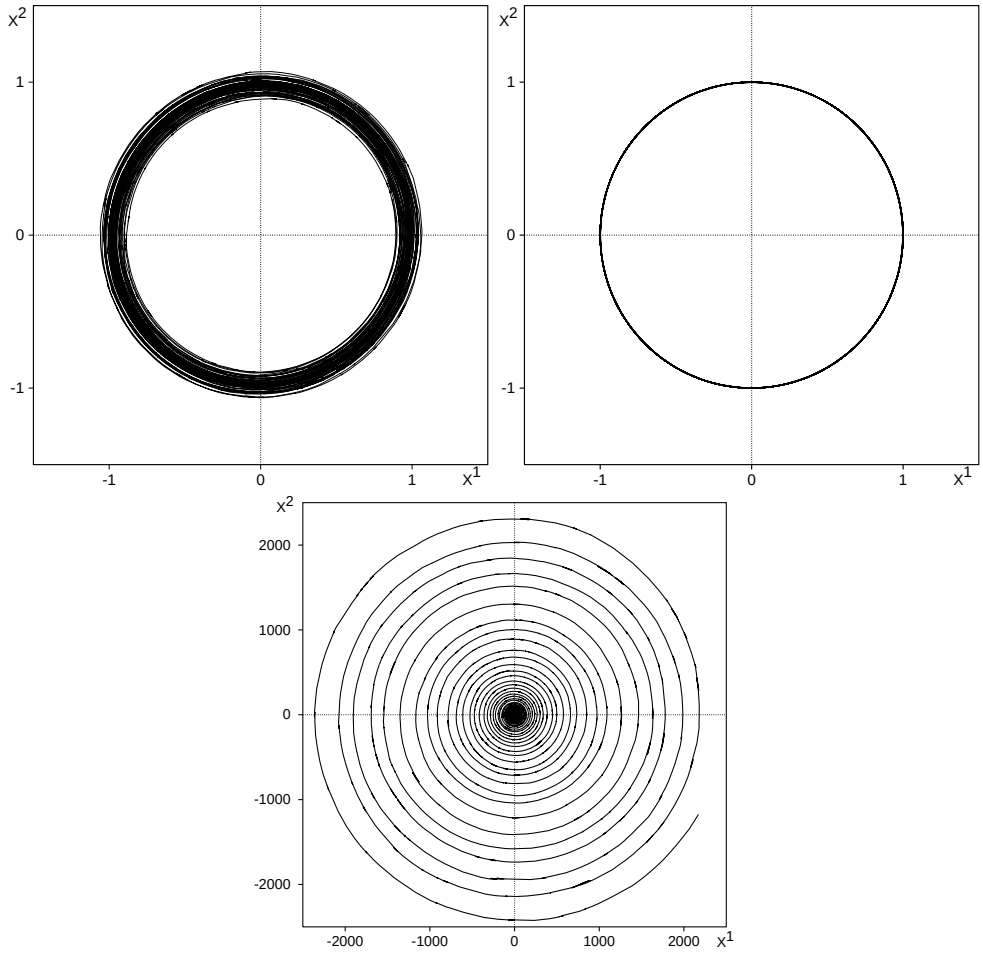

FIG. 1. *A sample phase trajectory of* (5.1) *with* $X^1(0) = 1$, $X^2(0) = 0$ *obtained by the symplectic method* (5.2) *(top left), the midpoint method* (5.3) *(top right), and by the Euler method* (5.4) *(bottom) for* $a = 2$, $\sigma = 0.3$, $h = 0.02$ *on the time interval* $t \le 200$.

The Euler method for (5.5) takes the form

$$P_{k+1} = P_k - h\omega^2 \sin(Q_k) - h^{1/2}(\sigma_1 \cos(Q_k)\Delta_k w_1 + \sigma_2 \sin(Q_k)\Delta_k w_2), \tag{5.6}$$
$$Q_{k+1} = Q_k + hP_k.$$

In application to (5.5) the explicit symplectic method (4.5)–(4.6) with $\alpha = 1$ is written as

$$\mathcal{Q} = Q_k + hP_k, \tag{5.7}$$
$$P_{k+1} = P_k - h\omega^2 \sin(\mathcal{Q}) - h^{1/2}(\sigma_1 \cos(\mathcal{Q})\Delta_k w_1 + \sigma_2 \sin(\mathcal{Q})\Delta_k w_2), \qquad Q_{k+1} = \mathcal{Q}.$$

Both methods are of the first mean-square order.

Approximations of a sample trajectory of (5.5) simulated by the symplectic method (5.7) and the Euler method (5.6) are plotted on Figure 2. The trajectory obtained by the symplectic method with $h = 0.02$ (solid line) visually coincides with

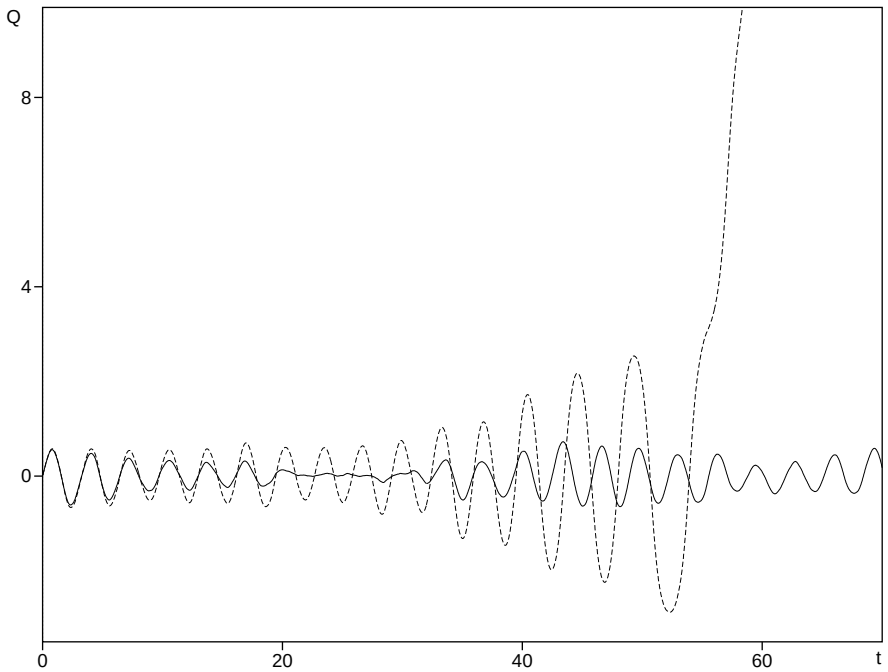

FIG. 2. *A sample trajectory of* (5.5) *for* $\omega = 2$, $\sigma_1 = 0.2$, $\sigma_2 = 0.1$, $h = 0.02$. *Solid line—the symplectic method* (5.7), *dashed line—the Euler method* (5.6).

the one obtained for a smaller step, e.g., for $h = 0.002$, using the same sample paths for the Wiener processes; i.e., this trajectory visually coincides with the exact solution of (5.5). This figure clearly demonstrates that the Euler method (dashed line) is unacceptable for simulation of the solution to (5.5) on a long time interval, while the symplectic method (5.7) produces quite accurate results despite both methods having the same mean-square order of accuracy.

A ROBUST FINITE ELEMENT METHOD FOR DARCY–STOKES FLOW*

KENT ANDRE MARDAL†, XUE-CHENG TAI‡, AND RAGNAR WINTHER§

Abstract. Finite element methods for a family of systems of singular perturbation problems of a saddle point structure are discussed. The system is approximately a linear Stokes problem when the perturbation parameter is large, while it degenerates to a mixed formulation of Poisson's equation as the perturbation parameter tends to zero. It is established, basically by numerical experiments, that most of the proposed finite element methods for Stokes problem or the mixed Poisson's system are not well behaved uniformly in the perturbation parameter. This is used as the motivation for introducing a new "robust" finite element which exhibits this property.

Key words. singular perturbation problems, Darcy–Stokes flow, nonconforming finite elements, uniform error estimates

1. Introduction.

Let $\Omega \subset \mathbb{R}^2$ be a bounded and connected polygonal domain with boundary $\partial\Omega$. In this paper we shall consider finite element methods for the following singular perturbation problem:

$$\begin{aligned} (\boldsymbol{I} - \varepsilon^2 \boldsymbol{\Delta})\boldsymbol{u} - \mathbf{grad}\, p &= \boldsymbol{f} \quad \text{in } \Omega, \\ \operatorname{div} \boldsymbol{u} &= g \quad \text{in } \Omega, \\ \boldsymbol{u} &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

Here $\varepsilon \in (0, 1]$ is a parameter, while $\boldsymbol{\Delta} = \mathbf{diag}(\Delta, \Delta)$ is the Laplace operator on vector fields. The vector field $\boldsymbol{f}$ and scalar field g represent the data. The problem (1.1) admits only a solution if the function g has mean value zero on Ω and "the pressure" p is determined only up to addition of a constant.

We note that when ε is not too small, and $g = 0$, this problem is simply a standard Stokes problem but with an additional nonharmful lower order term. However, if $\boldsymbol{f} = 0$ and ε approaches zero, then the model problem formally tends to a mixed formulation of the Poisson equation with homogeneous Neumann boundary conditions.

When $\varepsilon = 0$ the first equation in (1.1) has the form of Darcy's law for flow in a homogeneous porous medium, where $\boldsymbol{u}$ is a volume averaged velocity. In fact, the system (1.1) can be regarded as a macroscopic model for flow in an "almost porous media," where $\boldsymbol{u}$ and p represent volume averaged velocity and pressure, respectively. The zero order velocity term in the first equation of (1.1) then typically represents a *Stokes drag*. An attempt to derive Darcy's law from volume averaged Stokes flow is, for example, discussed in [16]. Generalizations of the system (1.1) have also been proposed in the modeling of macrosegregation formation in binary alloy solidification;

cf. [13]. Systems of the form (1.1) may also arise from time discretizations of the Navier–Stokes equation, where the parameter ε corresponds to the square root of the time step; cf. [4]. However, the study of such time discretizations is not the motivation for the present paper.

The purpose of the present paper is to discuss a finite element method for the model problem (1.1) with convergence properties that are uniform with respect to the perturbation parameter ε. In section 2 we will introduce some notations and discuss various properties of the model (1.1). Discretizations of the model problem by the finite element method is described in section 3. In particular, we will state stability conditions which are uniform with respect to the parameter ε and show, by numerical experiments, that the standard discretizations, proposed either for $\varepsilon = 1$ or $\varepsilon = 0$, do not satisfy these stability conditions. A new nonconforming finite element discretization is then proposed in section 4. We show that this new discretization is uniformly stable, and, as a consequence, we establish in section 5 error estimates which are uniform in ε under the assumption that proper regularity estimates hold for the solution. In section 6 we then study the asymptotic smoothness of the solution of (1.1) as ε tends to zero. Based on these regularity results we show that, for fixed data $\boldsymbol{f}$ and g, a uniform $O(h^{1/2})$ error estimate in a suitable energy norm can be derived.

In the final section of this paper we study an elliptic system which formally is a generalization of (1.1). This system is given by

$$\begin{aligned} (\boldsymbol{I} - \varepsilon^2 \boldsymbol{\Delta})\boldsymbol{u} - \delta^{-2}\,\mathbf{grad}(\operatorname{div} \boldsymbol{u} - g) &= \boldsymbol{f} \quad && \text{in } \Omega, \\ \boldsymbol{u} &= 0 \quad && \text{on } \partial\Omega, \end{aligned} \tag{1.2}$$

where $\varepsilon, \delta \in (0, 1]$. By introducing $p = \delta^{-2}(\operatorname{div} \boldsymbol{u} - g)$ this system can be alternatively written on the mixed form

$$\begin{aligned} (\boldsymbol{I} - \varepsilon^2 \boldsymbol{\Delta})\boldsymbol{u} - \mathbf{grad}\, p &= \boldsymbol{f} \quad && \text{in } \Omega, \\ \operatorname{div} \boldsymbol{u} - \delta^2 p &= g \quad && \text{in } \Omega, \\ \boldsymbol{u} &= 0 \quad && \text{on } \partial\Omega. \end{aligned} \tag{1.3}$$

Note that this system also has meaning when $\delta = 0$, and in this case the system reduces to (1.1).

The symmetric and positive definite system (1.2) is discretized by a straightforward finite element approach, utilizing the new nonconforming velocity space constructed earlier in this paper; i.e., the mixed system (1.3) is not introduced in the discretization. We show, by numerical experiments and theory, that under the assumption of sufficiently regular solutions we obtain error estimates which are uniform both in ε and δ.

2. Preliminaries. We will use $H^m = H^m(\Omega)$ to denote the Sobolev space of scalar functions on Ω with m derivatives in $L^2 = L^2(\Omega)$, with norm $\|\cdot\|_m$. Furthermore, the notation $\|\cdot\|_{m,K}$ is used to indicate that the norm is defined with respect to a domain K different from Ω. The seminorm derived from the partial derivatives of order equal m is denoted $|\cdot|_m$, i.e., $|\cdot|_m^2 = \|\cdot\|_m^2 - \|\cdot\|_{m-1}^2$. The space $H_0^m = H_0^m(\Omega)$ will denote the closure in H^m of $C_0^\infty(\Omega)$. The dual space of H_0^m with respect to the L^2 inner product will be denoted by H^{-m}. Furthermore, L_0^2 will denote the space of L^2 functions with mean value zero. A space written in boldface denotes a 2-vector valued analogue of the corresponding scalar space. The notation $(\cdot, \cdot)$ is used to denote the L^2 inner product on scalar, vector, and matrix valued functions.

Below we shall encounter the intersection and sum of Hilbert spaces. We therefore recall the basic definitions of these concepts. If X and Y are Hilbert spaces, both continuously contained in some larger Hilbert spaces, then the intersection $X \cap Y$ and the sum $X + Y$ are themselves Hilbert spaces with the norms

$$\|z\|_{X\cap Y} = (\|z\|_X^2 + \|z\|_Y^2)^{1/2}$$

and

$$\|z\|_{X+Y} = \inf_{\substack{z=x+y \\ x\in X,\, y\in Y}} (\|x\|_X^2 + \|y\|_Y^2)^{1/2}.$$

Furthermore, if $X \cap Y$ is dense in both X and Y, then $(X \cap Y)^* = X^* + Y^*$. We refer the reader to [3, Chapter 2] for these results.

If q is a scalar field, then $\mathbf{grad}\, q$ will denote the gradient of q, while $\operatorname{div} \boldsymbol{v}$ denotes the divergence of a vector field $\boldsymbol{v}$. We shall also use the differential operators

$$\mathbf{curl}\, q = \begin{pmatrix} -\partial q/\partial x_2 \\ \partial q/\partial x_1 \end{pmatrix} \quad \text{and} \quad \operatorname{rot} \boldsymbol{v} = \partial \boldsymbol{v}_1/\partial x_2 - \partial \boldsymbol{v}_2/\partial x_1.$$

Note that, due to Green's theorem, these definitions lead to the following "integration by parts formula":

$$\int_\Omega \mathbf{curl}\, q \cdot \boldsymbol{v}\, dx = \int_\Omega q \operatorname{rot} \boldsymbol{v}\, dx + \int_{\partial\Omega} q(\boldsymbol{v} \cdot \boldsymbol{t})\, d\tau, \tag{2.1}$$

where $\boldsymbol{t}$ is the unit tangent vector in the counterclockwise direction on $\partial\Omega$, and τ is the arclength.

The gradient of a vector field $\boldsymbol{v}$ is denoted $\boldsymbol{D}\boldsymbol{v}$; i.e., $\boldsymbol{D}\boldsymbol{v}$ is the 2×2 matrix with elements

$$(\boldsymbol{D}\boldsymbol{v})_{i,j} = \partial \boldsymbol{v}_i/\partial x_j, \qquad 1 \le i, j \le 2.$$

Hence, for any $\boldsymbol{u} \in \boldsymbol{H}^2$ and $\boldsymbol{v} \in \boldsymbol{H}_0^1$ we have

$$-(\boldsymbol{\Delta}\boldsymbol{u}, \boldsymbol{v}) = (\boldsymbol{D}\boldsymbol{u}, \boldsymbol{D}\boldsymbol{v}) \equiv \int_\Omega \boldsymbol{D}\boldsymbol{u} : \boldsymbol{D}\boldsymbol{v}\, dx,$$

where the colon denotes the scalar product of matrix fields. Recall also the identity

$$\boldsymbol{\Delta} = \mathbf{grad} \operatorname{div} - \mathbf{curl} \operatorname{rot}, \tag{2.2}$$

which can be verified by a direct computation. As a consequence, we obtain the identity

$$(\boldsymbol{D}\boldsymbol{u}, \boldsymbol{D}\boldsymbol{v}) = (\operatorname{div} \boldsymbol{u}, \operatorname{div} \boldsymbol{v}) + (\operatorname{rot} \boldsymbol{u}, \operatorname{rot} \boldsymbol{v}) \quad \forall \boldsymbol{u} \in \boldsymbol{H}^1,\ \boldsymbol{v} \in \boldsymbol{H}_0^1. \tag{2.3}$$

In addition to the function spaces introduced above we will also use the space $\boldsymbol{H}(\operatorname{div}) = \boldsymbol{H}(\operatorname{div}; \Omega)$ consisting of all vector fields in $\boldsymbol{L}^2$ with divergence in L^2, i.e.,

$$\boldsymbol{H}(\operatorname{div}) = \{\boldsymbol{v} \in \boldsymbol{L}^2 : \operatorname{div} \boldsymbol{v} \in L^2\}.$$

Similarly,

$$\boldsymbol{H}(\operatorname{rot}) = \{\boldsymbol{v} \in \boldsymbol{L}^2 : \operatorname{rot} \boldsymbol{v} \in L^2\},$$

and the norms of these spaces are denoted by $\|\cdot\|_{\mathrm{div}}$ and $\|\cdot\|_{\mathrm{rot}}$, respectively. Furthermore, $\boldsymbol{H}_0(\mathrm{div})$ is the closed subspace of $\boldsymbol{H}(\mathrm{div})$ consisting of functions with vanishing normal components on the boundary; i.e.,

$$\boldsymbol{H}_0(\mathrm{div}) = \{\boldsymbol{v} \in \boldsymbol{H}(\mathrm{div}) : \boldsymbol{v} \cdot \boldsymbol{n} = 0 \quad \text{on } \partial\Omega\},$$

where $\boldsymbol{n}$ is the unit outward normal vector.

Throughout this paper $a_\varepsilon(\cdot,\cdot) : \boldsymbol{H}^1 \times \boldsymbol{H}^1 \mapsto \mathbb{R}$ will denote the bilinear form

$$a_\varepsilon(\boldsymbol{u},\boldsymbol{v}) = (\boldsymbol{u},\boldsymbol{v}) + \varepsilon^2(\boldsymbol{D}\boldsymbol{u},\boldsymbol{D}\boldsymbol{v}).$$

A weak formulation of problem (1.1) is given by the following:

Find $(\boldsymbol{u},p) \in \boldsymbol{H}_0^1 \times L_0^2$ such that

$$\begin{aligned} a_\varepsilon(\boldsymbol{u},\boldsymbol{v}) + (p, \operatorname{div}\boldsymbol{v}) &= (\boldsymbol{f},\boldsymbol{v}) \quad && \forall \boldsymbol{v} \in \boldsymbol{H}_0^1, \\ (\operatorname{div}\boldsymbol{u}, q) &= (g,q) && \forall q \in L_0^2. \end{aligned} \tag{2.4}$$

Here we assume that data $(\boldsymbol{f},g)$ is given in $\boldsymbol{H}^{-1} \times L_0^2$.

The problem (2.4) has a unique solution $(\boldsymbol{u},p) \in \boldsymbol{H}_0^1 \times L_0^2$. This follows from standard results for Stokes problem; cf., for example, [11]. However, the bound on $(\boldsymbol{u},p) \in \boldsymbol{H}_0^1 \times L_0^2$ will degenerate as ε tends to zero. In fact, for the reduced problem (2.4) with $\varepsilon = 0$ the space $\boldsymbol{H}_0^1 \times L_0^2$ is not a proper function space for the solution. However, the theory developed in [6] can be applied in this case if we seek $(\boldsymbol{u},p)$ either in $\boldsymbol{H}_0(\mathrm{div}) \times L_0^2$ or in $\boldsymbol{L}^2 \times (H^1 \cap L_0^2)$, and with data $(\boldsymbol{f},g)$ in the proper dual spaces. These results are, in fact, consequences of standard results for the Poisson equation.

The fact that the regularity of the solution is changed when ε becomes zero strongly suggests that ε-dependent norms and function spaces are required in order to obtain stability estimates independent of ε. Furthermore, since the reduced problem is well posed for two completely different choices of function spaces, this indicates that there are at least two different choices of ε-dependent norms. In the present paper we will study the problem (1.1) with respect to an ε-dependent norm which reduces to the norm in $\boldsymbol{H}_0(\mathrm{div}) \times L_0^2$ when $\varepsilon = 0$. Our goal is to derive discretizations which are uniformly stable with respect to ε in this norm. This appears to be the proper choice if we want to study discretizations which also can be generalized to nonmixed approximations of elliptic problems of the form (1.2).

Remark. When we refer to the *reduced system* corresponding to (1.1) we refer to the system (1.1) with $\varepsilon = 0$ and the boundary condition $\boldsymbol{u} = 0$ replaced by $\boldsymbol{u} \cdot \boldsymbol{n} = 0$. This system has a weak formulation given by (2.4) but with the solution space $\boldsymbol{H}_0^1$ replaced by $\boldsymbol{H}_0(\mathrm{div})$. ∎

The space $\boldsymbol{H}_0(\mathrm{div}) \cap \varepsilon \cdot \boldsymbol{H}_0^1$, with norm $|\!|\!| \cdot |\!|\!|_\varepsilon$ given by

$$|\!|\!|\boldsymbol{v}|\!|\!|_\varepsilon^2 = \|\boldsymbol{v}\|_0^2 + \|\operatorname{div}\boldsymbol{v}\|_0^2 + \varepsilon^2\|\boldsymbol{D}\boldsymbol{v}\|_0^2,$$

is equal to $\boldsymbol{H}_0^1$ as a set for $\varepsilon > 0$ but equal to $\boldsymbol{H}_0(\mathrm{div})$ for $\varepsilon = 0$. The system (2.4) can alternatively be written as the system

$$\mathcal{A}_\varepsilon \begin{pmatrix} \boldsymbol{u} \\ p \end{pmatrix} = \begin{pmatrix} \boldsymbol{f} \\ g \end{pmatrix},$$

where the coefficient operator $\mathcal{A}_\varepsilon$ is given by

$$\mathcal{A}_\varepsilon = \begin{pmatrix} \boldsymbol{I} - \varepsilon^2\boldsymbol{\Delta} & -\mathbf{grad} \\ \operatorname{div} & 0 \end{pmatrix}. \tag{2.5}$$

Let $\boldsymbol{X}_\varepsilon$ be the product space $(\boldsymbol{H}_0(\mathrm{div}) \cap \varepsilon \cdot \boldsymbol{H}_0^1) \times L_0^2$ and $\boldsymbol{X}_\varepsilon^*$ the corresponding dual space with respect to the L^2 inner product. This space can also be expressed as

$$\boldsymbol{X}_\varepsilon^* = (\boldsymbol{H}^{-1}(\mathrm{rot}) + \varepsilon^{-1}\boldsymbol{H}^{-1}) \times L_0^2.$$

Here the + sign has the interpretation as the sum of Hilbert spaces, and the space $\boldsymbol{H}^{-1}(\mathrm{rot})$ is given by

$$\boldsymbol{H}^{-1}(\mathrm{rot}) = \{\boldsymbol{v} \in \boldsymbol{H}^{-1} : \mathrm{rot}\, \boldsymbol{v} \in H^{-1}\}.$$

The operator $\mathcal{A}_\varepsilon$ can be seen to be an isomorphism mapping $\boldsymbol{X}_\varepsilon$ into $\boldsymbol{X}_\varepsilon^*$. Furthermore, the corresponding operator norms

$$||\mathcal{A}_\varepsilon||_{\mathcal{L}(X_\varepsilon, X_\varepsilon^*)} \quad \text{and} \quad ||\mathcal{A}_\varepsilon^{-1}||_{\mathcal{L}(X_\varepsilon^*, X_\varepsilon)}$$

are independent of ε. In fact, with the definitions above, this is also true for $\varepsilon \in [0, 1]$; i.e., the endpoint $\varepsilon = 0$ can be included.

The uniform boundedness of $\mathcal{A}_\varepsilon$ is straightforward to check from the definitions above, while the uniform boundedness of the inverse can be verified from the two Brezzi conditions; cf. [6]. For the present problem these conditions read as follows:

There are constants $\alpha_0, \beta_0 > 0$, independent of ε, such that

$$\sup_{\boldsymbol{v} \in \boldsymbol{H}_0(\mathrm{div}) \cap \varepsilon \cdot \boldsymbol{H}_0^1} \frac{(q, \mathrm{div}\, \boldsymbol{v})}{|\!|\!| \boldsymbol{v} |\!|\!|_\varepsilon} \geq \alpha_0 \|q\|_0 \quad \forall q \in L_0^2 \tag{2.6}$$

and

$$a_\varepsilon(\boldsymbol{v}, \boldsymbol{v}) \geq \beta_0 |\!|\!| \boldsymbol{v} |\!|\!|_\varepsilon^2 \quad \forall \boldsymbol{v} \in \boldsymbol{Z}, \tag{2.7}$$

where $\boldsymbol{Z} = \{\boldsymbol{v} \in \boldsymbol{H}_0^1 : \mathrm{div}\, \boldsymbol{v} = 0\}$.

Since it is well known (cf., for example, [11, Chapter 1, Corollary 2.4]) that condition (2.6) holds for $\varepsilon = 1$, it also holds for all $\varepsilon \in [0, 1]$ with the same constant α_0. Furthermore, condition (2.7) holds trivially with $\beta_0 = 1$ for $\varepsilon \in [0, 1]$.

3. Uniformly stable discretizations. The purpose of this section is to discuss finite element discretizations of the system (1.1). In particular, we shall be interested in discretizations which are stable uniformly in the parameter $\varepsilon \in (0, 1]$.

Let $\boldsymbol{V}_h \subset \boldsymbol{H}_0^1$ and $Q_h \subset L_0^2$ be finite element spaces, where $h \in (0, 1]$ is a discretization parameter. The weak formulation (2.4) leads to the following corresponding finite element discretization:

Find $(\boldsymbol{u}_h, p_h) \in \boldsymbol{V}_h \times Q_h$ such that

$$\begin{aligned} a_\varepsilon(\boldsymbol{u}_h, \boldsymbol{v}) + (p_h, \mathrm{div}\, \boldsymbol{v}) &= (\boldsymbol{f}, \boldsymbol{v}) \quad && \forall \boldsymbol{v} \in \boldsymbol{V}_h, \\ (\mathrm{div}\, \boldsymbol{u}_h, q) &= (g, q) \quad && \forall q \in Q_h. \end{aligned} \tag{3.1}$$

Remark. Below we shall also encounter several examples of nonconforming approximations of (2.4), i.e., the space $\boldsymbol{V}_h \not\subseteq \boldsymbol{H}_0^1$. In all these examples the bilinear form $a_\varepsilon(\cdot, \cdot)$ is understood to be the sum of the corresponding integrals over each element. No extra jump terms are added. The same remark applies to the energy norm, $|\!|\!| \cdot |\!|\!|_\varepsilon$. □

The discretization (3.1) is stable in the sense of [6] if proper discrete analogues of the conditions (2.6) and (2.7) hold. These conditions are the following.

Stability conditions. The discretization (3.1) is said to be uniformly stable if there exist constants $\alpha, \beta > 0$, independent of ε and h, such that

$$\sup_{\boldsymbol{v}\in\boldsymbol{V}_h} \frac{(q, \operatorname{div} \boldsymbol{v})}{|\!|\!|\boldsymbol{v}|\!|\!|_\varepsilon} \geq \alpha \|q\|_0 \quad \forall q \in Q_h \tag{3.2}$$

and

$$a_\varepsilon(\boldsymbol{v}, \boldsymbol{v}) \geq \beta |\!|\!|\boldsymbol{v}|\!|\!|_\varepsilon^2 \quad \forall \boldsymbol{v} \in \boldsymbol{Z}_h, \tag{3.3}$$

where $\boldsymbol{Z}_h = \{\boldsymbol{v} \in \boldsymbol{V}_h : (\operatorname{div} \boldsymbol{v}, q) = 0 \quad \forall q \in Q_h\}$.

For the case $\varepsilon = 1$, or more precisely for ε bounded away from zero, the second condition is obvious. In this case there are several choices of pairs of finite element spaces which satisfy (3.2) with α independent of h. We mention, for example, the Mini element proposed in [1] or the $P_2 - P_0$ element; i.e., we choose continuous quadratic velocities for $\boldsymbol{V}_h$ and the corresponding space of piecewise constants for Q_h; cf. [10]. For a general review of stable Stokes elements we refer the reader to [8].

However, most of these spaces do *not* lead to discretizations which are stable uniformly in ε. The main reason for this is that when ε approaches zero the second condition is no longer obvious. In fact, for the reduced problem with $\varepsilon = 0$ the condition (3.3) requires

$$\|\boldsymbol{v}\|_0^2 \geq \beta \|\boldsymbol{v}\|_{\operatorname{div}}^2 \quad \forall \boldsymbol{v} \in \boldsymbol{Z}_h.$$

Hence, we must have

$$\|\operatorname{div} \boldsymbol{v}\|_0 \leq c \|\boldsymbol{v}\|_0 \quad \forall \boldsymbol{v} \in \boldsymbol{Z}_h \tag{3.4}$$

for a suitable constant c independent of h, and this condition does not hold for the common conforming stable Stokes elements.

Example 3.1. We consider the problem (1.1) with Ω taken as the unit square. The domain is triangulated by first dividing it into $h \times h$ squares. Then, each square is divided into two triangles by the diagonal with a negative slope. The system is then discretized using the $P_2 - P_0$ element with respect to this triangulation; i.e., $\boldsymbol{V}_h \subset \boldsymbol{H}_0^1$ consists of piecewise quadratic functions, while $Q_h \subset L_0^2$ is the space of discontinuous piecewise constants. This discretization is known to be stable when $\varepsilon > 0$ is fixed; cf. [10]. However, our purpose here is to investigate how the convergence behaves as ε becomes small.

We consider the system (1.1) with the function g chosen to be identical zero, while $\boldsymbol{f} = \boldsymbol{u} - \varepsilon^2 \boldsymbol{\Delta} \boldsymbol{u} - \mathbf{grad}\, p$, where $\boldsymbol{u} = \mathbf{curl} \sin^2(\pi x_1) \sin^2(\pi x_2)$ and $p = \sin(\pi x_1)$. Hence, in this example the solution is independent of ε.

In Table 3.1 we have computed the relative L^2 error in the velocity $\boldsymbol{u}$; i.e., $e(h) = \|\boldsymbol{u} - \boldsymbol{u}_h\|_0 / \|\boldsymbol{u}\|_0$ for different values of ε and h. A third order Gauss–Legendre rule (cf. [17]) was used here, and in all the other examples of this section, to perform the necessary integrations. For each fixed ε the convergence rate with respect to h, γ is estimated by assuming $e(h) = ch^\gamma$ and by computing a least squares fit to this log-linear relation.

When $\varepsilon = 1$ the convergence seems to be at least quadratic with respect to h in this case. However, the convergence deteriorates as ε becomes smaller, and for $\varepsilon = 0$ there is no convergence.

Table 3.2 is based on the corresponding relative errors in the energy norm, i.e., the norm $|\!|\!| \cdot |\!|\!|_\varepsilon$ for velocity and the L^2 norm for pressure. For simplicity only the estimated convergence rates are given.

TABLE 3.1
The relative L^2 error in velocity obtained by the $P_2 - P_0$ element.

$\varepsilon \backslash$ h	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1	3.84e-2	4.75e-3	6.41e-4	1.04e-4	2.11e-5	2.72
2^{-2}	6.15e-2	1.73e-2	4.65e-3	1.20e-3	3.05e-4	1.92
2^{-4}	4.55e-1	2.10e-1	6.78e-2	1.86e-2	4.79e-3	1.67
2^{-8}	9.31e-1	9.68e-1	9.43e-1	8.14e-1	5.32e-1	0.19
0	9.35e-1	9.84e-1	1.00	1.01	1.02	-0.03

TABLE 3.2
Estimated convergence rates for the velocity and pressure, measured in the energy norm, for the $P_2 - P_0$ element.

ε	1	2^{-2}	2^{-4}	2^{-8}	0
rate, velocity	1.84	1.01	0.70	-0.79	-1.03
rate, pressure	1.06	1.01	1.09	0.13	-0.20

These results indicate a similar degenerate behavior with respect to ε. In fact, when $\varepsilon = 0$ the norm, $\|\boldsymbol{u}_h\|_\varepsilon$, seems to grow like h^{-1} as h approaches zero. This must be due to the fact that only the projection of $\operatorname{div} \boldsymbol{u}_h$ into piecewise constants is controlled by the method in this case. □

Example 3.2. We repeat the experiment above but with the difference that we use the nonconforming Crouzeix–Raviart element instead of the $P_2 - P_0$ element; i.e., $\boldsymbol{V}_h$ consists of piecewise linear vector fields which are continuous at the midpoint of each edge of the triangulation, while $Q_h \subset L_0^2$ is the space of piecewise constants. It is well known that for any fixed $\varepsilon > 0$ this element leads to a stable discretization; cf. [10].

In Table 3.3 we have again computed the relative L^2 error in the velocity $\boldsymbol{u}$ for different values of ε and h.

TABLE 3.3
The relative L^2 error in velocity obtained by the nonconforming Crouzeix–Raviart element.

$\varepsilon \backslash$ h	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1	1.83e-1	4.89e-2	1.26e-2	3.19e-3	8.02e-4	1.96
2^{-2}	2.19e-1	6.89e-2	1.91e-2	4.96e-3	1.26e-3	1.87
2^{-4}	6.42e-1	3.86e-1	1.53e-1	4.58-2	1.21-3	1.45
2^{-8}	9.51e-1	1.00	1.01	9.43e-1	7.44e-1	0.08
0	9.53e-1	1.01	1.04	1.05	1.06	-0.04

The L^2 convergence appears to be quadratic when ε is large. However, also in this case the convergence deteriorates as ε decreases, and for the reduced problem, with $\varepsilon = 0$, the observed values for the relative error is monotonically increasing.

The corresponding estimates of the convergence rates in the energy norm decreases from approximately linear convergence to no convergence as is shown by Table 3.4.

In fact, the divergence of the Crouzeix–Raviart element in the case $\varepsilon = 0$ is not surprising. Since the divergence-free vector fields in this case can be realized as the curl operator applied to the corresponding Morley space, this behavior of the Crouzeix–Raviart element is closely tied to the divergence of the Morley element for the Poisson equation; cf. [14]. □

TABLE 3.4
Estimated convergence rates for the velocity and pressure, measured in the energy norm, for the Crouzeix–Raviart element.

ε	1	2^{-2}	2^{-4}	2^{-8}	0
rate, velocity	0.98	0.97	0.74	0.03	-0.03
rate, pressure	1.00	0.93	0.98	0.12	-0.03

The two examples above show that the $P_2 - P_0$ element and the nonconforming Crouzeix–Raviart element, which both are known to be stable for $\varepsilon = 1$, fail to give methods which converge uniformly in ε. The divergence of the $P_2 - P_0$ element for $\varepsilon = 0$ is basically due to the fact that the estimate (3.4) does not hold, and therefore the method is unstable, while the divergence of the Crouzeix–Raviart method is caused by the inconsistency of the method.

Example 3.3. We repeat the experiment above once more, but this time the system (1.1) is discretized by using the Mini element; i.e., $\boldsymbol{V}_h \subset \boldsymbol{H}_0^1$ consists of linear combinations of piecewise linear functions and cubic bubble functions with support on a single triangle, while $Q_h \subset L_0^2$ is the space of continuous piecewise linear functions.

In Table 3.5 we have computed the relative error in the velocity, with respect to the energy norm $|||\cdot|||_\varepsilon$, for different values of ε and h.

TABLE 3.5
The relative error in velocity, measured in the energy norm, for the Mini element.

$\varepsilon\backslash$ h	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1	3.01	1.65	8.42e-1	4.22e-1	2.11e-1	0.96
2^{-2}	2.70	1.55	7.80e-1	3.90e-1	1.95e-1	0.96
2^{-4}	3.71	1.67	7.89e-1	3.87e-1	1.92e-1	1.07
2^{-8}	7.32	4.28	2.79	1.64	6.51e-1	0.84
0	7.44	4.76	3.70	3.39	3.30	0.28

When $\varepsilon = 1$ the convergence seems to be linear with respect to h. This agrees with the theoretical results given in [1]. The convergence deteriorates as ε becomes smaller, and for $\varepsilon = 0$ there seems to be essentially no convergence in the energy norm.

An interesting observation can be made for the Mini element if we consider the corresponding errors for the pressure p. In Table 3.6 we study the relative error given by $\|p - p_h\|_0 / \|p\|_0$.

TABLE 3.6
The relative L^2 error in the pressure obtained by the Mini element.

$\varepsilon\backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1	8.78	2.81	8.85e-1	2.95e-1	1.02e-1	1.61
2^{-2}	6.09e-1	1.84e-1	5.62e-2	1.85e-2	6.40e-3	1.64
2^{-4}	6.08e-2	1.51e-2	3.88e-3	1.21e-3	4.07e-4	1.81
2^{-8}	3.58e-2	9.93e-3	2.34e-3	4.10e-4	6.00e-5	2.30
0	3.59e-2	1.02e-2	2.75e-3	7.23e-4	1.87e-4	1.90

The surprising observation is that for the pressure the convergence seems to be uniform with respect to ε. In fact, the convergence rate seems to improve as ε tends

to zero, and for ε small the convergence with respect to h appears to be quadratic. This is a striking difference to what we observed in Examples 3.1 and 3.2. In both these cases the error in the pressure diverges as ε tend to zero; cf. Tables 3.2 and 3.4.

What we have observed here is not special to the present example. The Mini element leads to a discretization which is uniformly stable with respect to ε in a proper ε-dependent norm different from $|||\cdot|||_\varepsilon$. If we define the solution space $\boldsymbol{X}_\varepsilon$ by

$$\boldsymbol{X}_\varepsilon = (\boldsymbol{L}^2 \cap \varepsilon \cdot \boldsymbol{H}_0^1) \times ((\boldsymbol{H}^1 \cap L_0^2) + \varepsilon^{-1} \cdot L^2), \tag{3.5}$$

then it can be shown that the Mini element will in fact produce a uniformly stable discretization in the corresponding energy norm. This norm degenerates to the norm of $\boldsymbol{L}^2 \times H^1$ as ε tends to zero; cf. the discussion in section 2. In order to confirm this behavior we computed the relative error in velocity once more, but this time we used the L^2 norm instead of $|||\cdot|||_\varepsilon$. The results are given in Table 3.7.

TABLE 3.7
The relative L^2 error in velocity obtained by the Mini element.

$\epsilon \backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1	3.54e-1	1.03e-1	2.64e-2	6.60e-3	1.65e-3	1.95
2^{-2}	3.16e-1	8.79e-2	2.20e-2	5.48e-3	1.37e-3	1.97
2^{-4}	1.90e-1	4.60e-2	1.07e-2	2.59e-3	6.42e-4	2.06
2^{-8}	1.81e-1	7.23e-2	2.87e-2	8.70e-3	1.74e-3	1.64
0	1.82e-1	7.66e-2	3.59e-2	1.76e-2	8.75e-3	1.09

We observe that as ε decreases from one to zero the corresponding convergence rate decreases from approximately two to one. However, there is no sign which indicates that the behavior will deteriorate below linear convergence. To complete the picture we have also computed the estimated convergence rates for the pressure in H^1. The results are given in Table 3.8.

TABLE 3.8
Estimated convergence rates for the H^1 error of the pressure obtained by the Mini element.

ε	1	2^{-2}	2^{-4}	2^{-8}	0
rate	0.61	0.64	0.86	0.99	0.99

The estimated convergence rate is clearly below one when $\varepsilon = 1$, while it improves towards one as ε is decreased. This is consistent with the fact that the norm of the pressure component of the product space (3.5) is weaker than the H^1 norm for each $\varepsilon > 0$ but approaches the H^1 norm as ε approaches zero.

The results above seem to confirm that the Mini element leads to a uniformly convergent discretization as long as the error is properly measured. However, as motivated in section 2, in the present paper we are interested in a discretization of the system (1.1) which has a uniform behavior when the error is measured in $(\boldsymbol{H}_0(\mathrm{div}) \cap \varepsilon \cdot \boldsymbol{H}_0^1) \times L_0^2$. Therefore, for our purpose here, the Mini element should not be regarded as a uniformly stable element. ∎

Let us recall that if a standard conforming Stokes element is not uniformly stable with respect to ε, then this instability must be caused by the failure of the second stability condition (3.3) or, equivalently, (3.4). Note that the stability condition (3.4) will be trivially satisfied if the spaces $\boldsymbol{V}_h \times Q_h$ are constructed such that all elements of $\boldsymbol{Z}_h$ are divergence-free, i.e., $\boldsymbol{Z}_h \subset \boldsymbol{Z}$. In fact, nearly all proposed finite element

methods for the reduced problem will have this property. This is, for example, true for the Raviart–Thomas spaces (cf. [15]) and for the Brezzi–Douglas–Marini spaces of [7]. However, in all these cases the spaces $\boldsymbol{V}_h$ will be only a subspace of $\boldsymbol{H}_0(\mathrm{div})$ and not of $\boldsymbol{H}_0^1$, due to the fact that only the normal components of the elements of $\boldsymbol{V}_h$ are required to be continuous across element edges. It is therefore not clear that these spaces will be useful for problems of the form (1.1) with $\varepsilon > 0$.

Example 3.4. We repeat the calculation done in the three examples above, but now we use the lowest order Raviart–Thomas space for the discretization. Hence, for $\varepsilon = 0$ we will expect to obtain linear convergence with respect to h. On the other hand, for $\varepsilon > 0$ the method is nonconforming and there seems to be no reason to expect that the method is convergent in this case. In Table 3.9 we have computed the estimated convergence rates with respect to h for the relative L^2 errors of the velocity $\boldsymbol{u}$ and the pressure p for different values of ε.

TABLE 3.9
Estimated convergence rates for the L^2 errors of the velocity and pressure for the Raviart–Thomas element.

ε	1	2^{-2}	2^{-4}	2^{-8}	0
rate, velocity	-0.07	-0.07	0.28	0.97	0.97
rate, pressure	-0.04	0.08	0.86	1.01	1.01

As expected, the method appears to be divergent for $\varepsilon > 0$. ∎

4. A robust nonconforming finite element space. The four examples presented above illustrate that none of the standard elements proposed for the case $\varepsilon = 1$ or $\varepsilon = 0$ will lead to a discretization of the problem (1.1) with uniform convergence properties with respect to ε, when the error is measured in the norm of the space $(\boldsymbol{H}_0(\mathrm{div}) \cap \varepsilon \cdot \boldsymbol{H}_0^1) \times L_0^2$. The purpose of the rest of this paper is therefore to construct and analyze a new finite element space which has this property.

4.1. The finite element space. In order to describe the new finite element space we will first define the proper polynomial space, or shape functions, on a given triangle. Let $T \subset \mathbb{R}^2$ be a triangle and consider the polynomial space of vector fields on T given by

$$\boldsymbol{V}(T) = \{\boldsymbol{v} \in \mathbb{P}_3^2 : \operatorname{div} \boldsymbol{v} \in \mathbb{P}_0, \quad (\boldsymbol{v} \cdot \boldsymbol{n})|_e \in \mathbb{P}_1 \quad \forall e \in \mathcal{E}(T)\}.$$

Here $\mathbb{P}_k$ denotes the set of polynomials of degree k and $\mathcal{E}(T)$ denotes the set of the edges of T. Furthermore, $\boldsymbol{n}$ is the unit normal vector on the edge e. Below we will also use $\boldsymbol{t}$ to denote the unit tangent vector on e, while τ denotes the arc length along e.

The space $\mathbb{P}_3^2$ is a vector space of dimension 20. Furthermore, the conditions

$$\operatorname{div} \boldsymbol{v} \in \mathbb{P}_0 \quad \text{and} \quad (\boldsymbol{v} \cdot \boldsymbol{n})|_e \in \mathbb{P}_1 \quad \forall e \in \mathcal{E}(T)$$

represent at most 11 linearly independent constraints on this space. Therefore we must have

$$\dim \boldsymbol{V}(T) \geq 9.$$

In fact, we shall show that $\dim \boldsymbol{V}(T) = 9$.

LEMMA 4.1. *The space $\boldsymbol{V}(T)$ is a linear space of dimension nine. Furthermore, an element $\boldsymbol{v} \in \boldsymbol{V}(T)$ is uniquely determined by the following degrees of freedom:*

- $\int_e (\boldsymbol{v}\cdot\boldsymbol{n})\tau^k\,d\tau$, $k=0,1$, *for all* $e\in\mathcal{E}(T)$.
- $\int_e (\boldsymbol{v}\cdot\boldsymbol{t})\,d\tau$ *for all* $e\in\mathcal{E}(T)$.

Proof. Since $\boldsymbol{V}(T)$ is a vector space of dimension ≥ 9 it is enough to show that elements of $\boldsymbol{V}(T)$ are uniquely determined by the given nine degrees of freedom. Assume that $\boldsymbol{v}\in\boldsymbol{V}(T)$ with all the degrees of freedom equal zero. In particular, this implies that

$$(\boldsymbol{v}\cdot\boldsymbol{n})|_{\partial T}\equiv 0.$$

As a consequence of this

$$\int_T \operatorname{div}\boldsymbol{v}\,dx=\int_{\partial T}\boldsymbol{v}\cdot\boldsymbol{n}\,d\tau=0.$$

Hence, since $\operatorname{div}\boldsymbol{v}\in\mathbb{P}_0$, we conclude that $\boldsymbol{v}$ is divergence-free.

However, since $\boldsymbol{v}\in\mathbb{P}_3^2$ is divergence-free we must have $\boldsymbol{v}=\mathbf{curl}\,w$ for a suitable scalar function $w\in\mathbb{P}_4$. Furthermore, since

$$(\mathbf{grad}\,w\cdot\boldsymbol{t})|_e=(\boldsymbol{v}\cdot\boldsymbol{n})|_e=0$$

for each edge e, we conclude that $\mathbf{grad}\,w\cdot\boldsymbol{t}\equiv 0$ on ∂T. Since w is uniquely determined only up to a constant, we can therefore assume that $w\equiv 0$ on ∂T.

Hence, w is of the form $w=pb$, where $p\in\mathbb{P}_1$ and b is the cubic bubble function with respect to T; i.e., $b=\lambda_1\lambda_2\lambda_3$, where $\lambda_i(x)$ are the barycentric coordinates of x with respect to the three corners of T. In particular, $\frac{\partial b}{\partial\boldsymbol{n}}|_e$ does not change sign on e. Furthermore,

$$\left.\frac{\partial w}{\partial\boldsymbol{n}}\right|_{\partial T}=p\left.\frac{\partial b}{\partial\boldsymbol{n}}\right|_{\partial T}$$

and

$$\int_e p\frac{\partial b}{\partial\boldsymbol{n}}\,d\tau=\int_e\frac{\partial w}{\partial\boldsymbol{n}}\,d\tau=\int_e\boldsymbol{v}\cdot\boldsymbol{t}\,d\tau=0\quad\forall e\in\mathcal{E}(T).$$

We can therefore conclude that p has a root in the interior of e. However, if $p\in\mathbb{P}_1$ with a root in the interior of each edge of T, then $p\equiv w\equiv 0$. ∎

Let $\{\mathcal{T}_h\}$ be a shape regular family of triangulations of Ω, where h is the maximal diameter. Furthermore, let $\mathcal{E}_h$ be the set of edges of $\mathcal{T}_h$. Define a finite element space of vector fields $\boldsymbol{V}_h$, associated with the triangulation $\mathcal{T}_h$, as all functions $\boldsymbol{v}\in\boldsymbol{V}_h$ such that

- $\boldsymbol{v}|_T\in\boldsymbol{V}(T)$ for all $T\in\mathcal{T}_h$,
- $\int_e(\boldsymbol{v}\cdot\boldsymbol{n})\tau^k\,d\tau$ is continuous for $k=0,1$ for all $e\in\mathcal{E}_h$,
- $\int_e(\boldsymbol{v}\cdot\boldsymbol{t})\,d\tau$ is continuous for all $e\in\mathcal{E}_h$.

Here we assume that $\boldsymbol{v}$ is extended to be zero outside Ω; i.e., if e is an edge on the boundary of Ω, then we require

$$\int_e(\boldsymbol{v}\cdot\boldsymbol{n})\tau^k\,d\tau=0,\quad k=0,1,\quad\text{and}\quad\int_e(\boldsymbol{v}\cdot\boldsymbol{t})\,d\tau=0.$$

It follows from Lemma 4.1 that any function $\boldsymbol{v}\in\boldsymbol{V}_h$ is uniquely determined by the two lowest order moments of $\boldsymbol{v}\cdot\boldsymbol{n}$ and by the mean value of $\boldsymbol{v}\cdot\boldsymbol{t}$ for all interior edges; cf. Figure 4.1.

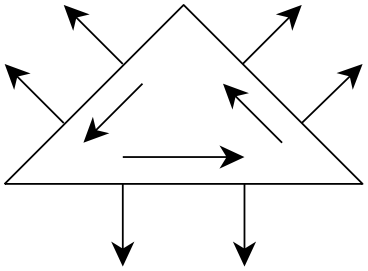

FIG. 4.1. *The degrees of freedom of the new nonconforming element.*

If $\boldsymbol{v} \in \boldsymbol{V}_h$, then the normal component $\boldsymbol{v} \cdot \boldsymbol{n}$ is continuous for all interior edges. Therefore, $\boldsymbol{V}_h \subset \boldsymbol{H}_0(\mathrm{div})$. However, the tangential component of $\boldsymbol{v}$ is not continuous; only the mean value with respect to each edge is continuous. Therefore, $\boldsymbol{V}_h \not\subseteq \boldsymbol{H}_0^1$. In addition to the space $\boldsymbol{V}_h$ we let $Q_h \subset L_0^2$ denote the space of scalar piecewise constants with respect to the triangulation $\mathcal{T}_h$.

In the rest of this paper $\boldsymbol{V}_h$ and Q_h will always refer to the finite element spaces just introduced. The corresponding nonconforming finite element approximation of the system (1.1) is defined by the system (3.1).

4.2. Properties of the new finite element space. It follows from the definition of $\boldsymbol{V}_h$ that $\operatorname{div} \boldsymbol{V}_h \subset Q_h$. Hence, if we define $\boldsymbol{Z}_h \subset \boldsymbol{V}_h$ as the weakly divergence-free elements of $\boldsymbol{V}_h$, i.e.,

$$\boldsymbol{Z}_h = \{\boldsymbol{v} \in \boldsymbol{V}_h : (\operatorname{div} \boldsymbol{v}, q) = 0 \quad \forall q \in Q_h\},$$

then these elements are in fact divergence-free.

Remark. It can be seen that

$$\boldsymbol{Z}_h = \mathbf{curl}\, W_h, \tag{4.1}$$

where W_h is an associated nonconforming H^2-element. Locally, on each triangle, W_h consists of all $\mathbb{P}_4$ polynomials which reduce to a quadratic on each edge. In addition, $W_h \subset H_0^1$ and the average of the normal derivatives of functions in W_h are continuous on each edge. The finite element space W_h is precisely described and analyzed in [14]. The identity (4.1) was actually the main motivation for the construction of the space $\boldsymbol{V}_h$. More precisely, the spaces W_h, $\boldsymbol{V}_h$, and Q_h are related such that the sequence

$$0 \longrightarrow W_h/\mathbb{R} \xrightarrow{\mathbf{curl}} \boldsymbol{V}_h \xrightarrow{\operatorname{div}} Q_h \longrightarrow 0$$

is exact. In particular, $\operatorname{div} \boldsymbol{V}_h = Q_h$. ∎

Define an interpolation operator $\boldsymbol{\Pi}_h : \boldsymbol{H}_0^1 \mapsto \boldsymbol{V}_h$ by

$$\int_e (\boldsymbol{\Pi}_h \boldsymbol{v} \cdot \boldsymbol{n}) \tau^k \, d\tau = \int_e (\boldsymbol{v} \cdot \boldsymbol{n}) \tau^k \, d\tau, \qquad k = 0, 1,$$
$$\int_e (\boldsymbol{\Pi}_h \boldsymbol{v} \cdot \boldsymbol{t}) \, d\tau = \int_e (\boldsymbol{v} \cdot \boldsymbol{t}) \, d\tau$$

for all $e \in \mathcal{E}_h$. In addition, let $P_h : L_0^2 \mapsto Q_h$ be the L^2 projection. From the definition of the operator $\boldsymbol{\Pi}_h$ we easily verify the commutativity property

$$\operatorname{div} \boldsymbol{\Pi}_h \boldsymbol{v} = P_h \operatorname{div} \boldsymbol{v} \quad \forall \boldsymbol{v} \in \boldsymbol{H}_0^1. \tag{4.2}$$

In fact, for all $T \in \mathcal{T}_h$

$$\int_T \operatorname{div} \boldsymbol{\Pi}_h \boldsymbol{v}\, dx = \int_{\partial T} (\boldsymbol{\Pi}_h \boldsymbol{v} \cdot \boldsymbol{n})\, d\tau = \int_{\partial T} (\boldsymbol{v} \cdot \boldsymbol{n})\, d\tau = \int_T \operatorname{div} \boldsymbol{v}\, dx,$$

and hence (4.2) follows.

Since Q_h is the space of piecewise constants the L^2 projection P_h onto Q_h satisfies

$$\|w - P_h w\|_0 \le ch\|w\|_1 \tag{4.3}$$

for all $w \in H^1 \cap L_0^2$, where $c > 0$ is independent of h and w. The operator $\boldsymbol{\Pi}_h$ is well defined on $\boldsymbol{H}_0^1$, it is locally defined on each triangle, and it preserves linear functions locally. Furthermore, the polynomial space $\boldsymbol{V}(T)$ is invariant under affine Piola transformations. More precisely, let $T \in \mathcal{T}_h$ and let $\phi(x) = Bx + c$ be an affine map of T onto a reference triangle $\hat{T}$. Then the Piola transform, $\boldsymbol{v} \mapsto \hat{\boldsymbol{v}}$, where

$$\hat{\boldsymbol{v}}(\hat{x}) = (\det B)^{-1} B v(x), \qquad \hat{x} = \phi(x),$$

maps $\boldsymbol{V}(T)$ onto $\boldsymbol{V}(\hat{T})$. Therefore, approximation estimates for the operator $\boldsymbol{\Pi}_h$ can be derived from standard scaling arguments utilizing the shape regularity of $\{\mathcal{T}_h\}$. In particular, there exists a constant $c > 0$, independent of h, such that

$$\|\boldsymbol{\Pi}_h \boldsymbol{v}\|_{\operatorname{div}} \le \|\boldsymbol{\Pi}_h \boldsymbol{v}\|_{1,h} \le c\|\boldsymbol{v}\|_1. \tag{4.4}$$

In addition, from the Bramble–Hilbert lemma, using the fact that $\boldsymbol{\Pi}_h$ preserves linears locally, we can further conclude that

$$\|\boldsymbol{\Pi}_h \boldsymbol{v} - \boldsymbol{v}\|_{j,h} \le ch^{k-j}|\boldsymbol{v}|_k \quad \text{for } 0 \le j \le 1 \le k \le 2 \tag{4.5}$$

and for all $\boldsymbol{v} \in \boldsymbol{H}_0^1 \cap \boldsymbol{H}^k$. Here $\|\cdot\|_{j,h}$ denotes the piecewise $\boldsymbol{H}^j$-norm

$$\|\boldsymbol{v}\|_{j,h}^2 = \sum_{T \in \mathcal{T}_h} \|\boldsymbol{v}\|_{j,T}^2.$$

In fact, if $\hat{T}$ is a reference triangle, and $\hat{\boldsymbol{\Pi}} : \boldsymbol{H}^1(\hat{T}) \mapsto \boldsymbol{V}(\hat{T})$ the corresponding interpolation operator, then for all $\boldsymbol{v} \in H^1(\hat{T})$

$$\|\hat{\boldsymbol{\Pi}}\boldsymbol{v}\|_{0,\hat{T}} \le c_1\|\boldsymbol{v}\|_{0,\partial\hat{T}} \le c_2\|\boldsymbol{v}\|_{0,\hat{T}}^{1/2}\|\boldsymbol{v}\|_{1,\hat{T}}^{1/2},$$

where c_1 and c_2 depend only on $\hat{T}$. Hence, from a scaling argument we also obtain the low order estimate

$$\|\boldsymbol{\Pi}_h \boldsymbol{v} - \boldsymbol{v}\|_0 \le ch^{1/2}\|\boldsymbol{v}\|_0^{1/2}\|\boldsymbol{v}\|_1^{1/2} \tag{4.6}$$

for all $\boldsymbol{v} \in \boldsymbol{H}_0^1$.

Next we will verify the stability conditions (3.2) and (3.3) for the product space $\boldsymbol{V}_h \times Q_h$. However, due to the fact that we are considering a nonconforming finite element approximation of the system (1.1), where $\boldsymbol{V}_h \not\subseteq \boldsymbol{H}_0^1$, the norm $|||\cdot|||_\varepsilon$ has to be properly modified. For each $\boldsymbol{v} \in \boldsymbol{V}_h$ we define

$$|||\boldsymbol{v}|||_{\varepsilon,h}^2 = \|\boldsymbol{v}\|_{\operatorname{div}}^2 + \varepsilon^2 \sum_{T \in \mathcal{T}_h} \|\boldsymbol{D}\boldsymbol{v}\|_{0,T}^2.$$

Note that for $\varepsilon = 0$ this norm is simply equal to $\|\cdot\|_{\mathrm{div}}$, while for $\varepsilon = 1$ it is equivalent, uniformly in h, to the piecewise $\boldsymbol{H}^1$-norm $\|\cdot\|_{1,h}$.

LEMMA 4.2. *There exists a constant $\alpha_1 > 0$, independent of h, such that*

$$\sup_{\boldsymbol{v}\in\boldsymbol{V}_h} \frac{(q, \operatorname{div} \boldsymbol{v})}{\|\boldsymbol{v}\|_{1,h}} \geq \alpha_1 \|q\|_0 \quad \forall q \in Q_h.$$

Proof. This follows by a standard argument from the properties of the interpolation operator $\boldsymbol{\Pi}_h$ and the corresponding continuous result (2.6). In fact, since for any $\boldsymbol{v} \in \boldsymbol{H}_0^1$ and $q \in Q_h$ we have

$$(q, \operatorname{div} \boldsymbol{\Pi}_h \boldsymbol{v}) = (q, \operatorname{div} \boldsymbol{v})$$

and

$$\|\boldsymbol{\Pi}_h \boldsymbol{v}\|_{1,h} \leq c_1 \|\boldsymbol{v}\|_1,$$

we can take $\alpha_1 = \alpha_0/c_1$. ∎

The following uniform stability result is an immediate consequence of the previous lemma.

THEOREM 4.1. *The pair of spaces $(\boldsymbol{V}_h, Q_h)$ satisfies the uniform stability conditions* (3.2) *and* (3.3) *but with the norm $|||\cdot|||_\varepsilon$ replaced by $|||\cdot|||_{\varepsilon,h}$.*

Proof. The norms $|||\cdot|||_{1,h}$ and $\|\cdot\|_{1,h}$ are equivalent on $\boldsymbol{V}_h$, and $|||\cdot|||_{\varepsilon,h}$ decreases as ε decreases. It follows from Lemma 4.2 that condition (3.2) holds. Since $\boldsymbol{Z}_h \subset \boldsymbol{Z}$ the second condition (3.3) holds with $\beta = 1$. ∎

5. Error estimates for smooth solutions. Since our new finite element space $(\boldsymbol{V}_h, Q_h)$ satisfies the proper stability conditions (3.2) and (3.3), uniformly with respect to ε, it seems probable that the corresponding finite element method will in fact have uniform convergence properties. In the present section we shall investigate this question under the assumption that the solution (u, p) of the continuous problem is sufficiently smooth, while the effect of the ε-dependent boundary layers will be taken into account in the next section.

We will start the discussion here with a numerical example which is completely similar to Examples 3.1–3.3.

Example 5.1. We redo the computations done in Examples 3.1–3.3, but this time we use the finite element spaces constructed above. In all the numerical examples with the new element we used a fifth order Gauss–Legendre method (cf. [17]) as integration rule.

In Table 5.1 we have computed the estimated convergence rates with respect to h for the velocity and the pressure.

TABLE 5.1
Estimated convergence rates for the velocity and the pressure for the new nonconforming element.

ε	1	2^{-2}	2^{-4}	2^{-8}	0
rate, velocity in L^2	1.93	1.94	1.94	1.90	1.92
rate, velocity in $\|\|\|\cdot\|\|\|_\varepsilon$	0.98	0.99	1.05	1.72	1.92
rate, pressure in L^2	0.98	1.00	1.00	1.00	1.00

We observe that the convergence rates in L^2 appear to be close to quadratic in velocity and linear in pressure uniformly with respect to $\varepsilon \in [0, 1]$, while the

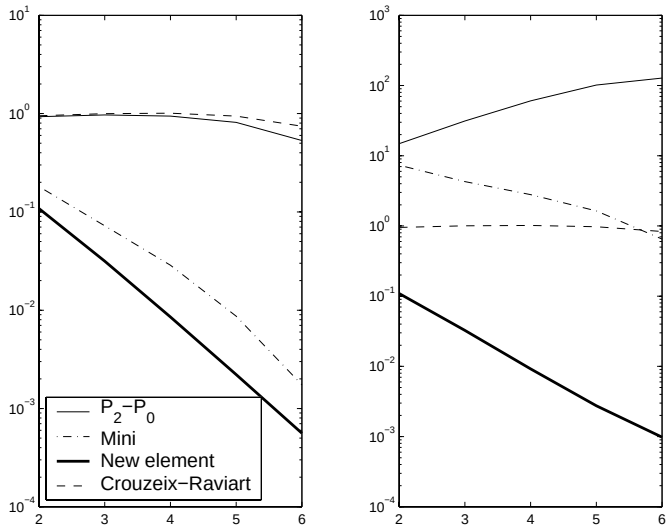

FIG. 5.1. *The errors in velocity, measured in the L^2 norm and the energy norm, as functions of $\sigma = -\log(h)/\log(2)$.*

convergence in the energy norm appears to be at least linear for each $\varepsilon > 0$. In fact, as ε approaches zero the convergence rate tends to two. This improved convergence is partly due to the fact that the exact solution $\boldsymbol{u}$ is divergence-free in this case.

To make a direct comparison between the $P_2 - P_0$ element, the Crouzeix–Raviart element, the Mini element, and the new element when ε is small compared to h, we have plotted the errors in velocity for the different methods as functions of σ, where $h = 2^{-\sigma}$. Here we have chosen $\varepsilon = 2^{-8}$. The errors are plotted, in a logarithmic scale, in Figure 5.1.

To the left the L^2 errors are plotted, while the errors in the energy norm are depicted to the right. We observe that the Mini element and the new element behave comparably with respect to the L^2 norm, while the new element clearly is superior to all the other methods with respect to the energy norm. ∎

The rest of this section will be devoted to establishing error estimates for the new nonconforming finite element method. Throughout this section we will assume that $\boldsymbol{u} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$, where $(\boldsymbol{u}, p)$ is the weak solution of (2.4). For convenience we also introduce the notation $\|\cdot\|_a$ for the norm on $\boldsymbol{V}_h$ associated with the bilinear form a_ε, i.e.,

$$\|\boldsymbol{v}\|_a^2 = \|\boldsymbol{v}\|_0^2 + \sum_{T \in \mathcal{T}_h} \|\boldsymbol{D}\boldsymbol{v}\|_{0,T}^2.$$

For any $\boldsymbol{v} \in \boldsymbol{V}_h$, we define the consistency error $E_{\varepsilon,h}(\boldsymbol{u}, \boldsymbol{v})$ by

$$E_{\varepsilon,h}(\boldsymbol{u}, \boldsymbol{v}) = \varepsilon^2 \sum_{e \in \mathcal{E}_h} \int_e (\operatorname{rot} \boldsymbol{u}) \ [\boldsymbol{v} \cdot \boldsymbol{t}] \, d\tau.$$

Here, if T_- and T_+ are two triangles, sharing an edge e, then $[w] = [w]_e = w|_{T_+} - w|_{T_-}$ denotes the jump of w across e, while $\boldsymbol{t}$ is the unit tangent vector along e corresponding to the clockwise direction on T_+. Since $[\boldsymbol{v} \cdot \boldsymbol{n}]_e = 0$ for any $\boldsymbol{v} \in \boldsymbol{V}_h$ it follows from

(2.2) and Green's theorem, in particular from (2.1), that

$$\begin{aligned} a_\varepsilon(\boldsymbol{u},\boldsymbol{v}) + (p, \operatorname{div}\boldsymbol{v}) &= (\boldsymbol{f},\boldsymbol{v}) + E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v}) \quad && \forall \boldsymbol{v} \in \boldsymbol{V}_h, \\ (\operatorname{div}\boldsymbol{u}, q) &= (g, q) && \forall q \in L^2_0, \end{aligned} \tag{5.1}$$

where the term $E_{\varepsilon,h}$ appears due to the fact that $\boldsymbol{V}_h \not\subseteq \boldsymbol{H}^1_0$.

In the error analysis below we will need proper estimates on the consistency error $E_{\varepsilon,h}$. The following bounds are therefore useful.

LEMMA 5.1. *If $\boldsymbol{u} \in \boldsymbol{H}^2 \cap \boldsymbol{H}^1_0$, then*

$$\sup_{\boldsymbol{v}\in\boldsymbol{V}_h} \frac{|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})|}{\|\boldsymbol{v}\|_a} \le c\,\varepsilon \begin{cases} h\|\operatorname{rot}\boldsymbol{u}\|_1, \\ h^{1/2}\|\operatorname{rot}\boldsymbol{u}\|_1^{1/2}\|\operatorname{rot}\boldsymbol{u}\|_0^{1/2}, \end{cases}$$

where $c > 0$ is independent of ε and h.

Proof. Let $e \in \mathcal{E}_h$ and $\boldsymbol{v} \in \boldsymbol{H}^1_0 + \boldsymbol{V}_h$. Since the mean value with respect to e of $\boldsymbol{v}\cdot\boldsymbol{t}$ is zero, it follows from a standard scaling argument (cf., for example, [5, section 8.3] or [14, section 4] for similar arguments) that for any $\phi \in H^1$

$$\begin{aligned} \textstyle\int_e \phi[\boldsymbol{v}\cdot\boldsymbol{t}]d\tau &\le \inf_{\lambda,\mu\in\mathbb{R}} \|\phi-\lambda\|_{0,e}\|[\boldsymbol{v}\cdot\boldsymbol{t}-\mu]\|_{0,e} \\ &\le \begin{cases} ch|\phi|_{1,\Omega_e}(|\boldsymbol{v}|_{1,T_-}+|\boldsymbol{v}|_{1,T_+}), \\ ch^{1/2}|\phi|^{1/2}_{1,\Omega_e}\|\phi\|^{1/2}_{0,\Omega_e}(|\boldsymbol{v}|_{1,T_-}+|\boldsymbol{v}|_{1,T_+}). \end{cases} \end{aligned} \tag{5.2}$$

Here T_- and T_+ denote the two triangles meeting the edge e and $\Omega_e = T_- \cup T_+$. Since

$$|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})| \le \varepsilon^2 \sum_{e\in\mathcal{E}_h} \left| \int_e (\operatorname{rot}\boldsymbol{u})\ [\boldsymbol{v}\cdot\boldsymbol{t}]\, d\tau \right|,$$

the desired estimate follows by applying the estimate (5.2) with $\phi = \operatorname{rot}\boldsymbol{u}$, summing over all edges, and using the fact that

$$\sum_{e\in\mathcal{E}_h} |\boldsymbol{v}|^2_{1,T} \le \varepsilon^{-2} a_\varepsilon(\boldsymbol{v},\boldsymbol{v}). \qquad \square$$

Let $(\boldsymbol{u}_h, p_h) \in \boldsymbol{V}_h \times Q_h$ be the approximation of $(\boldsymbol{u}, p)$ derived from the discrete system (3.1). From (3.1) and (5.1) we obtain

$$a_\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h,\boldsymbol{v}) + (p-p_h, \operatorname{div}\boldsymbol{v}) = E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v}) \tag{5.3}$$

for all $\boldsymbol{v} \in \boldsymbol{V}_h$. Furthermore,

$$\operatorname{div}\boldsymbol{u}_h = P_h \operatorname{div}\boldsymbol{u} = \operatorname{div}\boldsymbol{\Pi}_h\boldsymbol{u}.$$

Therefore, taking $\boldsymbol{v} = \boldsymbol{\Pi}_h\boldsymbol{u} - \boldsymbol{u}_h$ in (5.3) we obtain

$$a_\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h, \boldsymbol{\Pi}_h\boldsymbol{u}-\boldsymbol{u}_h) = E_{\varepsilon,h}(\boldsymbol{u}, \boldsymbol{\Pi}_h\boldsymbol{u}-\boldsymbol{u}_h).$$

Since a_ε is an inner product we further have

$$\begin{aligned} \|\boldsymbol{\Pi}_h\boldsymbol{u}-\boldsymbol{u}_h\|^2_a &\le \|\boldsymbol{u}-\boldsymbol{\Pi}_h\boldsymbol{u}\|^2_a + 2a_\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h, \boldsymbol{\Pi}_h\boldsymbol{u}-\boldsymbol{u}_h) \\ &\le \|\boldsymbol{u}-\boldsymbol{\Pi}_h\boldsymbol{u}\|^2_a + 2E_{\varepsilon,h}(\boldsymbol{u}, \boldsymbol{\Pi}_h\boldsymbol{u}-\boldsymbol{u}_h). \end{aligned}$$

Hence, we conclude that

$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_a \le 2\left(\|\boldsymbol{u}-\boldsymbol{\Pi}_h\boldsymbol{u}\|_a + \sup_{\boldsymbol{v}\in\boldsymbol{V}_h}\frac{|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})|}{\|\boldsymbol{v}\|_a}\right). \tag{5.4}$$

From this basic bound we easily derive the following error estimate.

THEOREM 5.1. *If $\boldsymbol{u}\in\boldsymbol{H}^2\cap\boldsymbol{H}_0^1$ and $p\in H^1\cap L_0^2$, then the following estimates hold:*

$$\begin{aligned}\|\boldsymbol{u}-\boldsymbol{u}_h\|_0+\varepsilon\|\operatorname{rot}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 &\le c(h^2+\varepsilon h)\|\boldsymbol{u}\|_2,\\ \|\operatorname{div}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 &\le ch\|\operatorname{div}\boldsymbol{u}\|_1,\\ \|p-p_h\|_0 &\le ch(\|p\|_1+(\varepsilon+h)\|\boldsymbol{u}\|_2).\end{aligned}$$

Here $c>0$ is a constant independent of ε and h.

Remark. Here, and below, the differential operators $\boldsymbol{D}$ and rot, applied to vector fields in $\boldsymbol{V}_h$, are defined locally on each triangle of the triangulation $\mathcal{T}_h$. ∎

Proof. The first estimate is a direct consequence of (4.5), (5.4), and Lemma 5.1. The second estimate follows from the bound (4.3) and the fact that $\operatorname{div}\boldsymbol{u}_h = P_h\operatorname{div}\boldsymbol{u}$.

In order to establish the third estimate we first observe that (4.3) implies that

$$\|p-P_hp\|_0 \le ch\|p\|_1. \tag{5.5}$$

Hence, it remains only to estimate P_hp-p_h. However, from the modified inf-sup condition (3.2) (cf. Theorem 4.1) we obtain

$$\|P_hp-p_h\|_0 \le \alpha^{-1}\sup_{\boldsymbol{v}\in\boldsymbol{V}_h}\frac{(P_hp-p_h,\operatorname{div}\boldsymbol{v})}{|\!|\!|\boldsymbol{v}|\!|\!|_{\varepsilon,h}}.$$

Furthermore, for any $\boldsymbol{v}\in\boldsymbol{V}_h$ we have

$$\begin{aligned}(P_hp-p_h,\operatorname{div}\boldsymbol{v}) &= (p-p_h,\operatorname{div}\boldsymbol{v})\\ &= -a_\varepsilon(\boldsymbol{u}-\boldsymbol{u}_h,\boldsymbol{v})+E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v}),\end{aligned}$$

which implies that

$$|(P_hp-p_h,\operatorname{div}\boldsymbol{v})| \le \left(\|\boldsymbol{u}-\boldsymbol{u}_h\|_a+\sup_{\boldsymbol{v}\in\boldsymbol{V}_h}\frac{|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})|}{\|\boldsymbol{v}\|_a}\right)|\!|\!|\boldsymbol{v}|\!|\!|_{\varepsilon,h}$$

or

$$\|P_hp-p_h\|_0 \le \alpha^{-1}\left(\|\boldsymbol{u}-\boldsymbol{u}_h\|_a+\sup_{\boldsymbol{v}\in\boldsymbol{V}_h}\frac{|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})|}{\|\boldsymbol{v}\|_a}\right). \tag{5.6}$$

From the previous estimates we therefore obtain

$$\|P_hp-p_h\|_0 \le c(h^2+\varepsilon h)\|\boldsymbol{u}\|_2,$$

and together with (5.5) this establishes the desired estimate on the error $\|p-p_h\|_0$. ∎

Remark. As an alternative to the estimates given in Theorem 5.1 we can also obtain

$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_0+\varepsilon\|\operatorname{rot}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 \le ch(\|\boldsymbol{u}\|_1+\varepsilon\|\boldsymbol{u}\|_2) \tag{5.7}$$

and

$$\|p - p_h\|_0 \leq ch(\|p\|_1 + \|\boldsymbol{u}\|_1 + \varepsilon\|\boldsymbol{u}\|_2). \tag{5.8}$$

These modifications are obtained if we use the estimate

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u}\|_0 \leq ch\|\boldsymbol{u}\|_1,$$

obtained from (4.5), in (5.4) instead of the corresponding quadratic estimate. Even if the modified estimates are weaker for uniformly smooth solutions, they are sometimes preferable for more singular solutions. □

6. Boundary layers and uniform error estimates. In general, we cannot expect that the norm $\|\boldsymbol{u}\|_2$ of the solution of (1.1) is bounded independently of ε. In fact, as ε approaches zero even $\|\operatorname{rot} \boldsymbol{u}\|_0$ should be expected to blow up. Hence, the convergence estimates given in Theorem 5.1 will deteriorate as ε becomes small. The following example shows that this behavior of the error is in fact real.

Example 6.1. In this example we study the convergence for an ε-dependent solution. Let $\boldsymbol{u} = \varepsilon \operatorname{\mathbf{curl}} e^{-x_1 x_2/\varepsilon}$, $p = \varepsilon e^{-x_1/\varepsilon}$, $\boldsymbol{f} = \boldsymbol{u} - \varepsilon^2 \boldsymbol{\Delta} \boldsymbol{u} - \operatorname{\mathbf{grad}} p$, and let g be identical zero. In fact, $\boldsymbol{u}$ is not the solution of the corresponding system (1.1), since the boundary conditions are not satisfied. However, the adaption of the new method to nonhomogeneous boundary conditions is straightforward.

The significance of the solution $\boldsymbol{u}$ just given is related to the fact that the quantities $\|\operatorname{rot} \boldsymbol{u}\|_0$ and $\varepsilon\|\operatorname{rot} \boldsymbol{u}\|_1$ both are of order $\varepsilon^{-1/2}$ as ε tends to zero. As we will see in Lemma 6.1, this behavior is typical for solutions of the singular perturbation problem (1.1). For solutions with this singular behavior the estimates (5.7) and (5.8) lead to error bounds of the form

$$|||\boldsymbol{u} - \boldsymbol{u}_h|||_\varepsilon, \|p - p_h\|_0 \leq ch\varepsilon^{-1/2}, \tag{6.1}$$

where c is a constant independent of ε and h. In Table 6.1 we have computed the absolute error $|||\boldsymbol{u} - \boldsymbol{u}_h|||_\varepsilon$ for different values of ε and h. For each fixed ε the convergence rate with respect to h is estimated.

TABLE 6.1
The absolute error in velocity, measured in the energy norm, obtained by the new nonconforming element.

$\varepsilon \backslash$ h	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
2^{-2}	7.29e-2	3.60e-2	1.77e-2	8.75e-3	4.36e-3	0.98
2^{-6}	8.89e-2	5.88e-2	3.71e-2	2.06e-2	1.05e-2	0.77
2^{-8}	1.12e-1	6.89e-2	4.07e-2	2.66e-2	1.73e-2	0.67
2^{-10}	1.17e-1	8.16e-2	5.48e-2	3.34e-2	1.93e-2	0.65
2^{-12}	1.17e-1	8.20e-2	5.74e-2	4.02e-2	2.71e-2	0.52

We observe that for ε sufficiently large the convergence rate is approximately one, but the estimated rate decreases when ε approaches zero. These results seem to confirm the claim that the convergence is linear with respect to h for each fixed ε. However, when h is sufficiently large compared to ε we do not observe this linear rate.

In Table 6.2 we give the corresponding absolute L^2 errors for the pressure.

Again the estimated convergence rate is approximately one for ε large. Then it starts to decrease with ε as in Table 6.1. However, in this case the convergence rate

TABLE 6.2
The absolute L^2 error in the pressure obtained by the new nonconforming element.

$\varepsilon\backslash$ h	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
2^{-2}	2.32e-2	1.11e-2	5.36e-3	2.64e-3	1.31e-3	1.04
2^{-6}	9.00e-3	5.33e-3	2.62e-3	1.15e-3	4.61e-4	1.07
2^{-8}	5.28e-3	3.24e-3	2.18e-3	1.23e-3	5.97e-4	0.77
2^{-10}	4.93e-3	2.54e-3	1.33e-3	7.93e-4	5.32e-4	0.81
2^{-12}	4.92e-3	2.51e-3	1.24e-3	6.22e-4	3.27e-4	0.98

increases roughly back to one when ε is superclose to zero. We will comment on this phenomenon for the error of the pressure at the end of this section.

The estimate (6.1) does not imply uniform convergence with respect to ε for our new finite element method. However, as a consequence of the theory below, we will obtain an improved estimate of the form

$$|||\boldsymbol{u}-\boldsymbol{u}_h|||_\varepsilon, \|p-p_h\|_0 \le c\min(h^{1/2}, h\varepsilon^{-1/2}) \tag{6.2}$$

for solutions with a singular behavior similar to the solution $\boldsymbol{u}$ studied here. Note that this is in fact consistent with the results of Tables 6.1 and 6.2, where we never observe a convergence rate below a half. □

The main purpose of this section is to establish error estimates which are uniform with respect to the perturbation parameter ε. We shall show a uniform $O(h^{1/2})$ error estimate in the energy norm. We observe that if $g \in H^1 \cap L_0^2$, then it follows directly from Theorem 5.1 that

$$\|\operatorname{div}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 \le c\,h\|g\|_1, \tag{6.3}$$

where the constant c is independent of ε and h. Hence, we have uniform linear convergence for the error of the divergence. In contrast to this, the remaining part of the error will be affected by boundary layers as ε becomes small. However, the following uniform convergence estimate will be derived.

THEOREM 6.1. *If $\boldsymbol{f} \in \boldsymbol{H}(\mathrm{rot})$ and $g \in H_+^1$, then there is a constant c, independent of $\boldsymbol{f}$, g, ε, and h, such that*

$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_0 + \varepsilon\|\operatorname{rot}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 + \|p-p_h\|_0 \le c\,h^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}).$$

Here the Sobolev space H_+^1 is a space contained in H^1, with an associated norm, $\|\cdot\|_{1,+}$, slightly stronger than $\|\cdot\|_1$. This space will be precisely defined below.

The derivation of the uniform error estimate above will depend heavily on certain regularity estimates for the solution of the system (1.1). For example, we shall estimate the blowup of $\|\operatorname{rot}\boldsymbol{u}\|_1$ as ε approaches zero. We shall therefore first derive these regularity estimates.

For convenience of the reader we repeat the system (1.1):

$$\begin{aligned} (\boldsymbol{I}-\varepsilon^2\boldsymbol{\Delta})\boldsymbol{u} - \mathbf{grad}\,p &= \boldsymbol{f} \quad \text{in } \Omega,\\ \operatorname{div}\boldsymbol{u} &= g \quad \text{in } \Omega,\\ \boldsymbol{u} &= 0 \quad \text{on } \partial\Omega. \end{aligned} \tag{6.4}$$

We also repeat that the domain Ω is a polygonal domain in $\mathbb{R}^2$. In fact, in the discussion of this section we shall assume that Ω in addition is *convex*. If $\varepsilon \in (0,1]$,

$\boldsymbol{f} \in \boldsymbol{L}^2$, and $g = 0$, then the corresponding weak solution admits the additional regularity that $(\boldsymbol{u}, p) \in (\boldsymbol{H}_0^1 \times L_0^2) \cap (\boldsymbol{H}^2 \times H^1)$. This regularity result follows directly from the result for the corresponding Stokes problem on a convex domain which can be found in [12, Corollary 7.3.3.5]. In fact, the same regularity holds for $g \neq 0$ if we restrict the data g to the space H_+^1.

In order to define this space let $x_1, x_2, \ldots, x_N \in \partial\Omega$ denote the vertices of Ω. The space H_+^1 is given by

$$H_+^1 = \left\{ g \in H^1 \cap L_0^2 : \int_\Omega \frac{|g(x)|^2}{|x - x_j|^2}\, dx < \infty,\ j = 1, 2, \ldots, N \right\},$$

with associated norm

$$\|g\|_{1,+}^2 = \|g\|_1^2 + \sum_{j=1}^{N} \int_\Omega \frac{|g(x)|^2}{|x - x_j|^2}\, dx.$$

Hence, functions in H_+^1 vanish weakly at each vertex of Ω.

It is established in [2] that

$$\operatorname{div}(\boldsymbol{H}^2 \cap \boldsymbol{H}_0^1) = H_+^1.$$

Furthermore, the divergence operator has a bounded right inverse, $\boldsymbol{R} : H_+^1 \mapsto \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$; i.e., $\operatorname{div} \boldsymbol{R}g = g$ for all $g \in H_+^1$ and

$$\|\boldsymbol{R}g\|_2 \leq c\|g\|_{1,+}.$$

Note that if $(\boldsymbol{u}, p)$ solves (6.4), then $(\boldsymbol{u} - \boldsymbol{R}g, p)$ solves a corresponding problem with $g = 0$. From the result in the case $g = 0$ we can therefore conclude that $(\boldsymbol{u}, p) \in (\boldsymbol{H}_0^1 \times L_0^2) \cap (\boldsymbol{H}^2 \times H^1)$ for any $(\boldsymbol{f}, g) \in \boldsymbol{L}^2 \times H_+^1$.

The following result gives an upper bound for the blowup of the norm $\|\operatorname{rot} \boldsymbol{u}\|_1$ as ε tends to zero.

LEMMA 6.1. *Assume that $\boldsymbol{f} \in \boldsymbol{H}(\mathrm{rot})$, $g \in H_+^1$, and let $(\boldsymbol{u}, p)$ be the corresponding solution of* (6.4). *There exists a constant $c > 0$, independent of ε, $\boldsymbol{f}$ and g, such that*

$$\varepsilon^{1/2} \|\operatorname{rot} \boldsymbol{u}\|_0 + \varepsilon^{3/2} \|\operatorname{rot} \boldsymbol{u}\|_1 \leq c\, (\|\operatorname{rot} \boldsymbol{f}\|_0 + \|g\|_{1,+}). \tag{6.5}$$

Proof. We first construct a function $\hat{\boldsymbol{u}} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$ such that

$$\operatorname{div} \hat{\boldsymbol{u}} = g \quad \text{and} \quad \operatorname{rot} \boldsymbol{\Delta} \hat{\boldsymbol{u}} = 0. \tag{6.6}$$

In fact, the function $\hat{\boldsymbol{u}}$ can be constructed by defining

$$\hat{\boldsymbol{u}} = \boldsymbol{R}g + \mathbf{curl}\, \psi,$$

with $\psi \in H_0^2$ being the weak solution of the biharmonic equation

$$\begin{aligned} \Delta^2 \psi &= \operatorname{rot} \boldsymbol{\Delta} \boldsymbol{R} g \qquad \text{in } \Omega, \\ \psi &= \frac{\partial \psi}{\partial \boldsymbol{n}} = 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

We observe that, since $\boldsymbol{R}g \in \boldsymbol{H}^2$, the right-hand side is in H^{-1}. Therefore, from the regularity of solutions of the biharmonic equation on convex domains (cf. [12,

Theorem 7.2.2.3]), we have that $\psi \in H^3$, and $\|\psi\|_3 \le c\|\operatorname{rot} \boldsymbol{\Delta R} g\|_{-1}$. Hence, $\hat{\boldsymbol{u}} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$, and

$$\|\hat{\boldsymbol{u}}\|_2 \le c\,\|g\|_{1,+}. \tag{6.7}$$

Furthermore, clearly $\operatorname{div} \hat{\boldsymbol{u}} = \operatorname{div} \boldsymbol{R} g = g$, and for any $\mu \in C_0^\infty$ we have

$$(\boldsymbol{\Delta}\hat{\boldsymbol{u}}, \mathbf{curl}\,\mu) = (\boldsymbol{\Delta R} g, \mathbf{curl}\,\mu) - (\Delta\psi, \Delta\mu) = 0.$$

Hence, the second property in (6.6) also holds.

Define $\boldsymbol{v} = \boldsymbol{u} - \hat{\boldsymbol{u}}$. Then $(\boldsymbol{v}, p) \in (\boldsymbol{H}_0^1 \times L_0^2) \cap (\boldsymbol{H}^2 \times H^1)$ is the weak solution of the problem

$$\begin{aligned} (\boldsymbol{I} - \varepsilon^2\boldsymbol{\Delta})\boldsymbol{v} - \mathbf{grad}\, p &= \hat{\boldsymbol{f}} && \text{in } \Omega, \\ \operatorname{div} \boldsymbol{v} &= 0 && \text{in } \Omega, \\ \boldsymbol{v} &= 0 && \text{on } \partial\Omega, \end{aligned} \tag{6.8}$$

where $\hat{\boldsymbol{f}} = \boldsymbol{f} + \varepsilon^2\boldsymbol{\Delta}\hat{\boldsymbol{u}} - \hat{\boldsymbol{u}}$. Clearly, $\hat{\boldsymbol{f}} \in \boldsymbol{L}^2$. In fact, $\hat{\boldsymbol{f}} \in \boldsymbol{H}(\mathrm{rot})$, since

$$\operatorname{rot} \hat{\boldsymbol{f}} = \operatorname{rot} \boldsymbol{f} - \operatorname{rot} \hat{\boldsymbol{u}}.$$

Furthermore, there is a constant c, independent of ε, $\boldsymbol{f}$ and g, such that

$$\|\operatorname{rot} \hat{\boldsymbol{f}}\|_0 \le c\,(\|\operatorname{rot} \boldsymbol{f}\|_0 + \|g\|_{1,+}). \tag{6.9}$$

Since $\boldsymbol{v} \in \boldsymbol{L}^2$ and $\operatorname{div} \boldsymbol{v} = 0$ there exists $\phi \in H^1$, uniquely determined up to a constant, such that $\boldsymbol{v} = \mathbf{curl}\,\phi$ [11, Theorem I.3.1]. Hence, since $\boldsymbol{v} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$, we can choose $\phi \in H^3 \cap H_0^2$. In fact, by applying the rot operator, as a map from $\boldsymbol{L}^2$ to H^{-1}, to the first equation of (6.8) we obtain

$$\begin{aligned} -\Delta\phi + \varepsilon^2\Delta^2\phi &= \operatorname{rot} \hat{\boldsymbol{f}} && \text{in } \Omega, \\ \phi = \frac{\partial\phi}{\partial \boldsymbol{n}} &= 0 && \text{on } \partial\Omega. \end{aligned}$$

The function ϕ is uniquely determined by this problem. This singular perturbation problem was in fact studied in [14], where it was established that [14, Lemma 5.1]

$$\varepsilon^{1/2}\|\phi\|_2 + \varepsilon^{3/2}\|\phi\|_3 \le c\|\operatorname{rot} \hat{\boldsymbol{f}}\|_0,$$

and as a consequence

$$\varepsilon^{1/2}\|\operatorname{rot} \boldsymbol{v}\|_0 + \varepsilon^{3/2}\|\operatorname{rot} \boldsymbol{v}\|_1 \le c\|\operatorname{rot} \hat{\boldsymbol{f}}\|_0.$$

Therefore, since $\boldsymbol{u} = \boldsymbol{v} + \hat{\boldsymbol{u}}$, (6.7) and (6.9) imply

$$\begin{aligned} \varepsilon^{1/2}\|\operatorname{rot} \boldsymbol{u}\|_0 + \varepsilon^{3/2}\|\operatorname{rot} \boldsymbol{u}\|_1 &\le c\|\operatorname{rot} \hat{\boldsymbol{f}}\|_0 + \varepsilon^{1/2}(\|\operatorname{rot} \hat{\boldsymbol{u}}\|_0 + \varepsilon\|\operatorname{rot} \hat{\boldsymbol{u}}\|_1) \\ &\le c(\|\operatorname{rot} \boldsymbol{f}\|_0 + \|g\|_{1,+}). \end{aligned}$$

This completes the proof. ∎

In addition to the ε-dependent bound on the solution $(\boldsymbol{u}, p)$ of (6.4) derived above, we shall also need convergence estimates on how fast these solutions converge to the solution of the reduced system.

The reduced system corresponding to (6.4) is of the form

$$\begin{aligned} \boldsymbol{u}^0 - \mathbf{grad}\, p^0 &= \boldsymbol{f} && \text{in } \Omega, \\ \operatorname{div} \boldsymbol{u}^0 &= g && \text{in } \Omega, \\ \boldsymbol{u}^0 \cdot \boldsymbol{n} &= 0 && \text{on } \partial\Omega. \end{aligned} \tag{6.10}$$

A precise weak formulation of this system is given by the following:

Find $(\boldsymbol{u}^0, p^0) \in \boldsymbol{H}_0(\operatorname{div}) \times L^2_0$ such that

$$\begin{aligned} (\boldsymbol{u}^0, \boldsymbol{v}) + (p^0, \operatorname{div} \boldsymbol{v}) &= (\boldsymbol{f}, \boldsymbol{v}) && \forall \boldsymbol{v} \in \boldsymbol{H}_0(\operatorname{div}), \\ (\operatorname{div} \boldsymbol{u}^0, q) &= (g, q) && \forall q \in L^2_0. \end{aligned} \tag{6.11}$$

If $(\boldsymbol{f}, g) \in \boldsymbol{H}^{-1}(\operatorname{rot}) \times L^2_0$, then this system admits a unique solution. In fact, if $\boldsymbol{f} \in \boldsymbol{H}(\operatorname{rot})$, then $\boldsymbol{u}^0 \in \boldsymbol{H}(\operatorname{rot})$ with $\operatorname{rot} \boldsymbol{u}^0 = \operatorname{rot} \boldsymbol{f}$. Therefore,

$$\boldsymbol{u}^0 \in \boldsymbol{H}_0(\operatorname{div}) \cap \boldsymbol{H}(\operatorname{rot}),$$

and hence (cf. [11, Proposition 3.1, Chapter 1]) $\boldsymbol{u}^0 \in \boldsymbol{H}^1$. As a consequence, $p^0 \in H^1$. Furthermore, the corresponding solution map is continuous; i.e., there exists a constant c, independent of $\boldsymbol{f}$ and g, such that

$$\|\boldsymbol{u}^0\|_1 + \|p^0\|_1 \le c\,(\|\boldsymbol{f}\|_{\operatorname{rot}} + \|g\|_0). \tag{6.12}$$

LEMMA 6.2. *Assume that $\boldsymbol{f} \in \boldsymbol{H}(\operatorname{rot})$, $g \in H^1_+$, and let $(\boldsymbol{u}, p)$ be the corresponding solution of* (6.4). *There exists a constant $c > 0$, independent of ε, $\boldsymbol{f}$ and g, such that*

$$\|\boldsymbol{u} - \boldsymbol{u}^0\|_0 + \|p - p^0\|_1 \le c\,\varepsilon^{1/2}(\|\boldsymbol{f}\|_{\operatorname{rot}} + \|g\|_{1,+}).$$

Proof. It follows from (2.2), the weak formulation of (6.4), and Green's theorem that for any $\boldsymbol{v} \in \boldsymbol{H}^1 \cap \boldsymbol{H}_0(\operatorname{div})$ the solution $(\boldsymbol{u}, p)$ satisfies

$$\begin{aligned} (\boldsymbol{u}, \boldsymbol{v}) + \varepsilon^2(\operatorname{div} \boldsymbol{u}, \operatorname{div} \boldsymbol{v}) + \varepsilon^2(\operatorname{rot} \boldsymbol{u}, \operatorname{rot} \boldsymbol{v}) + \varepsilon^2 \int_{\partial\Omega} (\operatorname{rot} \boldsymbol{u})(\boldsymbol{v} \cdot \boldsymbol{t}) d\tau \\ + (p, \operatorname{div} \boldsymbol{v}) = (\boldsymbol{f}, \boldsymbol{v}). \end{aligned}$$

By subtracting from this the first equation of (6.11), we obtain

$$(\boldsymbol{u} - \boldsymbol{u}^0, \boldsymbol{v}) + \varepsilon^2(\operatorname{rot} \boldsymbol{u}, \operatorname{rot} \boldsymbol{v}) + \varepsilon^2 \int_{\partial\Omega} (\operatorname{rot} \boldsymbol{u})(\boldsymbol{v} \cdot \boldsymbol{t}) d\tau = 0$$

for any $\boldsymbol{v} \in \boldsymbol{H}^1 \cap \boldsymbol{H}_0(\operatorname{div})$ with $\operatorname{div} \boldsymbol{v} = 0$. Hence, if we take $\boldsymbol{v} = \boldsymbol{u} - \boldsymbol{u}^0$, and observe that $\operatorname{rot} \boldsymbol{u}^0 = \operatorname{rot} \boldsymbol{f}$ and $\operatorname{div}(\boldsymbol{u} - \boldsymbol{u}^0) = 0$, we derive the identity

$$\|\boldsymbol{u} - \boldsymbol{u}^0\|_0^2 + \varepsilon^2 \|\operatorname{rot} \boldsymbol{u}\|_0^2 = \varepsilon^2 \int_{\partial\Omega} (\operatorname{rot} \boldsymbol{u})(\boldsymbol{u}^0 \cdot \boldsymbol{t}) d\tau + \varepsilon^2(\operatorname{rot} \boldsymbol{u}, \operatorname{rot} \boldsymbol{f}),$$

which immediately leads to the bound

$$\|\boldsymbol{u} - \boldsymbol{u}^0\|_0^2 + \frac{\varepsilon^2}{2} \|\operatorname{rot} \boldsymbol{u}\|_0^2 \le \varepsilon^2 \|\operatorname{rot} \boldsymbol{f}\|_0^2 + \varepsilon^2 \int_{\partial\Omega} (\operatorname{rot} \boldsymbol{u})(\boldsymbol{u}^0 \cdot \boldsymbol{t}) d\tau. \tag{6.13}$$

In order to estimate the boundary integral we note that it follows from Lemma 6.1 and [12, Theorem 1.5.1.10] that

$$\|\operatorname{rot} \boldsymbol{u}\|_{0,\partial\Omega} \le c \|\operatorname{rot} \boldsymbol{u}\|_0^{1/2} \|\operatorname{rot} \boldsymbol{u}\|_1^{1/2} \le c\varepsilon^{-1} (\|\operatorname{rot} \boldsymbol{f}\|_0 + \|g\|_{1,+}).$$

Together with the estimate (6.12) this leads to

$$\varepsilon^2 \int_{\partial\Omega} (\operatorname{rot} \boldsymbol{u})(\boldsymbol{u}^0 \cdot \boldsymbol{t}) d\tau \le \varepsilon^2 \| \operatorname{rot} \boldsymbol{u}\|_{0,\partial\Omega} \|\boldsymbol{u}^0\|_1 \le c\,\varepsilon(\|\boldsymbol{f}\|^2_{\mathrm{rot}} + \|g\|^2_{1,+}).$$

Hence, the estimate

$$\|\boldsymbol{u} - \boldsymbol{u}^0\|_0 + \varepsilon^2 \| \operatorname{rot} \boldsymbol{u}\|_0^2 \le c\,\varepsilon^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}) \tag{6.14}$$

follows.

The estimate for $\|p - p^0\|_1$ is now a direct consequence of the identity

$$\begin{aligned} \mathbf{grad}(p - p^0) &= \boldsymbol{u} - \boldsymbol{u}^0 - \varepsilon^2 \boldsymbol{\Delta} \boldsymbol{u} \\ &= \boldsymbol{u} - \boldsymbol{u}^0 + \varepsilon^2(\mathbf{curl} \operatorname{rot} \boldsymbol{u} - \mathbf{grad}\, g) \end{aligned}$$

and the previously established bounds. In fact, it follows from Lemma 6.1 and (6.14) that

$$\begin{aligned} \| \mathbf{grad}(p - p^0)\|_0 &\le \|\boldsymbol{u} - \boldsymbol{u}^0\|_0 + \varepsilon^2(\| \operatorname{rot} \boldsymbol{u}\|_1 + \|g\|_1) \\ &\le c\,\varepsilon^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}). \end{aligned}$$

Since $p - p^0 \in L^2_0$, an application of the Poincaré inequality completes the proof. ∎

The regularity bounds derived above will now be used to prove the uniform convergence estimates.

Proof of Theorem 6.1. Recall that since $\boldsymbol{u} \in \boldsymbol{H}^1_0$ it follows from [11, Proposition 3.1, Chapter 1] that

$$\|\boldsymbol{u}\|_1 \le c(\| \operatorname{div} \boldsymbol{u}\|_0 + \| \operatorname{rot} \boldsymbol{u}\|_0).$$

Furthermore, by the standard H^2-regularity for solutions of the Poisson equation on convex domains, and (2.2), we obtain

$$\|\boldsymbol{u}\|_2 \le c\|\boldsymbol{\Delta} \boldsymbol{u}\|_0 \le c(\| \operatorname{div} \boldsymbol{u}\|_1 + \| \operatorname{rot} \boldsymbol{u}\|_1).$$

Hence, from the estimates given in Lemmas 6.1 and 6.2 we conclude that

$$\varepsilon^2 \|\boldsymbol{u}\|_2 + \varepsilon \|\boldsymbol{u}\|_1 + \|\boldsymbol{u} - \boldsymbol{u}^0\|_0 + \|p - p^0\|_1 \le c\varepsilon^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}). \tag{6.15}$$

The desired estimate on the velocity error will be derived from (5.4). We will first establish the interpolation estimate

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u}\|_0 + \varepsilon \|\boldsymbol{D}(\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u})\|_1 \le c\, h^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}). \tag{6.16}$$

From (4.6), (6.12), and (6.15) we have

$$\begin{aligned} \|\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u}\|_0 &\le \|(\boldsymbol{I} - \boldsymbol{\Pi}_h)(\boldsymbol{u} - \boldsymbol{u}^0)\|_0 + \|\boldsymbol{u}^0 - \boldsymbol{\Pi}_h \boldsymbol{u}^0\|_0 \\ &\le c h^{1/2} \left(\|\boldsymbol{u} - \boldsymbol{u}^0\|_0^{1/2} \|\boldsymbol{u} - \boldsymbol{u}^0\|_1^{1/2} + h^{1/2} \|\boldsymbol{u}^0\|_1\right) \\ &\le c h^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}} + \|g\|_{1,+}). \end{aligned}$$

Furthermore, from (4.4), (4.5), and (6.15),

$$\varepsilon\|\boldsymbol{D}(\boldsymbol{u}-\boldsymbol{\Pi}_h\boldsymbol{u})\|_0 \le c\varepsilon\|\boldsymbol{u}\|_1^{1/2}\|\boldsymbol{u}-\boldsymbol{\Pi}_h\boldsymbol{u}\|_1^{1/2} \le c\varepsilon h^{1/2}\|\boldsymbol{u}\|_1^{1/2}\|\boldsymbol{u}\|_2^{1/2} \le ch^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+}).$$

The estimate (6.16) is therefore verified.

Similarly, since $\|\boldsymbol{u}\|_1^{1/2}\|\boldsymbol{u}\|_2^{1/2} \le c\varepsilon^{-1}(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+})$, we obtain from Lemma 5.1 that

$$\sup_{\boldsymbol{v}\in\boldsymbol{V}_h}\frac{|E_{\varepsilon,h}(\boldsymbol{u},\boldsymbol{v})|}{\|\boldsymbol{v}\|_a} \le ch^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+}). \tag{6.17}$$

However, by combining (5.4), (6.3), (6.16), and (6.17), this implies

$$\|\boldsymbol{u}-\boldsymbol{u}_h\|_0+\varepsilon\|\operatorname{rot}(\boldsymbol{u}-\boldsymbol{u}_h)\|_0 \le ch^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+}). \tag{6.18}$$

In order to establish the estimate for the $\|p-p_h\|_0$ note that (4.3) and (6.15) imply

$$\|P_hp-p\|_0 \le ch\|p\|_1 \le ch(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+}).$$

Finally, by (5.6), (6.17), and (6.18),

$$\|P_hp-p_h\|_0 \le ch^{1/2}(\|\boldsymbol{f}\|_{\mathrm{rot}}+\|g\|_{1,+}).$$

This completes the proof of Theorem 6.1. ∎

Remark. Even if Lemma 6.2 states that $\|p\|_1$ is uniformly bounded with respect to ε, we are not able to prove that $\|p-p_h\|_0$ converges linearly in h uniformly in ε. The convergence rate is polluted by the blowup of $\boldsymbol{u}$. This seems to agree with what we observed in Example 6.1; cf. Table 6.2. ∎

7. An associated elliptic system. In this section we shall study the elliptic system (1.2) given by

$$\begin{aligned}(\boldsymbol{I}-\varepsilon^2\boldsymbol{\Delta})\boldsymbol{u}-\delta^{-2}\,\mathbf{grad}(\operatorname{div}\boldsymbol{u}-g) &= \boldsymbol{f} \quad \text{in } \Omega,\\ \boldsymbol{u} &= 0 \quad \text{on } \partial\Omega,\end{aligned} \tag{7.1}$$

where $\varepsilon,\delta \in (0,1]$. Recall that by introducing $p=\delta^{-2}\operatorname{div}\boldsymbol{u}$ this system can be alternatively written on the mixed form (1.3). Hence, as δ approaches zero the system formally reduces to (1.1).

The system (7.1) will be discretized by a standard finite element approach; i.e., the mixed system (1.3) is not introduced in the discretization. Let the bilinear form $b_{\varepsilon,\delta}(\cdot,\cdot)$ be defined by

$$\begin{aligned}b_{\varepsilon,\delta}(\boldsymbol{u},\boldsymbol{v}) &= a_\varepsilon(\boldsymbol{u},\boldsymbol{v})+\delta^{-2}(\operatorname{div}\boldsymbol{u},\operatorname{div}\boldsymbol{v})\\ &= (\boldsymbol{u},\boldsymbol{v})+\varepsilon^2(\boldsymbol{D}\boldsymbol{u},\boldsymbol{D}\boldsymbol{v})+\delta^{-2}(\operatorname{div}\boldsymbol{u},\operatorname{div}\boldsymbol{v}).\end{aligned}$$

For a given finite element space $\boldsymbol{V}_h$, the corresponding standard finite element discretization of (7.1) is given by the following:

Find a $\boldsymbol{u}_h \in \boldsymbol{V}_h$ such that

$$b_{\varepsilon,\delta}(\boldsymbol{u}_h,\boldsymbol{v}) = (\boldsymbol{f},\boldsymbol{v})+\delta^{-2}(g,\operatorname{div}\boldsymbol{v}) \qquad \forall\boldsymbol{v}\in\boldsymbol{V}_h. \tag{7.2}$$

Our purpose here is to discuss this discretization when the finite element space $\boldsymbol{V}_h$ is the space introduced in section 4. Since this space is not a subspace of $\boldsymbol{H}_0^1$ this will lead to a nonconforming discretization of the system (7.1). However, before we analyze this discretization, we will present some numerical experiments based on the system (7.1).

Example 7.1. In all the examples presented in this section we consider the system (7.1) with $\boldsymbol{u} = \mathbf{curl}\sin^2(\pi x_1)\sin^2(\pi x_2)$, $g = 0$, and $\boldsymbol{f} = \boldsymbol{u} - \varepsilon^2\boldsymbol{\Delta u}$. Hence, the solution is independent of ε and δ.

We consider the problem (7.1) with Ω taken as the unit square. The domain is triangulated as described in Example 3.1. The system is then discretized by solving the system (7.2), where the space $\boldsymbol{V}_h$ is the standard space of continuous piecewise linear functions with respect to this triangulation.

In the present example we have used $\varepsilon = 1$, while δ and h vary. In Table 7.1 we have computed the relative error in the L^2 norm for different values of δ and h.

TABLE 7.1
The relative L^2 error using piecewise linear elements, $\varepsilon = 1$.

$\delta\backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1.00	3.87e-1	1.32e-1	3.69e-2	9.52e-3	2.39e-3	1.85
0.10	9.19e-1	7.28e-1	4.34e-1	1.88e-1	6.20e-2	0.97
0.01	1.00	9.96e-1	9.82e-1	9.32e-1	7.88e-1	0.08

As expected we observe approximately quadratic convergence with respect to h for $\delta = 1$. However, the convergence clearly deteriorates as δ tends to zero. □

Example 7.2. We repeat the experiment above, but we extend the finite element space and use the corresponding velocity space of the Mini element instead of the piecewise linear space. It is interesting to note that the L^2 convergence deteriorates, as δ gets small, also in this case, in contrast to what we have observed in Table 3.7. The relative L^2 error is given in Table 7.2.

TABLE 7.2
The relative L^2 error using the Mini element, $\varepsilon = 1$.

$\delta\backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1.00	3.80e-1	1.30e-1	3.62e-2	9.34e-3	2.35e-3	1.85
0.10	9.19e-1	7.28e-1	4.34e-1	1.88e-1	6.20e-2	0.97
0.01	9.99e-1	9.96e-1	9.82e-1	9.33e-1	7.88e-1	0.08

We observe that the results are almost identical to the ones we obtained in the piecewise linear case. Hence, the extra bubble functions have almost no effect. Of course, the main reason for the difference between the results given here, for δ small, and the results given in Example 3.3, where $\delta = 0$, is that the second equation of the mixed method used previously implicitly introduces a reduced integration in the divergence term. □

Example 7.3. We repeat the experiment above once more, but this time we use the new nonconforming element. In Table 7.3 we have computed the relative error in the energy norm, i.e., the norm generated by the form $b_{\varepsilon,\delta}$, for different values of δ and h.

In contrast to the other examples above, in this case the convergence seems to be linear with respect to h, uniformly in δ. We also observe that the errors are almost

TABLE 7.3
The relative error in energy norm for the new nonconforming element, $\varepsilon = 1$.

$\delta \backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1.00	1.84	9.83e-1	4.98e-1	2.50e-1	1.25e-1	0.97
0.10	1.83	9.66e-1	4.87e-1	2.44e-1	1.22e-1	0.98
0.01	1.83	9.66e-1	4.87e-1	2.44e-1	1.22e-1	0.98

TABLE 7.4
The relative error in energy norm for the new nonconforming element, $\varepsilon = 0.01$.

$\delta \backslash h$	2^{-2}	2^{-3}	2^{-4}	2^{-5}	2^{-6}	Rate
1.00	1.04e-1	3.23e-2	8.94e-3	2.21e-3	5.29e-4	1.91
0.10	1.04e-1	3.23e-2	8.94e-3	2.21e-3	5.29e-4	1.91
0.01	1.04e-1	3.23e-2	8.94e-3	2.21e-3	5.29e-4	1.91

independent of δ.

Next, we reduce ε and take $\varepsilon = 0.01$ and redo the experiment. The results are given in Table 7.4.

We observe that to the given accuracy the numerical solution is independent of δ, clearly indicating that the numerical solutions are close to a pure curl field independent of δ, which is precisely the form of the exact solution in this case. A similar observation is done if we take $\varepsilon = 0$. □

The numerical experiments just presented indicate that the nonconforming space $\boldsymbol{V}_h$, introduced in section 4 above, is well suited for problem (7.1). We will give a partial theoretical justification for this claim by deriving a generalization of Theorem 5.1.

We assume throughout this section that $\boldsymbol{u} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$. Let $\|\cdot\|_b$ be the energy norm associated with the system (7.1), i.e.,

$$\|\boldsymbol{v}\|_b^2 = b_{\varepsilon,\delta}(\boldsymbol{v}, \boldsymbol{v}).$$

It is a straightforward consequence of the second Strang lemma (cf. [9, Theorem 4.2.2]) that there exists a $c > 0$, independent of ε, h and $\boldsymbol{u}$, such that

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_b^2 \leq \|\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u}\|_b^2 + c \sup_{\boldsymbol{v} \in \boldsymbol{V}_h} \frac{|E_{\varepsilon,h}(\boldsymbol{u}, \boldsymbol{v})|^2}{\|\boldsymbol{v}\|_b^2}, \tag{7.3}$$

where the inconsistency error $E_{\varepsilon,h}$ is introduced in section 5. However, since $\|\boldsymbol{v}\|_b \geq \|\boldsymbol{v}\|_a$, the inconsistency term can be bounded as in Lemma 5.1. Furthermore, (4.5) implies

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u}\|_a \leq c(h^2 + \varepsilon h)\|\boldsymbol{u}\|_2.$$

As a consequence of the fact that $\operatorname{div} \boldsymbol{\Pi}_h \boldsymbol{u} = P_h \operatorname{div} \boldsymbol{u}$, it is also true that

$$\|\operatorname{div}(\boldsymbol{u} - \boldsymbol{u}_h)\|_0^2 = \|\operatorname{div}(\boldsymbol{u} - \boldsymbol{\Pi}_h \boldsymbol{u})\|_0^2 + \|\operatorname{div}(\boldsymbol{\Pi}_h \boldsymbol{u} - \boldsymbol{u}_h)\|_0^2.$$

Thus, we can conclude from (7.3) that

$$\begin{aligned} \|\boldsymbol{u} - \boldsymbol{u}_h\|_a^2 + \delta^{-2}\|(I - P_h)\operatorname{div} \boldsymbol{u}\|_0^2 + \delta^{-2}\|\operatorname{div}(\boldsymbol{\Pi}_h \boldsymbol{u} - \boldsymbol{u}_h)\|_0^2 \\ \leq c(h^2 + \varepsilon h)^2 \|\boldsymbol{u}\|_2^2 + \delta^{-2}\|(I - P_h)\operatorname{div} \boldsymbol{u}\|_0^2. \end{aligned}$$

We therefore have established the following convergence result.

THEOREM 7.1. *If* $\boldsymbol{u} \in \boldsymbol{H}^2 \cap \boldsymbol{H}_0^1$, *then*

$$\|\boldsymbol{u} - \boldsymbol{u}_h\|_0 + \varepsilon \|\operatorname{rot}(\boldsymbol{u} - \boldsymbol{u}_h)\|_0 + \delta^{-1} \|\operatorname{div}(\boldsymbol{\Pi}_h \boldsymbol{u} - \boldsymbol{u}_h)\|_0 \leq c(h^2 + \varepsilon h)\|\boldsymbol{u}\|_2.$$

Here $c > 0$ *is a constant independent of* ε, δ, *and* h.

Note that from this result we can conclude that if ε and h are fixed, and δ approaches zero, then $\operatorname{div} \boldsymbol{u}_h$ converges in L^2 to $P_h \operatorname{div} \boldsymbol{u}$. Furthermore, the divergence of the error can be controlled by this estimate since

$$\begin{aligned} \|\operatorname{div}(\boldsymbol{u} - \boldsymbol{u}_h)\|_0 &\leq \|(I - P_h) \operatorname{div} \boldsymbol{u}\|_0 + \|\operatorname{div}(\boldsymbol{\Pi}_h \boldsymbol{u} - \boldsymbol{u}_h)\|_0 \\ &\leq ch \|\operatorname{div} \boldsymbol{u}\|_1 + c\delta(\varepsilon^2 + h\varepsilon)\|\boldsymbol{u}\|_2. \end{aligned}$$

Of course, exactly as for the problem (1.1) we can argue that, in general cases, the norm $\|\boldsymbol{u}\|_2$ will not remain bounded as ε and δ approach zero. Hence, ideally we would like to generalize the results of section 6 to the problem (7.1). However, this discussion is outside the scope of this paper.

Acknowledgments. The authors are grateful to Professors D.N. Arnold, R.S. Falk, and Z. Cai for many useful discussions.

BENDING MOMENT MIXED METHOD FOR THE KIRCHHOFF–LOVE PLATE MODEL*

MOHAMED AMARA†, DANIELA CAPATINA-PAPAGHIUC†, AND AMNA CHATTI‡

Abstract. We deal with the Kirchhoff–Love model for a bending thin plate with physical boundary conditions. We propose here a new mixed formulation, based on a decomposition of the bending moment. For its discretization, we employ classical low-order conforming finite elements. Then the discrete formulation allows us to obtain directly an approximation of the bending moment, while the deflection is recovered by solving an additional second order elliptic problem. We establish optimal error estimates which prove that the method is unconditionally convergent. Moreover, its convergence rate is optimal whenever the exact solution is sufficiently smooth.

Key words. Kirchhoff–Love model, mixed formulation, finite element, error estimates

1. Introduction.

We are interested in this paper in the analysis, from the theoretical and the numerical point of view, of the Kirchhoff–Love model for a bending thin plate satisfying physical boundary conditions; cf. [4]. The unknowns of the problem are the plate's deflection and the bending moment, which is a second order symmetric tensor. The usual approach for solving the Kirchhoff–Love model consists of eliminating the stress tensor and calculating next the displacement, which satisfies a fourth order elliptic problem. However, due to the boundary conditions considered here, this approach is not possible, and, moreover, our goal is to obtain a good approximation for the stress tensor, which represents in practice the quantity of physical interest.

Therefore, we propose a new mixed formulation whose main unknown is the bending moment, while the multiplier is the gradient of the displacement on the lateral boundary. In order to avoid the discretization of the constraint imposed on the bending moment and on the test-functions, $div\,\mathbf{div} = 0$, the main idea is to decompose them by applying twice the Tartar lemma [9] and also by using the symmetry of the above tensors. A similar idea is used by Destuynder and Salaun [4], but they apply only once Tartar's lemma, so they get a completely different problem.

We thus obtain an equivalent mixed formulation of the problem, whose main unknown is not a physical variable but whose spaces are very easy to approximate. Indeed, we are now dealing with classical Sobolev spaces, $H^1(\Omega)$ and $H^{1/2}(\Gamma)$, respectively. We employ for the approximation conforming low-order finite elements, for which we prove a uniform inf-sup condition with respect to the discretization parameter. So, thanks to the Babuška–Brezzi theory (cf., for instance, [2]), we establish the unconditional convergence of the proposed method. Moreover, the convergence rate is proved to be optimal $O(h)$ whenever the continuous solution is sufficiently smooth. It is then obvious how to obtain an approximate bending tensor, while the deflection of the plate is recovered by solving an additional Laplacian problem.

The same idea of decomposing the bending moment applies to the Reissner–Mindlin thin plate model, with natural boundary conditions. The variational formulations presented here can then be generalized to the Reissner–Mindlin case, and they lead to a discrete conforming method whose convergence is uniform with respect to the plate's thickness, which means that no locking phenomenon occurs.

The paper is organized as follows. In section 2 we introduce the continuous Kirchhoff–Love problem, and in section 3 we state and analyze a first mixed variational formulation with respect to the bending moment. Section 4 deals with an equivalent variational problem, obtained by decomposing the above tensor. Finally, in section 5 we study its discretization by means of classical finite elements; we establish optimal error estimates and deduce the unconditional convergence of the finite element method. We conclude with the approximation of the quantities which interested us at the beginning of the paper, that is, the bending moment and the deflection of the plate.

2. Presentation of the continuous problem. Let $\Omega \subset \mathbb{R}^2$ denote the medium surface of the thin plate and Γ its lateral boundary. We suppose that Γ is decomposed into three disjoint open parts,

$$\Gamma = \Gamma_0 \cup \Gamma_1 \cup \Gamma_2.$$

On each part we impose different boundary conditions. More precisely, we suppose that the plate is clamped on Γ_0, simply supported on Γ_1, while Γ_2 represents the free boundary. In view of the finite element approximation of the problem, we also suppose that Ω is a polygonal and connected bounded domain. The hypothesis of connectivity is not essential but permits an easier presentation of the method.

The mechanical framework considered here is linear elasticity, and, in order to simplify the writing, the constitutive material is taken to be homogeneous and isotropic. Then the equations describing the Kirchhoff–Love model may be written as below (see, for instance, [4] for more details):

$$\left\{\begin{array}{ll} \Delta^2 u = f & \text{in } \Omega, \\ u = \partial_n u = 0 & \text{on } \Gamma_0, \\ u = 0, \quad \sigma_{ij} n_i n_j = 0 & \text{on } \Gamma_1, \\ \sigma_{ij} n_i n_j = \partial_t(\sigma_{ij} t_i n_j) + \partial_j \sigma_{ij} n_i = 0 & \text{on } \Gamma_2, \\ \sigma_{ij} = (1-\nu)\partial_{ij} u + \nu \Delta u \delta_{ij} & \text{in } \Omega, \end{array}\right. \tag{2.1}$$

where ν is the Poisson coefficient. The unknowns of the problem are the deflection of the plate u and the bending moment $\underline{\sigma} = (\sigma_{ij})_{1\le i,j\le 2}$, which is a symmetric second order tensor. A transverse loading is applied, of force density denoted (after scaling) by f. In what follows, we will take $f \in L^2(\Omega)$. We will suppose for technical reasons that Ω has no cuts, Γ_0 is not empty, and, moreover, $\Gamma_0 \cup \Gamma_1$ is connected.

We denote $\mathbf{n} = (n_i)_{1\le i\le 2}$ the unit outward normal vector along Γ and $\mathbf{t} = (t_i)_{1\le i\le 2}$ the unit tangent vector to Γ oriented such that $t_1 = n_2$, $t_2 = -n_1$. We also employ in this paper the summation convention of Einstein, and we denote by the letter c any positive constant independent of the discretization. We agree to write the vectors in bold letters and the tensors in underlined letters.

Let us also recall here some classical notation which will be used in what follows; for any vector function $\mathbf{v}$ and any scalar function v we denote

$$curl\, \mathbf{v} = \partial_1 v_2 - \partial_2 v_1, \qquad div\, \mathbf{v} = \partial_i v_i,$$
$$\mathbf{curl}\, v = \begin{pmatrix} \partial_2 v \\ -\partial_1 v \end{pmatrix}, \qquad \underline{curl}\, \mathbf{v} = \begin{pmatrix} \partial_2 v_1 & -\partial_1 v_1 \\ \partial_2 v_2 & -\partial_1 v_2 \end{pmatrix},$$

and we also put

$$\mathbf{div}\underline{\tau} = \begin{pmatrix} \partial_1\tau_{11} + \partial_2\tau_{12} \\ \partial_1\tau_{21} + \partial_2\tau_{22} \end{pmatrix}, \quad \underline{I} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \underline{J} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

We also introduce the tangential, respectively, the normal, derivative on the boundary for a scalar function v:

$$\partial_t v = \nabla v \cdot \mathbf{t} \quad \text{and} \quad \partial_n v = \nabla v \cdot \mathbf{n}.$$

We will denote by $\langle \cdot, \cdot \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}$ and $\langle \cdot, \cdot \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}$ the duality pairings between the spaces $H^{1/2}(\Gamma)$ and its topological dual $H^{-1/2}(\Gamma)$, respectively, $H^{3/2}(\Gamma)$ and its dual $H^{-3/2}(\Gamma)$. Let us also recall that $H^{1/2}(\Gamma)$ and $H^{3/2}(\Gamma)$ are the spaces of traces of functions belonging to $H^1(\Omega)$, respectively, to $H^2(\Omega)$. The Kirchhoff–Love model (2.1) is a rather general one. It includes the case of a clamped plate (obtained for $\Gamma_1 = \Gamma_2 = \emptyset$ and modelled by a classical biharmonic problem), as well as the case of a simply supported plate (obtained when $\Gamma_0 = \Gamma_2 = \emptyset$).

One of the first questions which arise in the analysis of problem (2.1) is how to give a mathematical framework in which the above problem is well-posed. For that, we consider the following spaces:

$$V = \left\{ v \in H^1(\Omega);\ v = 0 \text{ on } \Gamma_0 \cup \Gamma_1 \right\},$$
$$\underline{X} = \left\{ \underline{\tau} = (\tau_{ij})_{1 \le i,j \le 2};\ \tau_{ij} \in L^2(\Omega),\ \ D(\underline{\tau}) \in L^2(\Omega) \right\},$$

endowed with the natural norms

$$\|v\|_V = |v|_{1,\Omega},$$
$$\| \underline{\tau} \|_{\underline{X}} = (\| \underline{\tau} \|_{0,\Omega}^2 + \| D(\underline{\tau}) \|_{0,\Omega}^2)^{1/2},$$

where $D(\underline{\tau}) = div(\mathbf{div}\underline{\tau}) = \partial_{ij}\tau_{ij}$. It is obvious that V and $\underline{X}$ are Hilbert spaces with respect to these norms, and, moreover, we have the following result.

PROPOSITION 2.1. *The space $(\mathcal{D}(\overline{\Omega}))^4$ is a dense subspace of $\underline{X}$.*

Proof. Let $\underline{\sigma} \in \underline{X}$ belong to the orthogonal complement of $(\mathcal{D}(\overline{\Omega}))^4$ in $\underline{X}$; that is,

$$\forall \underline{\tau} \in (\mathcal{D}(\overline{\Omega}))^4, \quad \langle \underline{\sigma}, \underline{\tau} \rangle_{\underline{X}} = \int_\Omega \underline{\sigma} : \underline{\tau}\, d\Omega + \int_\Omega D(\underline{\sigma}) D(\underline{\tau})\, d\Omega = 0.$$

By taking $\underline{\tau} \in (\mathcal{D}(\Omega))^4 \subset (\mathcal{D}(\overline{\Omega}))^4$ one obtains, for all $i, j \in \{1, 2\}$, the following equality in the sense of distributions:

$$\sigma_{ij} + \partial_{ij} D(\underline{\sigma}) = 0 \quad \text{in } \mathcal{D}'(\Omega).$$

This immediately implies that $D(\underline{\sigma}) \in H^2(\Omega)$. By taking next as test-function $\underline{\tau} = \alpha \underline{I}$ with $\alpha \in \mathcal{D}(\overline{\Omega})$, one obtains that

$$D(\underline{\sigma}) = \partial_n D(\underline{\sigma}) = 0 \ \text{ on } \Gamma.$$

So, $D(\underline{\sigma})$ satisfies the following boundary value problem:

$$\begin{cases} D(\underline{\sigma}) \in H_0^2(\Omega), \\ D(\underline{\sigma}) + \Delta^2 D(\underline{\sigma}) = 0 \quad \text{in } \Omega, \end{cases}$$

which admits a unique solution $D(\underline{\sigma}) = 0$. Therefore, we obtain that $\underline{\sigma} = \underline{0}$. We have thus established that $(\mathcal{D}(\overline{\Omega})^4)^\perp = \{\underline{0}\}$ for the scalar product of $\underline{X}$, and the Hahn–Banach theorem completes the proof. ∎

This preliminary result allows us to define rigorously the trace operators for the bending moment $\underline{\sigma}$. We proceed in the usual way; that is, we first consider the operators γ_0 and γ_1 defined by

$$\gamma_0 : (\mathcal{D}(\overline{\Omega}))^4 \longrightarrow L^2(\Gamma), \qquad \gamma_0(\underline{\tau}) = \underline{\tau}\mathbf{n}\cdot\mathbf{n} = \tau_{ij}n_in_j$$

and, respectively,

$$\gamma_1 : (\mathcal{D}(\overline{\Omega}))^4 \longrightarrow L^2(\Gamma), \qquad \gamma_1(\underline{\tau}) = \partial_t(\underline{\tau}\mathbf{n}\cdot\mathbf{t}) + \mathbf{div}\underline{\tau}\cdot\mathbf{n} = \partial_t(\tau_{ij}t_in_j) + \partial_j\tau_{ij}n_i,$$

and we establish the following result.

THEOREM 2.2. *Operators* $\gamma_0 : ((\mathcal{D}(\overline{\Omega}))^4, \|\cdot\|_{\underline{X}}) \longrightarrow (L^2(\Gamma), \|\cdot\|_{-\frac{1}{2},\Gamma})$ *and* $\gamma_1 : ((\mathcal{D}(\overline{\Omega}))^4, \|\cdot\|_{\underline{X}}) \longrightarrow (L^2(\Gamma), \|\cdot\|_{-\frac{3}{2},\Gamma})$ *are linear and continuous. They can be extended by continuity to the whole space* $\underline{X}$*, with values in* $H^{-1/2}(\Gamma)$ *and* $H^{-3/2}(\Gamma)$*, respectively. Moreover, for any* $v \in H^2(\Omega)$ *one has the following Green-type formula:*

$$\int_\Omega D(\underline{\tau})v\, d\Omega = \int_\Omega \tau_{ij}\partial_{ij}v\, d\Omega - \langle\gamma_0(\underline{\tau}), \partial_n v\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle\gamma_1(\underline{\tau}), v\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}. \tag{2.2}$$

Proof. Let us consider any $\underline{\tau} \in (\mathcal{D}(\overline{\Omega}))^4$. Then by classical Green's formula one has, for any $v \in H^2(\Omega)$, that

$$\begin{aligned}\int_\Omega D(\underline{\tau})v\, d\Omega &= -\int_\Omega \mathbf{div}\underline{\tau}\cdot\nabla v\, d\Omega + \int_\Gamma (\mathbf{div}\underline{\tau}\cdot\mathbf{n})v\, d\Gamma \\ &= \int_\Omega \tau_{ij}\partial_{ij}v\, d\Omega + \int_\Gamma (\mathbf{div}\underline{\tau}\cdot\mathbf{n})v\, d\Gamma - \int_\Gamma (\underline{\tau}\mathbf{n})\cdot\nabla v\, d\Gamma.\end{aligned}$$

One can next write

$$\begin{aligned}\int_\Gamma (\underline{\tau}\mathbf{n})\cdot\nabla v\, d\Gamma &= \int_\Gamma (\underline{\tau}\mathbf{n}\cdot\mathbf{n})\partial_n v\, d\Gamma + \int_\Gamma (\underline{\tau}\mathbf{n}\cdot\mathbf{t})\partial_t v\, d\Gamma \\ &= \int_\Gamma (\underline{\tau}\mathbf{n}\cdot\mathbf{n})\partial_n v\, d\Gamma - \int_\Gamma \partial_t(\underline{\tau}\mathbf{n}\cdot\mathbf{t})v\, d\Gamma\end{aligned}$$

and finally obtain, for any $\underline{\tau} \in (\mathcal{D}(\overline{\Omega}))^4$,

$$\int_\Omega D(\underline{\tau})v\, d\Omega = \int_\Omega \tau_{ij}\partial_{ij}v\, d\Omega - \langle\gamma_0(\underline{\tau}), \partial_n v\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle\gamma_1(\underline{\tau}), v\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}.$$

We next establish the continuity of the linear operators γ_0 and γ_1 defined on the space $(\mathcal{D}(\overline{\Omega}))^4$. For that, it is sufficient to write that

$$\begin{aligned}(\|\gamma_0(\underline{\tau})\|^2_{-1/2,\Gamma} + \|\gamma_1(\underline{\tau})\|^2_{-3/2,\Gamma})^{1/2} &\le c \sup_{\substack{\lambda\in H^{1/2}(\Gamma)\\ \mu\in H^{3/2}(\Gamma)}} \frac{\langle\gamma_0(\underline{\tau}),\lambda\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle\gamma_1(\underline{\tau}),\mu\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}}{(\|\lambda\|^2_{1/2,\Gamma} + \|\mu\|^2_{3/2,\Gamma})^{1/2}} \\ &\le c' \sup_{v\in H^2(\Omega)} \frac{\langle\gamma_0(\underline{\tau}),\partial_n v\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} - \langle\gamma_1(\underline{\tau}),v\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}}{\|v\|_{2,\Omega}}.\end{aligned}$$

The last inequality comes by associating, to any $(\lambda,\mu) \in H^{1/2}(\Gamma)\times H^{3/2}(\Gamma)$, a function $v \in H^2(\Omega)$ defined as the unique solution of the biharmonic problem

$$\begin{cases}\Delta^2 v = 0 & \text{in } \Omega,\\ v = -\mu & \text{on } \Gamma,\\ \partial_n v = \lambda & \text{on } \Gamma\end{cases}$$

and by noticing that $\|v\|_{2,\Omega} \leq c(\|\lambda\|^2_{1/2,\Gamma} + \|\mu\|^2_{3/2,\Gamma})^{1/2}$. Then one obviously has

$$\| \gamma_0(\underline{\tau}) \|_{-1/2,\Gamma} + \| \gamma_1(\underline{\tau}) \|_{-3/2,\Gamma} \leq c \sup_{v \in H^2(\Omega)} \frac{\displaystyle\int_\Omega D(\underline{\tau})v \, d\Omega - \int_\Omega \tau_{ij}\partial_{ij}v \, d\Omega}{\|v\|_{2,\Omega}} \leq c \, \| \underline{\tau} \|_{\underline{X}}$$

and by density (cf. Proposition 2.1) it comes that γ_0 and γ_1 can be continuously extended to $\underline{X}$. Green-type formula (2.2) also holds, due to the density of $(\mathcal{D}(\overline{\Omega}))^4$ in $\underline{X}$. ∎

3. Formulation with respect to the bending moment. In this section we propose a first variational formulation of the initial plate problem, whose main unknown will be the bending moment $\underline{\sigma}$. For that, let us begin by introducing the Hilbert spaces

$$\begin{aligned} M &= \left\{ v \in H^{3/2}(\Gamma) ; \ v = 0 \text{ on } \Gamma_0 \cup \Gamma_1 \right\}, \\ N &= \left\{ v \in H^{1/2}(\Gamma) ; \ v = 0 \text{ on } \Gamma_0 \right\}, \\ \underline{X}^0 &= \{ \underline{\tau} \in \underline{X}; \ D(\underline{\tau}) = 0 \}, \end{aligned}$$

as well as the subset of $\underline{X}$:

$$\underline{X}^f = \{ \underline{\tau} \in \underline{X}; \ D(\underline{\tau}) = f \}.$$

Let us also define the following continuous bilinear forms:

$$\forall (\underline{\sigma}, \underline{\tau}) \in \underline{X} \times \underline{X}, \qquad a(\underline{\sigma}, \underline{\tau}) = \frac{1}{1-\nu} \int_\Omega \underline{\sigma} : \underline{\tau} \, d\Omega - \frac{\nu}{1-\nu^2} \int_\Omega (tr\underline{\sigma})(tr\underline{\tau}) \, d\Omega;$$

$$\forall \underline{\tau} \in \underline{X}, \ \forall (\mu, \lambda) \in M \times N, \quad b(\underline{\tau}, (\mu, \lambda)) = \langle \gamma_1(\underline{\tau}), \mu \rangle_{-\frac{3}{2}, \frac{3}{2}, \Gamma} - \langle \gamma_0(\underline{\tau}), \lambda \rangle_{-\frac{1}{2}, \frac{1}{2}, \Gamma}.$$

It is also useful to introduce the boundary value problem

$$\left\{ \begin{array}{ll} \Delta\phi = f & \text{in } \Omega, \\ \phi = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ \partial_n \phi = 0 & \text{on } \Gamma_2, \end{array} \right. \tag{3.1}$$

which admits a unique solution $\phi^f \in V$. Thus, the set $\underline{X}^f$ is not empty since $\underline{\tau} = \phi^f \underline{I}$ belongs to $\underline{X}^f$.

Next, we consider the mixed formulation of the Kirchhoff–Love model given by

$$\left\{ \begin{array}{ll} \text{find } \underline{\sigma} \in \underline{X}^f, \ (u_0, u_1) \in M \times N \quad \text{such that,} & \\ \quad \forall \underline{\tau} \in \underline{X}^0, & a(\underline{\sigma}, \underline{\tau}) + b(\underline{\tau}, (u_0, u_1)) = 0; \\ \quad \forall (v_0, v_1) \in M \times N, & b(\underline{\sigma}, (v_0, v_1)) = 0. \end{array} \right.$$

Obviously, one can write the solution $\underline{\sigma} \in \underline{X}^f$ in the following way:

$$\underline{\sigma} = \underline{\sigma}^0 + \phi^f \underline{I},$$

with ϕ^f verifying (3.1) and $\underline{\sigma}^0 \in \underline{X}^0$. By the means of this decomposition, we can work from now on with the new unknown $\underline{\sigma}^0$. Since one has

$$\gamma_0(\phi^f \underline{I}) = \phi^f, \qquad \gamma_1(\phi^f \underline{I}) = 0,$$

the previous variational problem now writes under the equivalent form

$$(3.2)\quad \left\{\begin{array}{ll} \text{find } \underline{\sigma}^0 \in \underline{X}^0,\ (u_0,u_1)\in M\times N \quad \text{such that,} & \\ \forall \underline{\tau}\in \underline{X}^0, & a(\underline{\sigma}^0,\underline{\tau})+b(\underline{\tau},(u_0,u_1)) = -a(\phi^f \underline{I},\underline{\tau});\\ \forall (v_0,v_1)\in M\times N, & b(\underline{\sigma}^0,(v_0,v_1)) = \langle \phi^f, v_1\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}. \end{array}\right.$$

We establish in the next theorem the well-posedness of this problem, as well as its link with the initial Kirchhoff–Love model.

THEOREM 3.1. *Problem* (3.2) *has a unique solution* $(\underline{\sigma}^0,u_0,u_1)$. *Moreover, one has that*

$$\left\{\begin{array}{ll} \underline{\sigma}^0+\phi^f\underline{I}=\underline{\sigma} & \text{in } \Omega\\ u_0=u & \text{on } \Gamma\\ u_1=\partial_n u & \text{on } \Gamma, \end{array}\right.$$

where $(\underline{\sigma},u)$ *satisfies the Kirchhoff–Love equations* (2.1).

Proof. We make use of the classical Babuška–Brezzi theory for mixed formulations in order to obtain the existence and the uniqueness of the solution of (3.2).

First of all, let us note that the bilinear form $a(\cdot,\cdot)$ is elliptic on $\underline{X}^0\times\underline{X}^0$; indeed, the inequality

$$(tr\underline{\tau})^2 \le 2\underline{\tau}:\underline{\tau}$$

implies that,

$$\forall \underline{\tau}\in\underline{X}^0, \qquad a(\underline{\tau},\underline{\tau}) \ge \frac{1}{1+\nu}\parallel \underline{\tau}\parallel^2_{0,\Omega}.$$

Second, we verify the inf-sup condition for the bilinear form $b(\cdot,\cdot)$. For that, let us consider an arbitrary couple $(v_0,v_1)\in M\times N$, to which we associate the unique solution $w\in H^2(\Omega)$ of the following boundary value problem:

$$(3.3)\quad \left\{\begin{array}{ll} \Delta^2 w=0 & \text{in } \Omega,\\ w=-v_0 & \text{on } \Gamma,\\ \partial_n w=-v_1 & \text{on } \Gamma. \end{array}\right.$$

We define next $\tau_{ij}=\partial_{ij}w$ for $1\le i,j\le 2$; then we have that $\underline{\tau}=(\tau_{ij})_{1\le i,j\le 2}\in\underline{X}^0$ and also that $\parallel\underline{\tau}\parallel_{\underline{X}}=|w|_{2,\Omega}$. Green's formula (2.2) gives

$$\langle\gamma_1(\underline{\tau}),v_0\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}-\langle\gamma_0(\underline{\tau}),v_1\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}=\int_\Omega \tau_{ij}\partial_{ij}w\,d\Omega=|w|^2_{2,\Omega},$$

so, using the continuity of the trace operators for w, we get that

$$\sup_{\underline{\tau}\in\underline{X}^0}\frac{\langle\gamma_1(\underline{\tau}),v_0\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}-\langle\gamma_0(\underline{\tau}),v_1\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}}{\parallel\underline{\tau}\parallel_{\underline{X}}}\ge |w|_{2,\Omega}\ge c(\|v_0\|_{\frac{3}{2},\Gamma}+\|v_1\|_{\frac{1}{2},\Gamma}).$$

The hypotheses of the Babuška–Brezzi theorem are now satisfied, so problem (3.2) admits a unique solution.

In order to interpret this variational problem in the sense of distributions, let us begin by taking as test-function in the first equation of (3.2) a tensor $\underline{\tau}\in(\mathcal{D}(\Omega))^4$ with $D(\underline{\tau})=0$. Then we have

$$(3.4)\qquad \int_\Omega \underline{\chi}:\underline{\tau}\,d\Omega=0,$$

where we have put, for the simplicity of the writing,

$$\underline{\chi} = \frac{1}{1-\nu}\left(\underline{\sigma} - \frac{\nu}{1+\nu}(tr\underline{\sigma})\underline{I}\right), \qquad \underline{\sigma} = \underline{\sigma}^0 + \phi^f \underline{I}.$$

By taking next in the relation (3.4) $\underline{\tau} = \rho \underline{J}$ with $\rho \in \mathcal{D}(\Omega)$, we obtain that the tensor $\underline{\chi}$ is symmetric. For the test-function $\underline{\tau} = \underline{curl}\,\varphi$ with $\varphi \in (\mathcal{D}(\Omega))^2$, we get

$$curl \begin{pmatrix} \chi_{11} \\ \chi_{12} \end{pmatrix} = curl \begin{pmatrix} \chi_{21} \\ \chi_{22} \end{pmatrix} = 0,$$

so there exists $\theta \in (H^1(\Omega)/\mathbb{R})^2$ such that $\underline{\chi} = \underline{\nabla}\theta$. The symmetry of $\underline{\chi}$ then implies $\theta = \nabla u$, where $u \in H^2(\Omega)$. Therefore, we finally obtain that $\chi_{ij} = \partial_{ij} u$ or, equivalently,

$$\sigma_{ij} = (1-\nu)\partial_{ij} u + \nu \Delta u \delta_{ij},$$

with $u \in H^2(\Omega)$ unique up to a first order polynomial. The Green-type formula (2.2) and the first equation of (3.2) next give, for all $\underline{\tau} \in \underline{X}^0$, that

$$\langle \gamma_1(\underline{\tau}), u_0 - u\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} - \langle \gamma_0(\underline{\tau}), u_1 - \partial_n u\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0.$$

Consequently, by using the same idea as in the proof of the inf-sup condition for $b(\cdot,\cdot)$, we get that $|w|_{2,\Omega} = 0$, where w now satisfies the following biharmonic problem:

$$\begin{cases} \Delta^2 w = 0 & \text{in } \Omega, \\ w = u_0 - u & \text{on } \Gamma, \\ \partial_n w = u_1 - \partial_n u & \text{on } \Gamma. \end{cases}$$

So w is a first order polynomial, which we can take to be null, and thus we obtain that

$$u_{|\Gamma} = u_0 \in M, \qquad \partial_n u_{|\Gamma} = u_1 \in N.$$

Finally, since $D(\underline{\sigma}) = f$ and since $\underline{\sigma}$ satisfies, from the second equation of (3.2), the boundary conditions $\gamma_1(\underline{\sigma}) = 0$ on Γ_2, $\gamma_0(\underline{\sigma}) = 0$ on $\Gamma_1 \cup \Gamma_2$, we now get that $(\underline{\sigma}, u)$ satisfies the equations of the Kirchhoff–Love model (2.1), which ends the proof. ∎

REMARK 1. *This result allows us to recover the deflection of the plate, too. Indeed, u is the unique solution of the biharmonic problem*

$$\begin{cases} \Delta^2 u = f & in\ \Omega, \\ u = u_0 & on\ \Gamma, \\ \partial_n u = u_1 & on\ \Gamma. \end{cases}$$

However, in what follows we will calculate the displacement u more directly, as the solution of a second order elliptic problem.

4. Equivalent mixed formulation. We introduce in this section another variational formulation for (2.1), which is equivalent to (3.2) and whose unknowns now belong to classical Sobolev spaces. Then we will approximate this new problem, and thus we will avoid the discretization of the constraint $div(\mathbf{div}\underline{\tau}) = 0$ imposed on the test-functions of (3.2). This equivalent formulation is based on the decomposition of the elements of $\underline{X}^0$, which is presented in the next paragraph.

4.1. Characterization of the subspace $\underline{\boldsymbol{X}}^{\mathbf{0}}$. For any $\underline{\tau} \in \underline{X}^0$, one has $D(\underline{\tau}) = 0$ that is $div(\mathbf{div}\underline{\tau}) = 0$. Applying Tartar's lemma (see [5] or [9] for instance), one gets the existence of a unique $\rho \in L_0^2(\Omega)$ such that $\mathbf{div}\,\underline{\tau} = \mathbf{curl}\,\rho$. This translates into the relations

$$\begin{cases} \partial_1\tau_{11} + \partial_2\tau_{12} = \partial_2\rho, \\ \partial_1\tau_{21} + \partial_2\tau_{22} = -\partial_1\rho \end{cases}$$

or, equivalently,

$$\begin{cases} \partial_1\tau_{11} + \partial_2(\tau_{12} - \rho) = 0, \\ \partial_1(\tau_{21} + \rho) + \partial_2\tau_{22} = 0. \end{cases}$$

We have employed above the usual notation

$$L_0^2(\Omega) = \left\{ \rho \in L^2(\Omega); \quad \int_\Omega \rho \, d\Omega = 0 \right\}.$$

By setting $\mathbf{q}_1 = \begin{pmatrix} \tau_{11} \\ \tau_{12} - \rho \end{pmatrix}$ and $\mathbf{q}_2 = \begin{pmatrix} \tau_{21} + \rho \\ \tau_{22} \end{pmatrix}$, the previous relations write $div\,\mathbf{q}_i = 0$ for $1 \le i \le 2$. One more application of the Tartar lemma gives the existence of a unique function $\varphi = (\varphi_1, \varphi_2) \in (H^1(\Omega))^2$, with $\int_\Omega \varphi \, d\Omega = 0$, such that

$$\begin{cases} \tau_{11} = \partial_2\varphi_1, \\ \tau_{12} = \rho - \partial_1\varphi_1, \\ \tau_{21} = -\rho + \partial_2\varphi_2, \\ \tau_{22} = -\partial_1\varphi_2. \end{cases}$$

So, $\underline{\tau}$ belongs to $\underline{X}^0$ if and only if there exist two functions $\varphi \in (H^1(\Omega))^2$ and $\rho \in L^2(\Omega)$, both unique up to a constant, such that

$$\underline{\tau} = \underline{curl}\,\varphi + \rho\underline{J}.$$

It follows that if $\underline{\tau} \in \underline{X}^f$, then there exist unique functions $\widetilde{\varphi} \in (H^1(\Omega))^2$ with $\int_\Omega \widetilde{\varphi} \, d\Omega = 0$ and $\widetilde{\rho} \in L_0^2(\Omega)$ such that

$$\underline{\tau} = \underline{curl}\,\widetilde{\varphi} + \widetilde{\rho}\underline{J} + \phi^f \underline{I},$$

with $\phi^f \in V$ the solution of problem (3.1).

Concerning the trace operators γ_0 and γ_1, we can express them for every $\underline{\tau} \in \underline{X}^0$ in the following way:

$$\begin{cases} \gamma_0(\underline{\tau}) = (\underline{curl}\,\varphi\,\mathbf{n}) \cdot \mathbf{n} = -\partial_t\varphi \cdot \mathbf{n}, \\ \gamma_1(\underline{\tau}) = \partial_t(\underline{\tau}\mathbf{n} \cdot \mathbf{t}) + \mathbf{div}\underline{\tau} \cdot \mathbf{n} = -\partial_t(\partial_t\varphi \cdot \mathbf{t}). \end{cases} \tag{4.1}$$

If, moreover, the tensor $\underline{\tau} \in \underline{X}^0$ is symmetric, then

$$2\rho = div\varphi.$$

In this case we write $\underline{\tau}$ as below:

$$\underline{\tau} = \underline{curl}\,\varphi + \frac{1}{2}(div\varphi)\underline{J} = \begin{pmatrix} \partial_2\varphi_1 & (\partial_2\varphi_2 - \partial_1\varphi_1)/2 \\ (\partial_2\varphi_2 - \partial_1\varphi_1)/2 & -\partial_1\varphi_2 \end{pmatrix}, \tag{4.2}$$

with a unique function φ now belonging to

$$\mathbf{H} = \left\{ \varphi \in (H^1(\Omega))^2; \ \int_\Omega \varphi \, d\Omega = 0, \ \int_\Omega div\varphi \, d\Omega = 0 \right\}.$$

Obviously, $\mathbf{H}$ is a Hilbert space with respect to the norm

$$[\varphi]_{\mathbf{H}} = \left(\|\partial_2\varphi_1\|^2_{0,\Omega} + \frac{1}{2}\|\partial_2\varphi_2 - \partial_1\varphi_1\|^2_{0,\Omega} + \|\partial_1\varphi_2\|^2_{0,\Omega} \right)^{1/2}.$$

By the means of the operator $T : (H^1(\Omega))^2 \to (H^1(\Omega))^2$ defined by $T(\varphi) = (\varphi_2, -\varphi_1)$, one can immediately see that $[\varphi]_{\mathbf{H}} = \| \underline{\varepsilon}(T(\varphi)) \|_{0,\Omega}$ and $div\varphi = curl\, T(\varphi)$. Here, $\underline{\varepsilon}(\mathbf{v})$ is the strain tensor associated to a function $\mathbf{v}$ with $\varepsilon_{ij}(v) = \frac{1}{2}(\partial_i v_j + \partial_j v_i)$ for $1 \le i, j \le 2$, and the L^2-norm of a tensor is the square root of the sum of the squares of the L^2-norms of the tensor elements. So, by Korn's inequality we have that $[\cdot]_{\mathbf{H}}$ and $\|\cdot\|_{1,\Omega}$ are equivalent norms on $\mathbf{H}$.

From now on, since we know that $\|\cdot\|_{1,\Omega}$ and $|\cdot|_{1,\Omega}$ are also equivalent norms on $\mathbf{H}$, we shall consider the space $\mathbf{H}$ endowed with the norm $|\cdot|_{1,\Omega}$.

REMARK 2. *Let us point out here that to any $\varphi \in (H^1(\Omega))^2$ we can associate a function $\widetilde{\varphi} \in \mathbf{H}$ such that*

$$\underline{curl}\, \varphi + \frac{1}{2}(div\varphi)\underline{J} = \underline{curl}\, \widetilde{\varphi} + \frac{1}{2}(div\widetilde{\varphi})\underline{J},$$
$$\partial_t\varphi \cdot \mathbf{n} = \partial_t\widetilde{\varphi} \cdot \mathbf{n}, \quad \partial_t(\partial_t\varphi \cdot \mathbf{t}) = \partial_t(\partial_t\widetilde{\varphi} \cdot \mathbf{t}), \quad [\varphi]_{\mathbf{H}} = [\widetilde{\varphi}]_{\mathbf{H}}.$$

Indeed, let us put $a = \int_\Omega div\varphi \, d\Omega$ and consider the function $\varphi' = \frac{a}{2m(\Omega)}\binom{x}{y} + \mathbf{c}$, with $\mathbf{c} \in \mathbb{R}^2$ chosen such that $\int_\Omega \varphi \, d\Omega = \int_\Omega \varphi' \, d\Omega$. Clearly, one has $\partial_t\varphi' = \frac{a}{2m(\Omega)}\mathbf{t}$ on Γ which leads to $\partial_t\varphi' \cdot \mathbf{n} = 0$, $\partial_t(\partial_t\varphi' \cdot \mathbf{t}) = 0$. Thus, we can take $\widetilde{\varphi} = \varphi - \varphi'$ which satisfies the above conditions.

4.2. New variational formulation of the Kirchhoff–Love model. In what follows, since we know that the bending moment $\underline{\sigma}$ is symmetric, we will use the decomposition (4.2) for the symmetric elements of $\underline{X}^0$ in order to write down and to study a new equivalent formulation of problem (3.2), whose main unknown will now be a function ψ belonging to $\mathbf{H}$.

To do that, let us define a bilinear continuous form $A(\cdot,\cdot)$ on $\mathbf{H} \times \mathbf{H}$ by putting

$$A(\psi,\varphi) = a\left(\underline{curl}\, \psi + \frac{1}{2}(div\psi)\underline{J}, \underline{curl}\, \varphi + \frac{1}{2}(div\varphi)\underline{J} \right)$$
$$= \frac{1}{1-\nu}\int_\Omega \left[\partial_2\psi_1\partial_2\varphi_1 + \partial_1\psi_2\partial_1\varphi_2 + \frac{1}{2}(\partial_2\psi_2 - \partial_1\psi_1)(\partial_2\varphi_2 - \partial_1\varphi_1) \right] d\Omega$$
$$- \frac{\nu}{1-\nu^2}\int_\Omega (\partial_2\psi_1 - \partial_1\psi_2)(\partial_2\varphi_1 - \partial_1\varphi_2) \, d\Omega.$$

Let us also calculate from (4.1), for any $(v_0, v_1) \in M \times N$,

$$b\left(\underline{curl}\, \varphi + \frac{1}{2}(div\varphi)\underline{J}, (v_0, v_1) \right) = -\langle \partial_t(\partial_t\varphi \cdot \mathbf{t}), v_0 \rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} + \langle \partial_t\varphi \cdot \mathbf{n}, v_1 \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}.$$

Considering a lifting $w \in H^2(\Omega)$ which satisfies $w = v_0$ on Γ and $\partial_n w = v_1$ on Γ, one can now write

$$b\left(\underline{curl}\, \varphi + \frac{1}{2}(div\varphi)\underline{J}, (v_0, v_1) \right) = \langle \partial_t\varphi \cdot \mathbf{t}, \partial_t v_0 \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t\varphi \cdot \mathbf{n}, v_1 \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}$$
$$= \langle \partial_t\varphi \cdot \mathbf{t}, \nabla w \cdot \mathbf{t} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t\varphi \cdot \mathbf{n}, \nabla w \cdot \mathbf{n} \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}$$
$$= \langle \partial_t\varphi, \nabla w \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = -\langle \partial_t \nabla w, \varphi \rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}.$$

REMARK 3. *In order to establish in a rigorous manner the previous relations, one may use the continuity of the trace operators* $\gamma_0,\ \gamma_1$ *and the density of* $\mathcal{D}(\overline{\Omega})$ *in* $H^1(\Omega)$.

This leads us to introduce a new bilinear form $B(\cdot,\cdot)$ on $\mathbf{H}\times\mathbf{Z}$ by setting

$$B(\varphi,\mathbf{q}) = -\langle \partial_t \mathbf{q}, \varphi\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma},$$

where

$$\mathbf{Z} = \left\{ \mathbf{q}\in (H^{1/2}(\Gamma))^2;\ \mathbf{q}=0 \text{ on } \Gamma_0,\ \mathbf{q}\cdot\mathbf{t}=0 \text{ on } \Gamma_1,\ \int_\Gamma \mathbf{q}\cdot\mathbf{t}\, d\Gamma = 0 \right\}$$

is endowed with the usual norm $\|\cdot\|_{1/2,\Gamma}$. It is obvious that to any $\mathbf{q}\in\mathbf{Z}$, one can now associate a unique couple $(v_0,v_1)\in M\times N$ by putting

$$\mathbf{q} = (\partial_t v_0)\mathbf{t} + v_1\mathbf{n}.$$

We also introduce the linear continuous forms $F(\cdot)$ and $G(\cdot)$ defined on $\mathbf{H}$, respectively, on $\mathbf{Z}$, by

$$F(\varphi) = -a\left(\phi^f \underline{I}, \underline{curl}\,\varphi + \frac{1}{2}(div\varphi)\underline{J}\right) = -\frac{1}{1+\nu}\int_\Omega \phi^f\,(\partial_2\varphi_1 - \partial_1\varphi_2)\ d\Omega,$$

$$G(\mathbf{q}) = \int_\Gamma \phi^f \mathbf{q}\cdot\mathbf{n}\, d\Gamma.$$

We are now able to write the following mixed variational problem:

$$\left\{\begin{array}{lll} \text{find } \psi\in\mathbf{H},\ \mathbf{p}\in\mathbf{Z} & \text{such that,} & \\ \forall\varphi\in\mathbf{H}, & A(\psi,\varphi)+B(\varphi,\mathbf{p}) & = F(\varphi); \\ \forall\mathbf{q}\in\mathbf{Z}, & B(\psi,\mathbf{q}) & = G(\mathbf{q}), \end{array}\right. \tag{4.3}$$

and we are able to prove in the next result that it is well-posed.

THEOREM 4.1. *Problem* (4.3) *has a unique solution.*

Proof. We use, once more, the Babuška–Brezzi theory for mixed formulations. We begin by establishing that the bilinear form $A(\cdot,\cdot)$ is $\mathbf{H}$-elliptic. Indeed, let φ be an arbitrary element of $\mathbf{H}$. We put $\underline{\tau} = \underline{curl}\,\varphi + \frac{1}{2}(div\varphi)\underline{J}$; then we clearly have $\underline{\tau}\in\underline{X}^0$, and we already know that there exists a constant $c>0$ depending only on ν such that

$$A(\varphi,\varphi) = a(\underline{\tau},\underline{\tau}) \geq c\,\|\,\underline{\tau}\,\|^2_{0,\Omega}\,.$$

On the other hand, one has

$$\|\,\underline{\tau}\,\|_{0,\Omega} = [\varphi]_{\mathbf{H}} \geq c\,|\varphi|_{1,\Omega}\,,$$

so we deduce the ellipticity of $A(\cdot,\cdot)$ on $\mathbf{H}\times\mathbf{H}$.

The continuity of the bilinear form $B(\cdot,\cdot)$ on $\mathbf{H}\times\mathbf{Z}$ may be established by classical means:

$$|\,B(\varphi,\mathbf{q})\,| \leq \|\partial_t\mathbf{q}\|_{-1/2,\Gamma}\cdot\|\varphi\|_{1/2,\Gamma} \leq c\,\|\mathbf{q}\|_{1/2,\Gamma}\cdot|\varphi|_{1,\Omega}\,.$$

As to the inf-sup condition for $B(\cdot,\cdot)$, let us consider for any $\mathbf{q}\in\mathbf{Z}$ the boundary value problem

$$\left\{\begin{array}{ll} \Delta\mathbf{w} = 0 & \text{in } \Omega, \\ \mathbf{w} = \mathbf{q} & \text{on } \Gamma. \end{array}\right.$$

Since $\partial_t \mathbf{q} = -(\underline{curl}\,\mathbf{w})\mathbf{n} \in (H^{-1/2}(\Gamma))^2$, we can write that

$$\sup_{\varphi\in\mathbf{H}} \frac{B(\varphi,\mathbf{q})}{|\varphi|_{1,\Omega}} = \sup_{\varphi\in\mathbf{H}} \frac{\displaystyle\int_\Omega \underline{curl}\,\mathbf{w} : \underline{\nabla}\varphi \, d\Omega}{|\varphi|_{1,\Omega}}.$$

On the other hand, since $\Delta w_i = -curl(\mathbf{curl}\, w_i) = 0$, for $1 \le i \le 2$, one gets that there exists $\mathbf{z} \in (H^1(\Omega))^2$, unique up to a constant, such that $\underline{curl}\,\mathbf{w} = \underline{\nabla}\mathbf{z}$. We can take $\mathbf{z}$ such that $\int_\Omega \mathbf{z}\, d\Omega = 0$. Moreover, we have

$$\int_\Omega div\mathbf{z}\, d\Omega = \int_\Omega (\partial_2 w_1 - \partial_1 w_2)\, d\Omega = \int_\Gamma \mathbf{w}\cdot\mathbf{t}\, d\Gamma = \int_\Gamma \mathbf{q}\cdot\mathbf{t}\, d\Gamma = 0,$$

so $\mathbf{z}$ belongs to $\mathbf{H}$. This implies

$$\sup_{\varphi\in\mathbf{H}} \frac{\displaystyle\int_\Omega \underline{curl}\,\mathbf{w} : \underline{\nabla}\varphi \, d\Omega}{|\varphi|_{1,\Omega}} \ge \frac{\displaystyle\int_\Omega \underline{curl}\,\mathbf{w} : \underline{\nabla}\mathbf{z} \, d\Omega}{|\mathbf{z}|_{1,\Omega}} = |\mathbf{z}|_{1,\Omega} = \| \underline{curl}\,\mathbf{w} \|_{0,\Omega}\,.$$

So, we have now established that

$$\sup_{\varphi\in\mathbf{H}} \frac{B(\varphi,\mathbf{q})}{|\varphi|_{1,\Omega}} \ge \| \underline{curl}\,\mathbf{w} \|_{0,\Omega} = |\mathbf{w}|_{1,\Omega}\,.$$

However, $\mathbf{q} = 0$ on Γ_0 and, since we supposed that $m(\Gamma_0) > 0$, by Poincaré's inequality and by trace theorem we obtain that

$$|\mathbf{w}|_{1,\Omega} \ge c' \|\mathbf{w}\|_{1,\Omega} \ge c \|\mathbf{q}\|_{\frac{1}{2},\Gamma}\,,$$

which allows us to conclude that problem (4.3) admits a unique solution. ∎

4.3. Equivalence with the initial problem. We present here the link between the solution of the previous variational problem (4.3) and the solution of the initial Kirchhoff–Love model. This is stated in the next theorem.

THEOREM 4.2. *Let* $(\psi, \mathbf{p}) \in \mathbf{H}\times\mathbf{Z}$ *be the unique solution of* (4.3). *Then one has*

$$\begin{cases} \underline{\sigma\prime} = \underline{curl}\,\psi + \dfrac{1}{2}(div\psi)\underline{J} + \phi^f \underline{I} & \text{in } \Omega, \\ \nabla u = \mathbf{p} \quad \text{on} \quad \Gamma, \end{cases} \tag{4.4}$$

where $(\underline{\sigma\prime}, u)$ *is the solution of* (2.1) *and* ϕ^f *the solution of* (3.1).

Proof. Let us consider the tensor $\underline{\sigma}'$ associated to the function ψ by means of the relation

$$\underline{\sigma}' = \underline{curl}\,\psi + \frac{1}{2}(div\psi)\underline{J} + \phi^f \underline{I}.$$

Then obviously $D(\underline{\sigma}') = f$ and $\underline{\sigma}'$ is symmetric. Moreover, to any $(v_0, v_1) \in M \times N$ we associate, as in Theorem 3.1, the auxiliary problem (3.3), and we set $\mathbf{q} = \nabla w$. Then one has $\mathbf{q} \in \mathbf{Z}$ and the second equation of (4.3) implies that

$$\langle \partial_t\psi, \nabla w\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = \int_\Gamma \phi^f \partial_n w \, d\Gamma$$

$$\Leftrightarrow \langle \partial_t\psi\cdot\mathbf{t}, \partial_t w\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} + \langle \partial_t\psi\cdot\mathbf{n} - \phi^f, \partial_n w\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0$$

$$\Leftrightarrow \langle \partial_t(\partial_t\psi\cdot\mathbf{t}), v_0\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma} - \langle \partial_t\psi\cdot\mathbf{n} - \phi^f, v_1\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma} = 0,$$

which gives

$$\left\{\begin{array}{ll}\partial_t(\partial_t\psi\cdot\mathbf{t})=0 & \text{in } H^{-3/2}(\Gamma_2),\\ \partial_t\psi\cdot\mathbf{n}-\phi^f=0 & \text{in } H^{-1/2}(\Gamma_1\cup\Gamma_2),\end{array}\right. \Longleftrightarrow \left\{\begin{array}{ll}\gamma_1(\underline{\sigma}')=0 & \text{on } \Gamma_2,\\ \gamma_0(\underline{\sigma}')=0 & \text{on } \Gamma_1\cup\Gamma_2.\end{array}\right.$$

Next, to any $\varphi\in\mathbf{H}$ we associate $\underline{\tau}\in\underline{X}^0$ by putting $\underline{\tau}=\underline{curl}\,\varphi+\frac{1}{2}(div\varphi)\underline{J}$. We take (cf. Remark 2) in the first equation of (4.3) a test-function $\varphi=\varphi^*-\binom{ax+c_1}{ay+c_2}\in\mathbf{H}$ with $\varphi^*\in(\mathcal{D}(\Omega))^2$ arbitrary, and we thus get that

$$a(\underline{\sigma}',\underline{\tau})=0.$$

By introducing the symmetric tensor

$$\underline{\chi}'=\frac{1}{1-\nu}\left(\underline{\sigma}'-\frac{\nu}{1+\nu}(tr\underline{\sigma}')\,\underline{I}\right),$$

we may write this last relation as

$$\int_\Omega \underline{\chi}':\underline{\tau}\,d\Omega=0 \iff \int_\Omega(\chi'_{11}\partial_2\varphi_1^*-\chi'_{12}\partial_1\varphi_1^*)+(\chi'_{12}\partial_2\varphi_2^*-\chi'_{22}\partial_1\varphi_2^*)\,d\Omega=0$$

for every $\varphi^*\in(\mathcal{D}(\Omega))^2$. We deduce, exactly as in the proof of Theorem 3.1, the existence of a function $u'\in H^2(\Omega)$, unique up to a first order polynomial, such that

$$\chi'_{ij}=\partial_{ij}u' \quad \text{for} \quad 1\le i,j\le 2;$$

that is,

$$\underline{\sigma}'=(1-\nu)\begin{pmatrix}\partial_{11}u' & \partial_{12}u'\\ \partial_{21}u' & \partial_{22}u'\end{pmatrix}+\nu(\Delta u')\underline{I}.$$

Now, for $\varphi^*\in(H^1(\Omega))^2$, the Green-type formula (2.2) gives that

$$\langle\gamma_1(\underline{\tau}),u'\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}-\langle\gamma_0(\underline{\tau}),\partial_n u'\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}=-a(\underline{\sigma}',\underline{\tau})=-\langle\partial_t\mathbf{p},\varphi^*\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}.$$

The above relation can be written as below:

$$-\langle\partial_t(\partial_t\varphi^*\cdot\mathbf{t}),u'\rangle_{-\frac{3}{2},\frac{3}{2},\Gamma}+\langle\partial_t\varphi^*\cdot\mathbf{n},\partial_n u'\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}=-\langle\partial_t\mathbf{p},\varphi^*\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}$$

$$\Leftrightarrow\langle\partial_t(\nabla u'-\mathbf{p}),\varphi^*\rangle_{-\frac{1}{2},\frac{1}{2},\Gamma}=0$$

for all $\varphi^*\in(H^1(\Omega))^2$. So we see that $\mathbf{p}=\nabla u'+\mathbf{c}$ on Γ with $\mathbf{c}\in\mathbb{R}^2$, and since $\nabla u'\in(H^1(\Omega)/\mathbb{R})^2$ we can choose $\mathbf{c}=0$. So we obtain, because $\mathbf{p}\in\mathbf{Z}$, that

$$\left\{\begin{array}{ll}\nabla u'=0 & \text{on } \Gamma_0,\\ \partial_t u'=0 & \text{on } \Gamma_1,\end{array}\right. \Longleftrightarrow \left\{\begin{array}{ll}\partial_n u'=0 & \text{on } \Gamma_0,\\ u'=c & \text{on } \Gamma_0\cup\Gamma_1.\end{array}\right.$$

However, now u' belongs to $H^2(\Omega)/\mathbb{R}$, so we can fix the constant c by taking $u'=0$ on $\Gamma_0\cup\Gamma_1$. We have thus proved that $(\underline{\sigma}',u')$ satisfies the Kirchhoff–Love problem (2.1), and the theorem is established. □

As a conclusion, it is sufficient to solve the mixed problem (4.3) and use relation (4.4) to see that $\underline{\sigma}^0=\underline{curl}\,\psi+\frac{1}{2}(div\psi)\underline{J}$ and, implicitly, the tensor $\underline{\sigma}=\underline{\sigma}^0+\phi^f\underline{I}$ is the solution of the initial Kirchhoff–Love model.

REMARK 4. *Let us notice that we can also calculate the displacement u as the unique solution of the following second order elliptic problem:*

$$\begin{cases} \Delta u = \dfrac{1}{1+\nu}(tr\underline{\sigma}) & \text{in } \Omega, \\ u = 0 & \text{on } \Gamma_0 \cup \Gamma_1, \\ \partial_n u = \mathbf{p}\cdot\mathbf{n} & \text{on } \Gamma_2. \end{cases} \tag{4.5}$$

The equation in Ω is obtained by taking the trace in the constitutive law of the plate, and it can also be written in terms of the solution ψ of (4.3) *as* $\Delta u = \frac{1}{1+\nu}(-curl\,\psi + 2\phi^f)$.

So, from now on, we shall study the variational problem (4.3). More precisely, we are interested in its finite element approximation, which will be presented in the next section.

5. Finite element approximation.

5.1. Discrete variational formulation. Let $(\mathcal{T}_h)_{h>0}$ be a regular family of triangulations of the polygonal domain $\overline{\Omega}$, each $\mathcal{T}_h$ consisting of triangles K : $\overline{\Omega} = \bigcup_{K\in\mathcal{T}_h} K$. For every triangle K of $\mathcal{T}_h$, we denote by h_K its diameter, and we define the discretization parameter $h = \max_{K\in\mathcal{T}_h} h_K$. We also introduce the set of edges of the triangulation $\mathcal{T}_h$ situated on $\Gamma_1 \cup \Gamma_2$,

$$\partial\mathcal{T}_h^1 = \{T;\ T \text{ edge of } K \in \mathcal{T}_h, T \subset (\Gamma_1 \cup \Gamma_2)\},$$

and we agree to denote by $\mathcal{T}_h^*$ the set of triangles $K \in \mathcal{T}_h$ which have at least an edge situated on $\Gamma_1 \cup \Gamma_2$. We consider two finite dimensional spaces $\mathbf{H}_h \subset \mathbf{H}$ and $\mathbf{Z}_h \subset \mathbf{Z}$ which we take as below:

$$\begin{aligned} H_h^1 &= \{\varphi_h \in H^1(\Omega);\ \forall K \in \mathcal{T}_h,\ \varphi_{h|K} \in P_1(K) \text{ if } K \notin \mathcal{T}_h^* \\ &\qquad\qquad \text{and } \varphi_{h|K} \in P_2(K) \text{ if } K \in \mathcal{T}_h^*\}, \\ \mathbf{H}_h &= \mathbf{H} \cap (H_h^1)^2, \\ \mathbf{Z}_h &= \left\{\mathbf{q}_h \in \mathbf{Z};\ \mathbf{q}_h \in (\mathcal{C}^0(\Gamma))^2 \text{ and } \forall T \in \partial\mathcal{T}_h^1,\ \mathbf{q}_{h|T} \in (P_1(T))^2\right\}. \end{aligned}$$

The degrees of freedom of $\varphi_h \in \mathbf{H}_h$ are the values of φ_h at the nodes of the triangulation $\mathcal{T}_h$, to which we add the values at the midpoints of the edges situated on $\Gamma_1 \cup \Gamma_2$ (i.e., the bubble-functions on the boundary $\Gamma_1 \cup \Gamma_2$).

Let us now write down the discrete version of the continuous problem (4.3) as follows:

$$\begin{cases} \text{find } \psi_h \in \mathbf{H}_h,\ \mathbf{p}_h \in \mathbf{Z}_h \quad \text{such that,} \\ \quad \forall \varphi_h \in \mathbf{H}_h, \quad A(\psi_h, \varphi_h) + B(\varphi_h, \mathbf{p}_h) = F_h(\varphi_h); \\ \quad \forall \mathbf{q}_h \in \mathbf{Z}_h, \quad B(\psi_h, \mathbf{q}_h) = G_h(\mathbf{q}_h). \end{cases} \tag{5.1}$$

The linear forms $F(\cdot)$ and $G(\cdot)$ are replaced in the discrete case by

$$\begin{aligned} F_h(\varphi_h) &= -\frac{1}{1+\nu}\int_\Omega \phi_h^f\,(\partial_2\varphi_{1h} - \partial_1\varphi_{2h})\ d\Omega, \\ G_h(\mathbf{q}_h) &= \int_\Gamma \phi_h^f\,\mathbf{q}_h\cdot\mathbf{n}\ d\Gamma. \end{aligned}$$

The discrete function ϕ_h^f is a P_1-continuous finite element approximation of ϕ^f, the solution of the auxiliary problem (3.1). In order to calculate it explicitly, one can

discretize the variational formulation of (3.1) and solve

$$\left\{ \begin{array}{l} \text{find } \phi_h^f \in V_h \quad \text{such that,} \\ \forall v_h \in V_h, \quad \displaystyle\int_\Omega \nabla \phi_h^f \cdot \nabla v_h \, d\Omega = \int_\Omega f v_h \, d\Omega, \end{array} \right. \tag{5.2}$$

where

$$V_h = \left\{ v_h \in V;\ v_{h|K} \in P_1(K)\ \forall K \in \mathcal{T}_h \right\}.$$

It is then obvious that

$$| \phi^f - \phi_h^f |_{1,\Omega} = \inf_{v_h \in V_h} | \phi^f - v_h |_{1,\Omega} .$$

5.2. Error estimates. With the above choice for the finite element spaces, we can show that the variational problem (5.1) has a unique solution. Moreover, the discrete inf-sup condition of Babuška–Brezzi holds uniformly with respect to the discretization parameter h, a result which is stated in the next lemma.

LEMMA 5.1. *There exists a positive constant c independent of h such that,*

$$\forall \mathbf{q}_h \in \mathbf{Z}_h, \quad \sup_{\varphi_h \in \mathbf{H}_h} \frac{B(\varphi_h, \mathbf{q}_h)}{|\varphi_h|_{1,\Omega}} \geq c \parallel \mathbf{q}_h \parallel_{1/2,\Gamma} .$$

Proof. We apply Fortin's trick (see [2], [8]). For that, we will use the continuous inf-sup condition, established in Theorem 4.1, and the interpolation operator $P_h : (H^1(\Omega))^2 \to (H_h^1)^2$ defined hereafter.

Let us denote by P_{1h} the classical Lagrange interpolation operator which satisfies, for any $\varphi \in (H^1(K))^2 \cap (\mathcal{C}^0(\overline{K}))^2$,

$$P_{1h}\varphi \in (\mathcal{P}_1(K))^2 \quad \text{and} \quad P_{1h}\varphi(S) = \varphi(S)$$

for every vertex S of $K \in \mathcal{T}_h$. For the triangles satisfying $K \in \mathcal{T}_h^*$ we also introduce the operator P_{2h} defined by $P_{2h}\varphi \in (\mathcal{P}_2(K))^2$ and

$$\begin{gathered} P_{2h}\varphi(S) = 0 \text{ for every vertex } S \text{ of } K, \\ \int_T (\varphi - P_{2h}\varphi) \, d\Gamma = 0, \end{gathered}$$

where T represents the edge of K situated on $\Gamma_1 \cup \Gamma_2$. Then we put (see also [2]) on every triangle $K \in \mathcal{T}_h$

$$P_h\varphi = \left\{ \begin{array}{ll} P_{1h}\varphi & \text{if} \quad K \notin \mathcal{T}_h^*, \\ P_{1h}\varphi + P_{2h}(\varphi - P_{1h}\varphi) & \text{if} \quad K \in \mathcal{T}_h^*, \end{array} \right.$$

which clearly has the property

$$\forall T \subset \Gamma_1 \cup \Gamma_2, \quad \int_T P_h\varphi \, d\Gamma = \int_T \varphi \, d\Gamma. \tag{5.3}$$

If $\varphi \in \mathbf{H} \cap (\mathcal{C}^0(\overline{\Omega}))^2$, then we have only $P_h\varphi \in (H_h^1)^2$. We construct, according to Remark 2,

$$\widetilde{P_h\varphi} = P_h\varphi - \left(\begin{array}{c} ax + c_1 \\ ay + c_2 \end{array} \right) \in \mathbf{H}_h.$$

Now let us come back to the proof of the uniform inf-sup condition for problem (5.1). To any $\mathbf{q}_h \in \mathbf{Z}_h$, we associate exactly as in Theorem 4.1 a function $\mathbf{z} \in \mathbf{H}$ such that

$$\frac{B(\mathbf{z}, \mathbf{q}_h)}{|\mathbf{z}|_{1,\Omega}} \geq c \, \|\mathbf{q}_h\|_{\frac{1}{2},\Gamma} \geq |\mathbf{z}|_{1,\Omega} \, .$$

We note that $\underline{\nabla}\mathbf{z} = \underline{curl}\, \mathbf{w}$ with $\mathbf{w} \in (H^1(\Omega))^2$ and $\Delta \mathbf{w} = 0$ in Ω and $\mathbf{w} = \mathbf{q}_h$ on Γ. We have $\mathbf{q}_h \in (H^1(\Gamma))^2$; then by classical results of regularity of the Laplace operator (see [6], [7]) we have that $\mathbf{w} \in (H^{1+a}(\Omega))^2$ with $a \in]0, \frac{3}{2}]$. We deduce that $\mathbf{z} \in (H^{1+a}(\Omega))^2 \hookrightarrow (\mathcal{C}^0(\overline{\Omega}))^2$, so we can define $P_h\mathbf{z}$.

Then by considering the discrete function $\mathbf{z}_h = \widetilde{P_h\mathbf{z}} \in \mathbf{H}_h$ and using (5.3) we obtain

$$B(\mathbf{z}, \mathbf{q}_h) = B(P_h\mathbf{z}, \mathbf{q}_h) = B\left(\widetilde{P_h\mathbf{z}}, \mathbf{q}_h\right).$$

The last equality comes from the fact that

$$B\left(\begin{pmatrix} ax + c_1 \\ ay + c_2 \end{pmatrix}, \mathbf{q}_h\right) = a \int_\Gamma \mathbf{q}_h \cdot \mathbf{t} \, d\Gamma = 0.$$

On the other hand, we obtain by passing to the reference finite element and using the Bramble–Hilbert lemma (see [1], [3]), for any K such that $K \in \mathcal{T}_h^*$, that $|\mathbf{z} - P_{2h}\mathbf{z}|_{1,K} \leq c \, |\mathbf{z}|_{1,K}$. This implies

$$\forall K \in \mathcal{T}_h, \quad |\mathbf{z} - P_h\mathbf{z}|_{1,K} \leq c \, |\mathbf{z} - P_{1h}\mathbf{z}|_{1,K} \leq c \, |\mathbf{z}|_{1,K} \, ,$$

so, by the triangle inequality,

$$|P_h\mathbf{z}|_{1,\Omega} \leq c \, |\mathbf{z}|_{1,\Omega} \, .$$

By taking into account the fact that

$$c' \left|\widetilde{P_h\mathbf{z}}\right|_{1,\Omega} \leq \left[\widetilde{P_h\mathbf{z}}\right]_{\mathbf{H}} = [P_h\mathbf{z}]_{\mathbf{H}} \leq c \, |P_h\mathbf{z}|_{1,\Omega} \, ,$$

we now obtain that

$$\sup_{\varphi_h \in \mathbf{H}_h} \frac{B(\varphi_h, \mathbf{q}_h)}{|\varphi_h|_{1,\Omega}} \geq \frac{B\left(\widetilde{P_h\mathbf{z}}, \mathbf{q}_h\right)}{\left|\widetilde{P_h\mathbf{z}}\right|_{1,\Omega}} \geq c \frac{B(\mathbf{z}, \mathbf{q}_h)}{|\mathbf{z}|_{1,\Omega}} \geq c \, \|\mathbf{q}_h\|_{\frac{1}{2},\Gamma} \, ,$$

which completes the proof of the lemma. □

This allows us to get the following error estimate (cf. [2], [8]):

$$\begin{aligned} |\psi - \psi_h|_{1,\Omega} + \|\mathbf{p} - \mathbf{p}_h\|_{\frac{1}{2},\Gamma} \leq c \Bigg\{ & \inf_{\varphi_h \in \mathbf{H}_h} |\psi - \varphi_h|_{1,\Omega} + \inf_{\mathbf{q}_h \in \mathbf{Z}_h} \|\mathbf{p} - \mathbf{q}_h\|_{\frac{1}{2},\Gamma} \\ & + \sup_{\varphi_h \in \mathbf{H}_h} \frac{F_h(\varphi_h) - F(\varphi_h)}{|\varphi_h|_{1,\Omega}} + \sup_{\mathbf{q}_h \in \mathbf{Z}_h} \frac{G_h(\mathbf{q}_h) - G(\mathbf{q}_h)}{\|\mathbf{q}_h\|_{\frac{1}{2},\Gamma}} \Bigg\} , \end{aligned} \tag{5.4}$$

with c independent of the triangulation. It is obvious that

$$\sup_{\varphi_h \in \mathbf{H}_h} \frac{F_h(\varphi_h) - F(\varphi_h)}{|\varphi_h|_{1,\Omega}} \leq c \mid \phi^f - \phi_h^f \mid_{1,\Omega} \leq c \inf_{v_h \in V_h} \mid \phi^f - v_h \mid_{1,\Omega},$$

while the last term can be bounded as below:

$$\sup_{\mathbf{q}_h\in\mathbf{Z}_h}\frac{G_h(\mathbf{q}_h)-G(\mathbf{q}_h)}{\|\mathbf{q}_h\|_{\frac12,\Gamma}}=\sup_{\mathbf{q}_h\in\mathbf{Z}_h}\frac{\displaystyle\int_\Gamma(\phi_h^f-\phi^f)\,\mathbf{q}_h\cdot\mathbf{n}\,d\Gamma}{\|\mathbf{q}_h\|_{\frac12,\Gamma}}\le c\parallel(\phi_h^f-\phi^f)\mathbf{n}\parallel_{-\frac12,\Gamma}$$
$$\le c\parallel\phi_h^f-\phi^f\parallel_{0,\Gamma}\le c\parallel\phi_h^f-\phi^f\parallel_{1,\Omega}\le c\inf_{v_h\in V_h}\mid\phi^f-v_h\mid_{1,\Omega}.$$

So, we have now established the following result.

THEOREM 5.2. *The approximation method* (5.1) *of the variational problem* (4.3) *is unconditionally convergent and satisfies the following error estimate:*

$$|\psi-\psi_h|_{1,\Omega}+\|\mathbf{p}-\mathbf{p}_h\|_{\frac12,\Gamma}$$
$$\le c\left\{\inf_{\varphi_h\in\mathbf{H}_h}|\psi-\varphi_h|_{1,\Omega}+\inf_{\mathbf{q}_h\in\mathbf{Z}_h}\|\mathbf{p}-\mathbf{q}_h\|_{\frac12,\Gamma}+\inf_{v_h\in V_h}\mid\phi^f-v_h\mid_{1,\Omega}\right\},$$

with a constant c independent of the discretization.

5.3. Convergence rate. First of all, let us recall that the function ϕ^f belonging to $H^1(\Omega)$ satisfies the boundary value problem (3.1):

$$\begin{cases}\Delta\phi^f=f & \in L^2(\Omega),\\ \phi^f=0 & \text{on }\Gamma_0\cup\Gamma_1,\\ \partial_n\phi^f=0 & \text{on }\Gamma_2.\end{cases}$$

The regularity results for the Laplace operator ensure (see [6], [7]) that there exists $b\in]\frac12,1]$ such that

$$\phi^f\in H^{1+b}(\Omega),\qquad||\phi^f||_{1+b,\Omega}\le c\parallel f\parallel_{0,\Omega}.$$

Then we get

$$\inf_{v_h\in V_h}\mid\phi^f-v_h\mid_{1,\Omega}\le ch^b\parallel f\parallel_{0,\Omega}.$$

If Ω is convex, we have $b=1$ and then we obtain an optimal behavior of the approximation method given in (5.2). If the domain Ω is not convex but has no cuts, then we have $b\in]\frac12,1[$.

In order to give the convergence rate of the discretization method proposed in (5.1), we assume that the solution $(\underline{\sigma},u)$ of the initial Kirchhoff–Love model (2.1) has the following smoothness:

$$\underline{\sigma}\in(H^a(\Omega))^4,\qquad u\in H^{2+a}(\Omega),\qquad 0<a\le1,\qquad \parallel\underline{\sigma}\parallel_{a,\Omega}+\parallel u\parallel_{2+a,\Omega}\le c\parallel f\parallel_{0,\Omega}. \tag{5.5}$$

Then we immediately obtain from Theorem 5.2 and standard interpolation results that

$$|\psi-\psi_h|_{1,\Omega}+\|\mathbf{p}-\mathbf{p}_h\|_{\frac12,\Gamma}\le ch^{\min\{a,b\}}\parallel f\parallel_{0,\Omega}. \tag{5.6}$$

5.4. Approximate bending tensor and displacement. It is now easy to come back to the calculus of the quantities which interested us at the beginning of this paper, that is, the bending moment $\underline{\sigma}$ and the deflection of the plate u. Concerning the tensor $\underline{\sigma}$, we already know from Theorem 4.2 that

$$\underline{\sigma} = \underline{curl}\,\psi + \frac{1}{2}(div\psi)\underline{J} + \phi^f \underline{I},$$

where ψ satisfies the equations (4.3). Therefore we set

$$\underline{\sigma}_h = \underline{curl}\,\psi_h + \frac{1}{2}(div\psi_h)\underline{J} + \phi_h^f \underline{I}, \tag{5.7}$$

with ψ_h the solution of (5.1) and with ϕ_h^f given by (5.2). Then it is obvious that

$$\| \underline{\sigma} - \underline{\sigma}_h \|_{0,\Omega} \leq c\,|\psi - \psi_h|_{1,\Omega} + || \phi^f - \phi_h^f ||_{0,\Omega} \leq ch^{\min\{a,b\}} \| f \|_{0,\Omega}\ . \tag{5.8}$$

One equally obtains the following estimate, with respect to the norm of $H^{-1}(\Omega)$:

$$\| D(\underline{\sigma}) - D(\underline{\sigma}_h) \|_{-1,\Omega} = \| \Delta(\phi^f - \phi_h^f) \|_{-1,\Omega} \leq | \phi^f - \phi_h^f |_{1,\Omega} \leq ch^b \| f \|_{0,\Omega}\ .$$

Now, concerning the plate's deflection, we know that the continuous solution u satisfies the boundary value problem (4.5), which may be written in variational form

$$\begin{cases} \text{find } u \in V \quad \text{such that,} \\ \forall v \in V, \quad \displaystyle\int_\Omega \nabla u \cdot \nabla v\, d\Omega = \frac{-1}{1+\nu} \int_\Omega (tr\underline{\sigma}) v\, d\Omega + \int_{\Gamma_2} \mathbf{p} \cdot \mathbf{n}\, v\, d\Gamma. \end{cases}$$

Then we calculate the approximation u_h of u as the solution of the next discrete problem:

$$\begin{cases} \text{find } u_h \in V_h \quad \text{such that,} \\ \forall v_h \in V_h, \quad \displaystyle\int_\Omega \nabla u_h \cdot \nabla v_h\, d\Omega = \frac{-1}{1+\nu} \int_\Omega (tr\underline{\sigma}_h) v_h\, d\Omega + \int_{\Gamma_2} \mathbf{p}_h \cdot \mathbf{n}\, v_h\, d\Gamma, \end{cases} \tag{5.9}$$

where $\underline{\sigma}_h$ is of course given by (5.7) and $\mathbf{p}_h$ by the problem (5.1). We obtain the same matrix in the relations (5.9) and (5.2), so we have to compute it only once. This leads us to the following error bound:

$$\begin{aligned} |u - u_h|_{1,\Omega} &\leq c \left\{ \inf_{v_h \in V_h} |u - v_h|_{1,\Omega} + \| \underline{\sigma} - \underline{\sigma}_h \|_{0,\Omega} + \| (\mathbf{p} - \mathbf{p}_h) \cdot \mathbf{n} \|_{-\frac{1}{2},\Gamma_2} \right\} \\ &\leq c \left\{ \inf_{v_h \in V_h} |u - v_h|_{1,\Omega} + \| \underline{\sigma} - \underline{\sigma}_h \|_{0,\Omega} + \| \mathbf{p} - \mathbf{p}_h \|_{\frac{1}{2},\Gamma_2} \right\}. \end{aligned} \tag{5.10}$$

Thanks to Theorem 5.2 and to estimates (5.8) and (5.10), we immediately obtain the convergence rate of the approximation of the bending moment $\underline{\sigma}$, as well as of the deflection u. As a conclusion, we finally state the following result.

THEOREM 5.3. *Under the previous smoothness hypotheses on the solution* $(\underline{\sigma}, u)$*, one has*

$$\| \underline{\sigma} - \underline{\sigma}_h \|_{0,\Omega} + \| u - u_h \|_{1,\Omega} + \| D(\underline{\sigma}) - D(\underline{\sigma}_h) \|_{-1,\Omega} \leq ch^{\min\{a,b\}} \| f \|_{0,\Omega},$$

where the constant c *is independent of the discretization.*

So, the approximation method of the Kirchhoff–Love model described in this paper is unconditionally convergent and is optimal whenever the solution $(\underline{\sigma}, u)$ of (2.1), as well as the solution ϕ^f of the Laplacian (3.1), are sufficiently smooth. More precisely, if $\underline{\sigma} \in (H^1(\Omega))^4$ and $\phi^f \in H^2(\Omega)$ (which is the case, for instance, when Ω is convex since $a = b = 1$), then the convergence rate is $O(h)$.

CONSTRUCTING RANDOMLY SHIFTED LATTICE RULES IN WEIGHTED SOBOLEV SPACES*

I. H. SLOAN†, F. Y. KUO‡, AND S. JOE‡

Abstract. Shifted rank-1 lattice rules, a special class of quasi-Monte Carlo methods, have recently been proposed by the present authors for the integration of functions belonging to certain "weighted" Sobolev spaces. The shifts in these rules were generated in a deterministic manner. In contrast, in this paper we generate these shifts randomly. This allows probabilistic estimates for the error in a given integral. It also reduces the number of operations required to find the generating vectors for the underlying lattice rules component-by-component. The rules thus constructed achieve a worst-case strong tractability error bound in an average or probabilistic sense.

Key words. randomized quasi-Monte Carlo methods, shifted lattice rules, worst-case error, tractability

1. Introduction.

In the recent paper [8] by the present authors, quasi-Monte Carlo (QMC) rules of the form

$$R_{n,d}(f,\boldsymbol{\Delta}) = \frac{1}{n}\sum_{i=1}^{n} f\left(\left\{\frac{i\boldsymbol{z}}{n}+\boldsymbol{\Delta}\right\}\right) \tag{1.1}$$

were constructed for the approximation of integrals over the d-dimensional unit cube. Here n is assumed to be prime, and $\boldsymbol{z}\in\{1,2,\ldots,n-1\}^d$ is an integer vector, with the braces around a vector indicating that we take the fractional part of each component of the vector. In the given construction the components of $\boldsymbol{z}$ were constructed one component at a time, as were the components of $\boldsymbol{\Delta}$, the "shift". Rules of the form (1.1) are called "shifted rank-1 lattice rules", the rank-1 lattice rules being rules of the form

$$R_{n,d}(f) := R_{n,d}(f,\mathbf{0}) = \frac{1}{n}\sum_{i=1}^{n} f\left(\left\{\frac{i\boldsymbol{z}}{n}\right\}\right). \tag{1.2}$$

Further information about lattice rules may be found in [7]. The shifted rank-1 lattice rules constructed in [8] had the advantage that they achieved the worst-case strong tractability error bounds in certain weighted Sobolev spaces.

The construction of the rules in [8] for fixed n and all dimensions up to d required $O(n^3d^2)$ operations, making the construction computationally expensive for large n. Moreover, like other QMC rules, the application of those rules did not yield a practical error estimate.

In [8], the components of the shift $\boldsymbol{\Delta}$ were taken from the set $\{1/(2n), 3/(2n), \ldots, (2n-1)/(2n)\}$, with the successive components of the shift being obtained in a deterministic manner through minimizing a certain functional over the finite set. Here we propose the alternative of allowing the components of $\boldsymbol{\Delta}$ to be random numbers in $[0,1]$, opening the possibility of repeating the calculation with a number of independent shifts so as to allow error estimation. The underlying idea is not new. For example, as early as 1976 Cranley and Patterson [1] pointed out the benefits of using random shifts with rank-1 lattice rules; later this idea was generalized to other lattice rules by Joe [5]. Later still, Owen in [6] introduced a similar randomization idea ("scrambled (t,m,s)-nets") into nets. By now the idea of combining randomization (or "Monte Carlo") ideas with deterministic QMC ideas is commonplace. The key underlying concepts behind such randomized QMC methods are discussed in [3]. The novel element of the present paper is that the lattice rules that we construct here, one component at a time, are specifically designed for use with random shifts, and are in a certain sense optimal for this purpose. An important advantage is that, as we shall see, the cost of constructing rules with n points and all dimensions up to d is reduced to $O(n^2d^2)$, allowing calculations with much larger values of n.

Let q be a positive integer. In this paper we approximate the integral

$$I_d(f) = \int_{[0,1]^d} f(\boldsymbol{x})\, \mathrm{d}\boldsymbol{x}, \tag{1.3}$$

where f is at least continuous, by

$$\bar{R}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q) = \frac{1}{q}\sum_{m=1}^{q} R_{n,d}(f, \boldsymbol{\Delta}_m) = \frac{1}{qn}\sum_{m=1}^{q}\sum_{i=1}^{n} f\left(\left\{\frac{i\boldsymbol{z}}{n} + \boldsymbol{\Delta}_m\right\}\right), \tag{1.4}$$

where $\boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q$ are q independent random shifts drawn from a uniform distribution on $[0,1]^d$. In section 2 we will show that $\bar{R}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$ is an unbiased estimator of $I_d(f)$.

In this work the quality of the approximation (1.4) to the integral (1.3) is measured by the root-mean-square value of the worst-case error for f in the unit ball for a particular Hilbert space H_d, that is, by the square root of

$$E\left[D^2(\bar{R}_{n,d})\right] := \int_{[0,1]^{qd}} D^2\left(\bar{R}_{n,d}(\boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)\right)\, \mathrm{d}\boldsymbol{\Delta}_1 \cdots \mathrm{d}\boldsymbol{\Delta}_q,$$

where

$$\begin{aligned} &D\left(\bar{R}_{n,d}(\boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)\right) \\ &:= \sup\left\{|\bar{R}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q) - I_d(f)| : \|f\|_{H_d} \le 1, f \in H_d\right\}. \end{aligned} \tag{1.5}$$

The Hilbert space H_d in which our functions f lie is taken here, as in [8], to be a slight generalization of the weighted Sobolev spaces introduced by Sloan and Woźniakowski in [9]. In that work the successive coordinate directions were associated with a nonincreasing sequence of "weights" $\gamma_1, \gamma_2, \ldots$ to express the common reality that successive coordinate directions become less important. The integration problem was found to be "strongly QMC tractable" if and only if

$$\sum_{j=1}^{\infty} \gamma_j < \infty.$$

(The integration problem is said to be strongly QMC tractable if the minimal number of function evaluations n in a QMC rule

$$Q_{n,d}(f) = \frac{1}{n}\sum_{i=1}^{n} f(\boldsymbol{t}_i) \tag{1.6}$$

needed to reduce the initial error $I_d(f)$ by a factor of $\varepsilon > 0$ is bounded by a polynomial in ε^{-1} independently of d.) In the present generalization, there are two additional sequences $\{\beta_j\}$ and $\{a_j\}$ of positive real numbers, and H_d is a tensor product of 1-dimensional Hilbert spaces,

$$H_d = H_1^{(1)} \otimes H_1^{(2)} \otimes \cdots \otimes H_1^{(d)}$$

with the inner product of 1-dimensional functions f and g in the jth 1-dimensional space $H_1^{(j)}$ being

$$\beta_j^{-1} f(a_j) g(a_j) + \gamma_j^{-1} \int_0^1 f'(x) g'(x)\,\mathrm{d}x;$$

the function spaces of [9] are recovered by setting $a_j = 1$ and $\beta_j = 1$. The necessary and sufficient condition for strong tractability now becomes (see [8])

$$\sum_{j=1}^{\infty} \frac{\gamma_j}{\beta_j} < \infty. \tag{1.7}$$

Under this condition the precise result of [9, Lemma 8], appropriately generalized, is that for each $n \ge 1$ and $d \ge 1$ there exist QMC rules of the form (1.6) such that

$$D(Q_{n,d}) \le \frac{C_d}{n^{1/2}}, \tag{1.8}$$

where $D(Q_{n,d})$ is defined analogously to (1.5), and

$$C_d := \left(\prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \tfrac{1}{2}\right)\right] - \prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \tfrac{1}{3}\right)\right] \right)^{\frac{1}{2}}$$

which is bounded independently of d by

$$C_\infty := \left(\prod_{j=1}^{\infty} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \tfrac{1}{2}\right)\right] - \prod_{j=1}^{\infty} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \tfrac{1}{3}\right)\right] \right)^{\frac{1}{2}},$$

a finite number if and only if (1.7) holds. In [10] the stronger result was established that (for prime n) there even exist shifted lattice rules (i.e., QMC rules of the special form (1.1)) that satisfy (1.8). However, the results in both [9] and [10] were not constructive.

A crucial aspect of the arguments in this paper, as in [8], [9] and [10], is that H_d is a reproducing kernel Hilbert space with a simple kernel. In section 3 we study the worst-case error $D(Q_{n,d})$ in a reproducing kernel Hilbert space, specialize to our particular Hilbert space H_d, and discuss tractability. In section 4 we explain the

component-by-component construction of a generating vector $\boldsymbol{z}$ such that at every step the strong tractability bound (1.8) is preserved. The final algorithm (Algorithm 4.2) can be written in a few lines, and for a given (prime) n yields all components of $\boldsymbol{z}$ up to the dth in a time of at most $O(n^2d^2)$, and gives $\sqrt{E\left[D^2(\bar{R}_{n,d})\right]}$ satisfying (1.8). Section 5 gives the results of some searches, and some comparisons of computed worst-case errors with the bound (1.8), for n up to approximately 32000 and d up to 100.

2. An unbiased estimator. First we show that the approximation $\bar{R}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$ is an unbiased estimator of $I_d(f)$. Since this result is true not only for rank-1 lattice rules but also for all other integration rules, we state the result in its general form.

Let $Q_{n,d}(f)$ be an n-point general quadrature rule with $n \geq 1$,

$$Q_{n,d}(f) := \sum_{i=1}^{n} w_i f(\boldsymbol{t}_i), \tag{2.1}$$

where $\boldsymbol{t}_i \in [0,1]^d$, $w_i \in \mathbb{R}$, and $\sum_{i=1}^{n} w_i = 1$. For $\boldsymbol{\Delta} \in [0,1]^d$, let $Q_{n,d}(f, \boldsymbol{\Delta})$ denote the $\boldsymbol{\Delta}$-shifted rule by

$$Q_{n,d}(f, \boldsymbol{\Delta}) := \sum_{i=1}^{n} w_i f(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}).$$

For q a positive integer and $\boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q \in [0,1]^d$, let $\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$ denote the approximation obtained by taking an average over q random shifts; that is,

$$\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q) := \frac{1}{q} \sum_{m=1}^{q} Q_{n,d}(f, \boldsymbol{\Delta}_m) = \frac{1}{q} \sum_{m=1}^{q} \sum_{i=1}^{n} w_i f(\{\boldsymbol{t}_i + \boldsymbol{\Delta}_m\}),$$

where $\boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q \in [0,1]^d$ are independent random vectors having a uniform distribution on $[0,1]^d$.

The proof that (1.4) is an unbiased estimator of the integral rests on the following easily established property.

LEMMA 2.1. *Let $f \in L_1([0,1]^d)$. For all $\boldsymbol{t} \in \mathbb{R}^d$,*

$$\int_{[0,1]^d} f(\{\boldsymbol{t} + \boldsymbol{x}\}) \, \mathrm{d}\boldsymbol{x} = \int_{[0,1]^d} f(\boldsymbol{x}) \, \mathrm{d}\boldsymbol{x} = I_d(f).$$

The theorem below then follows easily.

THEOREM 2.2. *The family of shifted rules $Q_{n,d}(f, \boldsymbol{\Delta})$ is an unbiased estimator of the integral $I_d(f)$, in the sense that*

$$E\left[Q_{n,d}(f, \cdot)\right] := \int_{[0,1]^d} Q_{n,d}(f, \boldsymbol{\Delta}) \, \mathrm{d}\boldsymbol{\Delta} = I_d(f).$$

Proof. We have

$$\begin{aligned} E\left[Q_{n,d}(f,\cdot)\right] &= \int_{[0,1]^d} \sum_{i=1}^{n} w_i f(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta} \\ &= \sum_{i=1}^{n} w_i \int_{[0,1]^d} f(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta} \\ &= \sum_{i=1}^{n} w_i I_d(f) = I_d(f), \end{aligned}$$

which completes the proof. □

COROLLARY 2.3 (cf. Corollary 3 of [5]). *The mean* $\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$ *is an unbiased estimate of* $I_d(f)$ *and has variance*

$$\sigma^2 = \frac{1}{q} E\left[\left(Q_{n,d}(f,\cdot) - I_d(f)\right)^2\right] = \frac{1}{q} \int_{[0,1]^d} \left(Q_{n,d}(f,\boldsymbol{\Delta}) - I_d(f)\right)^2 \mathrm{d}\boldsymbol{\Delta}.$$

Remark 1. Since the theorem and the corollary hold for any general quadrature rule $Q_{n,d}$, then it certainly holds for rank-1 lattice rules, thus the shifted rank-1 lattice rules given in (1.1) and (1.4) are unbiased estimates of the integral $I_d(f)$.

Remark 2. It is well known that an unbiased estimate of σ, the standard error of the mean $\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$, is

$$\tilde{\sigma} = \left(\frac{1}{q(q-1)} \sum_{m=1}^{q} \left(Q_{n,d}(f,\boldsymbol{\Delta}_m) - \bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)\right)^2 \right)^{1/2}.$$

By using the well-known Chebyshev inequality,

$$\text{probability}\left(\left|\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q) - I_d(f)\right| < k\sigma\right) \ge 1 - \frac{1}{k^2},$$

this estimate of σ allows us to calculate confidence intervals for the error, that is, an interval in which the true error must lie with a fixed probability.

3. Hilbert spaces and tractability. We recall that a d-dimensional reproducing kernel Hilbert space consists of a Hilbert space H_d along with a reproducing kernel $K(\boldsymbol{x}, \boldsymbol{y})$ which has the property that $f(\boldsymbol{x}) = \langle f, K(\cdot, \boldsymbol{x})\rangle_{H_d}$ for $f \in H_d$ and $\boldsymbol{x} \in [0,1]^d$, where $\langle \cdot, \cdot \rangle_{H_d}$ is the inner product in H_d. The corresponding norm in H_d is $\|f\|_{H_d} = \langle f, f\rangle_{H_d}^{1/2}$.

Let $D(Q_{n,d}, K)$ denote the corresponding "discrepancy" for the rule $Q_{n,d}$ given by (2.1), which we recall is the same as the worst-case error for all f in the unit ball in H_d. Thus,

$$D(Q_{n,d}, K) = \sup\{|Q_{n,d}(f) - I_d(f)| : \|f\|_{H_d} \le 1,\ f \in H_d\}.$$

One may show (for example, see [9]) that

$$\begin{aligned} D^2(Q_{n,d}, K) = &\int_{[0,1]^{2d}} K(\boldsymbol{x}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y} - 2\sum_{i=1}^{n} w_i \int_{[0,1]^d} K(\boldsymbol{t}_i, \boldsymbol{y})\,\mathrm{d}\boldsymbol{y} \\ &+ \sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k K(\boldsymbol{t}_i, \boldsymbol{t}_k). \end{aligned} \tag{3.1}$$

Since the approximation we are interested in is $\bar{Q}_{n,d}(f, \boldsymbol{\Delta}_1, \ldots, \boldsymbol{\Delta}_q)$, we shall follow the usual analysis of QMC methods and consider the mean square discrepancy given by

$$E\left[D^2(\bar{Q}_{n,d}, K)\right] = \int_{[0,1]^{qd}} D^2\left(\frac{1}{q}\sum_{m=1}^{q}\sum_{i=1}^{n} w_i f(\{\boldsymbol{t}_i + \boldsymbol{\Delta}_m\}), K\right) \mathrm{d}\boldsymbol{\Delta}_1 \cdots \mathrm{d}\boldsymbol{\Delta}_q.$$

THEOREM 3.1. *The mean square discrepancy is given by*

$$E\left[D^2(\bar{Q}_{n,d}, K)\right] = \frac{1}{q}\left[\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta} - \int_{[0,1]^{2d}} K(\boldsymbol{x}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y}\right].$$

Proof. It follows from (3.1) that

$$\begin{aligned} D^2(\bar{Q}_{n,d}, K) = {} & \int_{[0,1]^{2d}} K(\boldsymbol{x}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y} - \frac{2}{q}\sum_{m=1}^{q}\sum_{i=1}^{n} w_i \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}_m\}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{y} \\ & + \frac{1}{q^2}\sum_{m=1}^{q}\sum_{\ell=1}^{q}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}_m\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}_\ell\}). \end{aligned} \tag{3.2}$$

It is clear that the expectation of the first term on the right-hand side of this expression is just itself and that the expectation value of the second term is

$$\begin{aligned} -2\sum_{i=1}^{n} w_i \int_{[0,1]^{2d}} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{y} &= -2\sum_{i=1}^{n} w_i \int_{[0,1]^{2d}} K(\boldsymbol{\Delta}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{y} \\ &= -2\int_{[0,1]^{2d}} K(\boldsymbol{\Delta}, \boldsymbol{y})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{y}, \end{aligned} \tag{3.3}$$

where we have made use of Lemma 2.1 and $\sum_{i=1}^{n} w_i = 1$. For the third term, we note that the $m \neq \ell$ case is different from the $m = \ell$ case. It is then not too hard to see that the expectation of the third term is given by

$$\begin{aligned} & \frac{q^2 - q}{q^2}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^{2d}} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}'\})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{\Delta}' \\ & \qquad + \frac{q}{q^2}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta} \\ & = \frac{q-1}{q}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^{2d}} K(\boldsymbol{\Delta}, \boldsymbol{\Delta}')\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{\Delta}' \\ & \qquad + \frac{1}{q}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta} \\ & = \frac{q-1}{q}\int_{[0,1]^{2d}} K(\boldsymbol{\Delta}, \boldsymbol{\Delta}')\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{\Delta}' \\ & \qquad + \frac{1}{q}\sum_{i=1}^{n}\sum_{k=1}^{n} w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta}, \end{aligned} \tag{3.4}$$

where again we have made use of Lemma 2.1 and $\sum_{i=1}^n w_i = 1$. The result now follows from (3.2), (3.3), and (3.4). □

To relate the result given in Theorem 3.1 to past results, we recall that associated with any reproducing kernel $K(\boldsymbol{x}, \boldsymbol{y})$ is the "shift-invariant" kernel $K^*(\boldsymbol{x}, \boldsymbol{y})$ defined by

$$K^*(\boldsymbol{x}, \boldsymbol{y}) := \int_{[0,1]^d} K(\{\boldsymbol{x} + \boldsymbol{\Delta}\}, \{\boldsymbol{y} + \boldsymbol{\Delta}\}) \, \mathrm{d}\boldsymbol{\Delta}. \tag{3.5}$$

By shift-invariant, we mean that for arbitrary $\boldsymbol{\Delta} \in [0,1]^d$

$$K^*(\boldsymbol{x}, \boldsymbol{y}) = K^*(\{\boldsymbol{x} + \boldsymbol{\Delta}\}, \{\boldsymbol{y} + \boldsymbol{\Delta}\}),$$

so by taking $\boldsymbol{\Delta} = -\boldsymbol{y}$ we can write

$$K^*(\boldsymbol{x}, \boldsymbol{y}) = K^*(\{\boldsymbol{x} - \boldsymbol{y}\}, \boldsymbol{0}), \qquad \boldsymbol{x}, \boldsymbol{y} \in [0,1]^d. \tag{3.6}$$

We then have from Hickernell and Woźniakowski [4] that

$$E\left[D^2(Q_{n,d}, K)\right] = D^2(Q_{n,d}, K^*);$$

that is, the expected value of the squared discrepancy for the shifted rule in the Hilbert space with reproducing kernel K is exactly the same as the squared discrepancy for the original unshifted rule in the Hilbert space with reproducing kernel K^*. Thus we would expect the expression for $E\left[D^2(\bar{Q}_{n,d}, K)\right]$ given in Theorem 3.1 to match this result in the case when $q = 1$. In fact, we have the following result.

THEOREM 3.2.

$$E\left[D^2(\bar{Q}_{n,d}, K)\right] = \frac{1}{q} D^2(Q_{n,d}, K^*),$$

with

$$D^2(Q_{n,d}, K^*) = \sum_{i=1}^n \sum_{k=1}^n w_i w_k K^*(\{\boldsymbol{t}_i - \boldsymbol{t}_k\}, \boldsymbol{0}) - \int_{[0,1]^d} K^*(\boldsymbol{x}, \boldsymbol{0}) \, \mathrm{d}\boldsymbol{x}. \tag{3.7}$$

Proof. The expression for $D^2(Q_{n,d}, K^*)$ in (3.7) (given in section 4 of [4]) follows easily from (3.1) by using (3.6) and Lemma 2.1.

We see from Theorem 3.1 that $E\left[D^2(\bar{Q}_{n,d}, K)\right]$ depends on the expressions

$$\sum_{i=1}^n \sum_{k=1}^n w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\}) \, \mathrm{d}\boldsymbol{\Delta} \quad \text{and} \quad \int_{[0,1]^{2d}} K(\boldsymbol{x}, \boldsymbol{y}) \, \mathrm{d}\boldsymbol{x} \, \mathrm{d}\boldsymbol{y}.$$

By making use of (3.5) and then (3.6), we see that

$$\begin{aligned} &\sum_{i=1}^n \sum_{k=1}^n w_i w_k \int_{[0,1]^d} K(\{\boldsymbol{t}_i + \boldsymbol{\Delta}\}, \{\boldsymbol{t}_k + \boldsymbol{\Delta}\}) \, \mathrm{d}\boldsymbol{\Delta} \\ &= \sum_{i=1}^n \sum_{k=1}^n w_i w_k K^*(\boldsymbol{t}_i, \boldsymbol{t}_k) = \sum_{i=1}^n \sum_{k=1}^n w_i w_k K^*(\{\boldsymbol{t}_i - \boldsymbol{t}_k\}, \boldsymbol{0}). \end{aligned} \tag{3.8}$$

Application of Lemma 2.1 shows that

$$\int_{[0,1]^{2d}} K(\boldsymbol{x}, \boldsymbol{y}) \, \mathrm{d}\boldsymbol{x} \, \mathrm{d}\boldsymbol{y} = \int_{[0,1]^{2d}} K(\{\boldsymbol{x} + \boldsymbol{y}\}, \boldsymbol{y}) \, \mathrm{d}\boldsymbol{x} \, \mathrm{d}\boldsymbol{y}.$$

Upon changing the order of integration in this last integral as well as replacing $\boldsymbol{y}$ by $\boldsymbol{\Delta}$, we obtain

$$\begin{aligned}\int_{[0,1]^{2d}} K(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y} &= \int_{[0,1]^{2d}} K(\{\boldsymbol{x}+\boldsymbol{\Delta}\},\boldsymbol{\Delta})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{x}\\ &= \int_{[0,1]^{2d}} K(\{\boldsymbol{x}+\boldsymbol{\Delta}\},\{\boldsymbol{0}+\boldsymbol{\Delta}\})\,\mathrm{d}\boldsymbol{\Delta}\,\mathrm{d}\boldsymbol{x} = \int_{[0,1]^d} K^*(\boldsymbol{x},\boldsymbol{0})\,\mathrm{d}\boldsymbol{x},\end{aligned}$$

where the final step follows from (3.5). The result then follows from Theorem 3.1, together with this expression and (3.8). ∎

We then see that $E\left[D^2(\bar{Q}_{n,d},K)\right]$ may be calculated by making use of (3.7). In the case when the quadrature points of $Q_{n,d}$ are the points of a rank-1 lattice rule $R_{n,d}$, namely, the points $\{i\boldsymbol{z}/n\}$, $i=1,\ldots,n$ (cf. (1.2)), the double sum in (3.7) may be reduced to a single sum.

COROLLARY 3.3. *With $\boldsymbol{t}_i=\{i\boldsymbol{z}/n\}$, we have*

$$D^2(R_{n,d},K^*) = \frac{1}{n}\sum_{i=1}^{n} K^*(\boldsymbol{t}_i,\boldsymbol{0}) - \int_{[0,1]^d} K^*(\boldsymbol{x},\boldsymbol{0})\,\mathrm{d}\boldsymbol{x}.$$

Proof. In this case $w_i=1/n$ and by the properties of a rank-1 lattice rule, we have

$$\{\{\boldsymbol{t}_i-\boldsymbol{t}_k\}:1\le i,k\le n\} = \{\boldsymbol{t}_i:1\le i\le n\},$$

from which the result follows. ∎

So far we have looked at the general theory and have not specified the reproducing kernel Hilbert space. To specify the space, let $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ be two sequences of positive numbers. We shall consider the d-dimensional weighted Sobolev spaces that have reproducing kernels of the form

$$K(\boldsymbol{x},\boldsymbol{y}) = K_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^{d}\left(\beta_j+\gamma_j\mu_{a_j}(x_j,y_j)\right), \tag{3.9}$$

where

$$\mu_a(x,y) = \begin{cases} \min(|x-a|,|y-a|) & \text{if } (x-a)(y-a)>0,\\ 0 & \text{if } (x-a)(y-a)\le 0.\end{cases}$$

These and similar Sobolev spaces have been considered previously in works such as [2], [4], [8], and [9]. Common choices of the parameters are $a_j=1$ or $a_j=1/2$ for $1\le j\le d$. Then it may be shown (see [8]) that the associated shift-invariant kernel $K^*(\boldsymbol{x},\boldsymbol{y})$ defined by (3.5) is given by

$$K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^{d}\left[\beta_j+\gamma_j\left(|x_j-y_j|^2-|x_j-y_j|+a_j^2-a_j+\tfrac{1}{2}\right)\right],$$

which may be written as

$$K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^{d}\left[\beta_j+\gamma_j\left(B_2\left(|x_j-y_j|\right)+a_j^2-a_j+\tfrac{1}{3}\right)\right],$$

where $B_2(x) = x^2 - x + 1/6$ is the second-degree Bernoulli polynomial. Upon making use of Corollary 3.3, we find that

$$D^2(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}) = \frac{1}{n}\sum_{i=1}^{n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(B_2\left(\left\{\frac{iz_j}{n}\right\}\right) + a_j^2 - a_j + \frac{1}{3}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]. \tag{3.10}$$

The integration problem is said to be "QMC tractable" if the minimal number $n_0(\varepsilon, d)$ of quadrature points $\boldsymbol{t}_i$ needed in (2.1) with $w_i = 1/n$ to reduce the worst-case error from its initial value $\|I_d\|$ by a factor $\varepsilon > 0$ is bounded by a polynomial in ε^{-1} and d. The problem is said to be "strongly QMC tractable" if that bound is independent of d.

To show that there exist rules of the form (1.4) which achieve strongly tractability error bounds in a probabilistic sense, we need to show that there exist rules for which $D^2(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}})$ given in (3.10) satisfies a corresponding bound. It follows from Lemma 8 in [9] that for $a_j = 1$, $j = 1, \ldots, d$, there exists a generating vector $\boldsymbol{z}$ such that

$$D^2(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}) \le \frac{1}{n}\left(\prod_{j=1}^{d}\left(\beta_j + \frac{\gamma_j}{2}\right) - \prod_{j=1}^{d}\left(\beta_j + \frac{\gamma_j}{3}\right)\right), \tag{3.11}$$

whereas $\|I_d\|$ for this case is given by (see [8])

$$\|I_d\| = \prod_{j=1}^{d}\left(\beta_j + \frac{\gamma_j}{3}\right). \tag{3.12}$$

Moreover, arguments similar to those in the proof of Theorem 5.2 in that paper show that if $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ satisfy

$$\sum_{j=1}^{\infty}\frac{\gamma_j}{\beta_j} < \infty,$$

then the ratio of the bound in (3.11) to $\|I_d\|$ is bounded independently of d, demonstrating the strong QMC tractability of multivariate integration under this condition.

4. Construction of the lattice rule $\boldsymbol{R_{n,d}}$. From the preceding discussion, it is clear that if we wish to use random shifts of rank-1 lattice rules to estimate the integral $I_d(f)$, then we should choose rank-1 lattice rules which give the best value of $D(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}})$. This means finding a $\boldsymbol{z}$ for the rule in (1.2) in some class so as to obtain the best value of $D(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}})$.

Here we propose finding such a $\boldsymbol{z} = (z_1, z_2, \ldots, z_d)$ by doing a search one component at a time. Thus we fix $z_1 = 1$ and find $z_2 \in \{1, 2, \ldots, n-1\}$ to minimize $D(R_{n,2}, K^*_{2,\boldsymbol{\beta},\boldsymbol{\gamma}})$. With z_1 and z_2 fixed, we then find $z_3 \in \{1, 2, \ldots, n-1\}$ to minimize $D(R_{n,3}, K^*_{3,\boldsymbol{\beta},\boldsymbol{\gamma}})$, and so on.

We first give the theoretical foundation which ensures that the resulting rank-1 lattice rule achieves a bound (3.11) that corresponds to strong tractability. In fact, the bound that we obtain in Theorem 4.1 below (for the case $a_j = 1$) is exactly the

bound given in (3.11). Throughout the rest of the paper, we will use the shorter notation

$$D^2(\boldsymbol{z}) := D^2(R_{n,d}, K^*_{d,\boldsymbol{\beta},\boldsymbol{\gamma}}),$$

where $\boldsymbol{z}$ is the generating vector for the rank-1 lattice rule $R_{n,d}$.

THEOREM 4.1. *Let n be a prime number, $n > 1$. Suppose there exists an integer vector $\hat{\boldsymbol{z}} \in \{1, 2, \ldots, n-1\}^d$ such that*

$$D^2(\hat{\boldsymbol{z}}) \le \frac{1}{n}\left(\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{2}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{3}\right)\right]\right). \tag{4.1}$$

Then there exists $z_{d+1} \in \{1, 2, \ldots, n-1\}$ such that

$$D^2\left(\hat{\boldsymbol{z}}, z_{d+1}\right) \le \frac{1}{n}\left(\prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{2}\right)\right] - \prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{3}\right)\right]\right).$$

Moreover, the bound (4.1) *holds for $d = 1$.*
(Here $(\hat{\boldsymbol{z}}, z_{d+1}) \in \{1, 2, \ldots, n-1\}^{d+1}$ is just $\hat{\boldsymbol{z}}$ with the one additional component z_{d+1}.)

Proof. It follows from (3.10) that, for any $\boldsymbol{z} \in \{1, 2, \ldots, n-1\}^d$ and $z_{d+1} \in \{1, 2, \ldots, n-1\}$, we have

$$\begin{aligned}
&D^2\left(\boldsymbol{z}, z_{d+1}\right) \\
&= \frac{1}{n}\sum_{i=1}^{n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(B_2\left(\left\{\frac{iz_j}{n}\right\}\right) + a_j^2 - a_j + \frac{1}{3}\right)\right] \\
&\qquad \times \left[\beta_{d+1} + \gamma_{d+1}\left(B_2\left(\left\{\frac{iz_{d+1}}{n}\right\}\right) + a_{d+1}^2 - a_{d+1} + \frac{1}{3}\right)\right] \\
&\quad - \prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right] \\
&= \left[\beta_{d+1} + \gamma_{d+1}\left(a_{d+1}^2 - a_{d+1} + \frac{1}{3}\right)\right] D^2(\boldsymbol{z}) \\
&\quad + \frac{\gamma_{d+1}}{n}\sum_{i=1}^{n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(B_2\left(\left\{\frac{iz_j}{n}\right\}\right) + a_j^2 - a_j + \frac{1}{3}\right)\right] B_2\left(\left\{\frac{iz_{d+1}}{n}\right\}\right).
\end{aligned}$$

Upon separating out the $i = n$ term and using $B_2(0) = 1/6$, this expression for $D^2\left(\boldsymbol{z}, z_{d+1}\right)$ becomes

$$\begin{aligned}
&\left[\beta_{d+1} + \gamma_{d+1}\left(a_{d+1}^2 - a_{d+1} + \frac{1}{3}\right)\right] D^2(\boldsymbol{z}) + \frac{\gamma_{d+1}}{6n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] \\
&+ \frac{\gamma_{d+1}}{n}\sum_{i=1}^{n-1}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(B_2\left(\left\{\frac{iz_j}{n}\right\}\right) + a_j^2 - a_j + \frac{1}{3}\right)\right] B_2\left(\left\{\frac{iz_{d+1}}{n}\right\}\right).
\end{aligned} \tag{4.2}$$

In this expression, the only z_{d+1} dependence is in the last term. Suppose we average this last term over all the possible values of z_{d+1} to form

$$\Theta = \frac{\gamma_{d+1}}{n} \sum_{i=1}^{n-1} \prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(B_2 \left(\left\{ \frac{i z_j}{n} \right\} \right) + a_j^2 - a_j + \frac{1}{3} \right) \right] \times \frac{1}{n-1} \sum_{z_{d+1}=1}^{n-1} B_2 \left(\left\{ \frac{i z_{d+1}}{n} \right\} \right).$$

When n is prime, for fixed i satisfying $1 \le i \le n-1$ the values of $\{iz_{d+1}/n\}$ as z_{d+1} runs from 1 to $n-1$ are just $1/n, 2/n, \ldots, (n-1)/n$ in some order, and hence we have

$$\frac{1}{n-1} \sum_{z_{d+1}=1}^{n-1} B_2 \left(\left\{ \frac{i z_{d+1}}{n} \right\} \right) = \frac{1}{n-1} \left(\sum_{z_{d+1}=1}^{n} B_2 \left(\frac{z_{d+1}}{n} \right) - B_2(1) \right).$$

By recalling that $B_2(x) = x^2 - x + 1/6$ and using the well-known sums for the first n positive integers and the squares of the first n positive integers, we have

$$\begin{aligned} \sum_{z_{d+1}=1}^{n} B_2 \left(\frac{z_{d+1}}{n} \right) &= \sum_{z_{d+1}=1}^{n} \left[\left(\frac{z_{d+1}}{n} \right)^2 - \left(\frac{z_{d+1}}{n} \right) + \frac{1}{6} \right] \\ &= \frac{(n+1)(2n+1)}{6n} - \frac{n+1}{2} + \frac{n}{6} = \frac{1}{6n}. \end{aligned} \tag{4.3}$$

It then follows that

$$\frac{1}{n-1} \sum_{z_{d+1}=1}^{n-1} B_2 \left(\left\{ \frac{i z_{d+1}}{n} \right\} \right) = \frac{1}{n-1} \left(\frac{1}{6n} - \frac{1}{6} \right) = -\frac{1}{6n},$$

and hence

$$\begin{aligned} \Theta &= -\frac{\gamma_{d+1}}{6n^2} \sum_{i=1}^{n-1} \prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(B_2 \left(\left\{ \frac{i z_j}{n} \right\} \right) + a_j^2 - a_j + \frac{1}{3} \right) \right] \\ &= -\frac{\gamma_{d+1}}{6n} \left(D^2(\boldsymbol{z}) - \frac{1}{n} \prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \frac{1}{2} \right) \right] + \prod_{j=1}^{d} \left[\beta_j + \gamma_j \left(a_j^2 - a_j + \frac{1}{3} \right) \right] \right), \end{aligned}$$

where we have made use of (3.10). Since Θ involves an average over z_{d+1}, it follows

that there exists $z_{d+1} \in \{1, 2, \ldots, n-1\}$ for which

$$
\begin{aligned}
&D^2(\boldsymbol{z}, z_{d+1}) \\
&\le \left[\beta_{d+1} + \gamma_{d+1}\left(a_{d+1}^2 - a_{d+1} + \frac{1}{3}\right)\right] D^2(\boldsymbol{z}) + \frac{\gamma_{d+1}}{6n} \prod_{j=1}^{d} \left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] \\
&\quad - \frac{\gamma_{d+1}}{6n}\left(D^2(\boldsymbol{z}) - \frac{1}{n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right]\right. \\
&\qquad\qquad \left. + \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right) \\
&= \left[\beta_{d+1} + \gamma_{d+1}\left(a_{d+1}^2 - a_{d+1} + \frac{1}{3} - \frac{1}{6n}\right)\right] D^2(\boldsymbol{z}) \\
&\quad + \frac{\gamma_{d+1}}{6n}\left(\left(1 + \frac{1}{n}\right)\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right).
\end{aligned}
$$

Using the hypothesis in the theorem, we now obtain

$$
\begin{aligned}
&D^2(\hat{\boldsymbol{z}}, z_{d+1}) \\
&\le \left[\beta_{d+1} + \gamma_{d+1}\left(a_{d+1}^2 - a_{d+1} + \frac{1}{3} - \frac{1}{6n}\right)\right] \\
&\qquad \times \frac{1}{n}\left(\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right) \\
&\quad + \frac{\gamma_{d+1}}{6n}\left(\left(1 + \frac{1}{n}\right)\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right) \\
&= \frac{1}{n}\left(\prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] - \prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right) \\
&\quad - \gamma_{d+1}\left(\frac{1}{6n} - \frac{1}{6n^2}\right)\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right] \\
&\le \frac{1}{n}\left(\prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{2}\right)\right] - \prod_{j=1}^{d+1}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]\right),
\end{aligned}
$$

which is the desired result.

In one dimension, it is known that there is only one n-point lattice rule, namely, the n-point rectangle rule. Thus we may take $z_1 = 1$ and obtain from (3.10) that

$$
\begin{aligned}
D^2(1) &= \frac{1}{n}\sum_{i=1}^{n}\left[\beta_1 + \gamma_1\left(B_2\left(\left\{\frac{i}{n}\right\}\right) + a_1^2 - a_1 + \frac{1}{3}\right)\right] - \left[\beta_1 + \gamma_1\left(a_1^2 - a_1 + \frac{1}{3}\right)\right] \\
&= \frac{\gamma_1}{n}\sum_{i=1}^{n} B_2\left(\left\{\frac{i}{n}\right\}\right) = \frac{\gamma_1}{6n^2} \le \frac{\gamma_1}{6n},
\end{aligned}
$$

where we have made use of (4.3). Thus (4.1) holds for $d = 1$. □

Given n (a prime number) and d, Theorem 4.1 leads to an algorithm for finding a generating vector $\boldsymbol{z} = (z_1, z_2, \dots)$ such that

$$D^2(z_1, z_2, \dots, z_d) \le \frac{1}{n}\left(\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{2}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \tfrac{1}{3}\right)\right]\right)$$

for arbitrarily large values of d. We note that this bound is the average of $D^2(Q_{n,d}, K_{d,\boldsymbol{\beta},\boldsymbol{\gamma}})$ over all the points $\boldsymbol{t}_1, \dots, \boldsymbol{t}_n$ of an n-point QMC rule $Q_{n,d}$.

ALGORITHM 4.2.

1. *Set z_1, the first component of $\boldsymbol{z}$, to* 1.
2. *For $d = 2, 3, \dots, d_{\max} - 1, d_{\max}$, find $z_d \in \{1, 2, \dots, n-1\}$ such that*

$$D^2(z_1, z_2, \dots, z_d) = \frac{1}{n}\sum_{i=1}^{n}\prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(B_2\left(\left\{\frac{iz_j}{n}\right\}\right) + a_j^2 - a_j + \frac{1}{3}\right)\right] - \prod_{j=1}^{d}\left[\beta_j + \gamma_j\left(a_j^2 - a_j + \frac{1}{3}\right)\right]$$

is minimized.

We see from the algorithm that the cost of constructing a rank-1 lattice rule for all dimensions up to $d_{\max}$ is $O(n^2 d_{\max}^2)$. This can be reduced to $O(n^2 d_{\max})$ if we store (at a cost of $O(n)$ storage) the products during the search. Also, if at a later time components of $\boldsymbol{z}$ for further dimensions are needed, the algorithm can be restarted in an obvious way.

5. Numerical searches. Here we present some results from implementing the algorithm given in the previous section for dimensions d up to $d_{\max} = 100$. We consider only values of z_d satisfying $1 \le z_d \le (n-1)/2$, since

$$B_2\left(\left\{\frac{iz_d}{n}\right\}\right) = B_2\left(1 - \left\{\frac{i(n-z_d)}{n}\right\}\right) = B_2\left(\left\{\frac{i(n-z_d)}{n}\right\}\right).$$

All the runs had $\beta_j = 1$ and $a_j = 1$ for $1 \le j \le d$. The values of n used were the prime numbers 2003, 8009, and 32003, so $n^{1/2}$ approximately doubles from one value of n to the next. The results are mainly presented in graphical form. However, in Table 5.1, we present d, z_d, and the corresponding value of $D(\boldsymbol{z})$ for the case when $\gamma_j = 0.9^j$ and $n = 2003$ to allow readers to check their own implementation of Algorithm 4.2.

Figure 5.1 shows a graph of $D(\boldsymbol{z})$ against d, for d increasing in steps of 5, in the case when $\gamma_j = 0.9^j$. Figure 5.2 shows the same information for the case $\gamma_j = 1/j^2$. It seems, on comparing the results with $n = 2003$, 8009, and 32003, that the convergence of $D(\boldsymbol{z})$ to zero as n increases is faster than the theoretically predicted $O(n^{-1/2})$ (since the latter would predict that successive errors would halve from one value of n to the next).

From the discussion preceding Algorithm 4.2, we see that the $\boldsymbol{z}$ constructed using the algorithm is such that $D(\boldsymbol{z}) \le C_d n^{-1/2}$, where (since $\beta_j = 1$ and $a_j = 1$)

$$C_d = \left(\prod_{j=1}^{d}\left(1 + \frac{\gamma_j}{2}\right) - \prod_{j=1}^{d}\left(\beta_j + \frac{\gamma_j}{3}\right)\right)^{1/2}.$$

To get an idea of how much smaller the actual values of $D(\boldsymbol{z})$ are compared to the bound of $C_d n^{-1/2}$, we take $d = 100$ and for the three values of n calculate the ratio $D(\boldsymbol{z})/(C_d n^{-1/2})$. The three values of this ratio in the two cases $\gamma_j = 0.9^j$ and $\gamma_j = 1/j^2$ are plotted against n (on a log scale) and displayed in Figure 5.3. The straight lines in the figure are intended to make it easier to view the data.

Figure 5.3 also provides some information about how good the rules are compared to the classical Monte Carlo algorithm. As is well known, this is a randomized algorithm in which the quadrature points are chosen randomly from a uniform distribution on $[0,1]^d$. For any particular sampling of n points, we can compute a worst-case error in our space H_d by using (3.7) with $w_i = 1/n$. It is shown in [9] that the expected value of the squared worst-case error is given by C_d^2/n. In this sense Figure 5.3 indicates that the rules constructed here on average make better point selections than classical Monte Carlo, with the advantage increasing with n.

COMPUTING ZEROS ON A REAL INTERVAL THROUGH CHEBYSHEV EXPANSION AND POLYNOMIAL ROOTFINDING*

JOHN P. BOYD†

Abstract. Robust polynomial rootfinders can be exploited to compute the roots on a real interval of a *nonpolynomial* function $f(x)$ by the following: (i) expand f as a Chebyshev polynomial series, (ii) convert to a polynomial in ordinary, series-of-powers form, and (iii) apply the polynomial rootfinder. (Complex-valued roots and real roots outside the target interval are discarded.) The expansion is most efficiently done by adaptive Chebyshev interpolation with N equal to a power of two, where N is the degree of the truncated Chebyshev series. All previous evaluations of f can then be reused when N is increased; adaption stops when N is sufficiently large so that further increases produce no significant change in the interpolant. We describe two conversion strategies. The "convert-to-powers" method uses multiplication by mildly ill-conditioned matrices to create a polynomial of degree N. The "degree-doubling" strategy defines a polynomial of larger degree $2N$ but is very well-conditioned. The "convert-to-powers" method, although faster, restricts N to moderate values; this can always be accomplished by subdividing the target interval. Both these strategies allow simultaneous approximation of many roots on an interval, whether simple or multiple, for nonpolynomial $f(x)$.

Key words. rootfinding, single transcendental equation, Chebyshev series

1. Introduction.

One irony of the history of mathematics is that the problem of finding the roots of a polynomial, which taxed the brains of mathematicians from the Babylonians to Diophantus to Omar Khayyam to Cardano and Tartaglia in the Renaissance to Lagrange, Abel, Gauss, and Galois around the turn of the 19th century, is now largely uninteresting. Reliable polynomial rootfinding software, which requires no a priori estimates for the zeros, is now a part of almost all language packages (Matlab, Maple, Mathematica) and Fortran libraries (NAG, IMSL, etc.). The undergraduate who casually executes the one-line Matlab command, **roots(p)**, where **p** is a vector containing the coefficients of the polynomial, is blissfully ignorant of the three centuries of struggle to move from Ferrari's literal solution of the quartic, published in 1545, to Hermite's solution of the quintic 320 years later.

Nevertheless, the problem of finding the roots of a single transcendental equation in a single unknown is still a staple of numerical analysis courses. The reason is that, until recently, there was no black box for computing the zeros of a nonpolynomial $f(x)$. Bisection and Brent's algorithm will reliably find *some* roots, but this is not the same as finding *all roots* on an interval. It is particularly easy to miss zeros that are closely spaced or multiple.

Kavvadias and Vrahatis [10], Kavvadias, Makri, and Vrahatis [11], and Smiley and Chun [13] have developed bisection-like but more sophisticated subdivision strategies for reliable transcendental rootfinding. However, these algorithms are relatively slow. Later, we shall explain how these subdivision strategies can in principle be accelerated

(or replaced!) by the ideas introduced here.

We show that it is easy to extend the existing library software for *polynomial* f to *general* f merely by a simple intervention: expanding f as a Chebyshev series and then converting the Chebyshev approximation to an ordinary polynomial. As seen through the lens of Chebyshev polynomials, there is no such thing as a "transcendental" function: all rootfinding problems are polynomial rootfinding problems.

In his book *Applied Analysis* (1956) [12], Lanczos published the first example of the "Chebyshevization" of rootfinding. At a time when general polynomial solvers did not exist, he collapsed a cubic equation (hard) to a quadratic (easy!) by expanding the cubic as a Chebyshev series and then neglecting the third degree term.

In an earlier paper [5], we extended Lanczos's strategy to complicated $f(x)$. However, our earlier work was criticized because it did not provide estimates for the condition number of the conversion-to-powers step. Since Wilkinson's famous example of a very badly conditioned polynomial (well illustrated on pp. 330–331 of [1]), all right-thinking numerical analysts have cringed at working with a polynomial expressed as a sum of powers of x. In this work, we show that, although there is some ill-conditioning, the convert-to-powers strategy is robust and reliable if the degree of the Chebyshev expansion is restricted to moderate N (i.e., $N < 18$ or so). By subdividing an interval with many roots into subintervals, and applying a separate Chebyshev expansion to each one, the Chebyshev-to-powers strategy can be applied to almost all functions which are analytic on a desired target interval.

Furthermore, there is an alternative strategy, discussed here for the first time, which allows extraction of roots from a polynomial $h_{2N}(z)$ whose coefficients are simply those of the Chebyshev series. The ill-conditioning is completely eliminated. However, the degree of $h_{2N}(z)$ is twice that of the truncated Chebyshev series from whence it came.

Figure 1 schematically summarizes our algorithm.

The first issue is, How is the Chebyshev series computed? The answer is that $f(x)$ must be evaluated at a set of discrete points on the target interval; the Chebyshev coefficients are then given by a matrix-vector multiply where the vector holds the set of grid-point values of $f(x)$ and the elements of the matrix are trigonometric functions. The complete procedure is described in the appendix.

The second issue is, How does one determine when the truncation N is large enough? There is a well-established theory for doing this as reviewed in our book [6] and previous article [5]. The most systematic strategy mimics that of the Clenshaw–Curtis quadrature: the number of points is doubled until the approximation ceases to change; all previously used values of $f(x)$ are reused by finer approximations so that nothing is wasted. We shall briefly review stopping criteria below.

The third issue is, How does one convert a truncated Chebyshev series to an ordinary polynomial? We offer two ways. In the "convert-to-powers" strategy, the coefficients of the powers of x are the product of an upper triangular matrix with the vector of Chebyshev coefficients; the matrix elements are integers computed by a simple recurrence.

The "degree-doubling" algorithm defines an associated polynomial whose degree is twice that of the truncation of the Chebyshev series. However, the real part of the roots of this polynomial which lie on the unit circle in the complex plane are the roots of $f(x)$ on the real interval $x \in [a, b]$.

The fourth issue is, Given that the roots of a polynomial are notoriously sensitive to small perturbations to the coefficients of the powers of x, how ill-conditioned is the

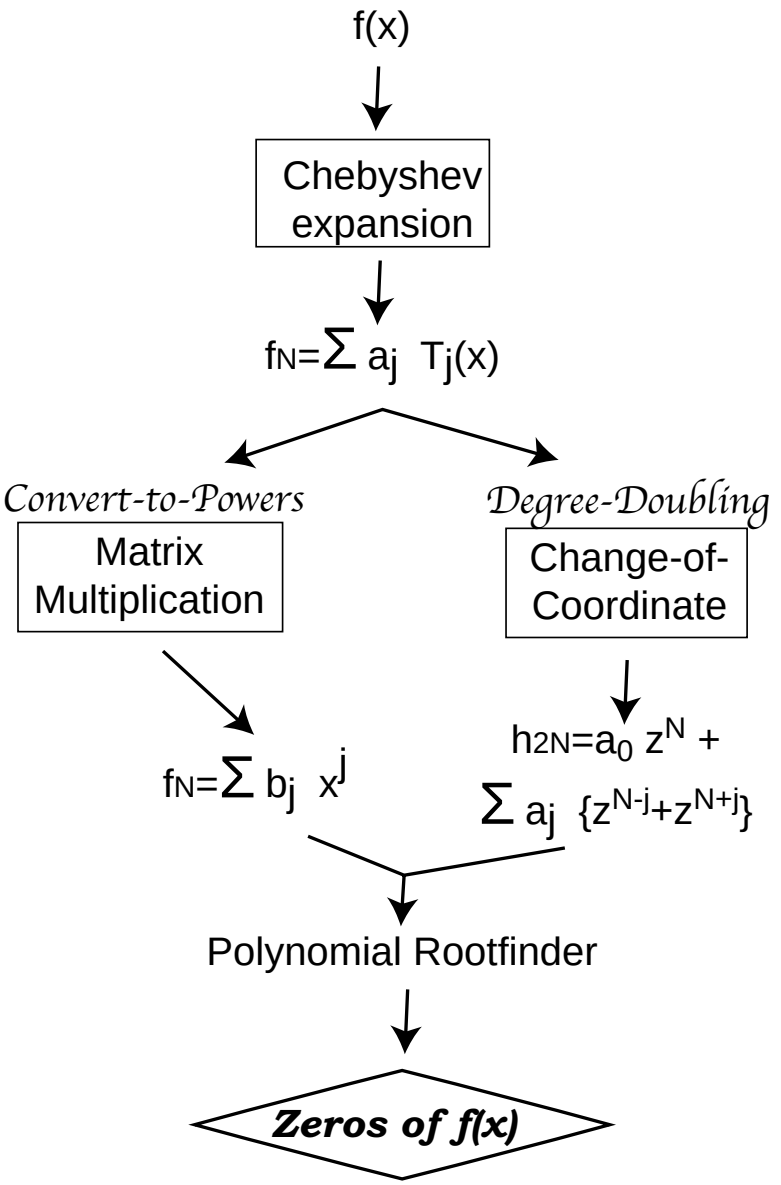

FIG. 1. *Schematic of rootfinding for a nonpolynomial* $f(x)$.

convert-to-powers algorithm? The answer is that if the Chebyshev degree is restricted, the roots of the polynomial *on the target interval* will be very good approximations to those of the truncated Chebyshev series, whose zeros are in turn very good approximations to those of the original $f(x)$. Small errors can easily be corrected by one or two secant or Newton iterations with $f(x)$. If the interval is large and has many roots, it may be necessary to subdivide the interval into subdomains and compute a different moderate degree Chebyshev series on each. With these precautions of degree restriction and interval subdivision followed by iteration with $f(x)$ itself, the convert-to-powers algorithm can yield roots to full machine precision.

In this article, we offer four novelties (beyond the earlier work of Lanczos and [5]):

1. Condition number estimates for the triangular matrices that convert Chebyshev coefficients to the coefficients of the same polynomial expressed as a sum of powers of x.
2. A second strategy for converting a truncated Chebyshev polynomial to a different polynomial of twice the degree but with (effectively) the same roots; the coefficients of the new polynomial are the same as the Chebyshev coefficients.
3. The Chebyshev-to-polynomial method is extended to *unbounded* intervals, either infinite or semi-infinite, so long as $f(x)$ asymptotes to a constant at infinity and has only a finite number of real roots.
4. A different, grid-point-value-based "stopping" criterion for assessing when f is approximated to sufficient accuracy by a Chebyshev series truncated after the Nth term.

The strength of the algorithm is that no a priori knowledge of the roots is needed. The reliability of existing polynomial solvers is extended to nonpolynomial $f(x)$.

The sections of the article are as follows:

Sec. 2: first two issues (computing the Chebyshev expansion).
Sec. 3: convert-to-powers and its condition number.
Sec. 4: bounds on errors in roots and their application.
Sec. 5: the degree-doubling theorem.
Sec. 6: numerical example: roots of $J_0(x)$.
Sec. 7: searching a region in the complex plane instead of a real interval.
Sec. 8: rootfinding on an infinite interval.
Sec. 9: summary and open problems.

2. Adaptive computation of the Chebyshev coefficients. Our Chebyshev approximation is a finite series of Chebyshev polynomials which interpolates $f(x)$ at a set of $(N+1)$ points known as the Chebyshev–Lobatto grid. This differs little from the truncation of the infinite Chebyshev polynomial series of f [6]. One must evaluate $f(x)$, the function whose roots are sought, at $(N+1)$ points on the target interval $x \in [a,b]$. The Chebyshev coefficients are then the vector which is the product of a square matrix with the column vector of grid-point values of f. (The grid points and the matrix elements are given in the appendix for arbitrary N.)

If $f(x)$ is expensive to evaluate, the best strategy is to restrict N to be a power of two. In this case, all previously computed grid-point values of $f(x)$ can be reused when N is doubled so that the maximum number of evaluations of f is never more than the smallest (power-of-two) N for which the "stopping criteria," is met. A similar strategy is employed in the adaptive, spectrally accurate Clenshaw–Curtis quadrature scheme [6].

As explained in [6], Chebyshev series for a function f which is *analytic* on the interval $x \in [a,b]$ converge *geometrically* fast; that is, the jth term (and also the absolute value of the jth coefficient) are bounded by ρ^j for some $\rho < 1$. The error in the $(N+1)$-point interpolation is typically the same order of magnitude as the last computed Chebyshev coefficient a_N [6]. [5] proposed a cautious "stopping criterion": increase N until $\sum_{j=[(2/3)N]}^{N} |a_j| < \epsilon$, where $[(2/3)N]$ denotes the integer closest to $2N/3$.

One can also use a grid-point value criterion which is given here for the first time:

$$\max |f_{2N}(x_j) - f_N(x_j)| < \epsilon, \tag{1}$$

where the difference is calculated for all the points on the grid of $(2N+1)$ points which are not on the coarser grid of $(N+1)$ points. (At points common to both grids, both interpolants equal f and therefore each other.) Since the error of f_N tends to be a maximum roughly halfway between the points of the coarse grid, the difference at these intermediate points is likely to be quite close to the true maximum pointwise error of f_N.

Both these stopping criteria are *very conservative*; f_{2N} will usually have an error much smaller than ϵ with the grid-point criterion, which forces the error of the lower order approximation f_N to be less than ϵ. Reliability is built on conservative strategies, however.

2.1. Subdivision. As explained in the next section, conversion-to-powers is a well-conditioned process only if N is restricted to moderate degree. What if large N is needed to obtain an accurate Chebyshev approximation?

The answer is that one can divide the interval into subintervals. Our recommendation is to expand f on the entire interval first, even if this requires using large N. If the maximum degree that allows satisfactory conversion-to-powers is $N_{\max}$, the asymptotic theory of Chebyshev expansions [6] suggests that one should subdivide into $[N/N_{\max}]$ subintervals where the square brackets denote the integer closest to the ratio of $N/N_{\max}$. Cautious arithmurgists are encouraged to use a somewhat larger number of subdivisions.

Once the split into subdomains has been made, the algorithm can be applied on each subinterval without modification.

2.2. Scaling. Chebyshev expansions are highly uniform in the sense that the maximum pointwise error (absolute error) oscillates with peaks and troughs of similar amplitude over the entire expansion interval, $x \in [a,b]$. If $f(x)$ is itself highly *nonuniform*, such as $\exp(10x)\sin(x)$, then the Chebyshev series will have large *relative* errors where $f(x)$ is very small.

There are two remedies. The first is to subdivide into subintervals sufficiently small so that $f(x)$ varies only mildly over each subdomain. The second is to multiply f by a smooth scaling function that eliminates the large fluctuations in magnitude. For our example, $\tilde{f} \equiv \exp(-10x)f(x) = \sin(x)$ has the same roots as f, but, because it is much more uniform, the Chebyshev expansion of $\tilde{f}$ will have much smaller relative error and yield much more accurate approximations to the roots. Devising a smooth scaling function may be difficult, however, as illustrated in [5].

2.3. Nonanalytic/nonsmooth $f(x)$. Chebyshev expansions converge, but at a very slow rate, if $f(x)$ has poles, branch points, discontinuities, or other singularities on the expansion interval, $x \in [a,b]$, including singularities at the endpoints. We therefore caution the reader that Chebyshev rootfinding methods are useful only when $f(x)$ is analytic everywhere on the expansion interval including the endpoints. (Singularities off the expansion interval, whether at real or complex locations, however, are powerless to destroy the good properties of the algorithm and are thus largely irrelevant.)

3. Converting Chebyshev series to polynomials, I: Convert-to-powers. The Chebyshev expansion of $f(x)$ on $x \in [a,b]$ is

$$f_N \equiv \sum_{j=0}^{N} a_j T_j(y) = \sum_{j=}^{N} b_j\, y^j, \qquad y(x) \in [-1,1], \tag{2}$$

where

$$y \equiv \frac{2x-(b+a)}{b-a}, \qquad y \in [-1,1] \;\leftrightarrow\; x \in [a,b], \tag{3}$$

is the stretched-and-translated argument of the Chebyshev polynomials. The cost of transforming from $\{a_j\}$ to $\{b_j\}$ can be halved by splitting f_N into its even and odd parts: let $\vec{a}^{even}$ and $\vec{b}^{even}$ be vectors containing the even degree coefficients $\{a_0, a_2, a_4 \ldots\}$ and $\{b_0, b_2, b_4 \ldots\}$, respectively. Then

$$\vec{b}^{even} = \vec{\vec{Q}}^{even}\, \vec{a}^{even}. \tag{4}$$

Explicitly, the upper left block is given by

$$\vec{\vec{Q}}^{even,block} = \begin{vmatrix} 1 & -1 & 1 & -1 & 1 & -1 & 1 & -1 & 1 \\ 0 & 2 & -8 & 18 & -32 & 50 & -72 & 98 & -128 \\ 0 & 0 & 8 & -48 & 160 & -400 & 840 & -1568 & 2688 \\ 0 & 0 & 0 & 32 & -256 & 1120 & -3584 & 9408 & -21504 \\ 0 & 0 & 0 & 0 & 128 & -1280 & 6912 & -26880 & 84480 \\ 0 & 0 & 0 & 0 & 0 & 512 & -6144 & 39424 & -180224 \\ 0 & 0 & 0 & 0 & 0 & 0 & 2048 & -28672 & 212992 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 8192 & -131072 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 32768 \end{vmatrix}. \tag{5}$$

The jth column is composed of the coefficients of T_{2j-2} in powers of x.

Similarly,

$$\vec{\vec{Q}}^{odd,block} = \begin{vmatrix} 1 & -3 & 5 & -7 & 9 & -11 & 13 & -15 & 17 \\ 0 & 4 & -20 & 56 & -120 & 220 & -364 & 560 & -816 \\ 0 & 0 & 16 & -112 & 432 & -1232 & 2912 & -6048 & 11424 \\ 0 & 0 & 0 & 64 & -576 & 2816 & -9984 & 28800 & -71808 \\ 0 & 0 & 0 & 0 & 256 & -2186 & 16640 & -70400 & 239360 \\ 0 & 0 & 0 & 0 & & 1024 & -13312 & 92160 & -452608 \\ 0 & 0 & 0 & 0 & 0 & 0 & 4096 & -61440 & 487424 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 16384 & -278528 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 65536 \end{vmatrix}. \tag{6}$$

The elements can be computed by recurrence relation:

$$Q_{11}^{even} = 1, \qquad Q_{jj}^{even} = 2^{2j-3}, \qquad j = 2, 3, \ldots. \tag{7}$$

The recurrence, vertically up the j-column from the diagonal, is then

$$Q_{j-K,j}^{even} = \text{round}\left\{ -\frac{(2j-2K)(2j-2K-1)}{2K\,(4j-2K-4)} Q_{j-K+1,j}^{even} \right\}, \tag{8}$$

$$Q_{jj}^{odd} = 2^{2j-2}, \qquad j = 1, 2, 3, \ldots, \tag{9}$$

$$Q_{j-K,j}^{odd} = \text{round}\left\{ -\frac{(2j-2K+1)(j-K)}{K\,(4j-2K-2)} Q_{j-K+1,j}^{odd} \right\}. \tag{10}$$

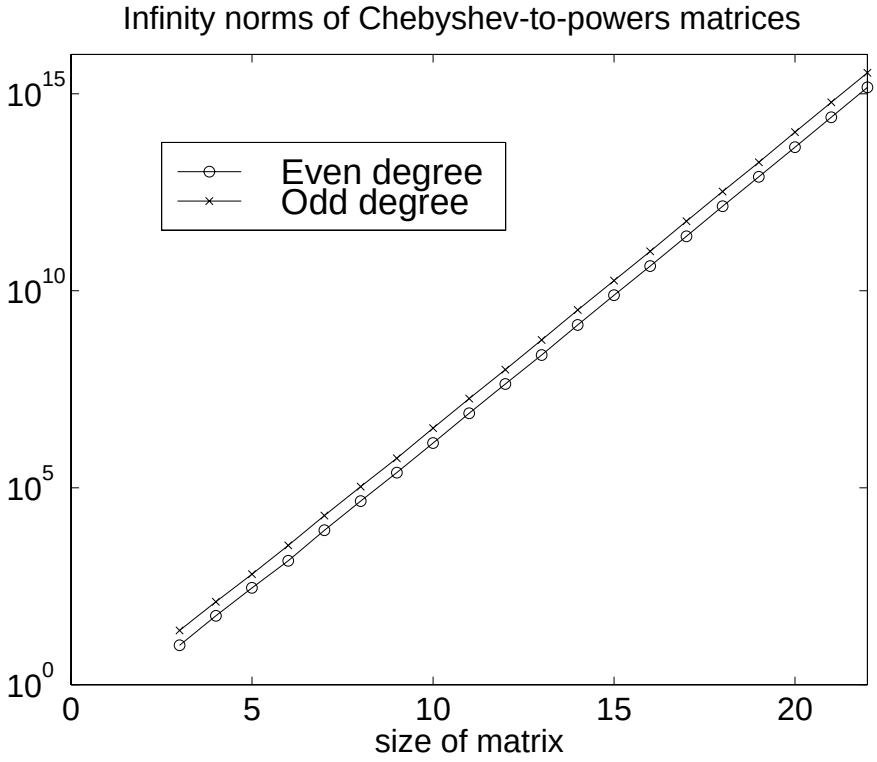

FIG. 2. *L_∞ matrix norms of $\vec{\vec{Q}}^{even}$ and $\vec{\vec{Q}}^{odd}$ versus the dimension of the matrix j.*

Because the elements are *integers*, we can eliminate roundoff error in the recurrences by rounding to the nearest integer.

Figure 2 shows how the norms of the transformed matrices grow exponentially, roughly as

$$||\vec{\vec{Q}}^{even}||_\infty \sim 0.016\,(5.8)^j, \qquad ||\vec{\vec{Q}}^{odd}||_\infty \sim 0.039\,(5.8)^j. \tag{11}$$

If we wish to avoid sacrificing more than six decimal places of accuracy or, more precisely, to guarantee that the errors in the coefficients of the power form are no more than a million times the floating point and truncation errors in the Chebyshev coefficients, we must restrict the size of $\vec{\vec{Q}}^{even}$ and $\vec{\vec{Q}}^{odd}$ to nine or less since

$$||\vec{\vec{Q}}^{even}||_\infty(9\times 9) = 243,712\,, \qquad ||\vec{\vec{Q}}^{odd}||_\infty(9\times 9) = 559,104. \tag{12}$$

If we put the even and odd polynomials together, we obtain a general nonsymmetric polynomial of degree 17.

4. Condition number of polynomial roots. Gautschi [8] and Winkler [14] give theorems on the condition number of polynomial roots. To give the flavor of these ideas without undue complexity, we shall state a simpler result applicable only in the limit of an arbitrarily small perturbation. Recall that the argument of the Chebyshev polynomials (and of the sum-of-powers into which it is transformed) is $y \in [-1, 1]$,

which is the image of the interval $x \in [a, b]$ through the linear change-of-coordinate $y \equiv (2x - (b + a))(b - a)$.

THEOREM 4.1 (sensitivity of polynomial roots). *Let y_* denote a real-valued root of multiplicity m on the interval $y \in [-1, 1]$ for a function f which is written terms of a basis as*

$$f(y) = \sum_{j=0}^{N} a_j \phi_j(y), \qquad y \in [-1, 1], \tag{13}$$

where the basis functions are either Chebyshev polynomials or powers of y and in either event satisfy

$$|\phi_j(y)| \le 1 \qquad \forall\, y \in [-1, 1]. \tag{14}$$

Let $\tilde{y}$ denote the root of the perturbed function $\tilde{f}$ which is equal to f except the kth coefficient has been altered by an amount ϵ:

$$\tilde{f}(y) = \sum_{j=0, j\neq k}^{N} a_j \phi_j(y) \; + (a_k + \epsilon)\, \phi_k(y), \qquad y \in [-1, 1]. \tag{15}$$

Then

$$|\tilde{y} - y_*| \le \epsilon^{1/m} \left| \frac{1}{m!} \frac{d^m f}{dy^m}(y_*) \right|^{-1/m} + O(\epsilon^{(m+1)/m}), \qquad |\epsilon| \ll 1. \tag{16}$$

Proof. Taylor's theorem at $y = y_*$ is

$$\tilde{f}(y) \approx \epsilon \phi_k(y) + \frac{1}{m!} \frac{d^m f}{dy^m}(y_*)(y - y_*)^m + O((y - y_*)^{m+1}), \tag{17}$$

since, at an mth order zero of f, the function itself and its first $(m - 1)$ derivatives are zero by definition. Solving the Taylor approximation for the root of the perturbed function, $\tilde{y}$, and then invoking the inequality that all basis functions are bounded in magnitude by one on the interval, is sufficient to prove the theorem.

The theorem implies that Wilkinson's famous example of an ill-conditioned polynomial, which has haunted the dreams of numerical analysts for a generation, is dreaded unduly. When the largest root of interest has magnitude $y_{\max} \gg 1$, then y^k can be become as large as $(y_{\max})^k$ at that root, and thus tiny changes in the coefficient of y^k can produce huge changes in the largest root. However, when $|y| \le 1$, all the powers of y are bounded by one, and a simple root will be altered only an $O(\epsilon)$ amount by an $O(\epsilon)$ perturbation of the coefficients.

Thus, for our purposes, the powers-of-x form is *not* ill-conditioned. The only difficulty is that the Chebyshev-to-powers matrix multiplication greatly magnifies small errors in the Chebyshev coefficients. Thus, when N is large, an alteration of ϵ in the kth Chebyshev coefficient will produce changes of millions or billions of ϵ in the coefficients of the powers-of-x form. This in turn will produce a comparable change in a simple root.

We conclude that if N is restricted to moderate values, such as $N < 18$, by subdividing the original interval, then the Chebyshev-to-powers algorithm will be reasonably well-conditioned, where "reasonably" means that we lose no more than six decimal places to the ugly condition numbers of the transformation matrices $\vec{Q}^{even}$, $\vec{Q}^{odd}$, and are still able to compute the roots to nine or ten decimal places.

5. Conversion to a polynomial, II: Degree-doubling. An alternative method for deriving a polynomial from a truncated Chebyshev series is given by the following.

THEOREM 5.1 (associated double-degree polynomial). *Let $f_N(x)$ be a polynomial:*

$$f_N(x) \equiv \sum_{j=0}^{N} a_j\, T_j(x). \tag{18}$$

Define a polynomial h of twice the degree through

$$h_{2N}(z) \equiv \sum_{j=0}^{2N} b_j z^j, \tag{19}$$

where

$$b_j = \begin{cases} a_{j-N}, & j > N, \\ 2\, a_0, & j = N, \\ a_{N-j}, & j < N. \end{cases} \tag{20}$$

Then the roots x_k of f_N on the real interval $x \in [-1, 1]$ are related to the roots z_k of $h_N(z)$ on the unit disk in the complex z-plane through

$$x_k = \Re(z_k). \tag{21}$$

Proof. The identity $T_j(x) = \cos(jt)$ when $x = \cos(t)$ plus $\cos(t) \equiv (\exp(it) + \exp(it))/2$ implies that

$$f_N(\cos(t)) \equiv \sum_{j=0}^{N} a_j\, \{\exp(it) + \exp(-it)\}\, /2. \tag{22}$$

Define

$$h_{2N}\left(\exp(it)\right) \equiv 2\, \exp(iNt) f_N(\cos(t)). \tag{23}$$

Because $\exp(iNt)$ never vanishes, the roots of the product are identical with those of $f_N(\cos(t))$. Defining $z \equiv \exp(it)$ and recalling $\exp(ijt) = [\exp(it)]^j$ proves the theorem.

6. Numerical example. Figure 3 shows the success of the Chebyshev algorithm using the two different strategies for polynomial creation: convert-to-powers on the left and degree-doubling on the right.

The left panel shows that, for some $f(x)$ at least, the restriction to $N \leq 17$ for convert-to-powers is very conservative. With $N = 40$, the maximum relative error is less than 1 part in 3800 in all of the first 19 roots of the J_0 Bessel function. By increasing N, the error can be reduced to $O(10^{-12})$ for some of the roots. However, there are signs of ill-conditioning: the roots at the ends of chosen expansion interval do not converge with increasing N.

The degree-doubling method requires more computation because the "black box" polynomial rootfinder is asked to solve a polynomial of degree $2N$ instead of N. (The cost of the triangular matrix multiplications of the convert-to-powers scheme is only $(N^2/2)$ multiplications and the same number of additions.) However, the right panel shows that the degree-doubling method is completely free of the ill-conditioning that dogs the convert-to-powers method for large N.

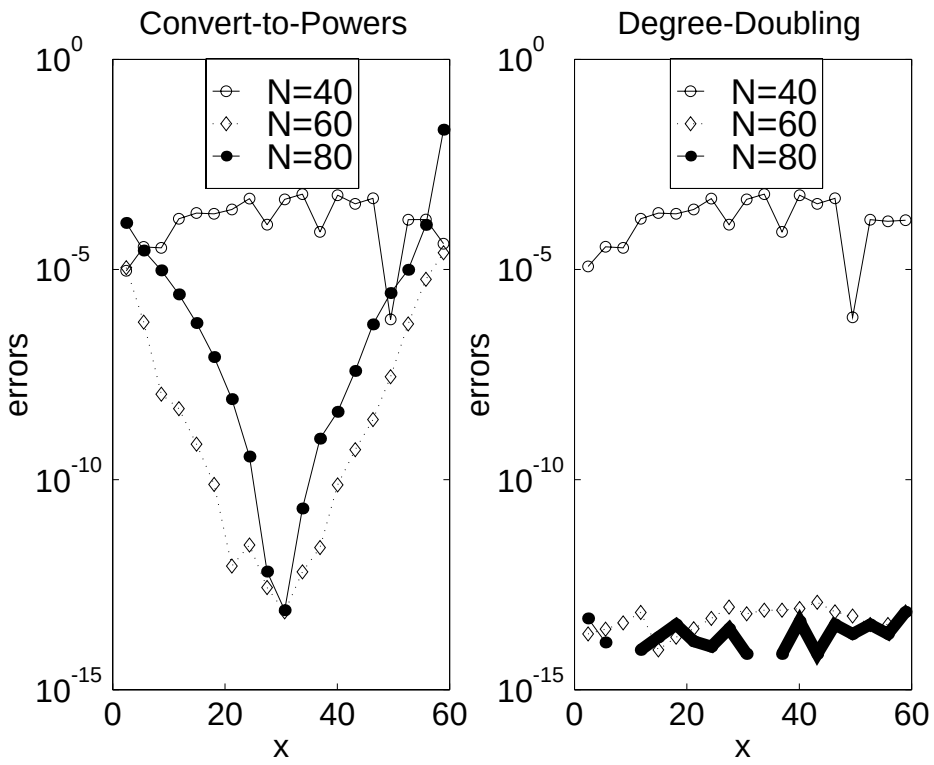

FIG. 3. *Comparison of the "convert-to-powers" method (left) and the "degree-doubling" algorithm (right) for computing the first* 19 *roots of* $J_0(x)$ *by Chebyshev expansions truncated after the Nth term on the interval* $x \in [0, 60]$.

Nevertheless, the convert-to-powers strategy is very effective even for N far larger than the restrictions suggested in earlier sections. Why is the ill-conditioning completely not ruinous for $N = 80$? Figure 4 (left) shows that the coefficients asymptote to a plateau of $O(10^{-16})$ for $N > 60$, which is a magnitude controlled by roundoff error. The very small size of the high degree Chebyshev coefficients keeps these coefficients from causing major problems when the series is converted to an ordinary polynomial of degree 80. It is important to the note from (5) and (6) that the size of the matrix elements increases rapidly with the column so that the elements that dominate the condition number of these matrices are the multipliers of very tiny coefficients in the Bessel–Chebyshev series.

Even with the mild ill-conditioning, it is remarkable that 19 roots can be captured so accurately with no more than two to four evaluations of $f(x)$ per root. Another robust interval rootfinding such as bisection would surely require far more evaluations of f.

When N is restricted to smaller values (and the expansion interval proportionately reduced), the ill-conditioning disappears as predicted. Figure 5 shows that, for a smaller interval, the errors are nearly uniform over the interval and decrease uniformly as N increases. (No comparison with the degree-doubling scheme is shown because for this case, where N is small and the convert-to-powers method is well-conditioned, there is no graphically discernible difference between the two algorithms.) With $N =$

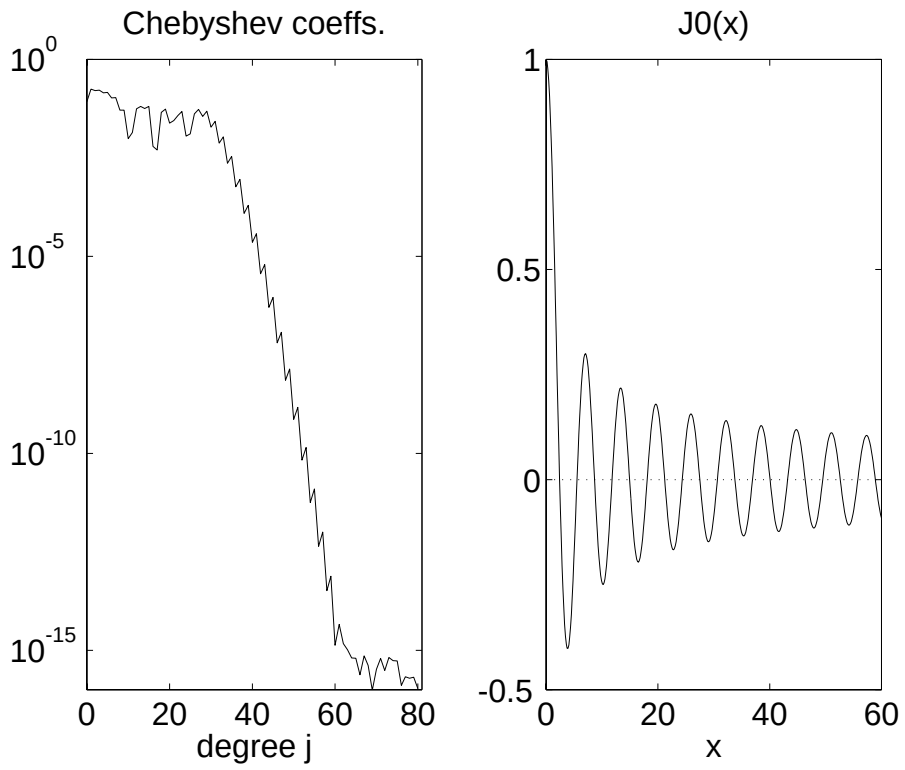

FIG. 4. *Left: absolute values of the Chebyshev coefficients of* $J_0(x)$ *for the interval* $x \in [0, 60]$. *Right: A plot of* J_0 *on this same interval, which contains* 19 *roots of* J_0.

28, somewhat larger than our ultraconservative recommended maximum of $N = 17$, the first six roots of J_0 are all approximated to within a relative error of less than 1 part in a hundred billion!

7. Generalization and alternative: Interpolation in powers around a circle in the complex plane. To generalize our method to the complex plane, the crucial fact is that a power series is optimal for interpolation in a *disk* in the complex plane in the same way that Chebyshev polynomials are optimal for interpolation on a real interval [9]. Interpolation by a series of Chebyshev polynomials on a real interval is replaced by interpolation of a series of powers of z on a circle in the complex z-plane. By applying interpolation-on-a-circle to many overlapping circles, polynomial rootsolvers can thus be applied to find roots of nontranscendental functions in arbitrary regions of the complex plane. Although they employ a different strategy to find roots within a circle, Delves and Lyness give a good discussion of such regional rootfinding methods [7].

8. Rootfinding on the whole real axis. If a function f has an *infinite* numbers of roots on the real axis, it is obviously impractical to find them all numerically. However, it is often possible to find an *asymptotic* approximation to the roots of large $|x|$ and then numerically compute the finite number of roots for which $|x|$ is too small for the asymptotic formula to be accurate. For the J_0 Bessel function used as an

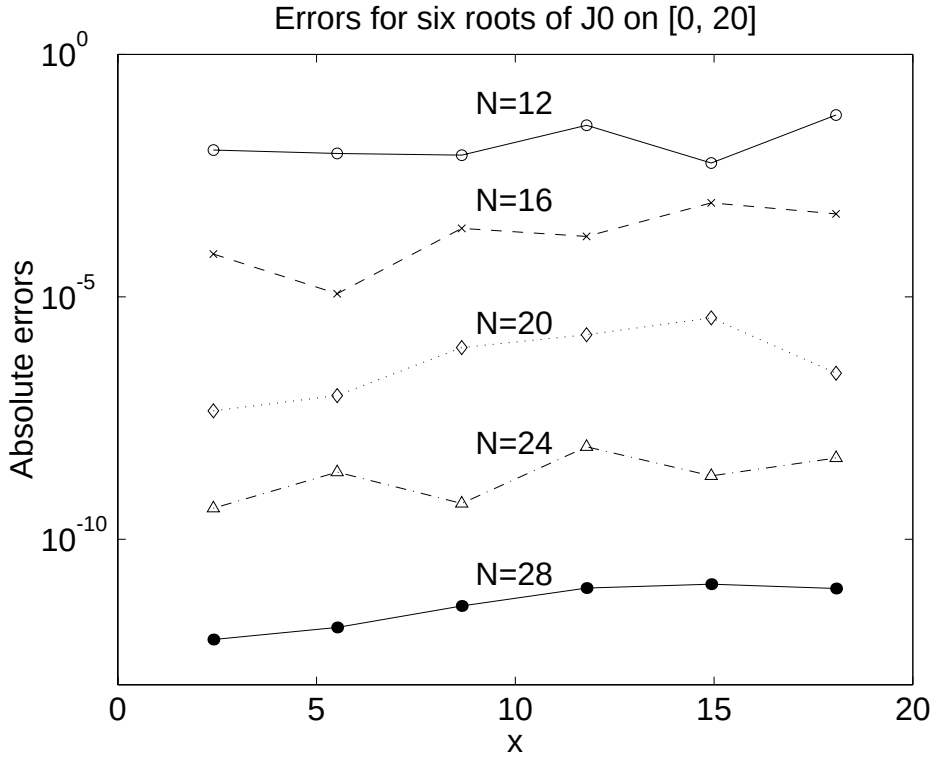

FIG. 5. *Absolute errors for the first six roots of the J_0 Bessel function. N is the degree of the Chebyshev approximation used to generate the polynomial whose roots were computed to approximate those of the Bessel function.*

example, for instance, the kth root, conventionally denoted by $j_{0,k}$, is asymptotically

$$j_{0,k} \sim (k - 1/4)\pi + \frac{1}{8(k-1/4)\pi} - \frac{31}{6(4k-1)^3\pi^3} + O(k^{-5}). \tag{24}$$

This approximation has an absolute error of only 0.0018 even for the first root and an error of just 2.7×10^{-10} for the 20th root.

When f has only a finite number of roots on an unbounded interval, it is possible to find them directly by using a change-of-coordinate that maps the infinite interval into the canonical interval for Chebyshev polynomials, $x \in [-1, 1]$. One can then apply the Chebyshev-to-polynomial algorithms, either convert-to-powers or degree-doubling, without modification.

If the coordinate on the infinite interval is denoted by y, then a good mapping [2] is

$$y = \frac{L\,x}{\sqrt{1-x^2}}; \qquad \leftrightarrow \qquad x = \frac{y}{\sqrt{L^2+y^2}}, \qquad x \in [-1, 1],\ \ y \in [-\infty, \infty], \tag{25}$$

where L is a constant, the user-choosable map parameter. Although the optimum L is problem-dependent [2, 6], the Chebyshev rate of convergence is not very sensitive to L, and $L = 1$ is a good choice in most applications. Other mappings can work, too, as discussed in [4] and [6]; a similar transformation for the semi-infinite interval is explained in [3] and [6].

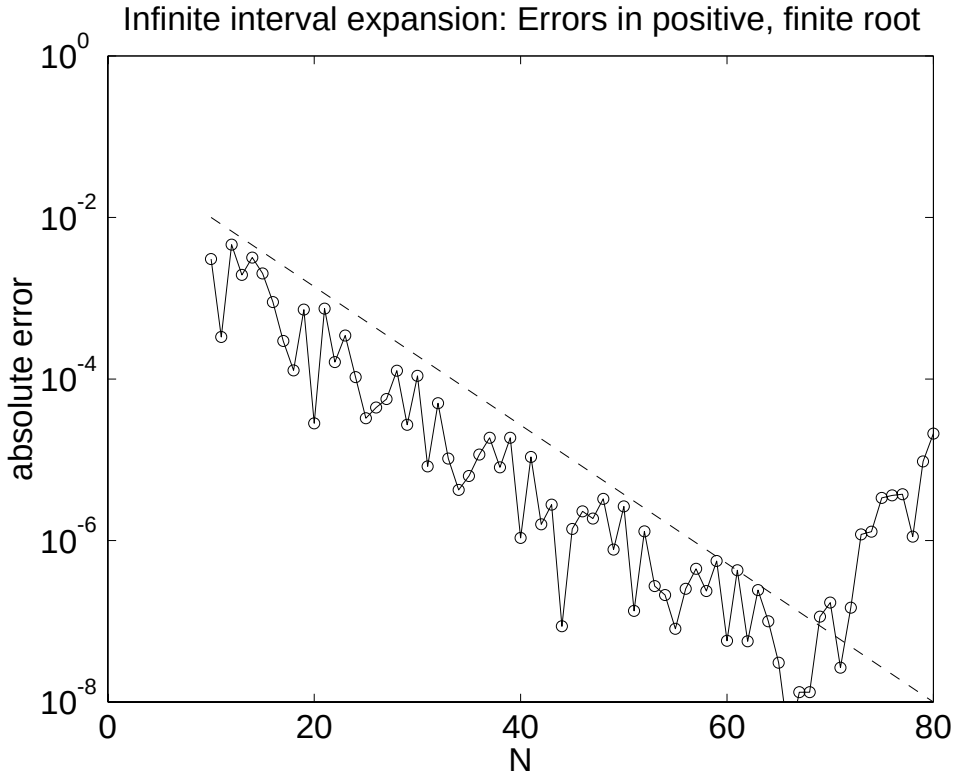

FIG. 6. *Infinite interval example,* $f(y) \equiv (2y^2 - 1)\exp(-[1/2]y^2)$*, with symmetry exploited by using Chebyshev expansion only on* $x \in [0, 1]$*, which is the image of the positive real axis. The dashed line is a guideline,* $0.072\exp(-0.197N)$*, to show that the trend of the error is exponential decrease with* N*. The rise in error for large* N *is due to the use of the "convert-to-powers" method of computing an ordinary polynomial from the Chebyshev series; the degree-doubling method is free of this problem.*

For example, the function

$$f(y) \equiv (2y^2 - 1)\exp(-[1/2]y^2) \tag{26}$$

has only two roots on the infinite interval, $y_* = \pm 1/\sqrt{2}$. Under the mapping, this becomes

$$f(y) = \left(2\frac{L^2x^2}{1-x^2} - 1\right)\exp\left(-\frac{1}{2}\frac{L^2x^2}{1-x^2}\right). \tag{27}$$

Because this is *symmetric* with respect to the origin, we can improve efficiency by computing a Chebyshev expansion only on $x \in [0, 1]$. The function has only a single finite root on the whole positive real axis at $y = 1/\sqrt{2}$, which is equivalent to $x = 1/\sqrt{3}$ in the transformed coordinate.

Figure 6 shows that the error decreases exponentially with N, the degree of the Chebyshev approximation, with oscillations in N superimposed. At $N = 70$, the roundoff error in the Chebyshev-to-powers conversion finally asserts itself so that further increases in N worsen the error compared to $N = 70$ where the root is approximated to a relative error of about 1 part in six million. This roundoff problem

can be suppressed, as in earlier examples, by using the "degree-doubling" conversion instead.

The accuracy is not as good for the finite interval example, which is hardly surprising. Nevertheless, with the added device of a mapping of the infinite interval into a finite interval, the Chebyshev-to-powers rootfinding method is successful.

9. Chebyshev methods and other "black box" rootfinders. The rootfinders of Kavvadias and Vrahatis [10], Kavvadias, Makri, and Vrahatis [11], and Smiley and Chun [13] both claim to be "black boxes," that is, to find the roots of a transcendental $f(x)$ without (i) requiring user input except for a subroutine to evaluate $f(x)$ and (ii) requiring the user to understand their algorithms—unnecessary because of their reliability. Both methods are a kind of "bisection-with-macho"; after the interval is subdivided, tests are applied to exclude subintervals which are root-free. Subdivision-and-test is then recursively applied until all the roots are isolated in sufficiently narrow intervals. Kavvadias and Vrahatis test for roots by numerically evaluating the Kronecker–Picard integral, whose value is the number of roots; Smiley and Chun use the cheaper but less precise criterion that if the Lipschitz constant L, defined by $L = \max(|f(x) - f(y)|/|x - y|)$ for all x, y on the interval is such that $|f(a)|, |f(b)| > L|b - a|$, then the interval $x \in [a, b]$ must be root-free. Refinements such as Newton–Ralphson iteration in the "end game" (when a root has been isolated within a small interval) and local Lipschitz constants are used to accelerate convergence for both methods.

We shall not attempt detailed comparisons between our algorithm and theirs. The efficiency of both Kronecker–Picard and Lipschitz-test algorithms strongly depend upon subdivision strategies, numerical quadrature tactics, Lipschitz constant approximation schemes, and so on. These black boxes will significantly improve as further experience allows better "tuning."

Instead, we will merely note that these algorithms require a large number of evaluations of $f(x)$ because of the repeated subdivisions and also the numerical quadratures or Lipschitz constant approximations. In principle, the cost of these evaluations could be dramatically reduced by replacing $f(x)$ by its Chebyshev interpolant. It follows that our ideas are perhaps complementary rather than competitive with subdivide-and-test methods.

However, our algorithm is completely self-contained. Kronecker–Picard and Lipschitz-test algorithms are useful in an $f \to Chebyshev$ approach only if these algorithms are superior to polynomial rootfinders. Are they? Alternatively, subdivide-and-test methods will fail to benefit from replacement of f by its Chebyshev proxy only for problems where f is cheap to evaluate and the subdivide-and-test methods converge faster than polynomial rootfinders. Such comparisons are highly problem-dependent and also implementation-dependent. We must leave these as open research questions.

10. Summary and open problems. Our main conclusion is that by "Chebyshevizing" a function $f(x)$, that is, by replacing $f(x)$ by its Chebyshev interpolant, the availability of robust polynomial rootfinders can be leveraged into reliable software for finding the roots of a *smooth, analytic* but otherwise *arbitrary* function $f(x)$ on a given *real interval*. Our Matlab subfunction that computes the roots using the convert-to-powers method has only 45 executable statements, and the degree-doubling algorithm is even shorter. Automation of subdivision would require a few additional lines, but the overall algorithms are commendably simple: all the complexity is in the polynomial rootfinder, which the user borrows from a software library.

By using an unbounded-interval-to-finite-interval mapping, the method easily generalizes to finding the real-valued roots of a function over the entire real axis if these roots are finite in number and the function is sufficiently smooth as $|x| \to \infty$ so that the transformed function is C^∞.

The "degree-doubling" method converts the truncated Chebyshev series of degree N into an ordinary polynomial of degree $2N$ whose coefficients are the same as the Chebyshev coefficients. This completely eliminates the ill-conditioning problem. However, because the degree is doubled, the computational cost is greater than for the convert-to-powers algorithm.

The convert-to-powers method has the flaw that it is mildly ill-conditioned. This difficulty can be cured by restricting N to moderate degree (less than 18) and subdividing the original target interval into as many subintervals as needed so that $f(x)$ is well-approximated by a Chebyshev series of restricted degree on each subinterval. However, degree restriction and subdivision are annoying complications. The reward is that the polynomial rootfinder is only asked to solve a polynomial of degree N rather than $2N$.

The numerical examples show that the convert-to-powers method is not as ill-conditioned as the norms of the conversion matrices would indicate. The reason is that, for a given problem, the true condition number depends upon the rate of convergence of the Chebyshev series as well as upon the matrix norms. The most extreme example is when $f(x)$ is a polynomial of finite degree k so that all Chebyshev coefficients a_j are zero for $j > k$. In this case, only the upper left $(k+1)/2 \times (k+1)/2$ blocks of the transformation matrices have anything to operate on. The effective condition number is determined by these blocks and not by the actual size of N, which may be much larger. For the Bessel function example, the Chebyshev series of J_0 is not identically zero for large degree, but the exponentially fast decrease of the Chebyshev coefficients does drastically reduce the effective condition number. An open problem is to develop a refined f-dependent condition number that takes the rate of Chebyshev convergence into account.

Because of the competing virtues and flaws of well-conditioned versus mildly ill-conditioned, fast versus slow, it is not possible to anoint either the degree-doubling or convert-to-powers algorithm as the "best" choice. What can be said is that both work well.

A minor unsolved problem, discussed at length in [5] but not here, is to find a good multiplicative scaling function when $f(x)$ varies by many orders of magnitude on the search interval $x \in [a, b]$. Because Chebyshev expansions are highly uniform in *absolute* error, there may be annoyingly large *relative* errors when $f(x)$ is badly scaled in the sense of having huge maxima on some parts of the interval but only tiny peaks and valleys on other subintervals. In theory, this difficulty can always be solved by subdividing the interval into subintervals and applying the algorithm on each subdomain.

The major unsolved problem is to find a good *direct* way to find all the roots of a polynomial on a real interval when the polynomial is defined by its Chebyshev coefficients without prior conversion to powers-of-x form. If such an algorithm could be found, then both the convert-to-powers and degree-doubling procedures become unnecessary.

Seen through the lens of Chebyshev polynomial series, there is no such thing as a nonpolynomial function. Every $f(x)$ is a truncated Chebyshev series in disguise. From the Chebyshev perspective, it is as easy to simultaneously find all roots of a

function $f(x)$ on a real interval, whether simple zeros or multiple roots, as it is for a polynomial.

Appendix A. Chebyshev interpolation of a function $f(x)$.

Goal. Compute a Chebyshev series, including terms up to and including T_N, on the interval $x \in [a, b]$.

Step 1. Create the interpolation points (Lobatto grid):

$$x_k \equiv \frac{b-a}{2} \cos\left(\pi \frac{k}{N}\right) + \frac{b+a}{2}, \qquad k = 0, 1, 2, \ldots, N. \tag{28}$$

Step 2. Compute the elements of the $(N+1) \times (N+1)$ interpolation matrix.

Define $p_j = 2$ if $j = 0$ or $j = N$ and $p_j = 1, j \in [1, N-1]$. Then the elements of the interpolation matrix are

$$I_{jk} = \frac{2}{p_j\, p_k\, N} \cos\left(j\pi \frac{k}{N}\right). \tag{29}$$

Step 3. Compute the grid-point values of $f(x)$, the function to be approximated:

$$f_k \equiv f(x_k), \qquad k = 0, 1, \ldots, N. \tag{30}$$

Step 4. Compute the coefficients through a vector-matrix multiply:

$$a_j = \sum_{k=0}^{N} I_{jk}\, f_k, \qquad j = 0, 1, 2, \ldots, N. \tag{31}$$

The approximation is

$$f \approx \sum_{j=0}^{N} a_j T_j\left(\frac{2x-(b+a)}{b-a}\right) = \sum_{j=0}^{N} a_j \cos\left\{j \arccos\left(\frac{2x-(b+a)}{b-a}\right)\right\}. \tag{32}$$

NONCONFORMING FINITE ELEMENT ANALYSIS FOR A PLATE CONTACT PROBLEM*

WEIMIN HAN† AND LIE-HENG WANG‡

Abstract. In this paper we analyze nonconforming finite element methods for solving a fourth order elliptic variational inequality of the second kind arising in a plate frictional contact problem. The variational inequality involves a nondifferentiable term due to the frictional contact. Optimal order error estimates are derived for both continuous and discontinuous nonconforming finite elements.

Key words. nonconforming finite element method, elliptic variational inequality of fourth order, plate frictional contact problem, optimal order error estimate

1. Introduction.

Variational inequalities form an important family of nonlinear boundary value or initial-boundary value problems. Interest in variational inequalities originates in applications from mechanics and physics. A partial list of the applications that lead to variational inequalities include the following: contact mechanics, non-Newtonian fluid flows such as Bingham fluids, obstacle problems, optimal control, plasticity, Stefan problems, unilateral problems, and so on. An early comprehensive reference on the topic is [8], where many problems in mechanics and physics are formulated and studied in the framework of variational inequalities. More recent references on the mathematical analysis of variational inequalities include [1, 10, 20, 22, 23]. Comprehensive references concerning the numerical analysis of variational inequalities, especially those arising in mechanical problems, include [12, 13, 14, 15, 16, 17, 19]. These references focus on numerical analysis for variational inequalities involving second order differential operators. Numerical study of fourth order variational inequalities is also available from some of these references; e.g., a duality approach based on conforming finite elements is analyzed in [16].

Nonconforming finite element methods are a natural choice in employing finite element methods for solving fourth order boundary value problems since the smoothness requirement on finite element functions is weakened. An early reference on the mathematical analysis of nonconforming finite element methods for the plate bending problem is [21]. Application of nonconforming finite element methods is not limited to fourth order problems; they offer more efficient solution algorithms for numerous other problems (cf. [3, p. 208]). Convergence and error estimation of nonconforming finite element methods are more involved compared to that of conforming finite element methods. A patch test was proposed and is widely used by engineers for convergence analysis of nonconforming finite element methods (cf. [2, 18]). However, it

is shown in [26] that the patch test is neither a necessary nor a sufficient condition for convergence. One finds in [26] a rigorous necessary and sufficient condition for convergence of nonconforming finite element solutions to variational equations of some boundary value problems. Some further developments along this line can be found in [25, 30], where convergence conditions are studied which are easier to examine. A summary account of nonconforming finite element methods can be found in [5] or, more recently, in [6]. In particular, in these latter references, one can find some discussions of the four nonconforming finite elements mentioned later in this paper: the continuous nonconforming elements of the Zienkiewicz triangle and Adini's rectangle, and the discontinuous nonconforming elements of Morley's triangle and the Fraeijs De Veubeke triangle.

In this paper, we derive error estimates for continuous and discontinuous nonconforming finite elements in solving a fourth order elliptic variational inequality of the second kind. A variational inequality of the second kind is featured by the presence of nondifferentiable terms in the formulation. Variational inequalities of the second kind are commonly seen in frictional contact problems. In this paper we adopt a plate frictional contact problem as our model fourth order variational inequality of the second kind for error analysis of nonconforming finite element methods; the ideas and results reported here can be extended to nonconforming finite element methods for other fourth order elliptic variational inequalities of the second kind. Literature on nonconforming finite element methods for fourth order variational inequalities is rather small at the moment. The only papers on this topic we know of are [27, 28, 29]. Note that in these papers the variational inequalities being approximated are of the first kind; i.e., they are imposed over convex sets, and no nondifferentiable terms are involved. To analyze nonconforming finite elements for fourth order variational inequalities of the second kind, we need to employ new techniques.

The paper is organized as follows. In section 2, we introduce the plate contact problem and show some properties for the solution of the problem. In section 3, we present an abstract result for nonconforming methods that will be used in deriving error estimates later in the paper. Sections 4 and 5 are devoted to error estimation of continuous and discontinuous nonconforming finite element methods for the plate contact problem, respectively.

2. The plate contact problem. Consider a thin flat plate $\Omega \times (-d/2, d/2)$, where $\Omega \subset \mathbb{R}^2$, $d > 0$ is the thickness of the plate and is assumed to be small. Assume the three-dimensional material is isotropic, linearly elastic with Poisson's ratio $\nu \in (0, 1/2)$ and Young's modulus $E > 0$. The plate is subject to a normal force of density $D_0 f(\boldsymbol{x})$ with the stiffness coefficient of the plate

$$D_0 = \frac{E\, d^3}{12\,(1-\nu^2)}.$$

Denote by $u = u(\boldsymbol{x})$, $\boldsymbol{x} \in \overline{\Omega}$, the vertical deflection of the plate. Let the boundary $\Gamma = \partial\Omega$ of the plate be decomposed into three mutually disjoint parts: $\Gamma = \overline{\Gamma}_1 \cup \overline{\Gamma}_2 \cup \overline{\Gamma}_3$ such that Γ_1, Γ_2, and Γ_3 are relatively open, $\overline{\Gamma}_1 \cap \overline{\Gamma}_3 = \emptyset$, and meas $(\Gamma_1) > 0$. The boundary is assumed to be Lipschitz continuous, and the unit outward normal vector is denoted by $\boldsymbol{n} = (n_1, n_2)^T$. The tangential vector is $\boldsymbol{\tau} = (\tau_1, \tau_2)^T$ with $\tau_1 = -n_2$, $\tau_2 = n_1$. Both $\boldsymbol{n}$ and $\boldsymbol{\tau}$ exist a.e. on Γ. Assume the plate is clamped on Γ_1:

$$u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \Gamma_1,$$

is free on Γ_2:

$$M(u) = N(u) = 0 \quad \text{on } \Gamma_2,$$

and is in frictional contact with a rigid foundation on Γ_3. Here,

$$M(u) = -\Delta u + (1-\nu)\,\partial_{\tau\tau} u,$$
$$N(u) = \partial_n \Delta u + (1-\nu)\,\partial_\tau(\partial_{n\tau} u).$$

Notice that for a smooth function u, $M(u)$ and $N(u)$ are defined a.e. on Γ. The quantity $M(u)$ can be interpreted as the tangential moment, while $-N(u)$ represents a force. Here and throughout the paper, we use the following notations:

$$\partial_{11} u = \frac{\partial^2 u}{\partial x_1^2}, \quad \partial_{12} u = \frac{\partial^2 u}{\partial x_1 \partial x_2}, \quad \partial_n u = \frac{\partial u}{\partial n}, \quad \partial_\tau u = \frac{\partial u}{\partial \tau}, \quad \cdots .$$

Introduce the function space

$$V = \{\, v \in H^2(\Omega) \mid v = \partial_n v = 0 \text{ on } \Gamma_1 \,\}. \tag{2.1}$$

Over the space V, we define a bilinear form

$$a(u,v) = \int_\Omega \left[\Delta u\, \Delta v + (1-\nu)\,(2\,\partial_{12} u\, \partial_{12} v - \partial_{11} u\, \partial_{22} v - \partial_{22} u\, \partial_{11} v)\right] dx, \tag{2.2}$$

and a functional

$$j(v) = \int_{\Gamma_3} g\,|v|\, ds, \tag{2.3}$$

where g is given. For the data of the problem, we assume

$$f \in L^2(\Omega), \quad g \in L^2(\Gamma_3),\ g > 0 \text{ a.e. on } \Gamma_3. \tag{2.4}$$

We will use the notation

$$(f,v) = \int_\Omega f\, v\, dx.$$

The plate frictional contact problem is defined through a minimal energy principle:

$$u \in V,\ J(u) = \inf_{v \in V} J(v),$$

where

$$J(v) = \frac{1}{2}\, a(v,v) + j(v) - (f,v).$$

The quantity $D_0 J(v)$ is the total energy, and $j(v)$ is the contribution from the frictional contact. It is easy to show that the minimization problem is equivalent to the following variational inequality.

PROBLEM 2.1. *Find $u \in V$ such that*

$$a(u, v-u) + j(v) - j(u) \geq (f, v-u) \quad \forall\, v \in V. \tag{2.5}$$

Wellposedness of Problem 2.1 follows from a standard argument.

THEOREM 2.2. *Problem* 2.1 *has a unique solution.*

Proof. Since meas $(\Gamma_1) > 0$, the bilinear form is coercive on V:

$$a(v,v) \geq \alpha \|v\|_V^2 \quad \forall\, v \in V.$$

We also observe that over the space V, $a(\cdot,\cdot)$ is continuous, $j(\cdot)$ is continuous and convex, and f defines a linear continuous functional. Thus Problem 2.1 is an elliptic variational inequality of the second kind and has a unique solution (cf. [12]). ∎

To obtain the corresponding strong form of the boundary value problem, we assume the solution u is smooth (say, $u \in C^4(\overline{\Omega})$). For any $v \in H^2(\Omega)$, we have

$$\int_\Omega \Delta^2 u\, v\, dx = \int_\Omega \Delta u\, \Delta v\, dx + \int_\Gamma \partial_n \Delta u\, v\, ds - \int_\Gamma \Delta u\, \partial_n v\, ds. \tag{2.6}$$

It is easy to verify the equality

$$\int_\Omega (2\,\partial_{12} u\,\partial_{12} v - \partial_{11} u\,\partial_{22} v - \partial_{22} u\,\partial_{11} v)\, dx = \int_\Gamma (-\partial_{\tau\tau} u\,\partial_n v + \partial_{n\tau} u\,\partial_\tau v)\; ds.$$

If the boundary Γ is smooth, we further have

$$\int_\Omega (2\,\partial_{12} u\,\partial_{12} v - \partial_{11} u\,\partial_{22} v - \partial_{22} u\,\partial_{11} v)\, dx = -\int_\Gamma (\partial_{\tau\tau} u\,\partial_n v + \partial_\tau(\partial_{n\tau} u)\, v)\; ds. \tag{2.7}$$

Then from (2.6) we have

$$a(u,v) = \int_\Omega \Delta^2 u\, v\, dx - \int_\Gamma N(u)\, v\, ds - \int_\Gamma M(u)\, \partial_n v\, ds \quad \forall\, v \in H^2(\Omega). \tag{2.8}$$

Using this relation in the variational inequality (2.5), we can follow a standard argument (cf., e.g., [8, 19]) to conclude that u satisfies the relations

$$\Delta^2 u = f \quad \text{in } \Omega, \tag{2.9}$$

$$u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \Gamma_1, \tag{2.10}$$

$$M(u) = N(u) = 0 \quad \text{on } \Gamma_2, \tag{2.11}$$

$$\left.\begin{array}{l} M(u) = 0, \quad |N(u)| \leq g, \\ |N(u)| < g \Longrightarrow u = 0, \\ |N(u)| = g \Longrightarrow u = \lambda\, N(u) \text{ for some } \lambda \geq 0 \end{array}\right\} \text{on } \Gamma_3. \tag{2.12}$$

This is the strong form of the plate contact problem studied in [8]. We comment that $g > 0$ can be interpreted as the frictional bound.

When the boundary Γ is only piecewise smooth, the right-hand side of the relation (2.7) needs to be replaced by

$$\sum_P \big(\partial_{n\tau} u(P_-) - \partial_{n\tau} u(P_+)\big)\, v(P) - \int_\Gamma (\partial_{\tau\tau} u\,\partial_n v + \partial_\tau(\partial_{n\tau} u)\, v)\; ds,$$

where P is any corner point on the boundary and $\partial_{n\tau} u(P_-)$ and $\partial_{n\tau} u(P_+)$ are the left and right limiting values of $\partial_{n\tau} u$ at P along Γ directed counterclockwise. Then the relations (2.9)–(2.12) are to be supplemented with continuity conditions of the form

$$\partial_{n\tau} u(P_-) = \partial_{n\tau} u(P_+).$$

Such conditions can be interpreted as "corner force conditions" (cf. [7]).

The main purpose of the paper is to analyze nonconforming finite element methods for Problem 2.1. For this, we need a characterization of the solution of Problem 2.1, following an idea found in [13]. Let

$$\Lambda = \{\, \mu \in L^\infty(\Gamma_3) \mid |\mu| \le 1 \text{ a.e. on } \Gamma_3 \,\}.$$

THEOREM 2.3. *A function u is a solution of Problem* 2.1 *if and only if there exists $\lambda \in \Lambda$ such that*

$$a(u,v) + \int_{\Gamma_3} g\,\lambda\, v\, ds = (f,v) \quad \forall\, v \in V, \tag{2.13}$$

$$\lambda\, u = |u| \quad \text{a.e. on } \Gamma_3. \tag{2.14}$$

Proof. Suppose u is a solution of Problem 2.1. By taking $v = 0$ and $2\,u$ in (2.5), we obtain

$$a(u,u) + j(u) = (f,u). \tag{2.15}$$

Then, from (2.5),

$$a(u,v) + j(v) \ge (f,v) \quad \forall\, v \in V. \tag{2.16}$$

It is easy to see that (2.5) is equivalent to (2.15) and (2.16). From (2.16), we get

$$(f,v) - a(u,v) \le j(v) \quad \forall\, v \in V.$$

Replacing v by $-v$ in this inequality, we obtain

$$(f,v) - a(u,v) \ge -j(v) \quad \forall\, v \in V.$$

Therefore,

$$|(f,v) - a(u,v)| \le j(v) \quad \forall\, v \in V. \tag{2.17}$$

Let γ be the trace operator defined on V and denote $H_{\Gamma_3} = \gamma(V)|_{\Gamma_3}$ with the norm

$$\|v\|_{H_{\Gamma_3}} = \inf\{\, \|w\|_V \mid w \in V,\, w|_{\Gamma_3} = v \,\}.$$

Then, from (2.17), we see that $H_{\Gamma_3} \ni v \mapsto (f,v) - a(u,v)$ defines a linear mapping on H_{Γ_3}; here, we use the same symbol v for a function from V with the trace v on Γ_3. Thus $\ell(v) = (f,v) - a(u,v)$ is a linear mapping on H_{Γ_3} and, from (2.17),

$$|\ell(v)| \le \int_{\Gamma_3} g\,|v|\, ds \quad \forall\, v \in H_{\Gamma_3}.$$

Obviously, $H_{\Gamma_3} \subset L^1(\Gamma_3)$. By the Hahn–Banach theorem, the linear functional ℓ can be the extended to the space $L^1(\Gamma_3)$, and we have the existence of $\lambda \in \Lambda$ such that

$$\ell(v) = \int_{\Gamma_3} g\,\lambda\, v\, ds \quad \forall\, v \in L^1(\Gamma_3).$$

Therefore, (2.13) holds. Using (2.15), we then have

$$\int_{\Gamma_3} g\,(\lambda\, u - |u|)\, ds = 0.$$

Since $|\lambda| \leq 1$ a.e. on Γ_3, we have the relation (2.14).

Proof of the converse statement is easy and is hence omitted. □

By comparing (2.8) with (2.13) and using the equality boundary conditions of the solution u, we find that

$$g\,\lambda = N(u) \quad \text{on } \Gamma_3.$$

Thus, the "Lagrange multiplier" λ can be interpreted as a scaled shearing force.

Note that the relations (2.9)–(2.12) are valid only if the solution $u \in V$ of Problem 2.1 is smooth, e.g., $u \in C^4(\overline{\Omega})$. Consequently, these relations cannot be used in error analysis. In finite element error analysis, we need a reasonable solution regularity stronger than $u \in V$. Such a regularity result for Problem 2.1 does not seem to be available in the current literature. In this paper, we will assume

$$u \in H^3(\Omega). \tag{2.18}$$

Now let us derive some relations for the solution $u \in V$ of Problem 2.1. In (2.13), we let $v \in C_0^\infty(\Omega)$ to obtain

$$\Delta^2 u = f \quad \text{in the sense of distributions.}$$

Since $f \in L^2(\Omega)$, we actually have

$$\Delta^2 u = f \quad \text{in } L^2(\Omega), \tag{2.19}$$

and then also

$$\Delta^2 u = f \quad \text{a.e. in } \Omega. \tag{2.20}$$

Since $\Delta^2 u \in L^2(\Omega)$ and $u \in H^3(\Omega)$, we can define $\partial_n \Delta u \in H^{-1/2}(\Gamma)$ by the relation (cf., e.g., [11])

$$\langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} = \int_\Omega \left[\Delta^2 u\, v + \nabla(\Delta u)\cdot\nabla v\right] dx \quad \forall\, v \in H^1(\Omega). \tag{2.21}$$

For the bilinear form (2.2), we then have

$$\begin{aligned} a(u,v) &= \int_\Omega \Delta^2 u\, v\, dx - \langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} + \int_\Gamma \Delta u\, \partial_n v\, ds \\ &\quad + (1-\nu)\int_\Gamma (-\partial_{\tau\tau} u\, \partial_n v + \partial_{n\tau} u\, \partial_\tau v)\, ds \\ &= (f,v) - \int_\Gamma M(u)\, \partial_n v\, ds - \langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} + (1-\nu)\int_\Gamma \partial_{n\tau} u\, \partial_\tau v\, ds. \end{aligned}$$

Thus by (2.13) we have

$$-\int_\Gamma M(u)\, \partial_n v\, ds - \langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} + (1-\nu)\int_\Gamma \partial_{n\tau} u\, \partial_\tau v\, ds + \int_{\Gamma_3} g\,\lambda\, v\, ds = 0 \quad \forall\, v \in V. \tag{2.22}$$

By a standard procedure (cf. [8]), it can then be established that

$$M(u) = 0 \quad \text{a.e. on } \Gamma_2 \cup \Gamma_3. \tag{2.23}$$

Then from (2.22) we obtain

$$-\langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} + (1-\nu)\int_\Gamma \partial_{n\tau} u\, \partial_\tau v\, ds + \int_{\Gamma_3} g\,\lambda\, v\, ds = 0 \quad \forall\, v \in V. \tag{2.24}$$

Now the closure of V in $H^1(\Omega)$ is

$$H^1_{\Gamma_1}(\Omega) = \{\, v \in H^1(\Omega) \mid v = 0 \text{ a.e. on } \Gamma_1 \,\}.$$

Denote

$$\tilde{H}^1_{\Gamma_1}(\Omega) = \{\, v \in H^1_{\Gamma_1}(\Omega) \mid \partial_\tau v \in L^2(\Gamma) \,\}.$$

Then from (2.24) we conclude that

$$-\langle \partial_n \Delta u, v\rangle_{1/2,\Gamma} + (1-\nu)\int_\Gamma \partial_{n\tau} u\, \partial_\tau v\, ds + \int_{\Gamma_3} g\,\lambda\, v\, ds = 0 \quad \forall\, v \in \tilde{H}^1_{\Gamma_1}(\Omega). \tag{2.25}$$

3. An abstract error estimate. Let $\{\mathcal{T}_h\}_h$ be a family of finite element partitions of the domain $\overline{\Omega}$. Here $h \to 0+$ is a discretization parameter. A typical element in $\mathcal{T}_h$ is denoted by T. Let $\{V_h\}_h$ be a family of corresponding finite element spaces used to approximate the space V. We consider the case of nonconforming approximation. Thus, in general, $V_h \not\subset V$. Then the discrete approximation problem is the following.

PROBLEM 3.1. *Find $u \in V_h$ such that*

$$a_h(u_h, v_h - u_h) + j(v_h) - j(u_h) \geq (f, v_h - u_h) \quad \forall\, v_h \in V_h, \tag{3.1}$$

where the discrete bilinear form is

$$a_h(u,v) = \sum_{T\in\mathcal{T}_h} \int_T \left[\Delta u\, \Delta v + (1-\nu)\,(2\,\partial_{12}u\,\partial_{12}v - \partial_{11}u\,\partial_{22}v - \partial_{22}u\,\partial_{11}v)\right] dx. \tag{3.2}$$

Assume

$$\|v_h\|_h = \left\{ \sum_{T\in\mathcal{T}_h} |v_h|^2_{2,T} \right\}^{1/2}, \quad v_h \in V_h,$$

is a norm on V_h. Then the bilinear form (3.2) is coercive on V_h. Obviously, $a_h(\cdot,\cdot)$ is continuous:

$$|a_h(u,v)| \leq M\, \|u_h\|_h \|v_h\|_h \quad \forall\, u_h, v_h \in V + V_h.$$

We also observe that $j(\cdot)$ is continuous and convex on V_h, and f defines a linear continuous functional on V_h. Therefore, Problem 3.1 has a unique solution.

The following abstract error estimate is inspired by Falk's work [9] and the work of Brezzi, Hager, and Raviart [4]. It plays an important role in error analysis for the approximation of the variational inequality and can be viewed as an extension of the Strang lemma (cf. [5]) for variational equations to variational inequalities.

THEOREM 3.2. *For the solutions of the Problems* 2.1 *and* 3.1, *we have the inequality*

$$\|u - u_h\|^2_h \leq c \inf_{v_h \in V_h} \left\{ \|u - v_h\|^2_h + R_h(v_h, u_h) \right\}, \tag{3.3}$$

where

$$R_h(v_h, u_h) = a_h(u, v_h - u_h) + j(v_h) - j(u_h) - (f, v_h - u_h) \tag{3.4}$$

is a discrete residual.

Proof. For any $v_h \in V_h$, we have

$$\begin{aligned}\alpha \|u_h - v_h\|_h^2 &\le a_h(u_h - v_h, u_h - v_h)\\ &= a_h(u - v_h, u_h - v_h) + a_h(u_h - u, u_h - v_h)\\ &\le M \|u - v_h\|_h \|u_h - v_h\|_h + a_h(u_h, u_h - v_h) - a_h(u, u_h - v_h)\\ &\le M \|u - v_h\|_h \|u_h - v_h\|_h + R_h(v_h, u_h),\end{aligned}$$

where in the last step we used the defining inequality (3.1). Using the inequality

$$M \|u - v_h\|_h \|u_h - v_h\|_h \le \frac{\alpha}{2} \|u_h - v_h\|_h^2 + \frac{M^2}{2\,\alpha} \|u - v_h\|_h^2$$

we obtain

$$\|u_h - v_h\|_h^2 \le c \{\|u - v_h\|_h^2 + R_h(v_h, u_h)\}.$$

Now the relation (3.3) follows from

$$\|u - u_h\|_h \le \|u - v_h\|_h + \|u - v_h\|_h$$

and the arbitrariness of $v_h \in V_h$. □

4. Continuous nonconforming finite element approximation. We consider some continuous nonconforming plate elements in this section. Let $\{\mathcal{T}_h\}_h$ be a family of regular triangulation of $\overline{\Omega}$, and let $\{V_h\}_h \subset C^0(\overline{\Omega})$ be a corresponding family of nonconforming finite element subspaces of V. We assume

$$\Big| \sum_T \int_{\partial T} w\, \partial_n v_h \, ds \Big| \le c\, h \, \|w\|_{1,\Omega} \|v_h\|_h \quad \forall\, v_h \in V_h, \tag{4.1}$$

and the finite element interpolation error estimate

$$\|w - \Pi_h w\|_h \le c\, h \, \|w\|_{3,\Omega} \quad \forall\, w \in V \cap H^3(\Omega). \tag{4.2}$$

Here $\Pi_h w \in V_h$ denotes the finite element interpolant of w.

THEOREM 4.1. *Assume* (2.18), (4.1), *and* (4.2). *Then we have the error estimate*

$$\|u - u_h\|_h \le c\, h \, (\|u\|_{3,\Omega} + h^{1/4} \|g\|_{0,\Gamma_3}). \tag{4.3}$$

Proof. Let us first estimate the terms involved in the residual $R_h(v_h, u_h)$. We have

(4.4)

$$\begin{aligned}a_h(u, u_h - v_h) &= \sum_T \int_T \big\{\Delta u\, \Delta(u_h - v_h) + (1 - \nu)\,(2\, \partial_{12} u\, \partial_{12}(u_h - v_h)\\ &\qquad - \partial_{11} u\, \partial_{22}(u_h - v_h) - \partial_{22} u\, \partial_{11}(u_h - v_h))\big\}\, ds\\ &= -\sum_T \int_T \nabla(\Delta u) \cdot \nabla(u_h - v_h)\, dx + \sum_T \int_{\partial T} \Delta u\, \partial_n(u_h - v_h)\, ds\\ &\quad + (1 - \nu) \sum_T \int_{\partial T} \big\{ - \partial_{\tau\tau} u\, \partial_n(u_h - v_h) + \partial_{n\tau} u\, \partial_\tau(u_h - v_h)\big\}\, ds.\end{aligned}$$

Since $V_h \subset C(\overline{\Omega})$, we have $u_h, v_h \in H^1(\Omega)$ and

(4.5)
$$-\sum_T \int_T \nabla(\Delta u)\cdot\nabla(u_h - v_h)\,dx = -\int_\Omega \nabla(\Delta u)\cdot\nabla(u_h - v_h)\,dx$$
$$= \int_\Omega \Delta^2 u\,(u_h - v_h)\,dx - \langle \partial_n \Delta u, u_h - v_h\rangle_{1/2,\Gamma}.$$

Then

$$\begin{aligned}
&(f, u_h - v_h) - a_h(u, u_h - v_h)\\
&\quad = -\sum_T \int_{\partial T} \left[\Delta u - (1-\nu)\,\partial_{\tau\tau} u\right] \partial_n(u_h - v_h)\,ds + \langle \partial_n \Delta u, u_h - v_h\rangle_{1/2,\Gamma}\\
&\qquad - (1-\nu)\sum_T \int_{\partial T} \partial_{n\tau} u\,\partial_\tau(u_h - v_h)\,ds\\
&\quad = -\sum_T \int_{\partial T} M(u)\,\partial_n(u_h - v_h)\,ds - (1-\nu)\sum_T \sum_{\substack{\gamma\subset\partial T\\ \gamma\not\subset\Gamma}} \int_\gamma \partial_{n\tau} u\,\partial_\tau(u_h - v_h)\,ds\\
&\qquad - (1-\nu)\sum_T \sum_{\substack{\gamma\subset\partial T\\ \gamma\subset\Gamma}} \int_\gamma \partial_{n\tau} u\,\partial_\tau(u_h - v_h)\,ds + \langle \partial_n \Delta u, u_h - v_h\rangle_{1/2,\Gamma}.
\end{aligned}$$

Since $u_h, v_h \in C(\overline{\Omega})$, we have

$$\sum_T \sum_{\substack{\gamma\subset\partial T\\ \gamma\not\subset\Gamma}} \int_\gamma \partial_{n\tau} u\,\partial_\tau(u_h - v_h)\,ds = 0.$$

Thus,

$$\begin{aligned}
(f, u_h - v_h) - a_h(u, u_h - v_h) = &-\sum_T \int_{\partial T} M(u)\,\partial_n(u_h - v_h)\,ds + \langle \partial_n \Delta u, u_h - v_h\rangle_{1/2,\Gamma}\\
&- (1-\nu)\int_\Gamma \partial_{n\tau} u\,\partial_\tau(u_h - v_h)\,ds.
\end{aligned}$$

Using the relation (2.25), we obtain

(4.6)
$$(f, u_h - v_h) - a_h(u, u_h - v_h) = -\sum_T \int_{\partial T} M(u)\,\partial_n(u_h - v_h)\,ds - \int_{\Gamma_3} g\,\lambda\,(u_h - v_h)\,ds.$$

Then

(4.7)
$$R_h(v_h, u_h) = \int_{\Gamma_3} g\,(|v_h| - \lambda\,v_h - |u_h| + \lambda\,u_h)\,ds - \sum_T \int_{\partial T} M(u)\,\partial_n(u_h - v_h)\,ds.$$

The last term on the right-hand side of (4.7) is estimated by (4.1):

$$\left|\sum_T \int_{\partial T} M(u)\,\partial_n(v_h - u_h)\,ds\right| \le c\,h\,\|u\|_{3,\Omega}\|v_h - u_h\|_h.$$

We now estimate the first term on the right-hand side of (4.7). Since $|\lambda| \le 1$ a.e. on Γ_3,

$$\int_{\Gamma_3} g\,(|v_h| - \lambda\, v_h - |u_h| + \lambda\, u_h)\, ds \le \int_{\Gamma_3} g\,(|v_h| - \lambda\, v_h)\, ds.$$

In the following, we choose $v_h = \Pi_h u$. We have

$$\begin{aligned}\int_{\Gamma_3} g\,(|\Pi_h u| - \lambda\,\Pi_h u)\, ds &= \int_{\Gamma_3} g\ (|\Pi_h u| - |u| - \lambda\,(\Pi_h u - u))\ ds \\ &\le 2\int_{\Gamma_3} g\,|u - \Pi_h u|\, ds \\ &\le 2\,\|g\|_{0,\Gamma_3}\|u - \Pi_h u\|_{0,\Gamma_3}.\end{aligned}$$

From [26], for any element side $\gamma \subset \Gamma_3$, denoting T the element that has the side γ, we have

$$\begin{aligned}\|u - \Pi_h u\|_{0,\gamma} &\le c\left(h^{-1}\|u - \Pi_h u\|_{0,T}^2 + h\,|u - \Pi_h u|_{1,T}^2\right)^{1/2} \\ &\le c\left(h^{-1}h^6|u|_{3,T}^2 + h\,h^4|u|_{3,T}^2\right)^{1/2} \\ &\le c\,h^{5/2}|u|_{3,T}.\end{aligned}$$

Thus,

$$\begin{aligned}\|u - \Pi_h u\|_{0,\Gamma_3} &= \left(\sum_{\gamma\subset\Gamma_3}\|u - \Pi_h u\|_{0,\gamma}^2\right)^{1/2} \\ &\le c\,h^{5/2}\left(\sum_{T:\partial T\cap\Gamma_3\ne\emptyset}|u|_{3,T}^2\right)^{1/2} \\ &\le c\,h^{5/2}|u|_{3,\Omega}.\end{aligned}$$

Summarizing, we have the bound

$$R_h(\Pi_h u, u_h) \le c\,h\,\|u\|_{3,\Omega}\|\Pi_h u - u_h\|_h + c\,h^{5/2}\|g\|_{0,\Gamma_3}\|u\|_{3,\Omega}.$$

So, from (3.3),

$$\|u - u_h\|_h^2 \le c\,\{\|u - \Pi_h u\|_h^2 + h\,\|u\|_{3,\Omega}\|\Pi_h u - u_h\|_h + h^{5/2}\|g\|_{0,\Gamma_3}\|u\|_{3,\Omega}\}.$$

The term $\|\Pi_h u - u_h\|_h$ is bounded by $\|\Pi_h u - u\|_h + \|u - u_h\|_h$. Using the interpolation error estimate (4.2), we then obtain the error estimate (4.3). □

One example of a continuous nonconforming finite element is the Zienkiewicz triangle. Assume $\overline{\Omega}$ is such that it is possible to split it into triangles with all sides parallel to three fixed directions. This property is valid if Ω is the union of rectangles with sides parallel to two fixed directions and right triangles with two sides parallel to the two fixed directions. Let $\{\mathcal{T}_h\}$ be a regular family of partitions of $\overline{\Omega}$ into such triangles. Then the Zienkiewicz triangle consists of piecewise incomplete polynomials of degree less than or equal to 3. On each triangle, the polynomial is determined by its values and the values of its two first order derivatives at the three vertices; for details, cf. [5]. For this element, we have (4.1) and (4.2) (cf. [24]).

Another example is Adini's rectangle. Assume $\overline{\Omega} \subset \mathbb{R}^2$ can be partitioned into rectangles (e.g., if Ω is the union of rectangles with sides parallel to two fixed directions). Let $\{\mathcal{T}_h\}_h$ be a regular family of partitions of $\overline{\Omega}$ into rectangles with sides parallel to the coordinate axes. Then Adini's rectangle is defined as a piecewise polynomial corresponding to the partition $\mathcal{T}_h$ such that, on each element, it is a polynomial from the space $\mathcal{P}_3(\mathbb{R}^2) + [x_1^3 x_2, x_1 x_2^3]$, with the values of function and of the two first partial derivatives with respect to x_1 and x_2 at the four vertices of the element as the finite element parameters. For the vertices on $\overline{\Gamma}_1$, the parameters are taken to be zero for V_h. Then, from [26], we have (4.1) and (4.2).

We conclude that for both the Zienkiewicz triangle and Adini's rectangle, the optimal order error estimate (4.3) holds.

5. Discontinuous nonconforming finite element approximation. In this section, we consider discontinuous nonconforming finite element approximations of the plate contact problem. Let $\{V_h\}_h \not\subset C^0(\overline{\Omega})$ be a family of nonconforming finite element subspaces of V corresponding to a regular family $\{\mathcal{T}_h\}_h$ of triangulations of $\overline{\Omega}$ such that the finite element functions are continuous at the vertices of the corresponding triangulation. We still assume (4.1) and (4.2).

THEOREM 5.1. *Assume* (2.18), (4.1), *and* (4.2). *Also assume the finite element functions are continuous at the vertices of the corresponding triangulation. Then we have the error estimate*

$$\|u - u_h\|_h \le c\, h \left\{ \|u\|_{3,\Omega} + h^{1/4} \|g\|_{0,\Gamma_3} + h\, \|f\|_{0,\Omega} \right\}. \tag{5.1}$$

Proof. Since $V_h \not\subset C(\overline{\Omega})$ implies $V_h \not\subset H^1(\Omega)$, we must modify the expression (4.5) as follows. Denote $w_h = u_h - v_h$ and let w_h^I be the continuous piecewise linear interpolant of w_h. Since $w_h^I \in C(\overline{\Omega})$, $w_h^I \in H^1(\Omega)$. First we write

$$\begin{aligned}
-\sum_T \int_T \nabla(\Delta u) \cdot \nabla(u_h - v_h)\, dx &= -\sum_T \int_T \nabla(\Delta u) \cdot \nabla w_h\, dx \\
&= -\sum_T \int_T \nabla(\Delta u) \cdot \nabla w_h^I\, dx \\
&\quad -\sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I)\, dx \\
&= \int_\Omega \Delta^2 u\, w_h^I\, dx - \langle \partial_n \Delta u, w_h^I \rangle_{1/2,\Gamma} \\
&\quad -\sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I)\, dx.
\end{aligned}$$

Then

$$\begin{aligned}
a_h(u, u_h - v_h) = \int_\Omega \Delta^2 u\, w_h^I\, dx - \langle \partial_n \Delta u, w_h^I \rangle_{1/2,\Gamma} - \sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I)\, dx \\
+ \sum_T \int_{\partial T} \Delta u\, \partial_n w_h ds + (1-\nu) \sum_T \int_{\partial T} (-\partial_{\tau\tau} u\, \partial_n w_h + \partial_{n\tau} u\, \partial_\tau w_h)\, ds.
\end{aligned}$$

Use the relation (2.20),

$$a_h(u, u_h - v_h) = (f, w_h^I) - \langle \partial_n \Delta u, w_h^I \rangle_{1/2,\Gamma} + \sum_T \int_{\partial T} \left\{ \Delta u - (1-\nu)\, \partial_{\tau\tau} u \right\} \partial_n w_h \, ds$$
$$+ (1-\nu) \sum_T \int_{\partial T} \partial_{n\tau} u \partial_\tau w_h \, ds - \sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I) \, dx.$$

Hence,

$$\begin{aligned}(f, u_h - v_h) - a_h(u, u_h - v_h) &= (f, w_h - w_h^I) + \sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I) \, dx + \langle \partial_n \Delta u, w_h^I \rangle_{1/2,\Gamma} \\ &\quad - \sum_T \int_{\partial T} M(u)\, \partial_n w_h \, ds - (1-\nu) \sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau w_h \, ds.\end{aligned}$$

Now

$$\sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau w_h \, ds = \sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau w_h^I \, ds + \sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau (w_h - w_h^I) \, ds.$$

For each side γ of the elements, define a piecewise constant projection operator $P_0^\gamma : L^1(\gamma) \to \mathbb{R}$ by

$$P_0^\gamma(v) = \frac{1}{|\gamma|} \int_\gamma v \, ds.$$

Since

$$\int_\gamma \partial_\tau (w_h - w_h^I) \, ds = 0,$$

we have

$$\begin{aligned}\sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau (w_h - w_h^I) \, ds &= \sum_T \sum_{\gamma \subset \partial T} \int_\gamma \partial_{n\tau} u \, \partial_\tau (w_h - w_h^I) \, ds \\ &= \sum_T \sum_{\gamma \subset \partial T} \int_\gamma (\partial_{n\tau} u - P_0^\gamma(\partial_{n\tau} u)) \, \partial_\tau (w_h - w_h^I) \, ds \\ &\le c\, h\, |u|_{3,\Omega} \|w_h\|_h.\end{aligned}$$

Using the fact $w_h^I \in C(\overline{\Omega})$ we have

$$\sum_T \int_{\partial T} \partial_{n\tau} u \, \partial_\tau w_h^I \, ds = \sum_{\gamma \subset \Gamma} \int_\gamma \partial_{n\tau} u \, \partial_\tau w_h^I \, ds.$$

Also,

$$(f, w_h - w_h^I) \le \|f\|_{0,\Omega} \|w_h - w_h^I\|_{0,\Omega} \le c\, h^2 \|f\|_{0,\Omega} \|w_h\|_h$$

and

$$\sum_T \int_T \nabla(\Delta u) \cdot \nabla(w_h - w_h^I) \le \sum_T |u|_{3,T} |w_h - w_h^I|_{1,T} \le c\, h\, |u|_{3,\Omega} \|w_h\|_h.$$

Using the estimate (4.1), we have

$$(f, u_h - v_h) - a_h(u, u_h - v_h) \le c\,h\,(|u|_{3,\Omega} + h\,\|f\|_{0,\Omega})\,\|w_h\|_h + \langle \partial_n \Delta u, w_h^I\rangle_{1/2,\Gamma} - (1-\nu)\int_\Gamma \partial_{n\tau} u\,\partial_\tau w_h^I\,ds.$$

By (2.25), we then obtain

$$(f, u_h - v_h) - a_h(u, u_h - v_h) \le c\,h\,(|u|_{3,\Omega} + h\,\|f\|_{0,\Omega})\,\|w_h\|_h + \int_{\Gamma_3} g\,\lambda\,w_h^I\,ds.$$

Thus, for the residual term defined in (3.4), we have

$$\begin{aligned} R_h(v_h, u_h) &\le \int_{\Gamma_3} g\,(|v_h| - |u_h| + \lambda\,w_h^I)\,ds + c\,h\,(|u|_{3,\Omega} + h\,\|f\|_{0,\Omega})\,\|w_h\|_h \\ &= \int_{\Gamma_3} g\,(|v_h| - |u_h| + \lambda\,w_h)\,ds + \int_{\Gamma_3} g\,\lambda\,(w_h^I - w_h)\,ds \\ &\quad + c\,h\,(|u|_{3,\Omega} + h\,\|f\|_{0,\Omega})\,\|w_h\|_h. \end{aligned} \tag{5.2}$$

The second term on the right is bounded as follows:

$$\begin{aligned} \int_{\Gamma_3} g\,\lambda\,(w_h^I - w_h)\,ds &\le \sum_{\gamma\subset\Gamma_3}\int_\gamma g\,|w_h - w_h^I|\,ds \\ &\le \|g\|_{0,\Gamma_3}\left(\sum_{\gamma\subset\Gamma_3}\|w_h - w_h^I\|_{0,\gamma}^2\right)^{1/2} \\ &\le c\,\|g\|_{0,\Gamma_3}\left(\sum_{\partial T\cap\Gamma_3\neq\emptyset}\left[h^{-1}\|w_h - w_h^I\|_{0,T}^2 + h\,|w_h - w_h^I|_{1,T}^2\right]\right)^{1/2} \\ &\le c\,\|g\|_{0,\Gamma_3} h^{3/2}\left(\sum_{T:\partial T\cap\Gamma_3\neq\emptyset}|w_h|_{2,T}^2\right)^{1/2} \\ &\le c\,h^{3/2}\|g\|_{0,\Gamma_3}\|w_h\|_h. \end{aligned}$$

The first term $\int_{\Gamma_3} g\,(|v_h| - |u_h| + \lambda\,w_h)\,ds$ can be handled similarly as in the proof of Theorem 4.1. So, with $v_h = \Pi_h u$ in (5.2), we have the bound

$$\begin{aligned} R_h(\Pi_h u, u_h) &\le c\,(h^{3/2}\|g\|_{0,\Gamma_3} + h\,|u|_{3,\Omega} + h^2\|f\|_{0,\Omega})\,\|\Pi_h u - u_h\|_h \\ &\quad + c\,h^{5/2}\|g\|_{0,\Gamma_3}\|u\|_{3,\Omega}. \end{aligned} \tag{5.3}$$

Now, by (3.3), we have

$$\begin{aligned} \|u - u_h\|_h^2 \le c\,(&\|u - \Pi_h u\|_h^2 + (h^{3/2}\|g\|_{0,\Gamma_3} + h\,|u|_{3,\Omega} + h^2\|f\|_{0,\Omega})\,\|\Pi_h u - u_h\|_h \\ &+ h^{5/2}\|g\|_{0,\Gamma_3}\|u\|_{3,\Omega}), \end{aligned}$$

from which we can derive the error estimate (5.1) as in the proof of Theorem 4.1. □

As examples of discontinuous nonconforming finite element spaces for the plate contact problem, we mention Morley's triangle and the Fraeijs De Veubeke triangle.

Assume Ω is a polygonal domain and let $\{\mathcal{T}_h\}$ be a regular family of partitions of $\overline{\Omega}$ into triangles. For Morley's triangle, on each element, the finite element function is quadratic and is uniquely determined by the function values at the three vertices and the normal derivative at the three midside nodes. For the Fraeijs De Veubeke triangle, on each element, the finite element function is cubic and is uniquely determined by the function values at the three vertices and at the center and the normal derivative at the Gaussian points of second order on each side. From their constructions, we see that for both Morley's triangle and the Fraeijs De Veubeke triangle, the finite element functions are continuous at the vertices of the corresponding triangulation. For both elements, (4.1) and (4.2) are valid (cf. [26]).

We conclude that for both Morley's triangle and the Fraeijs De Veubeke triangle, the optimal order error estimate (5.1) holds.

Acknowledgment. We thank the two referees whose suggestions led to an improvement of this paper.

A PRIORI ERROR ESTIMATES FOR MIXED FINITE ELEMENT APPROXIMATIONS OF THE ACOUSTIC WAVE EQUATION*

ELEANOR W. JENKINS†, BÉATRICE RIVIÈRE†, AND MARY F. WHEELER†

Abstract. In this paper we derive optimal a priori $L^\infty(L^2)$ error estimates for mixed finite element displacement formulations of the acoustic wave equation. The computational complexity of this approach is equivalent to the traditional mixed finite element formulations of the second order hyperbolic equations in which the primary unknowns are pressure and the gradient of pressure. However, the displacement formulations with the physical variables of interest, displacement and pressure, requires less regularity on the displacement.

Key words. acoustic wave equation, mixed finite elements, error estimation

1. Introduction.

There is significant interest in simulating the effects of wave propagation in heterogeneous media to aid in the interpretation of field data and to predict the damage patterns due to earthquakes. Simulated waveform data (seismograms) computed for an assumed earth model are compared against the recorded data. If the match is unacceptable, the model is perturbed, and the simulation is redone and compared again. This procedure is implemented formally by global optimization techniques [19] resulting in a description of an earth model (with its associated uncertainties) that explains the observations. Thus there is a need for a fast and accurate simulation technique that can be used for real time analysis of seismograms.

In the past, wave simulation has been successfully modeled using finite difference methods [10, 13], but these solutions have been expensive to compute. The use of structured finite differences in simulating earthquake responses in the Los Angeles Basin requires 35 billion grid points [3], which emphasizes the need for unstructured meshes. The staggered grid approach described in [10] may be used to solve problems on the order of millions using a workstation, but memory optimization routines must be used and it is unclear that the method is easily parallelized.

Finite element discretization methods have the advantage of handling complex geometries and straightforward local discretization techniques using error indicators. It is also easy to incorporate free surface boundary conditions and nonmatching grids. In [13], Marfurt concludes that finite element methods may be the most cost-effective way to simulate wave fields.

Previous attempts at wave simulation using finite elements have used continuous Galerkin methods [2, 3, 9, 13, 18], discontinuous Galerkin methods [11, 17], and mixed finite element methods [7, 8]. We propose mixed finite element displacement formulations for solving the acoustic wave equation, which are described below. These approximations can be defined for general meshes.

Let Ω be a bounded domain in $\mathbb{R}^n, n = 1, 2, 3$, with boundary $\partial\Omega = \Gamma_D \cup \Gamma_N$. The general form of the wave equation is

$$\rho \boldsymbol{u}_{tt} - \nabla \cdot \tilde{\boldsymbol{\tau}} = \boldsymbol{f} \qquad \text{in } \Omega \times (0,T)\,, \tag{1.1}$$

$$\nabla \cdot \boldsymbol{u} = 0 \qquad \text{on } \Gamma_D \times (0,T)\,, \tag{1.2}$$

$$\boldsymbol{u} \cdot \boldsymbol{\nu} = 0 \qquad \text{on } \Gamma_N \times (0,T)\,, \tag{1.3}$$

$$\boldsymbol{u}\,(\cdot,0) = \boldsymbol{u}_0 \qquad \text{in } \Omega, \tag{1.4}$$

$$\boldsymbol{u}_t\,(\cdot,0) = \boldsymbol{u}_1 \qquad \text{in } \Omega, \tag{1.5}$$

where $\boldsymbol{u}$ is the displacement, ρ is the density, and $\tilde{\boldsymbol{\tau}}$ is the stress tensor given by the generalized Hooke's law $\tilde{\boldsymbol{\tau}} = \lambda(\nabla \cdot \boldsymbol{u})\tilde{\boldsymbol{I}} + \mu(\nabla \boldsymbol{u} + (\nabla \boldsymbol{u})^T)$. Here $\lambda > 0$ and μ are the Lamé coefficients characterizing the material. We let $\boldsymbol{f}$ represent a general source term, and let $\boldsymbol{u}_0$ and $\boldsymbol{u}_1$ be the initial conditions on displacements and velocities, and we assume that $\boldsymbol{f}$, $\boldsymbol{u}_0$, and $\boldsymbol{u}_1$ are smooth enough so that there is a unique solution $\boldsymbol{u} \in \mathcal{C}^2\,((0,T) \times \Omega)$ to (1.1)–(1.5) [12].

The acoustic problem is the limiting case with $\mu = 0$. In this case, (1.1) becomes

$$\rho \boldsymbol{u}_{tt} - \nabla \cdot (\lambda(\nabla \cdot \boldsymbol{u})\tilde{\boldsymbol{I}}) = \boldsymbol{f}. \tag{1.6}$$

We assume that ρ and λ are bound above and below by the positive constants ρ_0, ρ_1, λ_0, and λ_1, respectively.

A standard approach in geophysics modeling is to solve a scalar wave equation. Here, since $p = \lambda \nabla \cdot \boldsymbol{u}$, we have $p_{tt} = \lambda \nabla \cdot \boldsymbol{u}_{tt}$. We substitute this expression into (1.6) to obtain

$$p_{tt} - \lambda \nabla \cdot \frac{1}{\rho}\,(\nabla p) = \tilde{f}, \tag{1.7}$$

where $\tilde{f} = \nabla \cdot \boldsymbol{f}$.

A priori error estimates for solving (1.7) with a constant λ were obtained by Cowsar, Dupont, and Wheeler [7, 8]. We propose an alternative mixed finite elements displacement formulation that requires less regularity on the displacement solution than the approach in [7, 8]. We describe this method in section 3. We derive the error estimates for the continuous-in-time problem in section 4. For the discrete-in-time problem, stability results and error estimates are obtained in section 5. In section 6 we present conclusions.

2. Preliminaries. In this section we describe the notation used in this paper, we introduce the functional spaces, two projection operators and their approximation properties, and we recall Gronwall's inequality, which is needed in the error analysis.

2.1. Inner products and norms. The L^2 inner product over Ω is defined as

$$(u, v) = \int_\Omega uv\, d\Omega,$$

and we denote by $\|\cdot\|_{L^2}$ the L^2 norm over Ω, i.e., $\|u\|_{L^2(\Omega)} = (u,u)^{\frac{1}{2}}$. The inner product over the boundary $\partial\Omega$ is denoted

$$\langle u, v \rangle = \int_{\partial\Omega} uv\, d\Omega$$

for $u, v \in H^{\frac{1}{2}+\epsilon}(\Omega)$, with $\epsilon > 0$. The time-space norm $\|\cdot\|_{L^2(0,T;L^2(\Omega))}$ is defined as

$$\|u\|_{L^2(0,T;L^2(\Omega))} = \|u\|_{L^2(L^2)} = \left(\int_0^T \|u\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}}.$$

The time-space norm $\|\cdot\|_{L^\infty(L^2)}$ is similarly defined.

2.2. Gronwall's inequality. We recall Gronwall's inequality, which states that if $y \geq 0$ satisfies $y_t \leq ky(t) + h(t)$ for $0 \leq t \leq \tau$, where $k \geq 0$ is a constant and $h(t) \geq 0$, $h \in L^1((0,\tau))$, then

$$y(t) \leq e^{k\tau} \left[y(0) + \int_0^\tau h(s)\, ds \right]$$

for all $t \in [0,\tau]$ [14].

2.3. Functional spaces and projections. We define the standard Sobolev spaces for mixed methods:

$$\begin{aligned} \boldsymbol{H}(\Omega, \mathrm{div}) &= \{\boldsymbol{v} : \boldsymbol{v} \in (\boldsymbol{L}^2(\Omega))^n, \nabla \cdot \boldsymbol{v} \in \boldsymbol{L}^2(\Omega)\}, \\ \boldsymbol{V} &= \{\boldsymbol{v} \in \boldsymbol{H}(\Omega, \mathrm{div}) : \boldsymbol{v} \cdot \boldsymbol{\nu}|_{\Gamma_N} = 0\}, \\ W &= H^{\frac{1}{2}+\epsilon}(\Omega) \text{ for any } \epsilon > 0. \end{aligned}$$

Let $\{\mathcal{E}_h\}_{h>0}$ be a quasi-uniform family of finite element partitions of Ω, where h is the maximal element diameter. Let $\boldsymbol{V}_h \times W_h$ be any of the usual mixed finite element approximating subspaces of $\boldsymbol{V} \times W$, that is, the Raviart–Thomas–Nedelec spaces [15, 16], Brezzi–Douglas–Marini spaces [5], or Brezzi–Douglas–Fortin–Marini spaces [4].

Each of these mixed spaces has a projection operator $\Pi_h : \boldsymbol{H}(\Omega, \mathrm{div}) \to \boldsymbol{V}_h$ such that for any $\boldsymbol{z} \in \boldsymbol{H}(\Omega, \mathrm{div})$

$$(\nabla \cdot \Pi_h \boldsymbol{z}, w) = (\nabla \cdot \boldsymbol{z}, w) \quad \forall w \in W_h. \tag{2.1}$$

In addition, if $\boldsymbol{z} \in \boldsymbol{H}(\Omega, \mathrm{div}) \cap \boldsymbol{H}^k(\Omega)$, we also have

$$\|\Pi_h \boldsymbol{z} - \boldsymbol{z}\|_0 \leq Ch^j \|\boldsymbol{z}\|_j, \quad 1 \leq j \leq k, \tag{2.2}$$

where k is associated with the degree of the polynomial, and $\|\cdot\|_s$ is the standard Sobolev norm on $(\boldsymbol{H}^s(\Omega))^n$ [1].

Let $\mathcal{P}_h$ be the L^2 projection of W onto W_h such that

$$(\mathcal{P}_h \phi, w) = (\phi, w) \quad \forall \phi \in W, \quad \forall w \in W_h. \tag{2.3}$$

In addition, if $\phi \in W \cap H^k(\Omega)$, then we also have

$$\|\mathcal{P}_h \phi - \phi\|_s \leq Ch^{j-s} \|\phi\|_j, \quad 0 \leq s \leq k, \quad 0 \leq j \leq k. \tag{2.4}$$

3. Model problem and scheme. We observe that $\nabla \cdot (\lambda(\nabla \cdot \boldsymbol{u})\tilde{\boldsymbol{I}}) = \nabla(\lambda \nabla \cdot \boldsymbol{u})$ so that (1.6) may be rewritten as

$$\rho \boldsymbol{u}_{tt} - \nabla(\lambda \nabla \cdot \boldsymbol{u}) = f. \tag{3.1}$$

By introducing $p = \lambda \nabla \cdot \boldsymbol{u}$, we present (3.1) in a mixed finite element form:

$$\rho \boldsymbol{u}_{tt} - \nabla p = \boldsymbol{f} \quad \text{in } \Omega \times (0,T)\,, \tag{3.2}$$

$$\lambda^{-1} p = \nabla \cdot \boldsymbol{u} \quad \text{in } \Omega \times (0,T)\,. \tag{3.3}$$

A similar approach for the linear elasticity problem has been presented by Brezzi and Fortin in [6].

Let $\boldsymbol{v} \in \boldsymbol{V}$ and $w \in W$. If we multiply (3.2) and (3.3) by $\boldsymbol{v}$ and w, respectively, and integrate over Ω we get the weak formulation

$$(\rho \boldsymbol{u}_{tt}, \boldsymbol{v}) - (\nabla p, \boldsymbol{v}) = (\boldsymbol{f}(t), \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \tag{3.4}$$

$$\left(\lambda^{-1} p, w\right) - (\nabla \cdot \boldsymbol{u}, w) = 0 \quad \forall\, w \in W. \tag{3.5}$$

Clearly, if $\boldsymbol{u}$, p satisfy (3.2) and (3.3), then $\boldsymbol{u}$, p satisfy (3.4) and (3.5).

If we integrate by parts in (3.4) we get, for any $\boldsymbol{v} \in \boldsymbol{V}$,

$$(\nabla p, \boldsymbol{v}) = \langle p, \boldsymbol{v} \cdot \nu \rangle - (p, \nabla \cdot \boldsymbol{v}) = -\,(p, \nabla \cdot \boldsymbol{v})\,,$$

and the weak formulation becomes the following:

For any $t \geq 0$, find $(\boldsymbol{u}(t), p(t)) \in \boldsymbol{V} \times W$ such that

$$(\boldsymbol{u}(0), \boldsymbol{v}) = (\boldsymbol{u}_0, \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \tag{3.6}$$

$$(\boldsymbol{u}_t(0), \boldsymbol{v}) = (\boldsymbol{u}_1, \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \tag{3.7}$$

$$\left(\lambda^{-1} p(0), w\right) = (\nabla \cdot \boldsymbol{u}_0, w) \quad \forall\, w \in W, \tag{3.8}$$

$$(\rho \boldsymbol{u}_{tt}(t), \boldsymbol{v}) + (p(t), \nabla \cdot \boldsymbol{v}) = (\boldsymbol{f}(t), \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \quad \forall\, t > 0, \tag{3.9}$$

$$\left(\lambda^{-1} p(t), w\right) - (\nabla \cdot \boldsymbol{u}(t), w) = 0 \quad \forall\, w \in W, \quad \forall\, t > 0. \tag{3.10}$$

Note that in [7, 8] it is necessary that $\nabla p \in \boldsymbol{H}(\Omega, \mathrm{div})$ so that $\nabla \cdot \boldsymbol{u} \in H^2(\Omega)$. Here, we require only that $\nabla \cdot \boldsymbol{u} \in H^{\frac{1}{2}}(\Omega)$. It is clear that the solution $\boldsymbol{u} \in \mathcal{C}^2((0,T) \times \Omega)$ of problem (1.1)–(1.5) with $p = \lambda \nabla \cdot \boldsymbol{u}$ is a solution to (3.6)–(3.10). The uniqueness is provided by the following lemma.

LEMMA 3.1. *Let* $(\boldsymbol{u}_a, p_a)$ *and* $(\boldsymbol{u}_b, p_b)$ *be two solutions of* (3.6)–(3.10). *Then* $\boldsymbol{u}_a = \boldsymbol{u}_b$ *and* $p_a = p_b$.

Proof. Let $\boldsymbol{\chi} = \boldsymbol{u}_a - \boldsymbol{u}_b$ and $\psi = p_a - p_b$. Then by subtracting the equations satisfied by these solutions we have

$$(\boldsymbol{\chi}(0), \boldsymbol{v}) = 0 \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \tag{3.11}$$

$$(\boldsymbol{\chi}_t(0), \boldsymbol{v}) = 0 \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \tag{3.12}$$

$$\left(\lambda^{-1} \psi(0), w\right) = 0 \quad \forall\, w \in W, \tag{3.13}$$

$$(\rho \boldsymbol{\chi}_{tt}(t), \boldsymbol{v}) + (\psi(t), \nabla \cdot \boldsymbol{v}) = 0 \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}, \quad \forall\, t > 0, \tag{3.14}$$

$$\left(\lambda^{-1} \psi(t), w\right) - (\nabla \cdot \boldsymbol{\chi}(t), w) = 0 \quad \forall\, w \in W, \quad \forall\, t > 0. \tag{3.15}$$

We differentiate (3.15) with respect to time:

$$\left(\lambda^{-1} \psi_t, w\right) - (\nabla \cdot \boldsymbol{\chi}_t, w) = 0 \quad \forall w \in W, \quad \forall t > 0. \tag{3.16}$$

We choose $\boldsymbol{v} = \boldsymbol{\chi}_t$ and $w = p$. Thus (3.14) and (3.16) become

$$(\rho \boldsymbol{\chi}_{tt}, \boldsymbol{\chi}_t) + (\psi, \nabla \cdot \boldsymbol{\chi}_t) = 0, \tag{3.17}$$

$$\left(\lambda^{-1} \psi_t, \psi\right) - (\nabla \cdot \boldsymbol{\chi}_t, \psi) = 0. \tag{3.18}$$

We add (3.17) and (3.16) so that

$$(\rho \boldsymbol{\chi}_{tt}, \boldsymbol{\chi}_t) + \left(\lambda^{-1}\psi_t, \psi\right) = 0 \tag{3.19}$$

and thus

$$\frac{1}{2}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\psi\right\|^2_{L^2(\Omega)} = 0. \tag{3.20}$$

We integrate (3.20) with respect to time to obtain

$$\frac{1}{2}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\left\|\lambda^{-\frac{1}{2}}\psi\right\|^2_{L^2(\Omega)} = C_1, \tag{3.21}$$

where C_1 is a constant independent of time. As (3.21) holds for any t, it holds in particular for $t = 0$. We have from the initial data that $\|\boldsymbol{\chi}_t(0)\|^2_{L^2(\Omega)} = \|\psi(0)\|^2_{L^2(\Omega)} = 0$, so $C_1 = 0$. Hence

$$\frac{1}{2}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\left\|\lambda^{-\frac{1}{2}}\psi\right\|^2_{L^2(\Omega)} = 0 \tag{3.22}$$

and therefore

$$\frac{1}{2}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} = \frac{1}{2}\left\|\lambda^{-\frac{1}{2}}\psi\right\|^2_{L^2(\Omega)} = 0. \tag{3.23}$$

However, we assume that both λ and ρ are bounded above and below away from 0. Hence we must have that

$$\boldsymbol{\chi}_t = \psi = 0.$$

Now we consider $\boldsymbol{\chi}_t = 0$. We integrate with respect to time and obtain

$$\boldsymbol{\chi} = C_2,$$

where C_2 is a constant independent of time. This holds for any t; in particular, it holds for $t = 0$. Again, we use the initial conditions and see that $\boldsymbol{\chi}(0) = 0$, and hence $C_2 = 0$. Thus $\boldsymbol{\chi} = 0$, which concludes the proof. ∎

The mixed finite element approximation to $(\boldsymbol{u}(t), p(t))$ for any $t \geq 0$ is given by the functions $(\boldsymbol{U}(t), P(t)) \in \boldsymbol{V}_h \times W_h$ satisfying

$$(\boldsymbol{U}(0), \boldsymbol{v}) = (\Pi_h \boldsymbol{u}_0, \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h, \tag{3.24}$$

$$(\boldsymbol{U}_t(0), \boldsymbol{v}) = (\Pi_h \boldsymbol{u}_1, \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h, \tag{3.25}$$

$$(P(0), w) = (p(0), w) \quad \forall\, w \in W_h, \tag{3.26}$$

$$(\rho \boldsymbol{U}_{tt}(t), \boldsymbol{v}) + (P(t), \nabla \cdot \boldsymbol{v}) = (\boldsymbol{f}(t), \boldsymbol{v}) \quad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h, \quad \forall\, t > 0, \tag{3.27}$$

$$\left(\lambda^{-1} P(t), w\right) - (\nabla \cdot \boldsymbol{U}(t), w) = 0 \quad \forall\, w \in W_h, \quad \forall\, t > 0. \tag{3.28}$$

The existence and uniqueness of a solution $(\boldsymbol{U}(t), P(t))$ to (3.24)–(3.28) is shown in the following lemma.

LEMMA 3.2. *A solution* $(\boldsymbol{U}(t), P(t))$ *to* (3.24)–(3.28) *exists and is unique.*

Proof. Because we are operating in a finite dimensional space, it suffices to show uniqueness. Uniqueness follows directly from the proof of the previous lemma. ∎

4. Continuous in time a priori error estimates. In this section, we prove the convergence of the scheme (3.24)–(3.28) in the $L^\infty(L^2)$ norm. We first derive an estimate for the error in the pressure and the velocity, then for the error in the displacement.

THEOREM 4.1. *For $t \geq 0$, let $(\boldsymbol{u}(t), p(t))$ be the solution of the problem (3.6)–(3.10). Assume that $\boldsymbol{u}_t \in L^\infty\left(\boldsymbol{L}^2(\Omega)\right)$, $\boldsymbol{u}_{tt} \in L^2(\boldsymbol{H}^k(\Omega))$, $p \in L^\infty\left(L^2(\Omega)\right)$, and $p_t \in L^2\left(H^k(\Omega)\right)$. Then there exists a constant C independent of h such that*

$$\left\|\rho^{\frac{1}{2}}(\boldsymbol{u}_t - \boldsymbol{U}_t)\right\|_{L^\infty(L^2)} + \left\|\lambda^{-\frac{1}{2}}(p - P)\right\|_{L^\infty(L^2)} \leq Ch^k\left(\|\boldsymbol{u}_{tt}\|_{L^2(H^k)} + \|p_t\|_{L^2(H^k)}\right), \tag{4.1}$$

where k is associated with the degree of the finite element polynomial.

Proof. For simplification, we denote $\boldsymbol{\chi} = \boldsymbol{U} - \Pi_h\boldsymbol{u}$, $\xi = P - \mathcal{P}_h p$, $\boldsymbol{\eta} = \boldsymbol{u} - \Pi_h\boldsymbol{u}$, and $\zeta = p - \mathcal{P}_h p$, where Π_h and $\mathcal{P}_h$ have been defined in section 2.3. These definitions hold throughout the paper. If we subtract $\Pi_h\boldsymbol{u}$ and $\mathcal{P}_h p$ from (3.9), (3.10), (3.27), and (3.28) we obtain

$$(\rho\boldsymbol{\chi}_{tt}, \boldsymbol{v}) + (\xi, \nabla\cdot\boldsymbol{v}) = (\rho\boldsymbol{\eta}_{tt}, \boldsymbol{v}) + (\zeta, \nabla\cdot\boldsymbol{v}) \qquad \forall \boldsymbol{v} \in \boldsymbol{V}_h, \tag{4.2}$$

$$\left(\lambda^{-1}\xi, w\right) - (\nabla\cdot\boldsymbol{\chi}, w) = \left(\lambda^{-1}\zeta, w\right) - (\nabla\cdot\boldsymbol{\eta}, w) \quad \forall w \in W_h. \tag{4.3}$$

Since $\boldsymbol{\chi} \in \boldsymbol{V}_h$, we can set $\boldsymbol{v} = \boldsymbol{\chi}_t$ in (4.2):

$$(\rho\boldsymbol{\chi}_{tt}, \boldsymbol{\chi}_t) + (\xi, \nabla\cdot\boldsymbol{\chi}_t) = (\rho\boldsymbol{\eta}_{tt}, \boldsymbol{\chi}_t) + (\zeta, \nabla\cdot\boldsymbol{\chi}_t). \tag{4.4}$$

We then differentiate (4.3) with respect to time to obtain

$$\left(\lambda^{-1}\xi_t, w\right) - (\nabla\cdot\boldsymbol{\chi}_t, w) = \left(\lambda^{-1}\zeta_t, w\right) - (\nabla\cdot\boldsymbol{\eta}_t, w) \quad \forall w \in W_h. \tag{4.5}$$

As $\xi \in W_h$, we can set $w = \xi$ in (4.5), which gives

$$\left(\lambda^{-1}\xi_t, \xi\right) - (\nabla\cdot\boldsymbol{\chi}_t, \xi) = \left(\lambda^{-1}\zeta_t, \xi\right) - (\nabla\cdot\boldsymbol{\eta}_t, \xi). \tag{4.6}$$

Adding (4.4) and (4.6) gives

$$\frac{1}{2}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)} = (\rho\boldsymbol{\eta}_{tt}, \boldsymbol{\chi}_t) + (\zeta, \nabla\cdot\boldsymbol{\chi}_t) + \left(\lambda^{-1}\zeta_t, \xi\right) - (\nabla\cdot\boldsymbol{\eta}_t, \xi). \tag{4.7}$$

If we use the definitions (2.1) and (2.3) of the Π_h and $\mathcal{P}_h$ projections, we obtain

$$\frac{1}{2}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)} = (\rho\boldsymbol{\eta}_{tt}, \boldsymbol{\chi}_t) + \left(\lambda^{-1}\zeta_t, \xi\right). \tag{4.8}$$

We use the Cauchy–Schwarz inequality to bound the right-hand side of (4.8) so that

$$\frac{1}{2}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{1}{2}\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)} \leq \left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|_{L^2(\Omega)}\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_{tt}\right\|_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\zeta_t\right\|_{L^2(\Omega)}\left\|\lambda^{-\frac{1}{2}}\xi\right\|_{L^2(\Omega)},$$

and use the fact that $2ab \le a^2 + b^2$ to get

$$\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)} \le \left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)} + \left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_{tt}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\zeta_t\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)}.$$

Now we can apply Gronwall's inequality and

$$\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^2(\Omega)}(t) + \left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^2(\Omega)}(t) \le \left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t(0)\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\xi(0)\right\|_{L^2(\Omega)} + \int_0^t \left(\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_{tt}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\zeta_t\right\|^2_{L^2(\Omega)}\right).$$

If we take the supremum over all t and use the initial conditions we obtain

$$\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}_t\right\|^2_{L^\infty(L^2)} + \left\|\lambda^{-\frac{1}{2}}\xi\right\|^2_{L^\infty(L^2)} \le \left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_{tt}\right\|^2_{L^2(L^2)} + \left\|\lambda^{-\frac{1}{2}}\zeta_t\right\|^2_{L^2(L^2)}.$$

We complete the proof by using the approximation properties (2.2) and (2.4) of the projections. ∎

We now derive an estimate of the error in the displacement in the $L^\infty(L^2)$ norm.

THEOREM 4.2. *For $t \ge 0$, let $(\boldsymbol{u}(t), p(t))$ be the solution of problem (3.6)–(3.10). Assume that $\boldsymbol{u} \in L^\infty\left(L^2(\Omega)\right)$, $\boldsymbol{u}_t \in L^2(\boldsymbol{H}^k(\Omega))$, $\boldsymbol{u}_t(0) \in \boldsymbol{H}^k(\Omega)$, and $p \in L^2\left(H^k(\Omega)\right)$. Then there exists a constant C independent of h such that*

$$\left\|\rho^{\frac{1}{2}}(\boldsymbol{u} - \boldsymbol{U})\right\|_{L^\infty(L^2)} \le Ch^k\left(\|\boldsymbol{u}_t\|_{L^2(H^k)} + \|\boldsymbol{u}_t(0)\|_{H^k} + \|p\|_{L^2(H^k)}\right), \tag{4.9}$$

where k is associated with the degree of the finite element polynomial.

Proof. We first obtain the same equations (4.2) and (4.3) that arrive after taking into account the definition of the Π_h and the $\mathcal{P}_h$ projections

$$(\rho\boldsymbol{\chi}_{tt}, \boldsymbol{v}) + (\xi, \nabla\cdot\boldsymbol{v}) = (\rho\boldsymbol{\eta}_{tt}, \boldsymbol{v}) \quad \forall \boldsymbol{v} \in \boldsymbol{V}_h, \tag{4.10}$$

$$\left(\lambda^{-1}\xi, w\right) - (\nabla\cdot\boldsymbol{\chi}, w) = (\lambda^{-1}\zeta, w) \quad \forall w \in W_h. \tag{4.11}$$

If we integrate (4.10) from 0 to t, noting that $\boldsymbol{\chi}_t(0) = 0$, we obtain

$$(\rho\boldsymbol{\chi}_t, \boldsymbol{v}) + \left(\int_0^t \xi, \nabla\cdot\boldsymbol{v}\right) = (\rho\boldsymbol{\eta}_t, \boldsymbol{v}) - (\rho\boldsymbol{\eta}_t(0), \boldsymbol{v}). \tag{4.12}$$

We set $\boldsymbol{v} = \boldsymbol{\chi}$, $\phi = \int_0^t \xi(s)\,ds$, and $w = \phi$. Then (4.12) and (4.11) become

$$(\rho\boldsymbol{\chi}_t, \boldsymbol{\chi}) + (\phi, \nabla\cdot\boldsymbol{\chi}) = (\rho\boldsymbol{\eta}_t, \boldsymbol{\chi}) - (\rho\boldsymbol{\eta}_t(0), \boldsymbol{\chi}), \tag{4.13}$$

$$\left(\lambda^{-1}\xi, \phi\right) - (\nabla\cdot\boldsymbol{\chi}, \phi) = (\lambda^{-1}\zeta, \phi). \tag{4.14}$$

Adding (4.13) and (4.14) gives

$$(\rho\boldsymbol{\chi}_t, \boldsymbol{\chi}) + \left(\lambda^{-1}\xi, \phi\right) = (\rho\boldsymbol{\eta}_t, \boldsymbol{\chi}) - (\rho\boldsymbol{\eta}_t(0), \boldsymbol{\chi}) + (\lambda^{-1}\zeta, \phi).$$

Therefore

$$(\rho\boldsymbol{\chi}_t, \boldsymbol{\chi}) + \left(\lambda^{-1}\phi_t, \phi\right) = (\rho\boldsymbol{\eta}_t, \boldsymbol{\chi}) - (\rho\boldsymbol{\eta}_t(0), \boldsymbol{\chi}) + (\lambda^{-1}\zeta, \phi)$$

so that

$$\frac{1}{2}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}+\frac{1}{2}\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}=(\rho\boldsymbol{\eta}_t,\boldsymbol{\chi})-(\rho\boldsymbol{\eta}_t(0),\boldsymbol{\chi})+(\lambda^{-1}\zeta,\phi).$$

Multiplying through by 2 and using the Cauchy–Schwarz inequality gives

$$\begin{aligned}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}+\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}&\le 2\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|_{L^2(\Omega)}\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t\right\|_{L^2(\Omega)}\\&\quad+2\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|_{L^2(\Omega)}\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t(0)\right\|_{L^2(\Omega)}+2\left\|\lambda^{-\frac{1}{2}}\zeta\right\|_{L^2(\Omega)}\left\|\lambda^{-\frac{1}{2}}\phi\right\|_{L^2(\Omega)}.\end{aligned}$$

Hence

$$\begin{aligned}\frac{d}{dt}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}+\frac{d}{dt}\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}&\le 2\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t\right\|^2_{L^2(\Omega)}\\&\quad+\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t(0)\right\|^2_{L^2(\Omega)}+\left\|\lambda^{-\frac{1}{2}}\zeta\right\|^2_{L^2(\Omega)}+\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}.\end{aligned}\tag{4.15}$$

We apply Gronwall's inequality to (4.15) and note that $\phi(0)=0$ and $\boldsymbol{\chi}(0)=0$ from (3.24). Then

$$\begin{aligned}&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}(t)+\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}(t)\\&\qquad\le\int_0^t\left(\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_s\right\|^2_{L^2(\Omega)}+\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_s(0)\right\|^2_{L^2(\Omega)}+\left\|\lambda^{-\frac{1}{2}}\zeta\right\|^2_{L^2(\Omega)}\right)ds\end{aligned}$$

and thus

$$\begin{aligned}&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^2(\Omega)}(t)+\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{L^2(\Omega)}(t)\\&\qquad\le Ct\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t(0)\right\|^2_{L^2(\Omega)}+C\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t\right\|^2_{L^2(L^2)}+C\left\|\lambda^{-\frac{1}{2}}\zeta\right\|^2_{L^2(L^2)}.\end{aligned}$$

We take the supremum over all t to get

$$\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{L^\infty(L^2)}\le C\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t\right\|^2_{L^2(L^2)}+C\left\|\rho^{\frac{1}{2}}\boldsymbol{\eta}_t(0)\right\|^2_{L^2(\Omega)}+C\left\|\lambda^{-\frac{1}{2}}\zeta\right\|^2_{L^2(L^2)}.$$

The final result is obtained by using the approximation properties (2.2) and (2.4). ∎

5. Explicit method. In this section, we define further notation, we formulate the fully discrete mixed finite element scheme, and we analyze the stability and the convergence of the discrete method.

5.1. Notation and scheme. Let $\Delta t>0$ be the time step size and define $t_i=i\Delta t$ with $t_N=T$. For any function ϕ of time, let ϕ^n denote $\phi(t_n)$. We denote $\phi^{n+\frac{1}{2}}=(\phi^n+\phi^{n+1})/2$, and we define the following terms for the discrete temporal derivatives:

$$\partial_t\phi^n=\frac{\phi^{n+1}-\phi^{n-1}}{2\Delta t},\quad \partial_t\phi^{n+\frac{1}{2}}=\frac{\phi^{n+1}-\phi^n}{\Delta t},\quad \partial_t^2\phi^n=\frac{\phi^{n+1}-2\phi^n+\phi^{n-1}}{\Delta t^2}.$$

We easily see that we have

$$\partial_t^2 \phi^n = \frac{\partial_t \phi^{n+\frac{1}{2}} - \partial_t \phi^{n-\frac{1}{2}}}{\Delta t} \quad \text{and} \quad \partial_t \phi^n = \frac{\partial_t \phi^{n+\frac{1}{2}} + \partial_t \phi^{n-\frac{1}{2}}}{2}. \tag{5.1}$$

The fully discrete mixed finite element scheme is as follows: find $\left(\boldsymbol{U}^{n+1}, P^{n+1}\right)$ in $V_h \times W_h$ such that

$$\left(\boldsymbol{U}^0, \boldsymbol{v}\right) = \left(\Pi_h \boldsymbol{u}_0, \boldsymbol{v}\right) \qquad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h \tag{5.2}$$

$$\left(P^0, w\right) = \left(p^0, w\right) \qquad \forall\, w \in W_h \tag{5.3}$$

$$\left(\rho \frac{2}{\Delta t} \partial_t \boldsymbol{U}^{\frac{1}{2}}, \boldsymbol{v}\right) + \left(P^0, \nabla \cdot \boldsymbol{v}\right) = \left(\boldsymbol{f}^0 + \rho \frac{2}{\Delta t} \Pi_h \boldsymbol{u}_1, \boldsymbol{v}\right) \qquad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h, \tag{5.4}$$

$$\left(\rho \partial_t^2 \boldsymbol{U}^n, \boldsymbol{v}\right) + \left(P^n, \nabla \cdot \boldsymbol{v}\right) = \left(\boldsymbol{f}^n, \boldsymbol{v}\right) \qquad \forall\, \boldsymbol{v} \in \boldsymbol{V}_h, \tag{5.5}$$

$$\left(\lambda^{-1} P^{n+1}, w\right) - \left(\nabla \cdot \boldsymbol{U}^{n+1}, w\right) = 0 \qquad \forall\, w \in W_h. \tag{5.6}$$

5.2. Stability condition for the discrete problem. We show that the scheme is stable for the Dirichlet (homogeneous) problem, and in particular show that the temporal iterates are bound by the initial data. We consider (5.5) and (5.6) for the homogeneous case,

$$\left(\rho \partial_t^2 \boldsymbol{U}^n, \boldsymbol{v}\right) + \left(P^n, \nabla \cdot \boldsymbol{v}\right) = 0 \qquad \forall \boldsymbol{v} \in \boldsymbol{V}_h, \tag{5.7}$$

$$\left(\lambda^{-1} P^{n+1}, w\right) - \left(\nabla \cdot \boldsymbol{U}^{n+1}, w\right) = 0 \qquad \forall w \in W_h. \tag{5.8}$$

As in [7], we use the "inverse assumption," which states that there exists a constant C_0, independent of h, such that

$$\|\nabla \cdot \phi\|_{L^2(\Omega)} \leq C_0 h^{-1} \|\phi\|_{L^2(\Omega)} \tag{5.9}$$

for $\phi \in W_h$.

THEOREM 5.1. *The explicit scheme defined by* (5.2)–(5.6) *is stable if* $\Delta t < \frac{2h\rho_0^{\frac{1}{2}}}{C_0 \lambda_1^{\frac{1}{2}}}$. *That is,*

$$\left(1 - \frac{\Delta t^2 C_0^2 \lambda_1}{4h^2 \rho_0}\right) \left\|\partial_t \boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2 + \left\|P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2 \tag{5.10}$$

is bound by initial data.

Proof. If we subtract (5.8) from itself, with $n+1$ replaced by $n-1$, we get

$$\left(\lambda^{-1}\left(P^{n+1} - P^{n-1}\right), w\right) - \left(\nabla \cdot \left(\boldsymbol{U}^{n+1} - \boldsymbol{U}^{n-1}\right), w\right) = 0, \quad w \in W_h. \tag{5.11}$$

As (5.7) holds for all $\boldsymbol{v} \in \boldsymbol{V}_h$ and (5.11) holds for all $w \in W_h$, we set $\boldsymbol{v} = \partial_t \boldsymbol{U}^n$ and $w = \frac{P^n}{2\Delta t}$. This gives

$$\left(\rho \partial_t^2 \boldsymbol{U}^n, \partial_t \boldsymbol{U}^n\right) + \left(P^n, \nabla \cdot \partial_t \boldsymbol{U}^n\right) = 0, \tag{5.12}$$

$$\left(\lambda^{-1}\left(P^{n+1} - P^{n-1}\right), \frac{P^n}{2\Delta t}\right) - \left(\nabla \cdot \left(\boldsymbol{U}^{n+1} - \boldsymbol{U}^{n-1}\right), \frac{P^n}{2\Delta t}\right) = 0. \tag{5.13}$$

If we add (5.12) and (5.13), we obtain

$$\left(\rho \partial_t^2 \boldsymbol{U}^n, \frac{\boldsymbol{U}^{n+1} - \boldsymbol{U}^{n-1}}{2\Delta t}\right) + \left(\lambda^{-1}\left(P^{n+1} - P^{n-1}\right), \frac{P^n}{2\Delta t}\right) = 0. \tag{5.14}$$

Substituting (5.1) into (5.14) above yields

$$\begin{aligned}(5.15)\quad &\frac{1}{2\Delta t}\left(\rho\left(\partial_t \boldsymbol{U}^{n+\frac{1}{2}}-\partial_t \boldsymbol{U}^{n-\frac{1}{2}}\right),\partial_t \boldsymbol{U}^{n+\frac{1}{2}}+\partial_t \boldsymbol{U}^{n-\frac{1}{2}}\right)+\left(\lambda^{-1}\partial_t P^n,P^n\right)\\ &=\frac{1}{2\Delta t}\left(\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\right)+\left(\lambda^{-1}\partial_t P^n,P^n\right)=0.\end{aligned}$$

We now examine $(\partial_t P^n, P^n)$. We have

$$(5.16)\qquad \partial_t P^n=\frac{P^{n+1}+P^n-P^n-P^{n-1}}{2\Delta t}=\frac{\left(P^{n+\frac{1}{2}}-P^{n-\frac{1}{2}}\right)}{\Delta t}.$$

We can rewrite P^n as

$$\begin{aligned}P^n&=\frac{P^n+P^{n+1}}{4}+\frac{P^{n-1}+P^n}{4}-\frac{\Delta t^2}{4}\left(\frac{P^{n+1}-2P^n+P^{n-1}}{\Delta t^2}\right)\\ &=\frac{P^n+P^{n+1}}{4}+\frac{P^{n-1}+P^n}{4}-\frac{\Delta t^2}{4}\partial_t^2 P^n\\ (5.17)\qquad &=\frac{P^{n+\frac{1}{2}}}{2}+\frac{P^{n-\frac{1}{2}}}{2}-\frac{\Delta t^2}{4}\partial_t^2 P^n.\end{aligned}$$

If we use (5.16) and (5.17) in $(\partial_t P^n, P^n)$, we have

$$\begin{aligned}\left(\lambda^{-1}\partial_t P^n,P^n\right)&=\frac{1}{2\Delta t}\left(\lambda^{-1}\left(P^{n+\frac{1}{2}}-P^{n-\frac{1}{2}}\right),P^{n+\frac{1}{2}}+P^{n-\frac{1}{2}}\right)\\ &\quad-\left(\lambda^{-1}\partial_t P^n,\frac{\Delta t^2}{4}\partial_t^2 P^n\right)\\ &=\frac{1}{2\Delta t}\left(\lambda^{-1}\left(P^{n+\frac{1}{2}}-P^{n-\frac{1}{2}}\right),P^{n+\frac{1}{2}}+P^{n-\frac{1}{2}}\right)\\ &\quad-\left(\frac{\lambda^{-1}}{2}\left(\partial_t P^{n+\frac{1}{2}}+\partial_t P^{n-\frac{1}{2}}\right),\frac{\Delta t^2}{4}\frac{\left(\partial_t P^{n+\frac{1}{2}}-\partial_t P^{n-\frac{1}{2}}\right)}{\Delta t}\right)\\ &=\frac{1}{2\Delta t}\left[\left\|\lambda^{-\frac{1}{2}}P^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\lambda^{-\frac{1}{2}}P^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\right.\\ &\qquad\left.-\frac{\Delta t^2}{4}\left(\left\|\lambda^{-\frac{1}{2}}\partial_t P^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\lambda^{-\frac{1}{2}}\partial_t P^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\right)\right].\end{aligned}$$

Thus (5.15) becomes

$$\begin{aligned}(5.18)\quad &\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\\ &\qquad+\left\|\lambda^{-\frac{1}{2}}P^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\lambda^{-\frac{1}{2}}P^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\\ &\qquad-\frac{\Delta t^2}{4}\left(\left\|\lambda^{-\frac{1}{2}}\partial_t P^{n+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\left\|\lambda^{-\frac{1}{2}}\partial_t P^{n-\frac{1}{2}}\right\|^2_{L^2(\Omega)}\right)=0.\end{aligned}$$

If we sum (5.18) from $n=1,\ldots,N$, we get

$$\begin{aligned}&\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{N+\frac{1}{2}}\right\|^2_{L^2(\Omega)}+\left\|\lambda^{-\frac{1}{2}}P^{N+\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\frac{\Delta t^2}{4}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}}\right\|^2_{L^2(\Omega)}\\ &\qquad=\left\|\rho^{\frac{1}{2}}\partial_t \boldsymbol{U}^{\frac{1}{2}}\right\|^2_{L^2(\Omega)}+\left\|\lambda^{-\frac{1}{2}}P^{\frac{1}{2}}\right\|^2_{L^2(\Omega)}-\frac{\Delta t^2}{4}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{\frac{1}{2}}\right\|^2_{L^2(\Omega)}.\end{aligned}$$

We recall from (5.11) that

$$\left(\lambda^{-1}\left(P^{n+1}-P^{n}\right),w\right)-\left(\nabla\cdot\left(\boldsymbol{U}^{n+1}-\boldsymbol{U}^{n}\right),w\right)=0.$$

Then, by the Cauchy–Schwarz inequality and (5.9),

$$\begin{aligned}\left(\lambda^{-\frac{1}{2}}\left(P^{N+1}-P^{N}\right),w\right)&=\left(\nabla\cdot\left(\boldsymbol{U}^{N+1}-\boldsymbol{U}^{N}\right),w\right)\\&\leq\left\|\nabla\cdot\left(\boldsymbol{U}^{N+1}-\boldsymbol{U}^{N}\right)\right\|_{L^2(\Omega)}\|w\|_{L^2(\Omega)}\\&\leq\frac{C_0}{h}\left\|\boldsymbol{U}^{N+1}-\boldsymbol{U}^{N}\right\|_{L^2(\Omega)}\|w\|_{L^2(\Omega)}\\&\leq\frac{C_0}{h}\left(\Delta t\right)\left\|\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\|w\|_{L^2(\Omega)}.\end{aligned}$$

Thus

$$\left(\Delta t\right)\left(\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}},w\right)\leq\frac{C_0}{h}\left(\Delta t\right)\left\|\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\|w\|_{L^2(\Omega)}.$$

We choose $w=\partial_t P^{N+\frac{1}{2}}$, so

$$\begin{aligned}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2&\leq\frac{C_0}{h}\left\|\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\left\|\partial_t P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\\&\leq\frac{C_0\lambda_1^{\frac{1}{2}}}{h\rho_0^{\frac{1}{2}}}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\end{aligned}$$

or

$$\left\|\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}\leq\frac{C_0\lambda_1^{\frac{1}{2}}}{h\rho_0^{\frac{1}{2}}}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}.$$

Hence

$$\begin{aligned}&\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{\frac{1}{2}}\right\|_{L^2(\Omega)}^2+\left\|\lambda^{-\frac{1}{2}}P^{\frac{1}{2}}\right\|_{L^2(\Omega)}^2-\frac{\Delta t^2}{4}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\quad=\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2+\left\|\lambda^{-\frac{1}{2}}P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\qquad-\frac{\Delta t^2}{4}\left\|\lambda^{-\frac{1}{2}}\partial_t P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\quad\geq\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2+\left\|\lambda^{-\frac{1}{2}}P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\qquad-\frac{\Delta t^2C_0^2\lambda_1}{4h^2\rho_0}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\quad=\left(1-\frac{\Delta t^2C_0^2\lambda_1}{4h^2\rho_0}\right)\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{U}^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2\\&\qquad+\left\|\lambda^{-\frac{1}{2}}P^{N+\frac{1}{2}}\right\|_{L^2(\Omega)}^2.\end{aligned}$$

Thus the temporal iterates are bound by the initial data and the discrete in time scheme is stable if $\Delta t<\frac{2h\rho_0^{\frac{1}{2}}}{\lambda_1^{\frac{1}{2}}C_0}$. ∎

5.3. Discrete in time a priori error estimates. We now can derive the estimates for the fully discrete scheme.

THEOREM 5.2. *If* $\boldsymbol{u} \in L^\infty(\boldsymbol{H}(\Omega;\mathrm{div}))$, $\frac{\partial^3 \boldsymbol{u}}{\partial t^3} \in L^1\left(\boldsymbol{L}^2(\Omega)\right)$ $\frac{\partial^4 \boldsymbol{u}}{\partial t^4} \in L^\infty\left(\boldsymbol{L}^2(\Omega)\right)$, *and* $p \in L^\infty(L^2(\Omega))$, *then for* $\{\boldsymbol{U}^n, P^n\}$ *defined by* (5.3)–(5.6) *there exists a constant* C *independent of* h *and* Δt *such that if* $\Delta t < \frac{2h\rho_0^{\frac{1}{2}}}{\lambda_1^{\frac{1}{2}} C_0}$, *then*

$$\begin{aligned}(5.19)\quad &\left\|\rho^{\frac{1}{2}}(\boldsymbol{u}-\boldsymbol{U})\right\|_{l^\infty(L^2)} + \left\|\lambda^{\frac{1}{2}}(p-P)\right\|_{l^\infty(L^2)} \\ &\qquad \le C\left(h^k + \Delta t^2\right)\left(\|\boldsymbol{u}\|_{L^\infty(H^k)} + \left\|\frac{\partial^3 \boldsymbol{u}}{\partial t^3}\right\|_{L^\infty(L^2)} + \|p\|_{L^\infty(L^2)}\right),\end{aligned}$$

where k *is associated with the degree of the finite element polynomial.*

Proof. From (3.9)–(3.10) and (5.5)–(5.6), and by the properties of the L^2 and Π_h projections, we can write

$$\left(\rho\partial_t^2 \boldsymbol{\chi}^n, \boldsymbol{v}\right) + \left(\xi^n, \nabla\cdot\boldsymbol{v}\right) = \left(\rho\partial_t^2\boldsymbol{\eta}^n, \boldsymbol{v}\right) + \left(\boldsymbol{r}^n, \boldsymbol{v}\right), \tag{5.20}$$

$$\left(\lambda^{-1}\xi^{n+1}, w\right) - \left(\nabla\cdot\boldsymbol{\chi}^{n+1}, w\right) = \left(\lambda^{-1}\zeta^{n+1}, w\right), \tag{5.21}$$

where $\boldsymbol{r}^n = \rho(\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^n) - \partial_t^2 \boldsymbol{u}^n)$. We introduce

$$\phi^0 = \frac{\Delta t}{2}\xi^0, \quad \phi^n = \frac{\Delta t}{2}\xi^0 + \Delta t\sum_{i=1}^n \xi^i.$$

Using (5.1) in (5.20) gives

$$\left(\rho\frac{\partial_t\boldsymbol{\chi}^{n+\frac{1}{2}} - \partial_t\boldsymbol{\chi}^{n-\frac{1}{2}}}{\Delta t}, \boldsymbol{v}\right) + \left(\xi^n, \nabla\cdot\boldsymbol{v}\right) = \left(\rho\frac{\partial_t\boldsymbol{\eta}^{n+\frac{1}{2}} - \partial_t\boldsymbol{\eta}^{n-\frac{1}{2}}}{\Delta t}, \boldsymbol{v}\right) + \left(\boldsymbol{r}^n, \boldsymbol{v}\right).$$

Summing over time levels and multiplying through by Δt gives

$$\begin{aligned}(5.22)\quad &\left(\rho\left(\partial_t\boldsymbol{\chi}^{n+\frac{1}{2}} - \partial_t\boldsymbol{\chi}^{\frac{1}{2}}\right), \boldsymbol{v}\right) + \left(\phi^n - \phi^0, \nabla\cdot\boldsymbol{v}\right) \\ &\qquad = \left(\rho\left(\partial_t\boldsymbol{\eta}^{n+\frac{1}{2}} - \partial_t\boldsymbol{\eta}^{\frac{1}{2}}\right), \boldsymbol{v}\right) + \left(\Delta t\sum_{i=1}^n \boldsymbol{r}^i, \boldsymbol{v}\right),\end{aligned}$$

since $\Delta t\sum_{i=1}^n \xi^i = \phi^n - \phi^0$.

Using (5.4), we obtain

$$\begin{aligned}&\left(\rho\partial_t\boldsymbol{\chi}^{\frac{1}{2}}, \boldsymbol{v}\right) + \frac{\Delta t}{2}\left(\xi^0, \nabla\cdot\boldsymbol{v}\right) \\ &\qquad = \left(\rho\partial_t\boldsymbol{\eta}^{\frac{1}{2}}, \boldsymbol{v}\right) + \left(\rho(\Pi\boldsymbol{u}_1 - \boldsymbol{u}_1), \boldsymbol{v}\right) - \frac{1}{2\Delta t}\int_0^{\Delta t}\rho\left(\Delta t - t\right)^2\left(\frac{\partial^3\boldsymbol{u}}{\partial t^3}, \boldsymbol{v}\right)dt,\end{aligned}$$

and thus (5.22) reduces to

$$\left(\rho\partial_t\boldsymbol{\chi}^{n+\frac{1}{2}}, \boldsymbol{v}\right) + \left(\phi^n, \nabla\cdot\boldsymbol{v}\right) = \left(\rho\partial_t\boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{v}\right) + \left(\boldsymbol{R}^n, \boldsymbol{v}\right), \tag{5.23}$$

where $\boldsymbol{R}^n$ is defined as

$$\boldsymbol{R}^n = \Delta t \sum_{i=1}^{n} \boldsymbol{r}^i + \rho(\Pi_h \boldsymbol{u}_1 - \boldsymbol{u}_1) - \frac{1}{2\Delta t} \int_0^{\Delta t} \rho \left(\Delta t - t\right)^2 \frac{\partial^3 \boldsymbol{u}}{\partial t^3}(t)\, dt.$$

We now rewrite (5.21) by noting that $\xi^{n+1} = \partial_t \phi^{n+\frac{1}{2}}$, so that

$$\left(\lambda^{-1} \partial_t \phi^{n+\frac{1}{2}}, w\right) - \left(\nabla \cdot \boldsymbol{\chi}^{n+1}, w\right) = (\lambda^{-1} \zeta^{n+1}, w). \tag{5.24}$$

We choose $\boldsymbol{v} = \boldsymbol{\chi}^{n+\frac{1}{2}}$ and $w = \phi^{n+\frac{1}{2}}$, which, when substituted into (5.23) and (5.24), gives

$$\left(\rho \partial_t \boldsymbol{\chi}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) + \left(\phi^n, \nabla \cdot \boldsymbol{\chi}^{n+\frac{1}{2}}\right) = \left(\rho \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) + \left(\boldsymbol{R}^n, \boldsymbol{\chi}^{n+\frac{1}{2}}\right), \tag{5.25}$$

$$\left(\lambda^{-1} \partial_t \phi^{n+\frac{1}{2}}, \phi^{n+\frac{1}{2}}\right) - \left(\nabla \cdot \boldsymbol{\chi}^{n+1}, \phi^{n+\frac{1}{2}}\right) = \left(\lambda^{-1} \zeta^{n+1}, \phi^{n+\frac{1}{2}}\right). \tag{5.26}$$

We expand (5.25) and (5.26) to get

$$\begin{aligned}
&\left(\rho \left(\frac{\boldsymbol{\chi}^{n+1} - \boldsymbol{\chi}^n}{\Delta t}\right), \frac{\boldsymbol{\chi}^{n+1} + \boldsymbol{\chi}^n}{2}\right) + \left(\phi^n, \frac{\nabla \cdot \left(\boldsymbol{\chi}^{n+1} + \boldsymbol{\chi}^n\right)}{2}\right) \\
&\qquad = \left(\rho \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) + \left(\boldsymbol{R}^n, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) \\
&\left(\lambda^{-1} \left(\frac{\phi^{n+1} - \phi^n}{\Delta t}\right), \frac{\phi^{n+1} + \phi^n}{2}\right) - \left(\nabla \cdot \boldsymbol{\chi}^{n+1}, \frac{\phi^{n+1} + \phi^n}{2}\right) = \left(\lambda^{-1} \zeta^{n+1}, \phi^{n+\frac{1}{2}}\right),
\end{aligned}$$

so that

$$\begin{aligned}
&\frac{1}{2\Delta t} \left(\left\|\rho^{\frac{1}{2}} \boldsymbol{\chi}^{n+1}\right\|_{L^2(\Omega)}^2 - \left\|\rho^{\frac{1}{2}} \boldsymbol{\chi}^n\right\|_{L^2(\Omega)}^2\right) + \frac{1}{2}\left(\phi^n, \nabla \cdot \boldsymbol{\chi}^{n+1}\right) + \frac{1}{2}\left(\phi^n, \nabla \cdot \boldsymbol{\chi}^n\right) \\
&\qquad = \left(\rho \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) + \left(\boldsymbol{R}^n, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) \qquad (5.27) \\
&\frac{1}{2\Delta t} \left(\left\|\lambda^{-\frac{1}{2}} \phi^{n+1}\right\|_{L^2(\Omega)}^2 - \left\|\lambda^{-\frac{1}{2}} \phi^n\right\|_{L^2(\Omega)}^2\right) = \frac{1}{2}\left(\nabla \cdot \boldsymbol{\chi}^{n+1}, \phi^n\right) + \frac{1}{2}\left(\nabla \cdot \boldsymbol{\chi}^{n+1}, \phi^{n+1}\right) \\
&\qquad + \left(\lambda^{-1} \zeta^{n+1}, \phi^{n+\frac{1}{2}}\right). \qquad (5.28)
\end{aligned}$$

Adding (5.27) and (5.28) and multiplying by $2\Delta t$ gives

$$\begin{aligned}
&\left\|\rho^{\frac{1}{2}} \boldsymbol{\chi}^{n+1}\right\|_{L^2(\Omega)}^2 - \left\|\rho^{\frac{1}{2}} \boldsymbol{\chi}^n\right\|_{L^2(\Omega)}^2 + \left\|\lambda^{-\frac{1}{2}} \phi^{n+1}\right\|_{L^2(\Omega)}^2 - \left\|\lambda^{-\frac{1}{2}} \phi^n\right\|_{L^2(\Omega)}^2 \\
&\qquad + \Delta t \left[\left(\phi^n, \nabla \cdot \boldsymbol{\chi}^n\right) - \left(\nabla \cdot \boldsymbol{\chi}^{n+1}, \phi^{n+1}\right)\right] \\
&\qquad = 2\Delta t \left[\left(\rho \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) + \left(\boldsymbol{R}^n, \boldsymbol{\chi}^{n+\frac{1}{2}}\right)\right] + 2\Delta t \left(\lambda^{-1} \zeta^{n+1}, \phi^{n+\frac{1}{2}}\right).
\end{aligned} \tag{5.29}$$

The terms on the right-hand side are bound using the Cauchy–Schwarz inequality as

$$\begin{aligned}
\left(\rho \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) &\le \left\|\rho^{\frac{1}{2}} \partial_t \boldsymbol{\eta}^{n+\frac{1}{2}}\right\|_{L^2(\Omega)} \left\|\boldsymbol{\chi}^{n+\frac{1}{2}}\right\|_{L^2(\Omega)} \\
\left(\boldsymbol{R}^n, \boldsymbol{\chi}^{n+\frac{1}{2}}\right) &\le \left\|\boldsymbol{R}^n\right\|_{L^2(\Omega)} \left\|\boldsymbol{\chi}^{n+\frac{1}{2}}\right\|_{L^2(\Omega)} \\
\left(\lambda^{-1} \zeta^{n+1}, \phi^{n+\frac{1}{2}}\right) &\le \left\|\lambda^{-\frac{1}{2}} \zeta^{n+1}\right\|_{L^2(\Omega)} \left\|\lambda^{-\frac{1}{2}} \phi^{n+\frac{1}{2}}\right\|_{L^2(\Omega)}.
\end{aligned}$$

Sum (5.29) over time levels to get

$$\begin{aligned}
&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} - \left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{0}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)} \\
&\quad - \left\|\lambda^{-\frac{1}{2}}\phi^{0}\right\|^2_{L^2(\Omega)} - \Delta t\left[\left(\nabla\cdot\boldsymbol{\chi}^{n+1},\phi^{n+1}\right) - \left(\phi^0,\nabla\cdot\boldsymbol{\chi}^0\right)\right] \\
&\le 2\Delta t\sum_{i=0}^{n}\left(\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} + \left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\right) \\
&\quad +\Delta t\sum_{i=0}^{n}\left(\left\|\lambda^{-\frac{1}{2}}\zeta^{i+1}\right\|_{L^2(\Omega)}\left(\left\|\lambda^{-\frac{1}{2}}\phi^{i+1}\right\|_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{i}\right\|_{L^2(\Omega)}\right)\right). \qquad (5.30)
\end{aligned}$$

After imposing the initial conditions (5.2) and (5.3) in (5.30) we have

$$\begin{aligned}
&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)} - \Delta t\left(\nabla\cdot\boldsymbol{\chi}^{n+1},\phi^{n+1}\right) \\
&\le 2\Delta t\sum_{i=0}^{n}\left(\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} + \left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\right) \\
&\quad + \Delta t\sum_{i=0}^{n}\left(\left\|\lambda^{-\frac{1}{2}}\zeta^{i+1}\right\|_{L^2(\Omega)}\left(\left\|\lambda^{-\frac{1}{2}}\phi^{i+1}\right\|_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{i}\right\|_{L^2(\Omega)}\right)\right).
\end{aligned}$$

Using the Cauchy–Schwarz inequality and the inverse assumption (5.9) and choosing h and Δt such that $\Delta t < \frac{2h\rho_0^{\frac{1}{2}}}{C_0\lambda_1^{\frac{1}{2}}}$, we have that

$$\begin{aligned}
\Delta t\left(\nabla\cdot\boldsymbol{\chi}^{n+1},\phi^{n+1}\right) &\le \Delta t\left\|\nabla\cdot\boldsymbol{\chi}^{n+1}\right\|_{L^2(\Omega)}\left\|\phi^{n+1}\right\|_{L^2(\Omega)} \\
&\le \Delta t C_0 h^{-1}\left\|\boldsymbol{\chi}^{n+1}\right\|_{L^2(\Omega)}\left\|\phi^{n+1}\right\|_{L^2(\Omega)} \\
&\le \frac{\Delta t C_0\lambda_1^{\frac{1}{2}}}{2h\rho_0^{\frac{1}{2}}}\left(\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)}\right) \\
&< \left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)}.
\end{aligned}$$

Thus we have

$$\begin{aligned}
&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)} \\
&\le C\Delta t\sum_{i=0}^{n}\left(\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} + \left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\right) \\
&\qquad + 2\left\|\lambda^{-\frac{1}{2}}\phi\right\|_{l^\infty(L^2)}\left(\Delta t\sum_{i=0}^{n}\left\|\lambda^{-\frac{1}{2}}\zeta^{i+1}\right\|_{L^2(\Omega)}\right).
\end{aligned}$$

Since $\left\|\boldsymbol{\chi}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} \leq \|\boldsymbol{\chi}\|_{l^\infty(L^2)}$, then

$$\begin{aligned}
&\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}^{n+1}\right\|^2_{L^2(\Omega)} + \left\|\lambda^{-\frac{1}{2}}\phi^{n+1}\right\|^2_{L^2(\Omega)} \\
&\quad\leq \frac{C2\Delta t}{\rho_0^{\frac{1}{2}}}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|_{l^\infty(L^2)}\left(\sum_{i=0}^{n}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} + \sum_{i=0}^{n}\left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\right) \\
&\qquad\quad + \frac{1}{4}\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{l^\infty(L^2)} + C\left(\Delta t\sum_{i=0}^{n}\left\|\lambda^{-\frac{1}{2}}\zeta^{i+1}\right\|_{L^2(\Omega)}\right)^2 \\
&\quad\leq \frac{1}{4}\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{l^\infty(L^2)} + C\Delta t^2\left(\sum_{i=0}^{N}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\right)^2 \\
&\qquad\quad + C\Delta t^2\left(\sum_{i=0}^{N}\left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\right)^2 + \frac{1}{4}\left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{l^\infty(L^2)} \\
&\qquad\quad + C\left(\Delta t\sum_{i=0}^{n}\left\|\lambda^{-\frac{1}{2}}\zeta^{i+1}\right\|_{L^2(\Omega)}\right)^2.
\end{aligned}$$

If we take the supremum on n on the left-hand side we get

$$\begin{aligned}
\left\|\rho^{\frac{1}{2}}\boldsymbol{\chi}\right\|^2_{l^\infty(L^2)} + \left\|\lambda^{-\frac{1}{2}}\phi\right\|^2_{l^\infty(L^2)} &\leq C\left\|\lambda^{-\frac{1}{2}}\zeta\right\|^2_{l^\infty(L^2)} \\
&\quad + C\Delta t^2\left(\sum_{i=0}^{N}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)}\right)^2 + C\Delta t^2\left(\sum_{i=0}^{N}\left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)}\right)^2.
\end{aligned}$$

The first two terms in the right-hand side of the previous inequality can be bound using the approximation properties and the bound

$$\Delta t\sum_{i=0}^{N}\left\|\rho^{\frac{1}{2}}\partial_t\boldsymbol{\eta}^{i+\frac{1}{2}}\right\|_{L^2(\Omega)} \leq C\left(h^k\left\|\boldsymbol{u}\right\|_{L^\infty(H^k(\Omega))} + \Delta t^2\left\|\frac{\partial^3\boldsymbol{u}}{\partial t^3}\right\|_{L^1(0,T;L^2(\Omega))}\right).$$

We bound the last term by

$$\begin{aligned}
\Delta t\sum_{i=0}^{N}\left\|\boldsymbol{R}^i\right\|_{L^2(\Omega)} &\leq C\left\|\boldsymbol{R}\right\|_{l^\infty(L^2)} \\
&\leq C\Delta t\sum_{i=1}^{N}\left\|\boldsymbol{r}^i\right\|_{L^2(\Omega)} + C\left\|\rho\left(\Pi_h\boldsymbol{u}_1 - \boldsymbol{u}_1\right)\right\|_{L^2(\Omega)} \\
&\quad + C\left\|\frac{1}{2\Delta t}\int_0^{\Delta t}\rho(\Delta t - t)^2\frac{\partial^3\boldsymbol{u}}{\partial t^3}(t)\,dt\right\|_{L^2(\Omega)}.
\end{aligned}$$

We obtain a bound on $\|\boldsymbol{r}^i\|_{L^2(\Omega)}$ by first expanding $\boldsymbol{r}^i$ as

$$\boldsymbol{r}^i = \rho(\boldsymbol{u}^i_{tt} - \partial_t^2\boldsymbol{u}^i). \tag{5.31}$$

We note that

$$\partial_t^2\boldsymbol{u}^i = \frac{\boldsymbol{u}^{i+1} - 2\boldsymbol{u}^i + \boldsymbol{u}^{i-1}}{\Delta t^2} \tag{5.32}$$

and use Taylor series to expand $\boldsymbol{u}^{i+1}$ and $\boldsymbol{u}^{i-1}$. We have

$$\begin{aligned}\boldsymbol{u}^{i-1} &= \boldsymbol{u}\left(t_i - \Delta t\right)\\ &= \boldsymbol{u}(t^i) - \Delta t\frac{\partial \boldsymbol{u}}{\partial t}(t^i) + \frac{\Delta t^2}{2}\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) - \frac{\Delta t^3}{6}\frac{\partial^3 \boldsymbol{u}}{\partial t^3}(t^i)\\ &\quad + \frac{1}{6}\int_{t^i-\Delta t}^{t^i}\left(t^i - \Delta t - t\right)^3\frac{\partial^4 \boldsymbol{u}}{\partial t^4}(t)\,dt\end{aligned}$$

and

$$\begin{aligned}\boldsymbol{u}^{i+1} &= \boldsymbol{u}(t_i + \Delta t)\\ &= \boldsymbol{u}(t^i) + \Delta t\frac{\partial \boldsymbol{u}}{\partial t}(t^i) + \frac{\Delta t^2}{2}\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) + \frac{\Delta t^3}{6}\frac{\partial^3 \boldsymbol{u}}{\partial t^3}(t^i)\\ &\quad + \frac{1}{6}\int_{t^i}^{t^i+\Delta t}\left(t^i + \Delta t - t\right)^3\frac{\partial^4 \boldsymbol{u}}{\partial t^4}(t)\,dt\end{aligned}$$

so that

$$\begin{aligned}\boldsymbol{u}^{i+1} + \boldsymbol{u}^{i-1} &= 2\boldsymbol{u}(t^i) + \Delta t^2\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) + \frac{1}{6}\left[\int_{t^i}^{t^i+\Delta t}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}(t)\left(t^i + \Delta t - t\right)^3\,dt\right.\\ &\qquad \left. + \int_{t^i-\Delta t}^{t^i}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}(t)\left(t^i - \Delta t - t\right)^2\,dt\right]\\ &= 2\boldsymbol{u}(t^i) + \Delta t^2\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) + \frac{1}{6}\int_{-\Delta t}^{\Delta t}\left(|t| - \Delta t\right)^3\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\left(t^i + t\right)\,dt. \qquad (5.33)\end{aligned}$$

When we use (5.33) and (5.32) in (5.31) we get

$$\begin{aligned}\boldsymbol{r}^i &= \rho\left(\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) - \partial_t^2\boldsymbol{u}^i\right)\\ &= \frac{\rho}{6\Delta t^2}\int_{-\Delta t}^{\Delta t}\left(|t| - \Delta t\right)^3\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\left(t^i + t\right)\,dt\end{aligned}$$

and thus

$$\boldsymbol{r}^i = \rho\left(\frac{\partial^2 \boldsymbol{u}}{\partial t^2}(t^i) - \partial_t^2\boldsymbol{u}^i\right) = \frac{\rho}{6\Delta t^2}\int_{-\Delta t}^{\Delta t}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\left(t^i + \Delta t\right)\left(|t| - \Delta t\right)^3\,dt.$$

Therefore

$$\begin{aligned}\left\|\boldsymbol{r}^i\right\|_{L^2(\Omega)}^2 &\le C\Delta t^2\int_\Omega\left[\int_{t^i-\Delta t}^{t^i+\Delta t}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}(t)\right]^2\,dt\\ &\le C\Delta t^3\int_{t^i-\Delta t}^{t^i+\Delta t}\left\|\rho^{\frac{1}{2}}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\right\|_{L^2(\Omega)}^2\\ &\le C\Delta t^4\left\|\rho^{\frac{1}{2}}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\right\|_{L^\infty(L^2)}^2,\end{aligned}$$

so that

$$\Delta t\sum_{i=1}^n\left\|\boldsymbol{r}^i\right\|_{L^2(\Omega)} \le C\Delta t^2\left\|\rho^{\frac{1}{2}}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\right\|_{L^\infty(L^2)}\sum_{i=1}^n\Delta t \le C\Delta t^2\left\|\rho^{\frac{1}{2}}\frac{\partial^4 \boldsymbol{u}}{\partial t^4}\right\|_{L^\infty(L^2)}.$$

Similarly,

$$\begin{aligned}\left\| \frac{1}{2\Delta t} \int_0^{\Delta t} \rho(\Delta t - t)^2 u^{(3)}(t) \right\|_{L^2(\Omega)} &\leq C\Delta t^2 \int_\Omega \left(\int_0^{\Delta t} \rho \frac{\partial^3 \boldsymbol{u}}{\partial t^3}(t)\, dt \right)^2 \\ &\leq C\Delta t^3 \int_0^{\Delta t} \left\| \rho^{\frac{1}{2}} \frac{\partial^3 \boldsymbol{u}}{\partial t^3} \right\|^2_{L^2(\Omega)} dt \\ &\leq C\Delta t^4 \left\| \rho^{\frac{1}{2}} \frac{\partial^3 \boldsymbol{u}}{\partial t^3} \right\|^2_{L^\infty(L^2)}.\end{aligned}$$

Finally, using the approximation result (2.2) and combining all the bounds, we get

$$\Delta t \sum_{i=0}^{N} \left\| \boldsymbol{R}^i \right\|_{L^2(\Omega)} \leq C(h^k + \Delta t^2),$$

which concludes the proof of the discrete estimate. ∎

Remark. The convergence rate in space can be at most quadratic, as $\Delta t < Ch$.

6. Conclusions. We have developed a priori error estimates for mixed finite element displacement formulations of the acoustic wave equation. Our scheme maintains the same computational complexity as earlier mixed finite element formulations for second order hyperbolic equations, as we have not introduced any additional unknowns. Our formulations require less regularity on the displacement than standard approaches.

We have shown convergence of the scheme via our continuous-in-time estimates, and we have shown that in the temporally discrete case we expect a quadratic convergence rate.

Acknowledgment. The authors would like to thank Dr. Mrinal Sen of the Institute for Geophysics at the University of Texas at Austin for his insights into this problem.

SIMULATION OF THE SOLUTION OF A VISCOUS POROUS MEDIUM EQUATION BY A PARTICLE METHOD*

KARL OELSCHLÄGER†

Abstract. To solve a particular partial differential equation, namely a viscous porous medium equation, we discuss a particle method, which is based on the concept of moderately interacting many-particle systems. Our approach may be classified as a combination of a smoothed particle hydrodynamics method and a particle-mesh method. Quantitatively, it is assessed in terms of estimates on the approximation error.

Key words. particle methods, many-particle systems, smoothed particle hydrodynamics

1. Introduction.

In this paper we consider the numerical simulation of a *viscous porous medium equation*,

$$\partial_t \rho = \frac{1}{2}\Delta\rho + \frac{1}{2}\Delta\rho^2 = \frac{1}{2}\Delta\rho + \nabla\cdot(\rho\nabla\rho), \qquad \rho(.,0) = \rho_0, \tag{1.1}$$

by a *particle method*, which is based on the concept of *moderately interacting many-particle systems*.

The approximation of the solution ρ of (1.1) by the *empirical processes* of such many-particle systems has been studied analytically in [12] and [13]. In those papers we have for any $N \in \mathbb{N}$ a family of N particles in $\mathbb{R}^d$, whose positions at time $t \geq 0$ are denoted by $X_N^k(t)$, $k = 1, \ldots, N$. It is assumed that they evolve according to the system

$$dX_N^k(t) = -\frac{1}{N}\sum_{\substack{m=1,\ldots,N\\ m\neq k}} \nabla\phi_N\big(X_N^k(t) - X_N^m(t)\big)dt + dW^k(t), \qquad k = 1, \ldots, N,\ t \geq 0, \tag{1.2}$$

of coupled *stochastic differential equations*. In (1.2) the processes $W^1, W^2, \ldots$ are independent, standard Brownian motions in $\mathbb{R}^d$. Moreover, the *interaction potential* ϕ_N is obtained from a fixed function ϕ_1 by the scaling

$$\phi_N(x) = \theta_N^d \phi_1(\theta_N x), \quad x \in \mathbb{R}^d,\ N \in \mathbb{N}, \tag{1.3}$$

where

$$\theta_N = N^{\beta/d} \quad \text{for some} \quad \beta \in \Big(0, \frac{d}{d+2}\Big), \tag{1.4}$$

and ϕ_1 is a differentiable, symmetric probability density, i.e.,

$$\phi_1 \in C_b^1(\mathbb{R}^d), \quad \phi_1 \geq 0, \quad \int_{\mathbb{R}^d} dx\ \phi_1(x) = 1, \quad \phi_1(x) = \phi_1(-x),\ x \in \mathbb{R}^d. \tag{1.5}$$

The scaling parameter θ_N represents the *inverse interaction range* in the system (1.2). In particular, β determines the decrease of the interaction range θ_N^{-1} in comparison to the *typical distance between neighboring particles*, which as explained below in this section is $O(N^{-1/d})$ as $N \to \infty$.

In [12] and [13] we discuss in particular the empirical processes

$$\mathbb{X}_N(t) = \frac{1}{N} \sum_{m=1}^{N} \delta_{X_N^m(t)}, \quad t \geq 0,\ N \in \mathbb{N}, \tag{1.6}$$

of the many-particle systems (1.2), where δ_a denotes the Dirac measure at $a \in \mathbb{R}^d$. If $\mathbb{X}_N(0)$, $N \in \mathbb{N}$, and ϕ_1 are sufficiently *regular*, the convergence

$$\lim_{N \to \infty} \mathbb{X}_N = \rho \tag{1.7}$$

of the empirical processes to the solution ρ of (1.1) can be demonstrated; cf. [12]. In particular, (1.7) is proved as L^2-convergence of a regularized version of $\mathbb{X}_N$ to ρ as $N \to \infty$. As an extension in [13] the rate of the convergence (1.7) is specified. More precisely, we deduce an expansion

$$\mathbb{X}_N(t) \sim \rho(.,t) + \sum_{r=1}^{\lfloor d/4\beta \rfloor} \theta_N^{-2r} \rho_r(.,t) + \frac{1}{\sqrt{N}} \zeta(t), \quad t \geq 0,\ N \to \infty,$$

where the functions ρ_r, $r = 1, \ldots, \lfloor d/4\beta \rfloor$, are solutions of suitable linear diffusion equations and ζ is some $\mathcal{S}'(\mathbb{R}^d)$-valued Gaussian process. Here, $\mathcal{S}'(\mathbb{R}^d)$ is the space of *tempered distributions* on $\mathbb{R}^d$ and $\lfloor z \rfloor = \max\{n \in \mathbb{Z} : n \leq z\}$, $z \in \mathbb{R}$.

The convergence result (1.7) suggests determining a numerical solution of the partial differential equation (1.1) by simulating the many-particle system (1.2) for sufficiently large N. Then, the associated empirical process can be considered as an approximation to the analytical solution of (1.1). Such an approach to solve an evolution equation by using a many-particle system as an auxiliary tool is called a *particle method*. Physically motivated applications can be found, e.g., in numerical studies in astro-, hydro-, or plasmaphysics, where they have a long tradition but very often a formal or heuristic basis; cf. [4], [8]. Mathematical investigations of particle methods usually refer to simpler evolution problems, which are considered to exhibit typical features and difficulties of more complex, realistic problems, and nevertheless are accessible to a detailed analysis. For example, particle simulations of the *Boltzmann equation*, cf., e.g., [11], or *Vlasov–Poisson–Fokker–Planck equations*, cf., e.g., [6], have been studied in detail. Furthermore, applications of particle methods to solve hydrodynamical equations, cf., e.g., [1], [10], or specific reaction-diffusion equations, cf., e.g., [2], [18], have been investigated. Also in the present paper we deal with a simple partial differential equation, namely (1.1), and utilize this context to propose a particular particle method together with an analytical investigation. We emphasize that our considerations should also be applicable in more general situations. In particular, it seems that they can be extended to such evolution equations, which like those in [14], [15], [16] can be approximated by suitable *moderately interacting many-particle systems*. Indeed, at least the computer program employed to perform the simulations, which will be described in section 6, has already been modified such that parabolic systems of partial differential equations as those discussed in [14] may be handled.

Moderately interacting many-particle systems are essentially characterized by the feature that the range of the different types of interactions between the particles is both large in comparison to the typical distance between neighboring particles and small in comparison to the spatial size of the whole system. For example, by (1.3)–(1.5) the range of the interaction in the system (1.2) is $O(\theta_N^{-1}) = O(N^{-\beta/d})$. On the other hand, the fact that to any particle the mass $1/N$ is attached, cf. (1.6), and the convergence relation (1.7) imply that in the situations studied in [12] and [13] the typical distance between neighboring particles is $O(N^{-1/d})$ as $N \to \infty$, and furthermore that the spatial size of the whole system is $O(1)$. In particular, since $\beta \in (0, d/(d+2))$, the above-mentioned characteristic of moderate interaction can be observed in this case. As an extension of [12] and [13] we have described and investigated in [14], [15], [16] various types of moderately interacting many-particle systems, which also may involve different species of particles. More precisely, we derive in these papers in the limit as the particle number tends to ∞ systems of reaction-diffusion equations, cf. [14], and particular systems of hydrodynamical equations, cf. [15] and [16], as limit dynamics for empirical processes. Although the dynamics of the many-particle systems in [14], [15], [16] may be much more complex than in (1.2), the crucial ideas to determine analytically the respective limit behavior are quite similar. In all these cases we consider vectors $(\mathbb{X}_{N,1}(t) * \kappa_N, \ldots, \mathbb{X}_{N,R}(t) * \kappa_N)$ of regularized versions of the empirical processes $\mathbb{X}_{N,1}(t), \ldots, \mathbb{X}_{N,R}(t)$, $t \geq 0$, $N \in \mathbb{N}$, for the various species, where R is the number of species and κ_N, $N \in \mathbb{N}$, a sequence of suitable convolution kernels converging to δ_0 as $N \to \infty$. As a result an L^2-convergence like $\lim_{N\to\infty} \sum_{r=1}^{R} \|\mathbb{X}_{N,r}(t) * \kappa_N - \rho_r(.,t)\|_2 = 0$, $t \geq 0$, to the solution $(\rho_1, \ldots, \rho_r)$ of the limit dynamics is deduced.

Of course, systems like (1.2), which are continuous in space and time, cannot be simulated directly on a computer. For that aim we have to deal with problems related to discretization. In particular, we have to replace the many-particle dynamics (1.2) by some modified version, where to a certain extent for *continuous features* discrete counterparts are employed. Consequently, we shall introduce in section 2 a family of many-particle systems, whose members differ in the number N of particles, a spatial mesh size δ, the time step h, and the scaling parameter θ for the interaction potential. In an extension, we shall also present a family of many-particle systems, whose members additionally differ in a parameter τ determining the adaption of the mesh to local spatial irregularities. More precisely, instead of (1.2) we shall define

- for any $N \in \mathbb{N}$ a family of systems of N coupled evolution equations
- in discrete time with time step $h \in (0,1)$ and
- an interaction potential ϕ_θ obtained by the scaling

$$\phi_\theta(x) = \theta^d \phi_1(\theta x), \quad x \in \mathbb{R}^d,\ \theta > 1, \tag{1.8}$$

such that

- the *force field* corresponding to $(x,t) \to (1/N) \sum_{m=1}^{N} \nabla\phi_N(x - X_N^m(t))$ in (1.2) is determined by the values of the *particle density*, which is defined in analogy to $(x,t) \to (1/N) \sum_{m=1}^{N} \phi_N(x - X_N^m(t))$, in a discrete spatial mesh with mesh size $\delta \in (0,1)$. Furthermore,
- depending on $\tau > 0$ this mesh may be adapted, i.e. refined, in those regions of space, where the particle density behaves irregularly.

Quite similarly as in [12], [13], [14], [15], [16] we shall study regularized versions of the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ of the discretized modifications of (1.2), namely functions like $(x,s) \to (\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(s) * \phi_\theta)(x)$. As a main result of the present paper,

which is formulated precisely in section 3.2, we shall demonstrate the convergence in an L^2-sense of these functions to the solution ρ of (1.1) as $N, \theta \to \infty$ and $\delta, h(,\tau) \to 0$. In particular, an estimate for the rate of that convergence will be provided. The crucial parts of the proofs of our results are contained in section 4, whereas some auxiliary ingredients are deferred to section 5. In section 6 we shall present the outcomes of some numerical simulations.

Regarding the technical basis of the present work, we have indicated in the previous paragraph that the interaction kernels ϕ_θ, $\theta > 1$, and also certain related functions are employed to regularize the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$. As a consequence, several technical properties of these kernels have to be assumed. These suppositions are collected in section 3.1. We note that a few estimates used in sections 4 and 5 in some possibly modified form also appear in [12], [13], [14], [15], [16]. A certain amount of the technical difficulties encountered in the present work is associated with the fact that in the many-particle system (1.2) and also in its discretized modifications the range of the interaction is strictly positive, whereas in the dynamics (1.1) of the limit ρ this range vanishes. To handle that problem a family ρ_θ, $\theta > 1$, of functions solving particular integro-differential equations, cf. (3.16), will be utilized as an auxiliary tool. The dynamics of both these functions and the discretized modifications of (1.2) is governed by the interaction kernels ϕ_θ, $\theta > 1$. Therefore, it will become possible to study the *distance* between $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ and ρ_θ as $N, \theta \to \infty$ and $\delta, h(,\tau) \to 0$ in detail. On the other hand, in an accompanying paper [17] it is demonstrated that $\lim_{\theta\to\infty} \rho_\theta = \rho$, where explicit relations for the rate of this convergence are also given. As a final consequence, the desired estimate on the rate of convergence of $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ to ρ as $N, \theta \to \infty$ and $\delta, h(,\tau) \to 0$ will follow.

The study in the present paper is essentially a theoretical investigation of the so-called *smoothed particle hydrodynamics*- (SPH-) method, which has been described, e.g., in [1], [5]. The crucial feature of that particular particle method is the use of regularizations of the particle configurations, which are obtained by convolutions with smooth kernels approaching δ_0 as the particle number tends to infinity, to determine estimates for densities and also their derivatives. In particular, we employ the close connection to moderately interacting many-particle systems, which is established by this property.

As mentioned above, to determine the force field describing the interaction between the particles we shall utilize the values of the particle density on a discrete spatial mesh. For this reason our approach here may also be classified as a *particle-mesh method*; cf., e.g., [8]. As an important consequence, we do not need to consider explicitly the interaction between individual pairs of particles, and therefore it will become less expensive to simulate systems with large particle numbers.

Sometimes in applications of particle methods to the solution of partial differential equations the particles represent point concentrations of some *derivative* of the solution. This happens, for example, in connection with the *vortex method* to solve equations for incompressible fluid motion, cf., e.g., [10], and also in related studies of particular reaction-diffusion equations in one dimension; cf., e.g., [3], [18]. In contrast, as usual in SPH-models the particles in the present paper describe concentrations of the solution itself.

To conclude this first section we mention some notation, which will be used in the remaining parts of this paper.

By

$$\widetilde{f}(\lambda) = (2\pi)^{-d/2} \int_{\mathbb{R}^d} dx \ \exp(i\lambda x) f(x), \quad \lambda \in \mathbb{R}^d, \ f \in L^1(\mathbb{R}^d),$$

we denote the *Fourier transform*. For its natural extensions to finite measures μ or square integrable functions g the notation $\widetilde{\mu}$ or $\widetilde{g}$ is also employed.

The set $\mathcal{M}(\mathbb{R}^d)$ contains the *finite measures* on $\mathbb{R}^d$. The *variation* of any $\mu \in \mathcal{M}(\mathbb{R}^d)$ is denoted by $|\mu|$.

To quantify regularity properties in some L^2-sense the *Sobolev norms*

$$\|f\|_{(m)} = \left(\sum_{k=0}^{m} \|\nabla^{\otimes k} f\|_2^2\right)^{1/2}, \tag{1.9}$$

$$\|f\|_{(m,1)} = \left(\sum_{k=0}^{m} \int_{\mathbb{R}^d} dy\ (1+|y|)|\nabla^{\otimes k} f(y)|^2\right)^{1/2}, \quad m = 0,1,2,\ldots,$$

for sufficiently regular real-valued functions f on $\mathbb{R}^d$ are utilized. Here, $\nabla^{\otimes k} f$ denotes the tensor of all partial derivatives of order k of a function f. The *Sobolev spaces* associated with the norms $\|.\|_{(m)}$, $m = 0,1,2,\ldots$, are

$$H_m^2(\mathbb{R}^d) = \big\{f \in L^2(\mathbb{R}^d) : \|f\|_{(m)} < \infty\big\}, \quad m = 0,1,2,\ldots.$$

As an abbreviation for integrals we shall apply the notations

$$\langle \mu, f\rangle = \int_{\mathbb{R}^d} \mu(dx) f(x), \qquad \langle f, g\rangle = \int_{\mathbb{R}^d} dx\ f(x)g(x),$$

whenever the right sides are well-defined for a measure μ and functions f and g.

The discrete sets

$$\mathcal{T}_h = \{0, h, 2h, \ldots\}, \quad h > 0,$$

represent collections of equidistant points on the time axis. For $s \geq 0$ we define

$$\lfloor s \rfloor_h = h\lfloor s/h \rfloor = \max\{ph : p \in \mathbb{Z},\ ph \leq s\};$$

i.e., $\lfloor s \rfloor_h$ is the largest element of $\mathcal{T}_h$, which is not larger than s. In addition to $\lfloor . \rfloor$ we will also use the notation

$$\lceil z \rceil = \min\{n \in \mathbb{Z} : n \geq z\}, \quad z \in \mathbb{R}.$$

For the cardinality of a finite set $\mathcal{N}$ the notation $|\mathcal{N}|$ will be employed.

Centered Gaussian densities in $\mathbb{R}^d$ are denoted as

$$\sigma_{d;\alpha}(x) = \frac{1}{(2\pi\alpha)^{d/2}} \exp\Big(-\frac{x^2}{2\alpha}\Big), \quad x \in \mathbb{R}^d,\ \alpha > 0.$$

To describe mathematically the randomness of the initial positions of the particles and the Brownian motions, which model the random part of their dynamics, we suppose the existence of some *probability space* $(\Omega, \mathcal{F}, \mathbb{P})$. Any random variable or random process appearing in this paper should be measurable with respect to $(\Omega, \mathcal{F}, \mathbb{P})$. The expectation operator in $(\Omega, \mathcal{F}, \mathbb{P})$ is denoted by $\mathbb{E}[.]$. Moreover, we assume that $(\mathcal{F}_s)_{s\geq 0}$ is a filtration of σ-algebras $\mathcal{F}_s \subseteq \mathcal{F}$ such that the initial positions of the particles are measurable with respect to $\mathcal{F}_0$ and any Brownian motion in this paper is *adapted* to $(\mathcal{F}_s)_{s\geq 0}$.

We denote by $C, C', C'', \ldots$ positive, finite constants, which may vary from place to place. In general, these constants are independent of the particle number N, the

discretization parameters δ and h, the scaling variable θ, the adaption parameter τ, or other variables with respect to those uniform estimates have to be deduced. If, however, the dependence on particular parameters $\alpha_1, \dots, \alpha_M$ is to be emphasized, the notation $C(\alpha_1, \dots, \alpha_M)$ is employed.

For the subsequent sections we choose some fixed $T \in (0, \infty)$ and then restrict our studies to the time interval $[0, T]$. As a simplification we also formulate our considerations only for $d = 2$. No essential new problems would be encountered for $d = 1$ or $d > 2$. Furthermore, our computer simulations described in section 6 are also performed for the two-dimensional case.

2. A discretized version of the many-particle system (1.2). In this section we describe how the many-particle system (1.2), which is continuous in space and time, may be discretized such that its simulation on a computer becomes possible. In other words, we construct a particle method, which can be used to solve (1.1) numerically.

First, we note that as a consequence of the symmetry of ϕ_1, cf. (1.5), the restriction "$m \neq k$" in the sum in (1.2) has no effect, and therefore to simplify the notation it will be omitted from now on.

To obtain a modification of the system (1.2), which is suitable for a numerical simulation,

(i) we discretize the time axis and utilize an *Euler scheme* based on this discretization to determine the evolution in time of the particle positions. Additionally,

(ii) we employ some *spatial mesh* and for any discrete time point we calculate at its vertices the *local population density*. Quite similarly as in moderately interacting many-particle systems this density is defined as the convolution of the empirical process of the particle positions with ϕ_θ; cf. (1.8). Depending on the spatial variations of the population density

(ii$_a$) the mesh size can be adapted locally. Furthermore,

(iii) we use the discrete set of values of the population density, which has been computed in (ii) (and (ii$_a$)), to determine by some interpolation procedure the *force field* at the particle positions. Together with some Gaussian random variables, which model the increments of the Brownian motions, this force field is employed to accomplish the evolution in time.

We note that the population density determined in (ii) (and (ii$_a$)) may also be used to obtain a graphical representation of the simulation results.

As a consequence of the rough outline (i)–(iii) our modification of the many-particle system (1.2) in the first case, when no adaption is performed, depends on four parameters, namely the particle number N, the mesh size δ of the nonadapted initial mesh, the time step h, and additionally on the scaling variable θ of the interaction potential ϕ_θ. Hence, we then typically need four indices N, δ, h, and θ to characterize the various mathematical objects appearing in the investigation of our particle method. Next, in the second case, when adaption is also included, the additional parameter τ has to be taken into account.

Subsequently in this section, we shall supplement (i)–(iii) by missing details. Especially, we have to describe the adaption procedure in (ii$_a$) and the interpolation step in (iii).

First, let us fix a particle number N, a mesh size δ, a time step h, a scaling parameter θ, and also for use in the second case an adaption parameter τ. We now will define a system of N particles, whose positions in $\mathbb{R}^2$ at time ph, $p = 0, 1, 2, \dots$, will be denoted by $Y^k_{N,\delta,h,\theta(,\tau)}(ph)$, $k = 1, \dots, N$. The relevant information about

these particle positions is summarized in the associated empirical process

$$\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(ph) = \frac{1}{N}\sum_{m=1}^{N} \delta_{Y^m_{N,\delta,h,\theta(,\tau)}(ph)}, \quad p = 0,1,2,\ldots; \tag{2.1}$$

i.e., $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(ph)$ is a finite measure having mass $1/N$ at the particle positions $Y^k_{N,\delta,h,\theta(,\tau)}(ph)$, $k = 1,\ldots,N$.

To characterize the time evolution of the particles, first their drift has to be described. Similarly as above in (1.2) in the original many-particle system this drift is determined by the interaction kernel ϕ_θ, which is defined in (1.8). A look at (1.2) suggests evaluating for any $p = 0,1,2,\ldots$ the sum $(1/N)\sum_{m=1}^N \nabla\phi_\theta\big(y - Y^m_{N,\delta,h,\theta(,\tau)}(ph)\big)$ at the particle positions $y \in \{Y^1_{N,\delta,h,\theta(,\tau)}(ph),\ldots,Y^N_{N,\delta,h,\theta(,\tau)}(ph)\}$. Evidently, for any time step the expense for computing these sums exactly would be proportional to N^2. This quadratic dependence on N would restrict severely the study of systems with large particle numbers. Hence, as indicated in (ii)–(iii) we shall provide an alternative expression for the drift on the particles. Ultimately, our analytical calculations summarized in Theorem 2 will imply that this expression is a good approximation as $N,\theta \to \infty$ and $\delta, h(,\tau) \to 0$.

Our starting point is the observation that for a smooth initial state ρ_0 the solution ρ of (1.1) also remains smooth for $t > 0$. Then, for any $t \geq 0$ the empirical measures $\mathbb{X}_N(t)$ of the system (1.2), which converge to $\rho(.,t)$ as $N \to \infty$, cf. [12], [13], should also be smooth in some generalized sense. Continuing this line of reasoning one may suspect that the empirical measures $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)$ associated with the simulation possess some smoothness properties too, at least, if they constitute the desired approximation to $\rho(.,t)$ at all. For this reason, to determine the drift acting on the particles and furthermore the particle density needed for a graphical representation of the simulation results, it should suffice to evaluate the function $y \to (1/N)\sum_{m=1}^N \phi_\theta\big(y - Y^m_{N,\delta,h,\theta(,\tau)}(t)\big)$ in some sufficiently dense discrete subset of $\mathbb{R}^2$.

More precisely, to implement (ii)–(iii) we proceed as follows:

(A) We choose some region $Q \subseteq \mathbb{R}^2$. This region should contain the positions of *most* of the particles during the time interval $[0,T]$ of our considerations. For simplicity we select a rectangle Q. Both Q and also the rectangles $R^1, R^2, \ldots$, which are constructed below in (B) and (C), are half open; i.e., they have the form $[a,b) \times [c,d)$ for suitable $a,b,c,d \in \mathbb{R}$. However, occasionally when considering a single R^m it will be convenient to assume that rectangle to be closed. In particular, the corners A^m, B^m, C^m and D^m, cf. Figure 1, are then contained in R^m. We denote the width of Q in the x_1- (x_2-) direction by w_1 (w_2). The introduction of the bounded set Q is necessary, since the lattices constructed below in (B) and (C) have to be finite.

(B) Within Q a regular, rectangular lattice $\mathcal{L}_0$, which consists of a set of rectangles $R^1,\ldots,R^{|\mathcal{L}_0|}$, whose sides have length $w_1/\lceil w_1/\delta\rceil$ ($w_2/\lceil w_2/\delta\rceil$) in the x_1- (x_2-) direction, is constructed. At any time point ph, when the drift of the particles has to be computed, the *density* $y \to d_{N,\delta,h,\theta(,\tau)}(y,ph) = (1/N)\sum_{m=1}^N \phi_\theta\big(y - Y^m_{N,\delta,h,\theta(,\tau)}(ph)\big)$ is determined both at the vertices of the lattice and the centers of the rectangles R^1, $\ldots, R^{|\mathcal{L}_0|}$. As indicated in Figure 1 the corners and the center of some rectangle R^m are denoted by A^m, B^m, C^m, D^m and M^m, respectively. We suppose that

$$\delta < \delta_0 = \min\{w_1, w_2\}/2, \tag{2.2}$$

in order that $\mathcal{L}_0$ contains a 3×3 submesh.

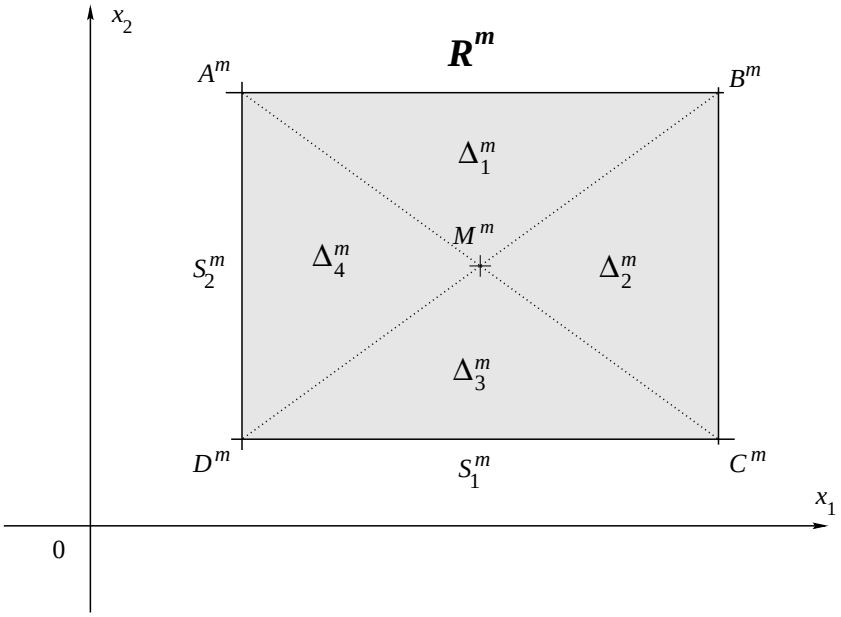

FIG. 1. *A typical rectangle within the mesh in Q.*

(C) For some time ph it may happen that the discretization of the function $y \to d_{N,\delta,h,\theta(,\tau)}(y, ph)$, which is associated with the lattice $\mathcal{L}_0$ as described in (B), is too coarse. In such a situation the above-mentioned local adaption of the mesh size, cf. (ii_a), may be performed. More precisely, the adaption procedure should be started, if in some rectangles the density $d_{N,\delta,h,\theta,\tau}(., ph)$ is not *flat* enough, where *flatness* is measured in terms of $|\nabla^{\otimes 2} d_{N,\delta,h,\theta,\tau}(., ph)|$.

In our situation we have given only the values of the function $d_{N,\delta,h,\theta,\tau}(., ph)$ in some discrete set of points in Q. These values can be utilized to compute for any R^m a quantity $\kappa^m_{N,\delta,h,\theta,\tau}(ph)$ related to $\text{diam}(R^m) \sup_{x \in R^m} |\nabla^{\otimes 2} d_{N,\delta,h,\theta,\tau}(x, ph)|$. For clarity in the present paragraph we defer the detailed description of the determination of $\kappa^m_{N,\delta,h,\theta,\tau}(ph)$ to (E). Employing now the adaption parameter $\tau > 0$ we consider $d_{N,\delta,h,\theta,\tau}(., ph)$ as not flat enough in R^m if

$$|\kappa^m_{N,\delta,h,\theta,\tau}(ph)| > \tau. \tag{2.3}$$

In this way in any rectangle the flatness of $d_{N,\delta,h,\theta,\tau}(., ph)$ is examined, and finally any R^m, where (2.3) holds, is divided into four smaller rectangles having equal scales and the point M^m as a common corner. Next, the density $d_{N,\delta,h,\theta,\tau}(., ph)$ is computed at the centers and those corners of the new rectangles, where it has not yet been calculated during previous calculations referring to time ph. If necessary, i.e., if as a consequence of divisions new rectangles have been created, the discretization of Q is checked again. More precisely, using (2.3) the flatness of $d_{N,\delta,h,\theta,\tau}(., ph)$ within the various rectangles is examined once more and perhaps further rectangles are divided. Continuing with this procedure we finally arrive at some possibly irregular lattice $\mathcal{L}(ph)$, which consists of rectangles $R^1, \ldots, R^{|\mathcal{L}(ph)|}$ and locally may have an appearance as in Figure 2. $\mathcal{L}(ph)$ is *adapted* to the density $d_{N,\delta,h,\theta,\tau}(., ph)$; i.e., the rectangles R^m, $m = 1, \ldots, |\mathcal{L}(ph)|$, constructed by the procedure described above are small enough such that within any R^m the function $y \to d_{N,\delta,h,\theta,\tau}(y, ph)$ is sufficiently

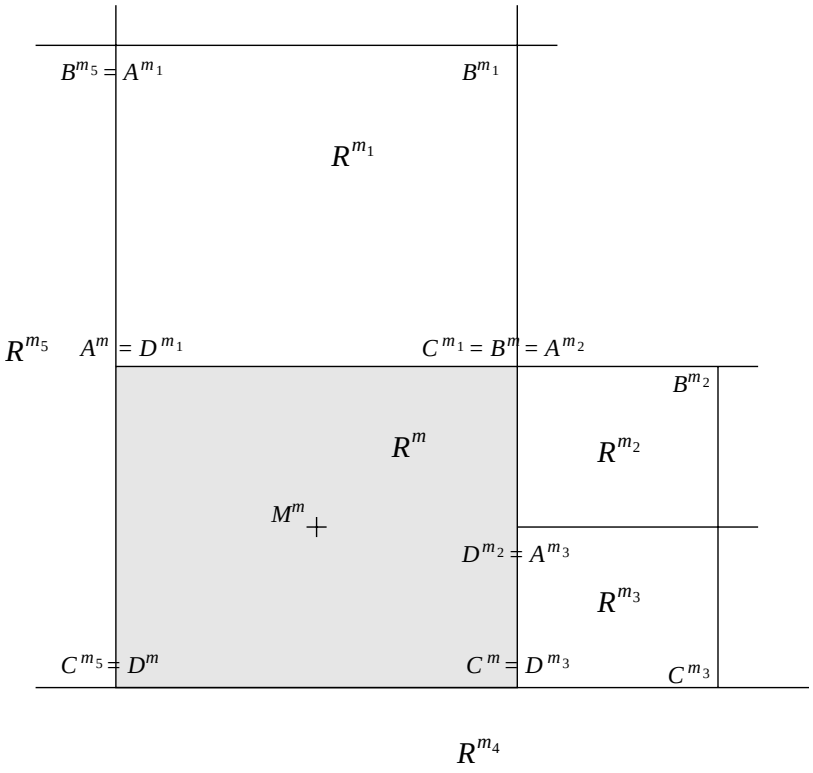

FIG. 2. *Details of a locally refined mesh.*

flat according to the criterion specified by (2.3).

Let

$$S_1^m = B_1^m - A_1^m = C_1^m - D_1^m,$$
$$S_2^m = A_2^m - D_2^m = B_2^m - C_2^m, \quad m = 1, \dots, |\mathcal{L}(ph)|, \tag{2.4}$$

with A_1^m (A_2^m), ... denoting the x_1- (x_2-) coordinate of A^m, ..., be the width of R^m in the x_1- (x_2-) direction. Obviously, the ratios S_1^m/S_2^m, $m = 1, 2, \dots$, coincide for $\mathcal{L}_0$ and equal $w_1\lceil w_2/\delta\rceil/(w_2\lceil w_1/\delta\rceil)$. Furthermore, they are preserved by the subsequent divisions of rectangles described above, and therefore we observe

$$\underline{C}(Q) \le \frac{S_1^m}{S_2^m} \le \overline{C}(Q),\ 0 \le S_1^m,\ S_2^m \le \delta, \quad m = 1, \dots, |\mathcal{L}(ph)|, \tag{2.5}$$

where $\underline{C}(Q), \overline{C}(Q) \in (0, \infty)$ are constants, which depend only on the rectangle Q, i.e., on w_1 and w_2.

(D) For the graphical representation of the *particle density* of the many-particle system defining the particle method the density values at the corners and the centers of the rectangles of the lattice $\mathcal{L}(ph)$, which are calculated by performing (B) and (C), may be used immediately. However, as indicated above in (iii) for the determination of the drift acting on the particles an *interpolation procedure* has to be utilized. To explain the details we fix one particle at position $y_P = Y^k_{N,\delta,h,\theta(,\tau)}(ph)$ at time ph.

If $y_P \notin Q$, where Q is the region introduced in (A), i.e., if y_P is not covered by some rectangle in the lattice $\mathcal{L}(ph)$, then in accordance with (1.2) we define

$$\widehat{D}_{N,\delta,h,\theta(,\tau)}(y_P, ph) = \nabla d_{N,\delta,h,\theta(,\tau)}(y_P, ph) = \frac{1}{N}\sum_{m=1}^{N} \nabla\phi_\theta\big(y_P - Y^m_{N,\delta,h,\theta(,\tau)}(ph)\big). \tag{2.6}$$

If $y_P \in Q$, we first determine the unique rectangle R^m such that $y_P \in R^m$. As shown in Figure 1, R^m is divided into four triangles Δ_1^m, Δ_2^m, Δ_3^m, and Δ_4^m, where these triangles have the corners A^m, B^m, M^m (for Δ_1^m), B^m, C^m, M^m (for Δ_2^m), C^m, D^m, M^m (for Δ_3^m), and D^m, A^m, M^m (for Δ_4^m). We suppose that the points on the diagonals of R^m belong to the respective adjacent triangle on the left and that $M^m \in \Delta_4^m$. For any triangle Δ_r^m the density values at its corners, which are calculated in (B) and (C), are employed to determine the drift acting on particles contained in its interior. For example, if $y_P \in \Delta_1^m$, we may define the vector

$$\widehat{D}_{N,\delta,h,\theta(,\tau)}(y_P, ph) = \begin{pmatrix} \dfrac{d_{N,\delta,h,\theta(,\tau)}(B^m, ph) - d_{N,\delta,h,\theta(,\tau)}(A^m, ph)}{S_1^m} \\ \dfrac{d_{N,\delta,h,\theta(,\tau)}(A^m, ph) + d_{N,\delta,h,\theta(,\tau)}(B^m, ph) - 2d_{N,\delta,h,\theta(,\tau)}(M^m, ph)}{S_2^m} \end{pmatrix}, \tag{2.7}$$

where S_1^m and S_2^m are introduced in (2.4). Obviously, (2.7) characterizes a particular discretization of $\nabla d_{N,\delta,h,\theta(,\tau)}(y_P, ph)$. If $y_P \in \Delta_r^m$, $r = 2, 3, 4$, immediate modifications of (2.7) may be used. For details we refer the reader to (5.1).

For convenience, we do not utilize $\widehat{D}_{N,\delta,h,\theta(,\tau)}$ as defined in (2.6) and (2.7) directly for the determination of the drift acting on the particles but employ a bounded modification. More precisely, we define

$$D_{N,\delta,h,\theta(,\tau)}(y, ph) = \begin{cases} \dfrac{\widehat{D}_{N,\delta,h,\theta(,\tau)}(y, ph)}{|\widehat{D}_{N,\delta,h,\theta(,\tau)}(y, ph)|} \min\{K, |\widehat{D}_{N,\delta,h,\theta(,\tau)}(y, ph)|\}, & \text{if } |\widehat{D}_{N,\delta,h,\theta(,\tau)}(y, ph)| \neq 0, \\ 0 & \text{if } |\widehat{D}_{N,\delta,h,\theta(,\tau)}(y, ph)| = 0, \end{cases} \quad y \in \mathbb{R}^2,\ p = 0, 1, 2, \ldots, \tag{2.8}$$

where the constant $K > 0$ is a suitable upper bound to the drift acting on the particles asymptotically as $N, \theta \to \infty$ and $\delta, h(, \tau) \to 0$; cf. (3.15).

(E) We still have to describe the determination of the quantity $\kappa_{\cdot N,\delta,h,\theta,\tau}(.)$ to complete the discussion in (C) of the adaption of the lattice $\mathcal{L}(.)$ to the local fluctuations of the density $d_{N,\delta,h,\theta,\tau}$. For that aim we suppose that for some fixed time ph after the division of several rectangles in an intermediate step the lattice $\mathcal{L}'(ph)$ has been obtained. Then a fixed rectangle R^m and its environment may look similarly as in Figure 2.

Within R^m the function $d_{N,\delta,h,\theta,\tau}(., ph)$ is given at least in A^m, B^m, C^m, D^m, and M^m, and therefore in any case four independent differences like $d_{N,\delta,h,\theta,\tau}(B^m, ph) - d_{N,\delta,h,\theta,\tau}(A^m, ph)$ or $d_{N,\delta,h,\theta,\tau}(M^m, ph) - d_{N,\delta,h,\theta,\tau}(D^m, ph)$ are available to estimate the five components of $\nabla d_{N,\delta,h,\theta,\tau}(x, ph)$ and $\nabla^{\otimes 2} d_{N,\delta,h,\theta,\tau}(x, ph)$ for $x \in R^m$. Consequently, if not by previous steps in the construction of $\mathcal{L}'(ph)$ sides of R^m have been

divided and thus the values of $d_{N,\delta,h,\theta,\tau}(.,ph)$ at some intermediate points are known, we possibly will also have to take into account some values of $d_{N,\delta,h,\theta,\tau}(.,ph)$ in points of neighboring rectangles to estimate those partial derivatives.

As far as $\nabla d_{N,\delta,h,\theta,\tau}(x,ph)$, $x \in R^m$, is concerned, our approximations are described in (D); cf. (2.7) and also (5.1). Obviously, for those approximations only the values of $d_{N,\delta,h,\theta,\tau}(.,ph)$ in $\{A^m, B^m, C^m, D^m, M^m\}$ are used. They are also sufficient to estimate some particular linear combinations of partial derivatives of second order. More precisely, we obtain

$$
\begin{aligned}
(2.9)\ & (S_1^m)^2\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(x,ph) + (S_2^m)^2\nabla_2\nabla_2 d_{N,\delta,h,\theta,\tau}(x,ph)\\
&\quad \simeq 2\big(d_{N,\delta,h,\theta,\tau}(A^m,ph) + d_{N,\delta,h,\theta,\tau}(B^m,ph)\\
&\qquad + d_{N,\delta,h,\theta,\tau}(C^m,ph) + d_{N,\delta,h,\theta,\tau}(D^m,ph) - 4d_{N,\delta,h,\theta,\tau}(M^m,ph)\big),\\
&S_1^m S_2^m \nabla_1\nabla_2 d_{N,\delta,h,\theta,\tau}(x,ph)\\
&\quad \simeq d_{N,\delta,h,\theta,\tau}(B^m,ph) + d_{N,\delta,h,\theta,\tau}(D^m,ph)\\
&\qquad - d_{N,\delta,h,\theta,\tau}(A^m,ph) - d_{N,\delta,h,\theta,\tau}(C^m,ph), \quad x \in R^m.
\end{aligned}
$$

To justify (2.9) the right sides may be expanded in a Taylor series of second order. Some hints can be found in the proof of Lemma 3.

Contrary to (2.9), in order to approximate the derivatives $\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(.,ph)$ and $\nabla_2\nabla_2 d_{N,\delta,h,\theta,\tau}(.,ph)$ separately $d_{N,\delta,h,\theta,\tau}(.,ph)$-values of some points belonging to neighboring rectangles are possibly needed. Let us consider first the upper boundary of R^m, i.e., the interval $[A^m, B^m]$ between A^m and B^m. It may happen that by previous divisions in $\mathcal{L}'(ph)$ the rectangle above R^m has been divided. Then as a particular consequence, $d_{N,\delta,h,\theta,\tau}((A^m + B^m)/2, ph)$ has been computed. In this case we define

$$
\begin{aligned}
(2.10)\quad K_{1,u}^m = 4\big(&d_{N,\delta,h,\theta,\tau}(A^m,ph)\\
&+ d_{N,\delta,h,\theta,\tau}(B^m,ph) - 2d_{N,\delta,h,\theta,\tau}((A^m + B^m)/2,ph)\big)/(S_1^m)^2
\end{aligned}
$$

as an approximation to $\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(x,ph)$, $x \in [A^m, B^m]$. Otherwise, i.e., if $d_{N,\delta,h,\theta,\tau}((A^m + B^m)/2, ph)$ is not known, we examine the structure of $\mathcal{L}'(ph)$ in the linear continuations of the interval $[A^m, B^m]$ beyond A^m and B^m, respectively. Since the lattice $\mathcal{L}'(ph)$, which represents the present state of refinement of the original lattice $\mathcal{L}_0$, is obtained by several divisions of rectangles as described in (C), either one or both continuations of $[A^m, B^m]$ belong to the respective boundary of another neighboring rectangle in $\mathcal{L}'(ph)$. With $\mathcal{E}_u^m \subseteq \{l, r\}$ we introduce an enumeration of those continuations. We suppose that $l \in \mathcal{E}_u^m$ ($r \in \mathcal{E}_u^m$) if and only if $[A^m, B^m]$ can be extended within $\mathcal{L}'(ph)$ on its left (right) side beyond A^m (B^m). For example, in Figure 2 we have $\mathcal{E}_u^m = \{r\}$ and $\mathcal{E}_u^{m_2} = \{r, l\}$. If $l \in \mathcal{E}_u^m$ ($r \in \mathcal{E}_u^m$), we define $E_{u,l}^m$ ($E_{u,r}^m$) as that vertex in $\mathcal{L}'(ph)$ on the extension of $[A^m, B^m]$ beyond A^m (B^m), whose distance to A^m (B^m) is minimal. In particular, in Figure 2 we get $E_{u,r}^m = B^{m_2}$ and $E_{u,l}^{m_2} = A^m$. We note that $d_{N,\delta,h,\theta,\tau}(E_{u,q}^m, ph)$, $q \in \mathcal{E}_u^m$, has been determined during the previous steps in the construction of $\mathcal{L}'(ph)$. Therefore, we may now introduce

$$K^m_{1,u,l} = \frac{2}{(A^m_1 - E^m_{u,l,1})(B^m_1 - A^m_1)}\Bigg(\frac{B^m_1 - A^m_1}{B^m_1 - E^m_{u,l,1}} d_{N,\delta,h,\theta,\tau}(E^m_{u,l}, ph) + \frac{A^m_1 - E^m_{u,l,1}}{B^m_1 - E^m_{u,l,1}} d_{N,\delta,h,\theta,\tau}(B^m, ph) - d_{N,\delta,h,\theta,\tau}(A^m, ph)\Bigg), \quad \text{if } l \in \mathcal{E}^m_u, \tag{2.11}$$

and

$$K^m_{1,u,r} = \frac{2}{(B^m_1 - A^m_1)(E^m_{u,r,1} - B^m_1)}\Bigg(\frac{E^m_{u,r,1} - B^m_1}{E^m_{u,r,1} - A^m_1} d_{N,\delta,h,\theta,\tau}(A^m, ph) + \frac{B^m_1 - A^m_1}{E^m_{u,r,1} - A^m_1} d_{N,\delta,h,\theta,\tau}(E^m_{u,r}, ph) - d_{N,\delta,h,\theta,\tau}(B^m, ph)\Bigg), \quad \text{if } r \in \mathcal{E}^m_u, \tag{2.12}$$

where $E^m_{u,q,k}$, $k = 1, 2$, denotes the x_k-coordinate of $E^m_{u,q}$, $q \in \mathcal{E}^m_u$. By employing Taylor expansions of second order for $d_{N,\delta,h,\theta,\tau}(., ph)$ at A^m and B^m it may be shown that $K^m_{1,u,l} \simeq \nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(A^m, ph)$ and $K^m_{1,u,r} \simeq \nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(B^m, ph)$, respectively. For details we refer to Lemma 3 and its proof. Consequently, in the case where $d_{N,\delta,h,\theta,\tau}((A^m + B^m)/2, ph)$ is not known we may use $K^m_{1,u,l}$ and $K^m_{1,u,r}$ to introduce an alternative to (2.10), namely

$$K^m_{1,u} = \frac{1}{|\mathcal{E}^m_u|} \sum_{q \in \mathcal{E}^m_u} K^m_{1,u,q}, \tag{2.13}$$

as an approximation to $\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in [A^m, B^m]$.

For the lower boundary of R^m, i.e., the interval $[C^m, D^m]$ between C^m and D^m, we can define a supplement $K^m_{1,l}$ to $K^m_{1,u}$. First, if $d_{N,\delta,h,\theta,\tau}((C^m + D^m)/2, ph)$ has been determined during previous calculations, an obvious modification of (2.10) may be used. Otherwise, the considerations leading to (2.13) have to be transferred from $[A^m, B^m]$ to $[C^m, D^m]$. More precisely, in a study of the continuations of $[C^m, D^m]$ beyond C^m and D^m we have to introduce the set $\mathcal{E}^m_l$, and then, similarly as in (2.11) and (2.12), we have to define $K^m_{1,l,q}$, $q \in \mathcal{E}^m_l$, such that finally an analogue of (2.13) for an approximation $K^m_{1,l}$ for $\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in [C^m, D^m]$, is obtained.

Now, with

$$K^m_1 = \frac{1}{2}(K^m_{1,u} + K^m_{1,l}) \tag{2.14}$$

an approximation to $\nabla_1\nabla_1 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in R^m$, can be defined.

Next, the considerations leading to (2.14) may be "rotated by $\pi/2$" to deduce quite analogously an approximation K^m_2 to $\nabla_2\nabla_2 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in R^m$.

For the definition of $\kappa^m_{N,\delta,h,\theta,\tau}(ph)$, which is employed in (C) to quantify *flatness* of $d_{N,\delta,h,\theta,\tau}(., ph)$ in R^m, we do not utilize approximations like K^m_1 or K^m_2 for spatial derivatives of second order of $d_{N,\delta,h,\theta,\tau}(., ph)$ in R^m directly but instead use a suitable upper bound for such approximations. Taking into account (2.10)–(2.14) and also their modifications, which refer to the intervals $[B^m, C^m]$, $[C^m, D^m]$, $[D^m, A^m]$ and have not been written down explicitly, we therefore introduce further definitions.

First, by $\mathcal{X}_1^m$ we denote the set of those intervals $\eta \in \mathcal{I} = \{[A^m, B^m], [B^m, C^m], [C^m, D^m], [D^m, A^m]\}$ such that during previous divisions of some rectangles in the neighborhood of R^m we have determined $d_{N,\delta,h,\theta,\tau}(M_\eta, ph)$ with M_η denoting the center of η. Let P_η and E_η be the endpoints of η. Next, by $\mathcal{X}_2^m$ we denote the set of all linear continuations of intervals in $\mathcal{I} \setminus \mathcal{X}_1^m$ beyond their respective endpoints, which belong to the boundary of a neighboring rectangle. Associated with any $\eta \in \mathcal{X}_2^m$ is a set $\Theta_\eta = \{P_\eta, M_\eta, E_\eta\}$ of three points such that P_η and M_η are neighboring corners of R^m, η is an extension of $[P_\eta, M_\eta]$ beyond M_η, and E_η is lying outside R^m but is contained both in η and $\mathcal{L}'(ph)$ with minimal distance to R^m. In the end we obtain for any R^m a set $\mathcal{X}^m = \mathcal{X}_1^m \cup \mathcal{X}_2^m$ with a set $\Theta_\eta = \{P_\eta, M_\eta, E_\eta\}$ of vertices in $\mathcal{L}'(ph)$ for any $\eta \in \mathcal{X}^m$.

Following (2.10)–(2.12) we then define

$$K_\eta = \frac{1}{|P_\eta - M_\eta||M_\eta - E_\eta|} \left| \frac{|M_\eta - E_\eta|}{|P_\eta - E_\eta|} d_{N,\delta,h,\theta,\tau}(P_\eta, ph) + \frac{|P_\eta - M_\eta|}{|P_\eta - E_\eta|} d_{N,\delta,h,\theta,\tau}(E_\eta, ph) - d_{N,\delta,h,\theta,\tau}(M_\eta, ph) \right|, \quad \eta \in \mathcal{X}^m. \tag{2.15}$$

These quantities K_η, $\eta \in \mathcal{X}^m$, may be combined with an analogous estimate for the approximation to $\nabla_1 \nabla_2 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in R^m$, given by (2.9). Consequently, we are directed to the definition

$$\kappa^m_{N,\delta,h,\theta,\tau}(ph) = \left(\frac{1}{S_1^m S_2^m} \big| d_{N,\delta,h,\theta,\tau}(A^m, ph) + d_{N,\delta,h,\theta,\tau}(C^m, ph) - d_{N,\delta,h,\theta,\tau}(B^m, ph) - d_{N,\delta,h,\theta,\tau}(D^m, ph) \big| + \sum_{\eta \in \mathcal{X}^m} K_\eta \right) \sqrt{S_1^m S_2^m}, \quad m = 1, \ldots, |\mathcal{L}'(ph)|. \tag{2.16}$$

With $\kappa^m_{N,\delta,h,\theta,\tau}(ph)$ we have provided the desired quantity to estimate flatness of $d_{N,\delta,h,\theta,\tau}(., ph)$ within R^m. Its use in a procedure to obtain a mesh $\mathcal{L}(ph)$, which is adapted to the local density fluctuations of $d_{N,\delta,h,\theta,\tau}(., ph)$ in Q, is explained in (C).

Remark 1. (i) The definition (2.16) of $\kappa^m_{N,\delta,h,\theta,\tau}(.)$ is symmetric; i.e., any corner of R^m and any direction is considered in the same way. However, to obtain the rate of convergence given by the right side of (3.24) in Theorem 2(b) with a possibly different $C(T)$ it would suffice to include in (2.16) instead of $\sum_{\eta \in \mathcal{X}^m} K_\eta$ only two terms accounting for the x_1- and x_2-direction, respectively. In particular, these terms would provide suitable upper bounds to approximations of $\nabla_1 \nabla_1 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in R^m$, and $\nabla_2 \nabla_2 d_{N,\delta,h,\theta,\tau}(x, ph)$, $x \in R^m$, which are needed in connection with the second part of Lemma 3.

(ii) Obviously, the choice of the region Q, which is that part of $\mathbb{R}^2$ where our simulation procedure may be characterized as a *particle-mesh method*, has a considerable influence on the expenses for the computations. In particular, if Q is large, it is left by only a few particles, and therefore for the determination of their drift only a small number of extensive summations as in (2.6) has to be performed. On the other hand, for any time ph the number of mesh points, where $d_{N,\delta,h,\theta(,\tau)}(., ph)$ has to be determined, being $\sim |\mathcal{L}(ph)|$ gets large with Q. For the determination of a convenient region Q we have not performed rigorous considerations but rely on some heuristic arguments. For details we refer to Remark 3(vi) in section 3.

(iii) The restriction (2.2) on the spatial discretization parameter δ ensures that $\mathcal{L}_0$ contains at least three mesh points in each direction. This is a necessary require-

ment in order that the adaption step described by (C) and (E) can be performed, in particular since only in this case sets like $\mathcal{E}_u^m$, which are introduced in the paragraph after (2.10), are always nonempty.

Having specified at some fixed time ph the negative drift acting on the respective particles according to (2.6)–(2.8) we may finally determine the particle positions at time $ph+h$ by following an Euler scheme; cf. (i). In particular, we may define

$$Y^k_{N,\delta,h,\theta(,\tau)}(ph+h) = Y^k_{N,\delta,h,\theta(,\tau)}(ph) - hD_{N,\delta,h,\theta(,\tau)}\big(Y^k_{N,\delta,h,\theta(,\tau)}(ph), ph\big) + \sqrt{h}Z^{k,p}, \quad k=1,\dots,N, \tag{2.17}$$

where $Z^{k,p}$, $k=1,\dots,N$, $p=0,1,2,\dots$, are independent $\mathbb{R}^2$-valued *Gaussian* random variables with mean 0 and variance 1. To justify (2.17) we remark that the random vector $(\sqrt{h}Z^{1,p},\dots,\sqrt{h}Z^{N,p})$ has the same distribution as $\big(W^1(ph+h) - W^1(ph),\dots,W^N(ph+h) - W^N(ph)\big)$, which describes the increments in the time interval $[ph, ph+h)$ of the Brownian motions $W^1,\dots,W^N$ appearing in (1.2).

The crucial ideas to discretize (1.2) are formulated in (i)–(iii), where the details of (ii)–(iii) can be found in (A)–(E). In short form the resulting procedure may be summarized as follows:

(0) First, as a domain, which may be regarded as the essential living space of the population of particles under consideration, some rectangle Q is chosen. Then, as discretization parameters the number N of particles, the mesh size $\delta \in (0,\delta_0)$ and the time step $h>0$ are selected. Moreover, $\theta>1$ is used as scaling parameter for the interaction, and some $\tau>0$ is introduced, if the adaption of the mesh should be performed.

(1) We determine suitable initial positions $Y^k_{N,\delta,h,\theta(,\tau)}(0)$, $k=1,\dots,N$, such that the initial population density $\rho(.,0)=\rho_0$ of the limit system (1.1) is *approximated* by the empirical measure $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0) = (1/N)\sum_{k=1}^N \delta_{Y^k_{N,\delta,h,\theta(,\tau)}(0)}$. Some hints on the choice of these initial positions can be found in Remark 3(iii) in section 3.

(2) For any time point ph, $p=0,1,2,\dots$, we first determine the population density at the points of some sufficiently fine mesh $\mathcal{L}(ph)$ in Q, cf. (B), (C), in the course of which the adaption procedure (C), (E) may also be performed. Next, following (D), cf. (2.6)–(2.8), we compute the negative drift acting on the respective particles. Finally, the new particle positions at time $ph+h$ are fixed according to (2.17).

(3) For sufficiently many time points the values of the population density at the corners and centers of the rectangles of the respective lattice $\mathcal{L}(ph)$ are saved in some file. These values can be used for a graphical representation of the simulation results.

Of course, for the computer simulations the particle positions $Y^k_{N,\delta,h,\theta(,\tau)}(t)$, $k=1,\dots,N$, need to be defined only for time points t in the discrete set $\mathcal{T}_h$. However, for our subsequent considerations, where the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ are compared analytically with processes in continuous time, it will be convenient to define $Y^k_{N,\delta,h,\theta(,\tau)}(t)$ for any $t\ge 0$. For that purpose, we extend the system (2.17) of *stochastic difference equations* to some system of *stochastic differential equations*, namely

$$Y^k_{N,\delta,h,\theta(,\tau)}(t) = Y^k_{N,\delta,h,\theta(,\tau)}(0) - \int_0^t ds\ D_{N,\delta,h,\theta(,\tau)}\big(Y^k_{N,\delta,h,\theta(,\tau)}(\lfloor s\rfloor_h), \lfloor s\rfloor_h\big) + W^k(t), \tag{2.18}$$

$$k = 1, \dots, N,\ t \geq 0,\ \delta \in (0, \delta_0),\ h > 0,\ \theta > 1,\ (\tau > 0,)\ N \in \mathbb{N}.$$

As we have indicated by our notation, the respective solutions $(Y^1_{N,\delta,h,\theta(,\tau)}(t), \dots, Y^N_{N,\delta,h,\theta(,\tau)}(t))$ of (2.17) and (2.18) coincide in distribution for $t \in \mathcal{T}_h$. This is fairly obvious, since in (2.18) the drift $-D_{N,\delta,h,\theta(,\tau)}$ acting on the particles remains constant between two successive time points $ph, ph + h \in \mathcal{T}_h$ and equals the "drift" at time ph in the system (2.17), and since the increments of the Brownian motions $W^k(ph + h) - W^k(ph)$ in (2.18) have the same law as the random variables $\sqrt{h}Z^{k,p}$ appearing in (2.17).

Now, with (2.18) definition (2.1) of the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)$ can be extended from $t \in \mathcal{T}_h$ to any $t \geq 0$. In our analytical investigation of the procedure sketched by (0)–(3) we shall study the convergence of those empirical processes in continuous time to the solution ρ of (1.1) in the limit as $N, \theta \to \infty$ and $\delta, h(, \tau) \to 0$. As a consequence of several similarities between (1.2) and (2.18) we can rely in these considerations on some ideas from [13]. Of course, the fact that in (2.18) the drift is determined by discretizing the gradient $(y, t) \to (1/N) \sum_{m=1}^N \nabla\phi_\theta(y - Y^m_{N,\delta,h,\theta(,\tau)}(t))$ of the population density both in space and time will lead to new problems, which did not appear in [13].

3. Results. In this section we first collect some assumptions, in particular on the kernel ϕ_1 and the initial state ρ_0 of the solution ρ of (1.1). Next, we shall describe the family ρ_θ, $\theta > 1$, of auxiliary functions, which had been mentioned in section 1. Finally, our main results and some supplementary remarks are presented.

3.1. Technical preliminaries. According to (1.8) the function ϕ_1 can be considered as the basis of the family of interaction kernels ϕ_θ, $\theta > 1$. Moreover, as indicated in section 1 these interaction kernels are used to regularize the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$, $N \in \mathbb{N}$, $\delta \in (0, \delta_0)$, $h > 0$, $\theta > 1(, \tau > 0)$. In view of those applications (1.5) has to be supplemented by various other assumptions on ϕ_1.

First, ϕ_1 is supposed to be a convolution product

$$\phi_1 = \phi_1^r * \phi_1^r, \tag{3.1}$$

where ϕ_1^r is a smooth, symmetric probability density, i.e.,

$$\phi_1^r \in C_b^1(\mathbb{R}^2), \quad \phi_1^r \geq 0, \quad \int_{\mathbb{R}^2} dx\ \phi_1^r(x) = 1, \quad \phi_1^r(x) = \phi_1^r(-x),\ x \in \mathbb{R}^2. \tag{3.2}$$

As far as smoothness properties of ϕ_1^r are concerned, we also need

$$\widetilde{\phi_1^r} \in C_b^2(\mathbb{R}^2), \qquad \int_{\mathbb{R}^2} dx\ |\nabla\phi_1^r(x)|^2 < \infty. \tag{3.3}$$

Functions related to ϕ_1^r are defined by

$$U_{k_1,k_2}(x) = (-1)^{k_1+k_2} \frac{x_1^{k_1} x_2^{k_2}}{k_1! k_2!} \phi_1^r(x), \qquad k_1, k_2 = 0, 1, \dots, \overline{k},\ k_1 + k_2 \leq \overline{k},\ x \in \mathbb{R}^2, \tag{3.4}$$

where

$$\overline{k} = 2. \tag{3.5}$$

They are supposed to satisfy

$$\left|\widetilde{U_{k_1,k_2}}(\lambda)\right| \le C\left|\widetilde{\phi_1^r}(\lambda)\right|, \quad k_1,k_2=0,1,\dots,\overline{k}-1,\ 1\le k_1+k_2\le\overline{k}-1,\ \lambda\in\mathbb{R}^2, \tag{3.6}$$

and

$$|U_{k_1,k_2}(x)| \le C\left(\frac{1}{1+|x|^3}\right)^{1/2}, \quad k_1,k_2=0,1,\dots,\overline{k},\ k_1+k_2=\overline{k},\ x\in\mathbb{R}^2. \tag{3.7}$$

Furthermore, we assume that ϕ_1 has bounded moments of all orders, i.e.,

$$\int_{\mathbb{R}^2} dx\ |x|^m\phi_1(x)<\infty, \quad m=1,2,\dots. \tag{3.8}$$

To regularize the empirical processes we shall use functions which are obtained from ϕ_1^r by the scaling (1.8), namely

$$\phi_\theta^r(x)=\theta^2\phi_1^r(\theta x), \quad x\in\mathbb{R}^2,\ \theta>1. \tag{3.9}$$

Obviously, modifications of (3.1) and (3.2) also hold for these functions, i.e.,

$$\phi_\theta=\phi_\theta^r*\phi_\theta^r, \tag{3.10}$$
$$\phi_\theta^r\in C_b^1(\mathbb{R}^2),\ \phi_\theta^r\ge 0,\ \int_{\mathbb{R}^2} dx\ \phi_\theta^r(x)=1,\ \phi_\theta^r(x)=\phi_\theta^r(-x),\ x\in\mathbb{R}^2,\quad \theta>1.$$

Moreover, by (1.5), (1.8), (3.2), and (3.9) the kernels ϕ_θ and ϕ_θ^r satisfy

$$\lim_{\theta\to\infty}\phi_\theta=\lim_{\theta\to\infty}\phi_\theta^r=\delta_0 \quad \text{in } \mathcal{S}'(\mathbb{R}^2). \tag{3.11}$$

In particular, by (3.11) the study of the limit behavior of the function $(x,t)\to(\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)*\phi_\theta^r)(x)$, $x\in\mathbb{R}^2$, $0\le t\le T$, in order to obtain information on the asymptotics of $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ as $N,\theta\to\infty$, $\delta,h(,\tau)\to 0$ is justified.

As a consequence of (3.1), (3.3), (3.9), and (3.10) we furthermore deduce with

$$\phi_1\in C_b^2(\mathbb{R}^2), \qquad \phi_\theta\in C_b^2(\mathbb{R}^2),\ \theta>1, \tag{3.12}$$

a strengthening of the first relation in (1.5). The remaining parts of (1.5) are obvious consequences of (3.1) and (3.2).

Remark 2. Similarly as in our analytical investigations of moderately interacting many-particle systems [12], [13], [14], [15], [16] the *factorization property* (3.1) will be needed to transfer crucial parts of the study of the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ to an L^2-context, where the attention is drawn to the functions $(x,t)\to(\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)*\phi_\theta^r)(x)$. For that purpose the assumption that ϕ_1^r and therefore also ϕ_θ^r is a symmetric probability density, cf. (3.2), (3.10), is essential. The remaining assumptions about ϕ_1 and ϕ_1^r are technical and needed only to deduce various estimates. We note that (3.2)–(3.8) are satisfied, in particular, if $\phi_1^r=C(-\Delta+1)^{-n}$, $n=2,3,\dots$, where C is a suitable constant.

Next, we suppose that the initial state ρ_0 of the limit process ρ is a smooth probability density, i.e.,

$$\rho_0\ge 0, \qquad \int_{\mathbb{R}^2} dx\ \rho_0(x)=1, \qquad \|\rho_0\|_{(m,1)}<\infty,\ m=0,1,2,\dots, \tag{3.13}$$

where the norms $\|.\|_{(m,1)}$, $m = 0, 1, 2, \ldots$, are introduced in (1.9).

We note that the limit dynamics (1.1) represents a simple nonlinear parabolic problem, which may be handled quite well by classical methods; cf. Remark (i) in [17, section 2]. In particular, (3.13) implies

$$\rho(.,t) \geq 0, \quad \int_{\mathbb{R}^2} dx\ \rho(x,t) = 1, \qquad t \geq 0, \tag{3.14}$$
$$\rho \in C_b^\infty\big(\mathbb{R}^2 \times [0,T]\big), \qquad \sup_{t \leq T} \|\rho(.,t)\|_{(m)} < \infty,\ m = 0, 1, 2, \ldots.$$

In (2.8) the constant K is introduced as upper bound for the absolute value of the drift acting on the particles in the many-particle system (2.17) or (2.18). The convergence $\lim_{N,\theta \to \infty,\ \delta,h(,\tau) \to 0} \mathbb{Y}_{N,\delta,h,\theta(,\tau)} = \rho$ of course can only be expected if K is also in this limit an upper bound to the drift. This is guaranteed, for example, if K satisfies

$$\sup_{t \leq T}\ \|\nabla \rho(.,t)\|_\infty + 1 < K. \tag{3.15}$$

We note that the left side of (3.15) is finite as a consequence of (3.14). We also mention that the interpretation of $-\nabla\rho(.,t)$ as *drift* is an immediate consequence of the fact that (1.1) may be considered as a *Fokker–Planck equation*.

As indicated in section 1 we have to take care of the range of the interaction in the various dynamical systems appearing in this paper. In particular, many-particle systems like (1.2) or its analogues conceived for computer simulations like (2.17) or (2.18) and the partial differential equation (1.1) differ in their range of interaction. By (1.3) the range in the system (1.2) is $O(\theta_N^{-1})$, and by (1.8) and the construction of $D_{N,\delta,h,\theta(,\tau)}$ in section 2 the systems (2.17) and (2.18) have a range of order $O(\theta^{-1})$. Hence, in (1.2) and (2.17) or (2.18) the interaction has strictly positive range for any $N \in \mathbb{N}$, $\delta \in (0, \delta_0)$, $h > 0$, $\theta > 1$ (and $\tau > 0$). On the other hand, in the partial differential equation (1.1) the interaction is strictly local; i.e., its range is 0. This essential difference in the structure of the many-particle systems and their limit, respectively, will lead to difficulties when the *distance* between $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ and ρ is studied analytically. For this reason we introduce as an auxiliary tool a family of deterministic functions ρ_θ, $\theta > 1$, whose time evolutions are governed by an interaction similar as in the many-particle systems (1.2), (2.17), or (2.18), and which furthermore are approximating the limit ρ as $\theta \to \infty$. In particular, we define ρ_θ as the solution of the integro-differential equation

$$\partial_t \rho_\theta = \frac{1}{2}\Delta\rho_\theta + \nabla \cdot \big(\rho_\theta \nabla(\rho_\theta * \phi_\theta)\big), \qquad \rho_\theta(.,0) = \rho_0, \tag{3.16}$$

where ϕ_θ is the interaction kernel employed in (2.17) or (2.18), and ρ_0 coincides with the initial state of ρ; cf. (1.1).

By (3.11) the *formal* convergence of ρ_θ to the solution ρ of (1.1) is quite obvious. The convergence can be stated rigorously, also quantitatively, and additional regularity properties, which hold uniformly in θ, can be deduced; cf. Theorem 3 in [17]. In particular, for any $\theta > \theta_0$, where $\theta_0 = \theta_0(T)$ is sufficiently large, there exists a unique solution $\rho_\theta \in C_b^\infty(\mathbb{R}^2 \times [0,T])$ of (3.16), which satisfies

$$\rho_\theta(.,t) \geq 0, \quad \int_{\mathbb{R}^2} dx\ \rho_\theta(x,t) = 1, \qquad t \leq T,\ \theta > \theta_0, \tag{3.17}$$

$$\sup_{t\le T,\theta>\theta_0} \|\rho_\theta(.,t)\|_{(m,1)} < \infty, \quad m = 0,1,2,\dots,$$
$$\sup_{x\in\mathbb{R}^2,t\le T,\theta>\theta_0} |\nabla^{\otimes m}\partial_t^k \rho_\theta(x,t)| < \infty, \quad m,k = 0,1,2,\dots,$$

and

$$\sup_{x\in\mathbb{R}^2,t\le T,\theta>\theta_0} \theta^2|\nabla^{\otimes m}\partial_t^k(\rho_\theta(x,t)-\rho(x,t))| < \infty, \quad m,k = 0,1,2,\dots. \tag{3.18}$$

We note that the conditions (3.1), (3.2), (3.8), and (3.13) are employed in [17, Theorem 3], to verify (3.17) and (3.18).

In particular, possibly after increasing θ_0, the relations (3.15) and (3.18) imply

$$\sup_{t\le T,\theta>\theta_0} \|\nabla\rho_\theta(.,t)\|_\infty < K. \tag{3.19}$$

So far the parameters N, δ, h, θ (and τ) have been considered as independent. However, the convergence $\lim_{N,\theta\to\infty,\ \delta,h\to 0} \mathbb{Y}_{N,\delta,h,\theta} = \rho$ or $\lim_{N,\theta\to\infty,\ \delta,h,\tau\to 0} \mathbb{Y}_{N,\delta,h,\theta,\tau} = \rho$ can only be expected when certain relations for these parameters hold. For example, the mesh size δ has to be much smaller than the interaction range θ^{-1}. In this context, we introduce some particular sets

$$\begin{aligned}\mathcal{P}_1 &= \big\{(N,\delta,h,\theta)\in\mathbb{N}\times(0,\delta_0)\times(0,\infty)\times(\theta_0,\infty) : (\delta^2+h)\theta^8 < \overline{C}\big\},\\ \mathcal{P}_2 &= \big\{(N,\delta,h,\theta,\tau)\in\mathbb{N}\times(0,\delta_0)\times(0,\infty)\times(\theta_0,\infty)\times(0,\infty) :\\ &\qquad\qquad \tau^2 + h\theta^8 + \delta^4\theta^{10} < \overline{C}\big\},\end{aligned} \tag{3.20}$$

where $\overline{C}$ is some arbitrary but fixed constant. Obviously, in order that the parameters N, δ, h, θ (and τ) stay in these sets, θ may grow only slowly as $\delta, h \to 0$.

3.2. Results and supplementary remarks. By (3.18) the convergence of ρ_θ to ρ as $\theta\to\infty$ is specified quite precisely. Hence, as a crucial part of our considerations we have to study the distance between $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ and ρ_θ. A result sufficient for our purposes is given by the following proposition.

PROPOSITION 1. *For any $N\in\mathbb{N}$, $\delta\in(0,\delta_0)$, $h>0$, $\theta>\theta_0$ (and $\tau>0$) we consider the solution ρ_θ of* (3.16) *and also the many-particle system as described in section* 2. *We emphasize that the positions $Y^k_{N,\delta,h,\theta(,\tau)}(t)$, $0\le t\le T$, $k=1,\dots,N$, of the particles of that many-particle system solve* (2.17) *or* (2.18)*, where the negative drift $D_{N,\delta,h,\theta(,\tau)}$ is determined according to the particular discretization procedure summarized essentially by* (2.6)–(2.8). *The associated empirical process $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ is introduced in* (2.1). *Moreover, the constants δ_0, θ_0, and K are characterized in* (2.2) *and the last part of section* 3.1*, respectively.*

We assume that the interaction kernels ϕ_θ, $\theta>\theta_0$, which determine the time evolution of the many-particle system and the solution of (3.16)*, satisfy* (1.8) *and* (3.1)–(3.8). *Furthermore, for the initial state ρ_0 of ρ and ρ_θ, $\theta>\theta_0$, the regularity properties* (3.13) *are supposed to hold. Then, the distance between $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ and ρ_θ may be estimated as follows.*

(a) *If the adaption step* (C) *in section* 2 *is not performed, we get*

$$\begin{aligned}\mathbb{E}\bigg[\sup_{t\le T}\|(\mathbb{Y}_{N,\delta,h,\theta}(t)-\rho_\theta(.,t))*\phi_\theta^r\|_2^2 + \int_0^T dt\ \|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(t)-\rho_\theta(.,t))*\phi_\theta^r)\|_2^2\bigg]\\ \le C(T)\left(\mathbb{E}\big[\|(\mathbb{Y}_{N,\delta,h,\theta}(0)-\rho_0)*\phi_\theta^r\|_2^2\big] + \frac{\theta^4}{N} + (\delta^2+h)\theta^8 + \theta^{2(1-\overline{k})}\right),\\ (N,\delta,h,\theta)\in\mathcal{P}_1.\end{aligned} \tag{3.21}$$

(b) *If the adaption step* (C) *in section* 2 *is included, we deduce*

$$\mathbb{E}\Big[\sup_{t\le T}\|(\mathbb{Y}_{N,\delta,h,\theta,\tau}(t)-\rho_\theta(.,t))*\phi_\theta^r\|_2^2+\int_0^T dt\ \|\nabla((\mathbb{Y}_{N,\delta,h,\theta,\tau}(t)-\rho_\theta(.,t))*\phi_\theta^r)\|_2^2\Big]$$
$$\le C(T)\Big(\mathbb{E}\big[\|(\mathbb{Y}_{N,\delta,h,\theta,\tau}(0)-\rho_0)*\phi_\theta^r\|_2^2\big]+\frac{\theta^4}{N}+\delta^4\theta^{10}+\tau^2+h\theta^8+\theta^{2(1-\overline{k})}\Big),$$
$$(N,\delta,h,\theta,\tau)\in\mathcal{P}_2. \tag{3.22}$$

By Proposition 1 and estimates for $\|\rho(.,t)-\rho_\theta(.,t)\|_2^2$ and $\|\rho_\theta(.,t)-\rho_\theta(.,t)*\phi_\theta^r\|_2^2$, which are provided by (3.17), (3.18) and Lemma 4, we may now quite easily deduce our main estimates.

THEOREM 2. *Let us consider the same situation as in Proposition* 1. *Then, the distance between* $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ *and* ρ *may be estimated as follows.*

(a) *If the adaption step* (C) *in section* 2 *is not performed, we get*

$$\mathbb{E}\Big[\sup_{t\le T}\|\mathbb{Y}_{N,\delta,h,\theta}(t)*\phi_\theta^r-\rho(.,t)\|_2^2+\int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta}(t)*\phi_\theta^r-\rho(.,t))\|_2^2\Big] \tag{3.23}$$
$$\le C(T)\left(\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta}(0)*\phi_\theta^r-\rho_0\|_2^2\big]+\frac{\theta^4}{N}+(\delta^2+h)\theta^8+\theta^{-2}\right),$$
$$(N,\delta,h,\theta)\in\mathcal{P}_1.$$

(b) *If the adaption step* (C) *in section* 2 *is included, we deduce*

$$\mathbb{E}\Big[\sup_{t\le T}\|\mathbb{Y}_{N,\delta,h,\theta,\tau}(t)*\phi_\theta^r-\rho(.,t)\|_2^2+\int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta,\tau}(t)*\phi_\theta^r-\rho(.,t))\|_2^2\Big] \tag{3.24}$$
$$\le C(T)\left(\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta,\tau}(0)*\phi_\theta^r-\rho_0\|_2^2\big]+\frac{\theta^4}{N}+\delta^4\theta^{10}+\tau^2+h\theta^8+\theta^{-2}\right),$$
$$(N,\delta,h,\theta,\tau)\in\mathcal{P}_2.$$

Remark 3. (i) The right sides of related estimates in Proposition 1 and Theorem 2 essentially coincide, since for any $t\ge 0$ the convergence $\lim_{\theta\to\infty}\rho_\theta(.,t)*\phi_\theta^r=\rho(.,t)$ is fast in comparison to the convergence $\lim_{N,\theta\to\infty,\ \delta,h(,\tau)\to 0}(\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)-\rho_\theta(.,t))*\phi_\theta^r=0$.

The factor $1/N$ on the right sides of (3.21)–(3.24) corresponds to the usual $1/\sqrt{N}$-dependence of the *distance* between some deterministic object and its *Monte-Carlo simulation* involving N quantities, which are stochastically independent.

(ii) As a consequence of the scaling relations (1.8) and (3.9) the diameters of the respective *supports* of the kernels ϕ_θ and ϕ_θ^r decrease with the same order $O(\theta^{-1})$ as $\theta\to\infty$. Here, we have to define "support" in a generalized sense, e.g., as the set of those points in $\mathbb{R}^2$, whose distance to the mean 0 of the probability densities ϕ_θ or ϕ_θ^r is less than the respective *standard error*. Hence, since the function ρ is smooth, cf. (3.14), Theorem 2 demonstrates that in our situation on the scale of its range of interaction, which obviously may be identified with the diameter of the support of ϕ_θ, the many-particle system (2.17) or (2.18) behaves regularly; i.e., the *interaction force* acting on the particles does not exhibit extreme *fluctuations*. In retrospect, this observation is a justification of the discretization step (B) and the subsequent interpolation step (D) in section 2.

(iii) In a simple method the initial positions $Y^k_{N,\delta,h,\theta(,\tau)}(0)$, $k=1,\dots,N$, of the particles may be chosen as independently and identically distributed (i.i.d.) random

variables in $\mathbb{R}^2$ with density ρ_0. By (3.10) we then obtain

$$\begin{aligned}
&\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0) * \phi_\theta^r - \rho_0\|_2^2\big] \\
&\quad = \mathbb{E}\big[\langle \mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0), \mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0) * \phi_\theta\rangle\big] - 2\mathbb{E}\big[\langle \mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0), \rho_0 * \phi_\theta^r\rangle\big] + \|\rho_0\|_2^2 \\
&\quad = \frac{1}{N^2}\sum_{k,l=1}^{N} \mathbb{E}\big[\phi_\theta\big(Y^k_{N,\delta,h,\theta(,\tau)}(0) - Y^l_{N,\delta,h,\theta(,\tau)}(0)\big)\big] \\
&\qquad - \frac{2}{N}\sum_{k=1}^{N} \mathbb{E}\big[(\rho_0 * \phi_\theta^r)\big(Y^k_{N,\delta,h,\theta(,\tau)}(0)\big)\big] + \|\rho_0\|_2^2 \\
&\quad = \frac{N(N-1)}{N^2}\int_{\mathbb{R}^2} dx \int_{\mathbb{R}^2} dy\ \rho_0(x)\rho_0(y)\phi_\theta(x-y) + \frac{1}{N}\phi_\theta(0) \\
&\qquad - 2\int_{\mathbb{R}^2} dx\ \rho_0(x)(\rho_0 * \phi_\theta^r)(x) + \|\rho_0\|_2^2 \\
&\quad = \frac{N-1}{N}\|\rho_0 * \phi_\theta^r\|_2^2 + \frac{1}{N}\phi_\theta(0) - 2\langle \rho_0, \rho_0 * \phi_\theta^r\rangle + \|\rho_0\|_2^2 \\
&\quad = \|\rho_0 * \phi_\theta^r - \rho_0\|_2^2 - \frac{1}{N}\|\rho_0 * \phi_\theta^r\|_2^2 + \frac{1}{N}\phi_\theta(0).
\end{aligned}$$

Consequently, (3.2), (3.3), (3.9), (3.13), and Lemma 4 imply

$$\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(0) * \phi_\theta^r - \rho_0\|_2^2\big] \le C\left(\theta^{-4} + \frac{\theta^2}{N}\right). \tag{3.25}$$

Since $N, \theta \ge 1$, we observe that for this particular choice of the initial positions of the particles (3.23) may be replaced by

$$\begin{aligned}
\mathbb{E}\bigg[\sup_{t\le T}\|\mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r - \rho(.,t)\|_2^2 + \int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r - \rho(.,t))\|_2^2\bigg] \\
\le C(T)\Big(\frac{\theta^4}{N} + (\delta^2 + h)\theta^8 + \theta^{-2}\Big), \quad (N,\delta,h,\theta) \in \mathcal{P}_1,
\end{aligned} \tag{3.26}$$

and that (3.24) turns into

$$\begin{aligned}
\mathbb{E}\bigg[\sup_{t\le T}\|\mathbb{Y}_{N,\delta,h,\theta,\tau}(t) * \phi_\theta^r - \rho(.,t)\|_2^2 + \int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta,\tau}(t) * \phi_\theta^r - \rho(.,t))\|_2^2\bigg] \\
\le C(T)\left(\frac{\theta^4}{N} + \delta^4\theta^{10} + \tau^2 + h\theta^8 + \theta^{-2}\right), \quad (N,\delta,h,\theta,\tau) \in \mathcal{P}_2.
\end{aligned} \tag{3.27}$$

These considerations demonstrate that in the present situation an optimized choice of the initial particle positions, e.g., by employing so-called *low-discrepancy methods*, cf. [11], does not lead to an improvement of the final bound for $\mathbb{E}\big[\sup_{t\le T}\|\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t) * \phi_\theta^r - \rho(.,t)\|_2^2 + \int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t) * \phi_\theta^r - \rho(.,t))\|_2^2\big]$.

(iv) Obviously, the CPU-time for the simulation of our many-particle system increases with decreasing δ, h, and τ and increasing N. Moreover, the various terms on the right sides of (3.23), (3.24), (3.26), and (3.27) exhibit opposing monotonicity properties as functions of θ. Hence, to achieve in the limit as $N, \theta \to \infty$ and $\delta, h(, \tau) \to 0$ with minimal efforts a fixed order of accuracy it is suggested to determine N, δ, h, θ (and τ) in such a way that the terms on the right sides of our estimates have equal

weights. Then, any modification of a parameter would lead to either an increasing approximation error or to an increasing CPU-time without improving the accuracy. In particular, first θ has to be chosen such that θ^{-2} corresponds to the desired accuracy. Next, in the case where the adaption step is not performed, N, δ, and h should satisfy

$$N \sim \theta^6, \quad h \sim \theta^{-10}, \quad \delta \sim \theta^{-5}. \tag{3.28}$$

On the other hand, if the adaption step is included, N, δ, h, and τ should be determined according to

$$N \sim \theta^6, \quad h \sim \theta^{-10}, \quad \delta \sim \theta^{-3}, \quad \tau \sim \theta^{-1}. \tag{3.29}$$

(v) Of course, in the derivation of the estimates (3.21)–(3.24) rigorous mathematical arguments will be used. As a supplement we shall present in section 4.3 some formal considerations, which lead to nonrigorous improvements of several intermediate results. Those considerations are essentially based on a hypothesis about the uniform regularity of the functions $\mathbb{R}^2 \times [0,T] \ni (x,t) \to (\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t) * \phi_\theta)(x)$, $N \in \mathbb{N}$, $\delta < \delta_0$, $h < T$, $\theta > \theta_0(, \tau > 0)$, and they finally amount to discard the θ-dependence of exactly those contributions to the right sides of (3.23) and (3.24), which emerge as a consequence of the space-time discretization in our simulation method; cf. (i)–(iii) in section 2.

In particular, if the adaption step (C) in section 2 is not performed, and if (4.8) and (4.11) are modified, the estimate (3.23) may formally be replaced by

$$\begin{aligned} \mathbb{E}\Big[\sup_{t\le T} \|\mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r - \rho(.,t)\|_2^2 + \int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r - \rho(.,t))\|_2^2\Big] \\ \lesssim C(T)\Big(\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta}(0) * \phi_\theta^r - \rho_0\|_2^2\big] + \frac{\theta^4}{N} + \delta^2 + h + \theta^{-2}\Big), \\ (N,\delta,h,\theta) \in \mathcal{P}_1,\ \theta \ll N^{1/2}. \end{aligned} \tag{3.30}$$

Now taking into account (3.25) we observe that for fixed θ instead of (3.28) the quantities N, δ, and h should satisfy

$$N \sim \theta^6, \quad h \sim \theta^{-2}, \quad \delta \sim \theta^{-1} \tag{3.31}$$

to guarantee an "optimal" performance of our simulation procedure.

In the case where the adaption step (C) in section 2 is included, the relation (4.8) has to be replaced by (4.18). As indicated in section 4.3, too, a formal improvement of that estimate is also possible and first leads to

$$\begin{aligned} \mathbb{E}\Big[\sup_{t\le T} \|\mathbb{Y}_{N,\delta,h,\theta,\tau}(t) * \phi_\theta^r - \rho(.,t)\|_2^2 + \int_0^T dt\ \|\nabla(\mathbb{Y}_{N,\delta,h,\theta,\tau}(t) * \phi_\theta^r - \rho(.,t))\|_2^2\Big] \\ \lesssim C(T)\Big(\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta,\tau}(0) * \phi_\theta^r - \rho_0\|_2^2\big] + \frac{\theta^4}{N} + \delta^4 + \tau^2 + h + \theta^{-2}\Big), \\ (N,\delta,h,\theta,\tau) \in \mathcal{P}_2,\ \theta \ll N^{1/2}, \end{aligned} \tag{3.32}$$

instead of (3.24), and subsequently to

$$N \sim \theta^6, \quad h \sim \theta^{-2}, \quad \delta \sim \theta^{-1/2}, \quad \tau \sim \theta^{-1}, \tag{3.33}$$

as a substitute for (3.29).

If in a computer simulation of $Y^k_{N,\delta,h,\theta(,\tau)}(.)$, $k = 1,\dots,N$, the choice of the parameters N, h, δ (and τ) is based on (3.31) or (3.33) instead of (3.28) or (3.29), for both discretization parameters δ and h much larger values may be chosen. In particular, a considerable reduction of the expenses may be expected.

Finally, we mention that those contributions to the derivations of (3.23) and (3.24), which are not related to the space-time discretization in our simulation procedure, have close analogues in the corresponding calculations in the study [13] of the asymptotics of the associated many-particle system (1.2) as $N \to \infty$. It therefore seems that also formally our estimates for those terms cannot be improved.

(vi) In step (A) in section 2 the region $Q \subseteq \mathbb{R}^2$ is characterized as a rectangle "containing most of the particles" during the simulation interval $[0,T]$. To determine Q heuristically we may first introduce some rectangle Q_0 satisfying $\int_{Q_0} dx\ \rho_0(x) \geq 1-\varepsilon$, where $\varepsilon > 0$ and ρ_0, which by (3.13) is a probability density, is the initial state of the solution ρ of (1.1). Next, we use the fact that (1.1) can be considered as a *Fokker–Planck equation* with diffusion coefficient $1/2$ and drift vector $-\nabla\rho(.,t)$, $t \geq 0$. In particular, together with Q_0 the diffusion coefficient and the drift vector can be employed to guess some rectangle $Q = Q_T$ satisfying $\int_Q dx\ \rho(x,t) \gtrsim 1-\varepsilon$, $0 \leq t \leq T$. Of course, in general $\nabla\rho(.,t)$, $t > 0$, is not known in advance. However, the maximum principle implies that the solution ρ of (1.1) in $\mathbb{R}^1$ satisfies $\|\rho'(.,t)\|_\infty \leq \|\rho_0'\|_\infty$, $t \geq 0$. Also in $\mathbb{R}^d$, $d > 1$, as a consequence of its nonsingular diffusion the dynamics (1.1) is smoothing. Hence, it seems to be justified to use $\|\nabla\rho_0\|_\infty$ as an estimate for $\sup_{t\leq T}\|\nabla\rho(.,t)\|_\infty$. When taking into account that a mass density subject to diffusion with coefficient $1/2$ spreads by $\sqrt{T}$ during $[0,T]$ we are led to define $Q = Q_T$ as that rectangle, whose boundaries have the distance $\sqrt{T} + \|\nabla\rho_0\|_\infty T$ to their counterparts in Q_0.

In the simulations described in section 6 the initial state ρ_0 is always a weighted superposition of Gaussian densities. In these cases it is particularly easy to determine Q_0 and $\|\nabla\rho_0\|_\infty$ in terms of the weights, the centers, and the standard deviations of the various Gaussians, and then to guess Q in the way sketched above.

We note that in some sense the quantity $1-\varepsilon$ may be considered as a measure for the fraction of the particle-mesh method within our procedure; cf. Remark 1(ii) in section 2.

(vii) The cut-off step (2.8) for the negative drift $D_{N,\delta,h,\theta(,\tau)}$ acting on the particles appears as a technical tool in the proofs of Proposition 1 and Theorem 2. In particular, for the estimation of the terms on the right side of (4.4) it will be useful that uniformly in $N \in \mathbb{N}$, $\delta < \delta_0$, $h > 0$, $\theta > \theta_0$ (and $\tau > 0$) the drift is bounded. Later on, in the simulations described in section 6 the vector $-\widehat{D}_{N,\delta,h,\theta(,\tau)}$ introduced in (2.6), (2.7), and the associated paragraph is employed as drift; i.e., (2.8) is omitted.

4. Proofs. In this section we present the main parts of the proofs. Several auxiliary results will be provided in section 5.

4.1. Proof of Proposition 1. To simplify our considerations we temporarily concentrate on the proof of (a); i.e., we suppose that in the determination of the negative drift $D_{N,\delta,h,\theta}$ acting on the particles the adaption step (C) in section 2 is not performed.

Essentially, we now proceed in a similar way as in [13] or [14]. In particular, we shall employ the integro-differential equation (3.16) for ρ_θ and the stochastic differential equations (2.18) for the positions $Y^k_{N,\delta,h,\theta}(.)$, $k = 1,\dots,N$, of the particles together with *Itô's formula*, cf. [9], to write down an equation describing the time

evolution of the stochastic process $t \to \|(\mathbb{Y}_{N,\delta,h,\theta}(t) - \rho_\theta(.,t)) * \phi_\theta^r\|_2^2$. As a result, with (2.1) and (3.10) we get

$$
\begin{aligned}
(4.1)\ & \|(\mathbb{Y}_{N,\delta,h,\theta}(t)-\rho_\theta(.,t)) * \phi_\theta^r\|_2^2 \\
&= \big\langle \mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r, \mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r \big\rangle \\
&\quad - 2\big\langle \mathbb{Y}_{N,\delta,h,\theta}(t) * \phi_\theta^r, \rho_\theta(.,t) * \phi_\theta^r \big\rangle + \big\langle \rho_\theta(.,t) * \phi_\theta^r, \rho_\theta(.,t) * \phi_\theta^r \big\rangle \\
&= \frac{1}{N^2} \sum_{k,l=1}^N \phi_\theta\big(Y^k_{N,\delta,h,\theta}(t) - Y^l_{N,\delta,h,\theta}(t)\big) \\
&\quad - \frac{2}{N} \sum_{k=1}^N \big(\rho_\theta(.,t) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(t)) + \big\langle \rho_\theta(.,t), \rho_\theta(.,t) * \phi_\theta \big\rangle \\
&= \|(\mathbb{Y}_{N,\delta,h,\theta}(0) - \rho_0) * \phi_\theta^r\|_2^2 \\
&\quad - \int_0^t ds\ \frac{2}{N^2} \sum_{k,l=1}^N \nabla\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s) - Y^l_{N,\delta,h,\theta}(s)\big) \cdot D_{N,\delta,h,\theta}\big(Y^k_{N,\delta,h,\theta}(\lfloor s \rfloor_h), \lfloor s \rfloor_h\big) \\
&\quad + \int_0^t ds\ \frac{1}{N^2} \sum_{\substack{k,l=1,\dots,N \\ k \neq l}} \Delta\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s) - Y^l_{N,\delta,h,\theta}(s)\big) \\
&\quad + \int_0^t \frac{2}{N^2} \sum_{k,l=1}^N \nabla\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s) - Y^l_{N,\delta,h,\theta}(s)\big) \cdot dW^k(s) \\
&\quad + \int_0^t ds\ \frac{2}{N} \sum_{k=1}^N \nabla\big(\rho_\theta(.,s) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s)) \cdot D_{N,\delta,h,\theta}\big(Y^k_{N,\delta,h,\theta}(\lfloor s \rfloor_h), \lfloor s \rfloor_h\big) \\
&\quad - \int_0^t ds\ \frac{1}{N} \sum_{k=1}^N \Delta\big(\rho_\theta(.,s) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s)) \\
&\quad - \int_0^t \frac{2}{N} \sum_{k=1}^N \nabla\big(\rho_\theta(.,s) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s)) \cdot dW^k(s) \\
&\quad + \int_0^t ds\ 2\big\langle \rho_\theta(.,s), \nabla(\mathbb{Y}_{N,\delta,h,\theta}(s) * \phi_\theta) \cdot \nabla(\rho_\theta(.,s) * \phi_\theta) \big\rangle \\
&\quad - \int_0^t ds\ \big\langle \rho_\theta(.,s), \Delta(\mathbb{Y}_{N,\delta,h,\theta}(s) * \phi_\theta) \big\rangle \\
&\quad - \int_0^t ds\ 2\big\langle \rho_\theta(.,s), |\nabla(\rho_\theta(.,s) * \phi_\theta)|^2 \big\rangle + \int_0^t ds\ \big\langle \rho_\theta(.,s), \Delta(\rho_\theta(.,s) * \phi_\theta) \big\rangle, \\
&\quad 0 \le t \le T,\ N \in \mathbb{N},\ \delta \in (0, \delta_0),\ h > 0,\ \theta > \theta_0.
\end{aligned}
$$

To determine an upper bound for the right side of (4.1) we collect the various terms in several groups.

First, we deduce for the terms which contain the Laplace operator and therefore represent the deterministic contributions of the Brownian motions the relation

$$
\begin{aligned}
(4.2)\ & \frac{1}{N^2} \sum_{\substack{k,l=1,\dots,N \\ k \neq l}} \Delta\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s) - Y^l_{N,\delta,h,\theta}(s)\big) - \frac{1}{N} \sum_{k=1}^N \Delta\big(\rho_\theta(.,s) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s)) \\
&\quad - \big\langle \rho_\theta(.,s), \Delta(\mathbb{Y}_{N,\delta,h,\theta}(s) * \phi_\theta) \big\rangle + \big\langle \rho_\theta(.,s), \Delta(\rho_\theta(.,s) * \phi_\theta) \big\rangle
\end{aligned}
$$

$$
\begin{aligned}
&= \big\langle \mathbb{Y}_{N,\delta,h,\theta}(s), \Delta(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta)\big\rangle - \frac{1}{N}\Delta\phi_\theta(0) - \big\langle \mathbb{Y}_{N,\delta,h,\theta}(s), \Delta(\rho_\theta(.,s)*\phi_\theta)\big\rangle \\
&\quad - \big\langle \rho_\theta(.,s), \Delta(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta)\big\rangle + \big\langle \rho_\theta(.,s), \Delta(\rho_\theta(.,s)*\phi_\theta)\big\rangle \\
&= -\big\langle \nabla(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta^r), \nabla(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta^r)\big\rangle - \frac{\theta^4}{N}\Delta\phi_1(0) \\
&\quad + 2\big\langle \nabla(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta^r), \nabla(\rho_\theta(.,s)*\phi_\theta^r)\big\rangle - \big\langle \nabla(\rho_\theta(.,s)*\phi_\theta^r), \nabla(\rho_\theta(.,s)*\phi_\theta^r)\big\rangle \\
&= -\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s))*\phi_\theta^r)\|_2^2 + \frac{\theta^4}{N}\int_{\mathbb{R}^2} dz\ |\nabla\phi_1^r(z)|^2, \\
&\quad 0 \le s \le T,\ N \in \mathbb{N},\ \delta \in (0,\delta_0),\ h > 0,\ \theta > \theta_0,
\end{aligned}
$$

where we have utilized in particular (1.8), (3.1), (3.2), (3.10), and (3.12).

Next, following (2.8) we introduce the notation

$$
\nabla_{(K)} f(y) = \begin{cases} \dfrac{\nabla f(y)}{|\nabla f(y)|}\min\{K, |\nabla f(y)|\} & \text{if } |\nabla f(y)| \neq 0, \\ 0 & \text{if } |\nabla f(y)| = 0, \end{cases} \qquad y \in \mathbb{R}^2,\ f \in C_b^1(\mathbb{R}^2), \tag{4.3}
$$

where the constant K is characterized by (3.15).

Now, collecting those terms on the right side of (4.1), which are related to the interaction, we get

$$
\begin{aligned}
&-\frac{2}{N^2}\sum_{k,l=1}^N \nabla\phi_\theta\big(Y_{N,\delta,h,\theta}^k(s) - Y_{N,\delta,h,\theta}^l(s)\big)\cdot D_{N,\delta,h,\theta}\big(Y_{N,\delta,h,\theta}^k(\lfloor s\rfloor_h), \lfloor s\rfloor_h\big) \\
&\quad + \frac{2}{N}\sum_{k=1}^N \nabla\big(\rho_\theta(.,s)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s))\cdot D_{N,\delta,h,\theta}\big(Y_{N,\delta,h,\theta}^k(\lfloor s\rfloor_h), \lfloor s\rfloor_h\big) \\
&\quad + 2\big\langle \rho_\theta(.,s), \nabla(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta)\cdot\nabla(\rho_\theta(.,s)*\phi_\theta)\big\rangle - 2\big\langle \rho_\theta(.,s), |\nabla(\rho_\theta(.,s)*\phi_\theta)|^2\big\rangle \\
&= \frac{2}{N}\sum_{k=1}^N \nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\qquad \cdot\big(D_{N,\delta,h,\theta}\big(Y_{N,\delta,h,\theta}^k(\lfloor s\rfloor_h), \lfloor s\rfloor_h\big) - \nabla_{(K)}\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(\lfloor s\rfloor_h))\big) \\
&\quad + \frac{2}{N}\sum_{k=1}^N \nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\qquad\qquad \cdot\big(\nabla_{(K)}\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(\lfloor s\rfloor_h)) \\
&\qquad\qquad\qquad - \nabla_{(K)}\big(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s))\big) \\
&\quad + \frac{2}{N}\sum_{k=1}^N \nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\qquad\qquad \cdot\nabla_{(K)}\big(\big(\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s)\big)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\quad + \frac{2}{N}\sum_{k=1}^N \nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\qquad\qquad \cdot\big(\nabla_{(K)}(\rho_\theta(.,s)*\phi_\theta) - \nabla(\rho_\theta(.,s)*\phi_\theta)\big)(Y_{N,\delta,h,\theta}^k(s)) \\
&\quad + 2\big\langle \mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s), \nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)\cdot\nabla(\rho_\theta(.,s)*\phi_\theta)\big\rangle
\end{aligned} \tag{4.4}
$$

$$= \quad \sum_{j=1}^{5} A^j_{N,\delta,h,\theta}(s), \quad 0 \le s \le T,\ N \in \mathbb{N},\ \delta \in (0,\delta_0),\ h > 0,\ \theta > \theta_0.$$

In the subsequent calculations we shall determine upper bounds for $A^j_{N,\delta,h,\theta}$, $j = 1,\dots,5$.

For $A^1_{N,\delta,h,\theta}$ we obtain

$$\begin{aligned}(4.5)\quad |A^1_{N,\delta,h,\theta}(s)| &\le \frac{2}{N}\sum_{k=1}^{N}\big|\nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\ &\qquad \big\|D_{N,\delta,h,\theta}(.,\lfloor s\rfloor_h) - \nabla_{(K)}(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta)\big\|_\infty \\ &= 2\big\langle \mathbb{Y}_{N,\delta,h,\theta}(s), |\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)) * \phi_\theta)|\big\rangle \\ &\qquad \big\|D_{N,\delta,h,\theta}(.,\lfloor s\rfloor_h) - \nabla_{(K)}(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta)\big\|_\infty.\end{aligned}$$

By (3.10) and (3.17) the first factor on the right side of (4.5) can be estimated as

$$\begin{aligned}(4.6)\quad &\big\langle \mathbb{Y}_{N,\delta,h,\theta}(s), |\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)) * \phi_\theta)|\big\rangle \\ &\quad \le \big\langle \mathbb{Y}_{N,\delta,h,\theta}(s), \phi^r_\theta * |\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)) * \phi^r_\theta)|\big\rangle \\ &\quad \le \|\mathbb{Y}_{N,\delta,h,\theta}(s) * \phi^r_\theta\|_2 \|\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)) * \phi^r_\theta)\|_2 \\ &\quad \le \big(\|(\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s)) * \phi^r_\theta\|_2 + 1\big)\|\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)) * \phi^r_\theta)\|_2.\end{aligned}$$

On the other hand, by (1.8), (2.1), (2.6)–(2.8), (3.1), (3.2), (3.12), (4.3), and Lemma 3 we also obtain

$$\begin{aligned}(4.7)\quad &\big\|D_{N,\delta,h,\theta}(.,\lfloor s\rfloor_h) - \nabla_{(K)}(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta)\big\|_\infty \\ &\qquad \le \big\|\widehat{D}_{N,\delta,h,\theta}(.,\lfloor s\rfloor_h) - \nabla(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta)\big\|_\infty \\ &\qquad \le C\delta\|\nabla^{\otimes 2}(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta)\|_\infty \\ &\qquad \le C\delta\theta^4.\end{aligned}$$

Hence, as a summary of (4.5)–(4.7) we deduce

$$\begin{aligned}(4.8)\quad |A^1_{N,\delta,h,\theta}(s)| &\le C\delta^2\theta^8\big(\|(\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s)) * \phi^r_\theta\|_2^2 + 1\big) \\ &\qquad + \frac{1}{8}\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s)) * \phi^r_\theta)\|_2^2, \\ &\qquad 0 \le s \le T,\ N \in \mathbb{N},\ \delta \in (0,\delta_0),\ h > 0,\ \theta > \theta_0.\end{aligned}$$

We note that (4.7) is the only estimate which has to be modified when the adaption step (C) in section 2 is included in our algorithm, i.e., when part (b) of Proposition 1 is proved. In that case we will have to take into account in particular the second part of (5.2).

Next, we turn to the estimation of $|A^2_{N,\delta,h,\theta}|$. By (1.8), (3.10), (3.12), and (4.3)we obtain

$$\begin{aligned}(4.9)\quad &|A^2_{N,\delta,h,\theta}(s)| \\ &\quad \le \frac{2}{N}\sum_{k=1}^{N}\big|\nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\ &\qquad \big|\nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)) \\ &\qquad\qquad -\nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(s) * \phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big|\end{aligned}$$

$$
\begin{aligned}
&= \frac{2}{N}\sum_{k=1}^{N}\big|\nabla\big(\big(\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)\big(Y^k_{N,\delta,h,\theta}(s)\big)\big| \\
&\qquad \bigg|\frac{1}{N}\sum_{l=1}^{N}\Big(\nabla\phi_\theta\big(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)\big) \\
&\qquad\qquad -\nabla\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s)-Y^l_{N,\delta,h,\theta}(s)\big)\Big)\bigg| \\
&\le C\theta^4\frac{1}{N^2}\sum_{k,l=1}^{N}\big|\nabla\big(\big(\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)\big(Y^k_{N,\delta,h,\theta}(s)\big)\big| \\
&\qquad \big(|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^k_{N,\delta,h,\theta}(s)|+|Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(s)|\big) \\
&\le C\theta^4\int_{\mathbb{R}^2}dx\,\big|\nabla\big(\big(\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi^r_\theta\big)(x)\big||\gamma_{N,\delta,h,\theta}(x,s)| \\
&\le C\theta^4\|\nabla((\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s))*\phi^r_\theta)\|_2\|\gamma_{N,\delta,h,\theta}(.,s)\|_2,
\end{aligned}
$$

where

$$
\begin{aligned}
\gamma_{N,\delta,h,\theta}(x,s) = \frac{1}{N^2}\sum_{k,l=1}^{N}\phi^r_\theta\big(x-Y^k_{N,\delta,h,\theta}(s)\big)\big(&|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^k_{N,\delta,h,\theta}(s)| \\
&+|Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(s)|\big).
\end{aligned}
$$

Equation (3.10) yields

$$
\begin{aligned}
&\mathbb{E}\big[\|\gamma_{N,\delta,h,\theta}(.,s)\|_2^2\big] \\
&= \mathbb{E}\bigg[\frac{1}{N^4}\sum_{k,k',l,l'=1}^{N}\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s)-Y^{k'}_{N,\delta,h,\theta}(s)\big) \\
&\qquad \big(|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^k_{N,\delta,h,\theta}(s)|+|Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(s)|\big) \\
&\qquad \big(|Y^{k'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^{k'}_{N,\delta,h,\theta}(s)|+|Y^{l'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^{l'}_{N,\delta,h,\theta}(s)|\big)\bigg] \\
&= \frac{1}{N^4}\sum_{k,k',l,l'=1}^{N}\mathbb{E}\Big[\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s)-Y^{k'}_{N,\delta,h,\theta}(s)\big) \\
&\qquad \big(|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^k_{N,\delta,h,\theta}(s)|+|Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(s)|\big) \\
&\qquad \big(|Y^{k'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^{k'}_{N,\delta,h,\theta}(s)|+|Y^{l'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^{l'}_{N,\delta,h,\theta}(s)|\big)\Big] \\
&\le \frac{2}{N^3}\sum_{k,k',l=1}^{N}\mathbb{E}\bigg[\mathbb{E}\Big[\phi_\theta\big(Y^k_{N,\delta,h,\theta}(s)-Y^{k'}_{N,\delta,h,\theta}(s)\big) \\
&\qquad \big(|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^k_{N,\delta,h,\theta}(s)|^2 \\
&\qquad\qquad +|Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^l_{N,\delta,h,\theta}(s)|^2\big)\Big|\mathcal{F}_{\lfloor s\rfloor_h}\Big]\bigg].
\end{aligned}
\tag{4.10}
$$

According to the definition of their dynamics, cf. (2.17) or (2.18), for any triple (k,k',l) with $k\neq k'\neq l\neq k$ the processes $Y^k_{N,\delta,h,\theta}$, $Y^{k'}_{N,\delta,h,\theta}$, and $Y^l_{N,\delta,h,\theta}$ have the form (5.23) in the time interval $\big[\lfloor s\rfloor_h,\lfloor s\rfloor_h+h\big)$, where their respective negative drift, namely $D_{N,\delta,h,\theta}(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h),\lfloor s\rfloor_h)$, $D_{N,\delta,h,\theta}(Y^{k'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h),\lfloor s\rfloor_h)$, and

$D_{N,\delta,h,\theta}(Y^l_{N,\delta,h,\theta}(\lfloor s\rfloor_h),\lfloor s\rfloor_h)$, is constant. Consequently, (1.8), (2.8), (3.10), (3.12), (3.17), (4.10), and Lemma 6 imply

$$\begin{aligned}
&\mathbb{E}\big[\|\gamma_{N,\delta,h,\theta}(.,s)\|_2^2\big]\\
&\quad\le Ch\bigg(\frac{\exp(2K^2T)}{N^3}\sum_{\substack{k,k',l=1,\dots,N\\ k\neq k'}}\mathbb{E}\Big[\big(\phi_\theta*\sigma_{2;8(s-\lfloor s\rfloor_h)}\big)\big(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-Y^{k'}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)\big)\Big]\\
&\qquad\qquad+\frac{\phi_\theta(0)}{N}\bigg)\\
&\quad\le Ch\big(\mathbb{E}\big[\|\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi^r_\theta*\sigma_{2;4(s-\lfloor s\rfloor_h)}\|_2^2\big]+\theta^2/N\big)\\
&\quad\le Ch\big(\mathbb{E}\big[\|(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-\rho_\theta(.,\lfloor s\rfloor_h))*\phi^r_\theta\|_2^2\big]+1+\theta^2/N\big),
\end{aligned}$$

where in the first line of the right side the terms with $k=k'$ contribute $Ch\phi_\theta(0)/N$. Therefore, (4.9) leads to

$$\begin{aligned}
\mathbb{E}\big[|A^2_{N,\delta,h,\theta}(s)|\big]&\le Ch\theta^8\big(\mathbb{E}\big[\|(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)-\rho_\theta(.,\lfloor s\rfloor_h))*\phi^r_\theta\|_2^2\big]+1+\theta^2/N\big)\\
&\quad+\frac{1}{8}\mathbb{E}\big[\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2^2\big],\\
&\quad 0\le s\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0.
\end{aligned}\tag{4.11}$$

Since for any $f\in C^1_b(\mathbb{R}^2)$ and any $x\in\mathbb{R}^2$ the vectors $\nabla f(x)$ and $\nabla_{(K)}f(x)$ are parallel, cf. (4.3), we immediately observe

$$A^3_{N,\delta,h,\theta}(s)\le 0,\quad 0\le s\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0.\tag{4.12}$$

Moreover, by (3.10) and (3.19), which is a consequence of the particular choice of the constants K and θ_0, we conclude

$$A^4_{N,\delta,h,\theta}(s)=0,\quad 0\le s\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0.\tag{4.13}$$

For the estimation of $|A^5_{N,\delta,h,\theta}(s)|$ we may employ Lemma 5 in the case $d=2$, $L=\overline{k}$, $\kappa=\phi^r_1$, and $\kappa_\theta=\phi^r_\theta$. In this situation the assumptions (5.9), (5.11), (5.13), and (5.14) are satisfied by (3.2), (3.6), (3.7), and (3.9). Additionally, we also choose $\mu(dx)=\mathbb{Y}_{N,\delta,h,\theta}(s)(dx)-\rho_\theta(x,s)dx$, $h=\nabla((\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s))*\phi^r_\theta)$, and $g=\nabla\rho_\theta(.,s)*\phi_\theta$. Although both g and h are $\mathbb{R}^2$-valued now, Lemma 5 may still be applied. In particular, with (2.1), (3.10), and (3.17) we obtain

$$\begin{aligned}
&|A^5_{N,\delta,h,\theta}(s)|\\
&\quad\le C\bigg(\|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta\|_2\sum_{l=0}^{\overline{k}-1}\theta^{-l}\|\nabla^{\otimes(l+1)}\rho_\theta(.,s)*\phi_\theta\|_\infty\\
&\qquad\qquad+\theta^{1-\overline{k}}\int_{\mathbb{R}^2}\big\{\mathbb{Y}_{N,\delta,h,\theta}(s)(dx)+\rho_\theta(x,s)dx\big\}\|\nabla^{\otimes(\overline{k}+1)}\rho_\theta(.,s)*\phi_\theta\|_\infty\bigg)\\
&\qquad\|\nabla((\rho_\theta(.,s)-\mathbb{Y}_{N,\delta,h,\theta}(s))*\phi^r_\theta)\|_2\\
&\quad\le C\big(\|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta\|_2+\theta^{1-\overline{k}}\big)\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2\\
&\quad\le C\big(\|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta\|_2^2+\theta^{2(1-\overline{k})}\big)\\
&\qquad+\frac{1}{8}\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2^2,\\
&\qquad 0\le s\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0.
\end{aligned}\tag{4.14}$$

Now, since we have completed the derivation of an upper bound for the right side of (4.4), we turn to those terms on the right side of (4.1) which explicitly contain the Brownian motions $W^1, W^2, \ldots$. For those contributions *Doob's inequality*, cf. [9], (2.1), (3.2), (3.9), and (3.10) imply

$$
\begin{aligned}
(4.15)\quad & \mathbb{E}\Big[\sup_{s\le t}\Big|\int_0^s \frac{2}{N^2}\sum_{k,l=1}^{N}\nabla\phi_\theta\big(Y^k_{N,\delta,h,\theta}(u)-Y^l_{N,\delta,h,\theta}(u)\big)\cdot dW^k(u)\\
&\qquad -\int_0^s \frac{2}{N}\sum_{k=1}^{N}\nabla(\rho_\theta(.,u)*\phi_\theta)(Y^k_{N,\delta,h,\theta}(u))\cdot dW^k(u)\Big|\Big]\\
&= \mathbb{E}\Big[\sup_{s\le t}\Big|\int_0^s \frac{2}{N}\sum_{k=1}^{N}\nabla\big((\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(u))\cdot dW^k(u)\Big|\Big]\\
&\le \frac{C}{\sqrt{N}}\Big(\mathbb{E}\Big[\int_0^t ds\frac{1}{N}\sum_{k=1}^{N}\big|\nabla\big((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big|^2\Big]\Big)^{1/2}\\
&= \frac{C}{\sqrt{N}}\Big(\int_0^t ds\ \mathbb{E}\big[\big\langle\mathbb{Y}_{N,\delta,h,\theta}(s),|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi_\theta)|^2\big\rangle\big]\Big)^{1/2}\\
&\le \frac{C}{\sqrt{N}}\Big(\int_0^t ds\ \mathbb{E}\big[\big\langle\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi^r_\theta,|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)|^2\big\rangle\big]\Big)^{1/2}\\
&\le \frac{C}{N}\|\phi^r_\theta\|_\infty+\frac{1}{8}\int_0^t ds\ \mathbb{E}\big[\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2^2\big]\\
&\le C\frac{\theta^2}{N}+\frac{1}{8}\int_0^t ds\ \mathbb{E}\big[\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2^2\big],\\
&\qquad 0\le t\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0.
\end{aligned}
$$

By (4.2), (4.4), (4.8), and (4.11)–(4.15) the estimates for the terms on the right side of (4.1) are now finished. If the parameters N, δ, h, and θ are restricted to the set $\mathcal{P}_1$, cf. (3.20), and if (3.3) is taken into account, we obtain as a summary

$$
\begin{aligned}
&\|(\mathbb{Y}_{N,\delta,h,\theta}(t)-\rho_\theta(.,t))*\phi^r_\theta\|_2^2\\
&\quad\le \|(\mathbb{Y}_{N,\delta,h,\theta}(0)-\rho_0)*\phi^r_\theta\|_2^2+C\left(\frac{\theta^4}{N}+\delta^2\theta^8+\theta^{2(1-\overline{k})}\right)\\
&\quad -\frac{3}{4}\int_0^t ds\ \|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta)\|_2^2\\
&\quad +C\int_0^t ds\ \|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta\|_2^2+\int_0^t ds\ |A^2_{N,\delta,h,\theta}(s)|\\
&\quad +\sup_{s\le t}\Big|\int_0^s\frac{2}{N}\sum_{k=1}^{N}\nabla\big((\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(u))\cdot dW^k(u)\Big|,\\
&\quad 0\le t\le T,\ (N,\delta,h,\theta)\in\mathcal{P}_1,
\end{aligned}
$$

and therefore

$$
\begin{aligned}
(4.16)\quad &\sup_{s\le t}\Big(\|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi^r_\theta\|_2^2\\
&\qquad +\frac{3}{4}\int_0^s du\ \|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi^r_\theta)\|_2^2\Big)
\end{aligned}
$$

$$\begin{aligned}
&\le \|(\mathbb{Y}_{N,\delta,h,\theta}(0)-\rho_0)*\phi_\theta^r\|_2^2 + C\left(\frac{\theta^4}{N}+\delta^2\theta^8+\theta^{2(1-\overline{k})}\right)\\
&\quad + C\int_0^t ds\ \|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi_\theta^r\|_2^2 + \int_0^t ds\ |A^2_{N,\delta,h,\theta}(s)|\\
&\quad + \sup_{s\le t}\left|\int_0^s \frac{2}{N}\sum_{k=1}^N \nabla\big((\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(u))\cdot dW^k(u)\right|,\\
&\quad 0\le t\le T,\ (N,\delta,h,\theta)\in\mathcal{P}_1.
\end{aligned}$$

Next, by (3.20), (4.11), (4.15), and (4.16) we deduce

$$\begin{aligned}
&\mathbb{E}\left[\sup_{s\le t}\left(\|(\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi_\theta^r\|_2^2\right.\right.\\
&\qquad\left.\left. + \frac{3}{4}\int_0^s du\ \|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi_\theta^r)\|_2^2\right)\right]\\
&\quad\le \mathbb{E}\big[\|(\mathbb{Y}_{N,\delta,h,\theta}(0)-\rho_0)*\phi_\theta^r\|_2^2\big] + C\left(\frac{\theta^4}{N}+(\delta^2+h)\theta^8+\theta^{2(1-\overline{k})}\right)\\
&\quad + \frac{1}{4}\int_0^t ds\ \mathbb{E}\big[\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s)-\rho_\theta(.,s))*\phi_\theta^r)\|_2^2\big]\\
&\quad + C\int_0^t ds\ \mathbb{E}\left[\sup_{u\le s}\|(\mathbb{Y}_{N,\delta,h,\theta}(u)-\rho_\theta(.,u))*\phi_\theta^r\|_2^2\right],\\
&\quad 0\le t\le T,\ (N,\delta,h,\theta)\in\mathcal{P}_1.
\end{aligned}$$

Now, by an application of Gronwall's lemma the relation (3.21) follows.

To prove (b) we have only to check the estimate (4.7) another time, since all remaining parts of the proof of (a) are independent of the adaption step (C) in section 2.

In particular, by Lemma 3 and the adaption rule introduced in step (C) in section 2 we obtain

$$\begin{aligned}
&\big\|\widehat{D}_{N,\delta,h,\theta,\tau}(.,\lfloor s\rfloor_h)-\nabla(\mathbb{Y}_{N,\delta,h,\theta,\tau}(\lfloor s\rfloor_h)*\phi_\theta)\big\|_\infty\\
&\quad\le C\left(\sup_{m=1,\dots,|\mathcal{L}(\lfloor s\rfloor_h)|}|\kappa^m_{N,\delta,h,\theta,\tau}(\lfloor s\rfloor_h)|+\delta^2\|\nabla^{\otimes 3}(\mathbb{Y}_{N,\delta,h,\theta,\tau}(\lfloor s\rfloor_h)*\phi_\theta)\|_\infty\right)\\
&\quad\le C(\tau+\delta^2\theta^5).
\end{aligned}\tag{4.17}$$

Consequently, with (4.5), (4.6), and the first part of (4.7) we deduce

$$\begin{aligned}
|A^1_{N,\delta,h,\theta,\tau}(s)| &\le C(\tau^2+\delta^4\theta^{10})\big(\|(\mathbb{Y}_{N,\delta,h,\theta,\tau}(s)-\rho_\theta(.,s))*\phi_\theta^r\|_2^2+1\big)\\
&\quad + \frac{1}{8}\|\nabla((\mathbb{Y}_{N,\delta,h,\theta,\tau}(s)-\rho_\theta(.,s))*\phi_\theta^r)\|_2^2,\\
&\quad 0\le s\le T,\ N\in\mathbb{N},\ \delta\in(0,\delta_0),\ h>0,\ \theta>\theta_0,\ \tau>0,
\end{aligned}\tag{4.18}$$

instead of (4.8).

Now, the proof of (b) may be finished in just the same way as that of (a).

4.2. Proof of Theorem 2. As consequence of (3.14), (3.17), and (3.18) we obtain

$$\begin{aligned}(4.19)\quad &\sup_{t\le T,\theta>\theta_0}\theta^2\|\nabla(\rho_\theta(.,t)-\rho(.,t))\|_2^2\\ &\quad=\sup_{t\le T,\theta>\theta_0}(-\theta^2)\big\langle\Delta(\rho_\theta(.,t)-\rho(.,t)),\rho_\theta(.,t)-\rho(.,t)\big\rangle\\ &\quad\le\sup_{t\le T,\theta>\theta_0}\theta^2\|\Delta(\rho_\theta(.,t)-\rho(.,t))\|_\infty\big\langle\rho_\theta(.,t)+\rho(.,t),1\big\rangle<\infty,\end{aligned}$$

and quite similarly

$$(4.20)\qquad \sup_{t\le T,\theta>\theta_0}\theta^2\|\rho_\theta(.,t)-\rho(.,t)\|_2^2<\infty.$$

By (1.9), (3.17), and Lemma 4 we also observe that

$$(4.21)\qquad \sup_{t\le T,\theta>\theta_0}\theta^4\big(\|\rho_\theta(.,t)-\rho_\theta(.,t)*\phi_\theta^r\|_2^2+\|\nabla(\rho_\theta(.,t)-\rho_\theta(.,t)*\phi_\theta^r)\|_2^2\big)<\infty.$$

We note here that the assumptions (5.9) and (5.10), which are needed for an application of Lemma 4 in the case $\kappa=\phi_1^r$, are satisfied by (3.2) and (3.3).

Now, (3.23) follows from (3.5), (3.21), and (4.19)–(4.21), whereas to obtain (3.24) we have to take into account (3.22) instead of (3.21).

4.3. Some formal improvements. In this subsection we present those formal considerations, which are mentioned in Remark 3(v) in section 3.

To support our arguments we introduce in $\mathbb{R}^2$ a many-particle system, whose dynamics is determined by a system of coupled stochastic differential equations like (1.2), where, however, the interaction is defined in terms of the kernel ϕ_θ; cf. (1.8), instead of ϕ_N; cf. (1.3), (1.4). Obviously, this many-particle system may be described by empirical processes $\mathbb{X}_{N,\theta}$, $N\in\mathbb{N}$, $\theta>1$, which are given in a similar way as in (1.6) or (2.1). As in (1.7) the convergence $\lim_{N,\theta\to\infty}\mathbb{X}_{N,\theta}=\rho$ may be expected, at least, if it is ensured that N and θ converge to their common limit ∞ in such a way that the range of the interaction ($=O(\theta^{-1})$) is much larger than the typical distance between neighboring particles ($=O(N^{-1/2})$). Moreover, $\lim_{N,\theta\to\infty}\partial_t^n\nabla^{\otimes m}(\mathbb{X}_{N,\theta}(.)*\phi_\theta)=\partial_t^n\nabla^{\otimes m}\rho$, $m=0,1,2,3$, $n=0,1$, should also hold. In particular, for $m=0,1,2,3$ and $n=0,1$ the functions $\mathbb{R}^2\times[0,T]\ni(x,t)\to\partial_t^n\nabla^{\otimes m}(\mathbb{X}_{N,\theta}(t)*\phi_\theta)(x)$ are supposed to be "bounded" uniformly in $N\in\mathbb{N}$ and $\theta\ll N^{1/2}$.

Next, we assume that the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}$ and $\mathbb{X}_{N,\theta}$ exhibit similar regularity properties if the discretization parameters δ and h are sufficiently small.

As a summary of the formal assumptions collected so far we are led to the following hypothesis:

(HS) The functions $\mathbb{R}^2\times[0,T]\ni(x,t)\to\partial_t^n\nabla^{\otimes m}(\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t)*\phi_\theta)(x)$, $m=0,1,2,3$, $n=0,1$, are bounded uniformly in $(N,\delta,h,\theta)\in\mathcal{P}_1$ (or $(N,\delta,h,\theta,\tau)\in\mathcal{P}_2$) and $\theta\ll N^{1/2}$.

Since the Brownian motions $W^1,W^2,\ldots$, which are not differentiable, and the negative drift $D_{N,\delta,h,\theta(,\tau)}$, which as a consequence of the space-time discretization is even discontinuous, contribute in the particular form determined by (2.1) and (2.18) to the functions considered in (HS), the regularity properties stated there cannot hold in a strong, classical sense. However, at least some weak version of (HS) is supposed to be valid. That should be sufficient for our purposes, since the calculations sketched below in the remaining part of this subsection are performed in a context, where an integration over $\mathbb{R}^2\times[0,t]$, $0\le t\le T$, is involved.

As a first consequence of (HS) we may omit θ^4 on the right side of (4.7). Subsequently, on the right side of (4.8) the term $\delta^2\theta^8$ may be replaced by δ^2.

Next, for the second contribution to the sum constituting the first estimate for $|A^2_{N,\delta,h,\theta}(s)|$ in (4.9) we deduce

$$\begin{aligned}
&\big|\nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)) - \nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\
&\quad\le \big|\nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h)) - \nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\
&\qquad + \big|\nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(\lfloor s\rfloor_h)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s)) - \nabla\big(\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\
&\quad= Q^{k,1}_{N,\delta,h,\theta}(s) + Q^{k,2}_{N,\delta,h,\theta}(s).
\end{aligned}$$

First, the hypothesis (HS) yields $Q^{k,2}_{N,\delta,h,\theta}(s) \lesssim Ch$. Furthermore, when taking into account additionally the fact that the processes $[v, v+h) \ni u \to Y^k_{N,\delta,h,\theta}(u)$, $v \in \mathcal{T}_h \cap [0,T]$, $k = 1,\dots,N$, are diffusion processes with constant drift bounded by K and diffusion coefficient $1/2$, we observe $Q^{k,1}_{N,\delta,h,\theta}(s) \le C|Y^k_{N,\delta,h,\theta}(\lfloor s\rfloor_h) - Y^k_{N,\delta,h,\theta}(s)| \lesssim C(\sqrt{h}+h)$. As a consequence, we may formally replace (4.9) by

$$\begin{aligned}
|A^2_{N,\delta,h,\theta}(s)| &\lesssim \frac{C\sqrt{h}}{N}\sum_{k=1}^N \big|\nabla\big(\big(\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s)\big)*\phi_\theta\big)(Y^k_{N,\delta,h,\theta}(s))\big| \\
&\le C\sqrt{h}\big\langle \mathbb{Y}_{N,\delta,h,\theta}(s)*\phi^r_\theta, |\nabla((\rho_\theta(.,s) - \mathbb{Y}_{N,\delta,h,\theta}(s))*\phi^r_\theta)|\big\rangle \\
&\le Ch\|\mathbb{Y}_{N,\delta,h,\theta}(s)*\phi^r_\theta\|_2^2 + \frac{1}{8}\|\nabla((\mathbb{Y}_{N,\delta,h,\theta}(s) - \rho_\theta(.,s))*\phi^r_\theta)\|_2^2.
\end{aligned}$$

Hence, on a formal level in (4.11) the factor θ^8 may be omitted.

By the modifications of (4.8) and (4.11) discussed so far we now can conclude that (3.30) may formally be used instead of (3.23).

In the case, where the adaption step (C) in section 2 is performed, we may utilize (HS) to omit on the right sides of (4.17) and (4.18) the factors θ^5 and θ^{10}, respectively. Since the remaining estimates are independent of the adaption step, the arguments leading to (3.30), (3.31) have to be modified only slightly to deduce (3.32), (3.33).

5. Some auxiliary results. The present section contains some auxiliary results, which are needed in the calculations of section 4. Apart from Lemma 3 those results are both formulated and proved essentially independently of the dimension; i.e., they are discussed for arbitrary $\mathbb{R}^d$, $d \ge 1$.

First, we study the approximation of the gradient of some smooth function $f : \mathbb{R}^2 \to \mathbb{R}$ by expressions like those on the right side of (2.7). On the one hand, the quality of that approximation is estimated in terms of $\|\nabla^{\otimes 2} f\|_\infty$. On the other hand, if the components of the tensor $\nabla^{\otimes 2} f$ are replaced by discrete approximations like those introduced in step (E) in section 2, an estimate involving $\|\nabla^{\otimes 3} f\|_\infty$ and an expression like $\kappa_{N,\delta,h,\theta,\tau}(.)$, cf. (2.16), is obtained.

For the subsequent considerations we choose some region $Q \subseteq \mathbb{R}^2$ and a discretization parameter $\delta \in (0, \delta_0)$ according to steps (A) and (B) in section 2. We also select a rectangle $R = R^m$ in $\mathcal{L}_0$ or any of its refinements, which are constructed according to step (C) in section 2. As indicated in section 2, Figure 1, and discussed in steps (B) and (C) in section 2, some points $A = A^m$, $B = B^m$, $C = C^m$, $D = D^m$, $M = M^m$ and some triangles $\Delta_1 = \Delta_1^m$, $\Delta_2 = \Delta_2^m$, $\Delta_3 = \Delta_3^m$, $\Delta_4 = \Delta_4^m$ are associated with R. Moreover, the width of R in x_1- (x_2-) direction is denoted by $S_1 = S_1^m$ ($S_2 = S_2^m$). We note that S_1 and S_2 satisfy (2.5).

Let $f \in C_b^1(\mathbb{R}^2)$ and $x \in R$. Similarly as in (2.7) we introduce an *approximation* $\widehat{\nabla}_R f(x)$ to $\nabla f(x)$ in terms of $f(A)$, $f(B)$, $f(C)$, $f(D)$, and $f(M)$. More precisely, we define

$$\widehat{\nabla}_R f(x) = \begin{cases} \left(\dfrac{f(B)-f(A)}{S_1}, \dfrac{f(A)+f(B)-2f(M)}{S_2}\right)^T & \text{if } x \in \Delta_1, \\ \left(\dfrac{f(B)+f(C)-2f(M)}{S_1}, \dfrac{f(B)-f(C)}{S_2}\right)^T & \text{if } x \in \Delta_2, \\ \left(\dfrac{f(C)-f(D)}{S_1}, \dfrac{2f(M)-f(C)-f(D)}{S_2}\right)^T & \text{if } x \in \Delta_3, \\ \left(\dfrac{2f(M)-f(A)-f(D)}{S_1}, \dfrac{f(A)-f(D)}{S_2}\right)^T & \text{if } x \in \Delta_4. \end{cases} \tag{5.1}$$

If $f \in C_b^2(\mathbb{R}^2)$, we may also apply the considerations in step (E) in section 2 to determine approximations to the components of the tensor $\nabla^{\otimes 2} f(x)$, $x \in R$, which quite similarly as in (2.9)–(2.14) involve only $f(A)$, $f(B)$, $f(C)$, $f(D)$, $f(M)$, and $f(G)$, $G \in \mathcal{G}$, where $\mathcal{G}$ is a set of corners of some rectangles, which are adjacent to R. The absolute value of the product of such an approximation to some component of $\nabla^{\otimes 2} f(x)$, $x \in R$, with $\sqrt{S_1 S_2}$ is bounded above by a quantity $\kappa_R(f)$ defined by an immediate analogue of the right side of (2.16). Since a detailed description of $\kappa_R(f)$ would amount to a more or less literal repetition of the considerations between the paragraph before (2.15) and (2.16), it is omitted here.

Now, we may state our estimates on the error, which is associated with the approximation of ∇ by $\widehat{\nabla}_R$.

LEMMA 3. *Let R be some rectangle as discussed above. Moreover, for $f : \mathbb{R}^2 \to \mathbb{R}$ let $\widehat{\nabla}_R f$ and $\kappa_R(f)$ be determined by* (5.1) *and the considerations in the subsequent paragraph. Then,*

$$\sup_{x \in R} |\nabla f(x) - \widehat{\nabla}_R f(x)| \le \begin{cases} C\|\nabla^{\otimes 2} f\|_\infty \delta & \text{if } f \in C_b^2(\mathbb{R}^2), \\ C\kappa_R(f) + C'\|\nabla^{\otimes 3} f\|_\infty \delta^2 & \text{if } f \in C_b^3(\mathbb{R}^2), \end{cases} \tag{5.2}$$

where the constants C and C' are independent of R and f.

Proof. For $f \in C_b^2(\mathbb{R}^2)$ and $x \in R$ the values $f(A)$, $f(B)$, $f(C)$, $f(D)$, and $f(M)$ may be obtained by a Taylor expansion of f at x. For example,

$$\begin{aligned} f(A) = f(x) &+ (A-x)\cdot \nabla f(x) \\ &+ \frac{1}{2}\sum_{i,j=1}^{2} (A_i - x_i)(A_j - x_j)\nabla_i \nabla_j f\big(x + \vartheta(A,x,f)(A-x)\big), \end{aligned} \tag{5.3}$$

where $0 \le \vartheta(\ldots) \le 1$. Employing (5.3) and a corresponding expression for $f(B)$ in the case where $x \in \Delta_1$ we immediately get

$$\begin{aligned} \frac{f(B)-f(A)}{S_1} &= \frac{f(B)-f(A)}{B_1 - A_1} \\ &= \frac{1}{B_1 - A_1}(B-A)\cdot \nabla f(x) + g_1(A,B,x,f) = \nabla_1 f(x) + g_1(A,B,x,f) \end{aligned}$$

with

$$|g_1(A,B,x,f)| \le 2\frac{|A-x|^2 + |B-x|^2}{S_1}\|\nabla^{\otimes 2} f\|_\infty \le C\delta\|\nabla^{\otimes 2} f\|_\infty,$$

where (2.5) is also used. For $x \in \Delta_1$ we additionally observe

$$\frac{f(A)+f(B)-2f(M)}{S_2} = \nabla_2 f(x) + g_2(A,B,M,x,f),$$

where $|g_2(A,B,M,x,f)| \le C\delta \|\nabla^{\otimes 2} f\|_\infty$. These relations and analogues for the remaining cases $x \in \Delta_2$, $x \in \Delta_3$, $x \in \Delta_4$ on the right side of (5.1) prove the first part of (5.2).

If $f \in C_b^3(\mathbb{R}^2)$ and $x \in R$, as an extension of (5.3) the relation

$$\begin{aligned} f(A) = f(x) + (A-x)\cdot\nabla f(x) + \frac{1}{2}\sum_{i,j=1}^{2}(A_i-x_i)(A_j-x_j)\nabla_i\nabla_j f(x) \\ + \frac{1}{6}\sum_{i,j,k=1}^{2}(A_i-x_i)(A_j-x_j)(A_k-x_k)\nabla_i\nabla_j\nabla_k f\big(x+\vartheta'(A,x,f)(A-x)\big) \end{aligned} \tag{5.4}$$

with $0 \le \vartheta'(\ldots) \le 1$ holds. With a similar expansion for $f(B)$ and by taking into account (2.5) we now deduce

$$\begin{aligned} \frac{f(B)-f(A)}{S_1} &= \frac{f(B)-f(A)}{B_1-A_1} \\ &= \nabla_1 f(x) + \frac{1}{2(B_1-A_1)}\sum_{i,j=1}^{2}\big((B_i-x_i)(B_j-x_j)-(A_i-x_i)(A_j-x_j)\big)\nabla_i\nabla_j f(x) \\ &\quad + g_3(A,B,x,f), \quad x \in \Delta_1, \end{aligned} \tag{5.5}$$

where

$$|g_3(A,B,x,f)| \le C\delta^2 \|\nabla^{\otimes 3} f\|_\infty, \quad x \in \Delta_1. \tag{5.6}$$

The partial derivatives $\nabla_i\nabla_j f(.)$ in (5.5) may be approximated by expressions like those introduced on the right sides of (2.9)–(2.12). For example, suppose $i=j=1$. The considerations in the paragraph preceding (2.15) demonstrate that there exists at least one η_1 in the set $\mathcal{X} = \mathcal{X}^m$ associated with $R = R^m$ such that $P_{\eta_1}, M_{\eta_1}, E_{\eta_1} \in \Theta_{\eta_1}$ are contained in a line parallel to the x_1-axis; i.e., for the x_2-coordinates of these points the relations $P_{\eta_1,2} = M_{\eta_1,2} = E_{\eta_1,2}$ hold. Moreover, M_{η_1} is contained in the closure of R. For convenience we may also suppose $P_{\eta_1,1} < M_{\eta_1,1} < E_{\eta_1,1}$ for the x_1-coordinates. Then by choosing $x = M_{\eta_1}$ in (5.4) and furthermore $A = P_{\eta_1}$ and $A = E_{\eta_1}$, respectively, and by employing (2.5) we deduce

$$\begin{aligned} &\frac{1}{(M_{\eta_1,1}-P_{\eta_1,1})(E_{\eta_1,1}-M_{\eta_1,1})} \\ &\qquad \left(\frac{E_{\eta_1,1}-M_{\eta_1,1}}{E_{\eta_1,1}-P_{\eta_1,1}} f(P_{\eta_1}) + \frac{M_{\eta_1,1}-P_{\eta_1,1}}{E_{\eta_1,1}-P_{\eta_1,1}} f(E_{\eta_1}) - f(M_{\eta_1})\right) \\ &\quad = \frac{1}{2}\nabla_1\nabla_1 f(M_{\eta_1}) + g_{11}(P_{\eta_1}, M_{\eta_1}, E_{\eta_1}, f) \end{aligned} \tag{5.7}$$

with

$$|g_{11}(P_{\eta_1}, M_{\eta_1}, E_{\eta_1}, f)| \le C\delta \|\nabla^{\otimes 3} f\|_\infty. \tag{5.8}$$

Further relations corresponding to (5.7), (5.8) may be deduced for $(i,j) \neq (1,1)$, where again (2.9)–(2.12) are used as a guide. As indicated in the paragraph after (5.1) the respective products of the left sides of (5.7) and its analogues with $\sqrt{S_1 S_2}$ are bounded by a multiple of $\kappa_R(f)$. Hence, with (2.5), (5.1), (5.5), (5.6) and since $\sup_{x\in\Delta_1} |\nabla^{\otimes 2} f(x) - \nabla^{\otimes 2} f(M_{\eta_1})| \leq C\delta \|\nabla^{\otimes 3} f\|_\infty$ we obtain

$$\sup_{x\in\Delta_1} |\nabla_1 f(x) - \widehat{\nabla}_{R,1} f(x)| \leq C\kappa_R(f) + C' \|\nabla^{\otimes 3} f\|_\infty \delta^2,$$

where $\widehat{\nabla}_{R,1} f$ is the x_1-component of $\widehat{\nabla}_R f$.

By repeating now the considerations after (5.4) for $(f(A) + f(B) - 2f(M))/S_2$ instead of $(f(B) - f(A))/S_1$ and then for $x \in \Delta_2, \Delta_3, \Delta_4$ the verification of the second part of (5.2) may be finished. □

Next, we provide estimates for the distance between some smooth function and its convolutions with kernels like ϕ_θ or ϕ_θ^r.

LEMMA 4. *Let κ be some symmetric probability density on $\mathbb{R}^d$; i.e.,*

$$\kappa \geq 0, \quad \int_{\mathbb{R}^d} dx\ \kappa(x) = 1, \quad \kappa(-x) = \kappa(x),\ x \in \mathbb{R}^d, \tag{5.9}$$

which satisfies

$$\widetilde{\kappa} \in C_b^2(\mathbb{R}^d), \tag{5.10}$$

and let

$$\kappa_\theta(x) = \theta^d \kappa(\theta x), \quad x \in \mathbb{R}^d,\ \theta > 1, \tag{5.11}$$

be a family of rescaled versions of κ.

Then, we get

$$\|f - f * \kappa_\theta\|_2 \leq C\theta^{-2} \|\Delta f\|_2 \|\nabla^{\otimes 2} \widetilde{\kappa}\|_\infty, \quad f \in H_2^2(\mathbb{R}^d), \tag{5.12}$$

where the constant C is independent of f and κ.

Proof. Assumptions (5.9)–(5.11) yield

$$\begin{aligned}
\|f - f * \kappa_\theta\|_2^2 &= \int_{\mathbb{R}^d} d\lambda\ |\widetilde{f}(\lambda)|^2 |1 - (2\pi)^{d/2} \widetilde{\kappa_\theta}(\lambda)|^2 \\
&= \int_{\mathbb{R}^d} d\lambda\ |\widetilde{f}(\lambda)|^2 |1 - (2\pi)^{d/2} \widetilde{\kappa}(\lambda/\theta)|^2 \\
&= (2\pi)^d \int_{\mathbb{R}^d} d\lambda\ |\widetilde{f}(\lambda)|^2 \Big| \widetilde{\kappa}(0) - \Big(\widetilde{\kappa}(0) + \frac{1}{\theta} \lambda \cdot \nabla \widetilde{\kappa}(0) \\
&\qquad + \frac{1}{2\theta^2} \sum_{i,j=1}^d \lambda_i \lambda_j \nabla_i \nabla_j \widetilde{\kappa}(\eta(\lambda,\theta)\lambda/\theta) \Big) \Big|^2,
\end{aligned}$$

where $0 \leq \eta(\ldots) \leq 1$. As a consequence of the symmetry of κ, cf. (5.9), we get $\nabla \widetilde{\kappa}(0) = 0$, and therefore

$$\|f - f * \kappa_\theta\|_2^2 \leq C\theta^{-4} \|\nabla^{\otimes 2} \widetilde{\kappa}\|_\infty^2 \int_{\mathbb{R}^d} d\lambda\ |\widetilde{f}(\lambda)|^2 |\lambda|^4,$$

which proves (5.12). □

For the estimation of $A^5_{N,\delta,h,\theta}(s)$, cf. (4.4), we have to study an expression like

$$\langle \mu, (h * \phi^r_\theta) g \rangle, \quad \mu \in \mathcal{M}(\mathbb{R}^2),\ h \in L^2(\mathbb{R}^2),\ g \in C^\infty_b(\mathbb{R}^2),$$

where ϕ^r_θ, $\theta > 1$, is the family of convolution kernels introduced in (3.9) by using the function ϕ^r_1, which in particular satisfies (3.2) and (3.4)–(3.7). As demonstrated by Lemma 5 the absolute value of such expressions may be estimated from above in terms of $\|h\|_2$, L^∞-norms of partial derivatives of g, the L^2-norm of the regularization $\mu * \phi^r_\theta$ of μ, and the total variation $|\mu|(\mathbb{R}^2)$ of μ. We note that some slightly different variant of Lemma 5 can be found in [15, section 4 (ii)].

LEMMA 5. *Suppose that κ and κ_θ, $\theta > 1$, satisfy* (5.9) *and* (5.11) *and let $L \in \{\lceil d/2 \rceil, \lceil d/2 \rceil + 1, \ldots\}$ be fixed. Moreover, assume that the functions*

$$V^l_{k_1,\ldots,k_d}(x) = (-1)^{k_1+\cdots+k_d} \frac{x_1^{k_1} \ldots x_d^{k_d}}{k_1! \ldots k_d!} \kappa(x),$$
$$k_1, \ldots, k_d = 0, \ldots, L,\ 0 \le l = k_1 + \cdots + k_d \le L,\ x \in \mathbb{R}^d,$$

satisfy

$$\left| \widetilde{V^l_{k_1,\ldots,k_d}}(\lambda) \right| \le C |\widetilde{\kappa}(\lambda)|, \tag{5.13}$$
$$k_1, \ldots, k_d = 0, \ldots, L-1,\ 1 \le l = k_1 + \cdots + k_d \le L-1,\ \lambda \in \mathbb{R}^d,$$

and

$$|V^L_{k_1,\ldots,k_d}(x)| \le C \left(\frac{1}{1+|x|^{d+1}} \right)^{1/2}, \tag{5.14}$$
$$k_1, \ldots, k_d = 0, \ldots, L,\ k_1 + \cdots + k_d = L,\ x \in \mathbb{R}^d.$$

Then,

$$\langle \mu, (h * \kappa_\theta) g \rangle = \langle \mu * \kappa_\theta, hg \rangle + R_{\kappa,\theta,L}(\mu, h, g),$$
$$\mu \in \mathcal{M}(\mathbb{R}^d),\ h \in L^2(\mathbb{R}^d),\ g \in C^L_b(\mathbb{R}^d),\ \theta > 1,$$

where

$$|R_{\kappa,\theta,L}(\mu,h,g)| \le C \left(\|\mu * \kappa_\theta\|_2 \sum_{l=1}^{L-1} \theta^{-l} \|\nabla^{\otimes l} g\|_\infty + \theta^{(d/2)-L} |\mu|(\mathbb{R}^d) \|\nabla^{\otimes L} g\|_\infty \right) \|h\|_2,$$
$$\mu \in \mathcal{M}(\mathbb{R}^d),\ h \in L^2(\mathbb{R}^d),\ g \in C^L_b(\mathbb{R}^d),\ \theta > 1.$$

Proof. Similarly as in [15, section 4 (ii)], we first observe that

$$\langle \mu, (h * \kappa_\theta) g \rangle = \left\langle \mu, \int_{\mathbb{R}^d} dz\ \kappa_\theta(z) h(.-z) g(.) \right\rangle \tag{5.15}$$
$$= \left\langle \mu, \int_{\mathbb{R}^d} dz\ \kappa_\theta(z) \Big\{ g(.-z) + \sum_{l=1}^{L-1} \sum_{\substack{s_1,\ldots,s_d=0,\ldots,l \\ s_1+\cdots+s_d=l}} \frac{z_1^{s_1} \ldots z_d^{s_d}}{s_1! \ldots s_d!} \nabla_1^{s_1} \ldots \nabla_d^{s_d} g(.-z) \right.$$
$$\left. + \sum_{\substack{s_1,\ldots,s_d=0,\ldots,L \\ s_1+\cdots+s_d=L}} \frac{z_1^{s_1} \ldots z_d^{s_d}}{s_1! \ldots s_d!} \nabla_1^{s_1} \ldots \nabla_d^{s_d} g(.-z+\vartheta(.,z)z) \Big\} h(.-z) \right\rangle,$$

where $|\vartheta(\ldots)| \leq 1$. In (5.15) we may rearrange the brackets and the integral. Consequently, we get

$$\langle \mu, (h*\kappa_\theta)g\rangle = \sum_{l=0}^{L-1} \sum_{\substack{s_1,\ldots,s_d=0,\ldots,l \\ s_1+\cdots+s_d=l}} R^l_{\theta;s_1,\ldots,s_d}(\mu,h,g) + \sum_{\substack{s_1,\ldots,s_d=0,\ldots,L \\ s_1+\cdots+s_d=L}} R^{*,L}_{\theta;s_1,\ldots,s_d}(\mu,h,g), \tag{5.16}$$

where

$$R^l_{\theta;s_1,\ldots,s_d}(\mu,h,g) = \big\langle \mu * V^l_{\theta;s_1,\ldots,s_d}, h\nabla_1^{s_1}\ldots\nabla_d^{s_d} g\big\rangle, \tag{5.17}$$

$$R^{*,L}_{\theta;s_1,\ldots,s_d}(\mu,h,g) = \left\langle \mu, \int_{\mathbb{R}^d} dz\ \kappa_\theta(z)\frac{z_1^{s_1}\ldots z_d^{s_d}}{s_1!\ldots s_d!}\nabla_1^{s_1}\ldots\nabla_d^{s_d} g(.-z+\vartheta(.,z)z)h(.-z)\right\rangle, \tag{5.18}$$

with

$$V^l_{\theta;s_1,\ldots,s_d}(x) = \theta^{d-l}V^l_{s_1,\ldots,s_d}(\theta x), \quad x\in\mathbb{R}^d. \tag{5.19}$$

Of course, in (5.17)–(5.19) the respective range of l and $s_1,\ldots,s_d$ is determined by (5.15) and (5.16).

For $l=0$ we also have $s_1=\ldots=s_d=0$. Since $V^0_{\theta;0,\ldots,0}(x) = \theta^d V^0_{0,\ldots,0}(\theta x) = \kappa_\theta(x)$, we deduce

$$R^0_{\theta;0,\ldots,0}(\mu,h,g) = \langle \mu*\kappa_\theta, hg\rangle \tag{5.20}$$

in this case. Next, for $l=1,\ldots,L-1$ we get

$$|R^l_{\theta;s_1,\ldots,s_d}(\mu,h,g)| \leq \|\mu * V^l_{\theta;s_1,\ldots,s_d}\|_2 \|h\|_2 \|\nabla_1^{s_1}\ldots\nabla_d^{s_d} g\|_\infty.$$

Since (5.11), (5.13), and (5.19) yield

$$\begin{aligned}
\|\mu * V^l_{\theta;s_1,\ldots,s_d}\|_2^2 &= (2\pi)^d \int_{\mathbb{R}^d} d\lambda\ |\widetilde{\mu}(\lambda)|^2 \left|\widetilde{V^l_{\theta;s_1,\ldots,s_d}}(\lambda)\right|^2 \\
&= \frac{(2\pi)^d}{\theta^{2l}} \int_{\mathbb{R}^d} d\lambda\ |\widetilde{\mu}(\lambda)|^2 \left|\widetilde{V^l_{s_1,\ldots,s_d}}(\lambda/\theta)\right|^2 \\
&\leq \frac{C}{\theta^{2l}} \int_{\mathbb{R}^d} d\lambda\ |\widetilde{\mu}(\lambda)|^2 |\widetilde{\kappa}(\lambda/\theta)|^2 \leq \frac{C}{\theta^{2l}} \|\mu*\kappa_\theta\|_2^2,
\end{aligned}$$

we obtain

$$|R^l_{\theta;s_1,\ldots,s_d}(\mu,h,g)| \leq \frac{C}{\theta^l}\|\mu*\kappa_\theta\|_2\|h\|_2\|\nabla^{\otimes l} g\|_\infty, \quad l=1,\ldots,L-1. \tag{5.21}$$

From (5.9), (5.11), (5.14), (5.18), and (5.19) we finally derive

$$\begin{aligned}
&|R^{*,L}_{\theta;s_1,\ldots,s_d}(\mu,h,g)| \\
&\quad\leq \left\langle |\mu|, \int_{\mathbb{R}^d} dz\ \kappa_\theta(z)\frac{|z_1|^{s_1}\ldots|z_d|^{s_d}}{s_1!\ldots s_d!}|h(.-z)|\right\rangle \|\nabla_1^{s_1}\ldots\nabla_d^{s_d} g\|_\infty \\
&\quad\leq \big\langle |\mu| * |V^L_{\theta;s_1,\ldots,s_d}|, |h|\big\rangle \|\nabla^{\otimes L} g\|_\infty
\end{aligned} \tag{5.22}$$

$$\le \|\nabla^{\otimes L} g\|_\infty \int_{\mathbb{R}^d} |\mu|(dx) \int_{\mathbb{R}^d} dy\ |V^L_{\theta;s_1,\dots,s_d}(y-x)||h(y)|$$
$$\le C\theta^{d-L}\|\nabla^{\otimes L} g\|_\infty \int_{\mathbb{R}^d} |\mu|(dx) \int_{\mathbb{R}^d} dy\ \left(\frac{1}{1+(\theta|y-x|)^{d+1}}\right)^{1/2} |h(y)|$$
$$\le C\theta^{d-L}\|\nabla^{\otimes L} g\|_\infty \int_{\mathbb{R}^d} |\mu|(dx) \left\| \left(\frac{1}{1+(\theta|.-x|)^{d+1}}\right)^{1/2} \right\|_2 \|h\|_2$$
$$\le C\theta^{(d/2)-L}\|\nabla^{\otimes L} g\|_\infty |\mu|(\mathbb{R}^d)\|h\|_2.$$

Equations (5.16) and (5.20)–(5.22) suffice to complete the proof of Lemma 5. □

In our estimate of $A^2_{N,\delta,h,\theta}(s)$; cf. (4.4), the term $\|\gamma_{N,\delta,h,\theta}(.,s)\|_2$ appears; cf. (4.9). As indicated in (4.10), to determine an upper bound of that quantity an estimate for some particular functional of three independent diffusion processes with constant drift and diffusion matrix is needed. This estimate is provided now.

LEMMA 6. *Let*

$$X^j(t) = x^j + D^j t + B^j(t), \quad t \ge 0,\ j = 1,2,3, \tag{5.23}$$

where $x^1, x^2, x^3, D^1, D^2, D^3 \in \mathbb{R}^d$, and B^1, B^2, B^3 are independent, standard Brownian motions in $\mathbb{R}^d$. Then, for any positive $\psi \in L^1(\mathbb{R}^d)$ we get

$$\mathbb{E}\big[\psi(X^1(t)-X^2(t))(X^n(t)-x^n)^2\big]$$
$$\le C(d)t\exp\Big(\frac{t}{2}\big(|D^1|^2+|D^2|^2+|D^3|^2\big)\Big)(\psi * \sigma_{d;8t})(x^1-x^2), \quad t\ge 0,\ n=1,2,3.$$

Proof. The family of transition densities for the standard Brownian motion in $\mathbb{R}^d$ is given by $\{\sigma_{d;s}(.) : s > 0\}$. These kernels can also be used to describe the time evolution of the processes X^j, $j = 1,2,3$, which obviously are obtained from B^1, B^2 and B^3, respectively, by a simple transformation. In particular, for any $n = 1,2,3$ we get

$$\mathbb{E}\big[\psi(X^1(t)-X^2(t))(X^n(t)-x^n)^2\big]$$
$$= \frac{1}{(2\pi t)^{3d/2}} \int_{\mathbb{R}^d} dz^1 \int_{\mathbb{R}^d} dz^2 \int_{\mathbb{R}^d} dz^3\ \psi(z^1-z^2)(z^n-x^n)^2$$
$$\exp\left(-\frac{(x^1-z^1+D^1t)^2}{2t}\right)\exp\left(-\frac{(x^2-z^2+D^2t)^2}{2t}\right)\exp\left(-\frac{(x^3-z^3+D^3t)^2}{2t}\right)$$
$$\le \frac{1}{(2\pi t)^{3d/2}}\exp\left(\frac{t}{2}\big(|D^1|^2+|D^2|^2+|D^3|^2\big)\right)$$
$$\int_{\mathbb{R}^d} dz^1 \int_{\mathbb{R}^d} dz^2 \int_{\mathbb{R}^d} dz^3\ \psi(z^1-z^2)(z^n-x^n)^2$$
$$\exp\left(-\frac{(x^1-z^1)^2}{4t}\right)\exp\left(-\frac{(x^2-z^2)^2}{4t}\right)\exp\left(-\frac{(x^3-z^3)^2}{4t}\right)$$
$$\le \exp\left(\frac{t}{2}\big(|D^1|^2+|D^2|^2+|D^3|^2\big)\right)\frac{t}{(2\pi t)^{3d/2}}\sup_{y\in\mathbb{R}^d}\left(y^2\exp\left(-\frac{y^2}{8}\right)\right)$$
$$\int_{\mathbb{R}^d} dz^1 \int_{\mathbb{R}^d} dz^2 \int_{\mathbb{R}^d} dz^3\ \psi(z^1-z^2)$$
$$\exp\left(-\frac{(x^1-z^1)^2}{8t}\right)\exp\left(-\frac{(x^2-z^2)^2}{8t}\right)\exp\left(-\frac{(x^3-z^3)^2}{8t}\right),$$

which completes the proof of Lemma 6, since $\sigma_{d;\alpha} * \sigma_{d;\beta} = \sigma_{d;\alpha+\beta}$, $\alpha,\beta > 0$. □

6. Computer simulations. To illustrate our results summarized in section 3 we now discuss computer simulations of the many-particle system described in section 2. First, we present some details of our algorithms in order to explain how the general description in section 2 is transfered to our computer program. In the second subsection the results of our simulations are exhibited, in particular in terms of three-dimensional visualizations of *particle densities* and associated approximation errors. We also add some notes on computational expenses. The final part of this section contains some remarks on the hardware and software employed to perform the simulations.

6.1. Algorithmical details. In general, our purpose is to simulate for fixed parameters $N \in \mathbb{N}$, $\delta \in (0, \delta_0)$, $h > 0$, $\theta > \theta_0$ (and $\tau > 0$) the system (2.17) or (2.18) describing the individual motion of the particles, to visualize regularizations of the empirical processes $\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(.)$, cf. (2.1), and also to compare our results with the solution ρ of the limit dynamics (1.1). Within our computer program needed for the simulation we tried to follow the description in section 2 and the assumptions in section 3.1 as close as possible. A few departures, which are subsequently described, should have no essential influence on the relevance of our simulation results.

As far as the negative drift $D_{N,\delta,h,\theta(,\tau)}$ acting on the individual particles is concerned, we omit the cut-off step in (2.8). The kernels ϕ_θ, $\theta > \theta_0$, which characterize the interaction between the particles, cf. (2.6), (2.7), are obtained in our simulations by the scaling (1.8) from a Gaussian density ϕ_1 with mean 0 and variance 0.5. Obviously, the natural choice for ϕ_1^r, cf. (3.1), would then be a centered Gaussian density with variance 0.25. With these functions ϕ_1 and ϕ_1^r the conditions (3.1)–(3.3), (3.7), and (3.8) are satisfied, whereas (3.6) does not hold. We note that this condition appears only as a technical ingredient needed for the application of Lemma 5 to prove (4.14).

Of course, to implement the Gaussian random variables $Z^{k,p}$, $k = 1, \dots, N$, $p = 0, 1, 2, \dots$, in (2.17), which correspond to the increments of the Brownian motions $W^1, W^2, \dots$ in (2.18), *pseudorandom numbers* produced by some random number generator, which is provided by the computer system, are employed.

This random number generator is also applied to determine the initial positions $Y^k_{N,\delta,h,\theta(,\tau)}(0)$, $k = 1, \dots, N$, of the particles according to the method proposed in Remark 3(iii) in section 3, i.e., as i.i.d. random variables with density ρ_0. Since in all our simulations the initial state ρ_0 of (1.1) is chosen as a weighted superposition of Gaussian densities that method is particularly convenient.

Furthermore, the choice of the rectangle Q, cf. step (A) and Remark 1(ii) in section 2, is facilitated for these special initial conditions. In particular, the method described in Remark 3(vi) in section 3 is utilized here.

For the calculation of $\kappa^m_{N,\delta,h,\theta,\tau}(ph)$, which is employed to decide whether a given rectangle R^m in some mesh $\mathcal{L}'(ph)$, cf. step (E) in section 2, should be divided, we do not follow the line leading to (2.16) quite exactly. More precisely, after interchanging S^m_1 and S^m_2 in several places and taking into account (2.5) we finally arrive at a quantity $\widehat{\kappa}^m_{N,\delta,h,\theta,\tau}(ph)$ satisfying $C_3\kappa^m_{N,\delta,h,\theta,\tau}(ph) \le \widehat{\kappa}^m_{N,\delta,h,\theta,\tau}(ph) \le C_4\kappa^m_{N,\delta,h,\theta,\tau}(ph)$, $m = 1, \dots, |\mathcal{L}'(ph)|$, $p = 0, 1, 2, \dots$, where $C_3 = C_3(Q)$ and $C_4 = C_4(Q)$ depend only on the region Q. Obviously, by (2.3) the use of $\widehat{\kappa}_{N,\delta,h,\theta,\tau}$ instead of $\kappa_{N,\delta,h,\theta,\tau}$ is essentially equivalent to the replacement of the adaption parameter τ by some $\widehat{\tau} = C\tau$.

To assess the approximation error of our simulation results we also solve the limit equation (1.1) numerically. Since this way to obtain the solution ρ of (1.1) is not of particular interest in the present paper, we use an extremely simple algorithm, namely

an *Euler scheme* with a *finite-difference method* to approximate the spatial partial derivatives. This approach is justified, since the viscous porous medium equation is a well-behaved partial differential equation for which we also consider only smooth initial conditions. To obtain a reliable representation of ρ we choose a very fine discretization both in space and time. In particular, this discretization is much finer than the discretizations employed for the corresponding particle simulations. In our numerical solution of (1.1) we completely neglect the mass of ρ outside the rectangle Q, which anyhow is chosen in such a way that the mass of ρ is concentrated essentially within Q; cf. Remark 3(vi) in section 3. In particular, we employ *Dirichlet conditions* at the boundary ∂Q of Q.

The discretization used to solve (1.1) is also applied to compute the L^2-norms in the second row of Table 1 in section 6.2.

6.2. Results of the simulations. In order that the quantitative behavior of the particle simulations is clearly displayed, we first consider a special case of (1.1), where the graph of the solution ρ has a particularly simple shape. More precisely, we suppose that ρ_0 is a Gaussian density with mean 0 and variance 1. Later on, we also consider a more complicated initial condition, namely a superposition of four Gaussian densities.

Our estimates in Theorem 2 or (3.26) and (3.27) and also in the formal results (3.30) and (3.32) provide upper bounds for the expectation of a *squared approximation error* $\mathbb{E}[\sup_{t\le T} \|Y_{N,\delta,h,\theta(,\tau)}(t) * \phi_\theta^r - \rho(.,t)\|_2^2]$. On the respective right sides of those estimates only the dependence on the simulation parameters N, δ, h, θ (and τ) is displayed explicitly. In particular, any dependence on the solution ρ of the limit dynamics (1.1) or on the region Q is subsumed in the constants $C(T)$. Hence, our results do not yield precise upper bounds for the approximation error. However, they indicate how a given set $\mathcal{M}_A = \{N_A, \delta_A, h_A, \theta_A(, \tau_A)\}$ of parameters may be modified, in order that the expected squared approximation error, whose exact value is unknown, is reduced by a certain factor $\alpha \in (0,1)$. For this reason we provide several sequences of simulations, where the squared error obtained with some parameter set $\mathcal{M}_A$ should be reduced successively by factors $\alpha_1, \alpha_2, \ldots$.

We first present the results of our simulations by three-dimensional visualizations of the *densities* $y \to d_{N,\delta,h,\theta(,\tau)}(y,t_i) = (\mathbb{Y}_{N,\delta,h,\theta(,\tau)}(t_i) * \phi_\theta)(y)$ for several time points $t_i \in [0,1]$, $i = 1,2,\ldots$. They may be compared to corresponding representations of the numerical solution ρ of (1.1). We note that in all pictures pertaining to the same initial condition ρ_0 any function depicted there is restricted to the respective domain Q. Moreover, the values of these functions are scaled in the same way, and the lighting conditions and the viewpoints do not vary. Since the factor for the scaling in z-direction is considerably larger than 1, the differences between $d_{N,\delta,h,\theta(,\tau)}$ and ρ are overaccentuated. To assess the different simulations quantitatively the respective L^2-norms of the difference $d_{N,\delta,h,\theta(,\tau)}(.,1) - \rho(.,1)$ are also given.

6.2.1. A simply structured initial condition ρ_0. In this first example we suppose that ρ_0 is a Gaussian density with mean 0 and variance 1. The simulation results refering to that situation are presented in Figures 3–5, where in particular the region Q is chosen as $[-5.38, 5.38] \times [-5.38, 5.38]$.

First, in Figure 3 we provide for $t = 0$, $t = 0.5$, and $t = 1$ in the right row three-dimensional visualizations of a numerical solution of (1.1). Additionally, the results of three simulations of the many-particle system (2.17) or (2.18) without the adaption

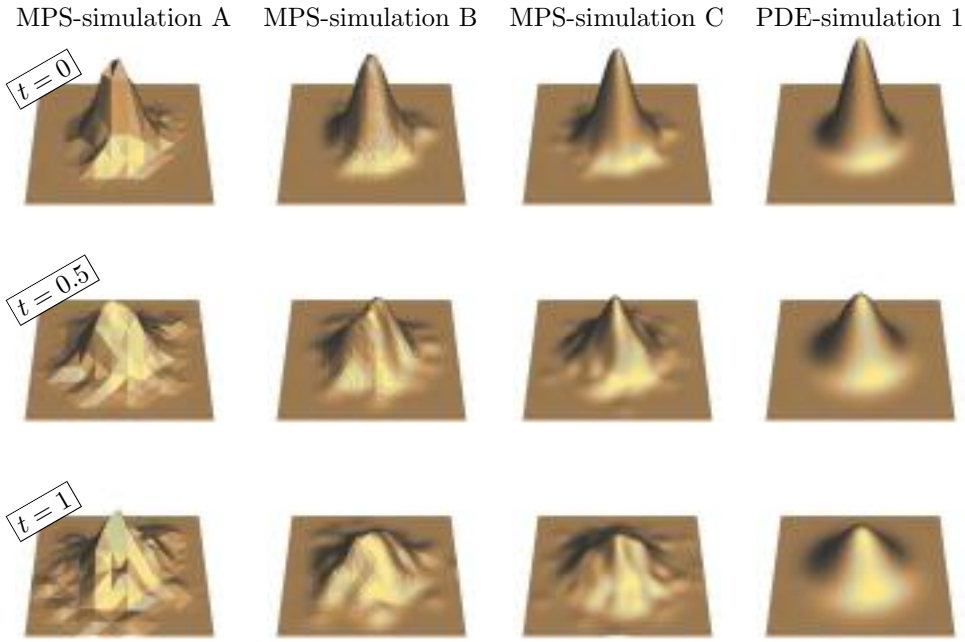

FIG. 3. *Simulations of* (1.1). *Reduction of the approximation error according to* (3.26) *and* (6.2).

step are shown. In MPS-simulation A the parameters

$$N = N_A = 100, \quad \delta = \delta_A = 1, \quad h = h_A = 0.1, \quad \theta = \theta_A = 2 \tag{6.1}$$

are used. In the remaining simulations these parameters are chosen in such a way that the expected squared approximation error estimated by the right side of (3.26) is reduced by the factors 0.75 and 0.5, respectively. In general, a reduction by $\alpha \in (0, 1)$ is achieved if the parameters $N = N_\alpha$, $\delta = \delta_\alpha$, $h = h_\alpha$, and $\theta = \theta_\alpha$ satisfy

$$\frac{1}{\theta_\alpha^2} = \frac{\alpha}{\theta_A^2}, \quad \frac{\theta_\alpha^4}{N_\alpha} = \alpha \frac{\theta_A^4}{N_A}, \quad \delta_\alpha^2 \theta_\alpha^8 = \alpha \delta_A^2 \theta_A^8, \quad h_\alpha \theta_\alpha^8 = \alpha h_A \theta_A^8,$$

i.e., if

$$N_\alpha = \frac{N_A}{\alpha^3}, \quad \delta_\alpha = \delta_A \sqrt{\alpha^5}, \quad h_\alpha = h_A \alpha^5, \quad \theta_\alpha = \frac{\theta_A}{\sqrt{\alpha}}. \tag{6.2}$$

Consequently, after some rounding we get

$$N_B = 300, \quad \delta_B = 0.487, \quad h_B = 0.0237, \quad \theta_B = 2.31$$

for MPS-simulation B with $\alpha = 0.75$, whereas

$$N_C = 800, \quad \delta_C = 0.177, \quad h_C = 0.0031, \quad \theta_C = 2.83$$

are employed for MPS-simulation C with $\alpha = 0.5$.

By (6.2) the discretization parameters δ_α and h_α with decreasing α get very small. Hence, the CPU-time for the particle method grows enormously if (3.26) and the

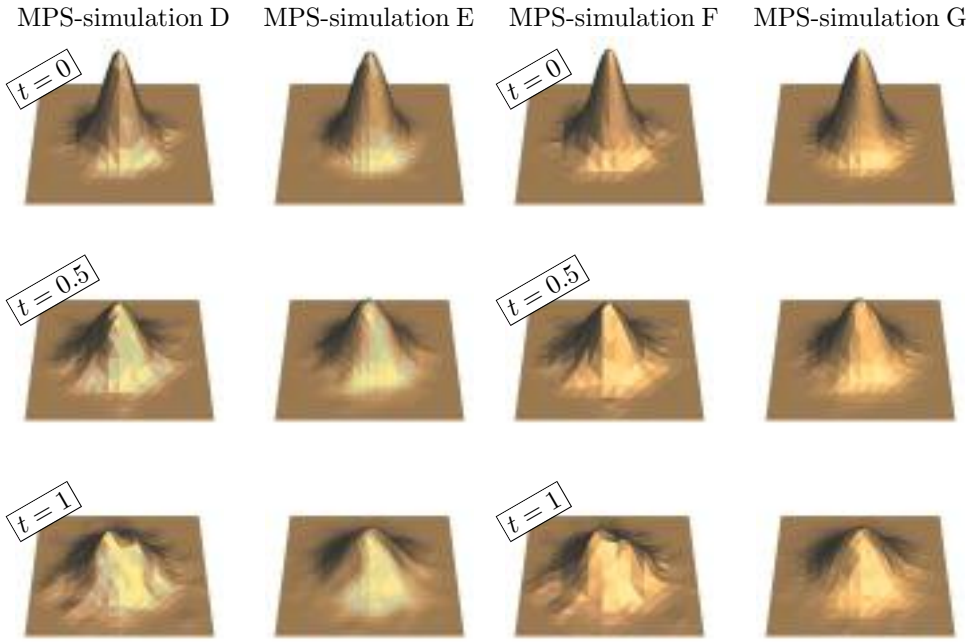

FIG. 4. *Simulations of* (1.1). *Reduction of the approximation error according to* (3.25), (3.30), *and* (6.3).

FIG. 5. *Simulations of* (1.1). *Reduction of the approximation error according to* (3.25), (3.32), *and* (6.5).

associated relations (6.2) are employed as the basis for the choice of the parameters in order to reduce the approximation error. In this respect a considerable improvement may be expected if (3.26) is replaced by the formal result (3.30) supplemented with (3.25). Then, instead of (6.2) the relations

$$N_\alpha = \frac{N_A}{\alpha^3}, \quad \delta_\alpha = \delta_A\sqrt{\alpha}, \quad h_\alpha = h_A\alpha, \quad \theta_\alpha = \frac{\theta_A}{\sqrt{\alpha}} \tag{6.3}$$

are obtained if a reduction of the expected squared approximation error by the factor α has to be attained.

Simulations of our many-particle system (2.17) or (2.18), where (6.3) is applied to improve the accuracy of MPS-simulation A, are presented in Figure 4. In particular, MPS-simulation D and MPS-simulation E refer to $\alpha = 0.5$ and $\alpha = 0.25$, respectively, where (6.3) suggests to use

$$N_D = 800, \quad \delta_D = 0.707, \quad h_D = 0.05, \quad \theta_D = 2.83$$

and

$$N_E = 6400, \quad \delta_E = 0.5, \quad h_E = 0.025, \quad \theta_E = 4. \tag{6.4}$$

The simulations related to Figure 4 are still unnecessarily expensive. In regions where the graph of the density is flat a larger spatial discretization parameter δ should suffice for our calculations. On the other hand, in regions with a large density curvature a finer mesh seems to be desirable, i.e., the use of a globally larger δ,

TABLE 1
Approximation errors and reduction factors for different variants of the particle method.

	$\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2$	α^R_{theor}	α^R_{obs}
MPS-simulation A	0.0440	1.000	1.000
MPS-simulation B	0.0331	0.866	0.752
MPS-simulation C	0.0266	0.707	0.605
MPS-simulation D	0.0217	0.707	0.493
MPS-simulation E	0.0083	0.500	0.189
MPS-simulation F	0.0216	0.707	0.491
MPS-simulation G	0.0086	0.500	0.195

which is reduced only locally in a few critical regions with high curvature, should be advantageous. Accordingly, we next present in Figure 5 some simulations including the adaption step (C) in section 2 in order to provide a local refinement of the spatial mesh.

Just as their counterparts in Figure 4 MPS-simulation F and MPS-simulation G are obtained by reducing the expected squared approximation error of MPS-simulation A by 0.5 and 0.25, respectively. Now, the determination of the simulation parameters is based on (3.25) and the formal estimate (3.32), which yield

$$N_\alpha = \frac{N_A}{\alpha^3}, \quad \delta_\alpha = \delta_A \alpha^{1/4}, \quad \tau_\alpha = \tau_A \sqrt{\alpha}, \quad h_\alpha = h_A \alpha, \quad \theta_\alpha = \frac{\theta_A}{\sqrt{\alpha}} \tag{6.5}$$

if a reduction by the factor α is desired. Therefore, with (6.1), which has been supplemented arbitrarily with $\tau = \tau_A = 0.1$, and (6.5) we get

$$N_F = 800, \quad \delta_F = 0.841, \quad \tau_F = 0.071, \quad h_F = 0.05, \quad \theta_F = 2.83$$

for MPS-simulation F and

$$N_G = 6400, \quad \delta_G = 0.707, \quad \tau_G = 0.05, \quad h_G = 0.025, \quad \theta_G = 4 \tag{6.6}$$

for MPS-simulation G.

So far in this section we have considered the application of several variants of our particle method to the same initial condition. The variants differ in the rule to modify the parameters N, δ, h, θ (and τ) in order to reduce the approximation error. In addition to their visual comparison given above we next in Tables 1 and 2 discuss them quantitatively.

First, in Table 1, in particular, the approximation errors $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2$ are collected. We also contrast the respective *theoretical reduction* α^R_{theor} of that error with its *observed reduction* α^R_{obs}. Here, for MPS-simulation X we use $\alpha^R_{theor} = \sqrt{\alpha}$, where α is the corresponding parameter for the *reduction of the expected squared approximation error* appearing in the preceding paragraphs in this section. Moreover, we define

$$\alpha^R_{obs} = \frac{\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2 \text{ for MPS-simulation X}}{\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2 \text{ for MPS-simulation A}}.$$

In any situation we get

TABLE 2
Comparison of the computational expenses for different variants of the particle method.

	CPU-time (Sec)	$SF(0)$ (Byte)	$SF(1)$ (Byte)
MPS-simulation C	21692.10	522445	518175
MPS-simulation D	113.70	32053	31693
MPS-simulation F	82.64	31851	23252

$$\frac{\alpha^R_{theor}}{\alpha^R_{obs}} > 1; \tag{6.7}$$

i.e., the observed reduction α^R_{obs} is always better than the predicted reduction α^R_{theor}. We additionally notice that the fraction on the left side of (6.7) seems to grow with decreasing $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2$. Perhaps this observation may be attributed to the fact that according to (3.26), (3.27), (3.30), or (3.32) also $\int_0^1 ds\ \|\nabla(d_{N,\delta,h,\theta(,\tau)}(.,s)-\rho(.,s))\|_2^2$ contributes to α and hence to α^R_{theor}. If $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2 \to 0$, this part of α^R_{theor} possibly becomes substantially larger than $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2^2$. To supplement Table 1 we also note that $\|\rho(.,1)\|_2 = 0.195$. In particular, we now may use the *absolute approximation error* $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2$ to determine the *relative approximation error* $\|d_{N,\delta,h,\theta(,\tau)}(.,1)-\rho(.,1)\|_2/\|\rho(.,1)\|_2$.

Table 2 may provide some insight into the computational expenses, which are associated with the different variants of our particle method. In particular, for MPS-simulations C, D, and F, which all serve to reduce a fixed expected squared approximation error by the factor $\alpha = 0.5$, we present the CPU-time for the simulation and additionally the size $SF(t)$ of the files used to store the particle density $d_{N,\delta,h,\theta(,\tau)}(.,t) = (1/N)\sum_{m=1}^N \phi_\theta(.-Y^m_{N,\delta,h,\theta(,\tau)}(t))$ for $t=0$ and $t=1$. As discussed in steps (B) and (C) in section 2 the domain of $d_{N,\delta,h,\theta(,\tau)}(.,t)$ consists of the set of corners and centers of the rectangles in the lattice $\mathcal{L}(t)$. Hence, for any $t = ph$, $p = 0,1,2,\ldots$, the quantity $SF(t)$ corresponds to the number of mesh points in $\mathcal{L}(t)$ and consequently reflects the amount of storage needed to perform the simulation.

Obviously, as a consequence of the small values of δ_C and h_C the expenses for MPS-simulation C are fairly large. On the other hand, Figures 3–5 and Table 1 indicate that apart from the higher resolution the quality of the simulation result associated with MPS-simulation C is not substantially better than the quality obtained with MPS-simulation D or MPS-simulation F, which are performed with much fewer computational efforts. In particular, the formal considerations from section 4.3, which present the background of MPS-simulation D and MPS-simulation F, seem to be quite reliable and useful when a higher computational efficiency is desired. We finally remark that the adaption step in MPS-simulation F in comparison to MPS-simulation D leads to reduced expenses, whereas the quality of the simulation result remains unchanged.

6.2.2. An initial condition with a nontrivial shape. To illustrate the performance of our particle method in a more complicated situation we now suppose that ρ_0 is a superposition of four Gaussian densities. These Gaussians have equal weight 0.25 and variance 1, and their centers span a "T"on the boundary of a rectangle Q' of size 2.5×5. As the domain of the densities obtained by our simulations we choose the rectangle Q of size 10.5×13, whose border lines have distance 4 to the corresponding borders of Q'.

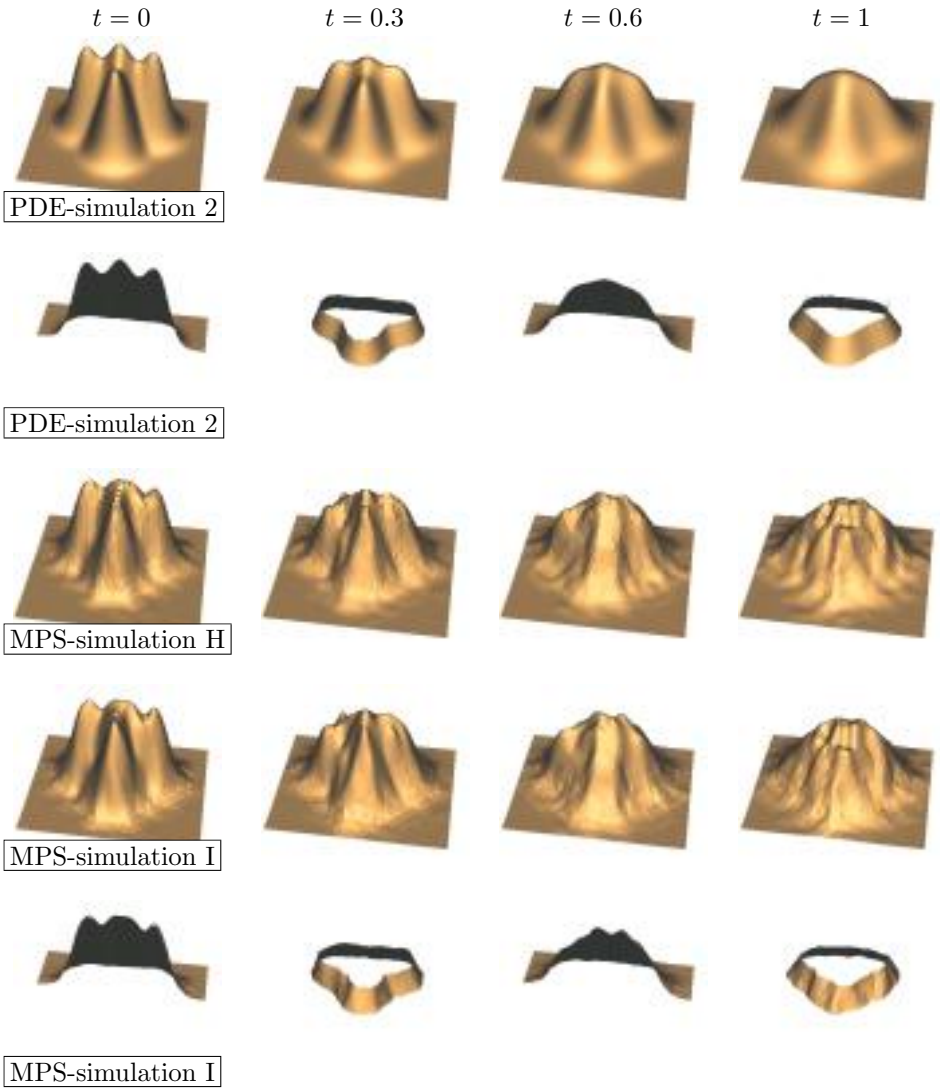

FIG. 6. *Simulations of* (1.1) *with "*T*"-initial condition.*

Our simulation results for $t = 0$, $t = 0.3$, $t = 0.6$, and $t = 1$ are presented in Figure 6. The first line contains three-dimensional visualizations of a numerical solution of (1.1). Modifications of these pictures can be found in the second line. More precisely, in the first and third row the graphs are cut along the line connecting those centers of the Gaussians, which characterize the top of the "T"-initial condition. In the second and fourth row cuts along two different level lines are performed. Visualizations of simulations of the many-particle system (2.17) or (2.18) are collected in the remaining lines of Figure 6. For the simulation parameters N, δ, h, θ (and τ) we essentially apply combinations also employed in the previous simulations described in section 6.2.1. In particular, for MPS-simulation H, where the adaption step is not included, the same parameters N_E, δ_E, h_E, and θ_E as in MPS-simulation E are taken;

cf. (6.4). Finally, the parameters N_G, δ_G, h_G, and θ_G from MPS-simulation G, cf. (6.6), are utilized again now in MPS-simulation I also featuring the adaption step. Since the adaption of the mesh did not begin to work, i.e., the resulting pictures did not differ from those in the third row, when $\tau_G = 0.05$ was chosen again, a smaller adaption parameter $\tau_I = 0.01$ was selected for this simulation. In the last row of Figure 6 modifications of the snapshots in the fourth row of MPS-simulation I are collected, where cuts are performed in exactly the same way as in the pictures in the second row.

6.3. Remarks on the hardware and software. Our simulations have been performed on a PC with an Intel Pentium processor working with 200 MHz, where first Slackware Linux by Patrick Volkerding and later on Redhat Linux was used as the operating system. The simulation program was written in C_{++}. In particular, we used the GNU C_{++}-library to obtain a random number generator and also in order to work with the vector classes and the set- and bag-class prototypes implemented there. To generate visualizations of our results we employed the Mesa 3D graphics library by Brian Paul. Finally, to control the various parts of the simulation program a graphical user interface generated with the XForms library by T. C. Zhao and Mark Overmars was utilized. Presently, efforts are made to replace the GNU C_{++}-library by the C_{++} standard library.

Concluding remarks. In this paper we employ a particular partial differential equation, namely the *viscous porous medium equation* (1.1), to discuss a special particle method based on the concept of *moderately interacting many-particle systems* to obtain an approximation to its solution. We propose an algorithm, which may be classified as a combination of a *smoothed particle hydrodynamics* and a *particle-mesh method*. This algorithm depends on several discretization parameters, namely on a particle number N, a spatial mesh size δ, a time step h, an inverse interaction range θ and, for some modified version, on an adaption parameter τ.

To assess this particle method we give upper bounds for the expected squared approximation error. In particular, our result provides some hints on how to modify the discretization parameters to obtain a desired reduction of the approximation error. Furthermore, the proof of our result suggests employing some regularity hypothesis (HS), cf. section 4.3, about the empirical processes associated with the particle method to deduce improved upper bounds for the approximation error. As a consequence of these formal considerations another approach to modify the discretization parameters is obtained.

To examine our mathematical considerations we perform some computer simulations, where in addition to tests of our particle method we also determine a numerical solution of (1.1) by a simple finite-difference method. We check the dependence of the performance of the particle method, i.e., its precision and its computational expenses, on the strategy to modify the discretization parameters. We observe that the strategy based on (HS) has a considerable advantage.

As mentioned in section 1 particle methods are established in several branches of computational physics. Studies like the present one may be helpful for their improvement. For example, our considerations demonstrate that a careful choice of discretization parameters can have a considerable influence on the performance of particle methods. In this context a mathematical justification of (HS) or an investigation of the dependence of the right side of estimates like (3.23) on the region Q, cf. step (A) in section 2, might be useful.

In our computer experiments the solution of (1.1) by finite differences turned out to be faster. More elaborate methods like finite elements should perform even better. Although in this paper we have not considered them in detail, we presently believe that for the solution of some more general reaction-diffusion equations in low-dimensional spaces those methods should also be preferred. An additional plus for finite elements is the availability of software packages like FEMLAB, cf. http://www.femlab.com/, or FREEFEM, cf. http://www-rocq.inria.fr/Frederic.Hecht/freefem++.htm or [7], for the solution of general partial differential equations. For reaction-diffusion equations in high-dimensional spaces further investigations seem to be needed. In such cases for finite differences or finite elements the number of nodes needed in the respective meshes grows enormously with increasing precision, which may lead to serious drawbacks for these methods.

Moreover, in many situations partial differential equations provide less useful models. For example, for the modelling of biological populations of moderate size, which typically exhibit stochastic fluctuations, many-particle models are more realistic than PDE models, which are conceived to describe the limit of infinite populations. Hence, in this field studies of the simulation of many-particle systems are important. In order to develop effective simulation methods, e.g., the "distance" between "true" many-particle systems like (1.2) and its modifications optimized for computer simulations as that considered in this paper should be investigated. As a first step in this direction the ideas exposed in section 2 have already been used to improve the computer program employed for obtaining the results described in section 6 such that many-particle systems as those described in [14] can be simulated.

DESCENT DIRECTIONS OF QUASI-NEWTON METHODS FOR SYMMETRIC NONLINEAR EQUATIONS*

GUANG-ZE GU†, DONG-HUI LI†‡, LIQUN QI‡, AND SHU-ZI ZHOU†

Abstract. In general, when a quasi-Newton method is applied to solve a system of nonlinear equations, the quasi-Newton direction is not necessarily a descent direction for the norm function. In this paper, we show that when applied to solve symmetric nonlinear equations, a quasi-Newton method with positive definite iterative matrices may generate descent directions for the norm function. On the basis of a Gauss–Newton based BFGS method [D. H. Li and M. Fukushima, *SIAM J. Numer. Anal.*, 37 (1999), pp. 152–172], we develop a norm descent BFGS method for solving symmetric nonlinear equations. Under mild conditions, we establish the global and superlinear convergence of the method. The proposed method shares some favorable properties of the BFGS method for solving unconstrained optimization problems: (a) the generated sequence of the quasi-Newton matrices is positive definite; (b) the generated sequence of iterates is norm descent; (c) a global convergence theorem is established without nonsingularity assumption on the Jacobian. Preliminary numerical results are reported, which positively support the method.

Key words. BFGS method, norm descent direction, global convergence, superlinear convergence

1. Introduction.

Let $F : R^n \to R^n$ be continuously differentiable. A general quasi-Newton method for solving the system of nonlinear equations

$$F(x) = 0 \tag{1.1}$$

generates a sequence of iterates $\{x_k\}$ by letting $x_{k+1} = x_k + d_k$, where d_k is a solution of the following system of linear equations:

$$B_k d + F(x_k) = 0. \tag{1.2}$$

If in (1.2), matrix B_k is replaced by $F'(x_k)$, the Jacobian of the function F at x_k, the method reduces to the well-known Newton method. An attractive feature of a quasi-Newton method is its local superlinear convergence property without computation of Jacobians. To enlarge the convergence domain of a quasi-Newton method, line search technique or trust region strategy can be exploited. In this paper, we use a backtracking line search technique to globalize a quasi-Newton method.

A line search step at iteration k of an iterative method determines a scalar $\lambda_k > 0$ which satisfies

$$\|F(x_k + \lambda_k d_k)\| < \|F(x_k)\|. \tag{1.3}$$

The next iterate is then determined by letting $x_{k+1} = x_k + \lambda_k d_k$. The scalar λ_k is called the steplength. Let θ be the norm function defined by

$$\theta(x) = \frac{1}{2}\|F(x)\|^2. \tag{1.4}$$

Then the nonlinear equation problem (1.1) is equivalent to the following global optimization problem:

$$\min \theta(x), \qquad x \in R^n, \tag{1.5}$$

and condition (1.3) is equivalent to

$$\theta(x_k + \lambda_k d_k) < \theta(x_k). \tag{1.6}$$

An iterative method that generates a sequence $\{x_k\}$ satisfying (1.3) or (1.6) is called a norm descent method. If d_k is a descent direction of θ at x_k, then inequality (1.6) holds for all $\lambda_k > 0$ sufficiently small. Accordingly, the related iterative method is a norm descent method. In particular, Newton's method with line search is norm descent. For a quasi-Newton method, however, d_k may not be a descent direction of θ at x_k even if B_k is symmetric and positive definite. To globalize a quasi-Newton method, Li and Fukushima [6] proposed an approximately norm descent line search technique and established global and superlinear convergence of a Gauss–Newton based BFGS method for solving symmetric nonlinear equations. The method in [6] is not norm descent. In addition, the global convergence theorem is established under the assumption that $F'(x)$ is uniformly nonsingular.

The purpose of this paper is to develop a norm descent Gauss–Newton based BFGS method. We adjust the steplength and the search direction simultaneously so that the generated iterate sequence satisfies (1.6). We update B_k by combining a modified BFGS formula [7] or the cautious BFGS update rule with the Gauss–Newton based BFGS method [6] such that B_{k+1} inherits positive definiteness of B_k no matter whatever line search is used. Under mild conditions, we establish a global convergence theorem which shows that there exists an accumulation point that is a stationary point of problem (1.5) even if $F'(x)$ is singular everywhere. We also get the superlinear convergence of the proposed method.

In the next section, we describe how to generate a quasi-Newton direction that is descent for θ. We also state the steps of the proposed method. In section 3, we establish the global and superlinear convergence of the proposed method. In section 4, we present some numerical results.

2. Descent direction in a quasi-Newton method. In this section, we describe a way to generate a descent quasi-Newton direction for θ and then propose a norm descent BFGS method for solving (1.1). We assume that the function F is continuously differentiable, and its Jacobian $F'(x)$ is symmetric for every $x \in R^n$.

Recall that in Newton's method, the Newton direction is a solution of the Newton equation

$$F'(x_k)d + F(x_k) = 0. \tag{2.1}$$

Equation (2.1) may have no solution if $F'(x_k)$ is singular. In the case where the solution set of (2.1) is empty, instead of solving (2.1), we may solve the least squares problem

$$\min \frac{1}{2}\|F'(x_k)d + F(x_k)\|^2$$

to get a direction d_k, which results in the so-called Gauss–Newton equation

$$F'(x_k)^2 d + F'(x_k)F(x_k) = 0. \tag{2.2}$$

Here we have used the symmetry of $F'(x_k)$. On the other hand, if $F'(x_k)$ is nonsingular, (2.2) is equivalent to (2.1). In [6], a Gauss–Newton based quasi-Newton method was proposed in which the quasi-Newton direction is the solution of the following system of linear equations:

$$B_k d + \bar{q}_k = 0, \tag{2.3}$$

where B_k is an approximation of matrix $F'(x_k)^2$, and $\bar{q}_k$ is an approximation of vector $F'(x_k)F(x_k)$. Specifically, let λ_{k-1} be the steplength used at the previous iteration. Then, vector $\bar{q}_k$ is defined by

$$\bar{q}_k = (F(x_k + \lambda_{k-1}F(x_k)) - F(x_k))/\lambda_{k-1} \approx F'(x_k)F(x_k),$$

and matrix B_k is updated by the BFGS formula

$$B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}, \tag{2.4}$$

where $s_k = x_{k+1} - x_k$, $y_k = F(x_k + \delta_k) - F(x_k)$, and $\delta_k = F(x_{k+1}) - F(x_k)$. It is clear that if $\|s_k\|$ is small, then $B_{k+1}s_k = y_k \approx F'(x_{k+1})^2 s_k$. Since the solution d_k of (2.3) may not be a descent direction of θ at x_k when x_k is far away from a solution of (1.1), it is generally not possible to get a steplength $\lambda_k > 0$ satisfying (1.6). Taking this into account, Li and Fukushima [6] proposed a nondescent line search in which the steplength $\lambda_k > 0$ satisfies the following inequality:

$$\theta(x_k + \lambda_k d_k) - \theta(x_k) \le -\sigma_1 \|\lambda_k d_k\|^2 - \sigma_2 \|\lambda_k F(x_k)\|^2 + \epsilon_k \|F(x_k)\|^2, \tag{2.5}$$

where σ_1 and σ_2 are positive constants, and $\epsilon_k > 0$ satisfies

$$\sum_{k=0}^{\infty} \epsilon_k < \infty.$$

Since ϵ_k is small, $\{x_k\}$ is approximately norm descent.

The purpose of this paper is to develop a norm descent BFGS method. In other words, we want to construct a system of linear equations like (2.3) such that its solution provides a descent direction of θ at x_k.

Observe that

$$\lim_{\lambda_{k-1} \to 0^+} \bar{q}_k = F'(x_k)F(x_k) \triangleq \tilde{q}_k.$$

Accordingly, the solution of (2.3) with $\tilde{q}_k$ instead of $\bar{q}_k$ is $\tilde{d}_k = -B_k^{-1}F'(x_k)F(x_k)$. If B_k is positive definite and $F'(x_k)$ is symmetric, then $\tilde{d}_k$ is a descent direction of θ at x_k. This observation prompts us to regard λ_{k-1} as a parameter. When this parameter is adjusted to be small enough, the solution of (2.3) is a descent direction of θ at x_k. The following process gives details to realize it.

Let

$$q_k(\lambda) = (F(x_k + \lambda F(x_k)) - F(x_k))/\lambda. \tag{2.6}$$

Consider the system of linear equations with parameter λ:

$$B_k d + q_k(\lambda) = 0. \tag{2.7}$$

Let $d(\lambda)$ be the solution of (2.7). The following lemma shows that when $\lambda > 0$ is sufficiently small, every solution of (2.7) is a descent direction of θ at x_k.

LEMMA 2.1. *Let σ_1 and σ_2 be positive constants and B_k be a symmetric and positive definite matrix. If x_k is not a stationary point of* (1.5)*, then there exists a constant $\bar{\lambda} > 0$ depending on k such that when $\lambda \in (0, \bar{\lambda})$, the unique solution $d(\lambda)$ of* (2.7) *satisfies*

$$\nabla\theta(x_k)^T d(\lambda) < 0. \tag{2.8}$$

Moreover, inequality

$$\theta(x_k + \lambda d(\lambda)) - \theta(x_k) \le -\sigma_1 \|\lambda d(\lambda)\|^2 - \sigma_2 \|\lambda F(x_k)\|^2 \tag{2.9}$$

holds for all $\lambda > 0$ sufficiently small.

Proof. It is clear that

$$\lim_{\lambda \to 0} q_k(\lambda) = F'(x_k)F(x_k).$$

Therefore, we get from (2.7) that

$$\begin{aligned}\lim_{\lambda \to 0^+} \nabla\theta(x_k)^T d(\lambda) &= -\lim_{\lambda \to 0^+} F(x_k)^T F'(x_k) B_k^{-1} q_k(\lambda) \\ &= -F(x_k)^T F'(x_k) B_k^{-1} F'(x_k) F(x_k).\end{aligned}$$

Since $F'(x_k)$ is symmetric and $F'(x_k)F(x_k) \neq 0$ as x_k is not a stationary point of (1.5), the last equality and the positive definiteness of B_k imply (2.8). We turn to verifying (2.9).

Notice that

$$\begin{aligned}\lim_{\lambda \to 0^+} (\theta(x_k + \lambda d(\lambda)) - \theta(x_k))/\lambda &= \lim_{\lambda \to 0^+} \nabla\theta(x_k)^T d(\lambda) \\ &= -F(x_k)^T F'(x_k) B_k^{-1} F'(x_k) F(x_k) < 0.\end{aligned}$$

However, the right-hand side of (2.9) is $o(\lambda)$. Therefore, inequality (2.9) holds for all $\lambda > 0$ sufficiently small. ∎

Lemma 2.1 motivates us to find a descent quasi-Newton direction by adjusting parameter λ.

Procedure 1. Let constant $\rho \in (0, 1)$ be given. Let i_k be the smallest nonnegative integer such that inequality (2.9) holds with $\lambda = \rho^i$, $i = 0, 1, \ldots$. Let $d_k = d(\rho^{i_k})$, and $q_k = q_k(\rho^{i_k})$.

Procedure 1 ensures that the value of θ at $x_k + \rho^{i_k} d_k$ is less than that of θ at x_k, though d_k may not necessarily be a descent direction of θ at x_k. It is reasonable to let the scalar ρ^{i_k} be the steplength. However, this steplength may be very small if i_k is large. To enlarge steplength, we exploit the following forward procedure.

Procedure 2. Let i_k and d_k be determined by Procedure 1. If $i_k = 0$, let $\lambda_k = 1$. Otherwise, let j_k be the largest positive integer $j \in \{0, 1, 2, \ldots, i_k - 1\}$ satisfying

$$\theta(x_k + \rho^{i_k - j} d_k) - \theta(x_k) \le -\sigma_1 \|\rho^{i_k - j} d_k\|^2 - \sigma_2 \|\rho^{i_k - j} F(x_k)\|^2. \tag{2.10}$$

Let $\lambda_k = \rho^{i_k - j_k}$.

Note that (2.10) is satisfied with $j = 0$. Therefore, Procedure 2 is well defined.

Procedures 1 and 2 describe a way to generate d_k and λ_k. It is easy to see from Procedures 1 and 2 that

$$\theta(x_k + \lambda_k d_k) - \theta(x_k) \le -\sigma_1 \|\lambda_k d_k\|^2 - \sigma_2 \|\lambda_k F(x_k)\|^2, \tag{2.11}$$

which corresponds to (2.5) with $\epsilon_k = 0$. It is also easy to see that if $\lambda_k \neq 1$, then $\lambda'_k = \lambda_k/\rho$ satisfies

$$\theta(x_k + \lambda'_k d_k) - \theta(x_k) > -\sigma_1 \|\lambda'_k d_k\|^2 - \sigma_2 \|\lambda'_k F(x_k)\|^2. \tag{2.12}$$

Notice that Procedure 1 generates a direction d_k which satisfies

$$B_k d_k + q_k = 0, \tag{2.13}$$

where $q_k = q_k(\rho^{i_k})$. Vector q_k differs from $q_k(\lambda_k)$ if $j_k \neq 0$.

Based on the above process, we propose a norm descent Gauss–Newton based BFGS method as follows.

Algorithm 1 (a descent BFGS method).

Initial Let $B_0 \in R^{n\times n}$ be symmetric and positive definite. Let $x_0 \in R^n$. Set $k = 0$.

Step 1 Determine d_k and λ_k by Procedures 1 and 2. Let $x_{k+1} = x_k + \lambda_k d_k$.

Step 2 Update B_k to get B_{k+1} by the modified BFGS formula

$$B_{k+1} = B_k - \frac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \frac{y_k y_k^T}{y_k^T s_k}, \tag{2.14}$$

where $s_k = x_{k+1} - x_k$,

$$y_k = \gamma_k + \Big(\max\Big\{0, -\frac{\gamma_k^T s_k}{\|s_k\|^2}\Big\} + \phi(\|F(x_k)\|)\Big)s_k,$$

$\gamma_k = F(x_k + \delta_k) - F(x_k)$, $\delta_k = F(x_{k+1}) - F(x_k)$, and function $\phi : R \to R$ satisfies (i) $\phi(t) > 0$ for all $t > 0$, (ii) $\phi(t) = 0$ if and only if $t = 0$, (iii) $\phi(t)$ is bounded if t is in a bounded set.

Step 3 Let $k := k + 1$ and go to Step 1.

In Step 2 of Algorithm 1, we use a modified BFGS update formula instead of the ordinary BFGS formula. The modified BFGS update formula was proposed by Li and Fukushima [7], where $\phi(t) = \mu t$ with some constant $\mu > 0$. A favorable property for this modification is that B_{k+1} inherits positive definiteness of B_k whatever line search is used [7]. Indeed, it is not difficult to get that

$$y_k^T s_k \ge \max\Big\{\gamma_k^T s_k,\ \phi(\|F(x_k)\|)\|s_k\|^2\Big\} > 0, \tag{2.15}$$

which is sufficient to guarantee positive definiteness of B_{k+1} as long as B_k is positive definite. Suppose that $\{x_k\}$ is contained in a bounded set at which F is continuously differentiable. It is not difficult to deduce that

$$\|y_k\| \le 2\|\gamma_k\| + \phi(\|F(x_k)\|)\ \|s_k\| \le 2L\|\delta_k\| + M\|s_k\| \le (2L^2 + M)\|s_k\|, \tag{2.16}$$

where $M > 0$ is an upper bound of $\phi(\|F(x)\|)$ and $L > 0$ is a Lipschitz constant of F. Inequalities (2.15) and (2.16) imply that

$$\max\Big\{\gamma_k^T s_k,\ \phi(\|F(x_k)\|)\|s_k\|^2\Big\} \le y_k^T s_k \le (2L^2 + M)\|s_k\|^2. \tag{2.17}$$

Another way to develop quasi-Newton methods is to adopt the so-called cautious update rule proposed by Li and Fukushima [8]. The steps of the related BFGS algorithm is stated as follows.

ALGORITHM 2 (a descent cautious BFGS method).

Initial Let $B_0 \in R^{n\times n}$ be symmetric and positive definite. Let $x_0 \in R^n$. Set $k = 0$.

Step 1 Determine d_k and λ_k by Procedures 1 and 2. Let $x_{k+1} = x_k + \lambda_k d_k$.

Step 2 Update B_k to get B_{k+1} by the cautious BFGS formula

$$B_{k+1} = \begin{cases} B_k - \dfrac{B_k s_k s_k^T B_k}{s_k^T B_k s_k} + \dfrac{\gamma_k \gamma_k^T}{\gamma_k^T s_k} & \text{if } \dfrac{\gamma_k^T s_k}{\|s_k\|^2} \geq \phi(\|F(x_k)\|), \\ B_k & \text{otherwise,} \end{cases} \tag{2.18}$$

where γ_k and ϕ are the same as those in Algorithm 1.

Step 3 Let $k := k + 1$ and go to Step 1.

The only difference between Algorithms 1 and 2 is the update formula. The cautious BFGS method possesses similar properties of the modified BFGS method. For details, we refer to [8].

3. Global and superlinear convergence. In this section, we prove the global and superlinear convergence of Algorithm 1. The global convergence of Algorithm 2 can be obtained in a similar way. Without specification, we let $\{x_k\}$ and $\{B_k\}$ stand for the sequences of iterates and matrices generated by Algorithm 1, respectively. The following lemma is straightforward from Algorithm 1.

LEMMA 3.1. *The sequence $\{\theta(x_k)\}$ is strictly decreasing. In addition, the following inequalities hold:*

$$\sum_{k=0}^{\infty} \|s_k\|^2 < \infty, \qquad \sum_{k=0}^{\infty} \|\lambda_k F(x_k)\|^2 < \infty. \tag{3.1}$$

We summarize the condition needed for the global convergence of Algorithm 1 as follows.

Assumption A.

(i) The level set

$$\Omega = \{x \in R^n \mid \theta(x) \leq \theta(x_0)\}$$

is bounded.

(ii) Function F is continuously differentiable on Ω, and $F'(x)$ is symmetric for every $x \in \Omega$.

It is clear that under condition (i) in Assumption A, sequence $\{x_k\} \subset \Omega$ is bounded.

We are going to establish a global convergence theorem of Algorithm 1 to show that under Assumption A, there exists an accumulation point of $\{x_k\}$ which is a stationary point of (1.5), namely,

$$\liminf_{k\to\infty} \|\nabla\theta(x_k)\| = 0. \tag{3.2}$$

It is easy to see from Lemma 3.1 that if $\limsup_{k\to\infty} \lambda_k > 0$, then $\liminf_{k\to\infty} \|F(x_k)\| = 0$ and, hence, (3.2) holds. So, we need only to show (3.2) for the case $\lim_{k\to\infty} \lambda_k = 0$. We do it by assuming

$$\liminf_{k\to\infty} \|\nabla\theta(x_k)\| > 0 \tag{3.3}$$

to deduce a contradiction.

Notice that (3.3) particularly implies that there is a constant $\eta > 0$ such that $\|F(x_k)\| \geq \eta$ for all k. It follows from (2.17) and the properties of ϕ that if (3.3) holds, then there are positive constants $c \leq C$ such that

$$c\|s_k\|^2 \leq y_k^T s_k \leq C\|s_k\|^2. \tag{3.4}$$

Therefore, we get the following lemma from (2.16), (3.4), and Theorem 2.1 of [1].

LEMMA 3.2. *If* (3.3) *holds, then there are positive constants* β_i, $i = 1, 2, 3$, *such that for any positive integer* k, *inequalities*

$$\|B_i s_i\| \leq \beta_1 \|s_i\|, \qquad \beta_2 \|s_i\|^2 \leq s_i^T B_i s_i \leq \beta_3 \|s_i\|^2 \tag{3.5}$$

hold for at least $\lceil k/2 \rceil$ *many* $i \leq k$.

Inequalities (3.5) together with (2.13) imply that there are at least $\lceil k/2 \rceil$ many $i \leq k$ satisfying

$$\|q_i\| = \|B_i d_i\| \leq \beta_1 \|d_i\|, \qquad \|d_i\| \leq \beta_2^{-1} \|q_i\|. \tag{3.6}$$

We now prove the global convergence of Algorithm 1.

THEOREM 3.3. *Let Assumption* A *hold and* $\{x_k\}$ *be generated by Algorithm* 1. *Then* (3.2) *holds.*

Proof. We need only to show (3.2) for the case $\lim_{k\to\infty} \lambda_k = 0$. In this case, inequality (2.12) holds for all k sufficiently large. Suppose contrarily that (3.2) does not hold or, equivalently, (3.3) holds. Denote by K the set of indices i such that (3.5) holds. Then K is infinite. Since $\{x_k\} \subset \Omega$ is bounded, it is clear that sequences $\{q_k\}_{k\in K}$ and $\{d_k\}_{k\in K}$ are bounded. Let $K_1 \subset K$ and subsequences $\{x_k\}_{k\in K_1}$ and $\{d_k\}_{k\in K_1}$ converge to x^* and d^*, respectively. Then we have

$$\lim_{k\in K_1} q_k = \nabla\theta(x^*). \tag{3.7}$$

Dividing both sides of (2.12) by λ_k' and then taking limits as $k \to \infty$ with $k \in K_1$, we get

$$\nabla\theta(x^*)^T d^* \geq 0. \tag{3.8}$$

On the other hand, taking the inner product with d_k in (2.13), we get

$$0 = d_k^T B_k d_k + q_k^T d_k \geq \beta_2 \|d_k\|^2 + q_k^T d_k.$$

Taking limits in both sides as $k \to \infty$ with $k \in K_1$ yields

$$\nabla\theta(x^*)^T d^* \leq -\beta_2 \|d^*\|^2.$$

This together with (3.8) implies that $d^* = 0$. It then follows from (3.6) that $\lim_{k\in K_1} q_k = 0$, which together with (3.7) yields a contradiction with (3.3). The contradiction proves (3.2). □

Remark. In [2] the global convergence of Broyden's class of variable metric methods except for DFP was proved. The proof there depends on the convexity of the objective function. A similar result was obtained by Powell [10] when the BFGS method is applied to convex minimization problems. For nonconvex minimization problems, no theory exists to support the global convergence of the BFGS method.

On the contrary, an example has been constructed [3] recently, which shows that the ordinary BFGS method with the Wolfe line search may fail to converge to a stationary point of a nonconvex unconstrained minimization.

On the other hand, a modified BFGS method was proposed by Li and Fukushima [7]. In the modified BFGS method, the iterative matrix B_k is always positive definite whatever line search is used as long as B_0 is positive definite. Moreover, a liminf result was obtained for nonconvex unconstrained minimization. Besides, another modified BFGS method called the cautious BFGS method was proposed by Li and Fukushima [8]. The cautious BFGS method also possesses global convergence in the sense $\liminf_{k\to\infty} \nabla f(x_k) = 0$ when it is applied to $\min f(x)$. In both papers, the results were obtained without the requirement of nonsingular Hessian. These two papers show the possibility to improve the unconstrained minimization result by Byrd, Nocedal, and Yuan [2] and Powell [10].

This paper adopts a similar updating technique as used in [4] and [5]. Consequently, we established Theorem 3.3, which shows that the iterative sequence has an accumulation point which is a stationary point of problem $\min \theta(x) = \frac{1}{2}\|F(x)\|^2$. It may not be a solution of the nonlinear equation (1.1) if the Jacobian is singular at that point.

The next theorem shows a strong convergence property of Algorithm 1.

THEOREM 3.4. *Let Assumption* A *hold. Suppose that the sequence* $\{x_k\}$ *generated by Algorithm* 1 *has a subsequence converging to a stationary* x^* *at which* $F'(x^*)$ *is nonsingular. Then* x^* *is a solution of* (1.1)*. Moreover, the whole sequence* $\{x_k\}$ *converges to* x^**.*

Proof. Since x^* satisfies $\nabla\theta(x^*) = F'(x^*)F(x^*) = 0$, we obviously have $F(x^*) = 0$ if $F'(x^*)$ is nonsingular. Since $\{\theta(x_k)\}$ converges, every accumulation point of $\{x_k\}$ is a solution of (1.1). By the nonsingularity of $F'(x^*)$ again, x^* is an isolated limit point of $\{x_k\}$. However, we have from (3.1) that $x_{k+1} - x_k \to 0$ as $k \to \infty$. Therefore, the whole sequence $\{x_k\}$ converges to x^*. □

In a way similar to the proof of Theorem 3.8 in [7], it is not difficult to prove the superlinear convergence of Algorithm 1. We state the theorem as follows but omit the proof.

THEOREM 3.5. *Let the conditions of Theorem* 3.4 *hold. Suppose further that* F' *is Lipschitz continuous. Then* $\{x_k\}$ *is superlinearly convergent.*

Similar to the above argument, we can establish the global and superlinear convergence of Algorithm 2. We state the results as follows but omit the proof.

THEOREM 3.6. *Let Assumption* A *hold and* $\{x_k\}$ *be generated by Algorithm* 2*. Then* (3.2) *holds. If the sequence* $\{x_k\}$ *has a subsequence converging to a stationary* x^* *at which* $F'(x^*)$ *is nonsingular, then* x^* *is a solution of* (1.1)*. Moreover, the whole sequence* $\{x_k\}$ *converges to* x^**. If we further suppose that* F' *is Lipschitz continuous, then* $\{x_k\}$ *is superlinearly convergent.*

4. Numerical results. In this section, we test the proposed descent BFGS methods on nonlinear equation problems obtained from [6, 9] and the unconstrained optimization problems obtained from the website ftp://ftp.mathworks.com/pub/contrib/v4/optim/uncprobs/. We call Algorithms 1 and 2 the DBFGS (descent BFGS) method and the CBFGS (cautious BFGS) method, respectively, and call the BFGS method based on the Gauss–Newton approach and the nondescent line search [6] the NBFGS (nondescent BFGS) method. Then we compare their performance.

The parameters are specified as follows. We take $\rho = 0.1$ and $\sigma_1 = \sigma_2 = 10^{-5}$

in (2.9). The initial quasi-Newton matrices are set to be $B_0 = A$ [6] for nonlinear equation problems and $B_0 = I$ for unconstrained optimization problems. The function ϕ is determined by

$$\phi(t) = \begin{cases} Ct^2 & \text{if } t \le 1, \\ Ct^{0.1} & \text{otherwise,} \end{cases}$$

where $C = 10^{-5}$. For the NBFGS method, we update B_k by the BFGS formula [6] if $y_k^T s_k \ge 10^{-5}$. Otherwise, we let $B_{k+1} = B_k$. We stop the iteration process if $\|F(x_k)\| \le 10^{-4}$.

The tested results are listed in Tables 1 and 2. Table 3 gives the average performance of the three methods for solving nonlinear equation problems. The columns of the tables have the following meaning:

Dim: the dimension of the problem.
Method: the name of the algorithm.
Init: the initial point, namely, integer l in Table 1 meaning $x_0 = (l, l, \ldots, l)^T$.
Iter: the total number of iterations.
Inner: for the NBFGS method, the number of iterations at which $y_k^T s_k \ge 10^{-5}$ is satisfied; for the DBFGS method and the CBFGS method, the maximum number of inner iterations to generate the descent direction d_k.
Numf: the number of the function evaluations.
Fnorm: the final value of $\|F(x_k)\|$.

All the three methods terminate at solutions of nonlinear equation problems for all tested starting points. However, for the 33 unconstrained optimization problems, all the three methods fail to converge to a solution for at least 10 problems. The numbers of problems for which the NBFGS method, the DBFGS method, and the CBFGS method fail to converge are 16, 19, and 12, respectively.

The numerical results show that for low dimensional problems, the performance of these three methods is not different very much. For most of the test problems, the DBFGS method and the CBFGS method perform better than the NBFGS method in the iteration number, but worse in the number of the function evaluation. However, for high dimensional problems ($n = 200$ in Tables 1 and 3), both the DBFGS and the CBFGS methods perform much better than the NBFGS method in the iteration number as well as the number of the function evaluation. The maximum numbers of the inner iteration to generate a descent direction of a DBFGS method are generally very small. We also note that the performance of the DBFGS and CBFGS methods is almost the same if the both methods terminate regularly. For unconstrained optimization problems, the DBFGS method fails more frequently than the CBFGS method does.

In summary, the presented numerical results reveal that the DBFGS and CBFGS methods, compared with the NBFGS method, have potential advantages when applied to solve symmetric nonlinear equation whose function is not difficult to compute.

In Tables 1–3, we simply denote the NBFGS method as the BFGS method.

TABLE 1
Test results for nonlinear equation problems $B_0 = A$.

NUMERICAL APPROXIMATION OF AN SQP-TYPE METHOD FOR PARAMETER IDENTIFICATION*

MARTIN BURGER† AND WOLFRAM MÜHLHUBER†

Abstract. This paper deals with the numerical approximation of the Levenberg–Marquardt SQP (LMSQP) method for parameter identification problems, which has been presented and analyzed in [M. Burger and W. Mühlhuber, *Inverse Problems*, 18 (2002), pp. 943–969]. It is shown that a Galerkin-type discretization leads to a convergent approximation and that the indefinite system arising from the Karush–Kuhn–Tucker (KKT) system is well-posed.

In addition, we present a multilevel version of the Levenberg–Marquardt method and discuss the simultaneous solution of the discretized KKT system by preconditioned iteration methods for indefinite problems. From a discussion of the numerical effort we conclude that these approaches may lead to a considerable speed-up with respect to standard iterative regularization methods that eliminate the underlying state equation. The numerical efficiency of the LMSQP method is confirmed by numerical examples.

Key words. parameter identification, sequential quadratic programming, iterative regularization, Galerkin methods, indefinite systems

1. Introduction.

Parameter identification denotes the procedure of determining unknown parameters appearing in an underlying state equation (usually a partial differential equation) from indirect measurements related to the solution of this equation. Such problems appear in many applications, where mathematical models of physical, chemical, biological, or economical processes are used (cf., e.g., [2, 13, 17] and the references therein).

Since such problems are *ill-posed* in general, i.e., the parameter to be reconstructed does not depend on the observation in a stable way, regularization methods have to be used in order to compute a stable approximation of the parameter in the presence of data noise. Due to the ill-posedness of the identification problem, the numerical approximation of such problems is not a simple task. The standard approach that can be found in literature is based on a priori elimination of the state equation, and an application of a discretized regularization method to the resulting operator equation involving the *parameter-to-output map*, which is the operator mapping the parameter to the corresponding observation. The main part in the evaluation of this map is the solution of the underlying state equation for a given parameter, which is numerically realized by standard discretizations such as finite elements.

The approach based on the parameter-to-output map, in particular combined with *iterative regularization methods* (cf. [18] for an overview), has been applied with success even to rather complicated parameter identification problems (cf., e.g., [10, 25, 26]). However, since these methods need a high number of direct solves (i.e., solutions of the state equation), fine discretizations of the parameter lead to a considerable compu-

tational effort, which results in high CPU times or even in the impossibility of using fine discretizations. Another drawback of this approach is that the discretizations of state and parameter are rather independent, which makes the numerical analysis extremely difficult. Therefore, fundamentally different methods for the solution of parameter identification problems have been investigated recently, whose common idea is to avoid a priori elimination of the state equation (cf. [11, 21, 27]). The aim of this paper is to discuss the numerical approximation of an iterative regularization method based on the idea of SQP (cf. [11]). We investigate Galerkin-type discretizations in the product space for parameter, state variable, and a corresponding Lagrangian variable, which leads to a sequence of well-posed indefinite systems. With this approach we are able to show convergence of the numerical approximation both for the quadratic programming problem arising in each iteration step and for the overall minimization procedure.

The general setup in this paper is as follows: we assume that we are given a noisy measurement z^δ satisfying

$$\|\hat{z} - z^\delta\|_Z \leq \delta, \tag{1.1}$$

where the exact data satisfy

$$\hat{z} := E\hat{u}, \tag{1.2}$$

with $E \in \mathcal{L}(X, Z)$ and $\hat{u} \in X$ solving $e(\hat{u}, \hat{q}) = f$ for some $\hat{q} \in Q_{ad} \subset Q$ (where Q_{ad} is a closed subset of Q with a nonempty interior). Our aim is to identify the parameter $q \in Q_{ad}$ in the underlying equation

$$e(u, q) = f, \tag{1.3}$$

where $e : X \times Q \to X^*$ is a continuous nonlinear operator with

$$e(0, 0) = 0. \tag{1.4}$$

In this setup X, X^*, Q, and Z are Hilbert spaces, and X^* can be identified with the dual of X. Finally, we assume that e is continuously Fréchet-differentiable on $X \times Q$ and that the partial derivative $e_u \in \mathcal{L}(X, X^*)$ is self-adjoint and satisfies the coercivity condition

$$\langle e_u(u, q)v, v\rangle \geq \alpha_e \|v\|_X^2 \qquad \forall (u, q, v) \in X \times Q_{ad} \times X \tag{1.5}$$

for some $\alpha_e \in \mathbb{R}^+$.

The above setup is typical for partial differential equations of elliptic type, which is also the main type of application we have in mind. We want to mention that the infinite-dimensional analysis carried out in the preceding paper [11] was not restricted to elliptic problems but only assumed the well-posedness of the state equation for a given parameter. However, since the numerical approximation techniques for elliptic problems differ from the ones for parabolic or hyperbolic problems (cf., e.g., [33] for an overview), one cannot expect a successful unified approach to corresponding parameter identification problems. For this reason we start with an investigation of the elliptic case in this paper, but we want to mention that the numerical identification of parameters in transient equations or even mixed systems of equations is an important and challenging problem for future research.

In [11], it has been mentioned that the parameter identification problem in the above setup is an *ill-posed inverse problem,* and we have proposed the following iterative regularization method based on the idea of SQP.

METHOD 1 (Levenberg–Marquardt SQP method). *Let*

$$(u_0, q_0) \in X \times Q$$

be a given initial value, and let $(\beta_k)_{k\in\mathbb{N}}$ *be a bounded sequence of positive real numbers. The* Levenberg–Marquardt SQP *(LMSQP) method consists of the iteration procedure*

$$(u_{k+1}, q_{k+1}) = (\overline{u}_k, \overline{q}_k), \tag{1.6}$$

where $(\overline{u}_k, \overline{q}_k)$ *is the minimizer of the quadratic programming problem*

$$\frac{1}{2}\|Eu - z^\delta\|_Z^2 + \frac{\beta_k}{2}\|q - q_k\|_Q^2 \to \min_{(u,q)\in X\times Q} \tag{1.7}$$

subject to the linear constraint

$$e(u_k, q_k) + e'(u_k, q_k)(u - u_k, q - q_k) = f. \tag{1.8}$$

The iteration procedure is stopped as soon as $k = k_*$*, where*

$$\|Eu_{k_*} - z^\delta\|_Z \le \tau\delta < \|Eu_k - z^\delta\| \qquad \forall\ k < k_*, \tag{1.9}$$

with appropriately chosen $\tau > 1$.

The motivation for the LMSQP method comes from two sources: a first guide for the design of this method are classical SQP methods, where one would minimize in each step a functional of the form

$$\frac{1}{2}\|Eu - z^\delta\|_Z^2 + \langle e''(u_k, q_k)(u - u_k, q - q_k)^2, \lambda_k\rangle \to \min_{(u,q)\in X\times Q}, \tag{1.10}$$

subject to the constraint (1.8), in order to obtain the new values u_{k+1}, q_{k+1} with corresponding Lagrangian variable λ_{k+1} (cf. [1, 14] and the references therein for further details on SQP methods). Since this approach results in a sequence of ill-posed quadratic minimization problems for typical cases in parameter identification (cf. [11]), it seems natural to add a regularizing term. This leads us to the second guide for the construction of the LMSQP method, namely the classical Levenberg–Marquardt method for nonlinear least-squares problems. For the solution of an unconstrained nonlinear least-squares problem of the form $\|F(q) - \hat{z}\| \to \min$ (which would arise, e.g., by a priori elimination of the state equation), the Levenberg–Marquardt method can be characterized via the sequence of minimization problems

$$\frac{1}{2}\|F(q_k) + F'(q_k)(q - q_k) - \hat{z}\|_Z^2 + \frac{\beta_k}{2}\|q - q_k\|_Q^2 \to \min_{q\in Q}. \tag{1.11}$$

The synthesis of Levenberg–Marquardt and SQP methods for ill-posed parameter identification problems is not unique; one possibility would be to minimize

$$\frac{1}{2}\|Eu - z^\delta\|_Z^2 + \langle e''(u_k, q_k)(u - u_k, q - q_k)^2, \lambda_k\rangle + \frac{\beta_k}{2}\|q - q_k\|_Q^2 \to \min_{(u,q)\in X\times Q}, \tag{1.12}$$

subject to (1.8), and another one would be the method given by (1.7), (1.8). Both of these methods have been introduced in [11], but since for least-squares systems the Lagrangian variable must be small close to a solution (note that we are interested in the case of attainable data here) we restrict our attention to the LMSQP method (1.7), (1.8).

Due to the results of [11], the LMSQP method is a convergent regularization method if the condition (1.9) is used as a stopping rule. We note that (1.9) is a standard stopping criterion for ill-posed inverse problems but a nonstandard one for SQP-type methods. However, the analysis in [11] and in the remainder of this paper shows that in this context it does not cause termination of the method at (largely) infeasible points. As a particular consequence of the results in [11], the quadratic programming problems of the form (1.7), (1.8), which have to be solved in each iteration step, are well-posed. Our aim in this paper is to investigate the numerical approximation of the LMSQP method by a Galerkin-type approach. We shall show below that this leads to an indefinite system in each iteration step, whose solution is an approximation of optimal order to the solution of (1.7), (1.8). Moreover, we show that the reconstructions obtained with the discretized LMSQP method converge to a solution of the parameter identification problem as the noise level and the discretization size tend to zero, if an appropriate stopping rule is used, which relates the residual to the noise level and some measures for the discretization.

Moreover, we shall discuss the solution of the discretized Karush–Kuhn–Tucker (KKT) system, which is an indefinite linear system to be solved for the discretized equivalents of state, parameter, and Lagrangian variable. The standard approaches to the solution of such discretized problems arising from partial differential equations are *reduced SQP methods*, where state and Lagrangian variable are eliminated a priori. We recall the basic properties of the reduced SQP approach, but we mainly focus on the iterative solution of the whole system with appropriate preconditioning. This promising approach has been employed recently for parameter identification (cf. [21, 27]) and optimal control problems (cf. [3, 4, 5, 6]) with good numerical results, in particular with respect to efficiency.

The paper is organized as follows: in section 2 we investigate the numerical approximation of the LMSQP method by a Galerkin-type approach and discuss the well-posedness, stability, and approximation properties of the discretized KKT system; the convergence of the discretized solutions is shown in section 3. Some further numerical methods and the implementation of the SQP iteration are examined in section 4. We briefly discuss the correct scaling of variables, the solution of the KKT system, and globalization strategies. Moreover, we present and analyze a multilevel approach, which leads to a further speed-up of the method. As a first application we investigate the identification of a potential in an elliptic boundary value problem, where we can give quantitative error estimates in terms of the discretization sizes. Some numerical experiments related to this identification problem are presented in section 6, before we conclude and give an outlook for further interesting problems related to this topic in section 7.

2. Discretization techniques. In the following we investigate the discretization of the LMSQP method by a Galerkin approach. First of all, we assume that we have discretized data $z^{\delta,\eta} \in Z_\eta \subset Z$ of the form

$$z^{\delta,\eta} = R_\eta z^\delta, \tag{2.1}$$

where $R_\eta : Z \to Z_\eta$ is the orthogonal projector onto the finite-dimensional subspace Z_η. Note that we can give an error estimate for $z^{\delta,\eta}$ using (1.1) and $\|R_\eta\| = 1$, which yields

$$\delta_\eta := \|R_\eta z^\delta - \hat{z}\|_Z \le \|R_\eta(z^\delta - \hat{z})\|_Z + \|R_\eta \hat{z} - \hat{z}\|_Z \le \delta + \inf_{y \in Z_\eta} \|y - \hat{z}\|_Z. \tag{2.2}$$

Now let $X_h \subset X$, $Q_h \subset Q$ be finite-dimensional subspaces of X and Q, with the corresponding orthogonal projectors $P_h : X \to X_h$ and $\tilde{P}_h : Q \to Q_h$. Then we can discretize the LMSQP method as follows.

METHOD 2 (Galerkin LMSQP method). *Let X_h, Q_h, and Z_η be as above, and let*

$$(u_0, q_0) \in X_h \times Q_h$$

be a given initial value. Moreover, let $(\beta_k)_{k\in\mathbb{N}}$ be a bounded sequence of positive real numbers. The Galerkin LMSQP *(GLMSQP) method consists of the iteration procedure*

$$(u_{k+1}, q_{k+1}) = (\overline{u}_k, \overline{q}_k), \tag{2.3}$$

where $(\overline{u}_k, \overline{q}_k) \in X_h \times Q_h$ is the minimizer of the quadratic programming problem

$$\frac{1}{2}\|R_\eta(Eu - z^\delta)\|_Z^2 + \frac{\beta_k}{2}\|q - q_k\|_Q^2 \to \min_{(u,q)\in X_h\times Q_h} \tag{2.4}$$

subject to the linear constraint

$$\langle e(u_k, q_k) + e'(u_k, q_k)(u - u_k, q - q_k), \varphi\rangle = \langle f, \varphi\rangle \qquad \forall\ \varphi \in X_h. \tag{2.5}$$

Note that the constraint (2.5) can be rewritten in operator form as

$$P_h^* K_k P_h(u - u_k) + P_h^* L_k \tilde{P}_h(q - q_k) = P_h^*(f - e(u_k, q_k)), \tag{2.6}$$

to be solved for $(u, q) \in X_h \times Q_h$, with the notation

$$K_k : X \to X^*, \qquad K_k u = e_u(u_k, q_k)u \quad \forall\ u \in X, \tag{2.7}$$

$$L_k : Q \to X^*, \qquad L_k q = e_q(u_k, q_k)q \quad \forall\ q \in Q, \tag{2.8}$$

and $P_h^* : X_h^* \to X^*$ is the adjoint of P_h. Under the assumption (1.5), we obtain that

$$\langle P_h^* K_k P_h v, v\rangle = \langle K_k P_h v, P_h v\rangle = \langle K_k v, v\rangle \ge \alpha_e \|v\|_X^2 \tag{2.9}$$

for all $v \in X_h$; i.e., the discrete bilinear form associated with the operator $P_h^* K_k P_h$ is coercive on X_h. This implies by the Lax–Milgram theorem that (2.6) is uniquely solvable with respect to u for given $q \in Q_h$. Consequently, in an analogous way to the proof of Proposition 2.1 in [11] we may show the following result on the well-posedness of the quadratic programming problem that has to be solved in each step of Method 2.

PROPOSITION 2.1. *Let e be continuously Fréchet-differentiable, let* (1.5) *hold, and let $\beta_k > 0$. Then the quadratic programming problem* (2.4), (2.5) *has a unique solution $(\overline{u}_k, \overline{q}_k) \in X_h \times Q_h$, which is also the only local minimum.*

2.1. The discretized KKT system. In [11], the KKT system for the infinite-dimensional version of the LMSQP method has been derived and analyzed in the framework of linear saddle-point problems. Now we will discuss the discretized analogue of this system, namely the first-order optimality conditions for the quadratic programming problem (2.4), (2.5).

The Lagrangian of (2.4), (2.5) is given by

$$\begin{aligned}\mathcal{L}_k(u,q;\lambda) &= \frac{1}{2}\|R_\eta(Eu - z^\delta)\|_Z^2 + \frac{\beta_k}{2}\|q - q_k\|_Q^2 \\ &\quad + \langle \lambda, e'(u_k,q_k)(u-u_k, q-q_k) + e(u_k,q_k) - f\rangle \end{aligned} \tag{2.10}$$

for $(u,q,\lambda) \in X_h \times Q_h \times X_h$. Since P_h and $\tilde{P}_h$ are equal to the identity on X_h and Q_h, respectively, we can rewrite the Lagrangian as

$$\begin{aligned}\mathcal{L}_k(u,q;\lambda) &= \frac{1}{2}\|R_\eta(EP_hu - z^\delta)\|_Z^2 + \frac{\beta_k}{2}\|\tilde{P}_h(q - q_k)\|_Q^2 \\ &\quad + \langle P_h\lambda, K_kP_h(u-u_k) + L_k\tilde{P}_h(q-q_k) + e(u_k,q_k) - f\rangle, \end{aligned} \tag{2.11}$$

with the operators K_k and L_k defined by (2.7), (2.8). The KKT system can now be deduced by computing the partial derivatives of the Lagrangian with respect to u, q, and λ; i.e., $(u_{k+1} - u_k, q_{k+1} - q_k, \lambda_{k+1})$ solves the linear saddle-point problem

$$\begin{pmatrix} P_h^*E^*R_\eta^*R_\eta EP_h & 0 & P_h^*K_k^*P_h \\ 0 & \beta_k\tilde{P}_h^*\tilde{P}_h & \tilde{P}_h^*L_k^*P_h \\ P_h^*K_kP_h & P_h^*L_k\tilde{P}_h & 0 \end{pmatrix} \begin{pmatrix} u \\ q \\ \lambda \end{pmatrix} = \begin{pmatrix} P_h^*E^*R_\eta^*R_\eta(z^\delta - Eu_k) \\ 0 \\ P_h^*(f - e(u_k,q_k)) \end{pmatrix}. \tag{2.12}$$

As in [11], we define the symmetric bilinear form $a_k : (X \times Q)^2 \to \mathbb{R}$ by

$$a_k^\eta(u,q;\varphi,\sigma) := \langle R_\eta Eu, R_\eta E\varphi\rangle_Z + \beta_k\langle q,\sigma\rangle_Q \tag{2.13}$$

and the bilinear form $b_k : (X \times Q) \times X \to \mathbb{R}$ by

$$b_k(u,q;\lambda) := \langle K_ku,\lambda\rangle + \langle L_ku,\lambda\rangle. \tag{2.14}$$

Moreover, we use the right-hand sides

$$f_k := f - e(u_k,q_k) \in X^*, \tag{2.15}$$

$$g_k^\eta := (E^*R_\eta^*R_\eta(z^\delta - Eu_k), 0) \in X^* \times Q. \tag{2.16}$$

Then the KKT system (2.12) can be interpreted as the Galerkin approximation of an indefinite variational problem; i.e., $(u,q,\lambda) \in X_h \times Q_h \times X_h$ is the solution of

$$a_k^\eta(u,q;\varphi,\sigma) + b_k(\varphi,\sigma;\lambda) = \langle g_k^\eta, (\varphi,\sigma)\rangle \qquad \forall\ (\varphi,\sigma) \in X_h \times Q_h, \tag{2.17}$$

$$b_k(u,q;\mu) = \langle f_k,\mu\rangle \qquad \forall\ \mu \in X_h. \tag{2.18}$$

In an analogous way to the proof of Theorem 2.3 in [11] we can show that the bilinear form a satisfies the kernel-ellipticity condition on $X_h \times Q_h$; i.e., there exists a constant $\alpha_a > 0$ such that

$$a_k^\eta(u,q;u,q) \geq \alpha_a\|(u,q)\|^2$$
$$\forall\ (u,q) \in \mathcal{K}_b^h := \{\ (v,s) \in X_h \times Q_h \mid b(v,s;\lambda) = 0,\ \forall\ \lambda \in X_h\ \}$$

and that b satisfies the LBB condition

$$\inf_{\lambda\in X_h}\sup_{(u,q)\in X_h\times Q_h}\frac{b_k(u,q;\lambda)}{\|(u,q)\|\,\|\lambda\|}\geq\alpha_b$$

for some $\alpha_b>0$. This implies the following well-posedness result (cf. [8, 9]) for the discretized problem (2.17), (2.18).

THEOREM 2.2. *Let e be continuously Fréchet-differentiable, let* (1.5) *hold, and let $\beta_k>0$. Then the indefinite system* (2.17), (2.18) *has a unique solution $(u,q,\lambda)\in X_h\times Q_h\times X_h$, which depends continuously on the right-hand sides f_k and g_k^η.*

Since the constants α_a and α_b are the same as in the corresponding infinite-dimensional conditions in $X\times Q$, they are, in particular, independent of the discrete subspaces X_h and Q_h. This allows us to deduce an approximation result for the solutions of (2.17), (2.18) to the solution $(u,q,\lambda)\in X\times Q\times X$ of the infinite-dimensional KKT system, given in variational form as

$$a_k(u,q;\varphi,\sigma)+b_k(\varphi,\sigma;\lambda)=\langle g_k,(\varphi,\sigma)\rangle\qquad\forall\,(\varphi,\sigma)\in X\times Q, \tag{2.19}$$

$$b_k(u,q;\mu)=\langle f_k,\mu\rangle\qquad\forall\,\mu\in X, \tag{2.20}$$

with a_k given by

$$a_k(u,q;\varphi,\sigma):=\langle Eu,E\varphi\rangle_Z+\beta_k\langle q,\sigma\rangle_Q, \tag{2.21}$$

b_k, f_k as above, and g_k defined by

$$g_k:=(E^*(z^\delta-Eu_k),0)\in X^*\times Q. \tag{2.22}$$

THEOREM 2.3. *Suppose that the assumptions of Theorem* 2.2 *are satisfied, and let*

$$(u_h,q_h,\lambda_h)\in X_h\times Q_h\times X_h$$

denote the unique solution of (2.17), (2.18). *Then there exists a constant $c>0$ independent of X_h and Q_h such that*

$$\|(u-u_h,q-q_h,\lambda-\lambda_h)\|\leq c\left(r_{\eta,h}^\delta+\inf_{(v,s,\mu)\in X_h\times Q_h\times X_h}\|(u-v,q-s,\lambda-\mu)\|\right), \tag{2.23}$$

where (u,q,λ) denotes the unique solution of (2.19), (2.20) *and*

$$r_{\eta,h}^\delta:=\|(R_\eta-I)z^\delta\|_Z+\sup_{v\in X_h,\|v\|=1}\|(R_\eta-I)Ev\|_Z. \tag{2.24}$$

Proof. First, let $(\tilde u_h,\tilde q_h,\tilde\lambda_h)$ denote the solution of (2.17), (2.18) with a_k^η, g_k^η replaced by a_k, g_k. Then Theorem 2.1 in [9] implies the existence of a constant $c_1>0$ (independent of X_h and Q_h) such that

$$\|(u-\tilde u_h,q-\tilde q_h,\lambda-\tilde\lambda_h)\|\leq c_1\inf_{(v,s,\mu)\in X_h\times Q_h\times X_h}\|(u-v,q-s,\lambda-\mu)\|.$$

Moreover, the stable dependence of the solutions of (2.17), (2.18) on the right-hand side implies the existence of $c_2 > 0$, $c_3 > 0$ with

$$\begin{aligned}
&\|(u_h - \tilde{u}_h, q_h - \tilde{q}_h, \lambda_h - \tilde{\lambda}_h)\| \\
&\quad \le c_2 \left(\sup_{v \in X_h, \|v\|=1} \langle g_k^\eta - g_k, (v,0) \rangle + \sup_{\varphi \in X_h, \|\varphi\|=1} |a_k^\eta(\tilde{u}_h, \tilde{q}_h, \varphi) - a_k(\tilde{u}_h, \tilde{q}_h, \varphi)| \right) \\
&\quad \le c_2 \left(\sup_{v \in X_h, \|v\|=1} \langle Ev, (R_\eta^* R_\eta - I)(z^\delta - Eu_k) \rangle + \sup_{\varphi \in X_h, \|\varphi\|=1} \langle E\varphi, (R_\eta^* R_\eta - I) E\tilde{u}_h \rangle \right) \\
&\quad \le c_3 \left(\|E\| \, \|(R_\eta - I) z^\delta\|_Z + \sup_{v \in X_h, \|v\|=1} \|(R_\eta - I) Ev\|_Z \right),
\end{aligned}$$

and with the triangle inequality we may conclude (2.23). ∎

Theorem 2.3 provides an error estimate for the solutions of the discretized saddle-point problem (2.17), (2.18), consisting of two parts corresponding to the numerical approximation in the image space Z and in the preimage spaces X and Q. An obvious estimate for the first term is

$$r_{\eta,h}^\delta \le \inf_{y \in Z_\eta} \|y - z^\delta\|_Z + \sup_{v \in X_h, \|v\|_X = 1} \inf_{\tilde{y} \in Z_\eta} \|\tilde{y} - Ev\|_Z,$$

which possibly does not lead to a quantitative estimate, since there is no additional information on the smoothness of the noisy data. An alternative estimate is

$$r_{\eta,h}^\delta \le \delta + \inf_{y \in Z_\eta} \|y - \hat{z}\|_Z + \sup_{v \in X_h, \|v\|_X = 1} \inf_{\tilde{y} \in Z_\eta} \|\tilde{y} - Ev\|_Z.$$

The infimum of $\|y - \hat{z}\|_Z$ can usually be estimated more easily, since the exact data $\hat{z}$ are smoother due to the fact that $\hat{u}$ is the solution of the state equation for some parameter $\hat{q}$. For example, if the state equation is of elliptic type with solution $\hat{u} \in H^1(\Omega)$, $E : H^1(\Omega) \to L^2(\Omega)$ is the embedding operator, and R_η results from a standard finite element discretization on a grid with fineness η, then we have at least

$$\inf_{y \in Z_\eta} \|y - \hat{z}\| = \mathcal{O}(\eta).$$

Another important observation is that the last term vanishes if the discrete spaces Z_η and X_h are equal, which can be achieved in some applications.

The second term in (2.23) shows that the Galerkin approximation of the KKT system is of optimal order in $X_h \times Q_h \times X_h$; it can be estimated by standard methods for finite element discretizations; quantitative estimates can be obtained using the regularity of the iterates. This part depends, of course, strongly on the specific application.

3. Convergence analysis. In this section we will analyze the GLMSQP method with respect to convergence, i.e., the convergence of the reconstruction obtained with an appropriate stopping rule as the noise level and the measure for the discretization fineness tend to zero. With $\eta = 0$, $h = 0$ we will identify the infinite-dimensional case, i.e., $X_0 = X$, $Q_0 = Q$, and $Z_0 = Z$. We assume that the discrete subspaces satisfy

$$\overline{\bigcup_{h>0} X_h} = X, \qquad \overline{\bigcup_{\eta>0} Z_\eta} = Z, \qquad \overline{\bigcup_{h>0} Q_h} = Q.$$

If we denote by d_k and f_k the error terms (note that $e(\hat{u},\hat{q}) = f$)

$$(d_k, f_k) := (P_h(u_k - \hat{u}), \tilde{P}_h(q_k - \hat{q})), \tag{3.1}$$

we can rewrite the KKT system (2.12) as

$$\begin{pmatrix} P_h^* E^* R_\eta^* R_\eta E P_h & 0 & P_h^* K_k^* P_h \\ 0 & \beta_k \tilde{P}_h^* \tilde{P}_h & \tilde{P}_h^* L_k^* P_h \\ P_h^* K_k P_h & P_h^* L_k \tilde{P}_h & 0 \end{pmatrix} \begin{pmatrix} d_{k+1} \\ f_{k+1} \\ \lambda_{k+1} \end{pmatrix} = \begin{pmatrix} P_h^* E^* R_\eta^* R_\eta (z^\delta - E P_h \hat{u}) \\ \beta_k \tilde{P}_h^* \tilde{P}_h (q_k - \hat{q}) \\ r_k \end{pmatrix}, \tag{3.2}$$

where the r_k denotes the remainder

$$r_k := P_h^* \left(e(\hat{u},\hat{q}) - e(u_k, q_k) + e'(u_k, q_k)(P_h d_k, \tilde{P}_h f_k) \right). \tag{3.3}$$

As in [11], we require a condition on the nonlinearity, which is summarized in the following.

ASSUMPTION 1. *Let* (1.5) *be satisfied and define the remainder* $r(u,q)$ *by*

$$r(u,q) := e(\hat{u},\hat{q}) - e(u,q) - e'(u,q)(\hat{u} - u, \hat{q} - q). \tag{3.4}$$

Then we assume that there exists a constant $\gamma_1 < 1$ *such that*

$$\|E e_u(u,q)^{-1} r(u,q)\|_Z \le \gamma_1 \|Eu - \hat{z}\|_Z \qquad \forall\ (u,q) \in B_{2\zeta}(u_0) \times B_{2\rho}(q_0) \tag{3.5}$$

and that there exists a solution $(\hat{u},\hat{q}) \in B_\zeta(u_0) \times B_\rho(q_0)$ *of the parameter identification problem.*

For a discussion of the nonlinearity condition (3.5) and a comparison with standard conditions used in the convergence analysis of nonlinear ill-posed problems we refer the reader to [11].

If we define the discretization measures ϵ_h, κ_h by

$$\epsilon_h = \|E(I - P_h)\hat{u}\|_Z, \qquad \kappa_h = c_{\zeta,\rho} \|(I - \tilde{P}_h)\hat{q}\|_Q, \tag{3.6}$$

where

$$c_{\zeta,\rho} = \sup_{(u,q) \in B_{2\zeta}(u_0) \times B_{2\rho}(q_0)} \|E e_u(u,q)^{-1} e_q(u,q)\|_Z, \tag{3.7}$$

and ϵ_η by

$$\epsilon_\eta = \gamma_1 \zeta^{-1} \sup_{\|v\|_X = 1} \|(R_\eta - I)Ev\|_Z, \tag{3.8}$$

then for all $(u,q) \in B_{2\zeta}(u_0) \times B_{2\rho}(q_0)$ the estimate

$$\|R_\eta E e_u(u,q)^{-1} r_h(u,q)\|_Z \le \gamma_1 \|R_\eta(Eu - \hat{z})\|_Z + \epsilon_\eta + \epsilon_h + \kappa_h \tag{3.9}$$

holds, where

$$r_h(u,q) := e(\hat{u},\hat{q}) - e(u,q) - e'(u,q)(P_h\hat{u} - u, \tilde{P}_h\hat{q} - q). \tag{3.10}$$

Remark 1. If X_h, Z_η, and Q_h are standard finite element spaces on some triangulations, then ϵ_h, ϵ_η, and κ_h can be estimated by the approximation error of these elements. In particular, if the discretization parameter (i.e., the maximal size of a triangle) tends to zero and if the triangulation is regular, one can guarantee that ϵ_h, ϵ_η, and κ_h tend to zero (cf. [33] for further details).

For the choice of the stopping index we use a numerical version of (1.9), which involves the discretization measures defined above:

$$\|R_\eta(Eu_{k_*} - z^\delta)\|_Z \le \tau(\delta_\eta + 2\epsilon_h + \kappa_h) < \|R_\eta(Eu_k - z^\delta)\|_Z \qquad \forall\ k < k_*. \tag{3.11}$$

For an appropriate choice of τ, this allows us to prove the following monotonicity property of the iterates.

LEMMA 3.1. *Let Assumption* 1 *be fulfilled, let the noise be bounded by* (1.1)*, and assume that*

$$\beta_0^{-1}(\|Ed_0\|_Z - \delta - \epsilon_h)^2 + \|f_0\|_Q^2 \le \rho^2. \tag{3.12}$$

In addition, β_k is chosen such that $\beta_k \le \beta_{k-1}$ for all $k \in \mathbb{N}$ and that

$$\overline{\gamma}_1 := \gamma_1 \sup_{k\in\mathbb{N}} \sqrt{\frac{\beta_{k-1}}{\beta_k}} < 1, \tag{3.13}$$

and the stopping index k_* is chosen according to the generalized discrepancy principle (3.11) *with*

$$\tau > 1 + \frac{\gamma_1 + \overline{\gamma}_1}{\gamma_1(1 - \overline{\gamma}_1)}; \tag{3.14}$$

then $q_k \in B_{2\rho}(q_0)$ and the estimates

$$\begin{aligned}(\|R_\eta Ed_{k+1}\|_Z - \delta - \epsilon_h)^2 + \beta_k\|f_{k+1}\|_Q^2 + \beta_k\|q_{k+1} - q_k\|_Q^2 \\ \le (\gamma_1\|R_\eta Ed_k\|_Z + \delta + \epsilon_\eta + 2\epsilon_h + \kappa_h)^2 + \beta_k\|f_k\|_Q^2\end{aligned} \tag{3.15}$$

and

$$\beta_k^{-1}(\|R_\eta Ed_{k+1}\|_Z - \delta - \epsilon_h)^2 + \|f_{k+1}\|_Q^2 \le \beta_{k-1}^{-1}(\|R_\eta Ed_k\|_Z - \delta - \epsilon_h)^2 + \|f_k\|_Q^2 \tag{3.16}$$

hold for all $k < k_*$.

Proof. Assume that $q_k \in B_{2\rho}(q_0)$. Then, with (3.2) and

$$\lambda_{k+1} = -(P_h^* K_k^* P_h)^{-1} P_h^* E^* R_\eta^* R_\eta(Eu_{k+1} - z^\delta)$$

we deduce the identity

$$\begin{aligned}2\|R_\eta Ed_{k+1}\|_Z^2 &+ \beta_k\|f_{k+1}\|_Q^2 + \beta_k\|q_{k+1} - q_k\|_Q^2 \\ &= 2\|R_\eta Ed_{k+1}\|_Z^2 + \beta_k\|f_k\|_Q^2 + 2\beta_k\langle f_{k+1}, q_{k+1} - q_k\rangle \\ &= 2\langle R_\eta(z^\delta - EP_h\hat{u}), R_\eta Ed_{k+1}\rangle_Z + \beta_k\|f_k\|_Q^2 \\ &\quad + 2\langle R_\eta(Eu_{k+1} - z^\delta), R_\eta EP_h(P_h^* K_k P_h)^{-1} P_h^* r_h(u_k, q_k)\rangle_Z.\end{aligned}$$

The noise bound (1.1) implies that

$$\|R_\eta(z^\delta - P_h\hat{u})\|_Z \le \|R_\eta(z^\delta - \hat{z})\|_Z + \|E(I - P_h)\hat{u}\|_Z \le \delta + \epsilon_h,$$

and using the Cauchy–Schwarz inequality together with (3.9) we obtain the estimate

$$(\|R_\eta E d_{k+1}\|_Z - \delta - \epsilon_h)^2 + \beta_k \|f_{k+1}\|_Q^2 + \beta_k \|q_{k+1} - q_k\|_Q^2 \\ \leq (\gamma_1 \|R_\eta E d_k\|_Z + \delta + \epsilon_\eta + 2\epsilon_h + \kappa_h)^2 + \beta_k \|f_k\|_Q^2.$$

Equation (3.16) follows from dividing (3.15) by β_k and the fact that

$$\sqrt{\frac{\beta_{k-1}}{\beta_k}}(\gamma_1 \|R_\eta E d_k\|_Z + \delta + \epsilon_\eta + 2\epsilon_h + \kappa_\eta) \leq \|R_\eta E d_k\|_Z - \delta - \epsilon_h.$$

By induction we can now show that $q_k \in B_\rho(q_0)$ for $k < k_*$ and τ satisfying (3.14). ∎

In an analogous way to the proof of Lemma 3.2 in [11] we can prove the following statement on the finiteness of the stopping index k_* if $\delta > 0$.

LEMMA 3.2. *Under the assumptions of Lemma* 3.1, *the discrepancy principle* (3.11) *yields a finite stopping index* k_* *if*

$$\delta_{\eta,h} := \delta + \epsilon_\eta + 2\epsilon_h + \kappa_h > 0, \tag{3.17}$$

and τ *is chosen according to* (3.14).

One observes that in the above estimates the term $\delta_{\eta,h}$ now plays the same role as the noise level δ in the infinite-dimensional setup. Therefore it is also possible to prove convergence as $\delta_{\eta,h} \to 0$ in the same way as convergence in the infinite-dimensional case for $\delta \to 0$ (cf. [11, Theorem 3.5]). Consequently, we do not give the detailed convergence proof but refer to [11] for further details on the technique of the proof. We recall only the basic assumptions on e and give the final convergence result, where we use the notation $(u_k^{\delta,\eta,h}, q_k^{\delta,\eta,h})$ for the iteration according to (2.12) with initial value $(P_h u_0, \tilde{P}_h q_0)$, noise level δ, and discretization parameters h and η.

ASSUMPTION 2. *In addition to Assumption* 1, *assume that* e *is of the form*

$$e(u,q) = A(u) + N(u,q) \qquad \forall\ (u,q) \in X \times Q, \tag{3.18}$$

with continuously Fréchet-differentiable (nonlinear) operators $A : X \to X^*$ *and* $N : X \times Q \to X^*$ *such that*

$$N(u,.) \in \mathcal{L}(Q, X^*) \qquad \forall\ u \in X. \tag{3.19}$$

Moreover, we assume that A *and* N *satisfy the nonlinearity conditions*

$$\|E e_u(u,q)^{-1} A'(v) w\|_{X^*} \leq \gamma_2 \|Ew\|_{X^*} \quad \forall\ (u,v,w,q) \in B_{2\zeta}(u_0)^2 \times X \times B_{2\rho}(q_0) \tag{3.20}$$

and

$$\|E e_u(u,q)^{-1} N_u(v,s) w\|_Y \leq \gamma_3 \|Ew\|_Y \quad \forall\ (u,v,w,q,s) \in B_{2\zeta}(u_0)^2 \times X \times B_{2\rho}(q_0)^2 \tag{3.21}$$

for some positive constants γ_2 *and* γ_3.

THEOREM 3.3 (convergence). *Let Assumption* 2 *and* (3.12) *be fulfilled with* ζ, ρ *sufficiently small, and let the noise be bounded by* (1.1). *Moreover, let* β_k *be chosen such that* $\beta_k \leq \beta_0$ *for all* $k \in \mathbb{N}$ *and that* (3.13) *is satisfied. If the perturbed iteration*

is stopped with $k_* = k_*(\delta, R_\eta z^\delta, h)$ *according to the generalized discrepancy principle* (3.11) *with* $\tau = \tau(h,\eta)$ *(uniformly bounded in* h *and* η*) satisfying* (3.14)*, then*

$$(q^{\delta,\eta,h}_{k_*(\delta,R_\eta z^\delta,h)}, u^{\delta,\eta,h}_{k_*(\delta,R_\eta z^\delta,h)}) \to (\overline{q},\overline{u}) \qquad \text{in } X\times Q \quad \text{as } \max\{\delta_\eta,\epsilon_h,\kappa_h\}\to 0, \tag{3.22}$$

where $(\overline{u},\overline{q})$ *is a solution of* (1.3) *with* $E\overline{u} = \hat{z}$*.*

Proof. The proof is analogous to the proof of Theorem 3.5 in [11]. ∎

4. Numerical realization. In the following we want to discuss some numerical methods and variants for the GLMSQP algorithm. We split this discussion into two parts, the first related to the *inner iteration*, i.e., the numerical solution of the discretized KKT system (2.12) for fixed iteration number k, and the second related to the *outer iteration*, i.e., the iteration in k defined by the LMSQP method.

4.1. The inner iteration. Using appropriate bases for all finite-dimensional subspaces, the discretized KKT system (with penalty parameter $\beta = \beta_k$) can be written as

$$\begin{pmatrix} G & 0 & K^T \\ 0 & \beta H & L^T \\ K & L & 0 \end{pmatrix} \begin{pmatrix} V \\ S \\ \Lambda \end{pmatrix} = \begin{pmatrix} f_1 \\ 0 \\ f_3 \end{pmatrix}, \tag{4.1}$$

to be solved for $V \in \mathbb{R}^m$, $S \in \mathbb{R}^n$, and $\Lambda \in \mathbb{R}^m$. One notices that due to the properties of the corresponding infinite-dimensional operators, the matrices $G \in \mathbb{R}^{m\times m}$ and $H \in \mathbb{R}^{n\times n}$ are symmetric and positive definite, $K \in \mathbb{R}^{m\times m}$ is regular, and $L \in \mathbb{R}^{m\times n}$ is of rather general form. An alternative formulation of (4.1) is

$$MX = F, \tag{4.2}$$

with

$$M = \begin{pmatrix} G & 0 & K^T \\ 0 & \beta H & L^T \\ K & L & 0 \end{pmatrix}, \qquad X = \begin{pmatrix} V \\ S \\ \Lambda \end{pmatrix}, \qquad F = \begin{pmatrix} f_1 \\ 0 \\ f_3 \end{pmatrix}.$$

From the analysis in section 2 we may conclude that M is a regular, indefinite matrix, whose further properties (such as distribution of eigenvalues) rely on the specific form of the state equation and the objective. For a first application, we will investigate these properties in section 5.

For the solution of the discretized KKT system (4.2), there are two basic possibilities. The first one is the so-called *reduced SQP* approach, which consists of eliminating the state and Lagrangian variable (using the regularity of K) and then solving the arising lower-dimensional system for the parameter, which has a symmetric positive definite system matrix $M_r \in \mathbb{R}^{n\times n}$. This approach is frequently used in optimal control and parameter identification (cf., e.g., [36, 37, 38]) and seems attractive, since the problem dimension is reduced significantly. However, the reduced matrix is of the same structure as the matrix arising from a discretization of a Newton method following the feasible path (in particular, it involves the inverses of K and K^T), and therefore one has to expect that the numerical effort is of the same order as for such well-known methods. Recently, the simultaneous solution of KKT systems by iterative methods has been investigated, in particular in connection with optimal control problems (cf. [3, 5, 6, 21]). Compared to the reduced SQP approach, a simultaneous solution strategy has the obvious advantage that the allocation and evaluation of the

system matrix M is much cheaper than of M_r. Also matrix-vector products with M_r are by far more effort than matrix-vector products with M.

At first glance, it seems rather straightforward to solve (4.2) by a standard iterative method for indefinite systems such as inexact Uzawa methods (cf. [7, 16, 40]) or Krylov-subspace correction methods such as GMRES (cf. [35]), MINRES (cf. [32]), and QMR (cf. [19]). However, in the case of large-scale problems, we have to expect a large condition number (note that β is usually small and that M is singular for $\beta = 0$) and a complicated eigenvalue pattern of the matrix M, which might cause iterative methods to diverge or to need a high number of iterations. Therefore, an appropriate preconditioning technique seems necessary for any of the methods. We do not go into detail here but refer to the forthcoming paper [12] for a discussion and comparison of different preconditioners.

4.2. The outer iteration. As usual for nonlinear optimization we have to take care of the following two aspects for the discretized LMSQP method:

- *Scaling* of the state variable, parameter, and Lagrangian variable is needed in order to ensure that all variables and all sensitivities are of the same magnitude. In addition, appropriate scaling is needed for balancing the set of constraints and the objective. Since this topic is of high practical importance for any optimization problem and well investigated, we refer to monographs on nonlinear optimization for a detailed discussion (cf., e.g., [20, 31]).
- *Globalization strategies* are important for any locally convergent optimization method such as Newton-type or SQP-type methods. The two most popular classes of globalization techniques in optimization are *trust region methods* and *line search strategies*, which can both be applied for a globalization of the LMSQP algorithm. For a comprehensive overview of trust region methods we refer to Conn, Gould, and Toint [14], and for details on line search strategies we refer the reader to Nocedal and Wright [31].

Important tools for the efficient numerical approximation of infinite-dimensional optimization problems are *multilevel optimization methods*. In the nested multilevel setup, one starts the optimization procedure at a coarse level $X_{h_1} \times Q_{h_1}$, where the iteration procedure can be carried out efficiently. If an appropriate stopping rule is satisfied, one interpolates the state and parameter obtained in this way to a finer level $X_{h_2} \times Q_{h_2}$ (for $h_2 < h_1$), serving now as a starting value on this level. This procedure is repeated until the finest level is reached. Usually, nested spaces are used in this approach, i.e., $X_{h_1} \subset X_{h_2}$, $Q_{h_1} \subset Q_{h_2}$ (for $h_2 < h_1$), which leads to simple interpolation operators. Since one cannot choose the discretization of the data arbitrarily, in general, we consider only the case of fixed η here, but a multilevel approach in η can be realized in an analogous way, if necessary.

Nested multilevel methods outperform standard discretization techniques in many cases (cf., e.g., [22, 23, 30]); usually a considerable number of iterations is needed on the coarse level only, where the numerical effort per iteration is very low. On the finest levels, the stopping rule is often satisfied already after one iteration step and so the overall effort is less than for a direct discretization on the finest level. For the GLMSQP method, we can formulate a multilevel algorithm as follows.

ALGORITHM 4.1 (nested multilevel GLMSQP).

Given a decreasing sequence $\{h_\ell\}_{\ell=1,\dots,L}$ with nested spaces $X_{h_\ell} \subset X_{h_{\ell+1}}$, $Q_{h_\ell} \subset Q_{h_{\ell+1}}$ (e.g., $h_\ell = 2^{-\ell} h_0$), and a nonincreasing sequence τ_ℓ satisfying (3.14)*, the nested multilevel GLMSQP method consists of the following iterative procedure:*

1. *Set $\ell = 1$, $h = h_1$ and start with $(u_0^1, q_0^1) \in X_{h_1} \times Q_{h_1}$.*

2. *Perform the GLMSQP method until the stopping criterion* (3.11) *is satisfied with stopping index* $k_*(\ell)$.
3. *If* $\ell = L$ *stop the iteration, else prolongate the iterate* $(u^\ell_{k_*}, q^\ell_{k_*})$ *to the finer level* $X_{h_{\ell+1}} \times Q_{h_{\ell+1}}$, *which results in a new starting value* $(u_0^{\ell+1}, q_0^{\ell+1})$. *Set* $h = h_{\ell+1}$, $\ell = \ell + 1$, *and go to step* 2.

The analysis in section 3 shows that for $\beta_0^\ell \geq \beta^{\ell-1}_{k_*(\ell-1)}$ the estimate

$$\begin{aligned}(\beta^\ell_{k_*(\ell)})^{-1}\|R_\eta E d^\ell_{k_*(\ell)}\|_Z^2 + \|f^\ell_{k_*(\ell)}\|_Q^2 + \sum_{j=0}^{k_*(\ell)-1} \|q^\ell_{j+1} - q^\ell_j\|_Q^2 \\ \leq (\beta_0^\ell)^{-1}\|R_\eta E d_0^\ell\|_Z^2 + \|f_0^\ell\|_Q^2 \\ \leq (\beta^{\ell-1}_{k_*(\ell-1)})^{-1}\|R_\eta E d^{\ell-1}_{k_*(\ell-1)}\|_Z^2 + \|f^{\ell-1}_{k_*(\ell-1)}\|_Q^2 + \theta_\ell\end{aligned}$$

holds, where θ_ℓ is the error corresponding to the interpolation of the iterates from level $\ell - 1$ to level ℓ, i.e.,

$$\theta_\ell = (\beta_0^\ell)^{-1}\left(\|R_\eta E d_0^\ell\|_Z^2 - \|R_\eta E d^{\ell-1}_{k_*(\ell-1)}\|_Z^2\right) + \left(\|f_0^\ell\|_Q^2 - \|f^{\ell-1}_{k_*(\ell-1)}\|_Q^2\right). \tag{4.3}$$

This monotonicity estimate corresponds very well to the intuition that only few iterations are needed on the fine levels, in particular if β_k^ℓ is decreasing, which leads to

$$\|R_\eta E d^\ell_{k_*(\ell)}\|_Z^2 \leq \beta^\ell_{k_*(\ell)}\left((\beta_0^\ell)^{-1}\tau_{\ell-1}\delta_{\eta,h_{\ell-1}} + \|f^{\ell-1}_{k_*(\ell-1)}\|_Q^2 + \theta_\ell\right).$$

For a fine level with small β, we can expect that

$$\beta^\ell_{k_*(\ell)}(\beta_0^\ell)^{-1}\tau_{\ell-1}\delta_{\eta,h_{\ell-1}} \approx \tau_\ell \delta_{\eta,h_\ell},$$

and the second term $\beta^\ell_{k_*(\ell)}(\|f^{\ell-1}_{k_*(\ell-1)}\|_Q^2 + \theta_\ell)$ can be expected to be negligible. In other words, the stopping rule at level ℓ is probably satisfied with $k_*(\ell) = 1$.

Under typical conditions, where X_{h_ℓ} and Q_{h_ℓ} correspond to standard finite element spaces on different refinement levels of an initial triangulation of a domain Ω, one can show that at least $\theta_\ell = \mathcal{O}(h_{\ell-1})$, and consequently

$$\sum_{\ell=2}^{L} \theta_\ell \leq c h_1 \left(1 + \sum_{j=0}^{L-2} r^j\right) \leq c h_1 \frac{2}{1-r}$$

for some constant $c \in \mathbb{R}_+$, where

$$r = \max_{1\leq \ell \leq L-1} \frac{h_{\ell+1}}{h_\ell} < 1.$$

Together with the above estimate one can show with a standard proof technique that the pair $(u^L_{k_*(L)}, q^L_{k_*(L)})$ converges to a solution $(\overline{u}, \overline{q})$ of the parameter identification problem for $\delta_{\eta,h_L} \to 0$.

5. Application to potential reconstruction. As a first application we investigate the identification of the potential q in the elliptic boundary value problem

$$-\Delta u + qu = f \qquad \text{in } \Omega, \tag{5.1}$$

$$u = 0 \qquad \text{on } \partial\Omega, \tag{5.2}$$

from a state observation in $L^2(\Omega)$, which is a well-studied problem in literature (cf., e.g., [34]). In [11], it has been shown that in the setup (d denotes the space dimension)

$$X = H_0^1(\Omega), \qquad X^* = H^{-1}(\Omega), \qquad Q = H^d(\Omega), \qquad Z = L^2(\Omega), \tag{5.3}$$

the operators

$$e : X \times Q \to X^*, (u, q) \mapsto (-\Delta u + qu) \tag{5.4}$$

$$E : X \to Z, u \mapsto u \tag{5.5}$$

satisfy all assumptions needed for the convergence analysis of the LMSQP method. Now we shall study a concrete finite element discretization of the KKT system and the derivation of estimates for the numerical errors ϵ_η, ϵ_h, and κ_h.

5.1. Error estimates for the discretized KKT system. If we denote the iterates for state and Lagrangian variable at step $k+1$ by u and λ, respectively, then we can write the whole KKT system in classical form as

$$-\Delta u + q_k u + q u_k = f + q_k u_k \qquad \text{in } \Omega, \tag{5.6}$$

$$-\Delta \lambda + q_k \lambda + u - z^\delta = 0 \qquad \text{in } \Omega, \tag{5.7}$$

$$\beta L_d(q - q_k) + u_k \lambda = 0 \qquad \text{in } \Omega, \tag{5.8}$$

again with homogenous Dirichlet boundary conditions upon u and λ on $\partial\Omega$, where L_d is a dimension-dependent differential operator of order $2d$ corresponding to the norm in $H^d(\Omega)$; e.g., we have

$$L_1 q = -q_{xx} + q, \tag{5.9}$$

$$L_2 q = \Delta(\Delta q + q) + q, \tag{5.10}$$

supplemented by homogenous boundary conditions up to order $d-1$. If $f \in L^2(\Omega)$ and $u_0 \in H^2(\Omega) \cap H_0^1(\Omega)$, a standard elliptic regularity argument shows that $\hat{u}, u_k \in H^2(\Omega) \cap H_0^1(\Omega)$ (where $\hat{u}$ is the exact solid state) for all $k \in \mathbb{N}$. In the same way we can show that $\lambda_k \in H^2(\Omega) \cap H_0^1(\Omega)$ and $s_{k+1} - s_k \in H^{2d}(\Omega)$. This additional regularity can be employed to derive standard error estimates for finite element discretizations of the KKT system (2.12).

If we use piecewise linear finite elements on regular triangulations $\mathcal{T}_\eta$ and $\mathcal{T}_h$ for the discretization spaces Z_η and X_h, where η and h represent the fineness of the grids, then a classical approximation result for finite elements (cf. [33, p. 96]) implies that

$$\epsilon_\eta = \mathcal{O}(\eta^2) \qquad \text{and} \qquad \epsilon_h = \mathcal{O}(h). \tag{5.11}$$

Of course, one could also use piecewise constant elements on $\mathcal{T}_\eta$, which would yield $\epsilon_\eta = \mathcal{O}(\eta)$. However, in practical applications a higher-order approximation in η is often desirable, since η can be significantly larger than a reasonable choice of h. A canonical approximation of the parameter q is a finite element space of order greater than or equal to d on a regular triangulation $\mathcal{T}_{\tilde{h}} \subset \mathcal{T}_h$; under a priori assumptions on the exact solution $\hat{q}$ one can obtain quantitative estimates for κ_h in terms $\tilde{h}$. At first glance it seems surprising that one needs a priori assumptions on the parameter but not on the state in order to derive error estimates. However, due to the ill-posedness of the identification problem with respect to the parameter q, such a priori knowledge seems to be necessary. The approximation of the state corresponds rather

to the approximation of the underlying elliptic state equation, which is well-posed with respect to u and yields further regularity. We finally want to mention that according to the theory developed above, one could choose $\mathcal{T}_{\tilde{h}}$ independent of $\mathcal{T}_h$, but this would cause unnecessary complications in the implementation of the method.

We note that alternatively one can use the space $Q = L^2(\Omega)$ for $d \leq 3$, which yields $L_d = I$; i.e., (5.8) becomes

$$\beta(q - q_k) + u_k\lambda = 0. \tag{5.12}$$

An appropriate discretization strategy is, e.g., to choose Q_h as the space of piecewise constant elements on an underlying grid $\mathcal{T}_{\tilde{h}}$. The advantage of this approach is that elements of order greater than one, which are necessary for $Q = H^d(\Omega)$ $(d \geq 2)$, can be avoided.

5.2. Structure of the system matrix. For the potential identification problem, some parts of the system matrix M in (4.1) are well-understood. First of all, G is an L^2-mass matrix and it is positive definite if the triangulations $\mathcal{T}_\eta$ and $\mathcal{T}_h$ coincide, which we assume in the following. The eigenvalues of G are then all of order h^d. The matrix H is the stiffness matrix for the differential operator L_d, with minimal eigenvalue of order h^d and maximal eigenvalue of order h^{-d}.

The matrix K is the sum of a stiffness matrix for the Laplacian and a weighted mass matrix (with weight q_k in the L^2-scalar product), where one can expect the first part in this sum to be dominating. Thus, the stiffness matrix $\hat{K}$ for the Laplacian will be a good preconditioner for K. The maximal and minimal eigenvalues of K and $\hat{K}$ are of order h^{d-2} and h^d, respectively. The remaining part in the system matrix, namely the matrix L, is difficult to understand, since its elements are weighted L^2-scalar products of basis functions of different finite element spaces. However, the spectral norm of L can be estimated; it is of order $\tilde{h}^d$.

The construction of preconditioners for G and H is well investigated; even exact preconditioning seems to be applicable. For K it seems reasonable to use a preconditioner $\hat{K}$ for the Laplacian, e.g., a multigrid preconditioner. With preconditioning for K, the system matrix can be transformed to

$$\tilde{M} = \begin{pmatrix} G & 0 & K\hat{K}^{-1} \\ 0 & \beta H & L^T\hat{K}^{-1} \\ \hat{K}^{-1}K & \hat{K}^{-1}L & 0 \end{pmatrix}, \tag{5.13}$$

with the corresponding Schur complement

$$\tilde{C} = \hat{K}^{-1}KG^{-1}K\hat{K}^{-1} + \beta^{-1}\hat{K}^{-1}LH^{-1}L^T\hat{K}^{-1}. \tag{5.14}$$

If $\hat{K}$ is an appropriate preconditioner for K, then we can estimate the minimal eigenvalue by

$$\lambda_{\min}(\tilde{C}) \geq \lambda_{\min}(\hat{K}^{-1}KG^{-1}K\hat{K}^{-1}) = \mathcal{O}(h^{-d}) \tag{5.15}$$

and the maximal eigenvalue by

$$\lambda_{\max}(\tilde{C}) \leq \|\hat{K}^{-1}KG^{-1}K\hat{K}^{-1}\|_2 + \beta^{-1}\|\hat{K}^{-1}LH^{-1}L^T\hat{K}^{-1}\|_2 \tag{5.16}$$

$$= \mathcal{O}\left(h^{-d}(1 + \beta^{-1}h^{-2d}\tilde{h}^{2d})\right). \tag{5.17}$$

Hence, the condition number of $\tilde{C}$ is independent of h but depends only on β and $\frac{\tilde{h}}{h}$. One observes that the condition number is decreasing as $\tilde{h}$ tends to h from above. (Note that usually $\tilde{h} \geq h$.) For the Uzawa iteration, one can choose the preconditioner $\hat{C}$ in this case as a multiple of $\hat{K}^{-1}KG^{-1}K\hat{K}^{-1}$ or even of G^{-1}. If $\tilde{h} \gg h$, the Uzawa iteration seems not to be optimal; in this case one can apply either a reduced SQP approach or use Krylov-subspace methods with different preconditioning strategies. For the details on the latter we refer the reader to [12].

6. Numerical experiments. In order to test our theoretical results, we numerically solve some model problems, which have already been investigated with respect to the convergence behavior of the LMSQP method in [11].

Example 6.1. Our first example is the identification of the potential q in (5.1), (5.2) from a state observation $u \in L^2(\Omega)$, with $\Omega = (0,1)$, homogeneous Dirichlet values for u, and

$$f(x) = \frac{1}{2} + \sin x, \qquad x \in \Omega.$$

The exact potential is given by

$$q(x) = x(1-x),$$

which is an element of $Q = H^1(\Omega)$.

This problem was implemented in the software system MATLAB as follows. The data are generated by solving the state equation on a fine grid and subsequent interpolation to a coarser grid; the noise is an additive high-frequency perturbation. We used uniform grids with m nodes for the discretization of the state u and the Lagrange parameter λ and n nodes for the parameter q, i.e., $h = (m-1)^{-1}$ and $\tilde{h} = (n-1)^{-1}$. This implies a rather simple structure of the KKT submatrices, in particular $G = g_0 I$ with $g_0 \in \mathbb{R}^+$ and I the identity matrix, and H is the H^1-stiffness matrix. The parameters β_k are chosen according to $\beta_{k+1} = 0.9\beta_k$, with $\beta_0 = 10^{-6}$, which led to convergence of the method even for starting value $q \equiv 0$. Roughly speaking, this choice of the regularization parameters corresponds to a globalization strategy of trust-region type, since it is well known that the diameter of the trust region is negative proportional to the parameter β_k for Levenberg–Marquardt methods. The KKT system (4.1) is solved using a direct solver in this case, which is probably not the best choice with respect to the numerical effort for fine discretizations, but it still leads to reasonable results in our case.

The convergence results for the overall LMSQP method have been shown in [11] and compared to a Levenberg–Marquardt method following the feasible path. It turned out that both methods lead to almost the same iteration sequence q_k. In particular, the number of iterations needed until the stopping rule is satisfied is the same for both methods. Now we compare the numerical efficiency of the LMSQP method with feasible path approaches, namely the Levenberg–Marquardt (LM) method on the feasible path (with the same Galerkin discretization as for LMSQP and solution of the Gauss–Newton system by a CG method) and a Broyden-type variant of the LM method (cf. [24] for further details).

For this sake we choose different discretization levels (fixed during the iteration) and measure the CPU time needed for the LMSQP method until the stopping rule is satisfied (for fixed noise level δ). From the results shown in Table 1 one observes that the LMSQP method with simultaneous solution of the KKT system outperforms

TABLE 1
CPU time (in seconds) needed for the LMSQP method, the LM method, and a Broyden-type variant of the LM method.

m	n	LMSQP	LM	Broyden
201	41	0.07	1.37	0.51
201	101	0.18	3.44	1.34
201	201	0.36	6.94	2.88
401	201	0.51	24.83	9.09
401	401	1.39	50.39	20.48
801	401	2.61	193.21	70.69
801	801	5.66	392.54	158.69
1601	801	7.91	1564.50	600.66
1601	1601	22.86	3144.40	1356.60

the feasible-path approaches for all different discretizations. Since the LMSQP and the LM method need the same number of outer iterations, the difference in the numerical effort is caused by the fact that the effort for matrix-vector products with the system matrix in the LM method is significantly higher than the preconditioning and performing of matrix-vector products with the system matrix in the simultaneous LMSQP method. Obviously, the gain in the numerical effort for the evaluation of the system matrix increases with the number of discretization points, which explains the extremely large CPU time for the LM method at the finest discretization level ($m = 1601$). For small m and n, the Broyden variant is much faster than the LM method, which is again caused by the fact that the evaluation of the system matrix can be carried out efficiently. However, the number of iterations needed for the Broyden-type variant is much larger than for the other two methods, which use the full information about the derivatives.

Finally, we investigate the spectral condition of the system matrix M as well as of the matrix $\tilde{M}$ defined by (5.13), where we use a Jacobi preconditioner for the Laplacian as $\hat{K}$. From the left picture in Figure 1, which shows the condition number as a function of the discretization size h (in logarithmic scale) for fixed $\beta = 10^{-5}$, one observes that the condition number of M grows quadratically with h^{-1}, while the condition number of $\tilde{M}$ is much smaller and almost independent of h. The second part of Figure 1 shows a plot of the condition numbers vs. the parameter β in doubly logarithmic scale, from which it seems that the growth of the condition number as $\beta \to 0$ is slower for $\tilde{M}$ than for the original matrix M. In both cases, the condition number seems to be a convex function of β, which has a unique minimum at some $\overline{\beta}$. However, this value $\overline{\beta}$ is rather large, and values of β that are significantly larger than $\overline{\beta}$ are not of interest for our purpose, since they would cause a tremendous slowdown of the outer iteration. Therefore we can focus our attention on the case $\beta < \overline{\beta}$, where the condition number increases monotonically with β^{-1}.

Example 6.2. Our second numerical example is the identification of the conductivity $q \in L^\infty(\Omega)$ in

$$-\operatorname{div}(q\nabla u) = f \qquad \text{in } \Omega, \tag{6.1}$$

$$u = g \qquad \text{on } \partial\Omega \tag{6.2}$$

from a state observation $u \in L^2(\Omega)$. The domain Ω is a ball in $\mathbb{R}^2$ with a missing first quadrant; i.e., in radial coordinates

$$\Omega = \{\ (r\cos\theta, r\sin\theta) \mid r \in [0,1), \theta \in (\pi/2, 2\pi)\ \}. \tag{6.3}$$

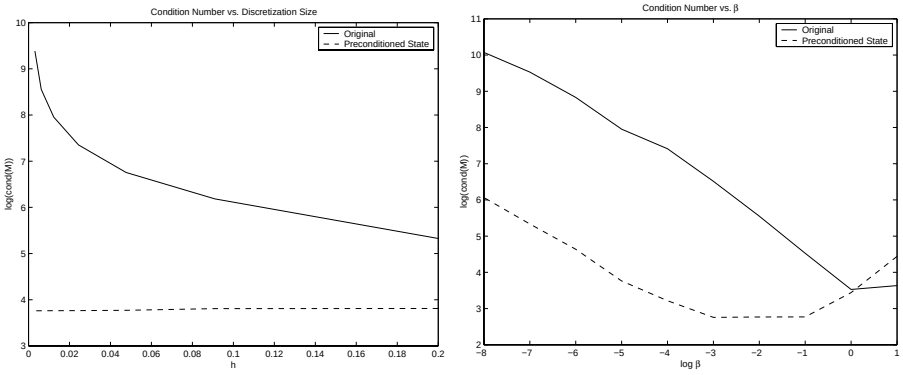

FIG. 1. *Plot of the spectral condition of the matrix M vs. the discretization size h (in logarithmic scale, left) and vs. the parameter β (in doubly logarithmic scale, right). The solid line shows the condition number of the original matrix M, the dashed line of the matrix $\tilde{M}$ with the preconditioned state equation.*

The exact parameter to be reconstructed is $\hat{q} \equiv 1$, and the right-hand side in (6.1) is given by

$$f = \frac{3\pi}{4}\left(3\pi\cos\left(\frac{3\pi}{2}r\right) + \frac{2}{r}\sin\left(\frac{3\pi}{2}r\right)\right) \qquad \text{with } r = \sqrt{x^2+y^2}.$$

The corresponding solution of the state equation is $\hat{u} = \cos(\frac{3\pi}{2}r)$. The data are generated using the exact solution $\hat{u}$ perturbed by uniformly distributed random noise. For the discretization we used triangular finite elements with piecewise quadratic shape functions for the state u and the Lagrange parameter λ and piecewise constant shape functions for the parameter q. The results were calculated using the finite element code FEPP [28], developed at the Institute of Computational Mathematics of the University of Linz.

We want to mention that this identification problem is quite challenging not only due to the complicated geometry, but also due to the fact that q is not identifiable along a level line in the interior, where u attains an extremum. This does not destroy the theoretical identifiability results, because it is a set of Lebesgue-measure zero, but it can be expected to create numerical difficulties.

The KKT system (4.1) was solved using a preconditioned QMR method with a block-factorization type preconditioner of the form

$$\hat{M} = \begin{pmatrix} G\hat{K}^{-1} & 0 & I \\ 0 & I & L^T\hat{K}^{-T} \\ I & 0 & 0 \end{pmatrix} \begin{pmatrix} \hat{K} & L & 0 \\ 0 & S_c & 0 \\ 0 & -G\hat{K}^{-1}L & \hat{K}^T \end{pmatrix} \tag{6.4}$$

(cf. [5, 6, 21]) with a multigrid preconditioner $\hat{K}$ and no preconditioning of the Schur complement S_c. Results for exact data can be found in Table 2. The good performance of the method with respect to both CPU time and the number of outer iterations can be observed clearly. Especially for problems with fine discretizations of the parameter q, this method can still be realized efficiently, while classical approaches do not yield results in reasonable time. A plot of the parameter q can be found in Figure 2, from which one observes that the parameter is reconstructed very well except in a neighborhood of the level curve $\{\nabla u = 0\}$.

TABLE 2
CPU time and number of inner (QMR) and outer (SQP) iterations for exact data

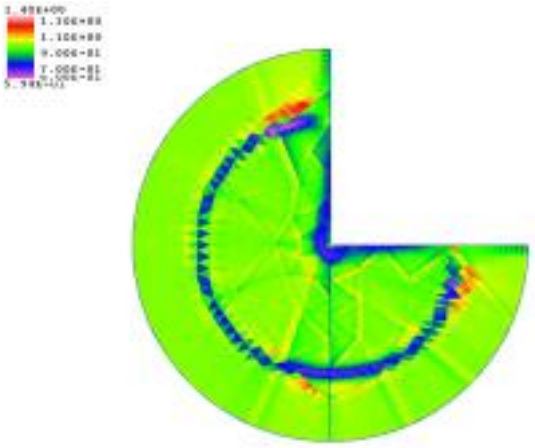

FIG. 2. *Parameter distribution for exact data at level* 4, $q_{min} = 0.59$, $q_{max} = 1.4$.

Additional speed-up can be gained using a multilevel approach as described in subsection 4.2. We used nested spaces for q and u by subdividing each triangular element into four smaller elements, when refining the mesh. Table 3 presents results for this approach. It can be seen that on fine discretization levels one SQP step is sufficient for fulfilling the stopping criterion, which corresponds very well to the theoretical predictions made in section 4.2. A comparison of the results to the ones in Table 2 shows that for fixed discretization level the solution of the identification problem on level 5 is only slightly faster than the identification of q on level 6 (with about the fourfold number of parameters) using a multilevel approach. A plot of the parameter can be found in Figure 3. Here the approximation of the parameter in the area where it cannot be identified is by far better than in the classical approach using only one discretization level (compare Figure 2). A possible explanation for this effect is the following: the influence of the level line $\{\nabla u = 0\}$ where q cannot be identified on the solution is smaller the coarser the discretization. The prolongation from coarse levels to finer ones adds information to the region where the parameter is not identifiable from its surrounding region. As long as the parameter is smooth this helps to improve the quality of the numerical results where the parameter cannot be identified.

7. Conclusions and outlook. We have developed a framework for Galerkin-type approximations of the LMSQP method for parameter identification problems in elliptic partial differential equations, and we have discussed the implementation of the GLMSQP method with iterative solution of the KKT system. The numerical results show that the resulting iteration method clearly outperforms state-of-the-art methods for iterative regularization and provides a tool for the efficient solution of identification

TABLE 3
CPU time per level, accumulated time, and number of inner (QMR) and outer (SQP) iterations for exact data using a nested multilevel approach.

problems with fine discretizations. Moreover, we have developed a multilevel version of the GLMSQP method, which yields a further speed-up.

The crucial point for the possibility to obtain an efficient implementation of the LMSQP method is the preconditioning of the KKT system, which is then solved iteratively as an indefinite problem in the product space for state, parameter, and Lagrangian variable. The construction of such preconditioners is not a simple task and has not been discussed in detail in the present paper, but will be investigated in [12], where different preconditioning techniques will be compared.

Other numerical aspects to be investigated in future research are adaptive discretization strategies and fast parallel solvers based on domain decomposition techniques. The adaptive discretization of optimal control problems, which is a closely related subject, has been discussed by Becker, Kapp, and Rannacher [4]; possibly the ideas of this work can be carried over to identification problems, too. The parallel solution of optimal control problems has been investigated by Lions and Pironneau [29] in the case of quadratic problems; recently Biros and Ghattas [5, 6] performed a numerical study of a parallel solver with an SQP method for the outer and preconditioned Krylov-subspace methods for the inner iteration. Many of their ideas seem to be applicable also for parameter identification problems that are solved with the LMSQP method, which raises the hope that efficient parallel versions of the LMSQP method can be designed also for large-scale identification problems such as impedance tomography.

Finally, we want to recall that the framework of this problem does not apply

to transient problems of parabolic or hyperbolic type. Since numerical methods for different types of partial differential equations have many type-specific features, in general, it is not surprising that also the numerical treatment of parameter identification problems should depend on the type of the underlying state equation. However, it seems possible to construct efficient and convergent discretized methods at least in the case of parabolic equations, which is an important task for future research.

Acknowledgments. The authors thank Dr. Walter Zulehner (University of Linz) and Dr. Joachim Schöberl (currently at Texas A & M University) for useful and stimulating discussions on the preconditioning of the indefinite system (4.1).

THE SPECTRUM OF CIRCULANT-LIKE PRECONDITIONERS FOR SOME GENERAL LINEAR MULTISTEP FORMULAS FOR LINEAR BOUNDARY VALUE PROBLEMS*

DANIELE BERTACCINI†

Abstract. The spectrum of the eigenvalues, the conditioning, and other related properties of circulant-like matrices used to build up block preconditioners for the nonsymmetric algebraic linear equations of time-step integrators for linear boundary value problems are analyzed. Moreover, results concerning the entries of a class of Toeplitz matrices related to the latter are proposed. Generalizations of implicit linear multistep formulas in boundary value form are considered in more detail.

It is proven that there exists a new class of approximations which are well conditioned and whose eigenvalues have positive and bounded real and bounded imaginary part. Moreover, it is observed that preconditioners based on other circulant-like approximations, which are well suited for Hermitian linear systems, can be severely ill conditioned even if the matrices of the nonpreconditioned system are well conditioned.

Key words. trigonometric preconditioners, nonsymmetric Toeplitz matrices, eigenvalues, linear systems of time-step integrators, general linear multistep formulas in boundary value form, boundary value problems

1. Introduction.

In this paper we investigate the properties of some classes of circulant approximations and some generalizations used in the preconditioners for (small rank perturbations of) block nonsymmetric Toeplitz matrices introduced in [4]. These matrices arise in the numerical approximation of time-dependent partial differential equations by means of generalizations of implicit linear multistep formulas.

An $n \times n$ matrix $A_n = (a_{j,k})$ is said to be Toeplitz if $a_{j,k} = a_{j-k}$, $j, k = 1, \dots, n$, i.e., A_n is constant along its diagonals, quasi Toeplitz if it is a small rank perturbation of a Toeplitz matrix. An $n \times n$ matrix $\breve{A}_n$ is said to be circulant if it is Toeplitz and its diagonals satisfy $\breve{a}_{n-j} = \breve{a}_{-j}$, $j = 1, \dots, n-1$. The circulant matrices $\breve{A}_n$ are diagonalized by the Fourier matrix $F = (F_{j,k})$, $F_{j,k} = e^{2\pi \mathbf{i} jk/n}/\sqrt{n}$, $j, k = 0, \dots, n-1$, $\mathbf{i}$ is the imaginary unit; see [13]. From the previous arguments, it follows that such matrices are easily and efficiently invertible using the fast Fourier transform (FFT); see, e.g., [11]. Other circulant-like matrices will be mentioned in section 4.

The matrices of the underlying linear systems can be written as follows:

$$M = A \otimes I - h\, B \otimes J, \tag{1.1}$$

where A and B are $n \times n$ (small rank perturbations of) band Toeplitz matrices whose entries are given by the coefficients of the scheme involved, I is the identity, and J is an $m \times m$ matrix which can be large and sparse. More precisely, J is the Jacobian matrix of a system of ordinary or partial differential equations discretized in space by

finite differences; see [4] for details. It is worth noting that J can have a (multilevel) structure as well. For example, J can be block-banded, block-Toeplitz, etc.

Unfortunately, when m and/or n are (even moderately) large, iterative solvers for (1.1), used without preconditioners or with general purpose preconditioners such as those based on incomplete factorizations, often converge very slowly or do not converge at all; see [4, section 5]. Moreover, direct methods are not appropriate because they cannot exploit the block structure of (1.1). On the other hand, the preconditioners we consider here take into account the block structure in (1.1). More precisely, they are block-circulant and, in matrix form, can be written as

$$P = \breve{A} \otimes I - h\,\breve{B} \otimes \tilde{J}, \tag{1.2}$$

where $\breve{A}$ and $\breve{B}$ are circulant-like approximations for A, B, respectively, and $\tilde{J}$ is a suitable approximation for J.

In [4] we have observed that $P^{-1}M$, the preconditioned matrix, can be written as a perturbation of the identity matrix (see also section 5.3), which can result in fast convergence of Krylov subspace methods for nonsymmetric linear systems such as GMRES and BiCG-like methods such as BiCGstab. The computational cost for a possible implementation has been considered in detail in [4, section 4.1], showing that the cost per iteration is of the order of $O(mn \log n)$ if J is banded, say.

Here we will prove that there exists a class of circulant approximations, introduced in [4], which have a moderate 2-norm condition number increasing at most linearly with their size n. Moreover, the spectrum of the eigenvalues of several of the possible approximations for the nonsymmetric matrices A, B in (1.1) will be investigated as well, showing that it lies in the right half plane. It is worth noting that this holds true for the original matrices A, B in (1.1) considered here; see [6].

We stress that the condition number and the spectrum of the component matrices $\breve{A}$ and $\breve{B}$ of the preconditioner (1.2) are very important to have fast convergence. Indeed, as observed in [4, 5, 6], the matrix J in (1.1) can have very small (and/or very large) singular values in different subintervals of integration (see [5]), and this is difficult (if not impossible) to know in advance. Recall that J is the Jacobian matrix of the given continuous time-dependent problem; see [15, 19]. Thus, if $\breve{A}$ or $\breve{B}$ are ill conditioned, we can have an ill conditioned preconditioner even if the original matrix M is well conditioned; see, e.g., the end of section 5.2 and Figure 5.3. As observed in [4, 5], this can slow down the convergence process (see [14]), giving unacceptably slowly convergent (or even divergent!) preconditioned iterations.

We observe that, in the case of nonsymmetric linear systems, solved by Krylov accelerators, the condition number of the *preconditioned* matrix $P^{-1}M$ (say), assumed to be not too large, is much less important for the convergence than the clustering of the spectrum of its eigenvalues; see, e.g., [18, 14]. On the other hand, the condition number of the matrix M in (1.1) is crucial for the rate of convergence of conjugate gradients preconditioned iterations for the normal linear system; see [6].

Here we will consider certain general linear multistep methods (or GLMs, see [19]) used in boundary value form and called boundary value methods. These methods are used to solve continuous boundary value problems for differential equations (see [2, 9] and references therein). However, the asymptotic techniques considered here could be adapted, at least in principle, to other discretization schemes.

Notice that, in this paper, we will consider multistep formulas of arbitrarily high order merely to state bounds and the asymptotic behavior of the spectrum of the underlying circulant(-like) approximations involved in (1.2). In practice, the best

performance of the underlying preconditioners seems to be achieved for formulas (2.3) whose number of steps k is not too large (typically 3 to 9, say). On the other hand, we have observed in [4, 5] that the preconditioners (1.2) can be effective for any order of magnitude of n, either if it is small (4 to 8, say) or (very) large ($n > 1024$, say) as well.

In section 2 we summarize some information on numerical integrators based on linear multistep formulas in boundary value form. Section 3 contains some introductory lemmas. In section 4 we recall some circulant approximations. Section 5 is devoted to the investigation on the spectrum and the conditioning of the underlying matrices. Finally, some remarks on the convergence of preconditioned iterations and the use of different approximations in (1.2) are given in section 5.3.

2. Families of numerical integrators.

2.1. Formulas in boundary value form. The boundary value methods for differential equations are a generalization of implicit linear multistep formulas; see [2, 9] and references therein. They approximate the solution of a continuous differential boundary value problem by means of a discrete boundary value problem. For simplicity, let us consider the linear boundary value problem

$$\begin{cases} y'(t) = f(t, y(t)) := J\, y(t) + g(t), \quad t \in (t_0, T], \\ y(t_0) = \eta_1, \quad y(T) = \eta_2, \end{cases} \tag{2.1}$$

where $y(t), g(t) : \mathbb{R} \to \mathbb{R}^m$, $J \in \mathbb{R}^{m\times m}$, $\eta_j \in \mathbb{R}^m$, $j = 1, 2$. The continuous problem (2.1) can be reduced to a discrete boundary value problem by the following k-step linear multistep formula of order p used with $\nu > 0$ initial and $k-\nu > 0$ final conditions over a uniform mesh $t_j = t_0 + j\, h,\ j = 0, \ldots, s$:

$$\sum_{i=0}^{k} \alpha_i y_{n+i} = h \sum_{i=0}^{k} \beta_i f_{n+i}, \qquad n = 0, \ldots, s-k, \tag{2.2}$$

where y_n is the discrete approximation to $y(t_n)$, $f_n = f(t_n, y_n) \equiv J\, y_n + g_n$, $g_n = g(t_n)$, while the values $y_0, \ldots, y_{\nu-1}, y_{s-k+\nu+1}, \ldots, y_s$ of the approximation computed in the mesh points $t_0, \ldots, t_{\nu-1}, t_{s-k+\nu+1}, \ldots, t_s$, respectively, are assumed to be given. We observe that the boundary value problem (2.1) provides only the initial and final values y_0 and y_s, respectively. The missing values are supplied by coupling the method (2.2) with other difference schemes of order p, sometimes called additional methods, which provide an additional set of equations, independent of those in (2.2). For simplicity, we can assume that these formulas have the same number of steps as (2.2) but different coefficients $\alpha_j^{(r)}$, $\beta_j^{(r)}$, $r = 1, \ldots, \nu-1, s-k+\nu+1, \ldots, s-1$, $j = 0, \ldots, k > \nu$; see [4] for details.

In order to stress the dependence of the formula on the ν initial and $k-\nu$ final values, it is useful to rewrite (2.2) in the following shifted form:

$$\sum_{i=-\nu}^{k-\nu} \alpha_{i+\nu} y_{n+i} = h \sum_{i=-\nu}^{k-\nu} \beta_{i+\nu} f_{n+i}, \qquad n = \nu, \ldots, s-k+\nu. \tag{2.3}$$

To have order $p \geq 1$, the coefficients α_j, β_j in (2.3) should satisfy the order conditions (see, e.g., [19])

$$\sum_{j=0}^{k} \left(j^i \alpha_j - i j^{i-1} \beta_j \right) = 0, \qquad i = 0, \ldots, p, \tag{2.4}$$

where the first two equations of (2.4) ($i = 0, 1$) are usually called consistency conditions. By rewriting (2.4) in shifted form we have

$$\sum_{j=-\nu}^{k-\nu} \left(j^r \alpha_{j+\nu} - r j^{r-1} \beta_{j+\nu} \right) = 0, \qquad r = 0, \dots, p, \tag{2.5}$$

where we assume, as is customary, that $0 j^{-1} = 0$, $j^0 = 1$ for all j.

For practical implementation, we cast the above discrete problem in matrix form:

$$\begin{aligned} &MY = b,\ Y = \left(y_0^T, y_1^T, \dots, y_s^T \right)^T, \qquad M = A \otimes I_m - hB \otimes J, \\ &b = e_1 \otimes \eta_1 + e_{s+1} \otimes \eta_2 + h(B \otimes I_m) g, \qquad g = (g(t_0) \cdots g(t_s))^T, \end{aligned} \tag{2.6}$$

where $e_i \in \mathbb{R}^{s+1}$, $i = 1, \dots, s+1$, is the ith column of the identity matrix and A, $B \in \mathbb{R}^{(s+1)\times(s+1)}$ are quasi-Toeplitz matrices whose pattern is

$$A = \begin{pmatrix} 1 & \cdots & 0 & & & \\ \alpha_0^{(1)} & \cdots & \alpha_k^{(1)} & & & \\ \vdots & \vdots & \vdots & & & \\ \alpha_0^{(\nu-1)} & \cdots & \alpha_k^{(\nu-1)} & & & \\ \alpha_0 & \cdots & \alpha_k & & & \\ & \alpha_0 & \cdots & \alpha_k & & \\ & & \ddots & \ddots & \ddots & \\ & & & \alpha_0 & \cdots & \alpha_k \\ & & & \alpha_0^{(s-k+\nu+1)} & \cdots & \alpha_k^{(s-k+\nu+1)} \\ & & & \vdots & \vdots & \vdots \\ & & & \alpha_0^{(s-1)} & \cdots & \alpha_k^{(s-1)} \\ & & & 0 & \cdots & 1 \end{pmatrix}, \tag{2.7}$$

where $\alpha_j^{(r)}$, $j = 0, \dots, k$, are the coefficients of the additional formulas. The matrix B is similarly defined, but with β_j ($\beta_j^{(r)}$) instead of α_j ($\alpha_j^{(r)}$) and with the entries of the first and last rows set to zero; see [4] for details. We stress that the matrix M in (2.6) is usually nonsymmetric, nondiagonally dominant, and large and sparse if, e.g., n or m are large and J is sparse.

2.2. Some linear multistep schemes. Let us recall some families of formulas (2.3) that will be considered in subsequent sections.

A minimal requirement for a multistep formula (2.3) is consistency, see, e.g., [19], i.e., they must satisfy the conditions $\rho(1) = 0$, $\rho'(1) = \sigma(1)$, where $\rho(z)$ and $\sigma(z)$ denote the two characteristic polynomials associated with the given method, i.e.,

$$\rho(z) = \sum_{j=0}^{k} \alpha_j \ z^j, \quad \sigma(z) = \sum_{j=0}^{k} \beta_j \ z^j$$

or, in shifted form,

$$\rho(z) = z^\nu \sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} \ z^j, \quad \sigma(z) = z^\nu \sum_{j=-\nu}^{k-\nu} \beta_{j+\nu} \ z^j. \tag{2.8}$$

The backward differentiation formulas are a class of well-known initial value methods for the numerical integration of stiff problems (see, e.g., [15, 19]). A generalization of these as a boundary value scheme, called generalized backward differentiation formulas, has been proposed in [9] and can be written in the form

$$\sum_{i=-\nu}^{k-\nu} \alpha_{i+\nu}\, y_{n+i} = h\, f_n, \qquad n = \nu, \dots, s-k+\nu, \tag{2.9}$$

where $\nu = (k+2)/2$ if k is even, and $\nu = (k+1)/2$ if k is odd; see [9]. Notice that backward differentiation formulas have $\nu = k$ in (2.9). The coefficients $\{\alpha_i\}$ are determined by imposing maximum order for (2.9), i.e., order k, $k \geq 1$.

Another popular class of initial value methods is the Adams–Moulton formulas; see, e.g., [15, 19]. Let us consider their generalization in the boundary value form, proposed in [9], called generalized Adams–Moulton methods, that can be written in the following form:

$$y_n - y_{n-1} = h \sum_{i=-\nu}^{k-\nu} \beta_{i+\nu}\, f_{n+i}, \qquad n = \nu, \dots, s-k+\nu, \tag{2.10}$$

i.e., the only nonzero coefficients in the first characteristic polynomial are $\alpha_\nu = 1$ and $\alpha_{\nu-1} = -1$, $\nu = k/2$ if k is even, and $\nu = (k+1)/2$ if k is odd. The coefficients $\{\alpha_i\}$ are determined by imposing that the method has maximum order, i.e., $k+1$. Notice that the classical Adams–Moulton methods have $\nu = k$; see, e.g., [19]. When k is odd, the scheme shares the same stability properties of the trapezoidal rule. Such methods can be suitable for approximating Hamiltonian problems and continuous boundary value problems.

Another generalization of the trapezoidal rule proposed in [9] is given by the following formula:

$$\sum_{i=-\nu}^{\nu-1} \alpha_{i+\nu}\, y_{n+i} = \frac{h}{2}(f_n + f_{n-1}), \qquad n = \nu, \dots, s-k+\nu, \tag{2.11}$$

where $\nu = (k+1)/2$ if k is odd and $\nu = k/2$ if k is even. The coefficients $\{\alpha_i\}$ are determined by imposing that the above formula has maximum order, i.e., $k+1$. Such methods can be suitable for approximating Hamiltonian problems and continuous boundary value problems.

It will be useful in the following sections to have some of the order conditions (2.4) for the above mentioned schemes written in a different form. For the formulas (2.11), we consider (2.4) with $\beta_\nu = \beta_{\nu-1} = 1/2$. Therefore, we have

$$\sum_{j=-\nu}^{\nu-1} j^r \alpha_{j+\nu} = (-1)^{r+1}\frac{r}{2}, \quad r = 0, 2, \dots, k+1, \qquad \sum_{j=-\nu}^{\nu-1} j\alpha_{j+\nu} = 1. \tag{2.12}$$

Similarly, for (2.9), $\beta_\nu = 1$, $\beta_j = 0$ for $j \neq \nu$. Thus, the α_j, $j = 0 \dots, k$, satisfy consistency conditions and

$$\sum_{j=-\nu}^{k-\nu} j^r \alpha_{j+\nu} = 0, \qquad r = 0, 2, \dots, k. \tag{2.13}$$

Finally, for (2.10), $\alpha_\nu = -\alpha_{\nu-1} = 1$ while the coefficients β_j, $j = 0 \dots, k$, satisfy

$$\sum_{j=-\nu}^{k-\nu} j^r \beta_{j+\nu} = (-1)^r \frac{1}{r+1}, \qquad r = 0, 1, \dots, k. \tag{2.14}$$

3. The entries of a class of Toeplitz matrices. Let us consider the $n \times n$ band Toeplitz matrix $\hat{A}_n = (\alpha_j)$, $n > k$,

$$\hat{A}_n = \begin{pmatrix} \alpha_\nu & \dots & \alpha_{k-1} & \alpha_k & 0 & \dots & 0 \\ \vdots & \alpha_\nu & \ddots & \alpha_{k-1} & \alpha_k & \ddots & \vdots \\ \alpha_0 & \ddots & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \ddots & \ddots & \ddots & \ddots & \alpha_{k-1} & \alpha_k \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \alpha_{k-1} \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & \dots & \dots & 0 & \alpha_0 & \dots & \alpha_\nu \end{pmatrix}, \tag{3.1}$$

and $\hat{B}_n = (\beta_j)$ having similar pattern, but with β_j instead of α_j, $j = 0, \dots, k$. If α_j, β_j, $j = 0, \dots, k$, are the coefficients of (2.3), $E_n^{(A)} = A_n - \hat{A}_n$, $E_n^{(B)} = B_n - \hat{B}_n$ are small rank matrices if $n \gg k$, where $A \equiv A_n$ is defined in (2.7) and similarly for $B \equiv B_n$.

It can be checked that all such matrices are, in general, nonsymmetric, nondiagonally dominant, with real entries of nonconstant sign. Moreover, let us associate to the matrices $\hat{A}_n$, $\hat{B}_n$ (A_n and B_n) as above the functions $g_A(z)$, $g_B(z)$, respectively. It is customary to call $g_A(z)$ the symbol of the matrix A_n, see, e.g., [8], where

$$g_A(z) = z^{-\nu}\rho(z) = \sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} z^j, \qquad z \in \mathbb{C}, \tag{3.2}$$

and $\rho(z)$ is the characteristic polynomial of $\hat{A}_n$ while $g_B(z)$ is defined similarly for $\hat{B}_n$ from $\sigma(z)$ in (2.8). The set $\{q \in \mathbb{C} : q = g_A(e^{\mathbf{i}\theta}), 0 \le \theta < 2\pi\}$ is called the boundary locus of the Toeplitz matrix $\hat{A}_n$. It is worth noting that $g_A(e^{\mathbf{i}j\theta})$, $g_B(e^{\mathbf{i}j\theta})$ are the generating functions of the band Toeplitz matrices $\hat{A}_n$, $\hat{B}_n$, respectively; see, e.g., [8, 11].

The Toeplitz matrices related to the linear multistep formulas considered in section 2.2 have the boundary locus and their spectrum of eigenvalues in the right half plane; see [9]. We recall that the families of matrices $\{\hat{A}_n\}$, $\{\hat{B}_n\}$ are such that their entries α_j, β_j, $j = 0, \dots, k$, satisfy the system of linear equations (2.4), where p in (2.4) is the largest integer such that those equations are independent. Notice that the choice of ν is strictly related to the condition number of the underlying Toeplitz matrices; see [6, 8, 9]. For example, with the choice suggested in section 2.2, the matrices $\{\hat{A}_n\}$, $\{\hat{B}_n\}$ related to the formulas (2.9), (2.10), (2.11) have a condition number which increases at most linearly with their size; see [6]. On the other hand, the boundary locus and the spectrum of the eigenvalues of the matrices related to linear multistep formulas are not necessarily contained in one half plane for all k. For example, one can consider the matrices associated with well-known families of formulas used as initial value methods for a sufficiently large value of k in (2.3). This is the

case of the backward differentiation formulas for $k > 2$ and of the Adams–Moulton methods for $k > 1$. However, if ν is chosen differently from the choice suggested in section 2.2, the eigenvalues of $\{\hat{A}_n\}$, $\{\hat{B}_n\}$ can have both positive and negative (or zero!) real part. Indeed, it is easy to check that this is the case of formulas (2.10) used with $k = 5$ but with $\nu = 4$ instead of $\nu = (k+1)/2 = 3$.

We will assume, as is the case in practice for the methods described in section 2.2, that the influence of the small rank perturbations $E_n^{(A)} = A_n - \hat{A}_n$, $E_n^{(B)} = B_n - \hat{B}_n$ on the spectral properties of $\hat{A}_n$, $\hat{B}_n$ is moderate. More precisely, here we refer to suitably chosen additional schemes such that their related matrices A_n, B_n have the spectrum of eigenvalues in the right half plane, and the condition number of these is still of the order of $O(n)$, where n is their size. These hypotheses are usually reasonable; see [6]. On the other hand, notice that, in general, the influence of low rank modifications in the non-Hermitian case can very much change the spectral properties of a given matrix; see [22]. However, in this paper we will focus mainly on the preconditioner and on the spectrum of the component matrices of the preconditioner (1.2), which are normal and defined by using the coefficients of (2.3), i.e., by the entries of $\hat{A}_n$, $\hat{B}_n$ only.

We will need an explicit expression of the coefficients of the formulas (2.9) and (2.10). To this end, there are at least two (equivalent) strategies. In the first one, the coefficients can be computed by writing the formula of the GLM in backward difference form; see, e.g., [19, chapter 3]. Thus, expanding the backward differences of y_{n+j} for the formulas (2.9) and of f_{n+j} for the formulas (2.10), equating the coefficients of y_{n+j} and of f_{n+j}, $j = 0, \dots, k$, to the corresponding expressions, and using an induction argument gives the coefficients α_j, β_j, $j = 0, \dots, k$.

PROPOSITION 3.1. *The coefficients of the formulas* (2.9) *are given by*

$$\alpha_i = (-1)^{k-i} \sum_{j=k-i}^{k} \binom{j}{k-i} \delta_j, \qquad i = 0, \dots, k, \tag{3.3}$$

where

$$\delta_i = \begin{cases} 0, & i = 0; \\ 1, & i = 1; \\ \dfrac{1}{i!} \displaystyle\sum_{s=0}^{i-1} \prod_{\substack{j=0, \\ j \neq s}}^{i-1} (-(k-\nu)+j), & i \leq k-\nu,\ i \geq 1; \\ \dfrac{1}{i!} \displaystyle\prod_{\substack{j=0, \\ j \neq k-\nu}}^{i-1} (-(k-\nu)+j), & i > (k-\nu) \geq 1. \end{cases}$$

The coefficients of the formulas (2.10) *are given by*

$$\beta_i = \frac{(-1)^{k-i}}{(k-i)!} \sum_{j=k-i}^{k} \frac{1}{(j-(k-i))!} \int_{-(k-\nu)-1}^{-(k-\nu)} \prod_{m=0}^{j-1} (r+m)\, dr, \quad i = 0, \dots, k. \tag{3.4}$$

Proof. The expression (3.3) is derived by writing (2.9) in backward difference form (see [19, chapter 3]), i.e.,

$$\sum_{j=0}^{k} \delta_i \nabla^i y_{n+k-\nu} = h\, f_n,$$

where

$$\delta_i = (-1)^i \frac{d}{dr}\binom{-r}{i},$$

and the above derivative is computed at $r = k - \nu$. Thus, by observing that

$$\binom{-r}{j} = \frac{(-r-j+1)\cdots(-r)}{j!} = \frac{(-1)^j}{j!}\prod_{m=0}^{j-1}(r+m), \tag{3.5}$$

we have (3.3). The other expression, i.e., (3.4), is derived by observing that (2.10) can be written as (see [19, chapter 3])

$$y_{n+1} - y_n = h\sum_{j=0}^{k}\gamma_i \nabla^i f_{n+k-\nu+1}, \tag{3.6}$$

where

$$\gamma_j = (-1)^j \int_{-(k-\nu)-1}^{-(k-\nu)} \binom{-r}{j}\, dr.$$

Thus, from (3.5), we have (3.4). ∎

The other strategy is based on the explicit solution of linear equations in the unknowns α_j, β_j, $j = 0, \ldots, k$, by writing (2.4) in matrix form. Thus, we have to solve a linear system whose matrix is a Vandermonde-like one, and several combinatorial identities can be used. The coefficients of (2.9) and of (2.10) were computed following this strategy in [3]. We stress that the derivation of a useful expression can be rather lengthy. Full details can be found in [3, pp. 46–50, 66–69].

PROPOSITION 3.2. *The coefficients of the formula* (2.9) *are given by*

$$\begin{aligned}
\alpha_i &= \frac{(-1)^{\nu-i}}{\nu-i}\frac{\nu!(k-\nu)!}{i!(k-i)!}, \qquad i \neq \nu,\ i = 0, \ldots, k,\\
&= \frac{1}{\nu} = \frac{2}{k+1}, \qquad i \equiv \nu,\ k\ \textit{odd},\\
&= \frac{2\nu-1}{\nu(\nu-1)} = \frac{4(k+1)}{k(k+2)}, \qquad i \equiv \nu,\ k\ \textit{even},\ k \geq 1.
\end{aligned} \tag{3.7}$$

The coefficients of the formula (2.10) *are given by*

$$\beta_i = \frac{(-1)^{k-i}}{i!\,(k-i)!}\int_{\nu}^{\nu+1}\prod_{\substack{m=0,\\ m\neq i}}^{k}(t-m)\, dt, \qquad i = 0, \ldots, k. \tag{3.8}$$

Proof. The proof follows after some manipulations of the results in Theorem 4.1.1 for (3.7) and in Remark 4.2.2 for (3.8) in [3] by recalling that $\nu = (k+1)/2$ if k is odd, while $\nu = (k+2)/2$ for (2.9), $\nu = k/2$ for (2.10) if k is even. ∎

We remark that there is a third approach to derive the coefficients of the formulas (2.9) and (2.10) that is simpler than the other two. It is based on generating functions and symbolic operators; see, e.g., [19, sections 3.9–3.12]. Using that approach, we have that the generating function for δ_i in (3.3) is given by

$$G_1(z) = -(1-z)^{k-\nu}\log(1-z) = \sum_{i=0}^{\infty}\delta_i z^i.$$

Therefore,

$$\delta_i = \sum_{s=0}^{i-1} (-1)^s \binom{k-\nu}{s} \frac{1}{i-s}.$$

Similarly, the generating function for γ_i in (3.6) is given by

$$G_2(z) = \frac{-z(1-z)^{k-\nu}}{\log(1-z)} = \sum_{i=0}^{\infty} \gamma_i z^i,$$

and an explicit expression for γ_i can be derived accordingly.

Obviously, suitably manipulating the expressions derived by one strategy (e.g., (3.3), (3.4)) gives the expressions derived by the others (see, e.g., (3.7), (3.8), respectively).

COROLLARY 3.3. *The coefficients of the formulas* (2.9) *are uniformly bounded by* 2 *for all* $k \geq 1$. *Moreover,* $|\alpha_{i+1}| < |\alpha_i|$ *for* $i = \nu+1, \ldots, k-1$; $|\alpha_{i+1}| > |\alpha_i|$ *for* $i = 0, \ldots, \nu-2$; $|\alpha_\nu| < |\alpha_{\nu+1}|$; $|\alpha_{\nu-1}| > |\alpha_\nu|$; *and* $\lim_{k\to\infty} \alpha_j = 0$, $j = 0, k, \nu$.

Proof. By considering the expression (3.7) we have that $|\alpha_{i+1}| < |\alpha_i|$ for $i = \nu+1, \ldots, k-1$ and $|\alpha_{i+1}| > |\alpha_i|$ for $i = 0, \ldots, \nu-2$. For k odd, $\nu = (k+1)/2$, and, by (3.7), we have $\alpha_{\nu-1} = -\frac{(k+1)/2}{k-(k+1)/2+1} = -1$ while, for k even, $\nu = (k+2)/2$ and $\alpha_{\nu-1} = \frac{k+2}{k} \leq 2$ for $k \geq 2$. Similarly, for k odd, we have $\alpha_{\nu+1} = (k-1)/(k+4) < 1$, otherwise $\alpha_{\nu+1} = (k-2)/(k+4) < 1$, $k \geq 2$, and the proof is complete by recalling (3.7) again for $i = 0, \nu, k$. ∎

On the other hand, we can observe that for many families of linear multistep formulas the above results do not hold. This is the case of popular initial value methods such as the backward differentiation formula and the Adams–Moulton methods or of the schemes in section 2.2 with some choices of ν different from those suggested there. More precisely, some of the coefficients α_j and β_j, $j = 0, \ldots, k$, for the methods above, can grow boundlessly very fast for $k \to \infty$.

4. Circulant approximations for general linear multistep formulas. Let us consider the block preconditioners in (1.2) for the linear systems in (2.6) based on circulant-like matrices introduced in [4, 5, 7]. The approximating operators $\breve{A}$, $\breve{B}$ in (1.2) are computed by taking into account the coefficients of the formula (2.3), i.e., they are defined for the Toeplitz matrices $\hat{A}_n$, $\hat{B}_n$.

In what follows, we will recall in brief the main trigonometric approximations for the nonsymmetric matrices $\hat{A}_n$, $\hat{B}_n$ (and for A, B in (1.1)) we have found effective for the preconditioner (1.2); see also section 5.3. To this end, let $T_n = (t_j)$ be an $n \times n$ Toeplitz matrix whose diagonal entries are t_j, $j = -(n-1), \ldots, n-1$.

Strang's $s(T_n)$ (see [21]), sometimes called simple circulant approximation, is such that if $s_0, \ldots, s_{n-1}$ are the entries of the first row of the corresponding $n \times n$ preconditioner for T_n, we have

$$s_j = \begin{cases} t_j, & 0 < j \leq \left\lfloor \frac{n}{2} \right\rfloor, \\ \\ t_{j-n}, & \left\lfloor \frac{n}{2} \right\rfloor < j < n, \end{cases} \qquad j = 0, \ldots, n-1. \tag{4.1}$$

The spectrum of the Hermitian Toeplitz matrices preconditioned using Strang's preconditioner was analyzed in [10]. Notice that $s(T_n)$ is singular for the Toeplitz matrices

T_n whose generating function $f(\theta)$ is zero in $\theta = 0$, as observed, e.g., in [5, 24]. Unfortunately, the generating function of the matrix $\hat{A}_n$ always has a zero of multiplicity one in $\theta = 0$ because of the consistency condition $0 = \rho(1) = \sum_{j=0}^{k} \alpha_j$. Thus, as observed in [5], the approximation (4.1) cannot be safely used in the preconditioner (1.2), e.g., when the Jacobian matrix J in (2.6) has some very small or zero eigenvalues; see [5] for more details.

T. Chan's circulant preconditioner for the Toeplitz matrix T_n, denoted by $c(T_n)$, is defined such that $\|c(T_n) - T_n\|_F$ is minimum, where $c(T_n)$ is chosen in the set of $n \times n$ circulant matrices and $\|\cdot\|_F$ is the Frobenius norm. If $c_0, \ldots, c_{n-1}$ are the entries of the first row of $c(T_n)$ and t_j, $j = -(n-1), \ldots, n-1$, are the elements on the diagonals of the Toeplitz matrix T_n, we have (see [12])

$$c_j = \frac{(n-j)t_j + jt_{j-n}}{n}, \qquad j = 0, \ldots, n-1. \tag{4.2}$$

If the Toeplitz matrix T_n is Hermitian and positive definite, then these properties hold true for $c(T_n)$ as well; see [23]. Unfortunately, if T_n is nonsymmetric, $s(T_n)$ and $c(T_n)$ can have eigenvalues in the right and left half plane or zero as well, even for those matrices T_n whose eigenvalues have strictly positive real part. For example, this holds true for the underlying linear systems based on the formulas in section 2. Moreover, there are families of formulas (2.3) such that the circulant approximation (4.2) can be ill conditioned or even singular (e.g., those based on the midpoint method in boundary value form; see at the end of section 5.2).

Let us consider the P-circulant approximation introduced in [4]. Again, if T_n is a Toeplitz matrix whose entries of the diagonals are $t_{-(n-1)}, \ldots, t_{n-1}$, we have that the entries $p_0, \ldots, p_{n-1}$ of the first row of the P-circulant preconditioner $p(T_n)$ for T_n are given by

$$p_j = \frac{(n+j)t_j + jt_{j-n}}{n}, \qquad j = 0, \ldots, n-1. \tag{4.3}$$

Notice that the P-circulant and simple and T. Chan's circulants are equivalent in the sense of the linear approximation processes; see [20]. In practice, P-circulant matrices come from using the Frobenius norm weight $(n-j)/n$ for the lower and the weight $(n+j)/n$ for the upper diagonals, respectively. The circulant matrices, whose entries are defined in (4.3), have been called P-circulant in [4] because, for some classes of Toeplitz matrices (and thus for formulas (2.3)), their eigenvalues have positive real part; see section 5.2. This property can speed up the convergence process with respect to the other basic approximations described here; see section 5.3. We stress that P-circulants neither preserve symmetry (but for our purpose this is not essential) nor minimize the "distance" with the original Toeplitz matrix. More precisely, $||p(T_n) - T_n||$ is not minimized with respect to the p-norms (e.g., $p = 1, 2, \infty$) nor the Frobenius norm.

The MS-circulant approximation for T_n is given by a rank-one perturbation of the simple circulant preconditioner whose zero eigenvalue in (5.1) is set to a suitable nonzero value c for those Toeplitz matrices T_n whose generating functions have a zero. We achieved interesting results in [5] by setting $c = 1/n$ and $c = \min_r\{\mathrm{Re}(\phi_r)\} > 0$, where ϕ_r, $r = 1, \ldots, n$, are the eigenvalues of $s(T_n)$.

Finally, the $\{\omega\}$-circulant approximation can be considered as another extension of the simple circulant approximation. Let T_n be a n_1-band Toeplitz matrix, $n_1 < \lceil n/2 \rceil$. The $\{\omega\}$-circulant matrix $\tilde{s}(t_n)$ differs from the simple circulant $s(T_n)$ because

the entries outside the diagonals $-n_1, \dots, n_1$ of $\tilde{s}(t_n)$ are given by those of $s(T_n)$ multiplied by $\omega = \exp(\mathbf{i}\theta)$, $0 < \theta \leq \pi$, and $\tilde{s}(T_n)$ is nonsingular even if the generating function of T_n has a zero for $\theta = 0$; see [7].

We observe that some combinations of the above approximations can give further useful preconditioners as well. For example, it is straightforward to define $\{\omega\}$–P-circulant preconditioners by using (4.3) and $\{\omega\}$-circulant matrices instead of circulant matrices. The arguments used in the following sections can be adapted for these preconditioners as well, in general, and we will focus only on the "basic" approximations above.

5. The spectrum of the circulant approximations. The Toeplitz matrices $\hat{A}_n$, $\hat{B}_n$ in (3.1) are positive stable for the linear multistep formulas (2.9), (2.10), (2.11); see [9, chapter 11]. We recall that a square matrix is said to be (semi)positive stable if its eigenvalues have positive (nonnegative) real part; see, e.g., [16]. It is straightforward to note that positive stable matrices are nonsingular.

Let us consider $n = s + 1$ and the $(s + 1) \times (s + 1)$ P-circulant matrix $p(A)$ defined in (4.3) for the Toeplitz matrix A in (2.7) (and then for $\hat{A}_{s+1}$ in (3.1)). The eigenvalues ϕ_j, $j = 0, \dots, s$, of $p(A)$ can be computed by a linear combination of the entries of the first row (see Davis [13]):

$$\phi_l = \sum_{j=0}^{s} p_j \epsilon^{jl}, \qquad l = 0, \dots, s, \quad \epsilon = e^{2\pi\,\mathbf{i}/(s+1)}. \tag{5.1}$$

From (4.3) we have

$$\phi_l = \sum_{j=0}^{s} \alpha_{j+\nu} \left(1 + \frac{j}{s+1}\right) \epsilon^{jl} + \sum_{j=0}^{s} \left(\frac{j}{s+1} \alpha_{j+\nu-(s+1)}\right) \epsilon^{jl}, \qquad l = 0, \dots, s.$$

Therefore,

$$\phi_l = \sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} \left(1 + \frac{j}{s+1}\right) \epsilon^{jl}, \qquad l = 0, \dots, s. \tag{5.2}$$

A similar expression holds for the eigenvalues $\psi_0, \dots, \psi_s$ of $p(B)$:

$$\psi_l = \sum_{j=-\nu}^{k-\nu} \beta_{j+\nu} \left(1 + \frac{j}{s+1}\right) \epsilon^{jl}, \qquad l = 0, \dots, s. \tag{5.3}$$

Notice that (5.2) and (5.3) are trigonometric sums. Let us define

$$\hat{\Phi}_k(x) = \sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} \left(1 + \frac{j}{s+1}\right) \cos(j\,x), \qquad x \in \mathbb{R}, \tag{5.4}$$

$$\hat{\Psi}_k(x) = \sum_{j=-\nu}^{k-\nu} \beta_{j+\nu} \left(1 + \frac{j}{s+1}\right) \cos(j\,x), \qquad x \in \mathbb{R}. \tag{5.5}$$

We observe that (5.4) and (5.5) are analytic functions (for $k < \infty$). From (5.2), we have that

$$\hat{\Phi}_k\left(\frac{2\pi l}{s+1}\right) = \mathrm{Re}(\phi_l), \quad \hat{\Psi}_k\left(\frac{2\pi l}{s+1}\right) = \mathrm{Re}(\psi_l), \qquad l = 0, \dots, s.$$

Thus, it is straightforward to see that if $\hat{\Phi}_k(x)$, $\hat{\Psi}_k(x)$ are positive for real values of x, then $p(A)$ and $p(B)$ are positive stable.

By using similar arguments, we can derive the expression of the eigenvalues of $s(A_{s+1})$, $s(B_{s+1})$ and $c(A_{s+1})$, $c(B_{s+1})$, respectively:

$$\gamma_l = \sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu}\epsilon^{jl}, \qquad \delta_l = \sum_{j=-\nu}^{k-\nu} \beta_{j+\nu}\epsilon^{jl}, \qquad l = 0, \ldots, s, \tag{5.6}$$

and

$$\sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu}\left(1 - \frac{|j|}{s+1}\right)\epsilon^{jl}, \qquad \sum_{j=-\nu}^{k-\nu} \beta_{j+\nu}\left(1 - \frac{|j|}{s+1}\right)\epsilon^{jl}, \qquad l = 0, \ldots, s. \tag{5.7}$$

Notice that the eigenvalues of $s(A_{s+1})$, $s(B_{s+1})$ lie on the boundary locus of A_{s+1}, B_{s+1}, respectively.

5.1. Preliminary results. First, let us give some properties of the trigonometric sums (5.4), (5.5).

We recall that a sequence $\{c_j\}$ is of bounded variation (see [25]) if the series $\sum_{j=0}^{\infty} |c_{j+1} - c_j|$ converges. If $\{c_j\}$ tends monotonically to zero, then $\{c_j\}$ is of bounded variation. It is useful to simplify the expressions (5.4) and (5.5) by observing that $\cos(x)$ is an even function.

LEMMA 5.1. *The function* $\hat{\Phi}_k(x)$ *in* (5.4) *can be expressed for* (2.9) *as*

$$\hat{\Phi}_k(x) = \frac{a_0}{2} + \sum_{n=1}^{k-\nu} (-1)^n a_n \cos(n\,x), \tag{5.8}$$

where $a_0 = 2\alpha_\nu$, $\nu = (k+1)/2$ *if* k *is odd,* $\nu = (k+2)/2$ *if* k *is even, and* $a_n = (-1)^n \tilde{a}_n$,

$$\tilde{a}_n = \alpha_{n+\nu}\left(1 + \frac{n}{s+1}\right) + \alpha_{-n+\nu}\left(1 - \frac{n}{s+1}\right), \qquad n = 1, \ldots, k-\nu. \tag{5.9}$$

It is intended that α_j *is zero if* $j < 0$ *or* $j > k$. *The sequence* $\{a_n\}$ *has the following properties:*

(1) $a_n \geq 0$, $n \geq 0$;
(2) a_n *tends to zero if* $n \to \infty$;
(3) a_n *is uniformly bounded (i.e.,* $0 \leq a_n < 2$, $n \geq 0$*);*
(4) $\{a_n\}$ *is monotonic decreasing;*
(5) $\{a_n\}$ *is of bounded variation.*

Proof. The expression (5.8) follows by observing that from (3.7), (5.4), and (5.9) we have

$$\tilde{a}_n = \frac{(-1)^n}{n}\left\{ -\frac{\binom{k}{\nu+n}}{\binom{k}{\nu}}\left(1 + \frac{n}{s+1}\right) + \frac{\binom{k}{\nu-n}}{\binom{k}{\nu}}\left(1 - \frac{n}{s+1}\right)\right\} = (-1)^n \cdot a_n.$$

(1) Let us check for first that $a_n > 0$ for $n \geq 1$, $n \leq k - \nu$ (recall that $a_0 = 2\alpha_\nu$ is positive; see (3.7)). From here on, it is intended that $a_n = 0$ if $n > k - \nu$. Again,

from the expression (3.7), we have

$$
\begin{aligned}
n\cdot a_n &= \frac{\binom{k}{\nu-n}}{\binom{k}{\nu}}\left(1-\frac{n}{s+1}\right)-\frac{\binom{k}{\nu+n}}{\binom{k}{\nu}}\left(1+\frac{n}{s+1}\right)\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\cdot\left(1-\frac{n}{s+1}\right)\right]-\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-n}{\nu+n}\cdot\left(1+\frac{n}{s+1}\right)\right]\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\left[\left(1-\frac{n}{s+1}\right)-\frac{\nu-n}{\nu+n}\left(1+\frac{n}{s+1}\right)\right]\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\frac{2n}{(\nu+n)(s+1)}\cdot(s+1-\nu)>0.
\end{aligned}
$$

Indeed, notice that the term in square brackets above can assume values in $(0,1)$, and $(s+1-\nu)$ is greater than zero because $s\geq k\geq\nu\geq 1$ by hypothesis; see section 2.2.

(2) Now, let us check that a_n converges to zero for $n\to\infty$. From the last expression, we have

$$
\begin{aligned}
a_n &= \left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\frac{2(s+1-\nu)}{(\nu+n)(s+1)}\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\frac{2}{\nu+n}\cdot\left(1-\frac{\nu}{s+1}\right)\\
&\leq\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\frac{2}{n}\leq\frac{2}{n} \qquad (5.10)
\end{aligned}
$$

because the term in square brackets above assumes values in $(0,1)$, $n\leq\nu$, and $0<1-\nu/(s+1)<1$ because $s\geq k\geq\nu\geq 1$.

(3) It is an immediate consequence of the bound in (5.10).

(4) $\{a_n\}$ is monotonic (decreasing). Indeed,

$$
\begin{aligned}
&a_{n+1}-a_n\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot\left[\frac{2\nu(\nu-n)}{(\nu+n+1)(s+1)(\nu+n)}-\frac{2\nu}{(\nu+n)(s+1)}\right]\\
&=\left[\frac{\nu-1}{\nu+1}\cdot\ldots\cdot\frac{\nu-(n-1)}{\nu+(n-1)}\right]\cdot-\frac{2\nu}{s+1}\cdot\frac{2n+1}{(\nu+n+1)(\nu+n)}<0
\end{aligned}
$$

by using similar arguments as in (1) and (2).

(5) Finally, for (1)–(4), $\{a_n\}$ is of bounded variation. □

We recall that a sequence of functions is said to converge locally uniformly on a set $\mathcal{S}$ if it converges uniformly on every compact subset of $\mathcal{S}$; see, e.g., [17, p. 160].

PROPOSITION 5.2. *The sequence of functions $\{\hat{\Phi}_k(x)\}$ for (2.9) converges locally uniformly with respect to k (and then with respect to $\nu=O(k)$, see section 2) in $(-\pi,\pi)$.*

Proof. It is a consequence of Lemma 5.1 and of [25, Theorem 2.7, p. 4]. □

COROLLARY 5.3. *Under the hypotheses of Proposition 5.2, the function*

$$\hat{\Phi}(x)=\lim_{k\to\infty}\hat{\Phi}_k(x) \qquad (5.11)$$

is an analytic function for $x\in(-\pi,\pi)$ and continuous for $x\in\mathbb{R}$.

Proof. It is a consequence of Proposition 5.2 and of [17, Corollary 3.4c, p. 161]. The continuity over the whole real axis derives from Abel's limit theorem applied in $x = \pm\pi$ and considering that, for n integer, we have

$$\hat{\Phi}_k(\pm x + 2n\pi) = \hat{\Phi}_k(x), \qquad \hat{\Phi}_k(2\pi - x)' = -\hat{\Phi}_k(x)', \tag{5.12}$$

$$\hat{\Psi}_k(\pm x + 2n\pi) = \hat{\Psi}_k(x), \qquad \hat{\Psi}_k(2\pi - x)' = -\hat{\Psi}_k(x)', \qquad x \in [0, 2\pi],\ k \geq 1. \tag{5.13}$$

Similar expressions hold true for $\hat{\Phi}(x)$ and $\hat{\Psi}(x)$. □

LEMMA 5.4. *Let k be an integer and $\nu = \lceil (k+1)/2 \rceil$ (k even or odd) or $\nu = (k+2)/2$ (k even). For $-(k-\nu) \leq n \leq (k-\nu)$, we have*

$$(\nu + n)!\,(k - \nu - n)! \geq (\nu - n)!\,(k - \nu + n)!, \tag{5.14}$$

$$\nu!\,(k-\nu)! \leq (\nu + n)!\,(k - \nu - n)!. \tag{5.15}$$

Proof. Let us consider (5.14). We have

$$\frac{(\nu-n)!(k-\nu+n)!}{(\nu+n)!(k-\nu-n)!} = \frac{(\nu-n)!(k-(\nu-n))!}{k!} \cdot \frac{k!}{(\nu+n)!(k-(\nu+n))!} = \frac{\binom{k}{\nu+n}}{\binom{k}{\nu-n}},$$

where the ratio above is equal to 1 if k is even and it is less than 1 otherwise. Indeed,

$$\binom{k}{\nu-n} = \binom{k}{k-(\nu-n)} = \begin{cases} \binom{k}{\nu+n} & \text{if } k-\nu = \nu \text{ (and } k \text{ is even)}, \\ \binom{k}{\nu+n-1} & \text{if } k-\nu = \nu-1 \text{ (and } k \text{ is odd)}\ . \end{cases}$$

Thus, for k odd, we have

$$\binom{k}{\nu+n-1} = \binom{k+1}{\nu+n} - \binom{k}{\nu+n} \Rightarrow \frac{\binom{k}{\nu+n}}{\binom{k}{\nu-n}} = \frac{1}{\frac{\nu+n-1}{\nu-n}} < 1, \quad 1 \leq n \leq (k-\nu).$$

Using similar arguments, we can see that (5.14) holds true for $\nu = (k+2)/2$ and k even as well. Now, let us consider (5.15) for $n \geq 1$ (for negative values of n a similar argument can be used). We have

$$\frac{\nu!\,(k-\nu)!}{(\nu+n)!\,(k-\nu-n)!} = \frac{k-\nu}{\nu+1} \cdot \frac{k-\nu-1}{\nu+2} \cdots \frac{k-\nu-(n-1)}{\nu+n},$$

where we have that the above expression is equal to

$$\begin{cases} \dfrac{\nu-1}{\nu+1} \cdots \dfrac{\nu-n}{\nu+n} < 1 & \text{if } k-\nu = \nu \text{ and } k \text{ is odd}, \\ \dfrac{\nu}{\nu+1} \cdots \dfrac{\nu-(n-1)}{\nu+n} < 1 & \text{if } k-\nu = \nu-1 \text{ and } k \text{ is even}\ . \end{cases}$$

Using similar arguments, we can see that (5.15) holds true for $\nu = (k+2)/2$ and k even as well. □

LEMMA 5.5. *The function* $\hat{\Psi}_k(x)$ *can be expressed for* (2.10) *as*

$$\hat{\Psi}_k(x) = \frac{b_0}{2} + \sum_{n=1}^{k-\nu} (-1)^{n+1} b_n \cos(n\,x), \tag{5.16}$$

where $b_0 = 2\beta_\nu$, $\nu = \lceil (k+1)/2 \rceil$, *and* $b_n = (-1)^{n+1}\tilde{b}_n$, $n \geq 1$,

$$\tilde{b}_n = \beta_{n+\nu}\left(1 + \frac{n}{s+1}\right) + \beta_{-n+\nu}\left(1 - \frac{n}{s+1}\right), \qquad n = 1, \ldots, k-\nu. \tag{5.17}$$

It is intended that β_j *is zero if* $j < 0$ *or* $j > k$. *The sequence* $\{b_n\}$ *has the following properties:*

(1) $b_n \geq 0$, $n \geq 0$;
(2) b_n *tends to zero if* $n \to \infty$;
(3) b_n *is uniformly bounded (i.e.,* $0 \leq b_n < 2$, $n \geq 0$*);*
(4) $\{b_n\}$ *is monotonic decreasing;*
(5) $\{b_n\}$ *is of bounded variation.*

Proof. (1) By expanding (5.17), we have

$$\begin{aligned}\tilde{b}_n = &\left[\frac{(-1)^{k-\nu-n}}{(\nu+n)!(k-\nu-n)!}\int_\nu^{\nu+1} \prod_{\substack{m=0,\\ m\neq\nu+n}}^{k} (t-m)\,dt\right]\left(1 + \frac{n}{s+1}\right)\\ &+ \left[\frac{(-1)^{k-\nu+n}}{(\nu-n)!(k-\nu+n)!}\int_\nu^{\nu+1} \prod_{\substack{m=0,\\ m\neq\nu-n}}^{k} (t-m)\,dt\right]\left(1 - \frac{n}{s+1}\right).\end{aligned} \tag{5.18}$$

Thus, for $n \geq 1$, we have

$$\begin{aligned}\tilde{b}_n = (-1)^{n+1}\int_\nu^{\nu+1} &\left[\frac{1+n/(s+1)}{(\nu+n)!(k-\nu-n)!}\frac{1}{|t-\nu-n|}\right.\\ &\left. - \frac{1-n/(s+1)}{(\nu-n)!(k-\nu+n)!}\frac{1}{(t-\nu+n)}\right]\prod_{m=0}^{k}|t-m|\,dt = (-1)^{n+1}\cdot b_n,\end{aligned} \tag{5.19}$$

while, by observing that $t-m$, $m = 0, \ldots, k$, do not change sign for $t \in (\nu, \nu+1)$,

$$\tilde{b}_0 \equiv b_0 = 2\beta_\nu = \frac{2(-1)^{k-\nu}}{\nu!(k-\nu)!}\int_\nu^{\nu+1}\prod_{\substack{m=0,\\ m\neq\nu}}^{k}(t-m)\,dt = \frac{2}{\nu!(k-\nu)!}\int_\nu^{\nu+1}\prod_{\substack{m=0,\\ m\neq\nu}}^{k}|t-m|\,dt, \tag{5.20}$$

therefore (5.20) is positive. To check that $b_n > 0$, $n \geq 1$, and $n \leq k-\nu$ (it is intended that $b_n = 0$ for $n > k-\nu$), it is enough to see that the part in square bracket in (5.19) is positive or zero. For brevity, let us consider k even. By Lemma 5.4, the part in square brackets in (5.19) can be rewritten as

$$\frac{1}{(\nu+n)!(k-\nu-n)!}\left(\frac{1+n/(s+1)}{n-(t-\nu)} - \frac{1-n/(s+1)}{n+(t-\nu)}\right)$$

$$= \frac{(s+1+n)\,(n+(t-\nu)) - (s+1-n)\,(n-(t-\nu))}{(\nu+n)!\,(k-\nu-n)!\,(n-(t-\nu))\,(n+(t-\nu))\,(s+1)}.$$

Then, we can observe that the ratio above is positive because the denominator of the related expression is positive, $s+1+n>0$, $n+(t-\nu)>0$, and

$$\frac{(s+1-n)(n-(t-\nu))}{(s+1+n)(n+(t-\nu))} < 1, \quad n \geq 1, \quad 0 \leq t \leq \nu+1.$$

For k odd a similar argument can be used, and (1) and the expression (5.16) are verified.

(2) Let us check first that b_0 is bounded. We observe that, for $t = t^* = \nu + \epsilon(\nu)$, $0 < \epsilon(\nu) \to 0$ for $k, \nu \to \infty$ (recall that $\nu = O(k)$), the following function

$$f(t) = \prod_{\substack{m=0,\\ m\neq\nu}}^{k} |t-m|, \qquad \nu \leq t \leq (\nu+1), \tag{5.21}$$

reaches its (unique) maximum in the segment $\nu \leq t \leq (\nu+1)$. This can be checked by considering the derivative df/dt of (5.21) in $(\nu, \nu+1)$ and applying an induction argument on k. Thus, $f(t^*) = c\cdot\nu!\,(k-\nu)!$, where $c = c(\nu)$ is a parameter of the order of 1 that converges fast to 1 as $\nu \to \infty$ and, by (5.20), b_0 is uniformly bounded above by 2. As a corollary of the above result, by (3.8), β_ν is uniformly bounded above by 1. Now, to check that b_n is bounded for $n \geq 1$, it is enough to observe that both the following factors in (5.19)

$$\frac{1}{(\nu+n)!(k-\nu-n)!}\int_{\nu}^{\nu+1}\prod_{m=0}^{k}|t-m|\,dt, \quad \frac{1}{(\nu-n)!(k-\nu+n)!}\int_{\nu}^{\nu+1}\prod_{m=0}^{k}|t-m|\,dt$$

are positive and bounded by a constant of the order of unity. To this end, notice that

$$G(t) = \prod_{m=0}^{k}(t-m) = \begin{cases} (-1)^{k+1}\cdot\dfrac{\Gamma(k+1-t)}{\Gamma(-t)}, & \nu < t < \nu+1, \\ 0, & t = \nu \text{ or } t = \nu+1, \end{cases} \tag{5.22}$$

where $\Gamma(z)$ is the Gamma function (see [1] for definitions and some properties). The equality (5.22) can be derived by using arguments in [1, pp. 12–13]. It is straightforward to observe that

$$\int_{\nu}^{\nu+1}\prod_{m=0}^{k}|t-m| \leq \sup_{\nu<t<\nu+1}\prod_{m=0}^{k}|t-m|.$$

Let us denote by t^* the maximum of the function $|G(t)|$ in $\nu \leq t \leq \nu+1$; $G(t)$ is defined in (5.22). By considering dG/dt in $(\nu, \nu+1)$ and using an induction argument on k, we have that $t^* = \nu + 1/2 + \epsilon(\nu)$, where $\epsilon(\nu) \to 0$ as $\nu \to \infty$ ($k \to \infty$). By using the definition of $\Gamma(z)$, we have $\Gamma(x+1) = x\,\Gamma(x) \Rightarrow \Gamma(x) = \Gamma(x+1)/x$, where x cannot be a negative integer or zero. Applying repeatedly $\Gamma(x) = \Gamma(x+1)/x$, we have

$$|\Gamma(-t)|^{-1} \leq \nu!\,(t^*-\nu)\,\frac{1}{|\Gamma(-t^*+\nu+1)|}. \tag{5.23}$$

By observing that

$$(k-\nu-1)! < \Gamma(k+1-t^*) < (k-\nu)!,\ 0 < c \equiv \Gamma(-t^*+\nu+1) < 1,\ 1 < 1/(t^*-\nu) < 2$$

and by recalling Lemma 5.4, we can write

$$|G(t)| \le c \cdot (t^*-\nu)^{-1} \cdot \nu! \cdot (k-\nu)!;$$

thus, b_n is bounded above by 2.

(3) To check that $\{b_n\}$ converges to zero as $n \to \infty$, arguments similar to those used to prove (1), (2) give that b_n in (5.19) can be written as $b_n = \frac{1}{n} \cdot h_n$, where $\{h_n\}$ is a uniformly bounded sequence.

(4) To check that $\{b_n\}$ is a monotonic nonnegative decreasing sequence, we observe that the expression (5.19) for $n > 1$ and for k even gives

$$\begin{aligned} b_n - b_{n+1} = \frac{1}{(\nu+n)!(k-\nu-n)!} \int_\nu^{\nu+1} \left\{ \left[\frac{1+n/(s+1)}{n-(t-\nu)} - \frac{1-n/(s+1)}{n+(t-\nu)} \right] \right. \\ \left. - \left[\frac{1+(n+1)/(s+1)}{(n+1)-(t-\nu)} - \frac{1-(n+1)/(s+1)}{(n+1)+(t-\nu)} \right] \right\} \prod_{m=0}^{k} |t-m|\, dt. \end{aligned} \tag{5.24}$$

Let us consider the expression in curly brackets in (5.24). We have the following lower bound:

$$\begin{aligned} \{\cdot\} &> \frac{1+n/(s+1)}{n-1} - \frac{1+(n+1)/(s+1)}{n+1} - \frac{1-n/(s+1)}{n-1} + \frac{1-(n+1)/(s+1)}{n+1} \\ &= \frac{2n}{(s+1)(n-1)} - \frac{2(n+1)}{(s+1)(n+1)} = \frac{2}{s+1}\left(\frac{n}{n-1} - 1\right) > 0, \end{aligned} \tag{5.25}$$

and thus, by (5.24), $b_n - b_{n+1} > 0$ and the sequence $\{b_n\}$ is monotonic decreasing.

(5) For (1)–(4), $\{b_n\}$ is of bounded variation. ∎

Finally, by using similar arguments such as in the Proposition 5.2 and Corollary 5.3, we have the following results.

PROPOSITION 5.6. *The sequence of functions* $\{\hat{\Psi}_k(x)\}$ *for* (2.10) *converges locally uniformly with respect to* k *(and thus with respect to* $\nu = O(k)$*) in* $(-\pi, \pi)$.

Proof. It is a consequence of Lemma 5.5 and of [25, Theorem 2.7, p. 4]. ∎

COROLLARY 5.7. *Under the hypotheses of Proposition* 5.6, *the function*

$$\hat{\Psi}(x) = \lim_{k\to\infty} \hat{\Psi}_k(x) \tag{5.26}$$

is analytic for $x \in (-\pi, \pi)$ *and continuous for* $x \in \mathbb{R}$. ∎

5.2. Main results. As a consequence of the results in the previous section, we can give bounds for the eigenvalues for some of the underlying approximations.

THEOREM 5.8. *The P-circulant matrices* $p(A_{s+1})$, $p(B_{s+1})$ *related to the formulas* (2.9), (2.10) *are positive stable and, if* ϕ_j, ψ_j, $j = 0, \dots, s$, *are the eigenvalues of* $p(A_{s+1})$, $p(B_{s+1})$, *respectively, we have*

$$\frac{1}{s+1} \le \mathrm{Re}(\phi_j) < 2, \qquad \mathrm{Re}(\psi_j) = 1 \text{ for } (2.9), \tag{5.27}$$

$$\frac{1}{s+1} \le \mathrm{Re}(\phi_j) < \frac{2s+1}{s+1} < 2, \qquad \frac{2}{\pi^2(s+1)} < \mathrm{Re}(\psi_j) < 1 \ \text{ for } (2.10). \tag{5.28}$$

Proof. Let us observe that, from (4.3) and (5.2), considering the scaling and consistency conditions $\rho(1) = 0$, $\sigma(1) = 1$, we have

$$\sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} = 0, \quad \sum_{j=-\nu}^{k-\nu} j\alpha_{j+\nu} = 1. \tag{5.29}$$

Thus, the expression (5.2) gives $\phi_0 = \hat{\Phi}(0) = 1/(s+1)$ for the formulas (2.3).

Let us check (5.27). To this end, we consider formulas (2.9) and expand $\cos(jx)$ in the right-hand side of (5.4) using power series in a neighborhood of the origin. If $\mathcal{P}(f)$ is the formal power series expansion of a function f, we can write

$$\mathcal{P}\left(\hat{\Phi}_k(x)\right) = \frac{1}{s+1} + \sum_{n=1}^{\infty} \left\{ (-1)^n \frac{x^{2n}}{(2n)!} \sum_{j=-\nu}^{k-\nu} j^{2n} \alpha_{j+\nu} \left(1 + \frac{j}{s+1}\right) \right\}. \tag{5.30}$$

For brevity, we consider k odd ($\Rightarrow \nu = (k+1)/2$). From (2.13), it is worth noting that (5.30) is equivalent to the following expression:

$$\mathcal{P}\left(\hat{\Phi}_k(x)\right) = \frac{1}{s+1} + \sum_{n=\nu}^{\infty} \left\{ (-1)^n \frac{x^{2n}}{(2n)!} \sum_{j=-\nu}^{k-\nu} j^{2n} \alpha_{j+\nu} \left(1 + \frac{j}{s+1}\right) \right\}. \tag{5.31}$$

However, in Proposition 5.2, we observed that $\{\hat{\Phi}_k(x)\}$ converges locally uniformly in $\mathcal{S} = (-\pi, \pi)$ with respect to k (i.e., to ν because $k = 2\nu - 1$) for (2.9). Moreover, the functions $f_n(x) = (-1)^n a_n \cos(n\,x)$ in (5.8) are analytic in $\mathcal{S}$. Then, by [17, Corollary 3.4c, p. 161], we have that $\sum f_n(x)$, i.e., $\hat{\Phi}(x)$ in (5.11), is analytic in $\mathcal{S}$ and that the sequence $\{\hat{\Phi}_k(x)\}$ converges in $\mathcal{S}$ and the series related to (5.30) (and (5.31)) is the Taylor series of $\hat{\Phi}(x)$. However, by Abel's limit theorem for the power expansions, we have that the Taylor expansion in (5.30) (and (5.31)) converges for $x = \pm\pi$ as well,

$$\hat{\Phi}(x) := \lim_{k\to+\infty} \hat{\Phi}_k(x) = \lim_{k\to+\infty} \mathcal{P}(\hat{\Phi}_k(x)), \qquad x \in [-\pi, \pi], \tag{5.32}$$

and thus, by (5.12), for $x \in \mathbb{R}$. To conclude the first part of the proof, we observe that the quantity in the curly brackets in (5.31) is positive for $n = \nu$ (i.e., the first term of the sum), vanishes fast for $k \to \infty$ (recall (2.4) and (2.13)), and we can see that (see Figure 5.1, right)

$$\frac{1}{s+1} \le \Phi_k(x) \le \Phi_1(x) \le 2, \qquad k \ge 1, \qquad -\pi \le x \le \pi.$$

Let us now check (5.28). We can expand $\cos(jx)$ in the expression (5.5) in Taylor series in a neighborhood of the origin, and, for $k < \infty$, we have

$$\hat{\Psi}_k(x) = \sum_{n=0}^{\infty} \left\{ (-1)^n \frac{x^{2n}}{(2n)!} \sum_{j=-\nu}^{k-\nu} j^{2n} \beta_{j+\nu} \left(1 + \frac{j}{s+1}\right) \right\}. \tag{5.33}$$

By considering the order conditions (2.14), recalling the power series expansion of $\sin(x)$ and of $\cos(x)$ in a neighborhood of the origin and arguments similar to those

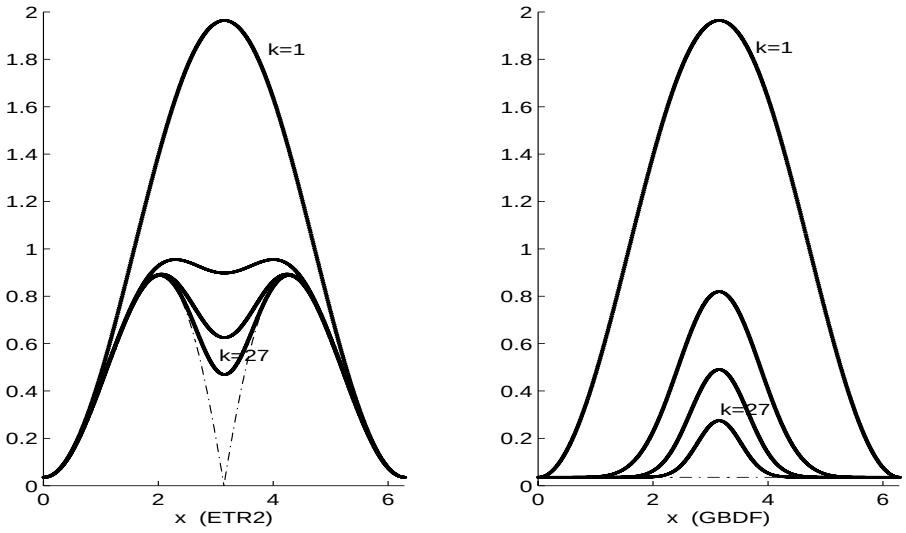

FIG. 5.1. $\hat{\Phi}_k(x)$, $k = 1, 7, 15, 27$, $s = 30$ *for formula* (2.11) *(left) and for formula* (2.9) *(right). The dashed curves give* $\hat{\Phi}(x)$.

used to prove (5.27), we have that, for $k \to \infty$ (i.e., $\nu \to \infty$ because $\nu = O(k)$),

$$\lim_{k\to\infty} \hat{\Psi}_k(x) = \hat{\Psi}(x) = \begin{cases} \dfrac{\sin(x)}{x} - \dfrac{1}{s+1}\left(\dfrac{\sin(x)}{x} - \dfrac{1}{2}\dfrac{\sin^2(x/2)}{(x/2)^2}\right), \\ \quad x \in (-\pi, 0) \cup (0, \pi), \\ \\ 1 - \dfrac{1}{2(s+1)}, \qquad x = 0. \end{cases}$$

Thus, by using similar arguments as before, the expressions (5.12), (5.13), and Abel's limit theorem, we see that the following inequalities hold true for (2.10):

$$\hat{\Psi}_k(x) \geq \hat{\Psi}(\pi) = \frac{2}{\pi^2(s+1)} > 0, \qquad x \in \mathbb{R},$$

$$\frac{1}{s+1} \leq \hat{\Phi}_k(x) \equiv \hat{\Phi}_1(x) \leq \frac{2s+1}{s+1} < 2, \qquad x \in \mathbb{R},\ k \geq 1.$$

The behavior of $\hat{\Psi}_k(x)$ for some values of k is displayed in Figure 5.2. □

We observe that the imaginary parts of the eigenvalues of the circulant approximations (4.1) and (4.3) for the matrices A and B in (2.6) for the formulas (2.9) and (2.10) are uniformly bounded by constants of the order of unity.

THEOREM 5.9. *If* ϕ_j, ψ_j, $j = 0, \ldots, s$, *are the eigenvalues of* $p(A_{s+1})$, $p(B_{s+1})$, *respectively, we have*

$$-\pi < \mathrm{Im}(\phi_j) < \pi, \qquad \mathrm{Im}(\psi_j) = 0 \qquad \textit{for } (2.9), \tag{5.34}$$

$$-\frac{s}{s+1} \leq \mathrm{Im}(\phi_j) < \frac{s}{s+1}, \qquad -c < \mathrm{Im}(\psi_j) < c \qquad \textit{for } (2.10),\ j = 0, \ldots, s, \tag{5.35}$$

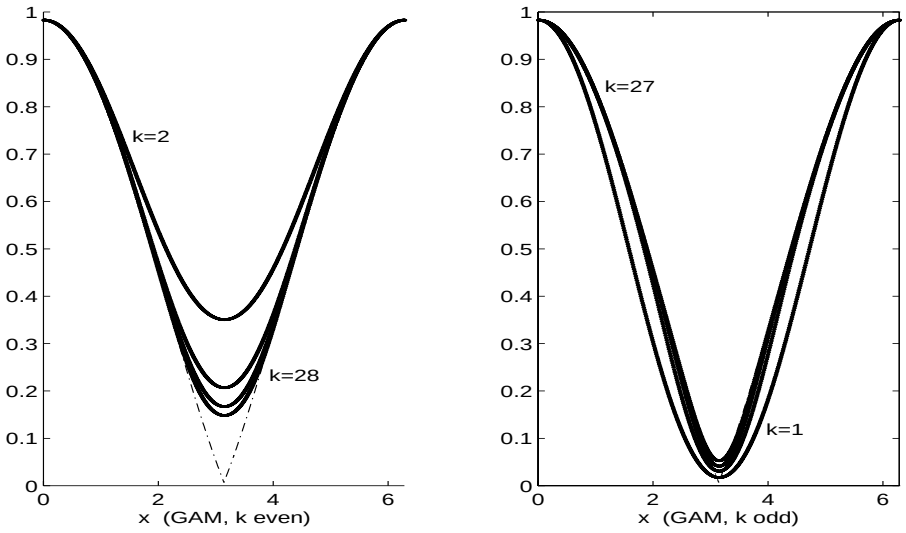

FIG. 5.2. *Left:* $\hat{\Psi}_k(x)$, $k = 2, 6, 14, 28$ *(k even); right:* $\hat{\Psi}_k(x)$, $k = 1, 7, 15, 27$ *(k odd) for formula* (2.10), $s = 28$. *The dashed curve gives* $\hat{\Psi}(x)$.

where

$$c = \max_{0<x<\pi} \left| \frac{\cos(x) - 1}{x} \right| \quad (\Rightarrow 0.7246 < c < 0.7247).$$

Proof. The proof uses arguments similar to those in the proof of Theorem 5.8. □

Again, as a corollary of Theorem 5.8, we have the following results.

THEOREM 5.10. *The preconditioners* $s(A_{s+1})$, $s(B_{s+1})$ *defined in* (4.1) *and related to the formulas* (2.9), (2.10) *are semipositive stable. If* γ_j, δ_j, $j = 0, \ldots, s$, *are the eigenvalues of* $s(A_{s+1})$, $s(B_{s+1})$, *respectively, we have*

$$0 \le \mathrm{Re}(\gamma_j) \le 2, \qquad \mathrm{Re}(\delta_j) = 1 \qquad \textit{for (2.9)}, \tag{5.36}$$

$$0 \le \mathrm{Re}(\gamma_j) \le 2, \qquad 0 \le \mathrm{Re}(\delta_j) \le 1 \qquad \textit{for (2.10)}, \ j = 0, \ldots, s. \tag{5.37}$$

THEOREM 5.11. *The* $\{\omega\}$*-circulant preconditioners* $\tilde{s}(A_{s+1})$, $\tilde{s}(B_{s+1})$ *for* $\omega = \exp(\mathbf{i}\theta)$, $0 < \theta \le \pi$, *and the MS-circulant preconditioners defined in section* 4, *related to the formulas* (2.9), (2.10), *are positive stable. If* $\tilde{\gamma}_j$, $\tilde{\delta}_j$, $j = 0, \ldots, s$, *are the eigenvalues of* $\tilde{s}(A_{s+1})$, $\tilde{s}(B_{s+1})$, *respectively, we have*

$$0 < \mathrm{Re}(\tilde{\gamma}_j) \le 2, \qquad \mathrm{Re}(\tilde{\delta}_j) = 1 \qquad \textit{for (2.9)}, \tag{5.38}$$

$$0 < \mathrm{Re}(\tilde{\gamma}_j) \le 2, \qquad 0 \le \mathrm{Re}(\tilde{\delta}_j) \le 1 \qquad \textit{for (2.10)}, \ j = 0, \ldots, s. \tag{5.39}$$

The bounds (5.38), (5.39) *hold true for the eigenvalues of the MS-circulant approximations as well.*

Similarly, it is straightforward to derive a result analogous to Theorem 5.9 for simple $\{\omega\}$-circulant and MS-circulant preconditioners by using the results in [7, 5].

It is worth noting that Theorems 5.8 and 5.10 can give results beyond linear algebra. The following corollary suggests a proof for the A-stability of formulas (2.9) using different tools, shorter than in [3, pp. 50–65].

COROLLARY 5.12. *The formulas* (2.9)*, used in boundary value form with* ν *initial and* $k-\nu$ *final conditions, are A-stable.*

Proof. As observed in [9], a linear multistep formula used in boundary value form is A-stable if its boundary locus is in the right half plane. In fact, the expression of the real part of the boundary locus of the formulas (2.9) is given by

$$\sum_{j=-\nu}^{k-\nu} \alpha_{j+\nu} \cos(j\,x), \qquad x \in \mathbb{R},\ k \geq 1;$$

see (5.6). Thus, by using the bound (5.36), we have that the boundary locus of formulas (2.9) is in the right half plane. ∎

Notice that the condition number of the underlying P-circulant approximations has a favorable behavior, e.g., for the methods based on formulas (2.9) and (2.10).

COROLLARY 5.13. *Consider the sequences* $\{K_2(p(A_{s+1}))\}$, $\{K_2(p(B_{s+1}))\}$. *We have that*

$$K_2(p(A_{s+1})) < (s+1)\sqrt{\pi^2+1}, \qquad K_2(p(B_{s+1})) = 1 \qquad \textit{for } (2.9),$$

and

$$K_2(p(A_{s+1})) < 2(s+1), \qquad K_2(p(B_{s+1})) < (s+1)\frac{\pi^2}{2} \qquad \textit{for } (2.10),$$

where $K_2(\cdot)$ *is the* 2*-norm condition number.*

Proof. The proof follows from Theorems 5.8 and 5.9 by considering that circulant matrices are normal (see [13]), and thus the singular values are given by the modulus of the eigenvalues. ∎

We observe that the bounds in the Corollary 5.13 could be not very tight for all values of k and s. However, for our purposes, it is enough to stress the linear dependence of the condition number from the size of the underlying matrices. Again, recall that $K_2(A_{s+1}) = O(s)$ and $K_2(B_{s+1}) = O(s)$ as well; see [6].

On the other hand, we cannot give an upper bound for $K_2(p(A_{s+1}))$ for the matrices related to the formulas in (2.11). Indeed, applying arguments similar to those used in the proofs of Theorem 5.8 and of Corollary 5.13, we would have $\hat{\Phi}(n\,\pi) = 0$, $n \neq 0$ integer (see Figure 5.1, left). Therefore, $K_2(p(A_{s+1}))$ cannot be bounded, and we have not considered in detail formulas (2.11). Moreover, we experienced that the methods based on formulas (2.9) and (2.10) can perform better than those based on (2.11) with the underlying preconditioners. For example, less preconditioned iterations are often required to solve the linear systems (2.6) for (2.9) and (2.10).

Notice that, for several families of non-Hermitian Toeplitz matrices, the real parts of the eigenvalues of their circulant approximations can be positive, negative, or zero even when the nonpreconditioned matrix is positive stable. For example, this is the case of backward differentiation formulas, Adams–Moulton methods, formulas in section 2.2 for choices of ν different from those suggested there. Moreover, for non-Hermitian matrices, the circulant approximation in (4.2) may give ill conditioned preconditioners as well. For example, the condition number of $c(A_{s+1})$ can grow fast with k, e.g., for the families of k-step formulas in section 2.2; see Figure 5.3. Moreover, the block preconditioners using the approximations (4.2) can be singular

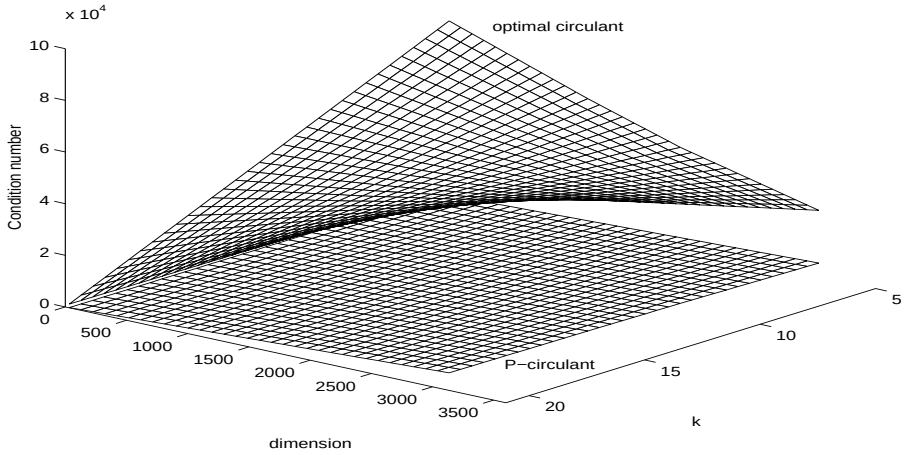

FIG. 5.3. *Condition number of the P-circulant and of the circulant approximation based on* (4.2) *for the matrices A as in* (2.7) *related to k-step formulas* (2.9).

for stable multistep formulas in boundary value form whose component matrices are nonsingular. This is the case of the midpoint method using with one initial and one final condition ($k = 2$, $\nu = 1$ in (2.3)) introduced in [2]. Indeed, by using (5.7), and by recalling that $\alpha_2 = 1 = -\alpha_0$ in (2.3), we have the expression of the eigenvalues of $c(A_{s+1})$ for the above-mentioned method:

$$\left(1 - \frac{1}{s+1}\right)(\epsilon^l - \epsilon^{-l}) = 2\mathbf{i}\left(1 - \frac{1}{s+1}\right)\sin\left(\frac{2\pi\mathbf{i}l}{s+1}\right), \qquad l = 0, \ldots, s,$$

which is zero for $l = 0$ for any $s \geq 2$ and, if s is odd, for $l = (s+1)/2$ as well. On the other hand, by (5.2), the eigenvalues of the corresponding P-circulant matrix $p(A_{s+1})$ are given by

$$\frac{1}{s+1}\cos\left(\frac{2\pi l}{s+1}\right) + \mathbf{i}\sin\left(\frac{2\pi l}{s+1}\right), \qquad l = 0, \ldots, s,$$

which cannot be zero. However, we have experienced that, for low order formulas in section 2.2, both the preconditioners based on P-circulants and on T. Chan's circulants (4.2) can be effective to solve (2.6) with Krylov subspace accelerators; see [4, 5].

5.3. How to choose the approximations and convergence of preconditioned iterations. In the previous sections, we have considered the spectrum of the component matrices of the block preconditioners in (1.2). Further information on the spectrum of the matrix M in (2.6) and its component matrices can be found in [2, 6, 9]. On the other hand, the convergence of preconditioned iterations using, e.g., GMRES, BiCGstab, and some other BiCG-like methods, is essentially decided by the distribution of the spectrum of the eigenvalues and by the eigenvectors of the preconditioned matrix; see, e.g., [18]. Notice that the analysis of the preconditioned linear system, in the nonsymmetric case, cannot be performed by using the arguments in the previous sections. In fact, one should explicitly manipulate the related characteristic polynomial. For example, if we consider the preconditioner (1.2) and the linear

systems (2.6), we need to derive an analytic expression for λ from

$$\det((1-\lambda)I_{m(s+1)} + P^{-1}E) = 0, \qquad E = (A - \breve{A}) \otimes I_m - h(B - \breve{B}) \otimes J, \tag{5.40}$$

where we recall that $I_{m(s+1)} + P^{-1}E = P^{-1}M$; see [4, Theorem 4.1] for details. Unfortunately, the above approach can fail to give complete and useful information on the convergence process. Indeed, the above analysis must consider a specific Jacobian matrix J and a formula (2.3) with k fixed. Moreover, the derivation of λ from (5.40) is usually rather lengthy even for low order schemes and sometimes it is difficult to handle in view of the behavior of the eigenvalues.

Therefore, in what follows, we will give some general suggestions in order to decide whether approximation could be more suitable to precondition the underlying linear system. These hints could be adapted for the solution of other problems based on nonsymmetric (block-)Toeplitz-like matrices.

Recall that, for Krylov subspace methods, we expect fast convergence of preconditioned iterations if the spectrum of the eigenvalues of the block preconditioned matrix is clustered around $(1, 0) \in \mathbb{C}$. Let T_n be a nonsymmetric band Toeplitz matrix, $p(T_n)$ the P-circulant approximation for T_n, and $l(T_n)$ a trigonometric approximation, e.g., one of those described in section 4. Defining $E_p = T_n - p(T_n)$, $E_l = T_n - l(T_n)$, and using similar arguments as in [4], we can write

$$p(T_n)^{-1}T_n = I + p(T_n)^{-1}E_p = I + p(T_n)^{-1}(E_p^{(1)} + E_p^{(2)}), \tag{5.41}$$

$$l(T_n)^{-1}T_n = I + l(T_n)^{-1}E_l = I + l(T_n)^{-1}(E_l^{(1)} + E_l^{(2)}), \tag{5.42}$$

where $E_p^{(2)}$, $E_l^{(2)}$ have small rank with respect to n and $E_p^{(1)}$, $E_l^{(1)}$ have small norm (with respect to T_n, say). From (5.41), (5.42), we expect that the P-circulant-based approximation will perform better than the other if, e.g.,

(C1) $||p(T_n)^{-1}||_2 < ||l(T_n)^{-1}||_2$;

(C2) $||p(T_n)^{-1}E_p^{(1)}||_2 < ||l(T_n)^{-1}E_l^{(1)}||_2$ (if the underlying approximation $l(T_n)$ is such that $||E_l^{(1)}|| \neq 0$; otherwise we require that $||p(T_n)^{-1}E_p^{(1)}||_2$ is moderate);

(C3) the outlying eigenvalues of $p(T_n)^{-1}T_n$ (i.e., the eigenvalues outside the cluster in $(1, 0) \in \mathbb{C}$) have positive real part whereas some of $l(T_n)^{-1}T_n$ have negative real part.

Notice that condition (C1) is equivalent to, say, that of $K_2(p(T_n)) < K_2(l(T_n))$ because $||p(T_n)||_2$, $||l(T_n)||_2$ are uniformly bounded with n. (We assume, as is customary, that the entries of T_n are uniformly bounded with respect to n.) By condition (C2) alone and (5.41), (5.42), it would appear that preconditioners based on simple circulant-like approximations such as Strang's, MS-circulant, and $\{\omega\}$-circulant will perform definitively better than a P-circulant based one (or, e.g., better than (4.2)) because they have $E_l^{(1)} = 0$ in (5.42), i.e., no small norm perturbation. Unfortunately, this is false in general. Finally, the third condition (C3) can be very important for the convergence of GMRES and BiCG-like Krylov methods. Indeed, as observed in [18], if the convex hull of the eigenvalues includes the origin of the complex plane, then the convergence can be slow.

Let us consider some examples in which P-circulant-like block preconditioners in (1.2) can outperform preconditioners based on other approximations for the linear systems (2.6). For simplicity, we assume $J = VDV^{-1}$ diagonalizable, $D =$

$diag(\mu_1, \dots, \mu_m)$, and $\mathrm{Re}(\mu_r) \leq 0$. By using the notation of the previous sections, we have the following decomposition for P as in (1.2):

$$P = (F^* \otimes V)\, \mathrm{diag}\,(\phi_0 - h\psi_0\mu_1, \dots, \phi_0 - h\psi_0\mu_m, \dots \\ \dots, \phi_s - h\psi_s\mu_1, \dots, \phi_s - h\psi_s\mu_m)\,(F \otimes V^{-1}). \tag{5.43}$$

Then, the eigenvalues of the block preconditioner are given by $\phi_j - h\psi_j\mu_r$, $j = 0, \dots, s$, $r = 1, \dots, m$, and

$$||P^{-1}||_2 \leq K_2(V) \min_{j,r}\{|\phi_j - h\psi_j\mu_r|\}^{-1},$$

where $K_2(V)$ does not depend on s. If we consider the matrices related to the schemes (2.9), we have $\psi_j \equiv 1$, $j = 0, \dots, s$, and using P-circulant approximations for $\breve{A}$, $\breve{B}$ in (1.2) gives

$$||P^{-1}||_2 \leq K_2(V) \frac{s+1}{1 + (T - t_0)\tilde{\mu}} = O(s), \qquad \tilde{\mu} = \min_r\{|\mu_r|\}.$$

On the other hand, similar bounds cannot be stated for non-P-circulant-like approximations because, in general, we have

$$||P^{-1}||_2 \leq K_2(V) \frac{s+1}{(T - t_0)\tilde{\mu}}, \qquad \tilde{\mu} = \min_r\{|\mu_r|\},$$

which can be unbounded if some eigenvalues of J are very small or zero in modulus. A similar effect can be observed for some classes of matrices J with purely imaginary eigenvalues and other matrices A, B in (2.6), T_n in (5.41), (5.42) as well.

Notice that, by using similar arguments as before, we can write $P^{-1}M = I + P^{-1}(E^{(1)} + E^{(2)})$; see, [4, Theorem 4.1]. Therefore, if we take the 2-norm of the perturbation of the identity in the right-hand side above, we get

$$||P^{-1}(E^{(1)} + E^{(2)})|| \leq ||P^{-1}|| \cdot (||E^{(1)}|| + ||E^{(2)}||).$$

By the above arguments, $||P^{-1}||$ can be larger for the preconditioner not based on P-circulant matrices. As a result, the amplification of the perturbations $E^{(1)} + E^{(2)}$ given by the multiplication by P^{-1} can give (C3); see (5.41), (5.42). Moreover, recall that the spectrum of the eigenvalues can be much more sensitive to perturbations with respect to the Hermitian case; see, e.g., [22].

On the other hand, if the eigenvalues μ_r, $r = 1, \dots, m$, are, e.g., negative and bounded from below by a constant $c < 0$, then preconditioners based on simple circulant-like approximations (i.e., based on Strang's, $\{\omega\}$-circulant, and MS-circulant matrices) may give better performances for large s as well. For numerical examples, see [4, 5, 7].

Acknowledgments. The author would like to thank three anonymous referees, Lionello Pasquini, and the editor for helpful comments and useful suggestions which have improved this presentation. This work is dedicated to my wife Vittoria.

A FINITE ELEMENT METHOD WITH LAGRANGE MULTIPLIERS FOR LOW-FREQUENCY HARMONIC MAXWELL EQUATIONS*

ALFREDO BERMÚDEZ†, RODOLFO RODRÍGUEZ‡, AND PILAR SALGADO†

Abstract. The aim of this paper is to analyze a finite element method to solve the low-frequency harmonic Maxwell equations in a bounded domain containing conductors and dielectrics. This system of partial differential equations is a model for the so-called eddy currents problem. After writing this problem in terms of the magnetic field, it is discretized by Nédélec edge finite elements on a tetrahedral mesh. Error estimates are easily obtained if the curl-free condition is imposed on the elements in the dielectric domain.

Then, the curl-free condition is imposed, at a discrete level, by introducing a piecewise linear multivalued potential. The resulting problem is shown to be a discrete version of other continuous formulation in which the magnetic field in the dielectric part of the domain has been replaced by a magnetic potential. Moreover, this approach leads to an important saving in computational effort. Problems related to the topology are also considered in that the possibility of having a nonsimply connected dielectric domain is taken into account.

Implementation issues are discussed, including an amenable procedure to impose the boundary conditions by means of a Lagrange multiplier. Finally, the method is applied to solve a three-dimensional model problem: a cylindrical electrode surrounded by dielectric.

Key words. low-frequency harmonic Maxwell equations, eddy currents problems, finite element computational electromagnetism

1. Introduction.

In this paper we analyze a finite element method with Lagrange multipliers to solve the eddy currents model in a bounded domain including conductors and dielectrics. This model can be obtained from Maxwell equations by assuming that all fields are harmonic and that the current frequency is low enough so that the term involving the displacement current in Ampère's law can be neglected. Such a situation happens, for instance, in problems related to machines working at power frequencies. In particular, this paper is motivated by the need for a three-dimensional numerical simulation of a metallurgical furnace. (See [6, 7] for related works concerning axisymmetric models.)

Because of many interesting applications in electrical engineering, numerical solution of eddy currents problems became an important research area, leading to a great number of publications in recent years. (See, for instance, [2, 3, 8, 9, 10, 12, 13, 16, 20, 29].) The books by Bossavit [11] and Silvester and Ferrari [28] also contain valuable material on this subject and include large reference lists.

While several papers deal with the mathematical and numerical analysis of the full harmonic Maxwell equations (see, for instance, the papers by Monk [23, 24, 25]

and Fernandes and Gilardi [17]), the number of papers concerning analysis of the eddy currents model is much smaller. Significant mathematical and numerical results have been obtained by MacCamy and coauthors [18, 21, 22] for a two-dimensional eddy currents problem. In the three-dimensional case, let us mention the article by Ammari, Buffa, and Nédélec [4], where a thorough justification of the eddy current model is given.

The above mentioned papers deal with the eddy currents problem in the whole space, the infinity being usually taken into account by means of integral equations. A useful alternative approach is considered by Alonso and Valli [2, 3], where the problem in a bounded domain is considered, including appropriate boundary conditions. In these papers, a formulation involving only the electric field is given and then numerically solved by using a domain decomposition technique and Nédélec edge finite elements.

In the present paper we also consider the eddy currents problem in a bounded domain which includes conductors and dielectrics. The conductors are not assumed to be totally included in the problem domain. We consider a formulation in terms of magnetic field with mixed Neumann and Dirichlet boundary conditions. The former are the natural conditions for the conducting part of the boundary. The latter are imposed on the dielectric part and allow taking into account all the electromagnetics effects outside the domain.

Then, following Bossavit and Vérité [13], we introduce a scalar magnetic potential in the domain occupied by the dielectric. This hybrid formulation is discretized by using Nédélec edge elements for the magnetic field and standard piecewise linear continuous elements for the magnetic potential.

The outline of the paper is as follows: In section 2, we recall the eddy currents model and obtain a weak formulation involving the magnetic field only. Section 3 concerns existence and uniqueness of a solution which are proved by using classical tools. Then, in section 4, we introduce a scalar magnetic potential in the dielectric domain and show that the resulting problem is completely equivalent to the previous one. The numerical discretization is introduced in section 5, where error estimates are obtained under mild regularity assumption on the solution.

In order to solve the discretized problem, a Lagrange multiplier is proposed in section 6 to impose the Dirichlet boundary conditions. The resulting mixed problem is shown to attain a unique solution and to be equivalent to the original discrete one. Finally, in section 7, we report numerical results for a test with known analytical solution; these results confirm the predicted order of convergence of the method.

2. The eddy currents problem. Eddy currents are usually modeled by the low-frequency harmonic Maxwell equations. First let us recall the governing equations of electromagnetism: Maxwell equations,

$$\frac{\partial \boldsymbol{\mathcal{D}}}{\partial t} - \mathbf{curl}\, \boldsymbol{\mathcal{H}} = -\boldsymbol{\mathcal{J}}, \tag{2.1}$$

$$\frac{\partial \boldsymbol{\mathcal{B}}}{\partial t} + \mathbf{curl}\, \boldsymbol{\mathcal{E}} = \mathbf{0}, \tag{2.2}$$

$$\operatorname{div} \boldsymbol{\mathcal{B}} = 0, \tag{2.3}$$

$$\operatorname{div} \boldsymbol{\mathcal{D}} = \rho; \tag{2.4}$$

constitutive laws,

$$\boldsymbol{\mathcal{B}} = \mu \boldsymbol{\mathcal{H}}, \tag{2.5}$$

$$\boldsymbol{\mathcal{D}} = \epsilon \boldsymbol{\mathcal{E}}; \tag{2.6}$$

and Ohm's law in conductors,

$$\boldsymbol{\mathcal{J}} = \sigma \boldsymbol{\mathcal{E}}. \tag{2.7}$$

We have used notations which are standard in electromagnetism:

- $\boldsymbol{\mathcal{D}}$ is the electric displacement,
- $\boldsymbol{\mathcal{E}}$ is the electric field,
- $\boldsymbol{\mathcal{B}}$ is the magnetic induction,
- $\boldsymbol{\mathcal{H}}$ is the magnetic field,
- $\boldsymbol{\mathcal{J}}$ is the current density,
- ρ is the electric charge density,
- μ is the magnetic permeability,
- ϵ is the electric permittivity,
- σ is the electric conductivity.

We use boldface letters to denote vector fields and variables, as well as vector-valued operators, throughout the paper.

When alternating currents are considered, all the fields have the following steady-state form:

$$\boldsymbol{\mathcal{F}}(\mathbf{x}, t) = \mathrm{Re}\left[\mathrm{e}^{\mathrm{i}\omega t}\mathbf{F}(\mathbf{x})\right],$$

where ω is the angular frequency. Moreover, in the low-frequency harmonic regime, the term in (2.1) including the electric displacement can be neglected. Under these assumptions, (2.1)–(2.7) reduce to the so-called eddy currents model:

$$\mathbf{curl}\,\mathbf{H} = \mathbf{J}, \tag{2.8}$$

$$\mathrm{i}\omega\mu\mathbf{H} + \mathbf{curl}\,\mathbf{E} = \mathbf{0}, \tag{2.9}$$

$$\mathrm{div}\,\mathbf{B} = 0, \tag{2.10}$$

$$\mathrm{div}\,\mathbf{D} = \rho, \tag{2.11}$$

with

$$\mathbf{B} = \mu\mathbf{H}, \tag{2.12}$$

$$\mathbf{D} = \epsilon\mathbf{E}, \tag{2.13}$$

$$\mathbf{J} = \sigma\mathbf{E}. \tag{2.14}$$

We are interested in solving these equations in a bounded domain Ω, which consists of two parts, Ω_{C} and Ω_{D}, occupied by conductors and dielectrics, respectively. The electric conductivity σ vanishes in the dielectric domain. The boundary of the domain Ω also splits into two parts: $\Gamma_{\mathrm{C}} := \partial\Omega_{\mathrm{C}} \cap \partial\Omega$ and $\Gamma_{\mathrm{D}} := \partial\Omega_{\mathrm{D}} \cap \partial\Omega$. Finally, we denote $\Gamma_{\mathrm{I}} := \partial\Omega_{\mathrm{C}} \cap \partial\Omega_{\mathrm{D}}$, the interface between dielectric and conductors.

Boundary conditions must be added to solve the eddy currents model in the bounded domain Ω. We consider

$$\mathbf{E} \times \mathbf{n} = \mathbf{0} \quad \text{on } \Gamma_{\mathrm{C}}, \tag{2.15}$$

$$\mathbf{H} \times \mathbf{n} = \mathbf{f} \quad \text{on } \Gamma_{\mathrm{D}}, \tag{2.16}$$

with $\mathbf{f}$ being a given tangential vector field (i.e., satisfying $\mathbf{f} \cdot \mathbf{n} = 0$ on Γ_{D}).

In the equations above, $\mathbf{n}$ denotes the outer unit normal vector to $\partial\Omega$. Throughout the paper, $\mathbf{n}$ will denote a unit vector normal to a given surface, not necessarily the same at each occurrence. In general, it will not be explicitly mentioned which surface this is, provided this is sufficiently clear from the context.

To obtain a weak formulation of the boundary value problem (2.8)–(2.16), consider a test function $\mathbf{G}$ such that $\mathbf{G} \times \mathbf{n} = \mathbf{0}$ on Γ_{D}. From (2.9) we have

$$\mathrm{i}\omega \int_\Omega \mu \mathbf{H} \cdot \bar{\mathbf{G}} + \int_\Omega \mathbf{curl}\, \mathbf{E} \cdot \bar{\mathbf{G}} = 0. \tag{2.17}$$

Now, we can transform the second term above by using Green's formula:

$$\begin{aligned} \int_\Omega \mathbf{curl}\, \mathbf{E} \cdot \bar{\mathbf{G}} &= \int_\Omega \mathbf{E} \cdot\, \mathbf{curl}\, \bar{\mathbf{G}} - \int_{\Gamma_{\mathrm{C}}} \mathbf{E} \cdot \mathbf{n} \times \bar{\mathbf{G}}\, d\Gamma \\ &= \int_\Omega \mathbf{E} \cdot\, \mathbf{curl}\, \bar{\mathbf{G}} - \int_{\Gamma_{\mathrm{C}}} \mathbf{E} \times \mathbf{n} \cdot \bar{\mathbf{G}}\, d\Gamma \;=\; \int_\Omega \mathbf{E} \cdot\, \mathbf{curl}\, \bar{\mathbf{G}}, \end{aligned} \tag{2.18}$$

where we have used the boundary condition (2.15) to obtain the last equality. We observe that (2.8) and (2.14), and the fact that σ is null in the dielectric domain, lead to

$$\mathbf{curl}\, \mathbf{H} = \mathbf{0} \quad \text{in } \Omega_{\mathrm{D}}.$$

Because of this, we need only to take test functions $\mathbf{G}$ satisfying $\mathbf{curl}\, \mathbf{G} = \mathbf{0}$ in Ω_{D}. By doing so, (2.17) and (2.18) yield

$$\mathrm{i}\omega \int_\Omega \mu \mathbf{H} \cdot \bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \mathbf{E} \cdot\, \mathbf{curl}\, \bar{\mathbf{G}} = 0.$$

Instead, in the conductors, (2.8) and (2.14) lead to $\mathbf{E} = \frac{1}{\sigma}\, \mathbf{curl}\, \mathbf{H}$, which allows us to eliminate $\mathbf{E}$ in the equation above. Thus, finally we obtain

$$\mathrm{i}\omega \int_\Omega \mu \mathbf{H} \cdot \bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma}\, \mathbf{curl}\, \mathbf{H} \cdot\, \mathbf{curl}\, \bar{\mathbf{G}} = 0.$$

3. Analysis of the magnetic field formulation of the eddy currents problem. Let us assume that Ω is simply connected, with a Lipschitz-continuous connected boundary. The subdomains Ω_{C} and Ω_{D} are also assumed to have Lipschitz-continuous boundaries, although not necessarily connected. Finally, the boundaries of Γ_{C}, Γ_{D}, and Γ_{I} are assumed to be Lipschitz-continuous, too.

We use standard notation for Sobolev spaces and norms. Moreover, we recall the definition of some functional spaces. Let

$$\mathrm{H}(\mathbf{curl}, \Omega) := \left\{ \mathbf{G} \in \mathrm{L}^2(\Omega)^3 : \;\; \mathbf{curl}\, \mathbf{G} \in \mathrm{L}^2(\Omega)^3 \right\}$$

endowed with the norm

$$\|\mathbf{G}\|_{\mathrm{H}(\mathbf{curl},\Omega)} := \left[\|\mathbf{G}\|^2_{\mathrm{L}^2(\Omega)^3} + \|\, \mathbf{curl}\, \mathbf{G}\|^2_{\mathrm{L}^2(\Omega)^3} \right]^{1/2},$$

and, for each positive real number r, let

$$\mathrm{H}^r(\mathbf{curl}, \Omega) := \left\{ \mathbf{G} \in \mathrm{H}^r(\Omega)^3 : \;\; \mathbf{curl}\, \mathbf{G} \in \mathrm{H}^r(\Omega)^3 \right\}$$

endowed with the norm

$$\|\mathbf{G}\|_{\mathrm{H}^r(\mathbf{curl},\Omega)} := \left[\|\mathbf{G}\|^2_{\mathrm{H}^r(\Omega)^3} + \|\,\mathbf{curl}\,\mathbf{G}\|^2_{\mathrm{H}^r(\Omega)^3}\right]^{1/2}.$$

Consider the following closed subspaces of $\mathrm{H}(\mathbf{curl},\Omega)$:

$$\boldsymbol{\mathcal{V}} = \{\mathbf{G} \in \mathrm{H}(\mathbf{curl},\Omega) :\ \ \mathbf{curl}\,\mathbf{G} = \mathbf{0} \text{ in } \Omega_{\mathrm{D}}\},$$
$$\boldsymbol{\mathcal{V}}^0 = \left\{\mathbf{G} \in \boldsymbol{\mathcal{V}} :\ \mathbf{G}\times\mathbf{n} = \mathbf{0} \text{ in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3\right\},$$

where $\mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3$ denotes the dual space of $\mathrm{H}_{00}^{1/2}(\Gamma_{\mathrm{D}})^3$, which, in its turn, is the space of functions defined on Γ_{D} that, extended by $\mathbf{0}$ on $\partial\Omega\setminus\Gamma_{\mathrm{D}}$, belong to $\mathrm{H}^{1/2}(\partial\Omega)^3$.

We assume that $\mu,\epsilon,\sigma \in \mathrm{L}^\infty(\Omega)$ and that there exist constants $\underline{\mu}$, $\underline{\epsilon}$, and $\underline{\sigma}$ such that

$$\begin{aligned}
&\mu(\mathbf{x}) \geq \underline{\mu} > 0, \quad \text{a.e. in } \Omega,\\
&\epsilon(\mathbf{x}) \geq \underline{\epsilon} > 0, \quad \text{a.e. in } \Omega,\\
&\sigma(\mathbf{x}) \geq \underline{\sigma} > 0, \quad \text{a.e. in } \Omega_{\mathrm{C}}, \qquad \sigma(\mathbf{x}) = 0 \quad \text{in } \Omega_{\mathrm{D}}.
\end{aligned}$$

Concerning the boundary data $\mathbf{f}$, we suppose there exists a field $\mathbf{H_f} \in \boldsymbol{\mathcal{V}}$ such that

$$\mathbf{H_f}\times\mathbf{n} = \mathbf{f} \text{ in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3. \tag{3.1}$$

Remark 3.1. We refer to [1] for necessary and sufficient conditions on $\mathbf{f}$ to ensure that there exists $\mathbf{H_f} \in \mathrm{H}(\mathbf{curl},\Omega)$ such that $\mathbf{H_f}\times\mathbf{n} = \mathbf{f}$ on Γ_{D} in a weak sense, in the case $\Gamma_{\mathrm{C}} = \emptyset$, $\Gamma_{\mathrm{D}} = \partial\Omega$ (i.e., when the conductors $\overline{\Omega}_{\mathrm{C}}$ are fully contained in Ω). We also refer to [14, 15] for similar conditions in the case that Ω is a Lipschitz polyhedron, and Γ_{C} and Γ_{D} are polyhedral surfaces with piecewise smooth boundaries.

Equation (3.1) implies an additional constraint on the data $\mathbf{f}$, since $\mathbf{H_f}$ has to be curl-free in Ω_{D}. A necessary condition for the existence of such $\mathbf{H_f}$ is that $\mathrm{div}_\Gamma\,\mathbf{f} = 0$ on Γ_{D}, where div_Γ stands for the tangential divergence operator. (See [1] for the result and a precise definition of div_Γ.) In the case $\Gamma_{\mathrm{C}} = \emptyset$, $\Gamma_{\mathrm{D}} = \partial\Omega$; then $\mathrm{div}_\Gamma\,\mathbf{f} = 0$ on Γ_{D} is also a sufficient condition, when Ω has a smooth boundary (see Theorem 4.1 of [1]).

Now, we can state a variational formulation of our problem in terms of the magnetic field $\mathbf{H}$.

Problem **MP**. *Find* $\mathbf{H} \in \boldsymbol{\mathcal{V}}$ *such that*

$$\mathbf{H}\times\mathbf{n} = \mathbf{f} \text{ in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3, \tag{3.2}$$

$$\mathrm{i}\omega\int_\Omega \mu\mathbf{H}\cdot\bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma}\,\mathbf{curl}\,\mathbf{H}\cdot\,\mathbf{curl}\,\bar{\mathbf{G}} = 0 \quad \forall\mathbf{G} \in \boldsymbol{\mathcal{V}}^0. \tag{3.3}$$

Let $a\colon \mathrm{H}(\mathbf{curl},\Omega)\times\mathrm{H}(\mathbf{curl},\Omega) \longrightarrow \mathbb{C}$ be the sesquilinear continuous form defined by

$$a(\mathbf{H},\mathbf{G}) := \mathrm{i}\omega\int_\Omega \mu\mathbf{H}\cdot\bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma}\,\mathbf{curl}\,\mathbf{H}\cdot\,\mathbf{curl}\,\bar{\mathbf{G}}.$$

This form clearly satisfies

$$|a\,(\mathbf{G},\mathbf{G})| \geq \alpha\|\mathbf{G}\|^2_{\mathrm{H}(\mathbf{curl},\Omega)} \quad \forall\mathbf{G} \in \boldsymbol{\mathcal{V}}. \tag{3.4}$$

Hence, the following existence result is immediately derived.

THEOREM 3.1. *If there exists* $\mathbf{H_f} \in \boldsymbol{\mathcal{V}}$ *such that* $\mathbf{H_f} \times \mathbf{n} = \mathbf{f}$ *in* $\mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3$*, then Problem* **MP** *attains a unique solution.*

Proof. Consider the translation $\hat{\mathbf{H}} = \mathbf{H} - \mathbf{H_f}$. Then Problem **MP** is equivalent to finding $\hat{\mathbf{H}} \in \boldsymbol{\mathcal{V}}^0$ such that

$$a(\hat{\mathbf{H}}, \mathbf{G}) = -a(\mathbf{H_f}, \mathbf{G}) \quad \forall \mathbf{G} \in \boldsymbol{\mathcal{V}}^0,$$

and this problem has a unique solution because of inequality (3.4) and the Lax–Milgram lemma. ∎

Once the magnetic field $\mathbf{H}$ is known, the current density $\mathbf{J}$ and the electric field $\mathbf{E}$ can be readily computed in the conductors by means of (2.8) and (2.14), respectively. These are the magnitudes actually needed in most applications.

In the following theorem we show that the solution of Problem **MP** satisfies some of the Maxwell equations (2.8)–(2.11) and the boundary conditions (2.15)–(2.16) in a weak sense.

THEOREM 3.2. *Let* $\mathbf{H} \in \boldsymbol{\mathcal{V}}$ *be the solution of Problem* **MP**. *Let* $\mathbf{B} = \mu\mathbf{H} \in \mathrm{L}^2(\Omega)$, $\mathbf{J} = \mathbf{curl}\,\mathbf{H} \in \mathrm{L}^2(\Omega)$, *and* $\mathbf{E} = (\frac{1}{\sigma}\mathbf{J})|_{\Omega_{\mathrm{C}}} \in \mathrm{L}^2(\Omega_{\mathrm{C}})$. *Then the following properties hold true:*

$$\operatorname{div}\mathbf{B} = 0 \quad \text{in } \Omega, \tag{3.5}$$

$$\mathrm{i}\omega\mu\mathbf{H} + \mathbf{curl}\,\mathbf{E} = \mathbf{0} \quad \text{in } \Omega_{\mathrm{C}}, \tag{3.6}$$

$$\mathbf{E} \times \mathbf{n} = \mathbf{0} \quad \text{in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{C}})^3, \tag{3.7}$$

$$\mathbf{H} \times \mathbf{n} = \mathbf{f} \quad \text{in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3, \tag{3.8}$$

$$\mathbf{J} = \mathbf{0} \quad \text{in } \Omega_{\mathrm{D}}. \tag{3.9}$$

Proof. Given $\Psi \in \mathcal{D}(\Omega) := \{\Psi \in \mathcal{C}^\infty(\Omega) : \operatorname{supp}\Psi \subset \Omega\}$, let $\mathbf{G} = \mathbf{grad}\,\Psi \in \boldsymbol{\mathcal{V}}^0$. Then, (3.3) yields

$$\int_\Omega \mu\mathbf{H} \cdot \mathbf{grad}\,\bar{\Psi} = 0.$$

Consequently, $\mathbf{B} = \mu\mathbf{H} \in \mathrm{H}(\mathrm{div}, \Omega)$, and (3.5) holds true.

Now, let $\mathbf{G} \in \mathcal{D}(\Omega)^3$ be such that $\operatorname{supp}\mathbf{G} \subset \Omega_{\mathrm{C}}$. Then $\mathbf{G} \in \boldsymbol{\mathcal{V}}^0$, and (3.3) yields

$$\mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu\mathbf{H} \cdot \bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma}\,\mathbf{curl}\,\mathbf{H} \cdot \mathbf{curl}\,\bar{\mathbf{G}} = 0.$$

Hence $\mathbf{E} = \frac{1}{\sigma}\mathbf{J} = \frac{1}{\sigma}\,\mathbf{curl}\,\mathbf{H} \in \mathrm{H}(\mathbf{curl}, \Omega_{\mathrm{C}})$, and (3.6) holds true.

To prove (3.7), given $\boldsymbol{\varphi} \in \mathrm{H}_{00}^{1/2}(\Gamma_{\mathrm{C}})^3$, we will show that $\langle \mathbf{E} \times \mathbf{n}, \widetilde{\boldsymbol{\varphi}} \rangle_{\partial\Omega_{\mathrm{C}}} = 0$, where $\langle \cdot, \cdot \rangle_{\partial\Omega_{\mathrm{C}}}$ denotes the duality pairing in $\mathrm{H}^{-1/2}(\partial\Omega_{\mathrm{C}})^3 \times \mathrm{H}^{1/2}(\partial\Omega_{\mathrm{C}})^3$, and $\widetilde{\boldsymbol{\varphi}} \in \mathrm{H}^{1/2}(\partial\Omega_{\mathrm{C}})^3$ is the natural extension of $\boldsymbol{\varphi}$ by $\mathbf{0}$ on $\partial\Omega_{\mathrm{C}} \setminus \Gamma_{\mathrm{C}}$. To this aim, let $\mathbf{G} \in \mathrm{H}^1(\Omega_{\mathrm{C}})^3$ be such that $\mathbf{G}|_{\partial\Omega_{\mathrm{C}}} = \widetilde{\boldsymbol{\varphi}}$, and $\widetilde{\mathbf{G}}$ is the extension by $\mathbf{0}$ of $\mathbf{G}$ to $\Omega \setminus \Omega_{\mathrm{C}}$. Then $\widetilde{\mathbf{G}} \in \boldsymbol{\mathcal{V}}^0$, and (3.3) yields

$$\begin{aligned} 0 &= \mathrm{i}\omega \int_\Omega \mu\mathbf{H} \cdot \bar{\widetilde{\mathbf{G}}} + \int_{\Omega_{\mathrm{C}}} \mathbf{E} \cdot \mathbf{curl}\,\bar{\widetilde{\mathbf{G}}} \\ &= \mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu\mathbf{H} \cdot \bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \mathbf{curl}\,\mathbf{E} \cdot \bar{\mathbf{G}} + \left\langle \mathbf{E} \times \mathbf{n}, \mathbf{G}|_{\partial\Omega_{\mathrm{C}}} \right\rangle_{\partial\Omega_{\mathrm{C}}} = \langle \mathbf{E} \times \mathbf{n}, \widetilde{\boldsymbol{\varphi}} \rangle_{\partial\Omega_{\mathrm{C}}}, \end{aligned}$$

where we have used that $\mathbf{E} = \frac{1}{\sigma}\,\mathbf{curl}\,\mathbf{H}$ in Ω_{C} and (3.6).

Finally, (3.8) and (3.9) arise explicitly in Problem **MP**. ∎

Remark 3.2. The theorem above shows that Problem **MP** allows us to determine uniquely the electric field $\mathbf{E}$ in the conductors. In its turn, $\mathbf{E}$ and Maxwell equation (2.11) determine the charge density ρ in Ω_{C}. In particular, in the interior of any homogeneous subdomain Ω' of Ω_{C} (i.e., $\Omega' \subset \Omega_{\mathrm{C}}$ such that $\epsilon|_{\Omega'}$ and $\sigma|_{\Omega'}$ are constant), $\rho|_{\Omega'} = \operatorname{div}\left(\frac{\epsilon}{\sigma}\,\mathbf{curl}\,\mathbf{H}\right)\big|_{\Omega'} = 0$.

Instead, the electric field $\mathbf{E}$ is not uniquely determined in the dielectric. Indeed, from the eddy currents model (2.8)–(2.14) we obtain the following equations for $\mathbf{E}|_{\Omega_{\mathrm{D}}}$:

$$\mathbf{curl}\,\mathbf{E} = -\mathrm{i}\omega\mu\mathbf{H} \quad \text{in } \Omega_{\mathrm{D}}, \tag{3.10}$$

$$\operatorname{div}(\epsilon\mathbf{E}) = \rho \quad \text{in } \Omega_{\mathrm{D}}, \tag{3.11}$$

$$\mathbf{E}\times\mathbf{n} = \mathbf{E}|_{\Omega_{\mathrm{C}}}\times\mathbf{n} \quad \text{on } \Gamma_{\mathrm{I}}. \tag{3.12}$$

The latter arises from the facts that $\mathbf{E}|_{\Omega_{\mathrm{C}}}$ is already known and that $\mathbf{E}$ is globally in $\mathrm{H}(\mathbf{curl},\Omega)$.

A boundary condition on Γ_{D} is needed to determine a unique solution, even in the simplest case of a topologically trivial Ω_{D} (i.e., when Ω_{D} is simply connected with a connected boundary). A natural condition would be to impose the normal component of the electric displacement $\mathbf{D}$ on Γ_{D}; namely,

$$\epsilon\mathbf{E}\cdot\mathbf{n} = \psi \quad \text{on } \Gamma_{\mathrm{D}}. \tag{3.13}$$

The data ψ amounts to eventual surface charges on the outer boundary of the dielectric domain.

Existence of the solution to (3.10)–(3.13) has been proved in Theorem 4.2 of [1] in the case that $\partial\Omega_{\mathrm{D}}$ is smooth and that $\Gamma_{\mathrm{I}}\cap\Gamma_{\mathrm{D}} = \emptyset$ (for instance, when $\overline{\Omega}_{\mathrm{C}} \subset \Omega$). Even in this simpler case, a number of additional constraints related to the topology of Ω_{D} must be added to have uniqueness, as can be seen in this reference.

To the best of the authors' knowledge, a similar result has not been proved for the general case of Ω_{D} being a Lipschitz polyhedron with $\Gamma_{\mathrm{I}}\cap\Gamma_{\mathrm{D}} \neq \emptyset$. Nevertheless, this is not a drawback for the application of this eddy currents model, since typically the goal of these problems is to compute the electric field only in the conductors, as mentioned above.

4. Introducing a magnetic potential. In this section we show how Problem **MP** can be transformed by replacing the magnetic field in the dielectric domain Ω_{D} by a (scalar) magnetic potential.

We recall that Ω is assumed to be simply connected with connected boundary $\partial\Omega$. Let $\Omega_{\mathrm{C}} = \bigcup_{j=0}^{j=J}\Omega_{\mathrm{C}}^j$, with Ω_{C}^0 being the union of all the connected components of Ω_{C} such that $\Omega\backslash\Omega_{\mathrm{C}}^0$ is simply connected, and Ω_{C}^j, $j = 1,\dots,J$, are the remaining connected components of Ω_{C} (see Figure 4.1).

We assume that for each Ω_{C}^j, $j = 1,\dots,J$, there exists an open "cut" surface $\Sigma_j \subset \Omega_{\mathrm{D}}$ such that $\partial\Sigma_j \subset \partial\Omega_{\mathrm{D}}$ and $\widetilde{\Omega}_{\mathrm{D}} := \Omega_{\mathrm{D}} \setminus \bigcup_{j=0}^{j=J}\overline{\Sigma}_j$ is pseudo-Lipschitz and simply connected (see Figure 4.1). We also assume that each one of these surfaces Σ_j is connected, and $\overline{\Sigma}_j \cap \overline{\Sigma}_k = \emptyset$ for $j \neq k$ (see, for instance, [5]).

Let us arrange the conductors Ω_{C}^j in such a way that the inner ones are numbered from $j = 1$ to K, and those going through $\partial\Omega$, from $j = K+1$ to J. In Figure 4.1, Ω_{C}^1 is an example of a conductor of the first kind, and Ω_{C}^2 of the second kind.

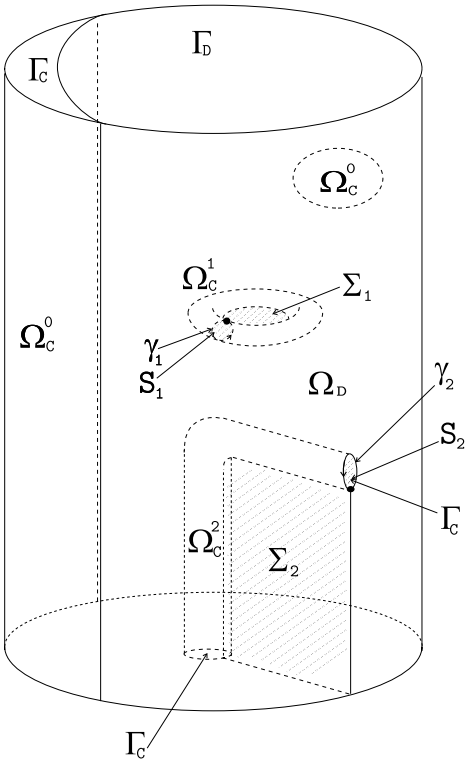

FIG. 4.1. *Sketch of the domain.*

We also assume that there exist cross sections of Ω_C^j, $j = 1 \dots J$; namely, open surfaces $S_j \subset \overline{\Omega}_C^j$, with respective boundaries $\partial S_j = \overline{S}_j \cap \Gamma_I$, which are assumed to be closed simple curves. We denote these curves γ_j. Moreover, for $j = K+1, \dots, J$, we take $S_j \subset \Gamma_C$ and $\gamma_j \subset \Gamma_C \cap \Gamma_D$ (see Figure 4.1 again).

Let $\widetilde{\Omega}_D^j := \Omega_D \setminus \overline{\Sigma}_j$, $j = 1 \dots J$. We fix a unit normal $\mathbf{n}_j$ on each Σ_j and denote its two faces by Σ_j^- and Σ_j^+, with $\mathbf{n}_j$ being the "outer" normal to $\widetilde{\Omega}_D^j$ along Σ_j^+. We choose an orientation for each γ_j by taking its initial and end points on $\overline{\Sigma}_j^-$ and $\overline{\Sigma}_j^+$, respectively. We denote by $\mathbf{t}_j$ the unit vector tangent to γ_j.

For any function $\widetilde{\Psi} \in \mathrm{H}^1(\widetilde{\Omega}_D)$, we denote by

$$[\![\widetilde{\Psi}]\!]_{\Sigma_j} := \widetilde{\Psi}|_{\Sigma_j^-} - \widetilde{\Psi}|_{\Sigma_j^+}$$

the jump of $\widetilde{\Psi}$ through Σ_j along $\mathbf{n}_j$. The gradient of $\widetilde{\Psi}$ in $\mathcal{D}'(\widetilde{\Omega}_D)$ can be extended to $\mathrm{L}^2(\Omega_D)^3$ and will be denoted by $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}$.

Let Θ be the linear space of $\mathrm{H}^1(\widetilde{\Omega}_D)$ defined by

$$\Theta = \left\{ \widetilde{\Psi} \in \mathrm{H}^1(\widetilde{\Omega}_D) : \ [\![\widetilde{\Psi}]\!]_{\Sigma_j} = \text{constant}, \ j = 1, \dots, J \right\}.$$

Then, for $\widetilde{\Psi} \in \mathrm{H}^1(\widetilde{\Omega}_D)$, we have that $\widetilde{\mathbf{grad}}\,\widetilde{\Psi} \in \mathrm{H}(\mathbf{curl}, \Omega_D)$ if and only if $\widetilde{\Psi} \in \Theta$, in which case $\mathbf{curl}\,(\widetilde{\mathbf{grad}}\,\widetilde{\Psi}) = \mathbf{0}$ (see Lemma 3.11 in [5]). Actually, the kernel of the operator $\mathbf{curl} : \ \mathrm{H}(\mathbf{curl}, \Omega_D) \longrightarrow \mathrm{L}^2(\Omega_D)^3$ is given by

$$\mathrm{Ker}\,(\mathbf{curl}) = \widetilde{\mathbf{grad}}\,\Theta = \mathbf{grad}\,\mathrm{H}^1(\Omega_D) \oplus \boldsymbol{\mathcal{C}}, \tag{4.1}$$

where $\boldsymbol{\mathcal{C}}$ is the space of the so-called *Neumann harmonic fields* in Ω_{D} defined by

$$\boldsymbol{\mathcal{C}} := \left\{ \mathbf{G} \in \mathrm{L}^2(\Omega_{\mathrm{D}})^3 : \ \mathbf{curl}\, \mathbf{G} = \mathbf{0}, \, \mathrm{div}\, (\mu \mathbf{G}) = 0 \text{ in } \Omega_{\mathrm{D}}, \text{ and } \mu \mathbf{G} \cdot \mathbf{n} = \mathbf{0} \text{ on } \partial\Omega_{\mathrm{D}} \right\}.$$

A basis of the space $\boldsymbol{\mathcal{C}}$ is given by the set of functions $\{ \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_j, \ j = 1, \ldots, J\}$, where, for each j, $\widetilde{\Phi}_j \in \mathrm{H}^1(\widetilde{\Omega}^j_{\mathrm{D}})$ is the solution of

$$\int_{\widetilde{\Omega}^j_{\mathrm{D}}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_j \cdot \mathbf{grad}\, \bar{\Psi} = 0 \quad \forall \Psi \in \mathrm{H}^1(\Omega_{\mathrm{D}}), \tag{4.2}$$

$$[\![\widetilde{\Phi}_j]\!]_{\Sigma_j} = 1. \tag{4.3}$$

By using the Lax–Milgram lemma, it is straightforward to see that $\widetilde{\Phi}_j$ is uniquely defined in $\mathrm{H}^1(\widetilde{\Omega}^j_{\mathrm{D}})/\mathbb{C}$. (See, for instance, [5] again.)

Therefore, according to (4.1), for all $\mathbf{G} \in \boldsymbol{\mathcal{V}}$, there exist unique constants c_j, $j = 1, \ldots, J$, and a unique scalar field $\Psi \in \mathrm{H}^1(\Omega_{\mathrm{D}})/\mathbb{C}$ such that $\mathbf{G}|_{\Omega_{\mathrm{D}}} = \widetilde{\mathbf{grad}}\, \widetilde{\Psi}$, with $\widetilde{\Psi} \in \Theta$ given by $\widetilde{\Psi} = \Psi + \sum_{j=1}^{J} c_j \widetilde{\Phi}_j$. Furthermore, because of (4.3), the constants c_j are the jumps of $\widetilde{\Psi}$ across the respective cuts Σ_j. Consequently, given $\widetilde{\Psi} \in \Theta$, we have that $\widetilde{\Psi} \in \mathrm{H}^1(\Omega)$ if and only if $[\![\widetilde{\Psi}]\!]_{\Sigma_j} = 0$ for $j = 1, \ldots, J$.

Remark 4.1. These jumps have a precise physical meaning. For instance, for the solution $\mathbf{H}$ of Problem **MP**, let us write $\mathbf{H}|_{\Omega_{\mathrm{D}}} = \widetilde{\mathbf{grad}}\, \widetilde{\Phi}$ with $\widetilde{\Phi} \in \Theta$. If $\mathbf{H}$ is sufficiently smooth, by using the Stokes theorem and (2.8) we have

$$\begin{aligned} [\![\widetilde{\Phi}]\!]_{\Sigma_j} &= \int_{\gamma_j} \widetilde{\mathbf{grad}}\, \widetilde{\Phi} \cdot \mathbf{t}_j \, d\gamma = \int_{\gamma_j} \mathbf{H}|_{\Omega_{\mathrm{D}}} \cdot \mathbf{t}_j \, d\gamma = \int_{\gamma_j} \mathbf{H}|_{\Omega_{\mathrm{C}}} \cdot \mathbf{t}_j \, d\gamma \\ &= \int_{S_j} \mathbf{curl}\, \mathbf{H}|_{\Omega_{\mathrm{C}}} \cdot \mathbf{n} \, d\Gamma = \int_{S_j} \mathbf{J} \cdot \mathbf{n} \, d\Gamma =: I_j, \qquad j = 1, \ldots, J. \end{aligned}$$

Thus, the jump of the magnetic potential $\widetilde{\Psi}$ across each cut surface Σ_j is exactly the current intensity I_j through the cross section S_j of the conductor Ω^j_{C} (as defined above).

We introduce the following notation: for $\mathbf{G}_{\mathrm{C}} \in \mathrm{L}^2(\Omega_{\mathrm{C}})^3$ and $\mathbf{G}_{\mathrm{D}} \in \mathrm{L}^2(\Omega_{\mathrm{D}})^3$, we denote by $(\mathbf{G}_{\mathrm{C}} | \mathbf{G}_{\mathrm{D}})$ the field $\mathbf{G} \in \mathrm{L}^2(\Omega)^3$ defined a.e. by

$$\mathbf{G}(\mathbf{x}) := \begin{cases} \mathbf{G}_{\mathrm{C}}(\mathbf{x}) & \text{if } \mathbf{x} \in \Omega_{\mathrm{C}}, \\ \mathbf{G}_{\mathrm{D}}(\mathbf{x}) & \text{if } \mathbf{x} \in \Omega_{\mathrm{D}}. \end{cases}$$

Let us denote by $\boldsymbol{\mathcal{W}}$ the linear space given by

$$\boldsymbol{\mathcal{W}} := \left\{ (\mathbf{G}, \widetilde{\Psi}) \in \mathrm{H}(\mathbf{curl}, \Omega_{\mathrm{C}}) \times (\Theta/\mathbb{C}) : \ (\mathbf{G} | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}) \in \mathrm{H}(\mathbf{curl}, \Omega) \right\}.$$

Clearly, the following application is an isomorphism:

$$\begin{array}{ccc} \boldsymbol{\mathcal{W}} & \longrightarrow & \boldsymbol{\mathcal{V}}, \\ (\mathbf{G}, \widetilde{\Psi}) & \longmapsto & (\mathbf{G} | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}). \end{array}$$

Similarly, we define the closed subspace of $\boldsymbol{\mathcal{W}}$

$$\boldsymbol{\mathcal{W}}^0 := \left\{ (\mathbf{G}, \widetilde{\Psi}) \in \boldsymbol{\mathcal{W}} : \ \widetilde{\mathbf{grad}}\, \widetilde{\Psi} \times \mathbf{n} = \mathbf{0} \text{ in } \mathrm{H}^{-1/2}_{00}(\Gamma_{\mathrm{D}})^3 \right\},$$

which is isomorphically equivalent to $\boldsymbol{\mathcal{V}}^0$.

Thus, we are led to define the following problem.

PROBLEM **HP**. *Find* $(\mathbf{H}, \widetilde{\Phi}) \in \boldsymbol{\mathcal{W}}$ *such that*

$$\widetilde{\mathbf{grad}}\, \widetilde{\Phi} \times \mathbf{n} = \mathbf{f} \text{ in } \mathrm{H}_{00}^{-1/2}(\Gamma_{\mathrm{D}})^3,$$
$$\mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu \mathbf{H} \cdot \bar{\mathbf{G}} + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma} \mathbf{curl}\, \mathbf{H} \cdot \mathbf{curl}\, \bar{\mathbf{G}} + \mathrm{i}\omega \int_{\Omega_{\mathrm{D}}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi} \cdot \widetilde{\mathbf{grad}}\, \bar{\widetilde{\Psi}} = 0 \quad \forall (\mathbf{G}, \widetilde{\Psi}) \in \boldsymbol{\mathcal{W}}^0.$$

This is the well-known magnetic field/magnetic potential hybrid formulation of the eddy currents problem introduced by Bossavit and Vérité [13]. One main advantage with respect to formulation (3.2)–(3.3) lies in the fact that a vector field is replaced by a scalar one in the dielectric domain.

The following lemma is an immediate consequence of the isomorphisms between $\boldsymbol{\mathcal{W}}$ and $\boldsymbol{\mathcal{V}}$, and between $\boldsymbol{\mathcal{W}}^0$ and $\boldsymbol{\mathcal{V}}^0$.

LEMMA 4.1. *The pair* $(\mathbf{H}, \widetilde{\Phi})$ *is solution of Problem* **HP** *if and only if* $(\mathbf{H}|\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi})$ *is solution of Problem* **MP**.

As a consequence of this lemma, Theorem 3.1 yields existence and uniqueness of solution for Problem **HP**.

COROLLARY 4.2. *Under the assumptions of Theorem* 3.1*, Problem* **HP** *has a unique solution* $(\mathbf{H}, \widetilde{\Phi})$*, with* $(\mathbf{H}|\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi})$ *being the unique solution of Problem* **MP**.

5. Numerical solution. In this section we first introduce a discretization of Problem **MP** and prove its convergence. Then we prove that the obtained discrete problem is completely equivalent to a convenient discrete version of Problem **HP**.

5.1. Discretizing the magnetic field. We employ "edge" finite elements to approximate the magnetic field, more precisely, the lowest-order finite element of the family introduced by Nédélec in [26]. This element belongs to the family of the so-called Whitney elements (see [9]).

We assume Ω, Ω_{C}, and Ω_{D} are Lipschitz polyhedra and consider a family of regular tetrahedral meshes $\{\mathcal{T}_h\}$ of Ω such that, for every mesh $\mathcal{T}_h$, each element $K \in \mathcal{T}_h$ is contained either in $\overline{\Omega}_{\mathrm{C}}$ or in $\overline{\Omega}_{\mathrm{D}}$. ($h$ stands as usual for the corresponding mesh-size.)

The magnetic field is approximated in each tetrahedron K by a polynomial vector field in the space

$$\boldsymbol{\mathcal{N}}(K) := \left\{ \mathbf{G}_h \in \mathcal{P}_1(K)^3 :\ \mathbf{G}_h(\mathbf{x}) = \mathbf{a} \times \mathbf{x} + \mathbf{b},\ \mathbf{a}, \mathbf{b} \in \mathbb{C}^3,\ \mathbf{x} \in K \right\}.$$

An explicit computation shows that vector fields of this type have constant tangential components along each straight line in the Euclidean space. Moreover, given six complex numbers β_n, $n = 1, \ldots, 6$, there exists a unique $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}(K)$ (i.e., unique $\mathbf{a}, \mathbf{b} \in \mathbb{C}^3$) such that its tangential component along the nth edge of K coincides with β_n for $n = 1 \ldots 6$, respectively. Thus, these tangential components along the edges of K can be taken as the degrees of freedom defining the elements in $\boldsymbol{\mathcal{N}}(K)$.

These elements are H(**curl**)-conforming in the sense that, for all $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}(K)$, their tangential traces on each triangular face T of K depend only on the degrees of freedom of $\mathbf{G}_h$ on the three edges of T. So, if we set

$$\boldsymbol{\mathcal{N}}_h(\Omega) := \{ \mathbf{G}_h \in \mathrm{H}(\mathbf{curl}, \Omega) :\ \mathbf{G}_h|_K \in \boldsymbol{\mathcal{N}}(K)\ \forall K \in \mathcal{T}_h \},$$

the elements in this space are piecewise linear vector fields with tangential traces that are continuous through the faces of the mesh. This is the lowest-order Nédélec

finite element space introduced in [26]. See [19] for a detailed mathematical analysis and [11] for useful implementation issues.

If $\mathbf{G}$ is smooth enough (e.g., $\mathbf{G} \in \mathrm{H}^2(\Omega)^3$), then its Nédélec interpolant $\mathbf{G}^{\mathrm{I}}$ is defined by

$$\mathbf{G}^{\mathrm{I}} \in \boldsymbol{\mathcal{N}}_h(\Omega): \quad \int_\ell \mathbf{G}^{\mathrm{I}} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{G} \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h, \tag{5.1}$$

where, from now on, $\mathbf{t}_\ell$ denotes a unit vector tangent to the edge ℓ. The Nédélec interpolation operator

$$\begin{array}{rcl} \mathrm{H}^2(\Omega)^3 & \longrightarrow & \boldsymbol{\mathcal{N}}_h(\Omega), \\ \mathbf{G} & \longmapsto & \mathbf{G}^{\mathrm{I}}, \end{array} \tag{5.2}$$

with $\mathbf{G}^{\mathrm{I}}$ defined by (5.1), extends uniquely to $\mathrm{H}^r(\mathbf{curl}, \Omega)$ with $r > 1/2$. Indeed, according to the Sobolev imbedding theorem and a trace theorem, for each $K \in \mathcal{T}_h$, $\mathbf{G}|_K \in \mathrm{L}^p(K)^3$, $\mathbf{curl}\, \mathbf{G}|_K \in \mathrm{L}^p(K)^3$, and $\mathbf{G} \times \mathbf{n}|_{\partial K} \in \mathrm{L}^p(\partial K)^3$, with $p = 4/(3-2r) > 2$. Then, the result follows by applying Lemma 4.7 of [5].

However, the solution $\mathbf{H}$ of Problem **MP** does not satisfy, in general, $\mathbf{curl}\, \mathbf{H} = \mathbf{J} \in \mathrm{H}^r(\Omega)^3$ with $r > 1/2$. In fact, $\mathbf{J}|_{\Omega_{\mathrm{D}}} = 0$, whereas $\mathbf{J}|_{\Omega_{\mathrm{C}}} \times \mathbf{n} = (\frac{1}{\sigma}\mathbf{E})|_{\Omega_{\mathrm{C}}} \times \mathbf{n}$ in general does not vanish on Γ_{I}; thus, $\mathbf{J} \times \mathbf{n}$ has a jump across Γ_{I}. (See, for instance, the problem in section 7.) Nevertheless, typically $\mathbf{H}|_{\Omega_{\mathrm{C}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})$ and $\mathbf{H}|_{\Omega_{\mathrm{D}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$ with $r > 1/2$. This is enough for $\mathbf{H}^{\mathrm{I}}$ to be well defined as shown in the following lemma, which also provides an error estimate for the Nédélec interpolant under these assumptions. (Here and thereafter, C denotes a generic constant, not necessarily the same at each occurrence, but always independent of the mesh-size h.)

LEMMA 5.1. *Let $r \in (\frac{1}{2}, 1]$. The operator defined by* (5.2)–(5.1) *extends uniquely to the space* $\{\mathbf{G} \in \mathrm{H}(\mathbf{curl}, \Omega) : \ \mathbf{G}|_{\Omega_{\mathrm{C}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})$ *and* $\mathbf{G}|_{\Omega_{\mathrm{D}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})\}$. *Furthermore, for all* $\mathbf{G}$ *in this space,*

$$\|\mathbf{G} - \mathbf{G}^{\mathrm{I}}\|_{\mathrm{H}(\mathbf{curl},\Omega)} \leq Ch^r \left[\|\mathbf{G}\|_{\mathrm{H}^r(\mathbf{curl},\Omega_{\mathrm{C}})} + \|\mathbf{G}\|_{\mathrm{H}^r(\mathbf{curl},\Omega_{\mathrm{D}})} \right].$$

Proof. According to the discussion above, since $\mathbf{G}|_{\Omega_{\mathrm{C}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})$ and $\mathbf{G}|_{\Omega_{\mathrm{D}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$, with $r > 1/2$, the Nédélec interpolants of $\mathbf{G}|_{\Omega_{\mathrm{C}}}$ and $\mathbf{G}|_{\Omega_{\mathrm{D}}}$ are well defined in $\boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{C}})$ and $\boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$, respectively. Moreover, since $\mathbf{G} \in \mathrm{H}(\mathbf{curl}, \Omega)$, a density argument shows that the degrees of freedom corresponding to the edges $\ell \subset \Gamma_{\mathrm{I}}$ coincide for both interpolants. Thus the global interpolant $\mathbf{G}^{\mathrm{I}} \in \boldsymbol{\mathcal{N}}_h(\Omega)$ is well defined also in this case.

On the other hand, the arguments in the proof of Theorem 5.4 in [19] can be extended to this case to prove the error estimate above. ∎

In order to use these elements to discretize Problem **MP**, we have to use an approximant $\mathbf{f}_{\mathrm{I}}$ of the boundary data $\mathbf{f}$ such that a discrete version of (3.2) can hold true, namely, such that there exists $\mathbf{H}_h \in \boldsymbol{\mathcal{N}}_h(\Omega)$ satisfying $\mathbf{H}_h \times \mathbf{n} = \mathbf{f}_{\mathrm{I}}$.

To attain this goal, we will use the two-dimensional Nédélec interpolant of $\mathbf{n} \times \mathbf{f}$ on the triangular mesh induced by $\mathcal{T}_h$ on the polyhedral surface Γ_{D}. To introduce this interpolant, let $\mathcal{T}_h^{\Gamma_{\mathrm{D}}} := \{T \subset \Gamma_{\mathrm{D}} : \ T \text{ face of } K \in \mathcal{T}_h\}$. For each triangle $T \in \mathcal{T}_h^{\Gamma_{\mathrm{D}}}$, consider local orthogonal coordinates (ξ, η, ζ) such that T is contained in the plane $\zeta = 0$. Let

$$\boldsymbol{\mathcal{N}}^2(T) := \left\{ \boldsymbol{\varphi}_h \in \mathcal{P}_1(T)^3 : \ \boldsymbol{\varphi}_h(\xi, \eta, 0) = (a - c\eta, b + c\xi, 0), \ a, b, c \in \mathbb{C}, \ (\xi, \eta, 0) \in T \right\}.$$

This is the lowest-order two-dimensional Nédélec finite element (see [26]) on the plane $\zeta = 0$. The tangential components of these vector fields along the three edges of the triangle T can also be taken as the degrees of freedom defining them. Therefore, we define

$$\boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}}) := \Big\{ \boldsymbol{\varphi}_h \in \mathrm{L}^2(\Gamma_{\mathrm{D}})^3 : \ \boldsymbol{\varphi}_h|_T \in \boldsymbol{\mathcal{N}}^2(T) \ \forall T \in \mathcal{T}_h^{\Gamma_{\mathrm{D}}} \\ \text{and } \boldsymbol{\varphi}_h \cdot \mathbf{t}_\ell \text{ is continuous on } \ell \ \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}} \Big\}.$$

Let $\boldsymbol{\varphi}$ be a tangential vector field on Γ_{D} (i.e., satisfying $\boldsymbol{\varphi} \cdot \mathbf{n} = 0$ on Γ_{D}). If $\boldsymbol{\varphi}$ is sufficiently smooth (e.g., $\boldsymbol{\varphi} \in \mathrm{H}^1(\Gamma_{\mathrm{D}})^3$), then its Nédélec interpolant on Γ_{D}, which we denote by $\boldsymbol{\varphi}^{\mathrm{I}_2}$, is defined by

$$\boldsymbol{\varphi}^{\mathrm{I}_2} \in \boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}}) : \quad \int_\ell \boldsymbol{\varphi}^{\mathrm{I}_2} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \boldsymbol{\varphi} \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}}. \tag{5.3}$$

If $\mathbf{G}$ is smooth enough in Ω_{D} (e.g., $\mathbf{G} \in \mathrm{H}^2(\Omega_{\mathrm{D}})^3$), then its tangential trace on Γ_{D}, $\mathbf{n} \times (\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n})$, is smooth too and satisfies

$$\Big[\mathbf{n} \times \Big(\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \Big]^{\mathrm{I}_2} = \mathbf{n} \times \Big(\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \quad \text{on } \Gamma_{\mathrm{D}}. \tag{5.4}$$

Indeed, a straightforward computation shows that the right-hand side above also belongs to $\boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}})$. On the other hand, (5.1) implies

$$\int_\ell \mathbf{n} \times \Big(\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{G}^{\mathrm{I}} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{G} \cdot \mathbf{t}_\ell \, d\gamma \\ = \int_\ell \mathbf{n} \times \Big(\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}}.$$

Thus, the degrees of freedom defining both sides of (5.4) coincide and, consequently, (5.4) holds true.

The following lemma shows that a similar result is valid for $\mathbf{G} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$.

LEMMA 5.2. *Let $r \in (\frac{1}{2}, 1]$. The linear operator*

$$\begin{array}{rcl} \mathrm{H}^2(\Omega_{\mathrm{D}})^3 & \longrightarrow & \boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}}), \\ \mathbf{G} & \longmapsto & \big[\mathbf{n} \times (\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}) \big]^{\mathrm{I}_2}, \end{array} \tag{5.5}$$

with $(\cdot)^{\mathrm{I}_2}$ defined by (5.3)*, extends uniquely to $\mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$. Furthermore,* (5.4) *holds true for all $\mathbf{G}$ in this space.*

Proof. As said above, if $\mathbf{G} \in \mathrm{H}^2(\Omega_{\mathrm{D}})^3$, then $\big[\mathbf{n} \times (\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}) \big]^{\mathrm{I}_2} \in \boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}})$ is defined by

$$\int_\ell \Big[\mathbf{n} \times \Big(\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \Big]^{\mathrm{I}_2} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{G} \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}}.$$

Then, by repeating the arguments in the proof of Lemma 5.1 (i.e., using the Sobolev imbedding theorem and Lemma 4.7 of [5]) we prove that the operator defined by (5.5) and (5.3) extends uniquely to $\mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$ for $r > 1/2$.

Furthermore, we have also shown above that, for $\mathbf{G} \in \mathrm{H}^2(\Omega_{\mathrm{D}})$,

$$\int_\ell \Big[\mathbf{n} \times \Big(\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \Big]^{\mathrm{I}_2} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{G} \cdot \mathbf{t}_\ell \, d\gamma \\ = \int_\ell \mathbf{n} \times \Big(\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n} \Big) \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}}.$$

Then, a density argument and the fact that $\mathbf{n} \times (\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}) \in \boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}})$ allow us to conclude that (5.4) holds true for all $\mathbf{G} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$. ∎

If the data $\mathbf{f}$ of Problem **MP** are sufficiently smooth, we define

$$\mathbf{f}_{\mathrm{I}} := (\mathbf{n} \times \mathbf{f})^{\mathrm{I}_2} \times \mathbf{n}; \tag{5.6}$$

that is, $\mathbf{f}_{\mathrm{I}}$ is such that $\mathbf{n} \times \mathbf{f}_{\mathrm{I}} = (\mathbf{n} \times \mathbf{f})^{\mathrm{I}_2}$, which means

$$\mathbf{n} \times \mathbf{f}_{\mathrm{I}} \in \boldsymbol{\mathcal{N}}_h^2(\Gamma_{\mathrm{D}}): \quad \int_\ell \mathbf{n} \times \mathbf{f}_{\mathrm{I}} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{n} \times \mathbf{f} \cdot \mathbf{t}_\ell \, d\gamma \quad \forall \ell \text{ edge of } \mathcal{T}_h^{\Gamma_{\mathrm{D}}}.$$

The following lemma shows that this definition also works under the same weak smoothness assumptions of the previous lemmas.

LEMMA 5.3. *Let* $\mathbf{G} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$*, with* $r > 1/2$*, and let* $\mathbf{g} = \mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}$*. Then* $\mathbf{g}_{\mathrm{I}} := (\mathbf{n} \times \mathbf{g})^{\mathrm{I}_2} \times \mathbf{n}$ *is well defined and satisfies*

$$\mathbf{n} \times \mathbf{g}_{\mathrm{I}} = \mathbf{n} \times (\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}) \quad \text{on } \Gamma_{\mathrm{D}}.$$

Proof. As a consequence of Lemma 5.2, $(\mathbf{n} \times \mathbf{g})^{\mathrm{I}_2} = \left[\mathbf{n} \times (\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n})\right]^{\mathrm{I}_2}$ is well defined. Hence $\mathbf{g}_{\mathrm{I}} := (\mathbf{n} \times \mathbf{g})^{\mathrm{I}_2} \times \mathbf{n}$ is well defined, too. Moreover, according to this lemma, (5.4) holds true for $\mathbf{G} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$; thus,

$$\mathbf{n} \times \mathbf{g}_{\mathrm{I}} = (\mathbf{n} \times \mathbf{g})^{\mathrm{I}_2} = \left[\mathbf{n} \times (\mathbf{G}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n})\right]^{\mathrm{I}_2} = \mathbf{n} \times (\mathbf{G}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}) \quad \text{on } \Gamma_{\mathrm{D}}. \qquad ∎$$

Now we are in a position to discretize Problem **MP**. We introduce the following finite-dimensional spaces:

$$\begin{aligned} \boldsymbol{\mathcal{V}}_h &:= \{\mathbf{G}_h \in \boldsymbol{\mathcal{N}}_h(\Omega): \ \mathbf{curl}\, \mathbf{G}_h = \mathbf{0} \ \text{ in } \Omega_{\mathrm{D}}\}, \\ \boldsymbol{\mathcal{V}}_h^0 &:= \{\mathbf{G}_h \in \boldsymbol{\mathcal{V}}_h: \ \mathbf{G}_h \times \mathbf{n} = \mathbf{0} \ \text{ on } \Gamma_{\mathrm{D}}\}. \end{aligned}$$

Finally, we define the discrete magnetic problem as follows.

PROBLEM **DMP**. *Find* $\mathbf{H}_h \in \boldsymbol{\mathcal{V}}_h$ *such that*

$$\begin{aligned} &\mathbf{H}_h \times \mathbf{n} = \mathbf{f}_{\mathrm{I}} \quad \text{on } \Gamma_{\mathrm{D}}, \\ &\mathrm{i}\omega \int_\Omega \mu \mathbf{H}_h \cdot \bar{\mathbf{G}}_h + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma} \mathbf{curl}\, \mathbf{H}_h \cdot \mathbf{curl}\, \bar{\mathbf{G}}_h = 0 \quad \forall \mathbf{G}_h \in \boldsymbol{\mathcal{V}}_h^0. \end{aligned}$$

It is straightforward to prove existence and uniqueness of solution for this problem under mild smoothness assumptions on the solution of Problem **MP**. Moreover, an error estimate can be deduced from the standard finite element approximation theory.

THEOREM 5.4. *Let us assume that the solution* $\mathbf{H}$ *of Problem* **MP** *satisfies* $\mathbf{H}|_{\Omega_{\mathrm{C}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})$ *and* $\mathbf{H}|_{\Omega_{\mathrm{D}}} \in \mathrm{H}^r(\Omega_{\mathrm{D}})^3$*, with* $r \in (\frac{1}{2}, 1]$*. Then,* $\mathbf{f}_{\mathrm{I}}$ *is well defined by* (5.6)*, Problem* **DMP** *attains a unique solution* $\mathbf{H}_h$*, and*

$$\|\mathbf{H} - \mathbf{H}_h\|_{\mathrm{H}(\mathbf{curl},\Omega)} \leq C h^r \left[\|\mathbf{H}\|_{\mathrm{H}^r(\mathbf{curl},\Omega_{\mathrm{C}})} + \|\mathbf{H}\|_{\mathrm{H}^r(\Omega_{\mathrm{D}})^3}\right].$$

Proof. Since $\mathbf{H} \in \boldsymbol{\mathcal{V}}$, $\mathbf{curl}\, \mathbf{H} = \mathbf{0}$ in Ω_{D}. Hence, $\mathbf{H}|_{\Omega_{\mathrm{D}}} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{D}})$. Therefore, according to Lemma 5.1, its Nédélec interpolant $\mathbf{H}^{\mathrm{I}} \in \boldsymbol{\mathcal{N}}_h(\Omega)$ is well defined and satisfies

$$\|\mathbf{H} - \mathbf{H}^{\mathrm{I}}\|_{\mathrm{H}(\mathbf{curl},\Omega)} \leq C h^r \left[\|\mathbf{H}\|_{\mathrm{H}^r(\mathbf{curl},\Omega_{\mathrm{C}})} + \|\mathbf{H}\|_{\mathrm{H}^r(\Omega_{\mathrm{D}})^3}\right]. \tag{5.7}$$

Moreover, the arguments of Remark 5.6 in [19] can be extended to this case to prove that $\mathbf{curl}\,\mathbf{H}|_{\Omega_{\mathrm{D}}} = \mathbf{0}$ implies that $\mathbf{curl}\,\mathbf{H}^{\mathrm{I}}|_{\Omega_{\mathrm{D}}} = \mathbf{0}$. Therefore, $\mathbf{H}^{\mathrm{I}} \in \boldsymbol{\mathcal{V}}_h$.

On the other hand, because of Lemma 5.3, $\mathbf{f}_{\mathrm{I}}$ is well defined by (5.6) and satisfies $\mathbf{f}_{\mathrm{I}} = \mathbf{H}^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}} \times \mathbf{n}$ on Γ_{D}. Thus, we have proved that there exists $\mathbf{H}^{\mathrm{I}} \in \boldsymbol{\mathcal{V}}_h$ such that $\mathbf{H}^{\mathrm{I}} \times \mathbf{n} = \mathbf{f}_{\mathrm{I}}$ on Γ_{D}. Hence, since $\boldsymbol{\mathcal{V}}_h^0 \subset \boldsymbol{\mathcal{V}}^0$, the arguments in the proof of Theorem 3.1 also apply to Problem **DMP**, allowing us to prove existence and uniqueness of a solution $\mathbf{H}_h$ of this problem.

Finally, to prove the error estimate, notice that since $\boldsymbol{\mathcal{V}}_h^0 \subset \boldsymbol{\mathcal{V}}^0$,

$$a(\mathbf{H} - \mathbf{H}_h, \mathbf{G}_h) = 0 \quad \forall \mathbf{G}_h \in \boldsymbol{\mathcal{V}}_h^0.$$

Hence, since $\mathbf{H}_h \times \mathbf{n} = \mathbf{f}_{\mathrm{I}} = \mathbf{H}^{\mathrm{I}} \times \mathbf{n}$ on Γ_{D}, $\mathbf{H}_h - \mathbf{H}^{\mathrm{I}} \in \boldsymbol{\mathcal{V}}_h^0$. Therefore, because of this and (3.4),

$$\begin{aligned}\alpha\|\mathbf{H} - \mathbf{H}_h\|^2_{\mathrm{H}(\mathbf{curl},\Omega)} &\le |a(\mathbf{H} - \mathbf{H}_h, \mathbf{H} - \mathbf{H}_h)| = \left|a(\mathbf{H} - \mathbf{H}_h, \mathbf{H} - \mathbf{H}^{\mathrm{I}})\right| \\ &\le C\|\mathbf{H} - \mathbf{H}_h\|_{\mathrm{H}(\mathbf{curl},\Omega)}\left\|\mathbf{H} - \mathbf{H}^{\mathrm{I}}\right\|_{\mathrm{H}(\mathbf{curl},\Omega)},\end{aligned}$$

which together with estimate (5.7) allow us to conclude the proof. ∎

5.2. Discretizing the magnetic potential. Problem **DMP** is actually just a "theoretical" method in that its solution requires to impose somehow the curl-free condition in the definition of $\boldsymbol{\mathcal{V}}_h$ to trial and test functions. In what follows we show how to deal efficiently with this curl-free condition by introducing a discrete multivalued magnetic potential in the dielectric domain.

We assume that the cut surfaces Σ_j are polyhedral and that the meshes are compatible with them, in the sense that each $\overline{\Sigma}_j$ is a union of faces of tetrahedra $K \in \mathcal{T}_h$ for each mesh $\mathcal{T}_h$. Therefore, $\mathcal{T}_h^{\Omega_{\mathrm{D}}} := \{K \in \mathcal{T}_h : \ K \subset \overline{\Omega}_{\mathrm{D}}\}$ can also be seen as a mesh of $\widetilde{\Omega}_{\mathrm{D}}$.

First, we introduce an approximation of the space Θ. Let us denote

$$\mathcal{L}_h(\widetilde{\Omega}_{\mathrm{D}}) := \left\{\widetilde{\Psi}_h \in \mathrm{H}^1(\widetilde{\Omega}_{\mathrm{D}}) : \ \widetilde{\Psi}_h|_K \in \mathcal{P}_1(K)\ \forall K \in \mathcal{T}_h^{\Omega_{\mathrm{D}}}\right\}.$$

Then, we consider the family of finite-dimensional subspaces of Θ given by

$$\Theta_h := \{\widetilde{\Psi}_h \in \mathcal{L}_h(\widetilde{\Omega}_{\mathrm{D}}) : \ [\![\widetilde{\Psi}_h]\!]_{\Sigma_j} = \text{constant},\ j = 1, \ldots, J\}.$$

The following lemma shows that the curl-free vector fields in $\boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$ admit a multivalued potential in Θ_h.

LEMMA 5.5. *Let $\mathbf{G}_h \in \mathrm{L}^2(\Omega_{\mathrm{D}})^3$. Then $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$ with $\mathbf{curl}\,\mathbf{G}_h = \mathbf{0}$ in Ω_{D} if and only if there exists $\widetilde{\Psi}_h \in \Theta_h$ such that $\mathbf{G}_h = \widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h$ in Ω_{D}. Such $\widetilde{\Psi}_h$ is unique up to an additive constant.*

Proof. According to (4.1), $\mathbf{curl}\,\mathbf{G}_h = \mathbf{0}$ in Ω_{D} if and only if there exists $\widetilde{\Psi}_h \in \Theta$ such that $\mathbf{G}_h = \widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h$ in $\widetilde{\Omega}_{\mathrm{D}}$. Moreover, since $\widetilde{\Omega}_{\mathrm{D}}$ is connected, $\widetilde{\Psi}_h$ is unique up to an additive constant. Now, let $K \in \mathcal{T}_h^{\Omega_{\mathrm{D}}}$ be a tetrahedron of the mesh. A direct calculation shows that $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}(K)$ with $\mathbf{curl}\,\mathbf{G}_h|_K = \mathbf{0}$ if and only if $\mathbf{G}_h|_K \in \mathcal{P}_0(K)^3$, or, equivalently, if and only if $\widetilde{\Psi}_h|_K \in \mathcal{P}_1(K)^3$. Thus the lemma follows from the definition of Θ_h. ∎

Let us introduce the following families of finite-dimensional approximations of $\boldsymbol{\mathcal{W}}$ and $\boldsymbol{\mathcal{W}}^0$, respectively:

$$\boldsymbol{\mathcal{W}}_h := \left\{ (\mathbf{G}_h, \widetilde{\Psi}_h) \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{C}}) \times (\Theta_h/\mathbb{C}) : \ (\mathbf{G}_h | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h) \in \mathrm{H}(\mathbf{curl}, \Omega) \right\},$$
$$\boldsymbol{\mathcal{W}}_h^0 := \left\{ (\mathbf{G}_h, \widetilde{\Psi}_h) \in \boldsymbol{\mathcal{W}}_h : \ \widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h \times \mathbf{n} = \mathbf{0} \text{ on } \Gamma_{\mathrm{D}} \right\}.$$

By virtue of Lemma 5.5, $\boldsymbol{\mathcal{W}}_h$ and $\boldsymbol{\mathcal{W}}_h^0$ are isomorphically equivalent to $\boldsymbol{\mathcal{V}}_h$ and $\boldsymbol{\mathcal{V}}_h^0$, respectively. Thus, we define the following discrete problem which turns out to be equivalent to Problem **DMP**.

PROBLEM **DHP**. *Find* $(\mathbf{H}_h, \widetilde{\Phi}_h) \in \boldsymbol{\mathcal{W}}_h$ *such that*

$$\widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \times \mathbf{n} = \mathbf{f}_{\mathrm{I}} \quad \text{on } \Gamma_{\mathrm{D}}, \tag{5.8}$$

$$\mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu \mathbf{H}_h \cdot \bar{\mathbf{G}}_h + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma} \mathbf{curl}\, \mathbf{H}_h \cdot \mathbf{curl}\, \bar{\mathbf{G}}_h + \mathrm{i}\omega \int_{\Omega_{\mathrm{D}}} \mu\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \cdot \widetilde{\mathbf{grad}}\, \bar{\widetilde{\Psi}}_h = 0 \qquad \forall (\mathbf{G}_h, \widetilde{\Psi}_h) \in \boldsymbol{\mathcal{W}}_h^0. \tag{5.9}$$

Clearly, the following discrete analogue of Lemma 4.1 holds true.

LEMMA 5.6. *The pair* $(\mathbf{H}_h, \widetilde{\Phi}_h)$ *is a solution of Problem* **DHP** *if and only if* $(\mathbf{H}_h | \, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h)$ *is a solution of Problem* **DMP**.

As an immediate consequence of these two lemmas, Theorem 5.4 yields an error estimate for the approximation obtained from Problem **DHP**.

COROLLARY 5.7. *Let us assume that the solution* $(\mathbf{H}, \widetilde{\Phi})$ *of Problem* **HP** *satisfies* $\mathbf{H} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})$ *and* $\widetilde{\mathbf{grad}}\, \widetilde{\Phi} \in \mathrm{H}^r(\Omega_{\mathrm{D}})^3$, *with* $r \in (\frac{1}{2}, 1]$. *Then, Problem* **DHP** *is well posed, it attains a unique solution* $(\mathbf{H}_h, \widetilde{\Phi}_h)$, *and*

$$\|\mathbf{H} - \mathbf{H}_h\|_{\mathrm{H}(\mathbf{curl}, \Omega_{\mathrm{C}})} + \|\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi} - \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h\|_{\mathrm{L}^2(\Omega_{\mathrm{D}})^3} \leq Ch^r \left[\|\mathbf{H}\|_{\mathrm{H}^r(\mathbf{curl}, \Omega_{\mathrm{C}})} + \|\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}\|_{\mathrm{H}^r(\Omega_{\mathrm{D}})^3} \right].$$

6. Computer implementation. For Problem **DHP** to be useful for computational purposes, we have to introduce effective procedures to impose the following constraints:

1. $(\mathbf{G}_h | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h) \in \mathrm{H}(\mathbf{curl}, \Omega)$, which arises in the definition of $\boldsymbol{\mathcal{W}}_h$;
2. $[\![\widetilde{\Psi}_h]\!]_{\Sigma_j} =$ constant, which arises in the definition of Θ_h;
3. the boundary condition $\widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \times \mathbf{n} = \mathbf{f}_{\mathrm{I}}$ on Γ_{D}.

We fix some notation to deal with these constraints. We choose an orientation for each edge ℓ of the mesh $\mathcal{T}_h$ and denote P_ℓ^- and P_ℓ^+ its initial and end points, respectively, and $\mathbf{t}_\ell$ its unit tangent vector pointing from P_ℓ^- to P_ℓ^+.

Regarding the first constraint we have the following result.

LEMMA 6.1. *Let* $(\mathbf{G}_h, \widetilde{\Psi}_h) \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{C}}) \times (\Theta_h/\mathbb{C})$. *Then,* $(\mathbf{G}_h, | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h) \in \mathrm{H}(\mathbf{curl}, \Omega)$ *if and only if*

$$\int_\ell \mathbf{G}_h \cdot \mathbf{t}_\ell \, d\gamma = \widetilde{\Psi}_h(P_\ell^+) - \widetilde{\Psi}_h(P_\ell^-) \quad \forall \ell \text{ edge of } \mathcal{T}_h : \ \ell \subset \Gamma_{\mathrm{I}}.$$

Proof. Since $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{C}})$ and $\widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$, $(\mathbf{G}_h | \, \widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h) \in \mathrm{H}(\mathbf{curl}, \Omega)$ if and only if the tangential traces on Γ_{I} of $\mathbf{G}_h$ and $\widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h$ coincide; that is, if and

only if

$$\mathbf{n}\times(\mathbf{G}_h\times\mathbf{n}) = \mathbf{n}\times\Big(\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h\times\mathbf{n}\Big) \quad \text{on } \Gamma_{\rm I}.$$

Now, the equation above holds true if and only if the degrees of freedom of $\mathbf{G}_h$ and $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h$ coincide on all the edges $\ell\subset\Gamma_{\rm I}$, and this reads as

$$\int_\ell \mathbf{G}_h\cdot\mathbf{t}_\ell\,d\gamma = \int_\ell \widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h\cdot\mathbf{t}_\ell\,d\gamma = \widetilde{\Psi}_h(P_\ell^+)-\widetilde{\Psi}_h(P_\ell^-). \qquad \square$$

This lemma shows that the constraint $(\mathbf{G}_h|\,\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h)\in \mathrm{H}(\mathbf{curl},\Omega)$ can be readily imposed by eliminating the degrees of freedom of $\mathbf{G}_h$ associated with the edges $\ell\subset\Gamma_{\rm I}$, in terms of those of $\widetilde{\Phi}_h$ corresponding to the vertices of the mesh on this interface.

Regarding the second constraint, for $\widetilde{\Psi}_h\in\Theta_h$, let us denote

$$c_{hj} := [\![\widetilde{\Psi}_h]\!]_{\Sigma_j}, \qquad j=1,\dots,J.$$

In order to handle the multivalued character of the functions $\widetilde{\Psi}_h\in\Theta_h$, for each cut surface Σ_j, we in principle distinguish the degrees of freedom of $\widetilde{\Psi}_h$ on $\overline{\Sigma}_j^+$ from those on $\overline{\Sigma}_j^-$. Then, the latter can be eliminated by using

$$\widetilde{\Psi}_h|_{\overline{\Sigma}_j^-} = \widetilde{\Psi}_h|_{\overline{\Sigma}_j^+} + [\![\widetilde{\Psi}_h]\!]_{\overline{\Sigma}_j} = \widetilde{\Psi}_h|_{\overline{\Sigma}_j^+} + c_{hj}, \qquad j=1,\dots,J.$$

This elimination must be carried out for the solution $(\mathbf{H}_h,\widetilde{\Phi}_h)\in\boldsymbol{\mathcal{W}}_h$ of Problem **DHP** as well as for the test functions $(\mathbf{G}_h,\widetilde{\Psi}_h)\in\boldsymbol{\mathcal{W}}_h^0$. For the former, the arguments in Remark 4.1 can be repeated at discrete level to show that each jump $[\![\widetilde{\Phi}_h]\!]_{\Sigma_j}$ represents the current intensity through the conductor $\Omega_{\rm C}^j$ corresponding to the discrete solution $(\mathbf{H}_h,\widetilde{\Phi}_h)$. Because of this, we denote these jumps

$$I_{hj} := [\![\widetilde{\Phi}_h]\!]_{\Sigma_j}, \qquad j=1,\dots,J.$$

For $j=1,\dots,K$ (i.e., for inner conductors $\Omega_{\rm C}^j$), I_{hj} are additional unknowns of the discrete problem. Instead, for $j=K+1,\dots,J$ (i.e., for conductors $\Omega_{\rm C}^j$ going through $\partial\Omega$), I_{hj} can be computed in advance from the data of the discrete problem. Indeed, since $\gamma_j\subset\Gamma_{\rm D}$ and $\widetilde{\mathbf{grad}}\,\widetilde{\Phi}_h\times\mathbf{n}=\mathbf{f}_{\rm I}$ on $\Gamma_{\rm D}$,

$$I_{hj} = \int_{\gamma_j}\widetilde{\mathbf{grad}}\,\widetilde{\Phi}_h\cdot\mathbf{t}_j\,d\gamma = \int_{\gamma_j}\mathbf{n}\times\Big(\widetilde{\mathbf{grad}}\,\widetilde{\Phi}_h\times\mathbf{n}\Big)\cdot\mathbf{t}_j\,d\gamma = \int_{\gamma_j}\mathbf{n}\times\mathbf{f}_{\rm I}\cdot\mathbf{t}_j\,d\gamma\,. \tag{6.1}$$

For the test functions $(\mathbf{G}_h,\widetilde{\Psi}_h)\in\boldsymbol{\mathcal{W}}_h^0$, by repeating these arguments and using that $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h\times\mathbf{n}=\mathbf{0}$ on $\Gamma_{\rm D}$, we have

$$c_{hj} = \int_{\gamma_j}\mathbf{n}\times\Big(\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h\times\mathbf{n}\Big)\cdot\mathbf{t}_j\,d\gamma = 0, \qquad j=K+1,\dots,J. \tag{6.2}$$

Hence, only the constants c_{hj}, for $j=1,\dots,K$, must be taken into account as genuine degrees of freedom in the definition of $\boldsymbol{\mathcal{W}}_h^0$.

Remark 6.1. The computed and exact intensities through the conductors $\Omega_{\rm C}^j$, $j = K+1, \ldots, J$, coincide. Indeed, because of (6.1), Lemma 5.3, (5.1), the fact that each γ_j is union of edges ℓ in $\mathcal{T}_h$, and Remark 4.1, we have

$$\begin{aligned} I_{hj} &= \int_{\gamma_j} \mathbf{n} \times \mathbf{f}_{\rm I} \cdot \mathbf{t}_j \, d\gamma = \int_{\gamma_j} \mathbf{n} \times \left[(\widetilde{\mathbf{grad}}\, \widetilde{\Phi})^{\rm I}|_{\Gamma_{\rm D}} \times \mathbf{n} \right] \cdot \mathbf{t}_j \, d\gamma \\ &= \int_{\gamma_j} (\widetilde{\mathbf{grad}}\, \widetilde{\Phi})^{\rm I} \cdot \mathbf{t}_j \, d\gamma = \int_{\gamma_j} \widetilde{\mathbf{grad}}\, \widetilde{\Phi} \cdot \mathbf{t}_j \, d\gamma = [\![\widetilde{\Phi}]\!]_{\Sigma_j} = I_j. \end{aligned}$$

Regarding the third constraint, we impose the boundary condition by means of a Lagrange multiplier. Let $\widetilde{\Gamma}_{\rm D}$ be the pseudo-Lipschitz connected polyhedral surface defined by

$$\widetilde{\Gamma}_{\rm D} := \Gamma_{\rm D} \setminus \bigcup_{j=K+1}^{J} \left(\overline{\Sigma}_j \cap \Gamma_{\rm D} \right).$$

Let

$$\begin{aligned} \mathcal{L}_h(\widetilde{\Gamma}_{\rm D}) &:= \left\{ \nu_h \in {\rm H}^1(\widetilde{\Gamma}_{\rm D}) : \ \nu_h|_T \in \mathcal{P}_1(T) \ \forall T \in \mathcal{T}_h^{\Gamma_{\rm D}} \right\}, \\ \mathcal{L}_h(\Gamma_{\rm D}) &:= \left\{ \nu_h \in {\rm H}^1(\Gamma_{\rm D}) : \ \nu_h|_T \in \mathcal{P}_1(T) \ \forall T \in \mathcal{T}_h^{\Gamma_{\rm D}} \right\}. \end{aligned}$$

Hence, given $\nu_h \in \mathcal{L}_h(\widetilde{\Gamma}_{\rm D})$, we have that $\nu_h \in \mathcal{L}_h(\Gamma_{\rm D})$ if and only if $[\![\nu_h]\!]_{\overline{\Sigma}_j \cap \Gamma_{\rm D}} = 0$ for $j = K+1, \ldots, J$.

Let $\widetilde{\mathbf{grad}}_{\,\Gamma}$ denote the surface gradient operator. Since we will use this operator acting only on piecewise linear functions, we give a definition valid in this case (for its general definition on polyhedral surfaces, see [14, 15]):

$$\widetilde{\mathbf{grad}}_{\,\Gamma} \ : \ \mathcal{L}_h(\widetilde{\Gamma}_{\rm D}) \longrightarrow {\rm L}^2_{\mathbf{t}}(\Gamma_{\rm D})^3 := \left\{ \boldsymbol{\varphi} \in {\rm L}^2(\Gamma_{\rm D})^3 : \ \boldsymbol{\varphi} \cdot \mathbf{n} = 0 \text{ on } \Gamma_{\rm D} \right\}$$

is defined, on each element $T \in \mathcal{T}_h^{\Gamma_{\rm D}}$, by $(\widetilde{\mathbf{grad}}_{\,\Gamma}\, \nu_h)|_T = \nabla_2(\nu_h|_T)$, where ∇_2 is the usual gradient of a function of two variables; i.e., using local coordinates (ξ, η, ζ) such that T is in the plane $\zeta = 0$,

$$(\widetilde{\mathbf{grad}}_{\,\Gamma}\, \nu_h)|_T := \left(\frac{\partial(\nu_h|_T)}{\partial \xi}, \frac{\partial(\nu_h|_T)}{\partial \eta}, 0 \right).$$

For all $\widetilde{\Psi}_h \in \mathcal{L}_h(\widetilde{\Omega}_{\rm D})$, we have $\widetilde{\Psi}_h|_{\Gamma_{\rm D}} \in \mathcal{L}_h(\widetilde{\Gamma}_{\rm D})$, and it is straightforward to show that

$$\widetilde{\mathbf{grad}}_{\,\Gamma}\, (\widetilde{\Psi}_h|_{\widetilde{\Gamma}_{\rm D}}) = \mathbf{n} \times \left[(\widetilde{\mathbf{grad}}\, \widetilde{\Psi}_h)|_{\Gamma_{\rm D}} \times \mathbf{n} \right] \quad \text{a.e. in } \Gamma_{\rm D}. \tag{6.3}$$

The following lemma provides a weak formulation of the boundary condition (5.8) in Problem **DHP**.

LEMMA 6.2. *Let* $\widetilde{\Psi} \in \Theta$ *be such that* $\widetilde{\mathbf{grad}}\, \widetilde{\Psi} \in {\rm H}^r(\Omega_{\rm D})$ *with* $r > 1/2$. *Let* $\mathbf{g} = \widetilde{\mathbf{grad}}\, \widetilde{\Psi}|_{\Gamma_{\rm D}} \times \mathbf{n}$ *and* $\mathbf{g}_{\rm I} = (\mathbf{n} \times \mathbf{g})^{{\rm I}_2} \times \mathbf{n}$ *(well defined because of Lemma* 5.3*). Let* $\widetilde{\Psi}_h \in \Theta_h$ *be such that*

$$[\![\widetilde{\Psi}_h]\!]_{\Sigma_j} = \int_{\gamma_j} \mathbf{n} \times \mathbf{g}_{\rm I} \cdot \mathbf{t}_j \, d\gamma, \qquad j = K+1, \ldots, J. \tag{6.4}$$

Then, $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h \times \mathbf{n} = \mathbf{g}_{\mathrm{I}}$ *on* Γ_{D} *if and only if*

$$\int_{\Gamma_{\mathrm{D}}} \widetilde{\mathbf{grad}}_{\,\Gamma}\,\widetilde{\Psi}_h \cdot \mathbf{grad}_{\Gamma}\,\bar{\nu}_h\,d\Gamma = \int_{\Gamma_{\mathrm{D}}} \mathbf{n}\times\mathbf{g}_{\mathrm{I}}\cdot\mathbf{grad}_{\Gamma}\,\bar{\nu}_h\,d\Gamma \quad \forall \nu_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}. \tag{6.5}$$

Proof. If $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}_h \times \mathbf{n} = \mathbf{g}_{\mathrm{I}}$ on Γ_{D}, then, because of (6.3), we have (6.5).

Conversely, let us assume that (6.5) holds true. Since $\widetilde{\Psi} \in \mathrm{H}^{1+r}(\widetilde{\Omega}_{\mathrm{D}})/\mathbb{C}$ with $r > 1/2$, its Lagrange interpolant $\widetilde{\Psi}^{\mathrm{L}} \in \mathcal{L}_h(\widetilde{\Omega}_{\mathrm{D}})/\mathbb{C}$ is well defined. Given a cut surface Σ_j, $j = 1,\dots,J$, for all the vertices P of $\mathcal{T}_h$ such that $P \in \Sigma_j$, we have $[\![\widetilde{\Psi}^{\mathrm{L}}(P)]\!]_{\Sigma_j} = [\![\widetilde{\Psi}(P)]\!]_{\Sigma_j} =$ constant (the same for all such P). Then $[\![\widetilde{\Psi}^{\mathrm{L}}]\!]_{\Sigma_j} =$ constant, and hence $\widetilde{\Psi}^{\mathrm{L}} \in \Theta_h/\mathbb{C}$. Thus, because of Lemma 5.5, $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}} \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$.

On the other hand, let $(\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}} \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$ be the Nédélec interpolant of $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}$. We have $\int_\ell (\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}}\cdot\mathbf{t}_\ell\,d\gamma = \int_\ell \widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}}\cdot\mathbf{t}_\ell\,d\gamma$ for all edges ℓ of $\mathcal{T}_h^{\Omega_{\mathrm{D}}}$. Indeed, if $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}$ were smooth (e.g., $\widetilde{\mathbf{grad}}\,\widetilde{\Psi} \in \mathrm{H}^2(\Omega_{\mathrm{D}})^3$), then

$$\begin{aligned}\int_\ell (\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}}\cdot\mathbf{t}_\ell\,d\gamma &= \int_\ell \widetilde{\mathbf{grad}}\,\widetilde{\Psi}\cdot\mathbf{t}_\ell\,d\gamma = \widetilde{\Psi}(P_\ell^+) - \widetilde{\Psi}(P_\ell^-)\\ &= \widetilde{\Psi}^{\mathrm{L}}(P_\ell^+) - \widetilde{\Psi}^{\mathrm{L}}(P_\ell^-) = \int_\ell \widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}}\cdot\mathbf{t}_\ell\,d\gamma\,.\end{aligned}$$

Hence, because of a density argument, this is also true for $\widetilde{\mathbf{grad}}\,\widetilde{\Psi} \in \mathrm{H}^r(\mathbf{curl},\Omega_{\mathrm{D}})^3$.

Therefore, since we have shown that $\widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}} \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{D}})$ and that its degrees of freedom coincide with those of $(\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}}$ for all edges ℓ of $\mathcal{T}_h^{\Omega_{\mathrm{D}}}$, we have

$$(\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}} = \widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}} \quad \text{in } \overline{\Omega}_{\mathrm{D}}. \tag{6.6}$$

Consequently,

$$\begin{aligned}[\![\widetilde{\Psi}^{\mathrm{L}}]\!]_{\Sigma_j} &= \int_{\gamma_j} \widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}}\cdot\mathbf{t}_j\,d\gamma = \int_{\gamma_j} (\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}}\cdot\mathbf{t}_j\,d\gamma\\ &= \int_{\gamma_j} \mathbf{n}\times\Big[(\widetilde{\mathbf{grad}}\,\widetilde{\Psi})^{\mathrm{I}}|_{\Gamma_{\mathrm{D}}}\times\mathbf{n}\Big]\cdot\mathbf{t}_j\,d\gamma = \int_{\gamma_j}\mathbf{n}\times\mathbf{g}_{\mathrm{I}}\cdot\mathbf{t}_j\,d\gamma\,,\quad j = K+1,\dots,J,\end{aligned}$$

the last equality because of Lemma 5.3.

Let $\nu_h := (\widetilde{\Psi}_h - \widetilde{\Psi}^{\mathrm{L}})|_{\widetilde{\Gamma}_{\mathrm{D}}} \in \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{D}})/\mathbb{C}$. Because of the equation above and (6.4), we have

$$[\![\nu_h]\!]_{\overline{\Sigma}_j\cap\Gamma_{\mathrm{D}}} = [\![\widetilde{\Psi}_h]\!]_{\Sigma_j} - [\![\widetilde{\Psi}^{\mathrm{L}}]\!]_{\Sigma_j} = 0, \qquad j = K+1,\dots,J.$$

Then, $\nu_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}$, and, because of (6.3), (6.6), and Lemma 5.3, we have

$$\mathbf{grad}_{\Gamma}\,\nu_h = \widetilde{\mathbf{grad}}_{\,\Gamma}\,(\widetilde{\Psi}_h|_{\widetilde{\Gamma}_{\mathrm{D}}}) - \mathbf{n}\times\Big[(\widetilde{\mathbf{grad}}\,\widetilde{\Psi}^{\mathrm{L}})|_{\Gamma_{\mathrm{D}}}\times\mathbf{n}\Big] = \widetilde{\mathbf{grad}}_{\,\Gamma}\,(\widetilde{\Psi}_h|_{\widetilde{\Gamma}_{\mathrm{D}}}) - \mathbf{n}\times\mathbf{g}_{\mathrm{I}}.$$

Thus, using this ν_h in (6.5), we obtain

$$\widetilde{\mathbf{grad}}_{\,\Gamma}\,(\widetilde{\Psi}_h|_{\widetilde{\Gamma}_{\mathrm{D}}}) - \mathbf{n}\times\mathbf{g}_{\mathrm{I}} = \mathbf{0}.$$

Hence, by using again (6.3), we conclude the proof. ∎

Now we are in a position to set a new discrete problem including the three constraints as we have just described. To this end, we introduce the following discrete spaces:

$$\boldsymbol{\mathcal{Z}}_h := \Big\{ (\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{N}}_h(\Omega_{\mathrm{C}}) \times (\Theta_h/\mathbb{C}) \times \mathbb{C}^J : \ [\![\widetilde{\Psi}_h]\!]_{\Sigma_j} = c_{hj},\ j = 1, \dots, J, \\ \text{and} \ \int_\ell \mathbf{G}_h \cdot \mathbf{t}_\ell \, d\gamma = \widetilde{\Psi}_h(P_\ell^+) - \widetilde{\Psi}_h(P_\ell^-) \ \ \forall \ell \text{ edge } \mathcal{T}_h : \ \ell \subset \Gamma_{\mathrm{I}} \Big\},$$

$$\boldsymbol{\mathcal{Z}}_h^0 := \Big\{ (\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{Z}}_h : \ c_{hj} = 0,\ j = K+1, \dots, J \Big\}.$$

The new discrete problem, which will be shown to be equivalent to Problem **DHP** in the next theorem, is the following one.

PROBLEM **DLP**. *Find* $(\mathbf{H}_h, \widetilde{\Phi}_h, I_h) \in \boldsymbol{\mathcal{Z}}_h$ *and* $\lambda_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}$ *such that*

$$I_{hj} = \int_{\gamma_j} (\mathbf{n} \times \mathbf{f}_{\mathrm{I}}) \cdot \mathbf{t}_j \, d\gamma, \qquad j = K+1, \dots, J, \tag{6.7}$$

$$\mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu \mathbf{H}_h \cdot \bar{\mathbf{G}}_h + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma} \, \mathbf{curl}\, \mathbf{H}_h \cdot \, \mathbf{curl}\, \bar{\mathbf{G}}_h + \mathrm{i}\omega \int_{\Omega_{\mathrm{D}}} \mu \, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \cdot \, \widetilde{\mathbf{grad}}\, \bar{\widetilde{\Psi}}_h \\ + \int_{\Gamma_{\mathrm{D}}} \mathbf{grad}_\Gamma \, \lambda_h \cdot \, \widetilde{\mathbf{grad}}_\Gamma \, \bar{\widetilde{\Psi}}_h \, d\Gamma = 0 \quad \forall (\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{Z}}_h^0, \tag{6.8}$$

$$\int_{\Gamma_{\mathrm{D}}} \widetilde{\mathbf{grad}}_\Gamma \, \widetilde{\Phi}_h \cdot \, \mathbf{grad}_\Gamma \, \bar{\nu}_h \, d\Gamma = \int_{\Gamma_{\mathrm{D}}} (\mathbf{n} \times \mathbf{f}_{\mathrm{I}}) \cdot \, \mathbf{grad}_\Gamma \, \bar{\nu}_h \, d\Gamma \quad \forall \nu_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}. \tag{6.9}$$

First we prove that Problem **DLP** is well posed.

THEOREM 6.3. *Let* $\mathbf{f}_{\mathrm{I}}$ *be any vector field defined on* Γ_{D}*, such that the integrals in the right-hand sides of* (6.7) *and* (6.9) *are well defined. Then, Problem* **DLP** *attains a unique solution.*

Proof. Problem **DLP** reduces to a linear system with the same number of equations and unknowns. Then, it is enough to prove that, for $\mathbf{f}_{\mathrm{I}} = \mathbf{0}$, this problem attains only the null solution. So let $(\mathbf{H}_h, \widetilde{\Phi}_h, I_h) \in \boldsymbol{\mathcal{Z}}_h$, and $\lambda_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}$ satisfying (6.7)–(6.9) with $\mathbf{f}_{\mathrm{I}} = \mathbf{0}$.

Equation (6.7) implies that $I_{hj} = 0$ for $j = K+1, \dots, J$; hence, $(\mathbf{H}_h, \widetilde{\Phi}_h, I_h) \in \boldsymbol{\mathcal{Z}}_h^0$, and $[\![\widetilde{\Phi}_h]\!]_{\Sigma_j} = I_{hj} = 0$, too. Thus, if we define $\nu_h := \widetilde{\Phi}_h|_{\widetilde{\Gamma}_{\mathrm{D}}} \in \mathcal{L}_h(\widetilde{\Gamma}_{\mathrm{D}})/\mathbb{C}$, we have $[\![\nu_h]\!]_{\overline{\Sigma}_j \cap \Gamma_{\mathrm{D}}} = 0$ for $j = K+1, \dots, J$, and, then, $\nu_h \in \mathcal{L}_h(\Gamma_{\mathrm{D}})/\mathbb{C}$.

Now, by testing (6.9) with this ν_h, we obtain $\widetilde{\mathbf{grad}}_\Gamma \, (\widetilde{\Phi}_h|_{\Gamma_{\mathrm{D}}}) = \mathbf{0}$. Hence, by testing (6.8) with $(\mathbf{H}_h, \widetilde{\Phi}_h, I_h)$ (which was already shown to belong to $\boldsymbol{\mathcal{Z}}_h^0$), we obtain

$$\mathrm{i}\omega \int_{\Omega_{\mathrm{C}}} \mu |\mathbf{H}_h|^2 + \int_{\Omega_{\mathrm{C}}} \frac{1}{\sigma} |\, \mathbf{curl}\, \mathbf{H}_h|^2 + \mathrm{i}\omega \int_{\Omega_{\mathrm{D}}} \mu |\, \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h|^2 = 0.$$

Hence, $\mathbf{H}_h = \mathbf{0}$ in Ω_{C}, and $\widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h = \mathbf{0}$ in Ω_{D}. Consequently, $\widetilde{\Phi}_h = 0$ in $\mathcal{L}_h(\widetilde{\Omega}_{\mathrm{D}})/\mathbb{C}$, and $I_{hj} = [\![\widetilde{\Phi}_h]\!]_{\Sigma_j} = 0$ for $j = 1, \dots, K$, too.

Thus, it remains only to prove that $\lambda_h = 0$. To do this, first let us show that there exists $(\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{Z}}_h^0$ satisfying $\widetilde{\Psi}_h|_{\Gamma_{\mathrm{D}}} = \lambda_h$. Indeed, let $\widetilde{\Psi}_h \in \mathcal{L}_h(\widetilde{\Omega}_{\mathrm{D}})/\mathbb{C}$ be the unique function in this space satisfying for each vertex P of $\mathcal{T}_h^{\Omega_{\mathrm{D}}}$,

$$\begin{aligned} &\widetilde{\Psi}_h(P) = \lambda_h(P) && \text{if } P \in \Gamma_{\mathrm{D}}, \\ &\widetilde{\Psi}_h(P) = 0 && \text{if } P \notin \Gamma_{\mathrm{D}}. \end{aligned}$$

Let $c_{hj} = [\![\widetilde{\Psi}_h]\!]_{\Sigma_j}$, $j = 1, \ldots, J$. Because of the definition of $\widetilde{\Psi}_h$, clearly $c_h = 0$. Then $\widetilde{\Psi}_h \in \Theta_h$. Finally, let $\mathbf{G}_h \in \boldsymbol{\mathcal{N}}_h(\Omega_{\rm C})$ be the unique function in this space satisfying for each edge ℓ of $\mathcal{T}_h$ such that $\ell \subset \overline{\Omega}_{\rm C}$,

$$\int_\ell \mathbf{G}_h \cdot \mathbf{t}_\ell \, d\gamma = \widetilde{\Psi}_h(P_\ell^+) - \widetilde{\Psi}_h(P_\ell^-) \quad \text{if } \ell \subset \Gamma_{\rm I},$$
$$\int_\ell \mathbf{G}_h \cdot \mathbf{t}_\ell \, d\gamma = 0 \quad \text{if } \ell \not\subset \Gamma_{\rm I}.$$

Therefore, $(\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{Z}}_h^0$, and $\widetilde{\Psi}_h|_{\Gamma_{\rm D}} = \lambda_h$. Now, by testing (6.8) with this $(\mathbf{G}_h, \widetilde{\Psi}_h, c_h)$, since we already know that $\mathbf{H}_h = \mathbf{0}$ in $\Omega_{\rm C}$ and that $\mathbf{grad}\, \widetilde{\Phi}_h = 0$ in $\Omega_{\rm D}$, we obtain

$$\int_{\Gamma_{\rm D}} |\, \mathbf{grad}_\Gamma \, \lambda_h|^2 \, d\Gamma = 0.$$

Then, $\lambda_h = 0$ in $\mathcal{L}_h(\Gamma_{\rm D})/\mathbb{C}$, and we conclude the proof. ∎

Now it is very simple to show that Problems **DHP** and **DLP** are equivalent.

THEOREM 6.4. *Let us assume that the solution* $(\mathbf{H}, \widetilde{\Phi})$ *of Problem* **HP** *satisfies* $\mathbf{H} \in \mathrm{H}^r(\mathbf{curl}, \Omega_{\rm C})$ *and* $\mathbf{grad}\, \widetilde{\Phi} \in \mathrm{H}^r(\Omega_{\rm D})^3$, *with* $r \in (\frac{1}{2}, 1]$.

If $((\mathbf{H}_h, \widetilde{\Phi}_h, I_h), \lambda_h)$ *is a solution of Problem* **DLP**, *then* $(\mathbf{H}_h, \widetilde{\Phi}_h)$ *is a solution of Problem* **DHP**.

Conversely, if $(\mathbf{H}_h, \widetilde{\Phi}_h)$ *is a solution of Problem* **DHP**, *and* $I_{hj} = [\![\widetilde{\Phi}_h]\!]_{\Sigma_j}$, $j = 1, \ldots, J$, *then there exists* $\lambda_h \in \mathcal{L}_h(\Gamma_{\rm D})/\mathbb{C}$ *such that* $((\mathbf{H}_h, \widetilde{\Phi}_h, I_h), \lambda_h)$ *is a solution of Problem* **DLP**.

Proof. Let $((\mathbf{H}_h, \widetilde{\Phi}_h, I_h), \lambda_h)$ be a solution of Problem **DLP**. Since $(\mathbf{H}_h, \widetilde{\Phi}_h, I_h) \in \boldsymbol{\mathcal{Z}}_h$, $(\mathbf{H}_h, \widetilde{\Phi}_h) \in \boldsymbol{\mathcal{W}}_h$ (because of Lemma 6.1), and $I_{hj} = [\![\widetilde{\Phi}_h]\!]_{\Sigma_j}$, $j = 1, \ldots, J$. Therefore, because of (6.7), $\widetilde{\Phi}_h$ satisfies assumption (6.4) in Lemma 6.2. Then, (6.9) implies (5.8).

On the other hand, let $(\mathbf{G}_h, \widetilde{\Psi}_h) \in \boldsymbol{\mathcal{W}}_h^0$ and $c_{hj} = [\![\widetilde{\Psi}_h]\!]_{\Sigma_j}$, $j = 1, \ldots, J$. Because of Lemma 6.1 and (6.2), $(\mathbf{G}_h, \widetilde{\Psi}_h, c_h) \in \boldsymbol{\mathcal{Z}}_h^0$. Since $\mathbf{grad}\, \widetilde{\Psi}_h \times \mathbf{n} = \mathbf{0}$ on $\Gamma_{\rm D}$, because of (6.3) we have $\mathbf{grad}_\Gamma\, (\widetilde{\Psi}_h|_{\Gamma_{\rm D}}) = \mathbf{0}$. Therefore, by testing (6.8) with such $(\mathbf{G}_h, \widetilde{\Psi}_h, c_h)$, we obtain (5.9). Thus, $(\mathbf{H}_h, \widetilde{\Phi}_h)$ is a solution of Problem **DHP**.

Conversely, let $(\mathbf{H}_h, \widetilde{\Phi}_h)$ be a solution of Problem **DHP**. Since the assumptions of Corollary 5.7 are fulfilled, this solution is unique. On the other hand, Theorem 6.3 shows that there also exists a unique solution $((\mathbf{H}'_h, \widetilde{\Phi}'_h, I_h), \lambda_h)$ of Problem **DLP**. But then we have already proved that $(\mathbf{H}'_h, \widetilde{\Phi}'_h)$ is a solution of Problem **DHP**. Hence, $(\mathbf{H}'_h, \widetilde{\Phi}'_h) = (\mathbf{H}_h, \widetilde{\Phi}_h)$, and we conclude the proof. ∎

Problem **DLP** is the one that we have actually implemented. The degrees of freedom for this problem are the following ones:

- for $\mathbf{H}_h \in \boldsymbol{\mathcal{N}}_h(\Omega_{\rm C})$: $\int_\ell \mathbf{H}_h \cdot \mathbf{t}_\ell \, d\gamma$, for all edge $\ell \subset \overline{\Omega}_{\rm C} \setminus \Gamma_{\rm I}$;
- for $\widetilde{\Phi}_h \in \mathcal{L}_h(\widetilde{\Omega}_{\rm D})/\mathbb{C}$: $\widetilde{\Phi}_h(P)$, for all vertices $P \in \overline{\Omega}_{\rm D}$ (one of them set to zero);
- for $I_h \in \mathbb{C}^J$: I_{hj}, $j = 1, \ldots, J$ ($I_{hK+1}, \ldots, I_{hJ}$ are directly computed from $\mathbf{f}$);
- for $\lambda_h \in \mathcal{L}_h(\Gamma_{\rm D})/\mathbb{C}$: $\lambda_h(P)$, for all vertices $P \in \Gamma_{\rm D}$ (one of them set to zero).

Remark 6.2. We have imposed the boundary condition of Problem **DHP** by means of a Lagrange multiplier. However, this is not the only way of doing it. An

alternative procedure consists of using the fact that, for each edge $\ell \subset \Gamma_{\mathrm{D}}$,

$$\widetilde{\Phi}_h(P_\ell^+) - \widetilde{\Phi}_h(P_\ell^-) = \int_\ell \widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{n} \times \left(\widetilde{\mathbf{grad}}\, \widetilde{\Phi}_h \times \mathbf{n} \right) \cdot \mathbf{t}_\ell \, d\gamma$$
$$= \int_\ell \mathbf{n} \times \mathbf{f}_{\mathrm{I}} \cdot \mathbf{t}_\ell \, d\gamma = \int_\ell \mathbf{n} \times \mathbf{f} \cdot \mathbf{t}_\ell \, d\gamma \,.$$

Therefore, the values of $\widetilde{\Phi}_h(P)$ can be obtained for each vertex $P \in \Gamma_{\mathrm{D}}$ by the following procedure:

1. Fix arbitrarily the value of $\widetilde{\Phi}_h$ at a given vertex $P_0 \in \Gamma_{\mathrm{D}}$:

$$\widetilde{\Phi}_h(P_0) = 0$$

   (this can be done because $\widetilde{\Phi}_h \in \Theta_h/\mathbb{C}$).
2. For each other vertex $P \in \Gamma_{\mathrm{D}}$ (those on $\Gamma_{\mathrm{D}} \cap \Sigma_j$, $j = K+1, \ldots, J$, must be counted twice),
   (a) find a path Γ_P joining P_0 with P, which does not cross any $\Sigma_j \cap \Gamma_{\mathrm{D}}$, $j = K+1, \ldots, J$, and which consists of adequately oriented edges $\ell \subset \Gamma_{\mathrm{D}}$:

$$\Gamma_P := \pm\ell_1 \cup \cdots \cup \pm\ell_{N_P};$$

   (b) evaluate

$$\widetilde{\Phi}_h(P) = \pm \int_{\ell_1} \mathbf{n} \times \mathbf{f} \cdot \mathbf{t}_{\ell_1} \, d\gamma \pm \ldots \pm \int_{\ell_{N_P}} \mathbf{n} \times \mathbf{f} \cdot \mathbf{t}_{\ell_{N_P}}.$$

The main drawback of this procedure is that step 2(a) is rather complicated to implement (see [11]). The strategy we have proposed is more expensive than this one in terms of degrees of freedom (one unknown per vertex on Γ_{D} is added, instead of being eliminated). Nevertheless, one neat advantage is that its implementation is quite straightforward.

7. Numerical experiments. In this section we present some numerical results obtained with a code developed by us, which implements in MATLAB the method described above.

We have solved a particular problem with a known analytical solution to validate the computer code and to test the performance and convergence properties of the method. The geometry of the domain is similar to that of an electric furnace with only one electrode.

More precisely, we consider a domain Ω containing a conductor Ω_{C} and dielectric Ω_{D}, as shown in Figure 7.1.

We assume that $\overline{\Omega}_{\mathrm{C}}$ and $\overline{\Omega} = \overline{\Omega}_{\mathrm{C}} \cup \overline{\Omega}_{\mathrm{D}}$ are coaxial cylinders of radius R_{C} and R_{D}, respectively, with height L. To obtain the data for a test problem in this domain with a known analytical solution, we consider that Ω_{C} and Ω are bounded sections of respective infinite cylinders. The electric conductivity σ is taken as a constant in Ω_{C}, and the magnetic permeability μ is constant in the whole Ω. We consider that an alternating current $\mathbf{J}$ goes through the conductor Ω_{C} in the direction of its axis; this current is assumed to be axially symmetric with an intensity $I(t) = I_0 \cos(\omega t)$.

We analyze this problem using a cylindrical coordinate system (r, θ, z) with the z-axis coinciding with the common axis of both cylinders (see Figure 7.1). We denote $\mathbf{e}_r$, $\mathbf{e}_\theta$, and $\mathbf{e}_z$ the unit vectors in the corresponding coordinate directions.

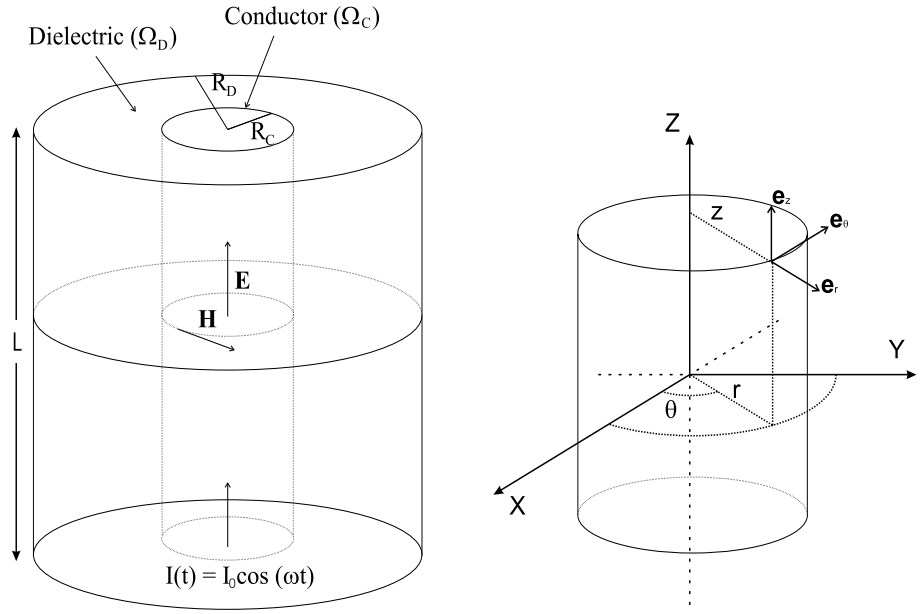

FIG. 7.1. *Sketch of the domain. Coordinate system.*

Because of the assumed conditions on $\mathbf{J}$, only the z-component of the electric field $\mathbf{E} = \frac{1}{\sigma}\mathbf{J}$ does not vanish in the conductor. Moreover, it depends on the radial coordinate r, but it is independent of the other two coordinates z and θ. Consequently, only the θ-component of the magnetic field $\mathbf{H} = \frac{\mathrm{i}}{\omega\mu}\,\mathbf{curl}\,\mathbf{E}$ does not vanish, and it also depends only on the coordinate r. Then, taking into account the expression of the **curl** operator in cylindrical coordinates, we have $\mathbf{H}(r,\theta,z) = H_\theta(r)\mathbf{e}_\theta$, with H_θ satisfying the equation

$$\mathrm{i}\omega\mu H_\theta(r) - \frac{d}{dr}\left\{\frac{1}{\sigma r}\frac{d}{dr}[rH_\theta(r)]\right\} = 0, \qquad r \in (0, R_C),$$

and the boundary conditions

$$|H_\theta(0)| < \infty, \qquad H_\theta(R_C) = \frac{I_0}{2\pi R_C}.$$

To solve this problem, we perform the change of variable $x = \gamma r$, where $\gamma = \sqrt{i\omega\mu\sigma} \in \mathbb{C}$. Then, we obtain the equation

$$x^2\frac{d^2}{dx^2}\widetilde{H}_\theta(x) + x\frac{d}{dx}\widetilde{H}_\theta(x) - (x^2+1)\widetilde{H}_\theta(x) = 0, \qquad x \in (0, \gamma R_C),$$

where $\widetilde{H}_\theta(x) = H_\theta(x/\gamma)$.

This is a Bessel equation, the solution of which is given by $\widetilde{H}_\theta(x) = \alpha \mathrm{I}_1(x)$, with I_1 being the modified Bessel function of the first kind, and α is a constant to be obtained from the boundary condition at $x = \gamma R_C$. Thus, the magnetic field in the conductor is given by

$$\mathbf{H}(r,\theta,z) = \frac{I_0}{2\pi R_C}\frac{\mathrm{I}_1(\gamma r)}{\mathrm{I}_1(\gamma R_C)}\mathbf{e}_\theta, \qquad r \in (0, R_C), \quad \theta \in [0, 2\pi], \quad z \in \mathbb{R}.$$

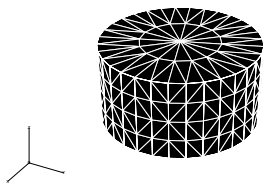

FIG. 7.2. *Coarsest mesh on the conductor domain.*

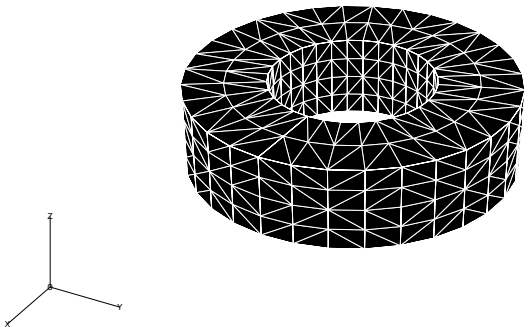

FIG. 7.3. *Coarsest mesh on the dielectric domain.*

On the other hand, the magnetic field created by an infinite circular cylindrical conductor of radius R_{C} carrying an axially aligned and symmetric current of intensity I_0 is computed using Ampère's circuital law (see, for instance, [27]). In cylindrical coordinates it is given by $\mathbf{H}(r,\theta,z) = H_\theta(r)\mathbf{e}_\theta$, with

$$H_\theta(r) = \frac{I_0}{2\pi r}, \qquad r \geq R_{\mathrm{C}}.$$

Once more, the magnitude of H_θ depends only on the radial coordinate r.

Moreover, from this expression, it is also possible to know the multivalued magnetic potential $\widetilde{\Phi}$, which corresponds to the magnetic field in the dielectric domain. Indeed, taking into account the expression of the gradient operator in cylindrical coordinates, we obtain

$$\widetilde{\Phi}(r,\theta,z) = \frac{I_0}{2\pi}\theta, \qquad r > R_{\mathrm{C}}, \quad \theta \in [0,2\pi], \quad z \in \mathbb{R}.$$

Notice that the scalar potential depends only on the variable θ and experiences a jump of magnitude I_0 across the cut surface Σ placed at $\theta = 0$.

Now, we again consider the bounded cylinder of Figure 7.1. The boundary conditions added to define properly this problem are the following:

- On the exterior boundary of the dielectric domain (i.e., the lateral surface of the cylinder Ω and the outer part of its top and bottom surfaces), we consider

TABLE 7.1
$\mathrm{H}(\mathbf{curl},\Omega)$-*norm of errors and exact solution.*

Mesh-size	Number d.o.f.	Computed solution	Error
h	1699	62257.66	36504.31
$h/2$	11285	64063.20	23591.63
$h/3$	35671	64296.90	16646.00
$h/4$	81769	64363.90	12709.90
$h/5$	156491	64391.83	10228.25

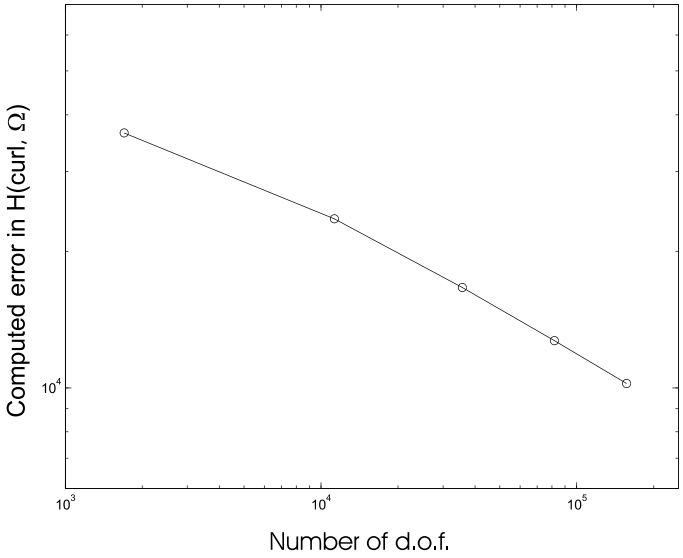

FIG. 7.4. *Error versus number of d.o.f. (log-log scale).*

the condition $\mathbf{H}\times\mathbf{n}=\mathbf{f}$, with $\mathbf{f}$ being obtained from the analytical solution:

$$\mathbf{f}(R_{\mathrm{D}},\theta,z)=-\frac{I_0}{2\pi R_{\mathrm{D}}}\mathbf{e}_z,\qquad \theta\in[0,2\pi],\quad z\in\left[-\tfrac{L}{2},\tfrac{L}{2}\right],$$

$$\mathbf{f}\left(r,\theta,\pm\tfrac{L}{2}\right)=\pm\frac{I_0}{2\pi R_{\mathrm{C}}}\frac{\mathrm{I}_1(\gamma r)}{\mathrm{I}_1(\gamma R_{\mathrm{C}})}\mathbf{e}_r,\qquad r\in[R_{\mathrm{C}},R_{\mathrm{D}}],\quad \theta\in[0,2\pi].$$

- On the top and bottom surfaces of the conducting cylinder Ω_{C}, we impose

$$\mathbf{E}\left(r,\theta,\pm\tfrac{L}{2}\right)\times\mathbf{n}=\mathbf{0},\qquad r\in(0,R_{\mathrm{D}}),\quad \theta\in[0,2\pi],$$

  which is true in this case, because the electric field has vanishing r- and θ-components, and, thus, it aligns with the normal vector $\mathbf{n}$ on these surfaces.

Finally, we have used the following geometrical and physical data:

- $R_{\mathrm{C}}=1\,\mathrm{m}$;
- $R_{\mathrm{D}}=2\,\mathrm{m}$;
- $L=1\,\mathrm{m}$;
- $\sigma=151565.8\,(\Omega\mathrm{m})^{-1}$;
- $\mu=\mu_0=4\pi\,10^{-7}\,\mathrm{Hm}^{-1}$ (magnetic permeability of free space);
- $I_0=62000\,\mathrm{A}$;
- $\omega=50\,\mathrm{H}z$.

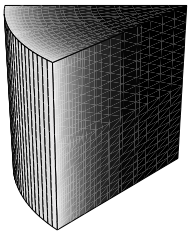

FIG. 7.5. *Intensity of the magnetic field* $|\mathbf{H}_h|$ *in the conductor.*

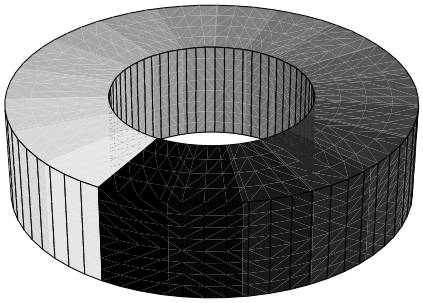

FIG. 7.6. *Magnetic potential* $\widetilde{\Phi}_h$ *in the dielectric.*

To determine the order of convergence, the numerical method has been used on several successively refined meshes, and we have compared the obtained numerical solutions with the analytical one. Figures 7.2 and 7.3 show the coarsest meshes used for conductor and dielectric domains, respectively.

Table 7.1 shows the $\mathrm{H}(\mathbf{curl}, \Omega)$ norms of the approximate solutions $\mathbf{H}_h$ computed on several meshes and their corresponding errors. The total number of degrees of freedom for each mesh are also included.

Figure 7.4 shows a log-log plot of the errors measured in $\mathrm{H}(\mathbf{curl}, \Omega)$-norm versus the number of degrees of freedom for the same meshes. A linear dependence on the mesh-size is obtained by calculating the slope of the line. These $\mathcal{O}(h)$ errors agree with the theoretical results, since the solution is smooth, and, hence, the hypotheses of Theorem 5.4 are fulfilled for $r = 1$.

Finally, Figures 7.5 and 7.6 show the intensity of the computed magnetic field $|\mathbf{H}_h|$ in the conductor domain Ω_{C} and the computed magnetic potential $\widetilde{\Phi}_h$ in the dielectric domain Ω_{D}. The former is presented in a section of Ω_{C} to show its behavior in the interior of this domain.

Acknowledgment. The authors thank Professor Alain Bossavit for many valuable discussions.

A POSTERIORI ERROR ESTIMATES FOR CONTROL PROBLEMS GOVERNED BY STOKES EQUATIONS*

WENBIN LIU† AND NINGNING YAN‡

Abstract. In this paper, we derive a posteriori error estimates for the finite element approximation of distributed optimal control problems governed by the Stokes equations. We obtain a posteriori error estimators for both the state and the control approximation in the L^2 norm and the H^1 norm. These estimates can be used to construct reliable adaptive finite element approximation for the control problems.

Key words. distributed optimal control, finite element approximation, adaptive finite element methods, a posteriori error estimates, Stokes equations

1. Introduction.

Flow control problems are crucial to many engineering applications. For the last decade, it has become a very active and successful research area. Extensive research has been carried out on various theoretical aspects of flow control problems; see, for example, [1], [14], [23], [20], [31], [32], [42], [45], and the references cited therein, for existence of optimal control, optimality conditions, regularity of the optimal solutions, and existence of Lagrange multipliers. The literature for engineering applications is too huge to give even a very brief review here. One can find some useful model optimal control problems of flow motion with the purpose of achieving some desired objective in real-life applications in, for example, [19], [20], [25], [42], [45], and some flavors of aeronautical and chemical engineering problems can be found in, e.g., [26], [27], and [28]. In flow control problems, boundary and shape control are widely used, though body (i.e., distributed) control is also available through a magnetic field, a heat source using radiation, or laser technology; see [20], [25], and [40].

It is obvious that efficient numerical methods are essential to successful applications of flow control (indeed of any other control). Nowadays, the finite element method is undoubtedly the most widely used numerical method in computing optimal control problems, including flow control problems. The literature on finite element approximation of optimal control is huge. Systematic introduction of the finite element method for PDEs and optimal control problems can be found in, for example, [11], [24], [43], and [45]. There have been extensive theoretical studies for finite element approximation of various optimal control problems. For instance, a priori error estimates of finite element approximation were established long ago for the optimal control problems governed by linear elliptic or parabolic state equations; see, for example, [13], [30], and [38]. Furthermore, finite element approximation of some

flow control has been studied, and a priori error estimates have been established; see [22], [23], [20], and [25]. A priori error estimates have also been obtained for a class of state constrained control problems in [48], though the state equation is assumed to be linear. In [33] this assumption has been removed by reformulating the control problem as an abstract optimization problem in some Banach spaces and then applying nonsmooth analysis. In fact, the state equation there can be a variational inequality.

In recent years, the adaptive finite element method has been extensively investigated, beginning with the pioneering work in [7]. Adaptive finite element approximation is among the most important means to boost the accuracy and efficiency of finite element discretizations. It ensures a higher density of nodes in a certain area of the given domain, where the solution is more difficult to approximate, using an a posteriori error indicator. The decision of whether further refinement of the meshes is necessary is based on the estimate of the discretization error. If further refinement is to be performed, then the error indicator is used as a guide to show how the refinement might be accomplished most efficiently. The literature in this area is huge. Some of techniques directly relevant to our work can be found in [6], [37], [46], [49], [50], and [51]. It is our belief that adaptive finite element enhancement is one of the future directions to pursue in developing sophisticated numerical methods for optimal design problems.

Although adaptive finite element approximation is widely used in numerical simulations, it has not yet been *fully* utilized in optimal design. Initial attempts in this aspect have only been reported recently for some design problems; see, e.g., [2], [4], [39], and [47]. However, a posteriori error indicators of a heuristic nature are widely used in most applications. For instance, in some existing work on adaptive finite element approximation of optimal design, the mesh refinement is guided by a posteriori error estimators based on a posteriori error estimates *solely* from the state equation for a fixed control. Thus error information from approximation of the control (design) is not utilized. This strategy was found to be inefficient in recent numerical experiments (see [8]). In other work (see [12]), a preassigned mesh refinement scheme is applied around the possible singularity points of the state equation. Although these methods may work well in some particular applications, they cannot be applied confidently in general. It is unlikely that the potential power of adaptive finite element approximation has been fully utilized due to the lack of more sophisticated a posteriori error indicators.

It is not straightforward to rigorously derive suitable a posteriori error estimators or monitors for general optimal control problems. For instance, it seems difficult to apply the gradient recovery techniques as the control is normally not differentiable. Recovering approximation in function value is in general difficult. For a similar reason, it also seems difficult to apply the local solution strategy.

Very recently, some error indicators of residual type were developed in [8], [9], [34], and [36]. These error estimators are based on a posteriori estimation of the discretization error for the state *and* the control (design). When there exists no inequality control constraint in a control problem, normally the optimality conditions consist of coupled partial differential equations only. Consequently, one may be able to write down the dual system of the *whole* optimality conditions and then apply the adjoint approach (see [16], [17], [44]) to obtain some error estimators. For example, one can then apply the weighted a posteriori error estimation technique to obtain a posteriori estimators for *objective functional* approximation error; see [8] and [9]. Such estimators have indeed been derived for some unconstrained elliptic control problems, and

have proved quite efficient in the numerical tests carried out in [8].

However, there frequently exist some inequality constraints for the control in applications. In such cases, the optimality conditions often contain a variational inequality and then have some very different properties. For example, the optimal control and the state may have very different regularity. Thus, it is not clear how to apply the adjoint techniques used in [8] and [9] to general constrained control problems. In our work, constrained cases are studied via residual estimation using the norms of energy type. A posteriori error estimators are derived for some constrained control problems governed by elliptic equations; see [34] and [36]. However, to our best knowledge, there has been a lack of a posteriori error indicators for finite element approximation of any constrained flow control problem, which is immensely important and yet far more complicated to analyze than an elliptic control problem.

In this work we investigate optimal control governed by stationary Stokes flows with general control constraints. The purpose of studying control for Stokes flows is twofold: On the one hand, the Stokes equations model the flows with low velocity, or very viscous fluids, e.g., many biological flows and non-Newtonian flows. Thus, such a control model can be used as the first approximation of more complex control problems; see [41], [42], and [45] for some examples. On the other hand, some of the problems encountered when studying control for the full Navier–Stokes equations are already present in this simpler model. Thus this investigation will pave the way for further research on adaptive finite element approximation of optimal control for the Navier–Stokes equations; see Remark 3.2 for some details.

In this paper we derive a posteriori error estimates for the conforming finite element approximation of distributed optimal control governed by the two-dimensional Stokes equations. The case of boundary control can be dealt with similarly by combining the ideas and techniques used in [36]. The obtained error estimates can then be used as a posteriori error indicators to construct reliable adaptive finite element methods.

The plan of the paper is as follows: In section 2 we shall give a weak formula for the control problem and then discuss the finite element approximation of the control problem. In section 3, a posteriori error bounds are derived for the control problem in L^2 and H^1 norms. Some applications are presented in section 4.

Let Ω and $\Omega_{\mathbf{U}}$ be two bounded open sets in R^2 with Lipschitz boundaries $\partial\Omega$ and $\partial\Omega_U$, respectively. In this paper we adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with norm $\|\cdot\|_{W^{m,q}(\Omega)}$ and seminorm $|\cdot|_{W^{m,q}(\Omega)}$ (or $\|\cdot\|_{m,q,\Omega}$, $|\cdot|_{m,q,\Omega}$ for simplification). We shall extend these (semi)norms to vector functions whose components belong to $W^{m,p}(\Omega)$. We set $W_0^{m,q}(\Omega) \equiv \{w \in W^{m,q}(\Omega) : w|_{\partial\Omega} = 0\}$. We denote $W^{m,2}(\Omega)$ ($W_0^{m,2}(\Omega)$) by $H^m(\Omega)$ ($H_0^m(\Omega)$). In addition, c or C denotes a general positive constant independent of h.

2. Finite element approximation of optimal control problems. In this section, we discuss the finite element approximation of distributed convex optimal control problems governed by the Stokes equations. Let $\mathbf{Y} = (H_0^1(\Omega))^2$, $\mathbf{U} = (L^2(\Omega_U))^2$, $\mathbf{H} = (L^2(\Omega))^2$, and $Q = L_0^2(\Omega) = \{q \in L^2(\Omega), \int_\Omega q = 0\}$. In this paper, the state space and the control space will be $\mathbf{Y} \times Q$ and $\mathbf{U}$, respectively. Let B be a linear continuous operator from $\mathbf{U}$ to $\mathbf{H}$, and let $\mathbf{K}$ be a closed convex subset of $\mathbf{U}$. Assume that g and h are strictly convex functionals which are differentiable on $\mathbf{H}$ and that $h(\mathbf{u}) \to +\infty$ as $\|\mathbf{u}\|_{\mathbf{U}} \to \infty$.

We are interested in the following optimal control problem: find $(\mathbf{y}, r, \mathbf{u}) \in$

$\mathbf{Y} \times Q \times \mathbf{U}$ such that

$$\begin{aligned} &\min_{\mathbf{u}\in\mathbf{K}\subset\mathbf{U}}\{g(\mathbf{y})+h(\mathbf{u})\},\\ -\Delta\mathbf{y}+\nabla r &= \mathbf{f}+B\mathbf{u} \text{ in } \Omega,\\ \operatorname{div}\mathbf{y} &= 0 \text{ in } \Omega,\\ \mathbf{y} &= 0 \text{ on } \partial\Omega, \end{aligned}$$

where $\mathbf{f} \in \mathbf{L} = (L^2(\Omega))^2$, $\mathbf{K}$ is a closed convex set in $\mathbf{U}$, and B is a continuous linear operator from $\mathbf{U}$ to $\mathbf{H}$. To consider the finite element approximation of the above optimal control problem, we have to give a weak formula for the state equations. Let

$$a(\mathbf{y},\mathbf{w}) = \int_\Omega \nabla\mathbf{y}\cdot\nabla\mathbf{w} \qquad \forall \mathbf{y},\mathbf{w}\in\mathbf{Y},$$

$$b(\mathbf{v},r) = \int_\Omega r\,\operatorname{div}\mathbf{v} \qquad \forall(\mathbf{v},r)\in\mathbf{Y}\times Q,$$

$$(\mathbf{f}+B\mathbf{u},\mathbf{w}) = \int_\Omega (\mathbf{f}+B\mathbf{u})\cdot\mathbf{w} \qquad \forall \mathbf{u},\mathbf{w}\in\mathbf{H}\times\mathbf{Y}.$$

Then the standard weak formula for the state equations reads as follows: Given $\mathbf{f}\in\mathbf{L}$, find $(\mathbf{y}(\mathbf{u}), r(\mathbf{u}))\in\mathbf{Y}\times Q$ such that

$$a(\mathbf{y}(\mathbf{u}),\mathbf{w}) - b(\mathbf{w},r(\mathbf{u})) = (\mathbf{f}+B\mathbf{u},\mathbf{w}) \qquad \forall\mathbf{w}\in\mathbf{Y}, \tag{2.1}$$

$$b(\mathbf{y}(\mathbf{u}),\phi) = 0 \qquad \forall\phi\in Q. \tag{2.2}$$

For the above problem, it is well known that the following Babuska–Brezzi condition holds (see [18], for example).

LEMMA 2.1. *Let* $ß = (H_0^1(\Omega))^2 \times L_0^2(\Omega)$, *and define a bilinear form* $Ł$ *on* $ß\times ß$ *by* $Ł([\mathbf{u},p];[\mathbf{v},q]) := a(\mathbf{u},\mathbf{v}) - b(\mathbf{v},p) - b(\mathbf{u},q)$; *then*

$$\inf_{[\mathbf{u},p]\in ß}\sup_{[\mathbf{v},q]\in ß}\frac{Ł([\mathbf{u},p];[\mathbf{v},q])}{(|\mathbf{u}|_1+\|p\|_0)(|\mathbf{v}|_1+\|q\|_0)} \ge c > 0,$$

where c *is a constant independent of* $\mathbf{u}$, $\mathbf{v}$, p, *and* q.

Furthermore, the following a priori estimates are well known (see [18], for example).

LEMMA 2.2. *Assume that* Ω *is convex. Let* (Ψ,ρ) *be the solution of the following equation:*

$$\begin{aligned} a(\Psi,\mathbf{w}) \pm b(\mathbf{w},\rho) &= (\Phi,w) \qquad \forall\mathbf{w}\in(H_0^1(\Omega))^2,\\ b(\Psi,q) &= 0 \qquad \forall q\in L_0^2(\Omega), \end{aligned} \tag{2.3}$$

where $a(\cdot,\cdot)$ *and* $b(\cdot,\cdot)$ *are defined as above. Then*

$$\|\Psi\|_{2,\Omega} + \|\rho\|_{1,\Omega} \le C\|\Phi\|_{0,\Omega}.$$

Using the weak formula, our control problem can be restated as the following (SCP):

$$\begin{aligned} &\min_{\mathbf{u}\in\mathbf{K}\subset\mathbf{U}}\{g(\mathbf{y})+h(\mathbf{u})\},\\ a(\mathbf{y}(\mathbf{u}),\mathbf{w}) - b(\mathbf{w},r(\mathbf{u})) &= (\mathbf{f}+B\mathbf{u},\mathbf{w}) \qquad \forall\mathbf{w}\in\mathbf{Y},\\ b(\mathbf{y}(\mathbf{u}),\phi) &= 0 \qquad \forall\phi\in Q. \end{aligned} \tag{2.4}$$

It is well known (see, e.g., [31]) that the control problem (SCP) has a unique solution $(\mathbf{y}^*, r^*, \mathbf{u}^*)$ and that $(\mathbf{y}^*, r^*, \mathbf{u}^*)$ is the solution of (SCP) if and only if there is a co-state $(\mathbf{p}^*, s^*) \in \mathbf{Y} \times Q$ such that $(\mathbf{y}^*, r^*, \mathbf{p}^*, s^*, \mathbf{u}^*)$ satisfies the following optimality conditions (SCP–OPT):

$$\begin{aligned} a(\mathbf{y}^*, \mathbf{w}) - b(\mathbf{w}, r^*) &= (\mathbf{f} + B\mathbf{u}^*, \mathbf{w}) && \forall \mathbf{w} \in \mathbf{Y}, \\ b(\mathbf{y}^*, \phi) &= 0 && \forall \phi \in Q, \\ a(\mathbf{q}, \mathbf{p}^*) + b(\mathbf{q}, s^*) &= (g'(\mathbf{y}^*), \mathbf{q}) && \forall \mathbf{q} \in \mathbf{Y}, \\ b(\mathbf{p}^*, \psi) &= 0 && \forall \psi \in Q, \\ (h'(\mathbf{u}^*) + B^*\mathbf{p}^*, \mathbf{v} - \mathbf{u}^*)_{\mathbf{U}} &\geq 0 && \forall \mathbf{v} \in \mathbf{K} \subset \mathbf{U}, \end{aligned} \tag{2.5}$$

where B^* is the adjoint operator of B, and $(\cdot, \cdot)_{\mathbf{U}}$ is the inner product of $\mathbf{U}$.

We note that for any $(\mathbf{y}, \mathbf{u}) \in \mathbf{V} \times \mathbf{U}$, $g'(\mathbf{y})$ and $h'(\mathbf{u})$ are in $\mathbf{H} = \mathbf{H}' = (L^2(\Omega))^2$ and $\mathbf{U}' = \mathbf{U} = (L^2(\Omega_{\mathbf{U}}))^2$, respectively. Therefore they can be viewed as functions in $(L^2(\Omega))^2$ and $(L^2(\Omega_{\mathbf{U}}))^2$, respectively, from the well-known representation theorem in a Hilbert space.

Let us consider finite element approximation of the control problem (SCP). Here we consider only triangular elements as they are among the most widely used ones. Also, we consider only conforming elements for the state and co-state equations.

Let Ω^h be a polygonal approximation of Ω with boundary $\partial\Omega^h$. Let T^h be a partitioning of Ω^h into disjoint regular triangular τ, so that $\bar{\Omega}^h = \bigcup_{\tau \in T^h} \bar{\tau}$. Each element has at most one edge on $\partial\Omega^h$, and $\bar{\tau}$ and $\bar{\tau}'$ have either only one common vertex or a whole edge if τ and $\tau' \in T^h$. We further require that $P_i \in \partial\Omega^h \Rightarrow P_i \in \partial\Omega$, where $\{P_i\}$ $(i = 1 \dots J)$ is the vertex set associated with the triangulation T^h. For ease of exposition, we will assume that $\Omega^h = \Omega$, though all the results can be extended to the more general case where $\Omega^h \subset \Omega$.

Associated with T^h is a finite dimensional subspace $\mathbf{Y}^h \times Q^h$ of $(H_0^1(\Omega^h))^2 \times L_0^2(\Omega^h)$. In this paper, we assume that $\mathbf{Y}^h$ and Q^h contain the functions which are piecewise polynomials of degree at least 1 and 0, respectively, and of degree at most l and m, respectively.

Then the discretized weak formula of the state equations reads as

$$a(\mathbf{y}_h, \mathbf{w}_h) - b(\mathbf{w}_h, r_h) = (\mathbf{f} + B\mathbf{u}_h, \mathbf{w}_h) \qquad \forall \mathbf{w}_h \in \mathbf{Y}^h \subset \mathbf{Y}, \tag{2.6}$$

$$b(\mathbf{y}_h, \phi_h) = 0 \qquad \forall \phi_h \in Q^h \subset Q. \tag{2.7}$$

In order to guarantee that the above problem is well-posed, we assume that the spaces $\mathbf{Y}^h$ and Q^h satisfy the well-known Babuska–Brezzi conditions: There is constant $c > 0$, independent of h, such that

$$\inf_{r_h \in Q^h} \sup_{\mathbf{y}_h \in \mathbf{Y}^h} (r_h, \nabla \cdot \mathbf{y}_h) / \|r_h\|_{0,\Omega} \|\mathbf{y}_h\|_{1,\Omega} \geq c.$$

These above assumptions are satisfied by many finite elements, e.g., the Taylor–Hood elements and the mini elements; see, [3], [15], [18], and [50] for the details.

Let $\Omega_{\mathbf{U}}^h$ be a polygonal approximation to Ω_U with boundary $\partial\Omega_{\mathbf{U}}^h$. Let $T_{\mathbf{U}}^h$ be a partitioning of $\Omega_{\mathbf{U}}^h$ into disjoint regular triangular $\tau_{\mathbf{U}}$ so that $\bar{\Omega}_{\mathbf{U}}^h = \bigcup_{\tau_{\mathbf{U}} \in T_{\mathbf{U}}^h} \bar{\tau}_{\mathbf{U}}$. Each element has at most one edge on $\partial\Omega_{\mathbf{U}}^h$, and $\bar{\tau}_{\mathbf{U}}$ and $\bar{\tau}'_{\mathbf{U}}$ have either only one common vertex or a whole edge if $\tau_{\mathbf{U}}$ and $\tau'_{\mathbf{U}} \in T_{\mathbf{U}}^h$. We further require that $P_i \in \partial\Omega_{\mathbf{U}}^h \Rightarrow P_i \in \partial\Omega_{\mathbf{U}}$, where $\{P_i\}$ $(i = 1 \dots J)$ is the vertex set associated with the triangulation $T_{\mathbf{U}}^h$.

Associated with $T_{\mathbf{U}}^h$ is another finite dimensional subspace $W_{\mathbf{U}}^h$ of $L^2(\Omega_{\mathbf{U}}^h)$, such that $\chi_{|\tau_{\mathbf{U}}}$ is a polynomial of k-order ($k \geq 0$) for all $\chi \in W_{\mathbf{U}}^h$ and $\tau \in T_{\mathbf{U}}^h$. Here there is no requirement for the continuity or boundary conditions. Due to the limited regularity of the optimal control $\mathbf{u}$ (which is at most in $(H^1(\Omega_{\mathbf{U}}))^2$ in general), we consider only the piecewise constant elements, that is, $k = 0$. For ease of exposition, we again assume that $\Omega_{\mathbf{U}}^h = \Omega_{\mathbf{U}}$.

Let $\mathbf{U}^h = (W_{\mathbf{U}}^h)^2$. It is easy to see that $\mathbf{U}^h \subset \mathbf{U}$. Let h_τ ($h_{\tau_{\mathbf{U}}}$) denote the maximum diameter of the element τ ($\tau_{\mathbf{U}}$) in T^h ($T_{\mathbf{U}}^h$); let ρ_τ ($\rho_{\tau_{\mathbf{U}}}$) denote the diameter of the largest ball contained in τ ($\tau_{\mathbf{U}}$). Assume that there is a regularity constant R such that $1 \leq \max_{\tau \in T^h}(h_\tau/\rho_\tau) \leq R$ ($1 \leq \max_{\tau_{\mathbf{U}} \in T_{\mathbf{U}}^h}(h_{\tau_{\mathbf{U}}}/\rho_{\tau_{\mathbf{U}}}) \leq R$). Let $h = \max_{\tau \in T^h} h_\tau$ ($h_{\mathbf{U}} = \max_{\tau_{\mathbf{U}} \in T_{\mathbf{U}}^h} h_{\tau_{\mathbf{U}}}$).

Then a possible finite element approximation of (SCP) is the control problem $(\mathrm{SCP})^h$:

$$\min_{\mathbf{u_h} \in \mathbf{K^h} \subset \mathbf{U_h}} \{g(\mathbf{y}_h) + h(\mathbf{u}_h)\},$$

$$\begin{aligned} a(\mathbf{y}_h, \mathbf{w}_h) - b(\mathbf{w}_h, r_h) &= (\mathbf{f} + B\mathbf{u}_h, \mathbf{w}_h) \qquad \forall \mathbf{w}_h \in \mathbf{Y}^h \subset \mathbf{Y}, \\ b(\mathbf{y}_h, \phi_h) &= 0 \qquad \forall \phi_h \in Q^h \subset Q, \end{aligned} \tag{2.8}$$

where $\mathbf{K}^h$ is a closed convex set in $\mathbf{U}^h$, an approximation of $\mathbf{K}$.

It follows that the control problem $(\mathrm{SCP})^h$ has a unique solution $(\mathbf{y}_h^*, r_h^*, \mathbf{u}_h^*)$ and that $(\mathbf{y}_h^*, r_h^*, \mathbf{u}_h^*) \in \mathbf{Y}^h \times Q^h \times \mathbf{U}^h$ is the solution of $(\mathrm{SCP})^h$ if and only if there is a co-state $(\mathbf{p}_h^*, s_h^*) \in \mathbf{Y}^h \times Q^h$ such that $(\mathbf{y}_h^*, r_h^*, \mathbf{p}_h^*, s_h^*, \mathbf{u}_h^*)$ satisfies the following optimality conditions $(\mathrm{SCP\text{–}OPT})^h$:

$$\begin{aligned} a(\mathbf{y}_h^*, \mathbf{w}_h) - b(\mathbf{w}_h, r_h^*) &= (\mathbf{f} + B\mathbf{u}_h^*, \mathbf{w}_h) \qquad \forall \mathbf{w}_h \in \mathbf{Y}^h \subset \mathbf{Y}, \\ b(\mathbf{y}_h^*, \phi_h) &= 0 \qquad \forall \phi_h \in Q^h \subset Q, \\ a(\mathbf{q}_h, \mathbf{p}_h^*) + b(\mathbf{q}_h, s_h^*) &= (g'(\mathbf{y}_h^*), \mathbf{q}_h) \qquad \forall \mathbf{q}_h \in \mathbf{Y}^h \subset \mathbf{Y}, \\ b(\mathbf{p}_h^*, \psi_h) &= 0 \qquad \forall \psi_h \in Q^h \subset Q, \\ (h'(\mathbf{u}_h^*) + B^*\mathbf{p}_h^*, \mathbf{v}_h - \mathbf{u}_h^*)_{\mathbf{U}} &\geq 0 \qquad \forall \mathbf{v}_h \in \mathbf{K}^h \subset \mathbf{U}^h \subset \mathbf{U}. \end{aligned} \tag{2.9}$$

To derive a posteriori error estimates, we need some stable interpolators from $\mathbf{Y}$ to $\mathbf{Y}^h$, and from Q to Q^h, respectively. These are given in the following lemmas, which are important in deriving residual-type a posteriori error estimates. These lemmas are well known, and can be found in, e.g., [11], [29], and [46].

LEMMA 2.3 (see [11]). *Let π_h be the standard piecewise linear Lagrange interpolation operator. Let $\bar{\pi}_h$ be such that*

$$\bar{\pi}_h p|_\tau = \int_\tau p/|\tau| \qquad \forall p \in L^2(\tau),\ \tau \in T^h,$$

where $|\tau|$ is the measure of τ. Then for $1 \leq q \leq \infty$ and $v \in W^{2,q}(\tau)$, $p \in W^{1,q}(\tau)$,

$$|v - \pi_h v|_{W^{m,q}(\tau)} \leq C h_\tau^{2-m} |v|_{W^{2,q}(\tau)}, \qquad m = 0, 1,$$

and

$$\|p - \bar{\pi}_h p\|_{L^q(\tau)} \leq C h_\tau |p|_{W^{1,q}(\tau)}.$$

LEMMA 2.4 (see [46]). *Let $\hat{\pi}_h$ be the average interpolation operator defined in* [46]. *For $m = 0$ or 1, $1 \leq q \leq \infty$, and $v \in W^{1,q}(\Omega)$,*

$$|v - \hat{\pi}_h v|_{W^{m,q}(\tau)} \leq \sum_{\bar{\tau}' \cap \bar{\tau} \neq \emptyset} C h_\tau^{1-m} |v|_{W^{1,q}(\tau')}.$$

LEMMA 2.5 (see [29]). *For $v \in W^{1,q}(\tau)$, $1 \le q < \infty$,*

$$\|v\|_{W^{0,q}(\partial\tau)} \le C(h_\tau^{-\frac{1}{q}}\|v\|_{W^{0,q}(\tau)} + h_\tau^{1-\frac{1}{q}}|v|_{W^{1,q}(\tau)}).$$

3. A posteriori error estimators for Stokes flow control. In order to obtain a numerical solution of acceptable accuracy for the optimal control problem, the finite element meshes have to be refined or adjusted according to a mesh refinement scheme. A widely used approach in engineering is adaptive finite element approximation. At the heart of any adaptive finite element method is an a posteriori error indicator. Adaptive finite element approximation refines or adjusts only the area where the error indicator is large so that a high density of nodes is distributed over the area where the solution is difficult to approximate. Therefore, the error indicator has to reflect reliably the approximation error distribution over the computational domain.

In this section we derive a posteriori error estimators for the optimal control of Stokes flows. It is fairly clear that this is not an easy task, as the solution of the control problem satisfies a complicated coupled variational inequality system (SCP–OPT). There seems to be no existing work in the literature on a posteriori error bounds for a system of such a type. Very recently in [34], [35], and [36] a posteriori error estimates were derived for the finite element approximation of constrained elliptic optimal control problems with distributed or boundary control. In general, the finite element approximation of a flow control problem is more complicated to analyze than that of an elliptic control problem. For example, one has to use the Babuska–Brezzi conditions to handle the mixed finite element formulations. Furthermore, we shall derive sharper a posteriori error estimates for the control approximation and error estimates in the L^2 norm for the state and co-state, since for the control problems of this type, one normally would be more interested in the approximation error of the values of the state and co-state than in their gradient. To this end, we have to modify some techniques from the adjoint approach. Although some of the ideas and techniques used in [34] and [36] are adopted here, we believe that there are substantial differences between the two problems in both the estimates obtained and the methods used.

We first derive a posteriori error bounds for the approximation of the optimal control of (SCP).

We shall first assume that the discretized constraint set $\mathbf{K}^h$ is such that $\mathbf{K}^h \subset \mathbf{K}$. For many cases, it is not difficult to construct such an approximation of $\mathbf{K}$. We shall briefly examine how to relax this condition at the end of this section. We shall further assume that there is a constant $c > 0$ such that

$$(h'(\mathbf{u}) - h'(\mathbf{v}), \mathbf{u} - \mathbf{v})_{\mathbf{U}} \ge c\|\mathbf{u} - \mathbf{v}\|_{\mathbf{U}}^2.$$

We first establish an important lemma for the approximation of the optimal control of (SCP).

LEMMA 3.1. *Let $(\mathbf{y}^*, r^*, \mathbf{p}^*, s^*, \mathbf{u}^*)$ and $(\mathbf{y}_h^*, r_h^*, \mathbf{p}_h^*, s_h^*, \mathbf{u}_h^*)$ be the solutions of (2.5) and (2.9), respectively. Assume that $(B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*))|_{\tau_{\mathbf{U}}} \in (H^1(\tau_{\mathbf{U}}))^2$ and that there is a $\mathbf{v}_h \in \mathbf{K}^h$ such that*

$$|(B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*), \mathbf{v}_h - \mathbf{u}^*)_{\mathbf{U}}| \le C\sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}|B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_{\mathbf{U}}}\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\tau_{\mathbf{U}}}. \tag{3.1}$$

Then we have

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}^2 \le C\sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2|B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_{\mathbf{U}}}^2 + C\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2, \tag{3.2}$$

where $\mathbf{p}(\mathbf{u}_h^*)$ *is the solution of the following system:*

$$\begin{aligned} a(\mathbf{y}(\mathbf{u}_h^*),\mathbf{w}) - b(\mathbf{w}, r(\mathbf{u}_h^*)) &= (\mathbf{f} + B\mathbf{u}_h^*, \mathbf{w}) && \forall \mathbf{w} \in \mathbf{Y}, \\ b(\mathbf{y}(\mathbf{u}_h^*), \phi) &= 0 && \forall \phi \in Q, \\ a(\mathbf{q}, \mathbf{p}(\mathbf{u}_h^*)) + b(\mathbf{q}, s(\mathbf{u}_h^*)) &= (g'(\mathbf{y}(\mathbf{u}_h^*)), \mathbf{q}) && \forall \mathbf{q} \in \mathbf{Y}, \\ b(\mathbf{p}(\mathbf{u}_h^*), \psi) &= 0 && \forall \psi \in Q. \end{aligned} \tag{3.3}$$

Proof. It follows from (SCP–OPT)–(SCP–OPT)^h that for all $\mathbf{v}_h \in \mathbf{K}^h \subset \mathbf{K}$,

$$\begin{aligned} c\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}^2 &\le (h'(\mathbf{u}^*), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} - (h'(\mathbf{u}_h^*), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} \\ &\le -(B^*\mathbf{p}^*, \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} - (h'(\mathbf{u}_h^*), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} \\ &= -(B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} + (B^*(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} \\ &\quad + (B^*(\mathbf{p}(\mathbf{u}_h^*) - \mathbf{p}^*), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} \\ &= -(B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*), \mathbf{u}^* - \mathbf{v}_h)_\mathbf{U} + (B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*), \mathbf{u}_h^* - \mathbf{v}_h)_\mathbf{U} \\ &\quad + (B^*(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U} + (g'(\mathbf{y}(\mathbf{u}_h^*)) - g'(\mathbf{y}^*), \mathbf{y}^* - \mathbf{y}(\mathbf{u}_h^*)) \\ &\le (B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*), \mathbf{v}_h - \mathbf{u}^*)_\mathbf{U} + (B^*(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \mathbf{u}^* - \mathbf{u}_h^*)_\mathbf{U}. \end{aligned}$$

Hence,

$$c\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}^2 \le C\sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}}^2 |B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_\mathbf{U}}^2 + C\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2 + \frac{c}{2}\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}^2.$$

This proves the lemma.

In the following we first derive a posteriori error estimates using the energy norms. We bound up $\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}$ with the energy norms and then obtain the following.

THEOREM 3.1. *Let* $(\mathbf{y}^*, r^*, \mathbf{p}^*, s^*, \mathbf{u}^*)$ *and* $(\mathbf{y}_h^*, r_h^*, \mathbf{p}_h^*, s_h^*, \mathbf{u}_h^*)$ *be the solutions of* (2.5) *and* (2.9)*, respectively. Assume that all the conditions in Lemma* 3.1 *hold. Then*

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_\mathbf{U}^2 + \|\mathbf{y}^* - \mathbf{y}_h^*\|_\mathbf{Y}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_\mathbf{Y}^2 \le C\hat{\eta}^2, \tag{3.4}$$

where

$$\hat{\eta}^2 = \sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}}^2 |B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_\mathbf{U}}^2 + \hat{\eta}_1^2,$$

where

$$\begin{aligned} \hat{\eta}_1^2 = &\sum_\tau h_\tau^2 \int_\tau (\Delta\mathbf{p}_h^* + \nabla s_h^* + g'(\mathbf{y}_h^*))^2 + \sum_l h_l \int_l [\mathbf{A}_l]^2 + \|\mathrm{div}\mathbf{p}_h^*\|_{0,\Omega}^2 \\ &+ \sum_\tau h_\tau^2 \int_\tau (\Delta\mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + B\mathbf{u}_h^*)^2 + \sum_l h_l \int_l [\mathbf{D}_l]^2 + \|\mathrm{div}\mathbf{y}_h^*\|_{0,\Omega}^2, \end{aligned}$$

where h_l *is the size of the edge* l*;* $[\mathbf{A}_l]$ *and* $[\mathbf{D}_l]$ *are jumps on the edge* $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^2$ *defined by*

$$[\mathbf{D}_l] = ((\nabla\mathbf{y}_h^*)_{\tau_l^1} - (\nabla\mathbf{y}_h^*)_{\tau_l^2}) \cdot \mathbf{n} - (r_h^*|_{\tau_l^1} - r_h^*|_{\tau_l^2})\mathbf{n},$$

$$[\mathbf{A}_l] = ((\nabla\mathbf{p}_h^*)_{\tau_l^1} - (\nabla\mathbf{p}_h^*)_{\tau_l^2}) \cdot \mathbf{n} + (s_h^*|_{\tau_l^1} - s_h^*|_{\tau_l^2})\mathbf{n},$$

where $\mathbf{n}$ *is the outer normal direction of* τ_l^1*. For ease of exposition, we let* $[\mathbf{A}_l] = [\mathbf{D}_l] = 0$ *when* $l \subset \partial\Omega$*.*

Proof. We need only to estimate $\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2$. Let $\mathbf{E_p} = \mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)$, and $E_s = s_h^* - s(\mathbf{u}_h^*)$. By Lemma 2.1, there exist $\mathbf{q}$, $\psi \in \mathbf{Y} \times Q$ such that

$$\begin{aligned} &c(\|\mathbf{E_p}\|_{1,\Omega} + \|E_s\|_{0,\Omega})(\|\mathbf{q}\|_{1,\Omega} + \|\psi\|_{0,\Omega}) \\ &\le (\nabla\mathbf{q}, \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}\mathbf{q}, s_h^* - s(\mathbf{u}_h^*)) + (\mathrm{div}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \psi). \end{aligned}$$

Let $\mathbf{q}_I = \hat{\pi}_h\mathbf{q} \in \mathbf{Y}^h$ be the interpolations of $\mathbf{q}$ defined in Lemma 2.4. By (2.9), (3.3) and Lemmas 2.4 and 2.5,

$$\begin{aligned} &c(\|\mathbf{E_p}\|_{1,\Omega} + \|E_s\|_{0,\Omega})(\|\mathbf{q}\|_{1,\Omega} + \|\psi\|_{0,\Omega}) \\ &\le (\nabla\mathbf{q}, \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}\mathbf{q}, s_h^* - s(\mathbf{u}_h^*)) + (\mathrm{div}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \psi) \\ &= (\nabla(\mathbf{q} - \mathbf{q}_I), \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}(\mathbf{q} - \mathbf{q}_I), s_h^* - s(\mathbf{u}_h^*)) + (\nabla\mathbf{q}_I, \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) \\ &\quad + (\mathrm{div}\mathbf{q}_I, s_h^* - s(\mathbf{u}_h^*)) + (\mathrm{div}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \psi) \\ &= -\sum_\tau \int_\tau \Delta(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))(\mathbf{q} - \mathbf{q}_I) + \sum_\tau \int_{\partial\tau} \frac{\partial}{\partial n}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))(\mathbf{q} - \mathbf{q}_I) \\ &\quad - \sum_\tau \int_\tau \nabla(s_h^* - s(\mathbf{u}_h^*))(\mathbf{q} - \mathbf{q}_I) + \sum_\tau \int_{\partial\tau} (s_h^* - s(\mathbf{u}_h^*))(\mathbf{q} - \mathbf{q}_I) \cdot \mathbf{n} \\ &\quad + (g'(\mathbf{y}_h^*) - g'(\mathbf{y}(\mathbf{u}_h^*)), \mathbf{q}_I) + (\mathrm{div}\mathbf{p}_h^*, \psi) \\ &= \sum_\tau \int_\tau (-\Delta\mathbf{p}_h^* - \nabla s_h^* - g'(\mathbf{y}(\mathbf{u}_h^*)))(\mathbf{q} - \mathbf{q}_I) + \sum_l \int_l [\mathbf{A}_l](\mathbf{q} - \mathbf{q}_I) \\ &\quad + (g'(\mathbf{y}_h^*) - g'(\mathbf{y}(\mathbf{u}_h^*)), \mathbf{q}_I) + (\mathrm{div}\mathbf{p}_h^*, \psi) \\ &= \sum_\tau \int_\tau (-\Delta\mathbf{p}_h^* - \nabla s_h^* - g'(\mathbf{y}_h^*))(\mathbf{q} - \mathbf{q}_I) + (g'(\mathbf{y}_h^*) - g'(\mathbf{y}(\mathbf{u}_h^*)), \mathbf{q} - \mathbf{q}_I) \\ &\quad + \sum_l \int_l [\mathbf{A}_l](\mathbf{q} - \mathbf{q}_I) + (g'(\mathbf{y}_h^*) - g'(\mathbf{y}(\mathbf{u}_h^*)), \mathbf{q}_I) + (\mathrm{div}\mathbf{p}_h^*, \psi) \\ &\le C\bigg(\sum_\tau h_\tau^2 \int_\tau (\Delta\mathbf{p}_h^* + g'(\mathbf{y}_h^*) + \nabla s_h^*)^2 + \sum_l h_l \int_l [\mathbf{A}_l]^2 + \|\mathrm{div}\mathbf{p}_h^*\|_{0,\Omega}^2 \\ &\quad + \|\mathbf{y}(\mathbf{u}_h^*) - \mathbf{y}_h^*\|_{0,\Omega}^2\bigg)^{\frac{1}{2}} (\|\mathbf{q}\|_{1,\Omega} + \|\psi\|_{0,\Omega}). \end{aligned}$$

Then, it follows that

$$\begin{aligned} \|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{1,\Omega} \le C\bigg(&\sum_\tau h_\tau^2 \int_\tau (\Delta\mathbf{p}_h^* + g'(\mathbf{y}_h^*) + \nabla s_h^*)^2 + \sum_l h_l \int_l [\mathbf{A}_l]^2 \\ &+ \|\mathrm{div}\mathbf{p}_h^*\|_{0,\Omega}^2 + \|\mathbf{y}(\mathbf{u}_h^*) - \mathbf{y}_h^*\|_{0,\Omega}^2\bigg)^{\frac{1}{2}}. \end{aligned} \tag{3.5}$$

Similarly, let $\mathbf{E_y} = \mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)$, $E_r = r_h^* - r(\mathbf{u}_h^*)$. Let $\mathbf{w}_I = \hat{\pi}_h\mathbf{w} \in \mathbf{Y}^h$ be the interpolation of $\mathbf{w} \in \mathbf{Y}$ defined in Lemma 2.4. Then, we can prove that

$$\begin{aligned} &c(\|\mathbf{E_y}\|_{1,\Omega} + \|E_r\|_{0,\Omega})(\|\mathbf{w}\|_{1,\Omega} + \|\phi\|_{0,\Omega}) \\ &\le (\nabla(\mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)), \nabla\mathbf{w}) - (\mathrm{div}\mathbf{w}, r_h^* - r(\mathbf{u}_h^*)) - (\mathrm{div}(\mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)), \phi) \\ &= (\nabla(\mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)), \nabla(\mathbf{w} - \mathbf{w}_I)) - (\mathrm{div}(\mathbf{w} - \mathbf{w}_I), r_h^* - r(\mathbf{u}_h^*)) - (\mathrm{div}(\mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)), \phi) \end{aligned}$$

$$
\begin{aligned}
&= -\sum_{\tau}\int_{\tau}\Delta(\mathbf{y}_h^*-\mathbf{y}(u_h^*))(\mathbf{w}-\mathbf{w}_I)+\sum_{\tau}\int_{\partial\tau}\frac{\partial}{\partial n}(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*))(\mathbf{w}-\mathbf{w}_I)\\
&\quad+\sum_{\tau}\int_{\tau}\nabla(r_h^*-r(\mathbf{u}_h^*))(\mathbf{w}-\mathbf{w}_I)-\sum_{\tau}\int_{\partial\tau}(r_h^*-r(\mathbf{u}_h^*))(\mathbf{w}-\mathbf{w}_I)\cdot\mathbf{n}-(\mathrm{div}\mathbf{y}_h^*,\phi)\\
&=\sum_{\tau}\int_{\tau}(-\Delta\mathbf{y}_h^*+\nabla r_h^*-\mathbf{f}-B\mathbf{u}_h^*)(\mathbf{w}-\mathbf{w}_I)+\sum_{l}\int_{l}[\mathbf{D}_l](\mathbf{w}-\mathbf{w}_I)-(\mathrm{div}\mathbf{y}_h^*,\phi)\\
&\le C\Bigg(\sum_{\tau}h_\tau^2\int_{\tau}(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*)^2\\
&\quad+\sum_{l}h_l\int_{l}[\mathbf{D}_l]^2+\|\mathrm{div}\mathbf{y}_h^*\|_{0,\Omega}^2\Bigg)^{\frac{1}{2}}(\|\mathbf{w}\|_{1,\Omega}+\|\phi\|_{0,\Omega}).
\end{aligned}
$$

It follows that

$$
\begin{aligned}
&\|\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)\|_{1,\Omega}^2\\
&\qquad\le C\Bigg(\sum_{\tau}h_\tau^2\int_{\tau}(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*)^2+\sum_{l}h_l\int_{l}[\mathbf{D}_l]^2+\|\mathrm{div}\mathbf{y}_h^*\|_{0,\Omega}^2\Bigg).
\end{aligned}
$$

Then, it follows from (3.5) that

$$\|\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)\|_{1,\Omega}^2\le C\hat{\eta}_1^2.$$

Then by Lemma 3.1,

$$\|\mathbf{u}_h^*-\mathbf{u}^*\|_{0,\Omega_{\mathbf{U}}}^2\le C\hat{\eta}^2. \tag{3.6}$$

Note that

$$\|\mathbf{y}^*-\mathbf{y}(\mathbf{u}_h^*)\|_{1,\Omega}\le C\|\mathbf{u}_h^*-\mathbf{u}^*\|_{0,\Omega_{\mathbf{U}}},$$

and

$$\|\mathbf{p}^*-\mathbf{p}(\mathbf{u}_h^*)\|_{1,\Omega}\le C\|\mathbf{y}^*-\mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega}\le C\|\mathbf{u}^*-\mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}.$$

We have

$$\|\mathbf{y}^*-\mathbf{y}_h^*\|_{1,\Omega}^2+\|\mathbf{p}^*-\mathbf{p}_h^*\|_{1,\Omega}^2\le C\hat{\eta}^2. \tag{3.7}$$

Then, the theorem follows from (3.6) and (3.7).

Remark 3.1. It is clear that the a posteriori error estimator $\hat{\eta}$ consists of two parts. The part $\hat{\eta}_1$ is contributed from the approximation error of the state and co-state equations, and the other part results from the approximation error of the variational inequality. Among them, $\hat{\eta}_1$ mainly indicates the approximation error for the state and co-state, and the term $\sum_{\tau_{\mathbf{U}}\subset T_{\mathbf{U}}^h}h_{\tau_{\mathbf{U}}}^2|h'(\mathbf{u}_h^*)+B^*\mathbf{p}_h^*|_{H^1(\tau_{\mathbf{U}})}^2$ mainly reflects the approximation error for the control. There does not have to exist a relationship between the computational meshes for the state and those for the control. Clearly, the most suitable implementation and thus the optimal mesh refinements will much depend on what is the most important quantity to be computed in a particular control problem. It also depends on the structure of the meshes used in the computations. Further investigation is still much needed.

The part $\hat{\eta}_1$ can be further divided into two parts: one from the approximation error of the state equation and the other from that of the co-state equation. Clearly, a posteriori error estimators obtained solely from the state equation may fail to reflect the main approximation error of the optimal control problem and thus fail to yield efficient mesh refinements. This will become even more clear after Theorem 3.2.

It follows from the above proof that when Ω is convex, one can bound up $\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}$ with the L^2 norm, using the dual equations, and thus derive the sharper estimates for $\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}$. This is what we are going to do in the following theorem. Furthermore we derive a posteriori error estimates for the control problem using the L^2 norms. If one is more interested in the control and the *values* of the state, then the following result may be very useful.

THEOREM 3.2. *Let* $(\mathbf{y}^*, r^*, \mathbf{p}^*, s^*, \mathbf{u}^*)$ *and* $(\mathbf{y}_h^*, r_h^*, \mathbf{p}_h^*, s_h^*, \mathbf{u}_h^*)$ *be the solutions of* (2.5) *and* (2.9)*, respectively. Assume that all the conditions in Lemma* 2.2 *and Lemma* 3.1 *hold. Then*

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}^2 + \|\mathbf{y}^* - \mathbf{y}_h^*\|_{0,\Omega}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_{0,\Omega}^2 \le C\eta^2, \tag{3.8}$$

where

$$\eta^2 = \sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}}^2 |B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_\mathbf{U}}^2 + \eta_1^2,$$

where

$$\begin{aligned}\eta_1^2 = {} & \sum_\tau h_\tau^4 \int_\tau (\Delta\mathbf{p}_h^* + \nabla s_h^* + g'(\mathbf{y}_h^*))^2 + \sum_l h_l^3 \int_l [\mathbf{A}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{p}_h^*)^2 \\ & + \sum_\tau h_\tau^4 \int_\tau (\Delta\mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + B\mathbf{u}_h^*)^2 + \sum_l h_l^3 \int_l [\mathbf{D}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{y}_h^*)^2,\end{aligned}$$

where h_l *is the size of the edge* l*;* $[\mathbf{A}_l]$ *and* $[\mathbf{D}_l]$ *are jumps on the edge* $l = \bar{\tau}_l^1 \cap \bar{\tau}_l^2$ *defined by*

$$[\mathbf{D}_l] = ((\nabla\mathbf{y}_h^*)_{\tau_l^1} - (\nabla\mathbf{y}_h^*)_{\tau_l^2}) \cdot \mathbf{n} - (r_h^*|_{\tau_l^1} - r_h^*|_{\tau_l^2})\mathbf{n},$$

$$[\mathbf{A}_l] = ((\nabla\mathbf{p}_h^*)_{\tau_l^1} - (\nabla\mathbf{p}_h^*)_{\tau_l^2}) \cdot \mathbf{n} + (s_h^*|_{\tau_l^1} - s_h^*|_{\tau_l^2})\mathbf{n},$$

where $\mathbf{n}$ *is the outer normal direction of* τ_l^1*. For ease of exposition, we let* $[\mathbf{A}_l] = [\mathbf{D}_l] = 0$ *when* $l \subset \partial\Omega$*.*

Proof. Let (Ψ, ρ) be the solution of (2.3) with $\Phi = \mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)$ and + sign. Let $\Psi_I = \pi_h\Psi \in \mathbf{Y}^h$ and $\rho_I = \bar{\pi}_h\rho \in Q^h$ be the interpolations of Ψ and ρ defined in Lemma 2.3. By (2.9), (3.3) and Lemmas 2.2, 2.3, and 2.5,

$$\begin{aligned}& \|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2 = (\Phi, \mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)) \\ & = (\nabla\Psi, \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \rho) + (\mathrm{div}\Psi, s_h^* - s(\mathbf{u}_h^*)) \\ & = (\nabla(\Psi - \Psi_I), \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}(\Psi - \Psi_I), s_h^* - s(\mathbf{u}_h^*)) \\ & \quad + (\nabla\Psi_I, \nabla(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))) + (\mathrm{div}\Psi_I, s_h^* - s(\mathbf{u}_h^*)) + (\mathrm{div}\mathbf{p}_h^*, \rho - \rho_I) \\ & = -\sum_\tau \int_\tau \Delta(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))(\Psi - \Psi_I) + \sum_\tau \int_{\partial\tau} \frac{\partial}{\partial n}(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))(\Psi - \Psi_I) \\ & \quad - \sum_\tau \int_\tau \nabla(s_h^* - s(\mathbf{u}_h^*))(\Psi - \Psi_I) + \sum_\tau \int_{\partial\tau} (s_h^* - s(\mathbf{u}_h^*))(\Psi - \Psi_I) \cdot \mathbf{n}\end{aligned}$$

$$
\begin{aligned}
&+(g'(\mathbf{y}_h^*)-g'(\mathbf{y}(\mathbf{u}_h^*)),\Psi_I)+(\mathrm{div}\mathbf{p}_h^*,\rho-\rho_I)\\
&\le C\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{p}_h^*+\nabla s_h^*+g'(\mathbf{y}_h^*))^2+C\sum_l h_l^3\int_l[\mathbf{A}_l]^2+C\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{p}_h^*)^2\\
&\quad+C\|\mathbf{y}(\mathbf{u}_h^*)-\mathbf{y}_h^*\|_{0,\Omega}^2+C\delta(\|\Psi\|_{2,\Omega}^2+\|\rho\|_{1,\Omega}^2)\\
&\le C\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{p}_h^*+\nabla s_h^*+g'(\mathbf{y}_h^*))^2+C\sum_l h_l^3\int_l[\mathbf{A}_l]^2+C\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{p}_h^*)^2\\
&\quad+C\|\mathbf{y}(\mathbf{u}_h^*)-\mathbf{y}_h^*\|_{0,\Omega}^2+C\delta\|\Phi\|_{0,\Omega}^2\\
&=C\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{p}_h^*+\nabla s_h^*+g'(\mathbf{y}_h^*))^2+C\sum_l h_l^3\int_l[\mathbf{A}_l]^2+C\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{p}_h^*)^2\\
&\quad+C\|\mathbf{y}(\mathbf{u}_h^*)-\mathbf{y}_h^*\|_{0,\Omega}^2+C\delta\|\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2.
\end{aligned}
$$

Then, let $\delta=\frac{1}{2C}$; it follows that

$$
\begin{aligned}
\|\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2&\le C\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{p}_h^*+\nabla s_h^*+g'(\mathbf{y}_h^*))^2+C\sum_l h_l^3\int_l[\mathbf{A}_l]^2\\
&\quad+C\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{p}_h^*)^2+C\|\mathbf{y}(\mathbf{u}_h^*)-\mathbf{y}_h^*\|_{0,\Omega}^2.
\end{aligned}
\tag{3.9}
$$

Similarly, let (Ψ,ρ) be the solution of (2.3) with $\Phi=\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)$ and $-$ sign. Let $\Psi_I=\pi_h\Psi\in\mathbf{Y}^h$ and $\rho_I=\bar{\pi}_h\rho\in Q^h$ be the interpolations of Ψ and ρ defined in Lemma 2.3. Again, we can prove that

$$
\begin{aligned}
&\|\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega}^2=(\Phi,\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*))\\
&=(\nabla(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)),\nabla\Psi)-(\mathrm{div}\Psi,r_h^*-r(\mathbf{u}_h^*))-(\mathrm{div}(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)),\rho)\\
&=(\nabla(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)),\nabla(\Psi-\Psi_I))-(\mathrm{div}(\Psi-\Psi_I),r_h^*-r(\mathbf{u}_h^*))-(\mathrm{div}\mathbf{y}_h^*,\rho-\rho_I)\\
&=-\sum_\tau\int_\tau\Delta(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*))(\Psi-\Psi_I)+\sum_\tau\int_{\partial\tau}\frac{\partial}{\partial n}(\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*))(\Psi-\Psi_I)\\
&\quad+\sum_\tau\int_\tau\nabla(r_h^*-r(\mathbf{u}_h^*))(\Psi-\Psi_I)-\sum_\tau\int_{\partial\tau}(r_h^*-r(\mathbf{u}_h^*))(\Psi-\Psi_I)\cdot\mathbf{n}\\
&\quad-(\mathrm{div}\mathbf{y}_h^*,\rho-\rho_I)\\
&=\sum_\tau\int_\tau(-\Delta\mathbf{y}_h^*+\nabla r_h^*-\mathbf{f}-B\mathbf{u}_h^*)(\Psi-\Psi_I)+\sum_l\int_l[\mathbf{D}_l](\Psi-\Psi_I)-(\mathrm{div}\mathbf{y}_h^*,\rho-\rho_I)\\
&\le C\Big(\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*)^2+\sum_l h_l^3\int_l[\mathbf{D}_l]^2+\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{y}_h^*)^2\Big)\\
&\quad+C\delta(\|\Psi\|_{2,\Omega}^2+\|\rho\|_{1,\Omega}^2)\\
&\le C\Big(\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*)^2\\
&\quad+\sum_l h_l^3\int_l[\mathbf{D}_l]^2+\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{y}_h^*)^2\Big)+C\delta\|\Phi\|_{0,\Omega}^2\\
&=C\Big(\sum_\tau h_\tau^4\int_\tau(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*)^2+\sum_l h_l^3\int_l[\mathbf{D}_l]^2+\sum_\tau h_\tau^2\int_\tau(\mathrm{div}\mathbf{y}_h^*)^2\Big)\\
&\quad+C\delta\|\mathbf{y}_h^*-\mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega}^2.
\end{aligned}
$$

It follows that

$$\|\mathbf{y}_h^* - \mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega}^2 \leq C\Big(\sum_\tau h_\tau^4 \int_\tau (\Delta \mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + B\mathbf{u}_h^*)^2 + \sum_l h_l^3 \int_l [\mathbf{D}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{y}_h^*)^2\Big).$$

Then, it follows from (3.9) that

$$\|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2 \leq C\eta_1^2.$$

Then by Lemma 3.1,

$$\|\mathbf{u}_h^* - \mathbf{u}^*\|_{0,\Omega_\mathbf{U}}^2 \leq C\eta^2. \tag{3.10}$$

Note that

$$\|\mathbf{y}^* - \mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega} \leq C\|\mathbf{u}_h^* - \mathbf{u}^*\|_{0,\Omega_\mathbf{U}},$$

and

$$\|\mathbf{p}^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega} \leq C\|\mathbf{y}^* - \mathbf{y}(\mathbf{u}_h^*)\|_{0,\Omega} \leq C\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}.$$

We have

$$\|\mathbf{y}^* - \mathbf{y}_h^*\|_{0,\Omega}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_{0,\Omega}^2 \leq C\eta^2. \tag{3.11}$$

Then, the theorem follows from (3.10) and (3.11).

It follows from Theorem 3.2 that when using the same meshes for the state and the control, the estimator

$$\sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}}^2 |B^*\mathbf{p}_h^* + h'(\mathbf{u}_h^*)|_{1,\tau_\mathbf{U}}^2$$

is *dominant*! This fact could be useful in simplifying implementation of the resulting error estimates in computations and have impacts on developing implementation techniques. Furthermore, it is not hard to see that one could use much coarser meshes for the state and co-state approximation, since η_1 has a different approximation order. Thus, computational efficiency could be further improved if we use different meshes for the state and the control. It is clear that much more research is needed to investigate possible implementations of these error indicators with multiset meshes.

Remark 3.2. The techniques developed in this paper can be extended to derive similar a posteriori error estimates for the optimal control problem governed by the Navier–Stokes equations (at least when the Reynolds number is small):

$$\begin{aligned} &\min_{\mathbf{u}\in\mathbf{K}\subset\mathbf{U}} \{g(\mathbf{y}) + h(\mathbf{u})\}, \\ &-\Delta\mathbf{y} + Re(\mathbf{y}\cdot\nabla)\mathbf{y} + \nabla r = \mathbf{f} + B\mathbf{u} \qquad \text{in } \Omega, \\ &\mathrm{div}\mathbf{y} = 0 \text{ in } \Omega, \ \ \mathbf{y} = 0 \ \text{ on } \ \partial\Omega, \quad \int_\Omega r = 0, \end{aligned}$$

where Re is the Reynolds number. It is well known that $(\mathbf{y}^*, r^*, \mathbf{u}^*)$ is the solution of above problem only if there is a co-state $(\mathbf{p}^*, s^*) \in \mathbf{Y}\times Q$ such that $(\mathbf{y}^*, r^*, \mathbf{p}^*, s^*, \mathbf{u}^*)$

satisfies the following optimality conditions:

$$
\begin{aligned}
(3.12)\quad a(\mathbf{y}^*,\mathbf{w})+(Re(\mathbf{y}^*\cdot\nabla)\mathbf{y}^*,\mathbf{w})-b(\mathbf{w},r^*)&=(\mathbf{f}+B\mathbf{u}^*,\mathbf{w}) && \forall \mathbf{w}\in\mathbf{Y},\\
b(\mathbf{y}^*,\phi)&=0 && \forall \phi\in Q,\\
a(\mathbf{q},\mathbf{p}^*)-Re((\mathbf{y}^*\cdot\nabla)\mathbf{p}^*,\mathbf{q})&\\
+Re((\nabla\mathbf{y}^*)^T\mathbf{p}^*,\mathbf{q})+b(\mathbf{q},s^*)&=(g'(\mathbf{y}^*),\mathbf{q}) && \forall \mathbf{q}\in\mathbf{Y},\\
b(\mathbf{p}^*,\psi)&=0 && \forall \psi\in Q,\\
(h'(\mathbf{u}^*)+B^*\mathbf{p}^*,\mathbf{v}-\mathbf{u}^*)_{\mathbf{U}}&\geq 0 && \forall \mathbf{v}\in\mathbf{K}\subset\mathbf{U},
\end{aligned}
$$

where B^* is the adjoint operator of B, $a(\cdot,\cdot)$, $b(\cdot,\cdot)$ are defined in section 2, and $(\cdot,\cdot)_{\mathbf{U}}$ is the inner product of $\mathbf{U}$.

Although rigorous proof details have yet to be worked out, one already should be in the position of seeing similar a posteriori error estimates for the above control problem with smaller Re by using the same ideas and techniques. For example, let $(\mathbf{y}^*,r^*,\mathbf{p}^*,s^*,\mathbf{u}^*)$ be the solutions of (3.12) and $(\mathbf{y}_h^*,r_h^*,\mathbf{p}_h^*,s_h^*,\mathbf{u}_h^*)$ be the finite element approximations of $(\mathbf{y}^*,r^*,\mathbf{p}^*,s^*,\mathbf{u}^*)$. Assume that all the conditions in Lemma 3.1 hold. Then

$$
(3.13)\qquad \|\mathbf{u}^*-\mathbf{u}_h^*\|_{\mathbf{U}}^2+\|\mathbf{y}^*-\mathbf{y}_h^*\|_{\mathbf{Y}}^2+\|\mathbf{p}^*-\mathbf{p}_h^*\|_{\mathbf{Y}}^2\leq C\tilde{\eta}^2,
$$

where

$$
\tilde{\eta}^2=\sum_{\tau_{\mathbf{U}}}h_{\tau_{\mathbf{U}}}^2|B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*)|_{1,\tau_{\mathbf{U}}}^2+\tilde{\eta}_1^2,
$$

where

$$
\begin{aligned}
\tilde{\eta}_1^2=&\sum_{\tau}h_\tau^2\int_\tau(\Delta\mathbf{p}_h^*+\nabla s_h^*+g'(\mathbf{y}_h^*)+Re(\mathbf{y}_h^*\cdot\nabla)\mathbf{p}_h^*-Re(\nabla\mathbf{y}_h^*)^T\mathbf{p}_h^*)^2\\
&+\sum_l h_l\int_l[\mathbf{A}_l]^2+\|\mathrm{div}\mathbf{p}_h^*\|_{0,\Omega}^2\\
&+\sum_\tau h_\tau^2\int_\tau(\Delta\mathbf{y}_h^*-\nabla r_h^*+\mathbf{f}+B\mathbf{u}_h^*-Re(\mathbf{y}_h^*\cdot\nabla)\mathbf{y}_h^*)^2+\sum_l h_l\int_l[\mathbf{D}_l]^2+\|\mathrm{div}\mathbf{y}_h^*\|_{0,\Omega}^2.
\end{aligned}
$$

One can also write down the error estimates in the L^2 norm.

In the following, we extend Lemma 3.1 to the cases where $\mathbf{K}^h\not\subset\mathbf{K}$. Consequently Theorems 3.1 and 3.2 can also be extended to the cases using the same methods used in the proofs of Theorems 3.1 and 3.2.

Remark 3.3. Assume that all the conditions in Lemma 3.1 hold except the condition that $\mathbf{K}^h\subset\mathbf{K}$. Use the same notation in Lemma 3.1. Assume that $(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*))|_{\tau_{\mathbf{U}}}\in(H^1(\tau_{\mathbf{U}}))^2$ and that there is a $\mathbf{v}_h\in\mathbf{K}^h$ such that

$$
\begin{aligned}
(3.14)\qquad &|(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*),\mathbf{v}_h-\mathbf{u}^*)_{\mathbf{U}}|\\
&\quad\leq C\sum_{\tau_{\mathbf{U}}\subset T_{\mathbf{U}}^h}h_{\tau_{\mathbf{U}}}|B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*)|_{1,\tau_{\mathbf{U}}}\|\mathbf{u}^*-\mathbf{u}_h^*\|_{0,\tau_{\mathbf{U}}}.
\end{aligned}
$$

Then for all $\mathbf{v}\in\mathbf{K}$ we have

$$
\|\mathbf{u}^*-\mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}^2\leq C\Bigg(\sum_{\tau_{\mathbf{U}}\subset T_{\mathbf{U}}^h}h_{\tau_{\mathbf{U}}}^2|B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*)|_{1,\tau_{\mathbf{U}}}^2+\|\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2
$$

$$+|(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|+|(B^*(\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}| \tag{3.15}$$
$$+|(B^*(\mathbf{p}(\mathbf{u}_h^*)-\mathbf{p}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|+|(h'(\mathbf{u}_h^*)-h'(\mathbf{u}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|\Big),$$

where $\mathbf{p}(\mathbf{u}_h^*)$ is defined in Lemma 3.1.

The proof of this estimate is similar to that of Lemma 3.1. First we have

$$(h'(\mathbf{u}^*),\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}\le -(B^*\mathbf{p}^*,\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}\qquad\forall\mathbf{v}\in\mathbf{K},$$

$$(h'(\mathbf{u}_h^*),\mathbf{u}_h^*-\mathbf{v}_h)_{\mathbf{U}}+(B^*\mathbf{p}_h^*,\mathbf{u}_h^*-\mathbf{v}_h)_{\mathbf{U}}\le 0\qquad\forall\mathbf{v}_h\in\mathbf{K}^h.$$

Then by applying the same techniques used in the proof of Lemma 3.1, we have for any $\mathbf{v}_h\in\mathbf{K}^h$ and $\mathbf{v}\in\mathbf{K}$ that

$$c\|\mathbf{u}^*-\mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}^2\le(h'(\mathbf{u}^*),\mathbf{u}^*-\mathbf{u}_h^*)_{\mathbf{U}}-(h'(\mathbf{u}_h^*),\mathbf{u}^*-\mathbf{u}_h^*)_{\mathbf{U}}$$
$$=(h'(\mathbf{u}^*),\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}+(h'(\mathbf{u}^*),\mathbf{v}-\mathbf{u}_h^*)_{\mathbf{U}}-(h'(\mathbf{u}_h^*),\mathbf{u}^*-\mathbf{u}_h^*)_{\mathbf{U}}$$
$$\le-(B^*\mathbf{p}^*,\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}+(h'(\mathbf{u}^*),\mathbf{v}-\mathbf{u}_h^*)_{\mathbf{U}}-(h'(\mathbf{u}_h^*),\mathbf{u}^*-\mathbf{u}_h^*)_{U}$$
$$=-(B^*\mathbf{p}_h^*,\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}+(B^*(\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)),\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}+(B^*(\mathbf{p}(\mathbf{u}_h^*)-\mathbf{p}^*),\mathbf{u}^*-\mathbf{u}_h^*)_{\mathbf{U}}$$
$$+(B^*(\mathbf{p}(\mathbf{u}_h^*)-\mathbf{p}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}+(h'(\mathbf{u}^*),\mathbf{v}-\mathbf{u}_h^*)_{\mathbf{U}}-(h'(\mathbf{u}_h^*),\mathbf{u}^*-\mathbf{v}+\mathbf{v}-\mathbf{u}_h^*)_{\mathbf{U}}$$
$$=(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*),(\mathbf{v}-\mathbf{u}_h^*)+(\mathbf{u}_h^*-\mathbf{v}_h)+(\mathbf{v}_h-\mathbf{u}^*))_{\mathbf{U}}$$
$$+(B^*(\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)),\mathbf{u}^*-\mathbf{v})_{\mathbf{U}}-(g'(\mathbf{y}^*)-g'(\mathbf{y}(\mathbf{u}_h^*)),\mathbf{y}^*-\mathbf{y}(\mathbf{u}_h^*))$$
$$+(B^*(\mathbf{p}(\mathbf{u}_h^*)-\mathbf{p}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}+(h'(\mathbf{u}^*)-h'(\mathbf{u}_h^*),\mathbf{v}-\mathbf{u}_h^*)_{\mathbf{U}}$$
$$\le|(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*),\mathbf{v}_h-\mathbf{u}^*)_{\mathbf{U}}|+|(B^*\mathbf{p}_h^*+h'(\mathbf{u}_h^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|$$
$$+|(B^*(\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)),\mathbf{u}^*-\mathbf{u}_h^*)_{\mathbf{U}}|+|(B^*(\mathbf{p}_h^*-\mathbf{p}(\mathbf{u}_h^*)),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|$$
$$+|(B^*(\mathbf{p}(\mathbf{u}_h^*)-\mathbf{p}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|+|(h'(\mathbf{u}_h^*)-h'(\mathbf{u}^*),\mathbf{u}_h^*-\mathbf{v})_{\mathbf{U}}|.$$

Then the desired result (3.15) follows.

4. Some examples. In this section we consider some applications of the results in section 3. First let $\Omega=[-1,1]\times[-1,1]$. Let $\mathbf{Y}=(H_0^1(\Omega))^2$, $\mathbf{U}=(L^2(\Omega))^2$, $\mathbf{H}=(L^2(\Omega))^2$, and $Q=L_0^2(\Omega)$. For any $\mathbf{u}\in\mathbf{U}$, let $B\mathbf{u}=\mathbf{u}$. Now let us consider the following well-known quadratic control problem (see [31]), (EXP):

$$\min_{\mathbf{u}\in\mathbf{K}\subset\mathbf{U}}\left\{\frac{1}{2}\|\mathbf{y}-\mathbf{z}_d\|_{\mathbf{H}}^2+\frac{1}{2}\|\mathbf{u}\|_{\mathbf{U}}^2\right\},$$
$$-\Delta\mathbf{y}+\nabla r=\mathbf{f}+\mathbf{u}\text{ in }\Omega,$$
$$\text{div}\mathbf{y}=0\text{ in }\Omega,$$
$$\mathbf{y}=0\ \text{ on }\ \partial\Omega,\quad\int_\Omega r=0,$$

where $\mathbf{f}\in\mathbf{L}=(L^2(\Omega))^2$, $\mathbf{z}_d\in\mathbf{H}$, and $\mathbf{K}$ is a closed convex set in $\mathbf{U}$.

Example 4.1. Let $\mathbf{K}_1 = \mathbf{U}$, $\mathbf{K}_2 = \{\mathbf{u} \in \mathbf{U} : \mathbf{u} \geq 0\}$, $\mathbf{K}_3 = \{\mathbf{u} \in \mathbf{U} : |\mathbf{u}| \leq 1\}$, and $\mathbf{K}_4 = \{\mathbf{u} \in \mathbf{U} : \int_\Omega \mathbf{u} \geq 0\}$. Here the notations $\mathbf{u} \geq 0$, $|\mathbf{u}| \leq 1$, $\int_\Omega \mathbf{u} \geq 0$ mean that $u_i \geq 0$, $|u_i| \leq 1$, $\int_\Omega u_i \geq 0$, with $i = 1, 2$, and $\mathbf{u} = (u_1, u_2)$. Construct the finite element approximation as in section 2. Especially, we take $\mathbf{U}^h = \{\mathbf{u} \in \mathbf{U} : \mathbf{u}|_{\tau_\mathbf{U}} \in (P_0)^2\}$, where P_0 is the 0-order polynomial space, and take $\mathbf{K}_1^h = \mathbf{U}^h$, $\mathbf{K}_2^h = \{\mathbf{u}_h \in \mathbf{U}^h : \mathbf{u}_h \geq 0\}$, $\mathbf{K}_3^h = \{\mathbf{u}_h \in \mathbf{U}^h : |\mathbf{u}_h| \leq 1\}$, and $\mathbf{K}_4^h = \{\mathbf{u}_h \in \mathbf{U}^h : \int_\Omega \mathbf{u}_h \geq 0\}$. For any $\mathbf{u} \in \mathbf{K}$, define $(\pi_h^c \mathbf{u})|_{\tau_\mathbf{U}} = \bar{\mathbf{u}}|_{\tau_\mathbf{U}}$, where $\bar{\mathbf{u}}|_{\tau_\mathbf{U}}$ is the integral average of $\mathbf{u}$ on the element $\tau_\mathbf{U}$. Then, it is easy to see that $\mathbf{K}_i^h \subset \mathbf{K}_i$, and $\pi_h^c \mathbf{u} \in \mathbf{K}_i^h$ if $\mathbf{u} \in \mathbf{K}_i$, $i = 1, 2, 3, 4$.

Let $\mathbf{u}^*$ be the solution of (EXP) and $\mathbf{u}_h^*$ be the solution of the finite element approximation of (EXP). It follows that $(\mathbf{p}_h^* + \mathbf{u}_h^*)|_{\tau_\mathbf{U}} \in (H^1(\tau_\mathbf{U}))^2$. Then

$$\begin{aligned}|(\mathbf{p}_h^* + \mathbf{u}_h^*, \pi_h^c \mathbf{u}^* - \mathbf{u}^*)_\mathbf{U}| &= |(\mathbf{p}_h^* + \mathbf{u}_h^* - \pi_h^c(\mathbf{p}_h^* + \mathbf{u}_h^*), \pi_h^c(\mathbf{u}^* - \mathbf{u}_h^*) - (\mathbf{u}^* - \mathbf{u}_h^*))_\mathbf{U}| \\ &\leq C \sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}} |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_\mathbf{U}} \|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\tau_\mathbf{U}}.\end{aligned}$$

Therefore, Theorems 3.1 and 3.2 hold:

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_\mathbf{U}^2 + \|\mathbf{y}^* - \mathbf{y}_h^*\|_\mathbf{Y}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_\mathbf{Y}^2 \leq C\hat{\eta}^2, \tag{4.1}$$

where

$$\hat{\eta}^2 = \sum_{\tau_\mathbf{U} \subset T_\mathbf{U}^h} h_{\tau_\mathbf{U}}^2 |\mathbf{u}_h^* + \mathbf{p}_h^*|_{1,\tau_\mathbf{U}}^2 + \hat{\eta}_1^2,$$

$$\begin{aligned}\hat{\eta}_1^2 = &\sum_\tau h_\tau^2 \int_\tau (\Delta \mathbf{p}_h^* + \nabla s_h^* + \mathbf{y}_h^* - \mathbf{z}_d)^2 + \sum_l h_l \int_l [\mathbf{A}_l]^2 + \|\mathrm{div}\mathbf{p}_h^*\|_{0,\Omega}^2 \\ &+ \sum_\tau h_\tau^2 \int_\tau (\Delta \mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + \mathbf{u}_h^*)^2 + \sum_l h_l \int_l [\mathbf{D}_l]^2 + \|\mathrm{div}\mathbf{y}_h^*\|_{0,\Omega}^2.\end{aligned}$$

Also,

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_\mathbf{U}}^2 + \|\mathbf{y}^* - \mathbf{y}_h^*\|_{0,\Omega}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_{0,\Omega}^2 \leq C\eta^2, \tag{4.2}$$

where

$$\eta^2 = \sum_{\tau_\mathbf{U} \subset T_\mathbf{U}^h} h_{\tau_\mathbf{U}}^2 |\mathbf{u}_h^* + \mathbf{p}_h^*|_{1,\tau_\mathbf{U}}^2 + \eta_1^2,$$

$$\begin{aligned}\eta_1^2 = &\sum_\tau h_\tau^4 \int_\tau (\Delta \mathbf{p}_h^* + \nabla s_h^* + \mathbf{y}_h^* - \mathbf{z}_d)^2 + \sum_l h_l^3 \int_l [\mathbf{A}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{p}_h^*)^2 \\ &+ \sum_\tau h_\tau^4 \int_\tau (\Delta \mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + \mathbf{u}_h^*)^2 + \sum_l h_l^3 \int_l [\mathbf{D}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{y}_h^*)^2.\end{aligned}$$

One can use $\sum_{\tau_\mathbf{U}} h_{\tau_\mathbf{U}}^2 |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_\mathbf{U}}^2$ as an error indicator for the control approximation mesh refinement and use η_1^2 (or $\hat{\eta}_1^2$) for the state and co-state mesh refinement.

The (single) obstacle problem case where the obstacle is not constant can be easily dealt with, for instance, by using the transformation $\mathbf{u}_{new} = \mathbf{u}_{old} - \Phi$, where Φ is the obstacle. Now let us consider the two side obstacle case.

Example 4.2. Let $K = \{\mathbf{u} \in \mathbf{U} : \mathbf{g}_0 \le \mathbf{u} \le \mathbf{g}_1\}$, where $\mathbf{g}_0, \mathbf{g}_1 \in (H^1(\Omega))^2$. Let $\mathbf{U}^h$ be the piecewise constant space. Let $\mathbf{K}^h = \{\mathbf{u}_h \in \mathbf{U}^h : \pi_h^c \mathbf{g}_0 \le \mathbf{u}_h \le \pi_h^c \mathbf{g}_1\}$. It is clear that $\mathbf{K}$ may not contain $\mathbf{K}^h$ this time. We then apply the estimates in Remark 3.2. Let $\mathbf{u}^*$ be the solution of (EXP) and $\mathbf{u}_h^*$ be the finite element approximation of the problem. It follows from [13] that one can construct $P(\mathbf{u}_h^*) \in \mathbf{K}$ such that

$$\pi_h^c(P(\mathbf{u}_h^*)) = \pi_h^c(\mathbf{u}_h^*), \qquad \|\mathbf{u}_h^* - P(\mathbf{u}_h^*)\|_{0,\Omega} \le C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}(|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}}).$$

First, as in Example 4.1, let $\mathbf{v}_h = \pi_h^c \mathbf{u}^*$,

$$|(\mathbf{p}_h^* + \mathbf{u}_h^*, \pi_h^c \mathbf{u}^* - \mathbf{u}^*)_{\mathbf{U}}| \le C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}} |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_{\mathbf{U}}} \|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\tau_{\mathbf{U}}}.$$

Let $\mathbf{v} = P(\mathbf{u}_h^*)$ in the estimate (3.15) of Remark 3.2. Then, first,

$$|(\mathbf{p}_h^* + \mathbf{u}_h^*, \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}| = |((\mathbf{p}_h^* + \mathbf{u}_h^* - \pi_h^c(\mathbf{p}_h^* + \mathbf{u}_h^*)), \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}|$$

$$\le C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_{\mathbf{U}}} (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}}),$$

since $\pi_h^c(P(\mathbf{u}_h^*)) = \pi_h^c(\mathbf{u}_h^*)$. Therefore

$$|(\mathbf{p}_h^* + \mathbf{u}_h^*, \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}| \le C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_{\mathbf{U}}}^2 + C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}})^2.$$

Second,

$$|((\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)), \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}| \le C \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}} \|(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))\|_{0,\tau_{\mathbf{U}}} (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}})$$
$$\le C \|(\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*))\|_{0,\Omega}^2 + C \sum_{\tau_U} h_{\tau_{\mathbf{U}}}^2 (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}})^2.$$

Third, from the proof of Theorem 3.1,

$$|((\mathbf{p}(\mathbf{u}_h^*) - \mathbf{p}^*), \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}| \le C \|\mathbf{p}(\mathbf{u}_h^*) - \mathbf{p}(\mathbf{u}^*)\|_{0,\Omega} \|\mathbf{u}_h^* - \mathbf{v}\|_{\mathbf{U}}$$

$$\le C \|\mathbf{u}_h^* - \mathbf{u}^*\|_{\mathbf{U}} \|\mathbf{u}_h^* - \mathbf{v}\|_{\mathbf{U}} \le \epsilon \|\mathbf{u}_h^* - \mathbf{u}^*\|_{\mathbf{U}}^2 + C \|\mathbf{u}_h^* - \mathbf{v}\|_{\mathbf{U}}^2,$$

where ϵ is positive but can be made very small. Finally,

$$|(\mathbf{u}_h^* - \mathbf{u}^*, \mathbf{u}_h^* - \mathbf{v})_{\mathbf{U}}| \le \epsilon \|\mathbf{u}_h^* - \mathbf{u}^*\|_{\mathbf{U}}^2 + C \|\mathbf{u}_h^* - \mathbf{v}\|_{\mathbf{U}}^2.$$

Therefore, we have

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}^2$$
$$\le C \bigg(\sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_{\mathbf{U}}}^2 + \|\mathbf{p}_h^* - \mathbf{p}(\mathbf{u}_h^*)\|_{0,\Omega}^2 + \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}})^2 \bigg).$$

Then it follows from the proof of Theorem 3.2; we finally have

$$\|\mathbf{u}^* - \mathbf{u}_h^*\|_{0,\Omega_{\mathbf{U}}}^2 + \|\mathbf{y}^* - \mathbf{y}_h^*\|_{0,\Omega}^2 + \|\mathbf{p}^* - \mathbf{p}_h^*\|_{0,\Omega}^2 \le C\eta_3^2,$$

with

$$\eta_3^2 = \eta_2^2 + \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 (|\mathbf{g}_0|_{1,\tau_{\mathbf{U}}} + |\mathbf{g}_1|_{1,\tau_{\mathbf{U}}})^2,$$
$$\eta_2^2 = \sum_{\tau_{\mathbf{U}}} h_{\tau_{\mathbf{U}}}^2 |\mathbf{p}_h^* + \mathbf{u}_h^*|_{1,\tau_{\mathbf{U}}}^2 + \eta_1^2,$$

and

$$\eta_1^2 = \sum_{\tau} h_\tau^4 \int_\tau (\Delta \mathbf{p}_h^* + \nabla s_h^* + \mathbf{y}_h^* - \mathbf{z}_d)^2 + \sum_l h_l^3 \int_l [\mathbf{A}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{p}_h^*)^2$$
$$+ \sum_{\tau} h_\tau^4 \int_\tau (\Delta \mathbf{y}_h^* - \nabla r_h^* + \mathbf{f} + \mathbf{u}_h^*)^2 + \sum_l h_l^3 \int_l [\mathbf{D}_l]^2 + \sum_\tau h_\tau^2 \int_\tau (\mathrm{div}\mathbf{y}_h^*)^2.$$

ON QUASI-NORM INTERPOLATION ERROR ESTIMATION AND A POSTERIORI ERROR ESTIMATES FOR p-LAPLACIAN*

WENBIN LIU† AND NINGNING YAN‡

Abstract. In this paper, we establish a series of interpolation error estimates for several widely used averaging interpolators in some quasi norms. These estimates are among the key ingredients in our improved a posteriori error analysis for the p-Laplacian. The quasi-norm interpolation error estimates are used to derive a posteriori error estimators for some conforming and nonconforming finite element approximation of the p-Laplacian, which are shown to provide upper and lower bounds for the discretization error.

Key words. finite element approximation, p-Laplacian, a posteriori error estimators, quasi norms, interpolation error estimates

1. Introduction.

In this work we derive a series of new interpolation error estimates for some well-known interpolators. These new estimates are among the key tools in our improved a posteriori error analysis for the finite element approximation of the p-Laplacian with Dirichlet data:

$$\begin{aligned} -\operatorname{div}(|\nabla u|^{p-2}\nabla u) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{1.1}$$

where $1 < p < \infty$ and Ω is a bounded open subset of R^2 with a Lipschitz boundary $\partial\Omega$. This equation is viewed as one of the typical examples of a large class of nonlinear problems—degenerate nonlinear systems. Indeed it is believed that this equation contains most of the essential difficulties in studies of finite element approximations for this class of degenerate nonlinear systems, where many existing techniques (such as the linearization or deformation procedure) in the finite element method do not seem to work well.

Finite element approximations of the p-Laplacian have been extensively studied in the literature, and one can find some previous work, for example, in [10], [11], and [13], and overviews of some recent work in [3], [4], [5], [16], [17], [18], and [19], where among others, the quasi-norm approach is developed. This approach has proved quite successful in deriving sharp a priori error bounds for the finite element approximation of the degenerate systems. Some accounts of very recent work on the p-Laplacian can be found in the papers [18] and [19] as well. Another important area is a posteriori error estimation of the p-Laplacian. The work in this area seems to date back to [20], and some of the recent work can be found in [2], [4], [8], [21], [23], and [25], where among other things, a posteriori error estimates on the conforming and nonconforming

discretization errors are derived with both upper and lower bounds. However, in all the cases there are *gaps* in the power between the existing upper and lower estimates.

Very recently in [18] and [19], we extended the quasi-norm techniques and developed some improved a posteriori error estimators of residual type for the conforming and nonconforming finite element approximation of the p-Laplacian. The structure of the new estimators seems very different from all the existing ones. The estimators are in fact shown to be equivalent up to higher order terms in the quasi norms. Initial analysis and numerical tests indicate that the new estimators are sharper than the existing ones, and indeed lead to more efficient computational meshes in some important cases. However, the error estimates in [18] and [19] are not fully a posteriori in the sense that some of the higher order terms in the error bounds contain a priori information of the solutions and therefore are not directly computable. This drawback is due to the lack of suitable interpolation error estimates in the quasi norms for the interpolators used in the papers. It is well known that suitable interpolation error estimation for averaging interpolators is one of the key ingredients in deriving full a posteriori error estimates of residual type for the finite element approximation of elliptic, and indeed more general, systems. Unfortunately such results in the quasi norms have not been available for the averaging interpolators used in the literature, and this leads to those a priori terms in the error bounds in [18] and [19]. It is far from straightforward to generalize the existing estimates on the interpolation error to the quasi norms, since some unique properties of a norm are essentially needed in all the existing proofs of the estimates.

In this work we address this very important issue. In particular, we establish a series of new interpolation error estimates for some of the most widely used interpolators in the literature. The results obtained are of their own importance. It is found that there sometimes exist essential differences between the quasi-norm estimates and the existing ones. We then utilized these results in deriving further improved new a posteriori error estimates for the finite element approximation of the p-Laplacian; see a further explanation at the end of section 2. The results and the methods developed in this paper are applicable to more general degenerate systems.

The plan of this paper is as follows: In section 2 we state the weak formulation of the p-Laplacian and its finite element approximation. Some important inequalities, the definition of the quasi norm, and related results are also presented in section 2. These inequalities are among the key ingredients of the quasi-norm a priori and a posteriori error analysis for the finite element approximation of the p-Laplacian. In section 3 we derive some quasi-norm interpolation error estimates, which can be viewed as the quasi-norm counterparts of some well-known results. In section 4 we use the interpolation error estimates obtained in section 3 to derive a posteriori error bounds for conforming and nonconforming finite element approximations of the p-Laplacian.

2. Preliminaries. Let Ω be a bounded open set in R^2 with a Lipschitz boundary $\partial\Omega$. In this paper we adopt the standard notation $W^{m,q}(\Omega)$ for Sobolev spaces on Ω with norm $\|\cdot\|_{m,q,\Omega}$ and seminorm $|\cdot|_{m,q,\Omega}$. We set $W_0^{m,q}(\Omega) \equiv \{w \in W^{m,q}(\Omega) : w|_{\partial\Omega} = 0\}$. We denote $W^{m,2}(\Omega)$ by $H^m(\Omega)$ with norm $\|\cdot\|_{m,\Omega}$ and seminorm $|\cdot|_{m,\Omega}$.

Consider the p-Laplacian with zero Dirichlet data:

$$\begin{aligned} -\mathrm{div}(|\nabla u|^{p-2}\nabla u) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{2.1}$$

where $1 < p < \infty$ and $f \in L^2(\Omega)$. The weak formulation of (2.1) is as follows (WP):

Find $u \in W_0^{1,p}(\Omega)$ such that

$$a(u,v) = (f,v) \quad \forall v \in W_0^{1,p}(\Omega), \tag{2.2}$$

where

$$a(u,v) = \int_\Omega |\nabla u|^{p-2}\nabla u \cdot \nabla v$$

and

$$(f,v) = \int_\Omega fv.$$

It is a simple matter to show that there exists a unique solution to (WP); see [11]. We note that for sufficiently regular data, global $C^{1,\alpha}$ regularity is established in [15].

Let Ω^h be a polygonal approximation to Ω with the boundary $\partial\Omega^h$. Let T^h be a partitioning of Ω^h into disjoint open regular simplices K, so that $\bar{\Omega}^h = \bigcup_{K\in T^h} \bar{K}$. $\bar{K}$ and $\bar{K}'$ have either an empty or only one common vertex, or a whole edge if K and $K' \in T^h$. We further require that $x_i \in \partial\Omega^h \Rightarrow x_i \in \partial\Omega$, where $\{x_i\}$ $(i = 1 \dots J)$ is the vertex set associated with the partitioning T^h. Let h_K denote the maximum diameter of the element K in T^h and let ρ_K denote the diameter of the largest ball contained in K. We assume that there is a regularity constant R of T^h such that $1 \le \max_{K\in T^h}(h_K/\rho_K) \le R$. For ease of exposition we will assume that $\Omega^h = \Omega$.

Due to limited regularity for the solution of the p-Laplacian, we shall only discuss the conforming piecewise linear elements and a simple nonconforming element—Crouzeix–Raviart—in this paper.

Conforming element. Associated with T^h is a finite dimensional subspace V^h of $C^0(\bar{\Omega}^h)$ such that $\chi|_K \in P_1$ for all $\chi \in V^h$ and $K \in T^h$, where P_1 is the space of polynomials of first degree. Let

$$V_0^h = \{\chi \in V^h : \chi(x_i) = 0 \ \ \forall x_i \in \partial\Omega^h\}.$$

Then the finite element approximation of (WP) is as follows $(WP)^h$: Find $u_h \in V_0^h$ such that

$$a(u_h, v_h) = (f, v_h) \qquad \forall v_h \in V_0^h, \tag{2.3}$$

where

$$a(u_h, v_h) = \int_{\Omega^h} |\nabla u_h|^{p-2}\nabla u_h \cdot \nabla v_h,$$

$$(f, v_h) = \int_{\Omega^h} f v_h.$$

It is a simple matter to show that $(WP)^h$ has a unique solution u_h; see [11] again. Analysis of the finite element approximation of (WP) and a priori error bounds for this approximation were first discussed in [11] and [13]. Some of the best results are obtained in [3].

Nonconforming element. Associated with T^h is the Crouzeix–Raviart-type finite dimensional subspace $\tilde{V}^h$ of $L^2(\Omega^h)$:

$$\tilde{V}^h = \{v \in L^2(\Omega^h) : v|_K \in P_1 \ \forall K \in T^h, v \text{ is continuous on the midpoints of edges}\}.$$

Let

$$\tilde{V}_0^h = \{v \in \tilde{V}^h : v = 0 \text{ on the midpoints of edges on } \partial\Omega\}.$$

Note that $\tilde{V}_0^h \bar{\in} W_0^{1,p}(\Omega)$. The finite element approximation of (WP) is as follows $(WP)_n^h$: Find $u_h \in \tilde{V}_0^h$ such that

$$a_h(u_h, v_h) = (f, v_h) \qquad \forall v_h \in \tilde{V}_0^h, \tag{2.4}$$

where

$$a_h(u_h, v_h) = \sum_K \int_K |\nabla u_h|^{p-2} \nabla u_h \cdot \nabla v_h,$$

$$(f, v_h) = \int_{\Omega^h} f v_h.$$

It also is a simple matter to show that $(WP)_n^h$ has a unique solution u_h. Analysis of the finite element approximation of (WP) and a priori error bounds for this approximation are discussed in [19]. In particular, the optimal a priori error bounds have been established there.

In the following we state some inequalities which play an essential role in our error analysis. In all these lemmas, C is a positive constant which depends only on p. The first two lemmas have been used in our work on a priori quasi-norm error bounds for the finite element approximation of degenerate nonlinear PDEs; see, e.g., [3], [16]. The proofs of Lemma 2.1 and 2.2 can be found in [5] and [18].

LEMMA 2.1. *For all $p > 1$, ξ, $\eta \in R^n$,*

$$| \, |\xi|^{p-2}\xi - |\eta|^{p-2}\eta \, | \le C|\xi - \eta|(|\xi| + |\eta|)^{p-2}, \tag{2.5}$$

$$(|\xi|^{p-2}\xi - |\eta|^{p-2}\eta, \xi - \eta) \ge C|\xi - \eta|^2(|\xi| + |\eta|)^{p-2}. \tag{2.6}$$

LEMMA 2.2. *For all a, σ_1, $\sigma_2 \ge 0$, $p > 1$, $\theta > 0$,*

$$(a + \sigma_1)^{p-2}\sigma_1\sigma_2 \le \theta^{-\gamma}(a + \sigma_1)^{p-2}\sigma_1^2 + \theta(a + \sigma_2)^{p-2}\sigma_2^2,$$

where

$$\gamma = \begin{cases} 1, & 1 < p \le 2, \ \theta \in [1, \infty) \quad \textit{or} \quad 2 < p < \infty, \ \theta \in (0, 1), \\ \dfrac{1}{p-1}, & 1 < p \le 2, \ \theta \in (0, 1) \quad \textit{or} \quad 2 < p < \infty, \ \theta \in [1, \infty). \end{cases}$$

The following lemma is essential for estimating a bilinear form via the quasi norms. It can be viewed as a generalization of the Young inequality where $a = 0$. A proof can be found in [18].

LEMMA 2.3. *For all $a, \sigma_1, \sigma_2 \ge 0$, $p > 1$, and $\delta > 0$,*

$$\sigma_1\sigma_2 \le \delta^{-\beta}(a^{p-1} + \sigma_1)^{p'-2}\sigma_1^2 + \delta(a + \sigma_2)^{p-2}\sigma_2^2,$$

where β is such that $\delta^{-\beta} = \max\{\delta^{-1}, \delta^{-\frac{1}{p-1}}\}$, and p' is such that $\frac{1}{p} + \frac{1}{p'} = 1$.

The following two lemmas will be used to prove some triangle inequality-like results for a power of the quasi norms. They have been proved in [18].

LEMMA 2.4. *For all* $1 < p < \infty$, $\sigma_1, \sigma_2 \in R^n$, *and* $a \geq 0$,

$$(a + |\sigma_1 + \sigma_2|)^{p-2}|\sigma_1 + \sigma_2|^2 \leq C(a + |\sigma_1|)^{p-2}|\sigma_1|^2 + C(a + |\sigma_2|)^{p-2}|\sigma_2|^2.$$

LEMMA 2.5. *For all* $1 < p < \infty$ *and* $\sigma, \sigma_1, \sigma_2 \in R^n$,

$$(|\sigma_1| + |\sigma_2|)^{p-2}|\sigma_1 - \sigma_2|^2 \leq C(|\sigma| + |\sigma - \sigma_1|)^{p-2}|\sigma - \sigma_1|^2 + C(|\sigma| + |\sigma - \sigma_2|)^{p-2}|\sigma - \sigma_2|^2.$$

One of the key ideas in our approach is to introduce some quasi norms to handle the possible degeneracy of the p-Laplacian in order to obtain sharp error bounds. Let us try to explain the main motivation of the method. A norm may be considered to be a "straight ruler" or measure in a linear space. It can handle the smooth nonlinear problems that can be linearized. However, a standard Sobolev norm may not be able to give sharp estimation for the errors of the finite element approximation of some nonlinear equations where, for instance, the locations of degeneracy points of the equations are solution dependent, since it has to assume the worst scenario that there exists the degeneracy everywhere. The type of the equation studied here, which may be degenerate and highly nonlinear, falls into this category. Naturally some "curved" solution dependent rulers or distances may have to be introduced to handle the degeneracy *adaptively* in order to present more accurate error analysis for the finite element approximation of the equation. Furthermore, these "rulers" should be consistent with the special structure of the equation studied, in particular, both monotone and continuous, see (2.11) and (2.12), and thus equivalent to the energy difference. In the case of the p-Laplacian, these rulers (or some of their powers) happen to be quasi norms. This idea has been widely used in our work; see [16], [18], and [19]. As seen later, this idea is also essential in deriving improved a posteriori error estimates for the p-Laplacian. In the following we very briefly introduce such a quasi-norm and some relations between it and the standard Sobolev norms. Let $W^{1,p}(\Omega, T^h) \equiv \{v \in L^p(\Omega) : v|_K \in W^{1,p}(K)\}\ \forall K \in T^h\}$. Let

$$\|v\|_{1,p,\Omega,T^h} = \left(\sum_{K \in T^h} \|v\|^p_{1,p,K}\right)^{1/p}$$

and

$$|v|_{1,p,\Omega,T^h} = \left(\sum_{K \in T^h} |v|^p_{1,p,K}\right)^{1/p}.$$

Let $w \in W^{1,p}(\Omega, T^h)$. Similarly as in [19], we define for any $v \in W^{1,p}(\Omega, T^h)$

$$|v|^2_{(w,p)} \equiv \sum_{K \in T^h} \int_K |\nabla v|^2 (|\nabla w| + |\nabla v|)^{(p-2)}. \tag{2.7}$$

Remark 2.1. It is easy to see that when $v \in W^{1,p}(\Omega)$, $\|v\|_{1,p,\Omega,T^h} = \|v\|_{1,p,\Omega}$, $|v|_{1,p,\Omega,T^h} = |v|_{1,p,\Omega}$, and

$$\sum_{K \in T^h} \int_K (|\nabla w| + |\nabla v|)^{p-2}|\nabla v|^2 = \int_{\Omega^h} (|\nabla w| + |\nabla v|)^{p-2}|\nabla v|^2$$

if $w, v \in W^{1,p}(\Omega)$. The quasi norm on the right side has been introduced in [3] and [18] to study $(WP)^h$.

We have the following proposition.

PROPOSITION 2.6. (i) $|v|_{(w,p)} \geq 0$, *and when* $v \in W_0^{1,p}(\Omega)$, $|v|_{(w,p)} = 0$ *if and only if* $v = 0$. (ii) $|v_1 + v_2|_{(w,p)} \leq C(|v_1|_{(w,p)} + |v_2|_{(w,p)})$ *for any* $v_1, v_2 \in W^{1,p}(\Omega, T^h)$, *where* C *depends only on* p.

Furthermore for $1 < p \leq 2$, *we have*

$$|v|_{1,p,\Omega,T^h} \leq C(1 + |w|_{1,p,\Omega,T^h} + |v|_{1,p,\Omega,T^h})^{(2-p)/2}|v|_{(w,p)}, \tag{2.8}$$

$$|v|^2_{(w,p)} \leq \sum_{K \in T^h} |v|^p_{1,p,K} = |v|^p_{1,p,\Omega,T^h}, \tag{2.9}$$

and for $2 \leq p < \infty$,

$$|v|^p_{1,p,\Omega,T^h} \leq \|v\|^2_{(w,p)} \leq C(1 + |w|_{1,r,\Omega,T^h} + |v|_{1,r,\Omega,T^h})^{(p-2)/2}|v|^2_{1,s,\Omega,T^h}, \tag{2.10}$$

where $s \in [2, p]$, $r = s(2-p)/(2-s)$.

The conclusion (ii) can be easily proved by Lemma 2.4. The rest of the proposition can be shown similarly as in [5].

Although in a priori error analysis we almost always take w to be u, the solution of (WP), it is sometimes desirable to replace it with u_h (see [18]) in a posteriori error analysis, where u_h is the finite element approximation of u, in order to make the quasi-norm "computable." It follows from the triangle inequality that there are constants $c, C > 0$, independent of h such that

$$c|u - u_h|_{(u,p)} \leq |u - u_h|_{(u_h,p)} \leq C|u - u_h|_{(u,p)}.$$

We shall simply write $|\cdot|_{(u,p)}$ as $|\cdot|_{(p)}$ when no confusion is likely caused.

The essential relations between the quasi norm and the equation are reflected in the following inequalities, which follow from Lemmas 2.1 and 2.2 (see [4] for a proof). Let u be the solution of (WP). For any $v \in W^{1,p}(\Omega)$,

$$a(u, u - v) - a(v, u - v) \geq C|u - v|^2_{(u,p)}, \tag{2.11}$$

and for any $\theta > 0$,

$$|a(u, w) - a(v, w)| \leq C\theta^{-\gamma}|u - v|^2_{(u,p)} + C\theta|w|^2_{(u,p)} \qquad \forall v, w \in W^{1,p}(\Omega), \tag{2.12}$$

where the constant $\gamma > 0$ is defined in Lemma 2.2. It follows from (2.11) and (2.12) that there are constants $c, C > 0$ such that for any $u, v \in W^{1,p}(\Omega)$

$$c(a(u, v - u) - a(v, u - v)) \leq |u - v|^2_{(u,p)} \leq C(a(u, u - v) - a(v, u - v)).$$

Thus the quasi norm is naturally related to the total energy difference $a(u, u - v) - a(v, u - v)$.

The relations (2.11) and (2.12) are important to prove the optimal a priori error bound in the quasi norm. For instance, for the conforming piecewise linear finite element solution u_h of the p-Laplacian, we have (see [3] and [16])

$$|u - u_h|^2_{(p)} \leq C \min_{v_h \in V_0^h} |u - v_h|^2_{(p)} \leq Ch^2$$

provided u is smooth enough. Thus when $1 < p \le 2$, for instance, one has the optimal a priori error bound in the $W^{1,p}$ norm:

$$\|u - u_h\|_{1,p,\Omega} \le C|u - u_h|_{(p)} \le Ch,$$

when u is smooth enough.

In [18] and [19], the quasi norm has been used to obtain improved a posteriori error estimators for the p-Laplacian. For instance, let u_h be the piecewise linear conforming finite element approximation of the p-Laplacian. Then

$$c(\eta_1^2 + \eta_2^2) + c\epsilon_1 \le |u - u_h|_{(p)}^2 \le C(\eta_1^2 + \eta_2^2) + C\epsilon_2,$$

where η_1, η_2 are defined in section 4, and ϵ_1, ϵ_2 are some higher order terms for smooth f and the smooth solutions, though ϵ_2 is not directly computable. The readers are referred to [18] and [19] for the details. However, it is not clear if ϵ_2 is always negligible. Thus the above estimators may not be fully reliable. This is an annoying theoretical problem, as logically one wishes to be assured that one's estimators are always reliable and at least efficient for the smooth data. In this paper, we shall derive new a posteriori error estimates, which are fully reliable. We will discuss and interpret these estimates in Remark 4.1 and Remark 4.3.

In the next section, we shall derive some important interpolation error estimates in the quasi norm for some well-known averaging interpolators, which are among the keys to our improved estimates.

3. Interpolation error estimates. In this section, we shall establish some interpolation error estimates in the quasi norm, which are essential in our a posteriori error analysis for the p-Laplacian. Some of the relevant ideas can be found in [9], [18], and [19]. First, let us prove a lemma which is a quasi-norm version of the inequalities of the Poincare type. The following proof was adopted from [9].

LEMMA 3.1. *Let Ω be a nonempty bounded connected open set in R^2. Let $1 < p < \infty$ and $f \in (W^{1,p}(\Omega))^*$ with $R \cap \mathrm{Ker}(f) = \{0\}$. Then there exists a constant $C = C(f, p, \Omega)$ such that, for all $a \in R$, $a \ge 0$, and $v \in W^{1,p}(\Omega)$,*

$$\int_\Omega (a + |v|)^{p-2}|v|^2 dx \le C(a + |f(v)|)^{p-2}|f(v)|^2 + C\int_\Omega (a + |\nabla v|)^{p-2}|\nabla v|^2\, dx.$$

Proof. We first introduce the following notation to simplify the proof. For $x, y \ge 0$, $1 < p < \infty$, let

$$G(x, y) := \begin{cases} y^2(x + y)^{p-2} & \text{if } x + y > 0, \\ 0 & \text{if } x = y = 0. \end{cases} \tag{3.1}$$

Then the lemma states that there exists a constant $C = C(f, p, \Omega)$ such that, for all $a \ge 0$ and for all $v \in W^{1,p}(\Omega)$,

$$\int_\Omega G(a, |v|)\, dx \le C\, G(a, |f(v)|) + C\int_\Omega G(a, |\nabla v|)\, dx. \tag{3.2}$$

Note that $G(x, y)$ is monotone increasing and convex with respect to the variable y.

We argue by contradiction and suppose that (3.2) is false. Then there would exist a sequence v_j in $W^{1,p}(\Omega)$ with $\delta_j := \|v_j\|_{1,q,\Omega} > 0$, $q = \min\{2, p\}$, and a sequence a_j of nonnegative real numbers such that

$$G(a_j, |f(v_j)|) + \int_\Omega G(a_j, |\nabla v_j|)\, dx \le \frac{1}{j}\int_\Omega G(a_j, |v_j|)\, dx \tag{3.3}$$

for all $j \in \mathcal{N}$. We observe in any case that there exists a $u \in W^{1,q}(\Omega)$ with

$$u_j := \frac{v_j}{\delta_j} \text{ satisfies } \|u_j\|_{1,q,\Omega} = 1, \qquad u_j \rightharpoonup u \text{ in } W^{1,q}(\Omega). \tag{3.4}$$

Here we have chosen a weak convergent subsequence with the Banach–Alaoglu theorem. In the first case we suppose that there exists a constant γ, $0 < \gamma < \infty$, with

$$a_j \le \gamma\, \delta_j \quad \text{for } j = 1, 2, 3, \ldots. \tag{3.5}$$

At least we suppose (3.5) for a subsequence we have not relabelled. If $1 < p \le 2$, then $G(a, x) \le x^p$ for all $x \ge 0$. Therefore,

$$\int_\Omega G\left(\frac{a_j}{\delta_j}, |u_j|\right) dx \le \|u_j\|^p_{0,p,\Omega} \le 1$$

even without (3.5). If $2 \le p$, then $G(\cdot, |u_j|)$ is monotone increasing. Hence, (3.4)–(3.5) yield

$$\begin{aligned}\int_\Omega G\left(\frac{a_j}{\delta_j}, |u_j|\right) dx &\le \int_\Omega (\gamma + |u_j|)^{p-2} |u_j|^2\, dx \\ &\le \|\gamma + |u_j|\|^p_{0,p,\Omega} \le (1 + \gamma |\Omega|^{\frac{1}{p}})^p.\end{aligned}$$

Hence, for all $1 < p < \infty$, $\int_\Omega G(a_j/\delta_j, |u_j|)\, dx$ is bounded. A scaling of (3.3) then shows

$$\lim_{j\to\infty} \int_\Omega G\left(\frac{a_j}{\delta_j}, |\nabla u_j|\right) dx = \lim_{j\to\infty} G\left(\frac{a_j}{\delta_j}, |f(u_j)|\right) = 0. \tag{3.6}$$

If $1 < p \le 2$, a Hölder inequality with exponents $2/p$ and $2/(2-p)$ leads to

$$\begin{aligned}\|\nabla u_j\|^p_{0,p,\Omega} &= \int_\Omega |\nabla u_j|^p \left(\frac{a_j}{\delta_j} + |\nabla u_j|\right)^{\frac{p(p-2)}{2}} \left(\frac{a_j}{\delta_j} + |\nabla u_j|\right)^{\frac{p(2-p)}{2}} dx \\ &\le \left(\int_\Omega G\left(\frac{a_j}{\delta_j}, |\nabla u_j|\right) dx\right)^{\frac{p}{2}} \left(\int_\Omega \left(\frac{a_j}{\delta_j} + |\nabla u_j|\right)^p dx\right)^{1-\frac{p}{2}}. \end{aligned} \tag{3.7}$$

The last factor is bounded as $j \to \infty$ by (3.4)–(3.5) and the second last tends to zero by (3.6). Again, for $1 < p \le 2$ (when $G(\cdot, |f(u_j)|)$ is monotone decreasing), (3.6) shows that $G(\gamma, |f(u_j)|)$ tends to zero and, hence, so does $|f(u_j)|$. Consequently,

$$\lim_{j\to\infty} \|\nabla u_j\|_{0,q,\Omega} = \lim_{j\to\infty} |f(u_j)| = 0. \tag{3.8}$$

So far we established (3.8) for $1 < p \le 2$. For $2 < p < \infty$, $|\nabla u_j|^p \le G(a_j/\delta_j, |\nabla u_j|)$ and $|f(u_j)|^p \le G(a_j/\delta_j, |f(u_j)|)$, and so (3.6) implies (3.8) directly. From (3.8) we deduce a contradiction to (3.4): Since $W^{1,q}(\Omega)$ is compactly embedded in $L^q(\Omega)$, we have $u_j \to u$ in $L^q(\Omega)$. With (3.8), $u_j \to u$ in $W^{1,q}(\Omega)$ and so $\|u\|_{1,q,\Omega} = 1$. Conversely, u is constant (as $\nabla u_j \to 0$ in $L^q(\Omega)$). Since f is a bounded linear form, $f(u_j) \to f(u)$ and $f(u) = 0$. Since $u \in R \cap \mathrm{Ker} f$, we have $u = 0$. This contradiction with $\|u\|_{1,q,\Omega} = 1$ concludes (3.2) in case (3.5).

In the remaining second case we suppose that a_j/δ_j is not bounded (not even for a subsequence). Hence, $\lim_{j\to\infty}(a_j/\delta_j) = +\infty$. One can assume that

$$\delta_j \le \gamma\, a_j \text{ for } q = \min\{2, p\} \text{ and for } j = 1, 2, 3, \ldots \tag{3.9}$$

for a constant γ (and at least for sufficiently large j which we have not relabelled). If $1 < p \le 2$, we use $(1 + (\delta_j/a_j)|u_j|)^{p-2} \le 1$. If $2 \le p < \infty$, we use $\delta_j/a_j \le \gamma$. This leads to

$$\begin{aligned}(3.10)\qquad &\frac{1}{j}\int_\Omega \left(1+\frac{\delta_j}{a_j}|u_j|\right)^{p-2}|u_j|^2\,dx \\ &\le \begin{cases} \dfrac{1}{j}\|u_j\|^2_{0,2,\Omega} & \text{if } 1<p\le 2,\\[2ex] \dfrac{1}{j}\,\gamma^{p-2}\left(\dfrac{1}{\gamma}\,|\Omega|^{1/p}+\|u_j\|_{0,p,\Omega}\right)^p & \text{if } 2\le p<\infty. \end{cases}\end{aligned}$$

Since $q = \min\{2, p\}$ and $\|u_j\|_{1,q,\Omega} = 1$, we conclude that (3.10) tends to zero as $j \to \infty$ from embedding. A scaling of (3.3) therefore yields

$$\begin{aligned}(3.11)\qquad &\lim_{j\to\infty}\int_\Omega \left(1+\frac{\delta_j}{a_j}\,|\nabla u_j|\right)^{p-2}|\nabla u_j|^2\,dx \\ &= \lim_{j\to\infty}\left(1+\frac{\delta_j}{a_j}\,|f(u_j)|\right)^{p-2}|f(u_j)|^2 = 0.\end{aligned}$$

If $2 \le p < \infty$, we directly deduce (3.8) for $q = 2$ and finish the proof of (3.2) as in the first case since $\|u_j\|_{1,2,\Omega} = 1$. If $1 < p \le 2$, we argue with a Hölder inequality analogy to (3.7) and infer

$$\|\nabla u_j\|^2_{0,p,\Omega} \le \int_\Omega \left(1+\frac{\delta_j}{a_j}\,|\nabla u_j|\right)^{p-2}|\nabla u_j|^2\,dx\,\left(\int_\Omega\left(1+\frac{\delta_j}{a_j}\,|\nabla u_j|\right)^p dx\right)^{\frac{2-p}{p}}.$$

The last factor is bounded according to (3.9) and $\|u_j\|_{1,p,\Omega} = 1$. This and (3.11) show (3.8) with $p = q \le 2$. (3.2) then follows as in the first case. Hence, Lemma 3.1 follows.

COROLLARY 3.2. *Let Ω be a nonempty bounded connected open set in R^2. Then, for any $a \ge 0$, $v \in W^{1,p}(\Omega)$, and $p > 1$, there exists a constant C, which is only dependent on Ω and p, such that*

$$\inf_{q\in R}\int_\Omega (a+|v+q|)^{p-2}|v+q|^2 \le C\int_\Omega (a+|\nabla v|)^{p-2}|\nabla v|^2.$$

Proof. It follows from (3.2) that for given $p > 1$ and $f \in (W^{1,p}(\Omega))^*$ with $R \cap \mathrm{Ker}(f) = \{0\}$ there exists a constant $C = C(f, p, \Omega)$ such that for all $v \in W^{1,p}(\Omega)$, $q \in R$,

$$\begin{aligned}&\int_\Omega (a+|v+q|)^{p-2}|v+q|^2 + \int_\Omega (a+|\nabla(v+q)|)^{p-2}|\nabla(v+q)|^2 \\ &\le C\left(\int_\Omega (a+|\nabla(v+q)|)^{p-2}|\nabla(v+q)|^2 + (a+|f(v+q)|)^{p-2}|f(v+q)|^2\right).\end{aligned}$$

Let us take a fixed linear functional f (say, $f(v) = \int_\Omega v$). Note that there exists a $q^*(v) \in R$ such that $f(v + q^*) = 0$. Then, we have

$$\inf_{q\in R}\left\{\int_\Omega (a+|v+q|)^{p-2}|v+q|^2 + \int_\Omega (a+|\nabla(v+q)|)^{p-2}|\nabla(v+q)|^2\right\}$$

$$\le \int_\Omega (a+|v+q^*|)^{p-2}|v+q^*|^2 + \int_\Omega (a+|\nabla(v+q^*)|)^{p-2}|\nabla(v+q^*)|^2$$
$$\le C\bigg(\int_\Omega (a+|\nabla(v+q^*)|)^{p-2}|\nabla(v+q^*)|^2 + (a+|f(v+q^*)|)^{p-2}|f(v+q^*)|^2\bigg)$$
$$= C\int_\Omega (a+|\nabla(v+q^*)|)^{p-2}|\nabla(v+q^*)|^2 = C\int_\Omega (a+|\nabla v|)^{p-2}|\nabla v|^2.$$

Hence, Corollary 3.2 follows.

Thanks to the above lemma and its corollary, now we can prove new quasi-norm interpolation error estimates for some finite element spaces.

First, let us consider the nonconforming finite element—Crouzeix–Raviart element—space $\tilde{V}^h$. An interpolation operator $\tilde{\pi}_h$ from $W^{1,1}(K)$ to $\tilde{V}^h$ is defined (see [12] and [24] for examples) such that for any $w \in W^{1,1}(K)$, $\tilde{\pi}_h w|_K \in P_1$ and

$$\int_{l_i} \tilde{\pi}_h w = \int_{l_i} w, \qquad i = 1,2,3,$$

where l_i are the edges of the element K. For the above interpolation, we have the following interpolation error estimate.

THEOREM 3.3. *Let $\tilde{\pi}_h$ be the interpolation operator defined as above. For all $K \in T^h$, $v \in W^{1,p}(K)$, and $p > 1$, one has*

$$\int_K (|\nabla u_h| + h_K^{-1}|v-\tilde{\pi}_h v|)^{p-2} h_K^{-2}|v-\tilde{\pi}_h v|^2 \le C\int_K (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2 \tag{3.12}$$

and

$$\int_K (|\nabla u_h| + |\nabla(v-\tilde{\pi}_h v)|)^{p-2}|\nabla(v-\tilde{\pi}_h v)|^2 \le C\int_K (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2\,. \tag{3.13}$$

Proof. Let $\hat{K}$ be a reference element of K; it is easy to see that

$$\int_K (|\nabla u_h| + h_K^{-1}|v-\tilde{\pi}_h v|)^{p-2} h_K^{-2}|v-\tilde{\pi}_h v|^2 \le C h_K^{2-p}\int_{\hat{K}} (|\nabla u_h| + |v-\tilde{\pi}_h v|)^{p-2}|v-\tilde{\pi}_h v|^2.$$

Note that for all $q \in R$, $\tilde{\pi}_h q = q$. It follows from Lemma 2.4 that

$$\begin{aligned}
&\int_K (|\nabla u_h| + h_K^{-1}|v-\tilde{\pi}_h v|)^{p-2} h_K^{-2}|v-\tilde{\pi}_h v|^2 \\
&\le C h_K^{2-p}\inf_{q\in R}\bigg\{\int_{\hat{K}} (|\nabla u_h| + |(I-\tilde{\pi}_h)(v+q)|)^{p-2}|(I-\tilde{\pi}_h)(v+q)|^2\bigg\} \\
&\le C h_K^{2-p}\inf_{q\in R}\bigg\{\int_{\hat{K}} (|\nabla u_h| + |v+q|)^{p-2}|v+q|^2 \\
&\qquad\qquad + \int_{\hat{K}} (|\nabla u_h| + |\tilde{\pi}_h(v+q)|)^{p-2}|\tilde{\pi}_h(v+q)|^2\bigg\}.
\end{aligned} \tag{3.14}$$

Note that by the definition of $\tilde{\pi}_h$ and a trace theorem,

$$\int_{\hat{K}} (|\nabla u_h| + |\tilde{\pi}_h(v+q)|)^{p-2}|\tilde{\pi}_h(v+q)|^2$$
$$\le \sum_{i=1}^3 C_i \int_{\hat{K}} \bigg(|\nabla u_h| + \int_{l_i}|v+q|\bigg)^{p-2}\bigg(\int_{l_i}|v+q|\bigg)^2$$

$$\le \sum_{i=1}^{3} C_i \int_{\hat{K}} \left(|\nabla u_h| + \int_{\hat{K}} |v+q| + \int_{\hat{K}} |\nabla(v+q)| \right)^{p-2} \left(\int_{\hat{K}} |v+q| + \int_{\hat{K}} |\nabla(v+q)| \right)^2$$
$$\le C \Bigg(\int_{\hat{K}} \left(|\nabla u_h| + \int_{\hat{K}} |v+q| \right)^{p-2} \left(\int_{\hat{K}} |v+q| \right)^2 + \int_{\hat{K}} \left(|\nabla u_h| + \int_{\hat{K}} |\nabla(v+q)| \right)^{p-2} \left(\int_{\hat{K}} |\nabla(v+q)| \right)^2 \Bigg).$$

Let $s(x) = (a+x)^{p-2}x^2$. Then it can be shown that $s(x)$ is increasing on $[0,\infty)$ for any $a \ge 0$ and is further a convex continuous function on $[0,\infty)$. Therefore it follows from the integral form of the Jensen inequality that

$$meas(\hat{K}) s \left(\int_{\hat{K}} r \right) \le \int_{\hat{K}} s(meas(\hat{K}) r). \tag{3.15}$$

Note that there exist constants c and C such that $c \le meas(\hat{K}) \le C$. Then applying the Jensen inequality, we have that

$$\int_{\hat{K}} (|\nabla u_h| + |\tilde{\pi}_h(v+q)|)^{p-2} |\tilde{\pi}_h(v+q)|^2$$
$$\le C \Bigg(\int_{\hat{K}} (|\nabla u_h| + |v+q|)^{p-2} |v+q|^2 + \int_{\hat{K}} (|\nabla u_h| + |\nabla(v+q)|)^{p-2} |\nabla(v+q)|^2 \Bigg).$$

Hence by (3.14) and Corollary 3.2, we have that

$$\int_K (|\nabla u_h| + h_K^{-1}|v - \tilde{\pi}_h v|)^{p-2} h_K^{-2} |v - \tilde{\pi}_h v|^2$$
$$\le C h_K^{2-p} \inf_{q \in R} \Bigg\{ \int_{\hat{K}} (|\nabla u_h| + |v+q|)^{p-2} |v+q|^2 + \int_{\hat{K}} (|\nabla u_h| + |\nabla(v+q)|)^{p-2} |\nabla(v+q)|^2 \Bigg\}$$
$$\le C h_K^{2-p} \int_{\hat{K}} (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2 \le C h_K^{2-p} h_K^{-2} h_K^p \int_K (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2$$
$$= C \int_K (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2 .$$

This proves (3.12). The estimate (3.13) can be proved similarly.

Now let us consider the conforming finite element space. Let π_h be the average interpolator defined in [22] from $H^1(\Omega)$ to V^h (or from $H_0^1(\Omega)$ to V_0^h); see [22] for details. For this average interpolator, we have the following quasi-norm interpolation error estimates.

THEOREM 3.4. *Let π_h be the average interpolation operator defined in* [22]. *Then, for all $p > 1$, constant $a \ge 0$, $K \in T^h$, and $v \in W^{1,p}(\Omega)$, one has*

$$\int_K (a + h_K^{-1}|v - \pi_h v|)^{p-2} h_K^{-2} |v - \pi_h v|^2 \le C \sum_{\bar{K}' \cap \bar{K} \ne \emptyset} \int_{K'} (a + |\nabla v|)^{p-2} |\nabla v|^2 \tag{3.16}$$

and

$$\int_K (a + |\nabla(v - \pi_h v)|)^{p-2} |\nabla(v - \pi_h v)|^2 \le C \sum_{\bar{K}' \cap \bar{K} \ne \emptyset} \int_{K'} (a + |\nabla v|)^{p-2} |\nabla v|^2 , \tag{3.17}$$

where the constant C depends only on Ω and p.

Proof. Let

$$S_i = \{\cup K' : K' \in T^h, \bar{K}' \cap x_i \neq \emptyset\},$$

where x_i, $i = 1, 2, 3$, are the vertices of the element K. Let $\hat{S}_i$ and $\hat{K}$ be reference elements of S_i and K, respectively, $q \in R$. By the definition of interpolation π_h and Lemma 2.4, we have that

$$\begin{aligned}
&\int_{\hat{K}} (a + |\pi_h(v+q)|)^{p-2} |\pi_h(v+q)|^2 \\
&\leq \sum_{i=1}^{3} C_i \int_{\hat{K}} \left(a + \int_{\hat{S}_i} |v+q| + \int_{\hat{S}_i} |\nabla(v+q)| \right)^{p-2} \left(\int_{\hat{S}_i} |v+q| + \int_{\hat{S}_i} |\nabla(v+q)| \right)^2 \\
&\leq C \sum_{i=1}^{3} \int_{\hat{K}} \left(a + \int_{\hat{S}_i} |v+q| \right)^{p-2} \left(\int_{\hat{S}_i} |v+q| \right)^2 \\
&\qquad + C \sum_{i=1}^{3} \int_{\hat{K}} \left(a + \int_{\hat{S}_i} |\nabla(v+q)| \right)^{p+2} \left(\int_{\hat{S}_i} |\nabla(v+q)| \right)^2.
\end{aligned}$$

Using the Jensen inequality (3.15), we have that

$$\int_{\hat{K}} \left(a + \int_{\hat{S}_i} |v+q| \right)^{p-2} \left(\int_{\hat{S}_i} |v+q| \right)^2 \leq C \int_{\hat{S}_i} (a + |v+q|)^{p+2} |v+q|^2$$

and

$$\int_{\hat{K}} \left(a + \int_{\hat{S}_i} |\nabla(v+q)| \right)^{p-2} \left(\int_{\hat{S}_i} |\nabla(v+q)| \right)^2 \leq C \int_{\hat{S}_i} (a + |\nabla(v+q)|)^{p+2} |\nabla(v+q)|^2.$$

Hence,

$$\begin{aligned}
&\int_{\hat{K}} (a + |\pi_h(v+q)|)^{p-2} |\pi_h(v+q)|^2 \\
&\leq C \sum_{i=1}^{3} \left(\int_{\hat{S}_i} (a + |v+q|)^{p-2} |v+q|^2 + \int_{\hat{S}_i} (a + |\nabla(v+q)|)^{p-2} |\nabla(v+q)|^2 \right).
\end{aligned}$$

Note that for all $q \in R$, $\pi_h q = q$ and $\cup_{i=1}^{3} S_i$ is a bounded open set and $meas(K) = O(h_K^2) meas(\hat{K})$. Then, similarly as in the proof of Theorem 3.3, we have that (using Corollary 3.2)

$$\begin{aligned}
&\int_K (a + h_K^{-1} |v - \pi_h v|)^{p-2} h_K^{-2} |v - \pi_h v|^2 dx \\
&\leq C \int_{\hat{K}} (a + h_K^{-1} |v - \pi_h v|)^{p-2} |v - \pi_h v|^2 d\hat{x} \\
&\leq C h_K^{2-p} \int_{\hat{K}} (h_K a + |v - \pi_h v|)^{p-2} |v - \pi_h v|^2 \\
&\leq C h_K^{2-p} \inf_{q \in R} \left\{ \int_{\hat{K}} (h_K a + |(I - \pi_h)(v+q)|)^{p-2} |(I - \pi_h)(v+q)|^2 \right\}
\end{aligned}$$

$$
\begin{aligned}
&\le Ch_K^{2-p}\inf_{q\in R}\Big\{\int_{\hat K}(h_Ka+|v+q|)^{p-2}|v+q|^2\\
&\qquad\qquad+\int_{\hat K}(h_Ka+|\pi_h(v+q)|)^{p-2}|\pi_h(v+q)|^2\Big\}\\
&\le Ch_K^{2-p}\inf_{q\in R}\Big\{\sum_{i=0}^{3}\int_{\hat S_i}(h_Ka+|v+q|)^{p-2}|v+q|^2\\
&\qquad\qquad+\int_{\hat S_i}(h_Ka+|\nabla(v+q)|)^{p-2}|\nabla(v+q)|^2)\Big\}\\
&\le Ch_K^{2-p}\inf_{q\in R}\Big\{\sum_{\bar K\cap\bar K'\neq\emptyset}\int_{\hat K'}(h_Ka+|v+q|)^{p-2}|v+q|^2\\
&\qquad\qquad+\int_{\hat K'}(h_Ka+|\nabla(v+q)|)^{p-2}|\nabla(v+q)|^2)\Big\}\\
&\le Ch_K^{2-p}\sum_{\bar K\cap\bar K'\neq\emptyset}\int_{\hat K'}(h_Ka+|\nabla v|)^{p-2}|\nabla v|^2\\
&\le Ch_K^{2-p}h_K^{-2}h_K^p\sum_{\bar K\cap\bar K'\neq\emptyset}\int_{K'}(a+|\nabla v|)^{p-2}|\nabla v|^2\\
&\le C\sum_{\bar K'\cap\bar K\neq\emptyset}\int_{K'}(a+|\nabla v|)^{p-2}|\nabla v|^2.
\end{aligned}
$$

This proves (3.16). The estimate (3.17) can be proved similarly.

However, in deriving a posteriori error estimates for the conforming finite element approximation of the p-Laplacian, a $(=|\nabla u_h|)$ is generally different on different elements. Thus Theorem 3.4 has to be generalized to accommodate the interactions across the elements.

To this end, we first introduce some notations, as in [18] and [19]. Let $u_h\in V^h$. Let l be an edge of an element $K\in T^h$. If l is on the boundary of Ω^h, then we define the element $K^l_{max}=K^l_{min}=K$. Otherwise let $l=\bar K^1_l\cap\bar K^2_l$, where K^1_l, K^2_l are the two elements sharing the common face l. Then we define the element $K^l_{max}(K^l_{min})=K^i_l$ $(i=1$ or $2)$ such that

$$|\nabla u_h|^{p-2}_{K^l_{max}}=\max_{i=1,2}\{|\nabla u_h|^{p-2}_{K^i_l}\},$$

$$|\nabla u_h|^{p-2}_{K^l_{min}}=\min_{i=1,2}\{|\nabla u_h|^{p-2}_{K^i_l}\}.$$

We will take $K^l_{max}=K^l_{min}=K^1_l$ just for fixing the idea if $|\nabla u_h|^{p-2}_{K^1_l}=|\nabla u_h|^{p-2}_{K^2_l}$. Let $[w]_l=w|_{K^1_l}-w|_{K^2_l}$. The purpose of introducing K_{min} and K_{max} is to make some estimators (like η below) sharper. We shall come back to this point at the end of section 4. Using Theorem 3.4, we shall derive two important interpolation error estimates for the conforming piecewise linear finite element which are stated in Theorems 3.3 and 3.4 and will be used in the proofs of Theorems 4.1 and 4.2. We first need a simple proposition, which was adopted from [9].

PROPOSITION 3.5. *Let $G(x,y)$ be defined in* (3.1). *For all $a_1,a_2,\dots,a_n\in R^2$,*

where n is a given positive integer, there exists a constant $C = C(p,n)$ such that

$$\sum_{j=1}^{n}\sum_{k=1}^{j-1} G(|a_j|,|a_j-a_k|) \le C\sum_{\ell=1}^{n-1}\min_{m=1,\dots,n} G(|a_m|,|a_{\ell+1}-a_\ell|). \tag{3.18}$$

Proof. Let $\alpha := (a_1+\cdots+a_n)/n \in R^2$ and $b_j := a_j-\alpha \in R^2$ so that $b_1+\cdots+b_n = 0$. Define

$$f(\alpha;b_1,\dots,b_n) := \sum_{j=1}^{n}\sum_{k=1}^{j-1} G(|\alpha+b_j|,|b_j-b_k|),$$
$$g(\alpha;b_1,\dots,b_n) := \sum_{\ell=1}^{n-1}\min_{m=1,\dots,n} G(|\alpha+b_m|,|b_{\ell+1}-b_\ell|).$$

Observe that $g(\alpha,\cdot)$ is positive for nonzero arguments on

$$X := \{(b_1,\dots,b_n)\in R^{2\times n} :\ b_1+\cdots+b_n = 0\}$$

since $g(\alpha;b_1,\dots,b_n) = 0$ implies $b_1 = b_2 = \ldots = b_n$. Let $B := \{(b_1,\dots,b_n)\in X :\ |b_1|^2+\cdots+|b_n|^2 = 1\}$ denote the unit ball surface in X. Then, for any $\beta\in R^2$,

$$c(\beta) := \max_{(b_1,\dots,b_n)\in B} f(\beta;b_1,\dots,b_n)/g(\beta;b_1,\dots,b_n) < \infty$$

since the denominator is positive and $f(\alpha;\cdot), g(\alpha;\cdot)$ are continuous on the compact set B. The same argument shows

$$c_\infty := \max_{(b_1,\dots,b_n)\in X\setminus\{0\}} \sum_{j=1}^{n}\sum_{k=1}^{j-1}|b_j-b_k|^2 / \sum_{\ell=1}^{n-1}|b_{\ell+1}-b_\ell|^2 < \infty.$$

Note that $\limsup_{|\beta|\to\infty} c(\beta) \le c_\infty < \infty$, and so $c(\beta)$ is a bounded continuous function in $\beta\in R^2$. For all $a_1,\dots,a_n\in R^2$, we have $\alpha\in R^2$, and $(b_1,\dots,b_n)\in X$ as above. Since f and g are positively homogeneous functions, we have, for $\lambda := (|b_1|^2+\cdots+|b_n|^2)^{1/2} > 0$,

$$\begin{aligned} f(\alpha;b_1,\dots,b_n) &= \lambda^p f(\alpha/\lambda;b_1/\lambda,\dots,b_n/\lambda)\\ &\le C\lambda^p g(\alpha/\lambda,b_1/\lambda,\dots,b_n/\lambda) = Cg(\alpha;b_1,\dots,b_n),\end{aligned}$$

where C is only dependent on p and n. This proves our conclusion.

THEOREM 3.6. *Let $u_h\in V^h$. Under the conditions of Theorem* 3.2*,*

$$\begin{aligned}&\sum_K\int_K (|\nabla u_h| + h_K^{-1}|v-\pi v|)^{p-2}h_K^{-2}|v-\pi v|^2\\ &\qquad\le C\sum_K\int_K (|\nabla u_h|+|\nabla v|)^{p-2}|\nabla v|^2 + C\eta^2,\end{aligned} \tag{3.19}$$

$$\begin{aligned}&\sum_K\int_K (|\nabla u_h| + |\nabla(v-\pi v)|)^{p-2}|\nabla(v-\pi v)|^2\\ &\qquad\le C\sum_K\int_K (|\nabla u_h|+|\nabla v|)^{p-2}|\nabla v|^2 + C\eta^2,\end{aligned} \tag{3.20}$$

where $\frac{\partial u_h}{\partial n}$ *is the normal derivative of* u_h*, and*

$$\eta^2 = \sum_l \int_{K^l_{min}} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 .$$

Proof. Note that for all $a \geq 0$, $p > 1$, $(a+x)^{p-2}x^2$ is a convex function, and for any real number a, b,

$$\frac{1}{2}(|a| + |b|) \leq |a| + |a+b| \leq 2(|a| + |b|). \tag{3.21}$$

It follows from Theorem 3.4, Lemma 2.4, and (3.21) that

(3.22)

$$\begin{aligned}
&\sum_K \int_K (|\nabla u_h| + h_K^{-1}|v - \pi v|)^{p-2} h_K^{-2} |v - \pi v|^2 \\
&\leq C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h|_K + |\nabla v|)^{p-2} |\nabla v|^2 \\
&\leq C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h|_K + |\nabla v| + |\nabla (u_h - u_h|_K)|)^{p-2} (|\nabla v| + |\nabla (u_h - u_h|_K)|)^2 \\
&\leq C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla v| + |\nabla (u_h - u_h|_K)|)^{p-2} (|\nabla v| + |\nabla (u_h - u_h|_K)|)^2 \\
&\leq C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla v|)^{p-2} |\nabla v|^2 \\
&\quad + C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla (u_h - u_h|_K)|)^{p-2} |\nabla (u_h - u_h|_K)|^2 \\
&\leq C \sum_K \int_K (|\nabla u_h| + |\nabla v|)^{p-2} (|\nabla v|)^2 \\
&\quad + C \sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla (u_h - u_h|_K)|)^{p-2} |\nabla (u_h - u_h|_K)|^2 .
\end{aligned}$$

We now apply Proposition 3.5. Let $a_j = \nabla u_h|_{K_j}$ with $K_1 \cup K_2 \cup \cdots \cup K_n = \{K' \in T^h : \ \bar{K}' \cap \bar{K} \neq \emptyset\}$. Then n is finite because that T^h is regular. Therefore, it follows from (3.18) that

$$\begin{aligned}
&\sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla (u_h - u_h|_K)|)^{p-2} |\nabla (u_h - u_h|_K)|^2 \\
&\leq C \sum_l \int_{K^l_{min}} (|\nabla u_h| + |[\nabla u_h]_l|)^{p-2} |[\nabla u_h]_l|^2 .
\end{aligned}$$

Note that $\frac{\partial u_h}{\partial t}|_l$ is continuous, where t is the tangent direction of l. We have that $[\frac{\partial u_h}{\partial n}]|_l = [\nabla u_h]|_l$. Hence,

$$\begin{aligned}
&\sum_K \sum_{\bar{K} \cap \bar{K}' \neq \emptyset} \int_{K'} (|\nabla u_h| + |\nabla (u_h - u_h|_K)|)^{p-2} |\nabla (u_h - u_h|_K)|^2 \\
&\leq C \sum_l \int_{K^l_{min}} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 = C\eta^2 .
\end{aligned} \tag{3.23}$$

Then (3.19) follows from (3.22) and (3.23). The estimate (3.20) can be proved similarly.

The following result is the dual version of Theorem 3.6.

THEOREM 3.7. *Let $u_h \in V^h$. Under the conditions of Theorem* 3.4*,*

$$\begin{aligned}&\sum_K \int_K (|\nabla u_h|^{p-1} + h_K^{-1}|v-\pi v|)^{p'-2} h_K^{-2}|v-\pi v|^2 \\ &\le C\sum_K \int_K (|\nabla u_h|^{p-1} + |\nabla v|)^{p'-2}|\nabla v|^2 + C\tilde{\eta}^2, \end{aligned} \tag{3.24}$$

$$\begin{aligned}&\sum_K \int_K (|\nabla u_h|^{p-1} + |\nabla (v-\pi v)|)^{p'-2}|\nabla (v-\pi v)|^2 \\ &\le C\sum_K \int_K (|\nabla u_h|^{p-1} + |\nabla v|)^{p'-2}|\nabla v|^2 + C\tilde{\eta}^2, \end{aligned} \tag{3.25}$$

where

$$\tilde{\eta}^2 = \sum_l \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_l|^2.$$

Proof. Similarly as in the proof Theorem 3.6, it follows from Theorem 3.4 that

$$\begin{aligned}&\sum_K \int_K (|\nabla u_h|^{p-1} + h_K^{-1}|v-\pi v|)^{p'-2} h_K^{-2}|v-\pi v|^2 \\ &\le C\sum_K \sum_{\bar{K}\cap\bar{K}'\neq\emptyset} \int_{K'} (|\nabla u_h|_K^{p-1} + |\nabla v|)^{p'-2}|\nabla v|^2 \\ &\le C\sum_K \int_K (|\nabla u_h|^{p-1} + |\nabla v|)^{p'-2}(|\nabla v|)^2 \\ &\quad + C\sum_K \sum_{\bar{K}\cap\bar{K}'\neq\emptyset} \int_{K'} (|\nabla u_h|^{p-1} + |\,|\nabla u_h|_{K'}^{p-1} - |\nabla u_h|_K^{p-1}|)^{p'-2} \\ &\qquad\qquad \times |\,|\nabla u_h|_{K'}^{p-1} - |\nabla u_h|_K^{p-1}|^2. \end{aligned} \tag{3.26}$$

Let $a_j = |\nabla u_h|^{p-2}\nabla u_h|_{K_j}$. Using Proposition 3.5 and

$$|\,|\nabla u_h|_{K'}^{p-1} - |\nabla u_h|_K^{p-1}| \le |\,|\nabla u_h|^{p-2}\nabla u_h|_{K'} - |\nabla u_h|^{p-2}\nabla u_h|_K|,$$

we have that

$$\begin{aligned}&\int_{K'} (|\nabla u_h|^{p-1} + |\,|\nabla u_h|_{K'}^{p-1} - |\nabla u_h|_K^{p-1}|)^{p'-2}|\,|\nabla u_h|_{K'}^{p-1} - |\nabla u_h|_K^{p-1}|^2 \\ &\le \int_{K'} (|\nabla u_h|^{p-1} + |\,|\nabla u_h|^{p-2}\nabla u_h|_{K'} - |\nabla u_h|^{p-2}\nabla u_h|_K|)^{p'-2} \\ &\quad \times |\,|\nabla u_h|^{p-2}\nabla u_h|_{K'} - |\nabla u_h|^{p-2}\nabla u_h|_K|^2 \\ &\le C\sum_{i=1}^m \int_{K^{l_i}_{max}} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_{l_i}|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_{l_i}|^2 = \tilde{\eta}^2. \end{aligned} \tag{3.27}$$

Then (3.24) follows from (3.26) and (3.27). The estimate (3.25) can be proved similarly.

Next is a well-known trace theorem.

LEMMA 3.8 (see [14]). *For all $v \in W^{1,q}(K)$, $1 \le q < \infty$,*

$$\|v\|_{0,q,\partial K} \le C(h_K^{-\frac{1}{q}}\|v\|_{0,q,K} + h_K^{1-\frac{1}{q}}|v|_{1,q,K}). \tag{3.28}$$

We need another lemma which is the quasi-norm version trace theorem for piecewise polynomials.

LEMMA 3.9. *Let $K \in T^h$ and v be an s-degree polynomial with $s \le k$, where k is a fixed nonnegative integer. Then*

$$h_K \int_{\partial K} (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2 \le C \int_K (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2, \tag{3.29}$$

where the constant C depends only on k, the maximum degree of the polynomials, and the regularity constant of T^h.

Proof. Because v is a polynomial in K, by an inverse inequality, we have that for any $x \in K$,

$$|\nabla v(x)| \le |v|_{1,\infty,K} \le Ch_K^{-2} \int_K |\nabla v| \, .$$

Therefore, it follows from the Jensen inequality (3.15) that

$$\begin{aligned} & h_K \int_{\partial K} (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2 \\ & \le Ch_K^2 \left(|\nabla u_h| + \int_K Ch_K^{-2}|\nabla v|\right)^{p-2} \left(\int_K Ch_K^{-2}|\nabla v|\right)^2 \\ & \le C \int_K (|\nabla u_h| + |\nabla v|)^{p-2}|\nabla v|^2 \, . \end{aligned}$$

This proves (3.29).

4. Applications for a posteriori error estimates. As applications of Theorems 3.3–3.7, we derive a posteriori error estimates for the finite element approximations of the p-Laplacian.

4.1. Conforming finite element. Let the finite element space V_0^h be the standard conforming piecewise linear triangular element defined in section 2. Using the quasi-norm interpolation error estimates in section 3, we can prove the following a posteriori error bounds.

THEOREM 4.1. *Let u and u_h be the solutions of (2.2) and (2.3), respectively. Let $p > 1$ and $p' > 1$ be such that $\frac{1}{p} + \frac{1}{p'} = 1$. Assume that $f \in L^{p'}(\Omega)$. Then, there is a $\delta_0 > 0$ for all $0 < \delta \le \delta_0$ such that*

$$|u - u_h|_{(p)}^2 \le C(\delta)(\eta_1^2 + \eta_2^2) + C\delta\eta^2, \tag{4.1}$$

$$\eta_1^2 + \eta_2^2 \le C|u - u_h|_{(p)}^2 + C\epsilon^2, \tag{4.2}$$

with

$$|u - u_h|_{(p)}^2 = \int_\Omega (|\nabla u_h| + |\nabla(u - u_h)|)^{p-2}|\nabla(u - u_h)|^2,$$

$$\eta_1^2 = \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2,$$

$$\eta_2^2 = \sum_l \int_{K_{max}^l} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2} A_l^2,$$

$$\eta^2 = \sum_l \int_{K_{min}^l} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2,$$

$$\epsilon^2 = \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f - \bar{f}|)^{p'-2} h_K^2 |f - \bar{f}|^2,$$

where $\bar{f}|_K = \int_K f/|K|$, *and* A_l *is the jump of the p-normal derivative of* u_h *over the interior edge* $l = \bar{K}_l^1 \cap \bar{K}_l^2$, *defined by*

$$A_l = \left[|\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} \right]_l = ((|\nabla u_h|^{p-2} \nabla u_h)_{K_l^1} - (|\nabla u_h|^{p-2} \nabla u_h)_{K_l^2}) \cdot n,$$

where n *is the unit normal vector of the face* l *outwards* K_l^1. *For later convenience, we shall define the jump* A_l *to be zero when an edge* l *is on the boundary.*

Proof. Let $e = u - u_h$. Then, it follows from Lemma 2.1, (2.2), and (2.3) that

$$\begin{aligned}
|u - u_h|_{(p)}^2 &= \int_\Omega (|\nabla u| + |\nabla(u - u_h)|)^{p-2} |\nabla(u - u_h)|^2 \\
&\le C \int_\Omega (|\nabla u|^{p-2} \nabla u - |\nabla u_h|^{p-2} \nabla u_h) \nabla(u - u_h) \\
&= C \int_\Omega (|\nabla u|^{p-2} \nabla u - |\nabla u_h|^{p-2} \nabla u_h) \nabla e \\
&= C \int_\Omega (|\nabla u|^{p-2} \nabla u - |\nabla u_h|^{p-2} \nabla u_h) \nabla(e - \pi_h e) \qquad (4.3) \\
&= -C \sum_K \int_K \operatorname{div}(|\nabla u|^{p-2} \nabla u - |\nabla u_h|^{p-2} \nabla u_h)(e - \pi_h e) \\
&\quad + C \sum_K \int_{\partial K} \left(|\nabla u|^{p-2} \frac{\partial u}{\partial n} - |\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} \right) (e - \pi_h e) \\
&= C \sum_K \int_K f(e - \pi_h e) - C \sum_l \int_l \left[|\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} \right] (e - \pi_h e) \\
&= I_1 + I_2,
\end{aligned}$$

where the average interpolator π_h is defined in section 3, and we have used the fact that $e \in W_0^{1,p}(\Omega)$ and $\pi_h e \in V_0^h$. By Lemma 2.3 and Theorem 3.6, for any $\delta_1 > 0$

$$\begin{aligned}
I_1 &= C \sum_K \int_K h_K f h_K^{-1} (e - \pi_h e) \\
&\le C \delta_1^{-\beta} \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2
\end{aligned}$$

$$
\begin{aligned}
&+ C\delta_1 \sum_K \int_K (|\nabla u_h| + h_K^{-1}|e-\pi_h e|)^{p-2} h_K^{-2} |e-\pi_h e|^2 \\
&\le C\delta_1^{-\beta}\eta_1^2 + C\delta_1 \sum_K \int_K (|\nabla u_h| + |\nabla e|)^{p-2} |\nabla e|^2 \\
&\quad + C\delta_1 \sum_l \int_{K^l_{min}} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 \\
&= C\delta_1^{-\beta}\eta_1^2 + C\delta_1 |u-u_h|^2_{(p)} + C\delta_1 \eta^2,
\end{aligned} \tag{4.4}
$$

where β is defined in Lemma 2.3. Similarly, it follows from Lemma 2.3, Lemma 3.8, and Theorem 3.6 that for any $\delta_2 > 0$

$$
\begin{aligned}
I_2 &= -C\sum_l \int_l \left[|\nabla u_h|^{p-2} \frac{\partial u_h}{\partial n} \right] (e-\pi_h e) \le C \sum_l \int_{\partial K^l_{max}} |A_l| \, |e-\pi_h e| \\
&\le C \sum_l \int_{K^l_{max}} |A_l| \, (h^{-1}_{K^l_{max}} |e-\pi_h e| + |\nabla (e-\pi_h e)|) \\
&\le C\delta_2^{-\beta} \sum_l \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |A_l|)^{p'-2} A_l^2 \\
&\quad + C\delta_2 \sum_l \int_{K^l_{max}} (|\nabla u_h| + h^{-1}_{K^l_{max}} |e-\pi_h e|)^{p-2} h^{-2}_{K^l_{max}} |e-\pi_h e|^2 \\
&\quad + C\delta_2 \sum_l \int_{K^l_{max}} (|\nabla u_h| + |\nabla (e-\pi_h e)|)^{p-2} |\nabla (e-\pi_h e)|^2 \\
&\le C\delta_2^{-\beta}\eta_2^2 + C\delta_2 \sum_K \int_K (|\nabla u_h| + |\nabla e|)^{p-2} |\nabla e|^2 \\
&\quad + C\delta_2 \sum_l \int_{K^l_{min}} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 \\
&= C\delta_2^{-\beta}\eta_2^2 + C\delta_2 |u-u_h|^2_{(p)} + C\delta_2 \eta^2.
\end{aligned} \tag{4.5}
$$

Then (4.1) follows from (4.3)–(4.5) if $\delta_0 \le \frac{1}{4C}$. The estimate (4.2) has been proved in [18].

Remark 4.1. Let us examine the structure of the estimators in Theorem 4.1. As in the linear case, the idea is to bound the residual

$$
R(u_h) = (f, u-\pi_h u) - a(u_h, u-\pi_h u) = \sum_K \int_K h_K f h_K^{-1} (e-\pi_h e) - \int_l A_l (e-\pi_h e).
$$

Thus the building blocks $h_K f$ and A_l enter the estimators η_1 and η_2 as usual. The reason why η_1 and η_2 have the unconventional formats is due to the fact we have to estimate the above bilinear terms in the quasi norm, and this needs to apply the generalized Young inequality in Lemma 2.3.

The term η comes from the interpolation error estimates in Theorem 3.6—due to the gradient jumps $|\nabla u_h|$ over the elements—and it seems to be indispensable in the estimates. The relative contribution of η may be controlled by δ to a certain degree; see below.

To see η more clearly, let

$$V_h^k = \{v \in C^1(\bar{\Omega}) : v|_K \in P_k \ \forall K \in T^h\},$$

where P_k is the space of k-degree polynomials, $k \geq 1$. It follows from Lemma 3.9 and Lemma 2.5 that for all $v_h^k \in V_h^k$,

$$\begin{aligned}
\eta^2 &= \sum_l \int_{K_{min}^l} \left(|\nabla u_h| + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 \\
&\leq C \sum_l h_{K_{min}^l} \int_l \left(|\nabla u_h|_{K_{min}^l} + \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} \right]_l \right|^2 \\
&= C \sum_l h_{K_{min}^l} \int_l \left(|\nabla u_h|_{K_{min}^l} + \left| \left[\frac{\partial u_h}{\partial n} - \frac{\partial v_h^k}{\partial n} \right]_l \right| \right)^{p-2} \left| \left[\frac{\partial u_h}{\partial n} - \frac{\partial v_h^k}{\partial n} \right]_l \right|^2 \\
&\leq C \sum_l \int_{K_l^1 \cup K_l^2} (|\nabla u_h|_{K_{min}^l} + |\nabla (u_h - v_h^k)|)^{p-2} |\nabla (u_h - v_h^k)|^2 \\
&\leq C \sum_K \int_K (|\nabla u_h| + |\nabla (u_h - v_h^k)|)^{p-2} |\nabla (u_h - v_h^k)|^2 \\
&\leq C |u - u_h|_{(p)}^2 + C |u - v_h^k|_{(p)}^2.
\end{aligned}$$

Then immediately we can obtain the upper error estimates derived in [18] by letting δ be small enough.

Furthermore it can be seen (ignoring ϵ for the time being) that

$$cE^2 - c\delta \inf_{v_h^k \in V_h^k} |u_h - v_h^k|_{(u_h,p)}^2 \leq |u - u_h|_{(p)}^2 \leq C(\delta) E^2,$$

where $E^2 = \eta_1^2 + \eta_2^2 + \delta \eta^2$ with $C(\delta)\delta \to 0$ as $\delta \to 0$. Thus

$$cE^2 - c\delta \inf_{v_h^k \in V_h^k} |u - v_h^k|_{(p)}^2 \leq |u - u_h|_{(p)}^2 \leq C(\delta) E^2.$$

A posteriori error estimates of this type have also been obtained recently for some well-known a posteriori error estimators based on gradient recovery, like the Z-Z estimator; see [6], [7] for instance. Clearly E is always reliable, and if u is smooth enough, then the estimator E is both reliable and efficient. It appears that our result is slightly stronger, as here δ can be made small. We tested the model problems Examples 5.3 and 5.4 in [3] for a range of $\delta \in [0.01, 0.1]$ by using the Polak–Ribiere conjugate gradient method. The implementation settings are similar to those in [3] and [18]. We found that the estimators $\eta_1^2 + \eta_2^2$ and E^2 behave quite similarly, at least for the tests problems. Thus it seems that $\delta \eta^2$ is serviced only as a deterrence for most applications.

4.2. Nonconforming finite element. Next, we shall discuss the nonconforming finite element approximation of the p-Laplacian stated in section 2. Thanks to Theorems 3.3–3.7, we can prove the following a posteriori error estimates.

THEOREM 4.2. *Let u and u_h be the solutions of* (2.2) *and* (2.4), *respectively. Let $p > 1$ and $p' > 1$ be such that $\frac{1}{p} + \frac{1}{p'} = 1$. Assume that $f \in L^{p'}(\Omega)$. Then there is a $\delta_0 > 0$ for all $0 < \delta \leq \delta_0$ such that*

$$|u - u_h|_{(p)}^2 \leq C(\delta)(\tilde{\eta}_1^2 + \tilde{\eta}_2^2) + C\delta \tilde{\eta}^2, \tag{4.6}$$

$$\tilde{\eta}_1^2 + \tilde{\eta}_2^2 \le C|u-u_h|_{(p)}^2 + C\epsilon^2, \tag{4.7}$$

with

$$|u-u_h|_{(p)}^2 = \sum_K \int_K (|\nabla u_h| + |\nabla(u-u_h)|)^{p-2}|\nabla(u-u_h)|^2,$$

$$\tilde{\eta}_1^2 = \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2,$$

$$\tilde{\eta}_2^2 = \sum_l \int_{K^l_{min}} (|\nabla u_h| + |B_l|)^{p-2} B_l^2,$$

$$\tilde{\eta}^2 = \sum_l \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2} |[|\nabla u_h|^{p-2}\nabla u_h]_l|^2,$$

$$\epsilon^2 = \sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f-\bar{f}|)^{p'-2} h_K^2 |f-\bar{f}|^2,$$

where B_l is the jump of the tangent derivative of u_h on edge $l = \bar{K}_l^1 \cap \bar{K}_l^2$:

$$B_l = \frac{\partial u_h}{\partial t}|_{K_l^1} - \frac{\partial u_h}{\partial t}|_{K_l^2},$$

t is the tangent direction of l. If $l \subset \partial\Omega$ and l is the edge of K^l, we denote $B_l = \frac{\partial u_h}{\partial t}|_{K^l}$.

Proof. Let $\nabla u_h|_K = \nabla(u_h|_K)$. Let us introduce an auxiliary function (see [21] for the details) $\phi \in W_0^{1,p}(\Omega)$ satisfying

$$\int_\Omega |\nabla\phi|^{p-2}\nabla\phi\nabla v = \int_\Omega |\nabla u_h|^{p-2}\nabla u_h \nabla v \quad \forall v \in W_0^{1,p}(\Omega). \tag{4.8}$$

It follows from Lemma 2.1 and Lemma 2.5 that

$$\begin{aligned} |u-u_h|_{(p)}^2 &\le C\sum_K \int_K (|\nabla\phi| + |\nabla(\phi-u)|)^{p-2}|\nabla(\phi-u)|^2 \\ &+ C\sum_K \int_K (|\nabla\phi| + |\nabla(\phi-u_h)|)^{p-2}|\nabla(\phi-u_h)|^2 = I_1 + I_2. \end{aligned} \tag{4.9}$$

Let $\tilde{\pi}_h$ be the interpolation operator defined in section 3. Note that $\tilde{\pi}_h w \in \tilde{V}_0^h$ if $w \in W_0^{1,p}(\Omega)$, and

$$\int_l \tilde{\pi}_h w = \int_l w,$$

where l are the edges of an element. It follows from (2.2), (2.4), (4.8), and Lemma 2.1 that

$$I_1 \le C\sum_K \int_K (|\nabla u|^{p-2}\nabla u - |\nabla\phi|^{p-2}\nabla\phi)\nabla(u-\phi)$$

$$= C\left(\sum_K \int_K f(u-\phi) - \sum_K \int_K |\nabla u_h|^{p-2}\nabla u_h \nabla(u-\phi)\right)$$
$$= C\left(\sum_K \int_K f((u-\phi)-\tilde{\pi}_h(u-\phi)) - \sum_K \int_K |\nabla u_h|^{p-2}\nabla u_h \nabla((u-\phi)-\tilde{\pi}_h(u-\phi))\right)$$
$$= C\sum_K \int_K f((u-\phi)-\tilde{\pi}_h(u-\phi)).$$

Let $\tilde{e} = u - \phi$. It follows from Lemmas 2.3–2.4 and Theorem 3.3 that

$$\begin{aligned} I_1 &= C\sum_K \int_K f((u-\phi)-\tilde{\pi}_h(u-\phi)) = C\sum_K \int_K h_K f h_K^{-1}(\tilde{e}-\tilde{\pi}_h\tilde{e}) \\ &\le C\delta_1^{-\beta}\sum_K \int_K (|\nabla u_h|^{p-1} + h_K|f|)^{p'-2} h_K^2 |f|^2 \\ &\quad + C\delta_1 \sum_K \int_K (|\nabla u_h| + h_K^{-1}|\tilde{e}-\tilde{\pi}_h\tilde{e}|)^{p-2} h_K^{-2}|\tilde{e}-\tilde{\pi}_h\tilde{e}|^2 \\ &\le C\delta_1^{-\beta}\tilde{\eta}_1^2 + C\delta_1 \sum_K \int_K (|\nabla u_h| + |\nabla \tilde{e}|)^{p-2}|\nabla \tilde{e}|^2 \qquad (4.10) \\ &\le C\delta_1^{-\beta}\tilde{\eta}_1^2 + C\delta_1 \sum_K \int_K (|\nabla u_h| + |\nabla(u-u_h)|)^{p-2}|\nabla(u-u_h)|^2 \\ &\quad + C\delta_1 \sum_K \int_K (|\nabla u_h| + |\nabla(\phi-u_h)|)^{p-2}|\nabla(\phi-u_h)|^2 \\ &\le C\delta_1^{-\beta}\tilde{\eta}_1^2 + C\delta_1(|u-u_h|_{(p)}^2 + I_2). \end{aligned}$$

Note the well-known fact (see [21]) that since $\mathrm{div}(|\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h) = 0$, there exists a function $\psi \in W^{1,p'}(\Omega)$ such that

$$|\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h = curl\,\psi. \qquad (4.11)$$

Moreover, note that for any continuous piecewise linear function $v_h \in V^h$,

$$\sum_K \int_K \nabla u_h curl\ v_h = 0.$$

Then it follows from Lemma 2.1, Lemma 3.8, (4.8), and integrating by parts that

$$\begin{aligned} I_2 &\le C\sum_K \int_K (|\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h)\nabla(\phi-u_h) \\ &= -C\sum_K \int_K (|\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h)\nabla u_h \\ &= -C\sum_K \int_K curl\ \psi \nabla u_h = -C\sum_K \int_K curl\ (\psi - \pi_h\psi)\nabla u_h \\ &= -C\sum_K \int_{\partial K} (\psi-\pi_h\psi)\frac{\partial u_h}{\partial t} \le C\sum_l \int_l |\psi-\pi_h\psi|\ \left|\left[\frac{\partial u_h}{\partial t}\right]\right| \\ &= C\sum_l \int_l |\psi-\pi_h\psi|\ |B_l| \le \sum_l \int_{\partial K_{min}^l} |B_l|\ |\psi-\pi_h\psi| \end{aligned}$$

$$\leq C\sum_l \int_{K^l_{min}} |B_l|\ (h^{-1}_{K^l_l}|\psi-\pi_h\psi| + |\nabla(\psi-\pi_h\psi)|),$$

where we have used the average interpolation operator π_h defined in section 3 and the fact that $\pi_h\psi \in V^h$ is a continuous piecewise linear function. It follows from Lemma 2.3 and Theorem 3.7 that

$$\begin{aligned}
I_2 &\leq C\sum_l \int_{K^l_{min}} |B_l|(h_K^{-1}|\psi-\pi_h\psi| + |\nabla(\psi-\pi_h\psi)|)\\
&\leq C\delta_2 \sum_l \int_{K^l_{min}} (|\nabla u_h| + |B_l|)^{p-2}|B_l|^2\\
&\quad + C\delta_2^{-\beta}\sum_l \int_{K^l_{min}} (|\nabla u_h|^{p-1} + h^{-1}_{K^l_{min}}|\psi-\pi_h\psi|)^{p'-2}\\
&\quad \times h^{-2}_{K^l_{min}}|\psi-\pi_h\psi|^2 + C\delta_2^{-\beta}\sum_l \int_{K^l_{min}} (|\nabla u_h|^{p-1} + |\nabla(\psi-\pi_h\psi)|)^{p'-2}|\nabla(\psi-\pi_h\psi)|^2\\
&\leq C\delta_2\tilde{\eta}_2^2 + C\delta_2^{-\beta}\sum_K \int_K (|\nabla u_h|^{p-1} + |\nabla\psi|)^{p'-2}|\nabla\psi|^2\\
&\quad + C\delta_2^{-\beta}\sum_l \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_l|^2\\
&\leq C\delta_2\tilde{\eta}_2^2 + C\delta_2^{-\beta}\sum_K \int_K (|\nabla u_h|^{p-1} + |curl\psi|)^{p'-2}|curl\psi|^2 + C\delta_2^{-\beta}\tilde{\eta}^2.
\end{aligned}$$

It follows from (4.11) and Lemma 2.1 that for all $K \in T^h$

$$\begin{aligned}
&\int_K (|\nabla u_h|^{p-1} + |curl\psi|)^{p'-2}|curl\psi|^2\\
&= \int_K (|\nabla u_h|^{p-1} + |\ |\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h|)^{p'-2}|\ |\nabla\phi|^{p-2}\nabla\phi - |\nabla u_h|^{p-2}\nabla u_h|^2\\
&\leq \int_K (|\nabla u_h|^{p-1} + (|\nabla u_h| + |\nabla(u_h-\phi)|)^{p-2}|\nabla(u_h-\phi)|)^{p'-2}\\
&\quad \times (|\nabla u_h| + |\nabla(u_h-\phi)|)^{2(p-2)}|\nabla(u_h-\phi)|^2\\
&= \int_K Q(|\nabla u_h| + |\nabla(u_h-\phi)|)^{p-2}|\nabla(u_h-\phi)|^2,
\end{aligned}$$

where

$$Q = \frac{[|\nabla u_h|^{p-1} + (|\nabla u_h| + |\nabla(u_h-\phi)|)^{p-2}|\nabla(u_h-\phi)|]^{p'-2}}{(|\nabla u_h| + |\nabla(u_h-\phi)|)^{2-p}}.$$

When $1 < p \leq 2$, for all $x \in K$, if $|\nabla u_h|^{p-1} \leq (|\nabla u_h| + |\nabla(u_h-\phi)|)^{p-2}|\nabla(u_h-\phi)|$,

$$Q \leq \frac{2^{p'-2}|\nabla(u_h-\phi)|^{(p-1)(p'-2)}}{|\nabla(u_h-\phi)|^{2-p}} = 2^{p'-2}.$$

If $(|\nabla u_h| + |\nabla(u_h-\phi)|)^{p-2}|\nabla(u_h-\phi)| < |\nabla u_h|^{p-1}$,

$$Q \leq \frac{2^{p'-2}|\nabla u_h|^{(p-1)(p'-2)}}{|\nabla u_h|^{2-p}} = 2^{p'-2}.$$

When $p > 2$, for all $x \in K$, if $|\nabla u_h| \le |\nabla(u_h - \phi)|$,

$$Q \le \frac{2^{p-2}|\nabla(u_h - \phi)|^{p-2}}{|\nabla(u_h - \phi)|^{(p-1)(2-p')}} = 2^{p-2}.$$

If $|\nabla(u_h - \phi)| < |\nabla u_h|$,

$$Q \le \frac{2^{p-2}|\nabla u_h|^{p-2}}{|\nabla u_h|^{(p-1)(2-p')}} = 2^{p-2}.$$

Hence, we have that for all $x \in K$, $Q \le C$, where C is only dependent on p. It follows that for all $K \in T^h$,

$$\begin{aligned}\int_K &(|\nabla u_h|^{p-1} + |curl\psi|)^{p'-2}|curl\psi|^2 \\ &\le C\int_K (|\nabla u_h| + |\nabla(u_h - \phi)|)^{p-2}|\nabla(u_h - \phi)|^2 = CI_2.\end{aligned}$$

Therefore,

$$I_2 \le C\delta_2\tilde{\eta}_2^2 + C\delta_2^{-\beta}I_2 + C\delta_2^{-\beta}\tilde{\eta}^2.$$

Then, we have

$$I_2 \le C\delta_2\tilde{\eta}_2^2 + C\delta_2^{-\beta}\tilde{\eta}^2\ . \tag{4.12}$$

By (4.10) and (4.12),

$$I_1 \le C(\delta)(\tilde{\eta}_1^2 + \tilde{\eta}_2^2) + \frac{1}{2}|u - u_h|_{(p)}^2 + C\delta\tilde{\eta}^2\ . \tag{4.13}$$

Hence, (4.6) follows from (4.9), (4.13), and (4.12). The estimate (4.7) has been proved in [19].

Remark 4.2. It can be seen that the purpose of introducing K_{min} and K_{max} is to make our estimators smaller (sharper). That is why we use either K_{max} or K_{min}, depending on whether the power in the estimators is $p' - 2$ or $p - 2$. Furthermore, it can be shown that the bubble function Lemma 3.1 in [18], which is needed to prove the lower bounds there, does not hold if K_{max} is not used. In this sense introducing K_{min} and K_{max} seems to be necessary.

Remark 4.3. Similar interpretations made in Remark 4.1 apply here. In particular, it follows from Lemma 2.1 that

$$|[|\nabla u_h|^{p-2}\nabla u_h]_l| \le C(|\nabla u_h|_{K_{min}^l} + |[\nabla u_h]_l|)^{p-2}|[\nabla u_h]_l|.$$

Then,

$$\begin{aligned}\tilde{\eta}^2 &= \sum_l \int_{K_{max}^l} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_l|^2 \\ &\le C\sum_l h_{K_{max}^l}\int_l (|\nabla u_h|_{K_{max}^l}^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_l|^2 \\ &\le C\sum_l h_{K_{max}^l}\int_l (|\nabla u_h|_{K_{max}^l}^{p-1} + (|\nabla u_h|_{K_{min}^l} + |[\nabla u_h]_l|)^{p-2}|[\nabla u_h]_l|)^{p'-2}\end{aligned}$$

$$\begin{aligned}
&\times (|\nabla u_h|_{K^l_{min}} + |[\nabla u_h]_l|)^{2(p-2)}|[\nabla u_h]_l|^2 \\
&= C\sum_l h_{K^l_{max}} \int_l Q(|\nabla u_h|_{K^l_{min}} + |[\nabla u_h]_l|)^{p-2}|[\nabla u_h]_l|^2 \\
&\le C\sum_l \int_{K^l_{min}} Q(|\nabla u_h| + |[\nabla u_h]_l|)^{p-2}|[\nabla u_h]_l|^2,
\end{aligned}$$

with

$$Q = \frac{(|\nabla u_h|^{p-1}_{K^l_{max}} + (|\nabla u_h|_{K^l_{min}} + |[\nabla u_h]_l|)^{p-2}|[\nabla u_h]_l|)^{p'-2}}{(|\nabla u_h|_{K^l_{min}} + |[\nabla u_h]_l|)^{2-p}} \le C,$$

where C is a constant only dependent on p. Hence, similarly as in Remark 4.1, it can be proved that for all $v_h^k \in V_h^k$,

$$\tilde{\eta}^2 \le C|u - u_h|^2_{(p)} + C|u - v_h^k|^2_{(p)}.$$

Thus the estimates in Theorem 4.2 seem to be sharp as well.

Remark 4.4. Note that

$$\begin{aligned}
\tilde{\eta}^2 &= \sum_l \int_{K^l_{max}} (|\nabla u_h|^{p-1} + |[|\nabla u_h|^{p-2}\nabla u_h]_l|)^{p'-2}|[|\nabla u_h|^{p-2}\nabla u_h]_l|^2 \\
&\le \sum_l \int_{K^l_{max}} \left(|\nabla u_h|^{p-1} + \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial t}\right]_l\right|\right)^{p'-2} \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial t}\right]_l\right|^2 \\
&\quad + \sum_l \int_{K^l_{max}} \left(|\nabla u_h|^{p-1} + \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial n}\right]_l\right|\right)^{p'-2} \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial n}\right]_l\right|^2,
\end{aligned}$$

where t and n are the tangent and normal directions of l, respectively. Moreover, it has been proved that (see Theorem 4.1 and [18] for the details)

$$\sum_l \int_{K^l_{max}} \left(|\nabla u_h|^{p-1} + \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial n}\right]_l\right|\right)^{p'-2} \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial n}\right]_l\right|^2 \le C|u-u_h|^2_{(p)} + C\epsilon^2,$$

where ϵ is defined in Theorem 4.1. Then, it can be proved that for all $\delta > 0$

$$|u - u_h|^2_{(p)} \le C(\delta)(\tilde{\eta}_1^2 + \tilde{\eta}_2^2) + C\delta\hat{\eta}^2 + C\delta\epsilon^2,$$

where $\tilde{\eta}_1^2$ and $\tilde{\eta}_2^2$ are defined in Theorem 4.2, ϵ is defined in Theorem 4.1, and

$$\hat{\eta}^2 = \sum_l \int_{K^l_{max}} \left(|\nabla u_h|^{p-1} + \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial t}\right]_l\right|\right)^{p'-2} \left|\left[|\nabla u_h|^{p-2}\frac{\partial u_h}{\partial t}\right]_l\right|^2.$$

5. Conclusions. We have established new interpolation error estimates for some well-known averaging interpolators. These estimates have proved essential in deriving improved a posteriori error estimates in the quasi norms.

Acknowledgments. The authors wish to express their sincere thanks to Mr. R. Klose for his computational work in Remark 4.1.

A CONSTRAINT SATISFACTION APPROACH FOR ENCLOSING SOLUTIONS TO PARAMETRIC ORDINARY DIFFERENTIAL EQUATIONS*

MICHA JANSSEN†, PASCAL VAN HENTENRYCK‡, AND YVES DEVILLE†

Abstract. This paper considers initial value problems for ordinary differential equations (ODEs), where some of the data is uncertain and given by intervals as is the case in many areas of science and engineering. Interval methods provide a way to approach these problems, but they raise fundamental challenges in obtaining high accuracy and low computation costs. This work introduces a constraint satisfaction approach to these problems which enhances traditional interval methods with a pruning step based on a global relaxation of the ODE. The relaxation uses Hermite interpolation polynomials and enclosures of their error terms to approximate the ODE. Our work also shows how to find an evaluation time for the relaxation that minimizes its local error. Theoretical and experimental results show that the approach produces significant improvements in accuracy over the best interval methods for the same computation costs. The results also indicate that the new algorithm should be significantly faster when the ODE contains many operations.

Key words. ordinary differential equation, interval methods, constraint satisfaction polynomial

1. Introduction.

Initial value problems (IVPs) for ordinary differential equations (ODEs) arise naturally in many applications in science and engineering, including chemistry, physics, molecular biology, and mechanics to name only a few. An ODE $\mathbb{O}$ is a system of the form

$$\begin{aligned} u_1'(t) &= f_1(u_1(t), \ldots, u_n(t)), \\ &\vdots \\ u_n'(t) &= f_n(u_1(t), \ldots, u_n(t)) \end{aligned}$$

often denoted in vector notation by $u'(t) = f(u(t))$ or $u' = f(u)$.[1] An IVP is an ODE with an initial condition $u(t_0) = u_0$. It is often the case that the parameters and/or the initial values are not known with certainty but are given as intervals. Hence, traditional methods may not be the simplest way to approach the resulting parametric ODEs since, in essence, they would have to solve infinitely many systems. *Interval methods*, pioneered by Moore [21], provide an approach to tackle parametric ODEs. They return enclosures of exact solutions at different points in time; i.e., for a given IVP, they are guaranteed to return intervals containing the exact solution. In addition, they inherently accommodate uncertainty in the parameters or initial values by using intervals instead of floating-point numbers. In this paper, we talk about ODEs to denote both traditional and parametric ODEs.

[1]Only autonomous systems are considered in this paper, but it is not difficult to generalize the results to nonautonomous systems.

Traditional interval methods usually consist of two processes applied at each integration step: (1) a *bounding box* process that proves existence and uniqueness of the solution and computes a rough enclosure (called a *bounding box*) of the solution over a time interval $[t_0, t_1]$; (2) a *forward* process that computes an enclosure of the solution at t_1. The bounding box process, which is specific to interval methods, is necessary to bound the error terms in the forward process. The forward process is generally realized by applying a one-step Taylor interval method and making extensive use of automatic differentiation [27] to obtain the Taylor coefficients [8, 16, 21, 22]. However, the major problem of such methods is the explosion of the size of the boxes at successive points as they often accumulate errors from point to point and lose accuracy by enclosing the solution by a box. (This is called the *wrapping effect*.) Lohner's AWA system [20] was an important step in interval methods which features efficient coordinate transformations to tackle the wrapping effect. More recently, Nedialkov and Jackson's interval Hermite-Obreschkoff method [24] improved on AWA by extending a Hermite–Obreschkoff's approach (which can be viewed as a generalized Taylor method) to intervals. Another recent approach, the Taylor models, was proposed by Berz and Makino [4] for reducing the wrapping effect. Their scheme validates existence and uniqueness and also computes tight enclosures of the solution in one process, contrary to the other methods mentioned above.

The research described in this work takes a constraint satisfaction approach to ODEs. Its basic idea [7, 13, 14] is to view the solving of ODEs as the iteration of three processes: (1) a *bounding box* process, (2) a *predictor* process that computes initial enclosures at given times from enclosures at previous times and bounding boxes, and (3) a *pruning* process that reduces the initial enclosures without removing solutions.[2] The real novelty in our approach is the pruning component. It is based on the construction of a nontrivial constraint from a *relaxation* of the ODE, a key concept in constraint satisfaction [32]. This constraint can then be used to prune the solution space at the various integration points.

The main contribution of this work is to show that an effective pruning technique can be derived from a relaxation of the ODE, importing a fundamental principle from constraint satisfaction into the field of validated differential equations. Four main steps are necessary to derive an effective pruning algorithm.

1. The first step consists of obtaining a relaxation of the ODE by safely approximating its solution using Hermite interpolation polynomials.
2. The second step consists of using the mean-value form of this relaxation for more accuracy and efficiency. Unfortunately, these two steps, which were sketched in [13], are not sufficient, and the resulting pruning algorithm still suffers from traditional problems of interval methods.
3. The third fundamental step [14] consists of globalizing the pruning by considering several successive relaxations together. This idea of generating a global constraint from a set of more primitive constraints is also at the heart of constraint satisfaction. It makes it possible, in this new context, to address the problem of dependencies (and hence the accumulation of errors) and the wrapping effect simultaneously.[3]
4. The fourth and final step consists of finding an evaluation time for the relax-

[2] Observe that interval extensions of predictor/corrector methods (e.g., [24]) can also be viewed as the composition of a predictor and a pruning step.

[3] Global constraints in ODEs have also been found useful in [6]. The problem and the techniques in [6] are, however, fundamentally different.

ation which minimizes the local error of the relaxation. Indeed, the global constraint generated in the third step, being a relaxation of the ODE, is parametrized by an evaluation time. Interestingly, for global filters based on Hermite interpolation polynomials, the (asymptotically) optimal evaluation time is independent from the ODE and induces negligible overhead on the computational cost of the methods.

Theoretical and experimental results show the benefits of the approach. From a theoretical standpoint, the constraint satisfaction approach provides a quadratic improvement in accuracy (asymptotically) over the best interval method we know of for the same computation costs. The theoretical results also show that our approach should be significantly faster for a given precision when the ODE contains many operations. Experimental results, obtained from an object-oriented implementation of our algorithms, confirm the theory. They show that the constraint satisfaction approach often produces significant improvements in accuracy over existing methods for the same computation costs and should produce significant gain in computation times when the ODE contains many operations. Of particular interest is the versatility of the approach which can be tailored to the problem at hand.

The rest of the paper is organized as follows. Section 2 introduces the main definitions and notations. Section 3 gives a high-level overview of the constraint satisfaction approach to parametric ODEs. The next four sections are the core of the paper. Section 4 introduces multistep filters, section 5 presents multistep Hermite filters as a special case of multistep filters, section 6 describes how to choose an evaluation time to minimize the local error of a multistep Hermite filter, and section 7 presents the overall algorithm. Sections 8 and 9 report the theoretical and experimental analyses, and section 10 concludes the paper.

2. Background and definitions.

2.1. Basic notational conventions. Small letters denote real values, vectors, and functions of real values. Capital letters denote matrices, sets, intervals, vectors, and functions of intervals. A vector of intervals $D \in \mathbb{IR}^n$ is called a *box*. If $A \subseteq \mathbb{R}^n$, then $\Box A$ denotes the smallest box $D \in \mathbb{IR}^n$ such that $A \subseteq D$, and $g(A)$ denotes the set $\{g(x) \mid x \in A\}$. If M is a regular (point or interval) matrix, then M^{-1} denotes an *enclosure*[4] of the inverse of M. A relation is a function $r : \mathbb{R}^n \to \mathit{Bool}$, where *Bool* denotes the booleans. We also assume that t_i, t_e, and t are reals, u_i is in $\mathbb{R}^n$, and D_i and B_i are in $\mathbb{IR}^n$ ($i \in \mathbb{N}$). We use $m(D)$ to denote the midpoint of D and $s(D)$ to denote $D - m(D)$. Observe that $m(D) + s(D) = D$. We use $\omega(D)$ to denote the width of a box. More precisely, $\omega([a,b]) = b - a$ and $\omega((I_1, \ldots, I_n)) = (\omega(I_1), \ldots, \omega(I_n))$ if $I_i \in \mathbb{IR}$. If $g : \mathbb{R}^m \to \mathbb{R}^n$, $x = (x_1, \ldots, x_m)$ and $\tilde{x} = (x_{i_1}, \ldots, x_{i_p})$ with $i_1, \ldots, i_p \in 1..m$, then $\mathcal{J}_{\tilde{x}} g(x)$ denotes the Jacobian matrix

$$\begin{bmatrix} \frac{\partial g_1}{\partial x_{i_1}}(x) & \cdots & \frac{\partial g_1}{\partial x_{i_p}}(x) \\ \vdots & \ddots & \vdots \\ \frac{\partial g_n}{\partial x_{i_1}}(x) & \cdots & \frac{\partial g_n}{\partial x_{i_p}}(x) \end{bmatrix}.$$

In particular, we write $\mathcal{J} g(x) = \mathcal{J}_x g(x)$ (differentiation w.r.t. all variables of g). If not specified, n denotes the dimension of the ODE (i.e., the number of scalar equations), $h > 0$ denotes the step size of the integration, and k denotes the number of previous

[4] By *enclosure* of a set A, we mean a set containing A.

values of the solution at times $t_0, \dots, t_{k-1}$ used to compute the new value at time t_k (k-step approach).

NOTATION 1 (boldface notations). *Let A be a set and $a_i \in A$, where $i \in \mathbb{N}$. We use the following boldface notations.*

$$\begin{array}{lcl} \mathbf{a} & = & (a_0, \dots, a_k) \in A^{k+1}, \\ \mathbf{a}_i & = & (a_{ik}, \dots, a_{(i+1)k-1}) \in A^k, \\ \mathbf{a}_{i..i+j} & = & (a_i, \dots, a_{i+j}) \in A^{j+1}. \end{array}$$

Observe that $\mathbf{a}_0 = (a_0, \dots, a_{k-1})$, $\mathbf{a}_1 = (a_k, \dots, a_{2k-1})$, and $\mathbf{a} = (a_0, \dots, a_k)$. The following asymptotical notations are standard.

NOTATION 2 (asymptotical notations). *Consider two functions $f, g : \mathbb{R} \to \mathbb{R}$ and let $x > 0$. We use the following standard notations:*

$$f(x) = \begin{cases} O(g(x)) & if \quad \exists c > 0, \exists \varepsilon > 0 : x \geq \varepsilon \Rightarrow |f(x)| \leq c|g(x)|, \\ \mathcal{O}(g(x)) & if \quad \exists c > 0, \exists \varepsilon > 0 : x \leq \varepsilon \Rightarrow |f(x)| \leq c|g(x)|, \\ \Omega(g(x)) & if \quad \exists c > 0, \exists \varepsilon > 0 : x \leq \varepsilon \Rightarrow |f(x)| \geq c|g(x)|, \\ \Theta(g(x)) & if \quad f(x) = \mathcal{O}(g(x)) \quad and \quad f(x) = \Omega(g(x)). \end{cases}$$

The notations extend componentwise for vectors and matrices of functions.

Finally we assume that the underlying interval arithmetic is exact for the theoretical parts of this work (i.e., there are no rounding errors). The implementation of course uses outwardly directed rounding.

2.2. Basic definitions. As is traditional, when we consider an ODE $u' = f(u)$ and an interval of integration T, we assume $f \in C^r(\Omega)$, where r is sufficiently large and Ω is an open set such that $T \times \Omega$ contains the trajectories of the solutions on T.[5] In addition, we restrict our attention to ODEs that have a unique solution for a given initial value. Techniques to verify this hypothesis numerically are well known [25, 21, 22, 5, 23]. In order to make the dependence on the initial condition (t_0, u_0) explicit, we introduce the following definition of the solution to an ODE.

DEFINITION 1 (solution of an ODE). *Let $\Lambda \subseteq \mathbb{R} \times \mathbb{R}^n \times \mathbb{R}$ be an open set. The* solution *of an ODE $u' = f(u)$ is the function $s : \Lambda \to \mathbb{R}^n$ such that*

$$\forall (t_0, u_0, t) \in \Lambda : \begin{cases} \frac{\partial s}{\partial t}(t_0, u_0, t) = f(s(t_0, u_0, t)), \\ s(t_0, u_0, t_0) = u_0. \end{cases}$$

Observe that, since we restrict attention to autonomous systems in this work, we can write

$$s(t_0, x, t) = s(0, x, \tau),$$

where $\tau = t - t_0$, and thus

$$\frac{\partial^j s}{\partial t^j}(t_0, x, t) = \frac{\partial^j s}{\partial \tau^j}(0, x, \tau).$$

In particular, when $t = t_0$, the function

$$\frac{\partial^j s}{\partial t^j}(t_0, x, t)\bigg|_{(t_0, x, t_0)} = \frac{\partial^j s}{\partial \tau^j}(t_0, x, \tau)\bigg|_{(0, x, 0)}$$

[5] The standard mathematical symbol $C^r(\Omega)$ denotes the set of all functions whose rth derivative exists and is continuous on Ω.

depends *only* on x. This justifies the following notation, which captures the notions of real and interval Taylor coefficients of the solution of an ODE as well as their Jacobians.

NOTATION 3 (Taylor coefficients and Jacobians). *Let s be the solution of an ODE $\mathbb{O}$, $x \in \mathbb{R}^n$, $D \in \mathbb{IR}^n$, and let t_0 be any real number. Then*

1. $(x)_j = \frac{1}{j!}\frac{\partial^j s}{\partial t^j}(t_0, x, t)\Big|_{(t_0,x,t_0)}$;
2. $\{(x)_j \mid x \in D\} \subseteq (D)_j \in \mathbb{IR}^n$;
3. $\mathcal{J}(x)_j = \mathcal{J}_x \frac{1}{j!}\frac{\partial^j s}{\partial t^j}(t_0, x, t)\Big|_{(t_0,x,t_0)}$;
4. $\{\mathcal{J}(x)_j \mid x \in D\} \subseteq \mathcal{J}(D)_j \in \mathbb{IR}^{n\times n}$;
5. $(x)_{j,l}$, $(D)_{j,l}$, $\mathcal{J}(x)_{j,l}$, *and* $\mathcal{J}(D)_{j,l}$ *denote, respectively, the lth component of* $(x)_j$, $(D)_j$, $\mathcal{J}(x)_j$, *and* $\mathcal{J}(D)_j$.

In the context of our multistep approach (to be presented in section 3), it is useful to generalize Definition 1 in order to make the dependence on the last $k+1$ redundant conditions $(t_0, u_0), \ldots, (t_k, u_k)$ explicit.

DEFINITION 2 (multistep solution of an ODE). *Let s be the solution of an ODE $\mathbb{O}$. The* multistep solution *of $\mathbb{O}$ is the* partial *function $ms : A \subseteq \mathbb{R}^{k+1} \times (\mathbb{R}^n)^{k+1} \times \mathbb{R} \to \mathbb{R}^n$:*

$$ms(\mathbf{t}, \mathbf{u}, t) = \begin{cases} s(t_0, u_0, t) \text{ if } u_i = s(t_0, u_0, t_i),\ 1 \le i \le k, \\ \textit{undefined otherwise.} \end{cases}$$

Since we are dealing with interval methods, we need to introduce the notions of interval extensions of a function and a relation. These notions were introduced in [31]. However, because the techniques proposed in this work use multistep solutions, which are *partial* functions, it is necessary to generalize the notion of interval extension to partial functions and relations.

DEFINITION 3 (interval extension of a partial function). *The interval function $G : \mathbb{IR}^n \to \mathbb{IR}^m$ is an* interval extension *of the partial function $g : E \subseteq \mathbb{R}^n \to \mathbb{R}^m$ if*

$$\forall D \in \mathbb{IR}^n : g(E \cap D) \subseteq G(D).$$

DEFINITION 4 (interval extension of a partial relation). *The interval relation $R : \mathbb{IR}^n \to Bool$ is an* interval extension *of the partial relation $r : E \subseteq \mathbb{R}^n \to Bool$ if*

$$\forall D \in \mathbb{IR}^n : (\exists x \in E \cap D : r(x)) \Rightarrow R(D).$$

Finally, we generalize the concept of bounding boxes, a fundamental concept in interval methods for ODEs, to multistep methods. Intuitively, a bounding box encloses all solutions of an ODE going through certain boxes at given times over a given time interval. Bounding boxes are needed to enclose error terms in validated methods for ODEs (see section 5).

DEFINITION 5 (bounding box). *Let $\mathbb{O}$ be an ODE system, ms be the multistep solution of $\mathbb{O}$, and $\{t_0, \ldots, t_k\} \subseteq T \in \mathbb{IR}$. A box B is a* bounding box *of $\mathbb{O}$ over T wrt $(\mathbf{t}, \mathbf{D})$ if, for all $t \in T$, $ms(\mathbf{t}, \mathbf{D}, t) \subseteq B$.*

2.3. The midpoint technique. The midpoint technique is a standard tool in interval computation. It consists of decomposing a matrix A as the sum of its midpoint matrix and the remainder matrix composed of symmetric intervals:

$$A = m(A) + s(A).$$

In this paper, the midpoint technique is used in the following two cases:

1. enclosing a set of real matrix-matrix-vector products (see sections 4.4 and 4.5);
2. converting an implicit interval linear system into an explicit one by matrix inversion (see section 4.2).

Assume that we are interested in enclosing the set

$$P = \{\mathcal{A}\mathcal{B}d \mid \mathcal{A} \in A,\ \mathcal{B} \in B,\ d \in D\},$$

where A, B are interval matrices and D is an interval vector. Assume also that $\omega(A)$ is small and that the wrapping effect in the product CD, where $C = AB$, is small. A straightforward and cheap way to enclose the set P consists of computing the product $A(BD)$. In general, this product does not yield accurate results because of the wrapping effect which occurs in the product $E = BD$ and in the product AE. Another straightforward way of enclosing the set P is to compute the product $(AB)D$. By hypothesis, the wrapping effect is small in this case, and the product is an accurate enclosure of P. However, the multiplication of the two interval matrices A and B is a costly process (due to costly sign tests and rounding mode switches in modern RISC architectures; see [15] for more details). In order to avoid this product, we apply the midpoint technique on A. By distribution and rearrangement of the parentheses, we can write

$$P \subseteq Q = (m(A)B)D + s(A)(BD). \tag{1}$$

It is interesting to observe that no multiplication between two interval matrices occurs in Q. (Note the importance of the parentheses!) From an accuracy standpoint, the wrapping effect in $(m(A)B)D$ is small (by hypothesis) and the remainder term $s(A)(BD)$ is small (because $\omega(A)$ is small). Hence, Q is an accurate enclosure of the set P which avoids the costly multiplication of two interval matrices.

Now consider the implicit interval linear system

$$\begin{aligned} &A_0X_0 + A_1X_1 = B, \\ &X_0 \subseteq D_0,\ X_1 \subseteq D_1, \end{aligned} \tag{2}$$

where A_0, A_1 are interval matrices and B, D_0, D_1 are interval vectors. We assume that A_0 contains no singular point matrix. The exact solution set to this system is given by

$$S = \{(x_0, x_1) \in (D_0, D_1) \mid \exists \mathcal{A}_0 \in A_0,\ \exists \mathcal{A}_1 \in A_1,\ \exists b \in B : \mathcal{A}_0x_0 + \mathcal{A}_1x_1 = b\}.$$

We are interested in converting the system (2) into a system

$$X_0 = CX_1 + E,$$

which is explicit in the variable X_0 and such that

$$S \subseteq \{(x_0, x_1) \in (D_0, D_1) \mid \exists \mathcal{C} \in C,\ \exists e \in E : x_0 = \mathcal{C}x_1 + e\}.$$

A straightforward solution consists of computing an enclosure A_0^{-1} of the inverse of A_0, multipling both sides of (2) by A_0^{-1}, and rearranging the parentheses:

$$X_0 = -(A_0^{-1}A_1)X_1 + A_0^{-1}B. \tag{3}$$

However, the system (3) suffers from two drawbacks:

- We have to invert the interval matrix A_0. Computing an accurate enclosure of the inverse of an interval matrix is a costly process [23]).
- We have to multiply the two interval matrices A_0^{-1} and A_1.

To eliminate these operations, we apply the midpoint technique both on A_0 and A_1 in (2). By distributivity, we have

$$m(A_0)X_0 = -m(A_1)X_1 + B - s(A_0)X_0 - s(A_1)X_1. \tag{4}$$

Since $X_0 \subseteq D_0$ and $X_1 \subseteq D_1$, we can replace X_0 by D_0 in the term involving $s(A_0)$ and X_1 by D_1 in the term involving $s(A_1)$:

$$m(A_0)X_0 = -m(A_1)X_1 + B - s(A_0)D_0 - s(A_1)D_1. \tag{5}$$

Note that it is important to have precise enclosures D_1 and D_2. To obtain a system which is explicit in the variable X_0, we compute an *enclosure* $m(A_0)^{-1}$ of the inverse of the *point* matrix $m(A_0)$, we multiply both sides of (5) by $m(A_0)^{-1}$, and we rearrange the parentheses:[6]

$$X_0 = -(m(A_0)^{-1}m(A_1))X_1 + m(A_0)^{-1}(B - s(A_0)D_0 - s(A_1)D_1).$$

Observe that, in this last system, there is no interval matrix inversion and no product of two interval matrices.

3. The constraint satisfaction approach. The constraint satisfaction approach followed in this work was first presented in [7]. It consists of a generic algorithm for ODEs that iterates three processes:

1. a *bounding box* process that computes bounding boxes for the current step and proves (numerically) the existence and uniqueness of the solution;
2. a *predictor* process that computes initial enclosures at given times from enclosures at previous times and bounding boxes;
3. a *pruning* process that reduces the initial enclosures without removing solutions.

The intuition of the successive steps is illustrated in Figure 1. Bounding box and predictor components are standard in interval methods for ODEs. This paper thus focuses on the pruning process, the main novelty of the approach. *Our pruning component is based on relaxations of the ODE, a fundamental concept in the field of constraint satisfaction.* To our knowledge, no other approach uses relaxations of the ODE to derive pruning operators, and the only other approaches using a pruning component [24, 28] were developed independently. Note also that, in the following, predicted boxes are generally superscripted with the symbol $-$ (e.g., D_1^-), while pruned boxes are generally superscripted with the symbol $*$ (e.g., D_1^*).

The pruning component uses *safe approximations* of the ODE to shrink the boxes computed by the predictor process. To understand this idea, it is useful to contrast the constraint satisfaction to nonlinear programming [30, 31] and to ODEs. In nonlinear programming, a constraint $c(x_1, \ldots, x_n)$ can be used almost directly for pruning the search space (i.e., the Cartesian product of the intervals I_i associated with the variables x_i). It suffices to take an interval extension $C(X_1, \ldots, X_n)$ of the constraint. Now if $C(I_1', \ldots, I_n')$ does not hold, it follows, by the definition of interval extensions, that no solution of c lies in $I_1' \times \cdots \times I_n'$. The interval extension can be seen as a filter

[6] Note that, even though $m(A_0)$ is a *point* matrix, the enclosure $m(A_0)^{-1}$ of its inverse is generally *not* a point matrix, because of rounding errors.

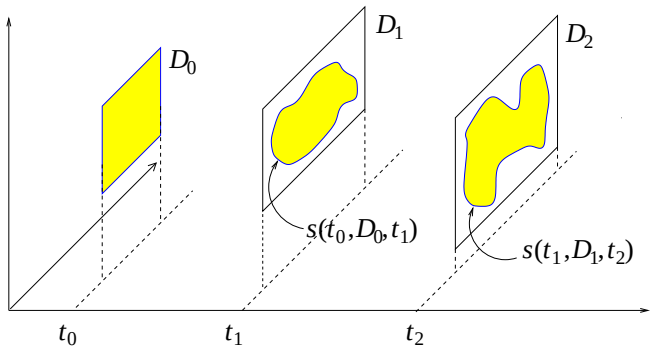

FIG. 1. *Successive integration steps.*

that can be used for pruning the search space in many ways. For instance, Numerica uses box(k)-consistency on these interval constraints [31]. ODEs raise new challenges. In an ODE for all $t:\ u' = f(u)$, functions u and u' are, of course, unknown. Hence, it is not obvious how to obtain a filter to prune boxes.

One of the main contributions of our approach is to show how to derive effective pruning operators for parametric ODEs. The first step consists of rewriting the ODE for all $t:\ u' = f(u)$ in terms of its multistep solution ms to obtain

$$\forall\, t:\ \frac{\partial ms}{\partial t}(\mathbf{t}, \mathbf{u}, t) = f(ms(\mathbf{t}, \mathbf{u}, t)). \tag{6}$$

Let us denote this relation for all $t : fl(\mathbf{t}, \mathbf{u}, t)$. This rewriting may not appear useful since ms is still an unknown function. However, it suggests a way to approximate the ODE. Indeed, we show in section 5 how to obtain interval extensions of ms and $\frac{\partial ms}{\partial t}$ by using Hermite polynomial interpolations together with their error terms. This simply requires a bounding box for the considered time interval and safe approximations of ms at successive times, both of which are available from the bounding box and predictor processes. Once these interval extensions are available, it is possible to obtain an interval relation of the form

$$\forall\, t : FL(\mathbf{t}, \mathbf{D}, t), \tag{7}$$

which approximates the original ODE *safely*; i.e., if $FL(\mathbf{t}, \mathbf{D}, t)$ does not hold for a time t, it follows that no solution of the ODE can go through boxes $D_0, \ldots, D_k$ at times $t_0, \ldots, t_k$. Relation (7) is still not ready to be used as a filter because t is universally quantified. The solution here is simpler and consists of restricting attention to a finite set T of times (possibly a singleton) to obtain the relation

$$\forall\, t \ \in\ T : FL(\mathbf{t}, \mathbf{D}, t),$$

which produces a computable filter. The relation FL is a *relaxation* of the ODE (6) in a constraint satisfaction sense [32]; i.e., given a time t, it produces a relation that can be used to prune the domain of the variables. The so-obtained relation is in fact a conservative approximation of the actual ODE at the given time. The following definition and proposition capture these concepts more formally.

DEFINITION 6 (multistep filter). *Let $\mathbb{O}$ be an ODE and s its solution. A* multistep filter *for $\mathbb{O}$ is an interval relation $FL : \mathbb{R}^{k+1} \times (\mathbb{IR}^n)^{k+1} \times \mathbb{R} \to Bool$ satisfying*

$$\left.\begin{array}{c} u_i \ \in\ D_i \\ s(t_0, u_0, t_i) = u_i\ (0 \le i \le k) \end{array}\right\} \Rightarrow\ \ \forall t:\ FL(\mathbf{t}, \mathbf{D}, t).$$

The variable t is called the evaluation time *of the multistep filter.*

PROPOSITION 1 (soundness of multistep filters). *Let $\mathbb{O}$ be an ODE, and let FL be a multistep filter for $\mathbb{O}$. If $FL(\mathbf{t}, \mathbf{D}, t)$ does not hold for some t, then there exists no solution of $\mathbb{O}$ going through $\mathbf{D}$ at times $\mathbf{t}$.*

How can we use this filter to obtain tighter enclosures of the solution? A simple technique consists of pruning the last box computed by the predictor process. Assume that D_i^* is a box enclosing the solution at time t_i $(0 \leq i < k)$ and that we are interested in pruning the last predicted box D_k^-. A subbox $D \subseteq D_k^-$ can be pruned away if the condition

$$FL(\mathbf{t}, (D_0^*, \ldots, D_{k-1}^*, D), t_e)$$

does not hold for some evaluation point t_e. Let us explain briefly the geometric intuition behind this relation by considering what we call *natural filters*. Given interval extensions *MS*, *DMS*, and F, respectively, of ms, $\frac{\partial ms}{\partial t}$, and f, it is possible to approximate the ODE $u' = f(u)$ by the relation

$$DMS(\mathbf{t}, \mathbf{D}, t) = F(MS(\mathbf{t}, \mathbf{D}, t)).$$

In this relation, the left-hand side of the equation represents *the approximation of the slope of u* while the right-hand side represents *the slope of the approximation of u*. Since the approximations are conservative, these two sides must intersect on boxes containing a solution. Hence an empty intersection means that the boxes used in the relation do not contain the solution to the ODE system. Figure 2 illustrates the intuition. It is generated from an actual ODE, considers only points instead of intervals, uses an interpolation polynomial as an approximation of u, and ignores error terms for simplicity. It illustrates how this technique can prune away a value as a potential solution at a given time. In the figure, we consider the solution to the equation that evaluates to u_0 and u_1 at t_0 and t_1, respectively. Two possible points u_2 and u_2' are then considered as possible values at t_2. The curve marked `KO` describes an interpolation polynomial going through u_0, u_1, u_2' at times t_0, t_1, t_2. To determine if u_2' is the value of the solution at time t_2, the idea is to test if the equation is satisfied at time t_e. (We will say more about how to choose t_e later in this paper.) As can be easily seen, the slope of the interpolation polynomial is different from the slope specified by f at time t_e, and hence u_2' cannot be the value of the solution at t_2 since we assume that the values u_0 and u_1 were correct at t_0 and t_1. The curve marked `OK` describes an interpolation polynomial going through u_0, u_1, u_2 at times t_0, t_1, t_2. In this case, the equation is satisfied at time t_e, which means that u_2 cannot be pruned away.

The filter proposed earlier generalizes this intuition to boxes. Both the left- and right-hand sides represent sets of slopes, and the filter fails when their intersection is empty. Traditional consistency techniques and algorithms based on this filter can now be applied. For instance, one may be interested in updating the last box computed by the predictor process using the operator

$$D_k^* = \Box\{r \in D_k^- \mid FL(\mathbf{t}, (D_0^*, \ldots, D_{k-1}^*, r), t_e)\},$$

which is defined in terms of an evaluation time t_e. *One of the main results of this paper consists of showing that t_e can be chosen optimally (in an asymptotic sense) to maximize pruning.* The following definition is a novel notion of consistency for ODEs to capture pruning of the last r boxes.[7]

[7] We will give an explicit form for D_k^* later in the paper.

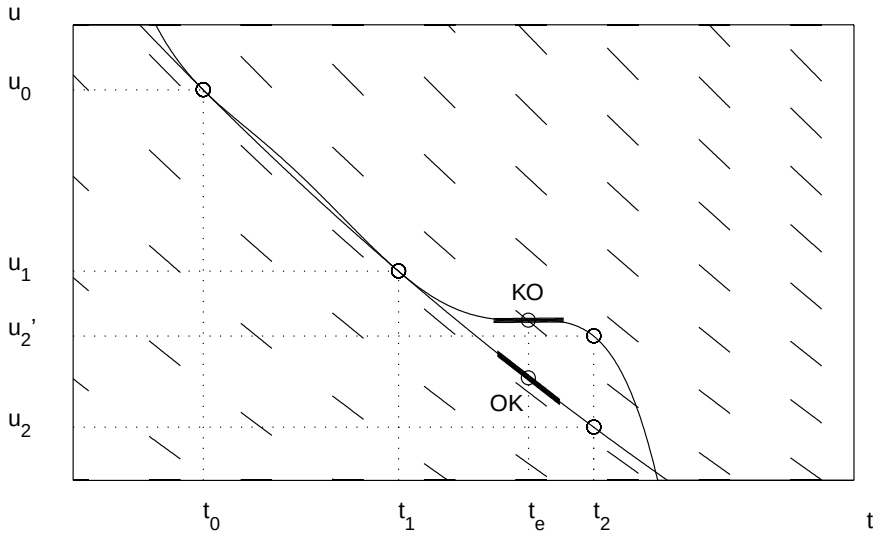

FIG. 2. *Geometric intuition of the multistep filter.*

DEFINITION 7 (backward consistency of multistep filters). *A multistep filter FL is* backward-consistent *in* $(\mathbf{t}, \mathbf{D})$ *for time* e *if*

$$D_k = \square \{u_k \in D_k \mid \exists \mathbf{u}_0 \in \mathbf{D}_0 : FL(\mathbf{t}, \mathbf{u}, e)\}.$$

A system of r *successive multistep filters* $\{FL_i\}_{0 \le i < r}$ *is* backward(r)-consistent *in* $(\mathbf{t}_{0..k+r-1}, \mathbf{D}_{0..k+r-1})$ *for time vector* $(e_0, \ldots, e_{r-1})$ *if*

$$\begin{aligned} \mathbf{D}_{k..k+r-1} = \square\{&\mathbf{u}_{k..k+r-1} \in \mathbf{D}_{k..k+r-1} \mid \exists \mathbf{u}_0 \in \mathbf{D}_0 : \\ &\forall\ 0 \le i < r : FL_i(\mathbf{t}_{i..k+i}, \mathbf{u}_{i..k+i}, e_i)\}. \end{aligned} \tag{8}$$

Informally speaking, the parameter r in the definition determines the strength of the consistency, i.e., the number of backward variables each variable depends on. The following proposition is an immediate consequence of Definition 7. It states that the strength of the consistency increases with parameter r.

PROPOSITION 2 (property of backward consistency). *If a system of* $r+1$ $(r > 0)$ *successive multistep filters* $\{FL_i\}_{0 \le i \le r}$ *is backward*$(r+1)$*-consistent in* $(\mathbf{t}_{0..k+r}, \mathbf{D}_{0..k+r})$ *for time vector* $(e_0, \ldots, e_r)$*, then the system*

1. $\{FL_i\}_{0 \le i < r}$ *is backward*(r)*-consistent in* $(\mathbf{t}_{0..k+r-1}, \mathbf{D}_{0..k+r-1})$ *for time vector* $(e_0, \ldots, e_{r-1})$*;*
2. $\{FL_i\}_{1 \le i \le r}$ *is backward*(r)*-consistent in* $(\mathbf{t}_{1..k+r}, \mathbf{D}_{1..k+r})$ *for time vector* $(e_1, \ldots, e_r)$*.*

In the next section, we introduce coordinate transformations in multistep filters to represent the sets of solutions compactly, i.e., to handle the wrapping effect (see section 4.5). It is thus useful to generalize the above definition by introducing affine transformations.

DEFINITION 8 (generalized backward consistency). *Let* $Y_i \in \mathbb{IR}^n$ $(i \in \mathbb{N})$*. A multistep filter FL is* backward-consistent *in* $(\mathbf{t}, \mathbf{Y})$ *for time* e *if there exists an invertible*

affine transformation $\mathbf{a} : \mathbb{R}^{n(k+1)} \rightarrow \mathbb{R}^{n(k+1)}$ *such that*

$$Y_k = \Box\{y_k \in Y_k \mid \exists \mathbf{y}_0 \in \mathbf{Y}_0 : FL(\mathbf{t}, \mathbf{a}(\mathbf{y}), e)\}.$$

A system of r *successive multistep filters* $\{FL_i\}_{0 \leq i < r}$ *is* backward(r)-consistent *in* $(\mathbf{t}_{0..k+r-1}, \mathbf{Y}_{0..k+r-1})$ *for time vector* $(e_0, \ldots, e_{r-1})$ *if there exists an invertible affine transformation* $\mathbf{a}_{0..k+r-1} : \mathbb{R}^{n(k+r)} \rightarrow \mathbb{R}^{n(k+r)}$ *such that*

$$\begin{aligned} \mathbf{Y}_{k..k+r-1} = \Box\{&\mathbf{y}_{k..k+r-1} \in \mathbf{Y}_{k..k+r-1} \mid \exists \mathbf{y}_0 \in \mathbf{Y}_0 : \\ &\forall 0 \leq i < r : FL_i(\mathbf{t}_{i..k+i}, \mathbf{a}_{i..k+i}(\mathbf{y}_{0..k+r-1}), e_i)\}. \end{aligned} \tag{9}$$

Note that Proposition 2 also holds for generalized backward consistency. In the rest of this paper, we use "backward consistency" instead of "generalized backward consistency" for simplicity. The algorithm used in our computational results enforces backward(k)-consistency of a system of k filters we now describe.

4. Multistep filters. Filters rely on interval extensions of the multistep solution and of its derivative w.r.t. t. These extensions are, in general, based on decomposing the (unknown) multistep solution into the sum of a computable approximation p and an (unknown) error term e, i.e.,

$$ms(\mathbf{t}, \mathbf{u}, t) = p(\mathbf{t}, \mathbf{u}, t) + e(\mathbf{t}, \mathbf{u}, t). \tag{10}$$

There exist standard techniques to build p and $\frac{\partial p}{\partial t}$ and to bound e and $\frac{\partial e}{\partial t}$. Section 5 reviews how they can be derived from Hermite interpolation polynomials. Here we simply assume that they are available, and we show how to use them to build filters.

4.1. Natural filters. Section 3 explained how natural multistep filters can be obtained by simply replacing the multistep solution *ms*, its derivative $\frac{\partial ms}{\partial t}$, and the function f by their interval extensions *MS*, *DMS*, and F to obtain

$$DMS(\mathbf{t}, \mathbf{D}, t) = F(MS(\mathbf{t}, \mathbf{D}, t)).$$

It is not easy, however, to enforce backward consistency on a natural filter since the variables may occur in complex nonlinear expressions. This problem is addressed by mean-value filters that we now study.

4.2. Mean-value filters.

Mean-value forms. Mean-value forms (MVFs) play a fundamental role in interval computations and are derived from the mean-value theorem. They correspond to problem linearizations around a point and result in filters that are systems of linear equations with interval coefficients and whose solutions can be enclosed reasonably efficiently. MVFs are effective when the sizes of the boxes are sufficiently small, which is the case in ODEs. In addition, being linear equations, they allow for an easier treatment of the so-called *wrapping effect*, a crucial problem in interval methods for ODEs to be discussed in sections 4.3 and 4.5. As a consequence, MVFs are especially appropriate in our context and will produce filters which are efficiently amenable to backward consistency. The rest of this section describes how to obtain mean-value filters.

Implicit mean-value filters. Consider the function

$$\delta(\mathbf{t},\mathbf{u},e,de,t)=\frac{\partial p}{\partial t}(\mathbf{t},\mathbf{u},t)+de-f(p(\mathbf{t},\mathbf{u},t)+e).$$

If the multistep solution ms is defined at $(\mathbf{t},\mathbf{u})$, i.e., the ODE has a solution going through $u_0,\dots,u_k$ at $t_0,\dots,t_k$, then, by (10), we have the relation

$$\delta\left(\mathbf{t},\mathbf{u},e(\mathbf{t},\mathbf{u},t),\frac{\partial e}{\partial t}(\mathbf{t},\mathbf{u},t),t\right)=0.$$

Let $\mathbf{u}^*,\mathbf{u}\in\mathbf{D}^0\in\mathbb{IR}^{n(k+1)}$, $e^*,e\in E\in\mathbb{IR}^n$, and $de^*,de\in DE\in\mathbb{IR}^n$. By the mean-value theorem, we can write $(1\le i\le n)$

$$\begin{aligned}\delta_i(\mathbf{t},\mathbf{u},e,de,t) &= \delta_i(\mathbf{t},\mathbf{u}^*,e^*,de^*,t)\\ &\quad+\mathcal{J}_{(\mathbf{u},e,de)}\delta_i(\mathbf{t},\mu_i,\xi_i,\zeta_i,t)\ (\mathbf{u}-\mathbf{u}^*,e-e^*,de-de^*)\\ &= \delta_i(\mathbf{t},\mathbf{u}^*,e^*,de^*,t)+\phi_i(\mathbf{t},\mu_i,\xi_i,t)(\mathbf{u}-\mathbf{u}^*)\\ &\quad+\psi_i(\mathbf{t},\mu_i,\xi_i,t)(e^*-e)+de_i-de_i^*,\end{aligned}$$

where

$$\begin{aligned}\phi_i(\mathbf{t},\mu_i,\xi_i,t)&=\mathcal{J}_{\mathbf{u}}\tfrac{\partial p_i}{\partial t}(\mathbf{t},\mu_i,t)-\mathcal{J}f_i(p(\mathbf{t},\mu_i,t)+\xi_i)\mathcal{J}_{\mathbf{u}}p(\mathbf{t},\mu_i,t),\\ \psi_i(\mathbf{t},\mu_i,\xi_i,t)&=\mathcal{J}f_i(p(\mathbf{t},\mu_i,t)+\xi_i)\end{aligned}$$

for some $\mu_i\in\mathbf{D}^0$, $\xi_i\in E$, and $\zeta_i\in DE$. This allows us to define a new multistep filter, which we will call an *implicit mean-value filter*. Such a filter is parametrized by the initial domain $\mathbf{D}^0$ of the variable $\mathbf{u}$.

Definition 9 (implicit mean-value filter). *An* implicit mean-value filter *for ODE* $u'=f(u)$ *in* $\mathbf{D}^0\in\mathbb{IR}^{n(k+1)}$ *is an interval relation*

(11)
$$\begin{gathered}FL(\mathbf{t},\mathbf{D},t)\Leftrightarrow\\ \delta(\mathbf{t},\mathbf{m}^0,m_e,m_{de},t)+\Delta(\mathbf{t},\mathbf{D}^0,E(\mathbf{t},\mathbf{D}^0,t),DE(\mathbf{t},\mathbf{D}^0,t),t)\ (\mathbf{X},E_m,DE_m)=0,\end{gathered}$$

where

(12)
$$\begin{aligned}&\Delta \text{ is an interval extension of the function } \mathcal{J}_{(\mathbf{u},e,de)}\delta,\\ &E \text{ and } DE \text{ are interval extensions, respectively, of } e \text{ and } \tfrac{\partial e}{\partial t},\\ &\mathbf{D}\subseteq\mathbf{D}^0,\\ &\mathbf{X}=\mathbf{D}-\mathbf{m}^0, E_m=E(\mathbf{t},\mathbf{D}^0,t)-m_e, DE_m=DE(\mathbf{t},\mathbf{D}^0,t)-m_{de},\\ &\mathbf{m}^0=m(\mathbf{D}^0), m_e=m(E(\mathbf{t},\mathbf{D}^0,t)), m_{de}=m(DE(\mathbf{t},\mathbf{D}^0,t)).\end{aligned}$$

Formula (11) is called implicit because $\mathbf{D}$ appears implicitly. The Jacobians in (12) can be computed by means of automatic differentiation tools (see, e.g., [27]). The following proposition states that an implicit mean-value filter does not eliminate any solution of the ODE. It is a direct consequence of the mean-value theorem.

Proposition 3. *An implicit mean-value filter for ODE* $\mathcal{O}$ *is a multistep filter for* $\mathcal{O}$.

Explicit mean-value filters. In general, for IVPs, we will be interested in pruning the last predicted box D_k^-. Hence, it is convenient to derive a mean-value filter which is explicit in D_k. Let $\mathbf{D}^-\in\mathbb{IR}^{n(k+1)}$ be the predicted box of variable $\mathbf{u}$ and define $\mathbf{X}$ as $\mathbf{D}-m(\mathbf{D}^-)$. An implicit mean-value filter is an interval constraint of the form

$$\Phi(t)\mathbf{X}=\Gamma(t),$$

where $\Phi(t) \in \mathbb{IR}^{n \times n(k+1)}$ and $\Gamma(t) \in \mathbb{IR}^n$. Let us apply the midpoint technique (see point 2 of section 2.3) on the matrix $\Phi(t)$. We can write $\Phi(t) = m(\Phi(t)) + s(\Phi(t))$, and

$$m(\Phi(t))\mathbf{X} = \Gamma(t) - s(\Phi(t))\mathbf{X}. \tag{13}$$

The term $s(\Phi(t))\mathbf{X}$ is normally small (of size $\mathcal{O}(\|\omega(\mathbf{D}^-)\|^2)$), and we can substitute $\mathbf{X}$ on the right side of (13) for $s(\mathbf{D}^-)$, since $\mathbf{X} = \mathbf{D} - m(\mathbf{D}^-)$ and we are looking for a pruned box $\mathbf{D}^* \subseteq \mathbf{D}^-$. We obtain the system

$$m(\Phi(t))\mathbf{X} = \Gamma(t) - s(\Phi(t))s(\mathbf{D}^-). \tag{14}$$

Equation (14) can be rewritten as

$$\sum_{i=0}^{k} A_i(t)X_i = K(t),$$

where $A_i(t) \in \mathbb{R}^{n \times n}$, $i = 0, \ldots, k$, and $K(t) \in \mathbb{IR}^n$. Let us isolate the term involving X_k:

$$A_k(t)X_k = K(t) - \sum_{i=0}^{k-1} A_i(t)X_i. \tag{15}$$

Multiplying both sides of (15) by $A_k(t)^{-1}$ (recall that $A_k(t)^{-1}$ denotes an enclosure of the inverse of $A_k(t)$) gives

$$X_k = A_k(t)^{-1}K(t) - \sum_{i=0}^{k-1} \left(A_k(t)^{-1}A_i(t)\right) X_i.$$

We are now in position to define explicit mean-value filters which play a fundamental role in our approach.

Definition 10 (explicit mean-value filter). *An* explicit mean-value filter *for ODE $\mathcal{O}$ in $\mathbf{D}^0 \in \mathbb{IR}^{n(k+1)}$ is an interval relation*

$$FL(\mathbf{t}, \mathbf{D}, t) \;\Leftrightarrow\; X_k = A_k(t)^{-1}K(t) - \sum_{i=0}^{k-1} \left(A_k(t)^{-1}A_i(t)\right) X_i,$$

where

$\mathbf{X} = \mathbf{D} - m(\mathbf{D}^0)$,
$\mathbf{D} \subseteq \mathbf{D}^0$,
$(A_0(t) \cdots A_k(t)) = m(\Phi(t)) \in \mathbb{R}^{n \times n(k+1)}$,
$K(t) = \Gamma(t) - s(\Phi(t))s(\mathbf{D}^0) \in \mathbb{IR}^n$,
the relation $\Phi(t)\mathbf{X} = \Gamma(t)$ is an implicit mean-value filter for $\mathcal{O}$ in $\mathbf{D}^0$.

Proposition 4. *An explicit mean-value filter for ODE $\mathcal{O}$ is a multistep filter for $\mathcal{O}$.*

It is easy to use an explicit mean-value filter to prune the predicted box D_k^- at time t_k given the boxes $D_0^*, \ldots, D_{k-1}^*$ from the previous integration steps, since X_k (and thus D_k) has been isolated. The filter simply becomes

$$D_k = m(D_k^-) + A_k(t)^{-1}K(t) - \sum_{i=0}^{k-1} \left(A_k(t)^{-1}A_i(t)\right) (D_i^* - m(D_i^*)), \tag{16}$$

and the pruned box D_k^* at time t_k is given by

$$D_k^* = D_k \cap D_k^-.$$

It follows directly that the explicit mean-value filter is backward-consistent in $\mathbf{D}^*$.

4.3. Problems in mean-value filters. Mean-value filters often produce significant pruning of the boxes computed by the predictor process. However, they suffer from two limitations: the *wrapping effect* which is inherent in interval analysis and a *variable dependency* problem induced by the use of a multistep method. We review both of these before describing how to address them.

Wrapping effect. The wrapping effect is the name given to the overestimation that arises from enclosing a set by a box. In the context of ODEs, the set of solutions at each integration step is overapproximated by a box. These overapproximations accumulate step after step and may result in an explosion in the sizes of the computed boxes. The standard solution used in interval methods for ODEs to obtain tighter solution bounds is to choose, at each step, an appropriate local coordinate system to represent the solutions compactly (see [20, 24]). How does the wrapping effect occur in our context? Let us rewrite an explicit mean-value filter from (16) as

$$X_k = K(t) + \sum_{i=0}^{k-1} A_i(t) X_i,$$

and let us assume that $A_0(t), \ldots, A_{k-1}(t)$ are point matrices and that $K(t)$ is a point vector. Given the boxes $X_0, \ldots, X_{k-1}$ computed at the previous steps, the exact solution set to be enclosed by X_k is

$$Z = \left\{ K(t) + \sum_{i=0}^{k-1} A_i(t) x_i \mid (x_0, \ldots, x_{k-1}) \in (X_0, \ldots, X_{k-1}) \right\}.$$

The set Z is called a *zonotope*[8] (i.e., a generalization of a parallelepiped). Figure 3(a) illustrates a zonotope in $\mathbb{R}^2$ (for $k = 3$) and its smallest enclosing box. As can be seen, the box significantly overestimates the zonotope. Figure 3(b) shows that the zonotope can be enclosed much more tightly by using a coordinate transformation. It should be mentioned, however, that finding a good coordinate system is not necessarily a trivial task (e.g., one idea is to find approximations of the main directions of the zonotope) and may not be sufficient because of the variable dependency problem that we now discuss.

Variable dependencies in explicit filters. Consider the application of an explicit mean-value filter at two successive time steps with respective evaluation times e_0 and e_1. We obtain equations of the form

$$\begin{aligned} X_k &= K_0(e_0) + A_{0,0}(e_0) X_0 + \cdots + A_{0,k-1}(e_0) X_{k-1}, \\ X_{k+1} &= K_1(e_1) + A_{1,0}(e_1) X_1 + \cdots + A_{1,k-1}(e_1) X_k. \end{aligned}$$

The second equation computes the box X_{k+1} assuming that $X_1, \ldots, X_k$ are independent, which is not the case because of the first equation. Hence, the dependencies between $X_1, \ldots, X_k$ are lost when moving from the first to the second time step.

[8] Note that Kühn uses zonotopes in another context, i.e., as compact enclosures of solutions [17, 18, 19].

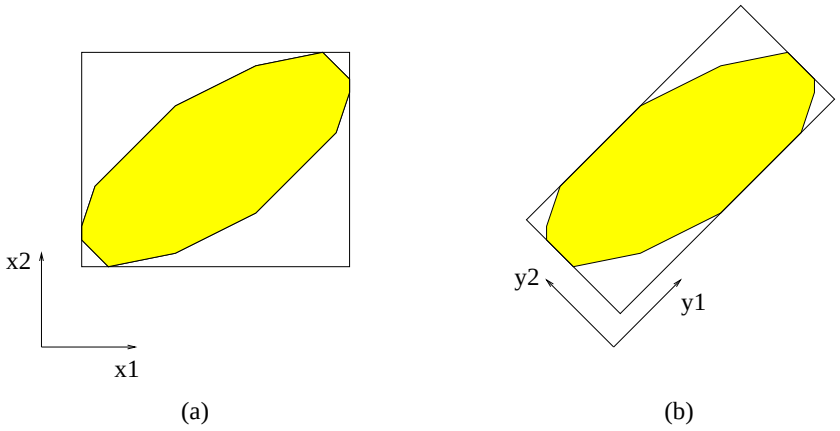

FIG. 3. (a) *A zonotope in* $\mathbb{R}^2$ *and the smallest enclosing box.* (b) *Coordinate transformation where the enclosing box better fits the zonotope.*

The variable dependency problem arises because successive explicit mean-value filters overlap; i.e., each computed box X_i is used in k successive filters. One-step methods do not encounter this problem because each computed box X_i is used only at one time step to compute the following box: X_{i+1}. *Global filters*, which are presented in the next section, avoid this variable dependency problem and make it possible to apply standard techniques for the wrapping effect.

4.4. Global filters. The main idea underlying global filters is to cluster several mean-value filters together so that they do not overlap. The intuition is illustrated in Figure 4 for $k = 3$. It can be seen that the global filter prunes the three predicted boxes D_3^-, D_4^-, and D_5^- for times t_3, t_4, and t_5 using the boxes D_0^*, D_1^*, and D_2^* computed for times t_0, t_1, and t_2. Observe also that global filters do not overlap; i.e., the boxes D_0^*, D_1^*, and D_2^* are not used in subsequent filters. More precisely, a global filter is a system of k successive explicit mean-value filters.

DEFINITION 11 (global filter). *A* global filter *for ODE* $\mathcal{O}$ *in* $\mathbf{D}^0_{0..2k-1}$ *is a system* $\{FL_i(\mathbf{t}_{i..k+i}, \mathbf{D}_{i..k+i}, e_i)\}_{0\le i<k}$ *of* k *successive explicit mean-value filters for* $\mathcal{O}$ *in* $\mathbf{D}^0_{0..k}, \ldots, \mathbf{D}^0_{k-1..2k-1}$ *respectively given as*

(17)
$$\begin{cases} X_k &= K_0(e_0) + A_{0,0}(e_0)X_0 + \cdots + A_{0,k-1}(e_0)X_{k-1}, \\ X_{k+1} &= K_1(e_1) + A_{1,0}(e_1)X_1 + \cdots + A_{1,k-1}(e_1)X_k, \\ &\vdots \\ X_{2k-1} &= K_{k-1}(e_{k-1}) + A_{k-1,0}(e_{k-1})X_{k-1} + \cdots + A_{k-1,k-1}(e_{k-1})X_{2k-2}, \end{cases}$$

where $\mathbf{X}_{0..2k-1} = \mathbf{D}_{0..2k-1} - m(\mathbf{D}^0_{0..2k-1})$.

The key idea to remove the variable dependency problem is to solve (17) globally by transforming the global filter into an explicit form

$$\begin{bmatrix} X_k \\ \vdots \\ X_{2k-1} \end{bmatrix} = C(\mathbf{e}_0) \begin{bmatrix} X_0 \\ \vdots \\ X_{k-1} \end{bmatrix} + R(\mathbf{e}_0)$$

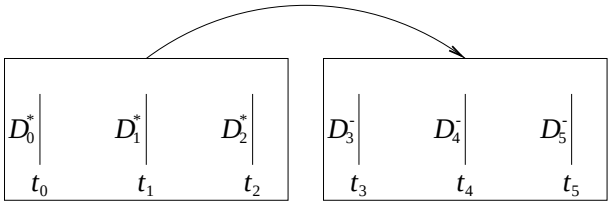

FIG. 4. *Intuition of the globalization process ($k = 3$): Predicted boxes D_3^-, D_4^-, and D_5^- for times t_3, t_4, and t_5 are pruned globally using boxes D_0^*, D_1^*, and D_2^* computed for times t_0, t_1, and t_2.*

or, more concisely,

$$\mathbf{X}_1 = C(\mathbf{e}_0)\mathbf{X}_0 + R(\mathbf{e}_0), \tag{18}$$

where $C(\mathbf{e}_0) \in \mathbb{IR}^{nk \times nk}$ and $R(\mathbf{e}_0) \in \mathbb{IR}^{nk}$.

An interesting property of global filters is that each pruned box at times t_3, t_4, or t_5 can be computed only in terms of the predicted boxes and the boxes at times t_0, t_1, and t_2 by using Gaussian elimination. Hence, it removes the dependencies introduced in D_3^- and D_4^-. Consider a system with $k = 3$:

$$\begin{cases} X_3 = A_{00}X_0 + A_{01}X_1 + A_{02}X_2 + K_0, \\ X_4 = A_{10}X_1 + A_{11}X_2 + A_{12}X_3 + K_1, \\ X_5 = A_{20}X_2 + A_{21}X_3 + A_{22}X_4 + K_2. \end{cases}$$

Variable X_4 can be eliminated from the last equation to obtain

$$X_5 = A_{20}X_2 + A_{21}X_3 + A_{22}(A_{10}X_1 + A_{11}X_2 + A_{12}X_3 + K_1) + K_2.$$

To avoid multiplying interval matrices (e.g., $A_{22}A_{10}$), we can apply the midpoint technique (see point 1 of section 2.3) to obtain

$$\begin{aligned} X_5 = {} & A_{20}X_2 + A_{21}X_3 + m(A_{22})(A_{10}X_1 + A_{11}X_2 + A_{12}X_3 + K_1) \\ & + K_2 + s(A_{22})s(D_4^-). \end{aligned} \tag{19}$$

By distribution and rearrangement of the parentheses, we can rewrite (19) as

$$\begin{aligned} X_5 = {} & (m(A_{22})A_{10})X_1 + (A_{20} + m(A_{22})A_{11})X_2 + (A_{21} + m(A_{22})A_{12})X_3 \\ & + m(A_{22})K_1 + K_2 + s(A_{22})s(D_4^-). \end{aligned}$$

Variable X_3 can be eliminated from this equation in a similar fashion to obtain a filter involving only X_5, X_0, X_1, and X_2. Similarly, variable X_3 can be eliminated from the second equation to obtain a filter involving only X_4, X_0, X_1, and X_2.[9]

A generic algorithm for computing an explicit global filter is given in Figure 5. It receives as input the ODE system $\mathbb{O}$, the previous integration times $\mathbf{t}_0$, the pruned boxes $\mathbf{D}_0^0$, and the bounding boxes $\mathbf{B}_{1..k-1}$, the new integration points $\mathbf{t}_1$, the predicted boxes $\mathbf{D}_1^0$ for these integration points, the bounding boxes $\mathbf{B}_1$ for the new integration points, and the evaluation times for the filters. It generates the matrix and vectors of the explicit global filter which can be used to compute the pruned boxes. The resulting filter is backward(k)-consistent w.r.t. the resulting boxes. Its precise specification is as follows.

[9] As observed by one of the reviewers, there are still some dependencies, but these are very small.

```
function ExplicitGlobalFilter(𝕆, t_0, D_0^0, B_{1..k-1}, t_1, D_1^0, B_1, e_0)
  begin
1   for i := 0 to k − 1 do
2     ⟨K_i, A_{i,0}, ..., A_{i,k-1}⟩ := EMVFL(𝕆, t_{i..i+k}, D^0_{i..i+k}, B_{i+1..i+k}, e_i);
3   endfor
4   for i := k − 1 downto 0 do
5     R_i := K_i;
6     for l := i downto 1 do
7       A* := m(A_{i,k-1});
8       R_i := R_i + A*K_{l-1} + s(A_{i,k-1})s(D^0_{k+l-1});
9       for j := k − 1 downto 1 do
10        A_{i,j} := A_{i,j-1} + A*A_{l-1,j}
11      endfor
12      A_{i,0} := A*A_{l-1,0}
13    endfor
14  endfor
15  return ⟨(A_{i,j})_{0≤i≤k-1, 0≤j≤k-1}, (R_i)_{0≤i≤k-1}⟩
  end
```

FIG. 5. *An algorithm for computing an explicit global filter.*

SPECIFICATION 1 (EXPLICITGLOBALFILTER). *Let B_i be a bounding box of ODE $\mathbb{O}$ over $[t_{i-1}, t_i]$ w.r.t. (t_0, D_0) for $1 \le i \le 2k-1$. Let*

$$\langle C(\mathbf{e}_0), R(\mathbf{e}_0)\rangle = \text{EXPLICITGLOBALFILTER}(\mathbb{O}, \mathbf{t}_0, \mathbf{D}_0^0, \mathbf{B}_{1..k-1}, \mathbf{t}_1, \mathbf{D}_1^0, \mathbf{B}_1, \mathbf{e}_0),$$

$\mathbf{X}_0 = \mathbf{D}_0 - m(\mathbf{D}_0^0)$, and $\mathbf{X}_1 = \mathbf{D}_1 - m(\mathbf{D}_1^0)$. Then the system $\mathcal{S} : \mathbf{X}_1 = C(\mathbf{e}_0)\mathbf{X}_0 + R(\mathbf{e}_0)$ is a global filter for $\mathbb{O}$ in $(\mathbf{D}_0^0, \mathbf{D}_1^0)$.

The algorithm is generic in the sense that it uses the function EMVFL to generate an explicit mean-value filter. How to generate such a filter is discussed in section 5, but its specification is given as follows.

SPECIFICATION 2 (EMVFL). *Let B_i be a bounding box of ODE $\mathbb{O}$ over $[t_{i-1}, t_i]$ w.r.t. (t_0, D_0) for $1 \le i \le k$. Let*

$$\langle K(t), A_0(t), \ldots, A_{k-1}(t)\rangle = \text{EMVFL}(\mathbb{O}, \mathbf{t}, \mathbf{D}^0, (B_1, \ldots, B_k), t).$$

Then the interval relation

$$FL(\mathbf{t}, \mathbf{D}, t) \Leftrightarrow X_k = K(t) + \sum_{i=0}^{k-1} A_i(t) X_i,$$

where $\mathbf{X} = \mathbf{D} - m(\mathbf{D}^0)$ and $\mathbf{D} \subseteq \mathbf{D}^0$ is an explicit mean-value filter for $\mathbb{O}$ in $\mathbf{D}^0$.

Finally, observe that global filters not only remove the variable dependency problem by globalizing the pruning process, but they also have the advantage of producing square systems which makes it possible to apply standard techniques to address the wrapping effect. The next section discusses the wrapping effect in detail.

4.5. The wrapping effect in global filters. The wrapping effect in global filters arises when multiplying a $nk \times nk$ matrix and a box of nk elements. Fortunately, since the matrices in global filters are square, the wrapping effect can be handled as

in one-step methods by using local coordinate transformations and QR factorizations [20]. We now explain this process in detail. Initially, starting from the previous boxes $\mathbf{D}_0^*$ and predicted boxes $\mathbf{D}_1^-$, we need to solve the system

$$\mathbf{D}_1 - m(\mathbf{D}_1^-) = C_1(\mathbf{e}_0)(\mathbf{D}_0^* - m(\mathbf{D}_0^*)) + R_1(\mathbf{e}_0)$$

or, equivalently, the system

$$\mathbf{X}_1 = C_1(\mathbf{e}_0)\mathbf{X}_0 + R_1(\mathbf{e}_0),$$

where $\mathbf{X}_1 = \mathbf{D}_1 - m(\mathbf{D}_1^-)$ and $\mathbf{X}_0 = \mathbf{D}_0^* - m(\mathbf{D}_0^*)$. The pruned boxes are then obtained by

$$\mathbf{D}_1^* = \mathbf{D}_1^- \cap (\mathbf{X}_1 + m(\mathbf{D}_1^-)).$$

The key idea in tackling the wrapping effect is to find a good coordinate system to represent the solution $\mathbf{X}_1$ compactly so that errors will not accumulate drastically in subsequent integration steps. For this purpose, we introduce a coordinate transformation

$$M_1\mathbf{y}_1 = \mathbf{u}_1 - m(\mathbf{D}_1^*)$$

which can be reexpressed in terms of the $\mathbf{x}$ variables as

$$M_1\mathbf{y}_1 = \mathbf{x}_1 + m(\mathbf{D}_1^-) - m(\mathbf{D}_1^*).$$

We then solve the system

$$M_1\mathbf{Y}_1 = C_1(\mathbf{e}_0)\mathbf{X}_0 + R_1(\mathbf{e}_0) + m(\mathbf{D}_1^-) - m(\mathbf{D}_1^*)$$

by inverting the matrix M_1:

$$\mathbf{Y}_1 = (M_1^{-1}C_1(\mathbf{e}_0))\mathbf{X}_0 + M_1^{-1}(R_1(\mathbf{e}_0) + m(\mathbf{D}_1^-) - m(\mathbf{D}_1^*)).$$

The matrix M_1 and the boxes $\mathbf{Y}_1$ and $\mathbf{D}_1^*$ are then sent to the next integration step. Observe that $\mathbf{Y}_1$ is a compact representation of $\mathbf{D}_1^*$ in the local coordinate system.

In the next integration step, the boxes $\mathbf{D}_1^*$ are used (together with other data) to compute new predicted boxes $\mathbf{D}_2^-$ as well as the new global filter

$$\mathbf{D}_2 - m(\mathbf{D}_2^-) = C_2(\mathbf{e}_1)(\mathbf{D}_1^* - m(\mathbf{D}_1^*)) + R_2(\mathbf{e}_1)).$$

Since $M_1\mathbf{y}_1 = \mathbf{u}_1 - m(\mathbf{D}_1^*)$ by the coordinate transformation, the above filter can be rewritten as

$$\mathbf{X}_2 = (C_2(\mathbf{e}_1)M_1)\mathbf{Y}_1 + R_2(\mathbf{e}_1),$$

where $\mathbf{X}_2 = \mathbf{D}_2 - m(\mathbf{D}_2^-)$. Observe the associativity of the multiplication which is critical in reducing the wrapping effect. The new boxes are computed as

$$\mathbf{D}_2^* = \mathbf{D}_2^- \cap (\mathbf{X}_2 + m(\mathbf{D}_2^-)).$$

Once again, we would like to represent the set of solutions $\mathbf{X}_2$ compactly, and we use a local coordinate transformation

$$M_2\mathbf{y}_2 = \mathbf{u}_2 - m(\mathbf{D}_2^*)$$

to obtain the system

$$M_2\mathbf{Y}_2 = (C_2(\mathbf{e}_1)M_1)\mathbf{Y}_1 + R_2(\mathbf{e}_1) + m(\mathbf{D}_2^-) - m(\mathbf{D}_2^*).$$

This equation system can be solved by inverting M_2:

$$\mathbf{Y}_2 = (M_2^{-1}(C_2(\mathbf{e}_1)M_1))\mathbf{Y}_1 + M_2^{-1}(R_2(\mathbf{e}_1) + m(\mathbf{D}_2^-) - m(\mathbf{D}_2^*)).$$

Once again, observe the associativity in the multiplication to tackle the wrapping effect. The hope is that the matrix $M_2^{-1}(C_2(\mathbf{e}_1)M_1)$ is diagonally dominant or triangular. Also, M_2, $\mathbf{Y}_2$, and $\mathbf{D}_2^*$ will be sent to the next integration step. As a consequence, at integration step i, we solve

$$\mathbf{X}_i = (C_i(\mathbf{e}_{i-1})M_{i-1})\mathbf{Y}_{i-1} + R_i(\mathbf{e}_{i-1}),$$

where $\mathbf{X}_i = \mathbf{D}_i - m(\mathbf{D}_i^-)$, and the new boxes are obtained by

$$\mathbf{D}_i^* = \mathbf{D}_i^- \cap (\mathbf{X}_i + m(\mathbf{D}_i^-)).$$

The local coordinate transformation

$$M_i\mathbf{y}_i = \mathbf{u}_i - m(\mathbf{D}_i^*)$$

is used to compute the new $\mathbf{Y}_i$ which is given by

$$\mathbf{Y}_i = (M_i^{-1}(C_i(\mathbf{e}_{i-1})M_{i-1}))\mathbf{Y}_{i-1} + M_i^{-1}(R_i(\mathbf{e}_{i-1}) + m(\mathbf{D}_i^-) - m(\mathbf{D}_i^*)).$$

In addition, in order to avoid the costly (see [15]) product of the two interval matrices M_i^{-1} and $C_i(\mathbf{e}_{i-1})M_{i-1}$, we use the standard midpoint technique (see point 1 of section 2.3) to obtain

$$\begin{aligned}\mathbf{Y}_i = {} & (m(M_i^{-1})(C_i(\mathbf{e}_{i-1})M_{i-1}))\mathbf{Y}_{i-1} + m(M_i^{-1})(R_i(\mathbf{e}_{i-1}) + \mathbf{d}_i) \\ & + s(M_i^{-1})((C_i(\mathbf{e}_{i-1})M_{i-1})\mathbf{Y}_{i-1} + R_i(\mathbf{e}_{i-1}) + \mathbf{d}_i),\end{aligned}$$

where $\mathbf{d}_i = m(\mathbf{D}_i^-) - m(\mathbf{D}_i^*)$. This last system can be rewritten as

$$\begin{aligned}\mathbf{Y}_i = {} & (m(M_i^{-1})(C_i(\mathbf{e}_{i-1})M_{i-1}))\mathbf{Y}_{i-1} + m(M_i^{-1})(R_i(\mathbf{e}_{i-1}) + \mathbf{d}_i) \\ & + s(M_i^{-1})(\mathbf{X}_i + \mathbf{d}_i)\end{aligned}$$

by the definition of $\mathbf{X}_i$. In this process, the choice of an appropriate matrix M_i is, of course, crucial. Lohner's QR factorization technique [20] is a very successful scheme to obtain such a matrix.

4.6. A pruning algorithm based on global filters. We are now in position to present a pruning algorithm based on global filters. The pruning algorithm enforces backward(k)-consistency on a global filter composed of k mean-value filters. The algorithm is shown in Figure 6, and its specification is as follows.

SPECIFICATION 3 (PRUNE). *Let ms be the multistep solution of ODE* $\mathbb{O}$ *and* B_i *a bounding box of* $\mathbb{O}$ *over* $[t_{i-1}, t_i]$ *w.r.t.* (t_0, D_0) *for* $1 \le i \le 2k-1$. *Let*

$$\langle \mathbf{D}_1^*, \mathbf{Y}_1, M_1 \rangle = \text{PRUNE}(\mathbb{O}, \mathbf{t}_0, \mathbf{D}_0^*, \mathbf{B}_{1..k-1}, \mathbf{Y}_0, M_0, \mathbf{t}_1, \mathbf{D}_1^-, \mathbf{B}_1),$$

$\mathcal{A}_0 = \{M_0\mathbf{y}_0 + m(\mathbf{D}_0^*) \mid \mathbf{y}_0 \in \mathbf{Y}_0\} \cap \mathbf{D}_0^*$, *and* $\mathcal{A}_1 = \{M_1\mathbf{y}_1 + m(\mathbf{D}_1^*) \mid \mathbf{y}_1 \in \mathbf{Y}_1\} \cap \mathbf{D}_1^*$. *Then*

function PRUNE($\mathbb{O}, \mathbf{t}_0, \mathbf{D}_0^*, \mathbf{B}_{1..k-1}, \mathbf{Y}_0, M_0, \mathbf{t}_1, \mathbf{D}_1^-, \mathbf{B}_1$)
begin
1 $\langle C_1, R_1\rangle := \text{EXPLICITGLOBALFILTER}(\mathbb{O}, \mathbf{t}_0, \mathbf{D}_0^*, \mathbf{B}_{1..k-1}, \mathbf{t}_1, \mathbf{D}_1^-, \mathbf{B}_1, \mathbf{e}_0)$;
2 $C_1^* = C_1 M_0$;
3 $\mathbf{X}_1 := C_1^* \mathbf{Y}_0 + R_1$;
4 $\mathbf{D}_1^* := (\mathbf{X}_1 + m(\mathbf{D}_0^-)) \cap (\mathbf{D}_0^-)$;
5 $M_1 := \text{COORDTRANSFO}(C_1^*, \mathbf{Y}_0)$;
6 $\mathbf{d}_1 := m(\mathbf{D}_1^-) - m(\mathbf{D}_1^*)$;
7 $\mathbf{Y}_1 := (m(M_1^{-1})C_1^*)\mathbf{Y}_0 + m(M_1^{-1})(R_1 + \mathbf{d}_1) + s(M_1^{-1})(\mathbf{X}_1 + \mathbf{d}_1)$;
8 **return** $\langle \mathbf{D}_1^*, \mathbf{Y}_1, M_1\rangle$
end

FIG. 6. *The pruning algorithm on global filters.*

1. $ms((\mathbf{t}_0, \mathbf{t}_1), (\mathcal{A}_0, \mathbf{D}_1^-), t_i) \subseteq ms((\mathbf{t}_0, \mathbf{t}_1), (\mathcal{A}_0, \mathcal{A}_1), t_i)$ *for* $k \le i \le 2k-1$;
2. $\mathbf{D}_1^* \subseteq \mathbf{D}_1^-$;
3. *there exists a global filter which is backward(k)-consistent in* $((\mathbf{t}_0, \mathbf{t}_1), (\mathbf{Y}_0, \mathbf{D}_1^*))$ *and in* $((\mathbf{t}_0, \mathbf{t}_1), (\mathbf{Y}_0, \mathbf{Y}_1))$ *for a given time vector.*

The algorithm receives as input the ODE $\mathcal{O}$, the previous integration times $\mathbf{t}_0$, the pruned boxes $\mathbf{D}_0^*$ computed at times $\mathbf{t}_0$, the bounding boxes $\mathbf{B}_{1..k-1}$ for all previous integration steps, the boxes $\mathbf{Y}_0$ and matrix M_0 from the previous integration step as well as the new integration times $\mathbf{t}_1$, the predicted boxes $\mathbf{D}_1^-$, and the bounding boxes $\mathbf{B}_1$ for these integration times. It returns the pruned boxes $\mathbf{D}_1^*$ for integration steps $\mathbf{t}_1$ as well as the new boxes $\mathbf{Y}_1$ and the new matrix M_1 to be used in the next integration step. The algorithm itself follows the same steps as outlined in the preceding section. It computes the explicit form of the global filter (line 1), the new boxes $\mathbf{X}_1$ (line 3), and the pruned boxes $\mathbf{D}_1^*$ (line 4). It then computes the new matrix M_1 (line 5) and the new boxes $\mathbf{Y}_1$ (line 7).

5. Hermite filters. In the previous section, we assumed the existence of interval extensions of p and $\partial p/\partial t$, and we assumed that we could bound the error terms e and $\partial e/\partial t$. We now show how to use Hermite interpolation polynomials for this purpose. Informally speaking, a Hermite interpolation polynomial approximates a function $g \in C^r$ (for sufficiently large r) which is known implicitly by its values and the values of its successive derivatives at various points. A Hermite interpolation polynomial is specified by imposing that its values and the values of its successive derivatives at some given points be equal to the values of g and of its derivatives at the same points. Note that the number of conditions (i.e., the number of successive derivatives that are considered) may vary at the different points [29, 1].

DEFINITION 12 (Hermite(σ) interpolation polynomial). *Consider the ODE* $u' = f(u)$ *and let* $\sigma = (\sigma_0, \ldots, \sigma_k) \in \mathbb{N}^{k+1}$, $\sigma_i \neq 0$ $(0 \le i \le k)$, *and* $\sigma_s = \sum_{i=0}^{k} \sigma_i$. *The* Hermite($\sigma$) interpolation polynomial *w.r.t.* f *and* $(\mathbf{t}, \mathbf{u})$ *is the unique polynomial* q *of degree* $\le \sigma_s - 1$ *satisfying*

$$q^{(j)}(t_i) = j!(u_i)_j \quad (0 \le j \le \sigma_i - 1,\ 0 \le i \le k). \tag{20}$$

PROPOSITION 5 (Hermite(σ) interpolation polynomial). *The polynomial* q *satisfying the conditions* (20) *is given by*

$$q(t) = \sum_{i=0}^{k} \sum_{j=0}^{\sigma_i - 1} j!(u_i)_j \varphi_{ij}(t), \tag{21}$$

where

$$\begin{aligned}
&\varphi_{i,\sigma_i-1}(t) = l_{i,\sigma_i-1}(t), \quad i = 0, \ldots, k, \\
&\varphi_{ij}(t) = l_{ij}(t) - \sum_{\nu=j+1}^{\sigma_i-1} l_{ij}^{(\nu)}(t_i)\varphi_{i\nu}(t), \quad i = 0, \ldots, k,\ j = 0, \ldots, \sigma_i - 2, \\
&l_{ij}(t) = \frac{(t-t_i)^j}{j!} \prod_{\substack{\nu=0 \\ \nu \neq i}}^{k} \left(\frac{t - t_\nu}{t_i - t_\nu} \right)^{\sigma_\nu}, \quad i = 0, \ldots, k,\ j = 0, \ldots, \sigma_i - 1.
\end{aligned} \tag{22}$$

It is easy to take interval extensions of a Hermite interpolation polynomial and of its derivative. The Taylor coefficients $(D_i)_j$ of the solution specifying the derivative conditions at the various interpolation points, as well as their Jacobians $\mathcal{J}(D_i)_j$ needed in the mean-value Hermite filters, can be computed by automatic differentiation techniques (see, e.g., [21, 22, 27]). The only remaining issue is to bound the error terms. The following standard theorem (e.g., [29, 1]) provides the necessary theoretical basis.

THEOREM 1 (Hermite error term). *Let $p(\mathbf{t}, \mathbf{u}, t)$ be the Hermite(σ) interpolation polynomial in t w.r.t. f and $(\mathbf{t}, \mathbf{u})$. Let $u(t) = ms(\mathbf{t}, \mathbf{u}, t)$, $ms(\mathbf{t}, \mathbf{u}, t) = p(\mathbf{t}, \mathbf{u}, t) + e(\mathbf{t}, \mathbf{u}, t)$, $T = \square\{t_0, \ldots, t_k, t\}$, $\sigma_s = \sum_{i=0}^{k} \sigma_i$, and $w(t) = \prod_{i=0}^{k}(t - t_i)^{\sigma_i}$. We have $(1 \leq i \leq n)$*

1. $\exists\ \xi_i \in T : e_i(\mathbf{t}, \mathbf{u}, t) = \frac{1}{\sigma_s!} u_i^{(\sigma_s)}(\xi_i) w(t)$;
2. $\exists\ \xi_{1,i}, \xi_{2,i} \in T : \frac{\partial e_i}{\partial t}(\mathbf{t}, \mathbf{u}, t) = \frac{1}{\sigma_s!} u_i^{(\sigma_s)}(\xi_{1,i}) w'(t) + \frac{1}{(\sigma_s+1)!} u_i^{(\sigma_s+1)}(\xi_{2,i}) w(t)$.

How do we use this theorem to bound the error terms? If B is a bounding box (produced by the bounding box process) for the ODE over $T = \square\{t_0, \ldots, t_k, t\}$ w.r.t. $(\mathbf{t}_0, \mathbf{u}_0)$, it suffices to compute two boxes $(B)_{\sigma_s}$ and $(B)_{\sigma_s+1}$ by automatic differentiation. We then obtain

$$\begin{aligned}
e(\mathbf{t}, \mathbf{u}, t) &\in (B)_{\sigma_s} w(t); \\
\frac{\partial e}{\partial t}(\mathbf{t}, \mathbf{u}, t) &\in (B)_{\sigma_s} w'(t) + (B)_{\sigma_s+1} w(t).
\end{aligned}$$

As a consequence, we can compute an effective relaxation of the ODE by specializing global filters with a Hermite interpolation polynomial and its error bound. In the following, filters based on Hermite(σ) interpolation are called *Hermite(σ) filters*, and a global Hermite(σ) filter is denoted by GHF(σ). Reference [12] discusses how to evaluate Hermite polynomials accurately.

6. Optimal Hermite filters. Let us summarize what we have achieved so far. The basic idea of our approach is to approximate the ODE for all $t:\ u' = f(u)$ by a filter

$$\forall\ t : FL(\mathbf{t}, \mathbf{D}, t).$$

We have shown that a global filter which prunes the last k boxes by using k successive mean-value filters addresses the wrapping effect and the variable dependency problem.

We have also shown that a global filter can be obtained by using Hermite interpolation polynomials together with their error bounds. As a consequence, we obtain a filter

$$\forall\ \mathbf{e}_0 : GHF(\sigma)(\mathbf{t}, \mathbf{D}, \mathbf{e}_0)$$

which can be used to prune the last k predicted boxes. The main remaining issue is to find an *evaluation time vector* $\mathbf{e}_0$ which miminizes the sizes of the solution boxes in

$$GHF(\sigma)(\mathbf{t}, \mathbf{D}, \mathbf{e}_0).$$

The purpose of this section is to show that there exists an optimal evaluation time vector (in a precise sense that we will define) and that it can be approximated or computed efficiently.

6.1. Preview of the approach. Our goal is to find an evaluation time vector $\mathbf{e}_0$ which miminizes the sizes of the solution boxes in a global Hermite filter. However, this is a difficult problem in general. We will thus solve a simpler problem, which consists of choosing an evaluation time that minimizes the *local error* of an individual filter, i.e., the size of the enclosure of $ms(\mathbf{t}_0, \mathbf{u}_0, t_k)$ produced by the filter, assuming that the *point* values $u_0, \ldots, u_{k-1}$ are given (and, of course, that $ms(\mathbf{t}_0, \mathbf{u}_0, t_k)$ is defined).[10]

DEFINITION 13 (local error of a filter). *Let FL be a filter for ODE $u' = f(u)$. The local error of FL w.r.t. $(\mathbf{t}_0, \mathbf{u}_0, t)$, denoted by $e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t)$, is defined as*

$$e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t) = \omega\left(\square\{u_k \in \mathbb{R}^n \mid FL(\mathbf{t}, \mathbf{u}, t)\}\right).$$

Since in a global filter we compute k boxes in one step, the step size is defined as $h = t_k - t_0$. Our analysis is based on the assumption that the step size h is sufficiently small. When we talk about an optimal evaluation time, the term *optimal* is thus to be understood in an *asymptotic* sense.

In the following, we restrict our attention to Hermite filters which satisfy a certain hypothesis (section 6.2). To find an optimal evaluation time, we first derive the local error (section 6.3). From the local error, we can then characterize the optimal evaluation time (section 6.4). Two of the main results of this section are as follows:

1. For a sufficiently small step size h, the relative distance $(t_e - t_k)/h$ between the optimal evaluation time t_e and the point t_k in a Hermite(σ) filter depends only on the relative distances $(t_{i+1} - t_i)/h$ $(i = 0, \ldots, k-1)$ between the interpolation points $t_0, \ldots, t_k$ and on σ.[11] In particular, it does not depend on the ODE itself.
2. From a practical standpoint, the computation of the optimal evaluation time induces a negligible overhead of the method. In particular, if we assume $t_{i+1} - t_i = h/k$ $(i \in \mathbb{N})$, the relative distance between the optimal evaluation time and t_k can be precomputed once for all for given k and σ.

The third main result is concerned with the order of a Hermite($(\sigma_0, \ldots, \sigma_k)$) filter which is shown to be $\mathcal{O}(h^{\sigma_s+1})$, where $\sigma_s = \sum_{i=0}^{k} \sigma_i$ when the evaluation point is chosen carefully.

[10] As observed by one of the reviewers, the local error may be called more appropriately excess-width, since the enclosure contains the exact solution. We kept the term "local error" because of the analogy with traditional methods.

[11] Note that $h = t_k - t_0$ (and not $h = t_k - t_{k-1}$) because of the globalization process.

6.2. Assumptions and notations. The following assumptions are used in this section. We assume that the integration times are increasing, i.e., $t_0 < \cdots < t_k$, and that $t - t_k = \mathcal{O}(h)$. We also assume that the function f satisfies a Lipschitz condition on $\Omega \subseteq \mathbb{R}^n$:

$$\exists c \in \mathbb{R} \quad \forall u, v \in \Omega : \|f(u) - f(v)\| \leq c\|u - v\|. \tag{23}$$

Note that (23) holds if we assume $f \in C^1(\Omega)$. We further assume that the interval extension F of function f satisfies ($D \subseteq \Omega$)

$$\omega(F(D)) = \mathcal{O}(\omega(D)). \tag{24}$$

For instance, (24) holds if F is the natural interval extension of f and (23) holds. We also assume that B is a bounding box of $u' = f(u)$ over $T = \square\{t_0, \ldots, t_k, t\}$ w.r.t. $(\mathbf{t}_0, \mathbf{u}_0)$ and that (see [23])

$$\omega\left((B)_j\right) = \Theta(\omega(B)) = \Theta(h), \qquad j \in \mathbb{N}. \tag{25}$$

From (23), the condition (25) holds if $(B)_j$ is a sufficiently tight enclosure of the set $\{(x)_j \mid x \in B\}$. In addition, we assume that the multistep solution *ms* is defined at $(\mathbf{t}_0, \mathbf{u}_0)$ or, in other words, that the ODE has a solution going through $u_0, \ldots, u_{k-1}$ at times $t_0, \ldots, t_{k-1}$. We also use the notations $\sigma = (\sigma_0, \ldots, \sigma_k)$, $\sigma_s = \sum_{i=0}^{k} \sigma_i$, and $w(t) = \prod_{i=0}^{k} (t - t_i)^{\sigma_i}$. Since we are interested in computing an enclosure of $ms(\mathbf{t}_0, \mathbf{u}_0, t_k)$ from the *point* values $u_0, \ldots, u_{k-1}$, we will consider a Hermite filter *FL* satisfying

$$FL(\mathbf{t}, (\mathbf{u}_0, v), t) \Rightarrow \frac{\partial p}{\partial t}(\mathbf{t}, (\mathbf{u}_0, v), t) + DE(t) - F(p(\mathbf{t}, (\mathbf{u}_0, v), t) + E(t)) = 0, \tag{26}$$

where

- F is an interval extension of f;
- $E(t) = (B)_{\sigma_s} w(t)$;
- $DE(t) = (B)_{\sigma_s} w'(t) + (B)_{\sigma_s + 1} w(t)$;
- $p(\mathbf{t}, (\mathbf{u}_0, v), t)$ is the Hermite(σ) interpolation polynomial in t w.r.t. f and $(\mathbf{t}, (\mathbf{u}_0, v))$.

Let us introduce the function

$$\delta(\mathbf{t}, (\mathbf{u}_0, v), t) = \frac{\partial p}{\partial t}(\mathbf{t}, (\mathbf{u}_0, v), t) - f(p(\mathbf{t}, (\mathbf{u}_0, v), t) + m_e(t)),$$

where $m_e(t) = m(E(t))$. From the hypothesis (24), the condition (26) can be rewritten as

$$FL(\mathbf{t}, (\mathbf{u}_0, v), t) \Rightarrow \delta(\mathbf{t}, (\mathbf{u}_0, v), t) = -DE(t) + \mathcal{O}(\omega(E(t))). \tag{27}$$

In case (24), the condition (27) is satisfied for natural Hermite filters (see section 4.1), provided that the interval extensions *MS* and *DMS* of *ms* and $\frac{\partial ms}{\partial t}$ yield point values when evaluated at point arguments. (Recall that we assume exact interval arithmetic for the theoretical parts of this paper.) If we assume that the interval extension of the Jacobian of f satisfies the same condition as F, i.e., $\omega(\mathcal{J}(D)_0) = \mathcal{O}(\omega(D))$, then (27) is satisfied for *implicit mean-value* Hermite filters. It is also a good approximation

for *explicit mean-value* Hermite filters if the matrix inversion is accurate (see section 4.2). We will also denote the Jacobian of δ w.r.t. variable v by

$$\begin{aligned}\Phi(t,v) &= \mathcal{J}_v\delta(\mathbf{t},(\mathbf{u}_0,v),t)\\ &= \mathcal{J}_v\frac{\partial p}{\partial t}(\mathbf{t},(\mathbf{u}_0,v),t) - \mathcal{J}f(p(\mathbf{t},(\mathbf{u}_0,v),t)+m_e(t))\mathcal{J}_v p(\mathbf{t},(\mathbf{u}_0,v),t).\end{aligned}$$

Finally, we introduce the following functions:

$$\begin{aligned}&\lambda(t) = \left(\left(\sum_{j=0}^{\sigma_k-2}\beta_{j+1}\tfrac{(t-t_k)^j}{j!}\right)+\left(\sum_{j=0}^{\sigma_k-1}\beta_j\tfrac{(t-t_k)^j}{j!}\right)\sum_{\nu=0}^{k-1}\tfrac{\sigma_\nu}{t-t_\nu}\right)\pi(t);\\ &\beta_0=1,\beta_j=-\pi^{(j)}(t_k),\ j=1,\dots,\sigma_k-1;\\ &\pi(t)=\prod_{\nu=0}^{k-1}\left(\tfrac{t-t_\nu}{t_k-t_\nu}\right)^{\sigma_\nu};\\ &\gamma(t)=\sum_{i=0}^{k}\tfrac{\sigma_i}{t-t_i}.\end{aligned}$$

6.3. Local error of a natural Hermite filter. To characterize the local error of a Hermite filter, we first need a technical lemma which characterizes the behavior of the derivatives of the filter.

LEMMA 1. *We have*

1. $\Phi(t,v) = I\lambda(t)+\mathcal{O}(1)$;
2. $\lambda(t)=\mathcal{O}(h^{-1})$;
3. $\lambda(t)=\Theta(h^{-1})$ *for* $t_{k-1}<t<t_k$.

This lemma shows that $\Phi(t,v)$ is a $\Theta(h^{-1})$ asymptotically diagonal matrix for $t_{k-1}<t<t_k$. Its proof is given in [12]. We are now in position to characterize the local error of a Hermite filter.

THEOREM 2 (local error of a Hermite filter). *Let FL be a Hermite(σ) filter for* $u'=f(u)$ *satisfying* (27). *We have*

1. $e_{loc}(FL,\mathbf{t}_0,\mathbf{u}_0,t) = |(I\lambda(t)+\mathcal{O}(1))^{-1}|\Theta(\omega(B))\left(|w'(t)|+|w(t)|\right)$;
2. $e_{loc}(FL,\mathbf{t}_0,\mathbf{u}_0,t) = \Omega(h^2)\left(|w'(t)|+|w(t)|\right)$;
3. *if* $t_{k-1}<t<t_k$, *then* $e_{loc}(FL,\mathbf{t}_0,\mathbf{u}_0,t)=\Theta(h^2)\left(|w'(t)|+|w(t)|\right)$.

Proof. Consider two arbitrary vectors $v_1,v_2\in\mathbb{R}^n$ such that

$$FL(\mathbf{t},(\mathbf{u}_0,v_1),t) \quad\text{and}\quad FL(\mathbf{t},(\mathbf{u}_0,v_2),t).$$

By the mean-value theorem, we can write

$$\delta(\mathbf{t},(\mathbf{u}_0,v_2),t)-\delta(\mathbf{t},(\mathbf{u}_0,v_1),t)=\Phi(t,\nu)(v_2-v_1),$$

where ν is on the straight line between v_1 and v_2. When the matrix $\Phi(t,\nu)$ is regular, we can write by Lemma 1 and (27)

$$\begin{aligned}v_2-v_1 &= \Phi^{-1}(t,\nu)\left(\delta(\mathbf{t},(\mathbf{u}_0,v_2),t)-\delta(\mathbf{t},(\mathbf{u}_0,v_1),t)\right)\\ &= \left(I\lambda(t)+\mathcal{O}(1)\right)^{-1}\left(DE(t)-DE(t)+\mathcal{O}(\omega(E(t)))\right).\end{aligned}$$

Since the two vectors v_1 and v_2 are chosen arbitrarily, it follows from (25) that

$$\begin{aligned}e_{loc}(FL,\mathbf{t}_0,\mathbf{u}_0,t) &= |(I\lambda(t)+\mathcal{O}(1))^{-1}|\left(\omega(DE(t))+\mathcal{O}(\omega(E(t)))\right)\\ &= |(I\lambda(t)+\mathcal{O}(1))^{-1}|\Theta(\omega(B))\left(|w'(t)|+|w(t)|\right),\end{aligned}$$

which proves point 1. Points 2 and 3 are now direct consequences of Lemma 1 and (25). ∎

We are now ready to show how to find an optimal evaluation time for Hermite filters.

6.4. Optimal evaluation time for a natural Hermite filter. Our first result characterizes the order of a Hermite filter. It also hints on how to obtain an optimal evaluation time. Recall that the order of a method (or of a filter) is the order of the local error minus 1.

THEOREM 3 (order of a Hermite filter). *Let FL be a Hermite(σ) filter for $u' = f(u)$ satisfying (27). Then*

1. *there exists t such that $t_{k-1} < t < t_k$, and $w'(t) = 0$;*
2. *if $t_{k-1} < t < t_k$ and $w'(t) = 0$, then $e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t) = \mathcal{O}(h^{\sigma_s+2})$;*
3. *if $w'(t) \neq 0$, then $e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t) = \Omega(h^{\sigma_s+1})$.*

Proof. Consider an evaluation time t such that $t - t_k = \mathcal{O}(h)$. We have $w(t) = \mathcal{O}(h^{\sigma_s})$ and $w'(t) = \mathcal{O}(h^{\sigma_s-1})$. First assume that $t_{k-1} < t < t_k$ and $w'(t) = 0$. By Rolle's theorem, since $w(t_{k-1}) = w(t_k) = 0$, there exists such an evaluation time t. By Theorem 2, $e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t) = \mathcal{O}(h^{\sigma_s+2})$. Now assume that $w'(t) \neq 0$. By Theorem 2, $e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t) = \Omega(h^{\sigma_s+1})$. ∎

Theorem 3 indicates that a better order for Hermite filters is obtained when we choose an evaluation time t that is a root of the polynomial w'. This is the basis of our next result which describes a necessary condition for optimality.

THEOREM 4 (necessary condition for optimal Hermite filters). *Let FL be a Hermite(σ) filter for $u' = f(u)$ satisfying (27), and let $t_e \in \mathbb{R}$ be such that*

$$e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t_e) = \min_{t - t_k = \mathcal{O}(h)} \{e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t)\}$$

for h sufficiently small. Then t_e is a zero of the function γ.

Proof. Assume that $t - t_k = \mathcal{O}(h)$ and that h is sufficiently small. By Theorem 3, $w'(t_e)$ must be zero to minimize the local error. Note that $FL(\mathbf{t}, (\mathbf{u}_0, v), t_i)$ holds for *any* $v \in \mathbb{R}^n$ if $w'(t_i) = 0$ $(0 \leq i \leq k)$. Thus $t_e \notin \{t_0, \ldots, t_k\}$ and $w(t_e) \neq 0$. Since $w'(t) = w(t)\gamma(t)$, we conclude that $\gamma(t_e) = 0$. ∎

Our next result specifies the number of zeros of the function γ as well as their locations.

PROPOSITION 6. *The function γ in Theorem 4 has exactly k zeros $s_0, \ldots, s_{k-1}$ such that $t_i < s_i < t_{i+1}$ $(0 \leq i < k)$.*

Proof. We have $w'(t) = w(t)\gamma(t)$. By Rolle's theorem, as $w(t_i) = w(t_{i+1}) = 0$, w' has a root s_i with $t_i < s_i < t_{i+1}$ and $w(s_i) \neq 0$ $(0 \leq i < k)$. Furthermore, the roots of w' are in $\{s_0, \ldots, s_{k-1}, t_0, \ldots, t_k\}$ because t_i is a root of multiplicity $\sigma_i - 1$ $(0 \leq i \leq k)$ and w' is of degree $\sigma_s - 1$, i.e., $k + \sum_{i=0}^{k}(\sigma_i - 1) = \sigma_s - 1$. Since γ is not defined at $t_0, \ldots, t_k$, its zeros are in $\{s_0, \ldots, s_{k-1}\}$. ∎

We are now ready to characterize precisely the optimal evaluation time for a Hermite filter.

THEOREM 5 (optimal evaluation time). *Let FL be a Hermite(σ) filter for $u' = f(u)$ satisfying (27), let $s_0 < \cdots < s_{k-1}$ be the zeros of γ, and let $t_e \in \mathbb{R}$ such that*

$$e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t_e) = \min_{t - t_k = \mathcal{O}(h)} \{e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, t)\}.$$

Then, for h sufficiently small,

$$|(w/\lambda)(t_e)| = \min_{s \in \{s_0, \ldots, s_{k-1}\}} \{|(w/\lambda)(s)|\}.$$

TABLE 1
Relative distance between the rightmost zero t_e of γ and t_k when $\sigma_0 = \cdots = \sigma_k$.

k	1	2	3	4	5	6
$(t_e - t_k)/h$	-0.5000	-0.2113	-0.1273	-0.0889	-0.0673	-0.0537

Proof. Let us assume that h is sufficiently small. From Theorem 4, we know that $t_e \in \{s_0, \ldots, s_{k-1}\}$. By definition, for $i = 0, \ldots, k-1$, $w'(s_i) = w(s_i)\gamma(s_i) = 0$ and, from Theorem 2,

$$e_{loc}(FL, \mathbf{t}_0, \mathbf{u}_0, s_i) = |(I\lambda(s_i) + \mathcal{O}(1))^{-1}|\Theta(\omega(B))|w(s_i)|.$$

From Proposition 6, if $t = s_i$ $(i = 0, \ldots, k-1)$, B is a bounding box over $T = \square\{t_0, \ldots, t_k, s_i\} = [t_0, t_k]$ w.r.t. $(\mathbf{t}_0, \mathbf{u}_0)$ and the factor $\Theta(\omega(B))$ does not depend on $t = s_i$. We have thus to minimize the function

$$\rho(t) = |(I\lambda(t) + \mathcal{O}(1))^{-1}||w(t)|$$

for $t \in \{s_0, \ldots, s_{k-1}\}$. By Lemma 1, $\lambda(s_{k-1}) = \Theta(h^{-1})$. Therefore, we must have $\lambda(t_e) = \Theta(h^{-1})$ and $\rho(t_e) \approx |(w/\lambda)(t_e)|$. Let us now assume that there exists $i \in 0..k-1$ such that $|(w/\lambda)(s_i)| < |(w/\lambda)(t_e)|$. We can write

$$\begin{aligned} |(w/\lambda)(s_i)| < |(w/\lambda)(t_e)| &\Rightarrow \lambda(s_i) = \Theta(h^{-1}) \\ &\Rightarrow \rho(s_i) \approx |(w/\lambda)(s_i)| \\ &\Rightarrow \rho(s_i) < \rho(t_e), \end{aligned}$$

which is a contradiction. ∎

6.5. Discussion. It is important to discuss the consequences of Theorem 4 in some detail. First observe that the *relative distance* $(t_e - t_k)/h$ between the optimal evaluation time t_e and the point t_k depends *only* on the *relative distances* $(t_{i+1} - t_i)/h$ $(i = 0, \ldots, k-1)$ between the interpolation points $t_0, \ldots, t_k$ and on the vector σ. In particular, it is independent from the ODE itself. For instance, for $k = 1$, we have $\gamma(t) = \frac{\sigma_0}{t - t_0} + \frac{\sigma_1}{t - t_1}$, and γ has a single zero given by $t_e = \frac{\sigma_1 t_0 + \sigma_0 t_1}{\sigma_0 + \sigma_1}$. In addition, if $\sigma_0 = \cdots = \sigma_k$, then the zeros of γ are independent from σ. In particular, for $k = 1$, we have $t_e = (t_0 + t_1)/2$. From a practical standpoint, the computation of the optimal evaluation time induces a negligible overhead of the method. In particular, if we assume $t_{i+1} - t_i = h/k$ $(i \in \mathbb{N})$, then the relative distance between t_k and the optimal evaluation time can be precomputed and stored for a variety of values of k and σ. Finally, it is worth stressing that any zero of function γ gives an $\mathcal{O}(h^{\sigma_s+1})$ order for the Hermite filter provided that $\lambda(t) = \Theta(h^{-1})$ at that zero. Hence any such zero is in fact a potential candidate for the optimal evaluation time. In our experiments (see the next section), the rightmost zero was always the optimal evaluation time when $\sigma_0 = \cdots = \sigma_k$, although we have not been able to prove this result.

6.6. Illustration. We now illustrate the theoretical results presented in this section. Table 1 gives approximative values of the relative distance $(t_e - t_k)/h$ between the rightmost zero t_e of the function γ and the point t_k $(1 \le k \le 6)$ for $\sigma_0 = \cdots = \sigma_k$ and $t_{i+1} - t_i = h/k$ $(i = 0, \ldots, k-1)$. For two interpolation points, t_e is in the middle of t_0 and t_1. It then moves closer and closer to t_k for larger values of k.

Figure 7 illustrates the functions γ, w, w', λ, and w/λ for $k = 4$ and $\sigma = (2, 2, 2, 2, 2)$. The top left figure shows the function w' and γ, as well as the zeros of

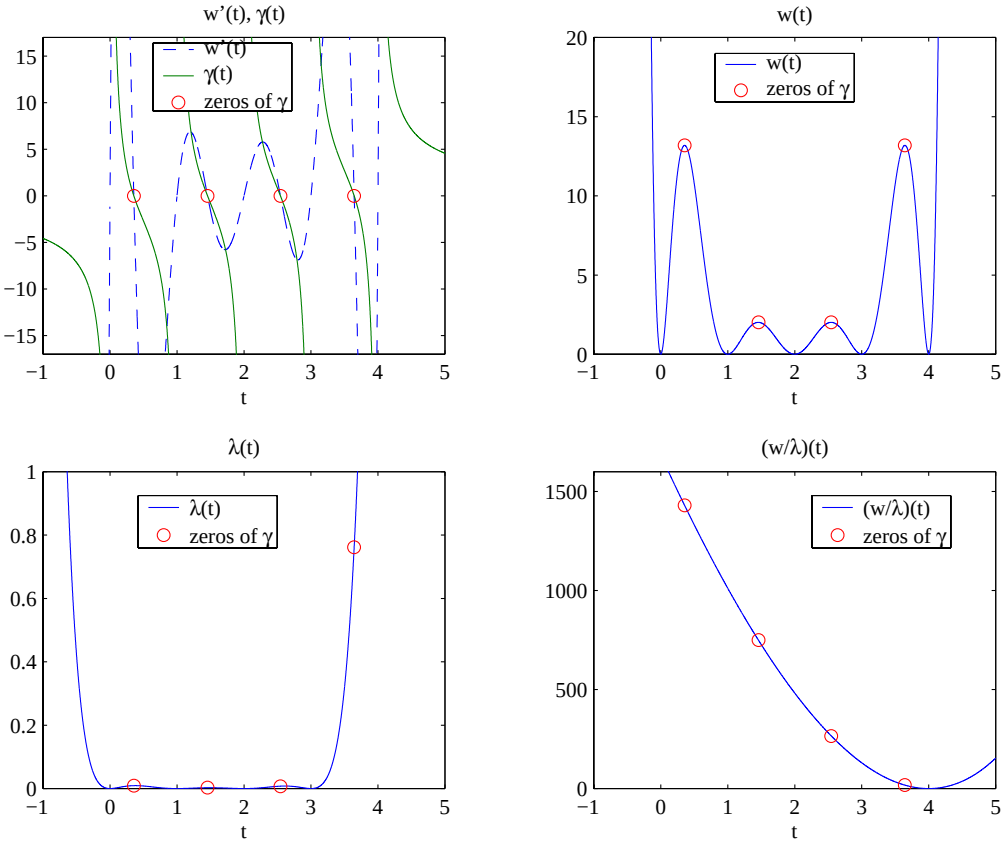

FIG. 7. *The functions* γ, w, w', λ *and* w/λ *for the case* $k = 4, \sigma = (2, 2, 2, 2, 2)$.

γ. The top right figure shows the function w with the zeros of γ in superposition. The bottom left figure shows function λ with the zeros of γ in superposition. The bottom right picture shows the function w/λ and the zeros of γ. It can be seen that the rightmost zero minimizes the local error in this example.

6.7. Validity of the asymptotic assumption. Our analysis is based on the assumption that the step size h is sufficiently small. But *how small is sufficiently small?* According to our experiments, the actual step sizes are generally small enough so that the *asymptotically* optimal evaluation times produced by the above theory are good approximations of the *real* optima. There are two reasons for these small actual step sizes:

1. the need to bound the local error, which limits the stability of validated methods and makes stiff problems more challenging;
2. the existing bounding box process, which often impose the strongest restriction on the step size, especially for stiff problems.

Figure 8 illustrates our theoretical results experimentally on a specific ODE. It plots the local error of several global Hermite filters (GHFs) as a function of the evaluation time for the Lorenz system (e.g., [10]). It is assumed that $t_{i+1} - t_i$ is constant $(0 \le i \le 2k - 2)$. In addition, we assume that, in each mean-value filter composing GHF, the distance between the evaluation time and the rightmost interpolation point

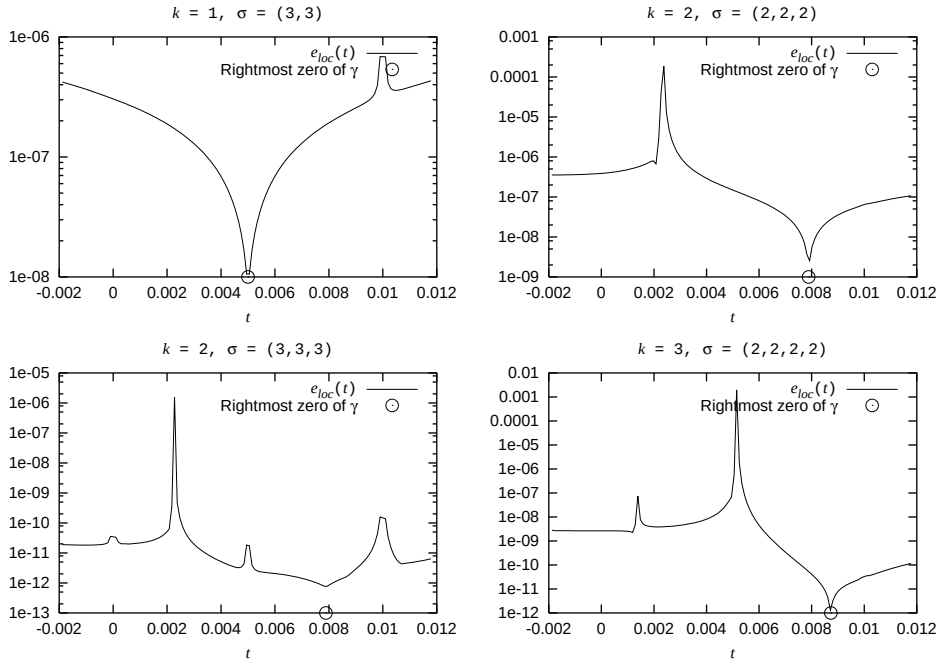

FIG. 8. *Local error of GHFs as a function of the evaluation time for the Lorentz system.*

is constant. In the graphs, $[t_0, t_k] = [0, 0.01]$ and $h = t_k - t_0 = 0.01$. The figure also shows the rightmost zero of the function γ as obtained from Table 1. As we can see, the rightmost zero of γ is a very good approximation of the optimal evaluation time of the filter for all the cases displayed.

7. The algorithm. We are now in position to present our algorithm for enclosing solutions of IVPs for parametric ODEs. The algorithm is presented in Figure 9, and Figure 10 gives the specification of the functions not covered so far. The first two lines initialize the integration process and compute the initial bounding boxes, pruned domains, and the boxes and matrices needed for the wrapping effect. The main step of the integration are lines 4-6. Line 4 computes the new bounding boxes, line 5 uses them to compute the new predicted boxes, and line 6 applies the pruning step to compute the new pruned boxes.

8. Theoretical analysis. This section presents theoretical results on the efficiency of our method and compares it to the best interval methods we are aware of.

8.1. Overview of the methods. We analyze the cost of our SOLVE algorithm based on the GHF method and compare it to Nedialkov's interval Hermite–Obreschkoff (IHO) method [24], the best interval method we know of. Indeed, the IHO method outperforms interval Taylor series methods such as Lohner's method [20]. Here are the various methods used in the theoretical and experimental comparisons.

The GHF method. In the GHF method, each iteration in the loop of function SOLVE is called a *step* of the integration. The (constant) step size in GHF is given by $h = t_k - t_0$. Assuming that $\sigma_m = \max(\sigma)$ and $\sigma_s = \sigma_0 + \cdots + \sigma_k$, the remaining components of GHF are specified as follows:

function SOLVE($\mathbb{O}, D_0, \mathbf{t}_{0..mk-1}$)
begin
1 $\mathbf{B}_0 := \text{BOUNDINGBOX}(\mathbb{O}, t_0, D_0, \mathbf{t}_0)$;
2 $\langle \mathbf{D}_0^*, \mathbf{Y}_0, M_0 \rangle := \text{INITIALIZEMULTISTEP}(\mathbb{O}, \mathbf{t}_0, D_0, \mathbf{B}_{1..k-1})$;
3 **for** $i := 1$ **to** $m-1$ **do**
4 $\mathbf{B}_i := \text{BOUNDINGBOX}(\mathbb{O}, t_{ik-1}, D_{ik-1}^*, \mathbf{t}_i)$;
5 $\mathbf{D}_i^- := \text{PREDICTOR}(\mathbb{O}, t_{ik-1}, D_{ik-1}^*, \mathbf{t}_i, \mathbf{B}_i)$;
6 $\langle \mathbf{D}_i^*, \mathbf{Y}_i, M_i \rangle := \text{PRUNE}(\mathbb{O}, \mathbf{t}_{i-1}, \mathbf{D}_{i-1}^*, \mathbf{B}_{(i-1)k+1..ik-1}, \mathbf{Y}_{i-1}, M_{i-1}, \mathbf{t}_i, \mathbf{D}_i^-, \mathbf{B}_i)$;
7 **endfor**
8 **return** $\mathbf{D}_{1..mk-1}^*$;
end

FIG. 9. *The constraint satisfaction algorithm for IVPs for parametric ODEs.*

SPECIFICATION 4 (SOLVE). *Let s be the solution of ODE $\mathbb{O}$ and $\mathbf{D}_{1..mk-1} = \text{SOLVE}(\mathbb{O}, D_0, \mathbf{t}_{0...mk-1})$. Then, for $1 \le i \le mk-1$, $s(t_0, D_0, t_i) \subseteq D_i$.*
SPECIFICATION 5 (BOUNDINGBOX). *Let $\mathbf{B}_{1..k} = \text{BOUNDINGBOX}(\mathbb{O}, t_0, D_0, \mathbf{t}_{1..k})$. Then, for $1 \le i \le k$, B_i is a bounding box of $\mathbb{O}$ over $[t_{i-1}, t_i]$ w.r.t. (t_0, D_0).*
SPECIFICATION 6 (INITIALIZEMULTISTEP). *Let ms be the multistep solution of ODE $\mathbb{O}$ and B_i be a bounding box of $\mathbb{O}$ over $[t_{i-1}, t_i]$ w.r.t. (t_0, D_0) for $1 \le i \le k-1$. Let*

$$\langle \mathbf{D}_0, \mathbf{Y}_0, M \rangle = \text{INITIALIZEMULTISTEP}(\mathbb{O}, \mathbf{t}_0, D_0, \mathbf{B}_{1..k-1})$$

and $\mathcal{A} = \{M\mathbf{y}_0 + m(\mathbf{D}_0) \mid \mathbf{y}_0 \in \mathbf{Y}_0\} \cap \mathbf{D}_0$. Then, for $0 \le i \le k-1$, $ms(t_0, D_0, t_i) \subseteq ms(\mathbf{t}_0, \mathcal{A}, t_i)$.
SPECIFICATION 7 (PREDICTOR). *Let s be the solution of ODE $\mathbb{O}$ and B_i a bounding box of $\mathbb{O}$ over $[t_{i-1}, t_i]$ w.r.t. (t_0, D_0) for $1 \le i \le k$. Let*

$$\mathbf{D}_{1..k} = \text{PREDICTOR}(\mathbb{O}, t_0, D_0, \mathbf{t}_{1..k}, \mathbf{B}_{1..k}).$$

Then, for $1 \le i \le k$, $s(t_0, D_0, t_i) \subseteq D_i$.

FIG. 10. *The specification of the main functions.*

1. The BOUNDINGBOX function in GHF uses a Taylor series method [21, 5, 25] of order $p+q+1$ to compute $\mathbf{B}_i$. Moreover, we assume that $B_{ik} = \cdots = B_{(i+1)k-1}$; i.e., the function computes a single bounding box over $[t_{ik-1}, t_{(i+1)k-1}]$ $(i \ge 1)$.
2. The PREDICTOR function uses Moore's Taylor method [21] of order $q+1$ to compute the boxes $\mathbf{D}_i^-$. Note that we compute the Taylor coefficients of f only once at (t_{ik-1}, D_{ik-1}^*).
3. The evaluation point in Hermite filters (i.e., in function EMVFL) is the rightmost zero of function γ (see section 6 and Table 1). GHF(σ) is thus a method of order $\sigma_s + 1$.
4. Function EXPLICITGLOBALFILTER needs $\sigma_m - 1$ Jacobians (i.e., $\mathcal{J}(D_j)_1, \ldots, \mathcal{J}(D_j)_{\sigma_m - 1}$) at each interpolation point t_j for $(i-1)k \le j \le (i+1)k - 1$ to compute the k explicit mean-value Hermite filters in EMVFL. GHF computes only Jacobians at predicted boxes and not at pruned boxes. More precisely, it computes only $k(\sigma_m - 1)$ Jacobians at $(\mathbf{t}_i, \mathbf{D}_i^-)$ and reuses the

$k(\sigma_m - 1)$ Jacobians at $(\mathbf{t}_{i-1}, \mathbf{D}_{i-1}^-)$ which were computed during the previous step $i-1$.

5. The function CoordTransfo uses Lohner's QR factorization technique (see [20]).
6. The function InitializeMultistep uses a one-step mean-value Taylor method.

The IHO method. The IHO method is implemented exactly as described in [24]. Its step size is h as in the GHF method. Besides the pruning, there are some interesting differences between GHF and IHO. First, the predictor function in IHO uses a mean-value Taylor method of order $q+1$. Second, the Jacobians in IHO are recomputed at pruned boxes. IHO uses a Taylor series method of order $p+q+1$ to compute a bounding box as in GHF.

The IHO* method. To obtain experimental results as informative as possible, we introduce IHO*, a variant of IHO that is closer to GHF. In particular, the predictor in IHO* uses Moore's Taylor method of order $q+1$ instead of the mean-value Taylor method of the same order. Also, IHO* does not recompute the Jacobians at pruned boxes; it reuses the Jacobians at predicted boxes instead as in GHF. IHO* and GHF differ only in the pruning step. Interestingly, IHO* is extremely close in precision to IHO on almost all benchmarks for a given step size. There are a few benchmarks where the loss of precision is significant or where a smaller step size must be used. Of course, IHO* is faster than IHO for a given step size.

8.2. Comparison hypotheses. We make the following assumptions and conventions for simplicity. Consider the ODE $u' = f(u)$. We assume that (the natural encoding of) function f contains only arithmetic operations. We denote by N_1 the number of $*, /$ operations in f, by N_2 the number of $\pm$ operations, and by N the sum $N_1 + N_2$. We also assume that the cost of evaluating $\mathcal{J}(D_i)_j$ is n times the cost of evaluating $(D_i)_j$. We report only the *main* operations of the methods, i.e., (1) products of a real and an interval matrix which arise in the pruning step and (2) the generation of Jacobians.[12] These are the main operations for problems of sufficiently high dimension where f contains sufficiently many operations. Note that products of a real and an interval matrix can be optimized to substantially reduce the number of sign tests and rounding mode switches, which are costly tasks (see [15]). As a consequence, the cost *per* interval arithmetic operation in a real-interval matrix product is less than the cost of an operation on two intervals in a Jacobian computation. We thus report separately the number of interval arithmetic operations involved in products of a real and an interval matrix in the pruning step (Cost-1) and the generation of Jacobians (Cost-2). Note that Cost-1 is a fixed cost in the sense that it is independent from the ODE. Cost-2 is a variable cost which increases as the expression of f contains more operations.

8.3. Methods of the same order. We first compare the costs of GHF(σ) and IHO$^{(*)}(p,q)$ for $p+q=\sigma_s$ and $q \in \{p, p+1\}$. The methods are thus of order $\sigma_s + 1$. Table 2 reports the main cost of a step in IHO, IHO*, and GHF. It also shows the complexity of two particular cases of GHF: GHF-1 is an implementation with only two interpolation points ($k=1$) and $|\sigma_1 - \sigma_0| \leq 1$, while GHF-2 is an implementation with two conditions on every interpolation points ($\sigma_0 = \cdots = \sigma_k = 2$).

The first main result is that GHF-1 is always cheaper than IHO$^{(*)}$. *Hence a GHF method with only two interpolation points is guaranteed to run faster than IHO$^{(*)}$.* The next section shows that an improvement in accuracy is also obtained in this case.

[12] Matrix inversions and the QR factorization in CoordTransfo are not counted here.

TABLE 2
Cost analysis: Methods of the same order.

	Cost-1	Cost-2
IHO	–	$2\lceil\frac{\sigma_s}{2}\rceil^2 nN_1 + O(\sigma_s nN_2)$
IHO*	–	$\lceil\frac{\sigma_s}{2}\rceil^2 nN_1 + O(\sigma_s nN_2)$
GHF	$7k^3n^3$	$((\sigma_m-1)^2+1)knN_1 + \sigma_m knN_2$
GHF-1	–	$(\lfloor\frac{\sigma_s-1}{2}\rfloor^2+1)nN_1 + O(\sigma_s nN_2)$
GHF-2	$(\frac{7}{8}\sigma_s - \frac{21}{4})\sigma_s^2 n^3$	$(\sigma_s-2)nN$

TABLE 3
Cost analysis: Methods of different orders but of similar cost.

	Cost-2
IHO	$2\lfloor\frac{\sigma_s-1}{2}\rfloor^2 nN_1 + O(\sigma_s nN_2)$
IHO*	$\lfloor\frac{\sigma_s-1}{2}\rfloor^2 nN_1 + O(\sigma_s nN_2)$
GHF-1	$(\lfloor\frac{\sigma_s-1}{2}\rfloor^2+1)nN_1 + O(\sigma_s nN_2)$

Observe that Cost-2 in IHO* is approximately half as much as in IHO because the Jacobians are not computed at pruned boxes in IHO*. Note also that Cost-2 is smaller in GHF-1 than in IHO* because IHO* evaluates one more Jacobian, i.e., $\mathcal{J}(D_i)_q$.

GHF-2 is more expensive than GHF-1 and IHO$^{(*)}$ when f contains few operations because the Jacobians are cheap to compute in this case and the fixed cost Cost-1 becomes large w.r.t. Cost-2. However, when f contains many $*, /$ operations (which is the case in many practical applications), GHF-2 becomes substantially faster because Cost-1 in GHF-2 is independent of f and Cost-2 is substantially smaller in GHF-2 than in GHF-1 and IHO$^{(*)}$. *This result shows the versatility of the approach that can be tailored to the application at hand.*

8.4. One-step methods of different orders but of similar cost. *We now show that GHF methods can be tailored to be asymptotically more precise than IHO methods for a similar cost.* Consider the costs of the IHO$^{(*)}(p,q)$ and GHF-1 methods when we assume that $p+q = \sigma_s - 2$ and $q \in \{p, p+1\}$. Under these conditions, IHO$^{(*)}$ is a method of order $\sigma_s - 1$, while GHF-1 is a method of order $\sigma_s + 1$. Table 3 reports the main cost of a step in IHO, IHO*, and GHF-1. Cost-2 is similar in GHF-1 and IHO* (and about twice as much in IHO). The GHF-1 method is thus asymptotically more precise (by two orders of magnitude) than IHO* for a similar cost.

9. Experimental analysis. We now report experimental results of a C++ implementation[13] of our SOLVE algorithm based on the GHF method GHF(σ). We performed our tests on a Sun Ultra 10 workstation with a 333 MHz UltraSparc CPU. The underlying interval arithmetic and automatic differentiation packages are PROFIL/BIAS [15] and FADBAD/TADIFF [3, 2].

The benchmarks. Many of the benchmarks are standard. They come from various domains, including chemistry, biology, mechanics, physics, and electricity. The equation, initial conditions, and interval of integration for each IVP are given in [12]. Note that the comparisons uses only point initial conditions; they could easily be generalized to interval conditions. The "full Brusselator" (BRUS), the "Oregonator" (OREG), and HIRES all model famous chemical reactions. Both OREG and HIRES are stiff problems. The Lorenz system (LOR) exemplifies the so-called strange at-

[13]The code is available at http://www.info.ucl.ac.be.

tractors. The two-body problem (2BP) comes from mechanics, and the van der Pol (VDP) equation describes an electrical circuit. All these problems are described in detail in [10, 11]. We also consider a problem from molecular biology (BIO) and the Stiff DETEST problem D1 [9]. Finally, we consider four dynamical systems (LIEN, P1, P2, P3), where the function f contains more operations. LIEN, P2, and P3 are taken from [26].

Overview of the experiments. The experimental results obey the same assumptions as the theoretical analysis. They include three types of comparisons:

1. one-step methods of the same order;
2. one-step methods of different orders but of similar cost;
3. multistep versus one-step methods of the same order.

The tables report, for a given step size, the global error, the error ratio (an error ratio higher than 1 means that GHF is more precise), the execution time of both methods (in seconds), and the time ratio (a time ratio higher than 1 means that GHF is faster). They also report the execution time of IHO* between parentheses. As mentioned, we observed small precision loss in IHO* over IHO and only for the larger step sizes. Since this was not very significant, we assume that the error values in IHO* are nearly the same as in IHO. A "-" symbol in the tables means that the method failed to integrate the ODE for the corresponding step size. Finally, note that the global error at point t_i is given by the infinity norm of the width of the enclosure D_i at t_i, i.e., the quantity $\|\omega(D_i)\|_\infty$ at the end of the interval of integration.

9.1. One-step methods.

Same order. Table 4 reports the experimental results for the IHO$^{(*)}(p,p)$ and GHF(p,p) methods of order $2p+1$ on several benchmarks, orders, and step sizes. In general, for a given step size, GHF and IHO* have a similar accuracy and execution time. GHF is usually slightly faster as predicted by the theoretical results. The difference should be larger for higher dimensional problems where f contains many operations. IHO is slower than GHF and IHO*. For a given problem and given order, the error ratio is generally constant w.r.t. the step size, confirming that GHF and IHO$^{(*)}$ are methods of the same order.

Different orders. The theoretical results indicated that, given a step size, the GHF method can always be tailored to be asymptotically more precise than IHO* for a similar computation cost. We now validate this claim experimentally. Table 5 compares IHO(p,p) (order $2p+1$) and GHF$(p+1,p+1)$ (order $2p+3$). On the benchmarks, GHF is always faster than IHO, and it produces significant improvements in accuracy. As expected, the gain in precision increases when the step size decreases, confirming that GHF is a method of higher order than IHO. GHF is slightly slower than IHO*, but, of course, it produces significant improvement in accuracy. GHF and IHO* should have a similar execution time for higher dimensional problems where f contains many operations, as predicted by the theoretical analysis.

Error w.r.t. time. It is interesting to compare the various methods by plotting the error as a function of the execution time. Figure 11 plots IHO$^{(*)}(p,p)$, GHF(p,p), and GHF$(p+1,p+1)$ using the results in Tables 4 and 5. We take $p=8$ for D1 and HIRES and $p=3$ for the other problems. The curve of IHO* is always slightly above the curve of GHF(p,p) (except for D1). GHF$(p+1,p+1)$ is almost always below the other curves, and IHO is always above the other curves. These results confirm the theoretical results and indicate that GHF$(p+1,p+1)$ is superior to the other methods.

9.2. Multistep versus one-step methods. We now compare multistep GHF methods versus IHO$^{(*)}$ and the one-step GHF method of the same order. We restrict our attention to problems where the function f contains more operations. Tables 6, 7, 8, and 9 report the results, respectively, for the four tested examples and for several orders and step sizes.[14] For a given step size, multistep GHF methods usually produce much more precise results than one-step methods (especially for large step sizes); they also allow for larger step sizes. Multistep GHF methods are generally as fast as the one-step GHF method and IHO*; they are faster when f has many operations, as is

[14]Note that in the LIEN problem, we used a bounding box computation method of order 13 for $\sigma_s \geq 12$.

the case in LIEN (which contains many multiplications). The tables also show that, for a given step size, the one-step GHF method is slightly more precise and faster than IHO* and that IHO is slower.

Figures 12, 13, 14, and 15 plot the error as a function of the execution time. The main result is that multistep GHF methods perform better than one-step methods on these problems. In general, multistep methods produce several orders of magnitude improvements in precision for a fixed execution time. The one-step GHF method performs slightly better than IHO*. Note that, for the LIEN problem, GHF methods with many interpolation points are more efficient and allow for smaller execution times.

9.3. Discussion. Before concluding this section, it is important to make a number of remarks.

In GHF, the enhancement in precision obtained by recomputing the Jacobians at pruned boxes is insignificant in all problems we tested. Instead, this recomputation increases the computational cost. Our experimental results showed that this also holds for the IHO method in general.

As pointed out by Nedialkov [23], the stability of interval methods depends not only on the stability of the underlying approximation formula (as in standard numerical methods) but also on the corresponding formula for the truncation error. Hence, interval extensions of standard numerical methods designed for stiff problems may need smaller step sizes. Another restriction on the step size in interval methods comes from the bounding box process, whose current implementations require very small step sizes to be able to compute bounding boxes in the case of stiff problems. This explains why the differences in efficiency between interval methods are not as sharp as for traditional methods.

In our experiments, we always chose $\sigma_0 = \cdots = \sigma_k$. Indeed, the main cost of the method is determined by $\max_{0 \leq i \leq k}\{\sigma_i\}$, and the order of the method is maximized when $\sigma_0 = \cdots = \sigma_k$. Since the actual step sizes are sufficiently small, this choice is thus always better. If we could use larger step sizes (e.g., by improving the bounding box process), then stability requirements might make other choices preferable.

The results close to machine precision are not very significant since rounding errors, not the actual method, are determining the accuracy. This explains why the curves in the figures tend to join for high precisions in some cases (e.g., in LIEN, P1, and P2).

9.4. Summary. We now summarize our experimental results. The main conclusions are as follows:

1. The one-step GHF method is almost always better than existing (one-step) interval methods.
2. When f contains few operations, the one-step GHF method outperforms multistep GHF methods (and other existing methods).
3. When f contains many operations, multistep GHF methods outperform the one-step GHF method (and other existing methods).
4. GHF methods are very versatile and can be tailored to the application at hand.
5. The experimental results confirm the theoretical analysis.

In particular, the one-step GHF method performs generally better than the IHO* method, a variant of Nedialkov's IHO method we proposed and which performed better than the original method on almost all our benchmarks. For low dimensional problems or when f contains few operations, the one-step GHF method is only slightly

better than IHO*. For higher dimensional problems where f contains many operations, the one-step GHF method is asymptotically more precise (by two orders of magnitude) than IHO* for the same cost. When f contains few operations, the one-step GHF method is more effective than multistep GHF methods which have a relatively high fixed cost. When f contains many operations, multistep GHF methods perform better than one-step methods. They may produce orders of magnitude improvements in accuracy for a given execution time. Alternatively, they may reduce computation times substantially for a given precision since they avoid expensive Jacobian computations. Finally note that, although our implementation used a constant order and step size, it can be easily enhanced to incorporate standard order and step size control strategies, e.g., Eijgenraam's [8] or Nedialkov's [23] techniques.

10. Conclusion. This paper described a constraint satisfaction approach to IVPs for parametric ODEs (i.e., ODEs where some data or initial conditions are

uncertain and given by intervals). *The main novelty of the constraint satisfaction approach is to introduce, inside traditional interval methods, a pruning component which reduces the size of the predicted boxes by using relaxations of the ODE (also called filters).* Then we presented an effective pruning algorithm which uses (1) relaxations of the ODE based Hermite interpolation polynomials and enclosures of their error terms; (2) a globalization process to reduce variable dependency problems and evaluation points that minimize the local error of the relaxations. The pruning component

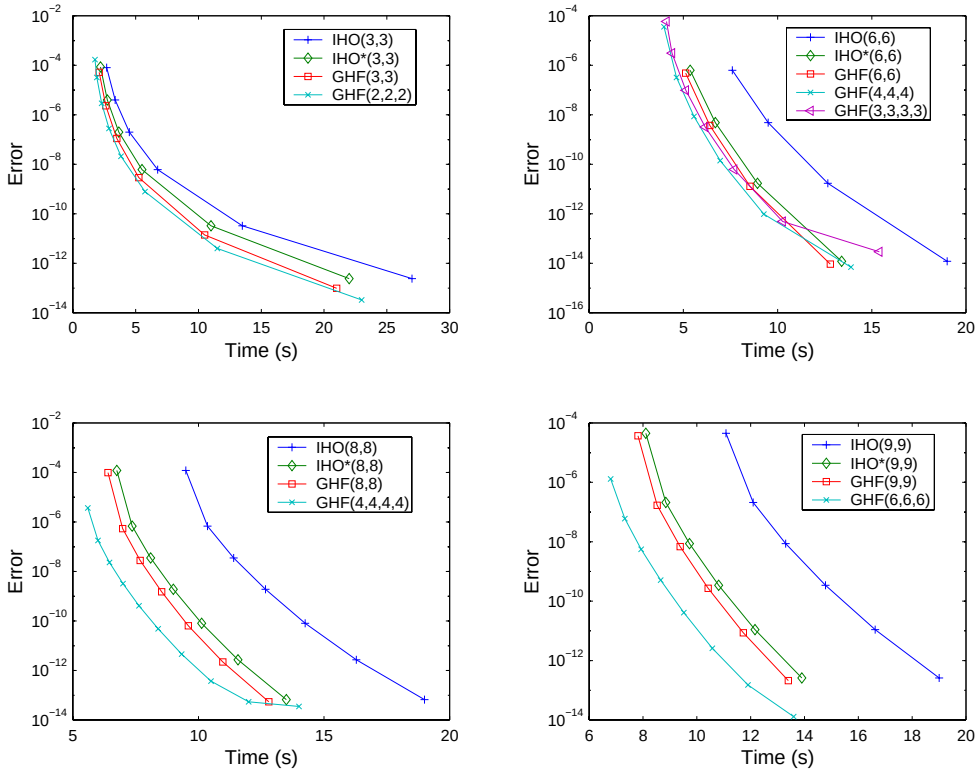

FIG. 14. *Multistep versus one-step methods: The P2 problem.*

was integrated in an integration algorithm which also uses traditional techniques to handle the wrapping effect.

The novel integration algorithm was analyzed both theoretically and experimentally. The theoretical results indicate that, for the same computation costs, our algorithm provides quadratic (asymptotic) improvement in accuracy over the best interval method we know of. They also show that our algorithm is significantly faster when the ODE contains many operations. Experimental results on a variety of standard and new benchmarks validated the theoretical results. The algorithm shows significant gains in accuracy, while not degrading computational performance. The experimental results also illustrate that the approach could produce significant gain in computation time when the ODE contains many operations.

It is also important to stress the versatility of our algorithm and of our approach. On the one hand, GHFs can be tailored to the problem at hand by choosing the number of interpolation points as well as the number of derivative conditions imposed at each interpolation point. On the other hand, the pruning algorithm itself is generic, and new pruning techniques may easily be incorporated.

There are a wealth of topics for further research:

1. The current algorithm can be enhanced in many ways to include, for instance, order and step size control strategies, and the automatic selection of the number of interpolation points and the number of derivative conditions imposed at each interpolation point.
2. The constraint satisfaction approach is clearly in its infancy and new relax-

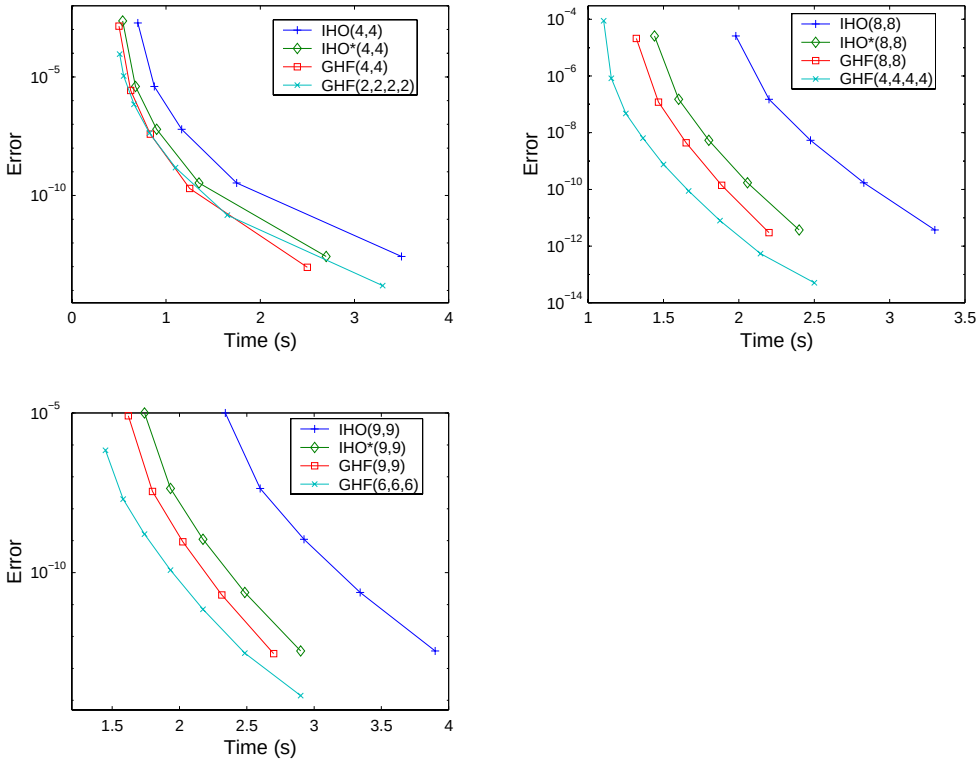

FIG. 15. *Multistep versus one-step methods: The P*3 *problem.*

ations (e.g., using splines, trigonometric interpolation, Legendre, Chebyshev, and Laguerre polynomials) should be investigated.

3. Compared to standard numerical methods, validated methods generally use smaller step sizes, and stiff problems are particularly challenging. The main factors that limit the step size are the need to enclose error terms and the bounding box process. Finding efficient bounding box techniques is probably the main bottleneck at this point, and it would be interesting to study how pruning techniques could help in this respect. Once we will be able to increase the step size, it will be important to analyze the stability of our approach and to compare it to the stability of other validated methods. The choice of many of the parameters mentioned in point (1) will be guided by stability requirements in the case of stiff problems. Furthermore, our asymptotic theory for choosing an optimal evaluation time may not be valid anymore, and we may have to find new techniques for choosing a good evaluation time.
4. A possible alternative to validated methods consists of dropping the enclosures of the error terms and the bounding box process in the interval method. We can thus keep the parametric aspect of the ODEs, but we lose the validated aspect of the method. However, the advantage is that larger step sizes can be used in this case. From our experimental results, we can expect a higher gain in performance of our GHF method over the IHO$^{(*)}$ method for those larger step sizes. In addition, if we consider an ODE for which it is not possible to compute the Taylor coefficients $(u)_2, (u)_3, \ldots$ of the solution,

a multistep GHF(σ) method with $\sigma_i \leq 2,\ i = 0, \ldots, k$, is the *only* interval method (we know of) which is able to integrate the ODE, since it does not need any Taylor coefficient.

5. A very promising direction of further research is the application of our approach to standard numerical methods for ODEs. Indeed, to our knowledge, the idea of evaluating a Hermite filter at a point which is different from the point at which the current value is computed is completely new. We can apply our asymptotic theory for the choice of an optimal evaluation time in the case of nonstiff problems. For stiff problems, the choice of a good evaluation time will be guided by stability requirements. Note that when $\sigma = (1, \ldots, 1)$, i.e., the Hermite interpolation polynomial reduces to a Lagrange interpolation polynomial, we can apply the classical linear stability theory to our approach.
6. Finally, it would be interesting to apply the constraint satisfaction approach to boundary value problems, where pruning arises naturally.

In summary, the constraint satisfaction approach should be a valuable addition to existing methods for the reliable solutions of differential equations, and there is considerable room for further research in this area.

Acknowledgments. We give special thanks to Philippe Delsarte for interesting discussions and for his detailed comments. We also would like to express our gratitude to the reviewers for their detailed suggestions.

DIFFERENCE APPROXIMATIONS FOR THE SECOND ORDER WAVE EQUATION*

HEINZ-OTTO KREISS†, N. ANDERS PETERSSON‡, AND JACOB YSTRÖM§

Abstract. Difference approximations are derived for the second order wave equation in one and two space dimensions, without first writing it as a first order system. Both the Dirichlet and the Neumann problems are treated for the one-dimensional case. Relations between the boundary error and the interior phase error are derived for a fully second order accurate discretization as well as a scheme that is fourth order accurate in the interior and second order accurate at the boundary. General two-dimensional domains are considered for the Dirichlet problem where the domain is embedded in a Cartesian grid and the boundary conditions are approximated by interpolation. A stable conservative scheme is derived where the time step is determined only by the interior discretization formula. Discretization cells cut by the boundary are treated implicitly, but the resulting scheme becomes explicit because the implicit dependence only is pointwise. Numerical examples are provided to verify the stability and accuracy of the proposed method.

Key words. wave equation, stability, accuracy, embedded boundary

1. Introduction.

The theory of difference approximations for first order strongly hyperbolic systems is by now very well developed. However, in many applications like seismology, acoustics, and general relativity the underlying differential equations are systems of second order hyperbolic partial differential equations. It is surprising that in this case the corresponding theory is much less developed. Instead, one often rewrites the equations as a first order system and then uses methods developed for such systems. While these methods provide the most natural way to solve problems that come as first order systems, we will argue that there can be drawbacks with rewriting second order systems into this form before they are discretized. Instead, we propose a numerical method that directly discretizes the second order system.

Consider, for example, the wave equation

$$u_{tt} = u_{xx} \tag{1.1}$$

in the strip $0 \le x \le 1,\ t \ge 0$. Thus we have to give initial conditions

$$u(x,0) = f(x), \quad u_t(x,0) = g(x), \tag{1.2}$$

and boundary conditions, for example,

$$u(0,t) = h_0(t), \quad u(1,t) = h_1(t). \tag{1.3}$$

§Department of Numerical Analysis and Computing Science, Royal Institute of Technology, S-100 44 Stockholm, Sweden (yxan@nada.kth.se).

To solve the problem numerically, we introduce a grid by

$$t_n = nk, \quad k > 0, \quad n = 0, 1, 2, \ldots, \quad x_\nu = \nu h, \quad h = 1/N, \quad \nu = 0, 1, 2, \ldots, N\,,$$

and approximate (1.1)–(1.3) by a completely centered approximation

$$\begin{aligned} D_+^t D_-^t v(x_\nu, t_n) &= D_+^x D_-^x v(x_\nu, t_n), \quad \nu = 1, 2, \ldots, N-1\,, \\ v(x_\nu, 0) &= f(x_\nu), \quad v(x_\nu, k) = f(x_\nu) + kg(x_\nu) + \frac{k^2}{2} D_+^x D_-^x f(x_\nu), \\ v(0, t_n) &= h_0(t_n), \quad v(1, t_n) = h_1(t_n). \end{aligned} \tag{1.4}$$

Here

$$\begin{aligned} hD_+^x v(x_\nu, t) &= v(x_{\nu+1}, t) - v(x_\nu, t), \\ hD_-^x v(x_\nu, t) &= v(x_\nu, t) - v(x_{\nu-1}, t), \\ D_0^x &= \frac{1}{2}(D_+^x + D_-^x) \end{aligned}$$

denote the usual forward, backward, and centered difference operators. As we will see, this approximation and its generalization to more space dimensions work very well. There are no difficulties with the boundary conditions; i.e., we do not need to supply any extrapolation conditions.

One can write (1.1) as a first order system

$$\mathbf{u}_t = A\mathbf{u}_x, \quad \mathbf{u} = \begin{pmatrix} u \\ v \end{pmatrix}, \quad A = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \tag{1.5}$$

with initial conditions

$$\mathbf{u}(x, 0) = \mathbf{f}, \quad \mathbf{f} = \left(f, \int_0^x g(\tilde{x}) d\tilde{x} \right)^T,$$

and boundary conditions (1.3). The leap-frog scheme is often used to solve wave propagation problems. For (1.5) it is, in its simplest form, given by

$$\begin{aligned} D_0^t \mathbf{u}(x_\nu, t_n) &= AD_0^x \mathbf{u}(x_\nu, t_n), \quad \nu = 1, 2, \ldots, N-1\,, \\ \mathbf{u}(x_\nu, 0) &= \mathbf{f}(x_\nu), \quad \mathbf{u}(x_\nu, k) = \mathbf{f}(x_\nu) + kAD_0^x \mathbf{u}(x_\nu, 0). \end{aligned} \tag{1.6}$$

There are a number of drawbacks with this procedure:

1. One needs to calculate two variables. (More variables are needed in several space dimensions.)
2. To obtain the same accuracy as (1.4), one needs to double the number of grid points in space and time.
3. Since there are no boundary conditions for v, one has to supply extrapolation conditions to obtain $v(0, t)$ and $v(1, t)$. This can be done, but one has to be careful not to introduce instabilities; see [5].
4. If the solution is not properly resolved, i.e., if one does not use enough points/wavelength, then one creates spurious waves which travel in the wrong direction; see [1].

To avoid the three latter difficulties, one may introduce a so-called staggered grid. However, this amounts to nothing else but solving (1.4) in disguise. In more space dimensions, staggered grids can lead to complications at the boundaries.

In the present paper, we directly approach the wave equation as a second order system. The equations are discretized on a Cartesian grid that covers the domain of interest, and the spatial derivatives are approximated by finite differences. On the boundary, which is embedded in the Cartesian grid, we use interpolation to approximate the boundary condition. This procedure results in a closed second order system of ordinary differential equations, and we derive an appropriate time-integration method for this system.

Numerical methods for first order systems are by now well developed, and many useful techniques have been established, such as higher order accurate boundary conditions [9], accurate treatment of discontinuous coefficients [4], and nonreflecting boundary conditions for external domains. The method presented here currently lacks these refinements, so a direct comparison on a realistic problem is hard to make. Instead, this work should be seen as a starting point for the development of a numerical technique that directly approaches second order hyperbolic systems.

Embedded boundary techniques for discretizing Laplace's equation subject to Dirichlet boundary conditions date back to Weller and Shortley [10], who used a finite-volume method (perhaps before that term was coined) to set up first order accurate difference approximations near the boundary. Collatz [2] derived higher order difference methods for both the Neumann and Dirichlet problems. More recently, several embedded boundary methods have been presented for various types of partial differential equations. For example, Pember et al. [8] used a Cartesian grid method for solving the time-dependent equations of gas dynamics. Zhang and LeVeque [11] solved the acoustic wave equation with discontinuous coefficients written as a first order system. They derived special difference stencils that satisfy the jump conditions at the interior interfaces, where the coefficients are discontinuous. A staggered grid method was used by Ditkowski, Dridi, and Hesthaven [3] for solving Maxwell's equations on a Cartesian grid. The methods described in these papers all solve first order systems (in time). Johansen and Colella [6] derived a finite-volume scheme for solving Poisson's equation with Dirichlet boundary conditions using an embedded boundary technique. Away from the boundary, the truncation error for the Laplace operator is $O(h^2)$, but in cells cut by the boundary it becomes $O(h/\Gamma)$. (Here h is the mesh spacing and Γ is the area fraction of the cut cell.) A potential theoretic argument is used to show that the solution of Poisson's equation is still second order accurate, even as $\Gamma \to 0$. However, the large truncation error in cells cut by the boundary makes this method unsuitable for solving the wave equation, where the truncation error for the Laplace operator also needs to be small near the boundary.

We shall now summarize the remainder of the paper. In section 2 we discuss a second order accurate time-integration method to solve the system of ordinary differential equations that arises after the wave equation is discretized in space. In particular, we derive a semi-implicit approach to avoid the severe time-step restriction that otherwise can occur from small cells cut by the boundary. When certain symmetry conditions are satisfied, the time-integration method is shown to be stable and conservative.

Section 3 contains a discussion of the stability and accuracy of semidiscrete approximations in one space dimension both for Dirichlet and Neumann boundary conditions. We consider methods that are second order accurate overall and methods

that are fourth order accurate in the interior and second order accurate at the boundary. Analytically, we derive the relation between the boundary error and the interior phase error. The analysis clearly shows that for the second order accurate method, the phase error dominates if we integrate over long distances. By using the fourth order method in the interior, we show that the phase error is greatly reduced.

The Dirichlet problem for the wave equation in general two-dimensional domains is treated in section 4. We show that we can construct stable energy conserving schemes that are either second order accurate overall or second order accurate at the boundary and fourth order accurate in the interior. We show that the scheme can be derived "dimension by dimension", essentially by employing the one-dimensional scheme in each direction. Since the semi-implicit treatment of the cut cells at the boundary is pointwise, the resulting scheme is fully explicit and therefore highly effective.

Numerical examples are provided in section 5, where we solve the two-dimensional Dirichlet problem to demonstrate the accuracy and stability of the proposed method. Future research is outlined in section 6.

2. Ordinary differential equations. Consider the initial value problem for the scalar equation

$$u_{tt} = \lambda u + F(t) \tag{2.1}$$

with initial conditions

$$u(0) = u_0, \quad u_t(0) = u_1. \tag{2.2}$$

Here $F(t)$ is a smooth function and $\lambda < 0$ is a negative constant.

The usual way to solve (2.1), (2.2) numerically is to rewrite the equation as a first order system and then apply any of the standard schemes. In this paper we solve the equation directly. Let k be the time step, $t_n = nk$, and denote the discrete approximation $v^n \approx u(t_n)$. We use two different second order accurate schemes:

1. If $\lambda \sim -1$, we use

$$v^{n+1} - 2v^n + v^{n-1} = k^2(\lambda v^n + F(t_n)). \tag{2.3}$$

2. If $\lambda \ll -1$, then we use instead

$$v^{n+1} - 2v^n + v^{n-1} = k^2 \left(\frac{\lambda}{2}(v^{n+1} + v^{n-1}) + F(t_n) \right).$$

The last method can also be written as

$$\left(1 - \frac{\lambda k^2}{2}\right)(v^{n+1} - 2v^n + v^{n-1}) = \lambda k^2 v^n + k^2 F(t_n). \tag{2.4}$$

We initialize the schemes by

$$v_0 = u_0, \quad v_1 = u(0) + k u_t(0) + \frac{k^2}{2} u_{tt}(0) = u_0 + k u_1 + \frac{k^2}{2}(\lambda u_0 + F(0)).$$

The characteristic equations for (2.3) and (2.4) are given by

$$(\kappa - 1)^2 - k^2 \lambda \kappa = 0, \quad \left(1 - \frac{\lambda k^2}{2}\right)(\kappa - 1)^2 - \lambda k^2 \kappa = 0,$$

respectively. Thus,

$$\kappa = 1 + \frac{1}{2}\zeta \pm \sqrt{\zeta + \frac{1}{4}\zeta^2},$$

where

$$\zeta = \lambda k^2 \quad \text{for (2.3)} \quad \text{and} \quad \zeta = \frac{\lambda k^2}{1 - \lambda k^2/2} \quad \text{for (2.4)}.$$

Thus, $|\kappa_1| = |\kappa_2| = 1,\ \kappa_1 \neq \kappa_2$, for $-4 < \zeta < 0$. Hence, the approximation (2.3) is stable for $k < 2/\sqrt{-\lambda}$, while the scheme (2.4) is unconditionally stable.

Now we consider systems

$$\begin{aligned} \boldsymbol{u}_{tt} &= A\boldsymbol{u} + F(t), \\ \boldsymbol{u}(0) = \boldsymbol{u}_0, &\quad \boldsymbol{u}_t(0) = \boldsymbol{u}_1, \end{aligned} \tag{2.5}$$

and the corresponding homogeneous problem

$$\begin{aligned} \boldsymbol{v}_{tt} &= A\boldsymbol{v}, \\ \boldsymbol{v}(0) = \boldsymbol{v}_0, &\quad \boldsymbol{v}_t(0) = \boldsymbol{v}_1. \end{aligned} \tag{2.6}$$

LEMMA 2.1. *The solutions of* (2.6) *are uniformly bounded in time if and only if the eigenvalues of A are real and negative and there is a complete system of eigenvectors.*

Proof. Let λ be an eigenvalue of A and φ_0 the corresponding eigenvector. Then, for any constants σ_1, σ_2,

$$\boldsymbol{v}_\lambda = \begin{cases} \left(\sigma_1 e^{\sqrt{\lambda}t} + \sigma_2 e^{-\sqrt{\lambda}t}\right)\varphi_0 & \text{if } \lambda \neq 0, \\ (\sigma_1 + \sigma_2 t)\varphi_0 & \text{if } \lambda = 0 \end{cases}$$

is a solution to $\boldsymbol{v}_{tt} = A\boldsymbol{v}$. Thus, $\boldsymbol{v}_\lambda$ is uniformly bounded in time if and only if λ is real and negative. If there is a complete eigensystem, then we can write the solutions to (2.6) as a sum of eigensolutions. The solutions are therefore uniformly bounded if and only if all the eigenvalues are real and negative.

An easy calculation shows that the solutions of

$$\boldsymbol{v}_{tt} = J\boldsymbol{v},$$

where J is a Jordan block, are not uniformly bounded. Therefore, if the eigensystem is incomplete, the solutions of (2.6) are not uniformly bounded. This proves the lemma.

If $A = A^* < 0$ is a negative definite symmetric matrix, then all conditions of the above lemma are satisfied and the solutions are uniformly bounded. We can also prove this by an energy estimate. We have

$$\begin{aligned} \frac{\partial}{\partial t}|\boldsymbol{v}_t|^2 &= \langle \boldsymbol{v}_t, \boldsymbol{v}_{tt}\rangle + \langle \boldsymbol{v}_t, \boldsymbol{v}_{tt}\rangle \\ &= \langle \boldsymbol{v}_t, A\boldsymbol{v}\rangle + \langle A\boldsymbol{v}, \boldsymbol{v}_t\rangle = \frac{\partial}{\partial t}\langle \boldsymbol{v}, A\boldsymbol{v}\rangle, \end{aligned}$$

i.e.,

$$\frac{\partial}{\partial t}\left(|\boldsymbol{v}_t|^2 + \langle \boldsymbol{v}, (-A)\boldsymbol{v}\rangle\right) = 0. \tag{2.7}$$

Since $-A$ is positive definite, boundedness follows.

We approximate the system (2.6) by

$$t_n = nk, \quad \boldsymbol{v}^n \approx \boldsymbol{v}(t_n),$$

and

$$\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1} = k^2 A\boldsymbol{v}^n \quad \text{if } |A| \sim 1, \tag{2.8}$$

$$\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1} = \frac{k^2}{2} A\left(\boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1}\right) \quad \text{if } |A| \gg 1. \tag{2.9}$$

We can write (2.9) in the form

$$\left(I - \frac{k^2}{2}A\right)\left(\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1}\right) = k^2 A\boldsymbol{v}^n.$$

Since we can reduce the system to scalar equations, the difference approximation corresponding to (2.3) is stable if

$$\max_j |\lambda_j| k^2 < 4.$$

The approximation (2.9) is unconditionally stable.

We proceed by using energy methods to derive the discrete counterpart of (2.7) to show that the discrete energy is conserved by the scheme (2.8). We write (2.8) in the form

$$\boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1} = (2I + k^2 A)\boldsymbol{v}^n.$$

Therefore,

$$\langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^{n-1}, \boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1}\rangle = \langle \boldsymbol{v}^{n+1}, (2I + k^2 A)\boldsymbol{v}^n\rangle - \langle \boldsymbol{v}^{n-1}, (2I + k^2 A)\boldsymbol{v}^n\rangle.$$

Assuming that $\boldsymbol{v}^n, A$ are real, we obtain

$$\begin{aligned} L(t_{n+1}, A) &=: |\boldsymbol{v}^{n+1}|^2 + |\boldsymbol{v}^n|^2 - \langle \boldsymbol{v}^{n+1}, (2I + k^2 A)\boldsymbol{v}^n\rangle \\ &= |\boldsymbol{v}^n|^2 + |\boldsymbol{v}^{n-1}|^2 - \langle \boldsymbol{v}^n, (2I + k^2 A)\boldsymbol{v}^{n-1}\rangle \\ &= L(t_n, A). \end{aligned}$$

Thus, we obtain an energy estimate if L is positive definite. We have

$$L(t_{n+1}, A) = \langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^n, \boldsymbol{v}^{n+1} - \boldsymbol{v}^n\rangle - k^2\langle \boldsymbol{v}^{n+1}, A\boldsymbol{v}^n\rangle.$$

Since $A = A^*$ is symmetric,

$$\langle \boldsymbol{v}^{n+1}, A\boldsymbol{v}^n\rangle = \frac{1}{4}\langle \boldsymbol{v}^{n+1} + \boldsymbol{v}^n, A(\boldsymbol{v}^{n+1} + \boldsymbol{v}^n)\rangle - \frac{1}{4}\langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^n, A(\boldsymbol{v}^{n+1} - \boldsymbol{v}^n)\rangle.$$

Hence,

$$\begin{aligned} L(t_{n+1}, A) = &\left\langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^n, \left(I + \frac{k^2}{4}A\right)(\boldsymbol{v}^{n+1} - \boldsymbol{v}^n)\right\rangle \\ &- \frac{k^2}{4}\langle \boldsymbol{v}^{n+1} + \boldsymbol{v}^n, A(\boldsymbol{v}^{n+1} + \boldsymbol{v}^n)\rangle. \end{aligned} \tag{2.10}$$

Let $\lambda_j < 0$ be the eigenvalues of A. For $4 - k^2 \max_j |\lambda_j| \geq k^2 \min_j |\lambda_j|$,

$$\left\langle \boldsymbol{v}, \left(I + \frac{k^2}{4} A \right) \boldsymbol{v} \right\rangle \geq \frac{k^2}{4} \min_j |\lambda_j| |\boldsymbol{v}|^2$$

and

$$L(t_{n+1}, A) \geq \frac{k^2}{4} \min_j |\lambda_j| \left(|\boldsymbol{v}^{n+1} - \boldsymbol{v}^n|^2 + |\boldsymbol{v}^{n+1} + \boldsymbol{v}^n|^2 \right).$$

Thus, $L(t_n, A)$ is positive definite if the time step satisfies

$$(\max_j |\lambda_j| + \min_j |\lambda_j|) k^2 \leq 4$$

and, essentially, we recover the previous time-step restriction.

By comparing (2.11) and (2.7) we note that $L(t_{n+1}, A)/k^2$ is a second order accurate approximation of the energy $|\boldsymbol{v}_t|^2 - \langle \boldsymbol{v}, A\boldsymbol{v} \rangle$, evaluated at time $t_n + k/2$.

Often there are only relatively few elements of A which are large, and we can write

$$A = A_1 + A_2, \quad A_1 = A_1^* \leq 0, \quad |A_1| \gg 1, \quad A_2 = A_2^* < 0, \quad |A_2| \sim 1.$$

To avoid severe restrictions of the step size, we can use the second order approximation

$$\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1} = \frac{k^2}{2} A_1 \left(\boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1} \right) + k^2 A_2 \boldsymbol{v}^n, \tag{2.11}$$

which we write as

$$\left(I - \frac{k^2}{2} A_1 \right) (\boldsymbol{v}^{n+1} - 2\boldsymbol{v}^n + \boldsymbol{v}^{n-1}) = k^2 (A_1 + A_2) \boldsymbol{v}^n$$

or

$$\left(I - \frac{k^2}{2} A_1 \right) (\boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1}) = \left(2I + k^2 A_2 \right) \boldsymbol{v}^n.$$

Thus,

$$\left\langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^{n-1}, \left(I - \frac{k^2}{2} A_1 \right) (\boldsymbol{v}^{n+1} + \boldsymbol{v}^{n-1}) \right\rangle = \langle \boldsymbol{v}^{n+1} - \boldsymbol{v}^{n-1}, \left(2I + k^2 A_2 \right) \boldsymbol{v}^n \rangle.$$

Similar to the scheme (2.8), we can derive a discrete energy that is conserved. Assuming that $\boldsymbol{v}^n$, A_1, A_2 are real, we have

$$\begin{aligned} L_1(t_{n+1}, A_1, A_2) =: & \left\langle \boldsymbol{v}^{n+1}, \left(I - \frac{k^2}{2} A_1 \right) \boldsymbol{v}^{n+1} \right\rangle + \left\langle \boldsymbol{v}^n, \left(I - \frac{k^2}{2} A_1 \right) \boldsymbol{v}^n \right\rangle \\ & - \langle \boldsymbol{v}^{n+1}, (2I + k^2 A_2) \boldsymbol{v}^n \rangle \\ = & \left\langle \boldsymbol{v}^n, \left(I - \frac{k^2}{2} A_1 \right) \boldsymbol{v}^n \right\rangle + \left\langle \boldsymbol{v}^{n-1}, \left(I - \frac{k^2}{2} A_1 \right) \boldsymbol{v}^{n-1} \right\rangle \\ & - \langle \boldsymbol{v}^n, (2I + k^2 A_2) \boldsymbol{v}^{n-1} \rangle \\ = & \; L_1(t_n, A_1, A_2). \end{aligned}$$

We have now to show that $L_1(t_n, A_1, A_2)$ is positive definite. Since $-A_1$ is positive semidefinite,

$$\left\langle \boldsymbol{v}^{n+1}, -\frac{k^2}{2} A_1 \boldsymbol{v}^{n+1} \right\rangle + \left\langle \boldsymbol{v}^n, -\frac{k^2}{2} A_1 \boldsymbol{v}^n \right\rangle \geq 0,$$

and it follows that

$$L_1(t_n, A_1, A_2) \geq L(t_n, A_2).$$

Thus $L_1(t_n, A_1, A_2)$ is positive definite since $L(t_n, A_2)$ is positive definite. Hence, the previous time-step restriction applies with A replaced by A_2. We summarize our results in the following lemma.

LEMMA 2.2. *The time-integration scheme* (2.11) *is stable and the discrete energy* $L_1(t_n, A_1, A_2)$ *is conserved if* $A_1 = A_1^* \leq 0$, $A_2 = A_2^* < 0$, *and the time step satisfies*

$$\left(\max_j |\lambda_j| + \min_j |\lambda_j| \right) k^2 < 4,$$

where λ_j *are the eigenvalues of* A_2.

All our results are also valid for systems

$$B\boldsymbol{u}_{tt} = A\boldsymbol{u}, \quad A = A^* < 0, \quad B = B^* > 0,$$

because the change of variables $B^{1/2}\boldsymbol{u} = \tilde{\boldsymbol{u}}$ gives us

$$\tilde{\boldsymbol{u}}_{tt} = \tilde{A}\tilde{\boldsymbol{u}}, \quad \tilde{A} = \tilde{A}^* = B^{-1/2} A B^{-1/2}.$$

3. The wave equation in one space dimension. We consider the wave equation

$$u_{tt} = u_{xx} \tag{3.1}$$

for $x \geq l,\ t \geq 0$. Here $l \geq 0$ is a small number. At $t = 0$ we give initial conditions

$$u(x, 0) = f(x), \quad u_t(x, 0) = g(x). \tag{3.2}$$

Here f is a smooth function with compact support.

3.1. Second order methods. At $x = l$ we give boundary conditions and we start by analyzing Dirichlet conditions

$$u(l, t) = 0. \tag{3.3}$$

Here we discuss second order difference approximations. We only discretize space. In the time direction we use the approximation discussed in the previous section. Let $h > 0$ be a step size. We assume that $l = \alpha h,\ 0 \leq \alpha < 1$. Grid points are given by $x_\nu = \nu h$ and grid functions by $w(x_\nu, t) = w_\nu(t)$. We approximate (3.1), (3.2) by

$$\begin{aligned} w_{\nu tt} &= D_+ D_- w_\nu, \\ w_\nu(0) &= f_\nu, \quad w_{\nu t}(0) = g_\nu, \quad \nu = 1, 2, \ldots. \end{aligned} \tag{3.4}$$

We shall use the simplest second order accurate boundary condition given by the interpolation condition

$$\alpha w_1 + (1 - \alpha) w_0 = 0. \tag{3.5}$$

We can express w_0 in terms of w_1 and eliminate w_0 from (3.4). Then the differential equation for w_1 becomes

$$w_{1tt} = \frac{w_2 - 2w_1 + w_0}{h^2} = \frac{1}{h^2}(aw_1 + bw_2),$$

where

$$a = -\left(2 + \frac{\alpha}{1-\alpha}\right), \quad b = 1.$$

In matrix form (3.4) can be written as

$$\mathbf{w}_{tt} = \frac{1}{h^2} \begin{pmatrix} a & 1 & 0 & 0 & \cdots & 0 \\ 1 & -2 & 1 & 0 & \cdots & \\ 0 & 1 & -2 & 1 & & \\ \vdots & & \ddots & \ddots & \ddots & \\ 0 & & & & & \end{pmatrix} \mathbf{w}, \quad \mathbf{w} = \begin{pmatrix} w_1 \\ w_2 \\ w_3 \\ \vdots \\ \vdots \end{pmatrix}.$$

The matrix is symmetric and negative definite. Since $|a|$ becomes large as $\alpha \to 1$, we split the matrix and use the scheme (2.11) with

$$A_1 = \frac{1}{h^2} \begin{pmatrix} -\frac{\alpha}{1-\alpha} & 0 & \cdots \\ 0 & 0 & \cdots \\ \vdots & \vdots & \ddots \end{pmatrix}.$$

We now consider Neumann boundary conditions. At $x = \alpha h$ we have

$$u_x(\alpha h) = u_x(0) + \alpha h u_{xx}(0) + \mathcal{O}(h^2).$$

Also,

$$D_+ u_0 = u_x(0) + \frac{h}{2} u_{xx}(0) + \mathcal{O}(h^2).$$

Therefore,

$$u_x(\alpha h) = D_+ u_0 + h\left(\alpha - \frac{1}{2}\right) D_+^2 u_0 + \mathcal{O}(h^2).$$

Thus, we approximate the boundary condition

$$u_x(\alpha h) = 0$$

by

$$D_+ w_0 + h\left(\alpha - \frac{1}{2}\right) D_+^2 w_0 = 0, \tag{3.6}$$

i.e.,

$$\left(\frac{3}{2}-\alpha\right)w_0=\left(\alpha-\frac{1}{2}\right)w_2+(2-2\alpha)w_1.$$

We eliminate w_0 from the differential equations (3.4) and obtain

$$\begin{aligned}w_{1tt}&=\frac{1}{h^2}(w_2-2w_1+w_0)=\frac{1}{h^2}\left(\left(1+\frac{\alpha-\frac{1}{2}}{\frac{3}{2}-\alpha}\right)w_2-\left(2-\frac{2-2\alpha}{\frac{3}{2}-\alpha}\right)w_1\right)\\&=\frac{1}{ah^2}(w_2-w_1),\quad a=\frac{3}{2}-\alpha.\end{aligned}$$

Thus, (3.4) can be written as

(3.7)

$$B\mathbf{w}_{tt}=:\begin{pmatrix}a&&&0\\&1&&\\&&\ddots&\\0&&&1\end{pmatrix}\mathbf{w}_{tt}=\frac{1}{h^2}\begin{pmatrix}-1&1&0&0&\cdots&0\\1&-2&1&0&\cdots&\\0&1&-2&1&&\\\vdots&&\ddots&\ddots&\ddots&\\0&&&&&\end{pmatrix}\mathbf{w}:=A\mathbf{w}.$$

The matrix A is symmetric and negative definite on the space of grid functions with bounded discrete l_2-norm. In this way we exclude solutions which are constant in x.

Note that $1/2\le a\le 3/2$, so the system does not become stiff for $0\le\alpha\le 1$. We can therefore apply the scheme (2.8) to integrate in time.

3.2. Higher order methods. It is well known that for the Cauchy problem fourth order methods are much more effective than second order methods when solving wave propagation problems. The number of points/wavelength analysis tells us that the phase error is very much decreased. However, for problems in bounded domains, it is often difficult to construct stable fourth order accurate approximations of the boundary conditions. We want to show that a method that is fourth order accurate in the interior but only second order accurate at the boundary is an acceptable compromise. In this way we control the phase error.

We consider the half-plane problem for the wave equation

$$u_{tt}=u_{xx}+F(x,t),\quad x\ge\alpha h,\ t\ge 0, \tag{3.8}$$

$$u(x,0)=f^{(1)}(x),\quad u_t(x,0)=f^{(2)}(x), \tag{3.9}$$

with Dirichlet boundary conditions

$$u(\alpha h,t)=g(t). \tag{3.10}$$

We approximate (3.8)–(3.10) by

$$v_{\nu tt}=D_+D_-v_\nu,\quad v_\nu=v(x_\nu,t),\ x_\nu=\nu h,\ \nu=0,1,2,\dots, \tag{3.11}$$

$$v_\nu(0)=f_\nu^{(1)},\quad v_{\nu t}(0)=f_\nu^{(2)}, \tag{3.12}$$

with boundary condition

$$\alpha v_0+(1-\alpha)v_1=g(t). \tag{3.13}$$

Here $F, f^{(j)}, g \in C_0^\infty$. Without restriction we can assume that $F \equiv 0, f^{(j)} \equiv 0$, because we can extend $F, f^{(j)}$ to the whole space, solve the Cauchy problem, and subtract its solution from u. For the Cauchy problem we know that the fourth order method is much more accurate.

Under the above assumption, we solve the above problems by Laplace transform. The transformed problems are

$$s^2\hat{u} = \hat{u}_{xx}, \quad \hat{u}(\alpha h, s) = \hat{g}, \quad s = i\xi + \eta, \quad \eta > 0, \tag{3.14}$$

$$s^2\hat{v}_\nu = D_+D_-\hat{v}_\nu, \quad \alpha v_1 + (1-\alpha)v_0 = \hat{g}, \quad \nu = 1, 2, \ldots, \tag{3.15}$$

and their solutions are given by

$$\hat{u}(x,t) = e^{-sx}e^{\alpha hs}\hat{g}, \tag{3.16}$$

$$\hat{v}_\nu = \kappa^\nu \hat{v}_0, \quad \big(\alpha\kappa + (1-\alpha)\big)\hat{v}_0 = \hat{g}, \tag{3.17}$$

respectively. Here κ with $|\kappa| < 1$ is the solution of the characteristic equation

$$\frac{(\kappa-1)^2}{\kappa} = s^2h^2.$$

For the discussion of accuracy, we can assume that $|sh| \le \delta \ll 1$. We obtain

$$\kappa = 1 + \frac{s^2h^2}{2} - \sqrt{s^2h^2 + \frac{s^4h^4}{4}} \sim 1 - sh + \frac{s^2h^2}{2} - \frac{s^3h^3}{8} \sim e^{-sh(1-\frac{s^2h^2}{24})}.$$

By (3.15)

$$v_0 = \frac{\hat{g}}{\alpha e^{-sh} + 1 - \alpha} \sim \hat{g}e^{\alpha hs}\left(1 - \frac{\alpha - \alpha^2}{2}s^2h^2\right).$$

Thus, for $x = x_\nu$,

$$\hat{v}(x,s) \sim e^{-sx(1-\frac{s^2h^2}{24})}e^{\alpha hs}\hat{g}\left(1 - \frac{\alpha-\alpha^2}{2}s^2h^2\right)$$

and

$$|\hat{u}(x,s) - \hat{v}(x,s)| \le |\hat{g}e^{\alpha hs}|\left\{\left|\frac{\alpha-\alpha^2}{2}s^2h^2\right| + |e^{-sx}|\left(1 - e^{\frac{sxh^2s^2}{24}}\right)\right\} \tag{3.18}$$

$$\sim |\hat{g}|\left(\frac{|sh|^2}{8} + \frac{|sx|}{24}|sh|^2\right) = \frac{|\hat{g}|\,|sh|^2}{8}\left(1 + \frac{|sx|}{3}\right). \tag{3.19}$$

We can invert the Laplace transform on the imaginary axis $s = i\xi$. Therefore, we can consider $u(x,t),\ v(x,t)$ as a superposition of waves which travel into the region. The error consists of the phase error $\frac{|sx|}{24}(sh)^2$ and the boundary error $\frac{|sh|^2}{8}$, due to the interpolation on the boundary. It shows that the phase error dominates the boundary error if $|sx| > 3$.

We now consider the fourth order method

$$v_{\nu tt} = D_+D_-v_\nu - \frac{h^2}{12}D_+^2D_-^2v_\nu, \quad \nu = 1, 2, \ldots, \tag{3.20}$$

with boundary condition

$$\alpha v_1 + (1-\alpha)v_0 = g. \tag{3.21}$$

Now the stencil depends also on v_{-1}. Therefore, we have to supply an extra boundary such that we can eliminate v_{-1}. This condition can have different forms, depending on our requirements.

3.2.1. A method that is fourth order accurate in the interior and on the boundary. Using the differential equation, the boundary condition

$$u(x,0) = g(t)$$

implies

$$u_{xx}(x,0) = u_{tt}(x,0) = g_{tt}.$$

Therefore, we obtain a method that is fourth order accurate overall if we add the condition

$$\alpha D_+D_-v_1 + (1-\alpha)D_+D_-v_0 = g_{tt}. \tag{3.22}$$

Another advantage of (3.22) is that in matrix form we obtain a symmetric system. We write (3.20) and (3.21), (3.22) in the form

$$\begin{aligned} &v_{\nu tt} = D_+D_-v_\nu - \frac{h^2}{12}D_+D_-w_\nu, \quad w_\nu = D_+D_-v_\nu, \quad \nu = 0,1,2,\dots,\\ &\alpha v_1 + (1-\alpha)v_0 = g, \quad \alpha w_1 + (1-\alpha)w_0 = g. \end{aligned}$$

Then we can eliminate v_0 and w_0 and obtain

$$\mathbf{v}_{tt} = A\mathbf{v} - \frac{h^2}{12}A\mathbf{w} + F = A\mathbf{v} - \frac{h^2}{12}A^2\mathbf{v} + F.$$

Since $A - \frac{h^2}{12}A^2$ is negative definite, we can apply our previous results and obtain a stable scheme. Unfortunately, this technique cannot easily be generalized to more space dimensions.

3.2.2. Methods that are fourth order accurate in the interior but only second order accurate on the boundary. As we have seen earlier, the error at the boundary is often much smaller than the phase error in the interior. Therefore, it is reasonable to use a method that is fourth order accurate in the interior and second order accurate at the boundary.

The simplest way to achieve this it to calculate the fourth order term only if its stencil does not depend on boundary or exterior points. The resulting scheme is not symmetric and, unfortunately, it is slightly unstable.

We can also replace (3.20) by

$$v_{\nu tt} = D_+D_-v_\nu - \frac{h^2}{12}D_+D_-(\gamma_\nu D_+D_-v_\nu), \quad \nu = 1,2,\dots, \tag{3.23}$$

with $\gamma_0 = \gamma_1 = 0,\ \gamma_2 = \gamma_3 = \cdots = 1$. Since

$$h^2D_+D_-(\gamma_\nu D_+D_-v_\nu) = \gamma_{\nu+1}D_+D_-v_{\nu+1} - 2\gamma_\nu D_+D_-v_\nu + \gamma_{\nu-1}D_+D_-v_{\nu-1}, \tag{3.24}$$

the matrix for the semidiscrete problem is again symmetric and negative definite and we obtain an energy estimate. We shall now discuss the accuracy of the new method. Since the fourth order terms do not depend on v_{-1} and v_0, we do not need to specify an extra boundary condition. Thus, we consider (3.23) with boundary condition (3.21) and solve the problem by Laplace transform.

Since $\gamma_\nu = 1$ for $\nu \geq 2$, the Laplace transformed problem becomes, using (3.24),

$$s^2\hat{v}_\nu = D_+D_-\hat{v}_\nu - \frac{h^2}{12}D_+^2D_-^2\hat{v}_\nu, \quad \mathrm{Re}(s) > 0, \quad \nu = 3, 4, \ldots, \tag{3.25}$$

$$s^2\hat{v}_2 = D_+D_-\hat{v}_2 - \frac{1}{12}D_+D_-\hat{v}_3 + \frac{1}{6}D_+D_-\hat{v}_2, \tag{3.26}$$

$$s^2\hat{v}_1 = D_+D_-\hat{v}_1 - \frac{1}{12}D_+D_-\hat{v}_2, \tag{3.27}$$

$$\alpha\hat{v}_1 + (1-\alpha)\hat{v}_0 = \hat{g}. \tag{3.28}$$

We can eliminate $\hat{v}_0$ by writing (3.27) and (3.28) in the form

$$-(1-\alpha)\left(h^2s^2\hat{v}_1 - h^2D_+D_-\hat{v}_1 + \frac{h^2}{12}D_+D_-\hat{v}_2\right) = \alpha\hat{v}_1 + (1-\alpha)\hat{v}_0 - \hat{g}. \tag{3.29}$$

We now solve (3.25), (3.26), and (3.29). The general solution of (3.25) is

$$\hat{v}_\nu = \sigma_1\kappa_1^\nu + \sigma_2\kappa_2^\nu, \tag{3.30}$$

where κ with $|\kappa| < 1$ are solutions of

$$s^2h^2 = \mu - \frac{1}{12}\mu^2, \quad \mu = \frac{(\kappa-1)^2}{\kappa}.$$

For small $|sh|$, the solutions of

$$\mu^2 - 12\mu + 12s^2h^2 = 0$$

are

$$\begin{aligned}
\mu_1 &= 6 + \sqrt{36 - 12s^2h^2} \sim 12,\\
\mu_2 &= 6 - \sqrt{36 - 12s^2h^2}\\
&= 6\left(1 - \sqrt{1 - \frac{1}{3}s^2h^2}\right)\\
&\sim 6\left(1 - \left(1 - \frac{1}{6}s^2h^2 - \frac{1}{72}s^4h^4 - \frac{1}{3^3\cdot 16}s^6h^6\right)\right)\\
&\sim s^2h^2 + \frac{1}{12}s^4h^4 + \frac{1}{72}s^6h^6.
\end{aligned}$$

The corresponding κ are solutions of

$$\kappa^2 - (2+\mu)\kappa + 1 = 0.$$

After some painful computations,

$$\kappa_1 \sim \frac{1}{12}, \tag{3.31}$$

$$\kappa_2 = 1 + \frac{\mu_2}{2} - \sqrt{\mu_2 + \frac{\mu_2^2}{4}} \sim e^{-sh(1+\gamma(sh)^4)}, \quad \gamma \sim \frac{1}{120}. \tag{3.32}$$

Inserting the ansatz (3.30) into (3.26),

$$\sigma_1\kappa_1^2\left(s^2h^2-\frac{7}{6}\frac{(\kappa_1-1)^2}{\kappa_1}+\frac{1}{12}(\kappa_1-1)^2\right)$$
$$+\ \sigma_2\kappa_2^2\left(s^2h^2-\frac{7}{6}\frac{(\kappa_2-1)^2}{\kappa_2}+\frac{1}{12}(\kappa_2-1)^2\right)=0,$$

and entering the above values of κ_1 and κ_2 yields

$$\frac{\sigma_1}{12^2}\left(\frac{11^2}{12^2}\left(-14+\frac{1}{12}\right)+s^2h^2\right)-\sigma_2\left(\frac{s^2h^2}{12}+O((sh)^3)\right)=0. \tag{3.33}$$

Thus we can neglect σ_1 in (3.29) and commit an error $O(h^2s^2)$ if we replace (3.29) by (3.28). The result is a solution with essentially the same amplitude as in the second order case but with a much improved phase error.

Similar arguments can be used for Neumann boundary conditions. In one space dimension we can obtain an approximation which is fourth order overall by using

$$u_x=g,\quad u_{xtt}=u_{xxx}=g_{tt},$$

as boundary conditions. That the approximation is second order accurate for Dirichlet conditions at the boundary depends crucially on the relation (3.33), which holds only because the boundary condition (3.28) has no influence on (3.26). Second order accurate discrete Neumann conditions depend on v_0, v_1, and v_2. Therefore, we will obtain (3.33) only if we replace (3.23) by

$$\gamma_0=\gamma_1=\gamma_2=0,\quad \gamma_\nu=1\quad\text{for}\quad \nu\geq 3. \tag{3.34}$$

In one space dimension this new approximation is stable. We will investigate the two-dimensional Neumann problem in a forthcoming paper.

4. The wave equation in two space dimensions with Dirichlet boundary condition. In this section we consider the scalar wave equation in the bounded domain $\Omega\subset\Re^2$, subject to Dirichlet conditions on the boundary Γ,

$$\begin{aligned} u_{tt}&=\Delta u,\quad \boldsymbol{x}\in\Omega,\quad t>0,\\ u(\boldsymbol{x},t)&=f(\boldsymbol{x},t),\quad \boldsymbol{x}\in\Gamma,\quad t>0,\\ u(\boldsymbol{x},0)&=u_0(\boldsymbol{x}),\quad u_t(\boldsymbol{x},0)=u_1(\boldsymbol{x}),\quad \boldsymbol{x}\in\Omega. \end{aligned} \tag{4.1}$$

4.1. Algorithm. We cover Ω by a Cartesian grid with step size h; see Figure 1. The grid points are given by $\boldsymbol{x}_{i,j}=(x_i,y_j)^T$,

$$x_i=x^{(0)}+(i-1)h,\quad i=1,2,\ldots,N,$$
$$y_j=y^{(0)}+(j-1)h,\quad j=1,2,\ldots,M,$$

where $h=(x^{(1)}-x^{(0)})/(N-1)\equiv(y^{(1)}-y^{(0)})/(M-1)$. Let all points $\boldsymbol{x}=(x,y)\in\Omega$ satisfy $x_{\min}\leq x\leq x_{\max}$, $y_{\min}\leq y\leq y_{\max}$. To make sure the grid covers Ω, we require $x^{(0)}\leq x_{\min}-h$, $x^{(1)}\geq x_{\max}+h$ and $y^{(0)}\leq y_{\min}-h$, $y^{(1)}\geq y_{\max}+h$.

Before we can discretize the problem, we need to classify each grid point. We denote the classification by $m_{i,j}$,

$$m_{i,j}=\begin{cases} 0, & \boldsymbol{x}_{i,j}\text{ outside of }\Omega,\\ 1, & \boldsymbol{x}_{i,j}\in\Omega,\boldsymbol{x}_{i\pm1,j}\in\Omega\text{ and }\boldsymbol{x}_{i,j\pm1}\in\Omega,\\ -1 & \text{otherwise.}\end{cases}$$

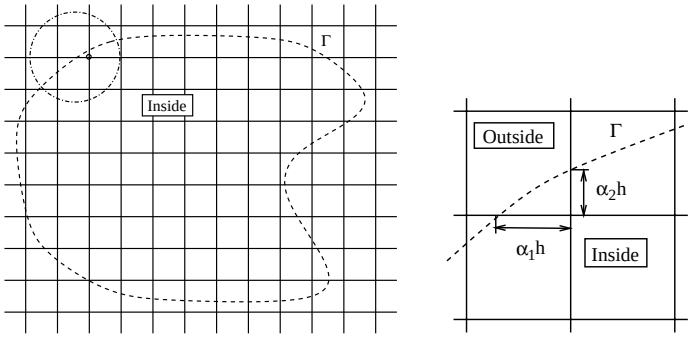

FIG. 1. *The computational grid and the embedded boundary (left) and a close-up of one boundary point (right).*

Hence, interior points have $m_{i,j} = 1$, exterior points have $m_{i,j} = 0$, and boundary points have $m_{i,j} = -1$. Let $u^n_{i,j}$ denote the difference approximation to $u(x_i, y_j, t_n)$. At interior points, we use a centered approximation both in space and time,

$$\frac{u^{n+1}_{i,j} - 2u^n_{i,j} + u^{n-1}_{i,j}}{k^2} = (D^x_+ D^x_- + D^y_+ D^y_-)u^n_{i,j} =: \Delta_h u^n_{i,j}, \quad m_{i,j} = 1. \tag{4.2}$$

At boundary points, the Dirichlet boundary condition is used to eliminate the exterior points from the centered difference formula. For example, let $\boldsymbol{x}_{i,j}$ be a boundary point and let the points $(x_i - \alpha_1 h, y_j)^T$ and $(x_i, y_j + \alpha_2 h)^T$ be on the boundary, as is shown in Figure 1. The Dirichlet conditions are approximated by linear interpolation,

$$\begin{aligned}(1-\alpha_1)u^n_{i,j} + \alpha_1 u^n_{i-1,j} &= f(x_i - \alpha_1 h, y_j, t_n),\\ (1-\alpha_2)u^n_{i,j} + \alpha_2 u^n_{i,j+1} &= f(x_i, y_j + \alpha_2 h, t_n).\end{aligned}$$

Assuming that $\alpha_1 > 0$, $\alpha_2 > 0$,

$$\begin{aligned}u^n_{i-1,j} &= -\frac{1-\alpha_1}{\alpha_1} u^n_{i,j} + \frac{1}{\alpha_1} f(x_i - \alpha_1 h, y_j, t_n),\\ u^n_{i,j+1} &= -\frac{1-\alpha_2}{\alpha_2} u^n_{i,j} + \frac{1}{\alpha_2} f(x_i, y_j + \alpha_2 h, t_n).\end{aligned}$$

Eliminating $u^n_{i-1,j}$ and $u^n_{i,j+1}$ from (4.2) results in

$$\frac{u^{n+1}_{i,j} - 2u^n_{i,j} + u^{n-1}_{i,j}}{k^2} = \frac{1}{h^2}\left(-(4 + d_{i,j})u^n_{i,j} + u^n_{i+1,j} + u^n_{i,j-1}\right) + \frac{\tilde{f}^n_{i,j}}{h^2} \tag{4.3}$$

$$=: \tilde{\Delta}_h u^n_{i,j} + \frac{\tilde{f}^n_{i,j}}{h^2}, \tag{4.4}$$

where $d_{i,j} = (1-\alpha_1)/\alpha_1 + (1-\alpha_2)/\alpha_2 > 0$ and $\tilde{f}^n_{i,j} = f(x_i - \alpha_1 h, y_j, t_n)/\alpha_1 + f(x_i, y_j + \alpha_2 h, t_n)/\alpha_2$. Since α_1 and α_2 can be arbitrarily close to zero, d can be very large, which makes the time-step restriction for (4.4) severe. To avoid this problem, we use the splitting discussed in section 2,

$$\begin{aligned}\frac{u^{n+1}_{i,j} - 2u^n_{i,j} + u^{n-1}_{i,j}}{k^2} &= \frac{1}{h^2}\left(-4u^n_{i,j} + u^n_{i+1,j} + u^n_{i,j-1}\right)\\ &\quad - \frac{d_{i,j}}{2h^2}\left(u^{n+1}_{i,j} + u^{n-1}_{i,j}\right) + \frac{\tilde{f}^n_{i,j}}{h^2}, \quad m_{i,j} = -1.\end{aligned}$$

In the general case, $d_{i,j}$ and $\tilde{f}^n_{i,j}$ get contributions from all exterior nearest neighbors, and the first term on the right-hand side includes all interior or boundary nearest neighbors,

$$\frac{u^{n+1}_{i,j} - 2u^n_{i,j} + u^{n-1}_{i,j}}{k^2} = \frac{1}{h^2}\Big(-4u^n_{i,j} + \sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}| u^n_{\boldsymbol{j}} \Big) - \frac{d_{i,j}}{2h^2}\left(u^{n+1}_{i,j} + u^{n-1}_{i,j}\right) + \frac{\tilde{f}^n_{i,j}}{h^2}, \quad m_{i,j} = -1. \tag{4.5}$$

Here $\boldsymbol{j}$ is a multi-index and the sum extends over all nearest neighbors $\boldsymbol{j} = (i+1,j),(i-1,j),(i,j+1),(i,j-1)$.

4.2. Stability. By letting $\boldsymbol{u}^n$ denote the vector containing the solution $u^n_{i,j}$ at all interior and boundary points (using line ordering, for example), we can write the time-integration scheme (4.2), (4.5) in the form (2.11). The matrix A_1, given by

$$A_1\boldsymbol{u} = \begin{cases} 0, & m_{i,j} = 1, \\ -\frac{d_{i,j}}{h^2}, & m_{i,j} = -1, \end{cases}$$

is negative semidefinite since it is diagonal and $-d_{i,j} < 0$. The matrix A_2 is defined by

$$A_2\boldsymbol{u} = \begin{cases} \frac{1}{h^2}\left(-4u_{i,j} + \sum_{\boldsymbol{j}} u_{\boldsymbol{j}}\right), & m_{i,j} = 1, \\ \frac{1}{h^2}\left(-4u_{i,j} + \sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}| u_{\boldsymbol{j}}\right), & m_{i,j} = -1. \end{cases}$$

Again, the sum extends over all nearest neighbors $\boldsymbol{j} = (i+1,j),(i-1,j),(i,j+1),(i,j-1)$.

To study the symmetry of A_2, we note that if (i,j) is an interior point, the corresponding row in $A_2\boldsymbol{u}$ contains the four off-diagonal terms $u_{i+1,j}+u_{i-1,j}+u_{i,j+1}+u_{i,j-1}$. On the other hand, the row in $A_2\boldsymbol{u}$ corresponding to point $(i+1,j)$ includes the term $u_{i,j}$, whether $(i+1,j)$ is an interior or a boundary point. The same argument applies to the other three off-diagonal terms. When (i,j) is a boundary point, the corresponding row in $A_2\boldsymbol{u}$ contains at most three off-diagonal terms. For example, let one of these terms be $u_{i+1,j}$. Again, the row in $A_2\boldsymbol{u}$ corresponding to point $(i+1,j)$ includes the term $u_{i,j}$. We conclude that the matrix A_2 is symmetric.

Since the sum of all elements on each row of A_2 is less than or equal to zero, the Gershgorin circle theorem implies that A_2 is negative semidefinite. We proceed by showing that A_2 is negative definite. We begin with the case when Γ is convex; see Figure 2. Let us define the inner product between two real-valued grid functions $\boldsymbol{u}$ and $\boldsymbol{v}$ by

$$(\boldsymbol{u},\boldsymbol{v})_h = \sum_{i=1}^{N}\sum_{j=js(i)}^{je(i)} u_{i,j}v_{i,j} \equiv \sum_{j=1}^{M}\sum_{i=is(j)}^{ie(j)} u_{i,j}v_{i,j}.$$

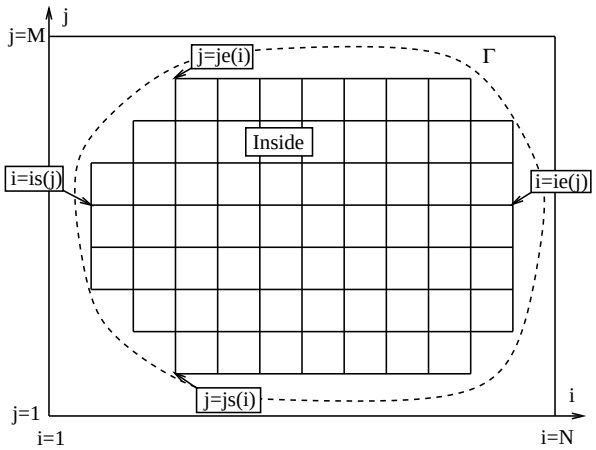

FIG. 2. *Notation used to show that A_2 is negative definite.*

It is convenient to treat the terms in $(\boldsymbol{u}, A_2\boldsymbol{u})_h$ "dimension by dimension." We have

$$
\begin{aligned}
(\boldsymbol{u}, A_2\boldsymbol{u})_h &= \sum_{i=1}^{N} S_1(i) + \sum_{j=1}^{M} S_2(j),\\
S_1(i) &= \sum_{j=js(i)+1}^{je(i)-1} u_{i,j} D_+^y D_-^y u_{i,j} + \frac{1}{h^2} u_{i,js(i)}(-2u_{i,js(i)} + u_{i,js(i)+1})\\
&\quad + \frac{1}{h^2} u_{i,je(i)}(-2u_{i,je(i)} + u_{i,je(i)-1}),\\
S_2(j) &= \sum_{i=is(j)+1}^{ie(j)-1} u_{i,j} D_+^x D_-^x u_{i,j} + \frac{1}{h^2} u_{is(j),j}(-2u_{is(j),j} + u_{is(j)+1,j})\\
&\quad + \frac{1}{h^2} u_{ie(j),j}(-2u_{ie(j),j} + u_{ie(j)-1,j}).
\end{aligned}
$$

The sum in $S_1(i)$ satisfies

$$
\begin{aligned}
\sum_{j=js(i)+1}^{je(i)-1} u_{i,j} D_+^y D_-^y u_{i,j} &= \sum_{j=js(i)+1}^{je(i)-1} u_{i,j} \frac{1}{h}(D_-^y u_{i,j+1} - D_-^y u_{i,j})\\
&= -\sum_{j=js(i)+1}^{je(i)-1} (D_-^y u_{i,j})^2 - \frac{u_{i,js(i)}}{h} D_-^y u_{i,js(i)+1} + \frac{u_{i,je(i)-1}}{h} D_-^y u_{i,je(i)}.
\end{aligned}
$$

Now, the two last terms in $S_1(i)$ satisfy

$$
\begin{aligned}
&\frac{u_{i,js(i)}}{h^2}(-2u_{i,js(i)} + u_{i,js(i)+1}) + \frac{u_{i,je(i)}}{h^2}(-2u_{i,je(i)} + u_{i,je(i)-1})\\
&\qquad = -\frac{u_{i,js(i)}^2}{h^2} + \frac{u_{i,js(i)}}{h} D_-^y u_{i,js(i)+1} - \frac{u_{i,je(i)}^2}{h^2} - \frac{u_{i,je(i)}}{h} D_-^y u_{i,je(i)}.
\end{aligned}
$$

Therefore,

$$S_1(i) = -\sum_{j=js(i)+1}^{je(i)} (D_-^y u_{i,j})^2 - \frac{u_{i,js(i)}^2}{h^2} - \frac{u_{i,je(i)}^2}{h^2}.$$

In the same way,

$$S_2(j) = -\sum_{i=is(j)+1}^{ie(j)} (D_-^x u_{i,j})^2 - \frac{u_{is(j),j}^2}{h^2} - \frac{u_{ie(j),j}^2}{h^2}.$$

Since all terms in $(\boldsymbol{u}, A_2\boldsymbol{u})_h$ are less than or equal to zero, $(\boldsymbol{u}, A_2\boldsymbol{u})_h$ can only be zero if all terms are zero. For example, $S_1(i) = 0$ if and only if

$$\begin{aligned} D_-^y u_{i,j} &= 0, \quad js(i)+1 \le j \le je(i), \\ u_{i,js(i)} &= 0, \\ u_{i,je(i)} &= 0, \end{aligned}$$

which implies $u_{i,j} \equiv 0$, $js(i) \le j \le je(i)$. In the same way, $S_2(j) = 0$ if and only if $u_{i,j} \equiv 0$, $is(j) \le i \le ie(j)$. This proves that $(\boldsymbol{u}, A_2\boldsymbol{u})_h = 0$ if and only if $\boldsymbol{u} \equiv 0$. The nonconvex case can be handled in the same way, except that the terms S_1 and S_2 must be divided into several parts, corresponding to the number of times the boundary splits the same grid line. Hence, the matrix A_2 is negative definite for both convex and nonconvex boundaries.

We have shown that both A_1 and A_2 are symmetric, A_1 is negative semidefinite, and A_2 is negative definite. Hence, Lemma 2.2 applies, so the time-step restriction of (4.2), (4.5) is determined only by A_2, i.e., the interior formula, and the solution is uniformly bounded in time. Moreover, the solution at the new time level, $\boldsymbol{u}^{n+1}$, can be computed pointwise since the matrix A_1 is diagonal.

4.3. Accuracy. We have constructed our difference approximation "dimension by dimension." If we write the approximation in matrix form, the coefficient matrix is symmetric and negative definite. Therefore, there are no stability problems. However, it is not obvious that the approximation is second order accurate. The reason is that an exterior point P can have two interior points P_1, P_2 as neighbors, P_1 in the x-direction and P_2 in the y-direction; see Figure 3. In this case the value of u at P is not unique, since it depends on which interpolation direction we use. For our scheme, this does not matter because we eliminate $u(P)$ both from $D_+^x D_-^x u(P_1)$ and $D_+^y D_-^y u(P_2)$, using the corresponding interpolation formula. However, the usual truncation error analysis fails.

We shall now use a more refined argument to show that the approximation is second order accurate. For simplicity, we study only the semidiscrete problem where time is left continuous,

$$\frac{\partial^2 u_h}{\partial t^2} = \tilde{\Delta}_h u_h + \frac{\tilde{f}}{h^2}, \tag{4.6}$$

$$u_h(\boldsymbol{x_j}, 0) = u_0(\boldsymbol{x_j}), \quad \frac{\partial u_h}{\partial t}(\boldsymbol{x_j}, 0) = u_1(\boldsymbol{x_j}).$$

We assume that the solution of the continuous wave equation (4.1) is smooth and can be extended smoothly from Ω to a larger region Ω_1 which contains all external points

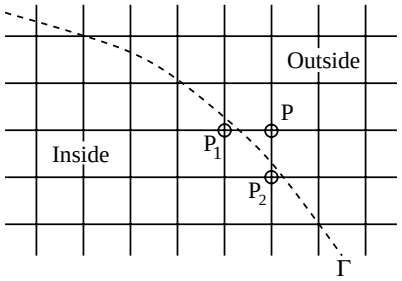

FIG. 3. *The outside point P is used when discretizing the Laplacian at both of the inside points P_1 and P_2.*

with boundary points as neighbors. Let $u(x, y, t)$ be the solution of (4.1). It solves the inhomogeneous difference equation

$$u_{tt} = \Delta_h u + h^2 G. \tag{4.7}$$

Here $h^2 G$ represents the truncation error. Let $P_1 = (x, y)$ be a boundary point and $(x + h, y)$ an exterior point. The extended solution satisfies an inhomogeneous interpolation formula:

$$(1 - \alpha_1)u(x, y, t) + \alpha_1 u(x + h, y, t) = f(x + \alpha_1 h, y, t) + h^2 g_1. \tag{4.8}$$

If also $(x, y + h)$ is an exterior point, then there is another interpolation formula:

$$(1 - \alpha_2)u(x, y, t) + \alpha_2 u(x, y + h, t) = f(x, y + \alpha_2 h, t) + h^2 g_2. \tag{4.9}$$

We use (4.8) and (4.9) to eliminate $u(x+h, y, t)$ and $u(x, y+h, t)$ from $D_+^x D_-^x u(x, y, t)$ and $D_+^y D_-^y u(x, y, t)$, respectively. After we have eliminated all exterior points, we obtain

$$u_{tt} = \tilde{\Delta}_h u + h^2 G + g + \frac{\tilde{f}}{h^2} \quad \text{for } \boldsymbol{x} = \boldsymbol{x_j},\ |m_{\boldsymbol{j}}| = 1,\ t > 0. \tag{4.10}$$

Note that $g \neq 0$ and $\tilde{f} \neq 0$ only at boundary points and $\tilde{\Delta}_h u = \Delta_h u$ at all interior points. At boundary points (x, y) (which have at least one neighboring exterior point), we obtain a q-point formula with $q \leq 4$ of the form

$$h^2 \tilde{\Delta}_h u(\boldsymbol{x}_{i,j}, t) = -(4 + d_{i,j})u(\boldsymbol{x}_{i,j}, t) + \sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}| u(\boldsymbol{x_j}, t), \tag{4.11}$$

where the sum extends over the nearest neighbors $(x_i \pm h, y_j)$, $(x_i, y_j \pm h)$, and $d_{i,j} > 0$.

Subtracting the difference approximation (4.6) from (4.10) gives us, for the error $e = u - u_h$,

$$\begin{aligned} e_{tt} &= \tilde{\Delta}_h e + h^2 G + g, \\ e(\cdot, 0) &= e_t(\cdot, 0) = 0. \end{aligned}$$

To analyze the effect the term g has on the error, we study

$$\tilde{\Delta}_h \varphi = g.$$

Away from the boundary, $g = 0$ and $\tilde{\Delta}_h = \Delta_h$. It is easy to show that the solution of

$$\begin{aligned} \Delta_h \phi_{i,j} &= 0, \qquad m_{i,j} = 1, \\ \phi_{i,j} &= \gamma_{i,j}, \quad m_{i,j} = -1, \end{aligned}$$

takes its maximum at a boundary point (where $m_{i,j} = -1$). Let (x_i, y_j) be the boundary point where $|\varphi(x_i, y_j)| = |\varphi|_\infty$. From (4.11) we have

$$(4 + d_{i,j})|\varphi|_\infty \le \sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}||\varphi|_\infty + h^2 |g|_\infty.$$

Hence,

$$|\varphi|_\infty \le \frac{h^2}{4 + d_{i,j} - \sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}|} |g|_\infty.$$

Since $d_{i,j} > 0$ and $\sum_{\boldsymbol{j}} |m_{\boldsymbol{j}}| \le 3$,

$$|\varphi|_\infty \le h^2 |g|_\infty.$$

From the definition of g, it is a smooth function of t. Therefore, $\tilde{e} = e + \varphi$ solves

$$\tilde{e}_{tt} = \tilde{\Delta}_h \tilde{e} + h^2 G + \varphi_{tt}, \quad |\varphi_{tt}|_\infty \le h^2 |g_{tt}|_\infty,$$

i.e.,

$$|e|_\infty = \mathcal{O}(h^2).$$

This shows that the approximation is second order accurate.

5. Numerical examples. In this section we consider (4.1) with a forcing function,

$$\begin{aligned} u_{tt} &= \Delta u + F(\boldsymbol{x}, t), && \boldsymbol{x} \in \Omega, \quad t > 0, \\ u(\boldsymbol{x}, t) &= f(\boldsymbol{x}, t), && \boldsymbol{x} \in \Gamma, \quad t > 0, \\ u(\boldsymbol{x}, 0) &= u_0(\boldsymbol{x}), \quad u_t(\boldsymbol{x}, 0) = u_1(\boldsymbol{x}), && \boldsymbol{x} \in \Omega. \end{aligned} \tag{5.1}$$

This problem will be solved by both a fully second and an internally fourth order accurate method, and the forcing functions will be chosen such that an exact solution is known. The second order scheme is given by (4.2) and (4.5), and the internally fourth order scheme is obtained by adding the correction term

$$\Delta_{h,4} v^n_{i,j} = -\frac{h^2}{12} \left(D^x_+ D^x_- \gamma_{i,j} D^x_+ D^x_- + D^y_+ D^y_- \gamma_{i,j} D^y_+ D^y_- \right) v^n_{i,j}$$

to the right-hand sides of (4.2) and (4.5), respectively. Here

$$\gamma_{i,j} = \begin{cases} 1, & m_{i,j} = 1, \\ 0 & \text{otherwise}, \end{cases}$$

where $m_{i,j}$ is defined in section 4.1.

The correction term $\Delta_{h,4} v^n_{i,j}$ gives a symmetric negative semidefinite contribution to the matrix representation of the scheme that does not involve the boundary.

TABLE 1
Grid refinement study for the Dirichlet problem for a trigonometric exact solution; CFL = 0.5.

	2'nd order error			4'th order error		
t	$N = 100$	$N = 200$	ratio	$N = 100$	$N = 200$	ratio
0.330	2.54e-02	5.77e-03	4.4	1.27e-02	3.58e-03	3.5
1.980	2.30e-02	5.47e-03	4.2	1.46e-02	3.97e-03	3.7

Hence, the internally fourth order scheme is stable. However, the internally fourth order scheme can be expected to be only second order accurate near the boundary, since a second order approximation of the Dirichlet boundary condition is used. For simplicity, the internally fourth order scheme will henceforth be called the fourth order scheme.

We start the numerical integration at $n = 0$. For the cases where an analytical solution is known, we use this solution to initialize the computation at time levels t_{-1} and t_0. For the cases where an analytical solution is not known we use the initialization

$$v_{i,j}^{-1} = u_0(x_i, y_j) - k u_1(x_i, y_j) + \frac{k^2}{2}(D_+^x D_-^x + D_+^y D_-^y) u_0(x_i, y_j),$$

and $v_{i,j}^0 = u_0(x_i, y_j)$.

We will denote the CFL-number by $\mathrm{CFL} \equiv k/h$. Note that for a two-dimensional periodic domain, the scheme (4.2) is stable for $\mathrm{CFL} \leq 1/\sqrt{2}$. Also note that all errors are measured in the max-norm.

5.1. Convergence study for a trigonometric exact solution. Let us choose the forcing function F and boundary data f such that the exact solution is the trigonometric traveling wave

$$u(x, y, t) = \sin(\omega(x - t)) \sin(\omega y), \quad \omega = 4\pi. \tag{5.2}$$

The domain Ω is taken to be an ellipse centered at the origin with semiaxes $x_s = 1$ and $y_s = 0.75$. The Cartesian grid covers the rectangle $-1.1 \leq x \leq 1.1$, $-0.85 \leq y \leq 0.85$. In Table 1, we present a grid refinement study for the two schemes with CFL= 0.5. In Table 2 we present the same study with CFL=0.1. Note that the error in the second order scheme is not improved by decreasing the CFL number, indicating that the error is dominated by spatial discretization errors. The error for the fourth order scheme is improved somewhat by decreasing the CFL number, implying that temporal discretization errors cannot be neglected when CFL= 0.5. For both CFL-numbers, the error is smaller for the fourth order scheme than for the second order scheme. However, the order of convergence is only around two for the fourth order scheme and CFL= 0.1. In section 3.2 the spatial discretization error is shown to consist of a second order amplitude error arising from the boundary discretization and a fourth order phase error originating from the discretization in the interior. It is therefore likely that the dominant errors for the fourth order scheme and CFL= 0.1 are generated at the boundary.

5.2. Convergence study for an inwards traveling wave solution in a circle. To illustrate the benefits of using a fourth order scheme away from the boundary, we select the forcing function F and boundary data f such that the exact solution

TABLE 2

TABLE 3
Grid refinement study for the Dirichlet problem for an inwards traveling wave solution. Here, CFL = 0.5.

	2'nd order error			4'th order error
t	$N = 400$	$N = 800$	ratio	$N = 400$
0.315	1.51e-02	3.66e-03	4.12	6.51e-03
0.525	3.29e-02	8.79e-03	3.75	1.15e-02
1.155	8.44e-02	2.67e-02	3.17	3.29e-02
1.365	1.03e-01	3.40e-02	3.03	4.16e-02

(in polar coordinates) is a spatially localized traveling wave,

$$u(r,t) = \phi(r+t), \quad \phi(\xi) = \frac{1}{4}\left(1 + \tanh\frac{\xi-\xi_0}{\epsilon}\right)\left(1 - \tanh\frac{\xi-\xi_1}{\epsilon}\right). \tag{5.3}$$

Note that such waves are exact solutions to the unforced wave equation in one and three space dimensions, but they are not in the two-dimensional case. The domain Ω is taken to be the circle, $|r| \le 2$, and the Cartesian grid covers the square $-2.1 \le x \le 2.1$, $-2.1 \le y \le 2.1$.

The parameters in the exact solution are chosen so that initially the wave is essentially outside the domain and enters the region through the boundary after some time. To make the problem challenging to solve numerically, we make the transitions around $\xi = \xi_0$ and $\xi = \xi_1$ rapid and close together by choosing

$$\xi_0 = 2.2, \quad \xi_1 = 2.4, \quad \epsilon = 0.035.$$

The maximum of the wave reaches the boundary at $t = 0.3$ and has passed through the boundary after $t \approx 0.4 - 0.5$. In Table 3 we present a study of the errors for the two schemes with CFL= 0.5 both when the wave has reached the boundary and after the wave has passed the boundary. In Table 4 we present a similar study but with CFL= 0.1. Note first that the error in the fourth order scheme is improved by decreasing the CFL-number for $N = 400$, indicating again that time discretization errors are not small when CFL= 0.5. Furthermore, note that the fourth order method with CFL= 0.1 gives close to fourth order accuracy after the wave has passed the boundary, implying that the phase error dominates; see the discussions in sections 5.1 and 3.2. Also, the error in the second order scheme does not improve when the CFL number is decreased, indicating again that the second order scheme is dominated by spatial discretization errors. When 400 grid points are used in each direction, the second order scheme produces a solution that has many spurious oscillations, while the fourth order scheme gives a much cleaner result; see Figure 4.

5.3. Convergence study for an outwards traveling wave solution in a circle. To further study the benefits of using a fourth order scheme away from the boundary, we let the exact solution be an outwards traveling wave,

$$u(r,t) = \phi(r-t), \tag{5.4}$$

where ϕ is given by (5.3). The domain Ω is in this case taken to be the unit circle, $|r| \le 1$, and the Cartesian grid covers the square $-1.1 \le x \le 1.1$, $-1.1 \le y \le 1.1$. Here, the parameters in ϕ are taken to be

$$\xi_0 = 0.2, \quad \xi_1 = 0.4, \quad \epsilon = 0.035.$$

The wave reaches the boundary at $t \approx 0.5 - 0.6$ and has passed through the boundary after $t \approx 0.8 - 0.9$. In Table 5 we present a grid convergence study for the two schemes with CFL= 0.5 before and after the wave has passed the boundary. In Table 6 we present the same study but with CFL= 0.1. Note that the fourth order method gives fourth order convergence for the smaller CFL-number before the wave reaches the boundary and gives second order convergence after the wave has reached the boundary. When 200 grid points are used in each direction, the second order scheme produces a solution that has many spurious oscillations, while the fourth order scheme gives a much cleaner result; see Figure 5.

5.4. Bouncing wave in an ellipse. Here we study the homogeneous problem

$$F(\boldsymbol{x}, t) \equiv 0, \quad f(\boldsymbol{x}, t) \equiv 0,$$

in a domain bounded by an ellipse centered at the origin, with semiaxes $x_s = 2.0$ and $y_s = 2.54$. The Cartesian grid covers the square $-2.1 \le x \le 2.1$, $-2.64 \le y \le 2.64$. We take initial data to be

$$u_0(x, y) = \phi(r),$$

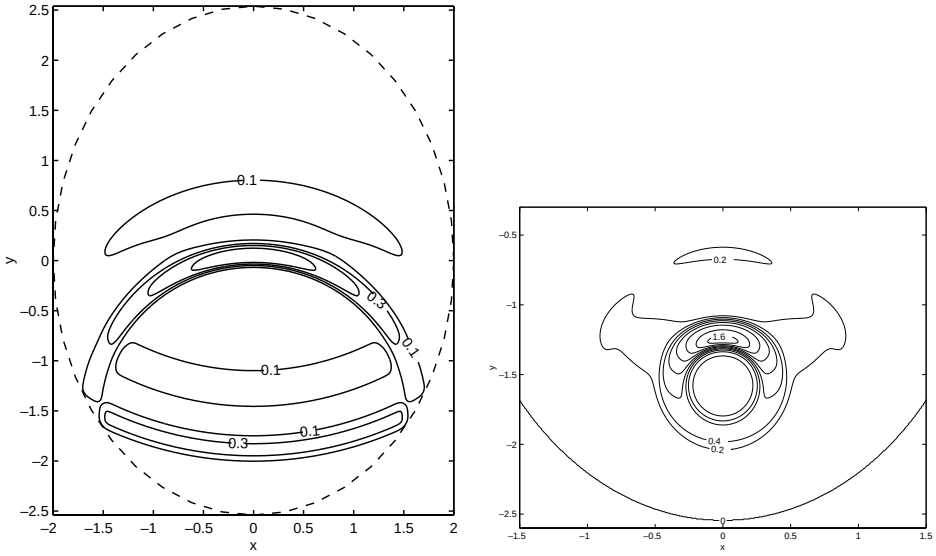

FIG. 6. *The bouncing wave reference solution for the Dirichlet problem with the fourth order scheme at* $t = 3.15$ *(left) and* $t = 4.41$ *(right). Here* $N = 800$, CFL $= 0.1$. *The contour spacing is* 0.2*, and the dashed curve in the left plot indicates the boundary.*

where $\phi(r)$ is given by (5.3) and $r = \sqrt{x^2 + (y - y_F)^2}$. The upper focal point is located at $y_F = \sqrt{y_s^2 - x_s^2} \approx 1.56$ and

$$u_1(\boldsymbol{x}) = u_1(r) = -\phi'(r).$$

The parameters in $\phi(r)$ are

$$\xi_0 = 0.2, \quad \xi_1 = 0.4, \quad \epsilon = 0.035.$$

Note that the initial data is chosen such that the wave is essentially traveling in the positive r-direction out from the focal point $(0, y_F)$. By making a ray-tracing argument, we see that a high frequency wave should reflect the boundary and refocus at the other focal point $(0, -y_F)$. To verify this behavior, we make a reference calculation using a fine grid with $N = 800$ and the fourth order method with CFL$=$ 0.1. We then make calculations with $N = 400$ and $N = 100$ for the fourth and the second order methods. These solutions are compared to the reference calculation at the time $t = 4.41$, just before the solution is refocused at the other focal point. In Figure 6, we show contour plots of the reference calculation at $t = 3.15$ and $t = 4.41$. In Figure 7, we display contour plots of the solutions using the fourth and second order schemes for $N = 400$ at $t = 4.41$. We also plot the numerical solutions along the line $x = 0$, where the deviation from the reference solution is the largest; see Figure 8. In Figures 9 and 10, the corresponding calculations are presented for $N = 100$. Clearly, the fourth order method gives the best result.

6. Conclusions. Numerical methods have been proposed and analyzed for solving a second order wave equation without first writing it as a first order system. Both the Dirichlet and the Neumann problems were treated for the one-dimensional case. The Dirichlet problem was analyzed in detail for general two-dimensional domains, and we proved that the proposed scheme is stable and conservative both for second and

fourth order spatial discretizations. We are currently working on the two-dimensional Neumann problem [7], and we plan to extend the approach to three space dimensions.

For the fourth order spatial discretization, we have seen that the second order temporal discretization error cannot be neglected unless the CFL-number is reduced substantially below the stability limit. In future work we intend to develop a higher order time integration method where the accuracy better matches that of the fourth order spatial discretization.

In many applications the wave propagation speed varies in space. We see no difficulty modifying our approach to handle smoothly varying coefficients, but additional work will be required to treat discontinuous coefficients. Systems of second order wave equations also occur in applications, for example in general relativity. Another example is Maxwell's equations for electromagnetic wave propagation, which often is given as a first order system, but also can be written as a second order system. We believe that generalizing the proposed method to systems will provide an accurate and straightforward technique for analyzing these types of problems.

FULLY DISCRETE, ENTROPY CONSERVATIVE SCHEMES OF ARBITRARY ORDER*

P. G. LEFLOCH†, J. M. MERCIER‡, AND C. ROHDE§

Abstract. We consider weak solutions of (hyperbolic or hyperbolic-elliptic) systems of conservation laws in one-space dimension and their approximation by finite difference schemes in conservative form. The systems under consideration are endowed with an entropy-entropy flux pair. We introduce a general approach to construct *second and third order accurate, fully discrete* (in both space and time) *entropy conservative schemes.* In general, these schemes are fully nonlinear implicit, but in some important cases can be explicit or linear implicit. Furthermore, semidiscrete entropy conservative schemes of *arbitrary order* are presented. The entropy conservative schemes are used to construct a numerical method for the computation of weak solutions containing nonclassical regularization-sensitive shock waves. Finally, specific examples are investigated and tested numerically. Our approach extends the results and techniques by Tadmor [in *Numerical Methods for Compressible Flows—Finite Difference, Element and Volume Techniques,* ASME, New York, 1986, pp. 149–158], LeFloch and Rohde [*SIAM J. Numer. Anal.,* 37 (2000), pp. 2023–2060].

1. Introduction.

In this paper, we are interested in the numerical approximation of discontinuous solutions of general systems of conservation laws of the form

$$\partial_t u + \partial_x f(u) = 0, \qquad u = u(x,t) \in \mathbb{R}^N, \qquad x \in \mathbb{R},\ t > 0, \tag{1.1}$$

endowed with a smooth entropy-entropy flux pair $(U, F) : \mathbb{R}^N \to \mathbb{R}^2$. In (1.1), the flux-function $f : \mathbb{R}^N \to \mathbb{R}^N$ is a smooth given mapping. As is well known, we should seek solutions satisfying the entropy inequality

$$\partial_t U(u) + \partial_x F(u) \leq 0 \tag{1.2}$$

understood in the sense of distributions.

From the numerical standpoint, following Lax and Wendroff [12], it is natural to search for (fully discrete in space and time) conservative schemes associated with (1.1) which, furthermore, satisfy a discrete version of the inequality (1.2). Whenever the Cauchy problem for (1.1)–(1.2) is well-posed (for instance, when (1.1) is a scalar conservation law with convex flux) such a scheme can converge only to the (so-called) entropy solution of interest.

Weak (entropy) solutions of (1.1) can be considered as limits of solutions of higher order systems with vanishing regularization terms. The physical meaning of these terms comes from viscosity, heat conduction, or capillarity usually leading to a smooth

solution that satisfies (1.2) in the pointwise sense. In some situations it is necessary to control explicitly the rate of dissipation that one introduces (in the continuous as well as in the discrete setting).

In this context it has been suggested that the numerical approximation of (1.1) should be based on schemes satisfying (1.2) as an *equality* (cf. [10]), that is

$$\partial_t U(u) + \partial_x F(u) = 0. \tag{1.3}$$

High order terms such as viscosity, heat conduction, capillarity, etc., should then be added to such an *entropy conservative scheme* in a way to get an *entropy dissipative scheme*, i.e., satisfying a discrete (consistent) version of (1.2). The notion of *entropy conservative* schemes for conservation laws was introduced first and investigated in a pioneering work by Tadmor [24, 25] when constructing semidiscrete difference schemes satisfying a discrete form of (1.2). For another approach we refer to [21]. In a close context, linear implicit, fully discrete, *energy conservative* schemes were designed in Aregba-Driollet and Mercier [4] (in the spirit of a fully nonlinear scheme introduced by Strauss and Vasquez [22]) to study solutions of semilinear hyperbolic systems satisfying an *energy conservation*, i.e., satisfying (1.3) for a (possibly nonconvex) energy U.

In the light of the above work, attention in the present paper is focused precisely on constructing fully discrete, conservative, and entropy conservative schemes for conservation laws, consistent with both (1.1) and (1.3).

The investigation of semidiscrete schemes (keeping the time variable continuous) was completed only recently. A second order entropy conservative scheme was discovered by Tadmor [24, 25] who introduced this notion in order to construct schemes satisfying a discrete form of (1.2). Next, the notion was further investigated by LeFloch and Rohde [16], who discovered a class of third order entropy conservative schemes.

The study of fully discrete schemes for diffusive-dispersive conservation laws was initiated by Chalons and LeFloch [5]. The authors made a direct use of the semidiscrete numerical fluxes proposed in the earlier papers. By enforcing a suitable CFL stability condition, the entropy inequality (1.2) holds, provided diffusive terms are taken into account in the right-hand side of (1.1).

Our motivation to construct entropy conservative schemes was to study systems of conservation laws that either have nonconvex modes or are of hyperbolic-elliptic type. In this paper we will focus on two representative examples: the first is the cubic scalar conservation law, a nonconvex hyperbolic equation, for which dynamics is well understood and which is used as a test model. The second is a p-system that models adiabatic phase transition dynamics, a hyperbolic-elliptic system; see Truskinovsky [26], Abeyaratne and Knowles [2, 3], and LeFloch [13] for related results in the linearly degenerate case, and see Mercier and Piccoli [18] and references therein for the genuinely nonlinear case. The main difficulty of a nonconvex hyperbolic or hyperbolic-elliptic system of conservation laws is that the single entropy inequality (1.2) does not characterize a unique solution of the system and further selection mechanisms must be added, specifically the so-called *kinetic relation.* For general nonconvex systems, we refer to Hayes and LeFloch [9], LeFloch and Thanh [17], and LeFloch [14].

Kinetic relations can be determined in several situations from physics. From the mathematical point of view they can be exhibited from regularization terms. Kinetic regularizations associated with difference schemes were numerically determined and

compared with analytical kinetic relations in [10]. The dependence of the kinetic relation upon physical and numerical parameters was discussed therein.

An important point is that capillarity terms require high order schemes (at least third order). Thus our first aim is to derive a general approach to construct finite difference schemes for systems of conservation laws that are

(1) fully discrete in space and time,
(2) conservative in the sense of Lax and Wendroff [12],
(3) entropy conservative in the sense of Tadmor [23, 24],
(4) and high order accurate (at least third order).

This program will be carried out in sections 2 and 3. First, we propose a general approach for the construction of such schemes in section 2. Next, in section 3, several classes of second and third order schemes are identified, which can be fully implicit, linear implicit, or explicit methods. This is certainly not a straightforward task. Recall that, for nonaffine f, there are no two time-level, fully discrete, *explicit,* and conservative schemes with smooth numerical flux satisfying a discrete version of the entropy equality; see [16].

In section 4 we return to the investigation of semidiscrete schemes. We will present entropy conservative schemes of *arbitrarily high order*. This can be transferred to the fully discrete case, however, only for a weaker form of entropy conservation.

Finally in section 5, adding appropriate dissipative terms, we will obtain schemes for the above mentioned model problems. Numerical experiments presented in particular in section 6 underline their good performance.

We emphasize that the techniques developed in this paper also apply to other types of evolution equations for which an energy conservation or dissipation is available, such as the heat, Schrödinger, or wave equations. A first result in this direction is given in the second part of subsection 5.2 (Theorem 5.2). Furthermore, these techniques, considered in the one dimensional case, apply straightforwardly to higher dimensions when using Cartesian grids.

2. A general approach to construct entropy conservative schemes. In this section we propose a general method to construct fully discrete, conservative, and entropy conservative schemes.

We follow the notation in Tadmor [24] and LeFloch and Rohde [16]. Call $v(u) = \nabla U(u)$ the *entropy variable* associated with the given entropy U. When the entropy is strictly convex, $v \mapsto v(u)$ is a one-to-one mapping. This can be used as a change of variable (Friedrichs and Lax [7]); that is, we can set

$$g(v) := f(u), \quad G(v) := F(u), \quad B(v) := Dg(v). \tag{2.1}$$

The matrix $B(v)$ is symmetric since $Dg(v) = Df(u)D^2U(u)^{-1}$ is symmetric matrix for U being a strictly convex entropy. It follows that there exists a scalar-valued function $\psi = \psi(v)$ such that $g = \nabla\psi$; in fact

$$\psi(v) = v \cdot g(v) - G(v), \tag{2.2}$$

uniquely defined up to a constant.

Furthermore, to deal with examples when U is not globally convex, the following assumption on the flux-function of (1.1) is made:

(2.3) $f(u)$ and $F(u)$ can be expressed as functions of the entropy variable v;

that is, (2.1) holds for some functions g and G. Then, again, ψ can be defined by (2.2). The assumption (2.3), which we make from now on, is motivated by several examples of interest; see [16] and section 5 below. We stress that (2.3) holds in $\mathbb{R}^N$ when U is strictly convex.

For mesh parameters $h, \tau > 0$, let $x_j = j\,h$, $j \in \mathbb{Z}$, and $t_n = n\,\tau$, $n \in \mathbb{N}_0$. We set $\lambda \equiv \tau/h$ and start discussing the (multilevel) time discretization. For $q \in \mathbb{N}$, choose a locally Lipschitz continuous mapping

$$u^* : \left(u^{-q+1}, \ldots, u^0\right) \in \mathbb{R}^{qN} \mapsto u^*\left(u^{-q+1}, \ldots, u^0\right) \in \mathbb{R}^N$$

consistent with the conservative variable u in the sense that

$$u^*(u, \ldots, u) = u, \quad u \in \mathbb{R}^N.$$

It will be called the *discrete conservative variable* in what follows. The integer q indicates the number of time-levels used by the scheme and is related to the order of accuracy in time. Setting $u_j^{*n} = u^*(u_j^{n-q+1}, \ldots, u_j^n)$, we approximate the continuous derivative $\partial_t u$ in (1.1) by the following discrete derivative:

$$\frac{u_j^{*n+1} - u_j^{*n}}{\tau}.$$

To guarantee that the difference equation is solvable in terms of the conservative variable u_j^{n+1}, we assume that

$$\text{(2.4)} \qquad \begin{array}{c} \text{the mapping } u \mapsto u^*\left(u^{n-q+1}, \ldots, u^n, u\right) \text{ is smoothly invertible} \\ \text{for all } u^{n-q+1}, \ldots, u^n \in \mathbb{R}^N. \end{array}$$

Next, choose some locally Lipschitz continuous mapping

$$U^* : (u^{-q+1}, \ldots, u^0) \in \mathbb{R}^{qN} \mapsto U^*\left(u^{-q+1}, \ldots, u^0\right) \in \mathbb{R}$$

consistent with the continuous entropy; i.e.,

$$U^*(u, \ldots, u) = U(u), \quad u \in \mathbb{R}^N.$$

It will be called the *discrete entropy function*. Also set $U_j^{*n} = U^*(u_j^{n-q+1}, \ldots, u_j^n)$.

As we will see below the two functions u^* and U^* cannot be chosen arbitrarily from each other. We make the following assumption.

Assumption 2.1. There exists a continuous mapping $v^* : \mathbb{R}^{(N+1)q} \to \mathbb{R}^N$ with the properties

$$\text{(2.5)} \qquad \begin{array}{ll} \text{(i)} & v^*(u, \ldots, u) = v(u) \qquad (v \in \mathbb{R}^N), \\ \text{(ii)} & U^*\left(u^{-q+1}, \ldots, u^0\right) - U^*\left(u^{-q}, \ldots, u^{-1}\right) \\ & \quad = \left(u^*\left(u^{-q+1}, \ldots, u^0\right) - u^*\left(u^{-q}, \ldots, u^{-1}\right)\right) \cdot v^*\left(u^{-q}, \ldots, u^0\right). \end{array}$$

v^* is called a discrete entropy variable.

Finally, we also set

$$v_j^{*n+1} = v^*\left(u_j^{n-q+1}, \ldots, u_j^{n+1}\right).$$

The validity of Assumption 2.1 will be discussed later on for specific examples.

We now turn to discuss the space discretization, based on a discrete flux

$$g^* : (v_{-p+1}, \dots, v_p) \in \mathbb{R}^{2pN} \mapsto g^*(v_{-p+1}, \dots, v_p) \in \mathbb{R}^N,$$

consistent with the continuous flux-function $g(v)$; i.e.,

$$g^*(v, \dots, v) = g(v), \quad v \in \mathbb{R}^N.$$

Observe that now we rely directly on the entropy variable v. Here the integer p indicates that the scheme uses $2p+1$ space-levels and is related to the order of accuracy in space: setting

$$g^{*n+1}_{j+1/2} = g^*\left(v^{*n+1}_{j-p+1}, \dots, v^{*n+1}_{j+p}\right),$$

we are led to a space discretization by replacing the continuous derivative $\partial_x g(v) = \partial_x f(u)$ in (1.1) with

$$\frac{g^{*n+1}_{j+1/2} - g^{*n+1}_{j-1/2}}{h}.$$

Our approach relies on entropy conservative discrete fluxes. Recall from [25] that a discrete flux g^* (expressed in the entropy variable v) is *entropy conservative* if there exists a *discrete entropy flux*

$$G^* : (v_{-p+1}, \dots, v_p) \in \mathbb{R}^{2pN} \mapsto G^*(v_{-p+1}, \dots, v_p) \in \mathbb{R}$$

consistent with the entropy flux $G(v)$ such that

$$\begin{aligned} v_0 \cdot \Big(g^*(v_{-p+1}, \dots, v_p) - g^*(v_{-p}, \dots, v_{p-1}) \Big) \\ = \quad G^*(v_{-p+1}, \dots, v_p) - G^*(v_{-p}, \dots, v_{p-1}). \end{aligned} \tag{2.6}$$

Finally, also set

$$G^{*n+1}_{j+1/2} = G^*\left(v^{*n+1}_{j-p+1}, \dots, v^{*n+1}_{j+p}\right).$$

The existence of such entropy conservative fluxes will be discussed below. First we state the central result of this section, providing a general approach to construct classes of fully discrete schemes.

THEOREM 2.2. *Consider a hyperbolic or hyperbolic-elliptic system of conservation laws* (1.1) *endowed with an entropy-entropy flux pair* (U, F) *satisfying condition* (2.3). *Consider a discrete conservative variable* u^* *and a discrete entropy function* U^* *such that Assumption* 2.1 *holds. For* $n \in \mathbb{N}$ *fixed, let the sequence* $\{u^n_j\}_{j\in\mathbb{Z}}$ *in* $\mathbb{R}^N$ *be given.*

Then, for any entropy conservative discrete flux g^* *and* $0 < \lambda << 1$, *the* $(q+1) \times (2p+1)$*-point difference equation*

$$u^{*n+1}_j - u^{*n}_j + \lambda \left(g^{*n+1}_{j+1/2} - g^{*n+1}_{j-1/2} \right) = 0 \qquad (j \in \mathbb{Z}) \tag{2.7}$$

has a unique solution $u^{n+1}_j \in \mathbb{R}^N$.

The associated scheme is entropy conservative with respect to U^* *in the sense that*

$$U^{*n+1}_j - U^{*n}_j + \lambda \left(G^{*n+1}_{j+1/2} - G^{*n+1}_{j-1/2} \right) = 0 \qquad (n \in \mathbb{N}, j \in \mathbb{Z}). \tag{2.8}$$

Proof. The result follows from the discussion preceding the theorem. Indeed, in view of (2.4) and (2.5) and by applying the inverse function theorem, there exists $0 < \lambda << 1$ for which (2.7) determines a unique solution u_j^{n+1}. Next, multiplying (2.7) by v_j^{*n+1}, we obtain

$$\left(u_j^{*n+1} - u_j^{*n}\right) \cdot v_j^{*n+1} = \lambda \left(g_{j+1/2}^{*n+1} - g_{j-1/2}^{*n+1}\right) \cdot v_j^{*n+1}.$$

The conservative form (2.8) is a direct consequence of the definitions of discrete entropy variable (2.5) and entropy conservative discrete flux (2.6). ∎

It is the main goal of the following sections to show precisely that the framework in Theorem 2.2 covers a variety of situations of practical interest.

NOTE 2.3.

(1) *The key points for using Theorem* 2.2 *are an appropriate choice of the functions* u^*, U^* *such that Assumption* 2.1 *holds and entropy conservative discrete fluxes* g^* *exist. The choice of the functions* u^*, U^* *will be discussed in section* 3. *A second order entropy conservative discrete flux has been designed in* [25]. *Third order entropy conservative fluxes have been derived in* [16]. *In section* 4 *below, we will return to constructing even higher order entropy conservative fluxes.*

(2) *The entropy equality* (2.8) *implies the following nonlinear stability property:*

$$\sum_{j=-\infty}^{\infty} U_j^{*n} = \text{const.}$$

Depending on the properties of the discrete entropy U^*, *this may provide us with some a priori bound on the discrete solution. For instance, if* U^* *is strictly convex, essentially we recover the* L^2*-stability of the scheme. In general,* (2.7) *is a fully nonlinear implicit scheme. As we have an implicit scheme we may expect to have stability for large CFL-numbers. However, convergence of an iterative method for solving the nonlinear system might enforce a stricter CFL-like condition.*

(3) *In general, the schemes* (2.7) *are fully implicit. However, in some situations of interest we obtain linear implicit or even explicit schemes (section* 3*).*

3. Two and three time-level entropy conservative schemes. In this section we give first applications of Theorem 2.2. We start investigating the simplest case of a two time-level discretization. We will see that such schemes are always fully nonlinear, except in the case of linear systems of conservation laws. Next we investigate three time-level schemes, for which there exists more freedom in choosing a convenient discretization of the entropy. We use this freedom to construct explicit or linear implicit schemes of third order.

We will rely on the consistent entropy conservative numerical flux-function g_2^* that has been constructed by Tadmor [25]; i.e.,

$$g_2^*(v_0, v_1) = \int_0^1 g(v_0 + s\,(v_1 - v_0))\, ds, \qquad v_0, v_1 \in \mathbb{R}^N. \tag{3.1}$$

The associated numerical entropy flux reads as

$$\begin{aligned} G_2^*(v_0, v_1) &= \frac{G(v_0) + G(v_1)}{2} + \frac{(v_0 + v_1)}{2} \cdot g_2^*(v_0, v_1) \\ &\quad - \frac{1}{2}\left(v_0 \cdot g(v_0) + v_1 \cdot g(v_1)\right). \end{aligned} \tag{3.2}$$

3.1. A class of two time-level entropy conservative schemes. We first consider schemes based on two time-levels only and on two-point discrete fluxes. Consider the following discretization

$$u_j^{n+1} = u_j^n - \lambda \left(g_{j+1/2}^{*n+1} - g_{j-1/2}^{*n+1} \right) \tag{3.3}$$

corresponding to the simple choice $q = 1$:

$$u^* \left(u^0 \right) = u^0.$$

For schemes with $q = 1$ the only consistent entropy is $U^*(u) = U(u)$. The only two-point entropy conservative flux is the one proposed by Tadmor. We get the following result from Theorem 2.2.

THEOREM 3.1. *Let $u^*(u) = u$, $U^*(u) = U(u)$. Let Assumption* 2.1 *be valid. Then the scheme* (3.3) *considered with Tadmor flux* (3.1) *is entropy conservative with respect to the entropy U^*. Furthermore, this scheme is second order accurate in space and time in the sense that its equivalent equation is*

$$\partial_t u(x_j, t^{n+1/2}) + \partial_x g(v(x_j, t^{n+1/2})) = \mathcal{O}(h^2).$$

To satisfy Assumption 2.1 we can choose v^* to be

$$v^*(u^0, u^1) = \int_0^1 v(su^*(u^1) + (1-s)u^*(u^0))\, ds. \tag{3.4}$$

Note that—at least in the linear case and with $U(u) = u^2/2$—the time discretization in (3.3) is exactly the Crank–Nicholson time discretization.

In general, (3.3) with (3.4) is fully nonlinear in u_j^{n+1}. To obtain an at least linear implicit scheme, g_2^* has to be linear, and $v^* = v^*(u^0, u^1)$ has to be linear with respect to u^1. The latter is true if and only if U is quadratic. By definition, the Tadmor flux g_2^* is linear if and only if g is linear. With U to be quadratic we obtain that the flux f has to be linear. In the next section we will provide explicit and linear implicit entropy conservative schemes.

Example 3.2. For the sake of illustration of the scheme (3.3) we present a numerical experiment. We consider the scalar case

$$f(u) = U(u) = \frac{u^2}{2}.$$

This leads to the scheme

$$\begin{aligned} u_j^{n+1} = u_j^n - \frac{\lambda}{24} \Big(& (u_j^n + u_j^{n+1})(u_{j+1}^n + u_{j+1}^{n+1} - u_{j-1}^n - u_{j-1}^{n+1}) \\ & + (u_{j+1}^n + u_{j+1}^{n+1})^2 - (u_{j-1}^n + u_{j-1}^{n+1})^2 \Big). \end{aligned} \tag{3.5}$$

For each time step, the nonlinear difference equation (3.5) is solved by a fixed-point iteration method which is stopped if the L^1-relative difference between two succeeding approximate solutions is less than a threshold. This fixed-point iteration approach will be used throughout this paper for all numerical experiments. Results for initial data $u_0(x) = \sin(2\pi x) + 1$ at different times are shown in the left picture of Figure 3.1. The computational domain is $[0, 1]$ with periodic boundary conditions. Here we chose 250 cells, and the CFL-number to be 0.25. As expected for a central scheme, the method leads to a highly oscillating wave pattern after formation of the shock wave, indicating that the method will not converge in any strong topology when refining the grid. We note that by adding artificial dissipation the oscillations can be suppressed (cf. section 5 for examples with nonclassical shocks).

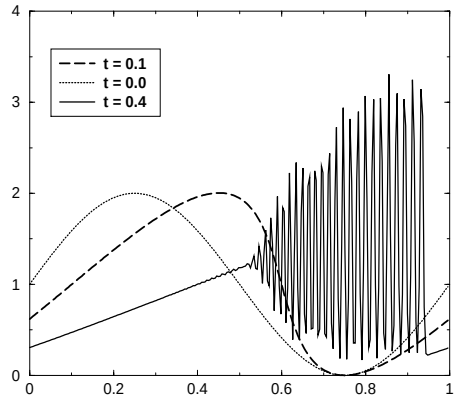

FIG. 3.1. *Numerical approximation of weak solutions of Burgers' equation with a two time-level entropy conservative scheme.*

3.2. A class of three time-level entropy conservative schemes. We consider three time-level schemes of the type

$$u_j^{*n+1} = u_j^{*n} - \lambda \left(g_{j+1/2}^{*n+1} - g_{j-1/2}^{*n+1} \right), \tag{3.6}$$

where the discrete conservative variable u^* is defined by

$$u^* \left(u^0, u^1 \right) = \alpha u^0 + (1-\alpha)\, u^1 \qquad (\alpha \in \mathbb{R}). \tag{3.7}$$

Straightforwardly we get the following theorem.

THEOREM 3.3. *Let $U^* \left(u^0, u^1 \right)$ be chosen such that Assumption* 2.1 *is satisfied for some entropy variable $v^* = v^* \left(u^{-1}, u^0, u^1 \right)$.*

Then the scheme (3.6) *considered with Tadmor flux* (3.1) *is a three time-level entropy conservative scheme with respect to the entropy $U^* \left(u^0, u^1 \right)$.*

To satisfy Assumption 2.1 we can always choose U^* and v^* as

$$\begin{aligned} U^*(u^0, u^1) &= U(u^*(u^0, u^1)), \\ v^*(u^{-1}, u^0, u^1) &= \int_0^1 v(su^*(u^0, u^1) + (1-s)u^*(u^{-1}, u^0))\, ds. \end{aligned} \tag{3.8}$$

If the entropy U is nonnegative, another possible choice for the discrete entropy is $U^* \left(u^0, u^1 \right) = \sqrt{U\left(u^1\right) U\left(u^0\right)}$, together with the entropy variable v^* as above.

3.3. Explicit three time-level schemes for quadratic entropies. Symmetric systems yield a general class of hyperbolic systems. For these systems, we can design three time-level explicit entropy conservative schemes. Let B be any constant positive symmetric matrix. For symmetric systems, the function

$$U(u) = u \cdot B\, u$$

is a strictly convex entropy for which the entropy variable is $v\left(u\right) = Bu$.

Let u^* be given by (3.7) for the special choice $\alpha = 1/2$, and choose the discrete entropy function

$$U^* \left(u^0, u^1 \right) = \frac{1}{2}\, u^0 \cdot B\, u^1.$$

To satisfy Assumption 2.1 define

$$v^*\left(u^{-1},u^0,u^1\right)=B\,u^0. \tag{3.9}$$

The Tadmor flux gives an *explicit* scheme.

PROPOSITION 3.4. *Suppose that Df is symmetric. Choose $U^*\left(u^0,u^1\right)=\frac{1}{2}\,u^0\cdot B\,u^1$ and Tadmor's flux* (3.1). *With v^* from* (3.9) *the scheme* (3.6) *is an explicit scheme, entropy conservative with respect to the entropy U^*.*

3.4. Linear implicit three time-level schemes. As pointed out in section 3.2, the three-point conservative scheme (3.6) allows different choices for the entropy U^*. Here we consider scalar conservation laws and highlight a choice of U^* that leads to a *linear implicit* scheme.

Consider the case $N=1$ with the flux $f(u)=u^3$ and entropy

$$U(u)=\int_0^u f(s)\,ds=\frac{u^4}{4}.$$

The flux written in the entropy variable is $g(v)=v$. Consider the discrete entropy

$$U_j^{*n}=U^{*n}\left(u_j^n,u_j^{n-1}\right)=\frac{1}{4}\left(u_j^n u_j^{n-1}\right)^2.$$

Assumption 2.1 is satisfied if the discrete entropy variable v^* is defined to be

$$v_j^{*n+1}=v^*(u_j^{n-1},u_j^n,u_j^{n+1})=\frac{1}{2}(u_j^n)^2(u_j^{n+1}+u_j^{n-1}).$$

For the flux we take

$$g_{j+1/2}^{*,n+1}=g_2^*\left(v_j^{*n+1},v_j^{*n+1}\right)=\frac{1}{4}\Big((u_j^n)^2(u_j^{n-1}+u_j^{n+1})+(u_{j+1}^n)^2(u_{j+1}^{n-1}+u_{j+1}^{n+1})\Big).$$

The resulting three time-level scheme (3.6) is linear implicit:

$$u_j^{n+1}=u_j^{n-1}-\frac{\lambda}{2}\left(\left(u_{j+1}^{n+1}+u_{j+1}^{n-1}\right)\left(u_{j+1}^n\right)^2-\left(u_{j-1}^{n+1}+u_{j-1}^{n-1}\right)\left(u_{j-1}^n\right)^2\right). \tag{3.10}$$

Example 3.5. We present a numerical experiment for scheme (3.10). Consider the cubic scalar conservation law for $u_0(x)=\sin(2x/\pi)$ on $[0,1]$ with periodic boundaries. The results for 250 cells and the CFL-number 0.25 are displayed in the right picture of Figure 3.2. Again we stress the fact that these schemes produce extreme oscillations after the shock has formed. When supplementing regularizing terms this effect will disappear.

3.5. Third order, three time-level entropy conservative schemes. Consider the following choice for the discrete entropy variable:

$$u^*\left(u^0,u^1\right)=\left(\frac{1}{2}-\frac{1}{\sqrt{2}}\right)u^0+\left(\frac{1}{2}+\frac{1}{\sqrt{2}}\right)u^1. \tag{3.11}$$

THEOREM 3.6. *Consider a hyperbolic or hyperbolic-elliptic system of conservation laws* (1.1) *endowed with an entropy-entropy flux pair (U,F) satisfying condition* (2.3). *Consider the discrete conservative variable u^* from* (3.11), *$U^*\left(u^0,u^1\right)=U\left(u^*\left(u^0,u^1\right)\right)$, and v^* to be*

$$v^*\left(u^{-1},u^0,u^1\right)=\int_0^1 v\left(su^*\left(u^0,u^1\right)+(1-s)\,u^*\left(u^{-1},u^0\right)\right)ds.$$

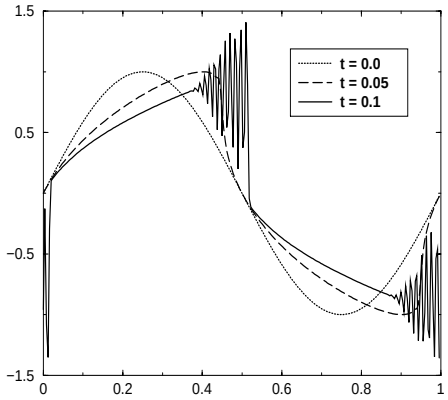

FIG. 3.2. *Numerical approximation of the cubic scalar conservation law with a three time-level entropy conservative scheme.*

For an entropy conservative flux g^* of order $2p$, $p \in \mathbb{N}$, the scheme

$$u_j^{*n+1} - u_j^{*n} + \lambda \left(g_{j+1/2}^{*n+1} - g_{j-1/2}^{*n+1} \right) = 0$$

has a unique solution u_j^{n+1} if and only if λ is small enough. The scheme is entropy conservative and third order accurate in time; i.e., its equivalent equation is

$$\partial_t u \left(x_j, t^n + \frac{\tau}{\sqrt{2}} \right) + \partial_x g \left(v \left(x_j, t^n + \frac{\tau}{\sqrt{2}} \right) \right) = O\left(\tau^3\right) + O\left(h^{2p}\right).$$

The order of accuracy of these scheme can be checked easily. See also section 4.2 for a constructive demonstration.

NOTE 3.7. *Using the Tadmor flux leads to a second order in space accurate conservative scheme ($p = 1$ in the previous formula). The next section provides the explicit construction of conservative fluxes of arbitrary higher order. A numerical example of this section is considered in section* 5.

4. Entropy conservative schemes of arbitrary order.

4.1. Semidiscrete entropy conservative schemes of arbitrary order. Consider the conservation law (1.1) with entropy-entropy flux pair (U, F). Let $x_j = jh$, $j \in \mathbb{Z}$, be a regular mesh, h denoting the grid point distance. For $v_j = \nabla U(u_j)$, we consider $(2p+1)$-point semidiscrete schemes of type

$$\begin{aligned} u_j'(t) &= -\frac{1}{h}\left(g_{2p,j+1/2}^* - g_{2p,j-1/2}^* \right) \\ &= -\frac{1}{h}\left(g_{2p}^*(v_{j-p+1}, \ldots, v_{j+p}) - g_{2p}^*(v_{j-p}, \ldots, v_{j+p-1}) \right), \end{aligned} \tag{4.1}$$

where $u_j(t)$ approximates the solution u of (1.1) in (x_j, t) and $'$ denotes time derivation. In this section we show that there exist smooth numerical fluxes $g_{2p}^* : \mathbb{R}^{2pN} \to \mathbb{R}^N$ satisfying the following conditions for all $j \in \mathbb{Z}$, $p \in \mathbb{N}$ and all smooth enough

functions $v = \nabla U(u)$ (denoting $v_j = v(x_j, t)$):

(i) $g^*(v_j, \dots, v_j) = g(v_j)$.

(ii) $$\frac{g^*_{2p}(v_{j-p+1}, \dots, v_{j+p}) - g^*_{2p}(v_{j-p}, \dots, v_{j+p-1})}{h} = \partial_x g(v_j) + \mathcal{O}(h^{2p}).$$

(iii) There is a function $G^*_{2p} : \mathbb{R}^{2pN} \to \mathbb{R}$ consistent with G such that

$$U(u_j(t))' = -\frac{1}{h}\Big(G^*_{2p}(v_{j-p+1}, \dots, v_{j+p}) - G^*_{2p}(v_{j-p}, \dots, v_{j+p-1})\Big).$$

In other words, we will show that there exist consistent semidiscrete entropy conservative schemes (4.1) of arbitrary order. So far, only fluxes of order two [23] or three [16] have been available.

For $\alpha_{1,p}, \dots, \alpha_{p,p} \in \mathbb{R}$, we make an ansatz for g^*_{2p} as a linear combination of Tadmor's flux g^*_2 (cf. (3.1)):

$$g^*_{2p}(v_{-p+1}, \dots, v_p) = \sum_{i=1}^{p} \alpha_{i,p}\Big(g^*_2(v_0, v_i) + \cdots + g^*_2(v_{-i+1}, v_1)\Big). \tag{4.2}$$

So the flux difference is given by

$$g^*_{2p}(v_{-p+1}, \dots, v_p) - g^*_{2p}(v_{-p}, \dots, v_{p-1}) = \sum_{i=1}^{p} \alpha_{i,p}\Big(g^*_2(v_0, v_i) - g^*_2(v_{-i}, v_0)\Big). \tag{4.3}$$

NOTE 4.1 (linear entropy flux). *Assume that the function g can be written as an affine function, say $g(v) = Av + b$, $A \in \mathbb{R}^{N\times N}, b \in \mathbb{R}^N$ (cf. sections* 3.4, 3.5*). Then the Tadmor flux difference is simply the centered difference $A(v_1 - v_{-1})/2$, and we get in our case*

$$g^*_{2p}(v_{-p+1}, \dots, v_p) - g^*_{2p}(v_{-p}, \dots, v_{p-1}) = A\sum_{i=1}^{p} \alpha_{i,p}(v_i - v_{-i}). \tag{4.4}$$

We show first that the general ansatz (4.2) leads to a scheme satisfying (i), (iii).

PROPOSITION 4.2. *Let $p \in \mathbb{N}$. Consider the scheme* (4.1) *for g^*_{2p} from* (4.2) *and $\alpha_{1,p}, \dots, \alpha_{p,p} \in \mathbb{R}$ satisfying*

$$2\sum_{i=1}^{p} i\alpha_{i,p} = 1. \tag{4.5}$$

Then (i) *and* (iii) *are satisfied for*

$$G^*_{2p} = G^*_{2p}(v_{-p+1}, \dots, v_p) = \sum_{i=1}^{p} \alpha_{i,p}\Big(G^*_2(v_0, v_i) + \cdots + G^*_2(v_{-i+1}, v_1)\Big), \tag{4.6}$$

where G^*_2 is given by (3.2).

Proof. Using (4.3) and Tadmor entropy fluxes $G^*_2(v_0, v_1)$, we get

$$\begin{aligned} & v_0 \cdot \Big(g^*_{2p}(v_{-p+1}, \dots, v_p) - g^*_{2p}(v_{-p}, \dots, v_{p-1})\Big) \\ &= v_0 \cdot \sum_{i=1}^{p} \alpha_{i,p}\Big(g^*_2(v_0, v_i) - g^*_2(v_{-i}, v_0)\Big) \\ &= \sum_{i=1}^{p} \alpha_{i,p}\Big(G^*_2(v_0, v_i) - G^*_2(v_{-i}, v_0)\Big). \end{aligned}$$

The last line equals $G^*_{2p}(v_{-p+1},\dots,v_p) - G^*_{2p}(v_{-p},\dots,v_{p-1})$, which proves (iii). The consistency of g^*_{2p}, G^*_{2p} with g, G follows from (4.5). ∎

Next, we fix the up-to-now free coefficients $\alpha_{1,p},\dots,\alpha_{p,p}$ to provide a high-order scheme.

PROPOSITION 4.3. *For $p \in \mathbb{N}$, assume that $\alpha_{1,p},\dots,\alpha_{p,p}$ solve the p linear equations*

$$2\sum_{i=1}^{p} i\alpha_{i,p} = 1, \quad \sum_{i=1}^{p} i^{2s-1}\alpha_{i,p} = 0 \quad (s = 2,\dots,p). \tag{4.7}$$

Then the flux g^*_{2p} given by formula (4.2) *satisfies* (ii)*; i.e., for smooth enough function v we have*

$$\frac{g^*_{2p}(v_{j-p+1},\dots,v_{j+p}) - g^*_{2p}(v_{j-p},\dots,v_{j+p-1})}{h} = \partial_x g(v_j) + \mathcal{O}(h^{2p}). \tag{4.8}$$

Here we used $C_{2p} = \sum_{i=1}^{p} \frac{\alpha_{i,p} i^{2p+1}}{(2p+1)!}$ and $v_j = v(x_j)$ for $j \in \mathbb{Z}$.

Proof. By Taylor expansion around x_0 we obtain for $i = 1,\dots,p$

$$g^*_2(v_0, v_i) - g^*_2(v_{-i}, v_0) = 2\sum_{k=0}^{p} \frac{(ih)^{2k+1}}{(2k+1)!}\partial_x^{(2k+1)} g(v_0) + \mathcal{O}(h^{2p+2}).$$

This leads by (4.3) to the expression

$$\begin{aligned} & g^*_{2p}(v_{-p+1},\dots,v_p) - g^*_{2p}(v_{-p},\dots,v_{p-1}) \\ &= 2\sum_{i=1}^{p} \alpha_{i,p} \left(\sum_{k=0}^{p} \frac{(ih)^{2k+1}}{(2k+1)!}\partial_x^{(2k+1)} g(v_0) \right) + \mathcal{O}(h^{2p+2}). \end{aligned}$$

The definition of $\alpha_{1,p},\dots,\alpha_{p,p}$ in (4.7) gives the statement of the proposition. ∎

Note that the first equation in (4.7) equals (4.5) and ensures consistency. We summarize Proposition 4.2 and 4.3 in the following theorem.

THEOREM 4.4. *Consider a hyperbolic or hyperbolic-elliptic system of conservation laws* (1.1) *with an entropy-entropy flux pair (U, F). Assume that $\alpha_{i,1},\dots,\alpha_{i,p}$ solve* (4.7).

Then the flux g^*_{2p} given by formula (4.2) *satisfies the conditions* (i), (ii), (iii).

The scheme (4.1) *is an entropy conservative semidiscrete scheme with respect to U which is of order $2p$.*

4.2. Fully discrete entropy conservative schemes of arbitrary order. In this section we present fully discrete schemes of arbitrary order verifying a weaker form of entropy conservation. For an integer $q \geq 1$, the schemes will use $q+1$ time-levels and be of order $q+1$ in time.

Let $j \in \mathbb{Z}$ and $n \in \mathbb{N}$. We approximate the continuous derivative $\partial_t u$ in (1.1) by

$$\frac{u_j^{*n} - u_j^{*n-1}}{\tau} := \sum_{i=0}^{q} \beta^t_{i,q} u_j^{n-q+i}. \tag{4.9}$$

In the formula above, $\beta^t_{0,q},\dots,\beta^t_{q,q} \in \mathbb{R}$ are parameters that have to be chosen according to the desired $(q+1)$st order of accuracy; i.e., for smooth enough function u, we

have the following expansion around a time $\bar{t}^q > 0$ to be determined:

$$\sum_{i=0}^{q} \beta_{i,q}^t u_j^{n-q+i} = \partial_t u\left(x_j, \bar{t}^n\right) + O\left(\tau^{q+1}\right). \tag{4.10}$$

Consider the $q+1$ linear equations

$$\sum_{i=0}^{q} (t^{n-q+i} - \bar{t}^{\,n})\beta_{i,q}^t = 1, \quad \sum_{i=0}^{q} (t^{n-q+i} - \bar{t}^{\,n})^s \beta_{i,q}^t = 0 \quad (s = 0, \dots, q,\ s \neq 1). \tag{4.11}$$

This last system is a Vandermonde system. If $\bar{t}^n$ does not belong to the set of time grid points $\{t^n\}_{n\geq 0}$, it also is nondegenerate. In this last case, the unique solutions $\beta_{0,q}^t, \dots, \beta_{q,q}^t \in \mathbb{R}$ of (4.11) provides via (4.9) an approximation of $\partial_t u(x_j, \bar{t}^n)$ with at least order q, as a straightforward Taylor expansion of $u(x_j, t^{n-q}), \dots, u(x_j, t^n)$ around $(x_j, \bar{t}^n)$ shows. Note that we are left with one degree of freedom, namely to choose $\bar{t}^n$. There exists a choice that allows us to gain one order of accuracy in time and obtain (4.10): choose $\bar{t}^n$ satisfying (4.11) and

$$\sum_{i=0}^{q} (t^{n-q+i} - \bar{t}^{\,n})^{s+1} \beta_{i,q}^t = 0. \tag{4.12}$$

To prove the existence of such an intermediate solution, we introduce the following polynomial

$$P(t) = \sum_{i=0}^{q} \frac{(-1)^i \prod_{\substack{0\leq l\leq q \\ l\neq i}} \left(t^{n-l} - t\right)^2}{\prod_{\substack{0\leq l\leq i \\ l\neq i}} |t^{n-i} - t^{n-l}|}.$$

One can check, using the explicit solution of the Vandermonde system (4.11), that any root of the previous polynomial provides a solution of (4.11), (4.12). It can be easily seen that this polynomial has q solutions, the ith solution ($i = 0, \dots, q-1$) lying in $\left[t^{n-i}, t^{n-i-1}\right]$. For stability reasons we always take the solution in $[t^{n-1}, t^n]$. For instance, in the case $q = 1$ we get $\bar{t}^n = \frac{t^{n-1}+t^n}{2}$, that is the Crank–Nicholson choice. For $q = 2$, we get $\bar{t}^n = t^n - \frac{\tau}{\sqrt{2}}$, that is, a third order scheme as considered in section 3.5. For $q > 2$, we compute numerically the solution that belongs to $[t^{n-1}, t^n]$.

In a similar way, define the coefficients $\beta_{0,q}^u, \dots, \beta_{q,q}^u \in \mathbb{R}$ to be such that the expansion

$$\sum_{i=0}^{q} \beta_{i,q}^u u_j^{n-q+i} = u\left(x_j, \bar{t}^q\right) + \mathcal{O}\left(\tau^{q+1}\right) \tag{4.13}$$

holds, that is, solving the equations

$$\sum_{i=0}^{q} \beta_{i,q}^u = 1, \quad \sum_{i=0}^{q} (t^{n-q+i} - \bar{t}^{\,n})^s \beta_{i,q}^u = 0 \quad (s = 1, \dots, q). \tag{4.14}$$

The entropy variable being $v(u)$, define the discrete entropy variable $v_{q+1}^{*n} : \mathbb{R}^{(q+1)N} \to \mathbb{R}^N$ to be

$$v_{q+1}^{*n}\left(u_j^{n-q}, \dots, u_j^n\right) = v\left(\sum_{i=0}^{q} \beta_{i,q}^u u_j^{n-q+i}\right), \tag{4.15}$$

and denote $v^{*n+1}_{q+1,j} := v^{*n+1}_{q+1}\left(u^{n-q}_j, \ldots, u^n_j\right)$. Now using the high order entropy conservative numerical fluxes constructed in the preceding section, we obtain arbitrarily high order fully discrete schemes, however, only satisfying a weaker form of entropy conservation.

THEOREM 4.5. *Consider a hyperbolic or hyperbolic-elliptic system of conservation laws* (1.1) *endowed with an entropy-entropy flux pair* (U, F) *satisfying condition* (2.3). *Let* u^{*n}_{q+1} *be a discrete conservative variable defined with* (4.9)–(4.10) *and a discrete entropy variable* v^*_{q+1} *satisfying* (4.13). *For a* $2p$*-point numerical flux* g^*_{2p} *from Theorem* 4.4, *consider the following* $(2p+1)\times(q+1)$*-point scheme:*

$$u^{*n+1}_j = u^{*n}_j - \lambda\left(g^{*n+1}_{j+1/2} - g^{*n+1}_{j-1/2}\right).$$

Then, for λ *small enough, there exists an unique solution* u^{n+1}_j. *The scheme is entropy conservative in the sense*

$$\left(u^{*n+1}_j - u^{*n}_j\right) v^{*n+1}_{q+1,j} + \lambda\left(G^{*n+1}_{j+1/2} - G^{*n+1}_{j-1/2}\right) = 0. \tag{4.16}$$

Furthermore, it is of order $(q+1)$ *in time and* $2p$ *in space in the sense that its equivalent equation is*

$$\partial_t u\left(x_j, \bar{t}^n\right) + \partial_x g\left(v\left(u\left(x_j, \bar{t}^n\right)\right)\right) = \mathcal{O}\left(h^{2p}\right) + \mathcal{O}\left(\tau^{q+1}\right).$$

Proof. The weak entropy conservation (4.16) follows from multiplying the scheme difference equation by $v^{*n+1}_{q+1}\left(u^{n-q}_j, \ldots, u^n_j\right)$ and using property (2.6) for g^*_{2p}.

The equivalent equation comes from (4.13) and Theorem 4.4. ∎

NOTE 4.6. *For* $q = 1$ *(Crank–Nicholson choice) and* $q = 2$, *the discrete entropy variable constructed above, i.e., satisfying* (4.13), *also verifies Assumption* 2.1 *for* U. *It follows that these schemes are entropy conservative in the sense*

$$U^{*n+1}_j - U^{*n}_j + \lambda\left(G^{*n+1}_{j+1/2} - G^{*n+1}_{j-1/2}\right) = 0 \qquad (n \in \mathbb{N}, j \in \mathbb{Z})$$

with $U^{*n+1}_j = U\left(u^{*n+1}_j\right)$.

We illustrate this section with a fully discrete, fourth order accurate entropy scheme for the system of nonlinear elasticity.

For a stress-strain function $w \mapsto \sigma(w)$, consider the system

$$\partial_t w - \partial_x V = 0, \qquad \partial_t V - \partial_x \sigma(w) = 0. \tag{4.17}$$

Here V is the particle velocity and w is the stress, collected in $u := (w, V)$. The mathematical entropy pair is

$$(U(u), F(u)) = \left(\int_0^w \sigma(s)\, ds + \frac{V^2}{2},\ \sigma(w)V\right).$$

We choose the stress-strain function σ given by

$$\sigma(w) = w^3 - w.$$

Then (4.17) represents a model for phase transitions in shape memory alloys. Note that, for $w \in [-1/\sqrt{3}, 1/\sqrt{3}]$, the problem is elliptic, and hyperbolic outside this interval. The flux in (4.17) can be written in terms of the entropy variable $v =$

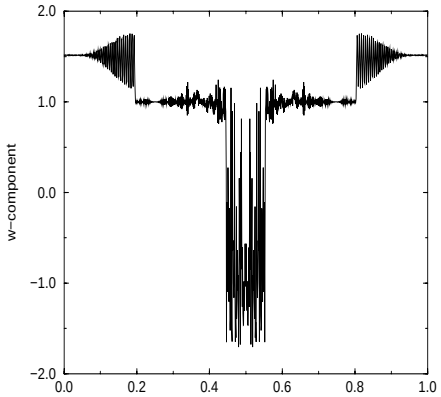

FIG. 4.1. *A fourth order in time, fourth order in space conservative scheme for the p-system (w-component).*

$(v_1, v_2)^T = (\sigma, V)^T$ and—as in the scalar case of section 3.4—is a linear function: $g(v_1, v_2) = -(v_2, v_1)^T$.

To discretize this system we design a four time-level scheme using the construction given in Theorem 3.6. We compute the values of the parameters $\beta^{t/u}_{0,q}, \dots, \beta^{t/u}_{q,q}$ and $\overline{t}^n$ as described above. Define

$$v_j^{*n+1} = \left(v_{1,j}^{*n+1}, v_{2,j}^{*n+1}\right)^T = \left(\sum_{i=0}^{3} \beta^u_{i,3} V_j^{n-3+i}, \sigma\left(\sum_{i=0}^{3} \beta^u_{i,3} w_j^{n-3+i}\right)\right)^T.$$

Consider now the fourth order conservative flux (cf. (4.2))

$$g_{j+1/2}^{*n+1} = g\left(\frac{2}{3}\left(v_j^{*n+1} + v_{j+1}^{*n+1}\right) - \frac{1}{12}\left(v_{j-1}^{*n+1} + \cdots + v_{j+2}^{*n+1}\right)\right).$$

The resulting scheme is, denoting componentwise $g_{j+1/2}^{*n+1} = (g_{1,j+1/2}^{*n+1}, g_{2,j+1/2}^{*n+1})^T$,

$$\left\{\begin{array}{rcl} w_j^{*n+1} - w_j^{*n} + \lambda\left(g_{1,j+1/2}^{*n+1} - g_{1,j-1/2}^{*n+1}\right) &=& 0, \\ V_j^{*n+1} - V_j^{*n} + \lambda\left(g_{2,j+1/2}^{*n+1} - g_{2,j-1/2}^{*n+1}\right) &=& 0 \end{array}\right. \qquad (j \in \mathbb{Z}). \tag{4.18}$$

Such a scheme is a fully nonlinear fourth order scheme. The numerical experiment takes place in the interval $[0, 5]$ with periodic boundaries. Choose initial data

$$u_0(x) = \left\{\begin{array}{l} (1,-1)^T : x \in [0, 2.5), \\ (1,1)^T \ : x \in [2.5, 5). \end{array}\right. \tag{4.19}$$

For such Riemann initial data, an intermediate middle state lying in the opposite phase, i.e., $\{w \in \mathbb{R} \,|\, w \le -1/\sqrt{3}\}$, must evolve for positive time [18]. The results for 1000 cells and the CFL-number 0.25 at time 0.1 are displayed in Figure 4.1.

5. Computation of regularization-sensitive weak solutions.

5.1. Analytical background and the basic numerical scheme. In the physical context the conservation law (1.1) is embedded into a higher order regularized but singularly perturbed model. For a small perturbation parameter $\varepsilon > 0$ and $D_2, D_3 : \mathbb{R}^N \to \mathbb{R}^{N\times N}$, let us consider systems of equations involving spatial derivatives up to order three:

$$\partial_t u^\varepsilon + \partial_x f(u^\varepsilon) = \varepsilon \partial_x \Big(D_2(u^\varepsilon)\partial_x u^\varepsilon \Big) + \varepsilon^2 \partial_x \Big(D_3(u^\varepsilon)\partial_{xx} u^\varepsilon \Big). \tag{5.1}$$

We are interested in weak solutions u of (1.1) that arise as limits of a sequence of smooth solutions $\{u^\varepsilon\}_{\varepsilon>0}$ of (5.1) for vanishing regularization parameter ε. While the second order derivatives in (5.1) correspond to physical effects like fluid viscosity or heat conduction, the third order term models capillarity phenomena [11, 15, 26].

A very interesting property of these *viscosity-capillarity* approximations u^ε is the fact that the limit solution u can contain undercompressive regularization-sensitive shock waves. Changing D_2, D_3 can produce a different weak solution; in other words, the limit function depends crucially on the entropy dissipation.

The numerical approximation of such weak solutions is a big challenge since also for the discrete counterpart the numerical entropy dissipation has to be tuned exactly. To overcome these difficulties Hayes and Lefloch suggested using *entropy conservative* numerical fluxes as a building block for finite difference schemes. To approximate the weak solution $u = \lim_{\varepsilon\to 0} u^\varepsilon$ of (1.1) they consider the following class of schemes (written down in the semidiscrete version, for simplicity):

$$\begin{aligned} u_j'(t) &= -\frac{1}{h}\left(\tilde g^*_{2p,j+1/2} - \tilde g^*_{2p,j+1/2} \right), \\ \tilde g^*_{2p,j+1/2} &:= g^*_{2p,j+1/2} - f^{2*}_{j+1/2} - f^{3*}_{j+1/2}. \end{aligned} \tag{5.2}$$

Here g^*_{2p} is the smooth entropy conservative numerical flux from (4.2), and

$$f^{2/3*}_{j+1/2} = f^{2/3*}(u_{j-r+1}, \ldots, u_{j+r}) \quad (r \in \mathbb{N}),$$

where $f^{2/3*} : \mathbb{R}^{2rN} \to \mathbb{R}^N$ are smooth and satisfy for all smooth enough functions u (denoting $u_j = u(x_j, t)$)

$$\begin{aligned} \frac{f^{2*}(u_{j-r+1}, \ldots, u_{j+r}) - f^{2*}(u_{j-r}, \ldots, u_{j+r-1})}{h} &= h\partial_x \Big(D_2(u_j)\partial_x u_j \Big) + \mathcal{O}(h^3), \\ \frac{f^{3*}(u_{j-r+1}, \ldots, u_{j+r}) - f^{3*}(u_{j-r}, \ldots, u_{j+r-1})}{h} &= h^2\partial_x \Big(D_3(u_j)\partial_{xx} u_j \Big) + \mathcal{O}(h^3). \end{aligned}$$

Then we obtain the following equivalent equation for the scheme (5.2):

$$\begin{aligned} &u_j'(t) + \partial_x f(u_j(t)) \\ &\quad = h\partial_x \Big(D_2(u_j(t))\partial_x u_j(t) \Big) + h^2 \partial_x \Big(D_3(u_j(t))\partial_{xx} u_j(t) \Big) + \mathcal{O}(h^{2p}) + \mathcal{O}(h^3). \end{aligned} \tag{5.3}$$

We observe that the equivalent equation mimics (5.1) provided we have $p \geq 2$. This is precisely the motivation for considering (5.2) with *high order* fluxes. While in

[9, 16] only semidiscrete entropy conservative schemes were available, here we have constructed fully discrete high order entropy conservative schemes.

In what follows we will consider numerical experiments. Furthermore, in a special case this construction allows us to consider a discrete counterpart for the entropy inequality.

5.2. Regularizations that are linear in the entropy variable. In this section we consider in this section a regularization mechanism of (1.1) in which the dissipative terms are *linear* functions of the entropy variable v:

$$\partial_t u^\varepsilon + \partial_x f(u^\varepsilon) = \varepsilon B_2 \partial_{xx} v + \varepsilon^2 B_3 \partial_{xxx} v^\varepsilon. \tag{5.4}$$

Here we assume that

$$B_2, B_3 \text{ are } (N \times N) \text{ constant matrices,} \tag{5.5}$$

and we make the hypothesis

$$B_2 \text{ is positive definite and } B_3 \text{ is symmetric.} \tag{5.6}$$

The advantage of this particular choice is the following. Multiplying (5.4) by v^ε and performing integration by parts, the hypothesis (5.6) leads immediately to the entropy stability estimate

$$\frac{d}{dt} \int_{\mathbb{R}} U\left(u^\varepsilon(x)\right) dx \leq 0. \tag{5.7}$$

In what follows we assume that there is a classical solution of the Cauchy problem for (5.4) and a weak solution u of the Cauchy problem for (1.1) such that $\lim_{\varepsilon \to 0} u^\varepsilon = u$. As we are interested in the numerical approximation of the function u we consider on the (semi)discrete level the scheme (5.2) together with smooth fluxes $f^{2/3*}_{j+1/2} : \mathbb{R}^{2rN} \to \mathbb{R}^N$, $r \in \mathbb{N}$, that are *linear* in v and satisfy for all smooth enough functions u,

$$\begin{aligned} \frac{f^{2*}(u_{j-r+1}, \ldots, u_{j+r}) - f^{2*}(u_{j-r}, \ldots, u_{j+r-1})}{h} &= hB_2 \partial_x^2 v_j + \mathcal{O}(h^3), \\ \frac{f^{3*}(u_{j-r+1}, \ldots, u_{j+r}) - f^{3*}(u_{j-r}, \ldots, u_{j+r-1})}{h} &= h^2 B_3 \partial_{xxx} v_j + \mathcal{O}(h^3). \end{aligned}$$

NOTE 5.1. *Since the estimate* (5.7) *is the immediate and natural a priori bound for* u^ε*, it should be also possible to prove a discrete entropy dissipation property for the approximate solution. For a result in a particular case we refer to* [16, Theorem 5.1] *and* [6].

Independent of these analytical issues, the numerical experiments in section 6.2 *below clearly demonstrate the benefits of the linear regularization.*

In the rest of this subsection we will focus on a somewhat different but strongly related issue: We consider special high order discretizations for smooth solutions of (5.4) (and not for weak solutions of (1.1) that arise as vanishing dissipation limits of (5.4)).

We introduce a discrete version of (5.7): a form $\tilde{g}^*(v_{-p+1}, \ldots, v_p)$ is entropy dissipative if, for any compactly supported sequence $(v_j)_{j \in \mathbb{Z}}$ in $\mathbb{R}^N$,

$$\sum_{j \in \mathbb{Z}} v_j \cdot \left(g^*(v_{-p+j+1}, \ldots, v_{p+j}) - g^*(v_{-p+j}, \ldots, v_{p+j-1})\right) \leq 0. \tag{5.8}$$

Note that a conservative form $\tilde{g}^* = \tilde{g}^*(v_{-p+j+1}, \ldots, v_{p+j})$ (i.e., a form satisfying (2.6)) verifies (5.8) as an equality.

To provide a $2p$ order discretization of the capillarity term $\partial_x^3 v$, let us introduce the coefficients $\alpha_{i,1}^{(3)}, \ldots, \alpha_{i,p}^{(3)}$ as the solutions of the p linear equations:

$$2\sum_{i=1}^{p} i^3 \alpha_{i,p} = 1, \quad \sum_{i=1}^{p} i^{2s-1} \alpha_{i,p}^{(3)} = 0 \quad (s = 1, \ldots, p, s \neq 2). \tag{5.9}$$

As for (4.7), the previous system is a Vandermonde system and thus has an unique solution. Let us introduce the form $v_{2p}^{(3)*}$, defined by

$$v_{2p}^{(3)*}(v_{-p+1}, \ldots, v_p) = \sum_{i=1}^{p} \alpha_{i,p}^{(3)} (v_i + v_{i-1} + \cdots + v_{-i+1}), \tag{5.10}$$

Here v_i stands for $v(x_i)$, v being any smooth enough vector-valued function $v(x) \in \mathbb{R}^N$. As for (4.7), the difference

$$v_{2p}^{(3)*}(v_{-p+1}, \ldots, v_p) - v_{2p}^{(3)*}(v_{-p}, \ldots, v_{p-1}) = \sum_{i=1}^{p} \alpha_{i,p}^{(3)} (v_i - v_{-i}) \tag{5.11}$$

provides a formula of order $2p$ for $\partial_x^3 v_0$. This is straightforward from Taylor expansions of order $2p$ around v_0. Also note that such a form is conservative in the sense of (2.6), because the structure exhibited in (5.11) corresponds to the special form exhibited in (4.4).

Now we turn to a $2p$ order discretization of the viscous term $\partial_x^2 v$. Let us introduce the coefficients $\alpha_{i,1}^{(2)}, \ldots, \alpha_{i,p}^{(2)}$ as the solutions of the p linear equations

$$\sum_{i=1}^{p} \alpha_{i,p}^{(2)} = 1, \quad \sum_{i=1}^{p} i^{2s} \alpha_{i,p}^{(2)} = 0 \quad (s = 1, \ldots, p-1). \tag{5.12}$$

We also introduce the form $v_{2p}^{(2)}$ defined by

$$v_{2p}^{(2)*}(v_{-p+1}, \ldots, v_p) = \sum_{i=1}^{p} \alpha_{i,p}^{(2)} (v_i + \cdots + v_1 - v_0 - \cdots - v_{-i+1}). \tag{5.13}$$

Straightforwardly from Taylor expansions around v_0, the difference

$$v_{2p}^{(2)*}(v_{-p+1}, \ldots, v_p) - v_{2p}^{(2)*}(v_{-p}, \ldots, v_{p-1}) = \sum_{i=1}^{p} \alpha_{i,p}^{(2)} (v_i + v_{-i} - 2v_0) \tag{5.14}$$

provides a $2p$ order discretization of $\partial_x^2 v_0$.

To provide a discretization for the whole equation (5.4), denote

$$\widetilde{g}_{2p}^* = g_{2p}^* - v_{2p}^{(2)*} - v_{2p}^{(3)*}, \tag{5.15}$$

where g_{2p}^* is defined in the previous section (see formula (4.2)). Set $\widetilde{g}_{2p,j+1/2}^{*n+1} = \widetilde{g}_{2p}^* \left(v_{j-p+1}^{*n+1}, \ldots, v_{j+p}^{*n+1}\right)$. The main theorem of this section follows.

THEOREM 5.2. *Consider the system of conservation laws* (5.4) *together with an entropy pair* (U, F) *and the compatibility conditions* (5.6). *Let* $p > 1$ *and consider the semidiscrete scheme*

$$u_j'(t) = -\frac{1}{h}\Big(\widetilde{g}^*_{2p,j+1/2} - \widetilde{g}^*_{2p,j-1/2}\Big), \qquad t > 0.$$

The equivalent equation of this scheme is the system (5.4) *evaluated in* (x_j, t) *up to a term of order* $2p$ *in space.*

Assume that $u_j(t)$ *vanishes for* $|j|$ *big enough for all* $t > 0$. *Then the scheme is entropy decreasing:*

$$\sum_{j\in\mathbb{Z}} U'(u_j(t)) \le 0, \qquad t > 0. \tag{5.16}$$

NOTE 5.3. *We could also have stated a fully discrete version of the previous theorem using the time discretization exhibited in Theorem* 4.5*: let* $q + 1$ *as defined in Theorem* 4.5 *be the number of time-levels used by the scheme. Then we are able to construct a fully discrete scheme of order* $q + 1$ *in time,* $2p$ *in space with respect to* (5.4) *It satisfies the entropy dissipation property*

$$\sum_{j\in\mathbb{Z}} \left(u_j^{*n+1} - u_j^{*n+1}\right) v_j^{*n+1} \le 0.$$

We notice also that, using an entropy variable satisfying Assumption 2.1, *we are led to a scheme verifying the strongest entropy dissipation property*

$$\sum_{j\in\mathbb{Z}} U\left(u_j^{*n+1}\right) \le 0. \tag{5.17}$$

In particular, consider the third order accurate conservative scheme described in section 3.5. *Following the guidelines described above, we are able to construct fully discrete schemes of accuracy order* 3 *in time,* $2p$ *in space with respect to* (5.4), *satisfying the entropy dissipation property* (5.17).

Proof of Theorem 5.2. It is enough to prove the dissipation property.

$$\sum_{i\in\mathbb{Z}} \Big(\widetilde{g}^*_{2p,j+1/2} - \widetilde{g}^*_{2p,j-1/2}\Big) v_j \le 0.$$

Since g^*_{2p} and $v^{(3)*}_{2p}$ are entropy conservative fluxes (i.e., they satisfy a stronger version of (5.8)), the only point is to show the statement for $v^{(2)*}_{2p}$.

Note that the elementary forms $(v_{-i} + v_i - 2v_0)$ are the building block of (5.14). We compute

$$(v_{-i} + v_i - 2v_0)\, v_0 = -\left(v_i - v_0\right)^2 + v_i^2 - v_i v_0 - \left(v_0^2 - v_0 v_{-i}\right).$$

Denoting $G_2^{(2)*}(v_0, v_i) = v_i^2 - v_i v_0$ and $G^{(2)*}_{2p,j+1/2} = \sum_{l=0}^{j-1} G_2^{(2)*}(v_{-l}, v_{j-l})$, we have

$$\begin{aligned}
(v_{-i} + v_i - 2v_0)\, v_0 &= -\left(v_i - v_0\right)^2 + G_2^{(2)*}(v_0, v_i) - G_2^{(2)*}(v_{-i}, v_0) \\
&= -\left(v_i - v_0\right)^2 + \sum_{l=0}^{i-1} G_2^{(2)*}(v_{-l}, v_{i-l}) - \sum_{l=0}^{i-1} G_2^{(2)*}(v_{-l-1}, v_{i-l-1}) \\
&= -\left(v_i - v_0\right)^2 + \Big(G^{(2)*}_{2p,i+1/2} - G^{(2)*}_{2p,i-1/2}\Big).
\end{aligned}$$

This proves that

$$\sum_{j\in\mathbb{Z}}\Big(v_j\Big(v^{(2)}_{2p,j+1/2}-v^{(2)}_{2p,j-1/2}\Big)\Big)+\sum_{i=1}^{p}\alpha^{(2)}_{i,p}\sum_{j\in\mathbb{Z}}\frac{\left(v_{i+j}-v_j\right)^2}{2}=0.$$

The last sum in the last equation can be estimated from below by a sum independent of i. Therefore $\sum_{i=1,..,p}\alpha^{(2)}_{i,p}=1$ from (5.12) shows that $v^{(2)}_{2p}$ is entropy decreasing. ∎

Further results on the discrete Laplace operator in this context can be found in [1], for instance.

6. Numerical experiments.

6.1. A shock-capturing method for the scalar cubic problem. For $\gamma>0$ fixed and some initial data $u_0:\mathbb{R}\to\mathbb{R}$, consider as a model problem the (regularized) scalar Cauchy problem

$$\begin{aligned} u^{\gamma,\epsilon}_t+\left((u^{\gamma,\epsilon})^3\right)_x &= \epsilon\, u^{\gamma,\epsilon}_{xx}+\gamma\epsilon^2\, u^{\gamma,\epsilon}_{xxx},\\ u^{\gamma,\epsilon}(.,0) &= u_0 \end{aligned} \tag{6.1}$$

corresponding to (5.1).

It is well known [20] that there exists a weak solution u^γ of the hyperbolic conservation law, i.e., (6.1) with $\epsilon=0$, which is the L^1-limit of a sequence of solutions $\{u^{\gamma,\epsilon}\}_{\epsilon>0}$ for vanishing ϵ. In particular for Riemann problem initial data u_0, the function u^γ might contain undercompressive shock waves which depend on u_0 and the coefficient γ [11, 8].

Following subsection 5.1, we choose our viscosity and capillarity fluxes according to

$$\begin{aligned} f^{2*}(u_{j-1},\ldots,u_{j+2}) &= \frac{\beta}{2}\Big(u_{j+1}-u_j\Big),\\ f^{3*}(u_{j-1},\ldots,u_{j+2}) &= \frac{\delta}{6}\Big(u_{j+2}-u_{j+1}-u_j+u_{j-1}\Big). \end{aligned}$$

To satisfy (5.3) assume $\delta/\beta^2=3\gamma/4$ for $\beta,\delta>0$. With the entropy of choice $U(u)=u^4/4$ the basic entropy conservative schemes are given by either

I scheme (3.6) with $\alpha=1/2$ and $p=1$ or

II scheme (3.6) with $\alpha=1/2-1/\sqrt{2}$ and $p=2$.

In both cases we use $U^*\left(u^0,u^1\right)=U\left(u^*\left(u^0,u^1\right)\right)$ and v^* to be

$$\begin{aligned} v^*\left(u^{-1},u^0,u^1\right) &= \int_0^1 v\left(su^*\left(u^0,u^1\right)+(1-s)\,u^*\left(u^{-1},u^0\right)\right)ds\\ &= \frac{1}{4}\Big(u^*(u^0,u^1)+u^*(u^{-1},u^0)\Big)\Big(u^*(u^0,u^1)^2+u^*(u^{-1},u^0)^2\Big). \end{aligned}$$

The basic entropy conservative scheme in case I (II) is of second (third) order in space and time.

In all numerical experiments described below, the viscosity and capillarity fluxes for fluxes $f^{2/3}_{j+1/2}$ are evaluated in $u^{n+1}_{j-1},\ldots,u^{n+1}_{j+2}$, i.e., we treat them implicitly.

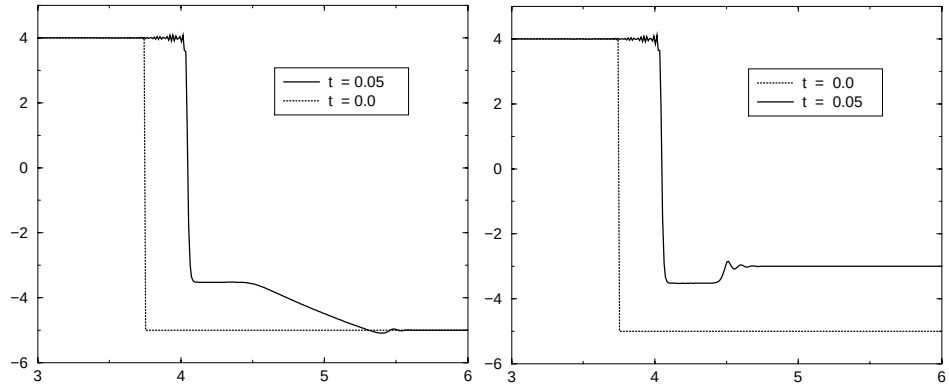

FIG. 6.1. *Typical wave patterns involving nonclassical shock waves. Results for scheme* II *are displayed.*

In Figure 6.1 we present the numerical results for two different choices of the initial data:

$$u_0^1(x) = \begin{cases} 4 : x < 0, \\ -5 : x > 0, \end{cases} \qquad u_0^2(x) = \begin{cases} 4 : x < 0, \\ -3 : x > 0. \end{cases} \tag{6.2}$$

For $\gamma = 2$ and initial data u_0^1, the weak solution u^γ consists of a slow nonclassical shock and a fast rarefaction, while u_0^2 enforces a slow nonclassical shock followed by a fast Lax shock. The numerical results have been performed with the discretization parameters

$$\beta = 5.0, \qquad \delta = 37.5, \qquad h = 0.005. \tag{6.3}$$

The figures demonstrate the ability of the scheme to reproduce nonclassical shock waves arising in Riemann problems together with shock and rarefaction waves. We approximately obtained the value -3.52 for the middle constant state in the second experiment with nonclassical and classical shock. This is better than the values obtained in [10, 16]. However, the correct value of the exact solution u^γ is $-11/3$.

To present a quantitative comparison we run the following experiment. We fix $\gamma = 2$ and choose the parameters according to (6.3). Now we compute the approximate solutions for both schemes I, II with the initial data

$$u_0(x) = \begin{cases} u_l : x < 0, \\ -\dfrac{5}{4} u_l : x > 0. \end{cases}$$

For $u_l > 1$, the exact solution u^γ consists of a nonclassical shock and a rarefaction connected by a middle state u_m as described above. In Figure 6.2 the approximate values of the middle state u_m obtained by schemes I and II are displayed for several values of $u_l \in [1, 11]$. The graphs describing the exact value $u_m = u_m(u_\gamma)$ in the cases $\gamma = 0, \gamma = 2, \gamma = \infty$ are also presented. The cases $\gamma = 0$, $\gamma = \infty$ give the exact middle value for the classical case, respectively, the extreme nonclassical case. We observe for small values of u_l a good approximation of the exact solution while bigger values of u_l lead to wrong solutions. The approximation of scheme II with the higher order

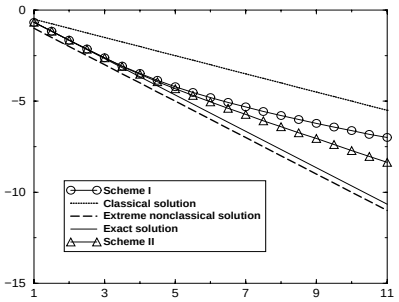

FIG. 6.2. *The (approximate) middle state u_m versus the state u_l.*

basic entropy flux is always better than the approximation by scheme I. We conclude by saying that our method seems to be reliable for computing nonclassical shocks at least for small amplitude initial data.

6.2. The "linear" shock capturing method for the scalar cubic problem. We now present numerical data for schemes approximating nonclassical weak solutions of the scalar cubic problem that are based on the regularization that is linear in the entropy variable $v = U'(u) = f(u) = u^3$ (while in subsection 6.1 the regularization was linear in the conservative variable u). Therefore, instead of (6.1), we consider

$$\begin{aligned} u_t^{\gamma,\epsilon} + f(u^{\gamma,\epsilon})_x &= \epsilon\, f(u^{\gamma,\epsilon})_{xx} + \gamma\epsilon^2\, f(u^{\gamma,\epsilon})_{xxx}, \\ u^{\gamma,\epsilon}(.,0) &= u_0. \end{aligned} \tag{6.4}$$

This leads to the following choice for the viscosity and capillarity fluxes:

$$\begin{aligned} f^{2*}(u_{j-1},\ldots,u_{j+2}) &= \frac{\beta}{2}\Big(f(u_{j+1}) - f(u_j)\Big), \\ f^{3*}(u_{j-1},\ldots,u_{j+2}) &= \frac{\delta}{6}\Big(f(u_{j+2}) - f(u_{j+1}) - f(u_j) + f(u_{j-1})\Big). \end{aligned}$$

As the basic entropy scheme we take (corresponding to scheme II in subsection 6.1) scheme (3.6) with $\alpha = 1/2 - 1/\sqrt{2}$ and $p = 2$. For the numerical parameters, let β, γ to be 37.5, respectively, 1. In Figure 6.3 we present computations for the Riemann initial data

$$u_0^1(x) = \begin{cases} 50 : x < 5, \\ -62.5 : x > 5, \end{cases} \qquad u_0^2(x) = \begin{cases} 100 : x < 5, \\ -125 : x > 5. \end{cases}$$

The calculations have been performed with discretization width $h = 0.005$. In the specific cases considered here we obtain a configuration with a slow nonclassical shock and a fast rarefaction.

Note that these type of schemes allow the stable computation of nonclassical shocks, even for *very large* amplitude data. This was not possible for the discretization based on (6.1).

6.3. The p-system with phase transition: A shape memory material. In this section, we perform long-time computations for the p-system (4.17). We consider

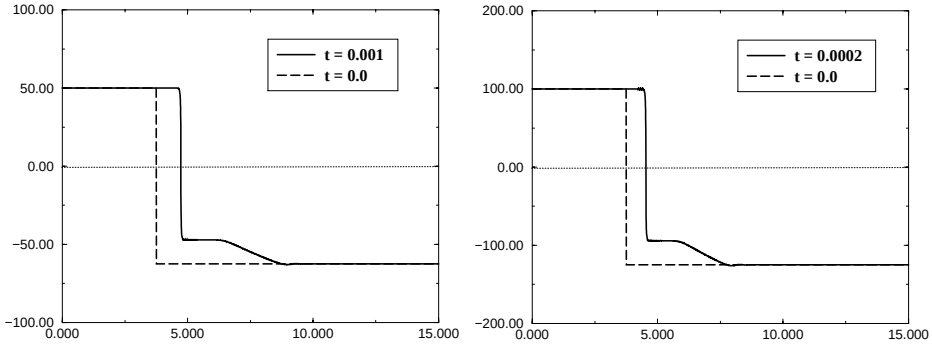

FIG. 6.3. *Stable computation of nonclassical shocks for large initial data* $u_0^{1/2}$.

the weak solution that is obtained as the limit (as $\varepsilon \to 0$) of classical solutions of the p-system with linear viscous regularization in the entropy variable:

$$\begin{aligned} \partial_t w^\varepsilon - \partial_x V^\varepsilon &= \varepsilon \partial_{xx} \sigma(w^\varepsilon), \\ \partial_t V^\varepsilon - \partial_x \sigma(w^\varepsilon) &= \varepsilon \partial_{xx} V^\varepsilon. \end{aligned} \tag{6.5}$$

The scheme that we consider here is the fourth order entropy conservative scheme (4.18) to which we add a viscous flux of fourth order. Following the notations introduced for scheme (4.18), we define the complete numerical flux by

$$\widetilde{g}_4^* = g_4^* - v_4^{(2)*},$$

where the entropy conservative flux g_4^* is given by

$$g_4^*(v_{j-1}, \ldots, v_{j+2}) = g\left(\frac{2}{3}(v_j + v_{j+1}) - \frac{1}{12}(v_{j-1} + \cdots + v_{j+2})\right),$$

whereas the viscous flux is defined by

$$v_4^{(2)*}(v_{j-1}, \ldots, v_{j+2}) = \frac{2h}{3}(v_{j+1} - v_j) - \frac{h}{24}(v_{j+1} + v_{j+2} - v_j - v_{j-1}).$$

Taylor expansion shows that this flux is of fourth order with respect to $h\partial_{xx} v$. The resulting scheme is, denoting $\widetilde{g}_{j+1/2}^{*n+1} = (\widetilde{g}_{1,j+1/2}^{*n+1}, \widetilde{g}_{2,j+1/2}^{*n+1})^T$,

$$\left\{ \begin{array}{rcl} w_j^{*n+1} - w_j^{*n} + \lambda \left(\widetilde{g}_{1,j+1/2}^{*n+1} - \widetilde{g}_{1,j-1/2}^{*n+1}\right) &=& 0, \\ V_j^{*n+1} - V_j^{*n} + \lambda \left(\widetilde{g}_{2,j+1/2}^{*n+1} - \widetilde{g}_{2,j-1/2}^{*n+1}\right) &=& 0 \end{array} \right. \qquad (j \in \mathbb{Z}).$$

We present two computations with periodic boundaries. The results have been obtained on a grid of 1000 cells and with CFL-number 0.25.

The first experiment deals with the same initial Riemann data as in the previous example (cf. (4.19)). We illustrate the effect of artificial viscous regularization on the results plotted in Figure 4.1. The numerical experiment is performed in the interval $[0, 1]$, with initial data

$$u_0(x) = \left\{ \begin{array}{l} (1,1)^T : x \in [0, 0.5), \\ (1,-1)^T : x \in [0.5, 1). \end{array} \right.$$

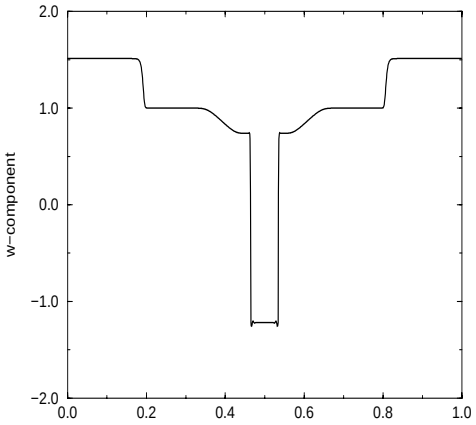

FIG. 6.4. *Numerical approximation of the p-system with artificial viscosity.*

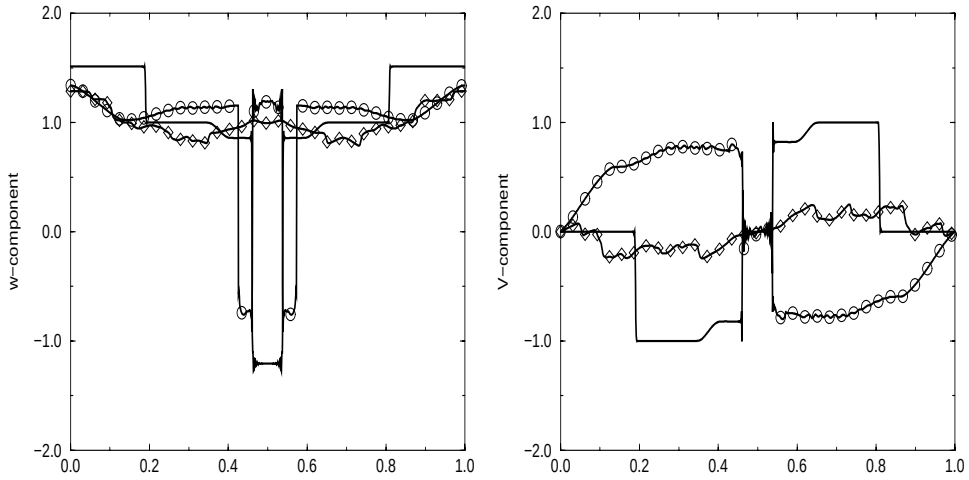

FIG. 6.5. *Time evolution of a diphasic stressed material for short time range (no symbols), intermediate time range (circles), and long time range (diamonds).*

Note that the computed solution (Figure 6.4) corresponds to the four wave "classical" pattern described by Shearer [19].

The second experiment corresponds to the same initial data, but now we performed a longer time computation. We illustrate the property of these materials to come back to their initial configuration at rest, i.e., the constant solution $(w, V) = (1, 0)$. During the computations, numerous phase transitions were created and canceled out. The evolution in time of the approximate solution is displayed in Figure 6.5 for different times. The left figure shows the w-component, and the right figure the V-component.

MULTIGRID METHODS FOR ANISOTROPIC EDGE REFINEMENT*

THOMAS APEL† AND JOACHIM SCHÖBERL‡

Abstract. A finite element method with optimal convergence on nonsmooth three dimensional domains requires anisotropic mesh refinement towards the edges. Multigrid methods for anisotropic tensor product meshes are available and are based either on line (or plane) smoothers or on semicoarsening strategies. In this paper we suggest and analyze a new multigrid scheme combining semicoarsening and line smoothers to obtain a solver of optimal algorithmic complexity for anisotropic meshes along edges.

Key words. multigrid, line Jacobi smoother, edge singularity, anisotropic mesh

1. Introduction.

The finite element simulation of three dimensional problems described by partial differential equations is a challenging task. To keep the simulation time low at least two aspects have to be taken into account. First, the underlying triangulation has to be efficient for approximating the (unknown) solution, and, second, the chosen algorithm for solving the large scale system of equations should be of optimal algorithmic complexity.

For two dimensional elliptic problems optimal triangulations for low order finite elements can be achieved by isotropic mesh refinement based on a posteriori error indicators [21]. The corresponding approach in three dimensions does not, in general, lead to optimal triangulations in the sense of an energy error of order $N^{-p/3}$, p being the polynomial degree. Besides local refinement towards the corners optimal triangulations require *anisotropic* mesh refinement towards the edges of the geometry [1, 2, 3].

Multigrid methods (see [13, 7] and many references therein) are algorithms of optimal (this means linear) complexity for the solution of the systems of linear equations obtained by the finite element method. Multigrid methods have been suggested and analyzed for anisotropic problems with tensor product structure. One approach is to take care of the strong connections by properly designing line or plane smoothers [22, 14, 20, 9], another is to build up the hierarchy of triangulations by semicoarsening [24, 12, 17].

Semicoarsening and line/plane smoothing can be combined. In [5], for example, a certain class of singular perturbed problems is considered, and it is suggested to use semicoarsening with respect to the "harmless" coordinate and line relaxation in the direction of the singular perturbation. In the case of edge singularities, the edge direction could be considered as the harmless direction, but then we need a good plane smoother in the orthogonal direction. Since this strategy is not easy to implement for a hierarchical smoother, we propose using a line smoother in the edge direction

and semicoarsening in the orthogonal plane, which turns out to be easy to implement and efficient in application. In this paper we prove robust V-cycle convergence rates of the suggested scheme. The framework is due to Braess and Hackbusch [6].

We note that this multigrid method is essentially a two dimensional standard multigrid where the third dimension is treated only in the smoother. The two dimensional method with mesh refinement towards singular corners is analyzed in [23]. While in that paper regularity and interpolation results have been cited from [4, 15], we cannot use results from literature immediately. The reason is that the two dimensional plane with mesh refinement is only a trace of the three dimensional domain where the problem is posed. In order to circumvent the loss of regularity due to trace theorems, we introduce an intermediate semidiscrete space $\widetilde{V}$ (see (4.4)) and prove regularity of an auxiliary problem and interpolation results ourselves.

The rest of the paper is organized as follows. In section 2 the investigated problem is formulated. Section 3 introduces the multigrid scheme. The multigrid analysis is performed in section 4; two proofs are postponed to sections 5 and 6. In section 7 we give numerical results confirming our theory.

2. Problem formulation and discretization. Let $\Omega = G \times Z$, where $G \subset \mathbb{R}^2$ is a polygonal domain and Z is a real interval. By the local nature of corner singularities (and then edge ones for Ω), we may suppose that G has possibly one corner with interior angle $\omega > \pi$ at the origin, the other interior angles being smaller than π. The corresponding edge of Ω is part of the z-axis and will be called the singular edge of Ω. Spatial variables are written as $(x, z) = (x_1, x_2, z)$ with $x \in G$ and $z \in Z$. Accordingly, the gradient is split into partial derivatives as $\nabla = (\partial_x, \partial_z)$. Let $V := H_0^1(\Omega)$ be the usual Sobolev space. We consider the Poisson equation with Dirichlet boundary conditions whose variational form is as follows: Find $u \in V$ such that

$$A(u, v) = f(v) \qquad \forall\, v \in V \tag{2.1}$$

with the symmetric, continuous, and elliptic bilinear form $A(.,.)$ and the continuous linear form $f(.)$ on V, namely,

$$A(u, v) := \int_\Omega \nabla u \cdot \nabla v \,\mathrm{d}x \qquad \text{and} \qquad f(v) := \int_\Omega f v \,\mathrm{d}x.$$

The energy norm is defined as $\|u\|_A := A(u, u)^{1/2}$.

The domain Ω is covered by a tensor product triangulation $\mathcal{T} = \mathcal{T}_x \otimes \mathcal{T}_z$, where $\mathcal{T}_x$ and $\mathcal{T}_z$ are conforming triangulations of G and Z, respectively [10]. The two dimensional triangulation $\mathcal{T}_x$ is assumed to fulfill the bounded minimal angle condition. The triangulation $\mathcal{T}_z$ is arbitrary. We define the mesh size functions

$$h_{L,x} = h_{L,x}(x, z) = \operatorname{diam} T_x \qquad \text{for } x \in T_x \in \mathcal{T}_x,\ z \in Z, \tag{2.2}$$

$$h_{L,z} = h_{L,z}(x, z) = \operatorname{diam} T_z \qquad \text{for } x \in G,\ z \in T_z \in \mathcal{T}_z \tag{2.3}$$

for plane and edge directions. The positive integer L denotes the final refinement level of the multigrid hierarchy defined below. We do not assume relations between $h_{L,x}$ and $h_{L,z}$, and thus anisotropic triangulations are included.

We introduce the piecewise affine finite element spaces

$$\mathcal{M}_0^1(\mathcal{T}_x) = \{u \in C^0(G) : u|_{\partial G} = 0, u|_{T_x} \in \mathcal{P}^1\ \forall\, T_x \in \mathcal{T}_x\},$$
$$\mathcal{M}_0^1(\mathcal{T}_z) = \{u \in C^0(Z) : u|_{\partial Z} = 0, u|_{T_z} \in \mathcal{P}^1\ \forall\, T_z \in \mathcal{T}_z\}$$

with the nodal bases $\{\varphi^i_{L,x}\}_{i=1}^{N_{L,x}}$ and $\{\varphi^i_{L,z}\}_{i=1}^{N_{L,z}}$ and space dimensions $N_{L,x}$ and $N_{L,z}$. Then the tensor product bilinear finite element space is defined by

$$V_L := \mathcal{M}^1_0(\mathcal{T}_x) \otimes \mathcal{M}^1_0(\mathcal{T}_z) = \left\{ u = \sum_{i,j} u_{i,j} \varphi^i_{L,x}(x) \varphi^j_{L,z}(z) \right\}.$$

The finite element approximation $u_L \in V_L$ of the variational problem (2.1) is defined by Galerkin projection:

$$A(u_L, v_L) = f(v_L) \qquad \forall\, v_L \in V_L. \tag{2.4}$$

Finally, we define the distance to the singular edge of Ω (the singular point of G, respectively) by

$$r = r(x,z) = r(x) = |x|. \tag{2.5}$$

For the following a priori estimate we refer to [1, 2].

THEOREM 2.1 (a priori estimate). *Let (x_T, z_T) denote the center of the element $T \in \mathcal{T}$. Assume that the mesh sizes fulfill*

$$\begin{array}{lcll} h_{L,x}(x,z) & \simeq & h_L\, r(x_T)^\beta & \forall\,(x,z) \in T \in \mathcal{T}, \\ h_{L,z}(x,z) & \simeq & h_L & \forall\,(x,z) \in T \in \mathcal{T} \end{array} \tag{2.6}$$

with the global (positive) mesh size parameter h_L. The grading parameter β is fixed and is assumed to fulfill

$$1 - \frac{\pi}{\omega} \cdot \frac{p}{2p-2} < \beta < 1. \tag{2.7}$$

Then there holds the a priori error estimate

$$\|u - u_h\|_1 \preceq h_L \|f\|_{0,p} \tag{2.8}$$

for $p > 2$. The number of elements is of optimal order h_L^{-3}.

The condition (2.7) shortens for $p = 2$ to the slightly weaker assumption

$$1 - \frac{\pi}{\omega} < \beta < 1, \tag{2.9}$$

but the estimate (2.8) has been proved in this case in [1] for certain mixed boundary conditions only. For the Dirichlet problem, only the result as stated in the theorem has been obtained yet. We underline that our multigrid theory is also valid under the weaker assumption (2.9).

3. Multigrid algorithm. The multigrid algorithm requires a sequence of triangulations $\mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_L$. We may and will assume that the triangulations and the generated finite element spaces are nested. The proposed refinement strategy is to perform first full refinement in the z-direction and then generate the hierarchy of meshes by refinement in the x-plane. Each triangulation in the hierarchy has the tensor product structure

$$\mathcal{T}_l = \mathcal{T}_{l,x} \otimes \mathcal{T}_z, \qquad 1 \le l \le L.$$

This means that there is the full refinement in z-direction for all levels l, $1 \le l \le L$. We define the mesh size functions $h_{l,x}$ and $h_{l,z} = h_z$ as analogies to (2.2) and (2.3). We assume that the triangulations $\mathcal{T}_{l,x}$ fulfill the bounded minimal angle condition. Further, the grading of the meshes fulfills

$$h_{l,x} = h_{l,x}(x,z) \simeq h_l\, r(x_T)^\beta \qquad \forall\, (x,z) \in T \in \mathcal{T}_l \tag{3.1}$$

with the global mesh size parameter h_l of level l and β from (2.9). The ratio of successive parameters h_{l-1}/h_l is assumed to be bounded.

We mention two methods to generate the sequence of meshes fulfilling (3.1). The first one is to split each triangle of $\mathcal{T}_{l-1,x}$ into four triangles, and move only new nodes next to the singular corner towards the corner. Another possibility, the so-called *dyadic partitioning*, is to use local mesh refinement of $\mathcal{T}_x$, where the elements with $h_{l,x} > C_0 h_l r(x_T)^\beta$ (with a suitably defined constant C_0) are marked for refinement. Both methods have advantages. The first one enables a more efficient data structure; the second one is related to a posteriori mesh size control.

We define the sequence of nested finite element spaces by

$$V_l := \mathcal{M}_0^1(\mathcal{T}_{l,x}) \otimes \mathcal{M}_0^1(\mathcal{T}_z)$$

and the linear operator $A_l : V_l \to V_l$ by

$$(A_l u_l, v_l)_0 = A(u_l, v_l) \qquad \forall\, u_l, v_l \in V_l,$$

$l = 1, 2, \ldots, L$. Additionally, we define for $u_L \in V_L$ the L_2 and energy projections $Q_l : V_L \to V_l$ and $P_l : V_L \to V_l$ by

$$\begin{aligned} (Q_l u_L, v_l)_0 &= (u_L, v_l)_0 \quad \forall v_l \in V_l, \\ A(P_l u_L, v_l) &= A(u_L, v_l) \quad \forall v_l \in V_l, \end{aligned}$$

$l = 1, \ldots, L$. For $1 \le l \le k \le L$ there holds the equation

$$P_l = A_l^{-1} Q_l A_k \qquad \text{on } V_k.$$

The smoother of the considered multigrid scheme is a line Jacobi or symmetric line Gauss–Seidel iteration along mesh lines in the z-direction. Let $\{\varphi_{l,i}^x\}_{i=1}^{N_{l,x}}$ be the nodal basis of $\mathcal{M}_0^1(\mathcal{T}_x)$ and $N_{l,x} = \dim \mathcal{M}_0^1(\mathcal{T}_x)$. We define on each level l the subspaces

$$V_{l,i} := \operatorname{span}\{\varphi_{l,i}^x\} \otimes \mathcal{M}_0^1(\mathcal{T}_z), \quad i = 1, \ldots, N_{l,x},$$

and the corresponding energy projections $P_{l,i} : V_l \to V_{l,i}$, determined for $u_l \in V_l$ by

$$A(P_{l,i} u_l, v_{l,i}) = A(u_l, v_{l,i}) \qquad \forall v_{l,i} \in V_{l,i}.$$

Then the (damped) line Jacobi smoother

$$S_l := I - \tau \sum_{i=1}^{N_{l,x}} P_{l,i}$$

with a suitable damping parameter $\tau \simeq 1$ can be written as

$$S_l = I - \tau D_l^{-1} A_l.$$

The operator D_l^{-1} is indeed the inverse of a self-adjoint and positive definite operator $D_l : V_l \to V_l$. It leads to the inner product

$$D_l(u_l, v_l) := (D_l u_l, v_l)_0 \qquad \forall\, u_l, v_l \in V_l$$

and the associated norm $\|u_l\|_{D_l} := D_l(u_l, u_l)^{1/2}$. By the technique of [8] the analysis of the present paper applies also to the symmetric multiplicative counterpart. The multiplicative version does not need damping at all.

Since the spaces are nested, the grid transfer operators are canonically defined by embedding. As usual, we define the V-cycle multigrid preconditioning operators $C_l^{-1} : V_l \to V_l$ by induction beginning with $C_1 = A_1$. For $l > 1$ and $f \in V_l$ we define $C_l^{-1} f = x_{2m+1}$ where $x_0 = 0$,

$$\left.\begin{aligned} x_i &= x_{i-1} + \tau D_l^{-1}(f - A_l x_{i-1}), \qquad i = 1, 2, \ldots, m, \\ x_{m+1} &= x_m + C_{l-1}^{-1} Q_{l-1}(f - A_l x_m), \\ x_i &= x_{i-1} + \tau D_l^{-1}(f - A_l x_{i-1}), \qquad i = m+2, m+3, \ldots, 2m+1. \end{aligned}\right\} \tag{3.2}$$

First, m steps of presmoothing are performed; then, the coarse grid correction takes place; finally, m steps of postsmoothing are applied. The self-adjoint operator C_L^{-1} can be used in the multigrid iteration with iteration matrix $I - C_L^{-1} A_L$ or as a preconditioner in the conjugate gradient iteration.

4. Multigrid analysis. In this section we analyze the convergence of the multigrid scheme formulated above. In order to apply the multigrid framework of Braess and Hackbusch [6] (see also Theorem 3.6 in [7]), we first need to verify the approximation property

$$\|u_l - P_{l-1} u_l\|_{D_l}^2 \le C \|u_l\|_A^2 \qquad \forall\, u_l \in V_l,\ l = 2, 3, \ldots L; \tag{4.1}$$

see Theorem 4.4. The V-cycle convergence rate estimate is then a corollary. We start with three lemmata.

LEMMA 4.1 (representation of D_l-norm). *For the norm induced by the line Jacobi preconditioner D_l, there holds the following equivalence:*

$$\|u_l\|_{D_l}^2 \simeq \|h_{l,x}^{-1} u_l\|_0^2 + \|\partial_z u_l\|_0^2 \qquad \forall\, u_l \in V_l. \tag{4.2}$$

Proof. Let $u_l \in V_l$. The decomposition $u_l = \sum_{i=1}^{N_{l,x}} u_{l,i}$ with $u_{l,i} \in V_{l,i}$ is unique. By the additive Schwarz method [11] (using the most similar notation) we obtain

$$\|u_l\|_{D_l}^2 = \sum_{i=1}^{N_{l,x}} \|u_{l,i}\|_A^2.$$

Inverse inequalities applied to the basis functions $\varphi_{l,x}^i$ give

$$\begin{aligned} \|u_l\|_{D_l}^2 &= \sum_{i=1}^{N_{l,x}} \left(\|\partial_x u_{l,i}\|_0^2 + \|\partial_z u_{l,i}\|_0^2 \right) \\ &\simeq \sum_{i=1}^{N_{l,x}} \left(\|h_{l,x}^{-1} u_{l,i}\|_0^2 + \|\partial_z u_{l,i}\|_0^2 \right). \end{aligned}$$

By mapping techniques one verifies the L_2 stability of the splitting (see [7, Chapter 5]):

$$\sum_{i=1}^{N_{l,x}} \|c_i \varphi_{l,i}^x\|_{0,T_x}^2 \simeq \left\| \sum_{i=1}^{N_{l,x}} c_i \varphi_{l,i}^x \right\|_{0,T_x}^2 \qquad \forall\, c \in \mathbb{R}^{N_{l,x}},\ \forall\, T_x \in \mathcal{T}_{l,x}. \tag{4.3}$$

Since the equivalence is local, we may insert the element-wise constant weight $h_{l,x}$. Summing over the elements $T_x \in \mathcal{T}_{l,x}$ gives

$$\sum_{i=1}^{N_{l,x}} \|h_{l,x}^{-1} c_i \varphi_{l,i}^x\|_{0,G}^2 \simeq \left\| \sum_{i=1}^{N_{l,x}} h_{l,x}^{-1} c_i \varphi_{l,i}^x \right\|_{0,G}^2.$$

Now set $u_{l,i} =: c_i(z)\varphi_{l,i}^x(x)$. Integration over $z \in Z$ leads to

$$\sum_{i=1}^{N_{l,x}} \|h_{l,x}^{-1} u_{l,i}\|_0^2 \simeq \|h_{l,x}^{-1} u_l\|_0^2.$$

By inserting $\partial_z u_{l,i} =: c_i(z)\varphi_{l,i}^x$ into (4.3), summing over the elements $T_x \in \mathcal{T}_{l,x}$, and integrating over $z \in Z$, we obtain

$$\sum_{i=1}^{N_{l,x}} \|\partial_z u_{l,i}\|_0^2 \simeq \|\partial_z u_l\|_0^2,$$

and the proof is complete. ∎

The sequence of nested spaces V_l is contained in the *semidiscrete* space

$$\widetilde{V} := H_0^1(G) \otimes \mathcal{M}_0^1(\mathcal{T}_z). \tag{4.4}$$

For our analysis we consider a subspace of $\widetilde{V}$,

$$V^+ := \{u \in \widetilde{V} : \|u\|_{V^+} < \infty\},$$
$$\|u\|_{V^+}^2 := \|r^\beta \partial_x \nabla u\|_0^2 + \|r^{\beta-1}\partial_x u\|_0^2,$$

with r and β defined in (2.5) and (2.9), respectively.

LEMMA 4.2 (regularity). *Let $u \in \widetilde{V}$ be the solution of the variational problem*

$$A(u,v) = (f,v)_0 \qquad \forall\, v \in \widetilde{V} \tag{4.5}$$

with f such that $r^\beta f \in L_2$, $1 - \pi/\omega < \beta < 1$. Then there holds the regularity estimate

$$\|u\|_{V^+} \preceq \|r^\beta f\|_0. \tag{4.6}$$

Note that the restriction $\beta < 1$ ensures that $f \in H^{-1}(\Omega)$ [16, Theorem 8.15], and therefore the right-hand side of (4.5) makes sense.

LEMMA 4.3 (interpolation error estimate). *There exists an interpolation operator $I_l : V^+ \to V_l$ such that the interpolation error satisfies*

$$\|u - I_l u\|_A \preceq h_l \|u\|_{V^+} \qquad \forall\, u \in V^+.$$

The proofs of Lemmata 4.2 and 4.3 are postponed to sections 5 and 6.

THEOREM 4.4 (approximation property). *The approximation property* (4.1) *is fulfilled for the considered multigrid method* (3.2).

Proof. We use the equivalence (4.2) and obtain

$$\|u_l - P_{l-1}u_l\|_{D_l}^2 \simeq \|h_{l,x}^{-1}(u_l - P_{l-1}u_l)\|_0^2 + \|\partial_z(u_l - P_{l-1}u_l)\|_0^2.$$

The second term of the right-hand side is simply estimated by

$$\|\partial_z(u_l - P_{l-1}u_l)\|_0 \le \|u_l - P_{l-1}u_l\|_A \le \|u_l\|_A.$$

It remains to show

$$\|h_{l,x}^{-1}(u_l - P_{l-1}u_l)\|_0 \preceq \|u_l\|_A. \tag{4.7}$$

As usual we formulate a dual problem. Since $V_l \subset \widetilde{V}$ for all l, we define $w \in \widetilde{V}$ by

$$A(w,v) = (h_{l,x}^{-2}(u_l - P_{l-1}u_l), v)_0 \qquad \forall\, v \in \widetilde{V}.$$

Lemma 4.2 and assumption (3.1) on $h_{l,x}$ yield

$$\|w\|_{V^+} \preceq \|r^\beta h_{l,x}^{-2}(u_l - P_{l-1}u_l)\|_0 \preceq h_l^{-1}\|h_{l,x}^{-1}(u_l - P_{l-1}u_l)\|_0.$$

Here, no special consideration of the origin is necessary. We continue with Galerkin orthogonality, approximation, and regularity:

$$\begin{aligned}
\|h_{l,x}^{-1}(u_l - P_{l-1}u_l)\|_0^2 &= A(w, u_l - P_{l-1}u_l)\\
&= A(w - I_{l-1}w, u_l - P_{l-1}u_l)\\
&\le \|w - I_{l-1}w\|_A \, \|u_l - P_{l-1}u_l\|_A\\
&\preceq h_l \|w\|_{V^+} \, \|u_l\|_A\\
&\preceq \|h_{l,x}^{-1}(u_l - P_{l-1}u_l)\|_0 \, \|u_l\|_A.
\end{aligned}$$

Dividing by one factor gives (4.7) and thus the desired approximation property. ∎

THEOREM 4.5 (convergence rate estimate). *For the V-cycle multigrid algorithm* (3.2) *with m presmoothing and m postsmoothing steps there holds the convergence rate estimate*

$$\|I - C_L^{-1}A_L\|_A \le \frac{C}{C+2m}. \tag{4.8}$$

Proof. The result follows from the general multigrid theory of Braess and Hackbusch [6] (see also Theorem 3.6 in [7]) by using the approximation property (4.1) which is proved in Theorem 4.4. ∎

5. Regularity.

Proof of Lemma 4.2. First, we use Fourier decomposition in the z-direction to transform the three dimensional problem into a sequence of two dimensional problems. For that, let $\{e_i\}_{i=1}^{N_z}$ be the Fourier basis in $\mathcal{M}_0^1(\mathcal{T}_z)$; that means $e_i = e_i(z)$ are the eigenvectors of

$$(e_i', v')_{0,Z} = \lambda_i^2 (e_i, v)_{0,Z} \qquad \forall\, v \in \mathcal{M}_0^1(\mathcal{T}_z)$$

with $\lambda_i > 0$, $(e_i, e_j)_{0,Z} = \delta_{ij}$, and $(e_i', e_j')_{0,Z} = \lambda_i^2 \delta_{ij}$. Inserting $u = \sum_{i=1}^{N_z} u_i(x) e_i(z)$ into (4.5) yields that $u_i(x)$ solves

$$(\partial_x u_i, \partial_x v)_{0,G} + \lambda_i^2 (u_i, v)_{0,G} = (f_i, v)_{0,G} \qquad \forall\, v \in H_0^1(G), \tag{5.1}$$

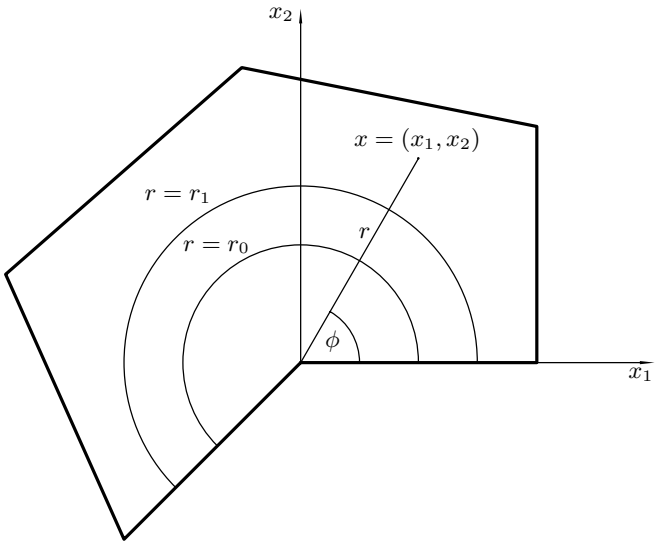

FIG. 5.1. *Illustration of the notation.*

with $f_i = (f, e_i)_{0,Z}$ and $r^\beta f_i \in L_2(G)$. Since

$$\begin{aligned}
\|u\|^2_{V^+} &= \|r^\beta \partial_x^2 u\|_0^2 + \|r^\beta \partial_x \partial_z u\|_0^2 + \|r^{\beta-1}\partial_x u\|_0^2 \\
&= \sum_{i=1}^{N_z} \left\{ \|r^\beta \partial_x^2 u_i\|_{0,G}^2 + \lambda_i^2 \|r^\beta \partial_x u_i\|_{0,G}^2 + \|r^{\beta-1}\partial_x u_i\|_{0,G}^2 \right\}, \\
\|r^\beta f\|_0^2 &= \sum_{i=1}^{N_z} \|r^\beta f_i\|_{0,G}^2,
\end{aligned}$$

the lemma follows after proving the regularity estimate

$$\|r^\beta \partial_x^2 u_i\|_{0,G}^2 + \lambda_i^2 \|r^\beta \partial_x u_i\|_{0,G}^2 + \|r^{\beta-1}\partial_x u_i\|_{0,G}^2 \le C \, \|r^\beta f_i\|_{0,G}^2, \tag{5.2}$$

for the family of two dimensional problems (5.1). The constant C does not depend on λ_i. In the following we will skip the subscript G.

Introduce now a cut-off function $\xi \in C^\infty(\mathbb{R}_+)$, $\xi(r) \in [0,1]$, $\xi(r) = 1$ for $r \le r_0$, $\xi(r) = 0$ for $r \ge r_1 > r_0$; see Figure 5.1 for an illustration. The regular part $u_i^R = (1-\xi)u_i$ satisfies

$$(\partial_x u_i^R, \partial_x v)_0 + \lambda_i^2 (u_i^R, v)_0 = (f_i^R, v)_0 \qquad \forall\, v \in H_0^1(G), \tag{5.3}$$

with $f_i^R = -\Delta[(1-\xi)u_i] + \lambda_i^2(1-\xi)u_i = (1-\xi)f_i - 2(\partial_x u_i)\partial_x(1-\xi) - u_i\Delta(1-\xi)$. Observe that $u_i^R = f_i^R = 0$ for $r \le r_0$. From

$$\|u_i\|_1 \preceq \|f_i\|_{-1} = \sup_{w \in H_0^1(G)} \frac{(f_i, w)}{\|w\|_1} \le \|r^\beta f_i\|_0 \sup_{w \in H_0^1(G)} \frac{\|r^{-\beta} w\|_0}{\|w\|_1} \preceq \|r^\beta f_i\|_0$$

($\|r^{-\beta} w\|_0 \preceq \sum_{j=0}^1 \|r^{1-\beta} D^j w\|_0 \preceq \|w\|_1$ for $\beta < 1$, see [16, Theorem 8.15], there follows

$$\|f_i^R\|_0 \preceq \|r^\beta f_i\|_0. \tag{5.4}$$

Inserting $v = u_i^R$ into (5.3), applying the Cauchy–Schwarz inequality, and dividing one factor $\|u_i^R\|_0$ leads to $\|u_i^R\|_0 \preceq \lambda_i^{-2}\|f_i^R\|_0$ and, consequently, to

$$\lambda_i \|\partial_x u_i^R\|_0 \preceq \|f_i^R\|_0. \tag{5.5}$$

Since u_i^R and f_i^R vanish in an r_0-neighborhood of the corner, a smoothed domain provides the same solution and the full regularity estimate (from the Poisson problem)

$$\|u_i^R\|_2 \preceq \|f_i^R - \lambda_i^2 u_i^R\|_0 \preceq \|f_i^R\|_0.$$

Thus, by using (5.4) and (5.5), the estimate

$$\|r^\beta \partial_x^2 u_i^R\|_0^2 + \lambda_i^2 \|r^\beta \partial_x u_i^R\|_0^2 + \|r^{\beta-1}\partial_x u_i^R\|_0^2 \preceq \|r^\beta f_i\|_0^2$$

is established, and we are left to prove the corresponding inequality for the singular part $u_i^S = \xi u_i$.

Since u_i^S and $f_i^S := f_i - f_i^R$ vanish for $r \geq r_1$, we can extend both by 0 onto the infinite cone $K := \{(r\cos\phi, r\sin\phi) \in \mathbb{R} : 0 < r < \infty, 0 < \phi < \omega\}$, where they fulfill the variational problem

$$(\partial_x u_i^S, \partial_x v)_{0,K} + \lambda_i^2 (u_i^S, v)_{0,K} = (f_i^S, v)_{0,K} \qquad \forall\, v \in H_0^1(K).$$

After the change of variables $\hat{x} = \lambda_i x$, we obtain that $\hat{u}_i^S(\hat{x}) = u_i^S(x)$ is the solution of the following problem with right-hand side $\hat{f}_i^S(\hat{x}) := f_i^S(x)$:

$$(\partial_{\hat{x}} \hat{u}_i^S, \partial_{\hat{x}} \hat{v})_{0,K} + (\hat{u}_i^S, \hat{v})_{0,K} = (\lambda_i^{-2} \hat{f}_i^S, \hat{v})_{0,K} \qquad \forall\, \hat{v} \in H_0^1(K).$$

We can now use the regularity result in Proposition 1.1 of [18, p. 385],

$$\|\hat{u}_i^S\|_{E^2_\beta(K)} \preceq \|\lambda_i^{-2}\hat{f}_i^S\|_{E^0_\beta(K)} \qquad \text{if } |\beta - 1| < \frac{\pi}{\omega},$$

where the space $E^\ell_\beta(K)$ is the completion of $C_0^\infty(\overline{K} \setminus 0)$ with respect to the norm

$$\|v\|^2_{E^\ell_\beta(K)} := \sum_{|\alpha| \leq \ell} \int_K \hat{r}^{2\beta}(1 + \hat{r}^{|\alpha|-\ell})^2 |\hat{D}^\alpha \hat{v}|^2 \, \mathrm{d}\hat{x}$$

[18, p. 300], $\hat{r} := |\hat{x}|$. By transforming the norms one obtains

$$\begin{aligned}
&\int_G \left(r^{2\beta}|\partial_x^2 u_i^S|^2 + (r^{2\beta}\lambda_i^2 + r^{2\beta-2})|\partial_x u_i^S|^2\right) \mathrm{d}x \\
&= \lambda_i^{-2\beta+2} \int_K \hat{r}^{2\beta} \left(|\partial_{\hat{x}}^2 \hat{u}_i^S|^2 + (1 + \hat{r}^{-2})|\partial_{\hat{x}} \hat{u}_i^S|^2\right) \mathrm{d}\hat{x} \\
&\preceq \lambda_i^{-2\beta+2} \int_K \hat{r}^{2\beta} |\lambda_i^{-2} \hat{f}_i^S|^2 \, \mathrm{d}\hat{x} \\
&= \int_G r^{2\beta} |f_i^S|^2 \, \mathrm{d}x.
\end{aligned}$$

Estimate (5.4) implies $\|r^\beta f_i^S\|_0 \preceq \|r^\beta f_i\|_0$, and the desired result is proved. ∎

6. Interpolation.

Proof of Lemma 4.3. Let $\mathrm{Z}_h : H^1(G) \to \mathcal{M}_0^1(\mathcal{T}_{l,x})$ be the Scott–Zhang interpolation operator [19]. For an arbitrary triangle $T_x \in \mathcal{T}_{l,x}$ and for $m = 0, 1$, $\ell = 1, 2$, $p \in [1, \infty]$, the error estimate

$$|u - \mathrm{Z}_h u|_{m,T_x} \preceq |T_x|^{1/2-1/p} h_{l,x}^{\ell-m} |u|_{\ell,p,\tilde{T}_x} \tag{6.1}$$

is satisfied [19], with $\tilde{T}_x$ being the union of T_x and the triangles adjacent to T_x.

Denote by $\{\varphi_i\}_{i=1}^{N_z}$ the nodal basis in $\mathcal{M}_0^1(\mathcal{T}_z)$ and split u with respect to this basis,

$$u = \sum_{i=1}^{N_z} u_i(x)\varphi_i(z).$$

Note that the u_i here are different from those used in section 5. Then we define the interpolation operator $\mathrm{I}_l : \widetilde{V} \to V_l$ by

$$\mathrm{I}_l u = \sum_{i=1}^{N_z} (\mathrm{Z}_h u_i)(x)\varphi_i(z).$$

For an arbitrary element $T = T_x \times (z_j, z_{j+1})$, $T_x \in \mathcal{T}_{l,x}$, $(z_j, z_{j+1}) \in \mathcal{T}_z$, introduce $\tilde{T} := \tilde{T}_x \times (z_j, z_{j+1})$. Now divide the set $\mathcal{T}_l$ into two subsets, $\mathcal{T}_l = \mathcal{T}_{l,R} \cup \mathcal{T}_{l,S}$,

$$\mathcal{T}_{l,R} := \left\{ T \in \mathcal{T}_l : \inf_{(x,z)\in\tilde{T}} |x| > 0 \right\},$$
$$\mathcal{T}_{l,S} := \left\{ T \in \mathcal{T}_l : \inf_{(x,z)\in\tilde{T}} |x| = 0 \right\},$$

namely (regular) elements away from the edge and (singular) elements close to the edge. For elements $T \in \mathcal{T}_{l,R}$ we obtain from (6.1) the estimates

$$\begin{aligned}
\|\partial_x(u - \mathrm{I}_l u)\|_{0,T} &\simeq \sum_{i=j}^{j+1} h_z^{1/2} \|\partial_x(u_i - \mathrm{Z}_h u_i)\|_{0,T_x} \\
&\preceq \sum_{i=j}^{j+1} h_z^{1/2} h_{l,x} \|\partial_x^2 u_i\|_{0,\tilde{T}_x} \\
&\simeq h_{l,x} \|\partial_x^2 u\|_{0,\tilde{T}}, \\
\|\partial_z(u - \mathrm{I}_l u)\|_{0,T} &= h_z^{-1/2} \|(u_{j+1} - u_j) - \mathrm{Z}_h(u_{j+1} - u_j)\|_{0,T_x} \\
&\preceq h_z^{-1/2} h_{l,x} \|\partial_x(u_{j+1} - u_j)\|_{0,\tilde{T}_x} \\
&= h_{l,x} \|\partial_x \partial_z u\|_{0,\tilde{T}}.
\end{aligned}$$

That means, by using (3.1) and $r(x_T) \simeq r(x)$ for $x \in \tilde{T}$,

$$\sum_{T\in\mathcal{T}_{l,R}} \|u - \mathrm{I}_l u\|_A^2 \preceq \sum_{T\mathcal{T}_{l,R}} h_{l,x}^2 \|\nabla\partial_x u\|_{0,\tilde{T}}^2 \preceq h_l^2 \|u\|_{\widetilde{V}}^2, \tag{6.2}$$

where we have also used that only a finite number of $\tilde{T}$ overlap in any point.

For elements $T \in \mathcal{T}_{l,S}$ we derive estimates in a weighted space, namely

$$\begin{aligned}\|\partial_x(u - \mathrm{I}_l u)\|_{0,T} &\simeq \sum_{i=j}^{j+1} h_z^{1/2} \|\partial_x(u_i - \mathrm{Z}_h u_i)\|_{0,T_x} \\ &\preceq \sum_{i=j}^{j+1} h_z^{1/2} \|\partial_x u_i\|_{0,\tilde{T}_x} \\ &\preceq \|\partial_x u\|_{0,\tilde{T}} \\ &\preceq h_{l,x}^{1-\beta} \|r^{\beta-1}\partial_x u\|_{0,\tilde{T}_x} \\ &\simeq h_l \|r^{\beta-1}\partial_x u\|_{0,\tilde{T}_x},\end{aligned}$$

which is valid due to $r \preceq h_{l,x},\ r(x_T) \simeq h_{l,x}$ (thus $h_{l,x}^{1-\beta} \simeq h_l$), and $\beta \leq 1$. Moreover, we get

$$\begin{aligned}\|\partial_z(u - \mathrm{I}_l u)\|_{0,T} &\simeq h_z^{-1/2} \|(u_{j+1} - u_j) - \mathrm{Z}_h(u_{j+1} - u_j)\|_{0,T_x} \\ &\preceq h_z^{-1/2} |T_x|^{-1/2} h_{l,x} \|\partial_x(u_{j+1} - u_j)\|_{0,1,\tilde{T}_x} \\ &\preceq h_z^{-1/2} |T_x|^{-1/2} h_{l,x} \|r^{-\beta}\|_{0,\tilde{T}_x} \|r^{\beta}\partial_x(u_{j+1} - u_j)\|_{0,\tilde{T}_x} \\ &\preceq h_{l,x}^{1-\beta} \|r^{\beta}\partial_x\partial_z u\|_{0,\tilde{T}} \\ &\simeq h_l \|r^{\beta}\partial_x\partial_z u\|_{0,\tilde{T}}.\end{aligned}$$

Consequently, we get

$$\sum_{T \in \mathcal{T}_{l,S}} \|u - \mathrm{I}_l u\|_A^2 \preceq h_{l,x}^{1-\beta} \|u\|_{\widetilde{V}}^2. \tag{6.3}$$

With (6.2) and (6.3) the lemma is proved. ∎

7. Numerical results. For verification of the analysis and to demonstrate the performance of the method, we present the following numerical results. We consider the three dimensional L-shaped domain

$$\Omega = G \times (0,1) \qquad \text{with} \qquad G = (-1,1)^2 \setminus [0,1]^2.$$

An initial triangulation was generated with sixteen nodes and six prismatic elements. For the first tests (Tables 7.1 and 7.2), the elements were successively bisected in the vertical direction until the triangulation $\mathcal{T}_1$ was obtained. For further tests (Table 7.3), we first split the prisms at $z = 0.05$ and proceeded with bisecting as before. The hierarchy of triangulations was obtained by bisecting the whole stack of elements based on a priori element markers. All those elements $T \in \mathcal{T}_l$ were refined for which

$$h_{T,x} r_T^{-\beta} \geq 0.3 \max_{T' \in \mathcal{T}_l} \{h_{T',x} r_{T'}^{-\beta}\}$$

holds. We chose the refinement factor $\beta = 1/2$, which fulfills the condition $\beta > 1/3$ to ensure an asymptotically optimal discretization error. Pictures of the meshes are shown in Figure 7.1 and Figure 7.2.

For preconditioning the resulting finite element system, the multigrid scheme (3.2) was applied with one multiplicative presmoothing and one reverse-order multiplicative

postsmoothing step. For comparison, we did all computations also with a multigrid method with the standard point smoother on the same hierarchy of meshes.

First we computed the condition numbers $\kappa\{C_L^{-1}A_L\}$ of the preconditioned matrix. In addition, we solved the Poisson problem

$$-\Delta u = 1 \text{ in } \Omega, \qquad u = 0 \text{ on } \partial\Omega,$$

and used the multigrid preconditioner in the CG method to reduce the residual error (measured by $\sqrt{r^T C_L^{-1} r}$) by a factor of 10^{-8}. Tables 7.1, 7.2, and 7.3 show the results

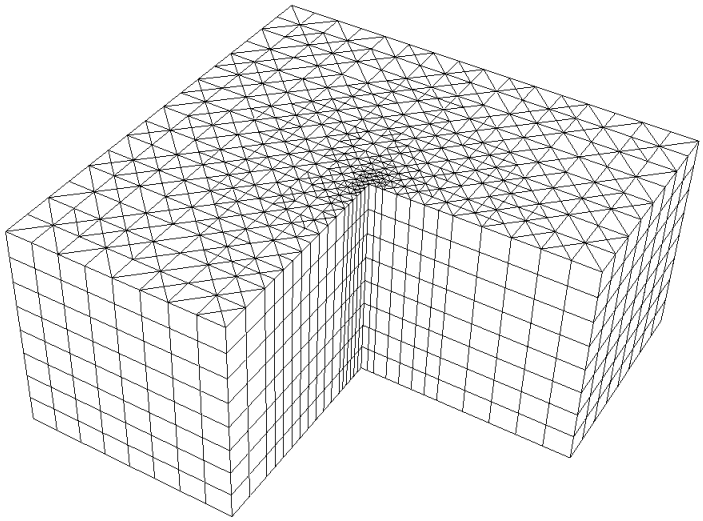

FIG. 7.1. *Mesh with* 8 *uniform layers and* 5013 *nodes.*

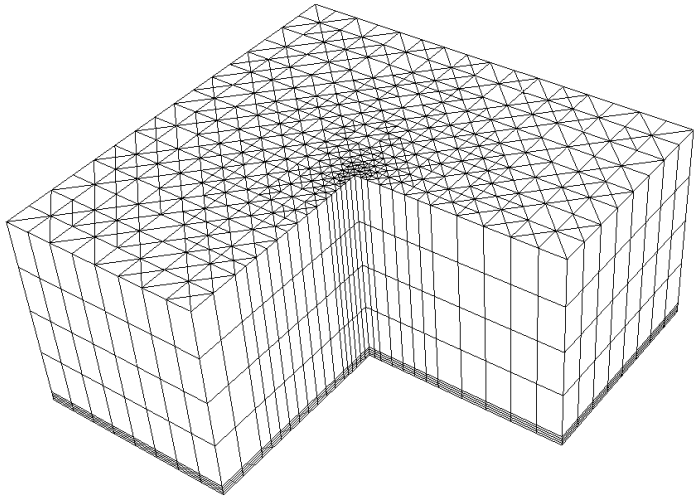

FIG. 7.2. *Mesh with boundary layer at* $z = 0.05$ *and* 5013 *nodes.*

for various numbers of layers in the vertical direction and numbers of nodes. Processor time refers to an SGI Octane R 10000, 250 MHz.

The tests show the robust performance of our multigrid method. The iteration numbers are independent of the refinement depth, and they are also independent of the mesh in edge direction. In comparison, the point smoother has problems with strongly anisotropic meshes, expressed through a large condition number and a large number of CG iterations. The ratio of CPU times is less since our implementation of the line smoother is about twice as expensive as the point smoother. Finally, we mention that the proposed multigrid algorithm can be extended to complicated geometries by macro element techniques.

Acknowledgment. The authors want to thank Prof. Serge Nicaise, Univ. Valenciennes, for his contribution to Lemma 4.2.

ANALYSIS OF A SEMIDISCRETE VERSION OF THE WIGNER EQUATION*

THIERRY GOUDON†

Abstract. We introduce a semidiscretized version of the Wigner equation—discretization concerning the velocity variable. We show that the corresponding discrete velocity problem is well-posed and permits us to approach the solution of the continuous problem when the mesh size of the discretization vanishes. The approximation shows spectral accuracy because the rate of convergence corresponds to the (Sobolev) regularity of the solution of the continuous problem. We also discuss the behavior of the solution with respect to the Planck constant.

Key words. Wigner equation, discrete velocity models, semiclassical limit.

1. Introduction.

We are concerned with the following Wigner (or "quantum Liouville") equation:

$$\partial_t f + \xi \cdot \nabla_x f = \Theta(V)(f) \qquad \text{in } \mathbb{R}_t^+ \times \mathbb{R}_x^N \times \mathbb{R}_\xi^N, \tag{1.1}$$

where the right-hand side is defined by the pseudodifferential operator

$$\Theta(V)(f) = i\mathcal{F}_{y\to\xi}^{-1}\big((V(x+y/2) - V(x-y/2))\widehat{f}(t,x,y)\big). \tag{1.2}$$

Throughout the paper we indifferently denote by $\mathcal{F}(f)$ or by $\widehat{f}$ the Fourier transform given, under suitable integrability conditions on f, by

$$\widehat{f}(y) = \int_{\mathbb{R}^N} e^{-iy\cdot\xi} f(\xi)\, d\xi,$$

and $\mathcal{F}^{-1}(f)(\xi) = \int e^{+iy\cdot\xi} f(y)\, dy/(2\pi)^N$.

This equation is intended to model the quantum transport of electrons in a semiconductor device. The unknown $f(t,x,\xi)$ is real valued, but, contrary to what happens usually in kinetic theory, it is not naturally nonnegative. Usually, the electric potential V is obtained in a self-consistent way through the Poisson equation $\Delta V(t,x) = \int f\, d\xi - D(x)$, D being a given doping profile. This relationship describes the Coulombian interactions between the electrons. Note that this definition is not obvious at all since the natural framework for f is the space $L^2(\mathbb{R}^N \times \mathbb{R}^N)$ so that it is not clear how the integral of f can make sense. However, here and below, we restrict ourselves to a linear situation where the potential V is given; it lies at least in $L^\infty(\mathbb{R}^N)$. Consequently, the operator $\Theta(V)$ is bounded in $L^2(\mathbb{R}^N)$ (see Lemma 3.1).

Equation (1.1) may be seen as the quantum equivalent of the classical Vlasov equation

$$\partial_t f + \xi \cdot \nabla_x f - \nabla_x V \cdot \nabla_\xi f = 0,$$

where we consider that electrons are moving along the trajectories of the Hamiltonian $\xi^2/2 + V$. Actually, the integro-differential equation (1.1) can be obtained by considering the Wigner transform, introduced in [15], of the solution of the Schrödinger equation with potential V. On the other hand, the Vlasov equation can be recovered as the Planck constant goes to 0 when dealing with suitably rescaled Wigner transforms. The mathematical analysis of these questions has been performed by Lions and Paul [11]. We also refer for further details and results on the model to the works of Markowich [6], Markowich and Ringhofer [9], Degond and Markowich [3], and the classical treatise of Markowich, Ringhofer, and Schmeiser [10]. We also quote for an extensive study and application of the Wigner transform the recent paper of Gérard, Markowich, Mauser, and Poupaud [4, 5].

In this work, we wish to introduce a semidiscrete version of the Wigner equation (1.1) and to discuss some properties of the approximation obtained in this way. Discretization here is performed with respect to the ξ variable and we search for a discrete model that looks like (1.1):

$$\partial_t w_n + \xi_n \cdot \nabla_x w_n = \big(\Theta_d(V)(w)\big)_n \qquad \text{in } \mathbb{R}_t^+ \times \mathbb{R}_x^N \times \mathcal{Z}, \tag{1.3}$$

where $\mathcal{Z}$ is some subset of $\mathbb{Z}^N$, possibly $\mathbb{Z}^N$ itself, and ξ_n belongs to a discrete set of velocities parametrized by $n \in \mathcal{Z}$. Therefore, our aim is two fold:

(1) On one hand, the problem (1.3) should be well-posed; see Theorem 3.4.

(2) On the other hand, we expect that (1.3) "approaches" (1.1) in the sense that we may construct from the w_n's a function $f^h(t, x, \xi)$ which converges to f, solution of (1.1), as the parameter h, related to some "mesh size," goes to 0; see Theorem 4.4.

This kind of question has been addressed, for instance, by Ringhofer, with a slightly different approach, in [13], [14] and in Arnold and Ringhofer [2]; more generally, we refer to the recent and complete review on computational methods for semiconductor models [12]. We also mention the work of Arnold, Lange, and Zweifel in [1] in a monodimensional and stationary framework, with a discussion of relevant inflow boundary conditions. Here, our approach is rather close to the analysis of finite difference schemes by Markowich and Poupaud [8]. Also notice the use of Wigner transform techniques to analyze numerical schemes by Markowich, Pietra, and Pohl [7]. Our paper is organized as follows. The next section will introduce the main ideas to achieve the program: it contains basic preliminaries and notations. Section 3 is devoted to the discrete problem: having defined the discrete operator Θ_d, we analyze well-posedness of the corresponding problem (1.3). Roughly speaking, we use the (formal) interpretation of Θ as a convolution to define the operator Θ_d as a discrete convolution. Then, in section 4, we define the approximation f^h from the discrete solution and show a convergence result to the solution of (1.1). Our method has infinite order: the rate of convergence is given by the degree of regularity on the Sobolev scale with respect to the ξ variable of the solution of the continuous problem. Eventually, section 5 is concerned with the semiclassical limit: we investigate the behavior of the solutions as the (scaled) Planck constant goes to 0, and we show convergence to the solution of the Vlasov equation.

2. Preliminaries. Roughly speaking, the idea consists of neglecting the large values of the dual variable, which is denoted $y \in \mathbb{R}^N$, of ξ: we restrict the band length. Then, our construction relies on the following simple observation. Let $g(\xi)$ be a smooth function, in the sense that its Fourier transform has a compact support, i.e., $\mathrm{supp}(\widehat{g}) \subset B(0, R)$. Let $Y = [-L/2, +L/2]^N$ be a box in $\mathbb{R}^N$ with length $L/2$ larger than R. We denote by $L^2_\#$ the set of square integrable functions on Y, which

are Y-periodically extended on $\mathbb{R}^N$. We associate with such a function g a function $G \in L^2_{\#}$ as follows:

$$\left\{ \begin{array}{l} Y = [-L/2, +L/2]^N, \qquad 0 < R < L/2, \\ G(y) = \widehat{g}(y) \quad \text{on } B(0,R), \quad G(y) = 0 \quad \text{on } Y \backslash B(0,R), \\ y \longmapsto G(y) \quad \text{is } Y\text{-periodic.} \end{array} \right. \tag{2.1}$$

A simple computation shows that the Fourier coefficients of G are given by discrete equidistributed values of g; namely, we have

$$\begin{aligned} \widehat{G}(n) &= L^{-N} \int_Y e^{i2\pi y \cdot n/L} G(y)\, dy \\ &= L^{-N} \int_{\mathbb{R}^N} e^{i2\pi y \cdot n/L} \widehat{g}(y)\, dy = (2\pi/L)^N g(2\pi n/L) \end{aligned}$$

by the inversion formula. Therefore, we naturally set $g_M(\xi) = \mathcal{F}^{-1}_{y \to \xi}(\widehat{g_M})(\xi)$ with $\widehat{g_M}(y) = \sum_{|n| \le M} \widehat{G}(n) e^{-i2\pi n \cdot y/L} \chi_{|y| \le R}(y)$. Here and below $|y|$ and $B(0,R)$ refer to the infinite norm on $\mathbb{R}^N$ and the corresponding ball, while, for a multi-integer $n \in \mathbb{Z}^N$, $|n|$ stands for the length $|n| = |n_1| + \cdots + |n_N|$. This actually means that

$$\begin{aligned} g_M(\xi) &= \sum_{|n| \le M} \int_{\mathbb{R}^N} e^{iy \cdot \xi} e^{i2\pi n \cdot y/L} \widehat{G}(n) \chi_{|y| \le R}(y)\, dy/(2\pi)^N \\ &= \sum_{|n| \le M} (2\pi/L)^N \; g(2\pi n/L) \int_{B(0,R)} \exp(iy \cdot (\xi - 2\pi n/L))\, dy/(2\pi)^N \\ &= \sum_{|n| \le M} \left(L^{-N} \; g(2\pi n/L) \prod_{j=1}^N \frac{2\sin(R(\xi_j - 2\pi n_j/L))}{\xi_j - 2\pi n_j/L} \right). \end{aligned}$$

Since, by definition of the Fourier series,

$$\sum_{|n| \le M} \widehat{G}(n) e^{-i2\pi n \cdot y/L} \xrightarrow[M \to \infty]{} G \qquad \text{in } L^2_{\#},$$

it follows that g_M tends to g in $L^2(\mathbb{R}^N)$ as M goes to ∞. Indeed, we have

$$\begin{aligned} \|g - g_M\|^2_{L^2(\mathbb{R}^N)} &= (2\pi)^{-N} \|\widehat{g} - \widehat{g_M}\|^2_{L^2(\mathbb{R}^N)} \\ &= (2\pi)^{-N} \int_{B(0,R)} \Big| \widehat{g}(y) - \sum_{|n| \le M} \widehat{G}(n) e^{-i2\pi n \cdot y/L} \Big|^2 dy \\ &\le (2\pi)^{-N} \int_Y \Big| \widehat{g}(y) - \sum_{|n| \le M} \widehat{G}(n) e^{-i2\pi n \cdot y/L} \Big|^2 dy \\ &\le (L/(2\pi))^N \; \Big\| G - \sum_{|n| \le M} \widehat{G}(n) e^{-i2\pi n \cdot y/L} \Big\|^2_{L^2_{\#}(Y)}. \end{aligned}$$

Let us summarize these simple facts in the following claim (which is known as the Shannon sampling theorem in signal processing).

LEMMA 2.1. *Let $g(\xi)$ be a smooth function whose Fourier transform has a compact support* $\operatorname{supp}(\widehat{g}) \subset B(0,R)$. *Let $Y = [-L/2, +L/2]^N$ with $L/2 > R$ and set*

$$g_M(\xi) = \sum_{|n| \le M} \left(L^{-N} \; g(2\pi n/L) \prod_{j=1}^N \frac{2\sin(R(\xi_j - 2\pi n_j/L))}{\xi_j - 2\pi n_j/L} \right).$$

Then, one has $\lim_{M\to\infty}\|g-g_M\|_2=0$.

Remark 1. In (1.1) the unknown f is obtained as the Wigner transform of some density matrix; in turn, the density $\rho(t,x)=\int f\,d\xi$ makes sense and remains nonnegative; see [11]. It is worth remarking that if g is given through a truncated Wigner transform, namely,

$$g(x,\xi)=\int_{\mathbb{R}^N}\psi(x+y/2)\,\overline{\psi(x-y/2)}\,\chi_{|y|\le R}\,e^{iy\cdot\xi}\,dy/(2\pi)^N$$

with, say, $\psi\in L^2(\mathbb{R}^N)$ (for the sake of simplicity), then the associated discrete density remains nonnegative. This means that

$$\begin{aligned}\sum_{n\in\mathbb{Z}^N}\widehat{G}(x,n)&=\sum_{n\in\mathbb{Z}^N}\widehat{G}(x,n)e^{in\cdot 0}=G(0)\\&=\widehat{g}(x,0)=\Big(\psi(x+y/2)\,\overline{\psi(x-y/2)}\,\chi_{|y|\le R}\Big)\Big|_{y=0}=\psi(x)\,\overline{\psi(x)}\ge 0.\end{aligned}$$

For future use, let us set up here the notations and classical formulae. For f,g in $L^2_\#$, we set

$$\begin{cases}\big(f,g\big)_{L^2_\#}=L^{-N}\displaystyle\int_Y f(y)\overline{g(y)}\,dy, & \|f\|^2_{L^2_\#}=L^{-N}\displaystyle\int_Y|f(y)|^2\,dy,\\ \widehat{f}(n)=\big(f,e^{-i2\pi y\cdot n/L}\big)_{L^2_\#}=L^{-N}\displaystyle\int_Y f(y)e^{+i2\pi y\cdot n/L}\,dy.\end{cases}$$

Note that in this definition the norm on $L^2_\#$ depends on the size of the box. For (complex valued) sequences u,v in $\ell^2=\ell^2(\mathbb{Z}^N)$, we set

$$\big(u,v\big)_{\ell^2}=\sum_{n\in\mathbb{Z}^N}u_n\overline{v_n}.$$

Of course, we have the Parseval formula

$$\big(f,g\big)_{L^2_\#}=\sum_{n\in\mathbb{Z}^N}\widehat{f}(n)\overline{\widehat{g}(n)}=\big(\widehat{f},\widehat{g}\big)_{\ell^2},\tag{2.2}$$

which holds for functions f,g in $L^2_\#$. We will also use the notation

$$(u*v)_n=\sum_{k\in\mathbb{Z}^N}u_kv_{n-k},$$

and we recall that, when u or v belongs to ℓ^1, we have

$$\sum_{n\in\mathbb{Z}^N}(u*v)_n=\sum_{n\in\mathbb{Z}^N}u_n\sum_{n\in\mathbb{Z}^N}v_n.\tag{2.3}$$

3. The discrete problem. In this section, we define the discrete operator by means of discrete convolution. Then, we also discuss its fundamental properties and the well-posedness of the semidiscrete evolution equation.

3.1. The discrete operator. We recall that the Vlasov–Wigner operator (1.2) reads as

$$\Theta(V)(f)(\xi) = i\mathcal{F}^{-1}_{y\to\xi}(D_V\widehat{f})(\xi) = i\int_{\mathbb{R}^N} e^{i\xi\cdot y} D_V(x,y)\widehat{f}(y)\,dy/(2\pi)^N,$$

where we note that

$$D_V(x,y) = V(x+y/2) - V(x-y/2).$$

Then, the Parseval equality gives

$$\begin{aligned}\|\Theta(V)(f)\|_2 &= (2\pi)^{-N/2}\|\mathcal{F}\big(\Theta(V)(f)\big)\|_2 = (2\pi)^{-N/2}\|D_V\mathcal{F}(f)\|_2\\ &\le 2(2\pi)^{-N/2}\|V\|_\infty\|\mathcal{F}(f)\|_2 = 2\|V\|_\infty\|f\|_2.\end{aligned}$$

As mentioned in the introduction, we deduce the following statement.

LEMMA 3.1. *Let V belong to $L^\infty(\mathbb{R}^N)$. The operator $\Theta(V)$ is continuous on $L^2(\mathbb{R}^N)$ with norm $|\!|\!|\Theta|\!|\!|_{\mathcal{L}(L^2(\mathbb{R}^N))} \le 2\|V\|_\infty$.*

Let us consider the action of this operator on the smooth function g studied in the previous section. The support property implies that

$$\Theta(V)(g)(\xi) = i\int_{B(0,R)} e^{i\xi\cdot y} D_V(x,y)\widehat{g}(y)\,dy/(2\pi)^N.$$

Since $\Theta(V)$ is continuous on $L^2(\mathbb{R}^N)$, by Lemma 2.1 $\Theta(V)(g_M)$ converges to $\Theta(V)(g)$ in $L^2(\mathbb{R}^N)$ as $M\to\infty$. However, we get

$$\begin{aligned}\Theta(V)(g_M)(\xi) &= i\int_{B(0,R)} D_V(x,y)\widehat{g_M}(y)e^{i\xi\cdot y}\,dy/(2\pi)^N\\ &= i\sum_{|n|\le M}\widehat{G}(n)\int_{B(0,R)} D_V(x,y)e^{i(\xi-2\pi n/L)\cdot y}\,dy/(2\pi)^N\\ &= \sum_{|n|\le M} g(2\pi n/L)\ a(\xi-2\pi n/L),\end{aligned}\tag{3.1}$$

where

$$a(\zeta) = i\ L^{-N}\ \int_{B(0,R)} D_V(x,y)e^{i\zeta\cdot y}\,dy.\tag{3.2}$$

These formulae will be our guide to write a relevant discrete operator.

In order to construct a discrete model, we set for $n\in\mathbb{Z}^N$ and a mesh size $h>0$,

$$\xi_n = 2\pi nh,$$

and we interpret the w_n's that will be naturally searched for in ℓ^2 as the Fourier coefficients of a function $G\in L^2_\#$ with an h-dependent box $Y^h = [-1/(2h),+1/(2h)]^N$:

$$G(y) = \sum_{n\in\mathbb{Z}^N} w_n e^{-i2\pi hy\cdot n} \in L^2_\#(Y^h).$$

This idea is reminiscient of the deep interpretation of finite difference schemes by the pseudodifferential formalism given by Markowich and Poupaud [8]. According to

(3.1)–(3.2), we define the discrete operator by convolution:

$$\left\{\begin{array}{l} \Big(\Theta_d(V)(w)\Big)_n = \displaystyle\sum_k w_k a_{n-k} = (a*w)_n, \\ a_n = i\ h^N \displaystyle\int_{\mathbb{R}^N} D_V(x,y)\chi_{|y|\leq R^h}(y)\ e^{i2\pi hn\cdot y}\,dy. \end{array}\right. \tag{3.3}$$

Now notice that the truncation acts on the potential with a radius $R^h < (2h)^{-1}$, where R^h is a sequence of positive numbers which tends to ∞ as $h \to 0$: we truncate the frequencies at a level less than the inverse of twice the mesh size. Following (2.1), we introduce

$$\left\{\begin{array}{l} \mathcal{V}(y) = D_V(x,y)\chi_{|y|\leq R^h}(y) \text{ on } B(0,R^h), \qquad \mathcal{V}(y) = 0 \text{ on } Y^h\backslash B(0,R^h), \\ y \longmapsto \mathcal{V}(y) \quad \text{is } Y^h\text{-periodic} \end{array}\right. \tag{3.4}$$

so that $\frac{1}{i}\ a_n$ appears as the nth Fourier coefficient of the Y^h-periodic function $\mathcal{V}$. We also remark that $\mathcal{V} \in L^\infty_\#$. Therefore, we are concerned with the following discrete problem:

$$\left\{\begin{array}{l} \partial_t w_n + \xi_n \cdot \nabla_x w_n = \Big(\Theta_d(V)(w)\Big)_n \qquad \text{in } \mathbb{R}^+_t \times \mathbb{R}^N_x \times \mathbb{Z}^N_n, \\ w_n(t=0,x) = w^0_n(x). \end{array}\right. \tag{3.5}$$

It is not clear at all that (3.3) defines a bounded operator on the natural functional space ℓ^2 for the w_n's since nothing, up to additional regularity assumptions on V, ensures that a belongs to ℓ^1. (See [1] for some comments on this difficulty.) However, we are able to establish this property, which is the discrete analogue of Lemma 3.1.

PROPOSITION 3.2. *The operator Θ_d is a bounded linear operator on ℓ^2, and its norm is estimated uniformly with respect to h by $|\!|\!|\Theta_d|\!|\!|_{\mathcal{L}(\ell^2)} \leq 2\|V\|_\infty$. Furthermore, the coefficients a_n which define the operator Θ_d are real and even; in turn, the operator is skew-symmetric.*

Proof. Let f and g be two functions in $L^2_\#$. In particular, we notice that the product fg lies in $L^1_\#$, and consequently the Fourier coefficients $\widehat{fg}$ belong to ℓ^∞. We shall use the following relation:

$$\widehat{fg}(n) = \widehat{f} * \widehat{g}(n). \tag{3.6}$$

Also note that if $f \in L^2_\#$ and $g \in L^\infty_\#$, we have $fg \in L^2_\#$; therefore, the corresponding coefficients $\widehat{fg}(n) = \widehat{f} * \widehat{g}(n)$ also belong to ℓ^2.

Here, the operator Θ_d is defined by

$$\Big[\Theta_d(v)w\Big](n) = a * w(n) = i\Big(\widehat{\mathcal{V}} * \widehat{G}\Big)(n) = i\widehat{\mathcal{V}G}(n)$$

by using the definitions (3.3) and (3.4), while G is the function in $L^2_\#$ having the w_n's as Fourier coefficients. Then it yields (recall that the norm $\|\cdot\|_{L^2_\#}$ depends on the size of the box Y^h)

$$\|\Theta_d(V)w\|_{\ell^2} = \|\widehat{\mathcal{V}G}\|_{\ell^2} = \|\mathcal{V}G\|_{L^2_\#} \leq \|\mathcal{V}\|_{L^\infty_\#}\|G\|_{L^2_\#} \leq 2\|V\|_{L^\infty}\|w\|_{\ell^2},$$

which proves the boundedness of Θ_d.

Let us go back to (3.6). Relation (2.2) yields

$$\big(fg,\varphi\big)_{L^2_\#} = \sum_{n\in\mathbb{Z}^N} \widehat{fg}(n)\overline{\widehat{\varphi}(n)} = \big(f,\overline{g}\varphi\big)_{L^2_\#} = \sum_{n\in\mathbb{Z}^N} \widehat{f}(n)\overline{\widehat{\overline{g}\varphi}(n)}, \tag{3.7}$$

where φ is a regular enough test function (so that $\widehat{\varphi}\in\ell^1$ for instance). We can write, by using (2.3),

$$\overline{g}\varphi(y) = \sum_{n\in\mathbb{Z}^N} \widehat{\overline{g}\varphi}(n)e^{-i2\pi n\cdot y/L} = \sum_{n\in\mathbb{Z}^N}\left(\sum_{k\in\mathbb{Z}^N}\widehat{\varphi}(k)\widehat{\overline{g}}(n-k)\right)e^{-i2\pi n\cdot y/L},$$

which leads to

$$\widehat{\overline{g}\varphi}(n) = \sum_{k\in\mathbb{Z}^N}\widehat{\varphi}(k)\widehat{\overline{g}}(n-k) = \widehat{\varphi}*\widehat{\overline{g}}(n).$$

Notice that

$$\widehat{\overline{g}}(n) = L^{-N}\int_Y e^{+in\cdot z}\overline{g(z)}\,dz = \overline{L^{-N}\int_Y e^{-in\cdot z}g(z)\,dz} = \overline{\widehat{g}(-n)}.$$

Let us temporarily assume that f and g also are regular functions. We can perform the following computations from (3.7):

$$\begin{aligned}\big(fg,\varphi\big)_{L^2_\#} &= \sum_{n\in\mathbb{Z}^N}\widehat{f}(n)\left(\overline{\sum_{k\in\mathbb{Z}^N}\widehat{\varphi}(k)\overline{\widehat{g}(k-n)}}\right)\\ &= \sum_{n\in\mathbb{Z}^N}\widehat{f}(n)\left(\sum_{k\in\mathbb{Z}^N}\overline{\widehat{\varphi}(k)}\widehat{g}(k-n)\right)\\ &= \sum_{k\in\mathbb{Z}^N}\left(\sum_{n\in\mathbb{Z}^N}\widehat{f}(n)\widehat{g}(k-n)\right)\overline{\widehat{\varphi}(k)}\end{aligned}$$

by using Fubini's theorem (which requires the regularity of the functions). Identifying with the second term in (3.7), we are led to

$$\big(fg,\varphi\big)_{L^2_\#} = \sum_{k\in\mathbb{Z}^N}\Big(\widehat{f}*\widehat{g}\Big)(k)\overline{\widehat{\varphi}(k)} = \sum_{k\in\mathbb{Z}^N}\widehat{fg}(k)\overline{\widehat{\varphi}(k)}.$$

Since this holds for any test function φ, we actually have

$$\widehat{fg}(k) = \widehat{f}*\widehat{g}(k).$$

By a suitable regularization of f and g, but keeping φ regular, we justify this equality that holds in ℓ^∞ for f and g in $L^2_\#$.

Finally, let us investigate the other properties of the operator Θ_d. We recall that

$$a_n(x) = i\ h^N\ \int_{\mathbb{R}^N} D_V(x,y)e^{i2\pi hn\cdot y}\chi_{|y|\le R^h}\,dy.$$

Therefore, we get (with $z=-y$ and using $D_V(x,y)=-D_V(x,-y)$)

$$\begin{aligned}\overline{a_n} &= \overline{i\ h^N \int_{\mathbb{R}^N} D_V(x,y) e^{i2\pi hn\cdot y}\chi_{|y|\leq R^h}\,dy}\\ &= -i\ h^N \int_{\mathbb{R}^N} D_V(x,y) e^{-i2\pi hn\cdot y}\chi_{|y|\leq R^h}\,dy\\ &= i\ h^N \int_{\mathbb{R}^N} D_V(x,z) e^{i2\pi hn\cdot z}\chi_{|z|\leq R^h}\,dz = a_n\\ &= -i\ h^N \int_{\mathbb{R}^N} D_V(x,y) e^{i2\pi h(-n)\cdot y}\chi_{|y|\leq R^h}\,dy = -a_{-n},\end{aligned}$$

which proves that the coefficients a_n are real and even. In turn, we readily check that Θ_d is skew-symmetric. □

Let us conclude with some remarks. Since the discrete operator (3.3) is essentially obtained by truncating the potential, it will be convenient to discuss some properties of the approximate operator

$$\Theta^h(V)(f) = \mathcal{F}^{-1}_{y\to\xi}\big(D_V\ \chi_{|y|\leq R^h}\ \widehat{f}(y)\big)$$

defined for any $f\in L^2(\mathbb{R}^N)$. The proof of the following claim is quite obvious.

LEMMA 3.3. *The approximated operator Θ^h fulfills the following properties:*

(i) *if* $\mathrm{supp}(\widehat{f})\subset B(0,R)$ *with* $0<R\leq R^h$, *then* $\Theta^h(f)=\Theta(f)$;

(ii) $\Theta^h(V)(f)$ *converges to* $\Theta(f)$ *in* $L^2(\mathbb{R}^N)$ *as* $h\to 0$. *If, furthermore,* f *lies in the Sobolev space* $H^s(\mathbb{R}^N)$, $s>0$, *we get*

$$\|\Theta^h(V)(f)-\Theta(V)(f)\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} \leq \frac{4\|V\|^2_\infty}{(2\pi)^N}\ \frac{\|f\|^2_{H^s(\mathbb{R}^N)}}{(1+(R^h)^2)^s}.$$

As an example, it is maybe worth writing the discrete problem in a usual matrix form, when considering the mono-dimensional situation and restricting to $2M+1$ unknowns $(w_{-M},\dots,w_M)=W$. We get

$$\partial_t W + \Lambda\partial_x W = AW,$$

where Λ is the $(2M+1)\times(2M+1)$ diagonal matrix $\Lambda=\mathrm{diag}(\xi_{-M},\dots,\xi_M)$, while the coefficients of $A\in\mathcal{M}_{(2M+1)\times(2M+1)}$ are defined by

$$A_{nk} = a_{n-k}(x) = i\ h\ \int_{-R^h}^{+R^h} D_V(x,y) e^{i2\pi h(n-k)y}\,dy.$$

A short computation leads to

$$A_{nk} = 4h\ \int_{x-R^h/2}^{x+R^h/2} V(z)\sin(4\pi h(n-k)(x-z))\,dz.$$

We see easily on this formula that A is skew-symmetric.

3.2. Analysis of the discrete problem. Now it is quite easy to prove existence-uniqueness for the discrete problem (3.5). It is convenient here to interpret $\ell^2(\mathbb{Z}^N)=L^2(\mathbb{Z}^N,dn)$, where dn stands for the counting measure on $\mathbb{Z}^N$, and to introduce

$$L^2(\mathbb{R}^N_x\times\mathbb{Z}^N_n) = \Big\{w:(x,n)\in\mathbb{R}^N_x\times\mathbb{Z}^N_n \longmapsto w(x,n)\in\mathbb{C},$$

$$\text{such that } \int_{\mathbb{R}^N_x\times\mathbb{Z}^N_n}|w(x,n)|^2\,dx\,dn = \sum_{n\in\mathbb{Z}^N}\int_{\mathbb{R}^N_x}|w(x,n)|^2\,dx<\infty\Big\}.$$

Accordingly, in what follows, it is convenient to denote by $u(n)$ instead of u_n the nth term of a sequence u parametrized by $n \in \mathbb{Z}^N$. When no confusion can arise we will also drop the variables t, x.

THEOREM 3.4. *Let $w^0 \in L^2(\mathbb{R}^N_x \times \mathbb{Z}^N_n)$, and $V \in L^\infty(\mathbb{R}^N)$. The problem (3.5) has a unique mild solution $w \in C^0([0,T]; L^2(\mathbb{R}^N_x \times \mathbb{Z}^N_n))$. Furthermore, if the initial data w^0 is real valued (i.e., $w^0(x,n) = \overline{w^0(x,n)}$ for all $n \in \mathbb{Z}^N$ and a.a. $x \in \mathbb{R}^N$), then the solution w remains real valued and the following relation*

$$\|w(t)\|_{L^2(\mathbb{R}^N \times \mathbb{Z}^N)} = \|w^0\|_{L^2(\mathbb{R}^N \times \mathbb{Z}^N)} \tag{3.8}$$

holds.

Proof. The proof is quite classical, and the argument is the same as for the continuous problem in [3], [9]. The key point is to interpret Θ_d as a bounded perturbation of the semigroup generator $-\xi_n \cdot \nabla_x$. Integrating along the characteristic lines $x + t\xi_n$ leads to

$$w(t,x,n) = w^0(x - t\xi_n, n) + \int_0^t \Theta_d(V) w(\tau, x - (t-\tau)\xi_n, n)\, d\tau.$$

Then, we show the existence-uniqueness of the solution by a classical contraction argument.

Since the $a(n)$'s are real, now we deduce that

$$\overline{\Theta_d(w)(n)} = \overline{\sum_{k \in \mathbb{Z}^N} a(n-k) w(k)} = \sum_{k \in \mathbb{Z}^N} a(n-k) \overline{w(k)} = \Theta_d(\overline{w})(n).$$

It follows that $\overline{w(n)}$ satisfies the same equation as $w(n)$; hence, if $w^0(n) = \overline{w^0(n)}$, we still have $w(n) = \overline{w(n)}$. In other words, w is real valued.

Finally, we are left with the task of proving the relation (3.8) in $L^\infty(\mathbb{R}^+, L^2(\mathbb{R}^N \times \mathbb{Z}^N,\, dx \otimes dn))$. Indeed, multiplying (3.5) by $\overline{w^h_n}$ and integrating yield

$$\|w^h(t)\|^2_{L^2(\mathbb{R}^N \times \mathbb{Z}^N)} + \int_0^t \int \big(\Theta_d(w), w\big)_{\ell^2}(s,x)\, dx\, ds = \|w^h(0)\|^2_{L^2(\mathbb{R}^N \times \mathbb{Z}^N)}.$$

Since $\big(\Theta_d(w), w\big)_{\ell^2} \in i\mathbb{R}$, we immediately obtain (3.8). ∎

4. Approximation and convergence analysis. In this section, we investigate the limit of vanishing mesh size $h \to 0$. We thus show that the discrete problem approaches the continuous one.

4.1. Construction of the approximation. In the previous section, we have obtained a sequence, parametrized by $t \in \mathbb{R}^+$ and $x \in \mathbb{R}^N$, $\big(w(t,x,n)\big)_{n \in \mathbb{Z}^N} \in \ell^2$, a solution of (3.5). Of course, this sequence depends on the parameter h through the truncation acting on the potential and the definition of the discrete velocities $\xi_n = 2\pi n h$. We emphasize this dependence from now on by denoting the solution $w^h(t,x,n)$.

According to the strategy described in section 2, let us introduce now for $(t,x,\xi) \in \mathbb{R}^+ \times \mathbb{R}^N \times \mathbb{R}^N$ the function

$$f^h(t,x,\xi) = \mathcal{F}^{-1}_{y \to \xi} \left(\sum_{n \in \mathbb{Z}^N} w^h(t,x,n)\; e^{-i2\pi h y \cdot n}\; \chi_{|y| \le R^h} \right).$$

It is maybe more explicit to write, as in Lemma 2.1,

$$f^h(t,x,\xi) = \sum_{n\in\mathbb{Z}^N} \left(w^h(t,x,n) \prod_{j=1}^N \frac{\sin(R^h(\xi_j - 2\pi h n_j))}{\pi(\xi_j - 2\pi h n_j)} \right).$$

Since we naturally choose $R^h \sim (2h)^{-1}$ for h small, this indicates that $f(\xi_n)$ is approximated by $(2\pi h)^{-N} w_n^h$.

Our final aim is to show that f^h approaches the solution f of (1.1) as the mesh size h goes to 0. Notice that here f is approximated by a formula looking like $\sum_{n\in\mathbb{Z}^N} w^h(t,x,n) S^h(\xi - \xi_n)$. In comparison to [13], [14], instead of approaching f by periodic functions, we use an expansion on cardinal sinus functions. In [13], [14] difficulties arise since we use a basis of functions that are not elements of the same space as the exact solution; in turn, our proof of convergence becomes very simple.

To this end, we naturally have to prepare in a suitable way the initial data $w^{h,0}$ for the discrete problem (3.5). They obtained by regularizing the initial data f^0 of the continuous problem. Precisely, we set, still using the arguments of section 2,

$$\begin{cases} f^{h,0}(x,\xi) = \mathcal{F}^{-1}_{y\to\xi}\big(\widehat{f^0}(x,y)\ \chi_{|y|\le R^h}\big), \\ G^{h,0}(x,y) = \widehat{f^0}(x,y) \quad \text{on } B(0,R^h), \qquad G^{h,0}(x,y) = 0 \quad \text{on } Y^h\backslash B(0,R^h), \\ G^{h,0}(x,y) = \quad \text{is } Y^h\text{-periodic}, \\ w^{h,0}(x,n) = \widehat{G^{h,0}(x,\cdot)}(n) = f^{h,0}(x,2\pi n h)(2\pi h)^N, \end{cases}$$

where f^0 is real valued and belongs to $L^2(\mathbb{R}^N\times\mathbb{R}^N)$. This construction leads to the following behavior of the discrete solution with respect to h.

LEMMA 4.1. *One has the estimate* $\|w^{h,0}\|^2_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)} \le (2\pi h)^N \ \|f^0\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}$. *Consequently, one deduces that* $\|w^h(t)\|^2_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)} \le (2\pi h)^N \ \|f^0\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}$.
