Proof. The estimate on the solution w^h is an immediate consequence of (3.8) combined with the estimate on the initial data. By construction, one has

$$\begin{aligned} \|w^{h,0}\|^2_{\ell^2} &= \|\widehat{G^{h,0}}\|^2_{\ell^2} = \|G^{h,0}\|^2_{L^2_\#} \\ &= h^N \int_{Y^h} |G^{h,0}(y)|^2\,dy = h^N \int_{\mathbb{R}^N} |\widehat{f^{h,0}}(y)|^2\,dy \\ &= h^N \int_{\mathbb{R}^N} |\widehat{f^0}(y)\chi_{|y|\le R^h}|^2\,dy \le h^N\ (2\pi)^N\ \|f^0\|^2_{L^2(\mathbb{R}^N)}, \end{aligned}$$

which establishes Lemma 4.1. ∎

One deduces that f^h is a bounded sequence in the natural functional space.

COROLLARY 4.2. *The sequence* $\big(f^h\big)_{h>0}$ *is bounded in* $L^\infty(\mathbb{R}^+, L^2(\mathbb{R}^N\times\mathbb{R}^N))$. *Furthermore,* f^h *is real valued.*

Proof. This is a consequence of Lemma 2.1 and Lemma 4.1. It is convenient to introduce the Y^h-periodic function G^h defined by the coefficients w_n^h:

$$G^h(t,x,y) = \sum_{n\in\mathbb{Z}^N} w^h(t,x,n)\ e^{-i2\pi h y\cdot n} \quad \in L^\infty(\mathbb{R}^+, L^2(\mathbb{R}^N; L^2_\#(Y^h))).$$

We have (omiting t, x variables for the sake of clarity)

$$\begin{aligned}
\|f^h\|^2_{L^2(\mathbb{R}^N_\xi)} &= (2\pi)^{-N}\ \|\widehat{f^h}\|^2_{L^2(\mathbb{R}^N_y)} \\
&= (2\pi)^{-N}\ \int_{\mathbb{R}^N} \left| \sum_{n\in\mathbb{Z}^N} w^h(n)\ e^{-i2\pi hy\cdot n} \right|^2 \ \chi_{|y|\le R^h}\, dy \\
&= (2\pi)^{-N}\ \int_{B(0,R^h)} \left| \sum_{n\in\mathbb{Z}^N} w^h(n)\ e^{-i2\pi hy\cdot n} \right|^2 \ dy \\
&\le (2\pi h)^{-N}\ h^N \int_{Y^h} \left| \sum_{n\in\mathbb{Z}^N} w^h(n)\ e^{-i2\pi hy\cdot n} \right|^2 \ dy \\
&\le (2\pi h)^{-N}\ h^N \int_{Y^h} |G^h(y)|^2\, dy \\
&\le (2\pi h)^{-N}\ \|G^h\|^2_{L^2_\#(Y^h)} = (2\pi h)^{-N}\ \|w^h\|^2_{\ell^2} \le \|f^0\|^2_{L^2(\mathbb{R}^N)},
\end{aligned}$$

which proves the asserted bound.

It remains to prove that $f^h \in \mathbb{R}$. Conjugating $\widehat{f^h}$ we get

$$\begin{aligned}
\overline{\widehat{f^h}(y)} &= \sum_{n\in\mathbb{Z}^N} \overline{w^h(n)}\ e^{+i2\pi hy\cdot n} \chi_{|y|\le R^h} \\
&= \sum_{n\in\mathbb{Z}^N} w^h(n)\ e^{-i2\pi h(-y)\cdot n} \chi_{|-y|\le R^h} = \widehat{f^h}(-y)
\end{aligned}$$

since, by Theorem 3.4, the w^h_n's are real valued. This ends the proof. □

Now let us show that f^h is not far from satisfying (1.1).

LEMMA 4.3. *The function f^h satisfies a approximate form of* (1.1) *in the sense that*

$$\langle (\partial_t + \xi\cdot\nabla_x) f^h - \Theta(V)(f^h), \varphi\rangle_{\mathcal{S}';\mathcal{S}} = 0$$

holds for all φ in $\mathcal{S}((0,T)\times\mathbb{R}^N\times\mathbb{R}^N)$ with $\mathrm{supp}(\widehat{\varphi}) \subset (0,T)\times\mathbb{R}^N\times B(0,R)$, $0 < R < R^h$.

Proof. Let us set

$$T^h(t,x,n) = (\partial_t + \xi_n\cdot\nabla_x) w^h(t,x,n) - \Theta_d(w^h(t,x,\cdot))(n).$$

We have to compute the action on φ of

$$\mathcal{F}^{-1}_{y\to\xi}\left(\sum_{n\in\mathbb{Z}^N} e^{-i2\pi hy\cdot n}\ T^h(t,x,n)\ \chi_{|y|\le R^h} \right).$$

Obviously, there is no difficulty with the time derivative, which commutes with the other operations. It leads to $\partial_t f^h$. Let us consider the Vlasov term. Since, by its definition, f^h has a Fourier transform compactly supported (with respect to the variable y) in $B(0,R^h)$, we have, by Lemma 3.3(i), $\Theta^h(f^h) = \Theta(f^h)$, with

$$\widehat{\Theta(f^h)}(t,x,y) = i\ D_V(x,y)\ \chi_{|y|\le R^h} \sum_{n\in\mathbb{Z}^N} w^h(t,x,n)\ e^{-i2\pi hy\cdot n}.$$

Let us denote this quantity by $\gamma^h(y)$. It corresponds to

$$\left\{\begin{array}{l}\Gamma^h(t,x,y)=\gamma^h(y)=i\ \mathcal{V}^h(x,y)\ G^h(t,x,y)\quad \text{on } y\in B(0,R^h),\\ \Gamma^h(t,x,y)=0\quad \text{on } y\in Y^h\backslash B(0,R^h),\\ \Gamma^h(t,x,y)\quad \text{is } Y^h\text{-periodic (with respect to } y).\end{array}\right.$$

The corresponding Fourier coefficients, therefore, are given by

$$\widehat{\Gamma^h}(n)=i\ \widehat{\mathcal{V}^h\ G^h}(n)=i\ \widehat{\mathcal{V}^h}*\widehat{G^h}(n)=a^h*w^h(n)=\Theta_d(w^h)(n)$$

by using the definitions of $a^h,\mathcal{V}^h$ and w^h,G^h.

Applying Lemma 2.1 yields the following equality:

$$\begin{aligned}\Theta(f^h)=\mathcal{F}^{-1}_{y\to\xi}(\gamma^h)&=\mathcal{F}^{-1}_{y\to\xi}\left(\sum_{n\in\mathbb{Z}^N}\widehat{\Gamma^h}(t,x,n)\ e^{-i2\pi hy\cdot n}\ \chi_{|y|\le R^h}\right)\\&=\mathcal{F}^{-1}_{y\to\xi}\left(\sum_{n\in\mathbb{Z}^N}\Theta_d(w^h)(t,x,n)\ e^{-i2\pi hy\cdot n}\ \chi_{|y|\le R^h}\right),\end{aligned}$$

which is exactly what we need when treating the right-hand side of (3.5). It remains to deal with the convective term. Difficulties could arise due to the truncation $\chi_{|y|\le R^h}$ in the Fourier variable; however, we have chosen a test function φ that does not feel the action of this operation. Set

$$\begin{aligned}&C^h(t,x,y)\\&=\sum_{n\in\mathbb{Z}^N}e^{-i2\pi hy\cdot n}\ \xi_n\cdot\nabla_x w^h(t,x,n)\ \chi_{|y|\le R^h}\\&=(-i)^{-1}\sum_{n\in\mathbb{Z}^N}\nabla_y\nabla_x\big(e^{-i2\pi hy\cdot n}\ w^h(t,x,n)\big)\ \chi_{|y|\le R^h}\in\mathcal{S}'(\mathbb{R}^+\times\mathbb{R}^N\times\mathbb{R}^N).\end{aligned}$$

We compute, by using the exchange formula,

$$\begin{aligned}&\langle\mathcal{F}^{-1}_{y\to\xi}(C^h(t,x,\cdot))(\xi),\varphi\rangle_{\mathcal{S}',\mathcal{S}}\\&=(2\pi)^{-N}\langle\overline{\mathcal{F}(\overline{C^h})},\varphi\rangle\\&=(2\pi)^{-N}\overline{\left\langle\overline{C^h},\mathcal{F}(\overline{\varphi})\right\rangle}\\&=(2\pi)^{-N}\overline{\left\langle\overline{(-i)^{-1}\nabla_y\nabla_x\big(e^{-i2\pi hy\cdot n}\ w^h(t,x,n)\big)},\mathcal{F}(\overline{\varphi})\right\rangle}\end{aligned}$$

since $\widehat{\varphi}\chi_{|y|\le R^h}=\widehat{\varphi}$ by using the support assumption. It follows that

$$\begin{aligned}&\langle\mathcal{F}^{-1}_{y\to\xi}(C^h(t,x,\cdot))(\xi),\varphi\rangle_{\mathcal{S}',\mathcal{S}}\\&=(2\pi)^{-N}\overline{\int\overline{(-i)^{-1}\sum_{n\in\mathbb{Z}^N}e^{-i2\pi hy\cdot n}\ w^h(t,x,n)}\ \nabla_y\nabla_x\mathcal{F}(\overline{\varphi})\,dy\,dx\,dt}.\end{aligned}$$

However, we have

$$\nabla_y\mathcal{F}(\overline{\varphi})=\nabla_y\left(\int_{\mathbb{R}^N}e^{-iy\cdot\xi}\overline{\varphi}(\xi)\,d\xi\right)=-i\mathcal{F}(\xi\overline{\varphi}),$$

which still has its support in $B(0,R^h)$ (with respect to the variable y). Hence, we obtain

$$\begin{aligned}&\langle \mathcal{F}^{-1}_{y\to\xi}(C^h(t,x,\cdot))(\xi),\varphi\rangle_{\mathcal{S}',\mathcal{S}}\\ &= (2\pi)^{-N}\overline{\int \overline{(-i)^{-1}\sum_{n\in\mathbb{Z}^N} e^{-i2\pi hy\cdot n}\ w^h(t,x,n)}\ (-i)\mathcal{F}\big(\xi\cdot\nabla_x\overline{\varphi}\big)\,dy\,dx\,dt}.\end{aligned}$$

We go back with the exchange formula to

$$\begin{aligned}&\langle \mathcal{F}^{-1}_{y\to\xi}(C^h(t,x,\cdot))(\xi),\varphi\rangle_{\mathcal{S}',\mathcal{S}}\\ &= -(2\pi)^{-N}\overline{\left\langle \mathcal{F}_{y\to\xi}\left(\overline{\sum_{n\in\mathbb{Z}^N} e^{-i2\pi hy\cdot n}w^h(t,x,n)\chi_{|y|\le R^h}}\right),\xi\cdot\nabla_x\overline{\varphi}\right\rangle}\\ &= \langle \xi\cdot\nabla_x f^h,\varphi\rangle.\end{aligned}$$

This ends the proof of Lemma 4.3. ∎

4.2. Convergence. Now we are able to establish the convergence of our scheme, which is shown to have spectral accuracy.

THEOREM 4.4. *Assume that f^0 belongs to $H^1(\mathbb{R}^N\times\mathbb{R}^N)$, and $V\in L^\infty(\mathbb{R}^N)$. Let $0<T<\infty$. Let $f\in C^0(\mathbb{R}^+;L^2(\mathbb{R}^N\times\mathbb{R}^N))\cap L^\infty(0,T;H^1(\mathbb{R}^N\times\mathbb{R}^N))$ be the associated solution of* (1.1). *Let $R^h\le(2h)^{-1}$, with $2R^h\sim 1/h$ as h goes to 0. Then, we have on the time interval $(0,T)$*

$$\|(f-f^h)(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\le C_T\ h,$$

where C_T depends on T and on these H^1 norms.

If, furthermore, $f^0\in L^2(\mathbb{R}^N_x;H^s(\mathbb{R}^N_\xi))$ with $f\in L^\infty(0,T;L^2(\mathbb{R}^N_x;H^s(\mathbb{R}^N_\xi)))$ and $\nabla_x f\in L^2((0,T)\times\mathbb{R}^N_x;H^{s-1}(\mathbb{R}^N_\xi))$ for some $s>0$, then the method becomes of order s since we have $\|(f-f^h)(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\le C_T\ h^s$.

Remark 2. In the statement, the Sobolev regularity of the solution is assumed. Then, the boundedness of the potential suffices to justify the spectral accuracy. However, regularity of the solution depends certainly on the regularity of the potential. For instance, one proves readily the H^1 regularity by assuming $V\in W^{1,\infty}(\mathbb{R}^N)$.

Proof. It would be tempting, in order to derive such an estimate, to multiply the equation satisfied by $f-f^h$ by $\overline{f-f^h}$. However, this function is not an admissible test function in the sense of Lemma 4.3 since its Fourier transform is not compactly supported. Then, let us introduce a function ζ that fulfills

$$\begin{cases}\zeta(y)=1 \quad \text{on } B(0,1/2), \qquad \zeta(y)=0 \quad \text{on } \mathbb{R}^N\backslash B(0,1),\\ 0\le\zeta(y)\le 1,\\ \zeta\in C^1(\mathbb{R}^N).\end{cases}$$

Set $\zeta^h(y)=\zeta(y/R^h)$, and $t^h(t,x,\xi)=\mathcal{F}^{-1}_{y\to\xi}(\widehat{f}(t,x,y)\ \zeta^h(y))$. Mainly, the rate of convergence is determined by the obvious estimate

$$\|f-t^h\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}=(2\pi)^{-N}\|\widehat{f}(1-\zeta^h)\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\le\frac{\|f\|^2_{L^2(\mathbb{R}^N_x;H^s(\mathbb{R}^N_\xi))}}{(2\pi)^N(1+(R^h/2)^2)^s}.$$

Furthermore, let us look at the equation satisfied by t^h: we shall show that it satisfies (1.1) up to an error term due to the truncation, which can be controlled in $\mathcal{O}(R^h)$ thanks to the H^1 regularity of the solution. From (1.1), we obtain

$$\partial_t t^h = \mathcal{F}^{-1}(\partial_t \widehat{f}\ \zeta^h) = \mathcal{F}^{-1}(\widehat{\Theta(f)}\ \zeta^h) - \mathcal{F}^{-1}(\widehat{\xi\cdot\nabla_x f}\ \zeta^h).$$

The Vlasov term simply gives

$$\begin{aligned}\mathcal{F}^{-1}(\widehat{\Theta(f)}\ \zeta^h) &= \mathcal{F}^{-1}(D_V\ \widehat{f}\ \zeta^h)\\ &= \mathcal{F}^{-1}(D_V\ \mathcal{F}\mathcal{F}^{-1}(\widehat{f}\ \zeta^h)) = \mathcal{F}^{-1}(D_V\ \mathcal{F}(t^h)) = \Theta(t^h).\end{aligned}$$

However, error terms are produced by the convective term. Indeed, we have

$$\begin{aligned}\mathcal{F}^{-1}(\widehat{\xi\cdot\nabla_x f}\ \zeta^h) &= \int_{\mathbb{R}^N} e^{iy\cdot\xi}\ \widehat{\xi\cdot\nabla_x f}(y)\ \zeta^h(y)\,dy/(2\pi)^N\\ &= \int_{\mathbb{R}^N_y} e^{iy\cdot\xi}\left(\int_{\mathbb{R}^N_\eta} e^{-iy\cdot\eta}\ \eta\cdot\nabla_x f(\eta)\,d\eta\right)\zeta^h(y)\,dy/(2\pi)^N\\ &= \int_{\mathbb{R}^N_\eta} \eta\cdot\nabla_x f(\eta)\left(\int_{\mathbb{R}^N_y} e^{iy\cdot(\xi-\eta)}\zeta^h(y)\,dy\right)\,d\eta/(2\pi)^N\\ &= \int_{\mathbb{R}^N_\eta} \eta\cdot\nabla_x f(\eta)\widehat{\zeta^h}(\eta-\xi)\,d\eta/(2\pi)^N\\ &= \left(\eta\cdot\nabla_x f(\eta) * \check{\widehat{\zeta^h}}(\eta)\right)(\xi)/(2\pi)^N.\end{aligned}$$

Let us split this expression as follows:

$$\mathcal{F}^{-1}(\widehat{\xi\cdot\nabla_x f}\ \zeta^h) = \xi\cdot\nabla_x t^h + E^h,$$

where

$$E^h = \left(\eta\cdot\nabla_x f * \check{\widehat{\zeta^h}}(\eta)\right)(\xi)/(2\pi)^N - \xi\cdot\nabla_x\big(\mathcal{F}^{-1}(\widehat{f}\ \zeta^h)\big).$$

Since

$$\xi\cdot\nabla_x\big(\mathcal{F}^{-1}(\widehat{f}\ \zeta^h)\big) = \int_{\mathbb{R}^N_y} e^{iy\cdot\xi}\zeta^h(y)\xi\cdot\left(\int_{\mathbb{R}^N_\eta} e^{-iy\cdot\eta}\nabla_x f(\eta)\,d\eta\right)\,dy/(2\pi)^N,$$

we get

$$\begin{aligned}E^h &= \int_{\mathbb{R}^N}\int_{\mathbb{R}^N} e^{iy\cdot(\xi-\eta)}(\eta-\xi)\cdot\nabla_x f(\eta)\ \zeta^h(y)\,d\eta\,dy/(2\pi)^N\\ &= \int_{\mathbb{R}^N_\eta}\nabla_x f(\eta)\left(\int_{\mathbb{R}^N_y}(\eta-\xi)e^{iy\cdot(\xi-\eta)}\zeta^h(y)\,dy\right)\,d\eta/(2\pi)^N\\ &= \int_{\mathbb{R}^N_\eta}\nabla_x f(\eta)\left(\frac{1}{i}\int_{\mathbb{R}^N_y} e^{iy\cdot(\xi-\eta)}\nabla_y(\zeta^h(y))\,dy/(2\pi)^N\right)\,d\eta\\ &= \big(\nabla_x f * \mathcal{F}^{-1}_{y\to\xi}(\nabla_y\zeta^h)/i\big)(\xi).\end{aligned}$$

This produces the estimate

$$\begin{aligned}\|E^h\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} &= (2\pi)^{-N}\|\widehat{\nabla_x f}\ \nabla_y(\zeta^h)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\\ &\le \|\nabla_x f\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\ \|\nabla_y(\zeta^h)\|_{L^\infty(\mathbb{R}^N)}\\ &\le \|\nabla_x f\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\ \|\nabla_y\zeta\|_{L^\infty(\mathbb{R}^N)}/R^h.\end{aligned}$$

Therefore, $e^h = t^h - f^h$ has a compactly supported Fourier transform in $B(0,R^h)$ and satisfies, in the sense of Lemma 4.3,

$$(\partial_t + \xi\cdot\nabla_x - \Theta^h)(e^h) = E^h.$$

Standard manipulations lead to the estimate

$$\|e^h(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} \le \|e^h(0)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} + \int_0^t \|E^h\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} \le C_T/R^h,$$

where C_T depends on T, $\|f^0\|_{H^1}$, and $\|f\|_{H^1}$. Now, we can estimate $\|f-f^h\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}$ $\le \|e^h(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} + \|f-t^h\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} \le C_T/R^h$, which concludes the proof.

Order s information on f leads to the following slight modification when estimating E^h:

$$\begin{aligned}&\|E^h\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\\ &\quad= (2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} |\widehat{\nabla_x f}(y)|^2\ |\nabla_y(\zeta^h)|^2\,dy\,dx\\ &\quad\le (2\pi)^{-N}\int_{\mathbb{R}^N}\int_{\mathbb{R}^N} |\widehat{\nabla_x f}(y)|\ \chi_{|y|\ge R^h/2}\ \frac{1}{(R^h)^2}\ \|\nabla_y\zeta\|^2_{L^\infty(\mathbb{R}^N)}\,dy\,dx\\ &\quad\le \|\nabla_x f\|^2_{L^2(\mathbb{R}^N_x;H^{s-1}(\mathbb{R}^N_\xi))}\ \|\nabla_y\zeta\|^2_{L^\infty(\mathbb{R}^N)}\ \frac{2\ (2\pi)^{-N}}{(1+(R^h)^2)^{s-1}\ (R^h)^2}.\end{aligned}$$

The announced rate of convergence follows easily. ∎

5. Semiclassical limit. Let us now take into account the (scaled) Planck constant $\varepsilon > 0$. Accordingly, the Wigner operator reads as

$$\begin{aligned}\Theta^\varepsilon(V)f &= \frac{i}{\varepsilon}\mathcal{F}^{-1}_{y\to\xi}\Big(\big(V(x+\varepsilon y/2) - V(x-\varepsilon y/2)\big)\ \widehat{f}(y)\Big)\\ &= \frac{i}{(2\pi)^N}\int_{\mathbb{R}^N}\frac{V(x+\varepsilon y/2)-V(x-\varepsilon y/2)}{\varepsilon}\,\widehat{f}(y)\ e^{iy\cdot\xi}\,dy.\end{aligned}$$

It is a well-established fact that the corresponding sequence $\big(f^\varepsilon\big)_{\varepsilon>0}$ of solutions of the Wigner equation

$$\partial_t f^\varepsilon + \xi\cdot\nabla_x f^\varepsilon = \Theta^\varepsilon(V)(f^\varepsilon)$$

converges, in some weak sense, to a solution F of the Vlasov equation

$$\partial_t F + \xi\cdot\nabla_x F = \nabla_x V\cdot\nabla_\xi F \tag{5.1}$$

as $\varepsilon\to 0$. We refer to Lions and Paul [11] for precise statements and rigorous proofs; this can be formally understood from the following facts:

$$\begin{cases} i\ \dfrac{V(x+\varepsilon y/2)-V(x-\varepsilon y/2)}{\varepsilon} \longrightarrow i\nabla_x V\cdot y \quad \text{as } \varepsilon\to 0,\\ \widehat{iy} = \nabla\delta_{\xi=0}.\end{cases}$$

Therefore, we would naturally expect that our discrete scheme reproduces this behavior. Let us first set up some definitions.

Recall that the discrete operator is defined, see (3.3), by

$$\left\{\begin{array}{l} a_n^{\varepsilon,h} = i\ h^N \displaystyle\int_{\mathbb{R}^N} \frac{V(x+\varepsilon y/2)-V(x-\varepsilon y/2)}{\varepsilon}\,\chi_{|y|\leq R^h}(y)\ e^{i2\pi hn\cdot y}\,dy, \\ \Big(\Theta_d^{\varepsilon,h}(V)(w)\Big)_n = (a^{\varepsilon,h}*w)_n = i\widehat{\mathcal{V}^{\varepsilon,h}G^h}(n), \end{array}\right. \tag{5.2}$$

where $w(x,n)$ belongs to $L^2(\mathbb{R}^N\times\mathbb{Z}^N)$, and $\mathcal{V}^{\varepsilon,h}(x,\cdot)$ and $G^h(x,\cdot)$ are the Y^h-periodic functions defined on the cell by

$$\left\{\begin{array}{l} \mathcal{V}^{\varepsilon,h}(x,y) = \dfrac{V(x+\varepsilon y/2)-V(x-\varepsilon y/2)}{\varepsilon}\,\chi_{|y|\leq R^h}(y), \\ G^h(x,y) = \displaystyle\sum_{n\in\mathbb{Z}^N} w(x,n)\ e^{-i2\pi hn\cdot y}. \end{array}\right.$$

For small ε, we expect that $\Theta_d^{\varepsilon,h}$ looks like the following discrete operator:

$$\Big(\mathbb{V}^h(V)(w)\Big)_n = (u^h*w)_n = i\widehat{\mathcal{Y}^hG^h}(n), \tag{5.3}$$

where $\mathcal{Y}^h(x,\cdot)$ is the Y^h-periodic function given by

$$\mathcal{Y}^h(x,y) = \nabla_x V(x)\cdot y\ \chi_{|y|\leq R^h}(y)$$

for $x\in\mathbb{R}^N$ and $y\in Y^h$. This discrete operator corresponds to our interpretation of the Vlasov term $\nabla_x V\cdot\nabla_\xi g$ when reasoning as in section 2 for a function g with $\widehat{g}$ compactly supported in $B(0,R)$. We remark that

$$u_n^h = i\int_{\mathbb{R}^N}\nabla_x V(x)\cdot y\ \chi_{|y|\leq R^h}(y)\ e^{i2\pi hn\cdot y}\,dy = \overline{u_n^h} = -u_{-n}^h$$

so that the coefficients are real and even; in turn, $\mathbb{V}^h$ is a skew-symmetric operator of $\mathcal{L}(\ell^2)$ for $h>0$ fixed, and $V\in W^{1,\infty}(\mathbb{R}^N)$. Hence, reproducing the arguments of the proof of Theorem 3.4, we show that the corresponding discrete problem is well-posed.

THEOREM 5.1. *Let $v^{h,0}\in L^2(\mathbb{R}^N_x\times\mathbb{Z}^N_n)$ and $V\in W^{1,\infty}(\mathbb{R}^N)$. The problem*

$$\left\{\begin{array}{ll} \partial_t v_n + \xi_n\cdot\nabla_x v_n = \mathbb{V}^h(V)(v)_n & \text{in } \mathbb{R}^+_t\times\mathbb{R}^N_x\times\mathbb{Z}^N_n, \\ v_{|t=0} = v^0 & \end{array}\right. \tag{5.4}$$

has a unique mild solution $v^h\in C^0([0,T];L^2(\mathbb{R}^N_x\times\mathbb{Z}^N))$. Furthermore, if the initial data $v^{h,0}$ are real valued (i.e., $v^{h,0}(x,n)=\overline{v^{h,0}(x,n)}$ for all $n\in\mathbb{Z}^N$ and a.a. $x\in\mathbb{R}^N$), then the solution v^h remains real valued, and the relation $\|v^h(t)\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)} = \|v^{h,0}\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}$ holds.

Let us denote, according to section 4,

$$\left\{\begin{array}{l} f^{\varepsilon,h}(t,x,\xi) = \mathcal{F}^{-1}_{y\to\xi}\Big(\displaystyle\sum_{n\in\mathbb{Z}^N} w^{\varepsilon,h}(t,x,n)\ e^{-i2\pi hy\cdot n}\ \chi_{|y|\leq R^h}\Big), \\ F^h(t,x,\xi) = \mathcal{F}^{-1}_{y\to\xi}\Big(\displaystyle\sum_{n\in\mathbb{Z}^N} v^h(t,x,n)\ e^{-i2\pi hy\cdot n}\ \chi_{|y|\leq R^h}\Big), \end{array}\right.$$

where $w^{\varepsilon,h}$ and v^h are the solutions of (3.5) and (5.4), respectively, obtained from well-prepared initial data as in Lemma 4.1. We naturally assume in this construction that $f^{\varepsilon,0}(x,\xi)$, which defines $w^{\varepsilon,h}_{t=0}$, tends (strongly in $L^2(\mathbb{R}^N\times\mathbb{R}^N)$) to $F^0(x,\xi)$, associated with $v^h_{t=0}$, when $\varepsilon\to 0$. Of course, we wish to justify the following diagram:

$$\begin{array}{ccc} w^{\varepsilon,h},\ f^{\varepsilon,h} & \xrightarrow{\quad h\to 0\quad} & f^{\varepsilon} \\ \text{discrete Wigner} & & \text{continuous Wigner} \\ \Big\downarrow \varepsilon\to 0 & & \Big\downarrow \varepsilon\to 0,\ [11] \\ v^h,\ F^h & \xrightarrow[\quad h\to 0\quad]{} & F \\ \text{discrete Vlasov} & & \text{continuous Vlasov} \end{array}$$

Obviously, Lemma 4.1 adapts to the scaling.

LEMMA 5.2. *We have*

$$\|w^{\varepsilon,h}(t)\|^2_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)} \le (2\pi h)^N\ \|f^{\varepsilon,0}\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)} \le (2\pi h)^N\ C_0,$$
$$\|v^h(t)\|^2_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)} \le (2\pi h)^N\ \|F^0\|^2_{L^2(\mathbb{R}^N\times\mathbb{R}^N)},$$

and the (real valued) sequences $\left(F^h\right)_{h>0}$, $\left(f^{\varepsilon,h}\right)_{\varepsilon>0,h>0}$ *are bounded in* $L^\infty(\mathbb{R}^+, L^2(\mathbb{R}^N\times\mathbb{R}^N))$, *uniformly with respect to* ε *and* h.

Next, the strategy developed in the proofs of Lemma 4.3 and Theorem 4.4 applies when dealing with v^h, F^h, and we are led to the following statement.

THEOREM 5.3. *Let* $V\in W^{1,\infty}(\mathbb{R}^N)$. *The function* F^h *satisfies an approximate form of* (5.1) *in the sense that*

$$\langle(\partial_t+\xi\cdot\nabla_x)F^h-\nabla_x V\cdot\nabla_\xi F^h,\varphi\rangle_{\mathcal{S}';\mathcal{S}}=0$$

holds for all φ *in* $\mathcal{S}((0,T)\times\mathbb{R}^N\times\mathbb{R}^N)$ *with* $\operatorname{supp}(\widehat{\varphi})\subset(0,T)\times\mathbb{R}^N\times B(0,R)$, $0<R<R^h$.

Assume that F^0 *belongs to* $H^1(\mathbb{R}^N\times\mathbb{R}^N)$. *Let* $0<T<\infty$. *Let* $F\in C^0(\mathbb{R}^+;L^2(\mathbb{R}^N\times\mathbb{R}^N))\cap L^\infty(0,T;H^1(\mathbb{R}^N\times\mathbb{R}^N))$ *be the associated solution of* (5.1). *Let* $R^h\le(2h)^{-1}$, *with* $2R^h\sim 1/h$ *as* h *goes to 0. Then, we have on the time interval* $(0,T)$,

$$\|(F-F^h)(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\le C_T\ h,$$

where C_T *depends on* T *and on these* H^1 *norms.*

If, furthermore, $F^0\in L^2(\mathbb{R}^N_x;H^s(\mathbb{R}^N_\xi))$ *with* $F\in L^\infty(0,T;L^2(\mathbb{R}^N_x;H^s(\mathbb{R}^N_\xi)))$, *and* $\nabla_x F\in L^2((0,T)\times\mathbb{R}^N_x;H^{s-1}(\mathbb{R}^N_\xi))$ *for some* $s>0$, *then the method becomes of order* s *since we have* $\|(F-F^h)(t)\|_{L^2(\mathbb{R}^N\times\mathbb{R}^N)}\le C_T\ h^s$.

We are left with the task of studying the behavior of $w^{\varepsilon,h}$ as $\varepsilon\to 0$. The convergence to the solution of the discrete Vlasov equation will be a consequence of the following claim.

PROPOSITION 5.4. *Let* $V\in C^1\cap W^{1,\infty}(\mathbb{R}^N)$. *The sequence of operators* $\Theta^{\varepsilon,h}_d$ *converges strongly to* $\mathbb{V}^h$: *for any* $h>0$ *and* $w\in L^2(\mathbb{R}^N\times\mathbb{Z}^N)$, *we have*

$$\lim_{\varepsilon\to 0}\|\Theta^{\varepsilon,h}_d(w)-\mathbb{V}^h(w)\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}=0.$$

Proof. We simply remark that

$$\mathcal{V}^{\varepsilon,h}(x,y)-\mathcal{Y}^h(x,y)=\int_0^1\Big(\nabla_x V(x+\varepsilon y(\theta-1/2))-\nabla_x V(x)\Big)\cdot y\ \chi_{|y|\le R^h}(y)\,d\theta.$$

Since $\nabla_x V$ is continuous and bounded, we can apply the Lebesgue theorem which yields for $h>0$, $x\in\mathbb{R}^N$, $y\in Y^h$,

$$\lim_{\varepsilon\to 0}\big(\mathcal{V}^{\varepsilon,h}(x,y)-\mathcal{Y}^h(x,y)\big)=0,$$

with the domination $|\mathcal{V}^{\varepsilon,h}(x,y)-\mathcal{Y}^h(x,y)|\leq 2\|\nabla_x V\|_{L^\infty(\mathbb{R}^N)}R^h$. Therefore, we deduce that

$$\begin{aligned}
&\|\Theta_d^{\varepsilon,h}(w)-\mathbb{V}^h(w)\|^2_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}\\
&\quad=\|(\mathcal{V}^{\varepsilon,h}-\mathcal{Y}^h)G^h\|^2_{L^2(\mathbb{R}^N;L^2(Y^h))}\\
&\quad=h^N\int_{\mathbb{R}^N}\int_{Y^h}\Big|\mathcal{V}^{\varepsilon,h}(x,y)-\mathcal{Y}^h(x,y)\Big|^2\,|G^h(x,y)|^2\,dy\,dx\\
&\quad\longrightarrow 0
\end{aligned}$$

as $\varepsilon\to 0$, still by using the Lebesgue theorem. □

THEOREM 5.5. *As ε goes to 0, the following convergences hold:*

$$\begin{cases}\displaystyle\lim_{\varepsilon\to 0}\|w^{\varepsilon,h}-v^h\|_{L^\infty(0,T;L^2(\mathbb{R}^N\times\mathbb{Z}^N))}=0,\\ \displaystyle\lim_{\varepsilon\to 0}\|f^{\varepsilon,h}-F^h\|_{L^\infty(0,T;L^2(\mathbb{R}^N\times\mathbb{R}^N))}=0.\end{cases}$$

Proof. It suffices to establish the convergence at the discrete level since the second follows easily (see the proof of Corollary 4.2). Set $e^{\varepsilon,h}(t,x,n)=w^{\varepsilon,h}(t,x,n)-v^h(t,x,n)$, which satisfies

$$\partial_t e_n^{\varepsilon,h}+\xi_n\cdot\nabla_x e_n^{\varepsilon,h}-\Theta_d^{\varepsilon,h}(V)(e^{\varepsilon,h})_n=\big[\big(\mathbb{V}^h-\Theta_d^{\varepsilon,h}(V)\big)v^h\big]_n.$$

Multiplying by $\overline{e^{\varepsilon,h}}$ and using that $\Theta_d^{\varepsilon,h}$ is skew-symmetric lead to the estimate

$$\|e^{\varepsilon,h}(t)\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}\leq\|e^{\varepsilon,h}(0)\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}+\int_0^t\|(\Theta_d^{\varepsilon,h}-\mathbb{V}^h)v^h(s)\|_{L^2(\mathbb{R}^N\times\mathbb{Z}^N)}\,ds$$

that tends to 0 when $\varepsilon\to 0$ by Proposition 5.4 and the hypothesis made on the initial data. □

As a concluding remark, let us show that the Vlasov equation can still be obtained from the discrete model when $\varepsilon,h\to 0$ together. Indeed, $f^{\varepsilon,h}$ satisfies a uniform L^2 estimate; see Lemma 5.2. Then, up to a subsequence, we can suppose that it has a weak limit

$$f^{\varepsilon,h}\rightharpoonup g\qquad\text{weakly}-*\text{ in }L^\infty(0,T;L^2(\mathbb{R}^N\times\mathbb{R}^N)).$$

Multiplying by a test function $\varphi\in\mathcal{S}(\mathbb{R}\times\mathbb{R}^N\times\mathbb{R}^N)$ with $\mathrm{supp}(\widehat{\varphi})\subset(0,T)\times\mathbb{R}^N\times B(0,R)$, $0<R<R^h$, we have the formula of Lemma 4.3:

$$\langle(\partial_t+\xi\cdot\nabla_x)f^{\varepsilon,h},\varphi\rangle_{\mathcal{S}';\mathcal{S}}=\langle f^{\varepsilon,h},\Theta^{\varepsilon,*}(V)\varphi\rangle_{\mathcal{S}';\mathcal{S}}.$$

When $\varepsilon,h\to 0$, the weak convergence of $f^{\varepsilon,h}$ combines to the strong convergence $\Theta^{\varepsilon,*}(V)\varphi\to-\nabla_x V\cdot\nabla_\xi\varphi$ in L^2, and we get

$$\langle(\partial_t+\xi\cdot\nabla_x)g-\nabla_x V\cdot\nabla_\xi g,\varphi\rangle_{\mathcal{S}';\mathcal{S}}=0$$

for any $\varphi \in \mathcal{S}$ whose Fourier transform is compactly supported. However, the set of admissible test functions is dense in $\mathcal{S}$ so that we deduce that g actually solves the Vlasov equation.

THEOREM 5.6. *When ε, h tend to 0 together, the sequence $f^{\varepsilon,h}$ converges weakly in $L^2((0,T)\times\mathbb{R}^N\times\mathbb{R}^N)$ to a solution of the Vlasov equation.*

Unfortunately, this result does not prevent oscillations that can occur in the limit $\varepsilon, h \to 0$: the convergence is obtained only in a weak sense, and we are not able to provide order of convergence for the norm of the error.

SYMMETRIC FUNCTIONS APPLIED TO DECOMPOSING SOLUTION SETS OF POLYNOMIAL SYSTEMS*

ANDREW J. SOMMESE†, JAN VERSCHELDE‡, AND CHARLES W. WAMPLER§

Abstract. Many polynomial systems have solution sets comprised of multiple irreducible components, possibly of different dimensions. A fundamental problem of numerical algebraic geometry is to decompose such a solution set, using floating-point numerical processes, into its components. Prior work has shown how to generate sets of generic points guaranteed to include points from every component. Furthermore, we have shown how monodromy can be used to efficiently predict the partition of these points by membership in the components. However, confirmation of this prediction required an expensive procedure of sampling each component to find an interpolating polynomial that vanishes on it. This paper proves theoretically and demonstrates in practice that linear traces suffice for this verification step, which gives great improvement in both computational speed and numerical stability. Moreover, in the case that one may still wish to compute an interpolating polynomial, we show how to do so more efficiently by building a structured grid of samples, using divided differences, and applying symmetric functions. Several test problems illustrate the effectiveness of the new methods.

1. Introduction.

Polynomial systems arising in scientific and engineering applications often have positive dimensional solution sets; moreover, the solution set may have components of different dimensions. For instance, in mechanical engineering, we may be given a set of rigid parts and a prescription for how they are to be connected by joints. These specifications can be formulated as a system of polynomial equations whose solution set describes the locations in space of all the parts. It may happen that some assemblies of the mechanism are rigid, whereas other assemblies of the same parts and joints allow an internal motion having one or more degrees of freedom. The notion of "degrees of freedom of motion" as used by a kinematician is thus equivalent to the "dimension of a solution set" for the polynomial system. Problems with similar characteristics arise in other disciplines.

For such polynomial systems, our task is to identify all irreducible components of the solution set, characterizing each component by its dimension and degree and providing witness points on the set. This problem is central in a developing new field: *numerical algebraic geometry*, a research program initiated in [33]. The goal is to

design numerically stable algorithms to efficiently solve polynomial systems arising in science and engineering. In the next two paragraphs we explain the relation of the current paper to previous work.

In [26], we presented a new method of embedding a polynomial system into a larger polynomial system, such that the numerical solution of a sequence of homotopies computes generic points on all solution components of the original polynomial system. These witness points form the basic data to decompose the solution sets into irreducible components, as we showed in [27]. Starting at any solution point, one may use numerical continuation to sample the component that contains it and construct an interpolation polynomial vanishing on the component. This polynomial can then be used as a filter to find all other witness points in the same component. In this way, all of the points can be sorted into components, eventually producing a list of all the components and certain properties of them, such as degree and dimension. However, the construction of the interpolating polynomial is both expensive and numerically difficult for high degree components in many variables. In [28], we reduced the number of variables by detecting the linear span of a component and reduced the degree of the interpolant by using central projections; but even so, numerically challenging cases remain.

An alternative approach to determining which witness points lie on the same component is to use monodromy to find paths connecting them [29]. In computational experiments, this approach has been found to be numerically stable on high degree components and highly successful in predicting the correct decomposition. However, it is heuristic in that connections are discovered via randomly generated monodromy loops, with no a priori way to know when all connections have been found. Thus, the prediction must still be validated by other means. In [29], this was accomplished by computing an interpolating polynomial, as before, so the problem of high degree polynomials was not eliminated.

The most significant contribution of this paper is to prove theoretically and demonstrate computationally that *linear* traces are sufficient for validating a proposed decomposition. Due to the superior numerical stability of linear systems, we are able to run our decomposition method entirely with standard machine arithmetic. For polynomial systems with coefficients given as double floating-point numbers, whose evaluation map is numerically well conditioned, and whose irreducible components have multiplicity one, our algorithm does not need multiprecision arithmetic to decompose the solution sets, even in the occurrence of high degree components. For components with multiplicity higher than one, multiprecision arithmetic is required to track the singular paths [31].

In the case that one still wishes to compute polynomials that vanish on a component, the higher order traces can be used to good effect. First, the witness points on a component can be marched forward together to provide a structured grid of sample points. Then, with a "bootstrapping" technique, we can construct the Newton form of the interpolating polynomial. The use of traces enables the direct application of Newton interpolation, eliminating the need for extra bootstrapping samples. A final improvement in efficiency is gained by using Newton identities to reduce the number of samples to the number of monomials in the interpolant, which is the minimum possible. However, this last shortcut is inadvisable for high degree components as our tests show that it is numerically less stable than using a full grid of samples.

Several test problems illustrate the effectiveness of the methods. Particularly notable are the results on a problem from mechanical engineering: a special Stewart–

Gough platform mechanism that has internal motion. For one case in which the motion is one irreducible component of degree 28, the computing time for validating the decomposition predicted by monodromy is reduced from 1.3 hours using our former methods to less than 5 seconds with the linear trace. This is now comparable to the time required for a related example in which the degree 28 component breaks up into several low degree irreducibles. Hence the running time of the algorithm is no longer sensitive to such changes in the geometry of the solution set. Moreover, it is interesting to note that the automated numerical method discovered a solution component that was missed by experts using a manual approach aided by computer symbolic processing.

In brief, the paper proceeds as follows. In the next section, we collect some results on traces, which are then applied to monodromy in section three. In sections four and five, we outline the interpolation algorithms and apply them in the last section on the cyclic 8-roots and 9-roots problems and on the mechanism problem just mentioned.

2. Traces of functions. The results in this section are quite old, e.g., Theorem 2.1 is for the most part just a statement of the constructions that go along with one of the main approaches to the Weierstrass preparation theorem [8, 9]. Since we do not know a reference for the full result, we include a proof. The statement in Corollary 2.2 is equivalent to the zero-sum relations that have been used in a similar context, e.g., [3, 6, 20, 21, 22, 23, 24].

It is natural to consider functions $f(x_1,\ldots,x_d)$ of points $(x_1,\ldots,x_d)\in\mathbb{C}^d$ which are invariant under the symmetric group S_d of permutations of the variables. To be precise, given any permutation, $\sigma(i)=j_i$ for $i=1,\ldots,d$, of the integers from 1 to d, we have a linear transformation of $\mathbb{C}^d$, which by abuse of notation we also label σ, which takes $(x_1,\ldots,x_d)$ to $(x_{j_1},\ldots,x_{j_d})$. A function on $\mathbb{C}^d$ is said to be *symmetric* if

$$f\circ\sigma = f(x_{j_1},\ldots,x_{j_d}) = f(x_1,\ldots,x_d) \tag{2.1}$$

for all $\sigma\in S_d$. It is a basic fact of invariant theory that the ring of symmetric polynomials on $\mathbb{C}^d$, denoted by $\mathbb{C}[x_1,\ldots,x_d]^{S_d}$, is abstractly isomorphic to the ring of polynomials on $\mathbb{C}^d$, i.e., there exists a ring isomorphism $\mathbb{C}[z_1,\ldots,z_d]\cong\mathbb{C}[x_1,\ldots,x_d]^{S_d}$. There are many useful choices of assignments of symmetric functions to the z_i making this isomorphism explicit. The two that we use are

1. the assignment leading to the elementary symmetric functions

$$z_i\mapsto t_i := \frac{1}{(d-i)!i!}\sum_{\sigma\in S_d} x_{\sigma(1)}\cdots x_{\sigma(i)} = \sum_{1\le j_1<\ldots<j_i\le d} x_{j_1}\ldots x_{j_i} \tag{2.2}$$

   for i from 1 to d, and
2. the assignment leading to the power sums

$$z_i\mapsto p_i := \frac{1}{(d-1)!}\sum_{\sigma\in S_d} x_{\sigma(1)}^i = \sum_{j=1}^{d} x_j^i \tag{2.3}$$

   for i from 1 to d.

The connection of t_i with roots of a polynomial of degree d is easy to see, upon noting that

$$(w-x_1)(w-x_2)\cdots(w-x_d) = w^d - t_1w^{d-1} + t_2w^{d-2} - \cdots + (-1)^d t_d. \tag{2.4}$$

If, in the right-hand side of (2.4), we (like in [16]) substitute w by x_i, for i from 1 to d, and add up these n sums, then we obtain Newton's relation:

$$p_d - t_1 p_{d-1} + t_2 p_{d-2} - \cdots + d(-1)^d t_d = 0. \tag{2.5}$$

Equation (2.5) allows us to write the elementary symmetric functions in terms of the power sums and vice versa.

The following fact is classical.

THEOREM 2.1. *Let $p : X \to Y$ be a proper, finite, d-sheeted surjective complex analytic morphism from a reduced pure n-dimensional complex analytic space X to a normal irreducible and reduced complex analytic variety Y. Given a holomorphic function $f : X \to \mathbb{C}$ and a symmetric polynomial $g : \mathbb{C}^d \to \mathbb{C}$, there is a unique holomorphic function $f_g : Y \to \mathbb{C}$ such that, for all points y in the Zariski open and dense set $U \subset Y$ such that $p : p^{-1}(U) \to U$ is an unramified cover, it follows that for the d points $\{x_1, \ldots, x_d\} = p^{-1}(y)$, we have $f_g(y) := g(f(x_1), \ldots, f(x_d))$.*

For the symmetric functions t_i we denote f_{t_i} by $\mathrm{tr}_{i,p}(f)$ and call it the ith trace. It is traditional to call $\mathrm{tr}_{1,p}(f)$, or $\frac{\mathrm{tr}_{1,p}(f)}{d}$, the trace and $\mathrm{tr}_{d,p}(f)$ the norm of f. In fact, the t_i all occur naturally as traces, e.g., letting $A : \mathbb{C}^d \to \mathbb{C}^d$ denote a matrix with eigenvalues $\{x_1, \ldots, x_d\}$, t_i is the trace of the matrix A induces on $\wedge^i \mathbb{C}^d \cong \mathbb{C}^{\binom{d}{i}}$, the ith exterior product of $\mathbb{C}^d$. The parameterized version of (2.4) is

$$f^d - \mathrm{tr}_{1,p}(f) f^{d-1} + \mathrm{tr}_{2,p}(f) f^{d-2} + \cdots + (-1)^d \mathrm{tr}_{d,p}(f) = 0. \tag{2.6}$$

This line of reasoning is used in one main approach to the Weierstrass preparation theorem [8, 9].

Proof of Theorem 2.1. The proof that f_g is holomorphic follows by a minor variant of the argument used in [8, Theorem A4]. To see this, note that there is a codimension one analytic subset $B \subset Y$ such that $X \setminus p^{-1}(B)$ and $Y \setminus B$ are smooth and such that $p_{X \setminus p^{-1}(B)} : X \setminus p^{-1}(B) \to Y \setminus B$ is a d-sheeted unramified cover. Indeed, define U' equal to Y minus the union of

1. the singular set $\mathrm{Sing}(Y)$ of Y, which is an analytic set of complex codimension 2 [8, Theorem Q12], and
2. the image under p of the singular set of X, which is an analytic set by Remmert's proper mapping theorem [8, Theorem N1].

Thus $p_{p^{-1}(U')} : p^{-1}(U') \to U'$ is a proper and finite map between complex manifolds. The set of branch points R of this map is an analytic set on U', since it is the set defined by the local condition that the determinant of the Jacobian of the mapping $p_{p^{-1}(U')}$ is zero. Define $U := U' \setminus p(R)$.

Thus for $y \in Y \setminus B$, $f_g(y) := g(f(x_1), \ldots, f(x_d))$ is a holomorphic function. Since p is proper, given any point $y \in B$, there is a relatively compact open set U containing y such that $p^{-1}(U)$ is relatively compact and f is bounded in absolute value on $p^{-1}(U)$. Thus f_g is bounded on $U \setminus (B \cap U)$. Thus by the Riemann extension theorem for bounded holomorphic functions, $f_{g|U}$ has a unique holomorphic extension to $Y \setminus \mathrm{Sing}(Y)$, where $\mathrm{Sing}(Y)$ denotes the singular set of Y. Since Y is normal, it follows from the Levi extension theorem [8, Theorem Q15i] that $f_{g|Y \setminus \mathrm{Sing}(Y)}$ has a unique holomorphic extension to Y. □

In Theorem 2.1, if in addition it is assumed that X, Y, p, and f are algebraic, then it follows that f_g is also algebraic. Rather than introduce all the needed definitions and algebraicity criteria to state the general case, we prove only a corollary that covers our needs.

COROLLARY 2.2. *Let $Z \subset \mathbb{C}^n$ be a pure k-dimensional algebraic subvariety of $\mathbb{C}^n$. Assume*

1. *that $\pi : \mathbb{C}^n \to \mathbb{C}^k$ is a generic linear projection, and*
2. *that ϕ is a linear function on $\mathbb{C}^n$, which is one-to-one on a fiber $\pi_Z^{-1}(y)$ for some $y \in \mathbb{C}^k$ with $\pi^{-1}(y)$ consisting of smooth points of Z at which the tangent space, $d\pi_Z$, has rank k.*

Then, it follows that for all j, $\mathrm{tr}_{j,\pi_Z}(\phi)$ is a polynomial on $\mathbb{C}^k$ of degree less than or equal to j. In particular, $\mathrm{tr}_{1,\pi_Z}(\phi)$ is linear or constant.

Proof. Let q denote the map $\mathbb{C}^n \to \mathbb{C}^{k+1}$ given by (ϕ, π). Let z denote the coordinate on $\mathbb{C}^{k+1}$ such that $z(q(\mathbf{x})) = \pi(\mathbf{x})$, and let L denote the projection of $\mathbb{C}^{k+1} \to \mathbb{C}^k$ such that $\pi = L \circ q$. By the Noether normalization theorem it follows that the genericity of π implies that $p := \pi_Z$ is a proper finite-to-one morphism. Since $\pi_Z = L \circ q_Z$, it follows by elementary point set topology that q_Z is proper and finite also. Moreover, by genericity it follows that the degree d of p is $\deg Z$, by the hypothesis on ϕ that q_Z maps Z generically one-to-one to $\mathbb{C}^{k+1}$, and, therefore, that $\deg q(Z) = \deg Z$. Since for a dense open set $U \subset \mathbb{C}^k$ q gives an isomorphism of $p^{-1}(U)$ with $L_{q(Z)}^{-1}(U)$, we conclude that $\mathrm{tr}_{j,p}(\phi_Z)$ and $\mathrm{tr}_{j,L_{q(Z)}}(z_{q(Z)}$ agree on U and hence on all of $\mathbb{C}^k$. Thus, with the convention that $\mathrm{tr}_{0,L_{q(Z)}}(z_{q(Z)}) = \mathrm{tr}_{0,p}(\phi_Z) = 1$, we have the equivalent relations given in (2.6) $f^d - \mathrm{tr}_{1,p}(f) f^{d-1} + \cdots + (-1)^d \mathrm{tr}_{d,p}(f) = 0$,

$$\sum_{i=0}^{d} (-1)^i \mathrm{tr}_{i,L_{q(Z)}}(z_{q(Z)}) z_{q(Z)}^{d-i} = 0, \tag{2.7}$$

$$\sum_{i=0}^{d} (-1)^i \mathrm{tr}_{i,p}(\phi_Z) {\phi_Z}^{d-i} = 0. \tag{2.8}$$

Since $q(Z)$ is a degree d hypersurface and $z^d - \mathrm{tr}_{1,p}(z_{q(Z)}) z^{d-1} + \cdots + (-1)^d \mathrm{tr}_{d,p}(z_{q(Z)})$ vanishes when restricted to it, we conclude that this must be a minimum degree defining polynomial of $q(Z)$. Thus we have proved the assertions of the corollary. ∎

Remark 2.3. Note that, assuming the genericity hypothesis on π in Corollary 2.2, the hypothesis on ϕ can be replaced by the equivalent more easily checked condition that ϕ is a linear function on $\mathbb{C}^n$, which is one-to-one on a fiber $\pi_Z^{-1}(y)$ for some $y \in \mathbb{C}^k$ with $\pi^{-1}(y)$ consisting of $\deg Z$ distinct points.

Remark 2.4. Note that, without the genericity assumption, Corollary 2.2 fails for a number of reasons. First, it might be that π_Z is not proper. In this case, the traces are only rational functions. For example, taking $Z := \{xy - 1 = 0\} \subset \mathbb{C}^2$ and $\pi : \mathbb{C}^2 \to \mathbb{C}$ given by $\pi(x, y) = x$, we get $\mathrm{tr}_{1,\pi_Z}(y) = \frac{1}{x}$. By the Noether normalization theorem, the genericity assumption about the linear projection π implies that π_Z is proper and finite, but even proper and finite, without the genericity assumption, is not enough. The key implication of genericity of the linear projection π, beyond the properness of π_Z, is the fact that for generic linear projections π, $\deg Z = \deg \pi_Z$. For example, taking $Z := \{y^2 - x^d = 0\} \subset \mathbb{C}^2$ and $\pi : \mathbb{C}^2 \to \mathbb{C}$ given by $\pi(x, y) = x$, we get $\mathrm{tr}_{2,\pi_Z}(y) = x^d$. In general, if

1. $Z \subset \mathbb{C}^n$ is a pure k-dimensional algebraic subvariety of $\mathbb{C}^n$,
2. f is linear on $\mathbb{C}^n$, and
3. $\pi : \mathbb{C}^n \to \mathbb{C}^k$ is a linear projection with π_Z proper, finite, but not necessarily satisfying $\deg Z = \deg \pi_Z$,

then it follows that $\deg \mathrm{tr}_{i,\pi_Z}(f) \leq \deg Z - \deg \pi + i$.

3. An application to monodromy. In this section we show that the linear trace gives necessary and sufficient conditions to determine the breakup of the set witness points of the algorithm of [27] into the disjoint subsets of generic points corresponding to the numerical irreducible decomposition. Usually, we use this result to give a very fast verification of the monodromy breakup of the algorithm of [29], but it is also called into play if the monodromy breakup is too fine. The algorithms will be described in the next section.

The important observation that the linear trace is sufficient is due to Rupprecht [20] in the case of curves. We note that there are two serious gaps in the argument of [20], which are filled by Theorems 3.3 and 3.4 below.

The strategy is to slice and project to reduce to the case of a curve in $\mathbb{P}^2$. To do this we need a number of lemmas on linear projections and the intersections with linear spaces that are general subject to certain constraints. Unless otherwise said, closure is in either the Zariski topology or the usual topology induced by the Euclidean metric on $\mathbb{C}^n$.

LEMMA 3.1. *Let A be a pure k-dimensional reduced algebraic subset of $\mathbb{C}^n$, with irreducible decomposition $\cup_{i=1}^r A_i$. Assume that L is an $(n-k)$-dimensional linear subspace of $\mathbb{C}^n$ meeting A in a finite set $\mathcal{A}$ consisting of $\deg A$ distinct isolated points. Then, taking closures in $\mathbb{P}^n$, $\overline{L} \cap \overline{A} = \mathcal{A}$. Moreover, if $k \geq 2$, then letting $\mathcal{L}$ be a general member of the set of $(n-k+1)$-dimensional linear subspaces of $\mathbb{C}^n$ that contain L, it follows that $\mathcal{L} \cap A_i$ is an irreducible curve for each $i = 1, \ldots, r$.*

Proof. The statement that $\overline{L} \cap \overline{A} = \mathcal{A}$ follows from any of a number of related results, e.g., [5, Example 8.4.6] or [5, Example 12.3.2].

To prove the second statement it suffices to prove the analogous result on $\mathbb{P}^n$ using the closures of the sets A_i, L, $\mathcal{L}$. Since $\overline{L} \cap \overline{A}$ is a set $\mathcal{A}$ of cardinality $\deg \overline{A}$, it follows that $\mathcal{A}$ consists of smooth points of $\overline{A}$, and that the intersection of $\overline{A}$ and $\overline{L}$ are transverse at the points of intersection. From this it follows from Bertini's theorem that the intersection with A_i of a general member of the set M of $(n-k+1)$-dimensional linear subspaces of $\mathbb{C}^n$ that contain L is smooth away from the singular locus of A_i. If $k = 2$, so that the set M consists of hyperplanes, the rest of the argument follows exactly as in [25, Theorem 3.42]. If $k \geq 2$, the result follows by a straightforward descending induction. For example, if $k = 3$, then it follows using [25, Theorem 3.42] that the intersection with A_i of a general member of the set of $(n-1)$-dimensional linear subspaces H of $\mathbb{C}^n$ that contain L is irreducible. Keeping L as it is, taking H in place of $\mathbb{C}^n$, and replacing the A_i with $A_i \cap H$, we now have $\dim A_i \cap H = 2$, i.e., we have reduced to the proven result. ∎

LEMMA 3.2. *Let n, L, $\mathcal{L}$, $\mathcal{A}$, $A = A_1 \cup \cdots \cup A_r$ be as in Lemma 3.1. Choose a general linear projection $\pi : L \to \mathbb{C}$, which is one-to-one on $\mathcal{A}$. Let $\widetilde{\pi} : \mathbb{C}^n \to \mathbb{C}^{k+1}$ be a linear map extending π, so that the fibers of $\widetilde{\pi}$ are parallel to the fibers of π. Then $\widetilde{\pi}_A$ and $\widetilde{\pi}_{A \cap \mathcal{L}}$ are generically one-to-one and proper. Moreover, $\widetilde{\pi}_A$ (respectively, $\widetilde{\pi}_{A \cap \mathcal{L}}$), maps a neighborhood of $\mathcal{A}$ in A (respectively, in $A \cap \mathcal{L}$) isomorphically onto a neighborhood of the image of $\mathcal{A}$ in A (respectively, in $A \cap \mathcal{L}$).*

Proof. We give the proof that $\widetilde{\pi}_A$ is generically one-to-one and proper, and we leave the remaining argument, which follows the same line of reasoning to the reader. We work in the projective space $\mathbb{P}^n$. As explained in [27], $\widetilde{\pi}$ corresponds to the central projection from a linear $I := \mathbb{P}^{n-k-2}$ contained in the linear $\mathbb{P}^{n-1}$ at infinity, i.e., in $\mathbb{P}^n \setminus \mathbb{C}^n$. The condition that L is mapped to a line corresponds to $I \subset \overline{L} \setminus L$. Since by Lemma 3.1 we know that $(\overline{L} \setminus L) \cap (\overline{A} \setminus A) = \emptyset$, we know, as discussed in [27], that $\widetilde{\pi}_A$ is proper and therefore finite-to-one on A. If $\widetilde{\pi}_A$ was not generically one-to-one, then

$\deg \widetilde{\pi}(A)$ would be less than $\deg A$. But this does not happen since $\widetilde{\pi}$ is one-to-one on $\mathcal{A}$, and the degree of $\widetilde{\pi}(A)$ is the cardinality of $\widetilde{\pi}(\mathcal{A})$, which is equal to the intersection of $\widetilde{\pi}(A)$ with the line $\widetilde{\pi}(L)$. ∎

THEOREM 3.3. *Let A be a reduced pure k-dimensional algebraic subset of $\mathbb{C}^n$. Let $A := A_1 \cup \cdots \cup A_r$ be the decomposition into distinct irreducible components. Let $L \subset \mathbb{C}^n$ be a general linear subspace of dimension $n-k$ meeting A transversely in the set $\mathcal{A} := A \cap L$. For all $i = 1, \ldots, r$, let $\mathcal{A}_i := A_i \cap L$, and let d_i be the cardinality of the set $\mathcal{A}_i$. Let d denote the cardinality of $\mathcal{A}$, i.e., $\sum_{i=1}^{r} d_i$. Let U denote the Zariski open set of the Grassmannian of $(n-k)$-dimensional linear subspaces of $\mathbb{C}^n$ consisting of linear spaces transverse to A. Let* $\mathrm{Sym}(\mathcal{A})$ *(respectively,* $\mathrm{Sym}(\mathcal{A}_i)$*) denote the symmetric group of all permutations of $\mathcal{A}$ (respectively, $\mathcal{A}_i$). Considering L as a basepoint of U, the image in* $\mathrm{Sym}(\mathcal{A})$ *of the natural monodromy action of $\pi_1(U, L)$ on $\mathcal{A}$ is the direct sum $\bigoplus_{i=1}^{r} \mathrm{Sym}(\mathcal{A}_i)$.*

Proof. We can assume without loss of generality that no components of A are linear, since such components do not affect the result.

Choose $\mathcal{L}$ and $\widetilde{\pi} : \mathbb{C}^n \to \mathbb{C}^{k+1}$ as in Lemma 3.2. Let U' denote the Zariski open set of the projective space of lines in $\mathbb{C}^{k+1}$, consisting of the lines transverse to $\widetilde{\pi}(A)$. Note that for $\ell \in U'$ we have that $\widetilde{\pi}^{-1}(\ell) \in U$. Thus identifying $\mathcal{A}$ with $\widetilde{\pi}(\mathcal{A})$, the homomorphism $\pi_1(U', \widetilde{\pi}(L)) \to \mathrm{Aut}(\mathcal{A})$ factors $\pi_1(U', \widetilde{\pi}(L)) \to \pi_1(U, L) \to \mathrm{Aut}(\mathcal{A})$. Thus, from here on we can assume without loss of generality that $n = k+1$. Moreover, a line in $\mathcal{L}$ transverse to $\mathcal{L} \cap A$ is transverse to A in $\mathbb{C}^n$. Thus, letting U'' denote the Zariski open set of lines in $\mathcal{L} \cong \mathbb{C}^2$ that are transverse to $\mathcal{L} \cap A$, we have a composition $\pi(U'', L) \to \pi_1(U, L) \to \mathrm{Aut}(\mathcal{A})$. Thus, without loss of generality we can assume that $n = 2$.

Thus we have $n = 2$ and $k = 1$. We have the classical fact [1, Lemma, p. 111] that the image of $\pi_1(U, L) \in \mathrm{Aut}(\mathcal{A})$ surjects onto $\mathrm{Sym}(\mathcal{A}_i)$ for each $i = 1, \ldots, r$. In particular, we can assume without loss of generality that $r \geq 2$. By elementary algebra, we see that using this surjectivity, we would be done if we showed that, for each i, there exist two distinct points $a, b \in \mathcal{A}_i$ and a $\gamma \in \pi_1(U, L)$ such that γ acts on $\mathcal{A}$ by sending $a \to b$, $b \to a$ and leaves the remaining points of $\mathcal{A}$ fixed. The classical argument for the existence of such a γ in the irreducible case [1, Lemma, p. 111] carries over with no change to the reducible case if we show that for each $i = 1, \ldots, r$, and a generic point $x \in \mathcal{A}_i$, the tangent line $\ell \subset \mathbb{C}^2$ to A_i at x is transverse to A_j for $j \neq i$. To show this, it suffices to work projectively, i.e., show the fact for the closures B_i in $\mathbb{P}^2$ of the A_i. To see this, consider the dual curves $\widehat{B}_i \subset (\mathbb{P}^2)^*$. Here $(\mathbb{P}^2)^*$ is the $\mathbb{P}^2$ whose points correspond to lines in the $\mathbb{P}^2$ that the B_i belong to, and $\widehat{B}_i$ is the closure in $(\mathbb{P}^2)^*$ of the set of points corresponding to tangent lines to smooth points of B_i. What we need is exactly that B_i and B_j for distinct i, j go to distinct curves $\widehat{B}_i$ and $\widehat{B}_j$. Noting that none of the B_i are linear, this would follow if we knew that the dual of $\widehat{B}_i$ is B_i. This is a basic fact about dual curves (and more generally varieties) [14]. ∎

To prove Corollary 3.5 below, we need the following generalization of the classical first Lefschetz theorem. This topological result is a special case of a useful general result of Goresky and MacPherson [7, Theorem, section 5.2, p. 199].

THEOREM 3.4 (Goresky–MacPherson). *Let D be an arbitrary algebraic subset of $\mathbb{C}^n$, and let $U := \mathbb{C}^n \setminus D$. Then given a general 1-dimensional linear subspace $L \subset \mathbb{C}^n$ and a point $x \in L \cap U$, it follows that we have a surjective map of fundamental groups*

$$\pi_1(L \cap U, x) \to \pi_1(U, x) \to 0.$$

Proof. Following the notation of [7, section 5.2, Theorem, p. 199], take X to be the Zariski open dense set U of $\mathbb{P}^n$ with $n := N$, π the inclusion, $c = n-1$, which gives $\phi(k) = n-1$ for $k = 0$, and $-\infty$ for $k \neq 0$, which gives $\hat{n} = 1$. □

COROLLARY 3.5. *Let A be a reduced pure k-dimensional algebraic subset of $\mathbb{C}^n$. Let $A := A_1 \cup \cdots \cup A_r$ be the decomposition into distinct irreducible components. Let $\pi : \mathbb{C}^n \to \mathbb{C}^k$ denote a generic linear projection, and let $x, y \in \mathbb{C}^k$ denote general points, with $L := \pi^{-1}(x) \subset \mathbb{C}^n$ a general linear subspace of dimension $n-k$ meeting A transversely in the set $\mathcal{A} := A \cap L$. For all $i = 1, \ldots, r$, let $\mathcal{A}_i := A_i \cap L$, and let d_i be the cardinality of the set $\mathcal{A}_i$. Let d denote the cardinality of $\mathcal{A}$, i.e., $\sum_{i=1}^r d_i$. Let U denote the Zariski open set of the line $\ell \subset \mathbb{C}^k$ containing x, y, consisting of the $u \in \ell$ such that $\pi^{-1}(u)$ is transverse to A. Let* $\mathrm{Sym}(\mathcal{A})$ *(respectively,* $\mathrm{Sym}(\mathcal{A}_i)$*) denote the symmetric group of all permutations of $\mathcal{A}$ (respectively, $\mathcal{A}_i$). Considering L as a basepoint of U, the image in* $\mathrm{Sym}(\mathcal{A})$ *of the natural monodromy action of $\pi_1(U, L)$ on $\mathcal{A}$ is the direct sum* $\bigoplus_{i=1}^r \mathrm{Sym}(\mathcal{A}_i)$.

Proof. By the same reduction as in Theorem 3.3, it can be assumed that $n = 2$, $k = 1$, and that we are working with compact curves in $\mathbb{P}^2$. Given the Zariski open set U' of points in $(\mathbb{P}^2)^*$ corresponding to lines transverse to A, and given a general line $\ell \subset (\mathbb{P}^2)^*$, with a point L on ℓ, then setting $U := \ell \cap U'$, we will be done if we show that $\pi_1(U, L) \to \pi_1(U, L) \to 0$. This is guaranteed by Theorem 3.4. □

THEOREM 3.6. *Let $A \subset \mathbb{C}^n$ be an affine algebraic set of pure dimension k. Let $A := A_1 + \cdots + A_r$ denote the irreducible decomposition of A. Let $\pi : \mathbb{C}^n \to \mathbb{C}^k$ be a generic linear projection, and let $\ell \subset \mathbb{C}^k$ be a general line. Let $L := \pi^{-1}(\mathbf{x})$ for a general point $\mathbf{x} \in \ell$. Let ϕ be a linear function on $\mathbb{C}^n$ which is one-to-one on $\mathcal{A} := \pi_A^{-1}(\mathbf{x})$. For all $i = 1, \ldots, r$, let $\mathcal{A}_i := \pi_{A_i}^{-1}(\mathbf{x})$. Let U denote the Zariski open set of the Grassmannian of $(n-k)$-dimensional linear spaces of $\mathbb{C}^n$ corresponding to $(n-k)$-dimensional linear spaces transverse to A. Let B denote a subset of $\mathcal{A}$. Then the following are equivalent:*

(1) *B is invariant under the monodromy action of $\pi_1(U, L)$ on $\mathcal{A}$;*
(2) *$B = \cup_{i \in I} \mathcal{A}_i$ for some subset $I \subset \{1, \ldots, r\}$;*
(3) *The analytic continuation of $\sum_{b \in B} \phi(b)$ as a function of $\mathbf{x}$ is linear.*

Proof. The equivalence of (1) and (2) follows from Theorem 3.3. Corollary 2.2 shows that (2) implies (3). So it remains to show that (3) implies (1).

To see this, assume that B contains a point $b \in \mathcal{A}_i$ but not a point $a \in \mathcal{A}_i$. Let $y_1, \ldots, y_N$ denote the points of $B \setminus b$. Let U' denote the Zariski open subset of ℓ consisting of the points $\mathbf{x}' \in \ell$ with $\pi^{-1}(\mathbf{x}')$ transverse to A. By Corollary 3.5, there is a $\gamma \in \pi_1(U', L)$ which takes $y_j \to y_j$ for all j and interchanges a and b. Thus, since the analytic continuation of $\sum_{b \in B} \phi(b)$ is linear in $\mathbf{x}$, we conclude that

$$\phi(a) + \sum_{j=1}^{N} \phi(y_j) = \phi(b) + \sum_{j=1}^{N} \phi(y_j), \tag{3.1}$$

and thus that $\phi(a) = \phi(b)$. But this contradicts ϕ being one-to-one on $\mathcal{A}$. Thus if $b \in \mathcal{A}_i$ for some point $b \in B$, we conclude that $\mathcal{A}_i \subset B$. □

Remark 3.7. Here is a simple example to show the sort of bad behavior that genericity rules out. Let A be the curve in $\mathbb{C}^2$ defined by $(y^2 - x)(y^2 - 4x)(y^2 - 9x) = 0$. Consider the projection $\pi : \mathbb{C}^2 \to \mathbb{C}$ given by $\pi(x, y) = x$. Note that π_A is proper and generically six-to-one with $\deg A = 6$. For the linear function ϕ on $\mathbb{C}^2$, choose y. Over $x \in \mathbb{C}$, the values of ϕ on the fiber $\pi_A^{-1}(y)$ are

$$\{\sqrt{x}, -\sqrt{x}, 2\sqrt{x}, -2\sqrt{x}, 3\sqrt{x}, -3\sqrt{x}\}. \tag{3.2}$$

The groupings corresponding to the irreducible components are $\{\sqrt{x}, -\sqrt{x}\}$, $\{2\sqrt{x}, -2\sqrt{x}\}$, and $\{3\sqrt{x}, -3\sqrt{x}\}$. Notice that the sum $(-1)\sqrt{x} + (-2)\sqrt{x} + 3\sqrt{x}$ is identically zero, and hence linear, even though the grouping $\{-\sqrt{x}, -2\sqrt{x}, 3\sqrt{x}\}$ does not correspond to a union of irreducible components of A.

Remark 3.8. In practice, when we use Theorem 3.6, it is convenient to use a generic projection $\pi : \mathbb{C}^n \to \mathbb{C}^{k+1}$. Letting $A := A_1 + \cdots + A_r$ be as in Theorem 3.6, it follows, e.g., from [27, section 5.2], that

1. the map π_A from A to its image $\pi(A)$ is proper,
2. the images of $A, A_1, \ldots, A_r$ under π are affine algebraic sets with $\pi(A)$ having the irreducible decomposition $\pi(A) := \pi(A_1) + \cdots + \pi(A_r)$,
3. $\deg \pi(A_i) = \deg A_i$ for all i, and
4. π_A is one-to-one on $\pi_A^{-1}(U)$ for some Zariski open dense set of $\pi(A)$.

Moreover, since the composition of π with the projection $\mathbb{C}^{k+1} \to \mathbb{C}^k$ given by $(z_1, \ldots, z_{k+1}) \to (z_1, \ldots, z_k)$ is generic, we can use $\pi(A)$ and this projection in place of A and the generic projection π of Theorem 3.6. Then, z_{k+1} has the properties required of ϕ in Theorem 3.6, and, since the projection $\pi : \mathbb{C}^n \to \mathbb{C}^{k+1}$ is generic, we can take one of the coordinate axes, e.g., the z_k axis, as ℓ.

It is worth noting that the defining equation of $\pi(A)$ under a generic projection will have every monomial of total degree less than or equal to the degree of A occurring, no matter how sparse the defining equations of A are.

4. Algorithms for the linear trace.

In this section we present an algorithm to verify the decomposition predicted by the monodromy algorithm. We first define a projection operator which organizes the samples in a structured grid. The main part of this section is the algorithm **Certify**, followed by comments on how to integrate this algorithm in the numerical irreducible decomposition of a pure dimensional component.

4.1. Sampling on parallel slices.

To compute the linear trace, a structured grid of sample points is useful. The same construction is used in the following section concerning higher traces. Our technique is to use random slicing hyperplanes to define the projection operator π, as follows.

DEFINITION 4.1. *Consider a k-dimensional component in $\mathbb{C}^n$ and suppose we use the k hyperplanes*

$$c_{i0} + c_{i1}x_1 + c_{i2}x_2 + \cdots + c_{in}x_n = 0, \qquad i = 1, 2, \ldots, k, \tag{4.1}$$

as slices to obtain generic points on the component. To project the generic points down to $\mathbb{C}^{k+1}$, we use the map $\pi : \mathbb{C}^n \to \mathbb{C}^{k+1}$ defined by

$$\begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_{n-1} \\ x_n \end{bmatrix} \mapsto \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_k \\ y_{k+1} \end{bmatrix} = \begin{bmatrix} c_{11} & c_{12} & \cdots & c_{1n} \\ c_{21} & c_{22} & \cdots & c_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ c_{k1} & c_{k2} & \cdots & c_{kn} \\ a_1 & a_2 & \cdots & a_n \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \\ \vdots \\ x_{n-1} \\ x_n \end{bmatrix}, \tag{4.2}$$

where the numbers a_i, $i = 1, 2, \ldots, k$ are chosen at random.

The main property of this projection operator is highlighted in the following proposition.

PROPOSITION 4.2. *For a k-dimensional component in $\mathbb{C}^n$, let $\pi : \mathbb{C}^n \to \mathbb{C}^{k+1}$ be as in* (4.2). *Then for any generic point $\mathbf{x} = (x_1, x_2, \ldots, x_n)$ on the slices used in the definition of π, we have*

$$\pi(\mathbf{x}) = (-c_{10}, -c_{20}, \ldots, -c_{k0}, a_1x_1 + a_2x_2 + \cdots + a_nx_n). \tag{4.3}$$

To obtained a structured grid of samples from the k-dimensional component, we let only the constant terms c_{i0} of the slicing planes vary, for $i = 1, 2, \ldots, k$. Geometrically this means we take samples on slices parallel to each other.

4.2. Certification of monodromy groupings with linear traces. Suppose we are given a set S of d generic points on random hyperplanes $L = (L_1, L_2, \ldots, L_k)$, where the points are known to be from the same k-dimensional irreducible component because the monodromy algorithm found loops connecting them. As the monodromy algorithm might miss some connections, the actual degree of the component could be higher than d. With linear traces we verify whether the degree of the component equals d, described by the **Certify** algorithm.

ALGORITHM 4.3. $b = \textbf{Certify}(f, L, S, \epsilon)$

Input: $f(\mathbf{x}) = \mathbf{0}$ is a polynomial system with $\mathbf{x} \in \mathbb{C}^n$;
$L = (L_1, L_2, \ldots, L_k)$ is a tuple of k random hyperplanes;
S is set of d generic points satisfying $f(\mathbf{x}) = \mathbf{0}$ and $L(\mathbf{x}) = \mathbf{0}$;
ϵ is tolerance to decide whether a number is close enough to zero.

Output: $b \in \{\text{false}, \text{true}\}$, b is true when S is a set of generic points on a degree d irreducible component, false otherwise.

let $S^{(0)} = S$, $c_0^{(0)} = c_0$; [*notational convenience*]
for $i = 1, 2$ do [*sample to get test points*]
  choose $c_0^{(i)} \in \mathbb{C}$ at random;
  $L_k^{(i)} := c_0^{(i)} + c_{k1}x_1 + c_{k2}x_2 + \cdots + c_{kn}x_n$; [$L_k^{(i)}$ *is parallel to* L_k]
  compute $S^{(i)}$ as solutions to $f(\mathbf{x}) = \mathbf{0}$, [*apply homotopy from* L_k *to* $L_k^{(i)}$
    and $L_1(\mathbf{x}) = L_2(\mathbf{x}) = \cdots = L_k^{(i)}(\mathbf{x}) = 0$; *using* S *as start solutions*]
end for;
use L to define $\pi : \mathbb{C}^n \to \mathbb{C}^{k+1}$ as in (4.2); [*projection operator*]
let $\phi(\mathbf{x}) = z_{k+1}$, where $z = \pi(\mathbf{x})$; [*definition of* ϕ *in Theorem* 3.6]
for $i = 0, 1, 2$ compute $s_i := \sum_{\mathbf{x} \in S^{(i)}} \phi(\mathbf{x})$; [*sum* $(k+1)$*st coordinate*]
find a, b such that $s_i = a + bc_0^{(i)}$ for $i = 0, 1$; [*linear interpolation of trace*]
return $(|s_2 - (a + bc_0^{(2)})| < \epsilon)$. [*the comparison certifies*]

The justification for this algorithm is Theorem 3.6. The first k coordinates of $\pi(\mathbf{x})$ in (4.2) are the generic projection required by the theorem and the $(k+1)$st coordinate is the linear function ϕ. We test linearity of the trace by sampling in a generic direction: the kth coordinate of $\pi(\mathbf{x})$ suffices due to the genericity of the coefficients used to define it. By the theorem, linearity implies that the set of points S is the union of witness points for irreducible sets whose degrees sum to d, while by assumption, monodromy has found that all the points are in one irreducible set. Thus, there is one set and its degree is d.

4.3. An integrated decomposition algorithm. The linear trace test can be used as a simple replacement for the filtering polynomials used in our earlier papers [27, 28, 29], but additional efficiencies can be gained by integrating the technique more deeply into the algorithms.

First, we can improve the termination condition for the monodromy method. Previously, we continued to compute monodromy loops until either all points are connected into one group or until some preset number of consecutive loops fails to find any new connections. Setting the number of these stable loops too high is costly, while too low means that some connections could be missed. With the linear trace test, one can determine when a group is complete and immediately remove it from further iterations. Once the number of uncertified groups is reduced to a small number, combinations of them can be examined to discover which ones sum to form linear traces, thereby completing the decomposition without further monodromy loops.

In this vein, it is possible to perform the decomposition only using linear traces, as is done for a single multivariate polynomial in [6, 20]. However, without monodromy, the algorithm is combinatorial and is likely to be too expensive for high degrees. The use of traces in [21] (with predecessors [22, 23, 24]) is followed by linear algebra techniques. Recently, monodromy and traces have been combined to factor a single multivariate polynomial in [3].

The factorization of a single multivariate polynomial can be regarded as a special case of the decomposition of the solution sets of polynomial systems. For this general problem, we indicate a second improvement. In implementing the monodromy algorithm in [29], it is worthwhile to compute the linear span of the components as we described in [28]. Generic points that lie in different spans lie on different irreducible components, so we have only to execute the monodromy starting at points that lie in the same linear span. Also, the restriction to the linear span will give a speedup when there is a gap between the dimension of the linear span and the dimension of the ambient space.

Finally, the main decomposition algorithm [27] requires a test to determine if a generic point obtained from the embedding algorithm at dimension k is a member of some irreducible set of dimension greater than k. Originally, we used the interpolating polynomials for these sets to determine membership, but as in [28], it is possible to use a homotopy test of membership. Using the homotopy membership test for higher dimensional sets and certifying irreducible groups by linear traces, we eliminate completely the expensive and numerically difficult step of computing interpolating polynomials, which represents a big improvement in our overall algorithm.

5. Interpolation algorithms via traces. As just mentioned, the computation of interpolating polynomials is no longer required to complete the numerical irreducible decomposition. Nevertheless, in the case that one still wishes to compute such polynomials, the higher order traces can be useful, as we show in this section. For components of low degree and span, interpolating polynomials can be competitive with a homotopy membership test.

Our techniques for computing interpolating polynomials can be briefly summarized as follows. Since the witness points for a component lie on a linear slice, they can be marched forward together to compute a structured grid of sample points. In [29], a "bootstrapping" technique was used to construct the Newton form of the interpolating polynomial. Here, by using traces, we eliminate the expense of extra samples for bootstrapping and apply Newton interpolation directly. Finally, using the Newton identities, we reduce the number of samples to the number of monomials, which is optimal.

5.1. Newton interpolation with divided differences. To interpolate a bivariate function $f(x, y)$ with a polynomial $p(x, y)$ of degree d, we need to sample

the function at points (a_i, b_j), for all i, j: $0 \leq i + j \leq d$. The Newton form of the interpolation polynomial $p(x, y)$ is classical (see, e.g., [12, 16]):

$$p(x,y) = \sum_{k=0}^{d} \sum_{l=0}^{d-k} f[a_0 \cdots a_k; b_0 \cdots b_l] \prod_{i=0}^{k-1} (x - a_i) \prod_{j=0}^{l-1} (y - b_j). \tag{5.1}$$

The coefficients $f[a_0 \cdots a_k; b_0 \cdots b_l]$ are divided differences, defined inductively. Starting with $f[a_k; b_l] = f(a_k, b_l)$, all divided differences are generated by

$$f[a_0 a_1 \cdots a_k; b_l] = \frac{f[a_0 a_1 \cdots a_{k-1}; b_l] - f[a_1 a_2 \cdots a_k; b_l]}{a_0 - a_k} \tag{5.2}$$

and

$$f[a_0 a_1 \cdots a_k; b_0 b_1 \cdots b_l]$$

$$= \frac{f[a_0 a_1 \cdots a_k; b_0 b_1 \cdots b_{l-1}] - f[a_0 a_1 \cdots a_k; b_1 b_2 \cdots b_l]}{b_0 - b_l}, \tag{5.3}$$

for $k = 0, 1, \ldots, d$ and $l = 0, 1, \ldots, d - k$. The efficient computation of divided differences is organized in a table, requiring only one vector of elements to store. Generalizing (5.1) to any number of variables is burdened only by notation.

The direct application of Newton interpolation is prevented because the interpolation points must lie on a grid structured for *all* directions. When we sample curves or surfaces we always have one last component which is different for all samples. To overcome this we may apply a "bootstrapping" technique. We explain the idea in the case of two variables. For $x = a_k$, we construct a univariate polynomial $p(y)$ interpolating through the roots. Note that at those roots, y is usually different from the chosen grid points b_l. Once we have $p(y)$, we use it to find $f(a_k, b_l) = p(b_l)$, and we have a complete structured grid on which the above formulas (5.1) apply. This construction generalizes to the Newton form of the interpolating polynomial to represent any surface of any degree and dimension. It was implemented and used in [29] to certify groupings predicted by the monodromy algorithm. We provide an alternative to the bootstrapping technique using traces, as explained next.

5.2. The trace form with a complete grid. With traces, the classical multivariate interpolation schemes with generalized divided differences are directly applicable. We will show how to interpolate with a polynomial p of degree d in three variables (x, y, z), where p is expressed like

$$p(x,y,z) = z^d - t_1(x,y) z^{d-1} + t_2(x,y) z^{d-2} - \cdots + (-1)^d t_d(x,y), \tag{5.4}$$

where $t_i(x, y)$ is the ith trace with $\deg(t_i(x, y)) = i$. To represent the polynomials $t_i(x, y)$ we use the Newton form (5.1) with coefficients constructed with divided differences, given in formulas (5.2) and (5.3).

The major cost in the construction of the interpolating polynomial is the number of required sample points. While the number of monomials grows exponentially as the degree d and dimension k of the irreducible component increases, the number of samples in a complete grid grows as $d(d+1)^k$, which is much faster than the number of monomials, as illustrated in Table 5.1.

TABLE 5.1

Number of terms for degrees d and dimensions k, respectively, increasing in the rows and columns, versus $d(d+1)^k$, which is the number of samples needed for the trace form using the full grid, without exploiting Newton identities.

Number of monomials					Number of samples				
$d\backslash k$	2	3	4	5	$d\backslash k$	2	3	4	5
1	3	4	5	6	1	2	4	8	16
2	6	10	15	21	2	6	18	54	162
3	10	20	35	56	3	12	48	192	768
4	15	35	70	126	4	20	100	500	2500
5	21	56	126	252	5	30	180	1080	6480

5.3. Using the Newton identities. Ideally, we would like to take no more samples than the number of monomials. Exploiting the Newton identities (2.5), we show how to achieve this goal on an example, the interpolation of a planar quartic. Figure 5.1 gives a schematic representation of the grid of sample points.

In the interpolation of a planar quartic, we compute the four traces consecutively. To compute the second trace t_2, we may already use t_1, and to compute t_3, we already dispose of t_1, t_2, and for t_4, we make use of t_1, t_2, and t_3. We show how this saves sample points:

1. At $x = a_2$, instead of four, we compute three samples (a_2, b_{21}), (a_2, b_{22}), (a_2, b_{23}) and compute b_{24} using the first trace t_1, evaluated at $x = a_2$:

$$b_{24} := t_1(a_2) - b_{21} - b_{22} - b_{23}. \tag{5.5}$$

2. At $x = a_3$, we know already the coefficient of the Newton forms of t_1 and t_2 and use continuation only for two samples: (a_3, b_{31}) and (a_3, b_{32}). For the values b_{33} and b_{34} we solve the system

$$\begin{cases} t_1(a_3) = b_{31} + b_{32} + b_{33} + b_{34}, \\ t_2(a_3) = b_{31}b_{32} + b_{31}b_{33} + b_{31}b_{34} + b_{32}b_{33} + b_{32}b_{34} + b_{33}b_{34}. \end{cases} \tag{5.6}$$

With the Newton identities (2.5), we compute from the values of the elementary symmetric functions $(t_1(a_3), t_2(a_3))$ the power sums for $x = a_3$: $(s_1(a_3), s_2(a_3))$. This means that the b_{ij}'s satisfy

$$\begin{cases} s_1(a_3) = b_{31} + b_{32} + b_{33} + b_{34}, \\ s_2(a_3) = b_{31}^2 + b_{32}^2 + b_{33}^2 + b_{34}^2 \end{cases} \tag{5.7}$$

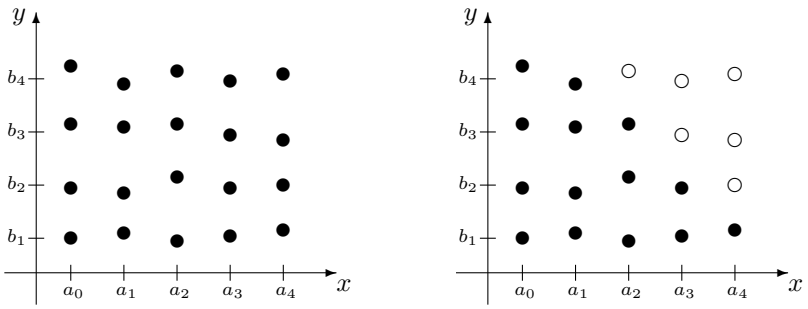

FIG. 5.1. *Two grids of sample points to interpolate a planar quartic: the grid on the left is complete, while on the right we find the white dots using Newton identities. The semiregularity of the grid (same x-value in one column, different y-values in each row) is typical.*

or

$$\begin{cases} b_{33} + b_{34} = s_1(a_3) - b_{31} - b_{32}, \\ b_{33}^2 + b_{34}^2 = s_2(a_3) - b_{31}^2 - b_{32}^2. \end{cases} \tag{5.8}$$

Let $\widetilde{s}_1(a_3) = s_1(a_3) - b_{31} - b_{32}$ and $\widetilde{s}_2(a_3) = s_2(a_3) - b_{31}^2 - b_{32}^2$. Then we invoke the Newton identities (2.5) to compute from the modified powers sums $(\widetilde{s}_1(a_3), \widetilde{s}_2(a_3))$ evaluated at a_3 into the values of the elementary symmetric functions at a_3: $(\widetilde{t}_1(a_3), \widetilde{t}_2(a_3))$. With $(\widetilde{t}_1(a_3), \widetilde{t}_2(a_3))$ we define

$$y^2 - t_1(a_3)y + t_2(a_3) = y^2 - (b_{33} + b_{34})y + b_{33}b_{34} \tag{5.9}$$

$$= (y - b_{33})(y - b_{34}) \tag{5.10}$$

$$= 0. \tag{5.11}$$

Thus, finding the missing samples (white dots on Figure 5.1 for $x = a_3$) has been reduced to solving a quadratic univariate equation.

3. At $x = a_4$ we apply the Newton identities also twice to construct a univariate equation of degree three to find the missing samples.

This procedure generalizes to any degree and any dimension, requiring only as many samples as the number of monomials.

To find the roots of univariate polynomials, we use the method of Weierstrass (also known as Durand–Kerner), described in [17] as "quite effective and increasingly popular." Convergence is global and quadratic in the limit [18]. Our implementation is basic; see [13] for algorithmic improvements to this method.

5.4. Numerical aspects and experiments. In this section we first compare our new algorithms with our approach to interpolation in [27], where we solved the linear system of interpolation conditions directly. Then we illustrate the numerical stability of the new algorithms on a test polynomial.

Compared to the direct approach of [27], we first observe an improved conditioning of the interpolation problem when a structured grid of samples is used. This improved conditioning leads to more accurate results regardless of the interpolation algorithm. In an unstructured grid, errors on the samples creep in with greater fluctuation than on a structured grid, where the ith coordinate, $i = 1, 2, \ldots, k$, is the same for all samples from a k-dimensional component. The second advantage of our new algorithms concerns time. Using divided differences to solve the linear system of N interpolation conditions requires $O(N^2)$ operations instead of $O(N^3)$ for plain Gaussian elimination or QR factorization.

The bootstrapping method for Newton interpolation we used in [29] and the basic interpolation with traces both require more samples than the number of monomials; see Table 5.1. Exploiting the Newton identities, we get the complete interpolating polynomial with an optimal number of samples. We next describe an experiment to illustrate that this exploitation is numerically stable.

We consider to interpolate the polynomial

$$p(x, y) = \sum_{0 \leq i+j \leq d} x^i y^j, \quad \text{for } d = 2, 3, \ldots, 10. \tag{5.12}$$

To this polynomial we apply our general implementation, treating $p(x, y)$ as a polynomial system. Assuming monodromy has shown the d generic points to belong to the

TABLE 5.2

Numerics on the dense polynomial with unit coefficients for degrees d from 2 up to 10, on square and triangular grids (i.e., without and with the exploitation of Newton identities) and in the last column for the linear traces. Because only magnitudes matter, 8.559E–16 is shortened to –16, and $-\infty$ stands for a zero residual. We list the accuracy of the grid (eps) and the magnitude of the highest residual after evaluation at the grid (gres) and at some test points (tres).

	Square grid			Triangular grid			Linear trace		
d	eps	gres	tres	eps	gres	tres	eps	gres	tres
2	–16	–15	–13	–15	–16	–13	–16	$-\infty$	–15
3	–15	–15	–14	–16	–15	–15	–16	$-\infty$	–15
4	–14	–14	–13	–15	–15	–14	–16	$-\infty$	–15
5	–14	–13	–12	–15	–15	–14	–16	$-\infty$	–15
6	–15	–13	–14	–16	–14	–12	–16	$-\infty$	–15
7	–15	–13	–10	–15	–14	–12	–16	$-\infty$	–15
8	–15	–12	–13	–15	–13	–11	–15	$-\infty$	–15
9	–15	–12	–14	–15	–13	–11	–16	$-\infty$	–15
10	–15	–11	–08	–14	–12	–10	–16	–16	–15

same connected component, as a test (because in this particular case there is nothing to certify) we compare three methods of certification:

1. construction of the complete trace form on a square grid;
2. construction of the complete trace form on a triangular grid, exploiting Newton identities;
3. construction of only the linear trace.

As in the general method for polynomial systems, we compute the magnitude of the highest value the interpolation polynomial returns at the grid and at some extra test points sampled from the component. These residuals would all be zero on exact data and with exact arithmetic. Due to approximate samples—accurate up to machine precision—and floating-point arithmetic, we observe errors when evaluating at the grid and at the test points; see Table 5.2.

In Table 5.2 we see an increasing loss of precision as the degree increases, for both with and without the exploitation of the Newton identities. This loss is due to the intrinsic complexity of high degree polynomials. There is no significant difference between the first two methods. From the last three columns of Table 5.2 we observe no error propagation; i.e., residuals at test points are of the same magnitude as the errors on the sample points. Compared to the complete trace form, linear traces are tolerant to approximate data and require no extra precision, at least not for the case of moderate degrees.

In Table 5.3 we list timings (on a Pentium III 800 MHz Linux machine) for the three certification methods. We see an efficiency gain with the exploitation of the Newton identities and a drastic difference when only the linear traces are computed.

In this experiment, the exploitation of the Newton identities is beneficial: fewer samples are needed and the loss of accuracy is not significantly different from the basic construction. However, for higher degrees, in situations where multiprecision arithmetic is necessary we experienced severe losses of accuracy. In particular, we applied this exploitation of Newton identities to one of the curves of degree 16 arising in the cyclic 8-roots problem (described in greater detail below). Even if the roots of the univariate polynomials were computed at full precision, the evaluation of those roots at high degree polynomials turned out to be insufficient to reach the same accuracy as without exploitation of the Newton identities. Based on these experiences, we recommend the exploitation of Newton identities only for moderate degrees.

TABLE 5.3

Timings on the dense polynomial with unit coefficients, for degrees d from 2 to 10 to construct the complete interpolator plainly on a square grid, exploiting Newton identities on a triangular grid. In the last column are timings to construct linear traces.

d	Square grid	Triangular grid	Linear traces
2	40 ms	50 ms	20 ms
3	110 ms	70 ms	30 ms
4	210 ms	170 ms	60 ms
5	420 ms	300 ms	110 ms
6	890 ms	480 ms	130 ms
7	1s 540 ms	760 ms	240 ms
8	2s 570 ms	1s 260 ms	320 ms
9	3s 730 ms	1s 800 ms	410 ms
10	4s 520 ms	3s 40 ms	600 ms

6. Applications. The algorithms have been implemented in a separate module of PHCpack [34], available online from http://www.math.uic.edu/∼jan and recently described in [30]. All reported timings are user cpu times on a Pentium III 800 Mhz Linux machine.

In the applications we consider here, the positive dimensional components are pure dimensional. Therefore, we restrict the numerical irreducible decomposition of [27] to the following three stages:

1. computation of the generic points with the embedding of [26];
2. application of monodromy [29], grouping the generic points which belong to the same irreducible component;
3. validation of the breakup predicted by monodromy by interpolation
   (a) either with the complete polynomials,
   (b) or with only the linear traces.

The methods presented in this paper only affect the last stage. We report timings for the other two stages to show the overall impact of our new approach. The experiments do not exploit the possible improvements that could result by integrating linear traces into the monodromy phase, as discussed in section 4.3.

6.1. The cyclic 8-roots and 9-roots problems. In [27] we had to limit ourselves to the *reduced* versions of those problems. With the recent advances in the decomposition algorithms we can factor the components into irreducibles *without* recourse to multiprecision arithmetic.

6.1.1. The cyclic 8-roots problem. In this section we confirm earlier results obtained in [2] by computer algebra methods. The timings for the three stages are as follows:

1. The computation of all 144 generic points on the one-dimensional components using the embedding in [26] takes 1h 12m 42s 650ms. Note that this computation also contains the calculation of the start solutions of paths leading to all isolated roots.
2. The set of 144 generic points breaks up into 8 subsets of 16 points and 8 subsets of 2 points. The monodromy breakup algorithm of [29] requires 6m 24s 930ms.
3. (a) In [29] we did the validation constructing interpolating polynomials, using standard arithmetic for the eight quadrics and using 32 decimal places for the eight curves of degree 16. This whole process took 41m 54s 780ms to complete. So stage three accounts for 35% of the total execution time.

TABLE 6.1

Numerical results of the certification of cyclic 8-roots. The columns contain the degree d, the accuracy of the samples in the grid, the largest value of the linear trace polynomial evaluated at the grid res, and the absolute value of the difference between the predicted and computed sum of the roots.

d	Accuracy of samples	Residual at grid	Difference at test pts
2	6.055E–16	1.110E–16	4.929E–14
2	4.733E–16	2.776E–16	4.308E–14
2	1.608E–15	8.882E–16	8.882E–15
2	4.143E–16	5.551E–17	5.551E–15

2	1.095E–15	8.882E–16	3.642E–14
2	5.403E–16	2.220E–16	8.238E–14
2	1.815E–15	5.551E–16	2.132E–14
16	1.318E–14	6.661E–16	2.665E–14
16	6.182E–14	8.882E–16	1.199E–13
16	2.991E–14	8.882E–16	9.326E–14
16	1.239E–13	8.882E–16	9.859E–14
16	1.667E–13	8.882E–16	2.167E–13
16	8.589E–14	8.882E–16	7.372E–14
16	9.708E–15	2.220E–16	1.030E–13
16	8.168E–15	1.776E–15	5.418E–14

(b) With linear traces we need fewer samples, and expensive multiprecision arithmetic can be avoided. This interpolation takes only 27s 540ms. Compared to the time needed in stage three with the complete interpolation polynomial, this runs more than 150 times faster. The total time for the three stages reduces from about two hours to one hour and 18 minutes.

We summarize the numerical results of this calculation in Table 6.1. See [28] for the computation of the linear span of the component.

We wish to point out that the sample points are distributed widely to have a good conditioning of the interpolating polynomial. Comparing the second column with column four in Table 6.1, we observe that there is hardly any loss of accuracy for any of the roots; neither the quadrics nor the 16th degree polynomials show any significant loss.

6.1.2. The cyclic 9-roots problem. This problem has been solved with Gröbner basis methods in [4]. The timings for the three stages with our approach are as follows:

1. To compute generic points, we used the mixed-volume calculator of T.Y. Li and X. Li [15] to set up the homotopy to solve the embedding of [26]. The mixed-volume computation took 13m 4s 540ms, and the total time to compute all 20,376 paths of the embedding for two-dimensional components was 9h 11m 27s 820ms. Only 18 of these paths land on two-dimensional components: the other paths either diverge to infinity or are paths destined to lead to the isolated solutions at a later stage of the embedding technique.
2. The set of 18 generic points breaks up into 6 subsets of 3 points each. The monodromy breakup algorithm of [29] requires 2m 32s 400ms.
3. (a) In [29] we did the validation constructing interpolating polynomials, with 32 decimal places, which took 14m 56s 570ms.
   (b) The validation using only linear traces took 9s 350ms. Details are in Table 6.2.

TABLE 6.2

Numerical results of the certification of cyclic 9-roots. The columns contain the degree d, the accuracy of the samples in the grid, the largest value of the linear trace polynomial evaluated at the grid res, and the absolute value of the difference between the predicted and computed sum of the roots.

d	Accuracy of samples	Residual at grid	Difference at test pts
3	3.507E-13	0.000E+00	6.864E-14
3	5.118E-13	2.776E-17	1.456E-13
3	9.343E-13	1.388E-17	2.313E-13
3	1.529E-13	5.551E-17	3.583E-14
3	6.984E-13	0.000E+00	8.460E-14
3	1.165E-13	0.000E+00	4.080E-15

6.2. A moving Stewart–Gough platform. A generic Stewart–Gough platform mechanism has forty isolated solutions, first established by continuation [19] and later proven analytically [10, 35]. A special case of this mechanism, due to Griffis and Duffy, has a solution curve of degree forty. This means that a Griffis–Duffy platform has a one-degree-of-freedom motion, whereas a generic Stewart–Gough platform is rigid. Husty and Karger [11] pointed out this fact and also identified a more special Griffis–Duffy platform for which the solution curve breaks up into lower degree irreducible components. We treat both cases here with our numerical methods and briefly discuss some differences we found from Husty and Karger's results.

For the general Griffis–Duffy platform, which herein we call case A, the solution set consists of 12 lines and one irreducible curve of degree 28. The lines all correspond to degeneracies that do not give actual assembly configurations of the mechanism. The specialized case B also has 12 degenerate lines, but now the curve of degree 28 breaks up into lower degree irreducible components—four sextics and a quartic. The timings for the three stages in our approach are as follows:

1. To compute forty generic points using the embedding of [26] requires 52s 490ms for case A and 55s 810ms for case B.
2. For case A, the monodromy algorithm of [29] takes 33s 430ms to predict a single component of degree 28. For case B, it takes 27s 630ms for the monodromy algorithm to group the 28 generic points into five sets; four of the five have cardinality six, and one set has four points.
3. (a) For case A, the validation with Newton interpolation for the curve of degree 28 requires multiprecision (with 64 decimal places) and 812 samples (for 435 monomials), and it completes in 1h 19m 13s 110ms. For case B, using 32 decimal places in constructing the complete interpolating polynomials with divided differences takes 2m 34s 50ms.
   (b) With linear traces, case A takes 4s 750ms and case B requires 4s 320ms.

This example shows several advantages of using linear traces for validation of the monodromy breakup. Compared to the use of interpolating polynomials, the computation time is not only drastically reduced when using linear traces, but also becomes nearly identical for both cases A and B. Interpolating a degree 28 polynomial in two variables for case A is expensive and requires high precision arithmetic. In fact, because of numerical instability of traces in this case, we used the bootstrapping Newton technique as in [29] to construct the complete interpolation filter. Case B, comprised of five irreducible curves whose degrees sum to 28, is much more tractable by interpolating polynomials, but still the use of only linear traces is much superior. Table 6.3 lists numerical results of the methods, showing that the linear traces are quite stable using only double precision arithmetic. In summary, compared to inter-

TABLE 6.3

Numerical results of the certification of case A ($d = 28$) and case B ($d = 6, 6, 6, 6, 4$) for the irreducible curves occurring in moving Stewart–Gough platforms. The columns contain the accuracy of the samples in the grid, the largest value of the interpolating filter (or the linear trace) evaluated at the grid, and the residual at the test points. With linear traces, we list the difference between the predicted and computed sum at the test points.

	With complete interpolation			Using linear traces only		
d	Accuracy of samples	Residual at grid	Residual at test pts	Accuracy of samples	Residual at grid	Difference at test pts
28	1.316E–59	3.800E–37	1.107E–20	4.013E–13	1.791E–12	1.791E–12
6	3.259E–28	2.800E–27	1.020E–20	1.272E–12	2.442E–15	4.694E–13
6	5.243E–29	8.495E–28	6.416E–21	9.944E–13	1.332E–15	3.659E–13
6	1.152E–28	6.000E–30	2.502E–21	8.660E–13	2.220E–16	5.853E–13
6	4.730E–29	2.540E–28	4.936E–20	7.438E–14	2.220E–15	1.083E–11
4	4.758E–30	4.300E–31	3.357E–27	1.063E–14	2.220E–16	3.408E–14

polating polynomials, our **Certify** algorithm, based on linear traces, eliminates the large fluctuation in timings with superior numerical stability and efficiency.

We show how we can observe the propagation of roundoff errors. Compare the accuracy of the samples with the residuals at the test points in Table 6.3. For case A, the accuracy of the samples is 10^{-59}, while the residuals at the test points evaluate to 10^{-20}. During the calculation we lost about 30 decimal places. The loss in case B is more modest, between 7 and 9 decimal places, and makes the difference in exponents in the second and fourth columns of Table 6.3. With linear traces, we observe from the data in Table 6.3 that we lose at most 3 decimal places.

While the reduction in execution times may turn modest in the near future as more and faster machines will become even more widely available, the major benefit of using linear traces is that reliable results are solely obtained with standard machine arithmetic, that is, without using any multiprecision numbers. This means that errors on the coefficients of the input system that are less than the standard machine precision can be neglected and the algorithm is numerically stable.

We conclude this section with some remarks not related to numerical performance, but rather concerning the decomposition itself. The decompositions we have computed for the Griffis–Duffy platforms differ from the results obtained by Husty and Karger in [11]; one discrepancy is reconcilable, but others are not. First, for the general example, case A, we find a degree 28 curve, which at first seems to conflict with their result of a degree 20 curve. This is not, however, a contradiction, because we have analyzed the curve in the full space of rotation and translation (represented in Study coordinates). The degree falls to 20 when the curve is projected onto its rotational component only, as done by Husty and Karger. However, we also find a significant difference for the specialized case B: Husty and Karger do not list one of the five irreducible components in their analysis. Their approach, using a combination of special reasoning and computer algebra, gives some extra insight in some respects, but our automated numerical method is less subject to human error. To tackle difficult problems, it will sometimes be beneficial to use both numeric and symbolic processes. In this case, knowing about the existence of the fifth irreducible component and seeing its numerical structure, one might return to the symbolic approach to further elucidate it. (Of course, one might also pursue a completely automated symbolic approach as well, but that is another story.)

We refer to [32] for a description of this and other applications of our approach to polynomial systems in mechanism design.

7. Conclusions. In [27], we presented a numerical algorithm to decompose solution sets of polynomial systems into irreducible components of various dimensions and degrees. The main drawback of that algorithm is numerical instability on components of high degree, due to the reliance on interpolating polynomials to filter generic points into irreducible components. To deal with this difficulty, multiprecision arithmetic was used whenever high degrees were encountered, requiring a high accuracy for the input coefficients of the polynomial systems and requiring much more computer time than standard precision for each arithmetic operation. While the sequels [28] and [29] lessened the need for high precision arithmetic to some extent, it is only in this paper that we can present a numerically stable decomposition algorithm to solve the cornerstone problem in numerical algebraic geometry [33].

We summarize how standard machine arithmetic can be employed throughout the numerical irreducible decomposition algorithm. The sequence of homotopies of [26] produces generic points on every positive dimensional component, mixed with "junk": points on higher solution components. To separate those junk points from the generic points, we now propose to use the homotopy membership test of [28] instead of the filtering polynomials in [27]. Unlike with high degree polynomials, this homotopy membership test does not require multiprecision arithmetic. Also the monodromy algorithm of [29] predicts the breakup of pure dimensional components using only standard machine arithmetic. With this paper, we finally remove any need for interpolating polynomials, because linear traces suffice to certify the predicted breakup. As linear polynomials are tolerant to roundoff and efficient to interpolate, our decomposition algorithms have gained significantly in speed and robustness. Practical evidence for these claims is provided in the reports on benchmark applications.

Acknowledgment. We would like to thank the referees for their helpful remarks.

hp-APPROXIMATION THEORY FOR BDFM AND RT FINITE ELEMENTS ON QUADRILATERALS*

MARK AINSWORTH† AND KATIA PINCHEDEZ†

Abstract. We study approximation properties of *hp*-finite element subspaces of $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$ on a polygonal domain Ω using Brezzi–Douglas–Fortin–Marini (**BDFM**) or Raviart–Thomas (**RT**) elements. Approximation theoretic results are derived for the *hp*-version finite element method on non-quasi-uniform meshes of quadrilateral elements with *hanging nodes* for functions belonging to weighted Sobolev spaces $\mathbf{H}^{s,\ell}_{\omega}(\Omega)$ and the countably normed spaces $\boldsymbol{\mathcal{B}}^{\ell}_{w}(\Omega)$. These results culminate in a proof of the characteristic exponential convergence property of the *hp*-version finite element method on suitably designed meshes under similar conditions needed for the analysis of the $\mathbf{H}^1(\Omega)$ case. By way of illustration, exponential convergence rates are deduced for mixed *hp*-approximation of flow in porous media.

Key words. mixed *hp*-finite elements, corner singularities, exponential convergence

1. Introduction.

The variational formulation of several important classes of problem arising in science and engineering involves the space

$$\mathbf{H}(\mathrm{div},\Omega) \;=\; \left\{\; \boldsymbol{v}\in\mathbf{L}^2(\Omega):\; \mathrm{div}\,\boldsymbol{v}\in\mathsf{L}^2(\Omega)\right\}$$

or the related space $\mathbf{H}(\mathrm{rot},\Omega)$. We mention flow through porous media, time-harmonic Maxwell's equations and elastostatics as particular examples. The finite element approximation of such problems entails the construction of finite dimensional subspaces of $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$. Many schemes have been proposed, such as Raviart–Thomas (**RT**) elements, Brezzi–Douglas–Fortin–Marini (**BDFM**) elements, and the related Nédélec, or edge, elements, to name but a few. We refer the interested reader to the book of Brezzi and Fortin [9] for further information.

If the physical domain Ω is polygonal, then it is well known [11] that the solutions of the governing equations exhibit singularities in the neighborhood of the vertices of the domain. The lack of smoothness in the underlying solution manifests itself in the form of a degraded rate of convergence as the finite element subspace is enriched. The *h*-version of the finite element method [10] seeks convergence through reduction of the mesh-size h (either uniformly or adaptively), whereas the *p*-version of the finite element method is based on increasing the degree of the polynomial while maintaining a fixed mesh. Both versions give at best *algebraic rates of convergence* on a polygonal domain. However, a proper combination of each, the *hp*-version, may deliver *exponential rates of convergence* [12, 13]. We refer to the extensive survey article of Babuška and Suri [7], Babuška and Guo [2], or the book by Schwab [20] for more details.

Although a great deal is known of *hp*-approximation of problems posed over the Sobolev space $\mathsf{H}^1(\Omega)$, comparatively little is known in the case of $\mathbf{H}(\mathrm{div},\Omega)$ and

$\mathbf{H}(\mathrm{rot},\Omega)$. Suri [22] and Milner and Suri [18] studied the properties of p-version finite element approximations of the spaces $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$ in two space dimensions with uniform order p on a regular mesh. Subsequently, the analysis was extended to the three dimensional case by Monk [19], working in the setting of Maxwell's equations again with uniform order p on a regular mesh, and then to the *hp*-version in two dimensions on a regular quasi-uniform mesh with uniform order p in [17]. One feature peculiar to the *hp*-version is the use of nonuniform polynomial degree distribution and graded, non-quasi-uniform meshes. Vardapetyan and Demkowicz [23] presented a construction allowing the generalization of certain types of Nédélec element to the *hp*-setting. These finite element subspaces of $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$ are part of a wider picture of discrete differential forms forming a bridge between the standard $\mathsf{H}^1(\Omega)$-conforming finite elements and $\mathsf{L}^2(\Omega)$-conforming elements [8, 14, 15, 16].

Despite increasing interest and use of *hp*-approximations of the spaces $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$, there has been no detailed study of the approximation properties. Specifically, there is no proof of the celebrated, characteristic, exponential convergence property of the *hp*-version. It is the aim of the present work to address this problem. Earlier work [21] dealt with *hp*-approximation on regular, globally quasi-uniform meshes based on regularity in standard Sobolev spaces. Here, we shall deal with approximation of functions belonging to the weighted Sobolev spaces $\mathbf{H}^{s,\ell}_{\omega}(\Omega)$ and the related spaces $\boldsymbol{\mathcal{B}}^{\ell}_{w}(\Omega)$, studied by Babuška and Guo [2, 3], that play a pivotal role in the analysis of the *hp*-version. We develop the approximation theoretic results needed to analyze the *hp*-version including non-quasi-uniform meshes with *hanging nodes*, culminating in a proof of exponential convergence for approximation of $\mathbf{H}(\mathrm{div},\Omega)$ and $\mathbf{H}(\mathrm{rot},\Omega)$ under the usual conditions assumed for the $\mathbf{H}^1(\Omega)$ case. By way of illustration, we deduce exponential convergence rates for mixed *hp*-finite element approximation of flow through porous media.

2. Model problem and its regularity. In the following, vector quantities shall always be represented by bold symbols and, for any real s, $[s]$ shall denote the integer part of s.

Let $\Omega \subset \mathbb{R}^2$ be a polygonal domain with vertices located at A_i, $i = 1,\ldots,M$. The Sobolev space $\mathsf{H}^r(\Omega)$, for $r \geq 0$ integer, consists of functions defined on Ω whose derivatives of order up to r are square integrable and is equipped with the usual norm and seminorm:

$$\|u\|^2_{\mathsf{H}^r(\Omega)} \quad \sum_{m=0}^{r} |u|^2_{\mathsf{H}^m(\Omega)}, \qquad |u|^2_{\mathsf{H}^r(\Omega)} \;=\; \| \,|\,\mathrm{D}^r\, u|\,\|^2_{\mathsf{L}^2(\Omega)},$$

where $|\,\mathrm{D}^r\, u|^2 = \sum_{i+j=r} |\,\mathrm{D}^{(i,j)}\, u|^2$. In particular, observe that $\mathsf{H}^0(\Omega) = \mathsf{L}^2(\Omega)$.

Next, let us introduce definitions and notations for certain weighted Sobolev spaces [12]. The distance between $\boldsymbol{x}$ and the vertex A_i is denoted by $r_i(\boldsymbol{x}) = |\boldsymbol{x} - A_i|$. Let $\omega = (\omega_1,\ldots,\omega_M)$ be an M-tuple of real numbers $0 \leq \omega_i < 1$ for $i = 1,\ldots,M$ and $\omega \neq 0$. We introduce weight functions defined by

$$\Phi_{\omega}(\boldsymbol{x}) \;=\; \textstyle\prod_{i=1}^{M} r_i^{\omega_i}(\boldsymbol{x}) \quad \text{and} \quad \Phi_{\omega\pm p}(\boldsymbol{x}) \;=\; \textstyle\prod_{i=1}^{M} r_i^{\omega_i \pm p}(\boldsymbol{x}),$$

where, for any integer p, the M-tuple $\omega \pm p$ is equal to $(\omega_1 \pm p,\ldots,\omega_M \pm p)$.

For integers $r \geq \ell \geq 0$, the weighted Sobolev space $\mathsf{H}^{r,\ell}_{\omega}(\Omega)$ denotes the completion of $\mathsf{C}^{\infty}(\overline{\Omega})$ under the norm defined by

$$\|u\|^2_{\mathsf{H}^{r,\ell}_\omega(\Omega)} \;=\; \|u\|^2_{\mathsf{H}^{\ell-1}(\Omega)} \;+\; |u|^2_{\mathsf{H}^{r,\ell}_\omega(\Omega)} \qquad \text{for } \ell \geq 1, \tag{1}$$

$$\|u\|^2_{\mathsf{H}^{r,0}_\omega(\Omega)} \;=\; \|u\|^2_{\mathsf{H}^{r}_\omega(\Omega)} \;=\; |u|^2_{\mathsf{H}^{r,0}_\omega(\Omega)} \qquad \text{for } \ell = 0, \tag{2}$$

where

$$|u|^2_{\mathsf{H}^{r,\ell}_\omega(\Omega)} \;=\; \sum_{k=\ell}^{r} \int_\Omega \left|\mathrm{D}^k\, u(\boldsymbol{x})\right|^2 \Phi^2_{\omega+k-\ell}(\boldsymbol{x})\, d\boldsymbol{x}. \tag{3}$$

For $r = \ell = 0$ we also write $\mathsf{H}^{0,0}_\omega(\Omega) = \mathsf{L}^2_\omega(\Omega)$. The weighted Sobolev space $\mathsf{H}^{s,\ell}_\omega(\Omega)$ for a noninteger s is defined using the K-method of interpolation [20]:

$$\mathsf{H}^{s,\ell}_\omega(\Omega) \;=\; \left[\mathsf{H}^{r,\ell}_\omega(\Omega), \mathsf{H}^{r+1,\ell}_\omega(\Omega)\right]_{\theta,\infty}$$

for $s = r + \theta$, with r integer and $0 < \theta < 1$.

For $\ell \geq 0$ integer, a function u belongs to the countably normed space $\mathcal{B}^\ell_\omega(\Omega)$ if there exist constants $C > 0$ and $d \geq 1$ such that, for any integer $r \geq \ell$,

$$u \;\in\; \mathsf{H}^{r,\ell}_\omega(\Omega) \quad \text{with} \quad \left(\int_\Omega |\,\mathrm{D}^r\, u|^2 \Phi^2_{\omega+r-\ell}\, d\boldsymbol{x}\right)^{1/2} \leq C\, d^{r-\ell}\, (r-\ell)! \tag{4}$$

Furthermore, if $u \in \mathcal{B}^\ell_\omega(\Omega)$ with the corresponding constants C and d, then u belongs to the space $\mathsf{H}^{s,\ell}_\omega(\Omega)$ for any real $s \geq \ell$ and satisfies the inequality

$$\|u\|_{\mathsf{H}^{s,\ell}_\omega(\Omega)} \;\leq\; C\, d^{s-\ell}\, \sqrt{s}\;\, \Gamma(s-\ell+1), \tag{5}$$

where Γ is the gamma function.

For given data $f \in \mathsf{L}^2(\Omega)$, we shall consider the following model problem: find p such that

$$-\,\mathrm{div}\;\, A\, \mathbf{grad}\, p(\boldsymbol{x}) \;=\; f(\boldsymbol{x}) \quad \text{ in } \Omega \tag{6}$$

subject to $p = 0$ on $\partial\Omega$, where A is a 2×2 symmetric positive definite matrix. Standard arguments lead to the existence of a unique solution $p \in \mathsf{H}^1_0(\Omega)$. The following result shows that if the data f belong to the space $\mathcal{B}^0_\omega(\Omega)$, then the solution p has additional smoothness properties relative to the countably normed spaces.

THEOREM 1. *If the data $f \in \mathcal{B}^0_\omega(\Omega)$, then the solution p of* (6) *satisfies $p \in \mathcal{B}^2_\omega(\Omega)$, and the flux $\boldsymbol{u} = A\, \mathbf{grad}\, p$ satisfies $\boldsymbol{u} \in \boldsymbol{\mathcal{B}}^1_\omega(\Omega)$.*

Proof. The regularity of p is established in [12], and the regularity of $\boldsymbol{u}$ follows as an immediate consequence. ∎

3. Finite element discretization.

3.1. Partitions. The polygonal domain Ω is assumed to be partitioned into the union of finitely many nonoverlapping quadrilaterals $\mathcal{T} = \{K\}$. Each element K is assumed to be the image of the reference element $\widehat{K} = (-1,+1)^2$ under a smooth, invertible mapping $F_K : \widehat{K} \longrightarrow K$. More generally, we consider a family of such partitions, and we suppose that the elements are shape regular in the sense that the ratio of the diameter h_K of the smallest circle containing an element K to the diameter ρ_K of the largest circle contained within K is bounded uniformly over the whole family.

A standard finite element partition generally consists of elements such that the nonempty intersection of any pair of distinct elements is either a single common vertex or a single common edge. In order to facilitate local refinements, this assumption is relaxed to allow *hanging nodes* [1]. Thus, in addition to the above conditions, it is permitted for a nonempty intersection to be a complete side of at least one element and a single portion of an edge or the neighboring element obtained by bisecting the edge (see Figure 1). The node located at the midpoint is said to be *hanging*. An edge containing a hanging node is said to be *broken*. It is also possible to break edges unevenly, which is advantageous in accelerating resolution of corner singularities to be considered later.

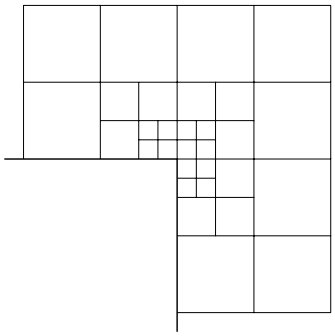

FIG. 1. *Geometric mesh with hanging nodes.*

3.2. Polynomial spaces on the reference element. For nonnegative integers k and ℓ, the space $\mathbb{Q}_{k,\ell}$ consists of polynomials of degree at most k and ℓ in the first and second variables, respectively. The notation $\mathbb{Q}_k = \mathbb{Q}_{k,k}$ is adopted in the case $k = \ell$. The space $\mathbb{P}_k$ consists of polynomials of total degree at most k.

The Brezzi–Douglas–Fortin–Marini space of order k ($\mathbf{BDFM}_k$) is defined [9, p. 123] by

$$\mathbf{BDFM}_k \;=\; \left\{\mathbb{P}_{k+1} \setminus (\eta^{k+1})\right\} \;\times\; \left\{\mathbb{P}_{k+1} \setminus (\xi^{k+1})\right\}$$

and is equipped with an interpolation operator $\widehat{\mathbf{\Pi}}_k$ satisfying $\widehat{\mathbf{\Pi}}_k \boldsymbol{u} \in \mathbf{BDFM}_k$ and

$$\text{(7)} \qquad \begin{cases} \int_{\widehat{K}} \left(\widehat{\mathbf{\Pi}}_k\, \boldsymbol{u} - \boldsymbol{u}\right) \cdot \boldsymbol{p}\, d\boldsymbol{x} \;=\; 0 \qquad \forall\, \boldsymbol{p} \;\in\; [\mathbb{P}_{k-1}]^2, \\ \int_{\gamma_m} \left(\widehat{\mathbf{\Pi}}_k\, \boldsymbol{u} - \boldsymbol{u}\right) \cdot \boldsymbol{n}\, q\, ds \;=\; 0 \quad \forall\, q \;\in\; \mathbb{R}_k(\gamma_m), \quad m = 1, 2, 3, 4, \end{cases}$$

where $\mathbb{R}_k(\gamma)$ denotes polynomials of degree at most k in the arclength s, and $\boldsymbol{n}$ is the unit outward normal on the edge. The Raviart–Thomas space of order k ($\mathbf{RT}_k$) is defined [9, p. 119] by

$$\mathbf{RT}_k \;=\; \mathbb{Q}_{k+1,k} \;\times\; \mathbb{Q}_{k,k+1}$$

with corresponding operator $\widehat{\mathbf{\Pi}}_k$ satisfying $\widehat{\mathbf{\Pi}}_k \boldsymbol{u} \in \mathbf{RT}_k$ and

$$(8)\qquad \begin{cases} \int_{\widehat{K}} \left(\widehat{\boldsymbol{\Pi}}_k\, \boldsymbol{u} - \boldsymbol{u}\right) \cdot \boldsymbol{p}\, d\boldsymbol{x} \;=\; 0 \qquad \forall\, \boldsymbol{p} \;\in\; \mathbb{Q}_{k-1,k} \times \mathbb{Q}_{k,k-1}, \\ \int_{\gamma_m} \left(\widehat{\boldsymbol{\Pi}}_k\, \boldsymbol{u} - \boldsymbol{u}\right) \cdot \boldsymbol{n}\, q\, ds \;=\; 0 \quad \forall\, q \;\in\; \mathbb{R}_k(\gamma_m), \quad m = 1,2,3,4. \end{cases}$$

The following result shows that these operators are well defined.

PROPOSITION 2. *The interpolation operators* $\widehat{\boldsymbol{\Pi}}_k$ *are unisolvent with respect to the* $\mathbf{BDFM}_k$ *and* $\mathbf{RT}_k$ *spaces. Furthermore, for sufficiently smooth functions* $\boldsymbol{u} \in \mathbf{H}(\mathrm{div}, \widehat{K})$*, the following "commuting diagram" property holds:*

$$(9)\qquad \mathrm{div}\left(\widehat{\boldsymbol{\Pi}}_k \boldsymbol{u}\right) = \widehat{\pi}_k(\mathrm{div}\, \boldsymbol{u}),$$

where $\widehat{\pi}_k$ *is the* $\mathsf{L}^2(\widehat{K})$*-orthogonal projection onto* $\mathbb{P}_k$ *(respectively,* $\mathbb{Q}_k$*) when* $\widehat{\boldsymbol{\Pi}}_k$ *is the operator associated with the space* $\mathbf{BDFM}_k$ *(respectively,* $\mathbf{RT}_k$*).*

Proof. Unisolvence follows using arguments given in [9, section III.3.2]. The commuting diagram property follows on observing that $\mathrm{div}\, \mathbf{BDFM}_k = \mathbb{P}_k$ (or $\mathrm{div}\, \mathbf{RT}_k = \mathbb{Q}_k$) and using [9, Proposition III.3.7]. ∎

3.3. Finite element spaces on a single physical element. Let $k \geq 1$ denote the polynomial degree of the space (either $\mathbf{BDFM}_k$ or $\mathbf{RT}_k$) used to construct the finite element space. The Piola transformation given by

$$(10)\qquad \mathcal{L}_K\, \widehat{\boldsymbol{u}} \;=\; \frac{1}{\det\left(J_K\right)}\, J_K\, \widehat{\boldsymbol{u}} \circ F_K^{-1}$$

defines a contravariant mapping and, in particular, preserves moments of the normal component of $\widehat{\boldsymbol{u}}$ on element edges [9, p. 97]. Here, J_K is the Jacobian matrix of the mapping F_K. The Piola transformation is used to define the local finite element spaces on the physical element K as follows:

$$\boldsymbol{\Gamma}_k^{\mathsf{BDFM}}(K) \;=\; \{\, \boldsymbol{u} \;:\quad \boldsymbol{u} \;=\; \mathcal{L}_K\, \widehat{\boldsymbol{u}}, \quad \widehat{\boldsymbol{u}} \;\in\; \mathbf{BDFM}_k \,\}$$

with $\boldsymbol{\Gamma}_k^{\mathsf{RT}}(K)$ defined in the same fashion. The space $\boldsymbol{\Gamma}_k^{\mathsf{BDFM}}(K)$ is equipped with an interpolation operator $\boldsymbol{\Pi}_k^{\mathsf{BDFM}}$ defined in terms of the local operator $\widehat{\boldsymbol{\Pi}}_k$ by the rule

$$(11)\qquad \boldsymbol{\Pi}_k \;=\; \mathcal{L}_K\, \widehat{\boldsymbol{\Pi}}_k\, \mathcal{L}_K^{-1}.$$

The global operator associated with the $\mathbf{RT}_k$ space is defined by the same expression.

3.4. Global finite element spaces. Let $\mathcal{T}$ be a partition of Ω. The global finite element spaces are defined by

$$(12)\qquad \boldsymbol{\Gamma}_k^{\mathsf{BDFM}}(\Omega) \;=\; \{\;\; \boldsymbol{u} \;\in \mathbf{H}(\mathrm{div}, \Omega) \;:\;\; \boldsymbol{u}|_K \;\in\; \boldsymbol{\Gamma}_k^{\mathsf{BDFM}}(K) \;\;\}$$

with a similar expression for $\boldsymbol{\Gamma}_k^{\mathsf{RT}}(\Omega)$. Although it is also possible to extend the analysis to the situation where combinations of the two local spaces are used in the construction of the global space, we shall not pursue this explicitly here.

If the partition $\mathcal{T}$ *contains no broken edges*, then the global interpolation operator $\boldsymbol{\Pi}$ associated with the global finite element space $\boldsymbol{\Gamma}_k(\Omega)$ may be defined in terms of the local interpolation operators in the usual way, as for example in [9, equation (3.71)]:

$$(13)\qquad (\boldsymbol{\Pi}\, \boldsymbol{u})|_K \;=\; \boldsymbol{\Pi}_{K,k}\, (\boldsymbol{u}|_K) \qquad \forall K \;\in\; \mathcal{T}.$$

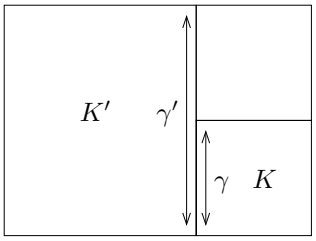

FIG. 2. *Broken edge γ' and subedge γ.*

This definition, albeit completely standard, *does not extend* to the situation where broken edges are present. For instance, consider the configuration shown in Figure 2.

The local interpolant $\boldsymbol{\Pi}_{K,k}\,\boldsymbol{u}$ on element K depends on the function $\boldsymbol{u}\cdot\boldsymbol{n}$ restricted to the edge γ. Equally well, $\boldsymbol{\Pi}_{K',k}\,\boldsymbol{u}$ depends on values of $\boldsymbol{u}\cdot\boldsymbol{n}$ on the entire edge γ'. It is not difficult to construct examples where the resulting normal components of $\boldsymbol{\Pi}_{K,k}\,\boldsymbol{u}$ and $\boldsymbol{\Pi}_{K',k}\,\boldsymbol{u}$ disagree on the common boundary γ:

$$(\boldsymbol{\Pi}_{K,k}\,\boldsymbol{u})\cdot\boldsymbol{n} \;\neq\; (\boldsymbol{\Pi}_{K',k}\,\boldsymbol{u})\cdot\boldsymbol{n} \qquad \text{on } \gamma. \tag{14}$$

This shows that it is not possible to define the global interpolant in terms of local interpolants using expression (13).

This difficulty is resolved by realizing that the degrees of freedom associated with the edges γ and γ' must be constrained to ensure $\mathbf{H}(\mathrm{div},\Omega)$ conformity holds. The degrees of freedom on the longer edge γ' take precedence over the values of the degrees of freedom on the shorter edge. Thus, for sufficiently smooth $\boldsymbol{u}\in\mathbf{H}(\mathrm{div},\Omega)$, the values of the global interpolant $\boldsymbol{\Pi u}$ on edge γ' are defined using global moment conditions on edge γ' as follows:

$$\int_{\gamma'}(\boldsymbol{\Pi u}-\boldsymbol{u})\cdot\boldsymbol{n}\;q\;ds \;=\; 0 \qquad \forall q\;\in\;\mathbb{R}_k(\gamma') \tag{15}$$

in place of (7). (Strictly speaking, q is a pull-back polynomial.) This definition coincides with (13) for a mesh containing no broken edges.

4. Approximation theory. The purpose of this section is to establish some basic approximation properties of the local interpolation operators $\widehat{\boldsymbol{\Pi}}_k$.

4.1. Explicit form for local interpolation operators. Let k specify the degree of polynomial on a reference $\widehat{K}$, as in Figure 3. First, we introduce the polynomial extension operator $\mathcal{E}_k^{\gamma_1}:\mathbb{R}_k(\gamma_1)\longrightarrow\mathbb{P}_{k+1}\setminus\{\eta^{k+1}\}$ defined by

$$(\mathcal{E}_k^{\gamma_1}\,w)\,(\xi,\eta) \;=\; \sum_{i=0}^{k} w_i\;\frac{(-1)^{k-i+1}}{2}\Big(L_{k-i+1}(\xi)-L_{k-i}(\xi)\Big)\;L_i(\eta),\quad (\xi,\eta)\in\widehat{K}, \tag{16}$$

where $w\in\mathbb{R}_k(\gamma_1)$ is of the form

$$w(\eta) \;=\; \sum_{i=0}^{k} w_i\;L_i(\eta),\quad \eta\in(-1,+1). \tag{17}$$

Here, $\{L_i\}$ are Legendre polynomials and (17) uniquely defines the coefficients w_i. Consequently, the extension is well defined by expression (16). Moreover, it possesses

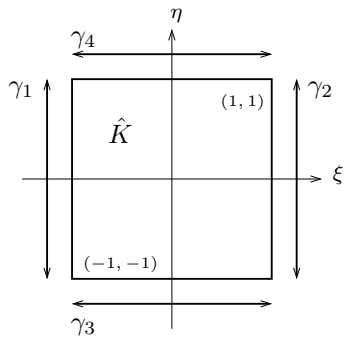

FIG. 3. *Notation for the reference element.*

the property that, for w in $\mathbb{R}_k(\gamma_1)$,

$$\mathcal{E}_k^{\gamma_1} w|_{\gamma_1} = w \qquad \text{and} \qquad \mathcal{E}_k^{\gamma_1} w|_{\gamma_2} = 0. \tag{18}$$

The extension operators $\mathcal{E}_k^{\gamma_2} : \mathbb{R}_k(\gamma_2) \longrightarrow \mathbb{P}_{k+1} \setminus \{\eta^{k+1}\}$ and $\mathcal{E}_k^{\gamma_m} : \mathbb{R}_k(\gamma_m) \longrightarrow \mathbb{P}_{k+1} \setminus \{\xi^{k+1}\}$, $m = 3, 4$, are defined in a similar way with properties analogous to (18).

The $\mathsf{L}^2(\widehat{K})$-orthogonal projection onto $\mathbb{P}_k$ is denoted by $\widehat{\pi}_k^{\mathsf{P}}$, the $\mathsf{L}^2(\gamma_m)$-orthogonal projector onto $\mathbb{R}_k(\gamma_m)$ is denoted by $\mathsf{R}_k^{\gamma_m}$, and Tr_{γ_m} denotes the trace operator. The next result provides an explicit expression for the interpolant $\widehat{\mathbf{\Pi}}_k$ associated with the space $\mathbf{BDFM}_k$.

LEMMA 3. *Let $k \geq 1$. Then the interpolation operator $\widehat{\mathbf{\Pi}}_k$ for the space $\mathbf{BDFM}_k$ is given by*

$$\begin{aligned} \widehat{\mathbf{\Pi}}_k \boldsymbol{u} \;=\; & \Big(\widehat{\pi}_{k-1}^{\mathsf{P}} u_x + \textstyle\sum_{m=1}^{2} \mathcal{E}_k^{\gamma_m} \left(\mathsf{R}_k^{\gamma_m} \mathrm{Tr}_{\gamma_m} u_x - \mathrm{Tr}_{\gamma_m} \widehat{\pi}_{k-1}^{\mathsf{P}} u_x \right), \\ & \widehat{\pi}_{k-1}^{\mathsf{P}} u_y + \textstyle\sum_{m=3}^{4} \mathcal{E}_k^{\gamma_m} \left(\mathsf{R}_k^{\gamma_m} \mathrm{Tr}_{\gamma_m} u_y - \mathrm{Tr}_{\gamma_m} \widehat{\pi}_{k-1}^{\mathsf{P}} u_y \right) \Big), \end{aligned} \tag{19}$$

where $\boldsymbol{u} = (u_x, u_y)$.

Proof. It is clear that the expression (19) defines a function belonging to $\mathbf{BDFM}_k$. It therefore suffices to verify that conditions (7) hold.

Let $\tilde{u}_x$ denote the first component of (19). Then, for $p \in \mathbb{P}_{k-1}$ we have, thanks to the orthogonality properties of Legendre polynomials,

$$\int_{\widehat{K}} \tilde{u}_x \, p \, d\xi \, d\eta = \int_{\widehat{K}} \widehat{\pi}_{k-1}^{\mathsf{P}} u_x \, p \, d\xi \, d\eta = \int_{\widehat{K}} u_x \, p \, d\xi \, d\eta.$$

Similarly, property (18) implies that, for $q \in \mathbb{R}_k(\gamma_m)$,

$$\begin{aligned} & \textstyle\int_{\gamma_m} (\mathrm{Tr}_{\gamma_m} \tilde{u}_x) \cdot q \, d\eta \\ & = \textstyle\int_{\gamma_m} \left(\mathrm{Tr}_{\gamma_m} \widehat{\pi}_{k-1}^{\mathsf{P}} u_x \right) \cdot q \, d\eta + \int_{\gamma_m} \left(\mathsf{R}_k^{\gamma_m} \mathrm{Tr}_{\gamma_m} u_x - \mathrm{Tr}_{\gamma_m} \widehat{\pi}_{k-1}^{\mathsf{P}} u_x \right) \cdot q \, d\eta \\ & = \textstyle\int_{\gamma_m} (\mathsf{R}_k^{\gamma_m} \mathrm{Tr}_{\gamma_m} u_x) \cdot q \, d\eta = \int_{\gamma_m} (\mathrm{Tr}_{\gamma_m} u_x) \cdot q \, d\eta, \end{aligned}$$

and the proof is complete. ∎

Extension operators for the $\mathbf{RT}_k$ space are defined by $\mathcal{E}_k^{\gamma_1} : \mathbb{R}_k(\gamma_1) \longrightarrow \mathbb{Q}_{k+1,k}$, where

$$\left(\mathcal{E}_k^{\gamma_1} w\right)(\xi,\eta) \;=\; \sum_{i=0}^{k} \frac{(-1)^{k+1}}{2}\; c_i\; \left(L_{k+1}(\xi) - L_k(\xi)\right) L_i(\eta)$$

with similar definitions for $\mathcal{E}_k^{\gamma_m}$, $m = 2, 3, 4$. There is no danger of confusion in using the same notation for the extension operators in both the $\mathbf{RT}$ and $\mathbf{BDFM}$ cases. The $\mathsf{L}^2(\widehat{K})$-orthogonal projection onto the space $\mathbb{Q}_{k,\ell}$ is denoted by $\widehat{\pi}_{k,\ell}^{\mathsf{Q}}$. Then, by analogy with Lemma 3, we have the following.

LEMMA 4. *Let $k \geq 1$. Then the interpolation operator $\widehat{\mathbf{\Pi}}_k$ for the space $\mathbf{RT}_k$ is given by*

$$\widehat{\mathbf{\Pi}}_k \boldsymbol{u} \;=\; \Bigg(\widehat{\pi}_{k-1,k}^{\mathsf{Q}}\, u_x + \textstyle\sum_{m=1}^{2} \mathcal{E}_k^{\gamma_m} \left(\mathsf{R}_k^{\gamma_m}\, \mathrm{Tr}_{\gamma_m}\, u_x - \mathrm{Tr}_{\gamma_m}\, \widehat{\pi}_{k-1,k}^{\mathsf{Q}}\, u_x \right), \qquad (20)$$

$$\widehat{\pi}_{k,k-1}^{\mathsf{Q}}\, u_y + \textstyle\sum_{m=3}^{4} \mathcal{E}_k^{\gamma_m} \left(\mathsf{R}_k^{\gamma_m}\, \mathrm{Tr}_{\gamma_m}\, u_y - \mathrm{Tr}_{\gamma_m}\, \widehat{\pi}_{k,k-1}^{\mathsf{Q}}\, u_y \right) \Bigg).$$

4.2. Approximation on the reference element. It is convenient to introduce the shorthand notation

$$[w]_{r,\widehat{\Omega}}^2 \;=\; \left(\frac{h_1}{2}\right)^{2r} \| \,\mathrm{D}^{(r,0)}\, w \,\|_{\mathsf{L}^2(\widehat{\Omega})}^2 \;+\; \left(\frac{h_2}{2}\right)^{2r} \| \,\mathrm{D}^{(0,r)}\, w \,\|_{\mathsf{L}^2(\widehat{\Omega})}^2$$

in the case where $\widehat{\Omega} = (0, h_1) \times (0, h_2)$ and $w \in \mathsf{H}^r(\widehat{\Omega})$, $r \in \mathbb{N}$. Furthermore, in what follows, C denotes positive constants that are independent of other quantities appearing in the same relation and whose values need not be the same in any two places.

The following result will prove useful.

LEMMA 5. *Suppose that $w \in \mathsf{H}^r(\widehat{K})$, $r \geq 0$, has Legendre series expansion*

$$w(\xi,\eta) \;=\; \sum_{i=0}^{\infty} \sum_{j=0}^{\infty}\; a_{i,j}\; L_i(\xi)\, L_j(\eta). \qquad (21)$$

Then, for all integers $0 \leq r_1 \leq p$, $0 \leq r_2 \leq q$, with $r_1 + r_2 \leq r$, there holds

$$\sum_{i=p}^{\infty} \sum_{j=q}^{\infty}\; \rho_i\, \rho_j\, a_{i,j}^2 \;\leq\; \frac{(p-r_1)!}{(p+r_1)!}\, \frac{(q-r_2)!}{(q+r_2)!}\, \| \,\mathrm{D}^{(r_1,r_2)}\, w \|_{\mathsf{L}^2(\widehat{K})}^2, \qquad (22)$$

where $\rho_i = (i + 1/2)^{-1}$.

Proof. If r_1 and r_2 satisfy the hypothesis, then it is well known (see, e.g., Lemma 4.1 [12]), that

$$\sum_{i=r_1}^{\infty} \sum_{j=r_2}^{\infty}\; \rho_i\, \rho_j\, a_{i,j}^2\, \frac{(i+r_1)!}{(i-r_1)!}\, \frac{(j+r_2)!}{(j-r_2)!} \;=\; \int_{\widehat{K}} \left(1-\xi^2\right)^{r_1} \left(1-\eta^2\right)^{r_2} \left| \,\mathrm{D}^{(r_1,r_2)}\, w \,\right|^2 d\xi\, d\eta.$$

Now, for p and q as in the statement, we have

$$\sum_{i=p}^{\infty} \sum_{j=q}^{\infty}\; \rho_i\, \rho_j\, a_{i,j}^2 \;\leq\; \left(\sum_{i=p}^{\infty} \sum_{j=q}^{\infty}\; \rho_i\, \rho_j\, a_{i,j}^2\, \frac{(i+r_1)!}{(i-r_1)!}\, \frac{(j+r_2)!}{(j-r_2)!} \right)\; \frac{(p-r_1)!}{(p+r_1)!}\, \frac{(q-r_2)!}{(q+r_2)!},$$

and the result follows at once. ∎

We begin with approximation properties for the $\mathsf{L}^2(\widehat{K})$-projections $\widehat{\pi}_k^{\mathsf{Q}}$ and $\widehat{\pi}_k^{\mathsf{P}}$.

LEMMA 6. *Let* $\widehat{\pi}_k^{\mathsf{Q}} : \mathsf{L}^2(\widehat{K}) \longrightarrow \mathbb{Q}_k$ *and* $\widehat{\pi}_k^{\mathsf{P}} : \mathsf{L}^2(\widehat{K}) \longrightarrow \mathbb{P}_k$ *denote orthogonal projections. Suppose* $w \in \mathsf{H}^r(\widehat{K})$*; then for* $0 \le r \le k+1$,

$$\|w - \widehat{\pi}_k^{\mathsf{Q}} w\|^2_{\mathsf{L}^2(\widehat{K})} \;\le\; \frac{(k+1-r)!}{(k+1+r)!}\; [w]^2_{r,\widehat{K}}, \tag{23}$$

and for $0 \le r \le [k/2]+1$,

$$\|w - \widehat{\pi}_k^{\mathsf{P}} w\|^2_{\mathsf{L}^2(\widehat{K})} \;\le\; \frac{([k/2]+1-r)!}{([k/2]+1+r)!}\; [w]^2_{r,\widehat{K}}. \tag{24}$$

Proof. By density, it suffices to consider w of the form (21) so that

$$\widehat{\pi}_k^{\mathsf{Q}} w(\xi,\eta) \;=\; \sum_{i=0}^{k}\sum_{j=0}^{k} a_{i,j}\; L_i(\xi)\; L_j(\eta).$$

Orthogonality of Legendre polynomials implies that

$$\|w - \widehat{\pi}_k^{\mathsf{Q}} w\|^2_{\mathsf{L}^2(\widehat{K})} \;\le\; \left(\sum_{i=k+1}^{\infty}\sum_{j=0}^{\infty} + \sum_{i=0}^{k}\sum_{j=k+1}^{\infty}\right) a_{i,j}^2\; \rho_i\; \rho_j. \tag{25}$$

The first term on the right-hand side of (25) is bounded using Lemma 5:

$$\sum_{i=k+1}^{\infty}\sum_{j=0}^{\infty} a_{i,j}^2\; \rho_i\; \rho_j \;\le\; \frac{(k+1-r)!}{(k+1+r)!}\, \|\,\mathrm{D}^{(r,0)}\, w\|^2_{\mathsf{L}^2(\widehat{K})}.$$

A similar bound applies for the second term and the first result follows at once.

The second bound follows trivially from the first thanks to the inclusion $\mathbb{Q}_{[k/2]} \subset \mathbb{P}_k$ and optimality of the $\mathsf{L}^2(\widehat{K})$-projection $\widehat{\pi}_k^{\mathsf{P}}$. ∎

The following technical lemma will be useful in deriving bounds for the accuracy of the interpolation operators.

LEMMA 7. *Let* $w \in \mathsf{H}^r(\widehat{K})$, $r > 1$, *be of the form* (21). *Then for fixed* $\varepsilon \in (0, r-1)$ *we have, for* $r \le k$,

$$\sum_{j=0}^{\infty} \rho_j \left(\sum_{i=k}^{\infty} a_{i,j}\; (-1)^i\right)^2 \;\le\; \frac{C\,k^2}{\varepsilon}\; \frac{(k-r)!}{(k+r)!}\; [w]^2_{r,\widehat{K}} \tag{26}$$

while, for $r \le \left[\frac{k+1}{2}\right]$,

$$\sum_{j=0}^{\infty} \rho_j \left(\sum_{i=\max(0,k-j)}^{\infty} a_{i,j}\; (-1)^i\right)^2 \;\le\; \frac{C\,k^2}{\varepsilon}\; \frac{\left(\left[\frac{k+1}{2}\right]-r\right)!}{\left(\left[\frac{k+1}{2}\right]+r\right)!}\; [w]^2_{r,\widehat{K}}. \tag{27}$$

Moreover, for $r \le k$,

$$\sum_{j=k}^{\infty} \rho_j \left(\sum_{i=0}^{\infty} a_{i,j}\; (-1)^i\right)^2 \;\le\; \frac{C\,k^2}{\varepsilon}\; \frac{(k-r)!}{(k+r)!}\; [w]^2_{r,\widehat{K}}. \tag{28}$$

In each case, $C > 0$ is independent of r and k.

Proof. Let $\varepsilon \in (0, r-1)$. Then, by the Cauchy–Schwarz inequality,

$$\sum_{j=0}^{\infty} \rho_j \left(\sum_{i=k}^{\infty} a_{i,j}\, (-1)^i \right)^2 \;\le\; \sum_{j=0}^{\infty} \sum_{i=k}^{\infty} \rho_i\, \rho_j\, a_{i,j}^2\, i^{2+2\varepsilon} \;\cdot\; \sum_{i=k}^{\infty} \rho_i^{-1}\, i^{-2-2\varepsilon}.$$

Bounding the second factor on the right-hand side by $\sum_{i=k}^{\infty} i^{-1-2\varepsilon} \;\le\; C/\varepsilon\, k^{-2\varepsilon}$, we obtain

$$\sum_{j=0}^{\infty} \rho_j \left(\sum_{i=k}^{\infty} a_{i,j}\, (-1)^i \right)^2 \;\le\; \frac{C\, k^{-2\varepsilon}}{\varepsilon} \sum_{i=k}^{\infty} \sum_{j=0}^{k} \rho_i\, \rho_j\, a_{i,j}^2\, \frac{(i+r)!}{(i-r)!}\, f(i),$$

where $f(x) = x^{2+2\varepsilon}\, (x-r)!/(x+r)!$, $x \ge k$. If $\varepsilon < r-1$, then, for k sufficiently large, f is decreasing. Hence,

$$\begin{aligned} \sum_{j=0}^{\infty}\, \rho_j \sum_{i=k}^{\infty} \Big(a_{i,j}\, (-1)^i \Big)^2 \;&\le\; \frac{C\, k^{-2\varepsilon}}{\varepsilon}\, f(k) \sum_{i=k}^{\infty} \sum_{j=0}^{\infty}\, \rho_i\, \rho_j\, a_{i,j}^2\, \frac{(i+r)!}{(i-r)!} \\ &\le\; \frac{C\, k^2}{\varepsilon}\, \frac{(k-r)!}{(k+r)!}\, \| \mathrm{D}^{(r,0)}\, w \|_{\mathsf{L}^2(\widehat{K})}^2, \end{aligned}$$

arguing as in Lemma 5. This completes the proof of the first result.

Turning to the second result, we begin by observing that

$$\begin{aligned} &\frac{1}{2} \sum_{j=0}^{\infty} \rho_j \left(\sum_{i=\max(0,k-j)}^{\infty} a_{i,j}\, (-1)^i \right)^2 \\ &\le \sum_{j=0}^{\infty}\, \rho_j \left(\sum_{i=k}^{\infty} a_{i,j}\, (-1)^i \right)^2 \;+\; \sum_{j=0}^{\infty}\, \rho_j \left(\sum_{i=\max(0,k-j)}^{k-1} a_{i,j}\, (-1)^i \right)^2. \end{aligned}$$

The first term is bounded using (26), and it suffices to consider the second term. Employing the Cauchy–Schwarz inequality once again gives

$$\sum_{j=0}^{\infty}\, \rho_j \left(\sum_{i=\max(0,k-j)}^{k-1} a_{i,j}\, (-1)^i \right)^2 \;\le\; \sum_{j=0}^{\infty} \sum_{i=\max(0,k-j)}^{k} \rho_i\, \rho_j\, a_{i,j}^2 \sum_{i=0}^{k} \rho_i^{-1}.$$

The second factor is bounded by Ck^2, where C is independent of k, whilst the first factor is bounded by observing that

$$\sum_{j=0}^{\infty} \sum_{i=\max(0,k-j)}^{k} \rho_i\, \rho_j\, a_{i,j}^2 \;\le\; \| w - \widehat{\pi}_{k-1}^{\mathsf{P}} w \|_{\mathsf{L}^2(\widehat{K})}^2 \;\le\; \frac{\big(\big[\frac{k+1}{2}\big] - r\big)!}{\big(\big[\frac{k+1}{2}\big] + r\big)!}\, [w]_{r,\widehat{K}}^2,$$

where Lemma 6 has been used. Consequently,

$$\sum_{j=0}^{\infty}\, \rho_j \left(\sum_{i=\max(0,k-j)}^{k-1} a_{i,j}\, (-1)^i \right)^2 \;\le\; C\, k^2\, \frac{\big(\big[\frac{k+1}{2}\big] - r\big)!}{\big(\big[\frac{k+1}{2}\big] + r\big)!}\, [w]_{r,\widehat{K}}^2,$$

and gathering results gives the second estimate.

In order to derive the final estimate, observe that

$$\frac{1}{2}\sum_{j=k}^{\infty}\rho_j\left(\sum_{i=0}^{\infty}a_{i,j}\,(-1)^i\right)^2 \le \sum_{j=k}^{\infty}\rho_j\left\{\left(\sum_{i=k}^{\infty}a_{i,j}\,(-1)^i\right)^2+\left(\sum_{i=0}^{k-1}a_{i,j}\,(-1)^i\right)^2\right\}.$$

The first term is bounded by

$$\sum_{j=0}^{\infty}\rho_j\left(\sum_{i=k}^{\infty}a_{i,j}\,(-1)^i\right)^2$$

and then applying the first part of Lemma 7. The second term is bounded using the Cauchy–Schwarz inequality to obtain

$$\sum_{j=k}^{\infty}\left(\sum_{i=0}^{k-1}a_{i,j}\,(-1)^i\right)^2 \le \sum_{i=0}^{k-1}\sum_{j=k}^{\infty}\rho_i\,\rho_j\,a_{i,j}^2\cdot\sum_{i=0}^{k}\rho_i^{-1}$$

$$\le C\,k^2\sum_{i=0}^{k-1}\sum_{j=k}^{\infty}\rho_i\,\rho_j\,a_{i,j}^2$$

and then using Lemma 5 to obtain, for $r\le k$,

$$\sum_{i=0}^{k-1}\sum_{j=k}^{\infty}\rho_i\,\rho_j\,a_{i,j}^2 \le \frac{(k-r)!}{(k+r)!}\,\|\,\mathrm{D}^{(0,r)}\,w\|^2_{\mathsf{L}^2(\widehat{K})}.$$

The estimate follows from these results. □

We now present bounds for the interpolation operators.

LEMMA 8. *Let $k\ge 1$. If $\boldsymbol{u}\in\mathbf{H}^r(\widehat{K})$, then, for $1<r\le k$,*

$$\|\boldsymbol{u}-\widehat{\boldsymbol{\Pi}}_k^{\mathsf{RT}}\boldsymbol{u}\|^2 \le \frac{C}{\varepsilon}\,k\,\frac{(k-r)!}{(k+r)!}\,[\boldsymbol{u}]^2_{r,\widehat{K}}, \tag{29}$$

and, for $1<r\le[k/2]$,

$$\|\boldsymbol{u}-\widehat{\boldsymbol{\Pi}}_k^{\mathsf{BDFM}}\boldsymbol{u}\|^2 \le \frac{C}{\varepsilon}\,k^2\,\frac{([k/2]-r)!}{([k/2]+r)!}\,[\boldsymbol{u}]^2_{r,\widehat{K}}, \tag{30}$$

where $\varepsilon\in(0,r-1)$.

Proof. Let $\boldsymbol{u}=(u_x,u_y)\in\mathbf{H}^r(\widehat{K})$. By a density argument, it suffices to consider u_x of the form (21). By Lemma 4,

$$\left(\boldsymbol{u}-\widehat{\boldsymbol{\Pi}}_k^{\mathsf{RT}}\boldsymbol{u}\right)_x = u_x-\widehat{\pi}^{\mathsf{Q}}_{k-1,k}u_x+\sum_{m=1}^{2}\mathcal{E}_k^{\gamma_m}\,w_m,$$

where

$$w_1(\eta) = \sum_{j=0}^{k}\left(\sum_{i=k}^{\infty}a_{i,j}\,(-1)^i\right)L_j(\eta)$$

with w_2 defined analogously. Applying the triangle inequality gives

$$\left\| \left(\boldsymbol{u} - \widehat{\boldsymbol{\Pi}}_k^{\mathsf{RT}} \boldsymbol{u} \right)_x \right\|^2_{\mathsf{L}^2(\widehat{K})} \;\leq\; \| u_x - \widehat{\pi}^{\mathsf{Q}}_{k-1,k} u_x \|^2_{\mathsf{L}^2(\widehat{K})} \;+\; \sum_{m=1}^{2} \| \mathcal{E}_k^{\gamma_m}\, w_m \|^2_{\mathsf{L}^2(\widehat{K})},$$

and the first term is bounded using Lemma 6 after observing that

$$\| u_x - \widehat{\pi}^{\mathsf{Q}}_{k-1,k} u_x \|_{\mathsf{L}^2(\widehat{K})} \;\leq\; \| u_x - \widehat{\pi}^{\mathsf{Q}}_{k-1} u_x \|_{\mathsf{L}^2(\widehat{K})}.$$

On recalling the definition of the extension operator $\mathcal{E}_k^{\gamma_1}$ associated with **RT** elements, we obtain

$$\begin{aligned} \| \mathcal{E}_k^{\gamma_1}\, w_1 \|^2_{\mathsf{L}^2(\widehat{K})} \;&=\; \frac{1}{4}\, (\rho_k + \rho_{k+1}) \sum_{j=0}^{k} \rho_j \left(\sum_{i=k}^{\infty} a_{i,j}\, (-1)^i \right)^2 \\ &\leq\; \frac{C\, k}{\varepsilon}\, \frac{(k-r)!}{(k+r)!}\, [u_x]^2_{r,\widehat{K}}, \end{aligned}$$

where the first part of Lemma 7 has been used along with $\rho_{k+1} < \rho_k \leq Ck^{-1}$. An analogous estimate holds for the remaining term. In conclusion, we obtain

$$\left\| \left(\boldsymbol{u} - \widehat{\boldsymbol{\Pi}}_k^{\mathsf{RT}} \boldsymbol{u} \right)_x \right\|^2_{\mathsf{L}^2(\widehat{K})} \;\leq\; C \left\{ \frac{(k-r)!}{(k+r)!} \;+\; \frac{k}{\varepsilon}\, \frac{(k-r)!}{(k+r)!} \right\} [u_x]^2_{r,\widehat{K}},$$

and the result follows at once using since the same estimate holds for the y-component.

The proof of the second estimate follows the same lines using instead the second parts of Lemmas 6 and 7. The only difference, compared with the **RT** case, is that an additional factor of k is present owing to bounding

$$\| \mathcal{E}_k^{\gamma_1} w_1 \|^2_{\mathsf{L}^2(\widehat{K})} \;=\; \frac{1}{4} \sum_{j=0}^{k} \rho_j\, (\rho_{k-j+1} + \rho_{k-j}) \left(\sum_{i=k-j}^{\infty} a_{i,j}\, (-1)^i \right)^2$$

by

$$\frac{1}{2}\, \rho_0 \sum_{j=0}^{k} \rho_j \left(\sum_{i=k-j}^{\infty} a_{i,j}\, (-1)^i \right)^2$$

and then using Lemma 7. ∎

4.3. Local approximation on a rectangular element. Consider the case when $K = (a,b) \times (c,d)$ is a rectangular element of size $h_K = \max(b-a, d-c)$. We shall be particularly concerned with the situation when the element is located near to a vertex of the domain Ω. For convenience, we assume the vertex is located at the origin $\mathbf{0}$ and assume that the function $\boldsymbol{u}$ belongs to a weighted space $\mathbf{H}^{s,\ell}_{\omega}(K)$ with weight function $\Phi_\omega(\boldsymbol{x}) = |\boldsymbol{x}|^\omega$.

First consider the case where the element is located away from the vertex, i.e., $\operatorname{dist}(\mathbf{0}, K) = \varrho_K > 0$. The following result then holds.

LEMMA 9. *Let K be a rectangular element as above, with degree $k \geq 2$. If $\boldsymbol{u} \in \mathbf{H}^{s,\ell}_{\omega}(K)$ with $\ell \in \{1,2\}$, then, for $2 \leq s \leq k$,*

$$\| \boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{RT}}\, \boldsymbol{u} \|^2_{\mathbf{L}^2(K)} \;\leq\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\, k\, \frac{\Gamma(k-s+1)}{\Gamma(k+s+1)}\, |\boldsymbol{u}|^2_{\mathbf{H}^{s,\ell}_{\omega}(K)}, \tag{31}$$

and, for $2 \le s \le \max(2, [k/2]) = \tilde{k}$,

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{BDFM}} \boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;\le\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\, \tilde{k}^2\, \frac{\Gamma(\tilde{k}-s+1)}{\Gamma(\tilde{k}+s+1)}\, |\boldsymbol{u}|_{\mathbf{H}_\omega^{s,\ell}(K)}^2. \tag{32}$$

Proof. Let $r \in [2, k]$ be an integer. Observe that

$$\|\,\mathrm{D}^{(r,0)}\,\boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;+\; \|\,\mathrm{D}^{(0,r)}\,\boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;\le\; C\, \varrho_K^{-2(\omega+r-\ell)}\, |\boldsymbol{u}|_{\mathbf{H}_\omega^{r,\ell}(K)}^2,$$

and consequently

$$[\boldsymbol{u}]_{r,K}^2 \;\le\; \frac{C\, h_K^{2r}}{\varrho_K^{2(\omega+r-\ell)}}\, |\boldsymbol{u}|_{\mathbf{H}_\omega^{r,\ell}(K)}^2. \tag{33}$$

Applying Lemma 8, we conclude that

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{RT}} \boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;\le\; \frac{C\, h_K^{2r}}{\varrho_K^{2(\omega+r-\ell)}}\, k\, \frac{(k-r)!}{(k+r)!}\, |\boldsymbol{u}|_{\mathbf{H}_\omega^{r,\ell}(K)}^2$$

This result is valid for integer values of r. Applying a standard interpolation argument (using the K-method) enables the result to be extended to noninteger $s \in [2, k]$. For full details, we refer to the proof of Lemma 4.48 [20].

The proof of the second result is divided into the case when $[k/2] \ge 2$, i.e., $k \ge 4$, and the case where $k = 2, 3$. The argument in the former case mirrors the one presented above. It therefore suffices to assume $k = 2$ or 3 and to show that, for $s = 2$,

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{BDFM}} \boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;\le\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\, |\boldsymbol{u}|_{\mathbf{H}_\omega^{s,\ell}(K)}^2.$$

It is shown in [21] that there exists a constant $\tilde{C}$ independent of k and h_K such that

$$\|\boldsymbol{\Pi}_k^{\mathsf{BDFM}} \boldsymbol{u}\|_{\mathbf{L}^2(K)} \;\le\; \tilde{C}\, \|\boldsymbol{u}\|_{\mathbf{H}^1(K)}.$$

Furthermore, thanks to the polynomial reproducing properties of $\widehat{\boldsymbol{\Pi}}_k$, for any first order pull-back function $\boldsymbol{u}_1$, we have

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{BDFM}} \boldsymbol{u}\|_{\mathbf{L}^2(K)} \;\le\; (1 + \tilde{C})\, \|\boldsymbol{u} - \boldsymbol{u}_1\|_{\mathbf{H}^1(K)}.$$

A routine scaling argument and use of the Bramble–Hilbert lemma reveals that, for $s = 2$,

$$\inf_{\boldsymbol{u}_1} \|\boldsymbol{u} - \boldsymbol{u}_1\|_{\mathbf{H}^1(K)} \;\le\; C\, [\boldsymbol{u}]_{s,K},$$

and applying (33) leads to

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k^{\mathsf{BDFM}} \boldsymbol{u}\|_{\mathbf{L}^2(K)}^2 \;\le\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\, |\boldsymbol{u}|_{\mathbf{H}^{s,\ell}(K)}^2$$

as claimed. ∎

Practically the same argument gives bounds for the accuracy of the L^2-projection operators.

LEMMA 10. *Let K be a rectangular element as above, with degree $k \geq 2$. If $p \in \mathsf{H}^{s,\ell}_\omega(K)$ with $\ell \in \{1,2\}$, then, for $2 \leq s \leq k+1$,*

$$\|p - \pi^{\mathsf{Q}}_k\, p\|^2_{\mathsf{L}^2(K)} \;\leq\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}} \frac{\Gamma(k-s+2)}{\Gamma(k+s+2)}\, |p|^2_{\mathsf{H}^{s,\ell}_\omega(K)}, \tag{34}$$

and, for $2 \leq s \leq \tilde{k}+1$,

$$\|p - \pi^{\mathsf{P}}_k\, p\|^2_{\mathsf{L}^2(K)} \;\leq\; \frac{C\, h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}} \frac{\Gamma(\tilde{k}-s+2)}{\Gamma(\tilde{k}+s+2)}\, |p|^2_{\mathsf{H}^{s,\ell}_\omega(K)}. \tag{35}$$

The next result deals with the situation where the element K has a vertex at corner of the domain, so that $\varrho_K = \operatorname{dist}(\mathbf{0}, K) = 0$.

LEMMA 11. *Let K be a rectangular element as above, with degree $k \geq 2$. If $\boldsymbol{u} \in \mathsf{H}^{2,\ell}_\omega(K)$ with $\ell \in \{1,2\}$, then*

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k \boldsymbol{u}\|_{\mathsf{L}^2(K)} \;\leq\; C\, h_K^{\ell-\omega}\, |\boldsymbol{u}|_{\mathsf{H}^{2,\ell}_\omega(K)}, \tag{36}$$

and if $p \in \mathsf{H}^{2,\ell}_\omega(K)$, then

$$\|p - \pi_k p\|_{\mathsf{L}^2(K)} \;\leq\; C\, h_K^{\ell-\omega}\, |p|_{\mathsf{H}^{2,\ell}_\omega(K)}, \tag{37}$$

where $\boldsymbol{\Pi}_k$ is the interpolant associated with the space BDFM_k (respectively, RT_k), and π_k is the L^2-projection associated with the space $\mathbb{P}_k$ (respectively, $\mathbb{Q}_k$).

Proof. We deal with the cases $\ell = 1$ and $\ell = 2$ separately. First, consider $\ell = 1$ and assume K is of unit size ($h_K = 1$) to begin with. By Theorem 2.1 [4], if $\boldsymbol{u} \in \mathsf{H}^{2,1}_\omega(K)$, then the trace of $\boldsymbol{u}$ on an edge $\gamma \subset \partial K$ satisfies the following properties:

(a) If $\omega \in (0, 1/2)$, then $\boldsymbol{u}|_\gamma \in \mathsf{H}^{2,1}_{\tilde{\omega}}(\gamma)$ for some $\tilde{\omega} \in (1/2, \omega + 1/2)$, and $\|\boldsymbol{u}\|_{\mathsf{H}^{2,1}_{\tilde{\omega}}(\gamma)} \leq C\, \|\boldsymbol{u}\|_{\mathsf{H}^{2,1}_\omega(K)}$.

(b) If $\omega \in (1/2, 1)$, then $\boldsymbol{u}|_\gamma \in \mathsf{H}^{2,0}_{\hat{\omega}}(\gamma)$ for some $\hat{\omega} \in (\omega - 1/2, 1/2)$, and $\|\boldsymbol{u}\|_{\mathsf{H}^{2,0}_{\hat{\omega}}(\gamma)} \leq C\, \|\boldsymbol{u}\|_{\mathsf{H}^{2,1}_\omega(K)}$.

In order to show that $\boldsymbol{\Pi}_k\, \boldsymbol{u}$ is well defined, it suffices to show that the degrees of freedom corresponding to moments on the edges

$$\boldsymbol{u} \;\longmapsto\; \int_\gamma (\boldsymbol{u} \cdot \boldsymbol{n})\; p\, ds \qquad \text{for } p \;\in\; \mathbb{R}_k(\gamma)$$

are well defined. This follows trivially in case (a) since $\boldsymbol{u}|_{\mathsf{L}^2(\gamma)}$ and we may bound the moment by $C_p\, \|\boldsymbol{u}\|_{\mathsf{H}^{2,1}_{\tilde{\omega}}(\gamma)}$. In case (b), we use the Cauchy–Schwarz inequality to deduce that

$$\left| \int_\gamma (\boldsymbol{u} \cdot \boldsymbol{n})\; p\, ds \right| \;\leq\; \| \, |s|^{\hat{\omega}}\, |\boldsymbol{u}| \, \|_{\mathsf{L}^2(\gamma)} \;\; \| \, |s|^{-\hat{\omega}}\, p \, \|_{\mathsf{L}^2(\gamma)},$$

and then, since $\hat{\omega} < 1/2$, we may bound this by $C_{p,\omega}\, \|\boldsymbol{u}\|_{\mathsf{H}^{2,0}_{\hat{\omega}}(\gamma)}$. This shows $\boldsymbol{\Pi}_k\, \boldsymbol{u}$ exists. Furthermore

$$\|\boldsymbol{\Pi}_k\, \boldsymbol{u}\|_{\mathsf{L}^2(K)} \;\leq\; C\, \left(\|\boldsymbol{u}\|_{\mathsf{L}^2(K)} + \|\boldsymbol{u}\|_{\mathsf{H}^{2,1}_\omega(K)} \right).$$

Therefore, for any constant $\boldsymbol{u}_0 \in \mathbb{R}^2$,

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k \boldsymbol{u}\|_{\mathbf{L}^2(K)} \;\leq\; (1 + C)\, \|\boldsymbol{u} - \boldsymbol{u}_0\|_{\mathbf{H}^{2,1}_{\omega}(K)}.$$

According to Lemma 4.3 [5], if v satisfies $\int_K |\boldsymbol{x}|^{2\omega} |\,\mathrm{D}^1 v|^2 d\boldsymbol{x} < \infty$, then there exists a constant $\bar{v}$ such that

$$\int_K |\boldsymbol{x}|^{2\omega-2}\, |v - \bar{v}|^2\, d\boldsymbol{x} \;\leq\; C \int_K |\boldsymbol{x}|^{2\omega}\, |\,\mathrm{D}^1 v|^2\, d\boldsymbol{x}.$$

Strictly speaking, this result was demonstrated for a triangular domain, but the argument generalizes to a rectangle K. Now, $|\boldsymbol{x}|^{-1} \geq 1/\sqrt{2}$ on K and hence

$$\|v - \bar{v}\|^2_{\mathsf{L}^2(K)} \;\leq\; C \int_K |\boldsymbol{x}|^{2\omega-2}\, |v - \bar{v}|^2\, d\boldsymbol{x} \;\leq\; C \int_K |\boldsymbol{x}|^{2\omega}\, |\,\mathrm{D}^1 v|^2\, d\boldsymbol{x}.$$

Applying this result to each component of $\boldsymbol{u}$ gives the existence of $\boldsymbol{u}_0 \in \mathbb{R}^2$ such that

$$\|\boldsymbol{u} - \boldsymbol{u}_0\|^2_{\mathbf{L}^2(K)} \;\leq\; C \,\|\, |\boldsymbol{x}|^{\omega}\, |\,\mathrm{D}^1 \boldsymbol{u}|\, \|^2_{\mathbf{L}^2(K)}.$$

Summarizing, we have shown in the case $K = (0,1)^2$ that

$$\|\boldsymbol{u} - \boldsymbol{u}_0\|^2_{\mathbf{L}^2(K)} \;\leq\; C\, |\boldsymbol{u}|^2_{\mathbf{H}^{2,1}_{\omega}(K)}.$$

The result for the general rectangular element follows from a scaling argument to obtain (36).

Next, consider the case when $\ell = 2$, and again assume K is of unit size. Arguing as in the proof of Lemma 9, we find that

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k \boldsymbol{u}\|_{\mathbf{L}^2(K)} \;\leq\; (1 + \tilde{C}) \inf_{\boldsymbol{u}_1} \|\boldsymbol{u} - \boldsymbol{u}_1\|_{\mathbf{H}^1(K)},$$

where $\boldsymbol{u}_1$ is a pull-back bilinear function. By Lemma 4.25 [20], we bound the right-hand side by

$$C \,\|\, |\boldsymbol{x}|^{\omega}\, |\,\mathrm{D}^2 \boldsymbol{u}|\, \|_{\mathbf{L}^2(K)}.$$

Hence, in the case when $K = (0,1)^2$, we have

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_k \boldsymbol{u}\|_{\mathbf{L}^2(K)} \;\leq\; C \,\|\, |\boldsymbol{x}|^{\omega}\, |\,\mathrm{D}^2 \boldsymbol{u}|\, \|_{\mathbf{L}^2(K)}.$$

The result for the general rectangular element again follows by a scaling argument. The estimate for the L^2-projection π_k is obtained using similar arguments. ∎

4.4. Approximation properties of the global interpolation operators. So far, we have restricted our attention to the approximation properties of the local interpolation operators $\boldsymbol{\Pi}_{K,k}$. In this section, these results are extended to the global interpolation operator defined in section 3.4. The main difference, it will be recalled, between the global and local interpolants concerns the values of the degrees of freedom on a broken edge, in the situation shown in Figure 2. Observe that we may use definition (10) to define a local counterpart of the global interpolant $\boldsymbol{\Pi}$ over the reference element corresponding to K by the rule

$$\widehat{\boldsymbol{\Pi}} \;=\; \mathcal{L}_K^{-1}\, \boldsymbol{\Pi}\, \mathcal{L}_K,$$

and hence, without loss of generality, we may assume K is the reference element. Equally well, we may assume K has only one edge (γ) that lies on a broken edge (γ'). For convenience, we consider the **RT** case in the first instance.

The difference between $\boldsymbol{\Pi}$ and the local interpolant $\boldsymbol{\Pi}_k$ arises from definition (15):

$$\int_{\gamma'} (\boldsymbol{\Pi}\,\boldsymbol{u})|_{\gamma'} \cdot \boldsymbol{n}\; q\; ds \;=\; \int_{\gamma'} (\boldsymbol{u}\cdot\boldsymbol{n})|_{\gamma'}\; q\; ds \qquad \forall q \in \mathbb{R}_k(\gamma').$$

The definition of the $\mathsf{L}^2(\gamma')$-projection $\mathsf{R}_k^{\gamma'} : \mathsf{L}^2(\gamma) \longrightarrow \mathbb{R}_k(\gamma')$ reveals that

$$(\boldsymbol{\Pi}\boldsymbol{u})|_{\gamma'} \cdot \boldsymbol{n} \;=\; \mathsf{R}_k^{\gamma'}\left(\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma'}\right) \quad \text{ on } \gamma'$$

while the local interpolant satisfies

$$(\boldsymbol{\Pi}_k\boldsymbol{u})|_{\gamma'} \cdot \boldsymbol{n} \;=\; \mathsf{R}_k^{\gamma}\left(\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma'}\right) \quad \text{ on } \gamma.$$

It is not difficult to verify that

$$\begin{aligned}(\boldsymbol{\Pi}_k\,\boldsymbol{u} - \boldsymbol{\Pi}\boldsymbol{u})_x &= \;\mathcal{E}_k^{\gamma}\left[\mathsf{R}_k^{\gamma}\left(\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma}\right) - \mathsf{R}_k^{\gamma'}\left(\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma'}\right)\Big|_{\gamma}\right]\\ &= \;\mathcal{E}_k^{\gamma}\;\mathsf{R}_k^{\gamma}\;\mathrm{Tr}_{\gamma}\left[\boldsymbol{u}\cdot\boldsymbol{n} - \mathsf{R}_k^{\gamma'}\left(\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma_{\prime}}\right)\right],\end{aligned}$$

and then, using the definition of the **RT**-extension $\mathcal{E}_k^{\gamma}$, we deduce that

$$\begin{aligned}\|\boldsymbol{\Pi}_k\,\boldsymbol{u} - \boldsymbol{\Pi}\,\boldsymbol{u}\|^2_{\mathsf{L}^2(K)} &\le C\;k^{-1}\;\Big\|\;\mathsf{R}_k^{\gamma}\,\mathrm{Tr}_{\gamma}\left[\boldsymbol{u}\cdot\boldsymbol{n} - \mathsf{R}_k^{\gamma'}(\,\boldsymbol{u}\cdot\boldsymbol{n}|_{\gamma'})\right]\;\Big\|^2_{\mathsf{L}^2(\gamma)}\\ &\le C\;k^{-1}\;\Big\|\;\boldsymbol{u}\cdot\boldsymbol{n} - \mathsf{R}_k^{\gamma'}\,(\boldsymbol{u}\cdot\boldsymbol{n})|_{\gamma'}\;\Big\|^2_{\mathsf{L}^2(\gamma)}\end{aligned}$$

thanks to the stability of the projection R_k^{γ}. Now, suppose that $\boldsymbol{u}|_{K'}$ is expanded as a Legendre series as in (21). Then, if $\gamma' = \gamma_1$,

$$\begin{aligned}\left\|\boldsymbol{u}\cdot\boldsymbol{n} - \mathsf{R}_k^{\gamma'}\,(\boldsymbol{u}\cdot\boldsymbol{n})|_{\gamma'}\right\|^2_{\mathsf{L}^2(\gamma)} \;&\le\; \left\|\boldsymbol{u}\cdot\boldsymbol{n} - \mathsf{R}_k^{\gamma'}(\boldsymbol{u}\cdot\boldsymbol{n})\right\|^2_{\mathsf{L}^2(\gamma')}\\ &=\; \textstyle\sum_{j=k+1}^{\infty}\rho_j\,\left(\sum_{i=0}^{\infty}a_{i,j}(-1)^i\right)^2\\ &\le\; C\;\tfrac{k^2}{\varepsilon}\;\tfrac{(k+1-r)!}{(k+1+r)!}\;[\boldsymbol{u}]^2_{r,K'} \qquad \text{for } r \le k+1,\end{aligned}$$

where the final part of Lemma 7 has been invoked. Hence,

$$\|\boldsymbol{\Pi}_k\,\boldsymbol{u} - \boldsymbol{\Pi}\,\boldsymbol{u}\|^2_{\mathsf{L}^2(K)} \;\le\; C\;\frac{k}{\varepsilon}\;\frac{(k+1-r)!}{(k+1+r)!}\;[\boldsymbol{u}]^2_{r,K'}.$$

A similar expression holds for the **BDFM** elements with an additional factor of k. Corresponding results hold on a rectangular element using a scaling argument as in Lemma 9. Consequently, using the triangle inequality

$$\|\boldsymbol{u} - \boldsymbol{\Pi}\,\boldsymbol{u}\|_{\mathsf{L}^2(K)} \;\le\; \|\boldsymbol{u} - \boldsymbol{\Pi}_k\,\boldsymbol{u}\|_{\mathsf{L}^2(K)} \;+\; \|\boldsymbol{\Pi}_k\,\boldsymbol{u} - \boldsymbol{\Pi}\,\boldsymbol{u}\|_{\mathsf{L}^2(K)},$$

we conclude the following.

LEMMA 12. *Let K be a rectangular element of size h_K with $\rho_K = \operatorname{dist}(\mathbf{0}, K)$, and degree $k \geq 2$. Let $K^\star$ denote the union of K and any elements with a broken edge neighboring K. If $\boldsymbol{u} \in \mathbf{H}^{2,\ell}(K^\star)$ with $\ell \in \{1,2\}$, then for $2 \leq s \leq k$,*

$$\|\boldsymbol{u} - \boldsymbol{\Pi}^{\mathsf{RT}}\,\boldsymbol{u}\|^2_{\mathbf{L}^2(K)} \;\leq\; \frac{C\,h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\;k\;\frac{\Gamma(k-s+1)}{\Gamma(k+s+1)}\;|\boldsymbol{u}|^2_{\mathbf{H}^{s,\ell}_\omega(K^\star)}, \tag{38}$$

and for $2 \leq s \leq \max(2, [k/2]) = \tilde{k}$,

$$\|\boldsymbol{u} - \boldsymbol{\Pi}^{\mathsf{BDFM}}\,\boldsymbol{u}\|^2_{\mathbf{L}^2(K)} \;\leq\; \frac{C\,h_K^{2s}}{\varrho_K^{2(\omega+s-\ell)}}\;\tilde{k}^2\;\frac{\Gamma(\tilde{k}-s+1)}{\Gamma(\tilde{k}+s+1)}\;|\boldsymbol{u}|^2_{\mathbf{H}^{s,\ell}_\omega(K^\star)}, \tag{39}$$

where $\boldsymbol{\Pi}$ is the global interpolation operator.

5. Finite element approximation of $\boldsymbol{\mathcal{B}^\ell_\omega(\Omega)}$.

5.1. Approximation on a square. Consider the approximation of a function $\boldsymbol{u} \in \boldsymbol{\mathcal{B}}^\ell_\omega(\widehat{\Omega})$ with $\ell \in \{1,2\}$, in the case where $\widehat{\Omega}$ is the unit square $(0,1)^2$ with the weight function given by $\Phi_\omega(\boldsymbol{x}) = |\boldsymbol{x}|^\omega$. This scenario models the typical situation where the function $\boldsymbol{u}$ is the solution of a boundary value problem in the neighborhood of a corner located at the origin. Later, we shall consider more general configurations.

The domain $\widehat{\Omega}$ is partitioned into elements as follows. Let $\sigma \in (0,1)$ and $M \in \mathbb{N}_0$ be given. The *basic geometric mesh* $\widehat{\mathcal{T}}^M_\sigma$ with $M+1$ *layers* and *grading factor* σ is defined inductively as follows. The initial mesh $\widehat{\mathcal{T}}^0_\sigma$ is taken to be the whole domain $\widehat{\Omega}$. For nonzero M, the mesh $\widehat{\mathcal{T}}^M_\sigma$ is obtained from $\widehat{\mathcal{T}}^{M-1}_\sigma$ by breaking the square element K, with a vertex at the origin, into four rectangles by subdividing its sides in the ratio $\sigma : 1-\sigma$. Figure 4 gives an example of the case of three layers with grading factor $\sigma = 1/2$. The elements forming the jth layer $\widehat{\mathcal{T}}^{M,j}_\sigma$ are numbered $\{K_{i,j}\}_{i=0}^3$ for $j > 1$, as shown in Figure 4. In general, we find that an element K in the jth layer satisfies

$$\begin{cases} \sigma^{M+2-j} \;\leq\; \varrho_K \;=\; \operatorname{dist}(\mathbf{0}, K) \;\leq\; \sqrt{2}\,\sigma^{M+2-j}, \\ \sigma^{M+1-j}\,(1-\sigma) \;\leq\; h_K \;=\; \operatorname{diam}(K) \;\leq\; \sqrt{2}\,\sigma^{M+1-j}\,(1-\sigma), \\ \frac{2}{\kappa} \;\leq\; \frac{h_K}{\varrho_K} \;\leq\; \kappa, \end{cases}$$

where $\kappa = \sqrt{2}\,(1-\sigma)/\sigma$, for $1 < j \leq M+1$. The first layer consists of the single element $K_{1,1} = (0, \sigma^M) \times (0, \sigma^M)$.

The global finite element space is based on the **RT** elements defined, as in (12), by

$$\boldsymbol{\Gamma}^{\mathsf{RT}}_N \;=\; \left\{\; \boldsymbol{u} \;\in\; \mathbf{H}(\operatorname{div}, \widehat{\Omega}) : \quad \boldsymbol{u}|_K \in \boldsymbol{\Gamma}^{\mathsf{RT}}_k \quad \forall K \in \widehat{\mathcal{T}}^M_\sigma \;\right\}$$

with the corresponding polynomial subspace of L^2 defined by

$$V^{\mathsf{Q}}_N = \left\{ q \in \mathsf{L}^2(\widehat{\Omega}) : q \circ F_K^{-1} \in \mathbb{Q}_k \quad \forall K \in \widehat{\mathcal{T}}^M_\sigma \right\}.$$

The spaces $\boldsymbol{\Gamma}^{\mathbf{BDFM}}_N$ and V^{P}_N, obtained from the combination of the $\mathbf{BDFM}_k$ elements with $\mathbb{P}_k$, are defined in the same fashion.

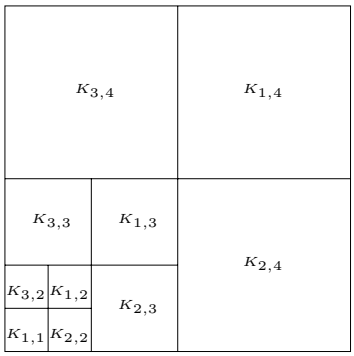

FIG. 4. *Geometric mesh $\widehat{\mathcal{T}}_\sigma^M$ for a grading factor $\sigma = 0.5$ and $M = 3$.*

The main result of this section can now be stated.

THEOREM 13. *Let $\widehat{\Omega} = (0,1)^2$, and $\widehat{\mathcal{T}}_\sigma^M$ is the basic geometric mesh with grading factor $\sigma \in (0,1)$ and $M+1$ layers. Let $\mathbf{\Gamma}_N$–V_N denote the mixed finite element spaces (based on* **RT** *or* **BDFM** *elements) with degree $k = \mu M \geq 2$, and let $\mathbf{\Pi}_N$ and π_N be the associated interpolation operators. If $\boldsymbol{u} \in \boldsymbol{\mathcal{B}}_\omega^\ell(\widehat{\Omega})$ and $p \in \mathcal{B}_\omega^\ell(\widehat{\Omega})$ with $\ell \in \{1,2\}$, then for sufficiently large $\mu > 0$,*

$$\|\boldsymbol{u} - \mathbf{\Pi}_N \boldsymbol{u}\|_{\mathbf{L}^2(\widehat{\Omega})} \;\leq\; C\, \exp(-b\, N^{1/3}),$$

and

$$\|p - \pi_N p\|_{\mathsf{L}^2(\widehat{\Omega})} \;\leq\; C\, \exp(-b\, N^{1/3}),$$

where C, b are positive constants, independent of the dimension N of the space $\mathbf{\Gamma}_N$.

Proof. Let $\boldsymbol{u} \in \boldsymbol{\mathcal{B}}_\omega^\ell(\widehat{\Omega})$. Then, there exist positive constants C and d such that for any element $K \in \widehat{\mathcal{T}}_\sigma^M$,

$$|\boldsymbol{u}|_{\mathbf{H}_\omega^{s,\ell}(K)} \;\leq\; |\boldsymbol{u}|_{\mathbf{H}_\omega^{s,\ell}(\widehat{\Omega})} \;\leq\; C\, d^{s-\ell}\, \sqrt{s}\, \Gamma(s-\ell+1).$$

In particular, applying Lemma 11, we conclude that, since $k \geq 2$,

$$\|\boldsymbol{u} - \mathbf{\Pi}_N \boldsymbol{u}\|^2_{\mathbf{L}^2(K_{1,1})} \;\leq\; Cd^{-2\ell}\sigma^{2M(\ell-\omega)}.$$

Consider the contributions from elements belonging to the jth layer $\widehat{\mathcal{T}}_\sigma^{M,j}$, $2 \leq j \leq M+1$. Recall that any element $K \in \widehat{\mathcal{T}}_\sigma^{M,j}$ has diameter $h_K \leq \kappa \varrho_K$ and that $\varrho_K \leq \sqrt{2}\,\sigma^{M+2-j}$. Inserting these quantities into the bound in Lemma 12 leads to the conclusion that for $2 \leq s \leq k$,

$$\begin{aligned}\|\boldsymbol{u} - \mathbf{\Pi}_N \boldsymbol{u}\|^2_{\mathbf{L}^2(K)} &\\ \leq\; C\, d^{-2\ell}\sigma^{2(M+2-j)(\ell-\omega)}\, &\frac{\Gamma(k-s+1)}{\Gamma(k+s+1)}\, s\, k\, \Gamma(s-\ell+1)^2\, (\kappa d)^{2s}\end{aligned}$$

for $K \in \widehat{\mathcal{T}}_\sigma^{M,j}$. Using Stirling's approximation $\Gamma(n+1) \sim \sqrt{2\pi n}\,(n/e)^n$, it is not difficult to show that if $s = \alpha k$, with constant $\alpha \in [2/k, 1)$ (to be chosen), then

$$\frac{\Gamma(k-s+1)}{\Gamma(k+s+1)}\, \Gamma(s-\ell+1)^2 (\kappa d)^{2s} \;\leq\; C\, k^{1-2\ell}\, F(2\kappa d, \alpha)^k,$$

where $F : (1,\infty) \times (0,1] \longrightarrow \mathbb{R}$ is the function

$$F(r,\alpha) \;=\; \frac{(1-\alpha)^{1-\alpha}}{(1+\alpha)^{1+\alpha}} \;\left(\frac{\alpha r}{2}\right)^{2\alpha}$$

considered in (3.3.73) [20]. In particular, the function $F(2\kappa d,\cdot)$ has minimum value $F_{\min} \in (0,1)$ at $\alpha_{\min} = (1+\kappa^2 d^2)^{-1/2}$.

Summing up the layer-wise contributions to the total error reveals that

$$\|\boldsymbol{u} - \boldsymbol{\Pi}_N\,\boldsymbol{u}\|^2_{\mathbf{L}^2(\widehat{\Omega})} \;\le\; C\;\sigma^{2M(\ell-\omega)}\left\{1 \;+\; k^{3-2\ell}F(2\kappa d,\alpha)^k \sum_{j=2}^{M+1} \sigma^{2(2-j)(\ell-\omega)}\right\}. \tag{40}$$

The second term in parentheses may be bounded by

$$C\;\sigma^{-2M(\ell-\omega)}k^{3-2\ell}F(2\kappa d,\alpha)^k, \tag{41}$$

and, inserting $k = \mu M$ and choosing $\alpha = \max(2/\mu M, \alpha_{\min}) = \alpha_{\min}$ (for M large), this is in turn bounded by

$$C\;M^{3-2\ell}\left(\frac{F_{\min}^{\mu}}{\sigma^{2(\ell-\omega)}}\right)^M. \tag{42}$$

Finally, choosing

$$\mu > \max\left\{1, \frac{2(\ell-\omega)\ln\sigma}{\ln F_{\min}}\right\}$$

ensures that the factor in parentheses has magnitude less than unity, and as a consequence, the multiplicative term in (40) is bounded above for all M. Hence,

$$\|\boldsymbol{u} - \boldsymbol{\Pi}^{\mathsf{RT}}_N\,\boldsymbol{u}\|^2_{\mathbf{L}^2(\Omega)} \;\le\; C\;\sigma^{2M(\ell-\omega)}.$$

The dimension N of the space $\boldsymbol{\Gamma}_N$ satisfies

$$N = (1+3(M-1))\dim \mathbf{RT}_{\mu M} \approx \mu^2 M^3, \tag{43}$$

and hence, since $\sigma < 1$, it follows that

$$\|\boldsymbol{u} - \boldsymbol{\Pi}^{\mathsf{RT}}_N\,\boldsymbol{u}\|^2_{\mathbf{L}^2(\Omega)} \;\le\; C\;\exp(\,-b\,N^{1/3}\,),$$

where C and b are positive constants independent of M and k. The estimate for $p \in \mathcal{B}^{\ell}_{\omega}$ follows similar lines, using the estimate for π_k in Lemma 10 in place of Lemma 12. ∎

5.2. Generalization to polygonal domains. So far, we have obtained exponential convergence for the basic square $\widehat{\Omega}$ when the function $\boldsymbol{u}$ has only one singularity. We now generalize to polygonal domains.

For a polygonal domain Ω, the geometric mesh $\mathcal{T}^M_\sigma$, with $M+1$ layers and the grading factor $0 < \sigma < 1$, is constructed by patching together affine images of basic geometric meshes $\widehat{\mathcal{T}}^M_\sigma$ near vertices in conjunction with a fixed, quasi-uniform partition of uniform polynomial order on the interior. Changes in type of boundary conditions are treated using two copies of $\widehat{\mathcal{T}}^M_\sigma$, while re-entrant corners use three (see Figure 5).

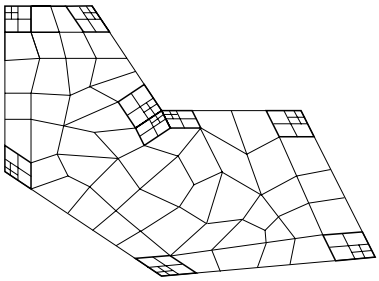

FIG. 5. *Typical mesh used on a polygonal domain.*

THEOREM 14. *Let $\Omega \subset \mathbb{R}^2$ be a polygonal domain partitioned into a geometric mesh $\mathcal{T}_\sigma^M$ of affine elements with grading factor $\sigma \in (0,1)$ and $M+1$ layers. Let $\mathbf{\Gamma}_N$–V_N denote the mixed finite element space (based on* **RT** *or* **BDFM** *elements) of degree $k = \mu M$, and let $\mathbf{\Pi}_N$ and π_N be the associated interpolation operators. Suppose $\boldsymbol{u} \in \boldsymbol{\mathcal{B}}^\ell_\omega(\Omega)$ and $p \in \mathcal{B}^\ell_\omega(\Omega)$, with $\ell \in \{1,2\}$, for $\omega = (\omega_1, \ldots, \omega_m)$, $0 < \omega_i < 1$, dependent on the angles. Then, there exists $\mu^\star > 0$ such that if $\mu > \mu^\star$, then*

$$\|\boldsymbol{u} - \mathbf{\Pi}_N \boldsymbol{u}\|_{\mathbf{L}^2(\Omega)} \;\le\; C\ \exp(-b\, N^{1/3}),$$

and

$$\|p - \pi_N p\|_{\mathsf{L}^2(\Omega)} \;\le\; C\ \exp(-b\, N^{1/3}),$$

where C, b are positive constants, independent of the dimension N of the space $\mathbf{\Gamma}_N$.

Proof. First consider the situation of a parallelogram $\tilde{\Omega}$ with a singularity at only one corner. The geometric mesh $\tilde{\mathcal{T}}_\sigma^M$ on $\tilde{\Omega}$ is then constructed using an affine image of the basic geometric mesh $\widehat{\mathcal{T}}_\sigma^M$ on the basic domain $\widehat{\Omega} = (0,1)^2$; see Figure 6.

Let $\tilde{F} : \widehat{\Omega} \longrightarrow \tilde{\Omega}$ denote the affine mapping between the basic square $\widehat{\Omega}$ and the parallelogram $\tilde{\Omega}$. Let $\tilde{\boldsymbol{u}} \in \boldsymbol{\mathcal{B}}^\ell_\omega(\tilde{\Omega})$ and denote $\widehat{\boldsymbol{u}} = \tilde{\mathcal{L}}\, \tilde{\boldsymbol{u}}$ where $\tilde{\mathcal{L}}$ is the Piola transformation. Then

$$\|\tilde{\boldsymbol{u}} - \mathbf{\Pi}_N\, \tilde{\boldsymbol{u}}\|_{\boldsymbol{L}^2(\tilde{\Omega})} \;\le\; C \|\widehat{\boldsymbol{u}} - \widehat{\mathbf{\Pi}}_N\, \widehat{\boldsymbol{u}}\|_{\boldsymbol{L}^2(\widehat{\Omega})},$$

where C is a positive constant independent of N, and $\widehat{\mathbf{\Pi}}_N$ is the interpolation operator on the domain $\widehat{\Omega}$. Since the function $\widehat{\boldsymbol{u}}$ belongs to the space $\boldsymbol{\mathcal{B}}^\ell_\omega(\widehat{\Omega})$, we may apply Theorem 13 and obtain exponential convergence on the parallelogram $\tilde{\Omega}$.

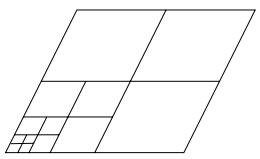

FIG. 6. *Geometric mesh $\tilde{\mathcal{T}}_\sigma^M$ on a parallelogram $\tilde{\Omega}$.*

The case of a general polygonal domain follows summing contributions to the error from the interpolant over each corner patch with the error arising from the approximation using the interpolant over the interior. Observe that the true solution is

analytic on the interior (see, for example, [20, Exercise 4.45]) so that a uniform polynomial distribution over a fixed meshing of the interior region will deliver exponential rates of convergence thanks to [21, Theorem 5.1]. ∎

6. Application to mixed finite element approximation. We illustrate the foregoing results by using them to derive exponential rates of convergence for mixed finite element approximation of problem (6). This problem may be formulated in mixed variational form as follows: find $(\boldsymbol{u}, p) \in \mathbf{H}(\mathrm{div}, \Omega) \times \mathsf{L}^2(\Omega)$ such that

$$\left\{ \begin{array}{lll} a(\boldsymbol{u}, \boldsymbol{v}) \ + \ (p, \mathrm{div}\, \boldsymbol{v}) = \ 0 & & \forall\, \boldsymbol{v} \ \in \ \mathbf{H}(\mathrm{div}, \Omega), \\ (\mathrm{div}\, \boldsymbol{u}, q) \ + \ (f, q) \ \ = \ 0 & & \forall\, q \in \mathsf{L}^2(\Omega), \end{array} \right. \tag{44}$$

where the bilinear form a is defined as follows:

$$a(\boldsymbol{u}, \boldsymbol{v}) \ = \ \int_\Omega A^{-1}\ \boldsymbol{u}(\boldsymbol{x}) \cdot \boldsymbol{v}(\boldsymbol{x})\ d\boldsymbol{x}.$$

Problem (44) will be approximated using a pair of *hp*-finite element spaces, based on **RT** or **BDFM** elements, $\boldsymbol{\Gamma}_N \subset \mathbf{H}(\mathrm{div}, \Omega)$, and $\mathsf{V}_N \subset \mathsf{L}^2(\Omega)$, giving the following discrete problem: find $(\boldsymbol{u}_N, p_N) \in \boldsymbol{\Gamma}_N \times \mathsf{V}_N$ such that

$$\left\{ \begin{array}{lll} a(\boldsymbol{u}_N, \boldsymbol{v}_N) \ + \ (p_N, \mathrm{div}\, \boldsymbol{v}_N) = \ 0 & & \forall\, \boldsymbol{v}_N \ \in \ \boldsymbol{\Gamma}_N, \\ (\mathrm{div}\, \boldsymbol{u}_N, q_N) - (f, q_N) \ \ = \ 0 & & \forall\, q_N \ \in \ \mathsf{V}_N. \end{array} \right. \tag{45}$$

Mixed approximations of this type are studied by Brezzi and Fortin [9, pp. 137–139].

THEOREM 15. *Let $\Omega \subset \mathbb{R}^2$ be a polygonal domain partitioned into geometric meshes $\mathcal{T}_\rho^M$ with grading factor $0 < \rho < 1$ and $M + 1$ layers, as described above. Suppose that the data f are analytic and $f \in \mathcal{B}^0_\omega(\Omega)$ for $\omega = (\omega_1, \ldots, \omega_m)$, $0 < \omega_i < 1$, dependent on the interior angles. Then, there exists $\mu^\star > 0$ such that if $k = \mu M$, with $\mu > \mu^\star$, then*

$$\|\boldsymbol{u} - \boldsymbol{u}_N\|_{\mathbf{H}(\mathrm{div},\Omega)} \ + \ \|p - p_N\|_{\mathsf{L}^2(\Omega)} \ \leq \ C\ \exp(\ -b\, N^{1/3}\ ),$$

where C and b are positive constants independent of N.

Proof. First, observe that thanks to the commuting diagram property,

$$\|\,\mathrm{div}(\boldsymbol{u} - \boldsymbol{\Pi}_N \boldsymbol{u})\|_{\mathsf{L}^2(\Omega)} = \|\,\mathrm{div}\, \boldsymbol{u} - \pi_N(\mathrm{div}\, \boldsymbol{u})\|_{\mathsf{L}^2(\Omega)} = \|f - \pi_N f\|_{\mathsf{L}^2(\Omega)},$$

and then, recalling that f is analytic, the approximation properties of the L^2-projection mean that a pure p-version procedure on *any* fixed partition (and a fortiori on those partitions considered here) will deliver exponential rates of convergence for this quantity. Applying [9, Proposition IV.1.1] leads to the abstract a priori error estimate

$$\|\boldsymbol{u} - \boldsymbol{u}_N\|_{\mathbf{H}(\mathrm{div},\Omega)} \ + \ \|p - p_N\|_{\mathsf{L}^2(\Omega)} \ \leq \ C\ \left(\ \|\boldsymbol{u} - \boldsymbol{\Pi}_N \boldsymbol{u}\|_{\mathbf{H}(\mathrm{div},\Omega)} + \|p - \pi_N p\|_{\mathsf{L}^2(\Omega)}\ \right),$$

and the result follows from the above observation and Theorem 14. ∎

A CLASS OF INTRINSIC SCHEMES FOR ORTHOGONAL INTEGRATION*

ELENA CELLEDONI† AND BRYNJULF OWREN‡

Abstract. Numerical integration of ODEs on the orthogonal Stiefel manifold is considered. Points on this manifold are represented as $n \times k$ matrices with orthonormal columns, of particular interest is the case when $n \gg k$. Mainly two requirements are imposed on the integration schemes. First, they should have arithmetic complexity of order nk^2. Second, they should be intrinsic in the sense that they require only the ODE vector field to be defined on the Stiefel manifold, as opposed to, for instance, projection methods. The design of the methods makes use of retractions maps. Two algorithms are proposed, one where the retraction map is based on the QR decomposition of a matrix, and one where it is based on the polar decomposition. Numerical experiments show that the new methods are superior to standard Lie group methods with respect to arithmetic complexity, and may be more reliable than projection methods, owing to their intrinsic nature.

Key words. time integration, geometric integration, numerical integration of ordinary differential equations on manifolds, numerical analysis, Stiefel manifold, homogeneous spaces

1. Introduction.

The elements of the orthogonal Stiefel manifold are often represented as $n \times k$ matrices with orthonormal columns, where $n \geq k$,

$$\mathcal{V}_{n,k} = \{Q \in \mathbb{R}^{n\times k} : Q^T Q = I_{k\times k}\}.$$

In particular, one has $\mathcal{V}_{n,n} = \mathcal{O}(n)$, the Lie group of $n \times n$ orthogonal matrices.

Many applications involve computations with such matrices. One is the calculation of Lyapunov exponents; see [7, 14] for an overview. Another involves optimization problems in multivariate data analysis [26].

In this paper, we shall study the problem of approximating a solution of an ODE system on $\mathcal{V}_{n,k}$. We think of $\mathcal{V}_{n,k}$ as a special case of a manifold $\mathcal{M}$, and we let $T\mathcal{M}$ denote the tangent bundle of $\mathcal{M}$. A vector field on $\mathcal{M}$ is then a section $F : \mathcal{M} \to T\mathcal{M}$ which assigns to each $Q \in \mathcal{M}$ a tangent vector $F(Q) \in T_Q\mathcal{M}$. The ODE system is also allowed to be nonautonomous, thus the vector field may also depend on $t \in \mathbb{R}$,

$$\dot{Q} = F(t, Q), \quad Q(t_0) = Q_0 \in \mathcal{M}.$$

As indicated above, the orthogonal Stiefel manifold is naturally embedded in the Euclidean space of all real $n \times k$ matrices, and it is also quite common to use this representation in computer programs. The situation is similar for other manifolds $\mathcal{M}$ embedded in a Euclidean space E. Nevertheless, one should distinguish numerical methods which are intrinsic and those which are extrinsic. The latter type of methods make use of an extension of the vector field F to all of E, or at least to some

neighborhood of $\mathcal{M}$. Such methods include the projection methods; see, for instance, [18, 13, 20]. More recently, symmetric projection methods have been proposed in [1] to enforce conservation of energy, and later in a more general setting by [16]. Another approach is to apply direct solvers for index-2 DAEs. In this case, it is useful to formulate the problem in terms of a constrained system with Lagrange multipliers, say

$$\dot{Q} = F(t, Q) + QH, \quad Q^T Q = I_k, \quad Q \in \mathbb{R}^{n\times k}, \quad H \in \mathbb{R}^{k\times k},$$

H being a symmetric matrix. Its elements are the Lagrange multipliers which can be determined by the differentiated constraint

$$\dot{Q}Q^T + Q\dot{Q}^T = 0.$$

More recently, there has been an increased interest in designing intrinsic integration methods for manifolds in general. Examples of such methods are the Crouch–Grossman methods [6] and the RKMK methods proposed by Munthe-Kaas; see, e.g., [21]. At least when used in a naive manner, these intrinsic methods are not entirely satisfactory from the point of view of computational complexity when applied to problems on Stiefel manifolds with $n \gg k$. The reason is that they usually demand operations to be performed on $n \times n$ matrices. In particular, one typically applies operations that cost $\mathcal{O}(n^3)$ flops. In comparison, the projection of a matrix in $\mathbb{R}^{n\times k}$ onto $\mathcal{M}$ by means of the QR factorization cost only $\mathcal{O}(nk^2)$ flops. In this paper, we will consider maps known as retractions to impose local coordinates on the Stiefel manifold. The methods presented here fall in the same category as the so-called methods based on local charts, the ones proposed by Potra and Rheinboldt in [23]; see also [24] and the recent monograph by Hairer, Lubich, and Wanner [17]. Our coordinate space is always the tangent space at the initial value of the next time step. The evaluation of the retraction map and its (inverse) derivative can be shown to have complexity $\mathcal{O}(nk^2)$. Thus, if the evaluation of the ODE vector field can be done with the same complexity, we obtain an integration method which has an overall complexity of $\mathcal{O}(nk^2)$.

We present numerical results which demonstrate the low cost compared to Lie group methods implemented in the standard way. We also give numerical evidence to show that intrinsic methods in some cases are more preferable than extrinsic methods like projection methods.

2. Using retraction as a coordinate map. To begin with, let us consider in general a differentiable manifold $\mathcal{M}$ and a differential equation given by means of a vector field $F(t, y)$ such that for each t, $F(t, \cdot)$ is a vector field $\mathcal{M} \to T\mathcal{M}$, so

$$y'(t) = F(t, y(t)). \tag{1}$$

We will here use a particular choice of local charts for the manifold $\mathcal{M}$ and obtain resulting locally defined vector fields similar to what is called state-space formulations in the DAE literature.

It has been proposed by Shub [25] to use a smooth mapping $\mathcal{R} : T\mathcal{M} \to \mathcal{M}$ in the design of Newton iterations on manifolds. For the restriction $\mathcal{R}_p$ of $\mathcal{R}$ to the tangent space $T_p\mathcal{M}$ of $\mathcal{M}$ at the point $p \in \mathcal{M}$ we require the following:

1. $\mathcal{R}_p$ is defined in some open ball $B(0, r_p)$ of radius r_p about $0 \in T_p\mathcal{M}$.
2. $\mathcal{R}_p(v) = p$ if and only if $v = 0 \in T_p\mathcal{M}$.
3. $\mathcal{R}'_p\big|_0 = Id_{T_p\mathcal{M}}$.

The essence of the idea we present here lies in the fact that $\mathcal{R}_p$ serves to define local coordinates of the manifold $\mathcal{M}$ in a neighborhood of the point p. We can thus represent the solution of the differential equation in the form

$$y(t) = \mathcal{R}_p(\sigma(t)), \quad \sigma(t) \in T_p\mathcal{M}. \tag{2}$$

By differentiating with respect to t and by using (1) we get

$$y'(t) = \mathcal{R}_p'\big|_{\sigma(t)}(\sigma'(t)) = F(t, \mathcal{R}_p(\sigma(t))).$$

For $\sigma(t)$ sufficiently close to $0 \in T_p\mathcal{M}$ the map $\mathcal{R}_p'\big|_{\sigma(t)}$ is invertible, so we obtain a differential equation for $\sigma(t)$ as follows:

$$\sigma'(t) = \big(\mathcal{R}_p'\big|_{\sigma(t)}\big)^{-1}(F(t, \mathcal{R}_p(\sigma(t)))). \tag{3}$$

We may now approximate (3) by using a standard ODE solver, and we may subsequently transform the result back to $\mathcal{M}$ via (2).

This approach is intrinsic in the sense that it does not depend on whether $\mathcal{M}$ has been embedded in a bigger (say Euclidean) space with a corresponding extension of the vector field F.

2.1. Lie group methods. The procedure we have just described is very similar to the Lie group methods proposed by, for instance, Munthe-Kaas [21], Owren and Marthinsen [22], and Diele, Lopez, and Peluso [10]. It also has a lot in common with the approach based on Givens–Householder transformations proposed by Dieci and Van Vleck [9]. In fact, the coordinates based on Givens's rotations is a special case of canonical coordinates of the second kind discussed in [22].

In the case where $\mathcal{M} = G$ is a Lie matrix group, the Lie groups methods are equivalent to what we get in the approach above by setting

$$\mathcal{R}_p(v) = \Phi(v \cdot p^{-1}) \cdot p,$$

where Φ is some sufficiently smooth mapping from $\mathfrak{g}$ to G and $\mathfrak{g}$ is the Lie algebra corresponding to the Lie group G. Typically, one may use $\Phi = \exp$, the matrix exponential Munthe-Kaas used in his first papers, but other choices are possible, as discussed in the other papers cited above.

For homogeneous spaces, of which the orthogonal Stiefel manifold is an example, the methods by Munthe-Kaas apply an action by a Lie group. $\mathcal{V}_{n,k}$ is acted upon by $\mathrm{SO}(n)$, the group of $n \times n$ matrices with unit determinant. As an example of a group action, one may use left multiplication:

$$\Lambda(g, p) := \Lambda_p(g) = g \cdot p, \quad p \in \mathcal{V}_{n,k},\ g \in \mathrm{SO}(n).$$

The linear space of $n \times n$ skew-symmetric matrices, denoted $\mathfrak{so}(n)$, is mapped by the matrix exponential into $\mathrm{SO}(n)$, and by composing this with the action Λ one obtains a map $\lambda_p = \Lambda_p \circ \exp : \mathfrak{so}(n) \to \mathcal{V}_{n,k}$. This map λ_p is a smooth map from some neighborhood of $0 \in \mathfrak{so}(n)$ onto some neighborhood of $p \in \mathcal{V}_{n,k}$. We thus get a representation of the solution $y(t)$ near the point $p \in \mathcal{V}_{n,k}$ quite similar to (2):

$$y(t) = \lambda_p(\sigma(t)).$$

By differentiation, this leads again to a differential equation for $\sigma(t)$ but now on the space $\mathfrak{so}(n)$ of skew-symmetric $n \times n$ matrices. The obvious drawback with this

approach is that we have replaced a differential system on the manifold $\mathcal{V}_{n,k}$ having dimension $nk - k(k-1)/2$ by an equation on a linear space which has dimension $n(n-1)/2$. Whenever $n \gg k$ this may lead to a large increase in the number of degrees of freedom. The advantage in using the retraction approach is that we always obtain a coordinate mapping for the manifold with exactly the same number of degrees of freedom as the dimension of the manifold.

2.2. Riemannian manifolds. In the context of a Riemannian manifold, one may use the exponential mapping as defined in terms of geodesics (geodesic flow) as a retraction map. Following, for instance, Chavel [5], we define

$$\mathcal{R}_p(v) = \exp_p(v) = \gamma_v(1),$$

where $\gamma_v(t)$ is the geodesic emanating from p with $\dot\gamma(0) = v$. It is known that $\exp_p$ is defined and of maximal rank in a neighborhood of $0 \in T_p\mathcal{M}$. The derivative map of $\mathcal{R}_p$ is related to the Jacobi field Y satisfying the Jacobi equation; see [5, pp. 70—82]. We let ∇ be the Levi-Civita connection with respect to the Riemannian metric on $\mathcal{M}$ and let $\mathbf{R}$ be the corresponding curvature tensor. We consider the vector field defined along the geodesic γ, $\gamma(0) = p,\ \dot\gamma(0) = v$, satisfying the boundary value problem

$$\nabla_t^2 Y + \mathbf{R}(\dot\gamma, Y)\dot\gamma = 0, \quad Y(0) = 0, \quad Y(1) = w.$$

Then

$$\left(\mathcal{R}_p'\big|_v\right)^{-1}(w) = (\nabla_t Y)(0).$$

In practice, Riemannian manifolds are often given naturally as a submanifold of a Euclidean space, say $V = \mathbb{R}^n$. In this case one can define at each point $p \in \mathcal{M}$ the orthogonal complement to $T_p\mathcal{M}$ which we denote by $N_p\mathcal{M}$, the normal space, so $V = T_p\mathcal{M} \oplus N_p\mathcal{M}$ for every $p \in \mathcal{M}$. Similar to what has been described in [17, 23], we introduce a map $n_p : T_p\mathcal{M} \to N_p\mathcal{M}$ and define a retraction as

$$\mathcal{R}_p(v) = p + v + n_p(v),$$

where $n_p(v)$ is defined such that $R_p(v) \in \mathcal{M}$ for each v belonging to a sufficiently small neighborhood of $0 \in T_p\mathcal{M}$. One calculates the derivative

$$\mathcal{R}_p'\big|_v(w) = w + n_p'\big|_v(w),$$

so the image of the derivative in $T_{\mathcal{R}_p(v)}\mathcal{M}$ is naturally split into components in $T_p\mathcal{M}$ and $N_p\mathcal{M}$. It follows that the inverse of the derivative map is obtained by applying the orthogonal projector $\mathbb{P}_p : V \to T_p\mathcal{M}$:

$$\left(\mathcal{R}_p'\big|_v\right)^{-1}(y) = \mathbb{P}_p y,\ y \in T_{R_p(v)}\mathcal{M} \subset V. \tag{4}$$

One may further characterize the map n_p in the case that the manifold is given locally in terms of constraint functions, say $g : V \to \mathbb{R}^m$, and we characterize open sets $U \in \mathcal{M}$ as

$$U = \{x \in V : g(x) = 0\}.$$

In fact, in many interesting cases, the constraint function defines the whole manifold; for instance, for Stiefel manifolds we obviously have $m = k(k+1)/2$ with the whole manifold $\mathcal{V}_{n,k}$ characterized by g inferred from the constraints $Y^TY = I_k,\ Y \in \mathcal{V}_{n,k}$.

Denote by $g'(x)$ the Jacobian matrix of g evaluated at x and suppose that $\operatorname{rank} g'(x) = m$. Clearly, in this setting, one can take $T_x\mathcal{M} = \ker g'(x)$, and following, for instance, Potra and Yen [24], one may calculate an orthonormal basis for $T_x\mathcal{M}$ by computing a QR decomposition

$$g'(x)^T = Q_x R_x = \begin{bmatrix} V_x & U_x \end{bmatrix} \cdot \begin{bmatrix} R_0 \\ 0 \end{bmatrix}.$$

A basis for $T_x\mathcal{M}$ is then given by the first $n-m$ columns of U_x. A map $\mathcal{R}_p : T_p\mathcal{M} \to \mathcal{M}$ is constructed by setting $q = \mathcal{R}_p(v)$, where $q-(p+v) \in N_p\mathcal{M}$. Using the representation $v = U_p y,\ y \in \mathbb{R}^m$, it follows immediately that the point q is obtained by solving the equations

$$U_p^T(q-p) - y = 0, \quad g(q) = 0. \tag{5}$$

It is straightforward to check that this map is a retraction. In [24] it is proposed to solve (5) by Newton iteration, but we shall see later that when applied on Stiefel manifolds one can find retraction maps which can be computed by direct methods, i.e., methods which do not involve iteration.

3. A retraction based on the reduced QR decomposition. The tangent spaces $T_P\mathcal{V}_{n,k}$ can be characterized in various different ways, and we refer to [12] for an introduction. In the following we shall just need the following characterization:

$$T_P\mathcal{V}_{n,k} = \{v \in \mathbb{R}^{n\times k} : P^T v \in \mathfrak{so}(k)\}.$$

This fact follows easily by letting $Q(t)$ be a smooth curve on $\mathcal{V}_{n,k}$ satisfying $Q(0) = P$ and $\dot{Q}(0) = v$, and thereafter differentiating the relation $Q^TQ = I_k$ at $t = 0$. Using the Frobenius inner product $\langle P, Q\rangle = \operatorname{tr}(Q^TP)$, one has the normal space characterization

$$N_P\mathcal{V}_{n,k} = \{PS \,|\, S \ k \times k \text{ symmetric}\}.$$

The retraction in section 2.2 applied to the Stiefel manifold was discussed in [17], and one uses the map

$$R_P(v) = P + v + n_P(v), \quad n_P(v) = PS_P(v),$$

where $S_P(v) =: S$ is a symmetric matrix satisfying the Riccati equation

$$S^2 + 2S + v^Tv + v^TPS + SP^Tv = 0.$$

It is straightforward to check that this map is a retraction. The Riccati equation can be solved by iteration. The important thing to note is that the iteration involves only computations with $k \times k$ matrices once the coefficient matrices have been set up. One therefore expects a complexity of order k^3 for each subsequent iteration.

From (4) we have

$$\left(\mathcal{R}'_P|_v\right)^{-1}(w) = \mathbb{P}_P(w), \quad w \in T_{R_P(v)}\mathcal{V}_{n,k},$$

and $\mathbb{P}_P : \mathbb{R}^{n\times k} \to T_P\mathcal{V}_{n,k}$ is the orthogonal projector with respect to the Frobenius inner product on $\mathbb{R}^{n\times k}$. Setting $M = (P^Tw + w^TP)/2$, one get the simple expression

$$\mathbb{P}_P(w) = w - PM.$$

We proceed to propose a retraction based on the QR decomposition which does not involve iteration. Now let $\mathcal{S}(n,k)$ be the manifold of $n \times k$ matrices of rank k. Given any matrix $A \in \mathcal{S}(n,k)$ one can apply an orthogonalization procedure to the columns of A and obtain a decomposition of the form $A = QR$, where $Q \in \mathcal{V}_{n,k}$ and $R \in \mathcal{T}_+(k)$, i.e., R being an upper triangular $k \times k$ matrix with positive diagonal elements. The complexity of this operation is $2nk^2$ flops [15, p. 232]. The decomposition is unique as described above. We denote the QR decomposition map (coproduct) by $\mathrm{qr} : \mathcal{S}(n,k) \to \mathcal{V}_{n,k} \times \mathcal{T}_+(k)$, and we let π_1 be the projection onto the first factor. For any vector $v \in T_P\mathcal{V}_{n,k}$ we define the retraction map $\mathcal{R}_P$ relative to $P \in \mathcal{V}_{n,k}$ as

$$\mathcal{R}_P(v) = (\pi_1 \circ \mathrm{qr})(P + v).$$

In other words, calculate the QR decomposition of the matrix $P + v$ and keep the matrix Q. In addition to being well defined, we can also show by construction that the inverse of $\mathcal{R}_P$ exists in some neighborhood of P. By writing

$$P + v = QR, \tag{6}$$

and showing that for a given $Q \in \mathcal{V}_{n,k}$ sufficiently close to P in some sense to be made clear below, we can calculate v satisfying (6) by an explicit procedure. Looking at (6) columnwise, we have

$$v_j = \sum_{i=1}^{j} R_{ij} Q_i - P_j. \tag{7}$$

We take the inner product on each side by P_m, $m = 1, \dots j$, and exploit the skew-symmetry of the matrix $P^T v$:

$$\sum_{i=1}^{j} R_{ij} \langle P_m, Q_i \rangle = \delta_{mj} - \langle v_m, P_j \rangle, \quad m = 1, \dots, j, \tag{8}$$

where δ_{mj} is the Kronecker function. This is a linear system of j equations for $R_{1j}, \dots, R_{jj}$ and can be solved as long as the jth principal minor of $P^T Q$ is nonsingular. One obtains successively v_j from (7). It is a crucial observation that $\langle v_j, P_j \rangle = 0$ such that the right-hand side of (8) depends only on $v_1, \dots, v_{j-1}$. The arithmetic complexity of this algorithm is $\mathcal{O}(nk^2 + k^3)$.

For the derivative mapping $(\mathcal{R}'_P|_v)^{-1}$, we first use the chain rule to infer that

$$\left(\mathcal{R}'_P\Big|_v\right)^{-1} = \left(\mathcal{R}_P^{-1}\big|_Q\right)', \quad \text{where} \quad Q = \mathcal{R}_P(v).$$

Thus, we let $Q(t)$ be a curve in $\mathcal{V}_{n,k}$ such that $Q(0) = Q \in \mathcal{V}_{n,k}$ and $\dot{Q}(0) = w \in T_Q\mathcal{V}_{n,k}$. By setting $v(t) = \mathcal{R}_P^{-1}(Q(t))$ we get the relation

$$P + v(t) = Q(t) \cdot R(t),$$

which we differentiate with respect to t, and set $t = 0$ to obtain $\dot{v} := \dot{v}(0) = (\mathcal{R}_P^{-1}|_Q)'(w)$. Due to the triangular structure of the matrix R, it makes sense to consider the differentiation columnwise, so we get

$$\dot{v}_j = \sum_{i=1}^{j} \left(w_i R_{ij} + Q_i \dot{R}_{ij}\right). \tag{9}$$

Here $R_{ij} = R_{ij}(0)$ and $\dot{R}_{ij} = \dot{R}_{ij}(0)$. We can solve for $R_{1j}, \ldots, R_{jj}$ by the procedure described above. However, in using retractions for solving ODEs on manifolds, we will see that the map $(\mathcal{R}_P^{-1}|_Q)'$ is always evaluated just after one has computed $Q = \mathcal{R}_P(v)$, and thus we would in practice store the R-matrix obtained as a by-product from this calculation.

Now we can use the fact that $\dot{v} \in T_P\mathcal{V}_{n,k}$ and take again the inner product with P_m:

$$\sum_{i=1}^{j} \langle P_m, Q_i \rangle \dot{R}_{ij} = -\sum_{i=1}^{j} \langle P_m, w_i \rangle R_{ij} - \langle \dot{v}_m, P_j \rangle, \quad m = 1, \ldots, j.$$

Thus, we have a linear system of j equations for the unknowns $\dot{R}_{1j}, \ldots, \dot{R}_{jj}$ whose solution exists whenever the principal minors of P^TQ are nonsingular. Finally, we substitute the obtained values for $\dot{R}_{ij}$ into (9) to obtain the desired tangent matrix $\dot{v}$.

Note that the linear systems for $R_{ij},\ i = 1, \ldots, j$, and $\dot{R}_{ij},\ i = 1, \ldots, j$, are the samep; thus one may use the same LU factorization of P^TQ. Note also that when the point $Q \in \mathcal{V}_{n,k}$ is "close" to the reference point P, we will have $P^TQ \approx I$, and the LU factorization can be done without pivoting. All the k linear systems of equations can be solved by means of the same factorization.

See also Appendix A of [3] for the `Matlab` implementation of this algorithm.

Complexity. The evaluation of $\mathcal{R}_P$ involves one addition of two $n \times k$ matrices and a reduced QR factorization. Using, for instance, the modified Gram–Schmidt algorithm [15], the cost of the QR decomposition is about $2nk^2$ flops.

The computation of $\mathcal{R}_P^{-1}$ itself is not needed in our algorithm, but we count a complexity of

$$(4k^2 + k)n + \frac{4}{3}k^3 - \frac{1}{2}k^2 - \frac{5}{6}k$$

flops. Now, for the calculation of the derivative $\left(\mathcal{R}_P^{-1}|_Q\right)'$, we found that it requires

$$(7k^2 + k)n + 2k^3 + \frac{3}{2}\,k^2 + \frac{1}{2}\,k$$

flops in the case that the matrix $R \in \mathcal{T}_+(k)$ is already given where $\mathcal{R}_P^{-1}(Q) + P = QR$. This is a reasonable assumption when integrating ODEs on the Stiefel manifold, because in the use of integration methods one first applies the retraction to a vector $v \in T_P\mathcal{V}_{n,k}$ to obtain $Q \in \mathcal{V}_{n,k}$ where the vector field F is to be evaluated, and the matrix R is obtained as a by-product.

We conclude this section by noting that in using the retraction approach for solving ODEs on the Stiefel manifold it is required to compute the retraction map and its inverse derivative an equal number of times. The dominating cost of these two operations together is about $9nk^2$ when $1 \ll k \ll n$. This is comparable to using the retraction proposed by Hairer, Lubich, and Wanner in [17]. However, a possible advantage with our approach is that we do not need any iteration and need not worry about convergence, etc. In the other approach one needs to iterate to machine accuracy when solving the Riccati equation to ensure that the retraction maps an element of the tangent space into the manifold.

4. A retraction based on the reduced polar decomposition. As an alternative to QR, one can use the reduced polar decomposition where a matrix $A \in \mathcal{S}(n, k)$

is factored as

$$A \to QH, \quad Q \in \mathcal{V}_{n,k},\ H \in \mathrm{Sym}^+(k),$$

where $\mathrm{Sym}^+(k)$ are the $k \times k$ symmetric positive definite matrices. Thus, in a very similar fashion to the retraction with QR decomposition above, we now define

$$\mathcal{R}_P(v) = (\pi_1 \circ \mathrm{pol})(P + v),$$

where $\mathrm{pol} : \mathcal{S}(n,k) \to \mathcal{V}_{n,k} \times \mathrm{Sym}^+(k)$ is the polar decomposition coproduct. It is well known that for any matrix $\mathcal{S}(n,k)$ the factors Q and H above can be calculated via the reduced singular value decomposition, say $A = V\Sigma W^T$, $V \in \mathcal{V}_{n,k}$, Σ is $k \times k$ diagonal and nonsingular, and $W \in \mathcal{O}(k)$. In this case, one obtains $Q = VW^T$ and $H = W\Sigma W^T$.

The derivative map $\dot{v} = (\mathcal{R}_P^{-1}|_Q)'(w)$ is obtained in a similar way as for the QR case, and we consider the curve $P + v(t) = Q(t)H(t)$ of a continuous reduced polar decomposition. Differentiating, we get

$$\dot{v} := \dot{v}(0) = wH + Q\dot{H}, \tag{10}$$

where we have set $Q = Q(0) \in \mathcal{V}_{n,k}$, $w = \dot{Q}(0) \in T_Q\mathcal{V}_{n,k}$, $H = H(0) \in \mathrm{Sym}^+(k)$, $\dot{H} = \dot{H}(0) \in \mathrm{Sym}(k)$. Now we multiply (10) by P^T from the left and consider the symmetric part of the resulting equation. This leads to the following Lyapunov equation for $\dot{H}$:

$$M\dot{H} + \dot{H}M^T + C = 0.$$

Here $M = P^TQ$ and $C = P^TwH + Hw^TP$. It is well known that this system has a unique solution $H \in \mathrm{Sym}(k)$ if and only if the eigenvalues of the matrix $M = P^TQ$ have nonzero real parts. So $\mathcal{R}_P'|_Q$ is invertible for every Q in some neighborhood of $P \in \mathcal{V}_{n,k}$. After solving for $\dot{H}$ we obtain $\dot{v}$ by substituting it into (10). The matrix $H \in \mathrm{Sym}^+(k)$ can be obtained by solving another Lyapunov equation, but as in the QR case it is for the applications we have in mind feasible to assume that this matrix is already known whenever needed in the calculation of $(\mathcal{R}_P^{-1}|_Q)'$.

See also Appendix A of [3] for `Matlab` implementations of these algorithms.

Complexity. Using the algorithm by Golub and Reinsch, it costs approximately $14nk^2 + \frac{22}{3}k^3$ flops to form the matrices V and Σ, and an additional $2nk^2$ flops to form U and then $k^3/2$ flops to form H. In conclusion, the dominating complexity terms for calculating $\mathcal{R}_P(v)$ is

$$16\,nk^2 + 7.83\,k^3$$

flops.

To obtain the corresponding map $(\mathcal{R}_P^{-1}|_Q)'$, the dominating cost consists of calculating two products of $n \times k$ with $n \times k$ matrices, then another two products of $n \times k$ with $k \times k$, each multiplication costing $2nk^2$ flops. The Lyapunov equation is solved only for a $k \times k$ matrix, and by using, e.g., the Bartels–Stewart algorithm the cost will be approximately $25k^3$ flops. For details about this and other algorithms for solving the Lyapunov equation, see [15, p. 367], [19], and the references therein. Summing up, we get approximately

$$8\,nk^2 + 25\,k^3$$

flops for calculating $(\mathcal{R}_P^{-1}|_Q)'(w)$.

5. Runge–Kutta methods based on retractions. We now consider in more detail how to solve ODEs on manifolds by using a retraction map. We will now assume that the problem is given by the user in the form (1) meaning that there is a procedure, say `F`, available which for any $(t, y) \in \mathcal{D} \subset \mathbb{R} \times \mathcal{M}$ returns the derivative $F(t, y) \in T_y\mathcal{M}$. In addition, the user must provide an initial value $y_0 \in \mathcal{M}$ and an initial stepsize h.

Suppose a Runge–Kutta (RK) method is given, with coefficients (a_{ij}), where $i, j = 1, \dots, s$, and (b_i), $i = 1, \dots, s$. As usual we denote $c_i = \sum_j a_{ij}$. The method is generally defined over one step as follows:

$$\left.\begin{aligned} u_i &= h \textstyle\sum_j a_{ij} k_j \\ k_i &= \big(\mathcal{R}'_{y_n}|_{u_i}\big)^{-1}\big(F(t_n + hc_i, \mathcal{R}_{y_n}(u_i))\big) \end{aligned}\right\}, \qquad i = 1, \dots, s,$$
$$y_{n+1} = \mathcal{R}_{y_n}\big(h \textstyle\sum_i b_i k_i\big).$$

In particular, the method is explicit if $a_{ij} = 0,\ j \geq i$. The following algorithm generalizes an explicit RK method to an arbitrary manifold in which a retraction $\mathcal{R}$ is defined.

Algorithm 5.1.

Input y_0, stepsize h, and RK parameters a_{ij}, b_i.
for $n = 0, 1, \dots$
  for $i = 1, \dots, s$
    $u_i := h \sum_j a_{ij} k_j$
    $Y := \mathcal{R}_{y_n}(u_i)$
    $m_i := F(t_n + hc_i, Y)$
    $k_i := \big(\mathcal{R}^{-1}_{y_n}|_Y\big)'\,(m_i)$
  end for
  $v := h \sum_i b_i k_i$
  $y_{n+1} := \mathcal{R}_{y_n}(v)$
  [Update stepsize h if desired]
end for

In the approach presented here, explicit methods are recommended because implicitness may cause an even higher increase in computational complexity than is the case for standard RK methods.

Remark. It is instructive to note that the algorithm described above is intrinsic in the sense that it works entirely within the realm of the manifold $\mathcal{M}$, and no reference is made to any Euclidean space. However, if this requirement is relaxed, suppose that $\mathcal{M} \subset V$, where V is a linear space, and that we consider instead

$$\dot{y} = \bar{F}(t, y), \quad \bar{F} : \mathbb{R} \times V \to V$$

such that $\bar{F}(t, \cdot)\big|_M = F(t, \cdot)$. Given a projector $\mathcal{P} : V \to \mathcal{M}$, we could consider the method defined simply as

$$\left.\begin{aligned} Z_i &= \mathcal{P}(y_n + h \textstyle\sum a_{ij} K_j) \\ K_i &= \bar{F}(t_n + c_i h, Z_i), \end{aligned}\right\}, \quad i = 1, \dots, s, \tag{11}$$
$$y_{n+1} = \mathcal{P}(y_n + h \textstyle\sum b_i K_i).$$

Since now $Y_i \in \mathcal{M}$, the extended vector field $\bar{F}$ is never evaluated outside $\mathcal{M}$, and the perturbation introduced by the projector $\mathcal{P}$ does not affect the order of the method. We have not pursued this approach any further, since in this particular paper we are primarily interested in methods that can be phrased independently of how the manifold is represented.

However, there is an interesting connection between this method and the method based on the retraction described in section 2.2. Suppose that we define a local projector $\mathcal{P}_{y_n}$ to be used in the step from t_n to t_{n+1} such that for points $m \in V$ near y_n we have

$$\mathcal{P}_{y_n}(m) = m + \bar{n}_{y_n}(m - y_n), \quad \bar{n}_{y_n} : V \to N_{y_n},$$

where $\bar{n}_{y_n}\big|_{T_{y_n}\mathcal{M}} = n_{y_n}$. Thus, the retraction is related to the projector as $\mathcal{R}_{y_n}(v) = \mathcal{P}_{y_n}(y_n + v)$ whenever $v \in T_{y_n}\mathcal{M}$. The map n_{y_n} is extended naturally to all of V so that $\bar{n}_{y_n}(v_t + v_n) = \bar{n}_{y_n}(v_t) + \bar{n}_{y_n}(v_n) = n_{y_n}(v_t) - v_n$ when $v_t \in T_{y_n}$ and $v_n \in N_{y_n}$, and we get

$$\mathcal{P}_{y_n}(m) = y_n + (I + n_{y_n}) \circ \mathbb{P}_{y_n}(m - y_n). \tag{12}$$

Now considering Algorithm 5.1 with this retraction, we get

$$\begin{aligned} Y_i &= \mathcal{P}_{y_n}\left(y_n + h\sum a_{ij}k_j\right), \\ k_i &= \mathbb{P}_{y_n}F(t_n + c_i h, Y_i), \\ y_{n+1} &= \mathcal{P}_{y_n}\left(y_n + h\sum b_i k_i\right). \end{aligned}$$

Now consider (11) with $\mathcal{P} = \mathcal{P}_{y_n}$ where we calculate by using (12)

$$\begin{aligned} Z_i &= \mathcal{P}_{y_n}\left(y_n + h\sum a_{ij}K_j\right) = y_n + (I + n_{y_n}) \circ \mathbb{P}_{y_n}\left(h\sum a_{ij}K_j\right) \\ &= \mathcal{P}_{y_n}\left(y_n + h\sum a_{ij}\mathbb{P}_{y_n}K_j\right) \end{aligned}$$

so we see that $Y_i = Z_i$ and $k_i = \mathbb{P}_{y_n}K_i$ and the two methods are equivalent.

6. Numerical experiments. All the numerical experiments are performed in `Matlab`. We compare the methods presented in this paper, RK methods based on retractions, RKRqr (based on the qr decomposition), and RKRp (based on the polar decomposition), with the following methods:

- Projection Runge–Kutta (PRK) method: the method that performs a projection based on the QR factorization at each time step of an explicit RK method (extrinsic).
- The method recently proposed in [2] (SPRK): a splitting method applied to the perturbed problem obtained by adding the term $-\tau y(I_k - y^T y)$ to the original vector field. The parameter τ is suitably chosen in order to make $\mathcal{V}_{n,k}$ an attracting manifold. (We took $h\tau = \frac{1}{2}$, which is indicated as the optimal choice in [2].) The resulting method is a projection method (extrinsic).
- Runge–Kutta Munthe-Kaas [21] (RKMK) methods: generalization of the classical RK methods based on the use of the Lie group actions $\Lambda(g, Y_0) = g \cdot Y_0$ and $g = \exp(\sigma)$ for $\sigma \in \mathfrak{so}(n)$ and $Y_0 \in \mathcal{V}_{n,k}$ (intrinsic).

The results obtained with the RKMK methods are not reported in the plots, but we will comment on their performance in the experiments in various points of this section.

All the methods are based on the classical explicit RK method of order 4.

The numerical experiments are divided in two parts. In the first section we will compare the intrinsic methods with the extrinsic ones.

In the second section we will illustrate the performance of the methods based on retractions when applied to the computation of the Lyapunov exponents of a ring of oscillators.

6.1. Intrinsic versus extrinsic. As a first experiment we consider the following initial value problem:

$$y' = F(y) = A(y)y + \lambda y(I_k - y^T y) \tag{13}$$

for $y(0) \in \mathcal{V}_{n,k}$, $n = 1000$, $k = 4$. Here $A(y)$ is a banded skew-symmetric $n \times n$ matrix whose nonzero entries are

$$A_{i,i+m} = -A_{i+m,i} = y_{i,m}, \quad 1 \le i \le n-m, \quad 1 \le m \le k. \tag{14}$$

The initial value, y_0, is obtained as the first factor of the reduced QR factorization of a random 1000×4 matrix, using the command `[y0,r]=qr(rand(n,k),0)` in `Matlab`.

Note that the term $y(I_k - y^T y)$ in (13) is zero for any $y \in \mathcal{V}_{n,k}$, thus the solution of (13) is independent of λ as long as $y_0 \in \mathcal{V}_{n,k}$. It might be desirable that the numerical approximation inherits this property. Although the extra term above may look artificial, it serves the purpose of illustrating that the way the vector field is extended affects the numerical solution obtained by a projection method.

In some cases it might be necessary or advantageous to rewrite (13) in a "strong skew-symmetric form"; i.e., $F(t,y) = H(t,y)y$ with $H(t,y) \in \mathfrak{so}(n)$ (for the RKMK methods for example). Note that in the numerical experiments we always assume the value of the vector field $F(t,y)$ to be given by a black box program that we are not allowed to modify. Since $A(y)$ is a banded matrix the cost of computing F, as given in (13), is effectively $\mathcal{O}(nk^2)$ flops.

Given $F = F(t,y)$ in the tangent space at y to the Stiefel manifold we then consider the following strong skew-symmetric formulation:

$$F = \big(\alpha(y)y^T - y\alpha^T(y)\big)\, y, \quad \alpha(y) = y\,\mathrm{tril}(y^T F) + (F - yy^T F). \tag{15}$$

Formulation (15) is then computed just assuming the knowledge of F and requires $\mathcal{O}(nk^2)$ flops.. Note that the formulation in the strong skew-symmetric form, as pointed out in [2], can be of crucial importance for extrinsic methods, as it makes $\mathcal{V}_{n,k}$ a strong invariant manifold. We apply the projection methods to this reformulation for problem (13) in the case $\lambda \neq 0$.

In Figure 1, for different values of the stepsize h, we plotted the norm of the difference of the numerical approximations produced by the methods after one time step for problem (13) with $\lambda = 0$ and $\lambda = 10$, respectively. The dependence on λ is quite evident for both the extrinsic methods, although the norm of the difference of the two numerical solutions decreases as the stepsize goes to zero. Note that the lines of the PRK and the SPRK lie on top of each other in the plot.

For the intrinsic methods the global error remains more or less the same for the two different values of λ, and as we can see from the figure the difference of the two approximate solutions is of the order of machine accuracy. Similar experiments gave analogous results for the RKMK methods.

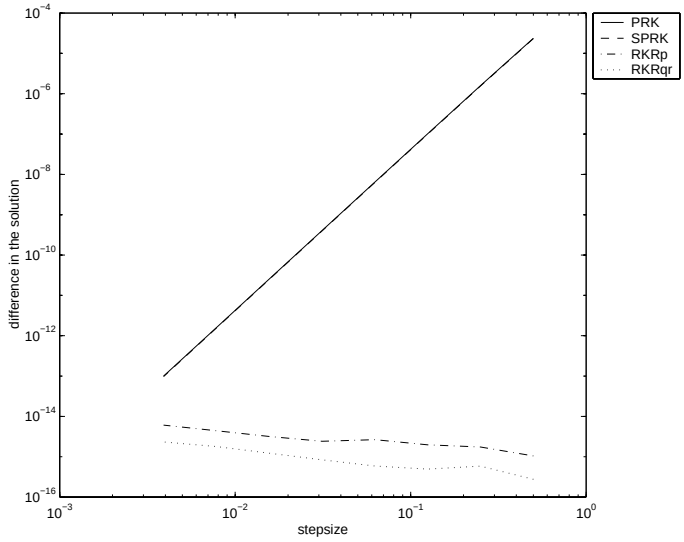

FIG. 1. *Difference in the solution for* $\lambda = 0$ *and* $\lambda = 10$.

In the next two figures we compare the cost of the four methods as applied to problem (13). We plot the global error at $T = 1$ on the y-axis against the number of flops on the x-axis in Figure 2 for $\lambda = 0$, and in Figure 3 for $\lambda = 10$.

As we can notice in the case $\lambda = 0$, the achieved global error per amount of flops for the two extrinsic methods is lower in norm than for the intrinsic methods.

However, for $\lambda = 10$ the RKRqr and the RKRp perform better than the two extrinsic methods.

The use of the RKMK methods in these experiments led to much more time consuming calculations. It seems that a naive implementation of these techniques causes unacceptable computational costs. Recently, new implementation techniques that can reduce the cost of the RKMK methods to a cost of $\mathcal{O}(nk^2)$ flops have been investigated [4].

6.2. Computing Lyapunov exponents. The Lyapunov exponents LEs of a continuous dynamical system $x' = F(x)$, $(x(t) \in \mathbb{R}^n)$ provide a qualitative measure of its complexity and can be defined as follows. Consider the linearization $A(t)$ of $x' = F(x)$ along a trajectory $x(t)$ and the solution U of the matrix problem

$$\dot{U} = A(t)U, \quad U(0) = U_0, \quad n \times n;$$

then the logarithms of the eigenvalues of the matrix

$$\Lambda = \lim_{t\to\infty} \left(U(t)^T U(t)\right)^{\frac{1}{2t}}$$

are the LEs for the given dynamical system. In [8] the authors describe a procedure for computing just k of the n LEs of a dynamical system. The strategy is based on solving a suitable initial value problem on $\mathcal{V}_{n,k}$ and computing a quadrature of the diagonal entries of a $k \times k$ matrix valued function. The initial value problem is defined as follows:

$$\dot{Q} = \left(A - QQ^T A + QSQ^T\right) Q,$$

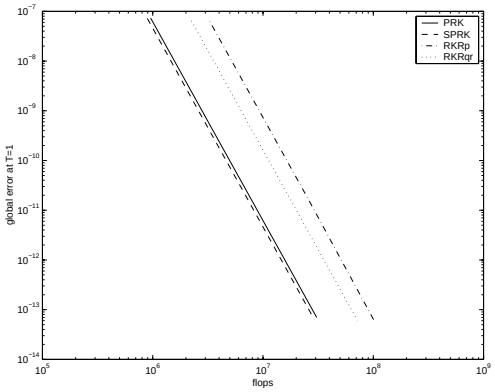

FIG. 2. *Global error versus the number of flops for* $\lambda = 0$.

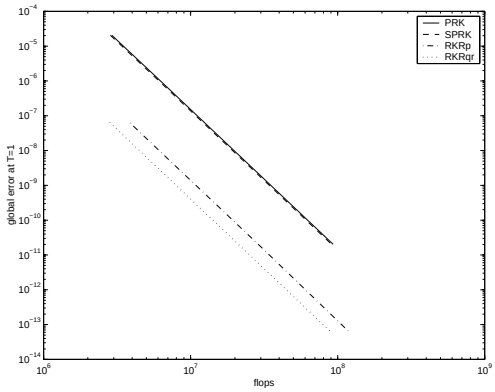

FIG. 3. *Global error versus the number of flops for* $\lambda = 10$.

with random initial value in $\mathcal{V}_{n,k}$ and

$$S_{k,j} = \begin{cases} (Q^T AQ)_{k,j}, & k > j, \\ 0, & k = j, \\ -(Q^T AQ)_{j,k}, & k < j, \end{cases} \qquad k, j = 1, \ldots, p.$$

It can be shown that the ith LE λ_i can be obtained as

$$\lambda_i = \lim_{t \to \infty} \frac{1}{t} \int_0^t B_{i,i}(s) ds, \quad i = 1, \ldots, k, \tag{16}$$

and

$$B = Q^T AQ - S.$$

In the numerical experiments we use the trapezoidal rule to approximate integral (16) and compute λ_i $(i = 1, \ldots, k)$, and we refer to the original paper [8] for further details on the method.

We first consider the following test problem previously proposed in [2]. Given a $n \times n$ diagonal matrix D we define the time dependent ODE

$$\dot{x} = A(t)x, \quad x \in \mathbb{R}^n, \quad A(t) = W(t)DW(t)^{\mathcal{T}} + J,$$

where J is the skew-symmetric part of a randomly generated matrix and $W(t) = \exp(tJ)$. The diagonal entries of D are the LEs of the constructed linear system. We took $D_{i,i} = C(3 - i)/n$ for $i = 1, \ldots, n$ and C a constant. Only the first three LEs are positive.

We considered the methods PRK, SPRK, RKRqr. In the tables we report the 2-norm of the error in the first k LEs and in the Stiefel matrix Q whose columns approximate the first k columns of $W(t)$, and in the last column we report the number of flops per step. The stepsize is the same for all methods and is $h = 0.1$.

The results of the first experiment are reported in Table 1, where we considered $n = 20$, $k = 6$, and $C = 1$, and the methods perform similarly.

In Table 2 are reported the results of the second experiment, where we have taken $n = 25$, $k = 4$, and $C = 27.5$.

TABLE 1
LE, first experiment: $n = 20$, $k = 6$, $C = 1$.

Methods	Error in LEs	Error in Q	Megaflops
PRK	0.0031	4.1361e-05	1.537
SPRK	0.0031	4.7595e-05	1.536
RKRqr	0.0030	2.6738e-05	1.566

TABLE 2
LE, second experiment: $n = 25$, $k = 4$, $C = 27.5$.

Methods	Error in LEs	Error in Q	Megaflops
PRK	0.0023	0.0013	2.992
SPRK	0.0023	0.0013	2.991
RKRqr	0.0014	0.0012	3.008

In the last numerical experiment we apply the RKRqr method to the computation of the LEs of the following ODEs system describing a ring of m Duffing oscillators:

$$\begin{aligned} &\ddot{y} + \alpha\left(y^2 - 1\right)\dot{y} + \omega^2 y = 0, \\ &\ddot{x}_i + d\dot{x}_i + \beta\left[V'(x_i - x_{i-1}) - V'(x_{i+1} - x_i)\right] = \sigma y \delta_{i,1}, \quad i = 1, \ldots, m. \end{aligned} \tag{17}$$

The ring is forced externally by $y(t)$. Here $V(x) = (\frac{x^2}{2}) + (\frac{x^4}{4})$, $\delta_{i,j} = 0$ for $i \neq j$ and $\delta_{i,i} = 1$, and we impose periodic boundary conditions ($x_0 = x_m$ and $x_{m+1} = x_1$). In the experiments $m = 15$ and $\alpha = 1$, $\omega = 1.6$, $\beta = 1$, $\sigma = 2$, and $d = 0.4$. This test problem has been considered in [11, 8, 2].

In this experiment we have considered a time interval $[0, 4000]$ and the stepsize $h = 0.01$. The trajectory is computed numerically using a midpoint rule with stepsize $h/8$.

Considering the error introduced by substituting the integral (16) with the quadrature, the results are in good agreement with those obtained in [11] and give the correct qualitative information about the considered dynamical system. (All LEs are negative.) The results are reported in Figures 4 and 5.

7. Conclusion. We have developed intrinsic integration methods of complexity $\mathcal{O}(n\,k^2)$ for solving ODEs on orthogonal Stiefel manifolds. We would like to emphasize that in order to see this complexity in actual computations it is important that the evaluation of the vector field F (as in $y' = F(t, y)$) does not involve cost of higher arithmetic complexity. It is, for instance, quite common to phrase problems on $\mathcal{V}_{n,k}$ in the form

$$\dot{y} = F(t, y) = A(t, y)y, \tag{18}$$

where $A(t, y) : \mathbb{R} \times \mathcal{V}_{n,k} \to \mathfrak{so}(n)$. If there is no sparsity in $A(t, y)$, it seems impossible to calculate $F(t, y)$ in less than $\mathcal{O}(n^2\,k)$ flops, and the gain in using the presented type of integration methods may not be significant. However, since each tangent space $T_p\mathcal{V}_{n,k}$ has only dimension $d_{n,k} = nk - k(k-1)/2$ it is always possible to find local parametrizations of the vector field F using only $d_{n,k}$ degrees of freedom.

There is no doubt that the methods presented here seem to have something in common with projection methods. Although we have seen no precise definition of a projection method, we still claim that there are important differences between the methods presented here and those normally referred to as projection methods. We have therefore chosen to focus on intrinsicness as the main feature to distinguish

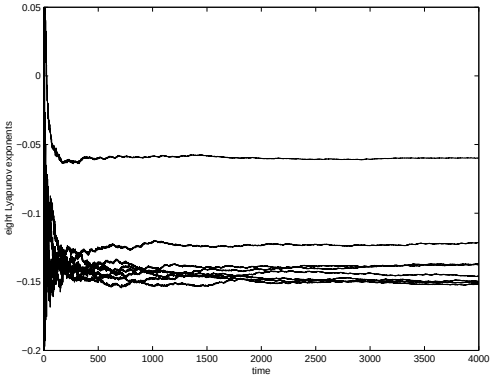

FIG. 4. *LEs for a ring of oscillators: RKRqr on the interval* $[0, 4000]$.

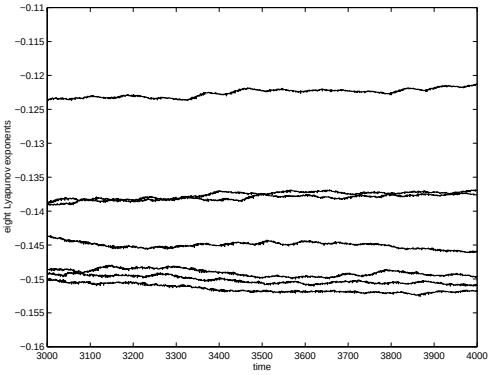

FIG. 5. *LEs for a ring of oscillators: RKRqr detail on the interval* $[3000, 4000]$.

the two types of methods. The term projection often indicates a map from higher to lower dimension, but in our case the retraction map is seen as a map from each tangent space $T_p\mathcal{V}_{n,k}$ onto a neighborhood of $p \in \mathcal{V}_{n,k}$, and in this sense it is a local diffeomorphism. Following the recent threads in the area of geometric integration, we find it useful to make a point out of constructing and analyzing schemes without appealing to the particular embedding of the manifold in a Euclidean space. This means, for instance, that we aim to avoid as much as possible working directly with algebraic constraints since they are closely linked to the realization of the manifold. Only in the explicit construction of specific retraction maps have we found it useful to apply properties of the embedding as a tool. Still, considering the retraction map as a black box, there are no traces of the embedding to be found in the method design. Furthermore, we have been reluctant to allow linear combinations of tangent vectors belonging to different tangent spaces. One may, of course, ask whether there are good reasons for requiring such properties in an integration method for ODEs on manifolds. We believe that there might be situations where intrinsic properties of the manifold itself are of importance for the behavior of the method, and it seems natural in such cases to apply integration methods that are not affected by how the manifold is embedded in a Euclidean space. Nevertheless, these new methods should be thought of as complementing rather than substituting the vast selection of DAE and projection methods available today. We also believe that more studies should be done towards understanding better the relation between established DAE methods and the approach presented here.

The main feature of the proposed methods is that they make no use of an extension of the vector field F to points not lying on the Stiefel manifold. It is certainly true that one can for all practical purposes find such an extension of the vector field F to all of $\mathbb{R}^{n\times k}$; for instance, the imbedding theorem of Nash ensures this for Riemannian manifolds. However, the extension is not unique, and we find it unnatural that the numerical approximation produced should depend on the particular extension which is chosen. Our numerical experiments confirm that different extensions can lead to completely different numerical approximations for projection methods, whereas the ones presented here yield identical results modulo rounding errors.

NUMERICAL METHODS FOR p-HARMONIC FLOWS AND APPLICATIONS TO IMAGE PROCESSING*

LUMINITA A. VESE† AND STANLEY J. OSHER†

Abstract. We propose in this paper an alternative approach for computing p-harmonic maps and flows: instead of solving a constrained minimization problem on S^{N-1}, we solve an unconstrained minimization problem on the entire space of functions. This is possible, using the projection on the sphere of any arbitrary function. Then we show how this formulation can be used in practice, for problems with both isotropic and anisotropic diffusion, with applications to image processing, using a new finite difference scheme.

Key words. energy minimization, p-harmonic maps, p-harmonic flows, directional diffusion, heat flow, total variation minimization, partial differential equations, finite differences, denoising

1. Introduction.

This paper is concerned with the minimization of constrained functionals, and in particular with p-harmonic maps. This problem has applications to liquid crystals, as well as to directional diffusion and chromaticity denoising.

Let $\Omega \subset \mathbb{R}^M$ be an open and bounded domain, and let S^{N-1} be the unit sphere in $\mathbb{R}^N$, for $M \geq 1$ and $N \geq 2$.

We first recall the following notations and terminology. The Euclidean norm of a vector y will be denoted by $|\cdot|$. The vector-valued function $U : \Omega \to \mathbb{R}^N$ belongs to S^{N-1} if and only if $|U(x)| = 1$, a.e. (for almost every) $x \in \Omega$.

The component gradient ∇U_i and its Euclidean norm are, respectively, defined by

$$\nabla U_i = \left(\frac{\partial U_i}{\partial x_1}, \frac{\partial U_i}{\partial x_2}, \ldots, \frac{\partial U_i}{\partial x_M}\right), \quad |\nabla U_i| = \sqrt{\left(\frac{\partial U_i}{\partial x_1}\right)^2 + \left(\frac{\partial U_i}{\partial x_2}\right)^2 + \cdots + \left(\frac{\partial U_i}{\partial x_M}\right)^2},$$

and the gradient matrix and its norm of the vector-valued function U are, respectively, defined by

$$\nabla U = \begin{pmatrix} \nabla U_1 \\ \vdots \\ \nabla U_N \end{pmatrix} = \begin{pmatrix} \frac{\partial U_1}{\partial x_1} & \cdots & \frac{\partial U_1}{\partial x_M} \\ \vdots & & \vdots \\ \frac{\partial U_N}{\partial x_1} & \cdots & \frac{\partial U_N}{\partial x_M} \end{pmatrix}, \quad |\nabla U| = \sqrt{\sum_{i=1}^{N}\sum_{j=1}^{M}\left(\frac{\partial U_i}{\partial x_j}\right)^2}.$$

For $U : \Omega \to S^{N-1}$ and $p \geq 1$, we consider the p-energy

$$E_p(U) = \int_\Omega |\nabla U|^p dx, \tag{1.1}$$

which is finite if U belongs to the Sobolev class

$$W^{1,p}(\Omega, S^{N-1}) = \{U \in W^{1,p}(\Omega, \mathbb{R}^N),\ |U| = 1 \text{ a.e.}\}.$$

Minimizing E_p over $U : \Omega \to S^{N-1}$, with associated boundary conditions on $\partial\Omega$, is a constrained minimization problem. Mappings which are stationary for E_p are called p-harmonic maps.

The associated boundary conditions can be, for example, the following: $U|_{\partial\Omega}$ equals a given map in $S^{N-1}(\partial\Omega)$, or the Neumann boundary conditions $\frac{\partial U}{\partial \vec{n}}|_{\partial\Omega} = 0$, where $\vec{n}$ denotes the exterior unit normal to $\partial\Omega$.

Many authors have studied harmonic maps between manifolds (existence, uniqueness or nonuniqueness, regularity; essentially most of them worked on the case $p = 2$): Bethuel, Brezis, and Coron [5]; Bethuel, Brezis, and Helein [6], [7]; Schoen and Uhlenbeck [29], [30], [31]; Struwe [34], [35], [36]; Courilleau and Demengel [15]; Coron and Gulliver [14]; Brezis, Coron, and Lieb [8]; and others. There are fewer results for the case $p = 1$ (for example by Giaquinta, Modica, and Soucek [19]).

We would also like to mention the following important contributions on harmonic maps for liquid crystals, both in theory and practice: Hardt, Kinderlehrer, and Luskin [20]; Lin and Luskin [24]; Cohen, Lin, and Luskin [12]; Cohen et al. [13]. The work on computational aspects of harmonic maps [13] was proposed before the analysis results on this problem. This paper deals with alternative formulations and numerical methods for computing harmonic maps.

There are difficulties finding numerically the minimizers or the p-harmonic maps, due to nonconvexity (the constraint $|U(x)| = 1$ a.e. is not convex), nonregularity, and nonuniqueness of minimizers.

There are several classical approaches used to solve the minimization problem (1.1).

A first approach is to solve the Euler–Lagrange equations associated with the minimization problem. These consist of a set of coupled PDEs:

$$-\text{div}(|\nabla U|^{p-2}\nabla U) = U|\nabla U|^p. \tag{1.2}$$

The above system of equations holds if and only if $U \in S^{N-1}$. However, in practice, the numerical solution does not necessarily satisfy the constraint $|U| = 1$ everywhere. To correct the numerical error, several authors [18], [38], [39] replace the solution U_*^n obtained at each iteration n by $U^n = \frac{U_*^n}{|U_*^n|}$, but then the question is whether one still decreases the energy. In this framework, we also refer the reader to [13]. It is known [1] that the energy decrease is guaranteed after this renormalization if $|U_*^n| \geq 1$, but the behavior of the energy is not known if $|U_*^n| < 1$. Also, if we would like to extend this numerical procedure involving the projection at each step to other manifolds, then the energy decrease is guaranteed only when the manifold is the boundary of a convex set, and again if, in addition, U_*^n does not belong to the interior of that convex domain.

This problem has been solved in [1] for the S^2 case and in three dimensions, where an interesting convergent algorithm is proposed, but it still involves a renormalization step at each iteration (ensuring now that the energy decreases after the renormalization step). Numerical methods for p-harmonic flows are also proposed in [18] and [13], again based on the renormalization procedure at each step.

The second classical approach is given by the Ginzburg–Landau functionals [6], [7]. Here, the problem is solved by approximation to eliminate the constraint. The minimization of the energy E_p from (1.1) under the constraint $|U(x)| = 1$ a.e. is approxi-

mated by the unconstrained minimization of the following energies, as $\varepsilon \to 0$:

$$E_\varepsilon(U) = \int_\Omega |\nabla U|^p dx + \frac{1}{\varepsilon}\int_\Omega (1-|U|^2)^2 dx. \tag{1.3}$$

In this paper, we introduce a different approach to solving minimization problems on S^{N-1}. We solve an unconstrained minimization problem on the entire space of functions and not only on S^{N-1}. The method uses the projection of an arbitrary function V to the sphere S^{N-1}. We will present our alternative approach for the case of S^{N-1}. Then we discuss how this approach can be extended to more general manifolds, and in particular to manifolds defined implicitly, via a level set function. By proposing numerical schemes in the S^1 and S^2 cases, we also show how our formulations can be used in practice, and in particular for applications to directional diffusion and color image denoising.

In the framework of image processing and directional diffusion, related works are [27], [33], [9], [38], [22], [39], [42], and [32], [23]. We also refer the reader to [17] for manifold constrained variational problems. In the framework of energy minimization with values in S^2, we refer the reader to [16], where the algorithm from [1] is applied in the presence of a data term.

Our main idea is as follows. For $U : \Omega \to S^{N-1}$, with $\Omega \subset \mathbb{R}^M$, consider $V : \Omega \to \mathbb{R}^N \setminus \vec{0}$ such that

$$U = \frac{V}{|V|}.$$

We minimize without constraint the corresponding energy with respect to V:

$$\inf_V \left\{ F(V) = \int_\Omega \left| \nabla\left(\frac{V}{|V|}\right)\right|^p dx \right\}, \tag{1.4}$$

and then we recover U, a minimizer of (1.1), projecting back on S^{N-1}, by $U = \frac{V}{|V|}$, where V is a minimizer of (1.4).

We would like to mention that the idea of solving constrained minimization problems for harmonic maps by associating unconstrained minimization problems has been used as a theoretical tool by Chen and Lin [10] and Struwe [37]. They find a smooth energy-minimizing harmonic map U as a weak limit of minimizers U_L to an unconstrained variational problem for $L \to \infty$.

The outline of the paper is as follows. In section 2, we consider the S^1 case: we derive the Euler–Lagrange equations associated with the unconstrained minimization problem, and in subsection 2.1 we propose a numerical scheme for this case. Similarly, section 3 and subsection 3.1 are devoted to the S^2 case. In section 4 we validate the proposed models and numerical schemes on several experimental results: in subsection 4.1, we consider the case with prescribed boundary conditions, and we make a comparison with the classical formulation (1.2) with the renormalization step at each iteration (we will see that, by the proposed approach, the numerical accuracy is improved in a test case where we know the exact solution); in subsection 4.2, we consider the case of directional diffusion, with Neumann boundary conditions, and applications to chromaticity denoising for color images. Finally, in section 5 we conclude with a discussion for more general manifolds.

2. The S^1 case. To develop our main idea, let us first consider the particular case $N = 2$ of S^1. Then, for $U : \Omega \to S^1$, consider $V = (u, v) : \Omega \to \mathbb{R}^2$ such that $U = \frac{V}{|V|}$.

In order to obtain in an elegant way the Euler–Lagrange equations associated with the minimization problem (1.4), we consider the orientation formulation (which is not always equivalent with the directional formulation). Let $U = (\cos\theta, \sin\theta)$, and let $V = (r\cos\theta, r\sin\theta)$. Then $u^2 + v^2 = r^2$, and we have

$$\left|\nabla\left(\frac{V}{|V|}\right)\right|^2 = |\nabla\theta|^2.$$

For $p = 2$ (the heat flow for harmonic maps), solving

$$\inf_\theta \int_\Omega |\nabla\theta|^2 dx,$$

and parameterizing the descent direction by an artificial time t, we obtain (denoting $u_t = \frac{\partial u}{\partial t}$, $v_t = \frac{\partial v}{\partial t}$)

$$\theta_t = \triangle\theta, \quad r_t = 0.$$

Using

$$\theta = \tan^{-1}\left(\frac{v}{u}\right), \quad \nabla\theta = \frac{u\nabla v - v\nabla u}{u^2 + v^2},$$

we first deduce that

$$\frac{uv_t - vu_t}{u^2 + v^2} = \operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2 + v^2}\right).$$

Now, using $uu_t + vv_t = 0$ (from $r_t = 0$), we obtain the associated Euler–Lagrange equations for $p = 2$:

$$u_t = -v\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2 + v^2}\right), \quad v_t = +u\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2 + v^2}\right). \tag{2.1}$$

For $p = 1$ (the total variation minimization of Rudin, Osher, and Fatemi [28]), on solving

$$\inf_\theta \int_\Omega |\nabla\theta| dx,$$

we obtain

$$\theta_t = \operatorname{div}\left(\frac{\nabla\theta}{|\nabla\theta|}\right), \quad r_t = 0.$$

Then, in a similar way, the associated Euler–Lagrange equations for $p = 1$ are

$$u_t = -v\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{|u\nabla v - v\nabla u|}\right), \quad v_t = +u\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{|u\nabla v - v\nabla u|}\right). \tag{2.2}$$

In the general case, i.e., for any $p \geq 1$, the corresponding linear system in u_t and v_t is

$$\begin{aligned} & uu_t + vv_t = 0, \\ & \frac{uv_t - vu_t}{u^2+v^2} = \operatorname{div}\left[\left(\frac{|u\nabla v - v\nabla u|}{u^2+v^2}\right)^{p-2}\left(\frac{u\nabla v - v\nabla u}{u^2+v^2}\right)\right]. \end{aligned}$$

Solving this linear system in the unknowns u_t and v_t yields similar equations in u and v, like those for the cases $p = 2$ and $p = 1$ from (2.1) and (2.2), respectively.

We will associate with the problems (2.1) and (2.2) initial conditions in the following form: $u(0, x) = u_0(x)$ and $v(0, x) = v_0(x)$ in Ω; at the boundary, we can prescribe either Dirichlet boundary conditions $V(t, x)/|V(t, x)| = F(x)$, with $F : \partial\Omega \to S^1$ given, for $t \geq 0$ and $x \in \partial\Omega$; or Neumann boundary conditions $\frac{\partial u}{\partial \vec{n}} = 0$ and $\frac{\partial v}{\partial \vec{n}} = 0$ on $\partial\Omega$.

We could add data terms in the energy, as in [9] or [16].

Remark. With these formulations, with both $p = 1$ and $p = 2$ (and, in fact, for any $p \geq 1$), we always have, for any fixed $x \in \Omega$, $u(t, x)u_t(t, x) + v(t, x)v_t(t, x) = 0$, or $u^2(t, x) + v^2(t, x) =$ constant in time for fixed x.

Remark. Note that we have used an artificial time, even if we compute a stationary solution of the problem. This is a common technique, and this artificial time represents a parameterization of the descent direction. It can be shown, in general, that the energy is decreasing in time, under such a time-dependent flow, for both Dirichlet or Neumann boundary conditions (as explained in detail in the appendix).

2.1. The numerical algorithm for the S^1 case. To discretize the systems (2.1) and (2.2), we use finite differences. Assume for simplicity that $U : [0, 1]^M \to S^1$, let h be the space step, and let $\triangle t$ be the time step. We denote by u^n and v^n the approximations of $u(n\triangle t, x)$ and of $v(n\triangle t, x)$, respectively, where x is a grid point. (To simplify the notation, we will not explicitly indicate the discrete point $x_{i,j}$ where the approximation is considered; for instance, if $M = 2$, u^n means $u^n_{i,j}$, etc.; similarly, any expression of the form $(E)^n$ denotes an approximation of the quantity E at $(n\triangle t, x)$, at the same discrete point x; this notational convention will allow us to consider any dimension $M \geq 1$.)

We use the following semi-implicit scheme for (2.1) ($p = 2$):

$$\begin{aligned} \frac{u^{n+1} - u^n}{\triangle t} &= -\frac{v^{n+1} + v^n}{2}\left[\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2+v^2}\right)\right]^n, \\ \frac{v^{n+1} - v^n}{\triangle t} &= +\frac{u^{n+1} + u^n}{2}\left[\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2+v^2}\right)\right]^n, \end{aligned}$$

and similarly for (2.2) ($p = 1$).

Denoting by $(Div)^n$ an approximation of the expression $\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2+v^2}\right)$ evaluated at $(n\triangle t, ih, jh, \ldots)$, and solving the previous algebraic system in u^{n+1} and v^{n+1}, we obtain, for both $p = 1$ and $p = 2$,

$$\begin{aligned} u^{n+1} &= \frac{u^n - \left(2v^n + u^n\frac{\triangle t(Div)^n}{2}\right)\frac{\triangle t(Div)^n}{2}}{1 + \left(\frac{\triangle t(Div)^n}{2}\right)^2}, \\ v^{n+1} &= \frac{v^n + \left(2u^n - v^n\frac{\triangle t(Div)^n}{2}\right)\frac{\triangle t(Div)^n}{2}}{1 + \left(\frac{\triangle t(Div)^n}{2}\right)^2}. \end{aligned}$$

To discretize the expression $\operatorname{div}\left(\frac{u\nabla v - v\nabla u}{u^2+v^2}\right)$, we use the finite difference scheme proposed in [28] for $\operatorname{div}\left(\frac{\nabla u}{|\nabla u|}\right)$ and which has also been used in [2] for a more general case.

Remark. As in the continuous case, it is easy to verify that the numerical solution exactly satisfies

$$(u^{n+1})^2 + (v^{n+1})^2 = (u^n)^2 + (v^n)^2$$

at any grid point x. This proves that the scheme produces bounded solutions independent of the relation between $\triangle t$ and h.

Remark. Note that we do not need to apply a renormalization step at every iteration. Only in the end of the algorithm we let $U = \frac{V}{|V|}$, with $V = (u, v)$. Note also that if the initial data $V_0 = (u_0, v_0)$ already satisfies $|V_0| = 1$ everywhere, then, due to the previous remark, this equality will be preserved in time, and therefore, in the end, the numerical solution U will be directly given by V. (In other words, in this case, there is no need to renormalize V at the steady state; we will simply have $U = V$.)

Remark. Although the solutions remain bounded regardless of the magnitude of $\triangle t$, the numerical domain of dependence of u^{n+1}, v^{n+1} is such that convergence for $p = 2$ is possible only if $\triangle t \leq Ch^2$. This follows from the fact that θ satisfies the heat equation. We verified this by numerical experiments, and found that the quantity θ is noisy if $\triangle t$ is too large, although the solution is bounded. (See Figure 7 for a comparison of results obtained for several values of $\triangle t$.) Convergence for $p = 1$ requires a more restrictive constraint on $\triangle t$, typical of that for total variation minimization [28] in θ.

Remark. Note that additional penalty terms obtained by imposing constraints on V or on $\frac{V}{|V|}$ could be added to the energy or to the Euler–Lagrange equations without any difficulty.

3. The S^2 case. We will follow the same idea as in the previous case, in order to derive the Euler–Lagrange equations associated with the unconstrained minimization problem (1.4), for any $M \geq 1$ and $N = 3$.

Using spherical coordinates, we let

$$U = (\cos\theta_1 \cos\theta_2, \cos\theta_1 \sin\theta_2, \sin\theta_1) \in S^2$$

and

$$V = (r\cos\theta_1 \cos\theta_2, r\cos\theta_1 \sin\theta_2, r\sin\theta_1) = (u, v, w).$$

We then have $r^2 = u^2 + v^2 + w^2$,

$$\theta_1 = \tan^{-1}\left(\frac{w}{\sqrt{u^2+v^2}}\right), \quad \theta_2 = \tan^{-1}\left(\frac{v}{u}\right),$$

and it can be shown that

$$|\nabla U|^2 = |\nabla\theta_1|^2 + \cos^2\theta_1 |\nabla\theta_2|^2.$$

Let us consider first the case $p = 2$. From

$$\inf_{\theta_1,\theta_2} \int_\Omega |\nabla\theta_1|^2 + \cos^2\theta_1 |\nabla\theta_2|^2 dx,$$

we obtain (parameterizing the descent directions by an artificial time t)

$$\theta_{1,t} = \triangle\theta_1 + \sin\theta_1 \cos\theta_1 |\nabla\theta_2|^2, \tag{3.1}$$

$$\theta_{2,t} = \operatorname{div}(\cos^2\theta_1 \nabla\theta_2). \tag{3.2}$$

Let us denote by E_1 and E_2, respectively, the expressions on the right-hand sides of (3.1) and (3.2), i.e.,

$$\theta_{1,t} = E_1, \quad \theta_{2,t} = E_2. \tag{3.3}$$

Again, from $r_t = 0$, we deduce that

$$uu_t + vv_t + ww_t = 0. \tag{3.4}$$

Computing and using

$$\nabla\theta_1 = \frac{(u^2+v^2)(\nabla w) - uw(\nabla u) - vw(\nabla v)}{(u^2+v^2+w^2)\sqrt{u^2+v^2}}, \tag{3.5}$$

$$\nabla\theta_2 = \frac{u(\nabla v) - v(\nabla u)}{u^2+v^2}, \tag{3.6}$$

we can then express E_1 and E_2 as functions of (u, v, w) by

$$E_1 = \triangle\theta_1 + \frac{w\sqrt{u^2+v^2}}{u^2+v^2+w^2}|\nabla\theta_2|^2, \quad E_2 = \operatorname{div}\left(\frac{u(\nabla v) - v(\nabla u)}{u^2+v^2+w^2}\right).$$

On the other hand, we have

$$\theta_{1,t} = \frac{(u^2+v^2)w_t - uwu_t - vwv_t}{(u^2+v^2+w^2)\sqrt{u^2+v^2}}, \quad \theta_{2,t} = \frac{uv_t - vu_t}{u^2+v^2}.$$

We now consider the system formed by (3.3), (3.4) in the unknowns u_t, v_t, and w_t:

$$uu_t + vv_t + ww_t = 0, \quad \frac{(u^2+v^2)w_t - uwu_t - vwv_t}{(u^2+v^2+w^2)\sqrt{u^2+v^2}} = E_1, \quad \frac{uv_t - vu_t}{u^2+v^2} = E_2.$$

Solving this linear system in the unknowns u_t, v_t, and w_t, we deduce the associated Euler–Lagrange equations

$$u_t = -\frac{uw}{\sqrt{u^2+v^2}}E_1 - vE_2, \tag{3.7}$$

$$v_t = -\frac{vw}{\sqrt{u^2+v^2}}E_1 + uE_2, \tag{3.8}$$

$$w_t = \sqrt{u^2+v^2}E_1. \tag{3.9}$$

For the case $p = 1$ of the total variation minimization of Rudin, Osher, and Fatemi [28], we consider first the problem in $\theta = (\theta_1, \theta_2) \in [-\frac{\pi}{2}, \frac{\pi}{2}]^2$:

$$\inf_{\theta_1,\theta_2} \int_\Omega \sqrt{|\nabla\theta_1|^2 + \cos^2\theta_1 |\nabla\theta_2|^2}\, dx,$$

which yields the equations

$$\theta_{1,t} = \operatorname{div}\left(\frac{\nabla\theta_1}{\sqrt{|\nabla\theta_1|^2+\cos^2\theta_1|\nabla\theta_2|^2}}\right) + \frac{\sin\theta_1\cos\theta_1|\nabla\theta_2|^2}{\sqrt{|\nabla\theta_1|^2+\cos^2\theta_1|\nabla\theta_2|^2}},$$
$$\theta_{2,t} = \operatorname{div}\left(\cos^2\theta_1\frac{\nabla\theta_2}{\sqrt{|\nabla\theta_1|^2+\cos^2\theta_1|\nabla\theta_2|^2}}\right).$$

Denoting again by E_1 and E_2 the expressions on the right-hand sides of the above equations (corresponding now to the case $p=1$), these can be expressed as functions of (u,v,w) using (3.5) and (3.6). The Euler–Lagrange equations for the case $p=1$, in (u,v,w), are therefore as in (3.7)–(3.9) but with the corresponding differential operators E_1 and E_2 for $p=1$.

3.1. The numerical algorithm for the S^2 case. The expressions E_1 and E_2 are discretized following [28] and [2] for both $p=1$ and $p=2$. (We will still denote their discretizations at a given point by E_1 and E_2.)

Let us denote by u^n, v^n, w^n the discrete solutions at a discrete point in two or three dimensions (but without writing $u^n_{i,j}$ or $u^n_{i,j,k}$, for simplicity). We discretize the system (3.7)–(3.9) using the following implicit scheme:

$$u^{n+1} = u^n - \frac{\triangle t}{\sqrt{(u^n)^2+(v^n)^2}}u^n\left(\frac{w^{n+1}+w^n}{2}\right)E_1 - \left(\frac{v^{n+1}+v^n}{2}\right)E_2\triangle t,$$
$$v^{n+1} = v^n - \frac{\triangle t}{\sqrt{(u^n)^2+(v^n)^2}}v^n\left(\frac{w^{n+1}+w^n}{2}\right)E_1 + \left(\frac{u^{n+1}+u^n}{2}\right)E_2\triangle t,$$
$$w^{n+1} = w^n + \triangle t\sqrt{(u^n)^2+(v^n)^2}E_1.$$

We will use the notations

$$A = \frac{E_1\triangle t}{2\sqrt{(u^n)^2+(v^n)^2}}, \quad B = \frac{E_2\triangle t}{2}, \quad C = \triangle t\sqrt{(u^n)^2+(v^n)^2}E_1.$$

The linear system in $u^{n+1}, v^{n+1}, w^{n+1}$ is nonsingular and has the unique solution

$$u^{n+1} = \frac{R_1 - BR_2}{1+B^2}, \quad v^{n+1} = \frac{R_2+BR_1}{1+B^2}, \quad w^{n+1} = w^n + C,$$

where $R_1 = u^n - Au^n(2w^n+C) - v^nB$ and $R_2 = v^n - Av^n(2w^n+C) + u^nB$.

Remark. The numerical scheme will exactly satisfy the relation

$$(u^{n+1})^2 + (v^{n+1})^2 + (w^{n+1})^2 = (u^n)^2 + (v^n)^2 + (w^n)^2$$

at each grid point, if in the above discretizations the expression $\sqrt{(u^n)^2+(v^n)^2}$ is replaced by $\sqrt{u^n\left(\frac{u^n+u^{n+1}}{2}\right)+v^n\left(\frac{v^n+v^{n+1}}{2}\right)}$, but this yields a nonlinear system in the unknowns u^{n+1}, v^{n+1}, and w^{n+1}, which could be solved by a fixed-point iteration.

4. Numerical experiments. In this section we present numerical experiments in the cases $M=2$, $N=2$, and $M=2,3$ and $N=3$. We will consider the cases with Dirichlet boundary conditions (subsection 4.1) and Neumann boundary conditions (subsection 4.2).

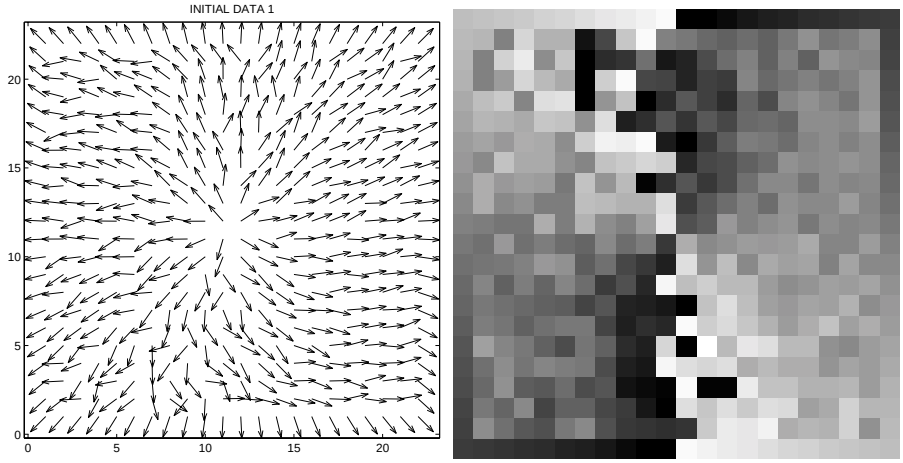

FIG. 1. *Left: initial condition for the Dirichlet problem, as a perturbation of* $\frac{x-x_0}{|x-x_0|}$ *in* $(0,1)^2$*, given by* (4.1)–(4.2)*, and agreeing with* $\frac{x-x_0}{|x-x_0|}$ *at the boundary, where* $x_0 = (0.5, 0.5)$*. Right: corresponding initial angle* $\theta = \tan^{-1}\left(\frac{v^0}{u^0}\right)$.

4.1. Numerical results for prescribed boundary conditions. In the S^1 case, we first consider the Dirichlet problem, with the boundary condition $U(x) = \frac{x-x_0}{|x-x_0|}$ on $\partial\Omega$, with $x_0 = (0.5, 0.5)$, where $\Omega = (0,1)^2$. In this case, it is known that the map $x \mapsto \frac{x-x_0}{|x-x_0|}$ is an exact solution and minimizer in $\overline{\Omega}$. We will show that the numerical solution has the correct behavior, approximating very well the exact solution.

Following [13], an initial condition $V^0 = (u^0, v^0)$ inside Ω can be a perturbation of $\frac{x-x_0}{|x-x_0|}$ (shown in Figure 1, after normalization):

$$u^0(x_1, x_2) = \frac{x_1 - .5}{|x - x_0|} + .6(1 + x_1^2 - x_2^2) - .8\eta, \tag{4.1}$$

$$v^0(x_1, x_2) = \frac{x_2 - .5}{|x - x_0|} + .6(x_1 - 2x_2) + .8\eta, \tag{4.2}$$

for all $(x_1, x_2) \in \Omega$, where η is random noise.

We will also consider another initial condition in this case, defined using the distance function to the boundary as follows: for $(x, y) \in \Omega$, find $(x_b, y_b) \in \partial\Omega$ as the closest point to the boundary $\partial\Omega$ from (x, y). Then let $(u^0(x, y), v^0(x, y)) = U(x_b, y_b)$, where U defines the boundary conditions on $\partial\Omega$. (This second initial condition is shown in Figure 2.)

We now consider the case $p = 2$ for these two initial conditions. For the initial data 1, we also compare the results (the error and the energy decrease) with the classical harmonic map formulation with numerical renormalization at each time step by solving the semidiscrete problem (using central difference approximations for the space derivatives, and with the same prescribed boundary conditions and the same time and space steps):

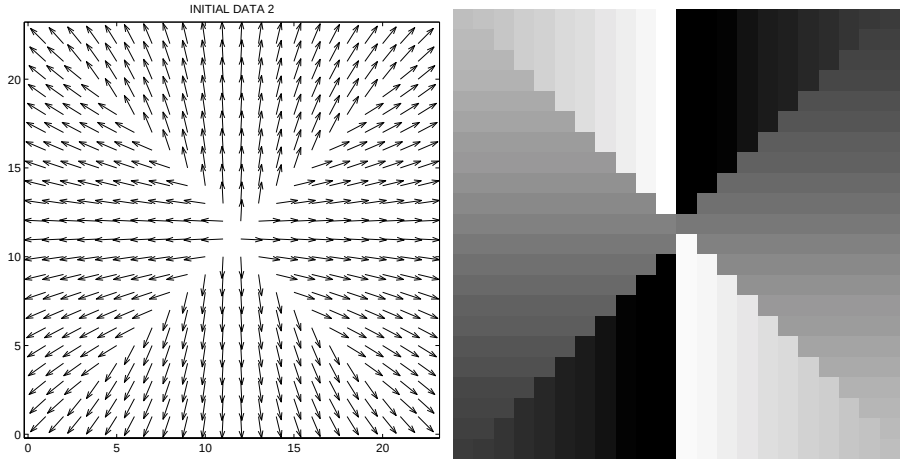

FIG. 2. *Left: another initial condition for the Dirichlet problem, constructed using the closest point to the boundary, and agreeing with* $\frac{x-x_0}{|x-x_0|}$ *at the boundary, where* $x_0 = (0.5, 0.5)$. *Right: corresponding initial angle* $\theta = \tan^{-1}\left(\frac{v^0}{u^0}\right)$.

$$\frac{u_*^{n+1} - u^n}{\triangle t} = \triangle u^n + u^n\Big[(u_x^n)^2 + (u_y^n)^2 + (v_x^n)^2 + (v_y^n)^2\Big],$$
$$\frac{v_*^{n+1} - v^n}{\triangle t} = \triangle v^n + v^n\Big[(u_x^n)^2 + (u_y^n)^2 + (v_x^n)^2 + (v_y^n)^2\Big],$$
$$(u^{n+1}, v^{n+1}) = \frac{(u_*^{n+1}, v_*^{n+1})}{|(u_*^{n+1}, v_*^{n+1})|}.$$

We show the energy decrease and the error versus iterations for the results obtained with the classical harmonic maps applied to the initial data 1, and with the proposed model applied to both initial data 1 and 2 (see Figure 3). Using the proposed model, the error is much smaller. Also, note that the initial data 2 produces a result very fast. For both initial data 1 and 2, by our proposed model, the numerical solution $U(x) = \frac{V(x)}{|V(x)|}$ at the steady state approximates very well the exact solution $\frac{x-x_0}{|x-x_0|}$ in $\Omega = [0,1]^2$, and it is better than using the classical harmonic map scheme with the renormalization at each step.

The results obtained with the proposed model for $p = 2$, for both data, are shown in Figure 4, together with the angle $\theta = \tan^{-1}\left(\frac{v}{u}\right)$.

Corresponding results obtained with the proposed model for $p = 1$ are shown in Figures 5 and 6.

In Figure 7 we show the angle $\theta = \tan^{-1}\left(\frac{v}{u}\right)$, obtained with the initial data 1, for $p = 2$, at the steady state using the proposed model, for different decreasing values of $\triangle t$. This test proves again that if $\triangle t$ is too large, then θ is noisy, but the numerical solution (u^n, v^n) remains bounded. Similar results can be obtained for $p = 1$, with a slightly stronger condition on $\triangle t$, to guarantee the stability of the numerical scheme.

We show next a numerical result for maps with values in S^2 in the three-dimensional case. Following [1], we perform a test, which shows again that, for the Dirichlet boundary conditions, the numerical solution approximates well the exact solution for $p = 2$: in Figure 8, the initial data is to the left, and the result is on the right. We see that the singularity has moved in the center of the domain, this being therefore

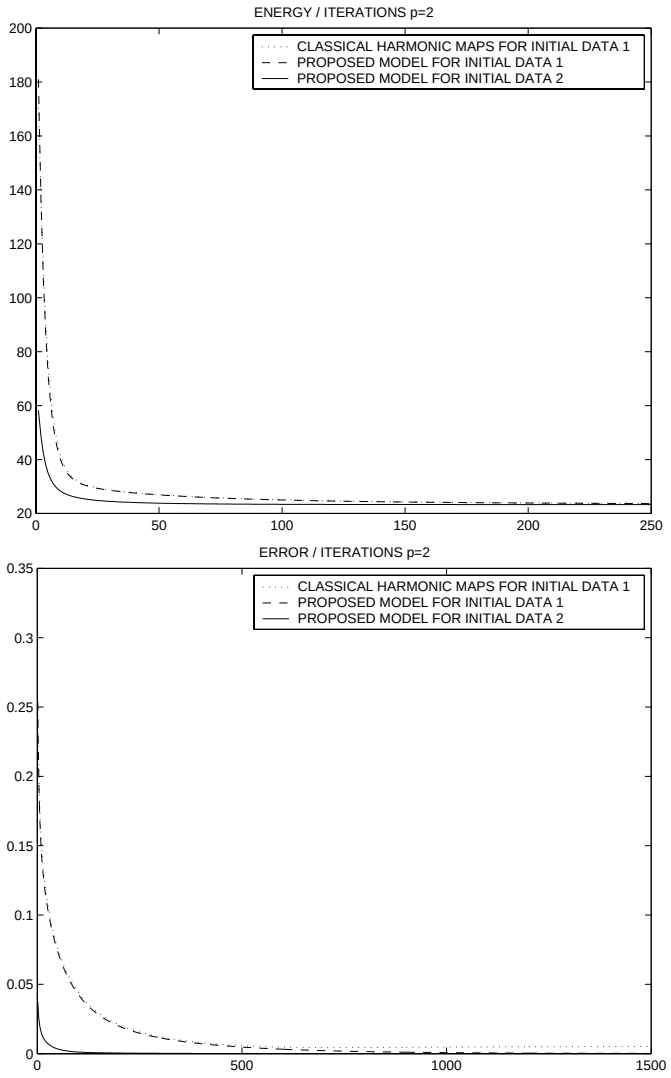

FIG. 3. *Energy and error versus iterations, for the classical harmonic map scheme applied to the initial data* 1*, and for the proposed model applied to both initial data* 1 *and* 2*. Note a much better accuracy obtained with the proposed model, compared with the classical formulation (we use the same* $\triangle t = 0.0001$*,* $h = 1./21$*), for both formulations.*

an approximation of $\frac{x-x_0}{|x-x_0|}$, with $x_0 = (0.5, 0.5, 0.5)$.

4.2. Application to directional denoising and color image denoising. Next, we consider the case with Neumann boundary conditions. For the initial data in Figure 9, the results for $p = 1$ and $p = 2$ are presented in Figure 10. Note that, for $p = 1$ (left), the "edges" are very well preserved, thanks to the total variation minimization [28], while denoising in the homogeneous regions. (We show the results at the steady state and without any fitting term.)

Finally, we show applications more related to denoising of color RGB images. In the first test (Figure 11), we consider a map from $\mathbb{R}^2 \to S^2$, but instead of vectors

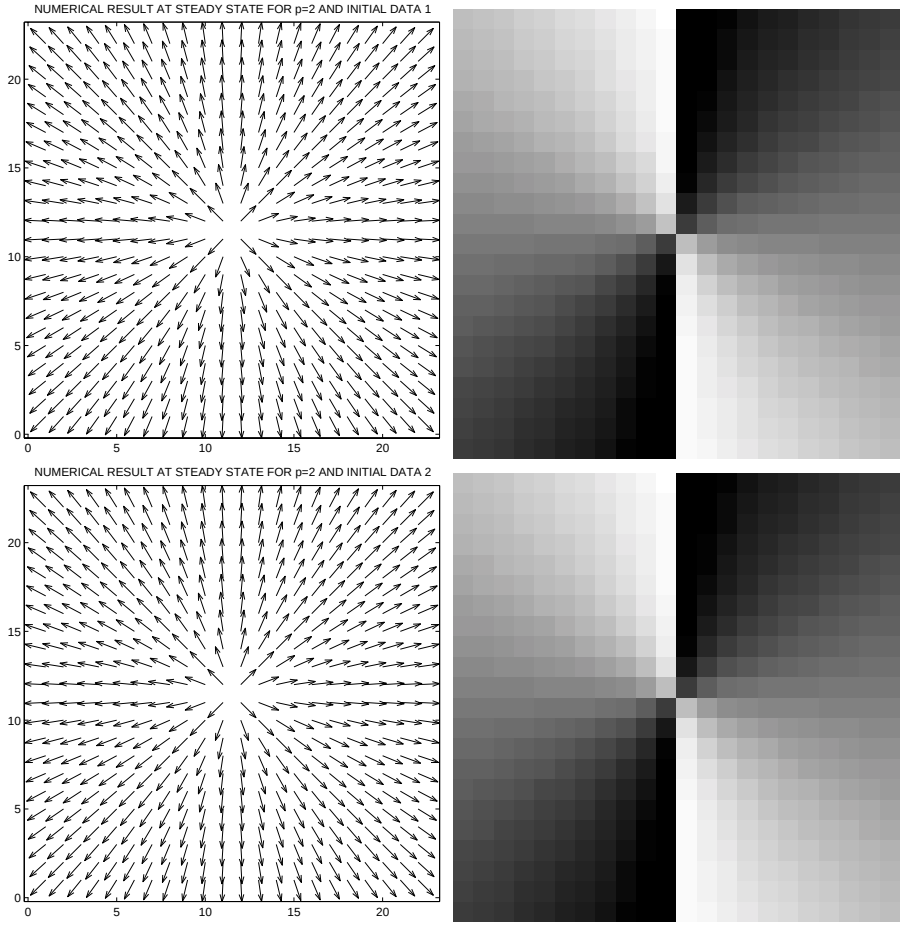

FIG. 4. *Left: numerical result, approximating well the exact solution and minimizer for* $p = 2$*, with Dirichlet boundary conditions* ($\triangle t = 0.0001$, $h = 1/21$)*. Right: corresponding angle* $\theta = \tan^{-1}\left(\frac{v}{u}\right)$.

we plot colors, using the rectangular color space RGB: in Figure 11 (left), we show an initial image of noisy directions. (The components of the unit vector (u, v, w) are visualized as channels in a color RGB picture.) We show in Figure 11 (middle and right) two numerical results in the case of directional diffusion, with $p = 1$ (middle) and $p = 2$ (right), with Neumann boundary conditions. As expected, in the case of the total variation [28], the edges are well preserved, while these are smeared out with the heat flow.

We end the paper with an application to denoising of color RGB images. We consider a color image $I = (I_R, I_G, I_B) \in \mathbb{R}^3$ from which we can extract the intensity or brightness $|I| = \sqrt{I_R^2 + I_G^2 + I_B^2}$ and the chromaticity

$$\frac{I}{|I|} = \left(\frac{I_R}{\sqrt{I_R^2 + I_G^2 + I_B^2}}, \frac{I_G}{\sqrt{I_R^2 + I_G^2 + I_B^2}}, \frac{I_B}{\sqrt{I_R^2 + I_G^2 + I_B^2}} \right) \in S^2.$$

Let us assume that noise has been added to the image but only to the chromaticity $\frac{I}{|I|}$.

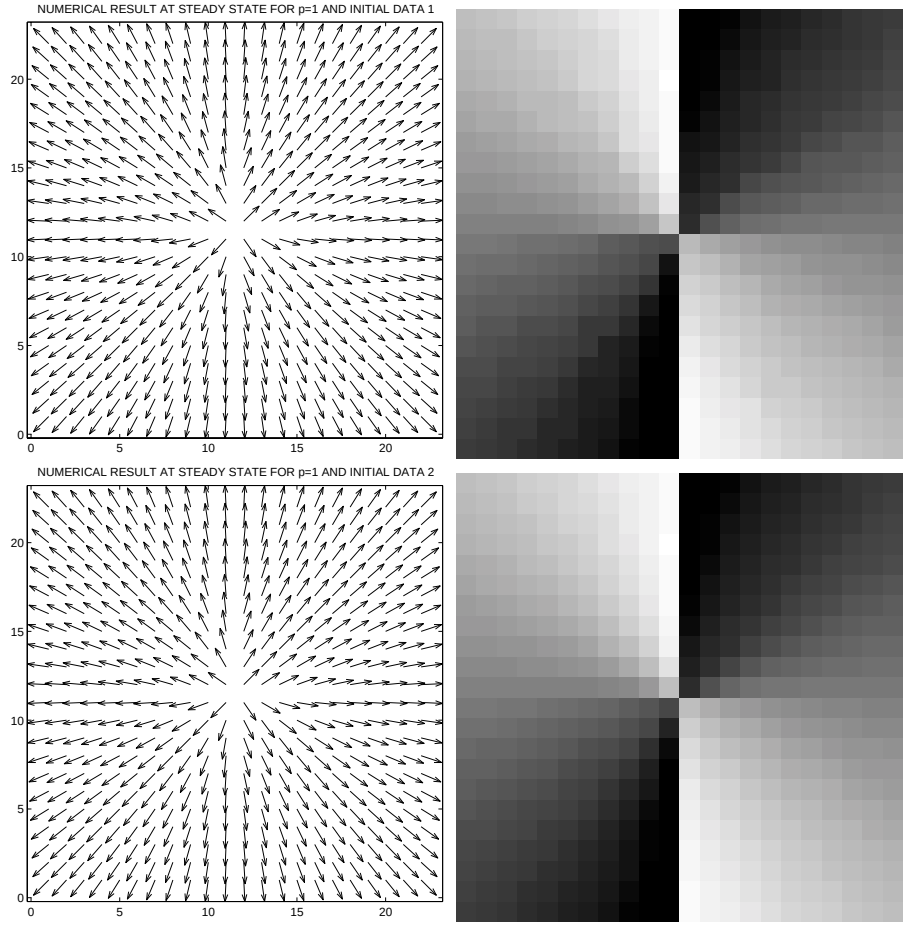

FIG. 5. *Left: numerical result, approximating well the exact solution and minimizer for* $p = 1$*, with Dirichlet boundary conditions* ($\triangle t = 0.00001$*,* $h = 1/21$*). Right: corresponding angle* $\theta = \tan^{-1}\left(\frac{v}{u}\right)$.

Then we can apply the above directional denoising method, with $p = 1$, to the chromaticity. (In this test case, we do not add noise to the brightness $|I|$.) If noise were also added to the brightness, then this could have been denoised, for example, with the corresponding total variation minimization [28] or any other anisotropic diffusion PDE. With the processed result, we obtain a denoised version of the image, using the unchanged brightness. We mention that the idea of decomposing a color RGB image into its brightness and chromaticity, and processing these two quantities separately, has been already used in other works (for example in [21], [40], [41], [38], [39], [9], [32], [23], [33]).

This type of application is illustrated in the last numerical example. In Figure 12, we show an original color RGB image $I = (I_R, I_G, I_B) \in \mathbb{R}^3$ (left), a noisy version (middle), where only the directions $\frac{I}{|I|}$ (the chromaticity) were noisy, keeping the brightness $|I|$ or magnitude of the vectors unchanged, and a denoised version obtained with $p = 1$ (right), where only the chromaticity or directions were denoised, keeping the brightness or magnitude unchanged from the original image, equal to $|I|$.

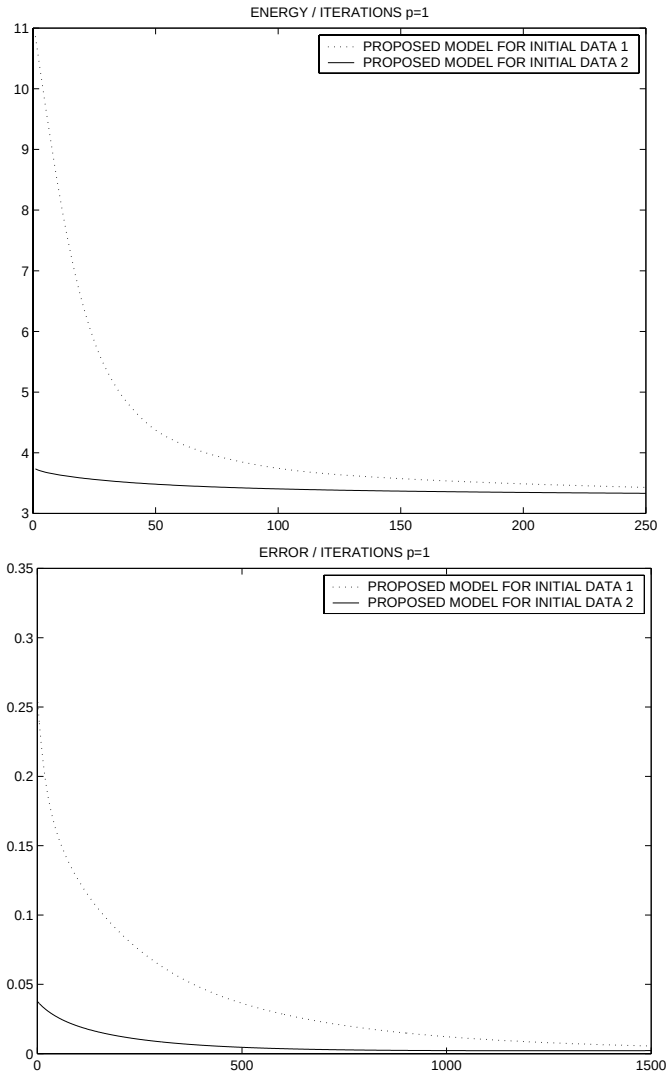

FIG. 6. *Energy and error versus iterations for $p = 1$ with Dirichlet boundary conditions, corresponding to the results in Figure* 5.

5. Concluding remarks and discussions for more general manifolds. In this paper, we have proposed an alternative approach for computing harmonic maps and harmonic flows. We have illustrated the proposed methods by experimental results and comparisons with classical schemes, and applications to directional diffusion and image processing.

It is easy to see that the minimization problems (1.1) and (1.4) have the same infimum, and that solving one problem yields a minimizer for the other one, and vice versa. Of course we cannot expect to have uniqueness of minimizers for (1.4), because λV is a minimizer for any nonzero constant λ if V is a minimizer. Showing the existence of minimizers for (1.4) may be a difficult problem, because the energy is not convex. We have also posed the following question: given Dirichlet boundary

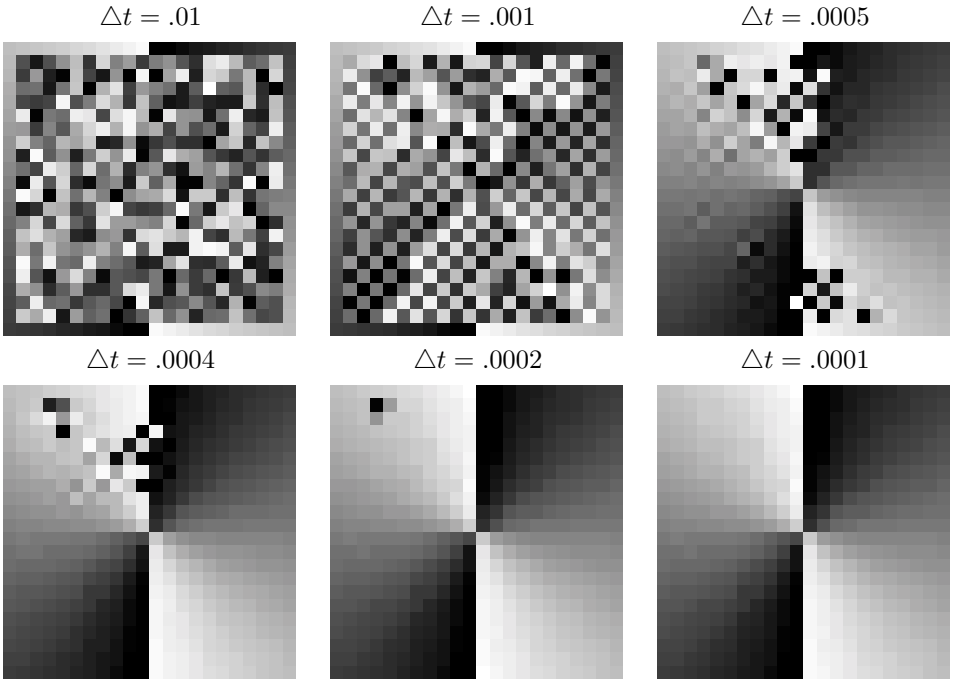

FIG. 7. *The angle* $\theta = \tan^{-1}\left(\frac{v}{u}\right)$ *at the steady state for* $p = 2$*, obtained using the proposed model with Dirichlet boundary conditions, for decreasing values of* $\triangle t$*. (If* $\triangle t$ *is too large,* θ *is noisy, but the numerical solution* (u^n, v^n) *always remains bounded.)*

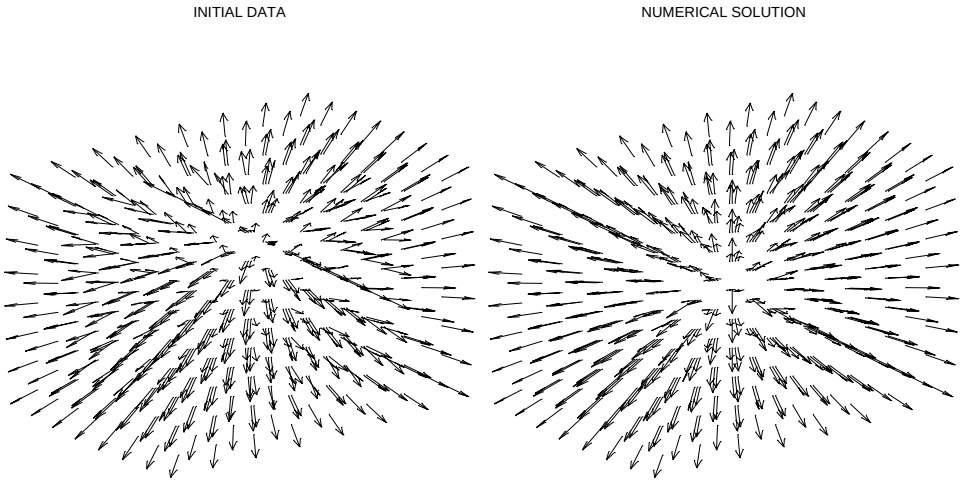

FIG. 8. *Top: initial flow* $\frac{x-x_1}{|x-x_1|}$ *from* $(0,1)^3$ *into* S^2 *with prescribed Dirichlet boundary conditions equal to* $\frac{x-x_0}{|x-x_0|}$*, where* $x_0 = (0.5, 0.5, 0.5)$ *and* $x_1 = (0.64, 0.64, 0.64)$*. Bottom: numerical solution obtained for* $p = 2$*. The singularity has moved to the center of the domain, approximating well the exact solution and minimizer (*$\triangle t = 0.00001$*,* $h = 1/7$*).*

conditions on $\partial\Omega$, what would be a good initial condition in Ω to guarantee a fast computation of a minimizer? (To find a particular initial condition, we have used the distance function to the boundary $\partial\Omega$, although perhaps other choices could also be constructed.)

This method can be extended to more general manifolds. For instance, if we consider a manifold $\mathcal{M} \subset \mathbb{R}^N$, then the associated constrained minimization problem can be formulated as follows:

$$\inf_{U:\Omega\to\mathcal{M}} F(U) = \int_\Omega |\nabla U|^p dx.$$

The proposed method for the case when $\mathcal{M} = S^{N-1}$ can be extended to such general cases if we assume, for example, that $\mathcal{M}$ can be represented implicitly, via a level set function, given by the signed distance function to $\mathcal{M}$, from any other point in $\mathbb{R}^N$. (We refer the reader to [26] for definitions and dynamics of closed hypersurfaces defined implicitly, via level set functions and signed distance functions.) Then we can write $\mathcal{M} = \{x \in \mathbb{R}^N : \ d(x) = 0\}$, where d is the signed distance function to $\mathcal{M}$ (in particular a Lipschitz function, taking real values). To any $U : \Omega \to \mathcal{M}$, we associate $V : \Omega \to \mathbb{R}^N$ such that U is the projection of V on the manifold $\mathcal{M}$. This can be done using the closest point or the projection $U = V - d(V)\nabla_V d(V)$, and we have $d(U) = 0$. Then we can associate the unconstrained minimization problem

$$\inf_{V:\Omega\to\mathbb{R}^N} \int_\Omega |\nabla(V - d(V)\nabla_V d(V))|^p dx.$$

This is a generalization of the case $\mathcal{M} = S^{N-1}$, because in this case we have $d(V) = |V| - 1$, and $V - d(V)\nabla_V d(V) = \frac{V}{|V|}$. We plan to consider in the future the solution of this general unconstrained minimization problem.

We would like to mention that the case of more general manifolds, and in particular of manifolds defined implicitly, has been considered in [3], [4] for the manifold of origin and in [25] for the target manifold, but using different formulations.

We would also like to mention that the idea of solving constrained minimization problems for harmonic maps by associating unconstrained minimization problems has been used as a theoretical tool by Chen and Lin [10], Chen and Struwe [11], and Struwe [37]. They find a smooth energy-minimizing harmonic map U as a weak limit

of minimizers U_L to an unconstrained variational problem for $L \to \infty$. They construct in a different way the unconstrained variational problems.

Appendix. We show here that, parameterizing the descent direction by an artificial time, the energy is still decreasing under the associated flow. (See the last remark from subsection 2.1.) We show this property in a general framework. In order to solve the minimization problem

$$\inf_{u_1,\dots,u_N} \int_\Omega f(u_1,\dots,u_N,\nabla u_1,\dots,\nabla u_N)dx,$$

where $\Omega \subset \mathbb{R}^N$, $x = (x_1,\dots,x_M) \in \mathbb{R}^M$, we associate the time-dependent coupled PDEs for $1 \le i \le N$ (the functions u_i take real values, and we use the notations $u = (u_1,\dots,u_N)$, $\nabla u = (\nabla u_1,\dots,\nabla u_N)$, $(u_i)_{x_j} = \frac{\partial u_i}{\partial x_j}$):

$$\frac{\partial u_i}{\partial t} = -\frac{\partial f(u,\nabla u)}{\partial u_i} + \sum_{j=1}^{M} \frac{\partial}{\partial x_j}\left(\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}\right),$$

with the initial conditions $u_i(0,x) = u_{0,i}(x)$ in Ω. On the boundary $\partial\Omega$, we can assume Dirichlet boundary conditions $u_i(t,x) = u_{0,i}(x)$ for $x \in \partial\Omega$ and $t > 0$, or free boundary conditions in the form $\sum_{j=1}^{M} \frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})} n_j = 0$, where $\vec{n} = (n_1,\dots,n_M)$ is the exterior unit normal to $\partial\Omega$.

We formally compute now $\frac{d}{dt}\int_\Omega f(u_1,\dots,u_N,\nabla u_1,\dots,\nabla u_N)dx = \frac{d}{dt}\int_\Omega f(u,\nabla u)dx$, and we show that this quantity is always negative or zero; therefore the energy is decreasing in time:

$$\begin{aligned}
&\frac{d}{dt}\int_\Omega f(u,\nabla u)dx \\
&= \sum_{i=1}^{N}\int_\Omega \left(\frac{\partial f(u,\nabla u)}{\partial u_i}\right)\left(\frac{\partial u_i}{\partial t}\right)dx + \sum_{i=1}^{N}\int_\Omega \left[\sum_{j=1}^{M}\left(\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}\right)\left(\frac{\partial (u_i)_{x_j}}{\partial t}\right)\right]dx \\
&= \sum_{i=1}^{N}\int_\Omega \left(\frac{\partial f(u,\nabla u)}{\partial u_i}\right)\left(\frac{\partial u_i}{\partial t}\right)dx + \sum_{i=1}^{N}\int_\Omega \left[\sum_{j=1}^{M}\left(\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}\right)\left(\frac{\partial (u_i)_t}{\partial x_j}\right)\right]dx \\
&= \sum_{i=1}^{N}\int_\Omega \left(\frac{\partial f(u,\nabla u)}{\partial u_i}\right)\left(\frac{\partial u_i}{\partial t}\right)dx + \sum_{i=1}^{N}\int_\Omega \left\{-\sum_{j=1}^{M}\left[\frac{\partial}{\partial x_j}\left(\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}\right)\right]\left(\frac{\partial u_i}{\partial t}\right)\right\}dx \\
&\quad + \sum_{i=1}^{N}\left\{\int_{\partial\Omega}\left(\frac{\partial u_i}{\partial t}\right)\left(\sum_{j=1}^{M}\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}n_j\right)dS\right\} \\
&= \sum_{i=1}^{N}\int_\Omega \left(\frac{\partial u_i}{\partial t}\right)\left[\frac{\partial f(u,\nabla u)}{\partial u_i} - \sum_{j=1}^{M}\frac{\partial}{\partial x_j}\left(\frac{\partial f(u,\nabla u)}{\partial((u_i)_{x_j})}\right)\right]dx \\
&= -\sum_{i=1}^{N}\int_\Omega \left(\frac{\partial u_i}{\partial t}\right)^2 dx \;\le\; 0.
\end{aligned}$$

Acknowledgments. The authors would like to thank Guillermo Sapiro for his interest in this work and for his very useful remarks and suggestions. The authors started to work on this subject after one of his visits at UCLA. We also thank him

for providing us the "clown" picture. We would also like to thank Ron Kimmel for interesting discussions and for pointing out to us some related references. Finally, we are grateful to the first unknown referee for his numerous typographical and stylistic corrections, helping to improve the presentation of the paper.

PIECEWISE SELF-SIMILAR SOLUTIONS AND A NUMERICAL SCHEME FOR SCALAR CONSERVATION LAWS*

YONG-JUNG KIM†

Abstract. The solution of the Riemann problem was a building block for general Cauchy problems in conservation laws. A Cauchy problem is approximated by a series of Riemann problems in many numerical schemes. But, since the structure of the Riemann solution holds locally in time only, and, furthermore, a Riemann solution is not piecewise constant in general, there are several fundamental issues in this approach such as the stability and the complexity of computation.

In this article we introduce a new approach which is based on piecewise self-similar solutions. The scheme proposed in this article solves the problem without the time marching process. The approximation error enters in the step for the initial discretization only, which is given as a similarity summation of base functions. The complexity of the scheme is linear. Convergence to the entropy solution and the error estimate are shown. The mechanism of the scheme is introduced in detail together with several interesting properties of the scheme.

Key words. self-similarity, characteristics, front tracking, gridless scheme

1. Introduction.

Self-similarity of the Cauchy problem for one-dimensional conservation laws,

$$\begin{aligned} &v_t + f(v)_x = 0, \\ &v(x,0) = v_0(x), \end{aligned} \qquad x, v \in \boldsymbol{R},\ t > 0, \tag{1.1}$$

with Riemann initial data

$$v(x,0) = \begin{cases} v_-, & x \le 0, \\ v_+, & x > 0, \end{cases} \tag{1.2}$$

has been the basis of various schemes devised for general initial value problems; see Glimm [10] and Godunov [11], for example. The self-similarity of the Riemann problem is the property that the solution is a function of the self-similarity variable $\xi = x/t$. In other words, the solution is constant along the self-similarity lines

$$\frac{x}{t} = \text{constant}. \tag{1.3}$$

The basic idea of the Godunov scheme for a general initial value problem is to approximate the initial data by a piecewise constant function and then apply the self-similarity structure to the series of Riemann problems.

There are two basic issues we have to consider immediately in this approach. First, since the self-similarity for a piecewise constant solution holds locally in time only, the structure of the Riemann solution can be applied for a small time period. In other words, the scheme is not free from the CFL condition (see [4], [5]), and,

hence, the scheme can march just a little amount of time every time step and it costs computation time. Furthermore, since rarefaction waves appear immediately, the solution is not piecewise constant anymore. So a numerical scheme contains a process which rearranges the rarefaction wave into a piecewise constant function every time step. The numerical viscosity enters in this process, and tracking down the behavior of the scheme becomes extremely hard.

LeVeque [20] considers a large time step technique based on the Godunov method for the genuinely nonlinear problem. In the scheme the CFL number may go beyond 1, and it is even possible to solve the propagation of a simple wave in a single step, i.e., $\Delta t = T$ for the given final time $T > 0$. However, the scheme handles interactions between waves incorrectly if the CFL number is so large.

One way to avoid the rearranging process is to consider a modified equation,

$$\begin{array}{l} u_t + h(u)_x = 0, \\ u(x,0) = u_0(x), \end{array} \qquad x, u \in \boldsymbol{R},\ t > 0, \tag{1.4}$$

where h and u_0 approximate f and v_0, respectively. Dafermos [7] considers a polygonal approximation $h \sim f$, i.e., h is continuous and piecewise linear. In this case the exact solution of (1.4) is piecewise constant. So the method does not require a rearranging process, and, therefore, the numerical viscosity is not introduced and the error is controlled by refining the polygonal approximation h. In this approach, the exact behavior of the numerical solution can be monitored more closely and we may get a more detailed understanding of the scheme. This idea has been developed in Holden and Holden [12], and it has been extended to multidimensional problems in Holden and Risebro [14] and to systems of conservation laws in Holden, Lie, and Risebro [13]. In particular, we refer to Bressan [2], [3] for systems. This front tracking method has been developed as a computational tool (e.g., [21], [22]).

Lucier [24] approximates the actual flux f by a piecewise parabolic function h and achieves a second order scheme. In this case, the initial data $v_0(x)$ are approximated by a piecewise linear function u_0 and the solution remains piecewise linear. The difference between the solutions of the original problem (1.1) and the modified problem (1.4) is estimated by

$$||v(\cdot,t) - u(\cdot,t)||_1 \le ||v_0 - u_0||_1 + t||f' - h'||_\infty ||v_0||_{BV}. \tag{1.5}$$

Since the linear approximation is of second order, he achieves a second order scheme for a fixed time $t > 0$.

If we want to design a numerical scheme which represents the exact solution, we have to find a way to choose grid points correctly. If they are simply fixed, it is clear that the scheme cannot represent the exact solution and, hence, we need to rearrange the solution to fit the solution to the fixed grid points. So it is natural to consider the moving mesh method; see Miller [25]. In Lucier [24] the moving mesh method is used to find the exact solution of (1.4), where mesh points move along characteristics. Another option is not to use any grid point. In numerical schemes based on the front tracking method mentioned earlier, grid points are used just for the initial discretization. The scheme we develop in this article does not use any grid point either.

This article has two goals. The first one is to introduce the mathematical idea which is behind the piecewise self-similar solutions. The second one is to demonstrate how to implement the idea into a numerical scheme and show properties of the scheme. From the study of the Burgers equation (see [17] or Whitham [26]), it is well known

that the primary structure which dominates the evolution is a saw-tooth profile. In fact, this profile is a series of N-waves and eventually the solution evolves to a single N-wave; see Liu and Pierre [23]. The starting point of our scheme is to use this structure as the unit of the scheme.

If a solution $u(x,t)$ is a function of the self-similarity variable $\xi = x/t$, then we can easily derive from (1.1) that

$$f'(u(x,t)) = x/t.$$

Roughly speaking, a piecewise self-similarity (initial) profile has the structure of

$$f'(u(x,0)) = \frac{x - c_k}{t_k}, \qquad x \in (a_k, b_k),\ c_k, t_k \in \boldsymbol{R}. \tag{1.6}$$

Note that the time index t_k can be a negative number. In this article, we observe that the solution of (1.1) with piecewise self-similarity initial profile has such a structure for all $t > 0$, i.e.,

$$f'(u(x,t)) = \frac{x - c_k}{t + t_k}, \qquad x \in (a_k(t), b_k(t)),\ c_k, t_k \in \boldsymbol{R},\ t \in \boldsymbol{R}^+, \tag{1.7}$$

and we give the explicit formula for this kind of solution in several situations. First we consider a convex flux with positive wave speed,

$$f''(u) \geq 0, \quad f'(u) \geq 0, \tag{H}$$

where f is locally Lipschitz continuous. The convexity of the flux $f''(u) \geq 0$ is used to get the explicit formula $g(x)$ of the self-similarity profile such that $f'(g(x)) = x$, and the self-similarity profile (1.7) can be written as

$$u(x,t) = g\Big(\frac{x - c_k}{t + t_k}\Big), \qquad x \in (a_k(t), b_k(t)),\ c_k, t_k \in \boldsymbol{R},\ t \in \boldsymbol{R}^+. \tag{1.8}$$

Note that the equality is included for the second derivative of the flux in (H), and, hence, the monotonicity of f' is not strict and $g(x)$ is not exactly the inverse function of f', and $g(f'(u)) \neq u$ in general. In this approach, we may include a piecewise linear flux of the front tracking method; see Remark 6.4.

Our approach is as follows. We start our discussion reviewing the self-similarity property in conservation laws in section 2. This discussion leads us to the study of piecewise self-similar solutions, which is the case when the self-similarity lines and characteristics are compatible. In section 3 we consider a piecewise self-similar solution which can be written as a *self-similarity summation* (or simply *S-summation*),

$$\bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x), \quad c_n < \cdots < c_2 < c_1, \tag{1.9}$$

of a finite number of base functions. We give definitions for the S-summation and base functions in the section and show that $u(x,t) = \bigodot_{k=1}^{n} B_{m_k,t+t_k,c_k}(x)$ is the solution of (1.1) with initial data $u_0(x) = \bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x)$; see Theorem 3.6. We consider u as an approximation of the solution v with the original initial data v_0. Then the L^1 contraction theory of conservation laws (see Hörmander [15], Kruzhkov [18], [19]) implies

$$||v(\cdot,t) - u(\cdot,t)||_1 \leq ||v_0 - u_0||_1. \tag{1.10}$$

It is the estimate corresponding to the error estimate (1.5), which does not have the time dependent term anymore. It is natural to expect that the error increases in time if the flux is changed. In our approach, we use the original flux and the error decreases in time. In fact, the left-hand side of (1.10) is of order $O(t^{-1})$; see [16]. The convergence of the scheme is now clear (see Theorem 3.6, Corollary 3.7). Note that the S-summation (1.9) represents only a special kind of piecewise self-similar profile in (1.6), which has positive indexes $t_k > 0$ and is ordered appropriately, i.e., $c_n < \cdots < c_2 < c_1$ if $a_n \le b_n \le \cdots \le a_2 \le b_2 \le \cdots \le a_1 \le b_1$.

The S-summation is successfully coded for a numerical scheme in section 4. This scheme has several unique properties. First, it does not require a time marching procedure. So the complexity of the scheme is of order $O(N)$, not $O(N^2)$. CPU times for several cases are compared in section 4.3. Second, it captures the shock location very well even if a small number of base functions (or mesh points) are used; see Figure 4.5. In the figure it is clearly observed that the solution with finer mesh always passes through bigger artificial shocks. Since it does not introduce numerical viscosity at all, we obtain a very good resolution for an inviscid problem. This scheme also distinguishes physical shocks and artificial ones clearly. Table 4.4 shows the time when the physical shock appears.

In section 5 we generalize the method. For a general convex flux, i.e.,

$$f''(u) \ge 0, \tag{H1}$$

the method is applied through the transformations (5.1) and (5.3). If the flux has inflection points, then the scheme becomes considerably complicated and it is beyond the purpose of this article. But, if the flux has only one inflection point, for example,

$$f''(u) \le 0 \text{ for } u \le A, \quad f''(u) \ge 0 \text{ for } u \ge A, \tag{H2}$$

then we can easily apply the scheme through a similar transformation (5.4). Dafermos [8] considers a flux with a single inflection point through generalized characteristics. The Buckley–Leverett equation satisfies this condition. The flux $f(u) = u^2 - u^3$, which appears in thin film flows (see Bertozzi, Münch, and Shearer [1]), also belongs to this category. Figure 5.2 shows the strength of our scheme over the Godunov scheme in this case.

The scheme is not good enough for a short time behavior $t \ll 1$ since the initial error $||v_0 - u_0||_1$ is not controlled efficiently. To resolve this issue we add an extra structure to base functions in section 6. Using these base functions, we can approximate the initial data with second order accuracy and solve the solution for the modified initial datum. Furthermore, a general piecewise self-similarity profile (1.6) can be written in terms of S-summation of these modified base functions.

2. Self-similarity in conservation laws. Consider one-dimensional scalar conservation laws,

$$\begin{array}{l} u_t + f(u)_x = 0, \\ u(x,0) = u_0(x), \end{array} \quad x, u \in \boldsymbol{R},\ t > 0, \tag{2.1}$$

where the flux f is locally Lipschitz continuous. For a nonlinear flux $f(u)$ the solution may have a singularity, and hence the solution is considered in the weak sense with the entropy admissibility condition:

$$\frac{f(\tilde{u}) - f(u_-)}{\tilde{u} - u_-} \ge \frac{f(u_+) - f(u_-)}{u_+ - u_-}, \tag{2.2}$$

for any number $\tilde{u}$ lying between $u_+ = u(x+,t)$ and $u_- = u(x-,t)$. It is well known that the self-similarity of a conservation law is inherited from the fact that a rescaled function,

$$w(x,t) = u(ax,at), \quad a > 0, \tag{2.3}$$

is also the solution of (2.1) if and only if the initial profile $u_0(x)$ satisfies

$$u_0(x) = u_0(ax), \quad a > 0. \tag{2.4}$$

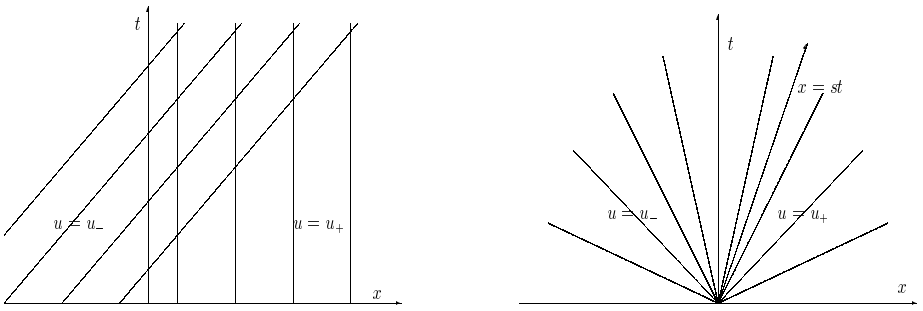
It is clear that, if the Riemann initial value,

$$u(x,0) = \begin{cases} u_-, & x < 0, \\ u_+, & x > 0, \end{cases} \tag{2.5}$$

is given, (2.4) is satisfied and, hence, $u(x,t) = u(ax,at)$ for all $a > 0$. Therefore, $u(x,t)$ is a function of the self-similarity variable,

$$u(x,t) = u(\xi), \qquad \xi = x/t. \tag{2.6}$$

The structure of a Riemann solution is given in Figure 2.1 together with characteristic lines. Note that, even though a self-similarity line $x/t = \xi$, $\xi \in \boldsymbol{R}$, is not a characteristic line, the solution is constant along it. This is a special property of the Riemann problem, and it is not expected in a general Cauchy problem.



(a) *Characteristic lines* (b) *Self-similarity lines*

FIG. 2.1. *Let $f'(u_+) = 0$ and $f'(u_-) = 1$. Then self-similarity lines are different from characteristic lines. However, the solution is constant along self-similarity lines.*

If the total mass of the initial data $u_0(x)$ is finite, i.e.,

$$\int |u_0(x)|dx < \infty, \tag{2.7}$$

then the relation (2.4) cannot be satisfied since the transformation $u_0(x) \to u_0(ax)$ does not preserve the total mass. So the solution cannot be a function of self-similarity variable $\xi = x/t$. In the following, we consider techniques to achieve the Riemann solution like self-similarity for general Cauchy problems.

Suppose that characteristic lines of the solution $u(x,t)$ pass through the origin. Then the relation between the wave speed and characteristics gives

$$f'(u) = \frac{x}{t}. \tag{2.8}$$

Since the right-hand side diverges as $t \to 0$, we consider the initial datum as the profile at a given time $t_0 > 0$. The simplest case of L^1 initial datum of the kind is

$$f'(u(x,0)) = \frac{x}{t_0} \text{ if } 0 < x < s_0, \qquad u(x,0) = 0 \quad \text{otherwise.} \tag{2.9}$$

Characteristic lines of this initial profile are given in Figure 2.2. Nonvertical characteristics pass through the point $(0, -t_0)$, and there is a region in which characteristic lines overlap with each other. The solution is given by finding the shock characteristic $x = s(t)$ correctly. In this case, the shock characteristic $x = s(t)$ is not a straight line and the solution is not a function of $x/(t+t_0)$. However, the solution is a function of $x/(t+t_0)$ in the region $0 < x < s(t)$, i.e.,

$$f'(u(x,t)) = \frac{x}{t+t_0} \text{ if } 0 < x < s(t), \qquad u(x,t) = 0 \quad \text{otherwise.} \tag{2.10}$$

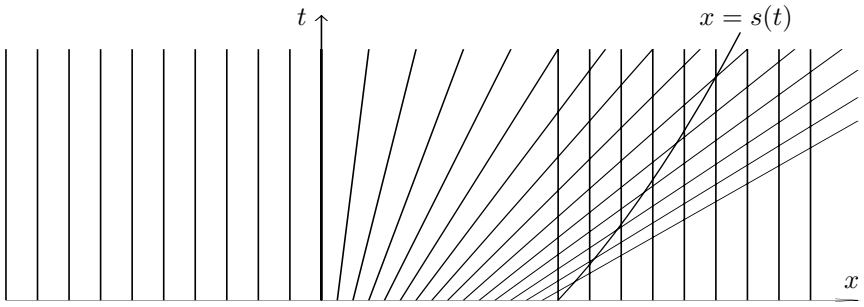


FIG. 2.2. *Characteristic lines of a self-similarity solution are similar to self-similarity lines. The main difference is that the shock characteristic is not a straight line anymore.*

Since the shock speed $s'(t)$ satisfies the Rankine–Hugoniot jump condition, the shock location $s(t)$ can be found by its integral form. On the other hand, if the convexity of the flux f is assumed, i.e.,

$$f''(u) \geq 0,$$

we may consider the self-similarity profile $g(x)$ such that $f'(g(x)) = x$. In this case we obtain

$$u(x,t) = g\big(x/(t+t_0)\big), \qquad 0 < x < s(t), \tag{2.11}$$

and we can easily find the shock location $s(t)$ using the equal area rule,

$$\int_0^{s(t)} g(x/(t+t_0))dx = \int_0^{s_0} g(x/t_0)dx, \quad t > 0. \tag{2.12}$$

Since the conservation law (2.1) does not explicitly depend on the x variable, we may translate the initial data (2.9) in the x-direction. We can also consider initial data which consist of a finite number of structures in (2.9). A simple example is

$$u_0(x) = \sum_{k=1}^{N} g\Big(\frac{x - c_k}{t_k}\Big)\chi_{(c_k, s_k)}, \tag{2.13}$$

where centers c_k and shock locations s_k satisfy

$$-\infty < c_N < s_N < \cdots < c_1 < s_1 < \infty. \tag{2.14}$$

The time indexes $t_k > 0$ in (2.13) decide the slope of the initial profile, and they do not need to be identical. Condition (2.14) implies that all the profiles in (2.13) are separated. If not, the simple summation in (2.13) breaks down the self-similarity structure we want to keep. In section 3 we consider an S-summation which preserves this structure. Figure 2.3 shows characteristic lines for initial data (2.13) with $N = 4$. In this case, tracking down a shock is more complicated and (2.12) is not valid anymore. The following section is devoted to handling the general case.

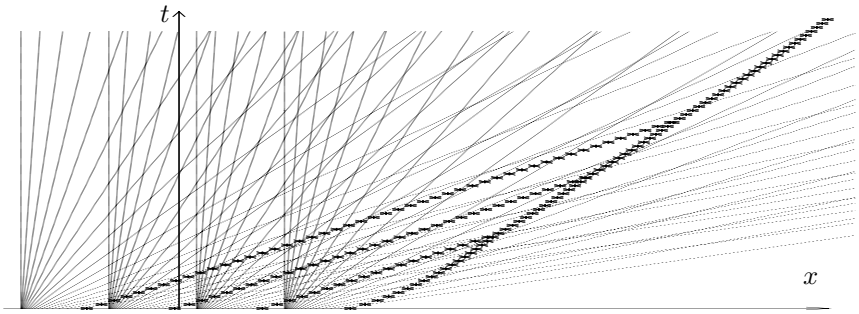

FIG. 2.3. *Shock characteristics (dots) are merged together after contacts among them, and a bigger shock appears which is a physical one.*

3. Piecewise self-similar solutions. In this section we define the S-summation and show that, if the initial value $u_0(x)$ is given as an S-summation, then so is the solution $u(x,t)$ of (2.1) at any given time $t > 0$. We consider the flux under the hypothesis,

$$f''(u) \geq 0, \quad f'(u) \geq 0, \tag{H}$$

and the self-similarity profile $g(x)$ satisfies $f'(g(x)) = x$. We may assume $f'(0) = 0$ without the loss of generality, and it implies that the solution is actually assumed to be positive under (H). The results in this section are generalized in section 5.

3.1. Base functions. As was mentioned earlier, the self-similarity profile

$$u(x,t) = g(x/t), \qquad t > 0, \tag{3.1}$$

represents the asymptotic behavior of the conservation law (1.1). A triple index function $B_{t,c,s}(x)$, defined by

$$B_{t,c,s}(x) = \begin{cases} g\big((x-c)/t\big), & c < x < s, \\ 0, & \text{otherwise}, \end{cases} \tag{3.2}$$

serves as a base function in this article. A base function has the self-similarity profile over the interval between the *center* c and the *shock location* s. The *area* (or *mass*) m enclosed by the x-axis and the base function is given by

$$m = \int_c^s B_{t,s,c}(x)dx = \int_0^{s-c} g(x/t)dx =: m(t,c,s). \tag{3.3}$$

It is convenient to consider the mass m as the fourth index of the base function, say, $B_{m,t,c,s}(x)$, or any three of them as an index set. In any case we always assume that indexes m, t, c, s satisfy the relation (3.3), i.e., if any three of them are given, the fourth one is decided by the relation.

Consider a Cauchy problem,

$$\begin{aligned} u_t + f(u)_x &= 0, \\ u(x,0) &= B_{m_0,t_0,c_0,s_0}(x). \end{aligned} \tag{3.4}$$

It is already observed in (2.10) that the solution $u(\cdot,t)$ has the self-similarity profile with time index $t+t_0$ between the original center c_0 and a new shock location $s(t)$. Since the initial total mass m_0 should be preserved, the solution of (3.4) is

$$u(x,t) = B_{m_0,t+t_0,c_0}(x), \tag{3.5}$$

where the shock location $x = s(t)$ is decided by the relation (3.3).

Remark 3.1. If we take a δ-function as the initial datum, for example, $u_0(x) = m_0\delta(x-c_0)$, then the solution is $u(x,t) = B_{m_0,t,c_0}(x)$. So the slope of the base function represents the time of the evolution starting from the δ-function-like initial data, and that is why we take index t for the base function.

Remark 3.2. For the Burgers case, $f(u) = u^2/2$, the self-similarity profile is the identity function, $g(x) = x$. In this case, (3.3) gives explicit relations,

$$m = (s-c)^2/(2t), \quad t = (s-c)^2/2m, \quad s = c + \sqrt{2mt}, \quad c = s - \sqrt{2mt}\,. \tag{3.6}$$

Remark 3.3. The rescaling (2.3) does not preserve the total mass. So it can not measure the invariance property for L^1 solutions of conservation laws. For the Burgers case, $f(u) = u^2/2$, we may consider

$$v(x,t) = au(ax, a^2t), \quad a > 0, \tag{3.7}$$

where the rescaling preserves the total mass. We can easily check that variables

$$w = \sqrt{t+t_0}\,u, \qquad \zeta = (x-c_0)/\sqrt{t+t_0}, \qquad \tau = \ln(t+t_0), \tag{3.8}$$

are invariant under the rescaling after the translation $x - c_0 \to x$, $t + t_0 \to t$. These variables are called self-similarity variables for L^1 Cauchy problems, and the Cauchy problem (3.4) is transformed to

$$\begin{aligned} w_\tau + \tfrac{1}{2}(w^2 - \zeta w)_\zeta &= 0, \\ w(\zeta, \ln(t_0)) &= B_{m_0,t_0=1,c_0=0}(\zeta). \end{aligned} \tag{3.9}$$

We can easily check that $B_{m_0,t_0=1,c_0=0}(\zeta)$ is an admissible steady state of the equation, and hence $w(\zeta,\tau) = B_{m_0,t_0=1,c_0=0}(\zeta)$ is the solution of (3.9). If we transform the variables back to u, t, x, then we get $u(x,t) = B_{m_0,t+t_0,c_0=0}(x)$. This is another way to show (3.5). In this example we can see that the approach with piecewise self-similar solutions captures the self-similarity of the general Cauchy problems exactly. For a detailed study of the transformed problem (3.9), we refer to [17].

3.2. S-summation. Since the solution of (3.4) is given by (3.5), we can easily guess that

$$u(x,t) = \sum_{k=1}^{n} B_{m_k,t_k+t,c_k}(x) \tag{3.10}$$

is the solution of the conservation law with initial data

$$u_0(x) = \sum_{k=1}^{n} B_{m_k,t_k,c_k}(x), \quad c_n < \cdots < c_2 < c_1, \tag{3.11}$$

if all the supports of the base functions in (3.10) are disjoint. But it is not usually the case since the support of a base function expands in time. The S-summation,

$$B_n(x) = \bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x), \quad c_n < \cdots < c_2 < c_1, \tag{3.12}$$

is to handle the case that supports of base functions overlap with each other. The definition is given inductively in the following.

Let $B_1(x) = B_{m_1,t_1,c_1}(x)$. Suppose that $B_{j-1}(x) = \bigodot_{k=1}^{j-1} B_{m_k,t_k,c_k}(x)$, $j \le n$, is well defined, $\mathrm{supp}(B_{j-1}) \subset [c_{j-1}, \infty)$, and that $\int_{c_{j-1}}^{\infty} B_{j-1}(x)dx = \sum_{k=1}^{j-1} m_k$. Consider a point $\xi_j \in \boldsymbol{R}$ such that $c_j < \xi_j$,

$$g\big((x-c_j)/t_j\big) > B_{j-1}(x), \qquad c_j < x < \xi_j, \tag{3.13}$$

$$\int_{c_j}^{\xi_j} g\big((x-c_j)/t_j\big)dx + \int_{\xi_j}^{\infty} B_{j-1}(x)dx = \sum_{k=1}^{j} m_k. \tag{3.14}$$

Under assumption (3.13), the left-hand side of (3.14) is monotone in ξ_j and, hence, such a point is unique. If there exists such a point $\xi_j > c_j$, we define

$$B_j(x) = \bigodot_{k=1}^{j} B_{m_k,t_k,c_k}(x) = \begin{cases} g\big((x-c_j)/t_j\big), & c_j < x < \xi_j, \\ B_{j-1}(x), & \text{otherwise.} \end{cases} \tag{3.15}$$

Clearly, $\mathrm{supp}(B_j) \subset [c_j, \infty)$ and $\int_{c_j}^{\infty} B_j(x)dx = \sum_{k=1}^{j} m_k$, and we may continue the inductive argument. If not, the S-summation (3.12) is not defined.

Base functions are ordered by centers c_k, and then the S-summation is given from the right-hand side. It is because of the positiveness assumption for the wave speed, $f'(u) \ge 0$, in (H). If the order of the summation is changed, the result is different. So the S-summation is not associative.

Remark 3.4. If the time indexes are identical, $t_k = t_0$, for all k, then we can show the S-summation (3.12) is well defined. Then, since the self-similarity profile $g(x)$ is an increasing function, we have $g\big((x-c_j)/t_0\big) > g\big((x-c_k)/t_0\big)$ for all $k < j$. Since $B_{j-1}(x)$ has values of $g\big((x-c_k)/t_0\big)$, $k < j$, piecewise, the inequality (3.13) is satisfied for all $\xi_j > c_j$. Furthermore the left-hand side of (3.14) has value $\sum_{k=1}^{j-1} m_k$ for $\xi_j = c_j$ and diverges to ∞ as $\xi_j \to \infty$. So there exists a point ξ_j satisfying (3.14), and the S-summation is well defined.

Remark 3.5. We may consider ξ_j as the location of the jth (artificial) shock generated by the base function B_{m_j,t_j,c_j}. Suppose that $\xi_{j-1} < \xi_j$, i.e., the jth shock caught up the $(j-1)$st shock. The definition (3.15) implies that the self-similarity profile $g\big((x-c_{j-1})/t_{j-1}\big)$ disappears. We can easily check that we will get the same S-summation (3.15) if we remove the $(j-1)$st base function and increase m_j by adding m_{j-1}. This property represents the irreversibility of conservation laws and plays the key role in the numerical scheme (see section 4.2, Step 2).

THEOREM 3.6. *Suppose that* $f''(u) \geq 0$ *and* $f'(u) \geq 0$. *If the S-summation* $u_0(x) \equiv \bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x)$ *is well defined, then* $u(x,t) \equiv \bigodot_{k=1}^{n} B_{m_k,t_k+t,c_k}(x)$ *is also well defined for all* $t > 0$ *and it solves* (1.1) *with its initial value* $u_0(x)$. *If* $v(x,t)$ *is the entropy solution of* (1.1) *with its initial value* $v_0 \in L^1$, *then*

$$||v(\cdot,t) - u(\cdot,t)||_1 \leq ||v_0 - u_0||_1. \tag{3.16}$$

Proof. We may assume $f'(0) = 0$ without the loss of generality. The proof is completed through inductive arguments. In section 2, we have shown the theorem for $n = 1$. Now we show the theorem for $n = j > 1$ assuming that it holds for $n = j - 1$. Note that, from the definition, the S-summation $\bigodot_{k=1}^{i} B_{m_k,t_k,c_k}(x)$ is well defined for any $i \leq n$.

Let $u_{j-1}(x,t)$ be the solution of (1.1) with its initial value $\bigodot_{k=1}^{j-1} B_{m_k,t_k,c_k}(x)$. From the assumption, $u_{j-1}(x,t) = \bigodot_{k=1}^{j-1} B_{m_k,t_k+t,c_k}(x)$. Let $u_j(x,t)$ be the solution with $u_j(x,0) = \bigodot_{k=1}^{j} B_{m_k,t_k,c_k}(x)$ and $x = \xi_j(t)$ be the shock characteristic given by the jth base function, i.e., $\xi_j(0)$ is the same as the ξ_j in (3.13)–(3.14). Consider a backward characteristic, associated with $u_j(x,t)$, that emanates from a point (x,t), $x > \xi_j(t)$. From the admissibility of the shock, it does not interact with $x = \xi_j(\tau)$, $\tau < t$, and, hence, it is actually the one associated with $u_{j-1}(x,t)$. So we have $u_j(x,t) = u_{j-1}(x,t)$.

For $x < c_j$, $u_j(x,t) = 0$ since the (vertical) forward characteristic that emanates from a point $(x,0)$, $x < c_j$, does not intersect with shock characteristics which move to the right-hand side under the assumption $f'(u) \geq 0$. The backward characteristic that emanates from a point (x,t), $c_j < x < \xi_j(t)$, is a straight line connecting $(c_j, -t_j)$ since the initial profile over the interval $(c_j, \xi_j(0))$ is self-similar. Hence, $u_j(x,t) = g\big((x-c_j)/(t+t_j)\big)$ for $c_j < x < \xi_j(t)$, and the shock location $x = \xi_j(t)$ should satisfy

$$\int_{c_j}^{\xi_j(t)} g\big((x-c_j)/(t+t_j)\big)dx + \int_{\xi_j(t)}^{\infty} u_{j-1}(x,t)dx = \sum_{k=1}^{j} m_k$$

since the total mass is preserved. So $u_j(x,t) = \bigodot_{k=1}^{j} B_{m_k,t_k+t,c_k}(x)$ from the definition of the S-summation, and the first part of the proof is complete. The second part (3.16) is simply the L^1 contraction theory for conservation laws. ∎

In the proof we employ the theory of characteristics (see [9, Chap. 11]). The error estimate (3.16) implies that the initial error decreases in time. In fact, the error is of order $O(t^{-1})$ as $t \to \infty$ (see [16] for detail). The scheme has ideal properties for the study of asymptotic behavior.

Now we consider $u_0(x) = \bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x)$ as an approximation of L^1 initial value v_0. Let a partition $\mathcal{C} = \{c_n < \cdots < c_1\}$ be the set of centers. Its norm is defined by $||\mathcal{C}|| = \max |c_k - c_{k-1}|$. There can be many ways to discretize the initial value. To guarantee the convergence of the scheme, we need the existence of $\delta, L > 0$ such that

$$||v_0(x) - u_0(x)||_1 \leq \varepsilon \quad \text{if} \quad ||\mathcal{C}|| \leq \delta \text{ and } c_n < -L, L < c_1, \tag{3.17}$$

where a constant $\varepsilon > 0$ is given. An example of such a discretization is given in section 4.2. The convergence of the scheme satisfying (3.17) is clear from (3.16).

COROLLARY 3.7 (convergence). *The scheme of the S-summation* $u(x,t) = \bigodot_{k=1}^{n} B_{m_k,t+t_k,c_k}(x)$ *with initial discretization* $u_0(x) = \bigodot_{k=1}^{n} B_{m_k,t_k,c_k}(x)$ *satisfying* (3.17) *converges to the entropy solution* $v(x,t)$ *with initial data* $v_0 \in L^1(\boldsymbol{R})$ *as* $\delta \to 0$, $L \to \infty$.

Remark 3.8. Now we consider the S-summation between two base functions, $\bigodot_{k=1}^{2} B_{m_k,t_k,c_k}(x)$, $c_2 \le c_1$ (see Figure 3.1). It gives a good example for figuring out the meaning of the S-summation. Furthermore, in the numerical computation, we can possibly compare only two base functions each time and, hence, it is worth considering it in detail. If these two base functions are separated, i.e., $s_2 < c_1$, then the shock place ξ of the definition (3.15) is simply $\xi = s_2$. If $c_1 < s_2$, then ξ satisfies

$$\int_{c_2}^{\xi} g\Big(\frac{x-c_2}{t_2}\Big)dx + \int_{\xi}^{\max(\xi,s_1)} g\Big(\frac{x-c_1}{t_1}\Big)dx = m_1 + m_2. \tag{3.18}$$

If $\xi > s_1$, (3.15) implies that two base functions are merged, i.e.,

$$\bigodot_{k=1}^{2} B_{m_k,t_k,c_k}(x) = B_{m_1+m_2,t_2,c_2}(x) \qquad \text{if} \quad s_1 < \xi. \tag{3.19}$$

For the Burgers case, $f(u) = u^2/2$, (3.18) implies that the trapezoid $BCs_2\xi$ in Figure 3.1 has the same area as the triangle $Ac_1\xi$.

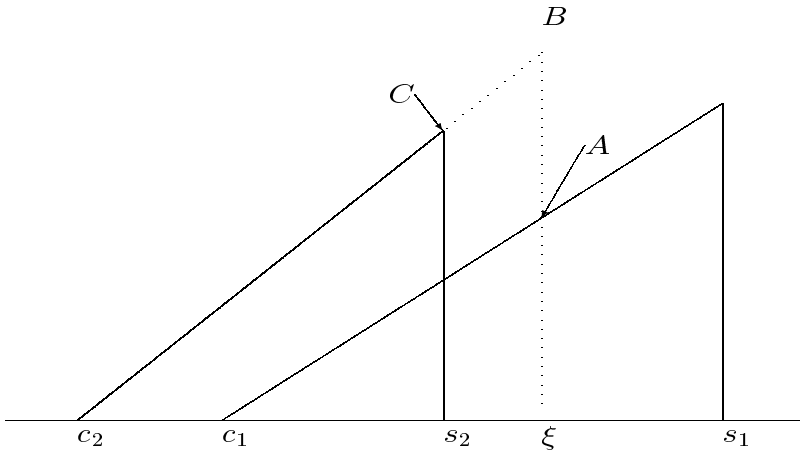

FIG. 3.1. *The equal area rule gives the shock location when two base functions interact together.*

4. S-summation as a numerical scheme. In this section we show how the S-summation can be implemented into a numerical scheme. We assume that the flux is convex $f''(u) \ge 0$ and the solution is positive and compactly supported. More general cases are considered in the following sections. To see what is really happening in each step, we consider a Cauchy problem for the Burgers equation,

$$\begin{array}{c} v_t + vv_x = 0, \\ v(x,0) = v_0(x), \end{array} \qquad v_0(x) = \begin{cases} \sin(\pi x)/\pi, & 0 < x < 1, \\ 0, & \text{otherwise.} \end{cases} \tag{4.1}$$

This simple example helps us to visualize the mechanism of the scheme. In section 4.3 we consider more complicated examples and compare CPU times of each computation to check the complexity of the method which is of order $O(N)$. Several properties of this scheme are compared with those of the Godunov method.

4.1. Preliminaries. First, we consider basic properties of the self-similarity profile $g(x)$, $x > 0$. If the flux is strictly convex, $f''(u) > 0$, then $f'(u)$ is invertible and the self-similarity profile is simply the inverse function of $f'(u)$. For example, if the flux is given by a power law

$$f(u) = \frac{1}{\gamma}\, u^{\gamma}, \qquad u \geq 0,\ \gamma > 1, \tag{4.2}$$

then the self-similarity profile $g(x)$ is simply

$$g(x) = \sqrt[\gamma-1]{x}, \qquad x > 0. \tag{4.3}$$

This is a case that the self-similarity profile is given explicitly. In general, the value of the self-similarity profile $\bar{u} = g(\bar{x})$ at a given point $\bar{x} \geq 0$ is obtained from the basic relation $f'(g(\bar{x})) = \bar{x}$, i.e., we need to solve

$$f'(\bar{u}) - \bar{x} = 0, \qquad \bar{u} \geq 0. \tag{4.4}$$

The relation between the self-similarity profile and the wave speed, $f'(g(x)) = x$, also makes it easy to handle the integrals of a base function. Let $\bar{u} = g(\bar{x}/t)$. Using the change of variables $u = g(x/t)$, we obtain

$$\int_0^{\bar{u}} t f'(u)du = \int_0^{\bar{x}} \frac{x}{t} g'\Big(\frac{x}{t}\Big)dx = \bar{x} g\Big(\frac{\bar{x}}{t}\Big) - \int_0^{\bar{x}} g\Big(\frac{x}{t}\Big)dx.$$

So the integral of the self-similarity profile is written as a function of $\bar{u}$ or $\bar{x}$ only, i.e.,

$$\int_0^{\bar{x}} g\Big(\frac{x}{t}\Big)dx = \bar{x} g\Big(\frac{\bar{x}}{t}\Big) - t f\Big(g\Big(\frac{\bar{x}}{t}\Big)\Big) = t\bar{u} f'(\bar{u}) - t f(\bar{u}). \tag{4.5}$$

Now we consider a simple lemma which is used in deciding the initial time index $t_0 > 0$. This lemma implies that the graph $y = g((x-c)/t_0)$, $x > c$, crosses over $y = v_0(x)$ just once.

LEMMA 4.1. *Suppose that the (smooth and bounded) initial value $v_0(x)$ satisfies*

$$v_0'(x) < \frac{1}{t_0 f''(v_0(x))}. \tag{4.6}$$

Then the point $\bar{x} \geq c$ satisfying $g((\bar{x}-c)/t_0) = v_0(\bar{x})$ is unique.

Proof. Differentiating both sides of $f'(g(x)) = x$, we obtain

$$g'(x) = \frac{1}{f''(g(x))} = \frac{1}{f''(v)}, \tag{4.7}$$

where $v = g(x)$. Let $g((x_1-c)/t_0) = v_0(x_1)$ for a point $x_1 \geq c$. Since

$$v_0'(x_1) < \frac{1}{t_0 f''(v_0(x_1))} = \frac{1}{t_0} g'\Big(\frac{x_1-c}{t_0}\Big) = \partial_x g\Big(\frac{x_1-c}{t_0}\Big), \tag{4.8}$$

we may choose $\delta > 0$ such that $g((x-c)/t_0) > v_0(x)$ for $x \in (x_1, x_1+\delta)$. Now we show that $g((x-c)/t_0) > v_0(x)$ for all $x > x_1$, which completes the proof. Suppose that $g((x_2-c)/t_0) = v_0(x_2)$ for $x_2 > x_1$. We may take x_2 as the smallest one. Then $g((x-c)/t_0) > v_0(x)$ on (x_1, x_2) and it implies $v_0'(x_2) \geq \partial_x g((x_2-c)/t_0)$. It contradicts the fact that (4.8) holds for $x = x_2$. ∎

4.2. Implementation. Here we introduce a gridless scheme based on the S-summation.

Step 1 (initial discretization). The first step is to design a method to approximate the initial value $v_0(x)$ by an S-summation $u_0(x)$ which satisfies (3.17). Consider n base functions $B[k]$, $k = 1, 2, \dots, n$. Each element $B[k]$ consists of two members $B[k].m, B[k].c$, which represent the mass (or area) and the center of the base function. We use the identical time index $t_k = t_0$ for all k, and, hence, we do not need an extra member for the time index. The first thing to do is to choose the time index $t_0 > 0$ satisfying (4.6). If (4.6) does not hold for any $t_0 > 0$, we need to use a different discretization (see section 6).

Next we decide the two members of the kth base function, $B[k].c$ and $B[k].m$. Let $[L_1, L_2]$ be the support of the initial value $v_0(x)$ and $L_1 = x_n < \cdots < x_1 < x_0 = L_2$ be mesh points. Consider the self-similarity profiles that emanate from points $(x_k, v_0(x_k))$. Then the center c_k satisfies $g((x_k - c_k)/t_0) = v_0(x_k)$. Taking the wave speed f' to both sides we get $c_k = x_k - t_0 f'(v_0(x_k))$. We assign this center to $B[k].c$, i.e.,

$$B[k].c = x_k - t_0 f'(v_0(x_k)). \tag{4.9}$$

Since $g((\bar{x} - c_1)/t_0) = g((\bar{x} - c_2)/t_0)$ at any point $\bar{x} > c_1, c_2$ implies $c_1 = c_2$, we can easily see that two self-similarity profiles with the same time index never cross over to each other. So Lemma 4.1 implies that those centers are ordered by $L_1 = B[n].c < \cdots < B[2].c < B[1].c$. Note that there is no self-similarity profile that emanates from the point $(x_0, v_0(x_0))$.

The value of the second member $B[k].m$ is given as the area enclosed by four (or three) curves, $y = v_0(x)$, $y = 0$, $y = g((x - c_k)/t_0)$, and $y = g((x - c_{k-1})/t_0)$, i.e.,

$$B[k].m = \int_{x_k}^{x_{k-1}} v_0(x)dx + \int_{c_k}^{x_k} g\Big(\frac{x - c_k}{t_0}\Big)dx - \int_{c_{k-1}}^{x_{k-1}} g\Big(\frac{x - c_{k-1}}{t_0}\Big)dx,$$

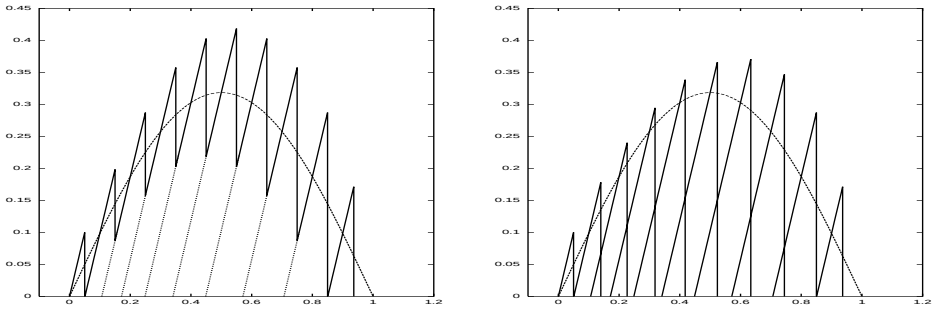
where $c_0 = L_2$. Using relation (4.5), this is written in terms of the initial value and the flux:

$$\begin{aligned} B[k].m = \int_{x_k}^{x_{k-1}} v_0(x)dx + t_0 v_0(x_k) f'(v_0(x_k)) - t_0 f(v_0(x_k)) \\ - t_0 v_0(x_{k-1}) f'(v_0(x_{k-1})) + t_0 f(v_0(x_{k-1})). \end{aligned} \tag{4.10}$$

Consider the Cauchy problem (4.1) as an example. Since $f''(v) = 1$ and $v_x(x, 0) \le 1$, we may take any $t_0 < 1$. In the following examples we use $t_0 = 0.5$. In Figure 4.1(a), 10 self-similarity profiles are shown which emanate from 10 points $(j/10, v_0(j/10))$, $j = 0, 1, \dots, 9$. The centers are their x-intercepts.

In Figure 4.1(b), 10 base functions are displayed with initial value $v_0(x)$. Supports of these base functions are overlapped with each other. Their S-summation $u_0(x) = \bigodot_{k=1}^{n} B[k]$ is considered as the initial discretization, which is the saw-tooth profile (solid lines) in Figure 4.1(a). Let u_0^ε be such an approximation with a uniform mesh size $x_{k-1} - x_k = \varepsilon$. Then the sizes of the triangle-like areas in Figure 4.1(a), added to and subtracted from the area enclosed by $y = v_0(x)$ and the x-axis, are proportional to ε^2, and the total number of them has order $O(1/\varepsilon)$. So we have $||v_0 - u_0^\varepsilon||_1 = O(\varepsilon)$ as $\varepsilon \to 0$, where $u_0^\varepsilon(x) = \bigodot_{k=1}^{n} B[k]$ with $t_k = t_0$ for all k. (Step 1 is complete.)

Theorem 3.6 implies that $u(x, t) = \bigodot_{k=1}^{n} B[k]$ with $t_k = t_0 + t$ is the solution with the modified initial data u_0. So the rest of the scheme is focused on how to



(a) *The equal area rule* (b) *Base functions with overlaps*

FIG. 4.1. *The initial value is approximated by a piecewise self-similar function, which is a saw-tooth profile in* (a). *It turns out to be an S-summation of base functions in* (b).

display the given solution. Even if it is possible to follow the inductive arguments of the definition, we will get serious complexity in the coding if behind shocks capture the front ones, $\xi_{j-1} < \xi_j$, where ξ_j is the shock location generated by the jth base function (see the definition (3.13)–(3.15)). Since the S-summation is not changed even if these two base functions are merged before the summation (see Remark 3.5), we consider the merging process first.

Suppose that $\bigodot_{k=1}^{j-1} B[k]$ is achieved and $\xi_{j-1} < \xi_{j-2} < \cdots < \xi_1$. To obtain $\bigodot_{k=1}^{j} B[k]$ we need to check if $\xi_j < \xi_{j-1}$. Since $\xi_{j-1} \neq s_{j-1}$ in general, an equation corresponding to (3.18) does not provide the information we need. In the following we define an operator using a modified version of (3.18).

DEFINITION 4.2. *We define a binary operator "$*$" between two base functions B_{m_k,t_k,c_k,s_k}, $k = 1, 2$, satisfying $c_2 < c_1$. First, if $s_2 \le c_1$, we define $B_{m_2,t_2,c_2} * B_{m_1,t_1,c_1} \equiv s_2$. If $c_1 < s_2$, $B_{m_2,t_2,c_2} * B_{m_1,t_1,c_1}$ $(\equiv \xi)$ is defined as the solution of*

$$F(\xi) \equiv \int_{c_2}^{\xi} g\Big(\frac{x-c_2}{t_2}\Big)dx - \int_{c_1}^{\xi} g\Big(\frac{x-c_1}{t_1}\Big)dx - m_2 = 0. \tag{4.11}$$

Let $\xi = B[j] * B[j-1]$. From (3.14) we can clearly see that $\xi = \xi_j$ if and only if $\xi \le \xi_{j-1}$. If $\xi_{j-1} < \xi$, we also have $\xi_{j-1} < \xi_j$ and we may merge two base functions, $B[j]$ and $B[j-1]$, before the S-summation. On the other hand, since we have assumed $\xi_{j-1} < \xi_{j-2} < \cdots < \xi_1$, we have $\xi_{j-1} = B[j-1] * B[j-2]$. So we may conclude that

$$\xi_j > \xi_{j-1} \quad \text{if and only if} \quad B[j] * B[j-1] > B[j-1] * B[j-2]. \tag{4.12}$$

So this operator gives the criterion for deciding if two base functions should be merged together or not. Furthermore, after the merging process, it gives the correct (artificial) shock locations $\xi_j(t)$ for the S-summation.

Step 2 (merging). In this step base functions are re-indexed for $k = 1, 2, \ldots, n'$ whenever two base functions are merged together and the total number of base functions is decreased. Suppose that this merging procedure has been completed for all $k < j$ and $\xi_{j-1} < \cdots < \xi_2 < \xi_1 = s_1$ holds. Then $\xi_k = B[k] * B[k-1]$ for $k = 2, \ldots, j-1$. Now we check the next base function $B[j]$.

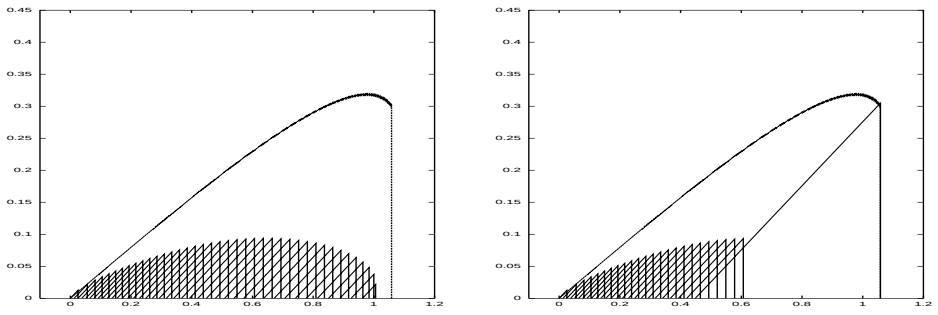
If $B[j] * B[j-1] < B[j-1] * B[j-2]$, then $\xi_j = B[j] * B[j-1]$ and this step is completed for $k \le j$. Suppose that $B[j] * B[j-1] > B[j-1] * B[j-2]$. Then (4.12)

implies that $\xi_j > \xi_{j-1}$, and we may merge $B[j]$ and $B[j-1]$ (see Remark 3.5). Put

$$B[j].m = B[j].m + B[j-1].m, \tag{4.13}$$

remove $B[j-1]$, and then rearrange the array $B[\cdot]$ from $k=1$ to $k=n'-1$, where n' is the total number of base functions left after the previous step. Since the combined base function may take over another one again, we continue this process until we get $\xi_j < \xi_{j-1}$ or $j=1$, decreasing the index j by 1. We continue this procedure from $j=2$ to $j=n'$. Note that there is no base function $B[0]$ and we use a convention $B[1]*B[0] := B[1].s$ in (4.12) for $j=2$, where $B[1].s$ is the shock location of the base function given by the relation (3.3).

In Figure 4.2(a), 40 base functions $B_{m_k,c_k,t+t_0}$, $k=1,\dots,40$, are given at $t=1.5$ together with the exact solution we want to find. During the merging step, Step 2, 16 of them are merged together and a big base function emerges. The location and the size of the discontinuity of the newborn base function are almost identical to those of the physical shock. This big base function can be considered as an accumulation of small artificial shocks, and it represents the physical shock. (Step 2 is complete.)



(a) 40 *base functions before merging* (b) 25 *base functions left after merging*

FIG. 4.2. 40 *base functions have the slope* $1/(t_0+t)$ *at time* $t>0$, *which is* 0.5 *in* (a). *After the merging process, Step* 2, 16 *of them are merged together and a big base function emerges in* (b). *The outside wave is the exact solution we want to approximate.*

Remark 4.3. In the previous algorithm, we solve (4.11) instead of doing the time marching. This relation gives the correct location of artificial shocks if the merging step is completed. Using the relation (4.5), the function $F(\xi)$ in (4.11) is written as

$$F(\xi) \equiv (\xi-c_2)g\Big(\frac{\xi-c_2}{t_2}\Big) - t_2 f\Big(g\Big(\frac{\xi-c_2}{t_2}\Big)\Big) - (\xi-c_1)g\Big(\frac{\xi-c_1}{t_1}\Big) + t_1 f\Big(g\Big(\frac{\xi-c_1}{t_1}\Big)\Big) - m_2. \tag{4.14}$$

So we can simplify the integral equation (4.11). To find the zero of $F(\xi)$ we may use the bisection method. If $B[j]*B[j-1] > B[1].s$, clearly we need to merge $B[j]$ and $B[j-1]$. So we may use $(B[j-1].c, B[1].s)$ as the initial interval.

If we use Newton's method, we need to study the structure of the self-similarity profile first. Let $t_1 = t_2$ $(\equiv t)$. The first two derivatives of $F(\xi)$ are

$$F'(\xi) = g\Big(\frac{\xi-c_2}{t}\Big) - g\Big(\frac{\xi-c_1}{t}\Big), \qquad F''(\xi) = \frac{1}{t}\Big(g'\Big(\frac{\xi-c_2}{t}\Big) - g'\Big(\frac{\xi-c_1}{t}\Big)\Big).$$

Since the self-similarity profile $g(x)$ is an increasing function, we have $F'(\xi) > 0$ and (4.11) has a unique solution. On the other hand, since there is no monotonicity on $g'(x)$ in general, we need to consider the structure $g(x)$ for the initial guess.

Remark 4.4. With the power law $f(u) = u^\gamma/\gamma$, $u > 0$, and the identical time index $t_1 = t_2 \equiv t$, (4.11) is written as

$$F(\xi) = (\xi - c_2)^{\frac{\gamma}{\gamma-1}} - (\xi - c_1)^{\frac{\gamma}{\gamma-1}} - \frac{\gamma}{\gamma-1} m_2 t^{\frac{1}{\gamma-1}} = 0.$$

For the Burgers case, $\gamma = 2$, the operator is explicitly given by

$$B_{m_2,t,c_2} * B_{m_1,t,c_1} = \frac{2m_2 t + c_1^2 - c_2^2}{2(c_1 - c_2)}. \tag{4.15}$$

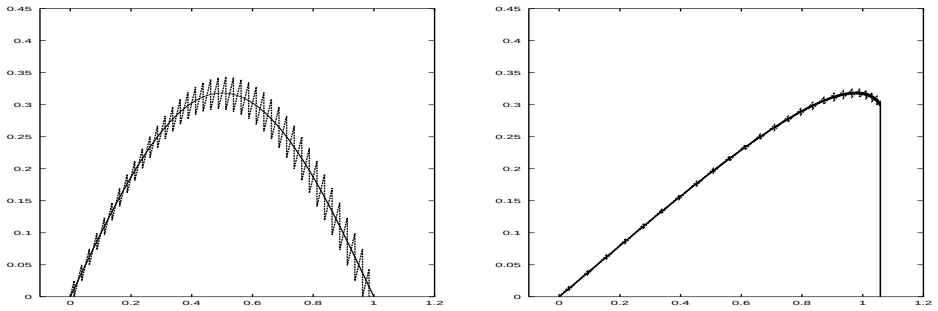
Remark 4.5. If there is no base function merged, there will be $n-1$ comparisons of (4.12). If m base functions are merged, then $n-m$ base functions are left and the maximum number of comparisons (4.12) is $n+m-1 < 2n$, which is of order $O(N)$.

Step 3 (displaying). Now we are ready to display the solution. Suppose that base functions $B[j]$, $j = 1, \ldots, n'$, are left after the merging step. Let $\xi_j = B[j] * B[j-1]$. Then the right- and the left-hand side limits are

$$\begin{aligned} u(\xi_j+, T) &= g\big((\xi_j - B[j-1].c)/(t+t_0)\big), \\ u(\xi_j-, T) &= g\big((\xi_j - B[j].c)/(t+t_0)\big). \end{aligned} \tag{4.16}$$

So to display the solution it is enough to plot the points $(\xi_j, u(\xi_j+, T)), (\xi_j, u(\xi_j-, T))$ for $j = 1, \ldots, n'$. Between these points the solution has the self-similarity profile. So if we connect these points with the self-similarity profile with time index $t + t_0$ and center $B[j].c$, we get the solution.

In Figure 4.3(b), the S-summation of the 25 base functions at time $t = 1.5$ (see Figure 4.2(b)) has been displayed. We may observe that the exact solution passes through the artificial discontinuities of the approximation. Furthermore, we can clearly see that the initial error $||v_0(x) - u_0(x)||_1$ has been decreased a lot. (Step 3 is complete.)



(a) *Initial discretizations* (b) *Solutions at* $t = 1.5$

FIG. 4.3. *The initial value of the problem* (4.1) *has been discretized using* 40 *base functions in* (a). 25 *base functions are left after the merging step with* $t = 1.5$*, Figure* 4.2(b)*, and the S-summation gives the final approximation for the solution. We may observe that the exact solution, which has obtained using finer mesh points, passes through each of the artificial shocks.*

Remark 4.6. One of the main features of the scheme introduced is that it has a complexity of order $O(N)$. Even though we have introduced extra complexities for solving (4.4) and (4.11), this does not increase the order of the complexity. On the other hand, for the convenience of the explanation, we have rearranged the whole array of base functions whenever one of them is merged to another. Since this rearranging

TABLE 4.1

CPU time comparison: Computations for (4.17) with $t_0 = \pi/2$, $t = 4.0$. The number of base functions used initially is N, and L of them are left after the merging step. CPU times for each step of the scheme are compared.

N	L	Discretization	Merging	Displaying	Total	Order α
10	8	0	0	1	1	
100	64	0	5	4	9	0.954
1000	628	0	57	34	91	1.005
10000	6272	2	617	357	976	1.030
100000	62707	22	7763	3956	11741	1.080

process will increase the order of the complexity, we need to use a different strategy in the actual computation. We may link the base functions pointing the adjacent ones so that one of them can be easily removed. These kinds of techniques are classical and we omit the details.

4.3. CPU time comparison. In this section we consider several numerical examples and show the CPU time for each case. In fact, the Burgers equation is the case that the self-similarity profile $g(x)$ and the binary operator "$*$" between base functions are given explicitly, (4.3) and (4.15). So that case does not show the complexity of the scheme well. In the examples in this section, we numerically solve (4.4) and (4.11) using Newton's method.

First, consider a Cauchy problem with the cubic law, $f(v) = v^3/3$,

$$\begin{array}{c} v_t + v^2 v_x = 0, \\ v(x,0) = v_0(x), \end{array} \qquad v_0(x) = \begin{cases} \sin(\pi x)/\pi, & 0 < x < 1, \\ 0, & \text{otherwise.} \end{cases} \tag{4.17}$$

In this case the self-similarity profile $g(x)$ is concave. Since $v_0'(x) = \cos(\pi x)$ and $f''(v) = 2v$, the condition (4.6) is written as

$$\cos(\pi x) < \frac{\pi}{2t_0 \sin(\pi x)}, \qquad 0 < x < 1.$$

We can easily check that it is satisfied for $t_0 = \pi/2$. In Table 4.1 we have compared the CPU time of the computations as we increase the number of base functions (or mesh points). The solution is computed for time $t = 4$.

Suppose that the CPU time $T(N)$ for the computation with N mesh points is $T(N) = cN^\alpha$ for some constants $c, \alpha > 0$. Then we can easily check that

$$\alpha = \frac{\ln(T(N_1)/T(N_2))}{\ln(N_1/N_2)}. \tag{4.18}$$

This number represents the complexity order of the scheme, and it is computed and shown in Table 4.1. We may observe that the order is about $\alpha = 1.08$. These computational results confirm that the complexity of the scheme is almost linear. The extra growth in the CPU time is caused by Newton's method. If we use finer base functions, we need to use smaller tolerances in finding the shock location.

Next we consider a problem with the flux $f(u) = \frac{2}{3}u^{3/2}$, where the self-similarity profile $g(x)$ is convex. In this case we cannot find the time index $t_0 > 0$ that satisfies (4.6) for the initial value given in the previous example. So we consider

$$\begin{array}{c} v_t + \sqrt{v}\, v_x = 0, \\ v(x,0) = v_0(x), \end{array} \qquad v_0(x) = \begin{cases} 5x^2(x-1)^2, & 0 < x < 1, \\ 0, & \text{otherwise.} \end{cases} \tag{4.19}$$

TABLE 4.2

CPU time comparison: Computations for (4.19) *with* $t_0 = 0.1$, $t = 1.0$. *The number of base functions used initially is N, and L of them are left after the merging step. CPU times for each step of the scheme are compared.*

N	L	Discretization	Merging	Displaying	Total	Order α
10	7	0	1	1	2	
100	62	0	13	7	20	1.000
1000	610	0	209	92	301	1.178
10000	6092	1	2785	1113	3899	1.112

TABLE 4.3

CPU time comparison: Computations for (4.20) *with* $t_0 = 0.1$, $t = 0.5$. *The number of base functions used initially is N, and L of them are left after the merging step. CPU times for each step of the scheme are compared.*

N	L	Discretization	Merging	Displaying	Total	Order α
10	7	0	1	0	1	
100	60	0	7	5	12	1.079
1000	589	1	113	53	167	1.144
10000	5878	1	1635	633	2269	1.133
100000	58767	13	19965	7114	27092	1.077

Since $v_0'(x) = 10x(x-1)(2x-1)$ and $f''(v) = 1/2\sqrt{v}$ in this case, the condition (4.6) is written as

$$-10(2x-1) < 2/t_0, \qquad 0 < x < 1.$$

It is satisfied for $t_0 < 0.2$, and we choose $t_0 = 0.1$. The solution has been computed at time $t = 1$, and their CPU times and the complexity of the scheme have been compared in Table 4.2. We observe a similar complexity order, $\alpha = 1.083$, as we do in the previous example.

As the last example, we consider a combination of three power laws,

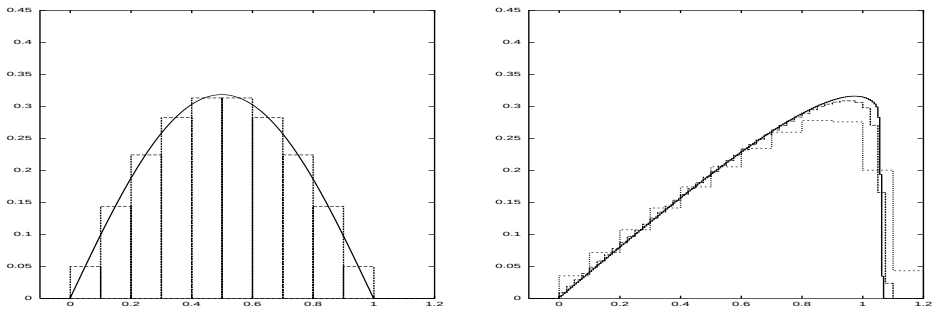
$$(4.20) \qquad \begin{array}{c} v_t + (\sqrt{v} + v + v^2)\, v_x = 0, \\ v(x,0) = v_0(x), \end{array} \qquad v_0(x) = \begin{cases} 5x^2(x-1)^2, & 0 < x < 1. \\ 0, & \text{otherwise.} \end{cases}$$

The solution has been computed at time $t = 0.5$ using an initial time index $t_0 = 0.1$. Their CPU times and the complexity of the scheme have been compared in Table 4.3. We observe a complexity order $\alpha = 1.077$ which is similar to the previous examples.

4.4. Comparison with Godunov. A typical way to discretize the initial data is to take the cell average (see Figure 4.4(a)). The Godunov scheme solves a series of Riemann problems between each cell for a short amount of time Δt and then repeats the process until it reaches a given time $t > 0$. In Figure 4.4(b) we can see that the numerical solution converges to the same limit as the S-summation shown in Figure 4.3(b), as $\Delta x \to 0$.

Remark 4.7 (computation time). Let N be the number of mesh points. Then the number of operations for the S-summation is of order $O(N)$ since the time marching process is not required, Theorem 3.6. The number of operations is almost independent from the final time $t > 0$. On the other hand, the Godunov scheme has operations of order $O(N^2)$ and the situation becomes worse if the final time t is increased.

Remark 4.8 (error estimate). We can clearly observe that the exact solution v of (4.1) (or $||\mathcal{C}|| \to 0$ limit of the S-summation) passes through artificial shocks of



(a) *Data discretization* (b) *Solutions at* $t = 1.5$

FIG. 4.4. *Three approximations by Godunov using* $\Delta x = 1/10, 1/40, 1/160$. *The scheme is convergent to the same limit of the S-summation. We can observe that numerical solutions are separated near the shock, and it is hard to guess where the limit is from a single computation.*

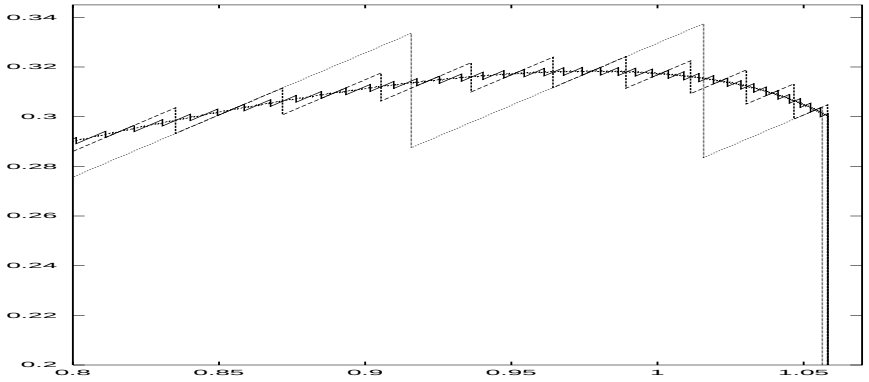


FIG. 4.5. *A magnification of Figure* 4.3(b) *near the physical shock shows that an S-summation with a finer mesh passes through the middle of the artificial shocks.* 10*,* 40*, and* 160 *base functions are used.*

self-similarity solutions (see Figure 4.3(b)). In Figure 4.5 a part of Figure 4.3(b) near the physical shock is magnified together with other similarity summations consisting of 10 and 160 base functions. In this figure we can also observe that S-summations are attached to each other in the middle of self-similar profiles. Noting that the sizes of artificial shocks decrease in time with order of $O(1/(t + t_0))$, these observations show the possibility for a good error estimate.

Remark 4.9 (shock appearance time). In a numerical scheme the solution is approximated by piecewise continuous functions, and it is hard to see if a discontinuity represents the physical shock or not. In our scheme, as we can see from Figure 4.2, the accumulation of base functions represents the physical shock. So, if a base function is merged to its behind one in the sense of (4.12), we may conclude that a physical shock has appeared. The physical shock appears at time $t = 1$ in the example (4.1) since $\min(\partial_x v_0(x)) = -1$. We can easily check whether (4.12) happens around that time. Table 4.4 shows the time when the number of initial base functions decreases by one.

TABLE 4.4

Shock appearance time. The exact solution with initial data (4.1) *blows up at* $t = 1$. *The time of shock appearance can be measured by counting the base functions after the merging step.*

Initial number of base functions	The time when the number is decreased by 1
25	$T = 1.02$
50	$T = 1.005$
100	$T = 1.0015$
200	$T = 1.0008$
400	$T = 1.0002$
800	$T = 1.00005$

5. General cases. The S-summation has been considered under hypothesis (H). In this section we generalize it under hypotheses (H1) and (H2).

5.1. General convex flux. We consider L^1 initial function u_0 which is uniformly bounded, say, $-A \le u_0(x) \le B$. Then the solution of (2.1) is bounded above and below:

$$-A \le u(x,t) \le B, \qquad A, B \in \boldsymbol{R}^+.$$

Consider a general convex flux, i.e.,

$$f''(u) \ge 0. \tag{H1}$$

If the flux satisfies $f''(u) \le 0$, we may change the variable $y = -x$ and get an equation $u_t + \bar{f}(u)_y = 0$ with $\bar{f}(u) = -f(u)$, where $\bar{f}$ satisfies (H1). Note that we include the equality in (H1) and a piecewise linear flux can be considered.

We can easily check that a new flux,

$$h(w) = f(w - A) - f'(-A)w - f(-A), \tag{5.1}$$

satisfies the hypothesis (H) and $h'(0) = 0$. Let $w(x,t)$ be the solution of

$$w_t + h(w)_x = 0, \qquad w(x,0) = u_0(x) + A. \tag{5.2}$$

We can easily check that

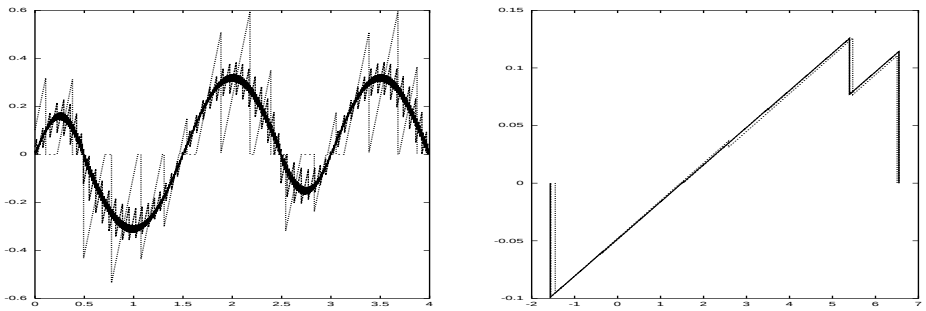
$$u(x,t) = w(x - f'(-A)t, t) - A \tag{5.3}$$

is the solution with the original flux f and initial data u_0. Since $u \ge -A$, the solution $w(x,t)$ is positive. Now we are in the exact same situation as in the previous sections, except with respect to the structure of the initial data. The initial data $w(\cdot, 0)$ is not L^1 anymore. To handle the situation, we consider two special base functions with infinite mass,

$$B_{t,c=-\infty,s}(x) = \begin{cases} A, & x < s + t\,h(A)/A, \\ 0, & x > s + t\,h(A)/A, \end{cases}$$

$$B_{t,c,s=\infty}(x) = \begin{cases} \max\bigl(g(\frac{x-c}{t}), A\bigr), & x > c, \\ 0, & x < c, \end{cases}$$

where $h'(g(x)) = x$, i.e., $g(x)$ is the similarity profile under the flux $h(w)$, not $f(u)$. These base functions handle the transformation $u_0(x) \to u_0(x) + A$. Note that the speed of the shock connecting the state $w = A$ and $w = 0$ is $h(A)/A$ in our case. The S-summation including these two base functions can be defined in a similar way. We omit the details. Figure 5.1 shows how the self-similar solution evolves for the Burgers case. In the figure even the solution with very rough initial discretization with only 16 base functions represents the asymptotic behavior very correctly.



(a) *Data discretization* (b) *Solutions at* $t = 30$

FIG. 5.1. *Three S-summations are displayed using* 16, 64, *and* 256 *base functions. It handles sign changing solutions correctly. This figure shows the time convergence to an inviscid N-wave.*

5.2. Flux without convexity. Consider a flux with a single inflection point:

$$f''(u) \le 0 \text{ for } u \le A, \quad f''(u) \ge 0 \text{ for } u \ge A. \tag{H2}$$

Then, under the change of variables,

$$h(w) = f(w + A) - f'(A)w - f(A), \qquad u(x,t) = w(x - f'(A)t, t) + A, \tag{5.4}$$

the problem (2.1) is transformed to

$$w_t + h(w)_x = 0, \qquad w(x,0) = u_0(x) - A.$$

Then the new flux h satisfies

$$h''(w) \le 0 \text{ for } w \le 0, \quad h''(w) \ge 0 \text{ for } w \ge 0, \quad h'(w) \ge 0 \text{ for all } w, \tag{5.5}$$

and $h(0) = h'(0) = h''(0) = 0$. Since A is not the lower bound of the solution $u(x,t)$ in general, we cannot expect $w \ge 0$. So in this case we have to consider the positive part and the negative part together. It is possible since $h'(w)$ is monotone on $(-\infty, 0)$ and $(0, \infty)$, respectively. All we have to do is to consider negative base functions together with positive ones. Since the wave speed $h'(w)$ is positive, the S-summation is defined from the right-hand side as in the previous cases.

Example 5.1. Consider an inviscid thin film flow in [1],

$$\begin{aligned} u_t + (u^2 - u^3)_x &= 0, \\ u(x,0) &= u_0(x), \end{aligned} \tag{5.6}$$

where the initial datum is compactly supported $\mathrm{supp}(u_0) \subset [L_1, L_2]$. The flux $f(u) = u^2 - u^3$ has a single inflection point $A = 1/3$ and, under the transformation (5.4), we get the flux $h(w) = -w^3$. It satisfies

$$h''(w) \ge 0 \text{ for } w \le 0, \qquad h''(w) \le 0 \text{ for } w \ge 0, \qquad h'(w) \le 0 \text{ for all } w,$$

which is not exactly the same as (5.5) but has the opposite direction in the inequalities. We may do the S-summation from the left-hand side instead of changing the space variable using $y = -x$. Now the original problem (5.6) is transformed to

$$\begin{aligned} w_t - (w^3)_x &= 0, \\ w(x,0) = w_0(x) &:= u_0(x) - A. \end{aligned} \tag{5.7}$$

In this case the self-similarity profile (2.8) is given by

$$g_{\pm}(x) = \pm\sqrt{-x/3}\,, \qquad x < 0, \tag{5.8}$$

and the corresponding base functions are

$$B^{\pm}_{t,s,c}(x) = \begin{cases} g_{\pm}((x-c)/t), & s < x < c, \\ 0, & \text{otherwise.} \end{cases} \tag{5.9}$$

The initial data $v_0(x)$ converges to $-A$ as $x \to \pm\infty$, and we need to consider two base functions with infinite mass that are

$$B_{t,s=L_2,c=\infty}(x) = \begin{cases} -A, & x > L_2 + t\,h(-A)/(-A), \\ 0, & x < L_2 + t\,h(-A)/(-A), \end{cases}$$

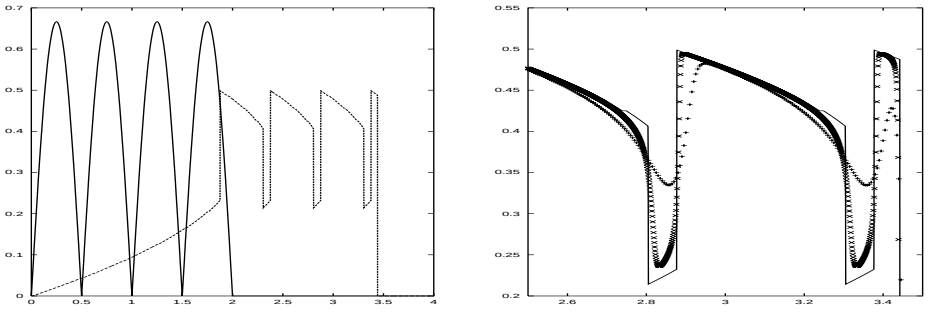
$$B_{t,s=-\infty,c=L_1}(x) = \begin{cases} \max\bigl(g_-((x-L_1)/t), -A\bigr), & x < L_1, \\ 0, & x > L_1. \end{cases}$$

Note again that in our example (5.6) the infinite state is $-A = -1/3$ and the shock speed is $h(-A)/(-A) = -1/9$.

Numerical solutions of (5.6) with initial data,

$$u_0(x) = \begin{cases} \frac{2}{3}|\sin(2\pi x)|, & 0 < x < 2, \\ 0, & \text{otherwise,} \end{cases} \tag{5.10}$$

are shown in Figure 5.2. The first picture shows the initial data and the S-summation of 200 base functions at time $t = 6$. A part of the summation has been magnified with numerical approximations of the Godunov scheme in the second picture. We can clearly see that the solution of the Godunov scheme converges to the S-summation. This example shows that the S-summation gives a very accurate resolution using a small number of mesh points.



(a) *Initial data and S-summation at* $t = 6$ (b) *Comparison with Godunov*

FIG. 5.2. *Flux is* $f(u) = u^2 - u^3$. (a) *shows the initial data and the S-summation at* $t = 6$. (b) *shows that the Godunov scheme converges to the S-summation.* 200 *base functions are used in the S-summation and* 800 *and* 4,000 *meshes are used in the Godunov scheme.*

5.3. Space dependent flux in multidimensional space. The self-similarity of the problem (2.1) relies on the fact that the flux depends only on the solution, i.e., $f = f(u)$. We have no clue how to generalize our scheme to a problem with a general space dependent flux, $f = f(u, x)$. However, if the space dependence is given by

$$u_t + a(x)f'(u)u_x = 0, \tag{5.11}$$

the equation is transformed into

$$u_t + f(u)_y = 0 \tag{5.12}$$

under the change of variable $y(x) = \int_0^x 1/a(s)ds$, and our scheme can be applied.

Since the self-similarity of hyperbolic conservation laws is the one-dimensional property, it should be possible to expand the scheme to multidimensional problems. Consider a two-dimensional problem,

$$u_t + f'(u)(a(x_1, x_2)u_{x_1} + b(x_1, x_2)u_{x_2}) = 0, \tag{5.13}$$

with a velocity vector field satisfying

$$\partial_{x_1} a(x_1, x_2) + \partial_{x_2} b(x_1, x_2) = 0. \tag{5.14}$$

Cvetkovic and Dagans [6] suggest space variables y_1, y_2 satisfying

$$\frac{dy_1}{dx_1} = \frac{1}{a(x_1, \eta)}, \qquad y_2 = x_2 - \eta, \qquad \frac{d\eta}{dx_1} = \frac{b(x_1, \eta)}{a(x_1, \eta)}, \tag{5.15}$$

which transform (5.14) into

$$u_t + f(u)_{y_1} = 0, \qquad u = u(y_1, y_2, t). \tag{5.16}$$

Problem (5.16) can be considered as a set of one-dimensional problems, and, hence, the complexity of the scheme for it is of order $O(N^2)$. Since the transformation (5.15) also has the complexity of $O(N^2)$, we eventually get a scheme of $O(N^2)$ for a two-dimensional problem. In this approach, each channel of the velocity vector field is considered separately and, hence, it seems useful to channel problems.

6. Second order approximation. The scheme introduced in the previous sections exactly solves the problem with modified initial data, and the size of the initial error decreases in time. However, the scheme is not good enough for the short time behavior since the error generated by the initial discretization can be huge. Here we add an extra structure to base functions and make the initial data discretization to be of second order. In this way we can handle general piecewise self-similar solutions in (1.7).

6.1. Modified base functions. The base function considered in the previous sections has three indexes, say, m, t, c. In this section we introduce two extra indexes, h and $\bar{t}$. Note that there are two time indexes t and $\bar{t}$ which play different roles. We assume $0 \le t < \infty$ and $-\infty < \bar{t} \le \infty$. For simplicity we assume (H). It can be easily generalized, as it was in section 5.

To figure out the structure of the new base function $B^{h,\bar{t}}_{m,t,c}(x)$, we introduce

$$x^* = c + tf'(h), \qquad 0 \le t < \infty, \tag{6.1}$$

and

$$\bar{c} = x^* - \bar{t} f'(h), \qquad -\infty < \bar{t} < \infty, \tag{6.2}$$

(see Figures 6.1 and 6.2). Let $g(x)$ be the self-similarity profile. As an intermediate step we define $B_{t,c}^{h,\bar{t}}(x)$ first. For $0 < \bar{t} < \infty$ it is defined by

$$B_{t,c}^{h,\bar{t}}(x) = \begin{cases} g\big((x-c)/t\big), & c < x < x^*, \\ g\big((x-\bar{c})/\bar{t}\,\big), & x^* < x, \\ 0, & \text{otherwise}, \end{cases} \tag{6.3}$$

and, for $-\infty < \bar{t} \le 0$, it is defined by

$$B_{t,c}^{h,\bar{t}}(x) = \begin{cases} g\big((x-c)/t\big), & c < x < x^*, \\ g\big((x-\bar{c})/\bar{t}\,\big), & x^* < x < \bar{c}, \\ 0, & \text{otherwise}. \end{cases} \tag{6.4}$$

The constant $\bar{c}$ is the center of the top self-similarity profile with time index $\bar{t}$, and the constant x^* is the x-coordinate of the intersection point between two self-similarity profiles with indexes t and $\bar{t}$ (see Figures 6.1 and 6.2). We can easily see from (6.2) that $\bar{c} < x^*$ for $\bar{t} > 0$ and $\bar{c} > x^*$ for $\bar{t} < 0$. The function $B_{t,c}^{h,\bar{t}}(x)$ is well defined for $t = 0$, $\bar{t} = 0$ since the corresponding domain is empty. For $\bar{t} = \infty$, we consider

$$B_{t,c}^{h,\infty}(x) = \begin{cases} g\big((x-c)/t\big), & c < x < x^*, \\ h, & x^* < x, \\ 0, & \text{otherwise}. \end{cases} \tag{6.5}$$

Now we introduce the index $m > 0$, which decides the support of the base function. Let $\xi > c$ be the solution of

$$\int_c^{\xi} B_{t,c}^{h,\bar{t}}(x)dx = m. \tag{6.6}$$

For $\bar{t} > 0$ it always has a solution. For $\bar{t} \le 0$ it has a solution only if $m < \int_c^{\bar{c}} B_{t,c}^{h,\bar{t}}(x)dx$. The base function is now defined by

$$B_{m,t,c}^{h,\bar{t}}(x) = \begin{cases} B_{t,c}^{h,\bar{t}}(x), & c < x < \xi, \\ 0, & \text{otherwise}. \end{cases} \tag{6.7}$$

Let $u(x,t)$ be the solution of the conservation law $u_t + f(u)_x = 0$ with its initial value $u(x,0) = B_{m,0,c}^{h,\bar{t}}(x)$. Then, from the well-known technique of equal area construction, we may easily see that the solution is simply $u(x,t) = B_{m,t,c}^{h,\bar{t}+t}(x)$ (see Figures 6.1 and 6.2). For this solution $u(x,t)$, the point $x^* = x^*(t)$ in (6.1) satisfies

$$x^*(t) = c + tf'(h) = c + tf'(u(x^*(t),t)), \qquad x^*(t) < \xi(t),$$

where $\xi = \xi(t)$ is the solution of (6.6). So $x = x^*(t)$ is a characteristic line for $x^*(t) < \xi(t)$. On the other hand, $\bar{c}$ is a constant with respect to $t > 0$:

$$\bar{c} = x^*(t) - (t + \bar{t})f'(h) = c - \bar{t} f'(h).$$

In Figures 6.1 and 6.2 base functions are displayed for positive and negative $\bar{t}$ together with self-similarity profiles. In these figures we can clearly observe the different roles of two self-similarity profiles generated by two index sets $\{c, t\}$ and $\{\bar{c}, \bar{t}\,\}$.

The S-summation among these base functions can be similarly defined using the profile $g\big((x-c)/t\big)$ in the domain $c < x < x^*$ and the profile $g\big((x-\bar{c})/\bar{t}\,\big)$ for $x^* < x$. We omit the details. We may consider the base function (3.2) as a special case of (6.7) with $\bar{t} = 0$.

6.2. Initial discretization and the approximation. Suppose the initial function $v_0 \in L^1$ has a compact support $\mathrm{supp}(v_0) \subset [L_1, L_2]$. Let $\mathcal{C} = \{c_n = L_1 < \cdots < c_1 < c_0 = L_2\}$ be a partition of the interval $[L_1, L_2]$. We can approximate v_0 with self-similarity profiles over interval (c_k, c_{k-1}) with time index $\bar{t}_k \in \boldsymbol{R}$, which is second order. For the Burgers case it is simply a piecewise linear approximation. The

approximation u_0 can be written as

$$u_0(x) = \bigodot_{k=1}^{n} B^{h_k,\bar{t}_k}_{m_k,0,c_k}(x) = \sum_{k=1}^{n} B^{h_k,\bar{t}_k}_{m_k,0,c_k}(x), \tag{6.8}$$

where $m_k = \int_{c_k}^{c_{k-1}} u_0(x)dx$ and $h_k = u_0(c_k)$. Initially, the supports of base functions are disjoint, and, hence, the self-similarity summation is the usual summation. The exact solution $v(x,t)$ of the conservation law (1.1) is approximated by

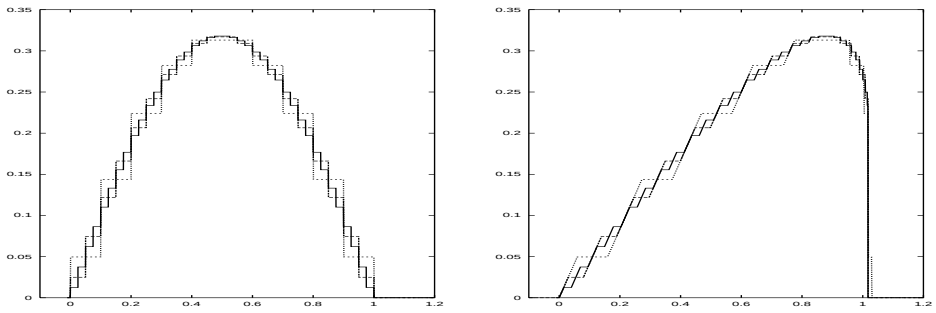
$$u(x,t) = \bigodot_{k=1}^{n} B^{h_k,t+\bar{t}_k}_{m_k,t,c_k}(x), \tag{6.9}$$

and we expect an error estimate similar to (3.16), i.e.,

$$||v(x,t) - u(x,t)||_1 \le ||v_0(x) - u_0(x)||_1 = O(||\mathcal{C}||^2) \quad \text{as} \quad ||\mathcal{C}|| \to 0. \tag{6.10}$$

Remark 6.1. The initial discretization (6.8) is trivial in comparison with Step 1 in section 4.2. It is an additional advantage we obtain when the modified base function is used in a numerical scheme. However, this additional structure may cause extra complexity when it is used as an analytical tool.

Remark 6.2 (piecewise constant data). In many cases initial data are given as piecewise constant functions from the beginning. In this case the initial data can be considered as a summation of base functions with $\bar{t} = \infty$; see (6.5). In Figure 6.3 we consider the Burgers case (4.1) using base functions $B^{h,\infty}_{m,t,c}(x)$. We can clearly see that these approximations represent the shock location very well. Unlike the previous case, the solution with finer mesh always passes though the constant parts of coarse ones.

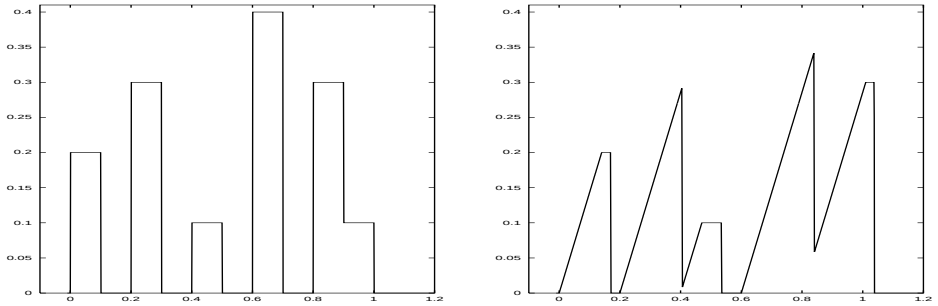


(a) *Data discretization* (b) *Solutions at* $t = 1.2$

FIG. 6.3. *The S-summation for the modified base functions* (6.7) *with* $\bar{t} = \infty$ *gives a piecewise constant, piecewise self-similar solution. In the figure,* 3 *summations are displayed together using* 10, 20, 40 *base functions. We observe that the finer one always passes the constant parts.*

Remark 6.3 (singular initial data). If singular initial data are given, then extra mesh points are usually introduced to capture the effect of the singularity of the data. But since our method handles initial data individually, extra mesh points are not needed. In Figure 6.4(a) the Burgers equation is solved with singular initial data. We use 6 modified base functions with $\bar{t} = \infty$.

Remark 6.4 (front tracking). It is possible to consider the front tracking method in terms of the S-summation. Consider an L^1 solution of the Burgers equation



(a) *Singular initial data* (b) *Solutions at* $t = 0.7$

FIG. 6.4. *The scheme does not require extra meshes to handle singular initial data* (a). *In the S-summation every datum is handled exactly by a base function. Only* 6 *base functions solve this example.*

bounded by $0 \le u(x,t) \le 1$. Let $h(u)$ be the polygonal approximation of the flux $f(u) = u^2/2$ with the partition $\{0, 1/n, \dots, n/n = 1\}$. Then $h'(u)$ is a step function,

$$h'(u) = (2k-1)/2n, \qquad (k-1)/n < u < k/n, \quad k = 1, \dots, n, \tag{6.11}$$

and the self-similarity profile $g(x)$ is given by

$$g(x) = (k-1)/n, \qquad (2k-1)/2n < x < (2k+1)/2n, \quad k = 1, \dots, n. \tag{6.12}$$

So the values of $g(x)$ are the *breaking points* of the flux $h(u)$. We can approximate the given initial data v_0 by taking a cell average, not just breaking points. Then the initial discretization u_0 can be written in the form of (6.8) with $\bar{t}_k = \infty$. This is a simplified version of the front tracking method under (H).

A NEW SUPERCONVERGENCE FOR MIXED FINITE ELEMENT APPROXIMATIONS*

RICHARD E. EWING†, MINGJUN LIU‡, AND JUNPING WANG§

Abstract. A new superconvergence result is established for numerical solutions of elliptic problems obtained from the mixed finite element method of Raviart–Thomas over rectangular partitions. The well-known optimal order error estimate in L^2-norm for the flux approximation is of order $\mathcal{O}(h^{k+1})$, where $k \geq 0$ is the order of polynomials employed in the Raviart–Thomas element. The new superconvergence shows an improved accuracy of order $\mathcal{O}(h^{k+3})$ between the mixed finite element approximation and an appropriately defined local projection of the flux variable when $k > 0$. A postprocessing technique using local projection methods is proposed and analyzed in order to provide a new approximate solution with the superconvergent order $\mathcal{O}(h^{k+3})$.

1. Introduction.

In this paper we are concerned with error analysis for numerical solutions of elliptic problems by mixed finite element methods over rectangular finite element partitions. In particular, we shall investigate some superconvergence properties of the numerical solution obtained from the Raviart–Thomas rectangular element [15, 7].

The model problem under consideration seeks $p \in H^1(\Omega)$ satisfying

$$-\nabla \cdot (\boldsymbol{a} \nabla p) = f \qquad \text{in } \Omega \tag{1.1}$$

and the boundary condition

$$\boldsymbol{a} \nabla p \cdot \mathbf{n} = g \qquad \text{on } \partial\Omega, \tag{1.2}$$

where Ω is an open bounded domain in $\mathbb{R}^2$, $\boldsymbol{a} = \boldsymbol{a}(x, y)$ is a 2×2 tensor which is symmetric and uniformly positive definite in Ω, $\mathbf{n}$ is the outward unit normal vector on $\partial\Omega$, and $f = f(x, y)$, $g = g(x, y)$ are two given functions defined on Ω and its boundary $\partial\Omega$, respectively. The functions f and g are assumed to satisfy the compatibility condition $\int_\Omega f(x, y) d\Omega + \int_{\partial\Omega} g(x, y) ds = 0$ so that (1.1) and (1.2) has a solution. The mixed finite element method [15, 7, 8] is a method that approximates the scalar $p = p(x, y)$ and the flux variables $\mathbf{u} = -\boldsymbol{a}\nabla p$ simultaneously in two different finite element spaces. The corresponding scheme is outlined in section 2.

Optimal order error estimates have been derived in [8] for all the existing mixed finite elements [4, 5, 6, 10, 15] satisfying the inf-sup condition of Brezzi [3] and

Babuška [1]. For the Raviart–Thomas element of order $k \geq 0$ on triangles or rectangles, the optimal order error estimate in L^2-norm for the flux and the scalar variables is of order $\mathcal{O}(h^{k+1})$, where h is the mesh size of the corresponding finite element partition. The optimal order error estimate is generally the best one can get between the exact solution and its numerical approximation when measured globally on the computational domain. But when compared with a certain local projection of the exact solution, the finite element solution often possesses a supercloseness property over the optimal order error estimate. More precisely, if $\mathbf{u}_h$ is the finite element approximation, then for an appropriately defined local projection $\pi_h\mathbf{u}$ [8, 7, 9] one may have

$$\|\mathbf{u}_h - \pi_h\mathbf{u}\|_{L^2(\Omega)} \leq C(\mathbf{u})h^{k+s} \tag{1.3}$$

for some parameters $s > 1$. For example, for rectangular finite element partitions, the mixed finite element solution from using either the Raviart–Thomas or the Brezzi–Douglas–Fortin–Marini (BDFM) [5] elements was proved to satisfy

$$\|\mathbf{u}_h - \pi_h\mathbf{u}\|_{L^2(\Omega)} \leq C(\mathbf{u})h^{k+2}, \tag{1.4}$$

where $C(\mathbf{u})$ is a constant independent of the mesh size h. The estimate (1.4) is certainly much better than the optimal order error estimate and can be used to construct a new numerical solution with the same order of accuracy. We refer to [9, 13, 11, 12, 16] for a detailed discussion of (1.4) on rectangular elements. The estimate (1.4) was also derived for the triangular Raviart–Thomas element of order $k = 0$ when the underlying partition is uniform [2].

In their numerical experiments conducted in 1989 for reservoir simulation, Ewing and Shen [14] observed that the numerical flux $\mathbf{u}_h$ actually approximates the exact solution $\mathbf{u}$ at an order of $\mathcal{O}(h^4)$ on the two diagonal lines of each rectangular element when $k = 1$ for the Raviart–Thomas element. This means that the true rate of superconvergence for the mixed finite element approximation was significantly underestimated by the supercloseness estimate (1.4). Our main objective of this paper is to provide a theoretical justification for the super-superconvergence observed by Ewing and Shen. In particular, for diagonal tensors $\boldsymbol{a} = \boldsymbol{a}(x, y)$ with piecewise constant entries, we show that there is a constant $C = C(\mathbf{u})$ independent of the mesh size h such that

$$\|\mathbf{u}_h - \pi_h\mathbf{u}\|_{L^2(\Omega)} \leq C(\mathbf{u})h^{k+3} \tag{1.5}$$

for any $k \geq 1$.

The analysis for (1.5) is different from that of (1.4) as presented in [9, 13, 11, 12]. The difference lies in the treatment of a linear form

$$\mathcal{F}(\mathbf{v}) = (\boldsymbol{a}^{-1}(\mathbf{u} - \pi_h\mathbf{u}), \mathbf{v}) \tag{1.6}$$

for any finite element function $\mathbf{v}$. Traditionally, this linear form is estimated by expanding the interpolation error $\mathbf{u} - \pi_h\mathbf{u}$ as a Taylor-like series. Leading terms in the expansion are proved to be orthogonal with arbitrary finite element functions $\mathbf{v}$. If so, one would be able to derive a superconvergence estimate. In the analysis to be presented in this paper, the above linear form is studied by expanding $\mathbf{v}$ as a Taylor series involving only finite number of terms. Each of the terms in the Taylor expansion is a polynomial. The orthogonality of $\mathbf{u} - \pi_h\mathbf{u}$ with a certain class of polynomials then plays an important role for the desired superconvergence result.

The paper is organized as follows. In section 2, we provide a short review of the mixed finite element method. In section 3, we establish a general framework of superconvergence. In section 4, we derive some estimates useful for analyzing the linear form (1.6). In section 5, we obtain some superconvergence results for the mixed finite element solutions by combining the results of sections 3 and 4. In section 6, we present a local projection method that can be used to provide a numerical solution with the desired superconvergence.

2. Preliminaries in mixed methods. With the flux variable $\mathbf{u} = -\boldsymbol{a}\nabla p$, our model problem (1.1) can be rewritten as a system of linear equations

$$\begin{aligned} \boldsymbol{a}^{-1}\mathbf{u} + \nabla p &= 0 \qquad \text{in } \Omega, \\ \nabla \cdot \mathbf{u} &= f \qquad \text{in } \Omega, \\ \mathbf{u} \cdot \mathbf{n} &= -g \qquad \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

The new variable $\mathbf{u}$ is known as Darcy's velocity in the numerical simulation of fluid flow in porous media.

The mixed finite element method for (1.1) is based on a weak form for the mixed formulation (2.1). To this end, let $(\cdot,\cdot)$ denote the standard inner product in $L^2(\Omega)$ or $\left[L^2(\Omega)\right]^2$, as appropriate. The corresponding norm is denoted by $\|\cdot\|_0$. Let

$$\mathbf{V} = \{\mathbf{v} = \mathbf{v}(x) : \quad \mathbf{v} \in L^2(\Omega),\, \nabla \cdot \mathbf{v} \in L^2(\Omega)\}$$

be a Sobolev space equipped with the norm

$$\|\mathbf{v}\|_{\mathbf{V}} = \left(\|\mathbf{v}\|_0^2 + \|\nabla \cdot \mathbf{v}\|_0^2\right)^{1/2}.$$

Let $W = L_0^2(\Omega)$ consisting of functions in $L^2(\Omega)$ with mean value zero, and

$$\mathbf{V}_g = \{\mathbf{v} : \quad \mathbf{v} \in \mathbf{V},\, \mathbf{v} \cdot \mathbf{n} = g \text{ on } \partial\Omega\},$$

where $g = g(x,y) \in H^{-1/2}(\partial\Omega)$ is a given function on the boundary $\partial\Omega$. A weak form for (2.1) seeks $\mathbf{u} \in \mathbf{V}_g$ and $p \in W$ satisfying

$$\begin{aligned} (\boldsymbol{a}^{-1}\mathbf{u}, \mathbf{v}) - (\nabla \cdot \mathbf{v}, p) &= 0, \qquad && \mathbf{v} \in \mathbf{V}_0, \\ (\nabla \cdot \mathbf{u}, w) &= (f, w), && w \in W. \end{aligned} \tag{2.2}$$

The mixed finite element method for (1.1)–(1.2) is based on the weak formulation (2.2) and two finite element subspaces $\mathbf{V}_h \subset \mathbf{V}$ and $W_h \subset W$ associated with a prescribed finite element partition $\mathcal{T}_h$ for the domain Ω. For the purpose of this paper, we consider a special case of the finite element partition $\mathcal{T}_h$ consisting of rectangular elements only. This means that the domain Ω would have to be made of rectangular subdomains with boundaries parallel to either the x or y axis.

Of particular interest in this paper, we consider the Raviart–Thomas finite elements on the rectangular partition $\mathcal{T}_h$. Let $Q_{r,s}$ be the space of polynomials with degree no more than r in the x direction and no more than s in the y direction. The Raviart–Thomas finite element space of order $k \geq 0$ is given as follows:

$$\begin{aligned} \mathbf{V}_h &= \{\mathbf{v} \in \mathbf{V},\, \mathbf{v}|_e \in Q_{k+1,k} \times Q_{k,k+1},\, e \in \mathcal{T}_h\}, \\ W_h &= \{w \in W,\, w|_e \in Q_{k,k},\, e \in \mathcal{T}_h\}. \end{aligned}$$

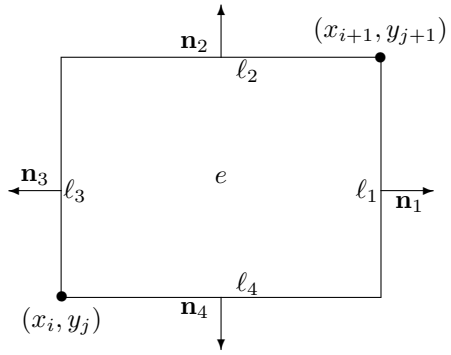

FIG. 1. *A rectangular element e and its four edges.*

Let Λ_h be a finite element space on $\partial\Omega$ obtained as the normal component of functions in $\mathbf{V}_h$:

$$\Lambda_h = \{\mathbf{v}\cdot\mathbf{n} \quad \forall \mathbf{v} \in \mathbf{V}_h\}.$$

It is not hard to see that Λ_h contains piecewise polynomials of degree k in either the x or y directions. Denote by $g_h \in \Lambda_h$ an approximation of the boundary data g such that

$$\langle g_h, \chi\rangle = g(\chi), \qquad \chi \in \Lambda_h,$$

where $g(\chi)$ is the duality pair and $\langle\cdot,\cdot\rangle$ denotes the standard inner product in $L^2(\partial\Omega)$. Let

$$\mathbf{V}_{g,h} = \{\mathbf{v} \in \mathbf{V}_h,\ \mathbf{v}\cdot\mathbf{n} = g_h \text{ on } \partial\Omega\}$$

be a hyper-plane in $\mathbf{V}_h$. The Raviart–Thomas mixed finite element approximation is given by $\mathbf{u}_h \in \mathbf{V}_{g,h}$ and $p_h \in W_h$ satisfying

$$\begin{aligned} (\boldsymbol{a}^{-1}\mathbf{u}_h, \mathbf{v}) - (\nabla\cdot\mathbf{v}, p_h) &= 0, \qquad && \mathbf{v} \in \mathbf{V}_{0,h}, \\ (\nabla\cdot\mathbf{u}_h, w) &= (f, w), && w \in W_h. \end{aligned} \tag{2.3}$$

We emphasize that $\mathbf{V}_{0,h}$ consists of all finite element functions which have a vanishing component on the boundary $\partial\Omega$ in the normal direction.

The discrete problem (2.3) is known to satisfy the inf-sup condition of Brezzi [3] and Babuška [1]. The inf-sup condition can be verified by using a projection operator $\pi_h : \mathbf{V} \to \mathbf{V}_h$ satisfying

$$(\nabla\cdot(\mathbf{v} - \pi_h\mathbf{v}), w) = 0 \tag{2.4}$$

for all $w \in W_h$. The required boundedness of the projection operator π_h can be easily verified.

To construct such a projection operator π_h, let e be any rectangular element depicted in Figure 1. For any sufficiently smooth vector-valued function $\mathbf{v} \in \mathbf{V}$, define its projection $\pi_e\mathbf{v} \in Q_{k+1,k} \times Q_{k,k+1}$ by using the following system of linear equations:

$$\begin{aligned} \int_{\ell_i} (\mathbf{v} - \pi_e\mathbf{v})\cdot\mathbf{n}_i\phi ds &= 0, \qquad && \phi \in P_k(\ell_i),\ i = 1,2,3,4, \\ \int_e (\mathbf{v} - \pi_e\mathbf{v})\cdot\psi dxdy &= 0, && \psi \in Q_{k-1,k}(e) \times Q_{k,k-1}(e), \end{aligned}$$

where $\{\ell_i,\ i=1,2,3,4\}$ stand for the edges of the element e.

Using the local operator π_e, we can define a global projection operator $\pi_h : \mathbf{V} \to \mathbf{V}_h$ by setting

$$(\pi_h \mathbf{v})(x,y) = \pi_e \mathbf{v}(x,y) \qquad \forall (x,y) \in e,\ e \in \mathcal{T}_h. \tag{2.5}$$

It is not hard to see that the projection operator π_h satisfies the desired relation (2.4). In addition, the operator π_h can be split into two components:

$$\pi_h \mathbf{v} = (\pi_1 v_1, \pi_2 v_2),$$

where π_1 and π_2 are defined independently to each other.

Denote by P_h the L^2 projection from $L^2(\Omega)$ onto the pressure finite element space W_h.

3. A general framework in superconvergence. Let $(\mathbf{u}_h; p_h)$ be the mixed finite element approximation of (2.1) arising from the scheme (2.3). Our objective here is to establish a general framework for superconvergence estimation of the errors

$$\mathbf{e}_h = \mathbf{u}_h - \pi_h \mathbf{u}; \qquad \xi_h = p_h - P_h p.$$

THEOREM 3.1. *Assume that* $(\mathbf{u}; p)$ *solves the mixed problem* (2.2). *Let* $(\mathbf{u}_h; p_h)$ *solve* (2.3). *Assume that there is a constant* $M = M(\mathbf{u}, p)$ *and a parameter* $s \geq 0$ *satisfying*

$$\sup_{\mathbf{v} \in \mathbf{V}_{0,h}} \frac{(\boldsymbol{a}^{-1}(\mathbf{u} - \pi_h \mathbf{u}), \mathbf{v})}{\|\mathbf{v}\|_{\mathbf{V}}} \leq M(\mathbf{u}, p) h^{k+s}. \tag{3.1}$$

Then there is a generic constant C *independent of* h *and the solution* p *such that*

$$\|\mathbf{u}_h - \pi_h \mathbf{u}\|_0 + \|p_h - P_h p\|_0 \leq C M(\mathbf{u}, p) h^{k+s}.$$

Proof. By subtracting (2.3) from (2.2) we obtain

$$\begin{aligned} (\boldsymbol{a}^{-1}(\mathbf{u} - \mathbf{u}_h), \mathbf{v}) - (\nabla \cdot \mathbf{v}, p - p_h) &= 0, \qquad \mathbf{v} \in \mathbf{V}_{0,h}, \\ (\nabla \cdot (\mathbf{u} - \mathbf{u}_h), w) &= 0, \qquad w \in W_h. \end{aligned} \tag{3.2}$$

Using the error equation (3.2) and (2.4) we see that

$$\begin{aligned} (\boldsymbol{a}^{-1}\mathbf{e}_h, \mathbf{v}) - (\nabla \cdot \mathbf{v}, \xi_h) &= (\boldsymbol{a}^{-1}(\mathbf{u} - \pi_h \mathbf{u}), \mathbf{v}), \qquad \mathbf{v} \in \mathbf{V}_{0,h}, \\ (\nabla \cdot \mathbf{e}_h, w) &= 0, \qquad w \in W_h. \end{aligned} \tag{3.3}$$

The second equation in (3.3) implies that

$$\nabla \cdot \mathbf{e}_h = 0. \tag{3.4}$$

By letting $\mathbf{v} = \mathbf{e}_h$ in the first equation and $w = \xi_h$ in the second equation of (3.3), we arrive at

$$(\boldsymbol{a}^{-1}\mathbf{e}_h, \mathbf{e}_h) - (\nabla \cdot \mathbf{e}_h, \xi_h) = (\boldsymbol{a}^{-1}(\mathbf{u} - \pi_h \mathbf{u}), \mathbf{e}_h).$$

Substituting (3.4) into above equation we obtain

$$(\boldsymbol{a}^{-1}\mathbf{e}_h, \mathbf{e}_h) = (\boldsymbol{a}^{-1}(\mathbf{u} - \pi_h \mathbf{u}), \mathbf{e}_h). \tag{3.5}$$

It follows from the condition (3.1) that

$$(\boldsymbol{a}^{-1}\mathbf{e}_h, \mathbf{e}_h) \le Ch^{k+s} M(\mathbf{u}, p)\|\mathbf{e}_h\|_{\mathbf{V}},$$

which, along with (3.4), leads to

$$(\boldsymbol{a}^{-1}\mathbf{e}_h, \mathbf{e}_h) \le Ch^{k+s} M(\mathbf{u}, p)\|\mathbf{e}_h\|_0. \tag{3.6}$$

Thus,

$$\|\mathbf{e}_h\|_0 \le Ch^{k+s} M(\mathbf{u}, p). \tag{3.7}$$

This completes the estimate for the vector component.

Next, we estimate the L^2-norm of ξ_h. From the inf-sup condition and (3.2) we obtain

$$\begin{aligned}
\|\xi_h\|_0 &\le C \sup_{\mathbf{v}\in\mathbf{V}_{0,h}} \frac{(\nabla\cdot\mathbf{v}, \xi_h)}{\|\mathbf{v}\|_{\mathbf{V}}} \\
&= C \sup_{\mathbf{v}\in\mathbf{V}_{0,h}} \frac{(\nabla\cdot\mathbf{v}, p_h - p)}{\|\mathbf{v}\|_{\mathbf{V}}} \\
&= C \sup_{\mathbf{v}\in\mathbf{V}_{0,h}} \frac{(\boldsymbol{a}^{-1}\mathbf{v}, \mathbf{u}_h - \mathbf{u})}{\|\mathbf{v}\|_{\mathbf{V}}} \\
&= C \sup_{\mathbf{v}\in\mathbf{V}_{0,h}} \frac{(\boldsymbol{a}^{-1}\mathbf{v}, \mathbf{u}_h - \pi_h\mathbf{u}) + (\boldsymbol{a}^{-1}\mathbf{v}, \pi_h\mathbf{u} - \mathbf{u})}{\|\mathbf{v}\|_{\mathbf{V}}}, \\
&\le C \sup_{\mathbf{v}\in\mathbf{V}_{0,h}} \frac{(\boldsymbol{a}^{-1}\mathbf{v}, \mathbf{u} - \pi_h\mathbf{u})}{\|\mathbf{v}\|_{\mathbf{V}}} + C\|\mathbf{u}_h - \pi_h\mathbf{u}\|_0,
\end{aligned} \tag{3.8}$$

which, together with the error estimate (3.7) and the condition (3.1), gives

$$\|\xi_h\|_0 \le Ch^{k+s} M(\mathbf{u}, p). \tag{3.9}$$

The proof is then completed by combining (3.7) with (3.9). ∎

4. Some estimates for linear forms. Theorem 3.1 indicates that a superconvergence is guaranteed if one can establish a corresponding estimate for the linear form $\mathcal{F}(\mathbf{v}) = (\boldsymbol{a}^{-1}(\mathbf{u}-\pi_h\mathbf{u}), \mathbf{v})$ in the mixed finite element space $\mathbf{V}_{0,h}$. Our objective here is to study this linear form and derive some useful estimates.

Denote by

$$|\mathbf{u}|_{m,q;\Omega} = \sum_{|\alpha|=m} \|D^\alpha \mathbf{u}\|_{L^q(\Omega)}$$

the seminorm in the Sobolev space $W^{m,q}(\Omega)$ with integer $m \ge 0$ and real number $q \ge 1$. The norm in $W^{m,q}(\Omega)$ is denoted by

$$\|\mathbf{u}\|_{m,q;\Omega} = \sum_{j=0}^{m} |\mathbf{u}|_{j,q;\Omega}.$$

In addition, denote by

$$|w|_{m,q,h} = \sum_{|\alpha|=m} \left(\sum_{e\in\mathcal{T}_h} \|D^\alpha w\|^q_{L^q(e)} \right)^{1/q}$$

a discrete seminorm for any piecewise polynomials $w = w(x, y)$. The following estimate turns out to be critical in our analysis.

LEMMA 4.1. *Let $e \in \mathcal{T}_h$ be a rectangular element as illustrated in Figure 1 with $e = [x_i, x_{i+1}] \times [y_j, y_{j+1}]$. Let ψ be a sufficiently smooth function defined on e, and satisfy*

$$\int_{\ell_i} \psi dy = 0, \qquad i = 1, 3, \tag{4.1}$$

$$\int_e x^j \psi dx dy = 0, \qquad 0 \le j \le \tilde{k} - 1. \tag{4.2}$$

Then for any integer $m \le \tilde{k} + 1$, we have

$$\int_e (x - x_e)^m \psi dx dy = \frac{(-1)^m m!}{(2m+2)!} \int_e E^{m+1}(x) \partial_x^{m+2} \psi dx dy, \tag{4.3}$$

where ℓ_1, ℓ_3 are two vertical edges of the element e, $2h_e = x_{i+1} - x_i$ is the length of ℓ_2, (x_e, y_e) is the center of e, and $E(x) = (x - x_e)^2 - h_e^2$.

Proof. Let us apply the integration by parts to

$$\int_e E^{m+1}(x) \partial_x^{m+2} \psi(x, y) dx dy.$$

Notice that the function $E(x)$ vanishes at edges ℓ_1 and ℓ_3 where $x = x_{j+1}$ and $x = x_i$, respectively. Thus,

$$\int_e E^{m+1}(x) \partial_x^{m+2} \psi dx dy = (-1)^{m+1} \int_e \partial_x^{m+1} E^{m+1}(x) \partial_x \psi dx dy, \tag{4.4}$$

where contributions from the boundary integral are trivial due to the fact that $\partial_x^t E^{m+1}(x) = 0$ for $0 \le t < m + 1$ at $x = x_i$ and $x = x_{i+1}$. Next, using the integration by parts again we obtain

$$\int_e E^{m+1}(x) \partial_x^{m+2} \psi dx dy = (-1)^m \int_e \partial_x^{m+2} E^{m+1}(x) \psi dx dy, \tag{4.5}$$

where the boundary contribution vanishes because of the assumption (4.1).

Now we observe that

$$\partial_x^{m+2} E^{m+1}(x) = \frac{(2m+2)!}{m!} (x - x_e)^m + r(x), \tag{4.6}$$

where $r(x)$ is a polynomial of degree no more than $m - 2 \le \tilde{k} - 1$. By substituting (4.6) into (4.5) and then using the condition (4.2) we obtain

$$\int_e E^{m+1}(x) \partial_x^{m+2} \psi dx dy = \frac{(-1)^m (2m+2)!}{m!} \int_e (x - x_e)^m \psi dx dy,$$

which is (4.3). ∎

Let $\boldsymbol{a}^{-1}$ be a diagonal tensor given by

$$\boldsymbol{a}^{-1} = \begin{bmatrix} \alpha_1 & 0 \\ 0 & \alpha_2 \end{bmatrix}. \tag{4.7}$$

By expressing the vector-valued function $\mathbf{v}$ as $\mathbf{v} = (v_1, v_2)$, we arrive at

$$\mathcal{F}(\mathbf{v}) = (\alpha_1(u_1 - \pi_1 u_1), v_1) + (\alpha_2(u_2 - \pi_2 u_2), v_2). \tag{4.8}$$

The following lemma is concerned with the first linear form on the right-hand side of (4.8).

LEMMA 4.2. *Let $k \geq 1$ be an integer and u_1 be a sufficiently smooth function on the rectangle depicted in Figure* 1. *Let v_1 be a polynomial of degree no more than $k+1$ in x and k in y, respectively. Let v_2 be any sufficiently smooth function on e and $\mathbf{v} = (v_1, v_2)$. Then there is a $J_{1,e}$ such that*

$$(u_1 - \pi_1 u_1, v_1)_e = J_{1,e} + \frac{(-1)^k}{(2k+2)!}\left(\int_{\ell_4} - \int_{\ell_2}\right) E^{k+1}(x)\partial_x^{k+2} u_1 \partial_x^{k-1} v_2 dx. \tag{4.9}$$

The term $J_{1,e}$ can be represented as area integrals over the element e with the following estimate:

$$\begin{aligned} |J_{1,e}| \leq \frac{h_e^{2k+2}}{(2k+2)!}\Bigg(&\frac{h_e^2}{2k+3}|u_1|_{k+3,p;e}|v_1|_{k+1,q;e} \\ &+ |u_1|_{k+2,p;e}|\nabla\cdot\mathbf{v}|_{k-1,q;e} + |u_1|_{k+3,p;e}|v_2|_{k-1,q;e}\Bigg), \end{aligned} \tag{4.10}$$

where $2h_e = x_{i+1} - x_i$ is the width of the element and q is the conjugate of $p \geq 1$ satisfying $1/p + 1/q = 1$.

Proof. Let us expand the polynomial v_1 in x as follows:

$$v_1(x,y) = \sum_{i=0}^{k+1} \frac{1}{i!}(x - x_e)^i \partial_x^i v_1(x_e, y).$$

Each of $\partial_x^i v_1(x_e, y)$ is a polynomial of degree no more than k in y. The definition of π_1 implies that $u_1 - \pi_1 u_1$ is orthogonal to the polynomial space $Q_{k-1,k}$ (polynomials of degree no more than $k-1$ in x and k in y). Thus,

$$\begin{aligned} (u_1 - \pi_1 u_1, v_1)_e &= \frac{1}{k!}\int_e (x - x_e)^k (u_1 - \pi_1 u_1)\partial_x^k v_1(x_e, y) dxdy \\ &+ \frac{1}{(k+1)!}\int_e (x - x_e)^{k+1}(u_1 - \pi_1 u_1)\partial_x^{k+1} v_1(x_e, y) dxdy \\ &= I_1 + I_2, \end{aligned} \tag{4.11}$$

where I_j, $j = 1, 2$, are defined accordingly. Notice that $\partial_x^k v_1(x_e, y) \in Q_{0,k}$. By letting $\psi = (u_1 - \pi_1 u_1)\partial_x^k v_1(x_e, y)$ we see that conditions of Lemma 4.1 are satisfied with $\tilde{k} = k - 1$ and $m = k$. Thus, it follows from (4.3) that

$$I_1 = \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2} u_1 \partial_x^k v_1(x_e, y) dxdy. \tag{4.12}$$

Since $\partial_x^k v_1(x, y)$ is linear in x, then

$$\partial_x^k v_1(x_e, y) = \partial_x^k v_1(x, y) + (x_e - x)\partial_x^{k+1} v_1(x, y).$$

Substituting the above into (4.12) gives

$$\begin{aligned} I_1 &= \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^k v_1(x,y)dxdy \\ &\quad - \frac{(-1)^k}{(2k+2)!}\int_e (x-x_e)E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k+1}v_1(x,y)dxdy. \end{aligned} \tag{4.13}$$

To deal with the second term of (4.13), we use

$$(x-x_e)E^{k+1}(x) = \frac{1}{2k+4}\partial_x E^{k+2}(x)$$

to obtain

$$\begin{aligned} &\int_e (x-x_e)E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k+1}v_1(x,y)dxdy \\ &= \frac{1}{2k+4}\int_e \partial_x E^{k+2}(x)\partial_x^{k+2}u_1\partial_x^{k+1}v_1(x,y)dxdy \\ &= \frac{-1}{2k+4}\int_e E^{k+2}(x)\partial_x^{k+3}u_1\partial_x^{k+1}v_1(x,y)dxdy. \end{aligned} \tag{4.14}$$

Substituting (4.14) into (4.13) yields

$$\begin{aligned} I_1 &= \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^k v_1(x,y)dxdy \\ &\quad + \frac{(-1)^k}{(2k+4)(2k+2)!}\int_e E^{k+2}(x)\partial_x^{k+3}u_1\partial_x^{k+1}v_1(x,y)dxdy \\ &= I_{11} + I_{12}. \end{aligned} \tag{4.15}$$

With any given smooth function v_2, we rewrite the first term I_{11} of I_1 as follows:

$$\begin{aligned} I_{11} &= \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}(\partial_x v_1 + \partial_y v_2)dxdy \\ &\quad - \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}\partial_y v_2 dxdy. \end{aligned} \tag{4.16}$$

The second term above can be further simplified by using the integration by parts in y, yielding

$$\begin{aligned} I_{11} &= \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}\nabla\cdot\mathbf{v}\ dxdy \\ &\quad + \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_y\partial_x^{k+2}u_1\partial_x^{k-1}v_2 dxdy \\ &\quad + \frac{(-1)^k}{(2k+2)!}\left(\int_{\ell_4} - \int_{\ell_2}\right)E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}v_2 dx. \end{aligned} \tag{4.17}$$

Combining the above equations we see that

$$(u_1 - \pi_1 u_1, v_1)_e = I_1 + I_2 = I_{11} + I_{12} + I_2,$$

where I_{11} is given in (4.17), I_{12} can be seen in (4.15), and I_2 is the corresponding integral in (4.11). By letting $J_{1,e}$ represent the combined area integrals,

$$\begin{aligned} J_{1,e} = I_{12} + I_2 &+ \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}\nabla\cdot\mathbf{v}dxdy \\ &+ \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_y\partial_x^{k+2}u_1\partial_x^{k-1}v_2dxdy, \end{aligned} \tag{4.18}$$

we arrive at

$$(u_1 - \pi_1 u_1, v_1)_e = J_{1,e} + \frac{(-1)^k}{(2k+2)!}\left(\int_{\ell_4} - \int_{\ell_2}\right) E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}v_2dx.$$

Now we estimate the total area integrals $J_{1,e}$. The term I_{12} is given in (4.15), which is already well expressed. The term I_2 can be estimated by using Lemma 4.1. To this end, observe that the conditions of Lemma 4.1 are satisfied with $\tilde{k} = k$, $m = k+1$, and $\psi = (u_1 - \pi_1 u_1)\partial_x^{k+1}v_1$. Thus, it follows from Lemma 4.1 that

$$\begin{aligned} I_2 &= \frac{1}{(k+1)!}\int_e (x - x_e)^{k+1}(u_1 - \pi_1 u_1)\partial_x^{k+1}v(x,y)dxdy \\ &= \frac{(-1)^{k+1}}{(2k+4)!}\int_e E^{k+2}(x)\partial_x^{k+3}u_1\partial_x^{k+1}v_1dxdy. \end{aligned} \tag{4.19}$$

Substituting the above into (4.18) we obtain

$$\begin{aligned} J_{1,e} = I_{12} &+ \frac{(-1)^{k+1}}{(2k+4)!}\int_e E^{k+2}(x)\partial_x^{k+3}u_1\partial_x^{k+1}v_1dxdy \\ &+ \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_x^{k+2}u_1\partial_x^{k-1}\nabla\cdot\mathbf{v}dxdy \\ &+ \frac{(-1)^k}{(2k+2)!}\int_e E^{k+1}(x)\partial_y\partial_x^{k+2}u_1\partial_x^{k-1}v_2dxdy. \end{aligned} \tag{4.20}$$

Since $|E(x)| \le h_e^2$, using the Hölder inequality, we obtain the following estimate:

$$\begin{aligned} |J_{1,e}| \le \frac{h_e^{2k+2}}{(2k+2)!}\Bigg(&\frac{h_e^2}{2k+3}|u_1|_{k+3,p;e}|v_1|_{k+1,q;e} \\ &+ |u_1|_{k+2,p;e}|\nabla\cdot\mathbf{v}|_{k-1,q;e} + |u_1|_{k+3,p;e}|v_2|_{k-1,q;e}\Bigg), \end{aligned} \tag{4.21}$$

which is the desired inequality in Lemma 4.2. ∎

A similar estimate can be derived for the second linear form on the right-hand side of (4.8). The result is stated as follows without any proof.

LEMMA 4.3. *Let $k \ge 1$ be an integer and u_2 be a sufficiently smooth function on the rectangle depicted in Figure* 1. *Let v_2 be a polynomial of degree no more than $k+1$ in y and k in x, respectively. Let v_1 be any sufficiently smooth function on e*

and $\mathbf{v} = (v_1, v_2)$. *Then there is a term* $J_{2,e}$ *such that*

$$(u_2 - \pi_2 u_2, v_2)_e = J_{2,e} + \frac{(-1)^k}{(2k+2)!}\left(\int_{\ell_3} - \int_{\ell_1}\right) E^{k+1}(y)\partial_y^{k+2} u_2 \partial_y^{k-1} v_1 dy. \tag{4.22}$$

The term $J_{2,e}$ *can be represented as area integrals over the element* e *with the following estimate:*

$$\begin{aligned} |J_{2,e}| \le \frac{\tau_e^{2k+2}}{(2k+2)!}\Bigg(&\frac{\tau_e^2}{2k+3}|u_2|_{k+3,p;e}|v_2|_{k+1,q;e} \\ &+ |u_2|_{k+2,p;e}|\nabla\cdot\mathbf{v}|_{k-1,q;e} + |u_2|_{k+3,p;e}|v_1|_{k-1,q;e}\Bigg), \end{aligned} \tag{4.23}$$

where $2\tau_e = y_{j+1} - y_j$ *is the height of the element and* q *is the conjugate of* $p \ge 1$ *satisfying* $1/p + 1/q = 1$.

5. Superconvergence. Our objective here is to derive some superconvergence for the mixed finite element methods by combining Theorem 3.1 with the estimates established in the previous section. From Theorem 3.1, it is sufficient to investigate the condition (3.1) with a maximum value for the parameter s.

Let us recall that the linear form $\mathcal{F}(\mathbf{v})$ consists of two components:

$$\mathcal{F}_1(v_1) = (\alpha_1(u_1 - \pi_1 u_1), v_1), \qquad \mathcal{F}_2(v_2) = (\alpha_2(u_2 - \pi_2 u_2), v_2).$$

We intend to deal with $\mathcal{F}_1(v_1)$ and $\mathcal{F}_2(v_2)$ by using Lemmas 4.2 and 4.3, respectively.

Assume that α_1 and α_2 are two constants in the computational domain Ω. It is easy to see that

$$\mathcal{F}_1(v_1) = \alpha_1 \sum_{e\in\mathcal{T}_h} (u_1 - \pi_1 u_1, v_1)_e.$$

On each element e, Lemma 4.2 can be employed to give

$$\mathcal{F}_1(v_1) = \alpha_1 \sum_{e\in\mathcal{T}_h} J_{1,e} + \alpha_{1,k} \sum_{e\in\mathcal{T}_h} \left(\int_{\ell_4} - \int_{\ell_2}\right) E^{k+1}(x)\partial_x^{k+2} u_1 \partial_x^{k-1} v_2 dx, \tag{5.1}$$

where $\alpha_{1,k} = \frac{(-1)^k \alpha_1}{(2k+2)!}$ and v_2 is chosen to be the second component of the vector-valued function $\mathbf{v}$. Observe that the line integral over ℓ_4 is given as an integral along the bottom edge and the integral over ℓ_2 is given as one on the top edge of e. If ℓ_4 is not a boundary edge, then there will be another element, say $\tilde{e}$, for which ℓ_4 is seen as the top edge and the corresponding integral on ℓ_4 has an opposite sign from the contribution of e. Thus, all the line integrals over interior edges must cancel each other in the second summation of (5.1). The line integrals on the boundary edges vanish due to the fact that $v_2 = 0$ along all the horizontal boundary edges (which stems from $\mathbf{v} \in \mathbf{V}_{0,h}$). Thus, we obtain

$$\mathcal{F}_1(v_1) = \alpha_1 \sum_{e\in\mathcal{T}_h} J_{1,e}. \tag{5.2}$$

Now we use the estimate (4.10) with $p = q = 2$ to obtain

$$
\begin{aligned}
|\mathcal{F}_1(v_1)| &\le \alpha_1 \sum_{e\in\mathcal{T}_h} |J_{1,e}| \\
&\le \alpha_1 \sum_{e\in\mathcal{T}_h} \frac{h_e^{2k+2}}{(2k+2)!} \left(\frac{h_e^2}{2k+3} |u_1|_{k+3,2;e} |v_1|_{k+1,2;e} \right. \\
&\qquad \left. + |u_1|_{k+2,2;e} |\nabla\cdot\mathbf{v}|_{k-1,2;e} + |u_1|_{k+3,2;e} |v_2|_{k-1,2;e} \right) \qquad (5.3) \\
&\le \alpha_1 \frac{\tilde{h}^{2k+2}}{(2k+2)!} \left(\frac{\tilde{h}^2}{2k+3} |u_1|_{k+3,2,h} |v_1|_{k+1,2,h} \right. \\
&\qquad \left. + |u_1|_{k+2,2,h} |\nabla\cdot\mathbf{v}|_{k-1,2,h} + |u_1|_{k+3,2,h} |v_2|_{k-1,2,h} \right),
\end{aligned}
$$

where $\tilde{h} = \max_{e\in\mathcal{T}_h} h_e$. By applying the standard inverse inequality to various norms of $\mathbf{v}$ in (5.3), we arrive at

$$
\begin{aligned}
|\mathcal{F}_1(v_1)| &\le C\tilde{h}^{k+3} \|u_1\|_{k+3,2;\Omega} \left(\|\mathbf{v}\|_0 + \|\nabla\cdot\mathbf{v}\|_0 \right) \\
&\le C\tilde{h}^{k+3} \|u_1\|_{k+3,2;\Omega} \|\mathbf{v}\|_{\mathbf{V}}.
\end{aligned} \qquad (5.4)
$$

The above argument can be extended to the linear form $\mathcal{F}_2(v_2)$ by using Lemma 4.3. With $\tilde{\tau} = \max_{e\in\mathcal{T}_h} \tau_e$, the corresponding estimate is given by

$$
|\mathcal{F}_2(v_2)| \le C\tilde{\tau}^{k+3} \|u_2\|_{k+3,2;\Omega} \|\mathbf{v}\|_{\mathbf{V}}. \qquad (5.5)
$$

Substituting (5.4) and (5.5) into (4.8), we obtain

$$
|\mathcal{F}(\mathbf{v})| \le C(\tilde{h}^{k+3} + \tilde{\tau}^{k+3}) \|\mathbf{u}\|_{k+3,2;\Omega} \|\mathbf{v}\|_{\mathbf{V}}.
$$

Thus, the condition (3.1) holds true with $s = 3$ and $h = \max(\tilde{h}, \tilde{\tau})$. To summarize, we have proved the following superconvergence result.

THEOREM 5.1. *Assume that* $(\mathbf{u}; p)$ *solves the mixed problem* (2.2) *and* $\mathbf{u} \in \left[H^{k+3}\right]^2$. *Let the tensor* $\boldsymbol{a}^{-1}$ *in* (2.2) *be given by* (4.7) *with constant entries* α_i. *Let* $(\mathbf{u}_h; p_h)$ *solve* (2.3). *Then there is a generic constant* C *independent of* h *and the solution* p *such that*

$$
\|\mathbf{u}_h - \pi_h\mathbf{u}\|_0 + \|p_h - P_h p\|_0 \le Ch^{k+3} \|\mathbf{u}\|_{k+3,2;\Omega}. \qquad (5.6)
$$

The cancellation of line integrals in (5.1) is crucial for the superconvergence estimate (5.6). Let us recall that in (5.1), the line segments ℓ_2 and ℓ_4 correspond to the top and bottom edge of the element e (see Figure 1). The cancellation of the line integral over ℓ_2 occurs if either ℓ_2 is on the boundary of Ω (hence, $v_2 = 0$) or there is another integral over ℓ_2 with opposite sign that was contributed from the element $\tilde{e}$ right above e. In the later case, the function $\alpha_1 = \alpha_1(x, y)$ must have the same value on e and $\tilde{e}$ in order to have a complete cancellation. Thus, all the line integrals in (5.1) cancel each other as long as the function $\alpha_1 = \alpha_1(x, y)$ is a constant on each vertical strip $\{[x_i, x_{i+1}] \times (-\infty, \infty)\} \cap \Omega$. Similarly, the function $\alpha_2 = \alpha_2(x, y)$ must be a constant on each horizontal strip $\{(-\infty, \infty) \times [y_j, y_{j+1}]\} \cap \Omega$ in order to have a full cancellation of the line integrals in the linear form $\mathcal{F}_2(v_2)$. The remaining area

integrals can be handled in the same manner by using the estimates (4.10) and (4.23). The result is summarized as follows.

THEOREM 5.2. *Assume that* $(\mathbf{u};p)$ *solves the mixed problem* (2.2) *and* $\mathbf{u} \in \left[H^{k+3}\right]^2$. *Let the tensor* $\boldsymbol{a}^{-1}$ *be given in* (4.7), *where* $\alpha_1 = \alpha_1(x)$ *and* $\alpha_2 = \alpha_2(y)$ *are piecewise constant functions. Let* $(\mathbf{u}_h;p_h)$ *solve* (2.3). *Then there is a generic constant* C *independent of* h *and the solution* p *such that*

$$\|\mathbf{u}_h - \pi_h\mathbf{u}\|_0 + \|p_h - P_hp\|_0 \le Ch^{k+3}\|\mathbf{u}\|_{k+3,2;\Omega}. \tag{5.7}$$

In the rest of this section, we derive a superconvergence for (2.3) when the tensor $\boldsymbol{a}^{-1}$ has piecewise constant entries in both x and y direction. To this end, let $\bar{\Omega} = \bigcup_{s=1}^{m} \bar{\Omega}_s$ be a nonoverlapping coarse partition of the domain Ω. Assume that the entries $\alpha_i = \alpha_i(x,y)$, $i = 1,2$, have constant values on each subdomain Ω_s. Assume that the finite element partition $\mathcal{T}_h$ aligns with the above coarse partition in the sense that each element $e = [x_i, x_{i+1}] \times [y_j, y_{j+1}] \in \mathcal{T}_h$ intersects with one and only one of the subdomains Ω_s, $s = 1,\ldots,m$.

How do the line integrals cancel each other in the representation (5.1) for the linear form $\mathcal{F}(\mathbf{v})$? It is clear that all the line integrals which are interior to any subdomain Ω_s cancel each other in the way that was explained earlier. But the line integrals along the boundary of Ω_s will not go away from (5.1) because there is no counterpart from their neighbors for a complete cancellation. Let Γ_s be the part of the boundary of Ω_s where the line integrals do not vanish. Using the Hölder inequality, such line integrals can be estimated by

$$B = Ch^{2k+2}|u_1|_{k+2,\infty;\Omega_s}\int_{\Gamma_s} |\partial_\gamma^{k-1}v_2|d\Gamma_s, \tag{5.8}$$

where ∂_γ is the tangential derivative operator along Γ_s. It is routine to show that

$$\int_{\Gamma_s} |\partial_\gamma^{k-1}v_2|d\Gamma_s \le C\left(h^{-1/2}|v_2|_{k-1,2;\Omega_s} + h^{1/2}|v_2|_{k,2;\Omega_s}\right). \tag{5.9}$$

By first substituting the above into (5.8) and then using the inverse inequality on $|v_2|_{k-1,2;\Omega_s}$ and $|v_2|_{k,2;\Omega_s}$, we obtain

$$B \le Ch^{k+2.5}|u_1|_{k+2,\infty;\Omega_s}\|v_2\|_{0,2;\Omega_s}.$$

The corresponding superconvergence is summarized as follows.

THEOREM 5.3. *Assume that* $(\mathbf{u};p)$ *solves the mixed problem* (2.2) *and* $\mathbf{u} \in \left[H^{k+3}\right]^2$. *Let the tensor* $\boldsymbol{a}^{-1}$ *be given in* (4.7), *where* $\alpha_1 = \alpha_1(x,y)$ *and* $\alpha_2 = \alpha_2(x,y)$ *are piecewise constant functions on* Ω. *Let* $(\mathbf{u}_h;p_h)$ *solve* (2.3). *Then there is a generic constant* C *independent of* h *and the solution* p *such that*

$$\|\mathbf{u}_h - \pi_h\mathbf{u}\|_0 + \|p_h - P_hp\|_0 \le Ch^{k+2.5}\left(\|\mathbf{u}\|_{k+2,\infty;\Omega} + \|\mathbf{u}\|_{k+3,2;\Omega}\right). \tag{5.10}$$

6. Postprocessing by patch recovery. The results developed in Theorems 5.1–5.3 indicate a supercloseness between the mixed finite element approximation $\mathbf{u}_h$ and the locally defined projection $\pi_h\mathbf{u}$ of the exact flux variable $\mathbf{u}$. This supercloseness estimate does not mean any superconvergence between $\mathbf{u}$ and its finite element approximation $\mathbf{u}_h$ because no superconvergence is known between $\pi_h\mathbf{u}$ and the exact solution $\mathbf{u}$. In general, $\pi_h\mathbf{u}$ does not have any superconvergence to $\mathbf{u}$ globally in the L^2-norm.

Our objective in this section is to provide a new approximation based on a patch recovery approach that postprocesses $\mathbf{u}_h$ locally on each element. A general framework can be described as follows. Let $\mathbf{u}_h$ be a certain finite element approximation of the exact solution $\mathbf{u}$ with the following error estimate:

$$\|\mathbf{u}_h - \pi_h \mathbf{u}\|_0 \leq Ch^{k+3}\|\mathbf{u}\|_{k+3}, \tag{6.1}$$

where $\pi_h\mathbf{u}$ is a projection of $\mathbf{u}$ into the same finite element space. The interpolation error between $\mathbf{u}$ and $\pi_h\mathbf{u}$ is assumed to be worse than the order $\mathcal{O}(h^{k+3})$. However, thanks to the estimate (6.1) and the locality of $\pi_h\mathbf{u}$, it is possible to construct a new approximate solution based on $\mathbf{u}_h$ which approximates $\mathbf{u}$ with the superconvergence order of $\mathcal{O}(h^{k+3})$. This new approximate solution is often realized through an operator Q_h from the finite element space to a new finite element space consisting of high order (e.g., of order $k+s$ on each element) of polynomials with the following property:

$$Q_h\pi_h\mathbf{u} = Q_h\mathbf{u}. \tag{6.2}$$

If so, the accuracy of the new approximate solution $Q_h\mathbf{u}_h$ can be justified as follows:

$$\begin{aligned} \|\mathbf{u} - Q_h\mathbf{u}_h\|_0 &\leq \|\mathbf{u} - Q_h\mathbf{u}\|_0 + \|Q_h\mathbf{u} - Q_h\mathbf{u}_h\|_0 \\ &\leq \|\mathbf{u} - Q_h\mathbf{u}\|_0 + \|Q_h(\pi_h\mathbf{u} - \mathbf{u}_h)\|_0 \\ &\leq Ch^{k+s+1}\|\mathbf{u}\|_{k+s+1} + Ch^{k+3}\|\mathbf{u}\|_{k+3}. \end{aligned} \tag{6.3}$$

Here we have assumed the L^2-boundedness of the operator Q_h. In general, the boundedness of Q_h depends on the property of the corresponding finite element partition and the choice of interpolating spaces.

The rest of this section will give a constructive approach to a postprocessing operator Q_h for the mixed finite element approximations.

6.1. Some technical tools. It is well known that polynomials can be uniquely determined by their values at a set of points. In the mixed finite element method, the local projection operator π_h is defined by using both line and area moments which must be examined carefully in the construction of our postprocessing operator Q_h. Let us provide some new characterization for polynomials by using line moments. To this end, let

$$M_0(x) = 1 - x, \quad M_1(x) = 1 + x, \quad M_j(x) = \frac{d^{j-2}\left((1-x^2)^{j-1}\right)}{dx^{j-2}}, \qquad j \geq 2,$$

be a set of polynomials. The set of derivatives $\{L_j(x) \equiv M_{j+1}^{'}(x),\ j = 0, 1, \dots\}$ is the set of well-known Legendre polynomials.

LEMMA 6.1. *Let $I = [-1, 1]$ and x_0 be a fixed, but arbitrary, point in $(-1, 1)$. Then any polynomial $w = w(x) \in P_{k+2}(I)$ is uniquely determined by the following set of degrees of freedom:*

$$w(\pm 1), \quad \int_{-1}^{1} w(s)\phi(x)dx, \quad \int_{-1}^{x_0} w(s)(x - x_0)^{k-1}dx \tag{6.4}$$

for all $\phi \in P_{k-1}(I)$.

Proof. The total number of degrees of freedom in (6.4) is given by $2+k+1 = k+3$, which is the same as the dimension of the polynomial space $P_{k+2}(I)$. It is therefore

sufficient to verify the uniqueness. To this end, let $w \in P_{k+2}(I)$ satisfy

$$w(\pm 1) = 0, \tag{6.5}$$

$$\int_{-1}^{1} w(s)\phi(x)dx = 0 \qquad \forall \phi \in P_{k-1}(I), \tag{6.6}$$

$$\int_{-1}^{x_0} w(s)(x - x_0)^{k-1}dx = 0. \tag{6.7}$$

Let us show that $w \equiv 0$. We express $w = w(x)$ as follows:

$$w(x) = \sum_{i=0}^{k+2} \alpha_i M_i(x), \tag{6.8}$$

where α_i are real numbers. Notice that $M_j(\pm 1) = 0$ for any $j \geq 2$. Thus, the condition $w(\pm 1) = 0$ implies that $\alpha_0 = \alpha_1 = 0$.

Next, let us test (6.8) against any $M_j^{''}(x)$ for $2 \leq j \leq k+1$. It follows from the condition (6.6) that

$$\int_{-1}^{1} w(x)M_j^{''}(x)dx = 0.$$

On the other hand, using the integration by parts, we obtain

$$\int_{-1}^{1} w(x)M_j^{''}(x)dx = -\int_{-1}^{1} w'(x)M_j^{'}(x)dx = \alpha_j c_j$$

for some constant $c_j \neq 0$. Hence, $\alpha_j = 0$ for any $2 \leq j \leq k+1$.

It remains to show that $\alpha_{k+2} = 0$. To this end, we use the condition (6.7) to obtain

$$\begin{aligned}
0 &= \int_{-1}^{x_0} w(x)(x - x_0)^{k-1}dx \\
&= \alpha_{k+2} \int_{-1}^{x_0} M_{k+2}(x)(x - x_0)^{k-1}dx \\
&= \alpha_{k+2} \int_{-1}^{x_0} \left((1 - x^2)^{k+1}\right)^{(k)} (x - x_0)^{k-1}dx \\
&= \alpha_{k+2}(-1)^{k-1}(k-1)! \int_{-1}^{x_0} ((1 - x^2)^{k+1})^{'}dx \\
&= \alpha_{k+2}(-1)^{k-1}(k-1)!(1 - x_0^2)^{k+1},
\end{aligned}$$

which implies that $\alpha_{k+2} = 0$. This completes the proof. □

Our next result will determine a polynomial of degree $k+2$ by using a different set of degrees of freedom.

LEMMA 6.2. *Let $w = w(x) \in P_{k+2}(I)$ be a polynomial of degree $k+2$ satisfying*

$$\int_{-1}^{1} w(s)\phi(x)dx = 0 \qquad \forall \phi \in P_k(I), \tag{6.9}$$

$$\int_{-1}^{x_0} (x - x_0)^{k-i} w(x)dx = 0, \qquad i = 0, 1, \tag{6.10}$$

where $x_0 \in (-1, 1)$ is a fixed, but arbitrary, point. Then one has $w \equiv 0$.

Proof. The polynomial $w = w(x)$ can be represented by using the Legendre polynomials as follows:

$$w(x) = \sum_{i=0}^{k+2} \alpha_i L_i(x),$$

where $L_i(x) = M_{i+1}^{'}(x)$ is the Legendre polynomial of order i. From (6.9) we have

$$\alpha_i = 0, \qquad i = 0, 1, \ldots, k.$$

It remains to show that $\alpha_{k+1} = \alpha_{k+2} = 0$. To this end, we use the second momentum condition (6.10) to obtain

$$\begin{aligned}
0 &= \int_{-1}^{x_0} (x - x_0)^k w(x)dx \\
&= \sum_{i=k+1}^{k+2} \alpha_i \int_{-1}^{x_0} (x - x_0)^k L_i(x) \\
&= \sum_{i=k+1}^{k+2} \alpha_i \int_{-1}^{x_0} (x - x_0)^k M_{i+1}^{'}(x) \\
&= (-1)^k k! \alpha_{k+1} (1 - x_0^2)^{k+1} + \alpha_{k+2} (-1)^k k! \int_{-1}^{x_0} \frac{d^2 \left((1 - x^2)^{k+2}\right)}{dx^2} dx \\
&= (-1)^k k! (1 - x_0^2)^{k+1} \left(\alpha_{k+1} - 2x_0 \alpha_{k+2}(k+2)\right)
\end{aligned}$$

and

$$\begin{aligned}
0 &= \int_{-1}^{x_0} (x - x_0)^{k-1} w(x)dx \\
&= \sum_{i=k+1}^{k+2} \alpha_i \int_{-1}^{x_0} (x - x_0)^{k-1} M_{i+1}^{'}(x) \\
&= (-1)^{k-1} (k-1)! \left(\alpha_{k+1} \frac{d\left((1 - x^2)^{k+1}\right)}{dx} + c_{k+2} \frac{d^2 (1 - x^2)^{k+2}}{dx^2} \right) \Bigg|_{x = x_0} \\
&= 2(-1)^k (k-1)! (1 - x_0^2)^k \left(\alpha_{k+1}(k+1)x_0 + \alpha_{k+2}(k+2)(1 - 2x_0^2(k+1)) \right).
\end{aligned}$$

The above two equations imply that

$$\begin{aligned}
\alpha_{k+1} - 2x_0(k+2)\alpha_{k+2} &= 0, \\
x_0(k+1)\alpha_{k+1} + (k+2)(1 - 2x_0^2(k+1))\alpha_{k+2} &= 0,
\end{aligned}$$

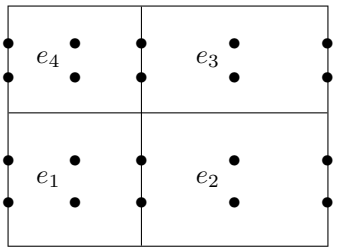

FIG. 2. *A patch K of four rectangular elements.*

which has only a trivial solution since the determinant of the coefficient matrix is

$$(k+2)(1-2x_0^2(k+1))+2x_0^2(k+1)(k+2)=k+2\neq 0.$$

This completes the proof of the lemma. □

6.2. Patch recovery for mixed finite element approximations. Recall that the general theory requires a locally defined operator Q_h satisfying the property (6.2). Here we construct such an operator by using the technical results developed in the previous subsection.

Let $e_1 \in \mathcal{T}_h$ be any element in the finite element rectangular partition. First, we find three neighboring elements, e_i, $i = 2, 3, 4$, such that $K = \bigcup_{i=1}^4 e_i$ forms a larger rectangle (it is a patch of rectangular elements). Second, we construct a polynomial of degree $k + 2$ in both x and y direction on the patch K by using certain degrees of freedom. Does $\pi_h \mathbf{u}$ contain enough information on K to guarantee the existence of an operator Q_h satisfying (6.2)? To answer this question, let us take for example $k = 1$ and consider only the first component of $\pi_h \mathbf{u}$. As a piecewise polynomial, the first component $\pi_h u_1$ has 20 degrees of freedom on K (dotted points in Figure 2). On the other hand, the new interpolation space $Q_{3,3}(K)$ has dimension 16. This simple dimension counting indicates that $\pi_h \mathbf{u}$ *may* contain enough information for the construction of a projection operator Q_h satisfying (6.2). The rest of this section gives a rigorous approach.

For the sake of discussion, let the patch K be given by

$$K = [-1, 1] \times [-1, 1],$$

which consists of four elements:

$$\begin{aligned} e_1 &:= [-1, x_0] \times [-1, y_0], \qquad & e_2 &= [x_0, 1] \times [-1, y_0], \\ e_3 &:= [x_0, 1] \times [y_0, 1], \qquad & e_4 &:= [-1, x_0] \times [y_0, 1]. \end{aligned}$$

Notice that the patch K is normally nonuniform. Our projection operator Q_h can be given as the product of two operators S_1^x and S_2^y defined in the x and the y direction, respectively. More precisely, the operator S_1^x takes a function to a polynomial $\phi = \phi(x)$ of degree $k + 2$ by using the degrees of freedom specified in Lemma 6.1 and the operator S_2^y makes use of the degrees of freedom given in Lemma 6.2. On the target element e_1, the first component of $Q_h \mathbf{u}$ is defined as the restriction of $S_2^y S_1^x u_1$ to e_1. Similarly, the second component of $Q_h \mathbf{u}$ is defined as the restriction of $S_2^x S_1^y u_2$ to e_1. This operator Q_h can be easily verified to satisfy the crucial condition (6.2) on the target element e_1. It is also not hard to see that Q_h is bounded in the L^2-norm

for regular partitions. Consequently, we have proved the following superconvergence result.

THEOREM 6.1. *Let Q_h be the locally defined operator outline as above and $\mathbf{u}_h$ be the mixed finite element approximation obtained from* (2.3)*. Under the same assumption of Theorem* 5.1*, there exists a constant C independent of the exact solution $(\mathbf{u}; p)$ and the mesh size h such that*

$$\|\mathbf{u} - Q_h\mathbf{u}_h\|_0 \leq Ch^{k+3}\|\mathbf{u}\|_{k+3}.$$

Similar superconvergence can be established for the mixed finite element method by using Theorems 5.2 and 5.3. The details are omitted.

THE $\mathcal{P}^{K+1} - \mathcal{S}^K$ LOCAL DISCONTINUOUS GALERKIN METHOD FOR ELLIPTIC EQUATIONS*

CLINT DAWSON†

Abstract. A local discontinuous Galerkin (LDG) method using approximating spaces of order $k+1$ for the gradient and order k for the state variable, with $k \geq 0$, is presented for an elliptic boundary value problem. A priori error estimates are derived and numerical results presented, which demonstrate that this method is order $k+1$ for both the gradient and state variable in the L^2 norm. This improves upon earlier LDG methods which use equal order approximating spaces for both variables, but lose an order of accuracy in the gradient approximation. This approach is also the first convergent LDG method which allows for piecewise constant approximations for the state variable.

Key words. discontinuous Galerkin method, elliptic flow problem, a priori error estimate

1. Introduction.

In this paper, we consider the solution $(\mathbf{u}, p)$ of the second order elliptic problem,

$$cp + \nabla \cdot \mathbf{u} = f \qquad \text{in } \Omega, \tag{1}$$

$$\mathbf{u} = -K\nabla p \qquad \text{in } \Omega, \tag{2}$$

satisfying the boundary conditions

$$p = g_D \qquad \text{on } \partial\Omega, \tag{3}$$

by a local discontinuous Galerkin (LDG) approach. Because of the similarity to porous media flow, we will often refer to the variable p as a fluid "pressure" and $\mathbf{u}$ as fluid "velocity." In this context, c is a compressibility factor and K a permeability tensor. We assume K is uniformly symmetric and positive definite, with

$$K^* \geq K^{-1} \geq K_* > 0, \tag{4}$$

and throughout most of the paper, we assume

$$c^* \geq c(x) \geq c_* > 0. \tag{5}$$

We will consider the case $c = 0$ in section 6.

The LDG method is a type of classical mixed method, whereby the state variable (p) and its flux ($\mathbf{u}$) are simultaneously approximated. The LDG method was introduced by Cockburn and Shu in [13], and since then has been rigorously studied by a number of researchers for convection-diffusion problems [9, 1, 8, 15], purely elliptic problems [7, 11, 6], and Stokes problems [12]. The analysis and implementation of the LDG method to date has primarily used equal order approximating spaces for

the state variable and the gradient. We refer to this approach as the $\mathcal{P}^k - \mathcal{P}^k$ LDG method, where $\mathcal{P}^k$ denotes the set of complete polynomials of degree k. This method has been shown to give optimal order (h^{k+1}) convergence for p in the L^2 norm, but loses an order of accuracy for $\mathbf{u}$. It also requires that $k \geq 1$. In [12], an LDG method with the gradient approximated in $\mathcal{P}^{k-1}$ and the state variable in $\mathcal{P}^k$ was investigated for the Stokes system, but no advantage in efficiency was seen over the $\mathcal{P}^k - \mathcal{P}^k$ method.

The initial motivation for the work presented here was to develop an LDG method that allows for the pressure to be approximated in $\mathcal{P}^0$, as the ability to use piecewise constant approximations is often desirable in practice. This led to the development of the so-called $\mathcal{P}^1 - \mathcal{P}^0$ LDG method [14], which uses a piecewise constant approximation of p and a piecewise linear approximation of $\mathbf{u}$. This approach relies on the construction of a sufficiently accurate and stable numerical flux on the interface between elements. The construction of this flux differs from that proposed in any discontinuous Galerkin (DG) method to date. In fact, the method does not fall within the unified approach for DG methods given in [2], and thus cannot be analyzed using the techniques described therein. Still, first order convergence in L^2 for p and $\mathbf{u}$ was demonstrated in [14].

In this paper, we outline an extension of the $\mathcal{P}^1 - \mathcal{P}^0$ method to any order $k \geq 0$. We call the resulting approach the $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG method. In this approach, $\mathbf{u}$ is approximated by polynomials of degree $k+1$, and p is approximated in a space $\mathcal{S}^k$ predominantly consisting of polynomials of degree k, although some terms of order $k+1$ may be needed in the approximation of p when $k > 0$, as we will see below. Thus, in general $\mathcal{S}^k$ is somewhere "between" $\mathcal{P}^k$ and $\mathcal{P}^{k+1}$, but in the case $k = 0$, $\mathcal{S}^0 = \mathcal{P}^0$. A primary motivation for this approach is that, unlike the standard LDG methods mentioned above, pressure and velocity are approximated to the same order of accuracy. In many physical applications, porous media flow being a prime example, it is the velocity $\mathbf{u}$ that is the quantity of interest, therefore it is important to approximate this variable as accurately as p is approximated. The $\mathcal{P}^{k+1} - \mathcal{S}^k$ method gives h^{k+1} convergence for both variables, while still requiring only the solution of a linear system for the approximation to p. As in the $\mathcal{P}^1 - \mathcal{P}^0$ method, a necessary ingredient in our approach is the construction of a stable, accurate numerical flux. We will also improve upon our earlier results in [14] for the $\mathcal{P}^1 - \mathcal{P}^0$ method by extending our analysis to the case $c = 0$ in (1).

Since the LDG method is a type of classical mixed method, the $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG scheme is very similar in spirit to the mixed finite element method as described in, for example, [20, 5]. Mixed finite element approximating spaces, for example the Raviart–Thomas spaces, typically employ polynomials of degree $k+1$ for the velocity and k for pressure, with convergence rates of order h^{k+1} for both variables. In the standard mixed method, the velocities are constrained to be in $H(\Omega; \mathrm{div})$, which requires that the normal component of velocity must be continuous across element faces. In the LDG method, we drop this continuity requirement on the normal flux, the result being that the velocity unknowns can be resolved locally (element by element) in terms of the pressure unknowns.

In the next section, we will outline the $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG method. We then give an error analysis of the method in standard L^2 norms. In section 4, we discuss in some detail the construction of a numerical flux, $\widehat{w}$, which is crucial to the method. In section 5, we present some numerical results which confirm our theory. Finally, in section 6, we consider the case $k = 0$ again with the assumption that the coefficient

$c = 0$.

2. The $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG method. In this section, we define the $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG method. First, we introduce some notation.

Let $\mathcal{T}_h$ denote a triangulation of Ω into elements Ω_e. We will make the following fairly standard assumptions on $\mathcal{T}_h$; see [4]. We assume each element Ω_e is affinely equivalent to one of several reference elements. We also assume $\mathcal{T}_h$ is regular; that is, the ratio of the diameter h_e of Ω_e and the diameter ρ_e of the largest ball contained in Ω_e (the "chunkiness parameter" [4]) is bounded by a positive constant:

$$\frac{h_e}{\rho_e} \leq \sigma_1 \qquad \forall \Omega_e. \tag{6}$$

The interior element boundaries need not align; however, we assume that Ω_e has a fixed, maximum number of neighbors. A neighbor of Ω_e is defined to be any element $\Omega_{e'}$ such that

$$\text{interior of } \partial\Omega_e \cap \partial\Omega_{e'} \neq \emptyset. \tag{7}$$

For such neighboring elements, we will assume a local quasi uniformity; that is, we assume a positive constant $\sigma_2 < 1$ exists, independent of Ω_e and $\Omega_{e'}$, such that

$$\sigma_2 \leq \frac{h_e}{h_{e'}} \leq \sigma_2^{-1}. \tag{8}$$

Finally, let

$$h = \max_e h_e.$$

We denote by $(\cdot,\cdot)_R$ the usual L^2 inner product over a d dimensional domain R; to emphasize that the integration is over $(d-1)$ dimensional surfaces, we write $\langle \cdot,\cdot \rangle_{\partial R}$. We denote by $||\cdot||_R$ the L^2 norm on R. Norms in other Sobolev spaces $H(R)$ will be denoted by $||\cdot||_{H(R)}$.

Suppose Ω_e^- and Ω_e^+ are adjacent elements with unit outward normals $\mathbf{n}^-$ and $\mathbf{n}^+$, and $(\mathbf{v}, w)$ are smooth functions defined on these elements, with $\mathbf{v}$ vector-valued and w a scalar. Let $(\mathbf{v}^\pm, w^\pm)$ denote the traces of $(\mathbf{v}, w)$ on the face γ between Ω_e^+ and Ω_e^- from the interiors of the elements. We define the average $\{\cdot\}$ and jump $[\![\cdot]\!]$ for $\mathbf{x} \in \gamma$ as follows:

$$\{w\} = (w^- + w^+)/2, \qquad \{\mathbf{v}\} = (\mathbf{v}^- + \mathbf{v}^+)/2, \tag{9}$$

$$[\![w]\!] = w^+\mathbf{n}^+ + w^-\mathbf{n}^-, \qquad [\![\mathbf{v}]\!] = \mathbf{v}^+ \cdot \mathbf{n}^+ + \mathbf{v}^- \cdot \mathbf{n}^-. \tag{10}$$

Let W_h, $\mathbf{V}_h$ denote discontinuous, piecewise polynomial approximating spaces defined on the triangulation $\mathcal{T}_h$. The variable p will be approximated in the space W_h. We will assume W_h on Ω_e contains $\mathcal{P}^k(\Omega_e)$ and may also contain some but not necessarily all polynomial terms of degree $k+1$. For example, an xy term may be included with terms of degree one. We call the resulting space $\mathcal{S}^k$. Therefore,

$$W_h = \{w \in L^2(\Omega) : w|_{\Omega_e} \in \mathcal{S}^k(\Omega_e) \ \forall\ \Omega_e \in \Omega\},$$

where $\mathcal{P}^k(\Omega_e) \subset \mathcal{S}^k(\Omega_e) \subset \mathcal{P}^{k+1}(\Omega_e)$. The variable $\mathbf{u}$ will be approximated in the space $\mathbf{V}_h$, where

$$\mathbf{V}_h = \{\mathbf{v} \in L^2(\Omega)^d : \mathbf{v}|_{\Omega_e} \in (\mathcal{P}^{k+1}(\Omega_e))^d \ \forall\ \Omega_e \in \Omega\}.$$

We will utilize the fact that

$$\nabla \cdot \mathbf{V}_h|_{\Omega_e} \subset W_h|_{\Omega_e} \tag{11}$$

in our analysis.

The $\mathcal{P}^{k+1} - \mathcal{S}^k$ LDG solution $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times W_h$ is determined by requiring that

$$\begin{aligned} \mathcal{A}_{LDG}(\mathbf{u}_h, p_h; w_h) &\equiv \sum_e [(cp_h, w_h)_{\Omega_e} + (\nabla \cdot \mathbf{u}_h, w_h)_{\Omega_e}] - \langle [\![\mathbf{u}_h]\!], \widehat{w}_h \rangle_{\mathcal{E}_i} \\ &= \sum_e (f, w_h)_{\Omega_e}, \end{aligned} \tag{12}$$

$$\begin{aligned} \mathcal{B}_{LDG}(\mathbf{u}_h, p_h; \mathbf{v}_h) &\equiv \sum_e [(K^{-1}\mathbf{u}_h, \mathbf{v}_h)_{\Omega_e} - (p_h, \nabla \cdot \mathbf{v}_h)_{\Omega_e}] + \langle \widehat{p}_h, [\![\mathbf{v}_h]\!] \rangle_{\mathcal{E}_i} \\ &= -\langle g_D, \mathbf{v}_h \cdot \mathbf{n} \rangle_{\partial\Omega} \end{aligned} \tag{13}$$

for all $(\mathbf{v}_h, w_h) \in \mathbf{V}_h \times W_h$, where $\mathbf{n}$ is the outward unit normal to $\partial\Omega$, and $\mathcal{E}_i$ denotes the set of all interior faces in the triangulation $\mathcal{T}_h$. It remains to define the numerical flux $\widehat{w}_h$ on each interior face for $w_h \in W_h$.

The numerical flux $\widehat{w}_h$ should be easy to compute. We also need it to be sufficiently accurate, as we will see below. We will give specific examples of $\widehat{w}_h$ in section 4. For now, we outline two requirements on $\widehat{w}_h$ needed for the error analysis to go through.

The numerical flux $\widehat{w}_h$ should be constructed on each interior face γ from the degrees of freedom of w_h in an $\mathcal{O}(h)$ neighborhood of γ. Let $\{\Omega_{e_\gamma}\}$ denote the collection of elements adjacent to γ, that is, the interior of $\partial\Omega_{e_\gamma} \cap \gamma \neq \emptyset$, along with any other elements used to compute $\widehat{w}_h$. Let $h_\gamma = \max_{e_\gamma} h_{e_\gamma}$. The requirements on $\widehat{w}_h$ are outlined as follows.

(A1) We require $\widehat{w}_h$ to satisfy the trace (or stability) inequality,

$$||\widehat{w}_h||_\gamma^2 \leq C_1 h_\gamma^{-1} \sum_{e_\gamma} ||w_h||_{\Omega_{e_\gamma}}^2, \qquad w_h \in W_h, \tag{14}$$

where C_1 is independent of h. In the examples in section 4, we will see that C_1 can depend on σ_1 and σ_2.

(A2) For ϕ a smooth function, let $\pi\phi$ be the L^2 projection of ϕ into W_h:

$$(\phi - \pi\phi, w_h)_{\Omega_e} = 0, \qquad w_h \in W_h. \tag{15}$$

We require the following accuracy condition, namely,

$$||\phi - \widehat{\pi\phi}||_\gamma \leq C_{2,\gamma} h_\gamma^{k+3/2}, \tag{16}$$

where

$$\sum_\gamma C_{2,\gamma}^2 \equiv C_2^2, \tag{17}$$

and C_2 is independent of h. In general, C_2 will depend on the smoothness of ϕ (e.g., $\phi \in H^{k+2}(\Omega)$ as we will see in section 4) and the triangulation $\mathcal{T}_h$ (i.e., σ_1 and σ_2).

Returning to (12)–(13), note that in (13) the variable $\mathbf{u}_h$ can be easily eliminated from the equations since it can be expressed *locally* on each element Ω_e in terms of p_h

by choosing $\mathbf{v}_h$ such that it is zero everywhere except on Ω_e. Substituting into (12), the system can be reduced to a system in the variable p_h alone.

If we define the bilinear form

$$\mathcal{A}(\mathbf{q}, r; \mathbf{v}, w) = \mathcal{A}_{LDG}(\mathbf{q}, r; w) + \mathcal{B}_{LDG}(\mathbf{q}, r; \mathbf{v}) \tag{18}$$

and the linear form

$$\mathcal{C}(\mathbf{v}, w) = (f, w)_\Omega - \langle g_D, \mathbf{v} \cdot \mathbf{n} \rangle_{\partial\Omega}, \tag{19}$$

then we can characterize the approximate solution $(\mathbf{u}_h, p_h)$ of the method as the element of $\mathbf{V}_h \times W_h$ such that

$$\mathcal{A}(\mathbf{u}_h, p_h; \mathbf{v}, w) = \mathcal{C}(\mathbf{v}, w) \qquad \forall\, (\mathbf{v}, w) \in \mathbf{V}_h \times W_h. \tag{20}$$

Existence and uniqueness of the approximate solution can be easily shown. Setting the data to zero, that is, $f = 0$ and $g_D = 0$, implies that

$$\mathcal{A}(\mathbf{u}_h, p_h; \mathbf{v}, w) = 0 \qquad \forall\, (\mathbf{v}, w) \in \mathbf{V}_h \times W_h.$$

Setting $\mathbf{v} = \mathbf{u}_h$ and $w = p_h$ and using the definitions of $\mathcal{A}_{LDG}$ and $\mathcal{B}_{LDG}$, we see that

$$0 = \mathcal{A}(\mathbf{u}_h, p_h; \mathbf{u}_h, p_h) = \sum_e [(K^{-1}\mathbf{u}_h, \mathbf{u}_h)_{\Omega_e} + (cp_h, p_h)_{\Omega_e}]; \tag{21}$$

thus, by (4) and (5), $\mathbf{u}_h = p_h = 0$.

3. Error estimates. In this section, we present our main results: error bounds for $||\mathbf{u} - \mathbf{u}_h||_\Omega$ and $||p - p_h||_\Omega$.

THEOREM 3.1. *Let* $(\mathbf{u}, p)$ *be the solution of problem* (1), (2), (3) *and let* $(\mathbf{u}_h, p_h)$ *be the approximate solution given by the* $\mathcal{P}^{k+1} - \mathcal{S}^k$ *LDG method* (12)–(13) *for* $k \geq 0$. *Assume the numerical flux* $\widehat{w}_h$ *satisfies* (14) *and* (16), *and the triangulation* $\mathcal{T}_h$ *satisfies* (6) *and* (8). *Assume* K *and* c *satisfy the bounds* (4) *and* (5). *Then for* $(\mathbf{u}, p)$ *sufficiently smooth,*

$$||\mathbf{u} - \mathbf{u}_h||_\Omega + ||p - p_h||_\Omega \leq C_3 h^{k+1},$$

where C_3 *is a constant independent of* h, *but depends on* C_1, C_2, c^*, c_*, K^*, K_*, σ_1, σ_2, $||p||_{H^{k+1}(\Omega)}$, *and* $||\mathbf{u}||_{H^{k+2}(\Omega)}$.

3.1. Proof of Theorem 3.1. In the arguments below, C will denote a generic, positive constant, independent of h, and ϵ will denote a generic, small positive constant. The dependence of C on quantity a will be denoted by $C(a)$.

We begin by noticing that the error $(e_\mathbf{u}, e_p) = (\mathbf{u} - \mathbf{u}_h, p - p_h)$ satisfies

$$\mathcal{A}(e_\mathbf{u}, e_p; \mathbf{v}, w) = \langle \widehat{p} - p, [\![\mathbf{v}]\!] \rangle_{\mathcal{E}_i} \qquad \forall\, (\mathbf{v}, w) \in \mathbf{V}_h \times W_h. \tag{22}$$

If we write $(e_\mathbf{u}, e_p) = (\psi_\mathbf{u} - \theta_\mathbf{u}, \psi_p - \theta_p)$, where $(\theta_\mathbf{u}, \theta_p) = (\mathbf{u}_h - \pi\mathbf{u}, p_h - \pi p)$ belongs to the finite element space $\mathbf{V}_h \times W_h$, and $(\psi_\mathbf{u}, \psi_p) = (\mathbf{u} - \pi\mathbf{u}, p - \pi p)$ is the interpolation error, we find, setting $(\mathbf{v}, w) = (\theta_\mathbf{u}, \theta_p)$,

$$\begin{aligned}\sum_e \left[||K^{-1/2}\theta_\mathbf{u}||^2_{\Omega_e} + ||c^{1/2}\theta_p||^2_{\Omega_e} \right] &= \mathcal{A}(\theta_\mathbf{u}, \theta_p; \theta_\mathbf{u}, \theta_p) \\ &= \mathcal{A}(\psi_\mathbf{u}, \psi_p; \theta_\mathbf{u}, \theta_p) - \langle \widehat{p} - p, [\![\theta_\mathbf{u}]\!] \rangle_{\mathcal{E}_i}.\end{aligned}$$

From this equality, and using the assumed lower bounds on K^{-1} and c, we obtain an estimate of $\sum_e[||\theta_{\mathbf{u}}||^2_{\Omega_e} + ||\theta_p||^2_{\Omega_e}]$. The theorem then follows from the triangle inequality and an estimate on $\sum_e[||\psi_{\mathbf{u}}||^2_{\Omega_e} + ||\psi_p||^2_{\Omega_e}]$, given below.

Thus

$$\begin{aligned}\sum_e[||K^{-1/2}\theta_{\mathbf{u}}||^2_{\Omega_e} + ||c^{1/2}\theta_p||^2_{\Omega_e}] &= \mathcal{A}(\psi_{\mathbf{u}}, \psi_p; \theta_{\mathbf{u}}, \theta_p) - \langle \widehat{p} - p, [\![\theta_{\mathbf{u}}]\!]\rangle_{\mathcal{E}_i} \\ &= \Theta_1 + \Theta_2, \end{aligned} \tag{23}$$

where

$$\Theta_1 = \sum_e \left[(K^{-1}\psi_{\mathbf{u}}, \theta_{\mathbf{u}})_{\Omega_e} - (\psi_p, \nabla\cdot\theta_{\mathbf{u}})_{\Omega_e}\right] + \langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!]\rangle_{\mathcal{E}_i}, \tag{24}$$

and

$$\Theta_2 = \sum_e \left[(c\psi_p, \theta_p)_{\Omega_e} + (\nabla\cdot\psi_{\mathbf{u}}, \theta_p)_{\Omega_e}\right] - \langle [\![\psi_{\mathbf{u}}]\!], \widehat{\theta}_p\rangle_{\mathcal{E}_i}. \tag{25}$$

We take πp and $\pi\mathbf{u}$ to be the standard L^2 projections of p and $\mathbf{u}$ into W_h and $\mathbf{V}_h$, respectively. It is well known that

$$||p - \pi p||_{\Omega_e} \le C(\sigma_1)||p||_{H^{k+1}(\Omega_e)} h_e^{k+1}, \tag{26}$$

$$||\mathbf{u} - \pi\mathbf{u}||_{\Omega_e} + h_e||\mathbf{u} - \pi\mathbf{u}||_{H^1(\Omega_e)} \le C(\sigma_1)||\mathbf{u}||_{H^{k+2}(\Omega_e)} h_e^{k+2}. \tag{27}$$

With these definitions of πp and $\pi\mathbf{u}$, we immediately see by (11) that

$$\Theta_1 = \sum_e (K^{-1}\psi_{\mathbf{u}}, \theta_{\mathbf{u}})_{\Omega_e} + \langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!]\rangle_{\mathcal{E}_i}. \tag{28}$$

To bound Θ_1 and Θ_2, we will utilize the following well-known results [4]. For a function w in any of the finite dimensional spaces described above, we have that

$$||w||_{H^1(\Omega_e)} \le C(\sigma_1) h_e^{-1} ||w||_{L^2(\Omega_e)}. \tag{29}$$

Also, for any sufficiently smooth function ϕ,

$$||\phi||^2_{L^2(\partial\Omega_e)} \le C(\sigma_1)||\phi||_{L^2(\Omega_e)}||\phi||_{H^1(\Omega_e)}. \tag{30}$$

Thus if ϕ is in one of the finite dimensional spaces above,

$$||\phi||^2_{L^2(\partial\Omega_e)} \le C(\sigma_1) h_e^{-1} ||\phi||^2_{L^2(\Omega_e)}. \tag{31}$$

We will also use the Cauchy–Schwarz inequality, and the standard inequality,

$$ab \le \frac{1}{2\delta}a^2 + \frac{\delta}{2}b^2 \tag{32}$$

for real numbers a, b, and $\delta > 0$.

It is easily seen that Θ_2 is bounded by

$$\sum_e [||c^{1/2}\psi_p||_{\Omega_e}||c^{1/2}\theta_p||_{\Omega_e} + ||c^{-1/2}\nabla\cdot\psi_{\mathbf{u}}||_{\Omega_e}||c^{1/2}\theta_p||_{\Omega_e}] - \langle [\![\psi_{\mathbf{u}}]\!], \widehat{\theta}_p\rangle_{\mathcal{E}_i}. \tag{33}$$

For the last term, let γ be an interior face, and $\{\Omega_{e_\gamma}\}$ and h_γ defined as above. Then

$$\begin{aligned}\langle [\![\psi_{\mathbf{u}}]\!], \widehat{\theta}_p\rangle_\gamma &\le ||[\![\psi_{\mathbf{u}}]\!]||_\gamma ||\widehat{\theta}_p||_\gamma \\ &\le C(\epsilon^{-1}) h_\gamma^{-1} ||[\![\psi_{\mathbf{u}}]\!]||_\gamma^2 + \epsilon h_\gamma ||\widehat{\theta}_p||_\gamma^2 \\ &\le C(\sigma_1, \sigma_2, \epsilon^{-1}) \sum_{e_\gamma} h_{e_\gamma}^{-1} ||\psi_{\mathbf{u}}||_{\Omega_{e_\gamma}} ||\psi_{\mathbf{u}}||_{H^1(\Omega_{e_\gamma})} + C_1 \epsilon \sum_{e_\gamma} ||\theta_p||_{\Omega_{e_\gamma}}^2, \end{aligned} \tag{34}$$

where we have used (30), (8), and (14). Summing over γ, choosing ϵ appropriately, and applying (27), we find

$$\langle [\![\psi_{\mathbf{u}}]\!], \widehat{\theta}_p\rangle_{\mathcal{E}_i} \le C(C_1, \sigma_1, \sigma_2, c_*^{-1}) \sum_e h_e^{2(k+1)} ||\mathbf{u}||_{H^{k+2}(\Omega_e)}^2 + \frac{c_*}{4} \sum_e ||\theta_p||_{\Omega_e}^2. \tag{35}$$

Thus, by (33), (35), (26), and (27),

$$\begin{aligned}\Theta_2 \le{}& \frac{1}{4} \sum_e ||c^{1/2}\theta_p||_{\Omega_e}^2 + \frac{c_*}{4} \sum_e ||\theta_p||_{\Omega_e}^2 \\ &+ C(c_*^{-1}, c^*, C_1, \sigma_1, \sigma_2) \sum_e \left[||\mathbf{u}||_{H^{k+2}(\Omega_e)}^2 + ||p||_{H^{k+1}(\Omega_e)}^2 \right] h_e^{2k+2}. \end{aligned} \tag{36}$$

Now we turn to Θ_1. By (27), we easily see that

$$\sum_e (K^{-1}\psi_{\mathbf{u}}, \theta_{\mathbf{u}})_{\Omega_e} \le C(\sigma_1, K^*) \sum_e ||\mathbf{u}||_{H^{k+2}(\Omega_e)}^2 h_e^{2k+4} + \frac{1}{4} \sum_e ||K^{-1/2}\theta_{\mathbf{u}}||_{\Omega_e}^2. \tag{37}$$

Next, consider $\langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!]\rangle_{\mathcal{E}_i}$. By (30), (16), and (8),

$$\begin{aligned}\langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!]\rangle_\gamma &\le C(\epsilon^{-1}) h_\gamma^{-1} ||p - \widehat{\pi p}||_\gamma^2 + \epsilon h_\gamma ||[\![\theta_{\mathbf{u}}]\!]||_\gamma^2 \\ &\le C(\epsilon^{-1}) C_{2,\gamma}^2 h_\gamma^{2k+2} + C(\sigma_1, \sigma_2) \epsilon \sum_{e_\gamma} ||\theta_{\mathbf{u}}||_{\Omega_{e_\gamma}}^2. \end{aligned} \tag{38}$$

Summing over γ and choosing ϵ appropriately, we find

$$\langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!]\rangle_{\mathcal{E}_i} \le C(K_*^{-1}, \sigma_1, \sigma_2) C_2^2 h^{2k+2} + \frac{K_*}{4} \sum_e ||\theta_{\mathbf{u}}||_{\Omega_e}^2. \tag{39}$$

Substituting the bounds (36), (37), and (39) into (23), we obtain

$$\begin{aligned}&K_* ||\theta_{\mathbf{u}}||^2 + c_* ||\theta_p||^2 \\ &\le C(C_1, c_*^{-1}, c^*, K^*, K_*^{-1}, \sigma_1, \sigma_2) \\ &\quad \times \left\{ \sum_e \left[||\mathbf{u}||_{H^{k+2}(\Omega_e)}^2 + ||p||_{H^{k+1}(\Omega_e)}^2 \right] h_e^{2k+2} + C_2^2 h^{2k+2} \right\}, \end{aligned}$$

from which the result follows.

4. Examples of $\widehat{w}$. Suppose $w \in W_h$. In this section, we discuss the construction of $\widehat{w}$ in more detail and show that, in fact, (14) and (16) can be satisfied for certain standard choices of meshes and spaces W_h. Recall the space $\mathcal{S}^k$ used to define W_h contains $\mathcal{P}^k$ and possibly some functions in $\mathcal{P}^{k+1}$.

On most standard elements Ω_e, we have or can construct an orthogonal set of polynomials $\mathcal{B} = \{l_{\mathbf{i}}(\mathbf{x})\}_{\{\mathbf{i}\in I, |\mathbf{i}|\le k+1\}}$ which serve as basis functions for W_h. In one

dimension, for example, we can use standard Legendre polynomials. In higher dimensions on rectangular or hexahedral elements, tensor products of Legendre polynomials can be used to construct an orthogonal basis. On triangles, such a basis is given in [16]. In general, Gram–Schmidt orthogonalization can be used to construct such a basis on each element.

If ϕ is a smooth function, and $\pi\phi$ its L^2 projection into W_h, then we have an error expansion

$$\phi(\mathbf{x}) - \pi\phi(\mathbf{x}) = \sum_{\{\mathbf{i}:|\mathbf{i}|=k+1,\mathbf{i}\notin I\}} \alpha_{\mathbf{i}} l_{\mathbf{i}}(\mathbf{x}) + \mathcal{O}(h^{k+2}), \qquad \mathbf{x} \in \Omega_e. \tag{40}$$

Thus, at the common roots $\bar{\mathbf{x}}$ of the functions $l_{\mathbf{i}}(\mathbf{x})$, where $|\mathbf{i}| = k+1$ and $\mathbf{i} \notin I$ (if such roots exist), we have superconvergence of $\pi\phi$:

$$\phi(\bar{\mathbf{x}}) - \pi\phi(\bar{\mathbf{x}}) = \mathcal{O}(h^{k+2}). \tag{41}$$

If we define $\pi_{k+1}\phi$ to be the L^2 projection of ϕ into $\mathcal{P}^{k+1}$, then

$$\pi_{k+1}\phi(\mathbf{x}) = \pi\phi(\mathbf{x}) + \sum_{\{\mathbf{i}:|\mathbf{i}|=k+1,\mathbf{i}\notin I\}} \alpha_{\mathbf{i}} l_{\mathbf{i}}(\mathbf{x}), \tag{42}$$

and the superconvergence at $\bar{x}$ can be easily seen since

$$\pi\phi(\bar{\mathbf{x}}) = \pi_{k+1}\phi(\bar{\mathbf{x}}). \tag{43}$$

At such superconvergence points, one can interpolate $\pi\phi$ by a higher order polynomial, say a complete polynomial of degree $k+1$, and this interpolant is a more accurate approximation to ϕ. Such an interpolation procedure will be used in defining the numerical flux $\widehat{w}$. Furthermore, by (43),

$$\widehat{\pi\phi} = \widehat{\pi_{k+1}\phi}. \tag{44}$$

We consider some examples.

***k* = 0.** Suppose W_h is the space of piecewise constants; then as we stated in the introduction, $\mathcal{S}^0 = \mathcal{P}^0$. It is well known that the L^2 projection $\pi\phi$ of ϕ into piecewise constants is superconvergent at the barycenter $\mathbf{x}_e$ of each element Ω_e. The barycentric values can be interpolated to construct a linear approximation to ϕ which is second order accurate. This linear approximation can then be used to define the numerical flux $\widehat{w}$ on interior faces.

In one space dimension, given any interior face point γ, we can linearly interpolate the piecewise constant values of w on either side of γ and evaluate this linear interpolant at γ to determine $\widehat{w}$. In particular, if $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$ are elements on either side of γ with midpoints x_1, x_2, and diameters h_1 and h_2 satisfying (8), let α_i be the linear satisfying

$$\alpha_i(x_j) = \delta_{ij}, \qquad i,j = 1,2.$$

At γ, define

$$\widehat{w}(\gamma) = \sum_{i=1}^{2} w(x_i)\alpha_i(\gamma).$$

Let $\Omega_\gamma = \Omega_{1,\gamma} \cup \Omega_{2,\gamma}$, $h_\gamma = \max(h_1, h_2)$.

By the trace inequality (30),

$$||\widehat{w}||_\gamma^2 = \left| \sum_{i=1}^{2} w(x_i)\alpha_i(\gamma) \right|^2 \leq C \sum_{i=1}^{2} |w(x_i)|^2 ||\alpha_i||_{L^2(\Omega_\gamma)} ||\alpha_i||_{H^1(\Omega_\gamma)}.$$

It is easily seen that

$$||\alpha_i||_{L^2(\Omega_\gamma)} \leq C h_\gamma^{1/2},$$
$$||\alpha_i||_{H^1(\Omega_\gamma)} \leq C(\sigma_2) h_\gamma^{-1/2}.$$

Thus,

$$||\widehat{w}||_\gamma^2 \leq C(\sigma_2) \sum_{i=1}^{2} |w(x_i)|^2 = C(\sigma_2) h_\gamma^{-1} \sum_{i=1}^{2} ||w||_{\Omega_{i,\gamma}}^2,$$

and (14) is satisfied.

If ϕ is a smooth function, then $\widehat{\phi}$ is the linear interpolant of ϕ given by

$$\widehat{\phi} = \sum_{i=1}^{2} \phi(x_i)\alpha_i. \tag{45}$$

By interpolation theory [4],

$$|(\phi - \widehat{\phi})(\gamma)|^2 \leq C h_\gamma^{2m+1} ||\phi||_{H^{m+1}(\Omega_\gamma)}^2, \tag{46}$$

where $m = 1$ in this case, thus $2m + 1 = 3$. Recalling (44), consider

$$|(\widehat{\phi} - \widehat{\pi_1 \phi})(\gamma)|.$$

The error in the L^2 projection into the space $\mathcal{P}^{k+1}$ satisfies

$$|\phi(x_i) - \pi_{k+1}\phi(x_i)| \leq C h_i^{k+2-n/2} ||\phi||_{H^{k+2}(\Omega_{i,\gamma})}, \tag{47}$$

where $n = 1$ (space dimension) and $k = 0$ in this case; hence $k + 2 - n/2 = 3/2$. Thus

$$\begin{aligned} |(\widehat{\phi} - \widehat{\pi_1 \phi})(\gamma)|^2 &= |(\phi(x_1) - \pi_1\phi(x_1))\alpha_1(\gamma) + (\phi(x_2) - \pi_1\phi(x_2))\alpha_2(\gamma)|^2 \\ &\leq C h_\gamma^3 ||\phi||_{H^2(\Omega_\gamma)}^2. \end{aligned}$$

Writing

$$\phi - \widehat{\pi\phi} = \phi - \widehat{\phi} + \widehat{\phi} - \widehat{\pi_1 \phi},$$

(16) is satisfied, with $C_{2,\gamma}^2$ dependent on $||\phi||_{H^2(\Omega_\gamma)}^2$. Summing on γ we find

$$\begin{aligned} \sum_\gamma C_{2,\gamma}^2 &= C \sum_\gamma ||\phi||_{H^2(\Omega_\gamma)}^2 \\ &\leq C ||\phi||_{H^2(\Omega)}^2 \\ &\equiv C_2. \end{aligned}$$

For a mesh consisting of rectangles and/or triangles in two space dimensions, the construction of $\widehat{w}$ is similar to the piecewise linear reconstruction procedures commonly used in finite volume schemes for conservation laws; see, for example, [3, 10, 17]. In order to simplify the discussion, suppose $\mathcal{T}_h$ is a regular, conforming triangulation. If γ is an interior face, suppose $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$ are the two elements sharing face γ; see Figure 1. Given a piecewise constant w associated with the barycenter of each triangle, to construct a linear interpolant from these values we obviously need three triangles. If we look to the neighbors of the two elements to obtain this third value, we have many possibilities from which to choose. One such procedure for constructing $\widehat{w}$ then would be the following.

First, suppose $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$ are interior elements, each with two other neighboring elements. Label these four elements $\Omega_{3,\gamma}, \ldots, \Omega_{6,\gamma}$. Consider the four triangles obtained by connecting the midpoints of $\Omega_{1,\gamma}$, $\Omega_{2,\gamma}$ and each of the four neighboring elements. Let T_γ be the triangle with smallest chunkiness parameter $h_{T_\gamma}/\rho_{T_\gamma}$; see Figure 1. Construct a linear interpolant $L_\gamma(w)$ using the values of w at the three vertices of T_γ. Take

$$\widehat{w}|_\gamma = L_\gamma(w)|_\gamma.$$

The chunkiness parameters for T_γ should satisfy

$$\frac{h_{T_\gamma}}{\rho_{T_\gamma}} \leq C(\sigma_1, \sigma_2). \tag{48}$$

If this is not the case, then one can widen the search for T_γ, for example, by examining the triangle obtained by connecting the midpoint of $\Omega_{1,\gamma}$ with those of the other two neighbors of $\Omega_{2,\gamma}$.

If $\Omega_{1,\gamma}$ (and/or $\Omega_{2,\gamma}$) is near the boundary, the number of possible triangles to construct a T_γ satisfying (48) may be limited. In the most extreme case, if $\Omega_{1,\gamma}$ is a boundary element, it may have no neighbor other than $\Omega_{2,\gamma}$, and $\Omega_{2,\gamma}$ could have only one other neighbor. In this case, it is possible (but highly unlikely) that the three midpoints of these triangles could be colinear, and it would be impossible to construct a linear interpolant using these midpoints. In any case where (48) is not satisfied to within some reasonable tolerance, we may have to widen our search to include neighbors of neighboring elements. Essentially, any three triangles near the interface γ could be used to construct T_γ.

Consider the construction of L_γ and assume (48) holds. For ease of notation, denote by Ω_1, Ω_2, and Ω_3 the triangles whose midpoints are used to construct T_γ. Let (x_i, y_i) denote the barycenter of Ω_i (which is also a vertex of T_γ), let h_i denote the element diameter, and let w_i denote the value of $\widehat{w}$ at (x_i, y_i), $i = 1, 2, 3$. Define linear basis functions α_i by

$$\alpha_i(x_j, y_j) = \delta_{ij}, \qquad i, j, = 1, 2, 3.$$

Since we are working in two space dimensions, (48) implies

$$||\alpha_i||_{\Omega_{j,\gamma}} \leq C(\sigma_1, \sigma_2) h_{j,\gamma}, \tag{49}$$

$$||\alpha_i||_{H^1(\Omega_{j,\gamma})} \leq C(\sigma_1, \sigma_2), \tag{50}$$

where $h_{j,\gamma}$ is the diameter of $\Omega_{j,\gamma}$, $j = 1, 2$. To show that (14) is satisfied, by (30) and the above bounds on α_i,

$$||\widehat{w}||_\gamma^2 = ||L_\gamma(w)||_\gamma^2 = \left\| \sum_{i=1}^{3} w_i \alpha_i \right\|_\gamma^2$$

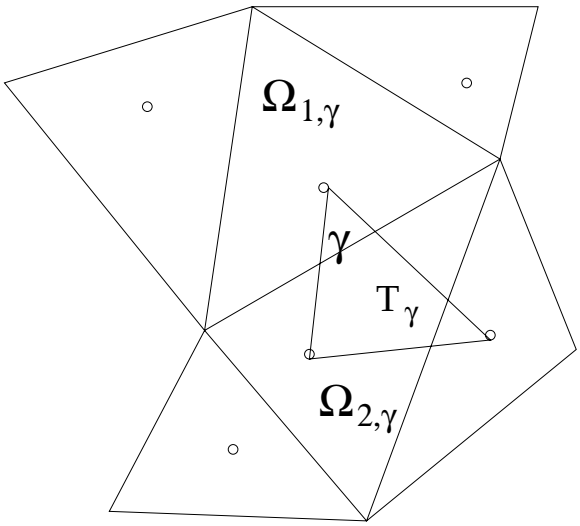

FIG. 1. *An interior face γ with neighbors $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$.*

$$\begin{aligned} &\leq C \sum_{i=1}^{3} |w_i|^2 ||\alpha_i||_{\Omega_{j,\gamma}} ||\alpha_i||_{H^1(\Omega_{j,\gamma})} \\ &\leq C h_{j,\gamma} \sum_{i=1}^{3} |w_i|^2 \\ &\leq C h_\gamma^{-1} \sum_{i=1}^{3} ||w||_{\Omega_i}^2, \end{aligned} \tag{51}$$

where C depends on σ_1 and σ_2.

To derive (16), let Ω_γ denote $\cup_{i=1}^3 \Omega_i \cup \Omega_{1,\gamma} \cup \Omega_{2,\gamma}$. Applying (30) and error estimates similar to (46) and (47) with $m = 1$, $k = 0$, and $n = 2$, and using (49) and (50), we find for smooth ϕ,

$$\begin{aligned} ||\phi - L_\gamma(\pi_1\phi)||_\gamma^2 &\leq C||\phi - L_\gamma(\pi_1\phi)||_{\Omega_{j,\gamma}} ||\phi - L_\gamma(\pi_1\phi)||_{H^1(\Omega_{j,\gamma})} \\ &\leq C h_\gamma^3 ||\phi||_{H^2(\Omega_\gamma)}^2, \end{aligned}$$

where C depends on σ_1 and σ_2. Thus (16) holds, with

$$C_{2,\gamma} = C(\sigma_1, \sigma_2)||\phi||_{H^2(\Omega_\gamma)}.$$

Summing on all faces γ we find

$$\sum_\gamma C_{2,\gamma}^2 \leq C(\sigma_1, \sigma_2)||\phi||_{H^2(\Omega)}^2 \equiv C_2,$$

and C_2 is independent of h.

We remark that the above procedure can be applied to nonconforming triangulations as long as a triangle T_γ in a neighborhood of γ satisfying (48) can be found.

***k* = 1.** Next, suppose W_h contains the space of piecewise linears. In this case, we may need to add second degree terms into the definition of $\mathcal{S}^1$. The procedure is

then to find the common roots of the quadratic orthogonal polynomials omitted from the definition of $\mathcal{S}^1$, use these roots in interpolating w by a complete quadratic, and evaluate this interpolant on interior faces to determine $\widehat{w}$.

In one dimension, we can take $\mathcal{S}^1 = \mathcal{P}^1$. The L^2 projection $\pi\phi$ of ϕ into the space of piecewise linears is superconvergent at the roots of the quadratic Legendre polynomial. On any interval $[a, b]$, these roots are located at

$$\frac{a+b}{2} - \frac{b-a}{2\sqrt{3}}, \quad \frac{a+b}{2} + \frac{b-a}{2\sqrt{3}}. \tag{52}$$

At an interface γ between two elements $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$, one can interpolate w at any collection of three such roots within these two elements by a quadratic (or if desired, at all four roots by a cubic) and evaluate this interpolant at γ to determine $\widehat{w}$. For example, labeling the four roots x_j, $j = 1, \ldots, 4$, we construct four cubic basis functions $\alpha_i(x)$, satisfying $\alpha_i(x_j) = \delta_{ij}$. Then

$$\widehat{w}(\gamma) = \sum_{i=1}^{4} w(x_i)\alpha_i(\gamma).$$

Following the above arguments with $k = 1$, $m = 2$, and $n = 1$, one can show this interpolant satisfies (14) and (16), with C_2 dependent on $||\phi||_{H^3(\Omega)}$.

On rectangles, using tensor product linears to define $\mathcal{S}^1$ and hence W_h, the L^2 projection is superconvergent at the tensor products of the roots in (52). Thus there are four roots per element. Given rectangles $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$ sharing a face γ, we can interpolate w at any six of these roots in the two elements by a quadratic in x and y (or at all eight roots by a tensor product quadratic without the x^2y^2 term). By arguments similar to those above with $k = 1$, $m = 2$, and $n = 2$, this quadratic satisfies (14) and (16).

On triangles, a set of orthogonal polynomials through second degree on the reference element $\widehat{\Omega}$ bounded by $\xi = 0$, $\eta = 0$, $\xi + \eta = 1$ is given by

$$\begin{aligned}
l_{0,0}(\xi, \eta) &= 1, \\
l_{1,0}(\xi, \eta) &= 1 - 3\xi, \\
l_{0,1}(\xi, \eta) &= 1 - \xi - 2\eta, \\
l_{0,2}(\xi, \eta) &= (5\xi - 4)\xi + (-15\eta + 12)\eta - 1, \\
l_{1,1}(\xi, \eta) &= (3\xi + 8\eta - 4)\xi + (3\eta - 4)\eta + 1, \\
l_{2,0}(\xi, \eta) &= (10\xi - 8)\xi + 1.
\end{aligned}$$

We choose $\mathcal{S}^1(\widehat{\Omega})$ to be the span of the linear terms plus one of the quadratic terms, in this case $l_{0,2}$. A basis for $\mathcal{S}^1(\Omega_e)$ and hence W_h is obtained by mapping these functions through an affine map from $\widehat{\Omega}$ to Ω_e. Thus the L^2 projection $\pi\phi$ into W_h is superconvergent to ϕ at the common roots of $l_{2,0}$ and $l_{1,1}$. There are three such roots in the master element, located at

$$(.155051, .706707), \quad (.155051, .213157), \quad (.644949, .191431).$$

For neighboring triangles $\Omega_{1,\gamma}$ and $\Omega_{2,\gamma}$ sharing face γ, we interpolate w by a complete quadratic at the six roots contained in these two elements and evaluate the quadratic

at γ to determine $\widehat{w}$. That is, labeling the six roots (x_j, y_j), $j = 1, \ldots, 6$, we construct six quadratic basis functions α_i satisfying $\alpha_i(x_j, y_j) = \delta_{ij}$; then

$$\widehat{w}|_\gamma = \sum_{i=1}^{6} w(x_i, y_i)\alpha_i|_\gamma.$$

5. Numerical results. In this section, we give one and two dimensional examples which confirm our theoretical results, and in one dimension, we compare the results of our method to a more standard implementation of the LDG method with equal order approximating spaces for p and $\mathbf{u}$ (the $\mathcal{P}^k - \mathcal{P}^k$ method).

5.1. One dimensional results. First, we consider the method (12)–(13) in one space dimension with $k = 0$. Recall that in this case, $\mathcal{S}^0 = \mathcal{P}^0$. The numerical flux $\widehat{w}$ is constructed using the linear interpolation procedure outlined in section 4. We consider the problem

$$cp - p_{xx} = (c + \pi^2)\sin(\pi x), \qquad 0 < x < 1, \tag{53}$$

$$p(0) = p(1) = 0, \tag{54}$$

which has the solution $p(x) = \sin(\pi x)$. We will take $c = 1$. Suppose the domain $\Omega = [0, 1]$ is partitioned into subintervals $\Omega_i = [x_{i-1/2}, x_{i+1/2}]$ of length h_i, $i = 1, \ldots, N$, with midpoint x_i.

First, consider a sequence of uniform meshes $h_i = 1/N$. The L^2 errors for p and $\mathbf{u}$ for the $\mathcal{P}^1 - \mathcal{S}^0$ method are given in Table 1. First order convergence for both variables is seen, as expected from the theory. Next, we consider a sequence of nonuniform meshes, given by

$$h_i = \begin{cases} \frac{1}{2N}, & i \text{ odd}, \\ \frac{3}{2N}, & i \text{ even}. \end{cases} \tag{55}$$

The L^2 errors for p and $\mathbf{u}$ are given in Table 2. Again, first order convergence for both variables is observed, with errors comparable to the uniform mesh case, though somewhat smaller for p and somewhat larger for $\mathbf{u}$.

Next, we consider (12)–(13) with $k = 1$. For comparison purposes, we also consider the standard $\mathcal{P}^1 - \mathcal{P}^1$ LDG method. To avoid confusion, we denote the numerical

flux for this method by $\tilde{w}$ instead of $\widehat{w}$. We will consider two choices for the numerical flux: $\tilde{w} = \{w\} = (w^- + w^+)/2$ and $\tilde{w} = w^-$. In [8], it was shown that in one space dimension, with the latter choice of $\tilde{w}$, the $\mathcal{P}^k - \mathcal{P}^k$ method gives optimal convergence for both p and $\mathbf{u}$. We also add a stabilization term involving $[\![p_h]\!]$ to (12). Thus, we define the standard LDG method by

$$\begin{aligned}\mathcal{A}^s_{LDG}(\mathbf{u}_h, p_h; w_h) &\equiv \sum_e [(cp_h, w_h)_{\Omega_e} + (\nabla \cdot \mathbf{u}_h, w_h)_{\Omega_e}] - \langle [\![\mathbf{u}_h]\!], \tilde{w}_h \rangle_{\mathcal{E}_i} \\ &\quad + \langle C_{11} [\![p_h]\!], [\![w_h]\!] \rangle_{\mathcal{E}_i} \\ &= \sum_e (f, w_h)_{\Omega_e}, \end{aligned} \tag{56}$$

$$\begin{aligned}\mathcal{B}^s_{LDG}(\mathbf{u}_h, p_h; \mathbf{v}_h) &\equiv \sum_e [(K^{-1}\mathbf{u}_h, \mathbf{v}_h)_{\Omega_e} - (p_h, \nabla \cdot \mathbf{v}_h)_{\Omega_e}] + \langle \tilde{p}_h, [\![\mathbf{v}_h]\!] \rangle_{\mathcal{E}_i} \\ &= -\langle g_D, \mathbf{v}_h \cdot \mathbf{n} \rangle_{\partial\Omega}, \end{aligned} \tag{57}$$

where $C_{11} \geq 0$.

For the $\mathcal{P}^2 - \mathcal{S}^1$ method, following section 4, the numerical flux $\widehat{w}$ is constructed by interpolating w at the roots of the second degree Legendre polynomial on each interval Ω_i, given by (52). Specifically, in neighboring intervals $\Omega_{1,\gamma}$, $\Omega_{2,\gamma}$ between interface point γ, we compute the cubic Lagrange polynomial which interpolates w at each of the two roots in each element and evaluate this interpolant at the interface point γ to obtain $\widehat{w}$.

First, consider (53)–(54) with the domain discretized with a sequence of uniform meshes. The L^2 errors for p and $\mathbf{u}$ for the $\mathcal{P}^2 - \mathcal{S}^1$ method are given in Table 3. Second order accuracy is observed for both p_h and $\mathbf{u}_h$, as expected from the theory.

We also computed the $\mathcal{P}^1 - \mathcal{P}^1$ LDG solution given by (56)–(57), with $C_{11} = 0$ (Table 4) and $C_{11} = 1$ (Table 5), and $\tilde{w} = \{w\}$. These tables indicate that to obtain

full second order accuracy for p in this version of the LDG method, $C_{11} > 0$ is necessary. First order accuracy in $\mathbf{u}_h$ was observed; furthermore, note that the errors in $\mathbf{u}_h$ are an order of magnitude larger when compared to the $\mathcal{P}^2 - \mathcal{S}^1$ solution. We repeated this experiment with $\tilde{w} = w^-$. Again, the accuracy of the pressure solution depends on having a positive penalty parameter C_{11}. In this case, as seen in Tables 6 and 7, full second order accuracy for $\mathbf{u}$ is observed for both choices of C_{11}, with errors actually smaller than the $\mathcal{P}^2 - \mathcal{S}^1$ method. This optimal convergence for $\mathbf{u}$ agrees with the one dimensional theory in [8].

Next, we consider the nonuniform mesh given by (55). The errors for p_h and $\mathbf{u}_h$ for the $\mathcal{P}^2 - \mathcal{S}^1$ LDG method are given in Table 8. We compare these results to the $\mathcal{P}^1 - \mathcal{P}^1$ LDG method results with $\tilde{w} = w^-$ and $C_{11} = 1$ given in Table 9.

5.2. Two dimensional results. In this section, we present two dimensional results for the $\mathcal{P}^1 - \mathcal{S}^0$ and $\mathcal{P}^2 - \mathcal{S}^1$ methods on triangular grids. Convergence tests for the $\mathcal{P}^k - \mathcal{P}^k$ LDG method ($k \geq 1$) in two dimensions can be found in [7], which demonstrate order $k+1$ convergence for p and k for $\mathbf{u}$ in L^2. We consider

$$cp - \Delta p = f, \quad \Omega, \tag{58}$$

$$p = g, \quad \partial\Omega. \tag{59}$$

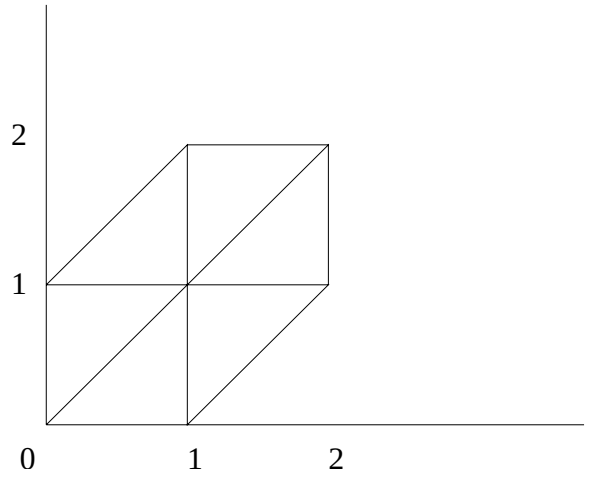

FIG. 2. *Domain Ω for two dimensional test problem* (58)*, discretized by six triangles.*

The domain Ω is given in Figure 2, with a coarse mesh of six elements discretizing Ω. All subsequent meshes are obtained from uniform refinements of this initial mesh.

For this test case, we have chosen $c = 1$ and f and g so that $p = x^3 + y^3$. The construction of the numerical flux $\widehat{w}$ follows the procedures described in section 4. The errors in L^2 for p and $\mathbf{u}$ for the two methods are given in Tables 10 ($k = 0$) and 11 ($k = 1$). Here mesh 1 refers to the initial coarse mesh, meshes 2–6 are uniform refinements of this mesh. As seen in the tables, first order convergence is observed for p when $k = 0$ and second order convergence when $k = 1$. The errors in $\mathbf{u}$ are also approaching first ($k = 0$) and second order ($k = 1$) as the mesh is refined.

6. The case $c = 0$ and $k = 0$. We again consider the important case where W_h is the space of piecewise constant functions and $\mathbf{V}_h$ is in the space of piecewise linears. We will consider the purely elliptic case with $c = 0$ and assume that Ω is discretized by a triangulation $\mathcal{T}_h$ as defined above, with the exception that $\mathcal{T}_h$ is conforming. Let $(W_{h,RT}, \mathbf{V}_{h,RT})$ denote the lowest order Raviart–Thomas mixed finite element

space on $\mathcal{T}_h$. The lowest order space consists of piecewise constant approximations for p ($W_{h,RT} = W_h$) and piecewise linear approximations for $\mathbf{u}$. The properties of $(W_h, \mathbf{V}_{h,RT})$ we require are

$$\mathbf{V}_{h,RT} \subset H(\mathrm{div}; \Omega), \tag{60}$$

$$\mathbf{V}_{h,RT} \subset \mathbf{V}_h, \tag{61}$$

and

$$\nabla \cdot \mathbf{V}_{h,RT} = W_h. \tag{62}$$

(60) implies that if $\mathbf{v} \in \mathbf{V}_{h,RT}$, then the normal component of $\mathbf{v}$ is continuous across interior faces. See [20, 19] for descriptions of such spaces on standard types of elements (rectangular parallelepipeds, triangles, tetrahedra, and prisms).

The method is given by (12)–(13) with $c = 0$. The numerical flux $\widehat{p}_h$ is assumed to still satisfy (16). Assuming zero data, existence and uniqueness of $\mathbf{u}_h$ is proved by the same arguments which lead to (21). Uniqueness of p_h is proved by a duality argument. Let $\sigma_h \in \mathbf{V}_{h,RT}$ be such that $\nabla \cdot \sigma_h = p_h$. This is possible by (62). Then by (13),

$$\begin{aligned} ||p_h||^2 &= \sum_e (p_h, \nabla \cdot \sigma_h)_{\Omega_e} \\ &= \sum_e (K^{-1}\mathbf{u}_h, \sigma_h)_{\Omega_e} + \langle \widehat{p}_h, [\![\sigma_h]\!] \rangle_{\mathcal{E}_i} \\ &= 0, \end{aligned}$$

since $\mathbf{u}_h = 0$ and $[\![\sigma_h]\!] = 0$ (by (60)) on interior faces. Thus existence and uniqueness of p_h are established.

The error estimates follow slightly different arguments. In particular, instead of comparing $\mathbf{u}_h$ to the L^2 projection of $\mathbf{u}$, we compare it to the "divergence projection" $\pi\mathbf{u} \in \mathbf{V}_{h,RT}$ satisfying

$$\sum_e (\nabla \cdot (\mathbf{u} - \pi\mathbf{u}), w)_{\Omega_e} = 0, \qquad w \in W_h. \tag{63}$$

This projection is a standard projection used in mixed finite element analysis. In [20], it is shown that

$$||\mathbf{u} - \pi\mathbf{u}|| \leq C(\sigma_1, \sigma_2)||\mathbf{u}||_{H^1(\Omega)} h. \tag{64}$$

Furthermore $[\![\pi\mathbf{u}]\!] = 0$ across interior faces. Again using the L^2 projection πp of p, and defining $\theta_{\mathbf{u}}$, θ_p, $\psi_{\mathbf{u}}$, and ψ_p as in section 3, we find that

$$\begin{aligned} ||K^{-1/2}\theta_{\mathbf{u}}||^2 &= \mathcal{A}(\psi_{\mathbf{u}}, \psi_p; \theta_{\mathbf{u}}, \theta_p) - \langle \widehat{p} - p, [\![\theta_{\mathbf{u}}]\!] \rangle_{\mathcal{E}_i} \\ &= \Theta_1 + \Theta_2, \end{aligned} \tag{65}$$

where

$$\Theta_1 = \sum_e (K^{-1}\psi_{\mathbf{u}}, \theta_{\mathbf{u}})_{\Omega_e} + \langle p - \widehat{\pi p}, [\![\theta_{\mathbf{u}}]\!] \rangle_{\mathcal{E}_i}, \tag{66}$$

and

$$\Theta_2 = 0. \tag{67}$$

Following the same arguments given above to bound Θ_1, we find that

$$||K^{-1/2}(\mathbf{u}-\mathbf{u}_h)||_\Omega \le C(\sigma_1,\sigma_2,K_*^{-1},K^*)\left[||\mathbf{u}||_{H^1(\Omega)}+C_2\right]h. \tag{68}$$

To estimate the error in p_h, we again use a duality argument and define ϕ and σ to satisfy

$$\nabla\cdot\sigma \equiv -\nabla\cdot(\nabla\phi) = e_p, \quad \Omega, \tag{69}$$

$$\phi = 0, \quad \partial\Omega. \tag{70}$$

By elliptic regularity [18], we have that

$$||\sigma||_{H^1(\Omega)} \le C||e_p||_\Omega. \tag{71}$$

Therefore, letting σ_h be the divergence projection of σ,

$$\begin{aligned} ||e_p||_\Omega^2 &= \sum_e (e_p, \nabla\cdot\sigma)_{\Omega_e} \\ &= \sum_e [(e_p, \nabla\cdot(\sigma-\sigma_h))_{\Omega_e} + (e_p, \nabla\cdot\sigma_h)_{\Omega_e}] \\ &= \sum_e [(e_p, \nabla\cdot(\sigma-\sigma_h))_{\Omega_e} + (K^{-1}e_{\mathbf{u}}, \sigma_h)_{\Omega_e}], \end{aligned} \tag{72}$$

where in the last step we have used (13) and the fact that $[\![\sigma_h]\!] = 0$. By the definition of σ_h,

$$\begin{aligned} \sum_e (e_p, \nabla\cdot(\sigma-\sigma_h))_{\Omega_e} &= \sum_e (p, \nabla\cdot(\sigma-\sigma_h))_{\Omega_e} \\ &= \sum_e (p-\pi p, \nabla\cdot(\sigma-\sigma_h))_{\Omega_e} \\ &\le \sum_e ||p-\pi p||_{\Omega_e}\ ||\nabla\cdot(\sigma-\sigma_h)||_{\Omega_e} \\ &\le C(\sigma_1)h||p||_{H^1(\Omega)}||\sigma||_{H^1(\Omega)} \\ &\le C(\sigma_1)h||p||_{H^1(\Omega)}||e_p||_\Omega. \end{aligned}$$

Furthermore, by (68) and (71),

$$\begin{aligned} \sum_e (K^{-1}e_{\mathbf{u}}, \sigma_h)_{\Omega_e} &\le C(K^*)||e_{\mathbf{u}}||_\Omega\ ||\sigma_h||_\Omega \\ &\le Ch||e_p||_\Omega. \end{aligned}$$

Substituting these bounds into (72), we obtain the following result.

THEOREM 6.1. *Let $(\mathbf{u},p)$ be the solution of problem* (1), (2), (3) *with $c=0$. Assume K satisfies* (4). *Let $(\mathbf{u}_h,p_h)$ be the approximate solution given by the $\mathcal{P}^1-\mathcal{S}^0$ LDG method* (12)–(13). *Assume a conforming triangulation $\mathcal{T}_h$, with the lowest order Raviart–Thomas mixed finite element space $W_h\times\mathbf{V}_{h,RT}$ satisfying* (60)–(62) *defined on $\mathcal{T}_h$. Assume the numerical flux $\widehat{p}$ satisfies* (16) *with $k=0$. Then for $(\mathbf{u},p)$ sufficiently smooth,*

$$||\mathbf{u}-\mathbf{u}_h||_\Omega + ||p-p_h||_\Omega \le C_4 h,$$

TABLE 12
Case 2-1D*: $\mathcal{P}^1 - \mathcal{S}^0$ LDG method, nonuniform mesh, $c = 0$.*

N	$\|\|p - p_h\|\|$	rate	$\|\|\mathbf{u} - \mathbf{u}_h\|\|$	rate
16	.0917	–	.3695	–
32	.0459	1.0	.1878	1.0
64	.0230	1.0	.0943	1.0
128	.0115	1.0	.0472	1.0

TABLE 13
Case 3-2D*: $\mathcal{P}^1 - \mathcal{S}^0$ LDG method for two dimensional case with $c = 0$, $p = x^3 + y^3$.*

mesh	$\|\|p - p_h\|\|$	rate	$\|\|\mathbf{u} - \mathbf{u}_h\|\|$	rate
1	3.3403	–	4.6781	–
2	1.7665	1.0	3.5167	.41
3	.8717	1.0	2.1455	.71
4	.4302	1.0	1.0351	1.05
5	.2146	1.0	.5863	.82
6	.1072	1.0	.2674	1.13

where C_4 is a constant independent of h but depends on C_2, K_*^{-1}, K^*, σ_1, σ_2, $||\mathbf{u}||_{H^1(\Omega)}$, and $||p||_{H^1(\Omega)}$.

Numerical validation of this result in one and two dimensions can be seen as follows. First, consider (53)–(54), now with $c = 0$. We consider the nonuniform mesh given by (55). In Table 12, we measure the errors $||p - p_h||_\Omega$ and $||\mathbf{u} - \mathbf{u}_h||_\Omega$ for the $\mathcal{P}^1 - \mathcal{S}^0$ approximation. In this case, we obtain the expected first order convergence rates for p and $\mathbf{u}_h$. Second, we consider (58) with $c = 0$ and $p = x^3 + y^3$. The L^2 errors for p and $\mathbf{u}$ are given in Table 13; again, first order convergence is observed.

Theorem 6.1 can be extended to the case $k > 0$ if spaces W_h and $\mathbf{V}_{h,RT}$ satisfying (16) and (60)–(62) can be found. Since W_h must be a rich enough space so that (16) is satisfied, it may not in general be possible to satisfy both this property and (62).

7. Concluding remarks. In this paper, we have formulated and analyzed a variant of the LDG method which uses higher degree polynomials for approximating the flux $\mathbf{u} = -K\nabla p$ over those used for approximating p. The advantage of this approach over the standard LDG method, which uses equal order spaces for $\mathbf{u}$ and p is that it gives a more accurate approximation of the flux. Furthermore, this approach allows for the possibility of piecewise constant approximations to p, which is useful for a number of fluid applications.

MIXED *hp*-DGFEM FOR INCOMPRESSIBLE FLOWS*

DOMINIK SCHÖTZAU†, CHRISTOPH SCHWAB‡, AND ANDREA TOSELLI‡

Abstract. We consider several mixed discontinuous Galerkin approximations of the Stokes problem and propose an abstract framework for their analysis. Using this framework, we derive a priori error estimates for *hp*-approximations on tensor product meshes. We also prove a new stability estimate for the discrete divergence bilinear form.

Key words. *hp*-FEM, discontinuous Galerkin methods, Stokes problem

1. Introduction.

Discontinuous Galerkin (DG) methods for incompressible flow problems allow one to use discrete velocity spaces consisting of piecewise polynomial functions with no interelement continuity. Well-posedness of the discrete formulations is then achieved by numerical fluxes, i.e., by introducing suitable bilinear forms defined on the interfaces between the elements of the mesh. This choice presents considerable advantages for certain types of problems, especially those modeling phenomena where transport is dominant; see the state-of-the-art surveys in [18], the monograph [15], the recent review [20], and the references therein. In addition, DG approximations allow for nonconforming meshes.

Even if transport may be the dominant effect of a problem, diffusive terms still need to be accounted for and correctly discretized in a DG framework. For the Oseen or the incompressible Navier–Stokes equations, for instance, if advective terms are properly treated by, e.g., suitable upwinding techniques, stability and convergence only depend on the diffusive part of the operator and can then be studied for the simpler Stokes problem; see, e.g., [39, 25, 10, 33, 9]. In particular, suitable velocity-pressure space pairs are required to ensure stability and convergence. This separation of advective and diffusive effects was employed in [5] for the first definition of DG methods for convection-diffusion problems, in [19, 16, 7] for the so-called local discontinuous Galerkin and Baumann–Oden methods, respectively, and also in [27] for the *hp*-DG approximation of scalar advection-diffusion problems.

The recent works in [32] and [2] have unified the formulation and analysis of DG approximations for purely diffusive problems, where virtually all the available DG methods can be analyzed in a unified framework. In particular, several assumptions on the discrete spaces and bilinear forms have been given and analyzed that can be used to ensure a priori error estimates for the methods.

While extensive work has been done for diffusion or advection-diffusion problems, there are considerably fewer works for DG discretizations of saddle-point problems describing, e.g., nearly incompressible solids or incompressible fluid flows. We mention [4, 28], where an interior penalty approximation with discontinuous, piecewise

divergence-free velocities and continuous pressures is employed for the Stokes and incompressible Navier–Stokes equations, respectively. In [17], a local discontinuous Galerkin approximation for the Stokes problem is proposed. There, the introduction of certain pressure stabilization terms allows one to choose velocity and pressure spaces of the same polynomial order k. Optimal error estimates for h-approximations are proved. In [26], an h-approximation for incompressible and nearly incompressible elasticity based on an interior penalty DG method is introduced and studied. Triangular and tetrahedral meshes are employed, together with polynomial spaces of total degree k and $k-1$ for the velocity and pressure, respectively. Optimal error estimates in h are derived, which remain valid in the incompressible limit. A similar approach was considered in [40] for hp-approximations of the Stokes problem on tensor product meshes in two and three dimensions. Stability estimates for the discrete divergence bilinear form that are explicit in h and k are obtained. Numerical results point out that these estimates are not sharp in the order k, at least for conforming two-dimensional meshes. In the present work we indeed prove sharper estimates for the same DG approximation.

The present work has two purposes. In the first part, we develop an abstract framework for mixed DG approximations of the Stokes problem. In particular, we give a set of assumptions on the approximation spaces and on the velocity and divergence bilinear forms which allows us to obtain a priori error estimates. All available mixed DG methods for the Stokes problem can be analyzed in the presented framework by introducing lifting operators similar to the ones used in [2] for the Laplace equation. However, unlike in the analysis of [2], our error estimates are derived by using a variant of Strang's lemma, combined with the techniques developed in [40] that give abstract estimates for the errors in the velocity and the pressure. With respect to the use of Strang's lemma, our approach is closely related to the setting proposed in [30, 31] for the analysis of local discontinuous Galerkin methods for purely elliptic problems.

Our second result is a new proof of the inf-sup condition of the discrete DG divergence bilinear form for tensor product meshes and $\mathbb{Q}_k - \mathbb{Q}_{k-1}$ elements. In particular, we prove a bound sharper than that given in [40]. Our analysis is valid for shape-regular two- and three-dimensional tensor product meshes, possibly with hanging nodes. Even though our estimate does not appear to be sharp, at least in two dimensions (see the numerical results in [40]), we are able to ensure the same convergence rate for the velocity and the pressure as that of conforming $\mathbb{Q}_k - \mathbb{Q}_{k-2}$ elements in three dimensions, but with a gap in the polynomial degree of the velocity-pressure pair of just one.

Our framework and analysis can be adapted to the case of nearly incompressible elasticity in a straightforward way. We note that equal-order conforming discretizations are possible both in nearly incompressible elasticity and incompressible flows, but that the bilinear forms need to be suitably modified. These stabilization techniques typically rely on local terms that are added to the bilinear forms and are constructed with the residual of the differential equations on each element; see [22, 21, 24]. The calculation of these terms is not often a simple matter for higher-order hp-approximations. On the other hand, DG approximations allow us to narrow or eliminate the polynomial degree gap between the velocity and pressure spaces by employing a discontinuous velocity space and suitable bilinear forms on the interfaces. This results in an increase of the velocity degrees of freedom that, in the case of p- and hp-approximations, is not, however, of the same order of magnitude as the number of degrees of freedom of the corresponding conforming discretization, as is the case for lower-order approximations.

The rest of this paper is organized as follows: We start by reviewing the Stokes problem in section 2 and then present our abstract framework in section 3. Suitable assumptions on the bilinear forms allow us to derive a priori error estimates in section 4. In section 5 we discuss some particular choices for the bilinear forms and the approximation spaces. Section 6 contains the proofs of the inf-sup condition of the discrete divergence bilinear form. In sections 7 and 8 we establish the remaining assumptions for our DG approximations. Finally, we derive hp-error estimates in section 9.

2. The Stokes problem. Let Ω be a bounded polygonal or polyhedral domain in $\mathbb{R}^d$, $d = 2, 3$, respectively, with $\mathbf{n}$ denoting the outward normal unit vector to its boundary $\partial\Omega$. Given a source term $\mathbf{f} \in L^2(\Omega)^d$ and a Dirichlet datum $\mathbf{g} \in H^{1/2}(\partial\Omega)^d$ satisfying the usual compatibility condition $\int_{\partial\Omega} \mathbf{g} \cdot \mathbf{n}\, ds = 0$, the Stokes problem in incompressible fluid flow is to find a velocity field $\mathbf{u}$ and a pressure p such that

$$\begin{aligned} -\nu\Delta\mathbf{u} + \nabla p &= \mathbf{f} && \text{in } \Omega, \\ \nabla \cdot \mathbf{u} &= 0 && \text{in } \Omega, \\ \mathbf{u} &= \mathbf{g} && \text{on } \partial\Omega. \end{aligned} \tag{2.1}$$

If we define

$$\mathbf{V} := H^1(\Omega)^d, \qquad Q := L^2_0(\Omega) = \left\{ q \in L^2(\Omega) : \int_\Omega q\, d\mathbf{x} = 0 \right\},$$

and

$$A(\mathbf{u}, \mathbf{v}) = \int_\Omega \nu \nabla\mathbf{u} : \nabla\mathbf{v}\, d\mathbf{x}, \qquad B(\mathbf{u}, p) = -\int_\Omega p\, \nabla \cdot \mathbf{u}\, d\mathbf{x},$$

then the corresponding variational problem consists of finding $(\mathbf{u}, p) \in \mathbf{V} \times Q$, with $\mathbf{u} = \mathbf{g}$ on $\partial\Omega$, such that

$$\begin{cases} A(\mathbf{u}, \mathbf{v}) + B(\mathbf{v}, p) = \int_\Omega \mathbf{f} \cdot \mathbf{v}\, d\mathbf{x}, \\ B(\mathbf{u}, q) = 0 \end{cases} \tag{2.2}$$

for all $\mathbf{v} \in H^1_0(\Omega)^d$ and $q \in Q$.

The well-posedness of (2.2) is ensured by the continuity of $A(\cdot,\cdot)$ and $B(\cdot,\cdot)$, the coercivity of $A(\cdot,\cdot)$, and the following inf-sup condition

$$\inf_{0 \neq q \in L^2_0(\Omega)} \sup_{\mathbf{0} \neq \mathbf{v} \in H^1_0(\Omega)^d} \frac{-\int_\Omega q\, \nabla \cdot \mathbf{v}\, d\mathbf{x}}{|\mathbf{v}|_1 \|q\|_0} \geq \gamma > 0, \tag{2.3}$$

with an inf-sup constant γ only depending on Ω; see, e.g., [10, 25]. Here, we denote by $\|\cdot\|_{s,\mathcal{D}}$ and $|\cdot|_{s,\mathcal{D}}$ the norm and seminorm of $H^s(\mathcal{D})$ and $H^s(\mathcal{D})^d$, $s \geq 0$. In case $\mathcal{D} = \Omega$, we drop the subscript.

3. Mixed discretizations with nonconforming velocity spaces. Let $\mathbf{V}_h$ be a nonconforming finite element space approximating the velocities. We introduce the space

$$\mathbf{V}(h) := \mathbf{V} + \mathbf{V}_h$$

and endow it with a suitable norm $\|\cdot\|_h$. Furthermore, let $Q_h \subset Q$ be a conforming finite element space for the pressure, equipped with the L^2-norm $\|\cdot\|_0$.

Given linear forms $A_h : \mathbf{V}(h) \times \mathbf{V}(h) \to \mathbb{R}$, $B_h : \mathbf{V}(h) \times Q \to \mathbb{R}$ and continuous linear functionals $F_h : \mathbf{V}_h \to \mathbb{R}$, $G_h : Q_h \to \mathbb{R}$, chosen to discretize the Laplacian and the divergence constraint, we consider mixed methods of the following form: find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ such that

$$\left\{ \begin{array}{rcrcl} A_h(\mathbf{u}_h, \mathbf{v}) & + & B_h(\mathbf{v}, p_h) & = & F_h(\mathbf{v}), \\ B_h(\mathbf{u}_h, q) & & & = & G_h(q) \end{array} \right. \tag{3.1}$$

for all $(\mathbf{v}, q) \in \mathbf{V}_h \times Q_h$.

Let us make precise our assumptions on the forms A_h and B_h. First, they are assumed to satisfy the following continuity properties:

$$|A_h(\mathbf{v}, \mathbf{w})| \le \alpha_1 \|\mathbf{v}\|_h \|\mathbf{w}\|_h, \qquad \mathbf{v}, \mathbf{w} \in \mathbf{V}(h), \tag{3.2}$$

$$|B_h(\mathbf{v}, q)| \le \alpha_2 \|\mathbf{v}\|_h \|q\|_0, \qquad (\mathbf{v}, q) \in \mathbf{V}(h) \times Q, \tag{3.3}$$

with constants $\alpha_1 > 0$ and $\alpha_2 > 0$. Further, let us define $\mathbf{Z}(G_h) \subset \mathbf{V}_h$ by

$$\mathbf{Z}(G_h) = \{\, \mathbf{v} \in \mathbf{V}_h : B_h(\mathbf{v}, q) = G_h(q) \ \forall q \in Q_h \,\}. \tag{3.4}$$

We require the form A_h to be coercive on the kernel of B_h, i.e.,

$$A_h(\mathbf{v}, \mathbf{v}) \ge \beta \|\mathbf{v}\|_h^2, \qquad \mathbf{v} \in \mathbf{Z}(0), \tag{3.5}$$

for a coercivity constant $\beta > 0$. The form B_h is assumed to satisfy the discrete inf-sup condition

$$\inf_{0 \ne q \in Q_h} \sup_{\mathbf{0} \ne \mathbf{v} \in \mathbf{V}_h} \frac{B_h(\mathbf{v}, q)}{\|\mathbf{v}\|_h \|q\|_0} \ge \gamma_h, \tag{3.6}$$

with a stability constant $\gamma_h > 0$. Finally, we assume the exact solution $\mathbf{u} \in \mathbf{V}$ to fulfill the consistency condition

$$B_h(\mathbf{u}, q) = G_h(q) \qquad \forall q \in Q_h. \tag{3.7}$$

We do not impose any consistency requirements on the form A_h; instead we will work with the residual

$$R_h(\mathbf{u}, p; \mathbf{v}) := A_h(\mathbf{u}, \mathbf{v}) + B_h(\mathbf{v}, p) - F_h(\mathbf{v}), \qquad \mathbf{v} \in \mathbf{V}_h, \tag{3.8}$$

where $(\mathbf{u}, p) \in \mathbf{V} \times Q$ again is the exact solution. Our abstract error estimates will then be expressed in terms of $\mathcal{R}_h(\mathbf{u}, p)$ given by

$$\mathcal{R}_h(\mathbf{u}, p) := \sup_{\mathbf{0} \ne \mathbf{v} \in \mathbf{V}_h} \frac{|R_h(\mathbf{u}, p; \mathbf{v})|}{\|\mathbf{v}\|_h}. \tag{3.9}$$

For all the DG methods we introduce in section 5, the quantity $\mathcal{R}_h(\mathbf{u}, p)$ is optimally convergent.

The mixed problem (3.1) has a unique solution $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ and $\mathbf{Z}(G_h)$ is nonempty.

REMARK 3.1. *If $\mathbf{V}_h \subset \mathbf{V}$ is chosen to be a conforming finite element space, the setting of this section coincides with the standard mixed finite element setting; see* [10].

REMARK 3.2. *For the DG forms in section* 5 *the constants α_1 and β depend on the viscosity ν whereas α_2 and γ_h are independent of ν. More precisely, we have that $\alpha_1 = \nu\bar{\alpha}_1$ and $\beta = \nu\bar{\beta}$ with $\bar{\alpha}_1$ and $\bar{\beta}$ independent of ν.*

4. Abstract error estimates. Abstract error bounds for the mixed method in (3.1) can be obtained by proceeding as in [40, sect. 8]. We give the details of the proofs for the sake of completeness.

4.1. Error in the velocity. First, we prove an error estimate for the velocities following [40, Lemma 8.1].

PROPOSITION 4.1. *Let $(\mathbf{u},p)\in\mathbf{V}\times Q$ be the exact solution of the Stokes problem and $(\mathbf{u}_h,p_h)\in\mathbf{V}_h\times Q_h$ the mixed finite element approximation. Under the assumptions of section* 3*, we have*

$$\|\mathbf{u}-\mathbf{u}_h\|_h\le\left(1+\frac{\alpha_1}{\beta}\right)\left(1+\frac{\alpha_2}{\gamma_h}\right)\inf_{\mathbf{v}\in\mathbf{V}_h}\|\mathbf{u}-\mathbf{v}\|_h+\frac{\alpha_2}{\beta}\inf_{q\in Q_h}\|p-q\|_0+\beta^{-1}\mathcal{R}_h(\mathbf{u},p).$$

Proof. First, we fix $\mathbf{w}\in\mathbf{Z}(G_h)$ and $q\in Q_h$. Since $\mathbf{w}-\mathbf{u}_h\in\mathbf{Z}(0)$, (3.5) and the definition of the residual yield

$$\begin{aligned}\beta\|\mathbf{w}-\mathbf{u}_h\|_h^2&\le A_h(\mathbf{w}-\mathbf{u}_h,\mathbf{w}-\mathbf{u}_h)\\&=A_h(\mathbf{w}-\mathbf{u},\mathbf{w}-\mathbf{u}_h)-B_h(\mathbf{w}-\mathbf{u}_h,p-p_h)+R_h(\mathbf{u},p;\mathbf{w}-\mathbf{u}_h).\end{aligned}$$

Since $\mathbf{w}-\mathbf{u}_h\in\mathbf{Z}(0)$, we can replace p_h by q in the form B_h. Using the continuity properties in (3.2), (3.3), and the triangle inequality, we obtain

$$\|\mathbf{u}-\mathbf{u}_h\|_h\le\left(1+\frac{\alpha_1}{\beta}\right)\|\mathbf{u}-\mathbf{w}\|_h+\frac{\alpha_2}{\beta}\|p-q\|_0+\beta^{-1}\mathcal{R}_h(\mathbf{u},p)\tag{4.1}$$

for any $\mathbf{w}\in\mathbf{Z}(G_h)$ and $q\in Q_h$.

Second, we fix $\mathbf{v}\in\mathbf{V}_h$ and consider the problem of finding $\mathbf{z}(\mathbf{v})\in\mathbf{V}_h$ such that

$$B_h(\mathbf{z}(\mathbf{v}),q)=B_h(\mathbf{u}-\mathbf{v},q)\qquad\forall q\in Q_h.$$

Thanks to the discrete inf-sup condition in (3.6), the continuity of B_h in (3.3) and [10, Proposition 1.2, p. 39], a solution $\mathbf{z}(\mathbf{v})$ is defined. Furthermore,

$$\gamma_h\|\mathbf{z}(\mathbf{v})\|_h\le\sup_{0\neq q\in Q_h}\frac{B_h(\mathbf{z}(\mathbf{v}),q)}{\|q\|_0}=\sup_{0\neq q\in Q_h}\frac{B_h(\mathbf{u}-\mathbf{v},q)}{\|q\|_0}\le\alpha_2\|\mathbf{u}-\mathbf{v}\|_h,\tag{4.2}$$

where we have used the continuity of B_h. By construction and assumption (3.7), we have $\mathbf{z}(\mathbf{v})+\mathbf{v}\in\mathbf{Z}(G_h)$. Inserting $\mathbf{z}(\mathbf{v})+\mathbf{v}$ in (4.1) yields

$$\|\mathbf{u}-\mathbf{u}_h\|_h\le\left(1+\frac{\alpha_1}{\beta}\right)\|\mathbf{u}-\mathbf{v}\|_h+\left(1+\frac{\alpha_1}{\beta}\right)\|\mathbf{z}(\mathbf{v})\|_h+\frac{\alpha_2}{\beta}\|p-q\|_0+\beta^{-1}\mathcal{R}_h(\mathbf{u},p).$$

This, together with (4.2), proves the assertion. ∎

REMARK 4.2. *Assuming that α_1, α_2, and β are independent of the discretization parameter h, the bound in Proposition* 4.1 *can be expressed in a simpler fashion as*

$$\|\mathbf{u}-\mathbf{u}_h\|_h\le C\big[\gamma_h^{-1}\inf_{\mathbf{v}\in\mathbf{V}_h}\|\mathbf{u}-\mathbf{v}\|_h+\inf_{q\in Q_h}\|p-q\|_0+\mathcal{R}_h(\mathbf{u},p)\big].$$

4.2. Error in the pressure. Next, we prove an error estimate for the pressure following the arguments in [40, Lemma 8.2].

PROPOSITION 4.3. *Let $(\mathbf{u},p)\in\mathbf{V}\times Q$ be the exact solution of the Stokes problem and $(\mathbf{u}_h,p_h)\in\mathbf{V}_h\times Q_h$ the mixed finite element approximation. Under the assumptions of section* 3*, we have*

$$\|p-p_h\|_0\le\left(1+\frac{\alpha_2}{\gamma_h}\right)\inf_{q\in Q_h}\|p-q\|_0+\frac{\alpha_1}{\gamma_h}\|\mathbf{u}-\mathbf{u}_h\|_h+\gamma_h^{-1}\mathcal{R}_h(\mathbf{u},p).$$

Proof. Fix $q \in Q_h$. From the inf-sup condition in (3.6) we have

$$\gamma_h \|q - p_h\|_0 \le \sup_{\mathbf{0} \neq \mathbf{v} \in \mathbf{V}_h} \frac{B_h(\mathbf{v}, q - p_h)}{\|\mathbf{v}\|_h}.$$

Since $B_h(\mathbf{v}, q - p_h) = B_h(\mathbf{v}, q - p) - A_h(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) + R_h(\mathbf{u}, p; \mathbf{v})$ for any $\mathbf{v} \in \mathbf{V}_h$, we obtain from the continuity properties in (3.2) and (3.3) and the definition of $\mathcal{R}_h$ in (3.9)

$$\gamma_h \|q - p_h\|_0 \le \alpha_2 \|p - q\|_0 + \alpha_1 \|\mathbf{u} - \mathbf{u}_h\|_h + \mathcal{R}_h(\mathbf{u}, p).$$

The assertion then follows from the triangle inequality. ∎

REMARK 4.4. *Taking into account the estimate for* $\|\mathbf{u} - \mathbf{u}_h\|_h$ *in Proposition* 4.1 *and assuming again that* α_1, α_2, *and* β *are independent of the discretization parameter* h, *the bound in Proposition* 4.3 *reduces to*

$$\|p - p_h\|_0 \le C\big[\gamma_h^{-1} \inf_{q \in Q_h} \|p - q\|_0 + \gamma_h^{-2} \inf_{\mathbf{v} \in \mathbf{V}_h} \|\mathbf{u} - \mathbf{v}\|_h + \gamma_h^{-1} \mathcal{R}_h(\mathbf{u}, p)\big].$$

5. Discontinuous Galerkin discretizations. In this section, we give several examples of mixed discontinuous Galerkin methods that can be cast into the setting of section 3 by using lifting operators similar to the ones introduced in [2] for the Laplacian.

5.1. Triangulations and finite element spaces. Let $\mathcal{T}_h$ be a shape-regular affine quadrilateral or hexahedral mesh on Ω. We denote by h_K the diameter of the element $K \in \mathcal{T}_h$. Further, we assign to each element $K \in \mathcal{T}_h$ an approximation order $k_K \ge 1$. The local quantities h_K and k_K are stored in the vectors $\underline{h} = \{h_K\}_{K \in \mathcal{T}_h}$ and $\underline{k} = \{k_K\}_{K \in \mathcal{T}_h}$, respectively. We set $h = \max_{K \in \mathcal{T}_h} h_K$ and $|\underline{k}| = \max_{K \in \mathcal{T}_h} k_K$. Finally, $\mathbf{n}_K$ denotes the outward normal unit vector to the boundary ∂K.

An interior face of $\mathcal{T}_h$ is the (nonempty) interior of $\partial K^+ \cap \partial K^-$, where K^+ and K^- are two adjacent elements of $\mathcal{T}_h$. Similarly, a boundary face of $\mathcal{T}_h$ is the (nonempty) interior of $\partial K \cap \partial\Omega$ which consists of entire faces of ∂K. We denote by $\mathcal{E}_\mathcal{I}$ the union of all interior faces of $\mathcal{T}_h$, by $\mathcal{E}_\mathcal{D}$ the union of all boundary faces, and set $\mathcal{E} = \mathcal{E}_\mathcal{I} \cup \mathcal{E}_\mathcal{D}$. Here and in the following, we refer generically to a "face" even in the two-dimensional case.

We allow for irregular meshes, i.e., meshes with hanging nodes (see [37, sect. 4.4.1]), in general, but suppose that the intersection between neighboring elements is either a common vertex, or a common edge, or a common face, or an entire face of one of the two elements. We also assume the local mesh-sizes and approximation degrees to be of bounded variation, that is, there is a constant $\kappa > 0$ such that

$$\kappa h_K \le h_{K'} \le \kappa^{-1} h_K, \qquad \kappa k_K \le k_{K'} \le \kappa^{-1} k_K, \tag{5.1}$$

whenever K and K' share a common face.

We wish to approximate the velocities and pressures in the discontinuous finite element spaces $\mathbf{V}_h$ and Q_h given by

$$\begin{aligned} \mathbf{V}_h &= \{\, \mathbf{v} \in L^2(\Omega)^d : \mathbf{v}|_K \in \mathbb{Q}_{k_K}(K)^d,\ K \in \mathcal{T}_h \,\}, \\ Q_h &= \{\, q \in L^2_0(\Omega) : q|_K \in \mathbb{Q}_{k_K - 1}(K),\ K \in \mathcal{T}_h \,\}, \end{aligned} \tag{5.2}$$

respectively, where $\mathbb{Q}_k(K)$ is the space of polynomials of maximum degree k in each variable on K.

For the derivation and analysis of the methods, we will make use of the auxiliary space $\underline{\Sigma}_h$ defined by

$$\underline{\Sigma}_h := \{\, \underline{\tau} \in L^2(\Omega)^{d\times d} : \underline{\tau} \in \mathbb{Q}_{k_K}(K)^{d\times d},\ K \in \mathcal{T}_h \,\}.$$

Note that $\nabla_h \mathbf{V}_h \subset \underline{\Sigma}_h$, where ∇_h is the discrete gradient, taken elementwise, and given by $[\nabla \mathbf{v}]_{ij} = \partial_j v_i = \frac{\partial v_i}{\partial x_j}$ on $K \in \mathcal{T}_h$.

5.2. Trace operators. In this section, we define the trace operators needed in our discontinuous Galerkin discretizations. To this end, let $e \subset \mathcal{E}_\mathcal{I}$ be an interior face shared by K^+ and K^-. Let $(\mathbf{v}, q, \underline{\tau})$ be a function smooth inside each element $K^\pm$ and let us denote by $(\mathbf{v}^\pm, q^\pm, \underline{\tau}^\pm)$ the traces of $(\mathbf{v}, q, \underline{\tau})$ on e from the interior of $K^\pm$. Then, we define the mean values $\{\!\{\cdot\}\!\}$ and normal jumps $[\![\cdot]\!]$ at $\mathbf{x} \in e$ as

$$\begin{aligned}
\{\!\{\mathbf{v}\}\!\} &:= (\mathbf{v}^+ + \mathbf{v}^-)/2, & [\![\mathbf{v}]\!] &:= \mathbf{v}^+ \cdot \mathbf{n}_{K^+} + \mathbf{v}^- \cdot \mathbf{n}_{K^-},\\
\{\!\{q\}\!\} &:= (q^+ + q^-)/2, & [\![q]\!] &:= q^+ \,\mathbf{n}_{K^+} + q^- \,\mathbf{n}_{K^-},\\
\{\!\{\underline{\tau}\}\!\} &:= (\underline{\tau}^+ + \underline{\tau}^-)/2, & [\![\underline{\tau}]\!] &:= \underline{\tau}^+ \,\mathbf{n}_{K^+} + \underline{\tau}^- \,\mathbf{n}_{K^-}.
\end{aligned}$$

Note that the jumps $[\![q]\!]$ and $[\![\underline{\tau}]\!]$ are both vectors whereas the jump $[\![\mathbf{v}]\!]$ is a scalar. We also need to define a jump of the velocity $\mathbf{v}$ which is a matrix, namely,

$$\underline{[\![\mathbf{v}]\!]} := \mathbf{v}^+ \otimes \mathbf{n}_{K^+} + \mathbf{v}^- \otimes \mathbf{n}_{K^-},$$

where, for two vectors $\mathbf{a}$ and $\mathbf{b}$, we set $[\mathbf{a} \otimes \mathbf{b}]_{ij} = a_i b_j$.

On a boundary face $e \subset \mathcal{E}_\mathcal{D}$ given by $e = \partial K \cap \partial\Omega$, we accordingly set

$$\{\!\{\mathbf{v}\}\!\} := \mathbf{v}, \qquad \{\!\{q\}\!\} := q, \qquad \{\!\{\underline{\tau}\}\!\} := \underline{\tau},$$

as well as

$$[\![\mathbf{v}]\!] := \mathbf{v} \cdot \mathbf{n}, \qquad \underline{[\![\mathbf{v}]\!]} := \mathbf{v} \otimes \mathbf{n}, \qquad [\![q]\!] := q\mathbf{n}, \qquad [\![\underline{\tau}]\!] := \underline{\tau}\,\mathbf{n}.$$

We remark that, for the exact solution $(\mathbf{u}, p) \in \mathbf{V} \times Q$, there holds $\underline{[\![\mathbf{u}]\!]} = \underline{0}$ and $[\![\nu\nabla\mathbf{u} - p\underline{I}]\!] = \mathbf{0}$ on $\mathcal{E}_\mathcal{I}$. The last property follows from the fact that $\nu\nabla\mathbf{u} - p\underline{I}$ belongs to $H(\mathrm{div}; \Omega)$; see [40].

5.3. Lifting operators. We introduce the following lifting operators. First, for a face $e \subset \mathcal{E}$ we define $\underline{\mathcal{L}}_e : \mathbf{V}(h) \to \underline{\Sigma}_h$ by

$$\int_\Omega \underline{\mathcal{L}}_e(\mathbf{v}) : \underline{\tau}\, d\mathbf{x} = \int_e \underline{[\![\mathbf{v}]\!]} : \{\!\{\underline{\tau}\}\!\}\, ds \qquad \forall \underline{\tau} \in \underline{\Sigma}_h.$$

Note that the support of $\underline{\mathcal{L}}_e(\mathbf{v})$ is contained in the elements that share the face e. For a boundary face $e \subset \mathcal{E}_\mathcal{D}$, we introduce the lifting $\underline{\mathcal{G}}_e \in \underline{\Sigma}_h$ of the Dirichlet datum $\mathbf{g}$ given by

$$\int_\Omega \underline{\mathcal{G}}_e : \underline{\tau}\, d\mathbf{x} = \int_e (\mathbf{g} \otimes \mathbf{n}) : \underline{\tau}\, ds \qquad \forall \underline{\tau} \in \underline{\Sigma}_h.$$

For the exact solution $\mathbf{u} \in \mathbf{V}$, we have

$$\underline{\mathcal{L}}_e(\mathbf{u}) = \underline{0} \quad \forall e \subset \mathcal{E}_\mathcal{I}, \qquad \underline{\mathcal{L}}_e(\mathbf{u}) = \underline{\mathcal{G}}_e \quad \forall e \subset \mathcal{E}_\mathcal{D}. \tag{5.3}$$

Globally, we define $\underline{\mathcal{L}} : \mathbf{V}(h) \to \underline{\Sigma}_h$ and $\underline{\mathcal{G}} \in \underline{\Sigma}_h$ by

$$\underline{\mathcal{L}} := \sum_{e \subset \mathcal{E}} \underline{\mathcal{L}}_e, \qquad \underline{\mathcal{G}} := \sum_{e \subset \mathcal{E}_\mathcal{D}} \underline{\mathcal{G}}_e.$$

These operators can be characterized by

$$\int_\Omega \underline{\mathcal{L}}(\mathbf{v}) : \underline{\tau}\, d\mathbf{x} = \int_\mathcal{E} \underline{[\![\mathbf{v}]\!]} : \{\!\{\underline{\tau}\}\!\}\, ds \qquad \forall \underline{\tau} \in \underline{\Sigma}_h,$$
$$\int_\Omega \underline{\mathcal{G}} : \underline{\tau}\, d\mathbf{x} = \int_{\mathcal{E}_\mathcal{D}} (\mathbf{g} \otimes \mathbf{n}) : \underline{\tau}\, ds \qquad \forall \underline{\tau} \in \underline{\Sigma}_h.$$

Finally, we need the lifting operator $\mathcal{M} : \mathbf{V}(h) \to Q_h$ defined by

$$\int_\Omega \mathcal{M}(\mathbf{v}) \varphi\, d\mathbf{x} = \int_\mathcal{E} [\![\mathbf{v}]\!]\, \{\!\{\varphi\}\!\}\, ds \qquad \forall \varphi \in Q_h.$$

For the exact solution $\mathbf{u} \in \mathbf{V}$, there holds

$$\int_\Omega \mathcal{M}(\mathbf{u})\, \varphi\, d\mathbf{x} = \int_{\mathcal{E}_\mathcal{D}} \varphi\, \mathbf{g} \cdot \mathbf{n}\, ds \qquad \forall \varphi \in Q_h. \tag{5.4}$$

5.4. Mixed discontinuous Galerkin problems. We introduce mixed discontinuous Galerkin methods of the form (3.1) for the mixed-order spaces in (5.2): find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ such that

$$\left\{ \begin{array}{lcl} A_h(\mathbf{u}_h, \mathbf{v}) + B_h(\mathbf{v}, p_h) &=& F_h(\mathbf{v}), \\ B_h(\mathbf{u}_h, q) &=& G_h(q) \end{array} \right. \tag{5.5}$$

for all $(\mathbf{v}, q) \in \mathbf{V}_h \times Q_h$.

The form $B_h : \mathbf{V}(h) \times Q \to \mathbb{R}$ and the functional $G_h : Q_h \to \mathbb{R}$ will always be chosen as

$$B_h(\mathbf{v}, q) = -\int_\Omega q\, [\nabla_h \cdot \mathbf{v} - \mathcal{M}(\mathbf{v})]\, d\mathbf{x}, \qquad \mathbf{v} \in \mathbf{V}(h),\ q \in Q,$$
$$G_h(q) = \int_{\mathcal{E}_\mathcal{D}} q\, \mathbf{g} \cdot \mathbf{n}\, ds, \qquad q \in Q_h,$$

Restricted to discrete functions $(\mathbf{v}, q) \in \mathbf{V}_h \times Q_h$, we have

$$B_h(\mathbf{v}, q) = -\int_\Omega q\, \nabla_h \cdot \mathbf{v}\, d\mathbf{x} + \int_\mathcal{E} \{\!\{q\}\!\} [\![\mathbf{v}]\!]\, ds. \tag{5.6}$$

Thus, we exactly obtain the form B_h and the functional G_h considered in the mixed DG approaches in [17, 26, 40]. We remark that (3.7) is satisfied thanks to (5.4).

For discrete functions, we equivalently have

$$B_h(\mathbf{v}, q) = \int_\Omega \nabla_h q \cdot \mathbf{v}\, d\mathbf{x} - \int_{\mathcal{E}_\mathcal{I}} [\![q]\!] \cdot \{\!\{\mathbf{v}\}\!\}\, ds, \qquad (\mathbf{v}, q) \in \mathbf{V}_h \times Q_h. \tag{5.7}$$

This follows from integration by parts and elementary manipulations; see equation (4.7) in [40].

The space $\mathbf{V}(h) = \mathbf{V} + \mathbf{V}_h$ is endowed with the broken norm

$$\|\mathbf{v}\|_h^2 = \sum_{K\in\mathcal{T}_h} |\mathbf{v}|_{1,K}^2 + \int_{\mathcal{E}} \sigma |\underline{[\![\mathbf{v}]\!]}|^2 \, ds, \qquad \mathbf{v} \in \mathbf{V}(h), \tag{5.8}$$

where $\sigma \in L^\infty(\mathcal{E})$ is the so-called discontinuity stabilization function that we choose in terms of the local mesh-sizes and the polynomial degrees as follows. Define the functions $\mathtt{h} \in L^\infty(\mathcal{E})$ and $\mathtt{k} \in L^\infty(\mathcal{E})$ by

$$\mathtt{h}(\mathbf{x}) := \begin{cases} \min\{h_K, h_{K'}\}, & \mathbf{x} \text{ in the interior of } \partial K \cap \partial K', \\ h_K, & \mathbf{x} \text{ in the interior of } \partial K \cap \partial\Omega, \end{cases}$$

$$\mathtt{k}(\mathbf{x}) := \begin{cases} \max\{k_K, k_{K'}\}, & \mathbf{x} \text{ in the interior of } \partial K \cap \partial K', \\ k_K, & \mathbf{x} \text{ in the interior of } \partial K \cap \partial\Omega. \end{cases}$$

Then we set

$$\sigma = \sigma_0 \mathtt{h}^{-1}\mathtt{k}^2, \tag{5.9}$$

with a parameter $\sigma_0 > 0$ that is independent of $\mathtt{h}$ and $\mathtt{k}$.

For the form A_h related to the Laplacian, several choices are possible. Let us discuss the stable and consistent forms in the sense of [2].

The interior penalty forms A_h. The symmetric interior penalty (IP) form has been used in the mixed DG method introduced in [26]. It is obtained by first defining the stabilization form I_h^σ as

$$I_h^\sigma(\mathbf{u},\mathbf{v}) := \nu \int_{\mathcal{E}} \sigma \underline{[\![\mathbf{u}]\!]} : \underline{[\![\mathbf{v}]\!]} \, ds, \qquad \mathbf{u},\mathbf{v} \in \mathbf{V}(h), \tag{5.10}$$

where σ is the discontinuity stabilization function in (5.9), and then by taking, for $\mathbf{u},\mathbf{v} \in \mathbf{V}(h)$,

$$\begin{aligned} A_h(\mathbf{u},\mathbf{v}) &= \int_\Omega \nu \big[\nabla_h \mathbf{u} : \nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{u}) : \nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v}) : \nabla_h \mathbf{u}\big] \, d\mathbf{x} + I_h^\sigma(\mathbf{u},\mathbf{v}), \\ F_h(\mathbf{v}) &= \int_\Omega \mathbf{f}\cdot\mathbf{v} \, d\mathbf{x} - \nu \int_\Omega \underline{\mathcal{G}} : \nabla_h \mathbf{v} \, d\mathbf{x} + \nu \int_{\mathcal{E}_\mathcal{D}} \sigma \mathbf{g}\cdot\mathbf{v} \, ds. \end{aligned} \tag{5.11}$$

Restricted to discrete functions $\mathbf{u},\mathbf{v} \in \mathbf{V}_h$, we have

$$A_h(\mathbf{u},\mathbf{v}) = \int_\Omega \nu \nabla_h \mathbf{u} : \nabla_h \mathbf{v} \, d\mathbf{x} - \int_{\mathcal{E}} \big(\{\!\{\nu \nabla_h \mathbf{v}\}\!\} : \underline{[\![\mathbf{u}]\!]} + \{\!\{\nu \nabla_h \mathbf{u}\}\!\} : \underline{[\![\mathbf{v}]\!]} \big) \, ds + I_h^\sigma(\mathbf{u},\mathbf{v}).$$

The nonsymmetric variant of the IP form has been studied in the mixed DG approach in [40] (see also [35, 27] for scalar convection-diffusion problems). It is obtained by choosing, for $\mathbf{u},\mathbf{v} \in \mathbf{V}(h)$,

$$\begin{aligned} A_h(\mathbf{u},\mathbf{v}) &= \int_\Omega \nu \big[\nabla_h \mathbf{u} : \nabla_h \mathbf{v} + \underline{\mathcal{L}}(\mathbf{u}) : \nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v}) : \nabla_h \mathbf{u}\big] \, d\mathbf{x} + I_h^\sigma(\mathbf{u},\mathbf{v}), \\ F_h(\mathbf{v}) &= \int_\Omega \mathbf{f}\cdot\mathbf{v} \, d\mathbf{x} + \nu \int_\Omega \underline{\mathcal{G}} : \nabla_h \mathbf{v} \, d\mathbf{x} + \nu \int_{\mathcal{E}_\mathcal{D}} \sigma \mathbf{g}\cdot\mathbf{v} \, ds. \end{aligned} \tag{5.12}$$

REMARK 5.1. *For $\sigma \equiv 0$ the form A_h in (5.12) coincides with the form given by the so-called Baumann–Oden method* [7, 29]. *Further, realizations of the methods of Baker, Jureidini, and Karakashian* [4] *and Karakashian and Jureidini* [28] *are obtained with the IP form A_h in* (5.11), *if we choose the spaces $\widetilde{\mathbf{V}}_h = \{\mathbf{v} \in \mathbf{V}_h : \mathbf{v}|_K$ is divergence free on each $K \in \mathcal{T}_h\}$ and $\widetilde{Q}_h = Q_h \cap C^0(\overline{\Omega})$, respectively.*

The LDG form A_h. The local discontinuous Galerkin (LDG) form is closely related to the IP forms since it is also expressed in terms of the stabilization form I_h^σ in (5.10). In the context of the Stokes problem, it has been studied in [17] (see also [19, 13, 31]). In the primal variables, the LDG form is given by taking, for $\mathbf{u}, \mathbf{v} \in \mathbf{V}(h)$,

$$\begin{aligned} A_h(\mathbf{u},\mathbf{v}) &= \int_\Omega \nu \left[\nabla_h \mathbf{u} - \underline{\mathcal{L}}(\mathbf{u})\right] : \left[\nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v})\right] d\mathbf{x} + I_h^\sigma(\mathbf{u},\mathbf{v}), \\ F_h(\mathbf{v}) &= \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} - \nu \int_\Omega \underline{\mathcal{G}} : \left(\nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v})\right) d\mathbf{x} + \nu \int_{\mathcal{E}_\mathcal{D}} \sigma \mathbf{g}\cdot\mathbf{v}\, ds. \end{aligned} \tag{5.13}$$

The Bassi–Rebay forms A_h. These forms were inspired by the original Bassi–Rebay method in [5], which, in fact, is unstable. They are defined by introducing a different stabilization form I_h^η given by

$$I_h^\eta(\mathbf{u},\mathbf{v}) = \nu \sum_{e\subset\mathcal{E}} \int_\Omega \eta\, \underline{\mathcal{L}}_e(\mathbf{u}) : \underline{\mathcal{L}}_e(\mathbf{v})\, d\mathbf{x}, \qquad \mathbf{u},\mathbf{v} \in \mathbf{V}(h), \tag{5.14}$$

for a parameter $\eta > 0$. The first form we present here was introduced in [6] and is obtained by choosing, for $\mathbf{u}, \mathbf{v} \in \mathbf{V}(h)$,

$$\begin{aligned} A_h(\mathbf{u},\mathbf{v}) &= \int_\Omega \nu \left[\nabla_h \mathbf{u} : \nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{u}) : \nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v}) : \nabla_h \mathbf{u}\right] d\mathbf{x} + I_h^\eta(\mathbf{u},\mathbf{v}), \\ F_h(\mathbf{v}) &= \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} - \nu \int_\Omega \underline{\mathcal{G}} : \nabla_h \mathbf{v}\, d\mathbf{x} + \nu \sum_{e\subset\mathcal{E}_\mathcal{D}} \int_\Omega \eta\, \underline{\mathcal{G}}_e : \underline{\mathcal{L}}_e(\mathbf{v})\, d\mathbf{x}. \end{aligned} \tag{5.15}$$

In [11], the following variant of the Bassi–Rebay form has been proposed:

$$\begin{aligned} A_h(\mathbf{u},\mathbf{v}) &= \int_\Omega \nu \left[\nabla_h \mathbf{u} - \underline{\mathcal{L}}(\mathbf{u})\right] : \left[\nabla_h \mathbf{v} - \underline{\mathcal{L}}(\mathbf{v})\right] d\mathbf{x} + I_h^\eta(\mathbf{u},\mathbf{v}), \\ F_h(\mathbf{v}) &= \int_\Omega \mathbf{f}\cdot\mathbf{v}\, d\mathbf{x} - \nu \int_\Omega \underline{\mathcal{G}} : \nabla_h \mathbf{v}\, d\mathbf{x} + \nu \sum_{e\subset\mathcal{E}_\mathcal{D}} \int_\Omega \eta\, \underline{\mathcal{G}}_e : \underline{\mathcal{L}}_e(\mathbf{v})\, d\mathbf{x}. \end{aligned} \tag{5.16}$$

6. Divergence stability. In this section, we establish an inf-sup condition for the form $B_h(\cdot,\cdot)$ with respect to the norm $\|\cdot\|_h$ in (5.8)–(5.9) and for the $\mathbb{Q}_k - \mathbb{Q}_{k-1}$ spaces in (5.2). We recall that the divergence bilinear form is the same for all the methods that we consider.

6.1. The discrete inf-sup condition. Let us begin by stating our main stability result.

PROPOSITION 6.1. *Let $k_K \geq 2$ for all $K \in \mathcal{T}_h$. Then there are constants $c_1 > 0$ and $c_2 > 0$, independent of $\underline{h}$ and $\underline{k}$, such that for each $q \in Q_h$ there exists a discrete velocity field $\mathbf{v} \in \mathbf{V}_h$ such that*

$$B_h(\mathbf{v},q) \geq c_1 \|q\|_0^2, \qquad \|\mathbf{v}\|_h \leq c_2 |\underline{k}|\, \|q\|_0.$$

From the above result, we immediately find the following stability result.

THEOREM 6.2. *There exists a constant $c > 0$, independent of $\underline{h}$ and $\underline{k}$, such that, for $k_K \geq 2$,*

$$\inf_{0\neq q\in Q_h} \sup_{\mathbf{0}\neq\mathbf{v}\in\mathbf{V}_h} \frac{B_h(\mathbf{v},q)}{\|\mathbf{v}\|_h \|q\|_0} \geq \gamma_h \geq c\, |\underline{k}|^{-1}. \tag{6.1}$$

REMARK 6.3. *Theorem* 6.2 *establishes an hp-version divergence stability result for the* $\mathbb{Q}_k - \mathbb{Q}_{k-1}$ *element family where the difference in the approximation orders for the velocity and the pressure is exactly one. It is well known that these elements are unstable in a conforming setting, although they are optimal in terms of the approximation properties of the finite element spaces. The use of discontinuous velocities overcomes these usual stability problems in a natural way. In addition, the bound* (6.1) *holds in two and three dimensions, and it is identical to the bound established in* [38] *for conforming mixed hp-FEM in three dimensions, although there* $\mathbb{Q}_k - \mathbb{Q}_{k-2}$ *spaces have been used.*

REMARK 6.4. *The technique we use to prove this result is a combination of the h-version approach in* [26] *that makes use of* $H(\mathrm{div})$*-conforming projectors and of the work* [40] *that allows us to deal with hanging nodes. Indeed, we also decompose the pressure into piecewise constants and polynomials whose mean values vanish elementwise as in* [40] *(see also the analysis for conforming hp-methods in* [38]*) and use the low-order stability results in two and three dimensions of* [36, 41] *for* $\mathbb{Q}_2 - \mathbb{Q}_0$ *elements on irregular meshes. That is the reason why we assume* $k_K \geq 2$ *in Proposition* 6.1. *We remark that for* $\mathbb{Q}_1 - \mathbb{Q}_0$ *elements and conforming meshes, divergence stability can be obtained by establishing directly a Fortin property. We report on this case in more detail in section* 6.5.

REMARK 6.5. *The numerical tests in* [40] *show that in two dimensions a stability constant independent of* h and k *is expected, indicating that the dependence on* k *in* (6.1) *is not likely to be sharp.*

REMARK 6.6. *As can be inferred from its proof, the result of Theorem* 6.2 *holds, in fact, for the strictly smaller velocity space* $\widetilde{\mathbf{V}}_h \subset \mathbf{V}_h$ *given by*

$$\widetilde{\mathbf{V}}_h = \{\mathbf{v} \in \mathbf{V}_h \cap H_0(\mathrm{div};\Omega) : \mathbf{v}|_K \in RT_{k_K-1}(K),\ K \in \mathcal{T}_h\},$$

for the Raviart–Thomas space $RT_{k_K-1}(K)$ *of degree* $k_K - 1$ *introduced in the next section. Here,* $H_0(\mathrm{div};\Omega) = \{\mathbf{v} \in L^2(\Omega)^d : \nabla \cdot \mathbf{v} \in L^2(\Omega),\ \mathbf{v} \cdot \mathbf{n} = 0 \text{ on } \partial\Omega\}$. *Whether or not the dependence of the inf-sup constant* γ_h *on the polynomial degree in* (6.1) *is sharp for this space is an open issue.*

The remaining part of this section is devoted to the proof of Proposition 6.1. We will carry out the proof for the three-dimensional case and note that the result in two dimensions is obtained completely analogously. We start in section 6.2 by defining Raviart–Thomas interpolation operators that we shall use as Fortin operators. In section 6.3, we establish new stability results for these operators. The proof of Proposition 6.1 is then given in section 6.4. In section 6.5, we report on some extensions of our stability result to uniform approximation orders and conforming meshes, also including $\mathbb{Q}_1 - \mathbb{Q}_0$ elements.

6.2. Raviart–Thomas spaces and interpolants. Given the reference cube $\hat{K} = (-1,1)^3$ and an integer $k \geq 0$, we consider the space

$$RT_k(\hat{K}) = \mathbb{Q}_{k+1,k,k}(\hat{K}) \times \mathbb{Q}_{k,k+1,k}(\hat{K}) \times \mathbb{Q}_{k,k,k+1}(\hat{K}),$$

where $\mathbb{Q}_{k_1,k_2,k_3}(\hat{K})$ is the space of polynomials of degree at most k_i in the ith variable. For an affinely mapped element $K \in \mathcal{T}_h$ the space $RT_k(K)$ is defined by suitably mapping functions in $RT_k(\hat{K})$ using a Piola transformation; see [10, sect. 3.3] or [1, sect. 3.3] for further details.

We denote the faces of $\hat{K}$ by γ_m, $m = 1, \dots, 6$. In particular, we set

$$\begin{aligned} \gamma_1 &= \{x = -1\}, \qquad \gamma_2 = \{x = 1\}, \\ \gamma_3 &= \{y = -1\}, \qquad \gamma_4 = \{y = 1\}, \\ \gamma_5 &= \{z = -1\}, \qquad \gamma_6 = \{z = 1\}. \end{aligned}$$

We use the same notation for an affinely mapped element K, where the faces are obtained by mapping the corresponding ones of $\hat{K}$. Moreover, we denote by $\mathbb{Q}_{k,k}(\gamma_m)$ the space of polynomials of degree at most k in each variable on the face γ_m.

On the reference cube, there is a unique interpolation operator $\Pi_{\hat{K}} : H^1(\hat{K})^3 \to RT_k(\hat{K})$ such that

$$\begin{aligned} &\int_{\hat{K}} \big(\Pi_{\hat{K}}\mathbf{w} - \mathbf{w}\big) \cdot \mathbf{r}\, d\mathbf{x} = 0, \quad \mathbf{r} \in \mathbb{Q}_{k-1,k,k}(\hat{K}) \times \mathbb{Q}_{k,k-1,k}(\hat{K}) \times \mathbb{Q}_{k,k,k-1}(\hat{K}), \\ &\int_{\gamma_m} \big(\Pi_{\hat{K}}\mathbf{w} - \mathbf{w}\big) \cdot \mathbf{n}\, \varphi\, ds = 0, \quad \varphi \in \mathbb{Q}_{k,k}(\gamma_m), \quad m = 1, \dots, 6; \end{aligned} \tag{6.2}$$

see [10] or [1]. For $k = 0$, the first condition in (6.2) is void. For an element $K \in \mathcal{T}_h$, the interpolant $\Pi_K : H^1(K)^3 \to RT_k(K)$ can be defined by using a Piola transform in such a way that the orthogonality conditions in (6.2) also hold for Π_K; see, e.g., [1, sect. 3.5].

6.3. Stability of the Raviart–Thomas interpolant. In order to prove our stability results for the operator Π_K, we need to introduce a representation formula, originally proposed in [1] for the two-dimensional case. We start by defining some additional operators for the reference cube $\hat{K}$. Given integers k_1, k_2, and k_3, we define

$$\hat{Q}_{k_1,k_2,k_3} = \pi^z_{k_3} \otimes \pi^y_{k_2} \otimes \pi^x_{k_1} : L^2(\hat{K}) \to \mathbb{Q}_{k_1,k_2,k_3}(\hat{K})$$

as the L^2-orthogonal projection onto $\mathbb{Q}_{k_1,k_2,k_3}(\hat{K})$. We note that $\hat{Q}_{k_1,k_2,k_3}$ is the tensor product of one-dimensional L^2-projections π_{k_i} on the reference interval $I = (-1, 1)$.

We next introduce extension operators from the faces γ_m. To that end, we denote by L_k, $k \geq 0$, the Legendre polynomial of degree k in I; see [9, sect. 3]. For the face γ_1, we define $\mathcal{E}^{\gamma_1}_k : \mathbb{Q}_{k,k}(\gamma_1) \to \mathbb{Q}_{k+1,k,k}(\hat{K})$ as

$$(\mathcal{E}^{\gamma_1}_k \varphi)(x, y, z) := M^{\gamma_1}_k(x)\varphi(y, z), \qquad M^{\gamma_1}_k(x) := \frac{(-1)^{k+1}}{2}(L_{k+1}(x) - L_k(x)).$$

We note that

$$(\mathcal{E}^{\gamma_1}_k \varphi)|_{\gamma_1} = \varphi, \qquad (\mathcal{E}^{\gamma_1}_k \varphi)|_{\gamma_2} = 0,$$

and that $(\mathcal{E}^{\gamma_1}_k \varphi)|_{\gamma_m}$, $m = 3, \dots, 6$, does not vanish in general. Analogous definitions hold for the other faces γ_m, $m = 2, \dots, 6$.

Similar to [1, Lemma 3], for $\mathbf{w} = (w_x, w_y, w_z) \in H^1(\hat{K})^3$, the interpolant $\mathbf{v} = \Pi_{\hat{K}}\mathbf{w}$ can be written as $\mathbf{v} = (v_x, v_y, v_z)$ with

$$\begin{aligned} v_x &= \hat{Q}_{k-1,k,k} w_x + \sum_{m=1}^{2} \mathcal{E}^{\gamma_m}_k (\pi^y_k \circ \pi^z_k) \left(w_x - \hat{Q}_{k-1,k,k} w_x \right), \\ v_y &= \hat{Q}_{k,k-1,k} w_y + \sum_{m=3}^{4} \mathcal{E}^{\gamma_m}_k (\pi^x_k \circ \pi^z_k) \left(w_y - \hat{Q}_{k,k-1,k} w_y \right), \\ v_z &= \hat{Q}_{k,k,k-1} w_z + \sum_{m=5}^{6} \mathcal{E}^{\gamma_m}_k (\pi^x_k \circ \pi^y_k) \left(w_z - \hat{Q}_{k,k,k-1} w_z \right), \end{aligned} \tag{6.3}$$

where, e.g., $(\pi_k^y \circ \pi_k^z)(w_x - \hat{Q}_{k-1,k,k} w_x)$ is understood as $\pi_k^y \circ \pi_k^z$ applied to the restriction of $(w_x - \hat{Q}_{k-1,k,k} w_x)$ to γ_m, $m = 1, 2$.

Before proving our stability results, we need some technical lemmas. The results in the following lemma can be found using similar techniques as in Theorem 2.2 in [12], Lemma 3.9 in [27], and Theorems 3.91 and 3.92 in [37].

LEMMA 6.7. *We have the following estimates.*

1. *Let $w \in H^1(\hat{K})$. Then there exists a constant $C > 0$ independent of k such that*

$$|\hat{Q}_{k-1,k,k} w|^2_{1,\hat{K}} \le C\, k\, |w|^2_{1,\hat{K}}, \tag{6.4}$$

$$\|w - \hat{Q}_{k-1,k,k} w\|^2_{0,\gamma_m} \le C\, k^{-1}\, |w|^2_{1,\hat{K}}, \qquad m = 1, \dots, 6. \tag{6.5}$$

2. *Let $I = (-1, 1)$ and $w \in \mathbb{Q}_k(I)$. Then there exists a constant $C > 0$ such that*

$$|w|_{1,I} \le Ck^2 \|w\|_{0,I}, \tag{6.6}$$

$$\|w\|_{\infty,I} \le Ck \|w\|_{0,I}. \tag{6.7}$$

The following lemma can be proved by using the properties of the Legendre polynomials given, e.g., in Theorem 3.2 and Remark 3.2 in [9], and Theorem 3.96 in [37].

LEMMA 6.8. *Let*

$$M_k^{\gamma_1}(x) = \frac{(-1)^{k+1}}{2}(L_{k+1}(x) - L_k(x)).$$

Then

$$\|M_k^{\gamma_1}\|^2_{0,I} \le Ck^{-1}, \qquad |M_k^{\gamma_1}|^2_{1,I} \le Ck^3.$$

Similar estimates hold for the other faces γ_m.

We have the following stability result.

LEMMA 6.9. *There exists a constant $C > 0$, independent of h_K and k, such that, for $\mathbf{w} \in H^1(K)^3$,*

$$|\Pi_K \mathbf{w}|^2_{1,K} \le Ck^2 |\mathbf{w}|^2_{1,K}.$$

Proof. Let $\mathbf{w} = (w_x, w_y, w_z)$. We set $\mathbf{v} = \Pi_K \mathbf{w}$ and $\mathbf{v} = (v_x, v_y, v_z)$. We only find a bound for the first component v_x. Bounds for v_y and v_z can be similarly obtained. In addition, we only consider the reference cube $\hat{K} = (-1, 1)^3$ since a bound for an affinely mapped K can be easily deduced using a scaling argument. We consider the two terms of v_x in (6.3). Thanks to (6.4), we have

$$|\hat{Q}_{k-1,k,k} w_x|_{1,\hat{K}} \le Ck^{\frac{1}{2}} |w_x|_{1,\hat{K}}. \tag{6.8}$$

We now consider the face γ_1. Using Lemma 6.8 and the stability of the L^2-projection, we can write

$$\begin{aligned}\|\partial_x(\mathcal{E}_k^{\gamma_1}(\pi_k^y \circ \pi_k^z)(w_x - \hat{Q}_{k-1,k} w_x))\|^2_{0,\hat{K}} &= |M_k^{\gamma_1}|^2_{1,I}\, \|(\pi_k^y \circ \pi_k^z)(w_x - \hat{Q}_{k-1,k,k} w_x)\|^2_{0,\gamma_1} \\ &\le Ck^3 \|w_x - \hat{Q}_{k-1,k,k} w_x\|^2_{0,\gamma_1},\end{aligned}$$

and, thanks to the estimate (6.5),

$$\|\partial_x(\mathcal{E}_k^{\gamma_1}(\pi_k^y \circ \pi_k^z)(w_x - \hat{Q}_{k-1,k,k} w_x))\|^2_{0,\hat{K}} \le Ck^2 |w_x|^2_{1,\hat{K}}. \tag{6.9}$$

Using Lemma 6.8 and the inverse estimate (6.6), we find

$$\begin{aligned}\|\partial_y(\mathcal{E}_k^{\gamma_1}(\pi_k^y\circ\pi_k^z)(w_x-\hat{Q}_{k-1,k,k}w_x))\|_{0,\hat{K}}^2 &= \|M_k^{\gamma_1}\|_{0,I}^2\,\|\partial_y((\pi_k^y\circ\pi_k^z)(w_x-\hat{Q}_{k-1,k}w_x))\|_{0,\gamma_1}^2\\ &\le Ck^{-1}k^4\|w_x-\hat{Q}_{k-1,k,k}w_x\|_{0,\gamma_1}^2,\end{aligned}$$

and, due to the estimate (6.5),

$$\|\partial_y(\mathcal{E}_k^{\gamma_1}(\pi_k^y\circ\pi_k^z)(w_x-\hat{Q}_{k-1,k,k}w_x))\|_{0,\hat{K}}^2 \le Ck^2|w_x|_{1,\hat{K}}^2. \tag{6.10}$$

Analogously,

$$\|\partial_z(\mathcal{E}_k^{\gamma_1}(\pi_k^y\circ\pi_k^z)(w_x-\hat{Q}_{k-1,k,k}w_x))\|_{0,\hat{K}}^2 \le Ck^2|w_x|_{1,\hat{K}}^2. \tag{6.11}$$

Similar estimates can be found for the face γ_2. The proof is completed by combining (6.3), (6.8), (6.9), (6.10), and (6.11) with a scaling argument. ∎

On the boundary ∂K of an element K, we have the following bound.

LEMMA 6.10. *There exists a constant $C>0$, independent of h_K and k, such that, for $\mathbf{w}\in H^1(K)^3$,*

$$\|\mathbf{w}-\Pi_K\mathbf{w}\|_{0,\partial K}^2 \le Ch_K|\mathbf{w}|_{1,K}^2.$$

Proof. Let $\mathbf{v}=\Pi_K\mathbf{w}$. First, we find a bound for the first component v_x of $\mathbf{v}$ on the reference cube $\hat{K}=(-1,1)^3$.

On the face γ_1, we have

$$w_x-v_x = w_x-\hat{Q}_{k-1,k,k}w_x-(\pi_k^y\circ\pi_k^z)(w_x-\hat{Q}_{k-1,k,k}w_x).$$

Hence, by the triangle inequality, (6.5), and by the stability of the L^2-projection, we obtain

$$\|w_x-v_x\|_{0,\gamma_1}^2 \le Ck^{-1}|w_x|_{1,\hat{K}}^2.$$

An analogous estimate holds on γ_2.

Consider now the face γ_3. We have

$$\begin{aligned}\|w_x-v_x\|_{0,\gamma_3}^2 \le{}& C\|w_x-\hat{Q}_{k-1,k,k}w_x\|_{0,\gamma_3}^2\\ &+C\sum_{m=1}^{2}\left\|\mathcal{E}_k^{\gamma_m}(\pi_k^y\circ\pi_k^z)\left(w_x-\hat{Q}_{k-1,k,k}w_x\right)\right\|_{0,\gamma_3}^2.\end{aligned}$$

The first term above can be bounded again by using (6.5). Further, using Lemma 6.8, the inverse estimate (6.7), and the estimate (6.5), we find, for $m=1,2$,

$$\begin{aligned}&\int_{\gamma_3}\left(\mathcal{E}_k^{\gamma_m}(\pi_k^y\circ\pi_k^z)\left(w_x-\hat{Q}_{k-1,k,k}w_x\right)\right)^2 dx\,dz\\ &\quad= \|M_k^{\gamma_m}\|_{0,I}^2\int_{-1}^{1}\left((\pi_k^y\circ\pi_k^z)\left(w_x-\hat{Q}_{k-1,k,k}w_x\right)\right)^2_{|_{y=-1}} dz\\ &\quad\le C\,k^{-1}\,k^2\int_{\gamma_m}\left((\pi_k^y\circ\pi_k^z)\left(w_x-\hat{Q}_{k-1,k,k}w_x\right)\right)^2 dy\,dz\\ &\quad\le C\,|w_x|_{1,\hat{K}}^2.\end{aligned}$$

Hence, we obtain

$$\|w_x - v_x\|^2_{0,\gamma_3} \le C\,|w_x|^2_{1,\hat{K}}.$$

The analogous bounds are obtained on γ_4, γ_5, and γ_6. This gives the desired result for the first component of $\mathbf{w} - \Pi_K \mathbf{w}$.

The proof is completed by observing that the same techniques give analogous bounds for the other components of $\mathbf{w} - \Pi_K \mathbf{w}$ and by a scaling argument. ∎

6.4. Proof of Proposition 6.1. Fix $q \in Q_h$. We first proceed as in [40, Lemma 6.3] (see also [38] for conforming mixed *hp*-FEM) and decompose q into

$$q = q_0 + \bar{q}, \tag{6.12}$$

where q_0 is the L^2-projection of q into the subspace of $L^2_0(\Omega)$ consisting of piecewise constant pressures.

Owing to the results in [25, 38] for conforming meshes and the results in [36, 41] (valid for two- and three-dimensional domains) for meshes with hanging nodes (see also [40]), there exists a piecewise quadratic velocity field $\mathbf{v}_0 \in \mathbf{V}_h \cap H^1_0(\Omega)^3$ such that

$$B_h(\mathbf{v}_0, q_0) = -\int_\Omega q_0 \nabla \cdot \mathbf{v}_0 \, d\mathbf{x} \ge \|q_0\|^2_0, \qquad \|\mathbf{v}_0\|_h = |\mathbf{v}_0|_1 \le C_0 \|q_0\|_0. \tag{6.13}$$

Further, for $K \in \mathcal{T}_h$, we set $\bar{q}_K = \bar{q}|_K$ and have, by construction, $\int_K \bar{q}_K \, d\mathbf{x} = 0$. Due to the continuous inf-sup condition [10, 25], there is a velocity field $\bar{\mathbf{w}}_K \in H^1_0(K)^3$ such that

$$-\int_K \bar{q}_K \nabla \cdot \bar{\mathbf{w}}_K \, d\mathbf{x} \ge \|\bar{q}_K\|^2_{0,K}, \qquad |\bar{\mathbf{w}}_K|_{1,K} \le C \|\bar{q}_K\|_{0,K}, \tag{6.14}$$

with a constant $C > 0$ solely depending on the shape-regularity of the mesh. Define $\bar{\mathbf{w}} \in H^1_0(\Omega)^3$ by $\bar{\mathbf{w}}|_K = \bar{\mathbf{w}}_K$ for all $K \in \mathcal{T}_h$, and let $\bar{\mathbf{v}} \in \mathbf{V}_h$ be given by

$$\bar{\mathbf{v}}|_K = \bar{\mathbf{v}}_K := \Pi_K \bar{\mathbf{w}}_K \in RT_{k_K - 1}(K), \qquad K \in \mathcal{T}_h,$$

for the Raviart–Thomas projector Π_K of degree $k_K - 1$ on K. Since $\bar{\mathbf{w}}_K \in H^1_0(K)^3$, we have

$$\bar{\mathbf{v}}_K \cdot \mathbf{n}_K = 0 \qquad \text{on } \partial K \tag{6.15}$$

due to the second conditions in (6.2) (valid for an affinely mapped element), and hence $[\![\bar{\mathbf{v}}]\!] = 0$ on $\mathcal{E}$. From the definition of B_h in (5.6), we thus have

$$B_h(\bar{\mathbf{v}}, \bar{q}) = -\int_\Omega \bar{q}\, \nabla_h \cdot \bar{\mathbf{v}} \, d\mathbf{x} = \sum_{K \in \mathcal{T}_h} \int_K \nabla \bar{q}_K \cdot \bar{\mathbf{v}}_K \, d\mathbf{x}.$$

Mapping $\bar{q}_K$ to $\hat{\bar{q}}_{\hat{K}}$ via the usual pullback operator and $\bar{\mathbf{v}}_K$ to $\hat{\bar{\mathbf{v}}}_{\hat{K}}$ via the Piola transformation, we obtain from [10, sect. 3.1]

$$\int_K \nabla \bar{q}_K \cdot \bar{\mathbf{v}}_K \, d\mathbf{x} = \int_{\hat{K}} \hat{\nabla} \hat{\bar{q}}_{\hat{K}} \cdot \hat{\bar{\mathbf{v}}}_{\hat{K}} \, d\hat{\mathbf{x}}.$$

We then note that, since $\hat{\bar{q}}_{\hat{K}} \in \mathbb{Q}_{k_K - 1}(\hat{K})$, we have

$$\hat{\nabla} \hat{\bar{q}}_{\hat{K}} \in \mathbb{Q}_{k_K - 2, k_K - 1, k_K - 1}(\hat{K}) \times \mathbb{Q}_{k_K - 1, k_K - 2, k_K - 1}(\hat{K}) \times \mathbb{Q}_{k_K - 1, k_K - 1, k_K - 2}(\hat{K}).$$

Using the orthogonality conditions in (6.2), we obtain

$$\int_{\hat{K}} \hat{\nabla}\hat{\bar{q}}_{\hat{K}} \cdot \hat{\bar{\mathbf{v}}}_{\hat{K}}\, d\hat{\mathbf{x}} = \int_{\hat{K}} \hat{\nabla}\hat{\bar{q}}_{\hat{K}} \cdot \hat{\bar{\mathbf{u}}}_{\hat{K}}\, d\hat{\mathbf{x}} = \int_K \nabla \bar{q}_K \cdot \bar{\mathbf{w}}_K\, d\mathbf{x}$$

and, therefore, from (6.14),

$$B_h(\bar{\mathbf{v}}, \bar{q}) = \sum_{K\in\mathcal{T}_h} \int_K \nabla \bar{q}_K \cdot \bar{\mathbf{w}}_K\, d\mathbf{x} = -\sum_{K\in\mathcal{T}_h} \int_K \bar{q}_K \nabla\cdot \bar{\mathbf{w}}_K\, d\mathbf{x} \geq \|\bar{q}\|_0^2. \tag{6.16}$$

Further, from the stability result in Lemma 6.9 and (6.14), we obtain

$$\sum_{K\in\mathcal{T}_h} |\bar{\mathbf{v}}_K|_{1,K}^2 \leq C \sum_{K\in\mathcal{T}_h} k_K^2 |\bar{\mathbf{w}}_K|_{1,K}^2 \leq C|\underline{k}|^2 \|\bar{q}\|_0^2. \tag{6.17}$$

Then, since $\underline{[\![\bar{\mathbf{w}}]\!]} = \underline{0}$ on $\mathcal{E}$, we have with Lemma 6.10 and (5.1)

$$\begin{aligned}\int_{\mathcal{E}} \sigma \underline{[\![\bar{\mathbf{v}}]\!]}^2 ds &= \int_{\mathcal{E}} \sigma \underline{[\![\bar{\mathbf{w}} - \bar{\mathbf{v}}]\!]}^2 ds \\ &\leq C \sum_{K\in\mathcal{T}_h} \frac{k_K^2}{h_K} \|\bar{\mathbf{w}}_K - \bar{\mathbf{v}}_K\|_{0,\partial K}^2 \leq C|\underline{k}|^2 \sum_{K\in\mathcal{T}_h} |\bar{\mathbf{w}}_K|_{1,K}^2 \leq C|\underline{k}|^2 \|\bar{q}\|_0^2.\end{aligned}$$

Combining this estimate with (6.16) and (6.17) yields

$$B_h(\bar{\mathbf{v}}, \bar{q}) \geq \|\bar{q}\|_0, \qquad \|\bar{\mathbf{v}}\|_h^2 \leq \bar{C}|\underline{k}|^2 \|\bar{q}\|_0. \tag{6.18}$$

Next, we define

$$\mathbf{v} = \mathbf{v}_0 + \delta \bar{\mathbf{v}}$$

for a parameter $\delta > 0$ still at our disposal. First, we note that from (5.6) and (6.15),

$$B_h(\bar{\mathbf{v}}, q_0) = -\sum_{K\in\mathcal{T}_h} q_0|_K \int_K \nabla\cdot \bar{\mathbf{v}}_K\, d\mathbf{x} = -\sum_{K\in\mathcal{T}_h} q_0|_K \int_{\partial K} \bar{\mathbf{v}}_K \cdot \mathbf{n}_K\, ds = 0$$

since q_0 is piecewise constant. Further, $\mathbf{v}_0 \in \mathbf{V}_h \cap H_0^1(\Omega)^3$ and, therefore, we obtain from (6.13) and the arithmetic-geometric mean inequality

$$|B_h(\mathbf{v}_0, \bar{q})| = \left| \int_\Omega \bar{q}\, \nabla\cdot \mathbf{v}_0\, d\mathbf{x} \right| \leq C\|q_0\|_0 \|\bar{q}\|_0 \leq \frac{C_1}{\varepsilon}\|q_0\|_0^2 + \varepsilon C_2 \|\bar{q}\|_0^2,$$

with another parameter $\varepsilon > 0$ to be properly chosen. Combining the above results with (6.13) and (6.18) gives

$$\begin{aligned}B_h(\mathbf{v}, q) &= B_h(\mathbf{v}_0, q_0) + B_h(\mathbf{v}_0, \bar{q}) + \delta B_h(\bar{\mathbf{v}}, \bar{q}) \\ &\geq \left(1 - \frac{C_1}{\varepsilon}\right) \|q_0\|_0^2 + (\delta - \varepsilon C_2)\|\bar{q}\|_0^2.\end{aligned}$$

It is then clear that we can choose δ and ε in such a way that

$$B_h(\mathbf{v}, q) \geq c_1 \|q\|_0^2, \tag{6.19}$$

with a constant c_1 independent of $\underline{h}$ and $\underline{k}$. Furthermore, from (6.13) and (6.18),

$$\|\mathbf{v}\|_h \leq |\mathbf{v}_0|_1 + \delta \|\bar{\mathbf{v}}\|_h \leq c_2 |\underline{k}| \|q\|_0, \tag{6.20}$$

with c_2 independent of $\underline{h}$ and $\underline{k}$. The assertion of Proposition 6.1 follows from (6.19) and (6.20).

6.5. Uniform approximation degrees and conforming meshes. For uniform approximation degrees $k_K = k$, $K \in \mathcal{T}_h$, and conforming meshes, the decomposition (6.12) is not necessary and we can establish the inf-sup condition directly via a Fortin property. In particular, this allows us to cover the case of $\mathbb{Q}_1 - \mathbb{Q}_0$ elements as well.

To do this, define the global interpolation operator Π by

$$\Pi \mathbf{w}_{|_K} = \Pi_K \mathbf{w}, \quad K \in \mathcal{T}_h,$$

where Π_K is the Raviart–Thomas projector of degree $k-1$ on K. We note that $\Pi\mathbf{w}$ belongs to $\mathbf{V}_h$ and, in case $\mathbf{w} \in H_0^1(\Omega)^3$, the normal component of $\Pi\mathbf{w}$ is continuous across the interelement boundaries and vanishes on $\partial\Omega$, i.e., $[\![\Pi\mathbf{w}]\!] = 0$ on $\mathcal{E}$. This last property is no longer true if the mesh has hanging nodes.

We have the following Fortin property.

LEMMA 6.11. *Assume that $\mathcal{T}_h$ is conforming and $k_K = k$, $K \in \mathcal{T}_h$. We have, for $\mathbf{w} \in H_0^1(\Omega)^3$ and $k \geq 1$,*

$$B_h(\Pi\mathbf{w}, q) = -\int_\Omega q \nabla \cdot \mathbf{w}\, d\mathbf{x}, \qquad q \in Q_h, \tag{6.21}$$

$$\|\Pi\mathbf{w}\|_h \leq Ck|\mathbf{w}|_1, \tag{6.22}$$

where $C > 0$ is independent of h and k.

Proof. We first note that, from (5.7), we have

$$\begin{aligned} B_h(\Pi\mathbf{w}, q) &= \sum_{K\in\mathcal{T}_h} \int_K \Pi\mathbf{w} \cdot \nabla q d\mathbf{x} - \int_{\mathcal{E}_\mathcal{I}} (q^+ - q^-)\, \frac{(\Pi\mathbf{w})^+ \cdot \mathbf{n}_{K^+} + (\Pi\mathbf{w})^- \cdot \mathbf{n}_{K^-}}{2}\, ds \\ &= \sum_{K\in\mathcal{T}_h} \int_K \Pi\mathbf{w} \cdot \nabla q d\mathbf{x} - \int_{\mathcal{E}_\mathcal{I}} (q^+ - q^-)\, \Pi\mathbf{w} \cdot \mathbf{n}_{K^+}\, ds, \end{aligned}$$

where we have used obvious notation to express the jumps and mean values. Again using the orthogonality conditions in (6.2), valid for an affinely mapped element K, we find

$$\begin{aligned} B_h(\Pi\mathbf{w}, q) &= \sum_{K\in\mathcal{T}_h} \int_K \mathbf{w} \cdot \nabla q d\mathbf{x} - \int_{\mathcal{E}_\mathcal{I}} (q^+ - q^-)\, \mathbf{w} \cdot \mathbf{n}_{K^+}\, ds \\ &= -\int_\Omega q \nabla \cdot \mathbf{w}\, d\mathbf{x}. \end{aligned}$$

The stability estimate in (6.22) follows from Lemma 6.9 and Lemma 6.10 as in the proof of Proposition 6.1. ∎

We note that the previous lemma is not true for irregular meshes. Combining Lemma 6.11 and the inf-sup condition (2.3) of the continuous problem, we find the following stability result.

THEOREM 6.12. *Assume that $\mathcal{T}_h$ is conforming and $k_K = k$, $K \in \mathcal{T}_h$. There exists a constant $c > 0$, independent of h and k, such that for $k \geq 1$*

$$\inf_{0\neq q\in Q_h} \sup_{\mathbf{0}\neq\mathbf{v}\in\mathbf{V}_h} \frac{B_h(\mathbf{v}, q)}{\|\mathbf{v}\|_h \|q\|_0} \geq \gamma_h \geq ck^{-1}. \tag{6.23}$$

We emphasize that, in particular, this result holds true for $k = 1$, thus covering $\mathbb{Q}_1 - \mathbb{Q}_0$ elements. We also remark that a similar nonconforming Stokes element,

the so-called $\widetilde{\mathbb{Q}}_1 - \mathbb{Q}_0$ element, has been proposed and studied in [34, 8]. However, this element can be viewed as a natural quadrilateral analogue of the well known Crouzeix–Raviart element whereas the $\mathbb{Q}_1 - \mathbb{Q}_0$ element here is based on completely discontinuous finite element spaces.

7. Continuity and coercivity. In this section, we establish the continuity and coercivity of the forms $A_h(\cdot,\cdot)$ and $B_h(\cdot,\cdot)$ with respect to the norm $\|\cdot\|_h$ in (5.8)–(5.9).

7.1. Stability of the lifting operators. We start by investigating the stability properties of the lifting operators. To this end, we need the following lemma concerning traces of polynomials, where we denote by $\mathbb{Q}_k(\gamma_m)$ the polynomials of degree at most k in each variable on the face γ_m.

LEMMA 7.1. *Let $K \in \mathcal{T}_h$ and γ_m be a face of ∂K. Then we have*

$$\|\varphi\|_{0,\gamma_m} \le C h_K^{-\frac{1}{2}} k \|\varphi\|_{0,K} \qquad \forall \varphi \in \mathbb{Q}_k(K), \tag{7.1}$$

with a constant $C > 0$ just depending on the shape-regularity of the mesh.

Conversely, for $\varphi \in \mathbb{Q}_k(\gamma_m)$ there is a polynomial extension $E(\varphi) \in \mathbb{Q}_k(K)$ with $E(\varphi)|_{\gamma_m} = \varphi$ and

$$\|E(\varphi)\|_{0,K} \le C h_K^{\frac{1}{2}} k^{-1} \|\varphi\|_{0,\gamma_m}, \tag{7.2}$$

with a constant $C > 0$ just depending on the shape-regularity of the mesh.

Proof. The first assertion follows from standard inverse inequalities; see, e.g., [37, Theorem 4.76].

We prove the second assertion only in three dimensions (the two-dimensional case is completely analogous). To this end, we consider first the reference cube $\hat{K} = (-1,1)^3$ and may assume that the face γ_m is given by $x = 1$. Fix $\varphi \in \mathbb{Q}_k(\gamma_m)$. Moreover, we consider the case where k is even and set

$$E(\varphi)(x,y,z) = \left(\frac{2}{k} \sum_{j=\frac{k}{2}+1}^{k} L_j(x) \right) \varphi(y,z),$$

where L_j denotes the Legendre polynomial of degree j on $(-1,1)$. Since $L_j(1) = 1$, we have

$$E(\varphi)|_{\gamma_m} = E(\varphi)(1,y,z) = \frac{2}{k}\,\frac{k}{2}\,\varphi(y,z) = \varphi(y,z).$$

Further,

$$\|E(\varphi)\|_{0,\hat{K}}^2 = \|\varphi\|_{0,\gamma_m}^2 \,\frac{4}{k^2} \sum_{j=\frac{k}{2}+1}^{k} \frac{2}{2j+1}.$$

We have

$$\begin{aligned} \sum_{j=\frac{k}{2}+1}^{k} \frac{2}{2j+1} &= \sum_{j=\frac{k}{2}+1}^{k} \frac{1}{(j+1)-\frac{1}{2}} \le \int_{\frac{k}{2}+1}^{k+1} \frac{1}{t-\frac{1}{2}}\,dt \\ &= \log\left(k+\frac{1}{2}\right) - \log\left(\frac{k}{2}+\frac{1}{2}\right) = \log\left(\frac{2k+1}{k+1}\right). \end{aligned}$$

The bound $\log(\frac{2k+1}{k+1}) \le C$, independent of k, proves the assertion for k even. If k is odd, the extension $E(\cdot)$ can be constructed similarly. This proves the assertion on the reference cube; the general case follows from a standard scaling argument. ∎

We are now ready to prove the following stability result for the lifting $\underline{\mathcal{L}}_e$.

LEMMA 7.2. *For a face $e \subset \mathcal{E}$, we have*

$$\|\underline{\mathcal{L}}_e(\mathbf{v})\|_0^2 \ge C_1 \int_e \mathtt{k}^2\mathtt{h}^{-1}|\underline{[\![\mathbf{v}]\!]}|^2\,ds \qquad \forall \mathbf{v} \in \mathbf{V}_h,$$
$$\|\underline{\mathcal{L}}_e(\mathbf{v})\|_0^2 \le C_2 \int_e \mathtt{k}^2\mathtt{h}^{-1}|\underline{[\![\mathbf{v}]\!]}|^2\,ds \qquad \forall \mathbf{v} \in \mathbf{V}(h),$$

with constants $C_1 > 0$ and $C_2 > 0$ depending on the shape-regularity of the mesh. If e contains a hanging node, C_1 also depends on κ in (5.1).

Proof. To prove the first estimate, fix $\mathbf{v} \in \mathbf{V}_h$ and let K be the element such that e is an entire face of ∂K. By Lemma 7.1, we can find a polynomial $\underline{\tau} \in \mathbb{Q}_{k_K}(K)^{d\times d}$ such that $\underline{\tau}|_e = \underline{[\![\mathbf{v}]\!]}$ and such that

$$\|\underline{\tau}\|_{0,K} \le C h_K^{\frac{1}{2}} k_K^{-1} \|\underline{[\![\mathbf{v}]\!]}\|_{0,e}.$$

Extending $\underline{\tau}$ by zero, we obtain a function also denoted by $\underline{\tau}$ in the finite element space $\underline{\Sigma}_h$. By definition of $\underline{\mathcal{L}}_e$ and construction of $\underline{\tau}$, we have

$$\frac{1}{2}\|\underline{[\![\mathbf{v}]\!]}\|_{0,e}^2 = \int_e \underline{[\![\mathbf{v}]\!]} : \{\!\{\underline{\tau}\}\!\}\,ds \le \int_K |\underline{\mathcal{L}}_e(\mathbf{v}) : \underline{\tau}|\,d\mathbf{x} \le C h_K^{\frac{1}{2}} k_K^{-1} \|\underline{\mathcal{L}}_e(\mathbf{v})\|_0 \|\underline{[\![\mathbf{v}]\!]}\|_{0,e}.$$

If e is also an entire face of a possible neighboring element K', we combine the above bound with the one for K' and obtain the desired result. If e is not an entire face of a neighboring element, we invoke (5.1) and obtain the bound.

Conversely, for $\mathbf{v} \in \mathbf{V}(h)$, we have

$$\begin{aligned}
\|\underline{\mathcal{L}}_e(\mathbf{v})\|_0 &= \sup_{\underline{\tau}\in\underline{\Sigma}_h} \frac{\int_\Omega \underline{\mathcal{L}}_e(\mathbf{v}) : \underline{\tau}\,d\mathbf{x}}{\|\underline{\tau}\|_0} = \sup_{\underline{\tau}\in\underline{\Sigma}_h} \frac{\int_e \underline{[\![\mathbf{v}]\!]} : \{\!\{\underline{\tau}\}\!\}\,ds}{\|\underline{\tau}\|_0} \\
&\le \sup_{\underline{\tau}\in\underline{\Sigma}_h} \frac{\big(\int_e \mathtt{k}^2\mathtt{h}^{-1}|\underline{[\![\mathbf{v}]\!]}|^2\,ds\big)^{\frac{1}{2}} \big(C\sum_{K\in\mathcal{T}_h} k_K^{-2} h_K \|\underline{\tau}\|_{0,\partial K}^2\big)^{\frac{1}{2}}}{\|\underline{\tau}\|_0} \\
&\le \sup_{\underline{\tau}\in\underline{\Sigma}_h} \frac{\big(\int_e \mathtt{k}^2\mathtt{h}^{-1}|\underline{[\![\mathbf{v}]\!]}|^2\,ds\big)^{\frac{1}{2}} \big(C\sum_{K\in\mathcal{T}_h} \|\underline{\tau}\|_{0,K}^2\big)^{\frac{1}{2}}}{\|\underline{\tau}\|_0} \\
&\le C\left(\int_e \mathtt{k}^2\mathtt{h}^{-1}|\underline{[\![\mathbf{v}]\!]}|^2\,ds\right)^{\frac{1}{2}},
\end{aligned}$$

where we used the definition of $\underline{\mathcal{L}}_e$, the Cauchy–Schwarz inequality, and the trace estimate (7.1) from Lemma 7.1. ∎

REMARK 7.3. *Due to* (5.3)*, we also have*

$$\|\underline{\mathcal{G}}_e\|_0^2 \le C \int_e \mathtt{k}^2\mathtt{h}^{-1}|\mathbf{g}|^2\,ds$$

for any boundary face $e \subset \mathcal{E}_\mathcal{D}$.

In the same manner, we obtain the following stability estimates for $\underline{\mathcal{L}}$, $\mathcal{M}$, and $\underline{\mathcal{G}}$.

LEMMA 7.4. *We have the stability estimates*

$$\|\mathcal{M}(\mathbf{v})\|_0^2 \le C \int_{\mathcal{E}} \mathtt{k}^2\mathtt{h}^{-1} |\underline{[\![\mathbf{v}]\!]}|^2 \, ds, \qquad \mathbf{v} \in \mathbf{V}(h),$$

$$\|\underline{\mathcal{L}}(\mathbf{v})\|_0^2 \le C \int_{\mathcal{E}} \mathtt{k}^2\mathtt{h}^{-1} |\underline{[\![\mathbf{v}]\!]}|^2 \, ds, \qquad \mathbf{v} \in \mathbf{V}(h),$$

as well as

$$\|\underline{\mathcal{G}}\|_0^2 \le C \int_{\mathcal{E}_\mathcal{D}} \mathtt{k}^2\mathtt{h}^{-1} |\mathbf{g}|^2 \, ds,$$

with constants $C > 0$ solely depending on the shape-regularity of the mesh.

7.2. Continuity. The continuity conditions of $A_h(\cdot,\cdot)$ and $B_h(\cdot,\cdot)$ with respect to the the discrete norm $\|\cdot\|_h$ in (5.8) are established in the following lemma.

LEMMA 7.5. *Let σ be given as in* (5.9) *with $\sigma_0 > 0$. Then, we have the following.*

1. *All the forms A_h considered in section* 5.4 *are continuous,*

$$|A_h(\mathbf{v},\mathbf{w})| \le \nu\bar{\alpha}_1 \|\mathbf{v}\|_h \|\mathbf{w}\|_h, \qquad \mathbf{v},\mathbf{w} \in \mathbf{V}(h),$$

   with a constant $\bar{\alpha}_1 > 0$ independent of $\underline{h}$ and $\underline{k}$. Hence, condition (3.2) *is satisfied with $\alpha_1 = \nu\bar{\alpha}_1$.*
2. *The form B_h is continuous,*

$$|B_h(\mathbf{v},q)| \le \alpha_2 \|\mathbf{v}\|_h \|q\|_0, \qquad (\mathbf{v},q) \in \mathbf{V}(h) \times Q,$$

   with a constant $\alpha_2 > 0$ independent of $\underline{h}$ and $\underline{k}$.

Proof. This follows immediately from Lemma 7.2, Lemma 7.4, and Cauchy–Schwarz inequalities. ∎

7.3. Coercivity of A_h. The coercivity condition in (3.5) of the different forms A_h is established in the following lemma.

LEMMA 7.6. *Let σ be given as in* (5.9) *with $\sigma_0 > 0$. Then, we have the following.*

1. *There is a constant $\sigma_{min} > 0$ (independent of $\underline{h}$ and $\underline{k}$) such that for $\sigma_0 \ge \sigma_{min}$ the symmetric interior penalty form A_h in* (5.11) *is coercive,*

$$A_h(\mathbf{v},\mathbf{v}) \ge \nu\bar{\beta} \|\mathbf{v}\|_h^2, \qquad \mathbf{v} \in \mathbf{V}_h,$$

   with a constant $\bar{\beta} > 0$ independent of $\underline{h}$ and $\underline{k}$. Hence, condition (3.5) *is satisfied with $\beta = \nu\bar{\beta}$.*
2. *The nonsymmetric interior penalty form A_h in* (5.12) *is coercive on $\mathbf{V}(h)$ for any $\sigma_0 > 0$, with coercivity constant $\beta = \nu$.*
3. *The LDG form A_h in* (5.13) *is coercive on $\mathbf{V}_h$ for any $\sigma_0 > 0$, with a coercivity constant $\beta = \nu\bar{\beta}$, where $\bar{\beta} > 0$ is independent of $\underline{h}$ and $\underline{k}$.*
4. *There is a constant $\eta_{min} > 0$ (independent of $\underline{h}$ and $\underline{k}$) such that for $\eta \ge \eta_{min}$ the Bassi–Rebay form A_h in* (5.15) *is coercive on $\mathbf{V}_h$, with a coercivity constant $\beta = \nu\bar{\beta}$, where $\bar{\beta} > 0$ is independent of $\underline{h}$ and $\underline{k}$.*
5. *The Bassi–Rebay form A_h in* (5.16) *is coercive on $\mathbf{V}_h$ for any $\eta > 0$, with a coercivity constant $\beta = \nu\bar{\beta}$, where $\bar{\beta} > 0$ is independent of $\underline{h}$ and $\underline{k}$.*

Proof. These coercivity properties are obtained from Lemma 7.2, Lemma 7.4, and the arithmetic-geometric mean inequality $2ab \le \varepsilon a^2 + \varepsilon^{-1} b^2$ for all $\varepsilon > 0$; see [2]. ∎

REMARK 7.7. *We chose to express the continuity and coercivity properties of the Bassi–Rebay methods in terms of the discrete norm* $\|\cdot\|_h$ *in* (5.8)–(5.9) *since this norm is explicit in the mesh-sizes and the approximation degrees. Instead, it is also possible to work with*

$$\|\mathbf{v}\|_h^2 = \sum_{K\in\mathcal{T}_h} |\mathbf{v}|_{1,K}^2 + \sum_{e\subset\mathcal{E}} \int_\Omega \eta |\underline{\mathcal{L}}_e(\mathbf{v})|^2 \, d\mathbf{x}.$$

8. The residual. In this section, we study the residual $R_h(\mathbf{u}, p; \mathbf{v})$ in (3.8) for our DG methods and show that it is optimally convergent.

PROPOSITION 8.1. *Let the exact solution* $(\mathbf{u}, p)$ *of the Stokes system* (2.1) *be in* $H^{s_K+1}(K)^d \times H^{s_K}(K)$ *for all* $K \in \mathcal{T}_h$ *and* $s_K \geq 1$. *Let* $\underline{Q}$ *and* Q *be the* L^2*-projections onto* $\underline{\Sigma}_h$ *and* Q_h, *respectively. Then the residual in* $R_h(\mathbf{u}, p; \mathbf{v})$ *in* (3.8) *is given by*

$$R_h(\mathbf{u}, p; \mathbf{v}) = \nu \int_{\mathcal{E}} \{\!\{\nabla \mathbf{u} - \underline{Q}(\nabla \mathbf{u})\}\!\} : \underline{[\![\mathbf{v}]\!]} \, ds - \int_{\mathcal{E}} \{\!\{p - Qp\}\!\} [\![\mathbf{v}]\!] \, ds \qquad \forall \mathbf{v} \in \mathbf{V}_h,$$

for all forms discussed in section 5.4.

Furthermore, we have that $\mathcal{R}_h(\mathbf{u}, p)$ *in* (3.9) *can be estimated by*

$$\mathcal{R}_h(\mathbf{u}, p)^2 \leq C \sum_{K\in\mathcal{T}_h} \frac{h^{2\min(s_K, k_K)}}{k_K^{2s_K+1}} \big[\nu \|\mathbf{u}\|_{s_K+1,K}^2 + \nu^{-1} \|p\|_{s_K,K}^2\big],$$

with a constant $C > 0$ *independent of* $\underline{h}$, $\underline{k}$, *and* ν.

Proof. By (5.3), we have $\underline{\mathcal{L}}(\mathbf{u}) = \underline{\mathcal{G}}$ and obtain for all forms

$$R_h(\mathbf{u}, p; \mathbf{v}) = \nu \int_\Omega [\nabla \mathbf{u} : \nabla_h \mathbf{v} - \nabla \mathbf{u} : \underline{\mathcal{L}}(\mathbf{v})] \, d\mathbf{x} - \int_\Omega p[\nabla \cdot \mathbf{v} - \mathcal{M}(\mathbf{v})] \, d\mathbf{x} - \int_\Omega \mathbf{f} \cdot \mathbf{v} \, d\mathbf{x}.$$

Note that

$$\int_\Omega \nabla \mathbf{u} : \underline{\mathcal{L}}(\mathbf{v}) \, d\mathbf{x} = \int_\Omega \underline{Q}(\nabla \mathbf{u}) : \underline{\mathcal{L}}(\mathbf{v}) \, d\mathbf{x} = \int_{\mathcal{E}} \{\!\{\underline{Q}(\nabla \mathbf{u})\}\!\} : \underline{[\![\mathbf{v}]\!]} \, ds$$

and

$$\int_\Omega p\mathcal{M}(\mathbf{v}) \, d\mathbf{x} = \int_\Omega Qp\mathcal{M}(\mathbf{v}) \, d\mathbf{x} = \int_\Omega \{\!\{Qp\}\!\} [\![\mathbf{v}]\!] \, ds.$$

If now the exact solution belongs to $H^2(K)^d \times H^1(K)$ for all $K \in \mathcal{T}_h$, we obtain by integration by parts and elementary manipulations

$$\begin{aligned} R_h(\mathbf{u}, p; \mathbf{v}) = &\int_\Omega [-\nu \Delta \mathbf{u} + \nabla p - \mathbf{f}] \cdot \mathbf{v} \, d\mathbf{x} \\ &+ \nu \int_{\mathcal{E}} \{\!\{\nabla \mathbf{u} - \underline{Q}(\nabla \mathbf{u})\}\!\} : \underline{[\![\mathbf{v}]\!]} \, ds - \int_{\mathcal{E}} \{\!\{p - Qp\}\!\} [\![\mathbf{v}]\!] \, ds. \end{aligned}$$

Here, we also used that $[\![\nu \nabla \mathbf{u} - p\underline{I}]\!] = \mathbf{0}$ on $\mathcal{E}_\mathcal{I}$. From the Stokes equations in (2.1) we obtain the first assertion.

From (5.1) and since $|[\![\mathbf{v}]\!]|^2 \leq C |\underline{[\![\mathbf{v}]\!]}|^2$, the Cauchy–Schwarz equation yields

$$\begin{aligned} &R_h(\mathbf{u}, p; \mathbf{v}) \\ &\leq C \|\mathbf{v}\|_h \left(\nu \sum_{K\in\mathcal{T}_h} \frac{h_K}{k_K^2} \|\nabla \mathbf{u} - \underline{Q}(\nabla \mathbf{u})\|_{0,\partial K}^2 + \nu^{-1} \sum_{K\in\mathcal{T}_h} \frac{h_K}{k_K^2} \|p - Q(p)\|_{0,\partial K}^2 \right)^{\frac{1}{2}}, \end{aligned}$$

from where the error estimate follows with the *hp*-approximation properties of the L^2-projection in [27]. ∎

9. Error estimates. In this section, we make the abstract error estimates in section 4 explicit for our DG methods.

9.1. The main result. First, we consider general meshes with hanging nodes. We have the following result.

THEOREM 9.1. *Let the exact solution* $(\mathbf{u}, p)$ *of the Stokes system* (2.1) *be in* $H^{s_K+1}(K)^d \times H^{s_K}(K)$ *for all* $K \in \mathcal{T}_h$ *and* $s_K \geq 1$. *Then we have*

$$\|\mathbf{u}-\mathbf{u}_h\|_h^2 \leq C \sum_{K\in\mathcal{T}_h} \left[\gamma_h^{-2} \frac{h_K^{2\min(s_K,k_K)}}{k_K^{2s_K-1}} \|\mathbf{u}\|_{s_K+1,K}^2 + \frac{h_K^{2\min(s_K,k_K)}}{k_K^{2s_K}} \|p\|_{s_K,K}^2 \right],$$

$$\|p-p_h\|_0^2 \leq C \sum_{K\in\mathcal{T}_h} \left[\gamma_h^{-4} \frac{h_K^{2\min(s_K,k_K)}}{k_K^{2s_K-1}} \|\mathbf{u}\|_{s_K+1,K}^2 + \gamma_h^{-2} \frac{h_K^{2\min(s_K,k_K)}}{k_K^{2s_K}} \|p\|_{s_K,K}^2 \right],$$

with $C > 0$ *independent of* $\underline{h}$ *and* $\underline{k}$.

Proof. This follows from the choice of the stabilization parameter σ in (5.9), Proposition 4.1, Proposition 4.3, Proposition 8.1, and standard approximation properties of the finite element spaces; see, e.g., [3, Lemma 4.5] or [37]. In particular, we choose $\mathbf{v}$ in Proposition 4.1 and q in Proposition 4.3 as the locally constructed interpolants of $\mathbf{u}$ and p, respectively, given in [3, Lemma 4.5]. ∎

REMARK 9.2. *The above hp-version estimates are optimal in the mesh-size* $\underline{h}$, *and slightly suboptimal in* $\underline{k}$ *(half a power is lost), up to the inf-sup constant* γ_h *(which depends on the polynomial degree* $\underline{k}$*). In the mesh-size* $\underline{h}$, *the same optimal bounds have been obtained in* [26] *for the IP method on simplicial and conforming meshes and for* $\mathcal{P}_k - \mathcal{P}_{k-1}$ *elements, with* $\mathcal{P}_k$ *denoting polynomials of total degree at most* k. *We further note that, in the hp-version context, the same result was recently obtained in* [40] *for the nonsymmetric interior penalty method, with different techniques.*

REMARK 9.3. *The loss of half a power of* k *is typical of DG methods for second-order problems. Indeed, in the case of elliptic diffusion problems in two- or three-dimensional domains, no better p-bounds can be found in the DG literature on general unstructured grids (see, e.g., the hp-version analyses in* [27, 32, 35, 31]*). Improved p-bounds have been obtained in* [14] *for one-dimensional convection-diffusion problems, and recently in* [23] *for two-dimensional reaction-diffusion problems on affine quadrilateral grids containing hanging nodes and for solutions that belong to augmented Sobolev spaces. The latter results can be immediately carried over to the Stokes setting considered here.*

REMARK 9.4. *Combining the above bound with the inf-sup constant* γ_h *in Theorem* 6.2 *results in a loss of* $k^{3/2}$ *in the approximation of the velocity and in a loss of* $k^{5/2}$ *for the approximation of the pressure.*

9.2. Uniform approximation degrees and conforming meshes. In this section, we specialize the result of Theorem 9.1 to the case of uniform approximation orders, $k_K = k$, and conforming meshes with no hanging nodes. We also assume that the Dirichlet boundary datum $\mathbf{g}$ is piecewise polynomial; more precisely, we assume that there is a finite element function $\mathbf{G}_h \in \mathbf{V}_h$ such that $\mathbf{G}_h|_{\partial\Omega} = \mathbf{g}$.

In this particular situation, as in the analysis of [31] for the LDG method for pure diffusion problems, we can choose $\mathbf{v}$ in Proposition 4.1 as an optimal *hp*-approximant for the velocity which is continuous in the whole domain Ω according to [3, Theorem 4.6]. The discrete pressure q in Proposition 4.3 can be chosen as before. Since

the residual $\mathcal{R}_h(\mathbf{u}, p)$ is optimally convergent, we obtain the following result.

THEOREM 9.5. *Let the exact solution* $(\mathbf{u}, p)$ *of the Stokes system* (2.1) *be in* $H^{s+1}(\Omega)^d \times H^s(\Omega)$ *for* $s \geq 1$. *Then we have*

$$\|\mathbf{u} - \mathbf{u}_h\|_h \leq C \frac{h^{\min(s,k)}}{k^s} \Big[\gamma_h^{-1} \|\mathbf{u}\|_{s+1} + \|p\|_s\Big],$$
$$\|p - p_h\|_0 \leq C \frac{h^{\min(s,k)}}{k^s} \Big[\gamma_h^{-2} \|\mathbf{u}\|_{s+1} + \gamma_h^{-1} \|p\|_s\Big],$$

with $C > 0$ *independent of* $\underline{h}$ *and* $\underline{p}$.

This estimate is *optimal* in h and k, up to the inf-sup constant (which is independent of $\underline{h}$). With Theorem 6.2, we obtain exactly the same result as Stenberg and Suri in [38] for conforming mixed *hp*-FEM in three dimensions, but with an optimal gap of one order in the finite element spaces for the velocity and the pressure.

REMARK 9.6. *The estimate in Theorem* 9.5 *also holds on meshes with certain kinds of hanging nodes provided that a conforming and optimal hp-approximant can be constructed. In two dimensions, results in this direction can be found in, e.g.,* [37].

COUPLING FLUID FLOW WITH POROUS MEDIA FLOW*

WILLIAM J. LAYTON†, FRIEDHELM SCHIEWECK‡, AND IVAN YOTOV†

Abstract. The transport of substances back and forth between surface water and groundwater is a very serious problem. We study herein the mathematical model of this setting consisting of the Stokes equations in the fluid region coupled with the Darcy equations in the porous medium, coupled across the interface by the Beavers–Joseph–Saffman conditions. We prove existence of weak solutions and give a complete analysis of a finite element scheme which allows a simulation of the coupled problem to be uncoupled into steps involving porous media and fluid flow subproblems. This is important because there are many "legacy" codes available which have been optimized for uncoupled porous media and fluid flow.

Key words. coupled porous media and fluid flow, Stokes and Darcy equations, Beavers–Joseph–Saffman condition, weak solutions, finite element scheme, error estimates

1. Introduction and the model.

There are many serious problems currently facing the world in which the coupling between groundwater and surface water is important. These include questions such as predicting how pollution discharged into streams, lakes, and rivers makes its way into the water supply. This coupling is also important in technological applications involving filtration.

The aim of our research is to begin the study of the following problem: an incompressible fluid in a region Ω_1 can flow both ways across an interface Γ_I into a domain Ω_2 which is a porous medium saturated with the same fluid. The mathematical theory and numerical analysis of each subproblem is well developed, and reliable codes are available. Nevertheless, the mathematical theory of the coupled problem seems to be not completely understood. The model of this situation which is most accessible to large scale computations consists of the Navier–Stokes equations (or Stokes equations) in the fluid region coupled across an interface with the Darcy equations for the filtration velocity in the porous medium. This leads to mathematical difficulties arising from the coupled system of equations of different orders in different regions. See Jäger and Mikelić [16], Payne and Straughan [22] for the beginning of analytical studies of this problem. (For the Brinkman model of porous media flow this difficulty does not occur; see Jäger and Mikelić [17], Angot [1].) The second issue concerns the correct transmission conditions on the interface. The Beavers–Joseph–Saffman interface conditions [3, 25] are now well established. The third difficulty is technical: where the interface meets the other boundaries, there are incompatibilities between the imposed boundary conditions.

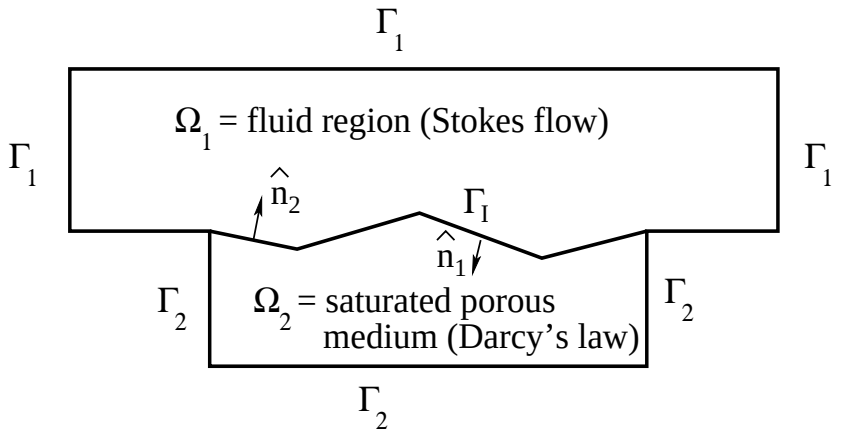

FIG. 1. *The model problem.*

One goal of this report is to find a variational formulation (section 2) for which weak solutions can be guaranteed to exist (section 3) and which can be used as a basis for a domain decomposition strategy for its approximate solution. The main goal is then to develop a finite element procedure with mathematical support (section 4). The method we study imposes the interface conditions using Lagrange multipliers. Thus, it can be used in a heterogeneous domain decomposition procedure in which each subproblem is alternately or simultaneously solved with codes (possibly "legacy" codes) developed and optimized for the physics of fluid motion and of porous media flow. In section 4 we give a complete analysis of this convergent finite element procedure. Because of the importance of the coupled problem, there are many computations of coupled surface water-groundwater flows in the applied literature, using various ad hoc interface decoupling strategies. See, for example, Salinger, Aris, and Derby [26], Gartling, Hickox, and Givler [14], and Prasad [23] for recent and interesting computational studies of the coupled problem.

The coupling strategy via Lagrange multipliers we consider herein has been proven in other applications and we are working towards practical tests of our ideas.

1.1. The model. The model we consider consists of Stokes flow in the fluid region Ω_1 and Darcy's law in the porous medium domain Ω_2. These are separated by an interface Γ_I. Here $\Omega_j \subset \mathbb{R}^d$ ($d = 2$ or 3) are bounded domains with outward unit normal vectors $\hat{n}_j$, $j = 1, 2$. Let $\Gamma_j := \partial\Omega_j \setminus \Gamma_I$. Each interface and boundary is assumed to be polygonal ($d = 2$) or polyhedral ($d = 3$). Figure 1 gives a schematic representation of the geometry.

The fluid velocities and pressures in Ω_1 and Ω_2 are denoted by

$$u_j : \Omega_j \to \mathbb{R}^d, \text{ fluid velocity in } \Omega_j,$$
$$p_j : \Omega_j \to \mathbb{R}\ , \text{ fluid pressure in } \Omega_j.$$

It is important to keep in mind that the velocities and pressures play different mathematical (and physical) roles in the fluid region and in the porous medium.

Recall that the deformation rate tensor $\mathbf{D}$ and stress tensor $\mathbf{T}$ associated with (u_1, p_1) are defined by

$$\mathbf{D}(u_1) := \frac{1}{2}\left(\frac{\partial u_{1i}}{\partial x_j} + \frac{\partial u_{1j}}{\partial x_i}\right), \qquad \mathbf{T}(u_1, p_1) := -p_1\mathbf{I} + 2\mu\mathbf{D}(u_1),$$

where μ is the viscosity. Assuming Stokes flow, (u_1, p_1) satisfies on Ω_1

$$\begin{cases} -\nabla \cdot \mathbf{T}(u_1, p_1) = f_1 \quad \text{in } \Omega_1 \quad \text{(conservation of momentum)}, \\ \nabla \cdot u_1 = 0 \quad \text{in } \Omega_1 \quad \text{(conservation of mass)}, \\ u_1 = 0 \quad \text{on } \Gamma_1 \quad \text{(no slip)}. \end{cases} \tag{1.1}$$

Assuming Darcy's law and no flow through Γ_2, (u_2, p_2) satisfies on Ω_2

$$\begin{cases} u_2 = -k\nabla p_2 \quad \text{in } \Omega_2 \quad \text{(Darcy's law)}, \\ \nabla \cdot u_2 = f_2 \quad \text{in } \Omega_2 \quad \text{(conservation of mass)}, \\ u_2 \cdot \hat{n}_2 = 0 \quad \text{on } \Gamma_2 \quad \text{(no flow)}, \end{cases} \tag{1.2}$$

where k is a symmetric and uniformly positive definite tensor representing the rock permeability divided by the fluid viscosity. The source f_2 is assumed to satisfy the solvability condition

$$\int_{\Omega_2} f_2 \, dx = 0, \tag{1.3}$$

which makes physical sense due to the no-flow boundary condition on $\partial\Omega$ and to (1.4) below. The mixed formulation (1.2) is the most natural one for computations in the porous medium region since it leads to direct approximation of the velocity.

1.2. Interface conditions. The problems (1.1)–(1.2) must be coupled across Γ_I by the correct interface conditions. *Mass conservation* across Γ_I is expressed by

$$u_1 \cdot \hat{n}_1 + u_2 \cdot \hat{n}_2 = 0 \quad \text{on} \quad \Gamma_I. \tag{1.4}$$

The second interface condition is *balance of normal forces* across Γ_I. Recall from, e.g., Serrin [28], that the Cauchy stress vector or traction vector $\vec{t}$ is the force on $\partial\Omega_1$ acting on the fluid volume inside Ω_1 and that

$$\vec{t}(u_1, p_1) = \hat{n}_1 \cdot \mathbf{T}(u_1, p_1)$$

(see Figure 2). Thus, the force on Γ_I exerted by the fluid volume is $-\vec{t}$. The only force in Ω_2 acting on Γ_I is the Darcy pressure p_2. Continuity of forces gives

$$-\vec{t}(u_1, p_1) \cdot \hat{n}_1 = p_2 \quad \text{on} \quad \Gamma_I.$$

This gives the interface condition

$$p_1 - 2\mu \hat{n}_1 \cdot \mathbf{D}(u_1) \cdot \hat{n}_1 = p_2 \quad \text{on} \quad \Gamma_I. \tag{1.5}$$

Finally, since the fluid model is viscous, a condition on the tangential fluid velocity on Γ_I must be given. Let $\hat{\tau}_j, \ j = 1, d-1$, denote an orthonormal system of tangent vectors on Γ_I. The simplest assumption is no-slippage along Γ_I, i.e., $u_1 \cdot \hat{\tau}_j = 0, \ j = 1, d-1$. This is not in good accord with experiment. The boundary condition in best agreement with experimental evidence evolved from the work of Beavers and Joseph [3] and states that

(slip velocity along Γ_I) is proportional to (shear stress along Γ_I).

Mathematically, this can be represented by

$$(u_1 - u_2) \cdot \hat{\tau}_j = \left(\frac{\sqrt{\tilde{k}_j}}{\mu \alpha_1} \right) \ (-\vec{t}(u_1, p_1)) \cdot \hat{\tau}_j, \qquad j = 1, d-1, \quad \text{on} \quad \Gamma_I,$$

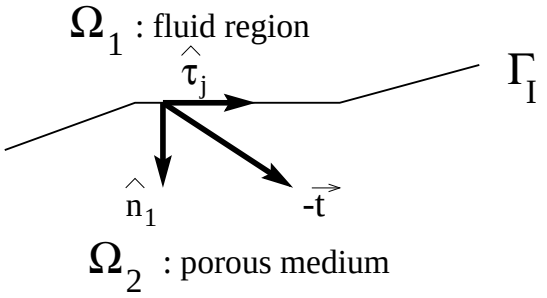

FIG. 2. *The traction vector on* Γ_I.

where $\tilde{k}_j = \hat{\tau}_j \cdot \mu k \cdot \hat{\tau}_j$. However, it is still unclear if this leads to a well-posed problem and it has been observed that the term on the left-hand side "$u_2 \cdot \hat{\tau}_j$" is much smaller than the other terms. Thus, its inclusion in this linear approximation is unclear. The most accepted interface condition was derived by Saffman [25] using a statistical approach and the Brinkman approximation and also by Jones [18] (also see Jäger and Mikelić [17]). This condition, which drops this term, is now known as the Beavers–Joseph–Saffman law and is thus given by

$$u_1 \cdot \hat{\tau}_j = -\frac{\sqrt{\tilde{k}_j}}{\alpha_1}\, 2\hat{n}_1 \cdot \mathbf{D}(u_1) \cdot \hat{\tau}_j, \qquad j = 1, d-1, \text{ on } \Gamma_I. \tag{1.6}$$

Here the form $\sqrt{\tilde{k}_j}/\alpha_1$ for the friction constant arises from dimensional analysis and experimental evidence. The parameter α_1 must be experimentally determined; it seems to depend on many particular features of Γ_I, including its geometry. See, e.g., Beavers and Joseph [3], Payne and Straughan [22], Saffman [25], and Jäger and Mikelić [16, 17] (among roughly 500 papers studying or using this interface condition) for more information.

2. Weak formulation of the coupled problem. This section is devoted to developing suitable weak formulations of the problem (1.1)–(1.6). The weak formulations have two important purposes. One formulation is used to show well-posedness of (1.1)–(1.6). This is already nontrivial because of the incompatibility of the boundary and interface conditions where Γ_I, Γ_1, and Γ_2 meet. Thus, the conditions at these points must be interpreted correctly. A second closely related weak form is developed which is suitable for efficiently splitting the coupled problem into two subproblems. In this formulation the coupling conditions (1.4)–(1.5) are viewed as constraints and imposed via Lagrange multipliers.

Notation. For a subdomain $G \subset \mathbb{R}^d$, the $L^2(G)$ inner product (or duality pairing) and norm are denoted $(\cdot,\cdot)_G$ and $\|\cdot\|_G$, respectively, for scalar, vector, and tensor valued functions. For example, for tensor valued functions $A, B : G \to \mathbb{R}^{d\times d}$,

$$(A,B)_G := \sum_{i,j=1}^{d} \int_G A_{ij}(x) B_{ij}(x) dx = \int_G A : B \; dx.$$

For a connected open subset of the boundary $\Gamma \subset \partial\Omega_1 \cup \partial\Omega_2$, we write $\langle\cdot,\cdot\rangle_\Gamma$ and $\|\cdot\|_\Gamma$ for the $L^2(\Gamma)$ inner product (or duality pairing) and norm, respectively, for

scalar valued functions λ, μ and vector valued functions u, v:

$$\langle \lambda, \mu \rangle_\Gamma := \int_\Gamma \lambda\mu \, ds, \quad \langle u, v \rangle_\Gamma := \int_\Gamma \sum_{i=1}^{d} u_i v_i \, ds.$$

The Sobolev spaces $H^k(\Omega) = W^{k,2}(\Omega)$ are defined in the usual ways for $\Omega = \Omega_1$ or Ω_2 with the usual norm and seminorm $\|\cdot\|_{k,\Omega}$ and $|\cdot|_{k,\Omega}$, respectively. Let

$$X_1 := \{v_1 \in (H^1(\Omega_1))^d : v_1 = 0 \text{ on } \Gamma_1\}, \quad M_1 := L^2(\Omega_1)$$

denote the usual velocity-pressure spaces on Ω_1. The norm on X_1 is given by

$$\|v_1\|_{X_1} := |v_1|_{1,\Omega_1} := \|\nabla v_1\|_{\Omega_1}.$$

The velocity space X_2 on Ω_2 [24, 15, 7] is the subspace of

$$H(\mathrm{div}; \Omega_2) = \{v_2 \in (L^2(\Omega_2))^d : \nabla \cdot v_2 \in L^2(\Omega_2)\}$$

consisting of functions with zero normal trace on Γ_2 and equipped with the norm

$$\|v_2\|_{H(\mathrm{div};\Omega_2)} := (\|v_2\|^2_{\Omega_2} + \|\nabla \cdot v_2\|^2_{\Omega_2})^{1/2}.$$

It is well known [24, 15, 7] that for all $v_2 \in H(\mathrm{div}; \Omega_2)$, $v_2 \cdot \hat{n}_2 \in H^{-1/2}(\partial\Omega_2)$ and there exists a positive constant C such that

$$\|v_2 \cdot \hat{n}_2\|_{-1/2,\partial\Omega_2} \le C \|v_2\|_{H(\mathrm{div};\Omega_2)}. \tag{2.1}$$

The restriction of $v_2 \cdot \hat{n}_2$ to Γ_2, however, may not lie in $H^{-1/2}(\Gamma_2)$. We define the velocity-pressure spaces on Ω_2 as follows [30], [7, sect. III.1]:

$$X_2 := \{v_2 \in H(\mathrm{div}; \Omega_2) : \langle v_2 \cdot \hat{n}_2, w \rangle_{\partial\Omega_2} = 0 \text{ for all } w \in H^1_{0,\Gamma_I}(\Omega_2)\}, \quad M_2 := L^2(\Omega_2),$$

where

$$H^1_{0,\Gamma_I}(\Omega_2) = \{w \in H^1(\Omega_2) : w = 0 \text{ on } \Gamma_I\}.$$

Defining $X := X_1 \times X_2$, a typical $v \in X$ takes the form (v_1, v_2) with $v_i \in X_i$. The norm on X is, as usual,

$$\|v\|_X := (\|v_1\|^2_{X_1} + \|v_2\|^2_{X_2})^{1/2} \qquad \text{for all } v \in X.$$

If $V \subset X$ is any closed subspace, then $\|\cdot\|_X$ is also the induced norm on V. Similarly, let

$$M := \left\{ q = (q_1, q_2) : q_i \in M_i \text{ and } \sum_{i=1}^{2} (q_i, 1)_{\Omega_i} = 0 \right\},$$

with norm

$$\|q\|_M := (\|q_1\|^2_{M_1} + \|q_2\|^2_{M_2})^{1/2}.$$

The coupling across Γ_I between the subproblems in Ω_1 and Ω_2 occurs in the interface conditions (1.4)–(1.5). The procedure for uncoupling the two subproblems is to pick one (we pick the second) and introduce the Lagrange multiplier λ:

$$p_1 - 2\mu\hat{n}_1 \cdot \mathbf{D}(u_1) \cdot \hat{n}_1 = \lambda = p_2 \qquad \text{on } \Gamma_I. \tag{2.2}$$

Considering λ to be known data for each subproblem, the weak formulation is then derived in the usual manner as follows. Beginning with a classical solution of (1.1), multiplying by a sufficiently smooth $v_1 \in X_1$, and integrating by parts gives

$$\begin{aligned}(f_1, v_1)_{\Omega_1} &= (-2\mu\nabla\cdot\mathbf{D}(u_1) + \nabla p_1, v_1)_{\Omega_1} \\ &= 2\mu(\mathbf{D}(u_1), \mathbf{D}(v_1))_{\Omega_1} - (p_1, \nabla\cdot v_1)_{\Omega_1} \\ &+ \langle\{p_1 - 2\mu\hat{n}_1\mathbf{D}(u_1)\hat{n}_1\}, v_1\cdot\hat{n}_1\rangle_{\Gamma_I} \\ &+ \sum_{j=1}^{d}\langle\{-2\mu\hat{n}_1\mathbf{D}(u_1)\hat{\tau}_j\}, v_1\cdot\hat{\tau}_j\rangle_{\Gamma_I}.\end{aligned}$$

The first term in the braces $\{\cdot\}$ is replaced by λ using (2.2) and the second by $(\mu\alpha_1/\sqrt{\tilde{k}_j})\; u_1\cdot\hat{\tau}_j$ using (1.6). Therefore, introducing the bilinear forms

$$a_1(u_1, v_1) := 2\mu(\mathbf{D}(u_1), \mathbf{D}(v_1))_{\Omega_1} + \sum_{j=1}^{d-1}\frac{\mu\alpha_1}{\sqrt{\tilde{k}_j}}\,\langle u_1\cdot\hat{\tau}_j, v_1\cdot\hat{\tau}_j\rangle_{\Gamma_I} \text{ for all } u_1, v_1 \in X_1,$$

and

$$b_1(v_1, q_1) := -(q_1, \nabla\cdot v_1)_{\Omega_1} \qquad \text{for all } v_1 \in X_1, q_1 \in M_1,$$

we obtain for all $v_1 \in X_1$ and $q_1 \in M_1$

$$\begin{aligned}a_1(u_1, v_1) + b_1(v_1, p_1) + \langle\lambda, v_1\cdot\hat{n}_1\rangle_{\Gamma_I} &= (f_1, v_1)_{\Omega_1}, \\ b_1(u_1, q_1) &= 0.\end{aligned}$$

In the porous medium region, multiplication of the first equation in (1.2) by $v_2 \in X_2$, integration over Ω_2, and integration by parts gives

$$0 = (k^{-1}u_2 + \nabla p_2, v_2)_{\Omega_2} = (k^{-1}u_2, v_2)_{\Omega_2} - (p_2, \nabla\cdot v_2)_{\Omega_2} + \langle\lambda, v_2\cdot\hat{n}_2\rangle_{\Gamma_I},$$

where, by (2.2), p_2 is replaced by λ in the last term. Introducing

$$a_2(u_2, v_2) := (k^{-1}u_2, v_2)_{\Omega_2}, \quad b_2(v_2, p_2) := -(p_2, \nabla\cdot v_2)_{\Omega_2},$$

we have

$$\begin{aligned}a_2(u_2, v_2) + b_2(v_2, p_2) + \langle\lambda, v_2\cdot\hat{n}_2\rangle_{\Gamma_I} &= 0 \qquad \text{for all } v_2 \in X_2, \\ b_2(u_2, q_2) &= -(f_2, q_2) \qquad \text{for all } q_2 \in M_2.\end{aligned}$$

The linking across Γ_I occurs through the condition $u_1\cdot\hat{n}_1 + u_2\cdot\hat{n}_2 = 0$ on Γ_I and the definition (2.2) of λ. This linkage is the key to the well-posedness of the coupled problem and it hinges on the choice of the space Λ for the Lagrange multipliers. Define

$$b_I(v, \lambda) := \langle v_1\cdot\hat{n}_1 + v_2\cdot\hat{n}_2, \lambda\rangle_{\Gamma_I} : X\times\Lambda \to \mathbb{R},$$

where Λ is not yet specified. The flux continuity condition (1.4) on Γ_I is then

$$b_I(v, \lambda) = 0 \qquad \text{for all } \lambda \in \Lambda.$$

Since $v_2 \in H(\mathrm{div}, \Omega_2)$, it holds that $v_2 \cdot \hat{n}_2 \in H^{-1/2}(\partial\Omega_2)$. We wish to pick $\Lambda \subset L^2(\Gamma_I)$ to be the largest space for which the pairing $\langle v_2 \cdot \hat{n}_2, \lambda \rangle_{\Gamma_I}$ is well defined. We show in Lemma 2.1 below (see also [20]) that

$$v_2 \cdot \hat{n}_2|_{\Gamma_I} \in (H_{00}^{1/2}(\Gamma_I))^*,$$

where $H_{00}^{1/2}(\Gamma_I)$ is the completion of the smooth functions with compact support in Γ_I with respect to the norm

$$\|\mu\|_{1/2,\partial\Omega_2} := \left(\|\mu\|_{\partial\Omega_2}^2 + \int_{\partial\Omega_2} \int_{\partial\Omega_2} \frac{|\mu(t_1) - \mu(t_2)|^2}{|t_1 - t_2|^d} ds_{t_1} ds_{t_2} \right)^{1/2}.$$

It is well known that $H_{00}^{1/2}(\Gamma_I)$ is the interpolation space

$$H_{00}^{1/2}(\Gamma_I) = [L^2(\Gamma_I), H_0^1(\Gamma_I)]_{1/2}.$$

Any function $\mu \in H_{00}^{1/2}(\Gamma_I)$ has the property that its extension by zero to $\partial\Omega_j$ gives a function $\tilde{\mu}_j \in H^{1/2}(\partial\Omega_j)$ with

$$\|\tilde{\mu}_j\|_{1/2,\partial\Omega_j} \le C \|\mu\|_{H_{00}^{1/2}(\Gamma_I)}, \quad j = 1, 2. \tag{2.3}$$

See Lions and Magenes [19] for background information on $H_{00}^{1/2}(\Gamma_I)$.

Accordingly, choose

$$\Lambda := H_{00}^{1/2}(\Gamma_I) \ (\subset L^2(\Gamma_I)).$$

LEMMA 2.1. *The bilinear form $b_I(\cdot, \cdot)$ is continuous on $X \times \Lambda$.*

Proof. First note that $v_j \cdot \hat{n}_j \in H^{-1/2}(\partial\Omega_j), j = 1, 2$. Let $\mu \in H_{00}^{1/2}(\Gamma_I)$ and let $\tilde{\mu}_j$ be its extension by zero to $\partial\Omega_j$. We have, for $j = 1, 2$,

$$\begin{aligned} \int_{\Gamma_I} v_j \cdot \hat{n}_j \mu \, ds &= \int_{\partial\Omega_j} v_j \cdot \hat{n}_j \tilde{\mu}_j \, ds \le \|v_j \cdot \hat{n}_j\|_{-1/2,\partial\Omega_j} \|\tilde{\mu}_j\|_{1/2,\partial\Omega_j} \\ &\le C \|v\|_X \|\mu\|_\Lambda, \end{aligned}$$

using (2.1) and (2.3) in the last inequality. ∎

Further, define

$$\begin{aligned} a(u, v) &:= \sum_{i=1}^{2} a_i(u_i, v_i) : X \times X \to \mathbb{R}, \\ b(v, p) &:= \sum_{i=1}^{2} b_i(v_i, p_i) : X \times M \to \mathbb{R}, \\ \ell(v) &:= (f_1, v_1)_{\Omega_1}, \quad g(q) := -(f_2, q_2)_{\Omega_2}. \end{aligned}$$

Then, (1.1)–(1.6) has the following weak formulation: find $(u, p, \lambda) \in X \times M \times \Lambda$ satisfying

$$\begin{cases} a(u, v) + b(v, p) + b_I(v, \lambda) = \ell(v) & \text{for all } v \in X, \\ b(u, q) = g(q) & \text{for all } q \in M, \\ b_I(u, \mu) = 0 & \text{for all } \mu \in \Lambda. \end{cases} \tag{2.4}$$

We next derive another weak formulation using the space V of functions in X with trace-continuous normal velocities:

$$V := \{v \in X : b_I(v, \mu) = 0 \text{ for all } \mu \in \Lambda\}.$$

The connection between the two formulations (2.4) and (2.5) is considered in Remark 3.1 in section 3. Note that, due to Lemma 2.1, V is a closed subspace of X, e.g., Brezzi and Fortin [7]. The next lemma indicates that a trace-continuous normal velocity has a well-defined divergence on the whole domain. Let

$$\Omega := \text{ interior}(\overline{\Omega}_1 \cup \overline{\Omega}_2).$$

For a given $v = (v_1, v_2) \in X$, define $\tilde{v} \in (L^2(\Omega))^d$ by $\tilde{v}|_{\Omega_j} := v_j$, $j = 1, 2$. To simplify notation we will omit the tilde in this construction since the meaning whether it is v or $\tilde{v}$ is clear from the context.

LEMMA 2.2. *If $v \in V$, then $v \in H(\text{div}; \Omega)$.*

Proof. Define

$$g(x) = \nabla \cdot v_j(x) \quad \text{for } x \in \Omega_j, \ j = 1, 2.$$

We will show that $g = \nabla \cdot v$. Since $v_j \in H(\text{div}; \Omega_j)$, $j = 1, 2$, we can apply the divergence theorem in each Ω_j. This gives, for all $\phi \in C_0^\infty(\Omega)$,

$$\begin{aligned}\int_\Omega v \nabla \phi \, dx &= \int_{\Omega_1} v_1 \nabla \phi \, dx + \int_{\Omega_2} v_2 \nabla \phi \, dx \\ &= -\int_{\Omega_1} (\nabla \cdot v_1)\phi \, dx - \int_{\Omega_2} (\nabla \cdot v_2)\phi \, dx \\ &\quad + \int_{\Gamma_I} (v_1 \cdot \hat{n}_1 + v_2 \cdot \hat{n}_2)\phi \, dx.\end{aligned}$$

The last term vanishes since $\phi \in C_0^\infty(\Omega)$ implies $\phi_{|\Gamma_I} \in H_{00}^{1/2}(\Gamma_I)$. Thus,

$$\int_\Omega v \nabla \phi \, dx = -\int_\Omega g \phi \, dx.$$

Since $\nabla \cdot v_j \in L^2(\Omega_j)$, $g \in L^2(\Omega)$, and hence g is the weak L^2 divergence of $v \in V$. ∎

We next define the subspace Z,

$$Z := \{v \in V : b(v, q) = 0 \qquad \text{for all } q \in M\}.$$

LEMMA 2.3. *The space Z is a closed subspace of V and X. Moreover, if $v \in Z$, then $\nabla \cdot v = 0$, a.e. $x \in \Omega$.*

Proof. Let $v \in Z$. Since $Z \subset V$, we know by Lemma 2.2 that $v \in H(\text{div}; \Omega)$. Thus, for any $q \in M$

$$b(v, q) = -\int_\Omega \nabla \cdot v \ q \, dx.$$

We claim that $\nabla \cdot v \in M$. Indeed, $\nabla \cdot v \in L^2(\Omega)$ and $\nabla \cdot v$ has zero mean value over Ω:

$$\int_\Omega \nabla \cdot v \, dx = \int_{\partial\Omega} v \cdot \hat{n} \, ds = 0$$

using the divergence theorem. Thus, $\nabla \cdot v \in M$. The second part of the lemma follows by setting $q = \nabla \cdot v$.

The space Z is a closed subspace of V since

$$\begin{aligned} b(v,q) &= -\int_\Omega \nabla \cdot v \; q \; dx \le \|\nabla \cdot v\|_\Omega \|q\|_\Omega \\ &\le \|v\|_X \|q\|_M, \end{aligned}$$

i.e., $b(\cdot,\cdot)$ is continuous on $V \times M$. ∎

Since V is a closed subspace of X, we can write the following variational formulation: find $(u,p) \in V \times M$ satisfying

$$\begin{cases} a(u,v) + b(v,p) = \ell(v) & \text{for all } v \in V, \\ b(u,q) = g(q) & \text{for all } q \in M. \end{cases} \tag{2.5}$$

We end this section noting that, under the solvability condition (1.3), any solution of (2.5) satisfies the mass conservation equations in (1.1) and (1.2). Indeed, define $f \in L^2(\Omega)$ such that $f = 0$ on Ω_1 and $f = f_2$ on Ω_2. If (u,p) is a solution to (2.5), then $\nabla \cdot u \in L^2(\Omega)$ due to Lemma 2.2. The second equation in (2.5) implies that $\nabla \cdot u - f = c$, where c is a constant. The divergence theorem gives

$$c|\Omega| = \int_\Omega (\nabla \cdot u - f)\, dx = \int_{\partial\Omega} u \cdot \hat{n}\, ds - \int_\Omega f\, dx = -\int_{\Omega_2} f_2\, dx = 0$$

using (1.3). Therefore $\nabla \cdot u = 0$ on Ω_1 and $\nabla \cdot u = f_2$ on Ω_2.

3. Analysis of the weak formulation. This section is devoted to a proof of existence of weak solutions to (1.1)–(1.6) based on the weak formulations (2.4) and (2.5). Existence depends on our choice of the Lagrange multiplier space $\Lambda = H_{00}^{1/2}(\Gamma_I)$ so that the problem is neither over nor underconstrained.

We begin with a few simple but useful estimates. Let

$$W_2 := \{v_2 \in X_2 : \nabla \cdot v_2 = 0, \text{ a.e. } x \in \Omega_2\} \subset X_2$$

denote the (closed) subspace of div-free functions in X_2.

LEMMA 3.1. *For $v_i \in H^1(\Omega_i)^d \cap X_i$ $(i = 1,2)$ we have*

$$C_1 \|v_i\|_{\Omega_i} \le \|v_i\|_{X_i} \le C_2 \|v_i\|_{1,\Omega_i}. \tag{3.1}$$

Furthermore, for $i = 1,2$, there holds

$$|a_i(u_i,v_i)| \le C_3 \|u_i\|_{X_i} \|v_i\|_{X_i} \text{ for all } u_i, v_i \in X_i, \tag{3.2}$$

$$a_1(v_1,v_1) \ge C_4 \|v_1\|_{X_1}^2 \text{ for all } v_1 \in X_1, \tag{3.3}$$

$$a_2(v_2,v_2) \ge C_5 \|v_2\|_{X_2}^2 \text{ for all } v_2 \in W_2, \tag{3.4}$$

$$|b_i(v_i,p_i)| \le C_6 \|v_i\|_{X_i}, \|p_i\|_{M_i} \text{ for all } v_i \in X_i, p_i \in M_i, \tag{3.5}$$

$$|a(u,v)| \le C_3 \|u\|_X \|v\|_X \text{ for all } u, v \in X, \tag{3.6}$$

$$|b(v,p)| \le C_6 \|v\|_X \|p\|_M \text{ for all } v \in X,\ p \in M, \tag{3.7}$$

$$a(v,v) \ge \min\{C_4, C_5\} \|v\|_X^2 \text{ for all } v \in X_1 \times W_2. \tag{3.8}$$

Proof. Inequalities (3.1) and (3.2) follow from the Poincaré–Friedrich inequality and the trace theorem. The Korn inequality implies (3.3) while (3.4) and (3.5) are immediate. Inequalities (3.6), (3.7), and (3.8) follow by combining earlier ones. ∎

The next lemma establishes the Ladyzhenskaya–Babuška–Brezzi condition required for the formulation (2.5) in $V \times M$.

LEMMA 3.2. *There is a constant $\beta > 0$ such that*

$$\inf_{q \in M \setminus \{0\}} \sup_{v \in V \setminus \{0\}} \frac{b(v,q)}{\|v\|_X \ \|q\|_M} \geq \beta. \tag{3.9}$$

Proof. Let $q \in M \setminus \{0\}$ be fixed but arbitrary. We construct a $v \in V$ satisfying

$$b(v,q) \geq \beta \|v\|_X \ \|q\|_M.$$

Given $q = (q_1, q_2) \in M$, the function $\tilde{q}(x)$ defined by $\tilde{q}|_{\Omega_i} = q_i$ has mean value zero over Ω; thus $\tilde{q} \in L^2_0(\Omega)$. Thus, (see, e.g., [15, 13]) there exists $\tilde{v} \in (H^1_0(\Omega))^d$ satisfying

$$\nabla \cdot \tilde{v} = \tilde{q}, \text{ in } \Omega, \ \tilde{v} = 0, \text{ on } \partial\Omega, \ \|\tilde{v}\|_{1,\Omega} \leq C_7 \|\tilde{q}\|_\Omega.$$

Given this $\tilde{v}$, define $v = (v_1, v_2) \in X$ by $v_i = \tilde{v}|_{\Omega_i}, (i = 1, 2)$. Since

$$\tilde{v} \in H^1_0(\Omega)^d, \text{ it follows that } v_1|_{\Gamma_1} = 0 \text{ and } v_2 \cdot \hat{n}_2|_{\Gamma_2} = 0.$$

Further, $v_1|_{\Gamma_I} = v_2|_{\Gamma_I} = \tilde{v}|_{\Gamma_I} \in (H^{1/2}_{00}(\Gamma_I))^d$ so that $v_i \cdot \hat{n}_i \in L^2(\Gamma_I)$ $(i = 1, 2)$ and

$$b_I(v, \mu) = \langle v_1 \cdot \hat{n}_1 + v_2 \cdot \hat{n}_2, \ \mu \rangle_{\Gamma_I} = 0$$

for all $\mu \in L^2(\Gamma_I)$. Thus, $v \in V$. Using (3.1) we find

$$\|v\|_X \leq C_2 \|\tilde{v}\|_{1,\Omega} \leq C_2 C_7 \|\tilde{q}\|_{0,\Omega} = C_2 C_7 \|q\|_M.$$

Finally, for this v

$$b(v,q) = \sum_{i=1}^{2} (-\nabla \cdot v_i, q_i) = -(\nabla \cdot \tilde{v}, \tilde{q})_\Omega \tag{3.10}$$

$$= \|\tilde{q}\|^2_{0,\Omega} \geq (C_2 C_7)^{-1} \|v\|_X \|q\|_M, \tag{3.11}$$

completing the proof with $\beta = (C_2 C_7)^{-1}$. ∎

To apply the abstract theory of mixed problems in, e.g., Girault and Raviart [15], Brezzi and Fortin [7], we must show $a(\cdot, \cdot)$ is coercive on the constraint set Z. This is accomplished in the next lemma.

LEMMA 3.3. *$a(\cdot, \cdot)$ is coercive on Z: there is an $\alpha > 0$ such that*

$$a(v,v) \geq \alpha \|v\|^2_X \qquad \textit{for all } v \in Z.$$

Proof. Note that by Lemma 2.3 if $v = (v_1, v_2) \in \ker(B)$, $\nabla \cdot v_2 = 0$, a.e. $x \in \Omega$, i.e., $v_2 \in W_2$. Coercivity now follows from (3.8) of Lemma 3.1. ∎

Lemmas 2.1, 3.2, and 3.3, together with the abstract theory of mixed problems [15, 7], immediately imply existence of a weak solution $(u, p) \in V \times M$ satisfying (2.5).

THEOREM 3.1. *There exists a unique solution $(u, p) \in V \times M$ to the problem (2.5).* ∎

To verify that the solution to (2.5) is also the solution to the formulation (2.4) in $X \times M \times \Lambda$ using the general saddle point problem theory [15, 7], we must verify the inf-sup condition

$$\inf_{0 \neq \lambda \in \Lambda} \sup_{0 \neq v \in X} \frac{b_I(v, \lambda)}{\|v\|_X \|\lambda\|_\Lambda} \geq \beta > 0. \tag{3.12}$$

Due to technical difficulties related to the restriction of $H^{-1/2}(\partial\Omega_2)$ functions to Γ_I, we are only able to show a modified inf-sup condition:

$$\inf_{0\neq\lambda\in\Lambda}\sup_{0\neq v\in X}\frac{b_I(v,\lambda)}{\|v\|_X\|\lambda\|_{1/2,\Gamma_I}}\geq\beta>0. \tag{3.13}$$

LEMMA 3.4. *The* inf-sup *condition* (3.13) *holds.*

Proof. Fix $\lambda\in H^{1/2}_{00}(\Gamma_I)$ and let $\tilde{\lambda}\in H^{1/2}(\partial\Omega_2)$ be its extension by zero to $\partial\Omega_2$. Since $H^{1/2}_{00}(\Gamma_I)\subset H^{1/2}(\Gamma_I)$, there exists $\hat{\lambda}_I\in H^{-1/2}(\Gamma_I)$ such that

$$\frac{\langle\hat{\lambda}_I,\lambda\rangle_{\Gamma_I}}{\|\hat{\lambda}_I\|_{-1/2,\Gamma_I}}\geq\frac{1}{2}\|\lambda\|_{1/2,\Gamma_I}. \tag{3.14}$$

We next define $\hat{\lambda}\in H^{-1/2}(\partial\Omega_2)$ by

$$\langle\hat{\lambda},w\rangle_{\partial\Omega_2}:=\langle\hat{\lambda}_I,w\rangle_{\Gamma_I}\quad\text{for all } w\in H^{1/2}(\partial\Omega_2).$$

We then have

$$\|\hat{\lambda}\|_{-1/2,\partial\Omega_2}=\sup_{0\neq w\in H^{1/2}(\partial\Omega_2)}\frac{\langle\hat{\lambda}_I,w\rangle_{\Gamma_I}}{\|w\|_{1/2,\partial\Omega_2}}\leq\|\hat{\lambda}_I\|_{-1/2,\Gamma_I}. \tag{3.15}$$

Since the normal trace operator maps $H(\mathrm{div},\Omega_2)$ onto $H^{-1/2}(\partial\Omega_2)$ (see [15, Corollary 2.8]) and it is continuous (see (2.1)), by the open mapping theorem there exists $v_2\in H(\mathrm{div},\Omega_2)$ such that $v_2\cdot\hat{n}_2=\hat{\lambda}$ on $\partial\Omega_2$ and

$$\|v_2\|_{X_2}\leq C\|\hat{\lambda}\|_{-1/2,\partial\Omega_2}\leq C\|\hat{\lambda}_I\|_{-1/2,\Gamma_I}, \tag{3.16}$$

using (3.15) for the second inequality. We note that $v_2\in X_2$ since, for all $w\in H^1_{0,\Gamma_I}(\Omega_2)$,

$$\langle v_2\cdot\hat{n}_2,w\rangle_{\partial\Omega_2}=\langle\hat{\lambda},w\rangle_{\partial\Omega_2}=\langle\hat{\lambda}_I,w\rangle_{\Gamma_I}=0.$$

Choosing $v=(0,v_2)\in X$ and using (3.14) and (3.16) we get

$$\begin{aligned}\frac{b_I(v,\lambda)}{\|v\|_X}&=\frac{\langle v_2\cdot\hat{n}_2,\tilde{\lambda}\rangle_{\partial\Omega_2}}{\|v_2\|_{X_2}}=\frac{\langle\hat{\lambda},\tilde{\lambda}\rangle_{\partial\Omega_2}}{\|v_2\|_{X_2}}\\&=\frac{\langle\hat{\lambda}_I,\lambda\rangle_{\Gamma_I}}{\|v_2\|_{X_2}}\geq\frac{1}{C}\frac{\langle\hat{\lambda}_I,\lambda\rangle_{\Gamma_I}}{\|\hat{\lambda}_I\|_{-1/2,\Gamma_I}}\geq\beta\|\lambda\|_{1/2,\Gamma_I}.\end{aligned}$$

∎

REMARK 3.1. *If the porous medium is entirely enclosed within the fluid region, then* $\Gamma_I=\partial\Omega_2$. *In this case there are no incompatible points and it is easy to extend slightly the proof of Lemma* 3.4 *to show that the stronger* inf-sup *condition* (3.12) *holds. In this case, the unique weak solution to* (2.5) *is also the unique weak solution to* (2.4) *and the two formulations are equivalent.*

4. Finite element discretization. This section considers the finite element discretization of the coupled problem. The interface conditions on Γ_I separate into tangential and normal conditions. This splitting on Γ_I introduces interesting features into the finite element procedure and its analysis.

Introduce upon Ω_j a mesh $\mathcal{T}_j^h$ $(j = 1, 2)$ with $\overline{\Omega}_j = \cup_{K\in\mathcal{T}_j^h}\overline{K}$. To simplify the notation we shall assume that the cells $K \in \mathcal{T}_j^h$ are affine equivalent, the grids $\mathcal{T}_1^h$ and $\mathcal{T}_2^h$ match at Γ_I, that Γ_I is polyhedral, and that no point of the interface boundary $\partial\Gamma_I$ belongs to the interior of an element face. We use the notation

$$\mathcal{E}_h(K) := \text{the set of all faces of the element } K,$$
$$\mathcal{E}_h(\Gamma_I) := \text{the set of all element faces } E \text{ with } E \subset \Gamma_I.$$

For the discretization of the fluid's variables we choose finite element spaces X_1^h and M_1^h which are assumed to be div-stable (also called LBB-stable),

$$\begin{cases} X_1^h \subset X_1,\ M_1^h \subset M_1, \text{ and} \\ \inf\limits_{0\neq q_1\in M_1^h}\ \sup\limits_{0\neq v_1\in X_1^h} \frac{b_1(v_1,q_1)}{\|v_1\|_{X_1}\|q_1\|_{M_1}} \ \geq\ \beta_1 > 0, \end{cases} \tag{4.1}$$

and to satisfy a discrete Korn inequality

$$(\mathbf{D}(v_1), \mathbf{D}(v_1))_{\Omega_1} \geq \alpha_1 |v_1|^2_{1,\Omega_1} \quad \text{for all } v_1 \in X_1^h. \tag{4.2}$$

We assume that X_1^h and M_1^h include at least polynomials of degree r_1 and $r_1 - 1$, respectively, $(r_1 \geq 1)$. Specifically, we assume that there exist (quasi) interpolation operators

$$I^h_{X_1} : X_1 \cap (H^s(\Omega_1))^d \to X_1^h \quad \text{and} \quad I^h_{M_1} : M_1 \cap H^s(\Omega_1) \ \to M_1^h$$

such that for all $K \in \mathcal{T}_1^h$

$$\begin{cases} |v_1 - I^h_{X_1} v_1|_{m,K} \leq C h_K^{s-m} |v_1|_{s,\delta(K)}, \quad m = 0, 1,\ 1 \leq s \leq r_1 + 1, \\ \|q_1 - I^h_{M_1} q_1\|_{0,K} \leq C h_K^s |q_1|_{s,\delta(K)}, \quad 0 \leq s \leq r_1. \end{cases} \tag{4.3}$$

Here $\delta(K)$ is equal to K in most cases of usual interpolation operators. However, in cases of quasi interpolation operators suited for H^1 functions like the Clement-operator [9] or the Scott–Zhang-operator [27], $\delta(K)$ denotes the vicinity of K consisting of all elements $\widetilde{K} \in \mathcal{T}_1^h$ that touch element K. We assume the grids $\mathcal{T}_1^h$ and $\mathcal{T}_2^h$ to be shape-regular in the usual sense such that cases with local grid refinement are allowed. For shape-regular grids, changes of the mesh size within the vicinity $\delta(K)$ of an element K are uniformly bounded by a constant C, i.e., in particular for $\mathcal{T}_1^h$,

$$C^{-1}\, h_K \leq h_{\widetilde{K}} \leq C\, h_K \qquad \text{for all } \widetilde{K} \subset \delta(K),\ \ \widetilde{K}, K \in \mathcal{T}_1^h. \tag{4.4}$$

This estimate is used to get rid of the $\delta(K)$-terms in final error estimates.

Examples of spaces satisfying (4.1)–(4.3) include the MINI elements [2], the Taylor–Hood elements [29], and the conforming Crouzeix–Raviart elements [10]. See, e.g., [15, 7], for a more complete list of such spaces.

REMARK 4.1. *The discrete Korn inequality* (4.2) *is inherited from the continuous inequality for all conforming elements. However, nonconforming spaces, in general, do not satisfy* (4.2)*; see* [12].

REMARK 4.2. *The* inf-sup *condition* (4.1) *differs from the usual one verified in the literature* [15, 7] *for various spaces because the pressure space M_1^h is not restricted to have zero mean over Ω_1, i.e., $M_1^h \subset L^2(\Omega_1)$, not $L_0^2(\Omega_1)$. However, the usual discrete* inf-sup *condition is almost enough to prove* (4.1). *The main extra ingredient*

needed is the existence of a (typically locally constructed, see [7, section VI.4]*) operator* $P_1^h : X_1 \to X_1^h$ *(not necessarily the same as* $I_{X_1}^h$*) satisfying, for all* $K \in \mathcal{T}_1^h$ *and all* $v_1 \in X_1$*,*

$$\int_K \nabla \cdot (P_1^h v_1 - v_1)\, dx = 0 \quad \text{and} \quad \|P_1^h v_1\|_{1,\Omega_1} \le C_8 \|v_1\|_{1,\Omega_1}, \tag{4.5}$$

where C_8 *is a constant independent of* v_1 *and* h*. In, e.g.,* [7]*, such an operator is locally constructed for all the aforementioned spaces.*

The following lemma gives sufficient conditions for the discrete LBB-stability (4.1) of the spaces X_1^h and M_1^h.

LEMMA 4.1. *Suppose that an operator* $P_1^h : X_1 \to X_1^h$ *satisfying the condition* (4.5) *exists. Suppose also the spaces* $X_1^h \cap (H_0^1(\Omega_1))^d$ *and* $M_1^h \cap L_0^2(\Omega_1)$ *satisfy the usual discrete* inf-sup *condition. Then, the spaces* X_1^h *and* M_1^h *satisfy* (4.1)*.*

Proof. Let $q_1^h \equiv q_0 \in \mathbb{R}$ be an arbitrary constant function of M_1^h. We first show that there exists a $v_1^h \in X_1^h$ such that

$$b_1(v_1^h, q_1^h) \ge \beta_0 \, \|v_1^h\|_{X_1} \|q_1^h\|_{M_1}$$

with a constant $\beta_0 > 0$ independent of v_1^h and h. To this end, let $\tilde{v}_1$ be a solution of the following problem: find $\tilde{v}_1 \in X_1$ satisfying

$$\nabla \cdot \tilde{v}_1 = q_1^h \ \text{ in } \Omega_1, \quad \tilde{v}_1 = g_1 \ \text{ on } \partial\Omega_1,$$

where g_1 is chosen suitably such that the compatibility condition $\langle g_1 \cdot \hat{n}_1, 1\rangle_{\partial\Omega_1} = (q_1^h, 1)_{\Omega_1} = q_0|\Omega_1|$ is fulfilled and $g_1 \in (H^{1/2}(\partial\Omega_1))^d$. By, e.g., [13, sect. III.3, Exercise 3.4], such a $\tilde{v}_1$ exists and satisfies the estimate

$$\|\tilde{v}_1\|_{1,\Omega_1} \le C_9 \{ \|q_1^h\|_{\Omega_1} + \|g_1\|_{1/2,\partial\Omega_1} \}.$$

For the construction of g_1, let $\varphi_0 \in C(\partial\Omega_1)$ be such that $\varphi_0 \equiv 0$ on Γ_1, φ_0 is quadratic on Γ_I, and $\langle \varphi_0, 1\rangle_{\Gamma_I} = 1$. Then, we choose g_1 as $g_1 := |\Omega_1| q_0 \varphi_0 \hat{n}_1$. One can easily verify that g_1 belongs to $(H^{1/2}(\partial\Omega_1))^d$ and satisfies the compatibility condition as well as the estimate $\|g_1\|_{1/2,\partial\Omega_1} \le c(\Omega_1, \varphi_0)\|q_1^h\|_{\Omega_1}$. This implies

$$\|\tilde{v}_1\|_{1,\Omega_1} \le C_9 \{1 + c(\Omega_1, \varphi_0)\} \, \|q_1^h\|_{\Omega_1}.$$

Defining $v_1^h := -P_1^h \tilde{v}_1$, we have

$$\frac{b_1(v_1^h, q_1^h)}{\|v_1^h\|_{X_1}\|q_1^h\|_{M_1}} = \frac{(\nabla \cdot \tilde{v}_1, q_1^h)_{\Omega_1}}{\|P_1^h \tilde{v}_1\|_{X_1}\|q_1^h\|_{M_1}} \ge \frac{\|q_1^h\|_{M_1}^2}{C_8 \|\tilde{v}_1\|_{X_1}\|q_1^h\|_{M_1}} \ge \beta_0 \tag{4.6}$$

with $\beta_0 := (C_8 C_9 \{1 + c(\Omega_1, \varphi_0)\})^{-1}$. Now, using this result and the assumed discrete inf-sup condition for the spaces $X_1^h \cap (H_0^1(\Omega_1))^d$ and $M_1^h \cap L_0^2(\Omega_1)$, we can show in the same way as in the proof of Theorem 1.12, section II.1.4 in [15] that the spaces X_1^h and M_1^h satisfy the inf-sup condition (4.1). ∎

For the discretization of the porous medium problem in Ω_2, we choose $X_2^h \times M_2^h \subset X_2 \times M_2$ to be any of the well-known mixed finite element spaces (see [7, section III.3]), the RT spaces [24, 21], the BDM spaces [6], the BDFM spaces [5], the BDDF spaces [4], or the CD spaces [8]. We assume that X_2^h and M_2^h contain at least polynomials of degree r_2 and l_2, respectively. It is known for these choices that

$$\nabla \cdot X_2^h = M_2^h$$

and that there exists an interpolation operator $I^h_{X_2} : (H^1(\Omega_2))^d \to X^h_2$ such that for all $v_2 \in (H^1(\Omega_2))^d$

$$(\nabla \cdot I^h_{X_2} v_2, w)_{\Omega_2} = (\nabla \cdot v_2, w)_{\Omega_2}, \quad w \in M^h_2. \tag{4.7}$$

Let $I^h_{M_2} : M_2 \to M^h_2$ be the L^2 orthogonal projection such that for all $q_2 \in M_2$

$$(I^h_{M_2} q_2, w)_{\Omega_2} = (q_2, w)_{\Omega_2}, \quad w \in M^h_2. \tag{4.8}$$

Our next lemma will collect some known useful results for these spaces. Their proof can be found in [7, section III.3].

LEMMA 4.2. *There holds, for all $v_2 \in (H^1(\Omega_2))^d$,*

$$\langle I^h_{X_2} v_2 \cdot \hat{n}_2, \mu \rangle_E = \langle v_2 \cdot \hat{n}_2, \mu \rangle_E \tag{4.9}$$
$$\text{for all } \mu \in R_{r_2}(E) \text{ and for all } E \in \mathcal{E}_h(\Gamma_I),$$

where

$$R_{r_2}(E) := \begin{cases} \mathcal{P}_{r_2}(E) \text{ if } d = 2 \text{ or } E \text{ is a triangle,} \\ \mathcal{Q}_{r_2}(E) \text{ if } d = 3 \text{ and } E \text{ is a quadrilateral,} \end{cases} \tag{4.10}$$

where $P_{r_2}(E)$ and $Q_{r_2}(E)$ are the usual polynomial spaces (see, e.g., [7].) For the restrictions to the element faces,

$$v^h_2 \cdot \hat{n}_2|_E \in R_{r_2}(E) \quad \text{for all } v^h_2 \in X^h_2,\ E \in \mathcal{E}(K),\ K \in \mathcal{T}^h_2. \tag{4.11}$$

Further, the operators $I^h_{X_2}$ and $I^h_{M_2}$ satisfy, for all $K \in \mathcal{T}^h_2$,

$$\|q_2 - I^h_{M_2} q_2\|_{0,K} \le C h^s_K |q_2|_{s,K},\ 0 \le s \le l_2 + 1, \tag{4.12}$$

$$|v_2 - I^h_{X_2} v_2|_{m,K} \le C h^{s-m}_K |v_2|_{s,K},\ m \in \{0, 1\},\ 1 \le s \le r_2 + 1, \tag{4.13}$$

$$\|\nabla \cdot (v_2 - I^h_{X_2} v_2)\|_{0,K} \le C h^s_K |\nabla \cdot\ v_2|_{s,K},\ 0 \le s \le l_2 + 1. \tag{4.14}$$

∎

4.1. The space V^h. Define the finite element spaces over Ω:

$$X^h := X^h_1 \times X^h_2,\ M^h := \left\{ (q_1, q_2) \in M^h_1 \times M^h_2 : \int_{\Omega_1} q_1 dx + \int_{\Omega_2} q_2 dx = 0 \right\}$$

and

$$\Lambda^h := \{\mu^h \in L^2(\Gamma_I) : \mu^h|_E \in \mathcal{R}_{r_2}(E) \text{ for all } E \in \mathcal{E}_h(\Gamma_I)\}.$$

Note that, since function $\mu^h \in \Lambda^h$ does not in general vanish on $\partial\Gamma_I$,

$$\Lambda^h \not\subset \Lambda.$$

With this Λ^h define

$$V^h := \{v = (v_1, v_2) \in X^h : b_I(v, \mu) = 0 \text{ for all } \mu \in \Lambda^h\}.$$

These choices result in an approximation which is nonconforming (since $\Lambda^h \not\subset \Lambda$) and exterior (since $V^h \not\subset V$).

REMARK 4.3. *The space Λ^h is the normal trace of X^h_2 on Γ_I.*

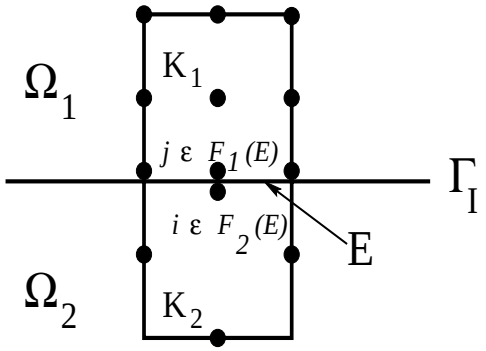

FIG. 3. *Degrees of freedom on* Γ_I.

We consider the following discrete problem: find $(u^h, p^h) \in V^h \times M^h$ satisfying

$$\begin{cases} a(u^h, v^h) + b(v^h, p^h) = \ell(v^h) & \text{for all } v^h \in V^h, \\ b(u^h, q^h) = g(q^h) & \text{for all } q^h \in M^h. \end{cases} \tag{4.15}$$

This is the natural discretization of (2.5). Since $V^h \not\subset V$, conservation of mass across Γ_I holds only in an approximate sense.

It is important to understand in exactly what sense mass conservation across Γ_I holds. To this end, a local characterization of the functions $v = (v_1, v_2) \in V^h$ is needed.

Characterization of $v = (v_1, v_2) \in V^h$. If a function $v = (v_1, v_2) \in X^h$ belongs to V^h, then the nodal values of $v_2 \cdot \hat{n}_2 \in X_2^h$ on Γ_I are linked to those of $v_1 \cdot \hat{n}_1$ on Γ_I. To be specific, let $\mathcal{F}_i$ denote the set of nodes of $X_i^h, i = 1, 2$, and $\mathcal{F}_i(E)$ the set of nodes $j \in \mathcal{F}_i$ belonging to an element face E, and let $\phi_j^{(i)},\ j \in \mathcal{F}_i$ $(i = 1, 2)$, be the associated basis functions of X_i^h. Let $E \in \mathcal{E}_h(\Gamma_I)$ be an element face on Γ_I associated with elements $K_1 \subset \Omega_1$ and $K_2 \subset \Omega_2$,

$$E \in \mathcal{E}(K_1) \cap \mathcal{E}(K_2),\ K_i \in \Omega_i,$$

as depicted in Figure 3.

From the construction of the basis functions, we have for $v = (v_1, v_2) \in X^h$

$$v_i \cdot \hat{n}_i|_E = \sum_{j \in \mathcal{F}_i(E)} (v_j^{(i)} \phi_j^{(i)}) \cdot \hat{n}_i, \qquad i = 1, 2, \tag{4.16}$$

where $v_j^{(i)} \in \mathbb{R}$ are the nodal values of v_i. By (4.10)

$$\dim(R_{r_2}(E)) = \text{ cardinality}(\mathcal{F}_2(E))$$

so that there is a one-to-one *correspondence between nodes* $i \in \mathcal{F}_2(E)$ *and basis functions* $\lambda_{E,i} \in R_{r_2}(E)$ *such that*

$$R_{r_2}(E) = \text{ span } \{\lambda_{E,i} :\ i \in \mathcal{F}_2(E)\}. \tag{4.17}$$

Consider a degree of freedom associated with a node $i \in \mathcal{F}_2(E)$ that is precisely the nodal functional

$$N_i^{(2)}(v_2) := |E|^{-1} \langle v_2 \cdot \hat{n}_2,\ \lambda_{E,i} \rangle_E, \qquad |E| = \text{ measure } (E). \tag{4.18}$$

The basis functions are, by construction, dual with respect to these functionals:

$$N_i^{(2)}(\phi_j^{(2)}) = \delta_{ij} \qquad \text{for all } i,j \in \mathcal{F}_2. \tag{4.19}$$

From (4.18), (4.19), and the formula (4.16) for $v_i \cdot \hat{n}_i|_E$, we get

$$v_i^{(2)} = |E|^{-1}\langle v_2 \cdot \hat{n}_2,\ \lambda_{E,i}\rangle_E \quad \text{for all } i \in \mathcal{F}_2(E), E \in \mathcal{E}_h(\Gamma_I),\ v_2 \in X_2^h. \tag{4.20}$$

Consider the condition defining $V^h, b_I(v,\mu) = 0$ for all $\mu \in \Lambda^h$. Restricting μ to a generic basis function $\lambda_{E,i}$ for Λ^h gives

$$\langle v_2 \cdot \hat{n}_2, \lambda_{E,i}\rangle_E = -\langle v_1 \cdot \hat{n}_1, \lambda_{E,i}\rangle_E \qquad \text{for all } i \in \mathcal{F}_2(E),\ E \in \mathcal{E}_h(\Gamma_I). \tag{4.21}$$

Combining this with (4.20) gives

$$v_i^{(2)} = -|E|^{-1}\langle v_1 \cdot \hat{n}_1, \lambda_{E,i}\rangle_E \qquad \text{for all } i \in \mathcal{F}_2(E), E \in \mathcal{E}_h(\Gamma_I). \tag{4.22}$$

Inserting the expression of v_1 in terms of its nodal values (4.16) into (4.22) gives the following pointwise characterization of the space $v \in V^h$.

PROPOSITION 4.1. *Let $v = (v_1, v_2) \in X^h$ be given. Then $v \in V^h$ is equivalent to the following relation between the nodal values $v_i^{(1)}$ and $v_i^{(2)}$ of v_1 and v_2 on E being satisfied:*

$$v_i^{(2)} = -|E|^{-1} \sum_{j \in \mathcal{F}_1(E)} v_j^{(1)} \langle \phi_j^{(1)} \cdot \hat{n}_1,\ \lambda_{E,i}\rangle_E \quad \text{for all } i \in \mathcal{F}_2(E),\ \ E \in \mathcal{E}_h(\Gamma_I). \tag{4.23}$$

∎

REMARK 4.4. *The relation* (4.23) *can be interpreted to mean that the nodes*

$$i \in \bigcup_{E \in \mathcal{E}_h(\Gamma_I)} \mathcal{F}_2(E)$$

are "hanging nodes" in that values of the function $v \in V^h$ are determined by the corresponding values at the nodes $j \in \cup_{E \in \mathcal{E}_h(\Gamma_I)}\ \mathcal{F}_1(E)$.

4.2. Inf-sup conditions for the coupled problem. The discrete formulation (4.15) leads to the question of an inf-sup condition in $V^h \times M^h$. We show next that the usual fluid's velocity-pressure discrete inf-sup condition (4.1) in fact implies the needed $V^h \times M^h$ inf-sup condition.

LEMMA 4.3. *Suppose that (X_1^h, M_1^h) satisfies the discrete* inf-sup *condition* (4.1). *Then, (V^h, M^h) is LBB-stable as well. Specifically,*

$$\inf_{q^h \in M^h} \sup_{V^h \in V^h} \frac{b(v^h, q^h)}{\|v^h\|_X\ \|q^h\|_M} \geq \beta > 0. \tag{4.24}$$

Proof. Let $q^h = (q_1^h, q_2^h) \in M^h \subset M$ be given and let $\tilde{q} \in L_0^2(\Omega)$ denote the function with $\tilde{q}|_{\Omega_i} = q_i^h$. Then it is known, e.g., [13, 15, 7], that there exists $\tilde{v} \in H^1(\Omega)^d$ with

$$\nabla \cdot \tilde{v} = -\tilde{q} \text{ in } \Omega,\ \tilde{v} = 0 \text{ on } \partial\Omega,$$

satisfying

$$\|\tilde{v}\|_{1,\Omega} \le C\|\tilde{q}\|_{0,\Omega}.$$

Define $v = (v_1, v_2) \in X$ by $v_i = \tilde{v}|_{\Omega_i},\ i = 1, 2$, so that

$$b(v, q^h) = -(\nabla \cdot \tilde{v}, \tilde{q})_\Omega = \|\tilde{q}\|^2_{0,\Omega} = \|q^h\|^2_M.$$

The above a priori bound on $\tilde{v}$ implies

$$b(v, q^h) \ge \frac{1}{C}\ \|\tilde{v}\|_{1,\Omega}\ \|q^h\|_M,$$

which implies an inf-sup condition, similar to (4.24), only over (V, M^h) rather than (V^h, M^h).

To prove the condition (4.24) over (V^h, M^h), we now construct (following Fortin's idea) an operator $\Pi^h : X_1 \times (X_2 \cap (H^1(\Omega_2))^d) \to V^h$ with

$$b(\Pi^h v - v, q^h) = 0 \text{ for all } q^h \in M^h \text{ and } \|\Pi^h v\|_X \le C\|\tilde{v}\|_{1,\Omega}.$$

Indeed, if such an operator exists, then we have

$$\frac{1}{C}\|q^h\|_M \le \frac{b(v, q^h)}{\|\tilde{v}\|_{1,\Omega}} = \frac{b(\Pi^h v, q^h)}{\|\tilde{v}\|_{1,\Omega}} \le \frac{b(\Pi^h v, q^h)}{\frac{1}{C}\|\Pi^h v\|_X} \qquad \text{for all } q^h \in M^h,$$

which would prove (4.24).

Let $\Pi^h v = (\Pi^h_1 v, \Pi^h_2 v) \in X^h_1 \times X^h_2$. To define Π^h_1, note that since (X^h_1, M^h_1) is LBB-stable, by Lemma 1.1 in Chapter II section 1.1 of [15], there exists an operator $i^h_1 : X_1 \to X^h_1$ satisfying, for all $v_1 \in X_1$,

$$b_1(i^h_1 v_1 - v_1, q^h_1) = 0 \qquad \text{for all } q^h_1 \in M^h_1$$

and

$$\|i^h_1 v_1\|_{X_1} \le C\|v_1\|_{X_1}.$$

Thus, define

$$\Pi^h_1 v := i^h_1 v_1 \in X^h_1.$$

Next, construct a $w_2 \in (H^1(\Omega_2))^d$ with

$$\begin{cases} \nabla \cdot w_2 = \nabla \cdot v_2 \text{ in } \Omega_2, \\ w_2 = 0 \text{ on } \Gamma_2 \text{ and } w_2 = \Pi^h_1 v \text{ on } \Gamma_I. \end{cases} \tag{4.25}$$

Indeed, let $g \in L^2(\partial\Omega_2)$ be given by

$$g = \begin{cases} 0 \text{ on } \Gamma_2, \\ \Pi^h_1 v \text{ on } \Gamma_I. \end{cases}$$

Since $\Pi^h_1 v = 0$ on $\partial\Gamma_I, \Pi^h_1 v \in H^{1/2}_{00}(\Gamma_I)^d$. Thus, $g \in H^{1/2}(\partial\Omega_2)^d$ and

$$\begin{aligned} \|g\|_{1/2,\partial\Omega_2} &\le C\|\Pi^h_1 v\|_{1/2,\Gamma_I} \le C\|\Pi^h_1 v\|_{1/2,\partial\Omega_1} \\ &\le C\|\Pi^h_1 v\|_{1,\Omega_1} \le C\|i^h_1 v_1\|_{X_1} \le C\|v_1\|_{1,\Omega_1}. \end{aligned}$$

Thus, there exists an extension $z \in H^1(\Omega_2)^d$ with

$$z = g \text{ on } \partial\Omega, \|z\|_{1,\Omega_2} \leq C\|g\|_{1/2,\partial\Omega_2} \leq C\|v_1\|_{1,\Omega_1}.$$

Next, write $w_2 = z + w_0$, where w_0 satisfies

$$\nabla \cdot w_0 = \nabla \cdot (v_2 - z) \text{ in } \Omega_2, w_0 = 0 \text{ on } \partial\Omega_2.$$

The solution to this problem $w_0 \in H^1(\Omega)^d$ exists [15] and satisfies

$$\begin{aligned}\|w_0\|_{1,\Omega_2} &\leq C\|\nabla \cdot (v_2 - z)\|_{0,\Omega_2} \leq C(\|v_2\|_{1,\Omega_2} + \|z\|_{1,\Omega_2}) \\ &\leq C\{\|v_2\|_{1,\Omega_2} + \|v_1\|_{1,\Omega_1}\} \leq C\|\tilde{v}\|_{1,\Omega}.\end{aligned}$$

The function w_2, so constructed, satisfies (4.25) and

$$\|w_2\|_{1,\Omega_2} \leq C\|\tilde{v}\|_{1,\Omega}. \tag{4.26}$$

Finally, define $\Pi_2^h v$ as the finite element (quasi) interpolant of $w_2 \in X_2$,

$$\Pi_2^h v := I_{X_2}^h w_2 \in X_2^h.$$

From the assumed properties of $I_{X_2}^h$, (4.14) with $s = m = 1$, we get

$$\|I_{X_2}^h w_2\|_{1,K} \leq C\|w_2\|_{1,K},$$

so that (squaring and summing over $K \in \mathcal{T}_2^h$)

$$\begin{aligned}\|I_{X_2}^h w_2\|_{X_2}^2 &= \sum_{K \in \mathcal{T}_2^h} \{\|I_{X_2}^h w_2\|_{0,K}^2 + \|\nabla \cdot I_{X_2}^h w_2\|_{0,K}^2\} \\ &\leq C\|w_2\|_{1,\Omega_2}^2.\end{aligned}$$

This with (4.26) gives

$$\|\Pi_2^h v\|_{X_2} \leq C\|\tilde{v}\|_{1,\Omega},$$

which is one of the two required conditions on Π^h. Next, we show

$$b(\Pi^h v - v, q^h) = 0 \qquad \text{for all } q^h \in M^h.$$

Let $q^h = (q_1^h, q_2^h) \in M^h$. Then, for all $K \in \mathcal{T}_2^h$, $q_2^h|_K \in \mathcal{P}_{r_2}(K)$. We thus get from (4.7) and (4.25) that

$$(\nabla \cdot \Pi_2^h v, q_2^h) = (\nabla \cdot I_{X_2}^h w_2, q_2^h)_K = (\nabla \cdot w_2, q_2^h)_K = (\nabla \cdot v_2, q_2^h)_K.$$

Thus, by summing over K, we get

$$b_2(\Pi_2^h v, q_2^h) = b_2(v_2, q_2^h) \qquad \text{for all } q_2^h \in M_2^h. \tag{4.27}$$

Now, let $E \in \mathcal{E}_h(\Gamma_I)$ be an element face on the interface and let $\mu \in R_{r_2}(E)$. Then, (4.9) in Lemma 4.2 implies (noting that $\Pi_2^h v = I_{X_2}^h w_2$)

$$\langle \Pi_2^h v \cdot \hat{n}_2, \mu\rangle_E = \langle I_{X_2}^h w_2 \cdot \hat{n}_2, \mu\rangle_E = \langle w_2 \cdot \hat{n}_2, \mu\rangle_E = \langle \Pi_1^h v \cdot \hat{n}_2, \mu\rangle_E,$$

where the fact that $w_2 = \Pi_1^h v$ on Γ_I (see (4.25)) was used. Thus

$$\langle \Pi_1^h v \cdot \hat{n}_1 + \Pi_2^h v \cdot \hat{n}_2, \mu \rangle_E = 0 \qquad \text{for all } \mu \in R_{r_2}(E).$$

The definition of Λ^h and summing over $E \subset \Gamma_I$ now implies that

$$\langle \Pi_1^h v \cdot \hat{n}_1 + \Pi_2^h v \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} = 0 \qquad \text{for all } \mu^h \in \Lambda^h. \tag{4.28}$$

In other words, $\Pi^h v = (\Pi_1^h v_1, \Pi_2^h v_2) \in V^h$. Since we have shown

$$b_j(\Pi_j^h v, q_j^h) = b_j(v_j, q_j^h), \ j = 1, 2,$$

it follows that

$$b(\Pi^h v, q^h) = b(v, q^h),$$

completing the proof. □

4.3. Approximation of the coupled problem in V^h. The finite element spaces X_1^h and X_2^h are well understood so the approximation properties of $X^h = X_1^h \times X_2^h$ are known and asymptotically optimal. On the other hand, the finite element space arising in the error analysis is V^h rather than X^h. If $X^h \times \Lambda^h$ satisfied a discrete inf-sup condition similar to (3.13), then the abstract theory of mixed methods [15, 7] would imply that the error in approximation in V^h would be comparable to that in $X^h \times \Lambda^h$. However, $\Lambda^h \not\subset \Lambda$ since functions in Λ^h do not vanish at $\partial\Gamma_I$ (a key condition in the continuous case). Therefore, we do not, in general, expect this discrete inf-sup condition to hold.

Thus, the approximation properties of

$$V^h = \{v^h \in X^h : \langle v_1^h \cdot \hat{n}_1 + v_2^h \cdot \hat{n}_2, \mu \rangle_{\Gamma_I} = 0 \text{ for all } \mu \in \Lambda^h\}$$

must be delineated by a direct construction. Herein, we shall construct an interpolation operator

$$I^h := W \to V^h,$$

where W is a subspace of V of sufficiently smooth functions. To that end, we choose s_i sufficiently large and define W as follows:

$$\begin{aligned} W := \{v = (v_1, v_2) \in X : v_i \in W_i := X_i \cap (H^{s_i}(\Omega_i))^d, \ i = 1, 2, \\ \text{and } v_1 \cdot \hat{n}_2|_{\Gamma_I} = v_2 \cdot \hat{n}_2|_{\Gamma_I} \text{ in } L^2(\Gamma_I)\}. \end{aligned} \tag{4.29}$$

The construction of I^h will be based on the finite element interpolation operators: $I_{X_i}^h : W_i \to X_i^h$ $(i = 1, 2)$. Define $I^h = (I_1^h v, I_2^h v) \in V^h$ via

$$I_1^h v = I_{X_1}^h v_1 \in X_1^h, \qquad I_2^h v = I_{X_2}^h v_2 - \delta_2^h \in X_2^h,$$

where the (small) correction $\delta_2^h \in X_2^h$ is chosen to enforce in a discrete sense continuity of the normal velocities across Γ_I in (4.29).

Construction of the correction δ_2^h enforcing $I^h v \in V^h$. By the choice of $I_{X_2}^h$ and Λ^h we get the following relation for all $\mu^h \in \Lambda^h$:

$$\begin{aligned} &\langle I_1^h v \cdot \hat{n}_1 + I_2^h v \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} \\ &\quad = -\langle I_{X_1}^h v_1 \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} + \langle v_2 \cdot \hat{n}_2, \mu_h \rangle_{\Gamma_I} - \langle \delta_2^h \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} \\ &\quad = \langle (v_1 - I_{X_1}^h v_1) \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} - \langle \delta_2^h \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I}. \end{aligned} \tag{4.30}$$

To construct δ_2^h we shall first construct $\delta_2 \in X_2 \cap (H^1(\Omega_2))^d$ such that

$$\delta_2 = v_1 - I_{X_1}^h v_1 \text{ on } \Gamma_I, \text{ and } \|\delta_2\|_{1,\Omega_2} \le C|v_1 - I_{X_1}^h v_1|_{1,\Omega_1}. \tag{4.31}$$

To this end, let g_2 extend $v_1 - I_{X_1}^h v_1$ by zero to $\partial\Omega_2$:

$$g_2 := \begin{cases} v_1 - I_{X_1}^h v_1 \text{ on } \Gamma_I, \\ 0 \text{ on } \Gamma_2 = \partial\Omega_2 \setminus \Gamma_I. \end{cases}$$

Since $(v_1 - I_{X_1}^h v_1) = 0$ on $\partial\Gamma_I, (v_1 - I_{X_1}^h v_1) \in H_{00}^{1/2}(\Gamma_I)$ so $g_2 \in H^{1/2}(\partial\Omega_2)^d$. Further, we have the bound

$$\begin{aligned} \|g_2\|_{1/2,\partial\Omega_2} &\le C\|v_1 - I_{X_1}^h v_1\|_{1/2,\Gamma_I} \le C\|v_1 - I_{X_1}^h v_1\|_{1/2,\partial\Omega_1} \\ &\le C\|v_1 - I_{X_1}^h v_1\|_{1,\Omega_1} \le C|v_1 - I_{X_1}^h v_1|_{1,\Omega_1}. \end{aligned}$$

Since $H^{1/2}(\partial\Omega_2)^d$ is the range of the trace operator on $H^1(\Omega_2)^d$, we can find a $\delta_2 \in H^1(\Omega_2)^d$ extending g_2 onto Ω_2 and satisfying

$$\|\delta_2\|_{1,\Omega_2} \le C\|g_2\|_{1/2,\partial\Omega_2} \le C|v_1 - I_{X_1}^h v_1|_{1,\Omega_1}.$$

Define δ_2^h as the interpolant of this extension:

$$\delta_2^h := I_{X_2}^h \delta_2. \tag{4.32}$$

The property (4.9) of $I_{X_2}^h(\cdot)$ implies that for $\mu^h \in \Lambda^h$

$$\langle \delta_2^h \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} = \langle \delta_2 \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} = \langle (v_1 - I_{X_1}^h v_1) \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I}.$$

Combining this with (4.30) gives

$$\langle I_1^h v \cdot \hat{n}_1 + I_2^h v \cdot \hat{n}_2, \mu^h \rangle_{\Gamma_I} = 0 \qquad \text{for all } \mu^h \in \Lambda^h, \tag{4.33}$$

implying that $(I_1^h v, I_2^h v) \in V^h$. Thus, this completes the construction of $I^h : W \to V^h$. We shall need an estimate of the correction term $\|\delta_2^h\|_{X_2}$ developed as follows.

From the interpolation error estimates we get, for every $K \in \mathcal{T}_2^h$,

$$\|\delta_2^h\|_{1,K} \le \|\delta_2\|_{1,K} + \|\delta_2 - I_{X_2}^h \delta_2\|_{1,K} \le C\|\delta_2\|_{1,K}.$$

Thus, (summing over $K \subset \Omega_2$)

$$\|\delta_2^h\|_{X_2} = \left\{ \|\delta_2^h\|_{0,\Omega_2}^2 + \|\nabla \cdot \delta_2^h\|_{0,\Omega_2}^2 \right\}^{1/2} \le \left\{ \sum_{K \in \mathcal{T}_2^h} \|\delta_2^h\|_{1,K}^2 \right\}^{1/2},$$

which implies

$$\|\delta_2^h\|_{X_2} \le C\|\delta_2\|_{1,\Omega_2} \le C|v_1 - I_{X_1}^h v_1|_{1,\Omega_1}. \tag{4.34}$$

Bound (4.34) now gives interpolation error estimates for $I_1^h v = I_{X_1}^h v_1$ and $I_2^h v = I_{X_2}^h v_2 - \delta_2^h$:

$$\begin{aligned} \|v - I^h v\|_X &\le |v_1 - I_1^h v|_{1,\Omega_1} + \|v_2 - I_2^h v\|_{X_2} \\ &\le C|v_1 - I_{X_1}^h v_1|_{1,\Omega_1} + \|v_2 - I_{X_2}^h v_2\|_{X_2}. \end{aligned} \tag{4.35}$$

Combining these with the estimates for $I^h_{X_j}$ (see (4.3)),

$$|v_1 - I^h_{X_1} v_1|_{1,\Omega_1} \le C \left\{ \sum_{K \in \mathcal{T}_1^h} \left(h_K^{r_1} |v_1|_{r_1+1,\delta(K)}\right)^2 \right\}^{1/2},$$

$$\|v_2 - I^h_{X_2} v_2\|_{X_2} \le C \left\{ \sum_{K \in \mathcal{T}_2^h} \left(h_K^{r_2+1} (|v_2|_{r_2+1,K} + |\nabla \cdot v_2|_{r_2+1,K})\right)^2 \right\}^{1/2},$$

and using (4.4) and the fact that an element $\widetilde{K}$ can belong at most to a finite number $n(\widetilde{K}) \le C$ of local patches $\delta(K)$ leads to the following result.

PROPOSITION 4.2. *For all $v \in W \subset V$ (given by (4.29)), the interpolation operator $I^h : W \to V^h$ satisfies*

$$\|v - I^h v\|_X \le C \left\{ \sum_{K \in \mathcal{T}_1^h} (h_K^{r_1} |v_1|_{r_1+1,K})^2 + \sum_{K \in \mathcal{T}_2^h} \left(h_K^{r_2+1} \left(|v_2|_{r_2+1,K} + |\nabla \cdot v_2|_{r_2+1,K}\right)\right)^2 \right\}^{1/2}. \qquad \square$$

4.4. Discretization error estimates. Since, as noted above, $\Lambda^h \not\subset \Lambda$ and $V^h \not\subset V$, the associated discretizations of *either* saddle point formulations contain an extra *consistency error* which must be estimated using the earlier constructions. Indeed, the abstract error estimates from Brezzi and Fortin [7, Chap. II, sect. 2.6, Proposition 2.16] give the following.

LEMMA 4.4. *Let $(u, p) \in V \times M$ be the solution of the weak formulation (2.5) of the coupled problem. Let $(u^h, p^h) \in V^h \times M^h$ be the solution of the discrete problem (4.15). Let the finite element spaces be chosen as in subsection 4.1, satisfying LBB-stability (subsection 4.2) and approximability (subsection 4.3). Then,*

$$\|u - u^h\|_X + \|p - p^h\|_M \le C \left\{ \inf_{v^h \in V^h} \|u - v^h\|_X + \inf_{q^h \in M^h} \|p - q^h\|_M \right\} + \mathcal{H}^h,$$

where

$$\mathcal{H}^h := \sup_{v^h \in V^h} \frac{|a(u, v^h) + b(v^h, p) - \ell(v^h)|}{\|v^h\|_X}$$

is the consistency error. $\square$

The error analysis thus depends on obtaining a bound on the consistency error term $\mathcal{H}^h$. To this end, suppose the weak solution (u, p) to the coupled problem is smooth enough (to be made precise soon) and that $\lambda \in H^s(\Gamma_I)$ (for some s depending on the smoothness of (u, p)), where λ is defined in (2.2).

The variational formulation (2.4) of (u, p, λ) in (X, M, Λ) implies that

$$a(u, v^h) + b(v^h, p) + \langle \lambda, v_1^h \cdot \hat{n}_1 + v_2^h \cdot \hat{n}_2 \rangle_{\Gamma_I} = \ell(v^h) \qquad \text{for all } v^h \in X^h.$$

Thus, if we define the consistency error functional

$$\theta(v^h) := a(u, v^h) + b(v^h, p) - \ell(v^h), \qquad v^h \in X^h,$$

it follows that

$$\theta(v^h) = -\langle v_1^h \cdot \hat{n}_1 + v_2^h \cdot \hat{n}_2, \lambda \rangle_{\Gamma_I} \qquad \text{for all } v^h \in V^h \subset X^h.$$

LEMMA 4.5 (consistency error estimate). *For all $v^h \in V^h$, there holds*

$$|\theta(v^h)| \le C \left\{ \sum_{E \in \mathcal{E}_h(\Gamma_i)} (h_E^s |\lambda|_{s,E})^2 \right\}^{1/2} \|v^h\|_X, \tag{4.36}$$

for $0 \le s \le r_2 + 1$.

Proof. Let $\mu^h \in \Lambda^h$ denote the $L^2(\Gamma_I)$ projection of λ into Λ^h. Since Λ^h consists of *discontinuous* piecewise polynomials, the orthogonality relation for μ^h holds edge by edge:

$$\langle \lambda - \mu^h, w \rangle_E = 0 \qquad \text{for all } w \in R_{r_2}(E), \text{ for all } E \in \mathcal{E}_h(\Gamma_I). \tag{4.37}$$

From the definition of V^h it follows that, for all $v^h \in V^h$,

$$\begin{aligned} \theta(v^h) &= \langle v_1^h \cdot \hat{n}_1 + v_2^h \cdot \hat{n}_2,\ \mu^h - \lambda \rangle_{\Gamma_I} \\ &= \langle v_1^h \cdot \hat{n}_1, \mu^h - \lambda \rangle_{\Gamma_I} + \sum_{E \in \mathcal{E}_h(\Gamma_I)} \langle \mu^h - \lambda, v_2^h \cdot \hat{n}_2 \rangle_E. \end{aligned}$$

By Lemma 4.2 we have that

$$w = v_2^h \cdot \hat{n}_2|_E \in R_{r_2}(E) \qquad \text{for all } E \in \mathcal{E}(K),\ K \in \mathcal{T}_2^h,$$

which implies

$$\langle \mu^h - \lambda, v_2^h \cdot \hat{n}_2 \rangle_E = 0 \qquad \text{for all } E \in \mathcal{E}_h(\Gamma_I).$$

Thus, $\theta(v^h) = \langle v_1^h \cdot \hat{n}_1, \mu^h - \lambda \rangle_{\Gamma_I}$, for all $v^h \in V^h$, and it follows that

$$\begin{aligned} |\theta(v^h)| &\le \sum_{E \in \mathcal{E}_h(\Gamma_I)} \|v_1^h\|_{0,E} \|\lambda - \mu^h\|_{0,E} \\ &\le \left(\sum_{E \in \mathcal{E}_h(\Gamma_I)} \|\lambda - \mu^h\|_{0,E}^2 \right)^{1/2} \|v_1^h\|_{0,\Gamma_I}. \end{aligned} \tag{4.38}$$

By the trace theorem and the Poincaré–Friedrichs inequality,

$$\|v_1^h\|_{0,\Gamma_I} \le C \|v^h\|_X.$$

Since μ^h is the $L^2(E)$ projection of λ into $R_{r_2}(E)$ by (4.37), it follows that

$$\|\lambda - \mu^h\|_{0,E} \le C h_E^s |\lambda|_{s,E}, \qquad \text{for } 0 \le s \le r_2 + 1,\ E \in \mathcal{E}_h(\Gamma_I).$$

Using the last two bounds in (4.38) completes the proof. ∎

Lemma 4.4 immediately yields a bound on the consistency error term $\mathcal{H}^h$.

COROLLARY 4.1. *There holds*

$$\mathcal{H}^h \le C \left\{ \sum_{E \in \mathcal{E}_h(\Gamma_I)} (h_E^s |\lambda|_{s,E})^2 \right\}^{1/2}, \quad \textit{for } 0 \le s \le r_2 + 1. \qquad \blacksquare$$

This bound can now be used in the abstract error estimate in Lemma 4.3 to yield a convergence theorem.

THEOREM 4.1. *Let the weak solution (u,p) to (2.5) be sufficiently smooth (that the norms in (4.39) are finite). Let $(u^h,p^h)\in V^h\times M^h$ be the finite element approximation to (u,p). Then,*

$$\begin{aligned}\|u-u^h\|_X+\|p-p^h\|_M \le C\Bigg\{&\Bigg\{\sum_{K\in\mathcal{T}_1^h}\left(h_K^{s_1}(|u_1|_{s_1+1,K}+|p_1|_{s_{1,K}})\right)^2\Bigg\}^{1/2}\\ &+\Bigg\{\sum_{K\in\mathcal{T}_2^h}\left(h_K^{\tilde{s}_2}|u_2|_{\tilde{s}_2,K}+h_K^{s_2}(|p_2|_{s_2,K}+|\nabla\cdot u_2|_{s_2,K})\right)^2\Bigg\}^{1/2}\\ &+\Bigg\{\sum_{E\in\mathcal{E}_h(\Gamma_I)}(h_E^{s_2}|\lambda|_{s_2,E})^2\Bigg\}^{1/2}\Bigg\},\\ &1\le s_1\le r_1,\ 1\le\tilde{s}_2\le r_2+1,\ 0\le s_2\le l_2+1.\end{aligned}\tag{4.39}$$

∎

REMARK 4.5. *Theorem 4.1 implies optimal error bounds in both the fluid region and in the porous medium region.*

REMARK 4.6. *We have just learned of the concurrent work of Discacciati, Miglio, and Quarteroni [11] on a closely related problem. They consider Stokes–Darcy coupling with a free slip condition on Γ_I (i.e., $\alpha_1=0$ in (1.6)) and the formulation of the Darcy model as a Poisson problem rather than as a mixed method, and they obtain interesting results.*

FLEXIBLE INNER-OUTER KRYLOV SUBSPACE METHODS*

VALERIA SIMONCINI† AND DANIEL B. SZYLD‡

Abstract. Flexible Krylov methods refers to a class of methods which accept preconditioning that can change from one step to the next. Given a Krylov subspace method, such as CG, GMRES, QMR, etc. for the solution of a linear system $Ax = b$, instead of having a fixed preconditioner M and the (right) preconditioned equation $AM^{-1}y = b$ ($Mx = y$), one may have a different matrix, say M_k, at each step. In this paper, the case where the preconditioner itself is a Krylov subspace method is studied. There are several papers in the literature where such a situation is presented and numerical examples given. A general theory is provided encompassing many of these cases, including truncated methods. The overall space where the solution is approximated is no longer a Krylov subspace but a subspace of a larger Krylov space. We show how this subspace keeps growing as the outer iteration progresses, thus providing a convergence theory for these inner-outer methods. Numerical tests illustrate some important implementation aspects that make the discussed inner-outer methods very appealing in practical circumstances.

Key words. flexible or inner-outer Krylov methods, variable preconditioning, nonsymmetric linear system, iterative solver

AMS subject classifications. 65F10, 15A06

1. Introduction.

Consider the iterative solution of large sparse (symmetric or) nonsymmetric linear systems of equations of the form

$$Ax = b. \tag{1.1}$$

In recent years, several authors studied Krylov subspace methods with variable (or flexible) preconditioning, i.e., preconditioning with a different (possibly nonlinear) operator at each iteration of a Krylov subspace method. These include [1], [17], [27], [29], [36], [37], and [39]. The usual (right) preconditioning consists of replacing (1.1) by

$$AM^{-1}y = b, \quad \text{with} \quad Mx = y, \tag{1.2}$$

for a suitable preconditioner M. One of the motivations for methods with variable preconditioners is the need to solve each preconditioning equation

$$Mz = v \tag{1.3}$$

only inexactly, as is done, e.g., in [12], using multigrid or, in [40], using a two-stage preconditioner, one of which is inexact; see also [4]. This implies that we have (implicitly) a different M at the kth step of the Krylov method. One can also consider preconditioners which might improve using information from previous iterations; cf. [2], [13], [21].

The research of this author was supported in part by the National Science Foundation under grant DMS-0207525. Part of this paper was prepared while this author visited the Università di Bologna, within the 2001 I.N.d.A.M. project "Problemi di perturbazione singolare: tecniche adattive e di decomposizione dei dominii."

Experiments have been reported in the literature, where the preconditioner in (1.3) is itself a Krylov subspace method. For example, some versions of GMRESR [37] fit this description [6]. We refer to [39] for a more detailed analysis specific to GMRESR versus FGMRES. In [5], [29], one has GMRES for the preconditioner, or inner iterations, and FGMRES as the (outer) flexible method. In [36], QMR is the preconditioner and FQMR is the outer method. In all these cases, we can say that at the kth outer step (or cycle) the inner iterative method is stopped after a certain number m_k of (inner) iterations. This number is either fixed a priori, such as in [5], [29], [37], or is the consequence of some stopping criteria often involving the inner residual [1], [17], [36], [38].

In this paper we analyze the convergence theory of these inner-outer methods, i.e., flexible Krylov subspace methods preconditioned by (a possibly different) Krylov subspace method. The resulting class of methods can be characterized as those choosing at the kth cycle the approximate solution to (1.1) from a particular k-dimensional subspace of a larger Krylov subspace; see sections 2–5. We show that, as the method progresses, the dimensions of this subspace keeps growing, and thus the method converges. This finite termination property is not available for restarted methods, such as GMRES(m). In other words, by restricting ourselves to preconditioners which are Krylov methods, we maintain the global iteration within a larger Krylov subspace.

An alternative view of these inner-outer methods is to consider a Krylov method with polynomial preconditioning (see, e.g., [2], [11], [15], [20], [21], [28], [30]), where a new polynomial is implicitly chosen at each cycle by a Krylov method; cf. [14], [37], [38].

Our approach is very general, and thus our analysis applies to a variety of inner-outer methods. In particular, it applies to truncated Krylov methods, such as DQGMRES [32], when preconditioned with a Krylov subspace method. Several authors have suggested strategies on how to choose which vectors to keep in the truncated basis; see, e.g., [7], [38]. Our results in section 5 provide a theoretical foundation for some of these empirical recommendations.

In section 6 we discuss the possibility of breakdown and stagnation of the inner-outer methods. Since the residual of the inner method is deflated with respect to the previous vectors in the outer basis, stagnation is much less prevalent than in restarted methods.

In section 7 we show in some particular cases why these methods behave better than the corresponding restarted counterparts and illustrate this with additional numerical experiments. In our (albeit limited) computational experience, even in cases where at intermediate steps the restarted methods have a lower residual norm, the inner-outer methods outperform the restarted methods. These experiments demonstrate how competitive these inner-outer methods are. They are a very good alternative to restarted methods such as GMRES(m). We hope that the theory presented here, assuring convergence, together with the numerical evidence, will encourage more practitioners to try these inner-outer methods.

In this paper we concentrate on nonsymmetric systems, but most of our observations are valid for symmetric systems as well, where flexible CG-type methods can be employed [17], [27]. We also note that in our descriptions the coefficient matrix is assumed to be A, as in (1.1), although everything applies to a preconditioned matrix AP^{-1} as in (1.2), or $P^{-1}A$, for a suitable fixed preconditioner P. In fact, some of our experiments in section 8 are of this type, where P corresponds to an incomplete factorization of A.

Finally, we note that exact arithmetic is assumed throughout the paper, and that numerical experiments were carried out using Matlab 5.3 with machine epsilon $\epsilon = 2.2 \cdot 10^{-16}$ [23].

2. General setup. Given an initial guess x_0 to the solution of (1.1), and the corresponding residual $r_0 = b - Ax_0$, a Krylov subspace method generates a basis $\{v_1, v_2, \ldots, v_m\}$ of the Krylov subspace $\mathcal{K}_m(A, r_0) = \text{span}\{r_0, Ar_0, A^2r_0, \ldots, A^{m-1}r_0\}$. Let $V_m = [v_1, v_2, \ldots, v_m]$. An approximation to the solution of (1.1) is sought in $x_0 + \mathcal{K}_m(A, r_0)$, i.e., of the form $x_m = x_0 + V_m y_m$ for some $y_m \in \mathbb{R}^m$. The different methods arise by different choices of the basis defined by V_m and by different choices of y_m; see, e.g., [19], [30], for detailed description of these methods.

For example, in GMRES [31], the vectors in V_m are orthonormal, produced by the Arnoldi method with $v_1 = r_0/\beta$, $\beta = \|r_0\|$, the norm of the initial residual. Thus, the following relation holds:

$$AV_m = V_{m+1}H_m, \tag{2.1}$$

where H_m is upper Hessenberg of size $(m+1) \times m$. The vector y_m is chosen to minimize the norm of the residual $r_m = b - Ax_m$, i.e., find y_m which is the minimizer of

$$\min_{y \in \mathbb{R}^m} \|r_0 - AV_m y\| = \min_{y \in \mathbb{R}^m} \|V_{m+1}(\beta e_1 - H_m y)\|, \tag{2.2}$$

where e_1 is the first Euclidean vector. Our general analysis also includes truncated methods such as DQGMRES [32] as a possible outer subspace method, where only certain vectors of V_m are kept in storage. For example, one can keep the last ℓ columns of V_m (denote the $n \times \ell$ matrix containing these by $V_{m[\ell]}$). In this case, the minimization (2.2) is replaced by the minimization of

$$\min_{y \in \mathbb{R}^m} \|\beta e_1 - H_m y\|, \tag{2.3}$$

where H_m is banded with upper semibandwidth ℓ. In QMR [16], a relation like (2.1) holds, but V_m is not an orthogonal matrix (the basis is bi-orthogonal to a basis of another Krylov subspace; these bases are obtained via a two-sided Lanczos process), the minimization of (2.3) is performed, and H_m is tridiagonal.

When a standard right preconditioner is used, as in (1.2), the expression (2.1) becomes

$$AM^{-1}V_m = V_{m+1}H_m.$$

When flexible preconditioning is used, this relation is replaced with

$$AZ_m = V_{m+1}H_m, \tag{2.4}$$

cf. (1.3), and storage has to be allocated for both the matrices Z_m and V_m, i.e., one needs approximately twice the storage of the standard preconditioned case; see, e.g., [29], [36].

In order to analyze the inner-outer method, when the outer method is a flexible Krylov subspace method and the inner is a Krylov subspace method, we consider the approximations of the solution of (1.1) at the kth (outer) cycle to be taken from the affine space $x_0 + \text{span}\{z_1, \ldots, z_k\}$, where $Z_k = [z_1, \ldots, z_k]$, i.e., of the form

$$x_k = x_0 + Z_k u_k \quad \text{for some } u_k \in \mathbb{R}^k. \tag{2.5}$$

We change the notation a bit, to make a distinction with the inner method, and rewrite (2.4) as

$$AZ_k = W_{k+1}T_k, \tag{2.6}$$

i.e., $W_k = [w_1, \ldots, w_k]$ is the matrix containing a basis of the outer subspace, and the $(k+1) \times k$ matrix T_k contains the coefficients used in the orthogonalization (or deflation). The matrix T_k is either upper Hessenberg (if orthogonalization is used via the Arnoldi method), banded (if a truncated method is used), or tridiagonal (if the two-sided Lanczos method is used).

In other words, given x_0 and the corresponding residual

$$r_0 = b - Ax_0, \qquad w_1 = r_0/\beta, \qquad \beta = \|r_0\|, \tag{2.7}$$

for each cycle k, first a new vector z_k is computed, which approximates the solution of

$$Az = w_k \tag{2.8}$$

(using an inner Krylov method). Then, the vector Az_k is computed, orthogonalized with respect to the previous vectors w_i, $i \le k$ (or with respect to the ℓ vectors kept in the truncated version), and normalized (or bi-orthogonalized with respect to some other vectors) to obtain the new vector w_{k+1}; cf. (2.6). Thus, the residual at the kth cycle is

$$r_k = b - Ax_k = r_0 - AZ_k u_k = r_0 - W_{k+1}T_k u_k = W_{k+1}(\beta e_1 - T_k u_k). \tag{2.9}$$

We point out that in the case of using an Arnoldi method in the outer scheme, orthogonalizing Az_k with respect to the vectors in W_k is equivalent to deflating the inner residual $w_k - Az_k$ with respect to the vectors in W_k, i.e., with respect to all previous inner Krylov subspace starting vectors. In fact, we have

$$\begin{aligned} t_{k+1,k}w_{k+1} &= (I - W_k W_k^T)Az_k \qquad (2.10)\\ &= w_k - (w_k - Az_k) - w_k + W_k W_k^T(w_k - Az_k)\\ &= -(I - W_k W_k^T)(w_k - Az_k), \qquad (2.11) \end{aligned}$$

where W_k^T stands for the transpose of W_k.

As we said, at the kth cycle a new vector z_k is computed, which approximates the solution of (2.8), using an inner Krylov method. The corresponding (inner) Krylov subspace is $\mathcal{K}_m(A, w_k)$, with $m = m_k$, and its basis is $\{v_1^{(k)}, \ldots, v_m^{(k)}\}$, with

$$v_1^{(k)} = w_k \tag{2.12}$$

(of unit norm). The matrix $V_m^{(k)} = [v_1^{(k)}, \ldots, v_m^{(k)}]$ satisfies (2.1), i.e.,

$$AV_m^{(k)} = V_{m+1}^{(k)} H_m^{(k)}, \tag{2.13}$$

and we have

$$z_k = V_m^{(k)} y_k \quad \text{for some } \; y_k \in \mathbb{R}^m, \; m = m_k. \tag{2.14}$$

It is important to realize that when the inner system is preconditioned from the right, this can be viewed as a global preconditioning strategy. More precisely, consider

preconditioning the inner system (2.8) from the right with a fixed matrix P, so that the inner system transforms into $AP^{-1}\hat{z} = w_k$, with $z = P^{-1}\hat{z}$. An approximation to $\hat{z}$ is determined in $\mathcal{K}_m(AP^{-1}, w_k)$, from which an approximation to z can be readily recovered. Note that we can write $\hat{z}_k = V_m^{(k)} y_k$, where $V_m^{(k)}$ is now a basis for $\mathcal{K}_m(AP^{-1}, w_k)$. Let $Z_k = P^{-1}\hat{Z}_k = [P^{-1}\hat{z}_1, \ldots, P^{-1}\hat{z}_k]$. Relation (2.6) transforms into

$$AP^{-1}\hat{Z}_k = W_{k+1}T_k,$$

which immediately shows that inner preconditioning corresponds to applying the flexible method to the system $AP^{-1}\hat{x} = b$, with $\hat{x} = Px$. In light of these considerations, from now on we shall work with the coefficient matrix A, where A could actually stand for any preconditioned matrix AP^{-1}.

The description of flexible inner-outer methods by (2.5), (2.6), (2.13), and (2.14) is pretty general, and many of our results, including the following proposition, apply to this general setting.

PROPOSITION 2.1. *Each new vector of the outer basis w_{k+1} is a linear combination of the orthogonal projections of the columns $V_{m+1}^{(k)}$ (i.e., of the basis of the inner space $\mathcal{K}_{m+1}(A, w_k)$), onto the (bi-)orthogonal complement of $\mathcal{R}(W_k)$ (or $\mathcal{R}(W_{k[\ell]})$).*

Proof. From (2.14) and (2.13), we have $Az_k = AV_m^{(k)} y_k = V_{m+1}^{(k)}(H_m^{(k)} y_k)$, and from (2.10) the proposition follows. ∎

Note that while for each of the cycles we have the columns of $V_m^{(k)}$ being a basis of a Krylov subspace, neither $\mathcal{R}(W_k)$ nor $\mathcal{R}(Z_k)$, the range of W_k or Z_k, respectively, is a Krylov subspace. This is in contrast to the standard (nonflexible) preconditioned case. As pointed out, e.g., in [9], minimal residual or orthogonal residual methods with these bases would converge, as long as $\dim \mathcal{R}(W_k) = k$ and $\dim \mathcal{R}(Z_k) = k$, i.e., as long as the new vectors z_k and w_k are linearly independent of the previous ones so that the subspaces keep growing. As we shall see, this is the case for the inner-outer methods studied here.

We can say more; the columns of Z_k and those of W_k are bases of (different) subspaces (of dimension k) of a larger Krylov subspace generated by the initial residual r_0.

LEMMA 2.2. *Assume that Z_k and W_{k+1} are full column rank. Then, $\mathcal{R}(Z_k) \subset \mathcal{K}_{q-1}(A, r_0)$, and $\mathcal{R}(W_{k+1}) \subset \mathcal{K}_q(A, r_0)$, where $q = q_k = p_k + k$ and p_k is given by $p = p_k = \sum_{j=1}^{k} m_j$.*

Proof. We use induction on k. From (2.7), $\operatorname{span}\{w_1\} = \operatorname{span}\{r_0\}$. Therefore $z_1 \in \mathcal{K}_{m_1}(A, w_1) = \mathcal{K}_{m_1}(A, r_0)$ and $w_2 \in \operatorname{span}\{Az_1, w_1\} \subset \mathcal{K}_{m_1+1}(A, r_0)$, so that $\mathcal{R}(W_2) \subset \mathcal{K}_q(A, r_0)$ with $q = p_1 + 1 = m_1 + 1$. Assume that the assertions hold for $k-1$, and thus $w_k \in \mathcal{R}(W_k) \subset \mathcal{K}_q(A, r_0)$, with $q = q_{k-1}$. From (2.12), it follows that z_k belongs to the inner Krylov subspace $\mathcal{K}_m(A, w_k)$ $(m = m_k)$, which is a subspace of $\mathcal{K}_q(A, r_0)$ with $q = q_{k-1} + m_k = p_{k-1} + k - 1 + m_k = q_k - 1$. We then have that $w_{k+1} \in \operatorname{span}\{Az_k, W_k\} \subset \mathcal{K}_q(A, r_0)$, with $q = q_k$. ∎

This lemma also applies to truncated Krylov methods, since the vectors kept in storage are chosen from W_{k+1}, i.e., we have

$$\mathcal{R}(W_{k+1[\ell]}) \subset \mathcal{R}(W_{k+1}) \subset \mathcal{K}_q(A, r_0). \tag{2.15}$$

In the special case that all inner subspaces have the same dimension $m_j = m$, we have $p = km$ and $q = km + k = k(m+1)$; cf. [37, Lemma 4.2], where a result similar to Lemma 2.2 is shown for this special case.

We also remark that in [18] and [34] the situation is analyzed when (2.1) is replaced with $AU_{k-1} = U_k B_k$ for some matrix B_k and $\mathcal{R}(U_k)$ is some general subspace; cf. (2.6). The question there is to find an appropriate matrix E for which the columns of U_k are the basis of a Krylov subspace of $A + E$, i.e., $\mathcal{R}(U_k) = \mathcal{K}_k(A + E, r_0)$. Here we instead have subspaces of a larger Krylov subspace of A.

3. The subspaces of the inner-outer methods. In this section, we further characterize the k-dimensional subspaces $\mathcal{R}(Z_k)$ and $\mathcal{R}(W_k)$. Our characterization is of interest but does not necessarily reveal the intrinsic form of these subspaces. It does help us, though, in providing part of the setup used in section 5, where we show how these subspaces grow with each cycle.

The first simple observation is that the approximation x_k can be expressed as a particular linear combination of all the bases of the k inner Krylov subspaces. Indeed, from (2.5) and (2.14), it follows that

$$x_k = x_0 + \sum_{j=1}^{k} (u_k)_j \; z_j = x_0 + \sum_{j=1}^{k} (u_k)_j \; V_{m_j}^{(j)} \; y_j = x_0 + \sum_{j=1}^{k} \sum_{i=1}^{m_j} (u_k)_j \; (y_j)_i \; v_i^{(j)} \; .$$

Equivalently, if we define

$$\mathcal{B}_k = [V_{m_1}^{(1)}, V_{m_2}^{(2)}, \ldots, V_{m_k}^{(k)}] \in \mathbb{R}^{n \times p} \; , \quad Y_k = \begin{bmatrix} y_1 & O & O & \cdots \\ O & y_2 & O & \cdots \\ \vdots & & \ddots & \\ O & \cdots & O & y_k \end{bmatrix} \in \mathbb{R}^{p \times k} \; , \tag{3.1}$$

where O stands for a submatrix with zero entries (in this case $m \times 1$ submatrices, for different values of m), we have, from (2.14),

$$Z_k = \mathcal{B}_k Y_k, \tag{3.2}$$

and thus $x_k = x_0 + Z_k u_k = x_0 + \mathcal{B}_k(Y_k u_k)$. If we write the $n \times q$ matrix $\mathcal{B}'_k = [V_{m_1+1}^{(1)}, V_{m_2+1}^{(2)}, \ldots, V_{m_k+1}^{(k)}]$ and the $q \times p$ matrix $\mathcal{H}_k$ as the "block diagonal collection" of all $H_m^{(i)}$'s, we obtain the relation

$$A\mathcal{B}_k = \mathcal{B}'_k \mathcal{H}_k, \tag{3.3}$$

reminiscent of (2.13) or (2.1). Therefore, using (3.2) and (3.3),

$$r_k = r_0 - AZ_k u_k = r_0 - A\mathcal{B}_k Y_k u_k = r_0 - \mathcal{B}'_k(\mathcal{H}_k Y_k u_k), \tag{3.4}$$

providing an explicit representation of the residual in terms of the complete set of inner bases collected in $\mathcal{B}'_k$.

Remark 3.1. In light of Proposition 2.1 and (2.12), the columns of $\mathcal{B}'_k$ are not linearly independent. We then consider the $n \times (p+1)$ matrix

$$\mathcal{V}_k = [w_1, V_{2:m_1+1}^{(1)}, V_{2:m_2+1}^{(2)}, \ldots, V_{2:m_k+1}^{(k)}], \tag{3.5}$$

where $V_{2:m+1}^{(j)} = [v_2^{(j)}, \ldots, v_m^{(j)}]$, $m = m_j$. If the matrix $\mathcal{V}_k$ is of full rank, we have

$$\mathcal{R}(\mathcal{V}_k) = \mathcal{K}_{p+1}(A, r_0).$$

In other words, the columns of the matrix $\mathcal{V}_k$ (if full rank) provides us with a basis for the Krylov subspace $\mathcal{K}_{p+1}(A, r_0)$ from where the global iterates are computed; see [33], where a similar construct is used. In general, we can conclude only that

$$\mathcal{R}(\mathcal{V}_k) \subseteq \mathcal{K}_{p+1}(A, r_0). \tag{3.6}$$

In light of Lemma 2.2, the relation (3.2) is natural, and by Remark 3.1 we can improve upon the dimension of the Krylov subspace from Lemma 2.2 to obtain

$$\mathcal{R}(Z_k) \subset \mathcal{K}_p(A, r_0), \qquad p = p_k. \tag{3.7}$$

We now want to find a similar explicit dependence of W_{k+1} on $\mathcal{B}'_k$ or $\mathcal{V}_k$. We consider two cases: when the columns of W_{k+1} are produced by an Arnoldi method or by a two-sided Lanczos algorithm.

LEMMA 3.2. *If the Arnoldi method is used to generate Z_k, W_k, the bases of the outer spaces, related by* (2.6)*, and these have full column rank, then,*

$$W_{k+1} = \mathcal{V}_k R_k, \tag{3.8}$$

with $R_k = G_k S_k^{-1}$, where the $(p+1) \times (k+1)$ matrix G_k and the $(k+1) \times (k+1)$ matrix S_k are given by

$$G_k = \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots \\ O & -\hat{g}_1 & O & O & \cdots \\ O & O & -\hat{g}_2 & O & \cdots \\ \vdots & & & \ddots & \\ O & O & O & \cdots & -\hat{g}_k \end{bmatrix}, \qquad S_k = \begin{bmatrix} 1 & 0 & t_{1,2} & t_{1,3} & \\ 0 & t_{2,1} & 0 & t_{2,3} & \ddots \\ 0 & 0 & t_{3,2} & 0 & \ddots \\ 0 & 0 & 0 & t_{4,3} & \ddots \\ \vdots & & & & \vdots \\ 0 & 0 & 0 & 0 & t_{k+1,k} \end{bmatrix},$$

$\hat{g}_k \in \mathbb{R}^m$ is defined through $g_k = e_1 - H_m^{(k)} y_k = [\gamma_k; \hat{g}_k^T]^T$, and the $(k+1) \times k$ upper Hessenberg matrix T_k has entries t_{ij}.

Proof. Using (2.13), (2.14), and the definition of g_k,

$$Az_k = AV_m^{(k)} y_k = V_{m+1}^{(k)} H_m^{(k)} y_k = V_{m+1}^{(k)}(e_1 - g_k).$$

Then, by (2.12) and the fact that we use the Arnoldi method,

$$t_{k,k} = w_k^T A z_k = w_k^T V_{m+1}^{(k)}(e_1 - g_k) = e_1^T(e_1 - g_k) = 1 - \gamma_k. \tag{3.9}$$

We can use these relations to write w_{k+1} as a linear combination of the inner bases.

$$\begin{aligned} w_{k+1} t_{k+1,k} &= Az_k - W_k T_{1:k,k} \\ &= V_{m+1}^{(k)}(e_1 - g_k) - W_{k-1} T_{1:k-1,k} - w_k t_{k,k} \\ &= v_1^{(k)}(1 - \gamma_k) - [v_2^{(k)}, \ldots, v_{m+1}^{(k)}]\hat{g}_k - W_{k-1} T_{1:k-1,k} - w_k t_{k,k} \\ &= -[v_2^{(k)}, \ldots, v_{m+1}^{(k)}]\hat{g}_k - [w_1, w_2, \ldots, w_{k-1}] T_{1:k-1,k}, \end{aligned}$$

that is,

$$[w_1, w_2, \ldots, w_{k+1}] \begin{bmatrix} T_{1:k-1,k} \\ 0 \\ t_{k+1,k} \end{bmatrix} = -V_{2:m+1}^{(k)} \hat{g}_k.$$

Collecting all terms, we obtain

$$W_{k+1}S_k = [w_1, V^{(1)}_{2:m+1}, V^{(2)}_{2:m+1}, \ldots, V^{(k)}_{2:m+1}] \begin{bmatrix} 1 & 0 & 0 & 0 & \cdots \\ O & -\hat{g}_1 & O & O & \cdots \\ O & O & -\hat{g}_2 & O & \cdots \\ \vdots & & & \ddots & \\ O & O & O & \cdots & -\hat{g}_k \end{bmatrix}.$$

The lemma follows from the nonsingularity of the upper triangular matrix S_k. ∎

The same result (3.8) holds in the case of two-sided Lanczos. The difference is that the matrix T_k is tridiagonal, so that the entries above the third diagonal in S_k are zero. The proof proceeds in the same manner as that of Lemma 3.2, except that in (3.9) w_k is replaced by the corresponding vector of the bi-orthogonal basis to $\mathcal{R}(W_k)$.

It follows from (3.8) and Remark 3.1 that

$$\mathcal{R}(W_{k+1[\ell]}) \subset \mathcal{R}(W_{k+1}) \subset \mathcal{K}_{p+1}(A, r_0), \qquad p = p_k;$$

cf. (2.15), Lemma 2.2, and (3.7).

To complete the picture, we want to obtain relations of the form (3.3) and (3.4), using the matrix $\mathcal{V}_k$. If full rank, its columns are a basis of the global subspace $\mathcal{K}_{p+1}(A, r_0)$.

Let P be the $q \times q$ permutation matrix that moves all vectors $v_1^{(2)}, v_1^{(3)}, \ldots, v_1^{(k)}$ in $\mathcal{B}'_k$ to the end (that is, as the last columns of the whole matrix). Then we can write $\mathcal{B}'_k P = [\mathcal{V}_k, v_1^{(2)}, v_1^{(3)}, \ldots, v_1^{(k)}] = [\mathcal{V}_k, W_{2:k}]$, where $W_{2:k} = [w_2, w_3, \ldots, w_k] = W_{k+1}[O, I_{k-1}, O]^T$, I_{k-1} is the identity of order $k-1$. Thus, using (3.8), we write

$$\mathcal{B}'_k = \mathcal{V}_k \, [I, R_k[O, I_{k-1}, O]^T]P^T, \tag{3.10}$$

where I is the identity of order $p+1$, obtaining from (3.3) the desired relation

$$A\mathcal{B}_k = \mathcal{V}_k \, [I, R_k[O, I_{k-1}, O]^T]P^T\mathcal{H}_k =: \mathcal{V}_k N_k. \tag{3.11}$$

Similarly, using the definition of N_k in (3.11), replacing (3.10) in (3.4), and using (2.7), we obtain,

$$r_k = r_0 - \mathcal{V}_k N_k Y_k u_k = \mathcal{V}_k(\beta e_1 - N_k Y_k u_k). \tag{3.12}$$

4. Minimal residuals and other methods. The discussion so far applies to any Krylov subspace method including CG, MINRES, GMRES, QMR, FOM, BiCG, etc. In principle, the outer (flexible) method can be any one of them, while the inner method can be any other. In practice, FGMRES-GMRES(m), GCR-GMRES(m), and FQMR-QMR were considered [5], [6], [29], [36], [37]. GMRES is a minimal residual method [31], while QMR [16] can be seen as one if the appropriate inner product and associated norm are considered; see [9]. In fact, the proof in [9, section 4.3] applies equally well to truncated GMRES methods such as DQGMRES; we more generally call these flexible truncated GMRES (FTGMRES). Therefore, when we consider that the inner-outer method is FGMRES-GMRES(m), our analysis will equally apply to the cases of FQMR-QMR and FTGMRES-GMRES(m) with the proviso that the norm at each cycle is a different one.

In FGMRES-GMRES(m), z_k in (2.14) is chosen as to minimize the inner residual in the kth cycle, i.e.,

$$\|w_k - Az_k\| = \|w_k - AV_m^{(k)}y_k\| = \|V_m^{(k)}(e_1 - H_m^{(k)}y_k)\| = \min_{y\in\mathbb{R}^m} \|e_1 - H_m^{(k)}y\|,$$

while u_k in (2.5) is chosen as to minimize the outer residual (2.9), i.e.,

$$\|r_k\| = \min_{u\in\mathbb{R}^k} \|W_{k+1}(\beta e_1 - T_k u)\| = \min_{u\in\mathbb{R}^k} \|\beta e_1 - T_k u\|. \tag{4.1}$$

Remark 4.1. We emphasize that the inner-outer methods we discuss do not consist of just the concatenation of the inner and the outer minimizations—there is also the orthogonalization with respect of the outer basis (see, e.g., Proposition 2.1), i.e., before the outer minimization takes place, there is also a deflation step, cf. [7], [10], where some Krylov spaces with deflation are studied; see further section 7.

In light of the discussion in section 3, the minimization (4.1) can be interpreted as being performed on a subspace of dimension k of the global Krylov space $\mathcal{K}_{p+1}(A, r_0)$. Indeed, from (3.12), now we can write

$$\|r_k\| = \min_{u\in\mathbb{R}^k} \|\mathcal{V}_k(\beta e_1 - N_k Y_k u)\|.$$

We note that the columns of $\mathcal{V}_k$ are not necessarily orthogonal.

One can explicitly say that the subspace of $\mathcal{K}_{p+1}(A, r_0)$ where the minimization takes place is spanned by the (k linearly independent) columns of $\mathcal{V}_k N_k Y_k$. Another characterization of this subspace can be obtained from (2.6) and (3.8) giving us the k columns of $AZ_k = \mathcal{V}_k R_k T_k$.

5. The growing subspaces. The main result of this section is that the subspace from where the approximations are chosen keeps growing. This provides convergence of the inner-outer methods. In exact arithmetic, these methods would then terminate in at most n steps, where n is the order of the matrix A.

We have noted that, in general, we have the inclusion (3.6). It is also well known that the matrix $[r_0, Ar_0, \ldots, A^p r_0]$ may have vectors which are almost linearly dependent. We therefore want to study what we can say about the rank of $\mathcal{B}_k$ defined in (3.1) or, equivalently, that of $\mathcal{V}_k$ defined in (3.5). We show here that as k grows, i.e., as a new cycle is computed, the rank of $\mathcal{B}_k$ is guaranteed to grow as well.

For simplicity of the exposition, we assume in this section that $m_k = m$ for all k, and thus $p = mk$. We further assume that the minimal polynomial of A has degree larger than p. (More precisely, this is assumed with respect to $v_1^{(k-1)}$; see (5.2) below. In other words, we assume that the grade of $v_1^{(k-1)}$ is less than p.) We comment at the end of the section the implications of these assumptions.

LEMMA 5.1. *Let* $\mathcal{R}(V_m^{(k-1)}) = \mathcal{K}_m(A, v_1^{(k-1)})$ *and* $\mathcal{R}(V_m^{(k)}) = \mathcal{K}_m(A, v_1^{(k)})$ *be both of dimension* m *(i.e.,* $V_m^{(k-1)}$ *and* $V_m^{(k)}$ *are of full rank), with*

$$v_1^{(k)} \in \mathcal{R}(AV_m^{(k-1)}) \tag{5.1}$$

and $v_1^{(k)}$ *and* $v_1^{(k-1)}$ *being linearly independent. Then* $\dim \mathcal{R}([V_m^{(k-1)}, V_m^{(k)}]) > m$.

Proof. Let $v = v_1^{(k-1)}$; then any element $w \in \mathcal{R}(V_m^{(k-1)}) = \mathcal{K}_m(A, v)$ can be written as $w = p(A)v$, with p a polynomial of degree $m-1$ at most. Thus, from (5.1) we have that $v_1^{(k)} = Ap(A)v = q(A)v$, with $q(z)$ a nonzero polynomial of degree at most m, such that $q(0) = 0$. In other words, $1 \le \deg q(z) \le m$. In fact, since $0 \neq v_1^{(k)} \neq \alpha v$, for any $\alpha \in \mathbb{R}$, we have $2 \le \deg q(z) \le m$. Now consider

$$A^{m-1} v_1^{(k)} = A^{m-1} q(A) v = \hat{q}(A) v, \tag{5.2}$$

where $\deg \hat{q}(z) = (m-1) + \deg q(z) \geq m+1$; then $A^{m-1}v_1^{(k)} \notin \mathcal{K}_m(A, v_1^{(k-1)})$. Therefore,

$$\dim \mathcal{R}\left([V_m^{(k-1)}, A^{m-1}v_1^{(k)}]\right) = m+1,$$

from which the result follows. ∎

We note that in Lemma 5.1 (as well as Theorem 5.2 below) the hypothesis on the bases $V_m^{(j)}$ of $\mathcal{K}_m(A, v_1^{(j)})$ is that they be of full column rank. There is no requirement that they be orthogonal. Similarly, the vectors $v_1^{(j)}$ and $v_1^{(j-1)}$ need only be linearly independent. This implies that Lemma 5.1 and Theorem 5.2 apply to any method that produces these pairwise linearly independent vectors. In particular, they apply to the cases when either Arnoldi or two-sided Lanczos are used for the construction of the matrix W_k.

In [7] and [38, section 3] it is recommended that when using truncated Krylov methods the last vector of the previous basis, say $V_m^{(k-1)}$, be kept in the new basis. This recommendation was based on empirical evidence on symmetric matrices. Lemma 5.1 provides a theoretical basis for such a recommendation. In fact, the last column of $V_m^{(k-1)}$ has a nonzero component in the direction of (5.2) (or of (5.6) below), which is the key quantity for the subspace to grow.

To evaluate how the subspaces $V_m^{(k-1)}$ and $V_m^{(k)}$ generated during the inner step behave vis-á-vis Lemma 5.1, we shall compute for some specific examples their canonical angles [35]; see later section 7. Consider the two subspaces $\mathcal{R}(V_m^{(k-1)})$ and $\mathcal{R}(V_m^{(k)})$, and let m_* be the smallest integer such that $\dim \mathcal{R}(V_{m_*}^{(j)}) = \dim \mathcal{R}(V_{m_*+1}^{(j)})$, $j = k-1,\ k$. We define $\bar{m} = m$ if $2m \leq m_*$ or $\bar{m} = m_* - m$ if $2m > m_*$. The canonical angles between these two subspaces can be computed as the nonzero singular values $\sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_{\bar{m}}$ of $P_m^{(k-1)}(I - P_m^{(k)})$, where $P_m^{(j)} = V_m^{(j)}(V_m^{(j)})^T$, $j = k-1, k$, are the orthogonal projectors onto $\mathcal{R}(V_m^{(j)})$, $j = k-1,\ k$, respectively.

We present now the main result of this section.

THEOREM 5.2. *Let $\mathcal{R}(V_m^{(j)}) = \mathcal{K}_m(A, v_1^{(j)})$ be of dimension m, for $j = 1, \ldots, k$. Assume that each $v_1^{(j)}$ is such that*

$$v_1^{(j)} = AV_m^{(j-1)}y_{j-1} + \mathcal{B}_{j-2}d_j, \tag{5.3}$$

with $0 \neq y_{j-1} \in \mathbb{R}^m$, $j = 2, \ldots, k$, and that

$$v_1^{(j)} \quad \text{and} \quad v_1^{(j-1)} \quad \text{are linearly independent.} \tag{5.4}$$

Then

$$\dim \mathcal{R}(\mathcal{B}_k) \geq m + k - 1, \qquad k \geq 2. \tag{5.5}$$

Proof. We use induction on k. For $k = 2$, (5.5) holds by Lemma 5.1. Assume that (5.5) holds for $k-1 > 1$. We prove it for k. That is, we show that the next basis $V_m^{(k)}$ of $\mathcal{K}_m(A, v_1^{(k)})$ contains at least a vector that is not a linear combination of elements in $\mathcal{B}_{k-1}$. Consider the starting vector $v_1^{(k)}$ for the new basis $V_m^{(k)}$. From (5.3) we have

$$v_1^{(k)} = AV_m^{(k-1)}y_{k-1} + \mathcal{B}_{k-2}d_k = A\sum_{j=0}^{m-1} A^j v_1^{(k-1)}\eta_j + \mathcal{B}_{k-2}d_k$$

for some values η_j, not all of which are zero. Therefore, for $A^{m-1}v_1^{(k)} \in \mathcal{K}_m(A, v_1^{(k)})$ we have

$$A^{m-1}v_1^{(k)} = A^m \sum_{j=0}^{m-1} A^j v_1^{(k-1)}\eta_j + A^{m-1}\mathcal{B}_{k-2}d_k. \tag{5.6}$$

Since not all η_j's are zero, using the same argument as in the proof of Lemma 5.1,

$$A^m \sum_{j=0}^{m-1} A^j v_1^{(k-1)}\eta_j \notin \mathcal{K}_m(A, v_1^{(k-1)}), \tag{5.7}$$

while the second term of (5.6) lies in $\mathcal{B}_{k-1}$; thus, $A^{m-1}v_1^{(k)} \notin \mathcal{B}_{k-1}$, and the result follows. ∎

Remark 5.3. The hypothesis for Lemma 5.1 and Theorem 5.2 that the degree of the minimal polynomial of A is larger than m and mk, respectively, though seldom violated in practice, is crucial. Otherwise the Krylov subspace might be invariant and one may have, e.g., $\dim \mathcal{R}([V_m^{(k-1)}, V_m^{(k)}]) = m$. We will assume that this hypothesis holds, else one may experience some early breakdown; see section 6 for the definition of breakdown and also [6] for a similar situation.

Several comments on Theorem 5.2 are in order. First, we comment on the hypothesis (5.4). In the case of (flexible) Arnoldi, this is automatically satisfied, since the columns of W_k are orthogonal. In the case of (flexible) two-sided Lanczos, one has a vector $\hat{w} = \hat{w}_{j-1}$ in the basis bi-orthogonal to W_k such that $(v_1^{(j-1)}, \hat{w}) \neq 0$, while $(v_1^{(j)}, \hat{w}) = 0$, implying (5.4); for details about two-sided Lanczos see, e.g., [19], [30]. We mention also that (5.4) implies that these vectors are not the zero vectors, i.e., $w_k \neq 0$, $k = j-1,\ j$. As described in section 6 this is equivalent to assuming that there is no breakdown of the inner-outer method.

Second, this theorem applies to the inner-outer methods described so far, including the truncated methods. The hypothesis (5.3) expresses what we have said in Proposition 2.1 and Lemma 3.2.

Third, we want to emphasize that while the proof of Theorem 5.2 implies that $\mathcal{R}(\mathcal{B}_k)$ grows in each cycle, (5.5) really provides a lower bound on its dimension, and we expect the dimension of $\mathcal{R}(\mathcal{B}_k)$ to be higher. We comment, though, that (5.5) can be rephrased as

$$\dim \mathcal{R}(\mathcal{B}_k) \geq \dim \mathcal{R}([V_m^{(1)}, W_k]) = m + k - 1,$$

where the last equality holds when $V_m^{(1)}$ and W_k are full rank.

Finally, a careful review of the proofs of Lemma 5.1 and Theorem 5.2 indicates that, for the case where m_k changes from one cycle to the next, (5.5) holds for $m = m_1$, and that one needs $m_j \geq m_{j-1}$ to guarantee (5.7).

6. Stagnation and breakdown. In this section we discuss the possibility of breakdown in the construction of the outer basis W_{k+1}, as well as the possibility of stagnation of the inner-outer methods. Some of our observations apply to the general setting described in sections 2, 3, and 5. In some other cases the discussion relates specifically to a minimal residual method, such as FGMRES-GMRES(m).

As we shall see, there are two elements that relate to the possibility of stagnation and breakdown: one is $\bar{T}_k$, the $k \times k$ principal matrix of T_k, and the other is the

next (outer) vector w_{k+1}. The situation on breakdown can be summarized as follows: If $w_{k+1} \neq 0$, there is no breakdown, even if $\bar{T}_k$ is singular. If $w_{k+1} = 0$, then the singularity of $\bar{T}_k$ matters. When $\bar{T}_k$ is singular we have (real) breakdown, while if $\bar{T}_k$ is nonsingular, we have what is usually called a "lucky" breakdown, meaning that this implies that x_k is the exact solution of (1.1); see [29, Proposition 2.2] where breakdown for FGMRES (using any inner solver) is considered. Stagnation of the inner-outer method is discussed at the end of the section.

In the case of FGMRES-GMRES(m), one example of breakdown ($w_{k+1} = 0$) occurs when there is stagnation in the inner iteration, i.e., in GMRES(m). In other words, given w_k, the approximation $z_k \in \mathcal{K}_m(A, w_k)$ is such that $w_k - Az_k = w_k$, cf. (2.11), implying $z_k = 0$. Unless the exact solution was found at the previous outer step, inner stagnation yields incurable breakdown, as the outer iteration no longer proceeds. Prevention of stagnation of the inner iteration has been addressed by other authors. In [37], if inner stagnation occurs, the inner step is replaced by a minimization step. At the end of section 2.2 of [29] there is a comment indicating that all that is needed to avoid stagnation is a direction of steepest descent. This is exactly what is guaranteed by the choice of the stopping criteria of the inner iterations in [17]. We also remark that in [1] a condition on the matrix A is introduced to avoid inner stagnation in the inner-outer generalized conjugate gradient method. Let $Q[w]$ denote the inner outcome. It is shown in [1] that if $AQ[\cdot]$ is coercive, that is, there exists $\delta > 0$ such that $(w, AQ[w]) \geq \delta(w, w)$ for all $w \neq 0$, then the inner iteration does not stagnate. Here (x, y) denotes the usual inner product. Note that in the symmetric positive definite case, coercivity implies that a steepest descent direction is obtained in the inner method; see, e.g., [22]. In the context of FGMRES-GMRES(m), coercivity also implies that the inner GMRES does not stagnate. Indeed, for each outer basis vector w_k and using $z_k = Q[w_k]$, we have

$$(w_k, AQ[w_k]) = (w_k, Az_k) = 1 - \|w_k - Az_k\|^2,$$

where $w_k - Az_k$ is the inner residual. Therefore, imposing $(w_k, AQ[w_k]) > 0$ implies $\|w_k - Az_k\|^2 < 1 = \|w_k\|$, which is equivalent to lack of stagnation. We should mention however that coercivity in our context is a very strong assumption. For GMRES as inner, it holds that $Q[w_k] = p_{m-1}(A)w_k$ for some polynomial p_{m-1} of degree not greater than $m-1$, where the polynomial changes at each outer cycle. Hence, $(w_k, AQ[w_k]) > 0$ is satisfied if the operator $Ap(A)$ is coercive for any polynomial p of degree at most $m-1$.

There are many examples where $\bar{T}_k$ is singular, even if T_k is of full rank. In these cases, having $t_{k+1,k} = \|w_{k+1}\| = 0$ implies real breakdown. In Lemma 5.1 and Theorem 5.2 it is assumed that there is no breakdown, see (5.4) and (2.12), and it is concluded that the space from where the solution is drawn keeps growing.

In the absence of breakdown ($w_{k+1} \neq 0$), $\bar{T}_k$ singular indicates stagnation of the outer process and thus of the overall inner-outer method. The following result is an adaptation of [3, Theorem 3.1] for FGMRES. The proof given in [3] can be used verbatim here, so we do not reproduce it.

THEOREM 6.1. *Suppose that k steps of the (outer) Arnoldi method have been taken, $w_{k+1} \neq 0$, and assume that $\bar{T}_k$ is singular. Then*

$$\min_{u \in \mathbb{R}^k} \|\beta e_1 - T_k u\| = \min_{u \in \mathbb{R}^{k-1}} \|\beta e_1 - T_{k-1} u\|. \tag{6.1}$$

If we denote by u_j the minimizer in (4.1) with j replacing k, for $j = k$ or $k-1$, then $u_k = ((u_{k-1})^T, 0)^T$, and it follows that $x_k = x_{k-1}$. Conversely, suppose that k

steps of the (outer) Arnoldi method have been taken and that (6.1) *holds; then* $\bar{T}_k$ *is singular.*

Note, however that since we assume that there is no breakdown, this stagnation can only be "temporary," since by Theorem 5.2 the subspace keeps growing, and therefore the inner-outer method converges [9].

7. Comparison with restarted methods. Let us consider restarted GMRES, i.e., GMRES(m). This method generates an approximate solution as sum of approximations obtained at each restart, that is,

$$x_k = x_0 + x^{(1)} + x^{(2)} + \cdots + x^{(k)}. \tag{7.1}$$

The single approximations are obtained in the following subspaces:

$$\begin{aligned} &K_m(A, r_0), && r_0 = b - Ax_0, \\ &K_m(A, r_0^{(1)}), && r_0^{(1)} = r_0 - Ax^{(1)} \equiv b - Ax_1, \\ &K_m(A, r_0^{(2)}), && r_0^{(2)} = r_0^{(1)} - Ax^{(2)} \equiv b - Ax_2, \\ &\quad \vdots \end{aligned}$$

where each starting vector $r_0^{(j)}$ is the residual in the previous Krylov subspace.

Intuitively, one can think of improving upon GMRES(m) by considering a linear combination (or weighted average) of the single approximations, say

$$\tilde{x}_k(\alpha) = x_0 + \alpha_1 x^{(1)} + \alpha_2 x^{(2)} + \cdots + \alpha_k x^{(k)}, \tag{7.2}$$

instead of (7.1); cf. [41, section 3]. One could require the parameters $\alpha \in \mathbb{R}^k$ to be constructed, for example, so as to minimize the norm of the residual, in which case we have

$$\|\tilde{r}_k\| = \min_{\alpha \in \mathbb{R}^k} \|b - A\tilde{x}_k(\alpha)\| \leq \|b - Ax_k\|,$$

where the last inequality follows from considering $\alpha = (1, \ldots, 1)^T$. In other words, such a method cannot be worse than restarted GMRES in terms of residual norms.

The inner-outer methods we study, such as FGMRES-GMRES(m), do more than just implicitly choose the k parameters in (7.2). It follows from Proposition 2.1 that one obtains an iteration of the form (7.2), but where the residual obtained for each single (inner) Krylov method is in turn deflated with respect to the previous (outer) vectors; cf. [13], [26]. We thus expect that the overall inner-outer method will perform at least as well as the restarted counterpart.

We prove this explicitly in some particular cases below ($k = 1$ or $m = 1$). For other cases, we show examples where at particular points in the computations, the inner-outer method may have a residual norm which is larger than the corresponding restarted one. Nevertheless, for these, as well as for all other numerical examples we ran, FGMRES-GMRES(m) always converges using fewer matrix-vector multiplications than GMRES(m).

In the following proposition we show that at the very first outer cycle the residual computed by FGMRES-GMRES(m) is the same as that of GMRES(m). Therefore, possible improvements versus the restarted approach are expected starting with the second outer cycle of the flexible method.

PROPOSITION 7.1. *Let r_k^F, r_k^G be the FGMRES-GMRES(m) and GMRES(m) residuals after k cycles, respectively. For $k = 1$ we have $r_1^F = r_1^G$.*

Proof. After m iterations of the first cycle of GMRES(m), we solve the problem (2.2) where V_m spans $\mathcal{K}_m(A, r_0)$, and we obtain $y^G = (H_m^T H_m)^{-1} H_m^T e_1 \beta$, so that $r_1^G = b - AV_m(H_m^T H_m)^{-1} H_m^T e_1 \beta$.

On the other hand, let $w_1 = r_0 \beta^{-1}$ be the first outer basis vector in FGMRES-GMRES(m). After m iterations of the first inner step we solve the problem

$$\min_{y \in \mathbb{R}^m} \|w_1 - AV_m y\| = \min_{y \in \mathbb{R}^m} \|e_1 - H_m y\|,$$

where V_m spans $\mathcal{K}_m(A, r_0) = \mathcal{K}_m(A, w_1)$. We obtain $y^F = (H_m^T H_m)^{-1} H_m^T e_1$ so that $z_1 = V_m y^F$. At the end of the first outer cycle we thus solve the problem

$$\min_{u \in \mathbb{R}} \|b - Az_1 u\| = \beta \min_{\hat{u} \in \mathbb{R}} \|w_1 - Az_1 \hat{u}\|, \qquad \hat{u} = \frac{1}{\beta} u.$$

We obtain $\hat{u} = ((Az_1)^T (Az_1))^{-1} (Az_1)^T w_1$. Explicitly writing $Az_1 = V_{m+1} H_m y^F$ and substituting into the previous expression, we derive $\hat{u} = ((y^F)^T H_m^T H_m y^F)^{-1} (y^F)^T H_m^T e_1 = 1$, from which it follows that $u = \beta \hat{u} = \beta$. Therefore, $r_1^F = b - Az_1 u = b - AV_m(H_m^T H_m)^{-1} H_m^T e_1 \beta = r_1^G$. ∎

Later in this section we provide an example that shows that Proposition 7.1 cannot be generalized to $k > 1$ for general m. Nonetheless, we can prove for $m = 1$ and for any $k > 0$ that the FGMRES-GMRES(m) iterates coincide with those of full GMRES.

PROPOSITION 7.2. *Let x_k^F be the approximate solution obtained after k outer cycles of FGMRES-GMRES(1), and assume that GMRES(1) does not stagnate. Let x_k^G be the approximate solution after k iterations of full GMRES. Then $x_k^F = x_k^G$.*

Proof. At each outer cycle k of FGMRES, the inner solver GMRES approximately solves $Az = w_k$. If GMRES(1) is used, then $z_k = \delta_k w_k$ for some scalar $\delta_k \neq 0$. Setting $D_k = \text{diag}(\delta_1, \ldots, \delta_k)$, we can write $Z_k = W_k D_k$ so that (2.6) becomes

$$AW_k = W_{k+1} T_k D_k^{-1},$$

and the latter is an Arnoldi relation so that $\mathcal{R}(W_k) = \mathcal{K}_k(A, w_1)$. Let $AV_k = V_{k+1} H_k$ be the Arnoldi relation associated with full GMRES. Since $\mathcal{R}(W_k) = \mathcal{R}(V_k)$, there exists an orthogonal $k \times k$ matrix R_k such that $W_k = V_k R_k$ and $H_k = R_{k+1} T_k D_k^{-1} R_k^{-1}$. Since $w_1 = v_1$, $(R_k)_{1,1} = 1$. Using $(H_k^T H_k)^{-1} H_k^T = R_k D_k (T_k^T T_k)^{-1} T_k^T R_{k+1}^T$, the solution $x_k^G = V_k (H_k^T H_k)^{-1} H_k^T e_1 \beta$ becomes

$$x_k^G = V_k R_k D_k (T_k^T T_k)^{-1} T_k^T R_{k+1}^T e_1 \beta = Z_k (T_k^T T_k)^{-1} T_k^T e_1 \beta = x_k^F. \qquad ∎$$

Unfortunately, the result of Proposition 7.2 and the implication that $\|r_k^F\| \leq \|r_k^G\|$ do not carry over to larger values of m, as experimentally shown in the next example.

Example 7.3. We consider the linear system $Ax = b$ of size $n = 100$, where $A = \text{bidiag}(d, 1)$, with $d = [0.01, 0.02, 0.03, 0.04, 10, 11, \ldots, 105] \in \mathbb{R}^n$. In Table 7.1 we report the residual norms for both FGMRES-GMRES(m) (F/G(m) for short) and GMRES(m) (GM(m) for short), with $m = 10$, when the right-hand side is $b_1 = (1, 2, 1, 2, \ldots)^T$ (left) and $b_2 = (1, -2, 1, -2, \ldots)^T$ (right). Both vectors were normalized so that $\|b_1\| = \|b_2\| = 1$. The reported results clearly show that $\|r_k^F\|$ is larger than $\|r_k^G\|$ at an early stage of the iterative process, highlighted in italics. Nonetheless, convergence is achieved after a few more iterations in the flexible method, whereas the restarted approach stagnates.

TABLE 7.1

⋮			⋮		
12	$6.4 \cdot 10^{-5}$	0.144093	13	0.00029268	0.136947

We recall here that each new vector is deflated before it is used as the initial vector for the inner iteration; see (2.11) or Proposition 2.1. As discussed in section 3, this deflation helps in providing inner subspaces $V_m^{(k)}$, which have a larger angle between them, justifying the good overall performance of the flexible method. This is illustrated in Table 7.2 below, where we considered the matrix in Example 7.3 and, as right-hand side b, the left singular vector corresponding to the smallest singular value of A; see [33]. Note that full GMRES reaches a residual norm less than 10^{-16} in 21 iterations; therefore in our tests we considered that an invariant subspace of A was found for $m_* = 20$.

For both FGMRES-GMRES(m) and GMRES(m), in Table 7.2 we report the smallest sine value of the canonical angles between the subspaces spanned by $V_m^{(k-1)}$ and $V_m^{(k)}$ for $k = 2, 3$; see the discussion in section 3. When using GM(12), we collected the value of the $\bar{m}$th singular value, with $\bar{m} = m_* - m = 20 - 12 = 8$.

TABLE 7.2
Smallest nonzero singular value of $V_m^{(k-1)}(V_m^{(k-1)})^T(I - V_m^{(k)}(V_m^{(k)})^T)$, measuring the sines of canonical angles between $\mathcal{R}(V_m^{(k-1)})$ and $\mathcal{R}(V_m^{(k)})$.

k		F/G(5)	F/G(10)	GM(5)	GM(10)	GMRES(12)
2	σ_{min}	$7 \cdot 10^{-5}$	$4 \cdot 10^{-8}$	$2 \cdot 10^{-16}$	$1 \cdot 10^{-16}$	$5 \cdot 10^{-6}$
3	σ_{min}	$1 \cdot 10^{-2}$	$9 \cdot 10^{-4}$	$4 \cdot 10^{-17}$	$3 \cdot 10^{-16}$	$3 \cdot 10^{-4}$

Table 7.2 shows that, for restarted GMRES, the distance between $V_m^{(1)}$ and $V_m^{(2)}$ is around machine precision for $m = 5, 10$, implying that the Krylov subspace generated after one restart is very close to the previous one. The same happens at the next outer cycle, for $V_m^{(2)}$ and $V_m^{(3)}$. Only for $m = 12$ do the subspaces generated after the first restart of GMRES provide new information. This is confirmed by the convergence history of the method, shown in the right plot of Figure 1.

Table 7.2 and Figure 1 also report results for the flexible method. In particular, by only deflating the starting vector of the first inner Krylov subspace, F/G(10) seems to be capable of capturing the information missed by restarted GMRES after one cycle, resulting in faster convergence. On the other hand, we notice that F/G(5) achieves its final approximation to the exact solution with a large delay.

8. Computational considerations. Computational efficiency leads us to consider truncated and restarted versions of optimal algorithms. This is the case both for the original GMRES method as well as for FGMRES [31], [32], [37]. In the case of a flexible method, Theorem 5.2 ensures that in exact arithmetic the method converges as long as condition (5.4) is satisfied. Therefore, if, for example,

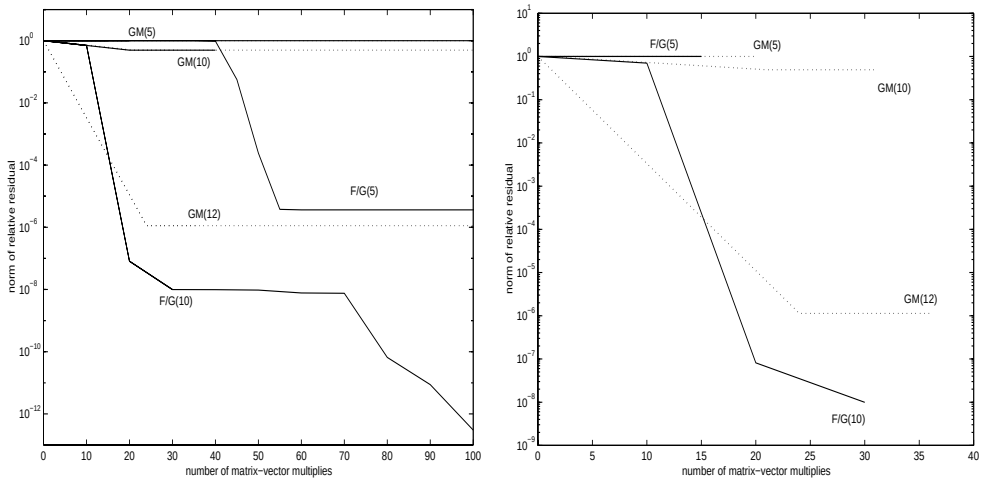

FIG. 1. *Convergence history of flexible and restarted methods for various values of m. Left: Entire picture. Right: Initial phase. See also Table* 7.2.

GMRES is used as the outer method, finite termination is obtained by orthogonalizing only the next outer basis vector w_{k+1} with respect to the previous vector w_k. By orthogonalizing w_{k+1} with respect to more basis vectors, i.e., to more columns of W_k, we expect the convergence to be faster.

In order to make fair comparisons, we recall that k cycles of FGMRES require m vectors for the inner space plus $2k$ vectors for the outer bases. These should be compared with the m vectors required by GMRES(m). A truncated version of FGMRES will instead require $2k_t$ outer vectors, where k_t is fixed beforehand. In our experiments, when using truncated flexible GMRES, we used m_t inner vectors and k_t outer vectors so that $m_t + 2k_t = m$, where m is the number of vectors used in restarted GMRES. We remark that such memory constraint on m_t, k_t forces us to work with a much smaller inner space than in restarted GMRES if outer orthogonality is maintained with respect to several vectors. Different selections of these parameters were analyzed and some of them are reported here. In addition, we mention that the larger k_t, the more expensive the reorthogonalization step. Clearly, the worst case scenario in this context is given by FGMRES, where all outer vectors are kept orthogonal.

We also remark that the matrix-vector multiplication required at each outer step of the flexible method can be avoided by exploiting the available inner residual. Therefore, at least for a low number of outer cycles, restarted and (truncated) flexible methods can be compared in terms of number of matrix-vector products, which in our experiments represents the highest computational cost. It is also customary to further precondition the flexible approach with a matrix P by applying the flexible method to the preconditioned matrix AP^{-1}. Due to the implementation consideration just mentioned, preconditioning the inner-outer method amounts to simply preconditioning the inner solver; see also the discussion in section 2.

Example 8.1. We consider the 900×900 matrix originating from the centered finite difference discretization of the operator

$$L(u) = -\Delta u + \mu x u_x, \qquad \text{for} \quad \mu = 100, 1000, \tag{8.1}$$

on $[0,1] \times [0,1]$ with zero Dirichlet boundary conditions. As a right-hand side we selected $b = Ae$, where e is a vector of all ones.

Figure 2 reports the convergence history of restarted GMRES(20), FGMRES-GMRES(20), and its truncated variant, using FTGMRES-GMRES(m_t, k_t) (FT/G(m-k) for short) as discussed above. In the left plot we displayed the results for $\mu = 100$, in the right plot for $\mu = 1000$. We observe that for $\mu = 100$ truncation is not harmful, especially when the generated inner space is sufficiently large, yielding similar convergence for the flexible method and its truncated variant. For $\mu = 1000$ the picture changes considerably and the convergence of the truncated methods reflects the influence of the two parameters m_t, k_t. Restarted GMRES clearly shows lack of information that is eventually recovered after many more iterations.

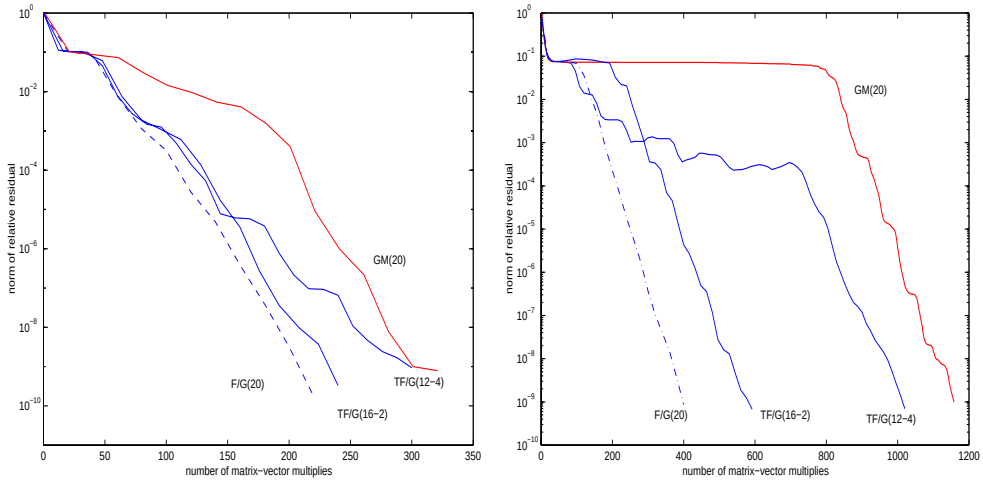

FIG. 2. *Convergence history for operator $L(u)$ in* (8.1). *Left:* $\mu = 100$. *Right:* $\mu = 1000$.

Example 8.2. We consider the operator

$$L(u) = -1000\Delta u + 2e^{4(x^2+y^2)}u_x - 2e^{4(x^2+y^2)}u_y \tag{8.2}$$

on $[0,1] \times [0,1]$, which was studied in [7, Problem 2]. Here we assume zero Dirichlet boundary conditions and a centered finite difference discretization, yielding a coefficient matrix A of size $n = 40000$. The right-hand side is determined as $b = Ae$, where e is the vector of all ones, and then normalized so as to have unit norm. The convergence history of restarted GMRES with $m = 30$ is reported in Figure 3 (left). The figure also shows the curves of the flexible variant and its truncated versions for two different values of the truncation parameter. On this problem, truncation is particularly effective. The results seem to suggest that on this problem, an inner subspace of small dimension suffices for the flexible method to converge rapidly. In the right plot of Figure 3 we show the convergence history of all methods for a larger Krylov subspace dimension, $m = 50$. Restarted GMRES considerably improves its performance; cf. [7]. On the other hand, flexible schemes do not seem to necessitate of a larger inner dimension, implying that information gathering in the outer process is very effective. Our findings corroborate similar experimental evidence in [7]. We also notice that for $m = 50$, the truncated variants converged in less than 20 outer iterations. Therefore, when large values of k_t are selected, truncation takes place only

very late in the convergence stage. As a consequence, the curves in the right plots of Figure 3 associated with the truncated methods FT/G(30-10) and FT/G(20-15) closely resemble the curves one would obtain with FGMRES(m) with $m = 30$ and $m = 20$; cf. the left plot of Figure 3 for $m = 30$.

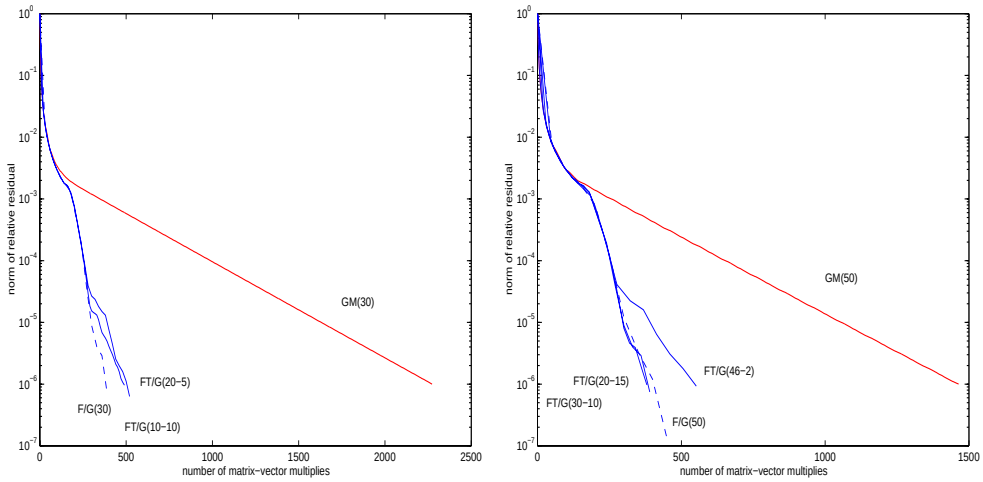

FIG. 3. *Convergence history for operator $L(u)$ in (8.2). Left: $m = 30$. Right: $m = 50$.*

Example 8.3. Our last set of experiments involves three matrices from the "Matrix Market" [8], [24]. For the first two matrices, the right-hand side was chosen to be the vector of all ones. Additional (fixed) incomplete LU preconditioning was applied [25], [30]. In our experiments, we used the Matlab function `luinc` with tolerance *tol* to build the preconditioning matrix P. As mentioned earlier in this section, in the flexible algorithm this amounts to run the inner solver with the preconditioned matrix AP^{-1}.

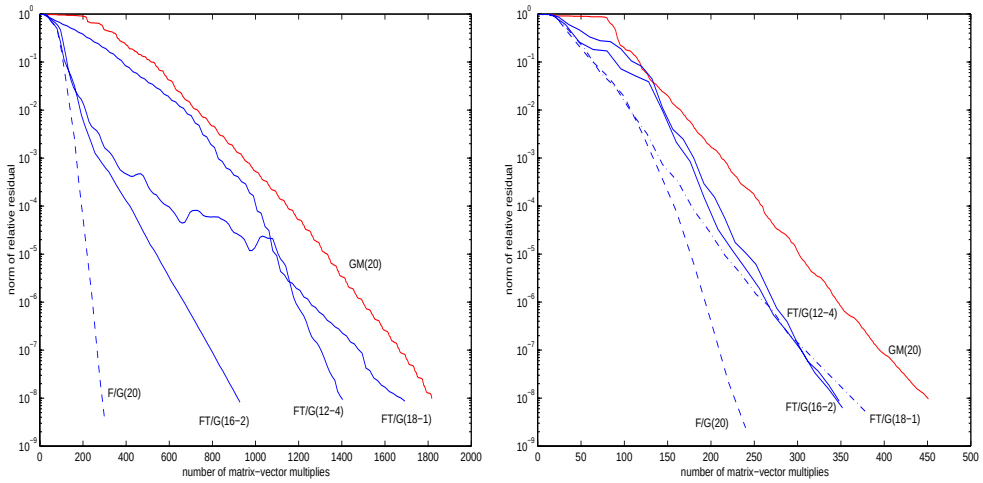

FIG. 4. *Convergence history for flexible and restarted methods on matrix Sherman5. Left: no preconditioning. Right: preconditioning using incomplete LU with tolerance tol* $= 10^{-2}$.

In Figure 4 we report experiments with the matrix SHERMAN5 from the Harwell–

Boeing set, a nonsymmetric 3312×3312 matrix stemming from a fully implicit black oil simulation [8]. The matrix was scaled using the absolute values of its diagonal entries. The fixed ILU preconditioner was built using $tol = 10^{-2}$.

The plots show that the behavior of the methods is more homogeneous after fixed preconditioning, while when no preconditioning is applied the convergence of the truncated flexible method is less predictable.

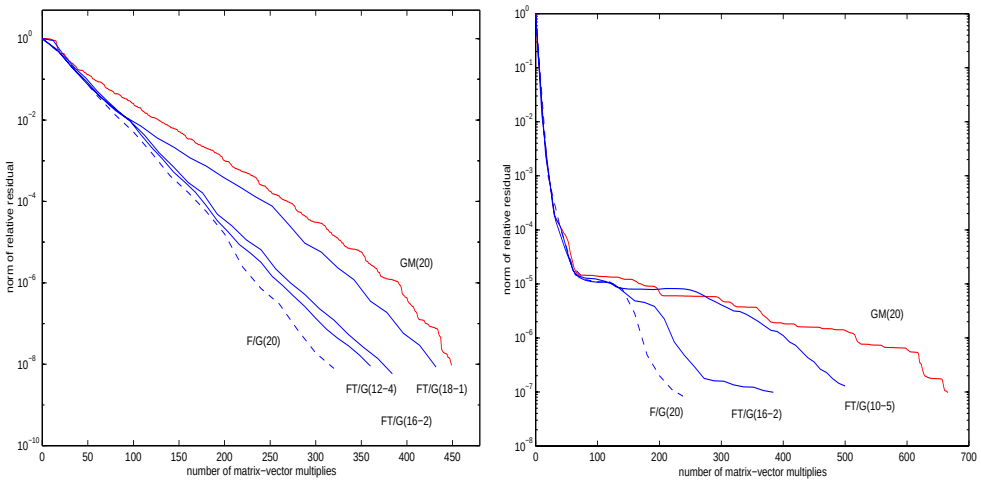

FIG. 5. *Convergence history for flexible and restarted methods on Preconditioned Oilgen (left) and on Scaled Fidap_ex*11 *(right).*

The second matrix in the set is the OILGEN 2205×2205 matrix from the same matrix set, originating from a three-dimensional oil reservoir simulation [8]. The fixed ILU preconditioning was applied with tolerance $tol = 0.5$. Convergence histories are reported in the left plot of Figure 5. The difference in the behavior of the methods is less pronounced.

Finally, we consider a larger matrix from the FIDAP group in the University of Florida collection [8], namely matrix EX11 of size $n = 16614$, which stems from a fully coupled Navier–Stokes problem. We set $b = Ae$, normalized so as to have unit norm, and we use diagonal preconditioning. The results reported in the right plot of Figure 5 show the dramatic improvements of the flexible methods over restarted GMRES with $m = 20$. These results are consistent with the other experiments on smaller matrices reported earlier.

We end this section with some comments on the behavior of the truncated schemes. By comparing the results in Figures 2, 4, and 5, we see that, except for Example 8.2, the curves of the flexible truncated variants quickly abandon the optimal curve of the flexible method, confirming that orthogonalization with respect to the previous inner starting vectors is crucial to obtain fast convergence. Among the choices we have analyzed, however, we see that maintaining orthogonality with respect to the two previous starting vectors ($k_t = 2$) seems to provide the closest to optimal convergence curve. Although in exact arithmetic $k_t = 1$ is sufficient to ensure termination, a larger value of k_t seems to pay off in our tests at the cost of a smaller inner subspace dimension (m_t). Not surprisingly, however, the performance for $k_t = 4$ indicates that a value of m_t that is too small may slow down convergence.

9. Conclusion. We have analyzed a class of flexible inner-outer iterative Krylov subspace methods in an unified manner. These are Krylov methods where the preconditioner is itself a (preconditioned) Krylov method. We have shown convergence of this class of methods by showing that the subspace from where the approximation is chosen keeps growing. This convergence is guaranteed as long as there is no stagnation in the inner iterations.

We have shown experimentally (and in some cases theoretically) that these methods can compete favorably with the standard restarted methods such as GMRES(m).

In the case of truncated methods, our theory indicates one way in which to choose the vectors to keep in order to guarantee convergence. Our experimental evidence confirms the effectiveness of this choice. These truncated methods appear to perform better than the standard restarted versions using the same amount of storage, and in some cases they are almost as good as the untruncated flexible method (which requires more storage).

Further analysis is needed to determine which vectors in the outer basis are the important ones to keep, allowing us to use the storage for more vectors in the inner basis; cf. [7].

Acknowledgments. We are indebted to Eric de Sturler for valuable comments on an earlier version of the manuscript. In particular, they led to Remark 5.3 and to a better proof of Proposition 7.2. We thank the editor, Martin Gutknecht, for his superb job in handling the paper. His questions and observations helped improve our presentation. We also benefited from comments and suggestions from T. Faraj and J. Mas and from the referees.

CONVERGENCE OF SEMI-LAGRANGIAN APPROXIMATIONS TO CONVEX HAMILTON–JACOBI EQUATIONS UNDER (VERY) LARGE COURANT NUMBERS*

ROBERTO FERRETTI†

Abstract. We consider a class of semi-Lagrangian high-order approximation schemes for convex Hamilton–Jacobi equations. In this framework, we prove that under certain restrictions on the relationship between Δx and Δt, the sequence of approximate solutions is uniformly Lipschitz continuous and hence, by consistency, that it converges to the exact solution. The argument is suitable for most reconstructions of interest, including high-order polynomials and ENO reconstructions.

Key words. convex Hamilton–Jacobi equations, high-order schemes, semi-Lagrangian schemes, convergence

1. Introduction.

Although the numerical solution of first-order Hamilton–Jacobi equations is a widely studied topic in many applications, it is well known that, when high-order schemes are considered (see [OS], [JP], [LT1]), very few convergence results are available. A key tool for proving convergence of numerical approximations would be some stability property for discrete solutions; when working with continuous solutions it is common to require boundedness of the family in $W^{1,\infty}$, so that compactness would be proved by the classical Ascoli–Arzela theorem. Bounds on the Lipschitz norm can generally be proved with reasonable effort in the case of low-order (usually monotone) schemes but can be really troublesome in high-order schemes, in which oscillations may occur. Lack of monotonicity also prevents using the result of Barles and Souganidis (see [BS]) which, roughly speaking, states that consistency, monotonicity, and L^∞ stability imply convergence. In the framework of Hamilton–Jacobi equations, we must also mention that a recent paper (see [LT2]) has proposed a different stability concept, that is, uniform semiconcavity of discrete solutions. A bound on the second incremental ratio is also exploited in [LS] to prove convergence of modified upwind scheme for conservation laws (MUSCL)-type schemes.

This paper is devoted to the study of the Hamilton–Jacobi equation

$$\begin{cases} v_t(x,t) + H(\nabla v(x,t)) = 0 & \text{in } \mathbb{R}^N \times [0,T], \\ v(x,0) = v_0(x). \end{cases} \tag{1.1}$$

The function $H(p)$ will be assumed to be smooth and to satisfy, for some $m_H > 0$, the condition

$$(H_{pp}\xi, \xi) \geq m_H |\xi|^2. \tag{1.2}$$

The purpose of the paper is precisely to obtain a result of convergence via uniform Lipschitz continuity for a semi-Lagrangian, high-order scheme. The scheme is described in several versions in [FF1], [FF3], [FFM], [FG], [CFF] (see also [SC] for a

general review on semi-Lagrangian approach in computational fluid dynamics), and its convergence for the low-order case is discussed in [FG], [FF3]. The high-order, linear case is analyzed in [FF2], whereas for the nonlinear equation (1.2) a weaker preliminary result of $W^{1,\infty}$ boundedness is given in [F].

For the reader's convenience, we briefly sketch the construction of the scheme for the Hamilton–Jacobi equation (1.1). Since the solution (see [L]) may be represented as

$$v(x,t) = \inf_{\alpha\in\mathbb{R}^N}\{tH^*(\alpha) + v_0(x+\alpha t)\} \tag{1.3}$$

(where $H^*(\alpha)$ is the Legendre transform of $H(p)$), using the representation formula (1.3) at each node and over each single time step, we get

$$v(x_j, t_{n-1}+\Delta t) = \inf_{\alpha}\{\Delta t H^*(\alpha) + v(x_j+\alpha\Delta t, t_{n-1})\},$$

and further replacing $v(x_j+\alpha\Delta t, t_{n-1})$ with a numerical reconstruction $I[V^{n-1}](x_j+\alpha\Delta t)$, we obtain at last the general form of the scheme for (1.1), namely,

$$\begin{cases} v_j^n = \min_{\alpha}\{\Delta t H^*(\alpha) + I[V^{n-1}](x_j+\alpha\Delta t)\}, \\ v_j^0 = v_0(x_j). \end{cases} \tag{1.4}$$

In (1.4), we have omitted for simplicity the treatment of boundary conditions, for which an explicit form can be found in [FFM].

It is worth pointing out that in (1.4) there is no need to let $\Delta t \to 0$ since characteristics are straight lines and the best accuracy is achieved with $\Delta t = t$ as in (1.3). However, this is no longer true if $H(p)$ is replaced by $H(x,p)$ (the scheme can also handle this case, see [FFM]), and in order for this simplified convergence analysis to give indications for the more general case, we will let $\Delta t \to 0$ anyway.

The outline of the paper is the following. We will prove in section 2 a bound on the second increment and deduce Lipschitz continuity for numerical solutions under suitable assumptions on the reconstruction operator and on the $\Delta t/\Delta x$ relationship. Section 3 takes into consideration polynomial reconstructions and checks the applicability of the theory. Lastly, section 4 gives the main result of convergence for the scheme.

2. Uniform Lipschitz continuity. Let (1.1) be discretized on an infinite grid with nodes x_j; moreover, let Δx be the space discretization parameter, so that

$$C_-\Delta x \le |x_i - x_j| \le C_+\Delta x$$

for any couple (x_i, x_j) of nodes on the boundary of the same cell. (For shortness of notation, nodes satisfying this condition will be referred to in what follows as *neighboring nodes*.) We will identify the numerical solution at time $n\Delta t$ with the sequence $V^n = \{v_j^n\}_j$, whose l^∞ norm will be defined as usual by $|V^n|_\infty := \sup_j |v_j^n|$. We will denote by $I[V](\cdot)$ the reconstruction (interpolation) operator which extends a sequence V on the whole of $\mathbb{R}^N$, by $U(x)$ the stencil of $I[V](x)$, and by $I_1[V]$ the P_1 (piecewise linear) interpolation on the sequence V.

For simplicity, the main technical difficulty of the paper, Lemma 2.1, will be stated in the one-dimensional case. In this case, we assume that $x_j = j\Delta x$ ($j = 0, \pm1, \pm2, \ldots$) and that given a Lipschitz continuous function $v(x)$ and the sequence $V = \{v_j\}_j = \{v(x_j)\}_j$, the operator $I[V]$ satisfies, for some constant $C < 1$,

$$I[V](x_j) = v(x_j)\ ,\quad |I[V](x) - I_1[V](x)| \le C \max_{x_{j-1},x_j,x_{j+1}\in U(x)} |v_{j+1} - 2v_j + v_{j-1}|, \tag{2.1}$$

where $I_1[V]$ and $U(x)$ have the same meaning as before. In $\mathbb{R}$, we can write $U(x)$ as $U(x) = (x - h_- \Delta x, x + h_+ \Delta x)$; for example, a quadratic Lagrange reconstruction can be performed taking one node on the left and two nodes on the right of the point x (in this case, $h_- = 1$, $h_+ = 2$), or two nodes on the left and one on the right (and in this case, $h_- = 2$, $h_+ = 1$). In a second-order ENO reconstruction (see [S]), both cases are possible depending on the solution (and thus, $h_- = h_+ = 2$). A third-order Lagrange reconstruction is typically performed using two nodes on the left and two on the right, so that $h_- = h_+ = 2$. In the third-order ENO case, $h_- = h_+ = 3$, and so forth.

We recall that condition (1.2) in the one-dimensional case reads as

$$H''(p) \geq m_H,$$

and this implies in terms of the Legendre transform that

$$H^{*''}(\alpha) \leq \frac{1}{m_H}. \tag{2.2}$$

It will also be useful to define the function

$$F_j(\alpha) := \Delta t H^*(\alpha) + I[V^{n-1}](x_j + \alpha \Delta t).$$

In what follows, we will denote by $\bar{\alpha}_j$ the value of α achieving the minimum in (1.4) and in F_j. In order to stress the "locality" in the above definition, the notation explicitly shows the dependence of F on the node index j, although for simplicity the dependence on the time step n has been dropped.

We give now a bound on the second increment of the numerical solution. The bound is globally one-sided, but becomes two-sided at the foot of characteristics (that is, in a neighborhood of fixed radius $h\Delta x$, with $h > \max(h_+, h_-)$, around the point $x_j + \bar{\alpha}_j \Delta t$). More precisely, we have the following technical result.

LEMMA 2.1. *Consider the scheme* (1.4) *applied to equation* (1.1)*, with* $N = 1$*. If* (2.2) *holds, then, for any* $j \in \mathbb{Z}$ *and* $n \geq 1$*,*

$$v_{j+1}^n - 2v_j^n + v_{j-1}^n \leq \frac{\Delta x^2}{m_H \Delta t}. \tag{2.3}$$

Moreover, assuming, in addition, that (2.1) *holds, then, for any* $j \in \mathbb{Z}$ *and* $n \geq 2$*,*

$$\max_{x_{i-1}, x_i, x_{i+1} \in \overline{U}(x_j + \bar{\alpha}_j \Delta t)} |v_{i+1}^{n-1} - 2v_i^{n-1} + v_{i-1}^{n-1}| \leq \bar{C} \frac{\Delta x^2}{\Delta t} \tag{2.4}$$

with $\overline{U}(x) = (x - h\Delta x, x + h\Delta x)$ *(*h *being a fixed positive integer such that* $h > \max(h_+, h_-)$*) and for some positive constant* $\bar{C}$ *depending on* C*,* h*, and* m_H*.*

Proof. We start by proving (2.3). By (1.4) we have, for $n \geq 1$,

$$\begin{aligned}
v_j^n &= \Delta t H^*(\bar{\alpha}_j) + I[V^{n-1}](x_j + \bar{\alpha}_j \Delta t), \\
v_{j-1}^n &= \Delta t H^*(\bar{\alpha}_{j-1}) + I[V^{n-1}](x_{j-1} + \bar{\alpha}_{j-1} \Delta t) \\
&\leq \Delta t H^* \left(\bar{\alpha}_j + \frac{\Delta x}{\Delta t} \right) + I[V^{n-1}](x_j + \bar{\alpha}_j \Delta t), \\
v_{j+1}^n &= \Delta t H^*(\bar{\alpha}_{j+1}) + I[V^{n-1}](x_{j+1} + \bar{\alpha}_{j+1} \Delta t) \\
&\leq \Delta t H^* \left(\bar{\alpha}_j - \frac{\Delta x}{\Delta t} \right) + I[V^{n-1}](x_j + \bar{\alpha}_j \Delta t)
\end{aligned}$$

(where the inequalities come from the use of $\bar\alpha_j \pm \Delta x/\Delta t$ instead of the actual minimizers $\bar\alpha_{j\mp1}$), so that

$$v_{j+1}^n - 2v_j^n + v_{j-1}^n \le \Delta t \left[H^*\left(\bar\alpha_j - \frac{\Delta x}{\Delta t}\right) - 2H^*(\bar\alpha_j) + H^*\left(\bar\alpha_j + \frac{\Delta x}{\Delta t}\right)\right] \le \Delta t \left(\frac{\Delta x}{\Delta t}\right)^2 \sup H^{*\prime\prime}, \tag{2.5}$$

which gives (2.3).

In order to prove (2.4), we take into consideration the values of $F_j(\alpha)$ for $x_j + \alpha\Delta t$ coinciding with a grid node, that is for $\alpha = k\Delta x/\Delta t$. Let k_j denote the index of the node for which $x_j + \bar\alpha_j \Delta t \in [x_{j+k_j}, x_{j+k_j+1}]$. We will denote by δ_j the (signed) maximal second increment of the numerical solution in the neighborhood $\overline{U}(x_j + \bar\alpha_j \Delta t)$ and by $j + k_j + l_j$ the index of the node at which this second increment occurs. If $\delta_j \ge 0$, then (2.4) follows from (2.3) and we have nothing else to prove. We will assume, therefore, that $\delta_j < 0$, so that

$$\begin{aligned}\delta_j &= - \max_{x_{i-1},x_i,x_{i+1}\in\overline{U}(x_j+\bar\alpha_j\Delta t)} |v_{i+1}^{n-1} - 2v_i^{n-1} + v_{i-1}^{n-1}| \\ &= v_{j+k_j+l_j+1}^{n-1} - 2v_{j+k_j+l_j}^{n-1} + v_{j+k_j+l_j-1}^{n-1}.\end{aligned} \tag{2.6}$$

We recall that $|l_j| < h$, and will also assume in what follows that $l_j \ge 0$, the reverse case being similar to prove.

As a first step, we can bound the second increment of the function F_j as follows:

$$\begin{aligned} &F_j\left((k+1)\frac{\Delta x}{\Delta t}\right) - 2F_j\left(k\frac{\Delta x}{\Delta t}\right) + F_j\left((k-1)\frac{\Delta x}{\Delta t}\right) \\ &= \Delta t\left[H^*\left((k+1)\frac{\Delta x}{\Delta t}\right) - 2H^*\left(k\frac{\Delta x}{\Delta t}\right) + H^*\left((k-1)\frac{\Delta x}{\Delta t}\right)\right] \\ &\quad + v_{j+k+1}^{n-1} - 2v_{j+k}^{n-1} + v_{j+k-1}^{n-1} \\ &\le \frac{\Delta x^2}{m_H \Delta t} + v_{j+k+1}^{n-1} - 2v_{j+k}^{n-1} + v_{j+k-1}^{n-1} \le \frac{2\Delta x^2}{m_H \Delta t}, \end{aligned} \tag{2.7}$$

where the second increment of H^* has been estimated as in (2.5), and the last inequality holds for $n \ge 2$.

In the second step, we prove that

$$F_j(\bar\alpha_j) \ge \min\left[F_j\left(k_j\frac{\Delta x}{\Delta t}\right), F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)\right] - \frac{\Delta x^2}{8m_H\Delta t} - C|\delta_j|. \tag{2.8}$$

In fact, set $\bar\alpha_j = (1-\bar\theta)k_j\Delta x/\Delta t + \bar\theta(k_j+1)\Delta x/\Delta t$, with $\bar\theta \in [0,1]$. Taking into account the uniform convexity of H^* implied by (2.2), we have

$$\begin{aligned} H^*(\bar\alpha_j) &\ge (1-\bar\theta)H^*\left(k_j\frac{\Delta x}{\Delta t}\right) + \bar\theta H^*\left((k_j+1)\frac{\Delta x}{\Delta t}\right) \\ &\quad - \frac{1}{2}\bar\theta(1-\bar\theta)\left(\frac{\Delta x}{\Delta t}\right)^2 \sup H^{*\prime\prime} \\ &\ge (1-\bar\theta)H^*\left(k_j\frac{\Delta x}{\Delta t}\right) + \bar\theta H^*\left((k_j+1)\frac{\Delta x}{\Delta t}\right) - \frac{\Delta x^2}{8m_H\Delta t^2} \end{aligned} \tag{2.9}$$

in which the third term has been minimized with respect to $\bar\theta$.

In a similar way, we also get, using (2.1) and the inclusion of $U(x)$ in $\overline{U}(x)$,

$$\begin{aligned}
&I[V^{n-1}](x_j+\bar\alpha_j\Delta t)\\
&\geq I_1[V^{n-1}](x_j+\bar\alpha_j\Delta t) - C\max_{x_{i-1},x_i,x_{i+1}\in U(x_j+\bar\alpha_j\Delta t)}|v_{i+1}-2v_i+v_{i-1}|\\
&\geq I_1[V^{n-1}](x_j+\bar\alpha_j\Delta t) - C\max_{x_{i-1},x_i,x_{i+1}\in \overline{U}(x_j+\bar\alpha_j\Delta t)}|v_{i+1}-2v_i+v_{i-1}|\\
&= (1-\bar\theta)v_{j+k_j}+\bar\theta v_{j+k_j+1} - C|\delta_j|\\
&= (1-\bar\theta)I[V^{n-1}]\left(x_j+k_j\frac{\Delta x}{\Delta t}\Delta t\right)+\bar\theta I[V^{n-1}]\left(x_j+(k_j+1)\frac{\Delta x}{\Delta t}\Delta t\right)-C|\delta_j|,
\end{aligned}$$

which, combined with (2.9), gives

$$F_j(\bar\alpha_j)\geq(1-\bar\theta)F_j\left(k_j\frac{\Delta x}{\Delta t}\right)+\bar\theta F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)-\frac{\Delta x^2}{8m_H\Delta t}-C|\delta_j|,$$

which in turn implies (2.8).

In the third step, we derive from (2.8) an estimate of the increment of F_j between $k_j\Delta x/\Delta t$ and $(k_j+1)\Delta x/\Delta t$.

Assume first that $F_j(k_j\Delta x/\Delta t)<F_j((k_j+1)\Delta x/\Delta t)$. Using (2.8) and the optimality of $\bar\alpha_j$, we obtain

$$F_j\left((k_j-1)\frac{\Delta x}{\Delta t}\right)\geq F_j(\bar\alpha_j)\geq F_j\left(k_j\frac{\Delta x}{\Delta t}\right)-\frac{\Delta x^2}{8m_H\Delta t}-C|\delta_j|,$$

that is, considering the extreme terms

$$F_j\left(k_j\frac{\Delta x}{\Delta t}\right)-F_j\left((k_j-1)\frac{\Delta x}{\Delta t}\right)\leq\frac{\Delta x^2}{8m_H\Delta t}+C|\delta_j|.$$

On the other hand, from (2.7) written with $k=k_j$, we also have

$$F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)-F_j\left(k_j\frac{\Delta x}{\Delta t}\right)\leq F_j\left(k_j\frac{\Delta x}{\Delta t}\right)-F_j\left((k_j-1)\frac{\Delta x}{\Delta t}\right)+\frac{2\Delta x^2}{m_H\Delta t}$$

and therefore, combining the last two inequalities, we get the desired bound on the first increment:

$$F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)-F_j\left(k_j\frac{\Delta x}{\Delta t}\right)\leq\frac{17\Delta x^2}{8m_H\Delta t}+C|\delta_j|. \tag{2.10}$$

Moreover, if $F_j((k_j+1)\Delta x/\Delta t)<F_j(k_j\Delta x/\Delta t)$, then

$$F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)-F_j\left(k_j\frac{\Delta x}{\Delta t}\right)\leq 0$$

and (2.10) is also trivially satisfied.

As a fourth step, we show that in order for $\bar\alpha_j$ to be a minimizer for F_j, δ_j must satisfy (2.4). To this end, we first assume that $F_j(k_j\Delta x/\Delta t)\leq F_j((k_j+1)\Delta x/\Delta t)$ and bound the values $F_j(k\Delta x/\Delta t)$ from above using a function $\tilde F_j(k\Delta x/\Delta t)$ constructed so as to coincide with F_j at $k_j\Delta x/\Delta t$ and to have first and second increments greater or equal to the corresponding increments of F_j. Taking into account the bounds on the first and second increment of F_j obtained in the previous steps of the proof, we

could define $\tilde{F}_j$ so that its first increment between $k_j\Delta x/\Delta t$ and $(k_j+1)\Delta x/\Delta t$ would be given by the right-hand side of (2.10), and the second increment would be obtained in view of (2.6), (2.7) as

$$\tilde{F}_j\left((k+1)\frac{\Delta x}{\Delta t}\right) - 2\tilde{F}_j\left(k\frac{\Delta x}{\Delta t}\right) + \tilde{F}_j\left((k-1)\frac{\Delta x}{\Delta t}\right) = \begin{cases} \dfrac{2\Delta x^2}{m_H\Delta t} & \text{if } k \neq k_j + l_j, \\ \dfrac{\Delta x^2}{m_H\Delta t} + \delta_j & \text{if } k = k_j + l_j. \end{cases} \tag{2.11}$$

We recall that, as it is easy to prove by induction, if a sequence f_i has a constant second increment,

$$f_{i+2} - 2f_{i+1} + f_i \equiv d,$$

then the values of the elements and of the first increments are given by

$$f_{k+l} = f_k + l(f_{k+1} - f_k) + (1 + 2 + \cdots + (l-1))d,$$

$$f_{k+l+1} - f_{k+l} = (f_{k+1} - f_k) + ld.$$

Using the previous equalities, a function $\tilde{F}_j$ suitable for our purpose could be defined more explicitly as

$$\tilde{F}_j\left(k_j\frac{\Delta x}{\Delta t}\right) = F_j\left(k_j\frac{\Delta x}{\Delta t}\right),$$

$$\tilde{F}_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right) = F_j\left(k_j\frac{\Delta x}{\Delta t}\right) + \frac{17\Delta x^2}{8m_H\Delta t} + C|\delta_j|,$$

$$\tilde{F}_j\left((k_j+2)\frac{\Delta x}{\Delta t}\right) = F_j\left(k_j\frac{\Delta x}{\Delta t}\right) + 2\left(\frac{17\Delta x^2}{8m_H\Delta t} + C|\delta_j|\right) + \frac{2\Delta x^2}{m_H\Delta t},$$

$$\vdots$$

$$\tilde{F}_j\left((k_j+l_j)\frac{\Delta x}{\Delta t}\right) = F_j\left(k_j\frac{\Delta x}{\Delta t}\right) + l_j\left(\frac{17\Delta x^2}{8m_H\Delta t} + C|\delta_j|\right) + (1+\cdots+(l_j-1))\frac{2\Delta x^2}{m_H\Delta t},$$

$$\begin{aligned}\tilde{F}_j\left((k_j+l_j+1)\frac{\Delta x}{\Delta t}\right) &= F_j\left(k_j\frac{\Delta x}{\Delta t}\right) + l_j\left(\frac{17\Delta x^2}{8m_H\Delta t} + C|\delta_j|\right) \\ &\quad + (1+\cdots+(l_j-1))\frac{2\Delta x^2}{m_H\Delta t} + \left(\frac{17\Delta x^2}{8m_H\Delta t} + C|\delta_j|\right) \\ &\quad + l_j\frac{2\Delta x^2}{m_H\Delta t} + \delta_j\end{aligned}$$

(note that the computation of $\tilde{F}_j((k_j+l_j+1)\Delta x/\Delta t)$ is "restarted" because of (2.11)) and last, for any integer $m>0$,

$$\begin{aligned}\tilde{F}_j\left((k_j+l_j+m)\frac{\Delta x}{\Delta t}\right) &= F_j\left(k_j\frac{\Delta x}{\Delta t}\right)\\ &\quad+(l_j+m)\left(\frac{17\Delta x^2}{8m_H\Delta t}+C|\delta_j|\right)\\ &\quad+(1+\cdots+(l_j+m-1))\frac{2\Delta x^2}{m_H\Delta t}+m\delta_j\\ &\le F_j\left(k_j\frac{\Delta x}{\Delta t}\right)+(h+m)\left(\frac{17\Delta x^2}{8m_H\Delta t}+C|\delta_j|\right)\\ &\quad+(1+\cdots+(h+m-1))\frac{2\Delta x^2}{m_H\Delta t}+m\delta_j.\end{aligned}\tag{2.12}$$

On the other hand, by (2.8) and the optimality of $\bar{\alpha}_j$, we also have, for any $m>0$,

$$\begin{aligned}\tilde{F}_j\left((k_j+l_j+m)\frac{\Delta x}{\Delta t}\right) &\ge F_j\left((k_j+l_j+m)\frac{\Delta x}{\Delta t}\right)\\ &\ge F_j(\bar{\alpha}_j)\\ &\ge \min\left[F_j\left(k_j\frac{\Delta x}{\Delta t}\right),F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)\right]\\ &\quad-\frac{\Delta x^2}{8m_H\Delta t}-C|\delta_j|.\end{aligned}\tag{2.13}$$

We explicitly note that in (2.13) the first inequality follows from the construction of $\tilde{F}_j$ as an upper bound for F_j, the second one from the optimality of $\bar{\alpha}_j$ in F_j, and the third one from the lower bound (2.8).

Recalling that we have assumed $F_j(k_j\Delta x/\Delta t)\le F_j((k_j+1)\Delta x/\Delta t)$ and $\delta_j<0$, and using (2.12), we obtain from the two extreme terms of (2.13)

$$\begin{aligned}&F_j\left(k_j\frac{\Delta x}{\Delta t}\right)+(h+m)\left(\frac{17\Delta x^2}{8m_H\Delta t}-C\delta_j\right)\\ &\quad+(1+\cdots+(h+m-1))\frac{2\Delta x^2}{m_H\Delta t}+m\delta_j\\ &\ge F_j\left(k_j\frac{\Delta x}{\Delta t}\right)-\frac{\Delta x^2}{8m_H\Delta t}+C\delta_j;\end{aligned}$$

that is,

$$\left[\frac{17}{8}(h+m)+2(1+\cdots+(h+m-1))+1\right]\frac{\Delta x^2}{m_H\Delta t}\ge\left[C(h+m)-m+C\right]\delta_j,$$

which gives, solving for δ_j,

$$-\frac{m(1+o(1))}{1-C}\frac{\Delta x^2}{m_H\Delta t}\le\delta_j<0\tag{2.14}$$

in which it is easy to recognize that the maximum of the left-hand side is $O(\Delta x^2/\Delta t)$, provided $C<1$. Using the reverse estimate (2.3), we get at last (2.4).

If otherwise $F_j((k_j+1)\Delta x/\Delta t) < F_j(k_j\Delta x/\Delta t)$, it is possible to redefine the function $\tilde{F}_j$ so that $\tilde{F}_j((k_j+1)\Delta x/\Delta t) = F_j((k_j+1)\Delta x/\Delta t)$, and the same upper bounds are used on the first and second increments. In this way, we replace (2.12) with

$$\begin{aligned}(2.12') \qquad \tilde{F}_j\left((k_j+l_j+m)\frac{\Delta x}{\Delta t}\right) &= F_j\left((k_j+1)\frac{\Delta x}{\Delta t}\right)\\ &\quad + (l_j+m-1)\left(\frac{17\Delta x^2}{8m_H\Delta t}+C|\delta_j|\right)\\ &\quad + (1+\cdots+(l_j+m-1))\frac{2\Delta x^2}{m_H\Delta t}+m\delta_j,\end{aligned}$$

which again implies (2.14). This construction completely parallels the previous one and is therefore left to the reader. □

Remark 2.1. The technique used in this lemma is not specifically suited for the one-dimensional case, although for higher dimensions (especially on unstructured grids), assumption (2.1) should be suitably redefined. The first part of Lemma 2.1 may be soon extended to higher dimensions, by using the same technique of making the feet of different characteristics coincide. The second part of the lemma would require a more technical construction of the function $\tilde{F}_j$. Also, the treatment of Dirichlet boundary conditions is not a major problem. Simply, the foot of characteristics might coincide with a point on the boundary, requiring again a proper, more technical definition of the functions F_j and $\tilde{F}_j$.

We can now prove Lipschitz continuity. We will assume that, given a Lipschitz continuous function $v(x)$ and the sequence $V = \{v_j\}_j = \{v(x_j)\}_j$, the condition

$$|I[V](x) - I_1[V](x)| \le \tilde{C}\Delta x \tag{2.15}$$

holds for any $x \in \mathbb{R}$, with a positive constant $\tilde{C}$. In the one-dimensional setting, this is a consequence of (2.1) since

$$\begin{aligned}|I[V](x) - I_1[V](x)| &\le C \max_{x_{i-1},x_i,x_{i+1}\in U(x)} |v_{i+1}-2v_i+v_{i-1}|\\ &\le C\left(\sup|v_{i+1}-v_i| + \sup|v_{i-1}-v_i|\right) = 2CL\Delta x.\end{aligned}$$

We will also assume that at the foot of a characteristic the stronger condition

$$|I[V^{n-1}](x_i+\bar{\alpha}_j\Delta t) - I_1[V^{n-1}](x_i+\bar{\alpha}_j\Delta t)| \le \hat{C}\frac{\Delta x^2}{\Delta t} \tag{2.16}$$

holds for any $j \in \mathbb{Z}$, $n \ge 2$ and for any node x_i neighboring x_j, with some positive constant $\hat{C}$. In the case of one-dimensional problems, (2.16) follows from (2.1) and Lemma 2.1. (In fact, $\overline{U}(x_j+\bar{\alpha}_j\Delta t)$ contains all the nodes involved in the reconstructions $I[V^{n-1}](x_{j\pm1}+\bar{\alpha}_j\Delta t)$.)

THEOREM 2.1. *Consider the scheme* (1.4) *applied to* (1.1). *Assume that* (2.15), (2.16) *hold, that* $\Delta x = O(\Delta t^2)$, *and that* v_0 *is Lipschitz continuous with Lipschitz constant* L_0. *Then, the numerical solutions* V^n *satisfy, for any* i *and* j, *the discrete Lipschitz estimate*

$$\frac{|v_i^n - v_j^n|}{|x_i - x_j|} \le L$$

for a constant L independent of Δx and Δt, and for $0 \le n \le T/\Delta t$, as $\Delta t \to 0$.

Proof. It clearly suffices to prove the claim for i, j such that x_i and x_j are neighboring nodes. Assume that at the previous step the discrete solution satisfies, for any i and j,

$$\frac{|v_i^{n-1} - v_j^{n-1}|}{|x_i - x_j|} \le L_{n-1}.$$

Making the argmin explicit and using (2.16), we have

$$\begin{aligned} v_j^n &= \min_\alpha \left\{ \Delta t H^*(\alpha) + I[V^{n-1}](x_j + \alpha \Delta t) \right\} \\ &= \Delta t H^*(\bar\alpha_j) + I[V^{n-1}](x_j + \bar\alpha_j \Delta t) \\ &\ge \Delta t H^*(\bar\alpha_j) + I_1[V^{n-1}](x_j + \bar\alpha_j \Delta t) - \hat C \frac{\Delta x^2}{\Delta t}. \end{aligned} \tag{2.17}$$

In order to estimate the discrete incremental ratio of V^n, we give on v_i^n the bound

$$\begin{aligned} v_i^n &= \Delta t H^*(\bar\alpha_i) + I[V^{n-1}](x_i + \bar\alpha_i \Delta t) \\ &\le \Delta t H^*(\bar\alpha_j) + I[V^{n-1}](x_i + \bar\alpha_j \Delta t) \\ &\le \Delta t H^*(\bar\alpha_j) + I_1[V^{n-1}](x_i + \bar\alpha_j \Delta t) + \hat C \frac{\Delta x^2}{\Delta t}, \end{aligned} \tag{2.18}$$

which results from both the optimality of $\bar\alpha_i$ and (2.16) and holds for any $n \ge 2$. If $n = 1$, applying (2.15) instead of (2.16), we obtain

$$\begin{aligned} v_i^1 &= \Delta t H^*(\bar\alpha_i) + I[V^0](x_i + \bar\alpha_i \Delta t) \\ &\le \Delta t H^*(\bar\alpha_j) + I[V^0](x_i + \bar\alpha_j \Delta t) \\ &\le \Delta t H^*(\bar\alpha_j) + I_1[V^0](x_i + \bar\alpha_j \Delta t) + \tilde C \Delta x. \end{aligned} \tag{2.19}$$

From (2.17) and (2.18) we obtain, for $n \ge 2$, the unilateral estimate

$$\begin{aligned} \frac{v_i^n - v_j^n}{|x_i - x_j|} &\le \frac{1}{|x_i - x_j|} \left[I_1[V^{n-1}](x_i + \bar\alpha_j \Delta t) - I_1[V^{n-1}](x_j + \bar\alpha_j \Delta t) \right] \\ &\quad + 2\hat C \frac{\Delta x^2}{\Delta t} \\ &\le L_{n-1} + \frac{2\hat C}{C_-} \frac{\Delta x}{\Delta t}, \end{aligned} \tag{2.20}$$

in which C_- is the constant defined at the start of the section, and we have used the fact that the first-order reconstruction I_1 at step $n-1$ has also Lipschitz constant L_{n-1}. Interchanging the role of $\bar\alpha_j$ and $\bar\alpha_{j+1}$, we get the reverse estimate

$$\frac{v_j^n - v_i^n}{|x_i - x_j|} \le L_{n-1} + \frac{2\hat C}{C_-} \frac{\Delta x}{\Delta t},$$

and therefore

$$\frac{|v_j^n - v_i^n|}{|x_i - x_j|} \le L_{n-1} + \frac{2\hat C}{C_-} \frac{\Delta x}{\Delta t}. \tag{2.21}$$

A similar computation yields, for $n = 1$,

$$\frac{|v_j^1 - v_i^1|}{|x_i - x_j|} \le L_0 + \frac{2\tilde{C}}{C_-}, \tag{2.22}$$

so that combining (2.21) with (2.22) and iterating back, we have

$$\begin{aligned} L_n &\le L_{n-1} + \frac{2\hat{C}}{C_-}\frac{\Delta x}{\Delta t} \\ &\le \cdots \le L_1 + \frac{T-\Delta t}{\Delta t}\frac{2\hat{C}}{C_-}\frac{\Delta x}{\Delta t} \le L_0 + \frac{T-\Delta t}{\Delta t}\frac{2\hat{C}}{C_-}\frac{\Delta x}{\Delta t} + \frac{2\tilde{C}}{C_-}. \end{aligned} \tag{2.23}$$

Last, it is possible to get a finite limit in (2.23), if and only if $\Delta x = O(\Delta t^2)$. □

Remark 2.2. Once we have proved Lipschitz continuity, we can also obtain L^∞ boundedness using the same arguments as in [F].

Remark 2.3. The condition $\Delta x/\Delta t \to 0$ is not unnatural in this class of schemes. As has been remarked elsewhere, the numerical domain of dependence enlarges (as it is easy to see from (1.4)) as Δt increases, so that very large Courant numbers are allowed without loss of stability. Of course, managing this larger domain of dependence requires some caution to keep the computational complexity as low as possible in the minimization phase. Roughly speaking, practical implementations of the scheme perform the minimization of F_j at any node and any time step by some suitable descent method. (The interested reader can find details in [CFF], [FF3].)

Remark 2.4. The local truncation error of the scheme (see [FF3]) is of order

$$\Delta t^p + \frac{\Delta x^{r+1}}{\Delta t}$$

(with order p of approximation of characteristics, order r of space interpolation) so that at least in the case $r = 0$ (piecewise constant reconstruction), the consistency of the scheme itself requires that the Courant number should diverge.

3. Applications to various reconstruction operators. In this section we prove the applicability of the previous results to one-dimensional high-order reconstruction of polynomial type. We assume the reconstruction to be of rth order in the Newton form

$$\begin{aligned} I[V](x) = V[x_{j_0}] &+ V[x_{j_0}, x_{j_1}](x - x_{j_0}) + \cdots \\ &+ V[x_{j_0}, \ldots, x_{j_r}](x - x_{j_0}) \cdots (x - x_{j_{r-1}}), \end{aligned} \tag{3.1}$$

where $x_{j_0}, \ldots, x_{j_r}$ are $r+1$ adjacent nodes so that $\max(x_{j_0}, \ldots, x_{j_r}) - \min(x_{j_0}, \ldots, x_{j_r}) = r\Delta x$ and, moreover,

$$x \in (\min(x_{j_0}, \ldots, x_{j_r}), \max(x_{j_0}, \ldots, x_{j_r})) \subset U(x). \tag{3.2}$$

This definition includes both Lagrange polynomial interpolations, for which the reconstruction stencil is fixed once x is fixed, and ENO reconstructions, for which it depends on the solution itself (see [S]). The divided differences are defined, as usual, by

$$V[x_{j_0}] = v_{j_0},$$

$$V[x_{j_0}, \ldots, x_{j_k}] = \frac{V[x_{j_1}, \ldots, x_{j_k}] - V[x_{j_0}, \ldots, x_{j_{k-1}}]}{x_{j_k} - x_{j_0}} \quad (k = 1, \ldots, r).$$

Note that, although in principle the nodes $x_{j_0},\dots,x_{j_k}$ need neither to be adjacent nor to satisfy $x\in(\min x_{j_i},\max x_{j_i})$, it is possible to reorder the nodes so that both conditions would be satisfied.

According to its definition, we can bound a generic kth order divided difference as follows:

$$|V[x_{j_0},\dots,x_{j_k}]|\le\frac{2\max|V[x_{j_i},\dots,x_{j_{k+i-1}}]|}{k\Delta x} \tag{3.3}$$

in which the max is performed for $x_{j_i},\dots,x_{j_{k+i-1}}\in U(x)$. Let us now denote more precisely the constant C in (2.1) by C_r (depending on the order r of the reconstruction). To prove (2.1), we start from the second divided difference

$$|V[x_{j_0},x_{j_1},x_{j_2}]|=\frac{|v_{j_0}-2v_{j_1}+v_{j_2}|}{2\Delta x^2},$$

and, hence,

$$\begin{aligned}|V[x_{j_0},x_{j_1},x_{j_2},x_{j_3}]|&\le\frac{2\max|v_{j_i}-2v_{j_{i+1}}+v_{j_{i+2}}|}{3!\Delta x^3}\\&\vdots\\|V[x_{j_0},\dots,x_{j_r}]|&\le\frac{2^{r-2}\max|v_{j_i}-2v_{j_{i+1}}+v_{j_{i+2}}|}{r!\Delta x^r}.\end{aligned}$$

Plugging such bounds into (3.1), we get an estimate in the form (2.1); that is,

$$\begin{aligned}|I[V](x)-I_1[V](x)|&\le|V[x_{j_0},x_{j_1},x_{j_2}](x-x_{j_0})(x-x_{j_1})\\&\quad+\cdots+V[x_{j_0},\dots,x_{j_r}](x-x_{j_0})\cdots(x-x_{j_{r-1}})|\\&\le\frac{|v_{j_0}-2v_{j_1}+v_{j_2}|}{2\Delta x^2}M_2\Delta x^2\\&\quad+\cdots+\frac{2^{r-2}\max|v_{j_i}-2v_{j_{i+1}}+v_{j_{i+2}}|}{r!\Delta x^r}M_r\Delta x^r\\&\le\max|v_{j_i}-2v_{j_{i+1}}+v_{j_{i+2}}|\sum_{k=2}^{r}\frac{M_k2^{k-2}}{k!},\end{aligned} \tag{3.4}$$

where

$$\begin{aligned}M_k&:=\frac{1}{\Delta x^k}\max_{x\in(x_{j_0},x_{j_{k-1}})}|(x-x_{j_0})\cdots(x-x_{j_{k-1}})|\\&=\max_{t\in(0,k-1)}|t(t-1)\cdots(t-k+1)|.\end{aligned}$$

It remains to check that $C_r<1$; that is,

$$\sum_{k=2}^{r}\frac{M_k2^{k-2}}{k!}<1. \tag{3.5}$$

Indeed, the first values M_k may be either computed by algebraic manipulations (up to M_5), or estimated by simply plotting the polynomials $t(t-1)\cdots(t-k+1)$ on the interval $[0,k-1]$. It turns out that $M_2=1/4$, $M_3=2\sqrt{3}/9\approx0.3849$, $M_4=1$,

$M_5 \approx 3.6314$, $M_6 < 17$, and so on. Accordingly, the computation of the left-hand side of (3.5) for various values of r gives $C_2 = 1/8 = 0.125$, $C_3 \approx 0.2533$, $C_4 \approx 0.42$, $C_5 \approx 0.6621$, $C_6 \approx 1.04$. We can conclude that by this technique, polynomial and ENO reconstructions up to the fifth order can be proved to satisfy (2.1).

Remark 3.1. While this paper was under review, we realized (see [CFR]) a property which allows us to extend this theory to Lagrange and weighted essentially nonoscillatory (WENO) interpolations up to the degree $r = 9$, provided the reconstruction stencil is "balanced" in the sense that

$$|h_+ - h_-| \le 1. \tag{3.6}$$

Roughly speaking, the idea is that the interpolation $I[V](x)$ could be obtained as a sum

$$I[V] = w_1(x)p_1(x) + \cdots + w_q(x)p_q(x) \tag{3.7}$$

in which the polynomials w_i and p_i are such that $\deg w_i + \deg p_i = r$ and the p_i are constructed on smaller stencils which include the point x (this form is at the base of WENO interpolations). With $\deg p_i \le 5$, one has $r \le 9$, and it turns out that $w_i(x) \ge 0$ for all i and $\sum_i w_i(x) = 1$, so that by (3.7)

$$\min(p_1(x), \dots, p_q(x)) \le I[V](x) \le \max(p_1(x), \dots, p_q(x))$$

and therefore (2.1), being satisfied by all p_i, is also satisfied by $I[V]$.

4. The main convergence result. Last, we present in this section the main result of the paper, that is, a convergence theorem for the scheme (1.4).

THEOREM 4.1. *Consider the scheme* (1.4) *applied to* (1.1). *Assume that* (2.15), (2.16) *hold, that* $\Delta x = O(\Delta t^2)$, *and that* v_0 *is Lipschitz continuous. Then, the numerical solutions* V^n *satisfy*

$$\|I[V^n] - v(n\Delta t)\|_\infty \to 0$$

for $0 \le n \le T/\Delta t$, *as* $\Delta t \to 0$.

Proof. We rewrite exact and approximate solutions at node x_j and time $n\Delta t$ as

$$v(x_j, n\Delta t) = \Delta t H^*(a_j) + v(x_j + a_j\Delta t, (n-1)\Delta t), \tag{4.1}$$

$$v_j^n = \Delta t H^*(\bar\alpha_j) + I[V^{n-1}](x_j + \bar\alpha_j \Delta t), \tag{4.2}$$

where the argmin in (1.3) and (1.4) has been made explicit. Working as in Theorem 2.1, we give a first unilateral bound as

$$\begin{aligned} v_j^n - v(x_j, n\Delta t) &\le v(x_j + a_j\Delta t, (n-1)\Delta t) - I[V^{n-1}](x_j + a_j\Delta t) \\ &\le |v(x_j + a_j\Delta t, (n-1)\Delta t) - I[W^{n-1}](x_j + a_j\Delta t)| \\ &\quad + |I[W^{n-1}](x_j + a_j\Delta t) - I[V^{n-1}](x_j + a_j\Delta t)|, \end{aligned} \tag{4.3}$$

in which we have used the sequence

$$W^k := \{v(x_i, t_k)\}_i.$$

Under our assumptions, the numerical solution is Lipschitz by Theorem 2.1. Since this is also true for the exact solution (see [L]), all reconstructions in the right-hand

side of (4.3) are performed on Lipschitz sequences and therefore (2.15) applies. (We note that, even in the one-dimensional case, we cannot apply the bound of Lemma 2.1 since a_j is used in the scheme instead of $\bar{\alpha}_j$.) Now, the first term of the right-hand side of (4.3) is the reconstruction error for the Lipschitz continuous function v, and we have

$$\begin{aligned}&|v(x_j + a_j\Delta t, (n-1)\Delta t) - I[W^{n-1}](x_j + a_j\Delta t)| \\ &\le |v(x_j + a_j\Delta t, (n-1)\Delta t) - I_1[W^{n-1}](x_j + a_j\Delta t)| \\ &\quad + |I_1[W^{n-1}](x_j + a_j\Delta t) - I[W^{n-1}](x_j + a_j\Delta t)| \to 0\end{aligned}$$

with first-order convergence with respect to Δx, resulting from the convergence of P_1 interpolation to a Lipschitz function and from (2.15) (written with W^{n-1} instead of V). For the second term in the right-hand side of (4.3) we can write, using (2.15) and the monotonicity of the reconstruction I_1,

(4.4)

$$\begin{aligned}|I[W^{n-1}](x_j + a_j\Delta t) - I[V^{n-1}](x_j + a_j\Delta t)| &\le |I_1[W^{n-1}](x_j + a_j\Delta t) \\ &\quad - I_1[V^{n-1}](x_j + a_j\Delta t)| + 2\tilde{C}\Delta x \\ &\le |W^{n-1} - V^{n-1}|_\infty + 2\tilde{C}\Delta x,\end{aligned}$$

and therefore, using the reverse estimate which can be obtained in the same way,

$$|W^n - V^n|_\infty \le |W^{n-1} - V^{n-1}|_\infty + 2\tilde{C}\Delta x,$$

which implies $|W^n - V^n|_\infty \to 0$ since $|W^0 - V^0|_\infty = 0$ and $\Delta x = O(\Delta t^2)$. Last, by (2.15) and the Lipschitz continuity of v, we easily get

$$\|I[V^n] - v(n\Delta t)\|_\infty \le |W^n - V^n|_\infty + \check{C}\Delta x$$

and this proves the theorem for $\Delta t, \Delta x \to 0$. □

Remark 4.1. In this theorem, the condition $\Delta x = O(\Delta t^2)$ is only required in order to ensure Lipschitz stability. The proof itself requires the weaker condition $\Delta x = o(\Delta t)$, which is in turn related to consistency as already remarked in section 2.

Remark 4.2. Since the scheme experimentally appears to be convergent under any $\Delta t/\Delta x$ relationship, we should infer that this convergence result is not optimal. This might be due to an intrinsic limitation of this technique of proof, as well as to the very weak assumptions on the reconstruction operator. In fact, assumption (3.2) alone does not even allow the scheme to be stable in the sense of Von Neumann (see [FF2] where a sort of "balancing" of the reconstruction stencil turns out to be necessary). Here, the nonlinear min operation plays a crucial role in stabilizing the scheme.

ON THE CONVERGENCE OF THE FOURIER APPROXIMATION FOR EIGENVALUES AND EIGENFUNCTIONS OF DISCONTINUOUS PROBLEMS*

M. S. MIN† AND D. GOTTLIEB†

Abstract. In this paper, we consider a model eigenvalue problem with discontinuous coefficients in order to study the convergence of the Fourier methods applied to this problem. We prove that the rate of convergence of the Fourier–Galerkin method is third order for the eigenvalues and order 2.5 for the eigenfunctions. For the Fourier collocation method we obtained only second order accuracy.

We also show that the Fourier collocation method can be improved by a preprocessing of the coefficients.

The theory is confirmed by numerical results.

1. Introduction.

The paper is motivated by an issue arising in the use of spectral methods in nonlinear optics. The Fourier methods when applied to problems in nonlinear optics are extremely fast, and if the problem is smooth they provide high order accuracy. However, when different media are considered, the coefficients are only piecewise smooth and the accuracy is lost.

In order to understand the phenomenon, and as a first step to improve the accuracy of the Fourier schemes in those circumstances, we consider in this paper a model eigenvalue problem with piecewise constant coefficients and study the convergence of the Fourier–Galerkin and Fourier collocation methods to the eigenvalues and the eigenfunctions of this problem. The surprising fact is that the order of convergence of the eigenvalues obtained by the Fourier–Galerkin method is cubic. When the Fourier collocation method is applied, the results are only second order. Those results are proven and supported by numerical computations.

It turns out that, by preprocessing the discontinuous coefficients, one can improve the accuracy of the collocation method. In fact, if one uses the point values of the finite Fourier series of the coefficients instead of the point values of the coefficients themselves, one recovers third order accuracy for the eigenvalues and order 2.5 for the eigenfunction.

The paper is organized as follows. In section 2, we present the problem and show some of the eigenvalues and eigenfunctions. In section 3, we rewrite the problem in its variational form and quote some relevant facts. In section 4, we discuss the Fourier–Galerkin method and prove the order of accuracy. Section 5 is devoted to the Fourier collocation method and the error estimates of this method. In section 6, we show how to improve the accuracy of the collocation method.

†Division of Applied Mathematics, Brown University, Providence, RI 02912 (msmin@cfm.brown.edu, dig@cfm.brown.edu).

We regard this paper as the first step toward recovering exponential accuracy for this problem.

2. The discontinuous eigenvalue problem. Consider the following eigenvalue problem with a piecewise constant coefficient:

$$-\frac{d^2u}{dx^2} = \lambda\epsilon(x)u \quad \text{for} \quad x \in (-\pi,\pi), \tag{2.1}$$

where $\epsilon(x) = 1$ in $(-\pi, 0)$ and $\epsilon(x) = \beta^2$ in $[0,\pi)$, $\beta \neq 1$. The $H_p^2[-\pi,\pi]$ eigenfunction $u_l(x)$ (the p stands for periodic) is given by

$$u_l(x) = \begin{cases} C\cos(\sqrt{\lambda}_l x) + \beta D\sin(\sqrt{\lambda}_l x), & -\pi \le x \le 0, \\ C\cos(\beta\sqrt{\lambda}_l x) + D\sin(\beta\sqrt{\lambda}_l x), & 0 \le x \le \pi, \end{cases} \tag{2.2}$$

where the constants C, D and the eigenvalue λ_l are determined by the demand that the system

$$\begin{aligned} C(\cos\sqrt{\lambda}\pi - \cos\beta\sqrt{\lambda}\pi) + D(-\beta\sin\sqrt{\lambda}\pi - \sin\beta\sqrt{\lambda}\pi) = 0, \\ C(\sin\sqrt{\lambda}\pi + \beta\sin\beta\sqrt{\lambda}\pi) + D(\beta\cos\sqrt{\lambda}\pi - \beta\cos\beta\sqrt{\lambda}\pi) = 0 \end{aligned}$$

has a nontrivial solution. Considering the case $\beta = 2$, for $y = \cos\sqrt{\lambda}\pi$, the eigenvalues λ satisfy the equation

$$(y-1)(9y^2 + 9y + 2) = 0,$$

and so there are families of eigenvalues determined by

$$\cos\sqrt{\lambda}\pi = 1, -\frac{1}{3}, \quad \text{or} \quad -\frac{2}{3}. \tag{2.3}$$

The first five analytic eigenvalues (with six digits of precision) and the corresponding eigenvectors are shown in Figure 1. For comparison, we also carry the same procedure for $\beta = 3$, where the analytic eigenvalues are determined by

$$\cos\sqrt{\lambda}\pi = \pm 1 \ \text{ or } \ \pm\frac{1}{4}. \tag{2.4}$$

In this paper, we examine the rate of convergence of the Fourier methods (Galerkin and collocation) as a first step in an effort to improve the rate of convergence and be able to also apply the Fourier methods for this discontinuous problem.

3. The variational formulation. We define two inner products:

$$a(u,v) = \int_{-\pi}^{\pi} u'(x)\overline{v'(x)}dx, \tag{3.1}$$

$$(u,v) = \int_{-\pi}^{\pi} u(x)\overline{v(x)}\epsilon(x)dx. \tag{3.2}$$

Following Strang and Fix [7, p. 220], the eigenvalue problem (2.1) can be presented in the following variational form: finding a scalar λ and a function $u \in H_p^1[-\pi,\pi]$ such that

$$a(u,v) = \lambda(u,v) \tag{3.3}$$

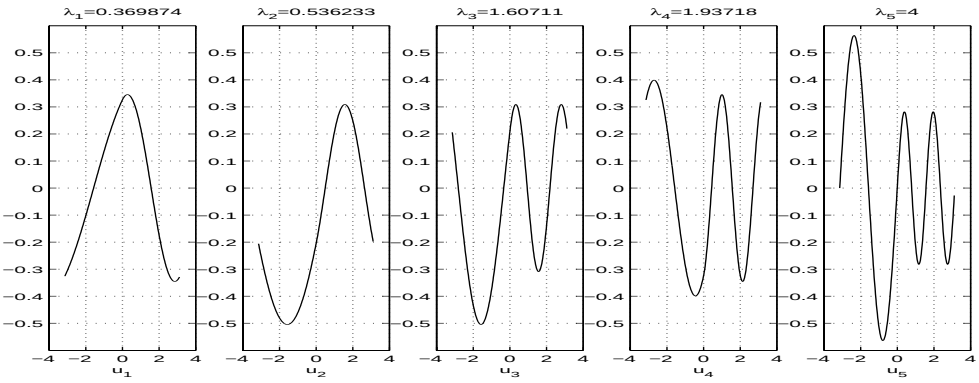

FIG. 1. *The first five analytic eigenvalues and eigenfunctions.*

for all v in the Hilbert space $H_p^1[-\pi,\pi]$. Note that $a(u,v)$ is Hermitian.

Our proofs will use extensively the minmax principle [3].

THEOREM 3.1. *Let λ_l denote the eigenvalues of* (2.1) *and S_l be any l-dimensional subspace of $H_p^1[-\pi,\pi]$. Then, for $\lambda_1 \le \lambda_2 \le \cdots \le \lambda_l \ldots$,*

$$\lambda_l = \min_{S_l \subset H_p^1[-\pi,\pi]} \max_{v \in S_l} \frac{a(v,v)}{(v,v)}. \tag{3.4}$$

In this paper, we will use sharper characterizations of the eigenvalues.

LEMMA 3.2. *Let λ_i be arranged in an ascending order and define*

$$E_{i,j} = span\{u_i, \ldots, u_j\},$$

where u_i is the eigenfunction corresponding to the eigenvalue λ_i. Then

$$\lambda_l = \max_{v \in E_{k,l}} \frac{a(v,v)}{(v,v)}, \quad k \le l, \tag{3.5}$$

$$\lambda_l = \min_{v \in E_{l,m}} \frac{a(v,v)}{(v,v)}, \quad l \le m. \tag{3.6}$$

4. Fourier–Galerkin method. It is natural to consider the Fourier method to approximate the periodic problem. Here, we introduce the Fourier–Galerkin method applied to the variational formulation for approximating the eigenvalues and eigenfunctions.

Let $\mathcal{P}_\mathcal{N}$ be the space of the trigonometric polynomials of degree $N/2$ defined as

$$\mathcal{P}_\mathcal{N} = \text{span}\{e^{ikx} | -N/2 \le k \le N/2\}. \tag{4.1}$$

In this subspace, we look for λ^N and u^N such that

$$a(u^N, v^N) = \lambda^N (u^N, v^N) \text{ for all } v^N \in \mathcal{P}_\mathcal{N}; \tag{4.2}$$

in other words,

$$\int_{-\pi}^{\pi} (u^N(x))' \overline{(v^N(x))'} dx = \lambda^N \int_{-\pi}^{\pi} u^N(x) \overline{v^N(x)} \epsilon(x) dx. \tag{4.3}$$

4.1. Numerical scheme and its results. The approximate eigenfunction u^N in the subspace $\mathcal{P}_\mathcal{N}$ is expanded by

$$u^N = \sum_{k=-\frac{N}{2}}^{\frac{N}{2}} (\hat{u}^N)_k e^{ikx}. \tag{4.4}$$

Substituting u^N into the variational formulation (4.2) with $v^N = e^{inx}$, and denoting the vector of the coefficients by $\hat{\mathbf{u}}^N$, we get a generalized eigenvalue problem in a matrix form as

$$K\hat{\mathbf{u}}^N = \lambda^N M\hat{\mathbf{u}}^N, \tag{4.5}$$

where

$$K_{nk} = \int_{-\pi}^{\pi} (k \cdot n) e^{i(k-n)x} dx \quad \text{and} \quad M_{nk} = \int_{-\pi}^{\pi} e^{i(k-n)x} \epsilon(x) dx. \tag{4.6}$$

Solving the matrix eigenvalue problem (4.5) computationally using a proper eigensolver, we obtain the approximate lth eigenvalues, $\lambda_l^N (l \le N)$, and the set of orthogonal vectors $\hat{\mathbf{u}}_l{}^N = [(\hat{u}_l^N)_{-N/2}, \ldots, (\hat{u}_l^N)_{N/2}]^T$ which is used to approximate the lth eigenfunction u_l as a finite Fourier series u_l^N. In Tables 1 and 2, the orders of the relative errors for $\lambda_l^N - \lambda_l$ and the discrete L_2-errors of $u_l - u_l^N$ are provided for the first five eigenvalues in ascending order and for the associated eigenfunctions. We note the surprising fact that the Galerkin approximation to the eigenvalue problem (2.1) converges with *third order accuracy* for the eigenvalues and order 2.5 for the eigenfunctions even though the eigenfunctions are only in H_p^2. In fact, we will show in Lemma 4.5 that the eigenfunctions are in $H_p^{\frac{5}{2}-\epsilon}$ for any $\epsilon > 0$.

4.2. Error estimates for eigenvalues and eigenfunctions. In this section, we provide the error estimates for the approximate eigenvalues and eigenfunctions for the Fourier–Galerkin method.

We first treat the approximate eigenvalues. Let $P_N u$ be the $\frac{N}{2}$th order truncated Fourier series of u. (We will denote also $P = P_N$.) It is clear that it satisfies

$$a(u - P_N u, v^N) = 0 \ \text{ for all } v^N \in \mathcal{P}_\mathcal{N}. \tag{4.7}$$

It is true that the minmax principle is also valid for the Galerkin procedure:

$$\lambda_l^N = \min_{S_l \subset \mathcal{P}_\mathcal{N}} \max_{v \in S_l} \frac{a(v,v)}{(v,v)}. \tag{4.8}$$

LEMMA 4.1. *Let λ_l^N be the approximation to λ_l which is obtained by the Galerkin procedure. Then*

$$\lambda_l \le \lambda_l^N \le \lambda_l \max_{v \in E_{1,l}} \frac{(v,v)}{(Pv,Pv)}.$$

Proof. Due to the minmax principle (3.4) and (4.8), we have

$$\begin{aligned} \lambda_l &= \min_{S_l \subset H_p^1[-\pi,\pi]} \max_{v \in S_l} \frac{a(v,v)}{(v,v)} \\ &\le \min_{S_l \subset \mathcal{P}_\mathcal{N}} \max_{v \in S_l} \frac{a(v,v)}{(v,v)} = \lambda_l^N. \end{aligned}$$

	256	2.49776	7.5555(-7)	2.9725	1.4749(-5)	2.4430

Thus only the upper bound of the approximate eigenvalue is left to be investigated.

Let $PE_{1,l}$ be spanned by $Pu_1, \ldots, Pu_l$. Then it is clear that $PE_{1,l}$ is the l-dimensional subspace of $\mathcal{P}_{\mathcal{N}}$. Using the minmax principle (4.8),

$$\lambda_l^N \le \max_{v \in PE_{1,l}} \frac{a(v,v)}{(v,v)} = \max_{v \in E_{1,l}} \frac{a(Pv,Pv)}{(Pv,Pv)}. \tag{4.9}$$

Note that in [7] we have

$$a(v,v) = a(Pv,Pv) + 2a(v-Pv,Pv) + a(v-Pv,v-Pv). \tag{4.10}$$

From (4.7), we know that $a(v-Pv,Pv)$ always vanishes for all Pv in the space $\mathcal{P}_{\mathcal{N}}$. Then we have $a(Pv,Pv) \le a(v,v)$. Thus,

$$\lambda_l^N \le \max_{v \in E_{1,l}} \frac{a(v,v)}{(Pv,Pv)} = \max_{v \in E1,_l} \frac{a(v,v)}{(v,v)} \cdot \frac{(v,v)}{(Pv,Pv)} \le \lambda_l \cdot \max_{v \in E_{1,l}} \frac{(v,v)}{(Pv,Pv)}.$$

The last inequality is a by-product of (3.5). Thus the lemma is proven. ∎

The issue is how close $(P_N v, P_N v)$ is to (v,v) for $v \in E_{1,l}$. One would expect the second order accuracy in N because of the smoothness of the eigenfunctions u_i. However, we will show that it is really third order. We start by examining the Fourier coefficients of the eigenfunctions.

LEMMA 4.2. *The Fourier coefficients $(\hat{u_l})_k$ of the eigenfunction u_l decay as $O(k^{-3})$; in fact,*

$$(\hat{u_l})_k \le Ck^{-3}\left\{|u_l(0)| + \frac{1}{k}|u_l^{'}(0)| + \frac{\lambda_l}{k}||u_l||\right\}, \tag{4.11}$$

where $||u_l||$ is the L_2-norm of u_l.

Proof. Letting $u_l = u$ for simplicity, and using the fact that $u^{'}$ is continuous,

$$\hat{u}_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} ue^{-ikx}dx = \frac{1}{2\pi ik}\int_{-\pi}^{\pi} u'e^{-ikx}dx = -\frac{1}{2\pi k^2}\int_{-\pi}^{\pi} u''e^{-ikx}dx. \tag{4.12}$$

Substituting $u'' = -\lambda\epsilon u$ into (4.12) and, for convenience, using the notation $\mu = \beta^2 - 1$, we have

$$\begin{aligned}
\hat{u}_k &= \frac{1}{2\pi k^2}\int_{-\pi}^{\pi} \lambda\epsilon ue^{-ikx}dx = \frac{\lambda}{2\pi k^2}\left(\int_{-\pi}^{0} ue^{-ikx}dx + \beta^2\int_{0}^{\pi} ue^{-ikx}dx\right) \\
&= \frac{\lambda}{2\pi ik^3}\left(\mu\{(-1)^k u(\pi) - u(0)\} + \int_{-\pi}^{0} u'e^{-ikx}dx + \beta^2\int_{0}^{\pi} u'e^{-ikx}dx\right) \\
&= \frac{\lambda}{2\pi ik^3}\left(\mu[(-1)^k u(\pi) - u(0)] + \frac{\mu}{ik}[(-1)^k u'(\pi) - u'(0)] + \frac{1}{ik}\int_{-\pi}^{\pi} \lambda\epsilon ue^{-ikx}dx\right).
\end{aligned}$$

Therefore, the lemma is proven. ∎

We are ready now for the next lemma.

LEMMA 4.3.

$$\max_{v \in E1,l} \frac{(v,v)}{(Pv,Pv)} \le 1 + ClN^{-3},$$

where the constant C is independent of N and l.

Proof. We first note that

$$\frac{(v,v)}{(Pv,Pv)} = \frac{1}{1-\frac{(v,v)-(Pv,Pv)}{(v,v)}}. \tag{4.13}$$

Since v is in $E_{1,l}$, it can be represented by $v = \sum_{i=1}^{l} \alpha_i u_i$. We also have

$$(Pv,Pv) = (v,v) - (v-Pv,v) - \overline{(v-Pv,v)} + (v-Pv, v-Pv).$$

Thus we get

$$\begin{aligned}\frac{(v,v)-(Pv,Pv)}{(v,v)} &\le \frac{2|(v-Pv,v)|}{(v,v)} \\ &= \frac{2\sum_{i,j=1}^{l}|\alpha_i||\bar{\alpha}_j||(u_i-Pu_i,u_j)|}{(\sum_{i=1}^{l}|\alpha_i|^2)} \\ &\le 2l \max_{i,j=1,\dots,l}|(u_i-Pu_i,u_j)|.\end{aligned}$$

Now we have

$$\begin{aligned}|(u_i-Pu_i,u_j)| &= \left|\left(\sum_{|k|>\frac{N}{2}}(\hat{u_i})_k e^{ikx}, \sum_{n=\infty}^{\infty}(\hat{u_j})_n e^{inx}\right)\right| \\ &= \left|\sum_{|k|>\frac{N}{2}}\sum_{n=\infty}^{\infty}(\hat{u_i})_k\overline{(\hat{u_j})_n}\int_{-\pi}^{\pi}e^{i(k-n)x}\epsilon(x)dx\right| \\ &\le \sum_{|k|>\frac{N}{2}}\sum_{\substack{n=\infty\\ n\neq k}}^{\infty}|(\hat{u_i})_k|\cdot\left|\overline{(\hat{u_j})_n}\right|\cdot\frac{(\beta^2-1)|((-1)^{k-n}-1)|}{|k-n|} \\ &\quad + \sum_{|k|>\frac{N}{2}}\sum_{\substack{n=\infty\\ n=k}}^{\infty}|(\hat{u_i})_k|\cdot\left|\overline{(\hat{u_j})_n}\right|\cdot(\beta^2+1)\pi.\end{aligned}$$

Recalling (4.11), where $|\hat{u}_k|$ decays like $O(k^{-3})$ at least, we get

$$|(u_i-Pu_i,u_j)| \le CN^{-3},$$

where C is a positive constant. Finally, we have

$$\begin{aligned}\frac{(v,v)}{(Pv,Pv)} &= \frac{1}{1-\frac{(v,v)-(Pv,Pv)}{(v,v)}} \\ &\le 1 + 2\frac{(v,v)-(Pv,Pv)}{(v,v)} \\ &\le 1 + ClN^{-3}.\end{aligned}$$

Thus the lemma is proven. ∎

We can now state the following theory.

THEOREM 4.4. *Let λ_l^N be the Fourier–Galerkin approximation to the eigenvalue λ_l. Then*

$$|\lambda_l - \lambda_l^N| \le Cl\lambda_l N^{-3},$$

where the constant C depends only on the values of $u_i(0)$, $u_i'(0)$, and the L_2-norm of u_i for all $i \le l$.

Now we are ready to treat the eigenvectors. Following Strang and Fix [7, p. 234], we can state

$$||u_l - u_l^N|| \le ||u_l - P_N u_l||,$$

where $P_N u_l$ is the finite Fourier series of u_l. For the right-hand side we have the following estimate.

LEMMA 4.5.

$$||u_l - P_N u_l|| \le CN^{-2.5}.$$

Proof. By the Parseval equality, and using Lemma 4.2, which states the Fourier coefficients of u_l decay cubicly, we get

$$\begin{aligned} ||u_l - P_N u_l|| &= \left(\sum_{|k|>\frac{N}{2}} |(\hat{u_l})_k|^2 \right)^{\frac{1}{2}} \\ &\le C \left(\sum_{|k|>\frac{N}{2}} |k|^{-6} \right)^{\frac{1}{2}} \\ &\le CN^{-2.5}. \end{aligned}$$

Thus the lemma is proven. □

We can therefore conclude the following theorem.

THEOREM 4.6. *Let u_l be the lth eigenfunction, and let u_l^N be the solution of the Fourier–Galerkin approximation* (4.2)*; then*

$$||u_l - u_l^N|| \le CN^{-2.5}. \tag{4.14}$$

The numerical results presented in Tables 1 and 2 conform to the theory.

5. Fourier collocation method. Let $\mathcal{I}_{\mathcal{N}}$ be the space of the trigonometric polynomial of degree $N/2$, defined as

$$\mathcal{I}_{\mathcal{N}} = \text{span}\{(\cos(kx)|0 \le k \le N/2) \cup (\sin(kx)|1 \le k \le N/2 - 1)\}. \tag{5.1}$$

For an even integer $N > 0$, we consider the set of points

$$x_j = -\pi + \frac{2\pi j}{N}, \quad j = 0, \dots, N. \tag{5.2}$$

The discrete approximations of the inner products (3.1) and (3.2) are defined by

$$a(u,v)_h = \frac{2\pi}{N} \sum_{j=0}^{N-1} u'(x_j)\overline{v'(x_j)}, \tag{5.3}$$

$$(u,v)_h = \frac{2\pi}{N} \sum_{j=0}^{N-1} u(x_j)\overline{v(x_j)}\epsilon(x_j). \tag{5.4}$$

Alternatively, defining $c_j = 1$, $0 \neq j \neq N$, and $c_N = c_0 = 2$, we can redefine

$$a(u,v)_h = \frac{2\pi}{N}\sum_{j=0}^{N} u'(x_j)\overline{v'(x_j)}\frac{1}{c_j}, \tag{5.5}$$

$$(u,v)_h = \frac{2\pi}{N}\sum_{j=0}^{N} u(x_j)\overline{v(x_j)}\epsilon(x_j)\frac{1}{c_j}. \tag{5.6}$$

Remark 5.1. Note that the bilinear form $a(u,v)_h$ coincides with the inner product $a(u,v)$ for trigonometrical polynomials of the right order:

$$a(u,v)_h = a(u,v) \quad \text{for all} \quad u, v \in \mathcal{I}_{\mathcal{N}}. \tag{5.7}$$

This is a result of the exactness of the quadrature formula if $u'v'$ is up to degree $N-1$ [1]. One can observe that the highest degree N for $u'v'$ is obtained when choosing $\cos(\frac{N}{2}x)$ for both u and v. However, $\{\cos(\frac{N}{2}x)\}' = -\frac{N}{2}\sin(\frac{N}{2}x)$ and $\sin(\frac{N}{2}x)$ vanishes at the grid points x_j so that the quadrature formula still remains valid also for the case of highest degree N. Thus (5.7) is true for any u, v in $\mathcal{I}_{\mathcal{N}}$.

Remark 5.2. Equation (5.6) can be rewritten as

$$\begin{aligned}(v,v)_h = {} & \frac{\pi}{N}(|v(x_0)|^2\epsilon(x_0) + |v(x_{\frac{N}{2}})|^2\epsilon(x_{\frac{N}{2}})) + \frac{2\pi}{N}\sum_{j=1}^{\frac{N}{2}-1}|v(x_j)|^2\epsilon(x_j) \\ & + \frac{2\pi}{N}\sum_{\frac{N}{2}+1}^{N-1}|v(x_j)|^2\epsilon(x_j) + \frac{\pi}{N}(|v(x_N)|^2\epsilon(x_N) + |v(x_{\frac{N}{2}})|^2\epsilon(x_{\frac{N}{2}})).\end{aligned}$$

The first two terms can be identified as the trapezoidal rule [6] for $\int_{-\pi}^{0}|v(\xi)|^2\epsilon(\xi)d\xi$, whereas the other two terms are the same rule for $\int_0^{\pi}|v(\xi)|^2\epsilon(\xi)d\xi$. We can therefore state

$$|(v,v) - (v,v)_h| \leq CN^{-2}\max\left\{\max_{-\pi\leq x<0}(|v|^2\cdot\epsilon)'', \max_{0\leq x\leq\pi}(|v|^2\cdot\epsilon)''\right\}. \tag{5.8}$$

5.1. Numerical scheme and its results. The collocation methods can be defined as finding λ^c and $u^c \in \mathcal{I}_N$ such that

$$a(u^c, v^c)_h = \lambda^c(u^c, v^c)_h \quad \text{for all} \quad v^c \in \mathcal{I}_N. \tag{5.9}$$

There are several ways to realize the abstract definition of the collocation methods, and we will quote one of them: u^c can be presented using the Lagrange trigonometrical polynomials as interpolation polynomials [4] as follows:

$$u^c = \sum_{j=0}^{N-1} u^c(x_j)l_j(x), \tag{5.10}$$

where

$$l_j(x) = \frac{1}{N}\sin\left[N\frac{(x-x_j)}{2}\right]\cot\left[\frac{x-x_j}{2}\right]. \tag{5.11}$$

Taking $v^c(x) = l_n(x)$, we have

$$\begin{aligned} a(u,v)_h &= \frac{2\pi}{N}\sum_{i=0}^{N-1}\sum_{j=0}^{N-1} u^c(x_j) l_j'(x_i) l_n'(x_i) \\ &= \frac{2\pi}{N}\sum_{j=0}^{N-1} u^c(x_j)\sum_{i=0}^{N-1} l_j'(x_i) l_n'(x_i) \\ &= \frac{2\pi}{N}\sum_{j=0}^{N-1} u^c(x_j) D_{nj}^2, \end{aligned}$$

where $D^2 = -D \cdot D$ and D is the first order differentiation matrix for even grid points [2], [4], [5]. Also,

$$\begin{aligned} (u,v)_h &= \frac{2\pi}{N}\sum_{i=0}^{N-1}\sum_{j=0}^{N-1} u^c(x_j) l_j(x_i) l_n(x_i)\epsilon(x_i) \\ &= \frac{2\pi}{N}\sum_{j=0}^{N-1} u^c(x_j)\sum_{i=0}^{N-1} l_j(x_i) l_n(x_i)\epsilon(x_i) \\ &= \frac{2\pi}{N}\sum_{j=0}^{N-1} u^c(x_j) A_{jn}, \end{aligned}$$

where $A = \mathrm{diag}\{\epsilon(x_0), \ldots, \epsilon(x_{N-1})\}$. Then we solve the matrix equation

$$D^2 \mathbf{u}^c = \lambda^c A \mathbf{u}^c \tag{5.12}$$

to get the approximate eigenvalues λ^c and eigenfunctions $\mathbf{u}^c = [u^c(x_0), \ldots, u^c(x_{N-1})]^T$.

Remark 5.3. In order to make (5.12) compatible with definition (5.6), we should replace $\epsilon(x_0)$ by the average $\frac{\epsilon(x_0)+\epsilon(x_N)}{2}$.

The variational formulation with odd grids can be obtained in a similar way. In Tables 3 and 4, we present the relative error for $\lambda_l^c - \lambda_l$. It is clear that we see *second order accuracy* with even grids as well as with odd grids as N increases. The discrete L_2-error of $u_l - u_l^c$ converges with *second order accuracy* with even and odd grids as N increases.

5.2. Error estimates for eigenvalues and eigenfunctions. Here we provide error estimates for the approximate eigenvalues and eigenfunctions of the Fourier collocation method. We first consider the approximate eigenvalues. Let S_l be any l-dimensional subspace of $\mathcal{I}_\mathcal{N}$.

LEMMA 5.1. *Let λ_l^c be the approximation to λ_l obtained by the collocation procedure, and let S_l be any l-dimensional subspace of $\mathcal{I}_\mathcal{N}$. Then*

$$\lambda_l^c \le \max_{v \in S_l} \frac{a(v,v)_h}{(v,v)_h}. \tag{5.13}$$

Proof. The space S_l is spanned by the eigenfunctions $u_{k_1}^c, \ldots, u_{k_l}^c$ for $k_1 < \cdots < k_l$. It follows that $k_l \ge l$. Now

$$\frac{a(u_{k_l}^c, u_{k_l}^c)_h}{(u_{k_l}^c, u_{k_l}^c)_h} = \lambda_{k_l}^c \ge \lambda_l^c. \tag{5.14}$$

	257	1.93715	-1.5904(-5)	2.0149	1.6529(-4)	1.9803

This concludes the proof. ∎

We are now ready to estimate λ_l^c from above.

LEMMA 5.2.

$$\lambda_l^c \le \lambda_l(1 + CN^{-2}), \tag{5.15}$$

where C is independent of N (but may depend linearly on l).

Proof. Let $J_N(= J)$ be the orthogonal projection (in the usual L^2 sense) of H^2 to $\mathcal{I}_{\mathcal{N}}$. Let $S_l = JE_{1,l} = \text{span}\{Ju_1, \dots, Ju_l\}$ in Lemma 5.1 to get

$$\lambda_l^c \le \max_{v \in JE_{1,l}} \frac{a(v,v)_h}{(v,v)_h} = \max_{v \in E_{1,l}} \frac{a(Jv,Jv)_h}{(Jv,Jv)_h}.$$

Then

$$\lambda_l^c \le \max_{v \in E_{1,l}} \frac{a(v,v)}{(v,v)} \cdot \frac{a(Jv,Jv)_h}{a(v,v)} \cdot \frac{(v,v)}{(Jv,Jv)} \cdot \frac{(Jv,Jv)}{(Jv,Jv)_h}. \tag{5.16}$$

From Lemma 3.2, we have

$$\max_{v \in E_{1,l}} \frac{a(v,v)}{(v,v)} = \lambda_l.$$

Also from the exactness of the trapezoidal rule and the fact that J is an orthogonal projection, it is true that

$$a(Jv,Jv)_h = a(Jv,Jv) \le a(v,v).$$

Due to Lemma 4.3 (with the same proof for J replacing P), we have

$$\max_{v \in E_{1,l}} \frac{(v,v)}{(Jv,Jv)} \le 1 + ClN^{-3}.$$

Also, Remark 5.2 gives

$$\frac{(Jv,Jv)}{(Jv,Jv)_h} \le 1 + CN^{-2},$$

and so the lemma is proven. ∎

We will now try to get a lower bound for λ_l^c. Define $E_{1,l}^c = \text{span}\{u_1^c, \dots, u_l^c\}$. From the minmax theorem, we have

$$\lambda_l \le \max_{v \in E_{1,l}^c} \frac{a(v,v)}{(v,v)}.$$

It is also clear that

$$\lambda_l^c = \max_{v \in E_{1,l}^c} \frac{a(v,v)_h}{(v,v)_h}.$$

We can now state the following lemma.

LEMMA 5.3.

$$\lambda_l \le \lambda_l^c(1 + CN^{-2}), \tag{5.17}$$

where C is independent of N (but may depend linearly on l).

Proof. We start from

$$\begin{aligned}\lambda_l &\le \max_{v\in E^c_{1,l}} \frac{a(v,v)}{(v,v)} \\ &= \max_{v\in E^c_{1,l}} \frac{a(v,v)_h}{(v,v)_h}\cdot\frac{a(v,v)}{a(v,v)_h}\cdot\frac{(v,v)_h}{(v,v)}.\end{aligned}$$

Since $v \in \mathcal{I}_{\mathcal{N}}$, we have $a(v,v) = a(v,v)_h$. Also, because of the trapezoidal rule estimate

$$|(v,v)_h - (v,v)| \le CN^{-2},$$

and therefore the lemma is proven. ∎

We can now conclude the following theorem.

THEOREM 5.4. *Let λ_l^c be the approximation to λ_l obtained by the collocation procedure. Then*

$$|\lambda_l^c - \lambda_l| \le C\lambda_l N^{-2}, \tag{5.18}$$

where C is independent of N.

We now turn to the eigenfunctions. The set $u_1^c, u_2^c, \dots, u_N^c$ forms an orthogonal basis for $\mathcal{I}_{\mathcal{N}}$. Then we can express the orthogonal projection Ju_l of u_l into the subspace $\mathcal{I}_{\mathcal{N}}$ as the following:

$$Ju_l = \sum_{j=1}^{N} (Ju_l, u_j^c)_h u_j^c. \tag{5.19}$$

By subtracting the following variational formulations,

$$\begin{aligned}\lambda_l(u_l, u_j^c) &= a(u_l, u_j^c),\\ \lambda_j^c(Ju_l, u_j^c)_h &= a(Ju_l, u_j^c)_h = a(Ju_l, u_j^c),\end{aligned}$$

we have

$$\begin{aligned}(\lambda_j^c - \lambda_l)(Ju_l, u_j^c)_h &= a(Ju_l, u_j^c) - a(u_l, u_j^c) - \lambda_l[(Ju_l, u_j^c)_h - (u_l, u_j^c)]\\ &= -a(u_l - Ju_l, u_j^c) + \lambda_l[(u_l, u_j^c) - (Ju_l, u_j^c)_h].\end{aligned}$$

Since $a(u_l - Ju_l, u_j^c) = 0$, we have

$$\begin{aligned}|(Ju_l, u_j^c)_h| &\le \frac{\lambda_l}{|\lambda_j^c - \lambda_l|}\cdot|(u_l, u_j^c) - (Ju_l, u_j^c)_h|\\ &\le \frac{\lambda_l}{|\lambda_j^c - \lambda_l|}\cdot\{|(u_l, u_j^c) - (u_l, u_j^c)_h| + |(u_l, u_j^c)_h - (Ju_l, u_j^c)_h|\}.\end{aligned}$$

From the Schwarz inequality and $(u_j^c, u_j^c)_h = 1$, we have

$$\begin{aligned}|(u_l - Ju_l, u_j^c)_h| &\le \|u_l - Ju_l\|_h \cdot \|u_j^c\|_h\\ &\le CN^{-2},\end{aligned}$$

where $\|u\|_h = \sqrt{(u,u)_h}$. Using the trapezoidal rule as in (5.8), we have

$$|(u_l, u_j^c) - (u_l, u_j^c)_h| \le CN^{-2}.$$

Then, following [7],

$$\|Ju_l - \beta u_l^c\|_h = \sqrt{\sum_{\substack{j=1 \\ j\neq l}}^{N} |(Ju_l, u_j^c)_h|^2} \le \rho CN^{-2},$$

where $\beta = (Ju_l, u_l^c)_h$ and ρ is a separation constant for the eigenvalues as in [7, pp. 234–235]. From (5.8) and $\|u_l\| = \|u_l^c\|_h = 1$,

$$\|u_l\|_h \le \|u_l\| + CN^{-2} = \|u_l^c\|_h + CN^{-2}.$$

Then, following [7], we have

$$\|u_l - u_l^c\|_h \le \|u_l - Ju_l\|_h + \|Ju_l - \beta u_l^c\|_h + \|\beta u_l^c - u_l^c\|_h \le CN^{-2}.$$

We can therefore conclude the following theorem.

THEOREM 5.5. *Let u_l be the lth eigenfunction, and let u_l^c be the solution of the Fourier collocation approximation* (5.9)*; then*

$$||u_l - u_l^c||_h \le CN^{-2}.$$

Due to the equivalence of the norms in finite space, the discrete L_2-error of $u_l - u_l^c$ also converges with $O(N^{-2})$.

6. Accuracy enhancement for the collocation method. A simple trick can be used in order to enhance the accuracy of the Fourier collocation method. We expand the discontinuous coefficient function $\epsilon(x)$ in the finite Fourier series represented by

$$\epsilon^N(x) = \sum_{k=-\frac{N}{2}}^{\frac{N}{2}} (\hat{\epsilon}^N)_k e^{ikx},$$

where the Fourier coefficients are defined as

$$(\hat{\epsilon}^N)_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} \epsilon(x) e^{-ikx} dx.$$

Now, instead of (5.4), defining

$$(u,v)_h = \frac{2\pi}{N} \sum_{j=0}^{N-1} u(x_j)\overline{v(x_j)}\epsilon^N(x_j) \tag{6.1}$$

in the variational formulation (5.9), we have the scheme as follows:

$$D^2\mathbf{u}^c = \lambda^c A\mathbf{u}^c, \tag{6.2}$$

where $A = \mathrm{diag}\{\epsilon^N(x_0), \ldots, \epsilon^N(x_{N-1})\}$ and D^2 is the same as defined in (5.12).

The numerical results are presented in the Tables 5 and 6 for even and odd grids, respectively. The accuracy is now the same accuracy as for the Galerkin method! An analysis for this will appear in a future paper.

TABLE 5

The accuracy enhancement for collocation with even grids: The relative errors of eigenvalues for the case $\beta = 2$ and the discrete L_2-errors of $u_i - u_i^c$ using $\epsilon^N(x)$.

SYMMETRIC ERROR ESTIMATES FOR MOVING MESH MIXED METHODS FOR ADVECTION-DIFFUSION EQUATIONS*

YINGJIE LIU†, RANDOLPH E. BANK‡, TODD F. DUPONT§, SONIA GARCIA¶, AND RAFAEL F. SANTOS‖

Abstract. A mixed method allowing a general class of mesh movements is proposed for an advection-diffusion equation in either conservative or nonconservative form. Several symmetric error estimates are derived for the method under certain conditions. In one space dimension, optimal order L^2 convergence and superconvergence are proved as corollaries of the symmetric estimates.

Key words. mixed methods, parabolic equations, finite elements, moving mesh

1. Introduction.

Moving mesh finite element methods have been widely studied; in [10, 9] methods based on Galerkin formulations were given. In [5, 2] error analysis was provided for related classes of moving mesh finite element methods which allow piecewise time continuous mesh movements. In this work, we examine moving mesh methods for mixed methods that incorporate some of the ideas in [4], where a procedure for including characteristics within finite element methods for advection-diffusion equations was proposed.

A symmetric error estimate is, to within a constant, a best approximation result. That is, if the error *can be* made small in the given norm, then it *is* small in that norm. Somewhat more precisely, there is a norm $\|\!| \cdot |\!\|$ and a constant C such that

$$\|\!|\text{error}|\!\| \le C \|\!|\text{best approximation error}|\!\|.$$

Dupont [5], Bank and Santos [2], Dupont and Liu [6], and sections 5 and 7 of this work establish bounds of this type. In [6] and this paper, the constant C does not increase as the advective term increases in size, provided that the mesh movement approximates the advective term sufficiently well. These results thus make it clear that the mesh movement is actually modeling the advection. Also, the norms in section 5 involve the convective derivative instead of the partial with respect to time, and as

Douglas and Russell pointed out in [4], for advection dominated problems the convective derivative will typically be much smoother, and therefore easier to approximate well. While symmetric error estimates for parabolic equations have a certain attractiveness in the simplicity of the statement that they make, it is sometimes hard to see the precise meaning of the result because the norms involved are made up of several parts. We exploit the idea of [6] to weaken some of these parts to "concentrate" the norm on certain terms.

Although the motivation for this research was an improved understanding of moving mesh methods, it is worth remarking that the symmetric error estimates provided here are valid even if the mesh does not move. While such estimates for parabolic equations have a thirty year history in the context of Galerkin methods, these are the first symmetric error estimates for mixed methods for parabolic problems even in the fixed mesh case.

Characteristics-type mixed methods have been studied in several papers (see, e.g., Yang [12] and Arbogast and Wheeler [1]), but the analytical understanding of mixed methods in combination with moving meshes is far from complete. Unlike Galerkin methods using conforming finite element spaces, moving mesh methods using mixed formulations and discontinuous approximation spaces can develop singularities in the time derivative at the edges between elements. Therefore it is critical to use directional time derivatives along the mesh movement direction throughout the analysis. The mesh movement that is considered here is more general than just a fixed mesh or a mesh that follows characteristics, for several reasons; two of the most significant are the following. First, the best mesh may not be fixed or follow the characteristics. Diffusion spreads things out and a mesh can follow such patterns; in fact, in [8] it is shown that in some situations mesh movement alone can model diffusion. Thus when diffusion and advection are both present, one may want to use a mesh that reflects the action of the two together. Second, the choice of mesh moving strategy will usually involve in a strong way considerations of the complexity of the program used to implement the mesh movement. One technique that we have used is to guess an analytic form for the mesh transformation based on a coarse grid calculation. Since the estimates here say that if you *can* approximate the solution, you *will*, this very simple-to-code approach is seen as a legitimate way to proceed. This technique is illustrated in an example in section 6.

In this paper, we first introduce our method and prove our symmetric error estimates. Next, an optimal order L^2 error estimate and a superconvergence result are proved for one space dimension as a corollary of the symmetric error estimate. The error bound gives considerable insight into the effectiveness of a given mesh movement. Aligning the mesh movement with the characteristics is not necessary as long as the difference between the advection velocity and the velocity of mesh movement remains bounded. The fact that the constants in the error bounds don't depend directly on the advection coefficient reflects the fact that mesh movement does indeed model advection. Furthermore, the analysis also shows that if the mesh is moved in such a way that it has a finer mesh where the solution has hard-to-approximate regions, then the bound on the error is decreased. These two observations give insight into what are good choices of mesh movement.

The remainder of this paper is organized as follows. In section 2, we discuss the advection-diffusion equation in conservative form, introduce several notations, and formulate the mixed method for general mesh movements. In section 3, we introduce a pseudoinverse operator "A" of "div," and in section 4 we develop the basic

properties of the directional derivative "D/Dt"; these concepts are used in section 5 to get symmetric error estimates. Optimal order error bounds are proved in section 6, and an example is presented that illustrates some of the issues associated with these techniques. In section 7, we consider a mixed method for an advection-diffusion equation in nonconservative form, allowing general mesh movements. Symmetric error analysis and one-dimensional applications are derived in a manner that parallels the earlier analysis.

2. Model problem and mixed method. Consider the following advection-diffusion model problem on $Q = \Omega \times (0,T)$:

$$\begin{cases} \partial_t u - \nabla \cdot (a\nabla u + bu) = f & \text{on } Q, \\ u = 0 & \text{on } \partial\Omega \times (0,T), \\ u = u_0 & \text{for } t = 0, \end{cases} \tag{2.1}$$

where $a(x)$, $b(x)$, and $f(x,t)$ are smooth and bounded and $a_1 \geq a(x) \geq a_0 > 0$ for some constants a_0, a_1. Here Ω is a bounded domain in R^n. For simplicity, we assume that Ω is a fixed polyhedron.

We use $\|\cdot\|_s$ to denote the $H^s(\Omega)$ norm. When $s = 0$, we usually use $\|\cdot\|$. If we use domains other than Ω, we will use $\|\cdot\|_{H^s(\Omega_i)}$ or $\|\cdot\|_{L^2(\Omega_i)}$. The norm for the dual space of $H_0^1(\Omega)$ is denoted $\|\cdot\|_{-1}$, and $\|\xi\|_{L^p(0,T;X)}$ denotes the $L^p(0,T)$ norm of $\|\xi(\cdot,t)\|_X$. We will use $(\cdot,\cdot)$ as the inner product on $L^2(\Omega)$ and on $(L^2(\Omega))^n$, and will rely on context to indicate which is intended.

We will study methods that approximate the solution u of (2.1) on a moving mesh, which is given as a time-dependent image of a fixed reference mesh. Suppose that $\bar{D} = \cup D_i$ is a fixed polyhedron, where D_i's are closed sets with nonvoid disjoint interiors. We need few assumptions on the D_i's for much of the argument, but to keep the discussion simple, we suppose that each D_i is a simplex and that they form a tessellation of $\bar{D}$. Further, we suppose that there is a continuous mapping $\mathcal{G}$ from $\bar{D} \times [0,T]$ onto $\bar{\Omega}$ such that

1. for each t, $\mathcal{G}(\cdot,t)$ is a one-to-one piecewise linear mapping (with respect to $\{D_j\}$) of $\bar{D}$ onto $\bar{\Omega}$;
2. $\mathcal{G}$ is continuously differentiable on each $D_i \times [0,T]$; and
3. $\partial\Omega = \mathcal{G}(\partial D, t)$.

Let $\Omega_i(t) = \mathcal{G}(D_i,t)$, $h_i(t)$ be the diameter of $\Omega_i(t)$, and $h(t) = \max_i\{h_i(t)\}$. Then $\Omega_i(t)$ is also a simplex and $\{\Omega_i(t)\}$ becomes the moving partition of Ω. It is sometimes convenient to think of this moving mesh as being generated by a mapping of Ω onto itself. Let $\mathcal{G}^{-1} = \mathcal{G}^{-1}(\cdot,t)$ denote the inverse of $\mathcal{G}$ as a map of D onto Ω; thus this function can be viewed as being defined on $\bar{Q}$. The partial derivative with respect to t of $\mathcal{G}$ is denoted $\mathcal{G}_t$. The finite element mesh is advected with a flow that is given by

$$\dot{x}(t) = \mathcal{G}_t(\mathcal{G}^{-1}(x,t),t).$$

Given the assumptions on $\mathcal{G}$, the function $\dot{x}$ is a continuous piecewise linear function over the partition $\{\Omega_i\}$ of Ω. Let $\tilde{V}_h$ be a finite-dimensional subspace of $L^2(D)$. Then the corresponding finite element space on Ω is defined by

$$V_h(t) = \{\phi(x,t) : \phi(\mathcal{G}(\cdot,t),t) \in \tilde{V}_h\}.$$

We will take $H_h(t)$ to be a finite-dimensional subspace of $H(div,\Omega)$ so that $div\, H_h = V_h$ for any t. In particular, we will take V_h to be the space of discontinuous polynomials

of total degree at most m, and H_h to be the Raviart–Thomas flux space. Let P_h denote the L^2 projection onto V_h. Let Π_h be the linear operator $H(div,\Omega) \to H_h$ satisfying $(div\,(W - \Pi_h W), r) = 0\ \forall r \in V_h$ and $div\,\Pi_h = P_h div$ as defined by Raviart and Thomas in [11].

Let $\underline{h}(x,t)$ denote the function that has the value $h_i(t)$ on each $\Omega_i(t)$. For a function φ such that its restriction to Ω_i is in $H^s(\Omega_i)$, let

$$\|\varphi\|^2_{\underline{H}^s} = \sum_i \|\varphi\|^2_{H^s(\Omega_i)}.$$

We denote a particular directional derivative DF/Dt as follows:

$$\frac{DF(x,t)}{Dt} = \frac{\partial F(x,t)}{\partial t} + \dot{x}\cdot\nabla_x F(x,t).$$

Note that if $F(\cdot,t) \in V_h(t)$ is differentiable on each Ω_i, then DF/Dt is also in V_h. Even though it might seem that both $\partial F/\partial t$ and $\nabla_x F$ are singular on the boundaries $\partial\Omega_i$, the directions involved in DF/Dt never cross the boundary of any Ω_i.

The first mixed method we consider uses a mesh movement induced flux across subdomain boundaries. Let $\sigma = -(a\nabla u + bu + \dot{x}u)$ and $\alpha = 1/a$, $\beta = b/a$. The exact solution u satisfies

$$\frac{Du}{Dt} + div\,\sigma + (\nabla\cdot\dot{x})u = f.$$

This leads to the following mixed formulation:

$$\text{(2.2)}\qquad \begin{cases} (\alpha\sigma + (\beta + \alpha\dot{x})u, \mathcal{X}) - (u, div\,\mathcal{X}) = 0 & \forall \mathcal{X} \in H(div,\Omega), \\ \left(\dfrac{Du}{Dt} + div\,\sigma + (\nabla\cdot\dot{x})u, r\right) = (f,r) & \forall r \in L^2(\Omega). \end{cases}$$

We define the mixed approximation to be functions $u_h : [0,T] \to V_h$ and $\sigma_h : [0,T] \to H_h$ such that $u_h(0) = P_h u(0)$ and

$$\text{(2.3)}\qquad \begin{cases} (\alpha\sigma_h + (\beta + \alpha\dot{x})u_h, \mathcal{X}) - (u_h, div\,\mathcal{X}) = 0 & \forall \mathcal{X} \in H_h, \\ \left(\dfrac{Du_h}{Dt} + div\,\sigma_h + (\nabla\cdot\dot{x})u_h, r\right) = (f,r) & \forall r \in V_h. \end{cases}$$

Note that this method is *locally conservative*, because the rate of change of the integral of u over each subdomain is given by the integral around the boundary of the normal component of σ, and the normal component of σ is continuous across subdomain boundaries. (If this is less than clear, please see the proof of Lemma 7.)

In proving the symmetric error estimates, we don't need specific approximation properties, but we will need such properties in order to obtain a priori error bounds based on the mesh size and the smoothness of the solution u. We summarize these additional conditions here.

CONDITION 1 (approximation). *There exists a constant C_1 such that for any $w \in H^{s_1}(\Omega)$, $s_1 \geq 0$, and any $t \in [0,T]$,*

$$\|w - P_h w\| \leq C_1 \|\underline{h}^{\min\{m+1,s_1\}} w\|_{\underline{H}^{s_1}},$$

and for any $W \in (H^{s_2}(\Omega))^n$, $s_2 \geq 1$, and any $t \in [0,T]$,

$$\|W - \Pi_h W\| \leq C_1 \|\underline{h}^{\min\{m_1+1,s_2\}} W\|_{\underline{H}^{s_2}},$$

where $m_1 = m+1$ in one dimension and $m_1 = m$ in higher space dimensions.

This condition holds for the Raviart–Thomas spaces, where C_1 depends on m and on a bound for $h_i/\tilde{h}_i$, where $\tilde{h}_i$ is the diameter of the largest ball in R^n contained in Ω_i.

CONDITION 2 (stability of Π_h). *There exists a constant C_2 such that for any $W \in (H^1(\Omega))^n$ and any $t \in [0,T]$*

$$\|\Pi_h W\| \le C_2 \|W\|_1.$$

If Condition 1 holds, then C_2 can be taken to be $1 + C_1 h$. But this condition is strictly weaker than Condition 1; it allows controlled degeneracy in the elements as the mesh size decreases.

CONDITION 3 (H^2 regularity). *The domain Ω is regular enough that there exists a C_3 such that, for any $\xi \in L^2(\Omega)$, the boundary value problem*

$$\begin{cases} \Delta g = \xi & \text{in } \Omega, \\ g = 0 & \text{on } \partial\Omega, \end{cases} \tag{2.4}$$

has a unique solution and $\|g\|_2 \le C_3 \|\xi\|$.

3. A pseudoinverse of *div*. In this section we define and explore the properties of a smoothing mapping that appears naturally in the symmetric error estimates. Let $A : L^2(\Omega) \to H_h$ be the pseudoinverse of *div* in the sense that

$$\begin{gathered} \varphi - div\,(A\varphi) \perp V_h, \\ \|A\varphi\| \text{ is minimal.} \end{gathered}$$

Note that $A(\varphi) = A(P_h\varphi)$; thus we can factor A as $A_{V_h} P_h$, where A_{V_h} is A restricted to V_h. Note that this factorization gives that A^* maps H_h into V_h. Let $H_h = \mathcal{O} \oplus \mathcal{O}^\perp$, where $\mathcal{O} = \{\mathcal{X} \in H_h : div\,\mathcal{X} = 0\}$ and $\mathcal{O}^\perp$ is its orthogonal complement with respect to the $(L^2(\Omega))^n$ inner product. Then *div* is a one-to-one mapping from $\mathcal{O}^\perp$ onto V_h, and A_{V_h} is its inverse. In the case of one dimension with $m = 0$, the operator A can be explicitly described: $A\varphi$ is the piecewise linear interpolant of a constant plus the integral of φ. The following result shows that in more general situations A behaves as a smoothing operator.

THEOREM 4. *If Conditions 1 and 3 hold, then there is a $C = C(C_1, C_3)$ such that for any $\xi \in L^2(\Omega)$*

$$\begin{aligned} \|A\xi\| &\le C\{h\|\xi\| + \|\xi\|_{-1}\}, \\ \|A\xi\| &\le C\{h\|P_h\xi\| + \|P_h\xi\|_{-1}\}. \end{aligned}$$

Proof. Let g be the solution of (2.4) and set $W = \nabla g$. Take $\rho \in H_h$ and $\nu \in V_h$ to be the mixed method approximation of W and g:

$$\begin{cases} (\rho, \mathcal{X}) + (\nu, div\,\mathcal{X}) = 0 & \forall \mathcal{X} \in H_h, \\ (div\,\rho, r) = (\xi, r) & \forall r \in V_h. \end{cases} \tag{3.1}$$

We want to show that $\rho = A\xi$. In fact, the second equation of (3.1) implies $div\,\rho = P_h\xi$, and the first one implies $(\rho, \mathcal{X}) = 0\ \forall \mathcal{X} \in \mathcal{O}$, which in turn implies that $\|\rho\|$ is minimal among all elements in H_h whose divergence is $P_h\xi$.

Next we need an approximation result for mixed methods (see, e.g., [7]) to see that

$$\begin{aligned} \|A\xi\|^2 &= (\rho,\rho) \\ &= (\rho,\rho - W) + (\rho, W) \\ &\le \|\rho\|\{Ch\|g\|_2 + \|W\|\} \\ &\le \|A\xi\|\{Ch\|\xi\| + \|W\|\}. \end{aligned} \tag{3.2}$$

It follows from (2.4) that

$$\|W\| = \|\nabla g\| \le C\|\xi\|_{-1}.$$

From this and (3.2) the first result of this theorem follows. The second follows since $A\xi = AP_h\xi$. ∎

Note that even if Ω fails to have the assumed H^2 regularity, the result may still be proved in some cases. Suppose that Ω can be expanded to $\tilde{\Omega}$, which has H^2 regularity, and the function spaces can be extended to $\tilde{\Omega}$ with the approximation properties still holding. Then extending ξ to be zero on $\tilde{\Omega} - \Omega$ and a slight modification of the above proof gives the conclusions of the theorem. For example, if Ω were an L-shaped region in two space dimensions, H^2 regularity would fail, but the extension to a square might be possible.

On H_h, the operator $A\ div$ does not increase the L^2 norm. Suppose that $\rho \in H_h$ and let $\psi = A\ div\,\rho$. Then $div\,\rho - div\,\psi \perp V_h$. Hence $\psi = \rho + z$, where $z \in \mathcal{O}$. Because $\|\psi\|$ is taken to be minimal and $z \equiv 0$ is possible, we see that

$$\|A\ div\,\rho\| = \|\psi\| \le \|\rho\|. \tag{3.3}$$

In one dimension the choice of discontinuous piecewise polynomial spaces allows a more local version of Theorem 4. In fact, let $\Omega = (x_0, x_N)$ and $\Omega_i = (x_{i-1}, x_i)$; then $A\xi = \int_{x_0}^{x} P_h\xi(s)ds + C$.

THEOREM 5. *If Condition* 2 *holds, then there is a* C *such that for any* $\xi \in L^2(\Omega)$

$$\|A\xi\| \le C\|\xi\|.$$

Proof. Take $\rho \in H_h$ and $\nu \in V_h$ to be defined by (3.1); thus we know that $A\xi = \rho$. From (3.1) with $\chi = A\xi$ and $r = \nu$ we see that

$$\|A\xi\|^2 = -(\xi,\nu) \le \|\xi\|\,\|\nu\|.$$

Let B be a cube that contains Ω, and take φ be the extension of ν to B by zero outside Ω. Take $g \in H_0^1(B)$ such that, on B, $\Delta g = \varphi$. Then, because the cube has H^2 regularity for the Laplacian, we see that ∇g is bounded in $(H^1(B))^2$ by $C\|\varphi\|_{L^2(B)} = C\|\nu\|$. Note that

$$\|\nu\|^2 = (\nu, div\nabla g) = (\nu, div\Pi_n\nabla g) = (-A\xi, \Pi_h\nabla g).$$

The operator Π_h is bounded as a map of H^1 into L^2 by Condition 2. Thus it follows that

$$\|\nu\|^2 \le \|A\xi\|\,\|\Pi_h\nabla g\| \le C\|A\xi\|\,\|g\|_2 \le C\|A\xi\|\,\|\nu\|.$$

The two displayed inequalities then give the desired result. ∎

4. Properties of D/Dt. From the definition of directional derivative we have the following basic relations, which we use later in energy-type arguments.

LEMMA 6.

$$\nabla_x \cdot \dot{x} = \frac{\partial |\det(\nabla_s \mathcal{G}(s,t))|/\partial t}{|\det(\nabla_s \mathcal{G})|}.$$

Proof. Take $D_0 \subset D$ to be an arbitrary small ball and let $\Omega_0(t) = \mathcal{G}(D_0, t)$. Then, with n as the outward normal to Ω_0,

$$\frac{\partial}{\partial t}\int_{\Omega_0(t)} dx = \int_{\partial\Omega_0(t)} \dot{x}\cdot n d\sigma = \int_{\Omega_0(t)} \nabla_x \cdot \dot{x} dx.$$

On the other hand,

$$\begin{aligned}\frac{\partial}{\partial t}\int_{\Omega_0(t)} dx &= \frac{\partial}{\partial t}\int_{D_0} |\det(\nabla_s \mathcal{G}(s,t))| ds = \int_{D_0} \frac{\partial}{\partial t}|\det(\nabla_s \mathcal{G}(s,t))| ds \\ &= \int_{\Omega_0(t)} \frac{\partial |\det(\nabla_s \mathcal{G}(s,t))|/\partial t}{|\det(\nabla_s \mathcal{G})|} dx.\end{aligned}$$

The result follows from the arbitrary choice of D_0. ∎

We will say that a function ξ on Q is piecewise C^1 if, when it is pulled back by $\mathcal{G}$ to $D_i^o \times (0,T)$, it can be extended to be C^1 on $D_i \times [0,T]$. A function that is the limit in $H^1(D_i \times [0,T])$ of piecewise C^1 functions will be called piecewise smooth on Q. We will usually operate formally on piecewise smooth functions without going through the step of approximating them by smooth functions and taking limits, since this is routine.

LEMMA 7. *Suppose that ξ is piecewise smooth on Q; then, with $\mathcal{R} = \Omega$ or Ω_i,*

$$\frac{d}{dt}\int_{\mathcal{R}} \xi dx = \int_{\mathcal{R}} \frac{D\xi}{Dt} dx + \int_{\mathcal{R}} \xi(\nabla_x \cdot \dot{x}) dx.$$

Proof. It suffices to show the result for Ω_i. Note that

$$\begin{aligned}\frac{d}{dt}\int_{\Omega_i} \xi dx &= \frac{d}{dt}\int_{D_i} \xi |\det(\nabla \mathcal{G})| ds \\ &= \int_{D_i} \frac{\partial \xi}{\partial t}|\det(\nabla \mathcal{G})| ds + \int_{D_i} \xi \frac{\partial}{\partial t}|\det(\nabla \mathcal{G})| ds \\ &= \int_{\Omega_i} \frac{D\xi}{Dt} dx + \int_{\Omega_i} \xi \left(\frac{\partial |\det(\nabla_s \mathcal{G}(s,t))|/\partial t}{|\det(\nabla_s \mathcal{G})|}\right) dx.\end{aligned}$$

Using Lemma 6, the proof is complete. ∎

D/Dt also has the following properties for any piecewise smooth functions ξ, η:

$$\begin{aligned}\frac{D}{Dt}(\xi\eta) &= \eta\frac{D\xi}{Dt} + \xi\frac{D\eta}{Dt}, \\ \frac{D}{Dt}\nabla_x \xi &= \nabla_x \frac{D\xi}{Dt} - (\nabla_x \dot{x})^T \nabla_x \xi,\end{aligned}$$

where $\nabla_x \xi$ is a column vector and $\nabla_x \dot{x}$ is the Jacobian of $\dot{x}$ with respect to x.

It easily follows from this and Lemma 7 that

$$\left(\frac{D\xi}{Dt}, \xi\right) = \frac{1}{2}\frac{d}{dt}\|\xi\|^2 - \frac{1}{2}(\xi, \xi(\nabla_x \cdot \dot{x})). \tag{4.1}$$

We denote the pseudoderivative of ξ by

$$D_t\xi = \frac{D\xi}{Dt} + (\nabla \cdot \dot{x})\xi,$$

and now show that D_t commutes with P_h.

LEMMA 8. *For function ξ that is piecewise smooth on Q, $P_h D_t \xi = D_t P_h \xi$.*

Proof. Let $\psi = P_h\xi$; then $(\xi - \psi, r) = 0$ for any $r \in V_h$. Given $t_0 \in [0,T]$, let $\phi(x)$ be any function in $V_h(t_0)$. Let $r(x,t) = \phi(\mathcal{G}(\mathcal{G}^{-1}(x,t),t_0))$. Then $r(x,t_0) = \phi(x)$, $r(\cdot,t) \in V_h(t)$, and $Dr/Dt = 0$ for any $t \in [0,T]$. Thus at t_0,

$$\begin{aligned} 0 &= \frac{d}{dt}(\xi - \psi, r) \\ &= \left(\frac{D}{Dt}(\xi - \psi), \phi\right) + \left(\xi - \psi, \frac{Dr}{Dt}\right) + (\xi - \psi, (\nabla_x \cdot \dot{x})\phi). \end{aligned}$$

That is,

$$0 = (D_t(\xi - \psi), \phi) = (P_h D_t \xi - D_t P_h \xi, \phi).$$

The proof is completed by observing $D_t P_h \xi \in V_h$. ∎

5. Symmetric error estimates. In this section, we prove four symmetric error estimates.

Let F_h be a linear operator $V_h(t) \to H_h(t)$ such that for any $v_h \in V_h(t)$

$$(\alpha F_h(v_h) + (\beta + \alpha\dot{x})v_h, \mathcal{X}) - (v_h, div\, \mathcal{X}) = 0 \quad \forall \mathcal{X} \in H_h.$$

Thus F_h is the flux operator associated with the space V_h. Using F_h and the norms $|||(\cdot,\cdot)|||$ and $|||(\cdot,\cdot)|||_*$ defined by

$$|||(\eta,\psi)|||^2 = \|\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \left\|A\frac{D\eta}{Dt}\right\|^2_{L^2(0,T:L^2(\Omega))} + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))},$$

$$|||(\eta,\psi)|||^2_* = \|P_h\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \left\|A\frac{D\eta}{Dt}\right\|^2_{L^2(0,T:L^2(\Omega))} + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))},$$

we have the following pair of symmetric error estimates.

THEOREM 9. *Suppose that Condition 2 holds and there exist constants c_1, c_2 such that for all $(x,t) \in Q$*

$$|\nabla_x \cdot \dot{x}| \le c_1 \quad \text{and} \quad |\beta + \alpha\dot{x}| \le c_2.$$

Then there exists a constant $C > 0$, depending only on C_2, c_1, c_2, T, the bounds of coefficient a, and Ω, such that for any piecewise smooth function v_h with $v_h(\cdot,t) \in V_h(t)$,

$$\begin{aligned} |||(u - u_h, \sigma - \sigma_h)||| &\le C|||(u - v_h, \sigma - F_h(v_h))|||, \\ |||(u - u_h, \sigma - \sigma_h)|||_* &\le C|||(u - v_h, \sigma - F_h(v_h))|||_*. \end{aligned}$$

Proof. Take v_h to be a piecewise C^1 function such that $v_h(\cdot,t) \in V_h(t)$. With $\mathcal{S}_h = F_h(v_h)$, adopt the notation

$$\begin{aligned} \nu &= u_h - v_h, \qquad \rho = \sigma_h - \mathcal{S}_h, \\ \eta &= u - v_h, \qquad \psi = \sigma - \mathcal{S}_h. \end{aligned}$$

Subtracting (2.2) from (2.3), we obtain the following orthogonalities:

$$(\alpha\rho + (\beta + \alpha\dot{x})\nu, \mathcal{X}) - (\nu, div\, \mathcal{X}) = 0 \qquad \forall \mathcal{X} \in H_h,$$

$$\left(\frac{D\nu}{Dt} + div\, \rho + (\nabla \cdot \dot{x})\nu, r\right) = \left(\frac{D\eta}{Dt} + div\, \psi + (\nabla \cdot \dot{x})\eta, r\right) \qquad \forall r \in V_h. \tag{5.1}$$

With $\mathcal{X} = \rho$ and $r = \nu$, these and (4.1) give

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nu\|^2 + (\alpha\rho + (\beta + \alpha\dot{x})\nu, \rho) \\
&\qquad = \left(\frac{D\eta}{Dt} + div\, \psi, \nu\right) + ((\nabla \cdot \dot{x})\eta, \nu) - \frac{1}{2}\int_\Omega \nu^2(\nabla \cdot \dot{x})dx \\
&\qquad = \left(div\, A\left(\frac{D\eta}{Dt} + div\, \psi\right), \nu\right) + ((\nabla \cdot \dot{x})\eta, \nu) - \frac{1}{2}\int_\Omega \nu^2(\nabla \cdot \dot{x})dx \qquad (5.2) \\
&\qquad = \left(\alpha\rho + (\beta + \alpha\dot{x})\nu, A\left(\frac{D\eta}{Dt} + div\, \psi\right)\right) + ((\nabla \cdot \dot{x})\eta, \nu) \\
&\qquad\quad - \frac{1}{2}\int_\Omega \nu^2(\nabla \cdot \dot{x})dx.
\end{aligned}$$

Therefore

$$\frac{d}{dt}\|\nu\|^2 + \alpha_1\|\rho\|^2 \le C\left\{\|\nu\|^2 + \left\|A\left(\frac{D\eta}{Dt} + div\, \psi\right)\right\|^2 + \|\eta\|^2\right\}, \tag{5.3}$$

where $\alpha_1 = 1/a_1$. It follows from Gronwall's inequality that

$$\|\nu\|^2_{L^\infty(0,T:L^2(\Omega))} + \|\rho\|^2_{L^2(0,T:L^2(\Omega))} \le C\{\|\nu(0)\|^2 + |||(\eta, \psi)|||^2\}.$$

The choice of $u_h(0) = P_h u(0)$ shows $\|\nu(0)\| \le \|\eta(0)\|$, and so the $\|\nu(0)\|$-term is bounded by $|||(\eta, \psi)|||$. Combining these results with (3.3), we see that

$$\|\nu\|^2_{L^\infty(0,T:L^2(\Omega))} + \|A\, div\, \rho\|^2_{L^2(0,T:L^2(\Omega))} \le C|||(\eta, \psi)|||^2.$$

Note that $\nu = P_h\nu$ and $((\nabla \cdot \dot{x})\eta, \nu) = ((\nabla \cdot \dot{x})P_h\eta, \nu)$, since $\nabla \cdot \dot{x}$ is constant on each Ω_i and V_h has no continuity between subdomains. Therefore we can replace $\|\nu\|$ by $\|P_h\nu\|$, $\|\eta\|$ by $\|P_h\eta\|$ in (5.3) to obtain

$$\|P_h\nu\|^2_{L^\infty(0,T:L^2(\Omega))} + \|A\, div\, \rho\|^2_{L^2(0,T:L^2(\Omega))} \le C|||(\eta, \psi)|||^2_*.$$

It remains to estimate $\|A(\frac{D\nu}{Dt})\|^2$. Using (5.1) and Theorem 5,

$$\begin{aligned}
\left(A\frac{D\nu}{Dt}, A\frac{D\nu}{Dt}\right) &= \left(\frac{D\nu}{Dt}, A^*A\frac{D\nu}{Dt}\right) \\
&= -\left(div\, \rho + (\nabla \cdot \dot{x})\nu, A^*A\frac{D\nu}{Dt}\right) \\
&\qquad + \left(\frac{D\eta}{Dt} + div\, \psi + (\nabla \cdot \dot{x})\eta, A^*A\frac{D\nu}{Dt}\right) \qquad (5.4) \\
&= -\left(A\, div\, \rho + A(\nabla \cdot \dot{x})\nu, A\frac{D\nu}{Dt}\right) \\
&\qquad + \left(A\frac{D\eta}{Dt} + A\, div\, \psi + A(\nabla \cdot \dot{x})\eta, A\frac{D\nu}{Dt}\right) \\
&\le C\left\|A\frac{D\nu}{Dt}\right\|\left\{\|A\, div\, \rho\| + \|\nu\| + \left\|A\frac{D\eta}{Dt}\right\| + \|A\, div\, \psi\| + \|\eta\|\right\}.
\end{aligned}$$

Therefore we have

$$\left\| A\frac{D\nu}{Dt} \right\|^2_{L^2(0,T:L^2(\Omega))} \le C|||(\eta,\psi)|||^2.$$

Since

$$\left(A(\nabla\cdot\dot{x})\eta, A\frac{D\nu}{Dt}\right) = \left(AP_h(\nabla\cdot\dot{x})\eta, A\frac{D\nu}{Dt}\right) = \left(A(\nabla\cdot\dot{x})P_h\eta, A\frac{D\nu}{Dt}\right),$$

we also have

$$\left\| A\frac{D\nu}{Dt} \right\|^2_{L^2(0,T:L^2(\Omega))} \le C|||(\eta,\psi)|||^2_*.$$

Hence,

$$|||(\nu,\rho)||| \le C|||(u-v_h, \sigma-\mathcal{S}_h)|||,$$
$$|||(\nu,\rho)|||_* \le C|||(u-v_h, \sigma-\mathcal{S}_h)|||_*.$$

Applying the triangle inequality completes the proof. □

Next we define two additional norms $|||(\cdot,\cdot)|||_{D_t}$, $|||(\cdot,\cdot)|||_{D_t^*}$ by

$$|||(\eta,\psi)|||^2_{D_t} = \|\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \|AD_t\eta\|^2_{L^2(0,T:L^2(\Omega))} + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))},$$
$$|||(\eta,\psi)|||^2_{D_t^*} = \|P_h\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \|AD_t\eta\|^2_{L^2(0,T:L^2(\Omega))} + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))}$$

and use them to get the following pair of symmetric error estimates.

THEOREM 10. *Suppose there exist constants $c_1, c_2 > 0$ such that*

$$-\nabla_x\cdot\dot{x} \le c_1 \quad \text{and} \quad |\beta+\alpha\dot{x}| \le c_2$$

$\forall(x,t)\in Q$. *Then there exists a constant $C>0$, depending only on c_1, c_2, T, the bounds of coefficient a, and Ω, such that, for any piecewise smooth function v_h with $v_h(\cdot,t)\in V_h(t)$,*

$$|||(u-u_h, \sigma-\sigma_h)|||_{D_t} \le C|||(u-v_h, \sigma-F_h(v_h))|||_{D_t},$$
$$|||(u-u_h, \sigma-\sigma_h)|||_{D_t^*} \le C|||(u-v_h, \sigma-F_h(v_h))|||_{D_t^*}.$$

Proof. We slightly modify the proof of Theorem 9. The inequality (5.2) becomes

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}\|\nu\|^2 + (\alpha\rho + (\beta+\alpha\dot{x})\nu, \rho) \\
&\qquad = (D_t\eta + div\,\psi, \nu) - \frac{1}{2}\int_\Omega \nu^2(\nabla\cdot\dot{x})dx \\
&\qquad = (div\,A(D_t\eta + div\,\psi), \nu) - \frac{1}{2}\int_\Omega \nu^2(\nabla\cdot\dot{x})dx \qquad (5.5)\\
&\qquad = (\alpha\rho + (\beta+\alpha\dot{x})\nu, A(D_t\eta + div\,\psi)) - \frac{1}{2}\int_\Omega \nu^2(\nabla\cdot\dot{x})dx.
\end{aligned}$$

Therefore

$$\frac{d}{dt}\|\nu\|^2 + \alpha_1\|\rho\|^2 \le C\{\|\nu\|^2 + \|A(D_t\eta + div\,\psi)\|^2\}. \qquad (5.6)$$

It then follows from Gronwall's inequality and (3.3) that

$$\|\nu\|^2_{L^\infty(0,T:L^2(\Omega))} + \|A\ div\ \rho\|^2_{L^2(0,T:L^2(\Omega))} \le C|\!|\!|(\eta,\psi)|\!|\!|^2_{D_t},$$

and, since $P_h\nu = \nu$,

$$\|P_h\nu\|^2_{L^\infty(0,T:L^2(\Omega))} + \|A\ div\ \rho\|^2_{L^2(0,T:L^2(\Omega))} \le C|\!|\!|(\eta,\psi)|\!|\!|^2_{D_t^*}.$$

It remains to estimate $\|AD_t\nu\|^2$.

$$\begin{aligned}(AD_t\nu, AD_t\nu) &= (D_t\nu, A^*AD_t\nu)\\ &= -(div\ \rho, A^*AD_t\nu) - (D_t\eta + div\ \psi, A^*AD_t\nu)\\ &= -(A\ div\ \rho, AD_t\nu) - (AD_t\eta + A\ div\ \psi, AD_t\nu)\\ &\le C\|AD_t\nu\|\{\|A\ div\ \rho\| + \|AD_t\eta\| + \|A\ div\ \psi\|\}.\end{aligned}$$

Therefore

$$\|AD_t\nu\|^2_{L^2(0,T:L^2(\Omega))} \le C(\|\nu(0)\|^2 + |\!|\!|(\eta,\psi)|\!|\!|^2_{D_t})$$

and

$$\|AD_t\nu\|^2_{L^2(0,T:L^2(\Omega))} \le C(\|P_h\nu(0)\|^2 + |\!|\!|(\eta,\psi)|\!|\!|^2_{D_t^*}).$$

As before, the triangle inequality completes the proof. ∎

Note that Theorem 10 uses A but does not rely on Theorem 5; hence it does not require Condition 2 to hold.

6. Optimal order and superconvergent $L^2(\Omega)$ bounds in one space dimension. In one dimension, Ω is an interval. Let c_4 be a constant satisfying $c_4 \ge \frac{1}{2}(a_0 + \frac{\tilde{c}_2}{a_0})$, where $\tilde{c}_2 = \|b + \dot{x}\|_{L^\infty([0,T],L^\infty(\Omega))}$. Assume that a, b are sufficiently regular such that for any $g \in L^2(\Omega)$, the elliptic equation

$$\begin{cases} -\partial_x(a\partial_x w) + (b+\dot{x})\partial_x w + c_4 w = g & \text{in } \Omega,\\ w|_{\partial\Omega} = 0 \end{cases} \tag{6.1}$$

has a unique solution w satisfying $\|w\|_2 \le C\|g\|$.

We have the following optimal order $L^2(\Omega)$ error estimate.

THEOREM 11. *Suppose that Condition* 1 *holds and there exist constants c_1, c_2, c_3 such that, for any $t \in [0,T]$, $\|\partial_x\dot{x}\|_\infty, \|\partial_x b\|_\infty \le c_1$; $\|\beta + \alpha\dot{x}\|_\infty, \|\frac{D}{Dt}(\beta+\alpha\dot{x})\|_\infty \le c_2$; $\|\partial_x a\|_\infty, \|\frac{D\alpha}{Dt}\|_\infty \le c_3$. Then there exists a constant C, depending on C_1, c_1, c_2, c_3, Ω, T, and the bounds of coefficient a, such that, for h sufficiently small,*

$$\begin{aligned}\|u - u_h\| \le C\Bigg\{ &\|\underline{h}^{\min\{m+1,s\}}u\|_{L^\infty[0,T,\underline{H}^s]} + \left\|h\underline{h}^{\min\{m+1,s-1\}}\frac{Du}{Dt}\right\|_{L^2[0,T;\underline{H}^{s-1}]}\\ &+ \|\underline{h}^{\min\{m+2,s\}}\sigma\|_{L^2[0,T;\underline{H}^s]} + \|h^2\underline{h}^{\min\{m+1,s-2\}}\sigma\|_{L^2[0,T;\underline{H}^{s-1}]}\\ &+ \left\|h^2\underline{h}^{\min\{m+1,s-2\}}\frac{D\sigma}{Dt}\right\|_{L^2[0,T;\underline{H}^{s-1}]}\Bigg\}.\end{aligned} \tag{6.2}$$

Proof. This is an application of Theorem 10 using $|\!|\!|\cdot|\!|\!|_{D_t}$. Since $|\!|\!|(u-u_h, \sigma-\sigma_h)|\!|\!|_{D_t}$ dominates the term we want to bound, it suffices to show that $|\!|\!|(u-v_h, \sigma - F_h(v_h))|\!|\!|_{D_t}$ can be bounded by terms on the right-hand side of (6.2) for a suitable choice of v_h.

At each time we take the elliptic projection (v_h, S_h) of (u, σ) into $V_h \times H_h$ to satisfy

$$\begin{cases} (\alpha(S_h - \sigma) + (\beta + \alpha\dot{x})(v_h - u), \mathcal{X}) - (v_h - u, \partial_x \mathcal{X}) = 0 & \forall \mathcal{X} \in H_h, \\ (\partial_x(S_h - \sigma) + c_4(v_h - u), r) = 0 & \forall r \in V_h. \end{cases} \tag{6.3}$$

Notice that $S_h = F_h(v_h)$.

Differentiating (6.3) with respect to time, using Lemma 7 and properties of $\frac{D}{Dt}$, we have

(6.4)

$$\begin{cases} \left(\alpha \dfrac{D}{Dt}(S_h - \sigma) + (\beta + \alpha\dot{x}) \dfrac{D}{Dt}(v_h - u), \mathcal{X}\right) - \left(\dfrac{D}{Dt}(v_h - u), \partial_x \mathcal{X}\right) \\ \qquad = (E_1(S_h - \sigma), \mathcal{X}) + (E_2(v_h - u), \mathcal{X}) & \forall \mathcal{X} \in H_h, \\ \left(\partial_x \dfrac{D}{Dt}(S_h - \sigma) + c_4 \dfrac{D}{Dt}(v_h - u), r\right) = (E_3(v_h - u), r) & \forall r \in V_h, \end{cases}$$

where

$$\begin{aligned} E_1 &= -\left(\frac{D}{Dt}\alpha + \alpha \partial_x \dot{x}\right), \\ E_2 &= -\left(\frac{D}{Dt}(\beta + \alpha\dot{x}) + (\beta + \alpha\dot{x})\partial_x \dot{x}\right), \\ E_3 &= -c_4 \partial_x \dot{x}. \end{aligned}$$

Here we are also using the fact that, for any given $t_0 \in [0, T]$, $\mathcal{X}(x) \in H_h(t_0)$, and $r(x) \in V_h(t_0)$, we can define $\tilde{\mathcal{X}}(x, t) = \mathcal{X}(\mathcal{G}(\mathcal{G}^{-1}(x, t), t_0)) \in H_h(t)$ and $\tilde{r}(x, t) = r(\mathcal{G}(\mathcal{G}^{-1}(x, t), t_0)) \in V_h(t)$ for any $t \in [0, T]$, so that $\tilde{\mathcal{X}}(x, t_0) = \mathcal{X}(x)$, $\tilde{r}(x, t_0) = r(x)$, and $\frac{D}{Dt}\tilde{\mathcal{X}} = \frac{D}{Dt}\tilde{r} = 0$.

Because of (6.1), using the duality lemma in [3], for any h sufficiently small we have

$$\|v_h - P_h u\| \le C\{h\|S_h - \sigma\| + h\|P_h u - u\| + h^2 \|\partial_x(S_h - \sigma)\|\}. \tag{6.5}$$

From the second equation of (6.3) we have

$$\|P_h \partial_x(S_h - \sigma)\| \le C\|v_h - P_h u\|. \tag{6.6}$$

Therefore, using the triangle inequality,

$$\|\partial_x(S_h - \sigma)\| \le C\|v_h - P_h u\| + \|P_h \partial_x \sigma - \partial_x \sigma\|. \tag{6.7}$$

Also from the first equation of (6.3)

$$\begin{aligned} \|S_h - \Pi_h \sigma\|^2 &\le C(\alpha(S_h - \sigma), S_h - \Pi_h \sigma) + C(\alpha(\sigma - \Pi_h \sigma), S_h - \Pi_h \sigma) \\ &= C(v_h - u, \partial_x(S_h - \Pi_h \sigma)) - C((\beta + \alpha\dot{x})(v_h - u), S_h - \Pi_h \sigma) \\ &\qquad + C(\alpha(\sigma - \Pi_h \sigma), S_h - \Pi_h \sigma). \end{aligned} \tag{6.8}$$

Note that

$$(v_h - u, \partial_x(S_h - \Pi_h \sigma)) = (v_h - P_h u, P_h \partial_x(S_h - \sigma)) \le C\|v_h - P_h u\|^2;$$

therefore

$$\begin{aligned}\|S_h - \Pi_h\sigma\|^2 &\le C\{\|v_h - P_h u\|^2 + \|u - P_h u\|^2 + \|\sigma - \Pi_h\sigma\|^2\},\\ \|S_h - \sigma\|^2 &\le C\{\|v_h - P_h u\|^2 + \|u - P_h u\|^2 + \|\sigma - \Pi_h\sigma\|^2\}.\end{aligned} \tag{6.9}$$

Substituting into (6.5), we have

$$\|v_h - P_h u\| \le C\{h\|u - P_h u\| + h\|\sigma - \Pi_h\sigma\| + h^2\|P_h\partial_x\sigma - \partial_x\sigma\|\}. \tag{6.10}$$

Using the triangle inequality,

$$\|v_h - u\| \le C\{\|u - P_h u\| + h\|\sigma - \Pi_h\sigma\| + h^2\|P_h\partial_x\sigma - \partial_x\sigma\|\}. \tag{6.11}$$

Substituting (6.10) into (6.9),

$$\|S_h - \sigma\| \le C\{\|u - P_h u\| + \|\sigma - \Pi_h\sigma\| + h^2\|P_h\partial_x\sigma - \partial_x\sigma\|\}. \tag{6.12}$$

Similarly applying the duality lemmas in [3] to (6.4), noting that $\|E_1\|_\infty$, $\|E_2\|_\infty$, $\|E_3\|_\infty \le C$, we have for h sufficiently small,

$$\begin{aligned}\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| \le C\Bigg\{&h\left\|\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right\| + h\left\|P_h\frac{D}{Dt}u - \frac{D}{Dt}u\right\|\\ &+ h^2\left\|\partial_x\left(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right)\right\| + \|S_h - \sigma\| + \|v_h - u\|\Bigg\}.\end{aligned} \tag{6.13}$$

From the second equation of (6.4), we have

$$\left\|P_h\partial_x\left(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right)\right\| \le C\left\{\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| + \|v_h - P_h u\|\right\}.$$

Therefore a triangle inequality yields

$$\begin{aligned}&\left\|\partial_x\left(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right)\right\|\\ &\qquad\le C\left\{\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| + \|v_h - P_h u\| + \left\|P_h\partial_x\frac{D}{Dt}\sigma - \partial_x\frac{D}{Dt}\sigma\right\|\right\}.\end{aligned}$$

Also, from the first equation of (6.4)

$$\begin{aligned}\left\|\frac{D}{Dt}S_h - \Pi_h\frac{D}{Dt}\sigma\right\|^2 \le C\Bigg\{&\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\|^2 + \|v_h - P_h u\|^2\\ &+ \left\|P_h\frac{D}{Dt}u - \frac{D}{Dt}u\right\|^2 + \left\|\frac{D}{Dt}\sigma - \Pi_h\frac{D}{Dt}\sigma\right\|^2 + \|S_h - \sigma\|^2 + \|v_h - u\|^2\Bigg\},\end{aligned}$$

and the triangle inequality gives the same bound for $\|\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\|^2$. Substituting these into (6.13),

$$\begin{aligned}\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| \le C\Bigg\{&h\|v_h - P_h u\| + h\left\|P_h\frac{D}{Dt}u - \frac{D}{Dt}u\right\|\\ &+ h\left\|\frac{D}{Dt}\sigma - \Pi_h\frac{D}{Dt}\sigma\right\| + \|S_h - \sigma\| + \|v_h - u\| + h^2\left\|P_h\partial_x\frac{D}{Dt}\sigma - \partial_x\frac{D}{Dt}\sigma\right\|\Bigg\}.\end{aligned} \tag{6.14}$$

Choosing v_h in Theorem 10 to be the solution of (6.3) and noticing that S_h of (6.3) is equal to $F_h(v_h)$, $\partial_x \dot{x}$ is piecewise constant and therefore commutes with P_h, we have $\|P_h(u - v_h)\| = \|P_h u - v_h\|$ and

$$\begin{aligned}
\|AD_t(u - v_h)\| &= \|AP_h D_t(u - v_h)\| \\
&= \left\| A\left(P_h \frac{D}{Dt} u - \frac{D}{Dt} v_h\right) + A(\partial_x \dot{x}) P_h(u - v_h) \right\| \\
&\le C \left\| P_h \frac{D}{Dt} u - \frac{D}{Dt} v_h \right\| + C\|P_h u - v_h\| \\
&\le C \left\{ h \left\| P_h \frac{D}{Dt} u - \frac{D}{Dt} u \right\| + h \left\| \frac{D}{Dt}\sigma - \Pi_h \frac{D}{Dt}\sigma \right\| \right. \\
&\qquad + h^2 \left\| P_h \partial_x \frac{D}{Dt}\sigma - \partial_x \frac{D}{Dt}\sigma \right\| + \|u - P_h u\| \\
&\qquad \left. + \|\sigma - \Pi_h \sigma\| + h^2 \|P_h \partial_x \sigma - \partial_x \sigma\| \right\}
\end{aligned}$$

and

$$\begin{aligned}
\|A\partial_x(\sigma - F_h(v_h))\| &\le C\|P_h \partial_x \sigma - \partial_x S_h)\| \\
&\le C\{h\|u - P_h u\| + h\|\sigma - \Pi_h \sigma\| + h^2 \|P_h \partial_x \sigma - \partial_x \sigma\|\}.
\end{aligned}$$

Using approximation properties of P_h and Π_h, the proof of Theorem 11 is then complete. □

With more restrictions on the coefficients and the mesh movement, we can obtain the following superconvergence result.

THEOREM 12. *Suppose that the conditions of Theorem* 11 *hold and that there exist constants* $c_5, c_6, c_7 > 0$ *such that* $\|\partial_x(\frac{D}{Dt}(\beta + \alpha\dot{x}))\|_\infty \le c_5$, $\|\partial_x \frac{D\alpha}{Dt}\|_\infty \le c_6$, *and* $|\partial_x \dot{x}(x_i-) - \partial_x \dot{x}(x_i+)| \le c_7 \min\{h_i, h_{i+1}\}$ $\forall i$. *Then there exists a constant* C, *depending on* $C_1, c_1, c_2, c_3, c_5, c_6, c_7$, Ω, T, *and the bounds of coefficient* a, *such that for any* h *sufficiently small*

$$\begin{aligned}
\|P_h u - u_h\| \le C \Bigg\{ & \|h\underline{h}^{\min\{m+1,s\}} u\|_{L^\infty[0,T;\underline{H}^s]} + \left\| h\underline{h}^{\min\{m+1,s-1\}} \frac{Du}{Dt} \right\|_{L^2[0,T;\underline{H}^{s-1}]} \\
& + \|h\underline{h}^{\min\{m+2,s-1\}} \sigma_{-L^2[0,T;\underline{H}^{s-1}]} + \|h^2 \underline{h}_i^{\min\{m+1,s-2\}} \sigma\|_{L^2[0,T;\underline{H}^{s-1}]} \\
& + \left\| h^2 \underline{h}^{\min\{m+1,s-2\}} \frac{D\sigma}{Dt} \right\|_{L^2[0,T;\underline{H}^{s-1}]} \Bigg\}.
\end{aligned}$$

Proof. We slightly modify the proof of Theorem 11. First we apply the duality argument in [3] to (6.3) to get

$$\|S_h - \sigma\|_{-1} \le C\{h^2 \|\partial_x(S_h - \sigma)\| + \|v_h - P_h u\| + h\|u - P_h u\|\}. \tag{6.15}$$

Let ω be a piecewise linear continuous function on $\{\Omega_i\}$ such that $\omega(x_i) = \{\partial_x \dot{x}(x_i-) + \partial_x \dot{x}(x_i+)\}/2$ for any i. Then it is easy to see that $\|\omega - \partial_x \dot{x}\|_\infty \le Ch$ and $\|\omega\|_1 \le C$.

From the right-hand side of (6.4) we have

$$\begin{aligned}
(E_3(v_h-u),r) &= (E_3(v_h-P_hu),r),\\
(E_2(v_h-u),\mathcal{X}) &= -\left(v_h-u,\frac{D}{Dt}(\beta+\alpha\dot{x})\,\mathcal{X}\right)\\
&\quad -((\partial_x\dot{x})(v_h-u),(\beta+\alpha\dot{x})\cdot\mathcal{X}-P_h((\beta+\alpha\dot{x})\cdot\mathcal{X}))\\
&\quad -((\partial_x\dot{x})(v_h-P_hu),P_h((\beta+\alpha\dot{x})\cdot\mathcal{X}))\\
&\le C\{\|v_h-u\|_{-1}+h\|v_h-u\|+\|v_h-P_hu\|\}\|\mathcal{X}\|_1\\
&\le C\{h\|u-P_hu\|+\|v_h-P_hu\|\}\|\mathcal{X}\|_1,\\
(E_1(S_h-\sigma),\mathcal{X}) &= -\left(S_h-\sigma,\frac{D\alpha}{Dt}\mathcal{X}\right)-(\alpha(\partial_x\dot{x}-\omega)(S_h-\sigma),\mathcal{X})\\
&\quad -(S_h-\sigma,\alpha\omega\mathcal{X})\\
&\le C\{\|S_h-\sigma\|_{-1}+h\|S_h-\sigma\|\}\|\mathcal{X}\|_1.
\end{aligned}$$

Following the duality lemmas in [3] again and also using (6.15), we have

$$\begin{aligned}
\left\|\frac{D}{Dt}v_h-P_h\frac{D}{Dt}u\right\| \le C\Bigg\{&\|v_h-P_hu\|+h\left\|P_h\frac{D}{Dt}u-\frac{D}{Dt}u\right\|\\
&+h\left\|\frac{D}{Dt}\sigma-\Pi_h\frac{D}{Dt}\sigma\right\|+h\|S_h-\sigma\|\\
&+h^2\left\|P_h\partial_x\frac{D}{Dt}\sigma-\partial_x\frac{D}{Dt}\sigma\right\|+h\|u-P_hu\|+h^2\|\partial_x(S_h-\sigma)\|\Bigg\}.
\end{aligned}\tag{6.16}$$

Note that $\|AD_t(u-v_h)\| \le C\|P_h\frac{D}{Dt}u-\frac{D}{Dt}v_h\|+C\|P_hu-v_h\|$, and $\|u_h-P_hu\|$ is dominated by $\|\!|(u-u_h,\sigma-\sigma_h)|\!\|_{D_t^*}$; the rest of the proof is similar to that of Theorem 11. □

We conduct a convergence test using the equation $u_t-(u_x-b_1u)_x=0$, for $(x,t)\in(0,10)\times(0,1)$, $u(0,t)=u(10,t)=0, t\in[0,1]$, $u(x,0)=u_0(x), x\in[0,10]$. Here $u_0(x)$ is a smooth nonnegative function with support in $[3,5]$; see Figure 1. $b_1(x)$ is a C^2 nonnegative function such that $b_1=3.5$ on $[2,7]$, $b_1=0$ on $[0,1]\cup[8,10]$, and b_1 is a 5th order polynomial in $(1,2)$ and $(7,8)$. Three cases are examined. The case referred to as "moving mesh" is based on a specified mesh technique discussed in the next paragraph. There is a characteristic moving mesh case in which the mesh points are moved along characteristics, starting from the same mesh as the first case. There is also a case that uses a fixed uniform mesh. In all cases, we have taken the time step sufficiently small that the time truncation can be ignored, i.e., we are looking at the continuous-time case.

We illustrate a simple, but powerful, moving mesh strategy in which the mesh is specified by giving the mesh at the initial and the final times, and the meshes are then connected. A specified mesh calculation is very easy to program if one has a code that allows for variable mesh spacing; all that is required is a change in the convective term to account for $\alpha\dot{x}$. The selection of the mesh is easier if one can look at a coarse grid calculation. (One can specify the mesh at more than two levels, and various techniques can be used to connect the mesh points.) The initial mesh is taken so that the density of mesh points in $(0,6)$ is about one third higher than the average density across the entire interval. In the specified movement case the mesh at the final time $T=1$ is such that the local mesh density is proportional to $\epsilon+|\frac{\partial^2u}{\partial x^2}|$, where u is approximated by a coarse uniform grid numerical solution, and ϵ is taken to be

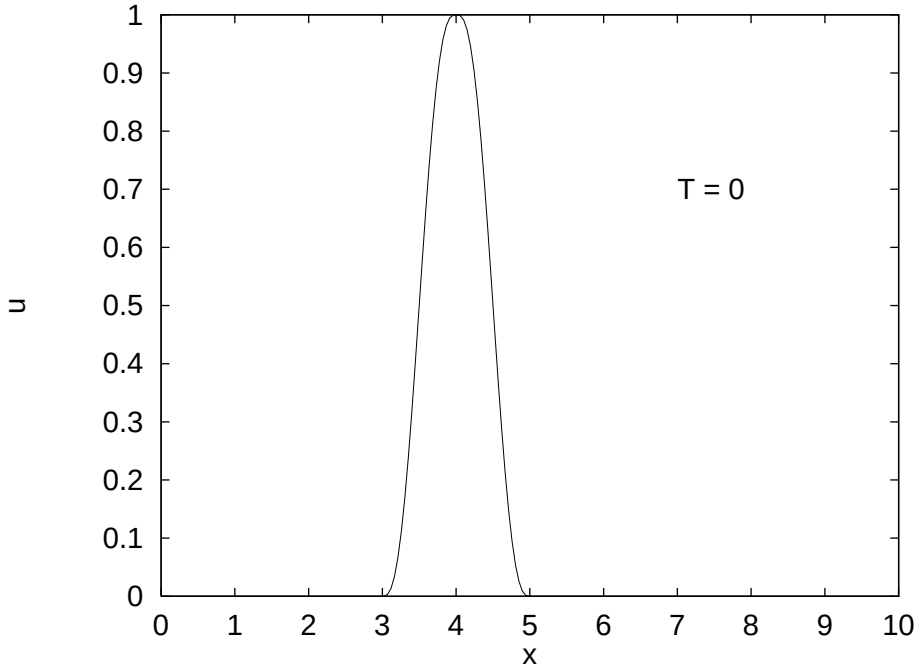

FIG. 1. *Initial value.*

0.2. (The value of ϵ is between the average and the maximum absolute value of the second derivative.) Figure 2 shows the mesh movement in the space time plane with mesh cell number $n = 40$.

In Figure 3, the final solution at $T = 1$ with $n = 20$ for the moving mesh mixed method is compared with the solution from the mixed method with an evenly distributed fixed mesh. Each of these solutions is used to produce a reconstructed continuous piecewise linear approximation $\tilde{u}_h$, through connecting the points $(x_i, u_h(x_i))$, where the x_i's are the cell centers. The "exact" solution is the result of a very fine grid calculation. As expected, higher resolution is achieved for the moving mesh near $(7, 8)$.

In Table 1 the comparison between the moving and fixed meshes is given in quantitative terms. The table clearly shows the first order convergence of the error and the second order convergence of the approximation built on the supercloseness of the midcell values.

TABLE 1
Comparative L^2 and L^∞ errors.

	Moving mesh			*Fixed mesh*		
n	$\|u - u_h\|$	$\|P_h u - u_h\|$	$\|u - \tilde{u}_h\|_\infty$	$\|u - u_h\|$	$\|P_h u - u_h\|$	$\|u - \tilde{u}_h\|_\infty$
20	0.052	0.0040	0.013	0.083	0.013	0.075
40	0.026	0.0010	0.0035	0.040	0.0027	0.025
80	0.013	0.00027	0.0011	0.020	0.00070	0.0066
160	0.0066	0.000072	0.00026	0.010	0.00020	0.0018

For this problem, using the same initial mesh as in the specified movement case, following the characteristics produces an overconcentration of mesh points in $(7, 8)$

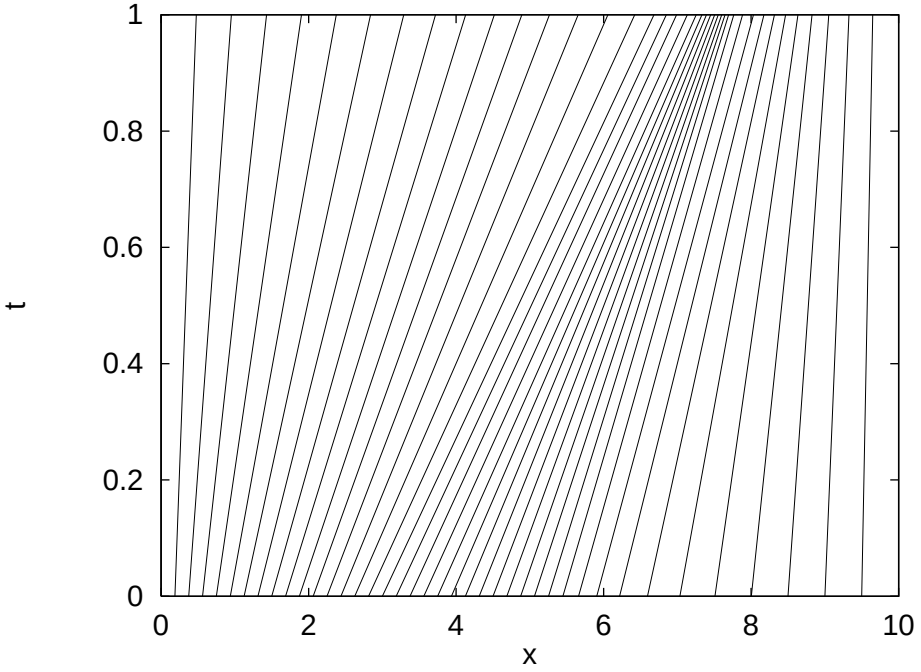

FIG. 2. *Moving mesh in the space time plane.*

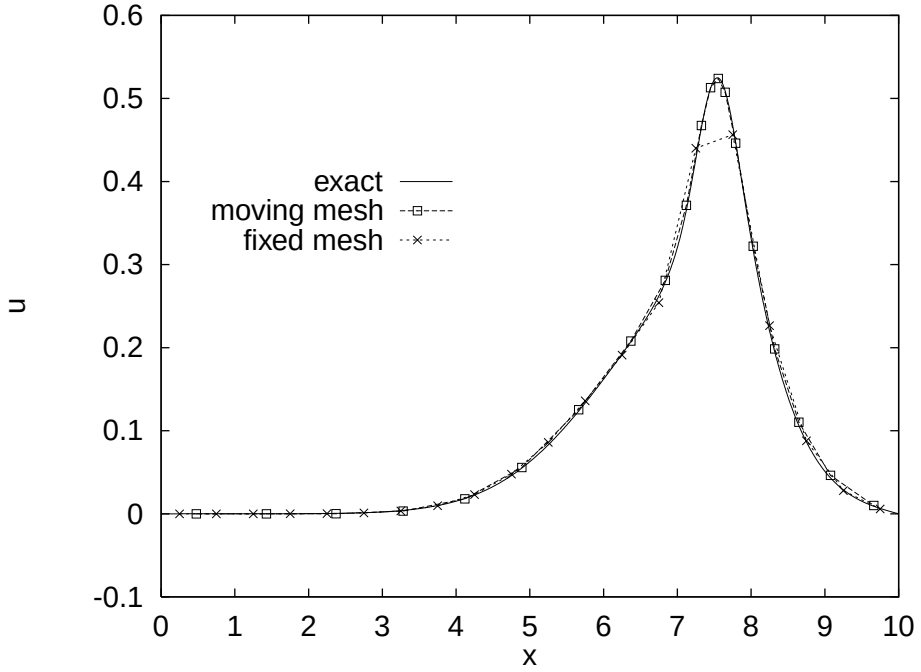

FIG. 3. *Specified and fixed mesh approximations at* $T = 1$.

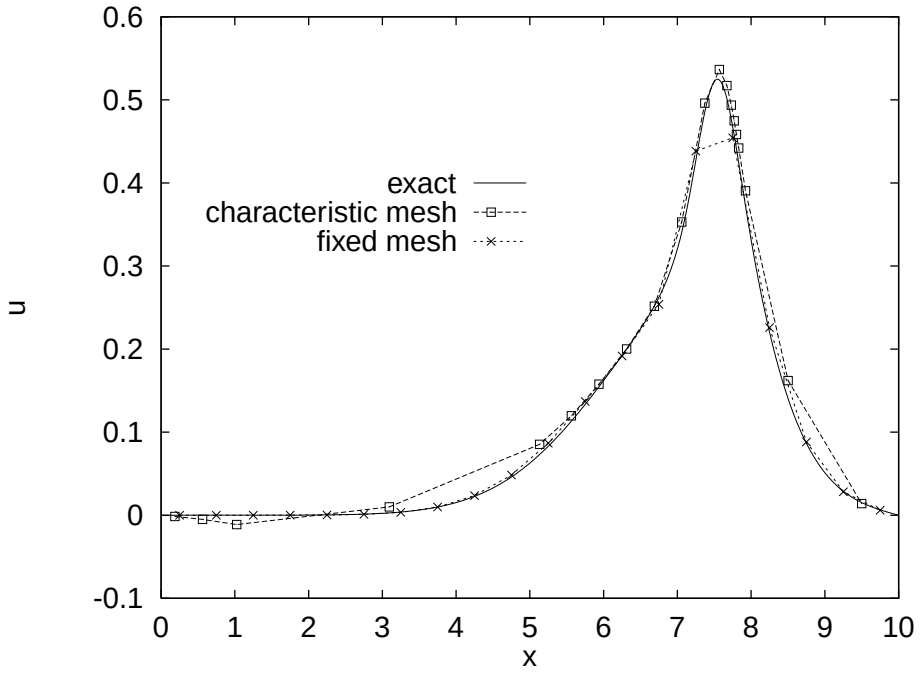

FIG. 4. *Characteristic and fixed mesh approximations at* $T = 1$.

TABLE 2
L^2 *and* L^∞ *errors with mesh moving along characteristics.*

n	$\|u - u_h\|$	$\|P_h u - u_h\|$	$\|u - \tilde{u}_h\|_\infty$
20	0.095	0.019	0.040
40	0.050	0.0063	0.018
80	0.026	0.0014	0.0059
160	0.013	0.00039	0.0016

but too few mesh points in $(1, 5.5)$. In Figure 4 and Table 2 computational results similar to those in Figure 3 and Table 1 are given. In this case the mesh is moving along characteristics.

7. Another mixed method. Consider the nonconservative form of (2.1):

$$\begin{cases} \partial_t u - \nabla \cdot (a \nabla u) + b \cdot \nabla u + cu = f & \text{on } Q, \\ u = 0 & \text{on } \partial\Omega \times (0, T), \\ u = u_0 & \text{for } t = 0. \end{cases} \tag{7.1}$$

Let $\sigma = a\nabla u$ and $\alpha = 1/a$, $\beta = b/a$. A natural mixed form is

$$\begin{cases} (\alpha\sigma, \mathcal{X}) + (u, div\, \mathcal{X}) = 0 & \forall \mathcal{X} \in H(div, \Omega), \\ \left(\dfrac{Du}{Dt} + div\, \sigma, r \right) + ((\beta - \dot{x}\alpha) \cdot \sigma, r) + (cu, r) = (f, r) & \forall r \in L^2(\Omega). \end{cases} \tag{7.2}$$

Note that, with a little abuse of the notations, $a, b, c, u, \alpha, \beta, \sigma$ have been redefined.

We will keep on using the relevant notations and results from previous sections unless otherwise specified.

The mixed method is to find $u_h : [0,T] \to V_h$ and $\sigma_h : [0,T] \to H_h$ such that

$$\begin{cases} (\alpha\sigma_h, \mathcal{X}) + (u_h, div\, \mathcal{X}) = 0 & \forall \mathcal{X} \in H_h, \\ \left(\dfrac{Du_h}{Dt} + div\, \sigma_h, r\right) + ((\beta - \dot{x}\alpha)\cdot\sigma_h, r) + (cu_h, r) = (f, r) & \forall r \in V_h. \end{cases} \tag{7.3}$$

The above formulas are introduced in [1]. But here we deal with general mesh movement, and therefore $\beta - \dot{x}\alpha$ is not necessarily zero.

We define the norm $|\!|\!|(\cdot,\cdot)|\!|\!|_c$ by

$$\begin{aligned} |\!|\!|(\eta,\psi)|\!|\!|_c^2 = \|\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \left\|A\frac{D\eta}{Dt}\right\|^2_{L^2(0,T:L^2(\Omega))} \\ + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))} + \|\psi\|^2_{L^2(0,T:L^2(\Omega))}. \end{aligned} \tag{7.4}$$

Let L_h be a linear operator $V_h(t) \to H_h(t)$ such that for any $v_h \in V_h(t)$

$$(\alpha L_h(v_h), \mathcal{X}) + (v_h, div\, \mathcal{X}) = 0 \quad \forall \mathcal{X} \in H_h.$$

We have the following theorem, whose proof is similar to that of Theorem 9.

THEOREM 13. *Suppose that Condition* 2 *holds and there exist constants* c_1, c_2 *such that*

$$\nabla_x \cdot \dot{x} \le c_1 \quad \text{and} \quad |\beta - \alpha\dot{x}| \le c_2$$

$\forall (x,t) \in Q$. *Then there exists a constant* $C > 0$, *depending only on* C_2, c_1, c_2, T, *the bounds of coefficients* a *and* c, *and* Ω, *such that, for any piecewise smooth function* v_h *with* $v_h(\cdot,t) \in V_h(t)$,

$$|\!|\!|(u - u_h, \sigma - \sigma_h)|\!|\!|_c \le C |\!|\!|(u - v_h, \sigma - L_h(v_h))|\!|\!|_c.$$

Introduce another norm $|\!|\!|(\cdot,\cdot)|\!|\!|_{c^*}$ by

$$\begin{aligned} |\!|\!|(\eta,\psi)|\!|\!|^2_{c^*} = \|P_h\eta\|^2_{L^\infty(0,T:L^2(\Omega))} + \left\|A\frac{D\eta}{Dt}\right\|^2_{L^2(0,T:L^2(\Omega))} + \|A(div\,\psi)\|^2_{L^2(0,T:L^2(\Omega))} \\ + \|A((\beta - \alpha\dot{x})\cdot\psi)\|^2_{L^2(0,T:L^2(\Omega))} + \|A(c\eta)\|^2_{L^2(0,T:L^2(\Omega))}. \end{aligned}$$

We have another theorem whose proof is similar to that of Theorem 10, also using Theorem 5.

THEOREM 14. *Suppose that Condition* 2 *holds and there exist constants* c_1, c_2 *such that*

$$\nabla_x \cdot \dot{x} \le c_1 \quad \text{and} \quad |\beta + \alpha\dot{x}| \le c_2$$

$\forall (x,t) \in Q$. *Then there exists a constant* $C > 0$, *depending only on* C_2, c_1, c_2, T, *the bounds of coefficients* a *and* c, *and* Ω, *such that, for any piecewise smooth function* v_h *with* $v_h(\cdot,t) \in V_h(t)$,

$$|\!|\!|(u - u_h, \sigma - \sigma_h)|\!|\!|_{c^*} \le C |\!|\!|(u - v_h, \sigma - L_h(v_h))|\!|\!|_{c^*}.$$

Parallel to what was done in section 6, we derive an optimal convergence result for one dimension in the next theorem. In particular, the L^2 norm of $u_h - P_h u$ is superconvergent.

Assume that a is sufficiently regular so that for any $\xi \in L^2(\Omega)$ the equation

$$\begin{cases} -\partial_x(a\partial_x w) = g & \text{in } \Omega, \\ w = 0 & \text{on } \partial\Omega \end{cases} \tag{7.5}$$

has a unique solution satisfying $\|w\|_2 \le C\|g\|$. We have the following theorem.

THEOREM 15. *Suppose that Condition* 1 *holds and there exist constants* c_1, c_2, c_3 *such that* $|\partial_x \dot{x}|, |\frac{D\alpha}{Dt}| \le c_1$; $|\beta + \alpha\dot{x}| \le c_2$; $|\partial_x c| \le c_3$ $\forall (x,t) \in Q$. *Then there exists a constant* $C > 0$, *depending only on* C_1, c_1, c_2, c_3, T, *the bounds on coefficients* a *and* c, *and* Ω, *such that for any* h *sufficiently small*

$$\begin{aligned} \|u_h - P_h u\| \le C\Bigg\{ & \|\underline{h}^{\min\{m+2,s+1\}}\sigma\|_{L^\infty[0,T;\underline{H}^{s+1}]} + \|h\underline{h}^{\min\{m+1,s\}}\sigma\|_{L^2[0,T;\underline{H}^{s+1}]} \\ & + \left\|h\underline{h}^{\min\{m+2,s\}}\frac{D\sigma}{Dt}\right\|_{L^2[0,T;\underline{H}^s]} + \left\|h^2\underline{h}^{\min\{m+1,s-1\}}\frac{D\sigma}{Dt}\right\|_{L^2[0,T;\underline{H}^s]} \\ & + \|h\underline{h}^{\min\{m+1,s\}}u\|_{L^2[0,T;\underline{H}^s]}\Bigg\} \end{aligned}$$

and

$$\begin{aligned} \|u - u_h\| \le C\Bigg\{ & \|\underline{h}^{\min\{m+2,s\}}\sigma\|_{L^\infty[0,T;\underline{H}^s]} + \|h\underline{h}^{\min\{m+1,s-1\}}\sigma\|_{L^2[0,T;\underline{H}^s]} \\ & + \left\|h\underline{h}^{\min\{m+2,s-1\}}\frac{D\sigma}{Dt}\right\|_{L^2[0,T;\underline{H}^{s-1}]} + \left\|h^2\underline{h}_i^{\min\{m+1,s-2\}}\frac{D\sigma}{Dt}\right\|_{L^2[0,T;\underline{H}^{s-1}]} \\ & + \|h\underline{h}^{\min\{m+1,s\}}u\|_{L^2[0,T;\underline{H}^s]}\Bigg\}. \end{aligned}$$

Proof. The proof of the first estimate is an application of Theorem 14. Since $\|\!|(u - u_h, \sigma - \sigma_h)|\!\|_{c^*}$ dominates the term we want to bound, it suffices to show that $\|\!|(u - v_h, \sigma - L_h(v_h))|\!\|_{c^*}$ can be bounded by terms on the right-hand side of the first estimate. The second estimate follows from a triangle inequality.

Consider the following elliptic projection:

$$\begin{cases} (\alpha(S_h - \sigma), \mathcal{X}) + (v_h - u, \partial_x \mathcal{X}) = 0 & \forall \mathcal{X} \in H_h, \\ (\partial_x(S_h - \sigma), r) = 0 & \forall r \in V_h. \end{cases} \tag{7.6}$$

Notice that $S_h = L_h(v_h)$.

Differentiating (7.6) with respect to time and using Lemma 7 and properties of $\frac{D}{Dt}$, we have

$$\begin{cases} \left(\alpha\dfrac{D}{Dt}(S_h - \sigma), \mathcal{X}\right) + \left(\dfrac{D}{Dt}(v_h - u), \partial_x \mathcal{X}\right) \\ \qquad = (E_4(S_h - \sigma), \mathcal{X}), & \forall \mathcal{X} \in H_h, \\ \left(\partial_x \dfrac{D}{Dt}(S_h - \sigma), r\right) = 0 & \forall r \in V_h, \end{cases} \tag{7.7}$$

where $E_4 = -(\frac{D}{Dt}\alpha + \alpha\partial_x\dot{x})$. Using the duality lemma in [3], we have

$$\|v_h - P_h u\| \le C\{h\|S_h - \sigma\| + h^2\|\partial_x(S_h - \sigma)\|\}. \tag{7.8}$$

Also from the second equation of (7.6),

$$\|\partial_x(S_h - \Pi_h\sigma)\| = 0 \quad \text{and} \quad \|P_h\partial_x(S_h - \sigma)\| = 0,$$

so $\|\partial_x(S_h - \sigma)\| = \|P_h\partial_x\sigma - \partial_x\sigma\|$. From the first equation of (7.6),

$$\|S_h - \Pi_h\sigma\| \le C\|\sigma - \Pi_h\sigma\|, \quad \text{and so} \quad \|S_h - \sigma\| \le C\|\sigma - \Pi_h\sigma\|.$$

Therefore

$$\|v_h - P_h u\| \le C\{h\|\sigma - \Pi_h\sigma\| + h^2\|P_h\partial_x\sigma - \partial_x\sigma\|\}.$$

Similarly for equation (7.7),

$$\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| \le C\left\{h\left\|\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right\| + h^2\left\|\partial_x\left(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right)\right\| + \|S_h - \sigma)\|\right\} \tag{7.9}$$

and $\|P_h\partial_x(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma)\| = 0$, $\|\partial_x(\frac{D}{Dt}S_h - \Pi_h\frac{D}{Dt}\sigma)\| = 0$. So

$$\left\|\partial_x\left(\frac{D}{Dt}S_h - \frac{D}{Dt}\sigma\right)\right\| = \left\|P_h\partial_x\frac{D}{Dt}\sigma - \partial_x\frac{D}{Dt}\sigma\right\|.$$

Also from the first equation of (7.7)

$$\left\|\frac{D}{Dt}S_h - \Pi_h\frac{D}{Dt}\sigma\right\| \le C\left\{\|S_h - \sigma\| + \left\|\frac{D}{Dt}\sigma - \Pi_h\frac{D}{Dt}\sigma\right\|\right\}.$$

Therefore

$$\begin{aligned}\left\|\frac{D}{Dt}v_h - P_h\frac{D}{Dt}u\right\| \le C\Bigg\{&\|S_h - \sigma\| + h\left\|\frac{D}{Dt}\sigma - \Pi_h\frac{D}{Dt}\sigma\right\| \\ &+ h^2\left\|\partial_x\frac{D}{Dt}\sigma - P_h\partial_x\frac{D}{Dt}\sigma\right\|\Bigg\}.\end{aligned} \tag{7.10}$$

In Theorem 15, choose v_h to be the solution of (7.6). Note that

$$\begin{aligned}\left\|A\frac{D}{Dt}(u - v_h)\right\| &\le C\left\|P_h\frac{D}{Dt}u - \frac{D}{Dt}v_h\right\|, \\ \|A((\beta - \alpha\dot{x})\cdot(\sigma - S_h))\| &\le C\|\sigma - S_h\| \\ &\le C\|\sigma - \Pi_h\sigma\|, \\ \|A(c(u - v_h))\| &\le \|A((c - \bar{c})(u - v_h))\| + \|A(\bar{c}(u - v_h))\| \\ &\le C\|(c - \bar{c})(u - v_h)\| + \|A(\bar{c}P_h(u - v_h))\| \\ &\le Ch(\|u - P_h u\| + \|P_h u - v_h\|) + C\|P_h u - v_h\|,\end{aligned}$$

where $\bar{c}|_{\Omega_i} \equiv (1/|\Omega_i|)\int_{\Omega_i} c dx\ \forall i$ is a piecewise constant function which commutes with P_h. The proof is completed using the approximation properties of the projections P_h and Π_h. ∎

A MONOTONIC METHOD FOR THE NUMERICAL SOLUTION OF SOME FREE BOUNDARY VALUE PROBLEMS*

RAPHAÈLE HERBIN†

Abstract. This work presents an efficient monotonic algorithm for the numerical solution of the obstacle problem and the Signorini problems, when they are discretized either by the finite element method or by the finite volume method. The convergence of this algorithm applied to the discrete problem is proven in both cases.

Key words. variational inequalities, iterative algorithm, obstacle problem, Signorini problem, finite element and finite volume methods

1. Introduction.

We are interested here in the numerical solution of some free boundary problems which are discretized by the finite element or the finite volume method. We introduce an efficient monotonic algorithm which applies to both the obstacle problem and the Signorini problem.

The obstacle problem is one of the simplest unilateral problems; it arises when modelling a constrained membrane in the classical linear elasticity theory. Signorini boundary conditions may be encountered in fluid mechanics and heat transfer problems when modelling, for instance, the flow through semipermeable boundaries. They are also encountered in contact problems in elasticity. The Signorini boundary conditions which we deal with here arise from modelling the so-called triple point of an electrochemical reaction (see [23]) and involve a diffusion operator. Both the obstacle and the Signorini problems may be written as variational inequalities.

The obstacle problem appeared in the mathematical literature in the work of Stampacchia [28] (see also [29], [30]), and the first rigorous analysis of a class of Signorini problems was published in 1963 by Fichera [12], [13]. The mathematical analysis including the study of existence, uniqueness, and regularity of the solution for the obstacle problem and Signorini problem may be found in [24], [25], and [7].

The obstacle problem and the Signorini problem are classically discretized by the finite element method formulated in [21], [16]; see also [27], [2], [1], [3] for more recent work (some of them subsequent to the submission of this paper) on elastic contact problems. In the case of diffusion problems, with which we are concerned here, a cell-center finite volume scheme was also recently applied and shown to converge [19].

The approximate problem can be solved by a duality method [16], [15], [22]. In [16], a point overrelaxation method with projection is also studied and found to be cheaper in terms of computational cost than the duality method. Another candidate for the resolution of the approximated Signorini problem is the penalty method (see [21] and references therein); it has the disadvantage of yielding ill-conditioned systems, while our algorithm deals only with submatrices of the whole discretization matrix.

We present here a particularly simple iterative monotonic algorithm that is inspired by a procedure used for multiphase flow modelling [8]. We show that it may be applied to the finite linear element approximation of the obstacle problem and the finite volume discretization of both the obstacle problem and the Signorini problem. In each case, we prove the monotonicity of the algorithm and its convergence in a finite number of iterations towards the exact solution to the discrete problem.

2. The obstacle problem. We consider here the so-called obstacle problem, which arises for instance in the modelling of contact problems (see [7]):

$$\text{(1)} \qquad \begin{cases} u \in \mathcal{K} = \{v \in H_0^1(\Omega),\ v \le \psi \text{ on } \Omega\}, \quad \text{satisfying} \\ \displaystyle\int_\Omega \nabla u(x) \cdot \nabla (v-u)(x) dx \ge \int_\Omega f(x)(v-u)(x) dx \qquad \forall v \in \mathcal{K}, \end{cases}$$

where the following holds.

Assumption 2.1.

1. Ω is a bounded open polygonal subset of $\mathbb{R}^d$, with $d = 2$ or 3.
2. $f \in L^2(\Omega)$ and $\psi \in H^1(\Omega) \cap C(\Omega)$ and $\psi \ge 0$ a.e. in the neighborhood of $\partial\Omega$.

Under these assumptions, it is well known that there exists a unique solution to problem (1), thanks to Stampacchia's theorem. Indeed, the set $\mathcal{K}$ is nonempty since $\min(0, \psi)$ belongs to $\mathcal{K}$. Furthermore, it is now classical that the solution to problem (1) belongs to $H^2(\Omega)$ (see [4]). Thanks to this H^2 regularity of the solution, it is easily shown that the variational inequality (1) can be written as a free boundary problem in the following way.

THEOREM 2.1. *Under Assumption* 2.1, *if u is a solution to the free boundary problem*

$$\text{(2)} \qquad \begin{cases} u \in H^2(\Omega) \cap H_0^1(\Omega), \quad \textit{satisfying} \\ u \le \psi \quad \textit{a.e. on } \Omega, \\ \Delta u + f \ge 0 \quad \textit{a.e. on } \Omega, \\ (\Delta u + f)(\psi - u) = 0 \quad \textit{a.e. on } \Omega, \end{cases}$$

then u is a solution to Problem (1).

Conversely, if $\psi \ge 0$ a.e. on Ω and u is a solution to Problem (1), *then u is a solution to Problem* (2).

We shall study the monotonic algorithm for both the finite element and the finite volume discretization of the above problem. Let us first start with the finite element method.

2.1. Approximation by the finite element method. Let $\mathcal{T}$ denote a "classical" triangulation of Ω (see, e.g., [6]).

DEFINITION 2.2 (triangulation $\mathcal{T}$ of Ω). *Let $\mathcal{T}$ be a finite set of triangles if $d = 2$, or tetrahedra if $d = 3$, such that*

(i) *$T \subset \overline{\Omega}\ \forall T \in \mathcal{T}$, and $\cup_{T\in\mathcal{T}} = \overline{\Omega}$;*

(ii) *for any $(T_1, T_2) \in \mathcal{T}^2$ with $T_1 \ne T_2$, either the $(d-1)$-dimensional Lebesgue measure of $\overline{T}_1 \cap \overline{T}_2$ is 0, or T_1 and T_2 have only a whole common edge (or face if $d = 3$).*

Let Σ be the set of vertices of triangles (tetrahedra) of $\mathcal{T}$ which belong to Ω (i.e., do not lie on the boundary) and $N = \operatorname{card}(\Sigma)$.

The set $H_0^1(\Omega)$ is classically approximated by

$$\text{(3)} \qquad V_h = \{v \in H_0^1(\Omega) \cap C^0(\overline{\Omega}),\ v_{|\partial\Omega} = 0,\ v_{|T} \in P_1\},$$

where $v_{|\partial\Omega}$ is the trace of v on $\partial\Omega$, $v_{|_T}$ denotes the restriction of v to T, and P_1 the space of polynomials in x_1 and x_2 of degree less than or equal to one. Assuming that $\Sigma = \{s_i,\ i \in \{1,\dots,N\}\}$, let $(\varphi_i)_{i\in\{1,\dots,N\}}$ be the N basis functions of V_h such that $\varphi_i(s_i) = 1$ and $\varphi_i(s_j) = 0\ \forall i \neq j$; notice that the functions φ_i are linear on each triangle for which s_i is a vertex.

We then consider the following approximate problem:

$$\text{(4)} \qquad \begin{cases} \tilde{u} \in K_h = \{v \in V_h,\ v(s) \leq \psi(s)\ \forall s \in \Sigma\}, \quad \text{satisfying} \\ \displaystyle\int_\Omega \nabla\tilde{u}(x)\cdot\nabla(v-\tilde{u})(x)dx \geq \int_\Omega f(x)(v-\tilde{u})(x)dx \qquad \forall v \in K_h. \end{cases}$$

By Stampacchia's theorem, problem (4) has a unique solution. Indeed, the set K_h is nonempty since the function $\min(\sum_{i=1,N}\psi_i\varphi_i, 0)$ belongs to K_h. Error estimates for the approximate finite element solution of the elliptic variational inequalities can be found in Falk [10], Mosco and Strang [26], Glowinski, Lions, and Trémolières [16], Ciarlet [6], Brezzi, Hager, and Raviart [5], and Falk and Mercier [11]. Error estimates of order 1 in the discretization step are known for the discretization of the obstacle problem using linear elements [10], [5].

Remark 2.1. In the present paper we shall use linear finite elements, and we shall avoid higher order finite elements for three reasons. First, it is well known that the maximum principle does not hold for higher order finite elements. In our underlying application, where the unknown is a concentration, it is absolutely necessary that it hold, since the electrical current, which we need to compute, depends on the logarithm of the concentration. The discrete maximum principle must therefore hold. Second, the precision obtained with the linear elements is, in general, largely sufficient for diffusion problems such as the one we consider. Third, our proof of convergence of the monotonic algorithm makes heavy use of the discrete maximum principle, and it is therefore not clear how the algorithm would behave in a setting where the maximum principle does not hold (in the case of higher order finite elements, or for the elasticity problem, for instance).

The monotonic algorithm is derived on a "strong formulation" of problem (4), which is easily shown to be equivalent to (4) as follows.

PROPOSITION 2.3. *Let $\tilde{u}$ be the unique solution to problem* (4) *and let $U = (u_1,\dots,u_N) \in \mathbb{R}^N$ be defined by $u_i = \tilde{u}(s_i)\ \forall i \in \{1,\dots,N\}$; then $\tilde{u}$ is a solution to* (4) *if and only if U is a solution to the following complementarity problem:*

$$\text{(5)} \qquad \begin{cases} u_i \leq \psi_i \quad \forall i \in \{1,\dots,N\}, \\ (AU)_i \leq F_i \quad \forall i \in \{1,\dots,N\}, \\ ((AU)_i - F_i)(\psi_i - u_i) = 0 \quad \forall i \in \{1,\dots,N\}, \end{cases}$$

with $\psi_i = \psi(s_i)$, $F_i = \int_\Omega f(x)\varphi_i(x)dx$, and A being the square matrix of order N whose coefficients satisfy $a_{i,j} = \int_\Omega \nabla\varphi_i(x)\cdot\nabla\varphi_j(x)dx$; therefore

$$(AU)_i = \sum_{j=1}^{N} u_j \int_\Omega \nabla\varphi_j(x)\cdot\nabla\varphi_i(x)dx.$$

Problem (5) is nonlinear. We shall solve it by an iterative algorithm that is adapted from a similar one used for multiphase flows in porous media [8]. Let us first remark that for $i \in \{1,\dots,N\}$ the last equation in (5) is equivalent to $(AU)_i = F_i$ or $u_i = \psi_i$. Therefore, there exist two disjoint subsets of $\{1,\dots,N\}$ such that $u_i = \psi_i$

and $(AU)_i \le F_i$ for any i in the first subset, and $(AU)_i = F_i$ and $u_i \le \psi_i$ for i in the second subset.

If we knew two disjoint subsets $\mathcal{J}$ and $\mathcal{I}$ of $\{1,\dots,N\}$ such that

$$\begin{aligned} u_i &\le \psi_i \quad \forall i \in \mathcal{J}, \\ (AU)_i &\le F_i \quad \forall i \in \mathcal{I}, \end{aligned}$$

then problem (5) would be solved by the solution of the following linear system:

$$\left\{ \begin{array}{l} u_i = 0 \quad \forall i \in \{1,\dots,N\} \quad \text{s.t. } s_i \in \partial\Omega \cap K_h, \\ (AU)_i = F_i \quad \forall i \in \mathcal{J}, \\ u_i = \psi_i \quad \forall i \in \mathcal{I}. \end{array} \right. \tag{6}$$

The algorithm which we propose here assumes the sets $\mathcal{J}$ and $\mathcal{I}$ to be known at each iteration, solves problem (6), and corrects the sets $\mathcal{J}$ and $\mathcal{I}$ by looking for the nodes where the corresponding constraints are violated. Let us write this algorithm as follows.

Monotonic algorithm, obstacle problem, finite element discretization.

- Initialization. Let $\mathcal{I}^{(0)}$ and $\mathcal{J}^{(0)}$ be such that

$$\mathcal{I}^{(0)} \subset \{1,\dots,N\} \text{ and } \mathcal{J}^{(0)} = \{1,\dots,N\} \setminus \mathcal{I}^{(0)}. \tag{7}$$

- Step (j), $j \ge 0$. For given sets $\mathcal{I}^{(j)}$ and $\mathcal{J}^{(j)} = \{1,\dots,N\} \setminus \mathcal{I}^{(j)}$, let $U^{(j)} = (u_1^{(j)},\dots,u_N^{(j)}) \in \mathbb{R}^N$ be the solution to the following set of equations:

$$\left\{ \begin{array}{l} (AU^{(j)})_i = F_i \quad \forall i \in \mathcal{J}^{(j)}, \\ u_i^{(j)} = \psi_i \quad \forall i \in \mathcal{I}^{(j)}, \end{array} \right. \tag{8}$$

  where $(AU^{(j)})_i = \sum_{k=1}^N u_k^{(j)} \int_\Omega \nabla\varphi_k(x) \cdot \nabla\varphi_i(x)dx$ and $F_i = \int_\Omega f(x)\varphi_i(x)dx$. Let $\mathcal{I}^{(j+1)}$ and $\mathcal{J}^{(j+1)}$ be defined by

$$\begin{array}{ll} \mathcal{I}^{(j,0)} = \{i \in \mathcal{I}^{(j)}; AU_i^{(j)} \le F_i\}, & \mathcal{I}^{(j,1)} = \mathcal{I}^{(j)} \setminus \mathcal{I}^{(j,0)}, \\ \mathcal{J}^{(j,0)} = \{i \in \mathcal{J}^{(j)}; u_i^{(j)} \le \psi_i\}, & \mathcal{J}^{(j,1)} = \mathcal{J}^{(j)} \setminus \mathcal{J}_j^{(0)}, \\ \mathcal{I}^{(j+1)} = \mathcal{I}^{(j,0)} \cup \mathcal{J}^{(j,1)}, & \mathcal{J}^{(j+1)} = \{1,\dots,N\} \setminus \mathcal{I}^{(j+1)}. \end{array} \tag{9}$$

- The algorithm stops if there exists a step n such that $\mathcal{I}^{(n)} = \mathcal{I}^{(n+1)}$.

Let us first remark that this algorithm is well defined.

Proposition 2.4. *Let $\Sigma = \{s_i, i = 1, N\}$ denote the set of nodes of a given triangulation of Ω, let $\mathcal{I}^{(j)} \subset \{1,\dots,N\}$ and $\mathcal{J}^{(j)} = \{1,\dots,N\} \setminus \mathcal{I}^{(j)}$; then problem (8) has a unique solution.*

Proof. The proof of this result follows immediately from the Lax–Milgram lemma by noting that under Assumptions 2.1 and with the notations of Definition 2.2 and Proposition 2.4, $U^{(j)} = (u_1^{(j)},\dots,u_N^{(j)}) \in \mathbb{R}^N$ is a solution to problem (8) if and only if $\tilde{u}^{(j)}(x) = \sum_{i=1}^N u_i^{(j)} \varphi_i(x)$ is a solution to the following variational problem:

$$\left\{ \begin{array}{l} \tilde{u}^{(j)} \in V_h \quad \text{s.t. } u_i^{(j)} = \psi_i \ \forall i \in \mathcal{I}^{(j)}, \\ \displaystyle\int_\Omega \nabla\tilde{u}^{(j)}(x) \cdot \nabla v(x)dx = \int_\Omega f(x)v(x)dx \quad \forall v \in V_h. \end{array} \right. \tag{10}$$

∎

Let us now show that the algorithm defined by (7)–(9) is monotonic.

LEMMA 2.5. *Under Assumption* 2.1 *and those of Definition* 2.2, *the sequence* $(U^{(j)})_{j\in\mathbb{N}}$ *constructed by the algorithm* (7)–(9), *where* $U^{(j)} = (u_1^{(j)}, \dots, u_N^{(j)})$, *satisfies*

$$u_i^{(j+1)} \leq u_i^{(j)} \quad \forall j \in \mathbb{N}, \forall i \in \{1, \dots, N\}. \tag{11}$$

Equivalently, the sequence of functions $(\tilde{u}^{(j)})_{j\in\mathbb{N}}$ *defined by* $\tilde{u}^{(j)}(x) = \sum_{i=1}^N u_i^{(j)}\varphi_i(x)$ *for all* $x \in \Omega$ *satisfies*

$$\tilde{u}^{(j+1)} \leq \tilde{u}^{(j)} \quad \forall j \in \mathbb{N}. \tag{12}$$

Proof. Let $j \in \mathbb{N}$ and $w_h = \tilde{u}^{(j)} - \tilde{u}^{(j+1)}$. Then

$$\int_\Omega |\nabla w_h^-(x)|^2 dx = -\sum_{i=1}^N w_i^- \int_\Omega \nabla w_h(x)\nabla\varphi_i(x)dx. \tag{13}$$

- If $i \in \mathcal{I}^{(j)} \cap \mathcal{I}^{(j+1)}$, one has $w_i = 0$, and therefore $\int_\Omega \nabla w_h(x)\cdot\nabla(w_i^-\varphi_i(x))dx = 0$.
- If $i \in \mathcal{J}^{(j)} \cap \mathcal{J}^{(j+1)}$, one has $\int_\Omega \nabla\tilde{u}^{(j)}(x) \cdot \nabla\varphi_i(x)dx = \int_\Omega \nabla\tilde{u}^{(j+1)}(x) \cdot \nabla\varphi_i(x)dx$, and therefore
$$\int_\Omega \nabla w_h(x) \cdot \nabla(w_i^-\varphi_i(x))dx = 0.$$
- If $i \in \mathcal{J}^{(j)} \cap \mathcal{I}^{(j+1)}$, one obtains $u_i^{(j)} > \psi_i$ and $u_i^{(j+1)} = \psi_i$, hence $w_i > 0$, and therefore
$$\int_\Omega \nabla w_h(x) \cdot \nabla(w_i^-\varphi_i(x))dx = 0.$$
- Finally if $i \in \mathcal{I}^{(j)} \cap \mathcal{J}^{(j+1)}$, then $(AU^{(j)})_i > F_i$ and $(AU^{(j+1)})_i = F_i$, so that
$$\int_\Omega \nabla w_h(x) \cdot \nabla(w_i^-\varphi_i(x))dx \geq 0.$$

These inequalities and (13) yield that $\int_\Omega |\nabla w_h^-(x)|^2 dx = 0$, and since $w_h^- \in H_0^1(\Omega)$, this implies that $w_h \geq 0$, which concludes the proof of the lemma. ∎

We may now turn to the convergence of the algorithm. We first state that if the sets $\mathcal{I}^{(j)}$ and $\mathcal{J}^{(j)}$ are left unchanged from one iteration to the next, then the algorithm has reached the unique solution to problem (5).

PROPOSITION 2.6. *Assume that the sequence of sets* $(\mathcal{I}^{(j)})_{j\in\mathbb{N}}$ *constructed by the algorithm* (7)–(9) *is such that there exists* $n \in \mathbb{N}$ *such that* $\mathcal{I}^{(n)} = \mathcal{I}^{(n+1)}$; *then the solution* $U^{(n)}$ *to* (8) *is the unique solution to problem* (5).

Proof. Under the assumptions of Proposition 2.6, let $\mathcal{I} = \mathcal{I}^{(n)}$, $\mathcal{J} = \mathcal{J}^{(n)}$; let $U^{(n)} = (u_1, \dots, u_n)$ be the solution to (8) with $j = n$. Since $\mathcal{J}^{(n)} = \mathcal{J}^{(n+1)}$, one has $u_i \leq \psi_i$ for any $i \in \mathcal{J}^{(n)}$. Furthermore, $u_i = \psi_i$ for any $i \in \mathcal{I}^{(n)}$, so that $u_i \leq \psi_i$ for any $i \in \{1, \dots, N\}$. In a similar way, one has that $(AU)_i \leq F_i$ for any $i \in \{1, \dots, N\}$, and from (8) one has that $((AU)_i - F_i)(u_i - \psi_i) = 0$ for any $i \in \{1, \dots, N\}$. ∎

Let us now show that the monotonic algorithm terminates in a finite number of iterations.

THEOREM 2.7. *Under Assumption* (2.1), *there exists* $n \in \mathbb{N}$ *such that the sequence* $(U^{(n)})_{n\in\mathbb{N}}$ *constructed by the algorithm* (7)–(9) *is such that* $U^{(n)}$ *is the exact solution to the discrete problem* (4) *for all* $j \geq n$. *Furthermore the integer* n *satisfies*

$$n \leq N + 1. \tag{14}$$

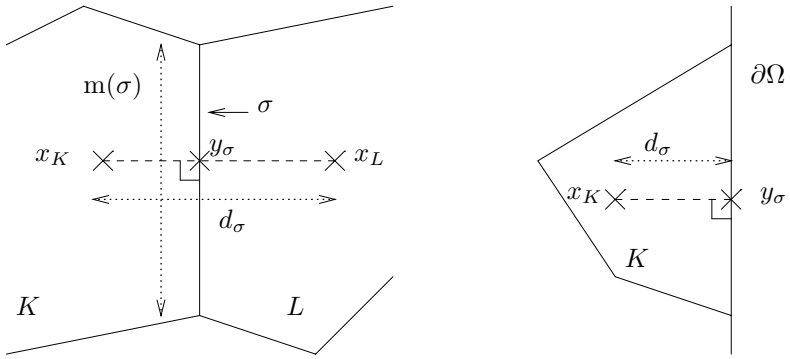

FIG. 1. *Admissible meshes.*

Proof. Let the sets $\mathcal{I}^{(j)}$ and $\mathcal{J}^{(j)}$ be defined by the algorithm (7)–(9) for any step (j); if there exists an integer n such that $\mathcal{I}^{(n)} = \mathcal{I}^{(n+1)}$, then, by Proposition 2.10, $U^{(n)}$ is the exact solution to the discrete problem (4), and the first part of the theorem is proven. It remains to prove that such a step exists and that it satisfies (14).

Let us first remark that for $i \in \{1, \dots, N\}$ if $u_i^{(0)} \leq \psi_i$, then $u_i^{(1)} \leq \psi_i$ by Lemma 2.5, and if $u_i^{(0)} > \psi_i$, then $u_i^{(1)} = \psi_i$ by (9) in the monotonic algorithm. Hence

$$u_i^{(1)} \leq \psi_i \text{ for any } i \in \{1, \dots, N\}. \tag{15}$$

Therefore, by an easy induction, one has that $\mathcal{I}^{(j)} = \mathcal{I}_0^{(j)}$ for any $j > 1$, which yields that $\mathcal{I}^{(j)} \subset \mathcal{I}^{(j+1)}$ for any $j > 1$. Since $\mathcal{I}^{(n)} \subset \{1, \dots, N\}$ is a finite set, this means that there exists an index n such that $\mathcal{I}^{(n)} = \mathcal{I}^{(n+1)}$.

Let us finally show that (14) holds true. Let n be the smallest integer such that $\mathcal{I}^{(n)} = \mathcal{I}^{(n+1)}$. Since $\mathcal{I}^{(j)}$ is strictly included in $\mathcal{I}^{(j+1)}$ for any $j > 1$, one has $N + 1 \geq \text{card}(\mathcal{I}^{(j+1)}) \geq \text{card}(\mathcal{I}^{(j+1)}) + 1$ for any $j < n$, which yields that $n \leq N + 1$. ∎

2.2. Approximation by the finite volume scheme. Let us now define a discretization mesh over Ω, which is assumed (following [9]) to be admissible for finite volumes in the following sense (see Figure 1).

DEFINITION 2.8 (admissible meshes). *Let Ω be an open bounded polygonal domain of $\mathbb{R}^d$. An admissible finite volume mesh of Ω, denoted by $\mathcal{T}$, is given by a family of "control volumes," which are disjoint polygonal convex subsets of Ω, a family of subsets of $\overline{\Omega}$ contained in hyperplanes of $\mathbb{R}^d$, denoted by $\mathcal{E}$ (these are the "sides" of the control volumes), with strictly positive one-dimensional measure, and a family of points of Ω, denoted by $\mathcal{P}$, satisfying the following properties (in fact, we shall denote, somewhat incorrectly, by $\mathcal{T}$ the family of control volumes):*

(i) *The closure of the union of all the control volumes is $\overline{\Omega}$.*
(ii) *For any $K \in \mathcal{T}$, there exists a subset $\mathcal{E}_K$ such that $\partial K = \overline{K} \setminus K = \cup_{\sigma \in \mathcal{E}_K} \overline{\sigma}$.*
(iii) *For any $(K, L) \in \mathcal{T}^2$ with $K \neq L$, either the one-dimensional Lebesgue measure of $\overline{K} \cap \overline{L}$ is 0 or $\overline{K} \cap \overline{L} = \overline{\sigma}$ for some $\sigma \in \mathcal{E}$, which will then be denoted by $K|L$.*
(iv) *The family $\mathcal{P} = (x_K)_{K \in \mathcal{T}}$ is such that $x_K \in K$ (for all $K \in \mathcal{T}$) and, if $\sigma = K|L$, it is assumed that $x_K \neq x_L$, and the straight line $\mathcal{D}_{K,L}$ going through x_K and x_L is assumed to be orthogonal to $K|L$.*

In what follows, the following notations are used. Let $\mathrm{size}(\mathcal{T}) = \sup\{\mathrm{diam}(K), K \in \mathcal{T}\}$. *For any* $K \in \mathcal{T}$ *and* $\sigma \in \mathcal{E}$, $\mathrm{m}(K)$ *is the two-dimensional Lebesgue measure of* K, *and* $\mathrm{m}(\sigma)$ *the one-dimensional measure of* σ. *The set of interior (resp., boundary) edges is denoted by* $\mathcal{E}_{\mathrm{int}}$ *(resp.,* $\mathcal{E}_{\mathrm{ext}}$*), that is,* $\mathcal{E}_{\mathrm{int}} = \{\sigma \in \mathcal{E};\ \sigma \not\subset \partial\Omega\}$ *(resp.,* $\mathcal{E}_{\mathrm{ext}} = \{\sigma \in \mathcal{E};\ \sigma \subset \partial\Omega\}$*). The set of neighbors of* K *is denoted by* $\mathcal{N}(K)$, *that is,* $\mathcal{N}(K) = \{L \in \mathcal{T};\ \exists \sigma \in \mathcal{E}_K\ \sigma = K \cap L\}$. *If* $\sigma = K|L$, *we denote by* d_σ *or* $d_{K|L}$ *the Euclidean distance between* x_K *and* x_L *(which is positive). If* $\sigma \in \mathcal{E}_K \cap \mathcal{E}_{\mathrm{ext}}$, *let* d_σ *denote the Euclidean distance between* x_K *and* y_σ. *For any* $\sigma \in \mathcal{E}$, *the transmissivity through* σ *is defined by* $\tau_\sigma = \frac{\mathrm{m}(\sigma)}{d_\sigma}$ *if* $d_\sigma \neq 0$.

Remark 2.2. The condition $x_K \neq x_L$ if $\sigma = K|L$ is in fact quite easy to satisfy: two neighboring control volumes K, L, which do not satisfy it, just have to be collapsed into a new control volume M with $x_M = x_K = x_L$, and the edge $K|L$ removed from the set of edges. The new mesh thus obtained is admissible.

We refer to, e.g., [9] or [14] for examples of admissible meshes. These include rectangular meshes, Delaunay triangulations, and Voronoi meshes.

Let us now define a "discrete" functional space and a discrete H_0^1 norm.

DEFINITION 2.9. *Let* Ω *be an open bounded polygonal domain of* $\mathbb{R}^d$, *and* $\mathcal{T}$ *be an admissible mesh in the sense of Definition* 2.8.

Define $Y(\mathcal{T})$ *as the set of the functions defined a.e. from* Ω *to* $\mathbb{R}$ *which are constant over each control volume of the mesh. We shall denote by* u_K *the value taken by* u *on the control volume* K.

For $u \in Y(\mathcal{T})$, *define the discrete* H_0^1 *norm by*

$$\|u\|_{1,\mathcal{T}}^2 = \sum_{\sigma \in \mathcal{E}} \tau_\sigma (D_\sigma u)^2, \tag{16}$$

with

$$|D_\sigma u| = |u_K - u_L| \text{ if } \sigma \in \mathcal{E}_{\mathrm{int}}, \qquad \sigma = K/L, \tag{17}$$

$$D_\sigma u = -u_K \text{ if } \sigma \subset \partial\Omega. \tag{18}$$

Let $\mathcal{T}$ be an admissible finite volume mesh in the sense of Definition 2.8, let $\psi_K = \psi(x_K)$ and $f_K = \frac{1}{m(K)} \int_K f(x)dx$ for any $K \in \mathcal{T}$. A cell-centered finite volume discretization of problem (1) is written with respect to the discrete unknowns $(u_K)_{K \in \mathcal{T}}$ in the following way (see [19] for a description of how this scheme is obtained):

$$-\sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma} + m(K) f_K \geq 0 \quad \forall K \in \mathcal{T}, \tag{19}$$

$$\left(-\sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma} + m(K) f_K \right) (\psi_K - u_K) = 0 \quad \forall K \in \mathcal{T}, \tag{20}$$

$$u_K \leq \psi_K \quad \forall K \in \mathcal{T}, \tag{21}$$

$$F_{K,\sigma} = -\tau_\sigma (u_L - u_K) \quad \forall \sigma \in \mathcal{E}_{\mathrm{int}} \text{ if } \sigma = K/L, \tag{22}$$

$$F_{K,\sigma} = \tau_\sigma u_K \quad \forall \sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}_K. \tag{23}$$

The proof of the existence and uniqueness of the solution to this scheme was given in [19]. It follows for the following remark: let $(u_K)_{K \in \mathcal{T}} \in \mathbb{R}^{\mathrm{card}(\mathcal{T})}$, and let $u_{\mathcal{T}} \in Y(\mathcal{T})$ be defined by $u_{\mathcal{T}}(x) = u_K$ for $x \in K\ \forall K \in \mathcal{T}$. Then one may show

that $(u_K)_{K\in\mathcal{T}}$ is a solution to problem (19)–(23) if and only if $u_\mathcal{T}$ is a solution to the following problem:

$$\left\{\begin{array}{l} u_\mathcal{T} \in \mathcal{K}_\mathcal{T} = \{v \in Y(\mathcal{T}),\ \text{s.t. } v_K \le \psi_K\ \forall K \in \mathcal{T}\}, \\ A(u_\mathcal{T}, v - u_\mathcal{T}) \ge L(v - u_\mathcal{T}) \quad \forall v \in \mathcal{K}_\mathcal{T}, \end{array}\right. \tag{24}$$

where for any $u = (u_K)_{K\in\mathcal{T}}$ and $v = (v_K)_{K\in\mathcal{T}} \in Y(\mathcal{T})$,

$$A(u,v) = \sum_{\sigma = K|L \in \mathcal{E}_{\rm int}} \tau_{K|L}(u_K - u_L)(v_K - v_L) + \sum_{\sigma\in\mathcal{E}_{\rm ext}\cap\mathcal{E}_K} \tau_\sigma u_K v_K, \tag{25}$$

and

$$L(v) = \sum_{K\in\mathcal{T}} m(K) f_K v_K. \tag{26}$$

Our goal here is to construct an algorithm yielding an approximate solution of problem (19)–(23). The iterative process which we described for the finite element discretization is easily adapted to the finite volume framework. Let $K \in \mathcal{T}$; then from (20) one has

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} = m(K) f_K \quad \text{or} \quad u_K = \psi_K.$$

Therefore, from (19) and (21), there exist two disjoint subsets of $\mathcal{T}$ such that on one subset one has

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} = m(K) f_K \text{ and } u_K \le \psi_K \quad \text{for } K \text{ in the first subset,}$$

and

$$u_K = \psi_K \text{ and } \sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} \le m(K) f_K \quad \text{for } K \text{ in the second subset.}$$

Now assume that we knew two subsets $\mathcal{T}_f$ and $\mathcal{T}_\psi$ of $\mathcal{T}$ such that $\mathcal{T}_f \cup \mathcal{T}_\psi = \mathcal{T}$, $\mathcal{T}_f \cap \mathcal{T}_\psi = \emptyset$, and

$$u_K \le \psi_K \quad \forall K \in \mathcal{T}_f, \tag{27}$$

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} \le m(K) f_K \quad \forall K \in \mathcal{T}_\psi. \tag{28}$$

Then, as in the finite element case, the solution of problem (19)–(23) could be obtained by solving the linear problem

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} = m(K) f_K \quad \forall K \in \mathcal{T}_f, \tag{29}$$

$$u_K = \psi_K \quad \forall K \in \mathcal{T}_\psi, \tag{30}$$

where the numerical fluxes $F_{K,\sigma}$ are defined by (22)–(23). As in the finite element case, we shall solve (29)–(30) at each iteration and iterate on the sets $\mathcal{T}_f$ and $\mathcal{T}_\psi$ by looking at the constraints which are violated after the solution of (29)–(30).

The algorithm that follows determines $\mathcal{T}_f$ and $\mathcal{T}_\psi$ by an iterative method.

MONOTONIC ALGORITHM, OBSTACLE PROBLEM, FINITE VOLUME DISCRETIZATION.

• Initialization. Let $\mathcal{T}_f^{(0)}$ and $\mathcal{T}_\psi^{(0)}$ be such that

$$\mathcal{T}_f^{(0)} \cap \mathcal{T}_\psi^{(0)} = \emptyset \quad \text{and} \quad \mathcal{T}_f^{(0)} \cup \mathcal{T}_\psi^{(0)} = \mathcal{T} \tag{31}$$

(for example, $\mathcal{T}_f^{(0)} = \mathcal{T}$ and $\mathcal{T}_\psi^{(0)} = \emptyset$).

• Step (j). Assume the sets $\mathcal{T}_f^{(j)}$ and $\mathcal{T}_\psi^{(j)}$ to be known such that $\mathcal{T}_f^{(j)} \cap \mathcal{T}_\psi^{(j)} = \emptyset$ and $\mathcal{T}_f^{(j)} \cup \mathcal{T}_\psi^{(j)} = \mathcal{T}$. Let $(u_K^{(j)})_{K\in\mathcal{T}}$ be the solution to the following set of equations:

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^{(j)} = m(K) f_K \quad \forall K \in \mathcal{T}_f^{(j)}, \tag{32}$$

$$u_K^{(j)} = = \psi_K \quad \forall K \in \mathcal{T}_\psi^{(j)}, \tag{33}$$

$$F_{K,\sigma}^{(j)} = \tau_\sigma (u_K^{(j)} - u_L^{(j)}) \quad \forall \sigma \in \mathcal{E}_{\text{int}} \text{ if } \sigma = K/L, \tag{34}$$

$$F_{K,\sigma}^{(j)} = \tau_\sigma u_K^{(j)} \quad \forall \sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K. \tag{35}$$

Let $\mathcal{T}_f^{(j+1)}$ and $\mathcal{T}_\psi^{(j+1)}$ be defined in the following way:

$$\begin{aligned}
&\mathcal{T}_f^{(j,0)} = \{K \in \mathcal{T}_f^{(j)}, ; u_K^{(j)} \le \psi_K\}, && \mathcal{T}_f^{(j,1)} = \mathcal{T}_f^{(j)} \setminus \mathcal{T}_f^{(j,0)},\\
&\mathcal{T}_\psi^{(j,0)} = \left\{ K \in \mathcal{T}_\psi^{(j)};\ \sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^{(j)} \le m(K) f_K \right\}, && \mathcal{T}_\psi^{(j,1)} = \mathcal{T}_\psi^{(j)} \setminus \mathcal{T}_\psi^{(j,0)},\\
&\mathcal{T}_f^{(j+1)} = \mathcal{T}_f^{(j,0)} \cup \mathcal{T}_\psi^{(j,1)}, && \mathcal{T}_\psi^{(j+1)} = \mathcal{T} \setminus \mathcal{T}_f^{(j+1)}.
\end{aligned} \tag{36}$$

• The algorithm stops if there exists a step (J) such that $\mathcal{T}_f^{(J)} = \mathcal{T}_f^{(J+1)}$ and $\mathcal{T}_\psi^{(J)} = \mathcal{T}_\psi^{(J+1)}$.

The above algorithm is well defined thanks to the following result.

PROPOSITION 2.10. *Let $\mathcal{T}$ be an admissible finite volume mesh in the sense of Definition* 2.8, *and assume that the sets $\mathcal{T}_f^{(j)}$ and $\mathcal{T}_\psi^{(j)}$ such that $\mathcal{T}_f^{(j)} \cap \mathcal{T}_\psi^{(j)} = \emptyset$ and $\mathcal{T}_f^{(j)} \cup \mathcal{T}_\psi^{(j)} = \mathcal{T}$ are known; then problem* (32)–(35) *admits a unique solution.*

Proof. Under the assumptions of Proposition 2.10, one may find an equivalent "variational" formulation to problem (32)–(35). Let $u_\mathcal{T}^{(j)} \in Y(\mathcal{T})$ be defined by $u_\mathcal{T}^{(j)}(x) = u_K^{(j)}$ for $x \in K$, $\forall K \in \mathcal{T}$; it is easy to prove that $u_\mathcal{T}^{(j)}$ is a solution to problem (32)–(35) if and only if $u_\mathcal{T}^{(j)}$ is a solution to the following problem:

$$\begin{cases}
u_K^{(j)} = \psi_K \quad \forall K \in \mathcal{T}_\psi^{(j)},\\
A(u_\mathcal{T}^{(j)}, v) = L(v) \quad \forall v = (v_K)_{K\in\mathcal{T}} \in Y(\mathcal{T}),\\
\qquad \text{such that } v_K = 0 \quad \forall K \in \mathcal{T}_\psi^{(j)},
\end{cases} \tag{37}$$

with A and L defined by (25) and (26). The existence and uniqueness of the solution to (32)–(35) (and (37)) follow from the Lax–Milgram lemma. □

The algorithm (31)–(36) is therefore well defined; let us now show its monotonicity. This property is much related to the discrete maximum principle, which holds for finite volume discretizations of the Laplace equation; see, e.g., [18].

LEMMA 2.11 (monotonicity of the scheme). *Under Assumption* 2.1, *let* $\mathcal{T}$ *be an admissible finite volume mesh in the sense of Definition* 2.8; *the sequences* $(u_K^{(j)})_{j\in\mathbb{N},K\in\mathcal{T}}$ *which are constructed by the algorithm* (31)–(36) *satisfy*

$$u_K^{(j+1)} \le u_K^{(j)} \quad \text{for } j \in \mathbb{N} \text{ and } K \in \mathcal{T}.$$

Proof. Define $v_{\mathcal{T}} = u_{\mathcal{T}}^{(j)} - u_{\mathcal{T}}^{(j+1)}$, $F_{K,\sigma} = F_{K,\sigma}^{(j)} - F_{K,\sigma}^{(j+1)}$ $\forall K \in \mathcal{T}$, $\forall \sigma \in \mathcal{E}_K$, and $\min(v_{\mathcal{T}}) = \min\{v_K = u_K^{(j)} - u_K^{(j+1)},\ K \in \mathcal{T}\}$; let us show that $\min(v_{\mathcal{T}}) \ge 0$. Let $K_0 \in \mathcal{T}$ such that $\min(v_{\mathcal{T}}) = v_{K_0}$. Then we have the following:

- If $K_0 \in \mathcal{T}_\psi^{(j)} \cap \mathcal{T}_\psi^{(j+1)}$, then $v_{K_0} = 0$ so that $\min(v_{\mathcal{T}}) = 0$.
- Now if $K_0 \in \mathcal{T}_f^{(j)} \cap \mathcal{T}_\psi^{(j+1)}$, one has $u_{K_0}^{(j)} > \psi_{K_0}$ and $u_{K_0}^{(j+1)} > \psi_{K_0}$ so that $\min(v_{\mathcal{T}}) > 0$.
- Assume next that $K_0 \in \mathcal{T}_\psi^{(j)} \cap \mathcal{T}_f^{(j+1)}$; then

$$\sum_{\sigma\in\mathcal{E}_{K_0}} F_{K_0,\sigma}^{(j)} < m(K_0) f_{K_0} < 0 \quad \text{and} \quad \sum_{\sigma\in\mathcal{E}_{K_0}} F_{K_0,\sigma}^{(j+1)} = m(K_0) f_{K_0}.$$

  Therefore $\sum_{\sigma\in\mathcal{E}_{K_0}} F_{K_0,\sigma} > 0$, and, since $v_{K_0} \le v_K$ $\forall K \in \mathcal{T}$, one has $\sum_{\sigma\in\mathcal{E}_{K_0}} F_{K_0,\sigma} \le 0$, which is impossible.
- Let us finally assume that $K_0 \in \mathcal{T}_f^{(j)} \cap \mathcal{T}_f^{(j+1)}$; in this case one has

$$\sum_{\sigma\in\mathcal{E}_{K_0}} F_{K_0,\sigma} = 0. \tag{38}$$

  1. If the control volume K_0 lies near the boundary, that is, $\mathcal{E}_{K_0} \cap \mathcal{E}_{\text{ext}} \ne \emptyset$, then (38) becomes

$$\sum_{\substack{\sigma\in\mathcal{E}_{K_0}\cap\mathcal{E}_{\text{int}} \\ \sigma = K_0|K}} \frac{v_{K_0} - v_{K_\sigma}}{d_\sigma} + v_{K_0}\left(\sum_{\sigma\in\mathcal{E}_{K_0}\cap\mathcal{E}_{\text{ext}}} \frac{1}{d_{K_0,\sigma}}\right) = 0.$$

     Since $\min(v_{\mathcal{T}}) = v_{K_0}$, all the terms in the first sum are nonpositive, and therefore v_{K_0} must be nonnegative, which proves that $\min(v_{\mathcal{T}}) \ge 0$.
  2. Now if the control volume K_0 lies in the interior domain in the sense that $\mathcal{E}_{K_0} \subset \mathcal{E}_{\text{int}}$, then one needs to consider one of the two following subcases:
     (a) There exists a "path" of control volumes, which are all in $\mathcal{T}_f^{(j)} \cap \mathcal{T}_f^{(j+1)}$, leading from K_0 to the boundary; that is, there exists $m \in \mathbb{N}$ and $(K_\ell)_{\ell=0,\dots,m}$ such that $K_\ell \in \mathcal{T}_f^{(j)} \cap \mathcal{T}_f^{(j+1)}$, $\mathcal{E}_{K_\ell} \cap \mathcal{E}_{K_{\ell+1}} \ne \emptyset$ $\forall \ell = 0, \dots, m-1$. In this case, one has $v_{K_0} = v_{K_1} = \cdots = v_{K_m} = \min(v_{\mathcal{T}})$, and since K_m lies near the boundary, $\min(v_{\mathcal{T}}) \ge 0$.
     (b) If there does not exist such a path, then there exists some control volume K which does not belong to $\mathcal{T}_f^{(j)} \cap \mathcal{T}_f^{(j+1)}$ and such that $\min(v_{\mathcal{T}}) = v_K$; this case falls into one of the three cases which were previously analyzed, and for which we proved that $\min(v_{\mathcal{T}}) \ge 0$. ∎

We may now turn to the convergence of the algorithm. As for the finite element discretization, we first state that if the sets $\mathcal{T}_f^{(j)}$ and $\mathcal{T}_\psi^{(j)}$ are left unchanged from

one iteration to the next, then the algorithm has reached the unique solution to problem (5).

PROPOSITION 2.12. *Assume that the sequence of sets* $(\mathcal{T}_f^{(j)})_{j\in\mathbb{N}}$ *and* $(\mathcal{T}_\psi^{(j)})_{j\in\mathbb{N}}$, *which are constructed by the algorithm* (31)–(36), *are such that there exists a step* (J) *such that* $\mathcal{T}_f^{(J)} = \mathcal{T}_f^{(J+1)}$ *and* $\mathcal{T}_\psi^{(J)} = \mathcal{T}_\psi^{(J+1)}$; *then the solution* $(u_K^{(J)})_{K\in\mathcal{T}}$ *to* (32)–(35) *is the unique solution to problem* (19)–(23).

Proof. Let $\mathcal{T}_f = \mathcal{T}_f^{(J)}$, $\mathcal{T}_\psi = \mathcal{T}_\psi^{(J)}$, and $u_\mathcal{T} = u_\mathcal{T}^{(J)}$; hence $u_\mathcal{T}$ satisfies the set of equations (32)–(35). Since $\mathcal{T}_\psi^{(J)} = \mathcal{T}_\psi^{(J+1)}$, one has $-\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} + m(K)f_K \geq 0$ $\forall K \in \mathcal{T}_\psi$, and, thanks to (32), one has $-\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} + m(K)f_K = 0$ $\forall K \in \mathcal{T}_f$; since $\mathcal{T} = \mathcal{T}_\psi \cup \mathcal{T}_f$, $u_\mathcal{T}$ satisfies (19). Similarly, since $\mathcal{T}_f^{(J)} = \mathcal{T}_f^{(J+1)}$, one has $u_K \leq \psi_K$ $\forall K \in \mathcal{T}_f$, and, thanks to (33), $u_\mathcal{T}$ satisfies (21), and finally, since $\mathcal{T}_f \cup \mathcal{T}_\psi = \mathcal{T}$, $u_\mathcal{T}$ satisfies (20). Hence $u_\mathcal{T}$ is the unique solution to problem (19)–(23). ∎

THEOREM 2.13. *Under Assumption* 2.1, *there exists an integer* $J \in \mathbb{N}$ *such that the sequence* $(u_K^{(j)})_{j\in\mathbb{N}}$, *which is constructed by the algorithm* (31)–(36), *is such that* $(u_K^{(j)}, K \in \mathcal{T})$ *is the exact solution to the discrete problem* (24) *for all* $j \geq J$. *Furthermore the integer* J *satisfies*

$$J \leq \mathrm{card}(\mathcal{T}) + 1, \tag{39}$$

where $\mathrm{card}(\mathcal{T})$ *denotes the number of cells of the mesh.*

Proof. Let the sets $\mathcal{T}_\psi^{(j)}$ and $\mathcal{T}_f^{(j)}$ be defined by the algorithm (31)–(36) for any step (j); if there exists an integer J such that $\mathcal{T}_\psi^{(J)} = \mathcal{T}_\psi^{(J+1)}$, then by Proposition 2.12, $(u_K^{(J)}, K \in \mathcal{T})$ is the exact solution to the discrete problem (24), and the first part of the theorem is proven. There remains to prove that such a step exists and that it satisfies (39).

As in the case of the finite element discretization, let us first remark that for $K \in \mathcal{T}$, if $u_K^{(0)} \leq \psi_K$, then $u_K^{(1)} \leq \psi_i$ by Lemma 2.11, and if $u_K^{(0)} > \psi_K$, then $u_K^{(1)} = \psi_K$ by step (9) of the algorithm. Hence

$$u_K^{(1)} \leq \psi_K \text{ for any } K \in \mathcal{T}; \tag{40}$$

therefore by an easy induction one has that $\mathcal{T}_\psi^{(j)} \subset \mathcal{T}_\psi^{(j+1)}$ for any $j > 1$. Since $\mathcal{T}_\psi^{(j)} \subset \mathcal{T}$, this means that there exists an index J such that $\mathcal{T}_\psi^{(J)} = \mathcal{T}_\psi^{(J+1)}$.

The proof of (39) is identical to the case of the finite element discretization (see the proof of Theorem 2.7). ∎

3. The Signorini problem. Let us now consider the following diffusion problem:

$$-\Delta u(x) = f, \quad x \in \Omega, \tag{41}$$

$$u(x) = 0, \quad x \in \Gamma^1, \tag{42}$$

$$\nabla u(x)\cdot\mathbf{n} = 0, \quad x \in \Gamma^2, \tag{43}$$

with a Signorini condition on a part of the boundary,

$$\left.\begin{array}{rcl} u(x) & \geq & a, \\ \nabla u(x)\cdot\mathbf{n} & \geq & b, \\ (u(x)-a)(\nabla u(x).\mathbf{n}-b) & = & 0, \end{array}\right\} \quad x \in \Gamma_3, \tag{44}$$

where the following holds.

Assumption 3.1.

1. Ω is an open bounded polygonal subset of $\mathbb{R}^d$.
2. The boundary $\partial\Omega$ of Ω is composed of three nonempty, disjoint connected sets Γ^1, Γ^2, and Γ^3 such that $\overline{\Gamma^1} \cup \overline{\Gamma^2} \cup \overline{\Gamma^3} = \overline{\partial\Omega}$.
3. $f \in L^2(\Omega)$, $a \leq 0$, and $b \in \mathbb{R}$.
4. $\mathbf{n}$ is the unit normal vector to $\partial\Omega$ outward to the domain Ω.

Under some regularity assumptions, problem (41)–(44) is equivalent to the following variational problem (see, e.g., [17]):

$$\left\{ \begin{array}{l} u \in \mathcal{K} = \{v \in H^1(\Omega),\ v_{|\partial\Omega} \geq a \text{ a.e.}\}, \quad \text{satisfying} \\ \displaystyle\int_\Omega \nabla u(x) \cdot \nabla(v-u)(x)dx \geq \int_{\partial\Omega} b(\gamma(v)-\gamma(u))(s)ds \quad \forall v \in \mathcal{K}, \end{array} \right. \tag{45}$$

with $v_{\partial\Omega} = \gamma(v)_{\partial\Omega}$, where γ is the trace operator from $H^1(\Omega)$ to $L^2(\partial\Omega)$. By Stampacchia's theorem, problem (45) has a unique solution.

The Signorini problem may be viewed as an obstacle problem in which the obstacle is located on the boundary. However, because the complementarity condition is written on the normal derivative on the boundary, one may not write the monotonic algorithm with piecewise linear finite elements in a straightforward way as in the case of the obstacle problem. Indeed, the normal derivative of the piecewise linear finite element approximate solution is defined on each edge of a triangle neighboring the boundary of the domain, but it is not defined at the nodes of the triangulation lying on the boundary. This problem could be solved by using higher order finite elements, but, as we already mentioned in Remark 2.1, a crucial issue in the underlying electrochemical application is that the maximum principle must hold, and this is not the case with higher order finite element methods. However, there is no such problem when using a finite volume discretization of the Signorini problem; the discrete normal derivative is well defined, and the maximum principle holds (see [19]). Hence the monotonic algorithm may be written quite easily.

We shall use here the same admissible finite volume meshes as for the discretization of the obstacle problem, which were defined in Definition 2.8, with the two following additional assumptions, which are needed because of the Signorini boundary conditions on the boundary:

(v) *For any $\sigma \in \mathcal{E}$ such that $\sigma \subset \partial\Omega$, there exists $i \in \{1,2,3\}$ such that $\sigma \subset \Gamma^i$.*

(vi) *For any $\sigma \in \mathcal{E}$ such that $\sigma \subset \partial\Omega$, let K be the control volume such that $\sigma \in \mathcal{E}_K$ and $\mathcal{D}_{K,\sigma}$ be the straight line going through x_K and orthogonal to σ; then $y_\sigma = \mathcal{D}_{K,\sigma} \cap \sigma$.*

Let us then define an appropriate "discrete" functional space.

DEFINITION 3.1 (discrete functional space). *Let Ω be an open bounded polygonal domain of $\mathbb{R}^d$, and $\mathcal{T}$ be an admissible mesh in the sense of Definition* 2.8. *Define $X(\mathcal{T})$ as the set of the functions defined a.e. from $\overline{\Omega}$ to $\mathbb{R}$ which are constant over each control volume of the mesh, and which are constant over each edge in $\mathcal{E}_3 = \mathcal{E}_{\text{ext}}$. We shall denote by u_K the value taken by u on the control volume K, and by u_σ the value taken by u on the edge $\sigma \in \mathcal{E}_{\text{ext}}$, $\sigma \subset \Gamma^3$.*

As in the case of the obstacle problem, a classical finite volume formulation is obtained by integrating the diffusion equation (41) over each control volume $\mathcal{T}$, using Green's formula and approximating the normal fluxes by a consistent difference quotient. Let us denote the discrete unknowns by $(u_K)_{K\in\mathcal{T}}$ for any $K \in \mathcal{T}$ and by $(u_\sigma)_{\sigma\subset\Gamma^3}$ for any $\sigma \in \mathcal{E}_{\text{ext}}$, and the "discrete flux" by $F_{K,\sigma}$, which is expected to

approximate the exact flux $-\int_\sigma \nabla u(s).\mathbf{n} ds$; the finite volume scheme can be written

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} = 0 \quad \forall K \in \mathcal{T}, \tag{46}$$

with

$$F_{K,\sigma} = -\tau_\sigma(u_L - u_K) \quad \forall \sigma \in \mathcal{E}_{\rm int} \text{ if } \sigma = K/L, \tag{47}$$

$$F_{K,\sigma} = \tau_\sigma u_K \quad \forall \sigma \subset \Gamma^1,\ \sigma \in \mathcal{E}_K, \tag{48}$$

$$F_{K,\sigma} = 0 \quad \forall \sigma \subset \Gamma^2,\ \sigma \in \mathcal{E}_K, \tag{49}$$

$$F_{K,\sigma} = -\tau_\sigma(u_\sigma - u_K) \quad \forall \sigma \in \mathcal{E}_3,\ \sigma \in \mathcal{E}_K, \tag{50}$$

with the Signorini boundary condition

$$u_\sigma \geq a \quad \forall \sigma \in \mathcal{E}_3, \tag{51}$$

$$-F_{K,\sigma} \geq \mathrm{m}(\sigma)\, b \quad \forall \sigma \in \mathcal{E}_3, \tag{52}$$

$$(u_\sigma - a)\left(\frac{F_{K,\sigma}}{\mathrm{m}(\sigma)} + b\right) = 0 \quad \forall \sigma \in \mathcal{E}_3, \tag{53}$$

where $\mathcal{E}_3$ denotes the set of edges of the mesh that are included in Γ^3.

In [19], we prove the following existence result.

PROPOSITION 3.2. *Let $\mathcal{T}$ be an admissible mesh of Ω; problem* (46)–(53) *admits a unique solution $(u_K)_{K\in\mathcal{T}}, (u_\sigma)_{\sigma\in\mathcal{E}_3}$.*

We may therefore define the approximate solution $u_\mathcal{T}$ from a.e. in $\Omega \cup \Gamma^3$ to $\mathbb{R}$ by

$$u_\mathcal{T}(x) = u_K \text{ for } x \in K \text{ and } K \in \mathcal{T}, \qquad u_\mathcal{T}(x) = u_\sigma \text{ for } x \in \sigma \text{ and } \sigma \in \mathcal{E}_3. \tag{54}$$

Remark 3.1. Under regularity assumptions on the exact solution, we give in [19] an estimate of order 1 with respect to the mesh size for the "discrete" H^1 norm and L^2 norm of the error on the solution. If the exact solution is no longer assumed to be regular, the convergence of the discrete solution towards the exact solution may still be proven; see [19].

The monotonic algorithm is again based on the obvious remark that, for a given $\sigma \in \mathcal{E}_3$, (53) is equivalent to $u_\sigma = a$ or $-F_{K,\sigma} = \mathrm{m}(\sigma)\, b$. Hence there exist two disjoint subsets of $\mathcal{E}_3$ such that on one subset one has

$$u_\sigma = a \quad \text{and} \quad -F_{K,\sigma} \geq \mathrm{m}(\sigma)\, b,$$

and on the other one,

$$-F_{K,\sigma} = \mathrm{m}(\sigma)\, b \quad \text{and} \quad u_\sigma \geq a.$$

Now if the subsets $\mathcal{E}_a$ and $\mathcal{E}_b$ of $\mathcal{E}_3$ such that $\mathcal{E}_a \cup \mathcal{E}_b = \mathcal{E}_3$, $\mathcal{E}_a \cap \mathcal{E}_b = \emptyset$ and such that

$$-F_{K,\sigma} \geq \mathrm{m}(\sigma)\, b \quad \forall \sigma \in \mathcal{E}_a, \tag{55}$$

$$u_\sigma \geq a \quad \forall \sigma \in \mathcal{E}_b \tag{56}$$

were known, then the solution to problem (46)–(53) could be obtained by solving the linear problem (46)–(50), together with

$$u_\sigma = a \quad \forall \sigma \in \mathcal{E}_a, \tag{57}$$

$$-F_{K,\sigma} = \mathrm{m}(\sigma)\, b \quad \forall \sigma \in \mathcal{E}_b. \tag{58}$$

The algorithm which follows determines the sets $\mathcal{E}_a$ and $\mathcal{E}_b$ by an iterative method.

MONOTONIC ALGORITHM, SIGNORINI PROBLEM, FINITE VOLUME DISCRETIZATION.

• Initialization. Let $\mathcal{E}_a^{(0)}$ and $\mathcal{E}_b^{(0)} \subset \mathcal{E}_3$ be such that

$$\mathcal{E}_a^{(0)} \cap \mathcal{E}_b^{(0)} = \emptyset \quad \text{and} \quad \mathcal{E}_a^{(0)} \cup \mathcal{E}_b^{(0)} = \mathcal{E}_3. \tag{59}$$

• Step (j). Assume that the sets $\mathcal{E}_a^{(j)}$ and $\mathcal{E}_b^{(j)}$ are known such that $\mathcal{E}_a^{(j)} \cap \mathcal{E}_b^{(j)} = \emptyset$ and $\mathcal{E}_a^{(j)} \cup \mathcal{E}_b^{(j)} = \mathcal{E}_3$.

Let $u_{\mathcal{T}}^{(j)} \in X(\mathcal{T})$ be defined by $u_{\mathcal{T}}^{(j)}(x) = u_K^{(j)}$ for $x \in K$, $\forall K \in \mathcal{T}$, and by $u_{\mathcal{T}}^{(j)}(x) = u_\sigma^{(j)}$ for $x \in \sigma$, $\forall \sigma \in \mathcal{E}_3$, and let $u_{\mathcal{T}}^{(j)}$ be the solution to the set of equations (46)–(50) and

$$u_\sigma^{(j)} = a \quad \forall \sigma \in \mathcal{E}_a^{(j)}, \tag{60}$$

$$F_{K,\sigma}^{(j)} = -\mathrm{m}(\sigma)\, b \quad \forall \sigma \in \mathcal{E}_b^{(j)}. \tag{61}$$

Let $\mathcal{E}_a^{(j+1)}$ and $\mathcal{E}_b^{(j+1)}$ be defined in the following way:

$$\begin{array}{ll} \mathcal{E}_a^{(j,0)} = \{\sigma \in \mathcal{E}_a^{(j)}; -F_{K,\sigma}^{(j)} \geq \mathrm{m}(\sigma)\, b\}, & \mathcal{E}_a^{(j,1)} = \mathcal{E}_a^{(j)} \setminus \mathcal{E}_a^{(j,0)}, \\ \mathcal{E}_b^{(j,0)} = \{\sigma \in \mathcal{E}_b^{(j)}; u_\sigma^{(j)} \geq a\}, & \mathcal{E}_b^{(j,1)} = \mathcal{E}_b^{(j)} \setminus \mathcal{E}_b^{(j,0)}, \\ \mathcal{E}_a^{(j+1)} = \mathcal{E}_a^{(j,0)} \cup \mathcal{E}_b^{(j,1)}, & \mathcal{E}_b^{(j+1)} = \mathcal{E}_3 \setminus \mathcal{E}_b^{(j+1)}. \end{array} \tag{62}$$

• The algorithm stops if there exists a step (J) such that $\mathcal{E}_a^{(J)} = \mathcal{E}_a^{(J+1)}$ and $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$.

The above algorithm is well defined, thanks to the following result.

PROPOSITION 3.3. *Under Assumption* 3.1, *let* $\mathcal{T}$ *be an admissible finite volume mesh in the sense of Definition* 2.8; *then problem* (46)–(50), (60)–(61) *has a unique solution* $u_{\mathcal{T}}^{(j)}$.

Proof. Under Assumption 3.1, let $\mathcal{T}$ be an admissible finite volume mesh in the sense of Definition 2.8, and $u_{\mathcal{T}}^{(j)} \in X(\mathcal{T})$ be defined by $u_{\mathcal{T}}^{(j)}(x) = u_K^{(j)}$ for $x \in K$, $\forall K \in \mathcal{T}$, and by $u_{\mathcal{T}}^{(j)}(x) = u_\sigma^{(j)}$ for $x \in \sigma$, $\forall \sigma \in \mathcal{E}_3$, and let the sets $\mathcal{E}_a^{(j)}$ and $\mathcal{E}_b^{(j)}$ be such that $\mathcal{E}_a^{(j)} \cap \mathcal{E}_b^{(j)} = \emptyset$ and $\mathcal{E}_a^{(j)} \cup \mathcal{E}_b^{(j)} = \mathcal{E}_3$. It is easily seen that $u_{\mathcal{T}}^{(j)}$ is solution to problem (46)–(50), (60)–(61) if and only if $u_{\mathcal{T}}^{(j)}$ is a solution to the following problem:

$$\left\{ \begin{array}{l} u_{\mathcal{T}}^{(j)} \in \mathcal{K}_{\mathcal{T}}^{(j)} = \{v \in X(\mathcal{T}) \text{ s.t. } v_\sigma = a\ \forall \sigma \subset \mathcal{E}_a^{(j)}\} \text{ such that} \\ \mathcal{A}(u_{\mathcal{T}}^{(j)}, v) = \mathcal{L}^{(j)}(v) \quad \forall v \in X(\mathcal{T}) \text{ s.t. } v_\sigma = 0\ \forall \sigma \in \mathcal{E}_a^{(j)}, \end{array} \right. \tag{63}$$

with

$$\begin{array}{rl} \mathcal{A}(u,v) = & \displaystyle\sum_{\sigma = K|L \in \mathcal{E}_{\mathrm{int}}} \tau_{K|L}(u_K - u_L)(v_K - v_L) + \sum_{\sigma \in \mathcal{E}_K,\, \sigma \subset \Gamma^1} \tau_\sigma u_K v_K \\ & + \displaystyle\sum_{\sigma \in \mathcal{E}_K \cap \mathcal{E}_3} \tau_\sigma (u_\sigma - u_K)(v_\sigma - v_K) \qquad \forall u,\ v \in X(\mathcal{T}), \end{array} \tag{64}$$

$$\mathcal{L}^{(j)}(v) = \sum_{\sigma \in \mathcal{E}_b^{(j)}} b v_\sigma \mathrm{m}(\sigma) \quad \forall v \in X(\mathcal{T}). \tag{65}$$

Then the existence and uniqueness of the solution to (46)–(50) follows by the Lax–Milgram lemma. ∎

Let us now turn to the monotonicity property of the algorithm.

LEMMA 3.4 (monotonicity). *Under Assumption* 3.1, *let* $\mathcal{T}$ *be an admissible finite volume mesh in the sense of Definition* 2.8; *the sequences* $(u_K^{(j)})_{j\in\mathbb{N}}$, $K \in \mathcal{T}$, *and* $(u_\sigma^{(j)})_{j\in\mathbb{N}}$, $\sigma \in \mathcal{E}_3$, *which are constructed by the algorithm* (59)–(62), *satisfy*

$$\begin{aligned} u_K^{(j)} &\le u_K^{(j+1)} \quad \forall j \in \mathbb{N} \text{ and for } K \in \mathcal{T}, \\ u_\sigma^{(j)} &\le u_\sigma^{(j+1)} \quad \forall j \in \mathbb{N} \text{ and for } \sigma \in \mathcal{E}_3. \end{aligned} \tag{66}$$

Proof. Let v be defined by $v = u_{\mathcal{T}}^{(j+1)} - u_{\mathcal{T}}^{(j)}$, and let $\min(v_{\mathcal{T}})$ be defined by

$$\min(v_{\mathcal{T}}) = \min\left\{ \min_{K\in\mathcal{T}} v_K, \min_{\sigma\in\mathcal{E}_3} v_\sigma \right\}.$$

We note that v satisfies the set of equations (46)–(50).

- Assume first that $\min(v_{\mathcal{T}}) = v_{K_0}$, with $K_0 \in \mathcal{T}$ such that $\partial K_0 \cap \Gamma^1 = \emptyset$ or $\partial K_0 \cap \Gamma^1$ is a point. Since $v_{K_0} \le v_K \ \forall K \in \mathcal{T}$ and $v_{K_0} \le v_\sigma \ \forall \sigma \in \mathcal{E}_3$, one has $\min(v_{\mathcal{T}}) = v_K \ \forall K \in \mathcal{T}$, and $\min(v_{\mathcal{T}}) = v_\sigma \ \forall \sigma \in \mathcal{E}_3$. Therefore, the minimum is reached on a control volume neighboring Γ^1, or on an edge included in Γ^3.
- Assume next that $\min(v_{\mathcal{T}}) = v_{K_0}$, with $K_0 \in \mathcal{T}$ such that there exists $\sigma \subset \partial K_0 \cap \Gamma^1$; from (46)–(50), we deduce that $\min(v_{\mathcal{T}}) \ge 0$.
- Now assuming $\sigma \in \mathcal{E}_b^{(j)} \cap \mathcal{E}_b^{(j+1)}$ and $\min(v_{\mathcal{T}}) = v_\sigma$, we obtain $-\tau_\sigma(v_\sigma - v_K) = 0$ with K such that $\partial K \cap \sigma = \sigma$; then $\min(v_{\mathcal{T}}) = v_K \ \forall K \in \mathcal{T}$ and $\min(v_{\mathcal{T}}) = v_\sigma \ \forall \sigma \in \mathcal{E}_3$.
- Next if $\sigma \in \mathcal{E}_b^{(j)} \cap \mathcal{E}_a^{(j+1)}$ and $\min(v_{\mathcal{T}}) = v_\sigma$, one has $u_\sigma^{(j)} < a$ and $u_\sigma^{(j+1)} = a$; hence $\min(v_{\mathcal{T}}) > 0$.
- Finally if $\sigma \in \mathcal{E}_a^{(j)} \cap \mathcal{E}_b^{(j+1)}$ and $\min(v_{\mathcal{T}}) = v_\sigma$, one has $-\tau_\sigma(u_\sigma^{(j)} - u_K^{(j)}) < \mathrm{m}(\sigma)b$ and $-\tau_\sigma(u_\sigma^{(j+1)} - u_K^{(j+1)}) = \mathrm{m}(\sigma)b$; therefore $-\tau_\sigma(v_\sigma - v_K) > 0$, which is in contradiction with $\min(v_{\mathcal{T}}) = v_\sigma$. ∎

We now turn to the convergence of the algorithm.

PROPOSITION 3.5. *Assume that there exists a step* (J) *such that* $\mathcal{E}_a^{(J)} = \mathcal{E}_a^{(J+1)}$ *and* $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$ *and let* $u_{\mathcal{T}}^{(J)}$ *be the solution to* (46)–(50), (60)–(61); *then* $u_{\mathcal{T}}^{(J)}$ *is the unique solution to problem* (46)–(53).

Proof. Let $\mathcal{E}_a = \mathcal{E}_a^{(J)}$, $\mathcal{E}_b = \mathcal{E}_b^{(J)}$, and $u_{\mathcal{T}} = u_{\mathcal{T}}^{(J)}$; hence $u_{\mathcal{T}}$ satisfies the set of equations (46)–(50) and

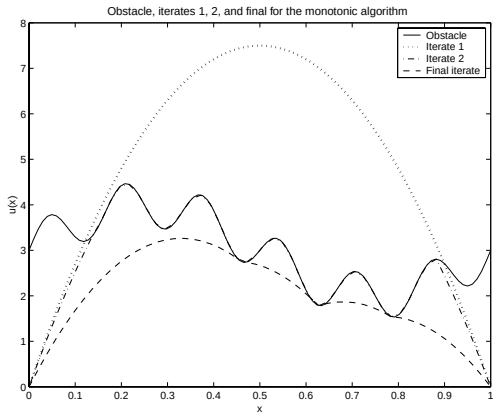
$$\begin{aligned} u_\sigma &= a \quad \forall \sigma \in \mathcal{E}_a, \\ F_{K,\sigma} &= -\mathrm{m}(\sigma)\, b \quad \forall \sigma \in \mathcal{E}_b. \end{aligned}$$

Since $\mathcal{E}_a^{(J)} = \mathcal{E}_a^{(J+1)}$, one has $F_{K,\sigma} \ge -\mathrm{m}(\sigma)\, b \ \forall \sigma \in \mathcal{E}_a$, and since $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$, one has $u_\sigma \ge a \ \forall \sigma \in \mathcal{E}_b$. Therefore, since $\mathcal{E}_a \cup \mathcal{E}_b = \mathcal{E}_3$, $u_{\mathcal{T}}$ satisfies the set of equations (46)–(53). ∎

THEOREM 3.6. *Under Assumption* 3.1, *there exists an integer* $J \in \mathbb{N}$ *such that the sequences* $(u_K^{(j)})_{j\in\mathbb{N}}$ $(u_\sigma^{(j)})_{j\in\mathbb{N}}$, *which are constructed by the algorithm* (31)–(36), *are such that* $(u_K^{(j)}, K \in \mathcal{T})$, $(u_\sigma^{(j)}, K \in \mathcal{E}_3)$ *is the exact solution to the discrete problem* (24) *for all* $j \ge J$. *Furthermore the integer* J *satisfies*

$$J \le \mathrm{card}(\mathcal{E}_3) + 1, \tag{67}$$

where $\mathrm{card}(\mathcal{E}_3)$ *denotes the number of edges of the mesh which are on the Signorini boundary* Γ_3.



N	ITER
20	6
50	7
100	8
500	31
1000	130

FIG. 2. *One-dimensional obstacle problem: the obstacle and some iterates (left), the number of discretization points N and number of iterations to convergence ITER (right).*

Proof. Let the sets $\mathcal{E}_a^{(j)}$ and $\mathcal{E}_b^{(j)}$ be defined by the algorithm (59)–(62) for any step (j); if there exists an integer J such that $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$, then by Proposition 2.12, $(u_K^{(J)}, K \in \mathcal{T})$ is the exact solution to the discrete problem (24), and the first part of the theorem is proven. There remains to prove that such a step exists and that it satisfies (67).

Similarly to the remark on the obstacle problem, let us first note that for $\sigma \in \mathcal{E}_3$ if $u_\sigma^{(0)} \geq a$, then $u_\sigma^{(1)} \geq a$ by Lemma 2.11, and if $u_\sigma^{(0)} < a$, then $u_\sigma^{(1)} = a$ by step (62) of the algorithm. Hence

$$u_\sigma^{(1)} \geq a \text{ for any } \sigma \in \mathcal{E}_3; \tag{68}$$

therefore by an easy induction one has that $\mathcal{E}_a^{(j)} \subset \mathcal{E}_a^{(j+1)}$ for any $j > 1$. Since $\mathcal{E}_a^{(j)} \subset \mathcal{E}_3$, this implies that there exists an index J such that $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$.

Let us now prove that (67) holds. Let J be the smallest integer such that $\mathcal{E}_b^{(J)} = \mathcal{E}_b^{(J+1)}$. Since $\mathcal{E}_b^{(J)} \subset \mathcal{E}_3 \ \forall j \in \mathbb{N}$, one has $\text{card}(\mathcal{E}_3) + 1 \geq \text{card}(\mathcal{E}_b^{(j+1)}) \geq \text{card}(\mathcal{E}_b^{(j)}) + 1$ for any $j > 1$, which yields that $J \leq \text{card}(\mathcal{E}_3) + 1$. □

3.1. Numerical tests. In order to test the efficiency of this new algorithm, some numerical experiments were performed. We first tested the algorithm on a one-dimensional obstacle problem, discretized by either the finite volume or the finite element method (in the one-dimensional case the two schemes differ by only the right-hand side and the boundary conditions). The results proved excellent. We show in Figure 2 a few iterations for $\psi(x) = 3 + \frac{1}{2}\sin(12\varphi_i x) + \sin(2\varphi_i x)$ and for a right-hand side equal to 1. We also give the number of iterations (ITER) required to convergence versus the number N of discretization points. Recall that we have a theoretical bound ITER $\leq$ N: the results show that this bound is far from optimal. Note also that we have taken the solution of the unconstrained problem (i.e., the solution of $-u'' = f$) as an initial guess; of course, one could decrease the number of iterations by taking a better-chosen initial guess.

A less academic study was performed by Herbin and Marchand [20] for a finite volume discretization of an electrochemical problem involving a Signorini boundary

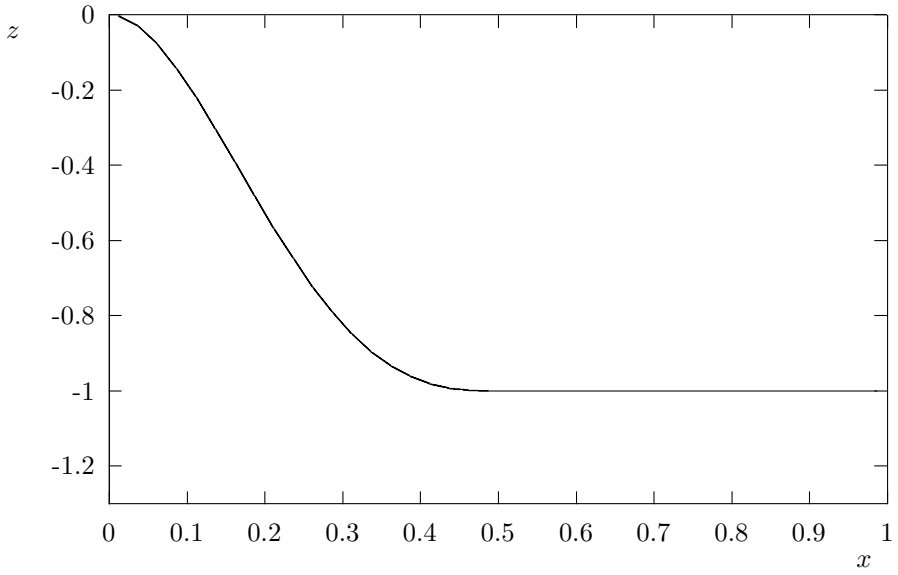


FIG. 3. $z = u(x,0)\ \forall x \in [0, x_m]$ *(on* Γ^3*: Signorini boundary).*

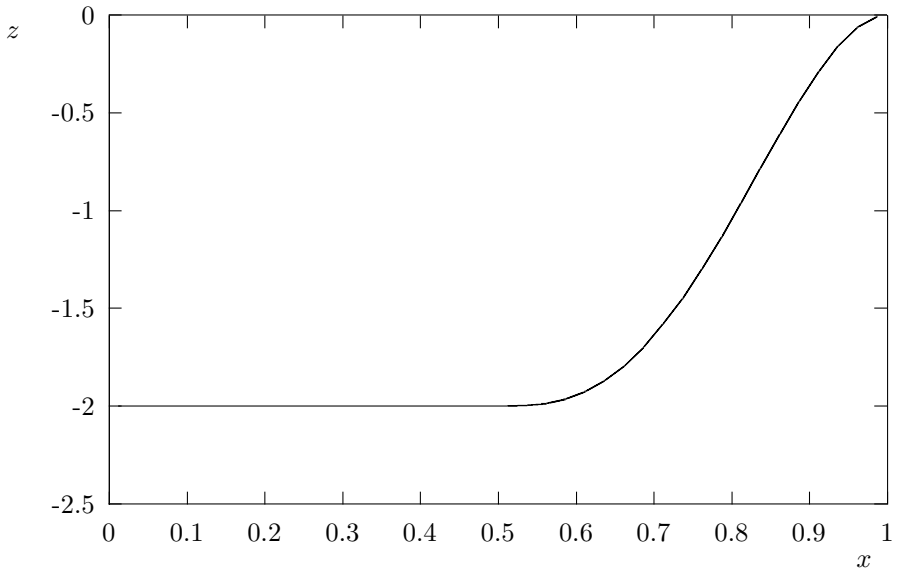

FIG. 4. $z = \nabla u \cdot \mathbf{n}(x,0)\ \forall x \in [0, x_m]$ *(on* Γ^3*: Signorini boundary).*

condition, which was introduced in [23], and which involved a two-dimensional problem. These results illustrate the performance of the monotonic algorithm quite well.

The domain Ω is taken to be the rectangle $(\Omega =]0, x_m[\ \times\ ]0, y_m[\,)$. We set the data such that the exact solution $u \in C^2(\overline{\Omega})$ is known. We show in Figures 3 and 4 the plots of the traces of u and of $\nabla u \cdot \mathbf{n}$ on the Signorini boundary Γ^3.

A rectangular mesh is used on the domain Ω. We vary the discretization step and the initial guess $\mathcal{E}_a^{(0)}$ and give the number of iterates required to converge to the (exact) solution of the discrete problem. Table 1 gives some results when taking the number of cells between 100 and 2500 with a uniform step.

TABLE 1
Number of iterations needed for the monotonicity algorithm.

$\mathcal{E}_3$ / grid size	10×10	20×20	30×30	40×40	50×50
$\mathcal{E}_{\text{ext}}$	4	6	7	7	8
$\emptyset$	4	6	7	7	7
$\{\sigma \subset \{x_m\} \times [0, x_m/2]\}$	4	7	7	7	8
$\{\sigma \subset \{x_m\} \times [x_m/2, x_m]\}$	2	3	2	2	2

These results show that the algorithm is quite efficient. The number of iterations does not vary much with respect to the grid size, and it is considerably less than the number of cells on $\mathcal{E}_3$, which was the upper bound given by Theorem 3.6. Of course, if one has a hint of how the Signorini boundary should be, then a good initial guess lowers the number of iterations, as may be seen from the last line of the table.

Let us also recall that at each iteration there is only one solve of a linear subproblem to be performed. Hence there are no ill-conditioned systems involved, such as those in penalty methods. Finally, let us point out that this algorithm may also be successfully implemented for other free boundary problems: we also tested it on the dam problem and it performs well. It is also used in multiphase problems [8], although in this last case no theoretical convergence result is known (in fact, existence and uniqueness of the solution are an open problem in this last case).

4. Conclusion. The monotonic algorithm which we have introduced for both the obstacle problem and the Signorini problems has been shown to be convergent for the linear finite element and finite volume discretizations in the case of the obstacle problem and the finite volume discretization in the case of the Signorini problem. Furthermore, a bound of the number of iterations is known. An important advantage of this algorithm is that, at each iteration, it necessitates only a linear solve involving a submatrix of the diffusion operator, and therefore no ill-conditioned system must be solved as would be the case with a penalty method. The actual implementation of the algorithm is very easy, and the computational cost is low, since the number of iterations is much lower than the theoretical bound, that is, the number of cells for which the constraint holds, even when the initial guess is not well chosen.

The limitation of the method is linked to the fact that it is proven to converge thanks to the discrete maximum principle, which holds for adequate discretizations of diffusion problems such as the ones we considered here. Note that the discretization is originally chosen such that the maximum principle holds, not because of the monotonic algorithm, but because the discrete maximum principle reflects a physical constraint which the approximate solution needs to satisfy (in the case of a chemical diffusion, the concentration should stay between 0 and 1). Hence it is natural in this type of problem to use the monotonic algorithm.

However, the efficiency (and proof of convergence) of the monotonic algorithm when the maximum principle does not hold (elasticity, higher order finite elements) is still an open question.

HALF-RANGE GENERALIZED HERMITE POLYNOMIALS AND THE RELATED GAUSSIAN QUADRATURES*

JAMES S. BALL†

Abstract. A method is developed for calculating the recurrence coefficients for half-range generalized Hermite polynomials. These are orthogonal polynomials with measure $x^\gamma e^{-x^2}$ on the interval $(0,\infty)$. The recurrence coefficients can then be used to generate the weights and nodes of the related Gaussian quadratures. These quadratures allow efficient high accuracy evaluation of many Gaussian integrals encountered in probability functions, statistical mechanics, and quantum mechanics. The number of steps for an accurate numerical calculation of the recurrence coefficients is proportional to N, the number of coefficients obtained. Extended precision arithmetic is not needed in these calculations.

Key words. Gaussian integrals, Gaussian-type quadrature rules, orthogonal polynomials

PII. S0036142900370939

1. Introduction. Gaussian integrals over the range $(0,\infty)$ are encountered quite often in probability calculations when normal distributions are considered, in statistical mechanics where the kinetic energy of a particle is proportional to the velocity squared, and in quantum mechanical calculations involving harmonic oscillator wave functions. The purpose of this paper is to develop a Gaussian-type quadrature for integrals of the following form:

$$\int_0^\infty dx x^\gamma e^{-x^2} f(x) \tag{1.1}$$

for $\gamma > -1$. The special case $\gamma = 0$ was treated by several groups in 1969 [1], [2]. In 1981 Shizgal [3] generalized the treatment to nonzero γ, his interest being solutions to the Boltzmann equation for which the values of $\gamma = 1$ and 2 play a special role. His final methods made use of extended precision arithmetic. Further work by Clarke and Shizgal [4] investigated the instability of the method for determining the recurrence coefficients and proposed the use of asymptotic expansions. Most recently Gautschi [5] used the half-range Hermite weight function in testing his general methods for obtaining recurrence coefficients for orthogonal polynomials with arbitrary weight functions.

2. The calculation of the recurrence coefficients for generalized half-range Hermite polynomials. The orthogonality formula for monic generalized half-range Hermite polynomials $\phi_n^\gamma(x)$ is

$$\int_0^\infty dx x^\gamma e^{-x^2} \phi_n^\gamma(x)\phi_m^\gamma(x) = \delta_{nm} T_n. \tag{2.1}$$

Here the notation follows that of Gautschi [5] and his implementation of the Stieltjes procedure. The three term recurrence formula satisfied by these polynomials is as

*Received by the editors April 19, 2000; accepted for publication (in revised form) July 24, 2002; published electronically January 14, 2003.

follows:

$$\phi^{\gamma}_{n+1}(x) = (x - \alpha_n)\phi^{\gamma}_n(x) - \beta_n \phi^{\gamma}_{n-1}(x). \tag{2.2}$$

Defining S_n as

$$S_n = \int_0^{\infty} dx x^{\gamma+1} e^{-x^2} \phi^{\gamma}_n(x)\phi^{\gamma}_n(x) \tag{2.3}$$

and applying the orthogonality relation to the recurrence formula, one obtains

$$\beta_n = T_n/T_{n-1} \tag{2.4}$$

and

$$\alpha_n = S_n/T_n. \tag{2.5}$$

Inserting the recurrence formula into the expression for T_n and using the orthogonality, one obtains

$$T_n = \int_0^{\infty} dx x^{\gamma+1} e^{-x^2} \phi^{\gamma}_n(x)\phi^{\gamma}_{n-1}(x). \tag{2.6}$$

Using the recurrence formula to replace $\phi^{\gamma}_n(x)$ results in the following identity:

$$\beta_n + \beta_{n-1} + \alpha^2_{n-1} = \frac{1}{T_{n-1}} \int_0^{\infty} dx x^{\gamma+2} e^{-x^2} (\phi^{\gamma}_{n-1}(x))^2. \tag{2.7}$$

Applying the same operations to S_n, one obtains a second identity:

$$\alpha_n + \alpha_{n-1} = \frac{1}{T_n} \int_0^{\infty} dx x^{\gamma+2} e^{-x^2} \phi^{\gamma}_n(x)\phi^{\gamma}_{n-1}(x). \tag{2.8}$$

Note that these are only algebraic manipulations, and they apply to any orthogonal polynomials.

The simplification that is possible for generalized half-range Hermite polynomials is that the integrals in (2.7), (2.8) can be integrated by parts. This fact was used by Shizgal [3], and although his procedure was somewhat different from the following discussion, it can be shown that the final results are in agreement. The by-parts integrals can be expressed in terms of α's and β's providing algebraic recurrence formulas for these quantities. This goes as follows:

$$\begin{aligned} \int_0^{\infty} dx x^{\gamma+2} e^{-x^2} (\phi^{\gamma}_{n-1}(x))^2 &= -\frac{1}{2} \int_0^{\infty} dx x^{\gamma+1} (\phi^{\gamma}_{n-1}(x))^2 \frac{d}{dx} e^{-x^2} \\ &= \frac{1}{2} \int_0^{\infty} dx e^{-x^2} \frac{d}{dx} [x^{\gamma+1} (\phi^{\gamma}_{n-1}(x))^2] = \frac{2n - 1 + \gamma}{2} T_{n-1}. \end{aligned} \tag{2.9}$$

This yields the following recurrence formula:

$$\beta_n + \beta_{n-1} + \alpha^2_{n-1} = \frac{2n - 1 + \gamma}{2}. \tag{2.10}$$

Integration by parts in (2.8) yields

$$T_n(\alpha_n + \alpha_{n-1}) = \frac{1}{2} \int_0^{\infty} dx x^{\gamma+1} e^{-x^2} \phi'^{\gamma}_n(x)\phi^{\gamma}_{n-1}(x). \tag{2.11}$$

After substituting the recurrence formulas for ϕ_{n-1} and ϕ_n' and using the orthogonality properties, one obtains a second recurrence formula:

$$\beta_n(\alpha_n + \alpha_{n-1}) = \frac{1}{2}\alpha_{n-1} + \beta_{n-1}(\alpha_{n-1} + \alpha_{n-2}). \tag{2.12}$$

Multiplying (2.12) by α_{n-1} and using (2.10) to replace α_{n-1}^2, we obtain

$$\begin{aligned}\alpha_n\alpha_{n-1}\beta_n = &\left[\left(\frac{n+\frac{\gamma}{2}}{2} - \beta_n\right) + \left(\frac{n-1+\frac{\gamma}{2}}{2} - \beta_{n-1}\right)\right] \\ &\cdot \left[\left(\frac{n+\frac{\gamma}{2}}{2} - \beta_n\right) - \left(\frac{n-1+\frac{\gamma}{2}}{2} - \beta_{n-1}\right)\right] + \alpha_{n-1}\alpha_{n-2}\beta_{n-1}.\end{aligned} \tag{2.13}$$

Multiplying out the factors in square brackets and rearranging the terms, we find

$$\alpha_n\alpha_{n-1}\beta_n - \left(\frac{n+\frac{\gamma}{2}}{2} - \beta_n\right)^2 = \alpha_{n-1}\alpha_{n-2}\beta_{n-1} - \left(\frac{n-1+\frac{\gamma}{2}}{2} - \beta_{n-1}\right)^2. \tag{2.14}$$

Evidently the quantities on either side of this equation are constant (i.e., independent of n). The $n = 0$ case determines this constant to be $-\gamma^2/16$. The final expression for the second recurrence formula is

$$\alpha_n\alpha_{n-1}\beta_n = \left(\frac{n+\frac{\gamma}{2}}{2} - \beta_n\right)^2 - \frac{\gamma^2}{16}. \tag{2.15}$$

Note that this equation involves only quantities at n and $n-1$.

The necessary starting values are given below:

$$\begin{aligned}T_0 &= \Gamma\left(\frac{\gamma+1}{2}\right)/2, \\ S_0 &= \Gamma\left(\frac{\gamma}{2}+1\right)/2.\end{aligned} \tag{2.16}$$

3. Evaluation of the recurrence formula. The recurrence procedure now appears straightforward. Given

$$\alpha_0 = \frac{\Gamma(\frac{\gamma}{2}+1)}{\Gamma(\frac{\gamma+1}{2})}, \tag{3.1}$$

one calculates β_1 from (2.10) by using the fact that $\beta_0 = 0$, and then one uses (2.15) to calculate α_1. This process is then repeated to obtain the desired values of α and β.

Unfortunately, as observed in earlier work, while the procedure is simple, the system is rather poorly conditioned, and in practice the error grows more than one order of magnitude per step. How this comes about and what methods can be used to overcome this problem can be seen by writing α_n and β_n in terms of a single set of functions g_n:

$$\alpha_n^2 = \frac{2n+\gamma+1}{3} - g_{n+1} - g_n \tag{3.2}$$

and

$$\beta_n = \frac{(n+\frac{\gamma}{2})}{6} + g_n. \tag{3.3}$$

In terms of these variables, (3.2) is identical to (2.10), and squaring (2.15) produces a nonlinear three term recurrence formula for the g's. The fact that n in all equations appears in the combination $n + \frac{\gamma}{2}$ suggests the following change of variable:

$$Y = Y(n) = 2n + \gamma. \tag{3.4}$$

The final recurrence formula is

$$\left(\frac{Y+1}{3} - g_{n+1} - g_n\right)\left(\frac{Y-1}{3} - g_n - g_{n-1}\right)\left(\frac{Y}{12} + g_n\right)^2 - \left[\left(\frac{Y}{6} - g_n\right)^2 - \frac{\gamma^2}{16}\right]^2 = 0. \tag{3.5}$$

This equation has the following properties: It is linear in g_{n+1} and g_{n-1}; the g_n^4 terms cancel out of this equation, and as a result of the choice relating β to g, the Y^4 terms also cancel out. The large n or Y behavior of (3.5) is determined by keeping only the cubic and quadratic terms in Y:

$$Y^3(14g_n - g_{n+1} - g_{n-1}) = Y^2\left(\frac{1}{3} - \frac{3\gamma^2}{2}\right). \tag{3.6}$$

The solution of interest for large n is that obtained by setting $g_{n+1} \simeq g_n \simeq g_{n-1}$, yielding

$$g_n \simeq \frac{2 - 9\gamma^2}{72Y}. \tag{3.7}$$

On the other hand, it is clear that if one calculates g_{n+1} or g_{n-1} from (3.6), the error in g_n increases by a factor of 14. Another way of saying this is in terms of the solution to the homogeneous version of (3.6) which has the following general solution:

$$g_n = A(7 + \sqrt{48})^n + B(7 + \sqrt{48})^{-n}. \tag{3.8}$$

Thus any error will excite these unwanted solutions, and both forward and backward recurrence will fail.

In previous work this stability problem was overcome with the brute force method of using arbitrary precision arithmetic and simply using as many significant figures as necessary so that the final result has the desired accuracy. For example, 75 significant figures are needed to calculate the first 50 values of α and β to 16 digits.

What is proposed here is a method that turns the factor 14, the source of the instability when one solves (3.6) for g_{n+1} or g_{n-1}, into a virtue. This can be done by solving (3.6) for g_n. What results is a fixed point method in which g_n is calculated in terms of g_{n+1} and g_{n-1}. The iterative solution will now converge rapidly, with the error now falling approximately one order of magnitude per iteration. In order to use this method one must have a set of starting values for $g_n, n = 0, 1, \ldots, N$, that are close enough to the solution to be convergent. Before proposing starting values and the procedure to follow, a couple of points should be made. The first involves the error introduced by the starting value of g_N. In the course of the fixed point iteration this value will stay fixed with whatever error it has. As a result, g_{N-1} will converge to a value with an error of 1/14, the fixed error in g_N. At each step down the ladder the error will decrease by 1/14. This error remains after the procedure has converged and is, therefore, a fixed permanent error. Thus one must adjust the value of N and the accuracy of the trial g_N so that accurate values are determined for the

range of interest. A second point is that if g_{n+1}, g_n, and g_{n-1} are calculated from the recurrence formula, that value of g_n will be unchanged by the iteration procedure and will appear to have converged. As a result one cannot simply apply this method to improve the accuracy of values obtained from the recurrence formula. Furthermore, if the first m trial values are obtained from the recurrence formula, m iterations are required before all of the first m terms have been modified. Since the first term is accurate, this doesn't produce a fixed error but does require a minimum number of iterations for accurate low n results.

Returning now to the actual recurrence formula, we first solve it for the linear term in g_n which will determine the new values from the iterative process. All other quantities are calculated from the old or input values of g_{n-1}, g_n, and g_{n+1}. This iterative process is again rapidly convergent, with behavior very similar to that of the large n case discussed above. This appears to be due to the fact that even the first few values of g are already quite small, making the quadratic and cubic terms which are ignored in (3.6) unimportant.

The remaining ingredient for this calculation is the starting values of the g_n's. Since the values of g_0 and g_1 are known functions which can be evaluated to near machine accuracy, the first 7 or 8 terms can be calculated from the recurrence formula with a loss of about 8 significant figures. For large n or Y, g_n can be expressed in terms of a Taylor series in $1/Y$. Although it has not been proven, it seems likely that this series has a zero radius of convergence and is therefore an asymptotic series. The first 4 terms of this series are

$$g_n(\gamma) = \frac{C_0}{Y} + \frac{C_1}{Y^3} + \frac{C_2}{Y^5} + \frac{C_3}{Y^7}, \tag{3.9}$$

where

$$C_0 = \frac{1}{36} - \frac{\gamma^2}{8}, \tag{3.10}$$

$$C_1 = \frac{23}{432} - \frac{11}{48}\gamma^2 + \frac{3}{32}\gamma^4, \tag{3.11}$$

$$C_2 = \frac{1189}{2592} - \frac{409}{192}\gamma^2 + \frac{75}{64}\gamma^4 + \frac{9}{64}\gamma^6, \tag{3.12}$$

and

$$C_3 = \frac{196057}{20736} - \frac{153559}{3456}\gamma^2 + \frac{7111}{256}\gamma^4 + \frac{639}{128}\gamma^6 + \frac{135}{512}\gamma^8. \tag{3.13}$$

Empirically, using these first 4 terms gives approximately 14 figure accuracy for β_{50}. The accuracy improves for larger n. For $n = 9$ this formula is good to 8 significant figures. Thus for a trial set of g's with minimum error one uses the recurrence formula for small n and switches to the asymptotic series at the point where the accuracy of both methods are about equal. For double precision this transition occurs near $n = 8$. The exact value is not particularly important because the trial input has small enough error to guarantee rapid convergence. For that matter, in the double precision calculation only three terms in the asymptotic expansion need be used if this is compensated for by increasing the number of g's involved in the iteration. Typical results in double precision are as follows: For accurate values of g_n up to $n = 50$, with g_1 and g_{51} fixed, the calculation required 10 iterations on the 49 intermediate g's for convergence, yielding 16 figure accuracy for the β's and α's. For quad precision it was necessary to increase the range to g_{66} to avoid the error caused by truncation.

The transition point could be shifted to a higher value of $n = 16$. The number of iterations required was 30 to produce 33 significant figures for the β's and α's. These results seem to apply to all values of γ, although only values $-1 < \gamma < 1$ were tested. This was considered the most interesting range because integrals with weight functions corresponding to $\gamma + 1$ and $\gamma + 2$ can be evaluated accurately by increasing the number of nodes in the quadrature for γ by one.

While this method is straightforward and has rapid linear convergence, we can in fact do much better by employing a method with quadratic convergence. This is provided by the well-known Newton's method, rather than by solving (3.5) for g_n and treating the resulting equation as a fixed point problem. We consider the problem of finding the N roots, g_n, of the N equations that (3.5) represents. This procedure goes as follows: Define

$$F^i = \left(\frac{Y(i)+1}{3} - g_{i+1} - g_i\right)\left(\frac{Y(i)-1}{3} - g_i - g_{i-1}\right)\left(\frac{Y(i)}{12} + g_i\right)^2 - \left[\left(\frac{Y(i)}{6} - g_i\right)^2 - \frac{\gamma^2}{16}\right]^2 \tag{3.14}$$

and

$$J_{i,j} = \partial_{g_j} F^i. \tag{3.15}$$

Here the g's are the input values. The new values are then given by

$$g_j^{new} = g_j^{old} - \sum_k J_{j,k}^{-1} F^k. \tag{3.16}$$

Note that J is a tridiagonal matrix because the recurrence formula involves only three terms. As a result all of the steps in this iteration are of $O(N)$. The results are rapidly convergent; only one iteration is required in double precision, although in practice a second is required to verify convergence. For quad precision two iterations are necessary, with one more to check convergence. It should be noted that this procedure does not have the problem with the use of the recurrence formula in the calculation of the starting values for small n that were encountered with the fixed point method.

Some of results of the actual calculation are as follows: In double precision the asymptotic expansion introduces no error for values of N greater than 50. For $N = 50$, the calculation on a Sun Ultra Sparc 2 with two processors requires approximately .0005 seconds. The results for larger values of N scale linearly with N. Applying this method to larger N is of no particular interest because (3.9) can be used directly to obtain the α and β for $N > 50$. The quad precision results required $N = 66$ to produce full machine accuracy for the first 50 values. The time required was much longer than that for double precision because quad arithmetic on this machine is implemented in software. The times were .053 seconds for 50 accurate terms, .088 seconds for 100 accurate terms, and .124 seconds for 150 terms. Note that the time grew less rapidly than the number of terms. This is because the number of extra terms necessary to eliminate the truncation error actually decreases with increasing N.

4. Conclusion. The Gaussian quadrature obtained from these coefficients behaves as expected. To check noninteger γ the test integrals used $\gamma = -\frac{1}{4}$. For $f(x) = \exp(-10x)$ the integral can be evaluated to a fractional error of 10^{-14} with a

25 node quadrature. The case $f(x) = \exp(10x)$ requires more nodes. For 40 nodes both integrals have a fractional error of approximately 10^{-14}. In the case of quad precision the case $f(x) = \exp(-10x)$ can be evaluated to 32 significant figures with 40 nodes. As in the double precision case more nodes were required for the accurate evaluation of $f(x) = \exp(10x)$. Obtaining 32 significant figures required 60 nodes.

The results obtained here can be compared to the tables published by Steen, Byrne, and Gelbard [1]. The tables are for the $\gamma = 0$ case only and are tables of the weights and nodes for half-range Hermite quadratures for 2 through 15 nodes. The results are quite surprising. For 8 or fewer nodes the results obtained here agree to 14 significant figures. For 10 nodes one finds 12 figure agreement. As the number of nodes increases, one loses 1 significant figure when the number of nodes is increased by 1. This is exactly the kind of behavior that might be expected from the recurrence calculation based on approximately 20 digit accuracy. For the largest number of nodes, 15, the nodes and weights obtained by Steen, Byrne, and Gelbard have an error in the seventh figure. On the other hand, if one uses these nodes and weights to perform an integral, the results are surprisingly good. Why this is true is not clear, but recall that only the large n polynomials have errors. Perhaps the set of polynomials generated corresponds to a weight in the orthogonality relation that is very close to $\exp(-x^2)$, and the fact that both the nodes and the weights are shifted conspires to produce good results for the integrals. This general kind of behavior was observed by Gautschi [6] in connection with a different Gaussian quadrature which, in spite of having series errors in the nodes, still produced good results for test integrals. See this work for a more detailed discussion of ways to test Gaussian quadratures.

For the special cases $\gamma = 0, 1, 2$ the nodes and weights for the Gaussian quadrature can be compared directly with those published by Shizgal [3]. The results obtained here agree to 15 figures with his $N = 16$ results given in Tables IIa, IIb, and IIc, with one exception, namely the last node in Table IIc, which has 8's as the ninth and tenth figures. This appears to be a misprint, and there should only be one 8. The fact that the location of this node has one more significant figure than the others also points to a misprint.

Finally, the quad precision results for the recurrence coefficients can be compared with the selected values for $\gamma = 0$ published by Gautschi [5] in his Table VIII. The results obtained here agree to all 25 figures published in his article.

It seems likely that the methods used here to calculate the recurrence coefficients can also be applied to other weight functions, such as those considered by Clark and Shizgal [4]. These possibilities are the subject of future work.

CONVERGENCE THEORY OF RESTRICTED MULTIPLICATIVE SCHWARZ METHODS*

REINHARD NABBEN† AND DANIEL B. SZYLD‡

Abstract. Convergence results for the restricted multiplicative Schwarz (RMS) method, the multiplicative version of the restricted additive Schwarz (RAS) method for the solution of linear systems of the form $Ax = b$, are provided. An algebraic approach is used to prove convergence results for nonsymmetric M-matrices. Several comparison theorems are also established. These theorems compare the asymptotic rate of convergence with respect to the amount of overlap, the exactness of the subdomain solver, and the number of domains. Moreover, comparison theorems are given between the RMS and RAS methods as well as between the RMS and the classical multiplicative Schwarz method.

Key words. restricted Schwarz methods, domain decomposition, multisplittings, parallel algorithms

1. Introduction.

We consider restricted Schwarz methods for the solution of linear systems of the form

$$Ax = b, \tag{1}$$

where A is $n \times n$ and nonsingular. These methods were introduced by Tai [26] and by Cai and Sarkis [10] for the parallel solution of (1); see also [8, 9]. In [10], it is shown by numerical examples that the restricted additive Schwarz (RAS) method is an efficient alternative to the classical additive Schwarz preconditioner. RAS preconditioners are widely used and are the default preconditioner in the PETSc software package [1]. In [26] and [10], the multiplicative variant of the RAS method, the restricted multiplicative Schwarz (RMS) method, is also mentioned; see also [9]. Although restricted Schwarz methods work very well in practice, until recently no theoretical results were available. In [16], convergence and comparison results for the RAS method were established when the matrix A in (1) is a (possibly nonsymmetric) M-matrix (or more generally an H-matrix). Those results use a new algebraic formulation of Schwarz methods and a connection with the well-known concept of multisplittings [7, 22]; see [2, 14, 15].

In this paper, we consider the RMS method. Again using the algebraic approach we are able to establish convergence results for the RMS method applied to M-matrices. Thus, this paper is the counterpart to [16] for the multiplicative case, although we prove some new results on RAS iterations as well. Furthermore, we are able to present a comparison result between the RMS and RAS methods. We show that, as measured in a certain norm, the convergence of the RMS method is never

worse than that of the RAS method. More precisely, if $M_{RAS}^{-1}A$ and $M_{RMS}^{-1}A$ are the preconditioned matrices using the RAS and RMS methods, respectively, we show that in some norm

$$\|I - M_{RMS}^{-1}A\| \leq \|I - M_{RAS}^{-1}A\|;$$

see section 3. In some cases, this comparison is valid for the spectral radii $\rho_1 := \rho(I - M_{RMS}^{-1}A) \leq \rho_2 := \rho(I - M_{RAS}^{-1}A)$. This implies that the spectrum of the preconditioned matrix with RAS $\sigma(M_{RAS}^{-1}A) \subseteq B(1, \rho_2)$, the ball centered at 1 with radius ρ_2, while the spectrum of the preconditioned matrix with RMS $\sigma(M_{RMS}^{-1}A)$ is contained in the smaller ball $B(1, \rho_1)$. These results remain true if we allow an inexact (or approximate) solution of the subdomain problems; see section 4. We point out that such a theoretical comparison has only recently become available between the classical additive and multiplicative Schwarz methods [20].

In section 3, we prove that the asymptotic rate of convergence of the RMS method is no faster than that of the classical multiplicative Schwarz method. The reason why the restricted Schwarz methods are attractive is that the communication time between processors is reduced, usually converging in less overall computational time [10].

We prove several other comparison theorems. We compare the speed of convergence with respect to the amount of overlap of the domains (section 5), the exactness of the subdomain solver (section 4), and the number of domains (section 6). Some variants of the RMS method are analyzed in section 7. We finish the paper with some comments on coarse grid corrections.

2. The algebraic representation and notations. As in [10, 16] we consider p nonoverlapping subspaces $W_{i,0}$, $i = 1, \ldots, p$, which are spanned by columns of the identity I over $\mathbb{R}^n$ and which are then augmented to produce overlap. For a precise definition, let $S = \{1, \ldots, n\}$, and let

$$S = \bigcup_{i=1}^{p} S_{i,0}$$

be a partition of S into p disjoint, nonempty subsets. For each of these sets $S_{i,0}$ we consider a nested sequence of larger sets $S_{i,\delta}$ with

$$S_{i,0} \subseteq S_{i,1} \subseteq S_{i,2} \subseteq \cdots \subseteq S = \{1, \ldots, n\}, \tag{2}$$

so that we again have $S = \cup_{i=1}^{p} S_{i,\delta}$ for all values of δ, but for $\delta > 0$ the sets $S_{i,\delta}$ are not pairwise disjoint; i.e., there is *overlap*. A common way to obtain the sets $S_{i,\delta}$ is to add those indices to $S_{i,0}$ which correspond to nodes lying at distance δ or less from those nodes corresponding to $S_{i,0}$ in the (undirected) graph of A. This approach is particularly adequate in discretizations of partial differential equations where the indices correspond to the nodes of the discretization mesh; see [6, 8, 9, 10, 13, 25].

Let $n_{i,\delta} = |S_{i,\delta}|$ denote the cardinality of the set $S_{i,\delta}$. For each nested sequence of the form (2) we can find a permutation π_i on $\{1, \ldots, n\}$ with the property that for all $\delta \geq 0$ we have $\pi_i(S_{i,\delta}) = \{1, \ldots, n_{i,\delta}\}$.

We now build matrices $R_{i,\delta} \in \mathbb{R}^{n_{i,\delta} \times n}$ whose rows are precisely those rows j of the identity for which $j \in S_{i,\delta}$. Formally, such a matrix $R_{i,\delta}$ can be expressed as

$$R_{i,\delta} = [I_{i,\delta}|O]\,\pi_i \tag{3}$$

with $I_{i,\delta}$ the identity on $\mathbb{R}^{n_{i,\delta}}$. Finally, we define the weighting (or masking) matrices

$$E_{i,\delta} = R_{i,\delta}^T R_{i,\delta} \ = \pi_i^T \begin{bmatrix} I_{i,\delta} & O \\ O & O \end{bmatrix} \pi_i \quad \in \mathbb{R}^{n\times n} \tag{4}$$

and the subspaces

$$W_{i,\delta} = \text{range}(E_{i,\delta}), \qquad i = 1, \ldots, p.$$

Note the inclusion $W_{i,\delta} \supseteq W_{i,\delta'}$ for $\delta \geq \delta'$ and, in particular, $W_{i,\delta} \supseteq W_{i,0}$ for all $\delta \geq 0$.

We view the matrices $R_{i,\delta}$ as restriction operators and $R_{i,\delta}^T$ as prolongations. We can identify the image of $R_{i,\delta}^T$ with the subspace $W_{i,\delta}$. For each subspace $W_{i,\delta}$ we define a restriction of the operator A on $W_{i,\delta}$ as

$$A_{i,\delta} = R_{i,\delta} A R_{i,\delta}^T.$$

To describe and analyze the classical Schwarz methods, the theory of orthogonal projections plays an important role; see, e.g., [17, Chap. 11], [25], and especially [5]. Therefore let

$$P_{i,\delta} = R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A, \tag{5}$$

provided that $A_{i,\delta}$ is nonsingular. It is not hard to see that this is a projection onto the subspace $W_{i,\delta}$. (In the case of symmetric A, this projection is orthogonal.) The additive Schwarz preconditioner is

$$M_{AS,\delta}^{-1} = \sum_{i=1}^{p} R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} \tag{6}$$

and the preconditioned matrix is

$$M_{AS,\delta}^{-1} A = \sum_{i=1}^{p} P_{i,\delta}.$$

Similarly, the multiplicative Schwarz preconditioner $M_{MS,\delta}^{-1}$ is such that

$$T_{MS,\delta} = I - M_{MS,\delta}^{-1} A = (I - P_{p,\delta})(I - P_{p-1,\delta}) \cdots (I - P_{1,\delta}) = \prod_{i=p}^{1} (I - P_{i,\delta}). \tag{7}$$

Next we describe the *restricted* additive and multiplicative Schwarz preconditioners. We introduce "restricted" operators

$$\tilde{R}_{i,\delta} = R_{i,\delta} E_{i,0} \in \mathbb{R}^{n_{i,\delta}\times n}.$$

The image of $\tilde{R}_{i,\delta}^T = E_{i,0} R_{i,\delta}^T$ can be identified with $W_{i,0}$, so $\tilde{R}_{i,\delta}^T$ "restricts" $R_{i,\delta}^T$ in the sense that the image of the latter, $W_{i,\delta}$, is restricted to its subspace $W_{i,0}$, the space from the nonoverlapping decomposition. In the restricted (additive and multiplicative) Schwarz methods from [8, 10] the prolongation operator $R_{i,\delta}^T$ is replaced by $\tilde{R}_{i,\delta}^T$ and the (oblique) projection

$$Q_{i,\delta} = \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A = E_{i,0} P_{i,\delta}$$

is used; see [16]. Thus, the restricted counterparts to the operators (6) and (7) are

$$M_{RAS,\delta}^{-1} = \sum_{i=1}^{p} \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta}$$

and

$$T_{RMS,\delta} = (I - Q_{p,\delta})(I - Q_{p-1,\delta}) \cdots (I - Q_{1,\delta}) = \prod_{i=p}^{1} (I - Q_{i,\delta}), \tag{8}$$

respectively. The iteration matrix of the RAS method is then

$$T_{RAS,\delta} = I - M_{RAS,\delta}^{-1} A = I - \sum_{i=1}^{p} \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A = I - \sum_{i=1}^{p} Q_{i,\delta}. \tag{9}$$

For practical parallel implementations, replacing $R_{i,\delta}^T$ by $\tilde{R}_{i,\delta}^T$ means that the corresponding part of the computation does not require any communication, since the images of the $\tilde{R}_{i,\delta}^T$ do not overlap. In addition, the numerical results in [10] indicate that the RAS method is faster (in terms of number of iterations and/or CPU time) than the classical one.

For the analysis of preconditioned Krylov subspace methods, the relevant matrices are $M_{AS,\delta}^{-1} A$ and $M_{RAS,\delta}^{-1} A$ for additive Schwarz and $I - T_{MS,\delta}$ and $I - T_{RMS,\delta}$ for multiplicative Schwarz. Alternatively, we can consider and compare the iteration matrices $T_{AS,\delta} = I - M_{AS,\delta}^{-1} A$, $T_{RAS,\delta}$ and $T_{MS,\delta}$, $T_{RMS,\delta}$. These correspond to stationary iterative methods, e.g., of the form

$$x^{k+1} = T_{RAS,\delta} x^k + M_{RAS,\delta}^{-1} b, \qquad k = 0, 1, \ldots,$$

for the RAS case; see, e.g., [18] for another example of such Schwarz iterations.

As in [2, 15, 16], the key to our analysis is a new (algebraic) representation of the restricted Schwarz methods. We construct a set of matrices $M_{i,\delta}$ associated with $R_{i,\delta}$ as follows:

$$M_{i,\delta} = \pi_i^T \begin{bmatrix} A_{i,\delta} & O \\ O & D_{\neg i,\delta} \end{bmatrix} \pi_i \tag{10}$$

and $D_{\neg i,\delta}$ is the diagonal part of the principal submatrix of A "complementary" to $A_{i,\delta}$; i.e.,

$$D_{\neg i,\delta} = \operatorname{diag}\left([O | I_{\neg i,\delta}] \cdot \pi_i \cdot A \cdot \pi_i^T \cdot [O | I_{\neg i,\delta}]^T \right)$$

with $I_{\neg i,\delta}$ the identity on $\mathbb{R}^{n - n_{i,\delta}}$. Here, we assume that $A_{i,\delta}$ and $D_{\neg i,\delta}$ are nonsingular. It can be shown (see [16]) that

$$\tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} = E_{i,0} M_{i,\delta}^{-1}, \qquad i = 1, \ldots, p,$$

and therefore

$$Q_{i,\delta} = \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A = E_{i,0} M_{i,\delta}^{-1} A, \qquad i = 1, \ldots, p.$$

With these fundamental identities the RAS and RMS methods can be described by the iteration matrices

$$T_{RAS,\delta} = I - \sum_{i=1}^{p} E_{i,0} M_{i,\delta}^{-1} A,$$

$$T_{RMS,\delta} = \prod_{i=p}^{1} (I - E_{i,0} M_{i,\delta}^{-1} A). \tag{11}$$

Moreover, we have

$$M_{RAS,\delta}^{-1} = \sum_{i=1}^{p} E_{i,0} M_{i,\delta}^{-1}.$$

In the rest of this section, we list some basic terminology and some well-known results which we use in the rest of the paper.

The natural partial ordering $\leq$ between matrices $A = (a_{ij})$, $B = (b_{ij})$ of the same size is defined componentwise; i.e., $A \leq B$ iff $a_{ij} \leq b_{ij}$ for all i, j. If $A \geq O$, we call A nonnegative. If all entries of A are positive, we say that A is positive and write $A > O$. This notation and terminology carries over to vectors as well.

A nonsingular matrix $A \in \mathbb{R}^{n\times n}$ is called monotone if $A^{-1} \geq O$. A monotone matrix $A \in \mathbb{R}^{n\times n}$ is called a (nonsingular) M-matrix if it has nonpositive off-diagonal elements. The following lemma states some useful properties of M-matrices; see, e.g., [4, 28].

LEMMA 2.1. *Let $A, B \in \mathbb{R}^{n\times n}$ be two nonsingular M-matrices with $A \leq B$. Then we have the following:*

(i) *Every principal submatrix of A or B is again an M-matrix.*
(ii) *Every matrix D such that $A \leq D \leq B$ is an M-matrix. In particular, if $A \leq D \leq \mathrm{diag}(A)$, then D is an M-matrix.*
(iii) *$B^{-1} \leq A^{-1}$.*

Our convergence results are formulated in terms of nonnegative splittings according to the following definition.

DEFINITION 2.2. *Consider the splitting $A = M - N \in \mathbb{R}^{n\times n}$ with M nonsingular. This splitting is said to be*

(i) regular *if $M^{-1} \geq O$ and $N \geq O$,*
(ii) weak nonnegative of the first type *(also called* weak regular*) if $M^{-1} \geq O$ and $M^{-1}N \geq O$,*
(iii) weak nonnegative of the second type *if $M^{-1} \geq O$ and $NM^{-1} \geq O$, and*
(iv) nonnegative *if $M^{-1} \geq O$, $M^{-1}N \geq O$, and $NM^{-1} \geq O$.*

Note that all the above splittings $A = M - N$ are *convergent* splittings for M-matrices A; i.e., the spectral radius $\rho(M^{-1}N)$ of the iteration matrix $M^{-1}N$ is less than one. Given an iteration matrix, there is a unique splitting for it, which is stated by the following result; see [3].

LEMMA 2.3. *Let A and T be square matrices such that A and $I - T$ are nonsingular. Then there exists a unique pair of matrices B, C such that B is nonsingular, $T = B^{-1}C$, and $A = B - C$. The matrices are $B = A(I - T)^{-1}$ and $C = B - A = A((I - T)^{-1} - I)$.*

For a positive vector w, we denote $\|x\|_w$ the weighted max norm in $\mathbb{R}^n$ given by

$$\|x\|_w = \max_{i=1,\ldots,n} |x_i|/w_i.$$

The resulting operator norm in $\mathbb{R}^{n\times n}$ is denoted similarly, and for $B = (b_{ij}) \in \mathbb{R}^{n\times n}$ we have (see, e.g., [24])

$$\|B\|_w = \max_{i=1,\ldots,n} \left(\sum_{j=1}^{n} |b_{ij}| w_j \right) / w_i. \tag{12}$$

The following lemma follows directly from (12).

LEMMA 2.4. *Let $T, \tilde{T}$ be nonnegative matrices. Assume that $Tw \le \tilde{T}w$ for some vector $w > 0$. Then $\|T\|_w \le \|\tilde{T}\|_w$.*

3. Convergence and comparisons of RMS. In this section, we show that for a monotone matrix A the restricted multiplicative Schwarz iteration is convergent. Moreover, we establish that the spectral radius of the RMS iteration matrix is less than or equal to the spectral radius of the RAS iteration matrix, and it is no smaller than the spectral radius of the classical multiplicative Schwarz method (Theorems 3.5 and 3.8).

We begin by stating a lemma proved in [2].

LEMMA 3.1. *Let A be monotone, and let a collection of p triples (E_i, M_i, N_i) be given such that $O \le E_i \le I$, $\sum_{i=1}^{p} E_i \ge I$, and $A = M_i - N_i$ is a weak regular splitting for $i = 1, \ldots, p$. Let*

$$T = (I - E_p M_p^{-1} A)(I - E_{p-1} M_{p-1}^{-1} A) \cdots (I - E_1 M_1^{-1} A).$$

Then T is nonnegative and, for any vector $w = A^{-1}e > 0$ with $e > 0$, $\rho(T) \le \|T\|_w < 1$.

Now we formulate one of the main results of this section. It is the counterpart to Theorem 4.4 [16], where it was shown that the RAS method is convergent, and the iteration matrix (9) induces a weak regular splitting.

THEOREM 3.2. *Let A be a nonsingular M-matrix. Then for each value of $\delta \ge 0$ and for any $w = A^{-1}e > 0$ with $e > 0$, we have $\rho(T_{RMS,\delta}) \le \|T_{RMS,\delta}\|_w < 1$. Furthermore, there exists a unique splitting $A = M_{RMS,\delta} - N_{RMS,\delta}$ such that $T_{RMS,\delta} = M_{RMS,\delta}^{-1} N_{RMS,\delta}$, and this splitting is weak regular (i.e., weak nonnegative of the first type). The matrix $M_{RMS,\delta}$ is given by $M_{RMS,\delta} = A(I - T_{RMS,\delta})^{-1}$.*

Proof. The proof we present is almost the same as the proof of the convergence of the classical multiplicative Schwarz method given in [2]. Let $E_{i,0}$ as in (4) and $M_{i,\delta}$ as in (10). Observe that $O \le E_{i,0} \le I$, $i = 1, \ldots, p$. We have already seen that

$$I - Q_{i,\delta} = I - E_{i,0} M_{i,\delta}^{-1} A, \qquad i = 1, \ldots, p.$$

Moreover, it is not hard to see that the splittings $A = M_{i,\delta} - N_{i,\delta}$ (with $N_{i,\delta} = M_{i,\delta} - A$) are regular. Hence, by Lemma 3.1, $T_{RMS,\delta} \ge O$ and $\rho(T_{RMS,\delta}) \le \|T_{RMS,\delta}\|_w < 1$ for any $w = A^{-1}e > 0$ with $e > 0$. Furthermore, by Lemma 2.3, there exists a unique splitting $A = M_{RMS,\delta} - N_{RMS,\delta}$ such that $T_{RMS,\delta} = M_{RMS,\delta}^{-1} N_{RMS,\delta}$. To prove that the splitting is weak regular it suffices to show that

$$M_{RAS,\delta}^{-1} = (I - T_{RMS,\delta}) A^{-1} \ge O \tag{13}$$

or, equivalently, that $M_{RAS,\delta}^{-1} z \ge 0$ for all $z \ge 0$. Letting $v = A^{-1}z \ge 0$, all we need to show is that $(I - T_{RMS,\delta})v \ge 0$ or $T_{RMS,\delta} v \le v$. This is proved in the same way as Lemma 3.1; see [2]. Hence, the unique splitting $A = M_{RMS,\delta} - N_{RMS,\delta}$ is weak regular. ∎

In Example 3.3, we show that the splittings induced by the RAS method and the RMS method are, in general, not nonnegative, i.e., are not weak nonnegative of the second type. This is in contrast with the classical Schwarz methods; see [2].

Example 3.3. For the RAS method, we have to consider

$$\bar{T} = I - AM_{RAS}^{-1} = I - A\sum_{i=1}^{p} E_{i,0}M_{i,\delta}^{-1},$$

while for the RMS method

$$\tilde{T} = N_{RMS,\delta}M_{RMS,\delta}^{-1} = I - AM_{RMS,\delta}^{-1} = I - A(I - T_{RMS,\delta})A^{-1}.$$

It is not hard to see that $\tilde{T} = \prod_{i=p}^{1}(I - \tilde{Q}_{i,\delta})$ with $\tilde{Q}_{i,\delta} = AE_{i,\delta}M_{i,\delta}^{-1}$. Now let

$$A = \begin{bmatrix} 6 & -1 & -2 \\ -2 & 8 & -3 \\ -1 & -1 & 4 \end{bmatrix}, \quad M_{1,\delta} = \begin{bmatrix} 6 & 0 & 0 \\ 0 & 8 & 0 \\ 0 & 0 & 4 \end{bmatrix}, \quad E_{1,0} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix},$$

$$M_{2,\delta} = \begin{bmatrix} 6 & 0 & 0 \\ 0 & 8 & 0 \\ 0 & 0 & 4 \end{bmatrix}, \quad E_{2,0} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix},$$

$$M_{3,\delta} = \begin{bmatrix} 6 & -1 & 0 \\ -2 & 8 & 0 \\ 0 & 0 & 4 \end{bmatrix}, \quad E_{3,0} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

We obtain

$$\bar{T} = I - A\sum_{i=1}^{3} E_{i,0}M_{i,\delta}^{-1} = \begin{bmatrix} 0.0435 & -0.0054 & 0.5000 \\ 0.3478 & 0.0435 & 0.7500 \\ 0.1739 & 0.1467 & 0 \end{bmatrix} \not\geq 0,$$

$$\tilde{T} = \prod_{i=3}^{1}(I - AE_{i,0}M_{i,\delta}^{-1}) = \begin{bmatrix} -0.0435 & -0.0054 & -0.0258 \\ 0.3478 & 0.0435 & 0.2065 \\ 0.1739 & 0.1467 & 0.1970 \end{bmatrix} \not\geq 0.$$

In the case of no overlap, the RMS method as well as the classical multiplicative Schwarz method reduce to a block Gauss–Seidel method. Similarly, with no overlap, the RAS and the classical additive Schwarz methods reduce to the block Jacobi method. The classical Stein–Rosenberg theorem (see, e.g., [28]) says that for M-matrices the Gauss–Seidel method converges faster than the Jacobi method. The next theorem extends this statement to the case of overlap. We are able to compare the RMS method with the RAS method. We point out that only recently a similar result was obtained for the classical Schwarz methods [20].

We need the following lemma; see [15, 21].

LEMMA 3.4. *Let $A^{-1} \geq O$. Let $A = \bar{M} - \bar{N} = M - N$ be two weak regular splittings such that*

$$\bar{M}^{-1} \geq M^{-1}.$$

Let $w > 0$ be such that $w = A^{-1}e$ for some $e > 0$. Then $\|\bar{M}^{-1}\bar{N}\|_w \leq \|M^{-1}N\|_w$.

THEOREM 3.5. *Let A be a nonsingular M-matrix, and let $w > 0$ be any positive vector such that $Aw > 0$, e.g., $w = A^{-1}v$ with $v > 0$. Then*

$$\|T_{RMS,\delta}\|_w \le \|T_{RAS,\delta}\|_w.$$

Moreover, if the Perron vector w_δ of $T_{RAS,\delta}$ satisfies $w_\delta > 0$ and $Aw_\delta \ge 0$, then we also have

$$\rho(T_{RMS,\delta}) \le \rho(T_{RAS,\delta}).$$

Proof. We will use Lemma 3.4. The splittings corresponding to the RAS and RMS methods are weak regular splittings, and, in particular, the matrices $M_{RAS,\delta}^{-1}$ and $M_{RMS,\delta}^{-1}$ are nonnegative; see (13). Next we show that

$$M_{RMS,\delta}^{-1} \ge M_{RAS,\delta}^{-1}.$$

To that end, we write explicitly $M_{RMS,\delta}^{-1}$ using (13) and (11) as follows:

$$\begin{aligned} M_{RMS,\delta}^{-1} &= \left(I - \prod_{i=p}^{1} (I - E_{i,0} M_{i,\delta}^{-1} A) \right) A^{-1} \\ &= \left(I - (I - E_{p,0} M_{p,\delta}^{-1} A)(I - E_{p-1,0} M_{p-1,\delta}^{-1} A) \cdots (I - E_{1,0} M_{1,\delta}^{-1} A) \right) A^{-1}. \end{aligned}$$

Thus, by computing the product $M_{RMS,\delta}^{-1}$ can be written as

$$\begin{aligned} M_{RMS,\delta}^{-1} = &\sum_{i=1}^{p} E_{i,0} M_{i,\delta}^{-1} - \sum_{i<j} E_{j,0} M_{j,\delta}^{-1} A E_{i,0} M_{i,\delta}^{-1} \\ &+ \sum_{m=3}^{p} \sum_{\substack{(j_1,\ldots,j_m) \\ j_i \in \{1,\ldots,p\}, \\ j_i > j_k \text{ if } i<k}} (-1)^{m+1} \left(\prod_{k=1}^{m} E_{j_k,0} M_{j_k,\delta}^{-1} A \right) A^{-1}. \end{aligned} \tag{14}$$

Note that in each product above all $E_{j_k,0}$ are different, i.e., $E_{j_k,0} \ne E_{j_i,0}$ for $k \ne i$.

The first sum in (14) is just $M_{RAS,\delta}^{-1}$. Thus, all that remains to be shown is that the remaining part of (14) is a nonnegative matrix. To do so, we first consider matrices of the form

$$E_{j,0} M_{j,\delta}^{-1} A E_{i,0} M_{i,\delta}^{-1}.$$

Since $E_{j,0} M_{j,\delta}^{-1} = E_{j,0} M_{j,\delta}^{-1} E_{j,\delta}$ and $E_{i,0} M_{i,\delta}^{-1} = E_{i,0} M_{i,\delta}^{-1} E_{i,\delta}$ we have that

$$E_{j,0} M_{j,\delta}^{-1} A E_{i,0} M_{i,\delta}^{-1} = E_{j,0} M_{j,\delta}^{-1} \left(E_{j,\delta} A E_{i,0} \right) M_{i,\delta}^{-1} E_{i,\delta}. \tag{15}$$

We consider two cases.

Case (a). $S_{j,\delta} \cap S_{i,0} = \emptyset$. Since A is an M-matrix,

$$\left(E_{j,\delta} A E_{i,0} \right)_{s,t} \begin{cases} \le 0 & \text{if } s \in S_{j,\delta},\ t \in S_{i,0} \\ = 0 & \text{otherwise.} \end{cases}$$

Thus, since $E_{j,0} M_{j,\delta}^{-1}$ and $M_{i,\delta}^{-1}$ are nonnegative, we obtain

$$E_{j,0} M_{j,\delta}^{-1} A E_{i,0} M_{i,\delta}^{-1} \le O.$$

Case (b). $S_{j,\delta} \cap S_{i,0} \neq \emptyset$. With the construction on $M_{j,\delta}^{-1}$ in (10), we obtain here

$$\left(E_{j,0}M_{j,\delta}^{-1}A\right)_{s,t} \begin{cases} = 0 & \text{if } s \notin S_{j,0} \\ = 1 & \text{if } s \in S_{j,0},\ s = t \\ = 0 & \text{if } s \in S_{j,0},\ t \in S_{j,\delta},\ s \neq t \\ \leq 0 & \text{otherwise.} \end{cases} \tag{16}$$

Since $S_{j,0} \cap S_{i,0} = \emptyset$ it follows that

$$E_{j,0}M_{j,\delta}^{-1}AE_{i,0}M_{i,\delta}^{-1} \leq O.$$

Therefore in both cases we obtain

$$-\sum_{i<j} E_{j,0}M_{j,\delta}^{-1}AE_{i,0}M_{i,\delta}^{-1} \geq O.$$

Moreover, in both cases we have with (15) that

$$\left(E_{j,0}M_{j,\delta}^{-1}AE_{i,0}M_{i,\delta}^{-1}\right)_{s,t} \begin{cases} \leq 0 & \text{if } s \in S_{j,0},\ t \in S_{i,\delta} \\ = 0 & \text{otherwise.} \end{cases} \tag{17}$$

Finally, consider the terms of the third sum in (14), i.e., consider

$$\begin{aligned} &(-1)^{m+1}\left(\prod_{k=1}^{m} E_{j_k,0}M_{j_k,\delta}^{-1}A\right)A^{-1} \\ &= (-1)^{m+1}\left(\prod_{k=1}^{m-2} E_{j_k,0}M_{j_k,\delta}^{-1}A\right)E_{j_2,0}M_{j_2,\delta}^{-1}AE_{j_1,0}M_{j_1,\delta}^{-1} \end{aligned}$$

with $m \geq 3$. Each of these contains one factor of the form (17), while the other $m-2$ factors are of the form (16). Since the matrices $E_{j_k,0}$ are different for different values of k, the entries with value 1 in (16) get multiplied by zeros when performing the product. This implies that in this case every entry in (16) is nonpositive.

We proceed now by induction on the number of factors. If we have an even number of factors, we have $(-1)^{m+1} = -1$, but since the factor of the form (17) is nonpositive and each of the other $m-2$ factors of the form (16) is also nonpositive, the product is a nonnegative matrix. Similarly, if m is odd $(-1)^{m+1} = 1$, but we have an odd number of nonpositive factors of the form (16) and the nonpositive factor of the form (17). Thus, the product is a nonnegative matrix. Hence in both cases we have

$$(-1)^{m+1}\left(\prod_{k=1}^{m} E_{j_k,0}M_{j_k,\delta}^{-1}A\right)A^{-1} \geq O.$$

Therefore $M_{RMS,\delta}^{-1} \geq M_{RAS,\delta}^{-1}$. Hence with Lemma 3.4 we obtain

$$\|T_{RMS,\delta}\|_w \leq \|T_{RAS,\delta}\|_w.$$

Now, if the Perron vector w_δ of $T_{RAS,\delta}$ satisfies $w_\delta > 0$ and $Aw_\delta \geq 0$, we also have $\|T_{RAS,\delta}\|_{w_\delta} = \rho(T_{RAS,\delta})$. Thus $\rho(T_{RMS,\delta}) \leq \rho(T_{RAS,\delta})$. ∎

To end this section, we compare the RMS method with its classical version. We need first the following two lemmas. The first one is well known and can be found, e.g., in [4], while the second is from [2].

LEMMA 3.6. *Assume that a square matrix T is nonnegative and that for some $\alpha \geq 0$ and for some nonzero vector $x \geq 0$ we have $Tx \geq \alpha x$. Then $\rho(T) \geq \alpha$. The inequality is strict if $Tx > \alpha x$.*

LEMMA 3.7. *Let $A^{-1} \geq O$. Let $A = M - N$ be a splitting such that $M^{-1} \geq O$ and $NM^{-1} \geq O$. Then $\rho(M^{-1}N) < 1$ and there exists a nonzero vector $x \geq 0$ such that $M^{-1}Nx = \rho(M^{-1}N)x$ and $Ax \geq 0$.*

THEOREM 3.8. *Let A be a nonsingular M-matrix, and let $w > 0$ be any positive vector such that $Aw > 0$. Let $T_{RMS,\delta}$ and $T_{MS,\delta}$ be as in (8) and (7); then, for any $\delta \geq 0$,*

$$\|T_{MS,\delta}\|_w \leq \|T_{RMS,\delta}\|_w < 1.$$

Moreover, $\rho(T_{MS,\delta}) \leq \rho(T_{RMS,\delta})$.

Proof. The proof is similar to that of Theorem 4.7 of [2]. We have already seen that $T_{RMS,\delta}$ and $T_{MS,\delta}$ are nonnegative matrices. By Theorem 3.5 of [2] the iteration matrix $T_{MS,\delta}$ induces a nonnegative splitting of A. Let $x \geq 0$, $x \neq 0$ be an eigenvector of $T_{MS,\delta}$ with eigenvalue $\rho(T_{MS,\delta})$. We will show that

$$T_{RMS,\delta}\, x \;\geq\; T_{MS,\delta}\, x \;=\; \rho(T_{MS,\delta})\, x, \tag{18}$$

so that by Lemma 3.6 we get the desired result $\rho(T_{RMS,\delta}) \geq \rho(T_{MS,\delta})$. Let $x^0 = \bar{x}^0 = x$ and define $x^i := (I - E_{i,\delta}M_{i,\delta}^{-1}A)x^{i-1}$ and $\bar{x}^i := (I - E_{i,0}M_{i,\delta}^{-1}A)\bar{x}^{i-1}$, $i = 1, \ldots, p$. Thus, $x^p = T_{MS,\delta}x$ and $\bar{x}^p = T_{RMS,\delta}x$. To establish (18) we proceed by induction and show that

$$Ax^i \geq 0, \qquad i = 1, \ldots, p-1, \tag{19}$$

and

$$0 \leq x^i \leq \bar{x}^i, \qquad i = 1, \ldots, p. \tag{20}$$

We then have (18) since $x^p = T_{MS,\delta}x$ and $\bar{x}^p = T_{RMS,\delta}x$; see (7) and (8).

For $i = 0$, (20) holds by assumption, while relation (19) is true by Lemma 3.7. Assume now that (19) and (20) are both true for some i. To obtain (19) for $i+1$, observe that $Ax^{i+1} = A(I - E_{i,\delta}M_{i,\delta}^{-1}A)x^i = (I - AE_{i,\delta}M_{i,\delta}^{-1})Ax^i$. We have $I - AE_{i,\delta}M_{i,\delta}^{-1} \geq O$, since

$$\begin{aligned} I - M_{i,\delta}^{-T}E_{i,\delta}^T A^T &= I - E_{i,\delta}M_{i,\delta}^{-T}A^T = I - E_{i,\delta} + E_{i,\delta}(I - M_{i,\delta}^{-T}A^T) \\ &= I - E_{i,\delta} + E_{i,\delta}M_{i,\delta}^{-T}N_{i,\delta}^T \geq O, \end{aligned}$$

with $N_{i,\delta} := M_{i,\delta} - A \geq 0$. Moreover, $Ax^i \geq 0$ by the induction hypothesis, and thus (19) holds for $i + 1$. To prove that (20) holds for $i + 1$, we use (19), the fact $E_{i,0} \leq E_{i,\delta}$, and the induction hypothesis to obtain

$$x^{i+1} = (I - E_{i,\delta}M_{i,\delta}^{-1}A)x^i \leq (I - E_{i,0}M_{i,\delta}^{-1}A)x^i \leq (I - E_{i,0}M_{i,\delta}^{-1}A)\bar{x}^i = \bar{x}^{i+1}.$$

To establish the inequalities for the weighted max norms, one proceeds in precisely the same manner as before (using w instead of x) to show $T_{RMS,\delta}w \geq T_{MS,\delta}w$. Since both matrices are nonnegative, by Lemma 2.4 we get $\|T_{MS,\delta}\|_w \leq \|T_{RMS,\delta}\|_w$. ∎

4. Inexact local solves. In the previous section, the subdomain problems were assumed to be solved exactly, and this is represented by the inverses of the matrices $A_{i,\delta}$. In this section, we consider the case were the subdomain problems are solved approximatively or, in other words, inexactly. We represent this fact by using an approximation $\tilde{A}_{i,\delta}$ of the matrix $A_{i,\delta}$. In practice, one uses, for example, an incomplete factorization of $A_{i,\delta}$; see, e.g., [19, 27].

As in [15], suppose that the inexact solves are such that the splittings

$$A_{i,\delta} = \tilde{A}_{i,\delta} - (\tilde{A}_{i,\delta} - A_{i,\delta}) \qquad \text{are weak regular splittings} \tag{21}$$

for $i = 1, \ldots, p$ or that

$$\tilde{A}_{i,\delta} \ \text{ is an } M\text{-matrix and } \ \tilde{A}_{i,\delta} \geq A_{i,\delta}, \qquad i = 1, \ldots, p. \tag{22}$$

Note that (22) implies (21). The incomplete factorizations satisfy (21) [19].

The restricted multiplicative Schwarz iteration with inexact solves on the subdomains is then given by

$$\tilde{T}_{RMS,\delta} = \prod_{i=p}^{1} (I - \tilde{R}_{i,\delta} \tilde{A}_{i,\delta}^{-1} R_{i,\delta} A).$$

In a way similar to (10), we construct matrices

$$\tilde{M}_{i,\delta} = \pi_i^T \begin{bmatrix} \tilde{A}_{i,\delta} & O \\ O & D_{\neg i,\delta} \end{bmatrix} \pi_i \tag{23}$$

such that

$$\tilde{R}_{i,\delta} \tilde{A}_{i,\delta}^{-1} R_{i,\delta} A = E_{i,0} \tilde{M}_{i,\delta}^{-1} A, \qquad i = 1, \ldots, p,$$

and thus

$$\tilde{T}_{RMS,\delta} = \prod_{i=p}^{1} (I - E_{i,0} \tilde{M}_{i,\delta}^{-1} A). \tag{24}$$

We can now establish our convergence result.

THEOREM 4.1. *Let A be a nonsingular M-matrix. Then the RMS iteration matrix* (24) *with inexact solves satisfying* (21) *satisfies $\rho(\tilde{T}_{RMS,\delta}) \leq \|\tilde{T}_{RMS,\delta}\|_w < 1$ for any $w = A^{-1}e > 0$ with $e > 0$. Furthermore, there exists a unique splitting $A = \tilde{B} - \tilde{C}$ such that $\tilde{T}_{RMS,\delta} = \tilde{B}^{-1}\tilde{C}$, and this splitting is weak regular.*

Proof. The proof proceeds in the same manner as that of Theorem 3.2. All we need to show is that each splitting $A = \tilde{M}_{i,\delta} - \tilde{N}_{i,\delta}$ with $\tilde{M}_{i,\delta}$ as in (23) is weak regular. Since $\tilde{A}_{i,\delta}$ is monotone, it follows from (23) that $\tilde{M}_{i,\delta}^{-1} \geq O$. With

$$\pi_i A \pi_i^T := \begin{bmatrix} A_{i,\delta} & K_i \\ L_i & A_{\neg i,\delta} \end{bmatrix}$$

and $\tilde{N}_{i,\delta} = \tilde{M}_{i,\delta} - A$ we have

$$\pi_i \tilde{M}_{i,\delta}^{-1} \tilde{N}_{i,\delta} \pi_i^T = \begin{bmatrix} \tilde{A}_{i,\delta}^{-1}(\tilde{A}_{i,\delta} - A_{i,\delta}) & -\tilde{A}_{i,\delta}^{-1} K_{i,\delta} \\ -D_{\neg i}^{-1} L_{i,\delta} & D_{\neg i}^{-1}(D_{\neg i} - A_{\neg i,\delta}) \end{bmatrix},$$

which, in view of (21) and the fact that A is an M-matrix, is nonnegative. ∎

Note that if (22) holds, then $\tilde{N}_{i,\delta} = \tilde{M}_{i,\delta} - A \geq O$ and $A = \tilde{M}_{i,\delta} - \tilde{N}_{i,\delta}$ is in fact a regular splitting.

It is shown in [16] that if (21) holds, the inexact RAS method given by

$$\tilde{T}_{RAS,\delta} = I - \sum_{i=1}^{p} \tilde{R}_{i,\delta}^T \tilde{A}_{i,\delta}^{-1} R_{i,\delta} A$$

is also convergent and that this matrix also induces a weak regular splitting. We use these properties to compare the inexact RMS method with the inexact RAS method.

THEOREM 4.2. *Let A be an M-matrix and consider the inexact RAS method and the inexact RMS method where the matrices $\tilde{A}_{i,\delta}$ corresponding to the inexact solves satisfy* (21)*. Then, for any positive vector w such that $Aw > 0$ and any $\delta \geq 0$, we have*

$$\|\tilde{T}_{RMS,\delta}\|_w \leq \|\tilde{T}_{RAS,\delta}\|_w < 1. \tag{25}$$

Moreover, if the Perron vector w_δ of $T_{RAS,\delta}$ satisfies $w_\delta > 0$ and $Aw_\delta \geq 0$, then we also have

$$\rho(\tilde{T}_{RMS,\delta}) \leq \rho(\tilde{T}_{RAS,\delta}). \tag{26}$$

Proof. The proof is similar to the proof of Theorem 3.5. With (21) and (23), all matrices $\tilde{M}_{i,\delta}^{-1}$ are nonnegative. We will show that

$$\tilde{M}_{RMS,\delta}^{-1} \geq \tilde{M}_{RAS,\delta}^{-1}.$$

Following the proof of Theorem 3.5 we have only to modify Case (b). However, with (21) we have $\tilde{A}_{i,\delta}^{-1} A_{i,\delta} \leq I$, and thus

$$\left(E_{j,0}\tilde{M}_{j,\delta}^{-1}A\right)_{s,t} \begin{cases} = 0 & \text{if } s \notin S_{j,0} \\ \leq 1 & \text{if } s \in S_{j,0},\ s = t \\ \leq 0 & \text{otherwise.} \end{cases}$$

We then proceed as in the proof of Theorem 3.5.

If the Perron vector w_δ can be chosen as w, we have $\|T_{RAS,\delta}\|_{w_\delta} = \rho(T_{RAS,\delta})$, so that (25) yields $\|T_{RMS,\delta}\|_{w_\delta} \leq \rho(T_{RAS,\delta})$, and since the spectral radius is never larger than any induced operator norm we have (26). ∎

Next we relate the speed of convergence to the exactness of the subdomain solver.

THEOREM 4.3. *Let A be an M-matrix. Consider two inexact RMS methods where the matrices $\tilde{A}_{i,\delta}$ and $\hat{A}_{i,\delta}$ corresponding to the inexact solves satisfy* (22) *and*

$$O \leq \hat{A}_{i,\delta}^{-1} \leq \tilde{A}_{i,\delta}^{-1} \leq A_{i,\delta}^{-1}, \qquad i = 1, \ldots, p.$$

Let the corresponding iteration matrices be as in (24)*. Then, for any positive vector w such that $Aw > 0$ and any $\delta \geq 0$, we have*

$$\|T_{RMS,\delta}\|_w \leq \|\tilde{T}_{RMS,\delta}\|_w \leq \|\hat{T}_{RMS,\delta}\|_w < 1. \tag{27}$$

Proof. From the hypothesis, (10), and (23) it follows that

$$M_{i,\delta}^{-1} \geq \tilde{M}_{i,\delta}^{-1} \geq \hat{M}_{i,\delta}^{-1}.$$

Following the proof of Theorem 3.5, this establishes (27). ∎

5. The effect of overlap on RMS. We study in this section the effect of varying the overlap. More precisely, we prove comparison results on the spectral radii and/or on weighted max norms for the corresponding iteration matrices

$$T_{RMS,\delta} = I - M_{RMS,\delta}^{-1} A$$

for different values of $\delta \geq 0$.

We start with a result which compares one RMS iterative process, defined through the sets $S_{i,\delta'}$, with another one with more overlap defined through sets $S_{i,\delta}$, where $S_{i,\delta'} \subseteq S_{i,\delta}$, $i = 1, \ldots, p$. We show that the larger the overlap ($\delta \geq \delta'$) the faster the RMS method converges as measured in certain weighted max norms.

THEOREM 5.1. *Let A be a nonsingular M-matrix, and let $w > 0$ be any positive vector such that $Aw > 0$. Then, if $\delta \geq \delta'$,*

$$\|T_{RMS,\delta}\|_w \leq \|T_{RMS,\delta'}\|_w < 1. \tag{28}$$

Moreover, if the Perron vector $w_{\delta'}$ of $T_{RMS,\delta'}$ satisfies $w_{\delta'} > 0$ and $Aw_{\delta'} \geq 0$, then we also have

$$\rho(T_{RMS,\delta}) \leq \rho(T_{RMS,\delta'}). \tag{29}$$

Proof. Since $S_{i,\delta'} \subseteq S_{i,\delta}$, $i = 1, \ldots, p$, we have $A \leq M_{i,\delta} \leq M_{i,\delta'} \leq \operatorname{diag}(A)$. Since A is an M-matrix, this yields

$$M_{i,\delta}^{-1} \geq M_{i,\delta'}^{-1} \quad \text{for} \quad i = 1, \ldots, p.$$

Next we compare the matrices $M_{RMS,\delta}^{-1}$ and $M_{RMS,\delta'}^{-1}$. To do so consider (14) in the proof of Theorem 3.5. Since all the parts in the sum are nonnegative, we get (28).

Now, if the Perron vector $w_{\delta'}$ can be chosen as w, we have $\|T_{RMS,\delta'}\|_{w_{\delta'}} = \rho(T_{RMS,\delta'})$ so that (28) yields (29). ∎

As a special case of Theorem 5.1 above we choose $\delta' = 0$, i.e., a block Gauss–Seidel method. In this case, we do not need any additional assumption for comparing the spectral radii. To that end, we use the following comparison theorem due to Woźnicki [29]; see also [12].

THEOREM 5.2. *Let $A^{-1} \geq O$ and two splittings $A = M - N = \tilde{M} - \tilde{M}$, where one of them is weak nonnegative of the first type (weak regular) and the other is weak nonnegative of the second type. If $M^{-1} \geq \tilde{M}^{-1}$, then*

$$\rho(M^{-1}N) \leq \rho(\tilde{M}^{-1}\tilde{N}).$$

THEOREM 5.3. *Let A be a nonsingular M-matrix. Then, for any value of $\delta \geq 0$, $\rho(T_{RMS,\delta}) \leq \rho(T_{RMS,0})$.*

Proof. The proof follows immediately from the above results and the fact that the block Gauss–Seidel splitting is a regular splitting. ∎

6. Varying the number of domains. In this section, we show how the partitioning of a subdomain into smaller subdomains affects the convergence of the restricted Schwarz method. In the M-matrix case, we show that, for both additive and multiplicative restricted Schwarz methods, the more subdomains the slower the convergence rate.

Formally, consider each block of variables $S_{i,\delta}$ partitioned into k_i subblocks; i.e., we have

$$S_{i_j,\delta} \subset S_{i,\delta}, \qquad j = 1, \ldots, k_i, \tag{30}$$

$\bigcup_{j=1}^{k_i} S_{i_j,\delta} = S_{i,\delta}$, and $S_{i_j,\delta} \cap S_{i_k,\delta} = \emptyset$ if $j \neq k$. Each set $S_{i_j,\delta}$ has associated matrices $R_{i_j,\delta}$ and $E_{i_j,\delta} = R_{i_j,\delta}^T R_{i_j,\delta}$. Since we have a partition,

$$E_{i_j,\delta} \leq E_{i,,\delta}, \qquad j = 1, \ldots, k_i, \quad \text{and} \quad \sum_{j=1}^{k_i} E_{i_j,\delta} = E_{i,\delta}, \qquad i = 1, \ldots, p. \tag{31}$$

We define the matrices $A_{i_j,\delta} = R_{i_j,\delta} A R_{i_j,\delta}^T$, and $M_{i_j,\delta}$ corresponding to the set $S_{i_j,\delta}$ as in (10) so that

$$E_{i_j,\delta} M_{i_j,\delta}^{-1} = R_{i_j,\delta}^T A_{i_j}^{-1} R_{i_j,\delta}, \qquad j = 1, \ldots, k_i, \qquad i = 1, \ldots, p.$$

The iteration matrix of the restricted additive Schwarz method with the refined partition is then

$$\bar{T}_{RAS,\delta} = I - \sum_{i=1}^{p} \sum_{j=1}^{k_i} E_{i_j,0} M_{i_j,\delta}^{-1} A, \tag{32}$$

and the unique induced splitting $A = \bar{M}_{RAS,\delta} - \bar{N}_{RAS,\delta}$ (which is a weak regular splitting) is given by

$$\bar{M}_{RAS,\delta}^{-1} = \sum_{i=1}^{p} \sum_{j=1}^{k_i} E_{i_j,0} M_{i_j,\delta}^{-1}.$$

THEOREM 6.1. *Let A be a nonsingular M-matrix. Consider two sets of subblocks of A defined by* (2) *and* (30)*, respectively, and the two corresponding RAS iterations* (9) *and* (32)*. Then, for every $\delta \geq 0$ and for any vector $w > 0$ for which $Aw > 0$, $\|T_{RAS,\delta}\|_w \leq \|\bar{T}_{RAS,\delta}\|_w$.*

Proof. The inclusion (30) implies that

$$M_{i_j,\delta}^{-1} \leq M_{i,\delta}^{-1}, \qquad j = 1, \ldots, k_i, \qquad i = 1, \ldots, p. \tag{33}$$

Thus, with (31) we have

$$\sum_{j=1}^{k_i} E_{i_j,0} M_{i_j,\delta}^{-1} \leq \sum_{j=1}^{k_i} E_{i_j,0} M_{i,\delta}^{-1} = E_{i,0} M_{i,\delta}^{-1}$$

and therefore $\bar{M}_{RAS,\delta}^{-1} \leq M_{RAS,\delta}^{-1}$, which implies the result, using Lemma 3.4. ∎

Next we consider the RMS method. The iteration matrix for the RMS method corresponding to the finer partition (more subdomains) is given by

$$\tilde{T}_{RMS,\delta} = \prod_{i=p}^{1} \prod_{j=k_i}^{1} (I - Q_{i_j,\delta}), \tag{34}$$

where $Q_{i_j,\delta} = E_{i_j,0} M_{i_j,\delta}^{-1} A = \tilde{R}_{i_j,\delta}^T A_{i_j,\delta}^{-1} R_{i_j,\delta} A$.

THEOREM 6.2. *Let A be a nonsingular M-matrix. Consider two sets of subblocks of A defined by* (2) *and* (30)*, respectively, and the two corresponding RMS iterations* (8) *and* (34)*. Then, for any $\delta \geq 0$ and for any vector $w > 0$ for which $Aw > 0$, $\|T_{RMS,\delta}\|_w \leq \|\tilde{T}_{RMS,\delta}\|_w$.*

Proof. Since each $Q_i = E_{i,0}M_{i,\delta}^{-1}A = R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A$ is a projection [16], we have

$$I - Q_i = (I - Q_i)^2 = \cdots = (I - Q_i)^{k_i}.$$

This allows us to represent $T_{RMS,\delta}$ and $\tilde{T}_{RMS,\delta}$ as a product with the same number of factors. We pair each factor $I - Q_{i_j} = I - E_{i_j,0}M_{i_j}^{-1}A$ of $\tilde{T}_{RMS,\delta}$ in (34) with the corresponding factor $I - Q_i = I - E_{i,0}M_{i,\delta}^{-1}A$ of $T_{RMS,\delta}$ in (8). The corresponding set of indices S_{i_j} and S_i satisfy $S_{i_j} \subseteq S_i$. By (31) and (33) we have that $E_{i_j,0}M_{i_j,\delta}^{-1} \leq E_{i,0}M_{i,\delta}^{-1}$. Therefore we can proceed in exactly the same manner as in the proof of Theorem 3.8 to establish the desired result. ∎

7. RMS variants: MSH, RMSH, WRMS, and WMSH. Cai and Sarkis [10] introduced restricted Schwarz methods with harmonic extension. In these variants, the projections $P_{i,\delta}$ in (5) of the classical Schwarz method are replaced by

$$H_{i,\delta} = R_{i,\delta}^T A_{i,\delta}^{-1} \tilde{R}_{i,\delta} A = R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} E_{i,0} A,$$

in contrast to the restricted methods where

$$Q_{i,\delta} = \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A = E_{i,0} R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} A$$

are used. The additive Schwarz method with harmonic extension (ASH method) can then be described in our notation by the iteration matrix $T_{ASH,\delta} = I - M_{ASH}^{-1}A$, where M_{ASH}^{-1} is given by

$$M_{ASH,\delta}^{-1} = \sum_{i=1}^{p} R_{i,\delta}^T A_{i,\delta}^{-1} \tilde{R}_{i,\delta} = \sum_{i=1}^{p} M_{i,\delta}^{-1} E_{i,0}.$$

Similarly, the multiplicative Schwarz method with harmonic extension (MSH method) is defined by

$$T_{MSH,\delta} = \prod_{i=p}^{1} (I - H_{i,\delta}) = \prod_{i=p}^{1} (I - M_{i,\delta}^{-1} E_{i,0} A).$$

It was observed in [10, Rem. 2.4] that the ASH method and the RAS method used as a preconditioner exhibit a similar convergence behavior. In fact, it was shown in [16] that in the case of a symmetric matrix A the two spectra coincide, i.e., $\sigma(M_{ASH,\delta}^{-1}A) = \sigma(M_{RAS,\delta}^{-1}A)$.

In the following, we establish similar results for the MSH method. We have, for a general nonsingular matrix A,

$$\begin{aligned} T_{MSH,\delta}^T &= \prod_{i=p}^{1} (I - R_{i,\delta}^T A_{i,\delta}^{-1} R_{i,\delta} E_{i,0} A)^T = \prod_{i=p}^{1} (I - A^T E_{i,0} R_{i,\delta}^T A_{i,\delta}^{-T} R_{i,\delta}) \\ &= A^T \left(\prod_{i=p}^{1} (I - E_{i,0} R_{i,\delta}^T A_{i,\delta}^{-T} R_{i,\delta} A^T) \right) A^{-T}. \end{aligned} \tag{35}$$

Hence the spectrum of the MSH method is the same as the spectrum of a RMS method for A^T. So, with the weighted column sum norm $\|\cdot\|_{1,w}$ defined for $B = (b_{ij}) \in \mathbb{R}^{n\times n}$ as

$$\|B\|_{1,w} = \max_{j=1,\ldots,n} \left(\sum_{i=1}^{n} |b_{ij}| w_i \right) / w_j,$$

we immediately obtain the following result.

THEOREM 7.1. *Let A be a nonsingular M-matrix. Then the following hold.*

(i) *For any value of $\delta \geq 0$, the splitting $A = M_{MSH,\delta} - N_{MSH,\delta}$, corresponding to the MSH method, is weak nonnegative of the second type, hence*

$$\rho(T_{MSH,\delta}) < 1.$$

(ii) *If $A = A^T$, then for any value of $\delta \geq 0$*

$$\sigma(T_{MSH,\delta}) = \sigma(T_{RMS,\delta}) \qquad \text{and} \qquad \sigma(M_{MSH,\delta}^{-1}A) = \sigma(M_{RMS,\delta}^{-1}A).$$

(iii) *For any positive vector w such that $w^T A > 0$ and for $\delta \geq \delta'$, we have*

$$\|T_{MSH,\delta}\|_{1,w} \leq \|T_{MSH,\delta'}\|_{1,w}.$$

Moreover, if the Perron vector $w_{\delta'}$ of $T_{MSH,\delta'}^T$ satisfies $w_{\delta'} > 0$ and $A^T w_{\delta'} \geq 0$, then we also have

$$\rho(T_{MSH,\delta}) \leq \rho(T_{MSH,\delta'}).$$

(iv) *For any value of $\delta \geq 0$, $\rho(T_{MSH,\delta}) \leq \rho(T_{MSH,0})$.*

In the same way that we showed that the RMS method is faster than the RAS method (Theorem 3.5), we show that the MSH method is faster than the ASH method.

THEOREM 7.2. *Let A be a nonsingular M-matrix. Then, for any value $\delta \geq 0$, we have*

$$\|T_{MSH,\delta}\|_{1,w} \leq \|T_{ASH,\delta}\|_{1,w}.$$

Proof. By Lemma 2.3, we have that $M_{MSH,\delta} = A(I - T_{MSH,\delta})^{-1}$. Thus, using (35), we write

$$M_{MSH,\delta}^{-T} = A^{-T}(I - T_{MSH,\delta}^T) = \left(I - \prod_{i=p}^{1} (I - E_{i,0} M_{i,\delta}^{-T} A^T) \right) A^{-T}.$$

Since

$$\left(M_{ASH,\delta}^{-1}\right)^T = \sum_{i=1}^{p} \tilde{R}_{i,\delta}^T \left(A_{i,\delta}^{-1}\right)^T R_{i,\delta},$$

every ASH-splitting of A gives rise to a corresponding RAS-splitting of A^T [16]. We can then follow the proof of Theorem 3.5 verbatim considering the M-matrix A^T. ∎

We note that Theorems 7.1 and 7.2 hold if inexact solves on the subdomains are used; see section 4.

Combining the restricted and the harmonic versions we obtain the RASH and RMSH methods of [10] with

$$T_{RASH,\delta} = I - M_{RASH,\delta}^{-1} A = I - \sum_{i=1}^{p} \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} \tilde{R}_{i,\delta} A,$$

$$T_{RMSH,\delta} = I - M_{RMSH,\delta}^{-1} A = \prod_{i=p}^{1} (I - \tilde{R}_{i,\delta}^T A_{i,\delta}^{-1} \tilde{R}_{i,\delta} A).$$

However, the RASH method is, in general, not convergent as observed in [16]. The same holds for the RMSH method, as the following example illustrates.

Example 7.3. Consider the symmetric M-matrix

$$A = \begin{bmatrix} 4 & -1 & -1 & -1 \\ -1 & 4 & -1 & -1 \\ -1 & -1 & 3 & -1 \\ -1 & -1 & -1 & 3 \end{bmatrix}.$$

Let

$$R_{1,0} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}, \quad R_{2,0} = \begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix},$$

and let $R_{1,1} = R_{2,1} = I$. We then have

$$T_{RMSH,1} = (I - E_{2,0}A^{-1}E_{2,0}A)(I - E_{1,0}A^{-1}E_{1,0}A) = \begin{bmatrix} -1 & -1 & 1 & 1 \\ -1 & -1 & 1 & 1 \\ -3 & -3 & 2 & 2 \\ -3 & -3 & 2 & 2 \end{bmatrix}$$

with $\rho(T_{RMSH,1}) = 2$.

Other variants of the classical Schwarz methods are the weighted restricted Schwarz methods introduced by Cai and Sarkis [10]. For these modifications, one introduces weighted restriction operators $R^{\omega}_{i,\delta}$ which result from $R_{i,\delta}$ by replacing the entry 1 in column j by $1/k$, where k is the number of sets $S_{i,\delta}$ the component j belongs to, or more generally by some weights adding up to 1. With this notation, we define

$$\tilde{E}_{i,\delta} = R^T_{i,\delta} R^{\omega}_{i,\delta},$$

and we have

$$\sum \tilde{E}_{i,\delta} = \sum R^T_{i,\delta} R^{\omega}_{i,\delta} = I.$$

Then the weighted restricted additive Schwarz (WRAS) method and the weighted restricted multiplicative Schwarz (WRMS) method can be described in our notation by the iteration matrices

$$T_{WRAS,\delta} = I - M^{-1}_{WRAS}A = I - \sum_{i=1}^{p} (R^{\omega}_{i,\delta})^T A^{-1}_{i,\delta} R_{i,\delta} A = I - \sum_{i=1}^{p} \tilde{E}_{i,\delta} M^{-1}_{i,\delta} A \tag{36}$$

and

$$T_{WRMS,\delta} = \prod_{i=p}^{1} (I - (R^{\omega}_{i,\delta})^T A^{-1}_{i,\delta} R_{i,\delta} A) = \prod_{i=p}^{1} (I - \tilde{E}_{i,\delta} M^{-1}_{i,\delta} A), \tag{37}$$

respectively. Similarly weighted Schwarz methods with harmonic extensions can be defined. Observe that $(R^{\omega}_{i,\delta})^T A^{-1}_{i,\delta} R_{i,\delta} A$ is not a projection.

If we compare the WRMS method with the classical multiplicative Schwarz method we obtain the following result.

THEOREM 7.4. *Let A be nonsingular M-matrix. Then, for any $\delta \geq 0$, we have*

$$\rho(T_{MS,\delta}) \leq \rho(T_{WRMS,\delta}) \leq 1. \tag{38}$$

Proof. Following our analysis in the previous sections, we obtain that $T_{WRMS,\delta}$ induces a weak regular splitting of A. Since $\tilde{E}_{i,\delta} \leq E_{i,\delta}$ we get (38) using the same techniques as in the proof of Theorem 3.8. ∎

A similar result holds for the weighted MSH method.

8. Coarse grid corrections. It has been shown theoretically, and confirmed in practice, that a coarse grid correction improves the performance of the classical Schwarz methods. This coarse grid correction can be applied either additively or multiplicatively; see, e.g., [2, 11, 15, 23, 25]. This corresponds to a two-level scheme, the coarse correction being the second level. In [26], a coarse grid correction was used in connection with RAS iterations.

The analysis done for the RAS case in [16] applies almost without changes to the RMS methods of this paper, so we omit the details. All we will say is that in all cases where we have shown convergence the coarse grid correction can never degrade, and often improves, the convergence rate.

Acknowledgments. We thank Michele Benzi and Andreas Frommer for a careful reading of the manuscript and their suggestions which helped improve our presentation.

CONVERGENCE THEORY OF A NUMERICAL METHOD FOR SOLVING THE CHAPMAN–KOLMOGOROV EQUATION*

YUZHI CAI†

Abstract. A convergence theory has been established for a new numerical method for solving the Chapman–Kolmogorov equation [Y. Cai, *A Numerical Forecasting Procedure for Nonlinear Autoregressive Time Series Model*, manuscript, Department of Mathematics and Statistics, University of Surrey, Surrey, UK, 2001]. The theory has been applied to many types of nonlinear time series models in order to obtain m-step ahead predictive probability density function, predictive cumulative distribution function, predictive mean, and predictive variance.

Key words. convergence theory, numerical procedure, nonlinear autoregressive time series models, forecasting

1. Introduction.

The nonlinear autoregressive time series model of order k (NLAR(k)) is given by

$$x_t = \lambda(\mathbf{x}_{t-1}) + \xi_t\,, \tag{1}$$

where $\lambda : R^k \to R$, $\mathbf{x}_s = (x_s, x_{s-1}, \ldots, x_{s-k+1})^\top$ and $\{\xi_t\}$ is a sequence of independently, identically distributed (i.i.d.) random variables with zero mean and constant variance σ^2. Let $g(\cdot)$ be the pdf of ξ_t and $f(x_{t+m} \mid \mathbf{x}_t)$ denote the m-step ahead predictive pdf. For convenience, we do not use a subscript on f but rely on its argument subscripts to indicate the random variables involved. Then the Chapman–Kolmogorov equation can be written in the following form:

$$f(x_{t+m} \mid \mathbf{x}_t) = \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}\,, \tag{2}$$

where

$$f(x_{t+1} \mid \mathbf{x}_t) = g(x_{t+1} - \lambda(\mathbf{x}_t)).$$

The m-step ahead predictive pdf given the history up to time t can be obtained by solving (2) recursively. However, in most cases it is impossible to solve (2) directly. Standard numerical integration methods can be used, but they can be very time consuming if accuracy checking procedures are involved. Otherwise the accuracy can not be guaranteed.

Several authors have tried to use (2) to obtain predictive values. For example, Tong and Moeanaddin [9] studied multistep least squares prediction methods for nonlinear autoregressive models and illustrated these with both real and simulated data. Moeanaddin and Tong [5] also studied the numerical evaluation of distributions in nonlinear autoregressions based on (2). In calculating the m-step ahead predictive

†Department of Mathematics and Statistics, University of Surrey, Guildford, Surrey GU2 7XH, United Kingdom (Y.Cai@surrey.ac.uk).

pdf from (2) recursively, they used the Gauss–Hermite quadrature with weights and abscissae supplied by NAG routine D01BCF directly with no accuracy checking at all. Pemberton [6] presented a numerical integration method for self-exciting threshold autoregressive (SETAR) models. Davies, Pemberton, and Petruccelli [3] developed a package for identification, estimation, and forecasting for SETAR models, where the forecasting method is also based on (2) but the numerical integration is based on Sack and Donovan [7]. Again the accuracy cannot be guaranteed numerically.

Although it was pointed out by Davies, Pemberton, and Petruccelli [3] that the Chapman–Kolmogorov equation could be used for general nonlinear models like (1), they did not carry out any numerical or other investigations. To the author's knowledge, up to now no further work has appeared on this aspect.

However, recently Cai [1] presented a numerical method for solving the Chapman–Kolmogorov equation by introducing an unusual accuracy checking procedure into the algorithm. This numerical method can be used to obtain the predictive pdf, cumulative density function (cdf), mean, and variance directly for a range of nonlinear autoregressive time series models, rather than just SETAR models.

The purpose of this paper is to develop a convergence theory for the algorithm presented in Cai [1] and to apply this theory to a range of nonlinear time series models.

After reviewing the algorithm in section 2, we present the convergence theory in section 3. The implementation issues are discussed in section 4. In section 5, we apply the theory to a range of nonlinear time series models. Conclusion and comments are given in section 6.

2. The algorithm. For simplicity, we assume that ξ_t is normally distributed with mean zero and variance σ^2, denoted by $\xi_t \sim N(0, \sigma^2)$. The algorithm can be easily modified for other distribution functions. The analysis is given in detail for the predictive pdf but can be extended to the predictive cdf, mean, and variance. The numerical algorithm for the predictive pdf can be described as follows.

Initially for $m = 1$, we have

$$f(x_{t+1} \mid \mathbf{x}_t) = g(x_{t+1} - \lambda(\mathbf{x}_t)) \quad = \quad \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x_{t+1}-\lambda(\mathbf{x}_t))^2}{2\sigma^2}},$$

and no numerical integration is required.

For $m = 2$, we note that $f(x_{t+2} \mid \mathbf{x}_t)$ can be approximated by $\int_a^b f(x_{t+2} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}$, where $|a|$ and b are sufficiently large. Let

$$f_I = \sum_{i_1} f(x_{t+2} \mid \mathbf{x}_{t+1} \simeq y_{i_1}^I) w_{i_1}^I ,$$

where $\{w_{i_1}^I\}$ and $\{y_{i_1}^I\}$ are the weights and abscissae obtained by applying a numerical quadrature rule (QR) on 2^I equal subintervals of $[a, b]$ with weight function $f(x_{t+1} \mid \mathbf{x}_t)$, and $\mathbf{x}_{t+1} \simeq y_{i_1}^I$ means the first element of $\mathbf{x}_{t+1}$ is replaced by $y_{i_1}^I$. If

$$|f_I - f_{I-1}| < \epsilon , \tag{3}$$

where ϵ is the required accuracy, then we take f_{I-1} as the approximate value of $f(x_{t+2} \mid \mathbf{x}_t)$ and denote the corresponding weights and abscissae as $\{w_{i_1}\}$ and $\{y_{i_1}\}$. Otherwise it is necessary to continue doubling the number of subintervals until (3) is satisfied. Thus an approximate value of $f(x_{t+2} \mid \mathbf{x}_t)$ is given by

$$f(x_{t+2} \mid \mathbf{x}_t) \approx \sum_{i_1} f(x_{t+2} \mid \mathbf{x}_{t+1} \simeq y_{i_1}) w_{i_1} .$$

Repeating the above procedure for a range of values of x_{t+2}, we obtain a discrete version of $f(x_{t+2} \mid \mathbf{x}_t)$ on $[a, b]$.

Generally, for the case $m \geq 3$ we have

$$\begin{aligned} f(x_{t+m} \mid \mathbf{x}_t) &\approx \textstyle\int_a^b f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} \\ &\approx \textstyle\sum_{i_1} f(x_{t+m} \mid \mathbf{x}_{t+1} \simeq y_{i_1}) w_{i_1} \\ &\approx \cdots \\ &\approx \textstyle\sum_{i_1} \sum_{i_2} \cdots \sum_{i_{m-1}} f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y^I_{i_{m-1} \cdots i_2 i_1}) w^I_{i_{m-1} \cdots i_2 i_1} \cdots w_{i_1}, \end{aligned}$$

where $\{w^I_{i_{m-1} \cdots i_2 i_1}\}$ and $\{y^I_{i_{m-1} \cdots i_2 i_1}\}$ are the weights and abscissae obtained by applying the numerical QR on 2^I subintervals of $[a, b]$ with weight function $f(x_{t+m-1} \mid \mathbf{x}_{t+m-2} \simeq y_{i_{m-2} \cdots i_1})$, and $\mathbf{x}_{t+m-1} \simeq y^I_{i_{m-1} \cdots i_2 i_1}$ means that the first $m-1$ elements of $\mathbf{x}_{t+m-1}$ are replaced by $y^I_{i_{m-1} \cdots i_2 i_1}, \ldots, y_{i_1}$.

Let

$$f_I = \sum_{i_{m-1}} f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y^I_{i_{m-1} \cdots i_2 i_1}) w^I_{i_{m-1} \cdots i_2 i_1}.$$

Then if (3) holds, we find a new set of weights $\{w_{i_{m-1} \cdots i_2 i_1}\}$ and abscissae $\{y_{i_{m-1} \cdots i_2 i_1}\}$. By using both the old and the new sets of weights and abscissae, we obtain

$$f(x_{t+m} \mid \mathbf{x}_t) \approx \sum_{i_1} \cdots \sum_{i_{m-1}} f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1} \cdots i_2 i_1}) w_{i_{m-1} \cdots i_2 i_1} \cdots w_{i_1}.$$

As in the case $m = 2$, we can obtain a discrete version of $f(x_{t+m} \mid \mathbf{x}_t)$ on $[a, b]$.

The above idea can be summarized as follows. Let γ_1 and γ_2 be sufficiently large integers (which could be provided by the user such that the difference between the integration on $(-\infty, \infty)$ and $(-10^{\gamma_1}, 10^{\gamma_2})$ is negligible), $\widetilde{M}$ the largest number of steps ahead we wish to forecast, and N the total number of points on which we want to obtain the values of the predictive pdf $f(x_{t+m} \mid \mathbf{x}_t)$. Furthermore, let $\mathbf{w}$ be the set of weights and $\mathbf{y}$ the set of abscissae. Suppose we use an n-point QR for our numerical method. Here Sack and Donovan's [7] numerical integration method is used to provide weights and abscissae on a finite interval. Then our numerical method can be described in the algorithm `FORECAST` (see Table 1) and in the algorithm `Weight` (see Table 2), which is used to calculate the weights and abscissae for the numerical QR.

It is noted that an unusual accuracy checking procedure is involved in the above algorithm, that is, we check the accuracy only for every two-step ahead predictive pdf. In the next section, we will show that, as long as $|a|$ and b are sufficiently large and the number of subintervals of $[a, b]$ is large enough, then the above accuracy checking procedure is sufficient to guarantee the accuracy of any finite m-step ahead predictive pdf.

3. Convergence theory. In this section we establish a convergence theory for the numerical procedure described in section 2.

First we restate a standard result.

THEOREM 3.1. *Let $w(x) \geq 0$ be a weight function defined on $[-1, 1]$ with corresponding orthonormal polynomials $p^*_n(x)$, and let $k^*_n \neq 0$ be the leading coefficient of*

TABLE 1
FORECAST algorithm. FORECAST is used to obtain the m-step ahead predictive pdf for $m = 1, \ldots, \widetilde{M}$.

```
FORECAST(γ1, γ2, n, M̃, N)
   Set a = −10^γ1 , b = 10^γ2
   For i = 0, ..., N
       For m = 1, ..., M̃
           Set x_{t+m,i} = a + (b−a)i/N
   For i = 0, ..., N
       Calculate f̂(x_{t+1,i} | x_t) = g(x_{t+1,i} − λ(x_t))
       For m = 2, ..., M̃
           I = 1
           Weight(m, w, y, n, a, b, I, x_{t+m,i})
           Calculate
               f̂(x_{t+m,i} | x_t) =
               Σ_{i_1} ··· Σ_{i_{m−1}} f(x_{t+m,i} | x_{t+m−1} ≃ y_{i_{m−1}...i_1}) w_{i_{m−1}...i_1} ··· w_{i_1}
   For m = 1, ..., M̃
       For i = 0, ..., N
           Return f̂(x_{t+m,i} | x_t)
```

TABLE 2
Weight algorithm. Weight is used to obtain the weights and the abscissae of the numerical QR.

```
Weight(m, w, y, n, a, b, I, x_{t+m,i})
   Divide interval (a, b) into 2^I equal subintervals
   Calculate abscissae y^I_{i_{m−1} i_{m−2} ... i_1}
       and weights w^I_{i_{m−1}...i_1} on each subinterval
   If |f_I − f_{I−1}| < ε,
       put weights and abscissae corresponding to 2^{I−1}
           subintervals into w, y
       return w, y
   otherwise,
       I = I + 1
       Weight(m, w, y, n, a, b, I, x_{t+m,i})
```

$p_n^*(x)$. *Suppose that* $f(x) \in C^{2n}_{[-1,1]}$. *Then*

$$\int_{-1}^{1} f(t)w(t)dt - \sum_{k=1}^{n} w_k f(x_k) = \frac{f^{(2n)}(\eta)}{(2n)!k_n^{*\,2}}, \quad -1 < \eta < 1,$$

where $\{w_k\}$ *and* $\{x_k\}$ *are the weights and abscissae, respectively.*

Proof. The proof can be found in most numerical analysis books. For example, see Hildebrand [4, pp. 319–321]. □

THEOREM 3.2. *Assume that the conditions of Theorem* 3.1 *hold. Let the interval* $[a, b]$ *be divided into* M *equal subintervals by* $a = u_0 < u_1 < \cdots < u_M = b$. *If the above*

n-point Gauss QR is applied to each subinterval, then there exists $\eta \in (a,b)$ *such that*

$$|R_M(f)| \le \left(\frac{b-a}{2M}\right)^{2n} \frac{(b-a)}{2} \frac{1}{(2n)!k_n^2} \left|f^{(2n)}(\eta)\right| ,$$

where $k_n \neq 0$ *is the smallest leading coefficient of the orthonormal polynomials in each interval, and*

$$R_M(f) = \int_a^b f(x)w(x)dx - \frac{b-a}{2M} \sum_{i=1}^{M} \sum_{k=1}^{n} f\left(u_{i-1} + \frac{b-a}{2M}(1+y_{ki})\right) w_{ki} ,$$

where y_{ki} (w_{ki}) *is the* k*th abscissa (weight) in the* i*th subinterval. Furthermore,* $R_M(f) \to 0$ *as* $M \to \infty$.

Proof. By applying an n-point Gauss QR on each subinterval and by Theorem 3.1, we have

$$\begin{aligned} R_M(f) &= \sum_{i=1}^{M} \left\{ \frac{b-a}{2M} \int_{-1}^{1} f\left(u_{i-1} + \frac{b-a}{2M}(1+y)\right) w\left(u_{i-1} + \frac{b-a}{2M}(1+y)\right) dy \right. \\ &\qquad \left. - \sum_{k=1}^{n} \frac{b-a}{2M} f\left(u_{i-1} + \frac{b-a}{2M}(1+y_{ki})\right) w_{ki} \right\} \\ &= \sum_{i=1}^{M} \left(\frac{b-a}{2M}\right)^{2n+1} \frac{f^{(2n)}(\eta_i)}{(2n)!k_{ni}^2} , \qquad u_{i-1} < \eta_i < u_i , \end{aligned}$$

where $k_{ni} \neq 0$ is the leading coefficient of the nth orthonormal polynomial on the ith subinterval.

Since $f^{(2n)}(x) \in C_{[a,b]}$, we have $\left|f^{(2n)}(x)\right| \in C_{[a,b]}$ and therefore there exist M_1, M_2 such that

$$M_1 \le \frac{1}{M} \sum_{i=1}^{M} \left|f^{(2n)}(\eta_i)\right| \le M_2 .$$

Therefore, from the intermediate value theorem, there exists $\eta \in (a,b)$ such that

$$\frac{1}{M} \sum_{i=1}^{M} \left|f^{(2n)}(\eta_i)\right| = \left|f^{(2n)}(\eta)\right| .$$

Let $k_n^2 = \min_i\{k_{ni}^2\}$. Then we have

$$|R_M(f)| \le \left(\tfrac{b-a}{2M}\right)^{2n} \tfrac{1}{(2n)!k_n^2} \tfrac{b-a}{2M} \textstyle\sum_{i=1}^{M} \left|f^{(2n)}(\eta_i)\right| = \left(\tfrac{b-a}{2M}\right)^{2n} \tfrac{1}{(2n)!k_n^2} \tfrac{b-a}{2} \left|f^{(2n)}(\eta)\right|$$

and

$$R_M(f) \to 0 \quad \text{as } M \to \infty. \qquad \square$$

Theorem 3.2 tells us that the numerical result of the integration on $[a,b]$ will converge to the theoretical value as the number of subintervals of $[a,b]$ tends to infinity. However, Theorem 3.2 is a rather general result on a finite interval. To apply this general result to our case, we also need to deal with the truncated error.

Let

$$\epsilon_{t+j,m-1} = \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+j}) f(x_{t+j} \mid \mathbf{x}_{t+j-1}) dx_{t+j} - \int_{a}^{b} f(x_{t+m} \mid \mathbf{x}_{t+j}) f(x_{t+j} \mid \mathbf{x}_{t+j-1}) dx_{t+j},$$

where a, b are the two chosen constants and $j = 1, 2, \ldots, m-1$. Then for sufficiently large values of $|a|$, b with $a < 0$, $b > 0$, the value of $\epsilon_{t+j,m-1}$ can be sufficiently small and greater than zero for all possible values of j. In the following, we will denote the truncation error by ϵ, the error due to numerical calculation by R, and the overall error $\epsilon + R$ by $\dot{\epsilon}$, all with appropriate subindices.

LEMMA 3.3.

$$\sum_{i_1} \sum_{i_2} \cdots \sum_{i_{m-1}} w_{i_{m-1} \ldots i_1} \ldots w_{i_2 i_1} w_{i_1} \leq 1 \tag{4}$$

and $0 < w_{i_{m-1} \ldots i_1}, \ldots, w_{i_1} < 1$, *where* $w_{i_{m-1} \ldots i_1}, \ldots, w_{i_1}$ *are obtained from the* `Weight` *algorithm (see Table* 2*).*

Proof. This is easily proved by induction, since any pdf must integrate to one. □

THEOREM 3.4. *Suppose that for* $l = 1, 2, \ldots, m-1$, *where* $m > 1$, $f(x_{t+m} \mid \mathbf{x}_{t+l})$ *has continuous* 2*nth derivatives about* x_{t+l} *on* $(-\infty, \infty)$. *Let* $\underline{m} = \min_k\{m_k\}$, *where* m_k *is the largest number of subintervals among all the numerical integrations for obtaining the* k*-step ahead predictive pdf. Then at any point of* x_{t+m}, *and for any* $\epsilon > 0$, *there exist* $a < 0$, $b > 0$, $\underline{M} > 0$ *such that, whenever* $\underline{m} \geq \underline{M}$,

$$\left| \widetilde{E}(f, x_{t+m}) \right| \leq \epsilon,$$

where

$$\widetilde{E}(f, x_{t+m}) = \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \sum_{i_1} \sum_{i_2} \cdots \sum_{i_{m-1}} f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1} \ldots i_1}) w_{i_{m-1} \ldots i_1} \ldots w_{i_1}.$$

Proof. Since $f^{(2n)}(x_{t+m} \mid \mathbf{x}_{t+l})$ is continuous about x_{t+l} on $(-\infty, \infty)$, where

$$f^{(2n)}(x_{t+m} \mid \mathbf{x}_{t+l}) = \frac{\partial^{2n} f(x_{t+m} \mid \mathbf{x}_{t+l})}{\partial x_{t+l}^{2n}},$$

we have for any $[a_1, b_1] \subset (-\infty, \infty)$ that there exists a constant A such that

$$\mid f^{(2n)}(x_{t+m} \mid \mathbf{x}_{t+l}) \mid \leq A$$

for $x_{t+l} \in [a_1, b_1]$, $l = 1, \ldots, m-1$, $m > 1$. Now for $m = 1$, $f(x_{t+1} \mid \mathbf{x}_t) = g(x_{t+1} - \lambda(\mathbf{x}_t))$, so there is no need to use the numerical QR.

For $m = 2$,

$$\sum_{i_1} f(x_{t+2} \mid \mathbf{x}_{t+1} \simeq y_{i_1}) w_{i_1} = \int_{-\infty}^{\infty} f(x_{t+2} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \dot{\epsilon}_{t+1}^{1},$$

where

$$\dot{\epsilon}^1_{t+1} = R_{t+1,1} + \epsilon_{t+1,1}\,,$$

$$R_{t+1,1} = \int_{a_1}^{b_1} f(x_{t+2} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \sum_{i_1} f(x_{t+2} \mid \mathbf{x}_{t+1} \simeq y_{i_1}) w_{i_1}\,,$$

$$\epsilon_{t+1,1} = \int_{-\infty}^{\infty} f(x_{t+2} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \int_{a_1}^{b_1} f(x_{t+2} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}\,.$$

It follows from Theorem 3.2 that there exist $\eta_1^{(1)} \in (a_1, b_1)$ such that

$$\begin{aligned} |R_{t+1,1}| &\le \left(\frac{b_1 - a_1}{2m_1}\right)^{2n} \frac{b_1 - a_1}{2(2n)! k_n^2} \left| f^{(2n)}(x_{t+2} \mid \mathbf{x}_{t+1} \simeq \eta_1^{(1)}) \right| \\ &\le \left(\frac{b_1 - a_1}{2m_1}\right)^{2n} \frac{b_1 - a_1}{2(2n)! k_n^2} A = \overline{R}_{t+1,1}, \qquad \text{say,} \end{aligned}$$

where

$$f^{(2n)}(x_{t+2} \mid \mathbf{x}_{t+1} \simeq \eta_1^{(1)}) = \frac{\partial^{2n} f(x_{t+2} \mid \mathbf{x}_{t+1})}{\partial x_{t+1}^{2n}} \mid_{x_{t+1} = \eta_1^{(1)}}$$

and m_1 is the number of subintervals used for the integration.

Generally, for $m \ge 3$, we have

$$\begin{aligned} &\textstyle\sum_{i_1} \sum_{i_2} \cdots \sum_{i_{m-1}} f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1} \ldots i_1}) w_{i_{m-1} \ldots i_1} \ldots w_{i_1} \\ &= \textstyle\int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \dot{\epsilon}_{t+1}^{m-1} - \sum_{i_1} w_{i_1} \dot{\epsilon}_{t+2}^{i_1} \\ &\quad - \cdots - \textstyle\sum_{i_1} \cdots \sum_{i_{m-2}} w_{i_{m-2}} \ldots w_{i_1} \dot{\epsilon}_{t+m-1}^{i_{m-2} \ldots i_1}\,, \end{aligned}$$

where

$$\dot{\epsilon}_{t+1}^{m-1} = R_{t+1,m-1} + \epsilon_{t+1,m-1}$$

and for $k = 2, 3, \ldots, m-1$

$$\dot{\epsilon}_{t+k}^{i_{k-1} \ldots i_1} = R_{t+k}^{i_{k-1} \ldots i_1} + \epsilon_{t+k}^{i_{k-1} \ldots i_1}$$

and

$$R_{t+1,m-1} = \int_{a_1}^{b_1} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} - \sum_{i_1} f(x_{t+m} \mid \mathbf{x}_{t+1} \simeq y_{i_1}) w_{i_1}\,,$$

$$\begin{aligned} \epsilon_{t+1,m-1} &= \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} \\ &\quad - \int_{a_1}^{b_1} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}\,, \end{aligned}$$

$$\begin{aligned} R_{t+k}^{i_{k-1} \cdots i_1} &= \int_{a_1}^{b_1} f(x_{t+m} \mid \mathbf{x}_{t+k}) f(x_{t+k} \mid \mathbf{x}_{t+k-1} \simeq y_{i_{k-1} \cdots i_1}) dx_{t+k} \\ &\quad - \sum_{i_k} f(x_{t+m} \mid \mathbf{x}_{t+k} \simeq y_{i_k \cdots i_1}) w_{i_k \cdots i_1}\,, \end{aligned}$$

$$\begin{aligned} \epsilon_{t+k}^{i_{k-1} \ldots i_1} &= \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+k}) f(x_{t+k} \mid \mathbf{x}_{t+k-1} \simeq y_{i_{k-1} \ldots i_1}) dx_{t+k} \\ &\quad - \int_{a_1}^{b_1} f(x_{t+m} \mid \mathbf{x}_{t+k}) f(x_{t+k} \mid \mathbf{x}_{t+k-1} \simeq y_{i_{k-1} \ldots i_1}) dx_{t+k}\,. \end{aligned}$$

Then it follows from Theorem 3.2 that, for $k = 2, 3, \dots, m-1$, there exist $\eta_{i_{k-1}\cdots i_1}$ and $\eta_1^{(m-1)} \in (a_1, b_1)$ such that

$$\begin{aligned}\left|R_{t+k}^{i_{k-1},\cdots,i_1}\right| &\le \left(\tfrac{b_1-a_1}{2m_{i_{k-1}\cdots i_1}}\right)^{2n} \tfrac{b_1-a_1}{2(2n)!k_n^2}\left|f^{(2n)}(x_{t+m} \mid \mathbf{x}_{t+k} \simeq \eta_{i_{k-1}\dots i_1})\right| \\ &\le \left(\tfrac{b_1-a_1}{2m_{i_{k-1}\cdots i_1}}\right)^{2n} \tfrac{b_1-a_1}{2(2n)!k_n^2} A = \overline{R}_{t+k}^{i_{k-1}\cdots i_1}, \quad \text{say,}\end{aligned}$$

and

$$\begin{aligned}|R_{t+1,m-1}| &\le \left(\frac{b_1-a_1}{2m_1}\right)^{2n} \frac{b_1-a_1}{2(2n)!k_n^2}\left|f^{(2n)}(x_{t+m} \mid \mathbf{x}_{t+1} \simeq \eta_1^{(m-1)})\right| \\ &\le \left(\frac{b_1-a_1}{2m_1}\right)^{2n} \frac{b_1-a_1}{2(2n)!k_n^2} A = \overline{R}_{t+1,m-1}, \quad \text{say.}\end{aligned}$$

Therefore

$$\begin{aligned}\left|\widetilde{E}(f, x_{t+m})\right| \le \left|\dot{\epsilon}_{t+1}^{m-1}\right| &+ \sum_{i_1}\left|\dot{\epsilon}_{t+2}^{i_1}\right| w_{i_1} + \cdots \\ &+ \sum_{i_1}\sum_{i_2}\cdots\sum_{i_{m-2}}\left|\dot{\epsilon}_{t+m-1}^{i_{m-2}\dots i_1}\right| w_{i_{m-2}\dots i_1}\cdots w_{i_1}.\end{aligned}$$

For $k = 2, 3, \dots, m-1$, set

$$\hat{\epsilon}_{t+k} = \max_{i_{k-1},\cdots,i_1}\left\{\left|\epsilon_{t+k}^{i_{k-1},\cdots,i_1}\right|\right\}, \qquad \hat{R}_{t+k} = \max_{i_{k-1},\cdots,i_1}\left\{\overline{R}_{t+k}^{i_{k-1},\cdots,i_1}\right\},$$

$$\hat{\epsilon}_{t+1} = |\epsilon_{t+1,m-1}|, \qquad \hat{R}_{t+1} = |R_{t+1,m-1}|.$$

Then it follows from Lemma 3.3 that

$$\begin{aligned}&\left|\widetilde{E}(f, x_{t+m})\right| \le |\epsilon_{t+1,m-1}| + |R_{t+1,m-1}| + \textstyle\sum_{i_1}\left(\left|\epsilon_{t+2}^{i_1}\right| + \left|R_{t+2}^{i_1}\right|\right) w_{i_1} + \cdots \\ &\qquad + \textstyle\sum_{i_1}\cdots\sum_{i_{m-2}}\left(\left|\epsilon_{t+m-1}^{i_{m-2}\dots i_1}\right| + \left|R_{t+m-1}^{i_{m-2}\dots i_1}\right|\right) w_{i_{m-2}\dots i_1}\cdots w_{i_1} \qquad (5) \\ &\qquad \le \textstyle\sum_{k=1}^{m-1}\hat{\epsilon}_{t+k} + \sum_{k=1}^{m-1}\hat{R}_{t+k} = \widetilde{\epsilon} + \widetilde{R}, \ \text{ say.}\end{aligned}$$

From the definition of $\hat{\epsilon}_{t+k,}$ we have

$$\hat{\epsilon}_{t+k} \to 0 \quad \text{as} \quad a_1 \to -\infty, \quad b_1 \to \infty.$$

Therefore, for any $\epsilon > 0$, there exist $a < 0, b > 0$ such that $\widetilde{\epsilon} < \frac{\epsilon}{2}$.

From the definition of $\overline{R}_{t+k}^{i_{k-1},\cdots,i_1}$ we have

$$\overline{R}_{t+k}^{i_{k-1},\cdots,i_1} \to 0 \quad \text{as} \qquad m_{i_{k-1},\cdots,i_1} \to \infty.$$

If we let

$$m_k = \max_{i_{k-1},\cdots,i_1}\left\{m_{i_{k-1},\cdots,i_1}\right\},$$

then from the definition of $\hat{R}_{t+k}$ we have $\hat{R}_{t+k} \to 0$ as $m_k \to \infty$. It follows that if $\underline{m} = \min_k\{m_k\}$, then

$$\widetilde{R} \to 0 \quad \text{as} \quad \underline{m} \to \infty.$$

That is, given $\epsilon > 0$, there exists $\underline{M} > 0$ such that, whenever $\underline{m} > \underline{M}$, $\widetilde{R} < \frac{\epsilon}{2}$.

Therefore, for any $\epsilon > 0$, there exist $a < 0, b > 0$, $\underline{M} > 0$ such that, whenever $\underline{m} > \underline{M}$,

$$\left|\widetilde{E}(f, x_{t+m})\right| \leq \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon\,. \qquad \square$$

It follows from (5) that the following corollary holds.

COROLLARY 3.5. *If for $k = 1, 2, \ldots, m-1$, we have $\hat{R}_{t+k} < \epsilon$ and $\hat{\epsilon}_{t+k} < \epsilon$, then* $|\widetilde{E}(f, x_{t+m})| \leq 2(m-1)\epsilon$.

Theorem 3.4 tells us that the numerical value obtained from our algorithm will converge to

$$\int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}$$

as $a \to -\infty$, $b \to \infty$ and the number of subintervals of $[a, b]$ tends to infinity. Corollary 3.5 shows that when m increases, the upper bound of the error will usually also increase. However, for any given finite value of m, we can still control the accuracy by appropriate choice of ϵ. They also show that as long as $|a|, b$ are sufficiently large and the number of subintervals of $[a, b]$ is large enough, such that the numerical result of every two-step ahead predictive pdf converges to the corresponding theoretical result, then the numerical result of any finite m-step ahead predictive pdf converges to the corresponding theoretical result. This justifies the accuracy checking procedure in our numerical method.

Note that the above results hold only at one value of x_{t+m}. The following theorem indicates that, under certain conditions, the accuracy can also be guaranteed at other values of x_{t+m} by using the same set of weights and abscissae.

THEOREM 3.6. *Suppose $f(x_{t+m} \mid \mathbf{x}_{t+m-1})$ is continuous about $x_{t+m} \in (-\infty, \infty)$, and we use Theorem 3.4 to calculate the value of $f(x^*_{t+m} \mid \mathbf{x}_t)$ such that*

$$\left|\widetilde{E}(f, x^*_{t+m})\right| < 2(m-1)\epsilon\,. \tag{6}$$

Then there exists a region $\widetilde{D}(x^*_{t+m})$ centered at x^*_{t+m} such that

$$\left|\widetilde{E}(f, x_{t+m})\right| < 6(m-1)\epsilon$$

holds for any $x_{t+m} \in \widetilde{D}(x^*_{t+m})$.

Proof.

$$\begin{aligned}
&\left|\widetilde{E}(f, x_{t+m})\right| \\
&\leq \textstyle\sum_{i_1} \cdots \sum_{i_{m-1}} \left| f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1} \ldots i_1}) \right. \\
&\quad \left. - f(x^*_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1} \ldots i_1}) \right| w_{i_{m-1} \ldots i_1} \cdots w_{i_1} \\
&\quad + \left|\widetilde{E}(f, x^*_{t+m})\right| + \textstyle\int_{-\infty}^{\infty} \left| f(x^*_{t+m} \mid \mathbf{x}_{t+1}) - f(x_{t+m} \mid \mathbf{x}_{t+1}) \right| f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} \\
&= I_1 + I_2 + I_3, \text{ say.}
\end{aligned}$$

Consider first I_1. Since $f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1}\ldots i_1})$ is continuous at any $x_{t+m} \in (-\infty, \infty)$, then for any $\epsilon > 0$ there exists $\delta > 0$ such that, whenever $\left|x_{t+m} - x^*_{t+m}\right| < \delta$,

$$\left|f(x_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1}\ldots i_1}) - f(x^*_{t+m} \mid \mathbf{x}_{t+m-1} \simeq y_{i_{m-1}\ldots i_1})\right| < 2(m-1)\epsilon\,.$$

It therefore follows from Lemma 3.3 that $I_1 < 2(m-1)\epsilon$.

For I_2, it follows from (6) that

$$I_2 = \left|\widetilde{E}(f, x^*_{t+m})\right| < 2(m-1)\epsilon\,.$$

For I_3, note that for $k = 1, 2, \ldots, m-2$ we have

$$\begin{aligned}&\left|f(x^*_{t+m} \mid \mathbf{x}_{t+k}) - f(x_{t+m} \mid \mathbf{x}_{t+k})\right| \\ &\le \textstyle\int_{-\infty}^{\infty} \left|f(x^*_{t+m} \mid \mathbf{x}_{t+k+1}) - f(x_{t+m} \mid \mathbf{x}_{t+k+1})\right| f(x_{t+k+1} \mid \mathbf{x}_{t+k}) dx_{t+k+1},\end{aligned}$$

and whenever $\left|x^*_{t+m} - x_{t+m}\right| < \delta$ we have

$$\left|f(x^*_{t+m} \mid \mathbf{x}_{t+m-1}) - f(x_{t+m} \mid \mathbf{x}_{t+m-1})\right| < 2(m-1)\epsilon\,.$$

Therefore

$$\begin{aligned}&\left|f(x^*_{t+m} \mid \mathbf{x}_{t+m-2}) - f(x_{t+m} \mid \mathbf{x}_{t+m-2})\right| \\ &\le 2(m-1)\epsilon \textstyle\int_{-\infty}^{\infty} f(x_{t+m-1} \mid \mathbf{x}_{t+m-2}) dx_{t+m-1} = 2(m-1)\epsilon\,.\end{aligned}$$

It is easy to see that for any $k = 1, 2, \ldots, m-1$ we have

$$\left|f(x^*_{t+m} \mid \mathbf{x}_{t+k}) - f(x_{t+m} \mid \mathbf{x}_{t+k})\right| \le 2(m-1)\epsilon\,. \tag{7}$$

Hence, by substituting (7) into I_3 we have

$$\begin{aligned}I_3 &= \textstyle\int_{-\infty}^{\infty} \left|f(x^*_{t+m} \mid \mathbf{x}_{t+1}) - f(x_{t+m} \mid \mathbf{x}_{t+1})\right| f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} \\ &\le 2(m-1)\epsilon \textstyle\int_{-\infty}^{\infty} f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} = 2(m-1)\epsilon\,.\end{aligned}$$

In summary, for any $\epsilon > 0$ there exists $\delta > 0$ such that whenever $|x_{t+m} - x^*_{t+m}| < \delta$ we have

$$\left|\widetilde{E}(f, x_{t+m})\right| \le I_1 + I_2 + I_3 = 6(m-1)\epsilon\,.$$

Therefore we can take

$$\widetilde{D}(x^*_{t+m}) = \{x_{t+m} : \ |x_{t+m} - x^*_{t+m}| < \delta\}$$

as required. □

Theorem 3.6 tells us that, with little loss of accuracy, we can use the same weights and abscissae to calculate the values of the predictive pdf $f(x_{t+m} \mid \mathbf{x}_t)$ at different points, say, x_{t+m} and x^*_{t+m}, as long as x_{t+m} and x^*_{t+m} are "close" enough. That means, in order to guarantee the accuracy on the whole interval $[a, b]$, we need to check the accuracy at a number of points. However, if the number of the points is infinite, we would not be able to do so. The following theorem solves this problem theoretically.

THEOREM 3.7. *Suppose* $f(x_{t+m} \mid \mathbf{x}_{t+m-1})$ *is continuous on* $(-\infty, \infty)$ *about* x_{t+m} *and that, for any* $x^*_{t+m} \in [a,b]$, $|\widetilde{E}(f, x^*_{t+m})| < 2(m-1)\epsilon$. *Then there exists a finite number of regions* $\widetilde{D}(x^{(i)}_{t+m})$ *centered at* $x^{(i)}_{t+m} \in [a,b]$, $i = 1, \ldots, l$, *such that* $[a,b] \subset \bigcup_{i=1}^{l} \widetilde{D}(x^{(i)}_{t+m})$ *and for any* $x_{t+m} \in [a,b]$ *we have*

$$\left|\widetilde{E}(f, x_{t+m})\right| \leq 6(m-1)\epsilon\,.$$

Proof. It follows from Theorem 3.6 that for any $x^*_{t+m} \in [a,b]$ there exists a region $\widetilde{D}(x^*_{t+m})$ centered at x^*_{t+m} such that for any $x_{t+m} \in \widetilde{D}(x^*_{t+m})$

$$\left|\widetilde{E}(f, x_{t+m})\right| < 6(m-1)\epsilon\,. \tag{8}$$

Therefore $[a,b] \subset \bigcup \widetilde{D}(x^*_{t+m})$. Then it follows from the Heine–Borel theorem that there exist a finite number of regions $\widetilde{D}(x^{(i)}_{t+m})$, say, $i = 1, \ldots, l$, such that $[a,b] \subset \bigcup_{i=1}^{l} \widetilde{D}(x^{(i)}_{t+m})$ and (8) holds for any $x_{t+m} \in [a,b]$. □

Theorem 3.7 tells us that we can find a finite number of nonoverlapping sets of weights and abscissae such that the numerical value of $f(x_{t+m} \mid \mathbf{x}_t)$ can be calculated at any $x_{t+m} \in [a, b]$. As we have seen from the above results, the error bound grows linearly with the lead time m. Therefore, in order to achieve the same accuracy we should decrease ϵ as m increases. However, given ϵ all the errors are upper bounded by $6(\widetilde{M}-1)\epsilon$, where $\widetilde{M}$ is the max-value of m. Further discussion about applications of the results will be given in the next section.

We have established a convergence theory for the numerical method for solving the Chapman–Kolmogorov equation in the case of the predictive pdf. It is not difficult to develop the corresponding theory for the predictive cdf, mean, and variance, because we can derive the required formulae as follows.

For the predictive cdf, we have

$$F(x_{t+m} \mid \mathbf{x}_t) = \int_{-\infty}^{\infty} F(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}, \quad m = 2, 3, \ldots,$$

$$F(x_{t+1} \mid \mathbf{x}_t) = \int_{-\infty}^{x_{t+1}} f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} = \int_{-\infty}^{x_{t+1}} g(x_{t+1} - \lambda(\mathbf{x}_t)) dx_{t+1}.$$

For the predictive mean, we have

$$E(x_{t+m} \mid \mathbf{x}_t) = \int_{-\infty}^{\infty} E(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}, \qquad m = 2, 3, \ldots,$$

$$E(x_{t+1} \mid \mathbf{x}_t) = \lambda(\mathbf{x}_t).$$

For the predictive variance, we have

$$\operatorname{var}(x_{t+m} \mid \mathbf{x}_t) = E(x^2_{t+m} \mid \mathbf{x}_t) - E^2(x_{t+m} \mid \mathbf{x}_t),$$

$$E(x^2_{t+m} \mid \mathbf{x}_t) = \int_{-\infty}^{\infty} E(x^2_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}, \quad m = 2, 3, \ldots,$$

$$\operatorname{var}(x_{t+1} \mid \mathbf{x}_t) = \sigma^2(\mathbf{x}_t),$$

$$E(x_{t+1} \mid \mathbf{x}_t) = \lambda(\mathbf{x}_t), \quad E(x^2_{t+1} \mid \mathbf{x}_t) = \sigma^2(\mathbf{x}_t) + \lambda^2(\mathbf{x}_t).$$

It is seen that the predictive cdf, mean, and variance can also be obtained by solving similar equations recursively. We do not give any details here for reasons of space. However, it is worth pointing out that the predictive pdf obtained from the numerical method is only a discrete version of the theoretical predictive pdf. We could use this discrete pdf to estimate the predictive cdf, mean, and variance. Alternatively, we could also use the numerical method to obtain a discrete version of the predictive cdf or find the predictive mean and variance. As long as the functions $F(x_{t+m} \mid \mathbf{x}_{t+l})$, $E(x_{t+m} \mid \mathbf{x}_{t+l})$, and $E(x_{t+m}^2 \mid \mathbf{x}_{t+l})$ satisfy similar conditions to those satisfied by $f(x_{t+m} \mid \mathbf{x}_{t+l})$, for $l = 1, 2, \ldots, m-1$ and $m > 1$, then the accuracy check procedure guarantees their accuracy too.

4. Implementation issues. In the previous section we have presented the convergence theory of our numerical integration method for solving the Chapman–Kolmogorov equation. Theoretically, under certain conditions, the numerical results will converge to the true values. However, several practical issues in applying the theory will be discussed in this section.

The first question is how to choose a and b. Generally, $|a|$ and b should be chosen as large as possible such that the difference between the integrations on $(-\infty, \infty)$ and $[a, b]$ is negligible. In our examples Cai [1] we take $\gamma_1 = \gamma_2 = 7$, which gives $a = -10^7$ and $b = 10^7$. Our experience indicates that, for the models we studied, the truncated errors are negligible for such large values of $|a|$ and b.

Since the metric space $(-\infty, \infty)$ is complete, it follows from Theorem 3.4 and its corollaries that we can check the accuracy according to (3). This is an unusual accuracy checking procedure, but it guarantees the accuracy and increases the speed of the calculations.

We have investigated different ways of obtaining the sets of weights and abscissae. Since our main purpose here is to obtain a discrete version of the m-step ahead predictive pdf, for $m = 1, 2, \ldots, \widetilde{M}$, we could divide the interval $[a, b]$ into N equal subintervals and then calculate $f(x_{t+m} \mid \mathbf{x}_t)$ at each end point of the subintervals with the accuracy checking procedure applied. Hence, as long as N is large enough, we can obtain a good discrete version of $f(x_{t+m} \mid \mathbf{x}_t)$ on $[a, b]$. In our examples in Cai [1] we take $N = 50$, which works very well and the results are very good.

We also carried out the following experiment. Since $f(x_{t+m} \mid \mathbf{x}_{t+m-1})$ is a normal density, given $\epsilon > 0$, we can actually write a program and find the value of a_i such that $a = a_0 < a_1 < \cdots < a_N = b$ and $|f(a_i \mid \mathbf{x}_{t+m-1}) - f(a_{i-1} \mid \mathbf{x}_{t+m-1})| < \epsilon$ for $i = 1, 2, \ldots, N$. Theorem 3.7 guarantees that N must be finite. Of course, in this case the lengths of the subintervals are not the same. Then we check the accuracy at each point a_i. Theorem 3.6 guarantees that we can also calculate $f(x_{t+m} \mid \mathbf{x}_t)$ for any $x_{t+m} \in (a_{i-1}, a_i)$ by using the set of weights and abscissae obtained at a_{i-1} with the desired accuracy. The disadvantage of this method is that for a very small value of ϵ, N can be very large, so the calculation can be time consuming. It is hoped that, with the development of modern technology, this will not be a serious problem in the near future.

In practice, what value of n in the n-point QR should be used? Because the accuracy is checked by doubling the number of subintervals, the length of the subintervals is usually small. Our experience shows that two- or three-point Gauss QR is good enough for satisfactory results. The accuracy of all the results in Cai [1] is so high that it is difficult to distinguish the numerical and theoretical values by graphs. All the results presented in the tables in Cai [1] show that our procedure works very well.

5. Applications to specific NLAR models. In this section, we will show that a range of NLAR time series models satisfy the conditions of Theorem 3.4, so the numerical procedure can be applied to these models. All the models mentioned below can be found in Tong [8].

Consider the following general nonlinear time series model:

(9)
$$x_t = \left(a_0 + \sum_{i=1}^{k} a_i x_{t-i}\right) + \left((b_0 G(u) + d_0 H(v)) + \sum_{i=1}^{k} (b_i G(u) + d_i H(v))\, x_{t-i}\right) + \xi_t\,,$$

where $k \geq 0$ is the order of the model, ξ_t are i.i.d. $N(0, \sigma^2)$ random variables, and u and v are functions of x_{t-d}, where $d \geq 1$ is the delay of the model. Then different models can be derived from (9) as follows.

1. Let $d_i = 0$ for $i = 0, 1, \ldots, k$, $u = (x_{t-d} - r)/c$, $G(u) = \Phi(u)$, where $\Phi(u)$ is the standard normal distribution function. Then we obtain a smooth threshold autoregressive model (STAR).
2. Let $d_i = 0$ for $i = 0, 1, \ldots, k$, $u = r_1(x_{t-d} - c_1)$, $r_1 > 0$, $G(u) = (1 + e^{-u})^{-1}$. Then we obtain a logistic STAR (LSTAR) model.
3. Let $b_i = 0$ for $i = 0, 1, \ldots, k$, $v = r_2(x_{t-d} - c_2)^2$, $r_2 > 0$, $H(v) = 1 - e^{-v}$. Then we obtain an exponential STAR (ESTAR) model.
4. Let $u, G(u)$ and $v, H(v)$ be given by 2 and 3 above. Then we obtain a hybrid STAR (HYSTAR) model.
5. Let $b_0 = 0$ and $d_i = 0$ for $i = 0, 1, \ldots, k$, $u = cx_{t-d}^2$, $G(u) = e^{-u}$. Then we obtain an exponential autoregressive (EXPAR) model.

For the above models, $g(\cdot)$ is a normal density function, g, G, H, u, $v \in C^{\infty}_{[a,b]}$. Furthermore, it follows from the Chapman–Kolmogorov equation that, for any $1 \leq l \leq m-2$,

$$f(x_{t+m} \mid \mathbf{x}_{t+l}) = \int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+m-1}) \ldots f(x_{t+l+1} \mid \mathbf{x}_{t+l}) dx_{t+m-1} \ldots dx_{t+l+1}\,.$$

Therefore, the integrand $f(x_{t+m} \mid \mathbf{x}_{t+m-1}) \ldots f(x_{t+l+1} \mid \mathbf{x}_{t+l}) \in C^{\infty}_{[a,b]}$. It can be shown that

$$\int_{-\infty}^{\infty} \cdots \int_{-\infty}^{\infty} \frac{\partial^{2n+1} f(x_{t+m} \mid \mathbf{x}_{t+m-1}) \ldots f(x_{t+l+1} \mid \mathbf{x}_{t+l})}{\partial x_{t+l}^{2n+1}} dx_{t+m-1} \ldots dx_{t+l+1} < \infty.$$

Therefore $f(x_{t+m} \mid \mathbf{x}_{t+l}) \in C^{2n}_{[a,\,b]}$ (for $1 \leq l \leq m-2$) about x_{t+l}. On the other hand, since $f(x_{t+m} \mid \mathbf{x}_{t+m-1})$, $F(x_{t+m} \mid \mathbf{x}_{t+m-1})$, $E(x_{t+m} \mid \mathbf{x}_{t+m-1})$, and $E(x_{t+m}^2 \mid \mathbf{x}_{t+m-1})$ are all continuous about $x_{t+m} \in (-\infty, \infty)$, we can use the methods mentioned in the previous sections to obtain forecast distributions for the above models.

Note that in the STAR model there is a parameter d. The predictive pdfs for up to d steps are easily shown to be

$$f(x_{t+m} \mid \mathbf{x}_t) = \frac{1}{\sigma_m \sqrt{2\pi}} e^{-\frac{(x_{t+m} - \mu_m)^2}{2\sigma_m^2}}\,, \qquad m \leq d\,,$$

where $\mu_m = E(x_{t+m} \mid \mathbf{x}_t)$, $\sigma_m^2 = \mathrm{var}(x_{t+m} \mid \mathbf{x}_t)$. Therefore, as long as we can obtain μ_m, σ_m, we can obtain the whole predictive pdf and cdf for $m \leq d$.

The following theorem provides the formulae for calculating the predictive means and variances when $m \leq d$. The detailed proof can be found in Cai [2].

THEOREM 5.1. *For the STAR model let $m \leq d$ and*

$$\widehat{x}_t(l) = \begin{cases} E\left(x_{t+l} \mid \mathbf{x}_t\right), & l > 0, \\ x_{t+l}, & l \leq 0. \end{cases}$$

Then the following hold:

$$\widehat{x}_t(m) = \left(a_0 + \sum_{i=1}^{k} a_i \widehat{x}_t(m-i)\right) + \left(b_0 + \sum_{i=1}^{k} b_i \widehat{x}_t(m-i)\right) \Phi\left(\frac{x_{t+m-d} - r}{c}\right)$$

and

$$\operatorname{var}(x_{t+m} \mid \mathbf{x}_t) = \sigma^2 \sum_{i=1}^{m} \left(\alpha_i^{(m)}\right)^2 ,$$

where

$$\begin{aligned} \alpha_m^{(m)} &= 1\,, \\ \alpha_{m-1}^{(m)} &= a_1 \alpha_{m-1}^{(m-1)} + b_1 \alpha_{m-1}^{(m-1)} \Phi\left(\tfrac{x_{t+m-d}-r}{c}\right)\,, \\ &\vdots \\ \alpha_{m-l}^{(m)} &= \textstyle\sum_{i=1}^{l} a_i \alpha_{m-l}^{(m-i)} + \left(\sum_{i=1}^{l} b_i \alpha_{m-l}^{(m-i)}\right) \Phi\left(\tfrac{x_{t+m-d}-r}{c}\right)\,, \\ &\vdots \\ \alpha_1^{(m)} &= \textstyle\sum_{i=1}^{m-1} a_i \alpha_1^{(m-i)} + \left(\sum_{i=1}^{m-1} b_i \alpha_1^{(m-i)}\right) \Phi\left(\tfrac{x_{t+m-d}-r}{c}\right)\,. \end{aligned}$$

Therefore, when we apply our numerical procedure to the STAR model, we need to use Theorem 5.1 to obtain the m-step ahead predictive pdf for $m \leq d$, while for $m > d$, we apply our numerical procedure.

Similarly, we can prove that our numerical method can be applied to the other models and that a similar result to Theorem 5.1 holds for each of these models.

Finally, a SETAR model is given by

$$x_t = a_0^{(j)} + \sum_{i=1}^{k} a_i^{(j)} x_{t-i} + \xi_t^{(j)} \qquad \text{if } x_{t-d} \in (r_{j-1}, r_j],$$

where $-\infty \leq r_0 < r_1 < \cdots < r_l \leq \infty$ are the threshold values. The order of the model is $k \geq 0$, the delay of the model is $d \geq 1$, and $\xi_t^{(j)}$ are i.i.d. $N(0,\ \sigma_j^2)$, $j = 1, \ldots, l$.

Using the expression

$$\begin{aligned} f(x_{t+m} \mid \mathbf{x}_t) &= \int_{-\infty}^{\infty} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1} \\ &= \sum_{i=1}^{l} \int_{r_{i-1}}^{r_i} f(x_{t+m} \mid \mathbf{x}_{t+1}) f(x_{t+1} \mid \mathbf{x}_t) dx_{t+1}, \end{aligned}$$

it is not difficult to modify the above theory in order to deal with SETAR model. Again we omit the details here. A similar result to Theorem 5.1 for the SETAR model was quoted by Tong [8, p. 356]. The examples in Cai [1] show that our forecasting procedure works very well for SETAR models.

6. Comments and conclusion. We have presented a convergence theory for our numerical method for solving the Chapman–Kolmogorov equation. We have shown that the method can be applied to a range of nonlinear autoregressive time series models, not only for obtaining the predictive pdf, but also for obtaining the predictive cdf, mean, and variance. The examples in Cai [1] indicate that our numerical method works very well for these models.

From our experience we see that the actual storage required by the numerical method depends on the models. Thus different forecasting horizons can be achieved with different models. The relationship between the storage requirement and the model needs to be investigated in the future.

We considered the case when the ξ_t are i.i.d. normal. Theoretically, for other continuous distributions we can also obtain the desired results. The performance of the algorithm for different distributional assumptions on ξ_t also needs to be compared and investigated in the future.

It may be possible to calculate predictive cdf, mean, and variance by using the weights and abscissae obtained for pdf. However, whether the accuracy can be guaranteed by the accuracy check on the pdf needs to be investigated in the future.

Finally, it is possible to extend the theory to autoregressive conditional heteroskedastic (ARCH) models in certain circumstances. The details will be presented elsewhere.

Acknowledgment. I would like to express my sincere thanks to the referees and to Professor Trevor Sweeting for their thoughtful comments which greatly enhanced the presentation of this paper.

STRONG SEMISMOOTHNESS OF EIGENVALUES OF SYMMETRIC MATRICES AND ITS APPLICATION TO INVERSE EIGENVALUE PROBLEMS*

DEFENG SUN† AND JIE SUN‡

Abstract. It is well known that the eigenvalues of a real symmetric matrix are not everywhere differentiable. A classical result of Ky Fan states that each eigenvalue of a symmetric matrix is the difference of two convex functions, which implies that the eigenvalues are semismooth functions. Based on a recent result of the authors, it is further proved in this paper that the eigenvalues of a symmetric matrix are strongly semismooth everywhere. As an application, it is demonstrated how this result can be used to analyze the quadratic convergence of Newton's method for solving inverse eigenvalue problems (IEPs) and generalized IEPs with multiple eigenvalues.

Key words. symmetric matrices, eigenvalues, strong semismoothness, Newton's method, inverse eigenvalue problems, quadratic convergence

1. Introduction.

The theory of semismooth functions developed in the last decade has been successful in analyzing the quadratic convergence of Newton's method for nondifferentiable (nonsmooth) equations; it is well received by the optimization community, but is perhaps not well known by researchers in numerical analysis. In this paper we take the inverse eigenvalue problem (IEP) as an example to show how this theory can be used in analyzing matrix-related equations. For applications of the IEP the interested reader is referred to the paper of Friedland, Nocedal, and Overton [10], the book of Xu [27], and the references therein. For general nonsmooth analysis involving eigenvalues of symmetric matrices and a survey on eigenvalue optimization, see Lewis [12] and Lewis and Overton [13], respectively.

Let $\mathcal{S}$ be the linear space of symmetric matrices of size n. Let $A : \Re^n \to \mathcal{S}$ be continuously differentiable. Given n real numbers $\{\lambda_i^*\}_{i=1}^n$, which are arranged in the decreasing order $\lambda_1^* \geq \cdots \geq \lambda_n^*$, the IEP is to find a vector $c^* \in \Re^n$ such that $\lambda_i(A(c^*)) = \lambda_i^*$ for $i = 1, \ldots, n$. A typical choice for $A(c)$ is

$$A(c) = A_0 + \sum_{j=1}^{n} c_j A_j, \tag{1}$$

where $A_0, A_1, \ldots, A_n \in \mathcal{S}$. In this case, $A(c)$ is an affine function of c.

Define $F : \Re^n \to \Re^n$ by

$$F(c) = \begin{bmatrix} \lambda_1(A(c)) - \lambda_1^* \\ \vdots \\ \lambda_n(A(c)) - \lambda_n^* \end{bmatrix}. \tag{2}$$

Then the IEP is equivalent to finding $c^* \in \Re^n$ to be a solution of the following equation:

$$F(c) = 0. \tag{3}$$

Of course, there are other ways to formulate the IEP as a system of equations. For instance, we may solve $F(c) = 0$, where

$$F(c) = \begin{bmatrix} \det(A(c) - \lambda_1^* I) \\ \vdots \\ \det(A(c) - \lambda_n^* I) \end{bmatrix}. \tag{4}$$

A Newton method was proposed by Biegler-König [2] for model (4), which generalizes an algorithm of Lancaster [11]. However, as analyzed by Friedland, Nocedal, and Overton [10], model (2) seems to be always preferred over model (4) both from theoretical and computational points of view. Thus, we concentrate on model (2) in this paper. The convergence theory we are going to present is based on a property of F called strong semismoothness (defined later). It is well known that for $X \in \mathcal{S}$ the eigenvalues of X, as functions of X, are not everywhere differentiable. However, we shall show that they are strongly semismooth and therefore quadratic convergence of Newton's method is a natural result when applied to equations involving eigenvalues. In doing so, we also give a constructive proof for a difficult result of Chen and Tseng [4] on upper semicontinuity of a set-valued mapping of orthogonal matrices.

The concept of semismoothness of functionals was originally studied by Mifflin [14] while strong semismoothness was introduced by Qi and Sun in [18] for vector valued functions. Recently, both concepts are further extended to matrix valued functions [24]. Generally speaking, *strong semismoothness* of an equation is tied with quadratic convergence of the Newton method applied to the equation and *semismoothness* corresponds to superlinear convergence. It was shown that smooth functions, piecewise smooth functions, and convex and concave functions are semismooth functions. They are not, however, necessarily strongly semismooth functions.

To see the motivation of this paper more clearly, let us consider the following example:

$$X = \begin{bmatrix} x_1 & x_2 \\ x_2 & x_3 \end{bmatrix},$$

where x_1, x_2, and x_3 are parameters. In this case, we have

$$\lambda_1(X) = \frac{x_1 + x_3 + \sqrt{(x_1 - x_3)^2 + 4x_2^2}}{2} \quad \text{and} \quad \lambda_2(X) = \frac{x_1 + x_3 - \sqrt{(x_1 - x_3)^2 + 4x_2^2}}{2}. \tag{5}$$

Since $\lambda_1(\cdot)$ and $\lambda_2(\cdot)$ are not differentiable at X with $x_1 = x_3$ and $x_2 = 0$, a gradient-dependent numerical method (e.g., Newton's method) may get into trouble when

hitting those points. In addition, theoretical analysis gets tricky without differentiability. Further inspection reveals that $\lambda_1(\cdot)$ is a convex function and $\lambda_2(\cdot)$ is a concave function. Hence, both of them are semismooth functions and a nonsmooth version of Newton's method [18] might be applied to equations containing $\lambda_1(\cdot)$ and $\lambda_2(\cdot)$. This should be not a coincidence. Let $f_m(X)$ be the sum of m largest eigenvalues of X. Then, Ky Fan's maximum principle [8, 1] says that for each $i = 1, \ldots, n$, $f_i(\cdot)$ is a convex function. This result implies that

- $\lambda_1(\cdot)$ is a convex function and $\lambda_n(\cdot)$ is a concave function; and,
- for $i = 2, \ldots, n-1$, $\lambda_i(\cdot)$ is the difference of two convex functions.

Since convex and concave functions are semismooth and the difference of two semismooth functions is still a semismooth function [14], Ky Fan's result shows that $\lambda_1(\cdot), \ldots, \lambda_n(\cdot)$ are all semismooth functions. It is therefore expected, when applying the nonsmooth Newton method to IEPs, the convergence rate is at least superlinear. A more interesting question is, Are all $\lambda_1(\cdot), \ldots, \lambda_n(\cdot)$ *strongly* semismooth functions (therefore implying quadratic convergence)? In this paper, based on a recent result of the authors [24], we will give an affirmative answer to the above question.

The organization of this paper is as follows. Some basic facts on semismoothness are presented in section 2. Some nonsmooth versions of the Newton method, which we call *relative generalized Newton methods,* are introduced in section 3. Section 4 concentrates on showing the strong semismoothness of eigenvalues of a symmetric matrix. The quadratic convergence of the relative generalized Newton methods for IEPs and generalized IEPs is proved in section 5. Section 6 gives a summary and a few possible future research topics.

Some notations to be used are as follows.

- $\mathcal{S}$ is the set of real symmetric matrices; $\mathcal{O}$ is the set of all $n \times n$ orthogonal matrices.
- A superscript "T" represents the transpose of matrices and vectors. For a matrix M, $M_{i\cdot}$, and $M_{\cdot j}$ represent the ith row and jth column of M, respectively.
- Unless otherwise specified, all vector norms are 2-norms and matrix norms are Frobenius norms: $\|M\| := \mathrm{trace}\,(M^T M)^{1/2}$.
- A diagonal matrix is written as $\mathrm{diag}\,(\beta_1, \ldots, \beta_n)$ and a block-diagonal matrix is denoted by $\mathrm{diag}\,(B_1, \ldots, B_s)$, where $B_1, \ldots, B_s$ are matrices.
- The eigenvalues of $X \in \mathcal{S}$ is designated by $\lambda_i(X)$, $i = 1, \ldots, n$, and $\Lambda(X) := \mathrm{diag}\,(\lambda_1(X), \ldots, \lambda_n(X))$.
- We write $X = O(\alpha)$ (respectively, $o(\alpha)$) if $\|X\|/|\alpha|$ is uniformly bounded (respectively, tends to zero) as $\alpha \to 0$.

2. Some basic facts on semismoothness.

2.1. Semismooth functions. Let $G : \Re^n \to \Re^m$ be a locally Lipschitz continuous function. We regard the $r \times r$ symmetric matrix space as a special case of $\Re^s$ with $s = r(r+1)/2$. Hence the discussions of this subsection apply to matrix variable and/or matrix valued functions as well.

According to Rademacher's theorem, G is differentiable almost everywhere. Let D_G be the set of differentiable points of G and let G' be the Jacobian of G whenever it exists. Denote

$$\partial_B G(x) := \{V \in \Re^{m\times n} |\ V = \lim_{x^k \to x} G'(x^k),\ x^k \in D_G\}.$$

Then Clarke's generalized Jacobian [5] is

$$\partial G(x) = \mathrm{conv}\{\partial_B G(x)\}, \tag{6}$$

where "conv" stands for the convex hull in the usual sense of convex analysis [20].

DEFINITION 2.1. *Suppose that $G : \Re^n \to \Re^m$ is a locally Lipschitz continuous function. G is said to be semismooth at $x \in \Re^n$ if G is directionally differentiable at x and for any $V \in \partial G(x + \Delta x)$*

$$G(x + \Delta x) - G(x) - V(\Delta x) = o(\|\Delta x\|).$$

G is said to be p-order ($0 < p < \infty$) semismooth at x if G is semismooth at x and

$$G(x + \Delta x) - G(x) - V(\Delta x) = O(\|\Delta x\|^{1+p}). \tag{7}$$

In particular, G is called strongly semismooth at x if G is 1-order semismooth at x.

A function G is said to be a (strongly) semismooth function if it is (strongly) semismooth everywhere on $\Re^n$. It is shown that the composition of (strongly) semismooth functions is still a (strongly) semismooth function (see [14, 9]).

The next result [24, Theorem 3.7] provides a convenient tool for proving strong semismoothness.

THEOREM 2.2. *Suppose that $G : \Re^n \to \Re^m$ is locally Lipschitzian and directionally differentiable in a neighborhood of x. Then for any $p \in (0, \infty)$ the following two statements are equivalent:*

(a) *for any $V \in \partial G(x + \Delta x)$,*

$$G(x + \Delta x) - G(x) - V(\Delta x) = O(\|\Delta x\|^{1+p});$$

(b) *for any $x + \Delta x \in D_G$,*

$$G(x + \Delta x) - G(x) - G'(x + \Delta x)(\Delta x) = O(\|\Delta x\|^{1+p}). \tag{8}$$

2.2. Generalized Newton methods. Suppose that $G : \Re^n \to \Re^n$ is locally Lipschitz continuous. Based on $\partial G(x)$, Qi and Sun [18] proposed the following Newton method for solving $G(x) = 0$.

Generalized Newton method I. Given $x^0 \in \Re^n$, for $k = 0, 1, \ldots,$

$$x^{k+1} = x^k - V_k^{-1} G(x^k), \tag{9}$$

where $V_k \in \partial G(x^k)$.

The following convergence theorem for the generalized Newton method I is established in [18].

THEOREM 2.3. *Suppose that $G(x^*) = 0$. If all $V \in \partial G(x^*)$ are nonsingular and G is semismooth at x^*, then there exists a neighborhood $N(x^*)$ of x^* such that for any $x^0 \in N(x^*)$ the generalized Newton method* I *is well defined and is Q-superlinearly convergent. Moreover, if G is strongly semismooth at x^*, then* (9) *converges Q-quadratically.*

To relax the nonsingularity assumption on $\partial G(x^*)$, Qi [17] introduced the following method based on the concept of $\partial_B G(x)$.

Generalized Newton method II. Given $x^0 \in \Re^n$, for $k = 0, 1, \ldots,$

$$x^{k+1} = x^k - V_k^{-1} G(x^k), \tag{10}$$

where $V_k \in \partial_B G(x^k)$.

The convergence theorem for the generalized Newton method II is the same as Theorem 2.3 except that ∂G is replaced by $\partial_B G$.

Now, let us consider the following composite nonsmooth equation:

$$G(x) := \Phi(\Psi(x)) = 0, \tag{11}$$

where $\Phi : \Re^n \to \Re^m$ is nonsmooth but of special structure and $\Psi : \Re^m \to \Re^n$ is continuously differentiable. It is noted that neither $\partial G(x)$ nor $\partial_B G(x)$ is easy to compute even if $\partial\Phi(y)$, $\partial_B\Phi(y)$, and $\Psi'(x)$ are available. To circumvent the difficulty in computing $\partial G(x)$ and $\partial G_B(x)$, Potra, Qi, and Sun [16] introduced the following concept of generalized Jacobian:

$$\partial_Q G(x) = \partial_B\Phi(\Psi(x))\Psi'(x),$$

where "Q" stands for "quasi." We shall see in the later discussion that $\partial_Q G(x)$ is more convenient to compute than $\partial G(x)$ and $\partial_B G(x)$ for IEPs.

Generalized Newton method III. Given $x^0 \in \Re^n$, for $k = 0, 1, \ldots,$

$$x^{k+1} = x^k - V_k^{-1} G(x^k), \tag{12}$$

where $V_k \in \partial_Q G(x^k)$.

The following convergence theorem for the generalized Newton method III for solving (11) is proved in [16, Theorem 5.3].

THEOREM 2.4. *Suppose that G is defined by* (11) *and $G(x^*) = 0$. If all $V \in \partial_Q G(x^*)$ are nonsingular and Φ is semismooth at $\Psi(x^*)$, then there exists a neighborhood $N(x^*)$ of x^* such that for any $x^0 \in N(x^*)$ the generalized Newton method* III *is well defined and is Q-superlinearly convergent. Moreover, if Φ is strongly semismooth at $\Psi(x^*)$ and Ψ' is Lipschitz continuous around x^*, then* (12) *converges Q-quadratically.*

3. Relative generalized Newton methods. It should be noted that, apart from the semismoothness, another key assumption for the superlinear convergence of the generalized Newton methods I–III is the nonsingularity of $\partial G(x^*)$, $\partial_B G(x^*)$, or $\partial_Q G(x^*)$. However, this may not be satisfied in general for IEPs with multiple eigenvalues. In order to weaken the nonsingularity assumption on the generalized Jacobians, we shall introduce the concept of *relative* generalized Jacobians and the corresponding generalized Newton methods based on the concept of relative generalized gradient introduced by Clarke [5, p. 231].

Let S be a subset of $\Re^n$. For instance, in the context of matrix functions, S could represent the set of all nonsingular matrices. The S-relative generalized Jacobian $\partial|_S G(x)$ of G at x is defined by

$$\partial|_S G(x) := \{V \mid V \text{ is a limit of } V_i \in \partial G(y_i),\ y_i \in S, y_i \to x\}.$$

The following result can be proved in an analogous way to [5, Proposition 6.2.1]. We omit the details.

LEMMA 3.1. *Let G be Lipschitz continuous near x. Then we have the following:*

(a) *$\partial|_S G(x)$ is a compact subset of $\partial G(x)$.*

(b) *$\partial|_S G(x) = \partial G(x)$ if x lies in the interior part of S; $\partial|_S G(x) = \emptyset$ if $(x+\varepsilon B)\cap S = \emptyset$ for some $\varepsilon > 0$; and $\partial|_S G(x)$ is nonempty if $x \in \mathrm{cl}(S)$, the closure of S.*

(c) *$\partial|_S G(\cdot)$ is upper semicontinuous at x.*

Now, we can introduce our first relative generalized Newton method for solving $G(x) = 0$.

Relative generalized Newton method I. Given $x^0 \in \Re^n$, for $k = 0, 1, \ldots,$ and $x^k \in S$,

$$x^{k+1} = x^k - V_k^{-1} G(x^k), \tag{13}$$

where $V_k \in \partial|_S G(x^k)$.

In the following analysis, we assume that the relative generalized Newton method I does not find a solution of $G(x) = 0$ in a finite number of steps.

THEOREM 3.2. *Suppose that $G(x^*) = 0$ and $x^* \in \mathrm{cl}(S)$. If all $V \in \partial|_S G(x^*)$ are nonsingular and G is semismooth at x^*, then there exists a neighborhood $N(x^*)$ of x^* such that for any $x^0 \in N(x^*) \cap S$ the relative generalized Newton method* I *either stops in a finite number of steps with some $x^k \notin S$ or generates an infinite sequence $\{x^k\} \in N(x^*) \cap S$ and the whole sequence converges Q-superlinearly to x^*. Moreover, if G is strongly semismooth at x^*, then the rate of convergence is Q-quadratic.*

Proof. By using Lemma 3.1, there exist a neighborhood $N(x^*)$ of x^* and a positive number κ such that for any $x \in N(x^*) \cap S$, all $V \in \partial|_S G(x)$ are nonsingular and

$$\|V^{-1}\| \le \kappa. \tag{14}$$

Since G is semismooth at x^*, by shrinking $N(x^*)$ if necessary, we have for all $x \in N(x^*) \cap S$ and $V \in \partial|_S G(x)$,

$$\|G(x) - G(x^*) - V(x - x^*)\| \le \frac{1}{2\kappa}\|x - x^*\|. \tag{15}$$

By using (14) and (15), we have for $k = 0, 1, \ldots$ that

$$\begin{aligned}
\|x^{k+1} - x^*\| &= \|x^k - V_k^{-1} G(x^k) - x^*\| \\
&= \|V_k^{-1}[G(x^k) - G(x^*) - V_k(x - x^*)]\| \\
&\le \|V_k^{-1}\|\|G(x^k) - G(x^*) - V_k(x - x^*)\| \\
&\le \tfrac{1}{2}\|x^k - x^*\|,
\end{aligned}$$

which implies that if (13) does not stop at some step with $x^k \notin S$, then $\{x^k\} \in N(x^*) \cap S$ and the whole sequence converges to x^* linearly.

Next, suppose that (13) does not stop at some step with $x^k \notin S$. Since G is semismooth at x^* and $x^k \to x^*$, we have

$$G(x^k) - G(x^*) - V_k(x^k - x^*) = o(\|x^k - x^*\|),$$

which, together with (13), implies that

$$\begin{aligned}
\|x^{k+1} - x^*\| &= \|x^k - V_k^{-1} G(x^k) - x^*\| \\
&= \|V_k^{-1}[G(x^k) - G(x^*) - V_k(x - x^*)]\| \\
&= O(\|G(x^k) - G(x^*) - V_k(x - x^*)\|) \\
&= o(\|x^k - x^*\|).
\end{aligned}$$

This proves the superlinear convergence of $\{x^k\}$.

By the above argument, we can see that if G is strongly semismooth at x^*, then (13) either stops in finitely many steps with some $x^k \notin S$ or generates an infinite

sequence $\{x^k\} \in N(x^*) \cap S$ and the whole sequence converges Q-quadratically to x^*. This completes the proof. □

The proof of Theorem 3.2 might serve as an example to show the simplicity of the analysis of Newton's method by using the concept of (strong) semismoothness. Parallel to the definition of $\partial_B G(x)$ and $\partial_Q G(x)$, we define

$$\partial_B|_S G(x) := \{V|\ V \text{ is a limit of } V_i \in \partial_B G(y_i),\ y_i \in S,\ y_i \to x\}$$

and

$$\partial_Q|_S G(x) := \{V|\ V \text{ is a limit of } V_i \in \partial_Q G(y_i),\ y_i \in S,\ y_i \to x\}.$$

Similar to Lemma 3.1, we have the following lemma.

LEMMA 3.3. *Let G be Lipschitz continuous near x. Then we have the following:*

(a) *$\partial_B|_S G(x)$ and $\partial_Q|_S G(x)$ are compact subsets of $\partial_B G(x)$ and $\partial_Q G(x)$, respectively.*

(b) *$\partial_B|_S G(x) = \partial_B G(x)$ and $\partial_Q|_S G(x) = \partial_Q G(x)$, if x lies in the interior part of S; $\partial_B|_S G(x) = \partial_Q|_S G(x) = \emptyset$ if $(x + \varepsilon B) \cap S = \emptyset$ for some $\varepsilon > 0$; both $\partial_B|_S G(x)$ and $\partial_Q|_S G(x)$ are nonempty if $x \in \mathrm{cl}(S)$, the closure of S.*

(c) *$\partial_B|_S G(\cdot)$ and $\partial_Q|_S G(\cdot)$ are upper semicontinuous at x.*

Analogously, we define the second and third relative generalized Newton methods.

Relative generalized Newton method II (III). Given $x^0 \in \Re^n$, for $k = 0, 1, \ldots$, and $x^k \in S$,

$$x^{k+1} = x^k - V_k^{-1} G(x^k), \tag{16}$$

where $V_k \in \partial_B|_S G(x^k)$ ($V_k \in \partial_Q|_S G(x^k)$ in method III).

The following theorem can be similarly proved by using Lemma 3.3 and the approach of proving Theorems 3.2. We omit the details.

THEOREM 3.4. *Suppose that $G(x^*) = 0$ and $x^* \in \mathrm{cl}(S)$. If all $V \in \partial_B|_S G(x^*)$ ($V \in \partial_Q|_S G(x^*)$ in method* III*) are nonsingular and G is semismooth at x^* (Φ is semismooth at $\Psi(x^*)$ in method* III*), then there exists a neighborhood $N(x^*)$ of x^* such that for any $x^0 \in N(x^*) \cap S$ the relative generalized Newton methods* II *and* III *either stop in a finite number of steps with some $x^k \notin S$ or generate an infinite sequence $\{x^k\} \in N(x^*) \cap S$ and the whole sequence converges Q-superlinearly to x^*. Moreover, if G (Φ in method* III*) is strongly semismooth at x^* (at $\Psi(x^*)$ and Ψ' is Lipschitz continuous around x^* in method* III*), then the rate of convergence is Q-quadratic.*

4. Strong semismoothness of eigenvalues. As a building block for applying relative generalized Newton methods, we shall prove the strong semismoothness of eigenvalues of symmetric matrices in this section. Suppose $X \in \mathcal{S}$. Then, there exists an orthogonal matrix $Q \in \mathcal{O}$ such that X satisfies

$$Q^T X Q = \Lambda(X) := \mathrm{diag}\,(\lambda_1(X), \ldots, \lambda_n(X)), \tag{17}$$

where $\lambda_1(X) \geq \cdots \geq \lambda_n(X)$.

We define a "configuration vector" K to distinguish different eigenvalues. Let

$$K := \{k_0, k_1, \ldots, k_l\} \tag{18}$$

with $1 = k_0 < k_1 < \cdots < k_l = n + 1$ such that there is a change of eigenvalues at k_i. Namely for $t = 1, \ldots, l$,

$$\lambda_s(X) = \lambda_{k_{t-1}}(X), \qquad s \in [k_{t-1}, k_t - 1], \tag{19}$$

where we use the simple notation $[k_{t-1}, k_t - 1]$ to represent the index set $\{k_{t-1}, k_{t-1} + 1, \ldots, k_t - 1\}$.

Let $H \in \mathcal{S}$ and let P (depending on H) be an orthogonal matrix such that

$$P^T(\Lambda(X) + H)P = \Lambda(Y) := \text{ diag}\,(\lambda_1(Y), \ldots, \lambda_n(Y)), \tag{20}$$

where $\lambda_1(Y) \geq \cdots \geq \lambda_n(Y)$ and $Y := \Lambda(X) + H$.

After the above preparation, we can state the following result, which was essentially proved in the derivation of Lemma 4.2 of [24].

LEMMA 4.1. *For any $H \in \mathcal{S}$ and $H \to 0$, we have*

$$P_{ij} = O(\|H\|), \qquad i, j = 1, \ldots, n, \ (i, j) \notin \bigcup_{t=1}^{l} \{[k_{t-1}, k_t - 1] \times [k_{t-1}, k_t - 1]\}. \tag{21}$$

Proof. It has been proved in the proof of Lemma 4.2 of [24] that (21) is true for any $H \in \mathcal{S}$ such that $\Lambda(X) + H$ is nonsingular and $H \to 0$.

Next, we prove that (21) is also true for the case that $\Lambda(X) + H$ is singular and $H \to 0$. It is easy to check that the conclusion of this lemma holds if $H = 0$. Hence, we can assume $H \neq 0$. Define

$$\lambda_{\min}(|Y|) = \min_{\lambda_i(Y) \neq 0} |\lambda_i(Y)| \quad \text{and} \quad \tilde{\Lambda} = \text{ diag}\,(\tilde{\lambda}_1, \ldots, \tilde{\lambda}_n),$$

where $|Y| := (Y^2)^{\frac{1}{2}}$ and for $i = 1, \ldots, n$

$$\tilde{\lambda}_i = \begin{cases} \lambda_i(Y) & \text{if } \lambda_i(Y) \neq 0, \\ \lambda_{\min}(|Y|) \min\{\frac{1}{2}, ||H||^2\} & \text{otherwise.} \end{cases}$$

Denote

$$\tilde{H} = P\tilde{\Lambda}P^T - \Lambda(X).$$

Hence, $P^T[\Lambda(X) + \tilde{H}]P = \tilde{\Lambda}$ is nonsingular. By noting the fact $\tilde{H} = H + O(\|H\|^2)$, it follows that (21) also holds for the case that $\Lambda(X) + H$ is singular and $H \to 0$. This completes the proof. ∎

Define a "truncated" matrix $W \in \Re^{n \times n}$ as follows:

$$W_{ij} = \begin{cases} P_{ij} & \text{if } (i, j) \in \bigcup_{t=1}^{l} \{[k_{t-1}, k_t - 1] \times [k_{t-1}, k_t - 1]\}, \\ 0 & \text{otherwise,} \end{cases} \qquad i, j = 1, \ldots, n. \tag{22}$$

Hence, from Lemma 4.1, we know that for any $H \to 0$,

$$W = P + O(\|H\|). \tag{23}$$

It is noted, however, that W may not be an orthogonal matrix but has a block-diagonal structure with each block corresponding to a set of identical eigenvalues of X. That is,

$$W = \text{ diag}\,(W_1, \ldots, W_l),$$

where

$$W_t = \left(P_{ij}\right)_{i,j=k_{t-1}}^{k_t - 1}, \qquad \text{for } t = 1, \ldots, l.$$

Since $P \in \mathcal{O}$, by using Lemma 4.1 and (22), for $t = 1, \ldots, l$ and $i, j = 1, \ldots, k_t - k_{t-1}$, we have for any $H \to 0$,

$$\|(W_t)_{\cdot j}\|^2 = 1 + O(\|H\|^2) \quad \text{and} \quad \langle (W_t)_{\cdot j}, (W_t)_{\cdot i} \rangle = O(\|H\|^2), \qquad i \neq j. \tag{24}$$

It is obvious from (24) that for any $H \in \mathcal{S}$ sufficiently close to 0 the columns of W_t are independent because

$$\sum_j \beta_j (W_t)_{\cdot j} = 0 \;\Rightarrow\; \beta_j[1 + O(\|H\|^2)] = O(\|H\|^2) \;\Rightarrow\; \beta_j = 0 \quad \forall\, j.$$

For each $t = 1, \ldots, l$, let $\tilde{P}_t$ be a matrix of the same order of W_t and be obtained by applying the Gram–Schmidt orthogonalization algorithm to each W_t; i.e., for $j = 1, \ldots, k_t - k_{t-1}$, let

$$(\tilde{W}_t)_{\cdot j} = (W_t)_{\cdot j} - \sum_{i=1}^{j-1} \langle (\tilde{P}_t)_{\cdot i}, (W_t)_{\cdot j} \rangle (\tilde{P}_t)_{\cdot i} \;\text{ and }\; (\tilde{P}_t)_{\cdot j} = (\tilde{W}_t)_{\cdot j} / \|(\tilde{W}_t)_{\cdot j}\|. \tag{25}$$

By (24) and (25), for $i, j = 1, \ldots, k_t - k_{t-1}$, $t = 1, \ldots, l$, we have for any $H \to 0$ that

$$\|(\tilde{P}_t)_{\cdot j}\|^2 = 1, \;\; (\tilde{P}_t)_{\cdot j} = (W_t)_{\cdot j} + O(\|H\|^2) \quad \text{and} \quad \langle (\tilde{P}_t)_{\cdot j}, (\tilde{P}_t)_{\cdot i} \rangle = 0, \quad i \neq j. \tag{26}$$

Denote

$$\tilde{P} = \operatorname{diag}(\tilde{P}_1, \ldots, \tilde{P}_l). \tag{27}$$

Then, we have the following lemma.

LEMMA 4.2. *For any $H \in \mathcal{S}$ sufficiently small, the matrix $\tilde{P}$ defined by* (27) *and* (25) *is an orthogonal matrix and satisfies*

$$\tilde{P}^T \Lambda(X) \tilde{P} = \Lambda(X). \tag{28}$$

Furthermore, for any $H \to 0$,

$$P = \tilde{P} + O(\|H\|). \tag{29}$$

Proof. By (26), we know that each $\tilde{P}_t$, $t = 1, \ldots, l$, is an orthogonal matrix. Since $\lambda_{k_{t-1}}(X) = \cdots = \lambda_{k_t - 1}(X)$, $t = 1, \ldots, l$, we have

$$\tilde{P}_t^{\,T} \operatorname{diag}(\lambda_{k_{t-1}}(X), \ldots, \lambda_{k_t-1}(X)) \tilde{P}_t = \operatorname{diag}(\lambda_{k_{t-1}}(X), \ldots, \lambda_{k_t-1}(X)).$$

Hence, $\tilde{P}$ is an orthogonal matrix and satisfies (28). By using (23) and (26), we directly obtain (29). This completes the proof. ∎

For any $\Delta X \in \mathcal{S}$, let $U \in \mathcal{O}$ (depending on X and ΔX) be any orthogonal matrix such that

$$U^T(X + \Delta X)U = \Lambda(X + \Delta X) := \operatorname{diag}(\lambda_1(X + \Delta X), \ldots, \lambda_n(X + \Delta X)), \tag{30}$$

where $\lambda_1(X + \Delta X) \geq \cdots \geq \lambda_n(X + \Delta X)$.

By using the above lemma, we have the following result.

LEMMA 4.3. *For any $\Delta X \in \mathcal{S}$ sufficiently small and U satisfying* (30)*, there exists a $V \in \mathcal{O}$ such that*

$$V^T X V = \Lambda(X) \quad \text{and} \quad U = V + O(\|\Delta X\|). \tag{31}$$

Proof. Let $P = Q^T U$ and $H = Q^T \Delta X Q$, where Q is defined in (17). Then, by Lemma 4.2, for any such defined P, there exists $\tilde{P} \in \mathcal{O}$ such that

$$\tilde{P}^T \Lambda(X) \tilde{P} = \Lambda(X)$$

and

$$P = \tilde{P} + O(\|H\|) = \tilde{P} + O(\|\Delta X\|).$$

Let $V = Q\tilde{P}$. Then $V \in \mathcal{O}$,

$$V^T X V = \tilde{P}^T Q^T X Q \tilde{P} = \tilde{P}^T \Lambda(X) \tilde{P} = \Lambda(X),$$

and for any $\Delta X \to 0$

$$U = V + O(\|\Delta X\|).$$

This completes the proof. ∎

A similar result to Lemma 4.3 has also been proved in [4] based on a so-called $\sin(\Theta)$ theorem in [21, Theorem 3.4]. The proof provided here is due to a direct comparison between entries of P and $\tilde{P}$ and it indeed furnishes an algorithm for computing V.

One direct result of Lemma 4.3 is that the (normalized) eigenvectors of symmetric matrices, though not continuous, are upper Lipschitz continuous. To see this, for any $Z \in \mathcal{S}$, let

$$\mathcal{U}(Z) := \{U \in \mathcal{O} |\ U^T Z U \text{ is diagonal}\},$$

and let

$$\mathcal{E} := \{M \in \mathcal{S} \mid\ |M_{i,j}| \leq 1,\ i, j = 1, \ldots, n\}.$$

PROPOSITION 4.4. *For any $X \in \mathcal{S}$, there exists a constant $\mu > 0$ such that*

$$\mathcal{U}(X + \Delta X) \subseteq \mathcal{U}(X) + \mu ||\Delta X|| \mathcal{E} \tag{32}$$

for all ΔX sufficiently small.

Proof. For any $U \in \mathcal{U}(X + \Delta X)$, there exists a diagonal matrix $D(X + \Delta X)$ such that

$$U^T (X + \Delta X) U = D(X + \Delta X).$$

Let $R \in \Re^{n \times n}$ be a permutation matrix such that

$$R D(X + \Delta X) R^T = \Lambda(X + \Delta X)$$

with $\lambda_1(X + \Delta X) \geq \cdots \geq \lambda_n(X + \Delta X)$. Let $\tilde{U} = U R^T$. Then we obtain $\tilde{U}^T (X + \Delta X) \tilde{U} = \Lambda(X + \Delta X)$. Hence, by Lemma 4.3, there exists a $\tilde{V} \in \mathcal{O}$ such that $\tilde{V}^T X \tilde{V} = \Lambda(X)$ and

$$\tilde{U} = \tilde{V} + O(\|\Delta X\|),$$

i.e.,

$$U = \tilde{V} R + O(\|\Delta X\|)$$

because $R^T = R^{-1}$ and $\|R^T\| = \sqrt{n}$. Let $V = \tilde{V}R$. Then

$$V^TV = R^T\tilde{V}^T\tilde{V}R = R^TR = I, \quad \text{and} \quad V^TXV = (\tilde{V}R)^TX\tilde{V}R = R^T\Lambda(X)R$$

is a diagonal matrix. Hence, we have proved $V \in \mathcal{U}(X)$ and for $\Delta X \to 0$

$$U = V + O(\|\Delta X\|).$$

This implies that there exists a $\mu > 0$ such that (32) holds. □

In section 1 we have seen from an example of a two by two matrix that the eigenvalues are not differentiable if X has multiple eigenvalues. This can be easily extended to the general case: $\Lambda(\cdot)$ is not differentiable at X if X has multiple eigenvalues. On the other hand, by [26, pp. 66–68] and [25, Theorem 2.3] we know that if X has distinct eigenvalues, then $\Lambda(\cdot)$ is analytic in a neighborhood of X. Hence, we have the following lemma.

LEMMA 4.5. *$\Lambda(\cdot)$ is analytic in a neighborhood of X if and only if $X \in \mathcal{S}$ has distinct eigenvalues.*

Next, we cite a useful formula for the derivative of $\Lambda(X)$ when $X \in \mathcal{S}$ has distinct eigenvalues.

LEMMA 4.6 (see [21, p. 185, Corollary 2.4]). *For any $X \in \mathcal{S}$, if X has distinct eigenvalues, then $\Lambda(\cdot)$ is continuously differentiable at X and for any $\Delta X \in S$*

$$\lambda_i'(X)(\Delta X) = q_i(X)^T\Delta X q_i(X), \quad i = 1, \ldots, n. \tag{33}$$

For any $X \in \mathcal{S}$, let $Q(X) \in \mathcal{O}$ be such that $Q(X)^TXQ(X) = \Lambda(X)$ with $\lambda_1(X) \geq \cdots \geq \lambda_n(X)$. Define

$$q_i(X) = (Q(X))_{\cdot i}, \quad i = 1, \ldots, n.$$

The following result is our main theorem of this section.

THEOREM 4.7. *$\Lambda(\cdot)$ is a strongly semismooth function.*

Proof. By Ky Fan [8] and Mifflin [14], $\Lambda(\cdot)$ is a semismooth function. Thus, we only have to prove (8) with $p = 1$. Let $D_\Lambda = \{Y \in \mathcal{S} |\ Y \text{ has distinct eigenvalues}\}$. By Lemma 4.5, D_Λ is the subset of $\mathcal{S}$ on which Λ is continuously differentiable. Clearly, D_Λ is dense in $\mathcal{S}$.

Suppose that $X_0 \in \mathcal{S}$ is a given matrix. For any $X \in D_\Lambda$, denote $\Delta X = X - X_0$. For $i = 1, \ldots, n$ from $Xq_i(X) = \lambda_i(X)q_i(X)$, we have

$$q_i(X)^TX_0q_i(X) + q_i(X)^T\Delta X q_i(X) = \lambda_i(X). \tag{34}$$

By Lemma 4.3, there exists a $\mu > 0$ such that for any X sufficiently close to X_0 there exists a matrix $Q(X_0) \in \mathcal{O}$ (depending on the choice of X) such that $Q(X_0)^TX_0Q(X_0) = \Lambda(X_0)$ and

$$\|q_i(X) - q_i(X_0)\| \leq \mu||X - X_0||, \tag{35}$$

where $q_i(X_0) := (Q(X_0))_{\cdot i}$, $i = 1, \ldots, n$. Hence, from (34), (35), and the local

Lipschitz continuity of $\Lambda(\cdot)$, for $i = 1, \ldots, n$, $X \in D_\Lambda$, and $\Delta X \to 0$, we have

$$\begin{aligned}
\lambda_i(X) &= q_i(X)^T \left[X_0 q_i(X_0) + X_0(q_i(X) - q_i(X_0))\right] + q_i(X)^T \Delta X q_i(X) \\
&= \lambda_i(X_0) q_i(X)^T q_i(X_0) + q_i(X)^T X \left[q_i(X) - q_i(X_0)\right] + O(\|\Delta X\|^2) \\
&\quad + q_i(X)^T \Delta X q_i(X) \\
&= \lambda_i(X_0) q_i(X)^T q_i(X_0) + \lambda_i(X) q_i(X)^T \left[q_i(X) - q_i(X_0)\right] \\
&\quad + q_i(X)^T \Delta X q_i(X) + O(\|\Delta X\|^2) \\
&= \lambda_i(X_0) q_i(X)^T q_i(X_0) + \left[\lambda_i(X_0) + O(\|\Delta X\|)\right] q_i(X)^T \left[q_i(X) - q_i(X_0)\right] \\
&\quad + q_i(X)^T \Delta X q_i(X) + O(\|\Delta X\|^2) \\
&= \lambda_i(X_0) q_i(X)^T q_i(X) + q_i(X)^T \Delta X q_i(X) + O(\|\Delta X\|^2) \\
&= \lambda_i(X_0) + q_i(X)^T \Delta X q_i(X) + O(\|\Delta X\|^2), \qquad (36)
\end{aligned}$$

which, according to Lemma 4.6, implies

$$\lambda_i(X) - \lambda_i(X_0) - \lambda_i'(X)(\Delta X) = O(\|\Delta X\|)^2, \quad i = 1, \ldots, n.$$

This, together with Theorem 2.2, implies that for $X \to X_0$ and $V \in \partial\Lambda(X)$,

$$\Lambda(X) - \Lambda(X_0) - V(X - X_0) = O(\|X - X_0\|^2).$$

Hence, (8), and therefore the strong semismoothness of $\Lambda(\cdot)$, is proved. □

5. Newton's method for inverse eigenvalue problems. In this section, we shall show how the strong semismoothness of eigenvalues of symmetric matrices can be used to analyze the quadratic convergence of Newton's method for solving IEPs. Unless stated otherwise, $A : \Re^n \to \mathcal{S}$ is assumed to be continuously differentiable everywhere and $F : \Re^n \to \Re^n$ is defined by (2), i.e.,

$$F(c) = \begin{bmatrix} \lambda_1(A(c)) - \lambda_1^* \\ \vdots \\ \lambda_n(A(c)) - \lambda_n^* \end{bmatrix},$$

where $\{\lambda^*\}_{i=1}^n$ are given n numbers and arranged in the decreasing order. Then the IEP is equivalent to finding $c^* \in \Re^n$ such that $F(c^*) = 0$.

For any $c \in \Re^n$, let $\mathcal{Q}(c) \subseteq \mathcal{O}$ be a subset of $\Re^{n\times n}$ such that for any $Q(c) \in \mathcal{Q}(c)$ we have

$$Q(c)^T A(c) Q(c) = \Lambda(A(c))$$

with $\lambda_1(A(c)) \geq \cdots \geq \lambda_n(A(c))$. For any $Q(c) \in \mathcal{Q}(c)$, define

$$q_i(c) = (Q(c))_{\cdot i}, \qquad i = 1, \ldots, n.$$

Let $\partial A(c)/\partial c_j$ be the partial derivative of $A(c)$ with respect to c_j, $j = 1, \ldots, n$. Then for any $c \in \Re^n$

$$\partial_Q F(c) = \partial_B \Lambda(A(c))(A'(c))$$

is well defined. By using Lemmas 4.5 and 4.6 and [24, Theorem 2.5], we have the following result.

PROPOSITION 5.1.

(a) *For any $c \in \Re^n$, $V \in \partial_Q F(c)$ if and only if there exists a $Q(c) \in \mathcal{Q}(c)$ such that*

$$V_{i\cdot} = \left[q_i(c)^T(\partial A(c)/\partial c_1)q_i(c), \ldots, q_i(c)^T(\partial A(c)/\partial c_n)q_i(c)\right]. \tag{37}$$

(b) *If $c \in \Re^n$ is such that $A(c)$ has distinct eigenvalues, then F is continuously differentiable at c and for any $Q(c) \in \mathcal{Q}(c)$*

$$F_i'(c) = \left[q_i(c)^T(\partial A(c)/\partial c_1)q_i(c), \ldots, q_i(c)^T(\partial A(c)/\partial c_n)q_i(c)\right]. \tag{38}$$

Hence, according to Proposition 5.1, a generalized Newton method for solving the IEP can be described as follows.

ALGORITHM 5.1 (a generalized Newton method).

Step 0. *Choose a starting point value c^0. $k := 0$.*

Step 1. *Compute a $Q(c^k) \in \mathcal{Q}(c^k)$ and form $V_k \in \partial_Q F(c^k)$ according to Proposition* 5.1.

Step 2. *Set $c^{k+1} := c^k + \Delta c^k$, where Δc^k is computed by $F(c^k) + V_k \Delta c^k = 0$.*

Step 3. *Replace k by $k+1$ and go to Step* 1.

In the above generalized Newton method, at the kth step one needs to compute eigenvectors $Q(c^k)$ and eigenvalues $\Lambda(A(c^k))$. Once they are computed, $F(c^k)$ and $V^k \in \partial_Q F(c^k)$ can be formulated easily. If $A(c)$ takes form (1) and at each step $A(c^k)$ has distinct eigenvalues, Algorithm 5.1 reduces to the Newton method considered by many authors, e.g., see [15, 10] and references therein.

THEOREM 5.2. *Suppose that F is defined by* (2) *and $F(c^*) = 0$. If all $V \in \partial_Q F(c^*)$ are nonsingular and A' is Lipschitz continuous around c^*, then there exists a neighborhood $N(c^*)$ of c^* such that for any $c^0 \in N(c^*)$ Algorithm* 5.1 *is well defined and the iterates $\{c^k\}$ converge to c^* Q-quadratically.*

Proof. From Theorem 4.7, we know that $\Lambda(\cdot)$ is strongly semismooth everywhere. Hence, by Theorem 2.4 we obtain the conclusion of this theorem. □

Theorem 5.2 contains a very general convergence result for the quadratic convergence of Newton's method for solving IEPs. However, the nonsingularity assumption on $\partial_Q F(c^*)$ is too strong for IEPs when $A(c^*)$ has multiple eigenvalues. To relax this condition, let $S \subseteq \Re^n$ be defined by

$$S = \{c \in \Re^n |\ A(c) \text{ has distinct eigenvalues}\}. \tag{39}$$

Then, by Lemma 4.5 and Proposition 5.1 for any $c \in S$, $F(\cdot)$ is continuously differentiable at c and

$$\partial_B F(c) = \partial_Q F(c) = \partial F(c) = \{F'(c)\}.$$

THEOREM 5.3. *Suppose that F is defined by* (2), *$F(c^*) = 0$, and S is defined by* (39). *If* (i) *for each k, $c^k \in S$ and $c^* \in \mathrm{cl}S$;* (ii) *all $V \in \partial_B|_S F(c^*)$ are nonsingular; and* (iii) *A' is Lipschitz continuous around c^*, then there exists a neighborhood $N(c^*)$ of c^* such that, for any $c^0 \in N(c^*)$, Algorithm* 5.1 *is well defined and the iterates $\{c^k\}$ converge to c^* Q-quadratically.*

Proof. By using Theorems 3.4 and 4.7, we obtain this theorem. □

In Theorem 5.3, we need only the nonsingularity of $\partial_B|_S F(c^*)$ rather than $\partial_Q F(c^*)$. The price to pay is that all the iterates must stay in S, where S is defined by (39).

Since $\Re^n \backslash S$ is usually a null set, this condition is reasonable for IEPs [10, pp. 647–648]. For illustration, let us consider the following IEP with

$$F(c) = \begin{bmatrix} \lambda_1(A(c)) - \lambda_1^* \\ \lambda_2(A(c)) - \lambda_2^* \end{bmatrix},$$

$$A(c) = c_1 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} + c_2 \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

and $\lambda_1^* = \lambda_2^* = 1$. Then, $\lambda_1(A(c)) = c_1 + |c_2|$, $\lambda_2(A(c)) = c_1 - |c_2|$, and $S = \{c \in \Re^2 |\ c_2 \neq 0\}$. The function F has a unique solution at $c^* = (1, 0)$. Note that $A(c^*)$ has a multiple eigenvalues at c^* and

$$\partial_B|_S F(c^*) = \left\{ \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}, \quad \begin{bmatrix} 1 & 1 \\ 1 & -1 \end{bmatrix} \right\}.$$

Therefore, all $V \in \partial_B|_S F(c^*)$ are nonsingular.

It was probably Nocedal and Overton [15] who first discussed the quadratic convergence of Newton's method for solving IEPs with multiple eigenvalues. In their proof, a theorem of Rellich [19] on analytic matrix functions was invoked. In [10], by using the eigenprojector, Friedland, Nocedal, and Overton presented a different elegant proof on the quadratic convergence of Newton's method for solving IEPs with multiple eigenvalues. The latter did not use Rellich's theorem. Our results in this paper could be thought of as a generalization of their method I by explicitly exploring the strong semismoothness of the eigenvalue functions.

Before we finish this section, let us consider the generalized inverse eigenvalue problem (GIEP). Let $C : \Re^n \to \mathcal{S}$ and $D : \Re^n \to \mathcal{S}$ be continuously differentiable and $D(c)$ be positive definite whenever $c \in \Omega$, an open subset of $\Re^n$. Given n real numbers $\{\lambda_i^*\}_{i=1}^n$, which are arranged in the decreasing order $\lambda_1^* \geq \cdots \geq \lambda_n^*$, the GIEP is to find a vector $c^* \in \Omega$ such that the symmetric generalized eigenvalue problem $C(c^*)x = \lambda D(c^*)x$ has the prescribed eigenvalues $\lambda_1^*, \ldots, \lambda_n^*$. If $D(c) \equiv I$, then the GIEP is the IEP considered above. It is readily seen that the GIEP can be converted into the form of solving $F(c) = 0$ with

$$F(c) = \begin{bmatrix} \lambda_1(A(c)) - \lambda_1^* \\ \vdots \\ \lambda_n(A(c)) - \lambda_n^* \end{bmatrix}, \quad c \in \Omega, \tag{40}$$

where $A(c) = D(c)^{-\frac{1}{2}} C(c) D(c)^{-\frac{1}{2}}$.

Dai and Lancaster [7] and Dai [6] considered a special case of the GIEP, i.e., $C(c)$ and $D(c)$ are defined by

$$C(c) = C_0 + \sum_{i=1}^n c_i C_i, \qquad D(c) = D_0 + \sum_{i=1}^n c_i D_i, \tag{41}$$

where $C_0, C_1, \ldots, C_n, D_0, D_1, \ldots D_n \in \mathcal{S}$ and $D(c)$ is positive definite whenever $c \in \Omega$.

When $C(c)$ and $D(c)$ take the form (41), Dai and Lancaster [7] proposed the following Newton method for solving the GIEP.

ALGORITHM 5.2 (a Newton method of Dai and Lancaster [7]).

Step 0. *Choose a starting point value* c^0. $k := 0$.

Step 1. *Compute* $C(c^k) = C_0 + \sum_{j=1}^n c_j^k C_j$, $D(c^k) = D_0 + \sum_{j=1}^n c_j^k D_j$.
Step 2. *Set* $c^{k+1} := c^k + \Delta c^k$, *where* Δc^k *is computed by* $F(c^k) + F'(c^k)\Delta c^k = 0$.
Step 3. *Replace* k *by* $k+1$ *and go to Step* 1.

The following theorem gives an affirmative answer to a conjecture made in [7, p. 11] on the quadratic convergence of Algorithm 5.2, which was supported by numerical experiments.

THEOREM 5.4. *Suppose that* $c^* \in \Omega$ *such that* $F(c^*) = 0$. *If* (i) *for each* k, $A(c^k)$ *has distinct eigenvalues and* $F'(c^k)$ *is invertible; and* (ii) $\limsup_{k\to\infty} \|F'(c^k)^{-1}\| < \infty$, *then there exists a neighborhood* $N(c^*)$ *of* c^* *such that for any* $c^0 \in N(c^*)$ *the iterates* $\{c^k\}$ *generated by Algorithm* 5.2 *converge to* c^* Q*-quadratically.*

Proof. Since $A(c^k)$ has distinct eigenvalues, F is continuously differentiable at c^k. Note that Algorithm 5.2 is a special case of Algorithm 5.1. By using Theorems 4.7 and 3.4 with $S = \{c^0, c^1, \ldots\}$, we get the conclusion of the theorem. □

6. Summary and possible future research topics. In this paper we review basic concepts of semismoothness and Newton's method for semismooth equations. We show the strong semismoothness of eigenvalues of symmetric matrices and demonstrate how this result can be used to provide a unified analysis for the quadratic convergence of the Newton-type methods for IEPs and GIEPs.

We feel that several topics could be further investigated. First, it would be interesting to look at the strong semismoothness of the functions arising from other IEPs, e.g., the least square IEPs [10]. Second, we could develop nonsmooth quasi-Newton [22] methods, rather than Newton's method, for IEPs and GIEPs. Chan and Tseng [3] provided such an approach for IEPs with distinct eigenvalues. The problem is still unsolved in the case of multiple eigenvalues. Third, it is desirable to have a "smoothing" version of the Newton method discussed in this paper; namely, we find a parameterized function $H(\varepsilon, x)$ for a strongly semismooth function $F(x)$ such that $H(\varepsilon, y) \to F(x)$ as $(\varepsilon, y) \to (0^+, x)$ and that $H(\varepsilon, x)$ is differentiable for $\varepsilon \neq 0$. It is proved in [23] that any nonsmooth function has approximate smoothing functions, but the proof does not give any concrete smoothing functions for IEPs. It is then interesting to ask what smoothing function could be used for IEPs.

Acknowledgment. The authors are grateful to the referees for their very constructive comments.

A MODEL FOR TWO COUPLED TURBULENT FLUIDS PART II: NUMERICAL ANALYSIS OF A SPECTRAL DISCRETIZATION*

C. BERNARDI†, T. CHACÓN REBOLLO‡, R. LEWANDOWSKI§, AND F. MURAT†

Abstract. We consider a system of equations that models the stationary flow of two immiscible turbulent fluids on adjacent subdomains. The equations are coupled by nonlinear boundary conditions on the interface which is here a fixed given surface. We propose a spectral discretization of this problem and perform its numerical analysis. The convergence of the method is proven in the two-dimensional case, together with optimal error estimates.

Key words. turbulent fluids, numerical analysis, spectral discretization

1. Introduction.

In this paper, we are interested in the numerical analysis of the spectral discretization of a model for two stationary turbulent fluids coupled by boundary conditions on the interface:

$$
\begin{cases}
-\operatorname{div}\big(\alpha_i(k_i)\,\nabla \boldsymbol{u}_i\big) + \mathbf{grad}\, p_i = \boldsymbol{f}_i & \text{in } \Omega_i,\ 1 \le i \le 2,\\
\operatorname{div} \boldsymbol{u}_i = 0 & \text{in } \Omega_i,\ 1 \le i \le 2,\\
-\operatorname{div}\big(\gamma_i(k_i)\,\nabla k_i\big) = \alpha_i(k_i)\,|\nabla \boldsymbol{u}_i|^2 & \text{in } \Omega_i,\ 1 \le i \le 2,\\
\boldsymbol{u}_i = \mathbf{0} & \text{on } \Gamma_i,\ 1 \le i \le 2,\\
k_i = 0 & \text{on } \Gamma_i,\ 1 \le i \le 2,\\
\alpha_i(k_i)\,\partial_{n_i} \boldsymbol{u}_i - p_i\,\boldsymbol{n}_i + (\boldsymbol{u}_i - \boldsymbol{u}_j)\,|\boldsymbol{u}_i - \boldsymbol{u}_j| = \mathbf{0} & \text{on } \Gamma,\ 1 \le i \ne j \le 2,\\
k_i = |\boldsymbol{u}_1 - \boldsymbol{u}_2|^2 & \text{on } \Gamma,\ 1 \le i \le 2,
\end{cases}
\tag{1.1}
$$

where each triple $(\boldsymbol{u}_i, k_i, p_i)$ is defined in the domain Ω_i, $1 \le i \le 2$. The vector field $\boldsymbol{u}_i$ represents the velocity of a turbulent fluid in Ω_i, p_i represents its pressure, and k_i represents its turbulent kinetic energy (TKE in what follows). The domains Ω_i are two- or three-dimensional bounded open sets with common interface Γ, while each Γ_i stands for $\partial\Omega_i \setminus \Gamma$.

System (1.1) is motivated by the coupling of two turbulent fluids F_i, $i = 1$ and 2, which appears in the framework ocean/atmosphere or in the case of two layers of a stratified fluid (see, e.g., [16, Chaps. 1 and 3] or [18]). Note that, in these situations, the operator $-\mathrm{div}\left(\alpha_i(k_i)\,\nabla\cdot\right)$ in (1.1) should be replaced by a different one, derived from the deformation rate tensor [11, sect. 2]. However, this change leads to more technical proofs, involving additional Korn-type inequalities, and we prefer to avoid it for simplicity of the presentation. These fluids F_i are coupled through the interface condition on their common boundary Γ, which is supposed to be fixed. Indeed, we assume that the so-called "rigid lid hypothesis" holds, which is standard in geophysics and oceanography. According to this assumption, Γ is a fixed mean interface and in fact the values of $\boldsymbol{u}_i$, p_i, and k_i on Γ are mean values of the velocity, pressure, and TKE. This law characterizes mean momentum exchanges between the fluids (see [16, Chap. 1] and [1]), and it is derived in a rather different way from standard wall laws [21] (but the mathematical formulation is rather similar): the turbulent mixed layer of the two turbulent fluids is modelled by the sixth and seventh lines in (1.1) which summarize the information related to a realistic interface ocean/atmosphere (see, e.g., [16, sect. 1.4] for more details about this model). Slightly more realistic models, obtained, for instance, by adding the convection term $\boldsymbol{u}_i \cdot \nabla \boldsymbol{u}_i$ in the first line of problem (1.1) and/or the dissipative term $-\frac{1}{L}\, k_i^{\frac{3}{2}}$ (where L represents the mixing length) in the right-hand side of the third line of this problem, can also be considered. Since their analysis relies on exactly the same arguments as for problem (1.1), we skip these further terms for brevity.

The analysis of problem (1.1) is performed in [3] for two- or three-dimensional domains Ω_i which are either convex or of class $\mathsf{C}^{1,1}$. In that paper, an equivalent variational formulation of problem (1.1) is written, where the equations for the TKE are taken in the transposition sense (see [23] and [17, Chap. 2, sect. 6] for the definition of a solution by tranposition). Indeed, due to the lack of regularity of the right-hand side in the third line of (1.1) which belongs only to $L^1(\Omega_i)$, a standard formulation cannot be used here. However, the present formulation by transposition allows one to derive a priori estimates. Next the existence of a solution is proved. The uniqueness of smooth solutions is also established under some rather restrictive assumptions on the parameters and the data, and some regularity properties of the solutions are derived when the domains Ω_i are two-dimensional rectangles. Note, moreover, that the transposition formulation of the equations on the TKE is equivalent to the standard variational one when the solution is sufficiently smooth. We also refer to [2] for a slightly different proof of the existence result.

In the present paper, we are interested in the spectral discretization of problem (1.1), which relies on the approximation by high-degree polynomials. For simplicity, we consider only the key geometry where the domains are rectangles or rectangular parallelepipeds. However, in order to take into account the possible anisotropy of the flows which can be induced by the large aspect ratios of the domains, we use different degrees of polynomials with respect to the horizontal and vertical variables. We propose a discrete problem which, as usual for spectral methods [7, Chap. III], relies on the variational formulation of the equations for the velocity, the pressure, and also the TKE: it combines a conforming approximation in these spaces of polynomials with the use of numerical integration relying on tensorized Gauss–Lobatto formulas.

As standard for nonlinear systems, the numerical analysis of the discrete problem is performed via the discrete implicit function theorem of Brezzi, Rappaz, and Raviart [10]. As for the continuous problem, the main difficulty is due to the lack of regularity of the right-hand sides in the discrete TKE equations, and, as far as we

know, the numerical analysis of problems with data in L^1 has been performed only in a few works (see [14], [13], and [12]). Thanks to the Brezzi–Rappaz–Raviart theory, in the two-dimensional case, we derive the existence of a solution of the discrete problem in a neighborhood of a nonsingular exact solution under some reasonable assumptions on its regularity. We also prove the convergence of the method, together with optimal error estimates. The same properties hold in the three-dimensional case; however, we think that the assumptions that are needed to prove them are no longer reasonable. A different analysis, leading to weaker convergence results, is under consideration.

To conclude, we propose an algorithm for solving the discrete problem. Its convergence is currently checked via numerical experiments and is likely at least for small variations of the functions α_i and γ_i.

The numerical analysis of the finite element discretization of system (1.1) is under consideration, and its convergence seems to be likely in the two- and three-dimensional cases under realistic assumptions.

An outline of the paper is as follows.

- In section 2, we recall from [3] the variational formulation and the main properties of problem (1.1). We also write a different formulation in view of the discretization.
- In section 3, we describe the choice of the approximation spaces and the discrete problem. We also write a different and equivalent formulation of this problem, which is needed for its analysis.
- Section 4 is devoted to the numerical analysis of the discrete linear Laplace and Stokes problems with variable coefficients that are involved in the discretization.
- In section 5, we perform the numerical analysis of the coupled system. We prove the existence of a solution and derive error estimates.
- In section 6, we propose some conclusions and present a numerical algorithm for solving the discrete problem in the two-dimensional case.

2. Main properties of the continuous problem. In what follows, Ω_1 and Ω_2 stand for disjoint bounded domains in $\mathbb{R}^d$, $d = 2$ or 3, which are either convex or of class $\mathtt{C}^{1,1}$. The generic point in $\mathbb{R}^2$ (resp., in $\mathbb{R}^3$) is denoted by $\boldsymbol{x} = (x, z)$ (resp., $\boldsymbol{x} = (x, y, z)$). We assume for simplicity that the interface $\Gamma = \partial\Omega_1 \cap \partial\Omega_2$ coincides with the intersection of both $\overline{\Omega}_1$ and $\overline{\Omega}_2$ with the hyperplane $z = 0$, while Ω_1 and Ω_2 are contained in the half-spaces $z > 0$ and $z < 0$, respectively. We denote by Γ_i the part of the boundary $\partial\Omega_i \backslash \Gamma$. It must be noted that, in a number of practical situations, the vertical heights of the Ω_i are much smaller than their horizontal diameters.

Throughout the paper, we assume that the functions α_i and γ_i, $1 \le i \le 2$, are continuous and bounded on $\mathbb{R}$, and are continuously differentiable with bounded derivatives. Moreover, we assume that there exists a positive constant ν such that, for $1 \le i \le 2$,

$$\forall k \in \mathbb{R}, \qquad \alpha_i(k) \ge \nu \quad \text{and} \quad \gamma_i(k) \ge \nu. \tag{2.1}$$

We now write a variational formulation of problem (1.1). Next we recall its properties. Finally, we write another formulation of it that relies on the introduction of the Stokes and Laplace operators.

The variational formulation. Throughout the paper, we use the spaces $L^p(\Omega_i)$, $1 \le p \le \infty$, and the Sobolev spaces $H^s(\Omega_i)$ and $H^s_0(\Omega_i)$ for any real number s, provided with the standard norm $\|\cdot\|_{H^s(\Omega_i)}$ and seminorm $|\cdot|_{H^s(\Omega_i)}$, together with their analogues on Γ. We also need the special space $H^{\frac{1}{2}}_{00}(\Gamma)$, defined, e.g., in [17, Chap. 1, Thm. 11.7].

For $1 \le i \le 2$, we introduce the spaces

$$X_i = \big\{ \boldsymbol{v}_i \in H^1(\Omega_i)^d;\ \boldsymbol{v}_i = \boldsymbol{0} \text{ on } \Gamma_i \big\}. \tag{2.2}$$

For reasons explained in [3, sect. 2], we also define the functions G_i, $1 \le i \le 2$, by

$$G_i(k) = \int_0^k \gamma_i(\kappa)\, d\kappa. \tag{2.3}$$

Problem (1.1) can be written (see [2] and [3]) as the following variational system of two coupled problems:

Find $(\boldsymbol{u}_i, p_i)$ *in* $X_i \times L^2(\Omega_i)$, $1 \le i \le 2$, *such that, for* $1 \le i \ne j \le 2$,

$$\begin{aligned} &\forall \boldsymbol{v}_i \in X_i, \quad \int_{\Omega_i} \alpha_i(k_i)\, \nabla \boldsymbol{u}_i \,:\, \nabla \boldsymbol{v}_i \, d\boldsymbol{x} - \int_{\Omega_i} p_i (\operatorname{div} \boldsymbol{v}_i)\, d\boldsymbol{x} \\ &\qquad + \int_\Gamma |\boldsymbol{u}_i - \boldsymbol{u}_j|\, (\boldsymbol{u}_i - \boldsymbol{u}_j) \cdot \boldsymbol{v}_i \, d\tau = \int_{\Omega_i} \boldsymbol{f}_i \cdot \boldsymbol{v}_i \, d\boldsymbol{x}, \\ &\forall q_i \in L^2(\Omega_i), \quad - \int_{\Omega_i} q_i (\operatorname{div} \boldsymbol{u}_i)\, d\boldsymbol{x} = 0; \end{aligned} \tag{2.4}$$

Find k_i *in* $L^2(\Omega_i)$, $1 \le i \le 2$, *such that, for* $1 \le i \le 2$,

$$\begin{aligned} &\forall \varphi_i \in H^2(\Omega_i) \cap H_0^1(\Omega_i), \\ &- \int_{\Omega_i} G_i(k_i)\, \Delta \varphi_i \, d\boldsymbol{x} = - \int_\Gamma G_i(|\boldsymbol{u}_1 - \boldsymbol{u}_2|^2)\, \partial_{n_i} \varphi_i \, d\tau \\ &\qquad + \int_{\Omega_i} \alpha_i(k_i)\, |\nabla \boldsymbol{u}_i|^2\, \varphi_i \, d\boldsymbol{x}. \end{aligned} \tag{2.5}$$

Note that the equations for the velocities and the pressure are of standard variational type and involve the bilinear forms, for $1 \le i \le 2$,

$$a_i(t_i; \boldsymbol{u}_i, \boldsymbol{v}_i) = \int_{\Omega_i} \alpha_i(t_i)\, \nabla \boldsymbol{u}_i \,:\, \nabla \boldsymbol{v}_i \, d\boldsymbol{x}, \quad b_i(\boldsymbol{v}_i, q_i) = - \int_{\Omega_i} q_i (\operatorname{div} \boldsymbol{v}_i)\, d\boldsymbol{x}. \tag{2.6}$$

However, the equation on the TKE is formulated in the transposition sense of Stampacchia [23] and of Lions and Magenes [17, Chap. 2, sect. 6].

As standard for the Stokes problem, we consider the kernel

$$V_i = \big\{ \boldsymbol{v}_i \in X_i;\ \operatorname{div} \boldsymbol{v}_i = 0 \text{ in } \Omega_i \big\},$$

and we observe that, for each solution $(\boldsymbol{u}_i, p_i)$ of problem (2.4), the velocity $\boldsymbol{u}_i$ is a solution of the following problem:

Find $\boldsymbol{u}_i$ *in* V_i, $1 \le i \le 2$, *such that, for* $1 \le i \ne j \le 2$,

$$\begin{aligned} &\forall \boldsymbol{v}_i \in V_i, \quad \int_{\Omega_i} \alpha_i(k_i)\, \nabla \boldsymbol{u}_i \,:\, \nabla \boldsymbol{v}_i \, d\boldsymbol{x} \\ &\qquad + \int_\Gamma |\boldsymbol{u}_i - \boldsymbol{u}_j|\, (\boldsymbol{u}_i - \boldsymbol{u}_j) \cdot \boldsymbol{v}_i \, d\tau = \int_{\Omega_i} \boldsymbol{f}_i \cdot \boldsymbol{v}_i \, d\boldsymbol{x}. \end{aligned} \tag{2.7}$$

Conversely, we recall from [3, Lem. 3.1] that, for $1 \le i \le 2$, there exists a positive constant β_i such that the following inf-sup condition holds:

$$\forall q_i \in L^2(\Omega_i), \quad \sup_{\boldsymbol{v}_i \in X_i} \frac{b_i(\boldsymbol{v}_i, q_i)}{\|\boldsymbol{v}_i\|_{H^1(\Omega_i)^d}} \ge \beta_i \, \|q_i\|_{L^2(\Omega_i)}. \tag{2.8}$$

This yields, for any solution $\boldsymbol{u}_i$ of problem (2.7), the existence of a unique function p_i in $L^2(\Omega_i)$ such that the pair $(\boldsymbol{u}_i, p_i)$ is a solution of problem (2.4). So, for the next results, we work with the simpler system (2.5)–(2.7).

Main properties. We first recall from [3, Lems. 3.3 and 4.2] the following a priori estimates: for any $\boldsymbol{f}_i$ in $L^2(\Omega_i)^d$, $1 \le i \le 2$, every solution $(\boldsymbol{u}_1, \boldsymbol{u}_2)$ of problem (2.7) satisfies

$$\|\boldsymbol{u}_1\|_{H^1(\Omega_1)^d} + \|\boldsymbol{u}_2\|_{H^1(\Omega_2)^d} \le \frac{c}{\nu}\left(\|\boldsymbol{f}_1\|_{L^2(\Omega_1)^d} + \|\boldsymbol{f}_2\|_{L^2(\Omega_2)^d}\right), \tag{2.9}$$

and, for any real number s, $0 \le s < \frac{1}{2}$, and for $1 \le i \le 2$, every solution ℓ_i of problem (2.5) satisfies

$$\|\ell_i\|_{H^s(\Omega_i)} \le c_s\left(\|\boldsymbol{u}_1\|^2_{H^1(\Omega_1)^d} + \|\boldsymbol{u}_2\|^2_{H^1(\Omega_2)^d}\right). \tag{2.10}$$

The constants c and c_s depend on the geometry of Ω, on ν, and on the maximal value of the α_i and γ_i; moreover, the constant c_s depends on s.

Using these estimates, an existence result is proved in [3, Cor. 5.3]. We only state it.

THEOREM 2.1. *For any $\boldsymbol{f}_i$ in $L^2(\Omega_i)^d$, $1 \le i \le 2$, system (2.4)–(2.5) has a solution $(\tilde{U}_1, \tilde{U}_2)$ with each $\tilde{U}_i = (\boldsymbol{u}_i, p_i, k_i)$ in $X_i \times L^2(\Omega_i) \times L^2(\Omega_i)$. Moreover, each function k_i, $i = 1$ and 2, is nonnegative and belongs to $H^s(\Omega_i)$ for all $s < \frac{1}{2}$.*

In contrast, the uniqueness result in [3] (see also [11] for a similar result) is rather disappointing. It states that, if system (2.4)–(2.5) admits a solution $(\boldsymbol{u}_i, p_i, k_i)_{1\le i\le 2}$ such that each $\boldsymbol{u}_i$ belongs to $W^{1,p}(\Omega_i)^d$ for some $p > 2d$, and if its norm in this space is small enough with respect to the relative variation of the α_i, then this solution $(\boldsymbol{u}_i, p_i, k_i)_{1\le i\le 2}$ is unique. So our idea is to give up making any uniqueness assumption for the analysis of the discretization.

Finally, let us recall the regularity property of the solution which is proved in [3, Thm. 7.5] when the domains Ω_1 and Ω_2 are two-dimensional rectangles: let $(\tilde{U}_1, \tilde{U}_2)$ be any solution of system (2.4)–(2.5), with $\tilde{U}_i = (\boldsymbol{u}_i, p_i, k_i)$, such that $\boldsymbol{u}_i$, $i = 1$ and 2, belong to $H^{s_-}(\Omega_i)^2$ for some $s_- > 1$; then, this solution satisfies

$$\tilde{U}_i \in H^s(\Omega_i)^d \times H^{s-1}(\Omega_i) \times H^s(\Omega_i), \qquad i = 1 \text{ and } 2,$$

for all $s \le s_0 \simeq 1.5946$, where the value of s_0 is derived from [20, Cor. 4.2]. So the following assumption seems reasonable, especially in dimension $d = 2$.

Hypothesis 2.2. System (2.4) and (2.5) admits a solution $(\tilde{U}_1^*, \tilde{U}_2^*)$ such that each $\tilde{U}_i^*$, $1 \le i \le 2$, belongs to $H^{s^*}(\Omega_i)^d \times H^{s^*-1}(\Omega_i) \times H^{s^*}(\Omega_i)$ for some $s^* > \frac{d}{2}$.

Remark 2.3. Assume that the functions $\boldsymbol{u}_i$, $i = 1$ and 2, belong to $H^s(\Omega_i)^d$, for some $s > \frac{d}{2}$. If a solution k_i of problem (2.5) belongs to $H^1(\Omega_i)$, then it satisfies the more standard formulation of this problem:

Find k_i in $H^1(\Omega_i)$, $1 \le i \le 2$, with

$$k_i = 0 \quad \text{on } \Gamma_i \qquad \text{and} \qquad k_i = |\boldsymbol{u}_1 - \boldsymbol{u}_2|^2 \quad \text{on } \Gamma,$$

such that, for $1 \le i \le 2$,

$$\forall \varphi_i \in H^1_0(\Omega_i), \quad c_i(k_i; k_i, \varphi_i) = \int_{\Omega_i} \alpha_i(k_i)\,|\nabla \boldsymbol{u}_i|^2\,\varphi_i\,d\boldsymbol{x}, \tag{2.11}$$

where the bilinear form $c_i(t_i; \cdot, \cdot)$ is defined by

$$c_i(t_i; \ell_i, \varphi_i) = \int_{\Omega_i} \gamma_i(t_i)\,\nabla \ell_i \cdot \nabla \varphi_i\,d\boldsymbol{x}. \tag{2.12}$$

The discretization below relies on this last formulation. However, for technical reasons, we consider in what follows its extension to the case where k_i is sought for in $H^{1-\varepsilon}(\Omega_i)$ and φ_i runs through $H^{1+\varepsilon}(\Omega_i)$ for a small positive ε.

Another presentation. For $1 \le i \le 2$, we first introduce a generalized Laplace operator, which we still denote by $\mathcal{L}_i$ for simplicity: for a fixed t_i in $L^1(\Omega_i)$, the operator $\mathcal{L}_i(t_i)$ associates with any g_i in $L^1(\Omega_i)$ and λ_i in $L^2(\Gamma)$ the solution $k_i = \mathcal{L}_i(t_i)(g_i, \lambda_i)$ in $H^s(\Omega_i)$, $s < \frac{1}{2}$, defined by transposition, of the problem

$$\begin{cases} -\operatorname{div}\left(\gamma_i(t_i)\,\nabla k_i\right) = g_i & \text{in } \Omega_i, \\ k_i = 0 & \text{on } \Gamma_i, \\ k_i = \lambda_i & \text{on } \Gamma,\ 1 \le i \le 2. \end{cases} \tag{2.13}$$

The existence and uniqueness of this solution are checked for instance in [3, sect. 4]. Similarly, we introduce the Stokes operator $\mathcal{S}_i$: for a fixed t_i in $L^1(\Omega_i)$, the operator $\mathcal{S}_i(t_i)$ associates with any $\boldsymbol{g}_i$ in the dual space of X_i and $\boldsymbol{\lambda}_i$ in the dual space of $H^{\frac{1}{2}}_{00}(\Gamma)$ the solution $\boldsymbol{u}_i = \mathcal{S}_i(t_i)(\boldsymbol{g}_i, \boldsymbol{\lambda}_i)$ in V_i of the Stokes problem

$$\begin{cases} -\operatorname{div}\left(\alpha_i(t_i)\,\nabla \boldsymbol{u}_i\right) + \mathbf{grad}\, p_i = \boldsymbol{g}_i & \text{in } \Omega_i, \\ \operatorname{div} \boldsymbol{u}_i = 0 & \text{in } \Omega_i, \\ \boldsymbol{u}_i = \mathbf{0} & \text{on } \Gamma_i, \\ \alpha_i(t_i)\,\partial_{n_i}\boldsymbol{u}_i - p_i\,\boldsymbol{n}_i = \boldsymbol{\lambda}_i & \text{on } \Gamma. \end{cases} \tag{2.14}$$

Next it is readily checked that problem (1.1) can be written as

$$\begin{pmatrix} \boldsymbol{u}_1 \\ k_1 \\ \boldsymbol{u}_2 \\ k_2 \end{pmatrix} + \begin{pmatrix} \mathcal{S}_1(k_1) & 0 & 0 & 0 \\ 0 & \mathcal{L}_1(k_1) & 0 & 0 \\ 0 & 0 & \mathcal{S}_2(k_2) & 0 \\ 0 & 0 & 0 & \mathcal{L}_2(k_2) \end{pmatrix} \begin{pmatrix} (-\boldsymbol{f}_1, \boldsymbol{\lambda}_1(\boldsymbol{u}_1, \boldsymbol{u}_2)) \\ (-g_1(k_1, \boldsymbol{u}_1), \lambda(\boldsymbol{u}_1, \boldsymbol{u}_2)) \\ (-\boldsymbol{f}_2, \boldsymbol{\lambda}_2(\boldsymbol{u}_1, \boldsymbol{u}_2)) \\ (-g_2(k_2, \boldsymbol{u}_2), \lambda(\boldsymbol{u}_1, \boldsymbol{u}_2)) \end{pmatrix} = 0, \tag{2.15}$$

with

$$\boldsymbol{\lambda}_i(\boldsymbol{u}_1, \boldsymbol{u}_2) = (\boldsymbol{u}_i - \boldsymbol{u}_j)\,|\boldsymbol{u}_i - \boldsymbol{u}_j|, \quad g_i(k_i, \boldsymbol{u}_i) = \alpha_i(k_i)\,|\nabla \boldsymbol{u}_i|^2, \qquad \lambda(\boldsymbol{u}_1, \boldsymbol{u}_2) = -|\boldsymbol{u}_1 - \boldsymbol{u}_2|^2. \tag{2.16}$$

Let $\mathcal{T}(k_1, k_2)$ denote the diagonal matrix made of the operators $\mathcal{S}_i(k_i)$ and $\mathcal{L}_i(k_i)$ that appears in (2.15), and let $\mathcal{G}(U_1, U_2)$ stand for the last vector in this formula. For technical reasons, we introduce a small parameter ε, $0 < \varepsilon < \frac{1}{2}$, and we consider the spaces

$$\mathcal{X}_i = X_i \times H^{1-\varepsilon}(\Omega_i), \qquad \mathcal{X} = \mathcal{X}_1 \times \mathcal{X}_2. \tag{2.17}$$

Then problem (1.1) is equivalent to finding a solution (U_1, U_2) in $\mathcal{X}$ of the equation

$$\begin{pmatrix} U_1 \\ U_2 \end{pmatrix} + \mathcal{T}(k_1, k_2)\,\mathcal{G}(U_1, U_2) = 0. \tag{2.18}$$

In view of [10], we work with a solution (U_1^*, U_2^*) of (2.18) which satisfies the following hypothesis, as usual for the discretization of nonlinear problems.

Hypothesis 2.4. The solution (U_1^*, U_2^*), of system (2.5)–(2.7), with each $U_i^* = (\boldsymbol{u}_i^*, k_i^*)$, is such that the operator

$$\mathrm{Id} + D\mathcal{T}(k_1^*, k_2^*)\mathcal{G}(U_1^*, U_2^*) + \mathcal{T}(k_1^*, k_2^*)D\mathcal{G}(U_1^*, U_2^*) \tag{2.19}$$

(where D stands for the differential operator) is an isomorphism of $\mathcal{X}$.

The idea is that the conditions for the global uniqueness of the solution (U_1^*, U_2^*), if they exist, are most often too restrictive (see [3, Thm. 6.3]). Hypothesis 2.4 ensures only the local uniqueness of the solution, which is much weaker. Indeed the analogous assumption for the standard Navier–Stokes equations is often used for the numerical analysis of the discretization and is not at all restrictive. Note that Hypothesis 2.4 is equivalent to the well-posedness of the linearized system for any data $(\boldsymbol{g}_i, \boldsymbol{\lambda}_i)$ in the dual space of $X_i \times H_{00}^{\frac{1}{2}}(\Gamma)$ and (g_i, λ_i) in $H^{-1-\varepsilon}(\Omega_i) \times H^{\frac{1}{2}-\varepsilon}(\Gamma)$:

Find $(\boldsymbol{w}_i, r_i)$ *in* $X_i \times L^2(\Omega_i)$, $1 \le i \le 2$, *such that, for* $1 \le i \ne j \le 2$,

$$\begin{aligned}
&\forall \boldsymbol{v}_i \in X_i,\\
&\int_{\Omega_i} \alpha_i(k_i^*)\,\nabla \boldsymbol{w}_i : \nabla \boldsymbol{v}_i\,d\boldsymbol{x} + \int_{\Omega_i} \alpha_i'(k_i^*)\ell_i\,\nabla \boldsymbol{u}_i^* : \nabla \boldsymbol{v}_i\,d\boldsymbol{x} - \int_{\Omega_i} r_i(\operatorname{div} \boldsymbol{v}_i)\,d\boldsymbol{x}\\
&+ \int_\Gamma \frac{(\boldsymbol{u}_i^* - \boldsymbol{u}_j^*)\cdot(\boldsymbol{w}_i - \boldsymbol{w}_j)}{|\boldsymbol{u}_i^* - \boldsymbol{u}_j^*|}\,(\boldsymbol{u}_i^* - \boldsymbol{u}_j^*)\cdot \boldsymbol{v}_i\,d\tau + \int_\Gamma |\boldsymbol{u}_i^* - \boldsymbol{u}_j^*|\,(\boldsymbol{w}_i - \boldsymbol{w}_j)\cdot \boldsymbol{v}_i\,d\tau\\
&\qquad = \int_{\Omega_i} \boldsymbol{g}_i \cdot \boldsymbol{v}_i\,d\boldsymbol{x} + \int_\Gamma \boldsymbol{\lambda}_i \cdot \boldsymbol{v}_i\,d\tau,
\end{aligned} \tag{2.20}$$

$$\forall q_i \in L^2(\Omega_i), \quad -\int_{\Omega_i} q_i(\operatorname{div} \boldsymbol{w}_i)\,d\boldsymbol{x} = 0;$$

Find ℓ_i *in* $H^{1-\varepsilon}(\Omega_i)$, $1 \le i \le 2$, *with*

$$\ell_i = 0 \quad \text{on } \Gamma_i \qquad \text{and} \qquad \ell_i = \lambda_i + 2\,(\boldsymbol{u}_1^* - \boldsymbol{u}_2^*)\cdot(\boldsymbol{w}_1 - \boldsymbol{w}_2) \quad \text{on } \Gamma,$$

such that, for $1 \le i \le 2$,

$$\begin{aligned}
&\forall \varphi_i \in H_0^{1+\varepsilon}(\Omega_i),\\
&\int_{\Omega_i} \gamma_i(k_i^*)\nabla \ell_i \cdot \nabla \varphi_i\,d\boldsymbol{x} + \int_{\Omega_i} \gamma_i'(k_i^*)\ell_i\,\nabla k_i^* \cdot \nabla \varphi_i\,d\boldsymbol{x} = \int_{\Omega_i} g_i\,\varphi_i\,d\boldsymbol{x}\\
&\qquad + 2\int_{\Omega_i} \alpha_i(k_i^*)\,\nabla \boldsymbol{u}_i^* : \nabla \boldsymbol{w}_i\,\varphi_i\,d\boldsymbol{x} + \int_{\Omega_i} \alpha_i'(k_i^*)\ell_i\,|\nabla \boldsymbol{u}_i^*|^2\,\varphi_i\,d\boldsymbol{x}.
\end{aligned} \tag{2.21}$$

Even if this is nothing but a linear problem, writing it is rather technical.

In what follows, we always assume that Hypotheses 2.2 and 2.4 hold. These assumptions are nearly realistic and seem necessary for proving the convergence of any type of discretization.

3. Description of the discrete problem. From now on, we assume that the Ω_i are rectangles in the case $d = 2$, and rectangular parallelepipeds in the case $d = 3$. More precisely, as illustrated in Figure 1, by an appropriate scaling, we take Ω_1 (resp., Ω_2) equal to $]-1, 1[^{d-1} \times]0, h_1[$ (resp., $]-1, 1[^{d-1} \times]-h_2, 0[$), where the h_i are positive real numbers. As already said, the h_i are often small in practical situations.

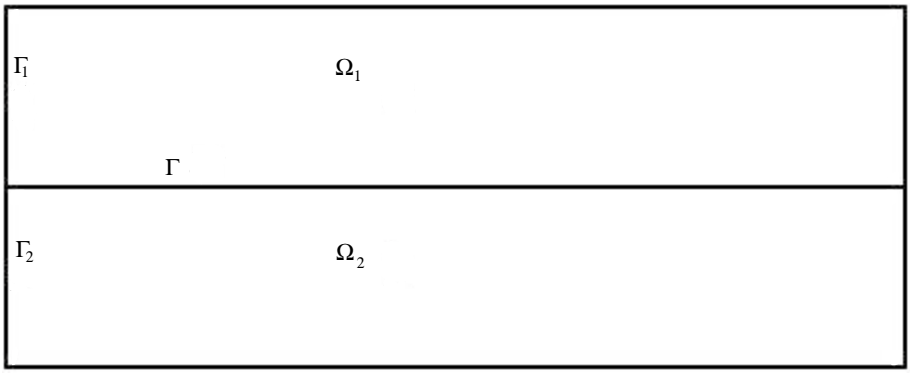

FIG. 1.

We first describe the discrete problem. Second, as for the continuous problem, we write it in a different form, in order to apply the theory of Brezzi, Rappaz, and Raviart [10] for its numerical analysis.

The discrete problem. For each pair of nonnegative integers (k, n), we introduce the space $\mathbb{P}_{k,n}(\Omega_i)$ of restrictions to Ω_i of polynomials with degree $\leq k$ with respect to x (and also to y in the case $d = 3$) and with degree $\leq n$ with respect to z. We denote by $\mathbb{P}_k(\Gamma)$ the space of restrictions to Γ of polynomials with degree $\leq k$ with respect to each tangential variable. We fix a 4-tuple $\delta = (K_1, N_1, K_2, N_2)$ of positive integers, in order to define the discrete spaces of velocities and turbulent energies,

$$X_{i\delta} = \mathbb{P}_{K_i,N_i}(\Omega_i)^d \cap X_i, \qquad Y_{i\delta} = \mathbb{P}_{K_i,N_i}(\Omega_i) \cap H_0^1(\Omega_i). \tag{3.1}$$

As for the standard Stokes problem, two different choices exist for the discrete spaces of pressures $M_{i\delta}$, namely

$$M_{i\delta}^1 = \mathbb{P}_{K_i-2,N_i-2}(\Omega_i) \quad \text{and} \quad M_{i\delta}^2 = \mathbb{P}_{K_i-2,N_i-2}(\Omega_i) \cap \mathbb{P}_{[\lambda K_i],[\lambda N_i]}(\Omega_i), \tag{3.2}$$

for a parameter λ, $0 < \lambda < 1$, where the brackets $[\cdot]$ denote the integral part.

We denote by $(L_n)_{n\geq 0}$ the orthogonal basis of $L^2(-1, 1)$ made by the Legendre polynomials. Each L_n has degree n and satisfies $L_n(1) = 1$. For any positive integer n, let ξ_j^n and ρ_j^n, $0 \leq j \leq n$, be the nodes (in increasing order) and weights of the Gauss–Lobatto formula on $]-1, 1[$, which is exact on all polynomials with degree $\leq 2n - 1$. We recall that ξ_0^n (resp., ξ_n^n) is equal to -1 (resp., 1), that the ξ_j^n, $1 \leq j \leq n-1$, are the zeros of L_n', and that the ρ_j^n are given by

$$\rho_j^n = \frac{2}{n(n+1)\, L_n^2(\xi_j^n)}, \qquad 0 \leq j \leq n. \tag{3.3}$$

For simplicity, we denote by x_{ik} and ρ_{ik}, $0 \leq k \leq K_i$, the nodes $\xi_k^{K_i}$ and weights $\rho_k^{K_i}$. In the z-direction, we set, for $0 \leq j \leq N_i$,

$$z_{ij} = \frac{h_i}{2}\left((-1)^{i+1} + \xi_j^{N_i}\right) \quad \text{and} \quad \omega_{ij} = \frac{h_i}{2}\,\rho_j^{N_i}.$$

We introduce the grids

$$\Xi_{i\delta} = \begin{cases} \left\{(x_{ik}, z_{ij});\ 0 \leq k \leq K_i,\ 0 \leq j \leq N_i\right\} & \text{in the case } d = 2, \\ \left\{(x_{ik}, x_{i\ell}, z_{ij});\ 0 \leq k, \ell \leq K_i,\ 0 \leq j \leq N_i\right\} & \text{in the case } d = 3, \end{cases}$$

and we denote by $\mathcal{I}_{i\delta}$ the Lagrange interpolation operator on the grid $\Xi_{i\delta}$ with values in $\mathbb{P}_{K_i,N_i}(\Omega_i)$. Two different grids are then defined on the interface Γ: we denote by $\mathcal{I}_{i\delta}^{\Gamma}$ the Lagrange interpolation operator on the grid $\Xi_{i\delta}\cap\Gamma$ with values in $\mathbb{P}_{K_i}(\Gamma)$.

Finally, we introduce the discrete product, for all functions u and v continuous on $\overline{\Omega}_i$,

$$\big(u,v\big)_{i\delta}=\begin{cases}\sum_{k=0}^{K_i}\sum_{j=0}^{N_i}u(x_{ik},z_{ij})v(x_{ik},z_{ij})\,\rho_{ik}\omega_{ij} & \text{in the case } d=2,\\ \sum_{k=0}^{K_i}\sum_{\ell=0}^{K_i}\sum_{j=0}^{N_i}u(x_{ik},x_{i\ell},z_{ij})v(x_{ik},x_{i\ell},z_{ij})\,\rho_{ik}\rho_{i\ell}\omega_{ij} & \text{in the case } d=3,\end{cases}$$

and its analogue on Γ

$$\big(u,v\big)_{i\delta}^{\Gamma}=\begin{cases}\sum_{k=0}^{K_i}u(x_{ik})v(x_{ik})\,\rho_{ik} & \text{in the case } d=2,\\ \sum_{k=0}^{K_i}\sum_{\ell=0}^{K_i}u(x_{ik},x_{i\ell})v(x_{ik},x_{i\ell})\,\rho_{ik}\rho_{i\ell} & \text{in the case } d=3.\end{cases}$$

We fix an operator $\Pi_{i\delta}^{\Gamma}$ from $H_{00}^{\frac12}(\Gamma)$ into $\mathbb{P}_{K_i}(\Gamma)\cap H_{00}^{\frac12}(\Gamma)$ which will be made precise later on. We are now in a position to state the discrete problem associated with problem (1.1). It reads as follows:

Find $(\tilde U_{1\delta},\tilde U_{2\delta})$, *with each* $\tilde U_{i\delta}=(\boldsymbol{u}_{i\delta},p_{i\delta},k_{i\delta})$ *in* $X_{i\delta}\times M_{i\delta}\times\mathbb{P}_{K_i,N_i}(\Omega_i)$, *such that, for* $1\le i\ne j\le 2$,

$$k_{i\delta}=0\quad\text{on }\Gamma_i\quad\text{and}\quad k_{i\delta}=\Pi_{i\delta}^{\Gamma}(|\boldsymbol{u}_{1\delta}-\boldsymbol{u}_{2\delta}|^2)\quad\text{on }\Gamma,\tag{3.4}$$

and

$$\begin{aligned}&\forall\boldsymbol{v}_{i\delta}\in X_{i\delta},\\ &\quad a_{i\delta}(k_{i\delta};\boldsymbol{u}_{i\delta},\boldsymbol{v}_{i\delta})+b_{i\delta}(\boldsymbol{v}_{i\delta},p_{i\delta})+\big(\,|\boldsymbol{u}_{i\delta}-\boldsymbol{u}_{j\delta}|\,(\boldsymbol{u}_{i\delta}-\boldsymbol{u}_{j\delta}),\boldsymbol{v}_{i\delta}\big)_{i\delta}^{\Gamma}=\big(\boldsymbol{f}_i,\boldsymbol{v}_{i\delta}\big)_{i\delta},\\ &\forall q_{i\delta}\in M_{i\delta},\quad b_{i\delta}(\boldsymbol{u}_{i\delta},q_{i\delta})=0,\\ &\forall\varphi_{i\delta}\in Y_{i\delta},\quad c_{i\delta}(k_{i\delta};k_{i\delta},\varphi_{i\delta})=\big(\alpha_i(k_{i\delta})\,|\nabla\boldsymbol{u}_{i\delta}|^2,\varphi_{i\delta}\big)_{i\delta},\end{aligned}\tag{3.5}$$

where, for any continuous function t_i, the bilinear forms $a_{i\delta}(t_i;\cdot,\cdot)$, $b_{i\delta}(\cdot,\cdot)$, and $c_{i\delta}(t_i;\cdot,\cdot)$ are now defined by

$$\begin{aligned}a_{i\delta}(t_i;\boldsymbol{u}_{i\delta},\boldsymbol{v}_{i\delta})=\big(\alpha_i(t_i)\,\nabla\boldsymbol{u}_{i\delta},\nabla\boldsymbol{v}_{i\delta}\big)_{i\delta},\quad b_{i\delta}(\boldsymbol{v}_{i\delta},q_{i\delta})=-\big(q_{i\delta},\operatorname{div}\boldsymbol{v}_{i\delta}\big)_{i\delta},\\ c_{i\delta}(t_i;k_{i\delta},\varphi_{i\delta})=\big(\gamma_i(t_i)\,\nabla k_{i\delta},\nabla\varphi_{i\delta}\big)_{i\delta}.\end{aligned}\tag{3.6}$$

Remark 3.1. A natural choice of operator $\Pi_{i\delta}^{\Gamma}$ would be the Lagrange interpolation operator $\mathcal{I}_{i\delta}^{\Gamma}$. However, for $K_1\ne K_2$, since two different discrete products are defined on the interface Γ, the trace of $\boldsymbol{u}_{1\delta}$ on Γ must be re-interpolated on the nodes of $\Xi_{2\delta}\cap\Gamma$ and conversely. Moreover, the convergence of the interpolate of a function φ toward this function in $H_{00}^{\frac12}(\Gamma)$ or even in $H^{\frac12-\varepsilon}(\Gamma)$ would require too much regularity of the function φ; see [7, sect. 14]. Other choices of operator $\Pi_{i\delta}^{\Gamma}$, such as orthogonal projection operators, are possible but seem more expensive to implement.

Remark 3.2. For the choices $M_{i\delta}^1$ and $M_{i\delta}^2$ of discrete pressure spaces introduced in (3.2), and thanks to the exactness property of the quadrature formula, each $b_{i\delta}(\cdot,\cdot)$ can be replaced by $b_i(\cdot,\cdot)$ in formulation (3.5).

The numerical analysis of system (3.4)–(3.5) is rather technical. However, we begin with the same simplication as for the continuous problem. For $i=1$ and 2, we introduce the discrete kernel

$$V_{i\delta}=\big\{\boldsymbol{v}_{i\delta}\in X_{i\delta};\ \forall q_{i\delta}\in M_{i\delta},\ b_{i\delta}(\boldsymbol{v}_{i\delta},q_{i\delta})=0\big\}.$$

Note that, for the two choices $M_{i\delta} = M^1_{i\delta}$ and $M_{i\delta} = M^2_{i\delta}$ proposed in (3.2), $V_{i\delta}$ is not contained in V_i, i.e., is not made of exactly divergence-free polynomials. It is readily checked with this definition that, for each pair $(\tilde{U}_{1\delta}, \tilde{U}_{2\delta})$ solution of system (3.4)–(3.5), the reduced pair $(U_{1\delta}, U_{2\delta})$ of discrete velocities and discrete turbulent energies is a solution of the following system:

Find $(U_{1\delta}, U_{2\delta})$, *with each* $U_{i\delta} = (\boldsymbol{u}_{i\delta}, k_{i\delta})$ *in* $V_{i\delta} \times \mathbb{P}_{K_i,N_i}(\Omega_i)$,
satisfying (3.4) *and such that, for* $1 \le i \ne j \le 2$,

$$
\begin{aligned}
&\forall \boldsymbol{v}_{i\delta} \in V_{i\delta}, \quad a_{i\delta}(k_{i\delta}; \boldsymbol{u}_{i\delta}, \boldsymbol{v}_{i\delta}) + \big(|\boldsymbol{u}_{i\delta} - \boldsymbol{u}_{j\delta}| \, (\boldsymbol{u}_{i\delta} - \boldsymbol{u}_{j\delta}), \boldsymbol{v}_{i\delta} \big)^{\Gamma}_{i\delta} = \big(\boldsymbol{f}_i, \boldsymbol{v}_{i\delta} \big)_{i\delta}, \\
&\forall \varphi_{i\delta} \in Y_{i\delta}, \quad c_{i\delta}(k_{i\delta}; k_{i\delta}, \varphi_{i\delta}) = \big(\alpha_i(k_{i\delta}) \, |\nabla \boldsymbol{u}_{i\delta}|^2, \varphi_{i\delta} \big)_{i\delta}.
\end{aligned} \tag{3.7}
$$

The converse property relies on a discrete inf-sup condition, which is derived in two steps, relying on the arguments in [8] and [9], respectively. For a while, let $\tilde{M}^m_{i\delta}$ stand for the subspace of $M^m_{i\delta}$ made of polynomials with a null integral on Ω_i.

LEMMA 3.3. *For* $i = 1$ *and* 2, *and for the discrete spaces* $\tilde{M}^m_{i\delta}$, $m = 1$ *and* 2, *there exists a constant* $\tilde{\beta}^m_{i\delta} > 0$ *such that*

$$
\forall q_{i\delta} \in \tilde{M}^m_{i\delta}, \qquad \sup_{\boldsymbol{v}_{i\delta} \in X_{i\delta} \cap H^1_0(\Omega_i)^d} \frac{b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta})}{\|\boldsymbol{v}_{i\delta}\|_{H^1(\Omega_i)^d}} \ge \tilde{\beta}^m_{i\delta} \, \|q_{i\delta}\|_{L^2(\Omega_i)}. \tag{3.8}
$$

Moreover, these constants $\tilde{\beta}^m_i$ *satisfy, for* $i = 1$ *and* 2,

$$
\tilde{\beta}^1_i \ge c \, K_i^{\frac{2-d}{2}} \inf\{K_i^{-\frac{1}{2}}, N_i^{-\frac{1}{2}}\} \qquad \textit{and} \qquad \tilde{\beta}^2_i \ge c. \tag{3.9}
$$

Proof. Since any $q_{i\delta}$ in $\tilde{M}_{i\delta}$ has a null integral on Ω_i, there exists [15, Chap. I, Cor. 2.4] a function $\boldsymbol{v}_i$ in $H^1_0(\Omega_i)^d$ such that

$$
\operatorname{div} \boldsymbol{v}_i = q_{i\delta} \quad \text{in } \Omega_i \quad \text{and} \quad \|\boldsymbol{v}_i\|_{H^1(\Omega_i)^d} \le c \, \|q_{i\delta}\|_{L^2(\Omega_i)}.
$$

Next, we recall from [8, Lems. 3.2 and 3.3] that, for any μ, $0 < \mu < 1$, there exists an operator π^μ_n from $H^1_0(-1,1)$ onto $\mathbb{P}_{[(1+\mu)n]}(-1,1) \cap H^1_0(-1,1)$ which preserves all polynomials in $\mathbb{P}_{n-1}(-1,1)$ and satisfies, for all φ in $H^1_0(-1,1)$,

$$
\|(\pi^\mu_n \varphi)'\|_{L^2(-1,1)} \le \|\varphi'\|_{L^2(-1,1)} \quad \text{and} \quad \|\pi^\mu_n \varphi\|_{L^2(-1,1)} \le c \, \mu^{-\frac{1}{2}} \, \|\varphi\|_{L^2(-1,1)}.
$$

The idea consists of choosing the operator $\pi^m_{K_i}$ in the x- or y-direction equal to $\pi^{\mu(K_i)}_M$, with

$$
(1 + \mu(K_i))M = K_i \quad \text{and} \quad M = \begin{cases} K_i - 1 & \text{if } m = 1, \\ [\frac{1+\lambda}{2} \, K_i] & \text{if } m = 2 \end{cases}
$$

(recall that λ is introduced in (3.2)), and denoting them by $\pi^{m(x)}_{K_i}$ and $\pi^{m(y)}_{K_i}$, respectively. Similarly, the operator $\pi^m_{N_i}$ in the z-direction is equal to $\pi^{\mu(N_i)}_M$, with

$$
(1 + \mu(N_i))M = N_i \quad \text{and} \quad M = \begin{cases} N_i - 1 & \text{if } m = 1, \\ [\frac{1+\lambda}{2} \, N_i] & \text{if } m = 2, \end{cases}
$$

and denoted by $\pi^{m(z)}_{N_i}$. Next we set

$$
\boldsymbol{v}^s_{i\delta} = \begin{cases} \pi^{m(x)}_{K_i} \circ \pi^{m(z)}_{N_i} \boldsymbol{v}_i & \text{in the case } d = 2, \\ \pi^{m(x)}_{K_i} \circ \pi^{m(y)}_{K_i} \circ \pi^{m(z)}_{N_i} \boldsymbol{v}_i & \text{in the case } d = 3. \end{cases}
$$

From the properties of these operators, it is readily checked that

$$b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta}) = -\int_{\Omega_i} q_{i\delta}\,(\operatorname{div}\boldsymbol{v}_i)\,d\boldsymbol{x} = \int_{\Omega_{i\delta}} (q_{i\delta})^2\,d\boldsymbol{x},$$

while the norm of $\boldsymbol{v}_{i\delta}$ in $H^1_0(\Omega)^d$ is bounded by

$$\|\boldsymbol{v}_{i\delta}\|_{H^1(\Omega_i)^d} \le c\,\sup\{\mu(K_i)^{\frac{2-d}{2}}\mu(N_i)^{-\frac12}, \mu(K_i)^{\frac{1-d}{2}}\}\,\|\boldsymbol{v}_i\|_{H^1(\Omega_i)^d}.$$

Evaluating the quantities $\mu(K_i)$ and $\mu(N_i)$ as a function of N_i or K_i for $m = 1$ or 2 leads to the desired result.

LEMMA 3.4. *For $i = 1$ and 2, and for the discrete spaces $M^m_{i\delta}$, $m = 1$ and 2, defined in* (3.2)*, there exists a constant $\beta^m_{i\delta} > 0$ such that*

$$\forall q_{i\delta} \in M^m_{i\delta}, \quad \sup_{\boldsymbol{v}_{i\delta}\in X_{i\delta}} \frac{b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta})}{\|\boldsymbol{v}_{i\delta}\|_{H^1(\Omega_i)^d}} \ge \beta^m_{i\delta}\,\|q_{i\delta}\|_{L^2(\Omega_i)}. \tag{3.10}$$

Moreover, these constants $\beta^m_{i\delta}$, $i = 1$ and 2, satisfy (3.9).

Proof. Any function $q_{i\delta}$ in $M^m_{i\delta}$ admits the expansion

$$q_{i\delta} = \tilde q_{i\delta} + \overline{q}_{i\delta}, \qquad \text{with} \quad \overline{q}_{i\delta} = \frac{1}{2^{d-1}\,h_i}\int_{\Omega_i} q_{i\delta}(\boldsymbol{x})\,d\boldsymbol{x}.$$

Since the function $\tilde q_{i\delta}$ belongs to $\tilde M^m_{i\delta}$, it follows from Lemma 3.3 that there exists a $\tilde{\boldsymbol{v}}_{i\delta}$ in $X_{i\delta}\cap H^1_0(\Omega_i)^d$ such that

$$b_{i\delta}(\tilde{\boldsymbol{v}}_{i\delta}, \tilde q_{i\delta}) = \|\tilde q_{i\delta}\|^2_{L^2(\Omega_i)} \quad \text{and} \quad \|\tilde{\boldsymbol{v}}_{i\delta}\|_{H^1(\Omega_i)^d} \le \frac{1}{\tilde\beta^m_{i\delta}}\,\|\tilde q_{i\delta}\|_{L^2(\Omega_i)}.$$

On the other hand, the function $\overline{\boldsymbol{v}}_{i\delta}$ equal to $(0, v_{i\delta})$ in dimension $d = 2$, and to $(0, 0, v_{i\delta})$ in dimension $d = 3$, with

$$v_{i\delta} = \begin{cases} \big(L_0(x) - L_2(x)\big)\,\big((-1)^{i+1}h_i - z\big)\,\overline{q}_{i\delta} & \text{in dimension } d = 2,\\ \big(L_0(x) - L_2(x)\big)\,\big(L_0(y) - L_2(y)\big)\,\big((-1)^{i+1}h_i - z\big)\,\overline{q}_{i\delta} & \text{in dimension } d = 3,\end{cases}$$

belongs to $X_{i\delta}$ and satisfies, for a fixed constant c_0,

$$b_{i\delta}(\overline{\boldsymbol{v}}_{i\delta}, \overline{q}_{i\delta}) = \|\overline{q}_{i\delta}\|^2_{L^2(\Omega_i)} \quad \text{and} \quad \|\overline{\boldsymbol{v}}_{i\delta}\|_{H^1(\Omega_i)^d} \le c_0\,\|\overline{q}_{i\delta}\|_{L^2(\Omega_i)}.$$

Next we take $\boldsymbol{v}_{i\delta}$ equal to $\tilde{\boldsymbol{v}}_{i\delta} + \lambda\,\overline{\boldsymbol{v}}_{i\delta}$ for a fixed constant λ. Indeed, it follows by integration by parts that $b_{i\delta}(\tilde{\boldsymbol{v}}_{i\delta}, \overline{q}_{i\delta})$ vanishes so that

$$b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta}) = b_{i\delta}(\tilde{\boldsymbol{v}}_{i\delta}, \tilde q_{i\delta}) + \lambda\,b_{i\delta}(\overline{\boldsymbol{v}}_{i\delta}, \overline{q}_{i\delta}) + \lambda\,b_{i\delta}(\overline{\boldsymbol{v}}_{i\delta}, \tilde q_{i\delta}).$$

The previous properties, together with the continuity of $b_{i\delta}(\cdot,\cdot)$ (which coincides with $b_i(\cdot,\cdot)$ everywhere in the previous equation), yield

$$\begin{aligned} b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta}) &\ge \|\tilde q_{i\delta}\|^2_{L^2(\Omega_i)} + \lambda\,\|\overline{q}_{i\delta}\|^2_{L^2(\Omega_i)} - c\lambda\,\|\overline{\boldsymbol{v}}_{i\delta}\|_{H^1(\Omega_i)^d}\,\|\tilde q_{i\delta}\|_{L^2(\Omega_i)}\\ &\ge \|\tilde q_{i\delta}\|^2_{L^2(\Omega_i)} + \lambda\,\|\overline{q}_{i\delta}\|^2_{L^2(\Omega_i)} - cc_0\lambda\,\|\tilde q_{i\delta}\|_{L^2(\Omega_i)}\,\|\overline{q}_{i\delta}\|_{L^2(\Omega_i)}, \end{aligned}$$

whence

$$b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta}) \ge \frac12\|\tilde q_{i\delta}\|^2_{L^2(\Omega_i)} + \lambda\Big(1 - \frac{c^2c_0^2\lambda}{2}\Big)\,\|\overline{q}_{i\delta}\|^2_{L^2(\Omega_i)}.$$

We now choose λ equal to $\frac{1}{c^2 c_0^2}$, which gives (note that $\tilde{q}_{i\delta}$ and $\overline{q}_{i\delta}$ are orthogonal in $L^2(\Omega_i)$)

$$b_{i\delta}(\boldsymbol{v}_{i\delta}, q_{i\delta}) \geq \inf\Big\{\frac{1}{2}, \frac{\lambda}{2}\Big\} \|q_{i\delta}\|^2_{L^2(\Omega_i)}.$$

We also have

$$\|\boldsymbol{v}_{i\delta}\|_{H^1(\Omega_i)^d} \leq \|\tilde{\boldsymbol{v}}_{i\delta}\|_{H^1(\Omega_i)^d} + \lambda \|\overline{\boldsymbol{v}}_{i\delta}\|_{H^1(\Omega_i)^d} \leq \left(\Big(\frac{1}{\tilde{\beta}^m_{i\delta}}\Big)^2 + c_0^2\lambda^2\right)^{\frac{1}{2}} \|q_{i\delta}\|_{L^2(\Omega_i)},$$

which concludes the proof.

Remark 3.5. From the previous proofs, the constants $\beta^m_{i\delta}$ given in (3.9) a priori depend on h_i. However, by using the vertical homothety that maps Ω_i onto the reference square or cube, it is readily checked that these constants satisfy

$$\beta^1_i \geq c\, K_i^{\frac{2-d}{2}} \inf\{h_i\, K_i^{-\frac{1}{2}}, N_i^{-\frac{1}{2}}\} \qquad \text{and} \qquad \beta^2_i \geq c\, h_i, \tag{3.11}$$

where c is now independent of h_i.

So we now work with system (3.4)–(3.7). The first idea consists of writing it in a more appropriate form which is the discrete analogue of (2.18).

Another presentation. For $i = 1$ and 2, we introduce the discrete Laplace operator $\mathcal{L}_{i\delta}$. For a fixed continuous function t_i, the operator $\mathcal{L}_{i\delta}(t_i)$ associates with any g_i in $H^{-1}(\Omega_i)$ and any function λ_i in $H^{\frac{1}{2}}_{00}(\Gamma)$, the solution $k_{i\delta} = \mathcal{L}_{i\delta}(t_i)(g_i, \lambda_i)$ of the following problem:

Find $k_{i\delta}$ in $\mathbb{P}_{K_i,N_i}(\Omega_i)$ such that

$$k_{i\delta} = 0 \quad \text{on } \Gamma_i \quad \text{and} \quad k_{i\delta} = \Pi^{\Gamma}_{i\delta}\lambda_i \quad \text{on } \Gamma, \tag{3.12}$$

and

$$\forall \varphi_{i\delta} \in Y_{i\delta}, \quad c_{i\delta}(t_i; k_{i\delta}, \varphi_{i\delta}) = \int_{\Omega_i} g_i\, \varphi_{i\delta}\, d\boldsymbol{x}. \tag{3.13}$$

It follows from (3.3) that the weights ρ_{ik} and ω_{ij} are positive. When combined with (2.1), this yields that the only solution of (3.12)–(3.13) for $g_i = 0$ and $\lambda_i = 0$ is zero. Hence, since problem (3.12)–(3.13) results into a square linear system, the operator $\mathcal{L}_{i\delta}(t_i)$ is well-defined.

Similarly, we introduce the discrete Stokes operator $\mathcal{S}_{i\delta}$. For a fixed continuous function t_i, the operator $\mathcal{S}_{i\delta}(t_i)$ associates with any $\boldsymbol{g}_i$ in the dual space of X_i and $\boldsymbol{\lambda}_i$ in the dual space of $H^{\frac{1}{2}}_{00}(\Gamma)^d$ the solution $\boldsymbol{u}_{i\delta} = \mathcal{S}_{i\delta}(t_i)(\boldsymbol{g}_i, \boldsymbol{\lambda}_i)$ in $V_{i\delta}$ of the following Stokes problem:

Find $\boldsymbol{u}_{i\delta}$ in $V_{i\delta}$ such that

$$\forall \boldsymbol{v}_{i\delta} \in V_{i\delta}, \quad a_{i\delta}(t_i; \boldsymbol{u}_{i\delta}, \boldsymbol{v}_{i\delta}) = \int_{\Omega_i} \boldsymbol{g}_i \cdot \boldsymbol{v}_{i\delta}\, d\boldsymbol{x} + \int_{\Gamma} \boldsymbol{\lambda}_i \cdot \boldsymbol{v}_{i\delta}\, d\tau. \tag{3.14}$$

There also it follows from (3.3) and (2.1) that the operator $\mathcal{S}_{i\delta}(t_i)$ is well-defined.

Finally, the matrix $\mathcal{T}_\delta(t_1, t_2)$ is defined by

$$\mathcal{T}_\delta(t_1, t_2) = \begin{pmatrix} \mathcal{S}_{1\delta}(t_1) & 0 & 0 & 0 \\ 0 & \mathcal{L}_{1\delta}(t_1) & 0 & 0 \\ 0 & 0 & \mathcal{S}_{2\delta}(t_2) & 0 \\ 0 & 0 & 0 & \mathcal{L}_{2\delta}(t_2) \end{pmatrix}. \tag{3.15}$$

We introduce the vector $\mathcal{G}_\delta(U_{1\delta}, U_{2\delta})$,

$$\mathcal{G}_\delta(U_{1\delta}, U_{2\delta}) = \begin{pmatrix} (-\boldsymbol{f}_{1\delta}, \boldsymbol{\lambda}_{1\delta}(\boldsymbol{u}_{1\delta}, \boldsymbol{u}_{2\delta})) \\ (-g_{1\delta}(k_{1\delta}, \boldsymbol{u}_{1\delta}), \lambda(\boldsymbol{u}_{1\delta}, \boldsymbol{u}_{2\delta})) \\ (-\boldsymbol{f}_{2\delta}, \boldsymbol{\lambda}_{2\delta}(\boldsymbol{u}_{1\delta}, \boldsymbol{u}_{2\delta})) \\ (-g_{2\delta}(k_{2\delta}, \boldsymbol{u}_{2\delta}), \lambda(\boldsymbol{u}_{1\delta}, \boldsymbol{u}_{2\delta})) \end{pmatrix}, \tag{3.16}$$

where the functions $\boldsymbol{f}_{i\delta}$, $g_{i\delta}$, and $\boldsymbol{\lambda}_{i\delta}$ are defined by duality, for smooth enough functions $\boldsymbol{v}_i$ and φ_i (we do not make precise the spaces),

$$\begin{gathered} \langle \boldsymbol{f}_{i\delta}, \boldsymbol{v}_i \rangle = \big(\boldsymbol{f}_i, \boldsymbol{v}_i\big)_{i\delta}, \qquad \big\langle \boldsymbol{\lambda}_{i\delta}(\boldsymbol{u}_{1\delta}, \boldsymbol{u}_{2\delta}), \boldsymbol{v}_i \big\rangle = \big(|\boldsymbol{u}_{i\delta} - \boldsymbol{u}_{j\delta}| \, (\boldsymbol{u}_{i\delta} - \boldsymbol{u}_{j\delta}), \boldsymbol{v}_i \big)_{i\delta}^{\Gamma}, \\ \big\langle g_{i\delta}(k_{i\delta}, \boldsymbol{u}_{i\delta}), \varphi_i \big\rangle = \big(\alpha_i(k_{i\delta}) \, |\nabla \boldsymbol{u}_{i\delta}|^2, \varphi_i\big)_{i\delta}. \end{gathered} \tag{3.17}$$

The quantity $\lambda(\boldsymbol{u}_1, \boldsymbol{u}_2)$ is defined in (2.16).

Thus, it is readily checked that problem (3.4)–(3.7) can be equivalently written

$$U_\delta + \mathcal{T}_\delta(k_{1\delta}, k_{2\delta}) \, \mathcal{G}_\delta(U_{1\delta}, U_{2\delta}) = 0, \qquad \text{with} \quad U_\delta = \begin{pmatrix} \boldsymbol{u}_{1\delta} \\ k_{1\delta} \\ \boldsymbol{u}_{2\delta} \\ k_{2\delta} \end{pmatrix}. \tag{3.18}$$

This formulation is fully appropriate for performing its numerical analysis thanks to the theory of Brezzi, Rappaz, and Raviart [10].

4. The discrete Laplace and Stokes operators. As a first step for the numerical analysis of the discrete problem (3.4)–(3.5), we investigate the properties of the discrete quasi-linear operators $\mathcal{L}_{i\delta}$ and $\mathcal{S}_{i\delta}$; more precisely, we prove stability and error estimates. In all that follows, c, c', and c'' stand for generic constants that may vary from one line to the other but are always independent of δ.

The discrete Laplace operator. For $i = 1$ and 2, and for a fixed continuous function t_i, let us first consider the operator $\mathcal{L}_{i\delta}(t_i)$ defined from problem (3.12)–(3.13). In order to prove its stability, we first recall [7, Form. (13.10)] that, for any polynomial φ_n of degree $\le n$ on $]-1, 1[$,

$$\|\varphi_n\|^2_{L^2(-1,1)} \le \sum_{j=0}^{n} \varphi_n^2(\xi_j^n) \, \rho_j^n \le 3 \, \|\varphi_n\|^2_{L^2(-1,1)}. \tag{4.1}$$

Combined with the boundedness and positivity of γ_i (see (2.1)), this obviously yields some basic properties of the form $c_{i\delta}(\cdot, \cdot)$ that we now state.

LEMMA 4.1. *For any continuous function t_i, the form $c_{i\delta}(t_i; \cdot, \cdot)$ satisfies the following properties of continuity:*

$$\begin{gathered} \forall \psi_{i\delta} \in \mathbb{P}_{K_i, N_i}(\Omega_i), \ \forall \varphi_{i\delta} \in \mathbb{P}_{K_i, N_i}(\Omega_i), \\ c_{i\delta}(t_i; \psi_{i\delta}, \varphi_{i\delta}) \le c \, \|\psi_{i\delta}\|_{H^1(\Omega_i)} \|\varphi_{i\delta}\|_{H^1(\Omega_i)}, \end{gathered} \tag{4.2}$$

and of ellipticity

$$\forall \psi_{i\delta} \in Y_{i\delta}, \quad c_{i\delta}(t_i; \psi_{i\delta}, \psi_{i\delta}) \ge c \, \|\psi_{i\delta}\|^2_{H^1(\Omega_i)}. \tag{4.3}$$

Let R_i be a continuous lifting operator form $H_{00}^{\frac{1}{2}}(\Gamma)$ into $H^1(\Omega_i)$, defined as follows. For any λ in $H_{00}^{\frac{1}{2}}(\Gamma)$, $R_i\lambda$ belongs to $H^1(\Omega_i)$, is equal to λ on Γ, vanishes

on Γ_i, and satisfies (this is proven by using the analogous lifting operator on the unit square or cube), for all $s \geq 1$,

$$\forall \lambda \in H_{\diamond}^{s-\frac{1}{2}}(\Gamma), \quad \|R_i\lambda\|_{H^s(\Omega_i)} \leq c\, h_i^{\frac{1}{2}-s}\, \|\lambda\|_{H_{\diamond}^{s-\frac{1}{2}}(\Gamma)}, \tag{4.4}$$

where $H_{\diamond}^{s-\frac{1}{2}}(\Gamma)$ stands for the intersection $H^{s-\frac{1}{2}}(\Gamma) \cap H_{00}^{\frac{1}{2}}(\Gamma)$, provided with the norm of $H_{00}^{\frac{1}{2}}(\Gamma)$ if s is equal to 1, of $H^{s-\frac{1}{2}}(\Gamma)$ if $s > 1$. A similar operator $R_{i\delta}$, satisfying the same properties, is constructed in [19] and [4], which maps polynomials in $\mathbb{P}_{K_i}(\Gamma)$ vanishing on $\partial\Gamma$ into $\mathbb{P}_{K_i,K_i}(\Omega_i)$. Moreover, this operator satisfies, for all $s \geq 1$,

$$\forall \lambda_\delta \in \mathbb{P}_{K_i}(\Gamma) \cap H_{00}^{\frac{1}{2}}(\Gamma), \quad \|R_{i\delta}\lambda_\delta\|_{H^s(\Omega_i)} \leq c\, h_i^{\frac{1}{2}-s}\, \|\lambda_\delta\|_{H_{\diamond}^{s-\frac{1}{2}}(\Gamma)}. \tag{4.5}$$

However, in order to obtain a lifting operator of the same space of polynomials into $\mathbb{P}_{K_i,N_i}(\Gamma)$, we apply the interpolation operator $\mathcal{I}_{i\delta}$ to $R_{i\delta}\lambda_\delta$ and derive from the stability properties of this operator on polynomials (see [7, Forms. (13.27) and (13.28)]) that

$$\forall \lambda_\delta \in \mathbb{P}_{K_i}(\Gamma) \cap H_{00}^{\frac{1}{2}}(\Gamma), \quad \|\mathcal{I}_{i\delta}R_{i\delta}\lambda_\delta\|_{H^1(\Omega_i)} \leq c\, \sup\Big\{h_i^{-\frac{1}{2}}, \frac{K_i}{N_i}\, h_i^{\frac{1}{2}}\Big\}\, \|\lambda_\delta\|_{H_{00}^{\frac{1}{2}}(\Gamma)}. \tag{4.6}$$

LEMMA 4.2. *For any continuous function t_i, the following stability property holds for any g_i in $H^{-1}(\Omega_i)$ and any continuous function λ_i on Γ:*

$$\|\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)} \leq c\left(\|g_i\|_{H^{-1}(\Omega_i)} + \sup\Big\{h_i^{-\frac{1}{2}}, \frac{K_i}{N_i}\, h_i^{\frac{1}{2}}\Big\}\, \|\Pi_{i\delta}^{\Gamma}\lambda_i\|_{H_{00}^{\frac{1}{2}}(\Gamma)}\right). \tag{4.7}$$

Proof. The function $k_{i\delta}^0 = \mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i) - \mathcal{I}_{i\delta}R_{i\delta}\Pi_{i\delta}^{\Gamma}\lambda_i$ belongs to $Y_{i\delta}$ so that applying the ellipticity property (4.3) leads to

$$c\,\|k_{i\delta}^0\|_{H^1(\Omega_i)}^2 \leq c_{i\delta}(t_i; k_{i\delta}^0, k_{i\delta}^0) = \int_{\Omega_i} g_i\, k_{i\delta}^0\, d\boldsymbol{x} - c_{i\delta}(t_i; \mathcal{I}_{i\delta}R_{i\delta}\Pi_{i\delta}^{\Gamma}\lambda_i, k_{i\delta}^0).$$

The continuity property (4.2) gives

$$\|k_{i\delta}^0\|_{H^1(\Omega_i)} \leq c\,\big(\|g_i\|_{H^{-1}(\Omega_i)} + \|\mathcal{I}_{i\delta}R_{i\delta}\Pi_{i\delta}^{\Gamma}\lambda_i\|_{H^1(\Omega_i)}\big),$$

whence, by a triangle inequality,

$$\|\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)} \leq c\,\big(\|g_i\|_{H^{-1}(\Omega_i)} + \|\mathcal{I}_{i\delta}R_{i\delta}\Pi_{i\delta}^{\Gamma}\lambda_i\|_{H^1(\Omega_i)}\big).$$

The desired estimate then follows from (4.6).

Remark 4.3. Note from the previous proof that estimate (4.7) can be replaced by

$$\|\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)} \leq c\left(\|g_i\|_{Y_{i\delta}'} + \sup\Big\{h_i^{-\frac{1}{2}}, \frac{K_i}{N_i}\, h_i^{\frac{1}{2}}\Big\}\, \|\Pi_{i\delta}^{\Gamma}\lambda_i\|_{H_{00}^{\frac{1}{2}}(\Gamma)}\right), \tag{4.8}$$

where the dual norm $\|\cdot\|_{Y_{i\delta}'}$ is defined in a trivial way by

$$\|g_i\|_{Y_{i\delta}'} = \sup_{\varphi_{i\delta}\in Y_{i\delta}} \frac{\int_{\Omega_i} g_i\varphi_{i\delta}\, d\boldsymbol{x}}{\|\varphi_{i\delta}\|_{H^1(\Omega_i)}}.$$

This modified estimate is needed later on.

Next we define the integers K_i' and N_i' as the integral parts of $\frac{K_i-1}{2}$ and $\frac{N_i-1}{2}$, respectively. For technical reasons, we introduce the modified parameter $\delta' = (K_1', N_1', K_2', N_2')$.

LEMMA 4.4. *For any continuous function t_i, the following error estimate holds for any g_i in $H^{-1}(\Omega_i)$ and any continuous function λ_i in $H^{\frac12}_{00}(\Gamma)$ such that $\mathcal{L}_i(t_i)(g_i,\lambda_i)$ belongs to $H^s(\Omega_i)$, $s>1$,*

$$
\begin{aligned}
&\|(\mathcal{L}_i-\mathcal{L}_{i\delta})(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)}\\
&\le c\,\sup\Big\{h_i^{-\frac12},\frac{K_i}{N_i}\,h_i^{\frac12}\Big\}\,\Big((K_i^{1-s}+h_i^{s-1}\,N_i^{1-s})\,h_i^{\frac12-s}\,\|\mathcal{L}_i(t_i)(g_i,\lambda_i)\|_{H^s(\Omega_i)}\\
&+\|\lambda_i-\Pi^\Gamma_{i\delta}\lambda_i\|_{H^{\frac12}_{00}(\Gamma)}\\
&+\inf_{\gamma_{i\delta'}\in\mathbb{P}_{K_i',N_i'}(\Omega_i)}\|\gamma_i(t_i)-\gamma_{i\delta'}\|_{L^\infty(\Omega_i)}\|\mathcal{L}_i(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)}\Big).
\end{aligned}
\tag{4.9}
$$

Proof. We set $k_i=\mathcal{L}_i(t_i)(g_i,\lambda_i)$, $k_{i\delta}=\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)$. The proof is performed in several steps.

(1) We introduce an approximation $\lambda_{i\delta'}$ of λ_i in $\mathbb{P}_{K_i'}(\Gamma)$ which vanishes on $\partial\Gamma$ and we take $k_i'=k_i-R_i(\lambda_i-\lambda_{i\delta'})$. It follows from (4.4) that

$$
\|k_i-k_i'\|_{H^1(\Omega_i)}\le c\,h_i^{-\frac12}\,\|\lambda_i-\lambda_{i\delta'}\|_{H^{\frac12}_{00}(\Gamma)}
$$

and also that

$$
\|k_i'\|_{H^s(\Omega_i)}\le\|k_i\|_{H^s(\Omega_i)}+c\,h_i^{\frac12-s}\,\big(\|\lambda_i\|_{H^{s-\frac12}(\Gamma)}+\|\lambda_{i\delta'}\|_{H^{s-\frac12}(\Gamma)}\big).
$$

Next we set $k_{i\delta}'=\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_{i\delta'})$ and we deduce from Lemma 4.2 that

$$
\|k_{i\delta}-k_{i\delta}'\|_{H^1(\Omega_i)}\le c\,\sup\Big\{h_i^{-\frac12},\frac{K_i}{N_i}\,h_i^{\frac12}\Big\}\,\Big(\|\lambda_i-\lambda_{i\delta'}\|_{H^{\frac12}_{00}(\Gamma)}+\|\lambda_i-\Pi^\Gamma_{i\delta}\lambda_i\|_{H^{\frac12}_{00}(\Gamma)}\Big).
$$

Thanks to the triangle inequality

$$
\|k_i-k_{i\delta}\|_{H^1(\Omega_i)}\le\|k_i-k_i'\|_{H^1(\Omega_i)}+\|k_i'-k_{i\delta}'\|_{H^1(\Omega_i)}+\|k_{i\delta}-k_{i\delta}'\|_{H^1(\Omega_i)},
$$

it remains to estimate $\|k_i'-k_{i\delta}'\|_{H^1(\Omega_i)}$.

(2) The functions $k_i^0=k_i'-R_{i\delta'}\lambda_{i\delta'}$ and $k_{i\delta}^0=k_{i\delta}'-\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}$ belong to $H_0^1(\Omega_i)$ and $Y_{i\delta}$, respectively, and satisfy

$$
\begin{aligned}
&\forall\varphi_i\in H_0^1(\Omega_i),\\
&c_i(t_i;k_i^0,\varphi_i)=\int_{\Omega_i}g_i\varphi_i\,d\boldsymbol{x}-c_i(t_i;R_{i\delta'}\lambda_{i\delta'},\varphi_i)-c_i(t_i;R_i(\lambda_i-\lambda_{i\delta'}),\varphi_i),\\
&\forall\varphi_{i\delta}\in Y_{i\delta},\quad c_{i\delta}(t_i;k_{i\delta}^0,\varphi_{i\delta})=\int_{\Omega_i}g_i\varphi_{i\delta}\,d\boldsymbol{x}-c_{i\delta}(t_i;\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'},\varphi_{i\delta}).
\end{aligned}
\tag{4.10}
$$

So, denoting by $\varphi_{i\delta'}^0$ the orthogonal projection of k_i^0 onto $Y_{i\delta'}$ for the norm of $H_0^1(\Omega_i)$ and adding the difference of these equations, we deduce from the ellipticity property (4.3) that

$$
\|k_{i\delta}^0-\varphi_{i\delta'}^0\|^2_{H^1(\Omega_i)}\le c\,c_{i\delta}(t_i;k_{i\delta}^0-\varphi_{i\delta'}^0,k_{i\delta}^0-\varphi_{i\delta'}^0)
$$

$$\le c\,\Big(c_i(t_i;k_i^0-\varphi_{i\delta'}^0,k_{i\delta}^0-\varphi_{i\delta'}^0)+c_i(t_i;R_i(\lambda_i-\lambda_{i\delta'}),k_{i\delta}^0-\varphi_{i\delta'}^0)$$
$$+c_i(t_i;(\mathrm{Id}-\mathcal{I}_{i\delta'})R_{i\delta'}\lambda_{i\delta'},k_{i\delta}^0-\varphi_{i\delta'}^0)$$
$$+(c_i-c_{i\delta})(t_i;\varphi_{i\delta'}^0,k_{i\delta}^0-\varphi_{i\delta'}^0)+(c_i-c_{i\delta})(t_i;\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'},k_{i\delta}^0-\varphi_{i\delta'}^0)\Big)$$

Thanks to a triangle inequality, this yields

$$\|k_i'-k_{i\delta}'\|_{H^1(\Omega_i)}$$
$$\le c\,\Bigg(\|k_i^0-\varphi_{i\delta'}^0\|_{H^1(\Omega_i)}+c\,h_i^{-\frac12}\,\|\lambda_i-\lambda_{i\delta'}\|_{H_{00}^{\frac12}(\Gamma)}+\|(\mathrm{Id}-\mathcal{I}_{i\delta'})R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}$$
$$+\sup_{\chi_{i\delta}\in Y_{i\delta}}\frac{\int_{\Omega_i}\gamma_i(t_i)\,\nabla(\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'})\cdot\nabla\chi_{i\delta}\,d\boldsymbol{x}-c_{i\delta}(t_i;\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'},\chi_{i\delta})}{\|\chi_{i\delta}\|_{H^1(\Omega_i)}}\Bigg).$$

(3) In order to evaluate the last term, we observe that, for any $\chi_{i\delta}$ in Y_δ, any $\psi_{i\delta'}$ in $\mathbb{P}_{K_i',N_i'}(\Omega_i)$, and any $\gamma_{i\delta'}$ in $\mathbb{P}_{K_i',N_i'}(\Omega_i)$,

$$\int_{\Omega_i}\gamma_{i\delta'}\,\nabla\psi_{i\delta'}\cdot\nabla\chi_{i\delta}\,d\boldsymbol{x}=(\gamma_{i\delta'}\,\nabla\psi_{i\delta'},\nabla\chi_{i\delta})_{i\delta}.$$

Adding and subtracting this quantity and using the continuity property (4.2) leads to, for any $\chi_{i\delta}$ in $Y_{i\delta}$,

$$\int_{\Omega_i}\gamma_i(t_i)\,\nabla(\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'})\cdot\nabla\chi_{i\delta}\,d\boldsymbol{x}-c_{i\delta}(t_i;\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'},\chi_{i\delta})$$
$$\le c\,\|\gamma_i(t_i)-\gamma_{i\delta'}\|_{L^\infty(\Omega_i)}\|\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}\|\chi_{i\delta}\|_{H^1(\Omega_i)}.$$

Moreover, it follows from the definition of $\varphi_{i\delta'}^0$ that

$$\|\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}\le\|k_i^0\|_{H^1(\Omega_i)}+\|\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}$$
$$\le\|k_i'\|_{H^1(\Omega_i)}+\|R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}+\|\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}.$$

Thanks to (4.5) and (4.6), we obtain

$$\|\varphi_{i\delta'}^0+\mathcal{I}_{i\delta'}R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}\le\|k_i'\|_{H^1(\Omega_i)}+c\sup\Big\{h_i^{-\frac12},\frac{K_i}{N_i}\,h_i^{\frac12}\Big\}\,\|\lambda_{i\delta'}\|_{H_{00}^{\frac12}(\Gamma)}.$$

(4) To conclude, we note that the trace λ_i of k_i belongs to $H^{s-\frac12}(\Gamma)$ and choose the polynomial $\lambda_{i\delta'}$ such that (see [7, Thm. 7.4])

$$\|\lambda_i-\lambda_{i\delta'}\|_{H_{00}^{\frac12}(\Gamma)}\le c\,K_i^{1-s}\,\|\lambda_i\|_{H^{s-\frac12}(\Gamma)},\quad\|\lambda_{i\delta'}\|_{H^{s-\frac12}(\Gamma)}\le c\,\|\lambda_i\|_{H^{s-\frac12}(\Gamma)}.$$

Next it can be observed that, for any polynomial $r_{i\delta'}$ in $\mathbb{P}_{K_i',N_i'}(\Omega_i)$,

$$\|(\mathrm{Id}-\mathcal{I}_{i\delta'})R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}=\|(\mathrm{Id}-\mathcal{I}_{i\delta'})(R_{i\delta'}\lambda_{i\delta'}-r_{i\delta'})\|_{H^1(\Omega_i)}.$$

Using the stability properties of the operator $\mathcal{I}_{i\delta'}$ on polynomials (see [7, Forms. (13.27) and (13.28)]) and taking $r_{i\delta'}$ equal to the orthogonal projection of $R_{i\delta'}\lambda_{i\delta'}$ in $H^1(\Omega_i)$ yields

$$\|(\mathrm{Id}-\mathcal{I}_{i\delta'})R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)}\le c\,\sup\Big\{h_i^{-\frac12},\frac{K_i}{N_i}\,h_i^{\frac12}\Big\}\,(K_i^{1-s}+h_i^{s-1}\,N_i^{1-s})\,\|R_{i\delta'}\lambda_{i\delta'}\|_{H^s(\Omega_i)},$$

whence, from (4.5),

$$\|(\mathrm{Id}-\mathcal{I}_{i\delta'})R_{i\delta'}\lambda_{i\delta'}\|_{H^1(\Omega_i)} \le c\,\sup\Big\{h_i^{-\frac12}, \frac{K_i}{N_i}\,h_i^{\frac12}\Big\}\,(K_i^{1-s}+h_i^{s-1}\,N_i^{1-s})\,h^{\frac12-s}\,\|\lambda_{i\delta'}\|_{H^{s-\frac12}(\Gamma)}.$$

Finally, using the previous estimates also yields

$$\|k_i^0-\varphi_{i\delta'}^0\|_{H^1(\Omega_i)} \le c\,(K_i^{1-s}+h_i^{s-1}N_i^{1-s})\Big(\|k_i'\|_{H^s(\Omega_i)}+h_i^{\frac12-s}\,\|\lambda_{i\delta'}\|_{H^{s-\frac12}(\Gamma)}\Big).$$

To conclude, we observe that $\|\lambda_i\|_{H^{s-\frac12}(\Gamma)}$ is bounded by a constant $\|k_i\|_{H^s(\Omega_i)}$. This ends the proof.

Remark 4.5. The following estimate can be derived by combining [7, Thm. 7.4] with a Gagliardo–Nirenberg inequality: if the function γ_i is of class $\mathtt{C}^{\,m}$ with bounded derivatives of order $\le m$ and if the function t_i belongs to $H^s(\Omega_i)$, $\frac{d}{2} < s \le m$,

$$\inf_{\gamma_{i\delta'}\in\mathbb{P}_{K_i,N_i}(\Omega_i)} \|\gamma_i(t_i)-\gamma_{i\delta'}\,\|_{L^\infty(\Omega_i)} \le c\,(K_i^{\frac d2-s}+h_i^{s-\frac d2}\,N_i^{\frac d2-s})\,\|t_i\|_{H^s(\Omega_i)}. \tag{4.11}$$

Moreover, a more sophisticated argument, using the full regularity of $\mathcal{L}_i(t_i)(g_i,\lambda_i)$ allows us to replace when s is $> \frac{d}{2}$ the last term in (4.9) by the better estimate

$$c\,(K_i^{1-s}+h_i^{s-1}\,N_i^{1-s})\,\|t_i\|_{H^s(\Omega_i)}\|\mathcal{L}_i(t_i)(g_i,\lambda_i)\|_{H^s(\Omega_i)}. \tag{4.12}$$

Remark 4.6. If the function γ_i is differentiable with bounded derivative and if the function t_i belongs to $H^r(\Omega_i)$ for $r>1$, the Aubin–Nitsche duality argument [7, Thm. 15.4] leads to the improved estimate

$$\begin{aligned}\|(\mathcal{L}_i-\mathcal{L}_{i\delta})(t_i)(g_i,\lambda_i)\|_{H^{1-\varepsilon}(\Omega_i)}&\\ \le c\,\Big((K_i^{-\varepsilon}+h_i^{\varepsilon}\,N_i^{-\varepsilon})\|(\mathcal{L}_i-\mathcal{L}_{i\delta})(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)}&\\ +\inf_{\gamma_{i\delta'}\in\mathbb{P}_{K_i',N_i'}(\Omega_i)}\|\gamma_i(t_i)-\gamma_{i\delta'}\,\|_{L^\infty(\Omega_i)}\|\mathcal{L}_i(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)}\Big).&\end{aligned} \tag{4.13}$$

Finally, we investigate the dependency of $\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)$ with respect to t_i.

LEMMA 4.7. *For any continuous functions t_i and t_i', the following stability property holds for any g_i in $H^{-1}(\Omega_i)$ and any continuous function λ_i on Γ:*

$$\begin{aligned}\|\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)-\mathcal{L}_{i\delta}(t_i')(g_i,\lambda_i)\|_{H^1(\Omega_i)}&\\ \le c\,\|\gamma_i(t_i)-\gamma_i(t_i')\|_{L^\infty(\Omega_i)}\|\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)\|_{H^1(\Omega_i)}.&\end{aligned} \tag{4.14}$$

Proof. Setting $k_{i\delta}=\mathcal{L}_{i\delta}(t_i)(g_i,\lambda_i)$ and $k_{i\delta}'=\mathcal{L}_{i\delta}(t_i')(g_i,\lambda_i)$, we observe that the function $k_{i\delta}-k_{i\delta}'$ belongs to $Y_{i\delta}$ and satisfies

$$\forall\varphi_{i\delta}\in Y_{i\delta},\quad \big(\gamma_i(t_i)\,\nabla k_{i\delta},\nabla\varphi_{i\delta}\big)_{i\delta}=\big(\gamma_i(t_i')\,\nabla k_{i\delta}',\nabla\varphi_{i\delta}\big)_{i\delta},$$

whence

$$\begin{aligned}c_{i\delta}(t_i';k_{i\delta}-k_{i\delta}',k_{i\delta}-k_{i\delta}')&=\big(\gamma_i(t_i')\,(\nabla k_{i\delta}-\nabla k_{i\delta}'),(\nabla k_{i\delta}-\nabla k_{i\delta}')\big)_{i\delta}\\ &=-\big(\big(\gamma_i(t_i)-\gamma_i(t_i')\big)\,\nabla k_{i\delta},(\nabla k_{i\delta}-\nabla k_{i\delta}')\big)_{i\delta}.\end{aligned}$$

So the desired estimated follows from the properties of $c_{i\delta}(\cdot;\cdot,\cdot)$; see Lemma 4.1.

The discrete Stokes operator. We now present similar properties for the Stokes operator $\mathcal{S}_{i\delta}$ defined by (3.14); however, we skip the proofs except for the error estimates.

LEMMA 4.8. *For any continuous function t_i, the form $a_{i\delta}(t_i;\cdot,\cdot)$ satisfies the following properties of continuity:*

$$\forall \boldsymbol{u}_{i\delta} \in X_{i\delta},\ \forall \boldsymbol{v}_{i\delta} \in X_{i\delta}, \quad a_{i\delta}(t_i;\boldsymbol{u}_{i\delta},\boldsymbol{v}_{i\delta}) \le c\,\|\boldsymbol{u}_{i\delta}\|_{H^1(\Omega_i)^d}\|\boldsymbol{v}_{i\delta}\|_{H^1(\Omega_i)^d}, \tag{4.15}$$

and of ellipticity:

$$\forall \boldsymbol{v}_{i\delta} \in X_{i\delta}, \quad a_{i\delta}(t_i;\boldsymbol{v}_{i\delta},\boldsymbol{v}_{i\delta}) \ge c\,\|\boldsymbol{v}_{i\delta}\|^2_{H^1(\Omega_i)^d}. \tag{4.16}$$

LEMMA 4.9. *For any continuous function t_i, the following stability property holds for any $\boldsymbol{g}_i$ in $L^2(\Omega_i)^d$ and any $\boldsymbol{\lambda}_i$ in the dual space of $H^{\frac12}_{00}(\Gamma)^d$:*

$$\|\mathcal{S}_{i\delta}(t_i)(\boldsymbol{g}_i,\boldsymbol{\lambda}_i)\|_{H^1(\Omega_i)^d} \le c\,\big(\|\boldsymbol{g}_i\|_{L^2(\Omega_i)^d} + \|\boldsymbol{\lambda}_i\|_{H^{\frac12}_{00}(\Gamma)'^d}\big). \tag{4.17}$$

Remark 4.10. As for the Laplace operator, the norms of $\boldsymbol{g}_i$ and $\boldsymbol{\lambda}_i$ in the right-hand side can be replaced, respectively, by the dual norms of $X_{i\delta}$ (when provided with the norm $\|\cdot\|_{H^1(\Omega_i)^d}$) and of $\mathbb{P}_{K_i}(\Gamma)^d \cap H^{\frac12}_{00}(\Gamma)^d$ (provided with the norm $\|\cdot\|_{H^{\frac12}_{00}(\Gamma)^d}$).

However, the proof of the convergence estimate is slightly different (but simpler).

LEMMA 4.11. *For any continuous function t_i, the following error estimate holds for any $\boldsymbol{g}_i$ in $L^2(\Omega_i)^d$ and any $\boldsymbol{\lambda}_i$ in the dual space of $H^{\frac12}_{00}(\Gamma)^d$:*

$$\begin{aligned}
&\|(\mathcal{S}_i - \mathcal{S}_{i\delta})(t_i)(\boldsymbol{g}_i,\boldsymbol{\lambda}_i)\|_{H^1(\Omega_i)^d} \\
&\quad\le c \inf_{\boldsymbol{w}_{i\delta}\in X_{i\delta'}\cap V_i}\Big(\|\mathcal{S}_i(t_i)(\boldsymbol{g}_i,\boldsymbol{\lambda}_i) - \boldsymbol{w}_{i\delta}\|_{H^1(\Omega_i)^d} \\
&\qquad\qquad + \inf_{\alpha_{i\delta'}\in\mathbb{P}_{K_i',N_i'}(\Omega_i)} \|\alpha_i(t_i) - \alpha_{i\delta'}\|_{L^\infty(\Omega_i)}\|\boldsymbol{w}_{i\delta}\|_{H^1(\Omega_i)^d}\Big).
\end{aligned} \tag{4.18}$$

Proof. Setting $\boldsymbol{u}_i = \mathcal{S}_i(t_i)(\boldsymbol{g}_i,\boldsymbol{\lambda}_i)$ and $\boldsymbol{u}_{i\delta} = \mathcal{S}_{i\delta}(t_i)(\boldsymbol{g}_i,\boldsymbol{\lambda}_i)$, we derive from (4.16) that, for any $\boldsymbol{w}_{i\delta'}$ in $X_{i\delta'}\cap V_i$,

$$\|\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}\|^2_{H^1(\Omega_i)^d} \le c\,a_{i\delta}(t_i;\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}, \boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}).$$

Using (2.14) (in variational form) and (3.14), we derive

$$\|\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}\|^2_{H^1(\Omega_i)^d} \le c\,\big(a_i(t_i;\boldsymbol{u}_i, \boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}) - a_{i\delta}(t_i;\boldsymbol{w}_{i\delta'}, \boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'})\big).$$

Next we deduce from the exactness of the quadrature formula that, for any $\alpha_{i\delta'}$ in $\mathbb{P}_{K_i',N_i'}(\Omega_i)$,

$$\int_{\Omega_i} \alpha_{i\delta'}\,\nabla\boldsymbol{w}_{i\delta'}\,\cdot\,\nabla(\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'})\,d\boldsymbol{x} = (\alpha_{i\delta'}\,\nabla\boldsymbol{w}_{i\delta'}, \nabla(\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}))_{i\delta}.$$

Adding and subtracting this quantity yield

$$\begin{aligned}
\|\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}\|^2_{H^1(\Omega_i)^d} \le c\,\Big(&a_i(t_i;\boldsymbol{u}_i - \boldsymbol{w}_{i\delta'}, \boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}) \\
&+ \int_{\Omega_i} (\alpha_i(t_i) - \alpha_{i\delta'})\,\nabla\boldsymbol{w}_{i\delta'}\,\cdot\,\nabla(\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'})\,d\boldsymbol{x} \\
&- ((\alpha_i(t_i) - \alpha_{i\delta'})\,\nabla\boldsymbol{w}_{i\delta'}, \nabla(\boldsymbol{u}_{i\delta} - \boldsymbol{w}_{i\delta'}))_{i\delta}\Big).
\end{aligned}$$

So the desired estimate follows from the continuity property (4.15), together with a triangle inequality.

Remark 4.12. In dimension $d = 2$, it is easy to evaluate the distance of a function $\boldsymbol{u}_i$ in V_i to $X_{i\delta} \cap V_i$ by introducing the stream function ψ_i such that $\boldsymbol{u}_i = \mathbf{curl}\ \psi_i$. Indeed, the functions $\mathbf{curl}\ \psi_{i\delta}$, where $\psi_{i\delta}$ belongs to $\mathbb{P}_{K_i,N_i}(\Omega_i)$, satisfies the desired boundary conditions and approximates ψ_i in $H^2(\Omega_i)$, belongs to $X_{i\delta} \cap V_i$, and provides a good approximation of $\boldsymbol{u}_i$. The case of dimension $d = 3$ is more complex; however, the right approximation properties have been proved in [22] for smooth functions and extended in [5] to arbitrary functions. So the general result reads as follows: for any function $\boldsymbol{u}_i$ in $H^s(\Omega_i)^d \cap V_i$, $s \geq 1$,

$$\inf_{\boldsymbol{w}_{i\delta} \in X_{i\delta} \cap V_i} \|\mathcal{S}_i(t_i)(\boldsymbol{g}_i, \boldsymbol{\lambda}_i) - \boldsymbol{w}_{i\delta}\|_{H^1(\Omega_i)^d} \leq c\,(K_i^{1-s} + h_i^{s-1}\, N_i^{1-s})\, \|\boldsymbol{u}_i\|_{H^s(\Omega_i)^d}. \tag{4.19}$$

Note also that the last term in (4.18) can be bounded analogously to (4.11) or (4.12).

LEMMA 4.13. *For any continuous functions t_i and t_i', the following stability property holds for any $\boldsymbol{g}_i$ in $L^2(\Omega_i)^d$ and any $\boldsymbol{\lambda}_i$ in the dual space of $H_{00}^{\frac{1}{2}}(\Gamma)^d$:*

$$\begin{aligned} &\|\mathcal{S}_{i\delta}(t_i)(\boldsymbol{g}_i, \boldsymbol{\lambda}_i) - \mathcal{S}_{i\delta}(t_i')(\boldsymbol{g}_i, \boldsymbol{\lambda}_i)\|_{H^1(\Omega_i)^d} \\ &\qquad \leq c\, \|\alpha_i(t_i) - \alpha_i(t_i')\|_{L^\infty(\Omega_i)} \|\mathcal{S}_{i\delta}(t_i)(\boldsymbol{g}_i, \boldsymbol{\lambda}_i)\|_{H^1(\Omega_i)^d}. \end{aligned} \tag{4.20}$$

5. Numerical analysis of the discrete problem. The aim of this section is to prove that, if Hypotheses 2.2 and 2.4 hold, problem (3.4)–(3.5) has a unique solution in a neighborhood of (U_1^*, U_2^*) and that this solution converges to (U_1^*, U_2^*). We also derive optimal error estimates. To this aim, we check the assumptions of the theorem of Brezzi, Rappaz, and Raviart [10] in Propositions 5.5 to 5.7.

From now on, we denote by $\mathcal{X}_{i\delta}$, $i = 1$ and 2, the space $X_{i\delta} \times \mathbb{P}_{K_i,N_i}(\Omega_i)$, provided with the norm of $\mathcal{X}_i$, and by $\mathcal{X}_\delta$ the product $\mathcal{X}_{1\delta} \times \mathcal{X}_{2\delta}$.

In view of (4.6), (4.9), and (4.19), for instance, we decide to take the N_i, $i = 1$ and 2, such that, for a fixed constant κ,

$$\kappa\, h_i\, K_i \leq N_i < \kappa\, h_i\, K_i + 1, \tag{5.1}$$

and we do not any longer take into account the dependency of the constants with respect to the h_i. We also choose an approximation $(U_{1\delta'}^*, U_{2\delta'}^*)$, with $U_{i\delta'}^* = (\boldsymbol{u}_{i\delta'}^*, k_{i\delta'}^*)$, of the solution (U_1^*, U_2^*) in $\prod_{i=1}^2 (X_{i\delta'} \times P_{K_i',N_i'}(\Omega_i))$ which satisfies the following approximation properties for $0 \leq r \leq s^*$, where s^* is introduced in Hypothesis 2.2:

$$\begin{aligned} &\|\boldsymbol{u}_i^* - \boldsymbol{u}_{i\delta'}^*\|_{H^r(\Omega_i)^d} \leq c\, K_i^{r-s^*}\, \|\boldsymbol{u}_i^*\|_{H^{s^*}(\Omega_i)^d}, \\ &\|k_i^* - k_{i\delta'}^*\|_{H^r(\Omega_i)} \leq c\, K_i^{r-s^*}\, \|k_i^*\|_{H^{s^*}(\Omega_i)}. \end{aligned} \tag{5.2}$$

The existence of such an approximation is stated in [7, Thm. 7.4]. Finally, we assume that the functions α_i and γ_i are of class $\mathtt{C}^{\,2}$, with bounded derivatives up to order 2 and also that the operators $\Pi_{i\delta}^\Gamma$ satisfy, for all $s \geq \frac{1}{2}$ (the notation $H_\diamond^{s-\frac{1}{2}}(\Gamma)$ is introduced in (4.4)),

$$\forall \lambda \in H_\diamond^{s-\frac{1}{2}}(\Gamma), \quad \|\lambda - \Pi_{i\delta}^\Gamma \lambda\|_{H_{00}^{\frac{1}{2}}(\Omega_i)} \leq c\, K_i^{1-s}\, \|\lambda\|_{H_\diamond^{s-\frac{1}{2}}(\Gamma)}. \tag{5.3}$$

In a first step, we must prove the analogue of Hypothesis 2.4 for the discrete operator. The proof relies on the expansion

$$\begin{aligned} &\mathrm{Id} + D\mathcal{T}_\delta(k_{1\delta'}^*, k_{2\delta'}^*)\mathcal{G}_\delta(U_{1\delta'}^*, U_{2\delta'}^*) + \mathcal{T}_\delta(k_{1\delta'}^*, k_{2\delta'}^*) D\mathcal{G}_\delta(U_{1\delta'}^*, U_{2\delta'}^*) \\ &\qquad = \mathrm{Id} + D\mathcal{T}(k_1^*, k_2^*)\mathcal{G}(U_1^*, U_2^*) + \mathcal{T}(k_1^*, k_2^*) D\mathcal{G}(U_1^*, U_2^*) + \sum_{j=1}^4 \mathcal{O}_j, \end{aligned}$$

with

$$\begin{aligned}
\mathcal{O}_1 &= -\big(D\mathcal{T}(k_1^*,k_2^*)\mathcal{G}(U_1^*,U_2^*) - D\mathcal{T}_\delta(k_1^*,k_2^*)\mathcal{G}(U_{1\delta'}^*,U_{2\delta'}^*)\big)\\
&\qquad - (\mathcal{T}-\mathcal{T}_\delta)(k_1^*,k_2^*)D\mathcal{G}(U_1^*,U_2^*),\\
\mathcal{O}_2 &= -\big(D\mathcal{T}_\delta(k_1^*,k_2^*) - D\mathcal{T}_\delta(k_{1\delta'}^*,k_{2\delta'}^*)\big)\mathcal{G}(U_{1\delta'}^*,U_{2\delta'}^*)\\
&\qquad - \big(\mathcal{T}_\delta(k_1^*,k_2^*) - \mathcal{T}_\delta(k_{1\delta'}^*,k_{2\delta'}^*)\big)D\mathcal{G}(U_1^*,U_2^*),\\
\mathcal{O}_3 &= -\mathcal{T}_\delta(k_{1\delta'}^*,k_{2\delta'}^*)\big(D\mathcal{G}(U_1^*,U_2^*) - D\mathcal{G}(U_{1\delta'}^*,U_{2\delta'}^*)\big),\\
\mathcal{O}_4 &= -D\mathcal{T}_\delta(k_{1\delta'}^*,k_{2\delta'}^*)\big(\mathcal{G}(U_{1\delta'}^*,U_{2\delta'}^*) - \mathcal{G}_\delta(U_{1\delta'}^*,U_{2\delta'}^*)\big)\\
&\qquad - \mathcal{T}_\delta(k_{1\delta'}^*,k_{2\delta'}^*)\big(D\mathcal{G}(U_{1\delta'}^*,U_{2\delta'}^*) - D\mathcal{G}_\delta(U_{1\delta'}^*,U_{2\delta'}^*)\big).
\end{aligned}$$

So we now prove that each $\mathcal{O}_j$ tends to zero when K_1 and K_2 go to $+\infty$, in the norm of the space $\mathsf{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)$ of linear mappings from $\mathcal{X}_\delta$ into itself. These properties are stated in the following lemmas.

Let us first observe that, for any $W=(W_1,W_2)$ in $\mathcal{X}$, with $W_i=(\boldsymbol{w}_i,m_i)$,

$$D\mathcal{G}(U_1^*,U_2^*)\cdot W = \begin{pmatrix} (\mathbf{0}, D\boldsymbol{\lambda}_1(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2))\\ (-Dg_1(k_1^*,\boldsymbol{u}_1^*).(m_1,\boldsymbol{w}_1), D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2))\\ (\mathbf{0}, D\boldsymbol{\lambda}_2(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2))\\ (-Dg_2(k_2^*,\boldsymbol{u}_2^*).(m_2,\boldsymbol{w}_2), D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2)) \end{pmatrix}, \tag{5.4}$$

with

$$\begin{aligned}
D\boldsymbol{\lambda}_i(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2) &= |\boldsymbol{u}_i^*-\boldsymbol{u}_j^*|\,(\boldsymbol{w}_i-\boldsymbol{w}_j) + \frac{(\boldsymbol{u}_i^*-\boldsymbol{u}_j^*)\cdot(\boldsymbol{w}_i-\boldsymbol{w}_j)}{|\boldsymbol{u}_i^*-\boldsymbol{u}_j^*|}\,(\boldsymbol{u}_i^*-\boldsymbol{u}_j^*),\\
Dg_i(k_i^*,\boldsymbol{u}_i^*).(m_i,\boldsymbol{w}_i) &= 2\,\alpha_i(k_i^*)\,\nabla\boldsymbol{u}_i^*\,\cdot\,\nabla\boldsymbol{w}_i + \alpha_i'(k_i^*)m_i\,|\nabla\boldsymbol{u}_i^*|^2,\\
D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2) &= -2\,(\boldsymbol{u}_1^*-\boldsymbol{u}_2^*)\,\cdot\,(\boldsymbol{w}_1-\boldsymbol{w}_2).
\end{aligned} \tag{5.5}$$

Moreover, we have the following formula (which can be derived from the explicit form (2.20)–(2.21) of the linearized problem):

$$\begin{aligned}
&D\mathcal{T}(k_1^*,k_2^*)\mathcal{G}(U_1^*,U_2^*) + \mathcal{T}(k_1^*,k_2^*)D\mathcal{G}(U_1^*,U_2^*)\\
&\qquad = \mathcal{T}(k_1^*,k_2^*)(D\mathcal{G}(U_1^*,U_2^*) + D\mathcal{H}(U_1^*,U_2^*)),
\end{aligned} \tag{5.6}$$

with

$$D\mathcal{H}(U_1^*,U_2^*).(m_1,m_2) = \begin{pmatrix} (-\mathrm{div}\ (\alpha_1'(k_1^*)m_1\nabla\boldsymbol{u}_1^*),\mathbf{0})\\ (-\mathrm{div}\ (\gamma_1'(k_1^*)m_1\nabla k_1^*),0)\\ (-\mathrm{div}\ (\alpha_2'(k_2^*)m_2\nabla\boldsymbol{u}_2^*),\mathbf{0})\\ (-\mathrm{div}\ (\gamma_1'(k_2^*)m_2\nabla k_2^*),0) \end{pmatrix}.$$

A similar formula would hold for the discrete problem

$$\begin{aligned}
&D\mathcal{T}_\delta(k_1^*,k_2^*)\mathcal{G}(U_1^*,U_2^*) + \mathcal{T}_\delta(k_1^*,k_2^*)D\mathcal{G}(U_1^*,U_2^*)\\
&\qquad = \mathcal{T}_\delta(k_1^*,k_2^*)(D\mathcal{G}(U_1^*,U_2^*) + D\mathcal{H}_\delta(U_1^*,U_2^*)),
\end{aligned} \tag{5.7}$$

where the duality product of the first part of the first and third components with a $\boldsymbol{v}_{i\delta}$ in $V_{i\delta}$, respectively, of the second and fourth components with a $\ell_{i\delta}$ in Y_δ, are given by the formulas

$$(\alpha_i'(k_i^*)m_{i\delta}\,\nabla\boldsymbol{u}_i^*,\nabla\boldsymbol{v}_{i\delta})_{i\delta}, \qquad (\gamma_i'(k_i^*)m_{i\delta}\,\nabla k_i^*,\nabla\ell_{i\delta})_{i\delta}.$$

(Here, the differential operator is applied to a $W_\delta = (W_{1\delta}, W_{2\delta})$ in $\mathcal{X}_\delta$, with each $W_{i\delta}$ equal to $(\boldsymbol{w}_{i\delta}, m_{i\delta})$.)

From now on, we fix ε such that $2\varepsilon < s^* - \frac{d}{2}$.

LEMMA 5.1. *If Hypothesis* 2.2 *is satisfied, the following property holds:*

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|\mathcal{O}_1\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)} = 0. \tag{5.8}$$

Proof. Due to formulas (5.6) and (5.7), we observe that

$$\begin{aligned}\|\mathcal{O}_1\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)} \le{}& \|(\mathcal{T}-\mathcal{T}_\delta)(k_1^*,k_2^*)\big(D\mathcal{G}(U_1^*,U_2^*)+D\mathcal{H}(U_1^*,U_2^*)\big)\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)}\\ &+\|\mathcal{T}_\delta(k_1^*,k_2^*)\big(D\mathcal{H}(U_1^*,U_2^*)-D\mathcal{H}_\delta(U_{1\delta'}^*,U_{2\delta'}^*)\big)\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)}.\end{aligned}$$

(1) To bound the first term, we note that, when $(W_{1\delta}, W_{2\delta})$ runs through the unit sphere of $\mathcal{X}_\delta$, the quantities

$$D\boldsymbol{\lambda}_i(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_{1\delta},\boldsymbol{w}_{2\delta}),\quad Dg_i(k_i^*,\boldsymbol{u}_i^*).(m_{i\delta},\boldsymbol{w}_{i\delta}),\quad \text{and}\quad D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_{1\delta},\boldsymbol{w}_{2\delta})$$

belong to a bounded set in $L^2(\Omega_i)^d$, $H^{-1}(\Omega_i)$, and $H_{00}^{\frac{1}{2}}(\Gamma)$, respectively. Then it can be checked that $\mathcal{S}_i(k_i^*)(\mathbf{0}, D\boldsymbol{\lambda}_i(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_{1\delta},\boldsymbol{w}_{2\delta}))$ remains inside a bounded set of $H^s(\Omega_i)^d$ for some $s>1$. Thanks to (4.18), (4.19), and the analogue of (4.11), this yields the uniform convergence of $(\mathcal{S}_i-\mathcal{S}_{i\delta})(k_i^*)(\mathbf{0}, D\boldsymbol{\lambda}_i(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_{1\delta},\boldsymbol{w}_{2_\delta}))$. The convergence of the other terms, say

$$(\mathcal{L}_i-\mathcal{L}_{i\delta})(k_i^*)(Dg_i(k_i^*,\boldsymbol{u}_i^*).(m_{i\delta},\boldsymbol{w}_{i\delta}), D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_{1\delta},\boldsymbol{w}_{2\delta})),$$

follows from (4.13) together with the fact that both

$$\mathcal{L}_i(Dg_i(k_i^*,\boldsymbol{u}_i^*).(m_i,\boldsymbol{w}_i), D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2))$$

and its discrete analogue

$$\mathcal{L}_{i\delta}(k_i^*)(Dg_i(k_i^*,\boldsymbol{u}_i^*).(m_i,\boldsymbol{w}_i), D\lambda(\boldsymbol{u}_1^*,\boldsymbol{u}_2^*).(\boldsymbol{w}_1,\boldsymbol{w}_2))$$

are bounded in $H^1(\Omega_i)$; see (4.7). So combining these facts yields

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|(\mathcal{T}-\mathcal{T}_\delta)(k_1^*,k_2^*)D\mathcal{G}(U_1^*,U_2^*)\|_{\mathcal{L}\ (\mathcal{X},\mathcal{X})} = 0.$$

(2) Similarly, we observe that, when $(W_{1\delta}, W_{2\delta})$ runs through the unit sphere of $\mathcal{X}_\delta$, the quantities $\alpha_i'(k_i^*)m_{i\delta}\,\nabla\boldsymbol{u}_i^*$ and $\gamma_i'(k_i^*)m_{i\delta}\,\nabla k_i^*$ belong to a bounded set of $H^s(\Omega_i)^{d^2}$ and $H^s(\Omega_i)^d$, for some $s>0$, so that their divergence belongs to $H^{s-1}(\Omega_i)^d$ and $H^{s-1}(\Omega_i)$, respectively. This implies

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|(\mathcal{T}-\mathcal{T}_\delta)(k_1^*,k_2^*)D\mathcal{H}(U_1^*,U_2^*)\|_{\mathcal{L}\ (\mathcal{X},\mathcal{X})} = 0.$$

(3) To prove the convergence of the last term, we observe from (4.8) that it suffices to prove, for any $m_{i\delta}$ in the intersection of $\mathbb{P}_{K_i,N_i}(\Omega_i)$ with the unit sphere of $H^{1-\varepsilon}(\Omega_i)$, the convergence of

$$\sup_{\ell_{i\delta}\in Y_{i\delta}} \frac{\int_{\Omega_i}\gamma_i'(k_i^*)m_{i\delta}\,\nabla k_i^*\,\cdot\,\nabla\ell_{i\delta}\,d\boldsymbol{x} - (\gamma_i'(k_i^*)m_{i\delta}\,\nabla k_{i\delta'}^*, \nabla\ell_{i\delta})_{i\delta}}{\|\ell_{i\delta}\|_{H^1(\Omega_i)}}.$$

Handling the other terms is similar. Denoting by δ'' the 4-tuple $(K_1'', N_1'', K_2'', N_2'')$ with each K_i'' equal to the integral part of $\frac{K_i-1}{4}$ and each N_i'' equal to the integral part of $\frac{N_i-1}{4}$, we derive from the exactness of the quadrature formula for any $\tilde{\gamma}_{i\delta''}$ and $m_{i\delta''}$ in $\mathbb{P}_{K_i'',N_i''}(\Omega_i)$,

$$\int_{\Omega_i} \gamma_{i\delta''} m_{i\delta''} \nabla k^*_{i\delta'} \cdot \nabla \ell_{i\delta}\, d\boldsymbol{x} = (\gamma_{i\delta''} m_{i\delta''} \nabla k^*_{i\delta'}, \nabla \ell_{i\delta})_{i\delta}.$$

By adding and subtracting this line, we prove that the previous quantity is bounded by the sum of the terms

$$\begin{aligned}
&\|\gamma_i'(k_i^*)\|_{L^\infty(\Omega_i)} \|m_{i\delta} \nabla(k_i^* - k^*_{i\delta'})\|_{L^2(\Omega_i)^d},\\
&\quad \|\gamma_i'(k_i^*)\|_{L^\infty(\Omega_i)} \|(m_{i\delta} - m_{i\delta''}) \nabla k^*_{i\delta'}\|_{L^2(\Omega_i)^d},\\
&\quad\quad \|\gamma_i'(k_i^*) - \tilde{\gamma}_{i\delta''}\|_{L^\infty(\Omega_i)} \|m_{i\delta''} \nabla k^*_{i\delta'}\|_{L^2(\Omega_i)^d},\\
&\quad\quad\quad \|\gamma_i'(k_i^*)\|_{L^\infty(\Omega_i)} \|\mathcal{I}_{i\delta}\big((m_{i\delta} - m_{i\delta''}) \nabla k^*_{i\delta'}\big)\|_{L^2(\Omega_i)^d},\\
&\quad\quad\quad\quad \|\gamma_i'(k^*_{i\delta}) - \tilde{\gamma}_{i\delta''}\|_{L^\infty(\Omega_i)} \|\mathcal{I}_{i\delta}\big(m_{i\delta''} \nabla k^*_{i\delta'}\big)\|_{L^2(\Omega_i)^d}.
\end{aligned}$$

Thanks to the choice of ε, the product of two functions is continuous from $H^{1-\varepsilon}(\Omega_i) \times H^{s^*-1-\varepsilon}(\Omega_i)$ into $L^2(\Omega_i)$ so that the uniform convergence of the first term follows from (5.2). Again, thanks to the choice of ε, the product of two functions is continuous from $H^{1-2\varepsilon}(\Omega_i) \times H^{s^*-1}(\Omega_i)$ into $L^2(\Omega_i)$ so that the uniform convergence of the second term is obtained by taking $m_{i\delta''}$ equal to the projection of $m_{i\delta}$ onto $\mathbb{P}_{K_i'',N_i''}(\Omega_i)$ for the scalar product of $H^{1-\varepsilon}(\Omega_i)$ and using the approximation properties of this projection operator; see [7, Thm. 7.4]. Similarly, the convergence of the third term follows from (4.11). The convergence of the last two terms is derived by similar arguments combined with the stability on the operator $\mathcal{I}_{i\delta}$ on polynomials; see [7, Form. (13.28)].

So the proof is complete.

LEMMA 5.2. *If Hypothesis* 2.2 *is satisfied, the following property holds:*

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|\mathcal{O}_2\|_{\mathcal{L}(\mathcal{X}_\delta, \mathcal{X}_\delta)} = 0. \tag{5.9}$$

Proof. From (5.7), we have

$$\|\mathcal{O}_2\|_{\mathcal{L}(\mathcal{X}_\delta,\mathcal{X}_\delta)} = \|\big(\mathcal{T}_\delta(k_1^*, k_2^*) - \mathcal{T}_\delta(k^*_{1\delta'}, k^*_{2\delta'})\big)\big(D\mathcal{G}(U_1^*, U_2^*) + D\mathcal{H}_\delta(U^*_{1\delta'}, U^*_{2\delta'})\big)\|_{\mathcal{L}(\mathcal{X}_\delta,\mathcal{X}_\delta)}.$$

When $(W_{1\delta}, W_{2\delta})$ runs through the unit sphere of $\mathcal{X}_\delta$, the quantity

$$\mathcal{T}_\delta(k_1^*, k_2^*)\big(D\mathcal{G}(U_1^*, U_2^*) + D\mathcal{H}_\delta(U_1^*, U^*_{2\delta'})\big)$$

remains bounded in $\mathcal{X}$ so that the desired convergence result follows from (4.14) and (4.20), combined with (5.2) and the embedding of $H^s(\Omega_i)$ into $L^\infty(\Omega_i)$ for all $s > \frac{d}{2}$.

LEMMA 5.3. *If Hypothesis* 2.2 *is satisfied, the following property holds:*

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|\mathcal{O}_3\|_{\mathcal{L}(\mathcal{X}_\delta, \mathcal{X}_\delta)} = 0. \tag{5.10}$$

Proof. Here, the convergence of each term is a straightforward consequence of (5.2).

LEMMA 5.4. *If Hypothesis* 2.2 *is satisfied and if the data* $\boldsymbol{f}_i$, $1 \le i \le 2$, *belong to* $H^\sigma(\Omega_i)^d$ *for some* $\sigma > \frac{d}{2}$, *the following property holds:*

$$\lim_{K_1\to+\infty, K_2\to+\infty} \|\mathcal{O}_4\|_{\mathcal{L}(\mathcal{X}_\delta, \mathcal{X}_\delta)} = 0. \tag{5.11}$$

Proof. Thanks to (4.8) and its analogue for the Stokes problem, the convergence of the term

$$\|\mathcal{T}_\delta(k^*_{1\delta},k^*_{2\delta})\big(D\mathcal{G}(U^*_{1\delta'},U^*_{2\delta'})-D\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})\big)\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)}$$

is a consequence of the convergence of the terms

$$\sup_{\boldsymbol{w}_{i\delta}\in X_{i\delta}}\frac{\int_{\Omega_i}\alpha_i(k^*_{i\delta})\,\nabla\boldsymbol{u}^*_{i\delta}\,\cdot\,\nabla\boldsymbol{w}_{i\delta}\,d\boldsymbol{x}-(\alpha_i(k^*_{i\delta})\nabla\boldsymbol{u}^*_{i\delta},\nabla\boldsymbol{w}_{i\delta})_{i\delta}}{\|\boldsymbol{w}_{i\delta}\|_{H^1(\Omega_i)^d}},$$
$$\sup_{m_{i\delta}\in Y_{i\delta}}\frac{\int_{\Omega_i}\alpha_i'(k^*_{i\delta})m_{i\delta}\,\nabla\boldsymbol{u}^*_{i\delta}\,\cdot\,\nabla\boldsymbol{u}^*_{i\delta}\,d\boldsymbol{x}-(\alpha_i'(k^*_{i\delta})m_{i\delta}\,\nabla\boldsymbol{u}^*_{i\delta},\nabla\boldsymbol{u}^*_{i\delta})_{i\delta}}{\|m_{i\delta}\|_{H^{1-\varepsilon}(\Omega_i)}}$$

and of their analogues for the Stokes problem. As in the end of the proof of Lemma 4.1, this is obtained by adding and subtracting appropriate terms of lower degree.

Similar arguments yield the convergence of $\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})$ toward $\mathcal{G}(U^*_{1\delta'},U^*_{2\delta'})$, whence the convergence of the second term in $\mathcal{O}_4$.

Combining the results of Lemmas 5.1 to 5.4 leads to the following result.

PROPOSITION 5.5. *If Hypotheses* 2.2 *and* 2.4 *are satisfied and if the data* $\boldsymbol{f}_i$, $1\le i\le 2$, *belong to* $H^\sigma(\Omega_i)^d$ *for some* $\sigma>\frac{d}{2}$, *there exists a constant* K *such that, for* $K_1\ge K$ *and* $K_2\ge K$, *the operator*

$$\mathrm{Id}+D\mathcal{T}_\delta(k^*_{1\delta'},k^*_{2\delta'})\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})+\mathcal{T}_\delta(k^*_{1\delta'},k^*_{2\delta'})D\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'}) \tag{5.12}$$

is an isomorphism of $\mathcal{X}_\delta$. *Moreover, the norm of its inverse is bounded by a constant* γ *independent of* K_1 *and* K_2.

The following proposition states a Lipschitz property for the discrete operator. Since its proof is simpler than for the previous result, we only sketch it.

PROPOSITION 5.6. *The following property holds for all nonnegative real numbers* α *and for any* $(Z_{1\delta},Z_{2\delta})$ *in* $\mathcal{X}_\delta$ *which satisfies* $\|(Z_{1\delta},Z_{2\delta})-(U^*_{1\delta'},U^*_{2\delta'})\|_{\mathcal{X}}\le\alpha$, *with* $Z_{i\delta}=(\boldsymbol{z}_{i\delta},r_{i\delta})$:

$$\begin{aligned}&\|D\mathcal{T}_\delta(k^*_{1\delta'},k^*_{2\delta'})\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})+\mathcal{T}_\delta(k^*_{1\delta'},k^*_{2\delta'})D\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})\\&\quad-D\mathcal{T}_\delta(r_{1\delta},r_{2\delta})\mathcal{G}_\delta(Z_{1\delta},Z_{2\delta})-\mathcal{T}_\delta(r_{1\delta},r_{2\delta})D\mathcal{G}_\delta(Z_{1\delta},Z_{2\delta})\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)}\le c\,\kappa_\delta\,\alpha,\end{aligned} \tag{5.13}$$

where according to the dimension d *the constant* κ_δ *is given by*

$$\kappa_\delta=K_i^{2(d-2)+2\varepsilon}\,(\log K_i)^{\frac{3-d}{2}}. \tag{5.14}$$

Proof. We must bound the four terms

$$\begin{aligned}&\|\mathcal{T}_\delta(r_{1\delta},r_{2\delta})\big(D\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})-D\mathcal{G}_\delta(Z_{1\delta},Z_{2\delta})\big)\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)},\\&\|\big(\mathcal{T}_\delta(k^*_{1\delta'},r^*_{2\delta'})-\mathcal{T}_\delta(r_{1\delta},r_{2\delta})\big)D\mathcal{G}_\delta(U^*_{1\delta'},U^*_{2\delta'})\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)},\\&\|\mathcal{T}_\delta(r_{1\delta},r_{2\delta})\big(D\mathcal{H}_\delta(U^*_{1\delta'},U^*_{2\delta'})-D\mathcal{H}_\delta(Z_{1\delta'},Z_{2\delta'})\big)\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)},\\&\|\big(\mathcal{T}_\delta(k^*_{1\delta'},r^*_{2\delta'})-\mathcal{T}_\delta(r_{1\delta},r_{2\delta})\big)D\mathcal{H}_\delta(U^*_{1\delta'},U^*_{2\delta'})\|_{\mathcal{L}\ (\mathcal{X}_\delta,\mathcal{X}_\delta)}.\end{aligned}$$

For instance, in the first term, we must bound the quantity, for $m_{i\delta}$ running through the unit ball of $Y_{i\delta}$,

$$\sum_{\ell_{i\delta}\in Y_{i\delta}}\frac{\big(\alpha_i'(k^*_{i\delta'})\,m_{i\delta}\,|\nabla(\boldsymbol{u}_{i\delta'}-z_{i\delta})|^2,\ell_{i\delta}\big)_{i\delta}}{\|\ell_{i\delta}\|_{H^1(\Omega_i)}}.$$

Applying the inverse inequalities

$$\forall \varphi_{i\delta} \in \mathbb{P}_{K_i,N_i}(\Omega_i), \quad \|\varphi_{i\delta}\|_{L^\infty(\Omega_i)} \le \begin{cases} c\, K_i^{d-2+2\varepsilon}\, \|\varphi_{i\delta}\|_{H^{1-\varepsilon}(\Omega_i)}, \\ c\, K_i^{d-2}\, (\log K_i)^{\frac{3-d}{2}}\, \|\varphi_{i\delta}\|_{H^1(\Omega_i)}, \end{cases}$$

we have to bound the term, for all $m_{i\delta}$ in $\mathbb{P}_{K_i,N_i}(\Omega_i)$,

$$K_i^{2(d-2)+2\varepsilon}\, (\log K_i)^{\frac{3-d}{2}}\, \|\nabla(\boldsymbol{u}^*_{i\delta'} - \boldsymbol{z}_{i\delta})\|_{L^2(\Omega_i)}\, \|\nabla(\boldsymbol{u}^*_{i\delta'} + \boldsymbol{z}_{i\delta})\|_{L^2(\Omega_i)}.$$

This yields the value of κ_δ. The other terms are simpler; they can be evaluated by similar arguments.

Finally, we must evaluate the quantity

$$\varepsilon_\delta = \left\| \begin{pmatrix} U^*_{1\delta'} \\ U^*_{2\delta'} \end{pmatrix} + \mathcal{T}_\delta(k^*_{1\delta'}, k^*_{2\delta'})\, \mathcal{G}_\delta(U^*_{1\delta'},\ U^*_{2\delta'}) \right\|_{\mathcal{X}}. \tag{5.15}$$

Proposition 5.7. *If Hypothesis* 2.2 *is satisfied and if the data* $\boldsymbol{f}_i$, $1 \le i \le 2$, *belong to* $H^\sigma(\Omega_i)^d$ *for some* $\sigma > \frac{d}{2}$, *the following estimate holds for a constant* C *only depending on the norm of* (U_1^*, U_2^*) *in* $\prod_{i=1}^2 \big(H^{s^*}(\Omega_i)^d \times H^{s^*}(\Omega_i)\big)$*:*

$$\varepsilon_\delta \le C\, (\inf\{K_1, K_2\})^{1-s^*}. \tag{5.16}$$

Proof. By using formulation (2.18), we observe that

$$\begin{aligned} \varepsilon_\delta \le{}& \|U_1^* - U^*_{1\delta}\|_{\mathcal{X}_1} + \|U_2^* - U^*_{2\delta}\|_{\mathcal{X}_2} \\ &+ \|(\mathcal{T} - \mathcal{T}_\delta)(k_1^*, k_2^*)\, \mathcal{G}(U_1^*,\ U_2^*)\|_{\mathcal{X}} + \|\big(\mathcal{T}_\delta(k_1^*, k_2^*) - \mathcal{T}_\delta(k^*_{1\delta'}, k^*_{2\delta'})\big)\, \mathcal{G}(U_1^*,\ U_2^*)\|_{\mathcal{X}} \\ &+ \|\mathcal{T}_\delta(k^*_{1\delta'}, k^*_{2\delta'})\, \big(\mathcal{G}(U_1^*,\ U_2^*) - \mathcal{G}(U^*_{1\delta'},\ U^*_{2\delta'})\big)\|_{\mathcal{X}} \\ &+ \|\mathcal{T}_\delta(k^*_{1\delta'}, k^*_{2\delta'})\, \big(\mathcal{G}(U^*_{1\delta'},\ U^*_{2\delta'}) - \mathcal{G}_\delta(U^*_{1\delta'},\ U^*_{2\delta'})\big)\|_{\mathcal{X}}. \end{aligned}$$

The bound for the first two terms in the right-hand side comes from (5.2), and the bound for the third term is derived from (4.9) and its analogue for the Stokes problem together with the regularity Hypothesis 2.2. The fourth term is easily bounded from (4.14) and (4.20), while estimating the fifth one relies on (4.7) and (4.17), combined with (5.2). Finally, estimating the last term also relies on (4.7) and (4.17) together with the introduction of approximations of $\alpha_i(k_i^*)$ and $\gamma_i(k_i^*)$ in $\mathbb{P}_{K'_i,N'_i}(\Omega_i)$; see (4.12).

We are now in a position to apply the Brezzi–Rappaz–Raviart theorem [10] (see also [15, Chap. IV, Thm. 3.1]).

Theorem 5.8. *If Hypotheses* 2.2 *and* 2.4 *are satisfied with* $s^* > 2(d-2)+1$ *and if the data* $\boldsymbol{f}_i$, $i = 1, 2$, *belong to* $H^\sigma(\Omega_i)^d$ *for some* $\sigma > \sup\{\frac{d}{2}, s^* - 1\}$, *there exist an integer* K_0 *and a constant* λ *such that, for* $K_1 \ge K_0$ *and* $K_2 \ge K_0$, *problem* (3.4)–(3.7) *has a unique solution* $(U_{1\delta}, U_{2\delta})$, *with each* $U_{i\delta}$ *equal to* $(\boldsymbol{u}_{i\delta}, k_{i\delta})$, *in the neighborhood* U *of* $U = (U_1^*, U_2^*)$ *defined as follows:*

$$\mathsf{U} = \Big\{ Z_\delta = (Z_{1\delta}, Z_{2\delta}) \in \mathcal{X}_\delta;\ \|U - Z_\delta\|_{\mathcal{X}} \le \lambda\, \kappa_\delta^{-1} \Big\}. \tag{5.17}$$

Moreover, the following error estimates hold for $i = 1$ *and* 2*:*

$$\|\boldsymbol{u}_i^* - \boldsymbol{u}_{i\delta}\|_{H^1(\Omega_i)^d} + \|k_i^* - k_{i\delta}\|_{L^2(\Omega_i)} \le C_0\, (\inf\{K_1, K_2\})^{1-s^*} \tag{5.18}$$

for a constant C_0 *depending only on the norms of* (U_1^*, U_2^*) *in* $\prod_{i=1}^2 (H^{s^*}(\Omega_i)^d \times H^{s^*}(\Omega_i))$ *and of* $(\boldsymbol{f}_1, \boldsymbol{f}_2)$ *in* $\prod_{i=1}^2 H^\sigma(\Omega_i)^d$.

We conclude with an estimate on the pressure, which is easily derived from the inf-sup condition established in Lemma 3.4.

COROLLARY 5.9. *If the assumptions of Theorem* 5.8 *are satisfied, for the solution* $(U_{1\delta}, U_{2\delta})$ *exhibited in Theorem* 5.8, *there exists a unique pair* $(p_{1\delta}, p_{2\delta})$ *in* $M^m_{1\delta} \times M^m_{2\delta}$ *such that* $(\tilde{U}_{1\delta}, \tilde{U}_{2\delta})$, *with each* $\tilde{U}_{i\delta}$ *equal to* $(\boldsymbol{u}_{i\delta}, p_{i\delta}, k_{i\delta})$, *is a solution of problem* (3.4)–(3.5). *Moreover, the following error estimates hold for* $i = 1$ *and* 2*:*

$$\|p_i^* - p_{i\delta}\|_{L^2(\Omega_i)} \le C_0' \, (\beta_{i\delta}^m)^{-1} \, (\inf\{K_1, K_2\})^{1-s^*} \tag{5.19}$$

for the constants $\beta_{i\delta}^m$ *evaluated in* (3.9) *and a constant* C_0' *depending only on the norms of* $(\tilde{U}_1^*, \tilde{U}_2^*)$ *in* $\prod_{i=1}^2 (H^s(\Omega_i)^d \times H^{s-1}(\Omega_i) \times H^s(\Omega_i))$ *and of* $(\boldsymbol{f}_1, \boldsymbol{f}_2)$ *in* $\prod_{i=1}^2 H^\sigma(\Omega_i)^d$.

6. Conclusions and numerical algorithms. The regularity assumptions in Theorem 5.8 in the three-dimensional case are very unlikely; however, they seem unavoidable. This comes from the fact that the linearized problem (2.20) and (2.21) makes sense only for a smooth solution U^*. Nevertheless, this does not prevent the convergence of numerical experiments.

In contrast, the assumptions of Theorem 5.8 are fully reasonable in the two-dimensional case and, if these assumptions hold, optimal error estimates are derived for the velocity, the kinetic energy, and the pressure for appropriate choices of the spaces $M_{i\delta}$. In this case, the maximal regularity s^* would very likely coincide with the $s_0 \simeq 1.5946$ introduced in section 2 so that the error would be smaller than $C_0 \, (\inf\{K_1, K_2\})^{-0.5946}$. Moreover, in the case of the rectangle, the explicit form of the singular functions associated with the Stokes operator with Dirichlet–Neumann boundary conditions is known [20]. As usual [6], this would lead to double the convergence order: for smooth enough data $\boldsymbol{f}_i$, $i = 1$ and 2, the error would be smaller than $C_0 \, (\inf\{K_1, K_2\})^{-1.1892}$.

The most standard choice of an operator $\Pi_{i\delta}^\Gamma$ satisfying (5.3) would be the orthogonal projection operator $\Pi_{K_i}^{\frac{1}{2}}$ from $H_{00}^{\frac{1}{2}}(\Gamma)$ onto $\mathbb{P}_{K_i}(\Gamma) \cap H_{00}^{\frac{1}{2}}(\Gamma)$; however, computing this operator is not easy. So we take $\Pi_{i\delta}^\Gamma$ equal to $\mathcal{I}_{i\delta}^\Gamma \, \Pi_{K_i}^{\frac{1}{2}}$. Indeed, estimate (5.3) is still satisfied by this operator and, in this case, the boundary conditions at the interface can be written in a very simple way:

$$k_{i\delta} = \mathcal{I}_{i\delta}^\Gamma(|\boldsymbol{u}_{1\delta} - \boldsymbol{u}_{2\delta}|^2) \quad \text{on} \quad \Gamma.$$

Note, moreover, that in the present situation there is no theoretical reason to choose $K_1 \neq K_2$ and that, when K_1 and K_2 coincide, these conditions are still less expensive to enforce. However, for more complex geometries (for instance, if the Ω_i are convex quadrilaterals), different values of K_1 and K_2 can be needed since the regularity properties of the velocities in Ω_1 and Ω_2 are different.

Exactly the same arguments as for Theorem 5.8 prove [10] the convergence of Newton's algorithm for solving the nonlinear problem (3.4)–(3.5), when the initial guess $(U_{1\delta}^0, U_{2\delta}^0)$ belongs to the domain U introduced in (5.17); however, this method seems too expensive for the present problem. Instead of this, for an initial guess $(U_{1\delta}^0, U_{2\delta}^0)$, we propose to solve iteratively the following problem: if the pair $(\tilde{U}_{1\delta}^n, \tilde{U}_{2\delta}^n)$, with $\tilde{U}_{i\delta}^n = (\boldsymbol{u}_{i\delta}^n, p_{i\delta}^n, k_{i\delta}^n)$, is supposed to be known, then we solve the following problem:

Find $(\boldsymbol{u}_{i\delta}^{n+1}, p_{i\delta}^{n+1})$ *in* $X_{i\delta} \times M_{i\delta}$ *such that*

$$\begin{aligned}
&\forall \boldsymbol{v}_{i\delta} \in X_{i\delta},\\
&\quad a_{i\delta}(k_{i\delta}^n; \boldsymbol{u}_{i\delta}^{n+1}, \boldsymbol{v}_{i\delta}) + b_{i\delta}(\boldsymbol{v}_{i\delta}, p_{i\delta}^{n+1})\\
&\qquad\qquad + \left(|\boldsymbol{u}_{i\delta}^n - \boldsymbol{u}_{j\delta}^n| \, (\boldsymbol{u}_{i\delta}^{n+1} - \boldsymbol{u}_{j\delta}^{n+1}), \boldsymbol{v}_{i\delta} \right)_{i\delta}^{\Gamma} = \left(\boldsymbol{f}_i, \boldsymbol{v}_{i\delta} \right)_{i\delta},\\
&\forall q_{i\delta} \in M_{i\delta}, \quad b_{i\delta}(\boldsymbol{u}_{i\delta}^{n+1}, q_{i\delta}) = 0;
\end{aligned} \tag{6.1}$$

Find $k_{i\delta}$ *in* $\mathbb{P}_{K_i,N_i}(\Omega_i)$*, such that*

$$k_{i\delta}^{n+1} = 0 \quad \text{on } \Gamma_i \quad \text{and} \quad k_{i\delta}^{n+1} = \mathcal{I}_{i\delta}^{\Gamma}(|\boldsymbol{u}_{1\delta}^{n+1} - \boldsymbol{u}_{2\delta}^{n+1}|^2) \quad \text{on } \Gamma, \tag{6.2}$$

and

$$\forall \varphi_{i\delta} \in Y_{i\delta}, \quad c_{i\delta}(k_{i\delta}^n; k_{i\delta}^{n+1}, \varphi_{i\delta}) = \left(\alpha_i(k_{i\delta}^n) \, |\nabla \boldsymbol{u}_{i\delta}^{n+1}|^2, \varphi_{i\delta} \right)_{i\delta}. \tag{6.3}$$

Clearly, these two linear problems are well-posed and the sequence $(\tilde{U}_{1\delta}^n, \tilde{U}_{2\delta}^n)_n$ converges. Numerical experiments to check the efficiency of the algorithm are under consideration.
