1. for each i,j,k: $\varphi_{i+\alpha,j,k} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(i,\alpha,\varphi_{*,j,k})$;
2. for each i,j,k: $\varphi_{i+\alpha,j+\alpha,k} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(j,\alpha,\varphi_{i+\alpha,*,k})$;
3. for each i,j,k: $\varphi_{i+\alpha,j+\alpha,k+\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(k,\alpha,\varphi_{i+\alpha,j+\alpha,*})$.

The reconstruction at $x_{i-\alpha,j-\alpha,k-\alpha}$ is handled similarly, and the same for the reconstruction of $\varphi'_{i+\alpha,j+\alpha,k+\alpha}$. In three dimensions, $\alpha = 1/(3+\sqrt{3})$.

A d-dimensional reconstruction based on d-dimensional stencils quickly becomes very large. It is readily apparent that the dimension-by-dimension approach will scale to high dimensions better than d-dimensional interpolants.

4. Numerical simulations.

In this section we present simulations that test the schemes we developed in this paper. In section 4.1 we demonstrate the third- and fifth-order methods in one dimension. Section 4.2 focuses on the fifth-order method in two and three space dimensions. In section 4.3 we compare the two-dimensional third-order method based on two-dimensional stencils with the dimension-by-dimension approach. In section 4.4 we examine, in detail, stability issues in two dimensions, including comparisons with [17]. Some of these examples are standard test cases that can be found, e.g., in [22, 31, 35].

We do not follow the practice in [17] of masking singular regions from our error measurements.

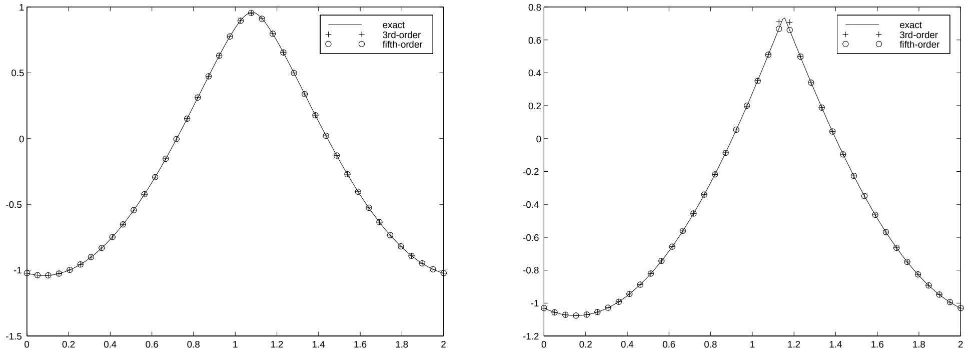

FIG. 4.1. *One-dimensional convex Hamiltonian* (4.1). *Left: the solution before the singularity formation, $T = 0.8/\pi^2$. Right: the solution after the singularity formation, $T = 1.5/\pi^2$. In both panels $N = 40$. Shown are the third- and fifth-order approximations and the exact solution.*

4.1. One-dimensional examples.

A convex Hamiltonian. We start by testing the performance of our schemes on a convex Hamiltonian. We approximate solutions of the one-dimensional equation

$$\phi_t + \frac{1}{2}\left(\phi_x + 1\right)^2 = 0, \tag{4.1}$$

subject to the initial data $\phi(x,0) = -\cos(\pi x)$ with periodic boundary conditions on $[0,2]$. The change of variables $u\,(x,t) = \phi_x\,(x,t) + 1$ transforms the equation into the Burgers equation $u_t + \frac{1}{2}\left(u^2\right)_x = 0$, which can be easily solved via the method of characteristics [35]. As is well known, the Burgers equation generally develops discontinuous solutions even with smooth initial data, and hence we expect the solutions of (4.1) to have discontinuous derivatives. In our case, the solution develops a singularity at time $t = \pi^{-2}$.

The results of our simulations are shown in Figure 4.1. The order of accuracy of these methods is determined from the relative L^1 error (see [30]), defined as the L^1-norm of the error divided by the L^1-norm of the exact solution. These results along with the relative L^∞-norm before the singularity, at $T = 0.8/\pi^2$, are given in Table 4.1, and after the singularity, at $T = 1.5/\pi^2$, in Table 4.2.

A nonconvex Hamiltonian. In this example we deal with nonconvex HJ equations. In one dimension we solve

$$\phi_t - \cos\left(\phi_x + 1\right) = 0, \tag{4.2}$$

subject to the initial data $\phi\,(x,0) = -\cos\,(\pi x)$ with periodic boundary conditions on $[0,2]$. In this case (4.2) has a smooth solution for $t \lesssim 1.049/\pi^2$, after which a singularity forms. A second singularity forms at $t \approx 1.29/\pi^2$. The results are shown in Figure 4.2. The convergence results before and after the singularity formation are given in Tables 4.3–4.4.

A linear advection equation. In this example (from [17], with a misprint corrected in [40]) we solve the one-dimensional linear advection equation, i.e., $H\,(\phi_x) = \phi_x$. We assume periodic boundary conditions on $[-1,1]$ and take the initial data as

4.2. Two-dimensional examples.

A convex Hamiltonian. In two dimensions we solve a problem similar to (4.1),

$$\phi_t + \frac{1}{2}\left(\phi_x + \phi_y + 1\right)^2 = 0, \tag{4.4}$$

which can be reduced to a one-dimensional problem via the coordinate transformation $\binom{\xi}{\eta} = \frac{1}{2}\left(\begin{smallmatrix}1 & 1\\ 1 & -1\end{smallmatrix}\right)\binom{x}{y}$. The results of the fifth-order calculations for the initial data $\phi(x, y, 0) = -\cos(\pi(x + y)/2) = -\cos(\pi\xi)$ are shown in Figure 4.4. The convergence rates for the two-dimensional fifth-order scheme before and after the singularity are shown in Table 4.5.

A nonconvex Hamiltonian. The two-dimensional nonconvex problem, which is analogous to the one-dimensional problem (4.2), is

$$\phi_t - \cos(\phi_x + \phi_y + 1) = 0. \tag{4.5}$$

Here we assume initial data, given by $\phi(x, y, 0) = -\cos(\pi(x + y)/2)$, and periodic boundary conditions. The results are shown in Figure 4.5. The convergence results for the two-dimensional fifth-order scheme before and after the singularity formation are given in Table 4.6.

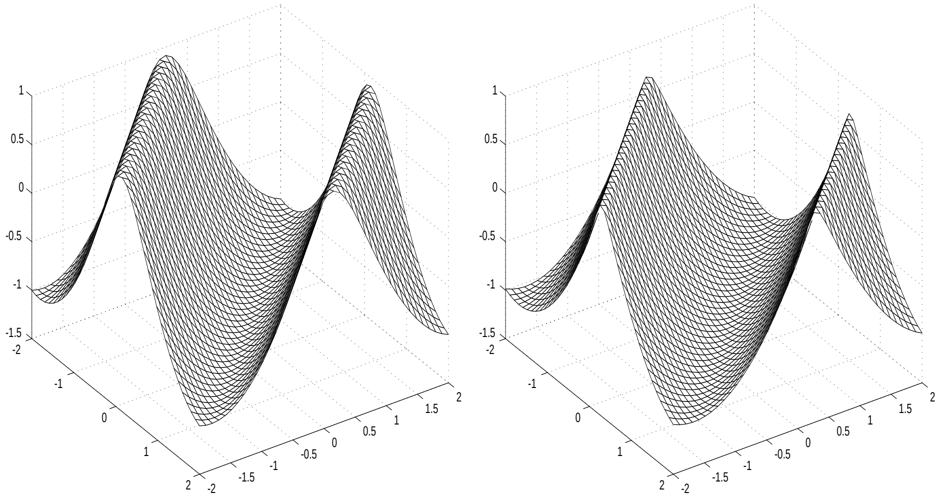

Fig. 4.4. *Two-dimensional convex Hamiltonian,* (4.4). *Left: the solution before the singularity formation, $T = 0.8/\pi^2$. Right: the solution after the singularity formation, $T = 1.5/\pi^2$. In both panels $N = 40 \times 40$. The solution is computed with the fifth-order method.*

200	4.86×10^{-5}	3.00	1.69×10^{-7}	4.41

A fully two-dimensional example. The above two-dimensional examples are actually one-dimensional along the diagonal. To check the performance of our methods on fully two-dimensional problems, we solve

$$\phi_t + \phi_x \phi_y = 0 \tag{4.6}$$

on $[-\pi,\pi]\times[-\pi,\pi]$, subject to the initial data $\phi(x,y,0) = \sin(x) + \cos(y)$ with periodic boundary conditions. The exact solution for this problem is given implicitly by $\phi(x,y,t) = -\cos(q)\sin(r) + \sin(q) + \cos(r)$, where $x = q - t\sin(r)$ and $y = r + t\cos(q)$. This solution is smooth for $t < 1$, continuous $\forall t$, and has discontinuous derivatives for $t \geq 1$. The results of our simulations at times $T = 0.8, 1.5$ are shown in Figure 4.6. The convergence results for the fifth-order two-dimensional schemes before the singularity formation are given in Table 4.7 and confirm the expected order of accuracy of our methods.

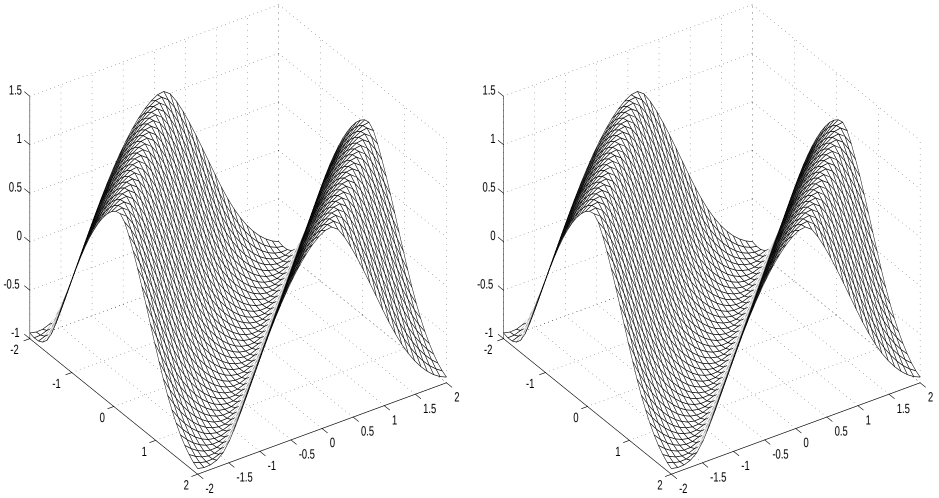

FIG. 4.5. *Two-dimensional nonconvex Hamiltonian,* (4.5). *Left: the solution before the singularity formation, $T = 0.8/\pi^2$. Right: the solution after the singularity formation, $T = 1.5/\pi^2$. $N = 40 \times 40$. The solution is computed with the fifth-order method.*

200	8.87×10^{-5}	1.12	3.09×10^{-7}	1.58

An eikonal equation in geometric optics. We consider a two-dimensional nonconvex problem that arises in geometric optics [20]:

$$\begin{cases} \phi_t + \sqrt{\phi_x^2 + \phi_y^2 + 1} = 0, \\ \phi(x, y, 0) = \frac{1}{4}(\cos(2\pi x) - 1)(\cos(2\pi y) - 1) - 1. \end{cases} \tag{4.7}$$

The results of our fifth-order method at time $T = 0.6$ are shown in Figure 4.7, where we see the sharp corners that develop in this problem.

An optimal control problem. We solve an optimal control problem related to cost determination [35]. Here the Hamiltonian is of the form $H(x, y, \nabla\phi)$:

$$\begin{cases} \phi_t - \sin(y)\,\phi_x + \sin(x)\,\phi_y + |\phi_y| - \frac{1}{2}\sin^2(y) - 1 + \cos(x) = 0, \\ \phi(x, y, 0) = 0. \end{cases} \tag{4.8}$$

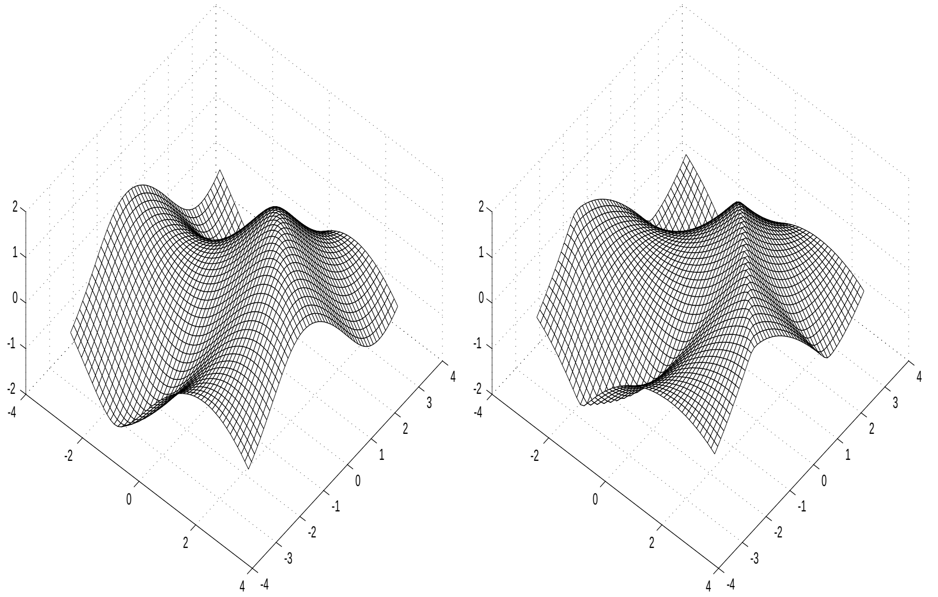

Fig. 4.6. *Fully two-dimensional Hamiltonian,* (4.6). *Left: the solution before the singularity formation, $T = 0.8$. Right: the solution after the singularity formation, $T = 1.5$. In both panels $N = 50 \times 50$. The solution is computed with the fifth-order method.*

Before singularity $T = 0.8$				
N	Relative L^1 error	L^1-order	Relative L^∞ error	L^∞-order
50	6.10×10^{-6}	–	8.15×10^{-8}	–
100	2.10×10^{-7}	4.86	7.35×10^{-10}	6.79
200	7.53×10^{-9}	4.80	5.59×10^{-12}	7.04

The result of our fifth-order scheme is presented in Figure 4.8 and is in qualitative agreement with [31].

4.3. A comparison of two-dimensional third-order interpolants. In this section we use the examples (4.4), (4.5), and (4.6) to compare the third-order method of section 3.2.1, based on interpolation via two-dimensional stencils, with that of section 3.2.2, where we used a dimension-by-dimension approach. The results are shown in Table 4.8. The dimension-by-dimension method produces errors that are approximately twice as large as those for the genuinely two-dimensional reconstruction. However, the convergence rate is qualitatively the same in both methods. These results motivated us to base our fifth-order scheme on the much simpler dimension-by-dimension reconstruction.

4.4. A stability study. In this section we present a couple of stability studies that we obtained in our simulations. We start by checking the stability properties of the third-order scheme with different reprojection steps. The reconstruction step

is done in all cases using the dimension-by-dimension interpolant. We compare the dimension-by-dimension reprojection and the diagonal reprojection (of section 3.2.3). In Figure 4.9 we plot the L^1 error as a function of the CFL number. The test problem is (4.6) with the fully two-dimensional Hamiltonian. The solution is computed at $T = 0.8$. We see that the use of a diagonal reprojection significantly reduces the maximum allowed CFL number.

We now turn to checking the stability properties of the two-dimensional fifth-order method of section 3.3 by computing the L^1 errors for various examples while varying the CFL number. In Figure 4.10 we compare the results obtained with our fifth-order scheme with the fifth-order method of [17], for which we used a local Lax–Friedrichs flux. The numerical tests indicate that larger CFL numbers can be used with our method.

4.5. Three-dimensional examples. We proceed with a three-dimensional generalization of the convex Hamiltonian (4.4),

$$\phi_t + \frac{1}{2}\left(\phi_x + \phi_y + \phi_z + 1\right)^2 = 0, \tag{4.9}$$

subject to the initial data $\phi(x, y, z, 0) = -\cos(\pi(x + y + z)/3)$. The convergence results for the three-dimensional fifth-order scheme before and after the singularity formation are given in Table 4.9. We also approximate the solution of the nonconvex

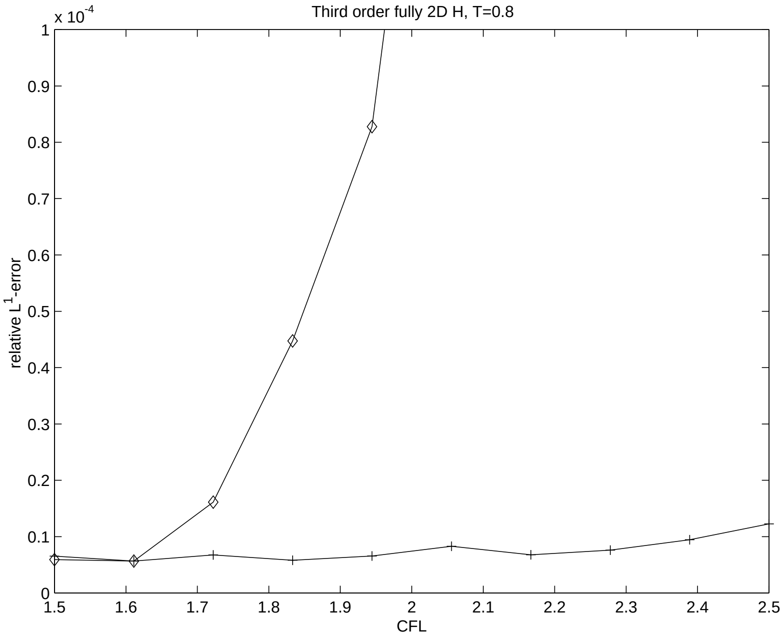

Fig. 4.9. *Stability of the two-dimensional third-order method with a dimension-by-dimension reprojection (crosses) vs. a diagonal reprojection (diamonds). Fully two-dimensional Hamiltonian* (4.6)*. $T = 0.8$ (before singularity), $N = 100 \times 100$.*

PSEUDOSPECTRAL LEAST-SQUARES METHOD FOR THE SECOND-ORDER ELLIPTIC BOUNDARY VALUE PROBLEM*

SANG DONG KIM†, HYUNG-CHUN LEE‡, AND BYEONG CHUN SHIN§

Abstract. The least-squares Legendre and Chebyshev pseudospectral methods are presented for a first-order system equivalent to a second-order elliptic partial differential equation. Continuous and discrete homogeneous least-squares functionals using Legendre and Chebyshev weights are shown to be equivalent to the $H^1(\Omega)$ norm and Chebyshev-weighted Div-Curl norm over appropriate polynomial spaces, respectively. The spectral error estimates are derived. The block diagonal finite element preconditioner is developed for the both cases. Several numerical tests are demonstrated on the spectral discretization errors and on performances of the finite element preconditioner.

Key words. pseudospectral method, first-order system least-squares method

1. Introduction.

Let Ω be the square $(-1,1)^2$. We consider the second-order elliptic boundary value problem

$$\left\{\begin{array}{rcll} -\nabla\cdot\nabla p+\mathbf{b}\cdot\nabla p+c_0\,p &=& f & \text{in } \Omega,\\ p &=& 0 & \text{on } \Gamma_D,\\ \mathbf{n}\cdot\nabla p &=& 0 & \text{on } \Gamma_N, \end{array}\right. \tag{1.1}$$

where $\partial\Omega=\Gamma_D\cup\Gamma_N$ denotes the boundary of Ω, f is a given continuous function, $\mathbf{b}$ and c_0 are given constant vector and scalar, respectively, and $\mathbf{n}$ is the outward unit vector normal to the boundary.

Introducing the flux variable $\mathbf{u}=\nabla p$, (1.1) can be written as an equivalent first-order system of linear equations (see [4], [5], and [21], for example). For the use of finite element methods, the least-squares approach was studied in [12], [13], and [14], for example, and it has been widely used by combining with functionals consisting of appropriate norms of residual equations (see [2], [3], [4], [5], [15], etc.). Then the homogeneous continuous and discrete least-squares functionals were shown to be equivalent to appropriate product norms. In this paper, the success of finite element least-squares methods for the last decade stimulated the usage of pseudospectral methods or Legendre (Chebyshev) spectral elements with a staggered grid, which is known to be a very accurate method (see [1], [6], [9], [10], [11], and [21]). Therefore we believe that it is worthwhile to develop the Legendre and Chebyshev pseudospectral least-squares methods for solving the first-order system corresponding to (1.1). Using the Legendre–Gauss–Lobatto (LGL) and Chebyshev–Gauss–Lobatto (CGL) points with corresponding quadrature weights, we define two discrete Legendre and Chebyshev least-squares functionals. For the continuous Legendre least-squares functional, we

adopt the continuous least-squares functional developed in [5]. The equivalence between the usual L^2-norm and the discrete Legendre spectral norm over an appropriate polynomial space yields that the discrete Legendre least-squares functional is equivalent to a product H^1-norm over a product of polynomial spaces. The continuous Chebyshev-weighted least-squares functional is also defined as the sum of L^2_w-norms of residual equations. Then the continuous and corresponding discrete Chebyshev-weighted least-squares functionals are shown to be equivalent to a product norm $\|\mathbf{u}\|^2_{L^2_w(\Omega)^2} + \|\nabla \cdot \mathbf{u}\|^2_{L^2_w(\Omega)^2} + \|\nabla \times \mathbf{u}\|^2_{L^2_w(\Omega)^2} + \|p\|^2_{H^1_w(\Omega)}$, in which we do not provide its equivalence to the Chebyshev-weighted H^1_w product norm. It is shown that the proposed methods have spectral convergence. Based on a norm equivalence, a block diagonal finite element preconditioner is developed for the use of an iterative method like the conjugate gradient method. Such finite element preconditioning techniques are discussed in [7], [8], [16], [20], and [24], for example. The finite element preconditioner for the Legendre case is optimal in the sense that the condition number of the preconditioned system behaves like $O(1)$. We also consider the Chebyshev weighted finite element preconditioner for the Chebyshev case. Some numerical experiments demonstrate that such a preconditioner seems to be optimal.

This paper consists of the following. In section 2, we provide definitions, notations, and basic known facts. In sections 3 and 4, we present Legendre and Chebyshev pseudospectral least-squares methods, respectively, including the norm equivalences and spectral convergences. In section 5, we explain how the linear system can be set up, and propose a block diagonal finite element preconditioner. Finally, we provide several numerical experiments including the condition numbers of the resulting linear system and preconditioned linear system, and spectral convergence of discretization errors in L^2, L^2_w- and H^1, H^1_w-norms.

2. Preliminaries.

In this section, we provide some preliminaries, definitions, and notations for future use. The standard notations and definitions are used for the weighted Sobolev spaces $H^s_w(\Omega)^2$ equipped with weighted inner products $(\cdot, \cdot)_{s,w}$ and corresponding weighted norms $\|\cdot\|_{s,w}$, $s \geq 0$, where $w(x,y) = \hat{w}(x)\hat{w}(y)$ is the Legendre weight function when $\hat{w}(t) = 1$ or Chebyshev weight function when $\hat{w}(t) = \frac{1}{\sqrt{1-t^2}}$. The space $H^0_w(\Omega)$ coincides with $L^2_w(\Omega)$, in which case the norm and inner product will be denoted by $\|\cdot\|_w$ and $(\cdot, \cdot)_w$, respectively. For the Legendre case, we simply write the notations without the subscript w, for example, $H^s(\Omega) := H^s_w(\Omega)$, $(\cdot,\cdot) := (\cdot,\cdot)_w$, $\|\cdot\| := \|\cdot\|_w$ if $w(x,y) = 1$.

Let $\mathcal{P}_N$ be the space of all polynomials of degree less than or equal to N. Let $\{\xi_i\}_{i=0}^N$ be the LGL or CGL points on $[-1,1]$ such that

$$-1 =: \xi_0 < \xi_1 < \cdots < \xi_{N-1} < \xi_N := 1.$$

For the Legendre case, $\{\xi_i\}_{i=0}^N$ are the zeros of $(1-t^2)L'_N(t)$, where L_N is the Nth Legendre polynomial and the corresponding quadrature weights $\{w_i\}_{i=0}^N$ are given by

$$\begin{aligned} w_j &= \frac{2}{N(N+1)}\frac{1}{[L_N(\xi_j)]^2}, \quad 1 \leq j \leq N-1, \\ w_0 = w_N &= \frac{2}{N(N+1)}. \end{aligned} \tag{2.1}$$

For the Chebyshev case, $\{\xi_i\}_{i=0}^N$ are the zeros of $(1-t^2)T'_N(t)$, where T_N is the Nth Chebyshev polynomial and the corresponding quadrature weights $\{w_i\}_{i=0}^N$ are given by

$$w_j = \frac{\pi}{N}, \quad 1 \le j \le N-1, \qquad w_0 = w_N = \frac{\pi}{2N}. \tag{2.2}$$

Then, we have the following LGL or CGL quadrature formula such that

$$\int_{-1}^{1} p(t)\hat{w}(t)\,dt = \sum_{i=0}^{N} w_i\, p(\xi_i) \quad \forall\, p \in \mathcal{P}_{2N-1}. \tag{2.3}$$

Let $\{\phi_i\}_{i=0}^N$ be the set of Lagrange polynomials of degree N with respect to LGL or CGL points $\{\xi_i\}_{i=0}^N$ which satisfy

$$\phi_i(\xi_j) = \delta_{ij} \quad \forall\, i, j = 0, 1, \dots, N,$$

where δ_{ij} denotes the Kronecker delta. The two-dimensional LGL or CGL nodes $\{\mathrm{x}_{ij}\}$ and weights $\{\mathrm{w}_{ij}\}$ are given by

$$\mathrm{x}_{ij} = (\xi_i, \xi_j), \quad \mathrm{w}_{ij} = w_i w_j, \quad i, j = 0, 1, \dots, N.$$

Let $\mathcal{Q}_N$ be the space of all polynomials of degree less than or equal to N with respect to each single variable x and y. Define the basis for $\mathcal{Q}_N$ as

$$\psi_{ij}(x, y) = \phi_i(x)\phi_j(y), \qquad i, j = 0, 1, \dots, N.$$

For any continuous functions u and v on $\bar{\Omega}$, the associated discrete scalar product and norm are

$$\langle u, v\rangle_{w,N} = \sum_{i,j=0}^{N} \mathrm{w}_{ij}\, u(\mathrm{x}_{ij})\, v(\mathrm{x}_{ij}) \quad \text{and} \quad \|v\|_{w,N} = \langle v, v\rangle_{w,N}^{\frac{1}{2}}. \tag{2.4}$$

Then, by (2.3) we have

$$\langle u, v\rangle_{w,N} = (u, v)_w \quad \text{for} \;\; uv \in \mathcal{Q}_{2N-1}. \tag{2.5}$$

It is well known that

$$\|v\|_w \le \|v\|_{w,N} \le \gamma^* \|v\|_w \quad \forall\, v \in \mathcal{Q}_N, \tag{2.6}$$

where $\gamma^* = 2 + \frac{1}{N}$ for the Legendre case and $\gamma^* = 2$ for the Chebyshev case. For any continuous function v on $\bar{\Omega}$, we denote by $I_N v \in \mathcal{Q}_N$ the interpolant of v at the LGL- or CGL-points $\{\mathrm{x}_{ij}\}$ such that

$$I_N v(\mathrm{x}) = \sum_{i,j=0}^{N} v(\mathrm{x}_{ij})\psi_{ij}(\mathrm{x}) \quad \forall\, \mathrm{x} \in \bar{\Omega}. \tag{2.7}$$

The following results are found in [1], [6], and [23]. The interpolation error estimate is known as

$$\|v - I_N v\|_{k,w} \le C\, N^{k-s} \|v\|_{s,w}, \quad k = 0, 1, \tag{2.8}$$

provided $v \in H_w^s(\Omega)$ for $s \ge 2$. Using (2.5)–(2.8), we can show that for any $u \in H_w^s(\Omega)$, $s \ge 2$, and any $v_N \in \mathcal{Q}_N$

$$|(u, v_N)_w - \langle u, v_N\rangle_{w,N}| \le C\, N^{-s}\, \|u\|_{s,w}\, \|v_N\|_w. \tag{2.9}$$

3. Legendre pseudospectral least-squares method. In this section, we investigate the Legendre pseudospectral least-squares method for the first-order system of linear equations equivalent to problem (1.1). Throughout this section, we set $w(x,y)=1$.

Let

$$V := \{v \in H^1(\Omega) : \, v = 0 \text{ on } \Gamma_D\}$$

and

$$\mathbf{W} := \{\mathbf{v} \in H^1(\Omega)^2 : \, \mathbf{n}\cdot\mathbf{v} = 0 \text{ on } \Gamma_N, \quad \boldsymbol{\tau}\cdot\mathbf{v} = 0 \text{ on } \Gamma_D\},$$

where $\mathbf{n}$ and $\boldsymbol{\tau}$ are unit normal and tangent vector, respectively. Let $\mathbf{W}_N = \mathcal{Q}_N^2 \cap \mathbf{W}$ and $V_N = \mathcal{Q}_N \cap V$. Let $\nabla\times$ denote the curl operator given by $\nabla\times\mathbf{v} = \partial_x v_2 - \partial_y v_1$ for a vector function $\mathbf{v} = (v_1, v_2)^T$.

Setting the flux variable $\mathbf{u} = \nabla p$ and using the identities

$$\nabla\times\mathbf{u} = 0 \quad \text{in } \Omega \quad \text{and} \quad \boldsymbol{\tau}\cdot\mathbf{u} = 0 \quad \text{on } \Gamma_D,$$

we employ the first-order system of linear equations equivalent to (1.1) such that

$$\left\{\begin{array}{rcll} \mathbf{u} - \nabla p &=& \mathbf{0} & \text{in } \Omega, \\ -\nabla\cdot\mathbf{u} + \mathbf{b}\cdot\mathbf{u} + c_0\, p &=& f & \text{in } \Omega, \\ \nabla\times\mathbf{u} &=& 0 & \text{in } \Omega, \\ p &=& 0 & \text{on } \Gamma_D, \\ \mathbf{n}\cdot\mathbf{u} &=& 0 & \text{on } \Gamma_N, \\ \boldsymbol{\tau}\cdot\mathbf{u} &=& 0 & \text{on } \Gamma_D. \end{array}\right. \tag{3.1}$$

Define the least-squares functional for the system (3.1) as

$$G(\mathbf{v},q;f) = \|f + \nabla\cdot\mathbf{v} - \mathbf{b}\cdot\mathbf{v} - c_0\, q\|^2 + \|\mathbf{v} - \nabla q\|^2 + \|\nabla\times\mathbf{v}\|^2 \tag{3.2}$$

for $(\mathbf{v},q) \in \mathbf{W}\times V$. The first-order system least-squares variational problem for (3.1) is to minimize the quadratic functional $G(\mathbf{v},q;f)$ over $\mathbf{W}\times V$: find $(\mathbf{u},p) \in \mathbf{W}\times V$ such that

$$G(\mathbf{u},p;f) = \inf_{(\mathbf{v},q)\in\mathbf{W}\times V} G(\mathbf{v},q;f). \tag{3.3}$$

The corresponding variational problem is to find $(\mathbf{u},p) \in \mathbf{W}\times V$ such that

$$a(\mathbf{u},p;\mathbf{v},q) = f(\mathbf{v},q) \quad \forall\, (\mathbf{v},q) \in \mathbf{W}\times V, \tag{3.4}$$

where the bilinear form $a(\cdot;\cdot)$ is given by

$$\begin{aligned} a(\mathbf{u},p;\mathbf{v},q) &= (\nabla\cdot\mathbf{u} - \mathbf{b}\cdot\mathbf{u} - c_0\, p,\ \nabla\cdot\mathbf{v} - \mathbf{b}\cdot\mathbf{v} - c_0\, q) \\ &\quad + (\mathbf{u} - \nabla p,\ \mathbf{v} - \nabla q) + (\nabla\times\mathbf{u},\ \nabla\times\mathbf{v}) \end{aligned} \tag{3.5}$$

and the linear form $f(\cdot)$ is given by

$$f(\mathbf{v},q) = -(f, \nabla\cdot\mathbf{v} - \mathbf{b}\cdot\mathbf{v} - c_0\, q). \tag{3.6}$$

THEOREM 3.1. *For any $(\mathbf{v},q) \in \mathbf{W}\times V$, there exists a positive constant C such that*

$$\frac{1}{C}\big(\|\mathbf{v}\|_1^2 + \|q\|_1^2\big) \le a(\mathbf{v},q;\mathbf{v},q) \le C\big(\|\mathbf{v}\|_1^2 + \|q\|_1^2\big). \tag{3.7}$$

Proof. The functional (3.2) is a special case of the general form given in [5]. Hence, the continuity and ellipticity of the bilinear form $a(\cdot;\cdot)$ are immediate consequences of [5]. □

Define the discrete least-squares functional using the discrete Legendre spectral norm as

$$G_N(\mathbf{v},q;f)=\|f+\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\|_N^2+\|\mathbf{v}-\nabla q\|_N^2+\|\nabla\times\mathbf{v}\|_N^2 \tag{3.8}$$

for $(\mathbf{v},q)\in\mathbf{W}_N\times V_N$. The discrete least-squares problem associated with (3.8) is then to minimize the quadratic functional $G_N(\mathbf{v},q;f)$ over $\mathbf{W}_N\times V_N$, and the corresponding variational problem (Legendre pseudospectral collocation problem) is to find $(\mathbf{u}_N,\,p_N)\in\mathbf{W}_N\times V_N$ such that

$$a_N(\mathbf{u}_N,\,p_N;\mathbf{v},q)=f_N(\mathbf{v},q)\quad\forall\,(\mathbf{v},q)\in\mathbf{W}_N\times V_N, \tag{3.9}$$

where the discrete bilinear form $a_N(\cdot;\cdot)$ and linear form $f_N(\cdot)$ are given by

$$\begin{aligned}a_N(\mathbf{u}_N,\,p_N;\mathbf{v},q)&=\langle\nabla\cdot\mathbf{u}_N-\mathbf{b}\cdot\mathbf{u}_N-c_0\,p_N,\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\rangle_N\\&\quad+\langle\mathbf{u}_N-\nabla p_N,\mathbf{v}-\nabla q\rangle_N+\langle\nabla\times\mathbf{u}_N,\nabla\times\mathbf{v}\rangle_N\end{aligned} \tag{3.10}$$

and

$$f_N(\mathbf{v},q)=-\langle f,\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\rangle_N. \tag{3.11}$$

The continuity and ellipticity of the discrete functional $G_N(\cdot;0)$ are shown in the following theorem.

THEOREM 3.2. *For any $(\mathbf{v},q)\in\mathbf{W}_N\times V_N$, there exists a constant C such that*

$$\frac{1}{C}\left(\|\mathbf{v}\|_1^2+\|q\|_1^2\right)\le G_N(\mathbf{v},q;0)\le C\left(\|\mathbf{v}\|_1^2+\|q\|_1^2\right). \tag{3.12}$$

Proof. Since $\mathbf{v}-\nabla q\in\mathcal{Q}_N^2$ and $\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q$, $\nabla\times\mathbf{v}\in\mathcal{P}_N$, we can easily show from (2.6) that

$$G(\mathbf{v},q;0)\le G_N(\mathbf{v},q;0)\le\left(2+\frac{1}{N}\right)^2G(\mathbf{v},q;0).$$

Hence, the bounds (3.12) are an immediate consequence of the Theorem 3.1. □

We show the spectral convergence in the H^1 product norm for the Legendre pseudospectral least-squares method following the same techniques used in [1] and [23]. Similarly one may show the L^2 convergence (see [1] or [23]).

THEOREM 3.3. *Assume that the solution $(\mathbf{u},p)$ of (3.4) is in $H^s(\Omega)^3$ for some $s\ge1$ and $f\in H^\ell(\Omega)$ for some integer $\ell\ge2$. Let $(\mathbf{u}_N,p_N)\in\mathbf{W}_N\times V_N$ be the discrete solution of the problem (3.9). Then there exists a constant C such that*

$$\|\mathbf{u}-\mathbf{u}_N\|_1+\|p-p_N\|_1\le C\left[N^{1-s}(\|\mathbf{u}\|_s+\|p\|_s)+N^{-\ell}\|f\|_\ell\right]. \tag{3.13}$$

Proof. Using the first Strang lemma, which uses the coercivity of $a_N(\cdot;\cdot)$ and the continuity of $a(\cdot;\cdot)$, one may easily verify from [23] (or see in [1, p. 88]) that

$$\begin{aligned}C\big(\|\mathbf{u}-\mathbf{u}_N\|_1+\|p-p_N\|_1\big)\le\inf_{(\mathbf{v},q)\in\mathbf{W}_N\times V_N}&\Bigg[\|\mathbf{u}-\mathbf{v}\|_1+\|p-q\|_1\\&+\sup_{(\mathbf{w},r)\in\mathbf{W}_N\times V_N}\frac{|a(\mathbf{v},q;\mathbf{w},r)-a_N(\mathbf{v},q;\mathbf{w},r)|}{\|\mathbf{w}\|_1+\|r\|_1}\Bigg]\\&+\sup_{(\mathbf{w},r)\in\mathbf{W}_N\times V_N}\frac{|f(\mathbf{w},r)-f_N(\mathbf{w},r)|}{\|\mathbf{w}\|_1+\|r\|_1}.\end{aligned} \tag{3.14}$$

If we take $\mathbf{v} \in \mathbf{W}_{N-1}$ and $q \in V_{N-1}$, we see from (2.5) that

$$a(\mathbf{v}, q; \mathbf{w}, r) = a_N(\mathbf{v}, q; \mathbf{w}, r) \quad \forall\, (\mathbf{w}, r) \in \mathbf{W}_N \times V_N.$$

Using the inequality (2.9) yields

$$|f(\mathbf{w}, r) - f_N(\mathbf{w}, r)| \le C\, N^{-\ell}\, \|f\|_\ell\, \|\nabla \cdot \mathbf{w} - \mathbf{b} \cdot \mathbf{w} - c_0\, r\|, \quad \ell \ge 2.$$

Since

$$\|\nabla \cdot \mathbf{w} - \mathbf{b} \cdot \nabla r - c_0\, r\| \le C \left(\|\mathbf{w}\|_1 + \|r\|_1\right) \quad \forall\, (\mathbf{w}, r) \in \mathbf{W}_N \times V_N,$$

we have

$$\frac{|f(\mathbf{w}, r) - f_N(\mathbf{w}, r)|}{\|\mathbf{w}\|_1 + \|r\|_1} \le C\, N^{-\ell}\, \|f\|_\ell, \quad \ell \ge 2.$$

Now, using (2.8), we deduce the conclusion (3.13). □

4. Chebyshev pseudospectral least-squares method. In this section, we investigate the Chebyshev pseudospectral least-squares method for the first-order system of linear equations equivalent to problem (1.1). We will use the same notation used in the previous section, but the definitions may be different from those of the previous section. Throughout this section, we set $w(x, y) = \hat{w}(x)\hat{w}(y)$, with $\hat{w}(t) = \frac{1}{\sqrt{1-t^2}}$ and $\Gamma_N = \emptyset$.

We redefine the spaces V and $\mathbf{W}$ such that

$$V := \{v \in H^1_w(\Omega) : \ v = 0 \text{ on } \ \partial\Omega\}$$

and

$$\mathbf{W} := \{\mathbf{v} \in L^2_w(\Omega)^2 : \ \|\mathbf{v}\|_W < \infty \quad \text{and} \quad \boldsymbol{\tau} \cdot \mathbf{v} = 0 \text{ on } \ \partial\Omega\},$$

which is a Hilbert space equipped with the norm

$$\|\mathbf{v}\|_W := \left(\|\mathbf{v}\|_w^2 + \|\nabla \cdot \mathbf{v}\|_w^2 + \|\nabla \times \mathbf{v}\|_w^2\right)^{\frac{1}{2}}.$$

Let $H^{-1}_w(\Omega)$ be the dual space of V equipped with the norm (see [1, p. 18])

$$\|u\|_{-1,w} := \sup_{0 \ne \phi \in V} \frac{(u, \phi)_w}{\|\phi\|_{1,w}}. \tag{4.1}$$

Let $\mathbf{W}_N = Q_N^2 \cap \mathbf{W}$ and $V_N = Q_N \cap V$. The first-order system (3.1) is rewritten as

$$\left\{\begin{array}{rcll} \mathbf{u} - \nabla p & = & \mathbf{0} & \text{in } \Omega, \\ -\nabla \cdot \mathbf{u} + \mathbf{b} \cdot \mathbf{u} + c_0\, p & = & f & \text{in } \Omega, \\ \nabla \times \mathbf{u} & = & 0 & \text{in } \Omega, \\ p & = & 0 & \text{on } \partial\Omega, \\ \boldsymbol{\tau} \cdot \mathbf{u} & = & 0 & \text{on } \partial\Omega. \end{array}\right. \tag{4.2}$$

Define the least-squares functional corresponding to (4.2) using the Chebyshev weighted L^2-norms as

$$G_w(\mathbf{v}, q; f) = \|f + \nabla \cdot \mathbf{v} - \mathbf{b} \cdot \mathbf{v} - c_0\, q\|_w^2 + \|\mathbf{v} - \nabla q\|_w^2 + \|\nabla \times \mathbf{v}\|_w^2 \tag{4.3}$$

for $(\mathbf{v}, q) \in \mathbf{W} \times V$. Then the first-order system least-squares variational problem for (4.2) is to minimize the quadratic functional $G_w(\mathbf{v}, q; f)$ over $\mathbf{W} \times V$: find $(\mathbf{u}, p) \in \mathbf{W} \times V$ such that

$$G_w(\mathbf{u}, p; f) = \inf_{(\mathbf{v},q)\in\mathbf{W}\times V} G_w(\mathbf{v}, q; f), \tag{4.4}$$

and the variational problem for (4.4) is to find $(\mathbf{u}, p) \in \mathbf{W} \times V$ such that

$$a_w(\mathbf{u}, p; \mathbf{v}, q) = f_w(\mathbf{v}, q) \quad \forall\, (\mathbf{v}, q) \in \mathbf{W} \times V, \tag{4.5}$$

where the bilinear form $a_w(\cdot;\cdot)$ is given by

$$\begin{aligned} a_w(\mathbf{u}, p; \mathbf{v}, q) = {} & (\nabla\cdot\mathbf{u} - \mathbf{b}\cdot\mathbf{u} - c_0\, p, \nabla\cdot\mathbf{v} - \mathbf{b}\cdot\mathbf{v} - c_0\, q)_w \\ & + (\mathbf{u} - \nabla p, \mathbf{v} - \nabla q)_w + (\nabla\times\mathbf{u}, \nabla\times\mathbf{v})_w \end{aligned} \tag{4.6}$$

and the linear form $f_w(\cdot)$ is given by

$$f_w(\mathbf{v}, q) = -(f, \nabla\cdot\mathbf{v} - \mathbf{b}\cdot\mathbf{v} - c_0\, q)_w. \tag{4.7}$$

From now on, we will establish the coercivity and continuity for the homogeneous Chebyshev functional $G_w(\cdot; 0)$ over $\mathbf{W} \times V$. We recall the Poincaré–Friedrichs inequality such that (see [6])

$$\|v\|_w \le C\|\nabla v\|_w \quad \forall\, v \in V, \tag{4.8}$$

where C is a positive constant.

LEMMA 4.1. *For $\phi(x, y) \in V$, the following hold:*

(a) *There are two positive constants c and C such that*

$$c\|\phi\|^2_{1,w} \le \int_\Omega \nabla\phi\cdot\nabla(\phi w)\, dxdy \le C\|\phi\|^2_{1,w}.$$

(b) *There is a constant C such that, with $t = x$ or y,*

$$\left| \int_\Omega \phi^2(x, y) \frac{t^2}{(1 - t^2)^2} \hat{w}(x)\hat{w}(y)\, dxdy \right| \le C\|\phi\|^2_{1,w}.$$

Proof. First note that (a) is found in, for example, [6], [10], or [19]. For the proof of (b), recall from Lemma 2 in [19] that

$$\left| \int_{-1}^{1} u^2(t) \frac{t^2}{(1 - t^2)^2} \hat{w}(t)\, dt \right| \le \frac{4}{9}|u|^2_{H^1_w(-1,1)} \quad \text{for} \quad u \in H^1_{0,w}(-1, 1).$$

From this estimate one may prove the conclusion (b). □

LEMMA 4.2. *For any $\mathbf{v} \in \mathbf{W}$, we have*

$$\|\nabla\cdot\mathbf{v}\|_{-1,w} \le C\,\|\mathbf{v}\|_w.$$

Proof. Using the divergence theorem yields that, for $\phi \in V$ and $\mathbf{v} = (v_1, v_2)^T \in \mathbf{W}$,

$$(\nabla\cdot\mathbf{v}, \phi)_w = -\,(\mathbf{v}, \nabla(\phi w)) = -(v_1, \phi_x w + \phi w_x) - (v_2, \phi_y w + \phi w_y), \tag{4.9}$$

where we define $\phi_t = \frac{\partial}{\partial t}\phi(x,y)$ for $t = x$ or y. By the Schwarz inequality, we have

$$|(v_i, \phi_t w)| = |(v_i, \phi_t)_w| \le \|v_i\|_w \, \|\phi\|_{1,w}, \quad i = 1, 2, \quad t = x, y. \tag{4.10}$$

On the other hand, with $t = x$ or y, the Schwarz inequality and Lemma 4.1 yield

$$\begin{aligned} |(v_i, \phi w_t)| &= \left| \int_\Omega v_i(x,y)\phi(x,y)\, \frac{t}{1-t^2}\, w(x,y)\, dxdy \right| \\ &\le \left(\int_\Omega v_i(x,y)^2 w(x,y)\, dxdy \right)^{\frac{1}{2}} \left(\int_\Omega \phi^2(x,y)\, \frac{t^2}{(1-t^2)^2}\, w(x,y)\, dxdy \right)^{\frac{1}{2}} \\ &\le C \, \|v_i\|_w \, \|\phi\|_{1,w}. \end{aligned} \tag{4.11}$$

Combining (4.9) with (4.10) and (4.11), we have

$$(\nabla \cdot \mathbf{v}, \phi)_w \le C \|\mathbf{v}\|_w \, \|\phi\|_{1,w} \quad \forall\, \phi \in V,$$

which completes the conclusion via the definition of $\| \cdot \|_{-1,w}$. □

LEMMA 4.3. *There exists a constant C such that*

$$\|p\|_{1,w} \le C \, \| - \Delta p\|_{-1,w} \quad \forall\, p \in V. \tag{4.12}$$

Proof. It is well known from Theorem 11.1 in [6] that there exists a constant C such that

$$\|p\|_{1,w}^2 \le C \, (\nabla p, \nabla(pw)) = C \, (-\Delta p, p)_w \quad \forall\, p \in V.$$

Hence, by the definition of $\| \cdot \|_{-1,w}$, we have the conclusion (4.12). □

Due to the above lemma, from now on we may assume that there are constant coefficients $\mathbf{b}$ and c_0 satisfying the following a priori estimate:

$$\|p\|_{1,w} \le C \, \| - \Delta p + \mathbf{b} \cdot \nabla p + c_0 \, p\|_{-1,w} \quad \forall\, p \in V. \tag{A_0}$$

Indeed, for the case $\mathbf{b} = \mathbf{0}$ and $c_0 > 0$ it is clear, and for the other case we can find the restrictions to $\mathbf{b}$ and c_0 following the arguments in [6].

Now, under the assumption (A_0), we establish the coercivity and continuity for the homogeneous Chebyshev least-squares functional $G_w(\cdot; 0)$ over $\mathbf{W} \times V$ as follows.

THEOREM 4.4. *Assume that (A_0) holds. Then there exists a positive constant C such that*

$$\frac{1}{C}\big(\|\mathbf{v}\|_W^2 + \|q\|_{1,w}^2\big) \le G_w(\mathbf{v}, q, ; 0) \le C\big(\|\mathbf{v}\|_W^2 + \|q\|_{1,w}^2\big) \quad \forall\, (\mathbf{v}, q) \in \mathbf{W} \times V. \tag{4.13}$$

Proof. The triangle inequality yields the upper bound. For the lower bound, let $(\mathbf{v}, q) \in \mathbf{W} \times V$. By (A_0), the triangle inequality, and Lemma 4.2, we have

$$\begin{aligned} \|q\|_{1,w}^2 &\le C \, \|\Delta q - \mathbf{b} \cdot \nabla q - c_0 \, q\|_{-1,w}^2 \\ &\le C \, \big(\|\nabla \cdot \mathbf{v} - \mathbf{b} \cdot \mathbf{v} - c_0 \, q\|_{-1,w}^2 + \|\nabla \cdot (\mathbf{v} - \nabla q)\|_{-1,w}^2 + \|\mathbf{b} \cdot (\mathbf{v} - \nabla q)\|_{-1,w}^2\big) \\ &\le C \, \big(\|\nabla \cdot \mathbf{v} - \mathbf{b} \cdot \mathbf{v} - c_0 \, q\|_w^2 + \|\mathbf{v} - \nabla q\|_w^2\big) \\ &\le C \, G_w(\mathbf{v}, q; 0). \end{aligned}$$

Using the triangle inequality together with the last inequality, we have

$$\|\mathbf{v}\|_w^2 \le C \, \big(\|\mathbf{v} - \nabla q\|_w^2 + \|\nabla q\|_w^2\big) \le C \, G_w(\mathbf{v}, q; 0)$$

and

$$\begin{aligned}\|\nabla\cdot\mathbf{v}\|_w^2 &\le C\,\left(\|\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\|_w^2+\|\mathbf{b}\cdot\mathbf{v}+c_0\,q\|_w\right)\\ &\le C\,(G_w(\mathbf{v},q;0)+\|\mathbf{v}\|_w^2+\|q\|_w^2)\le C\,G_w(\mathbf{v},q;0).\end{aligned}$$

Thus we have

$$\|\mathbf{v}\|_W^2=\|\mathbf{v}\|_w^2+\|\nabla\cdot\mathbf{v}\|_w^2+\|\nabla\times\mathbf{v}\|_w^2\le C\,G_w(\mathbf{v},q;0),$$

which completes the theorem. □

Define the discrete least-squares functionals using the discrete Chebyshev norm as

$$G_{w,N}(\mathbf{v},q;f)=\|f+\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\|_{w,N}^2+\|\mathbf{v}-\nabla q\|_{w,N}^2+\|\nabla\times\mathbf{v}\|_{w,N}^2 \tag{4.14}$$

for $(\mathbf{v},q)\in\mathbf{W}_N\times V_N$. The discrete least-squares problem associated with (4.14) is then to minimize the quadratic functional $G_{w,N}(\mathbf{v},q;f)$ over $\mathbf{W}_N\times V_N$, and the corresponding variational problem (Chebyshev pseudospectral collocation problem) is to find $(\mathbf{u}_N,\,p_N)\in\mathbf{W}_N\times V_N$ such that

$$a_{w,N}(\mathbf{u}_N,\,p_N;\mathbf{v},q)=f_{w,N}(\mathbf{v},q)\quad\forall\,(\mathbf{v},q)\in\mathbf{W}_N\times V_N, \tag{4.15}$$

where the discrete bilinear form $a_{w,N}(\cdot;\cdot)$ and linear form $f_{w,N}(\cdot)$ are given by

$$\begin{aligned}a_{w,N}(\mathbf{u}_N,\,p_N;\mathbf{v},q)&=\langle\nabla\cdot\mathbf{u}_N-\mathbf{b}\cdot\mathbf{u}_N-c_0\,p_N,\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\rangle_{w,N}\\ &\quad+\langle\mathbf{u}_N-\nabla p_N,\mathbf{v}-\nabla q\rangle_{w,N}+\langle\nabla\times\mathbf{u}_N,\nabla\times\mathbf{v}\rangle_{w,N}\end{aligned} \tag{4.16}$$

and

$$f_{w,N}(\mathbf{v},q)=-\langle f,\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q\rangle_{w,N}. \tag{4.17}$$

The continuity and coercivity of the discrete functional $G_{w,N}(\cdot;0)$ are given in the following theorem.

THEOREM 4.5. *Assume that* (A_0) *holds. There exists a constant* C *such that*

$$\frac{1}{C}\left(\|\mathbf{v}\|_W^2+\|q\|_{1,w}^2\right)\le G_{w,N}(\mathbf{v},q;0)\le C\left(\|\mathbf{v}\|_W^2+\|q\|_{1,w}^2\right) \tag{4.18}$$

for all $(\mathbf{v},q)\in\mathbf{W}_N\times V_N$.

Proof. Since $\mathbf{v}-\nabla q\in\mathcal{Q}_N^2$ and $\nabla\cdot\mathbf{v}-\mathbf{b}\cdot\mathbf{v}-c_0\,q$, $\nabla\times\mathbf{v}\in\mathcal{P}_N$, we can easily show from (2.6) that

$$G_w(\mathbf{v},q;0)\le G_{w,N}(\mathbf{v},q;0)\le 4G_w(\mathbf{v},q;0).$$

Now, the bounds (4.18) are an immediate consequence of Theorem 4.4. □

Applying again the same techniques in [1] and [23] to our case, we show the spectral convergence for the Chebyshev pseudospectral least-squares method.

THEOREM 4.6. *Assume that* (A_0) *holds and that the solution* $(\mathbf{u},p)$ *of* (4.5) *is in* $H_w^s(\Omega)^3$ *for some* $s\ge 1$ *and* $f\in H_w^\ell(\Omega)$ *for some integer* $\ell\ge 2$. *Let* $(\mathbf{u}_N,p_N)\in\mathbf{W}_N\times V_N$ *be the discrete solution of problem* (4.15). *Then there exists a constant* C *such that*

$$\|\mathbf{u}-\mathbf{u}_N\|_W+\|p-p_N\|_{1,w}\le C\left[N^{1-s}(\|\mathbf{u}\|_{s,w}+\|p\|_{s,w})+N^{-\ell}\|f\|_{\ell,w}\right]. \tag{4.19}$$

Proof. Using the first Strang lemma, which uses the coercivity of $a_{w,N}(\cdot;\cdot)$ and the continuity of $a_w(\cdot;\cdot)$, one may easily verify from [23] (or see [1, p. 88]) that

$$\begin{aligned} C\big(\|\mathbf{u}-\mathbf{u}_N\|_W + \|p-p_N\|_{1,w}\big) \le \inf_{(\mathbf{v},q)\in \mathbf{W}_N\times V_N} \Bigg[&\|\mathbf{u}-\mathbf{v}\|_W + \|p-q\|_{1,w} \\ &+ \sup_{(\mathbf{w},r)\in \mathbf{W}_N\times V_N} \frac{|a_w(\mathbf{v},q;\mathbf{w},r) - a_{w,N}(\mathbf{v},q;\mathbf{w},r)|}{\|\mathbf{w}\|_W + \|r\|_{1,w}} \Bigg] \\ &+ \sup_{(\mathbf{w},r)\in \mathbf{W}_N\times V_N} \frac{|f_w(\mathbf{w},r) - f_{w,N}(\mathbf{w},r)|}{\|\mathbf{w}\|_W + \|r\|_{1,w}}. \end{aligned} \tag{4.20}$$

If we take $\mathbf{v} \in \mathbf{W}_{N-1}$ and $q \in V_{N-1}$, we see from (2.5) that

$$a_w(\mathbf{v},q;\mathbf{w},r) = a_{w,N}(\mathbf{v},q;\mathbf{w},r) \quad \forall\,(\mathbf{w},r) \in \mathbf{W}_N \times V_N.$$

Using the inequality (2.9) yields

$$|f_w(\mathbf{w},r) - f_{w,N}(\mathbf{w},r)| \le C\,N^{-\ell}\,\|f\|_{\ell,w}\,\|\nabla\cdot\mathbf{w} - \mathbf{b}\cdot\mathbf{w} - c_0\,r\|_w, \quad \ell \ge 2.$$

Since

$$\|\nabla\cdot\mathbf{w} - \mathbf{b}\cdot\mathbf{w} - c_0\,r\|_w \le C\left(\|\mathbf{w}\|_W + \|r\|_{1,w}\right) \quad \forall\,(\mathbf{w},r) \in \mathbf{W}_N \times V_N,$$

we have

$$\frac{|f_w(\mathbf{w},r) - f_{w,N}(\mathbf{w},r)|}{\|\mathbf{w}\|_W + \|r\|_{1,w}} \le C\,N^{-\ell}\,\|f\|_{\ell,w}, \quad \ell \ge 2.$$

Now, using (2.8), we deduce the conclusion (4.19). □

5. Implementation and preconditioning.

5.1. Implementation. The computation for problems (3.9) and (4.15) can be easily implemented by using the one-dimensional pseudospectral matrix D_N associated with the $N+1$ values $\{p(\xi_j)\}_{j=0}^N$ and the $N+1$ values $\{(\partial_N p)(\xi_j)\}_{j=0}^N$ of the pseudospectral derivative of p at LGL or CGL points (see [6], [23]). In this section we give the implementation of Legendre pseudospectral least-squares approximation. One may similarly obtain the implementation for the Chebyshev approximation. First, we reorder the LGL points from bottom to top and then left to right such that $\mathrm{x}_{k(N+1)+l} := \mathrm{x}_{kl} = (\xi_k, \xi_l)$ for $k,l = 0,1,\ldots,N$. The basis functions $\psi_{k(N+1)+l}(x,y) := \psi_{kl}(x,y) = \phi_k(x)\phi_l(y)$ and quadrature weights $\mathrm{w}_{k(N+1)+l} := \mathrm{w}_{kl} = w_k w_l$ are reordered accordingly. Then two-dimensional Legendre pseudospectral matrices S_x and S_y related to $\{(\partial_x p)(\mathrm{x}_j)\}_{j=0}^{(N+1)^2-1}$ and $\{(\partial_y p)(\mathrm{x}_j)\}_{j=0}^{(N+1)^2-1}$ of the pseudospectral partial derivatives of p, respectively, are given by the tensor products of the identity matrix I_N and one-dimensional Legendre pseudospectral matrix D_N such that

$$S_x = D_N \otimes I_N \quad \text{and} \quad S_y = I_N \otimes D_N.$$

Indeed, the (i,j)-entries of S_x and S_y are given by $\partial_x\psi_j(\mathrm{x}_i)$ and $\partial_y\psi_j(\mathrm{x}_i)$, respectively. Let $W = \mathrm{diag}\{\mathrm{w}_i\}$ be the diagonal weight matrix.

Let $\mathcal{A}_N$ be the matrix corresponding to the bilinear form $a_N(\cdot;\cdot)$. Then $\mathcal{A}_N$ is a symmetric 3×3 block matrix. The same basis functions ψ_j, except for the basis functions corresponding to nodes on the boundaries where the solution is required to be 0, are used to approximate all components of the function $(\mathbf{u}_N, p_N) \in \mathbf{W}_N \times V_N$. Thus, it is more convenient to assemble the matrix $\mathcal{A}_N^*$ using all basis functions of $\mathcal{Q}_N$ and ignoring the boundary conditions. Then, the matrix $\mathcal{A}_N$ can be obtained from $\mathcal{A}_N^*$ by eliminating the rows and columns relative to the nodes on the appropriate boundaries. Hence, we will hereafter regard $\mathbf{W}_N \times V_N$ as $\mathcal{Q}_N^3$ in order to give a convenient description of assembly for $\mathcal{A}_N$. We denote by $\hat{\mathbf{s}}$ the vector containing the nodal values of a continuous function $\mathbf{s}$, that is,

$$\hat{\mathbf{s}} = (s(x_0), \ldots, s(x_{(N+1)^2-1}))^T.$$

Using the expressions of

$$\partial_t p(\mathrm{x}_i) = \sum_{j=0}^{(N+1)^2-1} \partial_t \psi_j(\mathrm{x}_i) p(\mathrm{x}_j) = (S_t \hat{\mathbf{p}})_i \quad \text{for } t = x \text{ or } y \text{ and } p \in \mathcal{Q}_N,$$

we have that, for every $p, q \in \mathcal{Q}_N$,

$$\langle p, q \rangle_N = \hat{\mathbf{q}}^T \, W \, \hat{\mathbf{p}} \quad \text{and} \quad \langle \partial_{t_1} p, \partial_{t_2} q \rangle_N = (S_{t_2} \hat{\mathbf{q}})^T \, W \, (S_{t_1} \hat{\mathbf{p}}),$$

where t_1 and t_2 are x or y. Then we obtain

$$\begin{aligned}
&\langle \mathbf{u} - \nabla p, \, \mathbf{v} - \nabla q \rangle_N = (\hat{\mathbf{v}}_1 - S_x \hat{\mathbf{q}})^T \, W \, (\hat{\mathbf{u}}_1 - S_x \hat{\mathbf{p}}) + (\hat{\mathbf{v}}_2 - S_y \hat{\mathbf{q}})^T \, W \, (\hat{\mathbf{u}}_2 - S_y \hat{\mathbf{p}}), \\
&\langle \nabla \cdot \mathbf{u} - \mathbf{b} \cdot \mathbf{u} - c_0 \, p, \, \nabla \cdot \mathbf{v} - \mathbf{b} \cdot \mathbf{v} - c_0 \, q \rangle_N \\
&\quad = (S_x \hat{\mathbf{v}}_1 + S_y \hat{\mathbf{v}}_2 - b_1 \hat{\mathbf{v}}_1 - b_2 \hat{\mathbf{v}}_2 - c_0 \hat{\mathbf{q}})^T \, W \, (S_x \hat{\mathbf{u}}_1 + S_y \hat{\mathbf{u}}_2 - b_1 \hat{\mathbf{u}}_1 - b_2 \hat{\mathbf{u}}_2 - c_0 \hat{\mathbf{p}}), \\
&\langle \nabla \times \mathbf{u}, \, \nabla \times \mathbf{v} \rangle_N = (-S_y \hat{\mathbf{v}}_1 + S_x \hat{\mathbf{v}}_2)^T \, W \, (-S_y \hat{\mathbf{u}}_1 + S_x \hat{\mathbf{u}}_2),
\end{aligned}$$

and

$$\langle f, \, \nabla \cdot \mathbf{v} - \mathbf{b} \cdot \mathbf{v} - c_0 \, q \rangle_N = (S_x \hat{\mathbf{v}}_1 + S_y \hat{\mathbf{v}}_2 - b_1 \hat{\mathbf{v}}_1 - b_2 \hat{\mathbf{v}}_2 - c_0 \hat{\mathbf{q}})^T \, W \, \hat{\mathbf{f}},$$

where $\mathbf{u} = (u_1, u_2)^T$, $\mathbf{v} = (v_1, v_2)^T$, and $\mathbf{b} = (b_1, b_2)^T$. Now, the symmetric matrix $\mathcal{A}_N^* = \big(A_{ij}\big)_{i,j=1,2,3}$ corresponding to $a_N(\cdot;\cdot)$ consists of

$$\begin{aligned}
A_{11} &= S_x^T \, W \, S_x + S_y^T \, W \, S_y + W - b_1 (S_x^T \, W + W \, S_x) + b_1^2 \, W, \\
A_{12} &= S_x^T \, W \, S_y - S_y^T \, W \, S_x - b_2 S_x^T \, W + b_1 b_2 \, W - b_1 \, W \, S_y, \\
A_{13} &= -W \, S_x - c_0 \, S_x^T \, W + b_1 c_0 \, W, \\
A_{22} &= S_x^T \, W \, S_x + S_y^T \, W \, S_y + W - b_2 (S_y^T \, W + W \, S_y) + b_2^2 \, W, \\
A_{23} &= -W \, S_y - c_0 \, S_y^T \, W + b_2 c_0 \, W, \\
A_{33} &= S_x^T \, W \, S_x + S_y^T \, W \, S_y + c_0^2 \, W.
\end{aligned}$$

Also, the vector F_N^* corresponding to $f_N(\mathbf{v}, q)$ consists of

$$F_N^* = \begin{pmatrix} -S_x^T \, W + b_1 \, W \\ -S_y^T \, W + b_2 \, W \\ c_0 \, W \end{pmatrix} \hat{\mathbf{f}}.$$

Let $\mathcal{A}_N$ and F_N be the matrix and vector eliminated rows and columns from $\mathcal{A}_N^*$ and F_N^* relative to the nodes on the boundary where the solution is required to be 0. Now, we are led to the matrix problem associated with (3.9):

$$\mathcal{A}_N \, X = F_N, \tag{5.1}$$

where $X = (\hat{\mathbf{u}}_1, \hat{\mathbf{u}}_2, \hat{\mathbf{p}})^T$.

5.2. Preconditioning. The spectral system (5.1) is generally handled with iterative methods due to the topological structure of $\mathcal{A}_N$, which makes direct methods unsuitable. One may employ a preconditioning conjugate gradient method for an efficient implementation of a linear system (5.1). In this section we use a finite element preconditioner generated by bilinear elements based on the Gauss–Lobatto nodes, which can be found in [7], [8], [19], [20], and [24].

Let B_N be the space of continuous piecewise bilinear functions with respect to the grid induced by the Gauss–Lobatto nodes $\{\mathrm{x}_i\}_{i=0}^{(N+1)^2-1}$, and let $\{\varphi_i\}_{i=0}^{(N+1)^2-1}$ be its nodal basis functions of B_N. Define the interpolation operator $J_N : \mathcal{Q}_N \to B_N$ by

$$J_N\, q = \sum_{j=0}^{(N+1)^2-1} q(\mathrm{x}_j)\varphi_j \in B_N \quad \text{for given } q = \sum_{j=0}^{(N+1)^2-1} q(\mathrm{x}_j)\psi_j \in Q_N.$$

Let $\mathcal{J}_N : \mathbf{W}_N \times V_N \to B_N^3$ be the interpolation operator given by

$$\mathcal{J}_N(v_1, v_2, q) = (J_N\, v_1, J_N\, v_2, J_N\, q) \qquad \forall\, (v_1, v_2, q) \in \mathbf{W}_N \times V_N.$$

Then, for the Legendre approximation we have from [20] that

$$\frac{1}{C}\, \|(\mathbf{v}, q)\|_1 \le \|\mathcal{J}_N(\mathbf{v}, q)\|_1 \le C\, \|(\mathbf{v}, q)\|_1 \qquad \forall\, (\mathbf{v}, q) \in \mathbf{W}_N \times V_N,$$

and for the Chebyshev approximation we have from [19] that

$$\frac{1}{C}\, \|(\mathbf{v}, q)\|_{1,w} \le \|\mathcal{J}_N(\mathbf{v}, q)\|_{1,w} \le C\, \|(\mathbf{v}, q)\|_{1,w} \qquad \forall\, (\mathbf{v}, q) \in \mathbf{W}_N \times V_N.$$

For the Legendre approximation, from (3.12) we have the following equivalent relation:

$$\frac{1}{C}\, \|\mathcal{J}_N(\mathbf{v}, q)\|_1 \le a_N(\mathbf{v}, q;\, \mathbf{v}, q) \le C\, \|\mathcal{J}_N(\mathbf{v}, q)\|_1 \quad \forall\, (\mathbf{v}, q) \in \mathbf{W}_N \times V_N. \tag{5.2}$$

Let $\mathcal{B}_{\mathcal{N}} := \mathcal{J}_N(\mathbf{W}_N \times V_N)$ be the subspace of B_N^3. Let the linear operator L be defined by $Lp = -\Delta p + x\mathbf{b} \cdot \nabla p + c_0 p$. The idea of optimal preconditioning in [16] is to consider preconditioning by the leading term $Bp = -\Delta p + \beta p$ for L, in which the choice of a nonnegative β is discussed so that B remains an optimal preconditioner. In this paper, using such ideas, we propose a finite element preconditioner. Let $\mathcal{R}_N :=$ diag(R_1, R_2, R_3) be the block diagonal stiffness matrix, where R_i is the stiffness matrix based on the continuous piecewise bilinear element space with respect to the operator $Bp := -\Delta p + \beta p$, with the boundary conditions shared with the ith component space of $\mathcal{B}_{\mathcal{N}}$, where β is a nonnegative constant. By (5.2) the matrix $\mathcal{R}_N$ is spectrally equivalent to $\mathcal{A}_N$ for any $\beta \ge 0$, and thus the spectral condition number of the preconditioned matrix $\mathcal{R}_N^{-1}\mathcal{A}_N$ is $O(1)$ in comparison with the spectral condition number $O(N^3)$ of $\mathcal{A}_N$ (see [1], [23]). In the next section, we perform some numerical experiments to find an optimal β which leads to the smallest spectral condition number of the preconditioned matrix $\mathcal{R}_N^{-1}\mathcal{A}_N$.

For the Chebyshev approximation, we cannot guarantee the norm equivalence

$$\frac{1}{C}\, \|(\mathbf{v}, q)\|_{1,w}^2 \le \|\mathbf{v}\|_W^2 + \|q\|_{1,w}^2 \le C\, \|(\mathbf{v}, q)\|_{1,w}^2 \qquad \forall\, (\mathbf{v}, q) \in \mathbf{W}_N \times V_N, \tag{5.3}$$

but we will propose a block diagonal finite element preconditioner based on the Chebyshev-weighted inner product. In the following section, we give some numerical evidence that the block diagonal finite element preconditioner $\mathcal{R}_{w,N}^{-1}$ associated

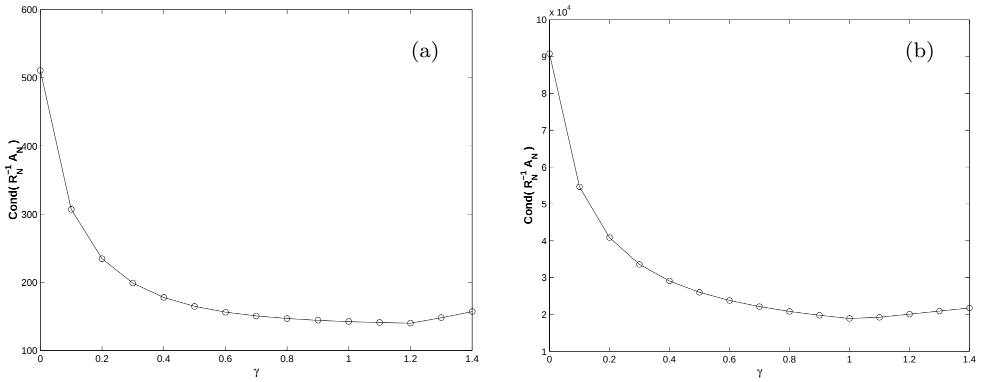

FIG. 1. *Spectral condition numbers of* $\mathcal{L}_{16} = \mathcal{R}_{16}^{-1}\mathcal{A}_{16}$ *for the Legendre cases* (a) $\mathbf{b} = (6,9)^t$, $c_0 = 0$, $\beta = \gamma\sqrt{b_1^2 + b_2^2}$; (b) $\mathbf{b} = (0,0)^t$, $c_0 = -10$, $\beta = \gamma\,|c_0|$.

with $Bp := -\Delta p + \beta p$ can be a good preconditioner, where the optimal choice of β is also discussed numerically. The spectral condition number of the preconditioned matrix $\mathcal{R}_{w,N}^{-1}\,\mathcal{A}_{w,N}$ seems to be bounded independently of N in comparison with the spectral condition number $O(N^4)$ of $\mathcal{A}_{w,N}$ (see [1], [23]). Also, one may consider a preconditioner $\widetilde{\mathcal{R}}_{w,N}^{-1}$ with respect to the norm $\|\mathbf{v}\|_W^2 + \|q\|_{1,w}^2$. However, $\widetilde{\mathcal{R}}_{w,N}$ is not a block diagonal matrix, and it is not easy to invert $\widetilde{\mathcal{R}}_{w,N}$, though it is spectrally equivalent to $\mathcal{A}_{w,N}$.

6. Numerical results. In this section, we present numerical experiments for the first-order system (3.1) associated with the elliptic partial differential equation

$$\left\{\begin{array}{rcll} -\nabla\cdot\nabla p + \mathbf{b}\cdot\nabla p + c_0\, p &=& f & \text{in } \Omega,\\ p &=& 0 & \text{on } \Gamma_D,\\ \mathbf{n}\cdot\nabla p &=& 0 & \text{on } \Gamma_N. \end{array}\right.$$

Let $\Omega = (-1,1)^2$. We take $\Gamma_D := (\{-1\}\times[-1,1])\cup([-1,1]\times\{-1\})$ and $\Gamma_N = \partial\Omega\backslash\Gamma_D$ for the Legendre approximation, and $\Gamma_D = \partial\Omega$ and $\Gamma_N = \emptyset$ for the Chebyshev approximation. Denote by $(\mathbf{u}_N, p_N)$ the discrete solution to (3.9) or (4.15), and by $e_{\mathbf{u}} = \mathbf{u} - \mathbf{u}_N$ and $e_p = p - p_N$ the errors.

6.1. Legendre pseudospectral approximation. We give the numerical experiments by Legendre pseudospectral least-squares approximation (3.9). Using the idea in [16], we first study the performance of the preconditioner $\mathcal{R}_N^{-1}$ for the system (5.1), where $\mathcal{R}_N$ is the block diagonal finite element stiffness matrix based on the continuous piecewise bilinear element space associated with the operator $Bp = -\Delta p + \beta p$. The constant β will be used to reduce the condition number of the preconditioned system for our examples. Define $\beta = \gamma\sqrt{b_1^2 + b_2^2}$ if $\mathbf{b} = (b_1, b_2)^t \neq \mathbf{0}$, and $\beta = \gamma|c_0|$ if $\mathbf{b} = (b_1, b_2)^t = \mathbf{0}$. Let $\mathcal{L}_N$ be the preconditioned matrix, i.e., $\mathcal{L}_N =: \mathcal{R}_N^{-1}\,\mathcal{A}_N$.

In Figure 1, we plot the spectral condition numbers of $\mathcal{L}_{16}$ along with γ for two different cases: (a) $\mathbf{b} = (6,9)^t$, $c_0 = 0$ and (b) $\mathbf{b} = (0,0)^t$, $c_0 = -10$. Numerical experiments indicate that the spectrum deforms smoothly as γ increases from zero to one for both cases, in which the best choice of γ is near 1. With $\gamma = 1$, we report the spectral condition numbers of $\mathcal{L}_N$ and $\mathcal{A}_N$ in Table 1 for several convection coefficients $\mathbf{b} = (0,0)^t, (2,3)^t, (4,6)^t, (6,9)^t$ and $c_0 = 0$, and in Table 2 for $c_0 = -1, -10$ and

Table 1
Condition numbers for $c_0 = 0$ *and* $\beta = \sqrt{b_1^2 + b_2^2}$.

	$\mathbf{b}^t = (0,0)$		$\mathbf{b}^t = (2,3)$		$\mathbf{b}^t = (4,6)$		$\mathbf{b}^t = (6,9)$	
N	$\mathcal{L}_N$	$\mathcal{A}_N$	$\mathcal{L}_N$	$\mathcal{A}_N$	$\mathcal{L}_N$	$\mathcal{A}_N$	$\mathcal{L}_N$	$\mathcal{A}_N$
4	11	177	28	129	87	246	199	448
8	14	710	31	393	73	503	147	689
12	15	1753	32	906	70	977	141	1172
16	15	3695	33	1864	69	1890	142	1986
20	16	6818	33	3419	69	3433	142	3541

Table 2
Condition numbers for $\mathbf{b}^t = (0,0)$ *and* $\beta = |c_0|$.

	$c_0 = -1$		$c_0 = -10$	
N	$\mathcal{L}_N$	$\mathcal{A}_N$	$\mathcal{L}_N$	$\mathcal{A}_N$
4	911	7552	4080	7817
8	1094	29587	20595	69107
12	1173	71838	19165	120819
16	1215	150524	18885	202646
20	1241	277620	19107	357455

$\mathbf{b} = (0,0)^t$. Both tables show that the spectral condition numbers of $\mathcal{A}_N$ behave like $O(N^3)$ for all cases, but those of $\mathcal{L}_N$ are bounded regardless of the degree N of polynomials, and they are increasing as the size $\sqrt{b_1^2 + b_2^2}$ of convection coefficient $\mathbf{b}$ or the absolute value $|c_0|$ of negative reaction coefficient c_0 increases.

We now present the discretization errors along with several coefficients $\mathbf{b}$ and c_0. The exact solutions p and $\mathbf{u} = \nabla p$ that we take are

$$p = \sin\left(\frac{7\pi}{4}(x+1)\right) \sin\left(\frac{7\pi}{4}(y+1)\right),$$

$$\mathbf{u} = \begin{pmatrix} \dfrac{7\pi}{4} \cos\left(\dfrac{7\pi}{4}(x+1)\right) \sin\left(\dfrac{7\pi}{4}(y+1)\right) \\ \dfrac{7\pi}{4} \sin\left(\dfrac{7\pi}{4}(x+1)\right) \cos\left(\dfrac{7\pi}{4}(y+1)\right) \end{pmatrix}.$$

The present solutions satisfy the given boundary conditions and, by substituting the solutions into (3.1), we have the right-hand side f along with various coefficients $\mathbf{b}$ and c_0. Table 3 shows that the spectral errors decay exponentially with respect to N, independent of the coefficients $\mathbf{b}$ and c_0.

6.2. Chebyshev pseudospectral approximation. We give the numerical experiments obtained by Chebyshev pseudospectral least-squares approximation (4.15). Let $\mathcal{A}_{w,N}$ be the matrix associated with the bilinear form $a_{w,N}(\cdot,\cdot)$. As a preconditioner for $\mathcal{A}_{w,N}$, we similarly take the inverse of the block diagonal finite element Chebyshev-weighted stiffness matrix $\mathcal{R}_{w,N}$ associated with the operator $Bp = -\Delta p + \beta p$ and based on the continuous piecewise bilinear element space with two-dimensional CGL grid points. Define $\beta = \gamma\sqrt{b_1^2 + b_2^2}$ if $\mathbf{b} = (b_1, b_2)^t \neq \mathbf{0}$, and $\beta = \gamma|c_0|$ if $\mathbf{b} = (b_1, b_2)^t = \mathbf{0}$. Let $\mathcal{L}_{w,N}$ be the preconditioned matrix, i.e., $\mathcal{L}_{w,N} =: \mathcal{R}_{w,N}^{-1} \mathcal{A}_{w,N}$.

We first give the performance of the preconditioner $\mathcal{R}_{w,N}^{-1}$. In Figure 2, we also plot the spectral condition numbers of $\mathcal{L}_{w,16}$ along with γ for two different cases: (a)

TABLE 3

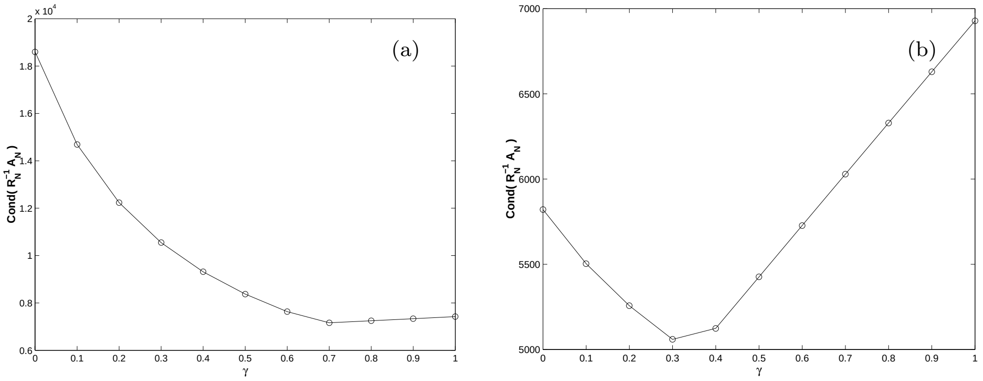

FIG. 2. *Spectral condition numbers of* $\mathcal{L}_{w,16} = \mathcal{R}_{w,16}^{-1}\mathcal{A}_{w,16}$ *for the Chebyshev cases* (a) $\mathbf{b} = (6,9)$, $c_0 = 0$, $\beta = \gamma\sqrt{b_1^2 + b_2^2}$; (b) $\mathbf{b} = (0,0)$, $c_0 = -10$, $\beta = \gamma\,|c_0|$.

$\mathbf{b} = (6,9)^t$, $c_0 = 0$ and (b) $\mathbf{b} = (0,0)^t$, $c_0 = -10$. We have the similar type of spectral condition numbers as in the Legendre case. The figure shows that the spectrum smoothly deforms as γ increases from zero to 0.7 for case (a) and to 0.3 for case (b); i.e., the best choice of γ is 0.7 for case (a) and 0.3 for case (b). We report the spectral condition numbers of $\mathcal{L}_{w,N}$ and $\mathcal{A}_{w,N}$ in Table 4 for $\mathbf{b} = (0,0)^t, (2,3)^t, (4,6)^t, (6,9)^t$ and $c_0 = 0$ with $\gamma = 0.7$, and in Table 5 for $c_0 = -1, -10$ and $\mathbf{b} = (0,0)^t$ with $\gamma = 0.3$. Both tables show that the spectral condition numbers of $\mathcal{A}_{w,N}$ behave like $O(N^3)$ for all cases, but those of $\mathcal{L}_{w,N}$ are bounded regardless of the degree N of polynomials, and they are increasing as the size $\sqrt{b_1^2 + b_2^2}$ of convection coefficient $\mathbf{b}$ or the absolute value $|c_0|$ of negative reaction coefficient c_0 increases. Tables 4 and 5 show that the condition numbers of $\mathcal{A}_{w,N}$ behave like $O(N^4)$ for all cases, but those of $\mathcal{L}_{w,N}$ are like $O(1)$. These numerical experiments demonstrate that $\mathcal{R}_{w,N}^{-1}$ can be a good preconditioner even though we could not prove the spectral equivalence (5.3).

		16	2.6919e−06	6.5936e−05	1.8115e−05	4.2733e−04
		20	1.4600e−09	4.6310e−08	1.1407e−08	3.4721e−07

Finally, we present the discretization errors with the following exact solutions p and $\mathbf{u} = \nabla p$:

$$p = \sin 2\pi x \, \sin 2\pi y, \qquad \mathbf{u} = \begin{pmatrix} 2\pi \cos 2\pi x \, \sin 2\pi y \\ 2\pi \sin 2\pi x \, \cos 2\pi y \end{pmatrix}.$$

Table 6 shows that the spectral errors decay exponentially with respect to N, independent of the coefficients $\mathbf{b}$ and c_0.

7. Conclusion. The analysis and computations for combining least-squares techniques and collocation methods using high-order elements have been shown for elliptic boundary value problems like (1.1). We saw that the continuous and discrete least-squares functionals are equivalent to a product H^1-norm, and we proved the spectral convergence consequently for the Legendre case. Hence the block finite element preconditioner corresponding to $-\Delta p + \beta p$ was demonstrated to be numerically optimal by emphasizing the importance of the choice of β, adopting the discussion in [16] for a finite difference case. For the Chebyshev case, convergence analysis was provided and the finite element preconditioner, which seems to be numerically optimal, was developed even though the continuous and discrete least-squares functionals were not shown to be equivalent to a product H^1_w-norm but to a product *div-curl* L^2_w-norm for the flux variable and $H^1_{0,w}$-norm for a primitive variable. In the near future we believe that it may be possible to analyze such an equivalence. The success of finite element least-squares (or fosls) can be fused over the Legendre (Chebyshev) pseudospectral method and the spectral method with a staggered grid for various kinds of partial differential equations. This fusion approach opens many possible applications. In particular, a practical application of these developed theories to transport-dominated problems by setting $c_0 = 0$ and making $|\mathbf{b}|$ large needs to be studied (see [22]). Incidentally, the neutron transported problem was analyzed for a finite element least-squares method in [17] and [18].

CONVERGENCE ANALYSIS OF THE GAUSS–SEIDEL PRECONDITIONER FOR DISCRETIZED ONE DIMENSIONAL EULER EQUATIONS[*]

ARNOLD REUSKEN[†]

Abstract. We consider the nonlinear system of equations that results from the Van Leer flux vector-splitting discretization of the one dimensional Euler equations. This nonlinear system is linearized at the discrete solution. The main topic of this paper is a convergence analysis of block-Gauss–Seidel methods applied to this linear system of equations. Both the lexicographic and the symmetric block-Gauss–Seidel method are considered. We derive results which quantify the quality of these methods as preconditioners. These results show, for example, that for the subsonic case the symmetric Gauss–Seidel method can be expected to be a much better preconditioner than the lexicographic variant. Sharp bounds for the condition number of the preconditioned matrix are derived.

1. Introduction.

In this paper we consider iterative methods for discrete stationary Euler equations. Two important solution approaches known from the literature are the following. First, one can use some "simple" explicit iterative method, like a block nonlinear Gauss–Seidel method or a Runge–Kutta method (obtained by introducing an artificial time variable), which then is accelerated by multigrid techniques (e.g., [12, 13, 16, 20, 25, 27]). The second approach is based on linearization combined with fast iterative solvers for large sparse linear systems, such as multigrid solvers or (preconditioned) Krylov-subspace methods. A typical example of this is the Newton–Krylov technique from [5, 14, 15, 18, 19, 24]. In the literature one can find many studies in which different iterative solution techniques for solving stationary (or instationary) discrete Euler equations are compared (e.g., [17, 26]). There are, however, as far as we know, no rigorous theoretical results available which yield any insight into convergence properties of certain iterative methods applied to (linearized) discrete Euler equations. In this paper a first step towards such theoretical results is made.

In this paper, as a model problem we consider the stationary Euler equations that model one dimensional subsonic and transonic flows through a nozzle [11, 21], and use the Van Leer flux vector-splitting method for discretization. The discrete nonlinear problem is linearized at the discrete solution. We apply a GMRES method with block-Gauss–Seidel preconditioning to this Jacobian linear problem. In the Gauss–Seidel preconditioner the three unknowns at each grid point are collected in a block and updated simultaneously. (This is also often called a collective Gauss–Seidel method.) Both a lexicographic (LGS) and a symmetric (SGS) Gauss–Seidel

method are used. We emphasize that we do not recommend using such an iterative method for these one dimensional linearized Euler equations, because the Jacobian matrix has a block-tridiagonal structure with 3 × 3 blocks, and thus a direct solver is efficient for this problem. Our main interest, however, is not the efficient solution of these one dimensional Euler equations, but a better understanding of convergence properties of the block-Gauss–Seidel method applied to discrete Euler equations.

As is well known, direction of flow essentially influences not only the discretization of Euler equations, but also the convergence of iterative methods. If the flow is subsonic, then even in the one dimensional case the LGS method cannot be consistent with the flow direction. In one dimensional flow one has only two directions, and thus the SGS method can be expected to be a fast iterative solver. These elementary observations are part of common knowledge. However, even for one dimensional flows many questions related to Gauss–Seidel preconditioning are still unanswered. As will be illustrated by numerical experiments, for GMRES with block-Gauss–Seidel preconditioning there are some interesting dependencies of the rate of convergence on the Mach number and the mesh size. As far as we know, there is no analysis available which explains these dependencies. The main topic of the paper is a theoretical analysis in which we try to explain some of the convergence phenomena that are observed in the numerical experiments. In this analysis we use the technique of "frozen coefficients"; i.e., we linearize the discrete Euler equations at a function triple (ρ, u, p) (density, velocity, pressure) which is constant as a function of the space variable and is such that the solution is subsonic. We consider the LGS and SGS methods applied to this problem and derive results which quantify the quality of these methods as a preconditioner. Our results show, for example, that the SGS method can be expected to be a (much) better preconditioner than the LGS method. Sharp bounds for the condition number of the preconditioned matrix are derived, which show that in case of the SGS preconditioner for a large range of Mach numbers $M \in (M_0, 1)$ this condition number increases only (very) slowly if the grid size decreases.

We realize that although some first theoretical results are given in this paper, we are still far from a complete theoretical convergence analysis of Gauss–Seidel methods applied to linearized discrete one dimensional Euler equations. The theoretical analysis presented supports the numerical observation that for many subsonic and transonic one dimensional linearized Euler equations the SGS method is a (very) effective preconditioner. However, as already noted above, in the one dimensional case a direct solver is the best choice. In two and three dimensional problems, however, block-Gauss–Seidel techniques or other basic iterative methods (ILU) combined with Krylov subspace methods can result in very efficient solvers [3, 4, 6, 19]. Clearly, in higher dimensions flow has many directions to go and the relation between a Gauss–Seidel-type splitting and direction of flow becomes much more complicated. This then makes the analysis of this class of iterative methods much more difficult, as in the one dimensional case. We do not claim that our analysis can easily be applied to the much more interesting higher dimensional case. Nevertheless, starting from the results presented in this paper we do see some possibilities for the analysis of a two dimensional problem. These are briefly discussed in Remark 3 at the end of the paper.

2. The one dimensional nozzle flow and its discretization. We consider the stationary quasi–one dimensional Euler flow in a channel of varying cross section

$S(x)$ $(x \in \mathbb{R})$. This problem can be modeled by the equations (cf. [11, 21])

$$\begin{cases} \frac{d(\rho u S)}{dx} = 0, \\ \frac{d(\rho u^2 S + pS)}{dx} = p\frac{dS}{dx}, \\ \frac{d(\rho u H S)}{dx} = 0, \end{cases}$$

with density ρ, velocity u, pressure p, and stagnation enthalpy $H = E + \frac{p}{\rho}$. Further relations are

$$E = e + \frac{1}{2}u^2, \quad p = (\gamma - 1)\rho e.$$

Here e denotes the internal energy and γ is a gas parameter (ratio of specific heats; $\gamma = 1.4$ for air). As unknowns one can take the primitive variables $V := (\rho, u, p)^T$. We introduce the conservative variables U, the source term Q_S, and the flux function f:

$$U = \begin{pmatrix} u_1 \\ u_2 \\ u_3 \end{pmatrix} := S \begin{pmatrix} \rho \\ \rho u \\ \rho E \end{pmatrix}, \quad Q_S(U) := \begin{pmatrix} 0 \\ \frac{dS}{dx} \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ (\gamma - 1)(u_3 - \frac{1}{2}\frac{u_2^2}{u_1})\frac{d \ln S}{dx} \\ 0 \end{pmatrix},$$

$$f(U) := S \begin{pmatrix} \rho u \\ \rho u^2 + p \\ \rho u H \end{pmatrix} = \begin{pmatrix} u_2 \\ \frac{1}{2}(3 - \gamma)\frac{u_2^2}{u_1} + (\gamma - 1)u_3 \\ \gamma \frac{u_2 u_3}{u_1} - \frac{1}{2}(\gamma - 1)\frac{u_2^3}{u_1^2} \end{pmatrix}.$$

In compact form the problem can be represented as

$$f(U)_x = Q_S(U). \tag{2.1}$$

Note that for $S(x) \equiv 1$ we obtain the homogeneous one dimensional Euler equations. Formulas for the transformation between the primitive variables V and the conservative variables U are known (cf. [11]). Important quantities are the speed of sound $c = (\gamma p \rho^{-1})^{\frac{1}{2}}$ and the Mach number $M = uc^{-1}$. In our experiments we take the following nozzle with throat at $x = 1$:

$$S(x) = \begin{cases} 1 + 1\frac{1}{2}\left(1 - \frac{1}{5}(x + 4)\right)^2 & \text{for } 0 \leq x \leq 1, \\ 1 + \frac{1}{2}\left(1 - \frac{1}{5}(x + 4)\right)^2 & \text{for } 1 \leq x \leq 4. \end{cases} \tag{2.2}$$

Nozzle flows are well-known test cases for steady-state computations (cf. [11, 13]). By specifying certain problem parameters (inflow Mach number and critical throat section), the problem (2.1) can have several types of solutions: a smooth subsonic flow, a smooth hypersonic flow, a transonic flow without shocks, or a transonic flow with shocks. Moreover, these solutions depend on only *one* parameter (for example, the Mach number $M = M(x)$), and a simple procedure for computing the exact solution of the continuous problem is available (cf. [11, section 16.6.4]). For two cases the function $x \to M(x)$ corresponding to the exact solution of the problem (2.1), (2.2) is shown in Figures 2.1 and 2.2. In Figure 2.1 we have a smooth subsonic flow with critical throat section $S^* = 0.5$. The solution in Figure 2.2 corresponds to a transonic flow with a critical throat value $S^* = 1$, which equals the throat value $S(1)$, and a shock at $x = 3$.

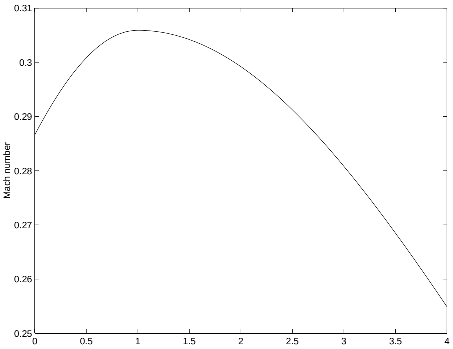

FIG. 2.1. $x \to M(x)$ *for a smooth subsonic flow.*

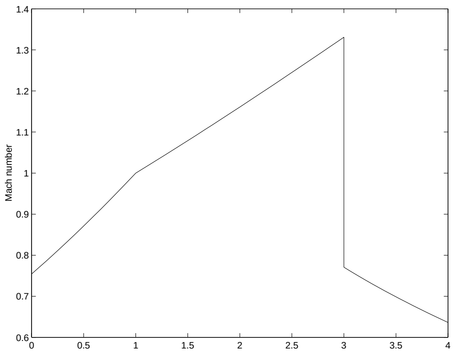

FIG. 2.2. $x \to M(x)$ *for a transonic flow with shock.*

We now outline the numerical solution method for this test problem (for which the exact solution is available). We consider only problems with subsonic inflow and outflow conditions ($0 < M(0) < 1$ and $0 < M(4) < 1$). For the boundary conditions we prescribe values for ρ and u at the inflow boundary $x = 0$, and for p at the outflow boundary $x = 4$. We use a uniform grid $x_i = ih$, $0 \le i \le n+1$, with a mesh size $h = 4/(n+1)$. We introduce the discrete unknowns

$$U_i := \begin{pmatrix} u_1(x_i) \\ u_2(x_i) \\ u_3(x_i) \end{pmatrix}, \quad \mathbf{U} := \big(U_i\big)_{0 \le i \le n+1}.$$

For the discretization at the boundaries we use compatibility relations as discussed in [11, section 19.1.2]; i.e., at the inflow boundary we discretize with one-sided differences the equation $(u-c)\big(\frac{du}{dx} - \frac{1}{\rho c}\frac{dp}{dx}\big) = uc\frac{d\ln S}{dx}$ that corresponds to the left-going characteristic. Similarly, the two right-going characteristic equations at $x = 4$ are discretized using one-sided differences. Together with the prescribed boundary values this yields equations

$$F_0 : \mathbb{R}^6 \to \mathbb{R}^3, \qquad F_0(U_0, U_1) = 0, \tag{2.3}$$

$$F_{n+1} : \mathbb{R}^6 \to \mathbb{R}^3, \qquad F_{n+1}(U_n, U_{n+1}) = 0. \tag{2.4}$$

For the discretization in the interior grid points we use an upwind method based on the Van Leer flux vector-splitting (see [11, 28]):

$$\begin{aligned} &f(V) = f^+(V) + f^-(V), \\ &f^+(V) := \frac{\rho}{4c}(u+c)^2 \begin{pmatrix} 1 \\ \frac{(\gamma-1)u+2c}{\gamma} \\ \frac{((\gamma-1)u+2c)^2}{2(\gamma^2-1)} \end{pmatrix} \quad \text{if} \quad -1 \le M \le 1, \\ &f^+ := 0 \quad \text{if} \quad M \le -1, \quad f^+ := f \quad \text{if} \quad M \ge 1. \end{aligned} \tag{2.5}$$

We use backward differences for the approximation of $f^+(U)_x$, and forward differences for the approximation of $f^-(U)_x$. This yields the equations

$$F_i(U_{i-1}, U_i, U_{i+1}) := -f^+(U_{i-1}) + f^+(U_i) - f^-(U_i) + f^-(U_{i+1}) - hQ_S(U_i) = 0 \tag{2.6}$$

for $i = 1, \dots, n$. The equations (2.3), (2.4), and (2.6) yield a nonlinear system of equations

$$F : \mathbb{R}^{3(n+2)} \to \mathbb{R}^{3(n+2)}, \quad F(\mathbf{U}) = 0. \tag{2.7}$$

For the iterative solution of this problem we apply the Newton method. The Jacobian matrices $DF(\mathbf{U}) \in \mathbb{R}^{3(n+2)\times 3(n+2)}$ have a block-tridiagonal structure. Hence, the linear systems in the Newton iteration can be solved efficiently using a direct method. The main topic of this paper is the analysis of block-Gauss–Seidel iterative methods applied to these linear systems. We emphasize that we do *not* suggest using such a Gauss–Seidel method as an efficient solver in this one dimensional setting. The analysis for the one dimensional case is a first step towards a better theoretical understanding of basic iterative methods applied to two or three dimensional linearized Euler equations.

3. Numerical experiments. In this section we show results of a few numerical experiments which illustrate some interesting phenomena related to the rate of convergence of block-Gauss–Seidel methods. Let $\mathbf{U}_h^*$ be the solution of the discrete problem (2.7). We consider the linear system

$$DF(\mathbf{U}_h^*)\mathbf{v} = \mathbf{b}. \tag{3.1}$$

In the experiments we take $\mathbf{b} = (1, \dots, 1)^T$, and for the starting vector in the iterative method we use $\mathbf{v}^0 = 0$. It turns out that in many cases (often due to the treatment of the boundary conditions) the block-Gauss–Seidel method does not converge. It turns out, however, that the method is a (very) good preconditioner. Hence, we use the block-Gauss–Seidel method in combination with a Krylov subspace method. We choose the GMRES(m) iterative method. Experiments with BiCGSTAB yielded similar results.

We use the LGS and SGS methods. In the GMRES method we make a restart after $m = 20$ iterations. The choice $m = 20$ is rather arbitrary, however; for other values of $m \in [10, 40]$ we observe similar phenomena. We use the GMRES(m) implementation in MATLAB. In a first experiment, as a comparison for other results, we consider a standard very simple model problem. We take the one dimensional diffusion equation $-u_{xx} = g$ discretized by second order differences. This results in an $n \times n$ tridiagonal matrix tridiag$(-1, 2, -1)$. For different n-values the convergence history of the SGS-GMRES(20) iterative solver applied to this problem is shown in Figure 3.1. For the linearized compressible Euler equations (3.1) we show results for the following problems.

Problem 1. We consider a problem with a smooth subsonic solution, as shown in Figure 2.1. The convergence history of the SGS-GMRES(20) method is shown in Figure 3.2.

Problem 2. We take a smooth subsonic flow with larger Mach numbers than in Problem 1. The solution is shown in Figure 3.3 (with critical throat value $S^* = 0.85$). The corresponding convergence history is presented in Figure 3.4.

Problem 3. We consider a transonic flow with a shock, as shown in Figure 2.2. The convergence behavior of the SGS-GMRES(20) solver is shown in Figure 3.5. If instead of SGS we use the LGS preconditioner, we obtain the results in Figure 3.6.

From these experiments we observe that in all three problems the rate of convergence of the SGS-GMRES(20) method is (much) higher than for the one dimensional discrete Poisson equation. We also see that in Problem 2 (subsonic flow with relatively high Mach numbers) the rate of convergence is much higher than in Problem

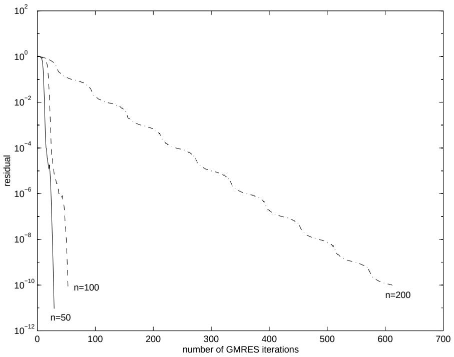

Fig. 3.1. *SGS-GMRES*(20) *method applied to a one dimensional Poisson equation.*

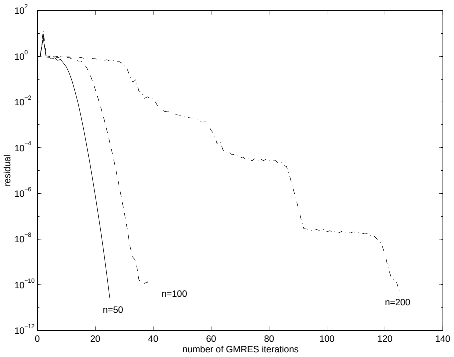

Fig. 3.2. *Problem* 1: *SGS-GMRES*(20) *method for the subsonic flow in Figure* 2.1.

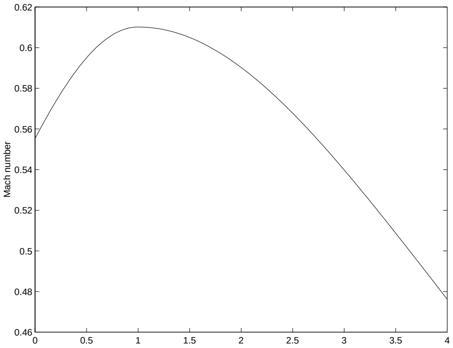

Fig. 3.3. *Problem* 2: $x \to M(x)$ *for a smooth subsonic flow.*

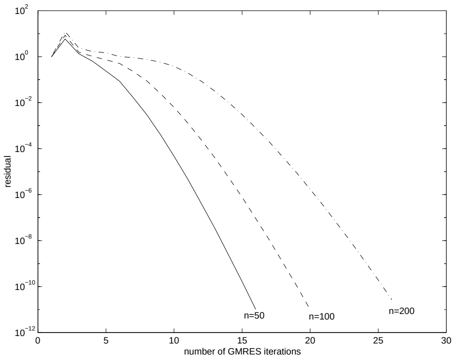

Fig. 3.4. *Problem* 2: *SGS-GMRES*(20) *method for the subsonic flow in Figure* 3.3.

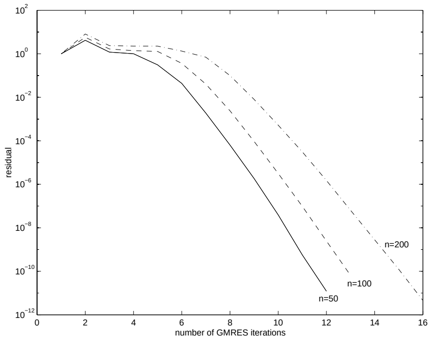

Fig. 3.5. *Problem* 3: *SGS-GMRES*(20) *method for the transonic flow in Figure* 2.2.

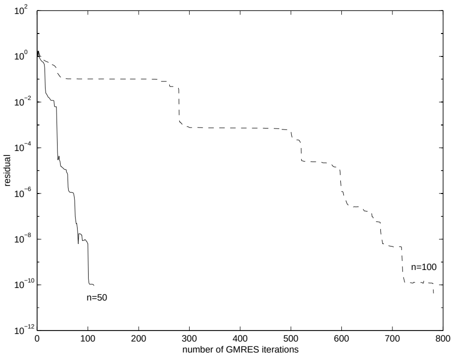

Fig. 3.6. *Problem* 3: *LGS-GMRES*(20) *method for the transonic flow in Figure* 2.2.

1. In the case of the transonic flow in Problem 3 the rate of convergence of the SGS-GMRES(20) method is even higher. We also note that the results presented in Figures 3.4 and 3.5 show a weak dependence of the rate of convergence on the mesh size h. Finally note that in Problem 3 the LGS-GMRES(20) method is much slower than the SGS-GMRES(20) method.

In the next section we present an analysis which yields some theoretical results on the quality of the block-Gauss–Seidel preconditioner. These theoretical results yield a better understanding of the convergence phenomena that are observed in the numerical experiments above.

4. Convergence analysis of the block-Gauss–Seidel method. For the (block) Gauss–Seidel method many convergence results are known in the literature (e.g., see [1, 2, 7, 8, 23]). These results apply to certain classes of matrices, like, for example, symmetric positive definite matrices or M-matrices. We did not find a convergence analysis which yields a satisfactory result when applied to the linearized discrete one dimensional Euler equations. In this section we present an analysis that partly fills this gap.

For the theoretical analysis we consider the homogeneous Euler equations $f(U)_x = 0$ with a *constant* solution $(\rho(x), u(x), p(x)) = (\rho, u, p) =: \bar{V}$ for all x. We consider only data with

$$\rho > 0, \quad p > 0, \quad M \in (0,1), \quad \gamma := 1.4. \tag{4.1}$$

The corresponding solution vector in conservative variables is denoted by $\bar{U}^*$. The Van Leer discretization method as described in section 2 results in a nonlinear system as in (2.3), (2.4), (2.6) with $Q_S = 0$. The treatment of the boundary conditions (first order accurate) is such that

$$F_0(\bar{U}_0^*, \bar{U}_1^*) = 0, \quad F_{n+1}(\bar{U}_n^*, \bar{U}_{n+1}^*) = 0$$

holds. Hence, the discrete problem has the constant solution $\bar{U}_h^*(x_i) := \bar{U}^*(x_i),\ i = 0, \ldots, n+1$. To avoid technical complications related to the specific treatment of the boundary conditions we consider the nonlinear system in the interior points only; i.e., as unknowns we take $\mathbf{U} = (U_1, \ldots, U_n)^T \in \mathbb{R}^{3n}$, and the system of nonlinear equations is given by

$$\begin{aligned} F_1(U_1, U_2) &:= f^+(U_1) - f^-(U_1) + f^-(U_2) = f^+(\bar{U}_0^*), \\ F_i(U_{i-1}, U_i, U_{i+1}) &:= -f^+(U_{i-1}) + f^+(U_i) - f^-(U_i) + f^-(U_{i+1}) = 0, \quad 2 \le i \le n-1, \\ F_n(U_{n-1}, U_n) &:= -f^+(U_{n-1}) + f^+(U_n) - f^-(U_n) = -f^-(\bar{U}_{n+1}^*). \end{aligned} \tag{4.2}$$

The vector $\bar{U}_h^*(x_i) = \bar{U}^*(x_i),\ i = 1, \ldots, n$, is a solution of this nonlinear system of equations. The Jacobian system

$$\mathbf{A}\mathbf{v} = \mathbf{b}, \quad \mathbf{A} := DF(\bar{\mathbf{U}}_h^*) \in \mathbb{R}^{3n \times 3n} \tag{4.3}$$

has a block-tridiagonal matrix

$$\begin{aligned} &\mathbf{A} = \text{blocktridiag}(-A^+, A^+ - A^-, A^-)_{1 \le i \le n}, \\ &A^+ := Df^+(\bar{U}_h^*) \in \mathbb{R}^{3\times 3}, \quad A^- := Df^-(\bar{U}_h^*) \in \mathbb{R}^{3\times 3}. \end{aligned} \tag{4.4}$$

The eigenvalues of $A^{\pm}$ are denoted by $\lambda_i^{\pm},\ i = 1, 2, 3$. The Van Leer splitting has been constructed in such a way that both A^+ and A^- have one zero eigenvalue: $\lambda_1^+ = \lambda_1^- = 0$. The other eigenvalues λ_2^+, λ_3^+ of A^+ and λ_2^-, λ_3^- of $A^-$are strictly positive and strictly negative, respectively. For these eigenvalues explicit formulas in terms of c and M are known [11, 28].

Using MAPLE, one obtains

$$\det(A^+ - A^-) = \frac{c^3}{24}(M^6 - 15M^4 + 3M^2 + 11).$$

The polynomial in M on the right-hand side has no zeros for $M \in (-1, 1)$. Hence (cf. (4.1)) the matrix $A^+ - A^-$ is nonsingular. The matrix

$$B = B(\bar{U}_h^*) := -(A^+ - A^-)^{-1} A^- \tag{4.5}$$

plays an important role in the analysis. From $\ker(B) = \ker(A^-)$ and $\ker(I - B) = \ker(A^+)$ it follows that

$$\sigma(B) = \{\, 1,\, 0,\, \mu(\rho, c, M) \,\}. \tag{4.6}$$

Using MAPLE, an explicit representation for B can be obtained. The resulting formulas are rather long and not relevant here. We note only that from these formulas it immediately follows that B can be factorized as

$$B = E\tilde{B}(M)E^{-1}, \quad E = \mathrm{diag}(1, c, c^2), \tag{4.7}$$

with a matrix $\tilde{B}(M)$ which depends only on M. Hence, the eigenvalue μ of B in (4.6) depends only on M. A further MAPLE computation yields a representation of an eigenvector basis of the matrix $\tilde{B}$:

$$\tilde{B}X = X\mathrm{diag}(1, 0, \mu(M)),$$

$$X = \begin{pmatrix} 1 & 1 & 1 \\ \frac{M^2+4M-5}{M+9} & \frac{M^2-4M-5}{M-9} & \frac{6M}{11} \\ \frac{7M^3-7M^2+5M+275}{14(M+9)} & \frac{7M^3+7M^2+5M-275}{14(M-9)} & \frac{16M^2}{77} \end{pmatrix}, \tag{4.8}$$

$$\mu(M) = \frac{1}{2}\frac{M^4 - 14M^2 + 24M - 11}{M^4 - 14M^2 - 11}. \tag{4.9}$$

The function $M \to \mu(M)$ is shown in Figure 4.1. An important observation is that for a large range of Mach numbers $M \in [M_0, 1]$ the eigenvalue $\mu(M)$ is small (e.g., $\mu(M) \in [0, 0.1]$ for $M \in [0.5, 1]$). The condition number of the matrix X is bounded uniformly in $M \in [0, 1]$. The function $M \to \|X\|_2 \|X^{-1}\|_2$ is given in Figure 4.2.

In the remainder of this section we analyze block-Gauss–Seidel methods applied to the system (4.3). For any block-tridiagonal matrix $\mathbf{C} = \mathrm{blocktridiag}(C_l, C_d, C_u)$ we introduce the decomposition $\mathbf{C} = \mathbf{D} - \mathbf{L} - \mathbf{U}$ with $\mathbf{D} := \mathrm{blockdiag}(C_d)$ and strictly lower and upper triangular matrices $\mathbf{L}$ and $\mathbf{U}$, respectively. We assume that the matrix $\mathbf{D}$ is nonsingular and define the lexicographic and symmetric Gauss–Seidel preconditioners:

$$\mathbf{W}_C^{LGS} := \mathbf{D} - \mathbf{L}, \quad \mathbf{W}_C^{SGS} := (\mathbf{D} - \mathbf{L})\mathbf{D}^{-1}(\mathbf{D} - \mathbf{U}).$$

Below, the symbol $\mathbf{W}_C$ is used to denote both $\mathbf{W}_C^{LGS}$ and $\mathbf{W}_C^{SGS}$; i.e., statements involving $\mathbf{W}_C$ hold both for the lexicographic and the symmetric block-Gauss–Seidel preconditioner. We apply these preconditioners to the matrix $\mathbf{A}$ in (4.4). The block-Gauss–Seidel methods are invariant under block-diagonal scaling, and thus the following result holds.

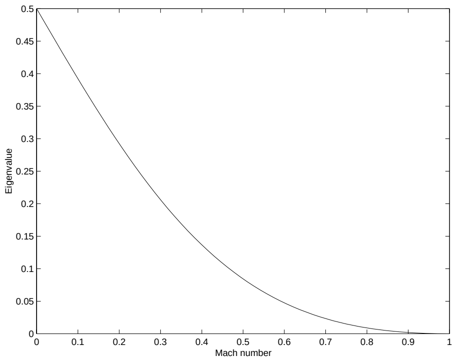

FIG. 4.1. *Function $M \to \mu(M)$.*

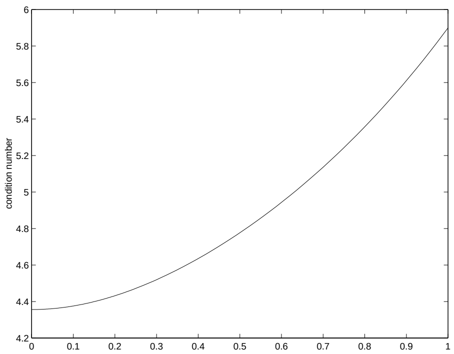

FIG. 4.2. *Function $M \to \|X\|_2\|X^{-1}\|_2$.*

LEMMA 4.1. *Define*

$$\tilde{\mathbf{A}} := \text{blocktridiag}\big(-(I-B), I, -B\big)_{1\le i\le n}, \quad \textit{with } B \textit{ as in } (4.5).$$

Then for the block-Gauss–Seidel preconditioner we have

$$\mathbf{W}_A^{-1}\mathbf{A} = \mathbf{W}_{\tilde{A}}^{-1}\tilde{\mathbf{A}}.$$

We apply a further transformation with the well-conditioned eigenvector basis X of the matrix $\tilde{B}$. For this we introduce

$$\mathbf{X} := \text{blockdiag}(X)_{1\le i\le n}, \quad \mathbf{E} := \text{blockdiag}\begin{pmatrix} 1 & 0 & 0 \\ 0 & c & 0 \\ 0 & 0 & c^2 \end{pmatrix}_{1\le i\le n}, \quad c := (\gamma p \rho^{-1})^{\frac{1}{2}}.$$

LEMMA 4.2. *Define*

$$\hat{\mathbf{A}} := \text{blocktridiag}\left(-\begin{pmatrix} 0 & & \emptyset \\ & 1 & \\ \emptyset & & 1-\mu \end{pmatrix}, \begin{pmatrix} 1 & & \emptyset \\ & 1 & \\ \emptyset & & 1 \end{pmatrix}, -\begin{pmatrix} 1 & & \emptyset \\ & 0 & \\ \emptyset & & \mu \end{pmatrix}\right) \in \mathbb{R}^{3n\times 3n},$$

with $\mu = \mu(M)$ as in (4.9). *Then*

$$\mathbf{W}_A^{-1}\mathbf{A} = \mathbf{E}\mathbf{X}\mathbf{W}_{\hat{A}}^{-1}\hat{\mathbf{A}}\mathbf{X}^{-1}\mathbf{E}^{-1}$$

holds.

Proof. This follows from

$$\tilde{\mathbf{A}} = \mathbf{E}\mathbf{X}\hat{\mathbf{A}}\mathbf{X}^{-1}\mathbf{E}^{-1}, \quad \mathbf{W}_{\tilde{A}} = \mathbf{E}\mathbf{X}\mathbf{W}_{\hat{A}}\mathbf{X}^{-1}\mathbf{E}^{-1},$$

and the result in Lemma 4.1. □

From Lemma 4.2 it follows that $\sigma(\mathbf{W}_A^{-1}\mathbf{A}) = \sigma(\mathbf{W}_{\hat{A}}^{-1}\hat{\mathbf{A}})$. However, it is well known that in a setting with strongly nonnormal matrices the eigenvalues (spectral radius) are in general not a good measure for the rate of convergence of an iterative method (cf. [8, 23]). Because the blocks in the block-tridiagonal matrix $\hat{\mathbf{A}}$ are diagonal, this matrix represents three decoupled systems of dimension n, and a block-Gauss–Seidel method applied to $\hat{\mathbf{A}}$ is the same as a *point* Gauss–Seidel method. To make this more precise we introduce for $\mathbf{H} = \mathbf{D} - \mathbf{L} - \mathbf{U}$ with $\mathbf{D} = \mathrm{diag}(\mathbf{H})$, $\mathbf{L}$ and $\mathbf{U}$ strictly lower and strictly upper triangular matrices, respectively, the *point* Gauss–Seidel splittings

$$\mathbf{G}_H^{LGS} := \mathbf{D} - \mathbf{L}, \quad \mathbf{G}_H^{SGS} := (\mathbf{D} - \mathbf{L})\mathbf{D}^{-1}(\mathbf{D} - \mathbf{U}).$$

The symbol $\mathbf{G}_H$ is used to denote both $\mathbf{G}_H^{LGS}$ and $\mathbf{G}_H^{SGS}$. Let $\mathbf{P} \in \mathbb{R}^{3n\times 3n}$ be the permutation matrix given by

$$(\mathbf{Px})_{k+3(i-1)} = x_{(k-1)n+i}, \quad k = 1, 2, 3, \quad i = 1, \dots, n.$$

We introduce the tridiagonal $n \times n$-matrices

(4.10)
$$\mathbf{L} := \begin{pmatrix} 1 & & & \\ -1 & 1 & & \\ & \ddots & \ddots & \\ & & -1 & 1 \end{pmatrix}, \quad \mathbf{T} = \mathbf{T}_\mu := \begin{pmatrix} 1 & -\mu & & \\ -(1-\mu) & 1 & \ddots & \\ & \ddots & \ddots & -\mu \\ & & -(1-\mu) & 1 \end{pmatrix}.$$

From the result in Lemma 4.2 one obtains the following.

Lemma 4.3. *The following holds:*

$$\mathbf{E}^{-1}\mathbf{W}_A^{-1}\mathbf{A}\mathbf{E} = \mathbf{X}\mathbf{P}\mathbf{Q}\mathbf{P}^{-1}\mathbf{X}^{-1}$$
$$\textit{with} \;\; \mathbf{Q} = \begin{pmatrix} \mathbf{Q}_1 & & \emptyset \\ & \mathbf{Q}_2 & \\ \emptyset & & \mathbf{Q}_3 \end{pmatrix} := \begin{pmatrix} \mathbf{G}_{L^T}^{-1}\mathbf{L}^T & & \emptyset \\ & \mathbf{G}_L^{-1}\mathbf{L} & \\ \emptyset & & \mathbf{G}_T^{-1}\mathbf{T} \end{pmatrix}.$$

We now consider a Krylov subspace method applied to the matrix $\mathbf{W}_A^{-1}\mathbf{A}$. Let $\mathcal{P}_k$ be the space of polynomials of degree less than or equal to k and $\mathcal{P}_k^* := \{\, p \in \mathcal{P}_k \,|\, p(0) = 1 \,\}$. A Krylov subspace method can be described by a corresponding polynomial $p_k \in \mathcal{P}_k^*$. Based on the result in Lemma 4.3 we use the problem dependent scaled Euclidean norm

$$\|\mathbf{y}\|_E := \|\mathbf{E}^{-1}\mathbf{y}\|_2, \quad \mathbf{y} \in \mathbb{R}^{3n}.$$

Let $\kappa_2(\mathbf{C}) := \|\mathbf{C}^{-1}\|_2\|\mathbf{C}\|_2$ be the spectral condition number. From Lemma 4.3 it follows that

$$\kappa_2(X)^{-1}\|p_k(\mathbf{Q})\|_2 \le \|p_k(\mathbf{W}_A^{-1}\mathbf{A})\|_E \le \kappa_2(X)\|p_k(\mathbf{Q})\|_2.$$

Since $\kappa_2(X)$ is independent of n and uniformly (w.r.t. M) bounded, the quantity $\|p_k(\mathbf{Q})\|_2$ is a reasonable measure for the rate of convergence of the Krylov subspace method applied to $\mathbf{W}_A^{-1}\mathbf{A}$. We therefore consider

$$\|p_k(\mathbf{Q})\|_2 = \max_{1\le i\le 3} \|p_k(\mathbf{Q}_i)\|_2 \,. \tag{4.11}$$

In order to derive bounds for $\|p_k(\mathbf{C})\|_2$, $\mathbf{C} \in \mathbb{R}^n$, one usually makes the natural assumption that the symmetric part of the matrix $\mathbf{C}$ is positive definite. This assumption is satisfied in our case.

Lemma 4.4. *The following holds:*

$$\frac{1}{2}\lambda_{\min}(\mathbf{Q}_i + \mathbf{Q}_i^T) := \min\{\, \mathbf{y}^T\mathbf{Q}_i\mathbf{y} \,|\, \mathbf{y} \in \mathbb{R}^n,\ \|\mathbf{y}\|_2 = 1 \,\} > 0 \quad \textit{for} \;\; i = 1, 2, 3.$$

Proof. Note that for the LGS and the SGS methods we have

$$\|\mathbf{I} - \mathbf{G}_T^{-1}\mathbf{T}\|_\infty < 1, \quad \|\mathbf{I} - \mathbf{G}_T^{-1}\mathbf{T}\|_1 < 1.$$

From this it follows that

$$\rho\left(\mathbf{I} - \frac{1}{2}(\mathbf{G}_T^{-1}\mathbf{T} + (\mathbf{G}_T^{-1}\mathbf{T})^T)\right) \leq \frac{1}{2}\|\mathbf{I} - \mathbf{G}_T^{-1}\mathbf{T}\|_\infty + \frac{1}{2}\|\mathbf{I} - \mathbf{G}_T^{-1}\mathbf{T}\|_1 < 1,$$

and thus

$$\lambda_{\min}\left(\frac{1}{2}(\mathbf{Q}_3 + \mathbf{Q}_3^T)\right) > 0.$$

Similar arguments can be used to prove the results for $i = 1$ and $i = 2$. □

In the literature one can find analyses in which for several classes of Krylov subspace methods, under the assumption that the symmetric part of $\mathbf{C}$ is positive definite, bounds for $\|p_k(\mathbf{C})\|_2$ in terms of the quantity

$$\xi(\mathbf{C}) := \frac{\|\mathbf{C}\|_2}{\frac{1}{2}\lambda_{\min}(\mathbf{C} + \mathbf{C}^T)} \tag{4.12}$$

are derived (cf. [9, 10, 22]). These bounds are in general very pessimistic but indicate that if $\xi(\mathbf{C})$ is "small" (i.e., close to one), one can expect fast convergence of the Krylov subspace method applied to $\mathbf{C}$. Another interesting quantity related to the rate of convergence is the spectral condition number $\kappa_2(\mathbf{C})$. Note that

$$1 \leq \kappa_2(\mathbf{C}) \leq \xi(\mathbf{C})$$

holds. Based on this and on the result in (4.11) we take

$$\xi_{\max} := \max_{1 \leq i \leq 3} \xi(\mathbf{Q}_i), \quad \kappa_{\max} := \max_{1 \leq i \leq 3} \kappa_2(\mathbf{Q}_i)$$

as measures for the quality of the block-Gauss–Seidel preconditioner.

We now distinguish between the LGS and SGS methods.

THEOREM 4.5. *For the lexicographic block-Gauss–Seidel method we have*

$$\mathbf{G} = \mathbf{G}^{LGS}, \quad \xi_{\max} = \max\{\xi(\mathbf{Q}_1), \xi(\mathbf{Q}_3)\}, \quad \kappa_{\max} = \max\{\kappa_2(\mathbf{Q}_1), \kappa_2(\mathbf{Q}_3)\}. \tag{4.13}$$

For the symmetric block-Gauss–Seidel method we have

$$\mathbf{G} = \mathbf{G}^{SGS}, \quad \xi_{\max} = \xi(\mathbf{Q}_3), \quad \kappa_{\max} = \kappa_2(\mathbf{Q}_3). \tag{4.14}$$

Proof. For the LGS method we have

$$\mathbf{G}_{L^T} = \mathbf{I}, \quad \mathbf{G}_L = \mathbf{L},$$

and for the SGS method

$$\mathbf{G}_{L^T} = \mathbf{L}^T, \quad \mathbf{G}_L = \mathbf{L}.$$

Hence $\mathbf{Q}_2 = \mathbf{I}$ for the LGS and for the SGS methods, and $\mathbf{Q}_1 = \mathbf{I}$ for the SGS method. □

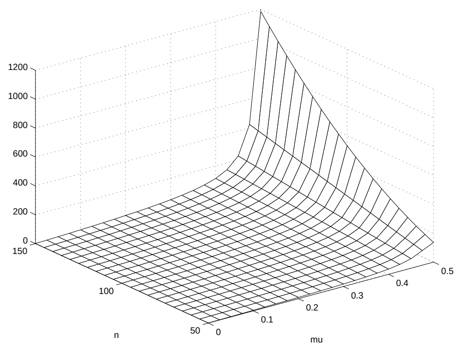

FIG. 4.3. $\kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$ *for* $\mathbf{G}_T = \mathbf{G}_T^{SGS}$.

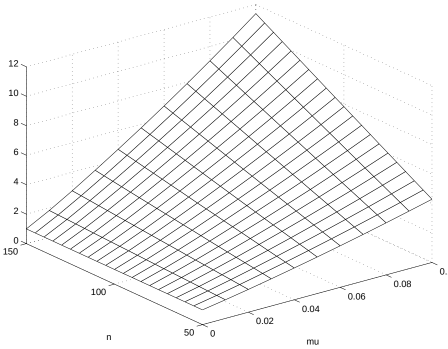

FIG. 4.4. $\kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$ *for* $\mathbf{G}_T = \mathbf{G}_T^{SGS}$.

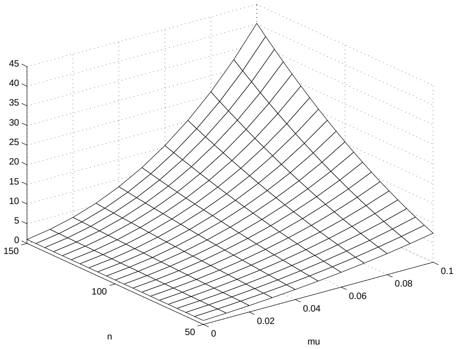

FIG. 4.5. $\xi(\mathbf{G}_T^{-1}\mathbf{T})$ *for* $\mathbf{G}_T = \mathbf{G}_T^{SGS}$.

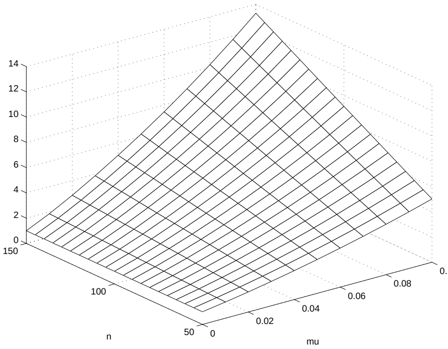

FIG. 4.6. $\kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$ *for* $\mathbf{G}_T = \mathbf{G}_T^{LGS}$.

In Figures 4.3 and 4.4 for the SGS method the dependence of $\kappa_2(\mathbf{Q}_3) = \kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$ on μ and n is shown.

From these figures and the result in (4.14) it follows that for $\mu \in (0, \mu_0)$ with $\mu_0 \ll \frac{1}{2}$ the function $n \to \kappa_{\max}(n)$ increases only slowly. Hence, for "small" μ-values the SGS-preconditioned matrix has a corresponding $\kappa_{\max}$-value which is small, even for "large" n-values. Now note that the dependence of μ on the Mach number M is as in (4.9) (Figure 4.1), and thus for a large range of Mach numbers $M \in [M_0, 1]$ the corresponding $\mu(M)$-values are (very) small, and thus the condition number $\kappa_{\max}$ is small, too. In Figure 4.5 for the SGS method we show, for small μ-values, the dependence of $\xi_{max} = \xi(\mathbf{G}_T^{-1}\mathbf{T})$ on μ and n. Note that for small μ-values the function $n \to \xi_{max}(n)$ increases slowly, too. These observations yield some theoretical explanation of the fast convergence of the SGS-GMRES(20) method in Problems 1 and 2 as compared to the diffusion problem (cf. Figures 3.1, 3.2, 3.4), and of the fact that in Problem 2 (Figure 3.4) the rate of convergence is much higher than in Problem 1 (Figure 3.2).

For the LGS method the term $\xi(\mathbf{Q}_1)$ in (4.13) has to be taken into account. For this term we have

$$\xi(\mathbf{Q}_1) = \frac{\|\mathbf{L}^T\|_2}{\frac{1}{2}\lambda_{\min}(\mathbf{L} + \mathbf{L}^T)} \approx 4\left(\frac{n}{\pi}\right)^2,$$

which is, independently of μ, large if n is large. This gives a theoretical justification of the intuitive conjecture that for a subsonic or transonic one dimensional flow problem with characteristics going in both directions the SGS method should perform (much) better than the LGS method (cf. also the large difference in the rates of convergence in Figures 3.5, 3.6).

The result in (4.14) relates the quality measure $\kappa_{\max}$ of the SGS-method to the condition number $\kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$. The behavior of the function $(\mu, n) \rightarrow \kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$ is shown in Figures 4.3 and 4.4. An important observation is that for "small" μ-values these condition numbers are small. The same holds for the LGS method (cf. Figure 4.6). One can derive (fairly sharp) bounds for $\kappa_2(\mathbf{G}_T^{-1}\mathbf{T})$, which show the dependence of this condition number on n and μ. Here we present such a result for the simplest case, namely for the LGS method. For completeness a proof is given in the appendix. A similar result can be shown to hold for the SGS method.

THEOREM 4.6. *Let $\mathbf{G} = \mathbf{G}_T^{LGS}$ be the LGS preconditioner for the matrix $\mathbf{T} = \mathbf{T}_\mu \in \mathbb{R}^{n\times n}$. For the condition number of the preconditioned matrix the following holds for $\mu \in [0, \frac{1}{2}]$:*

$$\|\mathbf{G}^{-1}\mathbf{T}\|_2\|\mathbf{T}^{-1}\mathbf{G}\|_2 \leq \left(1+\min\left\{\frac{\mu}{h},1\right\}\right)\frac{2\delta_\mu}{1-2\mu}\left(\frac{\mu}{h}+1+\frac{\mu\delta_\mu}{1-2\mu\delta_\mu}\frac{1}{\sqrt{h}}\right),$$
$$\textit{with}\ \ h=\frac{1}{n+1}, \quad \delta_\mu = \min\left\{1, \frac{1-2\mu}{8\mu}\frac{1}{h}\right\}.$$

Remark 1. In our model problem we are interested in the case $\mu \ll \frac{1}{2}$ (e.g., $\mu \in (0, 0.1)$) and $h \ll 1$. For this case we have $\delta_\mu = 1$, and we obtain the following bound for the condition number:

$$\|\mathbf{G}^{-1}\mathbf{T}\|_2\|\mathbf{T}^{-1}\mathbf{G}\|_2 \lesssim \begin{cases} 2(1+\frac{\mu}{h})^2 & \text{if } \frac{\mu}{h}<1, \\ 4(1+\frac{\mu}{h}) & \text{if } \frac{\mu}{h}\geq 1. \end{cases}$$

This bound clearly shows that for small μ there is (at worst) only a slow growth in the condition number as a function of $n = h^{-1} - 1$.

Remark 2. We briefly comment on the very high rate of convergence of the SGS-GMRES(20) method for the transonic flow problem in section 3 (Figures 2.2 and 3.5). In part of the domain the flow is supersonic ($M > 1$), and in another part of the domain the flow is subsonic with Mach numbers $M \in (0.6, 1)$. The upwind discretization in the supersonic part of the domain results in a block lower triangular matrix. Hence in this part of the domain the information is propagated exactly by the symmetric block-Gauss–Seidel method. In the subsonic part of the domain the Mach numbers are ≥ 0.6, and thus the corresponding $\mu(M)$-values lie in the interval $[0, 0.05]$. The analysis in this section shows that in such a case if we freeze the coefficients, the SGS method can be expected to be a very effective preconditioner. At the "critical" points $x = 1$ and $x = 3$ we do not have a smooth behavior, and this results in a low dimensional subspace in which the Gauss–Seidel preconditioner may perform relatively poorly. Due to its very low dimension the error components in this subspace can be reduced effectively by the GMRES method. These arguments give some heuristic explanation of the convergence behavior shown in Figure 3.5. A rigorous analysis for the transonic case is still lacking.

Remark 3. We briefly comment on possible topics for further research towards two dimensional problems. Consider a stationary two dimensional Euler equation that is discretized on a uniform square grid using the Van Leer flux vector-splitting method. The resulting nonlinear problem is linearized at the discrete solution. For the analysis we assume that $V = (\rho, u, v, p)$ is constant as a function of the space variable. In stencil notation the discrete problem has the structure (cf. (4.4))

$$\begin{bmatrix} & B^- & \\ -A^+ & A^+ - A^- + B^+ - B^- & A^- \\ & -B^+ & \end{bmatrix} \tag{4.15}$$

with $A^\pm, B^\pm \in \mathbb{R}^{4\times 4}$. For the Mach numbers in one direction we use the notation $M_u := \frac{u}{c}$, $M_v := \frac{v}{c}$. We consider only $M_u \geq 0, M_v \geq 0$.

In the supersonic case $M_u \geq 1, M_v \geq 1$ we have $B^- = A^- = 0$, and thus the matrix is block lower triangular. Hence the block-Gauss–Seidel method is a direct solver.

For the supersonic case $M_u \in (0,1), M_v \geq 1$ we have that $B^- = 0$, and thus the x-line block-Gauss–Seidel method is a direct solver. To analyze convergence properties of the symmetric block-Gauss–Seidel method (which is not a direct solver) one has to investigate the SGS method applied to the matrix

$$\text{blocktridiag}(-A^+ \ ,\ A^+ - A^- + B^+ \ ,\ A^-).$$

This corresponds to a one dimensional problem, and thus for the analysis one can try to use the same approach used in section 4. Note, however, that the matrix $A^+ \in \mathbb{R}^{4\times 4}$ differs from the one in (4.4).

For the subsonic case $M_u = M_v \in (0,1)$ one has nice symmetry properties. We have $PB^\pm = A^\pm$ with a simple permutation matrix P. Hence properties of the matrix corresponding to (4.15) essentially depend only on those of A^+ and A^-. Suitable transformations (as in section 4) based on the known eigenvector bases of $A^\pm$ may help to determine some of these properties.

Appendix. Proof of Theorem 4.6. In this appendix we give a proof of the result in Theorem 4.6. We consider the tridiagonal matrix $\mathbf{T} = \mathbf{T}_\mu$ as (4.10) with $\mu \in (0, \frac{1}{2})$, and for the preconditioner we take the LGS method:

$$\mathbf{G} = \text{tridiag}(-(1-\mu), 1, 0) \in \mathbb{R}^{n\times n}.$$

In Figure 4.6 we showed the numerically computed values of the function $(\mu, n) \to \kappa_2(\mathbf{G}^{-1}\mathbf{T})$. In this section we derive a rigorous (sharp) bound for this condition number, which shows its dependence on μ and $h = 1/(n+1)$.

We use the notation

$$\mathbf{S} = \begin{pmatrix} 0 & 1 & & \\ & 0 & \ddots & \\ & & \ddots & 1 \\ & & & 0 \end{pmatrix} \in \mathbb{R}^{n\times n}, \qquad \mathbf{W} = \mathbf{I} - \mathbf{S}^T.$$

LEMMA A.1. *The following holds:*

$$\|\mathbf{G}^{-1}\mathbf{T}\|_2 \leq 1 + \min\left\{\frac{\mu}{h}, 1\right\}.$$

Proof. Using $\mathbf{T} = \mathbf{G} - \mu\mathbf{S}$, we obtain

$$\begin{aligned} \|\mathbf{G}^{-1}\mathbf{T}\|_2 = \|\mathbf{I} - \mu\mathbf{G}^{-1}\mathbf{S}\|_2 &\leq 1 + \mu\big(\|\mathbf{G}^{-1}\mathbf{S}\|_\infty \|\mathbf{G}^{-1}\mathbf{S}\|_1\big)^{\frac{1}{2}} \\ &\leq 1 + \mu \sum_{k=0}^{n-1} (1-\mu)^k \leq 1 + \min\{\mu n, 1\}, \end{aligned}$$

and thus the result of this lemma holds. □

We now derive a bound for $\|\mathbf{T}^{-1}\mathbf{G}\|_2$. First we note that $\mathbf{T} = \mathbf{G} - \mu\mathbf{S}$ is a weakly regular splitting; i.e., $\mathbf{G}^{-1} \geq 0$ and $\mu\mathbf{G}^{-1}\mathbf{S} \geq 0$ hold. Moreover, $\mathbf{T}^{-1} \geq 0$ holds, and thus $\mu\rho(\mathbf{G}^{-1}\mathbf{S}) < 1$. From this we obtain that $\mathbf{T}^{-1}\mathbf{G}$ is a positive matrix:

$$\mathbf{T}^{-1}\mathbf{G} = (\mathbf{I} - \mu\mathbf{G}^{-1}\mathbf{S})^{-1} = \sum_{k=0}^{\infty}(\mu\mathbf{G}^{-1}\mathbf{S})^k \geq 0.$$

In our analysis we use the numerical radius

$$r(\mathbf{A}) := \max\{\, |\mathbf{x}^H\mathbf{A}\mathbf{x}| \mid \mathbf{x} \in \mathbb{C}^n, \|\mathbf{x}\|_2 = 1\,\}.$$

We also use the following properties:

$$\begin{aligned} &\|\mathbf{A}\|_2 \leq 2r(\mathbf{A}), \\ &r(\mathbf{A}) = \frac{1}{2}\rho(\mathbf{A} + \mathbf{A}^T) \quad \text{if } \ \mathbf{A} \geq 0. \end{aligned}$$

Using $\mathbf{G} = \mathbf{I} - (1-\mu)\mathbf{S}^T = \mathbf{W} + \mu\mathbf{S}^T$, we get

$$\begin{aligned} \|\mathbf{T}^{-1}\mathbf{G}\|_2 &\leq 2r(\mathbf{T}^{-1}\mathbf{G}) = \rho(\mathbf{T}^{-1}\mathbf{G} + \mathbf{G}^T\mathbf{T}^{-T}) \\ &= \rho\big((\mathbf{T}^{-1}\mathbf{W} + \mathbf{W}^T\mathbf{T}^{-T}) + \mu(\mathbf{T}^{-1}\mathbf{S}^T + \mathbf{S}\mathbf{T}^{-T})\big) \\ &\leq \rho(\mathbf{T}^{-1}\mathbf{W} + \mathbf{W}^T\mathbf{T}^{-T}) + \mu\rho(\mathbf{T}^{-1}\mathbf{S}^T + \mathbf{S}\mathbf{T}^{-T}). \end{aligned} \tag{A.1}$$

In the following two lemmas we derive bounds for the two terms in (A.1).

Lemma A.2. *The following holds:*

$$\mu\rho(\mathbf{T}^{-1}\mathbf{S}^T + \mathbf{S}\mathbf{T}^{-T}) \leq \frac{2\delta_\mu}{1-2\mu}\frac{\mu}{h},$$
$$\textit{with} \quad \delta_\mu := \min\left\{1, \frac{1-2\mu}{8\mu}\frac{1}{h}\right\}.$$

Proof. Note that

$$\rho(\mathbf{T}^{-1}\mathbf{S}^T + \mathbf{S}\mathbf{T}^{-T}) \leq \|\mathbf{T}^{-1}\mathbf{S}^T + \mathbf{S}\mathbf{T}^{-T}\|_\infty \leq \|\mathbf{T}^{-1}\|_\infty + \|\mathbf{T}^{-T}\|_\infty. \tag{A.2}$$

We derive a bound on $\|\mathbf{T}^{-1}\|_\infty$ using $\mathbf{T}^{-1} \geq 0$ and an appropriate barrier function. The difference operator corresponding to $\mathbf{T}$ is given by

$$\begin{aligned} [T]_{x_i} &= \mu[-1 \;\; 2 \;\; -1]_{x_i} + (1-2\mu)[-1 \;\; 1 \;\; 0]_{x_i} \\ &= (1-2\mu)h\left(\frac{\varepsilon}{h^2}[-1 \;\; 2 \;\; -1]_{x_i} + \frac{1}{h}[-1 \;\; 1 \;\; 0]_{x_i}\right), \end{aligned}$$

with $x_i = ih$, $0 \leq i \leq n+1$, and $\varepsilon = \frac{\mu h}{1-2\mu} \in (0, \infty)$. To obtain a suitable barrier function we consider the boundary value problem

$$-\varepsilon u''(x) + u'(x) = 1, \quad x \in (0,1), \quad u(0) = u(1) = 0,$$

with solution given by

$$\bar{u}(x) = x - \frac{\exp(\frac{x}{\varepsilon}) - 1}{\exp(\frac{1}{\varepsilon}) - 1} \ \in [0,1].$$

For $x \in (0,1)$ and $m \geq 2$, $\bar{u}^{(m)}(x) \leq 0$ holds. Using this, it follows from a Taylor expansion that

$$[T]_{x_i}\bar{u} \geq (1-2\mu)h\big(-\varepsilon\bar{u}''(x_i) + \bar{u}'(x_i)\big) = (1-2\mu)h.$$

From this and the fact that $\mathbf{T}$ is inverse positive we obtain

$$\|\mathbf{T}^{-1}\|_\infty \leq \frac{\|\bar{u}\|_{\infty,[0,1]}}{(1-2\mu)h}.$$

We introduce the notation $z_\varepsilon := \varepsilon(\exp(\frac{1}{\varepsilon}) - 1)$. A simple computation yields that on $[0,1]$ the function $\bar{u}$ attains its maximum at $x = \varepsilon \ln z_\varepsilon$, and this maximum is given by

$$\|\bar{u}\|_{\infty,[0,1]} = \varepsilon(\ln z_\varepsilon + z_\varepsilon^{-1} - 1) =: m(\varepsilon).$$

On $(0,\infty)$ the function $\varepsilon \to m(\varepsilon)$ has the following properties:

$$\begin{aligned}
&\lim_{\varepsilon\downarrow 0} m(\varepsilon) = 1, \quad m'(\varepsilon) < 0, \quad \lim_{\varepsilon\to\infty} m(\varepsilon) = 0,\\
&\lim_{\varepsilon\downarrow 0} \varepsilon m(\varepsilon) = 0, \quad (\varepsilon m(\varepsilon))' > 0, \quad \lim_{\varepsilon\to\infty} \varepsilon m(\varepsilon) = \frac{1}{8}.
\end{aligned}$$

It follows that

$$\begin{aligned}
\|\mathbf{T}^{-1}\|_\infty &\leq \frac{1}{(1-2\mu)h}\, m(\varepsilon) \leq \frac{1}{(1-2\mu)h},\\
\|\mathbf{T}^{-1}\|_\infty &\leq \frac{\varepsilon^{-1}}{(1-2\mu)h}\, \varepsilon m(\varepsilon) \leq \frac{1}{\mu h^2}\frac{1}{8},
\end{aligned}$$

and thus

$$\|\mathbf{T}^{-1}\|_\infty \leq \frac{1}{(1-2\mu)h}\delta_\mu.$$

The same bound can be derived for $\|\mathbf{T}^{-T}\|_\infty$ if one uses the (adjoint) equation $-\varepsilon u'' - u' = 1$. These bounds in combination with (A.2) prove the result. □

LEMMA A.3. *The following holds, with δ_μ as in Lemma* A.2*:*

$$\rho(\mathbf{T}^{-1}\mathbf{W} + \mathbf{W}^T\mathbf{T}^{-T}) \leq \frac{2\delta_\mu}{1-2\mu}\left(1 + \frac{\mu\delta_\mu}{1-2\mu+\mu\delta_\mu}\, h^{-\frac{1}{2}}\right).$$

Proof. We use the notation

$$\begin{aligned}
&\xi = \frac{\mu}{1-\mu}, \quad \mathbf{1} = (1,\dots,1)^T \in \mathbb{R}^n, \quad \mathbf{e}_1 = (1,0,\dots,0)^T \in \mathbb{R}^n,\\
&\mathbf{x} = (\mathbf{I} - \xi\mathbf{S})^{-1}\mathbf{1}, \quad \mathbf{y} = (\mathbf{I} - \xi\mathbf{S}^T)^{-1}\mathbf{e}_1 = (1,\xi,\xi^2,\dots,\xi^{n-1})^T,\\
&\beta = \|\mathbf{y}\|_1 = \sum_{k=0}^{n-1}\xi^k\ , \quad \tau = \frac{\xi}{1+\xi\beta}.
\end{aligned}$$

Note that

$$\begin{aligned}\mathbf{T}^{-1}\mathbf{W} &= \left(\mathbf{W}-\mu(\mathbf{S}-\mathbf{S}^T)\right)^{-1}\mathbf{W} = \left(\mathbf{I}-\mu\mathbf{W}^{-1}(\mathbf{S}-\mathbf{S}^T)\right)^{-1}\\ &= \left(\mathbf{I}-\mu(\mathbf{I}+\mathbf{S}-\mathbf{1}\mathbf{e}_1^T)\right)^{-1} = \frac{1}{1-\mu}(\mathbf{I}-\xi\mathbf{S}+\xi\mathbf{1}\mathbf{e}_1^T)^{-1}\\ &= \frac{1}{1-\mu}(\mathbf{I}+\xi\mathbf{x}\mathbf{e}_1^T)^{-1}(\mathbf{I}-\xi\mathbf{S})^{-1} = \frac{1}{1-\mu}(\mathbf{I}-\tau\mathbf{x}\mathbf{e}_1^T)(\mathbf{I}-\xi\mathbf{S})^{-1}\\ &= \frac{1}{1-\mu}\left((\mathbf{I}-\xi\mathbf{S})^{-1}-\tau\mathbf{x}\mathbf{y}^T\right).\end{aligned}$$

Using

$$\begin{aligned}\|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_2 &\le \left(\|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_\infty\|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_1\right)^{\frac{1}{2}} = \beta,\\ \|\mathbf{x}\|_2 &\le \|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_2\|\mathbf{1}\|_2 \le \beta\sqrt{n} \le \beta h^{-\frac{1}{2}},\\ \|\mathbf{y}\|_2 &\le \|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_2\|\mathbf{e}_1\|_2 \le \beta,\end{aligned}$$

we obtain

$$\begin{aligned}\rho(\mathbf{T}^{-1}\mathbf{W}+\mathbf{W}^T\mathbf{T}^{-T}) &= \frac{1}{1-\mu}\rho\left((\mathbf{I}-\xi\mathbf{S})^{-1}+(\mathbf{I}-\xi\mathbf{S}^T)^{-1}-\tau(\mathbf{x}\mathbf{y}^T+\mathbf{y}\mathbf{x}^T)\right)\\ &\le \frac{2}{1-\mu}\left(\|(\mathbf{I}-\xi\mathbf{S})^{-1}\|_2+\tau\|\mathbf{x}\|_2\|\mathbf{y}\|_2\right)\\ &\le \frac{2\beta}{1-\mu}\left(1+\frac{\xi\beta}{1+\xi\beta}h^{-\frac{1}{2}}\right). \qquad \text{(A.3)}\end{aligned}$$

We use

$$\begin{aligned}\beta &\le \min\left\{\frac{1}{1-\xi}, n\right\} \le \frac{1-\mu}{1-2\mu}\min\left\{1, \frac{1-2\mu}{1-\mu}h^{-1}\right\}\\ &\le \frac{1-\mu}{1-2\mu}\min\left\{1, \frac{1-2\mu}{8\mu}h^{-1}\right\} = \frac{1-\mu}{1-2\mu}\delta_\mu.\end{aligned}$$

Hence

$$\frac{2\beta}{1-\mu} \le \frac{2\delta_\mu}{1-2\mu} \qquad \text{(A.4)}$$

holds. Finally, note that

$$\frac{\xi\beta}{1+\xi\beta} \le \frac{\frac{\mu}{1-2\mu}\delta_\mu}{1+\frac{\mu}{1-2\mu}\delta_\mu} = \frac{\mu\delta_\mu}{1-2\mu+\mu\delta_\mu}. \qquad \text{(A.5)}$$

Combination of (A.3), (A.4), and (A.5) yields the result. □

Substitution of the results of Lemmas A.2 and A.3 into (A.1) yields

$$\|\mathbf{T}^{-1}\mathbf{G}\|_2 \le \frac{2\delta_\mu}{1-2\mu}\left(\frac{\mu}{h}+1+\frac{\mu\delta_\mu}{1-2\mu+\mu\delta_\mu}\frac{1}{\sqrt{h}}\right).$$

Combination of this result with the result of Lemma A.1 shows that the inequality in Theorem 4.6 holds.

AN EXPLICIT UNCONDITIONALLY STABLE NUMERICAL METHOD FOR SOLVING DAMPED NONLINEAR SCHRÖDINGER EQUATIONS WITH A FOCUSING NONLINEARITY*

WEIZHU BAO† AND DIETER JAKSCH‡

Abstract. This paper introduces an extension of the time-splitting sine-spectral (TSSP) method for solving damped focusing nonlinear Schrödinger equations (NLSs). The method is explicit, unconditionally stable, and time transversal invariant. Moreover, it preserves the exact decay rate for the normalization of the wave function if linear damping terms are added to the NLS. Extensive numerical tests are presented for cubic focusing NLSs in two dimensions with a linear, cubic, or quintic damping term. Our numerical results show that quintic or cubic damping always arrests blowup, while linear damping can arrest blowup only when the damping parameter δ is larger than a threshold value $\delta_{\rm th}$. We note that our method can also be applied to solve the three-dimensional Gross–Pitaevskii equation with a quintic damping term to model the dynamics of a collapsing and exploding Bose–Einstein condensate (BEC).

Key words. damped nonlinear Schrödinger equation (DNLS), time-splitting sine-spectral (TSSP) method, Gross–Pitaevskii equation (GPE), Bose–Einstein condensate (BEC), complex Ginzburg–Landau (CGL)

1. Introduction.

Since the first experimental realization of Bose–Einstein condensation (BEC) in dilute weakly interacting gases, the nonlinear Schrödinger equation (NLS) has been used extensively to describe the single particle properties of BECs. The results obtained by solving the NLS showed excellent agreement with most of the experiments (for a review, see [2, 3, 11, 10]). In fact, up to now there have been very few experiments in ultracold dilute bosonic gases which could not be described properly by using theoretical methods based on the NLS [20, 23].

Recent experiments by Donley et al. [12] provide new experimental results for checking the validity of describing a BEC by using the NLS in the case of attractive interactions (focusing nonlinearity) in three dimensions. Since the particle density might become very large in the case of attractive interactions, inelastic collisions become important and cannot be neglected. These inelastic collisions are assumed to be accounted for by adding damping terms to the NLS. Two particle inelastic processes are taken into account by a cubic damping term, while three particle inelastic collisions are described by a quintic damping term. Collisions with the background gas and feeding of the condensate can be studied by adding linear damping terms. One of the major theoretical challenges in comparing results obtained in the experiment with theoretical results is to find reliable methods for solving the NLS with a focusing

nonlinearity and damping terms in the parameter regime where the experiments are performed.

The aim of this paper is to extend the time-splitting sine-spectral (TSSP) method for solving the focusing NLS with additional damping terms and to present extensive numerical tests. The comparison of our numerical results with the experimental results obtained for a collapsing BEC [12] will be presented elsewhere [8].

We consider the NLS [7, 36]

$$i\,\psi_t = -\frac{1}{2}\,\Delta\psi + V(\mathbf{x})\,\psi - \beta|\psi|^{2\sigma}\psi, \qquad t>0, \qquad \mathbf{x}\in\mathbb{R}^d, \tag{1.1}$$

$$\psi(\mathbf{x},t=0) = \psi_0(\mathbf{x}), \qquad \mathbf{x}\in\mathbb{R}^d, \tag{1.2}$$

with $\sigma > 0$ a positive constant, where $\sigma = 1$ corresponds to a cubic nonlinearity, $\sigma = 2$ corresponds to a quintic nonlinearity, $V(\mathbf{x})$ is a real-valued potential whose shape is determined by the type of system under investigation, and β positive/negative corresponds to the focusing/defocusing NLS. In BEC, where (1.1) is also known as the Gross–Pitaevskii equation (GPE) [21, 26, 33], ψ is the macroscopic wave function of the condensate, t is time, $\mathbf{x}$ is the spatial coordinate, and $V(\mathbf{x})$ is a trapping potential which usually is harmonic and can thus be written as $V(\mathbf{x}) = \frac{1}{2}\left(\gamma_1^2x_1^2 + \cdots + \gamma_d^2x_d^2\right)$ with $\gamma_1,\ldots,\gamma_d \geq 0$. Two important invariants of (1.1) are the *normalization of the wave function*

$$N(t) = \int_{\mathbb{R}^d} |\psi(\mathbf{x},t)|^2\,d\mathbf{x}, \qquad t\geq 0, \tag{1.3}$$

and the *energy*

$$E(t) = \int_{\mathbb{R}^d} \left[\frac{1}{2}|\nabla\psi(\mathbf{x},t)|^2 + V(\mathbf{x})|\psi(\mathbf{x},t)|^2 - \frac{\beta}{\sigma+1}|\psi(\mathbf{x},t)|^{2\sigma+2}\right] d\mathbf{x}, \quad t\geq 0. \tag{1.4}$$

From the theory for the local existence of the solution of (1.1), it is well known that if $\|\psi(\cdot,t)\|_{H^1}$ is bounded, the solution exists for all t [36]. As a result, when the NLS is defocusing ($\beta < 0$), conservation of energy implies that $\int_{\mathbb{R}^d} |\nabla\psi(\mathbf{x},t)|^2\,d\mathbf{x}$ is bounded and the solution exists globally. On the other hand, if the NLS is focusing ($\beta > 0$) at critical ($\sigma d = 2$) or supercritical ($\sigma d > 2$) dimensions and for an initial energy $E(0) < 0$, then the solutions of (1.1) can self-focus and become singular in finite time; i.e., there exists a time $t_* < \infty$ such that (see [36])

$$\lim_{t\to t_*} |\nabla\psi|_{L^2} = \infty \qquad \text{and} \qquad \lim_{t\to t_*} |\psi|_{L^\infty} = \infty.$$

However, the physical quantities modeled by ψ do not become infinite, which implies that the validity of (1.1) breaks down near the singularity. Additional physical mechanisms, which were initially small, become important near the singular point and prevent the formation of the singularity. In BEC, the particle density $|\psi|^2$ becomes large close to the critical point, and inelastic collisions between particles which are negligible for small densities become important. Therefore, a small damping (absorption) term is introduced into the NLS (1.1) which describes inelastic processes. We are interested in the cases where these damping mechanisms are important and therefore restrict ourselves to the case of focusing nonlinearities $\beta > 0$, where β may also be time dependent. We consider the damped nonlinear Schrödinger equation (DNLS)

$$i\,\psi_t = -\frac{1}{2}\,\Delta\psi + V(\mathbf{x})\,\psi - \beta|\psi|^{2\sigma}\psi - i\,g(|\psi|^2)\psi, \qquad t>0, \quad \mathbf{x}\in\mathbb{R}^d, \tag{1.5}$$

$$\psi(\mathbf{x},t=0) = \psi_0(\mathbf{x}), \qquad \mathbf{x}\in\mathbb{R}^d, \tag{1.6}$$

where $g(\rho) \ge 0$ for $\rho = |\psi|^2 \ge 0$ is a real-valued monotonically increasing function.

The general form of (1.5) covers many DNLSs arising in various different applications. In BEC, for example, when $g(\rho) \equiv 0$, (1.5) reduces to the usual GPE (1.1); a linear damping term $g(\rho) \equiv \delta$ with $\delta > 0$ describes inelastic collisions with the background gas; cubic damping $g(\rho) = \delta_1 \beta \rho$ with $\delta_1 > 0$ corresponds to two-body loss [13, 35, 34]; and a quintic damping term of the form $g(\rho) = \delta_2 \beta^2 \rho^2$ with $\delta_2 > 0$ adds three-body loss to the GPE (1.1) [1, 35, 34]. It is easy to see that the decay of the normalization according to (1.5) due to damping is given by

$$(1.7)\quad N'(t) = \frac{d}{dt}\int_{\mathbb{R}^d} |\psi(\mathbf{x},t)|^2 \, d\mathbf{x} = -2\int_{\mathbb{R}^d} g(|\psi(\mathbf{x},t)|^2)|\psi(\mathbf{x},t)|^2 \, d\mathbf{x} \le 0, \quad t > 0.$$

In particular, if $g(\rho) \equiv \delta$ with $\delta > 0$, the normalization is given by

$$(1.8)\quad N(t) = \int_{\mathbb{R}^d} |\psi(\mathbf{x},t)|^2 \, d\mathbf{x} = e^{-2\delta\, t} N(0) = e^{-2\delta\, t} \int_{\mathbb{R}^d} |\psi_0(\mathbf{x})|^2 \, d\mathbf{x}, \quad t \ge 0.$$

There has been a series of recent studies which deals with the analysis and numerical solution of the DNLS. Fibich [14] analyzed the effect of linear damping (absorption) on the critical self-focusing NLS, Tsutsumi [37, 38] studied the global solutions of the NLS with linear damping, and the regularity of attractors and approximate inertial manifolds for a weakly damped NLS were given in Goubet [17, 19, 18] and by Jolly, Temam, and Xiong [24]. For numerically solving the linearly damped NLS, Peranich [32] proposed a finite difference scheme, and this method was revisited recently by Ciegis and Pakalnyte [9] and Zhang and Lu [39]. Moebs and Temam [30] presented a multilevel method for weakly damped NLS, and Moebs applied it to solve a stochastic weakly damped NLS in [29]. Variable mesh difference schemes for the NLS with a linear damping term were used by Iyengar, Jayaraman, and Balasubramanian [22].

Also, the TSSP method, which we will use in this paper to solve the DNLS, was already successfully used for solving the Schrödinger equation in the semiclassical regime and for describing BEC using the GPE by Bao et al. [4, 5, 7]. The TSSP method is explicit, unconditionally stable, and time transversal invariant. Moreover, it gives the exact decay rate of the normalization when linear damping is applied to the NLS (i.e., $g(\rho) \equiv \delta$ with $\delta > 0$ in (1.5)) and yields spectral accuracy for spatial derivatives and second-order accuracy for the time derivative. Thus this method is a very good candidate for solving the DNLS, especially in two or three dimensions. We test the novel numerical method extensively in two dimensions.

Finally, we want to emphasize that the NLS is also used in nonlinear optics, e.g., to describe the propagation of an intense laser beam through a medium with a Kerr nonlinearity [16, 36]. In nonlinear optics, $\psi = \psi(\mathbf{x}, t)$ describes the electrical field amplitude, t is the spatial coordinate in the direction of propagation, $\mathbf{x} = (x_1, \ldots, x_d)^T$ is the transverse spatial coordinate, and $V(\mathbf{x})$ is determined by the index of refraction. Nonlinear damping terms of the form $g(\rho) = \delta \beta^q \rho^q$ with $\delta, q > 0$ correspond to multiphoton absorption processes [14].

The paper is organized as follows. In section 2, we present the TSSP approximation for the damped nonlinear Schrödinger equation. In section 3, numerical tests are presented for the cubic focusing NLS in two dimensions with a linear, cubic, or quintic damping term. In section 4, some conclusions are drawn.

2. Time-splitting sine-spectral method.

In this section we present a time-splitting sine-spectral (TSSP) method for solving the problem (1.5), (1.6) with homogeneous periodic boundary conditions. For simplicity of notation, we shall introduce the method for the case of one spatial dimension ($d = 1$). Generalizations to $d > 1$ are straightforward for tensor product grids, and the results remain valid without modifications. For $d = 1$, the problem becomes

$$i\,\psi_t = -\frac{1}{2}\psi_{xx} + V(x)\psi - \beta|\psi|^{2\sigma}\psi - i\,g(|\psi|^2)\psi, \qquad a < x < b, \quad t > 0, \tag{2.1}$$

$$\psi(x, t = 0) = \psi_0(x), \quad a \le x \le b, \qquad \psi(a, t) = \psi(b, t) = \mathbf{0}, \quad t \ge 0. \tag{2.2}$$

2.1. General damping term. We choose the spatial mesh size $h = \Delta x > 0$ with $h = (b - a)/M$ and M an even positive integer. The time step is given by $k = \Delta t > 0$, and we define grid points and time steps by

$$x_j := a + j\,h, \qquad t_n := n\,k, \qquad j = 0, 1, \ldots, M, \qquad n = 0, 1, 2, \ldots.$$

Let ψ_j^n be the numerical approximation of $\psi(x_j, t_n)$ and ψ^n the solution vector at time $t = t_n = nk$ with components ψ_j^n.

From time $t = t_n$ to time $t = t_{n+1}$, the DNLS (2.1) is solved in two steps. One solves

$$i\,\psi_t = -\frac{1}{2}\psi_{xx} \tag{2.3}$$

for one time step, followed by solving

$$i\,\psi_t(x, t) = V(x)\psi(x, t) - \beta|\psi(x, t)|^{2\sigma}\psi(x, t) - i\,g(|\psi(x, t)|^2)\psi(x, t), \tag{2.4}$$

again for the same time step. Equation (2.3) is discretized in space by the sine-spectral method and integrated in time *exactly.* For $t \in [t_n, t_{n+1}]$, multiplying the ODE (2.4) by $\overline{\psi(x, t)}$, the conjugate of $\psi(x, t)$, one obtains

$$i\,\psi_t(x, t)\overline{\psi(x, t)} = V(x)|\psi(x, t)|^2 - \beta|\psi(x, t)|^{2\sigma+2} - i\,g(|\psi(x, t)|^2)|\psi(x, t)|^2. \tag{2.5}$$

Subtracting the conjugate of (2.5) from (2.5) and multiplying by $-i$, one obtains

$$\frac{d}{dt}|\psi(x, t)|^2 = \overline{\psi_t(x, t)}\psi(x, t) + \psi_t(x, t)\overline{\psi(x, t)} = -2g(|\psi(x, t)|^2)|\psi(x, t)|^2. \tag{2.6}$$

Let

$$f(s) = \int \frac{1}{s\,g(s)}\,ds, \qquad h(s, \tau) = \begin{cases} f^{-1}\left(f(s) - 2\tau\right), & s > 0,\ \tau \ge 0, \\ 0, & s = 0,\ \tau \ge 0. \end{cases} \tag{2.7}$$

Then, if $g(s) \ge 0$ for $s \ge 0$, we find

$$0 \le h(s, \tau) \le s \qquad \text{for} \quad s \ge 0, \quad \tau \ge 0, \tag{2.8}$$

and the solution of the ODE (2.6) can be expressed as (with $\tau = t - t_n$)

$$\begin{aligned} 0 \le \rho(t) = \rho(t_n + \tau) &:= |\psi(x, t)|^2 = h\left(|\psi(x, t_n)|^2, t - t_n\right) := h\left(\rho(t_n), \tau\right) \\ &\le \rho(t_n) = |\psi(x, t_n)|^2, \qquad t_n \le t \le t_{n+1}. \end{aligned} \tag{2.9}$$

Combining (2.9) and (2.4), we obtain

$$\begin{aligned} i\,\psi_t(x, t) = V(x)\psi(x, t) &- \beta\left[h\left(|\psi(x, t_n)|^2, t - t_n\right)\right]^{\sigma}\psi(x, t) \\ &- i\,g\left(h\left(|\psi(x, t_n)|^2, t - t_n\right)\right)\psi(x, t), \qquad t_n \le t \le t_{n+1}. \end{aligned} \tag{2.10}$$

Integrating (2.10) from t_n to t, we find

$$\begin{aligned}\psi(x,t) &= \exp\left\{i\left[-V(x)(t-t_n) + G\left(|\psi(x,t_n)|^2, t-t_n\right)\right] - F\left(|\psi(x,t_n)|^2, t-t_n\right)\right\}\\ &\quad\times \psi(x,t_n), \qquad t_n \le t \le t_{n+1}, \end{aligned} \tag{2.11}$$

where we have defined

$$F(s,r) = \int_0^r g(h(s,\tau))\, d\tau \ge 0, \quad G(s,r) = \int_0^r \beta\ [h(s,\tau)]^\sigma\ d\tau. \tag{2.12}$$

To find the time evolution between $t = t_n$ and $t = t_{n+1}$, we combine the splitting steps via the standard second-order Strang splitting TSSP method for solving the DNLS (2.1). In detail, the steps for obtaining ψ_j^{n+1} from ψ_j^n are given by

$$\begin{aligned}\psi_j^* &= \exp\left\{-F\left(|\psi_j^n|^2, k/2\right) + i\left[-V(x_j)k/2 + G\left(|\psi_j^n|^2, k/2\right)\right]\right\}\ \psi_j^n,\\ \psi_j^{**} &= \sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\ \widehat{\psi}_l^*\ \sin(\mu_l(x_j-a)), \qquad j = 1,2,\ldots,M-1,\\ \psi_j^{n+1} &= \exp\left\{-F\left(|\psi_j^{**}|^2, k/2\right) + i\left[-V(x_j)k/2 + G\left(|\psi_j^{**}|^2, k/2\right)\right]\right\}\ \psi_j^{**},\end{aligned} \tag{2.13}$$

where $\widehat{U}_l$ are the sine-transform coefficients of a complex vector $U = (U_0, U_1, \ldots, U_M)$ with $U_0 = U_M = \mathbf{0}$ which are defined as

$$\mu_l = \frac{\pi l}{b-a}, \quad \widehat{U}_l = \frac{2}{M}\sum_{j=1}^{M-1} U_j\ \sin(\mu_l(x_j-a)),\ l = 1,2,\ldots,M-1, \tag{2.14}$$

where

$$\psi_j^0 = \psi(x_j, 0) = \psi_0(x_j), \qquad j = 0,1,2,\ldots,M. \tag{2.15}$$

Note that the only time discretization error of the TSSP method is the splitting error, which is second-order in k if the integrals in (2.7) and (2.12) can be evaluated analytically.

2.2. Most frequently used damping terms. In this subsection we present explicit formulae for using the TSSP method when solving the NLS with those damping terms most frequently appearing in BEC and nonlinear optics.

Case I. *NLS with a linear damping term.* We choose $g(\rho) \equiv \delta$ with $\delta > 0$ in (1.5). In BEC, this damping term describes inelastic collisions of condensate particles with the background gas. From (2.7), we find

$$f(s) = \int \frac{1}{\delta s} ds = \frac{1}{\delta}\ln s \qquad \text{and} \qquad h(s,\tau) = e^{-2\delta\tau}\ s. \tag{2.16}$$

Substituting (2.16) into (2.9) and (2.12), we obtain

$$\rho(t) = e^{-2\delta(t-t_n)}\ |\psi(x,t_n)|^2, \quad t_n \le t \le t_{n+1}, \tag{2.17}$$

$$F(s,r) = \delta r, \tag{2.18}$$

$$G(s,r) = \frac{\beta s^\sigma}{2\delta\sigma}\left(1 - e^{-2\delta\sigma r}\right). \tag{2.19}$$

Substituting (2.18) and (2.19) into (2.13), we get the following second-order TSSP steps for the NLS with a linear damping term:

$$\begin{aligned}
&\psi_j^* = \exp\left\{-k\delta/2 + i\left[-V(x_j)k/2 + \beta|\psi_j^n|^{2\sigma}\left(1-e^{-\delta\sigma k}\right)/(2\delta\sigma)\right]\right\}\ \psi_j^n,\\
&\psi_j^{**} = \sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\ \widehat{\psi}_l^*\ \sin(\mu_l(x_j-a)), \qquad j=1,2,\dots,M-1, \qquad (2.20)\\
&\psi_j^{n+1} = \exp\left\{-k\delta/2 + i\left[-V(x_j)k/2 + \beta|\psi_j^{**}|^{2\sigma}\left(1-e^{-\delta\sigma k}\right)/(2\delta\sigma)\right]\right\}\ \psi_j^{**}.
\end{aligned}$$

Case II. *NLS with a damping term of the form $g(\rho) = \delta\beta^q\rho^q$, where δ, $q > 0$ in* (1.5). For $q = 1$ ($q = 2$), we obtain the damping term describing two (three) particle inelastic collisions in BEC. From (2.7) we get

$$f(s) = \int \frac{1}{\delta\beta^q s^{q+1}}ds = -\frac{1}{q\delta\beta^q s^q} \qquad \text{and} \qquad h(s,\tau) = \frac{s}{(1+2q\delta\tau\beta^q s^q)^{1/q}}. \qquad (2.21)$$

Substituting (2.21) into (2.9) and (2.12), we obtain

$$\rho(t) = \frac{|\psi(x,t_n)|^2}{[1+2q\delta\beta^q(t-t_n)|\psi(x,t_n)|^{2q}]^{1/q}}, \quad t_n \le t \le t_{n+1}, \qquad (2.22)$$

$$F(s,r) = \frac{1}{2q}\ln\left(1+2q\delta r\beta^q s^q\right), \qquad (2.23)$$

$$G(s,r) = \begin{cases} \dfrac{\beta^{1-q}}{2\delta q}\ln\left(1+2q\delta r\beta^q s^q\right), & q=\sigma,\\ \dfrac{\beta^{1-q}s^{\sigma-q}\left[-1+(1+2q\delta r\beta^q s^q)^{(q-\sigma)/q}\right]}{2\delta(q-\sigma)}, & \sigma\neq q. \end{cases} \qquad (2.24)$$

Substituting (2.23) and (2.24) into (2.13), we get the following second-order TSSP method for the NLS:

(2.25)

$$\psi_j^* = \begin{cases} \dfrac{\exp\left\{i\left[-V(x_j)k/2 + \beta^{1-q}\ln\left(1+\delta qk\beta^q|\psi_j^n|^{2q}\right)/(2\delta q)\right]\right\}}{\left(1+q\delta k\beta^q|\psi_j^n|^{2q}\right)^{1/2q}}\ \psi_j^n, & \sigma = q,\\ \dfrac{\exp\left\{i\left[-\frac{V(x_j)k}{2} + \frac{\beta^{1-q}|\psi_j^n|^{2\sigma-2q}}{2\delta(q-\sigma)}\left(-1+\left(1+\delta qk\beta^q|\psi_j^n|^{2q}\right)^{\frac{q-\sigma}{q}}\right)\right]\right\}}{\left(1+q\delta k\beta^q|\psi_j^n|^{2q}\right)^{1/2q}}\ \psi_j^n, & \sigma\neq q, \end{cases}$$

$$\psi_j^{**} = \sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\ \widehat{\psi}_l^*\ \sin(\mu_l(x_j-a)), \qquad j=1,2,\dots,M-1,$$

$$\psi_j^{n+1} = \begin{cases} \dfrac{\exp\left\{i\left[-V(x_j)k/2 + \beta^{1-q}\ln\left(1+\delta qk\beta^q|\psi_j^{**}|^{2q}\right)/(2\delta q)\right]\right\}}{\left(1+q\delta k\beta^q|\psi_j^{**}|^{2q}\right)^{1/2q}}\ \psi_j^{**}, & \sigma = q,\\ \dfrac{\exp\left\{i\left[-\frac{V(x_j)k}{2} + \frac{\beta^{1-q}|\psi_j^{**}|^{2\sigma-2q}}{2\delta(q-\sigma)}\left(-1+\left(1+\delta qk\beta^q|\psi_j^{**}|^{2q}\right)^{\frac{q-\sigma}{q}}\right)\right]\right\}}{\left(1+q\delta k\beta^q|\psi_j^{**}|^{2q}\right)^{1/2q}}\ \psi_j^{**}, & \sigma\neq q. \end{cases}$$

Case III. *Focusing cubic NLS with a damping term that accounts for two-body and three-body losses in a BEC* [35]. We choose $\sigma = 1$, $g(\rho) = \delta_1\beta\rho + \delta_2\beta^2\rho^2$ with

$\delta_1,\ \delta_2 > 0$, in (1.5). Using (2.7), we get

$$f(s) = \begin{cases} -\frac{1}{\delta_1\beta s} + \frac{\delta_2}{\delta_1^2}\ln\left(\delta_2\beta + \delta_1/s\right), & s > 0, \\ 0, & s = 0. \end{cases} \tag{2.26}$$

Substituting (2.7) into (2.12) and changing the variable of integration, we obtain

$$\begin{aligned} F(s,r) &= \int_0^r g\left(f^{-1}(f(s)-2\tau)\right)\,d\tau \overset{\tau=(f(s)-f(h))/2}{=} \int_s^{h(s,r)} -\frac{1}{2}g(h)f'(h)\,dh \\ &= \int_s^{h(s,r)} -\frac{1}{2h}\,dh = \begin{cases} -\frac{1}{2}\ln\left(h(s,r)/s\right), & s > 0, \\ 0, & s = 0, \end{cases} \end{aligned} \tag{2.27}$$

where $h(s,r)$ is the solution of

$$f(s) - f(h(s,r)) = 2r \qquad \text{for any } r > 0, \tag{2.28}$$

with f given in (2.26). Similarly we find

$$G(s,r) = \int_s^{h(s,r)} -\frac{\beta}{2g(h)}\,dh = \begin{cases} -\frac{1}{2\delta_1}\ln\frac{h(s,r)(\delta_1+\delta_2\beta s)}{s(\delta_1+\delta_2\beta h(s,r))}, & s > 0, \\ 0, & s = 0. \end{cases} \tag{2.29}$$

Substituting (2.27) and (2.29) into (2.13), we get the following second-order TSSP steps for the NLS with a combination of cubic and quintic damping terms:

(2.30)

$$\begin{aligned} \psi_j^* &= \begin{cases} \frac{\sqrt{h(|\psi_j^n|^2,k/2)}}{|\psi_j^n|}\exp\left\{i\left[-\frac{V(x_j)k}{2} - \frac{1}{2\delta_1}\ln\frac{h(|\psi_j^n|^2,k/2)(\delta_1+\delta_2\beta|\psi_j^n|^2)}{|\psi_j^n|^2(\delta_1+\delta_2\beta h(|\psi_j^n|^2,k/2))}\right]\right\}\psi_j^n, & \psi_j^n \neq 0, \\ 0, & \psi_j^n = 0, \end{cases} \\ \psi_j^{**} &= \sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\,\widehat{\psi}_l^*\ \sin(\mu_l(x_j-a)), \qquad j = 1,2,\dots,M-1, \\ \psi_j^{n+1} &= \begin{cases} \frac{\sqrt{h(|\psi_j^{**}|^2,k/2)}}{|\psi_j^{**}|}\exp\left\{i\left[-\frac{V(x_j)k}{2} - \frac{1}{2\delta_1}\ln\frac{h(|\psi_j^{**}|^2,k/2)(\delta_1+\delta_2\beta|\psi_j^{**}|^2)}{|\psi_j^{**}|^2(\delta_1+\delta_2\beta h(|\psi_j^{**}|^2,k/2))}\right]\right\}\psi_j^{**}, & \psi_j^{**} \neq 0, \\ 0, & \psi_j^{**} = 0. \end{cases} \end{aligned}$$

Remark 2.1. As demonstrated in this subsection, the integrals in (2.7) and (2.12) can be evaluated *analytically* for the damping terms which most frequently appear in physical applications. If the integrals in (2.7) or (2.12) cannot be evaluated analytically or the inverse of f in (2.7) cannot be expressed explicitly, e.g., if $g(\rho)$ in (1.5) is not a polynomial, one can solve the following ODE numerically by either the second- or fourth-order Runge–Kutta method

$$\begin{aligned} &\frac{dh(t)}{dt} = -2g(h(t))\,h(t), \qquad 0 \le t \le k/2, \\ &h(0) = s, \end{aligned}$$

to get $h(s,k/2)$ for any given $s > 0$ and set $h(s,k/2) = 0$ for $s = 0$. By changing the variable of integration in (2.12) (see detail in (2.27) and (2.29)), the first integral in (2.12), i.e., $F(s,k/2)$, can be evaluated exactly (see detail in (2.27)), and the second integral in (2.12), i.e., $G(s,k/2)=\int_s^{h(s,k/2)} -\frac{\beta h^{\sigma-1}}{2g(h)}\,dh$, can be evaluated numerically by using a numerical quadrature, e.g., the trapezoidal rule or Simpson's rule.

The TSSP scheme is explicit and is unconditionally stable as we will demonstrate in the next subsection. Another main advantage of the time-splitting method is its time transversal invariance, which also holds for the NLS and the DNLS themselves. If a constant α is added to the potential V, then the discrete wave functions $\psi_j^{\varepsilon,n+1}$ obtained from the TSSP method get multiplied by the phase factor $e^{-i\alpha(n+1)k}$, which leaves the discrete normalization unchanged. This property does not hold for finite difference schemes.

Remark 2.2. For the focusing cubic NLS with a quintic damping term describing three-body recombination loss and an additional feeding term for the BEC [25], we choose $\sigma=1$, $g(\rho)=-\delta_1+\delta_2\beta^2\rho^2$ with $\delta_1,\delta_2>0$ in (1.5). The idea of constructing the TSSP method is also applicable to this case, although we could not prove that it is unconditionally stable due to the feeding term. Inserting the above feeding term into (2.7), we get

$$f(s)=\begin{cases}\frac{1}{2\delta_1}\ln\left|\delta_2\beta^2-\delta_1/s^2\right|, & s>0,\\ 0, & s=0.\end{cases} \tag{2.31}$$

Inserting (2.31) into (2.9), we find

$$h(s,\tau)=\frac{s\sqrt{\delta_1}}{\sqrt{\delta_1 e^{-4\tau\delta_1}+(1-e^{-4\tau\delta_1})\delta_2\beta^2 s^2}}, \tag{2.32}$$

and substituting (2.32) into (2.9) and (2.12), we obtain

$$\rho(t)=\frac{|\psi(x,t_n)|^2\sqrt{\delta_1}}{\sqrt{\delta_1 e^{-4\tau\delta_1}+(1-e^{-4\tau\delta_1})\delta_2\beta^2|\psi(x,t_n)|^4}},\ t_n\le t\le t_{n+1}, \tag{2.33}$$

$$F(s,r)=-\delta_1 r+\frac{1}{4}\ln\left[1+\delta_2\beta^2 s^2(e^{4\delta_1 r}-1)/\delta_1\right], \tag{2.34}$$

$$G(s,r)=\frac{1}{2\sqrt{\delta_1\delta_2}}\ln\frac{\beta s\sqrt{\delta_2}e^{2r\delta_1}+\sqrt{\delta_1+\delta_2\beta^2 s^2\left(e^{4r\delta_1}-1\right)}}{\sqrt{\delta_1}+\beta s\sqrt{\delta_2}}. \tag{2.35}$$

Inserting (2.34) and (2.35) into (2.13), we get the following second-order TSSP steps for the NLS with a quintic damping term and a feeding term:

(2.36)

$$\psi_j^*=\frac{e^{k\delta_1/2}\exp\left[i\left(-\frac{V(x_j)k}{2}+\frac{1}{2\sqrt{\delta_1\delta_2}}\ln\frac{\beta|\psi_j^n|^2\sqrt{\delta_2}e^{k\delta_1}+\sqrt{\delta_1+\delta_2\beta^2|\psi_j^n|^4\left(e^{2k\delta_1}-1\right)}}{\sqrt{\delta_1}+\beta|\psi_j^n|^2\sqrt{\delta_2}}\right)\right]}{\left[1+\delta_2\beta^2|\psi_j^n|^4(e^{2k\delta_1}-1)/\delta_1\right]^{1/4}}\,\psi_j^n,$$

$$\psi_j^{**}=\sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\,\widehat{\psi}_l^*\,\sin(\mu_l(x_j-a)),\qquad j=1,2,\ldots,M-1,$$

$$\psi_j^{n+1}=\frac{e^{k\delta_1/2}\exp\left[i\left(-\frac{V(x_j)k}{2}+\frac{1}{2\sqrt{\delta_1\delta_2}}\ln\frac{\beta|\psi_j^{**}|^2\sqrt{\delta_2}e^{k\delta_1}+\sqrt{\delta_1+\delta_2\beta^2|\psi_j^{**}|^4\left(e^{2k\delta_1}-1\right)}}{\sqrt{\delta_1}+\beta|\psi_j^{**}|^2\sqrt{\delta_2}}\right)\right]}{\left[1+\delta_2\beta^2|\psi_j^{**}|^4(e^{2k\delta_1}-1)/\delta_1\right]^{1/4}}\,\psi_j^{**}.$$

Remark 2.3. The TSSP scheme (2.13) can easily be extended for solving the complex Ginzburg–Landau (CGL) equation [15, 28]

$$i\,\psi_t=-(1-i\,\varepsilon)\,\Delta\psi-|\psi|^2\psi-i\left(\delta_2|\psi|^2-\delta_1\right)\psi, \tag{2.37}$$

where ε, δ_1, and δ_2 are positive constants. The idea of constructing the TSSP method for the DNLS is also applicable to the CGL equation provided that we solve

$$i\,\psi_t = -\,(1 - i\,\varepsilon)\,\Delta\psi \tag{2.38}$$

in the first step instead of (2.3). Inserting $\sigma = 1$, $\beta = 1$, and $g(\rho) = \delta_2\rho - \delta_1$ with δ_1, $\delta_2 > 0$ into (1.5) and using (2.7), we get

$$f(s) = \begin{cases} \frac{1}{\delta_1}\ln|\delta_2 - \delta_1/s|\,, & s > 0, \\ 0, & s = 0. \end{cases} \tag{2.39}$$

Inserting (2.39) into (2.7), we find

$$h(s,\tau) = \frac{s\delta_1}{s\delta_2\left(1 - e^{-2\tau\delta_1}\right) + \delta_1 e^{-2\tau\delta_1}}, \tag{2.40}$$

and substituting (2.40) into (2.9) and (2.12), we obtain

$$\rho(t) = \frac{\delta_1\,|\psi(x,t_n)|^2}{\delta_2\,|\psi(x,t_n)|^2\left(1 - e^{-2\tau\delta_1}\right) + \delta_1 e^{-2\tau\delta_1}}, \quad t_n \le t \le t_{n+1}, \tag{2.41}$$

$$F(s,r) = -\frac{1}{2}\ln\frac{\delta_1}{s\delta_2 + (\delta_1 - s\delta_2)\,e^{-2r\delta_1}}, \tag{2.42}$$

$$G(s,r) = \frac{1}{2\delta_2}\ln\frac{\delta_1 - s\delta_2 + s\delta_2 e^{2r\delta_1}}{\delta_1}. \tag{2.43}$$

Inserting (2.42) and (2.43) into (2.13), we get the following second-order TSSP steps for the CGL equation (2.37):

(2.44)

$$\psi_j^* = \sqrt{\frac{\delta_1}{\delta_2|\psi_j^n|^2 + \left(\delta_1 - \delta_2|\psi_j^n|^2\right)e^{-k\delta_1}}}\exp\left[\frac{i}{2\delta_2}\ln\frac{\delta_1 - \delta_2|\psi_j^n|^2 + \delta_2|\psi_j^n|^2 e^{k\delta_1}}{\delta_1}\right]\,\psi_j^n,$$

$$\psi_j^{**} = \sum_{l=1}^{M-1} e^{-(\varepsilon+i)k\mu_l^2}\,\widehat{\psi}_l^*\,\sin(\mu_l(x_j - a)), \qquad j = 1, 2, \ldots, M-1,$$

$$\psi_j^{n+1} = \sqrt{\frac{\delta_1}{\delta_2|\psi_j^{**}|^2 + \left(\delta_1 - \delta_2|\psi_j^{**}|^2\right)e^{-k\delta_1}}}\exp\left[\frac{i}{2\delta_2}\ln\frac{\delta_1 - \delta_2|\psi_j^{**}|^2 + \delta_2|\psi_j^{**}|^2 e^{k\delta_1}}{\delta_1}\right]\,\psi_j^{**}.$$

Remark 2.4. If the homogeneous periodic boundary conditions in (2.2) are replaced by the periodic boundary conditions

$$\psi(a,t) = \psi(b,t), \qquad \psi_x(a,t) = \psi_x(b,t), \qquad t \ge 0, \tag{2.45}$$

the TSSP scheme (2.13) still works provided that one replaces the sine-series in (2.13) by a Fourier series [4, 5, 7].

2.3. Stability and decay rate. Let $U = (U_0, U_1, \ldots, U_M)^T$ with $U_0 = U_M = \mathbf{0}$ and $\|\cdot\|_{l^2}$ be the usual discrete l^2-norm on the interval (a,b), i.e.,

$$\|U\|_{l^2} = \sqrt{\frac{b-a}{M}\sum_{j=1}^{M-1}|U_j|^2}. \tag{2.46}$$

For the *stability* of the TSSP approximations (2.13), we have the following lemma, which shows that the total normalization does not increase.

LEMMA 2.1. *The TSSP schemes* (2.13) *are unconditionally stable if* $g(s) \geq 0$ *for* $s \geq 0$. *In fact, for every mesh size* $h > 0$ *and time step* $k > 0$,

$$\|\psi^{n+1}\|_{l^2} \leq \|\psi^n\|_{l^2} \leq \|\psi^0\|_{l^2} = \|\psi_0\|_{l^2}, \qquad n = 0, 1, 2, \ldots. \tag{2.47}$$

Furthermore, when a linear damping term is used in (1.5), *i.e., when we choose* $g(\rho) \equiv \delta$ *with* $\delta > 0$, *the decay rate of the normalization satisfies*

$$\|\psi^n\|_{l^2} = e^{-2\delta t_n}\|\psi^0\|_{l^2} = e^{-2\delta t_n}\|\psi_0\|_{l^2}, \qquad n = 1, 2, \ldots. \tag{2.48}$$

In fact, (2.48) *is a discretized version of the decay rate of the normalization* $N(t)$ *in* (1.8).

Proof. We combine (2.13), (2.14), and (2.46) and note that $F(s,\tau) \geq 0$ for $s \geq 0$ and $\tau \geq 0$ to obtain

$$\begin{aligned}
\frac{1}{b-a}\|\psi^{n+1}\|_{l^2}^2 &= \frac{1}{M}\sum_{j=1}^{M-1}\left|\psi_j^{n+1}\right|^2 \\
&= \frac{1}{M}\sum_{j=1}^{M-1}\exp\left[-2F\left(|\psi_j^{**}|^2, k/2\right)\right]\ \left|\psi_j^{**}\right|^2 \leq \frac{1}{M}\sum_{j=1}^{M-1}\left|\psi_j^{**}\right|^2 \\
&= \frac{1}{M}\sum_{j=1}^{M-1}\left|\sum_{l=1}^{M-1} e^{-ik\mu_l^2/2}\ \widehat{\psi}_l^*\ \sin(\mu_l(x_j-a))\right|^2 = \frac{1}{2}\sum_{l=1}^{M-1}\left|e^{-ik\mu_l^2/2}\ \hat{\psi}_l^*\right|^2 = \frac{1}{2}\sum_{l=1}^{M-1}\left|\hat{\psi}_l^*\right|^2 \\
&= \frac{1}{2}\sum_{l=1}^{M-1}\left|\frac{2}{M}\sum_{j=1}^{M-1}\psi_j^*\ \sin(\mu_l(x_j-a))\right|^2 = \frac{1}{M}\sum_{j=1}^{M-1}\left|\psi_j^*\right|^2 \\
&= \frac{1}{M}\sum_{j=1}^{M-1}\exp\left[-2F\left(|\psi_j^n|^2, k/2\right)\right]\left|\psi_j^n\right|^2 \leq \frac{1}{M}\sum_{j=1}^{M-1}\left|\psi_j^n\right|^2 \\
&= \frac{1}{b-a}\|\psi^n\|_{l^2}^2.
\end{aligned} \tag{2.49}$$

Here, we used the identity

$$\sum_{j=1}^{M-1}\sin\left(\frac{\pi r\, j}{M}\right)\ \sin\left(\frac{\pi s\, j}{M}\right) = \left\{\begin{array}{ll} 0, & r-s \neq 2mM, \\ M/2, & r-s = 2mM, r \neq 2nM, \end{array}\right. \qquad m, n \text{ integer.} \tag{2.50}$$

When a linear damping term is added to the NLS (1.5), the equality (2.48) follows from the above proof, (2.18), and

$$\sum_{j=1}^{M-1}\exp\left[-2F\left(|\psi_j^n|^2, k/2\right)\right]\left|\psi_j^n\right|^2 = \sum_{j=1}^{M-1}e^{-\delta k}\left|\psi_j^n\right|^2 = e^{-\delta k}\sum_{j=1}^{M-1}\left|\psi_j^n\right|^2.$$

3. Numerical examples. In this section, we present numerical tests of the TSSP scheme (2.13) for solving a focusing cubic NLS appearing in nonlinear optics [16, 36] and for the GPE in BEC [7] in two dimensions with a linear, a cubic, or a quintic

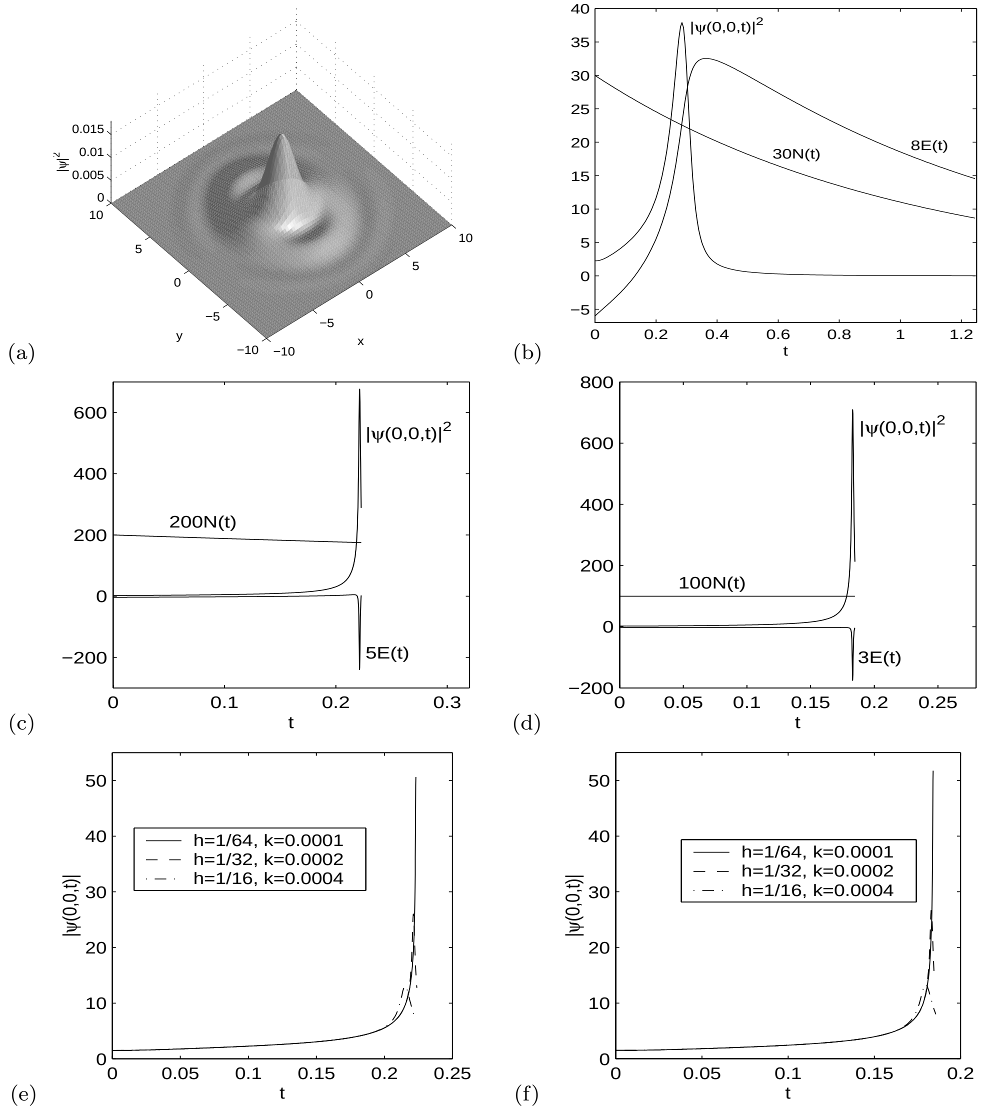

FIG. 1. *Numerical results in Example* 1, *case* I. damping term. In our computations, the initial condition (1.2) is always chosen such that $|\psi_0(\mathbf{x})|$ decays to zero sufficiently fast as $|\mathbf{x}| \to \infty$. We choose an appropriately large rectangle $[a, b] \times [c, d]$ in two dimensions to prevent the homogeneous periodic boundary condition (2.2) from introducing a significant (aliasing) error relative to the whole space problem. To quantify the numerical results of the GPE for a BEC, we define the condensate widths along the x, y, and z axes by

$$\sigma_\alpha^2 = \langle \alpha^2 \rangle = \frac{1}{N(t)} \int_{\mathbb{R}^d} \alpha^2 |\psi(\mathbf{x}, t)|^2 \, d\mathbf{x}, \qquad \text{with} \quad \alpha = x,\ y,\ \text{or } z.$$

Example 1. *Solution of the two-dimensional damped focusing cubic NLS*. We choose $d = 2$, $\sigma = 1$, and $V(x, y) \equiv 0$ in (1.5) and present computations for three different damping terms ($\delta > 0$):

I. A linear damping term; i.e., we choose $g(\rho) \equiv \delta$.

II. A cubic damping term; i.e., we choose $g(\rho) \equiv \delta\beta\rho$.

III. A quintic damping term; i.e., we choose $g(\rho) \equiv \delta\beta^2\rho^2$.

The initial condition (1.6) is taken to be

$$(3.1) \qquad \psi(x, y, 0) = \psi_0(x, y) = \frac{\gamma_y^{1/4}}{\sqrt{\pi\varepsilon}}\, e^{-(x^2+\gamma_y y^2)/2\varepsilon}, \qquad (x, y) \in \mathbb{R}^2.$$

We assume $\gamma_y = 2$, $\varepsilon = 0.2$, and $\beta = 8$ in (1.5) such that $E(0) = -0.751582 < 0$ in (1.4). We solve the NLS on the square $[-16, 16]^2$; i.e., $a = c = -16$ and $b = d = 16$ with mesh size $h = \frac{1}{32}$, time step $k = 0.0002$, and homogeneous periodic boundary conditions along the boundary of the square. We compare the effect of changing the damping parameter δ in the three different cases I, II, and III.

Figure 1 shows the surface plot of the density $|\psi(x, y, t)|^2$ at time $t = 1.25$ with $\delta = 0.5$; plots of the normalization, energy, and central density $|\psi(0, 0, t)|^2$ are shown

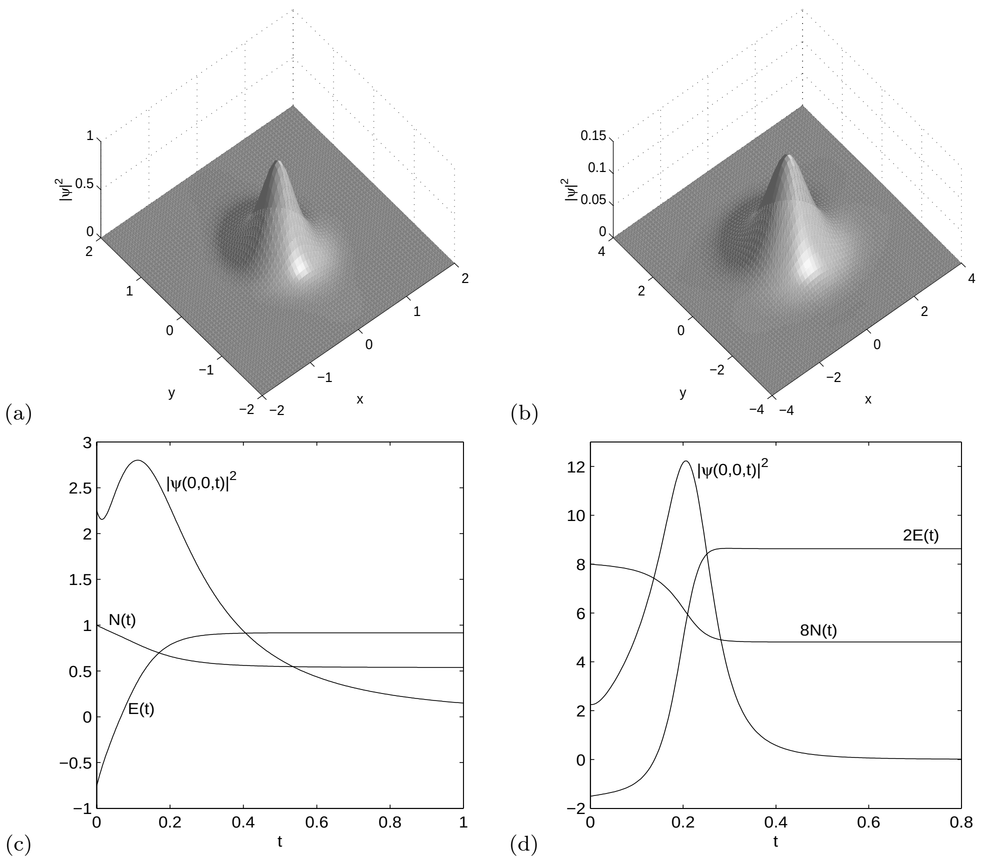

Fig. 3. *Numerical results in Example* 1, *case* III. *Surface plot of the density $|\psi|^2$ with $\delta = 0.01$:* (a) *At time $t = 0.4$,* (b) *$t = 1.0$. Normalization, energy, and central density $|\psi(0, 0, t)|^2$ as functions of time:* (c) *with $\delta = 0.01$,* (d) *$\delta = 0.001$.*

as functions of time with $\delta = 0.5,\ 0.3$, and $\delta = 0$ (no damping) for case I. Figure 2 shows similar results for case II and Figure 3 for case III. Furthermore, Figure 4 shows contour plots of the density $|\psi|^2$ at different times for case III with $\delta = 0.01$.

In the numerical computations, a blowup is detected either from the plot of the central density $|\psi(0, 0, t)|^2$, which at the blowup shows a very sharp spike with a peak value that increases when the mesh size h decreases, or from the plot of the energy $E(t)$, which has a very sharp spike with negative values at the blowup. In fact, the TSSP method (2.13) aims to capture the solution of the DNLS without blowup, i.e., physical relevant solution. If one wants to capture the blowup rate of the NLS, we refer to [27, 31].

From the numerical results we find the following conditions for arresting a blowup of the wave function with initial energy $E(0) < 0$. (1) For linear damping, the blowup is arrested if the damping parameter is bigger than a certain threshold value which we find to be $\delta_{\text{th}} \approx 0.461$ by numerical experiments. As shown in Figure 1(b), blowup is arrested for $\delta = 0.5 > \delta_{\text{th}}$, while the wave function blows up for $\delta < \delta_{\text{th}}$, as can be seen from Figure 1(c),(d), where we have chosen $\delta = 0.3 < \delta_{\text{th}}$ and $\delta = 0 < \delta_{\text{th}}$, respectively. The time at which the blowup of the wave function happens, however, increases with increasing δ (cf. Figure 1(c)(d)). (2) For a cubic damping term with

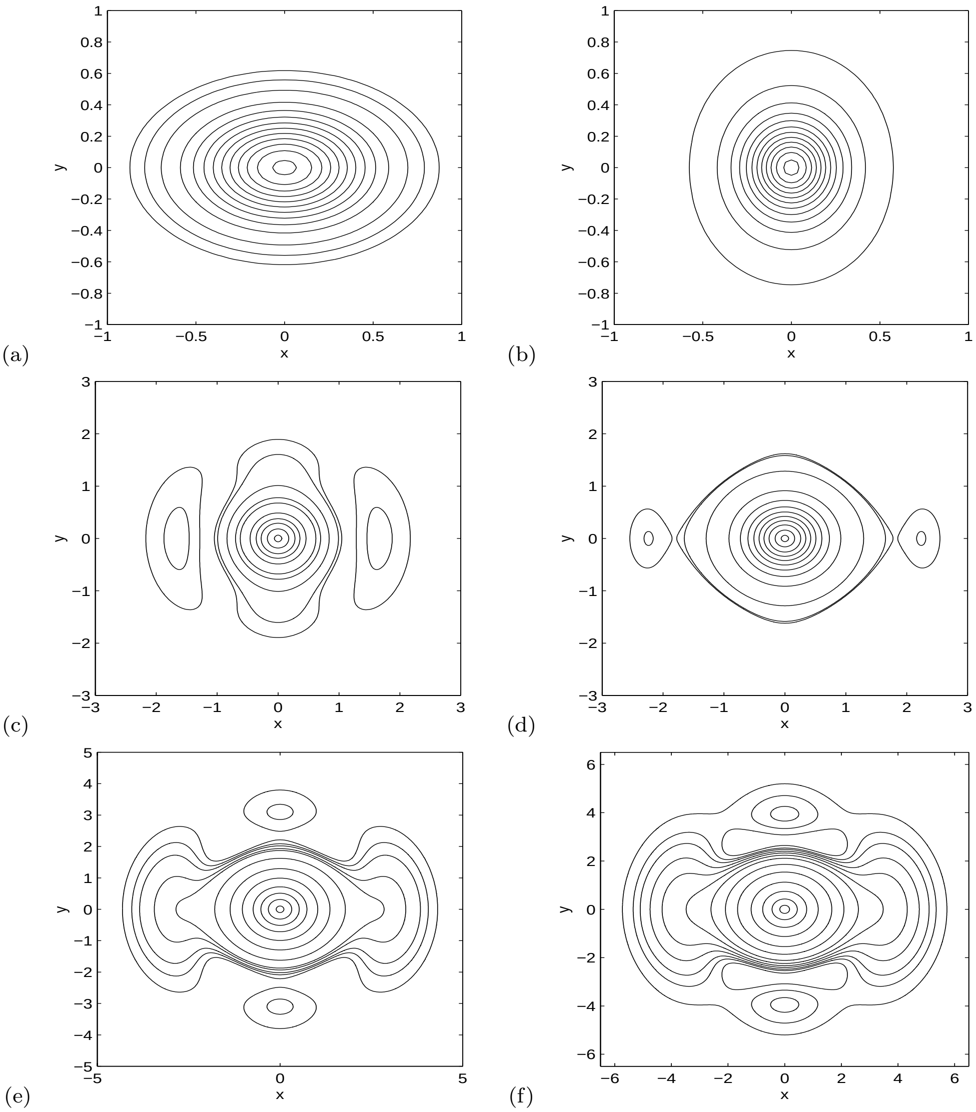

FIG. 4. *Contour plots of the density* $|\psi|^2$ *at different times in Example* 1, *case* III, *with* $\delta = 0.01$. (a) $t = 0$, (b) $t = 0.2$, (c) $t = 0.4$, (d) $t = 0.6$, (e) $t = 0.8$, (f) $t = 1$.

$\delta > 0$, the blowup of the wave function is always arrested (cf. Figure 2). (3) The above observation (2) also holds for a quintic damping term (cf. Figure 3).

For linear damping, we also test the dependence of the threshold value of the damping parameter δ_{th} on β and the initial data. First we take $\gamma_y = 2$ and $\varepsilon = 0.2$ in (3.1). Table 1 shows the threshold values δ_{th} for different β in (1.5), and $E(0)$ represents the initial energy. Then we choose $\beta = 16$ in (1.5) and $\gamma_y = 2$ in (3.1). Table 2 displays the threshold values δ_{th} for different values of ε in (3.1).

From Table 1, we find by a least square fitting

$$\delta_{\text{th}} = -0.6930E(0) \qquad \text{or} \qquad \delta_{\text{th}} = 0.3872\beta - 2.4627.$$

$\delta_{\rm th}$	0.895	1.845	3.655	7.25	14.55

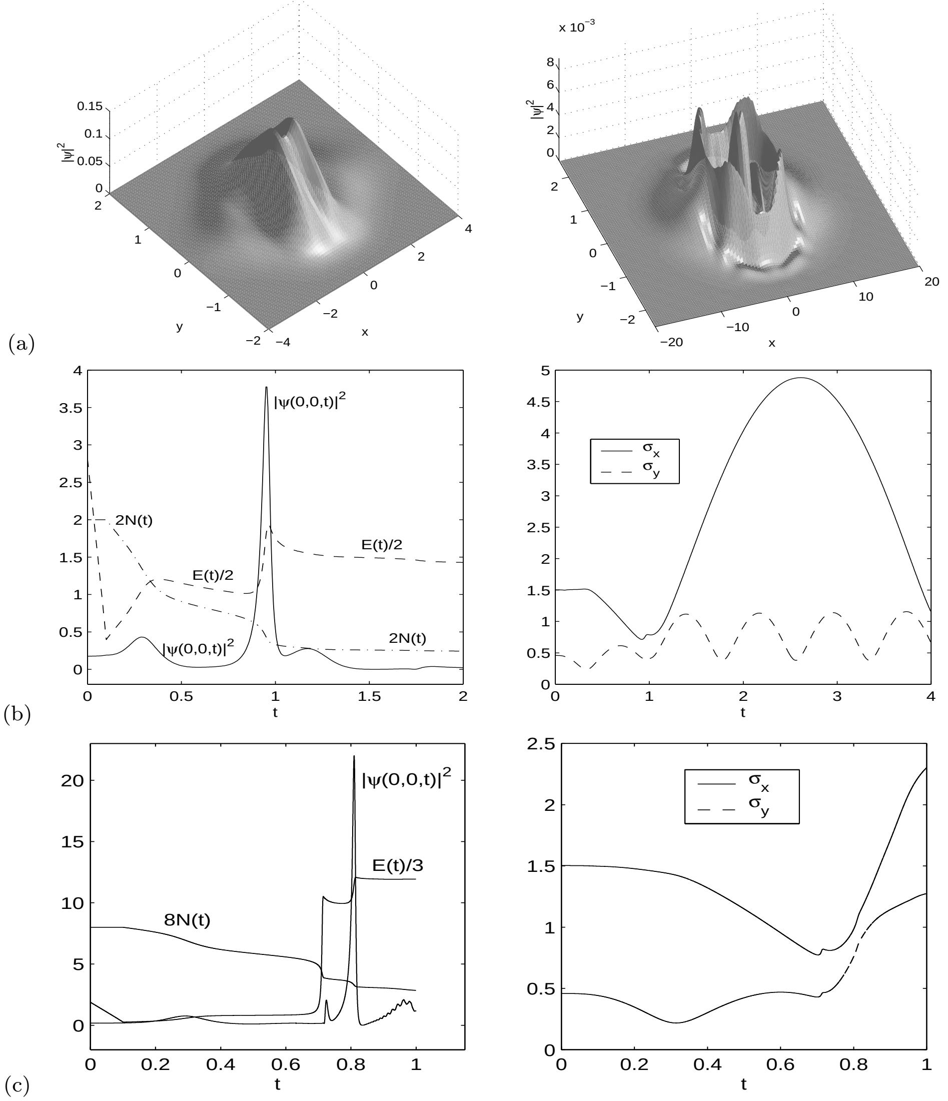

FIG. 6. *Numerical results in Example* 2*, case* II. (a) *Surface plot of the density* $|\psi|^2$ *with* $\delta = 0.15$*: At time* $t = 0.8$ *(left column) and* $t = 2.4$ *(right column). Normalization, energy, and central density* $|\psi(0,0,t)|^2$ *(left column) and condensate widths (right column) as functions of time:* (b) *With* $\delta = 0.15$*;* (c) $\delta = 0.04$ *(under* $h = 1/128, k = 0.00002$ *for* (c)*).*

Similarly, from Table 2, we obtain

$$\delta_{\mathrm{th}} = -0.6922E(0).$$

Based on this observation, we conclude that the threshold value of the linear damping parameter δ_{th} depends linearly on the initial energy $E(0)$.

Example 2. *Solution of the two-dimensional damped GPE with focusing nonlinearity.* We choose $d = 2$, $\sigma = 1$, and $V(x,y) = \frac{1}{2}(\gamma_x^2 x^2 + \gamma_y^2 y^2)$ to be a harmonic oscillator potential with $\gamma_x, \gamma_y > 0$ in (1.5). Again, we present computations for the same three different damping terms in (1.5) that we studied in Example 1.

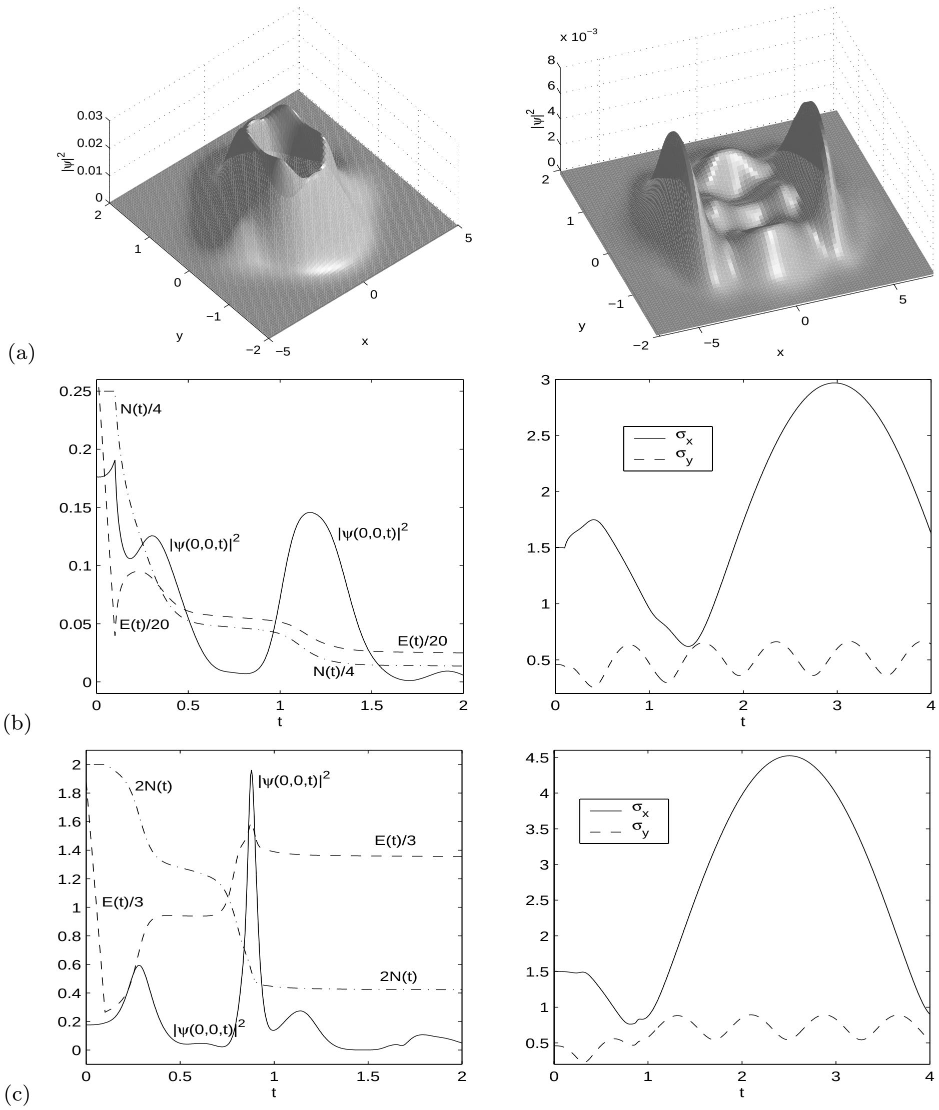

FIG. 7. *Numerical results in Example* 2*, case* III. (a) *Surface plot of the density* $|\psi|^2$ *with* $\delta = 0.15$*: At time* $t = 0.8$ *(left column) and* $t = 3.2$ *(right column). Normalization, energy, and central density* $|\psi(0,0,t)|^2$ *(left column) and condensate widths (right column) as functions of time:* (b) *With* $\delta = 0.15$*;* (c) $\delta = 0.005$.

We take $\gamma_x = 1$ and $\gamma_y = 4$. The initial condition (1.6) is assumed to be the ground-state solution of (1.5) with $g(\rho) \equiv 0$ (i.e., undamped case) and $\beta = -40$ [6]. The cubic nonlinearity is ramped linearly from $\beta = -40$ (defocusing) to $\beta = 50$ (focusing) during the time interval $[0, 0.1]$ and afterward kept constant. The absorption parameter was set to $\delta = 0$ during the time interval $[0, 0.1]$ and increased to a positive value $\delta > 0$ afterward.

We solve the GPE on the rectangle $[-24, 24] \times [-6, 6]$, i.e., for $a = -24$, $b = 24$, $c = -6$, and $d = 6$ with mesh size $h_x = \frac{3}{64}$, $h_y = \frac{3}{128}$, time step $k = 0.0005$, and homogeneous periodic boundary conditions along the boundary of the rectangle.

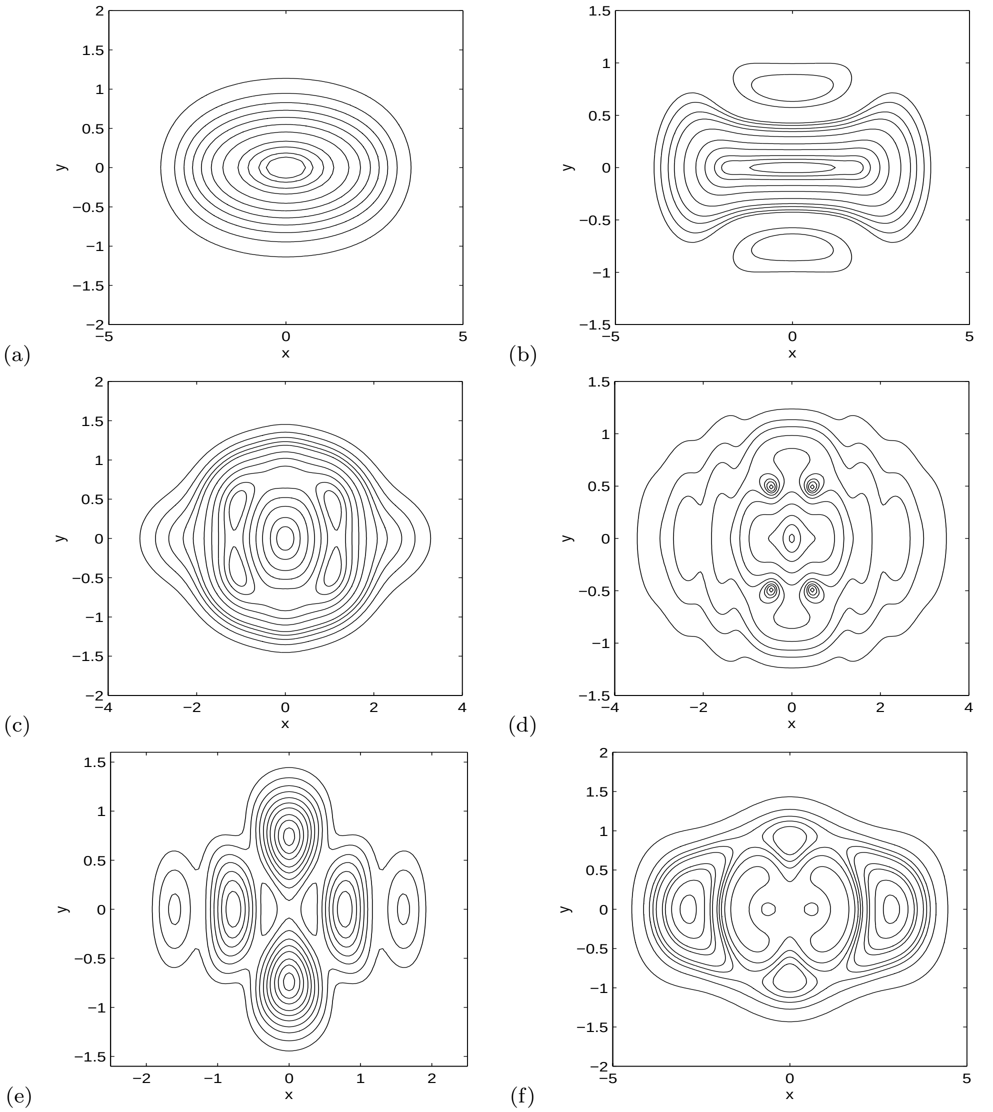

FIG. 8. *Contour plots of the density* $|\psi|^2$ *at different times in Example* 2, *case* III, *with* $\delta = 0.15$. (a) $t = 0$, (b) $t = 0.4$, (c) $t = 0.8$, (d) $t = 1.2$, (e) $t = 1.6$, (f) $t = 2.4$.

Again, we compare the effect of changing the damping parameter δ in the three different cases I, II, and III.

Figure 5 shows a surface plot of the density $|\psi(x, y, t)|^2$ at times $t = 0$ (ground-state solution) and $t = 2.8$ with $\delta = 1.25$; normalization, energy, and central density $|\psi(0, 0, t)|^2$ are shown as functions of time with $\delta = 1.25$, 1.1, and 0 (no damping) for case I. Figure 6 shows similar results for case II and Figure 7 for case III. Furthermore, Figure 8 shows contour plots of the density $|\psi|^2$ at different times for case III with $\delta = 0.15$.

From our numerical results we find that the observations (1)–(3) made for Example 1 are still valid with the additional trapping potential. However, the value of δ_{th} depends on β (or initial energy $E(0)$), and we find $\delta_{\text{th}} \approx 1.185$ for linear damping (cf. Figure 5).

3.1. Discussion. In this subsection, we discuss our numerical results in terms of physical properties of a BEC described by the GPE. We concentrate on those cases where a collapse of the wave function is arrested since this collapse leads to unphysical processes like the negative peaks in the energy $E(t)$ shown in Figures 1(c), (d) and 5(e), (f).

The general form of the time evolution in Example 1 is similar for all three cases. Initially the cloud of atoms contracts due to the attractive interaction between the particles. This contraction is accompanied by an increase in the energy due to particle loss which is most efficient in regions of high particle density. These regions are characterized by a negative local energy density leading to an increase in energy for each particle lost there. After the central particle density has reached a maximum, the cloud starts to expand due to the kinetic energy gained by the particles during the contraction. Particles are emitted from the cloud in burst-like pulses which can be seen in Figures 4 and 8. Such bursts have also been seen in BEC experiments [12]. The main differences between the three cases are the behavior of the energy and the number of particles as a function of time. In case I, where we assumed a linear damping term, the loss rate of particles from the condensate is independent of the shape of the condensate wave function. The energy decrease during the condensate expansion is determined by the loss of particles (cf. Figure 1(b)). In the cases of cubic and quintic damping, the loss term has a significant effect only on the time evolution of the condensate during the contraction. When the condensate expands, the density of particles is so low that the loss terms have only a very small effect and the energy $E(t)$ and the number of particles $N(t)$ remain almost constant (see Figures 2(c) and 3(c), (d)).

In Example 2, we add an additional trap potential which confines the BEC, and we assume a realistic scenario (described above) to prepare the condensate in the trap (cf. the experiments by Donley et al. [12]). We find that the initial process of turning on the attractive interactions between the particles leads to oscillations in the widths of the condensate [7] as can be seen from Figures 5, 6, and 7. However, neither the additional trap potential nor these oscillations significantly alter the behavior of the system compared to Example 1, when the condensate is strongly contracted. Before and after this contraction, some differences can be seen. By looking at Figures 5 and 6 we find that the first minimum in σ_y due to the oscillations of the condensate causes an increase in the central density and in the energy. For cubic and quintic damping, this is accompanied by an increased particle loss. However, an arrested collapse of the wave function happens only when both σ_x and σ_y attain a minimum value due to the attractive interactions (cf. Figures 5(d) and 6(b)). We also note that the frequency of the oscillations after an arrested collapse has happened is not significantly influenced by the damping terms. The amplitude of these oscillations is, however, strongly dependent on δ and decreases with increasing δ. Finally, we want to mention that a series of contractions and expansions of the condensate is possible. In Figure 7(b), we find three contractions of the condensate where only the first one reaches a sufficiently high particle density to lead to an increase in energy while the next two contractions show a rather smooth decrease in energy and particle number. For a smaller quintic damping term, we obtain two contractions of the condensate which increase the energy (see Figure 7(c)).

4. Conclusions. We extended the explicit unconditionally stable second-order TSSP method for solving damped focusing NLSs. We showed that this method is time transversal invariant and preserves the exact decay rate of the normalization for a linear damping of the NLS. Extensive numerical tests were presented for the cubic focusing NLS in two dimensions with linear, cubic, and quintic damping terms. Our numerical results show that quintic and cubic damping always arrest blowup, whereas linear damping can arrest blowup only when the damping parameter δ is bigger than a certain threshold value δ_{th}. We will apply this novel method to solve the three-dimensional GPE with a quintic damping term and will compare the numerical results with the experimental dynamics [12] of collapsing and exploding BECs [8].

FINITE ELEMENT APPROXIMATION OF SURFACTANT SPREADING ON A THIN FILM*

JOHN W. BARRETT[†][§], HARALD GARCKE[‡], AND ROBERT NÜRNBERG[†][¶]

Abstract. We consider a fully practical finite element approximation of the following system of nonlinear degenerate parabolic equations:

$$\frac{\partial u}{\partial t} + \tfrac{1}{2}\,\nabla.(u^2\,\nabla[\sigma(v)]) - \tfrac{1}{3}\,\nabla.(u^3\,\nabla w) = 0, \qquad w = -c\,\Delta u + a\,u^{-3} - \delta\,u^{-\nu},$$

$$\frac{\partial v}{\partial t} + \nabla.(u\,v\,\nabla[\sigma(v)]) - \rho\,\Delta v - \tfrac{1}{2}\,\nabla.(u^2\,v\,\nabla w) = 0.$$

The above models a surfactant-driven thin film flow in the presence of both attractive, $a > 0$, and repulsive, $\delta > 0$ with $\nu > 3$, van der Waals forces, where u is the height of the film, v is the concentration of the insoluble surfactant monolayer, and $\sigma(v) := 1 - v$ is the typical surface tension. Here $\rho \geq 0$ and $c > 0$ are the inverses of the surface Peclet number and the modified capillary number. In addition to showing stability bounds for our approximation, we prove convergence in one space dimension when $\rho > 0$ and either $a = \delta = 0$ or $\delta > 0$. Furthermore, iterative schemes for solving the resulting nonlinear discrete system are discussed. Finally, some numerical experiments are presented.

Key words. thin film flow, surfactant, fourth order degenerate parabolic system, finite elements, convergence analysis

1. Introduction.

The study of the motion of surfactants placed on a thin layer of a viscous fluid is motivated by applications ranging from the medical treatment of premature infants to industrial coating and drying processes (cf. [13, 18, 24, 26, 27]). We are interested in situations in which a free surface of a thin film contains a monolayer of a surfactant, which is a chemical that lowers the surface tension. Surface tension gradients then lead to shear stresses which force the liquid to flow toward regions of higher surface tension (Marangoni effect). In total, the liquid flow is driven by capillarity and surfactant gradient induced convection (Marangoni convection).

We consider a situation in which the thin layer of a viscous fluid spreads on a horizontal planar surface. The evolution then can be described by a free boundary problem for the Navier–Stokes equations coupled to a convection-diffusion equation for the surfactant, where the latter equation has to be solved only on the free surface. Starting from this complicated free boundary problem, it is possible, under appropriate assumptions, to use lubrication theory to derive a coupled set of nonlinear partial differential equations for the two unknowns: film thickness and surfactant concentration. It is the goal of this paper to develop and analyze a finite element method for this set of equations.

Denoting by u the height of the film, by w the pressure, and by v the concentration of the insoluble surfactant, the governing equations that one derives from lubrication theory (cf. [13, 18, 31]) are

$$\tag{1.1a} \tfrac{\partial u}{\partial t} + \tfrac{1}{2}\,\nabla.(u^2\,\nabla[\sigma(v)]) - \tfrac{1}{3}\,\nabla.(u^3\,\nabla w) = 0, \qquad w = -c\,\Delta u\,,$$

$$\tag{1.1b} \tfrac{\partial v}{\partial t} + \nabla.(u\,v\,\nabla[\sigma(v)]) - \rho\,\Delta v - \tfrac{1}{2}\,\nabla.(u^2\,v\,\nabla w) = 0.$$

In the following, we will denote by the vector x the horizontal variables and by $y \in \mathbb{R}$ the vertical variable. The functions u, v, and w are functions of x and the time t, and all spatial operators like $\nabla, \nabla.$, and Δ in this paper act on the horizontal variables only. The given data are $\rho \in \mathbb{R}_{\geq 0}$, the inverse of the surface Peclet number, and $c \in \mathbb{R}_{>0}$, the inverse of a modified capillary number. In addition, $\sigma : [0,1] \to [0,1]$ is the constitutive equation of state relating the surface tension σ to v, e.g.,

$$\tag{1.2} \sigma(s) := (\beta+1)\,[1+\theta(\beta)\,s]^{-3} - \beta, \quad \text{where} \quad \theta(\beta) := \big(\tfrac{\beta+1}{\beta}\big)^{\frac{1}{3}} - 1,$$

and $\beta \in \mathbb{R}_{>0}$ relates to the activity of the surfactant (cf. [24, p. 262]). It is reasonable to assume throughout that σ is a monotonically decreasing function of v, as the surfactant lowers surface tension.

Let us now discuss some properties of the system which are important for later developments. First, we want to show how one can recover the pressure and velocity in the fluid if one knows a solution $\{u, v, w\}$ of (1.1a,b). In lubrication theory (see [19]), it turns out that the pressure in the fluid is independent of the vertical variable y, and we obtain that $p(x,y,t) \equiv w(x,t) = -c\,\Delta u(x,t)$, where the right-hand side is an approximation to the mean curvature of the air/liquid interface. We remark that one obtains this identity from the leading order equation in lubrication theory. Another important quantity in lubrication theory is the horizontal component of the velocity, $\vec{\mathbf{V}}_H$, which can be computed from $\{u(x,t), v(x,t), w(x,t)\}$ as follows:

$$\tag{1.3} \vec{\mathbf{V}}_H(x,y,t) = y\,\nabla[\sigma(v)] + \big(\tfrac{1}{2}\,y^2 - y\,u\big)\,\nabla w,$$

where a no-slip condition has been assumed at $y = 0$. One notices that $\vec{\mathbf{V}}_H$ is quadratic in the y-direction. Furthermore, the fluid is driven by two effects: namely, by pressure gradients due to capillarity effects, $-c\,\nabla(\Delta u)$, and by surface tension gradients, $\nabla[\sigma(v)]$. Equation (1.3) evaluated for $y = u(x,t)$ yields the horizontal velocity on the free surface, and hence the equation for the surfactant concentration, (1.1b), can be rewritten as

$$\tfrac{\partial v}{\partial t} + \nabla.(v\,\vec{\mathbf{V}}_H(x, u(x,t), t)) = \rho\,\Delta v\,,$$

which shows that it can be interpreted as a convection-diffusion equation, where the surfactant is transported with the velocity of the fluid. In addition, the equation for the film height can be expressed with the help of the fluid velocity. A straightforward computation starting from (1.1a) shows that the change of height of the film is given in terms of the horizontal component of the velocity as follows:

$$\tfrac{\partial u}{\partial t} = -\nabla.\left(\int_0^{u(x,t)} \vec{\mathbf{V}}_H(x,y,t)\;\mathrm{d}y\right)\,.$$

A basic ingredient of our approach is an energy estimate for surfactant-driven flows. To derive an energy estimate involving a density function $F(v)$, we use some ideas from thermodynamics. First, we relate F to σ by the Gibbs identity

$$\sigma(v) = F(v) - v\,F'(v) \qquad \Rightarrow \qquad \sigma'(v) = -v\,F''(v)\,. \tag{1.4}$$

Knowing σ, the above identity determines F up to a linear term. Assuming appropriate boundary conditions, which will be specified later on, one can derive an energy estimate for the surfactant-driven thin film system as

$$\tfrac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \left[\tfrac{c}{2}\,|\nabla u|^2 + F(v)\right]\,\mathrm{d}x + \int_\Omega\int_0^u |\partial_y \vec{\mathbf{V}}_H|^2\,\mathrm{d}y\,\mathrm{d}x + \rho\int_\Omega F''(v)\,|\nabla v|^2\,\mathrm{d}x = 0\,, \tag{1.5}$$

where Ω is a bounded domain in $\mathbb{R}^d$, $d = 1$ or 2. To derive the above, we have used the identity

$$\int_0^u |\partial_y \vec{\mathbf{V}}_H|^2\,\mathrm{d}y = u\,|\nabla[\sigma(v)]|^2 - u^2\,\nabla[\sigma(v)]\,.\,\nabla w + \tfrac{1}{3}\,u^3\,|\nabla w|^2\,. \tag{1.6}$$

The identity (1.5) directly corresponds to the energy estimate for the free boundary value problem for the Navier–Stokes equations. The term $\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega [\frac{c}{2}\,|\nabla u|^2 + F(v)]\,\mathrm{d}x$ describes the rate of change of energy in time, and, since one neglects inertia effects, only capillarity terms appear in the energy. The two remaining terms in (1.5) represent energy dissipation due to friction in the fluid and diffusion of the surfactant, respectively.

On recalling that σ is monotonically decreasing, we deduce from (1.4) that F'' is nonnegative, and hence the identity (1.5) shows that the energy decreases in time. This energy estimate will lead to important a priori estimates. In particular, the identity (1.6) together with the inequality

$$u^2\,\nabla[\sigma(v)]\,.\,\nabla w \le \tfrac{\gamma}{2}\,u\,|\nabla[\sigma(v)]|^2 + \tfrac{1}{2\gamma}\,u^3\,|\nabla w|^2, \qquad \gamma \in (\tfrac{3}{2}, 2), \tag{1.7}$$

then shows that we can control $u\,|\nabla[\sigma(v)]|^2$ and $u^3\,|\nabla w|^2$ with the help of the energy estimate (1.5).

It is the goal of this paper to derive a finite element method that is consistent with the energy estimate (1.5); i.e., we want to derive a method that satisfies a discrete analogue.

To conclude the system, we need to specify initial and boundary conditions for (1.1a–c). One possibility that leads to the above energy estimate would be to describe periodic boundary conditions. Instead we prescribe the following conditions at the horizontal boundary: a no-penetration condition for the velocity, a 90° angle condition for the film height, and a no-flux condition for the surfactant concentration. This implies the following conditions for $x \in \partial\Omega$ and $0 \le y \le u(x,t)$:

$$\nu_{\partial\Omega}\,.\,\vec{\mathbf{V}}_H(x,y,t) \equiv \nu_{\partial\Omega}\,.\,\big(y\,\nabla[\sigma(v)] + \big(\tfrac{1}{2}\,y^2 - y\,u\big)\,\nabla w\big) = 0, \qquad \tfrac{\partial u}{\partial \nu_{\partial\Omega}} = 0, \tag{1.8a}$$

$$\nu_{\partial\Omega}.\,(v\,\vec{\mathbf{V}}_H(x,u(x,t),t) - \rho\,\nabla v) \equiv \nu_{\partial\Omega}.(v\,(u\,\nabla[\sigma(v)] - \tfrac{1}{2}\,u^2\,\nabla w) - \rho\,\nabla v) = 0, \tag{1.8b}$$

where $\nu_{\partial\Omega}$ is normal to $\partial\Omega$, the Lipschitz boundary of Ω. Integrating the first equation in (1.8a) with respect to y yields that

$$\tfrac{1}{2}\,u^2\,\tfrac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}} - \tfrac{1}{3}\,u^3\,\tfrac{\partial w}{\partial\nu_{\partial\Omega}} = 0 \qquad \text{on } \partial\Omega\,, \tag{1.9}$$

which means that the height averaged normal component of the horizontal velocity is zero on the boundary. Note that in the case that either $\rho > 0$ or $v\,\sigma'(v) \neq 0$, it can be seen that the first boundary condition in (1.8a) and (1.8b) are equivalent to (1.9) and (1.8b) (observe that (1.8a) holds for all $y \in [0, u(x,t)]$, $x \in \partial\Omega$).

In what follows, we will therefore specify the boundary conditions

$$\tfrac{1}{2}\, u^2\, \tfrac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}} - \tfrac{1}{3}\, u^3\, \tfrac{\partial w}{\partial\nu_{\partial\Omega}} = \tfrac{\partial u}{\partial\nu_{\partial\Omega}} = u\, v\, \tfrac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}} - \tfrac{1}{2}\, u^2\, v\, \tfrac{\partial w}{\partial\nu_{\partial\Omega}} - \rho\, \tfrac{\partial v}{\partial\nu_{\partial\Omega}} = 0 \quad \text{on } \partial\Omega\,.$$

We remark that if either $u\,\rho > 0$ or $-u\,v\,\sigma'(v) > 0$ on $\partial\Omega$, these boundary conditions are equivalent to $\frac{\partial u}{\partial\nu_{\partial\Omega}} = \frac{\partial w}{\partial\nu_{\partial\Omega}} = \frac{\partial v}{\partial\nu_{\partial\Omega}} = 0$ on $\partial\Omega$.

When surfactant is placed on the film, a thinning effect can be observed (see the numerical results in section 5). If the film thickness is in the range of a few hundred Angstroms, then molecular effects due to van der Waals forces become important. If van der Waals forces are included, an additional conservative body force enters the Navier–Stokes equations (see, e.g., [28]). In the thin film equations and in all the formulae above, the pressure w, related to the height u previously by (1.1a), is then replaced by the reduced pressure

$$w = -c\,\Delta u + \phi(u)\,, \qquad \text{where} \quad \phi(u) := a\,u^{-3} - \delta\,u^{-\nu}, \quad \nu > 3\,. \tag{1.10}$$

Here $a \in \mathbb{R}_{\geq 0}$ is the scaled dimensionless Hamaker constant and $\delta \in \mathbb{R}_{\geq 0}$ represents the effect of repulsive van der Waals forces; see, e.g., [28]. When van der Waals forces are included, the energy estimate (1.5) is replaced by

(1.11)
$$\frac{\mathrm{d}}{\mathrm{d}t}\int_\Omega \left[\tfrac{c}{2}\,|\nabla u|^2 + F(v) + \Phi(u)\right] \mathrm{d}x + \int_\Omega \int_0^u |\partial_y \vec{\mathbf{V}}_H|^2 \,\mathrm{d}y\,\mathrm{d}x + \rho \int_\Omega F''(v)\,|\nabla v|^2 \,\mathrm{d}x = 0,$$

where Φ is an antiderivative of ϕ, i.e., $\Phi' = \phi$, and the horizontal velocity $\vec{\mathbf{V}}_H$ is still given by (1.3) but with w now defined by (1.10).

Altogether, in this paper we consider the following initial boundary value problem.

(P) Find functions u, w, $v : \Omega \times [0,T] \to \mathbb{R}$ such that

$$\tfrac{\partial u}{\partial t} + \tfrac{1}{2}\,\nabla.(u^2\,\nabla[\sigma(v)]) - \tfrac{1}{3}\,\nabla.(u^3\,\nabla\,w) = 0 \quad \text{in } \Omega_T, \tag{1.12a}$$

$$w = -c\,\Delta u + \phi(u) \quad \text{in } \Omega_T, \text{ where } u > 0, \tag{1.12b}$$

$$\tfrac{\partial v}{\partial t} + \nabla.(u\,\lambda(v)\,\nabla[\sigma(v)]) - \rho\,\Delta v - \tfrac{1}{2}\,\nabla.(u^2\,\lambda(v)\,\nabla w) = 0 \quad \text{in } \Omega_T, \tag{1.12c}$$

$$u(x,0) = u^0(x), \qquad v(x,0) = v^0(x) \quad \forall\, x \in \Omega, \tag{1.12d}$$

$$\begin{aligned} &\tfrac{1}{2}\, u^2\, \tfrac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}} - \tfrac{1}{3}\, u^3\, \tfrac{\partial w}{\partial\nu_{\partial\Omega}} = \tfrac{\partial u}{\partial\nu_{\partial\Omega}} = u\,\lambda(v)\, \tfrac{\partial[\sigma(v)]}{\partial\nu_{\partial\Omega}} - \tfrac{1}{2}\, u^2\,\lambda(v)\, \tfrac{\partial w}{\partial\nu_{\partial\Omega}} \\ &-\rho\,\tfrac{\partial v}{\partial\nu_{\partial\Omega}} = 0 \quad \text{on } \partial\Omega \times (0,T), \end{aligned} \tag{1.12e}$$

where $\Omega_T := \Omega \times (0,T]$ and $T > 0$ is a fixed positive time. In the above, $c \in \mathbb{R}_{>0}$ and $\rho \in \mathbb{R}_{\geq 0}$ are given constants, while $\phi : \mathbb{R}_{>0} \to \mathbb{R}$ is defined as in (1.10); u^0 and v^0 are given nonnegative initial profiles (e.g., $u^0 \equiv 1$ for a film of uniform thickness and u^0 having support $\subset\subset \Omega$ for a drop). Throughout this paper, we will restrict ourselves to the model case $\sigma(v) := 1 - v$, the $\beta \to \infty$ limit of (1.2). We remark that physically relevant values of $v(x,t)$ lie in the interval $[0,1]$. Noting this, it is convenient for the analysis in this paper to replace the terms $u^i\,v$, $i = 1 \to 2$, in (1.1b) by $u^i\,\lambda(v)$, where $\lambda : \mathbb{R} \to (-\infty, 1]$ is defined as

$$\lambda(s) := [s-1]_- + 1, \qquad \text{with} \qquad [s]_- := \min\{s,\, 0\}. \tag{1.13}$$

As u and $\lambda(v)$ can take on zero values, (P) is a degenerate parabolic system, which is fourth order in u. This degeneracy makes the analysis/numerical analysis of (P) particularly difficult. Although we have assumed a no-slip condition at $y = 0$ in the derivation of (P) (see (1.3)) the results in this paper can easily be generalized to models allowing slip (see [31]).

Let us mention some work on problems that also lead to degenerate parabolic equations of fourth order. In particular, we would like to mention work on the following topics: thin film flow (cf. [9, 19, 10, 8, 11]), the Cahn–Hilliard equation with a degenerate mobility (cf. [14, 16, 17]), and models that describe dislocation densities in plasticity (cf. [20]). An existence result for the system (P) studied in this paper has been given by Wieland [31] in the case of one space dimension.

Problem (P) with $v^0 \equiv 0$ and $\phi \equiv 0$ collapses to the thin film equation, i.e., a degenerate parabolic equation of fourth order. Degenerate parabolic equations of higher order exhibit some new characteristic features which are fundamentally different from those for second order degenerate parabolic equations such as the porous medium equation $\frac{\partial u}{\partial t} - \nabla.(|u|^\alpha \nabla u) = 0$ for a given $\alpha \in \mathbb{R}_{>0}$. The key point is that there is no maximum or comparison principle for parabolic equations of higher order. This drastically complicates the analysis since many results which are known for second order equations are proven with the help of comparison techniques. Related to this is the fact that there is no uniqueness result known for the thin film equation. Although there is no comparison principle, one of the main features of the thin film equation is the fact that one can show existence of nonnegative solutions if given nonnegative initial data. This is in contrast to linear parabolic equations of fourth order, where solutions which are initially positive may become negative in certain regions.

There is very little work on the numerical analysis of degenerate parabolic equations of fourth order; for work on thin film flows in the absence of surfactants, see [4, 32, 22, 21] and for work on degenerate Cahn–Hilliard systems, see [5, 6, 3].

This paper is organized as follows. In section 2 we formulate a fully practical finite element approximation of problem (P). On the discrete level, the nonnegativity of the approximation to u is not guaranteed when we discretize the system (1.12a–e) in a naive way. Following [4], we impose the nonnegativity of the discrete approximation to u as a constraint and require (1.12b) only where u is positive. In addition, in order to derive a discrete analogue of the energy estimate (1.11), we adapt a technique introduced in [32] and [22] for deriving a discrete entropy bound for the thin film equation.

We can derive stability bounds in space dimensions $d = 1$ and 2, but we are only able to show convergence in one space dimension. This is due to the fact that the a priori bounds we derive guarantee in one space dimension only that the discrete approximation to u is uniformly bounded and equicontinuous, which is necessary to be able to pass to the limit in the discrete problem. For similar reasons, the results in [9, 4, 22, 5, 6, 3] were restricted to one space dimension. This convergence is carried out in section 3. A convergence result for a finite element method of the thin film equation in two dimensions has been given recently by Grün [21]. Unfortunately a generalization of Grün's result to the problem presented in this paper does not seem to be possible in a straightforward manner. In section 4, we introduce and analyze algorithms to solve the nonlinear algebraic systems at each time level. Finally, in section 5, we present some numerical computations in one and two space dimensions. We compare the computed discrete solutions with results published in [24, 26] and other papers.

Notation and auxiliary results. We adopt the standard notation for Sobolev spaces, denoting the norm of $W^{m,q}(\Omega)$ ($m \in \mathbb{N}$, $q \in [1,\infty]$) by $\|\cdot\|_{m,q}$ and the seminorm by $|\cdot|_{m,q}$. For $q = 2$, $W^{m,2}(\Omega)$ will be denoted by $H^m(\Omega)$ with the associated norm and seminorm written as, respectively, $\|\cdot\|_m$ and $|\cdot|_m$. Throughout $(\cdot,\cdot)$ denotes the standard L^2 inner product over Ω and $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $\big(H^1(\Omega)\big)'$ and $H^1(\Omega)$. In addition we define

$$(1.14)\qquad ⨍\eta := \tfrac{1}{\underline{m}(\Omega)}\,(\eta,1) \qquad \forall\ \eta \in L^1(\Omega), \qquad \text{where } \underline{m}(\Omega) \text{ is the measure of } \Omega\,.$$

We require also the Hölder space $C^{p_1,p_2}_{x,t}(\overline{\Omega}_T)$ for $p_i \in (0,1]$, which denotes those functions whose time (spatial) derivative(s) is (are) Hölder continuous over $\overline{\Omega}_T$ with exponent $p_1(p_2)$.

For later purposes, we recall the following well-known Sobolev interpolation result (see, e.g., [1]): Let $m \geq 1$, $q \in (\frac{d}{m},\infty]$, $r \in [q,\infty]$, and $\mu := \frac{d}{m}\left(\frac{1}{q} - \frac{1}{r}\right)$. Then there is a constant C depending only on Ω, m, q, r such that

$$(1.15)\qquad |z|_{0,r} \leq C\,|z|_{0,q}^{1-\mu}\,\|z\|_{m,q}^{\mu} \quad \forall\ z \in W^{m,q}(\Omega)\,.$$

It is convenient to introduce the "inverse Laplacian" operator $\mathcal{G} : \mathcal{F} \to Z$ such that

$$(1.16)\qquad (\nabla\mathcal{G}z, \nabla\eta) = \langle z, \eta\rangle \quad \forall\ \eta \in H^1(\Omega),$$

where $\mathcal{F} := \big\{z \in (H^1(\Omega))' : \langle z, 1\rangle = 0\big\}$ and $Z := \{z \in H^1(\Omega) : (z,1) = 0\}$. The well-posedness of $\mathcal{G}$ follows from the Lax–Milgram theorem and the Poincaré inequality

$$(1.17)\qquad |\eta|_{0,q} \leq C\,(\,|\eta|_{1,q} + |(\eta,1)|\,) \quad \forall\ \eta \in W^{1,q}(\Omega) \quad \text{and} \quad q \in [1,\infty].$$

One can define a norm on $\mathcal{F}$ by

$$(1.18)\qquad \|z\|_{-1} := |\mathcal{G}z|_1 = \langle z, \mathcal{G}z\rangle^{\frac{1}{2}} \quad \forall\ z \in \mathcal{F}.$$

We note also for future reference that using Young's inequality

$$(1.19)\qquad r\,s \leq \tfrac{\gamma}{2}\,r^2 + \tfrac{1}{2\gamma}\,s^2 \quad \forall\ r,s \in \mathbb{R},\ \gamma \in \mathbb{R}_{>0}$$

yields for all $\gamma \in \mathbb{R}_{>0}$ that

$$(1.20)\qquad \langle z, \eta\rangle = (\nabla\mathcal{G}z, \nabla\eta) \leq \|z\|_{-1}|\eta|_1 \leq \tfrac{\gamma}{2}\,|\eta|_1^2 + \tfrac{1}{2\gamma}\,\|z\|_{-1}^2 \quad \forall\ z \in \mathcal{F},\ \eta \in H^1(\Omega).$$

Throughout C denotes a generic constant independent of h, τ, and ε, the mesh and temporal discretization parameters and the regularization parameter. In addition, $C(a_1,\ldots,a_I)$ denotes a constant depending on the arguments $\{a_i\}_{i=1}^I$.

2. Finite element approximation. We consider the finite element approximation of (P) at first under the following assumptions on the mesh:

(A) Let Ω be a polygonal domain if $d = 2$. Let $\{\mathcal{T}^h\}_{h>0}$ be a quasi-uniform family of partitionings of Ω into disjoint open simplices κ with $h_\kappa := \text{diam}(\kappa)$ and $h := \max_{\kappa\in\mathcal{T}^h} h_\kappa$ so that $\overline{\Omega} = \cup_{\kappa\in\mathcal{T}^h}\overline{\kappa}$. In addition, it is assumed for $d = 2$ that all simplices $\kappa \in \mathcal{T}^h$ are right-angled.

We note that the quasi uniformity assumption can be avoided at the expense of a mild constraint on the minimum time step; see Remark 3.5 below. Furthermore we note that the right-angled simplices assumption is not a severe constraint, as there exist adaptive finite element codes that satisfy this requirement; see, e.g., [30].

Associated with $\mathcal{T}^h$ is the finite element space $S^h := \{\chi \in C(\overline{\Omega}) : \chi\,|_\kappa$ is linear for all $\kappa \in \mathcal{T}^h\} \subset H^1(\Omega)$. We introduce also $K^h := \{\chi \in S^h : \chi \geq 0 \text{ in } \Omega\} \subset K$, where $K := \{\eta \in H^1(\Omega) : \eta \geq 0 \text{ a.e. in } \Omega\}$. Let J be the set of nodes of $\mathcal{T}^h$ and $\{p_j\}_{j\in J}$ the coordinates of these nodes. Let $\{\chi_j\}_{j\in J}$ be the standard basis functions for S^h; that is, $\chi_j \in K^h$ and $\chi_j(p_i) = \delta_{ij}$ for all $i, j \in J$. We introduce $\pi^h : C(\overline{\Omega}) \to S^h$, the interpolation operator, such that $(\pi^h\eta)(p_j) = \eta(p_j)$ for all $j \in J$. A discrete semi-inner product on $C(\overline{\Omega})$ is then defined by

$$(\eta_1, \eta_2)^h := \int_\Omega \pi^h(\eta_1(x)\,\eta_2(x))\,\mathrm{d}x = \sum_{j\in J} m_j\,\eta_1(p_j)\,\eta_2(p_j), \tag{2.1}$$

where $m_j := (1, \chi_j) > 0$. The induced discrete seminorm is then $|\eta|_h := [\,(\eta,\eta)^h\,]^{\frac{1}{2}}$, where $\eta \in C(\overline{\Omega})$. We introduce also the L^2 projection $Q^h : L^2(\Omega) \to S^h$ defined by

$$(Q^h\eta, \chi)^h = (\eta, \chi) \qquad \forall\ \chi \in S^h. \tag{2.2}$$

In this paper, for simplicity, we consider only the model case when the surface tension is given by $\sigma(s) := 1-s$, which is the limit as $\beta \to \infty$ in (1.2) and is commonly used in the physics/engineering literature (cf. [27]). On recalling (1.4), we then define a function F such that $v\,\nabla[F'(v)] = -\nabla[\sigma(v)]$; that is, $F''(s) = -s^{-1}\,\sigma'(s) = s^{-1} \Rightarrow F(s) = s\,(\ln s - 1) + 1$. For computational purposes, we replace $F \in C^\infty(\mathbb{R}_{>0})$ for any $\varepsilon \in (0,1)$ by the regularized function $F_\varepsilon : \mathbb{R} \to \mathbb{R}_{\geq 0}$ such that

$$F_\varepsilon(s) := \begin{cases} \frac{s^2-\varepsilon^2}{2\,\varepsilon} + (\ln\varepsilon - 1)\,s + 1, & s \leq \varepsilon, \\ s\,(\ln s - 1) + 1, & \varepsilon \leq s \leq 1, \\ \frac{1}{2}\,(s-1)^2, & 1 \leq s\,. \end{cases}$$

Hence $F_\varepsilon \in C^{2,1}(\mathbb{R})$ with the first two derivatives of F_ε given by

$$F_\varepsilon'(s) := \begin{cases} \varepsilon^{-1}\,s + \ln\varepsilon - 1, & s \leq \varepsilon, \\ \ln s, & \varepsilon \leq s \leq 1, \\ s - 1, & 1 \leq s, \end{cases} \quad \text{and} \quad F_\varepsilon''(s) := \begin{cases} \varepsilon^{-1}, & s \leq \varepsilon, \\ s^{-1}, & \varepsilon \leq s \leq 1, \\ 1, & 1 \leq s\,, \end{cases} \tag{2.3}$$

respectively. For later purposes, we note that

$$F_\varepsilon(s) \geq \tfrac{s^2}{4} - \tfrac{1}{2} \quad \forall\ s \geq 0 \qquad \text{and} \qquad F_\varepsilon(s) \geq \tfrac{s^2}{2\,\varepsilon} \quad \forall\ s \leq 0\,. \tag{2.4}$$

This holds since

$$\begin{aligned} F_\varepsilon(s) := \tfrac{1}{2}(s-1)^2 \geq \tfrac{1}{2}(s-1)^2 - (\tfrac{1}{2}s - 1)^2 = \tfrac{s^2}{4} - \tfrac{1}{2} \qquad & \text{if } s \geq 1\,, \\ F_\varepsilon'(s) \leq 0 \quad \Rightarrow \quad F_\varepsilon(s) \geq F_\varepsilon(1) = 0 \geq \tfrac{s^2}{4} - \tfrac{1}{2} \qquad & \text{if } s \in [0,1]\,, \\ F_\varepsilon(s) := \tfrac{s^2-\varepsilon^2}{2\,\varepsilon} + (\ln\varepsilon - 1)\,s + 1 \geq \tfrac{s^2}{2\,\varepsilon} + (1 - \tfrac{\varepsilon}{2}) \geq \tfrac{s^2}{2\,\varepsilon} \qquad & \text{if } s \leq 0\,. \end{aligned}$$

Similarly to the approach in [32] and [22], we introduce $\Lambda_\varepsilon : S^h \to [L^\infty(\Omega)]^{d\times d}$ such that for all $z^h \in S^h$ and a.e. in Ω,

$$\Lambda_\varepsilon(z^h) \text{ is symmetric and positive semidefinite and } \Lambda_\varepsilon(z^h)\,\nabla\pi^h[F_\varepsilon'(z^h)] = \nabla z^h. \tag{2.5}$$

Following [22], we now give the construction of Λ_ε. Let $\{e_i\}_{i=1}^d$ be the orthonormal vectors in $\mathbb{R}^d$ such that the jth component of e_i is δ_{ij}, i, $j = 1 \to d$. Given nonzero constants α_i, $i = 1 \to d$, let $\widehat{\kappa}(\{\alpha_i\}_{i=1}^d)$ be the reference open simplex in $\mathbb{R}^d$ with vertices $\{\widehat{p}_i\}_{i=0}^d$, where $\widehat{p}_0$ is the origin and $\widehat{p}_i = \alpha_i\, e_i$, $i = 1 \to d$. Given a $\kappa \in \mathcal{T}^h$ with vertices $\{p_{j_i}\}_{i=0}^d$ such that p_{j_0} is the right-angled vertex, there exist a rotation matrix R_κ and nonzero constants $\{\alpha_i\}_{i=1}^d$ such that the mapping $\mathcal{R}_\kappa : \widehat{x} \in \mathbb{R}^d \to p_{j_0} + R_\kappa \widehat{x} \in \mathbb{R}^d$ maps the vertex $\widehat{p}_i$ to p_{j_i}, $i = 0 \to d$, and hence $\widehat{\kappa} \equiv \widehat{\kappa}(\{\alpha_i\}_{i=1}^d)$ to κ. For any $z^h \in S^h$, we then set

$$\Lambda_\varepsilon(z^h)\,|_\kappa := R_\kappa\, \widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\kappa}}\, R_\kappa^T, \tag{2.6}$$

where $\widehat{z}^h(\widehat{x}) \equiv z^h(\mathcal{R}_\kappa \widehat{x})$ for all $\widehat{x} \in \overline{\widehat{\kappa}}$ and $\widehat{\Lambda}_\varepsilon(\widehat{z}^h)\,|_{\widehat{\kappa}}$ is the $d \times d$ diagonal matrix with diagonal entries, $k = 1 \to d$,

$$[\widehat{\Lambda}_\varepsilon(\widehat{z}^h)]_{kk}\,|_{\widehat{\kappa}} := \begin{cases} \frac{\widehat{z}^h(\widehat{p}_k) - \widehat{z}^h(\widehat{p}_0)}{F'_\varepsilon(\widehat{z}^h(\widehat{p}_k)) - F'_\varepsilon(\widehat{z}^h(\widehat{p}_0))} \equiv \frac{z^h(p_{j_k}) - z^h(p_{j_0})}{F'_\varepsilon(z^h(p_{j_k})) - F'_\varepsilon(z^h(p_{j_0}))} & \text{if } z^h(p_{j_k}) \neq z^h(p_{j_0}), \\ \frac{1}{F''_\varepsilon(\widehat{z}^h(\widehat{p}_0))} \equiv \frac{1}{F''_\varepsilon(z^h(p_{j_0}))} & \text{if } z^h(p_{j_k}) = z^h(p_{j_0}). \end{cases} \tag{2.7}$$

As $R_\kappa^T \equiv R_\kappa^{-1}$, $\nabla z^h \equiv R_\kappa\, \widehat{\nabla} \widehat{z}^h$, where $x \equiv (x_1, \ldots, x_d)^T$, $\nabla \equiv (\frac{\partial}{\partial x_1}, \ldots, \frac{\partial}{\partial x_d})^T$, $\widehat{x} \equiv (\widehat{x}_1, \ldots, \widehat{x}_d)^T$, and $\widehat{\nabla} \equiv (\frac{\partial}{\partial \widehat{x}_1}, \ldots, \frac{\partial}{\partial \widehat{x}_d})^T$, it easily follows that $\Lambda_\varepsilon(z^h)$ constructed in (2.6) and (2.7) satisfies (2.5). It is this construction that requires the right angle constraint on the partitioning $\mathcal{T}^h$. Furthermore, we note from (2.3) that for all $\kappa \in \mathcal{T}^h$,

$$\begin{aligned} \nabla z^h . \nabla \pi^h[F'_\varepsilon(z^h)]\,|_\kappa &\equiv R_\kappa \widehat{\nabla} \widehat{z}^h . R_\kappa \widehat{\nabla} \widehat{\pi}^h[F'_\varepsilon(\widehat{z}^h)]\,|_{\widehat{\kappa}} \\ &\equiv \widehat{\nabla} \widehat{z}^h . \widehat{\nabla} \widehat{\pi}^h[F'_\varepsilon(\widehat{z}^h)]\,|_{\widehat{\kappa}} \geq |\widehat{\nabla} \widehat{z}^h|^2\,|_{\widehat{\kappa}} \equiv |\nabla z^h|^2\,|_\kappa \\ \Longrightarrow \quad (\nabla z^h, \nabla \pi^h[F'_\varepsilon(z^h)]) &\geq |z^h|_1^2 \qquad \forall\ z^h \in S^h, \end{aligned} \tag{2.8}$$

where $(\widehat{\pi}^h \widehat{\eta})(\widehat{x}) \equiv (\pi^h \eta)(\mathcal{R}_\kappa \widehat{x})$ and $\widehat{\eta}(\widehat{x}) \equiv \eta(\mathcal{R}_\kappa \widehat{x})$ for all $\widehat{x} \in \overline{\widehat{\kappa}}$.

To define our approximation of (P), it is convenient to split Φ (recall (1.11)) into its convex and concave parts. We have for given a, $\delta \in \mathbb{R}_{\geq 0}$, and $\nu > 3$ that for all $s \in \mathbb{R}_{>0}$

$$\begin{aligned} \Phi(s) &= \Phi^+(s) + \Phi^-(s), && \text{where} \quad \Phi^+(s) := \tfrac{\delta}{\nu - 1}\, s^{1-\nu}, \quad \Phi^-(s) := -\tfrac{a}{2}\, s^{-2}, \\ \phi(s) &= \Phi'(s) = \phi^+(s) + \phi^-(s), && \text{where} \quad \phi^+(s) := (\Phi^+)'(s) = -\delta\, s^{-\nu}, \\ & && \phantom{\text{where}} \quad \phi^-(s) := (\Phi^-)'(s) = a\, s^{-3}. \end{aligned} \tag{2.9}$$

For future reference, we note that the following hold for all $s \in \mathbb{R}_{>0}$:

$$\Phi(s) \geq \Phi(\,(\tfrac{\delta}{a})^{\frac{1}{\nu-3}}) = \tfrac{a\,(3-\nu)}{2\,(\nu-1)} (\tfrac{a}{\delta})^{\frac{2}{\nu-3}} \quad \text{and} \quad |\Phi^-(s)| \leq \tfrac{a\,(\nu-3)}{2\,(\nu-1)} (\tfrac{2\,a}{\delta})^{\frac{2}{\nu-3}} + \tfrac{1}{2}\, \Phi^+(s). \tag{2.10}$$

In addition to $\mathcal{T}^h$, let $0 = t_0 < t_1 < \cdots < t_{N-1} < t_N = T$ be a partitioning of $[0, T]$ into possibly variable time steps $\tau_n := t_n - t_{n-1}$, $n = 1 \to N$. We set $\tau := \max_{n=1 \to N} \tau_n$. For any given $\varepsilon \in (0, 1)$, we then consider the following fully practical finite element approximation of (P) with $\sigma(v) := 1 - v$ and $\delta = 0\,(\phi^+ \equiv 0)$.

$(\mathrm{P}_{\varepsilon}^{h,\tau})$ For $n \geq 1$ find $\{U_{\varepsilon}^{n}, W_{\varepsilon}^{n}, V_{\varepsilon}^{n}\} \in K^h \times [S^h]^2$ such that for all $\chi \in S^h$, $z^h \in K^h$,

$$\left(\frac{U_{\varepsilon}^{n}-U_{\varepsilon}^{n-1}}{\tau_n}, \chi\right)^h + \tfrac{1}{3}\left(\pi^h[(U_{\varepsilon}^{n-1})^3]\,\nabla W_{\varepsilon}^{n}, \nabla\chi\right) = -\tfrac{1}{2}\,(\pi^h[(U_{\varepsilon}^{n-1})^2]\nabla V_{\varepsilon}^{n-1}, \nabla\chi), \tag{2.11a}$$

$$c\,(\nabla U_{\varepsilon}^{n}, \nabla(z^h - U_{\varepsilon}^{n})) + (\phi^-(U_{\varepsilon}^{n-1}+\varepsilon), z^h - U_{\varepsilon}^{n})^h \geq (W_{\varepsilon}^{n}, z^h - U_{\varepsilon}^{n})^h, \tag{2.11b}$$

$$\begin{aligned}\left(\frac{V_{\varepsilon}^{n}-V_{\varepsilon}^{n-1}}{\tau_n}, \chi\right)^h &+ \rho\,(\nabla V_{\varepsilon}^{n}, \nabla\chi) + (U_{\varepsilon}^{n}\,\Lambda_{\varepsilon}(V_{\varepsilon}^{n})\,\nabla V_{\varepsilon}^{n}, \nabla\chi)\\ &= -\tfrac{1}{2}\,(\pi^h[(U_{\varepsilon}^{n})^{\frac{1}{2}}\,(U_{\varepsilon}^{n-1})^{\frac{3}{2}}]\,\Lambda_{\varepsilon}(V_{\varepsilon}^{n})\,\nabla W_{\varepsilon}^{n}, \nabla\chi),\end{aligned} \tag{2.11c}$$

where $U_{\varepsilon}^{0} \in K^h$ and $V_{\varepsilon}^{0} \in S^h$ are approximations of u^0 and v^0, respectively; e.g., $U_{\varepsilon}^{0} \equiv \pi^h u^0$ or $Q^h u^0$ and similarly V_{ε}^{0}.

If $a = 0\,(\phi^- \equiv 0)$, then setting $V_{\varepsilon}^{n} \equiv 0$, $n = 0 \to N$, (2.11a,b) collapses to the approximation of the thin film equation, (1.12a–e) with $v \equiv 0$, studied in [4], except that there $\pi^h[(U_{\varepsilon}^{n-1})^3]$ in (2.11a) is replaced by $(U_{\varepsilon}^{n-1})^3$ and so is less practical than (2.11a). If $\delta > 0\,(\phi^+ \not\equiv 0)$, then $(\mathrm{P}_{\varepsilon}^{h,\tau})$ above is modified as follows.

$(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$ For $n \geq 1$ find $\{U_{\varepsilon}^{n}, W_{\varepsilon}^{n}, V_{\varepsilon}^{n}\} \in [S^h]^3$ such that (2.11a,c) hold with (2.11b) replaced by

$$c\,(\nabla U_{\varepsilon}^{n}, \nabla\chi) + (\phi^+(U_{\varepsilon}^{n}) + \phi^-(U_{\varepsilon}^{n-1}), \chi)^h = (W_{\varepsilon}^{n}, \chi)^h \quad \forall\, \chi \in S^h\,, \tag{2.12}$$

where in addition it is assumed that $U_{\varepsilon}^{0} > 0$.

Note that the convex (concave) terms in Φ are approximated implicitly (explicitly) in (2.11b) and (2.12). If $\delta = 0$, we can guarantee only that $U_{\varepsilon}^{n-1} \geq 0$ and hence the choice of $\phi^-(U_{\varepsilon}^{n-1}+\varepsilon)$ instead of $\phi^-(U_{\varepsilon}^{n-1})$ on the left-hand side of (2.11b). Whereas if $\delta > 0$ and $U_{\varepsilon}^{0} > 0$, one can ensure that $\phi^-(U_{\varepsilon}^{n-1})$ is well defined for $n \geq 1$; see Theorem 2.6 below.

Below we recall some well-known results concerning S^h for any $\kappa \in \mathcal{T}^h$, $\chi, z^h \in S^h$, $\eta_1, \eta_2 \in C(\overline{\Omega})$ and for $m = 0$ or 1:

$$\lim_{h\to 0} |(I - \pi^h)\eta_1|_{0,\infty} = 0\,, \tag{2.13}$$

$$\textstyle\int_{\kappa} \chi^2\,\mathrm{d}x \leq \int_{\kappa} \pi^h[\chi^2]\,\mathrm{d}x \leq (d+2)\,\int_{\kappa} \chi^2\,\mathrm{d}x\,, \tag{2.14}$$

$$\textstyle\int_{\kappa} \pi^h[\eta_1\eta_2]\,\nabla\chi.\nabla z^h\,\mathrm{d}x \leq \left[\int_{\kappa} \pi^h[\eta_1^2]\,|\nabla\chi|^2\,\mathrm{d}x\right]^{\frac{1}{2}}\,\left[\int_{\kappa} \pi^h[\eta_2^2]\,|\nabla z^h|^2\,\mathrm{d}x\right]^{\frac{1}{2}}\,, \tag{2.15}$$

$$|\pi^h[\eta_1\eta_2](x)\,|^2 \leq |\pi^h\eta_1|_{0,\infty}^2\,\pi^h[\eta_2^2](x) \quad \forall\, x \in \overline{\Omega}; \tag{2.16}$$

$$|(\chi, z^h) - (\chi, z^h)^h| \leq |(I - \pi^h)(\chi\, z^h)|_{0,1} \;\leq\; C\,h^{1+m}\,|\chi|_m\,|z^h|_1\,. \tag{2.17}$$

If $d = 1$, then we have for $m = 0$ or 1 that

$$|(I - \pi^h)\eta|_{m,r} \leq C\,h^{1-m}\,|\eta|_{1,r} \quad \forall\, \eta \in W^{1,r}(\Omega), \quad \text{for any } r \in [1,\infty]; \tag{2.18}$$

$$\lim_{h\to 0} \|(I - \pi^h)\eta\|_1 = 0 \qquad \forall\, \eta \in H^1(\Omega). \tag{2.19}$$

It follows from (2.2) that

$$(Q^h\eta)(p_j) = \tfrac{(\eta,\chi_j)}{(1,\chi_j)} \quad \forall\, j \in J \quad\Longrightarrow\quad |Q^h\eta|_{0,\infty} \leq |\eta|_{0,\infty} \quad \forall\, \eta \in L^{\infty}(\Omega). \tag{2.20}$$

Finally, as we have a quasi-uniform family of partitionings, it holds for $m = 0$ or 1 that

$$|(I - Q^h)\eta|_m \leq C\,h^{1-m}\,\|\eta\|_1 \quad \forall\, \eta \in H^1(\Omega). \tag{2.21}$$

We define $Z^h := \{z^h \in S^h : (z^h, 1) = 0\} \subset \mathcal{F}^h := \{z \in C(\overline{\Omega}) : (z, 1)^h = 0\}$. Then, similarly to (1.16), we introduce $\mathcal{G}^h : \mathcal{F}^h \to Z^h$ such that

$$(\nabla \mathcal{G}^h z, \nabla \chi) = (z, \chi)^h \quad \forall\, \chi \in S^h\,. \tag{2.22}$$

It is easily established, as we have a quasi-uniform family of partitionings, that

$$|z^h|_0 \leq C\, h^{-1}\, |\mathcal{G} z^h|_1 \quad \forall\, z^h \in Z^h. \tag{2.23}$$

We now adapt and extend the approach in [4] to establish the existence of a solution $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\}_{n=1}^N$ to $(\mathrm{P}_\varepsilon^{h,\tau})$. First, we need to introduce some notation. In particular, we define sets $Z^h(U_\varepsilon^{n-1})$ in which we seek the update $U_\varepsilon^n - U_\varepsilon^{n-1}$. Given $q^h \in K^h$, we set $J_0(q^h) := \{j \in J : (\pi^h[(q^h)^3], \chi_j) = 0\}$. All other nodes we call active nodes, and they can be uniquely partitioned so that $J_+(q^h) := J \setminus J_0(q^h) = \bigcup_{m=1}^M I_m(q^h)$, $M \geq 1$, where $I_m(q^h)$, $m = 1 \to M$, are mutually disjoint and maximally connected in the following sense: $I_m(q^h)$ is said to be connected if for all j, $k \in I_m(q^h)$, there exist $\{\kappa_\ell\}_{\ell=1}^L \subseteq \mathcal{T}^h$, not necessarily distinct, such that

$$p_j \in \overline{\kappa}_1,\ p_k \in \overline{\kappa}_L; \qquad \overline{\kappa}_\ell \cap \overline{\kappa}_{\ell+1} \neq \emptyset,\ \ell = 1 \to L-1; \qquad q^h \not\equiv 0 \text{ on } \kappa_\ell,\ \ell = 1 \to L.$$

$I_m(q^h)$ is said to be maximally connected if there is no other connected subset of $J_+(q^h)$, which contains $I_m(q^h)$. We then set

$$\begin{aligned} Z^h(q^h) := \{z^h \in S^h : z^h(p_j) = 0 \ \ \forall\, j \in J_0(q^h) \quad \text{and} \\ (z^h, \Xi_m(q^h))^h = 0,\ m = 1 \to M\,\}, \end{aligned} \tag{2.24}$$

where $\Xi_m(q^h) := \sum_{j \in I_m(q^h)} \chi_j$ for $m = 1 \to M$. An immediate consequence of the above definitions is that on any $\kappa \in \mathcal{T}^h$ either

$$q^h \equiv 0 \qquad \text{or} \qquad \Xi_{m_\star}(q^h) \equiv 1 \text{ for some } m_\star \text{ and } \Xi_m(q^h) \equiv 0 \text{ for } m \neq m_\star. \tag{2.25}$$

This follows since if $q^h \not\equiv 0$ on κ, then all vertices of κ belong to the set of active nodes $J_+(q^h)$. Using the fact that $I_m(q^h)$, $m = 1 \to M$, are maximally connected, we can conclude that there exists an $m_\star$ such that all vertices of κ belong to $I_{m_\star}(q^h)$ and therefore, $\Xi_{m_\star}(q^h) \equiv 1$ on κ. The desired result now follows since $I_m(q^h)$, $m = 1 \to M$, are mutually disjoint.

For later reference, we state that any $z^h \in S^h$ can be written as

$$z^h \equiv \sum_{j \in J} z^h(p_j)\, \chi_j \ \equiv\ \overline{z}^h + \sum_{j \in J_0(q^h)} z^h(p_j)\, \chi_j + \sum_{m=1}^M \frac{(z^h, \Xi_m(q^h))^h}{(1, \Xi_m(q^h))}\, \Xi_m(q^h), \tag{2.26}$$

where $\overline{z}^h := \sum_{m=1}^M \sum_{j \in I_m(q^h)} [z^h(p_j) - \frac{(z^h, \Xi_m(q^h))^h}{(1, \Xi_m(q^h))}] \chi_j \in Z^h(q^h)$ is the projection with respect to the $(\cdot,\cdot)^h$ scalar product of z^h onto $Z^h(q^h)$. In order to express W_ε^n in terms of U_ε^n and U_ε^{n-1}, we introduce for all $q^h \in K^h$ the discrete anisotropic Green's operator $\mathcal{G}_{q^h}^h : Z^h(q^h) \to Z^h(q^h)$ such that

$$(\pi^h[(q^h)^3]\, \nabla \mathcal{G}_{q^h}^h z^h, \nabla \chi) = (z^h, \chi)^h \qquad \forall\, \chi \in S^h. \tag{2.27}$$

To show the well-posedness of $\mathcal{G}_{q^h}^h$, we first note that on choosing $\chi \equiv \chi_j$, $j \in J_0(q^h)$, in (2.27) leads to both sides vanishing on noting (2.24). Similarly, choosing $\chi \equiv \Xi_m(q^h)$,

$m = 1 \to M$, in (2.27) leads to both sides vanishing on noting (2.25) and (2.24). Therefore, for well-posedness, it remains to prove uniqueness as $Z^h(q^h)$ has finite dimension. If there exist two solutions $Z^{(i)}$, $i = 1, 2$, with $(\pi^h[(q^h)^3]\,\nabla Z^{(i)}, \nabla\chi) = (z^h, \chi)^h$ for all $\chi \in S^h$, then $Z := Z^{(2)} - Z^{(1)} \in Z^h(q^h)$ satisfies, on noting (2.25),

$$C(q^h, h) \sum_{m=1}^{M} \int_{\Omega_m} |\nabla Z|^2 \,\mathrm{d}x \le \sum_{m=1}^{M} \int_{\Omega_m} \pi^h[(q^h)^3]\,|\nabla Z|^2 \,\mathrm{d}x = \int_{\Omega} \pi^h[(q^h)^3]\,|\nabla Z|^2 \,\mathrm{d}x = 0$$

for some positive constant $C(q^h, h)$, where $\Omega_m := \{\cup_{\kappa \in \mathcal{T}^h} \overline{\kappa} : \Xi_m(q^h)|_\kappa \equiv 1\}$. Hence it follows that Z is constant on each Ω_m. However, as $Z \in Z^h(q^h)$, it follows that $Z \equiv 0$. Finally, note that $Z^h(q^h) \subseteq Z^h$ for all $q^h \in K^h$ and in addition that $Z^h(q^h)$ defined in (2.24) is equal to Z^h if q^h is strictly positive.

LEMMA 2.1. *Let the assumptions* (A) *hold, and let* $\|\cdot\|$ *denote the spectral norm on* $\mathbb{R}^{d\times d}$. *Then for any given* $\varepsilon \in (0, 1)$, *the function* $\Lambda_\varepsilon : S^h \to [L^\infty(\Omega)]^{d\times d}$ *satisfies*

$$\varepsilon\,\xi^T\xi \le \xi^T \Lambda_\varepsilon(z^h)\xi \le \xi^T\xi \qquad \forall\ \xi \in \mathbb{R}^d, \quad \forall\ z^h \in S^h \tag{2.28}$$

and is continuous. In particular, it holds for all z_1^h, $z_2^h \in S^h$, $\kappa \in \mathcal{T}^h$ *that*

$$\begin{aligned}
\|[\Lambda_\varepsilon(z_1^h) - \Lambda_\varepsilon(z_2^h)]\,|_\kappa\,\| &= \|[\widehat{\Lambda}_\varepsilon(\widehat{z}_1^h) - \widehat{\Lambda}_\varepsilon(\widehat{z}_2^h)]\,|_{\widehat{\kappa}}\,\| \\
&\le \max_{s\in\mathbb{R}} F_\varepsilon''(s)\ \max_{s\in\mathbb{R}} [F_\varepsilon''(s)]^{-1} \max_{k=1\to d} \left[\,|z_1^h(p_{j_k}) - z_2^h(p_{j_k})| + |z_1^h(p_{j_0}) - z_2^h(p_{j_0})|\,\right] \\
&\le \varepsilon^{-1} \max_{k=1\to d} \left[\,|z_1^h(p_{j_k}) - z_2^h(p_{j_k})| + |z_1^h(p_{j_0}) - z_2^h(p_{j_0})|\,\right],
\end{aligned} \tag{2.29}$$

where we have adopted the notation of (2.6) *and* (2.7).

Proof. It follows immediately from (2.6), (2.7), and (2.3) that (2.28) holds. The proof of (2.29) is a straightforward adaptation of the proof of Lemma 2.1 in [7], where a similar inequality is shown for a slightly modified F_ε. □

THEOREM 2.2. *Let the assumptions* (A) *hold and* $U_\varepsilon^{n-1} \in K^h$, $V_\varepsilon^{n-1} \in S^h$. *Then for all* $\varepsilon \in (0, 1)$ *and for all* h, $\tau_n > 0$, *there exists a solution* $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\}$ *to the* n*th step of* $(\mathrm{P}_\varepsilon^{h,\tau})$ *with* $⨍ U_\varepsilon^n = ⨍ U_\varepsilon^{n-1}$ *and* $⨍ V_\varepsilon^n = ⨍ V_\varepsilon^{n-1}$. *Moreover,* U_ε^n *is unique. In addition,* $W^n(p_j)$ *is unique if* $(\pi^h[(U_\varepsilon^{n-1})^3], \chi_j) > 0$ *for all* $j \in J$.

Proof. For $n \ge 1$, given $U_\varepsilon^{n-1} \in K^h$, $V_\varepsilon^{n-1} \in S^h$, we define $X_\varepsilon^{n-1} \in Z^h(U_\varepsilon^{n-1})$ such that

$$(X_\varepsilon^{n-1}, \chi)^h := \tfrac{1}{2}\,(\pi^h[(U_\varepsilon^{n-1})^2]\,\nabla V_\varepsilon^{n-1}, \nabla\chi) \qquad \forall\ \chi \in S^h\,. \tag{2.30}$$

It follows from (2.11a), (2.27), and (2.30) that we seek $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$, where for all $q^h \in K^h$

$$S^h(q^h) := \{\,\chi \in S^h : \chi - q^h \in Z^h(q^h)\,\} \qquad \text{and} \qquad K^h(q^h) := S^h(q^h) \cap K^h. \tag{2.31}$$

In addition, we have that (cf. (2.26))

$$W_\varepsilon^n \equiv -3\,\mathcal{G}^h_{U_\varepsilon^{n-1}} \left[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n} + X_\varepsilon^{n-1}\right] + \sum_{j\in J_0(U_\varepsilon^{n-1})} \alpha_j^n\,\chi_j + \sum_{m=1}^{M} \beta_m^n\,\Xi_m(U_\varepsilon^{n-1}), \tag{2.32}$$

where $\{\alpha_j^n\}_{j\in J_0(U_\varepsilon^{n-1})}$ and $\{\beta_m^n\}_{m=1}^M$ are arbitrary constants. Hence (2.11a) and (2.11b) can be restated as follows.

For $n \geq 1$, find $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$ and constant Lagrange multipliers $\{\alpha_j^n\}_{j\in J_0(U_\varepsilon^{n-1})}$, $\{\beta_m^n\}_{m=1}^M$ such that

$$\begin{aligned} & c\,(\nabla U_\varepsilon^n, \nabla(\chi - U_\varepsilon^n)) + 3\,\left(\mathcal{G}^h_{U_\varepsilon^{n-1}}\left[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}\right], \chi - U_\varepsilon^n\right)^h \\ & \qquad \geq \left(\sum_{j\in J_0(U_\varepsilon^{n-1})} \alpha_j^n\,\chi_j + \sum_{m=1}^M \beta_m^n\,\Xi_m(U_\varepsilon^{n-1}) + \overline{X}_\varepsilon^{n-1}, \chi - U_\varepsilon^n\right)^h \quad \forall\, \chi \in K^h, \end{aligned} \tag{2.33}$$

where $\overline{X}_\varepsilon^{n-1} \in S^h$ is such that

$$(\overline{X}_\varepsilon^{n-1}, \chi)^h := -(\phi^-(U_\varepsilon^{n-1} + \varepsilon) + 3\,\mathcal{G}^h_{U_\varepsilon^{n-1}}\,X_\varepsilon^{n-1}, \chi)^h \qquad \forall\, \chi \in S^h\,.$$

It follows from (2.33), (2.31), and (2.24) that $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$ is such that

$$A_{U_\varepsilon^{n-1}}(U_\varepsilon^n, \widetilde{z}^h - U_\varepsilon^n) \geq (\overline{X}_\varepsilon^{n-1}, \widetilde{z}^h - U_\varepsilon^n)^h \qquad \forall\, \widetilde{z}^h \in K^h(U_\varepsilon^{n-1}), \tag{2.34}$$

where $A_{U_\varepsilon^{n-1}} : S^h(U_\varepsilon^{n-1}) \times S^h \to \mathbb{R}$ is defined by

$$A_{U_\varepsilon^{n-1}}(z^h, \chi) := c\,(\nabla z^h, \nabla \chi) + 3\,(\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{z^h - U_\varepsilon^{n-1}}{\tau_n}], \chi)^h \quad \forall\, z^h \in S^h(U_\varepsilon^{n-1}),\ \chi \in S^h. \tag{2.35}$$

There exists $U_\varepsilon^n \in K^h(U_\varepsilon^{n-1})$ satisfying (2.34) since, on noting (2.27), this is the Euler–Lagrange variational inequality of the convex minimization problem

$$\min_{\widetilde{z}^h \in K^h(U_\varepsilon^{n-1})} \left\{ \tfrac{c}{2}\,|\widetilde{z}^h|_1^2 + \tfrac{3}{2\tau_n}\,|[\pi^h[(U_\varepsilon^{n-1})^3]]^{\frac{1}{2}}\,\nabla\mathcal{G}^h_{U_\varepsilon^{n-1}}(\widetilde{z}^h - U_\varepsilon^{n-1})|_0^2 - (\overline{X}_\varepsilon^{n-1}, \widetilde{z}^h)^h \right\}. \tag{2.36}$$

Furthermore, given any $z^h \in K^h$, similarly to (2.26) there exists a $\zeta \in \mathbb{R}_{>0}$ such that

$$\begin{aligned} \widetilde{z}^h &:= U_\varepsilon^n + \zeta\,\left\{ (z^h - U_\varepsilon^n) - \sum_{j\in J_0(U_\varepsilon^{n-1})} (z^h - U_\varepsilon^n)(p_j)\,\chi_j \right. \\ & \qquad\qquad \left. - \sum_{m=1}^M \frac{(z^h - U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h}{(U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h}\,\pi^h[U_\varepsilon^n\,\Xi_m(U_\varepsilon^{n-1})] \right\} \\ & \equiv \pi^h\left[\left(1 - \zeta\left(1 + \sum_{m=1}^M \frac{(z^h - U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h}{(U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h}\,\Xi_m(U_\varepsilon^{n-1})\right)\right)\,U_\varepsilon^n\right] \\ & \qquad\qquad + \ \zeta\,\left(z^h - \sum_{j\in J_0(U_\varepsilon^{n-1})} z^h(p_j)\,\chi_j\right) \in K^h(U_\varepsilon^{n-1}). \end{aligned} \tag{2.37}$$

Here we have used that $\Xi_m(U_\varepsilon^{n-1})(p_j) = U_\varepsilon^n(p_j) = 0$ for all $j \in J_0(U_\varepsilon^{n-1})$, and $(\pi^h[U_\varepsilon^n\,\Xi_m(U_\varepsilon^{n-1})], \Xi_m(U_\varepsilon^{n-1}))^h = (U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h = (U_\varepsilon^{n-1}, \Xi_m(U_\varepsilon^{n-1}))^h > 0$ for

$m = 1 \to M$. For all $z^h \in K^h$, choosing $\widetilde{z}^h \in K^h(U_\varepsilon^{n-1})$ (as constructed in (2.37)) in (2.34) yields the existence of a solution to (2.33) with

$$\alpha_j^n = \frac{A_{U_\varepsilon^{n-1}}(U_\varepsilon^n, \chi_j) - (\overline{X}_\varepsilon^{n-1}, \chi_j)^h}{(1, \chi_j)} \qquad \forall\ j \in J_0(U_\varepsilon^{n-1})$$

and

$$\beta_m^n = \frac{A_{U_\varepsilon^{n-1}}(U_\varepsilon^n, \pi^h[U_\varepsilon^n\, \Xi_m(U_\varepsilon^{n-1})]) - (\overline{X}_\varepsilon^{n-1}, U_\varepsilon^n\, \Xi_m(U_\varepsilon^{n-1}))^h}{(U_\varepsilon^n, \Xi_m(U_\varepsilon^{n-1}))^h} \quad m = 1 \to M.$$

Therefore, on noting (2.32), we have the existence of a solution $\{U_\varepsilon^n, W_\varepsilon^n\}$ to $(\mathrm{P}_\varepsilon^{h,\tau})$ with $⨍ U_\varepsilon^n = ⨍ U_\varepsilon^{n-1}$.

To prove the existence of V_ε^n, we will make use of the *Brouwer fixed point theorem* (see, e.g., [29, Theorem 9.36, p. 357]). Let $\mathcal{J} := \#J$, and let $g : \mathbb{R}^{\mathcal{J}} \to \mathbb{R}^{\mathcal{J}}$ be defined by

$$\begin{aligned} g_j(\underline{V}) :=& (V, \chi_j)^h + \rho\, \tau_n\, (\nabla V, \nabla \chi_j) + \tau_n\, (U_\varepsilon^n\, \Lambda_\varepsilon(V)\, \nabla V, \nabla \chi_j) \\ &+ \tfrac{\tau_n}{2}\, (\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\, (U_\varepsilon^{n-1})^{\frac{3}{2}}]\, \Lambda_\varepsilon(V)\, \nabla W_\varepsilon^n, \nabla \chi_j) \qquad \forall\ j \in J\,, \end{aligned}$$

where $V \equiv \sum_{j \in J} V_j\, \chi_j$ and $\underline{V} := (V_1, \ldots, V_{\mathcal{J}})^T \in \mathbb{R}^{\mathcal{J}}$. Noting Lemma 2.1, we have that g is continuous, and hence it is sufficient to show that g is coercive. We have that

$$\begin{aligned} \sum_{j \in J} g_j(\underline{V})\, V_j =& |V|_h^2 + \rho\, \tau_n\, |V|_1^2 + \tau_n\, (U_\varepsilon^n\, \Lambda_\varepsilon(V)\, \nabla V, \nabla V) \\ &+ \tfrac{\tau_n}{2}\, (\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\, (U_\varepsilon^{n-1})^{\frac{3}{2}}]\, \Lambda_\varepsilon(V)\, \nabla W_\varepsilon^n, \nabla V) \quad \forall\ V \in S^h\,. \end{aligned} \tag{2.38}$$

From (1.19), (2.15), and (2.28), we have

$$\begin{aligned} \tfrac{\tau_n}{2} & \left| (\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\, (U_\varepsilon^{n-1})^{\frac{3}{2}}]\, \Lambda_\varepsilon(V)\, \nabla W_\varepsilon^n, \nabla V) \right| \\ &\leq \tfrac{\tau_n}{2}\, (U_\varepsilon^n\, \Lambda_\varepsilon(V)\, \nabla V, \nabla V) + \tfrac{\tau_n}{8}\, (\pi^h[(U_\varepsilon^{n-1})^3]\, \Lambda_\varepsilon(V)\, \nabla W_\varepsilon^n, \nabla W_\varepsilon^n) \\ &\leq \tfrac{\tau_n}{2}\, (U_\varepsilon^n\, \Lambda_\varepsilon(V)\, \nabla V, \nabla V) + C(\tau_n,\, U_\varepsilon^{n-1},\, W_\varepsilon^n)\,. \end{aligned} \tag{2.39}$$

It follows from (2.38), (2.39), and (2.28) that

$$\sum_{j \in J} g_j(\underline{V})\, V_j \geq |V|_h^2 - C(\tau_n,\, U_\varepsilon^{n-1},\, W_\varepsilon^n) \qquad \forall\ V \in S^h\,. \tag{2.40}$$

Hence the coerciveness of g follows from (2.40) and (2.1). Therefore, on noting the aforementioned theorem, we have the existence of V_ε^n to (2.11c) and hence the existence of a solution $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\}$ to $(\mathrm{P}_\varepsilon^{h,\tau})$. Choosing $\chi \equiv 1$ in (2.11c) yields that $⨍ V_\varepsilon^n = ⨍ V_\varepsilon^{n-1}$.

If (2.33) has two solutions $\{\, U_\varepsilon^{n,i},\ \{\alpha_j^{n,i}\}_{j \in J_0(U_\varepsilon^{n-1})},\ \{\beta_m^{n,i}\}_{m=1}^M \,\}$, $i = 1, 2$, then it follows from (2.34) and (2.27) that $\widetilde{U}_\varepsilon^n := U_\varepsilon^{n,1} - U_\varepsilon^{n,2} \in Z^h(U_\varepsilon^{n-1})$ satisfies

$$c\, |\widetilde{U}_\varepsilon^n|_1^2 + 3\, \tau_n^{-1}\, |[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\, \nabla(\mathcal{G}_{U_\varepsilon^{n-1}}^h \widetilde{U}_\varepsilon^n)|_0^2 \leq 0.$$

Therefore, the uniqueness of U^n_ε follows from (1.17). For any $\zeta \in (0,1)$, choosing $\chi \equiv U^n_\varepsilon \pm \zeta\, \pi^h[U^n_\varepsilon\, \Xi_m(U^{n-1}_\varepsilon)] \equiv \pi^h[\,(1 \pm \zeta\, \Xi_m(U^{n-1}_\varepsilon))\, U^n_\varepsilon\,]$ in (2.33) for $m = 1 \to M$ yields the uniqueness of the Lagrange multipliers $\{\beta^n_m\}^M_{m=1}$. Hence the desired uniqueness result on W^n_ε follows from noting (2.32). □

LEMMA 2.3. *Let the assumptions of Theorem* 2.2 *hold. Then for all* $\varepsilon \in (0,1)$ *and for all* h, $\tau_n > 0$ *a solution* $\{U^n_\varepsilon, W^n_\varepsilon, V^n_\varepsilon\}$ *to the nth step of* $(\mathrm{P}^{h,\tau}_\varepsilon)$ *is such that*

$$\begin{aligned}\mathcal{E}(U^n_\varepsilon, V^n_\varepsilon) + \tfrac{c}{2}\, |U^n_\varepsilon - U^{n-1}_\varepsilon|^2_1 + \tfrac{1}{2}\, |V^n_\varepsilon - V^{n-1}_\varepsilon|^2_h + \rho\, \tau_n\, (\nabla V^n_\varepsilon, \nabla \pi^h[F'_\varepsilon(V^n_\varepsilon)]) \\ + \tfrac{\tau_n}{24}\, (\pi^h[(U^{n-1}_\varepsilon)^3]\, \nabla W^n_\varepsilon, \nabla W^n_\varepsilon) + \tfrac{5}{8}\, \tau_n\, (U^n_\varepsilon\, \nabla V^n_\varepsilon, \nabla V^n_\varepsilon) \\ \leq \mathcal{E}(U^{n-1}_\varepsilon, V^{n-1}_\varepsilon) + \tfrac{\tau_n}{2}\, (U^{n-1}_\varepsilon\, \nabla V^{n-1}_\varepsilon, \nabla V^{n-1}_\varepsilon)\,, \end{aligned} \tag{2.41}$$

where

$$\mathcal{E}(U^n_\varepsilon, V^n_\varepsilon) := \tfrac{c}{2}\, |U^n_\varepsilon|^2_1 + (F_\varepsilon(V^n_\varepsilon) + \Phi^-(U^n_\varepsilon + \varepsilon), 1)^h\,. \tag{2.42}$$

Proof. Choosing $\chi \equiv W^n_\varepsilon$ in (2.11a), $z^h \equiv U^{n-1}_\varepsilon$ in (2.11b), and $\chi \equiv \pi^h[F'_\varepsilon(V^n_\varepsilon)]$ in (2.11c) and noting (2.5) yield that

$$\begin{aligned}(U^n_\varepsilon - U^{n-1}_\varepsilon, W^n_\varepsilon)^h + \tfrac{\tau_n}{3}\, (\pi^h[(U^{n-1}_\varepsilon)^3]\, \nabla W^n_\varepsilon, \nabla W^n_\varepsilon) \\ = -\tfrac{\tau_n}{2}\, (\pi^h[(U^{n-1}_\varepsilon)^2]\, \nabla V^{n-1}_\varepsilon, \nabla W^n_\varepsilon)\,,\end{aligned} \tag{2.43a}$$

$$\begin{aligned}c\, (\nabla U^n_\varepsilon, \nabla (U^n_\varepsilon - U^{n-1}_\varepsilon)) + (\phi^-(U^{n-1}_\varepsilon + \varepsilon), U^n_\varepsilon - U^{n-1}_\varepsilon)^h \\ \leq (W^n_\varepsilon, U^n_\varepsilon - U^{n-1}_\varepsilon)^h\,,\end{aligned} \tag{2.43b}$$

$$\begin{aligned}(V^n_\varepsilon - V^{n-1}_\varepsilon, F'_\varepsilon(V^n_\varepsilon))^h + \rho\, \tau_n\, (\nabla V^n_\varepsilon, \nabla \pi^h[F'_\varepsilon(V^n_\varepsilon)]) \\ + \tau_n\, (U^n_\varepsilon\, \nabla V^n_\varepsilon, \nabla V^n_\varepsilon) \\ = -\tfrac{\tau_n}{2}\, (\pi^h[(U^n_\varepsilon)^{\frac{1}{2}}\, (U^{n-1}_\varepsilon)^{\frac{3}{2}}]\, \nabla W^n_\varepsilon, \nabla V^n_\varepsilon)\,.\end{aligned} \tag{2.43c}$$

On noting the elementary identity

$$2\, r\, (r - s) = (r^2 - s^2) + (r - s)^2 \quad \forall\ r, s \in \mathbb{R} \tag{2.44}$$

and the concavity of Φ^-, it follows from (2.43b) that

$$\begin{aligned}\tfrac{c}{2}\, |U^n_\varepsilon|^2_1 + \tfrac{c}{2}\, |U^n_\varepsilon - U^{n-1}_\varepsilon|^2_1 + (\Phi^-(U^n_\varepsilon + \varepsilon), 1)^h \\ \leq \tfrac{c}{2}\, |U^{n-1}_\varepsilon|^2_1 + (\Phi^-(U^{n-1}_\varepsilon + \varepsilon), 1)^h + (W^n_\varepsilon, U^n_\varepsilon - U^{n-1}_\varepsilon)^h\,.\end{aligned} \tag{2.45}$$

Combining (2.43a) and (2.45) yields that

$$\begin{aligned}\tfrac{c}{2}\, |U^n_\varepsilon|^2_1 + (\Phi^-(U^n_\varepsilon + \varepsilon), 1)^h + \tfrac{\tau_n}{3}\, (\pi^h[(U^{n-1}_\varepsilon)^3]\, \nabla W^n_\varepsilon, \nabla W^n_\varepsilon) + \tfrac{c}{2}\, |U^n_\varepsilon - U^{n-1}_\varepsilon|^2_1 \\ \leq \tfrac{c}{2}\, |U^{n-1}_\varepsilon|^2_1 + (\Phi^-(U^{n-1}_\varepsilon + \varepsilon), 1)^h - \tfrac{\tau_n}{2}\, (\pi^h[(U^{n-1}_\varepsilon)^2]\, \nabla V^{n-1}_\varepsilon, \nabla W^n_\varepsilon)\,.\end{aligned} \tag{2.46}$$

Now $F''_\varepsilon \geq 1$ implies that

$$(V^n_\varepsilon - V^{n-1}_\varepsilon, F'_\varepsilon(V^n_\varepsilon))^h \geq (F_\varepsilon(V^n_\varepsilon) - F_\varepsilon(V^{n-1}_\varepsilon), 1)^h + \tfrac{1}{2}\, |V^{n-1}_\varepsilon - V^n_\varepsilon|^2_h\,. \tag{2.47}$$

Combining (2.43c), (2.46), and (2.47) and noting (1.19), (2.15), and (2.42) yield that

$$\begin{aligned}\mathcal{E}(U^n_\varepsilon, V^n_\varepsilon) + \tfrac{c}{2}\, |U^n_\varepsilon - U^{n-1}_\varepsilon|^2_1 + \tfrac{1}{2}\, |V^n_\varepsilon - V^{n-1}_\varepsilon|^2_h + \rho\, \tau_n\, (\nabla V^n_\varepsilon, \nabla \pi^h[F'_\varepsilon(V^n_\varepsilon)]) \\ + \tfrac{\tau_n}{3}\, (\pi^h[(U^{n-1}_\varepsilon)^3]\, \nabla W^n_\varepsilon, \nabla W^n_\varepsilon) + \tau_n\, (U^n_\varepsilon\, \nabla V^n_\varepsilon, \nabla V^n_\varepsilon) \\ \leq \mathcal{E}(U^{n-1}_\varepsilon, V^{n-1}_\varepsilon) - \tfrac{\tau_n}{2}\, (\pi^h[(U^n_\varepsilon)^{\frac{1}{2}}\, (U^{n-1}_\varepsilon)^{\frac{3}{2}}]\, \nabla W^n_\varepsilon, \nabla V^n_\varepsilon) \\ - \tfrac{\tau_n}{2}\, (\pi^h[(U^{n-1}_\varepsilon)^2]\, \nabla W^n_\varepsilon, \nabla V^{n-1}_\varepsilon) \\ \leq \mathcal{E}(U^{n-1}_\varepsilon, V^{n-1}_\varepsilon) + \tfrac{\zeta + \gamma}{4}\, \tau_n\, (\pi^h[(U^{n-1}_\varepsilon)^3]\, \nabla W^n_\varepsilon, \nabla W^n_\varepsilon) \\ + \tfrac{\tau_n}{4\zeta}\, (U^{n-1}_\varepsilon\, \nabla V^{n-1}_\varepsilon, \nabla V^{n-1}_\varepsilon) + \tfrac{\tau_n}{4\gamma}\, (U^n_\varepsilon\, \nabla V^n_\varepsilon, \nabla V^n_\varepsilon)\end{aligned}$$

for arbitrary $\zeta, \gamma \in \mathbb{R}_{>0}$. Choosing $\zeta = \frac{1}{2}$ and $\gamma = \frac{2}{3}$ leads to the desired result (2.41). □

THEOREM 2.4. *Let the assumptions* (A) *hold and $U^0_\varepsilon \in K^h$, $V^0_\varepsilon \in S^h$. Then for all $\varepsilon \in (0,1)$, $h > 0$ a solution $\{U^n_\varepsilon, W^n_\varepsilon, V^n_\varepsilon\}_{n=1}^N$ to* $(\mathrm{P}^{h,\tau}_\varepsilon)$ *with $a = 0\,(\phi^- \equiv 0)$ is such that $⨍ U^n_\varepsilon = ⨍ U^0_\varepsilon$ and $⨍ V^n_\varepsilon = ⨍ V^0_\varepsilon$, and if $\tau_n \leq \frac{5}{4}\,\omega\,\tau_{n-1}$, $n = 2 \to N$, for an $\omega \in (0,1)$, then*

$$
\begin{aligned}
&c \max_{1\leq n\leq N} \|U^n_\varepsilon\|_1^2 + \max_{1\leq n\leq N} (F_\varepsilon(V^n_\varepsilon), 1)^h + \max_{1\leq n\leq N} |V^n_\varepsilon|_0^2 + \varepsilon^{-1} \max_{1\leq n\leq N} |\pi^h[V^n_\varepsilon]_-|_0^2 \\
&\quad + c\sum_{n=1}^N \|U^n_\varepsilon - U^{n-1}_\varepsilon\|_1^2 + \sum_{n=1}^N |V^n_\varepsilon - V^{n-1}_\varepsilon|_0^2 + \rho \sum_{n=1}^N \tau_n (\nabla V^n_\varepsilon, \nabla \pi^h[F'_\varepsilon(V^n_\varepsilon)]) \\
&\quad + \sum_{n=1}^N \tau_n\,(\pi^h[(U^{n-1}_\varepsilon)^3]\,\nabla W^n_\varepsilon, \nabla W^n_\varepsilon) + (1-\omega) \sum_{n=1}^N \tau_n\,(U^n_\varepsilon\,\nabla V^n_\varepsilon, \nabla V^n_\varepsilon) \\
&\quad + \rho \sum_{n=1}^N \tau_n \|V^n_\varepsilon\|_1^2 \;\leq C\left[\,1 + \|U^0_\varepsilon\|_1^2 + (U^0_\varepsilon\,\nabla V^0_\varepsilon, \nabla V^0_\varepsilon) + (F_\varepsilon(V^0_\varepsilon), 1)^h\,\right],
\end{aligned}
\tag{2.48a}
$$

$$
\begin{aligned}
&\sum_{n=1}^N \tau_n \left|\mathcal{G}[\tfrac{U^n_\varepsilon - U^{n-1}_\varepsilon}{\tau_n}]\right|_1^2 + \sum_{n=1}^N \tau_n \left|\mathcal{G}[\tfrac{V^n_\varepsilon - V^{n-1}_\varepsilon}{\tau_n}]\right|_1^2 \\
&\quad \leq C(\max_{n=0\to N} \|U^n_\varepsilon\|_{0,\infty})\left[\,1 + \|U^0_\varepsilon\|_1^2 + (U^0_\varepsilon\,\nabla V^0_\varepsilon, \nabla V^0_\varepsilon) + (F_\varepsilon(V^0_\varepsilon), 1)^h\,\right].
\end{aligned}
\tag{2.48b}
$$

Proof. Summing (2.41) from $n = 1 \to k$ and observing that $\tau_n \leq \frac{5}{4}\,\omega\,\tau_{n-1}$, $n = 2 \to k$, yield for any $k \leq N$ that

$$
\begin{aligned}
&\mathcal{E}(U^k_\varepsilon, V^k_\varepsilon) + \tfrac{1}{2} \sum_{n=1}^k \left[c\,|U^n_\varepsilon - U^{n-1}_\varepsilon|_1^2 + |V^n_\varepsilon - V^{n-1}_\varepsilon|_h^2\right] + \rho \sum_{n=1}^k \tau_n (\nabla V^n_\varepsilon, \nabla \pi^h[F'_\varepsilon(V^n_\varepsilon)]) \\
&\quad + \tfrac{1}{24} \sum_{n=1}^k \tau_n\,(\pi^h[(U^{n-1}_\varepsilon)^3]\,\nabla W^n_\varepsilon, \nabla W^n_\varepsilon) + \tfrac{5}{8}\,(1-\omega) \sum_{n=1}^k \tau_n\,(U^n_\varepsilon\,\nabla V^n_\varepsilon, \nabla V^n_\varepsilon) \\
&\quad \leq \mathcal{E}(U^0_\varepsilon, V^0_\varepsilon) + \tfrac{\tau_1}{2}\,(U^0_\varepsilon\,\nabla V^0_\varepsilon, \nabla V^0_\varepsilon)\,.
\end{aligned}
\tag{2.49}
$$

As $a = 0$, we have that

$$
\mathcal{E}(U^n_\varepsilon, V^n_\varepsilon) = \tfrac{c}{2}\,|U^n_\varepsilon|_1^2 + (F_\varepsilon(V^n_\varepsilon), 1)^h \geq 0\,. \tag{2.50}
$$

Therefore, the bounds $1 \to 2$ and $5 \to 9$ in (2.48a) follow from (2.49), (2.50), $U^n_\varepsilon - U^{n-1}_\varepsilon \in Z^h$, (1.17), (2.1), and (2.14). Combining the bound on $F_\varepsilon(V^n_\varepsilon)$ in (2.48a) and (2.4) yields the bounds $3 \to 4$ in (2.48a). Bounds 3 and 7 in (2.48a) yield, on noting (2.8), bound 10 in (2.48a).

From (1.16), (2.2), (2.11a), (2.21), and (1.17), we obtain that

$$\begin{aligned}\left|\mathcal{G}[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}]\right|_1^2 &= \left(\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}, \mathcal{G}[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}]\right) = \left(\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}, Q^h\,\mathcal{G}[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}]\right)^h \\ &= -\left(\tfrac{1}{3}\,\pi^h[(U_\varepsilon^{n-1})^3]\,\nabla W_\varepsilon^n + \tfrac{1}{2}\,\pi^h[(U_\varepsilon^{n-1})^2]\,\nabla V_\varepsilon^{n-1}, \nabla\left[Q^h\,\mathcal{G}[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}]\right]\right) \\ &\leq C\,|U_\varepsilon^{n-1}|_{0,\infty}^{\frac{3}{2}}\left[\,|\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0 + |(U_\varepsilon^{n-1})^{\frac{1}{2}}\,\nabla V_\varepsilon^{n-1}|_0\right]\left|Q^h\,\mathcal{G}[\tfrac{U_\varepsilon^n-U_\varepsilon^{n-1}}{\tau_n}]\right|_1 \\ &\leq C\,|U_\varepsilon^{n-1}|_{0,\infty}^{3}\left[\,|\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0^2 + |(U_\varepsilon^{n-1})^{\frac{1}{2}}\,\nabla V_\varepsilon^{n-1}|_0^2\right].\end{aligned}\tag{2.51}$$

Similarly to (2.51), from (1.16), (2.2), (2.11c), (2.28), (2.16), (2.21), and (1.17), we obtain that

$$\begin{aligned}\left|\mathcal{G}[\tfrac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}]\right|_1^2 &= \left(\tfrac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}, Q^h\,\mathcal{G}[\tfrac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}]\right)^h = -\rho\left(\nabla V_\varepsilon^n, \nabla\left[Q^h\,\mathcal{G}[\tfrac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}]\right]\right) \\ &\quad - \left(U_\varepsilon^n\,\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla V_\varepsilon^n + \tfrac{1}{2}\,\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\,(U_\varepsilon^{n-1})^{\frac{3}{2}}]\,\Lambda_\varepsilon(V_\varepsilon^n)\,\nabla W_\varepsilon^n, \nabla\left[Q^h\,\mathcal{G}[\tfrac{V_\varepsilon^n-V_\varepsilon^{n-1}}{\tau_n}]\right]\right) \\ &\leq C\left[\rho^2\,|\nabla V_\varepsilon^n|_0^2 + |U_\varepsilon^n|_{0,\infty}\left(|(U_\varepsilon^n)^{\frac{1}{2}}\,\nabla V_\varepsilon^n|_0^2 + |\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla W_\varepsilon^n|_0^2\right)\right].\end{aligned}\tag{2.52}$$

□

Combining (2.51), (2.52), the assumptions on τ_n, and the bounds 8 → 10 in (2.48a) yields the bounds (2.48b).

LEMMA 2.5. *Let u^0, $v^0 \in K$, and the assumptions* (A) *hold. On choosing $U_\varepsilon^0 \equiv Q^h u^0$ and $V_\varepsilon^0 \equiv Q^h v^0$, or $U_\varepsilon^0 \equiv \pi^h u^0$ and $V_\varepsilon^0 \equiv \pi^h v^0$ in the case $d = 1$, it follows that U_ε^0, $V_\varepsilon^0 \in K^h$ are such that for all $h > 0$*

$$\|U_\varepsilon^0\|_1^2 + (U_\varepsilon^0\,\nabla V_\varepsilon^0, \nabla V_\varepsilon^0) + (F_\varepsilon(V_\varepsilon^0), 1)^h \leq C\,.\tag{2.53}$$

Proof. The desired result (2.53) follows from (2.21), (2.20), and (2.18). □

2.1. Inclusion of repulsive van der Waals forces. We end this section by extending Theorems 2.2 and 2.4 and Lemmas 2.3 and 2.5 to the approximation $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$. In order to prove the existence of a solution to $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$, we need to go through a regularization procedure which is similar to that used for the logarithmic Cahn–Hilliard equation; see, e.g., [5, 3]. For this purpose we introduce, for any $\mu \in \mathbb{R}_{>0}$, the $C^{2,1}$ convex function $\Phi_\mu^+ : \mathbb{R} \to \mathbb{R}_{\geq 0}$ such that

$$\Phi_\mu^+(s) := \begin{cases} \Phi^+(\mu) + \phi^+(\mu)\,(s-\mu) + \frac{(s-\mu)^2}{2}\,(\phi^+)'(\mu), & s \leq \mu, \\ \Phi^+(s), & \mu \leq s\,. \end{cases}\tag{2.54}$$

We set $\phi_\mu^+(\cdot) := (\Phi_\mu^+)'(\cdot)$ and note that $\Phi^+(s) \geq \Phi_\mu^+(s) \geq 0$ for all $s \in \mathbb{R}_{>0}$.

A consequence of the monotonicity of ϕ_μ^+ and our mesh assumption (A) is that for all $\mu \in \mathbb{R}_{>0}$

$$|\pi^h[\phi_\mu^+(\chi)]\,|_1^2 \leq (\phi^+)'(\mu)\,(\nabla\chi, \nabla\pi^h[\phi_\mu^+(\chi)]\,) \qquad \forall\ \chi \in S^h;\tag{2.55}$$

see, for example, [15].

THEOREM 2.6. *Let the assumptions* (A) *hold and U_ε^{n-1}, $V_\varepsilon^{n-1} \in S^h$ with $U_\varepsilon^{n-1} > 0$. Then for all $\varepsilon \in (0,1)$ and for all h, $\tau_n > 0$ there exists a solution $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\}$ to the nth step of $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$ with $U_\varepsilon^n > 0$, $\fint U_\varepsilon^n = \fint U_\varepsilon^{n-1}$, and $\fint V_\varepsilon^n = \fint V_\varepsilon^{n-1}$. Moreover, U_ε^n and W_ε^n are unique.*

Proof. As $\mathcal{U}_\varepsilon^{n-1} := \min_{x\in\overline{\Omega}} U_\varepsilon^{n-1}(x) > 0$, we have in place of (2.32), on noting (2.12) for $\chi \equiv 1$, that

$$W_\varepsilon^n \equiv -3\,\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n} + X_\varepsilon^{n-1}] + \tfrac{1}{\underline{m}(\Omega)}\,(\phi^+(U_\varepsilon^n) + \phi^-(U_\varepsilon^{n-1}), 1)^h\,, \tag{2.56}$$

where $X_\varepsilon^{n-1} \in Z^h$ is defined by (2.30). Hence (2.11a) and (2.12) can be restated as follows.

Find $U_\varepsilon^n \in S^h(U_\varepsilon^{n-1})$ such that

$$A_{U_\varepsilon^{n-1}}(U_\varepsilon^n, \chi) + (\phi^+(U_\varepsilon^n), (I - \fint)\chi)^h = (\overline{X}_{\delta,\,\varepsilon}^{n-1}, \chi)^h \qquad \forall\, \chi \in S^h\,, \tag{2.57}$$

where $A_{U_\varepsilon^{n-1}}(\cdot,\cdot)$ is defined as in (2.35) and $\overline{X}_{\delta,\,\varepsilon}^{n-1} \in Z^h$ is such that

$$(\overline{X}_{\delta,\,\varepsilon}^{n-1}, \chi)^h := -(\phi^-(U_\varepsilon^{n-1}) + 3\,\mathcal{G}^h_{U_\varepsilon^{n-1}}\, X_\varepsilon^{n-1}, (I - \fint)\chi)^h \qquad \forall\, \chi \in S^h\,.$$

Due to the singular nature of the nonlinearity $\phi^+(s)$, we have to go through a regularization procedure in order to prove the existence of a solution to (2.57). For any $\mu \in \mathbb{R}_{>0}$, we introduce the regularized version of (2.57): Find $U_{\varepsilon,\,\mu}^n \in S^h(U_\varepsilon^{n-1})$ such that

$$A_{U_\varepsilon^{n-1}}(U_{\varepsilon,\,\mu}^n, \chi) + (\phi_\mu^+(U_{\varepsilon,\,\mu}^n), (I - \fint)\chi)^h = (\overline{X}_{\delta,\,\varepsilon}^{n-1}, \chi)^h \qquad \forall\, \chi \in S^h, \tag{2.58}$$

where ϕ_μ^+ is defined via (2.54). Similarly to (2.36), there exists a unique $U_{\varepsilon,\,\mu}^n$ satisfying (2.58) since this is the Euler–Lagrange equation of the convex minimization problem

$$\min_{\chi\in S^h(U_\varepsilon^{n-1})} \big\{\tfrac{c}{2}\,|\chi|_1^2 + (\Phi_\mu^+(\chi), 1)^h + \tfrac{3}{2\tau_n}\,|[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla\mathcal{G}^h_{U_\varepsilon^{n-1}}(\chi - U_\varepsilon^{n-1})|_0^2 - (\overline{X}_{\delta,\,\varepsilon}^{n-1}, \chi)^h\big\}.$$

Choosing $\chi \equiv U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1} \in Z^h$ in (2.58) and rearranging using (2.44), (2.27), (1.17), and the convexity of $\Phi_\mu^+ \leq \Phi^+$ yield that

$$\begin{aligned} &c\,\|U_{\varepsilon,\,\mu}^n\|_1^2 + \tau_n\,|\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1}}{\tau_n}]\,|_0^2 \\ &\qquad \leq C\,[\,(\Phi^+(U_\varepsilon^{n-1}), 1)^h + |\overline{X}_{\delta,\,\varepsilon}^{n-1}|_h^2 + \|U_\varepsilon^{n-1}\|_1^2\,] \leq C, \end{aligned} \tag{2.59}$$

where, in the above and below, $C \in \mathbb{R}_{>0}$ is also independent of μ. Choosing $\chi \equiv \pi^h[\phi_\mu^+(U_{\varepsilon,\,\mu}^n)]$ in (2.58) and noting (2.55), $\overline{X}_{\delta,\,\varepsilon}^{n-1} \in Z^h$, (2.27), (2.14), (1.17), and (2.59) yield that

$$\begin{aligned} &\tau_n\,|(I - \fint)\,\pi^h[\phi_\mu^+(U_{\varepsilon,\,\mu}^n)]\,|_h^2 \leq C\,\tau_n\,[\,|\overline{X}_{\delta,\,\varepsilon}^{n-1}|_h^2 + |\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1}}{\tau_n}]\,|_h^2\,] \\ &\quad \leq C(\mathcal{U}_\varepsilon^{n-1})\,\tau_n\,[\,|\overline{X}_{\delta,\,\varepsilon}^{n-1}|_h^2 + |\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac{1}{2}}\,\nabla\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1}}{\tau_n}]\,|_0^2\,] \;\leq\; C(\mathcal{U}_\varepsilon^{n-1})\,. \end{aligned} \tag{2.60}$$

Choosing $\chi \equiv U_{\varepsilon,\,\mu}^n$ in (2.58) and noting the convexity of Φ_μ^+, it follows for any constant $\zeta \in \mathbb{R}_{>0}$ that

$$\begin{aligned} &(\phi_\mu^+(U_{\varepsilon,\,\mu}^n), \zeta - \fint U_{\varepsilon,\,\mu}^n)^h \\ &\qquad \leq (\Phi_\mu^+(\zeta) - \Phi_\mu^+(U_{\varepsilon,\,\mu}^n), 1)^h + (\overline{X}_{\delta,\,\varepsilon}^{n-1} - 3\,\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1}}{\tau_n}], U_{\varepsilon,\,\mu}^n)^h \\ &\qquad \leq (\Phi^+(\zeta), 1)^h + (\overline{X}_{\delta,\,\varepsilon}^{n-1} - 3\,\mathcal{G}^h_{U_\varepsilon^{n-1}}[\tfrac{U_{\varepsilon,\,\mu}^n - U_\varepsilon^{n-1}}{\tau_n}], U_{\varepsilon,\,\mu}^n)^h\,. \end{aligned} \tag{2.61}$$

Choosing $\zeta = (⨍ U^n_{\varepsilon,\,\mu}) \pm \frac{1}{2}\,\mathcal{U}^{n-1}_\varepsilon = (⨍ U^{n-1}_\varepsilon) \pm \frac{1}{2}\,\mathcal{U}^{n-1}_\varepsilon \geq \frac{1}{2}\,\mathcal{U}^{n-1}_\varepsilon > 0$ in (2.61) and noting (2.59) and (2.60) yield that

$$\tau_n\,|\,⨍(\pi^h[\phi^+_\mu(U^n_{\varepsilon,\,\mu})]\,)|^2_h \leq C(\mathcal{U}^{n-1}_\varepsilon). \tag{2.62}$$

It follows from (2.59), (2.60), and (2.62) that there exist $U^n_\varepsilon \in S^h(U^{n-1}_\varepsilon)$, $\phi^+_h \in S^h$, and a subsequence $\{U^n_{\varepsilon,\,\mu'},\, \pi^h[\phi^+_{\mu'}(U^n_{\varepsilon,\,\mu'})]\,\}_{\mu'}$ such that $U^n_{\varepsilon,\,\mu'} \to U^n_\varepsilon$ and $\pi^h[\phi^+_{\mu'}(U^n_{\varepsilon,\,\mu'})] \to \phi^+_h$ as $\mu' \to 0$. Noting that for all $s \in \mathbb{R}$, $[\phi^+_\mu]^{-1}(s) \to [\phi^+]^{-1}(s)$ as $\mu \to 0$, we have that $(U^n_\varepsilon(p_j) - [\phi^+]^{-1}(s))\,(\phi^+_h(p_j) - s) \geq 0$ for all $s \in \mathbb{R}$, $j \in J$ and hence that $\phi^+_h \equiv \pi^h[\phi^+(U^n_\varepsilon)]$. Therefore, we may pass to the limit $\mu' \to 0$ in (2.58) to prove the existence of a solution $U^n_\varepsilon > 0$ to (2.57). Uniqueness of this solution follows from the monotonicity of ϕ^+. Hence noting (2.56), we have existence and uniqueness of a solution $\{U^n_\varepsilon,\, W^n_\varepsilon\}$ to (2.11a) and (2.12). Finally, existence of a solution V^n_ε to (2.11c) follows as in the proof of Theorem 2.2. □

LEMMA 2.7. *Let the assumptions of Theorem* 2.6 *hold. Then for all* $\varepsilon \in (0,1)$ *and for all* $h,\, \tau_n > 0$ *a solution* $\{U^n_\varepsilon, W^n_\varepsilon, V^n_\varepsilon\}$ *to the nth step of* $(\mathrm{P}^{h,\tau}_{\delta,\,\varepsilon})$ *is such that* (2.41) *holds with* $\mathcal{E}(\cdot,\cdot)$ *replaced by* $\mathcal{E}_\delta(U^n_\varepsilon, V^n_\varepsilon) := \frac{c}{2}\,|U^n_\varepsilon|^2_1 + (F_\varepsilon(V^n_\varepsilon) + \Phi(U^n_\varepsilon), 1)^h$.

Proof. The proof is a straightforward adaptation of the proof of Lemma 2.3 on noting (2.9) and the convexity of Φ^+. □

THEOREM 2.8. *Let the assumptions* (A) *hold and* $U^0_\varepsilon,\, V^0_\varepsilon \in S^h$ *with* $U^0_\varepsilon > 0$. *Then for all* $\varepsilon \in (0,1)$, $h > 0$, *a solution* $\{U^n_\varepsilon, W^n_\varepsilon, V^n_\varepsilon\}^N_{n=1}$ *to* $(\mathrm{P}^{h,\tau}_{\delta,\,\varepsilon})$ *is such that* $⨍ U^n_\varepsilon = ⨍ U^0_\varepsilon$ *and* $⨍ V^n_\varepsilon = ⨍ V^0_\varepsilon$, *and if* $\tau_n \leq \frac{5}{4}\,\omega\,\tau_{n-1}$, $n = 2 \to N$, *for an* $\omega \in (0,1)$, *then* (2.48a,b) *hold with the additional terms* $\max_{1\leq n\leq N}(\Phi(U^n_\varepsilon), 1)^h$ *on the left-hand side of* (2.48a) *and* $(\Phi(U^0_\varepsilon), 1)^h$ *inside the square brackets on the right-hand sides of* (2.48a,b).

Proof. A straightforward adaptation of the proof of Theorem 2.4 on noting (2.10) yields the desired result. □

LEMMA 2.9. *Let* u^0, $v^0 \in K$, *with* $u^0 \in L^\infty(\Omega)$ *and* $u^0(x) \geq \zeta > 0$ *for a.e.* $x \in \Omega$, *and let the assumptions* (A) *hold. On choosing* $U^0_\varepsilon \equiv Q^h u^0$ *and* $V^0_\varepsilon \equiv Q^h v^0$, *or* $U^0_\varepsilon \equiv \pi^h u^0$ *and* $V^0_\varepsilon \equiv \pi^h v^0$ *in the case* $d = 1$, *it follows that* U^0_ε, $V^0_\varepsilon \in K^h$ *with* $U^0_\varepsilon \geq \zeta$ *are such that for all* $h > 0$

$$\|U^0_\varepsilon\|^2_1 + (U^0_\varepsilon\,\nabla V^0_\varepsilon, \nabla V^0_\varepsilon) + (F_\varepsilon(V^0_\varepsilon) + \Phi(U^0_\varepsilon), 1)^h \leq C\,. \tag{2.63}$$

Proof. The desired result (2.63) follows from (2.21), (2.20), and (2.18). □

Remark 2.10. We note that Lemmas 2.3 and 2.7 are the discrete analogues of the energy estimates (1.5) and (1.11), respectively, on recalling (1.6), (1.7), and that $\sigma(s) := 1 - s$.

3. Convergence in one space dimension. Let

$$U_\varepsilon(t) := \tfrac{t-t_{n-1}}{\tau_n}\,U^n_\varepsilon + \tfrac{t_n-t}{\tau_n}\,U^{n-1}_\varepsilon, \qquad t \in [t_{n-1}, t_n], \quad n \geq 1, \tag{3.1a}$$

$$U^+_\varepsilon(t) := U^n_\varepsilon, \qquad U^-_\varepsilon(t) := U^{n-1}_\varepsilon, \qquad t \in (t_{n-1}, t_n], \quad n \geq 1. \tag{3.1b}$$

We note for future reference that

$$U_\varepsilon - U^\pm_\varepsilon = (t - t^\pm_n)\,\tfrac{\partial U_\varepsilon}{\partial t}, \qquad t \in (t_{n-1}, t_n) \quad n \geq 1, \tag{3.2}$$

where $t^+_n := t_n$ and $t^-_n := t_{n-1}$. We introduce also $\bar\tau(t) := \tau_n$ for $t \in (t_{n-1}, t_n]$ and $n \geq 1$. Using the above notation and introducing analogous notation for W_ε and V_ε, (2.11a–c) can be restated as follows.

Find $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\} \in H^1(0,T;S^h)\times L^2(0,T;S^h)\times H^1(0,T;S^h)$ such that $U_\varepsilon(\cdot,t)\in K^h$ and for all $\chi \in L^2(0,T;S^h)$, $z^h \in L^2(0,T;K^h)$,

(3.3a)
$$\int_0^T \Big[\big(\tfrac{\partial U_\varepsilon}{\partial t},\chi\big)^h + \tfrac13\,\big(\pi^h[(U_\varepsilon^-)^3]\,\nabla W_\varepsilon^+,\nabla\chi\big)\Big]\,\mathrm{d}t = -\tfrac12\int_0^T (\pi^h[(U_\varepsilon^-)^2]\,\nabla V_\varepsilon^-,\nabla\chi)\,\mathrm{d}t,$$

(3.3b)
$$\int_0^T \big[\,c\,(\nabla U_\varepsilon^+,\nabla(z^h-U_\varepsilon^+)) + (\phi^-(U_\varepsilon^-+\varepsilon)-W_\varepsilon^+,z^h-U_\varepsilon^+)^h\big]\,\mathrm{d}t \geq 0,$$

$$\int_0^T \Big[\big(\tfrac{\partial V_\varepsilon}{\partial t},\chi\big)^h + \rho\,\big(\nabla V_\varepsilon^+,\nabla\chi\big) + \big(U_\varepsilon^+\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla V_\varepsilon^+,\nabla\chi\big)\Big]\,\mathrm{d}t$$

(3.3c)
$$= -\tfrac12\int_0^T (\pi^h[(U_\varepsilon^+)^{\frac12}\,(U_\varepsilon^-)^{\frac32}]\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla W_\varepsilon^+,\nabla\chi)\,\mathrm{d}t.$$

LEMMA 3.1. *Let $d=1$, $a=0\,(\phi^-\equiv 0)$, $\rho>0$, and u^0, $v^0\in K$ with $u^0\not\equiv 0$. Let $\{\mathcal{T}^h, U_\varepsilon^0, V_\varepsilon^0, \{\tau_n\}_{n=1}^N, \varepsilon\}_{h>0}$ be such that*

(i) *$U_\varepsilon^0 \equiv \pi^h u^0$, $V_\varepsilon^0\equiv \pi^h v^0$;*

(ii) *Ω and $\{\mathcal{T}^h\}_{h>0}$ fulfil assumption* (A), *$\varepsilon\in(0,1)$, and $\tau_n \leq \frac54\,\omega\,\tau_{n-1}$, $n=2\rightarrow N$, for an $\omega\in(0,1)$;*

(iii) *ε, $\tau\rightarrow 0$ as $h\rightarrow 0$.*

Then there exist a subsequence of $\{U_\varepsilon, V_\varepsilon\}_h$, where $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\}$ solve $(\mathrm{P}_\varepsilon^{h,\tau})$, *and functions*

$$u \in L^\infty(0,T;K)\cap H^1(0,T;(H^1(\Omega))')\cap C^{\frac12,\frac18}_{x,t}(\overline{\Omega}_T), \tag{3.4a}$$

$$v \in L^\infty(0,T;L^2(\Omega))\cap L^2(0,T;K)\cap H^1(0,T;(H^1(\Omega))') \tag{3.4b}$$

with $u(x,0)=u^0(x)$ for all $x\in\overline{\Omega}$, $v(\cdot,0)=v^0(\cdot)$ in $(H^1(\Omega))'$, $⨍ u(\cdot,t)=⨍ u^0>0$ for all $t\in[0,T]$ and $⨍ v(\cdot,t)=⨍ v^0$ for a.e. $t\in[0,T]$ such that as $h\rightarrow 0$

(3.5a)	$U_\varepsilon,\, U_\varepsilon^\pm \rightarrow u$			*uniformly on* $\overline{\Omega}_T$,
(3.5b)	$U_\varepsilon,\, U_\varepsilon^\pm \rightarrow u$	*and*	$\mathcal{G}\frac{\partial U_\varepsilon}{\partial t}\rightarrow \mathcal{G}\frac{\partial u}{\partial t}$	*weakly in* $L^2(0,T;H^1(\Omega))$,
(3.6a)	$V_\varepsilon,\, V_\varepsilon^\pm \rightarrow v$	*and*	$\mathcal{G}\frac{\partial V_\varepsilon}{\partial t}\rightarrow \mathcal{G}\frac{\partial v}{\partial t}$	*weakly in* $L^2(0,T;H^1(\Omega))$,
(3.6b)	$V_\varepsilon,\, V_\varepsilon^\pm \rightarrow v$	*and*	$\Lambda_\varepsilon(V_\varepsilon^+)\rightarrow\lambda(v)$	*strongly in* $L^2(\Omega_T)$.

Proof. From (2.48a), (2.53), and (1.15), we have for $d=1$

$$\max_{1\leq n\leq N}\|U_\varepsilon^n\|_1 \leq C \qquad\Longrightarrow\qquad \max_{1\leq n\leq N}|U_\varepsilon^n|_{0,\infty}\leq C\,. \tag{3.7}$$

Noting the definitions (3.1a,b) and (3.7), the bounds in (2.48a,b) together with (1.17), (2.53), and the time step control in (ii) imply that

$$\begin{aligned}&\|U_\varepsilon\|^2_{L^\infty(0,T;H^1(\Omega))} + \|V_\varepsilon\|^2_{L^\infty(0,T;L^2(\Omega))} + \rho\,\|V_\varepsilon\|^2_{L^2(0,T;H^1(\Omega))} + \rho\,\|V_\varepsilon^\pm\|^2_{L^2(0,T;H^1(\Omega))}\\ &\quad + \varepsilon^{-1}\,\|\pi^h[V_\varepsilon^+]_-\|^2_{L^\infty(0,T;L^2(\Omega))} + \|\bar\tau^{\frac12}\,\tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} + \|\bar\tau^{\frac12}\,\tfrac{\partial V_\varepsilon}{\partial t}\|^2_{L^2(\Omega_T)}\\ &\quad + \|\,[\pi^h[(U_\varepsilon^-)^3]\,]^{\frac12}\,\nabla W_\varepsilon^+\|^2_{L^2(\Omega_T)} + \|\mathcal{G}\tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} + \|\mathcal{G}\tfrac{\partial V_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} \leq C.\end{aligned} \tag{3.8}$$

In addition, we deduce from (3.2) and (3.8) that

$$\|U_\varepsilon - U_\varepsilon^\pm\|^2_{L^2(0,T;H^1(\Omega))} + \|V_\varepsilon - V_\varepsilon^\pm\|^2_{L^2(\Omega_T)} \leq \|\bar\tau\,\tfrac{\partial U_\varepsilon}{\partial t}\|^2_{L^2(0,T;H^1(\Omega))} + \|\bar\tau\,\tfrac{\partial V_\varepsilon}{\partial t}\|^2_{L^2(\Omega_T)} \leq C\,\tau. \tag{3.9}$$

Moreover, the first and ninth bound in (3.8) imply that the $C^{\frac{1}{2},\frac{1}{8}}_{x,t}(\overline{\Omega}_T)$ norm of U_ε is bounded independently of h, τ, ε, and T; see, e.g., [4, Theorem 2.2]. Therefore, by the Arzelà–Ascoli theorem there exists a subsequence $\{U_\varepsilon, V_\varepsilon\}_h$ and a $u \geq 0$, as $U_\varepsilon(\cdot,t) \in K^h$, such that

$$U_\varepsilon,\ U_\varepsilon^\pm \to u \in C^{\frac{1}{2},\frac{1}{8}}_{x,t}(\overline{\Omega}_T) \qquad \text{uniformly on } \overline{\Omega}_T \text{ as } h \to 0. \tag{3.10}$$

Furthermore, (3.10), (3.8), (2.19), (3.1a,b), (3.9), $⨍ U_\varepsilon^n = ⨍ U_\varepsilon^0$, $⨍ V_\varepsilon^n = ⨍ V_\varepsilon^0$, and our assumptions (iii) imply, as $\rho > 0$, that this same subsequence $\{U_\varepsilon, V_\varepsilon\}_h$ can be chosen such that (3.4a), (3.4b) with K replaced by $H^1(\Omega)$, (3.5a,b), and (3.6a) hold. The strong convergence result for $V_\varepsilon^{(\pm)}$ in (3.6b) follows immediately from (3.6a) and a standard embedding result. Furthermore, it follows from (3.8), (3.6a), (1.18), and a standard compactness argument that

$$V_\varepsilon \to v \quad \text{in} \quad C([0,T];(H^1(\Omega))')\,. \tag{3.11}$$

Noting the assumptions (i) and (2.19), we have that

$$U_\varepsilon^0 \to u^0 \quad \text{and} \quad V_\varepsilon^0 \to v^0 \quad \text{strongly in} \quad H^1(\Omega)\,. \tag{3.12}$$

Combining (3.12), (3.11), and (3.10) yields that $u(\cdot,0) = u^0(\cdot)$ in $C(\overline{\Omega})$ and $v(\cdot,0) = v^0(\cdot)$ in $(H^1(\Omega))'$.

We now prove the remaining result in (3.6b). For this we introduce for all $\varepsilon \in (0,1)$, $\lambda_\varepsilon : \mathbb{R} \to [\varepsilon, 1]$ defined, on recalling (1.13), by

$$\lambda_\varepsilon(s) := [\lambda(s) - \varepsilon]_+ + \varepsilon, \qquad \text{where} \qquad [s]_+ := \max\{s,\,0\}. \tag{3.13}$$

Then we have that

$$\begin{aligned}\|\lambda(v) - \Lambda_\varepsilon(V_\varepsilon^+)\|_{L^2(\Omega_T)} &\leq \|\lambda(v) - \lambda(V_\varepsilon^+)\|_{L^2(\Omega_T)} + \|(I - \pi^h)\lambda(V_\varepsilon^+)\|_{L^2(\Omega_T)} \\ &\quad + \|\pi^h[\,\lambda(V_\varepsilon^+) - \lambda_\varepsilon(V_\varepsilon^+)\,]\|_{L^2(\Omega_T)} + \|\pi^h[\lambda_\varepsilon(V_\varepsilon^+)] - \Lambda_\varepsilon(V_\varepsilon^+)\|_{L^2(\Omega_T)}.\end{aligned} \tag{3.14}$$

Noting the global Lipschitz continuity of λ, (2.18), and (3.8), we have that

$$\begin{aligned}&\|\lambda(v) - \lambda(V_\varepsilon^+)\|_{L^2(\Omega_T)} + \|(I - \pi^h)\lambda(V_\varepsilon^+)\|_{L^2(\Omega_T)} \\ &\quad \leq \|v - V_\varepsilon^+\|_{L^2(\Omega_T)} + C\,h\,\|\nabla[\lambda(V_\varepsilon^+)]\|_{L^2(\Omega_T)} \\ &\quad \leq \|v - V_\varepsilon^+\|_{L^2(\Omega_T)} + C\,h\,\|\nabla V_\varepsilon^+\|_{L^2(\Omega_T)} \leq \|v - V_\varepsilon^+\|_{L^2(\Omega_T)} + C\,h\,.\end{aligned} \tag{3.15}$$

It follows from (2.1), (2.14), (3.1b), (1.13), (3.13), and (3.8) that

$$\begin{aligned}\|\pi^h[\,\lambda(V_\varepsilon^+) - \lambda_\varepsilon(V_\varepsilon^+)\,]\,\|^2_{L^2(\Omega_T)} &\leq \sum_{n=1}^N \tau_n\,|\pi^h[\,\lambda(V_\varepsilon^n) - \lambda_\varepsilon(V_\varepsilon^n)\,]|_h^2 \\ &\leq \sum_{n=1}^N \tau_n\,|\pi^h[\varepsilon - [V_\varepsilon^n]_-]\,|_h^2 \leq C\left[\varepsilon^2 + \sum_{n=1}^N \tau_n\,|\pi^h[V_\varepsilon^n]_-\,|_0^2\right] \leq C\,\varepsilon^2.\end{aligned} \tag{3.16}$$

From (2.7), (2.3), and (3.13), we have that $\Lambda_\varepsilon(V_\varepsilon^n)\,|_{(p_{j-1},p_j)}$ lies between $\lambda_\varepsilon(V_\varepsilon^n(p_{j-1}))$ and $\lambda_\varepsilon(V_\varepsilon^n(p_j))$ for $j = 1 \to J$ and $n = 1 \to N$. This together with (2.18), the global Lipschitz continuity of λ_ε, and (3.8) implies that

$$\begin{aligned}\|\pi^h[\lambda_\varepsilon(V_\varepsilon^+)] - \Lambda_\varepsilon(V_\varepsilon^+)\|_{L^2(\Omega_T)} &\leq C\,h\,\|\nabla\pi^h[\lambda_\varepsilon(V_\varepsilon^+)]\|_{L^2(\Omega_T)}\\ &\leq C\,h\,\|\nabla[\lambda_\varepsilon(V_\varepsilon^+)]\|_{L^2(\Omega_T)} \leq C\,h\,\|\nabla V_\varepsilon^+\|_{L^2(\Omega_T)} \leq C\,h\,.\end{aligned}\tag{3.17}$$

Combining (3.14), (3.15), (3.16), and (3.17) and noting the result on V_ε^+ in (3.6b) and our assumption (iii) on ε yield the desired result on $\Lambda_\varepsilon(V_\varepsilon^+)$ in (3.6b). Finally, we note that $\Lambda_\varepsilon(V_\varepsilon^+) \geq 0$ and (3.6b) $\Rightarrow$ $\lambda(v) \geq 0$ a.e. $\Rightarrow$ $v \geq 0$ a.e. $\Rightarrow$ K in (3.4b). □

For any $\alpha > 0$, we set

$$B_\alpha := \{\,(x,t) \in \overline{\Omega}_T : u(x,t) > \alpha\,\} \quad\text{and}\quad B_\alpha(t) := \{\,x \in \overline{\Omega} : u(x,t) > \alpha\,\}.\tag{3.18}$$

From (3.4a), we have that there exist positive constants C_x and C_t such that

$$|u(y_2,t) - u(y_1,t)| \leq C_x\,|y_2 - y_1|^{\frac{1}{2}} \qquad \forall\; y_1,\, y_2 \in \overline{\Omega}, \qquad \forall\; t \in [0,T];\tag{3.19a}$$

$$|u(x,t_b) - u(x,t_a)| \leq C_t\,|t_b - t_a|^{\frac{1}{8}} \qquad \forall\; t_a,\, t_b \in [0,T], \quad \forall\; x \in \overline{\Omega}.\tag{3.19b}$$

As $⨍ u(\cdot,t) = ⨍ u^0 > 0$ for all $t \in [0,T]$, it follows that there exists an $\alpha_0 \in (0, ⨍ u^0)$ such that $B_{\alpha_0}(t) \neq \emptyset$ for all $t \in [0,T]$. It immediately follows from (3.18) and (3.19a,b) for any t_a, $t_b \in [0,T]$ and for any α_1, $\alpha_2 \in (0,\alpha_0)$ with $\alpha_1 > \alpha_2$ that

$$\begin{aligned}&y_1 \in B_{\alpha_1}(t_a) \text{ and } y_2 \in \partial B_{\alpha_2}(t_b) \text{ with } y_2 \notin \partial\Omega \quad \Longrightarrow\\ &C_x\,|y_2 - y_1|^{\frac{1}{2}} + C_t\,|t_b - t_a|^{\frac{1}{8}} \geq u(y_1,t_a) - u(y_2,t_b) > (\alpha_1 - \alpha_2),\end{aligned}\tag{3.20}$$

where $\partial B_\alpha(t)$ is the boundary of $B_\alpha(t)$. Therefore, (3.20) implies that for any $\alpha \in (0,\alpha_0)$, there exists an $h_0(\alpha)$ such that for all $h \leq h_0(\alpha)$ and $t \in [0,T]$ there exists a collection of simplices $\mathcal{T}_\alpha^h(t) \subset \mathcal{T}^h$ such that

$$B_\alpha(t) \subset B_\alpha^h(t) := \cup_{\kappa \in \mathcal{T}_\alpha^h(t)}\,\overline{\kappa} \subset B_{\frac{\alpha}{2}}(t) \qquad \forall\; t \in [0,T].\tag{3.21}$$

Similarly, it follows from (3.20) that for any $\alpha \in (0,\alpha_0)$, there exists a $\tau_0(\alpha)$ such that for all $\tau \leq \tau_0(\alpha)$

$$B_\alpha(t) \subset B_{\frac{\alpha}{2}}(t_n) \subset B_{\frac{\alpha}{4}}(t) \qquad \forall\; t \in (t_{n-1},t_n], \quad n = 1 \to N.\tag{3.22}$$

Clearly, we have from (3.21) and (3.22) that $\alpha_2 < \alpha_1 < \alpha_0$ implies that $h_0(\alpha_2) \leq h_0(\alpha_1)$ and $\tau_0(\alpha_2) \leq \tau_0(\alpha_1)$. For a fixed $\alpha \in (0,\alpha_0)$, it follows from (3.18), (3.5a), and our assumption (iii) of Lemma 3.1 that there exists an $\widehat{h}_0(\alpha) \leq h_0(\alpha)$ such that for $h \leq \widehat{h}_0(\alpha)$

$$\begin{array}{lll} 0 \;\leq U_\varepsilon^\pm(x,t) \leq 2\,\alpha & \forall\;(x,t) \notin B_\alpha, & \\ \frac{1}{2}\,\alpha \;\leq U_\varepsilon^\pm(x,t) & \forall\;(x,t) \in B_\alpha, & \end{array} \quad \text{and} \quad \tau \leq \tau_0(\alpha).\tag{3.23}$$

THEOREM 3.2. *Let the assumptions of Lemma* 3.1 *hold. Then there exist a subsequence of* $\{U_\varepsilon, W_\varepsilon, V_\varepsilon\}_h$*, where* $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\}$ *solve* $(\mathrm{P}_\varepsilon^{h,\tau})$*, and functions* $\{u,w,v\}$ *satisfying* (3.4a,b) *and*

$$w \in L^2_{loc}(\{u > 0\}) \qquad \textit{with} \qquad \nabla w \in L^2_{loc}(\{u > 0\}),\tag{3.24}$$

where $\{u > 0\} := \{(x,t) \in \Omega_T \,:\, u(x,t) > 0\,\}$ *such that as* $h \to 0$ (3.5a,b), (3.6a–c) *hold and* $W_\varepsilon^+ \to w$, $\nabla W_\varepsilon^+ \to \nabla w$ *weakly in* $L^2_{loc}(\{u > 0\})$. *Furthermore, we* *have that* u*,* v*, and* w *fulfil* $u(\cdot,0) = u^0(\cdot)$*,* $v(\cdot,0) = v^0(\cdot)$ *and are such that for all* $\eta, z \in L^2(0,T;H^1(\Omega))$*, with* $\mathrm{supp}(z) \subset \{u > 0\}$*,*

$$\int_0^T \langle \tfrac{\partial u}{\partial t}, \eta\rangle \,\mathrm{d}t + \tfrac{1}{3}\int_{\{u>0\}} u^3 \,\nabla w \,.\, \nabla \eta \,\mathrm{d}x\,\mathrm{d}t + \tfrac{1}{2}\int_{\Omega_T} u^2\,\nabla v \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t = 0, \tag{3.25a}$$

$$\int_{\{u>0\}} [\, c\,\nabla u \,.\, \nabla z - w\,z\,]\,\mathrm{d}x\,\mathrm{d}t = 0, \tag{3.25b}$$

$$\begin{aligned}\int_0^T \langle \tfrac{\partial v}{\partial t}, \eta\rangle \,\mathrm{d}t + \int_{\Omega_T} [\,\rho\,\nabla v \,.\, \nabla \eta + u\,\lambda(v)\,\nabla v \,.\, \nabla\eta\,]\,\mathrm{d}x\,\mathrm{d}t \\ + \tfrac{1}{2}\int_{\{u>0\}} u^2\,\lambda(v)\,\nabla w \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t = 0.\end{aligned} \tag{3.25c}$$

Proof. For any $\eta \in L^2(0,T;H^1(\Omega))$, we choose $\chi \equiv \pi^h\eta$ in (3.3a,c) and now analyze the subsequent terms. First, (2.17), (2.23), (2.18), (1.15) in time, and (3.8) yield for $Z \equiv U_\varepsilon$ and V_ε, respectively, and for all $\widetilde{\eta} \in H^1(0,T;H^1(\Omega))$ that

$$\begin{aligned}\left|\int_0^T \Big[\big(\tfrac{\partial Z}{\partial t}, \pi^h\eta\big)^h - \big(\tfrac{\partial Z}{\partial t}, \pi^h\eta\big)\Big]\,\mathrm{d}t\right| &\leq \left|\int_0^T \Big[\big(\tfrac{\partial Z}{\partial t}, \pi^h[\eta-\widetilde{\eta}]\big)^h - \big(\tfrac{\partial Z}{\partial t}, \pi^h[\eta-\widetilde{\eta}]\big)\Big]\,\mathrm{d}t\right| \\ &+ \left| -\int_0^T \Big(Z, \tfrac{\partial(\pi^h\widetilde{\eta})}{\partial t}\Big)^h \,\mathrm{d}t + (\,Z(\cdot,T), \pi^h\widetilde{\eta}(\cdot,T)\,)^h - (\,Z(\cdot,0), \pi^h\widetilde{\eta}(\cdot,0)\,)^h \right. \\ &\left. + \int_0^T \Big(Z, \tfrac{\partial(\pi^h\widetilde{\eta})}{\partial t}\Big)\,\mathrm{d}t - (\,Z(\cdot,T), \pi^h\widetilde{\eta}(\cdot,T)\,) + (\,Z(\cdot,0), \pi^h\widetilde{\eta}(\cdot,0)\,)\right| \\ \leq C\,\|\mathcal{G}\tfrac{\partial Z}{\partial t}\|_{L^2(0,T;H^1(\Omega))}\,\|\pi^h[\eta-\widetilde{\eta}]\|_{L^2(0,T;H^1(\Omega))} \\ + C\,h\,\|Z\|_{L^\infty(0,T;L^2(\Omega))}\,\|\pi^h\widetilde{\eta}\|_{H^1(0,T;H^1(\Omega))} \\ \leq C\,\|\eta-\widetilde{\eta}\|_{L^2(0,T;H^1(\Omega))} + C\,h\,\|\widetilde{\eta}\|_{H^1(0,T;H^1(\Omega))}\,.\end{aligned} \tag{3.26}$$

Furthermore, it follows from (1.16) and (3.8) that

$$\begin{aligned}\left|\int_0^T \big(\tfrac{\partial Z}{\partial t}, (I-\pi^h)\eta\big)\,\mathrm{d}t\right| &\leq C\,\|\mathcal{G}\tfrac{\partial Z}{\partial t}\|_{L^2(0,T;H^1(\Omega))}\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\ &\leq C\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))}.\end{aligned} \tag{3.27}$$

Combining (3.26), the denseness of $H^1(0,T;H^1(\Omega))$ in $L^2(0,T;H^1(\Omega))$, (3.27), (2.19), (1.20), (3.5b), and (3.6a) yields that for $z \equiv u$ and v, respectively,

$$\int_0^T \big(\tfrac{\partial Z}{\partial t}, \pi^h\eta\big)^h \,\mathrm{d}t \to \int_0^T \langle\tfrac{\partial z}{\partial t}, \eta\rangle\,\mathrm{d}t \quad \text{as } h \to 0. \tag{3.28}$$

In view of (2.28), (3.1b), (2.16), (3.7), and (3.8), as $\rho > 0$, we deduce that

$$\begin{aligned}&\left|\int_0^T \Big(\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}]\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla W_\varepsilon^+, \nabla(I-\pi^h)\eta\Big)\,\mathrm{d}t\right| \\ &\quad\leq \|\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}]\,\nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\ &\quad\leq C\,\|U_\varepsilon^+\|^{\frac{1}{2}}_{L^\infty(\Omega_T)}\,\|\,[\pi^h[(U_\varepsilon^-)^3]\,]^{\frac{1}{2}}\,\nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))} \\ &\quad\leq C\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))},\end{aligned} \tag{3.29a}$$

and similarly

$$\begin{aligned}
&\left|\int_0^T \big(\pi^h[(U_\varepsilon^-)^3]\,\nabla W_\varepsilon^+, \nabla(I-\pi^h)\eta\big)\ \mathrm{d}t\right| + \left|\int_0^T \big(U_\varepsilon^+\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla V_\varepsilon^+, \nabla(I-\pi^h)\eta\big)\ \mathrm{d}t\right| \\
&\quad + \left|\int_0^T \big(\pi^h[(U_\varepsilon^-)^2]\,\nabla V_\varepsilon^-, \nabla(I-\pi^h)\eta\big)\ \mathrm{d}t\right| + \left|\int_0^T \big(\nabla V_\varepsilon^+, \nabla(I-\pi^h)\eta\big)\ \mathrm{d}t\right| \\
&\quad + \left|\int_0^T \big(\nabla U_\varepsilon^+, \nabla(I-\pi^h)\eta\big)\ \mathrm{d}t\right| \ \le\ C\,\|(I-\pi^h)\eta\|_{L^2(0,T;H^1(\Omega))}.
\end{aligned} \tag{3.29b}$$

Noting (3.29b), (2.19), (3.5b), and (3.6a), we have for $Z^+ \equiv U_\varepsilon^+$ and V_ε^+, and $z \equiv u$ and v, respectively, that

$$\int_0^T (\nabla Z^+, \nabla(\pi^h\eta)\,)\,\mathrm{d}t \to \int_0^T (\nabla z, \nabla\eta)\,\mathrm{d}t \quad \text{as } h \to 0. \tag{3.30}$$

It also follows from (3.8), (2.28), (1.13), and (3.4a,b) that for all $\widetilde{\eta} \in L^\infty(0,T;W^{1,\infty}(\Omega))$

$$\begin{aligned}
&\left|\int_0^T \big(\,(\pi^h[(U_\varepsilon^-)^2] - u^2)\,\nabla V_\varepsilon^-, \nabla\eta\big)\ \mathrm{d}t\right| \\
&\quad \le \|\pi^h[(U_\varepsilon^-)^2] - u^2\|_{L^\infty(\Omega_T)}\,\|V_\varepsilon^-\|_{L^2(0,T;H^1(\Omega))}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\quad \le C\left[\|\pi^h[(U_\varepsilon^-)^2 - u^2]\|_{L^\infty(\Omega_T)} + \|(I-\pi^h)u^2\|_{L^\infty(\Omega_T)}\right]\ \|\eta\|_{L^2(0,T;H^1(\Omega))},
\end{aligned} \tag{3.31a}$$

$$\begin{aligned}
&\left|\int_0^T \big(\,(U_\varepsilon^+\,\Lambda_\varepsilon(V_\varepsilon^+) - u\,\lambda(v)\,)\,\nabla V_\varepsilon^+, \nabla\eta\big)\ \mathrm{d}t\right| \\
&\quad \le \left|\int_0^T \big(\,(U_\varepsilon^+ - u)\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla V_\varepsilon^+, \nabla\eta\big)\ \mathrm{d}t\right| \\
&\quad + \left|\int_0^T \Big[\,\big(u\,(\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\,)\,\nabla V_\varepsilon^+, \nabla(\eta - \widetilde{\eta})\,\big) + \big(u\,(\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\,)\,\nabla V_\varepsilon^+, \nabla\widetilde{\eta}\big)\,\Big]\,\mathrm{d}t\right| \\
&\quad \le \|U_\varepsilon^+ - u\|_{L^\infty(\Omega_T)}\,\|V_\varepsilon^+\|_{L^2(0,T;H^1(\Omega))}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|u\|_{L^\infty(\Omega_T)}\,\|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^\infty(\Omega_T)}\,\|V_\varepsilon^+\|_{L^2(0,T;H^1(\Omega))}\,\|\eta - \widetilde{\eta}\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|u\|_{L^\infty(\Omega_T)}\,\|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^2(\Omega_T)}\,\|V_\varepsilon^+\|_{L^2(0,T;H^1(\Omega))}\,\|\widetilde{\eta}\|_{L^\infty(0,T;W^{1,\infty}(\Omega))} \\
&\quad \le C\,\Big[\|U_\varepsilon^+ - u\|_{L^\infty(\Omega_T)}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} + \|\eta - \widetilde{\eta}\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^2(\Omega_T)}\,\|\widetilde{\eta}\|_{L^\infty(0,T;W^{1,\infty}(\Omega))}\Big].
\end{aligned} \tag{3.31b}$$

Noting that $L^\infty(0,T;W^{1,\infty}(\Omega))$ is dense in $L^2(0,T;H^1(\Omega))$, (3.29b), (2.19), (3.31a,b), (3.5a), (2.13), (3.6b), and (3.6a), we have that

$$\int_0^T \big(\pi^h[(U_\varepsilon^-)^2]\,\nabla V_\varepsilon^-, \nabla(\pi^h\eta)\big)\ \mathrm{d}t \to \int_0^T (u^2\,\nabla v, \nabla\eta)\,\mathrm{d}t \qquad \text{as } h \to 0, \tag{3.32a}$$

$$\int_0^T \big(\,U_\varepsilon^+\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla V_\varepsilon^+, \nabla(\pi^h\eta)\big)\ \mathrm{d}t \to \int_0^T (u\,\lambda(v)\,\nabla v, \nabla\eta)\,\mathrm{d}t \quad \text{as } h \to 0. \tag{3.32b}$$

We now show the compactness of $\{W_\varepsilon^+\}_h$ on compact subsets of $\{u > 0\}$. On noting (3.23), (3.8), (2.28), and (2.16), we have for all $h \leq \widehat{h}_0(\alpha)$, similarly to (3.29a), that

$$\begin{aligned}
&\left| \int_{\Omega_T \setminus B_\alpha} \pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}]\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla W_\varepsilon^+ \,.\, \nabla\eta \,\mathrm{d}x\,\mathrm{d}t \right| \\
&\qquad \leq C\,\|U_\varepsilon^+\|_{L^\infty(\Omega_T\setminus B_\alpha)}^{\frac{1}{2}}\,\|\,[\pi^h[(U_\varepsilon^-)^3]\,]^{\frac{1}{2}}\,\nabla W_\varepsilon^+\|_{L^2(\Omega_T)}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad \leq C\,\alpha^{\frac{1}{2}}\,\|\eta\|_{L^2(0,T;H^1(\Omega))}
\end{aligned} \tag{3.33a}$$

and similarly

$$\left| \int_{\Omega_T \setminus B_\alpha} \pi^h[(U_\varepsilon^-)^3]\,\nabla W_\varepsilon^+ \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t \right| \leq C\,\alpha^{\frac{3}{2}}\,\|\eta\|_{L^2(0,T;H^1(\Omega))}. \tag{3.33b}$$

It follows from (3.23), (3.21), and (3.8) that for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$

$$\begin{aligned}
C_1\,\alpha^3 \int_{B_{\frac{\alpha}{4}}} |\nabla W_\varepsilon^+|^2\,\mathrm{d}x\,\mathrm{d}t &\leq C_1\,\alpha^3 \int_{B^h_{\frac{\alpha}{4}}} |\nabla W_\varepsilon^+|^2\,\mathrm{d}x\,\mathrm{d}t \leq \int_{B^h_{\frac{\alpha}{4}}} \pi^h[(U_\varepsilon^-)^3]\,|\nabla W_\varepsilon^+|^2\,\mathrm{d}x\,\mathrm{d}t \\
&\leq C,
\end{aligned} \tag{3.34}$$

where $B_\alpha^h := \{(x,t) \in \overline{\Omega}_T : x \in B_\alpha^h(t)\}$. Similarly to (3.31a,b), it follows from (2.28), (3.34), (1.13), and (3.4a,b) that for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$ and for all $\widetilde{\eta} \in L^\infty(0,T;W^{1,\infty}(\Omega))$

$$\begin{aligned}
&\left| \int_{B_\alpha} (\pi^h[(U_\varepsilon^-)^3] - u^3)\,\nabla W_\varepsilon^+ \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t \right| \\
&\quad \leq \|\pi^h[(U_\varepsilon^-)^3] - u^3\|_{L^\infty(\Omega_T)}\,\|\nabla W_\varepsilon^+\|_{L^2(B_\alpha)}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\quad \leq C\,\alpha^{-\frac{3}{2}}\left[\,\|\pi^h[(U_\varepsilon^-)^3 - u^3]\|_{L^\infty(\Omega_T)} + \|(I-\pi^h)u^3\|_{L^\infty(\Omega_T)}\right]\|\eta\|_{L^2(0,T;H^1(\Omega))},
\end{aligned} \tag{3.35a}$$

$$\begin{aligned}
&\left| \int_{B_\alpha} (\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}]\,\Lambda_\varepsilon(V_\varepsilon^+) - u^2\,\lambda(v)\,)\,\nabla W_\varepsilon^+ \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t \right| \\
&\quad \leq \left| \int_{B_\alpha} (\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}] - u^2)\,\Lambda_\varepsilon(V_\varepsilon^+)\,\nabla W_\varepsilon^+ \,.\, \nabla\eta\,\mathrm{d}x\,\mathrm{d}t \right| \\
&\qquad + \left| \int_{B_\alpha} u^2\,(\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\,)\,\nabla W_\varepsilon^+ \,.\, [\,\nabla(\eta-\widetilde{\eta}) + \nabla\widetilde{\eta}\,]\,\mathrm{d}x\,\mathrm{d}t \right| \\
&\quad \leq \|\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}}] - u^2\|_{L^\infty(\Omega_T)}\,\|\nabla W_\varepsilon^+\|_{L^2(B_\alpha)}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|u^2\|_{L^\infty(\Omega_T)}\,\|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^\infty(\Omega_T)}\,\|\nabla W_\varepsilon^+\|_{L^2(B_\alpha)}\,\|\eta-\widetilde{\eta}\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|u^2\|_{L^\infty(\Omega_T)}\,\|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^2(\Omega_T)}\,\|\nabla W_\varepsilon^+\|_{L^2(B_\alpha)}\,\|\widetilde{\eta}\|_{L^\infty(0,T;W^{1,\infty}(\Omega))} \\
&\quad \leq C\,\alpha^{-\frac{3}{2}}\Big[\,\|\pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\,(U_\varepsilon^-)^{\frac{3}{2}} - u^2] - (I-\pi^h)u^2\,\|_{L^\infty(\Omega_T)}\,\|\eta\|_{L^2(0,T;H^1(\Omega))} \\
&\qquad + \|\Lambda_\varepsilon(V_\varepsilon^+) - \lambda(v)\|_{L^2(\Omega_T)}\,\|\widetilde{\eta}\|_{L^\infty(0,T;W^{1,\infty}(\Omega))} + \|\eta-\widetilde{\eta}\|_{L^2(0,T;H^1(\Omega))}\Big].
\end{aligned} \tag{3.35b}$$

From (3.23) we have for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$ and for a.e. $t \in (0,T)$ that $\xi^h(\cdot,t) := U_\varepsilon^+(\cdot,t) \pm \frac{\alpha}{16}\,\zeta^h(\cdot,t)/\|\zeta^h(\cdot,t)\|_{L^\infty(\Omega)} \in K^h$ for any $\zeta^h \in L^2(0,T;S^h)$ with $\mathrm{supp}(\zeta^h) \subset B_{\frac{\alpha}{8}}$.

Choosing $z^h \equiv \xi^h$ in (3.3b) yields, as $\phi^- \equiv 0$, for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$ that

$$\int_0^T \left[\, c\,(\nabla U_\varepsilon^+, \nabla \zeta^h) - (W_\varepsilon^+, \zeta^h)^h \,\right] \mathrm{d}t = 0 \quad \forall\, \zeta^h \in L^2(0,T;S^h) \;\; \text{with}\, \mathrm{supp}(\zeta^h) \subset B_{\frac{\alpha}{8}}. \tag{3.36}$$

Next we derive a bound on W_ε^+ locally on the set $\{u > 0\}$. For any $\alpha \in (0, \alpha_0)$ and any $t \in [0,T]$, we choose a cut-off function $\theta_\alpha(\cdot,t) \in C^\infty(\overline{\Omega})$ such that

$$\begin{aligned} &\theta_\alpha(\cdot,t) \equiv 1 \quad \text{on}\, B_\alpha(t), \qquad 0 \leq \theta_\alpha(\cdot,t) \leq 1 \quad \text{on}\, B_{\frac{\alpha}{2}}(t) \setminus B_\alpha(t), \\ &\theta_\alpha(\cdot,t) \equiv 0 \quad \text{on}\, \overline{\Omega} \setminus B_{\frac{\alpha}{2}}(t) \qquad \text{and} \qquad |\nabla \theta_\alpha(\cdot,t)| \leq C\,\alpha^{-2}. \end{aligned} \tag{3.37}$$

It follows from (3.20) that this last property can be achieved. We have from (3.37) and (3.21) that

$$\mathrm{supp}(\pi^h[\theta_{\frac{\alpha}{2}}^2\, W_\varepsilon^+]\,) \subset B^h_{\frac{\alpha}{4}} \subset B_{\frac{\alpha}{8}} \qquad \forall\, h \leq \widehat{h}_0(\tfrac{\alpha}{8}). \tag{3.38}$$

Next we note, as $d = 1$, that for any $\kappa = (p_j, p_{j+1}) \in \mathcal{T}^h$ and any $z_1, z_2 \in C(\overline{\kappa})$

$$\nabla \pi^h[z_1^2\, z_2] = [\,(z_1\, z_2)(p_j) + (z_1\, z_2)(p_{j+1})\,]\, \nabla \pi^h[z_1] + z_1(p_j)\, z_1(p_{j+1})\, \nabla \pi^h[z_2] \quad \text{on}\ \kappa. \tag{3.39}$$

It follows from (2.1), (3.36), (3.38), (3.39), (3.37), (3.21), and (1.19) that for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$

$$\begin{aligned} \int_{\Omega_T} \pi^h[(\theta_{\frac{\alpha}{2}}\, W_\varepsilon^+)^2]\, \mathrm{d}x\, \mathrm{d}t &= \int_0^T (W_\varepsilon^+, \pi^h[\theta_{\frac{\alpha}{2}}^2\, W_\varepsilon^+]\,)^h\, \mathrm{d}t = \int_0^T c\,(\nabla U_\varepsilon^+, \nabla(\pi^h[\theta_{\frac{\alpha}{2}}^2\, W_\varepsilon^+]\,)\,)\, \mathrm{d}t \\ &\leq C\, \|U_\varepsilon^+\|_{L^2(0,T;H^1(\Omega))} \left[\|\nabla \theta_{\frac{\alpha}{2}}\|_{L^\infty(\Omega_T)} \left[\int_{\Omega_T} \pi^h[(\theta_{\frac{\alpha}{2}}\, W_\varepsilon^+)^2]\, \mathrm{d}x\, \mathrm{d}t \right]^{\frac{1}{2}} + \|\nabla W_\varepsilon^+\|_{L^2(B^h_{\frac{\alpha}{4}})} \right] \\ &\leq C\,(1 + \alpha^{-4})\, \|U_\varepsilon^+\|^2_{L^2(0,T;H^1(\Omega))} + C\, \|\nabla W_\varepsilon^+\|^2_{L^2(B^h_{\frac{\alpha}{4}})}\,. \end{aligned} \tag{3.40}$$

From (3.21), (3.37), and (2.14), we obtain that for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$

$$\int_{\Omega_T} \pi^h[(\theta_{\frac{\alpha}{2}}\, W_\varepsilon^+)^2]\, \mathrm{d}x\, \mathrm{d}t \geq \int_{B^h_\alpha} \pi^h[(W_\varepsilon^+)^2]\, \mathrm{d}x\, \mathrm{d}t \geq \int_{B^h_\alpha} (W_\varepsilon^+)^2\, \mathrm{d}x\, \mathrm{d}t \geq \|W_\varepsilon^+\|^2_{L^2(B_\alpha)}. \tag{3.41}$$

Therefore, combining (3.34), (3.40), (3.41), (3.9), and (3.8) yields that

$$\|W_\varepsilon^+\|_{L^2(0,T;H^1(B_\alpha(t)))} \leq C(\alpha^{-1}) \qquad \forall\, h \leq \widehat{h}_0(\tfrac{\alpha}{8}). \tag{3.42}$$

The bound (3.42) implies the existence of a subsequence and a function $w \in L^2(0,T;H^1(B_\alpha(t)))$ such that

$$W_\varepsilon^+ \to w, \quad \nabla W_\varepsilon^+ \to \nabla w \qquad \text{weakly in}\ L^2(B_\alpha) \quad \text{as}\ h \to 0. \tag{3.43}$$

On noting that $L^\infty(0,T;W^{1,\infty}(\Omega))$ is dense in $L^2(0,T;H^1(\Omega))$, (3.29a,b), (2.19), (3.35a,b), (3.5a), (2.13), (3.6b), and (3.43), we have that as $h \to 0$

$$\int_{B_\alpha} \pi^h[(U_\varepsilon^-)^3]\, \nabla W_\varepsilon^+ . \nabla(\pi^h \eta)\, \mathrm{d}x\, \mathrm{d}t \to \int_{B_\alpha} u^3\, \nabla w\, . \nabla \eta\, \mathrm{d}x\, \mathrm{d}t, \tag{3.44a}$$

$$\int_{B_\alpha} \pi^h[(U_\varepsilon^+)^{\frac{1}{2}}\, (U_\varepsilon^-)^{\frac{3}{2}}]\, \Lambda_\varepsilon(V_\varepsilon^+)\, \nabla W_\varepsilon^+ .\, \nabla(\pi^h \eta)\, \mathrm{d}x\, \mathrm{d}t \to \int_{B_\alpha} u^2 \lambda(v)\, \nabla w\, . \nabla \eta\, \mathrm{d}x\, \mathrm{d}t. \tag{3.44b}$$

Using (2.1), (2.18), and (3.42), we deduce for all $\zeta \in L^2(0,T;H^1(\Omega))$ with $\operatorname{supp}(\zeta) \subset B_\alpha$ and for all $h \leq \widehat{h}_0(\frac{\alpha}{8})$ that

$$\begin{aligned} \left| \int_0^T \left[(W_\varepsilon^+, \pi^h \zeta)^h - (W_\varepsilon^+, \zeta) \right] \mathrm{d}t \right| &= \left| \int_{\Omega_T} (I - \pi^h)(W_\varepsilon^+ \zeta) \, \mathrm{d}x \, \mathrm{d}t \right| \\ &\leq C\, h \int_{\Omega_T} |\nabla (W_\varepsilon^+ \zeta)| \, \mathrm{d}x \, \mathrm{d}t \\ &\leq C\, h \, \|W_\varepsilon^+\|_{L^2(0,T;H^1(B_\alpha(t)))} \, \|\zeta\|_{L^2(0,T;H^1(\Omega))} \\ &\leq C(\alpha^{-1})\, h \, \|\zeta\|_{L^2(0,T;H^1(\Omega))}. \end{aligned} \tag{3.45}$$

It follows from (3.45) and (3.43) that for all $\zeta \in L^2(0,T;H^1(\Omega))$ with $\operatorname{supp}(\zeta) \subset B_\alpha$,

$$\int_0^T (W_\varepsilon^+, \pi^h \zeta)^h \, \mathrm{d}t \to \int_0^T (w, \zeta) \, \mathrm{d}t = \int_{B_\alpha} w \, \zeta \, \mathrm{d}x \, \mathrm{d}t \quad \text{as } h \to 0\,. \tag{3.46}$$

Combining (3.30) for u and (3.46) and noting (3.36) yield that

$$\int_{B_\alpha} [\, c \nabla u \,.\, \nabla \zeta - w\, \zeta \,] \, \mathrm{d}x \, \mathrm{d}t = 0 \quad \forall\, \zeta \in L^2(0,T;H^1(\Omega)) \;\; \text{with } \operatorname{supp}(\zeta) \subset B_\alpha. \tag{3.47}$$

This uniquely defines w in terms of u on the set B_α. Repeating (3.44a,b) for all $\alpha > 0$ and noting (3.33a,b) and (2.19) yield for all $\eta \in L^2(0,T;H^1(\Omega))$ that as $h \to 0$

$$\int_{\Omega_T} \pi^h[(U_\varepsilon^-)^3] \, \nabla W_\varepsilon^+ . \nabla (\pi^h \eta) \, \mathrm{d}x \, \mathrm{d}t \to \int_{B_0} u^3 \, \nabla w \,. \nabla \eta \, \mathrm{d}x \, \mathrm{d}t, \tag{3.48a}$$

$$\int_{\Omega_T} \pi^h[(U_\varepsilon^+)^{\frac{1}{2}} \, (U_\varepsilon^-)^{\frac{3}{2}}] \, \Lambda_\varepsilon(V_\varepsilon^+) \, \nabla W_\varepsilon^+ . \nabla (\pi^h \eta) \, \mathrm{d}x \, \mathrm{d}t \to \int_{B_0} u^2 \, \lambda(v) \, \nabla w \,. \nabla \eta \, \mathrm{d}x \, \mathrm{d}t. \tag{3.48b}$$

Combining (3.3a,c), (3.28), (3.30), (3.32a,b), and (3.48a,b) and repeating (3.47) for all $\alpha > 0$ yield that the functions $\{u,\, w,\, v\}$ satisfy (3.4a,b), (3.24), and (3.25a–c). □

Remark 3.3. If $v^0 \equiv 0$, then (3.25a–c) collapses to

$$\int_0^T \langle \tfrac{\partial u}{\partial t}, \eta \rangle \, \mathrm{d}t - \tfrac{c}{3} \int_{\{u>0\}} u^3 \, \nabla (\Delta u) \,.\, \nabla \eta \, \mathrm{d}x \, \mathrm{d}t = 0 \quad \forall\, \eta \in L^2(0,T;H^1(\Omega)) \tag{3.49}$$

since $v \equiv \lambda(v) \equiv 0$ in Ω_T and $w \equiv -c\, \Delta u$ on $\{u > 0\}$. This is the Bernis–Friedman weak formulation of the degenerate fourth order equation $\frac{\partial u}{\partial t} + \frac{c}{3} \nabla . (u^3 \, \nabla (\Delta u)) = 0$; see [9]. Note that (3.49) incorporates a weak formulation of the boundary condition $\frac{c}{3} \, u^3 \, \frac{\partial \Delta u}{\partial \nu_{\partial\Omega}} = 0$. In addition, (3.25b) implies that $\frac{\partial u}{\partial \nu_{\partial\Omega}}(x,t) = 0$ for $(x,t) \in \partial\Omega \times (0,T)$ whenever $u(x,t) > 0$. Therefore, (3.25a–c) is the natural extension of the Bernis–Friedman weak formulation to the problem (P) in the presence of surfactant ($v^0 \not\equiv 0$).

Remark 3.4. The obstacle formulation in $(\mathrm{P}_\varepsilon^{h,\tau})$ is not crucial in proving well-posedness and convergence of the resulting approximation $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\}$ to a solution,

$\{u,\, w,\, v\}$, of (P). Replacing $\pi^h[(U_\varepsilon^{n-1})^3]$, $\pi^h[(U_\varepsilon^{n-1})^2]$ by $\pi^h[\,[U_\varepsilon^{n-1}]_+^3]$, $\pi^h[\,[U_\varepsilon^{n-1}]_+^2]$ in (2.11a), the inequality by an equality, K^h by S^h in (2.11b), and $U_\varepsilon^n\,\Lambda_\varepsilon(V_\varepsilon^n)$, $\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\,(U_\varepsilon^{n-1})^{\frac{3}{2}}]$ by $\pi^h[\,[U_\varepsilon^n]_+]\,\Lambda_\varepsilon(V_\varepsilon^n)$, $\pi^h[\,[U_\varepsilon^n]_+^{\frac{1}{2}}\,[U_\varepsilon^{n-1}]_+^{\frac{3}{2}}]$ in (2.11c), one can easily adapt the proofs of Theorems 2.2, 2.4, and 3.2 and Lemmas 2.3, 2.5, and 3.1. Hence one can pass to a limit $\{u,\, w,\, v\}$ which solves (P) in the sense of (3.25a–c) with u^2 replaced by $[u]_+^2$ in (3.25a) and $u\,\lambda(v)$ replaced by $[u]_+\,\lambda(v)$ in (3.25c). Using $[u]_-$ as a test function in the modified (3.25a), one recovers the nonnegativity of u and hence the weak formulation (3.25a–c). However, as $U_\varepsilon^n(\cdot)$ can now become negative in many disconnected regions where $u(\cdot, t_n) \equiv 0$, this makes the location of the approximate free boundary more difficult.

Remark 3.5. On choosing $U_\varepsilon^0 \equiv \pi^h u^0$ and $V_\varepsilon^0 \equiv \pi^h v^0$, we need the quasi uniformity assumption on the partitioning $\mathcal{T}^h$ only in order to obtain the bound (2.48b) via (2.51), (2.52), and (2.21) and the bound (3.26) via (2.23). However, we can replace this with the far milder assumption that $\{\mathcal{T}^h\}_{h>0}$ is a regular partitioning at the expense of a minimum time step constraint as in [4]. It is easily established from (1.16), (2.22), $\{\mathcal{T}^h\}_{h>0}$ being a regular partitioning, elliptic regularity, assuming that Ω is convex polygonal if $d=2$, and (2.17) that

$$\|(\mathcal{G}-\mathcal{G}^h)z^h\|_1 \leq C\,h\,\|z^h\|_0 \qquad \forall\; z^h \in Z^h\,. \tag{3.50}$$

Then choosing $\chi \equiv \mathcal{G}^h[\frac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}]$ and $\chi \equiv \mathcal{G}^h[\frac{V_\varepsilon^n - V_\varepsilon^{n-1}}{\tau_n}]$ in (2.11a) and (2.11c), respectively, we obtain, similarly to (2.51) and (2.52), that

$$\|\mathcal{G}^h\tfrac{\partial U_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} + \|\mathcal{G}^h\tfrac{\partial V_\varepsilon}{\partial t}\|_{L^2(0,T;H^1(\Omega))} \leq C(\|U_\varepsilon\|_{L^\infty(\Omega_T)}) \tag{3.51}$$

on noting (2.53). Combining (3.50) and (3.51) and noting the fifth and sixth bound in (2.48a), it follows for $Z \equiv U_\varepsilon$ or V_ε that

$$\begin{aligned}
\|\mathcal{G}\tfrac{\partial Z}{\partial t}\|_{L^2(0,T;H^1(\Omega))} &\leq \|(\mathcal{G}-\mathcal{G}^h)\tfrac{\partial Z}{\partial t}\|_{L^2(0,T;H^1(\Omega))} + \|\mathcal{G}^h\tfrac{\partial Z}{\partial t}\|_{L^2(0,T;H^1(\Omega))}\\
&\leq C\,h\,\|\tfrac{\partial Z}{\partial t}\|_{L^2(\Omega_T)} + C(\|U_\varepsilon\|_{L^\infty(\Omega_T)})\\
&\leq C(\|U_\varepsilon\|_{L^\infty(\Omega_T)})\,(\tau_{\min}^{-\frac{1}{2}}\,h+1) \leq C(\|U_\varepsilon\|_{L^\infty(\Omega_T)})
\end{aligned}$$

if the mild time step constraint $C\,h^2 \leq \tau_{min} := \min_{n=1\to N}\tau_n$ is satisfied.

3.1. Inclusion of van der Waals forces.

We now extend Lemma 3.1 and Theorem 3.2 to the approximation $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$.

Lemma 3.6. *Let $d=1, \rho>0$ and $u^0,\, v^0 \in K$, with $u^0(x) \geq \zeta > 0$ for all $x \in \Omega$. Let $\{\mathcal{T}^h, U_\varepsilon^0, V_\varepsilon^0, \tau,\, \varepsilon\}_{h>0}$ be such that assumptions* (i), (ii), *and* (iii) *of Lemma* 3.1 *hold. Then there exist a subsequence of $\{U_\varepsilon, V_\varepsilon\}_h$, where $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\}$ solve $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$, and functions $\{u,\, v\}$ satisfying* (3.4a,b) *with $u(x,0) = u^0(x)$ for all $x \in \overline{\Omega}$, $v(\cdot,0) = v^0(\cdot)$ in $(H^1(\Omega))'$, $⨍ u(\cdot,t) = ⨍ u^0 > 0$ for all $t \in [0,T]$, and $⨍ v(\cdot,t) = ⨍ v^0$ for a.e. $t \in [0,T]$, such that as $h \to 0$* (3.5a,b) *and* (3.6a–c) *hold.*

Proof. The proof is exactly the same as that of Lemma 3.1. □

Theorem 3.7. *Let the assumptions of Lemma* 3.6 *hold. Then there exist a subsequence of $\{U_\varepsilon, W_\varepsilon, V_\varepsilon\}_h$, where $\{U_\varepsilon,\, W_\varepsilon,\, V_\varepsilon\}$ solve $(\mathrm{P}_{\delta,\,\varepsilon}^{h,\tau})$, and functions $\{u, w, v\}$ satisfying* (3.4a,b), *$w \in L^2(0,T;H^1(\Omega))$, and $u>0$ on $\overline{\Omega}_T$. In addition, as $h \to 0$,* (3.5a,b), (3.6a–c), *and $W_\varepsilon^+ \to w$ weakly in $L^2(0,T;H^1(\Omega))$ hold. Furthermore, we* *have that* u, v, *and* w *fulfil* $u(\cdot,0) = u^0(\cdot)$, $v(\cdot,0) = v^0(\cdot)$ *and are such that for all* $\eta \in L^2(0,T;H^1(\Omega))$,

$$\int_0^T \langle \tfrac{\partial u}{\partial t}, \eta\rangle \,\mathrm{d}t + \tfrac{1}{3}\int_{\Omega_T} u^3\, \nabla w \,.\, \nabla \eta \,\mathrm{d}x\,\mathrm{d}t + \tfrac{1}{2}\int_{\Omega_T} u^2\, \nabla v \,.\, \nabla\eta \,\mathrm{d}x\,\mathrm{d}t = 0,$$
$$\int_{\Omega_T} [\, c\,\nabla u \,.\, \nabla \eta + \phi(u)\,\eta - w\,\eta\,]\,\mathrm{d}x\,\mathrm{d}t = 0,$$
$$\int_0^T \langle \tfrac{\partial v}{\partial t}, \eta\rangle \,\mathrm{d}t + \int_{\Omega_T} [\,\rho\,\nabla v \,.\, \nabla\eta + u\,\lambda(v)\,\nabla v \,.\, \nabla \eta\,]\,\mathrm{d}x\,\mathrm{d}t + \tfrac{1}{2}\int_{\Omega_T} u^2\,\lambda(v)\,\nabla w \,.\, \nabla\eta \,\mathrm{d}x\,\mathrm{d}t = 0.$$

Proof. Theorem 2.8 and Lemma 2.9 imply that

$$\max_{t\in[0,T]} \int_\Omega \pi^h[\Phi(U_\varepsilon^+)](x,t)\,\mathrm{d}x \leq C. \tag{3.52}$$

From the uniform Hölder continuity of U_ε^+ and (3.52), it follows that there exists $\underline{u} \in \mathbb{R}_{>0}$ independent of h, τ, and ε such that $U_\varepsilon^+(x,t) \geq \underline{u} > 0$ for all $(x,t) \in \overline{\Omega}_T$; see, e.g., [23, Corollary 5.3]. Combining this with (3.5a) yields that u is strictly positive.

The rest of the proof is similar to that of Theorem 3.2 with the following minor modifications. We have that (3.36) holds with the extra term $(\phi^+(U_\varepsilon^+)+\phi^-(U_\varepsilon^-),\zeta^h)^h$ inside the square brackets on the left-hand side. Since u is strictly positive, it is straightforward to show convergence of this extra term to the corresponding term in the weak formulation of the continuous problem. ∎

4. Solution of the nonlinear discrete system. We now discuss algorithms for solving the resulting system of nonlinear equations for $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\}$ at each time level for the approximations $(\mathrm{P}_\varepsilon^{h,\tau})$ and $(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$. As (2.11a,b) for $(\mathrm{P}_\varepsilon^{h,\tau})$ and (2.11a), (2.12) for $(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$ are independent of V_ε^n, we first solve these to obtain $\{U_\varepsilon^n, W_\varepsilon^n\}$; then we solve (2.11c) for V_ε^n. First, we consider $(\mathrm{P}_\varepsilon^{h,\tau})$. Adapting the techniques in [4, section 3] we introduce $R_\varepsilon^n \in S^h$ by

$$(R_\varepsilon^n, \chi)^h = c\,(\nabla U_\varepsilon^n, \nabla \chi) + (\phi^-(U_\varepsilon^{n-1}+\varepsilon),\chi)^h - (W_\varepsilon^n,\chi)^h \quad \forall\, \chi\in S^h. \tag{4.1}$$

Hence, for any $\mu \in \mathbb{R}_{>0}$ and on recalling (3.13), $(\mathrm{P}_\varepsilon^{h,\tau})$ is equivalent to the following.

Given $U_\varepsilon^0 \in K^h$, $V_\varepsilon^0 \in S^h$, for $n \geq 1$ find $\{U_\varepsilon^n, W_\varepsilon^n, V_\varepsilon^n\} \in [S^h]^3$ such that (2.11a), (4.1), $R_\varepsilon^n = \pi^h[R_\varepsilon^n - \mu\, U_\varepsilon^n]_+$, and (2.11c) hold. We use this formulation in constructing our iterative method to solve $(\mathrm{P}_\varepsilon^{h,\tau})$.

Given $\{W_\varepsilon^{n,0}, R_\varepsilon^{n,0}\} \in [S^h]^2$, for $k \geq 1$ find $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}, R_\varepsilon^{n,k}\} \in [S^h]^3$ such that for all $\chi \in S^h$

$$\begin{aligned}\left(\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n},\chi\right)^h + \tfrac{b^{n-1}}{3}\,(\nabla W_\varepsilon^{n,k},\nabla\chi) &= \tfrac{1}{3}\,((b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3])\nabla W_\varepsilon^{n,k-1},\nabla\chi)\\ &\quad - \tfrac{1}{2}\,(\pi^h[(U_\varepsilon^{n-1})^2]\,\nabla V_\varepsilon^{n-1},\nabla\chi),\end{aligned} \tag{4.2a}$$

(4.2b)
$$c\,(\nabla U_\varepsilon^{n,k},\nabla\chi) + (\phi^-(U_\varepsilon^{n-1}+\varepsilon),\chi)^h = (W_\varepsilon^{n,k} + R_\varepsilon^{n,k-1},\chi)^h,$$

$$R_\varepsilon^{n,k} = \pi^h[R_\varepsilon^{n,k-1} - \mu\, U_\varepsilon^{n,k}]_+, \tag{4.2c}$$

where $b^{n-1} := |U_\varepsilon^{n-1}|_{0,\infty}^3$.

Then, having obtained $\{U_\varepsilon^n, W_\varepsilon^n\}$, we find V_ε^n as follows. Given $V_\varepsilon^{n,0} \in S^h$, for $k \geq 1$ find $V_\varepsilon^{n,k} \in S^h$ such that

$$\begin{aligned}\Big(\tfrac{V_\varepsilon^{n,k}-V_\varepsilon^{n-1}}{\tau_n},\chi\Big)^h &+ \rho\,(\nabla V_\varepsilon^{n,k},\nabla\chi) + (U_\varepsilon^n\,\Lambda_\varepsilon(V_\varepsilon^{n,k-1})\,\nabla V_\varepsilon^{n,k},\nabla\chi)\\ &= -\tfrac{1}{2}\,(\pi^h[(U_\varepsilon^n)^{\frac{1}{2}}\,(U_\varepsilon^{n-1})^{\frac{3}{2}}]\,\Lambda_\varepsilon(V_\varepsilon^{n,k-1})\,\nabla W_\varepsilon^n,\nabla\chi)\quad\forall\,\chi\in S^h.\end{aligned}\tag{4.3}$$

Equation (4.3) is the natural extension of the iterative procedure proposed in [22] for solving a finite element approximation of the thin film equation. As (4.3) is linear, existence of $V_\varepsilon^{n,k}$ follows from uniqueness; and this is easily established on noting $\rho \geq 0$, (2.5), and $U_\varepsilon^n \in K^h$. Hence the iteration (4.3) is well defined.

The algorithm (4.2a–c) is a simple adaptation of the algorithm in [4, section 3] for problem $(\mathrm{P}_\varepsilon^{h,\tau})$ in the absence of the surfactant and van der Waals forces, i.e., $V_\varepsilon^n \equiv 0$ and $a = 0\,(\phi^- \equiv 0)$.

Defining $A^{n,k-1} \in Z^h$ such that

$$(A^{n,k-1},\chi)^h := \tfrac{1}{3}\,(\pi^h[(U_\varepsilon^{n-1})^3]\,\nabla W_\varepsilon^{n,k-1},\nabla\chi)\quad\forall\,\chi\in S^h\tag{4.4}$$

and $X_\varepsilon^{n-1} \in S^h$ as in (2.30), it follows from (4.2a), (2.22), (4.2b) with $\chi \equiv 1$, (1.17), and (1.14) that

$$\begin{aligned}W_\varepsilon^{n,k} = (I-\fint)W_\varepsilon^{n,k-1} &- \tfrac{3}{b^{n-1}}\,\mathcal{G}^h[\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n} + A^{n,k-1} + X_\varepsilon^{n-1}]\\ &+ \fint\pi^h[\phi^-(U_\varepsilon^{n-1}+\varepsilon)] - \fint R_\varepsilon^{n,k-1}\,.\end{aligned}\tag{4.5}$$

Therefore, (4.2a,b) may be written equivalently as follows: Find $U_\varepsilon^{n,k} \in \overline{S}^h(U_\varepsilon^{n-1}) := \{\,\chi \in S^h : \chi - U_\varepsilon^{n-1} \in Z^h\,\}$ such that

$$\begin{aligned}c\,(\nabla U_\varepsilon^{n,k},\nabla\chi) &+ \tfrac{3}{b^{n-1}}\,(\mathcal{G}^h[\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n}],\chi)^h\\ &= ((I-\fint)(W_\varepsilon^{n,k-1} + R_\varepsilon^{n,k-1} + \overline{X}_\varepsilon^{n,k-1}),\chi)^h\quad\forall\,\chi\in S^h,\end{aligned}\tag{4.6}$$

where $\overline{X}_\varepsilon^{n,k-1} \in S^h$ is such that

$$(\overline{X}_\varepsilon^{n,k-1},\chi)^h := -(\phi^-(U_\varepsilon^{n-1}+\varepsilon) + \tfrac{3}{b^{n-1}}\,\mathcal{G}^h[A^{n,k-1} + X_\varepsilon^{n-1}],\chi)^h\quad\forall\,\chi\in S^h\,.$$

Existence and uniqueness of $U_\varepsilon^{n,k} \in \overline{S}^h(U_\varepsilon^{n-1})$ satisfying (4.6) then follows since, on noting (2.22), this is the Euler–Lagrange equation of the convex minimization problem

$$\min_{\chi\in\overline{S}^h(U_\varepsilon^{n-1})}\Big\{\tfrac{c}{2}\,|\chi|_1^2 + \tfrac{3}{2\,b^{n-1}\,\tau_n}|\nabla\mathcal{G}^h(\chi - U_\varepsilon^{n-1})|_0^2 - (W_\varepsilon^{n,k-1} + R_\varepsilon^{n,k-1} + \overline{X}_\varepsilon^{n,k-1},\chi)^h\Big\}.\tag{4.7}$$

Finally, $W_\varepsilon^{n,k}$ and $R_\varepsilon^{n,k}$ are uniquely defined by (4.5) and (4.2c), respectively. Hence the iterative procedure (4.2a–c) is well defined for any $\mu > 0$.

THEOREM 4.1. *Let the assumptions* (A) *hold. Then there exists a* μ_0 *such that for all* $\mu \in (0,\mu_0)$ *and* $\{W_\varepsilon^{n,0}, R_\varepsilon^{n,0}\} \in [S^h]^2$ *the sequence* $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}\}_{k\geq 0}$ *generated by the algorithm* (4.2a–c) *satisfies*

$$U_\varepsilon^{n,k} \to U_\varepsilon^n \quad \textit{and} \quad \int_\Omega \pi^h[(U_\varepsilon^{n-1})^3]\,|\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|^2\,\mathrm{d}x \to 0 \qquad \textit{as } k\to\infty.\tag{4.8}$$

Proof. This is a simple adaptation of the proof of Theorem 3.1 in [4]. On letting

$$E^k := U_\varepsilon^n - U_\varepsilon^{n,k} \in Z^h, \quad F^k := W_\varepsilon^n - W_\varepsilon^{n,k} \in S^h, \quad \text{and} \quad D^k := R_\varepsilon^n - R_\varepsilon^{n,k} \in S^h,$$

it is an easy exercise to show that

$$\begin{aligned} &|D^k|_h^2 + \tfrac{\mu\,\tau_n}{3}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla F^k|_0^2 + \tfrac23\,\mu\,\tau_n\,|\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla F^k|_0^2 \\ &+ (2\,\mu\,c - C\,\mu^2)\,|E^k|_1^2 \;\leq\; |D^{k-1}|_h^2 + \tfrac{\mu\,\tau_n}{3}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla F^{k-1}|_0^2. \end{aligned} \tag{4.9}$$

Now (4.9) yields that $\{\,|D^k|_h^2 + \frac{\mu\,\tau_n}{3}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla F^k|_0^2\,\}_{k\geq 0}$ is a decreasing sequence for μ sufficiently small and hence has a limit. Therefore, the desired results (4.8) follow from this and (4.9). □

Remark 4.2. The linear system (4.3) can be solved efficiently using a conjugate gradient algorithm. Although we are unable to show convergence of the iteration (4.3) for V_ε^n, we observed good convergence properties in practice.

4.1. Inclusion of repulsive van der Waals forces. We now consider an algorithm for solving the nonlinear algebraic system at each time level in $(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$. Our method for $\{U_\varepsilon^n, W_\varepsilon^n\}$ satisfying (2.11a) and (2.12) is based on the general splitting algorithm of [25]; see also [2, 5], where this algorithm has been adapted to solve similar variational inequality problems arising from Cahn–Hilliard systems. V_ε^n satisfying (2.11c) is solved as before using (4.3). We now introduce our algorithm for $\{U_\varepsilon^n, W_\varepsilon^n\}$. Let $\mathcal{B}_n : S^h \to S^h$ be such that for all $q^h \in S^h$, $\chi \in S^h$

$$(\mathcal{B}_n(q^h), \chi)^h := c\,(\nabla q^h, \nabla \chi) + (\phi^-(U_\varepsilon^{n-1}), \chi)^h\,.$$

Hence (2.12) can be rewritten as

$$(\mathcal{B}_n(U_\varepsilon^n) + \phi^+(U_\varepsilon^n), \chi)^h = (W_\varepsilon^n, \chi)^h \qquad \forall\ \chi \in S^h\,. \tag{4.10}$$

Now, for n fixed, multiplying (4.10) with $\mu \in \mathbb{R}_{>0}$, adding $(U_\varepsilon^n, \chi)^h$ to both sides, rearranging on noting (2.11a), and defining $X_\varepsilon^{n-1} \in S^h$ as in (2.30), it follows that $\{U_\varepsilon^n,\, W_\varepsilon^n\} \in [S^h]^2$ solving (2.11a) and (2.12) satisfy for all $\chi \in S^h$

$$\begin{aligned} \left(\tfrac{U_\varepsilon^n - U_\varepsilon^{n-1}}{\tau_n}, \chi\right)^h + \tfrac{b^{n-1}}{3}\,(\nabla W_\varepsilon^n, \nabla \chi) = \tfrac13\,((b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3])\,\nabla W_\varepsilon^n, \nabla\chi) \\ - (X_\varepsilon^{n-1}, \chi)^h, \end{aligned} \tag{4.11a}$$

$$(U_\varepsilon^n + \mu\,\phi^+(U_\varepsilon^n), \chi)^h = (Y_\varepsilon^n, \chi)^h, \tag{4.11b}$$

where $Y_\varepsilon^n \in S^h$ is such that

$$(Y_\varepsilon^n, \chi)^h := (U_\varepsilon^n, \chi)^h - \mu\,(\mathcal{B}_n(U_\varepsilon^n) - W_\varepsilon^n, \chi)^h \qquad \forall\ \chi \in S^h\,. \tag{4.11c}$$

For later use we introduce also $\overline{Y}_\varepsilon^n \in S^h$ such that

$$(\overline{Y}_\varepsilon^n, \chi)^h := (U_\varepsilon^n, \chi)^h + \mu\,(\mathcal{B}_n(U_\varepsilon^n) - W_\varepsilon^n, \chi)^h \qquad \forall\ \chi \in S^h \tag{4.11d}$$

and note that $\overline{Y}_\varepsilon^n = 2\,U_\varepsilon^n - Y_\varepsilon^n$. We use this as a basis for constructing our iterative procedure to find $\{U_\varepsilon^n,\, W_\varepsilon^n\} \in [S^h]^2$ satisfying (4.11a,b).

Given $\{U_\varepsilon^{n,k-1},\, W_\varepsilon^{n,k-1}\} \in [S^h]^2$ for $k \geq 1$, we define $Y_\varepsilon^{n,k-1} \in S^h$ such that

$$(Y_\varepsilon^{n,k-1}, \chi)^h := (U_\varepsilon^{n,k-1}, \chi)^h - \mu\,(\mathcal{B}_n(U_\varepsilon^{n,k-1}) - W_\varepsilon^{n,k-1}, \chi)^h \qquad \forall\ \chi \in S^h\,. \tag{4.12a}$$

Then we find $U_\varepsilon^{n,k-\frac{1}{2}} \in S^h$ such that

$$(U_\varepsilon^{n,k-\frac{1}{2}} + \mu\,\phi^+(U_\varepsilon^{n,k-\frac{1}{2}}),\chi)^h = (Y_\varepsilon^{n,k-1},\chi)^h \qquad \forall\,\chi \in S^h \tag{4.12b}$$

and find $\{U_\varepsilon^{n,k},\, W_\varepsilon^{n,k}\} \in [S^h]^2$ such that for all $\chi \in S^h$

$$\begin{aligned}\left(\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n},\chi\right)^h &+ \tfrac{b^{n-1}}{3}\,(\nabla W_\varepsilon^{n,k},\nabla\chi)\\ &= \tfrac{1}{3}\,((b^{n-1}-\pi^h[(U_\varepsilon^{n-1})^3])\,\nabla W_\varepsilon^{n,k-1},\nabla\chi) - (X_\varepsilon^{n-1},\chi)^h,\end{aligned} \tag{4.12c}$$

$$(U_\varepsilon^{n,k},\chi)^h + \mu\,(\mathcal{B}_n(U_\varepsilon^{n,k}) - W_\varepsilon^{n,k},\chi)^h = (\overline{Y}_\varepsilon^{n,k},\chi)^h, \tag{4.12d}$$

where $\overline{Y}_\varepsilon^{n,k} := 2\,U_\varepsilon^{n,k-\frac{1}{2}} - Y_\varepsilon^{n,k-1}$. Existence and uniqueness of $U_\varepsilon^{n,k-\frac{1}{2}} > 0$ in (4.12b) follow from the monotonicity of $\varphi : \mathbb{R}_{>0} \to \mathbb{R}$, where $\varphi(s) := s + \mu\,\phi^+(s)$, and the fact that $\lim_{s\to\infty}\varphi(s) = -\lim_{s\searrow 0}\varphi(s) = \infty$.

It remains to show that (4.12c,d) possess a unique solution $\{U_\varepsilon^{n,k},\, W_\varepsilon^{n,k}\} \in [S^h]^2$. This is a simple adaptation of the existence and uniqueness proof for $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}, R_\varepsilon^{n,k}\}$ in (4.2a–c). Similarly to (4.5), it follows from (4.12c), (2.22), (4.12d) with $\chi \equiv 1$, (1.17), and (1.14) that

$$\begin{aligned}W_\varepsilon^{n,k} = (I - \fint)W_\varepsilon^{n,k-1} &- \tfrac{3}{b^{n-1}}\,\mathcal{G}^h[\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n} + A^{n,k-1} + X_\varepsilon^{n-1}]\\ &+ \fint\pi^h[\phi^-(U_\varepsilon^{n-1})] + \mu^{-1}\,\fint(U_\varepsilon^{n,k} - \overline{Y}_\varepsilon^{n,k})\,,\end{aligned} \tag{4.13}$$

where $A^{n,k-1} \in Z^h$ is defined as in (4.4). Then similarly to (4.6), (4.12c,d) may be written equivalently as follows: Find $U_\varepsilon^{n,k} \in \overline{S}^h(U_\varepsilon^{n-1}) \equiv S^h(U_\varepsilon^{n-1})$ such that for all $\chi \in S^h$

$$\begin{aligned}(U_\varepsilon^{n,k},(I-\fint)\chi)^h &+ \mu\left[c\,(\nabla U_\varepsilon^{n,k},\nabla\chi) + \tfrac{3}{b^{n-1}}\,(\mathcal{G}^h[\tfrac{U_\varepsilon^{n,k}-U_\varepsilon^{n-1}}{\tau_n}],\chi)^h\right]\\ = (\overline{Y}_\varepsilon^{n,k} &+ \mu\left[W_\varepsilon^{n,k-1} - \phi^-(U_\varepsilon^{n-1}) - \tfrac{3}{b^{n-1}}\,\mathcal{G}^h[A^{n,k-1}+X_\varepsilon^{n-1}]\right],(I-\fint)\chi)^h.\end{aligned} \tag{4.14}$$

Similarly to (4.7), existence and uniqueness of $U_\varepsilon^{n,k} \in \overline{S}^h(U_\varepsilon^{n-1})$ satisfying (4.14) then follow since this is the Euler–Lagrange equation of the convex minimization problem

$$\begin{aligned}\min_{\chi\in\overline{S}^h(U_\varepsilon^{n-1})} &\left\{\tfrac{1}{2}\,|\chi|_h^2 + \mu\left[\tfrac{c}{2}\,|\chi|_1^2 + \tfrac{3}{2\,b^{n-1}\,\tau_n}|\nabla\mathcal{G}^h(\chi - U_\varepsilon^{n-1})|_0^2\right]\right.\\ &\left. -(\overline{Y}_\varepsilon^{n,k} + \mu\left[W_\varepsilon^{n,k-1} - \phi^-(U_\varepsilon^{n-1}) - \tfrac{3}{b^{n-1}}\,\mathcal{G}^h[A^{n,k-1}+X_\varepsilon^{n-1}]\right],\chi)^h\right\}.\end{aligned}$$

Finally, $W_\varepsilon^{n,k}$ is uniquely defined by (4.13). Hence the iterative procedure (4.12a–d) is well defined for any $\mu > 0$.

THEOREM 4.3. *Let the assumptions* (A) *hold. Then for all* $\mu \in \mathbb{R}_{>0}$ *and* $\{U_\varepsilon^{n,0}, W_\varepsilon^{n,0}\} \in [S^h]^2$ *the sequence* $\{U_\varepsilon^{n,k}, W_\varepsilon^{n,k}\}_{k\geq 0}$ *generated by the algorithm* (4.12a–d) *satisfies*

$$U_\varepsilon^{n,k} \to U_\varepsilon^n \quad \textit{and} \quad \int_\Omega \pi^h[(U_\varepsilon^{n-1})^3]\,|\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|^2\,\mathrm{d}x \to 0 \qquad \textit{as } k \to \infty. \tag{4.15}$$

In addition, it holds that $U_\varepsilon^{n,k-\frac{1}{2}} \to U_\varepsilon^n$ *as* $k \to \infty$.

Proof. A simple adaptation of the proof of Theorem 3.1 in [5] yields that

$$\begin{aligned} & c\,|U_\varepsilon^n - U_\varepsilon^{n,k}|_1^2 + \tfrac{1}{4\mu}\,|Y_\varepsilon^n - Y_\varepsilon^{n,k}|_h^2 + \tfrac{\tau_n}{6}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|_0^2 \\ & \quad + \tfrac{\tau_n}{3}\,|\,[\pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|_0^2 + (\phi^+(U_\varepsilon^n) - \phi^+(U_\varepsilon^{n,k-\frac12}), U_\varepsilon^n - U_\varepsilon^{n,k-\frac12})^h \\ & \qquad \leq \tfrac{1}{4\mu}\,|Y_\varepsilon^n - Y_\varepsilon^{n,k-1}|_h^2 + \tfrac{\tau_n}{6}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla(W_\varepsilon^n - W_\varepsilon^{n,k-1})|_0^2\,. \end{aligned} \tag{4.16}$$

Therefore, on noting the monotonicity of ϕ^+, we have that $\{\,\frac{1}{4\mu}\,|Y_\varepsilon^n - Y_\varepsilon^{n,k}|_h^2 + \frac{\tau_n}{6}\,|\,[b^{n-1} - \pi^h[(U_\varepsilon^{n-1})^3]\,]^{\frac12}\,\nabla(W_\varepsilon^n - W_\varepsilon^{n,k})|_0^2\,\}_{k\geq 0}$ is a decreasing sequence for all $\mu > 0$. Since it is bounded below, the sequence has a limit. Hence the desired results follow from this and (4.16). □

Remark 4.4. Note that the algorithm (4.12a–d) can easily be modified to solve the variational inequality that arises at each time step in $(\mathrm{P}_\varepsilon^{h,\tau})$. In particular, let $\overline{\mathcal{B}}_n : S^h \to S^h$ be such that $(\overline{\mathcal{B}}_n(q^h), \chi)^h := c\,(\nabla q^h, \nabla\chi) + (\phi^-(U_\varepsilon^{n-1} + \varepsilon), \chi)^h$ for all $q^h \in S^h$, $\chi \in S^h$, substitute $\overline{\mathcal{B}}_n$ for $\mathcal{B}_n$ in (4.12a–d), and replace (4.12b) with the following: Find $U_\varepsilon^{n,k-\frac12} \in K^h$ such that $(U_\varepsilon^{n,k-\frac12} - Y_\varepsilon^{n,k}, \eta - U_\varepsilon^{n,k-\frac12})^h \geq 0$ for all $\eta \in K^h$. Then this new procedure satisfies the statement of Theorem 4.3 as well; see [5, section 3] for a similar proof. However, we employed algorithm (4.2a–c) to solve $(\mathrm{P}_\varepsilon^{h,\tau})$ since in practice it exhibited superior convergence properties.

Remark 4.5. We see from (4.6) for $(\mathrm{P}_\varepsilon^{h,\tau})$ and (4.14) for $(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$ that at each iteration for U_ε^n one needs to solve only a fixed linear system with constant coefficients. On a uniform mesh this can be done efficiently using a discrete cosine transform; see [12, section 5], where a similar problem is solved.

5. Numerical results. First, we present numerical experiments in one space dimension in the absence of van der Waals forces, $a = \delta = 0\,(\phi \equiv 0)$. Throughout we chose a uniform partitioning of $\Omega = (-L, L)$, where $L \geq 1$, with mesh points $p_j = -L + (j-1)h$, $j = 1 \to \#J$, where $h = \frac{2L}{\#J-1}$. In addition, we chose uniform time steps $\tau_n = \tau = 1.28 \times 10^{-2}h$ and set the regularization parameter $\varepsilon = 1.28 \times 10^{-3}h$. For the initial profiles $u^0(x)$ and $v^0(x)$, we chose either

$$\text{(i)} \qquad u^0(x) = [\tfrac14 - x^2]_+ \qquad \text{or} \qquad \text{(ii)} \qquad u^0(x) = 1 \tag{5.1a}$$

$$\text{with} \qquad v^0(x) = \tfrac{v_{\max}^0}{2}\,[(1-\gamma) - \tanh(A(|x| - x_0))]_+\,, \tag{5.1b}$$

where $v_{\max}^0 \geq 0$, $\gamma \in [0,1)$, $A > 0$, and $x_0 \in (0, L)$. (i) with $v_{\max}^0 > 0$, (i) with $v_{\max}^0 = 0$, and (ii) with $v_{\max}^0 > 0$ resemble a liquid drop on a plain surface with and without surfactant on top of it and a uniform liquid film with surfactant, respectively. Note that for $\gamma > 0$ the surfactant v^0 has compact support $[-l, l]$, where $l = x_0 + A^{-1}\tanh^{-1}(1-\gamma)$. Throughout we chose $U_\varepsilon^0 \equiv \pi^h u^0$ and $V_\varepsilon^0 \equiv \pi^h v^0$ as the discrete initial data for $(\mathrm{P}_\varepsilon^{h,\tau})$ and $(\mathrm{P}_{\delta,\varepsilon}^{h,\tau})$.

For the iterative algorithms (4.2a–c), (4.12a–d), and (4.3), we set, for $n \geq 1$, $Z^{n,0} \equiv Z^{n-1}$ for $Z = U_\varepsilon, W_\varepsilon, V_\varepsilon$, and R_ε, where

$$R_\varepsilon^0 = 0 \quad \text{and} \quad (W_\varepsilon^0, \chi)^h = c\,(\nabla U_\varepsilon^0, \nabla\chi) + (\phi(U_\varepsilon^0), \chi)^h \qquad \forall\, \chi \in S^h\,,$$

and for each n adopted the stopping criteria

$$|U_\varepsilon^{n,k} - U_\varepsilon^{n,k-1}|_{0,\infty} < tol \quad \text{and} \quad |V_\varepsilon^{n,k} - V_\varepsilon^{n,k-1}|_{0,\infty} < tol, \tag{5.2}$$

respectively, with $tol = 10^{-8}$. Furthermore, we chose $\mu = \frac{1}{1.13\,h}$ and set $\{U^n_\varepsilon, W^n_\varepsilon, R^n_\varepsilon\} \equiv \{\pi^h[U^{n,k}_\varepsilon]_+, W^{n,k}_\varepsilon, R^{n,k}_\varepsilon\}$ for (4.2a–c), while we used $\mu = 0.625\,h$ and set $\{U^n_\varepsilon, W^n_\varepsilon\} \equiv \{U^{n,k}_\varepsilon, W^{n,k}_\varepsilon\}$ if $U^{n,k}_\varepsilon > 0$ and $\{U^n_\varepsilon, W^n_\varepsilon\} \equiv \{U^{n,k-\frac{1}{2}}_\varepsilon, W^{n,k}_\varepsilon\}$ otherwise for (4.12a–d). For the iteration (4.3) we set $V^n_\varepsilon \equiv V^{n,k}_\varepsilon$.

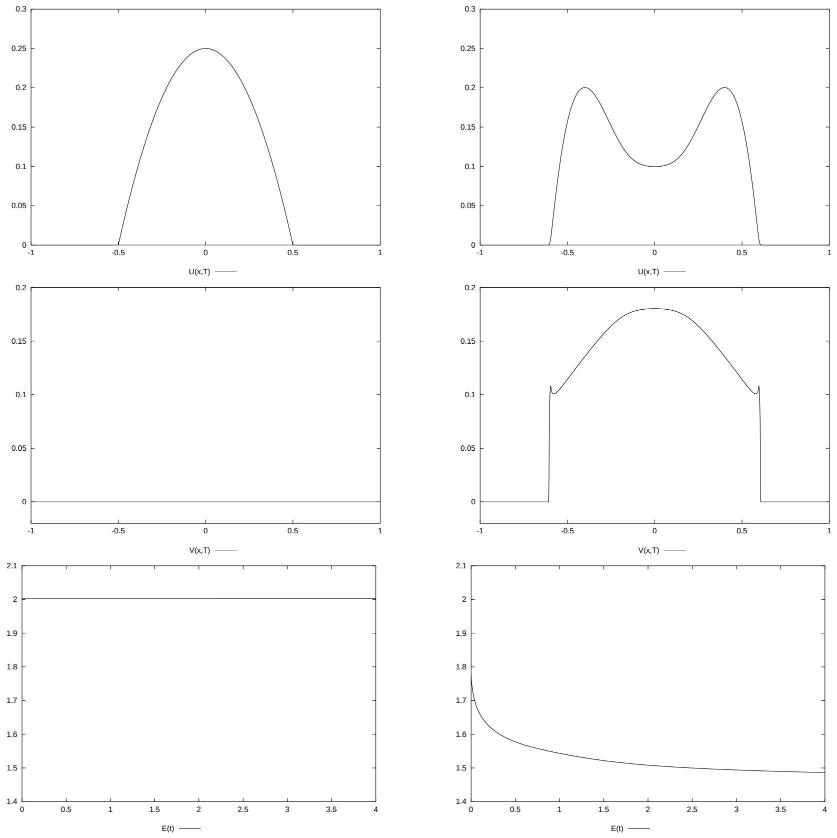
In our first set of experiments we set the parameters $L = 1$, $c = 2 \times 10^{-2}$, $\rho = 0$, and we chose the initial data (i) with $v^0_{\max} = 0$ and a final time $T = 4$. We note from the weak formulation (3.25a–c) that this initial data is a steady state for (P); that is, $u(x,t) = u^0(x)$, $v(x,t) = 0$ for all $(x,t) \in \Omega_T$. The results for various choices of h are displayed in Table 1, where all values are correct to four significant figures.

Remark 5.1. In order to obtain a discretization that leads to a discrete analogue of the energy estimate (1.5) we needed to approximate $\lambda(v)$ in a subtle way; see (2.7). In particular, the resulting scheme does not guarantee that $V_\varepsilon \equiv 0$ if the initial data have this property. However, the results in Table 1 show that the error between V_ε and v is small.

In Figure 1 we plot $\pi^h u^0(x) - U_\varepsilon(x,T)$ for $\#J = 2^k + 1$, $k = 6 \to 11$, on a short interval about the initial free boundary point on the right-hand side, $x = 0.5$. For each $\#J$ there are a few points outside the support of $u^0(x)$ which are much larger than $tol = 10^{-8}$. Outside the region plotted $|\pi^h u^0(x) - U_\varepsilon(x,T)|$ is "zero," i.e., much smaller than tol. This behavior compares with results in [4], where similar errors can be observed. Note that the different choice of c here acts as a time scaling factor.

We see from Figure 2 that for $\#J = 2^{10} + 1$ the initial profile $U^0_\varepsilon \equiv \pi^h u^0$ is graphically preserved in the absence of surfactant. This is underlined by the fact that the energy

$$E(t) := \tfrac{t-t_{n-1}}{\tau_n}\,\mathcal{E}(U^n_\varepsilon, V^n_\varepsilon) + \tfrac{t_n-t}{\tau_n}\,\mathcal{E}(U^{n-1}_\varepsilon, V^{n-1}_\varepsilon), \qquad t \in [t_{n-1}, t_n], \quad n \geq 1,$$



(a) (b)

FIG. 2. *Comparison of* $U_\varepsilon(x,T)$*,* $V_\varepsilon(x,T)$ *at* $T = 4$ *and* $E(t)$ *for* $t \in [0,T]$ *in the* (a) *absence and* (b) *presence of surfactant, respectively.*

remains constant over the whole time period $[0,T]$. When surfactant is included, however, this has a dramatic effect on the shape of the solution $U_\varepsilon(x,T)$. For the plot in Figure 2, we took v^0 as described in (5.1b) with $A = 50$, $x_0 = 0.1$, $\gamma = 10^{-4}$, and $v^0_{\max} = 0.9$ so that the support of $v^0 \subset (-0.2, 0.2) \subset [-0.5, 0.5]$, the support of u^0. Eventually the solutions U_ε and V_ε reach a "numerical steady state"; i.e., we obtain that $\{U^n_\varepsilon, W^n_\varepsilon, V^n_\varepsilon\} \equiv \{U^{n,1}_\varepsilon, W^{n,1}_\varepsilon, V^{n,1}_\varepsilon\}$ for n sufficiently large for the stated stopping criteria on U_ε and V_ε (see (5.2)). For the parameters mentioned above and a stopping tolerance of $tol = 10^{-10}$ this state is reached at $T = 3413$. In Figure 3 we plot $U_\varepsilon(\cdot,t)$ and $V_\varepsilon(\cdot,t)$ for $t = 0$, $t = 50$, $t = 200$, and $t = 3413$, respectively.

Remark 5.2. In the case $\rho = 0$, the only mechanism for surfactant spreading is transport via the fluid velocity. If the support of the initial data of the surfactant is contained in the set of points initially wetted, then one can show that the support of the surfactant at time t is contained in the set $\mathcal{W}(t) := \{x : u(x,\tau) > 0 \text{ for some } \tau \in [0,t]\}$, which is the set of points which have been wetted at some time in the past. For the discrete problem a similar property follows directly from (2.11c), since $V^n_\varepsilon(p_j)$ can only be nonzero if either $V^{n-1}_\varepsilon(p_j) \neq 0$ or $(U^n_\varepsilon, \chi_j) \neq 0$. Therefore, the only modification is that the support of the surfactant can be one mesh point ahead of the discrete analogue of $\mathcal{W}(t)$.

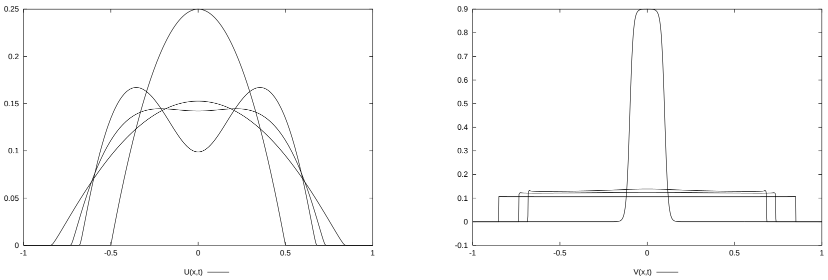


FIG. 3. *$U_\varepsilon(x,t)$ and $V_\varepsilon(x,t)$ for $t = 0, 50, 200, 3413$.*

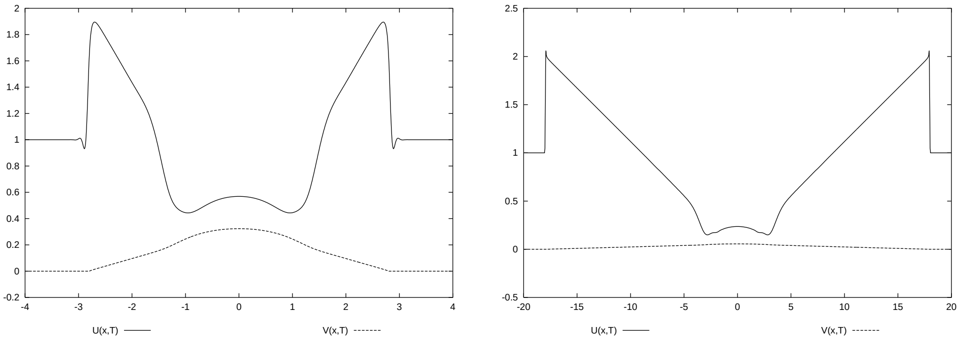

FIG. 4. *$U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ plotted against x for $T = 4$ (left) and $T = 1000$ (right).*

Remark 5.3. A parabolic profile for the drop together with a constant surfactant density on the support of the drop is a steady state for the system (1.1a–c) if $\rho = 0$. It is the discrete analogue of such a steady state that we observe for large times in Figure 3.

Remark 5.4. For the thin film equation (in the no-slip case) it is conjectured that the support of the film does not increase. In the case that a surfactant is placed on the film this property does not seem to be true any longer.

In addition, we performed experiments for a uniform liquid layer, i.e., $u^0 \equiv 1$. We chose the parameters similar to the ones reported in [26]. In particular, we took $L = 4$, $T = 4$, $c = 10^{-5}$, $\rho = 2 \times 10^{-4}$, $v^0_{\max} = 1$, $\gamma = 0$, $A = 10$, $x_0 = 0.5$, and $\#J = 2^{10} + 1$. The computed solutions $U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ can be seen on the left-hand side of Figure 4.

We note that $U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ approach similarity solutions of (P) for the case $\rho = c = a = \delta = 0$; see [24]. This can be seen on the right-hand side of Figure 4, where we plot the two functions for the values $L = 20$, $T = 1000$, $c = 10^{-8}$, $\rho = 0$, $\gamma = 0$, $v^0_{\max} = 1$, $A = 10$, $x_0 = 0.5$, and $\#J = 2^{10} + 1$. We recall that $(\mathrm{P}^{h,\tau}_\varepsilon)$ is only well-posed for $c > 0$. In order to formulate the similarity solutions, we make use of the following transformation of coordinates. Let $\xi := (1+t)^{-\frac{1}{3}}\, x$, $\overline{u}(\xi,t) := U_\varepsilon(x,t)$ and $\overline{v}(\xi,t) := (1+t)^{\frac{1}{3}}\, V_\varepsilon(x,t)$. Then the similarity solutions for $\overline{u}$ and $\overline{v}$ are given by

$$\overline{u}_0(\xi) = \begin{cases} \frac{2\,\xi}{\xi_s}, & 0 \le \xi < \xi_s, \\ 1, & \xi_s \le \xi, \end{cases} \quad \text{and} \quad \overline{v}_0(\xi) = \begin{cases} \frac{\xi_s}{6}\,(\xi_s - \xi), & 0 \le \xi < \xi_s, \\ 0, & \xi_s \le \xi, \end{cases}$$

where $\xi_s := (12 \int_0^L v^0(x)\,\mathrm{d}x)^{\frac{1}{3}}$ is the position of the shock. The corresponding plot is shown on the left-hand side of Figure 5.

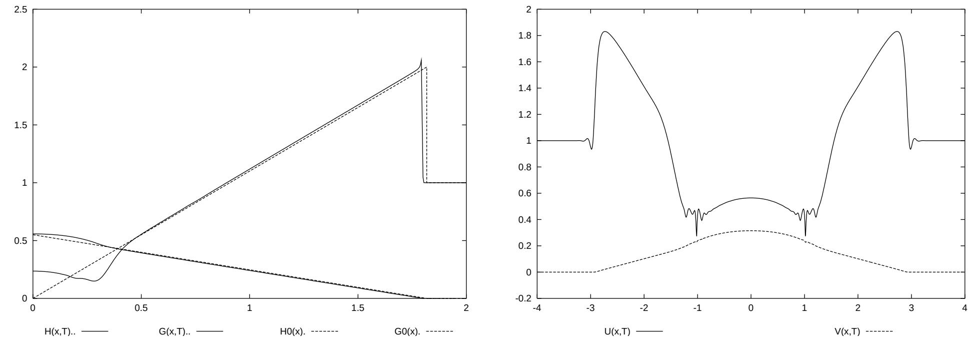

FIG. 5. $\overline{u}(\xi, T)$, $\overline{v}(\xi, T)$ *with the corresponding similarity solutions* $\overline{u}_0(\xi)$, $\overline{v}_0(\xi)$ *plotted against* ξ *for* $T = 1000$ *(left) and* $U_\varepsilon(x, T)$, $V_\varepsilon(x, T)$ *plotted against* x *for* $T = 4.33$ *when* $\phi \not\equiv 0$ *(right).*

5.1. Inclusion of van der Waals forces. In addition, we conducted numerical experiments in which we considered the effect of both attractive and repulsive van der Waals forces being present. Note that this corresponds to $a > 0$ and $\delta > 0$, respectively.

We note that (4.12b) is a decoupled system of $\#J$ equations and that for $\chi \equiv \chi_j$ one has to find $s = U_\varepsilon^{n,k-\frac{1}{2}}(p_j) \in \mathbb{R}_{>0}$ that satisfies

$$\psi(s) := s^2\,(\varphi(s) - Y_\varepsilon^{n,k}(p_j)) = 0, \tag{5.3}$$

where $\varphi(s) := s + \mu\,\phi^+(s)$ as in section 4. To solve $\psi(s) = 0$, we use Newton's method:

$$s^{\ell+1} = s^\ell - [\psi'(s^\ell)]^{-1}\psi(s^\ell), \qquad \ell \geq 0, \tag{5.4}$$

with $|s^{\ell+1} - s^\ell| < tol$ as the stopping criterion and $s^0 = U_\varepsilon^{n,k-\frac{3}{2}}(p_j)$ for $k \geq 2$ and $s^0 = U_\varepsilon^{n,0}(p_j)$ otherwise. Note that we introduced the term s^2 in (5.3) in order to stabilize the Newton iteration. Although other powers of s are possible, this particular choice seemed preferable in practice. In fact, the iteration (5.4) always converged.

On the right-hand side of Figure 5, we plot $U_\varepsilon(x, T)$ and $V_\varepsilon(x, T)$ for $a = 2 \times 10^{-3}$, $\delta = 10^{-5}$, and $\nu = 4$. The other parameters were chosen as follows: $c = 10^{-5}$, $\rho = 2 \times 10^{-3}$, initial data (ii) with $v^0_{\text{max}} = 1$, $\gamma = 0$, $A = 10$, $x_0 = 0.5$, $L = 4$, $T = 4.33$, and $\#J = 2^{10} + 1$. One can clearly see the effect of modeling the van der Waals forces. Once the film thickness reaches a certain threshold, the film tries to rupture in the effected regions. Note that we have plotted the solutions just before such a "rupture" occurs. Although the film height might become extremely thin, it can never actually rupture ($U_\varepsilon = 0$) due to the presence of the repulsive van der Waals forces. We would also like to mention that we repeated the experiment with the parameters mentioned above on a very fine mesh. As we obtained virtually identical results, we are satisfied that the oscillations shown in Figure 5 are not due to mesh effects. In fact, the instabilities are in agreement with linear stability analysis for the thin film equation in the presence of van der Waals forces (see [28, 27]).

5.2. Numerical results for $d = 2$. Finally, we present numerical experiments in two space dimensions with $\Omega = (-L, L) \times (-L, L)$. We took a uniform mesh of squares ς of length $h = \frac{2L}{128}$, each of which was divided into two triangles by its north

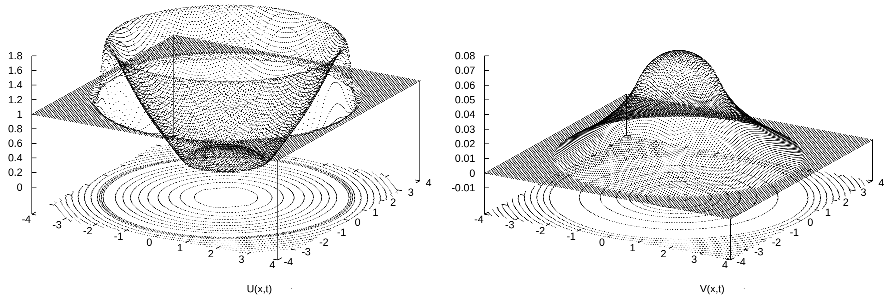

FIG. 6. *$U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ plotted against x for $T = 35$.*

east diagonal. We used the modified discrete semi-inner product on $C(\overline{\Omega})$:

$$(\eta_1, \eta_2)^h_* := \int_\Omega \Pi^h(\eta_1(x)\,\eta_2(x))\,\mathrm{d}x\,. \tag{5.5}$$

Here Π^h is the piecewise continuous bilinear interpolant on $\overline{\Omega}$, which on each square ς is bilinear and interpolates at the vertices. Using (5.5) instead of (2.1) enables us to solve (4.6) efficiently using a "discrete cosine transform" approach; see [2]. We note that similarly to (2.1) and (2.14), the semi-inner product (5.5) is equivalent on S^h to the standard L^2 inner product, and in place of (2.17), we have that

$$|(z^h,\chi)^h - (z^h,\chi)^h_*| \leq C h^{1+m}[\ln(\tfrac{1}{h})]^2\,\|z^h\|_m \|\chi\|_1 \qquad \forall\ z^h,\ \chi \in S^h\,, \quad m = 0 \text{ or } 1.$$

Therefore, it is easy to adapt the proofs to show that all the results in this paper remain unchanged with the choice (5.5).

We report on an experiment with the same parameters for (P) as in $d = 1$ for Figure 4. In particular, we set $a = \delta = 0$, $c = 10^{-5}$, $\rho = 2 \times 10^{-4}$, $L = 4$, $T = 35$, $\tau_n = \tau = 10^{-3}$, and $\varepsilon = 10^{-5}$, and for the initial profiles we chose $u^0 \equiv 1$ and (5.1b) for v^0 with $v^0_{\max} = 1$, $\gamma = 0$, $A = 10$, and $x_0 = 0.5$. We set $U^0_\varepsilon \equiv \pi^h u^0$ and $V^0_\varepsilon \equiv \pi^h v^0$. Note that u^0, $v^0 \in W^{1,\infty}(\Omega)$, and hence the results of Lemma 2.5 still hold for the chosen U^0_ε, V^0_ε on noting a standard interpolation result. Note, furthermore, that here we integrate until $T = 35$ as opposed to $T = 4$ in one space dimension. This is due to the slower speed of propagation; e.g., the corresponding similarity solution for $c = \rho = 0$ advances proportionally to $(1+t)^{\frac{1}{4}}$ for $d = 2$ as opposed to $(1+t)^{\frac{1}{3}}$ for $d = 1$ (see [24]). We chose $tol = 10^{-8}$ and $\mu = 400$ for the iterative method (4.2a–c). In Figure 6, we plot $U_\varepsilon(x,T)$ and $V_\varepsilon(x,T)$ for $T = 35$, respectively.

COMPONENT-BY-COMPONENT CONSTRUCTION OF GOOD INTERMEDIATE-RANK LATTICE RULES[*]

F. Y. KUO[†] AND S. JOE[‡]

Abstract. It is known that the generating vector of a rank-1 lattice rule can be constructed component-by-component to achieve strong tractability error bounds in both weighted Korobov spaces and weighted Sobolev spaces. Since the weights for these spaces are nonincreasing, the first few variables are in a sense more important than the rest. We thus propose to copy the points of a rank-1 lattice rule a number of times in the first few dimensions to yield an intermediate-rank lattice rule. We show that the generating vector (and in weighted Sobolev spaces, the shift also) of an intermediate-rank lattice rule can also be constructed component-by-component to achieve strong tractability error bounds. In certain circumstances, these bounds are better than the corresponding bounds for rank-1 lattice rules.

Key words. quasi-Monte Carlo methods, intermediate-rank lattice rules, worst-case error, tractability

AMS subject classifications. 65D30, 65D32, 68Q25

DOI. 10.1137/S0036142902407162

1. Introduction.

The d-dimensional integral

$$I_d(f) = \int_{[0,1]^d} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$$

may be approximated using rank-1 lattice rules. These are equal-weight rules having quadrature points belonging to the set

$$\left\{ \left\{ \frac{i\boldsymbol{z}}{n} \right\} : 0 \le i \le n-1 \right\}.$$

Here $\boldsymbol{z}$, known as the generating vector, is an integer vector having no factor in common with n, and the braces around a vector indicate that we take the fractional part of each component of the vector. It is shown in [14] that every lattice rule may be written as a multiple sum involving one or more generating vectors; the minimum number of generating vectors required to generate a lattice rule is known as the "rank" of the rule. Besides rank-1 lattice rules involving just one generating vector, there exist lattice rules having rank up to d. More information about lattice rules may be found in [11].

The construction of rank-1 lattice rules for integrands belonging to weighted Korobov and weighted Sobolev spaces has been studied in various papers. These weighted function spaces are tensor product reproducing kernel Hilbert spaces. Recall that a

quasi-Monte Carlo (QMC) rule

$$Q_{n,d}(f) = \frac{1}{n}\sum_{i=0}^{n-1} f(\boldsymbol{x}_i) \tag{1.1}$$

is an equal-weight quadrature rule with the quadrature points chosen in a deterministic way. The "worst-case error" of a QMC rule in some Hilbert space H_d is defined to be

$$e_{n,d}(Q_{n,d}, H_d) := \sup\{|Q_{n,d}(f) - I_d(f)| : \|f\|_{H_d} \le 1, f \in H_d\},$$

and the initial error is

$$e_{0,d}(H_d) := \sup\{|I_d(f)| : \|f\|_{H_d} \le 1, f \in H_d\}.$$

Following the analysis by Sloan and Woźniakowski in [16], the integration problem is said to be "strongly QMC tractable" in the Hilbert space H_d if the minimal number of function evaluations n in a QMC rule (1.1) needed to reduce the initial error $e_{0,d}(H_d)$ by a factor of $\varepsilon > 0$ is bounded by a polynomial in ε^{-1} independently of d.

In [15], a component-by-component algorithm was developed for constructing rank-1 lattice rules in unweighted Korobov spaces. The algorithm was later extended to shifted rank-1 lattice rules (see [12]) in weighted Sobolev spaces, and the rules constructed achieve strong QMC tractability error bounds. Both these constructions assumed that n, the number of quadrature points, was a prime number. The construction was later generalized in [10] to rules with a composite number of points. Construction of rank-1 lattice rules in the randomized setting has been considered in [13]. Recently, it was shown in [9] that the constructions achieve the optimal rate of convergence in the corresponding function spaces.

Lattice rules constructed in this manner are "extensible" in terms of the dimension d; that is, if further dimensions are needed at a later stage, the additional components can be constructed with the existing components kept unchanged. However, if more points are required, then the rules need to be reconstructed from scratch. A recent work [4] showed the existence of good rank-1 lattice rules that are extensible both in terms of the number of points n and the dimension d, but the proof is nonconstructive.

We are interested in "copying" rank-1 lattice rules. Since the weighted function spaces of interest have nonincreasing weights, the first few variables are in a sense more important than the rest. Therefore, it would seem intuitive to copy the points in the first few dimensions. Thus we may copy an n-point d-dimensional rank-1 lattice rule ℓ times in each of the first r dimensions, where $\ell \ge 1$, $\gcd(\ell, n) = 1$, and $0 \le r \le d$. We then obtain the rule with $N = \ell^r n$ points given by

$$Q_{n,d}(f) = \frac{1}{\ell^r n}\sum_{m_r=0}^{\ell-1}\cdots\sum_{m_1=0}^{\ell-1}\sum_{i=0}^{n-1} f\left(\left\{\frac{i\boldsymbol{z}}{n} + \frac{(m_1,\dots,m_r,0,\dots,0)}{\ell}\right\}\right).$$

We call the rule with these points "the (ℓ, r)-copy of a rank-1 lattice rule with generating vector $\boldsymbol{z}$." When $r = 0$ and/or $\ell = 1$, we get just the original n-point rank-1 lattice rule. For $r \ge 1$, the resulting rule is a rank-r lattice rule. These intermediate-rank lattice rules have previously been considered in [7] and [8]. Typically, for reasons of tractability, we will take r to be a fixed number, say, $r = 1$, 2, or 3. For the choice of ℓ it would seem reasonable on practical grounds and theoretical grounds (see Theorem 2.3 and Lemma 2.4) to take ℓ to be 2 in actual calculations. This value of $\ell = 2$ has been used previously in [7] and [8].

Our plan is to construct intermediate-rank lattice rules in both weighted Korobov and weighted Sobolev spaces that achieve strong QMC tractability error bounds. In section 2, we consider intermediate-rank lattice rules in weighted Korobov spaces. We show that the intermediate-rank lattice rule we consider has the same worst-case error as a certain rank-1 lattice rule in a slightly different weighted Korobov space. We then show that there exist intermediate-rank lattice rules with error bounds which are better than the corresponding bounds for rank-1 lattice rules with approximately the same number of points. Moreover, we shall see that the generating vectors constructed component-by-component satisfy strong QMC tractability bounds and achieve the optimal rate of convergence in weighted Korobov spaces. In section 3, we give a brief discussion on the construction of shifted intermediate-rank lattice rules in weighted Sobolev spaces. The final section, section 4, contains numerical results.

Throughout the paper, we will assume that n is a prime number to simplify the analysis. More general results for any positive integer n can be obtained by emulating the more complicated analysis found in [10]. When n is a prime number, $\boldsymbol{z}$ can be chosen from $\mathbb{Z}_n^d$, where $\mathbb{Z}_n := \{1, 2, \ldots, n-1\}$.

2. Intermediate-rank lattice rules in weighted Korobov spaces.

We are interested in the weighted Korobov spaces of periodic functions considered in [10]. These spaces are parameterized by a real parameter $\alpha > 1$ and two sequences of positive weights $\boldsymbol{\beta} = \{\beta_j\}$ and $\boldsymbol{\gamma} = \{\gamma_j\}$ satisfying

$$\frac{\gamma_1}{\beta_1} \geq \frac{\gamma_2}{\beta_2} \geq \cdots .$$

The inner product in these spaces is given by

$$\langle f, g \rangle_d = \sum_{\boldsymbol{h} \in \mathbb{Z}^d} \left(\hat{f}(\boldsymbol{h}) \overline{\hat{g}(\boldsymbol{h})} \prod_{j=1}^{d} r(\alpha, \beta_j, \gamma_j, h_j) \right),$$

where

$$r(\alpha, \beta, \gamma, h) = \begin{cases} \beta^{-1} & \text{if } h = 0, \\ \gamma^{-1} |h|^{\alpha} & \text{otherwise.} \end{cases}$$

Here α is a smoothness parameter characterizing the rate of decay of the Fourier coefficients. Various variations of these spaces have previously been considered in works such as [5], [6], [15], and [16]. The worst-case error in these Korobov spaces for a QMC rule (1.1) is given by

$$e_{n,d}^2(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}) = -\prod_{j=1}^{d} \beta_j + \frac{1}{n^2} \sum_{i=0}^{n-1} \sum_{k=0}^{n-1} \prod_{j=1}^{d} \left(\beta_j + \gamma_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h (x_{i,j} - x_{k,j})}}{|h|^{\alpha}} \right), \tag{2.1}$$

where the $'$ on the sum indicates that we omit the $h = 0$ term. This expression may be written in terms of Bernoulli polynomials if α is chosen to be a positive even number. The initial error is

$$e_{0,d} = \prod_{j=1}^{d} \beta_j^{\frac{1}{2}}.$$

Following the analysis of tractability in [16], it is possible to show that if the weights satisfy

$$\sum_{j=1}^{\infty} \frac{\gamma_j}{\beta_j} < \infty, \tag{2.2}$$

then an upper bound for the square worst-case error of the form

$$\frac{b}{n} \prod_{j=1}^{d} \left(\beta_j + a\gamma_j\right), \tag{2.3}$$

where $a, b > 0$ are bounded independently of d, is enough to ensure strong QMC tractability, with the rate of convergence being $O(n^{-1/2})$. Moreover, the optimal rate of convergence $O(n^{-\alpha/2+\delta})$, for any $\delta > 0$, can be achieved if the weights satisfy a stronger condition,

$$\sum_{j=1}^{\infty} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} < \infty.$$

It is worth mentioning that the condition (2.2) is also necessary for strong QMC tractability (see [6]).

We now consider the (ℓ, r)-copy of a rank-1 lattice rule with generating vector $\boldsymbol{z}$, that is, a rule with points belonging to the set

$$\left\{\left\{\frac{i\boldsymbol{z}}{n} + \frac{(m_1, \dots, m_r, 0, \dots, 0)}{\ell}\right\} : 0 \le i \le n-1,\ 0 \le m_1, \dots, m_r \le \ell - 1\right\},$$

where $\ell \ge 1$, $\gcd(\ell, n) = 1$, and $0 \le r \le d$. An expression for $e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z})$, the worst-case error for such a rule, is given in the next lemma. Note that though this intermediate-rank lattice rule has $N = \ell^r n$ points, the lemma shows that the worst-case error may be calculated by using a rule having just n points. We will explore this further in the next subsection.

LEMMA 2.1. *We have*

$$e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) = -\prod_{j=1}^{d} \beta_j + \frac{1}{n} \sum_{k=0}^{n-1} \left[\prod_{j=1}^{r} \left(\beta_j + \frac{\gamma_j}{\ell^\alpha} {\sum_{h=-\infty}^{\infty}}' \frac{e^{2\pi \mathrm{i} h \ell k z_j/n}}{|h|^\alpha}\right) \times \prod_{j=r+1}^{d} \left(\beta_j + \gamma_j {\sum_{h=-\infty}^{\infty}}' \frac{e^{2\pi \mathrm{i} h k z_j/n}}{|h|^\alpha}\right)\right].$$

Proof. We have from (2.1) that

$$e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) = -\prod_{j=1}^{d} \beta_j + \frac{1}{\ell^{2r} n^2} \sum_{q_r=0}^{\ell-1} \cdots \sum_{q_1=0}^{\ell-1} \sum_{m_r=0}^{\ell-1} \cdots \sum_{m_1=0}^{\ell-1} \sum_{i=0}^{n-1} \sum_{k=0}^{n-1} \left[\prod_{j=1}^{r} \left(\beta_j + \gamma_j {\sum_{h=-\infty}^{\infty}}' \frac{e^{2\pi \mathrm{i} h \left(\left\{\frac{iz_j}{n} + \frac{q_j}{\ell}\right\} - \left\{\frac{kz_j}{n} + \frac{m_j}{\ell}\right\}\right)}}{|h|^\alpha}\right) \times \prod_{j=r+1}^{d} \left(\beta_j + \gamma_j {\sum_{h=-\infty}^{\infty}}' \frac{e^{2\pi \mathrm{i} h \left(\left\{\frac{iz_j}{n}\right\} - \left\{\frac{kz_j}{n}\right\}\right)}}{|h|^\alpha}\right)\right].$$

The second term can be written as

$$\frac{1}{n^2}\sum_{i=0}^{n-1}\sum_{k=0}^{n-1}\left[\prod_{j=1}^{r}\left(\frac{1}{\ell^2}\sum_{q=0}^{\ell-1}\sum_{m=0}^{\ell-1}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h((i-k)z_j/n+(q-m)/\ell)}}{|h|^\alpha}\right)\right)\right.$$
$$\left.\times\prod_{j=r+1}^{d}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h(i-k)z_j/n}}{|h|^\alpha}\right)\right]. \tag{2.4}$$

For $0\le q,m\le \ell-1$, the values of $(q-m) \bmod \ell$ are just 0 to $\ell-1$ in some order, with each value occurring ℓ times. Thus we have

$$\frac{1}{\ell^2}\sum_{q=0}^{\ell-1}\sum_{m=0}^{\ell-1}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h((i-k)z_j/n+(q-m)/\ell)}}{|h|^\alpha}\right)$$
$$=\frac{1}{\ell}\sum_{m=0}^{\ell-1}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h((i-k)z_j/n+m/\ell)}}{|h|^\alpha}\right).$$

Now since

$$\sum_{m=0}^{\ell-1} e^{2\pi \mathrm{i} hm/\ell}=\begin{cases}\ell & \text{if } h \text{ is a multiple of } \ell,\\ 0 & \text{otherwise,}\end{cases} \tag{2.5}$$

we have

$$\frac{1}{\ell}\sum_{m=0}^{\ell-1}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h((i-k)z_j/n+m/\ell)}}{|h|^\alpha}\right)$$
$$=\beta_j+\frac{\gamma_j}{\ell}\sum_{h=-\infty}^{\infty}{}'\left(\frac{e^{2\pi \mathrm{i} h(i-k)z_j/n}}{|h|^\alpha}\sum_{m=0}^{\ell-1}e^{2\pi \mathrm{i} hm/\ell}\right)$$
$$=\beta_j+\frac{\gamma_j}{\ell}\sum_{m=-\infty}^{\infty}{}'\left(\frac{e^{2\pi \mathrm{i} m\ell(i-k)z_j/n}}{|m\ell|^\alpha}\cdot\ell\right)$$
$$=\beta_j+\frac{\gamma_j}{\ell^\alpha}\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h\ell(i-k)z_j/n}}{|h|^\alpha}.$$

Thus (2.4) can be simplified to

$$\frac{1}{n^2}\sum_{i=0}^{n-1}\sum_{k=0}^{n-1}\left[\prod_{j=1}^{r}\left(\beta_j+\frac{\gamma_j}{\ell^\alpha}\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h\ell(i-k)z_j/n}}{|h|^\alpha}\right)\right.$$
$$\left.\times\prod_{j=r+1}^{d}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h(i-k)z_j/n}}{|h|^\alpha}\right)\right],$$

which can be simplified even further to

$$\frac{1}{n}\sum_{k=0}^{n-1}\left[\prod_{j=1}^{r}\left(\beta_j+\frac{\gamma_j}{\ell^\alpha}\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h\ell kz_j/n}}{|h|^\alpha}\right)\prod_{j=r+1}^{d}\left(\beta_j+\gamma_j\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} hkz_j/n}}{|h|^\alpha}\right)\right],$$

since for $0\le i,k\le n-1$, the values of $(i-k) \bmod n$ are just 0 to $n-1$ in some order, with each value occurring n times. This completes the proof. □

2.1. Relationship with rank-1 lattice rules based on worst-case error. Let us define the sequence $\bar{\boldsymbol{\gamma}}$ by

$$\bar{\gamma}_j := \begin{cases} \dfrac{\gamma_j}{\ell^\alpha} & \text{if } 1 \le j \le r, \\ \gamma_j & \text{otherwise} \end{cases}$$

and set $\bar{\boldsymbol{z}}$ to be the d-dimensional vector with components given by

$$\bar{z}_j := \begin{cases} \ell z_j & \text{if } 1 \le j \le r, \\ z_j & \text{otherwise.} \end{cases}$$

Then the expression in Lemma 2.1 may be rewritten in the form

$$e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) = -\prod_{j=1}^d \beta_j + \frac{1}{n}\sum_{k=0}^{n-1}\prod_{j=1}^d \left(\beta_j + \bar{\gamma}_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} hk\bar{z}_j/n}}{|h|^\alpha}\right) = e^2_{n,d}(\bar{\boldsymbol{z}}, \bar{\boldsymbol{\gamma}}); \tag{2.6}$$

that is, *the worst-case error of an intermediate-rank lattice rule with generating vector $\boldsymbol{z}$ in the weighted Korobov space with weights $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ is the same as the worst-case error of a rank-*1 *lattice rule with generating vector $\bar{\boldsymbol{z}}$ in the weighted Korobov space with weights $\boldsymbol{\beta}$ and $\bar{\boldsymbol{\gamma}}$.*

Since $\ell \ne 0$ and $\gcd(\ell, n) = 1$, for fixed r there exist a unique $\bar{\boldsymbol{z}}$ for each $\boldsymbol{z}$ and vice versa. Because of this one-to-one correspondence between $\boldsymbol{z}$ and $\bar{\boldsymbol{z}}$, all the known results on rank-1 lattice rules in weighted Korobov spaces can be applied here, with generating vector $\bar{\boldsymbol{z}}$ and weights $\boldsymbol{\beta}$ and $\bar{\boldsymbol{\gamma}}$. Note that the effect of copying in the first r dimensions can be interpreted as a reduction of the first r terms of $\boldsymbol{\gamma}$ by a factor of $1/\ell^\alpha$.

The following theorem is a slight generalization of Lemma 2 in [16]. (There $\boldsymbol{\beta}$ is assumed to be $\mathbf{1}$.)

THEOREM 2.2. *Let n be a prime number, and define $M_{n,d,\mathrm{copy}(\ell,r)}$ to be the mean given by*

$$M_{n,d,\mathrm{copy}(\ell,r)} := \frac{1}{(n-1)^d}\sum_{\boldsymbol{z}\in\mathbb{Z}_n^d} e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}).$$

Then an expression for $M_{n,d,\mathrm{copy}(\ell,r)}$ is given by

$$\begin{aligned} &-\prod_{j=1}^d \beta_j + \frac{1}{n}\prod_{j=1}^r \left(\beta_j + \frac{2\gamma_j\zeta(\alpha)}{\ell^\alpha}\right)\prod_{j=r+1}^d (\beta_j + 2\gamma_j\zeta(\alpha)) \\ &+ \left(1-\frac{1}{n}\right)\prod_{j=1}^r \left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{(n-1)\ell^\alpha}\right)\prod_{j=r+1}^d \left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{n-1}\right), \end{aligned}$$

where $\zeta(\alpha)$ is the Riemann zeta function. Moreover, if n satisfies $n \ge 1 + \frac{\gamma_1}{\beta_1}\zeta(\alpha)$, then

$$M_{n,d,\mathrm{copy}(\ell,r)} \le \frac{1}{n}\prod_{j=1}^r \left(\beta_j + \frac{2\gamma_j\zeta(\alpha)}{\ell^\alpha}\right)\prod_{j=r+1}^d (\beta_j + 2\gamma_j\zeta(\alpha)).$$

Clearly there must exist at least one vector $\boldsymbol{z}$ such that

$$e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) \le M_{n,d,\mathrm{copy}(\ell,r)} \le \frac{1}{n}\prod_{j=1}^{d}\left(\beta_j + 2\gamma_j\zeta(\alpha)\right).$$

Now let $N = \ell^r n$ denote the total number of quadrature points. It is obvious that this last bound is of the form (2.3) with $a = 2\zeta(\alpha)$, $b = \ell^r$, and $n = N$. Since ℓ and r are fixed, we conclude that there exist intermediate-rank lattice rules that achieve strong QMC tractability error bounds for weighted Korobov spaces.

2.2. Comparison with rank-1 lattice rules based on mean. It follows from Theorem 2.2 with $\ell = 1$ and $n = N$ that for N prime, the mean for rank-1 lattice rules is

$$\widehat{M}_{N,d} = -\prod_{j=1}^{d}\beta_j + \frac{1}{N}\prod_{j=1}^{d}\left(\beta_j + 2\gamma_j\zeta(\alpha)\right) + \left(1-\frac{1}{N}\right)\prod_{j=1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-N^{1-\alpha})}{N-1}\right).$$

Suppose we replace N by $N = \ell^r n$ in this last expression. This is not valid because N is not prime, but calculations using the correct (but more complicated) expression for the mean found in [10] indicate that this yields an underestimate of the true mean.

Now let

$$R_{n,d,\ell,r} := \frac{M_{n,d,\mathrm{copy}(\ell,r)}}{\widehat{M}_{N,d}}.$$

As an indication of whether these intermediate-rank lattice rules are better than rank-1 lattice rules having approximately the same number of points, we would like a result which shows that $R_{n,d,\ell,r} < 1$. A preliminary result of this type is given in the following theorem.

THEOREM 2.3. *Suppose that n is a prime number satisfying $n \ge 1 + \frac{2\gamma_1}{\beta_1}\zeta(\alpha)$. If*

$$\rho_{\ell,r} := \prod_{j=1}^{r}\frac{\ell\beta_j + \frac{2\gamma_j\zeta(\alpha)}{\ell^{\alpha-1}}}{\beta_j + 2\gamma_j\zeta(\alpha)} < 1$$

and

$$\ell^r(n-1)\prod_{j=1}^{r}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{(n-1)\ell^{\alpha}}\right)\prod_{j=r+1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{n-1}\right)$$

$$< (\ell^r n - 1)\prod_{j=1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-(\ell^r n)^{1-\alpha})}{\ell^r n - 1}\right), \tag{2.7}$$

then

$$R_{n,d,\ell,r} < \rho_{\ell,r}.$$

Proof. By multiplying both $M_{n,d,\mathrm{copy}(\ell,r)}$ and $\widehat{M}_{N,d}$ by $N = \ell^r n$, we can write

$$R_{n,d,\ell,r} = \frac{t_1 + t_2 - c}{b_1 + b_2 - c} \quad \text{and} \quad \rho_{\ell,r} = \frac{t_1}{b_1},$$

where

$$\begin{aligned}
t_1 &= \prod_{j=1}^{r}\left(\ell\beta_j + \frac{2\gamma_j\zeta(\alpha)}{\ell^{\alpha-1}}\right)\prod_{j=r+1}^{d}\left(\beta_j + 2\gamma_j\zeta(\alpha)\right),\\
t_2 &= \ell^r(n-1)\prod_{j=1}^{r}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{(n-1)\ell^{\alpha}}\right)\prod_{j=r+1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-n^{1-\alpha})}{n-1}\right),\\
b_1 &= \prod_{j=1}^{d}\left(\beta_j + 2\gamma_j\zeta(\alpha)\right),\\
b_2 &= (\ell^r n-1)\prod_{j=1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)(1-(\ell^r n)^{1-\alpha})}{\ell^r n-1}\right),\\
c &= \ell^r n\prod_{j=1}^{d}\beta_j.
\end{aligned}$$

It is not hard to prove that

$$\frac{t_1+t_2-c}{b_1+b_2-c} < \frac{t_1}{b_1}$$

is true if b_1, b_2, t_1, t_2, and c are positive quantities satisfying

$$t_1 < b_1, \quad b_1 + b_2 > c, \quad \text{and} \quad t_2 < b_2 < c. \tag{2.8}$$

Thus the result is proved if we can prove that all these conditions hold.

It may not be obvious that b_2 and t_2 are positive quantities, but one can see that this is the case when $\beta_j - 2\gamma_j\zeta(\alpha)/(n-1) > 0$ for $j = 1, 2\ldots, d$, which is equivalent to the requirement on n given in the statement of the theorem. The requirement that $t_1 < b_1$ comes from the assumption that $\rho_{\ell,r} < 1$, while the requirement that $t_2 < b_2$ comes from the assumption given in (2.7). Also, it is clear that $b_2 < c$.

Let

$$\hat{b}_2 = (\ell^r n - 1)\prod_{j=1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)}{\ell^r n-1}\right).$$

It is clear that $b_2 > \hat{b}_2$. Thus we can prove that $b_1 + b_2 > c$ by proving that $b_1 + \hat{b}_2 - c > 0$. Using the result that

$$\prod_{j=1}^{d}(\beta_j + a_j) = \sum_{\mathfrak{u}\subseteq\mathcal{D}}\left(\prod_{j\notin\mathfrak{u}}\beta_j\prod_{j\in\mathfrak{u}}a_j\right) = \prod_{j=1}^{d}\beta_j + \sum_{\emptyset\neq\mathfrak{u}\subseteq\mathcal{D}}\left(\prod_{j\notin\mathfrak{u}}\beta_j\prod_{j\in\mathfrak{u}}a_j\right),$$

where $\mathcal{D} = \{1, 2, \ldots, d\}$, we have

$$\begin{aligned}
b_1 + \hat{b}_2 - c &= \prod_{j=1}^{d}\left(\beta_j + 2\gamma_j\zeta(\alpha)\right) + (\ell^r n-1)\prod_{j=1}^{d}\left(\beta_j - \frac{2\gamma_j\zeta(\alpha)}{\ell^r n-1}\right) - \ell^r n\prod_{j=1}^{d}\beta_j\\
&= \sum_{\emptyset\neq\mathfrak{u}\subseteq\mathcal{D}}\left(\prod_{j\notin\mathfrak{u}}\beta_j\prod_{j\in\mathfrak{u}}(2\gamma_j\zeta(\alpha))\right) + (\ell^r n-1)\sum_{\emptyset\neq\mathfrak{u}\subseteq\mathcal{D}}\left(\prod_{j\notin\mathfrak{u}}\beta_j\prod_{j\in\mathfrak{u}}\left(-\frac{2\gamma_j\zeta(\alpha)}{\ell^r n-1}\right)\right)\\
&= \sum_{\emptyset\neq\mathfrak{u}\subseteq\mathcal{D}}\left(S(\mathfrak{u})\prod_{j\notin\mathfrak{u}}\beta_j\prod_{j\in\mathfrak{u}}(2\gamma_j\zeta(\alpha))\right),
\end{aligned}$$

where

$$S(\mathfrak{u}) = 1 + (\ell^r n - 1)\left(-\frac{1}{\ell^r n - 1}\right)^{|\mathfrak{u}|}.$$

Clearly $S(\mathfrak{u}) > 0$ if $|\mathfrak{u}|$ is even. For $|\mathfrak{u}| \geq 1$ odd, we have

$$S(\mathfrak{u}) = 1 - (\ell^r n - 1)^{1-|\mathfrak{u}|} \geq 1 - 1 = 0.$$

Thus we conclude that $b_1 + \hat{b}_2 - c > 0$ and hence $b_1 + b_2 > c$. □

In the previous theorem, we made the assumption that $\rho_{\ell,r} < 1$ and that (2.7) was true. Attempts to prove that (2.7) is always true have not been successful. However, all our numerical test calculations with $\ell = 2$, $\alpha = 2$, $\beta_j = 1$, and various choices of γ_j indicate that (2.7) does at least hold for this set of parameters. For other sets of parameters, readers will need to be content with doing their own calculations to see whether it holds or not for their particular situation.

The next result gives some sufficient conditions for $\rho_{2,r}$ to be less than one.

LEMMA 2.4. *Let $\rho_{\ell,r}$ be defined as in Theorem* 2.3*, and set $\ell = 2$. If $\alpha \geq 2$ and*

$$\frac{\gamma_r}{\beta_r} > \frac{1}{(2 - 2^{2-\alpha})\zeta(\alpha)},$$

then $\rho_{2,r} < 1$.

Proof. A product of positive terms is guaranteed to be less than one when each of the terms is less than one. From the definition of $\rho_{\ell,r}$, we see that if $\ell = 2$, then this is the case when

$$\frac{2\beta_j + 2^{2-\alpha}\gamma_j\zeta(\alpha)}{\beta_j + 2\gamma_j\zeta(\alpha)} < 1$$

for all $j = 1, 2, \ldots, r$. When rearranged, this yields

$$\frac{\gamma_j}{\beta_j} > \frac{1}{(2 - 2^{2-\alpha})\zeta(\alpha)}.$$

Since the sequence $\{\frac{\gamma_j}{\beta_j}\}$ is nonincreasing, this completes the proof. □

In the case when $\alpha = 2$, the condition of the lemma becomes $\gamma_r/\beta_r > 1/\zeta(2) = 6/\pi^2 \approx 0.6079$. This suggests that when $\alpha = 2$, it is worthwhile to take r to be at least one when $\gamma_1/\beta_1 > 6/\pi^2$.

In a sense, the quantity $\rho_{\ell,r}$ gives an indication of how much we can gain (or lose) by copying. Later in section 4, we will see that though $\sqrt{\rho_{2,r}}$ is concerned with a ratio of means, the values of $\sqrt{\rho_{2,r}}$ nevertheless provide a measure of the ratios of the worst-case errors between intermediate-rank lattice rules and rank-1 lattice rules with approximately the same number of points.

2.3. Component-by-component construction. We now consider finding the components of the generating vector $\boldsymbol{z}$ one at a time. Keeping in mind the relationship of our intermediate-rank lattice rules with rank-1 lattice rules, we can construct $\bar{\boldsymbol{z}}$ for the rank-1 lattice rule with weights $\boldsymbol{\beta}$ and $\bar{\boldsymbol{\gamma}}$ using the component-by-component Algorithm 8 of [9] from which we can then obtain the corresponding $\boldsymbol{z}$. This yields the same result as constructing $\boldsymbol{z}$ directly using Algorithm 2.5 below.

ALGORITHM 2.5. *Given $1 \leq r \leq d$ and n a prime number:*

1. *Set z_1, the first component of $\boldsymbol{z}$, to* 1.

2. *For $s = 2, 3, \dots, r$, find $z_s \in \mathbb{Z}_n = \{1, 2, \dots, n-1\}$ such that*

$$e^2_{n,s,\mathrm{copy}(\ell,s)}(1, z_2, \dots, z_s) = -\prod_{j=1}^{s} \beta_j + \frac{1}{n}\sum_{k=0}^{n-1}\prod_{j=1}^{s}\left(\beta_j + \frac{\gamma_j}{\ell^\alpha}\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h\ell k z_j/n}}{|h|^\alpha}\right)$$

is minimized.

3. *For $s = r+1, r+2, \dots, d$, find $z_s \in \mathbb{Z}_n$ such that*

$$\begin{aligned} &e^2_{n,s,\mathrm{copy}(\ell,r)}(1, z_2, \dots, z_s) \\ &= -\prod_{j=1}^{s}\beta_j + \frac{1}{n}\sum_{k=0}^{n-1}\left[\prod_{j=1}^{r}\left(\beta_j + \frac{\gamma_j}{\ell^\alpha}\sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h\ell k z_j/n}}{|h|^\alpha}\right)\right. \\ &\qquad\qquad \left.\times \prod_{j=r+1}^{d}\left(\beta_j + \gamma_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi \mathrm{i} h k z_j/n}}{|h|^\alpha}\right)\right] \end{aligned}$$

is minimized.

Theorem 1 and Corollary 2 in [9] give the theoretical foundation behind such a construction for rank-1 lattice rules. We present the corresponding results here for intermediate-rank lattice rules. Note that Theorem 2.6 below is a slight improvement over the corresponding Theorem 1 of [9]. The proof is thus included in the appendix for completeness. (Such an improvement for rank-1 lattice rules was first obtained in [1] by using a different argument.)

THEOREM 2.6. *Let $\boldsymbol{z} = (1, z_2, \dots, z_d)$ be constructed component-by-component as in Algorithm* 2.5.

(a) *For each $s = 1, 2, \dots, r$, we have*

$$e^2_{n,s,\mathrm{copy}(\ell,s)}(1, z_2, \dots, z_s) \le (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s}\left(\beta_j^\lambda + \frac{2\gamma_j^\lambda \zeta(\alpha\lambda)}{\ell^{\alpha\lambda}}\right)^{\frac{1}{\lambda}}$$

for all λ satisfying $\frac{1}{\alpha} < \lambda \le 1$.

(b) *For each $s = r+1, r+2, \dots, d$, we have*

$$\begin{aligned} &e^2_{n,s,\mathrm{copy}(\ell,r)}(1, z_2, \dots, z_s) \\ &\le (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{r}\left(\beta_j^\lambda + \frac{2\gamma_j^\lambda\zeta(\alpha\lambda)}{\ell^{\alpha\lambda}}\right)^{\frac{1}{\lambda}} \prod_{j=r+1}^{s}\left(\beta_j^\lambda + 2\gamma_j^\lambda\zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} \end{aligned}$$

for all λ satisfying $\frac{1}{\alpha} < \lambda \le 1$.

It can be shown from the bounds above that the intermediate-rank lattice rules constructed using Algorithm 2.5 satisfy strong QMC tractability error bounds and achieve the optimal rate of convergence.

THEOREM 2.7. *For fixed r satisfying $1 \le r \le d$ and n a prime number, let $N = \ell^r n$ denote the total number of quadrature points, and let $\boldsymbol{z}$ be constructed component-by-component as in Algorithm* 2.5. *Then this $\boldsymbol{z}$ satisfies*

$$e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) \le C_d(\delta)\, N^{-\frac{\alpha}{2}+\delta} e_{0,d} \quad \textit{for all} \quad 0 < \delta \le \tfrac{\alpha-1}{2},$$

where

$$C_d(\delta) = (2\ell^r)^{\frac{\alpha}{2}-\delta} \prod_{j=1}^{r} \left[1 + 2\ell^{-\frac{\alpha}{\alpha-2\delta}} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta}$$
$$\times \prod_{j=r+1}^{d} \left[1 + 2\left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta}$$

is independent of N. Moreover, if

$$\sum_{j=r+1}^{\infty} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} < \infty,$$

then

$$C_d(\delta) \le C_\infty(\delta) < \infty;$$

that is, $e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z})$ is $O(N^{-\alpha/2+\delta})$ for $\delta > 0$, independently of d.

Proof. It follows from Theorem 2.6 that the $\boldsymbol{z}$ constructed by Algorithm 2.5 satisfies

$$e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z})$$
$$\le (n-1)^{-\frac{1}{2\lambda}} \prod_{j=1}^{r} \left(\beta_j^\lambda + \frac{2\gamma_j^\lambda \zeta(\alpha\lambda)}{\ell^{\alpha\lambda}}\right)^{\frac{1}{2\lambda}} \prod_{j=r+1}^{d} \left(\beta_j^\lambda + 2\gamma_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{2\lambda}}$$
$$\le \left(\frac{n\ell^r}{2\ell^r}\right)^{-\frac{1}{2\lambda}} \prod_{j=1}^{r} \left(1 + 2\ell^{-\alpha\lambda} \left(\frac{\gamma_j}{\beta_j}\right)^{\lambda} \zeta(\alpha\lambda)\right)^{\frac{1}{2\lambda}} \prod_{j=r+1}^{d} \left(1 + 2\left(\frac{\gamma_j}{\beta_j}\right)^{\lambda} \zeta(\alpha\lambda)\right)^{\frac{1}{2\lambda}} \prod_{j=1}^{d} \beta_j^{\frac{1}{2}}$$

for all $\frac{1}{\alpha} < \lambda \le 1$. Now with the substitution of

$$-\frac{\alpha}{2} + \delta = -\frac{1}{2\lambda},$$

the condition $\frac{1}{\alpha} < \lambda \le 1$ becomes $0 < \delta \le \frac{\alpha-1}{2}$, and we obtain

$$e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) \le C_d(\delta)\, N^{-\frac{\alpha}{2}+\delta} e_{0,d} \quad \text{for all } 0 < \delta \le \tfrac{\alpha-1}{2},$$

where

$$C_d(\delta) = (2\ell^r)^{\frac{\alpha}{2}-\delta} \prod_{j=1}^{r} \left[1 + 2\ell^{-\frac{\alpha}{\alpha-2\delta}} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta}$$
$$\times \prod_{j=r+1}^{d} \left[1 + 2\left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta} \le C_\infty(\delta),$$

and

$$
\begin{aligned}
C_\infty(\delta) &= (2\ell^r)^{\frac{\alpha}{2}-\delta} \prod_{j=1}^{r} \left[1 + 2\ell^{-\frac{\alpha}{\alpha-2\delta}} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta} \\
&\quad \times \exp\left(\left(\tfrac{\alpha}{2}-\delta\right) \sum_{j=r+1}^{\infty} \log\left(1 + 2\left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right)\right) \\
&\le (2\ell^r)^{\frac{\alpha}{2}-\delta} \prod_{j=1}^{r} \left[1 + 2\ell^{-\frac{\alpha}{\alpha-2\delta}} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right)\right]^{\frac{\alpha}{2}-\delta} \\
&\quad \times \exp\left((\alpha-2\delta)\, \zeta\left(\tfrac{\alpha}{\alpha-2\delta}\right) \sum_{j=r+1}^{\infty} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}}\right),
\end{aligned}
$$

where we have used the fact that $\log(1+x) \le x$ for $x \ge 0$. It is clear from this expression that for $\delta > 0$, $C_\infty(\delta) < \infty$ if

$$
\sum_{j=r+1}^{\infty} \left(\frac{\gamma_j}{\beta_j}\right)^{\frac{1}{\alpha-2\delta}} < \infty.
$$

This completes the proof. □

3. Shifted intermediate-rank lattice rules in weighted Sobolev spaces.

Now we change the function spaces to weighted Sobolev spaces considered in [10]. These spaces are also parameterized by two sequences of positive weights $\boldsymbol{\beta}$ and $\boldsymbol{\gamma}$ satisfying

$$
\frac{\gamma_1}{\beta_1} \ge \frac{\gamma_2}{\beta_2} \ge \cdots .
$$

The inner product in these spaces is given by

$$
\langle f, g \rangle_d := \sum_{\mathfrak{u} \subseteq \{1,2,\ldots,d\}} \left(\prod_{j \notin \mathfrak{u}} \beta_j^{-1} \prod_{j \in \mathfrak{u}} \gamma_j^{-1} \int_{[0,1]^{|\mathfrak{u}|}} \frac{\partial^{|\mathfrak{u}|}}{\partial \boldsymbol{x}_\mathfrak{u}} f(\boldsymbol{x}_\mathfrak{u}, \mathbf{1}) \frac{\partial^{|\mathfrak{u}|}}{\partial \boldsymbol{x}_\mathfrak{u}} g(\boldsymbol{x}_\mathfrak{u}, \mathbf{1})\, \mathrm{d}\boldsymbol{x}_\mathfrak{u} \right),
$$

where $(\boldsymbol{x}_\mathfrak{u}, \mathbf{1})$ is a d-dimensional vector whose jth component is x_j if $j \in \mathfrak{u}$ and 1 if $j \notin \mathfrak{u}$. Similar spaces have been considered previously (for example, see [12], [13], and [16]). The worst-case error for a QMC rule (1.1) in these spaces is given by

$$
\begin{aligned}
e_{n,d}^2(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}) &= \prod_{j=1}^{d} \left(\beta_j + \frac{\gamma_j}{3}\right) - \frac{2}{n} \sum_{i=0}^{n-1} \prod_{j=1}^{d} \left(\beta_j + \frac{\gamma_j}{2}\left(1 - x_{i,j}^2\right)\right) \\
&\quad + \frac{1}{n^2} \sum_{i=0}^{n-1} \sum_{k=0}^{n-1} \prod_{j=1}^{d} \left(\beta_j + \gamma_j \left[1 - \max\left(x_{i,j}, x_{k,j}\right)\right]\right), \qquad (3.1)
\end{aligned}
$$

and the initial error is

$$
e_{0,d} = \prod_{j=1}^{d} \left(\beta_j + \frac{\gamma_j}{3}\right)^{\frac{1}{2}}.
$$

Similar to the weighted Korobov spaces, it can be shown that if the weights satisfy (2.2), then an upper bound for the square worst-case error of the form (2.3) is enough to ensure strong QMC tractability in weighted Sobolev spaces.

We now consider the $\boldsymbol{\Delta}$-shift of the (ℓ, r)-copy of a rank-1 lattice rule with generating vector $\boldsymbol{z}$, that is, a rule with points given by

$$\left\{ \left\{ \frac{i\boldsymbol{z}}{n} + \frac{(m_1, \ldots, m_r, 0, \ldots, 0)}{\ell} + \boldsymbol{\Delta} \right\} : 0 \le i \le n-1,\ 0 \le m_1, \ldots, m_r \le \ell - 1 \right\},$$

where $\ell \ge 1$, $\gcd(\ell, n) = 1$, and $0 \le r \le d$. Let $e_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}, \boldsymbol{\Delta})$ denote the worst-case error for such a rule. An expression for $e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}, \boldsymbol{\Delta})$ can be derived from (3.1).

Here we give just the general ideas of the existence and the construction of a good shifted intermediate-rank lattice rule. The full details follow closely the arguments from [12] and [13].

To obtain an upper bound on the square worst-case error, we define the mean of $e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}, \boldsymbol{\Delta})$ over all values of $\boldsymbol{z} \in \mathbb{Z}_n^d$ and $\boldsymbol{\Delta} \in [0,1]^d$ by

$$M_{n,d,\mathrm{copy}(\ell,r)} := \frac{1}{(n-1)^d} \sum_{\boldsymbol{z} \in \mathbb{Z}_n^d} \left(\int_{[0,1]^d} e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}, \boldsymbol{\Delta}) \, \mathrm{d}\boldsymbol{\Delta} \right).$$

Using a known relationship between weighted Korobov spaces and weighted Sobolev spaces (see [5]), we see that this mean is exactly the mean given in Theorem 2.2 with α replaced by 2, β_j replaced by $\beta_j + \frac{\gamma_j}{3}$, and γ_j replaced by $\frac{\gamma_j}{2\pi^2}$. An upper bound for $M_{n,d,\mathrm{copy}(\ell,r)}$ follows in the same way from Theorem 2.2:

$$M_{n,d,\mathrm{copy}(\ell,r)} \le \frac{1}{n} \prod_{j=1}^{d} \left(\beta_j + \frac{\gamma_j}{3} + \frac{2\gamma_j}{2\pi^2} \zeta(2) \right) = \frac{1}{n} \prod_{j=1}^{d} \left(\beta_j + \frac{\gamma_j}{2} \right).$$

We thus conclude that there exists at least one pair $(\boldsymbol{z}, \boldsymbol{\Delta})$ such that $e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}, \boldsymbol{\Delta})$ is bounded by this upper bound on the mean. Since this bound is of the form (2.3), we conclude that shifted intermediate-rank lattice rules achieve strong QMC tractability error bounds in weighted Sobolev spaces.

Let $e_{n,d+1,\ell}(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}; z_{d+1}, \Delta_{d+1})$ denote the worst-case error for a QMC rule with the set of points

$$\left\{ \left(\boldsymbol{x}_i, \left\{ \frac{i z_{d+1}}{n} + \frac{m}{\ell} + \Delta_{d+1} \right\} \right) : 0 \le i \le n-1,\ 0 \le m \le \ell - 1 \right\}.$$

These are $(d+1)$-dimensional points obtained by appending $\{\frac{iz_{d+1}}{n} + \frac{m}{\ell} + \Delta_{d+1}\}$ to the existing d components of $\boldsymbol{x}_i$. To construct the pair (z_{d+1}, Δ_{d+1}) component-by-component, we define the following mean:

$$m_{n,d+1,\ell}(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}; z_{d+1}) := \int_0^1 e^2_{n,d+1,\ell}(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}; z_{d+1}, \Delta_{d+1}) \, \mathrm{d}\Delta_{d+1}.$$

Let us assume that the points $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}$ satisfy

$$e^2_{n,d}(\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{n-1}) \le \frac{1}{n} \prod_{j=1}^{d} (\beta_j + \gamma_j).$$

Suppose we choose z_{d+1} from the set $\mathbb{Z}_n$ to minimize $m_{n,d+1,\ell}(\boldsymbol{x}_0, \dots, \boldsymbol{x}_{n-1}; z_{d+1})$ and then choose Δ_{d+1} from the set $\left\{\frac{2m-1}{2n} : 1 \le m \le n-1\right\}$ so that the square worst-case error $e^2_{n,d+1,\ell}(\boldsymbol{x}_0, \dots, \boldsymbol{x}_{n-1}; z_{d+1}, \Delta_{d+1})$ is minimized. Then by using involved algebraic manipulations and the arguments from [12], these choices of z_{d+1} and Δ_{d+1} can be shown to satisfy

$$e^2_{n,d+1,\ell}(\boldsymbol{x}_0, \dots, \boldsymbol{x}_{n-1}; z_{d+1}, \Delta_{d+1}) \le \frac{1}{n} \prod_{j=1}^{d+1} (\beta_j + \gamma_j)\,.$$

Note that the result also holds for $\ell = 1$; that is, there is no "copying" in the $(d+1)$th dimension. For $d = 1$, we can show that there exists (z_1, Δ_1) satisfying

$$e^2_{n,1,\mathrm{copy}(\ell,1)}(z_1, \Delta_1) \le \frac{1}{n} (\beta_1 + \gamma_1)\,.$$

All of the above leads us to the following algorithm for constructing a pair $(\boldsymbol{z}, \boldsymbol{\Delta})$ such that for all $s = 1, \dots, d$,

$$e^2_{n,s,\mathrm{copy}(\ell,\min(s,r))}((z_1, \dots, z_s), (\Delta_1, \dots, \Delta_s)) \le \frac{1}{n} \prod_{j=1}^{s} (\beta_j + \gamma_j)\,.$$

In the following algorithm, the notation

$$m_{n,s,\mathrm{copy}(\ell,r)}((1, z_2, \dots, z_{s-1}), (\Delta_1, \Delta_2, \dots, \Delta_{s-1}); z_s)$$

is used to denote the quantity $m_{n,s,\ell}(\boldsymbol{x}_0, \dots, \boldsymbol{x}_{n-1}; z_s)$ in the situation when $\boldsymbol{x}_0, \dots, \boldsymbol{x}_{n-1}$ are the points from an (ℓ, r)-copy of an $(s-1)$-dimensional rank-1 lattice rule.

```
ALGORITHM 3.1. Given $n$ a prime number and $1 \le r \le d$:
  1. Set $z_1$, the first component of $\boldsymbol{z}$, to 1.
  2. Find $\Delta_1 \in \left\{\frac{1}{2n}, \frac{3}{2n}, \dots, \frac{2n-1}{2n}\right\}$ to minimize $e^2_{n,1,\mathrm{copy}(\ell,1)}(1, \Delta_1)$.
  3. For $s = 2, 3, \dots, r$, do the following:
     (a) Find $z_s \in \{1, 2, \dots, n-1\}$ to minimize
             $m_{n,s,\mathrm{copy}(\ell,s)}((1, z_2, \dots, z_{s-1}), (\Delta_1, \Delta_2, \dots, \Delta_{s-1}); z_s)$.
     (b) Find $\Delta_s \in \left\{\frac{1}{2n}, \frac{3}{2n}, \dots, \frac{2n-1}{2n}\right\}$ to minimize
             $e^2_{n,s,\mathrm{copy}(\ell,s)}((1, z_2, \dots, z_s), (\Delta_1, \Delta_2, \dots, \Delta_s))$.
  4. For $s = r+1, r+2, \dots, d$, do the following:
     (a) Find $z_s \in \{1, 2, \dots, n-1\}$ to minimize
             $m_{n,s,\mathrm{copy}(\ell,r)}((1, z_2, \dots, z_{s-1}), (\Delta_1, \Delta_2, \dots, \Delta_{s-1}); z_s)$.
     (b) Find $\Delta_s \in \left\{\frac{1}{2n}, \frac{3}{2n}, \dots, \frac{2n-1}{2n}\right\}$ to minimize
             $e^2_{n,s,\mathrm{copy}(\ell,r)}((1, z_2, \dots, z_s), (\Delta_1, \Delta_2, \dots, \Delta_s))$.
```

The cost for the construction is $O(n^3 d^2)$ operations, and it is dominated by the construction of the shift. In [13] the idea of using a number of random shifts was introduced. This not only cuts the cost of the construction down to $O(n^2 d^2)$ operations; it also allows error estimation. The reference [3] contains detailed discussions on randomized QMC methods. Following [13], we can construct the generating vector component-by-component by minimizing over the mean

$$F_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) := \int_{[0,1]^d} e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z},\boldsymbol{\Delta})\,\mathrm{d}\boldsymbol{\Delta}.$$

ALGORITHM 3.2. *Given n a prime number and $1 \le r \le d$:*

1. *Set z_1, the first component of $\boldsymbol{z}$, to* 1.
2. *For $s = 2, 3, \dots, r$, find $z_s \in \{1, 2, \dots, n-1\}$ to minimize*
$$F_{n,s,\mathrm{copy}(\ell,s)}(1, z_2, \dots, z_s).$$
3. *For $s = r+1, r+2, \dots, d$, find $z_s \in \{1, 2, \dots, n-1\}$ to minimize*
$$F_{n,s,\mathrm{copy}(\ell,r)}(1, z_2, \dots, z_s).$$

Using again the relationship between weighted Korobov spaces and weighted Sobolev spaces, we can obtain the corresponding value of the quantity $\rho_{\ell,r}$ given in Theorem 2.3 for weighted Sobolev spaces by replacing α with 2, β_j with $\beta_j + \frac{\gamma_j}{3}$, and γ_j with $\frac{\gamma_j}{2\pi^2}$. This yields

$$\rho_{\ell,r} = \prod_{j=1}^{r} \frac{\ell\beta_j + \gamma_j\left(\frac{\ell}{3} + \frac{1}{6\ell}\right)}{\beta_j + \frac{\gamma_j}{2}},$$

which is greater than 1 for all $\ell \ge 2$. This means that it is unlikely for the ratio $R_{n,d,\ell,r}$ to be less than 1, and thus copying may not give better results in weighted Sobolev spaces.

4. Numerical results. We will consider weighted Korobov spaces with $\alpha = 2$. In this case, the square worst-case error can be written as

$$e^2_{n,d,\mathrm{copy}(\ell,r)}(\boldsymbol{z}) = -\prod_{j=1}^{d}\beta_j + \frac{1}{n}\sum_{k=0}^{n-1}\left[\prod_{j=1}^{r}\left(\beta_j + \frac{2\pi^2\gamma_j}{\ell^2}B_2\left(\left\{\frac{\ell k z_j}{n}\right\}\right)\right)\right.$$
$$\left.\times\prod_{j=r+1}^{d}\left(\beta_j + 2\pi^2\gamma_j B_2\left(\left\{\frac{k z_j}{n}\right\}\right)\right)\right],$$

where for $x \in [0,1]$, $B_2(x) = x^2 - x + 1/6$ is the Bernoulli polynomial of degree 2. In the implementation of Steps 2 and 3 of Algorithm 2.5, we will consider only values of z_s in $\{1, 2, \dots, (n-1)/2\}$, since

$$B_2\left(\left\{\frac{k z_s}{n}\right\}\right) = B_2\left(\left\{\frac{k(n-z_s)}{n}\right\}\right) \text{ and } B_2\left(\left\{\frac{\ell k z_s}{n}\right\}\right) = B_2\left(\left\{\frac{\ell k(n-z_s)}{n}\right\}\right).$$

For $\alpha = 2$, $\boldsymbol{\beta} = \mathbf{1}$, and two different sequences of $\boldsymbol{\gamma}$,

$$\gamma_j = 0.9^j \quad \text{and} \quad \gamma_j = \frac{1}{j^2},$$

we want to see if intermediate-rank lattice rules are better than rank-1 lattice rules with approximately the same number of points. More precisely, when $\ell = 2$, we

want to know in how many dimensions to copy, that is, which value of $r = 1, 2$, or higher should we choose to get better rules than rank-1 lattice rules. We compare the worst-case errors for rules with approximately 4000, 16000, and 64000 points up to 100 dimensions. (Note that since $\boldsymbol{\beta} = \mathbf{1}$, the initial error $e_{0,d}$ is 1.) The results are presented in Tables 4.1 to 4.6. The second column of each of these tables contains the worst-case error for rank-1 rules, while the other three columns contain the worst-case error for r going from $r = 1$ to $r = 3$. To get a better picture of the results of copying, we divide the worst-case errors of intermediate-rank lattice rules at $d = 100$ by those of rank-1 lattice rules with approximately the same number of points. These ratios are presented in Table 4.7.

We can see from the results that for $\gamma_j = 0.9^j$, copying is good in at least the first three dimensions, but for $\gamma_j = 1/j^2$, it is only good to copy in the first dimension. This seems reasonable as in the first few dimensions the sequence $0.9, 0.81, 0.729, \ldots$

decays more slowly than $1, 1/4, 1/9, \ldots$, and so in the former case, the third variable is still fairly important, while this is not the situation in the latter case.

The phenomenon is also supported by our earlier analysis. Since it may be verified numerically that (2.7) holds, Theorem 2.3 and Lemma 2.4 together suggest that it would be advantageous to copy in the first r dimensions if $\ell = 2$, $\alpha = 2$, and

$$\frac{\gamma_r}{\beta_r} > \frac{6}{\pi^2} \approx 0.6079.$$

For $\gamma_j = 0.9^j$, this is obviously satisfied when $r = 1$, $r = 2$, and $r = 3$. For $\gamma_j = 1/j^2$, this is satisfied only when $r = 1$. Because Lemma 2.4 provides only a sufficient

condition for $\rho_{2,r}$ to be less than one, a direct calculation of $\rho_{2,r}$ was done, and the results (see Table 4.8) show the same conclusion.

If we compare the values of $\sqrt{\rho_{2,r}}$ in Table 4.8 with the ratios in Table 4.7, we see that the values of $\sqrt{\rho_{2,r}}$ are reasonably close to the ratios. So, although $\rho_{2,r}$ is essentially a ratio of means, there is numerical evidence here that it provides a measure of the ratios of the square worst-case errors obtained from intermediate-rank lattice rules and rank-1 lattice rules in the weighted Korobov space setting.

For our choices of weights, it follows from Theorem 2.7 that the rate of convergence is $O(N^{-1+\delta})$ for $\delta > 0$, independently of the dimension d. However, the numerical results presented show a rate of convergence of roughly $O(N^{-1/2})$ for the case $\gamma_j = 0.9^j$ and a somewhat better rate for the case $\gamma_j = 1/j^2$. The observed rates of convergence also appear to be higher for the smaller values of d. This agrees with the numerical results in [9], where the predicted rate of convergence is not observed when moderate values of n are used relative to the dimension. In that situation, the observed rate of convergence depends on the rate of decay of the weights, with faster decaying weights yielding higher convergence rates. To get an observed rate of convergence close to $O(N^{-1})$, we need to have weights that decay much faster, for example, $\gamma_j = 0.1^j$ or $\gamma_j = 1/j^6$. However, if weights such as these were used, the theory would suggest that there would not be much benefit in doing any copying.

Appendix. Let $(1, z_2, \ldots, z_d)$ be constructed using Algorithm 2.5. Here we prove Theorem 2.6; that is, for each $s = 1, 2, \ldots, d$, we have

$$e^2_{n,s,\mathrm{copy}(\ell,\min(s,r))}(1, z_2, \ldots, z_s) \le (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}}$$

for all λ satisfying $\frac{1}{\alpha} < \lambda \le 1$, where

$$\bar{\gamma}_j := \begin{cases} \dfrac{\gamma_j}{\ell^\alpha} & \text{if } 1 \le j \le r, \\ \gamma_j & \text{otherwise.} \end{cases}$$

The proof makes use of one form of Jensen's inequality (see Theorem 19 of [2]), which states that for $\{a_i\}$ a sequence of positive numbers,

$$\sum a_i \le \left(\sum a_i^\lambda\right)^{\frac{1}{\lambda}} \quad \text{for } 0 < \lambda \le 1.$$

Proof. For $s = 1$, it is not hard to show that for all z_1 we have

$$e^2_{n,1,\text{copy}(\ell,1)}(z_1) = \frac{2\bar{\gamma}_1\zeta(\alpha)}{n^\alpha},$$

and for any λ satisfying $\frac{1}{\alpha} < \lambda \le 1$, we have

$$\frac{2\bar{\gamma}_1\zeta(\alpha)}{n^\alpha} \le n^{-\alpha}\left(\beta_1 + 2\bar{\gamma}_1\zeta(\alpha)\right) \le n^{-\alpha}\left(\beta_1^\lambda + 2^\lambda\bar{\gamma}_1^\lambda[\zeta(\alpha)]^\lambda\right)^{\frac{1}{\lambda}},$$

where the second inequality follows by applying Jensen's inequality to the sum $\beta_1 + 2\bar{\gamma}_1\zeta(\alpha)$. It can be easily verified that $n^{-\alpha} < (n-1)^{-\frac{1}{\lambda}}$, $2^\lambda < 2$, and by Jensen's inequality, $[\zeta(\alpha)]^\lambda \le \zeta(\alpha\lambda)$. Hence the result holds for $s = 1$.

For s satisfying $2 \le s \le d$, suppose that an $(s-1)$-dimensional vector $(1, z_2, \ldots, z_{s-1})$ has already been constructed using Algorithm 2.5 such that it satisfies

$$e^2_{n,s-1,\text{copy}(\ell,\min(s-1,r))}(1, z_2, \ldots, z_{s-1}) \le (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s-1} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda\zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} \tag{A.1}$$

for all λ satisfying $\frac{1}{\alpha} < \lambda \le 1$. For any $z_s \in \mathbb{Z}_n$, there is a corresponding $\bar{z}_s$ (recall that $\bar{z}_s = \ell z_s$ if $s \le r$ and $\bar{z}_s = z_s$ if $s > r$), and it follows from (2.6) that

$$\begin{aligned} &e^2_{n,s,\text{copy}(\ell,\min(s,r))}(1, z_2, \ldots, z_s) \\ &= \beta_s e^2_{n,s-1,\text{copy}(\ell,\min(s-1,r))}(1, z_2, \ldots, z_{s-1}) + \theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \ldots, z_s), \end{aligned} \tag{A.2}$$

where

$$\begin{aligned} &\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \ldots, z_s) \\ &= \frac{\bar{\gamma}_s}{n} \sum_{k=0}^{n-1} \left[\prod_{j=1}^{s-1} \left(\beta_j + \bar{\gamma}_j \sideset{}{'}\sum_{h=-\infty}^{\infty} \frac{e^{2\pi \mathrm{i} hk\bar{z}_j/n}}{|h|^\alpha} \right) \sideset{}{'}\sum_{h=-\infty}^{\infty} \frac{e^{2\pi \mathrm{i} hk\bar{z}_s/n}}{|h|^\alpha} \right]. \end{aligned} \tag{A.3}$$

Later we shall prove the following:

(i) For given α, $\boldsymbol{\beta}$, and $\bar{\boldsymbol{\gamma}}$, there exists $z_s = z_s(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}})$ such that

$$\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \ldots, z_s) \le \frac{2\bar{\gamma}_s\zeta(\alpha)}{n-1} \prod_{j=1}^{s-1} \left(\beta_j + 2\bar{\gamma}_j\zeta(\alpha)\right).$$

(ii) For all $\frac{1}{\alpha} < \lambda \le 1$,

$$\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \ldots, z_s) \le \left[\theta_{n,s}(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda; 1, z_2, \ldots, z_s)\right]^{\frac{1}{\lambda}},$$

where $\boldsymbol{\beta}^\lambda = \{\beta_j^\lambda\}$ and $\bar{\boldsymbol{\gamma}}^\lambda = \{\bar{\gamma}_j^\lambda\}$.

We see from (i) with α, $\boldsymbol{\beta}$, and $\bar{\boldsymbol{\gamma}}$ replaced by $\alpha\lambda$, $\boldsymbol{\beta}^\lambda$, and $\bar{\boldsymbol{\gamma}}^\lambda$, respectively, that there exists $z_s = z_s(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda)$ such that

$$\theta_{n,s}(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda; 1, z_2, \ldots, z_s) \le \frac{2\bar{\gamma}_s^\lambda\zeta(\alpha\lambda)}{n-1} \prod_{j=1}^{s-1} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda\zeta(\alpha\lambda)\right).$$

For this $z_s = z_s(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda)$, it then follows from (ii) that

$$\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \le \frac{2^{\frac{1}{\lambda}} \bar{\gamma}_s [\zeta(\alpha\lambda)]^{\frac{1}{\lambda}}}{(n-1)^{\frac{1}{\lambda}}} \prod_{j=1}^{s-1} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} .$$

Thus it follows from (A.1) and (A.2) that this $z_s = z_s(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda)$ satisfies

$$\begin{aligned} &e^2_{n,s,\mathrm{copy}(\ell,\min(s,r))}(1, z_2, \dots, z_s) \\ &\le \left(\beta_s + 2^{\frac{1}{\lambda}} \bar{\gamma}_s [\zeta(\alpha\lambda)]^{\frac{1}{\lambda}}\right) (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s-1} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} \\ &\le \left(\beta_s^\lambda + 2\bar{\gamma}_s^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s-1} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} \\ &= (n-1)^{-\frac{1}{\lambda}} \prod_{j=1}^{s} \left(\beta_j^\lambda + 2\bar{\gamma}_j^\lambda \zeta(\alpha\lambda)\right)^{\frac{1}{\lambda}} , \end{aligned}$$

where the second inequality follows from applying Jensen's inequality to the sum in the first factor. Now since we choose z_s in Algorithm 2.5 to minimize the square worst-case error $e^2_{n,s,\mathrm{copy}(\ell,\min(s,r))}(1, z_2, \dots, z_s)$, this choice of z_s must satisfy the same bound. Hence it follows inductively that the result holds for all $s = 2, 3, \dots, d$.

To complete the proof, we need to prove (i) and (ii).

Proof of (i). Clearly there exists a $z_s = z_s(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}})$ (and hence $\bar{z}_s$) such that

$$\begin{aligned} &\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \\ &\le \frac{1}{n-1} \sum_{z_s=1}^{n-1} \theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \\ &= \frac{\bar{\gamma}_s}{n} \sum_{k=0}^{n-1} \left[\prod_{j=1}^{s-1} \left(\beta_j + \bar{\gamma}_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi i h k \bar{z}_j / n}}{|h|^\alpha} \right) \left(\frac{1}{n-1} \sum_{z_s=1}^{n-1} \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi i h k \bar{z}_s / n}}{|h|^\alpha} \right) \right] . \end{aligned} \tag{A.4}$$

Since n is prime and $\gcd(\ell, n) = 1$, it can be shown for $q = 1$ and $q = \ell$ that

$$\frac{1}{n-1} \sum_{z=1}^{n-1} \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi i h k q z / n}}{|h|^\alpha} = \begin{cases} 2\zeta(\alpha) & \text{if } k \text{ is a multiple of } n, \\ -\dfrac{2\zeta(\alpha)(1 - n^{1-\alpha})}{n-1} & \text{otherwise.} \end{cases}$$

Upon separating out the $k = 0$ term and using the result above, (A.4) becomes

$$\frac{2\bar{\gamma}_s \zeta(\alpha)}{n} \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j \zeta(\alpha)) - \frac{2\bar{\gamma}_s \zeta(\alpha)(1 - n^{1-\alpha})}{n(n-1)} \sum_{k=1}^{n-1} \prod_{j=1}^{s-1} \left(\beta_j + \bar{\gamma}_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi i h k \bar{z}_j / n}}{|h|^\alpha} \right) .$$

It follows from (2.6) (with the $k = 0$ term separated out) that

$$\begin{aligned} &\frac{1}{n} \sum_{k=1}^{n-1} \prod_{j=1}^{s-1} \left(\beta_j + \bar{\gamma}_j \sum_{h=-\infty}^{\infty}{}' \frac{e^{2\pi i h k \bar{z}_j / n}}{|h|^\alpha} \right) \\ &= e^2_{n,s-1,\mathrm{copy}(\ell,\min(s-1,r))}(1, z_2, \dots, z_{s-1}) + \prod_{j=1}^{s-1} \beta_j - \frac{1}{n} \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j \zeta(\alpha)) . \end{aligned}$$

Hence there exists a $z_s = z_s(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}})$ such that

$$\begin{aligned}
&\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \\
&\le \frac{2\bar{\gamma}_s\zeta(\alpha)}{n} \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j\zeta(\alpha)) + \frac{2\bar{\gamma}_s\zeta(\alpha)(1-n^{1-\alpha})}{n(n-1)} \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j\zeta(\alpha)) \\
&\le \frac{2\bar{\gamma}_s\zeta(\alpha)}{n} \left(1 + \frac{1}{n-1}\right) \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j\zeta(\alpha)) \\
&= \frac{2\bar{\gamma}_s\zeta(\alpha)}{(n-1)} \prod_{j=1}^{s-1} (\beta_j + 2\bar{\gamma}_j\zeta(\alpha)) .
\end{aligned}$$

Proof of (ii). Let

$$r(\alpha, \beta, \gamma, h) := \begin{cases} \beta^{-1} & \text{if } h = 0, \\ \gamma^{-1}|h|^\alpha & \text{if } h \neq 0. \end{cases}$$

With this notation we can write $\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s)$ in (A.3) as

$$\begin{aligned}
&\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \\
&= \frac{\bar{\gamma}_s}{n} \sum_{k=0}^{n-1} \sum_{\substack{\boldsymbol{h}\in\mathbb{Z}^s \\ h_s\neq 0}} \frac{e^{2\pi \mathrm{i} k(h_1,h_2,\dots,h_s)\cdot(\bar{z}_1,\bar{z}_2,\dots,\bar{z}_s)/n}}{|h_s|^\alpha \prod_{j=1}^{s-1} r(\alpha, \beta_j, \bar{\gamma}_j, h_j)} \\
&= \bar{\gamma}_s \sum_{\substack{\boldsymbol{h}\in\mathbb{Z}^s \\ h_s\neq 0 \\ (h_1,h_2,\dots,h_s)\cdot(\bar{z}_1,\bar{z}_2,\dots,\bar{z}_s)\equiv 0 \,(\mathrm{mod}\, n)}} \left(|h_s|^{-\alpha} \prod_{j=1}^{s-1} r(\alpha, \beta_j, \bar{\gamma}_j, h_j)^{-1} \right)
\end{aligned}$$

since

$$\sum_{k=0}^{n-1} e^{2\pi \mathrm{i} k(h_1,h_2,\dots,h_s)\cdot(\bar{z}_1,\bar{z}_2,\dots,\bar{z}_s)/n} = \sum_{k=0}^{n-1} \left(e^{2\pi \mathrm{i}(h_1,h_2,\dots,h_s)\cdot(\bar{z}_1,\bar{z}_2,\dots,\bar{z}_s)/n} \right)^k = 0$$

if $(h_1, h_2, \dots, h_s) \cdot (\bar{z}_1, \bar{z}_2, \dots, \bar{z}_s)$ is not a multiple of n. It now follows from Jensen's inequality that

$$\begin{aligned}
&\theta_{n,s}(\alpha, \boldsymbol{\beta}, \bar{\boldsymbol{\gamma}}; 1, z_2, \dots, z_s) \\
&\le \bar{\gamma}_s \left[\sum_{\substack{\boldsymbol{h}\in\mathbb{Z}^s \\ h_s\neq 0 \\ (h_1,h_2,\dots,h_s)\cdot(\bar{z}_1,\bar{z}_2,\dots,\bar{z}_s)\equiv 0 \,(\mathrm{mod}\, n)}} \left(|h_s|^{-\alpha\lambda} \prod_{j=1}^{s-1} r(\alpha, \beta_j, \bar{\gamma}_j, h_j)^{-\lambda} \right) \right]^{\frac{1}{\lambda}} \\
&= \left[\theta_{n,s}(\alpha\lambda, \boldsymbol{\beta}^\lambda, \bar{\boldsymbol{\gamma}}^\lambda; 1, z_2, \dots, z_s) \right]^{\frac{1}{\lambda}},
\end{aligned}$$

where the last step follows from the property $r(\alpha, \beta, \gamma, h)^\lambda = r(\alpha\lambda, \beta^\lambda, \gamma^\lambda, h)$. This completes the proof. □

NUMERICAL SOLUTION OF A THERMOVISCOELASTIC CONTACT PROBLEM BY A PENALTY METHOD*

M. I. M. COPETTI[†] AND D. A. FRENCH[‡]

Abstract. We consider the numerical approximation of a one-dimensional quasi-static contact problem in linear thermoviscoelasticity. A finite element approximation based on a penalized problem is proposed and analyzed. We furnish an a priori estimate of the difference between the true and numerical solutions. The results of some computations are also presented.

Key words. thermoviscoelasticity, contact problem, penalty method

1. Introduction.

Consider the quasi-static Signorini contact problem in linear thermoviscoelasticity:

$$\theta_t - \theta_{xx} = -au_{xt}, \qquad 0 < x < 1, \quad t > 0, \tag{1.1}$$

$$\sigma_x = 0, \qquad 0 < x < 1, \quad t > 0, \tag{1.2}$$

with initial conditions

$$\theta(x,0) = \theta_0(x), \quad u(x,0) = u_0(x), \qquad 0 < x < 1, \tag{1.3}$$

and boundary conditions

$$u(0,t) = 0, \quad \theta(0,t) = 0, \quad -\theta_x(1,t) = k(\theta(1,t) - \theta_A), \qquad t > 0, \tag{1.4}$$

$$\sigma(1,t) \le 0, \quad u(1,t) \le g, \quad \sigma(1,t)(u(1,t) - g) = 0, \qquad t > 0, \tag{1.5}$$

with $\sigma = u_x + \zeta u_{xt} - a\theta$. This initial-boundary value problem models the deformations, due to thermal effects, of a homogeneous viscoelastic rod which moves along the x-axis. The temperature of the rod and the displacement from its reference configuration, assumed to be the interval $I = [0,1]$, are denoted by $\theta(x,t)$ and $u(x,t)$, respectively. At its left end the rod is fixed and has zero temperature, while at the right end it is free to expand up to a rigid obstacle, at temperature θ_A, located at distance $g > 0$ from the rest position. When there is no contact with the obstacle, the stress σ vanishes. Here the viscosity is represented by ζu_{xt}, $\zeta > 0$, and describes materials with short memory effect. The constant a is a small positive constant which arises from the physical properties of the rod; we assume $0 < a < 1$ (see [1] for comments on the size of a and [7] for a full nondimensionalization that provides a situation where $a << 1$).

The one-dimensional problem with $\zeta = 0$ has received considerable attention from both mathematicians and engineers as a basic model of expansion and contact. The papers [2] and [13] provide examples of early studies of this problem in the engineering literature. Long-time behavior issues are tackled in [12].

In many papers (see [12], for instance), the heat exchange coefficient k is a nonlinear function of the actual distance between the end of the rod and the obstacle when there is no contact and the contact pressure otherwise. In [1], a lengthy proof of solution existence is furnished for the $\zeta = 0$ case with this nonlinear k; this is one of the few papers that addresses this case in a rigorous way. We make the less realistic but more theoretically tractable assumption that $k > 0$ is a constant.

In this paper, we produce error estimates for a finite element approximation based on a penalty formulation. The unilateral constraint $u(1, t) \leq g$ is relaxed by assuming that the obstacle is elastic with rigidity constant $1/\epsilon > 0$. In this situation, the obstacle can be deformed, and the displacement $u(1, t)$ can be greater than g.

We also use the penalty formulation to establish existence and uniqueness results for the continuous problem. Previously, Kuttler and Shillor [11], using tools from convex analysis, proved existence results when the heat transfer coefficient may depend on the gap between the rod and the obstacle.

The contact problem for an elastic rod ($\zeta = 0$) and a rigid obstacle was studied numerically by Copetti [4]. Dirichlet boundary conditions for the temperature at both ends were considered by Copetti and Elliott [6]. In [5], the obstacle was elastic. In these cases, the resulting equations decouple and can be rewritten in terms of the temperature only. This does not appear to be possible for the viscoelastic problem.

We now outline the remainder of this paper. In section 2, we introduce the penalty formulation and show that it has a unique solution. We also identify its regularity properties. In section 3, we prove there exists a unique solution to (1.1)–(1.5) which is a limit of the solution to the penalty problem as the penalty parameter $\epsilon \to 0$. In section 4, we produce an estimate on the size of the difference between the penalty and true solutions. In section 5, we introduce the numerical scheme. Section 6 contains the main result of the paper which is the error estimate for the scheme. Finally, in section 7, we show the results of some numerical simulations using the new method.

We denote the norms of $L^2(I)$ and $H^s(I)$ by $\|\cdot\|$ and $\|\cdot\|_s$, respectively. We will analyze functions in the space $H^1_E(I) = \{\chi \in H^1(I) \mid \chi(0) = 0\}$.

We assume throughout that the initial data is sufficiently regular and compatible. Thus

$$\theta_0 \in H^1_E(I), \quad u_0 \in H^1_E(I), \quad \text{and} \quad u_0(1, \cdot) \leq g. \tag{1.6}$$

Throughout the paper, C denotes positive constants which are allowed to depend on data and norms of u, θ, and σ; these constants are not necessarily the same at each occurrence. Although we do not exploit this fact, note that $\sigma = \sigma(t)$ since $\sigma_x = 0$.

2. Penalized problem—definition and analysis.

In this section, we introduce a penalty formulation for (1.1)–(1.5) which will be used in our existence proof and will be a critical part of the definition of our numerical method.

The following initial-boundary value problem constitutes our penalized problem:

$$\theta^\epsilon_t - \theta^\epsilon_{xx} = -a u^\epsilon_{xt}, \tag{2.1}$$

$$\sigma^\epsilon_x = 0, \tag{2.2}$$

where $\sigma^\epsilon = u^\epsilon_x + \zeta u^\epsilon_{xt} - a\theta^\epsilon$, with initial conditions

$$\theta^\epsilon(x,0) = \theta_0(x), \quad u^\epsilon(x,0) = u_0(x), \tag{2.3}$$

and boundary conditions

$$u^\epsilon(0,t) = 0, \quad \theta^\epsilon(0,t) = 0, \quad -\theta^\epsilon_x(1,t) = k(\theta^\epsilon(1,t) - \theta_A), \tag{2.4}$$

$$\sigma^\epsilon(1,t) = -\frac{1}{\epsilon}[u^\epsilon(1,t) - g]_+. \tag{2.5}$$

The condition (2.5) treats the obstacle as elastic. Note that $\sigma^\epsilon = \sigma^\epsilon(t)$. It is important for us that the functional on the right side is now Lipschitz.

We first prove an existence and uniqueness theorem for the penalized problem, (2.1)–(2.5). This will eventually lead to an existence and uniqueness theorem for (1.1)–(1.5).

THEOREM 2.1. *For any $\epsilon > 0$, there exists a unique $\{\theta^\epsilon,\ u^\epsilon\}$ satisfying* (2.1)–(2.5) *with*

$$\theta^\epsilon \in L^\infty(0,T;H^1_E(I)),\ \theta^\epsilon_t,\ \theta^\epsilon_{xx} \in L^2(0,T;L^2(I)),$$

$$u^\epsilon \in L^\infty(0,T;H^1_E(I)),\ u^\epsilon_t \in L^2(0,T;H^1_E(I)),\ \sigma^\epsilon \in L^2(0,T).$$

Moreover, if $u_0 \in H^2(I)$, then $u^\epsilon_{xx} \in L^\infty(0,T;L^2(I))$.

Remark. Note that the functions u^ϵ, θ^ϵ, and σ^ϵ are bounded in the norms of the above spaces uniformly in ϵ.

Proof. It is helpful to study a modified version of (2.1)–(2.5) in which the dependent variables have zero initial data. Thus consider

$$\tilde{\theta}^\epsilon(x,t) = \theta^\epsilon(x,t) - \theta_0(x) \text{ and } \tilde{u}^\epsilon(x,t) = u^\epsilon(x,t) - u_0(x).$$

Then $\tilde{\theta}^\epsilon,\ \tilde{u}^\epsilon$ satisfy, $\forall\ w,\ v \in H^1_E(I)$,

$$(\tilde{\theta}^\epsilon_t, w) + (\tilde{\theta}^\epsilon_x + \theta_{0x}, w_x) + a(\tilde{u}^\epsilon_{xt}, w) + k(\tilde{\theta}^\epsilon(1,\cdot) + \theta_0(1) - \theta_A)w(1) = 0,$$

$$(\tilde{u}^\epsilon_x + \zeta\tilde{u}^\epsilon_{xt} - a\tilde{\theta}^\epsilon - a\theta_0 + u_{0x}, v_x) + \frac{1}{\epsilon}[\tilde{u}^\epsilon(1,\cdot) + u_0(1) - g]_+ v(1) = 0.$$

Let $\{\phi_i\}_{i=1}^\infty \subset C^\infty(I)$ be an orthogonal basis for $H^1_E(I)$ and orthonormal for $L^2(I)$. Let $V^m = span\{\phi_i\}_{i=1}^m$, and look for

$$\theta^m(x,t) = \sum_{i=1}^m c_i(t)\phi_i(x), \quad u^m(x,t) = \sum_{i=1}^m d_i(t)\phi_i(x),$$

satisfying, $\forall\ w,\ v \in V^m$,

$$(\theta^m_t, w) + (\theta^m_x + \theta_{0x}, w_x) + a(u^m_{xt}, w) + k(\theta^m(1,\cdot) + \theta_0(1) - \theta_A)w(1) = 0,$$

$$(u^m_x + \zeta u^m_{xt} - a\theta^m - a\theta_0 + u_{0x}, v_x) + \frac{1}{\epsilon}[u^m(1,\cdot) + u_0(1) - g]_+ v(1) = 0,$$

with initial conditions $\theta^m(\cdot,0) = u^m(\cdot,0) = 0$. Since the nonlinearity involved is Lipschitz continuous, we know from the theory of ordinary differential equations (see [14]) that there exists a short-time solution (θ^m, u^m). We now proceed to show that this solution exists on a full interval $[0,T]$ for any given T by producing the appropriate a priori estimates.

Taking $w=\theta^m$, $v=u_t^m$ and adding the resulting equations, we find that

$$\frac{1}{2}\frac{d}{dt}\|\theta^m\|^2+\|\theta_x^m\|^2+k(\theta^m(1,\cdot))^2+\frac{1}{2}\frac{d}{dt}\|u_x^m\|^2+\zeta\|u_{xt}^m\|^2+\frac{1}{2\epsilon}\frac{d}{dt}[u^m(1,\cdot)+u_0(1)-g]_+^2$$

$$=k(\theta_A-\theta_0(1))\theta^m(1,\cdot)-(\theta_{0x},\theta_x^m)+(a\theta_0-u_{0x},u_{xt}^m)$$

$$\leq\frac{k}{2}(\theta_A-\theta_0(1))^2+\frac{k}{2}(\theta^m(1,\cdot))^2+\frac{1}{2}\|\theta_{0x}\|^2+\frac{1}{2}\|\theta_x^m\|^2+\frac{1}{2\zeta}\|a\theta_0-u_{0x}\|^2+\frac{\zeta}{2}\|u_{xt}^m\|^2.$$

Thus, integrating the resulting inequality from 0 to T and recalling (1.6), we obtain

$$\|\theta^m(\cdot,T)\|^2+\int_0^T\|\theta_x^m\|^2dt+\int_0^T(\theta^m(1,t))^2dt+\|u_x^m(\cdot,T)\|^2+\int_0^T\|u_{xt}^m\|^2dt$$

$$+\frac{1}{\epsilon}[u^m(1,T)+u_0(1)-g]_+^2\leq C.$$

Choosing $w=\theta_t^m$ yields

$$\|\theta_t^m\|^2+\frac{1}{2}\frac{d}{dt}\|\theta_x^m\|^2+\frac{k}{2}\frac{d}{dt}(\theta^m(1,\cdot)+\theta_0(1)-\theta_A)^2=-a(u_{xt}^m,\theta_t^m)-(\theta_{0x},\theta_{xt}^m)$$

$$\leq\frac{a^2}{2}\|u_{xt}^m\|^2+\frac{1}{2}\|\theta_t^m\|^2-\frac{d}{dt}(\theta_{0x},\theta_x^m),$$

so

$$\int_0^T\|\theta_t^m\|^2dt+\|\theta_x^m(\cdot,T)\|^2+k(\theta^m(1,T)+\theta_0(1)-\theta_A)^2$$

$$\leq a^2\int_0^T\|u_{xt}^m\|^2dt+2\|\theta_{0x}\|\|\theta_x^m(\cdot,T)\|+k(\theta_0(1)-\theta_A)^2.$$

It follows that

$$\int_0^T\|\theta_t^m\|^2dt+\|\theta_x^m(\cdot,T)\|^2+(\theta^m(1,T)+\theta_0(1)-\theta_A)^2\leq C.$$

Therefore,

$$\theta^m,\ u^m \text{ are bounded in } L^\infty(0,T;H_E^1(I)),$$

$$\theta_t^m \text{ is bounded in } L^2(0,T;L^2(I)),$$

$$u_t^m \text{ is bounded in } L^2(0,T;H_E^1(I)),$$

$$\theta^m(1,\cdot),\ [u^m(1,\cdot)+u_0(1)-g]_+ \text{ are bounded in } L^\infty(0,T).$$

We are now in a position to pass to the limit as $m \to \infty$. As a consequence, there exists $\tilde{\theta}^\epsilon,\ \tilde{u}^\epsilon$, and subsequences $\{\theta^m\},\ \{u^m\}$ such that

$$\theta^m \to \tilde{\theta}^\epsilon \text{ in } L^\infty(0,T;H^1_E(I)) \text{ weak-star},$$

$$\theta^m_t \to \tilde{\theta}^\epsilon_t \text{ in } L^2(0,T;L^2(I)) \text{ weakly},$$

$$\theta^m(1,\cdot) \to \tilde{\theta}^\epsilon(1,\cdot) \text{ in } L^\infty(0,T) \text{ weak-star},$$

$$u^m \to \tilde{u}^\epsilon \text{ in } L^\infty(0,T;H^1_E(I)) \text{ weak-star,} \quad \text{and}$$

$$u^m_t \to \tilde{u}^\epsilon_t \text{ in } L^2(0,T;H^1_E(I)) \text{ weakly.}$$

Also, since $u^m(1,\cdot) \to \tilde{u}^\epsilon(1,\cdot)$ in $H^1(0,T)$ weakly and the injection of $H^1(0,T)$ into $L^2(0,T)$ is compact, we have that $u^m(1,\cdot) \to \tilde{u}^\epsilon(1,\cdot)$ in $L^2(0,T)$ strongly.

Because

$$\|[u^m(1,\cdot)+u_0(1)-g]_+ - [\tilde{u}^\epsilon(1,\cdot)+u_0(1)-g]_+\|_{L^2(0,T)} \le \|u^m(1,\cdot)-\tilde{u}^\epsilon(1,\cdot)\|_{L^2(0,T)},$$

we find that

$$[u^m(1,\cdot)+u_0(1)-g]_+ \to [\tilde{u}^\epsilon(1,\cdot)+u_0(1)-g]_+ \text{ in } L^2(0,T) \text{ strongly.}$$

Passing to the limit on m and reversing the change of variables, we find that θ^ϵ, u^ϵ solve, $\forall\ w,\ v \in H^1_E(I)$, the weak form

$$(\theta^\epsilon_t, w) + (\theta^\epsilon_x, w_x) + a(u^\epsilon_{xt}, w) + k(\theta^\epsilon(1,\cdot)-\theta_A)w(1) = 0, \tag{2.6}$$

$$(u^\epsilon_x + \zeta u^\epsilon_{xt} - a\theta^\epsilon, v_x) + \frac{1}{\epsilon}[u^\epsilon(1,\cdot)-g]_+ v(1) = 0. \tag{2.7}$$

Choosing $w,\ v \in C_0^\infty(I)$, it follows that $\theta^\epsilon_{xx} = \theta^\epsilon_t + au^\epsilon_{xt} \in L^2(0,T;L^2(I))$, $(u^\epsilon_x + \zeta u^\epsilon_{xt})_x = a\theta^\epsilon_x \in L^\infty(0,T;L^2(I))$, and (2.1)–(2.2) hold a.e. in Ω_T. It is now straightforward to deduce (2.3)–(2.5) also. In order to obtain H^2 regularity for $u^\epsilon(\cdot,t)$, we observe that, from the defining equations,

$$u^\epsilon_x + \zeta u^\epsilon_{xt} = a\theta^\epsilon + \sigma^\epsilon.$$

If we multiply by the appropriate integrating factor, we can rewrite this as

$$\frac{d}{dt}\left(e^{t/\zeta}u^\epsilon_x(\cdot,t)\right) = \frac{1}{\zeta}(a\theta^\epsilon(\cdot,t)+\sigma^\epsilon(t))e^{t/\zeta}.$$

So, we can integrate and obtain the following representation for u^ϵ_x:

$$u^\epsilon_x(\cdot,t) = e^{-t/\zeta}\left(u^\epsilon_x(\cdot,0) + \frac{1}{\zeta}\int_0^t (a\theta^\epsilon(\cdot,s)+\sigma^\epsilon(s))e^{s/\zeta}ds\right).$$

Differentiating with respect to x, we find that $u^\epsilon_{xx}(\cdot,t) \in L^2(I)$.

It remains to prove uniqueness. We follow the argument suggested in [1]. Let $\{\theta^\epsilon_1, u^\epsilon_1\}$, $\{\theta^\epsilon_2, u^\epsilon_2\}$ be two solutions, and define $\psi = \int_0^t(\theta^\epsilon_1 - \theta^\epsilon_2)ds$, $\eta = u^\epsilon_1 - u^\epsilon_2$. Then we can show from (2.1)–(2.5) that

$$(\psi_t, v) + (\psi_x, v_x) + k\psi(1,\cdot)v(1) + a(\eta_x, v) = 0,$$

$$(\sigma_1(\cdot) - \sigma_2(\cdot), w_x) = -\frac{1}{\epsilon}\left([u_1^\epsilon(1,\cdot) - g]_+ - [u_2^\epsilon(1,\cdot) - g]_+\right) w(1).$$

Now we let $v = \psi_t$, $w = \eta$ and add the resulting equations to obtain the following estimate:

$$\|\psi_t\|^2 + \|\eta_x\|^2 + \frac{1}{2}\frac{d}{dt}(\|\psi_x\|^2 + k\psi(1,\cdot)^2 + \zeta\|\eta_x\|^2) = -\frac{1}{\epsilon}([u_1^\epsilon(1,\cdot) - g]_+$$

$$-[u_2^\epsilon(1,\cdot) - g]_+)(u_1^\epsilon(1,\cdot) - u_2^\epsilon(1,\cdot)) \leq 0,$$

where the last inequality followed from the monotonicity of the $[\cdot]_+$ functional. We can now conclude $\psi_t = \eta = 0$, which finishes the proof. □

3. Existence and uniqueness. In this section, we obtain a solution to (1.1)–(1.5) as the limit of solutions to the penalized problem.

THEOREM 3.1. *There exists a unique* $\{\theta,\ u\}$ *satisfying* (1.1)–(1.5) *with*

$$\theta \in L^\infty(0,T; H_E^1(I)),\ \theta_t,\ \theta_{xx} \in L^2(0,T;L^2(I)),$$

$$u \in L^\infty(0,T;H_E^1(I)),\ u_t \in L^2(0,T;H_E^1(I)),\ \sigma \in L^2(0,T).$$

If in addition $u_0 \in H^2(I)$, *then* $u_{xx} \in L^\infty(0,T;L^2(I))$.

Proof. Setting $w = \theta^\epsilon$ in (2.6) and $v = u_t^\epsilon$ in (2.7), we obtain

$$\|\theta^\epsilon(\cdot,T)\|^2 + \int_0^T \|\theta_x^\epsilon\|^2 dt + \int_0^T (\theta^\epsilon(1,t))^2 dt + \|u_x^\epsilon(\cdot,T)\|^2 + \int_0^T \|u_{xt}^\epsilon\|^2 dt$$

$$+\frac{1}{\epsilon}[u^\epsilon(1,T) - g]_+^2 \leq C.$$

Let $\Delta t > 0$, and define $w(x,t) = (\theta^\epsilon(x,t+\Delta t) - \theta^\epsilon(x,t))/\Delta t$ for $0 \leq t \leq T - \Delta t$ and $w(x,t) = (\theta^\epsilon(x,T) - \theta^\epsilon(x,t))/\Delta t$ for $T - \Delta t \leq t \leq T$. With this choice of w in (2.6), integrating from 0 to T and letting Δt tend to zero, we get

$$\int_0^T \|\theta_t^\epsilon\|^2 dt + \|\theta_x^\epsilon(\cdot,T)\|^2 + (\theta^\epsilon(1,T))^2 \leq C.$$

Thus there exist functions θ and u which are limits of subsequences of $\{\theta^\epsilon\}$ and $\{u^\epsilon\}$ such that, as $\epsilon \to 0$,

$$\theta^\epsilon \to \theta \text{ in } L^\infty(0,T;H_E^1(I)) \text{ weak-star},$$

$$\theta_t^\epsilon \to \theta_t \text{ in } L^2(0,T;L^2(I)) \text{ weakly},$$

$$\theta^\epsilon(1,\cdot) \to \theta(1,\cdot) \text{ in } L^\infty(0,T) \text{ weak-star},$$

$$u^\epsilon \to u \text{ in } L^\infty(0,T;H_E^1(I)) \text{ weak-star}, \quad \text{and}$$

$$u_t^\epsilon \to u_t \text{ in } L^2(0,T;H_E^1(I)) \text{ weakly}.$$

In addition, we have that

$$u^\epsilon \to u \text{ in } L^2(0,T;L^2(I)) \text{ strongly,}$$

$$[u^\epsilon(1,\cdot)-g]_+ \to [u(1,\cdot)-g]_+ \text{ in } L^2(0,T) \text{ strongly, and}$$

$$\theta^\epsilon \to \theta \text{ in } L^2(0,T;L^2(I)) \text{ strongly.}$$

From our first estimate in this proof, we have $[u^\epsilon(1,\cdot)-g]_+^2 \leq C\epsilon$. Thus we conclude that

$$[u^\epsilon(1,\cdot)-g]_+ \to 0 \text{ in } L^2(0,T) \text{ strongly.}$$

As a consequence, $u(1,t)-g \leq 0$ for almost all $t \in (0,T)$. Observing that, for $w \in H_E^1(I)$ which satisfies $w(1) \leq g$, we have

$$-\frac{1}{\epsilon}[u^\epsilon(1,\cdot)-g]_+(w(1)-u^\epsilon(1,\cdot)) = -\frac{1}{\epsilon}[u^\epsilon(1,\cdot)-g]_+(w(1)-g)+\frac{1}{\epsilon}[u^\epsilon(1,\cdot)-g]_+^2 \geq 0,$$

and letting $v = w - u^\epsilon$ in (2.7), we conclude that, $\forall w \in L^2(0,T;H_E^1(I))$ with $w(1,\cdot) \leq g$,

$$\int_0^T (u_x^\epsilon + \zeta u_{xt}^\epsilon - a\theta^\epsilon, w_x - u_x^\epsilon)dt \geq -\int_0^T \frac{1}{\epsilon}[u^\epsilon(1,\cdot)-g]_+(w(1)-u^\epsilon(1,\cdot))dt \geq 0.$$

From this we obtain that

$$\int_0^T (u_x^\epsilon + \zeta u_{xt}^\epsilon, w_x)dt - \int_0^T (a\theta^\epsilon, w_x - u_x^\epsilon)dt \geq \int_0^T \|u_x^\epsilon\|^2 dt$$

$$+\frac{\zeta}{2}\|u_x^\epsilon(\cdot,T)\|^2 - \frac{\zeta}{2}\|u_{0x}\|^2. \tag{3.1}$$

The weak convergence of $u_x^\epsilon(\cdot,t)$ to $u_x(\cdot,t)$ in $L^2(I)$ implies that

$$(u_x^\epsilon(\cdot,t), u_x(\cdot,t)) \to \|u_x(\cdot,t)\|^2,$$

and the Cauchy–Schwarz inequality yields

$$\liminf_{\epsilon\to 0} \|u_x^\epsilon\| \geq \|u_x\|.$$

This allows us to now let $\epsilon \to 0$ on the right side of (3.1) and retain the inequality. We can also let $\epsilon \to 0$ on the first integral on the left side of (3.1) due to the weak convergence properties of u_x^ϵ and u_{xt}^ϵ. We can take the limit on the second integral on the left side due to the strong convergence of θ^ϵ. We can now conclude that θ, u satisfy, $\forall\ w \in H_E^1(I)$ and $\forall\ v \in L^2(0,T;H_E^1(I))$ with $v(1,t) \leq g$,

$$(\theta_t, w) + (\theta_x, w_x) + a(u_{xt}, w) + k(\theta(1,\cdot)-\theta_A)w(1) = 0,$$

$$\int_0^T (u_x + \zeta u_{xt} - a\theta, v_x - u_x)dt \geq 0.$$

Following standard techniques (see [9], [10]), we can now show that θ and u satisfy the claimed regularity properties and (1.1)–(1.5). Uniqueness follows similarly as it did for the penalized problem. □

4. Penalization error. In this section, we provide an estimate of the difference between the true and penalty solutions in terms of the parameter ϵ.

THEOREM 4.1. *There exists a constant C such that for any $T > 0$ the following holds:*

$$\left\| \int_0^T (\theta_x - \theta_x^\epsilon) dt \right\|^2 + \|(u - u^\epsilon)(\cdot, T)\|^2 \leq C\epsilon \|\sigma\|^2_{L^2(0,T)}.$$

Proof. As we did in the uniqueness argument, let $\psi = \int_0^t (\theta - \theta^\epsilon) ds$ and $\eta = u - u^\epsilon$. Then

$$\|\psi_t\|^2 + \|\eta_x\|^2 + \frac{1}{2}\frac{d}{dt}(\|\psi_x\|^2 + k\psi(1,\cdot)^2 + \zeta\|\eta_x\|^2) = (\sigma(\cdot) - \sigma^\epsilon(\cdot))(u(1,\cdot) - u^\epsilon(1,\cdot)).$$

Setting $I = (\sigma(\cdot) - \sigma^\epsilon(\cdot))(u(1,\cdot) - u^\epsilon(1,\cdot))$, we have the following cases:

1. If $u(1,\cdot) - g < 0$ and $u^\epsilon(1,\cdot) - g < 0$, then $\sigma(\cdot) = \sigma^\epsilon(\cdot) = 0$ and $I = 0$.
2. If $u(1,\cdot) - g < 0$ and $u^\epsilon(1,\cdot) - g \geq 0$, then $\sigma(\cdot) = 0$, $\sigma^\epsilon(\cdot) < 0$, and
$$I = -\sigma^\epsilon(\cdot)(u(1,\cdot) - g + g - u^\epsilon(1,\cdot)) \leq 0.$$
3. If $u(1,\cdot) - g = 0$ and $u^\epsilon(1,\cdot) - g < 0$, then $\sigma(\cdot) \leq 0$, $\sigma^\epsilon(\cdot) = 0$, and
$$I = \sigma(\cdot)(g - u^\epsilon(1,\cdot)) \leq 0.$$
4. If $u(1,\cdot) - g = 0$ and $u^\epsilon(1,\cdot) - g \geq 0$, then $\sigma^\epsilon(\cdot) = -(u^\epsilon(1,\cdot) - g)/\epsilon$, so

$$I = \left(\sigma(\cdot) + \frac{1}{\epsilon}(u^\epsilon(1,\cdot) - g)\right)\eta(1,\cdot) = \left(\sigma(\cdot) - \frac{1}{\epsilon}\eta(1,\cdot)\right)\eta(1,\cdot) \leq \frac{\epsilon}{2}\sigma(\cdot)^2 - \frac{1}{2\epsilon}\eta(1,\cdot)^2.$$

Hence, combining these four cases and integrating in t, we have

$$\int_0^T \|\psi_t\|^2 dt + \int_0^T \|\eta_x\|^2 dt + \frac{1}{2}(\|\psi_x(\cdot,T)\|^2 + k\psi(1,T)^2 + \zeta\|\eta_x(\cdot,T)\|^2) + \frac{1}{2\epsilon}\int_0^T \eta(1,t)^2 dt$$

$$\leq \frac{\epsilon}{2}\|\sigma\|^2_{L^2(0,T)}.$$

It follows from the Poincaré inequality that

$$\|\psi_x(\cdot,T)\|^2 + \|\eta(\cdot,T)\|^2 \leq C\epsilon\|\sigma\|^2_{L^2(0,T)},$$

which proves the theorem. □

5. Numerical approximation. We now introduce our finite element numerical method with the backward Euler scheme for the time discretization. We briefly describe the implementation of this method in this section.

Partition the interval $(0,1)$ into subintervals $I_j = (x_{j-1}, x_j)$ of length $h = 1/J$, with $0 = x_0 < x_1 < \cdots < x_J = 1$, and denote by $S_E^h \subset H_E^1(I)$ the space of continuous piecewise linear functions defined on this partition. Our finite element method for

(2.1)–(2.5) on each time step is to find Θ^n, $U^n \in S_E^h$, $n = 1,\dots,N$, such that, $\forall\, W,\ V \in S_E^h$,

$$\frac{1}{\Delta t}(\Theta^n - \Theta^{n-1}, W) + (\Theta^n_x, W_x) + k(\Theta^n(1) - \theta_A)W(1)$$

$$+\frac{a}{\Delta t}(U^n_x - U^{n-1}_x, W) = 0, \tag{5.1}$$

$$(U^n_x - a\Theta^n, V_x) + \frac{\zeta}{\Delta t}(U^n_x - U^{n-1}_x, V_x) + \beta_\epsilon(\Gamma^n)V(1) = 0, \tag{5.2}$$

where $\Theta^0 \in S_E^h$ and $U^0 \in S_E^h$ are given approximations of θ_0 and u_0, respectively, $\beta_\epsilon(\chi) = \frac{1}{\epsilon}[\chi]_+$, $\Gamma^n = U^n(1) - g$, and $\Delta t = T/N$. Assuming that Θ^{n-1} and U^{n-1} are known, we need to iterate to find Θ^n and U^n:

$$\frac{1}{\Delta t}(\Theta^{n,l} - \Theta^{n-1}, W) + (\Theta^{n,l}_x, W_x) + k(\Theta^{n,l}(1) - \theta_A)W(1)$$

$$+\frac{a}{\Delta t}(U^{n,l-1}_x - U^{n-1}_x, W) = 0, \tag{5.3}$$

$$(U^{n,l}_x - a\Theta^{n,l}, V_x) + \frac{\zeta}{\Delta t}(U^{n,l}_x - U^{n-1}_x, V_x) + \beta_\epsilon(\Gamma^{n,l-1})V(1) = 0, \tag{5.4}$$

where $\Theta^{n,0} = \Theta^{n-1}$ and $U^{n,0} = U^{n-1}$. The method defined requires that the systems of algebraic equations

$$(M + \Delta tK + \Delta tkB)\underline{c}^{n,l} = M\underline{c}^{n-1} + \Delta tk\theta_A\underline{e} + aC(\underline{d}^{n-1} - \underline{d}^{n,l-1}),$$

$$(\Delta t + \zeta)K\underline{d}^{n,l} = \zeta K\underline{d}^{n-1} + \Delta taC^T\underline{c}^{n,l} - \frac{\Delta t}{\epsilon}[d_J^{n,l-1} - g]_+\underline{e}$$

be solved at each iteration. We used the representations

$$\Theta^n = \sum_{i=1}^J c_i^n \eta_i, \qquad U^n = \sum_{i=1}^J d_i^n \eta_i,$$

with $\{\eta_i\}_{i=1}^J$ the usual basis for S_E^h, and

$$M_{ij} = (\eta_i, \eta_j),\ K_{ij} = (\eta_{ix}, \eta_{jx}),\ B_{ij} = \eta_i(1)\eta_j(1), C_{ij} = (\eta_i, \eta_{jx}),\ \{\underline{e}\}_i = \eta_i(1).$$

We now show that if Δt is sufficiently small to a reasonable degree, then the iterations are guaranteed to converge for the system (5.1)–(5.2).

THEOREM 5.1. *Suppose that $a < 1$ and $\Delta t < \epsilon\zeta$. Then there exists a unique solution $\{\Theta^n,\ U^n\}$ for problem* (5.1)–(5.2).

Proof. We will show that the iteration converges for the scheme (5.3)–(5.4). Let $e^j = \Theta^{n,j} - \Theta^{n,j-1}$ and $q^j = U^{n,j} - U^{n,j-1}$. Thus e^j and q^j satisfy

$$\|e^j\|^2 + \Delta t\|e^j_x\|^2 + \Delta tk(e^j(1))^2 = -a(q^{j-1}_x, e^j),$$

$$\left(1 + \frac{\zeta}{\Delta t}\right)\|q^j_x\|^2 + (\beta_\epsilon(\Gamma^{n,j-1}) - \beta_\epsilon(\Gamma^{n,j-2}))q^j(1) = a(e^j, q^j_x).$$

Adding the equations, using the Lipschitz continuity of β_ϵ and the Cauchy–Schwarz inequality, yields, for $\delta > 0$ and $\alpha > 0$,

$$\|e^j\|^2 + \Delta t\|e^j_x\|^2 + \Delta tk(e^j(1))^2 + \left(1 + \frac{\zeta}{\Delta t}\right)\|q^j_x\|^2 \leq \frac{\delta}{2}\|q^j_x - q^{j-1}_x\|^2$$

$$+\frac{1}{2\delta}\|e^j\|^2 + \frac{\alpha}{2\epsilon}(q^{j-1}(1))^2 + \frac{1}{2\alpha\epsilon}(q^j(1))^2.$$

Using the fact that $(q^j(1))^2 \leq \|q^j_x\|^2$, we find

$$\left(1 - \frac{1}{2\delta}\right)\|e^j\|^2 + \Delta t\|e^j_x\|^2 + \Delta tk(e^j(1))^2 + \left(1 + \frac{\zeta}{\Delta t} - \delta - \frac{1}{2\alpha\epsilon}\right)\|q^j_x\|^2$$

$$\leq \left(\delta + \frac{\alpha}{2\epsilon}\right)\|q^{j-1}_x\|^2,$$

and taking $\delta = 1/2$ and $\alpha = 1$, we now have

$$\left(\frac{1}{2} + \frac{\zeta}{\Delta t} - \frac{1}{2\epsilon}\right)\|q^j_x\|^2 \leq \left(\frac{1}{2} + \frac{1}{2\epsilon}\right)\|q^{j-1}_x\|^2.$$

Note that our assumption $\Delta t < \epsilon\zeta$ implies $1/\epsilon < \zeta/\Delta t$, so we know the factor on the left side of the inequality above is positive. Moreover,

$$\frac{1}{2} + \frac{\zeta}{\Delta t} - \frac{1}{2\epsilon} > \frac{1}{2} + \frac{1}{\epsilon} - \frac{1}{2\epsilon} = \frac{1}{2} + \frac{1}{2\epsilon},$$

and thus there exists M, with $0 < M < 1$, such that

$$\|q^j_x\|^2 \leq M\|q^{j-1}_x\|^2.$$

One can now show using standard contraction arguments that the sequences $\{\Theta^{n,j}\}$, $\{U^{n,j}\}$ converge to Θ^n, $U^n \in S^h_E$ and that these limits solve the Galerkin approximation (5.1)–(5.2). A similar argument yields the uniqueness of $\{\Theta^n,\ U^n\}$. □

6. Error bound. In this section, we obtain an error bound for the numerical approximation of the contact problem. Set $U^0 = P^h_E u_0$, where $P^h_E : H^1_E(I) \to S^h_E$ is defined by $((\eta - P^h_E\eta)_x, \chi_x) = 0\ \forall\ \chi \in S^h_E$ and satisfies (see [8])

$$\|\eta - P^h_E\eta\| \leq h\|\eta_x\|, \qquad P^h_E\eta(x_i) = \eta(x_i)$$

for $i = 0, 1, \ldots, J$. Also, if η is sufficiently smooth, it follows that

$$\|P^h_E\eta - \eta\| + h\|(P^h_E\eta - \eta)_x\| \leq Ch^2\|\eta\|_2.$$

The error analysis uses a triangle inequality estimate involving $(\theta, u), (\theta^\epsilon, u^\epsilon)$, and (Θ, U). Attempts to obtain an error estimate directly are difficult because of the need to differentiate the monotone graph

$$\beta(v) = \begin{cases} [0,\infty), & v = 0, \\ \emptyset, & v > 0, \\ 0, & v < 0. \end{cases}$$

Approximating this quantity by the penalty formulation allows the discretization analysis to go through more easily since $\beta(v)$ is replaced by the Lipschitz function

$\beta_\epsilon(v) = \epsilon^{-1}[v]_+$. The final estimate, of course, is then subject to the unpleasant ϵ^{-1} factors.

We now state and prove the main theorem of this paper.

THEOREM 6.1. *There exists a constant C such that*

$$\left\| \int_0^{t_n} \theta_x dt - \Delta t \sum_{i=1}^n \Theta_x^i \right\|^2 \leq C \left(\|\Theta^0 - \theta_0\|^2 + \epsilon + h^2 + \frac{h^2}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2} \right),$$

$$\|u(\cdot, t_n) - U^n\|^2 \leq C \left(\|\Theta^0 - \theta_0\|^2 + \epsilon + h^2 + \frac{h^2}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2} \right),$$

where $t_n = n\Delta t$.

Remark. The $\epsilon, h^2/\Delta t$, and $(\Delta t)^2/\epsilon^2$ terms will surely be the least accurate on the right side of the estimate. (We expect $\|\Theta^0 - \theta_0\| = O(h^2)$.) Balancing these three terms, we find that $\epsilon = h^{4/5}$ and $\Delta t = h^{6/5}$ (which satisfies the condition in Theorem 5.1 for h small enough). Thus the rates of convergence for this theorem are essentially

$$\left\| \int_0^{t_n} \theta_x dt - \Delta t \sum_{i=1}^n \Theta_x^i \right\|^2 \leq C h^{4/5} \quad \text{and} \quad \|u(\cdot, t_n) - U^n\|^2 \leq C h^{4/5}.$$

Proof. First we estimate the error due to the discretization of the penalized problem. Let $\theta^n = \theta^\epsilon(\cdot, t_n)$ and $u^n = u^\epsilon(\cdot, t_n)$. Integrating (2.6) from 0 to t_n and (2.7) from t_{n-1} to t_n, we obtain, $\forall\ w,\ v \in H_E^1(I)$,

$$(\theta^n - \theta_0, w) + (\hat{\theta}_x^n, w_x) + k(\hat{\theta}^n(1) - t_n\theta_A)w(1) + a(u_x^n - u_{0x}, w) = 0,$$

$$(\overline{u}_x^n - a\overline{\theta}^n, v_x) + \frac{\zeta}{\Delta t}(u_x^n - u_x^{n-1}, v_x) + \overline{\beta}_\epsilon^n(\gamma_\epsilon)v(1) = 0,$$

with

$$\hat{\theta}^n = \int_0^{t_n} \theta^\epsilon(\cdot, t)dt, \quad \overline{u}^n = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} u^\epsilon(\cdot, t)dt, \quad \overline{\theta}^n = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \theta^\epsilon(\cdot, t)dt,$$

$$\overline{\beta}_\epsilon^n(\gamma_\epsilon) = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \beta_\epsilon(\gamma_\epsilon(t))dt, \quad \text{and} \quad \gamma_\epsilon(t) = u^\epsilon(1, t) - g.$$

Summing (5.1) from 1 to n gives, $\forall\ W \in S_E^h$,

$$(\Theta^n - \Theta^0, W) + \left(\Delta t \sum_{i=1}^n \Theta_x^i, W_x\right) + k\left(\Delta t \sum_{i=1}^n \Theta^i(1) - t_n\theta_A\right)W(1)$$
$$+ a(U_x^n - U_x^0, W) = 0.$$

Thus, $\forall\ W,\ V \in S_E^h$,

$$(\Theta^n - \theta^n, W) + \left(\Delta t \sum_{i=1}^n \Theta_x^i - \hat{\theta}_x^n, W_x\right) + k\left(\Delta t \sum_{i=1}^n \Theta^i(1) - \hat{\theta}^n(1)\right)W(1)$$

$$+ a(U_x^n - u_x^n, W) = (\Theta^0 - \theta_0, W) + a(U_x^0 - u_{0x}, W),$$

and

$$(U_x^n - \overline{u}_x^n, V_x) + \frac{\zeta}{\Delta t}((U_x^n - u_x^n) - (U_x^{n-1} - u_x^{n-1}), V_x) - a(\Theta^n - \overline{\theta}^n, V_x)$$
$$+ (\beta_\epsilon(\Gamma^n) - \overline{\beta}_\epsilon^n(\gamma_\epsilon))V(1) = 0.$$

Defining $\varepsilon^j = \Delta t \sum_{i=1}^j \Theta^i - P_E^h \hat{\theta}^j$, $j = 1, \ldots, n$, $\varepsilon^0 = 0$, $e^n = U^n - P_E^h u^n$, and recalling the properties of P_E^h, we find that, $\forall\ W,\ V \in S_E^h$,

$$\frac{1}{\Delta t}(\varepsilon^n - \varepsilon^{n-1}, W) + (\varepsilon_x^n, W_x) + k\varepsilon^n(1)W(1) = (\Theta^0 - \theta_0, W)$$
$$+ a(U_x^0 - u_{0x}, W) - a(U_x^n - u_x^n, W) + (\theta^n - P_E^h\overline{\theta}^n, W),$$
$$(e_x^n, V_x) + \frac{\zeta}{\Delta t}(e_x^n - e_x^{n-1}, V_x) + (\beta_\epsilon(\Gamma^n) - \beta_\epsilon(\gamma_\epsilon^n))V(1) = \frac{a}{\Delta t}(\varepsilon^n - \varepsilon^{n-1}, V_x)$$
$$+ a(P_E^h\overline{\theta}^n - \overline{\theta}^n, V_x) + (\overline{u}_x^n - u_x^n, V_x) + (\overline{\beta}_\epsilon^n(\gamma_\epsilon) - \beta_\epsilon(\gamma_\epsilon^n))V(1),$$

where $\gamma_\epsilon^n = \gamma_\epsilon(t_n)$. Note that

$$\beta_\epsilon(\Gamma^n) - \beta_\epsilon(\gamma_\epsilon^n) = \beta_\epsilon'(\xi)(U^n(1) - u^n(1)) = \beta_\epsilon'(\xi)(U^n(1) - P_E^h u^n(1)) = \beta_\epsilon'(\xi)e^n(1),$$

where ξ is between Γ^n and γ_ϵ^n. Thus

$$(\beta_\epsilon(\Gamma^n) - \beta_\epsilon(\gamma_\epsilon^n))e^n(1) = \beta_\epsilon'(\xi)(e^n(1))^2 \geq 0,$$
$$a(U_x^n - u_x^n, W) = a(U^n(1) - u^n(1))W(1) - a(U^n - u^n, W_x),$$

and

$$\frac{a}{\Delta t}(\varepsilon^n - \varepsilon^{n-1}, V_x) = \frac{a}{\Delta t}(\varepsilon^n(1) - \varepsilon^{n-1}(1))V(1) - \frac{a}{\Delta t}(\varepsilon_x^n - \varepsilon_x^{n-1}, V).$$

Choosing $W = (\varepsilon^n - \varepsilon^{n-1})/\Delta t$, $V = e^n$ and adding the resulting equations, we obtain

$$\frac{1}{(\Delta t)^2}\|\varepsilon^n - \varepsilon^{n-1}\|^2 + \frac{1}{2\Delta t}(\|\varepsilon_x^n - \varepsilon_x^{n-1}\|^2 + \|\varepsilon_x^n\|^2 - \|\varepsilon_x^{n-1}\|^2)$$
$$+\frac{k}{2\Delta t}\left((\varepsilon^n(1) - \varepsilon^{n-1}(1))^2 + (\varepsilon^n(1))^2 - (\varepsilon^{n-1}(1))^2\right) + \|e_x^n\|^2$$
$$+\frac{\zeta}{2\Delta t}(\|e_x^n - e_x^{n-1}\|^2 + \|e_x^n\|^2 - \|e_x^{n-1}\|^2) \leq \frac{1}{\Delta t}(\Theta^0 - \theta_0, \varepsilon^n - \varepsilon^{n-1})$$
$$-\frac{a}{\Delta t}(U^0 - u_0, \varepsilon_x^n - \varepsilon_x^{n-1}) + \frac{a}{\Delta t}(P_E^h u^n - u^n, \varepsilon_x^n - \varepsilon_x^{n-1})$$
$$+\frac{1}{\Delta t}(\theta^n - P_E^h\overline{\theta}^n, \varepsilon^n - \varepsilon^{n-1}) + a(P_E^h\overline{\theta}^n - \overline{\theta}^n, e_x^n) + (\overline{u}_x^n - u_x^n, e_x^n) + (\overline{\beta}_\epsilon^n(\gamma_\epsilon) - \beta_\epsilon(\gamma_\epsilon^n))e^n(1)$$
$$\leq \|\Theta^0 - \theta_0\|^2 + \frac{2a^2}{\Delta t}\|U^0 - u_0\|^2 + \frac{1}{2(\Delta t)^2}\|\varepsilon^n - \varepsilon^{n-1}\|^2$$
$$+\frac{1}{4\Delta t}\|\varepsilon_x^n - \varepsilon_x^{n-1}\|^2 + \frac{2a^2}{\Delta t}\|P_E^h u^n - u^n\|^2 + 2a^2\|\overline{\theta}^n - P_E^h\overline{\theta}^n\|^2$$
$$+\|\theta^n - P_E^h\overline{\theta}^n\|^2 + 2\|u_x^n - \overline{u}_x^n\| + \frac{1}{4}\|e_x^n\|^2 + (\overline{\beta}_\epsilon^n(\gamma_\epsilon) - \beta_\epsilon(\gamma_\epsilon^n))^2 + \frac{1}{4}(e^n(1))^2.$$

Since $(e^n(1))^2 \le \|e_x^n\|^2$, we have

$$\begin{aligned}&\frac{1}{2(\Delta t)^2}\|\varepsilon^n-\varepsilon^{n-1}\|^2+\frac{1}{4\Delta t}\|\varepsilon_x^n-\varepsilon_x^{n-1}\|^2+\frac{1}{2\Delta t}(\|\varepsilon_x^n\|^2-\|\varepsilon_x^{n-1}\|^2)\\ &\quad+\frac{k}{2\Delta t}((\varepsilon^n(1)-\varepsilon^{n-1}(1))^2+(\varepsilon^n(1))^2-(\varepsilon^{n-1}(1))^2)+\frac{1}{2}\|e_x^n\|^2\\ &\quad+\frac{\zeta}{2\Delta t}(\|e_x^n-e_x^{n-1}\|^2+\|e_x^n\|^2-\|e_x^{n-1}\|^2)\le\|\Theta^0-\theta_0\|^2\\ &\quad+\frac{2a^2}{\Delta t}\|U^0-u_0\|^2+I_1+I_2+I_3+I_4+I_5,\end{aligned}\tag{6.1}$$

where we identify and estimate I_1-I_5 below.

$$I_1=\frac{2a^2}{\Delta t}\|P_E^h u^n-u^n\|^2\le C\frac{h^2}{\Delta t}\|u_x^\epsilon(\cdot,t_n)\|^2,$$

$$I_2=2a^2\|\overline{\theta}^n-P_E^h\overline{\theta}^n\|^2\le C\frac{h^4}{\Delta t}\int_{t_{n-1}}^{t_n}\|\theta^\epsilon\|_2^2dt,$$

$$\begin{aligned}I_3&=\|\theta^n-P_E^h\overline{\theta}^n\|^2=\|\theta^n-\overline{\theta}^n+\overline{\theta}^n-P_E^h\overline{\theta}^n\|^2\\ &=\left\|\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}\int_t^{t_n}\theta_t^\epsilon(\cdot,s)ds\;dt+\overline{\theta}^n-P_E^h\overline{\theta}^n\right\|^2\\ &\le C\left(\Delta t\int_{t_{n-1}}^{t_n}\|\theta_t^\epsilon\|^2dt+\frac{h^4}{\Delta t}\int_{t_{n-1}}^{t_n}\|\theta^\epsilon\|_2^2dt\right),\end{aligned}$$

$$I_4=2\|u_x^n-\overline{u}_x^n\|^2=2\left\|\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}(u_x^\epsilon(\cdot,t_n)-u_x^\epsilon(\cdot,t))dt\right\|^2\le C\Delta t\int_{t_{n-1}}^{t_n}\|u_{xt}^\epsilon\|^2dt,$$

$$\begin{aligned}I_5&=(\overline{\beta}_\epsilon^n(\gamma_\epsilon)-\beta_\epsilon(\gamma_\epsilon^n))^2=\left(\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}(\beta_\epsilon(\gamma_\epsilon)-\beta_\epsilon(\gamma_\epsilon^n))dt\right)^2\\ &\le\left(\frac{1}{\epsilon\Delta t}\int_{t_{n-1}}^{t_n}|u^\epsilon(1,t)-u^\epsilon(1,t_n)|dt\right)^2\le\left(\frac{1}{\epsilon\Delta t}\int_{t_{n-1}}^{t_n}\left|\int_{t_n}^t u_t^\epsilon(1,s)ds\right|dt\right)^2\\ &\le\frac{\Delta t}{\epsilon^2}\int_{t_{n-1}}^{t_n}(u_t^\epsilon(1,\cdot))^2dt\le\frac{\Delta t}{\epsilon^2}\int_{t_{n-1}}^{t_n}\|u_{xt}^\epsilon\|^2dt.\end{aligned}$$

We used the estimate for I_2 on the second term in I_3 and the fact that $|\beta_\epsilon'|\le 1/\epsilon$ on the last series of inequalities. We now multiply (6.1) by Δt, sum from 1 to n, note that $n\Delta t=C$, note that the bounds given by Theorem 2.1 are independent of ϵ, and use the fact that $\varepsilon^0=e^0=0$ to obtain

$$\|\varepsilon_x^n\|^2+\|e_x^n\|^2\le C\left(\|\Theta^0-\theta_0\|^2+\frac{h^2}{\Delta t}+h^4+(\Delta t)^2+\frac{(\Delta t)^2}{\epsilon^2}\right).$$

The Poincaré inequality yields

$$\|U^n - P_E^h u^\epsilon(\cdot, t_n)\|^2 \le C\left(\|\Theta^0 - \theta_0\|^2 + \frac{h^2}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2}\right).$$

Using the triangle inequality, we have

$$\begin{aligned}\|u^\epsilon(\cdot, t_n) - U^n\| &\le \|u^\epsilon(\cdot, t_n) - P_E^h u^\epsilon(\cdot, t_n)\| + \|P_E^h u^\epsilon(\cdot, t_n) - U^n\| \\ &\le Ch\|u_x^\epsilon(\cdot, t_n)\| + \|P_E^h u^\epsilon(\cdot, t_n) - U^n\|,\end{aligned}$$

and, as a consequence of the boundedness of u_x^ϵ, it results

$$\|u^\epsilon(\cdot, t_n) - U^n\|^2 \le C\left(\|\Theta^0 - \theta_0\|^2 + h^2 + \frac{h^2}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2}\right).$$

Similarly,

$$\left\|\int_0^{t_n} \theta_x^\epsilon dt - \Delta t \sum_{i=1}^n \Theta_x^i\right\| = \|(\hat{\theta}^n - P_E^h\hat{\theta}^n)_x - \varepsilon_x^n\| \le Ch\left(\int_0^{t_n} \|\theta^\epsilon\|_2^2 dt\right)^{1/2} + \|\varepsilon_x^n\|$$

and Theorem 2.1 yield

$$\left\|\int_0^{t_n} \theta_x^\epsilon dt - \Delta t \sum_{i=1}^n \Theta_x^i\right\|^2 \le C\left(\|\Theta^0 - \theta_0\|^2 + h^2 + \frac{h^2}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2}\right).$$

Combining these estimates with the penalty errors (Theorem 4.1), we obtain the result. □

Corollary 6.2. *If $u_0 \in H^2(I)$, there exists a constant C such that*

$$\left\|\int_0^{t_n} \theta_x dt - \Delta t \sum_{i=1}^n \Theta_x^i\right\|^2 \le C\left(\|\Theta^0 - \theta_0\|^2 + \epsilon + h^2 + \frac{h^4}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2}\right),$$

$$\|u(\cdot, t_n) - U^n\|^2 \le C\left(\|\Theta^0 - \theta_0\|^2 + \epsilon + \frac{h^4}{\Delta t} + h^4 + (\Delta t)^2 + \frac{(\Delta t)^2}{\epsilon^2}\right).$$

Remark. In this case, the rates of convergence are, for $\epsilon = h^{8/5}$ and $\Delta t = h^{12/5}$,

$$\left\|\int_0^{t_n} \theta_x dt - \Delta t \sum_{i=1}^n \Theta_x^i\right\|^2 \le Ch^{8/5} \text{ and } \|u(\cdot, t_n) - U^n\|^2 \le Ch^{8/5}.$$

Proof. If we look at the proof of Theorem 6.1, we see that if $u_0 \in H^2(I)$ and $u^\epsilon(\cdot, t)$ is bounded in $H^2(I)$, independently of ϵ, then the term $h^2/\Delta t$ becomes $h^4/\Delta t$. In the estimate for the displacement, h^2 turns into h^4. □

7. Numerical simulations. In this section, we describe some numerical calculations. In the first experiment, the initial data and the values of a and g, $a = 0.017$, $g = 0.1$, are the same as those in the work of Copetti [4]. Since in [4] the temperature difference is reversed, i.e., the left end of the rod has temperature θ_A and the obstacle is at temperature zero, the numerical scheme was modified accordingly. We

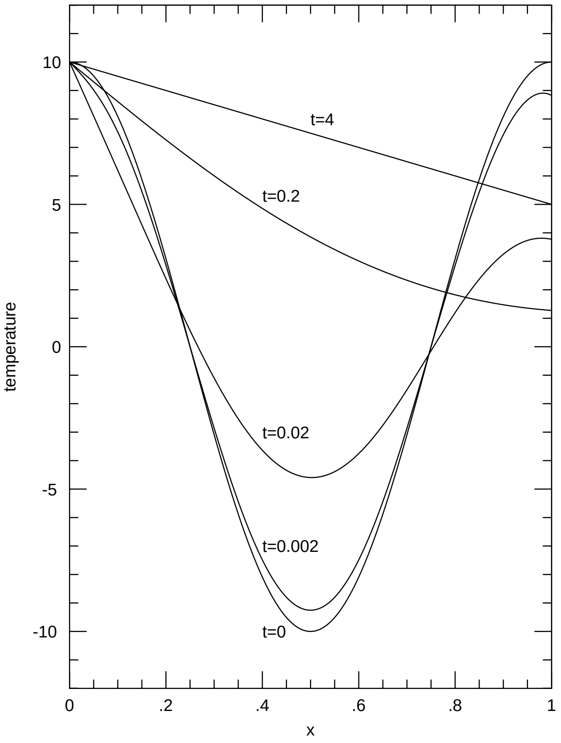

FIG. 7.1. *The evolution in time of the temperature for $\zeta = 10$.*

let $\epsilon = 0.01$, $k = 1$, $h = 1/250$, and $\Delta t = 0.001$, and we took four values for the viscosity coefficient ζ, $\zeta = 0.1$, 0.2, 1, and 10. We observed that the temperature profiles obtained are virtually identical for all values of ζ and are very similar to those presented by Copetti [4], [5], where the rod was only elastic ($\zeta = 0$). This observation was reported also by Copetti [5] for different values of rigidity $1/\epsilon$. Figure 7.1 is a representation of the evolution of temperature in these experiments.

On the other hand, the displacements of the rod are strongly dependent on ζ. When $\zeta = 10$, the deformations are slow in time, and it takes longer for the rod to reach the steady-state configuration (see Figure 7.2). These results support the usual assumption (see Boley and Weiner [3]) that, for small a, the temperature does not depend on the displacement. (Usually the term au_{xt} is then dropped from (1.1).) Note that the final states shown are in agreement with the steady-state solutions as described by Copetti [5].

To examine the error estimates numerically, we performed two experiments with a known solution

$$\theta(x,t) = \exp(t)\cos\left(\frac{3\pi x}{4} + \frac{\pi}{2}\right),$$

$$u(x,t) = \begin{cases} \frac{g \sin x \exp(t)}{\sin 1 \exp(\sqrt{2})}, & 0 < t \leq \sqrt{2}, \\ \frac{g \sin x}{\sin 1}, & \sqrt{2} < t \leq 2, \end{cases}$$

$$\sigma(x,t) = \begin{cases} 0, & 0 < t \leq \sqrt{2}, \\ -t, & \sqrt{2} < t \leq 2, \end{cases}$$

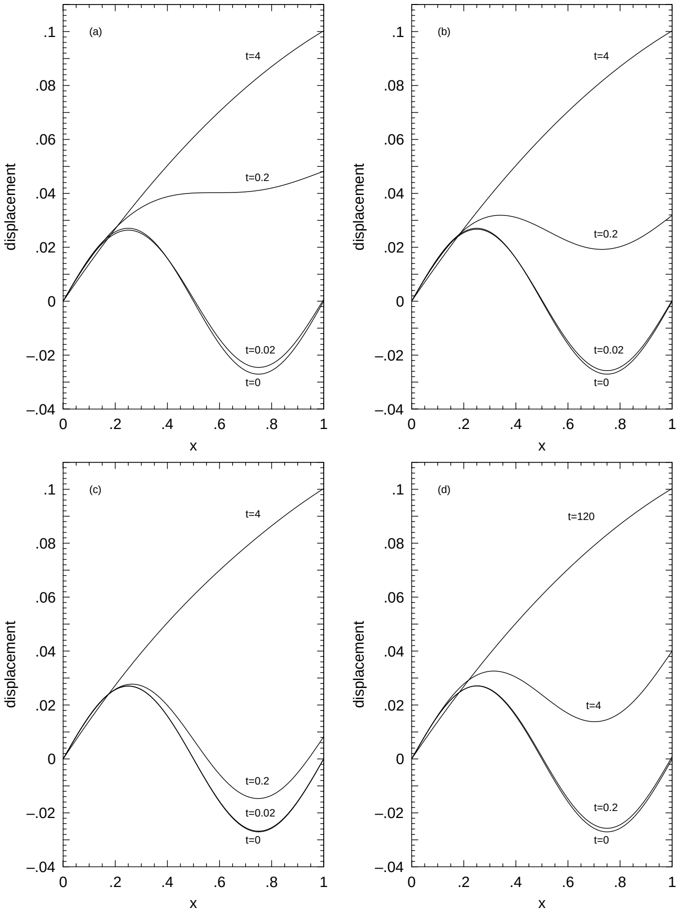

FIG. 7.2. *The evolution in time of the displacement for* (a) $\zeta = 0.1$, (b) $\zeta = 0.2$, (c) $\zeta = 1$, (d) $\zeta = 10$.

satisfying

$$\theta_t - \theta_{xx} = -au_{xt} + f(x,t),$$

$$\sigma_x = 0,$$

where $\sigma = u_x + \zeta u_{xt} - a\theta + g(x,t)$ and θ_0, u_0, f, g, and k are calculated from the exact solution. We let $\theta_A = 0$, $\zeta = 1$, $a = 0.017$, and $g = 0.1$, and Θ^0 was the interpolant of θ_0. In Table 7.1, we report the results of several runs with different values of h, $\epsilon \approx h^{4/5}$, and $\Delta t \approx h^{6/5}$. The computed errors when $\epsilon \approx h^{8/5}$ and $\Delta t \approx h^{12/5}$ are shown in Table 7.2. In both experiments, we observed convergence rates larger than those given by Theorem 6.1 and Corollary 6.2. This is not surprising since we have introduced the penalized problem, and, therefore, our a priori error analysis is probably pessimistic. Moreover, reviewing the proof of Theorem 6.1, we see that the factors $h^2/\Delta t$ and $h^4/\Delta t$ come from the coupling of the equations. If we assume, as suggested in the physical literature, that the temperature does not depend on the displacement, these factors disappear. In addition, for this particular example, the term $\|\Theta^0 - \theta_0\|^2$ converges at the rate h^4. A better-than-predicted rate of convergence

1/160	2.48×10^{-3}	2	1.20×10^{-7}	3.17
1/320	6.22×10^{-4}	2	1.33×10^{-8}	3.17

was also seen in the simulations run by Copetti and Elliott [6]. Note that, in the last experiment, a small time step was used, and for that situation an explicit-in-time scheme might be competitive. We performed the experiment again using the forward Euler approximation, and we obtained virtually the same results as in Table 7.2.

In our computations, the trapezoidal rule was used to evaluate spatial integrals, and the iterative process (5.3)–(5.4) was stopped when $\Vert\underline{c}^{n,l} - \underline{c}^{n,l-1}\Vert_\infty \leq 1 \times 10^{-7}$ and $\Vert\underline{d}^{n,l} - \underline{d}^{n,l-1}\Vert_\infty \leq 1 \times 10^{-7}$.

Acknowledgment. The authors wish to thank the referees for their valuable comments which improved the manuscript.

DISCRETE VECTOR POTENTIALS FOR NONSIMPLY CONNECTED THREE-DIMENSIONAL DOMAINS*

FRANCESCA RAPETTI†, FRANÇOIS DUBOIS‡, AND ALAIN BOSSAVIT§

Abstract. In this paper, we focus on the representation of a divergence-free vector field, defined, on a connected nonsimply connected domain $\Omega \subset \mathbb{R}^3$ with a connected boundary Γ, by its curl and its normal component on the boundary. The considered problem is discretized with $H(\mathbf{curl})$- and $H(\mathrm{div})$-conforming finite elements. In order to ensure the uniqueness of the vector potential, we propose a spanning tree methodology to identify the independent edges. The topological features of the domain under consideration are analyzed here by means of the homology groups of first and second order.

Key words. divergence-free vector fields, nonsimply connected domains, edge elements, discrete gauge condition, homology groups

AMS subject classification. 65N30

DOI. 10.1137/S0036142902412646

1. Introduction.

In numerical magnetostatics, an important task is the discretization of the magnetic induction field $\mathbf{u}$, verifying the following equations:

$$\mathbf{curl}\,\mathbf{u} = \omega \quad \text{in } \Omega, \tag{1}$$

$$\mathrm{div}\,\mathbf{u} = 0 \quad \text{in } \Omega, \tag{2}$$

$$\mathbf{u} \cdot \mathbf{n}_\Gamma = g \quad \text{on } \Gamma, \tag{3}$$

where Ω is an open subset of $\mathbb{R}^3$, Γ is its boundary, $\mathbf{n}_\Gamma$ is the outward going normal to Γ, ω is a given current density, and g is a scalar function defined on Γ. A conforming or nonconforming discretization that respects (2) is difficult to obtain with the finite element method [19]. On the other hand, a way to exactly satisfy (2) is to represent $\mathbf{u}$ in terms of a vector potential, i.e., a field $\mathbf{p}$ such that

$$\mathbf{u} = \mathbf{curl}\,\mathbf{p}. \tag{4}$$

The vector $\mathbf{p}$ is not unique but defined up to the gradient of a scalar function. A classical way to ensure the uniqueness of $\mathbf{p}$ is to prescribe a gauge condition such as the Coulomb gauge

$$\mathrm{div}\,\mathbf{p} = 0 \tag{5}$$

and suitable boundary conditions. Moreover, different choices of boundary conditions for the vector field $\mathbf{p}$ are possible, and we refer to [3, 4] for existence and uniqueness results. The vector potential is just a tool for representing the field $\mathbf{u}$ and must be

easily computable under some constraints on $\mathbf{u}$. In this paper, we choose to fix the current density ω and the magnetic induction flux g across the entire boundary. We remark that, if (2) and (3) are satisfied, then the mean value of the function g across the boundary of Ω is necessarily equal to zero; i.e., $\int_\Gamma g \, d\Gamma = 0$. The chosen problem can be also read in the framework of fluid dynamics: for a given vorticity ω in Ω and mass inflow g across the boundary Γ of Ω, we look for a velocity field $\mathbf{u}$ that satisfies (1) and (3) in the incompressible case, i.e., under the constraint (2).

We restrict ourselves to the previous problem in a nonsimply connected three-dimensional domain with a connected boundary. For the analysis of the mixed formulation of a similar problem in simply connected domains with a nonconnected boundary, see [10].

Concerning the outline of the paper, in section 2, after recalling classical results on vector fields, we split the linear problem in Ω into a homogeneous problem in Ω (i.e., $g = 0$) and a problem on the boundary of Ω (i.e., $g \neq 0$). Then a concrete construction method of a vector potential $\mathbf{p}$ from only the data ω and g is presented. In the discretized problem, the compatibility between these two subproblems requires that the discrete field $\mathbf{p}_m$ associated with a mesh m in Ω has a tangential component on each point of the boundary. The major difficulty is the definition of a "good" discrete space which guarantees the existence of the discrete potential. We start with a short introduction on the homology groups in sections 3 and 4. Then in sections 5 and 6, we adapt the discrete gauge initially proposed by a team of the École Polytechnique [10, 28] to the case of simply connected domains $\Omega \subset \mathbb{R}^3$. Developing the problem presented in [11] in more detail, we generalize in section 7 to the case of proposed nonsimply connected domains. We finally end in section 8 by a short overview on the adopted algorithms and their application in the case where Ω is a torus.

Let us introduce some notation. We consider Ω as a connected bounded domain of $\mathbb{R}^3$, with a connected regular boundary Γ. The scalar product between two vectors $\mathbf{a}$, $\mathbf{b}$ defined in Ω is denoted by $\mathbf{a}\cdot\mathbf{b}$, whereas their vector product is denoted by $\mathbf{a}\times\mathbf{b}$. The tangential component of a vector $\mathbf{v}$ on Γ is $\pi\mathbf{u} = (\mathbf{n}_\Gamma \times \mathbf{u}) \times \mathbf{n}_\Gamma$, and we have a Green formula for regular vector fields $\mathbf{u}$ and $\mathbf{v}$ that reads

$$(6) \qquad \int_\Omega \mathbf{v}\cdot\mathbf{curl}\,\mathbf{u} = \int_\Omega \mathbf{curl}\,\mathbf{v}\cdot\mathbf{u} + \int_\Gamma (\mathbf{n}_\Gamma \times \mathbf{v})\cdot\mathbf{u}.$$

The following operators are defined on Γ as in [9] as follows:

- the surface gradient, $\mathrm{grad}_\Gamma u$, and surface **curl**, $\mathbf{curl}_\Gamma u$, of a scalar function u defined on Γ: $\mathbf{curl}_\Gamma u = \mathrm{grad}_\Gamma u \times \mathbf{n}_\Gamma$;
- the surface curl, $\mathrm{curl}_\Gamma \mathbf{v}$, and surface divergence, $\mathrm{div}_\Gamma \mathbf{v}$, of a tangential vector function $\mathbf{v}$ defined on Γ: $\mathrm{div}_\Gamma \mathbf{v} = \mathrm{curl}_\Gamma(\mathbf{n}_\Gamma \times \mathbf{v})$.

By duality, these operators are also defined for a scalar t or vector $\mathbf{w}$ distributions on Γ as follows:

$$\begin{aligned}
\langle \mathrm{grad}_\Gamma t, \mathbf{v}\rangle_\Gamma &= -\langle t, \mathrm{div}_\Gamma \mathbf{v}\rangle_\Gamma \quad \forall\, \mathbf{v},\\
\langle \mathrm{curl}_\Gamma t, \mathbf{v}\rangle_\Gamma &= \langle t, \mathrm{curl}_\Gamma \mathbf{v}\rangle_\Gamma \quad \forall\, \mathbf{v},\\
\langle \mathrm{curl}_\Gamma \mathbf{w}, u\rangle_\Gamma &= \langle \mathbf{w}, \mathbf{curl}_\Gamma u\rangle_\Gamma \quad \forall\, u,\\
\langle \mathrm{div}_\Gamma \mathbf{w}, u\rangle_\Gamma &= \langle \mathbf{w}, \mathrm{grad}_\Gamma u\rangle_\Gamma \quad \forall\, u.
\end{aligned}$$

Here, the duality product $\langle\cdot,\cdot\rangle_\Gamma$ of two vectors is the scalar product on Γ [9]:

$$\langle \mathbf{w}, \mathbf{v}\rangle_\Gamma = \int_\Gamma \mathbf{w}\cdot\mathbf{v}.$$

The Sobolev spaces $L^2(\Omega)$, $H^1(\Omega)$ are Hilbert spaces with their natural norms $||.||_{0,\Omega}$ and $||.||_{1,\Omega}$, respectively [1]. Following [15], we define

$$H(\mathrm{div},\Omega) = \{\mathbf{u} \in L^2(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{u} \in L^2(\Omega)\},$$
$$H(\mathbf{curl},\Omega) = \{\mathbf{u} \in L^2(\Omega)^3 \,|\, \mathbf{curl}\,\mathbf{u} \in L^2(\Omega)^3\},$$

and associated norms $||.||_{\mathrm{div},\Omega}$ and $||.||_{\mathbf{curl},\Omega}$. We also need to introduce

$$\begin{aligned}
&H(\mathrm{div}_0,\Omega) = \{\mathbf{u} \in H(\mathrm{div},\Omega) \,|\, \mathrm{div}\,\mathbf{u} = 0\},\\
&H_0(\mathrm{div},\Omega) = \{\mathbf{u} \in H(\mathrm{div},\Omega) \,|\, \mathbf{u}\cdot\mathbf{n}_\Gamma = 0\},\\
&H_0(\mathbf{curl},\Omega) = \{\mathbf{u} \in H(\mathbf{curl},\Omega) \,|\, \mathbf{u}\times\mathbf{n}_\Gamma = \mathbf{0}\},\\
&L^2_0(\Omega) = \{u \in L^2(\Omega) \,|\, \textstyle\int_\Omega u = 0\},\\
&\mathcal{C}^{1,1}(\overline{\Omega}) = \{u \in \mathcal{C}^1(\overline{\Omega}) \,|\, \mathbf{grad}\,u \text{ is a vector of Lipschitz functions}\}.
\end{aligned}$$

In a few words, a domain Ω is of class $\mathcal{C}^{1,1}$ if it admits a representation through a $\mathcal{C}^{1,1}(\overline{\Omega})$ map [15]. Note that the boundary of such a domain has a normal vector almost everywhere. In the following, given a space S, the notation $\dim[S]$ denotes the dimension of S. If S is a set, its cardinality, i.e., the number of its elements, is denoted by $\#S$.

2. The continuous problem.

We are interested in the following problem: *given* $g \in L^2_0(\Gamma)$ *and* $\omega \in H(\mathrm{div}_0,\Omega)$, *find* $\mathbf{u} \in H^1(\Omega)^3$ *satisfying*

$$\begin{aligned}
\mathbf{curl}\,\mathbf{u} &= \omega && \text{in } \Omega,\\
\mathrm{div}\,\mathbf{u} &= 0 && \text{in } \Omega,\\
\mathbf{u}\cdot\mathbf{n}_\Gamma &= g && \text{on } \Gamma.
\end{aligned} \tag{7}$$

If Γ is smooth, the continuous problem can be easily analyzed, but the finite elements to discretize it are quite complicated [19, 10]. If Γ is polyhedric, then there are specific difficulties in studying the continuous problem [2, 7], but the finite elements are classical. We recall the main results of regularity for the solution of (7); these results depend on the regularity of the domain Ω. The first result is proven in [2, 15].

PROPOSITION 2.1. *Assume that the bounded domain Ω is of class $\mathcal{C}^{1,1}$ or a convex polyhedron. Then we have the following continuous embedding:*

$$\{\mathbf{v} \in L^2(\Omega)^3 \,|\, \mathbf{curl}\,\mathbf{v} \in L^2(\Omega)^3,\ \mathrm{div}\,\mathbf{v} \in L^2(\Omega),\ \mathbf{v}\cdot\mathbf{n}_\Gamma \in H^{1/2}(\Gamma)\,\} \hookrightarrow H^1(\Omega)^3;$$

as a consequence, problem (7) *has a unique solution, in the sense of distributions, that belongs to* $H^1(\Omega)^3$.

The solution $\mathbf{u}$ of problem (7) is computed as a sum of two functions that are solutions of two simpler problems, i.e., $\mathbf{u} = \mathbf{u}_0 + \hat{\mathbf{u}}$, where $\hat{\mathbf{u}}$ is a divergence-free lifting in $\overline{\Omega}$ of a function $\hat{\mathbf{u}}_\Gamma$ defined on Γ such that

$$\hat{\mathbf{u}}_\Gamma\cdot\mathbf{n}_\Gamma = g, \qquad \mathrm{div}_\Gamma\hat{\mathbf{u}}_\Gamma = 0, \tag{8}$$

and $\mathbf{u}_0$ satisfies

$$\begin{aligned}
\mathbf{curl}\,\mathbf{u}_0 &= \omega - \mathbf{curl}\,\hat{\mathbf{u}} && \text{in } \Omega,\\
\mathrm{div}\,\mathbf{u}_0 &= 0 && \text{in } \Omega,\\
\mathbf{u}_0\cdot\mathbf{n}_\Gamma &= 0 && \text{on } \Gamma\,.
\end{aligned} \tag{9}$$

Note that, thanks to the introduction of a vector potential, (2) is exactly verified, whereas (1) is satisfied in the sense of distributions. Thanks to a trace result proved in [5], problem (7) is well-posed even in nonconvex polyhedra of $\mathbb{R}^3$ (such as a discretized torus).

Proposition 2.2. *Let Γ_i, $i = 1, \dots, L$, be the faces of the boundary Γ of a bounded polyhedron Ω. There exists a real number $s > 1/2$ such that for any function $g \in H^{1/2}(\partial\Gamma_i)$, $i = 1, \dots, L$, problem* (8) *has a unique solution $\hat{\mathbf{u}} \in H^s(\Omega)^3$. In addition, for any $\omega \in H(\mathrm{div}_0, \Omega)$, problem* (9) *has a unique solution $\mathbf{u}_0 \in H^s(\Omega)^3$.*

We end this section by recalling and applying general results on vector fields defined on a regular bounded domain Ω of $\mathbb{R}^3$. We refer to [2, 3] and to their included references for the results. Let us introduce the following spaces:

$$X_T(\Omega) = \{\mathbf{v} \in L^2(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{v} \in L^2(\Omega),\ \mathbf{curl}\,\mathbf{v} \in L^2(\Omega)^3,\ \mathbf{v}\cdot\mathbf{n}_\Gamma \in H^{1/2}(\Gamma)\},$$

$$X_N(\Omega) = \{\mathbf{v} \in L^2(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{v} \in L^2(\Omega),\ \mathbf{curl}\,\mathbf{v} \in L^2(\Omega)^3,\ \mathbf{v}\times\mathbf{n}_\Gamma \in H^{1/2}(\Gamma)^3\},$$

$$H_T(\Omega) = \{\mathbf{v} \in L^2(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{v} = 0,\ \mathbf{curl}\,\mathbf{v} = \mathbf{0},\ \mathbf{v}\cdot\mathbf{n}_\Gamma = 0 \text{ on } \Gamma\},$$

$$H_N(\Omega) = \{\mathbf{v} \in L^2(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{v} = 0,\ \mathbf{curl}\,\mathbf{v} = \mathbf{0},\ \mathbf{v}\times\mathbf{n}_\Gamma = \mathbf{0} \text{ on } \Gamma\},$$

$$P_T : X_T(\Omega) \to H_T(\Omega) \text{ orthogonal projection operator},$$

$$P_N : X_N(\Omega) \to H_N(\Omega) \text{ orthogonal projection operator},$$

$$W^1(\Omega) = \{\mathbf{w} \in H^1(\Omega)^3 \,|\, \mathrm{div}\,\mathbf{w} = 0,\ \mathbf{w}\times\mathbf{n}_\Gamma = \mathbf{0},\ \textstyle\int_\Gamma \mathbf{w}\cdot\mathbf{n}_\Gamma \, d\Gamma = 0\}.$$

Theorem 2.3 (Hodge decomposition). *For a given $\mathbf{u} \in L^2(\Omega)^3$, we have two possible decompositions:*

$$\text{(i)} \qquad \mathbf{u} = \mathbf{grad}\,\phi + \mathbf{curl}\,\mathbf{w} + \theta$$

with $\theta \in H_T(\Omega)$ and a unique $(\phi, \mathbf{w})$ verifying $\phi \in H^1(\Omega) \cap L^2_0(\Omega)$, $\mathbf{w} \in W^1(\Omega)$;

$$\text{(ii)} \qquad \mathbf{u} = \mathbf{grad}\,\psi + \mathbf{curl}\,\mathbf{p} + \eta$$

with $\eta \in H_N(\Omega)$ and a unique $(\psi, \mathbf{p})$ verifying $\psi \in H^1_0(\Omega)$ and

$$\mathbf{p} \in H^1(\Omega)^3,\ \mathrm{div}\,\mathbf{p} = 0,\ \mathbf{p}\cdot\mathbf{n}_\Gamma = 0,\ P_T\mathbf{p} = \mathbf{0}.$$

The decomposition (i) (resp., (ii)) of a field $\mathbf{u}$ is into three orthogonal components of the type $\mathbf{grad}\,\phi$ (resp., $\mathbf{grad}\,\psi$) plus $\mathbf{curl}\,\mathbf{w}$ (resp., $\mathbf{curl}\,\mathbf{p}$) plus a vector lying in $H_T(\Omega)$ (resp., $H_N(\Omega)$).

Theorem 2.4 (Foias, Temam [12]). *Let $\mathbf{u} \in L^2(\Omega)^3$ and $\mathbf{p} \in H(\mathbf{curl}, \Omega)$ such that $\mathbf{u} = \mathbf{curl}\,\mathbf{p}$; then $P_N\mathbf{u} = \mathbf{0}$.*

If a vector $\mathbf{u}$ admits a representation in terms of a vector potential $\mathbf{p}$, i.e., $\mathbf{u} = \mathbf{curl}\,\mathbf{p}$, it clearly satisfies the condition $\mathrm{div}\,\mathbf{u} = 0$. Moreover, for any vector $\mathbf{u}$ of the form (ii), Theorem 2.4 yields $P_N\mathbf{u} = \mathbf{0}$, a condition which precludes flow problems with sources and sinks, as remarked in [10]. Finally, since the scalar $\psi \in H^1_0(\Omega)$, we have $\psi = 0$. The vector potential $\mathbf{p}$ is then the right tool to represent the field $\mathbf{u}$ solution of the considered problem.

In the next section, we recall the main properties of the finite elements we are going to use to discretize $\mathbf{p}$. These finite elements are $H(\mathbf{curl}, \Omega)$-conforming, and by consequence, the field $\mathbf{u}$ will be approximated by $H(\mathrm{div}, \Omega)$-conforming finite elements. Throughout the paper, we treat the three-dimensional case.

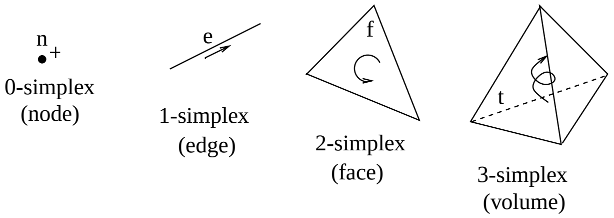

FIG. 1. *Example of oriented p-simplex, $p = 0, \ldots, 3$.*

3. Meshing the domain with cellular complexes. Given a domain $\Omega \subset \mathbb{R}^3$ with boundary Γ, a simplicial mesh m in Ω is a tessellation of $\overline{\Omega}$ by tetrahedra, under the condition that any two of them may intersect along a common face, edge, or node but in no other way. We denote by $\mathcal{N}_m$, $\mathcal{E}_m$, $\mathcal{F}_m$, and $\mathcal{T}_m$ (nodes, edges, faces, and tetrahedra, respectively) the sets of simplices of dimension 0 to 3 thus obtained, and by N_m, E_m, F_m, and T_m their cardinalities. The importance of simplicial meshes lies in the fact that any triangulated domain is homeomorphic to one in which the triangles are flat and the edges straight. Properties on the mesh will hold for the domain, as we are going to present in the following.

First we need to underline some combinatorial properties of the simplicial mesh. Let $\mathcal{M}(r, s)$ denote the set of matrices A whose elements are $A(i, j)$ with $1 \leq i \leq r$ and $1 \leq j \leq s$. In addition to the list of nodes and their positions, the mesh data structure also contains incidence matrices, saying which node belongs to which edge, which edge bounds which face, etc. [6, 14]. There is a notion of orientation for the simplex as in Figure 1 that has to be taken into account to define the incidence matrices. In short, an edge is not only a two-node subset of $\mathcal{N}_m$ but an ordered such set, where the order implies an orientation. Let $e = \{\ell, n\}$ be an edge of the mesh oriented from the node ℓ to n. We can define the incidence numbers $G_{e,n} = 1$, $G_{e,\ell} = -1$, and $G_{e,k} = 0$ for all nodes k other than ℓ and n. These numbers form a rectangular matrix $G \in \mathcal{M}(E_m, N_m)$, which describes how edges connect to nodes. A face $f = \{\ell, n, k\}$ has three vertices which are the nodes ℓ, n, k. Note that $\{n, k, l\}$ and $\{k, l, n\}$ denote the same face f, whereas $\{n, l, k\}$ denotes an oppositely oriented face, which is not supposed to belong to $\mathcal{F}_m$ if f does. An orientation of f induces an orientation of its boundary. So, with respect to the orientation of the face f, the one of the edge $\{l, n\}$ is positive, and the one of $\{k, n\}$ is negative. Then we can define the incidence number $R_{f,e} = 1$ (resp., -1) if the orientation of e matches (resp., does not match) the one on the boundary of f, and $R_{f,e} = 0$ if e is not an edge of f. These numbers form a matrix $R \in \mathcal{M}(F_m, E_m)$. Finally, let us consider the tetrahedron $t = \{k, l, m, n\}$ positively oriented if the three vectors $\{k, l\}$, $\{k, m\}$, and $\{k, n\}$ define a positive frame. ($t' = \{l, m, n, k\}$ has a negative orientation and does not belong to $\mathcal{T}_m$ if t does.) A third matrix $D \in \mathcal{M}(T_m, F_m)$ can be defined by setting $D_{t,f} = \pm 1$ if face f bounds the tetrahedron t, with the sign depending on whether the orientation of f and of the boundary of t match or not, and $D_{t,f} = 0$ in case f does not bound t. For consistency, we attribute an orientation to nodes as well. Implicitly, we have been orienting all nodes the same way (+1) up to now. Note that a sign (-1) to node n changes the sign of all entries of column n in the above G. It can be easily proven that $RG = 0$ and $DR = 0$ [6].

We now define the mixed finite elements we use [6, 23, 24, 26]: they are scalar functions or vector fields associated to all the simplices of the mesh m. We start by denoting φ_n the only continuous, piecewise affine function, which is equal to 1 at n and to 0 at other nodes. We set $W^0_m = \text{span}\,\{\varphi_n \,|\, n \in \mathcal{N}_m\}$. The degree (zero in this case) of the elements of W^0_m refers to the dimension of the simplices they are associated with (i.e., nodes) and not to the degree of φ_n as a polynomial. To the edge e, let us associate the vector field $\mathbf{w}_e$ of the form $\mathbf{a}\times\mathbf{x}+\mathbf{b}$ in each tetrahedron $t \in \mathcal{T}_m$; the two vectors $\mathbf{a}$ and $\mathbf{b}$ are determined by imposing that the circulation of $\mathbf{w}_e$ along $e \in t$ is 1 and 0 along the other edges of t. We denote $W^1_m = \text{span}\,\{\mathbf{w}_e \,|\, e \in \mathcal{E}_m\}$. Similarly, $W^2_m = \text{span}\,\{\mathbf{v}_f \,|\, f \in \mathcal{F}_m\}$ with $\mathbf{v}_f$ the vector of the form $a\,\mathbf{x}+\mathbf{b}$ in each tetrahedron $t \in \mathcal{T}_m$; the scalar a and the vector $\mathbf{b}$ are determined by imposing that the flux of $\mathbf{v}_f$ across the face $f \in t$ is 1 and 0 across the other faces of t. Finally, we introduce $W^3_m = \text{span}\,\{\mu_t \,|\, t \in \mathcal{T}_m\}$, where μ_t is the only scalar whose integral over t is 1 and 0 over the other tetrahedra.[1]

Note that, given two adjacent tetrahedra t and t' sharing a face f, the function φ_n and both the tangential component of $\mathbf{w}_e$ and the normal component of $\mathbf{v}_f$ are continuous across f, whereas the function μ_t is not. Thanks to these continuity properties, $W^0_m \subset H^1(\Omega)$, $W^1_m \subset H(\mathbf{curl},\Omega)$, $W^2_m \subset H(\text{div},\Omega)$, and $W^3_m \subset L^2(\Omega)$. The spaces W^p_m, $p = 0,1,2,3$, have finite dimension given by N_m, E_m, F_m, T_m, respectively, and they play the role of Galerkin approximation spaces for the latter functional spaces.

The properties introduced so far concern the spaces W^p_m taken one by one. There are properties of the structure made of the spaces W^p_m when taken together. We know that the following inclusions hold:

$$\mathbf{grad}\, W^0_m \subset W^1_m, \qquad \mathbf{curl}\, W^1_m \subset W^2_m, \qquad \text{div}\, W^2_m \subset W^3_m.$$

It is natural to ask when the sequence

$$\{0\} \longrightarrow W^0_m \xrightarrow{\mathbf{grad}} W^1_m \xrightarrow{\mathbf{curl}} W^2_m \xrightarrow{\text{div}} W^3_m \longrightarrow \{0\}$$

is exact at levels 1 and 2, i.e., when it happens that

$$\ker(\mathbf{curl}; W^1_m) = \mathbf{grad}\, W^0_m, \qquad \ker(\text{div}; W^2_m) = \mathbf{curl}\, W^1_m,$$

where

$$\ker(\mathbf{curl}; W^1_m) := W^1_m \cap \ker(\mathbf{curl}), \qquad \ker(\text{div}; W^2_m) := W^2_m \cap \ker(\text{div}).$$

At levels 0 and 3, we lose the property of exactitude for the previous sequence because, at level 0, the gradient operator is not injective, and, at level 3, the divergence operator is not surjective. The Poincaré lemma states that, when the domain Ω is contractible [14], the image fills the kernel in both cases. This is not the case with Ω nonsimply connected; for example, we have in fact that $\mathbf{grad}\,(W^0_m)$ is a proper subset of $\ker(\mathbf{curl}; W^1_m)$. This tells us something about the topology of Ω; namely, the

[1] Given the nodes n, l, m, k, the edge $e = \{l, m\}$, the face $f = \{l, m, k\}$, and the tetrahedron $t = \{i, j, k, l\}$, the generators of the spaces W^p_m, $p = 0,1,2,3$, respectively, can also be defined as follows (λ_n is the barycentric coordinate associated to n):

$$\begin{aligned}
\varphi_n &= \lambda_n, \qquad \mathbf{w}_e = \lambda_l\,\mathbf{grad}\,\lambda_m - \lambda_m \mathbf{grad}\,\lambda_l,\\
\mathbf{v}_f &= 2\,(\lambda_l\,\mathbf{grad}\,\lambda_m \times \mathbf{grad}\,\lambda_k + \lambda_m\,\mathbf{grad}\,\lambda_k \times \mathbf{grad}\,\lambda_l + \lambda_k\,\mathbf{grad}\,\lambda_l \times \mathbf{grad}\,\lambda_m),\\
\mu_t &= 6\,(\lambda_i\,\mathbf{grad}\,\lambda_j \times \mathbf{grad}\,\lambda_k \cdot \mathbf{grad}\,\lambda_l + \lambda_j\,\mathbf{grad}\,\lambda_k \times \mathbf{grad}\,\lambda_l \cdot \mathbf{grad}\,\lambda_i\\
&\qquad + \lambda_k\,\mathbf{grad}\,\lambda_l \times \mathbf{grad}\,\lambda_i \cdot \mathbf{grad}\,\lambda_j + \lambda_l\,\mathbf{grad}\,\lambda_i \times \mathbf{grad}\,\lambda_j \cdot \mathbf{grad}\,\lambda_k) = [\text{vol}(t)]^{-1}.
\end{aligned}$$

presence of b_1 "loops," where $b_1 = \dim[\ker(\mathbf{curl}; W_m^1)/\mathbf{grad}\,(W_m^0)]$ is the Betti number of dimension 1 of the domain. Solenoidal fields which are not curls indicate the presence of b_2 "holes," where $b_2 = \dim[\ker(\mathrm{div}; W_m^2)/\mathbf{curl}\,(W_m^1)]$ is the Betti number of dimension 2 of the domain. These are global topological properties of the meshed domain; they do not depend on the mesh that is used to compute them, but they are intrinsic to the considered domain Ω. The sequences are thus an algebraic tool by which the topology of Ω can be explored (and this was Whitney's concern [31]).

The connection between the vector field picture and the cohomological picture in the electromagnetic context has also been considered more recently in [22, 30].

4. Chains, boundary homomorphism, and homology groups. Let m be the simplicial mesh on $\Omega \subset \mathbb{R}^3$. A p-chain c is an assignement to each simplex of dimension p in m of a number α, and we denote by $C_p(m)$ the set of all p-chains. The set $C_p(m)$ has a structure of an abelian group with respect to the addition of p-chains; two p-chains are added by adding the corresponding coefficients.

To give an example, let us consider a path of edges of the mesh m to go from a point n_1 to a point n_2; it is an oriented line. Assigning an integer α_e equal to $+1$ or -1 when the edge e belongs to the path and its orientation is in agreement or in disagreement with that of the path and 0 for all edges e that do not belong to the path, we define a 1-chain. A circuit is a line plus a way to run along it; so, when the line is made of oriented edges, we need to tell the positive direction along each edge, which is precisely what the chain coefficient α_e does. We remark that "chain" is a more general concept than "path," "circuit," etc. In our case, we assume that all coefficients α_i are *relative integers.*

The next concept is the boundary operator $\partial_p : C_p(m) \to C_{p-1}(m)$, $p > 0$. By definition, we have

$$\partial_1(e) = \sum_{n \in \mathcal{N}_m} G_{e,n}\, n, \qquad \partial_2(f) = \sum_{e \in \mathcal{E}_m} R_{f,e}\, e, \qquad \partial_3(t) = \sum_{f \in \mathcal{F}_m} D_{t,f}\, f.$$

Note that ∂_p is represented by a matrix that is G^t, R^t, or D^t depending on the dimension $p > 0$. We remark, in particular, that $\partial_{p+1} \circ \partial_p = 0$, i.e. the boundary of a boundary is the zero chain.

We will say that a p-chain c is closed if $\partial_p c = 0$. Nontrivial closed p-chains are called p-cycles and constitute the subspace $Z_p(m) = \ker(\partial_p; C_p(m))$. A p-chain c is a boundary if there is a $(p+1)$-chain γ such that $c = \partial_{p+1}\gamma$. The p-boundaries constitute the subspace $B_p(m) = \partial_{p+1} C_{p+1}(m)$. Both $Z_p(m)$ and $B_p(m)$ are abelian groups with respect to the addition of p-chains. Boundaries are cycles, but not all cycles are boundaries; we have in fact that $B_p(m) \subset Z_p(m)$.

The quotient space $H_p(m) = [Z_p(m)/B_p(m)]$ is the *homology group* of order p of the mesh m, and the Betti number b_p is equal to $\dim[H_p(m)]$. In particular, we have that $b_0 = \dim[\ker(\mathbf{grad}; W_m^0)]$ is the number of connected components of Ω, and $b_3 = \dim[\mathrm{div}(W_m^3)]$ is the number of connected components of Γ minus one.

Our concern is to determine the cycles that are not boundaries for $p = 1$ and 2, i.e., to computate the generators of $H_1(m)$ and $H_2(m)$. Triangulating a domain reduces the calculation of $H_p(m)$ to a finite procedure (in section 8, we present an algebraic algorithm to define a basis of $H_p(m)$, $p = 1$ and 2); the remarkable thing is that homology groups, in spite of being defined via triangulation, do measure something intrinsic and geometrical (they are topological invariants; i.e., they depend on the domain up to a homeomorphism) that does not depend on the mesh. The homology groups of a surface have a direct link with the possibility of representing curl-free (resp., divergence-free) vectors as gradients (resp., curls). This link is a determinant in the construction of numerical algorithms for solving given problems in terms of scalar or vector potentials, as we are going to see. A key tool in this construction is the Euler–Poincaré characteristic of Ω and its boundary Γ [14].

Remark 4.1. Given a connected domain Ω, the Euler–Poincaré characteristic of Ω is the integer

$$\chi(\Omega) = N_m - E_m + F_m - T_m, \tag{10}$$

where N_m, E_m, F_m, and T_m denote, respectively, the number of nodes, edges, faces, and tetrahedra of the mesh m discretizing $\overline{\Omega}$.

Remark 4.2. Given a connected orientable surface Γ, the Euler–Poincaré characteristic of Γ is the integer

$$\chi(\Gamma) = N_m^\Gamma - E_m^\Gamma + F_m^\Gamma, \tag{11}$$

where N_m^Γ, E_m^Γ, and F_m^Γ denote, respectively, the number of nodes, edges, and triangles of the mesh m^Γ discretizing $\overline{\Gamma}$.

The Euler–Poincaré characteristic is linked to the homology groups' dimension as follows:

$$\chi(\Gamma) = b_0^\Gamma - b_1^\Gamma + b_2^\Gamma, \qquad \chi(\Omega) = b_0 - b_1 + b_2 - b_3,$$

where b_i^Γ, $i = 0, 1, 2$ (resp., b_i, $i = 0, 1, 2, 3$), are the Betti numbers of Γ (resp., Ω). The major point is that these numbers, and consequently the Euler–Poincaré characteristic, are topological invariants. For more details on the subject, see [29].

5. Some discrete spaces and tools. Let us consider a triangulation m of $\overline{\Omega}$, its restriction m^Γ to the boundary Γ of Ω. Let us define the following two functional spaces on Ω and their analogues on the boundary Γ:

$$\begin{aligned} W_{m,0}^2 &= \{\mathbf{v} \in W_m^2 \,|\, \mathbf{v} \cdot \mathbf{n}_\Gamma = 0 \text{ on } \Gamma\}, & W_{m^\Gamma}^2 &= \{\pi\mathbf{v} \,|\, \mathbf{v} \in W_m^2\}, \\ W_{m,0}^1 &= \{\mathbf{v} \in W_m^1 \,|\, \mathbf{v} \times \mathbf{n}_\Gamma = \mathbf{0} \text{ on } \Gamma\}, & W_{m^\Gamma}^1 &= \{\pi\mathbf{v} \,|\, \mathbf{v} \in W_m^1\}. \end{aligned}$$

Note that $W_{m^\Gamma}^1$ is the restriction to Γ of the space W_m^1 in the sense that its vectors are associated to the mesh edges belonging to m^Γ. Similarly, the space $W_{m^\Gamma}^2$, also known as the Raviart–Thomas element space, is the restriction to Γ of W_m^2. Its vectors $\mathbf{v}_e$ are tangential to Γ and, in each triangle $f \in m^\Gamma$, are determined by imposing that the flux of $\mathbf{v}_e$ across the edge $e \in f$ is 1 and 0 across the other edges of f. Vectors of the space $W_{m^\Gamma}^2$ are adapted to represent flux densities that are tangential to Γ.

We look for a discrete approximation $\mathbf{u}_m$ of $\mathbf{u}$ on the mesh m of the form

$$\mathbf{u}_m = \mathbf{curl}\, \mathbf{p}_m \tag{12}$$

with $\mathbf{u}_m$ (resp., $\mathbf{p}_m$) lying in W_m^2 (resp., W_m^1). The uniqueness of the potential $\mathbf{p}_m$ is automatically satisfied if we choose $\mathbf{p}_m \in W_m^1$ and we add a gauge condition. In the following, a linear space for the discrete potential $\mathbf{p}_m$ is proposed; we treat the gauge condition in an entirely algebraic way and obtain the so-called *axial gauge* [16].

To define the discrete space of the vector potential, we need some details on the graph defined in the set of vertices of m by the mesh edges. For a general reference on graph theory, we suggest [14].

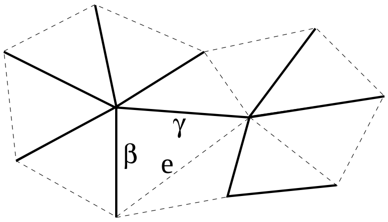

FIG. 2. *In the given mesh m, the thick dark edges compose the spanning tree $\mathcal{T}$, and the dashed ones compose the corresponding cotree $\mathcal{E}_m \setminus \mathcal{T}$. The coedge e closes a circuit together with the tree edges β and γ.*

A set $\mathcal{T}$ of edges of the mesh m such that $C_1(\mathcal{T})$ does not contain any cycle is called a tree. A tree is a spanning tree if there is no strictly larger tree containing it. The set of all left-over edges, i.e., $\mathcal{E}_m \setminus \mathcal{T}$, is called the associated cotree, and its elements are the coedges with respect to $\mathcal{T}$. Coedges thus furnish a basis for 1-cycles in the sense that, given a coedge e, there is a unique way to assign an integer α_ϵ to each edge ϵ of the tree in order to get a closed 1-chain: $\partial(e + \sum_{\epsilon \in \mathcal{T}} \alpha_\epsilon \, \epsilon) = 0$. In short, one says that each coedge $e \in \mathcal{E}_m \setminus \mathcal{T}$ "closes a circuit" C_e in conjunction with edges of the tree. (An example is given in Figure 2, where $C_e = \{e\} \cup \{\beta\} \cup \{\gamma\}$.)

Remark 5.1. For a given mesh m of the domain Ω, the number of edges contained in a spanning tree $\mathcal{T}$ can be expressed in terms of the Betti numbers of the domain by means of the following formula (with easy recursive proof):

$$\#\mathcal{T} = b_1 + (N_m - b_0). \tag{13}$$

For contractible domains, we have $\#\mathcal{T} = N_m - 1$. For noncontractible ones, the spanning tree is enriched with additional edges to take into account that there are 1-cycles that do not bound a surface ($b_1 \neq 0$). (The enriched spanning tree has been called a "belted spanning tree" in [6].)

Now, we explain how to use trees and cotrees to define the proper approximation space to solve the considered problem. In the following sections, $\mathcal{T}$ (resp., $\mathcal{T}^\Gamma$) always represents a spanning tree on Ω (resp., Γ).

6. Approximation of the problem in the simply connected case.

We are interested here in solving problem (7); the domain Ω and its boundary Γ are assumed to be connected and simply connected. We thus assume that Ω is a *sphere* (up to a homeomorphism). The nonsimply connected case is addressed in the next section.

6.1. Lifting the boundary condition for a sphere.

As in [10], given $\mathcal{T}^\Gamma$ and $g \in L^2_0(\Gamma)$, we construct a vector $\hat{\mathbf{u}}^\Gamma_m$ in $W^2_{m^\Gamma}$ such that $\operatorname{div}_\Gamma \hat{\mathbf{u}}^\Gamma_m = 0$, $\hat{\mathbf{u}}^\Gamma_m \cdot \mathbf{n}_\Gamma = g$ face by face on Γ, we show that $\hat{\mathbf{u}}^\Gamma_m$ is unique, and we define $\hat{\mathbf{u}} \in W^2_m$ as the divergence-free lifting of $\hat{\mathbf{u}}^\Gamma_m$ in Ω. Problem (8) is thus well-posed.

PROPOSITION 6.1. *Let us consider a triangulation m of $\overline{\Omega}$, its restriction m^Γ to the boundary Γ of Ω, and a spanning tree $\mathcal{T}^\Gamma$ in m^Γ. Let Γ be a* sphere *and $g \in L^2_0(\Gamma)$. There is a unique divergence-free vector $\hat{\mathbf{u}}^\Gamma_m \in W^2_{m^\Gamma}$ of the form*

$$\hat{\mathbf{u}}^\Gamma_m = \sum_{e \in \mathcal{E}^\Gamma_m \setminus \mathcal{T}^\Gamma} \hat{u}_e \, \mathbf{curl}\, \mathbf{w}_e, \qquad \mathbf{w}_e \in W^1_{m^\Gamma}, \tag{14}$$

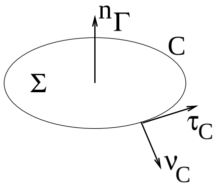

FIG. 3. *Due to the simple connectedness of* Γ*, any circuit* C *in* m^Γ *bounds a surface* $\Sigma \subset \Gamma$.

that satisfies

$$\int_f \hat{\mathbf{u}}_m^\Gamma \cdot \mathbf{n}_\Gamma = \int_f g \quad \forall f \in \mathcal{F}_m^\Gamma. \tag{15}$$

Proof. Let us introduce the two spaces $\ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ and

$$\mathcal{V}(\mathcal{T}^\Gamma) = \mathrm{span}\,\{\mathbf{w}_e \,|\, \mathbf{w}_e \in W^1_{m^\Gamma},\, e \in \mathcal{E}_m^\Gamma \setminus \mathcal{T}^\Gamma\}.$$

The **curl** operator is well defined as $\mathcal{V}(\mathcal{T}^\Gamma) \to \ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$.

The **curl** mapping $\mathcal{V}(\mathcal{T}^\Gamma) \to \ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ is injective. Let us consider the vector $\hat{\mathbf{p}}_m^\Gamma \in \mathcal{V}(\mathcal{T}^\Gamma)$ of the form

$$\hat{\mathbf{p}}_m^\Gamma = \sum_{e \in \mathcal{E}_m^\Gamma \setminus \mathcal{T}^\Gamma} \hat{u}_e \, \mathbf{w}_e.$$

Let $\alpha \in \mathcal{E}_m^\Gamma \setminus \mathcal{T}^\Gamma$ be a given coedge, and let $C \subset \{\alpha\} \cup \mathcal{T}^\Gamma$ be the associated cycle; then we have

$$\int_C \hat{\mathbf{p}}_m^\Gamma \cdot \tau_C = \hat{u}_\alpha \int_\alpha \mathbf{w}_\alpha \cdot \tau_C = \hat{u}_\alpha,$$

where τ_C is the tangential vector to C.

On the other hand, since Γ is simply connected, C is the boundary of a surface Σ contained in Γ. On Γ, the normal ν_C and tangential τ_C vectors to C are linked to $\mathbf{n}_\Gamma$ through the relation $\nu_C \times \tau_C = \mathbf{n}_\Gamma$ (see Figure 3). By definition, we have that

$$(\mathbf{curl}\, \hat{\mathbf{p}}_m^\Gamma) \cdot \mathbf{n}_\Gamma = \mathrm{curl}_\Gamma(\pi \hat{\mathbf{p}}_m^\Gamma) = \mathrm{div}_\Gamma(\hat{\mathbf{p}}_m^\Gamma \times \mathbf{n}_\Gamma).$$

The Stokes theorem and the previous tools yield

$$\hat{u}_\alpha = \int_C \hat{\mathbf{p}}_m^\Gamma \cdot \tau_C = \int_C (\hat{\mathbf{p}}_m^\Gamma \times \mathbf{n}_\Gamma) \cdot \nu_C = \int_\Sigma \mathrm{div}_\Gamma(\hat{\mathbf{p}}_m^\Gamma \times \mathbf{n}_\Gamma) = \int_\Sigma (\mathbf{curl}\, \hat{\mathbf{p}}_m^\Gamma) \cdot \mathbf{n}_\Gamma.$$

If $\mathbf{curl}\, \hat{\mathbf{p}}_m^\Gamma = \mathbf{0}$, then $\hat{u}_\alpha = 0$ for all $\alpha \in \mathcal{E}_m^\Gamma \setminus \mathcal{T}^\Gamma$, yielding $\hat{\mathbf{p}}_m^\Gamma = \mathbf{0}$.

Let W be the space composed of vectors in $\ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ verifying (15) with $g \in L_0^2(\Gamma)$. The linear spaces $\mathcal{V}(\mathcal{T}^\Gamma)$ and W have the same dimension. On one hand, we have $\dim[\mathcal{V}(\mathcal{T}^\Gamma)] = E_m^\Gamma - (N_m^\Gamma - 1)$ thanks to Remark 5.1, and on the other hand, $\dim[W] = F_m^\Gamma - 1$. Due to the fact that the Euler–Poincaré characteristic for a spherical surface is 2, Remark 4.2 yields

$$E_m^\Gamma - N_m^\Gamma + 1 = F_m^\Gamma - 1.$$

Given a spanning tree $\mathcal{T}^\Gamma$ and a scalar function $g \in L_0^2(\Gamma)$, there is a unique divergence-free vector of the form (14) and verifying (15). □

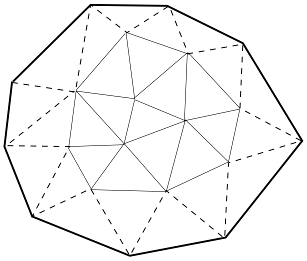

FIG. 4. *In this two-dimensional example, the thick dark edges constitute the set $\mathcal{E}_m^\Gamma$, the dashed edges define $\mathcal{E}_m^\ell$, and the light ones compose $\mathcal{E}_m^{\text{int}}$. Note that here $\mathcal{E}_m^B$ is empty but it is not always the case with more general three-dimensional meshes m.*

6.2. Interior problem for a sphere. At this point we can write

$$\mathbf{u}_m = \hat{\mathbf{u}}_m + \sum_{e \in ?} u_e \,\mathbf{curl}\, \mathbf{w}_e,$$

where $\hat{\mathbf{u}}_m$ is the solution of problem (8) in the sense given in Proposition 6.1 and the symbol "?" in the previous sum is there on purpose to indicate that we do not know yet to which set of internal coedges we have to extend the sum. We remark that

$$\mathcal{E}_m = \mathcal{E}_m^\Gamma \cup \mathcal{E}_m^{\text{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B,$$

where $\mathcal{E}_m^\ell$ is the set of mesh edges having only one extremity on Γ, $\mathcal{E}_m^{\text{int}}$ is the set of mesh edges having both extremities in Ω, and $\mathcal{E}_m^B$ is the set of mesh edges interior to Ω but with both extremities on Γ (see the example in Figure 4).

We denote $\mathcal{T}^{\text{int}}$ a spanning tree contained in $\mathcal{E}_m^{\text{int}}$ and $\mathcal{T}^\ell$ a subset of $\mathcal{E}_m^\ell$ composed of one edge since Γ is connected, linking $\mathcal{T}^{\text{int}}$ to $\mathcal{T}^\Gamma$ and

$$\mathcal{U}_m^0 = (\mathcal{E}_m^{\text{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B) \setminus (\mathcal{T}^{\text{int}} \cup \mathcal{T}^\ell).$$

In the next proposition, we prove that problem (9) is well-posed at the discrete level. In particular, given $\mathcal{T}^{\text{int}} \cup \mathcal{T}^\ell$ and a function $\omega \in \ker(\text{div}; W_m^2)$, we construct a divergence-free vector $\mathbf{u}_m^0 \in W_m^2$ such that $\mathbf{curl}\,\mathbf{u}_m^0 = \omega - \mathbf{curl}\,\hat{\mathbf{u}}_m$ in Ω and $\mathbf{u}_m^0 \cdot \mathbf{n}_\Gamma = 0$ face by face on Γ, and we show that $\mathbf{u}_m^0$ is unique.

PROPOSITION 6.2. *Let us consider a triangulation m of $\overline{\Omega}$ and a spanning tree $\mathcal{T}^{\text{int}} \cup \mathcal{T}^\ell$ in $m \setminus m^\Gamma$. Let us suppose that Ω is a* sphere *and $\omega \in \ker(\text{div}; W_m^2)$. There exists a unique divergence-free vector $\mathbf{u}_m^0 \in W_{m,0}^2$ of the form*

$$\mathbf{u}_m^0 = \sum_{e \in \mathcal{U}_m^0} u_e^0 \,\mathbf{curl}\, \mathbf{w}_e, \qquad \mathbf{w}_e \in W_m^1, \tag{16}$$

that satisfies

$$\mathbf{curl}\,\mathbf{u}_m^0 = \omega - \mathbf{curl}\,\hat{\mathbf{u}}_m \qquad \text{in } \Omega, \tag{17}$$

where $\hat{\mathbf{u}}_m$ is the divergence-free lifting in Ω of $\hat{\mathbf{u}}_m^\Gamma$ defined in Proposition 6.1.

Proof. Let us introduce the two spaces $\ker(\text{div}; W_{m,0}^2)$ and

$$\mathcal{V}(\mathcal{T}^{\text{int}}, \mathcal{T}^\ell) = \text{span}\,\{\mathbf{w}_e \,|\, \mathbf{w}_e \in W_m^1\,,\, e \in \mathcal{U}_m^0\}.$$

The **curl** operator is well defined as $\mathcal{V}(\mathcal{T}^{\text{int}}, \mathcal{T}^\ell) \to \ker(\text{div}; W_{m,0}^2)$.

The **curl** mapping $\mathcal{V}(\mathcal{T}^{\rm int},\mathcal{T}^\ell)\to\ker(\mathrm{div};W^2_{m,0})$ is injective. The proof given for Proposition 6.1 is the same with $\mathbf{p}^0_m\in\mathcal{V}(\mathcal{T}^{\rm int},\mathcal{T}^\ell)$ of the form

$$\mathbf{p}^0_m=\sum_{e\in\mathcal{U}^0_m}\hat{u}_e\,\mathbf{w}_e.$$

The linear spaces $\mathcal{V}(\mathcal{T}^{\rm int},\mathcal{T}^\ell)$ and $\ker(\mathrm{div};W^2_{m,0})$ have the same dimension. Because $\#\mathcal{T}^{\rm int}=(N_m-N^\Gamma_m-1)$, $\#\mathcal{T}^\ell=1$, on one hand we have

$$\dim\left[\mathcal{V}(\mathcal{T}^{\rm int}\,,\,\mathcal{T}^\ell)\right]=E_m-E^\Gamma_m-(N_m-N^\Gamma_m-1+1).$$

On the other hand, because $\dim\left[W^2_m\right]=F_m$ and $\dim\left[W^2_{m,0}\right]=F_m-F^\Gamma_m$, we get

$$\dim\left[\ker(\mathrm{div};W^2_{m,0})\right]=F_m-F^\Gamma_m-(T_m-1).$$

Note that we have T_m-1 independent relations since $\mathrm{div}\,\mathbf{v}=0$ and Ω is simply connected, as it is proved in Lemma 4.2 of [10]. By using the Euler–Poincaré characteristics and Remarks 4.1 and 4.2, we get

$$\begin{aligned}&E_m-E^\Gamma_m-(N_m-N^\Gamma_m)-(F_m-F^\Gamma_m-(T_m-1))\\&\quad=-(N_m-E_m+F_m-T_m)+(N^\Gamma_m-E^\Gamma_m+F^\Gamma_m)-1\\&\quad=-1+2-1=0.\end{aligned}$$

The present proof can also be carried out at an algebraic level. Proposition 6.2 states that, given $\mathcal{T}^{\rm int}\cup\mathcal{T}^\ell$, $\omega\in\ker(\mathrm{div};W^2_m)$, and $\hat{\mathbf{u}}_m$ the divergence-free lifting in Ω of $\hat{\mathbf{u}}^\Gamma_m$ defined in Proposition 6.1, there is a unique divergence-free vector $\mathbf{u}^0_m\in W^2_{m,0}$ of the form (16). Moreover, its coefficients u^0_e, $e\in\mathcal{U}^0_m$, on the chosen basis, are the components of the solution of the linear system

$$\sum_{e\in\mathcal{U}^0_m}u^0_e\int_\Omega\mathbf{curl}\,\mathbf{w}_e\cdot\mathbf{curl}\,\mathbf{w}_\gamma=\int_\Omega\omega\cdot\mathbf{w}_\gamma-\int_\Omega\hat{\mathbf{u}}_m\cdot\mathbf{w}_\gamma\qquad\forall\,\gamma\in\mathcal{U}^0_m.\tag{18}$$

The matrix

$$A=\left(\int_\Omega\mathbf{curl}\,\mathbf{w}_e\cdot\mathbf{curl}\,\mathbf{w}_\gamma\right)_{e,\gamma\in\mathcal{U}^0_m}$$

has full rank; it is in fact the mass matrix for the chosen basis $\{\mathbf{curl}\,\mathbf{w}_e\,|\,e\in\mathcal{U}^0_m\}$ (defined on the coedges) of the space $\ker(\mathrm{div};W^2_{m,0})$. Note that A is a symmetric and positive definite sparse matrix so that the linear system (18) can be solved iteratively by using a conjugate gradient method, as first done by Roux [28]. □

Remark 6.3. Note that $\mathcal{E}^{\rm int}_m$ and $\mathcal{E}^\ell_m$ can be empty. In this case, there is no interior spanning tree $(\mathcal{T}^{\rm int}\cup\mathcal{T}^\ell)$ and $\mathcal{U}^0_m=\mathcal{E}^B_m$. As $N_m=N^\Gamma_m$, Remarks 4.1 and 4.2 yield again

$$(\#\mathcal{U}^0_m=)\quad E_m-E^\Gamma_m=F_m-F^m_m-(T_m-1)\quad(=\dim\left[\ker(\mathrm{div};W^2_{m,0})\right]).$$

A similar remark can be done in the nonsimply connected case.

The function

$$\mathbf{u}_m=\hat{\mathbf{u}}_m+\sum_{e\in\mathcal{U}^0_m}u^0_e\,\mathbf{curl}\,\mathbf{w}_e\tag{19}$$

is then the approximated solution of problem (7). It is natural to ask whether the computed solution depends on the chosen spanning tree. The answer is no, as we state in the next subsection.

6.3. Independence on the spanning tree. We remark that the solution does not depend on the adopted spanning tree if $\omega \in \ker(\mathrm{div}; W_m^2)$. Let us consider two boundary and interior spanning trees as well as two sets of mesh edges:

$$\begin{array}{lll} \mathcal{T}_1^\Gamma, & \mathcal{T}_1 = \mathcal{T}_1^{\mathrm{int}} \cup \mathcal{T}_1^\ell, & \mathcal{U}_{m,1}^0 = (\mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B) \setminus \mathcal{T}_1, \\ \mathcal{T}_2^\Gamma, & \mathcal{T}_2 = \mathcal{T}_2^{\mathrm{int}} \cup \mathcal{T}_2^\ell, & \mathcal{U}_{m,2}^0 = (\mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B) \setminus \mathcal{T}_2. \end{array}$$

Let $\mathbf{u}_m^i$ be the solution associated with $\mathcal{E}_m^\Gamma \setminus \mathcal{T}_i^\Gamma$ on the boundary and with $\mathcal{U}_{m,i}^0$ at the interior ($i = 1, 2$). Let us denote $\mathbf{v}_m = \mathbf{u}_m^1 - \mathbf{u}_m^2$. We will prove that $\mathbf{v}_m = \mathbf{0}$.

On the boundary we consider $\mathbf{v}_m = \sum_{e \in \mathcal{E}_m^\Gamma} v_a \,\mathbf{curl}\,\mathbf{w}_e$; since $\mathbf{u}_m^1 \cdot \mathbf{n}_\Gamma = \mathbf{u}_m^2 \cdot \mathbf{n}_\Gamma = g$ on Γ, we have

$$\int_f \mathbf{v}_m \cdot \mathbf{n}_\Gamma = 0 \quad \forall f \in \mathcal{F}_m^\Gamma.$$

Thus $\mathbf{v}_m \cdot \mathbf{n}_\Gamma = 0$ on Γ, since the family $\{\mathbf{curl}\,\mathbf{w}_e \,|\, \mathbf{w}_e \in W_m^1,\ e \in \mathcal{E}_m^\Gamma \setminus \mathcal{T}_i^\Gamma\}$, $i = 1$ or 2, is a basis for the space span$\{\mathbf{curl}\,\mathbf{w}_e \,|\, \mathbf{w}_e \in W_m^1,\ e \in \mathcal{E}_m^\Gamma\}$.

In the interior, because $\omega \in \ker(\mathrm{div}; W_m^2)$, we can write that

$$\omega = \sum_{e \in \mathcal{E}_m} \omega_e \,\mathbf{curl}\,\mathbf{w}_e, \qquad \mathbf{w}_e \in W_m^1.$$

We have that, for all $\mathbf{w}_\gamma \in W_m^1$ with $\gamma \in \mathcal{U}_{m,1}^0$ or $\gamma \in \mathcal{U}_{m,2}^0$,

$$\int_\Omega \omega \cdot \mathbf{w}_\gamma = \sum_{e \in \mathcal{E}_m} \omega_e \int_\Omega \mathbf{w}_e \cdot \mathbf{curl}\,\mathbf{w}_\gamma.$$

The family $\{\mathbf{curl}\,\mathbf{w}_\gamma \,|\, \mathbf{w}_\gamma \in W_m^1,\ \gamma \in \mathcal{U}_{m,i}^0\}$, $i = 1$ or 2, is a basis for $\ker(\mathrm{div}; W_m^2)$, so we have that for all $\gamma \in \mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B$ and not only for all $\gamma \in \mathcal{U}_{m,i}^0$,

$$\int_\Omega \omega \cdot \mathbf{w}_\gamma = \sum_{e \in \mathcal{E}_m} \omega_e \int_\Omega \mathbf{w}_e \cdot \mathbf{curl}\,\mathbf{w}_\gamma.$$

Remarking that for all $\gamma \in \mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B$

$$\begin{aligned} \textstyle\int_\Omega \mathbf{u}_m^1 \cdot \mathbf{curl}\,\mathbf{w}_\gamma &= \textstyle\int_\Omega \omega \cdot \mathbf{w}_\gamma, \\ \textstyle\int_\Omega \mathbf{u}_m^2 \cdot \mathbf{curl}\,\mathbf{w}_\gamma &= \textstyle\int_\Omega \omega \cdot \mathbf{w}_\gamma, \end{aligned}$$

we have that, for all $\gamma \in \mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^\ell \cup \mathcal{E}_m^B$,

$$\int_\Omega \mathbf{v}_m \cdot \mathbf{curl}\,\mathbf{w}_\gamma = 0.$$

That together with $\mathbf{v}_m \in \ker(\mathrm{div}; W_m^2)$ implies $\mathbf{v}_m = \mathbf{0}$.

As we have seen, the final solution does not depend on the particular spanning tree to gauge the potential. In practice, however, the efficiency of the method does via the dependence on the particular tree of the condition number of the "stiffness" matrix A in (18). This dependence is not too dramatic anyway, as underlined by the numerical tests presented in the appendix of [10].

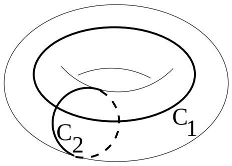

FIG. 5. *Two disjoint loops $\mathcal{C}_1$ and $\mathcal{C}_2$, an example of generators of the first homology group $H_1(m^\Gamma)$ of the torus surface Γ.*

7. Approximation of the problem in the nonsimply connected case.

In the following, we turn our attention to the case where Ω and its boundary are nonsimply connected. As an example of such a situation, we assume that Ω is a *torus*, up to a homeomorphism. For the torus, we have $\chi(\Gamma) = 0$ and $\chi(\Omega) = 0$. Note that Γ is an "empty" torus, while Ω is a "full" torus. Let us look at the differences between the simply connected and nonsimply connected cases.

7.1. Lifting the boundary condition for a torus.

Let $\mathcal{S}^\Gamma$ denote the belted spanning tree on the torus boundary, i.e., $\mathcal{S}^\Gamma = \mathcal{T}^\Gamma \cup \{\Pi_1, \Pi_2\}$, where $\mathcal{T}^\Gamma$ is the usual spanning tree without loops and Π_1, Π_2 are two suitable edges of $\mathcal{E}^\Gamma_m$. In particular, denote $\mathcal{C}_1$ and $\mathcal{C}_2$ two disjoint loops of Γ, as presented in Figure 5, and we have that

$$\mathcal{T}^\Gamma \cup \{\Pi_1\} \text{ contains a loop homologous to } \mathcal{C}_1,$$

$$\mathcal{T}^\Gamma \cup \{\Pi_2\} \text{ contains a loop homologous to } \mathcal{C}_2.$$

Note that, with respect to the simply connected case, the spanning tree on the surface has been enriched according to $\dim[H_1(m^\Gamma)]$ (two edges in the case of the torus surface), as explained in Remark 5.1. Thanks to these added edges, the circuits associated to all remaining coedges do bound a surface contained in Γ, and this is a property that will be exploited during the proof of the following proposition. See [27] for a method to build up a belted spanning tree.

PROPOSITION 7.1. *Let us consider a triangulation m of $\overline{\Omega}$, its restriction m^Γ to the boundary Γ of Ω, and a spanning tree $\mathcal{S}^\Gamma$ in m^Γ. Let Γ be a* torus*, and let $g \in L^2_0(\Gamma)$. There is a unique divergence-free vector $\hat{\mathbf{u}}^\Gamma_m \in W^2_{m^\Gamma}$ of the form*

$$\hat{\mathbf{u}}^\Gamma_m = \sum_{e \in \mathcal{E}^\Gamma_m \setminus \mathcal{S}^\Gamma} \hat{u}_e \, \mathbf{curl}\, \mathbf{w}_e, \qquad \mathbf{w}_e \in W^1_{m^\Gamma}, \tag{20}$$

that satisfies

$$\int_f \hat{\mathbf{u}}^\Gamma_m \cdot \mathbf{n}_\Gamma = \int_f g \quad \forall\, f \in \mathcal{F}^\Gamma_m. \tag{21}$$

Proof. The proof is similar to the proof of Proposition 6.1. We introduce the two spaces $\ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ and

$$\mathcal{V}(\mathcal{S}^\Gamma) = \mathrm{span}\,\{\mathbf{w}_e \,|\, \mathbf{w}_e \in W^1_{m^\Gamma},\, e \in \mathcal{E}^\Gamma_m \setminus \mathcal{S}^\Gamma\}.$$

The curl operator is well defined as $\mathcal{V}(\mathcal{S}^\Gamma) \to \ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$.

The curl mapping $\mathcal{V}(\mathcal{S}^\Gamma) \to \ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ is injective. Let us consider the vector $\hat{\mathbf{p}}^\Gamma_m \in \mathcal{V}(\mathcal{S}^\Gamma)$ of the form

$$\hat{\mathbf{p}}^\Gamma_m = \sum_{e \in \mathcal{E}^\Gamma_m \setminus \mathcal{S}^\Gamma} \hat{u}_e \, \mathbf{w}_e.$$

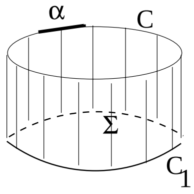

FIG. 6. *When the circuit $\mathcal{C}$ is homologous to one of the two independent loops, say, $\mathcal{C}_1$, it does not bound any surface. In this case, we have to consider the loop $\mathcal{C} \cup \mathcal{C}_1$ that bounds a (lateral, in this case) surface Σ.*

Let $\alpha \in \mathcal{E}^\Gamma_m \setminus \mathcal{S}^\Gamma$ be a given coedge, and let $\mathcal{C} \subset \{\alpha\} \cup \mathcal{S}^\Gamma$ be the associated cycle. It can happen either that $\mathcal{C}$ is the boundary of a surface Σ (in this case we repeat exactly the proof for the simply connected case) or that $\mathcal{C}$ is homologous to one of the two fundamental loops, say, $\mathcal{C}_1$, and so *it does not bound a surface.* To overcome the problem, we have to consider the loop $\mathcal{C} \cup \mathcal{C}_1$; now, this loop *does bound* a surface, and we denote by Σ the corresponding surface (see Figure 6).

We have then

$$\int_{\mathcal{C}\cup\mathcal{C}_1} \hat{\mathbf{p}}^\Gamma_m \cdot \tau_{\mathcal{C}\cup\mathcal{C}_1} = \hat{u}_\alpha \int_\alpha \mathbf{w}_\alpha \cdot \tau_{\mathcal{C}\cup\mathcal{C}_1} = \hat{u}_\alpha,$$

where $\tau_{\mathcal{C}\cup\mathcal{C}_1}$ is the tangential vector to $\mathcal{C} \cup \mathcal{C}_1$. We then conclude that $\hat{u}_\alpha = 0$ by following the same steps of the proof for Proposition 6.1.

Let W again be the space composed of vectors in $\ker(\mathrm{div}_\Gamma; W^2_{m^\Gamma})$ verifying (21) with $g \in L^2_0(\Gamma)$. The linear spaces $\mathcal{V}(\mathcal{S}^\Gamma)$ and W have the same dimension. On one hand, we have $\dim[\mathcal{V}(\mathcal{S}^\Gamma)] = E^\Gamma_m - (N^\Gamma_m - 1 + 2)$ thanks to Remark 5.1, and on the other hand, $\dim[W] = F^\Gamma_m - 1$. Due to the fact that the Euler–Poincaré characteristic for an empty torus is 0, the equality

$$E^\Gamma_m - N^\Gamma_m - 1 = F^\Gamma_m - 1$$

follows from Remark 4.2. $\square$

7.2. Interior problem for a torus. Let $\mathcal{C}_1$ be the loop that does not bound any surface of Ω, and let $\mathcal{C}_2$ be the one that bounds a surface Σ_2 when considered in Ω (see Figure 5). The flux condition

$$\int_{\Sigma_2} \mathbf{u} \cdot \mathbf{n}_\Sigma = \int_{\partial\Sigma_2} \mathbf{p} \cdot \tau_{\mathcal{C}_2} \neq 0$$

yields $\pi\mathbf{p}$ not identically null. In this case, to solve problem (9) we need to "reactivate" one of the two edges Π_1, Π_2 excluded in problem (8) and precisely the one associated with the loop that bounds when we pass from Γ to Ω. In any other case, the degree of freedom associated to Π_2 is zero. In the following, we take into account the more general case where $\pi\mathbf{p} \neq \mathbf{0}$ and we assume that $\Pi^*_2 = \mathrm{supp}(\pi\mathbf{p})$. The degree of freedom associated to this particular edge is equal to the flux of the field $\mathbf{u}$ across the transversal section of the torus. For this feature, from now on, we call Π^*_2 the "flux edge." Denoting by $\mathcal{T}^{\rm int}$ the usual spanning tree without loops, we have $\mathcal{S}^{\rm int} = \mathcal{T}^{\rm int} \cup \{\Pi_1\}$, and the set $\mathcal{U}^0_m$ is now defined as follows:

$$\tilde{\mathcal{U}}^0_m = (\mathcal{E}^{\rm int}_m \cup \mathcal{E}^\ell_m \cup \mathcal{E}^B_m \cup \{\Pi^*_2\}) \setminus (\mathcal{S}^{\rm int} \cup \mathcal{T}^\ell).$$

Proposition 7.2. *Let us consider a triangulation m of $\overline{\Omega}$, together with a spanning tree $\mathcal{S}^{\rm int} \cup \mathcal{T}^{\ell}$ in m. Let us suppose that Ω is a* torus *and $\omega \in \ker(\mathrm{div}; W^2_m)$. There exists a unique divergence-free vector $\mathbf{u}^0_m \in W^2_{m,0}$ of the form*

$$\mathbf{u}^0_m = \sum_{e \in \tilde{\mathcal{U}}^0_m} u^0_e \, \mathbf{curl}\, \mathbf{w}_e \qquad \mathbf{w}_e \in W^1_m, \tag{22}$$

that satisfies

$$\mathbf{curl}\, \mathbf{u}^0_m = \omega - \mathbf{curl}\, \hat{\mathbf{u}}_m \qquad \text{in} \;\; \Omega, \tag{23}$$

where $\hat{\mathbf{u}}_m$ is the divergence-free lifting in Ω of $\hat{\mathbf{u}}^{\Gamma}_m$ defined in Proposition 7.1.

Proof. Let us introduce the two spaces $\ker(\mathrm{div}; W^2_{m,0})$ and

$$\mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell}) = \mathrm{span}\, \{\mathbf{w}_e \,|\, \mathbf{w}_e \in W^1_m,\, e \in \tilde{\mathcal{U}}^0_m\}.$$

The curl operator is well defined as $\mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell}) \to \ker(\mathrm{div}; W^2_{m,0})$.

The curl mapping $\mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell}) \to \ker(\mathrm{div}; W^2_{m,0})$ is injective. The proof given for Proposition 7.1 is the same with $\mathbf{p}^0_m \in \mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell})$ of the form

$$\mathbf{p}^0_m = \sum_{e \in \tilde{\mathcal{U}}^0_m} \hat{u}_e \, \mathbf{w}_e.$$

The linear spaces $\mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell})$ and $\ker(\mathrm{div}; W^2_{m,0})$ have the same dimension. In fact, we have

$$\begin{aligned} &\dim\, [\mathcal{V}(\mathcal{S}^{\rm int}, \mathcal{T}^{\ell})] = E_m - E^{\Gamma}_m + 1 - (N_m - N^{\Gamma}_m - 1 + 1 + 1), \\ &\dim\, [\ker(\mathrm{div}; W^2_{m,0})] = F_m - F^{\Gamma}_m - (T_m - 1) - 1. \end{aligned}$$

Note that now, for the presence of "one hole" in Ω, the equation $\mathrm{div}\, \mathbf{u} = 0$ gives only T_m independent conditions. The two are coincident since the Euler–Poincaré characteristic for the "full" torus and its surface is 0.

Once again, the present proof can also be carried out at an algebraic level. Proposition 7.2 states that, given $\mathcal{S}^{\rm int} \cup \mathcal{T}^{\ell}$, $\omega \in \ker(\mathrm{div}; W^2_m)$, and $\hat{\mathbf{u}}_m$ the divergence-free lifting in Ω of $\hat{\mathbf{u}}^{\Gamma}_m$ defined in Proposition 7.1, there is a unique divergence-free vector $\mathbf{u}^0_m \in W^2_{m,0}$ of the form (22). Moreover, its coefficients u^0_e, $e \in \tilde{\mathcal{U}}^0_m$, on the chosen basis, are the components of the solution of the linear system

$$\sum_{e \in \tilde{\mathcal{U}}^0_m} u^0_e \int_{\Omega} \mathbf{curl}\, \mathbf{w}_e \cdot \mathbf{curl}\, \mathbf{w}_{\gamma} = \int_{\Omega} \omega \cdot \mathbf{w}_{\gamma} - \int_{\Omega} \hat{\mathbf{u}}_m \cdot \mathbf{w}_{\gamma} \qquad \forall\, \gamma \in \tilde{\mathcal{U}}^0_m. \tag{24}$$

The matrix

$$\tilde{A} = \left(\int_{\Omega} \mathbf{curl}\, \mathbf{w}_e \cdot \mathbf{curl}\, \mathbf{w}_{\gamma} \right)_{e, \gamma \in \tilde{\mathcal{U}}^0_m}$$

again has full rank, but it is no more sparse due to the presence of the basis function associated to $\{\Pi^*_2\}$. □

The function

$$\mathbf{u}_m = \hat{\mathbf{u}}_m + \sum_{e \in \tilde{\mathcal{U}}^0_m} u^0_e \, \mathbf{curl}\, \mathbf{w}_e \tag{25}$$

is then the approximated solution of problem (7) in the nonsimply connected case.

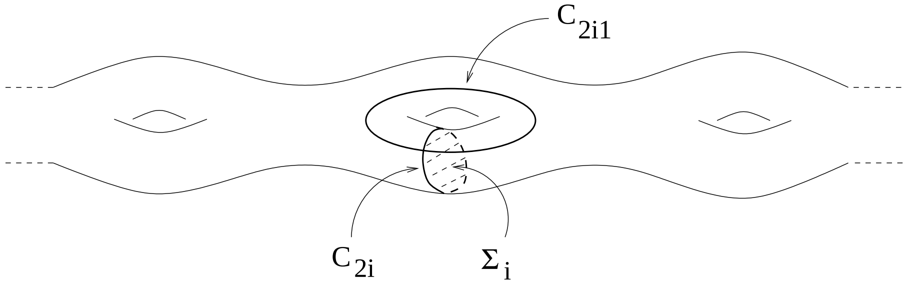

FIG. 7. *Two disjoint loops $\mathcal{C}_{2i-1}$ and $\mathcal{C}_{2i}$, $1 \leq i \leq \kappa$, example of generators of the first homology group of the ith "empty" torus belonging to the surface of the sum of κ tori.*

7.3. Case of the sum of κ tori. The theory that we have presented can be generalized to a domain Ω that is the sum of κ tori, with the integer $\kappa \geq 1$. We have that

$$\chi(\Gamma) = 1 - 2\kappa + 1 = 2(1-\kappa), \qquad \chi(\Omega) = 1 - \kappa.$$

For problem (8), we have to consider

$$\mathcal{S}^{\Gamma} = \left(\mathcal{T}^{\Gamma} \cup \bigcup_{i=1}^{\kappa} \{\Pi_{2i-1}, \Pi_{2i}\} \right),$$

where $\mathcal{T}^{\Gamma}$ is the usual spanning tree without loops and $\{\Pi_{2i-1}, \Pi_{2i}\}$ for $1 \leq i \leq \kappa$ is one pair of suitable edges of $\mathcal{E}_m^{\Gamma}$. In particular, denoting by $\mathcal{C}_{2i-1}$ and $\mathcal{C}_{2i}$ two disjoint loops as presented in Figure 7, we have that

$$\mathcal{T}^{\Gamma} \cup \{\Pi_{2i-1}\} \text{ contains a loop homologous to } \mathcal{C}_{2i-1},$$
$$\mathcal{T}^{\Gamma} \cup \{\Pi_{2i}\} \text{ contains a loop homologous to } \mathcal{C}_{2i}.$$

The spanning tree on the surface has been enriched according to $\dim [H_1(m^{\Gamma})]$ that is now 2κ, as explained in Remark 5.1. The proof of Proposition 7.1 for problem (8) does not change globally; concerning the dimension of the approximation and approximated spaces, we have now

$$\dim [\mathcal{V}(\mathcal{S}^{\Gamma})] = E_m^{\Gamma} - (N_m^{\Gamma} - 1 + 2\kappa), \qquad \dim [W] = F_m^{\Gamma} - 1.$$

The two coincide thanks to the Euler–Poincaré characteristic of Γ.

Similarly, for $1 \leq i \leq \kappa$, let $\mathcal{C}_{2i-1}$ be the loop that does not bound any surface of Ω, and let $\mathcal{C}_{2i}$ be the one that bounds a surface Σ_i when considered in Ω (see Figure 7). For problem (9) we need to "reactivate" one of the two edges Π_{2i-1}, Π_{2i} excluded in problem (8) and precisely the one associated with the loop that bounds a surface when we pass from Γ to Ω. So, because $\Pi_{2i}^{*} =$ supp $(\pi \mathbf{p})$, the flux edges, $1 \leq i \leq \kappa$, with the vector $\mathbf{p}$ as in section 7.2, and denoting by $\mathcal{T}^{\text{int}}$ the usual spanning tree without loops, we have

$$\mathcal{S}^{\text{int}} = \left(\mathcal{T}^{\text{int}} \cup \bigcup_{i=1}^{\kappa} \{\Pi_{2i-1}\} \right),$$

and the set $\mathcal{U}_m^0$ is now defined as follows:

$$\tilde{\mathcal{U}}_m^0 = \left(\mathcal{E}_m^{\mathrm{int}} \cup \mathcal{E}_m^{\ell} \cup \mathcal{E}_m^{B} \cup \bigcup_{i=1}^{\kappa} \{\Pi_{2i}^*\} \right) \setminus (\mathcal{S}^{\mathrm{int}} \cup \mathcal{T}^{\ell}).$$

The proof of Proposition 7.2 for problem (9) is unchanged; the dimension of the approximation and approximated spaces is now

$$\begin{aligned}\dim\,[\mathcal{V}(\mathcal{S}^{\mathrm{int}}, \mathcal{T}^{\ell})] &= E_m - E_m^{\Gamma} + \kappa - (N_m - N_m^{\Gamma} - 1 + \kappa + 1),\\ \dim\,[H_0(\mathrm{div}_0, m)] &= F_m - F_m^{\Gamma} - (T_m - 1) - \kappa,\end{aligned}$$

and the two coincide thanks to the Euler–Poincaré characteristic of Ω and Γ.

Remark 7.3. Another existing strategy to deal with potential problems in nonsimply connected domains relies on the introduction of "cuts" in the domain. The big difficulty with this method is the construction of cuts and understanding where they should be introduced. Kotiuga [21] and coworkers have provided a correct definition of a cut, a constructive algorithm, and an implementation of it (see [18], for example).

The "belted tree" approach proposed in this paper allows us to achieve knowledge of the topological features of the considered domain if this is not given a priori. This knowledge is a preliminary step to the introduction of cuts.

8. Algorithmics and a simple example. From a practical point of view, the determination of the set $\mathcal{U}_m^0$ for simply connected domains is standard, and we refer to [28] for a procedure to construct a particular spanning tree.

This is not the case for the nonsimply connected case. The problem is now to find out the independent loops in order to select explicitly the flux edges previously introduced. We have, in particular, to select the loops that bound a surface when we pass from the boundary to the interior. This question can be summarized by saying that we look for generators of $H_1(m)$ starting from those of $H_1(m^{\Gamma})$.

In section 8.1, we present the algebraic tools, and we explain how to use them in section 8.2. The very first results for a torus are presented in section 8.3. We remark that only the computation of a basis for $H_1(m)$ is useful to our purpose of solving problem (24). In any case, a basis for $H_2(m)$ can be computed with the same tools, and at the end of section 8.2 we give a few indications of how to proceed with it. See [20] for another type of algorithm.

8.1. An integer $\mathcal{QR}$ factorization. In this section, we present a matrix decomposition to compute a set of generators of the homology groups of order $p = 1$ and 2 of $\Omega \subset \mathbb{R}^3$. The same algorithm has been used in [25] to detect mesh defects. The basic idea is to make an integer $\mathcal{QR}$ factorization of the matrices G^t, R^t, and D^t. Given a matrix $A \in \mathcal{M}(r, s)$, we compute a nonsingular unimodular matrix $\mathcal{Q}$ (i.e., $\det(\mathcal{Q}) = \pm 1$) and a permutation matrix $\mathcal{P}$ such that $\mathcal{R} = \mathcal{Q}\, A\, \mathcal{P}$ is upper triangular. As shown later, the two matrices $\mathcal{Q}$ and $\mathcal{P}$ are obtained as products of a certain number of local matrices $\mathcal{Q}_{i,j}$ and $\mathcal{P}_{i,j}$ and exhibit the row and column rank deficiency of A [8]. The key point of the algorithm is the following property [17]: given a matrix $A \in \mathcal{M}(r, s)$ with integer elements, we have

$$Z^r = \ker{(A^t)} \,\oplus\, \mathrm{range}\,(A), \qquad Z^s = \ker{(A)} \,\oplus\, \mathrm{range}\,(A^t). \tag{26}$$

To define $\mathcal{Q}$ and $\mathcal{P}$, we need two elementary operations. First is the transformation π_1 of a vector $v = (\epsilon_i, \epsilon_j)^t$ into the vector $\tilde{v} = (1, 0)^t$. To this purpose, let us introduce the elementary matrices

$$\mathcal{Q}^{\mathrm{el}}_{i,j} = \begin{pmatrix} \epsilon_i & 0 \\ -\epsilon_i & \epsilon_j \end{pmatrix}, \quad (\mathcal{Q}^{\mathrm{el}}_{i,j})^{-1} = \begin{pmatrix} \epsilon_i & 0 \\ \epsilon_j & \epsilon_j \end{pmatrix}$$

and the matrix

$$\mathcal{Q}_{i,j}(\ell, q) = \begin{cases} \delta_{\ell,q}, & \ell \neq i\,, j, \quad q \neq i\,, j, \\ \mathcal{Q}^{\mathrm{el}}_{i,j}(1,1), & \ell = i, \quad q = i, \\ \mathcal{Q}^{\mathrm{el}}_{i,j}(1,2), & \ell = i, \quad q = j, \\ \mathcal{Q}^{\mathrm{el}}_{i,j}(2,1), & \ell = j, \quad q = i, \\ \mathcal{Q}^{\mathrm{el}}_{i,j}(2,2), & \ell = j, \quad q = j. \end{cases}$$

In our case, $\epsilon_i^2 = 1$, and the vector $\tilde{v} = \pi_1(v) = \mathcal{Q}^{\mathrm{el}}_{i,j} v$. Second, we need the permutation π_2 of a vector's components, i.e., the transformation of a vector $v = (\epsilon_i, \epsilon_j)^t$ into the vector $\tilde{v} = (\epsilon_j, \epsilon_i)^t$. To this purpose, we have $\tilde{v} = \pi_2(v) = \mathcal{P}^{\mathrm{el}}_{i,j} v$, where $\mathcal{P}^{\mathrm{el}}_{i,j}$ is a permutation matrix; moreover, we introduce a matrix $\mathcal{P}_{i,j}$ defined similarly to $\mathcal{Q}_{i,j}$ (using $\mathcal{P}^{\mathrm{el}}_{i,j}$ instead of $\mathcal{Q}^{\mathrm{el}}_{i,j}$). We remark that $(\mathcal{P}^{\mathrm{el}}_{i,j})^{-1} = \mathcal{P}^{\mathrm{el}}_{i,j}$, owing to the fact that $\mathcal{P}^{\mathrm{el}}_{i,j}$ is a permutation matrix and that $(\mathcal{Q}_{i,j})^{-1}$ is defined as $\mathcal{Q}_{i,j}$ (using $(\mathcal{Q}^{\mathrm{el}}_{i,j})^{-1}$ instead of $\mathcal{Q}^{\mathrm{el}}_{i,j}$). In the following, I_r denotes the identity matrix of dimension $r > 0$. Now we describe the adopted procedure to build up $\mathcal{Q}$ and $\mathcal{P}$ for a given matrix $A \in \mathcal{M}(r, s)$.

Procedure. We set $\mathcal{Q} = \mathcal{Q}^0 \in \mathcal{M}(r, r)$, $\mathcal{P} = \mathcal{P}^0 \in \mathcal{M}(s, s)$. We loop on the column index j, $1 \leq j \leq s$:

1. We define $\mathcal{V}_j = \{i \,|\, \min\{j, r\} \leq i \leq \min\{s, r\},\, A(i, j) \neq 0\}$, and we put k equal to the cardinality of $\mathcal{V}_j$, i_1 equal to the smallest integer in $\mathcal{V}_j$, and i_2 equal to the smallest integer in $\mathcal{V}_j \setminus \{i_1\}$.
2. In case $k = 0$, let $\mathcal{P}_{j,z}$ be the matrix of the transformation π_2 that permutes the jth column of A with the zth one. The zth column is chosen to be the first column, starting from the last one in A, for which there exists a row index s such that $A(s, z) \neq 0$. If the index z exists, $\mathcal{P} \longleftarrow \mathcal{P}\,\mathcal{P}_{j,z}$, $A \longleftarrow A\,\mathcal{P}_{j,z}$, and we go back to step 1; otherwise we stop the procedure.
3. In case $k \neq 0$ but $A(j, j) = 0$, we apply a partial pivot strategy. Let $\mathcal{Q}_{j,i_1}$ be the matrix of the transformation π_2 that permutes the jth row with the i_1th one; then $\mathcal{Q} \longleftarrow \mathcal{Q}_{j,i_1}\,\mathcal{Q}$, $A \longleftarrow \mathcal{Q}_{j,i_1}\,A$, $i_1 \longleftarrow j$, and we go to step 4.
4. In case $k \geq 2$ and $A(j, j) \neq 0$, let $\mathcal{Q}^{\mathrm{el}}_{i_1,i_2}$ be the matrix of the transformation π_1 applied to the vector $(A(i_1, j), A(i_2, j))^t$, and let $\mathcal{Q}_{i_1,i_2}$ be the associated matrix; then $\mathcal{Q} \longleftarrow \mathcal{Q}_{i_1,i_2}\,\mathcal{Q}$, $A \longleftarrow \mathcal{Q}_{i_1,i_2}\,A$, and we go back to step 1.
5. In case $k = 1$ and $A(j, j) \neq 0$, then $j \longleftarrow j + 1$, and we go back to step 1.

Starting with $\mathcal{Q}^0 = I_r$ and $\mathcal{P}^0 = I_s$, at the end of the procedure, the matrix A has been replaced by $\mathcal{R}$, an upper triangular one. If this new matrix $\mathcal{R}$ does not contain zero rows, then $\dim[\mathrm{range}(\mathcal{R})] = r$. Otherwise, $\dim[\ker(\mathcal{R}^t)] = r - \dim[\mathrm{range}(\mathcal{R})]$. We remark that the procedure converges and its computational cost is similar to that of a $\mathcal{QR}$ decomposition by using Givens transformations.

8.2. Computation of homology group generators. Now, the question is how we can use the previous procedure to compute the generators of $H_p(m)$ for $p = 1$ and 2. To compute a set of generators for $H_1(m)$, we proceed as follows.

(i) We apply the procedure with $A = R^t$, $\mathcal{Q}^0 = I_{E_m}$, and $\mathcal{P}^0 = I_{F_m}$, and we get two invertible matrices $\mathcal{Q}_R$ and $\mathcal{P}_R$ such that $\mathcal{R}_R = \mathcal{Q}_R\,R^t\,\mathcal{P}_R$ is upper

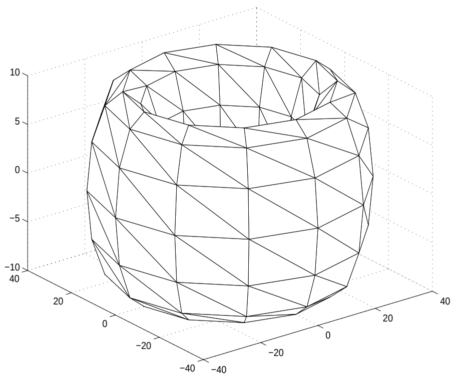

FIG. 8. *An example of surface discretization for the torus.*

triangular. The 1-cycles which bound a surface belong to the image of the matrix R^t that is also the image of $\mathcal{R}_R$.

(ii) We define $\tilde{G}^t = G^t \, \mathcal{Q}_R^{-1}$. In this way we make a change of basis for the 1-chains. Looking at $\tilde{G}^t$, we see immediately from the presence of n_c zero columns that the corresponding columns of $\mathcal{Q}_R^{-1}$ represent vectors that belong to the kernel of G^t. If $\dim[\mathrm{range}\,(R^t)] = \dim[\ker(G^t)]$, then any 1-cycle bounds. In the other case, we apply the procedure with $A = \tilde{G}^t$, $\mathcal{Q}^0 = I_{N_m}$, and $\mathcal{P}^0 = I_{E_m - n_c}$. We then obtain two invertible matrices $\mathcal{Q}_{\tilde{G}}$ and $\mathcal{P}_{\tilde{G}}$ such that $\mathcal{R}_{\tilde{G}} = \mathcal{Q}_{\tilde{G}} \, \tilde{G}^t \, \mathcal{P}_{\tilde{G}}$ is upper triangular.

(iii) The rows in $\mathcal{P}_{\tilde{G}}$, corresponding to zero rows in $\mathcal{R}_{\tilde{G}}$, represent the vectors that complete the kernel of G^t. In fact, we are looking for c such that $G^t \, c = 0$. This is equivalent to $\tilde{G}^t \, v = 0$, where v has zero in the first n_c components and, in the last $E_m - n_c$, any row in $\mathcal{P}_{\tilde{G}}$ corresponding to a new zero row in $\mathcal{R}_{\tilde{G}}$. Then the components of $c = \mathcal{Q}_R^{-1} \, v$ are the coefficients of a 1-chain generator of $H_1(m)$.

To determine the generators of $H_2(m)$, it is sufficient to perform parts (i), (ii), and (iii) with D^t at the place of R^t and R^t at the place of G^t.

8.3. Numerical results on the torus. As an application, we consider the case of a torus. We discretize it by means of a mesh m of 596 tetrahedra and 179 nodes. The discretization of Ω induces a discretization of the surface, denoted m^Γ, composed of 288 triangles and 144 nodes (see Figure 8).

We apply the procedure presented in section 8.2 to the matrices R^t and G^t of the surface Γ. At this point we have a basis for the 1-cycles of the mesh m^Γ that are not boundaries, i.e., a basis for $H_1(m^\Gamma)$ (see Figures 9 and 10). Note that the loops $\mathcal{C}_1$ and $\mathcal{C}_2$ run around the two "holes" of the torus surface.

We want now to make evident the loop that bounds a surface when considered as 1-cycles of the mesh m in Ω. In other terms, in the set of the two computed generators for $H_1(m^\Gamma)$, we look for the one that generates $H_1(m)$.

Let c be an element of $H_1(m^\Gamma)$ and v_c the vector whose components are the coefficients of c for the edges $e \in \mathcal{E}_m^\Gamma$ and zero for $e \in \mathcal{E}_m \setminus \mathcal{E}_m^\Gamma$. We apply the procedure to the matrix R^t associated to the mesh m in Ω, and we transform it into an upper triangular matrix of the form $\mathcal{R}_R = \mathcal{Q}_R \, R^t \, \mathcal{P}_R$. Finally, we consider the vector $w_c = \mathcal{Q}_R^{-1} \, v_c$. If $w_c = 0$, then the 1-chain c is homologous to zero in Ω (see

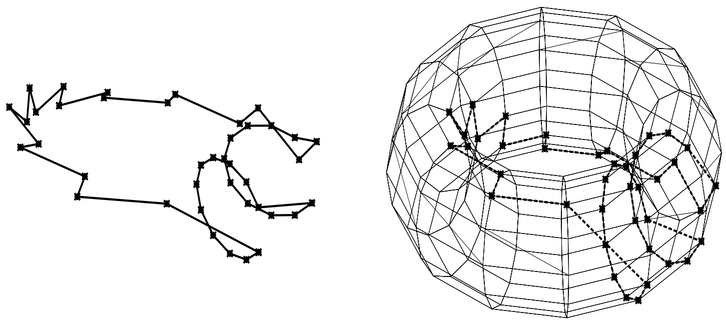

FIG. 9. *Wireframe representation of the loop $\mathcal{C}_2$, one of the two generators of the first homology group of the torus surface.*

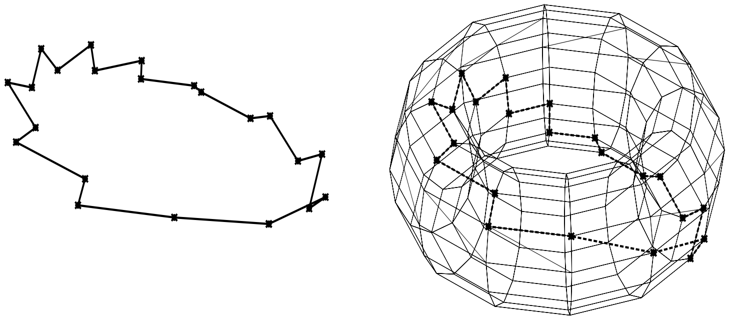

FIG. 10. *Wireframe representation of the loop $\mathcal{C}_1$, one of the two generators of the first homology group of the torus surface.*

Figure 9); if $w_c \neq 0$, then the 1-chain c is also a generator of $H_1(m)$ (see Figure 10). In our case, the loop $\mathcal{C}_1$ is detected to be the element of a basis for $H_1(m)$. Note that the adopted procedure can be optimized in several ways, such as, for example, by looking for those generators with the minimum number of edges or faces, by applying the procedure to suitable portions of the whole meshes, and by using a suitable data format [13].

The two loops $\mathcal{C}_1$ and $\mathcal{C}_2$ are used as follows. For the lifting of the boundary condition, the set $\mathcal{S}^\Gamma$ of "null degrees of freedom" is a belted spanning tree obtained by adding to the standard spanning tree $\mathcal{T}^\Gamma$ two edges, $\Pi_1 \in \mathcal{C}_1$ and $\Pi_2 \in \mathcal{C}_2$, chosen in an arbitrary way, with $\Pi_1 \neq \Pi_2$. These two edges correspond to nonzero components in the vector w_c of the coefficients of the 1-chains c that generate $H_1(m^\Gamma)$.

For the interior problem, the set of active edges $\tilde{\mathcal{U}}_m^0$ is obtained by adding a flux edge Π_2^* to the set $\mathcal{U}_m^0$, the latter selected with the algorithm devoted to a simply connected domain. We conclude by remarking that Π_2^*, the edge that has to be reactivated when passing from the boundary to the interior to solve problem (24), can be chosen to be any edge $e \in \mathcal{E}_m^\Gamma$ for which the corresponding coefficient in the 1-chain c is nonzero.

9. Conclusions. In this paper, we have studied the representation of a solenoidal vector field in terms of a vector potential. The considered problem has been split into two parts—a lifting problem of the boundary condition and an internal problem with homogeneous boundary conditions.

The edge elements are a natural tool to compute vector potentials. On the other hand, the gauge condition, which is necessary to ensure the potential uniqueness, is taken into account in a fully discrete way and expressed in terms of a suitable set of active mesh edges (active in the sense that the associated degree of freedom is a priori different from zero).

According to the authors' knowledge, the problem of the computation of the vector potential is well understood for three-dimensional bounded domains which are connected and simply connected, even with a connected but nonsimply connected boundary. Here, we have presented a method to compute the vector potential for three-dimensional bounded domains which are connected but nonsimply connected, with a connected boundary. The case of three-dimensional bounded domains which are nonsimply connected with a nonconnected boundary has not been considered in the present work.

QUASI OPTIMALITY OF THE SUPG METHOD FOR THE ONE-DIMENSIONAL ADVECTION-DIFFUSION PROBLEM[*]

GIANCARLO SANGALLI[†]

Abstract. In this paper, we propose quasi-optimal error estimates, in various norms, for the *streamline-upwind Petrov–Galerkin* (SUPG) method applied to the linear one-dimensional advection-diffusion problem. We follow the classical argument due to Babuška and Brezzi; therefore, the goal of this work is the proof of the inf-sup and of the continuity conditions for the bilinear stabilized variational form, with respect to suitable norms. These norms are suggested by our previous work [G. Sangalli, Technical report 1221, IAN-CNR, Pavia, Italy, 2001; *Numer. Math.*, to appear], in which we analyze the continuous multidimensional advection-diffusion operator. We obtain these results by means of function space interpolation.

Key words. convection-diffusion, finite element method, inf-sup condition

1. Introduction.

In this work, we shall consider the one-dimensional advection-diffusion operator

$$\mathcal{L}_\varepsilon w := -\varepsilon w'' + w' \tag{1.1}$$

and, given a source term f, the related Dirichlet homogeneous boundary value problem

$$\begin{cases} \mathcal{L}_\varepsilon u = f & \text{in } (0,1), \\ u(0) = 0, \\ u(1) = 0. \end{cases} \tag{1.2}$$

We assume the diffusion parameter ε to be positive; when it is small, i.e., in the advection-dominated regime, (1.2) represents one of the simplest examples of singularly perturbed boundary value differential problems. We think of it as a prototype of more general problems, where a skew-symmetric operator (represented by the first-order derivative) is perturbed by a symmetric operator of higher order (the second-order derivative in the example).

The associated variational problem reads

$$\begin{cases} \text{find } u \in H^1_0 \equiv H^1_0(0,1) \text{ such that} \\ a_\varepsilon(u,v) = {}_{H^{-1}}\langle f, v\rangle_{H^1_0} \qquad \forall v \in H^1_0, \end{cases} \tag{1.3}$$

where $a_\varepsilon(w,v) := \varepsilon \int_0^1 w'(x)v'(x)\,dx + \int_0^1 w'(x)v(x)\,dx$ and f is assumed to be in H^{-1}. This problem fits into the Lax–Milgram framework, but its solution, when ε is small, depends on the source term f in a very sensitive way with respect to the usual norms on H^1_0 and H^{-1}; actually,

$$\|\mathcal{L}_\varepsilon^{-1}\|_{L(H^{-1},H^1_0)} := \sup_{w\in H^1_0} \frac{\|w\|_{H^1_0}}{\|\mathcal{L}_\varepsilon w\|_{H^{-1}}} \approx \varepsilon^{-1}.$$

[†] Istituto di Matematica Applicata e Tecnologie Informatiche, Via Ferrata 1, 27100 Pavia, Italy (sangalli@imati.cnr.it).

Nevertheless, problem (1.2) is well posed for any $\varepsilon > 0$, and indeed in [14] and [13] we defined suitable norms $\|\cdot\|_W$ and $\|\cdot\|_V$ such that both the continuity and the inf-sup conditions

$$a_\varepsilon(w, v) \le \kappa \|w\|_W \|v\|_V \quad \forall w \in H_0^1, \forall v \in H_0^1, \tag{1.4}$$

$$\inf_{w \in H_0^1} \sup_{v \in H_0^1} \frac{a_\varepsilon(w, v)}{\|w\|_W \|v\|_V} \ge \gamma > 0, \tag{1.5}$$

hold true with κ and γ independent of ε. The results in this paper are based on the approach proposed in [13]; actually the analysis of [13] is more general since it deals with the multidimensional operator, where the advection term has an anisotropic structure. In section 2, we shall specialize the results of [13] to the simpler one-dimensional problem (1.2).

It is well known that the standard Galerkin numerical method, when applied to (1.2), is unstable (see, e.g., [11]). The most popular methods for (1.2) are actually the *streamline-upwind Petrov–Galerkin* (SUPG) method and its variants—e.g., the *Galerkin least squares* (GaLS) method—introduced by Hughes and coworkers (see [7] and [9]) in the eighties. In this work, we shall consider the one-dimensional version of the SUPG method, whose detailed presentation is postponed to section 2. We recall now only that even though these methods are quite satisfactory for practical situations, their error analysis does not fit into the classical theory due to Babuška and Brezzi (see [1] and [3] and (2.16)–(2.18) in what follows); as a result, it is usually very hard to prove that these methods are *quasi-optimal*, namely, to show that the their numerical solution u_h is close to the exact solution u as the best fit of u in the trial space W_h (up to a multiplicative constant C independent of ε and with respect to a suitable norm $\|\cdot\|$):

$$\|u - u_h\| \le C \inf_{w_h \in W_h} \|u - w_h\|.$$

More recent numerical methods for the advection-diffusion problem are, among others, the *residual-free bubbles* finite element method (*FEM*) (proposed in [6] and analyzed in [4], [5], [8], and [12]) and the method with *negative-order stabilization* (see [2]). Those methods are closely related to the SUPG method—in some cases they lead to the same numerical algorithm—but they actually improve the theoretical understanding of this subject; for our purposes here, we note only that those recent analyses are, roughly speaking, *close* to the ideal Babuška–Brezzi framework, and the methods are proved to be *close* to exhibiting the quasi-optimal behavior.

In this work, we actually prove a family of quasi-optimal error estimates for the SUPG method for solving (1.2). We apply the general theory stated in section 2, by showing that the method verifies the continuity and inf-sup conditions (2.16)–(2.17) with respect to suitable norms, by means of function space interpolation tools. In particular, we show that the method is quasi-optimal (see (3.37)) with respect to a norm whose part independent of ε is of differentiability-order 1/2, which is in accordance with [2], [5], and [13].

We are restricting this analysis to the one-dimensional problem because we are not able, at the present time, to deal with the anisotropic structure of the convection term from the numerical point of view; on the other hand, we will not exploit other special properties of the one-dimensional operator. We refer to section 4 for a discussion on further extensions of our approach.

The outline of the paper is as follows. In section 2, we present the notation and assumptions, recall the results of [13], and specialize and extend them to the one-dimensional case. In section 3, we develop the error analysis for the SUPG method in the present setting. Finally, in section 4, we give some comments about the results proved and outline possible extensions.

2. Preliminaries. We denote by $L^2 \equiv L^2(0,1)$ the usual Lebesgue space endowed with the norm $\|\cdot\|_{L^2}$, by $L^2_0 \equiv L^2_0(0,1)$ its subset containing zero mean-value functions, and by $\Pi_0 : L^2 \to L^2_0$ the L^2-projection onto L^2_0; we also denote by $\overline{w}$ the mean value of a generic function $w \in L^2$ so that $w = \Pi_0 w + \overline{w}$. Moreover, $H^1 \equiv H^1(0,1)$ is the usual Sobolev space endowed with the norm $\|\cdot\|_{H^1}$, and seminorm $|\cdot|_{H^1}$; $H^1_{\#}$ denotes its subspace of functions w such that $w(0) = w(1)$, while H^1_0 denotes the subspace of functions vanishing at 0 and 1, endowed with the norm $|\cdot|_{H^1}$. Finally, $H^{-1} \equiv H^{-1}(0,1) := (H^1_0)^*$ denotes the dual space of H^1_0 endowed with the dual norm $\|\cdot\|_{H^{-1}}$ and the usual pairing $\langle\cdot,\cdot\rangle \equiv {}_{H^{-1}}\langle\cdot,\cdot\rangle_{H^1_0}$; the dual (norm, space) is always denoted by the superscripted star. We shall make use of the interpolation theory of function spaces; more specifically, we shall use the *K-method*, and we refer to [15] for its definition, notation, and properties.

In what follows, C denotes a generic constant whose value, possibly different at various occurrences, does not depend on any other mathematical quantity appearing in the analysis (e.g., ε, θ, p, h, u, w, f, ϕ). We also adopt the notational convention

$$\begin{aligned} \alpha \preceq \beta \quad &\iff \quad \alpha \le C\beta, \\ \alpha \simeq \beta \quad &\iff \quad \alpha \preceq \beta \text{ and } \beta \preceq \alpha. \end{aligned}$$

We now revise the analysis proposed in [13] and specialize it to the one-dimensional case. Following [13], we define

$$\begin{aligned} \|w\|_{A_0} &:= \varepsilon|w|_{H^1} + \|\Pi_0 w\|_{L^2} \qquad && \forall w \in A_0 := H^1_0, \\ \|w\|_{A_1} &:= |w|_{H^1} && \forall w \in A_1 := H^1_0, \end{aligned} \tag{2.1}$$

where we have used $\|\Pi_0 w\|_{L^2}$ instead of the equivalent norm $\|w'\|_{H^{-1}}$. Therefore, one has the equivalence between $\|w\|_{A_0}$ and $\|\mathcal{L}_\varepsilon w\|_{A_1^*}$; i.e.,

$$\varepsilon|w|_{H^1} + \|\Pi_0 w\|_{L^2} \simeq \sup_{v \in H^1_0} \frac{a_\varepsilon(w,v)}{|v|_{H^1}} \quad \forall w \in H^1_0. \tag{2.2}$$

One half of (2.2)—the continuity of $\mathcal{L}_\varepsilon$—is obvious, while the other half actually follows from the coercivity $\varepsilon|w|^2_{H^1} \preceq a_\varepsilon(w,w)$. By means of a duality argument, we obtain from (2.2) the other estimate

$$|w|_{H^1} \simeq \sup_{v \in H^1_0} \frac{a_\varepsilon(w,v)}{\varepsilon|v|_{H^1} + \|\Pi_0 v\|_{L^2}} \quad \forall w \in H^1_0; \tag{2.3}$$

i.e., $\|w\|_{A_1}$ and $\|\mathcal{L}_\varepsilon w\|_{A_0^*}$ are equivalent.

Both (2.2) and (2.3) state that $\mathcal{L}_\varepsilon$ is an isomorphism uniformly with respect to ε; the dependence on ε of the operator has been included in the norms themselves.

We briefly comment on (2.3): it allows control of the H^1_0 norm of the solution u of (1.2) in terms of the source term f, despite the presence of the boundary layer near $x = 1$. It is due to the structure of $\|\cdot\|_{A_0^*}$; when $f \in L^2_0$, then $\|f\|_{A_0^*} \le \|f\|_{L^2}$, and actually there is no boundary layer; otherwise, if $f \in L^2$ has a nonzero mean value, then $\|f\|_{A_0^*}$ behaves asymptotically as $\varepsilon^{-1/2}$ for $\varepsilon \to 0$, and accordingly, the presence of a thin layer on the related solution u makes $|u|_{H^1}$ behave in the same way.

We can infer from (2.2)–(2.3) a family of intermediate estimates: given θ and p with $0 < \theta < 1$, $1 \leq p \leq +\infty$, and denoting by p' the conjugate of p, i.e., $1/p + 1/p' = 1$, by means of the interpolation theory we have (see [13])

$$\varepsilon^{1-\theta}|w|_{H^1} + \|w'\|_{(H^{-1},L_0^2)_{\theta,p}} \simeq \sup_{v\in H_0^1} \frac{a_\varepsilon(w,v)}{\varepsilon^{\theta}|v|_{H^1} + \|v'\|_{(H^{-1},L_0^2)_{1-\theta,p'}}} \quad \forall w \in H_0^1, \tag{2.4}$$

where we have also made use of the equivalence

$$\|w\|_{(A_0,A_1)_{\theta,p}} \simeq \varepsilon^{1-\theta}|w|_{H^1} + \|w'\|_{(H^{-1},L_0^2)_{\theta,p}}, \tag{2.5}$$

that is, the one-dimensional counterpart of [13, Proposition 2]. Condition (2.4) brings our model problem into the framework (1.4)–(1.5).

We also proved the Poincaré-like estimate

$$\|w\|_{L^2} \preceq \|w'\|_{(H^{-1},L_0^2)_{1/2,1}} \qquad \forall w \in H_0^1 \tag{2.6}$$

and, as a consequence,

$$\|w\|_{L^2} \preceq \|w\|_{(A_0,A_1)_{\theta,p}} \, \forall w \in H_0^1 \quad \Leftrightarrow \quad \theta > 1/2 \text{ or } (\theta,p) = (1/2,1), \tag{2.7}$$

$$\|\phi\|_{(A_0,A_1)_{\theta,p}^*} \preceq \|\phi\|_{L^2} \, \forall \phi \in H^{-1} \quad \Leftrightarrow \quad \theta > 1/2 \text{ or } (\theta,p) = (1/2,1). \tag{2.8}$$

Finally, we show the relation between the fractional-order norm appearing in the equivalence (2.4) and a more usual Besov norm. We focus our attention on the case $\theta = 1/2$, which will be of special interest in what follows; the case of a generic θ is similar but more technical (in order to obtain the optimal dependence on θ).

Proposition 2.1. *For $1 \leq p \leq +\infty$, we have*

$$(L^2, H^1_\#)_{1/2,p} = \{w \in L^2 | w' \in (H^{-1}, L_0^2)_{1/2,p}\}$$

and also

$$\|w\|_{(L^2,H^1_\#)_{1/2,p}} \simeq \|w\|_{L^2} + \|w'\|_{(H^{-1},L_0^2)_{1/2,p}} \tag{2.9}$$

for any $w \in (L^2, H^1_\#)_{1/2,p}$.

Proof. Let w be a generic function in L^2 and $p \neq +\infty$; we have, by definition and by the triangle inequality,

$$\begin{aligned}
\|w\|_{(L^2,H^1_\#)_{1/2,p}} &\leq \left[\int_0^{+\infty} \left(t^{-1/2}\|w_0(t)\|_{L^2} + t^{1/2}\|w_1(t)\|_{H^1}\right)^p \frac{dt}{t}\right]^{1/p} \\
&\leq \left[\int_0^{1} \left(t^{-1/2}\|w_0(t)\|_{L^2} + t^{1/2}\|w_1(t)\|_{H^1}\right)^p \frac{dt}{t}\right]^{1/p} \\
&\quad + \left[\int_1^{+\infty} \left(t^{-1/2}\|w_0(t)\|_{L^2} + t^{1/2}\|w_1(t)\|_{H^1}\right)^p \frac{dt}{t}\right]^{1/p} \\
&= \mathrm{I} + \mathrm{II}
\end{aligned}$$

for any $w_0(t)$ and $w_1(t)$ with $w = w_0(t) + w_1(t)$, $w_0(t) \in L^2$, $w_1(t) \in H^1_\#$, and $0 < t < +\infty$; I and II actually depend on $w_0(t)$ and $w_1(t)$. Moreover, we assume, for $0 < t < 1$, that $w_0(t) \in L^2_0$, yielding $\|w_0(t)\|_{L^2} = \|w_0'(t)\|_{H^{-1}}$. Recalling the notation $w_1(t) = \overline{w_1(t)} + \Pi_0 w_1(t)$, where $\overline{w_1(t)} = \overline{w}$, we use the continuity of the mean value in L^2 for $\overline{w}$ and the Bramble–Hilbert lemma for $\Pi_0 w_1(t)$ to get

$$\begin{aligned}\|w_1(t)\|_{H^1} &\le \|\overline{w_1(t)}\|_{H^1} + \|\Pi_0 w_1(t)\|_{H^1}\\ &\preceq \|\overline{w_1(t)}\|_{L^2} + |\Pi_0 w_1(t)|_{H^1}\\ &\preceq \|w\|_{L^2} + \|w_1'(t)\|_{L^2}.\end{aligned}$$

Therefore, we have

$$\begin{aligned}\mathrm{I} &\le \left[\int_0^1 \left(t^{-1/2}\|w_0'(t)\|_{H^{-1}} + t^{1/2}\|w_1'(t)\|_{L^2}\right)^p \frac{dt}{t}\right]^{1/p}\\ &\quad + \left[\int_0^1 \left(t^{1/2}\|w\|_{L^2}\right)^p \frac{dt}{t}\right]^{1/p}\\ &\preceq \left[\int_0^1 \left(t^{-1/2}\|w_0'(t)\|_{H^{-1}} + t^{1/2}\|w_1'(t)\|_{L^2}\right)^p \frac{dt}{t}\right]^{1/p} + \|w\|_{L^2}.\end{aligned} \tag{2.10}$$

Now the key point is that, for any decomposition $w' = \phi_0(t) + \phi_1(t)$, $\phi_0(t) \in H^{-1}$, $\phi_1(t) \in L^2_0$ on $0 < t < 1$, we can define $w_0(t)$ and $w_1(t)$ that satisfy $w_0'(t) = \phi_0(t)$, $w_1'(t) = \phi_1(t)$, and all the conditions given above: simply take, for any $0 < t < 1$, $w_1(t)$ as the primitive of $\phi_1(t)$ with $\overline{w_1(t)} = \overline{w}$ and $w_0(t) = w - w_1(t)$. In particular, $\phi_1(t) \in L^2_0$ yields $w_1(t) \in H^1_\#$. Therefore, we can rewrite (2.10) in terms of $\phi_0(t)$ and $\phi_1(t)$,

$$\mathrm{I} \preceq \left[\int_0^1 \left(t^{-1/2}\|\phi_0(t)\|_{H^{-1}} + t^{1/2}\|\phi_1(t)\|_{L^2}\right)^p \frac{dt}{t}\right]^{1/p} + \|w\|_{L^2}, \tag{2.11}$$

and take the infimum with respect to $\phi_0(t)$ and $\phi_1(t)$, obtaining

$$\mathrm{I} \preceq \|w'\|_{(H^{-1},L^2_0)_{1/2,p}} + \|w\|_{L^2}. \tag{2.12}$$

Otherwise, taking $w_0(t) = w$ and $w_1(t) = 0$ for $1 < t < +\infty$, we have

$$\begin{aligned}\mathrm{II} &\le \left[\int_1^{+\infty} \left(t^{-1/2}\|w\|_{L^2}\right)^p \frac{dt}{t}\right]^{1/p}\\ &\le \frac{2}{p}\|w\|_{L^2}.\end{aligned} \tag{2.13}$$

Therefore, (2.12) and (2.13) yield $\|w\|_{(L^2,H^1_\#)_{1/2,p}} \preceq \|w\|_{L^2} + \|w'\|_{(H^{-1},L^2_0)_{1/2,p}}$ and the inclusion $\{w \in L^2 | w' \in (H^{-1}, L^2_0)_{1/2,p}\} \subset (L^2, H^1_\#)_{1/2,p}$. With obvious modification, one could deal with the case $p = +\infty$.

The remaining part, i.e., the inclusion

$$(L^2, H^1_\#)_{1/2,p} \subset \left\{w \in L^2 | w' \in (H^{-1}, L^2_0)_{1/2,p}\right\}$$

and the related estimate, is given by the interpolation theorem [15, section 1.3.3 (a)] since the derivative operator is both continuous from $H^1_\#$ into L^2_0 and from L^2 into H^{-1}. □

We recall that $(L^2, H^1_\#)_{1/2,p}$ is the space of functions whose periodic extension, say, on $(-1,2)$, belongs to $B^{1/2}_{2,p}(-1,2)$.

It is useful in what follows to notice that (2.6) and (2.9) give a variant of (2.5), as stated in the following corollary.

Corollary 2.2. *We have*

$$\|w\|_{(A_0,A_1)_{1/2,1}} \simeq \varepsilon^{1/2}|w|_{H^1} + \|w\|_{(L^2,H^1_\#)_{1/2,1}} \quad \forall w \in H^1_0. \tag{2.14}$$

Now we turn our attention to the numerical solution of (1.2). We briefly recall the general error estimation theory, due to Babuška and Brezzi (see [10, Proposition 5.5.1]). Let u be the solution of (1.2); the finite element formulation reads

$$\begin{cases} \text{find } u_h \in W_h \text{ such that} \\ a_{\varepsilon,h}(u_h, v_h) = \langle f_h, v_h\rangle \qquad \forall v_h \in V_h, \end{cases} \tag{2.15}$$

where the spaces W_h and V_h are finite-dimensional subsets of H^1_0, while $a_{\varepsilon,h}$ and f_h give a consistent discretization of the continuous problem, namely, $a_{\varepsilon,h}(u, v_h) = \langle f_h, v_h\rangle$ for all $v_h \in V_h$. If there exist constants $\widetilde{\kappa} < +\infty$ and $\widetilde{\gamma} > 0$, independent of ε and h, such that

$$a_{\varepsilon,h}(u - w_h, v_h) \le \widetilde{\kappa}\|u - w_h\|_{W,h}\|v_h\|_{V_h} \quad \forall w_h \in W_h, \forall v_h \in V_h, \tag{2.16}$$

and

$$\inf_{w_h\in W_h}\sup_{v_h\in V_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{\|w_h\|_{W,h}\|v_h\|_{V_h}} \ge \widetilde{\gamma}, \tag{2.17}$$

then the method is *quasi-optimal*:

$$\|u - u_h\|_{W,h} \le (\widetilde{\kappa}\widetilde{\gamma}^{-1} + 1)\inf_{w_h\in W_h}\|u - w_h\|_{W,h}. \tag{2.18}$$

The notation $\|\cdot\|_{W,h}$ refers to a norm on the space W (we postpone the definition of W to (3.20)), which can depend on the discretization. Conditions (2.16)–(2.17) are the analogues of (1.4)–(1.5), and this motivates our interest in (2.4). In order to verify them, we shall look for norms $\|\cdot\|_{W,h}$ and $\|\cdot\|_{V_h}$ that are the discrete counterparts of the ones in (2.4).

We shall consider the very simple case of a uniform subdivision of $(0,1)$ into N open elements T_i of size $h = N^{-1}$,

$$T_i \equiv T_{i,h} := \{x : (i-1)h < x < ih\} \qquad \forall i = 1, 2, \ldots, N, \tag{2.19}$$

and the corresponding space of continuous piecewise linear elements,

$$W_h \equiv V_h := \left\{ \begin{matrix} v \in H^1_0 : v|_{T_i} \text{ is affine} \\ \forall i = 1, \ldots, N \end{matrix} \right\}; \tag{2.20}$$

the SUPG method, proposed by Hughes and coworkers in [7], adds a *weighted residual stabilization* to the continuous variational problem:

$$\begin{aligned} a_{\varepsilon,h}(w, v_h) &:= a_\varepsilon(w, v_h) + \sum_{i=1}^{N} \tau \int_{T_i} (\mathcal{L}_\varepsilon w)(x)\, v_h'(x)\, dx \\ \langle f_h, v_h\rangle &:= \langle f, v_h\rangle + \sum_{i=1}^{N} \tau \int_{T_i} f(x)\, v_h'(x)\, dx. \end{aligned} \tag{2.21}$$

This definition requires both f and w to be regular in the interior of the elements, which is not restrictive for applications. The amount of *streamline*[1] *diffusion* τ is a parameter of the method, and its value is a relevant point. It could depend on ε and h; here we assume that the problem is advection-dominated, namely, $\varepsilon \leq h$, and therefore a usual assumption is that

$$\tau \simeq h. \tag{2.22}$$

We shall return to a more detailed discussion of the optimal value of τ in section 4.

3. Main results. This section is devoted to the error analysis of the SUPG method in the framework (2.16)–(2.18).

First, we analyze the inf-sup condition (2.17).

LEMMA 3.1. *The SUPG method* (2.19)–(2.22) *satisfies the estimates*

$$\varepsilon|w_h|_{H^1} + \|\Pi_0 w_h\|_{L^2} \preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{|v_h|_{H^1}} \quad \forall w_h \in W_h, \tag{3.1}$$

$$|w_h|_{H^1} \preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{\varepsilon|v_h|_{H^1} + \|\Pi_0 v_h\|_{L^2}} \quad \forall w_h \in W_h. \tag{3.2}$$

Proof. First, recall that any $w_h \in W_h$ is piecewise linear; therefore, the higher-order term in (2.21) vanishes:

$$a_{\varepsilon,h}(w_h, v_h) = (\varepsilon + \tau) \int_0^1 w_h'(x) v_h'(x)\, dx + \int_0^1 w_h'(x) v_h(x)\, dx \quad \forall v_h \in V_h.$$

Thanks to the coercivity of $a_{\varepsilon,h}$,

$$\varepsilon|w_h|_{H^1}^2 \leq a_{\varepsilon,h}(w_h, w_h), \tag{3.3}$$

we have immediately

$$\varepsilon|w_h|_{H^1} \preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{|v_h|_{H^1}}. \tag{3.4}$$

We have therefore to prove that

$$\|\Pi_0 w_h\|_{L^2} \preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{|v_h|_{H^1}}. \tag{3.5}$$

In order to do this, we shall define $\widetilde{w}_h \in W_h$, depending on w_h, such that

$$a_{\varepsilon,h}(w_h, \widetilde{w}_h) = \|\Pi_0 w_h\|_{L^2}^2, \tag{3.6}$$

$$|\widetilde{w}_h|_{H^1} \preceq \|\Pi_0 w_h\|_{L^2}; \tag{3.7}$$

such a $\widetilde{w}_h$ is the solution of the discrete variational problem

$$a_{\varepsilon,h}(v_h, \widetilde{w}_h) = \int_0^1 (\Pi_0 w_h)(x) v_h(x)\, dx \quad \forall v_h \in W_h. \tag{3.8}$$

[1] In the one-dimensional case, there are no *streamline directions*; we are just following the general terminology.

To verify (3.7), we define $\widetilde{w} \in H_0^1$ as the solution of

$$-(\varepsilon+\tau)\widetilde{w}'' - \widetilde{w}' = \Pi_0 w_h, \tag{3.9}$$

such that $a_{\varepsilon,h}(v_h, \widetilde{w}_h - \widetilde{w}) = 0$ for all $v_h \in W_h$; moreover, (3.9) has the same structure as (1.2), with $\varepsilon + \tau \simeq h$ instead of ε, so that we can make use of the analogue of (2.3):

$$\begin{aligned}
|\widetilde{w}|_{H^1} &\preceq \sup_{v \in H_0^1} \frac{(\varepsilon+\tau)\int_0^1 \widetilde{w}'(x)v'(x)\,dx \;-\int_0^1 \widetilde{w}'(x)v(x)\,dx}{(\varepsilon+\tau)|v|_{H^1} + \|\Pi_0 v\|_{L^2}} \\
&= \sup_{v \in H_0^1} \frac{\int_0^1 \Pi_0 w_h(x)v(x)\,dx}{(\varepsilon+\tau)|v|_{H^1} + \|\Pi_0 v\|_{L^2}} \\
&\leq \sup_{v \in H_0^1} \frac{\int_0^1 \Pi_0 w_h(x)v(x)\,dx}{\|\Pi_0 v\|_{L^2}} \\
&= \sup_{v \in H_0^1} \frac{\int_0^1 \Pi_0 w_h(x)\Pi_0 v(x)\,dx}{\|\Pi_0 v\|_{L^2}} \\
&= \|\Pi_0 w_h\|_{L^2}.
\end{aligned} \tag{3.10}$$

We also need to introduce the nodal interpolant $\widetilde{w}_I \in W_h$ of $\widetilde{w}$, which satisfies

$$|\widetilde{w} - \widetilde{w}_I|_{H^1} + h^{-1}\|\widetilde{w} - \widetilde{w}_I\|_{L^2} \preceq |\widetilde{w}|_{H^1}. \tag{3.11}$$

Therefore, we have, by using the coercivity of $a_{\varepsilon,h}$, (3.8), (3.9), and (3.11),

$$\begin{aligned}
|\widetilde{w} - \widetilde{w}_h|_{H^1}^2 &= (\varepsilon+\tau)^{-1} a_{\varepsilon,h}(\widetilde{w} - \widetilde{w}_h, \widetilde{w} - \widetilde{w}_h) \\
&= (\varepsilon+\tau)^{-1} a_{\varepsilon,h}(\widetilde{w} - \widetilde{w}_I, \widetilde{w} - \widetilde{w}_h) \\
&\leq |\widetilde{w} - \widetilde{w}_h|_{H^1}\left[|\widetilde{w} - \widetilde{w}_I|_{H^1} + (\varepsilon+\tau)^{-1}\|\widetilde{w} - \widetilde{w}_I\|_{L^2}\right] \\
&\preceq |\widetilde{w} - \widetilde{w}_h|_{H^1}|\widetilde{w}|_{H^1},
\end{aligned}$$

which gives $|\widetilde{w} - \widetilde{w}_h|_{H^1} \preceq |\widetilde{w}|_{H^1}$, and then, by using (3.10),

$$\begin{aligned}
|\widetilde{w}_h|_{H^1} &\leq |\widetilde{w}|_{H^1} + |\widetilde{w} - \widetilde{w}_h|_{H^1} \\
&\preceq |\widetilde{w}|_{H^1} \\
&\preceq \|\Pi_0 w_h\|_{L^2},
\end{aligned}$$

which gives (3.7); (3.6) follows immediately from (3.8), and (3.1) is satisfied.

We obtain (3.2) from (3.1) by a duality argument. We now associate to a generic $w_h \in W_h$ the function $\widetilde{w}_h \in W_h$, which satisfies

$$a_{\varepsilon,h}(v_h, \widetilde{w}_h) = \int_0^1 w_h'(x)v_h'(x)\,dx \quad \forall v_h \in W_h. \tag{3.12}$$

The left-hand side of (3.12) is the dual of $a_{\varepsilon,h}(\widetilde{w}_h, v_h)$. We can proceed as before to obtain the analogue of (3.1); in particular,

$$\begin{aligned}
\varepsilon|\widetilde{w}_h|_{H^1} + \|\Pi_0 \widetilde{w}_h\|_{L^2} &\preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(v_h, \widetilde{w}_h)}{|v_h|_{H^1}} \\
&= \sup_{v_h \in W_h} \frac{\int_0^1 w_h'(x)v_h'(x)\,dx}{|v_h|_{H^1}} \\
&= |w_h|_{H^1};
\end{aligned}$$

then

$$\begin{aligned} |w_h|_{H^1} &= \frac{\int_0^1 w_h'(x) w_h'(x)\,dx}{|w_h|_{H^1}} \\ &= \frac{a_{\varepsilon,h}(w_h, \widetilde{w}_h)}{|w_h|_{H^1}} \\ &\preceq \frac{a_{\varepsilon,h}(w_h, \widetilde{w}_h)}{\varepsilon |\widetilde{w}_h|_{H^1} + \|\Pi_0 \widetilde{w}_h\|_{L^2}}, \end{aligned}$$

which gives (3.2). □

The estimates (3.1)–(3.2) state inf-sup conditions with respect to the same norms as in (2.2)–(2.3). Focusing on (3.1), for example, we see that one could replace $\varepsilon|w_h|_{H^1}$ on the left-hand side with $(\varepsilon+\tau)|w_h|_{H^1}$, as it seems natural from (3.3)–(3.4). Actually this leads to an equivalent estimate at the discrete level because of the inverse inequality $(\varepsilon+\tau)|w_h|_{H^1} \preceq \|\Pi_0 w_h\|_{L^2}$. On the other hand, in order to obtain in what follows a meaningful error estimate (2.18), our aim here is to make use of the "natural" norms (for the continuous problem).

Let us now define the discrete counterpart of (2.1):

$$\begin{aligned} &\|w_h\|_{A_{0,h}} := \varepsilon |w_h|_{H^1} + \|\Pi_0 w_h\|_{L^2} \qquad \forall w_h \in A_{0,h} := W_h, \\ &\|w_h\|_{A_{1,h}} := |w_h|_{H^1} \qquad \forall w_h \in A_{1,h} := W_h. \end{aligned} \tag{3.13}$$

We construct from (3.1)–(3.2) a family of intermediate inf-sup conditions by means of function space interpolation.

PROPOSITION 3.2. *Let $0<\theta<1$ and $1 \le p \le +\infty$. The one-dimensional SUPG method* (2.19)–(2.22) *satisfies the estimates*

$$\|w_h\|_{(A_{0,h},A_{1,h})_{\theta,p}} \preceq \sup_{v_h \in W_h} \frac{a_{\varepsilon,h}(w_h, v_h)}{\|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}}} \quad \forall w_h \in W_h, \tag{3.14}$$

where $1/p + 1/p' = 1$.

Proof. The bilinear form $a_{\varepsilon,h} : W_h \times W_h \to \mathbb{R}$ induces the linear operator $\mathcal{L}_{\varepsilon,h} : W_h \to W_h^*$ in the usual way,

$$_{W_h^*}\langle \mathcal{L}_{\varepsilon,h} w_h, v_h \rangle_{W_h} := a_{\varepsilon,h}(w_h, v_h) \quad \forall w_h, v_h \in W_h,$$

which turns out to be invertible, thanks to (3.1)–(3.2); in particular,

$$\|\mathcal{L}_{\varepsilon,h}^{-1} \phi_h\|_{A_{0,h}} \preceq \|\phi_h\|_{A_{1,h}^*}, \tag{3.15}$$

$$\|\mathcal{L}_{\varepsilon,h}^{-1} \phi_h\|_{A_{1,h}} \preceq \|\phi_h\|_{A_{0,h}^*} \tag{3.16}$$

for any $\phi_h \in W_h^*$. Therefore, by means of interpolation (see [15, section 1.3.3 (a)]), we obtain

$$\|\mathcal{L}_{\varepsilon,h}^{-1} \phi_h\|_{(A_{0,h},A_{1,h})_{\theta,p}} \preceq \|\phi_h\|_{(A_{1,h}^*,A_{0,h}^*)_{\theta,p}}. \tag{3.17}$$

By means of [15, section 1.11.2], we also have that the norm on $(A_{1,h}^*, A_{0,h}^*)_{\theta,p}$ is actually equivalent to the dual norm on $(A_{1,h}, A_{0,h})_{\theta,p'} \equiv (A_{0,h}, A_{1,h})_{1-\theta,p'}$; notice in particular that, for the case $p=1$ and $p'=+\infty$, the mentioned result follows because $(A_{1,h}, A_{0,h})_{\theta,+\infty} \equiv (A_{1,h}, A_{0,h})^0_{\theta,+\infty}$ in the algebraic sense. Actually, from the algebraic point of view $A_{0,h} \equiv A_{1,h} \equiv V_h$, we are just defining norms that have a different dependence on the parameter ε. Finally,

$$\|w_h\|_{(A_{0,h},A_{1,h})_{\theta,p}} \preceq \|\mathcal{L}_{\varepsilon,h} w_h\|_{(A_{0,h},A_{1,h})^*_{1-\theta,p}}, \tag{3.18}$$

which is just (3.14). □

Now we turn our attention to the continuity of $a_{\varepsilon,h}$ (i.e., estimate (2.16)), which is, contrary to expectation, the most difficult point. For the sake of clarity, we write $a_{\varepsilon,h}(\cdot,\cdot) = a_\varepsilon(\cdot,\cdot) + s(\cdot,\cdot) + c(\cdot,\cdot)$, where $s : H^1_0 \times H^1_0 \to \mathbb{R}$ denotes the stabilizing term

$$s(w,v) := \tau \int_0^1 w'(x)\, v'(x)\, dx, \tag{3.19}$$

while the term $c(\cdot,\cdot)$ makes the numerical formulation consistent. For the definition of $c(\cdot,\cdot)$, we need the trial functions w to be regular inside any element. Therefore, we set

$$W := \left\{ w \in H^1_0 | w''_{|T_i} \in L^2(T_i),\ i = 1, \dots, N \right\}, \tag{3.20}$$

equipped with the graph norm, and we define $c : W \times H^1_0 \to \mathbb{R}$ as

$$c(w,v) = -\tau\varepsilon \sum_{i=1}^{N} \int_{T_i} w''(x)\, v'(x)\, dx. \tag{3.21}$$

First, we consider $a_\varepsilon(\cdot,\cdot)$.

LEMMA 3.3. *Assume* $0 < \theta < 1$, $1 \le p \le +\infty$, *and* $1/p + 1/p' = 1$*; we have*

$$a_\varepsilon(w, v_h) \preceq \|w\|_{(A_0,A_1)_{\theta,p}} \|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}} \quad \forall w \in H^1_0, \forall v_h \in W_h. \tag{3.22}$$

Proof. Let $\widetilde{\mathcal{L}}_\varepsilon : H^1_0 \to W^*_h$ be the linear operator given by

$$_{W^*_h}\langle \widetilde{\mathcal{L}}_\varepsilon w, v_h \rangle_{W_h} := a_\varepsilon(w, v_h) \quad \forall w \in H^1_0, \forall v_h \in W_h.$$

(Notice that it differs from $\mathcal{L}_\varepsilon$ because we are now considering discrete test functions.) The Cauchy–Schwarz inequality gives, for any $w \in H^1_0$,

$$\|\widetilde{\mathcal{L}}_\varepsilon w\|_{A^*_{1,h}} \preceq \|w\|_{A_0}$$

and

$$\|\widetilde{\mathcal{L}}_\varepsilon w\|_{A^*_{0,h}} \preceq \|w\|_{A_1};$$

therefore, proceeding as in the proof of Lemma 3.2, we obtain

$$\|\widetilde{\mathcal{L}}_\varepsilon w\|_{(A_{1,h},A_{0,h})^*_{\theta,p}} \preceq \|w\|_{(A_0,A_1)_{\theta,p}},$$

which is (3.22). □

We need the following inverse inequalities for the forthcoming analysis.

LEMMA 3.4. *We have*

$$h\|v'_h\|_{L^2} \preceq \|v'_h\|_{H^{-1}} \quad \forall v_h \in W_h. \tag{3.23}$$

Proof. Actually, (3.23) follows from $\|v_h'\|_{L^2} = \|(\Pi_0 v_h)'\|_{L^2}$, $\|v_h'\|_{H^{-1}} = \|\Pi_0 v_h\|_{L^2}$, and from the more usual inverse inequality $h\|(\Pi_0 v_h)'\|_{L^2} \preceq \|\Pi_0 v_h\|_{L^2}$. □

LEMMA 3.5. *We have*

$$h\|v_h'\|_{(L^2,H_0^1)_{1/2,+\infty}} \preceq \|v_h'\|_{(H^{-1},L^2)_{1/2,+\infty}} \quad \forall v_h \in W_h. \tag{3.24}$$

Proof. We shall show that

$$h\|v_h'\|_{(L^2,H_0^1)_{1/2,+\infty}} \preceq h^{1/2}\|v_h'\|_{L^2} \quad \forall v_h \in W_h, \tag{3.25}$$

$$h\|v_h'\|_{(L^2,H_0^1)_{1/2,+\infty}} \preceq h^{-1/2}\|v_h'\|_{H^{-1}} \quad \forall v_h \in W_h, \tag{3.26}$$

which give (3.24) by means of the interpolation theorem [15, section 1.3.3 (a)]. We focus only on (3.25), as (3.26) follows from (3.25) and (3.23).

We have, by definition,

$$\|v_h'\|_{(L^2,H_0^1)_{1/2,+\infty}} \leq \sup_{0<t<+\infty} \left(t^{-1/2}\|\phi_0(t)\|_{L^2} + t^{1/2}\|\phi_1(t)\|_{H^1} \right) \tag{3.27}$$

for any $\phi_0(t)$ and $\phi_1(t)$ with $v_h' = \phi_0(t) + \phi_1(t)$, $\phi_0(t) \in L^2$, $\phi_1(t) \in H_0^1$, and $0 < t < +\infty$. We now choose suitable $\phi_0(t)$ and $\phi_1(t)$. If $t > h$, it suffices to take $\phi_0(t) = v_h'$ and, accordingly, $\phi_1(t) = 0$ to obtain

$$t^{-1/2}\|\phi_0(t)\|_{L^2} + t^{1/2}\|\phi_1(t)\|_{H^1} \leq h^{-1/2}\|v_h'\|_{L^2} \quad \forall v_h \in W_h. \tag{$t > h$ case}$$

Otherwise, when $t \leq h$, set $\delta \equiv \delta(t,x) := \min\{x, 1-x, t/2\}$ and

$$\phi_1(t)(x) := t^{-1} \int_{x-\delta}^{x+\delta} v_h'(\xi)\, d\xi;$$

the effect of this definition is shown in Figure 3.1. As a result, one has

$$t^{-1/2}\|\phi_0(t)\|_{L^2} + t^{1/2}\|\phi_1(t)\|_{H^1} \preceq \left[\sum_{i=0}^{N} \left(v_h'|_{T_{i+1}} - v_h'|_{T_i} \right)^2 \right]^{1/2},$$

where $v_h'|_{T_0} = v_h'|_{T_{N+1}} := 0$ by convention, and

$$\begin{aligned} \sum_{i=0}^{N} \left(v_h'|_{T_{i+1}} - v_h'|_{T_i} \right)^2 &\preceq \sum_{i=0}^{N} \left(v_h'|_{T_i} \right)^2 \\ &= h^{-1}\|v_h'\|_{L^2}^2; \end{aligned}$$

therefore,

$$t^{-1/2}\|\phi_0(t)\|_{L^2} + t^{1/2}\|\phi_1(t)\|_{H^1} \preceq h^{-1/2}\|v_h'\|_{L^2} \quad \forall v_h \in W_h. \tag{$t \leq h$ case}$$

Collecting the ($t > h$ case) and ($t \leq h$ case) with (3.27), we obtain (3.25). □

LEMMA 3.6. *Assume* $1/2 < \theta < 1$ *and* $1 \leq p \leq +\infty$ *or* $\theta = 1/2$ *and* $p = 1$*; we have*

$$s(w, v_h) \preceq \|w\|_{(A_0,A_1)_{\theta,p}} \|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}} \quad \forall w \in H_0^1, \forall v_h \in W_h, \tag{3.28}$$

where $1/p + 1/p' = 1$.

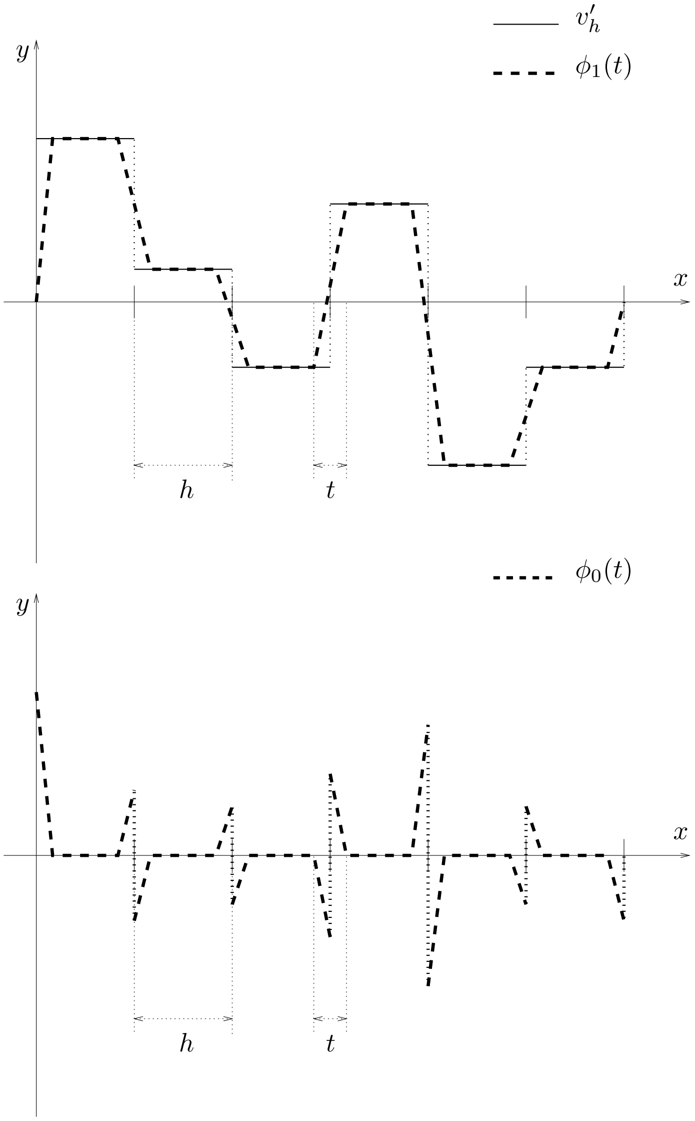

FIG. 3.1. *Construction of $\phi_0(t)$ and $\phi_1(t)$ inside the proof of Lemma* 3.5.

Proof. Let $w \in H_0^1$ and $v_h \in W_h$. Assume for a moment that the estimates

$$s(w, v_h) \preceq \|w'\|_{(H^{-1},L_0^2)_{1/2,1}} \|v_h'\|_{(H^{-1},L_0^2)_{1/2,+\infty}}, \tag{3.29}$$

$$s(w, v_h) \preceq \|w'\|_{L^2} \|v_h'\|_{H^{-1}} \tag{3.30}$$

hold true. Therefore, recalling (2.5) and as $\|v_h\|_{(A_0,A_1)_{1/2,+\infty}} \leq \|v_h\|_{(A_{0,h},A_{1,h})_{1/2,+\infty}}$, we also have

$$s(w, v_h) \preceq \|w\|_{(A_0,A_1)_{1/2,1}} \|v_h\|_{(A_{0,h},A_{1,h})_{1/2,+\infty}},$$
$$s(w, v_h) \preceq \|w\|_{A_1} \|v_h\|_{A_{0,h}},$$

and we can apply a new interpolation, with parameters $0 < \eta < 1$ and $1 \leq q \leq +\infty$, reasoning as in the proof of Lemma 3.3, in order to obtain

$$s(w,v_h) \preceq \|w\|_{((A_0,A_1)_{1/2,1},A_1)_{\eta,q}} \|v_h\|_{((A_{0,h},A_{1,h})_{1/2,+\infty},A_{0,h})_{\eta,q'}},$$

where $1/q + 1/q' = 1$. This gives (3.28), thanks to the reiteration theorem (see [15, section 1.10.2]), with $\theta = 1/2 + \eta/2$ and $p = q$.

First, let us focus on (3.30): it follows from the Cauchy–Schwarz inequality, Lemma 3.4, and (2.22).

Now we focus on (3.29). The Cauchy–Schwarz inequality yields

$$s(w,v_h) \preceq \|w'\|_{(H^{-1},L^2)_{1/2,1}} \|\tau v_h'\|_{(H^{-1},L^2)^*_{1/2,1}}, \tag{3.31}$$

and, of course, we have

$$\|w'\|_{(H^{-1},L^2)_{1/2,1}} \leq \|w'\|_{(H^{-1},L^2_0)_{1/2,1}}; \tag{3.32}$$

on the other hand, thanks to [15, section 1.11.2], (2.22), and Lemma 3.5, we also have

$$\begin{aligned} \|\tau v_h'\|_{(H^{-1},L^2)^*_{1/2,1}} &\preceq \|\tau v_h'\|_{(L^2,H^1_0)_{1/2,+\infty}} \\ &\preceq \|v_h'\|_{(H^{-1},L^2)_{1/2,+\infty}} \\ &\preceq \|v_h'\|_{(H^{-1},L^2_0)_{1/2,+\infty}}. \end{aligned} \tag{3.33}$$

Finally, (3.31)–(3.33) give (3.29). □

It is worth noting that the stabilizing term $s(\cdot,\cdot)$ is continuous, with respect to the norms $\|\cdot\|_{(A_0,A_1)_{\theta,p}}$ and $\|\cdot\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}}$, for any values of θ and p; nevertheless the uniformity with respect to ε requires the restrictions stated in Lemma 3.6. In this sense, these restrictions are optimal: notice that the norms in the left-hand side of (3.24) cannot be replaced by stronger norms since v_h' is discontinuous.

In order to deal with $c(\cdot,\cdot)$, we define an ad hoc seminorm:

$$|||\phi|||_{\theta-1,p} = \sup_{v_h \in W_h} \frac{\sum_{i=1}^{N} \tau \int_{T_i} \phi(x)\, v_h'(x)\, dx}{\|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}}}. \tag{3.34}$$

The continuity of $c(\cdot,\cdot)$ follows immediately.

LEMMA 3.7. *Assume* $0 < \theta < 1$, $1 \leq p \leq +\infty$, *and* $1/p + 1/p' = 1$*; we have*

$$c(w,v_h) \preceq \varepsilon |||w''|||_{\theta-1,p} \|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}}. \tag{3.35}$$

The framework is complete, and we can now state our main result.

THEOREM 3.8. *Assume that* $f \in L^2$, $1/2 < \theta < 1$, *and* $1 \leq p \leq +\infty$ *or* $\theta = 1/2$ *and* $p = 1$. *The one-dimensional SUPG method* (2.19)–(2.22) *satisfies the classical continuity and* inf-sup *conditions* (2.16)–(2.17) *with respect to the norms*

$$\begin{aligned} \|w\|_{W,h} &:= \|w\|_{(A_0,A_1)_{\theta,p}} + \varepsilon |||w''|||_{\theta-1,p}, \\ \|v_h\|_{V_h} &:= \|v_h\|_{(A_{0,h},A_{1,h})_{1-\theta,p'}}. \end{aligned}$$

Proof. The continuity (2.16) follows from Lemmas 3.3, 3.6, and 3.7. Moreover, since $\|w_h\|_{(A_0,A_1)_{\theta,p}} \leq \|w_h\|_{(A_{0,h},A_{1,h})_{\theta,p}}$ and $\varepsilon |||w_h''|||_{\theta-1,p} = 0$ for all $v_h \in W_h$, we get

$$\|w\|_{W,h} \leq \|w\|_{(A_{0,h},A_{1,h})_{\theta,p}}, \tag{3.36}$$

whence the inf-sup condition (2.17) follows from Proposition 3.2 and (3.36). □

As a result, we can state the *quasi optimality* (2.18) of the one-dimensional SUPG method with respect to the norm $\|\cdot\|_{W,h}$ (for $1/2<\theta<1$ or $\theta=1/2$ and $p=1$); the most interesting case is for $\theta=1/2$. Thanks to (2.6) and (2.9), we can state the following result.

COROLLARY 3.9. *Assume that $f\in L^2$; let u be the solution of* (1.2) *and u_h be the numerical solution given by the one-dimensional SUPG method* (2.19)–(2.22). *Then*

$$\begin{aligned}&\varepsilon^{1/2}|u-u_h|_{H^1}+\|u-u_h\|_{(L^2,H^1_{\#})_{1/2,1}}+\varepsilon|\!|\!|(u-u_h)''|\!|\!|_{-1/2,1}\\&\quad\preceq\inf_{w_h\in V_h}\left[\varepsilon^{1/2}|u-w_h|_{H^1}+\|u-w_h\|_{(L^2,H^1_{\#})_{1/2,1}}+\varepsilon|\!|\!|(u-w_h)''|\!|\!|_{-1/2,1}\right].\end{aligned}\tag{3.37}$$

Estimate (3.37) is interesting because the norm appearing there is "natural" for the problem, in the sense that $\varepsilon^{1/2}|u|_{H^1}+\|u\|_{(L^2,H^1_{\#})_{1/2,1}}+\varepsilon|\!|\!|u''|\!|\!|_{-1/2,1}$ does not grow as a negative power of ε when $\varepsilon\to0$. Actually, it is not uniformly bounded with respect to ε but behaves as $\log(\varepsilon)$ in the worst case. Indeed, we have

$$\begin{aligned}\sum_{i=1}^N\tau\int_{T_i}\varepsilon u''(x)\,v_h'(x)\,dx&=+\sum_{i=1}^N\tau\int_{T_i}u'(x)\,v_h'(x)\,dx\\&\quad-\sum_{i=1}^N\tau\int_{T_i}f\,v_h'(x)\,dx\\&\preceq s(u,v_h)+\|f\|_{L^2}\|\tau v_h'\|_{L^2}.\end{aligned}\tag{3.38}$$

This, together with (3.28), (2.22), and (3.23), yields $\varepsilon|\!|\!|u''|\!|\!|_{-1/2,1}\preceq\|u\|_{(A_0,A_1)_{1/2,1}}+\|f\|_{L^2}$; then, thanks to (2.4), (2.5), (2.8), (2.14), and [13, equation (22)], we finally get

$$\varepsilon^{1/2}|u|_{H^1}+\|u\|_{(L^2,H^1_{\#})_{1/2,1}}+\varepsilon|\!|\!|u''|\!|\!|_{-1/2,1}\preceq(1+|\log\varepsilon|)\,\|f\|_{L^2}.\tag{3.39}$$

Usually, one can infer the convergence of the numerical method from an estimate like (2.18) (in particular, (3.37)). This is not the case here. We recall that we are interested in uniform convergence with respect to ε in the advection-dominated regime $\varepsilon<h$. In fact, since we are using piecewise linear elements, we easily see that $|\!|\!|(u-u_h)''|\!|\!|_{-1/2,1}=|\!|\!|u''|\!|\!|_{-1/2,1}$. Furthermore, $\varepsilon^{1/2}|u-u_h|_{H^1}$, as well as $\|u-u_h\|_{(L^2,H^1_{\#})_{1/2,1}}$, cannot vanish uniformly with respect to ε when $h\to0$. This is because the boundary layer cannot be captured within the discrete space W_h when $\varepsilon\ll h$. On the other hand, this is not surprising; convergence results are indeed obtained from estimates like (2.18) by assuming *extra* regularity on the solution u. In our case, this is not possible since, for example, $\|u\|_{(A_0,A_1)_{\theta,p}}$ is strongly dependent on ε for $\theta>1/2$.

4. Conclusion and further extensions.

In this paper, we proved the *quasi optimality* of the SUPG method for the one-dimensional advection-diffusion problem on a uniform grid. Actually, it is a very simple case. Most of our analysis is based on our previous work [13] and therefore is suitable for an extension to the multidimensional case; in other parts it depends on some special properties of the one-dimensional problem. We do not know at the moment whether the SUPG method preserves its quasi optimality in the two-dimensional case or whether a modification of the method is required for this purpose. We shall focus on possible extensions of the theory in further works.

We have assumed the amount of *streamline diffusion* (or, better, *artificial diffusion*) τ to be proportional to the *mesh size h*. It is well known that, from a practical point of view, the particular choice of τ is relevant for the accuracy of the method. Our analysis does not give any suggestion for this because, for the sake of simplicity, our final estimate implicitly contains generic constants whose dependence on τ is not investigated. This investigation is indeed a very technical task, but one could perform this kind of analysis by a computational procedure. This has been done in a previous work [14] (see, in particular, section 3 therein), where we perform a fine-tuning of τ based on a similar idea.

IDENTIFICATION OF A TEMPERATURE DEPENDENT HEAT CONDUCTIVITY FROM SINGLE BOUNDARY MEASUREMENTS[*]

PHILIPP KÜGLER[†]

Abstract. Considering the identification of a temperature dependent conductivity in a quasilinear elliptic heat equation from single boundary measurements, we proof uniqueness in dimensions $n \geq 2$. Taking noisy data into account, we apply Tikhonov regularization in order to overcome the instabilities. By using a problem-adapted adjoint, we give convergence rates under substantially weaker and more realistic conditions than required by the general theory. Our theory is supported by numerical tests.

Key words. nonlinear inverse problem, Tikhonov regularization, nonlinear direct problem

AMS subject classifications. 47A52, 35J60

1. Introduction.

The issue of parameter identification is to determine unknown parameters, appearing, e.g., in state equations, from indirect measurements related to the physical state. This inverse problem can be considered as a (mostly) nonlinear operator equation

$$F(q) = z, \tag{1.1}$$

where the forward operator F maps the parameter q onto the output z. As the physical state often cannot be observed exactly, one finds oneself in the situation of given noisy data z^δ instead of z. Now, as parameter identification problems are frequently ill-posed, the estimation of the parameter can be strongly influenced in a negative way by even only small data noise. Hence, for their stable numerical solution, some type of regularization is required. Regularization techniques replace the ill-posed problem by a family of neighboring well-posed problems, leading to a stable approximation of q, called the regularized solution. Probably the most frequently used approach is Tikhonov regularization, where the regularized solutions are sought as the minimizers of

$$q \to \|F(q) - z^\delta\|^2 + \beta \|q\|^2,$$

with some regularization parameter β.

A careful mathematical analysis of the regularization method is needed in order to give useful guidance, under which conditions it will perform well, and confidence in its numerical results. Since for ill-posed problems, convergence of any numerical algorithm can be arbitrarily slow [21], conditions for convergence rates are of special theoretical interest. They are also practically relevant as they tell us for which problems fast convergence of numerical algorithms can be expected. However, according to the general theory [4], such convergence rates can only be obtained under strong

source conditions of the type

$$\exists w \;\; q - q^* = F'(q)^* w, \tag{1.2}$$

where q^* is an a priori guess for q, and $F'(q)^*$ is the adjoint of the Fréchet-derivative of F evaluated at q. This general theory has been applied to various inverse problems including parameter identification; see [14], [4] for elliptic problems and integral equations and [19] for a parabolic equation. All these applications are for one-dimensional problems, since only there, the source condition (1.2) has a rather immediate explicit interpretation (usually requiring some additional smoothness and prescribed boundary behavior for $q^\dagger - q^*$). In [16], condition (1.2) was weakened based on ideas from [8] and then fully interpreted for the identification of a nonlinearity $q(u)$ from distributed measurements of u in arbitrary dimensions.

However, before taking data perturbations and convergence rates into account, one has to consider if the given data z at all contain enough information in order to identify the parameter q, i.e., if the mapping F from q onto z is injective. Often, a limit on the amount of available data is given by the setup of the experiment. Frequently (for example, in nondestructive testing), measurements cannot be done within the material Ω but only on (parts of) the boundary $\partial\Omega$, leading to data containing less information.

Considering the inverse conductivity problem, one is interested in finding the conductivity $q(x)$ in

$$\begin{aligned} -\nabla \cdot (q(x)\nabla u) &= 0 \text{ in } \Omega, \\ u &= g \text{ on } \partial\Omega, \end{aligned} \tag{1.3}$$

given the additional boundary data

$$q(x)\frac{\partial u}{\partial n} = h \text{ on } \Gamma, \tag{1.4}$$

with $\Gamma \subset \partial\Omega$. For this case of single boundary measurements, the unique identifiability is widely investigated for parameters

$$q = 1 + \chi(D), \quad \bar{D} \subset \Omega,$$

where χ is the characteristic function of an unknown domain. Several partial results are given (see, e.g., [1], [10], and [13]); nonetheless a general uniqueness result is still missing. Turning to inverse problems for nonlinear elliptic equations

$$-\Delta u + q(u) = 0 \text{ in } \Omega, \tag{1.5}$$

only local uniqueness results for (small) q are available if, in addition to the Dirichlet data g, Neumann data are prescribed on $\partial\Omega$. See [12] and the references given there.

In order to enhance the chances of identifiability, one often resorts to many boundary measurements: For any Dirichlet data g in (1.3), one is given Neumann data h; in other words, the results of all possible boundary measurements are known. Then the information to identify the parameter is contained in the so-called Dirichlet to Neumann map

$$\Lambda : g \to h. \tag{1.6}$$

Based on these multiple boundary measurements, the aim of impedance tomography is the reconstruction of the conductivity $q(x)$ or $q(x,u)$ in (1.3) within the human body or some material. For the linear case, i.e., $q = q(x)$, global uniqueness was proven in [24] for dimensions $n \geq 3$ and in [18] for two dimensions. The uniqueness result for the quasi-linear case $q = q(x, u)$ can be found in [23] for dimensions $n \geq 2$. There also, the anisotropic case, i.e., q is a matrix, is investigated.

We now specify the inverse problem we are looking at in this paper. Our goal is to identify the temperature dependent heat conductivity q in

$$-\nabla \cdot (q(u)\nabla u) = f \text{ in } \Omega \tag{1.7}$$

from only single boundary measurements of the temperature u. Note that not only the inverse but also the forward problem is nonlinear. We show that the parameter is uniquely identifiable on the temperature range as a function of one variable. Besides, further developments of our Tikhonov regularization analysis from [16] allow us to provide a fully interpretable weak source condition for the convergence rate of the regularized solutions.

In section 2, we briefly discuss the nonlinear direct problem (1.7) with mixed boundary conditions for u. For a positive parameter q of H^1-regularity, we guarantee the existence of a unique weak solution $u \in H^1(\Omega)$. Furthermore, we give an estimate of the temperature range governed by u in Ω, which is equivalent to the one-dimensional domain the parameter q lives on. Together with the temperature data on the boundary, the a priori unknown interval, on which the parameter can be recovered, can then be estimated.

In sections 3 and 4, we investigate the inverse problem. First we show that the parameter is uniquely determined by single boundary temperature measurements. From [23], the uniqueness follows only for the case of multiple measurements. Afterward, we give a stability analysis for Tikhonov regularization and prove convergence rates under much weaker assumptions than required in the general theory by taking advantage of a special adjoint approach. This kind of approach was first introduced in [8] for the identification of a space dependent heat conductivity $q(x)$ from distributed temperature measurements.

Section 5 contains a detailed interpretation of the source condition needed for the convergence rate proof both in two and three dimensions. This is different from [8], where a full interpretation could only be given in the one-dimensional case.

Section 6 sketches variants in the setup for the inverse problem. In section 7, we present results of numerical tests which support our theory.

2. The direct problem.

In many applications modelled by the heat equation, for example, in the context of steel production (see [11], [6], [7]), the heat conductivity q does not vary spatially but rather depends on the temperature u itself. Considering the stationary case, the heat distribution is described by the nonlinear elliptic equation

$$-\nabla \cdot (q(u)\nabla u) = f \text{ in } \Omega \tag{2.1}$$

with, e.g., the boundary conditions

$$q(u)\frac{\partial u}{\partial n} = h \text{ on } \Gamma_1 \tag{2.2}$$

and

$$u(x) = g \text{ on } \Gamma_2. \tag{2.3}$$

Here, Ω is an open bounded connected domain in R^n, $n \geq 2$, with boundary $\partial\Omega \in C^2$. We assume $\Gamma_2 \subset \partial\Omega$ to be connected and to have positive measure and set

$\Gamma_1 = \partial\Omega \backslash \Gamma_2$. f is a given heat source density, h is a given temperature flux, and g is a prescribed (boundary) temperature.

We set

$$V = \left\{ v \in H^1(\Omega) \mid v|_{\Gamma_2} = 0 \right\}$$

and assume—already with respect to the inverse problem—that

$$g \text{ is constant, } h \in C(\Gamma_1), \text{ and } f \in C(\Omega).$$

By the trace theorem we then get a $\tilde{g} \in H^1(\Omega)$ such that $\tilde{g}|_{\Gamma_2} = g$. Now, by integration by parts we derive the variational formulation for problems (2.1)–(2.3).

Find $u \in H^1(\Omega)$ such that

$$u - \tilde{g} \quad \in \quad V \tag{2.4}$$

and

$$\int_\Omega q(u) \nabla u \cdot \nabla v \; dx = \int_\Omega f(x) v \; dx + \int_{\Gamma_1} hv \; d\Gamma_1 \quad \text{for all } \; v \in V \tag{2.5}$$

hold. Under the assumption

$$q \in H^1(R) \; \text{ and } \; 0 < \alpha_1 \le q \le \alpha_2, \tag{2.6}$$

there exists a unique solution to the variational problem (2.5) in $H^1(\Omega)$. The proof—based on the continuous embedding $H^1(R) \subseteq C(R)$ and the theory of quasi-monotone operators—can, for example, be found in [22] (see Proposition 5.1 and the subsequent relaxation to quasi-monotone operators). Furthermore, there is an a priori estimate for the solution, i.e., there is a constant $C > 0$ depending only on α_2, h, f, and g, such that

$$\|u_q\|_{H^1(\Omega)} \le C, \tag{2.7}$$

where, in order to emphasize the fact that the solution u depends on the parameter q, we use the notation u_q or $u_q(x)$.

Note that u_q can also be considered as the weak solution of the linear equation

$$\begin{aligned} -\nabla \cdot (\tilde{q}(x) \nabla u) &= f \; \text{ in } \; \Omega, \\ \tilde{q}(x) \frac{\partial u}{\partial n} &= h \; \text{ on } \; \Gamma_1, \\ u(x) &= g \; \text{ on } \; \Gamma_2, \end{aligned}$$

with $\tilde{q}(x) = q(u_q(x))$. Already with respect to the inverse problem, we cite [3] for the weak maximum principle: If we choose f and h such that

$$\int_\Omega f(x) v \; dx + \int_{\Gamma_1} hv \; d\Gamma_1 \le 0$$

holds for all essentially nonnegative $v \in V$, we get

$$\operatorname{ess.} \sup_{x \in \Omega} u_q \le \operatorname{ess.} \sup_{x \in \Gamma_1} \max \{u_q, 0\} \tag{2.8}$$

(or u_q is a positive constant). Hence, the upper bound of the temperature range covered by u_q in Ω is given by the maximum temperature on Γ_1 (or by 0 if the latter is negative).

3. The inverse problem. Given a single boundary observation of the solution of the direct problem, the inverse problem is to recover the physical parameter q on the real interval covered by the temperature using the observation data. In order to overcome the ill-posedness of this identification problem, we choose Tikhonov regularization for its stabilization.

3.1. The interval of identifiability. Identifying the nonlinearity $q(u)$ is theoretically and numerically challenging, since the interval, on which the parameter can be recovered, is a priori not known. Obviously, the parameter, as a function of one variable, cannot be reconstructed on the whole of R but at the most on the interval $[u_{\min}, u_{\max}]$, where $u_{\min}$ and $u_{\max}$ denote the extremal values of the temperature distributed over $\bar{\Omega}$. Outside this interval, no physical information is available, making the identification impossible in advance.

In the case that only boundary temperature measurements are given, the data need not necessarily cover all of $[u_{\min}, u_{\max}]$. If one still wants to recover the parameter on the whole interval, the following experimental setup for indirect measurements volunteers itself. Assume that the heat conductivity q is known up to a temperature value u_0 from possibly direct measurements but is inaccessible at temperatures above. Then we set

$$g = u_0 \ \ (\text{constant}) \tag{3.1}$$

in (2.3). By tuning f and h in (2.1) and (2.2), we drive the temperature on the boundary Γ_1 to values higher than u_0. Finally, we measure the temperature trace along Γ_1, whose maximum value we call u_1.

We know from the maximum principle (2.8) that

$$u_{\max} = u_1$$

holds (for f and h chosen appropriately). Unfortunately, we cannot guarantee $u_{\min} = u_0$ but have only $u_{\min} \leq u_0$. Nevertheless, since we assume to know q up to u_0, we can consider the identification of q on the interval

$$[u_{\min}, u_{\max}]. \tag{3.2}$$

3.2. Output least squares formulation. Denoting by $z(x)$ the measured temperature trace along Γ_1, we want to identify the true thermal conductivity $q^\dagger$ out of a set of admissible parameters, satisfying

$$\gamma u_{q^\dagger} = z, \tag{3.3}$$

where γ denotes the trace operator

$$\begin{aligned} \gamma : H^1(\Omega) &\to L^2(\Gamma_1), \\ u &\to u|_{\Gamma_1}, \end{aligned}$$

and $u_{q^\dagger}$ is the solution of the direct problem (2.1)–(2.3) with $q = q^\dagger$. We always assume the existence of a true parameter $q^\dagger$, i.e., that the exact data z are attainable. Of course, the measured (noisy) data need not be attainable.

We already mentioned in the previous section that $q^\dagger$ can at most be identified on the range of $u_{q^\dagger}$. Nevertheless, during the numerical solution of the inverse problem, temperature values corresponding to other parameters than $q^\dagger$ may occur. Hence the parameters have to be defined on an even larger range than that of $u_{q^\dagger}$. This crucial numerical point is discussed in [15] and [16] for the case of distributed temperature measurements.

For defining the set of admissible parameters, we choose positive constants α_1 and α_2 such that the temperatures u_{α_1} and u_{α_2} (obtained by solving the direct problem) contain (at least) the minimal and maximal values of the data, i.e., the measured temperature trace on Γ_1, respectively. Since α_1 and α_2 are constant and hence regular parameters, regularity results (see, for instance, [17]) yield that u_{α_1} and u_{α_2} are continuous on $\bar{\Omega}$; i.e., there are constants I_1 and I_2 such that

$$\begin{aligned} I_1 \leq u_{\alpha_1} \leq I_2, \\ I_1 \leq u_{\alpha_2} \leq I_2. \end{aligned}$$

Then we can use the finite interval

$$I = [I_1, I_2], \quad I_1, I_2 \in R, \tag{3.4}$$

in order to define the set of admissible parameters as

$$K = \left\{ q \in H^1(R) \mid \alpha_1 \leq q(\tau) \leq \alpha_2 \text{ for } \tau \in I \text{ and } q \text{ is fixed on } R \backslash I \right\}. \tag{3.5}$$

Here, the attribute fixed has to be understood as

$$q_1(\tau) - q_2(\tau) \equiv 0 \ \text{ on } R \backslash I \tag{3.6}$$

for any $q_1,\ q_2 \in K$. The only requirement for the behavior of q on $R \backslash I$ is that $q \in H^1(R)$ is not violated. Then any $q \in K$ is continuous and bounded due to the continuous embedding $H^1(R) \subseteq C_b(R)$. Of course, we can only identify $q^\dagger$ on a subdomain of I where we have information about the system from the data z. Outside this domain, we have no information, so an identification is impossible in advance. In this sense, we should look in (3.4) for an interval I of minimal length. Again, we refer to [16] for a possible numerical approach.

As we shall see below, this construction of K is mainly needed for technical reasons. Things would simplify if one assumes the existence (but not the exact knowledge) of a finite interval I that covers all temperatures u_q for q belonging to

$$\tilde{K} = \left\{ q \in H^1(I) \mid \alpha_1 \leq q(\tau) \leq \alpha_2 \text{ for } \tau \in I \right\} \tag{3.7}$$

with α_1, α_2 appropriately chosen. This assumption may be supported by the finiteness of physical temperatures.

For later use, we introduce the set of the indefinite integrals of the parameters $q \in K$

$$S = \left\{ Q \in H^2(R) \mid \frac{dQ}{d\tau} \in K \text{ and } Q(g) = 0 \right\}, \tag{3.8}$$

where $g \in I$ is the constant from (2.3), (3.1). Because of (3.5), we have a common Lipschitz constant, namely, α_2, for the functions $Q \in S$:

$$|Q(\tau_1) - Q(\tau_2)| \leq \alpha_2 |\tau_1 - \tau_2|, \ \tau_1,\ \tau_2 \in R, \tag{3.9}$$

for all $Q \in S$.

In applications, the exact data $z(x)$ are not known precisely due to measurement errors. Hence the actual data are available in the form

$$z^\delta(x) = z(x) + \text{noise},$$

where one needs some information

$$\|z - z^\delta\|_{L^2(\Gamma_1)} \leq \delta \tag{3.10}$$

about the noise level. Due to the data noise, the ill-posedness of the inverse problem requires some type of regularization in order to determine $q^\dagger$ in (3.3) in a stable way. Choosing Tikhonov regularization, we consider the following output-least-squares problem.

Let the set K of admissible parameters and noisy data z^δ be given as in (3.5) and (3.10). Assume that the exact data z is attainable from a parameter $q^\dagger \in K$. Then, for $\beta > 0$, find a parameter $q_\beta^\delta \in K$ that minimizes

$$J_\beta(q) = \int_{\Gamma_1} |\gamma u_q - z^\delta|^2 d\Gamma_1 + \beta\|q - q^*\|^2_{H^1(R)} \tag{3.11}$$

over K for an appropriate choice of β and $q^* \in K$. The selection of q^* is crucial for the results about the convergence rate in section 4. Available a priori information about the true parameter $q^\dagger$ should be used for the choice of q^*; i.e., q^* should be interpreted as some kind of a priori guess for $q^\dagger$. Because of (3.6), the $H^1(R)$-norm can be replaced by the $H^1(I)$-norm, which in the following is denoted by $\|\cdot\|_I$. (Other penalty terms are possible; see section 6.) Note that q^* also determines the "identified" parameter $q^\dagger$ outside the domain of information in the case of I chosen too large.

Before discussing aspects of stability and convergence of the regularized solutions q_β^δ toward $q^\dagger$, we make sure that the given boundary data are sufficient to identify the parameter uniquely.

3.3. Identifiability. Investigating the identifiability of q, we are interested in the injectivity of the parameter-to-output map

$$q \to \gamma u_q.$$

We show that the temperature trace on Γ_1 determines the parameter uniquely on that range.

THEOREM 3.1. *Let u_{q_1} and $u_{q_2} \in H^1(\Omega)$ be the solutions of the direct problem corresponding to parameters q_1 and $q_2 \in K$. Then $\gamma u_{q_1} = \gamma u_{q_2}$ implies $q_1 = q_2$ on the range of u_{q_1} on Γ_1.*

Proof. For $i = 1, 2$ we define $w_i = Q_i(u_{q_i})$, where $Q_i \in S$ is the antiderivative to q_i. Then w_i satisfies $w_i|_{\Gamma_2} = 0$ and the linear equation

$$\int_\Omega \nabla w_i \cdot \nabla v dx = \int_\Omega f(x) v dx + \int_{\Gamma_1} hv d\Gamma_1 \quad \text{for all } v \in V.$$

Hence the difference $w = w_1 - w_2$ fulfills

$$\int_\Omega \nabla w \cdot \nabla v dx = 0 \quad \text{for all } v \in V,$$

which gives $w = 0$ according to the unique solvability of the homogeneous problem. Hence we have $Q_1(u_{q_1}) = Q_2(u_{q_2})$ in Ω. From the trace theorem we get $\gamma Q_1(u_{q_1}) = \gamma Q_2(u_{q_2})$; the continuity of Q_i yields $Q_1(\gamma u_{q_1}) = Q_2(\gamma u_{q_2})$. From the assumption $\gamma u_{q_1} = \gamma u_{q_2}$, we then can conclude that $Q_1(\tau) = Q_2(\tau)$, and hence $q_1(\tau) = q_2(\tau)$ for τ out of the range of u_{q_1} on Γ_1. ☐

3.4. Existence, stability, and convergence of the regularized solutions. Returning to problem (3.11), we have to make sure that

- a minimizer q_β^δ exists for any data $z^\delta \in L^2(\Gamma_1)$ (existence);
- for a fixed regularization parameter β, the minimizers of (3.11) depend continuously on the data z^δ (stability);
- the regularized solutions q_β^δ converge toward the true parameter $q^\dagger$ as both the noise level δ and the regularization parameter β (chosen by an a priori rule) tend to zero (convergence).

The proof of the desired properties is standard (see [4], [5], [16], or [14]) once the weak closedness of the mapping $q \rightarrow \gamma u_q$ is provided.

PROPOSITION 3.2 (weak closedness). *For $q_n \rightharpoonup q \in K$ in $H^1(R)$ and $\gamma u_{q_n} \rightharpoonup y$ in $L^2(\Gamma_1)$, we have*

$$\gamma u_q = y. \tag{3.12}$$

Proof. From (2.7) we know that the sequence $\{u_{q_n}\}$ is bounded in $H^1(\Omega)$. Therefore, there exists a subsequence $\{u_{q_{n_k}}\}$ such that

$$u_{q_{n_k}} \rightharpoonup u^* \quad \text{in} \quad H^1(\Omega) \tag{3.13}$$

with $u^*|_{\Gamma_2} = g$. As the embedding of $H^1(\Omega)$ into $L^2(\Omega)$ is compact, we also have

$$u_{q_{n_k}} \rightarrow u^* \quad \text{in} \quad L^2(\Omega). \tag{3.14}$$

First, we prove that $u_{q_{n_k}} \rightharpoonup u_q$ in $H^1(\Omega)$, for which we have to show that $u^* = u_q$.

By the help of the triangle inequality, we get

$$\begin{aligned} &\left| \int_\Omega q_{n_k}(u_{n_k}) \nabla u_{n_k} \cdot \nabla v dx - \int_\Omega q(u^*) \nabla u^* \cdot \nabla v dx \right| \\ &\leq \left| \int_\Omega \{q_{n_k}(u_{n_k}) \nabla u_{n_k} - q(u^*) \nabla u_{n_k}\} \cdot \nabla v dx \right| \qquad (3.15) \\ &\quad + \left| \int_\Omega \{q(u^*) \nabla u_{n_k} - q(u^*) \nabla u^*\} \cdot \nabla v dx \right|. \qquad (3.16) \end{aligned}$$

Defining a linear functional l on $H^1(\Omega)$ by

$$l(u) = \int_\Omega q(u^*) \nabla v \cdot \nabla u dx,$$

we obtain from the weak convergence (3.13) that (3.16) vanishes for $k \rightarrow \infty$.

Applying once more the triangle inequality to (3.15) yields

$$\begin{aligned} &\left| \int_\Omega \{q_{n_k}(u_{n_k}) \nabla u_{n_k} - q(u^*) \nabla u_{n_k}\} \cdot \nabla v dx \right| \\ &\leq \left| \int_\Omega \{q_{n_k}(u_{n_k}) - q(u_{n_k})\} \nabla u_{n_k} \cdot \nabla v dx \right| \qquad (3.17) \\ &\quad + \left| \int_\Omega \{q(u_{n_k}) - q(u^*)\} \nabla u_{n_k} \cdot \nabla v dx \right|. \qquad (3.18) \end{aligned}$$

Because of (3.6) and the Cauchy–Schwarz inequality, we get

$$\begin{aligned} &\left| \int_\Omega (q_{n_k}(u_{n_k}) - q(u_{n_k}))\, \nabla u_{n_k} \cdot \nabla v dx \right| \\ &\le \|q_{n_k} - q\|_{C(I)} \|u_{n_k}\|_{H^1(\Omega)} \|v\|_{H^1(\Omega)} \\ &\le \tilde{C} \|q_{n_k} - q\|_{C(I)} \end{aligned} \tag{3.19}$$

for a constant $\tilde{C}$ not depending on n_k because of (2.7). Since the embedding of $H^1(I)$ into $C(I)$ is compact due to the finiteness of I, (3.17) tends to zero for $k \to \infty$.

Because of the boundedness of q, we also can apply the Cauchy–Schwarz inequality to (3.18) and obtain

$$\begin{aligned} &\left| \int_\Omega \{q(u_{n_k}) - q(u^*)\}\, \nabla u_{n_k} \cdot \nabla v dx \right| \\ &\le C \|q(u_{n_k})\nabla v - q(u^*)\nabla v\|_{L^2(\Omega)} \end{aligned} \tag{3.20}$$

by means of (2.7). Furthermore, the continuity of q and (3.14) yield $\lim_{k\to\infty} q(u_{n_k}(x)) = q(u_*(x))$ for almost every $x \in \Omega$. Because of $\partial v / \partial x_i \in L^2(\Omega)$ and the boundedness of q, the dominated convergence theorem (see [9]) shows that (3.20) vanishes for $k \to \infty$.

Summarizing these results, we obtain for $k \to \infty$ that

$$\int_\Omega q(u^*) \nabla u^* \cdot \nabla v dx = \int_\Omega f(x) v dx + \int_{\Gamma_1} h v d\Gamma_1 \quad \text{for all } \ v \in V$$

with $u^* - \tilde{g} \in V$. Hence u^* is the weak solution of (2.1)–(2.3) for the parameters q, f, g, and h. As the weak solution is unique, we conclude that $u^* = u_q$. Finally, as $u_{q_{n_k}} \rightharpoonup u_q$ holds for any subsequence $u_{q_{n_k}}$, we get

$$u_{q_n} \rightharpoonup u_q \ \text{ in } \ H^1(\Omega). \tag{3.21}$$

According to our assumption, we have $\gamma u_{q_n} \rightharpoonup y$ in $L^2(\Gamma_1)$; because of (3.21) and the continuity of the trace operator γ we also know $\gamma u_{q_n} \rightharpoonup \gamma u_q$ in $L^2(\Gamma_1)$. The uniqueness of the weak limit yields $\gamma u_q = y$. □

Hence existence, stability, and convergence of the regularized solutions are guaranteed. The special construction of the set K was only needed in order to derive estimate (3.19). Furthermore, the proof shows that Proposition 3.2 also holds if one considers $\tilde{K}$ as a set of admissible parameters.

4. Convergence rates.

Opposed to the general theory [4], we introduce a weak source condition for the convergence rate, which allows a full interpretation in section 5. Though based on concepts from [16], both the formulation and the proof of the convergence rate theorem are different from [16] since we now have to deal with boundary terms.

THEOREM 4.1. *Assume that there exists a function*

$$w \in V \tag{4.1}$$

such that

$$\left(q^\dagger - q^*, \psi\right)_I = \int_{\Gamma_1} \Psi(u_{q^\dagger}) \frac{\partial w}{\partial n} d\Gamma_1 \text{ for all } \psi \in H^1(I) \tag{4.2}$$

holds, where Ψ *is the antiderivative to* ψ*, fixed by*

$$\Psi(g) = 0. \tag{4.3}$$

Furthermore, assume that $\frac{\partial w}{\partial n} \in L^2(\Gamma_1)$ *with*

$$\Delta w = 0 \;\; in \;\; \Omega. \tag{4.4}$$

Then, with $\beta \sim \delta$*, we have*

$$\|\gamma u_{q_\beta^\delta} - z^\delta\|_{L^2(\Gamma_1)} = O(\delta)$$

and

$$\|q_\beta^\delta - q^\dagger\|_I = O(\sqrt{\delta}),$$

where q_β^δ *is the minimizer of* (3.11).

Proof. For the sake of simplicity, we now omit the explicit notation of γ. Then, as q_β^δ is a minimizer of (3.11), we get $J_\beta(q_\beta^\delta) \le J_\beta(q^\dagger)$. This implies

$$\|u_{q_\beta^\delta} - z^\delta\|_{L^2(\Gamma_1)}^2 + \beta\|q_\beta^\delta - q^*\|_I^2 \le \delta^2 + \beta\|q^\dagger - q^*\|_I^2,$$

from which we obtain

$$\begin{aligned} &\|u_{q_\beta^\delta} - z^\delta\|_{L^2(\Gamma_1)}^2 + \beta\|q^\dagger - q_\beta^\delta\|_I^2 \\ &\le \delta^2 + \beta\|q^\dagger - q^*\|_I^2 + \beta\left\{\|q^\dagger - q_\beta^\delta\|_I^2 - \|q_\beta^\delta - q^*\|_I^2\right\} \\ &= \delta^2 + 2\beta\left(q^\dagger - q^*, q^\dagger - q_\beta^\delta\right)_I . \end{aligned} \tag{4.5}$$

As integration by parts yields

$$\int_{\partial\Omega} \Psi(u_{q^\dagger})\frac{\partial w}{\partial n}dS - \int_\Omega \Psi(u_{q^\dagger})\Delta w dx = \int_\Omega \psi(u_{q^\dagger})\nabla u_{q^\dagger}\nabla w dx,$$

(4.3) and (4.4) give

$$\int_{\Gamma_1} \Psi(u_{q^\dagger})\frac{\partial w}{\partial n}d\Gamma_1 = \int_\Omega \psi(u_{q^\dagger})\nabla u_{q^\dagger}\nabla w dx$$

for the right-hand side of the source condition (4.2). Hence, choosing $\psi = q^\dagger - q_\beta^\delta$ in the source condition (4.2) leads to

$$\left(q^\dagger - q^*, q^\dagger - q_\beta^\delta\right)_I = \int_\Omega \left(q^\dagger(u_{q^\dagger}) - q_\beta^\delta(u_{q^\dagger})\right)\nabla u_{q^\dagger}\nabla w dx. \tag{4.6}$$

Using the direct problem formulation (see (2.5)) for $u_{q_\beta^\delta}$ and $u_{q^\dagger}$, we see by taking the difference that

$$\int_\Omega \left(q_\beta^\delta(u_{q_\beta^\delta})\nabla u_{q_\beta^\delta} - q^\dagger(u_{q^\dagger})\nabla u_{q^\dagger}\right)\cdot\nabla w dx = 0 \tag{4.7}$$

holds. Multiplying (4.6) by β and adding zero in the form of (4.7), it follows that

$$\begin{aligned} \beta\left(q^\dagger - q^*, q^\dagger - q_\beta^\delta\right)_I = \;\; &\beta\int_\Omega \left(q^\dagger(u_{q^\dagger}) - q_\beta^\delta(u_{q^\dagger})\right)\nabla u_{q^\dagger}\nabla w dx \\ &+ \beta\int_\Omega q_\beta^\delta(u_{q_\beta^\delta})\nabla u_{q_\beta^\delta}\cdot\nabla w dx \\ &- \beta\int_\Omega q^\dagger(u_{q^\dagger})\nabla u_{q^\dagger}\cdot\nabla w dx. \end{aligned} \tag{4.8}$$

We simplify the right-hand side of (4.8) to

$$I_1 = \beta \int_\Omega \left(q^\delta_\beta(u_{q^\delta_\beta})\nabla u_{q^\delta_\beta} - q^\delta_\beta(u_{q^\dagger})\nabla u_{q^\dagger}\right) \cdot \nabla w dx.$$

Using the antiderivative $Q^\delta_\beta \in S$ (see (3.8)) of q^δ_β, we obtain

$$I_1 = \beta \int_\Omega \left(\nabla Q^\delta_\beta(u_{q^\delta_\beta}) - \nabla Q^\delta_\beta(u_{q^\dagger})\right) \cdot \nabla w dx.$$

Integration by parts leads to

$$\begin{aligned} I_1 = \beta &\int_{\partial\Omega} \left(Q^\delta_\beta(u_{q^\delta_\beta}) - Q^\delta_\beta(u_{q^\dagger})\right)\frac{\partial w}{\partial n}\, dS \\ -\beta &\int_\Omega \left(Q^\delta_\beta(u_{q^\delta_\beta}) - Q^\delta_\beta(u_{q^\dagger})\right)\Delta w\, dx. \end{aligned}$$

Because of $u_{q^\delta_\beta}|_{\Gamma_2} = u_{q^\dagger}|_{\Gamma_2} = g$ and (4.4), we finally obtain

$$I_1 = \beta \int_{\Gamma_1} \left(Q^\delta_\beta(u_{q^\delta_\beta}) - Q^\delta_\beta(u_{q^\dagger})\right)\frac{\partial w}{\partial n}\, d\Gamma_1.$$

Next, we estimate I_1 by (3.9) and the Cauchy–Schwarz inequality in order to get

$$|I_1| \le \beta\alpha_2 \|u_{q^\dagger} - u_{q^\delta_\beta}\|_{L^2(\Gamma_1)} \left\|\frac{\partial w}{\partial n}\right\|_{L^2(\Gamma_1)}.$$

Applying the triangle inequality and Young's inequality

$$a \cdot b \le \varepsilon a^2 + \frac{b^2}{4\varepsilon}$$

for any $\varepsilon > 0$, we obtain

$$\begin{aligned} |I_1| &\le \beta\alpha_2 \|u_{q^\delta_\beta} - z^\delta\|_{L^2(\Gamma_1)} \left\|\frac{\partial w}{\partial n}\right\|_{L^2(\Gamma_1)} \\ &\quad + \beta\alpha_2 \|z^\delta - u_{q^\dagger}\|_{L^2(\Gamma_1)} \left\|\frac{\partial w}{\partial n}\right\|_{L^2(\Gamma_1)} \\ &\le \varepsilon\alpha_2^2\delta^2 + \frac{\beta^2}{2\varepsilon}\left\|\frac{\partial w}{\partial n}\right\|^2_{L^2(\Gamma_1)} \\ &\quad + \varepsilon\alpha_2^2 \|u_{q^\delta_\beta} - z^\delta\|^2_{L^2(\Gamma_1)}. \end{aligned}$$

Using this estimate for $|I_1|$, we get from (4.5) that

$$\begin{aligned} &\|u_{q^\delta_\beta} - z^\delta\|^2_{L^2(\Gamma_1)} + \beta\|q^\delta_\beta - q^\dagger\|^2_I \\ &\quad \le \delta^2 + 2\alpha_2^2\varepsilon\|u_{q^\delta_\beta} - z^\delta\|^2_{L^2(\Gamma_1)} \\ &\quad + 2\alpha_2^2\varepsilon\delta^2 + \frac{\beta^2}{\varepsilon}\left\|\frac{\partial w}{\partial n}\right\|^2_{L^2(\Gamma_1)}, \end{aligned}$$

which is equivalent to

$$\begin{aligned}\left\{1-2\alpha_2^2\varepsilon\right\}\|u_{q_\beta^\delta}-z^\delta\|^2_{L^2(\Gamma_1)}&\\ +\beta\|q_\beta^\delta-q^\dagger\|_I^2\le\delta^2+2\varepsilon\alpha_2^2\delta^2&\\ +\frac{\beta^2}{\varepsilon}\left\|\frac{\partial w}{\partial n}\right\|^2_{L^2(\Gamma_1)}&.\end{aligned}$$

With $\varepsilon<\frac{1}{2\alpha_2^2}$ we finally obtain that

$$\|u_{q_\beta^\delta}-z^\delta\|_{L^2(\Gamma_1)}=O(\delta) \tag{4.9}$$

(hence, by (3.10), also $\|u_{q_\beta^\delta}-z\|_{L^2(\Gamma_1)}=O(\delta)$) and

$$\|q_\beta^\delta-q^\dagger\|_I=O(\sqrt{\delta}) \tag{4.10}$$

hold. The constants in the O-terms in (4.9) and (4.10) can be derived from the proof. □

Now the theoretical analysis of our identification problem is complete. We have shown stability, convergence, and given conditions on the rate of convergence. In the next section, we give sufficient conditions for the existence of a source function w that satisfies (4.1)–(4.4), which allows the interpretation of the source condition (4.2). Again, we modify the approach of [16] appropriately.

5. Discussion of the source condition. Opposed to the general theory (compare with (1.2)), where Fréchet-differentiability of the forward operator F and Lipschitz continuity of $F'(q)$ already require a more regular parameter, the formulation of (4.2) itself does not impose any more regularity on q^* and on $q^\dagger$ than that they be in $H^1(I)$. Furthermore, in the general theory, the adjoint of $F'(q^\dagger)$ is needed, which makes the source condition usually very difficult to interpret. The new approach uses only the parameter-to-solution map $u_{q^\dagger}$ itself, which has a direct physical meaning, and not its linearization.

Usually, source conditions such as (1.2) mean severe restrictions on the parameter and are readily interpretable only in the one-dimensional case. We next construct a source function w for (4.2), even for the higher dimensional case, under quite natural conditions. The interpretation is based on our work in [16] but now for single boundary measurements.

If we denote the range of the true temperature $u_{q^\dagger}$ on Γ_1 (and hence on Ω (see section 3.1)) by the interval $I^\dagger=[I^\dagger_{\min},I^\dagger_{\max}]$, i.e.,

$$I^\dagger_{\min}=\min_{x\in\Gamma_1}u_{q^\dagger}\text{ and }I^\dagger_{\max}=\max_{x\in\Gamma_1}u_{q^\dagger},$$

we have

$$I^\dagger\subseteq I.$$

If we can assume to know the true parameter $q^\dagger$ outside the range $I^\dagger$ already from q^*, i.e., for $\rho:=q^\dagger-q^*$ we have

$$\rho=0\ \text{ for }\ \tau\in I\backslash I^\dagger, \tag{5.1}$$

the source condition (4.2) turns to

$$(\rho,\psi)_{I^\dagger} = \int_{\Gamma_1} \Psi(u_{q^\dagger}) \frac{\partial w}{\partial n} d\Gamma_1 \quad \text{for all } \psi \in H^1(I). \tag{5.2}$$

This is a very natural assumption as outside of $I^\dagger$ the parameter is of no use for the physical system. Also, from the inverse point of view, we can expect to identify only the parameter on the range of the true temperature as outside of $I^\dagger$ no information is available. Hence on $I \backslash I^\dagger$ $q^\dagger$ is already determined by the choice of q^*.

We now assume that

$$q^\dagger - q^* \in H^4(I) \tag{5.3}$$

and require the trace of the true temperature $u_{q^\dagger}$ to satisfy

$$\gamma u_{q^\dagger} : \Gamma_1 \to I^\dagger \ \text{ is Lipschitz.} \tag{5.4}$$

Then, because of the compact embedding $H^4(I^\dagger) \subset C^3(I^\dagger)$, our assumptions on the a priori knowledge about $\rho = q^\dagger - q^*$ (see (5.1)) result in

$$\rho^{(j)}(I^\dagger_{\text{min}}) = \rho^{(j)}(I^\dagger_{\text{max}}) = 0 \ \text{ for } \ j = 0, 1, 2, 3. \tag{5.5}$$

Because of assumption (5.4), the change of variables formula (see [9], [16]) can be applied with the transformation $t = \gamma u_{q^\dagger}$, whose level-sets are isotherms on Γ_1. This gives

$$\int_{\Gamma_1} s(x) J\gamma u_{q^\dagger}(x) d\Gamma_1 = \int_{I^\dagger} \left[\int_{\gamma u_{q^\dagger}^{-1}\{\tau\}} s dH^{n-2} \right] d\tau \tag{5.6}$$

for any L^{n-1}-summable function $s : R^{n-1} \to R$, where $J\gamma u_{q^\dagger}$ denotes the Jacobian of $\gamma u_{q^\dagger}$ and H^{n-2} is the $(n-2)$-dimensional Hausdorff measure. Next, we have to find a suitable function s in (5.6) for our purpose. First, we define m to be the $(n-2)$-dimensional Hausdorff-measure of the level sets of $\gamma u_{q^\dagger}$, i.e.,

$$m(\tau) = \int_{\gamma u_{q^\dagger}{}^{-1}\{\tau\}} dH^{n-2} \ \text{ for } \ \tau \in I^\dagger,$$

and assume the trace of $u_{q^\dagger}$ on Γ_1 to behave such that

$$(\rho'''(\gamma u_{q^\dagger}) - \rho'(\gamma u_{q^\dagger})) \cdot \frac{1}{m(\gamma u_{q^\dagger})} \cdot J\gamma u_{q^\dagger} \in L^2(\Gamma_1). \tag{5.7}$$

The only term that might cause a violation of (5.7) is $\frac{1}{m(\gamma u_{q^\dagger})}$. In two dimensions $(n = 2)$, the H^{n-2}-measure is the counting measure. Then we have $m(\tau) \neq 0$ on $I^\dagger$ as every $\tau \in I^\dagger$ is at least attained once by $u_{q^\dagger}$ for $x \in \Gamma_1$ (by definition). This is distinct from [16], where even in two dimensions condition (5.7) cannot be guaranteed a priori. In three dimensions (5.7) is certainly fulfilled if $m(\gamma u_{q^\dagger})$ is bounded away from 0, i.e., if all temperatures in $I^\dagger$ are assumed on sets of nonvanishing H^1-measure and if these measures depend in a reasonable way on the temperatures. This is a (weak) regularity condition on the measures of the isotherms, and it is reasonable, since one cannot expect identifiability of $q^\dagger$ for temperatures which are assumed only on a "small" set (of H^1-measure zero). But even such "small isotherms" are not excluded by (5.7): The only temperature values possibly attained by $\gamma u_{q^\dagger}$ at a set of H^1-measure zero are $I^\dagger_{\min}$ or $I^\dagger_{\max}$. This is a consequence of the continuity of the trace of $u_{q^\dagger}$ on Γ_1 and the intermediate value theorem. However, both the first term in the product (see (5.5)) and $J\gamma u_{q^\dagger}$ (necessary condition for an extremum) vanish in the respective critical situation. Now if the product of these two expressions tends faster to zero than $m(\gamma u_{q^\dagger})$, the L^2-boundedness in (5.7) is maintained even then.

Now we again omit the explicit notation of γ and look at the Poisson equation

$$\Delta w = 0 \text{ in } \Omega, \tag{5.8}$$

$$\frac{\partial w}{\partial n} = (\rho'''(u_{q^\dagger}) - \rho'(u_{q^\dagger})) \cdot \frac{1}{m(u_{q^\dagger})} \cdot J u_{q^\dagger} \text{ on } \Gamma_1, \tag{5.9}$$

$$w = 0 \text{ on } \Gamma_2, \tag{5.10}$$

for which the existence of a unique (weak) solution $w \in V$ is guaranteed because of (5.7). Similarly as in [16], one can show that the solution w of (5.8)–(5.10) satisfies the source condition (4.2). Note that the conditions (4.1) and (4.4) of the convergence rate theorem are automatically fulfilled by this approach. The essential assumptions needed for the proof are

- sufficient smoothness of $q^\dagger - q^*$ as required in (5.3);
- sufficient smoothness of the trace of $u_{q^\dagger}$ on Γ_1: (5.4);
- sufficient knowledge about $q^\dagger$ on the boundary of the temperature interval where measurements are available: (5.5);
- condition (5.7) (needed only for $n = 3$), which essentially says that the isotherms of $u_{q^\dagger}$ on Γ_1 depend in a sufficiently regular way on the temperature level, where this regularity is rather weak.

Since under these conditions the source condition can be verified, the convergence rates from Theorem 4.1 are valid.

In any dimension, the heat dependent conductivity is identified as a function of one variable. Hence it is remarkable that the interpretation edges down more in two dimensions, where the boundary temperature represents only a one-dimensional data manifold, than in three, where a two-dimensional data manifold is available.

6. Variants. In section 2, we introduced a nonlinear mixed boundary problem for which we considered in section 4 a constant boundary temperature u_0 on Γ_2 for technical reasons. From the practical (with respect to industry) point of view, the pure Neumann-type problem

$$-\nabla \cdot (q(u)\nabla u) = f(x) \text{ in } \Omega, \tag{6.1}$$

$$q(u)\frac{\partial u}{\partial n} = h \text{ on } \partial\Omega \tag{6.2}$$

could be more realistic, where (6.2) then describes, e.g., the cooling of a steel strand (see [11]). If we choose the space of test functions V as

$$V = \left\{ v \in H^1(\Omega) \mid \int_\Omega v dx = 0 \right\}$$

and require

$$\int_\Omega f dx + \int_{\partial\Omega} h dS = 0,$$

the existence of a unique weak solution u_q in V to (6.1)–(6.2) can be guaranteed by [22]. Then the theory developed in sections 3 and 4 remains valid if we replace Γ_1 by

$\partial\Omega$. This means that the measurements are now done on all of $\partial\Omega$, and the Tikhonov functional is

$$J_\beta(q) = \int_{\partial\Omega} |u_q - z^\delta|^2 dS + \beta\|q - q^*\|_I^2.$$

The source condition

$$\left(q^\dagger - q^*, \psi\right)_I = \int_{\partial\Omega} \Psi(u_{q^\dagger}) \frac{\partial w}{\partial n} dS \quad \text{for all } \psi \in H^1(I), \tag{6.3}$$

which yields the rates

$$\|u_{q_\beta^\delta} - z^\delta\|_{L^2(\partial\Omega)} = O(\delta)$$

and

$$\|q_\beta^\delta - q^\dagger\|_I = O(\sqrt{\delta}),$$

can be interpreted as in section 5. Note that in order to show the existence of a unique (weak) solution to problem (5.8)–(5.10) in V (with $\Gamma_1 = \partial\Omega$, $\Gamma_2 = \emptyset$), we now in addition have to check

$$\int_{\partial\Omega} \frac{\partial w}{\partial n} dS = 0. \tag{6.4}$$

However, this follows from applying the coarea formula (5.6) with

$$s(x) = (\rho'''(u_{q^\dagger}(x)) - \rho'(u_{q^\dagger}(x))) \frac{1}{m(u_{q^\dagger}(x))},$$

which gives

$$\begin{aligned}\int_{\partial\Omega} \frac{\partial w}{\partial n} dS &= \int_{I^\dagger} (\rho'''(\tau) - \rho'(\tau)) \frac{1}{m(\tau)} m(\tau) d\tau \\ &= \int_{I^\dagger} (\rho''' - \rho') d\tau \\ &= 0, \end{aligned} \tag{6.5}$$

where the last equality holds because of (5.5).

Finally, we change the settings of the direct problem to the pure Dirichlet case:

$$-\nabla \cdot (q(u)\nabla u) = f(x) \ \text{ in } \ \Omega, \tag{6.6}$$

$$u = g \ \text{ on } \ \partial\Omega. \tag{6.7}$$

The existence of a unique solution in $H^1(\Omega)$ is given by the theory quoted in section 2. As now the temperature flux $q(u)\frac{\partial u}{\partial n}$ is measured on (all of) the boundary $\partial\Omega$, we need a higher regularity of the solution u_q than in our previous discussions if we still want to measure our data in the L^2-setting, i.e., consider that the measurements are in L^2. If we choose the set of admissible parameters

$$\hat{K} = \left\{ q \in H^2(I) \mid \alpha_1 \le q(\tau) \le \alpha_2 \text{ for } \tau \in I \ \ \wedge \ \ \left\|\frac{dq}{d\tau}\right\|_{L^\infty(I)} \le \infty \right\}$$

and require

$$g \in H^{3/2}(\partial\Omega),$$

then, for $q \in \hat{K}$, the existence of a unique solution u_q even in $H^2(\Omega)$ can be shown (see [2]). Now, the continuous embedding $H^2(R) \subseteq C^1(R)$ and the trace theorem yield

$$q(u_q)\frac{\partial u_q}{\partial n} \in H^{1/2}(\partial\Omega).$$

Hence the Tikhonov functional

$$J_\beta(q) = \int_{\partial\Omega} |\gamma_q u_q - z^\delta|^2 dS + \beta\|q - q^*\|_I^2$$

with

$$\begin{aligned} \gamma_q : H^2(\Omega) &\to L^2(\partial\Omega), \\ u &\to q(u)\frac{\partial u}{\partial n} \end{aligned}$$

is meaningful. Under the source condition

$$\left(q^\dagger - q^*, \psi\right)_I = \int_{\partial\Omega} \Psi(g)\frac{\partial w}{\partial n} dS \quad \text{for all } \psi \in H^1(I) \tag{6.8}$$

(g now is no longer needed to be constant), the rates

$$\|q_\beta^\delta - q^\dagger\|_I = O(\sqrt{\delta})$$

and

$$\|\gamma_{q_\beta^\delta} u_{q_\beta^\delta} - z^\delta\|_{L^2(\partial\Omega)} = O(\delta)$$

can be shown. Note that now (6.8) does not even depend explicitly on the unknown temperature $u_{q^\dagger}$, which is a major difference from the theory of convergence rate developed so far. Once more, the source function $w \in H^1(\Omega)$ can be found as the solution of

$$\begin{aligned} &\Delta w = 0 \text{ in } \Omega, \\ &\frac{\partial w}{\partial n} = (\rho'''(u_{q^\dagger}) - \rho'(u_{q^\dagger})) \cdot \frac{1}{m(u_{q^\dagger})} \cdot J u_{q^\dagger} \text{ on } \partial\Omega, \end{aligned}$$

for the proof of the convergence rate the variational formulation

$$\int_\Omega q(u)\nabla u \cdot \nabla v dx = \int_\Omega h(x) v dx + \int_{\partial\Omega} q(u)\frac{\partial u}{\partial n} v dS$$

with test functions $v \in H^1(\Omega)$ is needed. The advantage of considering pure Dirichlet data for the direct problem is that the condition

$$\gamma u_{q^\dagger} : \partial\Omega \to I^\dagger \text{ is Lipschitz}$$

can now be automatically satisfied by choosing the problem input g regular enough because of

$$\gamma u_{q^\dagger} = g. \tag{6.9}$$

Furthermore, we now can drive the interval $I^\dagger$ on which we want to identify the parameter in a straightforward way by the choice of g.

Finally, we mention that in all our optimization problems, the H^1-regularization term can be replaced by a L^2-term; i.e., we can consider

$$\min J(q) := \left\{L^2\text{-norm of residual}\right\}^2 + \beta \int_I (q-q^*)^2 d\tau. \tag{6.10}$$

Results for stability, convergence, and rate of convergence can be proven in a completely analogous way, where the H^1-scalar product $(q^\dagger - q^*, \psi)_I$ in (4.2) is replaced by the L^2-scalar product $\int_I (q^\dagger - q^*)\psi d\tau$. A solution to the source condition can be constructed as in section 5 under even weaker regularity assumptions on $q^\dagger$.

The existence of minimizers of (6.10) cannot be guaranteed by Theorem 3.2, but this difficulty can be resolved by incorporating a tolerance η into the minimization, i.e., by replacing minimizers of (6.10) by elements $q^\delta_{\beta,\eta}$ such that

$$J(q^\delta_{\beta,\eta}) \le \inf J(q) + \eta.$$

As long as $\eta = O(\delta^2)$, all proofs carry over (see [5]). This can of course also be done for (3.11).

7. Numerical experiments.

In order to test the identification of the heat conductivity by Tikhonov regularization, we carry out numerical simulations using the temperature trace $u|_{\Gamma_1}$ as data. Considering a rectangular domain $\Omega = [0, 0.5] \times [0, 2]$ with boundaries $\Gamma_1 = \{0\} \times [0, 2] \cup [0, 0.5] \times \{2\} \cup \{0.5\} \times [0, 2]$ and $\Gamma_2 = [0, 0.5] \times \{0\}$ and a temperature field

$$u_{q^\dagger}(x, y) = \frac{y}{2}, \tag{7.1}$$

we want to recover the nonlinearity in

$$\begin{aligned} -\nabla \cdot ((2 + \cos(2\pi u))\nabla u) &= \pi \cdot \sin(\pi y) \ \text{ in } \ \Omega, \\ (2 + \cos(2\pi u))\frac{\partial u}{\partial n} &= 0 \ \text{ on } \ \Gamma_1, \\ u &= 0 \ \text{ on } \ \Gamma_2 \end{aligned}$$

from “observations” of

$$u|_{\Gamma_1}. \tag{7.2}$$

While we already know the true data $u_{q^\dagger}|_{\Gamma_1}$ by construction, a sequence of noisy data z^{δ_i} is generated by artificially perturbing $u_{q^\dagger}|_{\Gamma_1}$ with high frequency noise. Then the regularized solutions $q^{\delta_i}_\beta$ are defined as the minimizers of

$$J_\beta(q) = \int_{\Gamma_1} |\gamma u_q - z^{\delta_i}|^2 d\Gamma_1 + \beta \|q - q^*\|^2_I. \tag{7.3}$$

Though the true data $u_{q^\dagger}|_{\Gamma_1}$ (and hence the temperature distribution $u_{q^\dagger}$) cover only the range $I^\dagger = [0, 1]$, we choose a larger interval

$$I = [-0.2, 1.2] \tag{7.4}$$

in (7.3), as both noisy data and computed forward solutions during the minimization procedure may exceed $I^\dagger$. Of course, we can only expect to recover the heat conductivity on $I^\dagger$; that outside it will be determined by the initial guess q^*. With

$$q^* = 3, \tag{7.5}$$

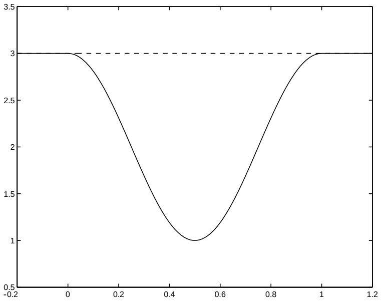

FIG. 1. $q^\dagger$ *and* q^*.

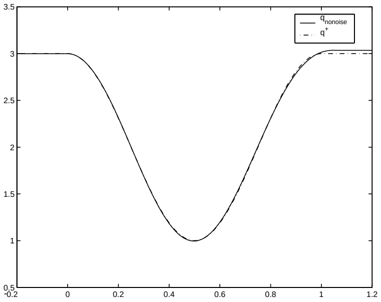

FIG. 2. $q_{nonoise}$ *identified from exact data.*

we then have (see Figure 1)

$$q^\dagger(\tau) = \begin{cases} 2 + \cos(2\pi\tau) & \text{for} \quad \tau \in I^\dagger, \\ 3 & \text{for} \quad \tau \in I \backslash I^\dagger. \end{cases} \tag{7.6}$$

Since we know the exact parameter $q^\dagger$, we can compute the error $\|q^\dagger - q_\beta^{\delta_i}\|_{H^1(I)}$, allowing us to investigate the behavior of Tikhonov regularization with respect to stability and rate of convergence. Note that we at least satisfy condition (5.5) for $j = 1, 2$ by the choice of q^* and in addition conditions (5.4) and (5.7) by the construction of our example.

For the minimization of (7.3) we use a quasi-Newton method, approximating the Hessian matrix of J_β by a BFGS-update formula in each iteration step k. Given a search direction p_k by that rule, the parameter q_k is updated by

$$q_{k+1} = q_k + \alpha_k p_k$$

until a minimum is reached. In order to raise the convergence speed of the optimization procedure, we also use a line search algorithm for the determination of the stepsize α_k. A more detailed discussion can be found in [15].

The first computations were done for $\beta = 0$, i.e., the approach to identify the parameter by simply minimizing the output least squares term

$$\int_{\Gamma_1} |\gamma u_q - z^{(\delta)}|^2 d\Gamma_1.$$

For the case of exact data $z = u_{q^\dagger}|_{\Gamma_1}$, the result $q_{nonoise}$ is shown in Figure 2. As predicted by our theory, the parameter is identifiable from observations of the temper-

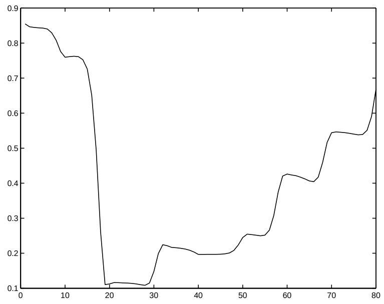

FIG. 3. $\frac{\|q^\dagger - q_k\|_I}{\|q^\dagger\|_I}$ *vs. k.*

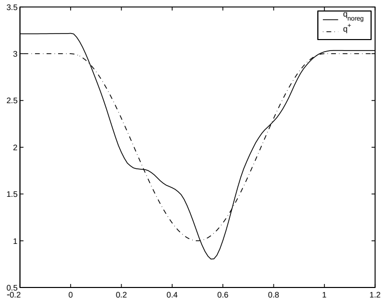

FIG. 4. *Solution* q_{noreg} *after* 80 *steps.*

ature trace on the boundary, but of course only on the interval $I^\dagger$, where the data is available. Outside, the solution is given by the initial guess q^*. Figures 3 and 4 illustrate the ill-posedness of the identification problem. Perturbed data z^{δ_7} with 4.61% noise already have a dramatic impact on the recovery process. On the left-hand side, the relative error $\frac{\|q^\dagger - q_k\|_I}{\|q^\dagger\|_I}$ is plotted vs. the iteration index k in the optimization routine; the right-hand sides records the result q_{noreg} after 80 steps. While the error in the residual $\|\gamma u_{q_k} - z^\delta\|_{L^2(\Gamma_1)}$ (not shown) is monotonically decreasing with k, the error in the parameter starts to increase after some 20 steps, leading to a solution that differs from $q^\dagger$ by more than 60% measured in the $H^1(I)$-norm. Only by introducing the penalty term

$$\beta\|q - q^*\|_I^2$$

(or, alternatively, stopping the iteration at "the right time" (see [4] for an introduction to iterative regularization methods)) these high numerical instabilities can be overcome. Though there are sophisticated methods for choosing the regularization parameter β from the knowledge of the noise level δ and the data z^δ (see [20]) itself, we content ourselves with the a priori choice

$$\beta_i = 4 \cdot 10^{-4} \cdot \delta_i \tag{7.7}$$

for the sequence of perturbed data z^{δ_i}. This relation was found by trial and error, which is sufficient for our purposes. In order to test the rate of convergence behavior of Tikhonov regularization predicted by Theorem 4.1, we need only to meet the requirement $\beta \sim \delta$. Figure 5 shows the error $\|q^\dagger - q_{\beta_i}^{\delta^i}\|_I$ plotted vs. the noise

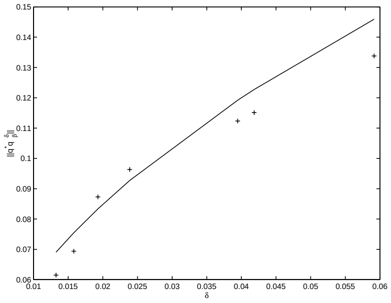

FIG. 5. *Convergence rate* $\|q^\dagger - q^{\delta_i}_{\beta_i}\|_I = O(\sqrt{\delta_i})$.

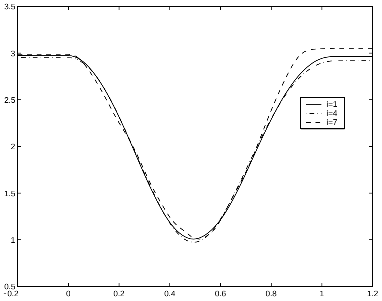

FIG. 6. *Regularized solutions* $q^{\delta_i}_{\beta_i}$.

level $\delta_i = \|\gamma u_{q^\dagger} - z^{\delta_i}\|_{L^2(\Gamma_1)}$. The solid line indicates that the convergence speed $\|q^\dagger - q^{\delta_i}_{\beta_i}\|_I = O(\sqrt{\delta_i})$ from Theorem 4.1 is obeyed, even though not all conditions of section 5 are satisfied by our example. This gives hope that a source function w in Theorem 4.1 can be found under even weaker assumptions than those made in section 5. Finally, Figure 6 shows the regularized solutions $q^{\delta_i}_{\beta_i}$ for $\delta_1 = 0.0132, \delta_4 = 0.0239$, and $\delta_7 = 0.0529$.

Acknowledgment. The author thanks Professor Masahiro Yamamoto (University of Tokyo) and Professor Jun Zou (Chinese University of Hong Kong) for fruitful discussions and the Sohmen Foundation (Linz) for funding the stay in Asia. The numerical part of this work was done while the author was visiting OCIAM (University of Oxford).

TIME INTEGRATION OF THE DUAL PROBLEM OF ELASTOPLASTICITY BY RUNGE–KUTTA METHODS*

JÖRG BÜTTNER[†] AND BERND SIMEON[‡]

Abstract. Implicit Runge–Kutta methods for the dual problem of elastoplasticity are analyzed and classified. The choice of Runge–Kutta time integration is inspired by the problem structure, which consists of a coupled system of balance equations and unilaterally constrained evolution equations and which can be viewed as an infinite-dimensional differential-algebraic equation. Focussing on the time axis and leaving the space variables continuous, a grid-independent existence and uniqueness result is given for the class of coercive Runge–Kutta methods. Moreover, contractivity preservation and convergence are shown for methods that are also algebraically stable.

Key words. elastoplasticity, implicit Runge–Kutta methods, time integration, PDAE

1. Introduction.

We analyze implicit Runge–Kutta methods for an infinite-dimensional system of constrained evolution equations, the so-called dual problem of elastoplasticity. Our approach discretizes only the time axis and leaves the space variables continuous. In this way, we obtain a grid-independent formulation and lay the foundation for an implementation in the fashion of Rothe's method. The main results are first existence and uniqueness of the numerical solution for coercive Runge–Kutta methods, second contractivity preservation for algebraically stable methods, and third convergence for methods that feature both properties as well as a certain stage order.

Elastoplastic models are used for materials where the deformation process shows a time-dependent and irreversible behavior. Applications comprise, e.g., the stretch formation of metal sheets, wear effects in turbine blades, and the behavior of micromechanical devices. The mathematical model consists of a coupled system of balance equations and unilaterally constrained evolution equations, where the first set of equations stands for the balance of momentum and the second for the properties of the material under consideration [16]. We consider here materials that satisfy the principle of maximum plastic dissipation and possess a quadratic internal free energy.

In elastoplasticity, numerical simulation is mostly based on the method of lines [15, 16]. More precisely, one discretizes the balance equations by the finite element method (FEM) and reduces at the same time the evolution equations to the quadrature nodes of the grid. In these nodes, the evolution is integrated in time, with the implicit Euler as standard method and the return-mapping scheme for the handling of the unilateral constraint. Due to this constraint, the so-called yield condition, one deals actually with a differential-algebraic equation (DAE) of index 2 [8, 12].

Numerical experiments [4, 7, 18] indicate that at least order 2 is possible for

the time integration. Clearly, higher order methods can use larger time steps than the implicit Euler method and promise a more efficient simulation, particularly if a variable stepsize algorithm is employed. But which methods should be applied to elastoplasticity?

Before discretization, the equations can be viewed as an infinite-dimensional system of DAEs or as a PDAE (partial differential-algebraic equation). With the numerical analysis of DAEs in mind (see [3, 10, 14]), we focus therefore on the versatile class of implicit Runge–Kutta methods. In combination with the method of lines, this choice turned out to be successful [4, 7], and our objective is now the extension to Rothe's method, i.e., the direct application to the infinite-dimensional problem.

For the special case of the implicit Euler method, existence and uniqueness of the numerical solution have been shown recently [9]. Going one step further, we present results for the large class of implicit Runge–Kutta methods. In particular, we use the notions of coercivity and of algebraic stability to characterize those methods that are applicable in elastoplasticity. Various time integration methods become available in this way, among them Gauss, Radau, Lobatto, and several DIRK (diagonally implicit Runge–Kutta) methods.

Many authors have considered numerical methods in elastoplasticity. We mention here the recent monograph of Han and Reddy [9], which serves as extensive reference and from which we adopted both notation and some fundamental techniques. Wieners [18, 19] concentrated on multigrid methods for large-scale problems but also introduced, in cooperation with Ellsiepen [7], DIRK methods for the time integration. Moreover, Carstensen [5] coupled FEM and BEM for this problem class and studied domain decomposition techniques, while Armero and Pérez-Foguet analyzed closest point projection algorithms [1, 13]. The monograph of Simo and Hughes [16] represents the basic reference of the engineering literature.

Figure 1.1 is a road map of the paper. It illustrates the relation between the original problem formulation and its regularized counterpart, the so-called viscoplastic regularization due to Duvaut and Lions [6]. The latter has no yield condition and is thus much easier to analyze. Using a limit process, the results on the regularized problem both in the time-continuous and in the time-discrete case can be carried over to the original problem.

More specifically, the outline of the paper is as follows: Section 2 summarizes the mathematical model and the necessary framework. On one hand, the principle of maximum plastic dissipation leads to the aforementioned coupled system, which we express, following the approach of [9], in terms of displacement and generalized stress. The corresponding weak form defines the dual problem of elastoplasticity. On the other hand, the viscoplastic regularization yields a time-dependent saddlepoint problem. We also provide in this section some basic results on the existence and uniqueness of solutions.

In section 3, the implicit Runge–Kutta discretization is introduced, and the main results of the paper are stated. It turns out that the coefficient matrix of the Runge–Kutta method plays a crucial role for existence, contractivity, and convergence of the numerical solution. The existence proof makes use of the viscoplastic regularization and starts with the corresponding time-discrete saddlepoint problem. Letting the viscosity parameter tend to zero, we obtain the desired result for the variational inequality that stems from the discretization of the dual problem. The stability and convergence results, however, use techniques from the theory of B-stability for ODEs. For better readability, the proofs are given in separate sections 4 and 5. A conclusion closes the paper.

2. Mathematical model.

Kinematics, dynamics, and material law fully describe the elastoplastic deformation process. More precisely, the kinematic equation determines the geometric properties of the deformation, the dynamic equation expresses the balance of momentum, and the constitutive equations characterize the material under consideration. In this section, we state these three ingredients of the mathematical model and summarize some important properties. We adopt the notation of [9] and refer the interested reader to [9, 11, 16] for more details.

2.1. Kinematic relations and balance law.

Let the undeformed elastoplastic body occupy the region $\Omega \subset \boldsymbol{R}^3$. The deformation maps each material point $x \in \Omega$ at time t to its current position $x + u(x,t)$ with displacement field u. Without loss of generality, homogeneous Dirichlet boundary conditions are assumed,

$$u = 0 \qquad \text{on } \partial\Omega.$$

Here and in the following, we mostly drop the arguments x and t for convenience.

We consider small strains only, and consequently the (total) strain tensor ε is given by

$$\varepsilon = \varepsilon(u) := \frac{1}{2}\left(\nabla u + \nabla u^T\right). \tag{2.1}$$

By a tensor we mean usually a second order tensor in matrix representation, i.e., $\varepsilon = (\varepsilon_{ij})_{3\times 3}$. Like the strain tensor ε, the stress tensor σ also depends on time t, i.e., $\sigma = \sigma(x,t)$.

Material laws or constitutive equations relate stress and strain. We will come to this point in the next subsection. Before that, however, we state the balance of momentum for the quasi-static case,

$$\operatorname{div} \sigma + f = 0 \qquad \text{in } \Omega, \tag{2.2}$$

where $f = f(x,t)$ denotes some given volume force.

2.2. Constitutive equations. The constitutive equations of an elastoplastic material follow from thermodynamical considerations; see [9, 11, 17]. One basic assumption is that the total strain ε of (2.1) splits into an elastic part ε^e and a plastic part ε^p,

$$\varepsilon = \varepsilon^e + \varepsilon^p.$$

Using plastic strain ε^p and a vector of r so-called internal variables $\xi = (\xi_1, \dots, \xi_r)$, the state of a material point at a certain instant of time is modelled by the generalized plastic strain $P := (\varepsilon^p, \xi)$.

Another important quantity is the internal free energy function $\psi = \psi(\varepsilon^e, \xi)$, which comprises the usual stored energy function of elasticity and additional contributions from processes like hardening. Furthermore, the free energy defines the generalized stress $\Sigma := (\sigma, \chi)$ with stress tensor σ and conjugate force χ by

$$\sigma = \frac{\partial}{\partial \varepsilon^e}\psi, \tag{2.3}$$

$$\chi = -\frac{\partial}{\partial \xi}\psi. \tag{2.4}$$

One also says that the generalized stress is conjugate to the generalized strain.

As an example, consider linear hardening, where the quadratic internal free energy reads

$$\psi(\varepsilon^e, \xi) = \underbrace{\frac{1}{2}\varepsilon^e : C : \varepsilon^e}_{=:\psi^e(\varepsilon^e)} + \underbrace{\frac{1}{2}\xi \cdot H \cdot \xi}_{=:\psi^p(\xi)}\ , \tag{2.5}$$

with elasticity tensor C, regular $r \times r$ symmetric positive-definite matrix H of hardening moduli, and hardening variables ξ. Here we abbreviate tensor products by a ":", whereas a "$\cdot$" (or a blank) stands for matrix-vector products.

In case of linear hardening, the derivative (2.3) yields Hooke's law

$$\sigma = C : (\varepsilon - \varepsilon^p), \tag{2.6}$$

and (2.4) becomes

$$\chi = -H\xi.$$

In this paper, we restrict the discussion to materials that possess an internal free energy of the form (2.5).

At this point, all relevant variables of the constitutive equations have been introduced. However, a restriction on the generalized stress Σ has still to be taken into account. More specifically, Σ is required to lie in the set E of admissible generalized stresses. This convex set is characterized by

$$E = \{\Sigma \,|\, \phi(\Sigma) \le 0\} \tag{2.7}$$

with convex function ϕ, the so-called yield function. In the particular example of linear isotropic hardening where we have only one scalar conjugate force χ and a scalar hardening modulus H, the yield function is

$$\phi(\sigma, \chi) = \|\text{dev } \sigma\| - \sqrt{\frac{2}{3}}(\sigma_0 - \chi), \tag{2.8}$$

with given constant $\sigma_0 > 0$ and dev $\sigma = \sigma - 1/3 \text{ tr } \sigma$.

The constitutive equations follow now from the local *principle of maximum plastic work*. The rate of plastic work at a point in the material body is given by

$$W(\dot{P}) = \Sigma : \dot{P} := \sigma : \dot{\varepsilon}^p + \chi \cdot \dot{\xi}\,.$$

Given a rate of change $\dot{P}$ in the generalized plastic strain, the actual stress $\Sigma \in E$ maximizes the plastic work. In other words, every plastic deformation process stores as much energy as possible:

$$W(\dot{P}) = \max_{T \in E} \{T : \dot{P}\}. \tag{2.9}$$

For the current generalized stress Σ the following therefore holds:

$$\Sigma : \dot{P} \geq T : \dot{P} \qquad \forall T \in E. \tag{2.10}$$

Using the method of Lagrange multipliers, it is easily concluded that, for the quadratic free energy (2.5) and the admissible domain (2.7), the Kuhn–Tucker optimality conditions for the maximum principle (2.10) yield the local constitutive equations

$$\begin{aligned}
&\dot{\sigma} = C : \dot{\varepsilon} - C : \frac{\partial}{\partial \sigma}\phi(\sigma,\chi)\gamma,\\
&\dot{\chi} = -H\frac{\partial}{\partial \chi}\phi(\sigma,\chi)\gamma,\\
&0 \geq \phi(\sigma,\chi), \quad \gamma \geq 0,\\
&0 = \phi(\sigma,\chi)\gamma.
\end{aligned} \tag{2.11}$$

With the Lagrange multiplier γ as an additional unknown, the system (2.11) is a differential-algebraic equation with inequality constraint and complementarity condition. The differential equation for σ is the analogue of the flow rule for plastic strain ε^p, and the equation for χ is the hardening rule.

As shown in [4, 12], the index of the DAE (2.11) is 2 if the constraint is active, i.e., if $0 = \phi(\sigma, \chi)$. Then, the Lagrange multiplier γ is positive and the plastic deformation proceeds. Otherwise, if the constraint is not active, the Lagrange multiplier vanishes and we have $\dot{\sigma} = C : \dot{\varepsilon}$ and $\dot{\chi} = 0$, which means that the material is in an elastic phase.

We want to give two remarks here. First, though the DAE (2.11) inspires our choice of time discretization, we prefer to work in a variational setting in the following. There, the Lagrange multipliers actually do not show up anymore. And second, the DAE (2.11) is closely related to a singularly perturbed ODE that is obtained from a regularization technique, the so-called Perzyna formulation. Another regularization due to Duvaut and Lions [6], which we call here viscoplastic regularization, will play a key role in the existence proof in section 4.

2.3. Viscoplastic regularization. In contrast to the elastoplastic case, viscoplastic materials feature a rate-dependent behavior. Their constitutive equations are derived by adding a regularization J_η to the principle (2.9),

$$W_\eta(\dot{P}) = \max_{\Sigma}(\{\Sigma : \dot{P}\} - J_\eta(\Sigma)). \tag{2.12}$$

A common choice for the convex function J_η is the Yosida regularization

$$J_\eta(\Sigma) = \frac{1}{2\eta}\|\Sigma - \Pi\Sigma\|^2, \tag{2.13}$$

where Π denotes the orthogonal projection onto the elastic domain E and η is the regularization parameter [6, 9, 11, 16]. Obviously, for η tending to zero, the penalty term $J_\eta(\Sigma)$ tends to infinity if $\Sigma \notin E$.

For further use below, we mention an important property of the Yosida regularization. Since J_η is convex, its Gâteaux derivative J'_η is monotone and given under the Riesz isomorphism by

$$J'_\eta(\Sigma) = \frac{1}{\eta}(\Sigma - \Pi\Sigma).$$

The monotonicity is expressed as

$$(J'_\eta(\Sigma) - J'_\eta(T), \Sigma - T) \geq 0 \qquad \text{for all generalized stresses } \Sigma, T; \tag{2.14}$$

see [9, Chapter 8.1] for details.

After this outline of the mathematical model, we pass now to the weak form and specify the appropriate function spaces.

2.4. The dual problem of elastoplasticity. We require stress, strain, internal variables, and conjugated forces to be square-integrable on the domain Ω at any time. Consequently, we introduce the space

$$\mathcal{S} := \{\tau = (\tau_{ij})_{3\times 3} \,:\, \tau_{ij} = \tau_{ji},\, \tau_{ij} \in L^2(\Omega)\}$$

for the symmetric tensors, and the space

$$\mathcal{M} := \{\mu = (\mu_j) \,:\, \mu_j \in L^2(\Omega),\, j = 1, \dots, r\}$$

for the conjugated forces. The product space

$$\mathcal{T} := \mathcal{S} \times \mathcal{M},$$

which is like the other spaces endowed with the natural L^2 inner product $(\cdot,\cdot)$, thus contains the square-integrable generalized stresses. Furthermore, we define the convex subset

$$\mathcal{P} := \{T = (\tau, \mu) \in \mathcal{T} \,:\, (\tau, \mu) \in E \quad \text{a.e. in}\, \Omega\}$$

for admissible states T.

In order to derive the variational formulation, we multiply the balance of momentum (2.2) by test functions belonging to

$$V = \{v \in H^1(\Omega)^3 : v = 0 \quad \text{on } \partial\Omega\}.$$

Using the Gauss divergence theorem, we arrive at

$$-\int_\Omega \varepsilon(v) : \sigma \, dx = -\int_\Omega f(t) \cdot v \, dx \qquad \forall v \in V.$$

From the principle of maximum plastic work (2.10), we obtain the variational inequality

$$\begin{aligned}0 &\leq \int_\Omega (\sigma - \tau) : \dot{\varepsilon}^p + (\chi - \mu) \cdot \dot{\xi}\, dx \\ &= -\int_\Omega (\sigma - \tau) : C^{-1}\dot{\sigma} + (\chi - \mu) \cdot H^{-1}\dot{\chi}\, dx + \int_\Omega (\sigma - \tau) : \dot{\varepsilon}\, dx\end{aligned}$$

for all $T = (\tau, \mu) \in \mathcal{P}$. To get a more compact notation, the integrals in the variational inequality are abbreviated by the bilinear forms

$$\begin{aligned} &A : \mathcal{T} \times \mathcal{T} \to \boldsymbol{R}, \qquad A(\Sigma, T) := \int_\Omega \sigma : C^{-1}\tau\, dx + \int_\Omega \chi \cdot H^{-1}\mu\, dx, \\ &b : V \times \mathcal{S} \to \boldsymbol{R}, \qquad b(v, \tau) := -\int_\Omega \varepsilon(v) : \tau\, dx \end{aligned}$$

for $\Sigma = (\sigma, \chi)$ and $T = (\tau, \mu)$. Finally, the integral on the right-hand side of the balance equation is identified with a time-dependent linear operator on the dual space, that is,

$$l(t) : V \to \boldsymbol{R}, \qquad \langle l(t), v \rangle = -\int_\Omega f(t) \cdot v\, dx.$$

Now we can state the dual problem as follows.

DUAL PROBLEM. *Given $l \in H^1(0, t_f; V')$ with $l(0) = 0$, find $(u, \Sigma) = (u, \sigma, \chi) : [0, t_f] \to V \times \mathcal{P}$ with $(u(0), \Sigma(0)) = (0, 0)$ such that for almost all $t \in (0, t_f)$ we have*

$$b(v, \sigma(t)) = \langle l(t), v \rangle \qquad \forall v \in V, \tag{2.15}$$

$$A(\dot{\Sigma}(t), T - \Sigma(t)) + b(\dot{u}(t), \tau - \sigma(t)) \geq 0 \qquad \forall T = (\tau, \mu) \in \mathcal{P}. \tag{2.16}$$

The name "dual," introduced in [9], is related to the use of the conjugate quantities, i.e., the generalized stress, instead of the primal unknowns plastic strain ε^p and internal variables ξ. Note that the dual problem can be viewed as an abstract constrained initial value problem. The generalized stress Σ is the main quantity of interest, whereas the displacement u is not unique since only the velocity $\dot{u}$ appears in the formulation.

2.5. Basic properties. The following assumptions on the shape of the admissible domain $\mathcal{P}$ are a fundamental prerequisite.

SAFE LOAD CONDITION SLC. *There is a constant $c > 0$ such that for any $T_1 = (\tau_1, \mu_1) \in \mathcal{P}$ and any stress tensor $\tau_2 \in \mathcal{S}$ there exists a conjugated force $\mu_2 \in \mathcal{M}$ such that*

$$\|\mu_2\| \leq c\|\tau_2\| \quad \textit{and} \quad (\tau_1, \mu_1) + (\tau_2, \mu_2) \in \mathcal{P}.$$

The safe load condition is fulfilled for various yield conditions, particularly for linear isotropic hardening (2.8). In some sense, it is necessary to complete the dual problem. The same holds true for the next assumption, which refers to the set E from (2.7).

ASSUMPTION A1. *For any $T \in E$ and any $\kappa \in [0, 1)$, we have $\kappa T \in E$ and*

$$\inf_{x \in \Omega} \operatorname{dist}(\kappa T(x), \partial E) > 0. \tag{2.17}$$

Under these assumptions, whose specific forms were first introduced in [9] and are easier to check than other variants, there exists a solution of the dual problem as follows.

THEOREM 2.1. *If the safe load condition SLC and Assumption A*1 *are fulfilled, then the dual problem has a solution* (u, Σ) *and* Σ *is unique.*

We briefly outline the idea of the proof given in [9] since our approach in section 4 will follow the same lines. The key idea is the viscoplastic regularization (2.12), which is an unconstrained optimization problem. Therefore taking the derivative of (2.12) and setting it to zero yields the variational equality

$$A(\dot{\Sigma}(t), T) + \big(J'_\eta(\Sigma(t)), T\big) + b(\dot{u}(t), \tau) = 0 \qquad \forall T = (\tau, \mu) \in \mathcal{T}, \tag{2.18}$$

$$b(v, \sigma(t)) = \langle l(t), v\rangle \qquad \forall v \in V. \tag{2.19}$$

The balance equation (2.15) has been added to show the connection to a saddlepoint problem. Next, for the bilinear form b there exists a constant $\beta_b > 0$ such that

$$\sup_{0\neq\tau\in\mathcal{S}} \frac{|b(v,\tau)|}{\|\tau\|_{\mathcal{S}}} \geq \beta_b \|v\|_V \quad \forall v \in V. \tag{2.20}$$

This is the Babuška–Brezzi condition, but note that b satisfies (2.20) only on $\mathcal{S}$ and not on $\mathcal{T}$. For this reason, we need in addition the SLC. This assumption guarantees a solution σ of (2.19) in the orthogonal complement of the kernel of b such that there exists χ with $(\sigma, \chi) \in \mathcal{P}$. Due to the coercivity of A, which means there exists a constant β_A such that

$$A(T, T) \geq \beta_A \|T\|^2_{\mathcal{T}} \qquad \forall T \in \mathcal{T},$$

and due to the monotonicity of J'_η, that is,

$$(J'_\eta(\Sigma) - J'_\eta(T), \Sigma - T) \geq 0,$$

there exists a solution $(\Sigma, \dot{u})$ of the regularized problem (2.18)–(2.19).

In the second step of the proof, one lets a suitable subsequence of η tend to zero and shows for this sequence that the limit with respect to Σ and $\dot{u}$ exists and solves the dual problem. Uniqueness follows from the coercivity of A.

At the end of this section, we mention another important fact. The solution of the dual problem possesses a contractivity property with respect to the norm

$$\|\cdot\|_A := \sqrt{A(\cdot,\cdot)},$$

the so-called complementary energy norm. The following result holds.

THEOREM 2.2. *Assume that* (u, Σ) *and* $(\widehat{u}, \widehat{\Sigma})$ *are solutions of the dual problem for different initial values. Then*

$$\|\Sigma(t) - \widehat{\Sigma}(t)\|_A \leq \|\Sigma(0) - \widehat{\Sigma}(0)\|_A$$

for all times $t > 0$.

Proofs of this property can be found in [9, 16].

3. Main results. In this section, the implicit Runge–Kutta discretization is introduced and the main results of the paper are stated. It turns out that the coefficient matrix of the Runge–Kutta method plays a crucial role for existence, contractivity, and convergence of the numerical solution. The existence proof makes use of the viscoplastic regularization and starts with the corresponding time-discrete saddlepoint problem. We postpone the details of this proof, however, to section 4.

3.1. Runge–Kutta method. We approximate the solution of the dual problem in time by implicit Runge–Kutta methods. For this purpose, the time derivatives in (2.15) and (2.16) are replaced by the stage derivatives of the Runge–Kutta method. Let s be the number of stages, $(a_{ij}) = \mathcal{A}$ the $s \times s$ coefficient matrix, (b_i) the vector of weights, (c_i) the vector of quadrature nodes, and h the stepsize. Moreover, the numerical approximations at time t_n are denoted by Σ_n and u_n.

One step of the Runge–Kutta method from t_n to $t_{n+1} = t_n + h$ is defined by

$$\Sigma_{n+1} = \Sigma_n + h \sum_{i=1}^{s} b_i \Psi_{n,i}, \qquad u_{n+1} = u_n + h \sum_{i=1}^{s} b_i w_{n,i},$$

where $\Psi_{n,i}$ and $w_{n,i}$ are the stage derivatives at time $t_{n,i} = t_n + c_i h$. The stages $\Sigma_{n,i} = (\sigma_{n,i}, \chi_{n,i}) \in \mathcal{P}$ and the stage derivatives $w_{n,i} \in V$ satisfy the nonlinear system

$$b(v, \sigma_{n,i}) = \langle l_{n,i}, v \rangle \qquad \forall v \in V, \tag{3.1}$$

$$A(\Psi_{n,i}, T - \Sigma_{n,i}) + b(w_{n,i}, \tau - \sigma_{n,i}) \geq 0 \qquad \forall T = (\tau, \nu) \in \mathcal{P} \tag{3.2}$$

for $i = 1, \ldots, s$, with right-hand sides $l_{n,i} = l(t_n + c_i h)$. Stages $\Sigma_{n,i}$ and stage derivatives $\Psi_{n,i}$ are coupled via

$$\Sigma_{n,i} = \Sigma_n + h \sum_{j=1}^{s} a_{ij} \Psi_{n,j}. \tag{3.3}$$

This method definition includes various schemes like implicit Euler, midpoint and generalized midpoint rule (θ-method), DIRK schemes, and further implicit discretizations (the methods of Gauss, Lobatto, or Radau type). Our focus will be on the latter class, but the results are not restricted to it.

3.2. Existence of the numerical solution. Does the nonlinear system (3.1)–(3.3) possesses a solution? The answer depends very much on the coefficient matrix $\mathcal{A}$. If one looks back to the proof of Theorem 2.1, one notices that the coercivity of the bilinear form A was a basic prerequisite. At first look, the coupling (3.3) destroys this property: Consider (3.2) and replace the stage derivatives $\Psi_{n,i}$ by the stages $\Sigma_{n,i}$ using the relation (3.3). Thereby the $\Sigma_{n,i}$ are multiplied in a certain sense by the inverse of the Runge–Kutta matrix before the bilinear form A is evaluated, and we obtain a new bilinear form that depends on the method coefficients. The crucial point is whether this new bilinear form is still coercive.

In the theory of stiff ODEs, similar problems occur [10]. In general, the Runge–Kutta matrix $\mathcal{A}$ is not positive definite, but in many cases it possesses a coercivity property.

DEFINITION 3.1. *We consider the inner product $(u, v)_D := u \cdot Dv$ on $\boldsymbol{R}^s$, where $D = \operatorname{diag}(d_1, \ldots, d_s)$ with positive entries $d_i > 0$. The Runge–Kutta matrix $\mathcal{A}$ is coercive iff there exists a positive diagonal matrix D and a constant α_D such that*

$$(u, \mathcal{A}^{-1} v)_D \geq \alpha_D (u, v)_D$$

for all $u, v \in \boldsymbol{R}^s$. In this case, we set

$$\alpha_0(\mathcal{A}^{-1}) := \sup_{D>0} \alpha_D.$$

Radau IA	$B(I - C)$	1 $s > 1$	1 $\frac{1}{2(1-c_2)}$
Radau IIA	BC^{-1}	1 $s > 1$	1 $\frac{1}{2c_{s-1}}$

$(B = \operatorname{diag}(b_1, \dots, b_s), \quad C = \operatorname{diag}(c_1, \dots, c_s))$

From [10, Theorem 14.5], we have the following classification.

THEOREM 3.2. *If the Runge–Kutta method belongs to one of the classes Gauss, Radau* IA*, or Radau* IIA*, then the Runge–Kutta matrix is coercive.*

For these method classes, the matrices D and the constants α_D are listed in Table 3.1.

We remark that DIRK methods with positive coefficients a_{ii} on the diagonal are coercive too [10, Theorem 14.6]. The constant α_D is here given by

$$\alpha_0(A^{-1}) = \min \frac{1}{a_{ii}}.$$

With the notion of coercivity for a Runge–Kutta method at hand, we are able to state the main result of this paper as follows.

THEOREM 3.3. *Let the Runge–Kutta matrix be coercive, and let the SLC and Assumption* A1 *be satisfied. Then the discretization scheme* (3.1)–(3.3) *possesses a solution* $(w_{n,i}, \Sigma_{n,i})$ *for* $i = 1, \dots, s$*, and the stages* Σ_i *of the generalized stresses are unique.*

The proof follows the same lines as the proof of Theorem 2.1. Since we have to consider s stages, however, many technical details need to be addressed. Our starting point is the Runge–Kutta discretization of the viscoplastic regularization (2.18) in combination with the balance equation (2.19). In order to simplify the notation, for the rest of the paper we write Σ_i instead of $\Sigma_{n,i}$ and omit the index n for all other stage variables. Furthermore, to distinguish between the original and the regularized problem, we now use the superscript η for the variables of the regularized problem and discretize it in the following way.

Find $(w_i^\eta, \Sigma_i^\eta) = (w_i^\eta, \sigma_i^\eta, \chi_i^\eta) \in V \times \mathcal{T}$ such that

$$b(v, \sigma_i^\eta) = \langle l_i, v \rangle \qquad \forall v \in V, \tag{3.4}$$

$$A(\Psi_i^\eta, T) + \left(J_\eta'(\Sigma_i^\eta), T\right)_{\mathcal{T}} + b(w_i^\eta, \tau) = 0 \qquad \forall T = (\tau, \nu) \in \mathcal{T} \tag{3.5}$$

for $i = 1, \dots, s$. Stages Σ_i^η and stage derivatives Ψ_i^η are related to each other via

$$\Sigma_i^\eta = \Sigma_n + h \sum_{j=1}^{s} a_{ij} \Psi_j^\eta. \tag{3.6}$$

Note that the solution (u_n, Σ_n) of the last step is taken from the original but not from the regularized problem.

In a certain product space, the discretized regularization represents a saddlepoint problem, and therefore the reasoning of the proof relies very much on the corresponding theory. We postpone the details of the proof to section 4.

3.3. Contractivity. In ODE theory, the differential equation

$$\dot{y} = f(t,y)$$

is called contractive if it satisfies a one-sided Lipschitz condition

$$(f(t,y) - f(t,z), y - z) \leq 0.$$

The elastoplastic contractivity of Theorem 2.2 can be seen as an analogue, and the question is whether time discretizations preserve this property. For generalized midpoint schemes, contractivity of the elastoplastic flow is shown in [15, 16]. Wieners [18] extended the result in the context of DIRK methods and proved that algebraic stability is sufficient to preserve the contractivity.

To be more precise, the notion of algebraic stability is defined as follows (see [10]).

Definition 3.4. *A Runge–Kutta method is called algebraically stable iff*

1. $b_i \geq 0$ *for all* $i = 1, \ldots, s$,
2. $M = (m_{ij}) = (b_i a_{ij} + b_j a_{ji} - b_i b_j)_{i,j=1}^{s}$ *is nonnegative definite.*

The contractivity result of [18] carries immediately over to the more general class considered here; cf. [4, 15, 16].

Theorem 3.5. *Algebraically stable Runge–Kutta methods preserve the contractivity of the elastoplastic flow; that is,*

$$\|\Sigma_n - \widehat{\Sigma}_n\|_A \leq \|\Sigma_0 - \widehat{\Sigma}_0\|_A \tag{3.7}$$

for different initial values Σ_0 *and* $\widehat{\Sigma}_0$.

The notions of algebraic stability and coercivity of a Runge–Kutta method are not equivalent. Remarkably, however, there are several classes, in particular Gauss, Radau IA, and Radau IIA, that feature both properties.

3.4. Convergence. We start by introducing consistency in terms of the stage order q, which is the positive integer such that conditions

$$B(q) \quad : \quad \sum_{i=1}^{s} b_i c_i^{r-1} = \frac{1}{r}, \quad r = 1, \ldots, q,$$

and

$$C(q) \quad : \quad \sum_{j=1}^{s} a_{ij} c_j^{r-1} = \frac{c_i^r}{r}, \quad r = 1, \ldots, q, \; i = 1, \ldots, s,$$

hold true. Thus the stage order defines the accuracy of the quadrature rule that is the basis of the Runge–Kutta method. We assume now that the generalized stresses are elements of the Sobolev space $H^{q+1}(0, t_f; \Omega)$. Then a weak Taylor expansion and conditions $B(q)$ and $C(q)$ imply

$$\Bigg\| \underbrace{\mathbf{\Sigma}(t_{n+1}) - \mathbf{\Sigma}(t_n) - h \sum_{i=1}^{s} b_i \mathbf{\Sigma}(t_n + c_i h)}_{=:Q_n} \Bigg\|_{\mathcal{T}} \leq c h^q \|\mathbf{\Sigma}^{(q+1)}\|_{L^1(t_n, t_{n+1}; \Omega)} =: Q_n^{\mathrm{Err}}$$

TABLE 3.2
The stage order; see Table IV.5.13 *in* [10].

Method	Consistency conditions	Stage order
Gauss	$B(2s), C(s)$	s
Radau IIA	$B(2s-1), C(s)$	s

and

$$\Bigg\| \underbrace{\boldsymbol{\Sigma}(t_n + c_i h) - \boldsymbol{\Sigma}(t_n) - h \sum_{j=1}^{s} a_{ij} \dot{\boldsymbol{\Sigma}}(t_n + c_j h)}_{=:S_n^i} \Bigg\|_{\mathcal{T}} \leq ch^q \|\boldsymbol{\Sigma}^{(q+1)}\|_{L^1(t_n,t_{n+1};\Omega)} =: S_n^{\mathrm{Err}}.$$

Note, that the error estimate on the right-hand side, S_n^{Err}, is independent of the stage number i. Stage orders for Gauss and Radau IIA methods are listed in Table 3.2.

THEOREM 3.6. *Assume that the Runge–Kutta method is coercive and algebraically stable, $B(q)$ and $C(q)$ are fulfilled, and $\Sigma \in H^{(q+1)}(0, t_f; \Omega)$. Then the following holds for the global error on $[0, t_f]$ with $N = [t_f/h]$:*

$$\max_{r=1,\ldots,N} \|\Sigma(t_r) - \Sigma_r\|_{\mathcal{T}} \leq ch^q \|\boldsymbol{\Sigma}^{(q+1)}\|_{L^1(0,t_f;\Omega)}.$$

Hence existence, stability, and consistency of the Runge–Kutta method imply convergence for the dual problem of elastoplasticity. The proof of Theorem 3.6 is postponed to section 5. We remark that the smoothness assumption $\Sigma \in H^{(q+1)}(0, t_f; \Omega)$ is not backed by the regularity provided by the theory; see also the discussion in Chapter 13.1 of [9] on the midpoint rule.

4. Proof of Theorem 3.3. The proof generalizes Theorem 8.12 of [9], which is formulated for the implicit Euler method. We first give an outline and provide some necessary framework.

The existence proof proceeds in three steps. In step one, it is shown that the discrete regularized system (3.4)–(3.6) possesses a solution $(w_i^\eta, \Sigma_i^\eta)$, $i = 1, \ldots, s$, depending on the parameter η. Step two constructs a uniform bound for $(w_i^\eta, \Sigma_i^\eta)$ and selects a weakly convergent subsequence. Finally, step three establishes the limit $\lim_{\eta\to 0}(w_i^\eta, \Sigma_i^\eta) = (w_i, \Sigma_i)$ as a solution of the dual problem. Uniqueness of the stages Σ_i follows from the coercivity of both the bilinear form A and the Runge–Kutta matrix $\mathcal{A}$.

Since the saddlepoint structure plays a crucial role in our first step, we next cite an important result concerning the bilinear form b. Related to b, one defines the operators $B : \mathcal{S} \to V'$ and $B' : V \to \mathcal{S}'$ by

$$\langle B\sigma, v\rangle := \langle B'v, \sigma\rangle := b(v, \sigma) \qquad \text{for } v \in V,\ \sigma \in \mathcal{S}.$$

If the Babuška-Brezzi condition holds (cf. (2.20)), we have the following (see [2, 9]).

PROPOSITION 4.1. *The operator B is an isomorphism from* $(\mathrm{Ker}\ B)^\perp$ *onto V', where*

$$\mathrm{Ker} B = \{\sigma \in \mathcal{S} : b(v, \sigma) = 0 \quad \forall v \in V\},$$

and the operator B' is an isomorphism from (Ker $B)^\circ$ *onto* V, *where*

$$(\mathrm{Ker}B)^\circ = \{f \in \mathcal{S}' : \langle f, \tau\rangle = 0 \quad \forall \tau \in \mathrm{Ker}B\}.$$

The framework is completed by a notational agreement. We abbreviate the array of s stages Σ_i by

$$\vec{\Sigma} := (\Sigma_1, \dots, \Sigma_s)^T.$$

In the same fashion, we extend the initial value Σ_n of the old time step to

$$\vec{\Sigma}_n := (\Sigma_n, \dots, \Sigma_n)^T.$$

Although $\vec{\Sigma}$ and $\vec{\Sigma}_n$ are not vectors of real numbers but of tensor-valued functions, we connect them like standard vectors with the Runge–Kutta matrix $\mathcal{A}$ and skip the introduction of an appropriate Kronecker product. As an example, the relation (3.6) between stages and stage derivatives reads in this notation

$$\vec{\Sigma}^\eta = \vec{\Sigma}_n + h\mathcal{A}\vec{\Psi}^\eta \quad \Leftrightarrow \quad \vec{\Psi}^\eta = \frac{1}{h}\mathcal{A}^{-1}(\vec{\Sigma}^\eta - \vec{\Sigma}_n).$$

4.1. Step one (regularized problem). The bilinear form b satisfies the Babuška–Brezzi condition (2.20). Due to Proposition 4.1 there is for each stage i a unique element $\sigma_i^0 \in (\mathrm{Ker}B)^\perp$ such that

$$b(v, \sigma_i^0) = \langle l_i, v\rangle \qquad \forall v \in V.$$

Taking the constant c as the operator norm of B^{-1}, we have

$$\|\sigma_i^0\|_S \le c\|l_i\|$$

for all stages. Applying the SLC to $2\sigma_i^0$, we find an element in $\mathcal{M}$, denoted by $2\chi_i^0$, such that $(2\sigma_i^0, 2\chi_i^0) \in \mathcal{P}$ and

$$\|\chi_i^0\| \le c\|\sigma_i^0\| \le c\|l_i\|.$$

We set $\Sigma_i^0 = (\sigma_i^0, \chi_i^0)$. Assumption A1 on the structure of the elastic domain ensures that $\Sigma_i^0 \in E$ almost everywhere and (see Figure 4.1)

$$r_i \equiv \inf_{x\in\Omega} \mathrm{dist}(\Sigma_i^0(x), \partial E) > 0. \tag{4.1}$$

Next, we look for a solution of (3.5) in the form $\Sigma_i^\eta = \Sigma_i^0 + \Sigma_i^{\delta\eta}$, where $\Sigma_i^{\delta\eta} = (\sigma_i^{\delta\eta}, \chi_i^{\delta\eta})$ is an element of $\mathrm{Ker}\, B \times \mathcal{M}$. We observe that the balance equation (3.4) still holds if Σ_i^0 is updated by an element of $\mathrm{Ker}\, B \times \mathcal{M}$.

At this point of the proof, the coupling (3.6) becomes important and we pass to the product space $\mathcal{T}^s$. We define a bilinear form on $\mathcal{T}^s$ by

$$\vec{A} : \begin{cases} \mathcal{T}^s \times \mathcal{T}^s & \to \quad \boldsymbol{R}, \\ \left(\vec{\Theta}, \vec{\Upsilon}\right) & \mapsto \quad d_1 A(\Phi_1, \Upsilon_1) + \dots + d_s A(\Phi_s, \Upsilon_s) \quad \text{with } \vec{\Phi} := \mathcal{A}^{-1}\vec{\Theta}, \end{cases}$$

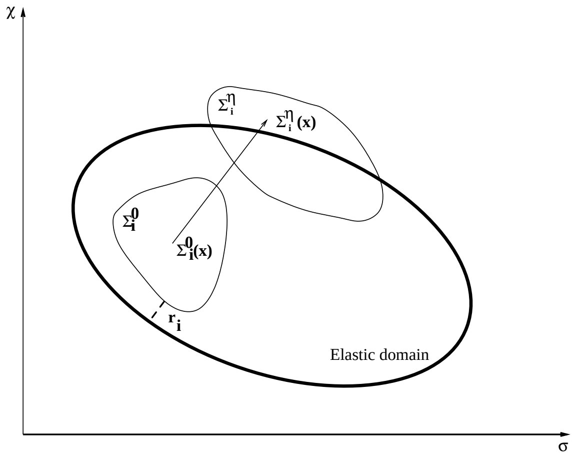

FIG. 4.1. *Situation in step* 1.

where D is the diagonal matrix related to the Runge–Kutta matrix $\mathcal{A}$ according to Definition 3.1. Since the bilinear form A is coercive on $\mathcal{T} \times \mathcal{T}$, its extension $\vec{A}$ defines a coercive bilinear form, that is,

$$\vec{A}(\vec{\Upsilon}, \vec{\Upsilon}) \geq \alpha_0(\mathcal{A}^{-1}) \min\{d_i\} \beta_A (\vec{\Upsilon}, \vec{\Upsilon})_{\mathcal{T}^s}$$

with the scalar product

$$(\vec{\Upsilon}, \vec{\Upsilon})_{\mathcal{T}^s} := (\Upsilon_1, \Upsilon_1)_{\mathcal{T}} + \cdots + (\Upsilon_s, \Upsilon_s)_{\mathcal{T}} \, .$$

In general, $\vec{A}$ is not symmetric. We also need to extend the scalar product of the regularization J'_η to the product space $\mathcal{T}^s$. For this purpose, a weighted sum with the elements of D is introduced, similar to the definition of $\vec{A}$:

$$\vec{J}'_\eta \begin{cases} \mathcal{T}^s \times \mathcal{T}^s & \rightarrow \quad \boldsymbol{R}, \\ \\ \left(\vec{\Theta}, \vec{\Upsilon}\right) & \mapsto \quad d_1 \left(J'_\eta(\Theta_1), \Upsilon_1\right) + \cdots + d_s \left(J'_\eta(\Theta_s), \Upsilon_s\right). \end{cases}$$

Now we can resume the proof and look for an element $\vec{\Sigma}^{\delta\eta} \in (\operatorname{Ker} B \times \mathcal{M})^s$ satisfying

$$\frac{1}{h}\vec{A}(\vec{\Sigma}^{\delta\eta}, \vec{T}) + \vec{J}'_\eta(\vec{\Sigma}^0 + \vec{\Sigma}^{\delta\eta}, \vec{T}) = \frac{1}{h}\vec{A}(\vec{\Sigma}_n - \vec{\Sigma}^0, \vec{T}) \tag{4.2}$$

for all $\vec{T} \in (\operatorname{Ker} B \times \mathcal{M})^s$. This is an operator equation with the nonlinear operator $L : \mathcal{T}^s \rightarrow (\mathcal{T}^s)'$ defined by

$$\langle L\cdot, \vec{T}\rangle := \frac{1}{h}\vec{A}(\cdot, \vec{T}) + \vec{J}'_\eta(\vec{\Sigma}^0 + \cdot, \vec{T}) \qquad \forall \vec{T} \in \mathcal{T}^s.$$

Because $\vec{A}$ is coercive and $\vec{J}'_\eta$ is monotone, the operator L is strongly monotone. [9, Theorem 5.10, p. 107] establishes the existence of a unique solution $\vec{\Sigma}^{\delta\eta}$ of (4.2).

Setting $T_i = T$ and $T_j = 0$ for $j \neq i$, (4.2) yields

$$A(\Psi_i^\eta, T) + \left(J'_\eta(\Sigma_i^\eta), T\right) = 0 \qquad \forall T \in \operatorname{Ker} B \times \mathcal{M}. \tag{4.3}$$

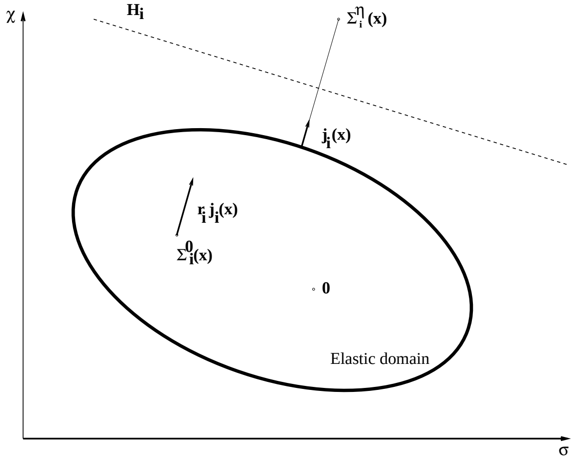

Fig. 4.2. *Situation in step* 2.

The left-hand side of (4.3) defines a continuous linear form on $\mathcal{T}$ and is also part of the left-hand side of (3.5). Though Proposition 4.1 is valid only for stresses $\sigma \in \mathcal{S}$, it is straightforward to extend it to generalized stresses $T \in \mathcal{T}$. Therefore, there exists an element $w_i^\eta \in V$ such that (3.5) is satisfied and consequently the regularized problem (3.4)–(3.6) has a solution $(w_i^\eta, \Sigma_i^\eta)$ for $i = 1, \dots, s$.

4.2. Step two (uniform boundedness). (a) First, we derive a uniform bound for $\vec{\Sigma}^\eta$. Setting $\vec{T} = \vec{\Sigma}^{\delta\eta}$ in (4.2) leads to

$$\frac{1}{h}\vec{A}(\vec{\Sigma}^{\delta\eta}, \vec{\Sigma}^{\delta\eta}) + \vec{J}'_\eta(\vec{\Sigma}^0 + \vec{\Sigma}^{\delta\eta}, \vec{\Sigma}^{\delta\eta}) = \frac{1}{h}\vec{A}(\vec{\Sigma}_n - \vec{\Sigma}^0, \vec{\Sigma}^{\delta\eta}).$$

The convexity of the Yosida regularization J_η implies for $\Sigma_i^0 \in \mathcal{P}$

$$0 = J_\eta(\Sigma_i^0) \geq J_\eta(\Sigma_i^0 + \Sigma_i^{\delta\eta}) + (J'_\eta(\Sigma_i^0 + \Sigma_i^{\delta\eta}), -\Sigma_i^{\delta\eta}).$$

Since $J_\eta(\Sigma_i^0 + \Sigma_i^{\delta\eta}) \geq 0$, we obtain

$$\vec{A}(\vec{\Sigma}^{\delta\eta}, \vec{\Sigma}^{\delta\eta}) \leq \vec{A}(\vec{\Sigma}_n - \vec{\Sigma}^0, \vec{\Sigma}^{\delta\eta}).$$

Next, the coercivity and the continuity of $\vec{A}$ yield the existence of a constant c such that

$$\|\vec{\Sigma}^\eta\| \leq c. \tag{4.4}$$

(b) Second, we show the uniform boundedness of w_i^η. For all $x \in \Omega$ with $\Sigma_i^\eta(x) \in E$, $J'_\eta(\Sigma_i^\eta)(x) = 0$ holds. Therefore we assume $\Sigma_i^\eta(x) \notin E$ and define

$$j_i(x) = \frac{\Sigma_i^\eta(x) - \Pi\Sigma_i^\eta(x)}{|\Sigma_i^\eta(x) - \Pi\Sigma_i^\eta(x)|}.$$

Since E is a closed convex set in the finite-dimensional vector space of generalized forces, $j_i(x)$ is normal to a hyperplane $H_i = \{T \mid j_i(x) : T = \rho_i\}$; see Figure 4.2.

Now we exploit (4.1). Since $\Sigma_i^0(x) + r_i j(x) \in E$ and $0 \in E$, we have

$$j_i(x) : \Sigma_i^\eta(x) \geq \rho_i \quad \text{and} \quad j_i(x) : \left(\Sigma_i^0(x) + r_i j(x)\right) \leq \rho_i.$$

Geometrically this means that $\Sigma_i^\eta(x)$ and $(\Sigma_i^0(x) + r_i j_i(x))$ are separated by the hyperplane H_i; see Figure 4.2. Hence

$$j_i(x) : \left(\Sigma_i^\eta - \Sigma_i^0(x)\right) \geq r_i,$$

that is,

$$|\Sigma_i^\eta(x) - \Pi\Sigma_i^\eta(x)| \leq \frac{1}{r_i}(\Sigma_i^\eta(x) - \Pi\Sigma_i^\eta(x)) : (\Sigma_i^\eta - \Sigma_i^0(x)).$$

Since the latter inequality holds also for all $x \in \Omega$ with $\Sigma_i^\eta(x) \in E$, we obtain

$$\|J_\eta'(\Sigma_i^\eta)\| \leq \frac{1}{r_i}\left(J_\eta'(\Sigma_i^\eta), \Sigma_i^\eta - \Sigma_i^0\right). \tag{4.5}$$

Now we return to (4.3). There we set $T_i = \Sigma_i^\eta - \Sigma_i^0 \in \operatorname{Ker} B \times \mathcal{M}$. Inserting (4.3) into (4.5) yields

$$\|J_\eta'(\Sigma_i^\eta)\|_{\mathcal{T}} \leq -\frac{1}{r_i}A(\Psi_i^\eta, \Sigma_i^\eta - \Sigma_i^0).$$

Since the uniform boundedness of $\vec{\Sigma}^\eta$ implies

$$|A(\Psi_i^\eta, \Sigma_i^\eta - \Sigma_i^0)| \leq \alpha\|\Psi_i^\eta\|_{\mathcal{T}}\|\Sigma_i^\eta - \Sigma_i^0\| \leq \tilde{c},$$

we conclude

$$\|J_\eta'(\Sigma_i^\eta)\|_{\mathcal{T}} \leq \tilde{c}.$$

From the Babuška–Brezzi condition in combination with (3.5) we obtain

$$\begin{aligned}
\beta_b\|w_i^\eta\|_V &\leq \sup_{\tau\in\mathcal{S}}\frac{|b(w_i^\eta,\tau)|}{\|\tau\|_{\mathcal{S}}} \\
&\leq \sup_{\tau\in\mathcal{S}}\frac{|-A(\Psi_i^\eta,(\tau,0)) - J_\eta'\left(\Sigma_i^\eta,(\tau,0)\right)|}{\|\tau\|_{\mathcal{S}}} \\
&\leq \tilde{c}\left(\|\Psi_i^\eta\|_{\mathcal{T}} + \|J_\eta'(\Sigma_i^\eta)\|\right) \leq \tilde{c}.
\end{aligned}$$

Extending this to the product space leads to the uniform bound of $\vec{w}^\eta$.

In parts (a) and (b) of step 2, we established the uniform boundedness of $\vec{\Sigma}^\eta$ and $\vec{w}^\eta$. Thus we can extract a subsequence that converges weakly in the dual space of $\mathcal{T}^s \times V^s$, still denoted by $\vec{\Sigma}^\eta$ and $\vec{w}^\eta$, such that $(\vec{\Sigma}^\eta, \vec{w}^\eta) \rightharpoonup (\vec{\Sigma}, \vec{w})$ as $\eta \to 0$.

4.3. Step three (proving (3.1) and (3.2)). The last part of the existence proof again splits into several parts. In part (a), we show that the limits Σ_i are admissible. In part (b), we prove the equality (3.1), and finally, in part (c), we establish the variational inequality (3.2).

(a) First, we prove that the limits Σ_i are admissible, that is, $\Sigma_i \in \mathcal{P}$. Since

$$\Sigma_i \in \mathcal{P} \Leftrightarrow \|\Sigma_i - \Pi\Sigma_i\| = 0,$$

we investigate the convex functional J_η. The convexity of J_η yields

$$J_\eta(\Sigma_i^\eta) \leq (J_\eta'(\Sigma_i^\eta), \Sigma_i^{\delta\eta}).$$

Equation (4.3) implies $A(\tilde{\Sigma}_i^\eta, \Sigma_i^{\delta\eta}) + J_\eta(\Sigma_i^\eta) \leq 0$, which is equivalent to

$$J_\eta(\Sigma_i^\eta) \leq -A(\Psi_i^\eta, \Sigma_i^{\delta\eta}) = -\frac{1}{h} A(A_i^{-1}(\vec{\Sigma}_n - \vec{\tilde{\Sigma}}_i^\eta), \Sigma_i^\eta - \Sigma_0^i).$$

Since Σ_i^η is uniformly bounded, we have $J_\eta(\Sigma_i^\eta) \leq c$. The Yosida regularization is convex and l.s.c.; hence the function

$$f(\Sigma) := \eta J_\eta = \|\Sigma - \Pi\Sigma\|^2$$

is weakly l.s.c. (see [9, p. 74]). Therefore

$$f(\Sigma_i) \leq \liminf_{\eta \to 0} f(\Sigma_i^\eta) \leq \lim_{\eta \to 0} c\eta = 0.$$

This implies $\|\Sigma_i - \Pi\Sigma_i\| = 0$, that is, $\Sigma_i \in \mathcal{P}$.

(b) Now we show (3.1). Since $b(v, \sigma_i^{\delta\eta}) = 0$ for all $v \in V$, we have

$$b(v, \sigma_i) = b(v, \sigma_i^0) = \langle l_i, v \rangle.$$

(c) Finally we consider the variational inequality (3.2). J_η is a convex function. Hence for all $\bar{T} \in \mathcal{P}$, the convexity implies

$$\begin{aligned} & 0 = J_\eta(\bar{T}) \geq J_\eta(\Sigma_i^\eta) + \left(J'_\eta(\Sigma_i^\eta), \bar{T} - \Sigma_i^\eta\right) \\ \Rightarrow \quad & 0 \geq -J_\eta(\Sigma_i^\eta) \geq \left(J'_\eta(\Sigma_i^\eta), \bar{T} - \Sigma_i^\eta\right). \end{aligned}$$

Setting $\bar{T} = T - \Sigma_i$, we insert the last inequality into (3.5) and arrive at

$$A(\Psi_i^\eta, T - \Sigma_i^\eta) + b(w_i, \tau - \sigma_i^\eta) \geq 0.$$

Now we pass to the product space to obtain

(4.6)
$$\frac{1}{h}\vec{A}(\vec{\Sigma}^\eta, \vec{T} - \vec{\Sigma}^\eta) + d_1 b(w_1^\eta, \tau_1 - \sigma_1^\eta) + \cdots + d_s b(w_s^\eta, \tau_s - \sigma_s^\eta) \geq \frac{1}{h}\vec{A}(\vec{\Sigma}_n, \vec{T} - \vec{\Sigma}^\eta).$$

It is our goal to preserve this inequality while η tends to zero. We proceed as follows:

1. Weak convergence and the relation $\sigma_i^{\delta\eta} \in \operatorname{Ker} B$ lead to

$$b(w_i^\eta, \sigma_i^\eta) = b(w_i^\eta, \sigma^0) \to b(w_i, \sigma^0) = b(w_i^\eta, \sigma_i).$$

2. Weak convergence also implies

$$\begin{aligned} \vec{A}(\vec{\Sigma}^\eta, \vec{T}) &\to \vec{A}(\vec{\Sigma}, \vec{T}), \\ \vec{A}(\vec{\Sigma}_n, \vec{T} - \vec{\Sigma}^\eta) &\to \vec{A}(\vec{\Sigma}_n, \vec{T} - \vec{\Sigma}). \end{aligned}$$

3. The last term of (4.6) needs some more effort. Since $\vec{A}(\cdot,\cdot)$ is not symmetric, we formulate the quadratic identity

(4.7) $$\vec{A}(\vec{\Sigma}^\eta, \vec{\Sigma}) + \vec{A}(\vec{\Sigma}, \vec{\Sigma}^\eta) - \vec{A}(\vec{\Sigma}, \vec{\Sigma}) = \vec{A}(\vec{\Sigma}^\eta, \vec{\Sigma}^\eta) - \vec{A}(\vec{\Sigma}^\eta - \vec{\Sigma}, \vec{\Sigma}^\eta - \vec{\Sigma}).$$

   From the coercivity of $\vec{A}$, passing to the lim inf yields

$$\vec{A}(\vec{\Sigma}, \vec{\Sigma}) \leq \liminf_{\eta \to 0} \vec{A}(\vec{\Sigma}^\eta, \vec{\Sigma}^\eta).$$

Applying the lim inf to (4.6) and inserting the last three limits, we arrive at

$$A(\tilde{\Sigma}_i, T - \Sigma_i) + b(w_i, \tau - \sigma_i) \geq 0.$$

Setting $T_i = T$ and $T_j = 0$ for $j \neq i$ proves the inequality (3.2).

4.4. Uniqueness. Suppose there exist two different solutions (w_i, Σ_i) with $\Sigma_i = (\sigma_i, \chi_i)$ and $(\tilde{w}_i, \tilde{\Sigma}_i)$ with $\tilde{\Sigma}_i = (\tilde{\sigma}_i, \tilde{\chi}_i)$ of the system (3.1)–(3.3).

The linearity of the variational equation (3.1) implies

$$b(v, \sigma_i - \tilde{\sigma}_i) = 0 \qquad \forall v \in V,$$

that is, $\sigma - \tilde{\sigma} \in \operatorname{Ker} B$. Therefore inserting Σ_i into the variational inequality (3.1) and setting $T = \tilde{\Sigma}_i$ yields

$$A(\Psi_i, \tilde{\Sigma}_i - \Sigma_i) \geq 0,$$

where Ψ_i again denotes the stage derivative. The same argument with Σ_i and $\tilde{\Sigma}_i$ interchanged gives

$$A(\tilde{\Psi}_i, \Sigma_i - \tilde{\Sigma}_i) \geq 0.$$

Adding these two equations and passing to the product space $\mathcal{T}^s$ leads to

$$\vec{A}(\vec{\Sigma} - \vec{\tilde{\Sigma}}, \vec{\Sigma} - \vec{\tilde{\Sigma}}) \leq 0.$$

Hence the coercivity of $\vec{A}$ implies $\Sigma_i = \tilde{\Sigma}_i$.

5. Proof of Theorem 3.6.

We use the same notation as in section 4 and extend the proof of Theorem IV.12.4 of [10]. The definitions of the errors Q_n and S_n^i (see subsection 3.4) lead to

$$\begin{aligned}
&\|\Sigma_{n+1} - \Sigma(t_{n+1})\|_{\mathrm{A}}^2 \\
&= \left\| \Sigma_n + h \sum_{j=1}^{s} b_j \Psi_j - \left(\Sigma(t_n) + h \sum_{j=1}^{s} b_j \dot{\Sigma}(t_j) \right) - Q_n \right\|_A^2 \\
&= \|\Sigma_n - \Sigma(t_n)\|_A^2 + 2h \sum_{j=1}^{s} b_j (\Psi_j - \dot{\Sigma}(t_j), \Sigma_j - \Sigma(t_j))_A \\
&\quad - h^2 \sum_{i,j=1}^{s} m_{ij} (\Psi_i - \dot{\Sigma}(t_i), \Psi_j - \dot{\Sigma}(t_j))_A + 2h \sum_{j=1}^{s} b_j (\Psi_j - \dot{\Sigma}(t_j), S_n^j)_A \\
&\quad - 2 \left(\Sigma_n - \Sigma(t_n) + h \sum_{j=1}^{s} b_j (\Psi_j - \dot{\Sigma}(t_j)), Q_n \right)_A + \|Q_n\|_A^2.
\end{aligned}$$

From (3.2) and (2.16) we derive

$$\begin{aligned}
(\Psi_j - \dot{\Sigma}(t_j), \Sigma_j - \Sigma(t_j))_A &\leq b(w_j - w(t_j), \sigma_j - \sigma(t_j)) \\
&= \langle l_j, w_j - w(t_j) \rangle - \langle l(t_j), w_j - w(t_j) \rangle \\
&= 0.
\end{aligned} \tag{5.1}$$

Hence with the coefficient matrix (m_{ij}) being nonnegative definite, we obtain

$$
\begin{aligned}
&\|\Sigma_{n+1} - \Sigma(t_{n+1})\|_A^2 \\
&\quad \le \|\Sigma_n - \Sigma(t_n)\|_A^2 - 2\left(\Sigma_n - \Sigma(t_n) + h\sum_{j=1}^{s} b_j(\Psi_j - \dot\Sigma(t_j)), Q_n\right)_A \\
&\qquad + \|Q_n\|_A^2 + 2h\sum_{j=1}^{s} b_j(\Psi_i - \dot\Sigma(t_i), S_n^j)_A \\
&\quad = \|\Sigma_n - \Sigma(t_n)\|_A^2 - 2(\Sigma_n - \Sigma(t_n), Q_n)_A \\
&\qquad - 2h\sum_{j=1}^{s} b_j(\Psi_j - \dot\Sigma(t_j), Q_n)_A + \|Q_n\|_A^2 + 2h\sum_{j=1}^{s} b_j(\Psi_j - \dot\Sigma(t_j), S_n^j)_A.
\end{aligned} \tag{5.2}
$$

To derive an estimate for the right-hand side of (5.2), we need an upper bound for $h\|\Psi_j - \dot\Sigma(t_j)\|$. Therefore we again pass to the product space $\mathcal{T}^s$ to exploit the coercivity of the Runge–Kutta matrix. In the notation of section 4, we set

$$\vec{\dot\Sigma}(t_j) = (\dot\Sigma(t_1),\dots,\dot\Sigma(t_s))^{\mathrm{T}}, \qquad \vec\Sigma(t_j) = (\Sigma(t_1),\dots,\Sigma(t_s))^{\mathrm{T}},$$

and $\vec\Sigma(t_n) = (\dot\Sigma(t_n),\dots,\dot\Sigma(t_n))^{\mathrm{T}}$. Then for each stage

$$\vec{\dot\Sigma}(t_j) = \frac{1}{h}\mathcal{A}^{-1}(\vec\Sigma(t_j) - \vec\Sigma(t_n)) - \frac{1}{h}\mathcal{A}^{-1}\underbrace{(S_n^1,\dots,S_n^s)^{\mathrm{T}}}_{=:\vec S}.$$

With inequality (5.1), we get

$$\vec A(\vec\Sigma - \vec\Sigma_n - (\vec\Sigma(t_j) - \vec\Sigma(t_n)) + \vec S, \vec\Sigma - \vec\Sigma(t_j)) \le 0$$

and hence

$$\vec A(\vec\Sigma - \vec\Sigma(t_j), \vec\Sigma - \vec\Sigma(t_j)) \le \vec A((\vec\Sigma_n - \vec\Sigma(t_n)) - \vec S, \vec\Sigma - \vec\Sigma(t_j)).$$

The coercivity and continuity of $\vec A$ imply

$$\|\vec\Sigma - \vec\Sigma(t_j)\|_{\mathcal{T}^s}^2 \le c(\|\vec\Sigma_n - \vec\Sigma(t_n)\|_{\mathcal{T}^s} + \|\vec S\|_{\mathcal{T}^s})\|\vec\Sigma - \vec\Sigma(t_j)\|_{\mathcal{T}^s}.$$

Therefore for each stage we have

$$\|\Sigma_j - \Sigma(t_j)\|_{\mathcal{T}} \le c(\|\Sigma_n - \Sigma(t_n)\|_{\mathcal{T}} + S_n^{\mathrm{Err}}). \tag{5.3}$$

The stage error is thus determined by the previous approximation error and the consistency error of the Runge–Kutta method. The identity

$$\vec\Psi - \vec{\dot\Sigma}(t_j) = \frac{1}{h}\mathcal{A}^{-1}(\vec\Sigma - \vec\Sigma(t_j) - \vec\Sigma_n + \vec\Sigma(t_n)) + \frac{1}{h}\mathcal{A}^{-1}\vec S$$

implies for the stage derivatives

$$h\|\Psi_j - \dot\Sigma(t_j)\|_{\mathcal{T}} \le c(\|\Sigma_j - \Sigma(t_j)\|_{\mathcal{T}} + \|\Sigma_n - \Sigma(t_n)\|_{\mathcal{T}} + S_n^{\mathrm{Err}}).$$

Hence with (5.3) we have

$$h\|\Psi_j - \dot\Sigma(t_j)\|_{\mathcal{T}} \le c(\|\Sigma_n - \Sigma(t_n)\|_{\mathcal{T}} + S_n^{\mathrm{Err}}). \tag{5.4}$$

Now we return to (5.2), insert the estimate (5.4), and combine it with the coercivity and continuity of the bilinear form A to obtain

$$\begin{aligned}&\|\Sigma_{n+1}-\Sigma(t_{n+1})\|_{\mathcal{T}}^2\\&\le c\|\Sigma_n-\Sigma(t_n)\|_{\mathcal{T}}(Q_n^{\mathrm{Err}}+S_n^{\mathrm{Err}})+cQ_n^{\mathrm{Err}}S_n^{\mathrm{Err}}+cS_n^{\mathrm{Err}^2}+cQ_n^{\mathrm{Err}^2}.\end{aligned}$$

Summation from 1 to n leads to

$$\begin{aligned}\|\Sigma_{n+1}-\Sigma(t_{n+1})\|_{\mathcal{T}}^2\le c\sum_{r=1}^{n}\|\Sigma_r-\Sigma(t_r)\|_{\mathcal{T}}(Q_r^{\mathrm{Err}}+S_r^{\mathrm{Err}})\\+c\sum_{r=1}^{n}(Q_r^{\mathrm{Err}^2}+S_r^{\mathrm{Err}^2}+S_r^{\mathrm{Err}}Q_r^{\mathrm{Err}}).\end{aligned}$$

With $M:=\max_{r=1,\dots,N}\|\Sigma_{n+1}-\Sigma(t_{n+1})\|_{\mathcal{T}}$ it follows that

$$M^2\le cM\sum_{r=1}^{N-1}(Q_r^{\mathrm{Err}}+S_r^{\mathrm{Err}})+c\sum_{r=1}^{N-1}(Q_r^{\mathrm{Err}^2}+S_r^{\mathrm{Err}^2}+S_r^{\mathrm{Err}}Q_r^{\mathrm{Err}}).$$

Furthermore, due to

$$\|\cdot\|_{L^1(0,t_1;\Omega)}+\dots+\|\cdot\|_{L^1(t_n,t_{n+1};\Omega)}=\|\cdot\|_{L^1(0,t_{n+1};\Omega)}$$

and the Cauchy–Schwarz inequality, we arrive at

$$M^2\le Mch^q\|\Sigma^{(q+1)}\|_{L^1(0,t_f;\Omega)}+ch^{2q}\|\Sigma^{(q+1)}\|_{L^1(0,t_f;\Omega)}.$$

Therefore

$$M\le ch^q\|\Sigma^{(q+1)}\|_{L^1(0,t_f;\Omega)}.$$

6. Conclusions. In this paper, we have extended implicit Runge–Kutta methods to the infinite-dimensional constrained evolution equations of elastoplasticity. Coercivity and algebraic stability, notions that are familiar from the finite-dimensional case, turned out to be sufficient to show existence, uniqueness, contractivity preservation, and convergence. Various time integration methods become available in this way, among them Gauss, Radau, Lobatto, and several DIRK methods.

While the proof for contractivity preservation is very similar to the one for ODEs, the existence proof presented here relies very much on the framework of variational inequalities. Though we have in each material point a DAE of index 2 with a certain Lagrange multiplier (cf. (2.11)), this multiplier showed up neither in the formulation of the dual problem nor in the Runge–Kutta method definition. For implementation, in the fashion of Rothe's method or in the method of lines, however, the multiplier will regain its importance.

ELLIPTIC RECONSTRUCTION AND A POSTERIORI ERROR ESTIMATES FOR PARABOLIC PROBLEMS[*]

CHARALAMBOS MAKRIDAKIS[†] AND RICARDO H. NOCHETTO[‡]

Abstract. It is known that the energy technique for a posteriori error analysis of finite element discretizations of parabolic problems yields suboptimal rates in the norm $L^\infty(0,T;L^2(\Omega))$. In this paper, we combine energy techniques with an appropriate pointwise representation of the error based on an elliptic reconstruction operator which restores the optimal order (and regularity for piecewise polynomials of degree higher than one). This technique may be regarded as the "dual a posteriori" counterpart of Wheeler's elliptic projection method in the a priori error analysis.

Key words. a posteriori error estimators, finite elements, semidiscrete parabolic problems, energy technique

AMS subject classification. 65N15

DOI. 10.1137/S0036142902406314

1. Introduction.

A posteriori error estimation and adaptivity are in many cases very successful tools for efficient numerical computations of linear as well as nonlinear PDEs. In particular, a posteriori error control provides a practical, as well as mathematically sound, means of detecting multiscale phenomena and doing reliable computations. Although the a posteriori error analysis of elliptic problems is now mature [2, 3, 6, 7, 18, 23], the time dependent case is still under development. Many papers have appeared for the discontinuous Galerkin method [9, 10, 11, 13, 14, 15, 20, 19] and other schemes [1, 4, 17, 21, 24, 25] mainly for linear parabolic problems.

One of the outstanding issues related to a posteriori estimation of (linear) time dependent problems is the known fact that the energy technique for a posteriori error analysis of finite element discretizations of parabolic problems yields suboptimal rates in the norm $L^\infty(0,T;L^2(\Omega))$. Since the energy method is the most elementary technique for estimating the error in the a priori analysis, the question of whether or not this method can be successfully applied in the a posteriori error analysis is very natural. In addition, we hope that examining this and related issues will enable us to increase our understanding on the important subject of error control for time dependent problems in general.

We will work with the following linear parabolic equation as a model:

$$\begin{aligned} &u_t + Au = f \quad \text{in } \Omega\times[0,T],\\ &u(\cdot,0) = u_0(\cdot) \quad \text{in } \Omega,\\ &u = 0 \quad \text{on } \partial\Omega\times[0,T]. \end{aligned} \tag{1.1}$$

Here A is a linear, symmetric, second order positive definite elliptic operator, and Ω is a bounded domain of $\mathbb{R}^d$ $(d \geq 1)$ with sufficiently smooth boundary for our purposes.

Let $H := L^2(\Omega)$, $V := H_0^1(\Omega)$, and $V^\star := H^{-1}(\Omega)$ be the dual of V. If $a(\cdot,\cdot)$ is the bilinear form that corresponds to A, our assumptions on A imply that

$$\|v\|_V := a(v,v)^{1/2}$$

defines a norm on V. We denote the norms on H and $V^\star$ by $\|\cdot\|_{V^\star}$ and $\|\cdot\|_H$, respectively, and we indicate with $\langle\cdot,\cdot\rangle$ the duality pairing in either H or $V^* - V$.

We assume that $f \in L^2(0,T;V^\star)$ and $u_0 \in H$ so that (1.1) admits a unique weak solution satisfying

$$\langle u_t(t), v\rangle + a(u(t),v) = \langle f, v\rangle \quad \text{for all } v \in V, \text{ a.e. } t \in [0,T] .$$

In this paper, we consider semidiscrete finite element discretizations of *arbitrary* degree. We combine energy techniques with an appropriate pointwise representation of the error based on a novel *elliptic reconstruction* operator which restores the optimal order in $L^\infty(0,T;L^2(\Omega))$. This technique may be regarded as the dual counterpart of Wheeler's elliptic projection method in the a priori error analysis [27]. In particular, for u_h as the finite element approximation, our estimates exhibit the following properties:

- the estimator is a computable quantity in terms of the approximate solution u_h and the data f, u_0, and Ω, but its actual form and quality depends only on the elliptic estimator at our disposal;
- the order is optimal in $L^\infty(0,T;L^2(\Omega))$ for any polynomial degree ≥ 1, and the regularity is the lowest compatible with (1.1) for polynomial degree > 1;
- the a posteriori estimates mimic completely the corresponding a priori estimates.

Hereafter, the use of "optimal order" and "optimal regularity" is consistent with classical terminology in approximation theory. Consequently, "optimal order" corresponds to the largest exponent r for which the error is $O(h^r)$, where h is the biggest element diameter of the partition. Likewise, "optimal regularity" refers to the lowest regularity which is compatible with (1.1) and an error of $O(h^r)$.

Finite element approximation. For $\mathcal{T}_h$, being a shape-regular partition of Ω, consider the finite element space

$$V_h = \{\chi \in H_0^1(\Omega) : \chi|_K \in \mathbb{P}_k(K) \quad \text{for all } K \in \mathcal{T}_h\},$$

where $\mathbb{P}_k(K)$ is the space of polynomials of degree $\leq k$ over K. The finite element approximation $u_h : [0,T] \to V_h$ of u is defined to satisfy the following linear ODE:

$$\begin{aligned} \langle u_{h,t}, \chi\rangle + a(u_h,\chi) &= \langle f, \chi\rangle \quad \text{for all } \chi \in V_h, \text{ a.e. } t \in [0,T], \\ u_h(\cdot,0) &= u_h^0 \in V_h . \end{aligned} \tag{1.2}$$

A posteriori error estimation. Residual-based a posteriori estimates are usually proved by estimating the linear functional $R \in V^\star$, so-called *residual*,

$$\begin{aligned} -\langle R, v\rangle &= \int_0^T \Big(\langle u_{h,t}, v\rangle + a(u_h,v) - \langle f, v\rangle\Big) dt \\ &= \int_0^T \Big(\langle u_{h,t}, v - I_h v\rangle + a(u_h, v - I_h v) - \langle f, v - I_h v\rangle\Big) dt, \end{aligned} \tag{1.3}$$

in appropriate norms. Here, in the second equality, we have used the definition of the semidiscrete scheme (1.2) and an interpolation operator $I_h : V \to V_h$ stable in V

(e.g., Clement's interpolant). Then, for $e = u - u_h$ as the error to be estimated, we have

$$\frac{1}{2}\|e\,(T)\|_H^2 + \int_0^T a(e,e)dt = \frac{1}{2}\|e\,(0)\|_H^2 + \langle R, e\rangle. \tag{1.4}$$

Due to the presence of $\int_0^T a(u_h, e - I_h e)dt$, which gives rise to the integral of an H^1 elliptic residual, the ensuing a posteriori estimate is of optimal order in $L^2(0,T;H_0^1(\Omega))$, as corresponds to an estimate of $\int_0^T a(e,e)dt$, but is *suboptimal* in $L^\infty(0,T;L^2(\Omega))$. It is well known that an analogous phenomenon occurs in the a priori analysis and that the use of an elliptic projection operator overcomes the difficulty [27]. This is now a standard tool in the finite element analysis.

In this paper, we introduce an *elliptic reconstruction* operator which restores the optimal order in the a posteriori error estimation in $L^\infty(0,T;L^2(\Omega))$. The key properties of the elliptic reconstruction U (cf. Definition 2.1) are (i) $u - U$ satisfies an appropriate pointwise equation (cf. (3.2)) that can be used to derive estimates in terms of $u_{h,t} - U_t$, and (ii) u_h is the finite element solution of an elliptic problem whose exact solution is U, and therefore $u_h - U$ (as well as $u_{h,t} - U_t$) can be estimated in various norms by any given a posteriori elliptic estimator. Note that a similar function U was introduced in [12] for a different purpose.

For clarity of exposition, we present the method in the simplest framework. The ideas of the present paper might be useful for linear problems of nondissipative character as well as for nonlinear dissipative problems. In this direction, they should be explored together with the recent a posteriori results of time discretization of nonlinear problems [17, 19]. The a posteriori analysis of [17, 19] is based on the same principles as those in the present paper, namely, an appropriate pointwise representation of the error and energy arguments.

Although it is possible to derive quasi-optimal order-regularity estimators in $L^\infty(0,T;L^2(\Omega))$ via *parabolic duality* [9, 22], this technique hinges on the parabolic regularizing effect which is not valid for estimates in $L^2(0,T;H_0^1(\Omega))$. For the latter, duality leads invariably to estimators similar to those obtained with the energy approach and which also bound the error in $L^\infty(0,T;L^2(\Omega))$ but with suboptimal order. In contrast, several contributions over the last few years are devoted to estimates that are based on the (forward) energy approach. Picasso [21] derives a posteriori error estimates of residual type that are optimal in $L^2(0,T;H_0^1(\Omega))$ for piecewise linear elements for space discretization and backward Euler for time discretization. Toward overcoming the barrier described above, Babuška, Feistauer, and Šolín [4] derive estimates in $L^2(0,T;L^2(\Omega))$ for (1.2) by a double integration in time; see also [1, 5]. In [24, 25], Verfürth proves a posteriori estimates in $L^r(0,T;L^\rho(\Omega))$, with $1 < r, \rho < \infty$, for fully discrete approximations of quasi-linear parabolic equations.

The paper is organized as follows. We introduce the elliptic reconstruction operator in section 2, and we derive abstract a posteriori error estimates in section 3. In particular, our estimator of Theorem 3.1 depends on an abstract *elliptic estimator function* for elliptic problems; any such estimator can be used. In section 4, we specify the form of the estimates for the classical residual-type elliptic estimators.

2. Elliptic reconstruction.

We now introduce the elliptic reconstruction operator $\mathcal{R} : V_h \to V$. To this end, let $P_h^1 : V \to V_h$ be the elliptic projection operator, i.e.,

$$a(P_h^1 w, \chi) = a(w, \chi) \quad \text{for all } \chi \in V_h, \tag{2.1}$$

and let $P_h^0 : H \to V_h$ be the L^2-projection operator, i.e.,

$$(P_h^0 w, \chi) = \langle w, \chi \rangle \quad \text{for all } \chi \in V_h. \tag{2.2}$$

Let $w \in V$ satisfy the elliptic problem $Aw = g \in V^\star$ or, in weak form,

$$w \in V : \qquad a(w, v) = \langle g, v \rangle \quad \text{for all } v \in V. \tag{2.3}$$

Let $w_h \in V_h$ be the corresponding finite element solution

$$w_h \in V_h : \qquad a(w_h, \chi) = \langle g, \chi \rangle \quad \text{for all } \chi \in V_h; \tag{2.4}$$

hence $w_h = P_h^1 w$. We assume that we have at our disposal a posteriori estimators that control the error $\|w - w_h\|_X$ in the spaces $X = H, V$, or $V^\star$.

ASSUMPTION 2.1. *Let w and w_h be the exact solution and its finite element approximation given in* (2.3) *and* (2.4) *above. We assume that there exists an a posteriori estimator function $\mathcal{E} = \mathcal{E}(w_h, g; X)$, which depends on w_h, g and the space $X = H, V$, or $V^\star$ such that*

$$\|w - w_h\|_X \le \mathcal{E}(w_h, g; X). \tag{2.5}$$

Let $A_h : V_h \to V_h$ be the following discrete version of A:

$$\langle A_h v, \chi \rangle = a(v, \chi) \quad \text{for all } \chi \in V_h. \tag{2.6}$$

Then we have the following definition.

DEFINITION 2.1. *Let u_h be the finite element solution of* (1.2) *and $f_h := P_h^0 f$. We define the elliptic reconstruction $U = \mathcal{R} u_h \in H_0^1(\Omega)$ of u_h to be the solution of the elliptic problem in weak form*

$$a(U(t), v) = \langle g_h(t), v \rangle \quad \textit{for all } v \in H_0^1(\Omega), \ \textit{a.e. } t \in [0, T], \tag{2.7}$$

where

$$g_h := A_h u_h - f_h + f. \tag{2.8}$$

We note that a similar function U was defined at the final time T in [12] in a different context, i.e., in postprocessing the Galerkin method at T with the aim of improving the order of convergence. We observe that U satisfies the strong form

$$AU = A_h u_h - f_h + f \tag{2.9}$$

as well as

$$a(U, \varphi) = a(u_h, \varphi) - \langle f_h - f, \varphi \rangle = a(u_h, \varphi) \quad \text{for all } \varphi \in V_h, \tag{2.10}$$

because $f_h = P_h^0 f$. This relation implies that u_h *is the finite element solution of the elliptic problem whose exact solution is the elliptic reconstruction* U, namely,

$$u_h = P_h^1 U. \tag{2.11}$$

Assume that $f \in H^1(0, T; V^*)$. Since $a(\cdot, \cdot)$ is independent of t, there holds $a(U_t, \varphi) = a(u_{h,t}, \varphi)$ for all $\varphi \in V_h$, or

$$u_{h,t} = P_h^1 U_t. \tag{2.12}$$

In addition,

$$a(U_t, v) = \langle g_{h,t}, v \rangle \quad \text{for all } v \in V. \tag{2.13}$$

3. Abstract a posteriori error analysis. In this section, we establish the improved a posteriori error estimate in H and make several comments about its optimality regarding both order and regularity.

THEOREM 3.1. *Assume that* u *is the solution of* (1.1) *and* u_h *is its finite element approximation* (1.2). *Let* U *be the elliptic reconstruction of* u_h *and* $\mathcal{E}$ *be as defined in Assumption* 2.1. *Then the following a posteriori error bounds hold for* $0 < t \leq T$*:*

$$\|(u-U)(t)\|_H^2 + \int_0^t \|u-U\|_V^2 ds \leq \|u(0)-U(0)\|_H^2 + \int_0^t \mathcal{E}(u_{h,t}, g_{h,t}; V^\star)^2 ds$$

and

$$\begin{aligned}\|(u-u_h)(t)\|_H \leq \|u_0 - u_h^0\|_H + \left(\int_0^t \mathcal{E}(u_{h,t}, g_{h,t}; V^\star)^2 ds\right)^{1/2} \\ + \mathcal{E}(u_h(0), g_h(0); H) + \mathcal{E}(u_h(t), g_h(t); H).\end{aligned}$$

Proof. By virtue of definitions (1.2) and (2.9) of u_h and U, we have

$$u_{h,t} + AU = f,$$

whence U satisfies the following pointwise equation:

$$U_t + AU = f + (U - u_h)_t\,. \tag{3.1}$$

Thus the error equation for $u - U$ reads

$$(u-U)_t + A(u-U) = (u_h - U)_t\,. \tag{3.2}$$

Multiplying by $u - U$ and using standard energy arguments yield

$$\begin{aligned}\|(u-U)(t)\|_H^2 + \int_0^t \|(u-U)(s)\|_V^2 ds \leq \|u(0)-U(0)\|_H^2 \\ + \int_0^t \|(u_{h,t} - U_t)(s)\|_{V^\star}^2 ds\,.\end{aligned} \tag{3.3}$$

Relations (2.12) and (2.13), in conjunction with Assumption 2.1, imply

$$\|u_{ht} - U_t\|_{V^\star} \leq \mathcal{E}(u_{h,t}, g_{h,t}; V^\star)\,,$$

which in turn leads to the first assertion of Theorem 3.1. To show the second one, it suffices to note that (2.11) and Assumption 2.1 yield

$$\|(u_h - U)(t)\|_H \leq \mathcal{E}(u_h(t), g_h(t); H) \quad \text{for all } 0 \leq t \leq T\,, \tag{3.4}$$

which, together with

$$\begin{aligned}\|u(0)-U(0)\|_H &\leq \|u(0)-u_h(0)\|_H + \|P_h^1 U(0) - U(0)\|_H \\ &\leq \|u_0 - u_h^0\|_H + \mathcal{E}(u_h(0), g_h(0); H),\end{aligned}$$

concludes the proof. □

Remark 3.1 (L^2-based estimate). An alternative estimate that follows from the proof of Theorem 3.1 is

$$\begin{aligned}\max_{0\le t\le T}\|u-U\|_H^2 &\le \|u(0)-U(0)\|_H^2+\max_{0\le t\le T}\|u-U\|_H\int_0^T\|u_{h,t}-U_t\|_H dt\\ &\le \max_{0\le t\le T}\|u-U\|_H\left(\|u(0)-U(0)\|_H+\int_0^T\|u_{h,t}-U_t\|_H dt\right).\end{aligned}$$

Therefore, (2.5) and (3.4) imply

$$\max_{0\le t\le T}\|u-U\|_H\le \|u(0)-U(0)\|_H+\int_0^T\mathcal{E}(u_{h,t},g_{h,t};H)dt,$$

along with the corresponding a posteriori error bound

$$\max_{0\le t\le T}\|u-u_h\|_H\le \|u_0-u_h^0\|_H+\mathcal{E}(u_h(0),g_h(0);H)\ +2\int_0^T\mathcal{E}(u_{h,t},g_{h,t};H)dt.$$

Remark 3.2 (a priori vs. a posteriori bounds). Note that the elliptic reconstruction is an “a posteriori dual” to Wheeler's elliptic projection [22, 27]. Furthermore, the two results in Theorem 3.1 are indeed an *a posteriori dual* to the classical a priori estimate for semidiscrete linear parabolic problems [22, 27]

$$\begin{aligned}&\|(u_h-P_h^1u)(t)\|_H^2+\int_0^t\|u_h-P_h^1u\|_V^2ds\\ &\qquad\le \|u_h(0)-P_h^1u(0)\|_H^2+\int_0^t\|u_t-P_h^1u_t\|_{V^\star}^2ds\end{aligned}\tag{3.5}$$

and

$$\begin{aligned}&\|(u-u_h)(t)\|_H\le \|(u-P_h^1u)(t)\|_H\\ &\qquad+\left(\|u_h(0)-P_h^1u(0)\|_H^2+\int_0^t\|u_t-P_h^1u_t\|_{V^\star}^2dt\right)^{1/2}.\end{aligned}\tag{3.6}$$

Remark 3.3 (optimal regularity). The a priori bound in (3.5) (and therefore in (3.6)) is of optimal order. The regularity required is optimal only for polynomial degree $k\ge 2$. Indeed, by exploiting standard results on superconvergence in negative norms of elliptic finite element problems, we see that the following bound for the error of the elliptic projection holds [22, 26]:

$$\|v-P_h^1v\|_{V^\star}\le Ch^{(k+1)}\|v\|_k.\tag{3.7}$$

This estimate follows from the definition of the dual norm $\|w\|_{V^\star}=\sup_{\|z\|_V=1}\langle w,z\rangle$ and a standard duality argument. Using (3.7), we obtain

$$\int_0^T\|u_t-P_h^1u_t\|_{V^\star}^2dt\le C\int_0^T h^{2(k+1)}\|u_t\|_k^2dt\le Ch^{2(k+1)}\int_0^T\|u\|_{k+2}^2dt\,;$$

here $\|\cdot\|_s$ denotes the Sobolev norm of $H^s(\Omega)$, and for simplicity take $A=-\Delta$ and $f=0$. For an (optimal) convergence rate of order $O(h^{k+1})$ in $L^\infty(0,T;L^2(\Omega))$, the minimal regularity required by our finite element space is $u \in L^\infty(0,T;H^{k+1}(\Omega))$. However, it is a simple matter to check that for (1.1) both

$$\int_0^T \|u\|_{k+2}^2 dt \quad \text{and} \quad \max_{0\le t\le T} \|u\|_{k+1}^2$$

are bounded by the same constant depending on data. Thus the classical a priori estimate (3.6) is of optimal order and regularity for $k \geq 2$. The negative norm $\|\cdot\|_{V^*}$ appears in a complete similar fashion in the a posteriori error analysis of Theorem 3.1, and thus for polynomial degree $k \geq 2$ this indicates that the estimator is of *optimal order-regularity.*

4. Application: Residual-type error estimators. In this section, we derive the specific form of the estimates of section 3 in case we choose the classical residual-type estimators for (2.5) [6, 23]. Of course, any other choice, such as solving local problems [2, 7, 18, 23] or averaging techniques [3], is possible according to Theorem 3.1. For simplicity, we assume that $A = -\Delta$ and that Ω is sufficiently smooth in order for (4.2) below to be valid. However, Theorem 3.1 is general enough to allow for geometric singularities and corresponding elliptic estimators. We refer to [16] for *weighted* a posteriori estimators, which account for corner singularities in both H and $V^\star$ in an optimal fashion, as well as to [8], where an error estimator is derived for an elliptic problem with curved boundaries.

We first calculate $\mathcal{E}(u_{h,t}, g_{h,t}; V^\star)$ or, equivalently, estimate

$$\|\rho\|_{V^\star} = \sup_{\|\phi\|_V \le 1} \langle \rho, \phi\rangle, \quad \rho = (U - u_h)_t.$$

We accomplish this via standard duality arguments. Given $\phi \in V$, let $\psi \in V$ be defined by

$$a(\psi, v) = \langle \nabla\psi, \nabla v\rangle = \langle v, \phi\rangle \quad \text{for all } v \in V, \tag{4.1}$$

and suppose there exists a constant $C_\Omega > 0$, depending on the domain Ω, such that

$$\|\psi\|_{H^3(\Omega)} \le C_\Omega \|\phi\|_{H^1(\Omega)}. \tag{4.2}$$

If $\mathcal{T}_h = \{K\}$ is a shape-regular partition of Ω into finite elements K, then $\mathcal{S}_h = \{S\}$ denotes the set of internal interelement sides and $\mathcal{N}_h(E)$ stands for the union of all elements of $\mathcal{T}_h$ intersecting the *closed* set E ($= K$ or S). Then, assuming for the time being that the polynomial degree is $k \geq 2$ and recalling (2.12), we can write

$$\begin{aligned}\langle \rho, \phi\rangle &= a(\psi, \rho) = a(\psi - I_h\psi, \rho) \\ &\le \sum_{K\in\mathcal{T}_h} |(\psi - I_h\psi, \Delta\rho)_K| + \sum_{S\in\mathcal{S}_h} \int_S |\psi - I_h\psi||[\partial_n\rho]|\, ds \\ &\le C_I \sum_{K\in\mathcal{T}_h} h_K^3 |\psi|_{3,\mathcal{N}_h(K)} \|\Delta\rho\|_{L^2(K)} \\ &\quad + C_I \sum_{S\in\mathcal{S}_h} h_S^{5/2} |\psi|_{3,\mathcal{N}_h(S)} \|[\partial_n\rho]\|_{L^2(S)},\end{aligned} \tag{4.3}$$

where $C_I > 0$ is an interpolation constant associated with the local interpolation operator I_h. If we further set

$$\eta_{-1}(u_{h,t})^2 = \sum_{K\in\mathcal{T}_h} h_K^6 \|\Delta\rho\|_{L^2(K)}^2 + \sum_{S\in\mathcal{S}_h} h_S^5 \|[\partial_n u_{h,t}]\|_{L^2(S)}^2$$

and make use of (4.2), then we end up with the a posteriori error estimate

$$\mathcal{E}(u_{h,t}, g_{h,t}; V^\star) = \|\rho\|_{V^\star} \le C_I C_\Omega \eta_{-1}(u_{h,t}),$$

where C_I now contains an additional factor to account for the h-independent overlap of sets $\mathcal{N}_h(E)$ in (4.3).

The form of $\eta_{-1}(u_{h,t})$ can be further simplified upon using the definition of the elliptic reconstruction and the semidiscrete scheme:

$$\Delta\rho = \Delta U_t - \Delta u_{h,t} = -A_h u_{h,t} + f_{h,t} - f_t - \Delta u_{h,t}\,.$$

Since $u_{h,tt} + A_h u_{h,t} = f_{h,t}$, we have

$$\Delta\rho = -f_{h,t} + u_{h,tt} + f_{h,t} - f_t - \Delta u_{h,t} = (u_{h,t} - \Delta u_h - f)_t\,.$$

If we denote the element residuals as

$$r|_K := u_{h,t} - \Delta u_h - f \quad \text{for all } K \in \mathcal{T}_h, \qquad j|_S := [\partial_n u_h] \quad \text{for all } S \in \mathcal{S}_h,$$

we finally get

$$\eta_{-1}(u_{h,t})^2 = \sum_{K\in\mathcal{T}_h} h_K^6 \|r_t\|^2_{L^2(K)} + \sum_{S\in\mathcal{S}_h} h_S^5 \|j_t\|^2_{L^2(S)}, \tag{4.4}$$

and

$$\mathcal{E}(u_{h,t}, g_{h,t}; V^\star) \le C_I C_\Omega \eta_{-1}(u_{h,t}) \quad \text{if } k \ge 2.$$

Using similar arguments, we can derive

$$\mathcal{E}(u_h, g_h; H) \le C_I C_\Omega \eta_0(u_h) \quad \text{if } k \ge 2,$$

where

$$\eta_0(u_h)^2 = \sum_{K\in\mathcal{T}_h} h_K^4 \|r\|^2_{L^2(K)} + \sum_{S\in\mathcal{S}_h} h_S^3 \|j\|^2_{L^2(S)}. \tag{4.5}$$

Note that the constants C_I, C_Ω may have different values now. Finally, in the case $k = 1$, the use of negative norm does not give better results because of the lack of superconvergence in $V^\star$. Hence

$$\mathcal{E}(u_{h,t}, g_{h,t}; V^\star) \le \mathcal{E}(u_{h,t}, g_{h,t}; H) \le C_I C_\Omega \eta_0(u_{h,t})\,. \tag{4.6}$$

In summary, in view of Theorem 3.1, we have derived the following *explicit* error estimate.

THEOREM 4.1 (a posteriori estimators of residual type). *Assume that the domain Ω is sufficiently smooth, and let $t \in (0,T]$. If $k = 1$, then the following a posteriori estimate holds:*

$$\|(u - u_h)(t)\|_H \le \|u^0 - u_h^0\|_H + C_I C_\Omega \left\{ \eta_0(u_h(0)) + \eta_0(u_h(t)) + \left(\int_0^t \eta_0(u_{h,t}(s))^2 ds \right)^{1/2} \right\}.$$

In addition, for $k \geq 2$, we have

$$\|(u-u_h)(t)\|_H \leq \|u^0 - u_h^0\|_H + C_I C_\Omega \left\{ \eta_0(u_h(0)) + \eta_0(u_h(t)) + \left(\int_0^t \eta_{-1}(u_{h,t}(s))^2 ds \right)^{1/2} \right\},$$

where the estimators η_0 and η_{-1} are given by (4.5) *and* (4.4)*, respectively.*

Remark 4.1. The reasoning of Remark 3.3 applies and indicates that the estimator in Theorem 4.1 is of optimal order for polynomial degree $k \geq 1$ and of optimal regularity for $k \geq 2$. We do not actually show an a priori convergence rate for the a posteriori estimators $\eta_0(u_h)$ and $\eta_1(u_h)$; this is of interest but lies outside the scope of this paper.

A NEW DUAL-PETROV–GALERKIN METHOD FOR THIRD AND HIGHER ODD-ORDER DIFFERENTIAL EQUATIONS: APPLICATION TO THE KDV EQUATION*

JIE SHEN†

Abstract. A new dual-Petrov–Galerkin method is proposed, analyzed, and implemented for third and higher odd-order equations using a spectral discretization. The key idea is to use trial functions satisfying the underlying boundary conditions of the differential equations and test functions satisfying the "dual" boundary conditions. The method leads to linear systems which are sparse for problems with constant coefficients and well conditioned for problems with variable coefficients. Our theoretical analysis and numerical results indicate that the proposed method is extremely accurate and efficient and most suitable for the study of complex dynamics of higher odd-order equations.

Key words. dual-Petrov–Galerkin, KDV equation, Legendre polynomials, spectral approximation

1. Introduction.

Over the last thirty years, spectral methods have been playing an increasingly important role in scientific and engineering computations. Most work on spectral methods is concerned with elliptic and parabolic-type equations; there has also been active research on spectral methods for hyperbolic problems (see, for instance, [11, 7, 14] and the references therein). However, there is only a limited body of literature on spectral methods for dispersive, namely, third and higher odd-order, equations. In particular, relatively few studies are devoted to third and higher odd-order equations in finite intervals. This is partly due to the fact that direct collocation methods for higher odd-order boundary problems lead to very much higher condition numbers—more precisely, of order N^{2k}, where N is the number of modes and k is the order of the equation—and often exhibit unstable modes if the collocation points are not properly chosen (see, for instance, [17, 21]).

In a sequence of papers [22, 23, 25, 26], the author constructed efficient spectral-Galerkin algorithms for elliptic equations in various situations. In this paper, we extend the main idea for constructing efficient spectral-Galerkin algorithms—using *compact combinations* of orthogonal polynomials, which satisfy *essentially* all the underlying homogeneous boundary conditions, as basis functions—to third and higher odd-order equations. Since the main differential operators in these equations are not symmetric, it is quite natural to employ a Petrov–Galerkin method.

The key idea of the new spectral dual-Petrov–Galerkin method is the innovative choice of the test and trial functional spaces. More precisely, we choose the trial functions to satisfy the underlying boundary conditions of the differential equations, and we choose the test functions to satisfy the "dual" boundary conditions.

Recently, Ma and Sun [19, 20] studied an interesting Legendre–Petrov–Galerkin method for third-order equations. The main difference between this paper and [19, 20]

lies in the choice of the test and trial function spaces and their basis functions. The critical feature of test and trial spaces used here is that they allow us to integrate by parts freely without introducing any additional boundary terms. With this property and our choice of using "compact combinations" (minimal interactions) of Legendre polynomials as basis functions for the test and trial spaces, we obtain linear systems which are *compactly sparse* for problems with constant coefficients and *well conditioned* (i.e., the condition number is independent of the number of unknowns) for problems with variable coefficients. This is rather remarkable considering the fact that the problems at hand are nonsymmetric and involve high-order derivatives.

Together with the so-called Chebyshev–Legendre approach [10, 24], i.e., using the Legendre formulation and Chebyshev–Gauss–Lobatto points, our method has a quasi-optimal computational complexity and is well conditioned to permit the use of very large numbers of modes without suffering from large round-off errors, which are necessary for simulations of very complex dynamics of challenging scientific and engineering problems.

The new spectral dual-Petrov–Galerkin method not only leads to quasi-optimal numerical algorithms; it is also equivalent to a *natural* weighted variational formulation for third and higher odd-order equations. By showing that the basis functions for the trial (and test) spaces form a sequence of orthogonal polynomials in a weighted Sobolev space, we are able to establish optimal error estimates in appropriate weighted Sobolev spaces.

The paper is organized as follows. In sections 2 and 3, we study the third-order and fifth-order equations, respectively. As an example of application, we consider the Korteweg–de Vries (KDV) equation on a finite interval in section 4. In section 5, we discuss miscellaneous issues/extensions of the spectral dual-Petrov–Galerkin methods. In section 6, we present various numerical results exhibiting the accuracy and efficiency of our numerical algorithms. We end the paper with a few concluding remarks.

We now introduce some notation. Let $\omega(x)$ be a positive weight function on $I=(-1,1)$. One usually requires that $\omega \in L^1(I)$. However, in this paper, we shall be interested mainly in the case $\omega \notin L^1(I)$. We shall use the weighted Sobolev spaces $H^m_\omega(\Omega)$ $(m=0,\pm1,\dots)$ whose norms are denoted by $\|\cdot\|_{m,\omega}$. In particular, the norm and inner product of $L^2_\omega(\Omega)=L^2_\omega(\Omega)$ are denoted by $\|\cdot\|_\omega$ and $(\cdot,\cdot)_\omega$, respectively. To account for homogeneous boundary conditions, we define

$$H^m_{0,\omega}(\Omega)=\{v\in H^m_\omega(\Omega): v(\pm1)=v'(\pm1)=\cdots=v^{(m-1)}(\pm1)=0\},\quad m=1,2,\dots.$$

The subscript ω will be omitted from the notation in the case where $\omega\equiv1$.

We denote by c a generic constant that is independent of any parameters and functions. In most cases, we shall simply use the expression $A\lesssim B$ to mean that there exists a generic constant c such that $A\le cB$.

Let L_k be the kth degree Legendre polynomial. We now recall some basic properties of Legendre polynomials (cf. [27]) which will be used in this paper.

$$(1.1)\qquad \int_{-1}^{1} L_k(x)L_j(x)dx=\frac{2}{2k+1}\delta_{kj};$$

$$(1.2)\qquad L_n(x)=\frac{1}{2n+1}(L'_{n+1}(x)-L'_{n-1}(x)),\qquad n\ge1;$$

$$L_n'(x) = \sum_{\substack{k=0\\ k+n \text{ odd}}}^{n-1} (2k+1)L_k(x); \tag{1.3a}$$

$$L_n''(x) = \sum_{\substack{k=0\\ k+n \text{ even}}}^{n-2} \left(k+\frac{1}{2}\right)(n(n+1)-k(k+1))\,L_k(x); \tag{1.3b}$$

$$L_n(\pm 1) = (\pm 1)^n, \tag{1.4a}$$

$$L_n'(\pm 1) = \frac{1}{2}(\pm 1)^{n-1}n(n+1), \tag{1.4b}$$

$$L_n''(\pm 1) = (\pm 1)^n (n-1)n(n+1)(n+2)/8. \tag{1.4c}$$

2. Third-order equations.

2.1. Dual-Petrov–Galerkin method. Consider the model third-order equation

$$\begin{aligned} &\alpha u - \beta u_x - \gamma u_{xx} + u_{xxx} = f, \quad x \in I = (-1,1),\\ &u(\pm 1) = u_x(1) = 0, \end{aligned} \tag{2.1}$$

where α, β, γ are given constants. Without loss of generality, we consider only homogeneous boundary conditions, for nonhomogeneous boundary conditions $u(-1) = c_1$, $u(1) = c_2$, and $u_x(1) = c_3$ can be handled easily by considering $v = u - \hat{u}$, where $\hat{u}$ is the unique quadratic polynomial satisfying the nonhomogeneous boundary conditions.

Denoting by P_N the space of polynomials of degree $\le N$, we set

$$V_N = \{u \in P_N:\ u(\pm 1) = u_x(1) = 0\}, \quad V_N^* = \{u \in P_N:\ u(\pm 1) = u_x(-1) = 0\}. \tag{2.2}$$

For any constants a and b, let $\omega^{a,b}(x) = (1-x)^a(1+x)^b$. We also define

$$V = \{u:\ u \in H_0^1(I),\ u_x \in L^2_{\omega^{-2,0}}(I)\}, \quad V^* = \{u:\ u \in H_0^1(I),\ u_x \in L^2_{\omega^{0,-2}}(I)\}. \tag{2.3}$$

It is clear that $V_N \subset V$ and $V_N^* \subset V^*$.

We consider the following Legendre dual-Petrov–Galerkin approximation for (2.1): Find $u_N \in V_N$ such that

$$\alpha(u_N, v_N) - \beta(\partial_x u_N, v_N) + \gamma(\partial_x u_N, \partial_x v_N) + (\partial_x u_N, \partial_x^2 v_N) = (f, v_N) \ \ \forall v_N \in V_N^*, \tag{2.4}$$

where $(u,v) = \int_I uv dx$, $\partial_x u$, and $\partial_x^2 u$ denote $\frac{du}{dx}$ and $\frac{d^2u}{dx^2}$, respectively.

Notice that for any $u_N \in V_N$ we have $\omega^{-1,1}u_N \in V_N^*$. Thus the above dual-Petrov–Galerkin formulation is equivalent to the following weighted spectral-Galerkin approximation: Find $u_N \in V_N$ such that

$$\begin{aligned} \alpha(u_N, v_N)_{\omega^{-1,1}} - \beta(\partial_x u_N, v_N)_{\omega^{-1,1}} + \gamma(\partial_x u_N, \omega^{1,-1}\partial_x(v_N\omega^{-1,1}))_{\omega^{-1,1}} \\ + (\partial_x u_N, \omega^{1,-1}\partial_x^2(v_N\omega^{-1,1}))_{\omega^{-1,1}} = (f, v_N)_{\omega^{-1,1}} \ \ \forall v_N \in V_N, \end{aligned} \tag{2.5}$$

where $(u,v)_{\omega^{-1,1}} = \int_I uv\omega^{-1,1}dx$.

We shall see that the dual-Petrov–Galerkin formulation (2.4) is most suitable for implementation, while the weighted Galerkin formulation (2.5) is more convenient for error analysis.

2.2. Basis functions and projection operators. As suggested in [22, 24], one should choose compact combinations of orthogonal polynomials as basis functions to minimize the bandwidth and the condition number of the coefficient matrix corresponding to (2.5). Let $\{p_k\}$ be a sequence of orthogonal polynomials. As a general rule, for one-dimensional differential equations with m boundary conditions, one should look for basis functions in the form

$$\phi_k(x) = p_k(x) + \sum_{j=1}^{m} a_j^{(k)} p_{k+j}(x), \tag{2.6}$$

where $a_j^{(k)}$ $(j = 1, \dots, m)$ are chosen so that $\phi_k(x)$ satisfy the m homogeneous boundary conditions.

Using (1.4), one verifies readily that

$$\begin{aligned} \phi_k(x) &= L_k(x) - \frac{2k+3}{2k+5}L_{k+1}(x) - L_{k+2}(x) + \frac{2k+3}{2k+5}L_{k+3}(x) \in V_{k+3}, \\ \psi_k(x) &= L_k(x) + \frac{2k+3}{2k+5}L_{k+1}(x) - L_{k+2}(x) - \frac{2k+3}{2k+5}L_{k+3}(x) \in V^*_{k+3}. \end{aligned} \tag{2.7}$$

Therefore, for $N \ge 3$, we have

$$\begin{aligned} V_N &= \operatorname{span}\{\phi_0, \phi_1, \dots, \phi_{N-3}\}; \\ V^*_N &= \operatorname{span}\{\psi_0, \psi_1, \dots, \psi_{N-3}\}. \end{aligned} \tag{2.8}$$

Next, we discuss the properties of $\{\phi_k\}$ and $\{\psi_k\}$ and related projection operators in $L^2_{\omega^{-2,-1}}$ and $L^2_{\omega^{-1,-2}}$. Since the procedures for $L^2_{\omega^{-2,-1}}$ and $L^2_{\omega^{-1,-2}}$ are completely parallel, we shall describe only the results for $L^2_{\omega^{-2,-1}}$. One can obtain the corresponding results for $L^2_{\omega^{-1,-2}}$ by making a change of variable $x \to -x$.

LEMMA 2.1. *Let $\{\phi_k\}$ be defined as in* (2.7). *Then*

$$\int_I \phi_k \phi_j \omega^{-2,-1} dx = 0, \; k \ne j, \tag{2.9}$$

and $\{\phi_k\}$ form a complete orthogonal basis in $L^2_{\omega^{-1,1}}$.

Furthermore, ϕ_k satisfies the following Sturm–Liouville equation:

$$A\phi_k := -(1-x)^2(1+x)\partial_x \left\{(1-x)^{-1}\partial_x \phi_k(x)\right\} = (k+1)(k+3)\phi_k(x). \tag{2.10}$$

Proof. By construction, $p_k(x) := \phi_k(x)\omega^{-2,-1}$ is a polynomial of degree $\le k$. Thanks to the orthogonality of the Legendre polynomials,

$$\int_I \phi_k \phi_j \omega^{-2,-1} dx = \int_I p_k \phi_j dx = 0 \;\; \forall k < j.$$

Hence $\{\phi_k\}$ is a sequence of orthogonal polynomials in $L^2_{\omega^{-2,-1}}$. One can verify that $\phi_k(x)$ is proportional to $(1-x)^2(1+x)J_k^{2,1}(x)$. Thus $\{\phi_k\}$ forms a complete orthogonal basis in $L^2_{\omega^{-2,-1}}$ since $\{J_k^{2,1}\}$ forms a complete orthogonal basis in $L^2_{\omega^{2,1}}$.

It is clear that $A\phi_k(x)$ is a polynomial of degree $\le k+3$ and $\partial_x\{(1-x)^{-1}\partial_x\phi_k(x)\}$ is a polynomial of degree $\le k$. Hence

$$\begin{aligned} \int_I A\phi_k(x)\phi_j(x)\omega^{-2,-1}dx &= -\int_I \partial_x\{(1-x)^{-1}\partial_x\phi_k(x)\}\phi_j dx \\ &= -\int_I \partial_x\{(1-x)^{-1}\partial_x\phi_j(x)\}\phi_k dx = 0 \;\; \forall j < k. \end{aligned}$$

Therefore, $A\phi_k$ must be proportional to ϕ_k; i.e., $A\phi_k = \lambda_k \phi_k$. By comparing the coefficients of x^{k+3}, we find that $\lambda_k = (k+1)(k+3)$. $\square$

Now, let π_N be the $L^2_{\omega^{-2,-1}}$-orthogonal projector $L^2_{\omega^{-2,-1}} \to V_N$ defined by

$$(u - \pi_N u, v_N)_{\omega^{-2,-1}} = 0 \ \ \forall v_N \in V_N. \tag{2.11}$$

We also define

$$B^m_{\omega^{-2,-1}}(I) = \{u \in L^2_{\omega^{-2,-1}}(I) : \partial^l_x u \in L^2_{\omega^{l-2,l-1}}(I), \ 1 \le l \le m\}. \tag{2.12}$$

Then, we have the following error estimates.

Theorem 2.1.

$$\|\partial^l_x (u - \pi_N u)\|_{\omega^{l-2,l-1}} \lesssim N^{l-m} \|\partial^m_x u\|_{\omega^{m-2,m-1}} \ \ \forall u \in B^m_{\omega^{-2,-1}}, \ 0 \le l \le m.$$

Proof. We recall that for $a, b > -1$, the Jacobi polynomials satisfy the following relations:

$$\partial^l_x J^{a,b}_k(x) = \kappa^{a,b}_{k,l} J^{a+l,b+l}_{k-l}(x), \ a, b > -1, \ k \ge l, \tag{2.13}$$

where

$$\kappa^{a,b}_{k,l} = \frac{\Gamma(k+l+a+b+1)}{2^l \Gamma(k+a+b+1)};$$

$$\int_I J^{a,b}_k(x) J^{a,b}_j(x) \omega^{a,b} dx = \gamma^{a,b}_k \delta_{kj}, \tag{2.14}$$

where

$$\gamma^{a,b}_k = \frac{2^{a+b+1}\Gamma(k+a+1)\Gamma(k+b+1)}{(2k+a+b+1)\Gamma(k+1)\Gamma(k+a+b+1)}.$$

We shall extend the definition of the Jacobi polynomials to $(a, b) = (-2, -1)$ such that the relations (2.13)–(2.14) are still valid. To this end, we define

$$\begin{aligned} J^{-1,0}_k(x) &= -\frac{1}{2}(1-x) J^{1,0}_{k-1}(x), \ k \ge 1, \\ J^{-2,-1}_k(x) &= \frac{1}{2}(k-2) \int_{-1}^{x} J^{-1,0}_{k-1}(t) dt, \ k \ge 3. \end{aligned} \tag{2.15}$$

One derives immediately that $\{J^{-1,0}_k\}$ are mutually orthogonal in $L^2_{\omega^{-1,0}}$. Note that $\{L_{k-1} - L_k\}$ are also mutually orthogonal in $L^2_{\omega^{-1,0}}$. Hence $J^{-1,0}_k$ is proportional to $\{L_{k-1} - L_k\}$. One can also derive from the properties of Legendre polynomials that $J^{-2,-1}_k(\pm 1) = \partial_x J^{-2,-1}_k(1) = 0$. We then derive from (1.2) and (2.15) that $J^{-2,-1}_k$ must be proportional to ϕ_{k-3}. Hence $\{J^{-2,-1}_k\}$ are mutually orthogonal in $L^2_{\omega^{-2,-1}}$. Moreover, one can verify that $J^{-1,0}_k$ and $J^{-2,-1}_k$ satisfy the relations (2.13)–(2.14).

For any $u \in L^2_{\omega^{-2,-1}}$, we write

$$u(x) = \sum_{k=3}^{\infty} \tilde{u}_k J^{-2,-1}_k(x) \ \text{ with } \ \tilde{u}_k = (u, J^{-2,-1}_k)_{\omega^{-2,-1}} / \|J^{-2,-1}_k\|^2_{\omega^{-2,-1}}.$$

Hence $u - \pi_{_N} u = \sum_{k=N+1}^{\infty} \tilde{u}_k J_k^{-2,-1}$. Let us define

$$C_{N,l,m} = \max_{k>N} \frac{(\kappa_{k,l}^{-2,-1})^2 \gamma_{k-l}^{l-2,l-1}}{(\kappa_{k,m}^{-2,-1})^2 \gamma_{k-m}^{m-2,m-1}}. \tag{2.16}$$

Then, by using (2.13)–(2.14), we find

$$\begin{aligned} \|\partial_x^l (u - \pi_{_N} u)\|^2_{\omega^{l-2,l-1}} &= \sum_{k=N+1}^{\infty} \tilde{u}_k^2 (\kappa_{k,l}^{-2,-1})^2 \|J_{k-l}^{l-2,l-1}\|^2_{\omega^{l-2,l-1}} \\ &\le C_{N,l,m} \sum_{k=N+1}^{\infty} \tilde{u}_k^2 (\kappa_{k,m}^{-2,-1})^2 \|J_{k-m}^{m-2,m-1}\|^2_{\omega^{m-2,m-1}} \\ &\le C_{N,l,m} \|\partial_x^m u\|^2_{\omega^{m-2,m-1}}. \end{aligned} \tag{2.17}$$

The desired results follow from the above inequality and the fact that

$$C_{N,l,m} \lesssim N^{2(l-m)}. \qquad \square$$

2.3. Error estimates. Let us first prove the following generalized Poincaré inequalities.

LEMMA 2.2.

$$\begin{aligned} \int_I \frac{u^2}{(1-x)^4} dx &\le \frac{4}{9} \int_I \frac{u_x^2}{(1-x)^2} dx \quad \forall u \in V_N, \\ \int_I \frac{u^2}{(1-x)^3} dx &\le \int_I \frac{u_x^2}{1-x} dx \quad \forall u \in V_N. \end{aligned} \tag{2.18}$$

Proof. Let $u \in V_N$ and $h \le 2$. Then, for any constant q, we have

$$\begin{aligned} 0 &\le \int_I \left(\frac{u}{1-x} + q u_x \right)^2 \frac{1}{(1-x)^h} dx \\ &= \int_I \left(\frac{u^2}{(1-x)^{2+h}} + q \frac{(u^2)_x}{(1-x)^{1+h}} + q^2 \frac{u_x^2}{(1-x)^h} \right) dx \\ &= (1 - (1+h)q) \int_I \frac{u^2}{(1-x)^{2+h}} dx + q^2 \int_I \frac{u_x^2}{(1-x)^h} dx. \end{aligned}$$

We obtain the first inequality by taking $h = 2$ and $q = \frac{2}{3}$ and the second inequality with $h = 1$ and $q = 1$. $\square$

Remark 2.1. We note that with a change of variable $x \to -x$ in the above lemma, we have corresponding inequalities for $u \in V_N^*$.

LEMMA 2.3.

$$\frac{1}{3} \|u_x\|^2_{\omega^{-2,0}} \le (u_x, (u\omega^{-1,1})_{xx}) \le 3 \|u_x\|^2_{\omega^{-2,0}} \ \forall u \in V_N. \tag{2.19}$$

Proof. For any $u \in V_N$, we have $u\omega^{-1,1} \in V_N^*$. Thanks to the homogeneous boundary conditions built into the spaces V_N and V_N^*, all the boundary terms from the integration by parts of the third-order term would vanish. Therefore, using the identity $\partial_x^k \omega^{-1,1}(x) = \frac{2\,k!}{(1-x)^{k+1}}$ and Lemma 2.2, we find

$$\begin{aligned}(u_x, (u\omega^{-1,1})_{xx}) &= (u_x, u_{xx}\omega^{-1,1} + 2u_x\omega_x^{-1,1} + u\omega_{xx}^{-1,1})\\ &= \frac{1}{2}\int_I \left((u_x^2)_x\omega^{-1,1} + (u^2)_x\omega_{xx}^{-1,1} + 4u_x^2\omega_x^{-1,1}\right) dx\\ &= \int_I \left(\frac{3}{2}u_x^2\omega_x^{-1,1} - \frac{1}{2}u^2\omega_{xxx}^{-1,1}\right) dx\\ &= 3\int_I \frac{u_x^2}{(1-x)^2}dx - 6\int_I \frac{u^2}{(1-x)^4}dx \geq \frac{1}{3}\int_I \frac{u_x^2}{(1-x)^2}dx.\end{aligned}$$

The desired results follow immediately from the above. □

Before we proceed with the error estimates, we make the following simple but important observation.

Lemma 2.4. *Let π_N be defined in* (2.11). *Then*

$$(\partial_x(u - \pi_N u), \partial_x^2 v_N) = 0 \ \ \forall u \in V, \ v_N \in V_N^*.$$

Proof. The result is a direct consequence of (2.11), the identity

$$(\partial_x(u - \pi_N u), \partial_x^2 v_N) = -(u - \pi_N u, \omega^{2,1}\partial_x^3 v_N)_{\omega^{-2,-1}},$$

and the fact that $\omega^{2,1}\partial_x^3 v_N \in V_N$. □

Let us denote $\hat{e}_N = \pi_N u - u_N$ and $e_N = u - u_N = (u - \pi_N u) + \hat{e}_N$.

Theorem 2.2. *For any α, $\beta \geq 0$ and $-\frac{1}{3} < \gamma < \frac{1}{6}$, there exists a unique solution for the system* (2.4). *Furthermore, for $u \in B^m_{\omega^{-2,-1}}$, we have*

$$\alpha\|e_N\|_{\omega^{-1,1}} + N^{-1}\|(e_N)_x\|_{\omega^{-1,0}} \lesssim (1 + |\gamma|N)N^{-m}\|\partial_x^m u\|_{\omega^{m-2,m-1}}, \ m \geq 1.$$

Proof. We derive from (2.1), (2.5), and Lemma 2.4 that

$$\begin{aligned}\alpha(e_N, v_N)_{\omega^{-1,1}} - \beta(\partial_x e_N, v_N)_{\omega^{-1,1}} + \gamma(\partial_x e_N, \omega^{1,-1}\partial_x(v_N\omega^{-1,1}))_{\omega^{-1,1}}\\ + (\partial_x \hat{e}_N, \omega^{1,-1}\partial_x^2(v_N\omega^{-1,1}))_{\omega^{-1,1}} = 0 \ \ \forall v_N \in V_N.\end{aligned} \tag{2.20}$$

Taking $v_N = \hat{e}_N$ in the above and using Lemma 2.3 and the identities

$$\begin{aligned}&-(v_x, v)_{\omega^{-1,1}} = -\frac{1}{2}\int_I (v^2)_x\omega^{-1,1}dx = \|v\|^2_{\omega^{-2,0}} \ \ \forall v \in V_N,\\ &(v_x, (v\omega^{-1,1})_x) = (v_x, v_x\omega^{-1,1} + 2v\omega^{-2,0}) = \|v_x\|^2_{\omega^{-1,1}} - 2\|v\|^2_{\omega^{-3,0}} \ \ \forall v \in V_N,\end{aligned} \tag{2.21}$$

we obtain

$$\begin{aligned}\alpha\|\hat{e}_N\|^2_{\omega^{-1,1}} + \beta\|\hat{e}_N\|^2_{\omega^{-2,0}} + \gamma\|(\hat{e}_N)_x\|^2_{\omega^{-1,1}} - 2\gamma\|\hat{e}_N\|^2_{\omega^{-3,0}} + \frac{1}{3}\|(\hat{e}_N)_x\|^2_{\omega^{-2,0}}\\ \leq -\alpha(u - \pi_N u, \hat{e}_N)_{\omega^{-1,1}} + \beta(\partial_x(u - \pi_N u), \hat{e}_N)_{\omega^{-1,1}}\\ - \gamma(\partial_x(u - \pi_N u), \partial_x(\hat{e}_N\omega^{-1,1})).\end{aligned}$$

The right-hand side can be bounded by using Lemma 2.2, the Cauchy–Schwarz inequality, and the fact that $\omega^{-1,2} \leq 2\omega^{-1,1} \leq 2\omega^{-2,0}$:

$$\begin{aligned}(u - \pi_N u, \hat{e}_N)_{\omega^{-1,1}} &\leq \|\hat{e}_N\|_{\omega^{-1,1}}\|u - \pi_N u\|_{\omega^{-1,1}} \leq 2\|\hat{e}_N\|_{\omega^{-1,1}}\|u - \pi_N u\|_{\omega^{-2,-1}},\\ ((u - \pi_N u)_x, \hat{e}_N)_{\omega^{-1,1}} &= (u - \pi_N u, \partial_x\hat{e}_N\omega^{-1,1} + 2\hat{e}_N\omega^{-2,0})\\ &\lesssim \|u - \pi_N u\|_{\omega^{-2,-1}}\|\partial_x\hat{e}_N\|_{\omega^{-2,0}},\\ ((u - \pi_N u)_x, (\hat{e}_N\omega^{-1,1})_x) &= ((u - \pi_N u)_x, (\hat{e}_N)_x\omega^{-1,1} + 2\hat{e}_N\omega^{-2,0})\\ &\leq \|(u - \pi_N u)_x\|_{\omega^{-1,0}}\|(\hat{e}_N)_x\|_{\omega^{-2,0}}.\end{aligned}$$

For $0 \leq \gamma < \frac{1}{6}$, we choose δ sufficiently small such that $\frac{1}{3} - 2\gamma - \delta > 0$. Combining the above inequalities, using the inequality

$$ab \leq \epsilon a^2 + \frac{1}{4\epsilon} b^2 \quad \forall \epsilon > 0, \tag{2.22}$$

and dropping some unnecessary terms, we get

$$\begin{aligned}\frac{\alpha}{2}\|\hat{e}_{\scriptscriptstyle N}\|^2_{\omega^{-1,1}} + \left(\frac{1}{3} - 2\gamma - \delta\right)&\|(\hat{e}_{\scriptscriptstyle N})_x\|^2_{\omega^{-2,0}} \\ &\lesssim \|u - \pi_{\scriptscriptstyle N} u\|^2_{\omega^{-2,-1}} + \gamma\|(u - \pi_{\scriptscriptstyle N} u)_x\|^2_{\omega^{-1,0}} \\ &\lesssim (1 + \gamma N^2) N^{-2m} \|\partial_x^m u\|_{\omega^{m-2,m-1}}.\end{aligned}$$

The last inequality follows from Theorem 2.1.

For $-\frac{1}{3} < \gamma < 0$, we choose δ sufficiently small such that $\frac{1}{3} + \gamma - \delta > 0$, and we derive similarly

$$\frac{\alpha}{2}\|\hat{e}_{\scriptscriptstyle N}\|^2_{\omega^{-1,1}} + \left(\frac{1}{3} + \gamma - \delta\right)\|(\hat{e}_{\scriptscriptstyle N})_x\|^2_{\omega^{-2,0}} \lesssim (1 + |\gamma| N^2) N^{-2m} \|\partial_x^m u\|_{\omega^{m-2,m-1}}.$$

The desired results follow from the triangular inequality, Theorem 2.1, and the fact that $\|u\|_{\omega^{-1,0}} \leq 2\|u\|_{\omega^{-1,0}}$. □

Remark 2.2. Note that the error estimate in the above theorem is optimal for $\gamma = 0$ but suboptimal for $\gamma \neq 0$.

2.4. Linear system and its coefficient matrices. Hence, by setting

$$\begin{aligned}&u_{\scriptscriptstyle N} = \sum_{k=0}^{N-3} \tilde{u}_k \phi_k, \quad \bar{u} = (\tilde{u}_0, \tilde{u}_1, \dots, \tilde{u}_{N-3})^t, \\ &\tilde{f}_k = (f, \psi_k), \quad \bar{f} = (\tilde{f}_0, \tilde{f}_1, \dots, \tilde{f}_{N-3})^t, \\ &m_{ij} = (\phi_j, \psi_i), \quad p_{ij} = -(\phi_j', \psi_i), \quad q_{ij} = (\phi_j', \psi_i'), \quad s_{ij} = (\phi_j', \psi_i''),\end{aligned} \tag{2.23}$$

the linear system (2.4) becomes

$$(\alpha M + \beta P + \gamma Q + S)\bar{u} = \bar{f}, \tag{2.24}$$

where M, P, Q, and S are $(N-2) \times (N-2)$ matrices with entries m_{ij}, p_{ij}, q_{ij}, and s_{ij}, respectively.

Thanks to the orthogonality of the Legendre polynomials, we have $m_{ij} = 0$ for $|i - j| > 3$. Therefore, M is a seven-diagonal matrix. We note that the homogeneous "dual" boundary conditions satisfied by ϕ_j and ψ_i allow us to integrate by parts freely without introducing additional boundary terms; namely, we have

$$s_{ij} = (\phi_j', \psi_i'') = (\phi_j''', \psi_i) = -(\phi_j, \psi_i''').$$

Thanks to the compact form of ϕ_j and ψ_i, we have $s_{ij} = 0$ for $i \neq j$. So S is a diagonal matrix. Similarly, we see that P is a pentadiagonal matrix and Q is a tridiagonal matrix. It is an easy matter to derive that

$$s_{ii} = 2(2i + 3)^2. \tag{2.25}$$

Nonzero elements of M, P, Q can be easily determined from the properties of Legendre polynomials. Hence the linear system (2.24), under the condition of Theorem 2.2, can be easily formed and inverted.

3. Fifth-order equations.

In this section, we shall consider an example of fifth-order equations. We shall follow essentially the same procedures as in the previous section and will omit some repetitive details.

3.1. Dual-Petrov–Galerkin method.

Consider the model fifth-order equation:

$$\begin{aligned} &\alpha u + \beta u_{xxx} - u_{xxxxx} = f, \quad x \in I = (-1,1), \\ &u(\pm 1) = u_x(\pm 1) = u_{xx}(1) = 0, \end{aligned} \tag{3.1}$$

where α and β are given constants. For the sake of simplicity and with the fifth-order KDV equation in mind, we included only zeroth- and third-order linear terms in the equation. Other linear terms as well as nonhomogeneous boundary conditions can be treated as in the previous section.

Similarly to the third-order equation, we define

$$\begin{aligned} W_N &= \{u \in P_N : u(\pm 1) = u_x(\pm 1) = u_{xx}(1) = 0\}, \\ W_N^* &= \{u \in P_N : u(\pm 1) = u_x(\pm 1) = u_{xx}(-1) = 0\}. \end{aligned} \tag{3.2}$$

We also define

$$\begin{aligned} W &= \{u : \ u \in H_0^2(I), \ u_{xx} \in L^2_{\omega^{-2,0}}\}, \\ W^* &= \{u : \ u \in H_0^2(I), \ u_{xx} \in L^2_{\omega^{0,-2}}\}. \end{aligned} \tag{3.3}$$

It is clear that $W_N \subset W$ and $W_N^* \subset W^*$.

We consider the following Legendre dual-Petrov–Galerkin approximation for (3.1): Find $u_N \in W_N$ such that

$$\alpha(u_N, v_N) - \beta(\partial_x^2 u_N, \partial_x v_N) + (\partial_x^2 u_N, \partial_x^3 v_N) = (f, v_N) \quad \forall v_N \in W_N^*. \tag{3.4}$$

Once again, the above dual-Petrov–Galerkin formulation is equivalent to the following weighted spectral-Galerkin approximation: Find $u_N \in W_N$ such that

$$\begin{aligned} &\alpha(u_N, v_N)_{\omega^{-1,1}} - \beta(\partial_x^2 u_N, \omega^{1,-1}\partial_x(v_N \omega^{-1,1}))_{\omega^{-1,1}} \\ &\qquad + (\partial_x^2 u_N, \omega^{1,-1}\partial_x^3(v_N \omega^{-1,1}))_{\omega^{-1,1}} = (f, v_N)_{\omega^{-1,1}} \quad \forall v_N \in W_N. \end{aligned} \tag{3.5}$$

Note in particular that $W \subset V$ and $W^* \subset V^*$. Hence the results proved in the previous section are still valid here.

3.2. Basis functions and projection operators.

The construction of suitable basis functions for W_N and W_N^* follows the general principle (2.6); i.e., we look for

$$\Phi_k = L_k + a_1^{(k)} L_{k+1} + a_2^{(k)} L_{k+2} + a_3^{(k)} L_{k+3} + a_4^{(k)} L_{k+4} + a_5^{(k)} L_{k+5} \tag{3.6}$$

such that $\Phi_k \in W$. Using (1.4) and after some simplifications, we find that $\{a_j^{(k)}\}$ satisfy the following relations:

$$\begin{aligned} a_2^{(k)} + a_4^{(k)} &= -1, \\ (k+2)(k+3)a_2^{(k)} + (k+4)(k+5)a_4^{(k)} &= -k(k+1), \end{aligned} \tag{3.7}$$

and

$$\begin{aligned} a_1^{(k)} + a_3^{(k)} + a_5^{(k)} &= 0, \\ (k+1)(k+2)a_1^{(k)} + (k+3)(k+4)a_3^{(k)} + (k+5)(k+6)a_5^{(k)} &= 0, \\ (k+1)^2(k+2)^2 a_1^{(k)} + (k+3)^2(k+4)^2 a_3^{(k)} + (k+5)^2(k+6)^2 a_5^{(k)} &= g_k, \end{aligned} \tag{3.8}$$

where $g_k = -k^2(k+1)^2 - (k+2)^2(k+3)^2 a_2^{(k)} - (k+4)^2(k+5)^2 a_4^{(k)}$.

One derives immediately from (3.7) that

$$a_2^{(k)} = -\frac{2(2k+5)}{2k+7},\ a_4^{(k)} = \frac{2k+3}{2k+7}. \tag{3.9}$$

We can then determine $a_1^{(k)},\ a_3^{(k)},\ a_5^{(k)}$ by solving the 3×3 system (3.8).

It is easy to verify that

$$\Psi_k = L_k - a_1^{(k)} L_{k+1} + a_2^{(k)} L_{k+2} - a_3^{(k)} L_{k+3} + a_4^{(k)} L_{k+4} - a_5^{(k)} L_{k+5} \in W^*. \tag{3.10}$$

Hence, for $N \geq 5$, we have

$$\begin{aligned} W_N &= \operatorname{span}\{\Phi_0, \Phi_1, \dots, \Phi_{N-5}\};\\ W_N^* &= \operatorname{span}\{\Psi_0, \Psi_1, \dots, \Psi_{N-5}\}. \end{aligned} \tag{3.11}$$

We define

$$L^2_{\omega^{-3,-2}}(I) = L^2_{\omega^{-3,-2}}(I) \cap W,\ L^2_{\omega^{-2,-3}}(I) = L^2_{\omega^{-2,-3}}(I) \cap W^* \tag{3.12}$$

equipped with the norm of $\|\cdot\|_{\omega^{-3,-2}}$ and $\|\cdot\|_{\omega^{-2,-3}}$, respectively. We shall only summarize the results for $L^2_{\omega^{-3,-2}}$ below. The corresponding results for $L^2_{\omega^{-2,-3}}$ are obtained by using the transform $x \to -x$. The proofs are essentially the same as in the previous section.

Lemma 3.1. *Let $\{\Phi_k\}$ be defined as in* (3.6). *Then*

$$\int_I \Phi_k \Phi_j \omega^{-3,-2} dx = 0,\ k \neq j, \tag{3.13}$$

and $\{\Phi_k\}$ forms a complete orthogonal basis in $L^2_{\omega^{-3,-2}}$.

Furthermore, Φ_k satisfies the following Sturm–Liouville equation:

(3.14)
$$B\Phi_k := -(1-x)^3(1+x)^2\partial_x\left\{(1-x)^{-2}(1+x)^{-1}\partial_x\Phi_k(x)\right\} = (k+1)(k+5)\Phi_k(x).$$

Now, let Π_N be the $L^2_{\omega^{-3,-2}}$-orthogonal projector $L^2_{\omega^{-3,-2}} \to W_N$ defined by

$$(u - \Pi_N u, v_N)_{\omega^{-3,-2}} = 0\ \ \forall v_N \in W_N. \tag{3.15}$$

We define

$$H^m_{\omega^{-3,-2}}(I) = \{u \in L^2_{\omega^{-3,-2}}(I) : \partial_x^l u \in L^2_{\omega^{l-3,l-2}}(I),\ 1 \leq l \leq m\}. \tag{3.16}$$

Theorem 3.1.

$$\|\partial_x^l(u - \Pi_N u)\|_{\omega^{l-3,l-2}} \lesssim N^{l-m}\|\partial_x^m u\|_{\omega^{m-3,m-2}}\ \ \forall u \in H^m_{\omega^{-3,-2}},\ 0 \leq l \leq m.$$

Proof. Let us define

$$J_k^{-3,-2}(x) = \frac{1}{2}(k-4)\int_{-1}^x J_{k-1}^{-2,-1}(t)dt,\ k \geq 5. \tag{3.17}$$

One can show that $J_k^{-3,-2}(\pm 1) = \partial_x J_k^{-3,-2}(\pm 1) = \partial_x^2 J_k^{-3,-2}(1) = 0$. Since $J_k^{-2,-1}$ is proportional to ϕ_{k-3}, we then derive from (1.2) and (3.17) that $J_k^{-3,-2}$ must be proportional to Φ_{k-5} so $\{J_k^{-3,-2}\}$ are mutually orthogonal in $L^2_{\omega^{-3,-2}}$. Moreover, one can verify that $J_k^{-3,-2}$ satisfies the relations (2.13)–(2.14). Thus the desired results follow from the same arguments as those in Theorem 2.1. ∎

3.3. Error estimates. We first prove the following generalized Poincaré inequalities.

LEMMA 3.2.

$$\int_I \frac{u^2}{(1-x)^6}dx \leq \frac{4}{25}\int_I \frac{u_x^2}{(1-x)^4}dx \leq \frac{16}{225}\int_I \frac{u_{xx}^2}{(1-x)^2}dx \;\; \forall u \in W_N, \tag{3.18}$$

and

$$\int_I \frac{u_x^2}{(1-x)^4}dx \leq \frac{1}{7}\int_I \frac{u_{xx}^2}{(1-x)^2}dx + 2\int_I \frac{u^2}{(1-x)^6}dx \;\; \forall u \in W_N. \tag{3.19}$$

Proof. The proof is similar to that of Lemma 2.2. Letting $u \in W_N$, for any constant q,

$$\begin{aligned} 0 \leq \int_I \left(\frac{u}{1-x} + qu_x\right)^2 \frac{1}{(1-x)^4}dx &= \int_I \left(\frac{u^2}{(1-x)^6} + q\frac{(u^2)_x}{(1-x)^5} + q^2\frac{u_x^2}{(1-x)^4}\right)dx \\ &= (1-5q)\int_I \frac{u^2}{(1-x)^6}dx + q^2\int_I \frac{u_x^2}{(1-x)^4}dx. \end{aligned}$$

We obtain the first part of (3.18) by taking $q = \frac{2}{5}$. The second part is a direct consequence of Lemma 2.2 since $u_x \in V_N$.

For (3.19), we consider the following relation with any constants q and r:

$$\begin{aligned} 0 &\leq \int_I \left(\frac{u}{(1-x)^2} + q\frac{u_x}{1-x} + ru_{xx}\right)^2 \frac{1}{(1-x)^2}dx \\ &= (1-5q+20r)\int_I \frac{u^2}{(1-x)^6}dx + (q^2-2r-4qr)\int_I \frac{u_x^2}{(1-x)^4}dx + r^2\int_I \frac{u_{xx}^2}{(1-x)^2}dx. \end{aligned}$$

We obtain (3.19) by taking $q = \frac{3}{2}$ and $r = \frac{1}{2}$. □

LEMMA 3.3.

$$\frac{5}{7}\int_I \frac{u_{xx}^2}{(1-x)^2}dx \leq (\partial_x^2 u, \partial_x^3(u\omega^{-1,1})) \leq \frac{203}{15}\int_I \frac{u_{xx}^2}{(1-x)^2}dx \;\; \forall u \in W_N. \tag{3.20}$$

Proof. For any $u \in W_N$, we set $u = \Phi(1-x)$ with $\Phi(\pm 1) = \Phi_x(\pm 1) = 0$. Then, by integrating by parts and using the fact that all boundary terms are zero, we find

$$\begin{aligned} (\partial_x^2 u, \partial_x^3(u\omega^{-1,1})) &= -(\partial_x^3 u, \partial_x^2(u\omega^{-1,1})) = -(\Phi_{xxx}(1-x) - 3\Phi_{xx}, \Phi_{xx}(1+x) + 2\Phi_x) \\ &= \int_I \left\{-\frac{1}{2}(\Phi_{xx}^2)_x(1-x^2) + 3\Phi_{xx}^2(1+x) + 3(\Phi_x^2)_x + 2\Phi_{xx}(\Phi_x(1-x))_x\right\}dx \\ &= 5\int_I \Phi_{xx}^2 dx = 5\int_I \left\{\partial_x^2\left(\frac{u}{1-x}\right)\right\}^2 dx. \end{aligned}$$

Expanding $\partial_x^2(\frac{u}{1-x})$ and integrating by parts, we get

$$\int_I \left\{\partial_x^2\left(\frac{u}{1-x}\right)\right\}^2 dx = \int_I \frac{u_{xx}^2}{(1-x)^2}dx - 6\int_I \frac{u_x^2}{(1-x)^4}dx + 24\int_I \frac{u^2}{(1-x)^6}dx. \tag{3.21}$$

We conclude by applying (3.18) and (3.19) to the above. □

Let Π_N be defined in (3.15). By definition, we have

$$(\partial_x^2(u-\Pi_N u), \partial_x^3 v_N) = (u-\Pi_N u, \omega^{3,2}\partial_x^5 v_N)_{\omega^{-3,-2}} = 0 \quad \forall u \in W,\ v_N \in W_N^*. \tag{3.22}$$

Letting u and u_N be, respectively, the solution of (3.1) and (3.4), we denote $\hat{e}_N = \Pi_N u - u_N$ and $e_N = u - u_N = (u - \Pi_N u) + \hat{e}_N$.

THEOREM 3.2. *For any α, $\beta \geq 0$, there exists a unique solution for the system* (3.4). *Furthermore, for $u \in H^m_{\omega^{-2,-1}}$, we have*

$$\begin{aligned}\alpha\|e_N\|_{\omega^{-1,1}} + \beta N^{-1}\|(e_N)_x\|_{\omega^{-2,0}} + N^{-2}\|(e_N)_{xx}\|_{\omega^{-1,0}}&\\ \lesssim (1+\beta N)N^{-m}\|\partial_x^m u\|_{\omega^{m-3,m-2}},\ m \geq 2.&\end{aligned}$$

Proof. We derive from (3.1), (3.5), and (3.22) that

$$\alpha(e_N, v_N)_{\omega^{-1,1}} - \beta(\partial_x^2 e_N, \partial_x(v_N\omega^{-1,1})) + (\partial_x^2\hat{e}_N, \partial_x^3(v_N\omega^{-1,1})) = 0 \quad \forall v_N \in W_N.$$

Taking $v_N = \hat{e}_N$ in the above and using Lemmas 2.3 and 3.3, we obtain

$$\begin{aligned}\alpha\|\hat{e}_N\|^2_{\omega^{-1,1}} + \frac{\beta}{9}\|(\hat{e}_N)_x\|^2_{\omega^{-2,0}} + \frac{5}{7}\|(\hat{e}_N)_{xx}\|^2_{\omega^{-2,0}}&\\ \leq -\alpha(u-\Pi_N u, \hat{e}_N)_{\omega^{-1,1}} + \beta(\partial_x^2(u-\Pi_N u), \partial_x(\hat{e}_N\omega^{-1,1}))&\\ = -\alpha(u-\Pi_N u, \hat{e}_N)_{\omega^{-1,1}}&\\ - \beta(\partial_x(u-\Pi_N u), (\partial_x^2\hat{e}_N\omega^{-1,1} + 4\partial_x\hat{e}_N\omega^{-2,0} + 4\hat{e}_N\omega^{-3,0})).&\end{aligned}$$

Using the Cauchy–Schwarz inequality, we bound the right-hand side as follows:

$$(u-\Pi_N u, \hat{e}_N)_{\omega^{-1,1}} \leq \|\hat{e}_N\|_{\omega^{-1,1}}\|u-\Pi_N u\|_{\omega^{-1,1}} \lesssim \|\hat{e}_N\|_{\omega^{-1,1}}\|u-\Pi_N u\|_{\omega^{-3,-2}};$$

and thanks to Lemma 2.2,

$$\begin{aligned}((u-\Pi_N u)_x, (\partial_x^2\hat{e}_N\omega^{-1,1} + 4\partial_x\hat{e}_N\omega^{-2,0} + 4\hat{e}_N\omega^{-3,0}))&\\ \lesssim \|(u-\Pi_N u)_x\|_{\omega^{-2,-1}}(\|\partial_x^2\hat{e}_N\|_{\omega^{0,3}} + \|\partial_x\hat{e}_N\|_{\omega^{-2,1}} + \|\hat{e}_N\|_{\omega^{-4,1}})&\\ \lesssim \|(u-\Pi_N u)_x\|_{\omega^{-2,-1}}(\|\partial_x^2\hat{e}_N\|_{\omega^{-2,0}} + \|\partial_x\hat{e}_N\|_{\omega^{-2,0}}).&\end{aligned}$$

Using (2.22) and combining the above inequalities, we arrive at

$$\begin{aligned}\frac{\alpha}{2}\|\hat{e}_N\|^2_{\omega^{-1,1}} + \frac{\beta}{18}\|\partial_x\hat{e}_N\|^2_{\omega^{-2,0}} + \frac{5}{14}\|\partial_x^2\hat{e}_N\|^2_{\omega^{-2,0}}&\\ \lesssim \|u-\Pi_N u\|^2_{\omega^{-3,-2}} + \beta\|(u-\Pi_N u)_x\|^2_{\omega^{-2,-1}}&\\ \lesssim (1+\beta N^2)N^{-2m}\|\partial_x^m u\|_{\omega^{m-3,m-2}}.&\end{aligned}$$

The last inequality follows from Theorem 3.1.

We can then conclude from the above inequality and the triangular inequality. □

Remark 3.1. Similarly as in the previous section, the error estimate in the above theorem is optimal for $\beta = 0$ but suboptimal for $\beta \neq 0$.

3.4. Linear system and its coefficient matrices. Similarly to the third-order equation, we set

$$\begin{aligned}&u_N = \sum_{k=0}^{N-5}\tilde{u}_k\Phi_k,\quad \bar{u} = (\tilde{u}_0, \tilde{u}_1, \dots, \tilde{u}_{N-5})^t,\\ &\tilde{f}_k = (f, \Psi_k),\quad \bar{u} = (\tilde{f}_0, \tilde{f}_1, \dots, \tilde{f}_{N-5})^t,\\ &m_{ij} = (\Phi_j, \Psi_i),\quad M = (m_{ij})_{i,j=0,1,\dots,N-5},\\ &p_{ij} = -(\Phi_j'', \Psi_i'),\quad P = (p_{ij})_{i,j=0,1,\dots,N-5},\\ &s_{ij} = (\Phi_j'', \Psi_i'''),\quad S = (s_{ij})_{i,j=0,1,\dots,N-5}\end{aligned} \tag{3.23}$$

so that the linear system (3.4) becomes

$$(\alpha M + \beta P + S)\bar{u} = \bar{f}. \tag{3.24}$$

Obviously, M is an eleven nonzero diagonal matrix, and with integration by parts, we find that P is a pentadiagonal matrix and S is a diagonal matrix. Repeatedly using (1.2), we can derive that

$$s_{ii} = 2(2i+3)(2i+5)(2i+7)(2i+9)a_5^{(i)}. \tag{3.25}$$

Nonzero elements of M and P can be determined accordingly using (1.2) and (1.3). Hence the linear system (3.24), under the condition of Theorem 3.1, can also be easily inverted.

4. Application to the KDV equation. There is a vast body of literature on various aspects of the KDV equation. Although most of these studies are concerned with initial value problems, the initial-boundary value problems also received considerable attention. The most natural initial-boundary value KDV equation is set in a quarter-plane (see, for instance, [28, 16, 3, 2, 12, 13, 5] and the references therein). The KDV equation on a finite spatial interval has also been considered by several authors [20, 9, 4]. Here, as an example of application to nonlinear equations, we consider the KDV equation on a finite interval:

$$\begin{aligned} &\alpha v_t + \beta v_x + \gamma v v_x + v_{xxx} = 0,\ x \in (-1,1),\ t \in (0,T], \\ &v(-1,t) = g(t),\ v(1,t) = v_x(1,t) = 0,\ \ t \in [0,T], \\ &v(x,0) = v_0(x),\ x \in (-1,1). \end{aligned} \tag{4.1}$$

The positive constants α, β, and γ are introduced to accommodate the scaling of the spatial interval. The existence and uniqueness of the solution for (4.1) can be established as in [9, 4]. Beside its own interests, (4.1) can also be viewed as a legitimate approximate model for the KDV equation on a quarter-plane before the wave reaches the right boundary.

Let us first reformulate (4.1) as an equivalent problem with homogeneous boundary conditions. To this end, let $\hat{v}(x,t) = \frac{(1-x)^2}{4}g(t)$, and write $v(x,t) = u(x,t) + \hat{v}(x,t)$. Then u satisfies the following equation with homogeneous boundary conditions:

$$\begin{aligned} &\alpha u_t + a(x,t)u + b(x,t)u_x + \gamma u u_x + u_{xxx} = f,\ x \in (-1,1),\ t \in (0,T], \\ &u(\pm 1,t) = u_x(1,t) = 0;\ t \in [0,T], \\ &u(x,0) = u_0(x) = v_0(x) - \hat{v}(x,0),\ x \in (-1,1), \end{aligned} \tag{4.2}$$

where $a(x,t) = \frac{\gamma}{2}(x-1)g(t)$, $b(x,t) = \beta + \gamma\hat{v}(x,t)$, and $f(x,t) = -\alpha\hat{v}_t(x,t)$.

For a given Δt, we set $t_k = k\Delta t$ and let $u_{\scriptscriptstyle N}^0 = \pi_{\scriptscriptstyle N} u_0$ and $u_{\scriptscriptstyle N}^1 \in V_N$ be an appropriate approximation of $u(\cdot,t_1)$, for instance; we can compute $u_{\scriptscriptstyle N}^1$ using one step of a semi-implicit first-order scheme so that for $u \in C^3(0,T; L^2_{\omega^{2,2}}(I)) \cap C(0,T; B^m_{\omega^{-2,-1}})$, we have

$$\|u_{\scriptscriptstyle N}^1 - \pi_{\scriptscriptstyle N} u(\cdot,t_1)\|_{\omega^{-1,1}} \lesssim \Delta t^2 + N^{-m}. \tag{4.3}$$

Let M be such that $|u(x,t)| \le M$ for $x \in [-1,1]$ and $t \in [0,T]$. We define a cut-off function

$$H(x) = \begin{cases} x, & |x| \le 2M, \\ 2M, & x > 2M, \\ -2M, & x < -2M. \end{cases} \tag{4.4}$$

It is easy to verify that

$$|H(x)-H(y)| \le |x-y| \ \ \forall x,\ y. \tag{4.5}$$

We consider first a modified Crank–Nicolson leap-frog dual-Petrov–Galerkin approximation:

$$\begin{aligned} &\frac{\alpha}{2\Delta t}(u_N^{k+1}-u_N^{k-1}, v_N)_{\omega^{-1,1}} + \frac{1}{2}(\partial_x(u_N^{k+1}+u_N^{k-1}), \partial_x^2(v_N\omega^{-1,1})) \\ &\quad = (f(\cdot,t_k), v_N)_{\omega^{-1,1}} + \frac{\gamma}{2}(H(u_N^k)u_N^k, \partial_x(v_N\,\omega^{-1,1})) \\ &\quad - (a\,u_N^k, v_N)_{\omega^{-1,1}} + (u_N^k, \partial_x(bv_N\,\omega^{-1,1})) \ \ \forall v_N \in V_N. \end{aligned} \tag{4.6}$$

We denote $\hat{e}_N^k = \pi_N u(\cdot,t_k) - u_N^k$, $\tilde{e}_N^k = u(\cdot,t_k) - \pi_N u(\cdot,t_k)$, and $e_N^k = u(\cdot,t_k) - u_N^k$.

THEOREM 4.1. *We assume $u \in C^3(0,T; L^2_{\omega^{2,2}}(I)) \cap C(0,T; B^m_{\omega^{-2,-1}})$ with $m > 1$. Then the scheme* (4.6) *is unconditionally stable, and the following error estimates hold:*

$$\|e_N^{n+1}\|_{\omega^{-1,1}} \lesssim \Delta t^2 + N^{-m}, \ \ 0 \le n \le [T/dt]-1,$$

$$\left(\Delta t \sum_{k=1}^{n} \|\partial_x(e_N^{k+1}+e_N^{k-1})\|^2_{\omega^{-1,0}}\right)^{\frac{1}{2}} \lesssim \Delta t^2 + N^{1-m}, \ \ 1 \le n \le [T/dt]-1.$$

Proof. Let E^k $(k=1,2,\dots)$ be the truncation error defined by

$$\begin{aligned} &\frac{\alpha}{2\Delta t}(u(\cdot,t_{k+1}) - u(\cdot,t_{k-1})) + a(\cdot,t_k)\,u(\cdot,t_k) + b(\cdot,t_k)\,u_x(\cdot,t_k) + \gamma u(\cdot,t_k)\partial_x u(\cdot,t_k) \\ &\qquad + \frac{1}{2}\partial_x^3(u(\cdot,t_{k+1}) + u(\cdot,t_{k-1})) - f(\cdot,t_k) = E^k(\cdot). \end{aligned} \tag{4.7}$$

Comparing (4.6) with (4.7) and using Lemma 2.4, we have

$$\begin{aligned} &\frac{\alpha}{2\Delta t}(\hat{e}_N^{k+1}-\hat{e}_N^{k-1}, v_N)_{\omega^{-1,1}} + \frac{1}{2}(\partial_x(\hat{e}_N^{k+1}+\hat{e}_N^{k-1}), \partial_x^2(v_N\omega^{-1,1})) \\ &\quad = \frac{\gamma}{2}(u(\cdot,t_k)^2 - H(u_N^k)u_N^k, \partial_x(v_N\,\omega^{-1,1})) \\ &\quad - (a\,(\hat{e}_N^k+\tilde{e}_N^k), v_N)_{\omega^{-1,1}} + \frac{1}{2}((\hat{e}_N^k+\tilde{e}_N^k), \partial_x(bv_N\,\omega^{-1,1})) \\ &\quad + (E^k, v_N)_{\omega^{-1,1}} - \frac{\alpha}{2\Delta t}(\tilde{e}_N^{k+1}-\tilde{e}_N^{k-1}, v_N)_{\omega^{-1,1}} \ \ \forall v_N \in V_N. \end{aligned} \tag{4.8}$$

Let $A = \max_{x\in[-1,1],\,t\in[0,T]}|a(x,t)|$ and $B = \max_{x\in[-1,1],\,t\in[0,T]}(|b(x,t)| + |\partial_x b(x,t)|)$. We now take $v_N = 2\Delta t(\hat{e}_N^{k+1}+\hat{e}_N^{k-1})$ in (4.8) and bound the right-hand side terms using repeatedly the Cauchy–Schwarz inequality and Lemma 2.2 as follows:

$$-2\Delta t(a\,(\hat{e}_N^k+\tilde{e}_N^k), \hat{e}_N^{k+1}+\hat{e}_N^{k-1})_{\omega^{-1,1}} \le \Delta t A(\|\tilde{e}_N^k\|^2_{\omega^{-1,1}} + \|\hat{e}_N^k\|^2_{\omega^{-1,1}} + \|\hat{e}_N^{k+1}+\hat{e}_N^{k-1}\|^2_{\omega^{-1,1}}),$$

$$\begin{aligned} 2\Delta t(E^k, \hat{e}_N^{k+1}+\hat{e}_N^{k-1})_{\omega^{-1,1}} &\le 2\Delta t\|E^k\|_{\omega^{2,2}}\|\hat{e}_N^{k+1}+\hat{e}_N^{k-1}\|_{\omega^{-4,0}} \\ &\le c\Delta t\|E^k\|^2_{\omega^{2,2}} + \frac{\Delta t}{36}\|\partial_x(\hat{e}_N^{k+1}+\hat{e}_N^{k-1})\|^2_{\omega^{-2,0}}. \end{aligned}$$

Let us denote $\tilde{E}_N^k = \frac{1}{2\Delta t}(\tilde{e}_N^{k+1}-\tilde{e}_N^{k-1})$. Similarly as above, we have

$$-\frac{\alpha}{2\Delta t}(\tilde{e}_N^{k+1}-\tilde{e}_N^{k-1}, \hat{e}_N^{k+1}+\hat{e}_N^{k-1})_{\omega^{-1,1}} \le c\Delta t\|\tilde{E}_N^k\|^2_{\omega^{2,2}} + \frac{\Delta t}{36}\|\partial_x(\hat{e}_N^{k+1}+\hat{e}_N^{k-1})\|^2_{\omega^{-2,0}}.$$

By the assumption $|u(x,t)| \le M$ for all x and t, we have

$$\begin{aligned}|u(\cdot,t_k)^2 - H(u_{_N}^k)u_{_N}^k| &= |u(\cdot,t_k)(H(u(\cdot,t_k)) - H(u_{_N}^k)) + H(u_{_N}^k)(u(\cdot,t_k) - u_{_N}^k)|\\ &\le 2M|u(\cdot,t_k) - u_{_N}^k| \le 2M(|\tilde{e}_{_N}^k| + |\hat{e}_{_N}^k|).\end{aligned}$$

Hence,

$$\begin{aligned}&\gamma\Delta t(u(\cdot,t_k)^2 - H(u_{_N}^k)u_{_N}^k, \partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\omega^{-1,1})\\ &\qquad\le \gamma\Delta t\|u(\cdot,t_k)^2 - H(u_{_N}^k)u_{_N}^k\|_{\omega^{0,2}}\|\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|_{\omega^{-2,0}}\\ &\qquad\le c\Delta t(\|\tilde{e}_{_N}^k\|^2_{\omega^{-2,-1}} + \|\hat{e}_{_N}^k\|^2_{\omega^{-1,1}}) + \frac{\Delta t}{36}\|\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|^2_{\omega^{-2,0}},\end{aligned}$$

To handle the remaining terms, we recall the following Hardy inequalities:

$$\int_a^b \left[\frac{1}{t-a}\int_a^t \psi(s)ds\right]^2 (t-a)^\alpha dt \le \frac{4}{1-\alpha}\int_a^b \psi^2(t)(t-a)^\alpha dt,$$

$$\int_a^b \left[\frac{1}{b-t}\int_t^b \psi(s)ds\right]^2 (b-t)^\alpha dt \le \frac{4}{1-\alpha}\int_a^b \psi^2(t)(b-t)^\alpha dt, \tag{4.9}$$

which hold for all measurable functions ϕ on (a,b) with $a<b$ and $\alpha < -1$.

Let $(a,b) = (-1,0)$, $\alpha = 0$, and $\phi(t) = \int_{-1}^t \psi(s)ds$. We find

$$\int_{-1}^0 \frac{1}{(1-t)^3(1+t)}\phi^2(t)dt \le \int_{-1}^0 \frac{1}{(t+1)^2}\phi^2(t)dt \le 4\int_{-1}^0 (\phi_t)^2 dt.$$

Let $(a,b) = (0,1)$, $\alpha = -1$, and $\phi(t) = \int_t^1 \psi(s)ds$. We find

$$\int_0^1 \frac{1}{(1-t)^3(1+t)}\phi^2(t)dt \le \int_0^1 \frac{1}{(1-t)^3}\phi^2(t)dt \le 2\int_0^1 (\phi_t)^2\frac{1}{1-t}dt.$$

Combining the above two inequalities, we obtain

$$\int_I \phi^2\omega^{-3,-1}dx \le 4\int_I (\phi_x)^2\omega^{-1,0}dx, \tag{4.10}$$

which holds for all ϕ such that $\phi(\pm1) = 0$ and $\int_I (\phi_x)^2\omega^{-1,0}dx < \infty$.

Thanks to Lemma 2.2 and (4.10),

$$\begin{aligned}&\gamma\Delta t(u(\cdot,t_k)^2 - H(u_{_N}^k)u_{_N}^k, (\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\partial_x\omega^{-1,1})\\ &\qquad\le 2\gamma\Delta t\|u(\cdot,t_k)^2 - H(u_{_N}^k)u_{_N}^k\|_{\omega^{-1,1}}\|(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|_{\omega^{-3,-1}}\\ &\qquad\le c\Delta t(\|\tilde{e}_{_N}^k\|^2_{\omega^{-2,-1}} + \|\hat{e}_{_N}^k\|^2_{\omega^{-1,1}}) + \frac{\Delta t}{36}\|\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|^2_{\omega^{-2,0}}.\end{aligned}$$

Similarly, we have

$$\begin{aligned}&\Delta t((\hat{e}_{_N}^k + \tilde{e}_{_N}^k), \partial_x(b(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\omega^{-1,1})) = \Delta t((\hat{e}_{_N}^k + \tilde{e}_{_N}^k), b\,\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\omega^{-1,1})\\ &\qquad + \Delta t((\hat{e}_{_N}^k + \tilde{e}_{_N}^k), b\,(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\partial_x\omega^{-1,1}) + \Delta t(\hat{e}_{_N}^k + \tilde{e}_{_N}^k, \partial_x b\,(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\,\omega^{-1,1})\\ &\qquad\le cB\Delta t(\|\tilde{e}_{_N}^k\|^2_{\omega^{-2,-1}} + \|\hat{e}_{_N}^k\|^2_{\omega^{-1,1}}) + \frac{\Delta t}{36}\|\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|^2_{\omega^{-2,0}}.\end{aligned}$$

Combining the above inequalities into (4.8) and using Lemma 2.3, we obtain

$$\begin{aligned}&\alpha(\|\hat{e}_{_N}^{k+1}\|^2_{\omega^{-1,1}} - \|\hat{e}_{_N}^{k-1}\|^2_{\omega^{-1,1}}) + \frac{\Delta t}{36}\|\partial_x(\hat{e}_{_N}^{k+1} + \hat{e}_{_N}^{k-1})\|^2_{\omega^{-2,0}}\\ &\quad\le c\Delta t(\|E^k\|^2_{\omega^{2,2}} + \|\tilde{E}_N^k\|^2_{\omega^{2,2}} + \|\hat{e}_{_N}^{k+1}\|^2_{\omega^{-1,1}} + \|\hat{e}_{_N}^k\|^2_{\omega^{-1,1}} + \|\hat{e}_{_N}^{k-1}\|^2_{\omega^{-1,1}} + \|\tilde{e}_{_N}^k\|^2_{\omega^{-2,-1}}).\end{aligned}$$

We can then apply the standard discrete Gronwall lemma to the above inequality to get

$$\begin{aligned}\|\hat{e}_{_N}^{n+1}\|^2_{\omega^{-1,1}} + \frac{\Delta t}{36}\sum_{k=1}^{n}\|\partial_x(\hat{e}_{_N}^{k+1}+\hat{e}_{_N}^{k-1})\|^2_{\omega^{-2,0}} &\lesssim \|\hat{e}_{_N}^{0}\|^2_{\omega^{-1,1}} + \|\hat{e}_{_N}^{1}\|^2_{\omega^{-1,1}} \\ &+ \Delta t\sum_{k=1}^{n}(\|\tilde{e}_{_N}^{k}\|^2_{\omega^{-2,-1}} + \|E^k\|^2_{\omega^{2,2}} + \|\tilde{E}_N^k\|^2_{\omega^{2,2}}),\ \ 1\le n\le [T/\Delta t]-1.\end{aligned}$$

Using the triangular inequality, we derive that

$$\begin{aligned}\|e_{_N}^{n+1}\|^2_{\omega^{-1,1}} &\lesssim \|\hat{e}_{_N}^{0}\|^2_{\omega^{-1,1}} + \|\hat{e}_{_N}^{1}\|^2_{\omega^{-1,1}} + \|\tilde{e}_{_N}^{n+1}\|^2_{\omega^{-1,1}} \\ &+ \Delta t\sum_{k=1}^{n}(\|\tilde{e}_{_N}^{k}\|^2_{\omega^{-2,-1}} + \|E^k\|^2_{\omega^{2,2}} + \|\tilde{E}_N^k\|^2_{\omega^{2,2}})\end{aligned}$$

and

$$\begin{aligned}\frac{\Delta t}{36}\sum_{k=1}^{n}\|\partial_x(e_{_N}^{k+1}+e_{_N}^{k-1})\|^2_{\omega^{-1,0}} &\lesssim \|\hat{e}_{_N}^{0}\|^2_{\omega^{-1,1}} + \|\hat{e}_{_N}^{1}\|^2_{\omega^{-1,1}} \\ &+ \Delta t\sum_{k=1}^{n}(\|\tilde{e}_{_N}^{k}\|^2_{\omega^{-2,-1}} + \|E^k\|^2_{\omega^{2,2}} + \|\tilde{E}_N^k\|^2_{\omega^{2,2}} + \|\partial_x(\tilde{e}_{_N}^{k+1}+\tilde{e}_{_N}^{k-1})\|^2_{\omega^{-1,0}}).\end{aligned}$$

We can then conclude from the assumptions and Theorem 2.1. □

Next, we consider the standard Crank–Nicolson leap-frog weighted Galerkin approximation:

(4.11)
$$\begin{aligned}&\frac{\alpha}{2\Delta t}(u_{_N}^{k+1}-u_{_N}^{k-1},v_{_N})_{\omega^{-1,1}} + \frac12(\partial_x(u_{_N}^{k+1}+u_{_N}^{k-1}),\partial_x^2(v_{_N}\omega^{-1,1})) \\ &\quad= -(a\,u_{_N}^{k},v_{_N})_{\omega^{-1,1}} + (u_{_N}^{k},\partial_x(bv_{_N}\omega^{-1,1})) \\ &\quad+ (f(\cdot,t_k),v_{_N})_{\omega^{-1,1}} + \frac{\gamma}{2}((u_{_N}^{k})^2,\partial_x v_{_N}\,\omega^{-1,1} + v_{_N}\partial_x\omega^{-1,1})\ \ \forall v_{_N}\in V_N.\end{aligned}$$

Corollary 4.1. *Under the conditions of Theorem* 4.1*, there exists* c_0 *such that for* $\Delta t\,N\le c_0$*, the two schemes* (4.6) *and* (4.11) *are equivalent.*

Proof. We need only to show that the scheme (4.6) reduces to (4.11) under the condition that $\Delta t\,N\le c_0$. Indeed, using the estimate in Theorem 4.1, the inverse inequality $\|u\|_{L^\infty}\lesssim N^2\|u\|_{\omega^{0,1}}$ for all $u\in P_N$ (see Lemma 4.1 below), and the assumptions on u, we find that there exists c_0 such that for $\Delta t\,N\le c_0$ we have

$$\begin{aligned}\|u_{_N}^k\|_{L^\infty} &\le \|u(\cdot,t_k)\|_{L^\infty} + \|\tilde{e}_{_N}^k\|_{L^\infty} + \|\hat{e}_{_N}^k\|_{L^\infty} \\ &\le M + \|\tilde{e}_{_N}^k\|_{L^\infty} + N^2\|\hat{e}_{_N}^k\|_{\omega^{0,1}} \\ &\le M + \|\tilde{e}_{_N}^k\|_{L^\infty} + cN^2(\Delta t^2 + N^{-m}) \le 2M.\end{aligned}$$

Hence (4.6) and (4.11) are equivalent. □

The following lemma is a special case of Theorem 2.1 in [15]. For the reader's convenience, we provide an elementary proof below.

Lemma 4.1.

$$\|u\|_{L^\infty}\lesssim N^2\|u\|_{\omega^{0,1}}\ \ \forall u\in P_N.$$

Proof. Let $J_k^{0,1}$ be the kth degree Jacobi polynomial of index $(0,1)$. We recall that (cf. [27])

$$\|J_k^{0,1}\|_{L^\infty} = k+1, \;\; \|J_k^{0,1}\|_{\omega^{0,1}} = \sqrt{\frac{2}{k+1}}. \tag{4.12}$$

For any $u \in P_N$, we write $u(x) = \sum_{k=0}^N u_k J_k^{0,1}(x)$. Then

$$\begin{aligned}\|u\|_{L^\infty}^2 &\le (N+1)^2 \left(\sum_{k=0}^N |u_k|\right)^2 \le (N+1)^3 \sum_{k=0}^N |u_k|^2 \\ &\le \frac{1}{2}(N+1)^4 \sum_{k=0}^N |u_k|^2 \frac{2}{k+1} = \frac{1}{2}(N+1)^4 \|u\|_{\omega^{0,1}}^2. \qquad \square\end{aligned}$$

Remark 4.1. In practice, the nonlinear term is usually computed using the pseudospectral approach (cf. [11, 7]), which is discussed in the next section. It is not difficult to show that the results in Theorem 4.1 apply to the pseudospectral scheme (see [20] for a similar result).

Remark 4.2. We note that the result obtained here for the third-order KDV equation (4.2) can be extended to the fifth-order KDV equation, which has also attracted considerable attention (see, for instance, [18]).

5. Miscellaneous issues. We discuss in this section several extensions and practical issues related to the dual-Petrov–Galerkin method. We note, in particular, that the dual-Petrov–Galerkin method can be used with any spatial discretization method based on a variational formulation such as the finite-element method.

5.1. Other higher odd-order equations. We have discussed in detail the Legendre dual-Petrov–Galerkin method for third- and fifth-order equations. It is evident that the method can be directly applied to other higher odd-order equations of the form

$$\sum_{j=0}^{2m} a_j u^{(j)}(x) + u^{(2m+1)}(x) = 0, \;\; m \ge 3, \tag{5.1}$$

with the boundary conditions

$$u(\pm 1) = u'(\pm 1) = \cdots = u^{(m-1)}(\pm 1) = 0, \;\; u^{(m)}(1) = 0. \tag{5.2}$$

Other boundary conditions and/or variable coefficients can be treated following the discussion below.

5.2. Other boundary conditions. It must be noted that our dual-Petrov–Galerkin approach is quite flexible and can be used for other unconventional boundary conditions. For instance, Colin and Ghidaglia [9] studied the KDV equation

$$u_t + \frac{2}{L}(u_x + uu_x) + \frac{8}{L^3} u_{xxx} = 0, \;\; x \in (-1,1), \;\; t > 0, \tag{5.3}$$

with the boundary conditions

$$u(-1) = g(t), \;\; u_x(1) = u_{xx}(1) = 0. \tag{5.4}$$

Note that we have scaled the interval from $(0, L)$, which was used in [9], to $(-1, 1)$.

Let us denote

$$X_N = \{u \in P_N : u(-1) = 0,\ u_x(1) = u_{xx}(1) = 0\}. \tag{5.5}$$

Then the "dual" space is

$$X_N^* = \{v \in P_N : v_x(-1) = v(-1) = 0,\ v_{xx}(1) = 0\}. \tag{5.6}$$

There exist unique coefficients $\{a_j^{(k)},\ \tilde{a}_j^{(k)}\}$ such that

$$\begin{aligned} \phi_k &= L_k + \sum_{j=1}^{3} a_j^{(k)} L_{k+j} \in X_N,\ k = 0, 1, \dots, N-3, \\ \psi_k &= L_k + \sum_{j=1}^{3} \tilde{a}_j^{(k)} L_{k+j} \in X_N^*,\ k = 0, 1, \dots, N-3. \end{aligned} \tag{5.7}$$

Then, the Legendre dual-Petrov–Galerkin method for (5.3)–(5.4) is to find $u_{_N} = v_{_N} + \frac{(1-x)^3}{8} g(t)$ with $v_{_N} \in X_N$ such that

$$(\partial_t u_{_N}, \psi_j) + \frac{2}{L}(\partial_x u_{_N} + u_{_N} \partial_x u_{_N}, \psi_j) + (\partial_x u_{_N}, \partial_x^2 \psi_j) = 0,\ j = 0, 1, \dots, N-3. \tag{5.8}$$

One can prove results which are similar to Theorem 4.1 for this problem.

5.3. Problems with variable coefficients: Pseudospectral method in modal basis.

Let us consider, as an example, the following third-order equation:

$$\begin{aligned} &a(x)u - b(x)u_x + u_{xxx} = f,\quad x \in I = (-1, 1), \\ &u(\pm 1) = u_x(1) = 0. \end{aligned} \tag{5.9}$$

The pseudospectral dual-Petrov–Galerkin method for (5.9) is to find $u_{_N} \in V_N$ such that

$$(a(x)u_{_N}, v_{_N})_N - (b(x)u'_{_N}, v_{_N})_N + (u'_{_N}, v''_{_N})_N = (f, v_{_N})_N \quad \forall v_{_N} \in V_N^*, \tag{5.10}$$

where

$$(u, v)_N = \sum_{k=0}^{N} u(x_k) v(x_k) \omega_k \tag{5.11}$$

is the discrete inner product of u and v associated with the Legendre–Gauss–Lobatto quadrature (cf. [7]). We recall that

$$(u, v)_N = (u, v) \quad \forall uv \in P_{2N-1}. \tag{5.12}$$

Let us denote $\tilde{\psi}_i = \frac{1}{(\phi'_i, \psi''_i)} \psi_i = \frac{1}{2(2i+3)^2} \psi_i$. Then we have

$$(\phi'_j, \tilde{\psi}''_i)_N = (\phi'_j, \tilde{\psi}''_i) = \delta_{ij},\quad 0 \le i,\ j \le N-3.$$

Hence, by setting

$$
\begin{aligned}
&u_N = \sum_{k=0}^{N-3} \tilde{u}_k \phi_k, \quad \bar{u} = (\tilde{u}_0, \tilde{u}_1, \dots, \tilde{u}_{N-3})^t, \\
&\tilde{f}_k = (f, \tilde{\psi}_k)_N, \quad \bar{f} = (\tilde{f}_0, \tilde{f}_1, \dots, \tilde{f}_{N-3})^t, \\
&m_{ij} = (a(x)\phi_j, \tilde{\psi}_i)_N, \quad p_{ij} = -(b(x)\phi'_j, \tilde{\psi}_i)_N,
\end{aligned} \tag{5.13}
$$

the linear system (5.10) becomes

$$
(M + P + I)\bar{u} = \bar{f}. \tag{5.14}
$$

It is clear that the matrices M and P are full and their formation involves N^3 operations as well as the inversion of (5.14). Hence a direct approach is advisable only if one uses a small or moderate number of modes. Otherwise, an iterative method can be efficiently implemented as follows:

- Note that a conjugate gradient type iterative method does not require the explicit formation of the matrix; only the action of the matrix upon a given vector is needed at each iteration. Although the formation of M and P involves N^3 operations, their action on a given vector $\bar{u}$, i.e., $M\bar{u}$ and $P\bar{u}$, can be computed in $O(N^2)$ operations.
- The number of operations can be further reduced to a quasi-optimal $O(N\log N)$ if we use the following Chebyshev–Legendre dual-Petrov–Galerkin method (cf. [10, 24]): Find $u_N \in V_N$ such that

  $$(I_N^c(a(x)u_N), v_N)_N - (I_N^c(b(x)u'_N), v_N)_N + (u'_N, v''_N)_N = (f, v_N)_N \;\; \forall v_N \in V_N^*,$$

  where I_N^c is the interpolation operator based on the Chebyshev–Gauss–Lobatto points, while $(\cdot,\cdot)_N$ is still the discrete inner product of u and v associated with the Legendre–Gauss–Lobatto quadrature. Hence the only difference between (5.3) and (5.10) is that $a(x)u_N$ and $b(x)u'_N$ in (5.10) are replaced by $I_N^c(a(x)u_N)$ and $I_N^c(b(x)u'_N)$. Thanks to the fast Fourier transform (FFT) and the fast Chebyshev–Legendre transform [1, 24], the Legendre coefficients of $I_N^c(a(x)u_N)$ and $I_N^c(b(x)u'_N)$ can be computed in $O(N \log N)$ operations given the Legendre coefficients of u_N (see [24] for details).
- Under reasonable assumptions on $a(x)$ and $b(x)$, the matrix $M+P+I$ is well conditioned; i.e, its condition number is independent of N. We now provide a heuristic argument for this statement.
  Since $\phi_k\omega^{-1,1} \in V^*$, there exists unique $\{h_{kj}\}$ such that

  $$\phi_k \omega^{-1,1} = \sum_{j=0}^{N-3} h_{kj}\psi_j, \quad k = 0, 1, \dots, N-3.$$

  Hence we have

  $$
  \begin{aligned}
  \langle H\bar{u}, \bar{u}\rangle &= \left(\sum_{j=0}^{N-3} \tilde{u}_j \phi'_j, \sum_{k,j=0}^{N-3} \tilde{u}_j h_{kj} \psi''_j \right)_N \\
  &= \left(\sum_{j=0}^{N-3} \tilde{u}_j \phi'_j, \sum_{j=0}^{N-3} \tilde{u}_j (\phi_j \omega^{-1,1})'' \right) = (\partial_x u_N, \partial_x^2 (u_N \omega^{-1,1}))
  \end{aligned}
  $$

and

$$\langle HM\bar{u},\bar{u}\rangle = \left(a(x)\sum_{j=0}^{N-3}\tilde{u}_j\phi_j, \sum_{k,j=0}^{N-3}\tilde{u}_j h_{kj}\psi_j\right)_N$$
$$= \left(a(x)\sum_{j=0}^{N-3}\tilde{u}_j\phi_j, \sum_{j=0}^{N-3}\tilde{u}_j\phi_j\omega^{-1,1}\right)_N = (a(x)u_{_N}, u_{_N}\omega^{-1,1})_N,$$

where $\langle \bar{v},\bar{v}\rangle := \sum_{j=0}^{N-3} v_j^2$ is the inner product in l^2.

Let us assume that $0 \le a(x) \le a_1$. Then, thanks to (2.2) and (2.3), we derive from the above that there exists a constant a_2 independent of N such that

$$\langle H\bar{u},\bar{u}\rangle \;\le\; \langle H(M+I)\bar{u},\bar{u}\rangle \;\le\; a_2\langle H\bar{u},\bar{u}\rangle.$$

Hence the condition number of $M+I$, in the norm $\|\bar{v}\|_H := \langle H\bar{v},\bar{v}\rangle^{\frac{1}{2}}$, is independent of N. Under assumptions similar to those in Theorem 2.2, one can also establish that the condition number of $M+P+I$ is independent of N. This statement is confirmed by our numerical results (see the next section).

Therefore, a conjugate gradient type iterative method like BICGSTAB or CGS for (5.14) will converge in a small and fixed number (i.e., independent of N) of steps. In short, the Chebyshev–Legendre dual-Petrov–Galerkin method for (5.9) can be solved in a quasi-optimal $O(N\log N)$ operation.

Since the unknowns are coefficients of the spectral expansion, instead of the nodal values of the approximate solution at the collocation points, we refer to the above as the pseudospectral dual-Petrov–Galerkin method in *modal* basis. The modal basis presents at least three distinct advantages compared with the nodal basis:

- As demonstrated in sections 2 and 3 (see also [22, 23, 24]), for problems with constant coefficients, using an appropriate modal basis leads to sparse matrices.
- With the nodal basis, the choice of quadrature rules/collocation points plays an important role and should be made in accordance with the underlying differential equations and boundary conditions (see, for instance, [17] and the references therein). For example, the Gauss–Lobatto points are not suitable for third-order equations (cf. [21]). With the modal basis, since the use of the quadrature rule is merely to approximate the integrals in the variational formulation, the choice of quadrature rules/collocation points is not important. Therefore, for the third-order equation (5.9), we can still use the usual Gauss–Lobatto quadrature.
- Most importantly, using an appropriate modal basis leads to well-conditioned matrices as we explained above.

6. Numerical results.

We present in this section some numerical results illustrating the nice properties of our dual-Petrov–Galerkin method.

6.1. Third- and fifth-order linear equations.

Let us first look at the conditioning of our dual-Petrov–Galerkin method. We list in Table 6.1 the condition numbers of $M+P+I$ in (5.14) with various $a(x)$ and $b(x)$. Notice that in all cases, the condition numbers are small and, more importantly, independent of N.

We list in Table 6.2 the condition numbers of $\alpha M+\beta P+S$ in (3.24) scaled by the diagonal matrix S with various α and β. Once again, the condition numbers are small and independent of N.

Table 6.1
Condition numbers of (5.14).

	$a(x) = 1$	$a(x) = 10$	$a(x) = 50$	$a(x) = \sin x$	$a(x) = 10\ \exp(x)$
N	$b(x) = 0$	$b(x) = 0$	$b(x) = 0$	$b(x) = 2x - 1$	$b(x) = \cos x$
16	1.119	2.218	7.219	1.188	2.393
64	1.119	2.218	7.219	1.188	2.393
128	1.119	2.218	7.219	1.188	2.393

Table 6.2
Condition numbers of (3.24) *scaled by* S.

	$\alpha = 1$	$\alpha = 100$	$\alpha = 100$	$\alpha = 1$	$\alpha = 0$

128	1.006	2.421	2.005	3.342	1.009

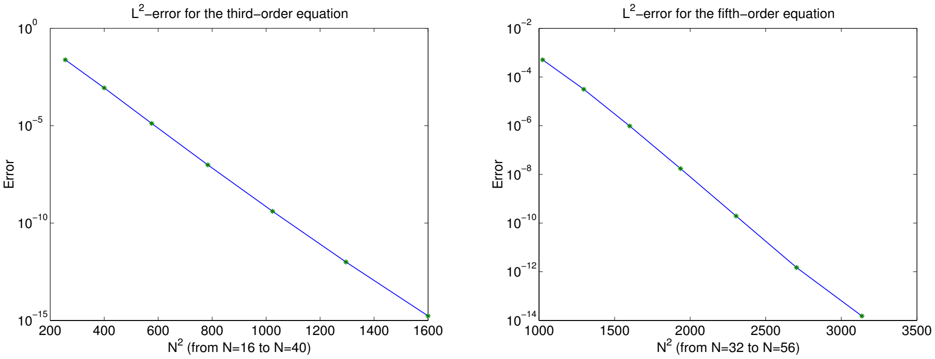

Fig. 6.1. *L^2-errors for the third- and fifth-order equations.*

Next, we look at the accuracy of our dual-Petrov–Galerkin method. We take $a(x) = \sin x$ and $b(x) = 2x-1$ in (2.4) and let the exact solution of (2.4) be $\cos(16\pi x)$. We plot in Figure 6.1 (left) the $\log_{10}$ of the L^2-error against N^2. For the fifth-order equation (3.1), we take $\alpha = \beta = 1$ and the exact solution to be $\sin^3(3\pi x)$. The $\log_{10}$ of the L^2-error against N^2 is presented in Figure 6.1 (right). The straight lines in these plots indicate that the L^2-errors converge like $\exp(-cN^2)$, a typical supergeometric convergence for analytic functions by spectral methods (cf. [6]).

6.2. KDV equation. Now, we present some numerical tests for the KDV equation. We first consider the initial value KDV problem

$$u_t + uu_x + u_{xxx} = 0, \quad u(x, 0) = u_0(x), \tag{6.1}$$

with the exact soliton solution

$$u(x, t) = 12\kappa^2 \text{sech}^2(\kappa(x - 4\kappa^2 t - x_0)).$$

Since $u(x,t)$ converges to 0 exponentially as $|x| \to \infty$, we can approximate the initial value problem (6.1) by an initial-boundary value problem for $x \in (-M, M)$ as long as the soliton does not reach the boundaries.

We take $\kappa = 0.3$, $x_0 = -20$, $M = 50$, and $\Delta t = 0.001$ so that for $N \lesssim 160$, the time discretization error is negligible compared with the spatial discretization error.

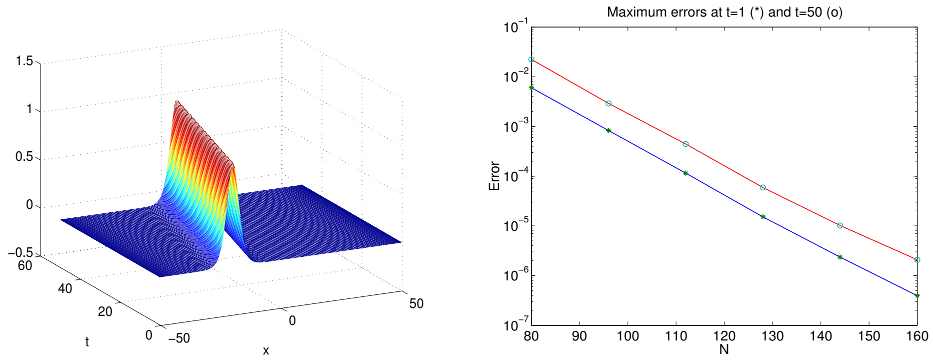

FIG. 6.2. *Exact solution for the KDV equation: Left, time evolution; right, maximum error vs. N.*

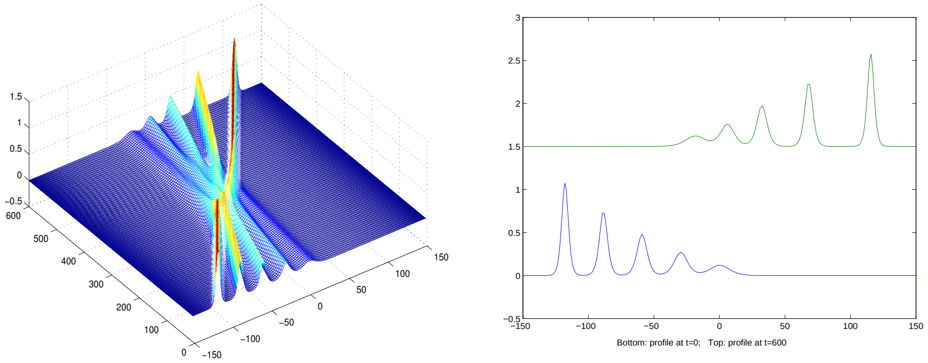

FIG. 6.3. *Interaction of five solitary waves.*

On the left of Figure 6.2, we plot the time evolution of the approximate solution, and on the right, we plot the maximum errors in the semi-log scale at $t = 1$ and $t = 50$. Note that the straight lines indicate that the errors converge like $\exp(-cN)$, which is typical for solutions that are infinitely differentiable but not analytic. The excellent accuracy for this known exact solution indicates that the KDV equation on a finite interval can be used to effectively simulate the KDV equation on a semi-infinite interval before the wave reaches the boundary.

In the following tests, we fix $M = 150$, $\Delta t = 0.02$, and $N = 256$.

Example 1: Interaction of five solitons. We start with the initial condition

$$u_0(x) = \sum_{i=1}^{5} 12\kappa_i^2 \operatorname{sech}^2(\kappa_i(x - x_i))$$

with

$$\kappa_1 = .3,\ \kappa_2 = .25,\ \kappa_3 = .2,\ \kappa_4 = .15,\ \kappa_5 = .1,$$
$$x_1 = -120,\ \ x_1 = -90,\ \ x_3 = -60,\ x_4 = -30,\ \ x_5 = 0.$$

In Figure 6.3 (left), we plot the time evolution of the solution in the (x, t) plane. We also plot the initial profile and the profile at the final step ($t = 600$) in Figure 6.3 (right). We observe that the soliton with higher amplitude travels with faster speed,

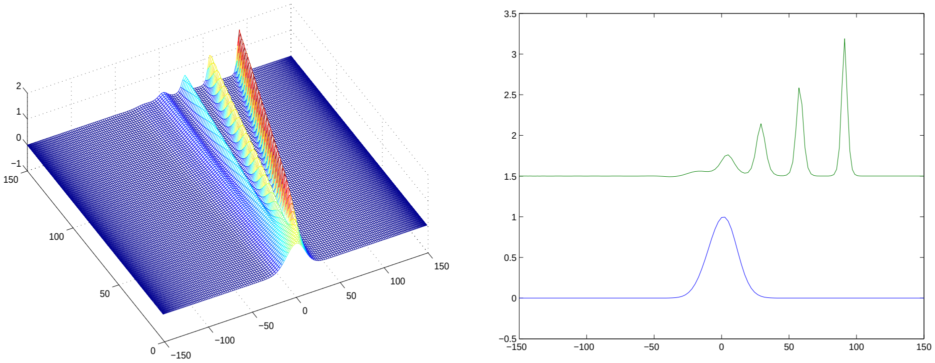

FIG. 6.4. *Solitary waves generated by an initial Gaussian profile.*

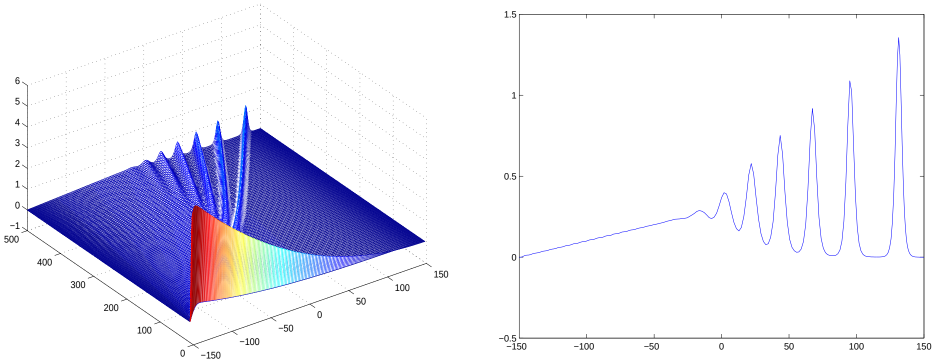

FIG. 6.5. *Solitary waves generated by a square pulse (in time) at the left boundary.*

and the amplitudes of the five solitary waves are well preserved at the final time. This indicates that our scheme has an excellent conservation property.

Example 2: Solitary waves generated by an initial Gaussian profile. We start with the initial condition $u_0(x) = \exp(-1.5x^2)$. We plot the time evolution of the solution on the left in Figure 6.4 and the profile at the final step ($t = 150$) on the right. The initial Gaussian profile has evolved into four separated solitary waves by the time $t = 150$.

Example 3: Solitary waves generated by a square pulse (in time) at the left boundary. In this example, we take $u_0(x) = 0$ but set

$$u(0,t) = \begin{cases} 5, & 0 \le t \le 5, \\ 0, & t > 5. \end{cases}$$

One may think of this situation as a dam of height five unit length that releases water for five unit time and is then shut off. We plot the time evolution of the solution on the left in Figure 6.5 and the profile at the final step ($t = 500$) on the right. The square pulse (in time) at the boundary generates a cascade of solitary waves as time evolves. This interesting phenomenon was first observed by Chu, Xiang, and Baransky in [8] (see also [12]).

7. Concluding remarks. We presented in this paper a new dual-Petrov–Galerkin method for third and higher odd-order equations. The key idea is to use test functions satisfying boundary conditions which are the "dual" of those for the trial functions. The resulting linear systems are sparse for problems with constant coefficients and well conditioned for problems with variable coefficients. By exploring the orthogonal properties of the test and trial basis functions in weighted Sobolev spaces, we were able to establish optimal error estimates for typical third-order and fifth-order linear equations and for a KDV equation on a finite interval. Obviously, the technique can be extended to other higher odd-order equations.

When combined with a Chebyshev–Legendre approach, our dual-Petrov–Galerkin method has a quasi-optimal computational complexity and is extremely accurate and efficient as illustrated by our numerical examples. Hence the method is most suitable for the study of complex dynamics of higher odd-order equations.

Finally, we note that the orthogonal polynomials $\{\phi_k\}$ and $\{\Phi_k\}$ introduced in this paper can be viewed as extensions of the Jacobi polynomials $J_k^{a,b}(x)$ with $(a, b) = (-2, -1)$ and $(a, b) = (-3, -2)$, respectively. They appear to be the most natural basis functions for, respectively, the third- and fifth-order equations (with the specified boundary conditions) considered in this paper. The extension of the Jacobi polynomials to more general (a, b) with $a,\ b < -1$ and their applications to spectral methods for other types of partial differential equations, including, in particular, hyperbolic systems, will be investigated in a forthcoming paper.

Acknowledgment. The author would like to thank Professor Benyu Guo for fruitful discussions and for carefully reading the first draft of the paper.

THE SDFEM FOR A CONVECTION-DIFFUSION PROBLEM WITH A BOUNDARY LAYER: OPTIMAL ERROR ANALYSIS AND ENHANCEMENT OF ACCURACY*

MARTIN STYNES[†] AND LUTZ TOBISKA[‡]

Abstract. The streamline-diffusion finite element method (SDFEM) is applied to a convection-diffusion problem posed on the unit square, using a Shishkin rectangular mesh with piecewise bilinear trial functions. The hypotheses of the problem exclude interior layers but allow exponential boundary layers. An error bound is proved for $\|u^I - u^N\|_{SD}$, where u^I is the interpolant of the solution u, u^N is the SDFEM solution, and $\|\cdot\|_{SD}$ is the streamline-diffusion norm. This bound implies that $\|u - u^N\|_{L^2}$ is of optimal order, thereby settling an open question regarding the L^2-accuracy of the SDFEM on rectangular meshes. Furthermore, the bound shows that u^N is superclose to u^I, which allows the construction of a simple postprocessing that yields a more accurate solution. Enhancement of the rate of convergence by using a discrete streamline-diffusion norm is also discussed. Finally, the verification of these rates of convergence by numerical experiments is examined, and it is shown that this practice is less reliable than was previously believed.

Key words. convection-diffusion problems, streamline-diffusion method, finite elements, error estimates

1. Introduction.

We consider the singularly perturbed boundary value problem

$$Lu := -\varepsilon\Delta u + b\cdot\nabla u + cu = f \quad \text{on } \Omega = (0,1)^2, \tag{1.1}$$

$$u = 0 \text{ on } \partial\Omega,$$

where ε is a small positive parameter, $b(x,y) = (b_1(x,y), b_2(x,y))$ with $b_1(x,y) > \beta_1 > 0$ and $b_2(x,y) > \beta_2 > 0$, $c(x,y) \geq 0$ on $\bar{\Omega}$, and

$$c(x,y) - \operatorname{div}\frac{b(x,y)}{2} \geq c_0 > 0 \text{ on } \bar{\Omega}, \tag{1.2}$$

where β_1, β_2, and c_0 are some constants. We assume that the functions b, c, and f are sufficiently smooth. These hypotheses ensure that (1.1) has a unique solution in $H_0^1(\Omega)\cap H^2(\Omega)$ for all $f \in L^2(\Omega)$. Note that for sufficiently small ε, the other hypotheses imply that (1.2) can always be ensured by the simple change of variable $v(x,y) = e^{-\sigma x}u(x,y)$ when σ is chosen suitably.

This elliptic boundary value problem, posed on a rectangular domain, is a simplification of more complex situations. In the numerical solution of models of fluid flow problems, the streamline-diffusion finite element method (SDFEM) is often used on meshes that are adapted to the flow's properties. Our aim in this paper is, on nonuniform meshes, to develop a deeper understanding of the behavior of that method that

will be of use to others. The precise degree of accuracy that the method achieves on certain highly nonuniform meshes has not been fully understood up to now—even for problems like (1.1)—and we shall throw fresh light on this fundamental question.

Layer-adapted meshes are usually used to solve (1.1), since its solution typically has boundary layers at the sides $x = 1$ and $y = 1$ of Ω. A piecewise uniform Shishkin mesh can be chosen a priori when one has some knowledge of the structure of these layers [4, 14, 19]. This mesh has $O(N^2)$ points in a rectangular grid that is refined near the sides $x = 1$ and $y = 1$.

Shishkin meshes were originally introduced in the context of finite difference methods. The first paper to consider a finite element method on such a mesh seems to be [20], where a standard Galerkin method with piecewise bilinear trial functions was used. It was shown that $\|u^I - u^N_{Gal}\|_{1,\varepsilon} = O(N^{-1} \ln N)$, where $\|\cdot\|_{1,\varepsilon}$ is the ε-weighted energy norm defined in (2.9) below, u^I is the interpolant of the solution u from the finite element space of piecewise bilinears, and u^N_{Gal} is the computed solution. Later papers on the same method [11, 23] improved this result to $O(N^{-2} \ln^2 N)$. (In [11], a graded Bakhvalov mesh replaces the Shishkin mesh, which improves the convergence rate by removing the factor $\ln^2 N$; in [23], a discrete version of the ε-weighted energy norm is used; thus these papers have some differences from [20].) Despite these convergence results, it is computationally expensive to solve the associated discrete system of equations [10, 13], and this makes the standard Galerkin method less attractive.

The popular SDFEM, on the other hand, yields a discrete system of equations that can be solved efficiently by standard iterative methods [13]. Furthermore, in the graphical results presented in [13] for solutions of (1.1) computed on Shishkin meshes, the plots show that the solution computed by the standard Galerkin method has many small oscillations, while no oscillations are visible in the plot of the SDFEM solution. (For nonlinear problems such oscillations are highly undesirable.) Finally, Galerkin methods are much more sensitive to the choice of transition point in the Shishkin mesh than the SDFEM. Roos [17, p. 294] is strongly critical of Galerkin methods on Shishkin meshes for all these reasons, and his Figure 4 shows the undesirable oscillations that they can produce. For theoretical comparisons of the two methods that show the superiority of the SDFEM, see Remarks 4.2 and 5.1 below.

The convergence properties of the SDFEM have been widely studied [5, 15, 16, 19, 21, 24, 25], but as we discuss below, up to now no satisfactory optimal convergence result has been proved. Consequently there is an impression among researchers that, compared with the standard Galerkin method, to achieve the extra stability of the SDFEM one must pay the price of reduced accuracy in the computed solution. We shall show that, at least in the case of a rectangular Shishkin mesh, the SDFEM is no less accurate than the standard Galerkin method.

In [21], the SDFEM was applied to (1.1) using a Shishkin mesh, and it was shown that $\|u^I - u^N\|_{SD} = O(\varepsilon^{1/2} N^{-1} \ln N + N^{-3/2})$, where u^N is the computed solution, once again u^I is the interpolant of the solution u from the finite element space of piecewise bilinears, and $\|\cdot\|_{SD}$ is the streamline-diffusion norm, which will be defined in (2.7). In the present paper, we shall use sharp interpolation error identities of Lin [7] to perform a more careful and incisive analysis than was given in [21], culminating in a proof that in fact $\|u^I - u^N\|_{SD} = O(\varepsilon N^{-3/2} + N^{-2} \ln^2 N)$.

Numerical experiments in [22] seemed to indicate that the earlier result that $\|u^I - u^N\|_{SD} = O(\varepsilon^{1/2} N^{-1} \ln N + N^{-3/2})$ was optimal. In the present paper, we shall show, however, that it is easy to misinterpret the rate of convergence obtained in numerical experiments, and it now seems likely that when $\varepsilon \leq N^{-1}$, the numerical results from [22] show that $\|u^I - u^N\|_{SD} = O(N^{-2}\ln^2 N)$. This warning about the indeterminate nature of computed rates of convergence has significant implications for the inferences drawn from numerical experiments in many papers on convection-diffusion problems.

Our main result settles a long-standing conjecture regarding the accuracy of the SDFEM on regions where the solution u is smooth (i.e., away from any layers). Standard analyses (see, e.g., [19]) showed only that the rate of convergence attained in L^2 was a half-order less than optimal. (By "optimal" we mean the order of the error between the solution and its interpolant from the finite element space.) Was this apparent deficiency of the SDFEM actually observed in practice? Numerical experiments in many papers seemed to indicate that in fact one always attained optimality. Then in [24], Zhou produced an example with a smooth solution where piecewise linears on a sequence of special triangular meshes of diameter h yielded convergence of only $O(h^{3/2})$ in L^2. On the other hand, in [25] the authors showed that, when the mesh is quadrilateral, isoparametric bilinear trial functions are used, the convective flow direction b closely follows (in a precise sense) the meshlines, and the solution u is smooth on the entire domain, then one attains second-order convergence in L^2 (in fact, in L^∞). This still left open the possibility that one could construct a Zhou-type counterexample for bilinears when the convective flow was transverse to the meshlines. We show (see Remark 4.1) that this will not occur on rectangular locally uniform meshes: for (1.1) one obtains full second-order convergence (up to a logarithmic factor) in L^2 when bilinears are used. It is therefore likely that for more general problems one could use cut-off functions to prove a similar result in regions that extend downstream from an inflow boundary and on which the solution is smooth.

Furthermore, our analysis is for a problem whose solution has exponential boundary layers, and the estimates proved are valid inside those layers also with absolute constants that are independent of the data of the problem.

Our main result (Theorem 4.5) bounds the error $\|u^I - u^N\|_{SD}$. Writing $\|\cdot\|_{1,\varepsilon}$ for the ε-weighted energy norm, which is weaker than $\|\cdot\|_{SD}$, it turns out that $\|u - u^I\|_{1,\varepsilon}$ has in general a lower order of convergence than $\|u^I - u^N\|_{1,\varepsilon}$, so Theorem 4.5 does not immediately yield a satisfactory convergence result for $\|u - u^N\|_{1,\varepsilon}$.

To obtain a high order of convergence for $\|u - u^N\|$ in some norm stronger than L^2, we discuss two separate methods. First, we show that for a discrete analogue $\|\cdot\|_{SD,d}$ of the norm $\|\cdot\|_{SD}$, one has $\|u - u^N\|_{SD,d} \leq C(\varepsilon N^{-3/2} + N^{-2}\ln^2 N)$. Second, we analyze a simple local postprocessing of u^N that yields a piecewise biquadratic solution $\tilde{u}^N$ for which $\|u - \tilde{u}^N\|_{1,\varepsilon}$ has the same order as $\|u^I - u^N\|_{1,\varepsilon}$.

The techniques and results of this paper are not restricted to bilinear elements; in a forthcoming paper we shall consider higher-order elements.

The paper is organized as follows. In section 2 we describe the Shishkin mesh and the SDFEM. A decomposition of the solution u and some theoretical facts about interpolation that we shall need later are presented in section 3. The convergence of the SDFEM is analyzed in section 4. Then in section 5 the results outlined in the previous paragraph are proved. Section 6 shows that the use of numerical results to confirm theoretical rates of convergence is less reliable than was previously supposed.

Notation. Throughout the paper C will denote a generic positive constant that is independent of ε and the mesh.

We use the standard Sobolev spaces $W^{k,p}(D)$, $H^k(D) = W^{k,2}(D)$, $H_0^k(D)$, $L^p(D) = W^{0,p}(D)$ for nonnegative integers k and $1 \leq p \leq \infty$ and write $(\cdot,\cdot)_D$ for the $L^2(D)$

inner product. Here D is any measurable subset of Ω. Then $|\cdot|_{k,D}$ and $\|\cdot\|_{k,D}$ are the usual Sobolev seminorm and norm on $H^k(D)$. When $D = \Omega$, we drop D from the notation for simplicity.

2. The Shishkin mesh and the SDFEM. In this section we describe the mesh and the finite element method.

Shishkin meshes are piecewise uniform meshes, constructed a priori, that are refined inside layers. See [14, 19, 17] for a detailed discussion of their properties and uses.

Let N be an even positive integer. We let λ_x and λ_y denote two mesh transition parameters that will be used to specify where the mesh changes from coarse to fine; these are defined by

$$\lambda_x = \min\left(\frac{1}{2}, \frac{5\varepsilon}{2\beta_1}\ln N\right) \quad \text{and} \quad \lambda_y = \min\left(\frac{1}{2}, \frac{5\varepsilon}{2\beta_2}\ln N\right).$$

In these formulae, different authors make slightly different choices for the multiplier of ε/β_1 and ε/β_2. Linß [11] takes this multiplier to be 2 (as was also done in [21]), while Zhang [23] chooses 5/2, as we do in the present paper. This choice of a larger value ensures that the solution layers have decayed sufficiently on the coarse part of the Shishkin mesh.

In fact we assume that $\lambda_x = (5\varepsilon/(2\beta_1))\ln N$ and $\lambda_y = (5\varepsilon/(2\beta_2))\ln N$, as otherwise we have $N \geq \min\{e^{\beta_1/(5\varepsilon)}, e^{\beta_2/(5\varepsilon)}\}$ (which is very unlikely in practice), and one can then analyze the method using standard classical techniques.

We divide Ω as in Figure 2.1: $\bar{\Omega} = \Omega_{11} \cup \Omega_{21} \cup \Omega_{12} \cup \Omega_{22}$, where $\Omega_{11} = [0, 1 - \lambda_x] \times [0, 1 - \lambda_y], \Omega_{21} = [1 - \lambda_x, 1] \times [0, 1 - \lambda_y]$, $\Omega_{12} = [0, 1 - \lambda_x] \times [1 - \lambda_y, 1], \Omega_{22} = [1 - \lambda_x, 1] \times [1 - \lambda_y, 1]$.

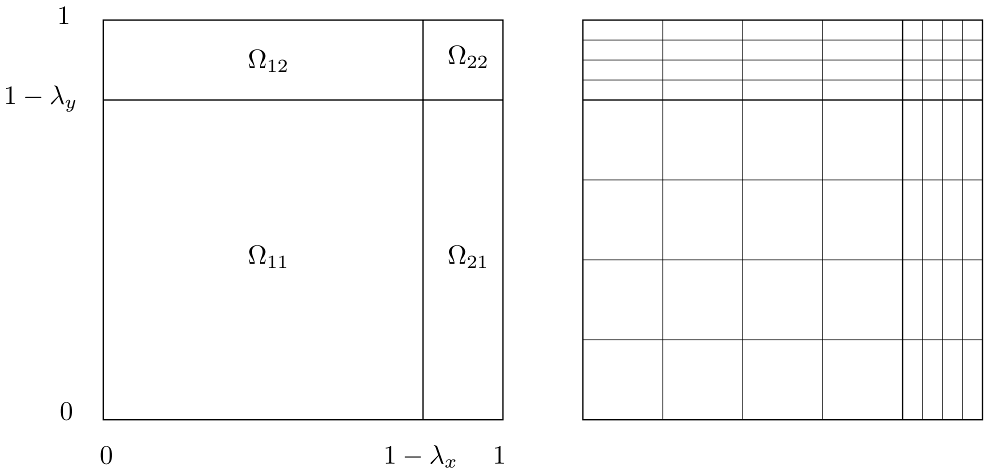

FIG. 2.1. *Division of Ω and Shishkin mesh for $\mathcal{T}_8$.*

The mesh points $\Omega^N = \{(x_i, y_j) \in \bar{\Omega} : i, j = 0, \ldots, N\}$ are the rectangular lattice defined by

$$x_i = \begin{cases} 2i(1 - \lambda_x)/N & \text{for} \quad i = 0, \ldots, N/2, \\ 1 - 2(N - i)\lambda_x/N & \text{for} \quad i = N/2 + 1, \ldots, N, \end{cases}$$

and

$$y_j = \begin{cases} 2j(1-\lambda_y)/N & \text{for} \quad j = 0, \dots, N/2, \\ 1 - 2(N-j)\lambda_y/N & \text{for} \quad j = N/2+1, \dots, N. \end{cases}$$

Our mesh is constructed by drawing lines parallel to the coordinate axes through these mesh points, so it is a tensor product of two one-dimensional piecewise uniform meshes. This divides Ω into a set $\mathcal{T}_N$ of mesh rectangles K whose sides are parallel to the axes—see Figure 2.1. The mesh is coarse on Ω_{11}, coarse/fine on $\Omega_{21} \cup \Omega_{12}$, and fine on Ω_{22}. The mesh is quasi-uniform on Ω_{11}, and its diameter d there satisfies $\sqrt{2}/N \le d \le 2\sqrt{2}/N$; on $\Omega_{12} \cup \Omega_{21}$, each mesh rectangle has dimensions $O(N^{-1})$ by $O(\varepsilon N^{-1} \ln N)$; and on Ω_{22} each rectangle is $O(\varepsilon N^{-1} \ln N)$ by $O(\varepsilon N^{-1} \ln N)$. We shall use these properties several times in our analysis. Given a mesh rectangle K, its dimensions are written as $h_{x,K}$ by $h_{y,K}$ and its barycenter is denoted by (x_K, y_K).

We now describe the SDFEM on this rectangular mesh. Our trial space V^N is the standard space of continuous piecewise bilinears that satisfy the boundary conditions of the problem:

$$V^N = \left\{ v \in C(\bar{\Omega}) : v|_{\partial\Omega} = 0 \ \text{ and } \ v|_K \in Q_1(K) \ \ \forall\, K \in \mathcal{T}_N \right\}.$$

Given any function $v(\cdot,\cdot) \in C(\bar{\Omega})$, we denote its piecewise bilinear interpolant on the mesh $\mathcal{T}_N$ by $v^I(\cdot,\cdot)$. We define the bilinear form $B_{SD}(\cdot,\cdot)$ used in the SDFEM by

$$B_{SD}(w,v) = B_{GAL}(w,v) + B_{STAB}(w,v),$$

where

$$B_{GAL}(w,v) = \varepsilon(\nabla w, \nabla v) + (b \cdot \nabla w + cw, v), \tag{2.1}$$

$$B_{STAB}(w,v) = \sum_{K \subset \Omega_{11}} \delta_K(-\varepsilon \Delta w + b \cdot \nabla w + cw, b \cdot \nabla v)_K \tag{2.2}$$

for all $(w,v) \in \tilde{H}^1(\Omega) \times H^1(\Omega)$, where $\tilde{H}^1(\Omega)$ denotes the set of functions in $H^1(\Omega)$ that lie in $H^2(K)$ for each K, and $\delta_K \ge 0$ is a user-chosen piecewise constant parameter. Now the SDFEM is defined as follows: Find $u^N \in V^N$ such that

$$B_{SD}(u^N, v^N) = (f, v^N) + \sum_{K \subset \Omega_{11}} \delta_K(f, b \cdot \nabla v^N)_K \qquad \forall v^N \in V^N. \tag{2.3}$$

The term Δu^N in $B_{STAB}(u^N, v^N)$ is zero on each K as our trial space is piecewise bilinear. We clearly have the Galerkin orthogonality property

$$B_{SD}(u - u^N, v^N) = 0 \quad \forall\, v^N \in V^N. \tag{2.4}$$

It is shown in, e.g., [19, section III.3.2.1], that if

$$0 \le \delta_K \le \frac{c_0}{(\max_K |c(x,y)|)^2} \quad \forall\, K \subset \Omega_{11}, \tag{2.5}$$

then

$$B_{SD}(v^N, v^N) \ge \frac{1}{2} \|v^N\|_{SD}^2 \quad \forall\, v^N \in V^N, \tag{2.6}$$

where we define

$$\|v\|_{SD} = \left(\varepsilon|v|_1^2 + \sum_{K\subset\Omega_{11}} \delta_K\|b\cdot\nabla v\|_{0,K}^2 + c_0\|v\|_0^2\right)^{1/2} \qquad \forall\, v\in H^1(\Omega). \tag{2.7}$$

(Here we simplified the result from [19] by observing that $\Delta v^N|_K = 0$ for each $K \in \mathcal{T}_N$.) It follows that (2.3) has a unique solution $u^N \in V^N$.

Similarly to [19, p. 233], we set

$$\delta_K = \begin{cases} N^{-1} & \text{if } K\subset\Omega_{11} \text{ and } \varepsilon\le N^{-1},\\ \varepsilon^{-1}N^{-2} & \text{if } K\subset\Omega_{11} \text{ and } \varepsilon> N^{-1},\\ 0 & \text{otherwise.}\end{cases} \tag{2.8}$$

This choice clearly satisfies (2.5) for N sufficiently large (independently of ε).

We shall also use the ε-weighted energy norm

$$\|v\|_{1,\varepsilon} = \left(\varepsilon|v|_1^2 + c_0\|v\|_0^2\right)^{1/2} \qquad \forall\, v\in H^1(\Omega). \tag{2.9}$$

This norm is clearly weaker than $\|\cdot\|_{SD}$.

3. Solution decomposition, a priori estimates. For the analysis we shall assume that the solution u can be decomposed in a way that reflects the typical behavior that is observed in solutions of (1.1) when interior layers are absent. The precise hypotheses follow.

Assumption 3.1. Assume that

$$u = S + E_{21} + E_{12} + E_{22}, \tag{3.1}$$

where there exists a constant C such that for all $(x,y)\in\Omega$ we have

$$\left|\frac{\partial^{i+j}S}{\partial x^i\partial y^j}(x,y)\right| \le C \quad \text{for } 0\le i+j\le 2, \tag{3.2}$$

$$\left|\frac{\partial^{i+j}E_{21}}{\partial x^i\partial y^j}(x,y)\right| \le C\varepsilon^{-i}e^{-\beta_1(1-x)/\varepsilon} \quad \text{for } 0\le i,j\le 2, \tag{3.3}$$

$$\left|\frac{\partial^{i+j}E_{12}}{\partial x^i\partial y^j}(x,y)\right| \le C\varepsilon^{-j}e^{-\beta_2(1-y)/\varepsilon} \quad \text{for } 0\le i,j\le 2, \tag{3.4}$$

$$\left|\frac{\partial^{i+j}E_{22}}{\partial x^i\partial y^j}(x,y)\right| \le C\varepsilon^{-(i+j)}e^{-(\beta_1(1-x)+\beta_2(1-y))/\varepsilon} \quad \text{for } 0\le i,j\le 2. \tag{3.5}$$

Furthermore, assume that $S\in H^3(\Omega)$ with

$$\|S\|_3 \le C. \tag{3.6}$$

Here S is the smooth part of u, E_{21} is an exponential boundary layer along the side $x=1$ of Ω, E_{12} is an exponential boundary layer along the side $y=1$, while E_{22} is an exponential corner layer at (1,1).

Remark 3.1. Linß [11] and Zhang [23] make assumptions close to those of Assumption 3.1. In [12] a proof is given that under certain compatibility conditions on the data f, the bounds (3.2)–(3.5) of Assumption 3.1 hold true. The extension of this result to the case $0\le i+j\le 3$ in (3.2)—which would imply (3.6)—is not trivial and furthermore would place an inordinate number of compatibility conditions on f, but it should be noted that the hypothesis (3.6) is weaker than requiring all third-order derivatives of u to be pointwise bounded.

The Shishkin mesh is highly anisotropic on $\Omega_{12} \cup \Omega_{21}$, and to obtain satisfactory interpolation error estimates on this region we invoke the sharp anisotropic interpolation analysis of [1], which includes the following result as a special case.

LEMMA 3.1. *Let K be any mesh rectangle of the Shishkin mesh $\mathcal{T}_N$. Let $v \in H^2(K)$. Then its piecewise bilinear interpolant v^I satisfies the bounds*

$$\begin{aligned}
\|v - v^I\|_{0,K} &\le C\left(h_{x,K}^2 \|v_{xx}\|_{0,K} + h_{x,K} h_{y,K} \|v_{xy}\|_{0,K} + h_{y,K}^2 \|v_{yy}\|_{0,K}\right), \\
\|(v - v^I)_x\|_{0,K} &\le C\left(h_{x,K} \|v_{xx}\|_{0,K} + h_{y,K} \|v_{xy}\|_{0,K}\right), \\
\|(v - v^I)_y\|_{0,K} &\le C\left(h_{x,K} \|v_{xy}\|_{0,K} + h_{y,K} \|v_{yy}\|_{0,K}\right).
\end{aligned}$$

The next lemma collects several results that involve the interpolants of the various terms in the decomposition (3.1).

LEMMA 3.2. *Let Assumption* 3.1 *hold true. Let S^I and E^I denote the piecewise bilinear interpolants of S and E, respectively, on the Shishkin mesh $\mathcal{T}_N$, where the function E can be any one of E_{12}, E_{21}, or E_{22}. Then there exists a constant C such that the following interpolation error estimates hold true:*

$$\|S - S^I\|_{0,\Omega} \le C\, N^{-2}, \tag{3.7}$$

$$\|E\|_{0,\Omega_{11}} \le C\, \varepsilon^{1/2} N^{-5/2}, \tag{3.8}$$

$$\varepsilon \|\Delta E\|_{L^1(\Omega_{11})} + \|\nabla E\|_{L^1(\Omega_{11})} \le C\, N^{-5/2}, \tag{3.9}$$

$$N^{-1} \|\nabla E^I\|_{0,\Omega_{11}} + \|E^I\|_{0,\Omega_{11}} \le C\left(\varepsilon^{1/2} N^{-5/2} + N^{-3}\right), \tag{3.10}$$

$$\|E - E^I\|_{0,\Omega} \le C N^{-2} \ln^2 N. \tag{3.11}$$

Proof. Inequality (3.7) is a standard classical result [2, Theorem 3.1.5]; it can also be deduced from Lemma 3.1 and (3.2).

We prove (3.8)–(3.10) only for $E = E_{21}$ since the proof for the other layer functions is similar. Applying (3.3), one gets

$$\begin{aligned}
\|E_{21}\|_{0,\Omega_{11}}^2 &\le C \int_0^{1-\lambda_y} \int_0^{1-\lambda_x} e^{-2\beta_1(1-x)/\varepsilon}\, dx\, dy \\
&\le C\varepsilon e^{-2\beta_1 \lambda_x/\varepsilon} \\
&\le C\varepsilon N^{-5},
\end{aligned}$$

which proves (3.8). For (3.9) we have similarly

$$\begin{aligned}
\varepsilon \|\Delta E_{21}\|_{L^1(\Omega_{11})} + \|\nabla E_{21}\|_{L^1(\Omega_{11})} &\le C\varepsilon^{-1} \int_0^{1-\lambda_y} \int_0^{1-\lambda_x} e^{-\beta_1(1-x)/\varepsilon}\, dx\, dy \\
&\le C e^{-\beta_1 \lambda_x/\varepsilon} \\
&\le C\, N^{-5/2}.
\end{aligned}$$

The proof of (3.10) is longer. An inverse inequality [2, Theorem 3.2.6] yields

$$N^{-1} \|\nabla E^I\|_{0,\Omega_{11}} + \|E^I\|_{0,\Omega_{11}} \le C\, \|E^I\|_{0,\Omega_{11}},$$

and it remains only to bound $\|E^I\|_{0,\Omega_{11}}$. Again invoking (3.3),

$$\|E^I_{21}\|^2_{0,\Omega_{11}} \le C \int_0^{1-\lambda_y} \sum_{i=1}^{N/2} \int_{x_{i-1}}^{x_i} e^{-2\beta_1(1-x_i)/\varepsilon}\, dx\, dy.$$

In this sum, each integral is small as a function of ε when $i < N/2$ but not when $i = N/2$, so we treat the final value of i differently. For $i = 1, \ldots, N/2-1$ and $x \in [x_{i-1}, x_i]$, we have

$$e^{-2\beta_1(1-x_i)/\varepsilon} = e^{2\beta_1(x_{N/2}-x_{N/2-1})/\varepsilon} e^{-2\beta_1(1-x_{i-1})/\varepsilon} \le e^{2\beta_1(x_{N/2}-x_{N/2-1})/\varepsilon} e^{-2\beta_1(1-x)/\varepsilon},$$

and for $i = N/2$,

$$e^{-2\beta_1(1-x_{N/2})/\varepsilon} = e^{-2\beta_1\lambda_x/\varepsilon} = N^{-5}.$$

Thus

$$\begin{aligned}
\|E^I_{21}\|^2_{0,\Omega_{11}} &\le Ce^{2\beta_1(x_{N/2}-x_{N/2-1})/\varepsilon} \int_0^{x_{N/2-1}} e^{-2\beta_1(1-x)/\varepsilon}\, dx + CN^{-6} \\
&\le C\varepsilon e^{-2\beta_1(1-x_{N/2})/\varepsilon} + CN^{-6} \\
&\le C\left(\varepsilon N^{-5} + N^{-6}\right),
\end{aligned}$$

which proves (3.10).

To get the final estimate (3.11), observe that (3.8) and (3.10) imply that

$$\|E - E^I\|_{0,\Omega_{11}} \le C(\varepsilon^{1/2}N^{-5/2} + N^{-3}) \le CN^{-2}\ln^2 N.$$

Furthermore,

$$\|E - E^I\|_{0,\Omega\setminus\Omega_{11}} \le CN^{-2}\ln^2 N.$$

To prove this inequality, apply Lemma 3.1 and the bounds (3.3)–(3.5) on each mesh rectangle, and then add the results; see [3]. □

4. Error bound for $u^I - u^N$.

The analysis of this section improves on that of [21] by invoking the sharp superconvergence results of Lin [7]. For each mesh rectangle K, we set

$$G_K(x) = \frac{1}{2}\left[(x-x_K)^2 - \left(\frac{h_{x,K}}{2}\right)^2\right], \quad F_K(y) = \frac{1}{2}\left[(y-y_K)^2 - \left(\frac{h_{y,K}}{2}\right)^2\right].$$

Denote the east, north, west, and south edges of K by $l_{i,K}$ for $i = 1, \ldots, 4$, respectively.

Lemma 4.1 (Lin identities). *Let K be a mesh rectangle. Let $w \in H^3(K)$, and let $w^I \in Q_1(K)$ be its bilinear interpolant. Then for each $v^N \in Q_1(K)$, we have*

$$\begin{aligned}
\int_K (w-w^I)_x v_x^N \,dx\,dy &= \int_K w_{xyy}\left(F_K v_x^N - \frac{1}{3}\left(F_K^2\right)' v_{xy}^N\right) dxdy,\\
\int_K (w-w^I)_x v_y^N \,dx\,dy &= \int_K \left(F_K w_{xyy}(v_y^N - G_K' v_{xy}^N) + G_K w_{xxy} v_x^N\right) dx\,dy\\
&\quad - \int_{l_{2,K}} G_K w_{xx} v_x^N \,dx + \int_{l_{4,K}} G_K w_{xx} v_x^N \,dx,\\
\int_K (w-w^I)_y v_x^N \,dx\,dy &= \int_K \left(G_K w_{xxy}(v_x^N - F_K' v_{xy}^N) + F_K w_{xyy} v_y^N\right) dx\,dy\\
&\quad - \int_{l_{1,K}} F_K w_{yy} v_y^N \,dy + \int_{l_{3,K}} F_K w_{yy} v_y^N \,dy,\\
\int_K (w-w^I)_y v_y^N \,dxdy &= \int_K w_{xxy}\left(G_K v_y^N - \frac{1}{3}\left(G_K^2\right)' v_{xy}^N\right) dx\,dy.
\end{aligned}$$

Proof. Start from the right-hand side of each identity. Since $(w^I)_{xx}$, $(w^I)_{yy}$, and all third-order derivatives of w^I vanish, these terms can be introduced at appropriate places in the right-hand side; then one integrates by parts and takes into consideration the definitions of F_K and G_K. For more details, see [7]. □

Lemma 4.2. *Let $\varphi \in W^{1,\infty}$ satisfy $\|\varphi\|_{W^{1,\infty}} \le C$ for some constant C. Let $w^I \in V^N$ be the piecewise bilinear interpolant of $w \in H^3(\Omega) \cap W^{2,\infty}(\Omega)$ on the Shishkin mesh $\mathcal{T}_N$. Then for all $v^N \in Q_1(K)$, we have*

$$\left|\int_{\Omega_{11}} \varphi(w-w^I)_x v_x^N \,dx\,dy\right| \le C\,N^{-2}\left(|w|_2 + |w|_3\right)\|v_x^N\|_0, \tag{4.1}$$

$$\begin{aligned}
\left|\int_{\Omega_{11}} \varphi(w-w^I)_x v_y^N \,dx\,dy\right| &\le C\,N^{-2}\left(|w|_{W^{2,\infty}} + \|w\|_3\right)\left(\|v_y^N\|_0 + \|v_x^N\|_0\right)\\
&\quad + C\varepsilon^{1/2}N^{-2}(\ln^{1/2} N)|w|_{W^{2,\infty}}\|v_{xy}^N\|_0,
\end{aligned}\tag{4.2}$$

$$\begin{aligned}
\left|\int_{\Omega_{11}} \varphi(w-w^I)_y v_x^N \,dx\,dy\right| &\le C\,N^{-2}\left(|w|_{W^{2,\infty}} + \|w\|_3\right)\left(\|v_x^N\|_0 + \|v_y^N\|_0\right)\\
&\quad + C\varepsilon^{1/2}N^{-2}(\ln^{1/2} N)|w|_{W^{2,\infty}}\|v_{xy}^N\|_0,
\end{aligned}\tag{4.3}$$

$$\left|\int_{\Omega_{11}} \varphi(w-w^I)_y v_y^N \,dx\,dy\right| \le C\,N^{-2}\left(|w|_2 + |w|_3\right)\|v_y^N\|_0. \tag{4.4}$$

Proof. We define a piecewise constant approximation $\bar{\varphi}$ of φ by

$$\bar{\varphi}\Big|_K = \frac{1}{\text{area K}}\int_K \varphi \,dx\,dy \quad \text{for all mesh rectangles } K.$$

Then we use the splitting

$$\begin{aligned}
&\int_{\Omega_{11}} \varphi(w-w^I)_x v_x^N \,dx\,dy\\
&\qquad = \int_{\Omega_{11}} (\varphi-\bar{\varphi})(w-w^I)_x v_x^N \,dx\,dy + \int_{\Omega_{11}} \bar{\varphi}(w-w^I)_x v_x^N \,dx\,dy.
\end{aligned}$$

The first term can be bounded using standard interpolation error estimates [2, Theorem 3.1.5] and the hypothesis $\|\varphi\|_{W^{1,\infty}} \le C$:

$$\left|\int_{\Omega_{11}} (\varphi - \bar{\varphi})(w - w^I)_x v_x^N \, dx\, dy\right| \le C\, N^{-2} |w|_2 \, \|v_x^N\|_0.$$

For the second term, we apply Lemma 4.1 and get

$$\begin{aligned}\left|\int_{\Omega_{11}} \bar{\varphi}(w - w^I)_x v_x^N \, dxdy\right| &\le C \sum_{K\subset\Omega_{11}} \|w_{xyy}\|_{0,K} \left(N^{-2}\|v_x^N\|_{0,K} + N^{-3}\|v_{xy}^N\|\right)\\ &\le C\, N^{-2}|w|_3 \, \|v_x^N\|_0\end{aligned}$$

by an inverse inequality [2, Theorem 3.2.6]. This proves (4.1). The inequality (4.4) can be shown in the same way.

To prove (4.2), we use the same technique and get

$$\begin{aligned}&\left|\int_{\Omega_{11}} \varphi(w - w^I)_x v_y^N \, dx\, dy\right|\\ &\quad\le C\, N^{-2} \left[|w|_2\|v_y^N\|_0 + |w|_3(\|v_x^N\|_0 + \|v_y^N\|_0)\right]\\ &\qquad + \left|\sum_{K\subset\Omega_{11}} \left(\int_{l_{2,K}} \bar{\varphi} G_K w_{xx} v_x^N \, dx - \int_{l_{4,K}} \bar{\varphi} G_K w_{xx} v_x^N \, dx\right)\right|.\end{aligned}$$

Set

$$\varphi_{i,j} = \bar{\varphi}(x,y) \quad \text{for } x_{i-1} < x < x_i \text{ and } y_{j-1} < y < y_j.$$

Since $v_x^N(x,0) = 0$, we have

$$\begin{aligned}&\sum_{K\subset\Omega_{11}} \left(\int_{l_{2,K}} \bar{\varphi} G_K w_{xx} v_x^N \, dx - \int_{l_{4,K}} \bar{\varphi} G_K w_{xx} v_x^N \, dx\right)\\ &\quad= \sum_{i,j=1}^{N/2} \int_{x_{i-1}}^{x_i} \varphi_{ij} \left[(G_K w_{xx} v_x^N)(x,y_j) - (G_K w_{xx} v_x^N)(x,y_{j-1})\right] dx\\ &\quad= \sum_{i=1}^{N/2} \sum_{j=1}^{N/2-1} \int_{x_{i-1}}^{x_i} (\varphi_{ij} - \varphi_{i,j+1})\, (G_K w_{xx} v_x^N)(x,y_j)\, dx\\ &\qquad\quad + \sum_{i=1}^{N/2} \int_{x_{i-1}}^{x_i} \varphi_{i,N/2} (G_K w_{xx} v_x^N)(x, y_{N/2})\, dx.\end{aligned} \tag{4.5}$$

Here we used the following observation: if K and K' are two mesh rectangles having a common horizontal edge, then v_x^N is continuous across this edge and G_K and $G_{K'}$

coincide there. Taking the first term in (4.5),

$$\begin{aligned}\left|\sum_{i=1}^{N/2}\sum_{j=1}^{N/2-1}\int_{x_{i-1}}^{x_i}(\varphi_{ij}-\varphi_{i,j+1})\,(G_K w_{xx}v_x^N)(x,y_j)\,dx\right|&\\ \le C\,N^{-3}|w|_{W^{2,\infty}}\sum_{i=1}^{N/2}\sum_{j=1}^{N/2-1}\int_{x_{i-1}}^{x_i}|v_x^N(x,y_j)|\,dx&\\ \le C\,N^{-3}|w|_{W^{2,\infty}}\sum_{i=1}^{N/2}\sum_{j=1}^{N/2-1}\sqrt{\int_{x_{i-1}}^{x_i}\int_{y_{j-1}}^{y_j}|v_x^N(x,y)|^2\,dx\,dy}&\\ \le C\,N^{-2}|w|_{W^{2,\infty}}\|v_x^N\|_0,&\end{aligned}$$

where the penultimate inequality is proved by transforming to the reference element and then scaling. To estimate the final term in (4.5), note first that $v_x^N(x,1)=0$. Starting with the representation

$$\begin{aligned}(G_K w_{xx}v_x^N)(x,y_{N/2})&=\sum_{j=N/2}^{N-1}\left[(G_K w_{xx}v_x^N)(x,y_j)-(G_K w_{xx}v_x^N)(x,y_{j+1})\right]\\ &=-\sum_{j=N/2}^{N-1}\int_{y_j}^{y_{j+1}}\frac{\partial(G_K w_{xx}v_x^N)}{\partial y}(x,y)\,dy,\end{aligned}$$

one has

$$\begin{aligned}\left|\sum_{i=1}^{N/2}\int_{x_{i-1}}^{x_i}\varphi_{i,N/2}(G_K w_{xx}v_x^N)(x,y_{N/2})\,dx\right|&\\ =\left|\sum_{i=1}^{N/2}\sum_{j=N/2}^{N-1}\int_{x_{i-1}}^{x_i}\int_{y_j}^{y_{j+1}}\varphi_{i,N/2}G_K\left(w_{xxy}v_x^N+w_{xx}v_{xy}^N\right)\,dx\,dy\right|&\\ \le CN^{-2}\sum_{K\subset\Omega_{12}}\int_K\left|w_{xxy}v_x^N+w_{xx}v_{xy}^N\right|\,dx\,dy&\\ \le CN^{-2}\left[|w|_3\|v_x^N\|_0+|w|_{W^{2,\infty}}\|v_{xy}^N\|_{L^1(\Omega_{12})}\right]&\\ \le CN^{-2}\left[|w|_3\|v_x^N\|_0+(\varepsilon\ln N)^{1/2}|w|_{W^{2,\infty}}\|v_{xy}^N\|_0\right],&\end{aligned}$$

where we used the Cauchy–Schwarz inequality to bound $\|v_{xy}^N\|_{L^1(\Omega_{12})}$. Collecting the various estimates now yields (4.2). One can similarly prove (4.3). □

Versions of the next lemma appear in both [11] and [23], but the proof of [11] contains the erroneous statement that $\|E-E^I\|_{\Omega_{22}}\le C\|E\|_{\Omega_{22}}$; Linß [9] gives a short alternative argument that fixes this mistake.

LEMMA 4.3. *Let Assumption* 3.1 *hold true. Then for all* $v^N\in V^N$, *we have*

$$\left|B_{GAL}(u-u^I,v^N)\right|\le C\big(\varepsilon N^{-3/2}+N^{-2}\ln^2 N\big)\|v^N\|_{1,\varepsilon}. \tag{4.6}$$

Proof. This result is proved in [23, section 4] under the assumption that $\|S\|_{W^{3,\infty}(\Omega)}\le C$, but this hypothesis can be relaxed. Indeed, the full regularity of S was used only in the following chain of arguments [23, (4.32)]:

$$\begin{aligned}\|S_{xxx}v^N + S_{xx}v_x^N\|_{L^1(\Omega_{21}\cup\Omega_{22})} &\le \|S\|_{W^{3,\infty}(\Omega)}\|v^N + v_x^N\|_{L^1(\Omega_{21}\cup\Omega_{22})}\\ &\le C\lambda_x^{1/2}\|v^N\|_{1,\Omega_{21}\cup\Omega_{22}}\\ &\le C(\ln^{1/2} N)\|v^N\|_{1,\varepsilon}\end{aligned}$$

for all $v^N \in V^N$. Replace this calculation by

$$\begin{aligned}\|S_{xxx}v^N + S_{xx}v_x^N\|_{L^1(\Omega_{21}\cup\Omega_{22})} &\le |S|_3\|v^N\|_0 + |S|_{W^{2,\infty}(\Omega)}\|v_x^N\|_{L^1(\Omega_{21}\cup\Omega_{22})}\\ &\le C\big[\|v^N\|_0 + (\varepsilon\ln N)^{1/2}|v^N|_1\big]\\ &\le C(\ln^{1/2} N)\|v^N\|_{1,\varepsilon},\end{aligned}$$

where we used the Cauchy–Schwarz inequality. □

LEMMA 4.4. *Let Assumption* 3.1 *hold true. Then*

$$\big|B_{STAB}(u-u^I, v^N)\big| \le CN^{-2}(\ln^{1/2} N)\|v^N\|_{SD} \qquad \forall v^N \in V^N.$$

Proof. Writing E for E_{12}, E_{21}, or E_{22}, we have

$$\begin{aligned}&\big|B_{STAB}(E-E^I, v^N)\big|\\ &\le CN^{-1}\left[\varepsilon\|\Delta E\|_{L^1(\Omega_{11})} + \|\nabla E\|_{L^1(\Omega_{11})}\right]\|b\cdot\nabla v^N\|_{L^\infty(\Omega_{11})}\\ &\quad + C\,N^{-1/2}\left(\|\nabla E^I\|_{0,\Omega_{11}} + \|E-E^I\|_{0,\Omega_{11}}\right)\|v^N\|_{SD}\\ &\le CN^{-5/2}\|b\cdot\nabla v^N\|_{0,\Omega_{11}} + CN^{-1/2}\big(\varepsilon^{1/2}N^{-3/2} + N^{-2}\ln^2 N\big)\|v^N\|_{SD}\\ &\le CN^{-2}\|v^N\|_{SD}, \end{aligned}\tag{4.7}$$

where we used Lemma 3.2 and an inverse inequality [2, Theorem 3.2.6]. Next,

$$\begin{aligned}&B_{STAB}(S-S^I, v^N)\\ &\quad = -\sum_{K\subset\Omega_{11}}\varepsilon\delta_K\left(\Delta S, b\cdot\nabla v^N\right)_K + \sum_{K\subset\Omega_{11}}\delta_K\left(b\cdot\nabla(S-S^I), b\cdot\nabla v^N\right)_K\\ &\qquad + \sum_{K\subset\Omega_{11}}\delta_K\left(c(S-S^I), b\cdot\nabla v^N\right)_K.\end{aligned}\tag{4.8}$$

For the first term in (4.8),

$$\begin{aligned}-\left(\Delta S, b\cdot\nabla v^N\right)_K &= \left(\Delta S, v^N\text{div } b\right)_K - \left(\Delta S, \text{div }(bv^N)\right)_K\\ &= \left(\Delta S, v^N\text{div } b\right)_K + \left(\nabla\Delta S, bv^N\right)_K - \int_{\partial K}\Delta S(b\cdot n_K)v^N\,d\gamma,\end{aligned}$$

after integrating by parts. Here n_K denotes the outward-pointing unit normal to the boundary ∂K of K. Now (2.8) implies that $\varepsilon\delta_K \le N^{-2}$, so

$$\begin{aligned}\left|\sum_{K\subset\Omega_{11}}\varepsilon\delta_K\left(\Delta S, b\cdot\nabla v^N\right)_K\right| &\le CN^{-2}\left(|S|_2 + |S|_3\right)\|v^N\|_0\\ &\quad + CN^{-2}\left|\int_{\partial\Omega_{11}}\Delta S(b\cdot n_K)v^N\,d\gamma\right|\end{aligned}$$

since the line integrals in the interior of Ω_{11} cancel. For the line integral over $\partial\Omega_{11}$, one can imitate our earlier analysis of the final term in (4.5) to get

$$\begin{aligned}\left|\int_{\partial\Omega_{11}} \Delta S(b\cdot n_K)v^N d\gamma\right| &= \left|-\int_{\Omega_{12}} (b_2 v^N \Delta S)_y\,dx\,dy - \int_{\Omega_{21}} (b_1 v^N \Delta S)_x\,dx\,dy\right| \\ &\le C\left[\|v^N\|_0 |S|_3 + \varepsilon^{1/2}(\ln^{1/2} N)\,|v^N|_1 |S|_{W^{2,\infty}}\right] \\ &\le C(\ln^{1/2} N)\|v^N\|_{SD}.\end{aligned}$$

Collecting these results, the first term in (4.8) is bounded by

$$\left|\sum_{K\subset\Omega_{11}} \varepsilon\delta_K \left(\Delta S, b\cdot\nabla v^N\right)_K\right| \le CN^{-2}(\ln^{1/2} N)\|v^N\|_{SD}.$$

The second term in (4.8) is handled by invoking Lemma 4.2:

$$\begin{aligned}\left|\sum_{K\subset\Omega_{11}} \delta_K \left(b\cdot\nabla(S-S^I), b\cdot\nabla v^N\right)_K\right| &\le C\,N^{-3}\left[|v^N|_1 + (\varepsilon\ln N)^{1/2}\|v^N_{xy}\|_0\right] \\ &\le C\,N^{-2}\left[|v^N|_0 + (\varepsilon\ln N)^{1/2}\|v^N\|_1\right] \\ &\le C\,N^{-2}(\ln^{1/2} N)\|v^N\|_{SD}.\end{aligned}$$

Finally, the third term in (4.8) can be bounded by

$$\left|\sum_{K\subset\Omega_{11}} \delta_K \left(c(S-S^I), b\cdot\nabla v^N\right)_K\right| \le C\,N^{-3}|v^N|_1 \le C\,N^{-2}\|v^N\|_{SD},$$

using an inverse inequality.

Each term in (4.8) has now been bounded. Recalling the estimate (4.7) for the layer part of u, the conclusion of the lemma follows. □

It is now straightforward to prove our main result.

THEOREM 4.5. *Let Assumption* 3.1 *hold true. Then the SDFEM solution* u^N *satisfies*

$$\|u^N - u^I\|_{SD} \le C\,(\varepsilon N^{-3/2} + N^{-2}\ln^2 N). \tag{4.9}$$

Proof. By (2.6) and (2.4), we have

$$\begin{aligned}\frac{1}{2}\|u^N - u^I\|_{SD}^2 &\le B_{SD}(u^N - u^I, u^N - u^I) \\ &= B_{SD}(u - u^I, u^N - u^I) \\ &= B_{GAL}(u - u^I, u^N - u^I) + B_{STAB}(u - u^I, u^N - u^I).\end{aligned}$$

Now invoke Lemmas 4.3 and 4.4 to complete the proof. □

Remark 4.1. Suppose that $\varepsilon \le N^{-1/2}\ln^2 N$, as is almost certainly true in practice. Then Theorem 4.5 implies that $\|u^I - u^N\|_0 \le CN^{-2}\ln^2 N$, which is optimal since by (3.7) and (3.11) one has $\|u - u^I\|_0 \le CN^{-2}\ln^2 N$, and this is the best possible result, as can be seen by considering $u(x,y) = e^{-\beta_1(1-x)/\varepsilon}$. Thus a triangle inequality yields $\|u - u^N\|_0 \le CN^{-2}\ln^2 N$. This optimal bound is obtained without using an Aubin–Nitsche trick.

Zhou and Rannacher [24, 25] prove a similar result on meshes that are almost uniform in the streamline direction but only when the convective flow is directed along or close to the meshlines, and they do not consider solutions that exhibit boundary layers.

Remark 4.2. Zhang [23] and Linß [11] obtain a result similar to Theorem 4.5 for the standard Galerkin method on Shishkin meshes but in the weaker norm $\|\cdot\|_{1,\varepsilon}$; compared with this, our theorem guarantees additional accuracy in the computed approximation of the streamline derivative.

Remark 4.3. It should be noted that when $\varepsilon \le N^{-1}$ (so $\delta_K = N^{-1}$ for $K \subset \Omega_{11}$), Theorem 4.5 implies, in particular, that

$$\left(\sum_{K\subset\Omega_{11}} \|b\cdot\nabla(u^I - u^N)\|_{0,K}^2 \right)^{1/2} \le CN^{-3/2}\ln^2 N,$$

although approximation theory predicts that, in general,

$$\left(\sum_{K\subset\Omega_{11}} \|b\cdot\nabla(u - u^I)\|_{0,K}^2 \right)^{1/2} \le CN^{-1}$$

is the best possible result. This phenomenon, where the order of accuracy of $\|u^I - u^N\|$ in some norm or seminorm $\|\cdot\|$ is greater than the optimal order of $\|u - u^N\|$, is called the superclose property by Lin [8], who shows that it can occur in the solution of many classical problems on rectangular meshes.

5. Error bounds for $u - u^N$.

One can use Lemma 3.1 to show that $\|u - u^I\|_{1,\varepsilon} \le CN^{-1}\ln N$ (see [3]), and this estimate is sharp. Consequently, despite the bound of Theorem 4.5, the triangle inequality yields only $\|u - u^N\|_{1,\varepsilon} \le CN^{-1}\ln N$. There are two possible ways of bypassing this barrier and proving higher-order estimates for $u - u^N$ in some H^1-type norm, as we now outline.

The first possibility is to exploit the fact that discrete norms are sometimes weaker than their continuous counterparts. For example, a discrete version of the $|\cdot|_1$ seminorm (where the H^1 integral has been replaced by a one-point quadrature rule at the barycenters of the rectangles) is used in [23]. One has superconvergence of the computed gradients at these barycenters, and this leads to an enhanced rate of convergence in the discrete norm. We follow a similar approach in section 5.1 and prove higher-order uniform convergence in a discrete version of the streamline-diffusion norm.

The second possibility is to apply to u^N a local postprocessing technique yielding a new discrete solution Pu^N for which $\|u - Pu^N\|_{1,\varepsilon} \ll \|u - u^N\|_{1,\varepsilon}$. In classical finite element computations, postprocessing is commonly used, but to the best of the authors' knowledge it has been applied only recently to singularly perturbed problems: a reaction-diffusion problem is considered in [6], while in [18] the authors show how in a convection-diffusion problem one can improve the accuracy of the computed gradient. In section 5.2, we construct a local postprocessing operator P and prove a higher-order error bound (uniformly in ε) for $\|u - Pu^N\|_{1,\varepsilon}$.

In analyzing each of these possibilities, we are forced to assume slightly more regularity of the solution than was required in previous sections, but our assumptions are no stronger than those of [18, 23].

Assumption 5.1. Assume that, for the decomposition $u = S + E_{21} + E_{12} + E_{22}$ of Assumption 3.1, there exists a constant C such that for all $(x, y) \in \Omega$ we have

$$\left|\frac{\partial^{i+j} E_{21}}{\partial x^i \partial y^j}(x,y)\right| \le C\varepsilon^{-i} e^{-\beta_1(1-x)/\varepsilon} \quad \text{for } 0 \le i+j \le 3, \tag{5.1}$$

$$\left|\frac{\partial^{i+j} E_{12}}{\partial x^i \partial y^j}(x,y)\right| \le C\varepsilon^{-j} e^{-\beta_2(1-y)/\varepsilon} \quad \text{for } 0 \le i+j \le 3, \tag{5.2}$$

$$\left|\frac{\partial^{i+j} E_{22}}{\partial x^i \partial y^j}(x,y)\right| \le C\varepsilon^{-(i+j)} e^{-(\beta_1(1-x)+\beta_2(1-y))/\varepsilon} \quad \text{for } 0 \le i+j \le 3. \tag{5.3}$$

5.1. Bound in discrete streamline-diffusion norm. Let us first introduce a discrete version $\|\cdot\|_{SD,d}$ of the streamline-diffusion norm $\|\cdot\|_{SD}$. This discrete norm is defined by replacing all integrals of derivatives in $\|\cdot\|_{SD}$ by a barycentric one-point quadrature rule. That is,

$$\begin{aligned}\|v\|_{SD,d} = \Bigg[&\sum_{K\in\mathcal{T}_N} \varepsilon\,(\operatorname{area} K)|\nabla v(x_K,y_K)|^2 \\ &+ \sum_{K\subset\Omega_{11}} \delta_K|(\operatorname{area} K)(b\cdot\nabla v)(x_K,y_K)|^2 + \|v\|_0^2\Bigg]^{1/2},\end{aligned} \tag{5.4}$$

where this norm is defined for all functions v such that $v|_K \in H^3(K)$ for all $K \in \mathcal{T}_N$.

The next result shows that the discrete streamline-diffusion norm (5.4) is weaker than the streamline-diffusion norm (2.7) on the discrete space V^N.

Lemma 5.1. *There exists a positive constant C such that*

$$\|v^N\|_{SD,d} \le C\,\|v^N\|_{SD} \quad \forall v^N \in V^N.$$

Proof. A direct calculation shows that for $K \in \mathcal{T}_N$ and $v^N \in V^N$,

$$(\operatorname{area} K)\,|(b\cdot\nabla v^N)(x_K,y_K)|^2 \le \int_K |b(x_K,y_K)\cdot\nabla v^N(x,y)|^2\,dxdy.$$

Thus

$$\sum_{K\in\mathcal{T}_N} (\operatorname{area} K)\,|\nabla v^N(x_K,y_K)|^2 \le |v^N|_1^2$$

and

$$\begin{aligned}&\sum_{K\subset\Omega_{11}} \delta_K(\operatorname{area} K)\,|(b\cdot\nabla v^N)(x_K,y_K)|^2 \\ &\qquad\le \sum_{K\subset\Omega_{11}} \int_K \delta_K|b(x_K,y_K)\cdot\nabla v^N(x,y)|^2\,dxdy.\end{aligned}$$

Using the splitting

$$|b(x_K,y_K)\cdot\nabla v^N(x,y)| \le |(b(x_K,y_K)-b(x,y))\cdot\nabla v^N(x,y)| + |(b\cdot\nabla v^N)(x,y)|$$

and an inverse inequality [2, Theorem 3.2.6], we get

$$\sum_{K\subset\Omega_{11}} \delta_K (\operatorname{area} K) |(b\cdot\nabla v^N)(x_K,y_K)|^2 \le C \sum_{K\subset\Omega_{11}} \delta_K \left(\|v^N\|_{0,K}^2 + \|b\cdot\nabla v^N\|_{0,K}^2\right).$$

As the norms $\|\cdot\|_{SD}$ and $\|\cdot\|_{SD,d}$ have identical L^2 terms, the statement of the lemma follows on putting together the above estimates. □

The next interpolation result is needed later.

LEMMA 5.2. *In addition to Assumptions* 3.1 *and* 5.1, *suppose that* $S\in W^{3,\infty}(\Omega)$ *with* $\|S\|_{W^{3,\infty}(K)} \le C$ *for some constant* C. *Then*

$$\|u-u^I\|_{SD,d} \le C\,N^{-2}\ln^2 N. \tag{5.5}$$

Proof. Combining (3.7) and (3.11), we get the estimate

$$\|u-u^I\|_0 \le C\,N^{-2}\ln^2 N. \tag{5.6}$$

At the barycenter of each rectangle $K\subset\Omega_{11}$, a Taylor expansion shows readily that the gradient of the interpolant to the smooth part of u is superconvergent:

$$|(S-S^I)_x(x_K,y_K)| \le C\,N^{-2}|S|_{3,\infty,K} \quad \forall\, K\in\mathcal{T}_N. \tag{5.7}$$

Moving on to the layer part of u, it is shown in [23, Theorem 4.1] that

$$\varepsilon \sum_{K\in\mathcal{T}_N} (\operatorname{area} K)\,|\nabla(E-E^I)(x_K,y_K)|^2 \le C\,N^{-4}\ln^4 N, \tag{5.8}$$

where the function E can be any one of E_{12}, E_{21}, or E_{22}.

Inequality (5.8) suffices to bound the ε-weighted H^1-norm component of $\|u-u^I\|_{SD,d}$, but it is inadequate for the streamline-diffusion-derivative component. Thus on Ω_{11} we shall prove a stronger result. Consider only the case $E=E_{21}$, since in the other cases the estimates are analogous. Using (3.3), for all $K\subset[x_{i-1},x_i]\times[0,1-\lambda_y]\subset\Omega_{11}$ we have

$$\begin{aligned}|\nabla E_{21}(x_K,y_K)|^2 &\le C(1+\varepsilon^{-2})e^{-2\beta_1(1-x_K)/\varepsilon}\\ &\le C\varepsilon^{-2}e^{-\beta_1 H/\varepsilon}\,e^{-2\beta_1(1-x_i)/\varepsilon},\end{aligned}$$

where we set $H=x_i-x_{i-1}$ for $1=1,2,\dots,N/2$. Hence

$$\sum_{K\subset\Omega_{11}} \delta_K(\operatorname{area} K)|\nabla E_{21}(x_K,y_K)|^2 \le C\varepsilon^{-2}e^{-\beta_1 H/\varepsilon}N^{-3}\sum_{i,j=1}^{N/2} e^{-2\beta_1(1-x_i)/\varepsilon}.$$

Now

$$\begin{aligned}\sum_{i,j=1}^{N/2} e^{-2\beta_1(1-x_i)/\varepsilon} &\le C\left(\sum_{i=1}^{N/2-1} N^2\int_{x_{i-1}}^{x_i} e^{-2\beta_1(1-x_{i-1}-H)/\varepsilon}\,dx + Ne^{-2\beta_1\lambda_x/\varepsilon}\right)\\ &\le CN^2\int_0^{1-\lambda_x-H} e^{-2\beta_1(1-x-H)/\varepsilon}\,dx + CN^{-4}\\ &\le C(\varepsilon N^{-3}+N^{-4}),\end{aligned}$$

so, since $H \geq 1/N$,

$$\sum_{K\subset\Omega_{11}} \delta_K(\operatorname{area} K)|\nabla E_{21}(x_K,y_K)|^2 \leq CN^{-5}\left[(\varepsilon N)^{-1}+(\varepsilon N)^{-2}\right]e^{-\beta_1/(\varepsilon N)}$$

$$\leq CN^{-5}, \tag{5.9}$$

as the mapping $t \mapsto (t+t^2)e^{-t}$ is bounded on $\mathbb{R}_+$. It remains only to estimate $|\nabla E_{21}^I(x_K,y_K)|$. First, (3.3) and $H \geq 1/N$ imply that

$$|\nabla E_{21}^I(x_K,y_K)| \leq CNe^{-\beta_1(1-x_i)/\varepsilon}$$

for all $K \subset [x_{i-1},x_i]\times[0,1-\lambda_y] \subset \Omega_{11}$. Then recalling the calculation above,

$$\sum_{K\subset\Omega_{11}} \delta_K(\operatorname{area} K)|\nabla E_{21}^I(x_K,y_K)|^2 \leq C\sum_{i,j=1}^{N/2} N^{-1}e^{-2\beta_1(1-x_i)/\varepsilon}$$

$$\leq C(\varepsilon N^{-4}+N^{-5}). \tag{5.10}$$

Combining (5.7)–(5.10) yields the statement of the lemma. □

THEOREM 5.3. *In addition to Assumptions* 3.1 *and* 5.1, *suppose that* $S \in W^{3,\infty}(\Omega)$ *with* $\|S\|_{W^{3,\infty}(K)} \leq C$ *for some constant* C. *Then*

$$\|u-u^N\|_{SD,d} \leq C\left(\varepsilon N^{-3/2}+N^{-2}\ln^2 N\right).$$

Proof. Lemmas 5.2 and 5.1 imply that

$$\begin{aligned}\|u-u^N\|_{SD,d} &\leq \|u-u^I\|_{SD,d}+\|u^I-u^N\|_{SD,d}\\ &\leq CN^{-2}\ln^2 N + C\,\|u^I-u^N\|_{SD}.\end{aligned}$$

Now invoke Theorem 4.5 to complete the proof. □

Remark 5.1. In practice one usually has $\varepsilon \leq N^{-1/2}\ln^2 N$, so the bound of Theorem 5.3 becomes $\|u-u^N\|_{SD,d} \leq CN^{-2}\ln^2 N$. Writing u_{Gal}^N for the numerical solution computed by the Galerkin finite element method, it is shown in [11, 23] that if $\varepsilon \leq N^{-1}$, then $\|u-u_{Gal}^N\|_{1,\varepsilon} \leq CN^{-2}\ln^2 N$, but the norm $\|\cdot\|_{1,\varepsilon}$ is weaker than $\|\cdot\|_{SD,d}$.

5.2. Postprocessing u^N.

As described at the beginning of section 5, we now show how a local postprocessing of u^N yields a piecewise biquadratic solution Pu^N for which in general $\|u-Pu^N\|_{1,\varepsilon} \ll \|u-u^N\|_{1,\varepsilon}$.

Consider a family of Shishkin meshes $\mathcal{T}_N$ with mesh points (x_i,y_j) for $i,j=0,\ldots,N$, where we require $N/2$ to be even. Then we can build a coarser mesh composed of disjoint macrorectangles M, each comprising four mesh rectangles from $\mathcal{T}_N$, where M belongs to only one of the four domains Ω_{11}, Ω_{12}, Ω_{21}, and Ω_{22}. See Figure 5.1. Associate with each macrorectangle M an interpolation operator $P_M : C(\bar{M}) \to Q_2(M)$ defined by the standard biquadratic interpolation at the barycenter, nodes, and midpoints of edges of the macrorectangle. As usual, P_M can be extended to a continuous global interpolation operator $P : C(\bar{\Omega}) \to W^N$, where W^N is the space of piecewise biquadratic finite elements, by setting

$$(Pv)|_M := P_M(v|_M) \quad \forall M.$$

Note that the macrorectangle M does not belong to $\mathcal{T}_{N/2}$ because the transition point values $1-\lambda_x$ and $1-\lambda_y$ associated with the Shishkin mesh $\mathcal{T}_N$ change when

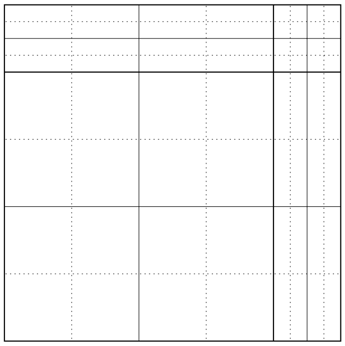

FIG. 5.1. *Macroelements built from the decomposition $\mathcal{T}_8$.*

N is replaced by $N/2$. We shall use the notation $\tilde{\mathcal{T}}_{N/2}$ for the family of macromeshes that is generated by the family of Shishkin meshes $\mathcal{T}_N$. Thus each macrorectangle $M \in \tilde{\mathcal{T}}_{N/2}$ is the union of four rectangles from $\mathcal{T}_N$.

LEMMA 5.4. *The piecewise biquadratic interpolation P has the following properties:*

$$P(v^I) = P(v) \qquad \forall v \in C(\bar{\Omega}), \tag{5.11}$$

$$\|Pv^N\|_{1,\varepsilon} \le C\|v^N\|_{1,\varepsilon} \quad \forall v^N \in V^N. \tag{5.12}$$

Proof. The identity (5.11) follows immediately from the definitions of the interpolation operators.

To prove (5.12), map the macroelement M onto the reference macroelement $\hat{M} = [-1,+1]^2$ that is the union of $M_1 = [0,1] \times [-1,0]$, $M_2 = [0,1]^2$, $M_3 = [-1,0] \times [0,1]$, and $M_4 = [-1,0]^2$. Then by scaling properties it is sufficient to show that

$$\|\hat{P}\hat{v}\|_{0,\hat{M}} \le C\|\hat{v}\|_{0,\hat{M}} \quad \text{and} \quad |\hat{P}\hat{v}|_{1,\hat{M}} \le C|\hat{v}|_{1,\hat{M}} \quad \forall \hat{v} \in Q(\hat{M}), \tag{5.13}$$

where

$$Q(\hat{M}) = \{\hat{w} \in C(\hat{M}) \;:\; \hat{w}|_{M_i} \in Q_1(M_i) \text{ for } i = 1, \dots, 4\}.$$

We have

$$\hat{P}\hat{v} = 0 \quad \Rightarrow \quad \hat{v} = 0 \qquad \forall \hat{v} \in Q(\hat{M}),$$

so the mapping $\hat{v} \mapsto \|\hat{P}\hat{v}\|_{0,\hat{M}}$ is a norm on the space $Q(\hat{M})$. Similarly

$$|\hat{P}\hat{v}|_{1,\hat{M}} = 0 \quad \Rightarrow \quad \hat{P}\hat{v} = \text{constant} \quad \Rightarrow \quad \hat{v} = \text{constant},$$

which shows that the mapping

$$\hat{v} \mapsto |\hat{P}\hat{v}|_{1,\hat{M}}$$

is a norm on the quotient space $Q(\hat{M})\backslash\mathbb{R}$. Then (5.13) follows from the equivalence of norms in finite-dimensional spaces. □

LEMMA 5.5. *Let Assumptions* 3.1 *and* 5.1 *hold true. Then*

$$\|Pu - u\|_{1,\varepsilon} \le C\big(\varepsilon N^{-3/2} + N^{-2}\ln^2 N\big). \tag{5.14}$$

Proof. When considering a family of Shishkin meshes $\mathcal{T}_N$ with $N/2$ even, the resulting family $\widetilde{\mathcal{T}}_{N/2}$ of macroelements has the same transition points as $\mathcal{T}_N$ but has $N/2$ elements in each coordinate direction. Using standard interpolation results, we get

$$\|PS - S\|_{1,\varepsilon} \le C(\varepsilon^{1/2}N^{-2} + N^{-3}) \le CN^{-2}. \tag{5.15}$$

The method of analysis of the layer parts of u varies with one's location in Ω. In order not to overburden the presentation with excessive detail, only the estimation of $\varepsilon^{1/2}\|(PE_{21} - E_{21})_x\|_0$ is described; the component $\varepsilon^{1/2}\|(PE_{21} - E_{21})_y\|_0$ of (5.14) is less badly behaved, and the treatment of E_{12} and E_{22} is broadly similar. A similar argument also shows that, analogously to (3.11),

$$\|PE - E\|_0 \le CN^{-2}\ln^2 N, \tag{5.16}$$

where E can be any one of E_{12}, E_{21}, or E_{22}.

Inside the layer (i.e., on $\Omega_{21} \cup \Omega_{22}$), one uses the following anisotropic error estimates from [1], which are analogous to those of Lemma 3.1:

$$\begin{aligned}
\|v - Pv\|_{0,M} &\le C \sum_{i+j=3} h_{x,M}^i h_{y,M}^j \left\| \frac{\partial^3 v}{\partial x^i \partial y^j} \right\|_{0,M} && \forall M \in \tilde{\mathcal{T}}_{N/2},\\
\|(v - Pv)_x\|_{0,M} &\le C \sum_{i+j=2} h_{x,M}^i h_{y,M}^j \left\| \frac{\partial^3 v}{\partial x^{i+1} \partial y^j} \right\|_{0,M} && \forall M \in \tilde{\mathcal{T}}_{N/2},\\
\|(v - Pv)_y\|_{0,M} &\le C \sum_{i+j=2} h_{x,M}^i h_{y,M}^j \left\| \frac{\partial^3 v}{\partial x^i \partial y^{j+1}} \right\|_{0,M} && \forall M \in \tilde{\mathcal{T}}_{N/2}.
\end{aligned}$$

These bounds yield

$$\begin{aligned}
&\varepsilon^{1/2}\|(E_{21} - PE_{21})_x\|_{0,\Omega_{21}\cup\Omega_{22}}\\
&\quad \le C\varepsilon^{1/2}\left[\left(\frac{\varepsilon \ln N}{N}\right)^2 \|(E_{21})_{xxx}\|_{0,\Omega_{21}\cup\Omega_{22}}\right.\\
&\qquad \left. + \left(\frac{\varepsilon \ln N}{N}\cdot\frac{1}{N}\right)\|(E_{21})_{xxy}\|_{0,\Omega_{21}\cup\Omega_{22}} + \frac{1}{N^2}\|(E_{21})_{xyy}\|_{0,\Omega_{21}\cup\Omega_{22}}\right]\\
&\quad \le CN^{-2}\ln^2 N,
\end{aligned} \tag{5.17}$$

by (5.1).

Outside the layer region $\Omega_{21} \cup \Omega_{22}$, it is best to apply the triangle inequality:

$$\varepsilon^{1/2}\|(E_{21} - PE_{21})_x\|_{0,\Omega_{12}\cup\Omega_{11}} \le \varepsilon^{1/2}\|(E_{21})_x\|_{0,\Omega_{12}\cup\Omega_{11}} + \varepsilon^{1/2}\|(PE_{21})_x\|_{0,\Omega_{12}\cup\Omega_{11}}.$$

Then (5.1) implies that

$$\varepsilon^{1/2}\|(E_{21})_x\|_{0,\Omega_{12}\cup\Omega_{11}} \le CN^{-5/2}. \tag{5.18}$$

For the other term $\varepsilon^{1/2}\|(PE_{21})_x\|_{0,\Omega_{12}\cup\Omega_{11}}$, on each $K \subset \Omega_{12}$ use the easily verified inequality $\|(PE_{21})_x\|_{L^\infty(K)} \le C\|(E_{21})_x\|_{L^\infty(K)}$, and then exploit the fact that the area of Ω_{12} is at most $C(\varepsilon \ln N)^{1/2}$, while on Ω_{11} simply invoke an inverse inequality. These techniques yield (compare with the derivation of (3.10))

$$\begin{aligned}\varepsilon\|(PE_{21})_x\|_{0,\Omega_{12}}^2 &\leq C\varepsilon^{-1}\int_{1-\lambda_y}^{1}\sum_{i=1}^{N/4}\int_{x_{2i-2}}^{x_{2i}} \exp\left(-\frac{2\beta_1(1-x_{2i})}{\varepsilon}\right) dx\, dy \\ &\leq C(\varepsilon N^{-5}+N^{-6})\ln N \qquad (5.19)\end{aligned}$$

and

$$\begin{aligned}\varepsilon^{1/2}\|(PE_{21})_x\|_{0,\Omega_{11}} &\leq C\varepsilon^{1/2}N\|PE_{21}\|_{0,\Omega_{11}} \\ &\leq C\varepsilon^{1/2}N\int_{0}^{1-\lambda_y}\sum_{i=1}^{N/4}\int_{x_{2i-2}}^{x_{2i}} \exp\left(-\frac{2\beta_1(1-x_{2i})}{\varepsilon}\right) dx\, dy \\ &\leq C\varepsilon^{1/2}(\varepsilon^{1/2}N^{-3/2}+N^{-2}). \qquad (5.20)\end{aligned}$$

Now combine (5.17)–(5.20) to get

$$\varepsilon^{1/2}\|(PE_{21}-E_{21})_x\|_0 \leq C\big(\varepsilon N^{-3/2}+N^{-2}\ln^2 N\big).$$

Recalling (5.15) and (5.16), we are done. □

Theorem 5.6. *Let Assumptions* 3.1 *and* 5.1 *hold true. Then after postprocessing by P, the numerical solution u^N generated by the SDFEM satisfies*

$$\|u-Pu^N\|_{1,\varepsilon} \leq C\big(\varepsilon N^{-3/2}+N^{-2}\ln^2 N\big).$$

Proof. The triangle inequality and Lemmas 5.4 and 5.5 yield

$$\begin{aligned}\|u-Pu^N\|_{1,\varepsilon} &\leq \|u-Pu\|_{1,\varepsilon}+\|P(u^I-u^N)\|_{1,\varepsilon} \\ &\leq C\big(\varepsilon N^{-3/2}+N^{-2}\ln^2 N+\|u^I-u^N\|_{1,\varepsilon}\big) \\ &\leq C(\varepsilon N^{-3/2}+N^{-2}\ln^2 N),\end{aligned}$$

where we invoked Theorem 4.5. □

Remark 5.2. In practice we can assume that $\varepsilon \leq N^{-1/2}\ln^2 N$ and obtain (aside from a logarithmic factor) second-order convergence in Theorem 5.6.

Remark 5.3. Theorem 5.6 implies that

$$\varepsilon^{1/2}\|\nabla u-\nabla Pu^N\|_0 \leq C(\varepsilon N^{-3/2}+N^{-2}\ln^2 N).$$

In [18] a recovery technique is applied to the solution u_{Gal}^N computed by the standard Galerkin method on the Shishkin mesh $\mathcal{T}_N$, producing a recovered gradient Ru_{Gal}^N for which $\varepsilon^{1/2}\|\nabla u - Ru_{Gal}^N\|_0 \leq CN^{-2}\ln^{5/2}N$ when $\varepsilon \leq N^{-1}$. Thus our postprocessed solution Pu^N includes a recovery of the gradient that is accurate to a slightly higher order. The two methods are not the same; ∇Pu^N is piecewise linear and discontinuous, while Ru_{Gal}^N is piecewise linear and continuous.

6. What rates of convergence are observed? In this section we give numerical results that appear to support our theoretical results, as is standard practice. However, we shall also reveal that in analyzing the numerical results of singularly perturbed problems solved on Shishkin meshes, it is easy to mistake one rate of convergence for another.

In Figure 6.1 is shown the experimental data from [22, Figure 2], which is for (1.1) with $b = (2 + x, 1 + y)$, $c = 2$, and the right-hand side f chosen so that

$$u(x, y) = 2(\sin x) \left(1 - \exp\left(-\frac{3(1 - x)}{\varepsilon}\right)\right) y^2 \left(1 - \exp\left(-\frac{2(1 - y)}{\varepsilon}\right)\right).$$

This is a typical problem of type (1.1). In [22], where only the comparison curve for $O(N^{-3/2})$ was drawn, the numerical results were interpreted as showing that experimentally one observes convergence of order $N^{-3/2}$. Of course Theorem 4.5 of the present paper predicts instead convergence of order $N^{-2} \ln^2 N$, so in Figure 6.1 we also draw this comparison curve. One can then see that indeed Theorem 4.5 does appear to predict the correct rate of convergence, but one can also see that the two comparison curves are quite similar, so it is easy to understand the misinterpretation made in [22].

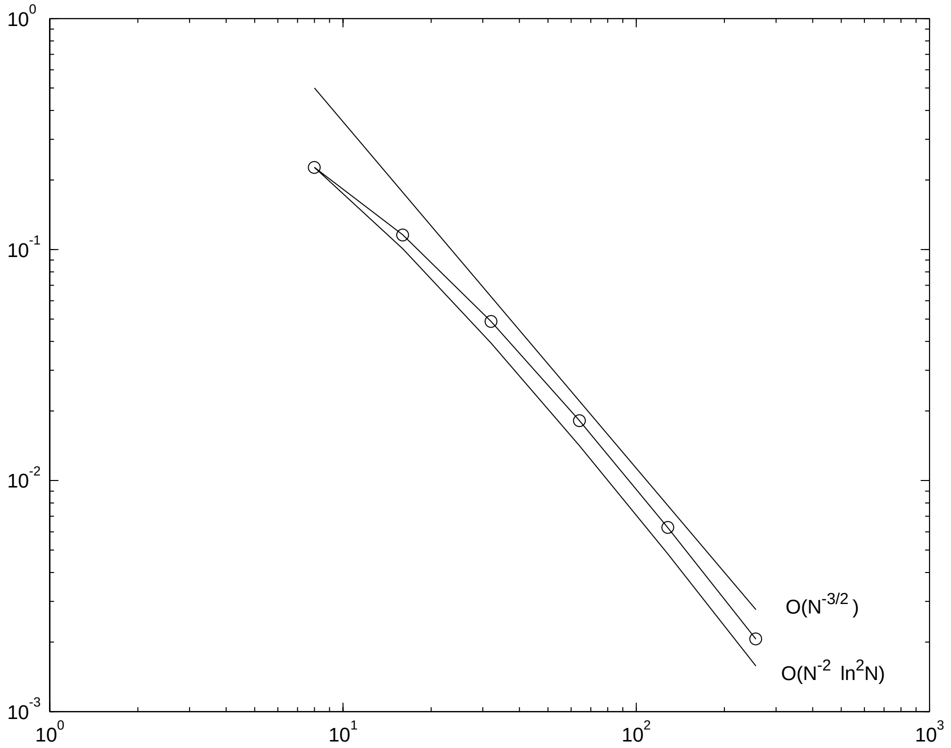

FIG. 6.1. *Error in* $\|u^I - u^N\|_{SD}$.

Can we be sure from Figure 6.1 that the experimental order of convergence is $N^{-2} \ln^2 N$? No. It is possible that a comparison curve for $O(N^{-\alpha} \ln^{\beta} N)$ (for some constants α and β) would look slightly more convincing.

Table 6.1 presents this data in another way. It gives the computed rates of convergence based on the errors in Figure 6.1 when one assumes that the error has the form $CN^{-\alpha}$ or $C(N^{-1} \ln N)^{-\alpha}$ for some constant α. Once again it is difficult to draw a firm conclusion about the actual rate that is observed.

By now, the reader may be of the opinion that these difficulties in interpretation of experimental results stem from the use of values of N that are too small. Surely

Table 6.1
Computed rates of convergence for errors from Figure 6.1.

N	16	32	64	128	256
Rate $N^{-\alpha}$; α value	0.9694	1.2455	1.4254	1.5365	1.6080
Rate $(N^{-1}\ln N)^{\alpha}$; α value	1.6572	1.8369	1.9341	1.9760	1.9917

Table 6.2
Convergence rates for $E(N) = CN^{-2}\ln^2 N$; rate of $N^{-\alpha}$ is assumed.

N	32	64	128	256	512	1024	2048	4096
α	1.3561	1.4739	1.5552	1.6147	1.6601	1.6960	1.7250	1.7489

for N sufficiently large there can be no doubt about the actual rate of convergence observed?

To throw some light on the answer to this question, Table 6.2 gives the rates of convergence, computed in the standard way when one assumes convergence of order $N^{-\alpha}$ for some constant α, from a function of the form $E(N) = CN^{-2}\ln^2 N$. That is, these numbers are not obtained by solving a boundary value problem but are computed by assuming that the numerical error function $E(N)$ has the exact form $CN^{-2}\ln^2 N$ for some constant C. If this table were computed from successive numerical solutions to a problem like (1.1) and one did not know a priori that the rates represent $O(N^{-2}\ln^2 N)$ convergence, one might easily interpret them as $O(N^{-7/4})$. Taking larger values of N would certainly reveal the misinterpretation, but already the table has reached $N = 4096$, which for our two-dimensional problem means that one has about 16 million unknowns. Thus taking a value of N sufficiently large to confirm beyond doubt a rate of convergence when solving (1.1) is in general impractical. It seems that Figure 6.1 is the best we can do.

OPTIMAL SCHWARZ WAVEFORM RELAXATION FOR THE ONE DIMENSIONAL WAVE EQUATION*

MARTIN J. GANDER†, LAURENCE HALPERN‡, AND FRÉDÉRIC NATAF§

Abstract. We introduce a nonoverlapping variant of the Schwarz waveform relaxation algorithm for wave propagation problems with variable coefficients in one spatial dimension. We derive transmission conditions which lead to convergence of the algorithm in a number of iterations equal to the number of subdomains, independently of the length of the time interval. These optimal transmission conditions are in general nonlocal, but we show that the nonlocality depends on the time interval under consideration, and we introduce time windows to obtain optimal performance of the algorithm with local transmission conditions in the case of piecewise constant wave speed. We show that convergence in two iterations can be achieved independently of the number of subdomains in that case. The algorithm thus scales optimally with the number of subdomains, provided the time windows are chosen appropriately. For continuously varying coefficients we prove convergence of the algorithm with local transmission conditions using energy estimates. We then introduce a finite volume discretization which permits computations on nonmatching grids, and we prove convergence of the fully discrete Schwarz waveform relaxation algorithm. We finally illustrate our analysis with numerical experiments.

1. Introduction.

Domain decomposition methods have been mainly developed and analyzed for elliptic coercive problems, and their convergence theory is well understood; see [42, 8, 38, 37] and references therein. When treating evolution problems, the classical approach consists of discretizing the time dimension uniformly on the whole domain by an implicit scheme and then treating the obtained problems at each time step by a classical domain decomposition method for steady problems. For parabolic problems, see, for example, [6, 30, 7], and for hyperbolic problems see [2, 41].

This approach has two disadvantages. First, one needs to impose a uniform time discretization for all subdomains, and thus one loses one of the main features of domain decomposition algorithms, namely, to adapt the solution process to the physical properties of the subdomain. It is still possible to refine in space, but for evolution problems this is not sufficient, since the space and time discretization are linked in general by stability constraints and conditions on the dispersion of the numerical scheme. Second, the algorithm needs to communicate small amounts of information at each time step. Each communication involves in addition to the cost for the data transmitted a startup cost independent of the amount of data transmitted. It can thus be of interest to communicate larger packages of data at once over several time steps instead of many small packages to save communication time. This factor can be-

come important if the algorithm runs on an existing network of workstations without special high performance links.

To avoid the above disadvantages, we propose in this paper an approach different from the classical one. We decompose the original domain into subdomains as in the classical case, but we do not discretize the time dimension. Instead we solve time dependent subproblems on each subdomain. This approach is related to waveform relaxation algorithms for ordinary differential equations and has first been considered for partial differential equations by Bjørhus in [5, 4], where first order hyperbolic problems were analyzed, in which case only incoming characteristic information can be imposed on subdomain interfaces. An overlapping Schwarz algorithm of this type has been analyzed for the heat equation in [13, 19, 18], and for more general parabolic problems in [20, 14], which led to a new understanding of the performance of the waveform relaxation algorithm when applied to parabolic partial differential equations; in particular, a new and faster asymptotic convergence rate is obtained with overlapping subdomain splitting compared to the classical waveform relaxation rate for Jacobi splittings. For overlapping and nonoverlapping Schwarz waveform relaxation methods for the wave equation and convection reaction diffusion equation, see [15].

We are focusing in this paper on wave propagation phenomena in the presence of variable and discontinuous coefficients. We first perform an analysis at the continuous level and derive transmission conditions for nonoverlapping Schwarz waveform relaxation algorithms which lead to optimal convergence. The optimal transmission conditions involve linear operators $\mathcal{S}_j$ related to the Dirichlet to Neumann maps at the artificial interfaces. For elliptic problems, results of this type have been studied in [9, 34, 33, 12, 17]. These optimal transmission conditions are nonlocal in general, but we show that the nonlocality depends on the time interval under consideration in the wave equation case. We introduce then time windows to obtain optimal performance of the algorithm with local transmission conditions for piecewise constant wave speed. We show that convergence in two iterations can be achieved independently of the number of subdomains in that case. The algorithm thus scales optimally with the number of subdomains, without any additional mechanism like a coarse grid. For continuously varying coefficients, we prove convergence of the algorithm with local transmission conditions using energy estimates. We then introduce a finite volume discretization and analyze the fully discrete Schwarz waveform relaxation algorithm. This algorithm allows us to use nonmatching grids both in space and time on different subdomains so that the resolution can be adapted to the underlying physical properties of the problem. For piecewise constant wave speed, we analyze the convergence of the algorithm using discrete Laplace transforms, a tool introduced for the continuous analysis of waveform relaxation algorithms by Miekkala and Nevanlinna in [31] and later used by Nevanlinna in [35, 36]. For an analysis of waveform relaxation algorithms discretized in time, see also Janssen and Vandewalle [22] and references therein. For continuously varying wave speed, we prove stability of the subdomain problems and convergence on nonmatching grids using energy estimates. Our approach is an alternative to the mortar method for nonmatching grids [3]; see also [1]. We finally illustrate the analysis with numerical experiments for model problems and a simulation for a typical underwater sound speed profile from an application. For a different approach of a space time decomposition for evolution problems using virtual controls, see [28], and for other ways of grid refinement in space and time, see [2, 10, 25].

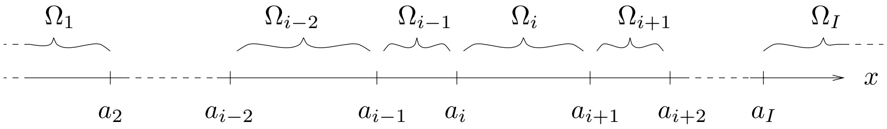

FIG. 2.1. *Domain decomposition into I nonoverlapping subdomains.*

2. The optimal Schwarz waveform relaxation algorithm.

We consider the second order wave equation with variable wave speed in one dimension,

$$\mathcal{L}(u) = \frac{1}{c^2(x)}\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} = f, \tag{2.1}$$

on the domain $\mathbb{R} \times (0, T)$ with initial conditions

$$u(x, 0) = p(x), \quad \frac{\partial u}{\partial t}(x, 0) = q(x).$$

For $0 < \underline{c} \leq c(x) \leq \bar{c} < \infty$ there exists a unique weak solution u of (2.1) on any bounded time interval $t \in [0, T]$; see [26, 27].

2.1. A general nonoverlapping Schwarz waveform relaxation algorithm.

We decompose the domain $\mathbb{R}$ into I nonoverlapping subdomains $\Omega_i = (a_i, a_{i+1})$, $a_j < a_i$, for $j < i$ and $a_1 = -\infty$, $a_{I+1} = +\infty$ as given in Figure 2.1. We introduce a general nonoverlapping Schwarz waveform relaxation algorithm

$$\begin{array}{rcll} \mathcal{L}(u_i^{k+1}) & = & f, & \text{in } \Omega_i \times (0, T), \\ \mathcal{B}_i^-(u_i^{k+1})(a_i, t) & = & \mathcal{B}_i^-(u_{i-1}^k)(a_i, t), & t \in (0, T), \\ \mathcal{B}_i^+(u_i^{k+1})(a_{i+1}, t) & = & \mathcal{B}_i^+(u_{i+1}^k)(a_{i+1}, t), & t \in (0, T), \\ u_i^{k+1}(x, 0) & = & p(x), & x \in \Omega_i, \\ \frac{\partial u_i^{k+1}}{\partial t}(x, 0) & = & q(x), & x \in \Omega_i, \end{array} \tag{2.2}$$

where $\mathcal{B}_i^{\pm}$ are linear transmission operators which we will determine to get optimal performance of the algorithm. For ease of notation, we define here

$$u_0^k := 0, \quad u_{I+1}^k := 0 \tag{2.3}$$

so that the index i in (2.2) ranges from $i = 1, 2, \ldots, I$. Note that we call this algorithm a waveform relaxation algorithm because time dependent problems are solved on subdomains as in the waveform relaxation algorithm for large systems of ordinary differential equations [24]. The algorithm we consider here is a Jacobi-type or additive Schwarz algorithm, since all the subdomains are treated in parallel. A Gauss–Seidel or multiplicative Schwarz algorithm could be considered as well. But since the analysis would be similar, we focus in this paper on the additive version of the algorithm only.

2.2. Transmission conditions for optimal convergence.

For elliptic problems, the Dirichlet to Neumann map has been used in [32] to define optimal transmission conditions. For wave propagation, it is more convenient to introduce the linear operator $\mathcal{S}_1(x_0)$ defined by

$$\mathcal{S}_1(x_0) : g(t) \mapsto \frac{\partial v}{\partial x}(x_0, t), \tag{2.4}$$

where $v(x,t)$ is the solution of

$$\begin{array}{rcll} \mathcal{L}(v) & = & 0, & \text{in } (-\infty, x_0) \times (0,T), \\ \frac{\partial v}{\partial t}(x_0,t) & = & g(t), & t \in (0,T), \\ v(x,0) = \frac{\partial v}{\partial t}(x,0) & = & 0, & x \in (-\infty, x_0), \end{array} \tag{2.5}$$

and the linear operator $\mathcal{S}_2(x_0)$ is defined by

$$\mathcal{S}_2(x_0) : g(t) \mapsto \frac{\partial v}{\partial x}(x_0,t), \tag{2.6}$$

where $v(x,t)$ is the solution of

$$\begin{array}{rcll} \mathcal{L}(v) & = & 0, & \text{in } (x_0, \infty) \times (0,T), \\ \frac{\partial v}{\partial t}(x_0,t) & = & g(t), & t \in (0,T), \\ v(x,0) = \frac{\partial v}{\partial t}(x,0) & = & 0, & x \in (x_0, \infty). \end{array} \tag{2.7}$$

The operators $\mathcal{S}_j$ defined in (2.5) and (2.7) are the key ingredients in obtaining an optimal Schwarz waveform relaxation algorithm. This algorithm is obtained by choosing the transmission operators $\mathcal{B}_i^{\pm}$ in the algorithm (2.2) to be

$$\mathcal{B}_i^- := \mathcal{S}_1(a_i)\partial_t - \partial_x, \quad \mathcal{B}_i^+ := \mathcal{S}_2(a_{i+1})\partial_t - \partial_x. \tag{2.8}$$

This choice is not arbitrary. The absorption property of these transmission operators allows the algorithm to compute subdomain solutions which do not see the interfaces and hence are exact; for the steady convection diffusion case, see [34].

Theorem 2.1 (convergence in I steps). *The nonoverlapping Schwarz waveform relaxation algorithm* (2.2) *with transmission operators defined by* (2.8) *converges in* I *iterations, where I denotes the number of subdomains.*

Proof. First note that convergence in less than I iterations, where I denotes the number of subdomains, is not possible over long time intervals, since the solution on each subdomain depends on the data on all the other subdomains and information is propagated only locally to neighboring subdomains. To show that the algorithm with the transmission operators (2.8) achieves convergence in I iterations and therefore is optimal, we rewrite the algorithm (2.2) in substructured form on the interfaces only. By linearity it suffices to consider the homogeneous case (the error equations) only $(f = p = q = 0)$ and to prove convergence to zero. We denote the interface values, which subdomain Ω_i obtains from its neighbors Ω_{i-1} and Ω_{i+1}, by

$$g_i^{k^-}(t) := \mathcal{B}_i^-(u_{i-1}^k)(a_i,t), \quad g_i^{k^+}(t) := \mathcal{B}_i^+(u_{i+1}^k)(a_{i+1},t) \quad \forall t \in (0,T)$$

and put all these values $g_i^{k^-}(t)$ and $g_i^{k^+}(t)$ together into the vector-valued function $g^k := (g_1^{k^+}, g_2^{k^-}, g_2^{k^+}, \ldots, g_I^{k^-})$. Note that there is only one element in g^k for the leftmost and rightmost subdomain, since they both extend to infinity. One step of the Schwarz waveform relaxation algorithm (2.2) can now be seen as a linear map taking a vector-valued function g^k as input and producing a new vector-valued function g^{k+1} as output. On each subdomain Ω_i for interior subdomains, $i = 2, \ldots I-1$, there are two linear mappings, both taking as input arguments the values of the neighboring subdomains and one producing a new value on the left boundary

$$A_i^- : (g_i^{k^-}, g_i^{k^+}) \mapsto \mathcal{B}_{i-1}^+\left(u_i^{k+1}\right)(a_i, \cdot)$$

and the other one a new value on the right boundary

$$A_i^+ : (g_i^{k^-}, g_i^{k^+}) \mapsto \mathcal{B}_{i+1}^- \left(u_i^{k+1}\right)(a_{i+1}, \cdot).$$

For the outermost subdomains there is only one linear map each, taking one input argument only,

$$A_1^+ : g_1^{k^+} \mapsto \mathcal{B}_2^- \left(u_1^{k+1}\right)(a_2, \cdot) \quad \text{and} \quad A_I^- : g_I^{k^-} \mapsto \mathcal{B}_{I-1}^+ \left(u_I^{k+1}\right)(a_I, \cdot).$$

Note that by the definition of the operators $\mathcal{S}_j$, both A_1^+ and A_I^- map any argument to zero: for any function $g(t)$ we have

$$A_1^+(g) \equiv A_I^-(g) \equiv 0. \tag{2.9}$$

This can be seen for A_1^+, for example, by

$$A_1^+(g) = \mathcal{B}_2^- (v)(a_2, \cdot) = (\mathcal{S}_1(a_2)\partial_t - \partial_x)v = v_x(a_2) - v_x(a_2) = 0,$$

where we have used that by the definition of $\mathcal{S}_1$ the function v is a solution of (2.5). Similarly for interior subdomains, we have for any function $g(t)$

$$A_i^-(g, 0) \equiv A_i^+(0, g) \equiv 0. \tag{2.10}$$

However, this implies by linearity that $A_i^+(g, h)$ depends only on g and $A_i^-(g, h)$ depends only on h, since

$$\begin{aligned} A_i^+(g, h) &= A_i^+(g, 0) + A_i^+(0, h) =: \widetilde{A}_i^+(g), \\ A_i^-(g, h) &= A_i^-(g, 0) + A_i^-(0, h) =: \widetilde{A}_i^-(h). \end{aligned} \tag{2.11}$$

Using these linear mappings on each subdomain, a complete step of the nonoverlapping Schwarz waveform relaxation algorithm can be described by the linear map $\mathcal{A} : g^k \mapsto g^{k+1}$, where $\mathcal{A}g^k$ is defined by

$$\begin{aligned} \mathcal{A}g^k &= \mathcal{A}(g_1^{k^+}, g_2^{k^-}, g_2^{k^+}, \dots, g_I^{k^-}) \\ &= (A_2^-(g_2^{k^-}, g_2^{k^+}), A_1^+(g_1^{k^+}), A_3^-(g_3^{k^-}, g_3^{k^+}), A_2^+(g_2^{k^-}, g_2^{k^+}), \dots, A_I^-(g_I^{k^-}), A_{I-1}^+(g_{I-1}^{k^-}, g_{I-1}^{k^+})) \\ &= (\widetilde{A}_2^-(g_2^{k^+}), 0, \widetilde{A}_3^-(g_3^{k^+}), \widetilde{A}_2^+(g_2^{k^-}), \dots, 0, \widetilde{A}_{I-1}^+(g_{I-1}^{k^-})) \end{aligned}$$

or, written in matrix form,

$$\mathcal{A} = \left[\begin{array}{ccccccccc} 0 & 0 & \widetilde{A}_2^- & & & & & & \\ 0 & 0 & 0 & 0 & & & & & \\ 0 & 0 & 0 & 0 & \widetilde{A}_3^- & & & & \\ & \widetilde{A}_2^+ & 0 & 0 & 0 & \ddots & & & \\ & & 0 & 0 & 0 & & 0 & & \\ & & & \widetilde{A}_3^+ & 0 & & 0 & \widetilde{A}_{I-1}^- & \\ & & & & \ddots & & 0 & 0 & 0 \\ & & & & & 0 & 0 & 0 & 0 \\ & & & & & & \widetilde{A}_{I-1}^+ & 0 & 0 \end{array}\right].$$

Now proving that the nonoverlapping Schwarz waveform relaxation algorithm (2.2) converges in I iterations is equivalent to showing that the Schwarz iteration map satisfies $\mathcal{A}^{I-1} = 0$ since then after $I-1$ iterations all the interface values are zero, and thus after one more iteration the solution will be converged to zero everywhere. We prove this by showing that $\mathcal{A}^{I-1}$ applied to an arbitrary vector-valued function $e(t) = (e_1(t), e_2(t), \ldots, e_{2I-2}(t))$ equals zero. The first application of $\mathcal{A}$ will delete the second and second to last entry in e. The second application therefore will delete the fourth and fourth to last entries in e because of the structure of $\mathcal{A}$. This process continues until the $I-1$ application of $\mathcal{A}$ deleted the $2I-2$, and the $2I-2$ to last entry, which is the first entry in e. Thus now $\mathcal{A}^{I-1}e$ is the zero vector, and in the next step the solution is zero everywhere. □

Note that the proof uses only the fundamental property of the linear operators $\mathcal{S}_j$ leading to the transparent transmission conditions and no special properties of the wave equation. The result is therefore valid for other partial differential equations as well where the appropriate operators $\mathcal{S}_j$ can be defined.

3. Optimal convergence with local transmission conditions for piecewise constant wave speed.

We now consider the wave equation (2.1) with piecewise constant wave speed to investigate the optimal transmission operators further. This will lead to the interesting result of convergence in fewer iterations than the number of subdomains on certain bounded time intervals. We consider first the wave equation (2.1) with two physical domains

$$O_1 = \mathbb{R}^- \text{ with } c(x) = c_1 \text{ and } O_2 = \mathbb{R}^+ \text{ with } c(x) = c_2. \tag{3.1}$$

In this case we can compute the linear operators $\mathcal{S}_j$ explicitly, and from them we gain more insight into the optimal Schwarz waveform relaxation algorithm. In subsection 3.3, we generalize the results to an arbitrary number of discontinuities.

3.1. Identification of the optimal nonlocal transmission conditions.

We define the ratio r by

$$r := \frac{c_2 - c_1}{c_2 + c_1}. \tag{3.2}$$

Lemma 3.1. *In the case of piecewise constant wave speed* (3.1), *the linear operators* $\mathcal{S}_j$ *in* (2.4), (2.6) *are given by*

$$(\mathcal{S}_1(x_0))\, g(t) = \begin{cases} \frac{1}{c_1} g(t), & x_0 \in O_1, \\ \frac{1}{c_2}\Big(g(t) + 2\sum_{k=1}^{\lfloor \frac{c_2 t}{2x_0} \rfloor} r^k g(t - 2kx_0/c_2)\Big), & x_0 \in O_2, \end{cases} \tag{3.3}$$

and

$$(\mathcal{S}_2(x_0))\, g(t) = \begin{cases} \frac{1}{c_1}\Big(g(t) + 2\sum_{k=1}^{\lfloor \frac{c_1 t}{2x_0} \rfloor} r^k g(t + 2kx_0/c_1)\Big), & x_0 \in O_1, \\ \frac{1}{c_2} g(t), & x_0 \in O_2. \end{cases} \tag{3.4}$$

Proof. This result can be obtained by explicitly computing the solutions; for details, see [16]. □

In this special case, one can see why the operators $\mathcal{S}_j$ are nonlocal in general: they have to include reflections stemming from the discontinuity in the wave speed between the two different physical domains. Using Theorem 2.1, the nonoverlapping Schwarz waveform relaxation algorithm for the wave equation with a discontinuity in the wave speed converges in I steps, where I denotes the number of subdomains. However, an implementation of these nonlocal transmission conditions is rather complicated, and we do not recommend this, especially if several discontinuities occur in the physical domain. However, the result indicates a better approach already, and we develop it in the next subsection.

3.2. Local transmission conditions using the time evolution. The optimal transmission operators (2.8) depend on the time interval under consideration, since the linear operators $\mathcal{S}_j$ in (3.3), (3.4) contain a sum with a number of terms proportional to the length of the time interval. In particular, for a given time interval $[0, T]$ we have at most

$$\max\left(\left\lfloor\frac{c_1 T}{2x_0}\right\rfloor, \left\lfloor\frac{c_2 T}{2x_0}\right\rfloor\right)$$

terms in the sum to obtain optimal convergence. We thus obtain the following important corollary of Theorem 2.1.

COROLLARY 3.2. *In the case of piecewise constant wave speed* (3.1), *if the discontinuity at $x = 0$ lies within the subdomain Ω_l, $a_l < 0 < a_{l+1}$, then the nonoverlapping Schwarz waveform relaxation algorithm* (2.2) *with local transmission operators*

$$\mathcal{B}_i^- := \frac{1}{c(a_i)}\partial_t - \partial_x, \quad \mathcal{B}_i^+ := \frac{1}{c(a_{i+1})}\partial_t + \partial_x \tag{3.5}$$

converges in I iterations, where I denotes the number of subdomains, if the computation is restricted to the time interval $t \in [0, T]$ with

$$T \leq T_1 = 2\min\left(\frac{|a_l|}{c(a_l)}, \frac{|a_{l+1}|}{c(a_{l+1})}\right). \tag{3.6}$$

Proof. If we choose T such that

$$\max_{1<j\leq I}\left\lfloor\frac{c(a_j)T}{2|a_j|}\right\rfloor \equiv 0, \tag{3.7}$$

then there are no terms left in the sum of the operators $\mathcal{S}_j$ in (3.3), (3.4), and thus the optimal transmission operators become the local operators (3.5). However, the maximum in condition (3.7) can only be attained for either $j = l$ or $j = l + 1$ because the discontinuity lies in subdomain Ω_l, and thus (3.7) is equivalent to the condition (3.6). □

This corollary suggests avoiding the costly nonlocal transmission conditions by cutting the given time domain $[0, T]$ into time windows of length T_1 given in (3.6). Then the algorithm can employ local transmission conditions and will still converge in at most I iterations.

However, condition (3.6) can impose very small time windows if a_l or a_{l+1} is very close to the discontinuity at $x = 0$. At first glance, this suggests that it is best to place the subdomains so that the discontinuities lie inside the subdomains, away from its boundaries. The optimal location for $a_l < 0 < a_{l+1}$ would be such that

$$\frac{|a_l|}{c(a_l)} = \frac{|a_{l+1}|}{c(a_{l+1})} \tag{3.8}$$

to maximize the time interval (3.6) one can use with the algorithm and local transmission conditions. There is, however, a better choice: taking the limit of the operators

$\mathcal{S}_j$ in (3.3,3.4) as x_0 goes to zero, we find

$$(\mathcal{S}_1(0))g(t) = \frac{1}{c_1}g(t), \quad (\mathcal{S}_2(0))g(t) = \frac{1}{c_2}g(t), \tag{3.9}$$

and thus the operators $\mathcal{S}_j$ become local operators in that case. This suggests that aligning physical domains with computational ones is an advantage for the transmission conditions. Defining

$$c(x^-) := c(x-0), \quad c(x^+) := c(x+0)$$

to include the correct limits when the discontinuity lies exactly at an interface between two subdomains, we obtain the following corollary.

COROLLARY 3.3. *In the case of piecewise constant wave speed* (3.1), *if the discontinuity lies on the interface between the two subdomains Ω_l and Ω_{l+1}, $a_{l+1} = 0$, then the nonoverlapping Schwarz waveform relaxation algorithm* (2.2) *with local transmission operators*

$$\mathcal{B}_i^- := \frac{1}{c(a_i^-)}\partial_t - \partial_x, \quad \mathcal{B}_i^+ := \frac{1}{c(a_{i+1}^+)}\partial_t + \partial_x \tag{3.10}$$

converges in I iterations, where I denotes the number of subdomains, if the computation is restricted to the time interval $t \in [0, T]$ with

$$T \leq T_2 = 2\min\left(\frac{|a_l|}{c(a_l)}, \frac{|a_{l+2}|}{c(a_{l+2})}\right). \tag{3.11}$$

Proof. If we place the discontinuity directly between the two subdomains Ω_l and Ω_{l+1}, then the optimal transmission conditions between Ω_l and Ω_{l+1} are local, as seen in (3.9). Therefore, the largest time interval we can choose for local transmission conditions depends now only on the total width of Ω_l and Ω_{l+1}, which leads to condition (3.11). □

Hence, with the discontinuity at $x = 0$ aligned with a subdomain boundary, say, at $a_{l+1} = 0$, one would choose the subdomain boundaries a_l and a_{l+2} such that

$$\frac{|a_l|}{c(a_l)} = \frac{|a_{l+2}|}{c(a_{l+2})} \tag{3.12}$$

to maximize the possible time interval in (3.11), where the algorithm can be used with local transmission conditions. This choice leads to a longer time interval than the choice with the discontinuity within one subdomain (3.8) since $a_l < a_{l+1} < a_{l+2}$.

3.3. Convergence in two iterations independent of the number of subdomains.

In more realistic situations, there will be more than one discontinuity in the computational domain, which seems to complicate the situation because for the global optimal transmission conditions of the type (3.3), (3.4), one would need to track more and more reflections from the various discontinuities in the wave speed. However, due to the finite speed of propagation in the wave equation, the previous analysis can be applied locally using time windows again. In addition, with time windows, not every subdomain solution depends on the solution on all the other subdomains if the time interval is short enough. Neighboring information suffices in that case, and it is thus possible to reduce the number of iterations below I for I subdomains.

Suppose we have J physical domains $O_j = (d_j, d_{j+1})$ with constant wave speed per physical domain, $c(x) = c_j$ for $d_j < x < d_{j+1}$, $j = 1, \ldots, J$, $d_1 = -\infty$, and

$d_{J+1} = \infty$. We decompose the physical domain $\mathbb{R}$ into I computational subdomains $\Omega_i = (a_i, a_{i+1})$ as before. We denote by n_i the number of discontinuities within each subdomain Ω_i, and we exclude for the moment the case where a discontinuity is aligned precisely between two computational subdomains. We also denote by m_i the index of the first physical domain O_{m_i} which intersects the computational subdomain Ω_i. We define the transmission time t_i of a signal across subdomain Ω_i by

$$t_i := \begin{cases} \dfrac{a_{i+1} - a_i}{c_{m_i}} & \text{if } n_i = 0, \\ \dfrac{d_{m_i+1} - a_i}{c_{m_i}} + \displaystyle\sum_{k=1}^{n_i-1} \dfrac{d_{m_i+k+1} - d_{m_i+k}}{c_{m_i+k}} + \dfrac{a_{i+1} - d_{m_i+n_i}}{c_{m_i+n_i}} & \text{if } n_i > 0. \end{cases} \tag{3.13}$$

We also define the reflection time at each interface a_i of the computational subdomains by

$$\tau_i := 2 \min_j \frac{|a_i - d_j|}{c(a_i)}. \tag{3.14}$$

These two time constants allow us to formulate conditions for convergence in less than I steps.

Theorem 3.4. *The overlapping Schwarz waveform relaxation algorithm* (2.2) *with local transmission conditions* (3.10) *and any discontinuities strictly in the interior of the computational subdomains converges in two iterations independently of the number of subdomains if the time interval* $[0, T]$ *is chosen such that*

$$T \leq T_3 = \min\left(\min_i t_i, \min_i \tau_i\right), \tag{3.15}$$

where t_i *is defined in* (3.13) *and* τ_i *is defined in* (3.14).

Proof. Consider one of the computational domains Ω_i. The solution on that domain depends only on the solution of the neighboring domains Ω_{i+1} and Ω_{i-1} determined by their initial conditions, because the time interval $[0, T]$ given by (3.15) is too short for any signal to reach domain Ω_i across the neighboring subdomains due to condition (3.15). So after one iteration, the exact boundary conditions for domain Ω_i are available if the transmission conditions employed at the boundary of Ω_i are exact absorbing boundary conditions. However, this is ensured by condition (3.15) as well because T is smaller than any reflection time τ_i so that the local transmission conditions (3.10) are indeed exactly absorbing. Thus the second iteration produces the exact solution on subdomain Ω_i. Since this argument holds for all computational subdomains, the result is established. □

As in Corollary 3.2, this result can require very small time intervals, since the reflection times τ_i can be very small when a discontinuity approaches a subdomain boundary. This can however be avoided as before by aligning physical discontinuities with the boundaries of the subdomains—a natural approach for domain decomposition. Doing this for all discontinuities, the minimal transmission time $\min_i t_i$ becomes necessarily smaller than the minimal reflection time $\min_i \tau_i$ because the reflection time requires the signal to go across a subdomain twice. (There are no discontinuities within subdomains anymore.) In addition, the transmission times formula (3.13) simplifies greatly, becoming

$$t_i = \frac{a_{i+1} - a_i}{c(a_i^+)}.$$

We therefore obtain the following theorem.

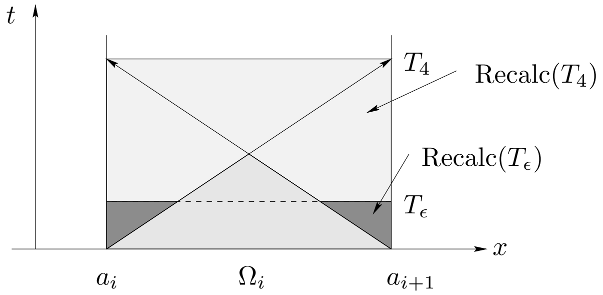

FIG. 3.1. *Toward the optimal algorithm: Unknowns to recompute for the time windows T_4 and T_ϵ, respectively.*

THEOREM 3.5. *The overlapping Schwarz waveform relaxation algorithm* (2.2) *with local transmission conditions* (3.10) *and any discontinuities aligned with the computational subdomain boundaries converges in two iterations independently of the number of subdomains if the time interval* $[0, T]$ *is chosen such that*

$$T \leq T_4 = \min_i \frac{a_{i+1} - a_i}{c(a_i^+)}. \tag{3.16}$$

Proof. The argument is the same as in the previous theorem. ☐

Further computation can be saved by noting that only values above the characteristics in each subdomain need to be recomputed during the second iteration, as shown in Figure 3.1. If the time window is chosen to be $[0, T_4]$ from Theorem 3.5, then convergence will be achieved in two iterations, and in the second iteration only the variables in the region denoted by Recalc(T_4) need to be recalculated. If we choose however an even smaller time window T_ϵ, then far fewer variables need to be recalculated in the second iteration, namely, the ones denoted by Recalc(T_ϵ). Thus, with our algorithm, the solution of the wave equation can be optimally parallelized: the parallel algorithm run on a sequential machine will run at a cost $1 + \epsilon$ of the optimal sequential code, provided the cost is linear in the number of unknowns. The optimal choice of T_ϵ depends on the latency time of the network linking the computational nodes. If the latency time is small, then a short T_ϵ will lead to the best performance, since almost no values need to be recomputed. If the latency time is important, however, it is better to communicate larger amounts of data each time a communication needs to be done. This can be achieved by choosing a larger T_ϵ and will lead to faster solution times even if more values need to be recomputed in the second iteration.

4. Convergence with local transmission conditions for continuous wave speed.

Discontinuous wave speeds allowed us to use local transmission conditions in the Schwarz waveform relaxation algorithm and still get optimal performance. If the wave speed is varying continuously, such a result cannot hold anymore, because reflections become relevant immediately. Nevertheless, the algorithm is well defined with local transmission conditions, and we prove that it converges using energy estimates. Energy estimates are useful tools for proving well-posedness of boundary or initial boundary value problems, in particular for variable coefficients. They have been used to analyze the convergence of Schwarz algorithms in the stationary case before; see, for example, [29], [11], or [33]. We extend these techniques here to time dependent problems.

Let u be a solution of the wave equation in the interval $[a,b]$ for $t \geq 0$,

$$\frac{1}{c^2(x)}\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial x^2} = 0, \tag{4.1}$$

where $c(x)$ is now any continuous function. We define the kinetic and potential energies by

$$E_K(u)(t) := \frac{1}{2}\int_a^b \frac{1}{c^2(x)}\left(\frac{\partial u}{\partial t}(x,t)\right)^2 dx,\ E_P(u)(t) := \frac{1}{2}\int_a^b \left(\frac{\partial u}{\partial x}(x,t)\right)^2 dx \tag{4.2}$$

and the total energy by the sum $E := E_K + E_P$. Multiplying (4.1) by $\frac{\partial u}{\partial t}$ and integrating on the interval $[a,b]$ yield the following theorem.

Theorem 4.1 (continuous energy identity). *The energy identity*

$$\frac{d}{dt}[E(u)(t)] + \frac{\partial u}{\partial t}(a,t)\frac{\partial u}{\partial x}(a,t) - \frac{\partial u}{\partial t}(b,t)\frac{\partial u}{\partial x}(b,t) = 0 \tag{4.3}$$

holds for any positive time t.

4.1. Well-posedness of the continuous subdomain problems. Introducing the general progressive and regressive transport operators

$$\mathcal{T}_\alpha^+ = \frac{1}{\alpha}\frac{\partial}{\partial t} + \frac{\partial}{\partial x}, \quad \mathcal{T}_\alpha^- = \frac{1}{\alpha}\frac{\partial}{\partial t} - \frac{\partial}{\partial x}, \tag{4.4}$$

where α is a positive real number, we can rewrite (4.3) for any positive α and β as

$$\frac{d}{dt}[E(u)(t)] + \frac{\alpha}{4}\left[\mathcal{T}_\alpha^+ u(a,t)\right]^2 + \frac{\beta}{4}\left[\mathcal{T}_\beta^- u(b,t)\right]^2 = \frac{\alpha}{4}\left[\mathcal{T}_\alpha^- u(a,t)\right]^2 + \frac{\beta}{4}\left[\mathcal{T}_\beta^+ u(b,t)\right]^2. \tag{4.5}$$

Suppose that the boundary conditions (4.4) are given by

$$\mathcal{T}_\alpha^- u(a,t) = g^-(t), \quad \mathcal{T}_\beta^+ u(b,t) = g^+(t). \tag{4.6}$$

Then we get a bound on the energy on any finite time interval.

Theorem 4.2. *For the wave equation* (4.1) *on* $[a,b]$ *with boundary conditions* (4.6), *the energy* $E(u)(t)$ *on* $[a,b]$ *stays bounded for all finite time* t,

$$E(u)(t) \leq E(u)(0) + \int_0^t \left[\frac{\alpha}{4}|g^-(\tau)|^2 + \frac{\beta}{4}|g^+(\tau)|^2\right] d\tau. \tag{4.7}$$

By standard techniques (see, for example, [26]), the well-posedness is then established.

4.2. Convergence with local transmission conditions. Consider now the domain decomposition algorithm (2.2) for continuously variable wave speed $c(x)$. By linearity, it suffices to consider the homogeneous wave equation with homogeneous initial conditions and prove convergence to zero. The local transmission operators (3.10) can be expressed in terms of the transport operators (4.4),

$$\mathcal{B}_i^- = \mathcal{T}_{c(a_i)}^-, \quad \mathcal{B}_i^+ = \mathcal{T}_{c(a_{i+1})}^+, \tag{4.8}$$

where $i = 1, \ldots, I$.

THEOREM 4.3. *Suppose the velocity is continuous on the interfaces a_i. Then on any time interval $[0,T]$, the nonoverlapping Schwarz waveform relaxation algorithm, with local transmission conditions*

$$\begin{aligned} \mathcal{T}^-_{c(a_i)}(u_i^{k+1})(a_i,\cdot) &= \mathcal{T}^-_{c(a_i)}(u_{i-1}^{k})(a_i,\cdot) && \text{on } (0,T),\\ \mathcal{T}^+_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot) &= \mathcal{T}^+_{c(a_{i+1})}(u_{i+1}^{k})(a_{i+1},\cdot) && \text{on } (0,T), \end{aligned} \tag{4.9}$$

converges in the energy norm,

$$\sum_{i=1}^{I} E(u_i^k)(T) \longrightarrow 0 \text{ as } k \longrightarrow \infty.$$

Proof. We can write (4.5) on the interval $[a_i, a_{i+1}]$, with $\alpha = c(a_i)$ and $\beta = c(a_{i+1})$, which gives

$$\begin{aligned} \tfrac{d}{dt}[E(u_i^{k+1})(\cdot)] &+ \tfrac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k+1})(a_i,\cdot)\right]^2 + \tfrac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot)\right]^2\\ &= \tfrac{c(a_i)}{4}\left[\mathcal{T}^-_{c(a_i)}(u_i^{k+1})(a_i,\cdot)\right]^2 + \tfrac{c(a_{i+1})}{4}\left[\mathcal{T}^+_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot)\right]^2 \end{aligned} \tag{4.10}$$

for $1 \le i \le I$, with the convention

$$\mathcal{T}^+_{c(a_1)}(u_1^{k+1})(a_1,\cdot) = 0, \quad \mathcal{T}^-_{c(a_{I+1})}(u_I^{k+1})(a_{I+1},\cdot) = 0, \tag{4.11}$$

and by using the boundary conditions, we obtain

$$\begin{aligned} \tfrac{d}{dt}[E(u_i^{k+1})(\cdot)] &+ \tfrac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k+1})(a_i,\cdot)\right]^2 + \tfrac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot)\right]^2\\ &= \tfrac{c(a_i)}{4}\left[\mathcal{T}^-_{c(a_i)}(u_{i-1}^{k})(a_i,\cdot)\right]^2 + \tfrac{c(a_{i+1})}{4}\left[\mathcal{T}^+_{c(a_{i+1})}(u_{i+1}^{k})(a_{i+1},\cdot)\right]^2. \end{aligned} \tag{4.12}$$

Summing these equations for $1 \le i \le I$ and shifting the indices of the two sums on the right-hand side, we find

$$\begin{aligned} \sum_{i=1}^{I}\frac{d}{dt}[E(u_i^{k+1})(\cdot)] + \sum_{i=1}^{I}\frac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k+1})(a_i,\cdot)\right]^2 + \sum_{i=1}^{I}\frac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot)\right]^2\\ = \sum_{i=0}^{I-1}\frac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k})(a_{i+1},\cdot)\right]^2 + \sum_{i=2}^{I+1}\frac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k})(a_i,\cdot)\right]^2. \end{aligned} \tag{4.13}$$

Now note that by (2.3) we have $u_{I+1}^k = u_0^k = 0$ and thus $\mathcal{T}^+_{c(a_{I+1})}(u_{I+1}^k)(a_{I+1},\cdot) = \mathcal{T}^-_{c(a_1)}(u_0^k)(a_1,\cdot) = 0$. Together with (4.11), we obtain the energy equality

$$\begin{aligned} \sum_{i=1}^{I}\frac{d}{dt}[E(u_i^{k+1})(\cdot)] + \sum_{i=2}^{I}\frac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k+1})(a_i,\cdot)\right]^2 + \sum_{i=1}^{I-1}\frac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k+1})(a_{i+1},\cdot)\right]^2\\ = \sum_{i=2}^{I}\frac{c(a_i)}{4}\left[\mathcal{T}^+_{c(a_i)}(u_i^{k})(a_i,\cdot)\right]^2 + \sum_{i=1}^{I-1}\frac{c(a_{i+1})}{4}\left[\mathcal{T}^-_{c(a_{i+1})}(u_i^{k})(a_{i+1},\cdot)\right]^2. \end{aligned} \tag{4.14}$$

Now we have the same terms on the boundary, on the left for iteration step $k+1$ and on the right for iteration step k. Defining

$$\hat{E}^k(t) := \sum_{i=1}^{I} E(u_i^{k+1})(t),$$

$$\hat{E}_B^k(t) := \sum_{i=2}^{I} \frac{c(a_i)}{4} \left[\mathcal{T}_{c(a_i)}^{+}(u_i^k, \cdot)(a_i)\right]^2 + \sum_{i=1}^{I-1} \frac{c(a_{i+1})}{4} \left[\mathcal{T}_{c(a_{i+1})}^{-}(u_i^k)(a_{i+1}, \cdot)\right]^2,$$

we find the energy equality

$$\frac{d}{dt}\hat{E}^{k+1} + \hat{E}_B^{k+1} = \hat{E}_B^k \quad \text{on } (0,T),$$

and thus summing up over all iteration steps $k = 0, \ldots, K$ and denoting the sum of the energies $\hat{E}^k$ at each step by

$$E^K := \sum_{k=0}^{K} \hat{E}^k,$$

we find by cancellation of the $\hat{E}_B^k$ terms

$$\frac{d}{dt}E^K + \hat{E}_B^K = \hat{E}_B^0 \quad \text{on } (0,T).$$

Since $\hat{E}_B^K \geq 0$, we obtain

$$\frac{d}{dt}E^K \leq \hat{E}_B^0 \quad \text{on } (0,T).$$

Now integrating over $(0,T)$ and noting that $E^K(0) = 0$, we find

$$E^K(T) \leq \int_0^T \hat{E}_B^0(t)dt,$$

and thus the total energy E^K is uniformly bounded independently of the number of iterations K. Hence the energy at each iteration must go to zero, and the algorithm converges. □

5. A finite volume discretization. We discretize the wave equation (2.1) on each subdomain $\Omega_i \times (0,T)$, $i = 1, \ldots, I$, separately, using a finite volume discretization on rectangular grids. For simplicity we set $f = 0$. We allow nonmatching grids on different subdomains, with $J_i + 2$ points in space numbered from 0 up to $J_i + 1$ and $\Delta x_i = (a_{i+1} - a_i)/(J_i + 1)$ and $N_i + 1$ grid points in time with $\Delta t_i = T/N_i$ numbered from 0 up to N_i. Note that we chose for the exposition here uniform spacing in time per subdomain, but the techniques developed are not limited to this special case. We denote the numerical approximation to $u_i^k(a_i + j\Delta x_i, n\Delta t_i)$ on Ω_i at iteration step k by $U_i^k(j,n)$. To simplify the notation, we omit the index i on quantities depending on the subdomain and the index k referring to the iteration as long as we are discussing one subdomain only.

5.1. Discretization of the subdomain problem.

5.1.1. Interior points. Denoting by D the volume around a grid point ($x = a_i + j\Delta x_i, t = n\Delta t_i$) in the interior of subdomain $\Omega_i \times (0,T)$, as shown in Figure 5.1 on the left, we obtain the finite volume scheme by integrating the equation over the

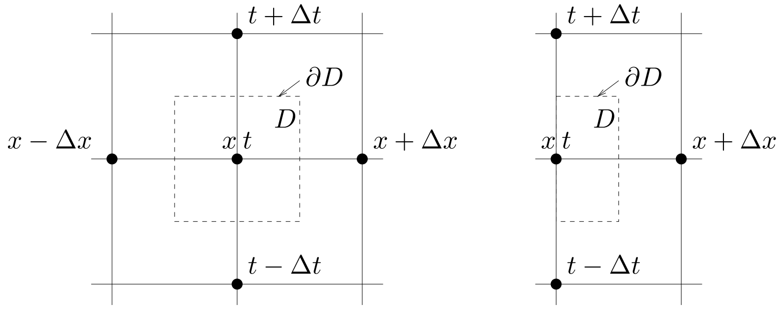

FIG. 5.1. *Control volume of an interior grid point and a boundary grid point.*

volume D and applying the divergence theorem,

$$\begin{aligned} 0 &= \int_{x-\Delta x/2}^{x+\Delta x/2}\int_{t-\Delta t/2}^{t+\Delta t/2}\left[\frac{1}{c^2(\xi)}\frac{\partial^2 u}{\partial t^2}(\xi,\tau)-\frac{\partial^2 u}{\partial x^2}(\xi,\tau)\right]d\tau d\xi \\ &= \int_{x-\Delta x/2}^{x+\Delta x/2}\frac{1}{c^2(\xi)}\frac{\partial u}{\partial t}(\xi,t+\Delta t/2)d\xi-\int_{x-\Delta x/2}^{x+\Delta x/2}\frac{1}{c^2(\xi)}\frac{\partial u}{\partial t}(\xi,t-\Delta t/2)d\xi \qquad (5.1)\\ &\quad -\int_{t-\Delta t/2}^{t+\Delta t/2}\frac{\partial u}{\partial x}(x+\Delta x/2,\tau)d\tau+\int_{t-\Delta t/2}^{t+\Delta t/2}\frac{\partial u}{\partial x}(x-\Delta x/2,\tau)d\tau. \end{aligned}$$

Now we approximate the remaining derivatives by finite differences on the grid:

$$\begin{aligned} D_t^+(U)(j,n) &:= \tfrac{U(j,n+1)-U(j,n)}{\Delta t} \approx \tfrac{\partial u}{\partial t}(\xi,t+\Delta t/2), \\ D_t^-(U)(j,n) &:= \tfrac{U(j,n)-U(j,n-1)}{\Delta t} \approx \tfrac{\partial u}{\partial t}(\xi,t-\Delta t/2), \qquad x-\tfrac{\Delta x}{2}\le\xi\le x+\tfrac{\Delta x}{2}, \\ D_x^+(U)(j,n) &:= \tfrac{U(j+1,n)-U(j,n)}{\Delta x} \approx \tfrac{\partial u}{\partial x}(x+\Delta x/2,\tau), \qquad (5.2)\\ D_x^-(U)(j,n) &:= \tfrac{U(j,n)-U(j-1,n)}{\Delta x} \approx \tfrac{\partial u}{\partial x}(x-\Delta x/2,\tau), \qquad t-\tfrac{\Delta t}{2}\le\tau\le t+\tfrac{\Delta t}{2}. \end{aligned}$$

We introduce a discrete speed function $C_i(j)$ which approximates $c(a_i+j\Delta x_i)$ through the integral relation

$$\frac{\Delta x_i}{C_i^2(j)} := \int_{x-\Delta x_i/2}^{x+\Delta x_i/2}\frac{1}{c^2(\xi)}d\xi, \qquad (5.3)$$

and we will omit the subdomain index i as long as we are on one subdomain. We thus obtain from (5.1) the discrete scheme

$$0=\frac{\Delta x}{C^2(j)}(D_t^+-D_t^-)(U)(j,n)-\Delta t(D_x^+-D_x^-)(U)(j,n),$$

which yields on using the identities $\Delta t D_t^+D_t^- = D_t^+-D_t^-$ and $\Delta x D_x^+D_x^- = D_x^+-D_x^-$ the well-known finite difference scheme

$$\left(\frac{1}{C^2(j)}D_t^+D_t^- - D_x^+D_x^-\right)(U)(j,n)=0, \quad 1\le j\le J, \qquad (5.4)$$

for points in the interior of subdomains.

5.1.2. Boundary points. So far the finite volume scheme led to a similar discretization as a finite difference scheme. On the boundary, however, the finite volume scheme leads automatically to a consistent discretization of the transmission conditions, whereas a finite difference discretization would require a special treatment. In addition, the finite volume scheme leads naturally to the correct transmission operators when using nonmatching grids in different subdomains.

Suppose the point $(x = a_i, t = n\Delta t_i)$ is on the left boundary of subdomain $\Omega_i \times (0, T)$, as shown in Figure 5.1 on the right. Then we have only half a volume D to integrate over. Proceeding as before, we obtain

$$\begin{aligned} 0 = &\int_{x}^{x+\Delta x/2} \frac{1}{c^2(\xi)} \frac{\partial u}{\partial t}(\xi, t + \Delta t/2) d\xi - \int_{x}^{x+\Delta x/2} \frac{1}{c^2(\xi)} \frac{\partial u}{\partial t}(\xi, t - \Delta t/2) d\xi \\ &- \int_{t-\Delta t/2}^{t+\Delta t/2} \frac{\partial u}{\partial x}(x + \Delta x/2, \tau) d\tau + \int_{t-\Delta t/2}^{t+\Delta t/2} \frac{\partial u}{\partial x}(x, \tau) d\tau. \end{aligned}$$

Again we can approximate $\frac{\partial u}{\partial t}$ and $\frac{\partial u}{\partial x}$ by the finite differences given in (5.2) except on the left side of the control volume where we cannot approximate $\frac{\partial u}{\partial x}(x, \tau)$ by a finite difference, since we are on the boundary and the point at $x - \Delta x$ is not available. We approximate only on the three other sides by finite differences and obtain

$$0 = \left(\frac{\Delta x}{2C^2(0)} (D_t^+ - D_t^-) - \Delta t D_x^+ \right) (U)(0, n) + \int_{t-\Delta t/2}^{t+\Delta t/2} \frac{\partial u}{\partial x}(x, \tau) d\tau. \tag{5.5}$$

Note that this equation defines the spatial derivative along the boundary, once all the grid values are known. However, to compute the grid values, we need to use the transmission condition imposed on the left boundary which also defines the spatial derivative at the boundary, since it is of the form

$$\mathcal{B}^-(u)(x, t) = \left(\frac{1}{c(x^-)} \frac{\partial u}{\partial t} - \frac{\partial u}{\partial x} \right) (x, t) = g^-(t), \tag{5.6}$$

where $g^-(t)$ is a given boundary condition. Solving for $\frac{\partial u}{\partial x}$ and integrating, we find

$$\int_{t-\Delta t/2}^{t+\Delta t/2} \frac{\partial u}{\partial x}(x, \tau) d\tau = \int_{t-\Delta t/2}^{t+\Delta t/2} \frac{1}{c(x^-)} \frac{\partial u}{\partial t}(x, \tau) d\tau - \int_{t-\Delta t/2}^{t+\Delta t/2} g^-(\tau) d\tau, \tag{5.7}$$

which gives us the missing expression for the spatial derivative in the discrete scheme (5.5). The newly introduced time derivative on the right can be approximated again by finite differences as in (5.2), on the upper part of the integral by D_t^+ and on the lower part by D_t^-. Summing those contributions, we obtain a centered finite difference,

$$D_t^0(U)(j, n) := \frac{U(j, n+1) - U(j, n-1)}{2\Delta t}, \tag{5.8}$$

and we get on denoting by $C^- := c(x^-)$ for the integral of $\frac{\partial u}{\partial x}$

$$\int_{t-\Delta t/2}^{t+\Delta t/2} \frac{\partial u}{\partial x}(x, \tau) d\tau = \frac{\Delta t}{C^-} D_t^0(U)(0, n) - \int_{t-\Delta t/2}^{t+\Delta t/2} g^-(\tau) d\tau, \tag{5.9}$$

which we insert into our scheme (5.5). Denoting the integral over the boundary condition $g^-(t)$ by

$$\Delta t G^-(n) := \int_{t-\Delta t/2}^{t+\Delta t/2} g^-(\tau)d\tau, \quad t = n\Delta t,$$

we obtain the discretization

$$0 = \left(\frac{\Delta x}{2C^2(0)} D_t^+ D_t^- - D_x^+ + \frac{1}{C^-} D_t^0\right)(U)(0,n) - G^-(n). \tag{5.10}$$

This result also defines the discrete transmission operator B^-. Comparing this with (5.6), we find (where we add now the subdomain index i for completeness)

$$B_i^-(U_i)(0,n) := \left(\frac{\Delta x_i}{2C_i^2(0)} D_t^+ D_t^- - D_x^+ + \frac{1}{C_{i-1}(J_{i-1}+1)} D_t^0\right)(U_i)(0,n), \tag{5.11}$$

where we used the fact that $C^- = C_{i-1}(J_{i-1}+1)$. Similarly, for a point (x,t) on the right boundary of a subdomain with imposed transmission condition

$$\mathcal{B}^+(u)(x,t) = \left(\frac{1}{c(x^+)}\frac{\partial u}{\partial t} + \frac{\partial u}{\partial x}\right)(x,t) = g^+(t), \tag{5.12}$$

one obtains on defining

$$\Delta t G^+(n) := \int_{t-\Delta t/2}^{t+\Delta t/2} g^+(\tau)d\tau, \quad t = n\Delta t,$$

and $C^+ := c(x^+)$ the discrete scheme

$$0 = \left(\frac{\Delta x}{2C^2(J+1)} D_t^+ D_t^- + D_x^- + \frac{1}{C^+} D_t^0\right)(U)(J+1,n) - G^+(n) \tag{5.13}$$

and thus the definition of the discrete transmission operator for subdomain i

$$B_i^+(U_i)(J_i+1,n) := \left(\frac{\Delta x_i}{2C_i^2(J_i+1)} D_t^+ D_t^- + D_x^- + \frac{1}{C_{i+1}(0)} D_t^0\right)(U_i)(J_i+1,n), \tag{5.14}$$

where we used that $C^+ = C_{i+1}(0)$.

5.1.3. Points on the initial line. Suppose $(x = a_i + j\Delta x_i, 0)$ is a grid point on the interior of the initial line of subdomain $\Omega_i \times (0,T)$. We have again half a volume D to integrate over, as shown in Figure 5.2 on the left. Integrating as before, we obtain

$$\begin{aligned} 0 = &\int_{x-\Delta x/2}^{x+\Delta x/2} \frac{1}{c^2(\xi)}\frac{\partial u}{\partial t}(\xi, \Delta t/2)d\xi - \int_{x-\Delta x/2}^{x+\Delta x/2} \frac{1}{c^2(\xi)}\frac{\partial u}{\partial t}(\xi, 0)d\xi \\ &- \int_0^{\Delta t/2} \frac{\partial u}{\partial x}(x+\Delta x/2, \tau)d\tau + \int_0^{\Delta t/2} \frac{\partial u}{\partial x}(x-\Delta x/2, \tau)d\tau. \end{aligned}$$

Now the remaining derivatives can be approximated by finite differences (5.2) except

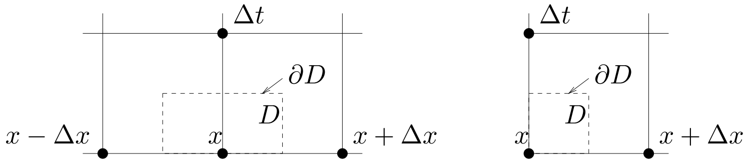

FIG. 5.2. *Control volume of a grid point on the initial line and in a corner.*

$\frac{\partial u}{\partial t}(\xi,0)$. However, this derivative is given explicitly by the initial condition, and approximating it on one grid cell by

$$\Delta x \frac{U_t(j)}{C^2(j)} := \int_{x-\Delta x/2}^{x+\Delta x/2} \frac{1}{c^2(\xi)} \frac{\partial u}{\partial t}(\xi,0)d\xi,$$

we obtain the scheme

$$\left(\frac{1}{C^2(j)}D_t^+ - \frac{\Delta t}{2}D_x^+D_x^-\right)(U)(j,0) - \frac{1}{C^2(j)}U_t(j) = 0. \tag{5.15}$$

5.1.4. Corner points. For the corner points on the initial line, there is only a quarter of the original finite volume left to integrate over. For example, on the left corner we obtain according to Figure 5.2

$$\begin{aligned} 0 = &\int_0^{\Delta x/2} \frac{1}{c^2(\xi)} \frac{\partial u}{\partial t}(\xi,\Delta t/2)d\xi - \int_0^{\Delta x/2} \frac{1}{c^2(\xi)} \frac{\partial u}{\partial t}(\xi,0)d\xi \\ &- \int_0^{\Delta t/2} \frac{\partial u}{\partial x}(\Delta x/2,\tau)d\tau + \int_0^{\Delta t/2} \frac{\partial u}{\partial x}(0,\tau)d\tau. \end{aligned}$$

Here two of the remaining derivatives can be approximated by the finite differences (5.2), whereas $\frac{\partial u}{\partial t}(\xi,0)$ is given by the initial condition and $\frac{\partial u}{\partial x}(0,\tau)$ has to be obtained from the transmission condition by proceeding as before along the boundary. We obtain the discrete scheme

$$0 = \left(\frac{\Delta x}{2C^2(0)}D_t^+ - \frac{\Delta t}{2}D_x^+ + \frac{\Delta t}{2C^-}D_t^+\right)(U)(0,0) - \frac{\Delta x}{2C^2(0)}U_t(0) - \frac{\Delta t}{2}G^-(0),$$

and thus the discrete transmission operator B^- on the initial line on the left is obtained by dividing through by $\Delta t/2$:

$$B_i^-(U_i)(0,0) = \left(\frac{\Delta x_i}{\Delta t C_i^2(0)}D_t^+ - D_x^+ + \frac{1}{C_{i-1}(J_{i-1}+1)}D_t^+\right)(U_i)(0,0) - \frac{\Delta x_i}{\Delta t C_i^2(0)}U_{t,i}(0). \tag{5.16}$$

Similarly, for the corner point on the right, we get

$$0 = \left(\frac{\Delta x}{2C^2(J+1)}D_t^+ + \frac{\Delta t}{2}D_x^- + \frac{\Delta t}{2C^+}D_t^+\right)(U)(J+1,0) - \frac{\Delta x}{2C^2(J+1)}U_t(J+1) - \frac{\Delta t}{2}G^+(0),$$

and thus the discrete transmission operator B^+ on the initial line on the right is

$$\begin{aligned} B_i^+(U_i)(J_i+1,0) = &\left(\frac{\Delta x_i}{\Delta t C_i^2(J_i+1)}D_t^+ + D_x^- + \frac{1}{C_{i+1}(0)}D_t^+\right)(U_i)(J_i+1,0) \\ &- \frac{\Delta x_i}{\Delta t C_i^2(J_i+1)}U_{t,i}(J_i+1). \end{aligned} \tag{5.17}$$

For given discrete transmission conditions $G^-(n)$ and $G^+(n)$, $n = 0, \dots, N$, the above discrete scheme describes a numerical method to solve one subproblem on one subdomain.

5.2. Extraction of the transmission conditions from neighboring subdomains. Now the boundary values $g_i^-(t)$ and $g_i^+(t)$ imposed through the transmission conditions on subdomain Ω_i have to come from the neighboring subdomains Ω_{i-1} and Ω_{i+1}. We thus need to calculate from our discrete scheme above on the neighboring subdomains the integrals

$$(5.18)\quad \int_{t_i-\Delta t_i/2}^{t_i+\Delta t_i/2} g_i^-(\tau)d\tau = \int_{t_i-\Delta t_i/2}^{t_i+\Delta t_i/2} \left[\frac{1}{c(x^-)}\frac{\partial u_{i-1}}{\partial t}(x,\tau) - \frac{\partial u_{i-1}}{\partial x}(x,\tau)\right] d\tau,$$

where (x,t) is on the right of subdomain Ω_{i-1} and similarly

$$(5.19)\quad \int_{t_i-\Delta t_i/2}^{t_i+\Delta t_i/2} g_i^+(\tau)d\tau = \int_{t_i-\Delta t/2}^{t_i+\Delta t_i/2} \left[\frac{1}{c(x^+)}\frac{\partial u_{i+1}}{\partial t}(x,\tau) + \frac{\partial u_{i+1}}{\partial x}(x,\tau)\right] d\tau,$$

where (x,t) is on the left of the subdomain Ω_{i+1}. Let us take, for example, the subdomain to the right, Ω_{i+1}. To perform the integration (5.19) we note that the numerical approximation to $\frac{\partial u_{i+1}}{\partial t}$ in the finite volume scheme is piecewise constant and according to (5.2) given by $D_t^+(U_{i+1})(0,n)$ for $t \in [n\Delta t_{i+1}, (n+1)\Delta t_{i+1})$. Similarly, the numerical approximation to $\frac{\partial u_{i+1}}{\partial x}$ is piecewise constant in the finite volume scheme. According to (5.5), it is given for $t \in [(n-\frac{1}{2})\Delta t_{i+1}, (n+\frac{1}{2})\Delta t_{i+1})$ by

$$\left(-\frac{\Delta x_{i+1}}{2\Delta t_{i+1}C_{i+1}^2(0)}(D_t^+ - D_t^-) + D_x^+\right)(U_{i+1})(0,n).$$

Inserting these two numerical approximations into (5.19), we obtain on one grid cell of Ω_{i+1}

$$\int_{(n-1/2)\Delta t_{i+1}}^{(n+1/2)\Delta t_{i+1}} g_i^+(\tau)d\tau = \left(-\frac{\Delta x_{i+1}\Delta t_{i+1}}{2C_{i+1}^2(0)}D_t^+D_t^- + \Delta t_{i+1}D_x^+ + \frac{\Delta t_{i+1}}{C_{i+1}(0)}D_t^0\right)(U_{i+1})(0,n),$$

and thus the definition of the discrete transmission operator $\widetilde{B}_i^+$ is

$$\widetilde{B}_i^+(U_{i+1})(0,n) := \left(-\frac{\Delta x_{i+1}}{2C_{i+1}^2(0)}D_t^+D_t^- + D_x^+ + \frac{1}{C_{i+1}(0)}D_t^0\right)(U_{i+1})(0,n) = \widetilde{G}_i^+(n).$$
(5.20)

Similarly, we find on the left subdomain Ω_{i-1} the discrete transmission operator $\widetilde{B}_i^-$ to be

$$\begin{aligned}\widetilde{B}_i^-(U_{i-1})(J_{i-1}+1,n) &:= \left(-\frac{\Delta x_{i-1}}{2C_{i-1}^2(J_{i-1}+1)}D_t^+D_t^- - D_x^- + \frac{1}{C_{i-1}(J_{i-1}+1)}D_t^0\right)(U_{i-1})(J_{i-1}+1,n)\\ &= \widetilde{G}_i^-(n).\end{aligned}$$
(5.21)

Note that in the discrete case $B_i^\pm$ and $\widetilde{B}_i^\pm$ are different operators, whereas in the continuous case we found the identical operator $\mathcal{B}_i^\pm$. On the initial line we find accordingly

$$\begin{aligned}
\widetilde{B}_i^+(U_{i+1})(0,0) &:= \left(-\tfrac{\Delta x_{i+1}}{\Delta t_{i+1} C_{i+1}^2(0)} D_t^+ + D_x^+ + \tfrac{1}{C_{i+1}(0)} D_t^+\right)(U_{i+1})(0,0) \\
&\quad + \tfrac{\Delta x_{i+1}}{\Delta t_{i+1} C_{i+1}^2(0)} U_t(0), \\
\widetilde{B}_i^-(U_{i-1})(J_{i-1}+1,0) &:= \left(-\tfrac{\Delta x_{i-1}}{\Delta t_{i-1} C_{i-1}^2(J_{i-1}+1)} D_t^+ - D_x^- + \tfrac{1}{C_{i-1}(J_{i-1}+1)} D_t^+\right)(U_{i-1})(J_{i-1}+1,0) \\
&\quad + \tfrac{\Delta x_{i-1}}{\Delta t_{i-1} C_{i-1}^2(J_{i-1}+1)} U_t(J_{i-1}+1),
\end{aligned} \tag{5.22}$$

and we have

$$\widetilde{B}_i^+(U_{i+1})(0,0) = \widetilde{G}_i^+(0), \quad \widetilde{B}_i^-(U_{i-1})(J_{i-1}+1,0) = \widetilde{G}_i^-(0).$$

5.3. Projections for different grids. If different grids are used on different subdomains, the extracted transmission condition $\widetilde{G}_i^+$ is a vector in $\mathbb{R}^{N_{i+1}+1}$ and $\widetilde{G}_i^-$ is a vector in $\mathbb{R}^{N_{i-1}+1}$ which both represent step functions on their corresponding grids, and what we need to impose on the boundary on Ω_i are vectors $G_i^\pm$ in $\mathbb{R}^{N_i+1}$. We thus need to introduce a projection operation to transfer the boundary values onto the grid of Ω_i. Suppose we are given a vector $\boldsymbol{v} = (v_0, \ldots, v_N) \in \mathbb{R}^{N+1}$ which represents the values of a step function on the corresponding intervals $I_n = (t_n, t_{n+1})$, where $t_0 = 0$, $t_{N+1} = T$, and $\cup_{n=0}^N \overline{I_n} = [0,T]$, and the intervals do not overlap. Then we define the scalar product on $\mathbb{R}^{N+1}$ by

$$(\boldsymbol{v}, \boldsymbol{w})_{N+1} := \sum_{n=0}^{N} |I_n| v_n w_n,$$

where $|I_n|$ denotes the length of the interval I_n. We thus obtain the induced norm on $\mathbb{R}^{N+1}$

$$||\boldsymbol{v}||_{N+1}^2 := (\boldsymbol{v}, \boldsymbol{v})_{N+1}.$$

We first define the operator $\mathbb{F} : \mathbb{R}^{N+1} \longrightarrow L^2(0,T)$, which constructs a piecewise constant function on the intervals I_n from the vector $\boldsymbol{v}$,

$$\mathbb{F} : \boldsymbol{v} \longmapsto f(t) := v_n, \quad t \in I_n.$$

Then we define the operator $\mathbb{E} : L^2(0,T) \longrightarrow \mathbb{R}^{N+1}$ which projects a given function $f(t)$ onto a vector $\boldsymbol{v} \in \mathbb{R}^{N+1}$ corresponding to a piecewise constant function in the intervals I_n:

$$\mathbb{E} : f(t) \longmapsto v_n := \frac{1}{|I_n|} \int_{I_n} f(t)dt.$$

Denoting by $\mathbb{F}_i$ and $\mathbb{E}_i$ the corresponding operators using the grid of Ω_i, we define the operator $\mathbb{P}_{i,j} : \mathbb{R}^{N_i+1} \longrightarrow \mathbb{R}^{N_j+1}$ by

$$\mathbb{P}_{i,j} := \mathbb{E}_j \circ \mathbb{F}_i. \tag{5.23}$$

A direct calculation shows that for any u in $\mathbb{R}^{N_i+1}$ we have

$$||\mathbb{P}_{i,j} u||_{N_j+1} \leq ||u||_{N_i+1}, \tag{5.24}$$

which is a natural consequence of the L^2 projection on piecewise constant functions. To perform the projection $\mathbb{P}_{i,j}$ between arbitrary grids is a nontrivial task, since one needs to find the intersections of corresponding arbitrary grid cells. For one dimension however, there is a short, concise algorithm; see the appendix.

5.4. The discrete Schwarz waveform relaxation algorithm. We obtain the discrete Schwarz waveform relaxation algorithm on subdomains Ω_i, $i = 1, \dots, I$, with nonmatching grids

$$\begin{aligned}
\left(\tfrac{1}{C_i^2(j)}D_t^+D_t^- - D_x^+D_x^-\right)(U_i^{k+1})(j,n) &= 0, \quad 1 \le j \le J_i,\ 1 \le n \le N_i,\\
\left(\tfrac{1}{C_i^2(j)}D_t^+ - \tfrac{\Delta t_i}{2}D_x^+D_x^-\right)(U_i^{k+1})(j,0) - \tfrac{1}{C_i^2(j)}U_{t,i}(j) &= 0, \quad 1 \le j \le J_i,\\
B_i^-(U_i^{k+1})(0,\cdot) &= \mathbb{P}_{i-1,i}\widetilde{B}_i^-(U_{i-1}^k)(J_{i-1}+1,\cdot),\\
B_i^+(U_i^{k+1})(J_i+1,\cdot) &= \mathbb{P}_{i+1,i}\widetilde{B}_i^+(U_{i+1}^k)(0,\cdot),
\end{aligned} \tag{5.25}$$

where the operators $\mathbb{P}_{i\pm1,i}$ are defined in (5.23), the discrete transmission operators $B_i^\pm$ for $n \ge 1$ are given in (5.11), (5.14), and the extraction operators $\widetilde{B}_i^\pm$ are for $n \ge 1$ given in (5.20), (5.21). For $n = 0$ the corresponding operators are given in (5.16), (5.17), and (5.22). For conforming grids with these transmission conditions, the solution obtained at convergence satisfies the finite volume discretization scheme without decomposition, as one can see by taking the difference of $B_i^\pm$ and $\widetilde{B}_i^\pm$. For example, for constant wave speed across the interface we obtain

$$B_i^+ - \widetilde{B}_i^+ = \frac{\Delta x}{C^2}D_t^+D_t^- + D_x^- - D_x^+ = \Delta x\left(\frac{1}{C^2}D_t^+D_t^- - D_x^-D_x^+\right),$$

which is the discretized wave operator (5.4). For nonconforming grids, (5.25) defines the solution when converged. For a different definition of a solution on nonmatching grids, see [10].

6. Normal mode analysis and convergence proof for piecewise constant wave speed and two subdomains.

We consider two subdomains $\Omega_i, i = 1, 2$, with piecewise constant velocity c_i per subdomain. We discretize the problem on each subdomain in space with spatial discretization parameter Δx_i, and we keep the time discretization uniform across the subdomains with discretization parameter Δt. Then there is no projection in the transmission operators in (5.25). We denote by γ_i the Courant–Friedrichs–Lewy (CFL) number in the corresponding subdomain Ω_i,

$$\gamma_i = c_i\frac{\Delta t}{\Delta x_i}. \tag{6.1}$$

For the stability of the Cauchy problem, we suppose that $\gamma_i < 1$ [39]. By linearity it suffices to analyze algorithm (5.25) for homogeneous initial conditions and to prove convergence to zero. To avoid the special case of the interface conditions for $n = 0$ in the analysis, we set $U(j,0) = U(j,1) = 0$, which corresponds to initial conditions $u(x,0) = u_t(x,0) = 0$.

6.1. Discrete Laplace transforms.

The discrete Laplace transform of a grid function $v = \{v_n\}_{n\ge0}$ on a regular grid with time step Δt is defined for $\eta > 0$ by [39]

$$\mathcal{L}v(s) = \hat{v}(s) = \frac{1}{\sqrt{2\pi}}\Delta t\sum_{n\ge0} e^{-sn\Delta t}v_n, \quad s = \eta + i\tau,\ |\tau| \le \frac{\pi}{\Delta t}, \tag{6.2}$$

and the inversion formula is given by

$$v_n = \frac{1}{\sqrt{2\pi}}\int_{-\frac{\pi}{\Delta t}}^{\frac{\pi}{\Delta t}} e^{sn\Delta t}\hat{v}(s)d\tau = -\frac{i}{\sqrt{2\pi}}\int_{|z|=e^{\eta\Delta t}} z^{n-1}\hat{v}(z)dz.$$

The corresponding norms are

$$(6.3)\qquad ||v||_{\eta,\Delta t} = \left(\Delta t \sum_{n\geq 0} e^{-2\eta n\Delta t}|v_n|^2\right)^{\frac{1}{2}}, \qquad ||\hat{v}||_\eta = \left(\int_{-\frac{\pi}{\Delta t}}^{\frac{\pi}{\Delta t}} |\hat{v}(\eta + i\tau)|^2 d\tau\right)^{\frac{1}{2}},$$

and we have Parseval's equality

$$(6.4)\qquad ||v||_{\eta,\Delta t} = ||\hat{v}||_\eta.$$

Suppose $U(j,n)$ is a solution of the difference equation

$$(6.5)\qquad \left(\frac{1}{C^2}D_t^+D_t^- - D_x^+D_x^-\right)(U)(j,n) = 0$$

with the initial condition $U(j,0) = U(j,1) = 0$. We denote by $\hat{U}(j,s)$ the discrete Laplace transform in time of $U(j,n)$. Equation (6.5) becomes the difference equation

$$(6.6)\qquad \gamma^2\hat{U}(j-1,s) - 2(\gamma^2 + h(z))\hat{U}(j,s) + \gamma^2\hat{U}(j+1,s) = 0,$$

with $z = e^{s\Delta t}$, $h(z) = \frac{1}{2}(z + \frac{1}{z}) - 1$, and $\gamma = c\Delta t/\Delta x$. The solutions of (6.6) are formed by powers of the roots of the second order equation

$$(6.7)\qquad \gamma^2r^2 - 2(\gamma^2 + h(z))r + \gamma^2 = 0.$$

We need several technical lemmas about these roots.

LEMMA 6.1. *For $\eta = 0$ and $\tau = 0$, (6.7) has one double root $r_\pm = 1$. For $\eta = 0$ and $|\sin(\frac{\tau\Delta t}{2})| = \gamma$, (6.7) has one double root $r_\pm = -1$.*

Proof. One can do the analysis on a case by case basis. □

LEMMA 6.2. *For $|z| > 1$ (i.e., $\eta > 0$), (6.7) has one root r_- whose modulus is strictly less than 1 and one root r_+ whose modulus is strictly bigger than 1.*

Proof. The discriminant of (6.7) is

$$(6.8)\qquad \Delta = h(z)(2\gamma^2 + h(z)),$$

and for it to vanish we have the sequence of necessary and sufficient conditions

$$\begin{aligned} \Delta = 0 \quad &\Longleftrightarrow \quad h(z) = 0 \quad \text{or} \quad 2\gamma^2 + h(z) = 0 \\ &\Longleftrightarrow \quad z = 1 \quad \text{or} \quad z + \tfrac{1}{z} - 2 + 4\gamma^2 = 0 \\ &\Longleftrightarrow \quad z = 1 \quad \text{or} \quad z = 1 - 2\gamma^2 \pm 2i\gamma\sqrt{1-\gamma^2}. \end{aligned}$$

In both cases $|z| = 1$, as a short computation in the second case shows, and $|z| = 1$ is excluded in this lemma and treated in Lemma 6.3. Hence for $|z| > 1$ there are two distinct roots whose product equals 1. Therefore, either they are a complex conjugate of modulus 1 or one is of modulus strictly bigger than 1 whereas the other is of modulus strictly less than 1. It thus remains to exclude the complex conjugate case. We find

$$\bar{r} = \frac{1}{r} \iff r + \bar{r} = r + \frac{1}{r} \iff \frac{\gamma^2 + h(z)}{\gamma^2} \in \mathbb{R} \iff h(z) \in \mathbb{R},$$

$$\bar{r} = \frac{1}{r} \iff z + \frac{1}{z} \in \mathbb{R} \iff \eta\Delta t = 0 \text{ or } \tau\Delta t = 0, \pm\pi.$$

If $\eta = 0$, we have $|z| = 1$, which is again excluded by the conditions of the lemma. If, on the other hand, $\tau\Delta t = 0$, we compute the real part of the root r and obtain

$$\Re(r) = 1 + \frac{h(z)}{\gamma^2} = 1 + \frac{2}{\gamma^2}\sinh^2\left(\frac{\eta\Delta t}{2}\right) \geq 1,$$

and if $\tau\Delta t = \pm\pi$, we have

$$\Re(r) = 1 - \frac{2}{\gamma^2}\cosh^2\left(\frac{\eta\Delta t}{2}\right) \leq -1,$$

and in both cases $|r| > 1$, a contradiction which excludes this case as well and hence proves the lemma. ◻

LEMMA 6.3. *For $|z| = 1$ (i.e., $\eta = 0$) and $|\sin(\frac{\tau\Delta t}{2})|$ different from 0 and γ, (6.7) has two distinct roots r_- and r_+,*

$$r_\pm = \begin{cases} \frac{1}{\gamma^2}\left[\gamma^2 - 2\sin^2(\frac{\tau\Delta t}{2}) \pm 2i\sin(\frac{\tau\Delta t}{2})\sqrt{\gamma^2 - \sin^2(\frac{\tau\Delta t}{2})}\right] & \textit{if } |\sin(\frac{\tau\Delta t}{2})| < \gamma, \\ \frac{1}{\gamma^2}\left[\gamma^2 - 2\sin^2(\frac{\tau\Delta t}{2}) \mp 2\,|\sin(\frac{\tau\Delta t}{2})|\sqrt{-\gamma^2 + \sin^2(\frac{\tau\Delta t}{2})}\right] & \textit{if } |\sin(\frac{\tau\Delta t}{2})| > \gamma. \end{cases}$$

Proof. For $\eta = 0$, one can compute the roots directly. The only difficulty is the determination of the signs in front of the square root. In the case $|\sin(\frac{\tau\Delta t}{2})| < \gamma$, the roots are complex conjugate. We compute the roots $r_\pm(z)$ for $z = (1+\epsilon)z_0$ with $z_0 = e^{i\theta}$ and let ϵ tend to zero. The sign is then defined by continuity. For $|\sin(\frac{\tau\Delta t}{2})| > \gamma$, there are two real roots, and the sign is determined by the fact that $|r_+| > 1$ and $|r_-| < 1$. ◻

LEMMA 6.4. *For z real positive, which corresponds to $\tau\Delta t = 0$, we have*

$$r_\pm = \frac{1}{\gamma^2}\left[\gamma^2 + 2\sinh^2\left(\frac{\eta\Delta t}{2}\right) \pm 2\sinh\left(\frac{\eta\Delta t}{2}\right)\sqrt{\gamma^2 + \sinh^2\left(\frac{\eta\Delta t}{2}\right)}\right],$$

and $0 < r_- < 1$, $r_+ > 1$.

For z real negative, which corresponds to $\tau\Delta t = \pi$, we have

$$r_\pm = \frac{1}{\gamma^2}\left[\gamma^2 - 2\cosh^2\left(\frac{\eta\Delta t}{2}\right) \mp 2\cosh\left(\frac{\eta\Delta t}{2}\right)\sqrt{-\gamma^2 + \cosh^2\left(\frac{\eta\Delta t}{2}\right)}\right],$$

and $-1 < r_- < 0$, $r_+ < -1$.

Proof. For $\tau\Delta t = 0, \pm\pi$, which means z real, one can do the analysis on a case by case basis. ◻

In all cases except for Lemma 6.1, there are functions $a_+(s)$ and $a_-(s)$ such that for all j the solution of (6.6) is given by

$$\hat{U}(j,s) = a_+(s)r_+^j + a_-(s)r_-^j. \tag{6.9}$$

In the case of Lemma 6.1 there exist functions $a(s)$ and $b(s)$ such that for all j

$$\hat{U}(j,s) = (a(s)j + b(s))r_\pm^j.$$

6.2. The discrete homogeneous subdomain problem. We consider, for example, the problem posed in Ω_1, with a nonhomogeneous boundary condition of type B_1^+,

$$\begin{aligned}
\left(\frac{1}{C^2}D_t^+D_t^- - D_x^+D_x^-\right)(U)(j,n) &= 0, && -\infty < j < 0,\ n \geq 1,\\
U(j,0) &= U(j,1) = 0, && -\infty < j < 0,\\
\left(\frac{\Delta x}{2C^2}D_t^+D_t^- + D_x^- + \frac{1}{\alpha C}D_t^0\right)(U)(0,n) &= g(n), && n \geq 1,
\end{aligned} \tag{6.10}$$

where α is a given, strictly positive real number. Applying the discrete Laplace transform, we obtain with the results of the previous subsection that every solution bounded in space is of the form

$$\hat{U}(j,s) = a_+(s)r_+^j.$$

Applying the discrete Laplace transform to the boundary condition, we get

$$\left(\frac{\Delta x}{C^2\Delta t^2}h(z) + \frac{1}{\Delta x}(1-r_-) + \frac{1}{\alpha C\Delta t}\left(z - \frac{1}{z}\right)\right)\hat{U}(0,s) = \hat{g}(s),$$

and introducing the notation

$$k(z) = \frac{1}{2}\left(z - \frac{1}{z}\right), \quad E(z,\gamma,\alpha) = \frac{1}{\gamma^2}h(z) + 1 - r_- + \frac{1}{\alpha\gamma}k(z), \tag{6.11}$$

the boundary condition becomes $E(z,\gamma,\alpha)a_+(s) = \Delta x\hat{g}(s)$. We call the problem well-posed in the sense of Gustafsson, Kreiss, and Sundstrom (GKS) if the preceding equation is invertible for all z with $|z| \geq 1$. If z_0 is such that $E(z_0,\gamma,\alpha) = 0$, we call z_0 a generalized eigenvalue [39].

THEOREM 6.5. *If $\gamma < 1$ and $|z| \geq 1$ with $z \neq 1$, then for any strictly positive α, $E(z,\gamma,\alpha) \neq 0$. The only generalized eigenvalues are $z = 1$ and if $\gamma = 1$, $z = -1$.*

Proof. Using the relation $r_+ + r_- = \frac{2}{\gamma^2}(\gamma^2 + h(z))$ satisfied by the roots of (6.7), we find

$$E(z,\gamma,\alpha) = \frac{1}{2}(r_+ - r_-) + \frac{k(z)}{\alpha\gamma}. \tag{6.12}$$

For $z = 1$ we obtain by Lemma 6.1 that $E(1,\gamma,\alpha) = 0$. If $\gamma = 1$, we also get for $z = -1$ by Lemma 6.1 that $E(-1,\gamma,\alpha) = 0$. We have to show now that there are no other generalized eigenvalues. For any generalized eigenvalue z, we must have $E(z,\gamma,\alpha) = 0$, which means

$$\frac{r_+ - r_-}{2} = -\frac{k(z)}{\alpha\gamma}. \tag{6.13}$$

Squaring both sides and using the relations of the roots r_+ and r_- of the quadratic equation (6.7) to the coefficients of that equation, we obtain

$$\frac{k^2(z)}{\alpha^2\gamma^2} = \frac{1}{4}(r_+ - r_-)^2 = \frac{1}{4}\left((r_+ + r_-)^2 - 4r_+r_-\right) = \frac{(\gamma^2 + h(z))^2}{\gamma^4} - 1 = \frac{h(z)\cdot(2\gamma^2 + h(z))}{\gamma^4}.$$

Inserting the definitions of $h(z)$ from (6.6) and $k(z)$ from (6.11) and factoring, we obtain that in order to be a generalized eigenvalue, z has to satisfy the following equation:

$$(z-1)^2\left((\gamma^2 - \alpha^2)z^2 + 2(\alpha^2 - 2\alpha^2\gamma^2 + \gamma^2)z + \gamma^2 - \alpha^2\right) = 0. \tag{6.14}$$

The first factor contains the generalized eigenvalue $z = 1$ we have found earlier. For $\gamma = 1$ the second factor contains the generalized eigenvalue $z = -1$, and for $\alpha = 1$ it contains again the generalized eigenvalue $z = 1$. It remains to show that for $\gamma < 1$ and $\alpha \neq 1$ the solutions of the second factor are introduced by the squaring, and they are not solutions to the original equation (6.13) and therefore not generalized eigenvalues. To do this, we perform the change of variables

$$a^2 = \frac{1}{\gamma^2} - 1, \quad \epsilon b^2 = \frac{1}{\alpha^2} - 1$$

with $\epsilon = \pm 1$, $\epsilon(\frac{1}{\alpha^2} - 1) > 0$, $a > 0$, $b > 0$ in the second factor of (6.14). Note that we exclude the case $b = 0 \Leftrightarrow \alpha = 1$ because then the only solution is $z = 1$. We obtain after the change of variables for the second factor of (6.14)

$$(\epsilon b^2 - a^2)z^2 + 2(\epsilon b^2 + a^2)z + \epsilon b^2 - a^2 = 0$$

or, equivalently,

$$\epsilon b^2(z+1)^2 = a^2(z-1)^2.$$

Now if $\epsilon = +1$, the only root with modulus greater than or equal to 1 is

$$z_1 = \frac{a+b}{a-b}.$$

Using Lemma 6.4, we see that the signs of $(r_+ - r_-)(z_1)$ and $k(z_1)$ are equal, which contradicts (6.13), and thus z_1 is not a generalized eigenvalue; $E(z_1) \neq 0$. If $\epsilon = -1$, there are two complex conjugate roots of modulus 1,

$$z_1 = \frac{a - ib}{a + ib} = e^{i\tau\Delta t}, \quad z_2 = \frac{a + ib}{a - ib} = e^{-i\tau\Delta t}.$$

To apply Lemma 6.3 we need to check that $|\sin(\tau\Delta t/2)|$ is different from 0 and γ. To do so, note that the real part of both z_1 and z_2 is given by $\cos\tau\Delta t = \frac{a^2-b^2}{a^2+b^2}$, and thus we obtain for $|\sin(\tau\Delta t/2)|$

$$\sin^2\frac{\tau\Delta t}{2} = \frac{1}{2} - \frac{1}{2}\cos(\tau\Delta t) = \frac{b^2}{a^2+b^2} > 0.$$

Now since $\epsilon = -1$, we have $b^2 < 1$, and therefore

$$\sin^2\frac{\tau\Delta t}{2} = \frac{b^2}{a^2+b^2} < \frac{1}{a^2+1} = \gamma^2.$$

Hence the first case of Lemma 6.3 applies and we obtain

$$r_+ - r_- = \frac{4i}{\gamma^2}\sin\left(\frac{\tau\Delta t}{2}\right)\sqrt{\gamma^2 - \sin^2\frac{\tau\Delta t}{2}}, \quad k(z) = 2i\sin\tau\Delta t,$$

which again contradicts (6.13) because of the sign. The results for z_2 are the same with a sign change. □

The values $z = 1$ (and $z = -1$ if $\gamma = 1$) are the generalized eigenvalues in the sense of GKS. Following the analysis of Trefethen [40], they correspond to stationary solutions which propagate at the same time toward the left and the right. We will see that this does not affect the convergence of the Schwarz method.

6.3. Convergence rate. We denote by $\hat{U}_i^k(j,s)$, $i=1,2$ the discrete Laplace transforms in time of the iterates $U_i^k(j,n)$, $i=1,2$, in algorithm (5.25). We obtain with the results from subsection 6.1

$$\hat{U}_1^k(j,s)=\hat{U}_1^k(0,s)r_{1,+}^j, \qquad \hat{U}_2^k(j,s)=\hat{U}_2^k(0,s)r_{2,-}^j, \tag{6.15}$$

where $r_{i,+}$and $r_{i,-}$ are the roots of the second order equation (6.7) defined in each subdomain,

$$\gamma_i^2 r^2 - 2(\gamma_i^2+h(z))r+\gamma_i^2=0, \quad \text{with } \gamma_i = c_i\tfrac{\Delta t}{\Delta x_i}.$$

The coefficients $\hat{U}_1^k(0,s)$ and $\hat{U}_2^k(0,s)$ are determined iteratively by the Laplace transform of the transmission conditions in (5.25). The discrete transmission operators in the Laplace transformed domain are given by

$$\begin{array}{rcccl} b_1^+(z) &=& E(z,\gamma_1,c_2/c_1) &=& \dfrac{1}{\gamma_1^2}h(z)+1-r_{1,-}+\dfrac{c_1}{c_2\gamma_1}k(z),\\ \widetilde{b}_1^+(z) &=& -E(z,\gamma_2,1) &=& -\dfrac{1}{\gamma_2^2}h(z)-1+r_{2,-}+\dfrac{1}{\gamma_2}k(z),\\ b_2^-(z) &=& E(z,\gamma_2,c_1/c_2) &=& \dfrac{1}{\gamma_2^2}h(z)+1-r_{2,-}+\dfrac{c_2}{c_1\gamma_2}k(z),\\ \widetilde{b}_2^-(z) &=& -E(z,\gamma_1,1) &=& -\dfrac{1}{\gamma_1^2}h(z)-1+r_{1,-}+\dfrac{1}{\gamma_1}k(z). \end{array} \tag{6.16}$$

The transmission conditions impose therefore

$$\frac{1}{\Delta x_1}b_1^+(z)\hat{U}_1^{k+1}(0,s)=\frac{1}{\Delta x_2}\widetilde{b}_1^+(z)\hat{U}_2^k(0,s),$$
$$\frac{1}{\Delta x_2}b_2^-(z)\hat{U}_2^{k+1}(0,s)=\frac{1}{\Delta x_1}\widetilde{b}_2^-(z)\hat{U}_1^k(0,s).$$

Inserting the second equation at iteration k into the first one, we find

$$\hat{U}_1^{k+1}(0,s)=\frac{\widetilde{b}_1^+(z)}{b_1^+(z)}\frac{\widetilde{b}_2^-(z)}{b_2^-(z)}\hat{U}_1^{k-1}(0,s)$$

and a similar relation for $\hat{U}_2^{k+1}(0,s)$. Defining

$$\sigma(z,\gamma)=\frac{1}{\gamma^2}h(z)+1-r_-=\frac{1}{2}(r_+-r_-), \quad \rho(z,\gamma,q)=\frac{-\sigma(z,\gamma)+\frac{1}{\gamma}k(z)}{\sigma(z,\gamma)+\frac{q}{\gamma}k(z)}, \tag{6.17}$$

we obtain for the convergence rate of the discrete Schwarz waveform relaxation algorithm

$$R(z,\gamma_1,\gamma_2,c_1/c_2):=\frac{\widetilde{b}_1^+(z)}{b_1^+(z)}\frac{\widetilde{b}_2^-(z)}{b_2^-(z)}=\rho(z,\gamma_2,c_2/c_1)\rho(z,\gamma_1,c_1/c_2), \tag{6.18}$$

and by induction we find

$$\hat{U}_i^{2k}(0,s)=R^k\hat{U}_i^0(0,s), \quad i=1,2. \tag{6.19}$$

LEMMA 6.6. *The convergence rate $R(z,\gamma_1,\gamma_2,c_1/c_2)$ is an analytic function of z for $|z|\geq 1$.*

Proof. By Theorem 6.5, for $\gamma < 1$, $z = 1$ is the only root of $E(z, \gamma, \alpha)$ such that $|z| \geq 1$. Furthermore, a Taylor expansion shows that it is a simple root; for z close to 1 we have

$$E(z, \gamma, \alpha) \approx \frac{\alpha + 1}{\alpha\gamma}(z - 1).$$

With (6.16) and (6.18) we see that $z = 1$ is only an apparent pole for R, which concludes the proof. □

Since R is analytic for $|z| \geq 1$, which corresponds to $\eta \geq 0$, R satisfies a maximum principle for $\eta \geq 0$ and hence attains its maximum on the boundary $\eta = 0$. It therefore suffices to study the behavior of R for $\eta = 0$, and we do this by studying the factors $\rho(z, \gamma, q)$ for $\eta = 0$. Setting $\omega := \frac{\tau\Delta t}{2}$, we consider ω varying between 0 and $\frac{\pi}{2}$. (The same computations apply for negative ω.) For $\eta = 0$ we have the explicit formulas

$$\rho(z, \gamma, q) = \begin{cases} \dfrac{-\sqrt{\gamma^2 - \sin^2\omega} + \gamma\cos\omega}{\sqrt{\gamma^2 - \sin^2\omega} + q\gamma\cos\omega} & \text{if } \sin\omega < \gamma, \\[2ex] \dfrac{\sqrt{\sin^2\omega - \gamma^2} + i\gamma\cos\omega}{-\sqrt{\sin^2\omega - \gamma^2} + iq\gamma\cos\omega} & \text{if } \sin\omega > \gamma, \\[2ex] \dfrac{1}{q} & \text{if } \sin\omega = \gamma. \end{cases}$$

To find a first necessary condition for convergence of the Schwarz method, we choose ω_1 such that $\sin\omega_1 = \gamma_1$, $\omega_1 \in (0, \frac{\pi}{2})$, and $q = \dfrac{c_1}{c_2}$. We obtain for the convergence rate at $\eta = 0$

$$R = \frac{1}{q}\begin{cases} \dfrac{\gamma_2\cos\omega_1 - \sqrt{\gamma_2^2 - \gamma_1^2}}{\gamma_2\cos\omega_1 + q\sqrt{\gamma_2^2 - \gamma_1^2}} & \text{if } \gamma_1 < \gamma_2, \\[2ex] \dfrac{i\gamma_2\cos\omega_1 + \sqrt{\gamma_2^2 - \gamma_1^2}}{i\gamma_2\cos\omega_1 - q\sqrt{\gamma_2^2 - \gamma_1^2}} & \text{if } \gamma_1 > \gamma_2. \end{cases}$$

In the first case, R is a real number strictly between 0 and 1, and in the second case, if $q < 1$, $|R| > 1$. We therefore have the following theorem.

THEOREM 6.7. *If the convergence rate R given in* (6.18) *of the discrete Schwarz waveform relaxation algorithm is bounded by* 1 *for all z of modulus larger than or equal to* 1, *then*

$$(c_1 - c_2)(\gamma_1 - \gamma_2) \geq 0; \tag{6.20}$$

in other words, $c_1 > c_2$ implies $\gamma_1 \geq \gamma_2$.

We now study the variations of $|\rho(z, \gamma, q)|$ for $\eta = 0$ as a function of ω. An example is shown in Figure 6.1 for the case $\gamma_1 < \gamma_2$ and $q = c_1/c_2 < 1$. The complete results are obtained by explicitly computing the derivatives and are summarized in Table 6.1. They rely on

$$\frac{d}{dz}\rho(z, \gamma, q) = \frac{(q + 1)(\gamma^2 - 1)}{\gamma^5}\frac{h(z)^2}{z\sigma(z)(\sigma(z) + \frac{q}{\gamma}k(z))^2}, \tag{6.21}$$

where h is given in (6.6), k in (6.11), and σ in (6.17). For $\omega \leq \arcsin(\gamma_2)$, we have

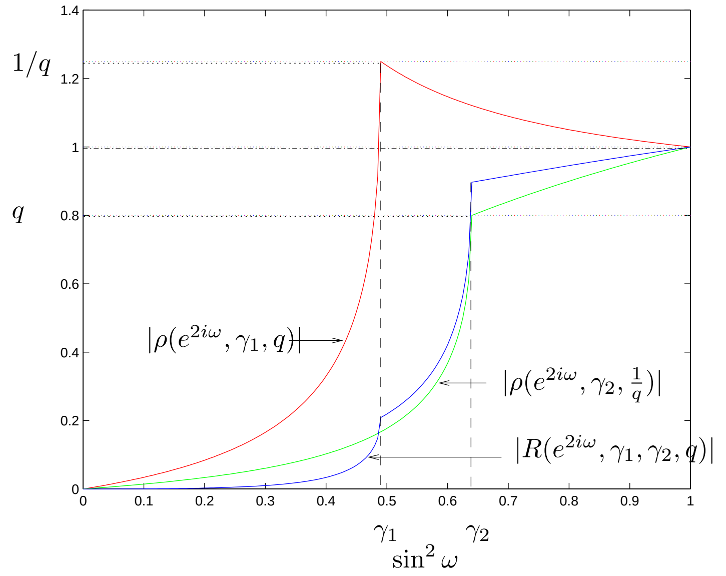

FIG. 6.1. *Example of the dependence of* $|\rho(e^{2i\omega},\gamma,q)|$ *as a function of* ω *at* $\eta=0$*,* $q=c_1/c_2$*.*

TABLE 6.1
Behavior of $|\rho(e^{2i\omega},\gamma,q)|$ *as a function of* $\omega>0$ *for* $\eta=0$*.*

	$\omega=0$	$0<\sin(\omega)<\gamma$	$\sin(\omega)=\gamma$	$\gamma<\sin(\omega)<1$	$\sin(\omega)=1$
$q<1$	0	$\nearrow$	$1/q$	$\searrow$	1
$q>1$	0	$\nearrow$	$1/q$	$\nearrow$	1

$|\rho(e^{2i\omega},\gamma_1,q)|\le 1/q$ and $|\rho(e^{2i\omega},\gamma_2,\frac{1}{q})|\le q$. By (6.21), a final explicit computation shows that the modulus of R is an increasing function of ω for $\omega\ge\arcsin(\gamma_2)$ and

$$\sup_{\omega\in[0,\frac{\pi}{2}]}|R(e^{2i\omega},\gamma_1,\gamma_2,q)|=|R(-1,\gamma_1,\gamma_2,q)|=1. \tag{6.22}$$

We therefore have the following theorem.

THEOREM 6.8. *For* $(c_1-c_2)(\gamma_1-\gamma_2)\ge 0$ *the convergence rate* $R(z,\gamma_1,\gamma_2,c_1/c_2)$ *satisfies*

$$\sup_{|z|=1}|R(z,\gamma_1,\gamma_2,c_1/c_2)|=1.$$

For purely propagating modes, $\eta=0$*, the convergence rate equals* 1*.*

For $\eta>0$, however, we have the following convergence result.

THEOREM 6.9. *For* $(c_1-c_2)(\gamma_1-\gamma_2)\ge 0$ *and* $\eta>0$ *fixed, there exists a constant* K *strictly positive such that, for* $\eta\Delta t$ *sufficiently small but nonzero, the convergence rate satisfies*

$$\sup_{|z|=e^{\eta\Delta t}}|R(z,\gamma_1,\gamma_2,c_1/c_2)|\le 1-K\eta\Delta t.$$

Proof. By (6.21) we can calculate the derivative of $|\rho|$ with respect to $\eta\Delta t$ and get

$$\frac{d}{d(\eta\Delta t)}(|\rho(z,\gamma,q)|^2)\bigg|_{\eta\Delta t=0}=2\frac{(q+1)(\gamma^2-1)}{\gamma^5}\Re\frac{h(z)^2\bar{\rho}(z)}{\sigma(z)(\sigma(z)+\frac{q}{\gamma}k(z))^2}.$$

For $\eta\Delta t = 0$, h is real, k is purely imaginary, and by Lemma 6.3 we have the explicit value of σ which is purely imaginary for $\sin(\omega) < \gamma$ and real negative for $\sin(\omega) > \gamma$. We thus have

$$\begin{cases} \frac{d}{d(\eta\Delta t)}(|\rho(z,\gamma,q)|^2)\Big|_{\eta\Delta t=0} = 0 & \text{if } \sin(\omega) < \gamma, \\ \frac{d}{d(\eta\Delta t)}(|\rho(z,\gamma,q)|^2)\Big|_{\eta\Delta t=0} < 0 & \text{if } \sin(\omega) > \gamma, \end{cases}$$

which together with (6.22) gives the desired result. □

6.4. Convergence of the discrete Schwarz waveform relaxation algorithm.

We introduce the discrete norms in space and time

$$||U||_{\Omega_i,\eta,\Delta t} = \left(\Delta t\Delta x_i \sum_{j\in\Omega_i}\sum_{n\geq 0} e^{-2\eta n\Delta t}|U(j,n)|^2\right)^{\frac{1}{2}}. \tag{6.23}$$

Theorem 6.10. *Let U_i^p be the iterates of algorithm* (5.25). *For* $(c_1-c_2)(\gamma_1-\gamma_2) \geq 0$ *there exists a positive constant K such that for $\eta\Delta t$ sufficiently small but nonzero, we have*

$$||U_i^p||_{\Omega_i,\eta,\Delta t} \leq (1-K\eta\Delta t)^{\lfloor \frac{p}{2}\rfloor} \max_{i=1,2} ||U_i^0||_{\Omega_i,\eta,\Delta t}.$$

Proof. By (6.15) and (6.19), we have $\hat{U}_i^{2k}(j,s) = R^k\hat{U}_i^0(j,s)$ for any j,s and therefore

$$\begin{aligned} ||U_i^{2k}||^2_{\Omega_i,\eta,\Delta t} &= \int_{|z|=e^{\eta\Delta t}} |R(z)|^{2k}||\hat{U}_i^0(z)||^2_{\Omega_i}dz \leq \sup_{|z|=e^{\eta\Delta t}}|R(z)|^{2k}\int_{|z|=e^{\eta\Delta t}}||\hat{U}^0(z)||^2_{\Omega_1}dz \\ &\leq \sup_{|z|=e^{\eta\Delta t}}|R(z)|^{2k}||U_i^0||^2_{\Omega_i,\eta,\Delta t} \ \leq\ (1-K\eta\Delta t)^{2k}||U_i^0||^2_{\Omega_i,\eta,\Delta t}. \end{aligned}$$

A similar argument holds for U_i^{2k+1}. □

7. Energy estimates and convergence proof for continuous wave speed.

We consider here the case of I subdomains, with a continuous velocity, and nonuniform grids in space and time. We use the same approach as in the continuous case to prove convergence of the discrete domain decomposition algorithm. Such estimates have been used in [21] in the context of discrete absorbing boundary conditions for the wave equation and in [10] to prove stability for a nonuniform scheme.

7.1. Stability for the discrete subdomain problem.

Let $U(j,n)$ for $0 \leq j \leq J+1$ and $0 \leq n \leq N$ solve the leap-frog scheme

$$\frac{1}{C^2(j)}D_t^+D_t^-(U)(j,n) - D_x^+D_x^-(U)(j,n) = 0, \quad 1 \leq j \leq J. \tag{7.1}$$

Here n stands for the discrete time variable and j for the discrete space variable. We define a discrete energy. First, we denote by $V = \{V(j)\}_{0\leq j\leq J+1}$ a sequence in $\mathbb{R}^{J+2}$, and we define for $V, W \in \mathbb{R}^{J+2}$ a bilinear form on $\mathbb{R}^{J+2}$ by

$$a_h(V,W) = \frac{\Delta x}{2}\sum_{j=1}^{J+1} D_x^-(V)(j)\cdot D_x^-(W)(j). \tag{7.2}$$

Accordingly, for any positive n, $V(n)$ stands for the sequence $\{V(j,n)\}_{0\leq j\leq J+1}$. The discrete energy E_n at time step n, global in space, is defined as the sum of a discrete kinetic energy $E_{K,n}$ and a discrete potential energy $E_{P,n}$ given by

$$\begin{aligned} E_{K,n} &= \frac{\Delta x}{2}\left[\frac{1}{2C^2(0)}(D_t^-(V)(0,n))^2 + \sum_{j=1}^{J}\frac{1}{C^2(j)}(D_t^-(V)(j,n))^2 \right. \\ &\qquad\qquad \left. + \frac{1}{2C^2(J+1)}(D_t^-(V)(J+1,n))^2\right], \\ E_{P,n} &= a_h(V(n),V(n-1)), \\ E_n &= E_{K,n} + E_{P,n}. \end{aligned} \tag{7.3}$$

The quantity $E_{K,n}$ is clearly a discrete kinetic energy. It is less evident to identify E_n as an energy. The following lemma gives a lower bound for E_n under a CFL condition and hence shows that E_n is indeed an energy.

LEMMA 7.1. *For any $n \geq 1$, we have*

$$E_n \geq \left(1 - \left(C\frac{\Delta t}{\Delta x}\right)^2\right)E_{K,n}, \tag{7.4}$$

where C is defined by $C = \sup_{1\leq j\leq J+1} C(j)$. Hence, under the CFL condition

$$C\frac{\Delta t}{\Delta x} < 1, \tag{7.5}$$

E_n is bounded from below by an energy.

Proof. For any $V, W \in \mathbb{R}^{J+2}$ we have

$$a_h(V,W) = \frac{1}{4}A_h(V+W) - \frac{1}{4}A_h(V-W) \tag{7.6}$$

with A_h defined by $A_h(V) = a_h(V,V)$. Since a_h is a positive bilinear form, the first term on the right-hand side is positive, which gives a first lower bound on E_n,

$$E_n \geq E_{K,n} - \frac{1}{4}A_h(V(n)-V(n-1)). \tag{7.7}$$

It remains to estimate the second term on the right-hand side. Using the well-known inequality

$$(a+b)^2 \leq 2(a^2+b^2), \tag{7.8}$$

we obtain

$$\begin{aligned} A_h(V(n)-V(n-1)) &= \frac{\Delta x}{2}\sum_{j=1}^{J+1}\left[D_x^-(V)(j,n) - D_x^-(V)(j,n-1)\right]^2 \\ &= \frac{\Delta x}{2}\sum_{j=1}^{J+1}\frac{\Delta t^2}{\Delta x^2}\left[D_t^-(V)(j,n) - D_t^-(V)(j-1,n)\right]^2 \\ &\leq C^2\frac{\Delta t^2}{\Delta x^2}\left[\Delta x\sum_{j=1}^{J+1}\frac{1}{C^2(j)}(D_t^-(V)(j,n))^2 \right. \\ &\qquad\qquad \left. + \Delta x\sum_{j=0}^{J}\frac{1}{C^2(j)}(D_t^-(V)(j,n))^2\right]. \end{aligned}$$

Thus

$$A_h(V(n) - V(n-1)) \leq 4C^2 \frac{\Delta t^2}{\Delta x^2} E_{K,n}, \tag{7.9}$$

which, together with (7.7), gives the desired result (7.4). □

Having defined a discrete energy, we obtain a discrete energy identity as stated in the following theorem.

THEOREM 7.2 (discrete energy identity). *For any $n \geq 1$, if $U(j,n)$ is a solution of* (7.1), *we have the energy identity*

$$\begin{aligned} E_{n+1} - E_n \ &+\ \Delta t D_t^0(U)(0,n) \cdot \left(D_x^+ - \frac{\Delta x}{2C^2(0)} D_t^+ D_t^- \right)(U)(0,n) \\ &= \Delta t D_t^0(U)(J+1,n) \cdot \left(D_x^- + \frac{\Delta x}{2C^2(J+1)} D_t^+ D_t^- \right)(U)(J+1,n). \end{aligned} \tag{7.10}$$

Furthermore, if $U(j,0)$ is a solution of (5.15), *we have the energy identity*

$$\begin{aligned} E_{K,1} + E_1 \quad &+ \quad \tfrac{\Delta t}{2} D_t^+(U)(0,0) \cdot \left(D_x^+ - \frac{1}{C^2(0)} D_t^+ \right)(U)(0,0) \\ &= \quad \frac{\Delta t}{2} D_t^+(U)(J+1,0) \cdot \left(D_x^- + \frac{1}{C^2(J+1)} D_t^+ \right)(U)(J+1,0) \\ &+ \quad \Delta x \sum_{j=1}^{J} \frac{1}{C^2(j)} U_t(j) D_t^+(U)(j,0) + \frac{\Delta x}{2} \sum_{j=1}^{J+1} (D_x^-(U)(j,0))^2. \end{aligned} \tag{7.11}$$

Proof. The proof is the discrete analogue to the proof in the continuous case. The problem here is that there is no canonical translation of the derivatives and the integrals. For $n \geq 1$, the appropriate choice is to multiply (7.1) by the centered finite differences $D_t^0(U)(j,n)$. Then we sum up for $1 \leq j \leq J$. We obtain for the derivatives in time denoted by I_1

$$\begin{aligned} I_1 &= \sum_{j=1}^{J} \frac{1}{C^2(j)} \left(D_t^+ D_t^-(U)(j,n) \right) \left(D_t^0(U)(j,n) \right) \\ &= \frac{1}{2\Delta t} \sum_{j=1}^{J} \frac{1}{C^2(j)} \left((D_t^+ - D_t^-)(U)(j,n) \right) \left((D_t^+ + D_t^-)(U)(j,n) \right) \\ &= \frac{1}{2\Delta t} \sum_{j=1}^{J} \frac{1}{C^2(j)} \left[\left(D_t^+(U)(j,n) \right)^2 - \left(D_t^+(U)(j,n-1) \right)^2 \right], \end{aligned}$$

where we used $D_t^-(U)(j,n) = D_t^+(U(j,n-1))$, and for the derivatives in space denoted by I_2

$$\begin{aligned} I_2 &= \sum_{j=1}^{J} D_x^+ D_x^-(U)(j,n) \cdot D_t^0(U)(j,n) \\ &= \frac{1}{\Delta x} \left[\sum_{j=1}^{J} D_x^+(U)(j,n) \cdot D_t^0(U)(j,n) - \sum_{j=1}^{J} D_x^-(U)(j,n) \cdot D_t^0(U)(j,n) \right]. \end{aligned}$$

By a translation of indices in the first sum of I_2 using $D_x^+(U)(j,n) = D_x^-(U(j+1,n))$, we get

$$\begin{aligned}
I_2 = {} & \frac{1}{\Delta x}\sum_{j=1}^{J+1} D_x^-(U)(j,n)\cdot\left(D_t^0(U)(j-1,n) - D_t^0(U)(j,n)\right)\\
& +\frac{1}{\Delta x}\left(-D_x^+(U)(0,n)\cdot D_t^0(U)(0,n) + D_x^-(U)(J+1,n))\cdot D_t^0(U)(J+1,n)\right)\\
= {} & \frac{1}{2\Delta t}\left[-\sum_{j=1}^{J+1} D_x^-(U)(j,n{+}1)\cdot D_x^-(U)(j,n) + \sum_{j=1}^{J+1} D_x^-(U)(j,n)\cdot D_x^-(U)(j,n-1)\right]\\
& +\frac{1}{\Delta x}\left(-D_x^+(U(0,n))\cdot D_t^0(U)(0,n) + D_x^-(U(J+1,n))\cdot D_t^0(U)(J+1,n)\right).
\end{aligned}$$

We now compute the difference $I_1 - I_2$ and find

$$\begin{aligned}
0 = {} & \frac{1}{\Delta t}\left[\frac{1}{2}\sum_{j=1}^{J}\frac{1}{C^2(j)}(D_t^-(U)(j,n+1))^2 - \frac{1}{2}\sum_{j=1}^{J}\frac{1}{C^2(j)}(D_t^-(U)(j,n))^2\right]\\
& +\frac{1}{\Delta t\Delta x}\left(a_h(U(n+1),U(n)) - a_h(U(n),U(n-1))\right)\\
& +\frac{1}{\Delta x}\left(D_x^+(U)(0,n)\cdot D_t^0(U)(0,n) - D_x^-(U)(J+1,n)\cdot D_t^0(U)(J+1,n)\right).
\end{aligned}$$

Using the definition of E_n, we finally obtain

$$\begin{aligned}
0 = {} & \frac{1}{\Delta t\Delta x}(E_{n+1} - E_n) + \frac{1}{4C^2(0)\Delta t}\left[-(D_t^+(U)(0,n))^2 + (D_t^-(U)(0,n))^2\right]\\
& +\frac{D_x^+(U)(0,n)\cdot D_t^0(U)(0,n)}{\Delta x} + \frac{-(D_t^+(U)(J{+}1,n))^2 + (D_t^-(U)(J{+}1,n))^2}{4C^2(J{+}1)\Delta t}\\
& -\frac{1}{\Delta x}D_x^-(U)(J+1,n)\cdot D_t^0(U)(J+1,n),
\end{aligned}$$

which gives (7.10) using the identities $D_t^+ - D_t^- = \Delta t D_t^+ D_t^-$ and $D_t^+ + D_t^- = 2D_t^0$. For $n = 0$, the appropriate choice is to multiply (5.15) by the forward finite difference $D_t^+(U)(j,0)$ and to perform the same computations. □

We define the discrete boundary operators

$$\begin{aligned}
T_{\alpha,C}^- &:= \frac{1}{\alpha}D_t^0 - D_x^+ + \frac{\Delta x}{2C^2}D_t^+D_t^-, & \widetilde{T}_{\alpha,C}^- &:= \frac{1}{\alpha}D_t^0 - D_x^- - \frac{\Delta x}{2C^2}D_t^+D_t^-,\\
T_{\alpha,C}^+ &:= \frac{1}{\alpha}D_t^0 + D_x^- + \frac{\Delta x}{2C^2}D_t^+D_t^-, & \widetilde{T}_{\alpha,C}^+ &:= \frac{1}{\alpha}D_t^0 + D_x^+ - \frac{\Delta x}{2C^2}D_t^+D_t^-,
\end{aligned}\tag{7.12}$$

to be applied to $U(j,n)$ for $n \geq 1$, where α is a positive real number. For $n = 0$, $D_t^+D_t^-/2$ above is replaced by $D_t^+/\Delta t$, and D_t^0 is replaced by D_t^+. Using the identity $ab = \frac{\alpha}{4}\left((\frac{1}{\alpha}a + b)^2 - (\frac{1}{\alpha}a - b)^2\right)$ for $\alpha > 0$, the energy identities (7.10), (7.11) can be rewritten for any positive α and β as

$$\begin{aligned}
E_{n+1} - E_n &+ \frac{\Delta t}{4}\Big(\alpha\big(\widetilde{T}_{\alpha,C(0)}^+(U)(0,n)\big)^2 + \beta\big(\widetilde{T}_{\beta,C(J+1)}^-(U)(J+1,n)\big)^2\Big)\\
&= \frac{\Delta t}{4}\Big(\alpha\big(T_{\alpha,C(0)}^-(U)(0,n)\big)^2 + \beta\big(T_{\beta,C(J+1)}^+(U)(J+1,n)\big)^2\Big),
\end{aligned}\tag{7.13}$$

$$
\begin{aligned}
2E_{K,1}+2E_1 \quad &+ \quad \frac{\Delta t}{4}\Big(\alpha\big(\widetilde{T}^{+}_{\alpha,C(0)}(U)(0,0)\big)^2+\beta\big(\widetilde{T}^{-}_{\beta,C(J+1)}(U)(J+1,0)\big)^2\Big)\\
&= \quad \frac{\Delta t}{4}\Big(\alpha\big(T^{-}_{\alpha,C(0)}(U)(0,0)\big)^2+\beta\big(T^{+}_{\beta,C(J+1)}(U)(J+1,0)\big)^2\Big)\\
&\qquad +2\Delta x\sum_{j=1}^{J}\frac{1}{C^2(j)}U_t(j)D_t^{+}(U)(j,0)+\Delta x\sum_{j=1}^{J+1}(D_x^{-}(U)(j,0))^2.
\end{aligned}
\tag{7.14}
$$

Suppose now the discrete boundary conditions are to be given for $n \geq 0$ by

$$
T^{-}_{\alpha,C(0)}(U)(0,n)=G^{-}(n),\quad T^{+}_{\beta,C(J+1)}(U)(J+1,n)=G^{+}(n)
\tag{7.15}
$$

and the initial conditions are to be given by $\{U(j,0)\}$, $\{U_t(j)\}$. Summing (7.13) in time and adding (7.14), we get

$$
\begin{aligned}
E_{n+1}+2E_{K,1}+E_1 \leq\ &\frac{1}{4}\Delta t\sum_{p=0}^{n}\big(\alpha(G^{-}(p))^2+\beta(G^{+}(p))^2\big)\\
&+2\Delta x\sum_{j=1}^{J}\frac{1}{C^2(j)}U_t(j)D_t^{+}(U)(j,0)+\Delta x\sum_{j=1}^{J+1}(D_x^{-}(U)(j,0))^2.
\end{aligned}
$$

Using the discrete Cauchy–Schwarz inequality on the right-hand side, we get stability for the numerical scheme.

THEOREM 7.3 (stability). *Suppose $U(j,n)$ is a solution of* (7.1), *together with initial conditions and boundary conditions* (7.15), *with α and β positive. For any positive time step n one has*

$$
\begin{aligned}
E_{n+1}+E_1 \leq\ &\frac{1}{4}\Delta t\sum_{p=0}^{n}(\alpha(G^{-}(p))^2+\beta(G^{+}(p))^2)\\
&+\ \Delta x\sum_{j=1}^{J+1}(D_x^{-}(U)(j,0))^2+\Delta x\sum_{j=1}^{J}\frac{1}{C^2(j)}(U_t(j))^2.
\end{aligned}
\tag{7.16}
$$

Thus, under the CFL condition $\sup_{1\leq j\leq J}C(j)\frac{\Delta t}{\Delta x}<1$ required in Lemma 7.1, *the scheme is stable.*

7.2. Convergence of the discrete Schwarz waveform relaxation algorithm. Corresponding to the continuous analysis, we take the velocity to be continuous at the interfaces. To shorten the notation we denote by T_i^{-} the operator $T^{-}_{C(a_i),C(a_i)}$ and the others accordingly. To analyze convergence of the discretized domain decomposition algorithm (5.25), it suffices to consider homogeneous initial conditions in (5.25) and to prove convergence to zero.

THEOREM 7.4. *Assume that the velocity is continuous on the interfaces a_i. If the CFL condition* (7.5) *is satisfied by the discretization in each subdomain, then the nonoverlapping discrete Schwarz waveform relaxation algorithm* (5.25) *with homogeneous initial condition converges to zero on any time interval $[0,T]$ in the energy norm*

$$
\sum_{i=1}^{I}E_{N_i}(U_i^k)\to 0 \text{ as } k\to\infty.
$$

Proof. The energy estimates (7.13) and (7.14) can be rewritten as

$$\begin{aligned} E_{n+1}^{k+1} - E_n^{k+1} + \frac{\Delta t_i}{4}\Big(c(a_i)\big(\widetilde{T}_i^+(U_i^{k+1})(0,n)\big)^2 + c(a_{i+1})\big(\widetilde{T}_{i+1}^-(U_i^{k+1})(J_i+1,n)\big)^2\Big) \\ = \frac{\Delta t_i}{4}\Big(c(a_i)\big(T_i^-(U_i^{k+1})(0,n)\big)^2 + c(a_{i+1})\big(T_{i+1}^+(U_i^{k+1})(J_i+1,n)\big)^2\Big), \end{aligned} \tag{7.17}$$

$$\begin{aligned} 2E_{K,1} + 2E_1 + \frac{\Delta t_i}{4}\Big(c(a_i)\big(\widetilde{T}_i^+(U_i^{k+1})(0,0)\big)^2 + c(a_{i+1})\big(\widetilde{T}_{i+1}^-(U_i^{k+1})(J_i+1,0)\big)^2\Big) \\ = \frac{\Delta t_i}{4}\Big(c(a_i)\big(T_i^-(U_i^{k+1})(0,0)\big)^2 + c(a_{i+1})\big(T_{i+1}^+(U_i^{k+1})(J_i+1,0)\big)^2\Big). \end{aligned} \tag{7.18}$$

We define the boundary energies

$$\begin{aligned} &\widetilde{F}_{i,n}^{k,+} = \tfrac{\Delta t_i}{4} c(a_i)(\widetilde{T}_i^+(U_i^k)(0,n))^2, && \widetilde{F}_{i,n}^{k,-} = \tfrac{\Delta t_{i-1}}{4} c(a_i)(\widetilde{T}_i^-(U_{i-1}^k)(J_{i-1}+1,n))^2, \\ &F_{i,n}^{k,+} = \tfrac{\Delta t_{i-1}}{4} c(a_i)(T_i^+(U_{i-1}^k)(J_{i-1}+1,n))^2, && F_{i,n}^{k,-} = \tfrac{\Delta t_i}{4} c(a_i)(T_i^-(U_i^k)(0,n))^2 \end{aligned} \tag{7.19}$$

and rewrite (7.17) and (7.18) as

$$\begin{aligned} [E_{n+1} - E_n](U_i^{k+1}) + \widetilde{F}_{i,n}^{k+1,+} + \widetilde{F}_{i+1,n}^{k+1,-} &= F_{i+1,n}^{k+1,+} + F_{i,n}^{k+1,-}, \\ [2E_{K,1} + 2E_1]\,(U_i^{k+1}) + \widetilde{F}_{i,0}^{k+1,+} + \widetilde{F}_{i+1,0}^{k+1,-} &= F_{i+1,0}^{k+1,+} + F_{i,0}^{k+1,-}. \end{aligned} \tag{7.20}$$

Summing these equations in every subdomain for $1 \le n \le N_i$, we find

$$\begin{aligned} [E_{N_i+1} + 2E_{K,1} + E_1](U_i^{k+1}) + \sum_{n=0}^{N_i} \widetilde{F}_{i,n}^{k+1,+} + \sum_{n=0}^{N_i} \widetilde{F}_{i,n}^{k+1,-} \\ = \sum_{n=0}^{N_i} F_{i,n}^{k+1,+} + \sum_{n=0}^{N_i} F_{i,n}^{k+1,-}. \end{aligned} \tag{7.21}$$

Using now the transmission conditions and the fact that the projection is a contraction in L^2, we get

$$\begin{aligned} [E_{N_i+1} + 2E_{K,1} + E_1](U_i^{k+1}) + \sum_{n=0}^{N_i} \widetilde{F}_{i,n}^{k+1,+} + \sum_{n=0}^{N_i} \widetilde{F}_{i,n}^{k+1,-} \\ \le \sum_{n=0}^{N_{i+1}} \widetilde{F}_{i+1,n}^{k,+} + \sum_{n=0}^{N_{i-1}} \widetilde{F}_{i-1,n}^{k,-}. \end{aligned} \tag{7.22}$$

Note now that by definition we have as in the continuous case $F_1^{k,\pm} = F_{I+1}^{k,\pm} = 0$. Thus, defining the total boundary energy at iteration k by

$$\widetilde{F}^k = \sum_{i=1}^{I} \sum_{n=0}^{N_i} [\widetilde{F}_{i,n}^{k,-} + \widetilde{F}_{i,n}^{k,+}],$$

we have, by summing in i and shifting the indices, the inequality

$$\sum_{i=1}^{I} [E_{N_i+1} + 2E_{K,1} + E_1](U_i^{k+1}) + \widetilde{F}^{k+1} \le \widetilde{F}^k. \tag{7.23}$$

Thus the same arguments as in the continuous case prove that $\sum_{i=1}^{I} E_{N_i}(U_i^k) \to 0$ as $k \to \infty$. □

8. Numerical experiments.

We perform the numerical experiments on the wave equation

$$\frac{\partial^2 u}{\partial t^2} = c^2(x)\frac{\partial^2 u}{\partial x^2}, \quad 0 < x < L,\ 0 < t < T, \tag{8.1}$$

where we truncate the spatial domain at 0 and L using absorbing boundary conditions so that the results obtained correspond to the analysis on an infinite domain. We discretize the wave equation and the optimal transmission conditions using the finite volume scheme presented in section 5.

8.1. Optimal global transmission conditions.

First we test the convergence result proved in Theorem 2.1 for a two subdomain problem with $L = 2$, $T = 2$, and a constant wave speed $c(x) = 1$. The domain is partitioned at $x = 1$, and the optimal transmission conditions at the continuous level are local. We use the initial conditions

$$\begin{aligned} u(x,0) &= 0, \\ \frac{\partial u}{\partial t}(x,0) &= -100(0.5-x)e^{-50(0.5-x)^2}, \end{aligned}$$

and we start the iteration with the initial guess zero. Table 8.1 shows for various mesh parameters the difference of the domain decomposition algorithm result after two iterations and the numerical solution on the whole domain and compares this value to the truncation error, the difference between the numerical solution on the whole domain, and the exact solution. One can see that the discretization of the optimal local transmission conditions leads to an algorithm which converges in two iterations to well below the accuracy of the numerical scheme.

Table 8.1
Convergence in two iterations to below the accuracy of the discretization.

Grid	Error after 2 iterations	Discretization error
50 x 50	2.6128e-04	2.1515e-02
100 x 100	2.7305e-05	4.9472e-03
200 x 200	3.2361e-06	1.2218e-03
400 x 400	3.9852e-07	3.0321e-04
800 x 800	4.9548e-08	7.5567e-05

For the next model problem, we choose $L = 6$, $T = 8$, and a speed function $c(x)$ with a discontinuity at $x = 1$,

$$c(x) = \begin{cases} 1 & 1 < x < 6, \\ 2 & 0 < x < 1. \end{cases}$$

We decompose the domain into three subdomains, $\Omega_1 = [0,2]\times[0,6]$, $\Omega_2 = [2,4]\times[0,6]$, and $\Omega_3 = [4,6]\times[0,6]$, and we use the initial conditions

$$\begin{aligned} u(x,0) &= 0, \\ \frac{\partial u}{\partial t}(x,0) &= -20(5-x)e^{-10(5-x)^2}. \end{aligned}$$

We use again a discretization of the optimal transmission conditions, which are nonlocal in this case. We start the Schwarz waveform relaxation with a zero initial guess. Table 8.2 shows that the algorithm converges at the third iteration to the discretization error level and illustrates Theorem 2.1, which states that we should find convergence in a number of iterations identical to the number of subdomains. More accuracy is achieved as the iteration progresses further. The nonlocal transmission conditions (2.8) require this value of T to include three terms of the sum of the operators $\mathcal{S}_j$ in (3.3), (3.4) on the middle subdomain and one term on the right subdomain. We computed the solution on a uniform grid with $\Delta x = 1/20$ and $\Delta t = 1/40$ for this example.

Table 8.2

Convergence for a 3 *subdomain problem and a discontinuity in the left subdomain.*

Iteration	0	1	2	3	4	5
$\lvert\lvert u - u_k\rvert\rvert_\infty$	5.0230e-01	5.0164e-01	5.0065e-01	4.0289e-03	3.9800e-03	3.9535e-05

8.2. Optimal local transmission conditions. Now we introduce time windows for the same example to be able to use optimal local transmission conditions. We cut the time domain into four equal pieces $[0, 2]$, $[2, 4]$, $[4, 6]$, and $[6, 8]$ such that the condition (3.15) according to Theorem 3.4 is satisfied. We solve the problem consecutively on the four time subdomains, and in each time window we expect the algorithm to converge in two iterations. We show the convergence results for the first time window only, $[0, T = 2]$. Table 8.3 shows the error in the infinity norm over five iterations for the same mesh parameters as before. The algorithm converges now already at the second iteration as predicted by Theorem 3.4 to the discretization error level, and more accuracy is achieved as the iteration progresses.

Table 8.3

Convergence with local transmission conditions over a shorter time interval.

Iteration	0	1	2	3	4	5
$\lvert\lvert u - u_k\rvert\rvert_\infty$	5.0200e-01	5.0135e-01	1.2089e-03	9.0654e-06	1.4775e-06	1.2551e-06

8.3. Nonconforming grids. As an illustration of Theorem 3.5 on nonconforming grids, we consider a problem with a layered medium of six layers, and we decompose the domain into six subdomains corresponding to the different layers, $\Omega_i = [i - 1, i]$ with corresponding wave speeds $c_i \in \{1, 2/3, 1/2, 3/4, 1, 4/5\}$. We discretize each subdomain with a grid in space using $\Delta x_i = 1/50$ and in time using an appropriate time step satisfying the CFL condition $c_i \frac{\Delta t_i}{\Delta x_i} < 1$ but close to 1, which is important for accuracy in the propagation properties of the solution, so different time steps are essential in different subdomains. This leads to nonconforming grids between subdomains. Since we have no algorithm that computes the entire solution over nonconforming grids to compare with, we choose to compute the zero solution to the homogeneous problem with zero initial conditions. We start with a nonzero initial guess on the artificial interfaces, $g^{\pm}(t) = 1$. According to Theorem 3.5 the algorithm will converge in two iterations if $T \leq 1$. Table 8.4 shows that this is also observed numerically. After two iterations the Schwarz waveform relaxation has converged to the precision of the numerical scheme. Figure 8.1 shows a solution computed on nonmatching grids with the optimal Schwarz waveform relaxation algorithm.

8.4. Variable wave speed and local transmission conditions. Now we consider a variable propagation speed $c(x)$ for which convergence of the Schwarz waveform relaxation algorithm with local transmission conditions was proved in Theorem 4.3

Table 8.4

Convergence with local transmission conditions in 2 iterations to the level of the truncation error for a problem with five discontinuities and six subdomains aligned with the discontinuities.

Iteration	0	1	2
$\|\|u-u_k\|\|_\infty$	5.0234e+00	5.0234e+00	1.1738e-02

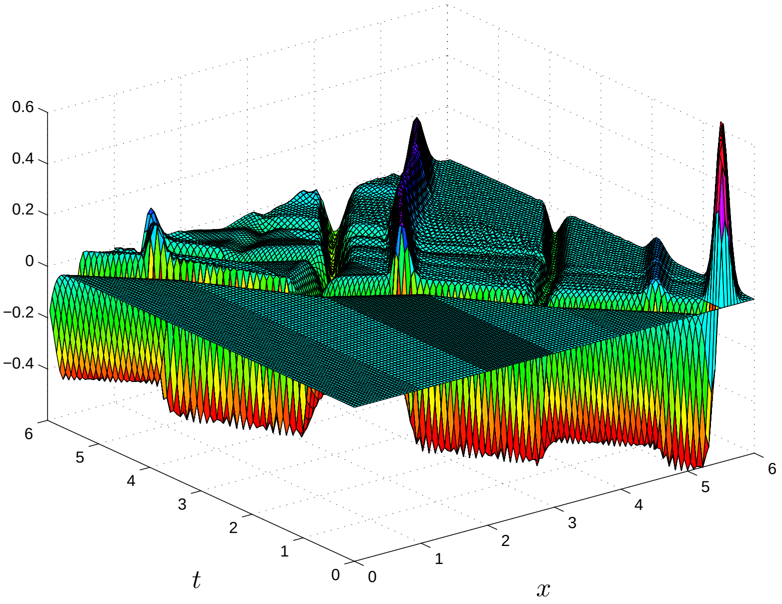

Fig. 8.1. *Computation with nonmatching grids on a layered medium with five discontinuities, a pulse created in the surface layer and propagating downward.*

using energy estimates. The speed profile, which is a typical underwater profile, was obtained from [23], and it is given as a function of depth by

$$c(x) = \begin{cases} 300, & \frac{m}{s}, \quad x < 0 \text{ (above ground)}, \\ 1500 - x/12, & \frac{m}{s}, \quad 0 < x < 120, \\ 1480 + x/12, & \frac{m}{s}, \quad 120 < x < 240, \\ 1505, & \frac{m}{s}, \quad x > 240. \end{cases}$$

We decompose the domain into two subdomains $\Omega_1 = [0, 300]$, and $\Omega_2 = [300, 600]$, and we apply the domain decomposition algorithm with the local transmission conditions (3.10), which would be exact if the sound speed was identically constant over both subdomains and equal to the sound speed at the artificial interface at $x = 300$. Table 8.5 shows the convergence of the algorithm for the variable sound speed for a time interval $[0, 1/2]$. The algorithm converges again to the accuracy of the scheme in two iterations, even though the sound speed is variable in this example. This is because the variation is small in scale, and thus the local approximations to the transmission conditions are sufficiently accurate to lead to the convergence in two steps. Note also that continuing the iteration, the error is further reduced.

Table 8.5

Convergence behavior of the algorithm for the variable sound speed profile from an application.

Iteration	0	1	2	3
$\|\|u - u_k\|\|_\infty$	5.0316e+00	5.0316e+00	9.9024e-03	6.2439e-04

9. Conclusions. We have presented and analyzed a nonoverlapping Schwarz waveform relaxation algorithm for the one dimensional wave equation with variable coefficients, both at the continuous and the discrete level. The algorithm permits the use of grid CFL conditions adapted to the local wave speeds and nonmatching grids on different subdomains, and it has optimal scalability when implemented on a parallel computer. The formulation of the algorithm is quite general; it can be applied to the wave equation in higher dimensions and even to other types of evolution equations. The convergence result with the optimal transmission conditions also holds in these more general situations; specific results for the wave equation in higher dimensions will be presented elsewhere. The convergence analysis for the discretized algorithm with approximate transmission conditions, however, is specific to the one dimensional wave equation with variable coefficients. Although the ideas can be generalized to higher dimensions, the discrete energy estimates present a real challenge. The advantage of the continuous analysis is, however, that convergence results similar to the continuous ones can be expected to hold when the algorithm is consistently discretized.

Appendix. A projection algorithm for nonmatching grids.

The projection operation between nonconforming grids as given in (5.23) is not an easy task in an algorithm, since one cell can intersect with an arbitrary number of neighboring ones or even not intersect at all if it is fully contained in the neighboring one. In one dimension, the following short algorithm in Matlab performs this task in an efficient manner:

```
function b=transfer(a,ta,tb);
% TRANSFER integrates a stepfunction between given intervals
%   b=transfer(a,ta,tb); computes the integral of the
%   stepfunction with values a(j) in [ta(j),ta(j+1)] in the
%   intervals [tb(i),tb(i+1)] and stores the result in b(i).
%   Note that the first and last entry in ta and tb must be equal.

n=length(tb);           % n-1 is the length of b
ta(length(ta))=tb(n);   % numerical equality for proper termination
j=1;
for i=1:n-1,
b(i)=0;
m=ta(j+1)-tb(i);
while ta(j+1)<tb(i+1),
b(i)=b(i)+m*a(j);
j=j+1;
m=ta(j+1)-ta(j);
end;
m=m-(ta(j+1)-tb(i+1));
b(i)=b(i)+m*a(j);
end;
```

Given a vector $\texttt{ta} = [0, t_a(1), \ldots, T]$ of arbitrary grid points in time and a piecewise constant function on the intervals between the grid points ta whose values are given in the vector a, the algorithm computes the integrals of a on the intervals between the grid points of a second grid given in the vector $\texttt{tb} = [0, t_b(1), \ldots, T]$. The algorithm does a single pass without any special cases using the fact that the grid points are sorted in time. It advances automatically on whatever side the next cell boundary is coming and handles any possible cases of nonmatching grids at a one dimensional interface.

Acknowledgment. We would like to thank the unknown referee for his detailed comments and suggestions, which were very helpful in the preparation of the final version of the manuscript.

A NONOVERLAPPING DOMAIN DECOMPOSITION METHOD FOR MAXWELL'S EQUATIONS IN THREE DIMENSIONS[*]

QIYA HU[†] AND JUN ZOU[‡]

Abstract. In this paper, we propose a nonoverlapping domain decomposition method for solving the three-dimensional Maxwell equations, based on the edge element discretization. For the Schur complement system on the interface, we construct an efficient preconditioner by introducing two special coarse subspaces defined on the nonoverlapping subdomains. It is shown that the condition number of the preconditioned system grows only polylogarithmically with the ratio between the subdomain diameter and the finite element mesh size but possibly depends on the jumps of the coefficients.

1. Introduction.

In the numerical solution of the Maxwell equations, one needs to repeatedly solve the following system [9], [12], [17], [21], [28], [30]:

$$\nabla\times(\alpha\,\nabla\times\mathbf{u})+\beta\mathbf{u}=\mathbf{f}\quad\text{in}\quad\Omega, \tag{1.1}$$

where Ω is an open polyhedral domain in $\mathbf{R}^3$ and the coefficients $\alpha(x)$ and $\beta(x)$ are two positive bounded functions in Ω. Among various boundary conditions for (1.1), we shall consider the perfect conductor condition

$$\mathbf{u}\times\mathbf{n}=0\quad\text{on}\quad\partial\Omega, \tag{1.2}$$

where $\mathbf{n}$ is the unit outward normal vector on $\partial\Omega$.

Both the nodal and edge finite element methods have been widely used for solving the system (1.1)–(1.2); see, for example, [5], [10], [11], [12], [22], [24]. However, the algebraic systems arising from the discretization by the edge element methods are very different from the ones arising from the discretization by the standard nodal finite element methods. So the nonoverlapping domain decomposition theory for the nodal element systems, which has been well developed for second order elliptic problems in the past two decades (see the survey articles [13] [33]), does not work for the edge element systems in general, especially in three dimensions. During the last five years, there has been a rapidly growing interest in domain decomposition methods (DDMs) for solving the system (1.1)–(1.2). Some substructuring DDMs were studied for two-dimensional Maxwell equations in [29], [30] and for a different three dimensional model problem in [31]. Overlapping Schwarz methods were investigated in

[15], [28], [16] for three-dimensional Maxwell equations. As far as the nonoverlapping DDMs are concerned, very few works can be found in the literature. A nonoverlapping DDM with two subdomains was proposed in [3] for Maxwell equations in three dimensions. The current work represents some initial efforts in the construction of efficient nonoverlapping DDMs for the case with general multiple subdomains. As we shall see, not only the construction of the coarse subspaces but also the estimates of the condition numbers of the preconditioned systems for the three-dimensional case with multiple nonoverlapping subdomains are much more difficult and tricky than in the two-dimensional case or the three-dimensional case with overlapping subdomains.

In this paper, we will propose an efficient preconditioner for the Schur complement system arising from the nonoverlapping DDM based on the edge element discretization. For the analysis of our new method, some important inequalities will be established for discrete functions in edge element spaces. We believe these inequalities should also be useful to the future developments in the field. It will be shown that the resulting preconditioned system has a nearly optimal condition number; namely, the condition number grows only polylogarithmically with the ratio between the subdomain diameter and the finite element mesh size. Unlike the optimal nonoverlapping domain decomposition preconditioners for elliptic problems [13], [25], [33], we are still unable to conclude whether the condition number of the preconditioned system generated by our nonoverlapping DDM is independent of the jumps of the coefficients. This is an important problem that we are currently working on.

The paper is arranged as follows. The edge element discretization of the system (1.1)–(1.2) and some basic formulae and definitions will be described in section 2. The construction of nonoverlapping domain decomposition preconditioners and the main results of the paper are discussed in section 3. Section 4 presents some auxiliary lemmas, which are needed in section 5 to deal with the technical difficulties in the estimates of the condition numbers.

2. Domain decompositions and discretizations. This section is devoted to the introduction of the nonoverlapping domain decomposition and the weak form and the edge element discretization of the system (1.1)–(1.2) as well as some discrete operators.

Domain decomposition. We decompose the physical domain Ω into N nonoverlapping tetrahedral subdomains $\{\Omega_i\}_i^N$, with each Ω_i of size d (see [7], [33]). The faces and vertices of the subdomains are always denoted by $\textsc{f}$ and $\textsc{v}$, while the common (open) face of the subdomains Ω_i and Ω_j are denoted by Γ_{ij}, and the union of all such common faces is denoted by Γ, i.e., $\Gamma = \cup\bar{\Gamma}_{ij}$. Γ will be called *the interface.* By Γ_i we denote the intersection of Γ with the boundary of the subdomain Ω_i. So we have $\Gamma_i = \partial\Omega_i$ if Ω_i is an interior subdomain of Ω.

Finite element triangulation. Further, we divide each subdomain Ω_i into smaller tetrahedral elements of size h so that elements from the neighboring two subdomains have an intersection which is either empty or a single nodal point or an edge or a face on the interface Γ. The resulting triangulation of the domain Ω is denoted by $\mathcal{T}_h$, which is assumed to be quasi-uniform (cf. [33]), while the set of edges and the set of nodes in $\mathcal{T}_h$ are denoted by $\mathcal{E}_h$ and $\mathcal{N}_h$, respectively.

Weak formulation. The primary goal of this paper is to construct an efficient nonoverlapping DDM for solving the discrete system arising from the edge element discretization of (1.1). For this, we first introduce its weak form and then the edge element discretization of the weak form. Let $H(\mathbf{curl};\Omega)$ be the Sobolev space consisting of all square integrable functions whose $\mathbf{curl}$'s are also square integrable in Ω, and let $H_0(\mathbf{curl};\Omega)$ be a subspace of $H(\mathbf{curl};\Omega)$ with all functions whose tangential components vanish on $\partial\Omega$, i.e., $\mathbf{v}\times\mathbf{n}=0$ on $\partial\Omega$ for all $\mathbf{v}\in H_0(\mathbf{curl};\Omega)$. Then, by integration by parts, one derives immediately the variational problem associated with the system (1.1)–(1.2).

Find $\mathbf{u}\in H_0(\mathbf{curl};\Omega)$ such that

$$A(\mathbf{u},\mathbf{v})=(\mathbf{f},\mathbf{v})\quad\forall\mathbf{v}\in H_0(\mathbf{curl};\Omega),\tag{2.1}$$

where $A(\cdot,\cdot)$ is a bilinear form given by

$$A(\mathbf{u},\mathbf{v})=(\alpha\nabla\times\mathbf{u},\nabla\times\mathbf{v})+(\beta\mathbf{u},\mathbf{v}),\quad \mathbf{u},\mathbf{v}\in H(\mathbf{curl};\Omega).$$

Here and in what follows, $(\cdot,\cdot)$ denotes the scalar product in $L^2(\Omega)$ or $L^2(\Omega)^3$.

Edge element discretization. The Nédélec edge element space, of the lowest order, is a subspace of piecewise linear polynomials defined on $\mathcal{T}_h$ (cf. [14] and [23]):

$$V_h(\Omega)=\Big\{\mathbf{v}\in H_0(\mathbf{curl};\Omega);\ \mathbf{v}\,|_K\in R(K)\ \forall K\in\mathcal{T}_h\Big\},$$

where $R(K)$ is a subset of all linear polynomials on the element K of the form

$$R(K)=\Big\{\mathbf{a}+\mathbf{b}\times\mathbf{x};\ \mathbf{a},\mathbf{b}\in\mathbf{R}^3,\ \mathbf{x}\in K\Big\}.$$

It is known [14], [23] that the tangential components of any edge element function $\mathbf{v}$ of $V_h(\Omega)$ are continuous on all edges of every element in the triangulation $\mathcal{T}_h$, and $\mathbf{v}$ is uniquely determined by its moments on edges of $\mathcal{T}_h$:

$$\left\{\lambda_e(\mathbf{v})=\int_e\mathbf{v}\cdot\mathbf{t}_e ds;\ e\in\mathcal{E}_h\right\},$$

where $\mathbf{t}_e$ denotes the unit vector on the edge e. Let $\{L_e;\ e\in\mathcal{E}_h\}$ be the edge element basis functions of $V_h(\Omega)$ satisfying

$$\lambda_{e'}(L_e)=\begin{cases}1 & \text{if } e'=e\,,\\ 0 & \text{if } e'\neq e\,;\end{cases}$$

then the edge element basis function L_e associated with the edge e has the representation

$$L_e=c_e\left(\lambda_1^e\nabla\lambda_2^e-\lambda_2^e\nabla\lambda_1^e\right),\tag{2.2}$$

where c_e is a constant independent of h, and λ_1^e and λ_2^e are two barycentric basis functions at the two endpoints of e. Furthermore, each function $\mathbf{v}$ of $V_h(\Omega)$ can be expressed as

$$\mathbf{v}(\mathbf{x})=\sum_{e\in\mathcal{E}_h}\lambda_e(\mathbf{v})L_e(\mathbf{x}),\quad \mathbf{x}\in\Omega\,.$$

With the above notation, the edge element approximation to the variational problem (2.1) can be formulated as follows: Find $\mathbf{u}_h\in V_h(\Omega)$ such that

$$A(\mathbf{u}_h,\mathbf{v}_h)=(\mathbf{f},\mathbf{v}_h)\quad\forall\mathbf{v}_h\in V_h(\Omega),\tag{2.3}$$

where $A_h(\cdot,\cdot)$ is a bilinear form given by

$$A_h(\mathbf{u}_h,\mathbf{v}_h)=\sum_{i=1}^{N}A_i(\mathbf{u}_h,\mathbf{v}_h)$$

with each $A_i(\cdot,\cdot)$ defined only on the subdomain Ω_i:

$$A_i(\mathbf{u},\mathbf{v})=(\alpha\,\nabla\times\mathbf{u},\nabla\times\mathbf{v})_{\Omega_i}+(\beta\,\mathbf{u},\mathbf{v})_{\Omega_i},\quad i=1,2,\ldots,N.$$

Some edge element subspaces. In section 3, we will formulate our DDM for solving the edge element system (2.3). Before doing so, we need to introduce more notation, subspaces, and discrete operation tools.

We will often use G to represent a subset of Γ, which may be the entire interface Γ or the local interface Γ_i or a face F of Γ_i. The notation e, with $e\subset G$, always means that e is an edge of $\mathcal{T}_h$ and lies on G. By restricting $V_h(\Omega)$ on G, we generate a subspace of $L^2(G)^3$:

$$V_h(G)=\Big\{\psi\in L^2(G)^3;\ \psi=\mathbf{v}\times\mathbf{n}\ \text{ on }\ G\ \text{ for some }\ \mathbf{v}\in V_h(\Omega)\Big\}.$$

By $V_h(\Omega_i)$ we denote the restriction of $V_h(\Omega)$ on the subdomain Ω_i. The following two local subspaces of $V_h(\Omega_i)$ and $V_h(\mathrm{F})$ will be important to our subsequent analysis:

$$V_h^0(\Omega_i)=\Big\{\mathbf{v}\in V_h(\Omega_i);\ \mathbf{v}\times\mathbf{n}=0\ \text{ on }\ \Gamma_i\Big\},$$

$$V_h^0(\mathrm{F})=\Big\{\Phi=\mathbf{v}\times\mathbf{n}\in V_h(\mathrm{F});\ \lambda_e(\mathbf{v})=0\ \ \forall\ e\subset\partial\mathrm{F}\cap\mathcal{E}_h\Big\}.$$

Discrete operators. We will often use the natural restriction operator from $V_h(\Gamma)$ onto $V_h(G)$, denoted by $\mathbf{I}_G$, and the natural zero extension operator from $V_h(G)$ into $L^2(\Gamma)^3$, denoted by $\mathbf{I}_G^t$. By definition it is clear that for a face F, $\mathbf{I}_\mathrm{F}^t\mathbf{v}\in V_h(\Gamma)$ if and only if $\mathbf{v}\in V_h^0(\mathrm{F})$, and $\mathbf{I}_G$ and $\mathbf{I}_G^t$ satisfy

$$\langle\mathbf{I}_G\Psi,\Phi\rangle_G=\langle\Psi,\mathbf{I}_G^t\Phi\rangle\quad\forall\,\Psi\in V_h(\Gamma),\ \Phi\in V_h(G),$$

where $\langle\cdot,\cdot\rangle_G$ stands for the L^2-inner product in $L^2(G)$ or $L^2(G)^3$, and the subscript G will be dropped when $G=\Gamma$. Also, we shall write $\mathbf{I}_i=\mathbf{I}_{\Gamma_i}$ and $\mathbf{I}_{ij}^t=\mathbf{I}_{\Gamma_{ij}}^t$.

For any face F of Ω_i, we use F_b to denote the union of all $\mathcal{T}_h$-induced (closed) triangles on F which have at least one edge lying on $\partial\mathrm{F}$ and F_∂ to denote the open set $\mathrm{F}\backslash\mathrm{F}_b$.

By definition, for any $\Phi\in V_h(\Gamma_i)$, there exists a $\mathbf{v}\in V_h(\Omega_i)$ such that $\Phi=\mathbf{v}\times\mathbf{n}$ on Γ_i. So Φ has the representation of the form

$$\Phi(\mathbf{x})=\sum_{e\subset\Gamma_i}\lambda_e(\mathbf{v})(L_e\times\mathbf{n})(\mathbf{x}),\quad \mathbf{x}\in\ \Gamma_i. \tag{2.4}$$

For any open face F on Γ_i, we define an operator $\mathbf{I}_{\mathrm{F}_\partial}^0:V_h(\Gamma_i)\rightarrow\mathbf{I}_\mathrm{F}^tV_h^0(\mathrm{F})$ by

$$(\mathbf{I}_{\mathrm{F}_\partial}^0\Phi)(\mathbf{x})=\sum_{e\subset\mathrm{F}_\partial}\lambda_e(\mathbf{v})(L_e\times\mathbf{n})(\mathbf{x}),\quad \mathbf{x}\in\Gamma_i, \tag{2.5}$$

and an operator $\mathbf{I}^0_{\mathrm{F}_b}$ by

$$(\mathbf{I}^0_{\mathrm{F}_b}\Phi)(\mathbf{x}) = \sum_{e\subset \mathrm{F}_b} \lambda_e(\mathbf{v})\,\mathbf{I}^t_{\mathrm{F}}(L_e \times \mathbf{n})(\mathbf{x}), \quad \mathbf{x}\in\Gamma_i.$$

Some nodal element spaces. From time to time, we shall also need some nodal element spaces in the analyses—for example, the continuous piecewise linear finite element space $Z_h(\Omega)$ of $H^1_0(\Omega)$, its restriction $Z_h(\Gamma)$ on Γ and $Z_h(\Omega_i)$ on any subdomain Ω_i, and the restriction $Z_h(\Gamma_i)$ of $Z_h(\Omega_i)$ on the local interface Γ_i and $Z_h(\mathrm{F})$ on a face F.

The operator $\mathrm{I}^t_{\mathrm{F}} : Z_h(\mathrm{F}) \to L^2(\Gamma)$ is defined similarly to $\mathbf{I}^t_{\mathrm{F}}$.

For a subset G of Γ_i, we introduce a "local" subspace

$$Z^0_h(G) = \{v\in Z_h(\Gamma_i);\ v = 0 \text{ at all nodes on } \Gamma_i\backslash G\}.$$

For any open face $\mathrm{F}\subset\Gamma_i$, we will use $\mathrm{I}^0_{\mathrm{F}} : Z_h(\Gamma_i)\to Z^0_h(\mathrm{F})$ and $\mathrm{I}^0_{\partial\mathrm{F}} : Z_h(\Gamma_i)\to Z^0_h(\partial\mathrm{F})$ to denote the natural restriction operators (see [33]).

curl- and harmonic extension operators. The next two extension operators will play an important role in the subsequent analysis. The first is the discrete **curl-**extension operator $\mathbf{R}^i_h : V_h(\Gamma_i)\to V_h(\Omega_i)$ defined as follows: For any $\Phi\in V_h(\Gamma_i)$, $\mathbf{R}^i_h\Phi\in V_h(\Omega_i)$ satisfies $\mathbf{R}^i_h\Phi\times\mathbf{n} = \Phi$ on Γ_i and solves

$$A_i(\mathbf{R}^i_h\Phi, \mathbf{v}_h) = 0 \quad \forall \mathbf{v}_h\in V^0_h(\Omega_i).$$

The second is the discrete harmonic extension operator $R^i_h : Z_h(\Gamma_i)\to Z_h(\Omega_i)$ defined as follows: For any $v_h\in Z_h(\Gamma_i)$, $R^i_h v_h\in Z_h(\Omega_i)$ satisfies $R^i_h v_h = v_h$ on Ω_i and

$$(\nabla R^i_h v_h, \nabla w_h) = 0 \quad \forall\, w_h\in Z_h(\Omega_i)\cap H^1_0(\Omega_i)\,.$$

3. Nonoverlapping DDMs.

In this section, we propose a nonoverlapping DDM for solving the edge element system (2.3). The notation $\langle\cdot,\cdot\rangle_{\Gamma_i}$ and $(\cdot,\cdot)_{\Omega_i}$ shall be used for the scalar products in $L^2(\Gamma_i)$ and $L^2(\Omega_i)$, respectively.

3.1. The interface equation.

For the solution $\mathbf{u}_h$ to the system (2.3), we write $\mathbf{u}_{hi} = \mathbf{u}_h|_{\Omega_i}$. It follows from (2.3) that

$$A_i(\mathbf{u}_{hi}, \mathbf{v}_h) = (\mathbf{f}, \mathbf{v}_h)_{\Omega_i} \quad \forall \mathbf{v}_h\in V^0_h(\Omega_i). \tag{3.1}$$

This indicates that if the tangential components $\mathbf{u}_{hi}\times\mathbf{n}_i$ are known on Γ_i the "local" unknown $\mathbf{u}_{hi}$ can be obtained by solving the local equation (3.1).

Next, we will establish an equation for the interface quantity $\Phi = \mathbf{u}_h\times\mathbf{n}$ on Γ. To do so, we introduce a "local" interface operator $\mathbf{S}_i : V_h(\Gamma_i)\to V_h(\Gamma_i)^*$ by

$$\langle \mathbf{S}_i\Phi_i, \Psi_i\rangle_{\Gamma_i} = A_i(\mathbf{R}^i_h\Phi_i, \mathbf{R}^i_h\Psi_i) \quad \forall \Psi_i, \Phi_i\in V_h(\Gamma_i).$$

Using the obvious decomposition

$$\mathbf{u}_{hi} = \mathbf{u}^0_{hi} + \mathbf{R}^i_h(\mathbf{u}_{hi}\times\mathbf{n}_i)$$

with $\mathbf{u}^0_{hi}\in V^0_h(\Omega_i)$, solving (3.1), (2.3) reduces to the interface equation (cf. [27])

$$\sum_{i=1}^N \langle \mathbf{S}_i\mathbf{I}_i\Phi, \mathbf{I}_i\Psi\rangle_{\Gamma_i} = \sum_{i=1}^N (\mathbf{f}, \mathbf{R}^i_h\mathbf{I}_i\Psi)_{\Omega_i} \quad \forall \Psi\in V_h(\Gamma). \tag{3.2}$$

Let $\mathbf{g} \in V_h(\Gamma)^*$ be defined by

$$\langle \mathbf{g}, \Psi \rangle_\Gamma = \sum_{i=1}^{N} (\mathbf{f}, \mathbf{R}_h^i \mathbf{I}_i \Psi)_{\Omega_i} \quad \forall \Psi \in V_h(\Gamma),$$

and let $\mathbf{S} = \sum_{i=1}^{N} \mathbf{I}_i^t \mathbf{S}_i \mathbf{I}_i$; then (3.2) may be written as

$$\langle \mathbf{S}\Phi, \Psi \rangle = \langle \mathbf{g}, \Psi \rangle \quad \forall \Psi \in V_h(\Gamma). \tag{3.3}$$

With $\Phi = \mathbf{u}_h \times \mathbf{n}$ available on Γ, the solution of (2.3) can be obtained by solving one subproblem, (3.1), on each subdomain Ω_i. Therefore, the solution of (2.3) reduces to the one of the interface problem (3.3). However, it is very expensive to solve this interface equation directly. Instead, we will construct an efficient preconditioner for $\mathbf{S}$; then (3.3) can be solved by the preconditioned CG method.

3.2. Preconditioners for the interface operator S. We now start to construct a preconditioner for $\mathbf{S}$. As usual, a good preconditioner should involve both local solvers and global coarse solvers.

First, the local solvers can be constructed on each local face Γ_{ij}. For each Γ_{ij}, we define a "local" operator $\mathbf{S}_{ij} : V_h^0(\Gamma_{ij}) \to V_h^0(\Gamma_{ij})^*$ by

$$\begin{gathered}\langle \mathbf{S}_{ij}\Phi_{ij}, \Psi_{ij} \rangle_{\Gamma_{ij}} = A_i(\mathbf{R}_h^i \mathbf{I}_{ij}^t \Phi_{ij}, \mathbf{R}_h^i \mathbf{I}_{ij}^t \Psi_{ij}) + A_j(\mathbf{R}_h^j \mathbf{I}_{ij}^t \Phi_{ij}, \mathbf{R}_h^j \mathbf{I}_{ij}^t \Psi_{ij}) \\ \forall \Phi_{ij}, \Psi_{ij} \in V_h^0(\Gamma_{ij}),\end{gathered}$$

and $\mathbf{S}_{ij}^{-1}$ will be our desired local solvers. The construction of the global coarse solvers is much more tricky and technical. Before doing this, we would like to illustrate our main idea about the construction. The essential difficulty in the construction of a coarse solver lies in two facts: (1) The edge element space $V_h(\Omega)$, different from the nodal element space, is not a subspace of $H^1(\Omega)^3$; (2) for any $\mathbf{v}_h \in V_h(\Omega)$, its tangential components are continuous on all *cross-edges*, namely, the edges which are shared by more than two fine elements (tangential components make no sense at the *cross-points* in two dimensions), but the moments on the *cross-edges* are not sufficient to determine the values of the tangential trace $\mathbf{v}_h \times \mathbf{n}$ on these edges. As one will see, we have the Helmholtz decomposition

$$V_h(\Omega) = \mathbf{grad}\, Z_h(\Omega) + \tilde{V}_h(\Omega),$$

where $\tilde{V}_h(\Omega)$ corresponds to the divergence-free part and is closely related to the space $H^1(\Omega)^3$. Thus it seems necessary to construct two coarse subspaces and coarse solvers, corresponding to the **curl**-free and divergence-free subspaces $\nabla Z_h(\Omega)$ and $\tilde{V}_h(\Omega)$, respectively.

For the construction of the coarse subspaces, we introduce some more notation below. For any subdomain Ω_i, by $\mathcal{W}_i$ we denote the set of the edges of Ω_i, which belong to at least two other local interfaces Γ_j, $j \neq i$. On each $\mathcal{W}_i$, we define the discrete L^2-scalar product

$$\langle \varphi, \psi \rangle_{h,\mathcal{W}_i} = h \sum_{\mathbf{x} \in \mathcal{N}_h \cap \mathcal{W}_i} \varphi(\mathbf{x})\psi(\mathbf{x}) \quad \forall\, \varphi, \psi \in Z_h(\Gamma_i)\,;$$

the corresponding norm is denoted by $\|\cdot\|_{h,\mathcal{W}_i}$. Let

$$\Delta_i = \bigcup_{\mathrm{F} \subset \Gamma_i} \mathrm{F}_b, \quad i = 1, \ldots, N.$$

We introduce a norm $\|\cdot\|_{*,\Delta_i}$ that is induced from the following inner product in $L^2(\Delta_i)^3$:

$$\langle \mathbf{v}\times\mathbf{n}, \mathbf{w}\times\mathbf{n}\rangle_{*,\Delta_i} = \sum_{K\subset\Delta_i} \langle \mathbf{v}\times\mathbf{n}, \mathbf{w}\times\mathbf{n}\rangle_{\partial K} \quad \forall\, \mathbf{v}\times\mathbf{n}, \mathbf{w}\times\mathbf{n} \in V_h(\Gamma_i),$$

where the summation is over all triangles K in Δ_i.

For any given subset G of Ω and function φ in $L^2(G)$, we use $\gamma_{_G}(\varphi)$ for the average value of φ on G. Similarly, for a vector $\mathbf{v} = (v_1, v_2, v_3)$ in $L^2(G)^3$, we use $\Upsilon_G(\mathbf{v})$ for the constant vector with three average values $\gamma_{_G}(v_1)$, $\gamma_{_G}(v_2)$, and $\gamma_{_G}(v_3)$ as its components.

Now we define two discrete operators in $Z_h(\Gamma)$ and $V_h(\Gamma)$ which will generate two coarse subspaces. For any $\varphi \in Z_h(\Gamma)$, we define $\pi_0\varphi \in Z_h(\Gamma)$ by

$$\pi_0\varphi(\mathbf{x}) = \begin{cases} \varphi(\mathbf{x}) & \text{for } \mathbf{x}\in \mathcal{W}_i \cap \mathcal{N}_h \ (i=1,\dots,N), \\ \gamma_{_{\partial \mathrm{F}}}(\varphi) & \text{for } \mathbf{x}\in \mathrm{F}\cap\mathcal{N}_h \ (\mathrm{F}\subset\Gamma). \end{cases} \tag{3.4}$$

Similarly, for each $\mathbf{v}\times\mathbf{n} \in V_h(\Gamma)$, we define $\Pi_0\mathbf{v}\times\mathbf{n} \in V_h(\Gamma)$ such that

$$\lambda_e(\Pi_0\mathbf{v}) = \begin{cases} \lambda_e(\mathbf{v}) & \text{for } e\subset \Delta_i\cup\Omega_i \ (i=1,\dots,N), \\ \lambda_e(\Upsilon_{\partial\mathrm{F}}(\mathbf{v})) & \text{for } e\subset \mathrm{F}_\partial \ (\mathrm{F}\subset\Gamma). \end{cases}$$

Note that although $\Pi_0\mathbf{v}$ involves the degrees of freedom inside Ω_i, $\Pi_0\mathbf{v}\times\mathbf{n}$ is determined on Γ uniquely by the moments $\lambda_e(\mathbf{v})$ for all $e\subset\Gamma$. Thus $\Pi_0\mathbf{v}\times\mathbf{n}\in V_h(\Gamma)$ can also be defined directly by

$$\Pi_0\mathbf{v}\times\mathbf{n} = \begin{cases} \mathbf{v}\times\mathbf{n} & \text{on } \Delta_i \ (i=1,\dots,N), \\ \Upsilon_{\partial\mathrm{F}}(\mathbf{v}\times\mathbf{n}) & \text{on } \mathrm{F}_\partial \ (\mathrm{F}\subset\Gamma), \end{cases}$$

where we have used the fact that the normal vector $\mathbf{n}$ is constant on any face $\mathrm{F}\subset\Gamma$ and

$$\Upsilon_{\partial\mathrm{F}}(\mathbf{v})\times\mathbf{n}\big|_{\mathrm{F}} = \Upsilon_{\partial\mathrm{F}}(\mathbf{v}\times\mathbf{n}).$$

Now, we can define the two coarse subspaces:

$$V_h^{01}(\Gamma) = \Big\{\Phi_0 \in V_h(\Gamma);\ \mathbf{I}_i\Phi_0 = \mathbf{grad}(R_0^i \mathrm{I}_i \pi_0\varphi)\times\mathbf{n} \text{ on } \Gamma_i \text{ for some } \varphi\in Z_h(\Gamma)\Big\},$$

$$V_h^{02}(\Gamma) = \Big\{\mathbf{v}_0\times\mathbf{n} \in V_h(\Gamma);\ \mathbf{v}_0 = \Pi_0\mathbf{v} \text{ for some } \mathbf{v}\times\mathbf{n}\in V_h(\Gamma)\Big\}.$$

The operator R_0^i used in $V_h^{01}(\Gamma)$ is the zero extension into the interior of Ω_i; namely, for any $v_h\in Z_h(\Gamma_i)$, $R_0^i v_h \in Z_h(\Omega_i)$ takes the same values as v_h on Γ_i and vanishes at all interior nodes of Ω_i. We can define two coarse solvers $\mathbf{S}_{0k} : V_h^{0k}(\Gamma)\to V_h^{0k}(\Gamma)^*$, $k=1,2$, associated with these coarse subspaces. For any $\Phi_0, \Psi_0 \in V_h^{01}(\Gamma)$, there exist $\varphi,\ \psi\in Z_h(\Gamma)$ such that on Γ_i,

$$\mathbf{I}_i\Phi_0 = \mathbf{grad}(R_0^i\mathrm{I}_i\pi_0\varphi)\times\mathbf{n}, \quad \mathbf{I}_i\Psi_0 = \mathbf{grad}(R_0^i\mathrm{I}_i\pi_0\psi)\times\mathbf{n}\,.$$

Then $\mathbf{S}_{01}$ is defined by

$$\langle \mathbf{S}_{01}\Phi_0, \Psi_0\rangle = [1+\log(d/h)]\sum_{i=1}^N \langle \pi_0\varphi - \gamma_{_{\mathcal{W}_i}}(\pi_0\varphi), \pi_0\psi - \gamma_{_{\mathcal{W}_i}}(\pi_0\psi)\rangle_{h,\mathcal{W}_i}.$$

Similarly, for any $\Phi_0, \Psi_0 \in V_h^{02}(\Gamma)$, there exist $\mathbf{v}$, $\mathbf{w} \in V_h(\Omega)$ such that on Γ_i,

$$\mathbf{I}_i\Phi_0 = \Pi_0\mathbf{v} \times \mathbf{n}, \quad \mathbf{I}_i\Psi_0 = \Pi_0\mathbf{w} \times \mathbf{n}.$$

Then $\mathbf{S}_{02}$ is defined by

$$\langle \mathbf{S}_{02}\Phi_0, \Psi_0\rangle = [1 + \log(d/h)] \sum_{i=1}^{N} \langle \Phi_0 - \Upsilon_{\Delta_i}(\mathbf{v}) \times \mathbf{n}, \Psi_0 - \Upsilon_{\Delta_i}(\mathbf{w}) \times \mathbf{n}\rangle_{*,\Delta_i} \\ + d^2\langle \Phi_0, \Psi_0\rangle_{*,\Delta_i}.$$

Hereafter, $\Upsilon_{\Delta_i}(\mathbf{v})$ is the constant vector satisfying

$$\|\Phi_0 - \Upsilon_{\Delta_i}(\mathbf{v}) \times \mathbf{n}\|^2_{*,\Delta_i} = \min_{C_{\Delta_i} \in \mathcal{R}^3} \|\Phi_0 - C_{\Delta_i} \times \mathbf{n}\|^2_{*,\Delta_i},$$

which can be viewed as some average of Φ_0 on Δ_i. And the average is well defined.

Finally, the preconditioner for the interface operator $\mathbf{S}$ can be defined as follows:

$$\mathbf{M}^{-1} = \mathbf{S}_{01}^{-1} + \mathbf{S}_{02}^{-1} + \sum_{\Gamma_{ij}} \mathbf{I}_{ij}^t \mathbf{S}_{ij}^{-1} \mathbf{I}_{ij}. \tag{3.5}$$

For this preconditioner, we have the following theorem.

THEOREM 3.1. *The condition number of the preconditioned system can be estimated by*

$$\text{cond}(\mathbf{M}^{-1}\mathbf{S}) \le C[1 + \log(d/h)]^3. \tag{3.6}$$

Remark 3.1. A simple algorithm to implement the coarse solver $\mathbf{S}_{01}$ can be found in [33]. By the minimum property of the average $\Upsilon_{\Delta_i}(\Phi_0)$, we can also derive a simple algorithm for implementing the coarse solver $\mathbf{S}_{02}$, which is similar to the one in [33]. Note that one may also use the inner product $h^{-1}\langle\cdot,\cdot\rangle_{\Delta_i}$ in the definition of $\mathbf{S}_{02}$ instead of the inner product $\langle\cdot,\cdot\rangle_{*,\Delta_i}$. Furthermore, one may use the discrete $L^2(\Delta_i)^3$-inner product

$$\langle\langle \mathbf{v} \times \mathbf{n}, \mathbf{w} \times \mathbf{n}\rangle\rangle_{h,\Delta_i} = \sum_{e \subset \Delta_i} \lambda_e(\mathbf{v})\lambda_e(\mathbf{w}) \quad \forall \mathbf{v} \times \mathbf{n}, \mathbf{w} \times \mathbf{n} \in V_h(\Gamma_i),$$

to define the coarse solver $\mathbf{S}_{02}$, but we do not know yet how to verify the existence of the corresponding average.

Remark 3.2. The "local" operator $\mathbf{S}_{ij}$ may be replaced by any other spectrally equivalent operator, for example, the operator defined by

$$\langle \mathbf{S}_{ij}^i \Phi_{ij}, \Psi_{ij}\rangle_{\Gamma_{ij}} = A_i(\mathbf{R}_h^i \mathbf{I}_{ij}^t \Phi_{ij}, \mathbf{R}_h^i \mathbf{I}_{ij}^t \Psi_{ij}) \quad \forall \Psi_{ij} \in V_h^0(\Gamma_{ij}).$$

$\mathbf{S}_{ij}^i$ is easier to implement than $\mathbf{S}_{ij}$, but it loses the symmetry with respect to the face Γ_{ij}.

Remark 3.3. Based on our current analysis in section 5, the constant C in the condition number estimate (3.6) may have a factor $\gamma_{\max}/\gamma_{\min}$ related to the coefficients in (1.1), where $\gamma_{\max}$ is the supremum of $\beta(x)$ and $\alpha^2(x)$ over $\bar{\Omega}$, and $\gamma_{\min}$ is the infimum of $\beta(x)$ and $\alpha^2(x)$ over $\bar{\Omega}$. It is possible to improve such dependence on the coefficients if a more localized and sharper analysis can be found.

Remark 3.4. The nodal element coarse interpolant π_0 is widely used in nonoverlapping DDMs for second order elliptic problems [13], [33]. The new edge element coarse interpolant Π_0 is very similar to π_0 but with some essential differences. For a $H^1(\Omega)^3$ vector-valued function $\mathbf{v}$, there is no trace on the wirebasket set $\mathcal{W}_i$, and the coarse interpolants $\pi_0\mathbf{v}$ and $\Pi_0\mathbf{v}$ make no sense. However, it is known that π_0 is stable in the nodal element space $Z_h(\Gamma_i)$ [13], [33]. Likewise, we shall show in section 4 that Π_0 is stable in the edge element space $V_h(\Gamma_i)$, with the stability constants growing only polylogarithmically with d/h. This explains somewhat why we can achieve a logarithmical bound (3.6) on the condition number.

4. Some auxiliary lemmas.

As we shall see, the estimate (3.6) of the condition number $\text{cond}(\mathbf{M}^{-1}\mathbf{S})$ for the preconditioned system is rather technical. This section presents some basic properties of Sobolev spaces and auxiliary lemmas, which are needed to deal with the technical difficulties in the estimate of the condition number. The proofs will be provided in the appendix. The constant C will be used often in what follows for the generic constant that may take different values at different occasions.

4.1. The scaled norms.

A large part of the condition number estimate will be carried out on the subdomains, for which we need some scaled norms. For the space $H^1(\Omega_i)^3$, we define a scaled norm by

$$\|\mathbf{v}\|_{1,\Omega_i} = (|\mathbf{v}|^2_{1,\Omega_i} + d^{-2}\|\mathbf{v}\|^2_{0,\Omega_i})^{\frac{1}{2}} \quad \forall\, \mathbf{v} \in H^1(\Omega_i)^3,$$

while for the space $H(\mathbf{curl};\Omega_i)$, the restriction of $H_0(\mathbf{curl};\Omega)$ on the subdomain Ω_i, and the interface space $H^{-\frac{1}{2}}(\Gamma_i)$, we define their scaled norms by

$$\|\mathbf{v}\|_{\mathbf{curl};\Omega_i} = \left(\|\mathbf{curl}\,\mathbf{v}\|^2_{0,\Omega_i} + d^{-2}\|\mathbf{v}\|^2_{0,\Omega_i}\right)^{\frac{1}{2}} \quad \forall\, \mathbf{v} \in H(\mathbf{curl};\Omega_i)\,,$$

$$\|\lambda\|_{-\frac{1}{2},\Gamma_i} = \sup_{v\in H^{\frac{1}{2}}(\Gamma_i)} \frac{|\langle\lambda, v\rangle_{\Gamma_i}|}{\|v\|_{\frac{1}{2},\Gamma_i}} \quad \forall\, \lambda \in H^{-\frac{1}{2}}(\Gamma_i),$$

where

$$\|v\|_{\frac{1}{2},\Gamma_i} = (|v|^2_{\frac{1}{2},\Gamma_i} + d^{-1}\|v\|^2_{0,\Gamma_i})^{\frac{1}{2}}.$$

For any $\Phi \in V_h(\Gamma_i)$, we use $\text{div}_\tau\Phi$ to denote the tangential divergence of Φ; see [2] and [3] for the definition of $\text{div}_\tau\Phi$. It is known that $\text{div}_\tau\Phi \in H^{-\frac{1}{2}}(\Gamma_i)$, so it makes sense to define the norm

$$\|\Phi\|_{\mathcal{X}_{\Gamma_i}} = d^{-1}\|\Phi\|_{-\frac{1}{2},\Gamma_i} + \|\text{div}_\tau\Phi\|_{-\frac{1}{2},\Gamma_i}.$$

The next two estimates on this norm $\|\cdot\|_{\mathcal{X}_{\Gamma_i}}$ can be found in [3].

LEMMA 4.1. *The discrete* **curl**-*extension* $\mathbf{R}^i_h\Phi \in V_h(\Omega_i)$ *satisfies*

$$\|R^i_h\Phi\|_{\mathbf{curl};\Omega_i} \le C\|\Phi\|_{\mathcal{X}_{\Gamma_i}}. \tag{4.1}$$

LEMMA 4.2. *Let* $\mathbf{u} \in V_h(\Omega_i)$, *which satisfies* $\mathbf{u}\times\mathbf{n} = \Phi$ *on* Γ_i. *Then*

$$\|\Phi\|_{\mathcal{X}_{\Gamma_i}} \le C\|\mathbf{u}\|_{\mathbf{curl};\Omega_i}. \tag{4.2}$$

4.2. Estimates with the norm $\|\cdot\|_{1/2,\Gamma_i}$ and the edge element interpolant. The results in Lemma 4.3 can be found in [7] and [33].

LEMMA 4.3. *For any $\varphi \in Z_h(\Gamma)$, we have*

$$C\,|\pi_0\varphi|^2_{\frac{1}{2},\Gamma_i} \le [1+\log(d/h)]\|\varphi - \gamma_{\mathcal{W}_i}(\varphi)\|^2_{h,\mathcal{W}_i} \le C[1+\log(d/h)]^2|\varphi|^2_{\frac{1}{2},\Gamma_i} \tag{4.3}$$

and for any face F $\subset \Gamma_i$,

$$\|\mathrm{I}^0_{\mathrm{F}}(\varphi - \pi_0\varphi)\|^2_{\frac{1}{2},\Gamma_i} \le C[1+\log(d/h)]^2|\varphi|^2_{\frac{1}{2},\Gamma_i}\,. \tag{4.4}$$

Now we define an interpolation operator $\mathbf{r}_h$ associated with the space $V_h(\Omega)$. For any appropriately smooth $\mathbf{v}$, $\mathbf{r}_h\mathbf{v} \in V_h(\Omega)$ is a function in $V_h(\Omega)$ which has the same moments on the edges of $\mathcal{T}_h$ as $\mathbf{v}$, namely,

$$\int_e \mathbf{r}_h\mathbf{v}\cdot\mathbf{t}_e ds = \int_e \mathbf{v}\cdot\mathbf{t}_e ds \quad \forall\, \mathbf{v}\in H^1(\Omega) \text{ and } \ e\in\mathcal{E}_h.$$

The interpolant $\mathbf{r}_h\mathbf{v}$ is well defined on each element K for all $\mathbf{v}$ lying in the space

$$\Big\{\mathbf{w}\in L^p(K)^3;\ \mathbf{curl}\,\mathbf{v}\in L^p(K)^3 \text{ and } \mathbf{v}\times\mathbf{n}\in L^p(\partial K)^3\Big\}$$

with $p > 2$; see Lemma 4.7 in [4]. From this we immediately know that $\mathbf{r}_h\mathbf{v}$ is well defined for all $\mathbf{v}$ in $H^1(\Omega)^3$ whose **curl** is in $L^p(K)^3$.

The following three lemmas present some estimates on the interpolation operator r_h. The proof of the first lemma below is quite similar to the proofs of Lemma 4.7 in [4] and Lemma 3.2 in [12], and details can be found in [20].

LEMMA 4.4. *Let $\mathbf{w}\in H^1(\Omega_i)^3$ and its interpolant $\mathbf{r}_h\mathbf{w}$ be well defined in $V_h(\Omega_i)$. Also, we assume that* $\mathbf{curl}\,\mathbf{w} = \mathbf{curl}\,\mathbf{v}_h$ *for some $\mathbf{v}_h\in V_h(\Omega_i)$. Then*

$$\|\mathbf{r}_h\mathbf{w}-\mathbf{w}\|_{0,\Omega_i} \le Ch(|\mathbf{w}|^2_{1,\Omega_i} + \|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i})^{\frac{1}{2}}. \tag{4.5}$$

LEMMA 4.5. *Under the same assumptions as in Lemma* 4.4, *for any face* F *of* Γ_i *we have*

$$\|(\mathbf{r}_h\mathbf{w})\times\mathbf{n}\|_{*,\mathrm{F}_b} \le C[1+\log(d/h)]^{\frac{1}{2}}(\|\mathbf{w}\|^2_{1,\Omega_i} + \|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i})^{\frac{1}{2}}. \tag{4.6}$$

LEMMA 4.6. *Under the same assumptions as in Lemma* 4.4, *for any face* F *of* Γ_i *we have*

$$d^{-2}\|\mathbf{r}_h\mathbf{w} - \Upsilon_{\partial\mathrm{F}}(\mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i} \le C[1+\log(d/h)](|\mathbf{w}|^2_{1,\Omega_i} + \|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i}), \tag{4.7}$$

$$d^{-2}\|\mathbf{w} - \Upsilon_{\partial\mathrm{F}}(\mathbf{r}_h\mathbf{w})\|_{0,\Omega_i} \le C[1+\log(d/h)](|\mathbf{w}|^2_{1,\Omega_i} + \|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i}). \tag{4.8}$$

4.3. Some estimates with the norm$\|\cdot\|_{\mathcal{X}_{\Gamma_i}}$.

LEMMA 4.7. *Let $\mathbf{w}$ and $\mathbf{v}_h$ be the same as specified in Lemma* 4.4, *and $\Phi = \mathbf{r}_h\mathbf{w}\times\mathbf{n}$ on Γ_i. Then for any face* F $\subset\Gamma_i$ *we have*

$$\|\mathbf{I}^0_{\mathrm{F}_\partial}\Phi\|_{\mathcal{X}_{\Gamma_i}} \le C[1+\log(d/h)](\|\Phi\|_{\mathcal{X}_{\Gamma_i}} + \|\mathbf{w}\|_{1,\Omega_i} + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_i}). \tag{4.9}$$

LEMMA 4.8. *Let $\Phi = \mathbf{v}\times\mathbf{n}\in V_h(\Gamma_i)$ on Γ_i, and*

$$\mathbf{I}^0_{\Delta_i}\Phi(\mathbf{x}) = \sum_{e\subset\Delta_i}\lambda_e(\mathbf{v})(L_e\times\mathbf{n}_i)(\mathbf{x}), \quad \mathbf{x}\in\Gamma_i.$$

We have

$$\|\mathbf{I}^0_{\Delta_i}\Phi\|_{\mathcal{X}_{\Gamma_i}} \le C[1+\log(d/h)]^{\frac{1}{2}}\|\Phi\|_{*,\Delta_i}. \tag{4.10}$$

LEMMA 4.9. *Assume that $\mathbf{v}\in V_h(\Omega)$ and* F $\subset\Gamma_k$. *Then*

$$\|\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})\|^2_{\mathcal{X}_{\Gamma_k}} \le C[1+\log(d/h)]\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\mathrm{F}_b}. \tag{4.11}$$

5. The estimate of condition number. This section is devoted to the estimate (3.6) of the condition number of the preconditioned system $\mathbf{M}^{-1}\mathbf{S}$. The estimation will be done by using the following additive Schwarz framework [26], [32], whose proof is standard (cf. [18] and [27]).

LEMMA 5.1. *Assume that the following two conditions hold:*

(i) *For any* $\Phi \in V_h(\Gamma)$ *there is a decomposition* $\Phi = \Phi_{01} + \Phi_{02} + \sum_{i<j} \mathrm{I}_{ij}^t \Phi_{ij}$, *with* $\Phi_{0k} \in V_h^{0k}(\Gamma)$ $(k = 1,\ 2)$ *and* $\Phi_{ij} \in V_h^0(\Gamma_{ij})$, *such that*

$$\langle \mathbf{S}_{01}\Phi_{01}, \Phi_{01}\rangle + \langle \mathbf{S}_{02}\Phi_{02}, \Phi_{02}\rangle + \sum_{i<j} \langle \mathbf{S}_{ij}\Phi_{ij}, \Phi_{ij}\rangle_{\Gamma_{ij}} \le C_1 \langle \mathbf{S}\Phi, \Phi\rangle; \tag{5.1}$$

(ii) *For any* $\Psi_{0k} \in V_h^{0k}(\Gamma)$ $(k = 1, 2)$ *and* $\Psi_{ij} \in V_h^0(\Gamma_{ij})$, *we have*

$$\left\langle \mathbf{S}\left(\sum_{i<j} \mathbf{I}_{ij}^t \Psi_{ij} + \Psi_{01} + \Psi_{02}\right),\ \sum_{i<j} \mathbf{I}_{ij}^t \Psi_{ij} + \Psi_{01} + \Psi_{02}\right\rangle \tag{5.2}$$
$$\le C_2 \left\{ \sum_{i<j} \langle \mathbf{S}_{ij}\Psi_{ij}, \Psi_{ij}\rangle_{\Gamma_{ij}} + \langle \mathbf{S}_{01}\Psi_{01}, \Psi_{01}\rangle + \langle \mathbf{S}_{02}\Psi_{02}, \Psi_{02}\rangle \right\}.$$

Then we have $\mathrm{cond}(\mathbf{M}^{-1}\mathbf{S}) \le C_1 C_2$.

The rest of this section applies Lemma 5.1 to show Theorem 3.1, the main result of this paper. First, we construct the important decomposition required in the lemma. For this, we will make use of the so-called regular decomposition instead of the usual $L^2(\Omega)$-orthogonal Helmholtz decomposition [14].

For any $\mathbf{v} \in H_0(\mathbf{curl};\Omega)$, there exist some $\mathbf{w} \in H_0^1(\Omega)^3$ and $p \in H_0^1(\Omega)$ such that the following regular decomposition holds (cf. [6], [16]):

$$\mathbf{v} = \nabla p + \mathbf{w} \tag{5.3}$$

with the estimates

$$\|w\|_{0,\Omega} + \|p\|_{1,\Omega} \le C\, \|\mathbf{v}\|_{0,\Omega}\,, \quad |\mathbf{v}|_{1,\Omega} \le C \|\mathbf{curl}\,\mathbf{v}\|_{0,\Omega}\,. \tag{5.4}$$

We remark that the use of Helmholtz-type or regular decompositions is a fundamental technique for the analysis of preconditioners for $H(\mathbf{curl};\Omega)$- and $H(\mathrm{div};\Omega)$-elliptic problems [1], [15], [17], [16], [28].

Now, for any $\Phi \in V_h(\Gamma)$, we define a $\mathbf{v}_h \in V_h(\Omega)$ such that $\mathbf{v}_h = \mathbf{R}_h^i \mathbf{I}_i \Phi$ in each subdomain Ω_i. By the regular decomposition (5.3), there exist $p \in H_0^1(\Omega)$ and $\mathbf{w} \in H_0^1(\Omega)^3$ such that

$$\mathbf{v}_h = \mathbf{grad}\ p + \mathbf{w}\,. \tag{5.5}$$

As $\mathbf{w} \in H_0^1(\Omega)^3$ and $\mathbf{curl}\,\mathbf{w} = \mathbf{curl}\,\mathbf{v}_h$, so $\mathbf{r}_h\mathbf{w}$ is well defined (see subsection 4.2). This, with (5.5), implies

$$\mathbf{v}_h = \mathbf{r}_h \mathbf{grad}\ p + \mathbf{r}_h \mathbf{w}\,.$$

By Lemma 5.10 in [14], there exists a function $p_h \in Z_h(\Omega)$ such that

$$\mathbf{v}_h = \mathbf{grad}\ p_h + \mathbf{r}_h \mathbf{w} = \mathbf{grad} p_h + \mathbf{w}_h \tag{5.6}$$

with $\mathbf{w}_h = \mathbf{r}_h \mathbf{w} \in V_h(\Omega)$. By (5.5) and (5.6), we know

$$\mathbf{curl}\ \mathbf{w}_h = \mathbf{curl}\ \mathbf{w} = \mathbf{curl}\ \mathbf{v}_h. \tag{5.7}$$

Now we are ready to show Theorem 3.1 using Lemma 5.1. We divide the proof into four steps.

Step 1. Establish a suitable decomposition for $\Phi \in V_h(\Gamma)$. For ease of notation, we introduce $p_h^0 \in Z_h(\Omega)$ and Φ_{01} by

$$\begin{aligned} p_h^0 &= R_h^i \mathrm{I}_i \pi_0 (p_h|_\Gamma) \quad \text{in} \quad \Omega_i, \quad i = 1, \ldots, N, \\ \Phi_{01}(\mathbf{x}) &= (\mathbf{grad}\ (p_h^0|_{\Omega_i}) \times \mathbf{n})(\mathbf{x}), \quad \mathbf{x} \in \Gamma_i,\ i = 1, 2, \ldots, N. \end{aligned}$$

By direct checking, we can also write

$$\Phi_{01}(\mathbf{x}) = (\mathbf{grad}\ (\tilde{p}_h^0|_{\Omega_i}) \times \mathbf{n})(\mathbf{x}), \quad \mathbf{x} \in \Gamma_i,$$

with $\tilde{p}_h^0 = R_0^i \mathrm{I}_i \pi_0 (p_h|_\Gamma)$. So we know $\Phi_{01}(\mathbf{x}) \in V_h^{01}(\Gamma)$. Next, we choose $\mathbf{w}_{02} = \Pi_0 \mathbf{w}_h \in V_h(\Omega)$ and let

$$\Phi_{02} = (\mathbf{w}_{02} \times \mathbf{n})|_\Gamma \in V_h^{02}(\Gamma).$$

Define $\Phi_{ij} \in V_h(\Gamma_{ij})$ by

$$\begin{aligned} \Phi_{ij} &= \mathbf{I}_{ij}((\mathbf{grad}\ p_h + \mathbf{w}_h) \times \mathbf{n}) - \mathbf{I}_{ij}(\Phi_{01} + \Phi_{02}) \\ &= \mathbf{I}_{ij}(\mathbf{grad}\ (p_h - p_h^0) \times \mathbf{n}) + \mathbf{I}_{ij}(\mathbf{w}_h \times \mathbf{n} - \Phi_{02}) \\ &= \mathbf{I}_{ij}(\mathbf{grad}\ (p_h - p_h^0) \times \mathbf{n}) + \mathbf{I}_{ij}((\mathbf{w}_h - \mathbf{w}_{02}) \times \mathbf{n}). \end{aligned}$$

Noting the fact that $p_h^0 - p_h$ vanishes on the wirebasket set $\mathcal{W}_i$, we can easily verify that $\lambda_e(\mathbf{grad}\ (p_h - p_h^0)) = 0$ for any $e \in \mathcal{E}_h \cap \mathcal{W}_i$. Also, we have $\lambda_e(\mathbf{w}_h - \mathbf{w}_{02}) = 0$ for any face e on Δ_i. Thus $\Phi_{ij} \in V_h^0(\Gamma_{ij})$, and the following decomposition holds:

$$\Phi = \Phi_{01} + \Phi_{02} + \sum_{\Gamma_{ij}} \mathbf{I}_{ij}^t \Phi_{ij}. \tag{5.8}$$

Step 2. Prove the estimate

$$\sum_{\Gamma_{ij}} \langle \mathbf{S}_{ij} \Phi_{ij}, \Phi_{ij} \rangle_{\Gamma_{ij}} \le C[1 + \log(d/h)]^3 \langle \mathbf{S}\Phi, \Phi \rangle. \tag{5.9}$$

For any face Γ_{ij} of Γ_i, we define

$$\begin{aligned} p_{ij}^i &= R_h^i \mathrm{I}_{ij}^t [(p_h - p_h^0)|_{\Gamma_{ij}}] \in Z_h(\Omega_i), \\ \mathbf{w}_{ij}^i &= \mathbf{R}_h^i \mathbf{I}_{ij}^t [((\mathbf{w}_h - \mathbf{w}_{02}) \times \mathbf{n})|_{\Gamma_{ij}}] \in V_h(\Omega_i), \\ \mathbf{v}_{ij}^i &= \mathbf{grad}\ p_{ij}^i + \mathbf{w}_{ij}^i \in V_h(\Omega_i). \end{aligned}$$

Using the fact that

$$\mathbf{R}_h^i \mathbf{I}_{ij}^t \Phi_{ij} \times \mathbf{n} = \mathbf{I}_{ij}^t \Phi_{ij} = \mathbf{v}_{ij}^i \times \mathbf{n} \quad \text{on} \quad \Gamma_i,$$

we obtain by the minimum **curl**-energy property of the discrete **curl**-extension that

$$\begin{aligned} A_i(\mathbf{R}_h^i \mathbf{I}_{ij}^t \Phi_{ij}, \mathbf{R}_h^i \mathbf{I}_{ij}^t \Phi_{ij}) \le A_i(\mathbf{v}_{ij}^i, \mathbf{v}_{ij}^i) &= \|\alpha^{\frac{1}{2}} \mathbf{curl}\ \mathbf{w}_{ij}^i\|_{0,\Omega_i}^2 + \|\beta^{\frac{1}{2}} \mathbf{v}_{ij}^i\|_{0,\Omega_i}^2 \\ &\le C(\|\mathbf{grad}\ p_{ij}^i\|_{0,\Omega_i}^2 + \|\mathbf{w}_{ij}^i\|_{\mathbf{curl},\Omega_i}^2). \end{aligned} \tag{5.10}$$

As $p_h^0 = \pi_0(p_h|_\Gamma)$ on Γ, we have

$$\mathrm{I}_{ij}^t[(p_h - p_h^0)|_{\Gamma_{ij}}] = \mathrm{I}_{ij}^0(p_h|_\Gamma - \pi_0(p_h|_\Gamma)).$$

Thus, using (4.4) and the trace theorem, we obtain

$$\begin{aligned}(5.11)\qquad \|\mathbf{grad}\ p_{ij}^i\|_{0,\Omega_i}^2 &= |p_{ij}^i|_{1,\Omega_i}^2 \le C|\mathrm{I}_{ij}^t[(p_h - p_h^0)|_{\Gamma_{ij}}]|_{\frac{1}{2},\Gamma_i}^2\\ &\le C[1+\log(d/h)]^2|p_h|_{\frac{1}{2},\Gamma_i}^2\\ &\le C[1+\log(d/h)]^2|p_h|_{1,\Omega_i}^2.\end{aligned}$$

We next estimate $\mathbf{w}_{ij}^i$. For each (open) common face $\mathrm{F} = \Gamma_{ij}$ shared by Ω_i and Ω_j, it follows from the definition of Π_0 that

$$\lambda_e(\mathbf{w}_h - \mathbf{w}_{02}) = \begin{cases} 0 & \text{if } e \subset \mathrm{F}_b,\\ \lambda_e(\mathbf{w}_h - \Upsilon_{\partial \mathrm{F}}(\mathbf{w}_h)) & \text{if } e \subset \mathrm{F}_\partial\,. \end{cases}$$

Then we derive by using (5.7) and Lemmas 4.1 and 4.7 that

$$\begin{aligned}(5.12)\qquad \|\mathbf{w}_{ij}^i\|_{\mathbf{curl},\Omega_i}^2 &\le C\|\mathbf{I}_{ij}^t[((\mathbf{w}_h - \mathbf{w}_{02})\times\mathbf{n})|_{\Gamma_{ij}}]\|_{\mathcal{X}_{\Gamma_i}}^2\\ &= C\|\mathbf{I}_{\mathrm{F}_\partial}^0[(\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h))\times\mathbf{n}]\|_{\mathcal{X}_{\Gamma_i}}^2\\ &\le C[1+\log(d/h)]^2(\|(\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h))\times\mathbf{n}\|_{\mathcal{X}_{\Gamma_i}}^2\\ &\quad +\|\mathbf{w} - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h)\|_{1,\Omega_i}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_i}^2).\end{aligned}$$

On the other hand, for the term $(\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h))\times\mathbf{n}$ we have by Lemma 4.2 and (5.5) that

$$\begin{aligned}&\|(\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h))\times\mathbf{n}\|_{\mathcal{X}_{\Gamma_i}}^2\\ &\le C\|\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h)\|_{\mathbf{curl};\Omega_i}^2\\ &= C(\|\mathbf{curl}\ \mathbf{w}_h\|_{0;\Omega_i}^2 + d^{-2}\|\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h)\|_{0;\Omega_i}^2)\\ &= C(\|\mathbf{curl}\ \mathbf{v}_h\|_{0;\Omega_i}^2 + d^{-2}\|\mathbf{w}_h - \Upsilon_{\partial\Gamma_{ij}}(\mathbf{w}_h)\|_{0;\Omega_i}^2).\end{aligned}$$

Combining this with (5.12) and using Lemma 4.6 give

$$\|\mathbf{w}_{ij}^i\|_{\mathbf{curl},\Omega_i}^2 \le C[1+\log(d/h)]^3(|\mathbf{w}|_{1,\Omega_i}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_i}^2).$$

With this estimate, (5.10), and (5.11), we come to

$$(5.13)\quad A_i(\mathbf{R}_h^i\mathbf{I}_{ij}^t\Phi_{ij}, \mathbf{R}_h^i\mathbf{I}_{ij}^t\Phi_{ij}) \le C[1+\log(d/h)]^3(|p_h|_{1,\Omega_i}^2 + |\mathbf{w}|_{1,\Omega_i}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_i}^2).$$

Similarly, we have

$$A_j(\mathbf{R}_h^j\mathbf{I}_{ij}^t\Phi_{ij}, \mathbf{R}_h^j\mathbf{I}_{ij}^t\Phi_{ij}) \le C[1+\log(d/h)]^3(|p_h|_{1,\Omega_j}^2 + |\mathbf{w}|_{1,\Omega_j}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_j}^2).$$

So we have proved

$$\begin{aligned}\langle S_{ij}\Phi_{ij}, \Phi_{ij}\rangle_{\Gamma_{ij}} \le C[1+\log(d/h)]^3(&|p_h|_{1,\Omega_i}^2 + |p_h|_{1,\Omega_j}^2 + |\mathbf{w}|_{1,\Omega_i}^2\\ &+|\mathbf{w}|_{1,\Omega_j}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_i}^2 + \|\mathbf{curl}\ \mathbf{v}_h\|_{0,\Omega_j}^2),\end{aligned}$$

or

$$\begin{aligned}(5.14)\quad \sum_{\Gamma_{ij}}\langle \mathbf{S}_{ij}\Phi_{ij},\Phi_{ij}\rangle_{\Gamma_{ij}} &\le C[1+\log(d/h)]^3\sum_{i=1}^{N}(|p_h|^2_{1,\Omega_i}+|\mathbf{w}|^2_{1,\Omega_i}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega_i})\\ &= C[1+\log(d/h)]^3\Bigg(|p_h|^2_{1,\Omega}+|\mathbf{w}|^2_{1,\Omega}\\ &\qquad + \sum_{i=1}^{N}\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega_i}\Bigg).\end{aligned}$$

To prove (5.9), it suffices to show

$$(5.15)\qquad |p_h|^2_{1,\Omega}+|\mathbf{w}|^2_{1,\Omega}\le C(\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega}),$$

as this, with (5.14), implies

$$\begin{aligned}\sum_{\Gamma_{ij}}\langle \mathbf{S}_{ij}\Phi_{ij},\Phi_{ij}\rangle_{\Gamma_{ij}} &\le C[1+\log(d/h)]^3\sum_{i=1}^{N}(\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega_i}+\|\mathbf{v}_h\|^2_{0,\Omega_i})\\ &\le C[1+\log(d/h)]^3\sum_{i=1}^{N}A_i(\mathbf{R}_h^i\mathbf{I}_i\Phi,\mathbf{R}_h^i\mathbf{I}_i\Phi).\end{aligned}$$

Next we show (5.15). It follows from (5.4) and (5.7) that

$$(5.16)\qquad |\mathbf{w}|^2_{1,\Omega}\le C\|\mathbf{curl}\ \mathbf{w}\|^2_{0,\Omega}=C\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega}\,.$$

However, by Lemma 4.4 and (5.4) we obtain that

$$\|\mathbf{r}_h\mathbf{w}\|^2_{0,\Omega}\le C\,(h^2\,\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega}+h^2\,|\mathbf{w}|^2_{1,\Omega}+\|\mathbf{w}\|^2_{0,\Omega})\le C\,\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega}.$$

Inequality (5.15) is then a consequence of this estimate, (5.16), and the triangle inequality

$$\|\nabla p_h\|_{0,\Omega}\le\|\mathbf{v}_h\|_{0,\Omega}+\|\mathbf{r}_h\mathbf{w}\|_{0,\Omega}\,.$$

Step 3. Derive the estimate

$$(5.17)\qquad \langle\mathbf{S}_{01}\Phi_{01},\Phi_{01}\rangle+\langle\mathbf{S}_{02}\Phi_{02},\Phi_{02}\rangle\le C[1+\log(d/h)]^2\langle\mathbf{S}\Phi,\Phi\rangle.$$

It follows from the definitions of $\mathbf{S}_{01}$ and Φ_{01} that

$$\langle\mathbf{S}_{01}\Phi_{01},\Phi_{01}\rangle=[1+\log(d/h)]\sum_{i=1}^{N}\|p_h^0-\gamma_{\Delta_i}p_h^0\|^2_{h,\Delta_i}.$$

Thus, by (4.3) and the trace theorem, we have

$$\begin{aligned}(5.18)\qquad \langle\mathbf{S}_{01}\Phi_{01},\Phi_{01}\rangle &\le C[1+\log(d/h)]^2\sum_{i=1}^{N}|p_h|^2_{\frac{1}{2},\Gamma_i}\\ &\le C[1+\log(d/h)]^2\sum_{i=1}^{N}|p_h|^2_{1,\Omega_i}\end{aligned}$$

$$\leq C[1+\log(d/h)]^2|p_h|^2_{1,\Omega}.$$

By the definitions of $\mathbf{S}_{02}$ and Φ_{02}, we know

$$\langle \mathbf{S}_{02}\Phi_{02},\Phi_{02}\rangle = [1+\log(d/h)]\sum_{i=1}^{N}(\|(\mathbf{w}_h-\Upsilon_{\Delta_i}(\mathbf{w}_h))\times\mathbf{n}\|^2_{*,\Delta_i}+d^2\|\mathbf{w}_h\times\mathbf{n}\|^2_{*,\Delta_i}). \tag{5.19}$$

From the definition of $\Upsilon_{\Delta_i}(\mathbf{w}_h)$, we have

$$\|(\mathbf{w}_h-\Upsilon_{\Delta_i}(\mathbf{w}_h))\times\mathbf{n}\|^2_{*,\Delta_i}\leq\|(\mathbf{w}_h-\Upsilon_{\Gamma_i}(\mathbf{w}))\times\mathbf{n}\|^2_{*,\Delta_i}.$$

This, with Lemma 4.5 and the Poincaré inequality, gives

$$\begin{aligned}\|(\mathbf{w}_h-\Upsilon_{\Delta_i}(\mathbf{w}_h))\times\mathbf{n}\|^2_{*,\Delta_i} &\leq \sum_{\mathrm{F}\subset\Gamma_i}\|(\mathbf{w}_h-\Upsilon_{\Gamma_i}(\mathbf{w}))\times\mathbf{n}\|^2_{*,\mathrm{F}_b}\\ &\leq C[1+\log(d/h)](\|\mathbf{w}-\Upsilon_{\Gamma_i}(\mathbf{w})\|^2_{1,\Omega_i}\\ &\quad+\|\mathbf{curl}\ (\mathbf{v}_h-\Upsilon_{\Gamma_i}(\mathbf{w}))\|^2_{0,\Omega_i})\\ &\leq [1+\log(d/h)](|\mathbf{w}|^2_{1,\Omega_i}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega_i}).\end{aligned} \tag{5.20}$$

The other terms in (5.19) are estimated by Lemma 4.5 and (5.5) as follows:

$$\begin{aligned}d^2\|\mathbf{w}_h\times\mathbf{n}\|^2_{*,\Delta_i} &= d^2\sum_{\mathrm{F}\subset\Gamma_i}\|\mathbf{w}_h\times\mathbf{n}\|^2_{*,\mathrm{F}_b}\\ &\leq Cd^2[1+\log(d/h)](\|\mathbf{w}\|^2_{1,\Omega_i}+\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i})\\ &= C[1+\log(d/h)](d^2|\mathbf{w}|^2_{1,\Omega_i}+\|\mathbf{w}\|^2_{0,\Omega_i}+d^2\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i})\\ &\leq C[1+\log(d/h)](|\mathbf{w}|^2_{1,\Omega_i}+\|\mathbf{v}_h\|^2_{0,\Omega_i}+\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i}).\end{aligned}$$

So we have proved by (5.19) that

$$\langle \mathbf{S}_{02}\Phi_{02},\Phi_{02}\rangle\leq C[1+\log(d/h)]^2(|\mathbf{w}|^2_{1,\Omega}+\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega}),$$

which, together with (5.18), yields

$$\begin{aligned}&\langle \mathbf{S}_{01}\Phi_{01},\Phi_{01}\rangle+\langle \mathbf{S}_{02}\Phi_{02},\Phi_{02}\rangle\\ &\leq C[1+\log(d/h)]^2(|p_h|^2_{1,\Omega}+|\mathbf{w}|^2_{1,\Omega}+\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega})\\ &\leq C[1+\log(d/h)]^2(|p_h|^2_{1,\Omega}+|\mathbf{curl}\ \mathbf{w}|^2_{1,\Omega}+\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega})\\ &\leq C[1+\log(d/h)]^2(|p_h|^2_{1,\Omega}+\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega})\\ &\leq C[1+\log(d/h)]^2(\|\mathbf{v}_h\|^2_{0,\Omega}+\|\mathbf{curl}\ \mathbf{v}_h\|^2_{0,\Omega})\\ &\leq C[1+\log(d/h)]^2\langle\mathbf{S}\Phi,\Phi\rangle.\end{aligned}$$

The estimates (5.9) and (5.17) indicate that the constant C_1 in (5.1) can be bounded by $C[1+\log(d/h)]^3$.

Step 4. Estimate the constant C_2 in (5.2). It is easy to see that

$$\mathbf{I}_k\left(\sum_{\Gamma_{ij}}\mathbf{I}^t_{ij}\Psi_{ij}+\Psi_{01}+\Psi_{02}\right)=\sum_{\Gamma_{ij}\subset\Gamma_k}\mathbf{I}^t_{ij}\Phi_{ij}+\mathbf{I}_k\Psi_{01}+\mathbf{I}_k\Psi_{02}.$$

Hence

(5.21)

$$\begin{aligned}&\left\langle \mathbf{S}\left(\sum_{\Gamma_{ij}} \mathbf{I}_{ij}^t\Psi_{ij}+\Psi_{01}+\Psi_{02}\right),\ \sum_{\Gamma_{ij}} \mathbf{I}_{ij}^t\Psi_{ij}+\Psi_{01}+\Psi_{02}\right\rangle\\ &\le C\sum_{k=1}^N\left\{\sum_{\Gamma_{ij}\subset\Gamma_k}\langle \mathbf{S}_k\mathbf{I}_{ij}^t\Psi_{ij},\mathbf{I}_{ij}^t\Phi_{ij}\rangle_{\Gamma_k}+\langle \mathbf{S}_k\mathbf{I}_k\Psi_{01},\mathbf{I}_k\Psi_{01}\rangle_{\Gamma_k}+\langle \mathbf{S}_k\mathbf{I}_k\Psi_{02},\mathbf{I}_k\Psi_{02}\rangle_{\Gamma_k}\right\}\\ &\le C\sum_{k=1}^N\left\{\sum_{\Gamma_{ij}\subset\Gamma_k}\langle \mathbf{S}_{ij}\Psi_{ij},\Psi_{ij}\rangle_{\Gamma_{ij}}+A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{01},\mathbf{R}_h^k\mathbf{I}_k\Psi_{01})+A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{02},\mathbf{R}_h^k\mathbf{I}_k\Psi_{02})\right\}.\end{aligned}$$

As each face Γ_{ij} is shared only by two subdomains Ω_i and Ω_j, we have

$$\sum_{k=1}^N\sum_{\Gamma_{ij}\subset\Gamma_k}\langle \mathbf{S}_{ij}\Psi_{ij},\Psi_{ij}\rangle_{\Gamma_{ij}}\le C\sum_{\Gamma_{ij}}\langle \mathbf{S}_{ij}\Psi_{ij},\Psi_{ij}\rangle_{\Gamma_{ij}}. \tag{5.22}$$

Note that $\Psi_{01}\in V_h^{01}(\Gamma)$ can be written as

$$\mathbf{I}_k\Psi_{01}=\mathbf{grad}(R_h^k\mathrm{I}_k\pi_0\psi)\times\mathbf{n}\quad\text{on}\ \ \Gamma_k$$

for some $\psi\in Z_h(\Gamma)$, so we have

$$\begin{aligned}A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{01},\mathbf{R}_h^k\mathbf{I}_k\Psi_{01})&\le A_k(\mathbf{grad}(R_h^k\mathrm{I}_k\pi_0\psi),\mathbf{grad}(R_h^k\mathrm{I}_k\pi_0\psi))\\ &=|\beta^{\frac12}R_h^k\mathrm{I}_k\pi_0\psi|_{1,\Omega_k}^2\le C|\pi_0\psi|_{\frac12,\Gamma_k}^2.\end{aligned}$$

Then it follows from (4.3) that

$$A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{01},\mathbf{R}_h^k\mathbf{I}_k\Psi_{01})\le C[1+\log(d/h)]\|\pi_0\psi-\gamma_{\mathcal{W}_k}(\pi_0\psi)\|_{h,\mathcal{W}_k}^2.$$

This, with the definition of $\mathbf{S}_{01}$, shows

$$\sum_{k=1}^N A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{01},\mathbf{R}_h^k\mathbf{I}_k\Psi_{01})\le C\langle \mathbf{S}_{01}\Psi_{01},\Psi_{01}\rangle. \tag{5.23}$$

We next estimate the last term in (5.21). We can write $\Psi_{02}\in V_h^{02}(\Gamma)$ as follows:

$$\mathbf{I}_k\Psi_{02}=\Pi_0\mathbf{v}\times\mathbf{n}=[\Pi_0\mathbf{v}-\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})]\times\mathbf{n}+\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\times\mathbf{n}\quad\text{on}\ \ \Gamma_i$$

for some $\mathbf{v}\in V_h(\Gamma)$. Then, by the triangle inequality, we obtain

$$\begin{aligned}&A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{02},\mathbf{R}_h^k\mathbf{I}_k\Psi_{02})\\ &\le 2A_k(\mathbf{R}_h^k\mathbf{I}_k[\Pi_0\mathbf{v}-\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})]\times\mathbf{n},\mathbf{R}_h^k\mathbf{I}_k[\Pi_0\mathbf{v}-\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\times\mathbf{n}])\\ &\quad+A_k(\mathbf{R}_h^k\mathbf{I}_k[\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\times\mathbf{n}],\mathbf{R}_h^k\mathbf{I}_k[\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\times\mathbf{n}])).\end{aligned}$$

Furthermore, using Lemma 4.1 and the minimum **curl**-energy property of the discrete **curl**-extension, we obtain (note that $\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})$ is a constant vector)

$$\begin{aligned}&A_k(\mathbf{R}_h^k\mathbf{I}_k\Psi_{02},\mathbf{R}_h^k\mathbf{I}_k\Psi_{02})\\ &\le C(\|[\Pi_0\mathbf{v}-\Upsilon_{\mathcal{W}_k}(\Pi_0\mathbf{v})]\times\mathbf{n}\|_{\mathcal{X}_{\Gamma_i}}^2+A_k(\Upsilon_{\Delta_k}(\Pi_0\mathbf{v}),\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})))\\ &=C(\|[\Pi_0\mathbf{v}-\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})]\times\mathbf{n}\|_{\mathcal{X}_{\Gamma_k}}^2+\|\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\|_{0,\Omega_k}^2),\end{aligned} \tag{5.24}$$

where the last term can be estimated using the Hölder inequality and direct computation:

$$\|\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\|^2_{0,\Omega_k} = d^3|\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})|^2 \leq Cd^2\|\Upsilon_{\Delta_k}(\Pi_0\mathbf{v})\|^2_{*,\Delta_k} \leq Cd^2\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\Delta_k}. \tag{5.25}$$

Next, we show that the first term in (5.28) has the following bound:

$$\|[\Pi_0\mathbf{v} - \Upsilon_{\Delta_k}(\Pi_0\mathbf{v})]\times\mathbf{n}\|^2_{\mathcal{X}_{\Gamma_k}} \leq C[1+\log(d/h)]\|[\Pi_0\mathbf{v} - \Upsilon_{\Delta_k}(\Pi_0\mathbf{v})]\times\mathbf{n}\|^2_{*,\Delta_k}. \tag{5.26}$$

For this, it suffices to prove

$$\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{\mathcal{X}_{\Gamma_k}} \leq C[1+\log(d/h)]\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\Delta_k} \quad \forall \mathbf{v}\in V_h(\Omega). \tag{5.27}$$

To see this, using the relation

$$\mathbf{I}_k[(\Pi_0\mathbf{v})\times\mathbf{n}] = \mathbf{I}^0_{\Delta_k}(\Pi_0\mathbf{v}\times\mathbf{n}) + \sum_{\mathrm{F}\subset\Gamma_k}\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}),$$

we have

$$\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{\mathcal{X}_{\Gamma_k}} \leq C\left(\|\mathbf{I}^0_{\Delta_i}(\Pi_0\mathbf{v}\times\mathbf{n})\|^2_{\mathcal{X}_{\Gamma_k}} + \sum_{\mathrm{F}\subset\Gamma_k}\|\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})\|^2_{\mathcal{X}_{\Gamma_k}}\right).$$

This, together with Lemmas 4.8 and 4.9, yields (5.27).

Finally, we obtain using (5.24), (5.25), and (5.26) that

$$A_k(\mathbf{R}^k_h\mathbf{I}_k\Psi_{02}, \mathbf{R}^k_h\mathbf{I}_k\Psi_{02}) \leq C([1+\log(d/h)]\|[\mathbf{v}-\Upsilon_{\Delta_k}(\mathbf{v})]\times\mathbf{n}\|^2_{*,\Delta_k} + d^2\|\mathbf{v}\times\mathbf{n}\|^2_{*,\Delta_k}),$$

which implies

$$\sum_{k=1}^N A_k(\mathbf{R}^k_h\mathbf{I}_k\Psi_{02}, \mathbf{R}^k_h\mathbf{I}_k\Psi_{02}) \leq C\langle\mathbf{S}_{02}\Psi_{02}, \Psi_{02}\rangle.$$

This estimate with (5.22)–(5.23) indicates that the constant C_2 in (5.2) is bounded by a constant independent of h and d.

6. Appendix.

This appendix provides the technical proofs for the auxiliary lemmas in Section 4.

6.1. Proofs of Lemmas 4.5 and 4.6.

In this subsection we shall prove Lemmata 4.5 and 4.6. For this, we first give some auxiliary results. The first lemma can be found in [7], [33].

LEMMA 6.1. *Let $v_h \in Z_h(\Gamma_i)$. Then, for any $\mathrm{F}\subset\Gamma_i$, we have*

$$\|v_h\|_{0,\partial\mathrm{F}} \leq C[1+\log(d/h)]^{\frac{1}{2}}\|v_h\|_{\frac{1}{2},\Gamma_i}, \tag{6.1}$$

$$\|\mathrm{I}^0_{\mathrm{F}}v_h\|_{\frac{1}{2},\Gamma_i} \leq C[1+\log(d/h)]\|v_h\|_{\frac{1}{2},\Gamma_i}, \tag{6.2}$$

$$|\mathrm{I}^0_{\partial\mathrm{F}}v_h|_{\frac{1}{2},\mathrm{F}} \leq C[1+\log(d/h)]^{\frac{1}{2}}\|v_h\|_{\frac{1}{2},\Gamma_i}. \tag{6.3}$$

LEMMA 6.2. *Assume that $\mathbf{v}_h \in Z_h(\Omega_i)^3$. Then, for any face F of Γ_i we have*

$$d^{-2}\|\mathbf{v}_h - \Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h)\|^2_{0,\Omega_i} \leq C[1+\log(d/h)]|\mathbf{v}_h|^2_{1,\Omega_i}. \tag{6.4}$$

Proof. Since $\Upsilon_{\partial\mathrm{F}}(\cdot)$ is invariant with constant vectors, we have

$$\begin{aligned} & d^{-2}\|\mathbf{v}_h - \Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h)\|^2_{0,\Omega_i} = d^{-2}\|\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h) - \Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h))\|^2_{0,\Omega_i} \\ (6.5)\quad & \le 2d^{-2}(\|\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h)\|^2_{0,\Omega_i} + \|\Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h))\|^2_{0,\Omega_i}). \end{aligned}$$

It can be verified, by the Hölder inequality, that

$$\|\Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h))\|^2_{0,\Omega_i} \le Cd^3|\Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h))|^2 \le Cd^2\|\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h)\|^2_{0,\partial\mathrm{F}}.$$

This, together with (6.1) and the trace theorem, yields

$$\begin{aligned} d^{-2}\|\Upsilon_{\partial\mathrm{F}}(\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h))\|^2_{0,\Omega_i} &\le C[1+\log(d/h)]\|\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h)\|^2_{\frac{1}{2},\Gamma_i} \\ &\le C[1+\log(d/h)]\|\mathbf{v}_h - \Upsilon_{\mathrm{F}}(\mathbf{v}_h)\|^2_{1,\Omega_i}. \end{aligned}$$

Now (6.4) follows from this, (6.5), and the Friedrich's inequality. □

For any face F of Γ_i, we define a quantity (not a norm) on F_b as follows:

$$\|\mathbf{v}\|_{*,\mathrm{F}_b} = \left(\sum_{K\in\mathrm{F}_b}\|\mathbf{v}\|^2_{0,\partial K}\right)^{\frac{1}{2}} \quad \forall\, \mathbf{v}\in Z_h(\Gamma_i)^3 \quad \text{or} \quad \mathbf{v}\in V_h(\Gamma_i).$$

Lemma 6.3. *Assume that* $\mathbf{v}_h \in Z_h(\Gamma_i)^3$. *Then*

$$\|\mathbf{v}_h\|_{*,\mathrm{F}_b} \le C[1+\log(d/h)]^{\frac{1}{2}}\|\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i}. \tag{6.6}$$

Proof. Consider a triangle $K\in\mathrm{F}_b$, and let e be one of its edges lying on $\partial\mathrm{F}$. Then we have

$$\|\mathbf{v}_h\|^2_{0,\partial K} \le 2(\|\mathbf{v}_h - \Upsilon_e(\mathbf{v}_h)\|^2_{0,\partial K} + \|\Upsilon_e(\mathbf{v}_h)\|^2_{0,\partial K}). \tag{6.7}$$

By the Poincaré inequality we obtain

$$h^{-1}\|\mathbf{v}_h - \Upsilon_e(\mathbf{v}_h)\|^2_{0,\partial K} \le h^{-2}\|\mathbf{v}_h - \Upsilon_e(\mathbf{v}_h)\|^2_{0,K} \le C|\mathbf{v}_h|^2_{1,K}.$$

Thus

$$\|\mathbf{v}_h - \Upsilon_e(\mathbf{v}_h)\|^2_{0,\partial K} \le Ch|\mathbf{v}_h|^2_{1,K}. \tag{6.8}$$

On the other hand, it can be verified directly that

$$\|\Upsilon_e(\mathbf{v}_h)\|^2_{0,\partial K} \le Ch|\Upsilon_e(\mathbf{v}_h)|^2 \le C\|\mathbf{v}_h\|^2_{0,e}.$$

Substituting this and (6.8) into (6.7) and then summing over all the edges e on K yield

$$\|\mathbf{v}_h\|^2_{0,\partial K} \le C(h|\mathbf{v}_h|^2_{1,\mathrm{F}} + \|\mathbf{v}_h\|^2_{0,\partial\mathrm{F}}) \le C(|\mathbf{v}_h|^2_{1/2,\mathrm{F}} + \|\mathbf{v}_h\|^2_{0,\partial\mathrm{F}}).$$

Now, (6.6) follows from (6.1). □

Proof of Lemma 4.5. Let $\mathbf{P}_h$: $L^2(\Omega_i)^3 \to Z_h(\Omega_i)^3$ be the L^2-projection operator, which is known to have the following H^s-stability (with $0\le s\le 1$) and estimate [8]:

$$\|\mathbf{P}_h\mathbf{w}\|_{s,\Omega_i} \le C\|\mathbf{w}\|_{s,\Omega_i}, \quad \|\mathbf{w} - \mathbf{P}_h\mathbf{w}\|_{0,\Omega_i} \le C\,h\,|\mathbf{w}|_{1,\Omega_i}\,. \tag{6.9}$$

It is easy to verify that

$$\|(\mathbf{r}_h\mathbf{w})\times\mathbf{n}\|_{*,\mathrm{F}_b}\le C\|\mathbf{r}_h\mathbf{w}\|^2_{*,\mathrm{F}_b}\le C\sum_{e\subset\mathrm{F}_b}(\|\mathbf{P}_h\mathbf{w}\|^2_{0,e}+\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,e}). \tag{6.10}$$

Let $K_e\in\mathcal{T}_h$ be an element in Ω_i with e being one of its edges, and $\{\lambda_i\}_{i=1}^4$ the barycentric basis functions at the four vertices of K_e, λ_1, and λ_2, correspond to two end-points of e. By the expression (2.2) of the edge element basis functions, it is easy to verify that $(\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w})$ can be written, in the element K_e, as

$$\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}=\left(\sum_{i=1}^4 a_i\lambda_i\,,\ \sum_{i=1}^4 b_i\lambda_i\,,\ \sum_{i=1}^4 c_i\lambda_i\right)^T\,,$$

where $a_i,\ b_i$, and c_i $(i=1,2,3,4)$ are constants which may depend on h. By the standard scaling argument, we obtain

$$\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,K_e}\ge\bar{C}h^3\sum_{i=1}^4(a_i^2+b_i^2+c_i^2)\,,$$
$$\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,e}\le\tilde{C}h\sum_{i=1}^2(a_i^2+b_i^2+c_i^2).$$

This implies

$$\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,e}\le Ch^{-2}\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,K_e}\,,$$

and so we have

$$\sum_{e\subset\mathrm{F}_b}\|\mathbf{r}_h\mathbf{w}–\mathbf{P}_h\mathbf{w}\|^2_{0,e}\le Ch^{-2}\sum_{e\subset\mathrm{F}_b}\|\mathbf{r}_h\mathbf{w}–\mathbf{P}_h\mathbf{w}\|^2_{0,K_e}\le Ch^{-2}\|\mathbf{r}_h\mathbf{w}–\mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i}. \tag{6.11}$$

This with (6.10) leads to

$$\|\mathbf{r}_h\mathbf{w}\|^2_{*,\mathrm{F}_b}\le C(\|\mathbf{P}_h\mathbf{w}\|^2_{*,\mathrm{F}_b}+h^{-2}\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i}). \tag{6.12}$$

On the other hand, by (6.6), the trace theorem, and (6.9), we obtain

$$\begin{aligned}\|\mathbf{P}_h\mathbf{w}\|_{*,\mathrm{F}_b}&\le C[1+\log(d/h)]^{\frac12}\|\mathbf{P}_h\mathbf{w}\|_{\frac12,\Gamma_i}\\&\le C[1+\log(d/h)]^{\frac12}\|\mathbf{P}_h\mathbf{w}\|_{1,\Omega_i}\\&\le C[1+\log(d/h)]^{\frac12}\|\mathbf{w}\|_{1,\Omega_i},\end{aligned} \tag{6.13}$$

while by the triangle inequality, (4.5), and (6.9), we deduce

$$\begin{aligned}h^{-1}\|\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w}\|_{0,\Omega_i}&\le h^{-1}(\|\mathbf{r}_h\mathbf{w}-\mathbf{w}\|_{0,\Omega_i}+\|\mathbf{P}_h\mathbf{w}-\mathbf{w}\|_{0,\Omega_i})\\&\le C(|\mathbf{w}|^2_{1,\Omega_i}+\|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i})^{\frac12}.\end{aligned} \tag{6.14}$$

Now, (4.6) follows readily from (6.12)–(6.14). □

Proof of Lemma 4.6. We can write

$$\mathbf{r}_h\mathbf{w}-\Upsilon_{\partial\mathrm{F}}(\mathbf{r}_h\mathbf{w})=(\mathbf{r}_h\mathbf{w}-\mathbf{P}_h\mathbf{w})+(\mathbf{P}_h\mathbf{w}-\Upsilon_{\partial\mathrm{F}}(\mathbf{P}_h\mathbf{w}))+\Upsilon_{\partial\mathrm{F}}(\mathbf{P}_h\mathbf{w}-\mathbf{r}_h\mathbf{w});$$

then, by the triangle inequality,

$$\|\mathbf{r}_h\mathbf{w} - \Upsilon_{\partial \mathrm{F}}(\mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i} \le 3(\|\mathbf{P}_h\mathbf{w} - \Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w})\|^2_{0,\Omega_i} + \|\mathbf{r}_h\mathbf{w} - \mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i} + \|\Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i}). \tag{6.15}$$

Using (6.4) and (6.9), we know

$$\|\mathbf{P}_h\mathbf{w} - \Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w})\|^2_{0,\Omega_i} \le Cd^2[1+\log(d/h)]|\mathbf{P}_h\mathbf{w}|^2_{1,\Omega_i} \le Cd^2[1+\log(d/h)]|\mathbf{w}|^2_{1,\Omega_i}. \tag{6.16}$$

On the other hand, by the definition of $\Upsilon_{\partial \mathrm{F}}$, one can verify directly that

$$\|\Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i} \le Cd^3|\Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w})|^2 \le C\, d^2\|\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w}\|^2_{0,\mathrm{F}_b}.$$

This with (6.11) gives

$$\|\Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i} \le Cd^2h^{-2}\,\|\mathbf{r}_h\mathbf{w} - \mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i},$$

and so we obtain by (6.14) that

$$\begin{aligned}&\|\mathbf{r}_h\mathbf{w} - \mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i} + \|\Upsilon_{\partial \mathrm{F}}(\mathbf{P}_h\mathbf{w} - \mathbf{r}_h\mathbf{w})\|^2_{0,\Omega_i}\\ &\le C(1+d^2h^{-2})\|\mathbf{r}_h\mathbf{w} - \mathbf{P}_h\mathbf{w}\|^2_{0,\Omega_i}\\ &\le C(h^2+d^2)(|\mathbf{w}|^2_{1,\Omega_i} + \|\mathbf{curl}\,\mathbf{v}_h\|^2_{0,\Omega_i}).\end{aligned}$$

Now (4.7) follows from this, (6.15), and (6.16).

Finally, the relation

$$\mathbf{w} - \Upsilon_{\partial \mathrm{F}}(\mathbf{r}_h\mathbf{w}) = (\mathbf{w} - \mathbf{r}_h\mathbf{w}) + (\mathbf{r}_h\mathbf{w} - \Upsilon_{\partial \mathrm{F}}(\mathbf{r}_h\mathbf{w})),$$

with (4.7) and Lemma 4.4, leads to (4.8) directly. □

6.2. Proofs of Lemmas 4.7, 4.8, and 4.9. The proofs of these lemmas are rather technical, and we will start with some auxiliary results.

LEMMA 6.4. *For any $\Phi \in V_h(\Gamma_i)$, we have*

$$\|\Phi\|_{0,\Gamma_i} \le Ch^{-\frac{1}{2}}\|\Phi\|_{-\frac{1}{2},\Gamma_i}, \quad \|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|_{0,\mathrm{F}} \le Ch^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b}. \tag{6.17}$$

Proof. The first estimate was proved in [3]. We prove only the second inequality in (6.17). For any $\Phi \in V_h(\Gamma_i)$, we can write $\Phi = \mathbf{v} \times \mathbf{n}$ on Γ_i for some $\mathbf{v} \in V_h(\Omega_i)$. Using the definitions of $\mathbf{I}^0_{\mathrm{F}_b}$, we deduce

$$\|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|^2_{0,\mathrm{F}} \le C\sum_{e\subset \mathrm{F}_b}\lambda^2_e(\mathbf{v})\|L_e \times \mathbf{n}_i\|^2_{0,\mathrm{F}}. \tag{6.18}$$

It follows by (2.2) that $\|L_e \times \mathbf{n}\|^2_{0,\mathrm{F}} \le C$. This, together with (6.18), yields

$$\|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|^2_{0,\mathrm{F}} \le C\sum_{e\subset \mathrm{F}_b}\lambda^2_e(\mathbf{v}).$$

Now we need only to prove

$$\lambda^2_e(\mathbf{v}) \le Ch\|\Phi\|^2_{0,e} \quad \forall\, e \subset \mathrm{F}_b \subset \Gamma_i. \tag{6.19}$$

Noting the fact that $\mathbf{v} = (\mathbf{v} \cdot \mathbf{n})\mathbf{n} + \mathbf{n} \times \mathbf{v} \times \mathbf{n}$ on F, for any $e \subset \mathrm{F}$ we have

$$\mathbf{v}|_{\mathrm{F}} \cdot \mathbf{t}_e = (\mathbf{n} \times \mathbf{v} \times \mathbf{n})|_{\mathrm{F}} \cdot \mathbf{t}_e.$$

Thus (6.19) comes readily from the following:

$$\lambda_e^2(\mathbf{v}) = \left|\int_e \mathbf{v} \cdot \mathbf{t}_e ds\right|^2 \leq \int_e |\mathbf{n} \times \mathbf{v} \times \mathbf{n}|^2 ds \int_e |\mathbf{t}_e|^2 ds \leq Ch \int_e |\mathbf{n} \times \mathbf{v}|^2 ds. \quad \square \tag{6.20}$$

LEMMA 6.5. *Let $\Phi \in V_h(\Gamma_i)$, and let $\mathbf{I}^0_{\mathrm{F}_\partial}\Phi$ be defined as in* (2.5). *Then*

$$\|\mathbf{I}^0_{\mathrm{F}_\partial}\Phi\|_{-\frac{1}{2},\Gamma_i} \leq C([1 + \log(d/h)]\|\Phi\|_{-\frac{1}{2},\Gamma_i} + h^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b}). \tag{6.21}$$

Proof. The proof is similar to that of Lemma 6 in [19]. However, for the reader's convenience, we still give a complete proof below.

For any $\mathbf{v} \in H^{1/2}(\Gamma_i)^3$, let $\mathbf{v}_h \in Z_h(\Gamma_i)^3$ be the $L^2(\Gamma_i)$-projection of $\mathbf{v}$. Then

$$|\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}\rangle_{\Gamma_i}| \leq |\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v} - \mathbf{v}_h\rangle_{\Gamma_i}| + |\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}_h\rangle_{\Gamma_i}|. \tag{6.22}$$

It is known that

$$\|\mathbf{v}_h - \mathbf{v}\|_{0,\Gamma_i} \leq Ch^{\frac{1}{2}}\|\mathbf{v}\|_{\frac{1}{2},\Gamma_i}, \quad \|\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i} \leq C\|\mathbf{v}\|_{\frac{1}{2},\Gamma_i}. \tag{6.23}$$

This, together with (6.17), leads to

$$\begin{aligned} |\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v} - \mathbf{v}_h\rangle_{\Gamma_i}| &\leq \|\mathbf{I}^0_{\mathrm{F}_\partial}\Phi\|_{0,\Gamma_i}\, \|\mathbf{v} - \mathbf{v}_h\|_{0,\Gamma_i} \\ &\leq Ch^{1/2}\|\Phi\|_{0,\Gamma_i}\|\mathbf{v}\|_{\frac{1}{2},\Gamma_i} \leq C\|\Phi\|_{-\frac{1}{2},\Gamma_i}\, \|\mathbf{v}\|_{\frac{1}{2},\Gamma_i}. \end{aligned} \tag{6.24}$$

On the other hand, from the definitions of the operators $\mathbf{I}^0_{\mathrm{F}_\partial}$ and $\mathbf{I}^0_{\mathrm{F}_b}$, we have $\mathbf{I}^0_{\mathrm{F}_\partial}\Phi = \Phi - \mathbf{I}^0_{\mathrm{F}_b}\Phi$ on F. Then

$$|\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}_h\rangle_{\Gamma_i}| = |\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| \leq |\langle \Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| + |\langle \mathbf{I}^0_{\mathrm{F}_b}\Phi, \mathbf{v}_h\rangle_{\mathrm{F}}|. \tag{6.25}$$

It follows from (6.17) that

$$|\langle \mathbf{I}^0_{\mathrm{F}_b}\Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| \leq \|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|_{0,\mathrm{F}}\, \|\mathbf{v}_h\|_{0,\mathrm{F}} \leq Ch^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b}\, \|\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i}. \tag{6.26}$$

For the term $\langle \Phi, \mathbf{v}_h\rangle_{\mathrm{F}}$ in (6.25), we use the simple decomposition

$$\mathbf{v}_h(\mathbf{x}) = \mathrm{I}^0_{\mathrm{F}}\mathbf{v}_h(\mathbf{x}) + \mathrm{I}^0_{\partial\mathrm{F}}\mathbf{v}_h(\mathbf{x}) \quad \forall\, \mathbf{x} \in \mathrm{F} \tag{6.27}$$

to derive (note that $\mathrm{I}^0_{\mathrm{F}}\mathbf{v}_h(\mathbf{x}) = \mathbf{0}$ on $\Gamma_i \backslash \mathrm{F}$)

$$\begin{aligned} |\langle \Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| &\leq |\langle \Phi, \mathrm{I}^0_{\mathrm{F}}\mathbf{v}_h\rangle_{\mathrm{F}}| + |\langle \Phi, \mathrm{I}^0_{\partial\mathrm{F}}\mathbf{v}_h\rangle_{\mathrm{F}}| \\ &\leq |\langle \Phi, \mathrm{I}^0_{\mathrm{F}}\mathbf{v}_h\rangle_{\Gamma_i}| + \|\Phi\|_{0,\mathrm{F}}\, \|\mathrm{I}^0_{\partial\mathrm{F}}\mathbf{v}_h\|_{0,\mathrm{F}} \\ &\leq \|\Phi\|_{-\frac{1}{2},\Gamma_i}\, \|\mathrm{I}^0_{\mathrm{F}}\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i} + Ch^{\frac{1}{2}}\|\Phi\|_{0,\Gamma_i}\, \|\mathbf{v}_h\|_{0,\partial\mathrm{F}}, \end{aligned}$$

where a direct computation is used to bound the term $\|\mathrm{I}^0_{\partial\mathrm{F}}\mathbf{v}_h\|_{0,\mathrm{F}}$ by $h^{1/2}\|\mathbf{v}_h\|_{0,\partial\mathrm{F}}$ using the discrete L^2-norm. This with (6.17), (6.2), and (6.1) yields

$$|\langle \Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| \leq C[1 + \log(d/h)]\|\Phi\|_{-\frac{1}{2},\Gamma_i}\, \|\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i}.$$

Substituting it and (6.26) into (6.25) yields

$$|\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}_h\rangle_{\mathrm{F}}| \leq C([1+\log(d/h)]\|\Phi\|_{-\frac{1}{2},\Gamma_i} + h^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b})\|\mathbf{v}_h\|_{\frac{1}{2},\Gamma_i},$$

which, along with (6.22) and (6.24), leads to

$$|\langle \mathbf{I}^0_{\mathrm{F}_\partial}\Phi, \mathbf{v}\rangle_{\Gamma_i}| \leq C([1+\log(d/h)]\|\Phi\|_{-\frac{1}{2},\Gamma_i} + h^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b})\|\mathbf{v}\|_{\frac{1}{2},\Gamma_i}.$$

Now (6.21) follows directly from the definition of the norm $\|\cdot\|_{-1/2,\Gamma_i}$. □

Next, we are going to prove Lemma 6.10 on the estimate of $\|\mathrm{div}_\tau(\mathbf{I}^0_{\mathrm{F}}\Phi)\|_{-\frac{1}{2},\Gamma_i}$ for all $\Phi \in V_h(\Gamma_i)$. To do so, we have to present some auxiliary results first (Lemmas 6.6–6.9).

LEMMA 6.6. *Let $\varphi \in L^2(\Gamma_i)$ be piecewise constant with respect to the $\mathcal{T}_h$-induced triangulation $\mathcal{T}_{h,i}$ on Γ_i. Then*

$$\|\varphi\|_{0,\Gamma_i} \leq Ch^{-\frac{1}{2}}\|\varphi\|_{-\frac{1}{2},\Gamma_i}. \tag{6.28}$$

Proof. By definition,

$$\|\varphi\|_{-\frac{1}{2},\Gamma_i} = \sup_{\psi\in H^{1/2}(\Gamma_i)} \frac{|\langle\varphi,\psi\rangle_{\Gamma_i}|}{\|\psi\|_{\frac{1}{2},\Gamma_i}}.$$

The inequality (6.28) then follows if we can construct a function $\psi_0 \in H^{\frac{1}{2}}(\Gamma_i)$ such that

$$|\langle\varphi,\psi_0\rangle_{\Gamma_i}| \geq C\|\varphi\|_{0,\Gamma_i}\|\psi_0\|_{0,\Gamma_i}, \quad \|\psi_0\|_{\frac{1}{2},\Gamma_i} \leq Ch^{-\frac{1}{2}}\|\psi_0\|_{0,\Gamma_i}. \tag{6.29}$$

To construct the function ψ_0 for each triangle $K \in \mathcal{T}_{h,i}$ and lying on Γ_i, with O_K being its barycenter, we refine K by connecting O_K with three vertices of K. Let a_K denote the (constant) value of φ on the triangle K, and let ψ_0 be a piecewise linear function on K with respect to this subdivision such that ψ_0 equals a_K at O_K and vanishes on the edges of K. It is clear that such a function ψ_0 is in $H^{1/2}(\Gamma_i)$. As ψ_0 is piecewise linear on the entire boundary Γ_i with respect to the subdivision of $\mathcal{T}_h$, the second inequality in (6.29) follows directly from the inverse inequality. Moreover, by the equivalent discrete L^2-norms we have

$$\|\psi_0\|^2_{0,\Gamma_i} \leq Ch^2 \sum_{K\in\mathcal{T}_{h,i}} |a_K|^2. \tag{6.30}$$

Let S_K be the area of the triangle K. We have

$$\begin{aligned}|\langle\varphi,\psi_0\rangle_{\Gamma_i}| &= \left|\sum_{K\in\mathcal{T}_{h,i}} \langle\varphi,\psi_0\rangle_K\right| = \left|\sum_{K\in\mathcal{T}_{h,i}} a_K\langle 1,\psi_0\rangle_K\right| \\ &= \frac{1}{3}\left|\sum_{K\in\mathcal{T}_{h,i}} a_K^2 S_K\right| \geq Ch^2\sum_{K\in\mathcal{T}_{h,i}}|a_K^2|.\end{aligned}$$

Now the first inequality of (6.29) follows readily from this and (6.30). □

The next lemma can be shown similarly as Lemma 6.5 by using Lemma 6.6.

LEMMA 6.7. *Let φ be the same as in Lemma 6.6; then*

$$\|\mathrm{I}^t_{\mathrm{F}}(\varphi|_{\mathrm{F}})\|_{-\frac{1}{2},\Gamma_i} \leq C[1+\log(d/h)]\|\varphi\|_{-\frac{1}{2},\Gamma_i}. \tag{6.31}$$

For the proof, we introduce some new functions. For any $\Phi = \mathbf{v}\times\mathbf{n} \in V_h(\Gamma_i)$ and any face $\mathrm{F} \subset \Gamma_i$, we define a function in $L^2(\Gamma_i)$ as follows:

$$\varphi_{\mathrm{F}_b}(\mathbf{x}) = \sum_{e\subset \mathrm{F}_b} \lambda_e(\mathbf{v})(\mathbf{n}_i\cdot \mathbf{curl}\, L_e)(\mathbf{x}), \quad \mathbf{x}\in \bar{\mathrm{F}};\quad \varphi_{\mathrm{F}_b}(\mathbf{x}) = 0, \quad \mathbf{x}\in \Gamma_i\backslash\bar{\mathrm{F}}, \tag{6.32}$$

where $\{L_e; e\in \mathcal{E}_h\}$ are the edge element basis functions defined in (2.2). One can see that φ_{F_b} is piecewise constant on Γ_i, and it vanishes everywhere except in those triangles which are in F and have a vertex on ∂F at least. We now present two estimates for $\varphi_{\mathrm{F}_b}(\mathbf{x})$ below.

Lemma 6.8. *For any $\Phi\in V_h(\Gamma_i)$ and any face* F *of Γ_i, we have*

$$\|\varphi_{\mathrm{F}_b}\|_{-\frac{1}{2},\Gamma_i} \le Ch^{\frac{1}{2}}[1+\log(d/h)]^{\frac{1}{2}}\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}. \tag{6.33}$$

Proof. For any $v\in H^{1/2}(\Gamma_i)$, let $v_h {\in} Z_h(\Gamma_i)$ be the $L^2(\Gamma_i)$-projection of v. We see directly from (6.27), (6.23), and (6.1) that

$$\begin{aligned}|\langle\varphi_{\mathrm{F}_b}, v\rangle_{\Gamma_i}| &\le |\langle\varphi_{\mathrm{F}_b}, v-v_h\rangle_{\Gamma_i} + |\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\partial\mathrm{F}}v_h\rangle_{\Gamma_i}| + |\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\Gamma_i}|\\ &\le Ch^{\frac{1}{2}}[1+\log(d/h)]^{\frac{1}{2}}\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}\,\|v\|_{\frac{1}{2},\Gamma_i} + |\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\mathrm{F}}|,\end{aligned}$$

where we have used the fact that $\varphi_{\mathrm{F}_b} = 0$ on $\Gamma_i\backslash$F. It remains to show that

$$|\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\mathrm{F}}| \le Ch^{\frac{1}{2}}[1+\log(d/h)]^{\frac{1}{2}}\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}\,\|\mathbf{v}\|_{\frac{1}{2},\Gamma_i}. \tag{6.34}$$

Let F_c denote the union of all triangles that have at least one of their vertices lying on ∂F. We regroup the triangles in F_c such that $\mathrm{F}_c = \cup K$, with each K being one triangle or a union of two triangles and having at least one of its edges lying on ∂F. Then by the definition of φ_{F_b} and the Hölder inequality, we have

$$\begin{aligned}|\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\mathrm{F}}| = |\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\mathrm{F}_c}| &= \left|\sum_K\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_K\right|\\ &\le \sum_K\|\varphi_{\mathrm{F}_b}\|_{0,K}\,\|\mathrm{I}^0_{\mathrm{F}}v_h\|_{0,K}.\end{aligned} \tag{6.35}$$

As each $K\in \mathrm{F}_c$ has an edge lying on ∂F, $\mathrm{I}^0_{\mathrm{F}}v_h$ vanishes on the edge. Then by Friedrich's inequality we obtain

$$\|\mathrm{I}^0_{\mathrm{F}}v_h\|_{0,K} \le Ch^{\frac{1}{2}}|\mathrm{I}^0_{\mathrm{F}}v_h|_{\frac{1}{2},K}.$$

Plugging this in (6.35) and using the Cauchy–Schwarz inequality, we derive

$$\begin{aligned}|\langle\varphi_{\mathrm{F}_b}, \mathrm{I}^0_{\mathrm{F}}v_h\rangle_{\mathrm{F}}| &\le Ch^{\frac{1}{2}}\left\{\sum_K\|\varphi_{\mathrm{F}_b}\|^2_{0,K}\right\}^{\frac{1}{2}}\left\{\sum_K|\mathrm{I}^0_{\mathrm{F}}v_h|^2_{\frac{1}{2},K}\right\}^{\frac{1}{2}}\\ &= Ch^{\frac{1}{2}}\{\|\varphi_{\mathrm{F}_b}\|^2_{0,\mathrm{F}_c}\}^{\frac{1}{2}}\,\{|\mathrm{I}^0_{\mathrm{F}}v_h|^2_{\frac{1}{2},\mathrm{F}_c}\}^{\frac{1}{2}}\\ &\le Ch^{\frac{1}{2}}\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}\;\;|\mathrm{I}^0_{\mathrm{F}}v_h|_{\frac{1}{2},\mathrm{F}}.\end{aligned} \tag{6.36}$$

On the other hand, it follows from (6.27) and (6.3) that

$$|\mathrm{I}^0_{\mathrm{F}}v_h|_{\frac{1}{2},\mathrm{F}} = |v_h - \mathrm{I}^0_{\partial\mathrm{F}}v_h|_{\frac{1}{2},\mathrm{F}} \le |v_h|_{\frac{1}{2},\mathrm{F}} + |\mathrm{I}^0_{\partial\mathrm{F}}v_h|_{\frac{1}{2},\mathrm{F}} \le C[1+\log(d/h)]^{\frac{1}{2}}\|v_h\|_{\frac{1}{2},\Gamma_i}.$$

This, together with (6.36), gives (6.34). □

LEMMA 6.9. *Assume that $\Phi = \mathbf{v} \times \mathbf{n} \in V_h(\Gamma_i)$. Then*

$$\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}} \le Ch^{-\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b}. \tag{6.37}$$

Proof. We have by the definitions of φ_{F_b} that

$$\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}^2 \le C \sum_{e\subset \mathrm{F}_b} \lambda_e^2(\mathbf{v})\|\mathbf{n}_i \cdot \mathbf{curl}\ L_e\|_{0,\mathrm{F}}^2. \tag{6.38}$$

It follows from (2.2) that $\mathbf{curl}\, L_e = c_e \nabla\lambda_1^e \times \nabla\lambda_2^e$, which gives $\|\mathbf{n}_i \cdot \mathbf{curl}\, L_e\|_{0,\mathrm{F}}^2 \le Ch^{-2}$. Then we derive from (6.38) that

$$\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}^2 \le Ch^{-2} \sum_{e\subset \mathrm{F}_b} \lambda_e^2(\mathbf{v}).$$

This, together with (6.20), gives the desired results. □

LEMMA 6.10. *For any $\Phi = \mathbf{v} \times \mathbf{n} \in V_h(\Gamma_i)$, we have*

$$\|\mathrm{div}_\tau(\mathbf{I}_\mathrm{F}^0\Phi)\|_{-\frac{1}{2},\Gamma_i} \le C[1+\log(d/h)]\|\mathrm{div}_\tau\Phi\|_{-\frac{1}{2},\Gamma_i} + C[1+\log(d/h)]^{\frac{1}{2}}\|\Phi\|_{*,\mathrm{F}_b}. \tag{6.39}$$

Proof. We use Lemmas 6.7, 6.8, and 6.9 to estimate $\mathrm{div}_\tau(\mathbf{I}_\mathrm{F}^0\Phi)$. By Green's formula and the definition of $\mathrm{div}_\tau\Phi$, one can verify (cf. [2]) that

$$\mathrm{div}_\tau\Phi = \mathrm{div}_\tau(\mathbf{v}\times\mathbf{n})|_{\Gamma_i} = -(\mathbf{n}_i \cdot \mathbf{curl}\ \mathbf{v})|_{\Gamma_i} \quad \text{in} \ \ H^{-\frac{1}{2}}(\Gamma_i).$$

Thus $\mathrm{div}_\tau\Phi$ is a piecewise constant function on Γ_i. It suffices to prove that

$$\mathrm{div}_\tau(\mathbf{I}_{\mathrm{F}_\partial}^0\Phi) = \mathrm{I}_\mathrm{F}^t(\mathrm{div}_\tau\Phi|_\mathrm{F}) + \varphi_{\mathrm{F}_b} \quad \text{in} \ \ H^{-\frac{1}{2}}(\Gamma_i). \tag{6.40}$$

As $\mathrm{div}_\tau(\mathbf{I}_{\mathrm{F}_\partial}^0\Phi) = 0$ on $\Gamma_i\backslash\bar{\mathrm{F}}$, the inequality (6.40) is valid in $\Gamma_i\backslash\bar{\mathrm{F}}$. However, on the face $\bar{\mathrm{F}}$, we have by (2.4) and (2.5) that

$$\mathrm{div}_\tau\Phi = \sum_{e\subset\overline{\mathrm{F}}} \lambda_e(\mathbf{v})\mathrm{div}_\tau(L_e\times\mathbf{n}_i)\,, \quad \mathrm{div}_\tau(\mathbf{I}_{\mathrm{F}_\partial}^0\Phi) = \sum_{e\subset\mathrm{F}_\partial} \lambda_e(\mathbf{v})\mathrm{div}_\tau(L_e\times\mathbf{n}_i)\,.$$

Hence

$$\mathrm{div}_\tau\Phi - \mathrm{div}_\tau(\mathbf{I}_{\mathrm{F}_\partial}^0\Phi) = \sum_{e\subset\mathrm{F}_b} \lambda_e(\mathbf{v})\mathrm{div}_\tau(L_e\times\mathbf{n}_i) \quad \text{on} \ \ \bar{\mathrm{F}}. \tag{6.41}$$

Noting that (see (2.10) in [2])

$$\mathrm{div}_\tau(L_e\times\mathbf{n}_i)|_{\Gamma_i} = -(\mathbf{n}_i\cdot\mathbf{curl}\ L_e)|_{\Gamma_i} \quad \text{in} \ \ H^{-\frac{1}{2}}(\Gamma_i),$$

we see that (6.40) holds also on $\bar{\mathrm{F}}$, using (6.41) and (6.32). □

The following result can be proved in an analogous way as Lemma 6.6.

LEMMA 6.11. *For any $\Phi \in V_h(\Gamma_i)$ and any face* F *of Γ_i, we have*

$$\|\mathbf{I}_{\mathrm{F}_b}^0\Phi\|_{-\frac{1}{2},\mathrm{F}} \le Ch^{\frac{1}{2}}[1+\log(d/h)]^{\frac{1}{2}}\|\mathbf{I}_{\mathrm{F}_b}^0\Phi\|_{0,\mathrm{F}}. \tag{6.42}$$

Below, we start to prove Lemmas 4.7, 4.8, and 4.9. Lemma 4.7 is a direct consequence of Lemmas 4.5, 6.5, and 6.10, and it indicates that the norm $\|\mathbf{I}_\mathrm{F}^0\Phi\|_{\mathcal{X}_{\Gamma_i}}$ cannot be bounded only by $\|\Phi\|_{\mathcal{X}_{\Gamma_i}}$ (compare to the estimate (6.2)).

Proof of Lemma 4.8. Using (6.40) and the relations

$$\mathbf{I}^0_{\Delta_i}\Phi=\sum_{\mathrm{F}\subset\Gamma_i}\mathbf{I}^t_{\mathrm{F}}(\mathbf{I}^0_{\mathrm{F}_b}\Phi)|_{\mathrm{F}},\quad \mathbf{I}^t_{\mathrm{F}}(\mathbf{I}^0_{\mathrm{F}_b}\Phi)|_{\mathrm{F}}=\mathbf{I}^t_{\mathrm{F}}\Phi-\mathbf{I}^0_{\mathrm{F}_\partial}\Phi$$

and the facts that $\mathbf{I}^t_{\mathrm{F}}\Phi)|_{\Gamma_i\backslash\bar{\mathrm{F}}}=\mathbf{0}$ but $(\mathbf{I}^0_{\mathrm{F}_b}\Phi)|_{\Gamma_i\backslash\bar{\mathrm{F}}}\neq\mathbf{0}$, we can write

$$\begin{aligned}\mathrm{div}_\tau(\mathbf{I}^0_{\Delta_i}\Phi)&=\mathrm{div}_\tau\left(\sum_{\mathrm{F}\subset\Gamma_i}\mathbf{I}^t_{\mathrm{F}}\Phi-\sum_{\mathrm{F}\subset\Gamma_i}\mathbf{I}^0_{\mathrm{F}}\Phi\right)=\mathrm{div}_\tau\left(\Phi-\sum_{\mathrm{F}\subset\Gamma_i}\mathbf{I}^0_{\mathrm{F}_\partial}\Phi\right)\\&=\mathrm{div}_\tau\Phi-\sum_{\mathrm{F}\subset\Gamma_i}\mathrm{div}_\tau(\mathbf{I}^0_{\mathrm{F}_\partial}\Phi)=\sum_{\mathrm{F}\subset\Gamma_i}(\mathbf{I}^t_{\mathrm{F}}\mathrm{div}_\tau(\Phi)|_{\mathrm{F}}-\mathrm{div}_\tau(\mathbf{I}^0_{\mathrm{F}_\partial}\Phi))\\&=\sum_{\mathrm{F}\subset\Gamma_i}\varphi_{\mathrm{F}_b}.\end{aligned}$$

This leads to

$$\|\mathbf{I}^0_{\Delta_i}\Phi\|_{-\frac12,\Gamma_i}\le\sum_{\mathrm{F}\subset\Gamma_i}\|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|_{-\frac12,\mathrm{F}}\,,\quad \|\mathrm{div}_\tau(\mathbf{I}^0_{\Delta_i}\Phi)\|_{-\frac12,\Gamma_i}\le\sum_{\mathrm{F}\subset\Gamma_i}\|\varphi_{\mathrm{F}_b}\|_{-\frac12,\Gamma_i}.$$

Using these two estimates, together with Lemmas 6.11 and 6.8, we have

$$\|\mathbf{I}^0_{\Delta_i}\Phi\|_{\mathcal{X}_{\Gamma_i}}\le Ch^{\frac12}[1+\log(d/h)]^{\frac12}\sum_{\mathrm{F}\subset\Gamma_i}(d^{-1}\|\mathbf{I}^0_{\mathrm{F}_b}\Phi\|_{0,\mathrm{F}}+\|\varphi_{\mathrm{F}_b}\|_{0,\mathrm{F}}).\tag{6.43}$$

Substituting (6.17) and (6.37) into (6.43), we obtain the desired result. □

Proof of Lemma 4.9. By Lemma 6.10 we have

$$\begin{aligned}&\|\mathrm{div}_\tau[\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})]\|^2_{-\frac12,\Gamma_k}\\&\le C([1+\log(d/h)]^2\|\mathrm{div}_\tau[\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}|_{\Gamma_k}]\|^2_{-\frac12,\Gamma_k}\\&\quad+[1+\log(d/h)]\|\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\mathrm{F}_b}).\end{aligned}\tag{6.44}$$

It is easy to see that

$$\|\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}_k\|^2_{*,\mathrm{F}_b}=\|\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}_k\|^2_{*,\mathrm{F}_b}\le C\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\mathrm{F}_b}.\tag{6.45}$$

Since $\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})$ is a constant vector, we have

$$\mathrm{div}_\tau(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}|_{\Gamma_k})=0\quad\text{in}\quad H^{-\frac12}(\Gamma_k).$$

Hence

$$\|\mathrm{div}_\tau(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}|_{\Gamma_k})\|_{-\frac12,\Gamma_k}=0.$$

Substituting (6.45) and the above inequality into (6.44) yields

$$\|\mathrm{div}_\tau[\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})]\|^2_{-\frac12,\Gamma_k}\le C[1+\log(d/h)]\|(\Pi_0\mathbf{v})\times\mathbf{n}\|^2_{*,\mathrm{F}_b}.\tag{6.46}$$

On the other hand, it follows from Lemmas 6.11 and 6.4 that

$$\begin{aligned}&d^{-1}\|\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})\|_{-\frac12,\Gamma_k}=d^{-1}\|\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n})\|_{-\frac12,\mathrm{F}}\\&\le C(d^{-1}\|\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}\|_{-\frac12,\mathrm{F}}+d^{-1}h[1+\log(d/h)]^{\frac12}\|\Upsilon_{\partial\mathrm{F}}(\Pi_0\mathbf{v})\times\mathbf{n}\|_{*,\mathrm{F}_b}).\end{aligned}\tag{6.47}$$

However, for any $\Psi \in (H^{\frac{1}{2}}(\mathrm{F}))^3$, we have

$$\begin{aligned} d^{-1}|\langle \Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v}) \times \mathbf{n}, \Psi\rangle_{\mathrm{F}}| &\le d^{-1}\|\Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{0,\mathrm{F}}\, \|\Psi\|_{0,\mathrm{F}} \\ &\le C d^{-\frac{1}{2}} \|\Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v} \times \mathbf{n})\|_{0,\mathrm{F}}\, \|\Psi\|_{\frac{1}{2},\mathrm{F}} \\ &\le C d^{\frac{1}{2}} |\Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v} \times \mathbf{n})|\, \|\Psi\|_{\frac{1}{2},\mathrm{F}} \\ &\le C \|(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{0,\partial \mathrm{F}}\, \|\Psi\|_{\frac{1}{2},\mathrm{F}} \\ &\le C \|(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{*,\mathrm{F}_b}\, \|\Psi\|_{\frac{1}{2},\mathrm{F}}, \end{aligned}$$

which implies

$$d^{-1}\|\Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{-\frac{1}{2},\mathrm{F}} \le C \|(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{*,\mathrm{F}_b}.$$

Plugging this and (6.45) in (6.47) leads to

$$d^{-1}\|\mathbf{I}^0_{\mathrm{F}_\partial}(\Upsilon_{\partial \mathrm{F}}(\Pi_0 \mathbf{v}) \times \mathbf{n})\|_{-\frac{1}{2},\Gamma_k} \le C[1 + \log(d/h)]^{\frac{1}{2}} \|(\Pi_0 \mathbf{v}) \times \mathbf{n}\|_{*,\mathrm{F}_b},$$

which, together with Lemmas 6.4 and 6.9, gives the desired result. □

A NONOVERLAPPING DOMAIN DECOMPOSITION METHOD FOR ORTHOGONAL SPLINE COLLOCATION PROBLEMS[*]

BERNARD BIALECKI[†] AND MAKSYMILIAN DRYJA[‡]

Abstract. A nonoverlapping domain decomposition approach is used on uniform and matching grids to first define and then to compute the orthogonal spline collocation solution of the Dirichlet boundary value problem for Poisson's equation on an L-shaped region. We prove existence and uniqueness of the collocation solution and derive optimal order H^s-norm error bounds for $s = 0, 1, 2$. The collocation solution on two interfaces is computed using the preconditioned conjugate gradient method, and the collocation solution on three squares is computed by a matrix decomposition method that uses fast Fourier transforms. The total cost of the algorithm is $O(N^2 \log N)$, where the number of unknowns in the collocation solution is $O(N^2)$.

Key words. spline collocation, nonoverlapping domain decomposition, Sobolev norms, Steklov–Poincaré operator, preconditioned conjugate gradient method, separation of variables, fast Fourier transforms

1. Introduction.

A thorough presentation of overlapping and nonoverlapping domain decomposition methods for solving finite difference and finite element boundary value problems is given in [8, 15, 16] and references therein. Some overlapping methods are considered in [4, 5, 11, 12, 13, 17] for the solution of boundary value problems discretized by orthogonal spline collocation (OSC). In [1], a nonoverlapping method is developed for computing the OSC solution of Poisson's equation on a rectangle. However, to the best of our knowledge, no analysis of nonoverlapping OSC methods for nonrectangular regions is available. In the present paper, we use a nonoverlapping domain decomposition approach on uniform and matching grids to first define and then to compute the OSC solution of the model Dirichlet boundary value problem for Poisson's equation on an L-shaped region. In principle, the proposed approach to define and then to compute the OSC solution can also be used for quasi-uniform and matching grids, more general partial differential equations with variable coefficients, and more general regions with sides parallel to the coordinate axes. Of course, any such extensions may require generalizations of the present proofs and modifications of the employed computational techniques.

Let Ω be the L-shaped region given by $\Omega = \bigcup_{i=1}^{3} \Omega_i \cup \bigcup_{i=1}^{2} \Gamma_i$, where the squares

$$\Omega_1 = (0,1) \times (0,1), \qquad \Omega_2 = (1,2) \times (0,1), \qquad \Omega_3 = (0,1) \times (1,2)$$

and the two interfaces

$$\Gamma_1 = \{1\} \times (0,1), \qquad \Gamma_2 = (0,1) \times \{1\}.$$

We consider the model Dirichlet boundary value problem for Poisson's equation

$$\Delta u = f \quad \text{in} \quad \Omega, \qquad u = g \quad \text{on} \quad \partial\Omega, \tag{1.1}$$

which is approximated using a domain decomposition approach and OSC discretization. On each square Ω_i, $i = 1, 2, 3$, the collocation solution is a piecewise Hermite bicubic that satisfies Poisson's equation at the collocation points in the square. The collocation solution is continuous throughout the region Ω, and its normal derivative is continuous at the collocation points on the interfaces Γ_1 and Γ_2. However, continuity of the normal derivative across the interfaces is not guaranteed. We prove existence and uniqueness of the collocation solution and derive optimal order H^s-norm error bounds for $s = 0, 1, 2$. The solution of the collocation problem is reduced to finding the collocation solution on the interfaces. The collocation Steklov–Poincaré operator corresponding to the interfaces is self-adjoint and positive definite with respect to the discrete inner product associated with the collocation points on the interfaces. The right-hand side in the collocation Steklov–Poincaré equation is obtained by solving a collocation problem on each square. With the use of a fast Fourier transform (FFT) matrix decomposition method of [7], this is accomplished at a cost of $O(N^2 \log N)$, where the number of unknowns in the collocation solution is $O(N^2)$. The collocation solution on the interfaces is computed using the preconditioned conjugate gradient (PCG) method with a preconditioner obtained from two collocation Steklov–Poincaré operators corresponding to two pairs of the adjacent squares. It is shown that this preconditioner is spectrally equivalent to the interface operator with spectral constants 1/2 and 2. The cost of each PCG iteration is $O(N^2)$. Once the collocation solution is computed on the interfaces, the collocation solution on each square is obtained at a cost $O(N^2 \log N)$ using the FFT matrix decomposition method of [7]. With the number of PCG iterations proportional to $\log N$, the total cost of the algorithm is $O(N^2 \log N)$.

In our earlier study of OSC for (1.1), we used two additional basis functions associated with the re-entrant corner to formulate a piecewise Hermite bicubic OSC scheme in which the number of unknowns was equal to the number of the collocation points in Ω. With the vertical interface Γ_1 dividing Ω into two rectangles only, we used continuity of the normal derivative of the collocation solution across Γ_1 to obtain a linear system for the coefficients of the collocation solution restricted to Γ_1. Surprisingly the resulting interface matrix was nonsymmetric even though it was an algebraic counterpart of the Steklov–Poincaré operator. The interface system was formed explicitly and then solved by Gauss elimination, which led to an algorithm whose cost was $O(N^3)$. We believe that the nonsymmetry of the interface matrix was a consequence of using two additional basis functions associated with the re-entrant corner.

An outline of this paper is as follows. In section 2, we introduce OSC concepts and state and prove basic results. The OSC problem is defined and analyzed in section 3. In section 4, we formulate an algorithm for solving the OSC problem. The solution of the interface problem is discussed in section 5. The total cost of solving the OSC problem is given in section 6. Finally, in section 7, we present numerical results.

2. Preliminaries. Let N be a positive integer. We set $h = 1/N$ and introduce $t_k = kh$, $k = 0, \dots, N$. Let P_3 be the set of polynomials of degree ≤ 3, and let $\mathcal{M}(0,1)$, $\mathcal{M}^0(0,1)$ be the spaces of piecewise Hermite cubics on $[0,1]$ defined by

$$\begin{aligned} \mathcal{M}(0,1) &= \{v \in C^1[0,1] : v|_{[t_{k-1},t_k]} \in P_3, k = 1, \dots, N\}, \\ \mathcal{M}^0(0,1) &= \{v \in \mathcal{M}(0,1) : v(0) = v(1) = 0\}. \end{aligned} \tag{2.1}$$

Let $\mathcal{G} = \{\xi_l\}_{l=1}^{2N}$ be the set of collocation points in $[0,1]$ given by

$$\xi_{2k-1} = t_{k-1} + h\eta_1, \qquad \xi_{2k} = t_{k-1} + h\eta_2, \tag{2.2}$$

where $k = 1, \ldots, N$, and

$$\eta_1 = \frac{3-\sqrt{3}}{6}, \qquad \eta_2 = \frac{3+\sqrt{3}}{6}. \tag{2.3}$$

The following result is a consequence of Lemma 2.3 in [10].

LEMMA 2.1. *Any $V \in \mathcal{M}^0(0,1)$ is uniquely determined by its values on the set $\mathcal{G}$.*

For V and W defined on $\mathcal{G}$, we introduce

$$\langle V, W\rangle_{\mathcal{G}} = \frac{h}{2}\sum_{\xi\in\mathcal{G}}(VW)(\xi), \qquad \|V\|_{\mathcal{G}} = \sqrt{\langle V, V\rangle}. \tag{2.4}$$

Throughout the paper, C denotes a generic positive constant that is independent of h. The following result is a special case of Lemma 3.1 in [10].

LEMMA 2.2. *For any $V, W \in \mathcal{M}(0,1)$,*

$$\langle -V'', W\rangle_{\mathcal{G}} = \int_0^1 (V'W')(t)\,dt - V'W|_0^1 + \frac{2}{3}Ch^5\sum_{k=1}^{N} V_k^{(3)}W_k^{(3)},$$

where, for $k = 1, \ldots, N$, $V_k^{(3)} = V^{(3)}(t)$, $W_k^{(3)} = W^{(3)}(t)$, $t \in (t_{k-1}, t_k)$.

The next result is a special case of Lemma 3.2 in [10].

LEMMA 2.3. *For any $V \in \mathcal{M}(0,1)$,*

$$Ch^5\sum_{k=1}^{N}\left[V_k^{(3)}\right]^2 \le \|V'\|^2_{L^2(0,1)},$$

where C is the same as in Lemma 2.2.

The next result is inequality (3.4) in [10] (cf. the first inequality in (5.25) of [14]).

LEMMA 2.4. *For any $V \in \mathcal{M}(0,1)$,*

$$\langle V, V\rangle_{\mathcal{G}} \le C\|V\|^2_{L^2(0,1)}.$$

The next result is a generalization of the second inequality in (5.25) of [14].

LEMMA 2.5. *For any $V \in \mathcal{M}(0,1)$,*

$$\|V\|^2_{L^2(0,1)} \le C\left(\|V\|^2_{\mathcal{G}} + hV^2(0) + hV^2(1)\right).$$

Proof. For $V \in \mathcal{M}(0,1)$, we introduce

$$\tilde{V}(t) = \begin{cases} V(0)g(1-t/h), & t \in [t_0, t_1], \\ 0, & t \in [t_1, t_{N-1}, \\ V(1)g(1+(t-1)/h), & t \in [t_{N-1}, t_N], \end{cases} \tag{2.5}$$

where $g(x) = -2x^2 + 3x^2$. Then it is easy to verify that $\tilde{V} \in \mathcal{M}(0,1)$, and $\tilde{V}(t_k) = V(t_k)$, $k = 0, N$. Hence applying the second inequality in (5.25) of [14] to $V - \tilde{V} \in \mathcal{M}^0(0,1)$, and using the triangle inequality, we have

$$\|V - \tilde{V}\|_{L^2(0,1)} \le C\|V - \tilde{V}\|_{\mathcal{G}} \le C\left(\|V\|_{\mathcal{G}} + \|\tilde{V}\|_{\mathcal{G}}\right). \tag{2.6}$$

The triangle inequality and (2.6) yield

$$\|V\|_{L^2(0,1)} \le \|V-\tilde{V}\|_{L^2(0,1)} + \|\tilde{V}\|_{L^2(0,1)} \le C\left(\|V\|_{\mathcal{G}} + \|\tilde{V}\|_{\mathcal{G}} + \|\tilde{V}\|_{L^2(0,1)}\right). \tag{2.7}$$

Using (2.5), it is easy to show that

$$\|\tilde{V}\|^2_{\mathcal{G}}, \|\tilde{V}\|^2_{L^2(0,1)} \le C\left(hV^2(0) + hV^2(1)\right). \tag{2.8}$$

Hence the required result follows from (2.7), the Cauchy–Schwarz inequality, and (2.8). □

Let $\delta_{n,k}$ be the Kronecker delta. The following two lemmas are Lemmas 2.1 and 2.2 in [1].

LEMMA 2.6. *There exist eigenfunctions $\psi_n \in \mathcal{M}^0(0,1)$, $n = 1,\dots,2N$, such that*

$$-\psi_n''(\xi) = \lambda_n \psi_n(\xi), \qquad \xi \in \mathcal{G},$$
$$\langle \psi_n, \psi_k \rangle_{\mathcal{G}} = \frac{h}{2}\delta_{n,k}, \qquad n,k = 1,\dots,2N,$$

where the eigenvalues λ_n, $n = 1,\dots,2N$, all of which are positive, are given by the formulas in Lemma 2.1 *of* [1].

LEMMA 2.7. *For each λ_n, $n = 1,\dots,2N$, of Lemma* 2.6 *there exists a unique $v_n \in \mathcal{M}(0,1)$ such that*

$$v_n''(\xi) = \lambda_n v_n(\xi), \qquad \xi \in \mathcal{G}, \qquad v_n(0) = 0, \qquad v_n(1) = 1.$$

Moreover, a nonzero value of $v_n'(1)$ is given by (2.4)*–*(2.6) *in* [1].

Let B and Z be the $2N \times 2N$ matrices defined, respectively, in (2.9) and (2.10) of [1]. The following lemma follows easily from Lemma 2.3 in [1].

LEMMA 2.8. *Let ψ_n, $n = 1,\dots,2N$, be as in Lemma* 2.6. *Assume $v \in \mathcal{M}^0(0,1)$, and hence $v = \sum_{n=1}^{2N} \alpha_n \psi_n$. If $\vec{\alpha} = [\alpha_1,\dots,\alpha_{2N}]^T$, then*

$$[v(\xi_1),\dots,v(\xi_{2N})]^T = BZ\vec{\alpha}, \qquad \vec{\alpha} = Z^T B^T [v(\xi_1),\dots,v(\xi_{2N})]^T.$$

The following remark follows from (2.9) and (2.10) in [1].

Remark 2.1. The cost of multiplying a vector by B or B^T is $O(N)$, and with the use of FFTs the cost of multiplying a vector by Z or Z^T is $O(N \log N)$.

3. The OSC problem. Let $\mathcal{M}(1,2)$ be the space of piecewise Hermite cubics on $[1,2]$ defined by

$$\mathcal{M}(1,2) = \{v \in C^1[1,2] : v|_{[t_{k-1},t_k]} \in P_3, k = N+1,\dots,2N\},$$

where $t_k = kh$, $k = N,\dots,2N$. We introduce the following spaces of piecewise Hermite bicubics:

$$\mathcal{M}_1 = \mathcal{M}(0,1) \otimes \mathcal{M}(0,1), \qquad \mathcal{M}_2 = \mathcal{M}(1,2) \otimes \mathcal{M}(0,1),$$
$$\mathcal{M}_3 = \mathcal{M}(0,1) \otimes \mathcal{M}(1,2), \tag{3.1}$$

$$X_i = \{v \in \mathcal{M}_i : v = 0 \text{ on } \partial\Omega \cap \partial\Omega_i\}, \qquad i = 1,2,3, \tag{3.2}$$

where $\mathcal{M}(0,1)$ is given by (2.1). We note that $v(1,1) = 0$ for any $v \in X_1$.

Let $\tilde{\mathcal{G}} = \{\xi_l\}_{l=2N+1}^{4N}$ be the set of the collocation points in $[1, 2]$, where ξ_{2k-1}, ξ_{2k}, $k = N+1, \dots, 2N$, are given by (2.2)–(2.3). Then the sets of the collocation points in Ω_1, Ω_2, Ω_3 are defined, respectively, by

$$\mathcal{G}_1 = \mathcal{G} \times \mathcal{G}, \qquad \mathcal{G}_2 = \tilde{\mathcal{G}} \times \mathcal{G}, \qquad \mathcal{G}_3 = \mathcal{G} \times \tilde{\mathcal{G}},$$

where $\mathcal{G} = \{\xi_l\}_{l=1}^{2N}$ is given by (2.2)–(2.3).

Let $\tilde{g}$ be the piecewise Hermite cubic interpolant of g on $\partial\Omega$. The OSC problem for (1.1) consists in finding $U_i \in \mathcal{M}_i$, $i = 1, 2, 3$, such that

$$\Delta U_i(\xi) = f(\xi), \quad \xi \in \mathcal{G}_i, \qquad U_i = \tilde{g} \ \text{ on } \ \partial\Omega \cap \partial\Omega_i, \qquad i = 1, 2, 3, \tag{3.3}$$

and

$$\frac{\partial^j U_1}{\partial x^j}(1, \xi) = \frac{\partial^j U_2}{\partial x^j}(1, \xi), \qquad \frac{\partial^j U_1}{\partial y^j}(\xi, 1) = \frac{\partial^j U_3}{\partial y^j}(\xi, 1), \qquad \xi \in \mathcal{G}, \qquad j = 0, 1. \tag{3.4}$$

It follows from (3.3), (3.4) with $j = 0$ and Lemma 2.1 that

$$U_1|_{\overline{\Gamma}_1} = U_2|_{\overline{\Gamma}_1}, \qquad U_1|_{\overline{\Gamma}_2} = U_3|_{\overline{\Gamma}_2}. \tag{3.5}$$

However, in general

$$\frac{\partial U_1}{\partial x}(1, 1) \neq \frac{\partial U_2}{\partial x}(1, 1), \qquad \frac{\partial U_1}{\partial y}(1, 1) \neq \frac{\partial U_3}{\partial y}(1, 1).$$

To carry out the analysis of the OSC problem, we introduce, for $V_i \in X_i$, $i = 1, 2, 3$,

$$\|(V_1, V_2, V_3)\|_h^2 = \sum_{i=1}^{3} \|V_i\|_{i,h}^2, \tag{3.6}$$

where

$$\|V_1\|_{1,h}^2 = \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left\| \frac{\partial V_1}{\partial x}(\cdot, \eta) \right\|_{L^2(0,1)}^2 + \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\| \frac{\partial V_1}{\partial y}(\xi, \cdot) \right\|_{L^2(0,1)}^2, \tag{3.7}$$

$$\|V_2\|_{2,h}^2 = \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left\| \frac{\partial V_2}{\partial x}(\cdot, \eta) \right\|_{L^2(1,2)}^2 + \frac{h}{2} \sum_{\xi \in \tilde{\mathcal{G}}} \left\| \frac{\partial V_2}{\partial y}(\xi, \cdot) \right\|_{L^2(0,1)}^2, \tag{3.8}$$

$$\|V_3\|_{3,h}^2 = \frac{h}{2} \sum_{\eta \in \tilde{\mathcal{G}}} \left\| \frac{\partial V_3}{\partial x}(\cdot, \eta) \right\|_{L^2(0,1)}^2 + \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\| \frac{\partial V_3}{\partial y}(\xi, \cdot) \right\|_{L^2(1,2)}^2. \tag{3.9}$$

It is not difficult to show that, for any stepsize h, $\|\cdot\|_h$ defined by (3.6) is a norm on $X_1 \times X_2 \times X_3$.

For $i = 1, 2, 3$ and V_i, W_i defined on $\mathcal{G}_i$, we introduce

$$\langle V_i, W_i \rangle_{\mathcal{G}_i} = \frac{h^2}{4} \sum_{\xi \in \mathcal{G}_i} (V_i W_i)(\xi), \qquad \|V_i\|_{\mathcal{G}_i} = \sqrt{\langle V_i, V_i \rangle_{\mathcal{G}_i}}. \tag{3.10}$$

To prove existence and uniqueness of the OSC solution, we require the following lemma.

LEMMA 3.1. *If $W_i \in X_i$, $i = 1, 2, 3$, and*

$$\frac{\partial^j W_1}{\partial x^j}(1,\xi) = \frac{\partial^j W_2}{\partial x^j}(1,\xi), \quad \frac{\partial^j W_1}{\partial y^j}(\xi,1) = \frac{\partial^j W_3}{\partial y^j}(\xi,1), \quad j = 0,1, \quad \xi \in \mathcal{G}, \tag{3.11}$$

then

$$\|(W_1, W_2, W_3)\|_h^2 \le \sum_{i=1}^{3} \langle -\Delta W_i, W_i \rangle_{\mathcal{G}_i} \le \frac{5}{3} \|(W_1, W_2, W_3)\|_h^2.$$

Proof. Using (3.10), we obtain

$$\sum_{i=1}^{3} \langle -\Delta W_i, W_i \rangle_{\mathcal{G}_i} = I_x + I_y, \tag{3.12}$$

where

$$\begin{aligned} I_x = {} & \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left\{ \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left(-\frac{\partial^2 W_1}{\partial x^2} W_1 \right)(\xi,\eta) + \frac{h}{2} \sum_{\xi \in \tilde{\mathcal{G}}} \left(-\frac{\partial^2 W_2}{\partial x^2} W_2 \right)(\xi,\eta) \right\} \\ & + \frac{h}{2} \sum_{\eta \in \tilde{\mathcal{G}}} \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left(-\frac{\partial^2 W_3}{\partial x^2} W_3 \right)(\xi,\eta), \end{aligned}$$

$$\begin{aligned} I_y = {} & \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\{ \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left(-\frac{\partial^2 W_1}{\partial y^2} W_1 \right)(\xi,\eta) + \frac{h}{2} \sum_{\eta \in \tilde{\mathcal{G}}} \left(-\frac{\partial^2 W_3}{\partial y^2} W_3 \right)(\xi,\eta) \right\} \\ & + \frac{h}{2} \sum_{\xi \in \tilde{\mathcal{G}}} \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left(-\frac{\partial^2 W_2}{\partial y^2} W_2 \right)(\xi,\eta). \end{aligned}$$

It follows from Lemma 2.2 and (3.11) that

$$\begin{aligned} I_x = {} & \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left\{ \left\| \frac{\partial W_1}{\partial x}(\cdot,\eta) \right\|_{L^2(0,1)}^2 + \frac{2}{3} C h^5 \sum_{k=1}^{N} \left[W_{1,k}^{(3,0)}(\eta) \right]^2 \right\} \\ & + \frac{h}{2} \sum_{\eta \in \mathcal{G}} \left\{ \left\| \frac{\partial W_2}{\partial x}(\cdot,\eta) \right\|_{L^2(1,2)}^2 + \frac{2}{3} C h^5 \sum_{k=N+1}^{2N} \left[W_{2,k}^{(3,0)}(\eta) \right]^2 \right\} \\ & + \frac{h}{2} \sum_{\eta \in \tilde{\mathcal{G}}} \left\{ \left\| \frac{\partial W_3}{\partial x}(\cdot,\eta) \right\|_{L^2(0,1)}^2 + \frac{2}{3} C h^5 \sum_{k=1}^{N} \left[W_{3,k}^{(3,0)}(\eta) \right]^2 \right\}, \end{aligned} \tag{3.13}$$

where, for $x \in (t_{k-1}, t_k)$,

$$W_{1,k}^{(3,0)}(\eta) = \frac{\partial^3 W_1}{\partial x^3}(x,\eta), \quad W_{2,k}^{(3,0)}(\eta) = \frac{\partial^3 W_2}{\partial x^3}(x,\eta), \quad W_{3,k}^{(3,0)}(\eta) = \frac{\partial^3 W_3}{\partial x^3}(x,\eta).$$

Hence the required inequalities follow from (3.13), a similar expression for I_y, and Lemma 2.3. □

THEOREM 3.1. *The OSC problem* (3.3)–(3.4) *has a unique solution.*

Proof. We assume that $U_i^I, U_i^{II} \in \mathcal{M}_i$, $i = 1, 2, 3$, are two solutions of the OSC problem (3.3)–(3.4). Let $W_i = U_i^I - U_i^{II}$, $i = 1, 2, 3$. Since $\|\cdot\|_h$ is a norm on $X_1 \times X_2 \times X_3$, Lemma 3.1 gives $U_i^I = U_i^{II}$, $i = 1, 2, 3$. This in turn implies existence and uniqueness of the collocation solution since the number of degrees of freedom in the OSC problem is equal to the number of constraints. □

The L^2-norm convergence analysis of the OSC problem is based on the following lemma.

LEMMA 3.2. *If h is sufficiently small, then*

$$\sum_{i=1}^{3} \|V_i\|^2_{L^2(\Omega_i)} \le C\|(V_1, V_2, V_3)\|_h^2, \qquad V_i \in X_i, \qquad i = 1, 2, 3.$$

Proof. Using (3.6)–(3.9) and the Poincaré inequality and interchanging the order in which summation and integration are carried out, we have

$$\begin{aligned} C\|(V_1, V_2, V_3)\|_h^2 &\ge \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\| \frac{\partial V_1}{\partial y}(\xi, \cdot) \right\|^2_{L^2(0,1)} \\ &+ \int_0^1 \|V_1(x, \cdot)\|_{\mathcal{G}}^2 \, dx + \int_1^2 \|V_2(x, \cdot)\|_{\mathcal{G}}^2 \, dx + \int_1^2 \|V_3(\cdot, y)\|_{\mathcal{G}}^2 \, dy. \end{aligned}$$

Adding and subtracting $hV_1^2(x, 1)$ to and from $\|V_1(x, \cdot)\|_{\mathcal{G}}^2$, and using Lemma 2.5, we obtain

$$\begin{aligned} C\|(V_1, V_2, V_3)\|_h^2 &\ge \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\| \frac{\partial V_1}{\partial y}(\xi, \cdot) \right\|^2_{L^2(0,1)} - h \int_0^1 V_1^2(x, 1) \, dx \\ &+ C\|V_1\|^2_{L^2(\Omega_1)} + \|V_2\|^2_{L^2(\Omega_2)} + \|V_3\|^2_{L^2(\Omega_3)}. \end{aligned} \tag{3.14}$$

We note that $V_1(\cdot, 1) \in \mathcal{M}^0(0, 1)$ and $V_1(\xi, 1) = \int_0^1 \frac{\partial V_1}{\partial y}(\xi, y) \, dy$, $\xi \in \mathcal{G}$. Hence Lemma 2.5 and the Cauchy–Schwarz inequality give

$$\int_0^1 V_1^2(x, 1) \, dx \le C \frac{h}{2} \sum_{\xi \in \mathcal{G}} V_1^2(\xi, 1) \le C \frac{h}{2} \sum_{\xi \in \mathcal{G}} \left\| \frac{\partial V_1}{\partial y}(\xi, \cdot) \right\|^2_{L^2(0,1)}. \tag{3.15}$$

Thus the required result follows from (3.14) and (3.15). □

THEOREM 3.2. *Assume that u is the solution of* (1.1) *such that* u, $\partial u/\partial x$, $\partial u/\partial y$, *and* $\partial^2 u/\partial x \partial y$ *are continuous on* $\overline{\Omega}$ *and such that* $u|_{\Omega_i} \in H^6(\Omega_i)$, $i = 1, 2, 3$. *Let* $U_i \in \mathcal{M}_i$, $i = 1, 2, 3$, *satisfy* (3.3)–(3.4). *Then, for h sufficiently small,*

$$\sum_{i=1}^{3} \|u - U_i\|_{H^s(\Omega_i)} \le Ch^{4-s} \sum_{i=1}^{3} \|u\|_{H^6(\Omega_i)}, \qquad s = 0, 1, 2.$$

Proof. Let $\tilde{u}_1 \in \mathcal{M}_1$ be the piecewise Hermite bicubic interpolant of $u|_{\Omega_1}$, that is,

$$\frac{\partial^{i+j} \tilde{u}_1}{\partial x^i \partial y^j}(t_k, t_l) = \frac{\partial^{i+j} u}{\partial x^i \partial y^j}(t_k, t_l), \qquad k, l = 0, \dots, N, \qquad i, j = 0, 1,$$

and let, for $i = 2, 3$, the piecewise Hermite bicubic interpolant $\tilde{u}_i \in \mathcal{M}_i$ of $u|_{\Omega_i}$ be defined in a similar way. Let

$$v_i = u|_{\Omega_i} - \tilde{u}_i, \qquad W_i = \tilde{u}_i - U_i, \qquad i = 1, 2, 3. \tag{3.16}$$

Then it follows from [9] that

$$\|v_i\|_{H^s(\Omega_i)} \le Ch^{4-s}\|u\|_{H^4(\Omega_i)}, \qquad i = 1, 2, 3, \qquad s = 0, 1, 2, \tag{3.17}$$

and (3.3), (1.1), and (3.4) imply that $W_i \in X_i$, $i = 1, 2, 3$, and that (3.11) holds. Also, using (3.16), (3.3), and (1.1), we have

$$\sum_{i=1}^{3}\langle -\Delta W_i, W_i\rangle_{\mathcal{G}_i} = \sum_{i=1}^{3}\langle \Delta v_i, W_i\rangle_{\mathcal{G}_i}. \tag{3.18}$$

First we bound $\langle \Delta v_1, W_1\rangle_{\mathcal{G}_1}$ on the right-hand side of (3.18). It follows from (2.20) in [2] and the proof of (2.22) in [2] that

$$\begin{aligned} &\|\Delta v_1\|_{\mathcal{G}_1} \le Ch^3\|u\|_{H^5(\Omega_1)}, \\ &S_1 \equiv \left(\frac{h^2}{16}\sum_{k,l=1}^{N}\left[\sum_{i,j=0}^{1}\Delta v_1(\xi_{2k-i}, \xi_{2l-j})\right]^2\right)^{1/2} \le Ch^4\|u\|_{H^6(\Omega_1)}. \end{aligned} \tag{3.19}$$

Let

$$\sigma_{k,l} = \frac{1}{4}\sum_{i,j=0}^{1} W_1(\xi_{2k-i}, \xi_{2l-j}), \qquad k, l = 1, \dots, N. \tag{3.20}$$

By (3.20), the Cauchy–Schwarz inequality, Lemma 2.4, the Poincaré inequality, and (3.7), we obtain

$$h^2\sum_{k,l=1}^{N}\sigma_{k,l}^2 \le \frac{h}{2}\sum_{\eta\in\mathcal{G}}\|W_1(\cdot,\eta)\|_{\mathcal{G}}^2 \le C\frac{h}{2}\sum_{\eta\in\mathcal{G}}\left\|\frac{\partial W_1}{\partial x}(\cdot,\eta)\right\|_{L^2(0,1)}^2 \le C\|W_1\|_{1,h}^2. \tag{3.21}$$

Also, by the Cauchy–Schwarz inequality, for $k, l = 1, \dots, N$, $i, j = 0, 1$, we have

$$[W_1(\xi_{2k-1}, \xi_{2l-j}) - W_1(\xi_{2k}, \xi_{2l-j})]^2 \le h\left\|\frac{\partial W_1}{\partial x}(\cdot, \xi_{2l-j})\right\|_{L^2(t_{k-1},t_k)}^2,$$

$$[W_1(\xi_{2k-i}, \xi_{2l-1}) - W_1(\xi_{2k-i}, \xi_{2l})]^2 \le h\left\|\frac{\partial W_1}{\partial y}(\xi_{2k-i}, \cdot)\right\|_{L^2(t_{l-1},t_l)}^2,$$

which imply

$$\begin{aligned} &\sum_{i,j=0}^{1}[W_1(\xi_{2k-i}, \xi_{2l-j}) - \sigma_{k,l}]^2 \\ &\le Ch\left(\sum_{j=0}^{1}\left\|\frac{\partial W_1}{\partial x}(\cdot, \xi_{2l-j})\right\|_{L^2(t_{k-1},t_k)}^2 + \sum_{i=0}^{1}\left\|\frac{\partial W_1}{\partial y}(\xi_{2k-i}, \cdot)\right\|_{L^2(t_{l-1},t_l)}^2\right), \end{aligned} \tag{3.22}$$

since, for example, (3.20) gives

$$\begin{aligned} &W_1(\xi_{2k-1}, \xi_{2l-1}) - \sigma_{k,l} = \frac{1}{4}[W_1(\xi_{2k-1}, \xi_{2l-1}) - W_1(\xi_{2k}, \xi_{2l-1})] \\ &+\frac{1}{4}[W_1(\xi_{2k-1}, \xi_{2l-1}) - W_1(\xi_{2k-1}, \xi_{2l})] \\ &+\frac{1}{4}[W_1(\xi_{2k-1}, \xi_{2l-1}) - W_1(\xi_{2k}, \xi_{2l}) \pm W_1(\xi_{2k}, \xi_{2l-1})]. \end{aligned}$$

It follows from (3.22) and (3.7) that

$$S_2 \equiv \left(\frac{h^2}{4} \sum_{k,l=1}^{N} \sum_{i,j=0}^{1} [W_1(\xi_{2k-i}, \xi_{2l-j}) - \sigma_{k,l}]^2 \right)^{1/2} \leq Ch\|W_1\|_{1,h}. \tag{3.23}$$

Using the Cauchy–Schwarz inequality, (3.23), (3.19), and (3.21), we obtain

$$\begin{aligned} \langle \Delta v_1, W_1 \rangle_{\mathcal{G}_1} &= \frac{h^2}{4} \sum_{k,l=1}^{N} \sum_{i,j=0}^{1} \Delta v_1(\xi_{2k-i}, \xi_{2l-j})[W_1(\xi_{2k-i}, \xi_{2l-j}) - \sigma_{k,l}] \\ &+ \frac{h^2}{4} \sum_{k,l=1}^{N} \sigma_{k,l} \sum_{i,j=0}^{1} \Delta v_1(\xi_{2k-i}, \xi_{2l-j}) \leq \|\Delta v_1\|_{\mathcal{G}_1} S_2 + \left(h^2 \sum_{k,l=1}^{N} \sigma_{k,l}^2 \right)^{1/2} S_1 \\ &\leq Ch^4 \|W_1\|_{1,h} \|u\|_{H^6(\Omega_1)}. \end{aligned}$$

In a similar way, we can show that

$$\langle \Delta v_i, W_i \rangle_{\mathcal{G}_i} \leq Ch^4 \|W_i\|_{i,h} \|u\|_{H^6(\Omega_i)}, \qquad i = 2, 3.$$

Hence the Cauchy–Schwarz inequality and (3.6) give

$$\sum_{i=1}^{3} \langle \Delta v_i, W_i \rangle_{\mathcal{G}_i} \leq Ch^4 \|(W_1, W_2, W_3)\|_h \sum_{i=1}^{3} \|u\|_{H^6(\Omega_i)}.$$

Using this inequality, (3.18), Lemmas 3.1 and 3.2, and inverse inequalities [9], we obtain

$$\sum_{i=1}^{3} \|W_i\|_{H^s(\Omega_i)} \leq Ch^{4-s} \sum_{i=1}^{3} \|u\|_{H^6(\Omega_i)}, \qquad s = 0, 1, 2. \tag{3.24}$$

The required inequalities now follow from (3.16), the triangle inequality, (3.17), and (3.24). □

It should be noted that while the exponent on h in the error bounds of Theorem 3.2 is optimal, the smoothness assumption on u is not. The same proof shows that Theorem 3.2 holds for quasi-uniform and matching grids.

4. The algorithm for solving OSC problem.

Taking advantage of uniform partitions of Ω_i, $i = 1, 2, 3$, we develop an FFT algorithm for the solution of the OSC problem (3.3)–(3.4). In the case of quasi-uniform partitions, the corresponding problems in this algorithm can be solved very efficiently by multilevel methods of [6].

Assume that $U_i \in M_i$, $i = 1, 2, 3$, satisfy (3.3)–(3.4). Let $U_{\Gamma_i} \in \mathcal{M}^0(0, 1)$, $i = 1, 2$, be defined by (cf. (3.5))

$$U_{\Gamma_1}(t_k) = U_1(1, t_k) = U_2(1, t_k), \qquad k = 1, \ldots, N-1, \tag{4.1}$$

$$U'_{\Gamma_1}(t_k) = \frac{\partial U_1}{\partial y}(1, t_k) = \frac{\partial U_2}{\partial y}(1, t_k), \qquad k = 0, \ldots, N, \tag{4.2}$$

$$U_{\Gamma_2}(t_k) = U_1(t_k, 1) = U_3(t_k, 1), \qquad k = 1, \ldots, N-1, \tag{4.3}$$

$$U'_{\Gamma_2}(t_k) = \frac{\partial U_1}{\partial x}(t_k, 1) = \frac{\partial U_3}{\partial x}(t_k, 1), \qquad k = 0, \ldots, N. \tag{4.4}$$

For $i = 1, 2, 3$, let $\hat{U}_i \in \mathcal{M}_i$ be such that

$$\Delta \hat{U}_i(\xi) = f(\xi), \quad \xi \in \mathcal{G}_i, \qquad \hat{U}_i = \tilde{g} \quad \text{on} \quad \partial\Omega \cap \partial\Omega_i, \tag{4.5}$$

$$\hat{U}_1(1, t_k) = \hat{U}_1(t_k, 1) = \hat{U}_2(1, t_k) = \hat{U}_3(t_k, 1) = 0, \qquad k = 1, \dots, N-1, \tag{4.6}$$

$$\frac{\partial \hat{U}_1}{\partial y}(1, t_k) = \frac{\partial \hat{U}_1}{\partial x}(t_k, 1) = \frac{\partial \hat{U}_2}{\partial y}(1, t_k) = \frac{\partial \hat{U}_3}{\partial x}(t_k, 1) = 0, \qquad k = 0, \dots, N, \tag{4.7}$$

and let

$$\tilde{U}_i = U_i - \hat{U}_i. \tag{4.8}$$

Then it follows from (4.8), (3.3), and (4.1)–(4.7) that $\tilde{U}_i \in X_i$, $i = 1, 2, 3$, and that

$$\Delta \tilde{U}_1(\xi) = 0, \qquad \xi \in \mathcal{G}_1, \qquad \tilde{U}_1|_{\overline{\Gamma}_1} = U_{\Gamma_1}, \qquad \tilde{U}_1|_{\overline{\Gamma}_2} = U_{\Gamma_2}, \tag{4.9}$$

$$\Delta \tilde{U}_2(\xi) = 0, \qquad \xi \in \mathcal{G}_2, \qquad \tilde{U}_2|_{\overline{\Gamma}_1} = U_{\Gamma_1}, \tag{4.10}$$

$$\Delta \tilde{U}_3(\xi) = 0, \qquad \xi \in \mathcal{G}_3, \qquad \tilde{U}_3|_{\overline{\Gamma}_2} = U_{\Gamma_2}. \tag{4.11}$$

Using (4.8) and (3.4) with $j = 1$, we also have

$$\begin{aligned} \frac{\partial \tilde{U}_1}{\partial x}(1, \xi) - \frac{\partial \tilde{U}_2}{\partial x}(1, \xi) &= \frac{\partial \hat{U}_2}{\partial x}(1, \xi) - \frac{\partial \hat{U}_1}{\partial x}(1, \xi), \qquad \xi \in \mathcal{G}, \\ \frac{\partial \tilde{U}_1}{\partial y}(\xi, 1) - \frac{\partial \tilde{U}_3}{\partial y}(\xi, 1) &= \frac{\partial \hat{U}_3}{\partial y}(\xi, 1) - \frac{\partial \hat{U}_1}{\partial y}(\xi, 1), \qquad \xi \in \mathcal{G}. \end{aligned} \tag{4.12}$$

Based on these derivations, we arrive at the following algorithm to compute $U_i \in \mathcal{M}_i$, $i = 1, 2, 3$, satisfying (3.3)–(3.4):

(4.13)
Step 1. With $\hat{U}_i \in \mathcal{M}_i$, $i = 1, 2, 3$, defined by (4.5)–(4.7), compute the right-hand sides of (4.12).
Step 2. Compute $U_{\Gamma_i} \in \mathcal{M}^0(0, 1)$, $i = 1, 2$, such that $\tilde{U}_i \in X_i$, $i = 1, 2, 3$, satisfy (4.9)–(4.12).
Step 3. Compute $U_i \in \mathcal{M}_i$, $i = 1, 2, 3$, satisfying (3.3) and (4.1)–(4.4).

In the remainder of the paper, we explain how to carry out each step of this algorithm.

5. The interface problem.

This section is concerned with performing step 2 of algorithm (4.13), which is equivalent to solving the interface problem.

5.1. Collocation Steklov–Poincaré operator *K*.

Let $K : [\mathcal{M}^0(0, 1)]^2 \to [\mathcal{M}^0(0, 1)]^2$ be defined for $V_{\Gamma_i} \in \mathcal{M}^0(0, 1)$, $i = 1, 2$, by

$$K(V_{\Gamma_1}, V_{\Gamma_2}) = (W_{\Gamma_1}, W_{\Gamma_2}), \tag{5.1}$$

where $W_{\Gamma_i} \in \mathcal{M}^0(0, 1)$, $i = 1, 2$, are uniquely determined by (cf. Lemma 2.1)

$$W_{\Gamma_1}(\xi) = \frac{\partial V_1}{\partial x}(1, \xi) - \frac{\partial V_2}{\partial x}(1, \xi), \quad W_{\Gamma_2}(\xi) = \frac{\partial V_1}{\partial y}(\xi, 1) - \frac{\partial V_3}{\partial y}(\xi, 1), \quad \xi \in \mathcal{G}, \tag{5.2}$$

and where $V_i \in X_i$, $i = 1, 2, 3$, satisfy

$$\Delta V_1(\xi) = 0, \qquad \xi \in \mathcal{G}_1, \qquad V_1|_{\overline{\Gamma}_1} = V_{\Gamma_1}, \qquad V_1|_{\overline{\Gamma}_2} = V_{\Gamma_2}, \tag{5.3}$$

$$\Delta V_2(\xi) = 0, \qquad \xi \in \mathcal{G}_2, \qquad V_2|_{\overline{\Gamma}_1} = V_{\Gamma_1}, \tag{5.4}$$

$$\Delta V_3(\xi) = 0, \qquad \xi \in \mathcal{G}_3, \qquad V_3|_{\overline{\Gamma}_2} = V_{\Gamma_2}. \tag{5.5}$$

Then step 2 of algorithm (4.13) is equivalent to finding $U_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$, such that

$$K(U_{\Gamma_1}, U_{\Gamma_2}) = (F_{\Gamma_1}, F_{\Gamma_2}), \tag{5.6}$$

where $F_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$, are given by

$$F_{\Gamma_1}(\xi) = \frac{\partial \hat{U}_2}{\partial x}(1,\xi) - \frac{\partial \hat{U}_1}{\partial x}(1,\xi), \qquad F_{\Gamma_2}(\xi) = \frac{\partial \hat{U}_3}{\partial y}(\xi,1) - \frac{\partial \hat{U}_1}{\partial y}(\xi,1), \qquad \xi \in \mathcal{G},$$

and where $\hat{U}_i \in \mathcal{M}_i$, $i = 1, 2, 3$, satisfy (4.5)–(4.7).

We define the inner product in $[\mathcal{M}^0(0,1)]^2$ by

$$\langle (V_{\Gamma_1}, V_{\Gamma_2}), (W_{\Gamma_1}, W_{\Gamma_2}) \rangle = \sum_{i=1}^{2} \langle V_{\Gamma_i}, W_{\Gamma_i} \rangle_{\mathcal{G}}, \tag{5.7}$$

where $\langle \cdot, \cdot \rangle_{\mathcal{G}}$ is given in (2.4).

THEOREM 5.1. *The operator* $K : [\mathcal{M}^0(0,1)]^2 \to [\mathcal{M}^0(0,1)]^2$ *defined by* (5.1)–(5.2) *is self-adjoint and positive definite with respect to the inner product* (5.7).

Proof. To prove that K is self-adjoint, we have to show that, for $V_{\Gamma_i}, W_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$,

$$\langle K(V_{\Gamma_1}, V_{\Gamma_2}), (W_{\Gamma_1}, W_{\Gamma_2}) \rangle = \langle (V_{\Gamma_1}, V_{\Gamma_2}), K(W_{\Gamma_1}, W_{\Gamma_2}) \rangle.$$

Using (5.1)–(5.2) and (5.7), we have

$$\begin{aligned} &\langle K(V_{\Gamma_1}, V_{\Gamma_2}), (W_{\Gamma_1}, W_{\Gamma_2}) \rangle \\ &= \left\langle \frac{\partial V_1}{\partial x}(1,\cdot) - \frac{\partial V_2}{\partial x}(1,\cdot), W_{\Gamma_1} \right\rangle_{\mathcal{G}} + \left\langle \frac{\partial V_1}{\partial y}(\cdot,1) - \frac{\partial V_3}{\partial y}(\cdot,1), W_{\Gamma_2} \right\rangle_{\mathcal{G}}, \end{aligned} \tag{5.8}$$

where $V_i \in X_i$, $i = 1, 2, 3$, satisfy (5.3)–(5.5). Let $W_i \in X_i$, $i = 1, 2, 3$, satisfy

$$\Delta W_1(\xi) = 0, \qquad \xi \in \mathcal{G}_1, \qquad W_1|_{\overline{\Gamma}_1} = W_{\Gamma_1}, \qquad W_1|_{\overline{\Gamma}_2} = W_{\Gamma_2}, \tag{5.9}$$

$$\Delta W_2(\xi) = 0, \qquad \xi \in \mathcal{G}_2, \qquad W_2|_{\overline{\Gamma}_1} = W_{\Gamma_1}, \tag{5.10}$$

$$\Delta W_3(\xi) = 0, \qquad \xi \in \mathcal{G}_3, \qquad W_3|_{\overline{\Gamma}_2} = W_{\Gamma_2}. \tag{5.11}$$

It follows from (5.3), Lemma 2.2, and (5.9) that

$$\begin{aligned} 0 &= \frac{h^2}{4} \sum_{(\xi,\eta)\in\mathcal{G}_1} (-\Delta V_1 W_1)(\xi,\eta) \\ &= \frac{h}{2} \sum_{\eta\in\mathcal{G}} \frac{h}{2} \sum_{\xi\in\mathcal{G}} \left(-\frac{\partial^2 V_1}{\partial x^2} W_1 \right)(\xi,\eta) + \frac{h}{2} \sum_{\xi\in\mathcal{G}} \frac{h}{2} \sum_{\eta\in\mathcal{G}} \left(-\frac{\partial^2 V_1}{\partial y^2} W_1 \right)(\xi,\eta) \\ &= \frac{h}{2} \sum_{\eta\in\mathcal{G}} \left[\int_0^1 \left(\frac{\partial V_1}{\partial x} \frac{\partial W_1}{\partial x} \right)(x,\eta)\, dx - \left(\frac{\partial V_1}{\partial x} W_{\Gamma_1} \right)(1,\eta) \right. \\ &\quad \left. + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{1,k}^{(3,0)} W_{1,k}^{(3,0)})(\eta) \right] \\ &\quad + \frac{h}{2} \sum_{\xi\in\mathcal{G}} \left[\int_0^1 \left(\frac{\partial V_1}{\partial y} \frac{\partial W_1}{\partial y} \right)(\xi,y)\, dy - \left(\frac{\partial V_1}{\partial y} W_{\Gamma_2} \right)(\xi,1) \right. \\ &\quad \left. + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{1,k}^{(0,3)} W_{1,k}^{(0,3)})(\xi) \right], \end{aligned} \tag{5.12}$$

where, for $t \in (t_{k-1}, t_k)$,

$$V_{1,k}^{(3,0)}(\eta) = \frac{\partial^3 V_1}{\partial x^3}(t, \eta), \qquad W_{1,k}^{(3,0)}(\eta) = \frac{\partial^3 W_1}{\partial x^3}(t, \eta),$$
$$V_{1,k}^{(0,3)}(\xi) = \frac{\partial^3 V_1}{\partial y^3}(\xi, t), \qquad W_{1,k}^{(0,3)}(\xi) = \frac{\partial^3 W_1}{\partial y^3}(\xi, t).$$

In a similar way, using (5.4), (5.5), Lemma 2.2, (5.10), and (5.11), we obtain

$$\begin{aligned} 0 &= \frac{h^2}{4} \sum_{(\xi,\eta)\in\mathcal{G}_2} (-\Delta V_2 W_2)(\xi, \eta) \\ &= \frac{h}{2} \sum_{\eta\in\mathcal{G}} \left[\int_1^2 \left(\frac{\partial V_2}{\partial x} \frac{\partial W_2}{\partial x} \right)(x, \eta)\, dx + \left(\frac{\partial V_2}{\partial x} W_{\Gamma_1} \right)(1, \eta) \right. \\ &\left. + \frac{2}{3} C h^5 \sum_{k=N+1}^{2N} (V_{2,k}^{(3,0)} W_{2,k}^{(3,0)})(\eta) \right] \\ &+ \frac{h}{2} \sum_{\xi\in\tilde{\mathcal{G}}} \left[\int_0^1 \left(\frac{\partial V_2}{\partial y} \frac{\partial W_2}{\partial y} \right)(\xi, y)\, dy + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{2,k}^{(0,3)} W_{2,k}^{(0,3)})(\xi) \right] \end{aligned} \tag{5.13}$$

and

$$\begin{aligned} 0 &= \frac{h^2}{4} \sum_{(\xi,\eta)\in\mathcal{G}_3} (-\Delta V_3 W_3)(\xi, \eta) \\ &= \frac{h}{2} \sum_{\eta\in\tilde{\mathcal{G}}} \left[\int_0^1 \left(\frac{\partial V_3}{\partial x} \frac{\partial W_3}{\partial x} \right)(x, \eta)\, dx + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{3,k}^{(3,0)} W_{3,k}^{(3,0)})(\eta) \right] \\ &+ \frac{h}{2} \sum_{\xi\in\mathcal{G}} \left[\int_1^2 \left(\frac{\partial V_3}{\partial y} \frac{\partial W_3}{\partial y} \right)(\xi, y)\, dy + \left(\frac{\partial V_3}{\partial y} W_{\Gamma_2} \right)(\xi, 1) \right. \\ &\left. + \frac{2}{3} C h^5 \sum_{k=N+1}^{2N} (V_{3,k}^{(0,3)} W_{3,k}^{(0,3)})(\xi) \right]. \end{aligned} \tag{5.14}$$

Hence (5.8) and (5.12)–(5.14) give

$$\langle K(V_{\Gamma_1}, V_{\Gamma_2}), (W_{\Gamma_1}, W_{\Gamma_2}) \rangle = \sum_{i=1}^{3} I_i(V_i, W_i), \tag{5.15}$$

where

$$\begin{aligned} I_1(V_1, W_1) &= \frac{h}{2} \sum_{\eta\in\mathcal{G}} \left[\int_0^1 \left(\frac{\partial V_1}{\partial x} \frac{\partial W_1}{\partial x} \right)(x, \eta)\, dx + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{1,k}^{(3,0)} W_{1,k}^{(3,0)})(\eta) \right] \\ &+ \frac{h}{2} \sum_{\xi\in\mathcal{G}} \left[\int_0^1 \left(\frac{\partial V_1}{\partial y} \frac{\partial W_1}{\partial y} \right)(\xi, y)\, dy + \frac{2}{3} C h^5 \sum_{k=1}^{N} (V_{1,k}^{(0,3)} W_{1,k}^{(0,3)})(\xi) \right], \end{aligned} \tag{5.16}$$

$$\begin{aligned} I_2(V_2,W_2) &= \frac{h}{2}\sum_{\eta\in\mathcal{G}}\left[\int_1^2 \left(\frac{\partial V_2}{\partial x}\frac{\partial W_2}{\partial x}\right)(x,\eta)\,dx + \frac{2}{3}Ch^5\sum_{k=N+1}^{2N}(V_{2,k}^{(3,0)}W_{2,k}^{(3,0)})(\eta)\right] \\ &\quad + \frac{h}{2}\sum_{\xi\in\tilde{\mathcal{G}}}\left[\int_0^1 \left(\frac{\partial V_2}{\partial y}\frac{\partial W_2}{\partial y}\right)(\xi,y)\,dy + \frac{2}{3}Ch^5\sum_{k=1}^{N}(V_{2,k}^{(0,3)}W_{2,k}^{(0,3)})(\xi)\right], \end{aligned} \tag{5.17}$$

$$\begin{aligned} I_3(V_3,W_3) &= \frac{h}{2}\sum_{\eta\in\tilde{\mathcal{G}}}\left[\int_0^1 \left(\frac{\partial V_3}{\partial x}\frac{\partial W_3}{\partial x}\right)(x,\eta)\,dx + \frac{2}{3}Ch^5\sum_{k=1}^{N}(V_{3,k}^{(3,0)}W_{3,k}^{(3,0)})(\eta)\right] \\ &\quad + \frac{h}{2}\sum_{\xi\in\mathcal{G}}\left[\int_1^2 \left(\frac{\partial V_3}{\partial y}\frac{\partial W_3}{\partial y}\right)(\xi,y)\,dy + \frac{2}{3}Ch^5\sum_{k=N+1}^{2N}(V_{3,k}^{(0,3)}W_{3,k}^{(0,3)})(\xi)\right]. \end{aligned} \tag{5.18}$$

Equations (5.15)–(5.18) imply that K is self-adjoint.

Clearly, (5.15)–(5.18) show that $\langle K(V_{\Gamma_1},V_{\Gamma_2}),(V_{\Gamma_1},V_{\Gamma_2})\rangle \geq 0$. To prove that K is positive definite, we assume $\langle K(V_{\Gamma_1},V_{\Gamma_2}),(V_{\Gamma_1},V_{\Gamma_2})\rangle = 0$. Then (5.16) gives

$$\frac{\partial V_1}{\partial x}(t,\xi) = \frac{\partial V_1}{\partial y}(\xi,t) = 0, \qquad t\in[0,1], \qquad \xi\in\mathcal{G}.$$

Since $V_1\in X_1$,

$$V_1(0,\xi) = V_1(\xi,0) = 0, \qquad \xi\in\mathcal{G}.$$

Therefore,

$$V_1(t,\xi) = V_1(\xi,t) = 0, \qquad t\in[0,1], \qquad \xi\in\mathcal{G}.$$

Taking $t=1$ and using Lemma 2.1 and (5.3), we obtain $V_{\Gamma_1} = V_{\Gamma_2} = 0$. □

It follows from Theorem 5.1 that the PCG method is a natural choice for solving the interface problem (5.6).

5.2. Collocation preconditioner P.

In this section, we define a preconditioner P for the operator K of (5.1)–(5.2) and show that K and P are spectrally equivalent.

Let $P:[\mathcal{M}^0(0,1)]^2\to[\mathcal{M}^0(0,1)]^2$ be defined for $V_{\Gamma_i}\in\mathcal{M}^0(0,1)$, $i=1,2$, by

$$P(V_{\Gamma_1},V_{\Gamma_2}) = (W_{\Gamma_1},W_{\Gamma_2}), \tag{5.19}$$

where $W_{\Gamma_i}\in\mathcal{M}^0(0,1)$, $i=1,2$, are uniquely determined by (cf. (5.2))

$$W_{\Gamma_1}(\xi) = \frac{\partial V_1^v}{\partial x}(1,\xi) - \frac{\partial V_2}{\partial x}(1,\xi), \quad W_{\Gamma_2}(\xi) = \frac{\partial V_1^h}{\partial y}(\xi,1) - \frac{\partial V_3}{\partial y}(\xi,1), \quad \xi\in\mathcal{G}, \tag{5.20}$$

and where $V_i\in X_i$, $i=2,3$, satisfy (5.4), (5.5), while $V_1^v, V_1^h\in X_1$ satisfy

$$\Delta V_1^v(\xi) = 0, \qquad \xi\in\mathcal{G}_1, \qquad V_1^v|_{\overline{\Gamma}_1} = V_{\Gamma_1}, \qquad V_1^v|_{\overline{\Gamma}_2} = 0, \tag{5.21}$$

$$\Delta V_1^h(\xi) = 0, \qquad \xi\in\mathcal{G}_1, \qquad V_1^h|_{\overline{\Gamma}_1} = 0, \qquad V_1^h|_{\overline{\Gamma}_2} = V_{\Gamma_2}. \tag{5.22}$$

THEOREM 5.2. *The operator* $P:[\mathcal{M}^0(0,1)]^2\to[\mathcal{M}^0(0,1)]^2$ *defined by* (5.19)–(5.20) *is self-adjoint and positive definite with respect to the inner product* (5.7).

Proof. Following the proof of Theorem 5.1, and using (5.19)–(5.20), (5.7), we have

$$\begin{aligned}&\langle P(V_{\Gamma_1},V_{\Gamma_2}),(W_{\Gamma_1},W_{\Gamma_2})\rangle\\ &=\left\langle \frac{\partial V_1^v}{\partial x}(1,\cdot)-\frac{\partial V_2}{\partial x}(1,\cdot),W_{\Gamma_1}\right\rangle_{\mathcal{G}}+\left\langle \frac{\partial V_1^h}{\partial y}(\cdot,1)-\frac{\partial V_3}{\partial y}(\cdot,1),W_{\Gamma_2}\right\rangle_{\mathcal{G}},\end{aligned}\tag{5.23}$$

where $V_i \in X_i$, $i=2,3$, satisfy (5.4), (5.5) and $V_1^v, V_1^h \in X_1$ satisfy (5.21), (5.22). Let $W_i \in X_i$, $i=2,3$, satisfy (5.10), (5.11), and let $W_1^v, W_1^h \in X_1$ satisfy

$$\Delta W_1^v(\xi)=0,\quad \xi\in\mathcal{G}_1,\quad W_1^v|_{\overline{\Gamma}_1}=W_{\Gamma_1},\quad W_1^v|_{\overline{\Gamma}_2}=0,\tag{5.24}$$

$$\Delta W_1^h(\xi)=0,\quad \xi\in\mathcal{G}_1,\quad W_1^h|_{\overline{\Gamma}_1}=0,\quad W_1^h|_{\overline{\Gamma}_2}=W_{\Gamma_2}.\tag{5.25}$$

Then, using (5.21), (5.22), Lemma 2.2, (5.24), and (5.25), we obtain (cf. (5.12))

$$\begin{aligned}0&=\frac{h^2}{4}\sum_{(\xi,\eta)\in\mathcal{G}_1}(-\Delta V_1^v W_1^v)(\xi,\eta)\\ &=\frac{h}{2}\sum_{\eta\in\mathcal{G}}\left[\int_0^1\left(\frac{\partial V_1^v}{\partial x}\frac{\partial W_1^v}{\partial x}\right)(x,\eta)\,dx-\left(\frac{\partial V_1^v}{\partial x}W_{\Gamma_1}\right)(1,\eta)\right.\\ &\left.+\frac{2}{3}Ch^5\sum_{k=1}^N(V_{1,k}^{v(3,0)}W_{1,k}^{v(3,0)})(\eta)\right]\\ &+\frac{h}{2}\sum_{\xi\in\mathcal{G}}\left[\int_0^1\left(\frac{\partial V_1^v}{\partial y}\frac{\partial W_1^v}{\partial y}\right)(\xi,y)\,dy+\frac{2}{3}Ch^5\sum_{k=1}^N(V_{1,k}^{v(0,3)}W_{1,k}^{v(0,3)})(\xi)\right]\end{aligned}\tag{5.26}$$

and

$$\begin{aligned}0&=\frac{h^2}{4}\sum_{(\xi,\eta)\in\mathcal{G}_1}(-\Delta V_1^h W_1^h)(\xi,\eta)\\ &=\frac{h}{2}\sum_{\eta\in\mathcal{G}}\left[\int_0^1\left(\frac{\partial V_1^h}{\partial x}\frac{\partial W_1^h}{\partial x}\right)(x,\eta)\,dx+\frac{2}{3}Ch^5\sum_{k=1}^N(V_{1,k}^{h(3,0)}W_{1,k}^{h(3,0)})(\eta)\right]\\ &+\frac{h}{2}\sum_{\xi\in\mathcal{G}}\left[\int_0^1\left(\frac{\partial V_1^h}{\partial y}\frac{\partial W_1^h}{\partial y}\right)(\xi,y)\,dy-\left(\frac{\partial V_1^h}{\partial y}W_{\Gamma_2}\right)(\xi,1)\right.\\ &\left.+\frac{2}{3}Ch^5\sum_{k=1}^N(V_{1,k}^{h(0,3)}W_{1,k}^{h(0,3)})(\xi)\right].\end{aligned}\tag{5.27}$$

Since V_i, W_i, $i=2,3$, are the same as in the proof of Theorem 5.1, (5.13) and (5.14) hold true. Hence (5.23)–(5.27), (5.13), and (5.14) give (cf. (5.15))

$$\langle P(V_{\Gamma_1},V_{\Gamma_2}),(W_{\Gamma_1},W_{\Gamma_2})\rangle=I_1(V_1^v,W_1^v)+I_1(V_1^h,W_1^h)+\sum_{i=2}^3 I_i(V_i,W_i),\tag{5.28}$$

where I_i, $i=1,2,3$, are defined in (5.16)–(5.18), respectively. Equations (5.28) and (5.16)–(5.18) imply that P is self-adjoint and positive definite. □

THEOREM 5.3. *The operators K and P are spectrally equivalent with respect to the inner product* (5.7). *In fact, for $V_{\Gamma_1},V_{\Gamma_2}\in\mathcal{M}^0(0,1)$,*

$$\frac{1}{2}\langle P(V_{\Gamma_1},V_{\Gamma_2}),(V_{\Gamma_1},V_{\Gamma_2})\rangle\le\langle K(V_{\Gamma_1},V_{\Gamma_2}),(V_{\Gamma_1},V_{\Gamma_2})\rangle\le 2\langle P(V_{\Gamma_1},V_{\Gamma_2}),(V_{\Gamma_1},V_{\Gamma_2})\rangle.$$

Table 5.1
$\kappa(P^{-1/2}KP^{-1/2})$ *and* $\kappa(K)$.

N	4	8	16	32	64
$\kappa(P^{-1/2}KP^{-1/2})$	2.51	2.62	2.69	2.75	2.79
$\kappa(K)$	8.96	17.79	35.50	70.93	141.81

Proof. Assume $V_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$. Then it follows from (5.15) that

$$\langle K(V_{\Gamma_1}, V_{\Gamma_2}), (V_{\Gamma_1}, V_{\Gamma_2})\rangle = \sum_{i=1}^{3} I_i(V_i, V_i), \tag{5.29}$$

where $V_i \in X_i$, $i = 1, 2, 3$, satisfy (5.3)–(5.4), and I_i, $i = 1, 2, 3$, are defined in (5.16)–(5.18). In a similar way, it follows from (5.28) that

$$\langle P(V_{\Gamma_1}, V_{\Gamma_2}), (V_{\Gamma_1}, V_{\Gamma_2})\rangle = I_1(V_1^v, V_1^v) + I_1(V_1^h, V_1^h) + \sum_{i=2}^{3} I_i(V_i, V_i), \tag{5.30}$$

where $V_i \in X_i$, $i = 2, 3$, satisfy (5.4), (5.5) and $V_1^v, V_1^h \in X_1$ satisfy (5.21), (5.22).

Since V_1, V_1^v, and $V_1^h \in X_1$ satisfy (5.3), (5.21), and (5.22), respectively, we have $V_1 = V_1^v + V_1^h$, which, by (5.16) and the inequality $(\alpha + \beta)^2 \leq 2(\alpha^2 + \beta^2), \alpha, \beta \in R$, gives

$$I_1(V_1, V_1) \leq 2[I_1(V_1^v, V_1^v) + I_1(V_1^h, V_1^h)]. \tag{5.31}$$

Hence (5.29), (5.30), and (5.31) imply that $K \leq 2P$.

Since $V_2 \in X_2$ and $V_1^v \in X_1$ satisfy (5.4) and (5.21), respectively, we have $V_1^v(x, y) = V_2(2 - x, y)$, $x, y \in [0, 1]$, which, by (5.16), (5.17), and the symmetry of $\mathcal{G}$ and $\tilde{\mathcal{G}}$ about 1, gives

$$I_1(V_1^v, V_1^v) = I_2(V_2, V_2). \tag{5.32}$$

In a similar way, for $V_3 \in X_3$ and $V_1^h \in X_1$ satisfying, respectively, (5.5) and (5.22), we have $V_1^h(x, y) = V_3(x, 2 - y)$, $x, y \in [0, 1]$, which, by (5.16), (5.18), and the symmetry of $\mathcal{G}$ and $\tilde{\mathcal{G}}$ about 1, gives

$$I_1(V_1^h, V_1^h) = I_3(V_3, V_3). \tag{5.33}$$

Hence (5.30), (5.32), (5.33), and (5.29) imply that $P \leq 2K$. □

With the preconditioner P, the convergence rate of the PCG method applied to (5.6) depends on $\kappa(P^{-1/2}KP^{-1/2})$, where, for a self-adjoint and positive definite operator A, $\kappa(A) = \lambda_{max}(A)/\lambda_{min}(A)$. Since $P^{-1/2}KP^{-1/2}$ and $P^{-1}K$ have the same eigenvalues,

$$\kappa(P^{-1/2}KP^{-1/2}) = \lambda_{max}(P^{-1}K)/\lambda_{min}(P^{-1}K).$$

This formula was used to compute $\kappa(P^{-1/2}KP^{-1/2})$ numerically for several values of N. The results in Table 5.1 confirm the theoretical result $\kappa(P^{-1/2}KP^{-1/2}) \leq 4$ of Theorem 5.3 and also indicate that $\kappa(K) = O(N)$.

5.3. Solving with P and multiplying by K. In this section, we discuss the cost of solving an operator equation with the preconditioner P and the cost of multiplying by the operator K. Throughout this section, ψ_n, γ_n, $n = 1, \dots, 2N$, are as in Lemma 2.6, and v_n, $n = 1, \dots, 2N$, are as in Lemma 2.7.

It follows from the definition (5.19)–(5.20) of the operator P that, given $W_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$, solving

$$P(V_{\Gamma_1}, V_{\Gamma_2}) = (W_{\Gamma_1}, W_{\Gamma_2})$$

for $V_{\Gamma_i} \in \mathcal{M}^0(0,1)$, $i = 1, 2$, is equivalent to solving two independent problems. The first problem consists in finding $V_{\Gamma_1} \in \mathcal{M}^0(0,1)$ such that

$$\frac{\partial V_1^v}{\partial x}(1,\xi) - \frac{\partial V_2}{\partial x}(1,\xi) = W_{\Gamma_1}(\xi), \qquad \xi \in \mathcal{G}, \tag{5.34}$$

where $V_1^v \in X_1$ satisfies (5.21) and $V_2 \in X_2$ satisfies (5.4). The second problem consists in finding $V_{\Gamma_2} \in \mathcal{M}^0(0,1)$ such that

$$\frac{\partial V_1^h}{\partial y}(\xi,1) - \frac{\partial V_3}{\partial y}(\xi,1) = W_{\Gamma_2}(\xi), \qquad \xi \in \mathcal{G},$$

where $V_1^h \in X_1$ satisfies (5.22) and $V_3 \in X_3$ satisfies (5.5). We explain how to solve (5.34) using separation of variables; the second problem can be solved in a similar way.

Using Lemmas 2.6 and 2.7, it is easy to show that V_1^v defined by

$$V_1^v(x,y) = \sum_{n=1}^{2N} \alpha_n v_n(x) \psi_n(y), \qquad x, y \in [0,1],$$

where the α_n are arbitrary constants, belongs to X_1 and satisfies $\Delta V_1^v(\xi) = 0$, $\xi \in \mathcal{G}_1$, and $V_1^v|_{\overline{\Gamma}_2} = 0$. Also, it is easy to verify that V_2 defined by

$$V_2(x,y) = V_1^v(2-x,y), \qquad x \in [1,2], \qquad y \in [0,1],$$

belongs to X_2 and satisfies $\Delta V_2(\xi) = 0$, $\xi \in \mathcal{G}_2$. Moreover, V_{Γ_1} defined by

$$V_{\Gamma_1}(y) = V_1^v(1,y) = V_2(1,y) = \sum_{n=1}^{2N} \alpha_n \psi_n(y), \qquad y \in [0,1],$$

belongs to $\mathcal{M}^0(0,1)$. Since $W_{\Gamma_1} \in \mathcal{M}^0(0,1)$, we have

$$W_{\Gamma_1}(y) = \sum_{n=1}^{2N} \beta_n \psi_n(y), \qquad y \in [0,1].$$

Therefore, (5.34) becomes

$$\sum_{n=1}^{2N} 2\alpha_n v_n'(1) \psi_n(\xi) = \sum_{n=1}^{2N} \beta_n \psi_n(\xi), \qquad \xi \in \mathcal{G},$$

which gives

$$\alpha_n = \frac{\beta_n}{2v_n'(1)}, \qquad n = 1, \dots, 2N,$$

where $v_n'(1)$ is as referred to in Lemma 2.7. If we introduce

$$\vec{\alpha} = [\alpha_1, \dots, \alpha_{2N}]^T, \qquad \vec{\beta} = [\beta_1, \dots, \beta_{2N}]^T,$$

then Lemma 2.8 yields

$$\vec{\beta} = Z^T B^T [W_{\Gamma_1}(\xi_1), \dots, W_{\Gamma_1}(\xi_{2N})]^T, \qquad [V_{\Gamma_1}(\xi_1), \dots, V_{\Gamma_1}(\xi_{2N})]^T = BZ\vec{\alpha}.$$

Thus, given $W_{\Gamma_1}(\xi)$, $\xi \in \mathcal{G}$, Remark 2.1 implies that $V_{\Gamma_1}(\xi)$, $\xi \in \mathcal{G}$, can be computed at a cost $O(N \log N)$.

If follows from the definition (5.1)–(5.2) of the operator K that, given $V_{\Gamma_1}, V_{\Gamma_2} \in \mathcal{M}^0(0,1)$, the computation of

$$(W_{\Gamma_1}, W_{\Gamma_2}) = K(V_{\Gamma_1}, V_{\Gamma_2}), \qquad W_{\Gamma_1}, W_{\Gamma_2} \in \mathcal{M}^0(0,1),$$

involves solving collocation problems (5.3)–(5.5). Let $V_1, V_1^v, V_1^h \in X_1$ be, respectively, solutions of (5.3), (5.21), (5.22). Then $V_1 = V_1^v + V_1^h$. Moreover, if $V_2 \in X_2$ and $V_3 \in X_3$ are solutions of (5.4) and (5.5), respectively, then, by the symmetry of $\mathcal{G}$ and $\tilde{\mathcal{G}}$ about 1, we have $V_2(x,y) = V_1^v(2-x, y)$, $x \in [1,2]$, $y \in [0,1]$, and $V_3(x,y) = V_1^h(x, 2-y)$, $x \in [0,1]$, $y \in [1,2]$. Hence, it follows from (5.2) that

$$W_{\Gamma_1}(\xi) = 2\frac{\partial V_1^v}{\partial x}(1,\xi) + \frac{\partial V_1^h}{\partial x}(1,\xi), \qquad W_{\Gamma_2}(\xi) = \frac{\partial V_1^v}{\partial y}(\xi,1) + 2\frac{\partial V_1^h}{\partial y}(\xi,1), \qquad \xi \in \mathcal{G}.$$

We explain how to compute $\frac{\partial V_1^v}{\partial x}(1,\xi)$, $\frac{\partial V_1^v}{\partial y}(\xi,1), \xi \in \mathcal{G}$; $\frac{\partial V_1^h}{\partial x}(1,\xi)$, $\frac{\partial V_1^h}{\partial y}(\xi,1)$, $\xi \in \mathcal{G}$, can be computed in a similar way. Since $V_{\Gamma_1} \in \mathcal{M}^0(0,1)$, we have

$$V_{\Gamma_1}(y) = \sum_{n=1}^{2N} \alpha_n \psi_n(y).$$

Lemmas 2.6 and 2.7 imply that

$$V_1^v(x,y) = \sum_{n=1}^{2N} \alpha_n v_n(x) \psi_n(y) \tag{5.35}$$

is a solution of (5.21). Hence

$$\frac{\partial V_1^v}{\partial x}(1,y) = \sum_{n=1}^{2N} \alpha_n v_n'(1) \psi_n(y),$$

where $v_n'(1)$ is referred to in Lemma 2.7. If we introduce

$$\vec{\alpha} = [\alpha_1, \dots, \alpha_{2N}]^T, \qquad \vec{\beta} = [\alpha_1 v_1'(1), \dots, \alpha_{2N} v_{2N}'(1)]^T,$$

then Lemma 2.8 yields

$$\vec{\alpha} = Z^T B^T [V_{\Gamma_1}(\xi_1), \dots, V_{\Gamma_1}(\xi_{2N})]^T, \qquad \left[\frac{\partial V_1^v}{\partial x}(1,\xi_1), \dots, \frac{\partial V_1^v}{\partial x}(1,\xi_{2N})\right]^T = BZ\vec{\beta}.$$

Thus, given $V_{\Gamma_1}(\xi)$, $\xi \in \mathcal{G}$, Remark 2.1 implies that $\frac{\partial V_1^v}{\partial x}(1,\xi)$, $\xi \in \mathcal{G}$, can be computed at a cost $O(N \log N)$. On the other hand, (5.35) gives

$$\frac{\partial V_1^v}{\partial y}(\xi,1) = \sum_{n=1}^{2N} \alpha_n v_n(\xi) \psi_n'(1), \qquad \xi \in \mathcal{G}.$$

Since explicit formulas for $v_n(\xi)$, $\xi \in \mathcal{G}$, and $\psi_n'(1)$, $n = 1, \ldots, 2N$, are known, $\frac{\partial V_1^v}{\partial y}(\xi, 1)$, $\xi \in \mathcal{G}$, can be computed at a cost $O(N^2)$ by multiplying the vector $[\alpha_1 \psi_1'(1), \ldots, \alpha_{2N} \psi_{2N}'(1)]^T$ by the matrix $C = (c_{k,n})_{k,n=1}^{2N}$, where $c_{k,n} = v_n(\xi_k)$.

6. Total cost of solving OSC problem. In this section, we give the total cost of solving OSC problem (3.3)–(3.4) using algorithm (4.13).

Step 1 of algorithm (4.13) involves computing $\frac{\partial \hat{U}_1}{\partial x}(1, \xi)$, $\frac{\partial \hat{U}_1}{\partial y}(\xi, 1)$, $\frac{\partial \hat{U}_2}{\partial x}(1, \xi)$, $\frac{\partial \hat{U}_3}{\partial y}(\xi, 1)$, $\xi \in \mathcal{G}$, where $\hat{U}_i \in \mathcal{M}_i$, $i = 1, 2, 3$, satisfies (4.5)–(4.7). Since only $\frac{\partial \hat{U}_1}{\partial x}(1, \xi)$, $\frac{\partial \hat{U}_1}{\partial y}(\xi, 1)$, $\xi \in \mathcal{G}$, are required when solving (4.5) with $i = 1$ and (4.6)–(4.7) for $\hat{U}_1$, these values can be obtained by applying steps 1 and 2 and only a part of step 3 of Algorithm II of section 3.3 in [7]. The costs of steps 1 and 2 of this algorithm are $O(N^2 \log N)$ and $O(N^2)$, respectively, and the cost of the part of step 3 is $O(N^2)$. When performing these calculations, we save the results obtained in step 2 of Algorithm II of [7] when solving partially for $\hat{U}_1$. In a similar way, we compute $\frac{\partial \hat{U}_2}{\partial x}(1, \xi)$, $\frac{\partial \hat{U}_3}{\partial y}(\xi, 1)$, $\xi \in \mathcal{G}$.

Step 2 of algorithm (4.13) is carried out using the PCG method with P as a preconditioner for K. It follows from section 5.3 that the cost of this step is $O(mN^2)$, where m is the number of PCG iterations.

In step 3 of algorithm (4.13), we have to compute $U_i \in \mathcal{M}_i$, $i = 1, 2, 3$, satisfying (3.3) and (4.1)–(4.4). It follows from (4.8) that $U_1 = \hat{U}_1 + \tilde{U}_1$, where $\hat{U}_1 \in \mathcal{M}_1$ is a solution of (4.5) with $i = 1$ and (4.6)–(4.7), and $\tilde{U}_1 \in X_1$ is a solution of (4.9). First, we apply steps 1 and 2 of Algorithm II of [7] when solving (4.9) for $\tilde{U}_1$. Because of the zero right-hand side in the first equation of (4.9), the cost of step 1 in this algorithm becomes $O(N^2)$, while the cost of step 2 remains $O(N^2)$. Next, we add the results obtained in step 2 of Algorithm II of [7] when solving for $\hat{U}_1$ and $\tilde{U}_1$. Finally, we perform, at a cost $O(N^2 \log N)$, step 3 of Algorithm II of [7] to obtain U_1. In a similar way, we compute U_2 and U_3.

It follows from the discussion in this section that the total cost of algorithm (4.13) for solving the OSC problem is $O(N^2 \log N) + O(mN^2)$, where m is the number of PCG iterations in the solution of the interface problem. With m proportional to $\log N$, the total cost becomes $O(N^2 \log N)$.

7. Numerical results. We used the method of this paper to solve (1.1) with f corresponding to the exact solution

$$u(x, y) = e^{x+y}.$$

The algorithm was run in double precision on a Gateway PC E-2000 400. The initial guess in the PCG method (for the solution of the interface problem) was 0, and the number of PCG iterations was set to $\log_2 N + 4$. Convergence rates in various norms were determined using the formula

$$\text{rate } = \frac{\log(e_{N/2}/e_N)}{\log 2},$$

where e_N is the error corresponding to the $N \times N$ partition of Ω_1.

In Table 7.1, we present errors and the corresponding convergence rates for U_1 using Sobolev norms. As expected, the convergence rates for the L^2-, H^1-, and H^2-norms are 4, 3, and 2, respectively.

Table 7.1
Sobolev norm errors and convergence rates.

	$\|u-U_1\|_{L^2(\Omega_1)}$		$\|u-U_1\|_{H^1(\Omega_1)}$		$\|u-U_1\|_{H^2(\Omega_1)}$

64	1.51–10	4.001	3.33–09	3.601	3.34–09	3.596	1.07–06	2.638

Table 7.3
CPU times for the OSC method.

N	64	128	256	512
CPU time	0.49	1.99	8.29	33.91

In Table 7.2, we give errors and the corresponding convergence rates for U_1 using the maximum nodal norm defined by

$$\|w\|_{C_h} = \max_{0\le k,l\le N} |w(t_k,t_l)|.$$

The convergence rate for $\|u-U_1\|_{C_h}$ is 4, while the convergence rates for $\|(u-U_1)_x\|_{C_h}$ and $\|(u-U_1)_y\|_{C_h}$ appear to be between 3.5 and 4. It was shown in [3] that the piecewise Hermite bicubic OSC solution U of Poisson's equation on Ω_1, with the nonzero Dirichlet boundary conditions approximated by the piecewise Hermite cubic interpolant, possesses superconvergence phenomena; that is, the convergence rates for $\|(u-U)_x\|_{C_h}$ and $\|(u-U)_y\|_{C_h}$ are 4. Numerical results, identical to those in Tables 7.1 and 7.2, were also obtained by first forming the symmetric positive definite matrix corresponding to the operator K and then solving the resulting linear system using Cholesky's method. Hence the presented convergence rates for $\|(u-U_1)_x\|_{C_h}$ and $\|(u-U_1)_y\|_{C_h}$ are due to the proposed OSC scheme for an L-shaped region and not an insufficient number of PCG iterations.

Finally, in Table 7.3, we give the CPU times for our OSC domain decomposition method. Clearly, as N increases by a factor of 2, the CPU time increases approximately by a factor of 4. This observation supports the theoretical result that the total cost of our algorithm is $O(N^2 \log N)$.

8. Concluding remarks.

We used a nonoverlapping domain decomposition approach to define the OSC solution of the Dirichlet boundary value problem for Poisson's equation on an L-shaped region. We proved existence and uniqueness of the collocation solution and derived optimal order H^s-norm error bounds for $s = 0, 1, 2$. The collocation solution on the interfaces is computed using the PCG method with a preconditioner obtained from two collocation Steklov–Poincaré operators corresponding to two pairs of the adjacent squares. The collocation solution on each square is obtained using the FFT matrix decomposition method. The total cost of computing the collocation solution is $O(N^2 \log N)$, where the number of unknowns in the collocation solution is $O(N^2)$.

COMPUTING ACOUSTIC WAVES IN AN INHOMOGENEOUS MEDIUM OF THE PLANE BY A COUPLING OF SPECTRAL AND FINITE ELEMENTS[*]

SALIM MEDDAHI[†], ANTONIO MÁRQUEZ[‡], AND VIRGINIA SELGAS[†]

Abstract. In this paper we analyze a Galerkin procedure, based on a combination of finite and spectral elements, for approximating a time-harmonic acoustic wave scattered by a bounded inhomogeneity. The finite element method used to approximate the near field in the region of inhomogeneity is coupled with a nonlocal boundary condition, which consists in a linear integral equation. This integral equation is discretized by a spectral Galerkin approximation method.

We provide error estimates for the Galerkin method, propose fully discrete schemes based on elementary quadrature formulas, and show that the perturbation due to this numerical integration gives rise to a quasi-optimal rate of convergence. We also suggest a method for implementing the algorithm using the preconditioned GMRES method and provide some numerical results.

1. Introduction.

The purpose of this paper is to introduce a new fully discrete method for a boundary element and finite element coupling strategy applied to an acoustic scattering problem in the plane. The difficulty related to the fact that the acoustic field extends over the whole space has been tackled in the literature by different strategies. For example, the problem may be posed in a bounded domain by reducing it to the Lippman–Schwinger integral equation (cf. [11]). However, the computational cost associated to the discretization of such an equation can be excessive: it requires numerical integration for singular volume integrals, and it leads to linear systems of equations with nonsparse matrices (cf. [10]).

The approaches based on a finite element approximation method require *absorbing boundary conditions* prescribed on an artificial boundary Γ enclosing the region of inhomogeneity. These boundary conditions that incorporate (approximately) the far-field effects into the finite element model may be of local (differential) or global type.

Most of the differential absorbing boundary conditions use a circle (or a sphere) as an artificial boundary, and they are more exact the larger the radius of the circle is (cf. [7, 2]). This can lead to a large nondimensional wave number in a scaled model and renders the numerical solution more difficult to compute. It is also worth mentioning here the *perfectly matched layer method* introduced recently by Bérenger [3].

Choosing a circle as an artificial boundary, one may also compute a series representation of the exterior solution by separation of variables and obtain on the way global absorbing boundary conditions (cf. [6, 13, 14]). However, when the region of

inhomogeneity is anisotropic, one may again be obliged to compute the numerical solution in a large domain. For more information about the previous methods we refer to the survey of Ihlenburg [8] and the references given therein.

We consider in this paper a nonlocal absorbing boundary condition based on boundary integral operators defined on Γ. It is a discretization procedure that combines finite elements (FEM) and boundary elements (BEM). In fact, we use the well-known Johnson–Nedelec BEM–FEM formulation introduced in [9] for an exterior Poisson problem and also used successfully for the Stokes system (cf. [18, 19]). We point out here that, in the Johnson–Nedelec method, the boundary integral equation coupled with the finite element problem must be posed on a smooth artificial interface in order to ensure the compactness of the double-layer potential. This is essential in the analysis of the discrete problem (see [9, 15] and the analysis given in section 5 of this paper).

Usually, the discrete problem is posed on a domain with a piecewise polynomial boundary that approximates the smooth artificial boundary in order to use isoparametric finite elements (cf. [9]). This strategy has a serious drawback since it renders difficult the approximation of the nearly singular boundary integrals by simple quadratures. Recently, a more efficient method that discretizes the integral operators on their natural boundary has been proposed. It permits one to design fully discrete schemes that require few kernel evaluations while preserving the stability and convergence properties obtained when the integrals are computed exactly (cf. [15, 16, 18]). This discretization method relies on exact triangulations of the domain. Hence curved triangles are needed all along the auxiliary interface.

Furthermore, these new BEM–FEM formulations permit one to approximate the periodic representation of the unknown defined on the boundary by trigonometric polynomials (cf. [17]). We apply here this mixed scheme that combines a finite element method and a spectral method to solve an acoustic scattering problem. Our analysis shows that stability and convergence are obtained for the Johnson–Nedelec method without any constraint involving the mesh size h for the interior finite elements and the dimension $2n$ of the space of trigonometric polynomials used for the approximation on the boundary. We also introduce a fully discrete scheme that requires elementary quadrature rules and converges at a quasi-optimal rate.

We notice that, as we have a spectral convergence for the variable defined on the boundary, few degrees of freedom are needed on the interface boundary in order to attain the order of convergence imposed by the finite element method. This permits us to eliminate the periodic unknown at matricial level by a static condensation process and reduce the complexity of the linear systems. The preconditioned GMRES method is used to solve the reduced linear systems of equations. The iterative method requires solving a short sequence of standard interior elliptic finite element problems. Furthermore, we do not need to store the unstructured and nonsymmetric global matrix, and the problems we have to solve during each iteration process are standard. We see from the numerical experiments that the method seems to be stable in the sense that the number of iterations does not increase with the finite element degrees of freedom.

We point out that our discretization method combines standard techniques of approximation since the schemes obtained here for the integral equation are directly derived from those described in [12, 5]; see also the references given therein. Nevertheless, to our knowledge, the only work where a coupling of finite elements and spectral methods is exploited to solve exterior Helmholtz problems is given by Kirsch and Monk in [20]. Their method relies on a Lagrange multiplier approach that is conceptually more complicated than the one we propose here, and they do not include the effects of numerical integration in their analysis. We also point out that Kirsch and Monk use a Nyström method for the unknown boundary, while we use a spectral Galerkin method. Our choice simplifies the analysis but, from the point of view of implementation, the computational work associated to a Nyström scheme is less than the computational work corresponding to a Galerkin method. We overcome this disadvantage by providing a fully discrete Galerkin method that may be interpreted in practice as a collocation method.

The paper is organized as follows. In the first part, which consists of sections 2, 3, and 4, we introduce the model problem, derive the Galerkin discretization of the Johnson–Nedelec method, and give its convergence analysis. In section 5, we describe the quadrature rules that we use to obtain the fully discrete schemes, and section 6 is devoted to the convergence analysis of these completely discrete problems. Finally, we present our numerical results in section 7.

1.1. Notation and Sobolev spaces.

In what follows, we deal with complex valued functions, and the symbol $\imath$ is used for $\sqrt{-1}$. We denote by $\overline{\alpha}$ the conjugate of a complex number $\alpha \in \mathbb{C}$ and by $|\alpha|$ its modulus. Let Ω be a bounded open set of $\mathbb{R}^2$. We denote by $\|\cdot\|_{0,\Omega}$ the $L^2(\Omega)$-norm corresponding to the inner product $\int_\Omega f\overline{g}\, d\boldsymbol{x}$. More generally, for any $m \in \mathbb{N}$, $\|\cdot\|_{m,\Omega}$ stands for the norm of the Sobolev space $H^m(\Omega)$; see [1].

On the other hand, we will also consider periodic Sobolev spaces. Let $\mathcal{C}^\infty_{2\pi}$ be the space of 2π-periodic and infinitely differentiable complex valued functions of a single variable. Given $g \in \mathcal{C}^\infty_{2\pi}$, we define its Fourier coefficients as

$$\widehat{g}(k) := \frac{1}{2\pi}\int_0^{2\pi} g(s)e^{-\imath ks}\, ds.$$

Then, for $p \in \mathbb{R}$, we define the Sobolev space $H^p(0, 2\pi)$ to be the completion of $\mathcal{C}^\infty_{2\pi}$ with the norm

$$\|g\|_p := \left(\sum_{k\in\mathbb{Z}}(1+|k|^2)^p|\widehat{g}(k)|^2\right)^{1/2}.$$

It is well known that $H^p(0, 2\pi)$ are Hilbert spaces and $H^p(0, 2\pi) \subset H^q(0, 2\pi)$ for every $p > q$, the inclusion being dense and compact; see [12]. Moreover, the $L^2(0,\ 2\pi)$-inner product $\int_0^{2\pi} \lambda(s)\overline{\eta}(s)\, ds$ can be extended to represent the duality of $H^{-p}(0, 2\pi)$ and $H^p(0, 2\pi)$ for all p.

Throughout this paper, C will denote positive constants, not necessarily the same at different occurrences, which are independent of the parameters h and n.

2. The model problem.

Let $\theta \in \mathcal{C}^2(\mathbb{R}^2)$ be a given function that satisfies $\operatorname{Re}\theta(\boldsymbol{x}) > 0$ and $\operatorname{Im}\theta(\boldsymbol{x}) \geq 0$ for all $\boldsymbol{x} \in \mathbb{R}^2$. We also assume that the function $1-\theta(\boldsymbol{x})$ has a compact support in $\mathbb{R}^2$. Let $k > 0$ be given together with a function w that satisfies the Helmholtz equation $\Delta w + k^2 w = 0$ in all $\mathbb{R}^2$. We seek the $u : \mathbb{R}^2 \to \mathbb{C}$ solution of

$$\begin{aligned} \Delta u + k^2\theta(\boldsymbol{x})\, u &= 0 && \text{in } \mathbb{R}^2, \\ u &= w + u^s && \text{in } \mathbb{R}^2 \end{aligned} \tag{2.1}$$

that satisfies the outgoing Sommerfeld radiation condition

$$\frac{\partial u^s}{\partial r} - \imath k u^s = o\left(\frac{1}{\sqrt{r}}\right), \tag{2.2}$$

when $r := |\boldsymbol{x}| \to \infty$ uniformly for all directions $\boldsymbol{x}/|\boldsymbol{x}|$.

The system (2.1)–(2.2) governs the propagation of time-harmonic acoustic waves of small amplitude in a slowly varying inhomogeneous and absorbing medium. The wave motion is caused by a time-harmonic incident field of amplitude w. A common choice for w is the plane wave $w(\boldsymbol{x}) := \exp(\imath k \boldsymbol{d} \cdot \boldsymbol{x})$, where $\boldsymbol{d}$ is a fixed unit vector. The solution u of our problem is determined by the scattered field u^s that satisfies the Sommerfeld radiation condition (2.2). We refer to [5] and [11] for more information about the physical background of the problem.

Let us introduce an artificial boundary Γ such that the support of $1-\theta$ lays in its interior. Then Γ separates $\mathbb{R}^2$ into a bounded domain Ω and an unbounded region Ω_e exterior to Γ.

We introduce the bilinear form

$$a^k(z,v) := \int_\Omega \nabla z \cdot \nabla v \, d\boldsymbol{x} - k^2 \int_\Omega \theta(\boldsymbol{x}) z v \, d\boldsymbol{x} \quad \forall z, v \in H^1(\Omega).$$

It is straightforward that u satisfies in Ω the following variational formulation:

$$\begin{aligned} &\text{find } u \in H^1(\Omega) \text{ such that} \\ &a^k(u,v) - \textstyle\int_\Gamma \frac{\partial u}{\partial \boldsymbol{\nu}} v \, d\sigma = 0 \quad \forall v \in H^1(\Omega), \end{aligned} \tag{2.3}$$

where the unit normal $\boldsymbol{\nu}$ on Γ is directed into Ω_e.

On the other hand, using a Green formula, the radiation condition (2.2), and the fact that $\Delta u^s + k^2 u^s = 0$ in Ω_e, one arrives at the integral representation

$$u^s(\boldsymbol{x}) = \int_\Gamma \frac{\partial E(\boldsymbol{x},\boldsymbol{y})}{\partial \boldsymbol{\nu}_y} u^s(\boldsymbol{y}) \, d\sigma_y - \int_\Gamma E(\boldsymbol{x},\boldsymbol{y}) \frac{\partial u^s}{\partial \boldsymbol{\nu}} \, d\sigma_y \quad \forall \boldsymbol{x} \in \Omega_e, \tag{2.4}$$

where

$$E(\boldsymbol{x},\boldsymbol{y}) := \frac{\imath}{4} H_0^{(1)}(k|\boldsymbol{x}-\boldsymbol{y}|)$$

is the radial outgoing fundamental solution of the Helmholtz equation and $H_0^{(1)}$ stands for the Hankel function of order 0 and first type. The Johnson–Nedelec BEM–FEM method introduced in [9] uses a boundary integral identity relating on Γ the trace of u^s and its normal derivative $\frac{\partial u^s}{\partial \boldsymbol{\nu}}$. This boundary integral equation arises from the integral representation formula (2.4) and the classical jump conditions for the double-layer potential. Our purpose is to perform the coupling of this boundary equation with (2.3), but let us first introduce some notation and basic properties.

In what follows, we choose Γ to be an infinitely differentiable boundary, and we denote by $\boldsymbol{x} : \mathbb{R} \to \mathbb{R}^2$ a regular 2π-periodic parametric representation of this curve:

$$|\boldsymbol{x}'(s)| > 0 \quad \forall s \in \mathbb{R} \quad \text{and} \quad \boldsymbol{x}(s) = \boldsymbol{x}(t) \quad \text{iff} \quad t - s \in 2\pi\mathbb{Z}.$$

Therefore, we can identify any function defined on Γ with a 2π-periodic function. We can also define the parameterized trace on Γ as the linear continuous extension of

$$\begin{aligned} \gamma : \mathcal{C}^\infty(\overline{\Omega}) &\to L^2(0,\, 2\pi), \\ u &\mapsto \gamma u(\cdot) := u|_\Gamma(\boldsymbol{x}(\cdot)) \end{aligned}$$

to $H^1(\Omega)$. The resulting linear application $\gamma : H^1(\Omega) \to H^{1/2}(0, 2\pi)$ is bounded and onto (cf. Theorem 8.15 of [12]).

We introduce the parameterized versions of the simple and double-layer acoustic potentials

$$\mathcal{S}g(s) := \int_0^{2\pi} V(s,t)g(t)dt \qquad \text{and} \qquad \mathcal{D}g(s) := \int_0^{2\pi} K(s,t)g(t)dt,$$

where

$$V(s,t) := \frac{\imath}{4} H_0^{(1)}(k|\boldsymbol{x}(s) - \boldsymbol{x}(t)|)$$

and

$$K(s,t) := -\frac{k\imath}{4} H_1^{(1)}(k|\boldsymbol{x}(t) - \boldsymbol{x}(s)|) \frac{x_2'(t)(x_1(t) - x_1(s)) - x_1'(t)(x_2(t) - x_2(s))}{|\boldsymbol{x}(t) - \boldsymbol{x}(s)|}$$

with $H_1^{(1)}$ being the Hankel function of first type and order one.

Parameterizing the integral identity relating u^s and $\frac{\partial u^s}{\partial \boldsymbol{\nu}}$ on Γ yields (a similar strategy is used in [15, 18])

$$\gamma u^s = \left(\frac{1}{2}\mathcal{I} + \mathcal{D}\right) \gamma u^s - \mathcal{S}\xi, \tag{2.5}$$

where $\mathcal{I}$ is the identity operator and the auxiliary unknown ξ is given in terms of the normal derivative of u^s on Γ by

$$\xi := |\boldsymbol{x}'| \, \frac{\partial u^s}{\partial \boldsymbol{\nu}} \circ \boldsymbol{x}.$$

Combining (2.3) with a variational version of (2.5), we arrive at the following global weak formulation of (2.1)–(2.2):

$$\begin{aligned} &\text{find } u \in H^1(\Omega) \text{ and } \xi \in H^{-1/2}(0, 2\pi) \text{ such that} \\ &a^k(u, v) - \int_0^{2\pi} \xi(t)\gamma v(t)\, dt = \int_0^{2\pi} \lambda(t)\gamma v(t)\, dt \quad \forall v \in H^1(\Omega), \\ &\qquad b(u, \mu) + c(\xi, \mu) = b(w, \mu) \qquad\qquad \forall \mu \in H^{-1/2}(0, 2\pi), \end{aligned} \tag{2.6}$$

where $\lambda := |\boldsymbol{x}'| \, \frac{\partial w}{\partial \boldsymbol{\nu}} \circ \boldsymbol{x}$,

$$c(\xi, \mu) := \int_0^{2\pi} \mu(t)(\mathcal{S}\xi)(t)\, dt, \qquad \text{and} \qquad b(v, \mu) := \int_0^{2\pi} \mu(t) \left(\frac{1}{2}\mathcal{I} - \mathcal{D}\right) (\gamma v)(t)\, dt.$$

Moreover, defining the Hilbert space $\mathbf{M} := H^1(\Omega) \times H^{-1/2}(0, 2\pi)$ and denoting $\mathbf{u} := (u, \xi)$, $\mathbf{v} := (v, \mu) \in \mathbf{M}$, we may formulate (2.6) equivalently by

$$\begin{aligned} &\text{find } \mathbf{u} \in \mathbf{M} \text{ such that} \\ &A(\mathbf{u}, \mathbf{v}) = L(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{M}, \end{aligned} \tag{2.7}$$

where $L(\mathbf{v}) = \int_0^{2\pi} \lambda(t)\gamma v(t)\, dt + 2b(w, \mu)$ and

$$A(\mathbf{u}, \mathbf{v}) = a^k(u, v) + 2c(\xi, \mu) + 2b(u, \mu) - \int_0^{2\pi} \xi(t)\gamma v(t)\, dt.$$

3. Existence and uniqueness. We will first give a brief account of some fundamental tools that concern the properties of $\mathcal{S}$ and $\mathcal{D}$ when mapping between Sobolev spaces. For $n = 0, 1, 2$ we introduce the auxiliary integral operators

$$\Lambda_n(\xi)(t) := \frac{-1}{2\pi}\int_0^{2\pi}\left(\sin\frac{t-s}{2}\right)^n \log\left(\frac{4}{e}\sin^2\frac{t-s}{2}\right)\xi(s)\,ds.$$

Lemma 3.1. *For any $p \in \mathbb{R}$ the mappings $\Lambda_0 : H^p(0,2\pi) \to H^{p+1}(0,2\pi)$, $\mathcal{S} : H^p(0,2\pi) \to H^{p+1}(0,2\pi)$, $\mathcal{D} : H^p(0,2\pi) \to H^{p+2}(0,2\pi)$, and $\mathcal{S}-\Lambda_0 : H^p(0,2\pi) \to H^{p+3}(0,2\pi)$ are bounded. Furthermore, Λ_0 is $H^{-1/2}(0,2\pi)$-elliptic; i.e., there exists $\alpha > 0$ such that*

$$\int_0^{2\pi}\overline{\xi}(t)(\Lambda_0\xi)(t)\,dt \geq \alpha\|\xi\|^2_{-1/2} \quad \forall\xi \in H^{-1/2}(0,2\pi). \tag{3.1}$$

Proof. Let $f_m(t) := \exp(\imath mt)$. One may deduce easily from the property (see [12])

$$\Lambda_0 f_m = \frac{1}{\max(1,|m|)} f_m \qquad \forall m \in \mathbb{Z} \tag{3.2}$$

that Λ_0 is a pseudodifferential operator of order -1 and that it satisfies (3.1).

In general, given a function $D(t,s)$ which is in $\mathcal{C}^\infty_{2\pi}$ with respect to each variable, it is shown in [21] that $\mu \mapsto \Lambda_n(D(t,\cdot)\mu(\cdot))$ is a pseudodifferential operator of order $-n-1$. Therefore, the results for $\mathcal{S}$, $\mathcal{D}$, and $\mathcal{S}-\Lambda_0$ are obtained by noticing that there exist two functions D_1 and D_2 that belong to $\mathcal{C}^\infty_{2\pi}$ in each of their two variables such that

$$(\mathcal{S}\mu)(t) = (\Lambda_0\mu)(t) + \Lambda_2(D_1(t,\cdot)\mu(\cdot)) + (\mathcal{F}\mu)(t)$$

and

$$(\mathcal{D}\mu)(t) = \Lambda_1(D_2(t,\cdot)\mu(\cdot))(t) + (\mathcal{G}\mu)(t),$$

where $\mathcal{F}$ and $\mathcal{G}$ are integral operators with 2π-periodic and infinitely differentiable kernels. □

Theorem 3.2. *Assume that k^2 is not an eigenvalue of the Laplacian in Ω with a Dirichlet boundary condition on Γ. Then problem* (2.7) *has a unique solution.*

Proof. We introduce the bilinear form

$$A_0(\mathbf{u},\mathbf{v}) := a(u,v) + 2\int_0^{2\pi}\mu(t)(\Lambda_0\xi)(t)\,dt - \int_0^{2\pi}\gamma v(t)\,\xi(t)\,dt + \int_0^{2\pi}\gamma u(t)\,\mu(t)\,dt,$$

where $a(u,v) := \int_\Omega \nabla u \cdot \nabla v\,d\boldsymbol{x} + \int_\Omega uv\,d\boldsymbol{x}$. We deduce from Lemma 3.1 that $A_0(\cdot,\cdot)$ is bounded on $\mathbf{M}\times\mathbf{M}$ and $\mathbf{M}$-elliptic:

$$\mathrm{Re}[A_0(\mathbf{v},\overline{\mathbf{v}})] \geq \min(1,\alpha)\|\mathbf{v}\|^2_{\mathbf{M}} \quad \forall\mathbf{v} \in \mathbf{M}.$$

Let $\mathbf{M}'$ be the dual of $\mathbf{M}$ pivotal to $L^2(\Omega) \times L^2(0,\,2\pi)$. Then $\mathbf{M} \subset L^2(\Omega) \times L^2(0,\,2\pi) \subset \mathbf{M}'$ with dense inclusions. We denote by $[\cdot,\,\cdot]$ the duality bracket between $\mathbf{M}$ and $\mathbf{M}'$. We consider the continuous linear mappings $\mathcal{A} : \mathbf{M} \to \mathbf{M}'$ and $\mathcal{A}_0 : \mathbf{M} \to \mathbf{M}'$ defined by

$$[\mathcal{A}\mathbf{u},\,\mathbf{v}] := A(\mathbf{u},\,\mathbf{v}) \quad \text{and} \quad [\mathcal{A}_0\mathbf{u},\,\mathbf{v}] := A_0(\mathbf{u},\,\mathbf{v})$$

for all $\mathbf{u}$, $\mathbf{v}$ in $\mathbf{M}$.

Now it is clear that $\mathcal{A}_0$ is an isomorphism, and we deduce easily from Lemma 3.1 and the compactness of the canonical injection from $H^1(\Omega)$ into $L^2(\Omega)$ that $\mathcal{A} - \mathcal{A}_0 : \mathbf{M} \mapsto \mathbf{M}'$ is compact. Hence $\mathcal{A}$ is a Fredholm operator of index zero. Thus the theorem reduces to prove uniqueness of the solution for (2.7).

Let $(u_0, \xi_0) \in H^1(\Omega) \times H^{-1/2}(0, 2\pi)$ be a solution of (2.6) with $w = 0$. We introduce the function

$$\widetilde{u}(\boldsymbol{x}) := \begin{cases} u_0(\boldsymbol{x}), & \boldsymbol{x} \in \Omega, \\ z(\boldsymbol{x}) := \displaystyle\int_0^{2\pi} \frac{\partial E}{\partial \boldsymbol{\nu}_y}(\boldsymbol{x}, \boldsymbol{x}(t)) u_0(\boldsymbol{x}(t)) |\boldsymbol{x}'(t)| dt - \int_0^{2\pi} E(\boldsymbol{x}, \boldsymbol{x}(t)) \xi_0(t) dt, & \boldsymbol{x} \in \Omega_e. \end{cases}$$

It is easy to verify that u_0 solves the equation

$$\Delta u_0 + k^2 \theta(\boldsymbol{x})\, u_0 = 0 \qquad \text{in } \Omega. \tag{3.3}$$

On the other hand, z solves the Helmholtz equation

$$\Delta z + k^2 z = 0 \qquad \text{in } \Omega_e \tag{3.4}$$

and satisfies the Sommerfeld radiation condition (2.2). Furthermore, using the jump relations of the acoustic potential layers (see section 2 of [21]), we obtain the following identities on Γ:

$$\gamma z = \left(\frac{1}{2}\mathcal{I} + \mathcal{D}\right) \gamma u_0 - \mathcal{S}\xi_0, \tag{3.5}$$

$$|\boldsymbol{x}'(t)| \frac{\partial z}{\partial \boldsymbol{\nu}}(\boldsymbol{x}(t)) = -\mathcal{H}\gamma u_0 + \left(\frac{1}{2}\mathcal{I} - \mathcal{D}^*\right) \xi_0, \tag{3.6}$$

where $\mathcal{D}^*$ is the adjoint of operator $\mathcal{D}$, i.e.,

$$\mathcal{D}^* g(t) := \int_0^{2\pi} K(s,t) g(s) ds.$$

We refer to [21] for the definition of the hypersingular operator $\mathcal{H}$. We point out that we are using a parameterized version of this operator.

By virtue of (2.5), (3.5) directly yields the identity

$$\gamma z = \gamma u_0. \tag{3.7}$$

Now we also deduce from the integral representation of z in Ω_e and the jump conditions that

$$|\boldsymbol{x}'(t)| \frac{\partial z}{\partial \boldsymbol{\nu}}(\boldsymbol{x}(t)) = -\mathcal{H}\gamma z + \left(\frac{1}{2}\mathcal{I} - \mathcal{D}^*\right) |\boldsymbol{x}'(t)| \frac{\partial z}{\partial \boldsymbol{\nu}}(\boldsymbol{x}(t)). \tag{3.8}$$

Subtracting (3.8) from (3.6) and using (3.7), we obtain that

$$\left(\frac{1}{2}\mathcal{I} - \mathcal{D}^*\right) \left(|\boldsymbol{x}'(t)| \frac{\partial z}{\partial \boldsymbol{\nu}}(\boldsymbol{x}(t)) - \xi_0 \right) = 0. \tag{3.9}$$

Theorem 3.3.4. of [21] proves that, under our hypothesis on k, operator $\frac{1}{2}\mathcal{I} - \mathcal{D}^*$ is one-to-one and thus (3.9) provides the identity

$$\frac{\partial z}{\partial \boldsymbol{\nu}} = \frac{\partial u_0}{\partial \boldsymbol{\nu}} \quad \text{on } \Gamma. \tag{3.10}$$

Now, (3.3), (3.4), (3.7), and (3.10) show that $\widetilde{u}$ is a solution of (2.1)–(2.2) when $w = 0$, and Theorem 8.7 of [5] ensures that such a function $\widetilde{u}$ should vanish identically in all $\mathbb{R}^2$, and the result follows. □

4. Finite elements with curved triangles.

Let N be a given integer. We consider the equidistant subdivision $\{\frac{i\pi}{N}; \quad i = 0, \dots, 2N-1\}$ of the interval $[0, 2\pi]$ with $2N$ grid points. We denote by Ω_h the polygonal domain whose vertices lying on Γ are $\{\boldsymbol{x}(\frac{i\pi}{N}); i = 0, \dots, 2N-1\}$. Let τ_h be a regular triangulation of $\overline{\Omega}_h$ by triangles T of diameter h_T not greater than $\max|\boldsymbol{x}'(s)|h$ with $h := \frac{\pi}{N}$. We assume that any vertex of a triangle lying on the boundary of Ω_h belongs to $\{\boldsymbol{x}(\frac{i\pi}{N}); i = 0, \dots, 2N-1\}$.

We obtain from τ_h a triangulation $\widetilde{\tau}_h$ of $\overline{\Omega}$ by replacing each triangle of τ_h with one side along $\partial\Omega_h$ by the corresponding curved triangle.

Let T be a curved triangle of $\widetilde{\tau}_h$. We denote its vertices by $\mathbf{a}_1^T$, $\mathbf{a}_2^T$, and $\mathbf{a}_3^T$, numbered in such a way that $\mathbf{a}_2^T$ and $\mathbf{a}_3^T$ are the endpoints of the curved side of T. Let $t_i, t_{i+1} \in [0, 1]$ be such that $\boldsymbol{x}(t_i) = \mathbf{a}_2^T$ and $\boldsymbol{x}(t_{i+1}) = \mathbf{a}_3^T$. Then $\boldsymbol{\varphi}(t) := \boldsymbol{x}\,(t_i + t\,h)$ $(t \in [0, 1])$ is a parameterization of the curved side of T. Let $\widehat{T}$ be the reference triangle with vertices $\widehat{\mathbf{a}}_1 := (0, 0)$, $\widehat{\mathbf{a}}_2 := (1, 0)$, and $\widehat{\mathbf{a}}_3 := (0, 1)$. Consider the affine map $\mathbf{G}_T$ defined by $\mathbf{G}_T(\widehat{\mathbf{a}}_i) = \mathbf{a}_i^T$ for $i \in \{1, 2, 3\}$. Consider also the function $\boldsymbol{\Theta}_T : \widehat{T} \to \mathbb{R}^2$,

$$\boldsymbol{\Theta}_T(\widehat{\boldsymbol{x}}) := \frac{\hat{x}_1}{1 - \hat{x}_2}\left(\boldsymbol{\varphi}(\hat{x}_2) - (1 - \hat{x}_2)\mathbf{a}_2^T - \hat{x}_2\mathbf{a}_3^T\right),$$

where the limiting value has to be taken as $\hat{x}_2$ goes to 1. Then there exists $h_0 > 0$ such that if $h \in (0, h_0)$, T is the range of $\widehat{T}$ by the $\mathcal{C}^\infty$ and the one-to-one mapping $\mathbf{F}_T : \widehat{T} \to \mathbb{R}^2$ given by

$$\mathbf{F}_T := \mathbf{G}_T + \boldsymbol{\Theta}_T.$$

Moreover, each side of $\widehat{T}$ is mapped onto the corresponding side of T; i.e., $\boldsymbol{\Theta}_T(0, t) = \boldsymbol{\Theta}_T(t, 0) = (0, 0)$ and $\mathbf{F}_T(t, 1 - t) = \boldsymbol{\varphi}(t)$ for all $t \in [0, 1]$. This type of diffeomorphism was first proposed by Zlámal [25] and studied by Scott [22]. If T is a straight (interior) triangle, we take the curving perturbation $\boldsymbol{\Theta}_T \equiv \mathbf{0}$, and thus $\mathbf{F}_T$ is the usual affine map from the reference triangle. This hypothesis will be implicit in the following. In the finite element analysis we need estimates on the derivatives of $\mathbf{F}_T$ and $\mathbf{F}_T^{-1}$. These estimates are classical in the affine case, and they are proven in Theorem 22.4 of [24] (cf. also [22]) when T is a curved triangle. We collect the properties used in the forthcoming analysis in the following lemma.

Lemma 4.1. *For all $h \in (0, h_0)$, the Jacobian J_T of $\mathbf{F}_T$ does not vanish on a neighborhood of $\widehat{T}$, and the following estimates hold:*

$$C_1 h_T^2 \leq |J_T(\widehat{\boldsymbol{x}})| \leq C_2 h_T^2 \quad \forall \widehat{\boldsymbol{x}} \in \widehat{T}, \tag{4.1}$$

$$\max_{\widehat{\boldsymbol{x}} \in \widehat{T}} |\partial^\alpha (\mathbf{F}_T)_i(\widehat{\boldsymbol{x}})| \leq C h_T^{|\alpha|}, \quad \max_{\boldsymbol{x} \in T} |\partial^\alpha (\mathbf{F}_T^{-1})_i(\boldsymbol{x})| \leq C h_T^{-1} \tag{4.2}$$

for all $i = 1, 2$ and for all multi-index α such that $|\alpha| = 1, 2$.

A finite element is defined on T by a triplet $(T, P_1(T), \Sigma_T)$, where $P_1(T)$ is the image under $\mathbf{F}_T$ of the space $P_1(\widehat{T})$ of polynomials of degree no greater than 1 on $\widehat{T}$,

$$P_1(T) := \{p : T \to \mathbb{C};\ p = \hat{p} \circ \mathbf{F}_T^{-1},\ \hat{p} \in P_1(\widehat{T})\},$$

and $\Sigma_T = \{N_i; i = 1, 2, 3\}$ is a set of linear functionals defined by $N_i(\phi) = \phi(\mathbf{a}_{i,T})$ for all $\phi \in P_1(T)$ and for $i = 1, 2, 3$.

Interpolation error bounds on curved triangles are obtained by the technique used generally in the affine case (cf. [4] or [24]). Namely, if h is sufficiently small, one may readily prove with the aid of Lemma 4.1 that there exists a constant C independent of T such that

$$\|v - \pi_T v\|_{1,T} \leq\ C h_T \|v\|_{2,T} \quad \forall v \in H^2(T), \tag{4.3}$$

where $\pi_T v \in P_1(T)$ is uniquely determined by $\pi_T v(\mathbf{a}_i^T) = v(\mathbf{a}_i^T)$ for all $i = 1, 2, 3$. Notice that the norm $\|\cdot\|_{2,T}$ in (4.3) may be substituted by the seminorm $|\cdot|_{2,T}$ when T is a straight triangle.

We define the finite-dimensional subspace $V_h \subset H^1(\Omega)$ by

$$V_h = \{v \in H^1(\Omega); \quad v|_T \in P_1(T) \quad \forall T \in \widetilde{\tau}_h\}.$$

We deduce from (4.3) that

$$\inf_{v \in V_h} \|u - v\|_{1,\Omega} \leq\ C h\, \|u\|_{2,\Omega} \qquad \forall u \in H^2(\Omega). \tag{4.4}$$

Let n be a given integer. We consider the $2n$-dimensional space

$$T_n := \left\{ \sum_{j=0}^{n} a_j \cos jt + \sum_{j=1}^{n-1} b_j \sin jt; \quad a_j, b_j \in \mathbb{C} \right\}.$$

We have the following approximation property (cf. [21]):

$$\inf_{\mu \in T_n} \|\lambda - \mu\|_s \leq 2^{t-s} n^{s-t} \|\lambda\|_t \quad \forall \lambda \in H^t(0, 2\pi), \forall t \geq s. \tag{4.5}$$

We will also need the two inverse inequalities (cf. [21])

$$\|\mu\|_q \leq \left(\frac{1}{2n}\right)^{p-q} \|\mu\|_p \quad \forall \mu \in T_n, \quad \forall p \leq q \tag{4.6}$$

and

$$\|\mu\|_\infty \leq C\, n \|\mu\|_{-1/2} \quad \forall \mu \in T_n, \tag{4.7}$$

where we denoted $\|\mu\|_\infty := \max_{t \in [0,\, 2\pi]} |\mu(t)|$.

5. The discrete problem. Let $\mathbf{M}_\delta = V_h \times T_n$, where $\delta := (h, 1/n)$ is the discretization parameter. In terms of this notation, the discrete version of (2.7) is given by

$$\begin{aligned} &\text{find } \mathbf{u}_\delta \in \mathbf{M}_\delta \text{ such that} \\ &A(\mathbf{u}_\delta, \mathbf{v}) = L(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{M}_\delta. \end{aligned} \tag{5.1}$$

THEOREM 5.1. *Assume that k^2 is not an eigenvalue of the Laplacian in Ω with a Dirichlet boundary condition on Γ. For all δ small enough, problem* (5.1) *has a unique solution. Moreover, the Galerkin method is stable, and we have Céa's estimate*

$$\|\mathbf{u}-\mathbf{u}_\delta\|_{\mathbf{M}} \leq C_1 \inf_{\mathbf{v}\in\mathbf{M}_\delta} \|\mathbf{u}-\mathbf{v}\|_{\mathbf{M}}.$$

In case the exact solution belongs to $H^2(\Omega)\times H^{\sigma-1/2}(0,2\pi)$ for some $\sigma>0$, we have

$$\|u-u_h\|_{1,\Omega}+\|\xi-\xi_n\|_{-1/2} \leq C_2\left(h\|u\|_{2,\Omega}+n^{-\sigma}\|\xi\|_{\sigma-1/2}\right).$$

Proof. The theorem is a consequence of a classical result for compact perturbations of operator equations. Indeed, let us consider the auxiliary problem

$$\begin{aligned}&\text{find } \mathbf{z}\in\mathbf{M} \text{ such that}\\ &A_0(\mathbf{z},\mathbf{v}) = L(\mathbf{v}) \quad \forall\mathbf{v}\in\mathbf{M}\end{aligned} \tag{5.2}$$

and its discrete counterpart

$$\begin{aligned}&\text{find } \mathbf{z}_\delta\in\mathbf{M}_\delta \text{ such that}\\ &A_0(\mathbf{z}_\delta,\mathbf{v}) = L(\mathbf{v}) \quad \forall\mathbf{v}\in\mathbf{M}_\delta.\end{aligned} \tag{5.3}$$

Both (5.2) and (5.3) are well posed by virtue of the $\mathbf{M}$-ellipticity of $A_0(\cdot,\cdot)$. Furthermore, Céa's lemma, the approximation properties (4.4) and (4.5), and the density of smooth functions in $\mathbf{M}$ yield

$$\lim_{\delta\to 0}\inf_{\mathbf{v}\in\mathbf{M}_\delta}\|\mathbf{z}-\mathbf{v}\|_{\mathbf{M}} = 0. \tag{5.4}$$

Now we proved that problem (2.7) is also well posed and that it is a compact perturbation of (5.2) (see Theorem 3.2). Under these hypotheses, Theorem 13.7 of [12] shows that, if δ is sufficiently small, (5.1) is also well posed and convergent. Finally, the convergence implies Céa's estimate, and the last assertion of the theorem follows from the approximation properties (4.4) and (4.5). □

6. Description of the fully discrete method.

6.1. Approximation of $a^k(\cdot,\cdot)$ on $V_h\times V_h$.

Consider first a quadrature formula on the reference triangle

$$\widehat{Q}(\widehat{\phi}) := \sum_{l=1}^{L}\widehat{\omega}_l\widehat{\phi}(\widehat{\boldsymbol{z}}_l) \simeq \int_{\widehat{T}}\widehat{\phi}\,d\widehat{x}$$

with weights $\widehat{\omega}_l>0$ such that $\sum_{l=1}^{L}\widehat{\omega}_l=\frac{1}{2}$. On each $T\in\widetilde{\tau}_h$ we define

$$Q_T(\phi) := \widehat{Q}(|J(F_T)|\phi\circ F_T) = \sum_{l=1}^{L}\widehat{\omega}_l|J(F_T)|(\widehat{\boldsymbol{z}}_l)\phi(F_T(\widehat{\boldsymbol{z}}_l)) \simeq \int_T \phi(\boldsymbol{x})\,d\boldsymbol{x}.$$

This induces us to define an approximation $a_h^k(\cdot,\cdot)$ of $a^k(\cdot,\cdot)$ by

$$a_h^k(u,v) = \sum_{K\in\widetilde{\tau}_h} Q_K(\nabla u\cdot\nabla v - k^2\theta uv) \qquad \forall u,v\in V_h.$$

6.2. Approximation of $c(\cdot,\cdot)$ on $T_n \times T_n$. For all continuous and 2π-periodic functions g, we consider the composite trapezoidal rule

$$\mathcal{Q}_n(g) := \frac{\pi}{n} \sum_{i=0}^{2n-1} g\left(\frac{i\pi}{n}\right)$$

associated to the partition of $[0,\ 2\pi]$ into $2n$ grid points.

We also need to construct approximations for the improper integral

$$(\Lambda_0 g)(t) := -\frac{1}{2\pi}\int_0^{2\pi} \log\left(\frac{4}{e}\sin^2\frac{t-s}{2}\right) g(s)\, ds. \tag{6.1}$$

We can proceed as in [12] and obtain a quadrature formula replacing $g(s)$ in (6.1) by its trigonometric interpolation polynomial

$$(\mathcal{P}_n g)(s) := \sum_{j=0}^{2n-1} g\left(\frac{j\pi}{n}\right) L_j(s),$$

where the Lagrange basis is given by

$$L_j(s) := \frac{1}{2n}\left\{1 + 2\sum_{k=1}^{n-1}\cos k\left(s - \frac{j\pi}{n}\right) + \cos n\left(s - \frac{j\pi}{n}\right)\right\} \quad \forall j = 0, \ldots, 2n-1.$$

Therefore, we obtain the formula

$$\widetilde{\mathcal{Q}}_n g(t) := \sum_{j=0}^{2n-1} R_j^{(n)}(t) g\left(\frac{j\pi}{n}\right),$$

where, for $j = 0, \ldots, 2n-1$, the weights

$$R_j^{(n)}(t) = \frac{1}{2n} + \frac{1}{n}\sum_{m=1}^{n-1}\frac{1}{m}\cos m\left(t - \frac{j\pi}{n}\right) + \frac{1}{2n^2}\cos n\left(t - \frac{j\pi}{n}\right)$$

are given explicitly by evaluating the integrals $(\Lambda_0 L_j)(t)$ with the aid of (3.2) (cf. [12]).

Using the splitting (cf. [5])

$$V(t,s) = -\frac{1}{2\pi}V_1(t,s)\log\left(\frac{4}{e}\sin^2\frac{t-s}{2}\right) + V_2(t,s) \tag{6.2}$$

of the single-layer acoustic potential, where $V_1(t,s) := \frac{1}{2}J_0(k|\boldsymbol{x}(t) - \boldsymbol{x}(s)|)$ and J_0 is the Bessel function of order zero, we obtain

$$c(\xi,\mu) = \int_0^{2\pi} \Lambda_0(V_1(t,\cdot)\xi(\cdot))(t)\mu(t)\, dt + \int_0^{2\pi}\left(\int_0^{2\pi} V_2(t,s)\xi(s)\, ds\right)\mu(t)\, dt. \tag{6.3}$$

Hereafter, taking into account that $V_1(\cdot,\cdot)$ and $V_2(\cdot,\cdot)$ are in $\mathcal{C}^\infty_{2\pi}$ with respect to each variable, the first term of the right-hand side in (6.3) may be approximated by using the quadrature rule $\widetilde{\mathcal{Q}}_n$ for the internal integral and $\mathcal{Q}_n$ for the external one. The two-dimensional quadrature rule derived from $\mathcal{Q}_n$ is applied to the second term. In other words, we are introducing an approximation of the bilinear form $c(\cdot,\cdot)$ on $T_n \times T_n$ given by

$$c_n(\xi,\mu) := \mathcal{Q}_n[\widetilde{\mathcal{Q}}_n[V_1(t,\cdot)\xi(\cdot)]\mu(t)] + \mathcal{Q}_n[\mathcal{Q}_n[V_2(t,\cdot)\xi(\cdot)]\mu(t)],$$

which may also be written in matricial form as follows:

$$c_n(\xi,\mu) = \sum_{i=0}^{2n-1}\left(\sum_{j=0}^{2n-1}\mathbf{C}_{i,j}\xi\left(\frac{j\pi}{n}\right)\right)\mu\left(\frac{i\pi}{n}\right).$$

The entries of the symmetric $2n \times 2n$ matrix $\mathbf{C}$ are

$$\mathbf{C}_{i,j} := \frac{\pi}{n}R_j^{(n)}\left(\frac{i\pi}{n}\right)V_1\left(\frac{i\pi}{n},\frac{j\pi}{n}\right) + \frac{\pi^2}{n^2}V_2\left(\frac{i\pi}{n},\frac{j\pi}{n}\right).$$

6.3. Approximation of $\boldsymbol{b(\cdot,\cdot)}$ on $\boldsymbol{V_h \times T_n}$. We point out that the kernel $K(\cdot,\cdot)$ associated to the bilinear form $b(\cdot,\cdot)$ is continuous but not derivable; therefore, it is necessary to split it, as we did for $V(\cdot,\cdot)$ in (6.2), before using any quadrature rule. We follow [5] and write

$$K(t,s) = -\frac{1}{2\pi}K_1(t,s)\log\left(\frac{4}{e}\sin^2\frac{t-s}{2}\right) + K_2(t,s), \tag{6.4}$$

with

$$K_1(s,t) := -\frac{k}{2}J_1(k|\boldsymbol{x}(t)-\boldsymbol{x}(s)|)\frac{x_2'(s)(x_1(t)-x_1(s)) - x_1'(s)(x_2(t)-x_2(s))}{|\boldsymbol{x}(t)-\boldsymbol{x}(s)|},$$

and J_1 being the Bessel function of order one. Here again, it turns out that K_1 and K_2 belong to $\mathcal{C}^\infty_{2\pi}$ in each variable.

We introduce the composite trapezoidal rule

$$\mathcal{Q}_N(g) := \frac{\pi}{N}\sum_{i=0}^{2N-1} g\left(\frac{i\pi}{N}\right)$$

associated to the uniform partition of $[0,\, 2\pi]$ into $2N$ grid points. Given $v \in V_h$ and $\mu \in T_n$, our strategy consists in approximating

$$b(v,\mu) = \frac{1}{2}\int_0^{2\pi}\gamma v(t)\mu(t)\,dt - \int_0^{2\pi}\Lambda_0(K_1(\cdot,s)\mu(\cdot))(s)\,\gamma v(s)\,ds \\ - \int_0^{2\pi}\left(\int_0^{2\pi}K_2(t,s)\gamma v(s)\,ds\right)\mu(t)\,dt$$

by employing $\mathcal{Q}_n$, $\widetilde{\mathcal{Q}}_n$, and $\mathcal{Q}_N$ as follows:

$$b_\delta(v,\mu) := \frac{1}{2}\int_0^{2\pi}\gamma v(t)\mu(t)\,dt - \mathcal{Q}_N[\widetilde{\mathcal{Q}}_n[K_1(\cdot,s)\mu(\cdot)]\gamma v(s)] \\ - \mathcal{Q}_N[\mathcal{Q}_n[K_2(\cdot,s)\mu(\cdot)]\gamma v(s)].$$

In other words,

$$b_\delta(v,\mu) = \frac{1}{2}\int_0^{2\pi}\gamma v(t)\mu(t)\,dt - \sum_{j=0}^{2N-1}\left(\sum_{i=0}^{2n-1}\mathbf{B}_{i,j}\mu\left(\frac{i\pi}{n}\right)\right)\gamma v\left(\frac{j\pi}{N}\right),$$

where $\mathbf{B}$ is the $2n \times 2N$ matrix with entries

$$\mathbf{B}_{i,j} := \frac{\pi}{N} R_i^{(n)}\left(\frac{j\pi}{N}\right) K_1\left(\frac{i\pi}{n}, \frac{j\pi}{N}\right) + \frac{\pi^2}{nN} K_2\left(\frac{i\pi}{n}, \frac{j\pi}{N}\right).$$

We note here that we did not propose a quadrature rule for $\int_0^{2\pi} \gamma v(t)\mu(t)\,dt$ since this integral may be easily evaluated analytically.

We are now in a position to propose a completely discrete version of the Galerkin scheme (5.1):

$$\text{(6.5)} \qquad \begin{aligned} &\text{find } \mathbf{u}_\delta^* \in \mathbf{M}_\delta \text{ such that} \\ &A_\delta(\mathbf{u}_\delta^*, \mathbf{v}) = L_\delta(\mathbf{v}) \quad \forall \mathbf{v} \in \mathbf{M}_\delta, \end{aligned}$$

where

$$A_\delta(\mathbf{u}, \mathbf{v}) = a_h^k(u, v) + 2c_n(\xi, \mu) + 2b_\delta(u, \mu) - \int_0^{2\pi} \xi(t)\gamma v(t)\,dt$$

and

$$L_\delta(\mathbf{v}) = \int_0^{2\pi} (\mathcal{P}_n \lambda)\,\gamma v\,dt + 2b_\delta(\Pi_h w, \mu),$$

with $\Pi_h : \mathcal{C}^0(\overline{\Omega}) \to V_h$ being the global Lagrange interpolation operator.

6.4. Matrix form of the fully discrete problem. Let us denote by $\mathbf{A}^k$ the symmetric $M_h \times M_h$ matrix whose entries are given by the complex numbers $\mathbf{A}_{i,j}^k := a_h^k(\varphi_i, \varphi_j)$, where $\{\varphi_i\,;\ i = 1, \ldots, M_h\}$ is the usual nodal basis of V_h. If we set

$$u_h(\boldsymbol{x}) = \sum_{i=1}^{M_h} \mathbf{u}_i \varphi_i(\boldsymbol{x}), \qquad \xi_h(t) = \sum_{i=0}^{2n-1} \boldsymbol{\xi}_i L_i(t),$$

then the matricial interpretation of (6.5) takes the form

$$\text{(6.6)} \qquad \begin{pmatrix} \mathbf{A}^k & -\mathbf{R}^t \\ \mathbf{K} & \mathbf{C} \end{pmatrix} \begin{pmatrix} \mathbf{u} \\ \boldsymbol{\xi} \end{pmatrix} = \begin{pmatrix} \mathbf{R}^t \boldsymbol{\lambda} \\ \mathbf{K}\mathbf{w} \end{pmatrix},$$

where

$$\mathbf{K}_{i,j} = b_\delta(\varphi_j, L_i) \quad \text{and} \quad \mathbf{R}_{i,j} = \int_0^{2\pi} \gamma \varphi_j(t) L_i(t)\,dt$$

for all $i = 0, \ldots, 2n-1$ and $j = 1, \ldots, M_h$. We also denoted by $\mathbf{w}$ the M_h-vector whose components are given by the values of the incident wave w at the nodes of the triangulation $\widetilde{\tau}_h$ and $\boldsymbol{\lambda}_k := \lambda(\frac{k\pi}{n})$ for $k = 0, \ldots, 2n-1$.

7. Analysis of the fully discrete method.

7. Analysis of the fully discrete method. We begin our analysis with the following classical result (see [4] or [24]).

LEMMA 7.1. *There exists $h_0 \in (0, 1]$ such that*

$$|a^k(u, v) - a_h^k(u, v)| \le Ch\|u\|_{1,\Omega}\|v\|_{1,\Omega} \quad \forall u, v \in V_h,$$

for some constant $C > 0$ independent of h for all $h \le h_0$.

We recall that $f_k(t) := \exp(\imath m t)$ and that $\mathcal{P}_n$ is the trigonometric interpolation operator. It is easy to check that $\mathcal{P}_n f_{2kn+m} = \mathcal{P}_n f_m$ for all $m, k \in \mathbb{Z}$. Furthermore, $\mathcal{P}_n f_m = f_m$ if $-n < m < n$ and $\mathcal{P}_n f_n = \frac{1}{2}(f_n + f_{-n})$. The following estimate is essential in the subsequent analysis, and we deduce it by just adapting the proof of Theorem 11.8 of [12].

Lemma 7.2. *Assume that* $p > 1/2$*; then there exists a constant* $C > 0$ *such that*

$$\|af_m - \mathcal{P}_n(af_m)\|_\infty \le C n^{-p+1/2} \|a\|_p \qquad \forall a \in H^p(0, 2\pi), \quad \forall m \in \mathbb{Z}.$$

Proof. Using the Fourier expansion

$$a(t) = \sum_{\rho=-n+1}^{n} \sum_{k\in\mathbb{Z}} \widehat{a}_{2kn+\rho} f_{2kn+\rho}(t)$$

of a, where $\widehat{a}_k := 1/2\pi \int_0^{2\pi} a(t) f_{-k}(t)\, dt$, we deduce that

$$(\mathcal{I} - \mathcal{P}_n)(af_m) = \sum_{\rho=-n+1}^{n} \sum_{k\in\mathbb{Z}} \widehat{a}_{2kn+\rho} (f_{2kn+\rho+m} - \mathcal{P}_n f_{\rho+m}).$$

Notice that we may always write $m = 2k_0 n + \overline{m}$ with $k_0 \in \mathbb{Z}$ and $-n < \overline{m} \le n$. We denote by $\varepsilon(\overline{m}) := \frac{\overline{m}}{|\overline{m}|}$ the sign of $\overline{m}$ with the convention $\varepsilon(0) = 1$. We remark that $-n < \overline{\rho} := \varepsilon(\overline{m})n - \overline{m} \le n$ and write $(\mathcal{I} - \mathcal{P}_n)(af_m) = S_1 + S_2$ with

$$S_1 = \sum_{\substack{\rho=-n+1\\ \rho\neq\overline{\rho}}}^{n} \sum_{k\in\mathbb{Z}^*} \widehat{a}_{2kn+\rho} (f_{2kn+\rho+m} - f_{\rho+m})$$

and

$$S_2 = \sum_{k\in\mathbb{Z}} \widehat{a}_{2kn+\overline{\rho}} \left(f_{2kn+\overline{\rho}+m} - \frac{1}{2} f_n - \frac{1}{2} f_{-n} \right),$$

where $\mathbb{Z}^* = \mathbb{Z} - \{0\}$.

A first bound of S_1 is obtained by using the Cauchy–Schwarz inequality

$$|S_1(t)|^2 \le \left(2 \sum_{\substack{\rho=-n+1\\ \rho\neq\overline{\rho}}}^{n} \sum_{k\in\mathbb{Z}^*} |\widehat{a}_{2kn+\rho}| \right)^2 \le 8n \sum_{\substack{\rho=-n+1\\ \rho\neq\overline{\rho}}}^{n} \left(\sum_{k\in\mathbb{Z}^*} |\widehat{a}_{2kn+\rho}| \right)^2.$$

The Cauchy–Schwarz inequality gives again

$$\begin{aligned}
\left(\sum_{k\in\mathbb{Z}^*} |\widehat{a}_{2kn+\rho}| \right)^2 &\le \sum_{k\in\mathbb{Z}^*} \frac{1}{(2kn+\rho)^{2p}} \sum_{k\in\mathbb{Z}^*} (2kn+\rho)^{2p} |\widehat{a}_{2kn+\rho}|^2 \\
&\le n^{-2p} \sum_{k\in\mathbb{Z}^*} \frac{1}{(2k+\frac{\rho}{n})^{2p}} \sum_{k\in\mathbb{Z}^*} (2kn+\rho)^{2p} |\widehat{a}_{2kn+\rho}|^2 \\
&\le C_1\, n^{-2p} \sum_{k\in\mathbb{Z}^*} (2kn+\rho)^{2p} |\widehat{a}_{2kn+\rho}|^2,
\end{aligned}$$

where $C_1 = \max_{t\in[-1,\,1]} \sum_{k\in\mathbb{Z}^*} \frac{1}{(2k+t)^{2p}} < \infty$ since $p > 1/2$. We deduce that

$$|S_1(t)|^2 \leq 8C_1\, n^{-2p+1} \sum_{\substack{\rho=-n+1\\ \rho\neq\overline{\rho}}}^{n} \sum_{k\in\mathbb{Z}^*} (2kn+\rho)^{2p}|\widehat{a}_{2kn+\rho}|^2 \quad \forall t\in[0,\ 2\pi]. \tag{7.1}$$

On the other hand,

$$|S_2(t)|^2 \leq \left(2\sum_{k\in\mathbb{Z}}|\widehat{a}_{2kn+\overline{\rho}}|\right)^2 \leq 4n^{-2p}\sum_{k\in\mathbb{Z}}\frac{1}{(2k+\varepsilon(\overline{m})-\frac{\overline{m}}{n})^{2p}}\sum_{k\in\mathbb{Z}}(2kn+\overline{\rho})^{2p}|\widehat{a}_{2kn+\overline{\rho}}|^2,$$

and then

$$|S_2(t)|^2 \leq 4\left(\max_{\rho\in[-1,\,1]}\sum_{k\in\mathbb{Z}}\frac{1}{(2k+\varepsilon(\overline{m})+\rho)^{2p}}\right)n^{-2p}\sum_{k\in\mathbb{Z}}(2kn+\overline{\rho})^{2p}|\widehat{a}_{2kn+\overline{\rho}}|^2 \tag{7.2}$$

for all $t\in[0,\ 2\pi]$.

Summing (7.1) and (7.2), we obtain that

$$|(\mathcal{I}-\mathcal{P}_n)(af_m)|^2 \leq C_2\, n^{-2p+1}\sum_{k\in\mathbb{Z}} k^{2p}|\widehat{a}_k|^2 \quad \forall t\in[0,\ 2\pi],$$

and the result follows. □

LEMMA 7.3. *There exists a constant C independent of n such that*

$$|c(\xi,\mu)-c_n(\xi,\mu)| \leq Cn^{-\sigma}\|\xi\|_{-1/2}\|\mu\|_{-1/2} \quad \forall\sigma>0,$$

for all ξ and μ in T_n.

Proof. We begin with the decomposition

$$\begin{aligned} c(\xi,\mu)-c_n(\xi,\mu) = \int_0^{2\pi}\Lambda_0(V_1(t,\cdot)\xi(\cdot))\mu(t)\,dt - \mathcal{Q}_n[\widetilde{\mathcal{Q}}_n[V_1(t,\cdot)\xi(\cdot)]\mu(t)] \\ + \int_0^{2\pi}\int_0^{2\pi}V_2(t,s)\xi(s)\mu(t)\,dsdt - \mathcal{Q}_n[\mathcal{Q}_n[V_2(t,\cdot)\xi(\cdot)]\mu(t)]. \end{aligned}$$

It is proved in Lemma 7 of [17] that there exists a constant C such that

$$\left|\int_0^{2\pi}\int_0^{2\pi}V_2(t,s)\xi(s)\mu(t)\,dsdt - \mathcal{Q}_n[\mathcal{Q}_n[V_2(t,\cdot)\xi(\cdot)]\mu(t)]\right| \leq Cn^{-\sigma}\|\xi\|_{-1/2}\|\mu\|_{-1/2}$$

for all $\sigma>0$.

Now, we have to prove the same estimate for the remaining term, which may be written

$$\int_0^{2\pi}\Lambda_0(V_1(t,\cdot)\xi(\cdot))\mu(t)\,dt - \mathcal{Q}_n[\widetilde{\mathcal{Q}}_n[V_1(t,\cdot)\xi(\cdot)]\mu(t)] = \int_0^{2\pi}E_1(t)\,dt + \mathcal{Q}_n[E_2(t)\mu(t)],$$

where

$$E_1(t) = (\mathcal{I}-\mathcal{P}_n)[\Lambda_0(V_1(t,\cdot)\xi(\cdot))\,\mu(t)] \quad\text{and}\quad E_2(t) = \Lambda_0(\mathcal{I}-\mathcal{P}_n)\,(V_1(t,\cdot)\xi(\cdot))\,.$$

We develop V_1 as

$$V_1(t,s) = \sum_{m\in\mathbb{Z}} \widehat{a}_m(t) f_m(s),$$

with $\widehat{a}_m(t) := 1/2\pi \int_0^{2\pi} V_1(t,s) f_{-m}(s)\,ds$, and we deduce that

$$\begin{aligned}\Lambda_0(V_1(\cdot,s)\xi(s))(t)\mu(t) &= \sum_{i,j=-n}^{n} \left(\sum_{m\in\mathbb{Z}} \widehat{a}_m(t)\Lambda_0(f_{m+j})(t) \right) f_i(t)\xi_j\mu_i \\ &= \sum_{i,j=-n}^{n} \left(\sum_{m\in\mathbb{Z}} \widehat{a}_m(t) \frac{f_{m+j+i}(t)}{\max(1,|m+j|)} \right) \xi_j \mu_i,\end{aligned}$$

where ξ_i and μ_i are the coefficients of $\xi,\mu \in T_n$ in the basis f_i. Therefore,

$$E_1(t) = \sum_{i,j=-n}^{n} \left(\sum_{m\in\mathbb{Z}} \frac{1}{\max(1,|m+j|)} (\mathcal{I}-\mathcal{P}_n)(\widehat{a}_m(t) f_{m+j+i}(t)) \right) \xi_j\mu_i,$$

and applying Lemma 7.2 with $p = \sigma + \frac{5}{2}$, we deduce that

$$|E_1(t)| \leq C_1\, n^{-\sigma-2} \left(\sum_{m\in\mathbb{Z}} \|\widehat{a}_m\|_{\sigma+5/2} \right) \sum_{i=-n}^{n} |\mu_i| \sum_{j=-n}^{n} |\xi_j| \quad \forall t \in [0,\, 2\pi].$$

Now, on the one hand, using (4.6) with $p = -1/2$ and $q = 0$, we have

$$\sum_{i=-n}^{n} |\mu_i| \leq \sqrt{2n}\|\mu\|_0 \leq 2n\|\mu\|_{-1/2} \quad \forall \mu \in T_n, \tag{7.3}$$

and on the other hand, the regularity of V_1 implies that

$$\sum_{m\in\mathbb{Z}} \|\widehat{a}_m\|_{\sigma+5/2} \leq \left(\sum_{m\in\mathbb{Z}} \frac{1}{1+m^2} \right)^{1/2} \left(\sum_{m,k\in\mathbb{Z}} (1+m^2)(1+k^2)^{\sigma+5/2}\, |\widehat{a}_{m,k}|^2 \right)^{1/2} < \infty,$$

where $\widehat{a}_{m,k} := 1/2\pi \int_0^{2\pi} \widehat{a}_m(t) f_{-k}(t)\,dt$. Consequently, we have the estimate

$$\left| \int_0^{2\pi} E_1(t)\,dt \right| \leq C_2\, n^{-\sigma} \|\mu\|_{-1/2} \|\xi\|_{-1/2}. \tag{7.4}$$

It remains to bound E_2. In this case we develop V_1 with respect to the variable t, considering s as a parameter:

$$V_1(t,s) = \sum_{m\in\mathbb{Z}} \widehat{b}_m(s) f_m(t), \qquad \left(\widehat{b}_m(s) := \frac{1}{2\pi} \int_0^{2\pi} V_1(t,s) f_{-m}(t)\,dt \right).$$

It follows that

$$E_2(t) = \sum_{j=-n}^{n} \xi_j \sum_{m\in\mathbb{Z}} \Lambda_0(\mathcal{I}-\mathcal{P}_n)(\widehat{b}_m f_j) f_m(t).$$

Let us denote by $\mathcal{C}^0_{2\pi}$ the space of 2π-periodic and continuous functions. By virtue of the Sobolev imbedding $H^1(0,2\pi) \hookrightarrow \mathcal{C}^0_{2\pi}$, we have that $\Lambda_0 :\ L^2(0,2\pi) \to \mathcal{C}^0_{2\pi}$ is bounded and

$$\|\Lambda_0(\mathcal{I}-\mathcal{P}_n)(\widehat{b}_m f_j)\|_\infty \leq C_3\|(\mathcal{I}-\mathcal{P}_n)(\widehat{b}_m f_j)\|_0 \leq \sqrt{2\pi}C_3\|(\mathcal{I}-\mathcal{P}_n)(\widehat{b}_m f_j)\|_\infty.$$

Thus applying Lemma 7.2 with $p=\sigma+5/2$ yields

$$|E_2(t)| \leq Cn^{-\sigma-2}\left(\sum_{m\in\mathbb{Z}}\|\widehat{b}_m\|_{\sigma+5/2}\right)\sum_{j=-n}^{n}|\xi_j| \quad \forall t\in[0,\ 2\pi],$$

and, here again, (7.3) and the regularity of V_1 permit us to obtain the bound

$$\|E_2(t)\|_\infty = \|(\mathcal{I}-\mathcal{P}_n)\,(V_1(t,\cdot)\xi(\cdot))\|_\infty \leq C_5\, n^{-\sigma-1}\|\xi\|_{-1/2}. \tag{7.5}$$

Now, by definition of the trapezoidal rule

$$\mathcal{Q}_n[E_2(t)\mu(t)] = \frac{\pi}{n}\sum_{i=0}^{2n-1}E_2(t_i)\mu(t_i)$$

and by virtue of (4.7), we obtain the inequality

$$|\mathcal{Q}_n[E_2(t)\mu(t)]| \leq 2\pi\|E_2(t)\|_\infty\|\mu\|_\infty \leq C_6\, n^{-\sigma}\|\xi\|_{-1/2}\|\mu\|_{-1/2}$$

that, joined to (7.4), gives the result. □

LEMMA 7.4. *There exists a constant C independent of $\delta=(h,1/n)$ such that*

$$|b(v,\mu)-b_\delta(v,\mu)| \leq C\left(h\frac{n\sqrt{\log n}}{N}+n^{-\sigma}\right)\|\mathbf{v}\|_{\mathbf{M}} \quad \forall\sigma>0,$$

for all $\mathbf{v} := (v,\mu)\in\mathbf{M}_\delta$.

Proof. We begin by noting that the parameterized trace $t\to\gamma v(\mathbf{x}(t))$ of a function $v\in V_h$ belongs to the space T_h of 2π-periodic, continuous, and piecewise linear functions on the uniform partition of $[0,\ 2\pi]$ into $2N$ subintervals.

We have the decomposition

$$\begin{aligned}b(v,\mu)-b_\delta(v,\mu) &= \int_0^{2\pi}\Lambda_0(K_1(\cdot,s)\mu(\cdot))\,\gamma v(s)\,ds - \mathcal{Q}_N[\widetilde{\mathcal{Q}}_n[K_1(\cdot,s)\mu(\cdot)]\gamma v(s)]\\ &\quad+\int_0^{2\pi}\int_0^{2\pi}K_2(t,s)\gamma v(s)\mu(t)\,dsdt - \mathcal{Q}_N[\mathcal{Q}_n[K_2(\cdot,s)\mu(\cdot)]\gamma v(s)].\end{aligned}$$

One can proceed as in Lemma 8 of [17] and prove that there exists a constant C_1 such that

$$\begin{aligned}&\left|\int_0^{2\pi}\int_0^{2\pi}K_2(t,s)\gamma v(s)\mu(t)\,dsdt - \mathcal{Q}_N[\mathcal{Q}_n[K_2(\cdot,s)\mu(\cdot)]\gamma v(s)]\right|\\ &\qquad\qquad\leq C_1\,(n^{-\sigma}+h)\|\mu\|_{-1/2}\|v\|_{1,\Omega}.\end{aligned}$$

We introduce the error operator $\mathcal{E}_N(g) := \int_0^{2\pi}g-\mathcal{Q}_N(g)$ corresponding to the quadrature formula $\mathcal{Q}_N$ and write

$$\begin{aligned}&\int_0^{2\pi}\Lambda_0(K_1(\cdot,s)\mu(\cdot))\gamma v(s)\,ds - \mathcal{Q}_N[\widetilde{\mathcal{Q}}_n[K_1(\cdot,s)\mu(\cdot)]\gamma v(s)]\\ &\qquad\qquad= \mathcal{E}_N[B_1(s)\gamma v] + \mathcal{Q}_N[B_2(s)\gamma v],\end{aligned}$$

where

$$B_1(s) = \Lambda_0(K_1(\cdot, s)\mu(\cdot)) \qquad \text{and} \qquad B_2(s) = \Lambda_0(\mathcal{I} - \mathcal{P}_n)\left(K_1(\cdot, s)\mu(\cdot)\right).$$

A simple change of variable yields

$$\mathcal{E}_N[B_1(s)\gamma v(s)] = h \sum_{i=0}^{2N-1} \mathcal{E}(B_1^i)\gamma v\left(\frac{i\pi}{N}\right),$$

where $\mathcal{E}(g) := \int_0^1 g(t)\,dt - \frac{g(1)+g(0)}{2}$ is the error operator of the basic trapezoidal rule on the reference interval [0, 1] and

$$B_1^i(s) := sB_1\left(\frac{(i-1)\pi}{N} + sh\right) + (1-s)B_1\left(\frac{i\pi}{N} + sh\right).$$

It follows readily from the Bramble–Hilbert lemma that

$$|\mathcal{E}(B_1^i)| \le C_2 \left\| \frac{d^2}{ds^2}(sB_1(t_{i-1} + sh) + (1-s)B_1(t_i + sh)) \right\|_\infty \le C_3 h^2 \|B_1''\|_\infty.$$

Using that for any $\varepsilon > 0$, $H^{\varepsilon+1/2}(0, 2\pi)$ is imbedded continuously in the space of 2π-periodic and continuous functions, we deduce that

$$\|B_1''\|_\infty \le C(\varepsilon)\|B_1''\|_{\varepsilon+1/2} \le C(\varepsilon)\|B_1\|_{\varepsilon+5/2}.$$

Moreover, it is easy to show that $C(\varepsilon) = \left(\sum_{k\in\mathbb{Z}} 1/\max(1, |k|)^{1+2\varepsilon}\right)^{1/2}$ behaves like $1/\sqrt{\varepsilon}$. Now, as we have already noticed in Lemma 3.1, $D_2(t, s) = K_1(t, s)/(\sin\frac{t-s}{2})$ belongs to $\mathcal{C}^\infty_{2\pi}$ in each of its two variables. It follows that we may write $B_1(s) = \Lambda_1(D_2(\cdot, s)\mu)$ and

$$\|\Lambda_1(D_2(\cdot, s)\mu)\|_{5/2+\varepsilon} \le C(\varepsilon)\|\mu\|_{1/2+\varepsilon} \le C(\varepsilon)n^{1+\varepsilon}\|\mu\|_{-1/2}$$

since $\mu \mapsto \Lambda_1(D_2(\cdot, s)\mu)$ is a pseudodifferential operator of index -2. We also used the inverse inequality (4.6).

Putting together the last estimates, we obtain, after using the Cauchy–Schwarz inequality and the fact that the norms

$$v(\boldsymbol{x}(t)) \to \|v(\boldsymbol{x}(t))\|_0 \qquad \text{and} \qquad v(\boldsymbol{x}(t)) \to \left(h \sum_{i=0}^{2N-1} \left|\gamma v\left(\frac{i\pi}{N}\right)\right|^2\right)^{1/2}$$

are uniformly equivalent on T_h, that

$$|\mathcal{E}_N[B_1(s)\gamma v(s)]| \le C_4\, h^2 \frac{n^{1+\varepsilon}}{\sqrt{\varepsilon}} \|\mu\|_{-1/2} \sum_{i=0}^{2N-1} h \left|\gamma v\left(\frac{i\pi}{N}\right)\right| \le C_5\, h^2 \frac{n^{1+\varepsilon}}{\sqrt{\varepsilon}} \|\mu\|_{-1/2}\|\gamma v\|_0$$

for all $\varepsilon > 0$. Furthermore, we notice that the function $\varepsilon \mapsto n^{1+\varepsilon}/\sqrt{\varepsilon}$ attains its minimum at a value proportional to $n\sqrt{\log n}$ when $\varepsilon = \frac{1}{2\log n}$, and hence

$$|\mathcal{E}_N[B_1(s)\gamma v(s)]| \le C_6\, h \frac{n\sqrt{\log n}}{N} \|\mu\|_{-1/2}\|v\|_{1,\Omega} \quad \forall \mu \in T_n, \quad \forall v \in V_h. \tag{7.6}$$

On the other hand,

$$|\mathcal{Q}_N[B_2(s)\gamma v(s)]| = h\left|\sum_{i=0}^{2N-1} B_2\left(\frac{i\pi}{N}\right)\gamma v\left(\frac{i\pi}{N}\right)\right|$$
$$\leq \|B_2\|_\infty \sum_{i=0}^{2N-1} h\left|\gamma v\left(\frac{i\pi}{N}\right)\right| \leq C_7\, \|B_2\|_\infty \|\gamma v\|_0,$$

and estimate (7.5) yields (after substituting V_1 by K_1)

$$\|B_2\|_\infty = \|\Lambda_0(\mathcal{I}-\mathcal{P}_n)\,(K_1(\cdot,s)\mu(\cdot))\|_\infty \leq C_8\, n^{-\sigma}\|\mu\|_{-1/2} \quad \forall \mu \in T_n.$$

Finally,

$$|\mathcal{Q}_N[B_2(s)\gamma v(s)]| \leq C_9\, n^{-\sigma}\|\mu\|_{-1/2}\|v\|_{1,\Omega} \quad \forall \mu \in T_n, \quad \forall v \in V_h,$$

and the result follows from the last inequality and (7.6). □

We conclude our analysis with the following result.

THEOREM 7.5. *Assume that k^2 is not an eigenvalue of the Laplacian in Ω with a Dirichlet boundary condition on Γ. We also assume that there exists $\kappa > 0$ such that $\frac{n}{N} \leq \kappa$. Then, for $\delta = (h, 1/n)$ small enough, the fully discrete scheme* (6.5) *is well posed and convergent. Moreover, we have*

$$\|u - u_h^*\|_{1,\Omega} + \|\xi - \xi_n^*\|_{-1/2} \leq\; C\,(h\sqrt{\log n} + n^{-\sigma})\big(\|u\|_{2,\Omega} + \|\xi\|_{\sigma-1/2}\big)$$

in case the exact solution belongs to $H^2(\Omega) \times H^{\sigma-1/2}(0,2\pi)$ for some $\sigma > 0$.

Proof. On the one hand, the convergence and stability of the Galerkin method (5.1) (see Theorem 5.1) is equivalent to the uniform inf-sup condition

$$\sup_{\mathbf{v}\in\mathbf{M}_\delta} \frac{A(\mathbf{u},\mathbf{v})}{\|\mathbf{v}\|_{\mathbf{M}}} \geq C\,\|\mathbf{u}\|_{\mathbf{M}} \qquad \forall \mathbf{u} \in \mathbf{M}_\delta.$$

On the other hand, Lemmas 7.3, 7.1, and 7.4 yield

$$(7.7) \qquad |A(\mathbf{u},\mathbf{v}) - A_\delta(\mathbf{u},\mathbf{v})| \leq C_1\,(h\sqrt{\log n} + n^{-\sigma})\|\mathbf{u}\|_{\mathbf{M}}\|\mathbf{v}\|_{\mathbf{M}} \quad \forall \mathbf{u},\mathbf{v} \in \mathbf{M}_\delta,$$

which permits us to deduce by standard arguments that, for δ small enough, $A_\delta(\cdot,\cdot)$ also satisfies a uniform inf-sup condition, and hence problem (6.5) has a unique solution.

Now, the second Strang lemma [23] gives the abstract estimate

$$\|\mathbf{u}_h^* - \mathbf{v}\|_{\mathbf{M}} \leq\; C_2\,\left(\sup_{\mathbf{z}\in\mathbf{M}_\delta}\frac{|A(\mathbf{u}-\mathbf{v},\mathbf{z})|}{\|\mathbf{z}\|_{\mathbf{M}}} + \sup_{\mathbf{z}\in\mathbf{M}_\delta}\frac{|A(\mathbf{v},\mathbf{z}) - A_\delta(\mathbf{v},\mathbf{z})|}{\|\mathbf{z}\|_{\mathbf{M}}}\right.$$
$$\left. + \sup_{\mathbf{z}\in\mathbf{M}_\delta}\frac{|L(\mathbf{z}) - L_\delta(\mathbf{z})|}{\|\mathbf{z}\|_{\mathbf{M}}}\right)$$

for all $\mathbf{v} \in \mathbf{M}_\delta$.

We can see from the right-hand side of the last inequality that it remains only to estimate the difference $L(\cdot) - L_\delta(\cdot)$ on $\mathbf{M}_\delta$ to obtain the asymptotic convergence annunciated in the theorem. We have that

$$|L(\mathbf{v}) - L_\delta(\mathbf{v})| \leq \left|\int_0^{2\pi}(\lambda - \mathcal{P}_n\lambda)\gamma v\, dt\right| + 2|b(w,\mu) - b_\delta(\Pi_h w,\mu)|.$$

On the one hand,

$$\left| \int_0^{2\pi} (\lambda - \mathcal{P}_n \lambda) \gamma v \, dt \right| \leq \|(\lambda - \mathcal{P}_n \lambda)\|_0 \|\gamma v\|_0 \leq C_3 \, n^{-\sigma} \|\lambda\|_\sigma \|v\|_{1,\Omega}$$

by virtue of the trace theorem and the well-known trigonometric interpolation error estimate in Sobolev spaces (cf. Theorem 11.8 of [12]).

On the other hand, using Lemma 7.4,

$$\begin{aligned} |b(w,\mu) - b_\delta(\Pi_h w, \mu)| &\leq |b(w - \Pi_h w, \mu)| + |b(\Pi_h w, \mu) - b_\delta(\Pi_h w, \mu)| \\ &\leq C_4 \left(\|w - \Pi_h w\|_{1,\Omega} \|\mu\|_{-1/2} + (h\sqrt{\log n} + n^{-\sigma}) \|\Pi_h w\|_{1,\Omega} \|\mu\|_{-1/2} \right), \end{aligned}$$

and by virtue of the Lagrange interpolation error estimate derived from (4.3) we deduce that

$$|b(w,\mu) - b_\delta(\Pi_h w, \mu)| \leq C_5 (h\sqrt{\log n} + n^{-\sigma}) \|w\|_{2,\Omega} \|\mu\|_{-1/2},$$

and consequently

$$|L(\mathbf{v}) - L_\delta(\mathbf{v})| \leq C_6 (h\sqrt{\log n} + n^{-\sigma}) (\|w\|_{2,\Omega} + \|\lambda\|_\sigma) \|\mathbf{v}\|_{\mathbf{M}}. \tag{7.8}$$

We deduce from the triangle inequality

$$\|\mathbf{u} - \mathbf{u}_h^*\|_{\mathbf{M}} \leq \|\mathbf{u} - \mathbf{u}_h\|_{\mathbf{M}} + \|\mathbf{u}_h^* - \mathbf{u}_h\|_{\mathbf{M}}$$

and the second Strang inequality that the asymptotic behavior of the fully discrete method is a direct consequence of (7.7), (7.8), the boundness of $A(\cdot,\cdot)$, and Theorem 5.1. □

We point out that the asymptotic behavior predicted by the last theorem is in fact too pessimistic. In practice, as we will show in the next section, n can be blocked at a very low value (which is independent of h) without influencing the accuracy of the method. Consequently, the convergence may still be considered as linear in h.

8. Numerical results.

We test our numerical method by using the same example given in section 5 of [20]. In all of what follows, the artificial boundary Γ is the ellipse of minor and major semiaxes $a = 1.1$ and $b = 1.5$. The incident wave is given by $w(\boldsymbol{x}) := \exp(\imath k x_1)$ and $\theta(\boldsymbol{x}) := 1 + \psi(|\boldsymbol{x}|)$ with

$$\psi(t) := \begin{cases} (1 - t^4)^2 & \text{for } t \in [0,\ 1], \\ 0 & \text{elsewhere.} \end{cases}$$

As $\theta(\boldsymbol{x})$ is radially symmetric, it is possible to use a separation of variable method and compute u explicitly in terms of the series

$$u(r\cos\phi, r\sin\phi) = \sum_{m=-\infty}^{\infty} y_m(r) \exp(\imath m \phi),$$

where y_m satisfies an integral equation described in section 5 of [20]. In the following, we compare our solution with

$$\overline{u}(r\cos\phi, r\sin\phi) = \sum_{m=-20}^{20} \overline{y}_m(r) \exp(\imath m \phi),$$

Table 8.1

Convergence history and number of iterations of the method for different values of the parameter n when $k = 1$ and $h = 2\pi/128$.

$2n$	$\text{error}_{\text{max}}$	Iterations
128	8.30×10^{-4}	10
64	8.62×10^{-4}	7
32	8.62×10^{-4}	6
16	8.62×10^{-4}	6
8	2.0×10^{-3}	6

Table 8.2

Convergence history and number of iterations of the method for different values of the parameter n when $k = 5$ and $h = 2\pi/256$.

$2n$	$\text{error}_{\text{max}}$	Iterations
256	3.22×10^{-2}	51
128	3.22×10^{-2}	42
64	3.22×10^{-2}	41
32	3.21×10^{-2}	40
16	3.75×10^{-1}	36

Table 8.3

Convergence history and number of iterations of the method for different values of the parameter h when $k = 2$ and $2n = 16$.

h	$\text{error}_{\text{max}}$	iterations
$2\pi/32$	7.57×10^{-2}	16
$2\pi/64$	2.29×10^{-2}	15
$2\pi/128$	5.8×10^{-3}	15
$2\pi/256$	1.5×10^{-3}	14

where $\overline{y}_m$ is an approximation of y_m obtained by solving the corresponding integral equation by a Nyström method as suggested in [20]. In all the tables, $\text{error}_{\text{max}} := \max |u_h(\mathbf{a}) - \overline{u}(\mathbf{a})|$, where the maximum is taken over the vertices $\mathbf{a}$ of $\widetilde{\mathcal{T}}_h$.

We take in Table 8.1 $k = 1$ and $h = 2\pi/128$, and we take in Table 8.2 $k = 5$ and $h = 2\pi/256$. In both cases we decrease the spectral parameter n until we obtain the smallest value that preserves the order of accuracy. We can see that the number of degrees of freedom is drastically reduced. This justifies the following strategy used to solve the linear systems: We eliminate the boundary variable from the system of linear equations (6.6) to obtain the reduced system

$$\left(\mathbf{A}^k + \mathbf{R}^t\mathbf{C}^{-1}\mathbf{K}\right)\mathbf{u} = \mathbf{f}, \tag{8.1}$$

where $\mathbf{f} := \mathbf{R}^t\boldsymbol{\lambda} + (\mathbf{R}^t\mathbf{C}^{-1}\mathbf{K})\mathbf{w}$. The system of equations (8.1) is solved by a GMRES method using $\mathbf{A} := (a(\varphi_i, \varphi_j))_{i,j}$ as a preconditioner. We use a version of GMRES without restarts. We take as an initial guess the solution of the Helmholtz equation in the bounded domain Ω, and iterations are continued until $\|r_{k+1}\|_2/\|r_k\|_2 < 10^{-6}$, where r_k is the kth residual.

Each iteration of the GMRES method entails the solution of a linear system with a full but small matrix $\mathbf{C}$ and another linear system with the sparse stiffness matrix

A. Furthermore, as **A** is symmetric and positive definite, this can be performed by a direct method through a Cholesky decomposition for matrix **A**. Table 8.3 shows the number of iterations against h with $n = 8$ and $k = 2$. The numerical results suggest that the method has a number of iterations bounded independently of the critical parameter h.

ERROR ESTIMATES FOR LOW-ORDER ISOPARAMETRIC QUADRILATERAL FINITE ELEMENTS FOR PLATES[*]

RICARDO G. DURÁN[†], ERWIN HERNÁNDEZ[‡], LUIS HERVELLA-NIETO[§], ELSA LIBERMAN[¶], AND RODOLFO RODRÍGUEZ[‖]

Abstract. This paper deals with the numerical approximation of the bending of a plate modeled by Reissner–Mindlin equations. It is well known that, in order to avoid locking, some kind of reduced integration or mixed interpolation has to be used when solving these equations by finite element methods. In particular, one of the most widely used procedures is based on the family of elements called *MITC* (mixed interpolation of tensorial components). We consider two lowest-order methods of this family on quadrilateral meshes.

Under mild assumptions we obtain optimal H^1 and L^2 error estimates for both methods. These estimates are valid with constants independent of the plate thickness. We also obtain error estimates for the approximation of the plate vibration problem. Finally, we report some numerical experiments showing the very good behavior of the methods, even in some cases not covered by our theory.

Key words. Reissner–Mindlin, *MITC* methods, isoparametric quadrilaterals

AMS subject classifications. 65N30, 74S05, 74K20

DOI. 10.1137/S0036142902409410

1. Introduction.

The Reissner–Mindlin model is the most widely used for the analysis of thin or moderately thick elastic plates. It is now very well understood that standard finite element methods applied to this model produce very unsatisfactory results due to the so-called *locking* phenomenon. Therefore, some special method based on reduced integration or mixed interpolation has to be used. Among them, the mixed interpolation of tensorial components (*MITC*) methods introduced by Bathe and Dvorkin in [7] or variants of them are very likely the most used in practice.

A great number of papers dealing with the mathematical analysis of this kind of method have been published (see, for example, [2, 6, 10, 12, 13, 18, 20, 23]). In those papers, optimal order error estimates, valid uniformly on the plate thickness, have been obtained for several methods. However, although some of the most commonly used elements in engineering applications are the isoparametric quadrilaterals (indeed, the original Bathe and Dvorkin paper deals with these elements), no available result seems to exist for this case.

On the other hand, it has been recently noted that the extension to general quadrilaterals of convergence results valid for rectangular elements is not straightforward, and, furthermore, the order of convergence can deteriorate when nonstandard finite elements are used in distorted quadrilaterals, even if they satisfy the usual shape regularity assumption (see [3, 4]).

The aim of this paper is to analyze two low-order methods based on quadrilateral meshes. One is the original $MITC4$ introduced in [7], while the other one is an extension to the quadrilateral case of a method introduced in [12] for triangular elements. (From now on the latter will be called $DL4$.) We are interested not only in load problems but also in the determination of the free vibration modes of the plate.

For nested uniform meshes of rectangles, an optimal order error estimate in H^1 norm has been proved in [6] for $MITC4$. However, the regularity assumptions on the exact solution required in that paper are not optimal. These assumptions have been weakened in [12], but they are still not optimal. Let us remark that to obtain approximation results for the plate vibration spectral problem, it is important to remove this extra regularity assumption.

On the other hand, for low-order elements as those considered here, an optimal error estimate in L^2 norm is difficult to obtain because of the consistency term arising in the error equation. For triangular elements, such an estimate has been only recently proved in [13]. However, the proof given in that paper cannot be extended straightforwardly, even for the case of rectangular elements.

In this paper we prove optimal in order and regularity H^1 and L^2 error estimates for both methods, $MITC4$ and $DL4$, under appropriate assumptions on the family of meshes. As a consequence, following the arguments in [13], we also obtain optimal error estimates for the approximation of the corresponding plate vibration spectral problem.

In order to prove the H^1 error estimate for $MITC4$, we require an additional assumption on the meshes (which is satisfied, for instance, by uniform refinements of any starting mesh). Instead, no assumption other than the usual shape regularity is needed for $DL4$.

On the other hand, a further assumption on the meshes is made to prove the L^2 error estimates: the meshes must be formed by higher-order perturbations of parallelograms. This restriction is related to approximation properties of the Raviart–Thomas elements which are used in our arguments and do not hold for general quadrilateral elements. However, this assumption is only needed for extremely refined meshes. Indeed, the L^2 estimate holds for any regular mesh as long as the mesh-size is comparable with the plate thickness. Moreover, we believe that this quasi-parallelogram assumption is of a technical character. In fact, the numerical experiments reported here seem to show that it is not necessary.

The rest of the paper is organized as follows. In section 2, we recall Reissner–Mindlin equations and introduce the two discrete methods. We prove optimal-order error estimates for both methods in H^1 and L^2 norms in sections 3 and 4, respectively. In section 5, we prove error estimates for the spectral plate vibration problem. Finally, in section 6, we report some numerical experiments.

Throughout the paper we denote by C a positive constant not necessarily the same at each occurrence but always independent of the mesh-size and the plate thickness.

2. Statement of the problem.

2.1. Reissner–Mindlin model. Let $\Omega \times (-\frac{t}{2}, \frac{t}{2})$ be the region occupied by an undeformed elastic plate of thickness t, where Ω is a convex polygonal domain of $\mathbb{R}^2$.

In order to describe the deformation of the plate, we consider the Reissner–Mindlin model, which is written in terms of the rotations $\beta = (\beta^1, \beta^2)$ of the fibers initially normal to the plate's midsurface and the transverse displacement w. The following equations describe the plate's response to conveniently scaled transversal and shear loads $f \in \mathrm{L}^2(\Omega)$ and $\theta \in \mathrm{L}^2(\Omega)^2$, respectively (see, for instance, [9, 13]).

Problem 2.1. *Find* $(\beta, w) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega)$ *such that*

$$\left\{\begin{array}{ll} a(\beta,\eta) + (\gamma, \nabla v - \eta) = (f,v) + \dfrac{t^2}{12}(\theta,\eta) & \forall (\eta, v) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega), \\ \gamma = \dfrac{\kappa}{t^2}(\nabla w - \beta). & \end{array}\right. \tag{2.1}$$

In this expression, $\kappa := Ek/2(1+\nu)$ is the shear modulus, with E being the Young modulus, ν the Poisson ratio, and k a correction factor. We have also introduced the shear stress γ and denoted by $(\cdot,\cdot)$ the standard L^2 inner product. Finally, a is the $\mathrm{H}^1_0(\Omega)^2$ elliptic bilinear form defined by

$$a(\beta,\eta) := \frac{E}{12(1-\nu^2)} \int_\Omega \left[\sum_{i,j=1}^{2} (1-\nu)\varepsilon_{ij}(\beta)\varepsilon_{ij}(\eta) + \nu \operatorname{div}\beta \operatorname{div}\eta \right],$$

with $\varepsilon_{ij}(\beta) = \frac{1}{2}(\partial\beta_i/\partial x_j + \partial\beta_j/\partial x_i)$ being the components of the linear strain tensor.

Let us remark that we have included in our formulation the shear load term $\frac{t^2}{12}(\theta,\eta)$ since it arises naturally when considering the free vibration plate problem. In fact, it is simple to see that the free vibration modes of the plate are determined by

$$t^3 a(\beta,\eta) + \kappa t \int_\Omega (\nabla w - \beta)\cdot(\nabla v - \eta) = \omega^2 \left(t \int_\Omega \rho\, wv + \frac{t^3}{12}\int_\Omega \rho\, \beta\cdot\eta \right) \qquad \forall (\eta, v) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega),$$

where ω denotes the angular vibration frequency, β and w the rotation and transversal displacement amplitudes, respectively, and ρ the plate density (see [13] for further details). Thus, rescaling the problem with $\lambda := \rho\,\omega^2/t^2$, we obtain the following, which is the spectral problem associated to Problem 2.1.

Problem 2.2. *Find* $\lambda \in \mathbb{R}$ *and* $0 \neq (\beta, w) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega)$ *such that*

$$\left\{\begin{array}{ll} a(\beta,\eta) + (\gamma, \nabla v - \eta) = \lambda \left[(w,v) + \dfrac{t^2}{12}(\beta,\eta) \right] & \forall (\eta, v) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega), \\ \gamma = \dfrac{\kappa}{t^2}(\nabla w - \beta). & \end{array}\right.$$

This paper deals with the finite element approximation of Problems 2.1 and 2.2. It is well known that both are well-posed (see [9] and [13]). Furthermore, we will use the following regularity result for the solution of (2.1) (see [2]):

$$\|\beta\|_{2,\Omega} + \|w\|_{2,\Omega} + \|\gamma\|_{0,\Omega} + t\,\|\gamma\|_{1,\Omega} \leq C\left(t^2\|\theta\|_{0,\Omega} + \|f\|_{0,\Omega}\right) \leq C\,|(\theta,f)|_t\,, \tag{2.2}$$

where, for any open subset O of Ω and any integer k, $\|\cdot\|_{k,O}$ denotes the standard norm of $\mathrm{H}^k(O)$ or $\mathrm{H}^k(O)^2$, as corresponds, and $|(\cdot,\cdot)|_t$ is the norm in $\mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega)$ induced by the weighted inner product on the right-hand side of the first equation in (2.1) (see [13]).

2.2. Discrete problems. In what follows, we consider two lowest-degree methods on isoparametric quadrilateral meshes for the approximation of Problem 2.1: the so-called *MITC*4 (see [7]) and an extension to quadrilaterals of a method introduced in [12] that we call *DL*4. Both methods are based on relaxing the shear terms in (2.1) by introducing an interpolation operator called a *reduction operator*.

Let $\{\mathcal{T}_h\}$ be a family of decompositions of Ω into convex quadrilaterals, satisfying the usual condition of regularity (see, for instance, [19]); i.e., there exist constants $\sigma > 1$ and $0 < \varrho < 1$ independent of h such that

$$h_K \le \sigma \rho_K, \qquad |\cos \vartheta_{iK}| \le \varrho, \quad i = 1, 2, 3, 4, \qquad \forall K \in \mathcal{T}_h,$$

where h_K is the diameter of K, ρ_K the diameter of the largest circle contained in K, and ϑ_{iK}, $i = 1, 2, 3, 4$, the four angles of K.

Let $\widehat{K} := [0, 1]^2$ be the reference element. We denote by $Q_{i,j}(\widehat{K})$ the space of polynomials of degree less than or equal to i in the first variable and to j in the second one. Also, we set $Q_k(\widehat{K}) = Q_{k,k}(\widehat{K})$.

Let $K \in \mathcal{T}_h$. We denote by F_K a bilinear mapping of $\widehat{K}$ onto K, with Jacobian matrix and determinant denoted by DF_K and J_{F_K}, respectively. The regularity assumptions above lead to

$$ch_K^2 \le J_{F_K} \le Ch_K^2,$$

with c and C depending only on σ and ϱ (see [19]). In particular, $J_{F_K} > 0$, and hence F_K is a one-to-one map. Let ℓ_i, $i = 1, 2, 3, 4$, be the edges of K; then $\ell_i = F_K(\widehat{\ell}_i)$, with $\widehat{\ell}_i$ being the edges of $\widehat{K}$. Let $\widehat{\tau}_i$ be a unit vector tangent to $\widehat{\ell}_i$ on the reference element; then $\tau_i := DF_K\widehat{\tau}_i / \|DF_K\widehat{\tau}_i\|$ is a unit vector tangent to ℓ_i on K (see Figure 2.1).

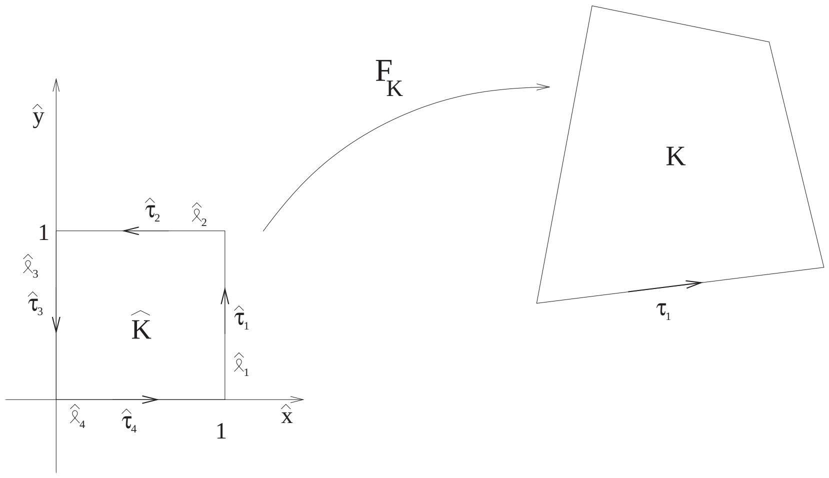

FIG. 2.1. *Bilinear mapping onto an element* $K \in \mathcal{T}_h$.

Let

$$\mathcal{N}(\widehat{K}) := \left\{ \widehat{p} : \ \widehat{p} \in Q_{0,1}(\widehat{K}) \times Q_{1,0}(\widehat{K}) \right\},$$

and, from this space, we define through covariant transformation

$$\mathcal{N}(K) := \left\{ p : \ p \circ F_K = DF_K^{-t} \widehat{p}, \ \widehat{p} \in \mathcal{N}(\widehat{K}) \right\}.$$

Let us remark that the mapping between $\mathcal{N}(K)$ and $\mathcal{N}(\widehat{K})$ is a kind of "Piola transformation" for the "rot" operator, $\operatorname{rot} p := \partial p_1/\partial x_2 - \partial p_2/\partial x_1$. (The Piola transformation is defined for the "div" operator in, for example, [9].) Then we have the following results which are easily established (see [23, 24]):

$$\int_{\ell_i} p \cdot \tau_i = \int_{\widehat{\ell}_i} \widehat{p} \cdot \widehat{\tau}_i, \qquad i = 1, 2, 3, 4, \tag{2.3}$$

and

$$(\operatorname{rot} p) \circ F_K = J_{F_K}^{-1} \, \widehat{\operatorname{rot}} \, \widehat{p} \qquad \text{in } \widehat{K}. \tag{2.4}$$

We define the lowest-order rotated Raviart–Thomas space (see [21, 24])

$$\Gamma_h := \left\{ \psi \in \mathrm{H}_0(\operatorname{rot}, \Omega) : \ \psi|_K \in \mathcal{N}(K) \ \forall K \in \mathcal{T}_h \right\},$$

which will be used to approximate the shear stress γ. We remark that, since $\Gamma_h \subset \mathrm{H}_0(\operatorname{rot}, \Omega)$, the tangential component of a function in Γ_h must be continuous along interelement boundaries and vanish on $\partial\Omega$. In fact, the integrals (2.3) of these tangential components are the degrees of freedom defining an element of Γ_h.

We consider the "interpolation" operator

$$R : \mathrm{H}^1(\Omega)^2 \cap \mathrm{H}_0(\operatorname{rot}, \Omega) \longrightarrow \Gamma_h, \tag{2.5}$$

defined by (see [21])

$$\int_\ell R\psi \cdot \tau_\ell = \int_\ell \psi \cdot \tau_\ell \qquad \forall \text{ edge } \ell \text{ of } \mathcal{T}_h, \tag{2.6}$$

where, from now on, τ_ℓ denotes a unit vector tangent to ℓ. Clearly, the operator R satisfies $\forall \psi \in \mathrm{H}^1(\Omega)^2$

$$\int_K \operatorname{rot}(\psi - R\psi) = 0 \qquad \forall K \in \mathcal{T}_h. \tag{2.7}$$

Taking into account the rotation mentioned above, it is proved in Theorem III.4.4 of [14] that

$$\| \operatorname{rot} R\psi \|_{0,\Omega} \leq C \|\psi\|_{1,\Omega} \tag{2.8}$$

and

$$\|\psi - R\psi\|_{0,\Omega} \leq Ch \|\psi\|_{1,\Omega}. \tag{2.9}$$

To approximate the transverse displacements, we will use the space of standard bilinear isoparametric elements

$$W_h := \left\{ v \in \mathrm{H}_0^1(\Omega) : \ v|_K \in Q(K) \ \forall K \in \mathcal{T}_h \right\},$$

where, $\forall K \in \mathcal{T}_h$, $Q(K) := \left\{ p \in \mathrm{L}^2(K) : \ p \circ F_K \in Q_1(\widehat{K}) \right\}$.

The following lemma establishes some relations between the spaces Γ_h and W_h.

LEMMA 2.1. *The following properties hold:*

$$\nabla W_h = \{\mu \in \Gamma_h : \ \operatorname{rot} \mu = 0\}$$

and

$$R(\nabla w) = \nabla(w^{\mathrm{I}}) \qquad \forall w \in \mathrm{H}^2(\Omega),$$

where w^{I} is the Lagrange interpolant of w on W_h.

Proof. For $\mu \in \Gamma_h$ and $K \in \mathcal{T}_h$, let $\widehat{\mu} \in \mathcal{N}(\widehat{K})$ be such that $\mu|_K \circ F_K = DF_K^{-\mathrm{t}}\widehat{\mu}$. Then, according to (2.4), we have $\operatorname{rot} \mu|_K \circ F_K = J_{F_K}^{-1} \widehat{\operatorname{rot}}\, \widehat{\mu}$. Hence, since $J_{F_K} > 0$, $\operatorname{rot} \mu = 0$ if and only if $\widehat{\operatorname{rot}}\, \widehat{\mu} = 0$.

On the other hand, note that if $\widehat{\mu} \in \mathcal{N}(\widehat{K})$, then $\widehat{\mu} = (a+b\widehat{y}, c+d\widehat{x})$, with $a, b, c, d \in \mathbb{R}$, and $\widehat{\operatorname{rot}}\, \widehat{\mu} = d - b$. Therefore, $\widehat{\operatorname{rot}}\, \widehat{\mu} = 0$ if and only if $\widehat{\mu} = (a + d\widehat{y}, c + d\widehat{x}) = \widehat{\nabla}\widehat{v}$ for $\widehat{v} = a\widehat{x} + c\widehat{y} + d\widehat{x}\widehat{y} \in Q_1(\widehat{K})$.

Thus $\operatorname{rot} \mu|_K = 0$ if and only if $\mu|_K = (DF_K^{-\mathrm{t}}\widehat{\mu}) \circ F_K^{-1} = \nabla v$, with $v = \widehat{v} \circ F_K^{-1} \in Q(K)$.

To prove the second property, since we have already proved that $\nabla w^{\mathrm{I}} \in \Gamma_h$, it is enough to show that the degrees of freedom defining $R(\nabla w)$ and ∇w^{I} coincide. Indeed, consider an edge ℓ with end points A and B as in Figure 2.2. Then,

$$\int_\ell R(\nabla w) \cdot \tau_\ell = \int_\ell \nabla w \cdot \tau_\ell = w(B) - w(A) = w^{\mathrm{I}}(B) - w^{\mathrm{I}}(A) = \int_\ell \nabla w^{\mathrm{I}} \cdot \tau_\ell,$$

and we conclude the proof. $\square$

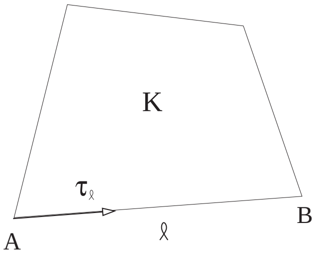

FIG. 2.2. *Geometry of K.*

The two methods that we analyze in this paper differ only in the space used to approximate the rotations. Let us now specify them:

*MITC*4: The spaces W_h and Γ_h are the ones defined above, whereas the space of standard isoparametric bilinear functions is used for the rotations; namely,

$$H_h^1 := \left\{\eta \in \mathrm{H}_0^1(\Omega)^2 : \ \eta|_K \in Q(K)^2 \ \forall K \in \mathcal{T}_h\right\}.$$

*DL*4: While for this method W_h and Γ_h are the same as for *MITC*4, the space for the rotations is enriched by using a rotation of a space used for the approximation of the Stokes problem in [14].

In fact, for each edge $\widehat{\ell}_i$ of $\widehat{K}$, $i = 1, 2, 3, 4$, let $\widehat{p}_i$ be cubic functions vanishing on $\widehat{\ell}_j$ for $j \neq i$. Namely, $\widehat{p}_1 = \widehat{x}\widehat{y}(1-\widehat{y})$, $\widehat{p}_2 = \widehat{x}\widehat{y}(1-\widehat{x})$, $\widehat{p}_3 = \widehat{y}(1-\widehat{x})(1-\widehat{y})$, and $\widehat{p}_4 = \widehat{x}(1-\widehat{x})(1-\widehat{y})$ (see Figure 2.1). Then we define $p_i := (\widehat{p}_i \circ F_K^{-1})\tau_i$, and we set

$$H_h^2 := \left\{\eta \in \mathrm{H}_0^1(\Omega)^2 : \ \eta|_K \in Q(K)^2 \oplus \langle p_1, p_2, p_3, p_4\rangle \ \forall K \in \mathcal{T}_h\right\}.$$

From now on we use H_h to denote any of the two spaces H_h^1 or H_h^2. In both methods we use R defined by (2.5)–(2.6) as *reduction operator*. Then, the discretization of Problem 2.1 can be written in both cases as follows.

Problem 2.3. *Find* $(\beta_h, w_h) \in H_h \times W_h$ *such that*

$$\left\{\begin{array}{ll} a(\beta_h,\eta) + (\gamma_h, \nabla v - R\eta) = (f, v) + \dfrac{t^2}{12}(\theta,\eta) & \forall(\eta, v) \in H_h \times W_h, \\ \gamma_h = \dfrac{\kappa}{t^2}(\nabla w_h - R\beta_h). & \end{array}\right. \tag{2.10}$$

On the other hand, the discretization of Problem 2.2 is as follows.

Problem 2.4. *Find* $\lambda_h \in \mathbb{R}$ *and* $0 \neq (\beta_h, w_h) \in H_h \times W_h$ *such that*

$$\left\{\begin{array}{ll} a(\beta_h,\eta) + (\gamma_h, \nabla v - R\eta) = \lambda_h \left[(w_h, v) + \dfrac{t^2}{12}(\beta_h,\eta)\right] & \forall(\eta, v) \in H_h \times W_h, \\ \gamma_h = \dfrac{\kappa}{t^2}(\nabla w_h - R\beta_h). & \end{array}\right.$$

Existence and uniqueness of solution for Problem 2.3 follow easily (see [12]). Regarding Problem 2.4, it leads to a well-posed generalized matrix eigenvalue problem, since the bilinear form in the right-hand side of the first equation is an inner product.

3. $\mathbf{H}^1$ error estimates.

To prove optimal error estimates in H^1 norm, we will use the abstract theory developed in [12]. In particular, sufficient conditions to obtain such estimates have been settled in Theorem 3.1 of this reference. By virtue of Lemma 2.1, this theorem reads as follows in our case.

Theorem 3.1. *Let* H_h, W_h, Γ_h, *and the operator* R *be defined as above. Let* (β, w, γ) *and* (β_h, w_h, γ_h) *be the solutions of* (2.1) *and* (2.10), *respectively. If there exist* $\widetilde{\beta} \in H_h$ *and an operator* $\Pi : \mathrm{H}_0(\mathrm{rot},\Omega) \cap \mathrm{H}^1(\Omega)^2 \longrightarrow \Gamma_h$ *satisfying*

$$\|\beta - \widetilde{\beta}\|_{1,\Omega} \leq Ch\|\beta\|_{2,\Omega}, \tag{3.1}$$

$$\|\eta - \Pi\eta\|_{0,\Omega} \leq Ch\|\eta\|_{1,\Omega} \qquad \forall \eta \in \mathrm{H}^1(\Omega)^2 \cap \mathrm{H}_0(\mathrm{rot},\Omega), \tag{3.2}$$

and

$$\mathrm{rot}\left(\frac{t^2}{\kappa}\Pi\gamma + R\widetilde{\beta}\right) = 0, \tag{3.3}$$

then the following error estimate holds true:

$$\|\beta - \beta_h\|_{1,\Omega} + t\|\gamma - \gamma_h\|_{0,\Omega} + \|w - w_h\|_{1,\Omega} \leq Ch\left(\|\beta\|_{2,\Omega} + t\|\gamma\|_{1,\Omega} + \|\gamma\|_{0,\Omega}\right).$$

Then, our next step is to construct an approximation $\widetilde{\beta}$ of β and an operator Π satisfying the hypotheses of the previous theorem for each one of the methods $MITC4$ and $DL4$.

3.1. *MITC4.* Several studies have been carried out for this method in, for example, [6], [12], and [17]. Since the variational equations for plates have a certain similitude with those of the Stokes problem, the main results are based on properties already known for the latter. An order h of convergence is obtained in those references only for uniform meshes of square elements. Moreover, more regularity of the solutions is also required. Although these results can be adapted for parallelogram meshes, they cannot be extended to general quadrilateral ones.

In what follows we obtain error estimates optimal in order and regularity for this method on somewhat more general meshes. We assume specifically the following condition.

ASSUMPTION 3.1. *The mesh $\mathcal{T}_h$ is a refinement of a coarser partition $\mathcal{T}_{2h}$, obtained by joining the midpoints of each opposite edge in each $M \in \mathcal{T}_{2h}$ (called macroelement). In addition, $\mathcal{T}_{2h}$ is a similar refinement of a still coarser regular partition $\mathcal{T}_{4h}$.*

Let

$$Q_h := \left\{q_h \in \mathrm{L}^2_0(\Omega) : \ q_h|_K = c_K, \ c_K \in \mathbb{R}, \ \forall K \in \mathcal{T}_h\right\},$$

where $\mathrm{L}^2_0(\Omega) := \left\{q \in \mathrm{L}^2(\Omega) : \ \int_\Omega q = 0\right\}$. Note that, for parallelogram meshes, we have $Q_h = \operatorname{rot}\Gamma_h$, but this does not hold for general quadrilateral meshes.

For each macroelement $M \in \mathcal{T}_{2h}$, we introduce four functions q_i, $i = 1, 2, 3, 4$, taking the values 1 and -1 according to the pattern of Figure 3.1.

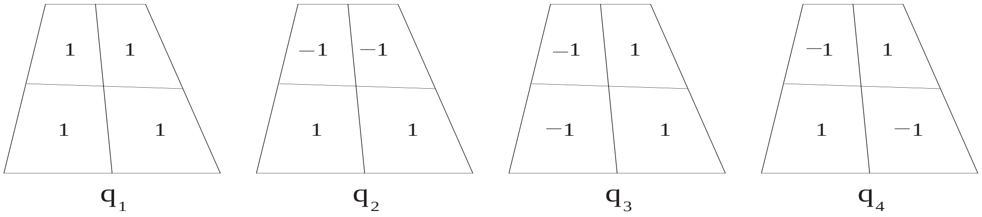

FIG. 3.1. *Bases for the macroelements.*

Let

$$Q_{h4} := \{q_h \in Q_h : \ q_h|_M = c_M q_4, \ c_M \in \mathbb{R} \ \forall M \in \mathcal{T}_{2h}\},$$

and let $\widetilde{Q}_h$ be its $\mathrm{L}^2(\Omega)$ orthogonal complement on Q_h; then

$$\widetilde{Q}_h := \{q_h \in Q_h : \ q_h|_M \in \langle q_1, q_2, q_3\rangle \ \forall M \in \mathcal{T}_{2h}\}.$$

We associate to these spaces the subspace of H^1_h defined by

$$\widetilde{H}^1_h := \left\{\eta_h \in H^1_h : \ \int_\Omega \operatorname{rot}\eta_h \, q_h = 0 \quad \forall q_h \in Q_{h4}\right\}.$$

The following lemma provides the approximation $\widetilde{\beta}$ required by Theorem 3.1. Moreover, this $\widetilde{\beta} \in \widetilde{H}^1_h$, and this fact will be used below to define the operator Π required by the same theorem.

Lemma 3.2. *Let $\beta \in \mathrm{H}_0^1(\Omega)$. Then there exists $\widetilde{\beta} \in \widetilde{H}_h^1$ such that*

$$\int_\Omega \operatorname{rot}(\widetilde{\beta} - \beta) q_h = 0 \qquad \forall q_h \in \widetilde{Q}_h,$$

and the estimate (3.1) *holds true.*

Proof. The proof follows from the results in section VI.5.4 of [9] by changing "div" to "rot" and rotating the fields 90°, which in their turn are based on the results for isoparametric elements in [22] (see also [19]). □

Our next step is to define the operator Π satisfying the requirements of Theorem 3.1. To do this, we will use a particular projector $\widetilde{P}$ onto $\operatorname{rot}\Gamma_h$.

We have already mentioned that, in general, $Q_h \neq \operatorname{rot}\Gamma_h$. In fact, it is simple to show that

$$\operatorname{rot}\Gamma_h = \left\{ \sum_{K \in \mathcal{T}_h} \frac{c_K}{J_{F_K}} \chi_K : \; c_K \in \mathbb{R} \; \forall K \in \mathcal{T}_h \right\} \cap \mathrm{L}_0^2(\Omega), \tag{3.4}$$

where χ_K denotes the characteristic function of K.

For each macroelement $M \in \mathcal{T}_{2h}$, we consider the bilinear mapping F_M as shown in Figure 3.2. Therefore, for any $\eta_h \in \Gamma_h$ we have

$$\operatorname{rot}\eta_h|_M = \frac{1}{J_{F_M}} \sum_{i=1}^4 c_i \chi_{K_i},$$

where K_i are the four elements in M (see Figure 3.2).

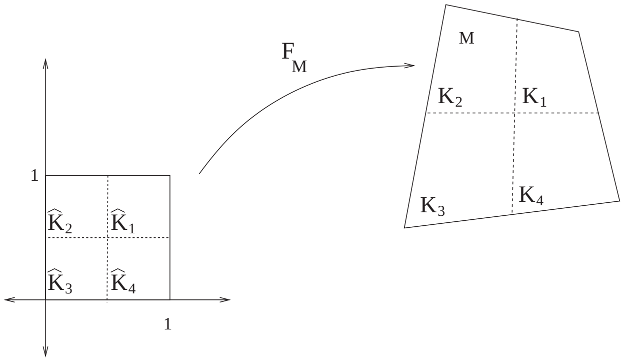

Fig. 3.2. *Bilinear mapping on macroelements.*

We define $\widetilde{P} : \mathrm{L}_0^2(\Omega) \longrightarrow \operatorname{rot}\Gamma_h$ as follows: given $p \in \mathrm{L}_0^2(\Omega)$,

$$\forall M = \bigcup_{i=1}^4 K_i \in \mathcal{T}_{2h}, \qquad \widetilde{P}p|_M = \sum_{i=1}^4 \frac{c_i}{J_{F_M}} \chi_{K_i},$$

with c_i chosen such that

$$\int_M \widetilde{P}p\, q_i = \int_M p q_i, \quad i = 1, 2, 3, \qquad \text{and} \qquad \int_M \widetilde{P}p\, q_4 = 0.$$

Straightforward computations show that $\widetilde{P}$ is well defined by the equations above and that they can be equivalently written

$$\int_\Omega \widetilde{P}p\, q_h = \int_\Omega pq_h \quad \forall q_h \in \widetilde{Q}_h \qquad \text{and} \qquad \int_\Omega \widetilde{P}p\, q_h = 0 \quad \forall q_h \in Q_{h4}. \tag{3.5}$$

The following properties of this operator will be used in what follows.

Lemma 3.3. *The following estimates hold* $\forall p \in \mathrm{L}^2(\Omega)$:

$$\|p - \widetilde{P}p\|_{0,\Omega} \le C\|p\|_{0,\Omega}, \tag{3.6}$$

$$\|p - \widetilde{P}p\|_{-1,\Omega} \le Ch\|p\|_{0,\Omega}. \tag{3.7}$$

Proof. To verify (3.6) it is enough to prove that $\|\widetilde{P}p\|_{0,\Omega} \le C\|p\|_{0,\Omega}$. From the definition of $\widetilde{P}$ we have

$$\int_M (\widetilde{P}p)^2 = \int_M \widetilde{P}p \left(\sum_{i=1}^4 \frac{c_i}{J_{F_M}} \chi_{K_i}\right) \le \frac{1}{\min\limits_M J_{F_M}} \int_M \widetilde{P}p \left(\sum_{i=1}^4 c_i \chi_{K_i}\right).$$

On the other hand, if we write $\sum_{i=1}^4 c_i\chi_{K_i}$ in terms of the basis functions q_i, we obtain $\sum_{i=1}^4 c_i\chi_{K_i} = \sum_{i=1}^4 d_i q_i$, with d_i related to c_i by

$$\begin{pmatrix} d_1 \\ d_2 \\ d_3 \\ d_4 \end{pmatrix} = \frac{1}{2} \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & -1 & -1 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \end{pmatrix} \begin{pmatrix} c_1 \\ c_2 \\ c_3 \\ c_4 \end{pmatrix}.$$

Hence

$$|d_i| \le 2 \max_{1\le j\le 4} |c_j|, \qquad i = 1, 2, 3, 4.$$

Therefore, from the definition of $\widetilde{P}$ we have

$$\begin{aligned} \int_M \widetilde{P}p \left(\sum_{i=1}^4 c_i\chi_{K_i}\right) &= \int_M \widetilde{P}p \left(\sum_{i=1}^4 d_i q_i\right) = \sum_{i=1}^3 d_i \left(\int_M pq_i\right) \\ &\le \|p\|_{0,M} \left(\sum_{i=1}^3 |d_i|\, \|q_i\|_{0,M}\right) \le C|M|^{1/2}\|p\|_{0,M} \left(\max_{1\le j\le 4} |c_j|\right) \\ &\le C \max_M J_{F_M} \|p\|_{0,M} \|\widetilde{P}p\|_{0,M}, \end{aligned}$$

where we have used that

$$\int_{K_j} (\widetilde{P}p)^2 = c_j^2 \int_{K_j} \frac{1}{J_{F_M}^2} \ge \frac{|K_j|}{\max\limits_M J_{F_M}^2} c_j^2$$

and that $|M| \le C|K_j|$, $j = 1, 2, 3, 4$, with C depending only on σ and ϱ. Now, using the inequalities above and noting that, for a quadrilateral regular mesh, $\max_M J_{F_M} \le C \min_M J_{F_M}$ with a constant C independent of h, we obtain (3.6).

To verify (3.7), let $P : \mathrm{L}^2(\Omega) \longrightarrow \widetilde{Q}_h$ be the orthogonal projection onto $\widetilde{Q}_h$. Let $v \in \mathrm{H}_0^1(\Omega)$ be such that $\|v\|_{1,\Omega} = 1$. By the definition of P, (3.6), and the fact that $\widetilde{Q}_h$ contains the piecewise constants over $\mathcal{T}_{2h}$, we have

$$\begin{aligned} (p - \widetilde{P}p, v) &= (p - \widetilde{P}p, v - Pv) \le \|p - \widetilde{P}p\|_{0,\Omega} \|v - Pv\|_{0,\Omega} \\ &\le C\|p\|_{0,\Omega}\|v - Pv\|_{0,\Omega} \le Ch\|p\|_{0,\Omega}\|v\|_{1,\Omega}. \end{aligned}$$

Thus we conclude (3.7). □

Now we are in order to define an operator Π as required in Theorem 3.1.

LEMMA 3.4. *Let (β, w, γ) be the solution of (2.1) and $\widetilde{\beta} \in \widetilde{H}_h^1$ be as in Lemma 3.2. Then there exists an operator $\Pi : \mathrm{H}_0(\mathrm{rot}, \Omega) \cap \mathrm{H}^1(\Omega)^2 \longrightarrow \Gamma_h$ such that (3.2) and (3.3) hold true.*

Proof. For $\eta \in \mathrm{H}_0(\mathrm{rot}, \Omega) \cap \mathrm{H}^1(\Omega)^2$, let $\Pi\eta := R(\eta - L\eta)$, where $L\eta := \mathbf{curl}\, \phi := (-\partial\phi/\partial x_2, \partial\phi/\partial x_1)$, with $\phi \in \mathrm{H}^1(\Omega)$ being a solution of

$$-\Delta\phi = \mathrm{rot}\, R\eta - \widetilde{P}(\mathrm{rot}\, R\eta) \quad \text{in } \Omega,$$

with homogeneous Neumann boundary conditions. Note that this problem is compatible since its right-hand side belongs to $\mathrm{rot}\,\Gamma_h \subset \mathrm{L}_0^2(\Omega)$. Then the standard estimates for the Neumann problem yield

$$\|L\eta\|_{m+1,\Omega} \leq \|\mathrm{rot}\, R\eta - \widetilde{P}(\mathrm{rot}\, R\eta)\|_{m,\Omega}, \qquad m = -1, 0. \tag{3.8}$$

Also note that

$$\mathrm{rot}\, L\eta = -\Delta\phi = \mathrm{rot}\, R\eta - \widetilde{P}(\mathrm{rot}\, R\eta). \tag{3.9}$$

From the definition of the operator Π, we have

$$\|\eta - \Pi\eta\|_{0,\Omega} \leq \|\eta - R\eta\|_{0,\Omega} + \|RL\eta\|_{0,\Omega}.$$

The first term on the right-hand side is bounded by (2.9), while for the second term we use again (2.9), (3.8), Lemma 3.3, and (2.8) to obtain

$$\begin{aligned}\|RL\eta\|_{0,\Omega} &\leq \|L\eta - RL\eta\|_{0,\Omega} + \|L\eta\|_{0,\Omega} \leq Ch\|L\eta\|_{1,\Omega} + \|L\eta\|_{0,\Omega} \\ &\leq Ch\|\mathrm{rot}\, R\eta - \widetilde{P}(\mathrm{rot}\, R\eta)\|_{0,\Omega} + C\|\mathrm{rot}\, R\eta - \widetilde{P}(\mathrm{rot}\, R\eta)\|_{-1,\Omega} \\ &\leq Ch\|\mathrm{rot}\, R\eta\|_{0,\Omega} \leq Ch\|\eta\|_{1,\Omega}.\end{aligned}$$

Thus we conclude (3.2).

To prove (3.3), note that (2.7) and Lemma 3.2 yield

$$\int_\Omega \mathrm{rot}\left[R(\widetilde{\beta} - \beta)\right] q_h = 0 \qquad \forall q_h \in \widetilde{Q}_h,$$

whereas, since $\widetilde{\beta} \in \widetilde{H}_h^1$, from (2.7) and the definition of $\widetilde{H}_h^1$ we have

$$\int_\Omega \mathrm{rot}\, R\widetilde{\beta}\, q_h = \int_\Omega \mathrm{rot}\, \widetilde{\beta}\, q_h = 0 \qquad \forall q_h \in Q_{h4}.$$

Hence, since $\mathrm{rot}\, R\widetilde{\beta} \in \mathrm{rot}\,\Gamma_h$, from (3.5) we conclude that $\widetilde{P}(\mathrm{rot}\, R\beta) = \mathrm{rot}\, R\widetilde{\beta}$. Therefore,

$$\mathrm{rot}\, R\widetilde{\beta} = \widetilde{P}(\mathrm{rot}\, R\beta) = -\frac{t^2}{\kappa}\widetilde{P}(\mathrm{rot}\, R\gamma), \tag{3.10}$$

because of the definition of γ in (2.1) and the fact that $\mathrm{rot}\, R(\nabla w)$ vanishes, as a consequence of Lemma 2.1.

On the other hand, note that

$$\mathrm{rot}\, RL\gamma = \mathrm{rot}\, L\gamma. \tag{3.11}$$

Indeed, $\operatorname{rot} RL\gamma$ and $\operatorname{rot} L\gamma$ both belong to $\operatorname{rot}\Gamma_h$ (the latter because of (3.9)). Then, from the characterization (3.4) of this space, it is enough to verify that $\int_K \operatorname{rot} RL\gamma = \int_K \operatorname{rot} L\gamma \ \forall K \in \mathcal{T}_h$, which in its turn is a consequence of (2.7). Therefore, from the definition of Π, (3.11), and (3.9), we obtain

$$\operatorname{rot}\Pi\gamma = \operatorname{rot} R(\gamma - L\gamma) = \operatorname{rot} R\gamma - \operatorname{rot} L\gamma = \widetilde{P}(\operatorname{rot} R\gamma),$$

which together with (3.10) allows us to conclude (3.2). □

3.2. ***DL*4.** The convergence of this method follows immediately from that of *MITC*4. However, we have an alternative proof valid for any regular mesh without the need of Assumption 3.1.

In this case, to define the approximation $\widetilde{\beta}$ of β and the operator Π satisfying the hypotheses of Theorem 3.1, we use some known results for the Stokes problem (see Girault and Raviart [14]).

LEMMA 3.5. *There exists $\widetilde{\beta} \in H_h^2$ such that* (3.1) *holds true. Furthermore, $R\widetilde{\beta} = R\beta$.*

Proof. By using results from [14] (section 3.1, chapter II) and taking into account a rotation of the space $\mathrm{H}(\operatorname{div},\Omega)$, it follows that for $\beta \in \mathrm{H}_0^1(\Omega)^2$ there exists $\widetilde{\beta} \in H_h^2$ such that

$$\int_\ell (\widetilde{\beta} - \beta)\cdot\tau_\ell = 0 \qquad \forall \ell \in \mathcal{T}_h,$$

and

$$|\widetilde{\beta} - \beta|_{m,\Omega} \le Ch^{k-m}|\beta|_{k,\Omega}, \qquad m = 0, 1, \quad k = 1, 2.$$

Then $R(\widetilde{\beta} - \beta) = 0$ because of the definition of R, whereas (3.1) corresponds to the inequality above for $k = 2$ and $m = 1$. □

LEMMA 3.6. *There exists an operator $\Pi : \mathrm{H}_0(\operatorname{rot},\Omega) \cap \mathrm{H}^1(\Omega)^2 \longrightarrow \Gamma_h$ such that* (3.3) *and* (3.2) *hold.*

Proof. Because of the previous lemma we have $R(\widetilde{\beta} - \beta) = 0$. On the other hand, $\operatorname{rot} R(\nabla w) = 0$ because of Lemma 2.1. Then it is enough to take $\Pi = R$ to obtain (3.3), whereas (3.2) follows from (2.9). □

3.3. Main result in $\mathbf{H}^1$ norm. Now we are in position to establish the error estimates. As above, in the case of *MITC*4, we consider meshes satisfying Assumption 3.1.

THEOREM 3.7. *Given $(\theta, f) \in \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega)$, let (β, w) and (β_h, w_h) be the solutions of Problems* 2.1 *and* 2.3, *respectively. Then there exists a constant C, independent of t and h, such that*

$$\|\beta - \beta_h\|_{1,\Omega} + \|w - w_h\|_{1,\Omega} \le Ch|(\theta, f)|_t.$$

Proof. The proof is a direct consequence of Lemmas 3.2, 3.4, 3.5 and 3.6, Theorem 3.1, and the a priori estimate (2.2). □

4. $\mathbf{L}^2$ error estimates. Our next goal is to prove L^2 error estimates optimal in order and regularity. To do this, we follow the techniques in [13], where a triangular element similar to *DL*4 is analyzed, although the arguments therein cannot be directly applied to our case. Let us remark that, in the case of *MITC*4, this result completes the analysis carried out in [10, 18] for higher-order methods.

Our proofs are based on a standard Nitsche duality argument. However, since the methods are nonconforming, additional consistency terms also arise. Then higher-order estimates must be proved for these terms too, which is the most delicate part of the paper.

First, we introduce the dual problem corresponding to (2.1). Let $(\varphi, u) \in \mathrm{H}_0^1(\Omega)^2 \times \mathrm{H}_0^1(\Omega)$ be the solution of

$$\left\{ \begin{array}{l} a(\eta, \varphi) + (\nabla v - \eta, \delta) = (v, w - w_h) + (\eta, \beta - \beta_h) \\ \qquad\qquad\qquad\qquad\qquad\qquad \forall (\eta, v) \in \mathrm{H}_0^1(\Omega)^2 \times \mathrm{H}_0^1(\Omega), \\ \delta = \dfrac{\kappa}{t^2}(\nabla u - \varphi). \end{array} \right. \tag{4.1}$$

By taking $\eta = 0$ in (4.1), we have

$$\operatorname{div} \delta = w_h - w. \tag{4.2}$$

An a priori estimate analogous to (2.2) yields for this problem

$$\|\varphi\|_{2,\Omega} + \|u\|_{2,\Omega} + \|\delta\|_{0,\Omega} + t\,\|\delta\|_{1,\Omega} \leq C\left(\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}\right). \tag{4.3}$$

The arguments in the proof of Lemma 3.4 in [13] can be used in our case leading to the following result.

Lemma 4.1. *Given $(\theta, f) \in \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega)$, let (β, w, γ) and (β_h, w_h, γ_h) be the solutions of* (2.1) *and* (2.10), *respectively. Let (φ, u, δ) be the solution of* (4.1). *Let $\widetilde{\varphi} \in H_h$ be the vector field associated to φ by Lemma* 3.2 *or* 3.5 *for MITC*4 *or DL*4, *respectively. Then there exists a constant C, independent of t and h, such that*

$$\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega} \leq Ch^2|(\theta, f)|_t + \frac{|(\beta_h - R\beta_h, \delta)| + |(\gamma, \widetilde{\varphi} - R\widetilde{\varphi})|}{\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}}.$$

Our next step is to prove that the last term in the inequality above is $\mathcal{O}(h^2)$ too. A similar result has been proved in [13] in the case of triangular meshes. That proof relies on a technical result for the rotated Raviart–Thomas interpolant R (Lemma 3.3 of that reference). It is easy to check that the arguments given there do not apply for quadrilateral elements. Therefore, we need to introduce new arguments, and this is the aim of the following lemma.

Lemma 4.2. *Given $\zeta \in H(\operatorname{div}, \Omega)$ and $\psi \in \mathrm{H}_0^1(\Omega)^2$, there holds*

$$|(\zeta, \psi - R\psi)| \leq Ch^2 \left(\sum_K |R\psi - \psi|_{1,K}^2 \right)^{1/2} \|\operatorname{div} \zeta\|_{0,\Omega} + Ch\|\operatorname{rot}(R\psi - \psi)\|_{0,\Omega}\,\|\zeta\|_{0,\Omega}.$$

Proof. For $K \in \mathcal{T}_h$, let $s_K \in \mathrm{H}^1(K)$ be a solution of

$$-\Delta s_K = \operatorname{rot}(R\psi - \psi) \quad \text{in } K,$$

with homogeneous Neumann boundary conditions. By virtue of (2.7) we know that the above problem is compatible. Hence s_K satisfies

$$\|\operatorname{curl} s_K\|_{m+1,K} \leq C\|\operatorname{rot}(R\psi - \psi)\|_{m,K}, \qquad m = -1, 0. \tag{4.4}$$

The Laplace equation above can be equivalently written

$$\operatorname{rot}\left[\operatorname{curl} s_K - (R\psi - \psi)\right] = 0,$$

and, hence, there exists $r_K \in \mathrm{H}^1(K)$ (unique up to an additive constant) such that

$$\nabla r_K = \operatorname{curl} s_K - (R\psi - \psi). \tag{4.5}$$

Moreover, from the homogeneous Neumann boundary condition satisfied by s_K, we have $\nabla r_K \cdot \tau_\ell = -R\psi \cdot \tau_\ell + \psi \cdot \tau_\ell$ for each edge ℓ of K. Thus, if we define $G \in \mathrm{L}^2(\Omega)^2$ such that $G|_K = \nabla r_K$, then $G \in \mathrm{H}_0(\mathrm{rot}, \Omega)$ and $\operatorname{rot} G = 0$.

Hence there exists $r \in \mathrm{H}^1(\Omega)/\mathbb{R}$ such that $G = \nabla r$ in Ω. Furthermore, since $G \in \mathrm{H}_0(\mathrm{rot}, \Omega)$, r can be chosen in $\mathrm{H}_0^1(\Omega)$ and the additive constants defining r_K on each $K \in \mathcal{T}_h$ can be fixed as to satisfy $r|_K = r_K$.

Let A and B be as in Figure 2.2. Then, because of (2.6), we have

$$r(B) = r(A) + \int_\ell \nabla r_K \cdot \tau_\ell = r(A) + \int_\ell (-R\psi + \psi) \cdot \tau_\ell = r(A).$$

Thus r vanishes at all nodes of $\mathcal{T}_h$, since $r|_{\partial\Omega} = 0$. Hence a standard scaling argument on each element K yields $\|r\|_{0,K} \leq Ch^2 |r_K|_{2,K}$ (see, for instance, [11]), and then, by using (4.5) and (4.4), we have

$$\begin{aligned} \|r\|_{0,K} &\leq Ch^2 \left|\nabla r_K\right|_{1,K} \leq Ch^2 \left(\left|\operatorname{curl} s_K\right|_{1,K} + \left|R\psi - \psi\right|_{1,K} \right) \\ &\leq Ch^2 \left[\left\|\operatorname{rot}(R\psi - \psi)\right\|_{0,K} + \left|R\psi - \psi\right|_{1,K} \right] \leq Ch^2 \left|R\psi - \psi\right|_{1,K}. \end{aligned} \tag{4.6}$$

On the other hand, let $(\cdot,\cdot)_K$ be the usual inner product in $\mathrm{L}^2(K)$ and P the orthogonal projection onto the constant functions. Because of (2.7), we have, $\forall \eta \in \mathrm{H}_0^1(\Omega)$,

$$\frac{\big(\operatorname{rot}(R\psi - \psi), \eta\big)_K}{\|\eta\|_{1,K}} = \frac{\big(\operatorname{rot}(R\psi - \psi), \eta - P\eta\big)_K}{\|\eta\|_{1,K}} \leq \frac{\left\|\operatorname{rot}(R\psi - \psi)\right\|_{0,K} \left\|\eta - P\eta\right\|_{0,K}}{\|\eta\|_{1,K}}.$$

Hence

$$\left\|\operatorname{rot}(R\psi - \psi)\right\|_{-1,K} \leq Ch \left\|\operatorname{rot}(R\psi - \psi)\right\|_{0,K}.$$

Now, let $S \in \mathrm{L}^2(\Omega)^2$ be such that $S|_K = \operatorname{curl} s_K$. Therefore, because of (4.4) we have

$$\begin{aligned} \|S\|_{0,\Omega}^2 &= \sum_{K \in \mathcal{T}_h} \left\|\operatorname{curl} s_K\right\|_{0,K}^2 \leq \sum_{K \in \mathcal{T}_h} \left\|\operatorname{rot}(R\psi - \psi)\right\|_{-1,K}^2 \\ &\leq Ch^2 \sum_{K \in \mathcal{T}_h} \left\|\operatorname{rot}(R\psi - \psi)\right\|_{0,K}^2 \leq Ch^2 \left\|\operatorname{rot}(R\psi - \psi)\right\|_{0,\Omega}^2. \end{aligned} \tag{4.7}$$

Finally, from (4.5) we obtain

$$|(\zeta, \psi - R\psi)| = \left| \int_\Omega \zeta \cdot \nabla r + \int_\Omega \zeta \cdot S \right| \leq \|\operatorname{div} \zeta\|_{0,\Omega} \|r\|_{0,\Omega} + \|\zeta\|_{0,\Omega} \|S\|_{0,\Omega},$$

and the lemma follows by using (4.6) and (4.7). □

To obtain a bound of the consistency term in Lemma 4.1, there remains only to estimate the terms involving $(R\psi - \psi)$ of the previous lemma. To this aim, we use the analogue of Theorem 4.3 in [24] applied to our situation in the space $\mathrm{H}(\mathrm{rot}, \Omega)$, which reads

$$|\psi - R\psi|_{1,K} \leq C \left(|\psi|_{1,K} + h_K \left|\operatorname{rot} \psi\right|_{1,K} \right) \leq \|\psi\|_{2,K} \tag{4.8}$$

and

$$\|\operatorname{rot}(\psi - R\psi)\|_{0,K} \le C\left(\frac{\delta_K}{h_K}|\operatorname{rot}\psi|_{0,K} + h_K|\operatorname{rot}\psi|_{1,K}\right), \tag{4.9}$$

where δ_K is a measure of the deviation of the quadrilateral K from a parallelogram, as defined in Figure 4.1.

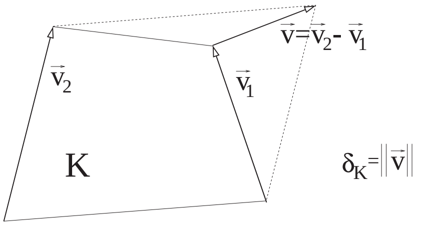

FIG. 4.1. *Geometrical definition of δ_K.*

Note that for shape-regular meshes clearly $\delta_K/h_K \le C\ \forall K \in \mathcal{T}_h$. On the other hand, $\{\mathcal{T}_h\}$ is said to be a family of *asymptotically parallelogram* meshes when there exists a constant C such that $\max_{K\in\mathcal{T}_h}(\delta_K/h_K) \le Ch$ for all the meshes.

Now we are in position to estimate the consistency term in Lemma 4.1.

LEMMA 4.3. *Let β_h, δ, γ, and $\widetilde{\varphi}$ be as in Lemma* 4.1. *Then there holds*

$$\frac{|(\beta_h - R\beta_h, \delta)| + |(\gamma, \widetilde{\varphi} - R\widetilde{\varphi})|}{\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}} \le Ch\left(h + t\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}\right)|(\theta, f)|_t.$$

Proof. First, we have

$$|(\beta_h - R\beta_h, \delta)| \le \left|\left((\beta_h - \beta) - R(\beta_h - \beta), \delta\right)\right| + |(\beta - R\beta, \delta)|.$$

By using (2.9), Theorem 3.7, and (4.3), we obtain

$$\begin{aligned}\left|\left((\beta_h - \beta) - R(\beta_h - \beta), \delta\right)\right| &\le Ch\|\beta_h - \beta\|_{1,\Omega}\|\delta\|_{0,\Omega} \le Ch^2|(\theta, f)|_t\|\delta\|_{0,\Omega}\\ &\le Ch^2|(\theta, f)|_t\left(\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}\right).\end{aligned}$$

On the other hand, by the definition of γ in (2.1) and the estimate (2.2), we have

$$|\operatorname{rot}\beta|_{0,K} = \frac{t^2}{\kappa}|\operatorname{rot}\gamma|_{0,K} \le Ct|(\theta, f)|_t.$$

Then, by using Lemma 4.2, (4.8), (4.9), the estimate above, (2.2), (4.2), and (4.3), we have

$$\begin{aligned}|(\beta - R\beta, \delta)| &\le Ch^2\left(\sum_K|R\beta - \beta|_{1,K}^2\right)^{1/2}\|\operatorname{div}\delta\|_{0,\Omega} + Ch\|\operatorname{rot}(R\beta - \beta)\|_{0,\Omega}\|\delta\|_{0,\Omega}\\ &\le Ch^2\|\beta\|_{2,\Omega}\|\operatorname{div}\delta\|_{0,\Omega} + Ch\left(\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}|\operatorname{rot}\beta|_{0,\Omega} + h|\operatorname{rot}\beta|_{1,\Omega}\right)\|\delta\|_{0,\Omega}\\ &\le Ch^2|(\theta, f)|_t\|\operatorname{div}\delta\|_{0,\Omega} + Ch\left(h + t\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}\right)|(\theta, f)|_t\|\delta\|_{0,\Omega}\\ &\le Ch\left(h + t\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}\right)|(\theta, f)|_t\left(\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}\right).\end{aligned}$$

The term $|(\gamma, \widetilde{\varphi} - R\widetilde{\varphi})|$ can be bounded almost identically by using Lemma 3.2 for *MITC*4 or Lemma 3.5 for *DL*4 to estimate $\|\widetilde{\varphi} - \varphi\|_{1,\Omega}$ and the fact that

$$-\operatorname{div}\gamma = f \qquad \text{in } \Omega,$$

which follows by taking $\eta = 0$ in the first equation of (2.1). Therefore, we obtain

$$|(\gamma, \widetilde{\varphi} - R\widetilde{\varphi})| \le Ch\left(h + t\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}\right)|(\theta, f)|_t\left(\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega}\right),$$

which allows us to conclude the proof. □

Finally, we can establish an $\mathrm{L}^2(\Omega)$ error estimate. As above, in the case of *MITC*4 elements, we consider meshes satisfying Assumption 3.1.

THEOREM 4.4. *Given $(\theta, f) \in \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega)$, let (β, w) and (β_h, w_h) be the solutions of Problems* 2.1 *and* 2.3*, respectively. Then there exists a constant C, independent of t and h, such that*

$$\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega} \le Ch\left(h + t\max_{K\in\mathcal{T}_h}\frac{\delta_K}{h_K}\right)|(\theta, f)|_t\,.$$

Proof. The proof is a direct consequence of Lemmas 4.1 and 4.3. □

COROLLARY 4.5. *The following error estimate holds for any family of asymptotically parallelogram meshes:*

$$\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega} \le Ch^2\,|(\theta, f)|_t\,.$$

Remark 4.1. The asymptotically parallelogram assumption on the meshes is not necessary as long as $h > \alpha t$ for α fixed. Indeed, according to Theorem 4.4, for general regular meshes with $h > \alpha t$, we have

$$\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega} \le C_\alpha h^2|(\theta, f)|_t.$$

Note that the condition $h > \alpha t$ is fulfilled in practice for reasonably large values of α.

5. The spectral problem.

The aim of this section is to study how the eigenvalues and eigenfunctions of Problem 2.4 approximate those of Problem 2.2. We do this in the framework of the abstract spectral approximation theory as stated, for instance, in the monograph by Babuška and Osborn [5]. In order to use this theory, we define operators T and T_h associated to the continuous and discrete spectral problems, respectively.

We consider the operator

$$T : \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega) \longrightarrow \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega),$$

defined by $T(\theta, f) := (\beta, w)$, where $(\beta, w) \in \mathrm{H}^1_0(\Omega)^2 \times \mathrm{H}^1_0(\Omega)$ is the solution of Problem 2.1. Note that T is compact as a consequence of estimate (2.2). Since the operator is clearly self-adjoint with respect to $(\cdot,\cdot)_t$, then, apart from $\mu = 0$, its spectrum consists of a sequence of finite multiplicity real eigenvalues converging to zero. Note that λ is an eigenvalue of Problem 2.2 if and only if $\mu := 1/\lambda$ is an eigenvalue of T, with the same multiplicity and corresponding eigenfunctions.

As shown in [13], each eigenvalue μ of Problem 2.1 converges to some limit μ_0 when the thickness $t \to 0$. Indeed, μ_0 is an eigenvalue of the operator associated with the Kirchhoff model of the same plate (see Lemma 2.1 in [13]). From now on, for simplicity, we assume that $\mu = 1/\lambda$ is an eigenvalue of T which converges to a simple eigenvalue μ_0, as t goes to zero (see section 2 in [13] for further discussions).

Now, analogously to the continuous case, we introduce the operator

$$T_h : \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega) \longrightarrow \mathrm{L}^2(\Omega)^2 \times \mathrm{L}^2(\Omega),$$

defined by $T_h(\theta, f) := (\beta_h, w_h)$, where $(\beta_h, w_h) \in H_h \times W_h$ is the solution of Problem 2.3. The operator T_h is also self-adjoint with respect to $(\cdot,\cdot)_t$. Clearly, the eigenvalues of T_h are given by $\mu_h := 1/\lambda_h$, with λ_h being the strictly positive eigenvalues of Problem 2.4, and the corresponding eigenfunctions coincide.

As a consequence of Theorem 3.7, for each simple eigenvalue μ of T, there is exactly one eigenvalue μ_h of T_h converging to μ as h goes to zero (see, for instance, [16]). The following theorem shows optimal t-independent error estimates. Let us remark that the results of this theorem are valid for both methods $MITC4$ and $DL4$, although, for the former, under Assumption 3.1 on the meshes as in the previous section.

THEOREM 5.1. *Let λ and λ_h be simple eigenvalues of Problems* 2.2 *and* 2.4*, respectively, such that $\lambda_h \to \lambda$ as $h \to 0$. Let (β, w) and (β_h, w_h) be corresponding eigenfunctions normalized in the same manner. Then, under the assumptions stated above, there exists $C > 0$ such that, for t and h small enough, there holds*

$$\|\beta - \beta_h\|_{1,\Omega} + \|w - w_h\|_{1,\Omega} \leq Ch.$$

Furthermore, for any family of asymptotically parallelogram meshes, there hold

$$\|\beta - \beta_h\|_{0,\Omega} + \|w - w_h\|_{0,\Omega} \leq Ch^2$$

and

$$|\lambda - \lambda_h| \leq Ch^2.$$

Proof. The proof, which relies on Theorem 3.7 and Corollary 4.5, is essentially the same as those of Theorems 2.1, 2.2, and 2.3 in [13]. □

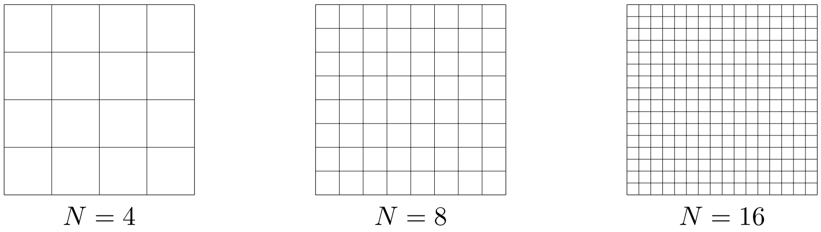
6. Numerical experiments. In this section, we report some numerical experiments carried out with both methods applied to the spectral problem, Problem 2.2.

First, we have tested the two methods by using different meshes, not necessarily satisfying the assumptions in the theorems above. We have considered a square clamped moderately thick plate of side-length L and thickness-to-span ratio $t/L = 0.1$. We report the results obtained with both types of elements using the following three families of meshes:

$\mathcal{T}_h^{\mathrm{U}}$ consists of uniform subdivisions of the domain into $N \times N$ subsquares for $N = 4, 8, 16, \ldots$ (see Figure 6.1). Clearly, these are parallelogram meshes satisfying Assumption 3.1.

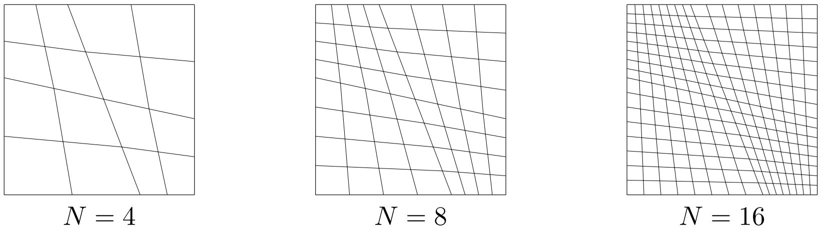
$\mathcal{T}_h^{\mathrm{A}}$ consists of "uniform" refinements of a nonuniform mesh obtained by splitting the square into four quadrilaterals. Each refinement step is obtained by subdividing each quadrilateral into the other four, by connecting the midpoints of the opposite edges. Thus we obtain a family of $N \times N$ asymptotically parallelogram-shape-regular meshes as shown in Figure 6.2. Furthermore, for $N = 4, 8, 16, \ldots$, these meshes satisfy Assumption 3.1.

$\mathcal{T}_h^{\mathrm{T}}$ consists of partitions of the domain into $N \times N$ congruent trapezoids, all similar to the trapezoid with vertices $(0,0)$, $(1/2,0)$, $(1/2,2/3)$, and $(0,1/3)$, as shown in Figure 6.3. Clearly, these are not asymptotically parallelogram meshes and they do not satisfy Assumption 3.1.



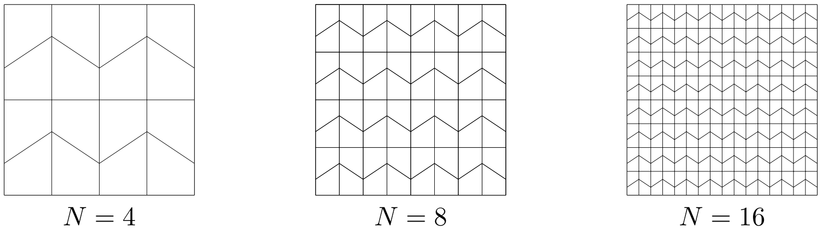
$N = 4$ $N = 8$ $N = 16$

FIG. 6.1. *Uniform square meshes* $\mathcal{T}_h^{\mathrm{U}}$.



$N = 4$ $N = 8$ $N = 16$

FIG. 6.2. *Asymptotically parallelogram meshes* $\mathcal{T}_h^{\mathrm{A}}$.



$N = 4$ $N = 8$ $N = 16$

FIG. 6.3. *Trapezoidal meshes* $\mathcal{T}_h^{\mathrm{T}}$.

Let us remark that the third family was used in [3, 4] to show that the order of convergence of some finite elements deteriorate on these meshes in spite of the fact that they are shape-regular.

We have computed approximations of the free-vibration angular frequencies $\omega = t\sqrt{\lambda/\rho}$ corresponding to the lowest-frequency vibration modes of the plate. In order to compare the obtained results with those in [1], we present the computed frequencies ω_{mn}^h in the nondimensional form

$$\hat{\omega}_{mn} := \omega_{mn}^h L \left[\frac{2(1+\nu)\rho}{E}\right]^{1/2},$$

m and n being the numbers of half-waves occurring in the mode shapes in the x and y directions, respectively.

Tables 6.1 and 6.2 show the four lowest-vibration frequencies computed by our method with successively refined meshes of each type, $\mathcal{T}_h^{\mathrm{U}}$, $\mathcal{T}_h^{\mathrm{A}}$, and $\mathcal{T}_h^{\mathrm{T}}$. Each table also includes the values of the vibration frequencies obtained by extrapolating the computed ones as well as the estimated order of convergence. Finally, each table also includes in its last column the results reported in [1]. In every case, we have used a Poisson ratio $\nu = 0.3$ and a correction factor $k = 0.8601$. The reported nondimensional frequencies are independent of the remaining geometrical and physical parameters, except for the thickness-to-span ratio.

Table 6.1
Scaled vibration frequencies $\hat{\omega}_{mn}$ computed with MITC4.

	$\hat{\omega}_{21}$	3.0606	3.0445	3.0403	3.0388	1.94	3.039
	$\hat{\omega}_{12}$	3.0654	3.0453	3.0405	3.0390	2.05	3.039
	$\hat{\omega}_{22}$	4.3131	4.2754	4.2657	4.2623	1.96	4.263

It can be clearly seen that both methods converge for the three types of meshes with an optimal $\mathcal{O}(h^2)$ order. Hence none of the two particular assumptions on the meshes (Assumption 3.1 and the assumption of being asymptotically parallelogram) seem to be actually necessary.

As a second test, we have made a numerical experiment to assess the stability of the methods as the thickness t goes to zero. We have used a sequence of clamped plates with decreasing values of the thickness-to-span ratios: $t/L = 0.1$, 0.01, 0.001, 0.0001. All the other geometrical and physical parameters have been taken as in the previous test.

We have computed again approximations of the free-vibration angular frequencies $\omega = t\sqrt{\lambda/\rho}$. The quotients ω/t are known to converge to the corresponding vibration frequencies of an identical Kirchhoff plate (i.e., to the frequencies obtained from the Kirchhoff model for the deflection of a similar zero-thickness ideal plate; see Lemma 2.1 from [13]). Because of this, we present now the computed frequencies ω_{mn}^h scaled in the following manner:

$$\tilde{\omega}_{mn} := \omega_{mn}^h \frac{L}{t} \left[\frac{2(1+\nu)\rho}{E} \right]^{1/2}.$$

Table 6.3
Scaled vibration frequency $\tilde{\omega}_{11}$ computed with $DL4$ for different thickness-to-span ratios t/L.

	0.0001	17.5903	17.5673	17.5611	17.5588	1.89
	0 (extrap.)	17.5903	17.5674	17.5611	17.5588	1.89

The obtained results have been qualitatively similar for both methods. We report only those obtained with $DL4$, since the performance of $MITC4$ has been assessed in many other papers (see, for instance, [8], as well as [15] for the vibration problem).

We present in Table 6.3 the results for the lowest-frequency vibration mode, with the same meshes as in the previous test. In each case, for each thickness-to-span ratio t/L, we have computed again an extrapolated, more accurate value of the scaled vibration frequency and the estimated order of convergence. Finally we have also estimated by extrapolation the limit values of the scaled frequencies $\tilde{\omega}_{mn}$ as t goes to zero.

Table 6.4
Extrapolated values as $(t/L) \to 0$ of the scaled vibration frequencies $\tilde{\omega}_{mn}$ computed with $DL4$.

Mesh	Mode	$N = 16$	$N = 32$	$N = 64$	Extrap.	Order
$\mathcal{T}_h^{\mathrm{U}}$	$\hat{\omega}_{11}$	17.5977	17.5687	17.5614	17.5590	2.00
	$\hat{\omega}_{21}$	36.2064	35.9115	35.8374	35.8125	1.99
	$\hat{\omega}_{12}$	36.2064	35.9115	35.8374	35.8126	1.99
	$\hat{\omega}_{22}$	53.4123	52.9570	52.8428	52.8045	1.99
$\mathcal{T}_h^{\mathrm{A}}$	$\hat{\omega}_{11}$	17.5565	17.5583	17.5588	17.5590	1.76
	$\hat{\omega}_{21}$	35.9947	35.8590	35.8243	35.8123	1.97
	$\hat{\omega}_{12}$	36.2003	35.9102	35.8371	35.8124	1.99
	$\hat{\omega}_{22}$	53.3174	52.9353	52.8374	52.8037	1.97
$\mathcal{T}_h^{\mathrm{T}}$	$\hat{\omega}_{11}$	17.5904	17.5673	17.5611	17.5588	1.89
	$\hat{\omega}_{21}$	36.0770	35.8823	35.8303	35.8113	1.90
	$\hat{\omega}_{12}$	36.2500	35.9259	35.8412	35.8112	1.94
	$\hat{\omega}_{22}$	53.5074	52.9936	52.8526	52.7993	1.87

Note that the extrapolated values for each thickness-to-span ratio are almost identical for the three meshes. Moreover, although the estimated orders of convergence seem to deteriorate a bit as t/L goes to zero for the nonuniform meshes, the values obtained with these meshes are better than those computed with the uniform mesh (i.e., closer to the extrapolated ones), even for the coarser meshes. Therefore, this test suggests that the method is locking-free for any kind of regular mesh.

Finally, we report in Table 6.4 the corresponding extrapolated values as t/L goes to zero for the four lowest-scaled vibration frequencies. It can be seen from this table that the results are essentially the same as for $\tilde{\omega}_{11}$. Furthermore, the computed orders of convergence are even closer to 2.

Further experiments with *MITC*4 have been reported in [15], including other boundary conditions and the extension of this method to compute the vibration modes of Naghdi shells.

$O(h^2)$ GLOBAL POINTWISE ALGORITHMS FOR DELAY QUADRATIC PROBLEMS IN THE CALCULUS OF VARIATIONS[*]

OM PRAKASH AGRAWAL[†] AND JOHN GREGORY[‡]

Abstract. The main purpose of this paper is to give numerical algorithms and the error analysis for delay quadratic problems in the calculus of variations. These methods are new, efficient, and accurate and have a global a priori error of $O(h^2)$, where h is the distance between any two successive node points.

We also derive the results for the general, numerical, delay problem, but we focus on proving our results in the simpler quadratic case since the extra technical numerical details have been given previously by the second author. In addition, the authors have previously shown how to reformulate general delay constrained problems in optimal control theory/constrained calculus of variations as unconstrained delay problems. Thus our numerical results and methods will hold for these general constrained problems also.

Finally, we note that our algorithm, which solves the stationary condition(s) numerically, avoids the more difficult problems of piecing the solution of second order equations together and requires less smoothness in the solution. Thus we replace difficult second order boundary value problems with the easier task of approximating definite integrals involving first order derivatives.

Key words. numerical delay extremal solutions, $O(h^2)$ global error

1. Introduction.

The specific purpose of this paper is to give numerical methods and efficient algorithms for extremal values of functionals in the form

$$J(y) = \frac{1}{2}\int_a^b [r(t)y'^2(t) + \bar{r}_\tau(t)y'^2_\tau(t) + p(t)y^2(t) + \bar{p}_\tau(t)y^2_\tau(t)]dt, \tag{1.1}$$

where $y_\tau(t) \equiv y(t-\tau)$, etc. and $0 < \tau < b-a$. This presentation represents the quadratic form theory for delay problems associated with the more general integral

$$I(y) = \int_a^b f(t, y, y', y_\tau, y'_\tau)dt. \tag{1.2}$$

For either (1.1) or (1.2), we assume

$$y(t) = \alpha(t), \quad t \in [a-\tau, \alpha], \tag{1.3}$$

and the usual smoothness conditions as in [3] to pose a well-defined problem.

The problems of the above type have been considered by several investigators. Eller and Aggarwal [5] presented an optimal control solution for a linear time varying system with delay. The formulation is complex because it requires solution of a system of partial differential equations. Several investigators have used Walsh, block pulse,

shifted Legendre, and other polynomial approaches to solve linear and nonlinear optimal control problems with delay [4, 5, 9, 11, 14]. Although these papers develop algorithms to solve the problems, they do not provide convergence proof for the algorithms. References [12] and [10, 13, 15] presented formulations and algorithms for optimal control computations for linear and nonlinear time delay systems. Although these papers provide some error bound and convergence criteria, they do not develop expressions for the order of convergence.

A complete variational theory for (1.2) has been given by the authors in [3, 1, 2], including constrained delay problems in optimal control theory/calculus of variations. Thus our methods in this paper will allow us to obtain numerical results for delay variational problems with linear constraints and, with a little more work, a *complete* numerical theory for general, constrained, delay problems. We have chosen to concentrate on (1.1) since the results are so important in applied problems, and by doing so we will avoid difficult technical problems and problems of exposition for the reader.

Our paper is divided as follows. In section 2 we give the basic variational theory for (1.1). This motivates section 3, where we derive our basic algorithm for (1.1). In section 4 we derive the local error for our algorithm and then our main result, that the algorithm has a global a priori error of $O(h^2)$, where h is the distance between node points.

In section 5 we derive our basic results a second way, using the more general results for (1.2) applied to (1.1). In section 6 we consider an example to demonstrate our numerical results.

2. The basic variational theory. The purpose of this section is to derive the necessary analytic conditions for the stationary conditions for our delay problem in (1.1), which, in turn, leads to our numerical algorithm in section 4. The three conditions we obtain, which are necessary (and sufficient) for the stationary condition $J'(y,z) = 0$ for all admissible arcs $z(t)$, exactly yield the tools to get an analytic/closed form solution if one can be easily calculated.

We will see in section 4 that our numerical methods follow from solving $J'(y_h, z_k) = 0$, where z_k is the kth linear spline element and $y_h(t)$ is the numerical solution for step size h.

Thus we have the following analytic results for (1.1).

Theorem 1. *If $y(t)$ yields an extremal value for $J(y)$ in* (1.1)*, then*

(i) $r(t)y'(t) = \int_{b-\tau}^{t} p(s)y(s)ds + c_1$ *or* $\frac{d}{dt}(ry') = py$ *for* $b-\tau < t < b$,

(i)$_T$ $y'(b) = 0$ *if* $y(b)$ *is not given,*

(ii) $R(t)y'(t) = \int_{a}^{t} P(s)y(s)ds + c_2$ *or* $\frac{d}{dt}(Ry') = Py$ *for* $a < t < b-\tau$, *and*

(ii)$_T$ $R(t)y'(t)|_{(b-\tau)^-} = r(t)y'(t)|_{(b-\tau)^+}$,

where c_1 and c_2 are constants and

$$R(t) = [r(t) + \bar{r}(t+\tau)], \qquad P(t) = [p(t) + \bar{p}(t)]. \tag{2.1}$$

We note that (i) is the well-known Euler–Lagrange equation for nondelay problems which, in this case, holds on $b-\tau < t < b$ while (ii) is the same with the delay. Condition (i)$_T$ is the expected transversality condition at $t = b$. There is no transversality condition at $t = a$ since $y(a) = \alpha(a)$ is specified in (1.3). Condition (ii)$_T$ is a piecing or consistency condition for the two second order equations. Thus we have two equations and three boundary conditions as required. Surprisingly, this delay problem, which initially looks quite formidable, can be profitably viewed as a translation problem on $a < t < b-\tau$, a classical problem on $b-\tau < t < b$, and a consistency condition at $t = b-\tau$.

To obtain these results we begin with $F'(0) = 0$, where $F(\epsilon) = J(y + \epsilon z)$, ϵ in $\mathbb{R}$. Thus

$$
\begin{aligned}
0 &= \frac{d}{d\epsilon} J(y+\epsilon z)\bigg|_{\epsilon=0} = J'(y,z) = \int_a^b [r(t)y'(t)z'(t) + \bar{r}_\tau(t)y'_\tau(t)z'_\tau(t) + p(t)y(t)z(t) \\
&\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad + \bar{p}_\tau(t)y_\tau(t)z_\tau(t)]dt \\
&= \int_a^{b-\tau} \{[r(t) + \bar{r}(t+\tau)]y'(t)z'(t) + [p(t) + \bar{p}(t+\tau)]y(t)z(t)\}dt \\
&\qquad + \int_{b-\tau}^{b} (r(t)y'(t)z'(t) + p(t)y(t)z(t))dt \\
&= \int_a^{b-\tau} [R(t)y'(t)z'(t) + P(t)y(t)z(t)]dt + \int_{b-\tau}^{b} (r(t)y'(t)z'(t) + p(t)y(t)z(t))dt \\
&= \int_a^{b-\tau} \left[R(t)y'(t) - \int_a^t P(s)y(s)ds\right] z'(t)dt \\
&\qquad + \int_{b-\tau}^{b} \left[r(t)y'(t) - \int_{b-\tau}^{t} p(s)y(s)ds\right] z'(t)dt \\
&\qquad + z(t)\int_a^t P(s)y(s)ds\bigg|_a^{b-\tau} + z(t)\int_{b-\tau}^{t} p(s)y(s)ds\bigg|_{b-\tau}^{b},
\end{aligned}
$$

where we have used integration by parts in the last equality and the change of variables $\bar{t} = t + \tau$ and then $t = \bar{t}$ for the previous equality.

We obtain (i) by choosing $z(t) \equiv 0$ on $[a, b-\tau]$ and $z(b) = 0$. Specifically, a fundamental lemma in the classical calculus of variations has the result that $\int_{t_1}^{t_2} q(t)z'(t)dt = 0$ for all $z(t)$ such that $z(t_1) = z(t_2) = 0$ implies $q(t) \equiv c_1$ on $[t_1, t_2]$.

Choosing $z(t) \equiv 0$ on $[a, b-\tau]$ and using (i) imply (i)$_T$ since

$$
\begin{aligned}
0 &= \int_{b-\tau}^{b} c_1 z'(t)dt + z(t)\int_{b-\tau}^{t} P(s)y(s)ds\bigg|_{b-\tau}^{b} \\
&= c_1[z(b) - z(b-\tau)] + z(b)\int_{b-\tau}^{b} P(s)y(s)ds \\
&= z(b)\left[c_1 + \int_{b-\tau}^{b} P(s)y(s)ds\right] = r(b)[R(b)y'(b)]
\end{aligned}
$$

so that if $y(b)$ is not specified, $z(b)$ is not zero, and hence $y'(b) = 0$.

To obtain (ii) we use (i) and (i)$_T$, and hence if $z(a) = z(b-\tau) = 0$, the fundamental lemma implies the result.

Finally, the earlier results imply

$$
\begin{aligned}
0 &= c_2[z(b-\tau) - z(a)] + c_1[z(b) - z(b-\tau)] + z(b-\tau)\int_a^{b-\tau} P(t)y(t)dt \\
&\qquad + z(b)\int_{b-\tau}^{b} p(t)y(t)dt \\
&= z(b-\tau)\left[-c_1 + c_2 + \int_a^{b-\tau} P(t)y(t)dt\right] + z(b)\left[c_1 + \int_{b-\tau}^{b} p(t)z(t)dt\right] \\
&= t(b-\tau)[-c_1 + R(b-\tau)y'(b-\tau)^-] + z(b)[r(b)y'(b)].
\end{aligned}
$$

Now $z(b)y'(b) = 0$, as before, so

$$c_1 = R(b-\tau)y'(b-\tau)^-,$$

and the result follows by taking $t \to (b-\tau)^+$ in (i).

3. Numerical algorithm.

In this section we develop our numerical algorithm for the quadratic problem defined by (1.1) and (1.3).

Taking the variation of $J(y)$ in (1.1) along the z direction, we obtain the condition

$$J'(y,z) = \int_a^b [ry'z' + pyz + \bar{r}y'_\tau z'_\tau + \bar{p}y_\tau z_\tau]dt = 0, \tag{3.1}$$

where z is an arbitrary function except that it vanishes at $t = b$ and for $t \in [a-\tau,\, a]$.

Intuitively, with $z^{(k)}(t)$ defined below, as the linear spline element of size h, we replace the exact condition (3.1) for arbitrary admissible $z(t)$ with $J'_h(y_h, z_h) = 0$, where $y_h = \sum A_k z^{(k)}$ is the approximate solution for each h.

For simplicity in the discussion to follow, we define

$$I'_1(y,z) = \int_a^b [r(t)y'(t)z'(t) + p(t)y(t)z(t)]dt, \tag{3.2}$$

$$I'_2(y,z) = \int_a^b [\bar{r}(t)y'_\tau(t)z'_\tau(t) + \bar{p}(t)y_\tau(t)z_\tau(t)]dt. \tag{3.3}$$

Hence

$$J'(y,z) = I'_1(y,z) + I'_2(y,z). \tag{3.4}$$

We begin our construction by a partition of $[a, b]$. Thus let N be a positive integer. Divide the interval $[a,\, b]$ into N equal parts; then the length of each part is $h = (b-a)/N$. Label the node points as $t_k = a + kh$ for $k = 0, 1, \ldots, N$. For $k = 1, 2, \ldots, N-1$, define the one dimensional spline hat functions as

$$z^{(k)}(t) = \begin{cases} 0, & t \le t_{k-1}, \\ \dfrac{t - t_{k-1}}{h}, & t_{k-1} \le t \le t_k, \\ \dfrac{t_{k+1} - t}{h}, & t_k \le t \le t_{k+1}, \\ 0, & t \ge t_{k+1}. \end{cases} \tag{3.5}$$

Using (3.5), the variation of $I_1(y)$ along $z^{(k)}$ can be written as

$$\begin{aligned} I_1(y, z^{(k)}) = \frac{1}{h}\int_{t_{k-1}}^{t_k} & [r(t)y'(t) + p(t)y(t)(t - t_{k-1})]dt \\ & + \frac{1}{h}\int_{t_k}^{t_{k+1}} [-r(t)y'(t) + p(t)y(t)(t_{k+1} - t)]dt. \end{aligned} \tag{3.6}$$

For computational purposes, (3.6) can be approximated as

$$\begin{aligned} I'_1(y, z^{(k)}) \doteq r(t^*_{k-1}) & \frac{y_k - y_{k-1}}{h} + p(t^*_{k-1})\frac{y_{k-1} + y_k}{2}\frac{h}{2} \\ & - r(t^*_k)\frac{y_{k+1} - y_k}{h} + p(t^*_k)\frac{y_{k+1} + y_k}{2}\frac{h}{2}, \end{aligned} \tag{3.7}$$

where

$$t_{k-1}^* = \frac{t_k + t_{k-1}}{2} \quad \text{and} \quad t_k^* = \frac{t_k + t_{k+1}}{2} \tag{3.8}$$

and y_k, $k = 0, 1, \ldots, N$, are the numerical values of $y(t_k)$. To compute $I_2'(y, z^{(k)})$, note that $z_\tau^{(k)}$ will be zero until $t = t_{k-1} + \tau$. Hence $I_2'(y, z^{(k)})$ can be written as

$$\begin{aligned} I_2'(y, z^{(k)}) = &\int_{t_{k-1}+\tau}^{t_k+\tau} [y_\tau'(t) z_\tau'(t) \bar{r}(t) + \bar{p}(t) y_\tau(t) z_\tau(t)] dt \\ &+ \int_{t_k+\tau}^{t_{k+1}+\tau} [\bar{r}(t) y_\tau'(t) z_\tau'(t) + \bar{p}(t) y_\tau(t) z_\tau(t)] dt. \end{aligned} \tag{3.9}$$

By a direct shift of time axis, (3.9) reduces to

$$\begin{aligned} I_2'(y, z^{(k)}) = &\int_{t_{k-1}}^{t_k} [\bar{r}(t+\tau) y'(t) z'(t) + \bar{p}(t+\tau) y(t) z(t)] dt \\ &+ \int_{t_k}^{t_{k+1}} [\bar{r}(t+\tau) y'(t) z'(t) + \bar{p}(t+\tau) y(t) z(t)] dt. \end{aligned} \tag{3.10}$$

Following the approach presented above, (3.10) can be approximated as

$$\begin{aligned} I_2'(y, z^{(k)}) = &\bar{r}(t_{k-1}^* + \tau) \frac{y_k - y_{k-1}}{h} + \bar{p}(t_{k-1}^* + \tau) \frac{y_{k-1} + y_k}{2} \frac{h}{2} \\ &- \bar{r}(t_k^* + \tau) \frac{y_{k+1} - y_k}{h} + \bar{p}(t_k^* + \tau) \frac{y_{k+1} + y_k}{2} \frac{h}{2}. \end{aligned} \tag{3.11}$$

Combining (3.7) and (3.11), we get

$$\begin{aligned} I'(y, z^{(k)}) \quad = \quad &\{r(t_{k-1}^*) + \bar{r}(t_{k-1}^* + \tau)\} \frac{y_k - y_{k-1}}{h} \\ &+ \{p(t_{k-1}^*) + \bar{p}(t_{k-1}^* + \tau)\} (y_{k-1} + y_k) \frac{h}{4} \\ &- \{r(t_k^*) + \bar{r}(t_k^* + \tau)\} \frac{y_{k+1} - y_k}{h} \\ &+ \{p(t_k^*) + \bar{p}(t_k^* + \tau)\} (y_{k+1} + y_k) \frac{h}{4}. \end{aligned} \tag{3.12}$$

Notice that for $b - \tau \le t_k \le b$, the $\bar{r}(t+\tau)$ and $\bar{p}(t+\tau)$ terms drop out.

Therefore, using (2.1), (3.12) can be written as follows.

For $a \le t_k < b - \tau$, we have

$$\begin{aligned} &R(t_{k-1}^*) \frac{y_k - y_{k-1}}{h} + P(t_{k-1}^*) (y_{k-1} + y_k) \frac{h}{4} \\ &\qquad - R(t_k^*) \frac{y_{k+1} - y_k}{h} + P(t_k^*) (y_k + y_{k+1}) \frac{h}{4} = 0. \end{aligned} \tag{3.13}$$

For $b - \tau < t_k \le b$, we have

$$\begin{aligned} &r(t_{k-1}^*) \frac{y_k - y_{k-1}}{h} + p(t_{k-1}^*) (y_{k-1} + y_k) \frac{h}{4} \\ &\qquad - r(t_k^*) \frac{y_{k+1} - y_k}{h} + p(t_k^*) (y_k + y_{k+1}) \frac{h}{4} = 0. \end{aligned} \tag{3.14}$$

For $t_k = b - \tau$, we have

$$R(t^*_{k-1})\frac{y_k - y_{k-1}}{h} + P(t^*_{k-1})(y_{k-1} + y_k)\frac{h}{4} - r(t^*_k)\frac{y_{k+1} - y_k}{2h} + p(t^*_k)(y_k + y_{k+1})\frac{h}{8} = 0. \tag{3.15}$$

Equations (3.13)–(3.15) provide the numerical algorithm to solve the quadratic optimal control problem defined in section 5. If $y(b)$ is given, we have exactly the number of equations we need. Otherwise, the condition $(\mathrm{i})_T$ in Theorem 1 is approximated by $y_N - y_{N-1} = 0$.

Two final comments are important:

1. For convenience, we have assumed in (3.15) that $b - \tau$ is a node point of our partition. If it is not, the numerical process ignores this continuity condition, and we obtain the same $O(h^2)$ result.
2. Anyone can present a heuristic algorithm as we have done in (3.13)–(3.15). The justification of the local error being $O(h^q)$, with $q \geq 2$, shows that our algorithm makes sense. The global error establishes the main claim for this algorithm.

4. Derivation of local and global errors. The purpose of this section is to derive the local and global errors for algorithm (3.13)–(3.15). In the previous section, different expressions were given: $a \leq t_k < b - \tau$, $b - \tau < t_k \leq b$, and $t_k = b - \tau$. Accordingly, the expressions for the local error for the three cases must be derived separately.

For $a \leq t_k < b - \tau$, we define $L(t, h)$ as

$$\begin{aligned} L(t,h) = R(t^*_{k-1})&\frac{y(t_k) - y(t_{k-1})}{h} + P(t^*_{k-1})(y(t_k) + y(t_{k-1}))\frac{h}{4} \\ &-R(t^*_k)\frac{y(t_{k+1}) - y(t_k)}{h} + P(t^*_k)(y(t_k) + y(t_{k+1}))\frac{h}{4} \end{aligned} \tag{4.1}$$

as the local error in $a \leq t_k < b - \tau$. In the discussion to follow, unless the time parameter is specified, it will be assumed that the functions are computed at t_k. The Taylor series for $y(t_{k+1})$, $y(t_{k-1})$, $R(t^*_k)$, $R(t^*_{k-1})$, $P(t^*_k)$, and $P(t^*_{k-1})$ can be written as

$$\begin{bmatrix} y_{t_{k+1}} \\ y_{t_{k-1}} \end{bmatrix} = y \pm hy' + \frac{1}{2}h^2y'' \pm \frac{1}{6}h^3y''' + \cdots, \tag{4.2}$$

$$\begin{bmatrix} R(t^*_k) \\ R(t^*_{k-1}) \end{bmatrix} = R \pm \frac{1}{2}hR' + \frac{1}{8}h^2R'' \pm \frac{1}{48}h^3R''' + \cdots, \tag{4.3}$$

$$\begin{bmatrix} P(t^*_k) \\ P(t^*_{k-1}) \end{bmatrix} = P \pm \frac{1}{2}hP' + \frac{1}{8}h^2P'' \pm \frac{1}{48}h^3P''' + \cdots. \tag{4.4}$$

Substituting (4.2)–(4.4) into (4.1) and simplifying, we obtain

$$\begin{aligned} L(t,h) = (-Ry'' - R'y' + Py)h + \Big(&-\frac{1}{6}R'y''' - \frac{1}{8}R''y'' - \frac{1}{24}R'''y' \\ &+ \frac{1}{4}Py'' + \frac{1}{4}P'y' + \frac{1}{8}P''y\Big)h^3 + O(h^5). \end{aligned} \tag{4.5}$$

Using the Euler–Lagrange equation in Theorem 1, it follows that

$$L(t,h) = O(h^3) \qquad \text{in} \qquad a \le t_k < b-\tau. \tag{4.6}$$

For $b-\tau \le t_k \le b$ we define the local error $L(t,h)$ as

$$\begin{aligned} L(t,h) = \frac{1}{2}\Bigg[& r(t^*_{k-1})\frac{y(t_k)-y(t_{k-1})}{h} + p(t^*_{k-1})(y(t_k)+y(t_{k-1}))\frac{h}{4} \\ & - r(t^*_k)\frac{y(t_{k+1})-y(t_k)}{h} + p(t^*_k)(y(t_k)+y(t_{k+1}))\frac{h}{4}\Bigg]. \end{aligned} \tag{4.7}$$

The Taylor series for $r(t^*_k)$, $r(t^*_{k-1})$, $p(t^*_k)$, and $p(t^*_{k-1})$ can be written as

$$\begin{bmatrix} r(t^*_k) \\ r(t^*_{k-1}) \end{bmatrix} = r \pm \frac{1}{2}hr' + \frac{1}{8}h^2r'' \pm \frac{1}{48}h^3r''' + \cdots, \tag{4.8}$$

$$\begin{bmatrix} p(t^*_k) \\ p(t^*_{k-1}) \end{bmatrix} = p \pm \frac{1}{2}hp' + \frac{1}{8}h^2p'' \pm \frac{1}{48}h^3p''' + \cdots. \tag{4.9}$$

Substituting (4.2), (4.8), and (4.9) into (4.7) and simplifying, we obtain

$$\begin{aligned} L(t,h) = (-ry'' - r'y' + py)h + \Bigg(& -\frac{1}{6}r'y''' - \frac{1}{8}r''y'' - \frac{1}{24}r'''y' \\ & + \frac{1}{4}py'' + \frac{1}{4}p'y' + \frac{1}{8}p''y\Bigg) h^3 + O(h^5). \end{aligned} \tag{4.10}$$

Using (5.9), it follows, once again, that

$$L(t,h) = O(h^3) \qquad \text{in} \qquad b-\tau < t_k \le b. \tag{4.11}$$

For $t_k = b-\tau$ we define the local error $L(t,h)$ as

$$\begin{aligned} L(t,h) = {} & R(t^*_{k-1})\frac{y(t_k)-y(t_{k-1})}{h} + P(t^*_{k-1})(y(t_k)+y(t_{k-1}))\frac{h}{4} \\ & - r(t^*_k)\frac{y(t_{k+1})-y(t_k)}{2h} + p(t^*_k)(y(t_k)+y(t_{k+1}))\frac{h}{8}. \end{aligned} \tag{4.12}$$

For simplicity in the derivation to follow, define $t_k = b-\tau = c$. Since $t_k = b-\tau$ is a corner point, $y(t_{k-1})$ and $y(t_{k+1})$ must be expanded at c^- and c^+, respectively. Keeping this in mind, the Taylor series for $y(t_{k+1})$ and $y(t_{k-1})$ can be written as

$$y(t_{k-1}) = y - hy'(c^-) + \frac{1}{2}h^2y''(c^-) - \frac{1}{6}h^3y'''(c^-) + \cdots, \tag{4.13}$$

$$y(t_{k+1}) = y + hy'(c^+) + \frac{1}{2}h^2y''(c^+) - \frac{1}{6}h^3y'''(c^+) + \cdots. \tag{4.14}$$

It is assumed that $R(t)$, $P(t)$, $r(t)$, and $p(t)$ are sufficiently smooth at $t = b-\tau$. Therefore, the Taylor expansions of $R(t^*_{k-1})$, $P(t^*_{k-1})$, $r(t^*_k)$, and $p(t^*_k)$ given by (4.3), (4.4), (4.8), and (4.9), respectively, are still valid for $t_k = b - \tau$. Substituting (4.3), (4.4), (4.8), (4.9), (4.13), and (4.14) into (4.12) and simplifying, we obtain

$$\begin{aligned} L(t,h) = {}& Ry'(c^-) - \frac{1}{2}ry'(c^+) \\ & + \left[-\frac{1}{2}Ry''(c^-) - \frac{1}{2}R'y'(c^-) + \frac{1}{2}Py - \frac{1}{4}ry''(c^+) - \frac{1}{4}r'y'(c^+) + \frac{1}{4}py \right] h \\ & + \left[\frac{1}{6}Ry'''(c^-) + \frac{1}{4}R'y''(c^-) + \frac{1}{8}R''y'(c^-) - \frac{1}{4}Py'(c^-) - \frac{1}{4}P'y \right. \\ & \left. - \frac{1}{12}ry'''(c^+) - \frac{1}{8}r'y''(c^+) - \frac{1}{16}r''y'(c^+) + \frac{1}{8}p'y + \frac{1}{8}py'(c^+) \right] h^2 \\ & + \left[-\frac{1}{12}R'y'''(c^-) - \frac{1}{16}R''y''(c^-) - \frac{1}{48}R'''y'(c^-) + \frac{1}{8}Py''(c^-) \right. \\ & + \frac{1}{8}P'y'(c^-) + \frac{1}{16}P''y - \frac{1}{24}r'y'''(c^+) - \frac{1}{32}r''y''(c^+) \\ & \left. - \frac{1}{96}r'''y'(c^+) + \frac{1}{16}py''(c^+) + \frac{1}{16}p'y'(c^+) + \frac{1}{32}p''y \right] h^3 \\ & + O(h^4). \end{aligned} \tag{4.15}$$

Using (4.15), the differential (5.4) and (5.5), and the corner condition (5.6), it follows that

$$L(t,h) = O(h^2) \qquad \text{at} \qquad t_k = b - \tau. \tag{4.16}$$

We note, once again, that we have established consistency for our algorithm by showing that if $y(t)$ satisfies the conditions in Theorem 1 or (5.8)–(5.10), then $L(t,h) = O(h^3)$ for $t \neq b - \tau$ and $L(t,h) = O(h^2)$ for $t = b - \tau$.

Thus we have the following theorem.

THEOREM 2. *The algorithm* (3.13)–(3.15) *is consistent as described directly above.*

We note that the algorithm along with the values for $y(a)$ and $y(b)$, or $y(b)$ replaced by the numerical transversality condition for $y'(b) = 0$, $y_N - y_{N-1} = 0$, leads immediately to a well-defined set of numerical values y_k, $k = 0, 1, \ldots, N$, which are approximation values of $y(a_k)$, where $y(t)$ is a unique solution to our problem. The purpose of Theorem 3 is to see how good the approximation is.

THEOREM 3. *If* $e_h = y(a_k) - y_h(a_k)$*, where* $y(t)$ *is the unique solution described above and* $y_h(a_k) = y_k$ *for fixed* $h > 0$*, given by our algorithm as described above in Theorem* 2*, then for* h *sufficiently small there exists* $C > 0$ *independent of* h *such that*

$$\|e_h\|_\infty \leq Ch^2 \quad \mathit{or} \quad \|e_h\|_2 \leq Ch^2. \tag{4.17}$$

In fact, this theorem will hold in a variety of situations: (a) when y is an m vector, (b) when the algorithm is generated in the obvious way with nonquadratic f as in section 3, and (c) when a constraint delay problem is reformulated as an unconstrained problem.

For example, in (a) above, for $y(t)$ an m vector, we use $\|x\|_2$ to denote the 2-norm and $\|x\|_\infty$ to denote the max-norm; thus, if $x = (x^1, x^2, \ldots, x^m)$, then

$$\begin{aligned} \|x\|_2 &= \sqrt{(x^1)^2 + (x^2)^2 + \cdots + (x^m)^2}, \\ \|x\|_\infty &= \max_{1 \leq k \leq m} |x^k|, \end{aligned}$$

and the equality $\|x\|_\infty \leq \|x\|_2 \leq m\|x\|_\infty$ follows immediately.

The proof of Theorem 3 is very long and complicated. It involves proving a long string of inequalities by use of Rayleigh–Ritz methods and Gershgorin's theorem. Details are found in [7] when the boundary conditions are given and in [6] when they are arbitrary.

For completeness, the inequalities are

$$\begin{aligned} C_1 h\|E_h\|_2^2 &\overset{\textcircled{1}}{=} C_1 \frac{h^2}{h} E_h^T E_h \overset{\textcircled{2}}{\le} C_2 E_h^T \frac{1}{h} J_h^m E_h \\ &\overset{\textcircled{3}}{=} C_2 \int_a^b e'^T_h e'_h dt \overset{\textcircled{4}}{=} C_2(e_h, e_h) \overset{\textcircled{5}}{\le} C_3 H_0(e_h) \overset{\textcircled{6}}{\le} \bar{\bar{H}}_h(e_h) \\ &\overset{\textcircled{7}}{=} E_h^T M^h E_h \overset{\textcircled{8}}{=} h^3(E_h^T Q_h + Q_h^T E_h) + O(h^5) \\ &\overset{\textcircled{9}}{=} C_4 h^3 \|E_h\|_2 \|Q_h\|_2 \overset{\textcircled{10}}{\le} C_5 h^{5/2} \|E_h\|_2. \end{aligned}$$

We will not define the symbols, to protect the innocent, but "T" denotes transpose. In the quadratic case, $\textcircled{8}$ can be omitted. The result $M^h E_h$ is obtained by using Theorem 2 and the definition of $y_h(a_k)$.

Thus $\|E_h\|_2 \le Ch^{3/2}$, and the final result can be obtained as described in [7] or [6] or by the results for sparse symmetric matrix.

5. The general problem. The purpose of this section is to briefly describe the results for the more general, delay calculus of variations problem, as given in [1]. We will show that these results lead to those in section 2 and motivate how the numerical algorithm in the more general case is obtained.

Thus our basic problem is

$$\min I(y) = \int_a^b f(t, y(t), y'(t), y_\tau(t), y'_\tau(t))dt, \tag{5.1}$$

subject to the terminal conditions given by

$$y(t) = \alpha(t), \quad t \in [a-\tau, a], \tag{5.2}$$

$$y(b) = y_b, \tag{5.3}$$

where $y_\tau(t)$, etc., is given above. It is shown in [1] that the above problem leads to the differential equations

$$\frac{d}{dt} f_{y'}(t) + \frac{d}{dt} f_{y'_\tau}(t+\tau) = f_y(t) + f_{y_\tau}(t+\tau), \quad a \le t \le b-\tau, \tag{5.4}$$

$$\frac{d}{dt} f_{y'}(t) = f_y(t), \quad b-\tau \le t \le b, \tag{5.5}$$

and the corner condition

$$f_{y'}((b-\tau)^-) - f_{y'}((b-\tau)^+) + f_{y'_\tau}(t+\tau)\big|_{t=(b-\tau)^-} = 0. \tag{5.6}$$

Recalling that our specialized quadratic problem was

$$J(y) = \frac{1}{2}\int_a^b [r(t)y'^2(t) + \bar{r}_\tau(t)y'^2_\tau(t) + p(t)y^2(t) + \bar{p}_\tau(t)y_\tau^2(t)]dt, \tag{1.1}$$

comparing (5.1) and (1.1), we observe that for the quadratic problem

$$f(t,y(t),y'(t),y_\tau(t),y'_\tau(t))=\frac{1}{2}[r(t)y'^2(t)+p(t)y^2(t)+\bar{r}(t)y'^2_\tau(t)+\bar{p}(t)y^2_\tau(t)]. \tag{5.7}$$

Substituting (5.7) into (5.5)–(1.1), we obtain the differential equations

$$\frac{d}{dt}[R(t)y'(t)]=P(t)y(t),\qquad a\le t\le b-\tau, \tag{5.8}$$

$$\frac{d}{dt}\left[r(t)y'(t)\right]=p(t)y(t),\qquad b-\tau\le t\le b, \tag{5.9}$$

and the corner conditions

$$R(b^--\tau)y'(b^--\tau)-r(b^+-\tau)y'(b^+-\tau)=0. \tag{5.10}$$

These results are those of Theorem 1 in slightly different notation.

A numerical algorithm for (5.1)–(5.3) which also results in an error bound of order $O(h^2)$ will be presented in a later paper.

6. Example. In this section, we consider a numerical example to describe the algorithm developed in the paper, and we show that the numerical results agree with the error bound given in (4.17).

The problem is described as follows: Find the minimum of the functional

$$I(y)=\frac{1}{2}\int_0^\pi((y')^2+(y'_\tau)^2-y^2-y_\tau^2)dt \tag{6.1}$$

such that

$$y(t)=0,\qquad t\in[-\pi/4,0], \tag{6.2}$$

and

$$y(\pi)=1, \tag{6.3}$$

where $\tau=\pi/4$. In this example, we have $r(t)=\bar{r}(t)=-p(t)=-\bar{p}(t)=1$. Following the approach presented in Theorem 1, it can be demonstrated that the solution of above problem is

$$y(t)=\begin{cases}-2\sin(t), & 0\le t<3\pi/4,\\ -3\sin(t)-\cos(t), & 3\pi/4<t\le\pi.\end{cases} \tag{6.4}$$

For computational purposes, the time domain is divided into n equal divisions. Substituting the values of $r(t)$, $\bar{r}(t)$, $p(t)$, and $\bar{p}(t)$ into (3.13)–(3.15), we arrive at the following algorithm for this example.

For $0\le t_k<3\pi/4$,

$$\frac{1}{h}(-y_{k-1}+2y_k-y_{k+1})+\frac{h}{4}(y_{k-1}+2y_k+y_{k+1})=0. \tag{6.5}$$

For $3\pi/4<t_k\le\pi$,

$$\frac{1}{2h}(-y_{k-1}+2y_k-y_{k+1})+\frac{h}{8}(y_{k-1}+2y_k+y_{k+1})=0. \tag{6.6}$$

For $t_k = 3\pi/4$,

$$\frac{1}{2h}(-2y_{k-1} + 3y_k - y_{k+1}) + \frac{h}{8}(2y_{k-1} + 3y_k + y_{k+1}) = 0. \tag{6.7}$$

Here $h = \pi/n$, and y_k, $k = 1, \ldots, n-1$, are the computed values of $y(t)$ at $t = t_k = kh$. Note that $y_0 = 0$ and $y_n = 1$.

For numerical simulation, we take $n = 8$, 16, and 32. The table below shows the analytical results and the numerical errors $e_{h1} = e_h(h = 1/8)$, $e_{h2} = e_h(h = 1/16)$, and $e_{h3} = e_h(h = 1/32)$ for $n = 8$, 16, and 32 and the error ratios $r_1 = e_{h1}/e_{h2}$ and $r_2 = e_{h2}/e_{h3}$. From the table it is clear that as the time interval is reduced from h to $h/2$, the error reduces by a factor of 4. Thus the numerical results also justify our claim that our algorithm leads to an $O(h^2)$ global pointwise error.

t	$y(t)$	$e_{h1}(h = 1/8)$	$e_{h2}(h = 1/16)$	$e_{h3}(h = 1/32)$	$r_1 = e_{h1}/e_{h2}$	$r_2 = e_{h2}/e_{h3}$

7. Conclusions. A numerical scheme has been presented for time delay quadratic problems in the calculus of variations. It has been demonstrated that the algorithm has a global a priori error of $O(h^2)$, where h is the distance between any two successive node points. As opposed to solving time delay differential equations, our methods require weaker smoothness conditions, and they avoid the need for satisfying the transversality and corner conditions explicitly.

A numerical example has been presented to demonstrate the numerical scheme and to verify the a priori error conditions. Numerical results agree with the proposed global error bound. Although numerical results have been presented in only one example, the algorithm can be applied to a large class of time delay quadratic problems.

ADAPTIVE WAVELET SCHEMES FOR NONLINEAR VARIATIONAL PROBLEMS[*]

ALBERT COHEN[†], WOLFGANG DAHMEN[‡], AND RONALD DEVORE[§]

Abstract. We develop and analyze wavelet based adaptive schemes for nonlinear variational problems. We derive estimates for convergence rates and corresponding work counts that turn out to be asymptotically optimal. Our approach is based on a new paradigm that has been put forward recently for a class of linear problems. The original problem is transformed first into an equivalent one which is well posed in the Euclidean metric ℓ_2. Then conceptually one seeks iteration schemes for the infinite dimensional problem that exhibits at least a fixed error reduction per step. This iteration is then realized approximately through an adaptive application of the involved operators with suitable dynamically updated accuracy tolerances. The main conceptual ingredients center around nonlinear tree approximation and the sparse evaluation of nonlinear mappings of wavelet expansions. We prove asymptotically optimal complexity for adaptive realizations of first order iterations and of Newton's method.

Key words. variational problems, wavelet representations, semilinear equations, mapping properties, gradient iteration, convergence rates, adaptive application of operators, sparse evaluation of nonlinear mappings of wavelet expansions, tree approximation, Newton's scheme

1. Introduction.

1.1. Background and objectives.

Adaptive wavelet schemes for numerically solving a wide class of variational problems have been recently studied in [8, 9] from the perspective of asymptotic estimates for convergence rates and corresponding work counts. The problems covered by that analysis include elliptic boundary integral equations and elliptic boundary value problems but also indefinite problems of elliptic type such as the Stokes problem. Two requirements were essential in this context: (i) the variational problem induces an operator $\mathcal{L}$ that is an isomorphism from some Hilbert space $\mathcal{H}$ onto its dual; (ii) this Hilbert space permits a wavelet characterization; i.e., the $\mathcal{H}$-norm of an element is equivalent to a weighted ℓ_2-norm of its wavelet coefficients. It could then be shown that certain adaptive schemes exhibit an *asymptotically optimal accuracy/work balance* within a certain range of convergence rates depending on the choice of wavelet bases. The precise meaning of this statement is explained in the Meta-Theorem below. To our knowledge for the above range of linear problems such complexity estimates have been established so far only for wavelet methods. Just recently, a similar result was proved for adaptive finite element methods for Laplace's

equation in two space dimensions [4].

In this paper we wish to explore the convergence rates and the computational complexity of certain new adaptive wavelet schemes for *nonlinear problems* for which no results of the above type seem to be known so far.

Our primary concern here is *not* to develop a specific algorithm for a concrete application. We are rather interested in developing a numerically realizable *new algorithmic paradigm* in a fairly general context of nonlinear problems and in analyzing its principal complexity features. Therefore, the various algorithmic ingredients will at times not be discussed in full detail but only to an extent that clarifies their principal asymptotic complexity.

The new paradigm is based upon the adaptive evaluation of (linear and nonlinear) operators in the course of an ideal iteration for the *infinite dimensional* problem formulated in the wavelet coordinate domain. Such perturbed iterations will lead to an algorithm **SOLVE** that (with a proper initialization) produces for any target accuracy ϵ a finitely supported vector of coefficients $\bar{\mathbf{u}}(\epsilon)$ that approximates the array of wavelet coefficients of the exact solution (of the underlying variational problem) in ℓ_2 with accuracy ϵ. The choice of wavelet basis will then imply that the corresponding finite expansion approximates the exact solution with accuracy $C\epsilon$ in the energy norm, where C depends only on the wavelet basis. In order to identify the essential mechanisms governing such schemes, we will consider nonlinear variational problems on various levels of generality. The results will be purely asymptotic in nature. They reveal asymptotically optimal work/accuracy balances interrelating the achieved target accuracy with the required computational work and associated adaptively generated number of degrees of freedom. More precisely, we shall prove results of the following type.

META-THEOREM. *If the exact solution can be approximated as a linear combination of N wavelets (subject only to certain tree restrictions on the distribution of active coefficients) to accuracy of order N^{-s} (for a certain range of s), then the support of the output $\bar{\mathbf{u}}(\epsilon)$ of* **SOLVE** *for target accuracy ϵ grows at most as $\epsilon^{-1/s}$, uniformly in ϵ, and the computational complexity also stays proportional to the support size. In this sense, the scheme tracks the exact solution at asymptotically minimal cost.*

Note that the above-mentioned *tree restriction* on the permitted distribution of active coefficients is the analogue of locally refined meshes in the finite element context.

We shall outline now how we approach results of the above type.

1.2. The basic paradigm. The *classical* approach to numerically solving (linear and nonlinear) variational problems is concerned with the following issues:

(c1) well-posedness of the given variational problem;
(c2) discretization of the infinite dimensional problem so as to obtain a finite system of algebraic equations;
(c3) well-posedness of the finite system of equations and error analysis;
(c4) numerical solution of the finite system of equations.

It is important to note that (c1) is often hidden in the analysis and that (c3) is, in general, *not* a direct consequence of (c1). Typical examples even in the linear case are *saddle point problems.* It is well known that, for Galerkin discretizations to be stable, the trial spaces for the different solution components have to satisfy a certain compatibility condition (Ladyšhenskaya–Babŭska–Brezzi (LBB)-condition). For nonlinear problems one can often establish only *local* uniqueness of solutions so that some care is required to ensure that the discrete problems approximate the correct solution branch. Thus the discrete problems do not necessarily inherit the “nice properties” of the original infinite dimensional problem. Depending on the choice of the discretization, one might introduce "new difficulties." The typical obstructions encountered in (c4) are the *large size* of the discrete systems and possible *ill-conditioning.* The latter issue interferes with the need to resort to iterative solvers, due to the size and sparsity of the systems. Attempts to reduce computational complexity are often based on adaptive and hence possibly economic discretizations. A reliable control of adaptive refinements, however, depends usually in a sensitive way on the particular type of the problem, and rigorous complexity estimates are generally not available yet.

A *new paradigm* has been explored in [9] for *linear variational problems.* It aims at closely intertwining the analysis–discretization–solution process. The basic steps there read as follows:

(n1) well-posedness of the given variational problem;

(n2) transformation of the infinite dimensional problem into an *equivalent* problem in ℓ_2 which is *well posed* in the Euclidean metric;

(n3) the derivation of an iterative scheme for the infinite dimensional ℓ_2-problem that exhibits a fixed error reduction per iteration step;

(n4) numerical realization of the iterative scheme by an *adaptive application* of the involved infinite dimensional operators within some finite dynamically updated accuracy tolerances.

Thus the starting point (n1) is the same as (c1), although it takes a somewhat more exposed and explicit role in the new setting, as will be explained later. The main difference is that one aims at staying as long as possible with the infinite dimensional problem, which one hopes is given in a favorable format. Of course, it remains to see in each concrete case how to exploit (n2) in order to guarantee a fixed error reduction in (n3). We shall present several strategies regarding this task. Only at the very end, when it comes to applying the operators in the ideal iteration scheme (n4), does one enter the finite dimensional realm. However, the finite number of degrees of freedom is determined at each stage by the adaptive application of the operator so that at *no* stage is any specific trial space fixed. Roughly speaking, the "nice properties" of the infinite dimensional problem are preserved through adaptive evaluations. In fact, one can show that thereby compatibility conditions like the LBB-condition indeed become void [9, 13].

The main goal of the present paper is to show how to carry over this paradigm, already existing for linear problems, to the nonlinear setting. On a theoretical level, one then encounters three major issues, namely,

(a) the choice of tolerances in (n4) to ensure that the perturbed iteration converges to the correct solution;

(b) the design of economic approximate application schemes for the possibly nonlinear infinite dimensional operators;

(c) estimating the complexity of the scheme.

Here (a) means that any given *target accuracy* ϵ is achieved after finitely many steps. (b) is the most crucial part and will be discussed in detail in the course of the paper. Clearly (b) is closely related to (c). As in [8, 9, 13], we will measure complexity by the *number of adaptively generated degrees of freedom* $N = N(\epsilon)$ required by the adaptive scheme to achieve the target accuracy ϵ and the corresponding number of floating point operations (which, of course, is aimed at staying proportional to $N(\epsilon)$). Estimating the asymptotic *work/accuracy balance* $N(\epsilon) \leftrightarrow \epsilon$ will be a central theme in the subsequent developments. This part differs significantly from the classical error analysis for finite element methods and relies on concepts from *harmonic analysis* and *nonlinear approximation*.

Of course, on a practical level one will encounter in each concrete case further obstacles concerning quantitative information about constants and initial guesses. We shall discuss variational problems on a different level of generality in order to indicate possible strategies of acquiring such information or to identify those issues that require additional work.

Finally, a comment on (n3) is in order. Aiming at a fixed error reduction per iteration step means that one is content with a *first order* scheme. So why not go for faster iteration schemes? The answer to this question is not completely clear. Indeed, a higher order method may not automatically win for the following reason. Usually a higher order method is more costly in function evaluations. In the present context this means, according to (n4), it is more costly in the adaptive application of the full infinite dimensional operators within some dynamically updated accuracy tolerance. Preserving the higher order of the ideal iteration also in its perturbed form in connection with the higher demands of function evaluations may very well increase the cost of each iteration step so as to offset the potential gain of a better error reduction. So with regard to the objective of reaching a target accuracy at possibly low overall computational cost, the role of higher order schemes remains unclear. In fact, it will be seen that *asymptotic optimality* can indeed be achieved already with simple *first order outer iterations*. Nevertheless, we shall show that it is also possible to retain second order convergence of the adaptive version of Newton's scheme so as to arrive at an overall scheme with asymptotically optimal solution complexity, which may offer quantitative advantages over the first order versions.

1.3. Organization of material. The paper is organized as follows. In section 2 we describe (n1), (n2), and (n3) for a general setting that will host all subsequent specifications. In section 3 we distinguish several classes of variational problems to which the subsequent developments will refer frequently, namely, (L) *linear* problems, (SL) semilinear elliptic problems, and (GNL) more general nonlinear problems where we have to assume the existence of locally unique solutions. In section 4 we formulate the prototype of an adaptive perturbed first order iteration which is based on two main ingredients, namely, approximate *residual evaluations* and a certain *coarsening scheme*. In particular, the residual approximations involve the *adaptive* application of linear or nonlinear (infinite dimensional) operators. Assuming at this stage that these ingredients are indeed available, we address for the most general setting first only issue (a) to clarify for which choice of dynamically updated accuracy tolerances is convergence guaranteed. The remaining sections will be devoted to issues (b) and (c) for the problem types (L), (SL), and (GNL).

In section 5 we review briefly concrete realizations of these ingredients for the linear case (L) and indicate the concepts needed for their complexity analysis. This serves two purposes. First, these results will be used in the last section in connection with Newton iterations. Second, they motivate our treatment of the nonlinear case. In section 6 we introduce some new concepts needed to deal with nonlinear problems. They center upon *tree approximation* and related coarsening techniques. This enables us to formulate the notion of s^*-sparsity as the key criterion for controlling the complexity of the adaptive schemes in the nonlinear case. Drawing on several results from [10], we develop in section 7 adaptive evaluation schemes that are proven to be s^*-sparse and thus lead to asymptotically optimal results in the sense of the above Meta-Theorem. To our knowledge these are the first convergence and complexity estimates for adaptive solvers for nonlinear problems. Finally, in section

8 we develop an adaptive Newton scheme and analyze its complexity. It differs in essential ways from the schemes discussed in the previous sections which are based on first order iterations. In particular, we show that the quadratic convergence of the outer iteration can in some sense be preserved in the adaptive context.

2. The setting.

We describe now the setting for which the above paradigm will be discussed.

2.1. The general problem format.

The variational problems mentioned in step (n1) above will always have the following format. Let $\mathcal{H}$ be a Hilbert space with norm $\|\cdot\|_{\mathcal{H}}$, and let $\mathcal{H}'$ denote its dual endowed with the norm

$$\|v\|_{\mathcal{H}'} := \sup_{w\in\mathcal{H}} \frac{\langle w, v\rangle}{\|w\|_{\mathcal{H}}},$$

where $\langle\cdot,\cdot\rangle$ is the dual pairing between $\mathcal{H}$ and $\mathcal{H}'$ (with respect to L_2 as the pivot space). The Hilbert space $\mathcal{H}$ will always refer to a bounded domain Ω with spatial dimension d. Suppose that $f \in \mathcal{H}'$ and

$$F : \mathcal{H} \to \mathcal{H}' \tag{2.1}$$

is a (possibly nonlinear) mapping. We consider the numerical solution of the problem: Find $u \in \mathcal{H}$ such that

$$\langle v, F(u) - f\rangle =: \langle v, R(u)\rangle = 0 \quad \forall v \in \mathcal{H}. \tag{2.2}$$

The objective in (n1) is the identification of a suitable space $\mathcal{H}$ so that (2.2) is well posed in the following sense. Recall that the Frechét derivative $DR(z) = DF(z)$ is a mapping from $\mathcal{H}$ to $\mathcal{H}'$, defined by the duality

$$\langle v, DR(z)w\rangle = \lim_{h\to 0} \frac{1}{h}\langle v, R(z+hw) - R(z)\rangle. \tag{2.3}$$

The problem (2.2) is called *well posed* if F has the following properties:

A1. F possesses a continuous Frechét derivative; i.e., $R \in C^1(\mathcal{H}, \mathcal{H}')$ as a mapping $v \mapsto R(v)$.

A2. There exists a solution $u \in \mathcal{H}$ to (2.2), and in addition to (2.1) the Frechét derivative DF of F at v in some neighborhood $\mathcal{U}$ of u is an isomorphism from $\mathcal{H}$ onto $\mathcal{H}'$; i.e., for $v \in \mathcal{U}$ there exist positive finite constants $c_{v,F}, C_{v,F}$ such that

$$c_{v,F}\|w\|_{\mathcal{H}} \le \|DF(v)w\|_{\mathcal{H}'} \le C_{v,F}\|w\|_{\mathcal{H}} \quad \forall\, w \in \mathcal{H},\ v \in \mathcal{U}. \tag{2.4}$$

Clearly A2 ensures that the solution u is locally unique.

2.2. Wavelet coordinates and an equivalent ℓ_2-problem.

The transformations for (n2) will be based on suitable wavelet bases. For a detailed discussion of such bases, we refer the reader to the literature (see, e.g., [5, 6, 14, 11]) and collect here only the relevant facts. A *wavelet basis* $\Psi = \{\psi_\lambda : \lambda \in \mathcal{J}\} \subset \mathcal{H}$ has the following properties: The indices $\lambda \in \mathcal{J}$ encode typical information about the wavelet ψ_λ, namely, its type, its location $k(\lambda)$, and its scale $|\lambda|$.

We shall now explain the meaning of "suitable" in the present context. We will always assume that the wavelets have compact support $S_\lambda := \operatorname{supp}\psi_\lambda$, $\lambda \in \mathcal{J}$, which scales as $\operatorname{diam}(S_\lambda) \sim 2^{-|\lambda|}$.

Furthermore, aside from finitely many functions $\psi_\lambda, \lambda \in \mathcal{J}_\phi \subset \mathcal{J}$, $|\lambda| = j_0$, representing the coarsest scale j_0, the wavelets ψ_λ, $\lambda \in \mathcal{J}\backslash\mathcal{J}_\phi$, have *vanishing moments* of some order $m \in \mathbb{N}$; i.e., these wavelets are orthogonal to all polynomials of order m.

Finally, each $v \in \mathcal{H}$ has a unique expansion $\sum_{\lambda\in\mathcal{J}} v_\lambda\psi_\lambda$ such that

$$c_1\|\mathbf{v}\|_{\ell_2(\mathcal{J})} \le \left\|\sum_{\lambda\in\mathcal{J}} v_\lambda\psi_\lambda\right\|_{\mathcal{H}} \le C_1\|\mathbf{v}\|_{\ell_2(\mathcal{J})} \tag{2.5}$$

holds for some positive constants c_1, C_1; i.e., Ψ forms a *Riesz basis* for $\mathcal{H}$. Note that (unlike the quoted references) we have normalized the wavelets here in the energy space $\mathcal{H}$ associated with the variational problem (2.1), (2.2); i.e., $\|\psi_\lambda\|_{\mathcal{H}} = 1$, $\lambda \in \mathcal{J}$. Again such bases are known whenever $\mathcal{H}$ is a product of Sobolev spaces (or closed subspaces of Sobolev spaces, determined, e.g., by homogeneous boundary conditions or vanishing integral means).

In the following, we will always use boldface notation $\mathbf{v}$ to denote the wavelet coefficients of a given function $v \in \mathcal{H}$ with respect to the basis Ψ (and analogously for $u, w \in \mathcal{H}$).

Next note that by duality (2.5) implies

$$C_1^{-1}\|(\langle w, \psi_\lambda\rangle)_{\lambda\in\mathcal{J}}\|_{\ell_2(\mathcal{J})} \le \|w\|_{\mathcal{H}'} \le c_1^{-1}\|(\langle w, \psi_\lambda\rangle)_{\lambda\in\mathcal{J}}\|_{\ell_2(\mathcal{J})}. \tag{2.6}$$

We can now transform (2.2) into wavelet coordinates. Defining

$$\mathbf{R}(\mathbf{v}) := (\langle\psi_\lambda, R(v)\rangle : \lambda \in \mathcal{J}) \quad \text{whenever} \quad v = \sum_{\lambda\in\mathcal{J}} v_\lambda\psi_\lambda, \tag{2.7}$$

the original problem (2.2) is obviously equivalent to finding $\mathbf{u} \in \ell_2(\mathcal{J})$ so that

$$\mathbf{R}(\mathbf{u}) = \mathbf{0}. \tag{2.8}$$

Now note that the Jacobian $D\mathbf{R}(\mathbf{v}) = D\mathbf{F}(v)$ is given by

$$D\mathbf{R}(\mathbf{v}) = (\langle\psi_\lambda, DR(v)\psi_\nu\rangle)_{\lambda,\nu\in\mathcal{J}}\,, \tag{2.9}$$

where again $DR = DF$ is the Frechét derivative of the mapping R. Combining the norm equivalences (2.5), (2.6) with the mapping property (2.4) shows in what sense (2.8) is now well posed in ℓ_2; see, e.g., [9] for a proof.

Remark 2.1. Under the above assumptions A1 and A2, one has for any $v = \sum_{\lambda\in\mathcal{J}} v_\lambda\psi_\lambda \in \mathcal{U}$

$$c_1^2 c_{v,F}\|\mathbf{w}\|_{\ell_2(\mathcal{J})} \le \|D\mathbf{F}(\mathbf{v})\mathbf{w}\|_{\ell_2(\mathcal{J})} \le C_1^2 C_{v,F}\|\mathbf{w}\|_{\ell_2(\mathcal{J})}, \quad \mathbf{w} \in \ell_2(\mathcal{J}). \tag{2.10}$$

2.3. The basic iteration. According to (n3), we wish to devise an iterative scheme for the problem (2.8) such that each step reduces the current error at least by a fixed rate $\rho < 1$. The schemes we shall consider will have the form

$$\mathbf{u}^{n+1} = \mathbf{u}^n - \mathbf{B}_n\mathbf{R}(\mathbf{u}^n), \tag{2.11}$$

where the (infinite, possibly stage dependent) matrix $\mathbf{B}_n$ is yet to be chosen. For instance, $\mathbf{B}_n = \alpha\mathbf{I}$ corresponds to a fixed point or Richardson iteration, while for $\mathbf{B}_n := D\mathbf{R}(\mathbf{u}^n)^{-1}$ (2.11) becomes Newton's method.

We proceed now to discuss several instances of this setting.

3. The scope of reference problems. We shall address the variational problem (2.2) for the following different levels of generality:

(SL) semilinear elliptic boundary value problems, covering the case (L) of *linear* problems as a special case;

(GNL) general nonlinear problems.

The explicit discussion of (SL) will serve several purposes. First, this class is specific enough to permit a complete complexity analysis for a *globally convergent* adaptive scheme. In particular, we shall be able to obtain in this case concrete bounds on initial guesses or how to find a suitable damping parameter in $\mathbf{B}_n = \alpha\mathbf{I}$. Second, this class is a model representative for the interplay between a linear (diffusion) operator and a nonlinear part. On one hand, it covers linear problems (L) as special cases. Briefly reviewing the essential features of linear problems in this context comes in handy for three reasons. It provides a guideline for the treatment of nonlinear problems. It is a necessary prerequisite for the later discussion of Newton's method. Most importantly, in the presence of a nonlinearity, the complexity analysis for the linear case has to be modified in order to treat problems where both linear and nonlinear operators are involved. It will be instructive to see the conceptual distinctions and how the treatment of nonlinear problems builds on ingredients from the linear case.

Finally, in (GNL) we relax our assumptions on the structure of R to a great extent. We pay for this by making stronger assumptions on initial guesses and being content with *locally convergent first order* iterations on the infinite dimensional level.

We shall exemplify step (n3) for all three cases (L), (SL), and (GNL) in this order. Except for the last section, this will be based on first order iteration schemes for the underlying infinite dimensional problem. It will be seen along the way that it then suffices to employ stationary "preconditioners" $\mathbf{B}_n = \mathbf{B}$ to obtain asymptotically optimal complexity estimates (although more flexible nonstationary choices may well result in quantitative improvements in practical realizations). The use of truly nonstationary $\mathbf{B}_n$ will be necessary only in connection with Newton's method in section 8.

3.1. Semilinear (SL) and linear (L) elliptic problems. Suppose that $a(\cdot,\cdot)$ is a continuous bilinear form on a Hilbert space $\mathcal{H}$ endowed with the norm $\|\cdot\|_{\mathcal{H}}$, which is $\mathcal{H}$-elliptic; i.e., there exist positive constants c, C such that

$$c\|v\|_{\mathcal{H}}^2 \leq a(v,v), \quad a(v,w) \leq C\|v\|_{\mathcal{H}}\|w\|_{\mathcal{H}} \quad \forall\ v,w \in \mathcal{H}. \tag{3.1}$$

The simplest example is

$$a(v,u) := \langle \nabla v, \nabla u\rangle + \kappa\langle v,u\rangle, \quad \kappa \geq 0, \ \ \langle v,w\rangle = \int_\Omega vw, \tag{3.2}$$

and $\mathcal{H} = H_0^1(\Omega)$ (the space of functions with first order weak derivatives in L_2 whose traces vanish on the boundary $\Gamma = \partial\Omega$) endowed with the norm $\|v\|_{\mathcal{H}}^2 := \|\nabla v\|_{L_2(\Omega)}^2 + \kappa\|v\|_{L_2(\Omega)}^2$.

In principle, the subsequent analysis will also cover elliptic integral operators with positive order such as the hypersingular operator.

To introduce a nonlinearity, we suppose that $G : \mathbb{R} \to \mathbb{R}$ is a function with the following property:

P1. The mapping $v \mapsto G(v)$ takes $\mathcal{H}$ into its dual $\mathcal{H}'$ and is *stable* in the sense that

$$\|G(u) - G(v)\|_{\mathcal{H}'} \le C_G(\max\{\|u\|_{\mathcal{H}}, \|v\|_{\mathcal{H}}\})\|u - v\|_{\mathcal{H}}, \quad u, v \in \mathcal{H}, \tag{3.3}$$

where $t \to C_G(t)$ is a nondecreasing function of t.

The problem: Given $f \in \mathcal{H}'$, find $u \in \mathcal{H}$ such that

$$\langle v, F(u)\rangle := a(v, u) + \langle v, G(u)\rangle = \langle v, f\rangle \quad \forall \ \ v \in \mathcal{H} \tag{3.4}$$

is of the form (2.2) with $R(v) = F(v) - f$.

Remark 3.1. If we assume in addition to P1 that G is monotone (as in (3.6)), i.e., $(u - v)(G(u) - G(v)) \ge 0$ for $u, v \in \mathbb{R}$, then (3.4) has for every $f \in \mathcal{H}'$ a unique solution $u \in \mathcal{H}$. Moreover, the problem is well posed in the sense of (2.4) with constants $c_{v,F} := c$, $C_{v,F} := C + C_G(\|v\|_{\mathcal{H}})$, where c, C are the constants from (3.1) and $C_G(s)$ is the constant from (3.3) in P1.

Proof. The argument follows standard lines. Under the above assumptions it is easy to show that the operator F, defined by (3.4), is also monotone and coercive. One can then invoke the Browder–Minty theorem (see, e.g., [22, Theorem 9.45]) to conclude existence, while the strict monotonicity guaranteed by the quadratic part also ensures uniqueness. To confirm the validity of (2.4) with the above constants, let $\mathcal{A}$ be the linear operator defined by $\langle w, \mathcal{A}v\rangle = a(w, v)$, for all $w, v \in \mathcal{H}$, and note that, in view of (3.1),

$$c\|v\|_{\mathcal{H}} \le \|\mathcal{A}v\|_{\mathcal{H}'} \le C\|v\|_{\mathcal{H}}, \quad v \in \mathcal{H}, \tag{3.5}$$

with c, C from (3.1). Since we have $DF(v)w = \mathcal{A}w + G'(v)w$, the assertion follows easily from (3.5), P1, and the monotonicity of G. □

Remark 3.2. Alternatively one can argue that, under the above assumptions, G is of potential type so that (3.4) is the Euler equation of a convex minimization problem with a strictly convex functional; see, e.g., [24, Proposition 42.6].

As an example, it is not hard to verify that the weak formulation of the boundary value problem

$$-\Delta u + u^3 = f \quad \text{in} \ \ \Omega, \quad u = 0 \ \ \text{on} \ \ \partial\Omega, \tag{3.6}$$

is of the form (3.4), where for $\mathcal{H} = H_0^1(\Omega)$ the above assumptions hold for $d \le 3$, and that it satisfies the monotonicity assumption of Remark 3.1.

An equivalent ℓ_2-formulation (n2). We turn now to step (n2) in the present setting. In order to rewrite (3.4) in wavelet coordinates, let $\mathbf{A} = (a(\psi_\lambda, \psi_\nu))_{\lambda,\nu\in\mathcal{J}}$ denote the wavelet representation of the operator $\mathcal{A}$, and set $\mathbf{f} = (\langle\psi_\lambda, f\rangle : \lambda \in \mathcal{J})^T$. In addition, define in analogy to (2.7) $\mathbf{G}(\mathbf{v}) := (\langle\psi_\lambda, G(v)\rangle)_{\lambda\in\mathcal{J}}$. Then $u = \sum_{\lambda\in\mathcal{J}} u_\lambda\psi_\lambda$ is the unique solution of (3.4) if and only if $\mathbf{u}$ solves

$$\mathbf{R}(\mathbf{u}) := \mathbf{A}\mathbf{u} + \mathbf{G}(\mathbf{u}) - \mathbf{f} = \mathbf{0}. \tag{3.7}$$

Note that, in view of (2.6), f belongs to $\mathcal{H}'$ if and only if $\mathbf{f} \in \ell_2(\mathcal{J})$. Clearly, by our assumptions on $a(\cdot,\cdot)$, $\mathbf{A}$ is symmetric positive definite. Moreover, it follows from Remarks 2.1 and 3.1 that (2.10) holds for $\mathbf{R}$ in (3.7). In particular, this covers the case $G \equiv 0$, where (2.10) takes the form

$$c_A\|\mathbf{v}\|_{\ell_2(\mathcal{J})} \le \|\mathbf{A}\mathbf{v}\|_{\ell_2(\mathcal{J})} \le C_A\|\mathbf{v}\|_{\ell_2(\mathcal{J})}, \quad \mathbf{v} \in \ell_2(\mathcal{J}), \tag{3.8}$$

with $c_A = c_1^2c$, $C_A = C_1^2C$, and c_1, C_1, c, C from (2.5) and (3.1).

We end this section with the simple observation that monotonicity of G carries over into the discrete setting, namely,

$$(\mathbf{u}-\mathbf{v})^T(\mathbf{G}(\mathbf{u})-\mathbf{G}(\mathbf{v})) \geq 0, \quad \mathbf{u},\mathbf{v} \in \ell_2(\mathcal{J}). \tag{3.9}$$

In fact, denoting by $\tilde{\Psi}$ the dual basis to Ψ, we have by definition of $\mathbf{G}(\mathbf{u})$

$$u - v = \sum_{\lambda\in\mathcal{J}}(u_\lambda - v_\lambda)\psi_\lambda, \quad G(u)-G(v) = \sum_{\lambda\in\mathcal{J}}\langle G(u)-G(v),\psi_\lambda\rangle\tilde{\psi}_\lambda.$$

Thus (3.9) follows from monotonicity of G and biorthogonality. Due to (3.1), F is also monotone so that (3.9) holds also for $\mathbf{F}$.

Gradient iterations (n3). We now address (n3) for the above class of semilinear elliptic problems. The simplest option is to take $\mathbf{B}_n = \alpha\mathbf{I}$, which gives the iteration

$$\mathbf{u}^{n+1} = \mathbf{u}^n - \alpha\mathbf{R}(\mathbf{u}^n), \quad n \in \mathbb{N}_0. \tag{3.10}$$

We have to find some $\alpha > 0$ for which this iteration converges in $\ell_2(\mathcal{J})$ with a guaranteed error reduction $\rho < 1$. To this end, note that, by (2.8), $\mathbf{u}^{n+1}-\mathbf{u} = \mathbf{u}^n - \mathbf{u} - \alpha(\mathbf{R}(\mathbf{u}^n)-\mathbf{R}(\mathbf{u}))$, so that

$$\begin{aligned}\mathbf{u}^{n+1}-\mathbf{u} &= \left(\mathbf{I} - \alpha\int_0^1(\mathbf{A}+D\mathbf{G}(\mathbf{u}+s(\mathbf{u}^n-\mathbf{u})))ds\right)(\mathbf{u}^n-\mathbf{u})\\ &=: (\mathbf{I}-\alpha\mathbf{M}(\mathbf{u}^n,\mathbf{u}))\,(\mathbf{u}^n-\mathbf{u}).\end{aligned} \tag{3.11}$$

By (3.9) and (3.8), the smallest eigenvalue of the matrix $\mathbf{M}(\mathbf{u}^n,\mathbf{u})$ is bounded from below by c_A. To bound the spectral radius of $\mathbf{M}(\mathbf{u}^n,\mathbf{u})$, note that, by (2.5) and (2.6), one has $\|\mathbf{G}(\mathbf{v})-\mathbf{G}(\mathbf{w})\|_{\ell_2(\mathcal{J})} \leq \hat{C}(\max\{\|\mathbf{v}\|_{\ell_2(\mathcal{J})},\|\mathbf{w}\|_{\ell_2(\mathcal{J})}\})\|\mathbf{v}-\mathbf{w}\|_{\ell_2(\mathcal{J})}$, where $\hat{C}(s) := C_1^2C_G(C_1s)$ and $C_1, C_G(s)$ are the constants from (2.5) and (3.3) for G, respectively. It follows from (3.8) and (3.3) in P1 that $\|\mathbf{M}(\mathbf{u}^n,\mathbf{u})\|_{\ell_2(\mathcal{J})\to\ell_2(\mathcal{J})} \leq C_A + \hat{C}(\|\mathbf{u}-\mathbf{u}^n\|_{\ell_2(\mathcal{J})})$. Given some knowledge about the behavior of the stability constant $C_G(s)$ when s increases, we can estimate $\hat{C}(\|\mathbf{u}-\mathbf{u}^n\|_{\ell_2(\mathcal{J})})$ with the aid of an a priori estimate for $\|\mathbf{u}^n-\mathbf{u}\|_{\ell_2(\mathcal{J})}$. To this end, note that again by (2.8) and (3.7), one has for any $\mathbf{v}\in\ell_2(\mathcal{J})$

$$\begin{aligned}\|\mathbf{u}-\mathbf{v}\|_{\ell_2(\mathcal{J})}\|\mathbf{R}(\mathbf{v})\|_{\ell_2(\mathcal{J})} \geq (\mathbf{u}-\mathbf{v})^T(\mathbf{R}(\mathbf{v})-\mathbf{R}(\mathbf{u})) = (\mathbf{u}-\mathbf{v})^T\big(\mathbf{A}(\mathbf{u}-\mathbf{v})\\ + \mathbf{G}(\mathbf{u})-\mathbf{G}(\mathbf{v})\big) \geq c_A\|\mathbf{u}-\mathbf{v}\|^2_{\ell_2(\mathcal{J})},\end{aligned}$$

where we have used (3.8) and (3.9) in the last step. Hence we obtain

$$\|\mathbf{u}-\mathbf{v}\|_{\ell_2(\mathcal{J})} \leq c_A^{-1}\|\mathbf{R}(\mathbf{v})\|_{\ell_2(\mathcal{J})}, \quad \|\mathbf{u}\|_{\ell_2(\mathcal{J})} \leq c_A^{-1}\big(\|\mathbf{G}(\mathbf{0})\|_{\ell_2(\mathcal{J})} + \|\mathbf{f}\|_{\ell_2(\mathcal{J})}\big). \tag{3.12}$$

Thus, for any fixed initial guess $\mathbf{v} = \mathbf{u}^0$, we have a computable bound

$$\|\mathbf{u}^0-\mathbf{u}\|_{\ell_2(\mathcal{J})} \leq c_A^{-1}\big(\|\mathbf{R}(\mathbf{u}^0)\|_{\ell_2(\mathcal{J})}\big) =: \delta_0 \tag{3.13}$$

and therefore a bound for $\hat{C}(\delta_0)$.

Remark 3.3. Given $\mathbf{u}^0$ and δ_0 from (3.13), suppose that $\alpha > 0$ satisfies

$$0 < \alpha < 2/(C_A + \hat{C}(\delta_0)) \tag{3.14}$$

for $\hat{C}(\delta_0)$ defined above so that

$$\rho = \rho(\alpha) := \max\{|1-c_A\alpha|, |1-\alpha(C_A+\hat{C}(\delta_0))|\} < 1. \tag{3.15}$$

Then, denoting by $B_\delta(\mathbf{u})$ the ball of radius δ with center $\mathbf{u}$, we have

$$\sup_{\mathbf{v}\in B_{\delta_0}(\mathbf{u})} \|\mathbf{I}-\alpha\big(\mathbf{A}+D\mathbf{G}(\mathbf{v})\big)\|_{\ell_2(\mathcal{J})\to\ell_2(\mathcal{J})} =: \rho < 1. \tag{3.16}$$

Hence we obtain $\|\mathbf{I}-\alpha\mathbf{M}(\mathbf{u}^n,\mathbf{u})\|_{\ell_2(\mathcal{J})\to\ell_2(\mathcal{J})} \le \rho$, which, in view of (3.11), yields

$$\|\mathbf{u}-\mathbf{u}^n\|_{\ell_2(\mathcal{J})} \le \rho\|\mathbf{u}-\mathbf{u}^{n-1}\|_{\ell_2(\mathcal{J})}, \quad n\in\mathbb{N}. \tag{3.17}$$

Of course, a better error reduction would result from an optimal stage dependent step size α_n. Keeping Remark 3.2 in mind, one can show that (3.7) are the Euler equations of a strictly convex minimization problem on $\ell_2(\mathcal{J})$. For a given $\mathbf{u}^n$ the residual $\mathbf{r} := \mathbf{f}-\mathbf{A}\mathbf{u}^n-\mathbf{G}(\mathbf{u}^n)$ is the direction of the corresponding steepest descent starting from $\mathbf{u}^n$. The minimum along this direction is given by the zero $\alpha=\alpha_n$ of the function $g(\alpha) = \big(\mathbf{f}-\mathbf{A}(\mathbf{u}^n+\alpha\mathbf{r})-\mathbf{G}(\mathbf{u}^n+\alpha\mathbf{r})\big)^T\mathbf{r} = \mathbf{0}$. We shall later discuss ways of approximately evaluating the terms in $g(\alpha)$. Noting that $g'(\alpha) = -\mathbf{r}^T(\mathbf{A}+D\mathbf{G}(\mathbf{u}^n+\alpha\mathbf{r}))\mathbf{r}$, one could think of using such routines for performing a Newton step with the above initial guess for α to solve approximately $g(\alpha)=0$.

We conclude this section with a remark on the linear case (L), which is to find $u\in\mathcal{H}$ such that

$$a(v,u) = \langle v,f\rangle \quad \forall\, v\in\mathcal{H} \quad\Longleftrightarrow\quad \mathbf{A}\mathbf{u}=\mathbf{f}. \tag{3.18}$$

Note that (3.5) follows from (3.1) but may still hold for indefinite problems, which still implies, in view of Remark 2.1, the validity of (3.8). In this case, when $G\equiv 0$, the matrix $\mathbf{A}^T\mathbf{A}$ is symmetric positive definite, and the iteration

$$\mathbf{u}^{n+1} = \mathbf{u}^n - \alpha\mathbf{A}^T(\mathbf{A}\mathbf{u}^n-\mathbf{f}), \quad n=0,1,2,\dots, \tag{3.19}$$

converges with a fixed error reduction $\rho<1$, provided that $0<\alpha<2/C_A^2$; i.e., (3.19) has the form (2.11) with $\mathbf{B}_n := \alpha\mathbf{A}^T$. An analogue for the general nonlinear case (GNL) will be given below.

For saddle point problems there are actually alternatives that avoid squaring the problem (in wavelet coordinates). One option is to employ an Uzawa iteration for applying the Schur complement operator, which conceptually also leads to an iteration of the form (3.10) for the Schur complement [13, 17].

Of course, in either case, step (n4) requires eventually approximating the *weighted residual* $\mathbf{B}_n\mathbf{R}(\mathbf{u}^n)$, which in the above linear case amounts to approximating $\mathbf{f}$ and approximately evaluating the infinite matrix $\mathbf{A}$ (respectively, $\mathbf{A}^T$). We shall address this issue later in some detail.

3.2. The general nonlinear case—locally convergent schemes (GNL).

While the assumptions in the previous setting allow us to conclude convergence of the ideal infinite dimensional scheme for *any* initial guess $\mathbf{u}^0$, one often has to be content with weaker assumptions (and correspondingly weaker conclusions). In the literature, variational problems of the type (2.2) are frequently studied under general assumptions on R, such as A1 and A2, that typically guarantee local convergence of an iterative scheme to a locally unique solution provided that a sufficiently good initial guess is known; see, e.g., [21, 23].

Our plan here is to exemplify the above paradigm under assumptions A1 and A2, provided that a sufficiently good initial approximation is known. According to (n2), we consider again the equivalent formulation (2.8) in wavelet coordinates and turn to devising a suitable iteration of the form (2.11) that converges for a sufficiently good initial guess. To this end, we assume that

$$\mathbf{u}^0 \in B_\delta(\mathbf{u}) := \{\mathbf{v} : \|\mathbf{v} - \mathbf{u}\|_{\ell_2(\mathcal{J})} < \delta\}, \tag{3.20}$$

where δ will be specified below.

As mentioned before, a possible choice for $\mathbf{B}_n$ could involve the Jacobian, which leads to Newton's method. However, under the above weak assumptions on R, we wish to avoid at this point requiring higher order smoothness conditions and consider first the following much simpler option. An analogue to the least squares iteration (3.19) would be $\mathbf{B}_n := D\mathbf{R}(\mathbf{u}^n)^T$. An even simpler alternative, which is presumably less computationally demanding, is to take the *stationary* matrix

$$\mathbf{B} = D\mathbf{R}(\mathbf{u}^0)^T, \tag{3.21}$$

provided that δ is sufficiently small. Let us point out next that for a sufficiently good initial guess $\mathbf{u}^0$

$$\mathbf{W}(\mathbf{v}) := \mathbf{v} - \alpha D\mathbf{R}(\mathbf{u}^0)^T\mathbf{R}(\mathbf{v})$$

is a contraction on $B_\delta(\mathbf{u})$. In fact,

$$\begin{aligned}\mathbf{W}(\mathbf{z}) - \mathbf{W}(\mathbf{v}) &= (\mathbf{z} - \mathbf{v}) - \alpha D\mathbf{R}(\mathbf{u}^0)^T(\mathbf{R}(\mathbf{z}) - \mathbf{R}(\mathbf{v}))\\ &= \left(\mathbf{I} - \alpha D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{v})\right)(\mathbf{z} - \mathbf{v}) + \mathrm{o}(\|\mathbf{z} - \mathbf{v}\|_{\ell_2(\mathcal{J})})\\ &= \left(\mathbf{I} - \alpha D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{u}^0)\right)(\mathbf{z} - \mathbf{v}) + \mathrm{o}(\|\mathbf{z} - \mathbf{v}\|_{\ell_2(\mathcal{J})})\\ &\qquad + \mathrm{O}(\epsilon(\delta)\|\mathbf{z} - \mathbf{v}\|_{\ell_2(\mathcal{J})}),\end{aligned} \tag{3.22}$$

where we have used assumption A1 and where $\epsilon(\delta)$ tends to zero as $\delta \to 0$. By A1 and A2, $DR(u^0)$ is still an isomorphism from $\mathcal{H}$ onto $\mathcal{H}'$ when δ is sufficiently small. Thus, by Remark 2.1, the positive definite matrix $D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{u}^0)$ is an automorphism on $\ell_2(\mathcal{J})$. Therefore, for $\alpha > 0$ satisfying

$$\alpha\|D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{u}^0)\|_{\ell_2(\mathcal{J})\to\ell_2(\mathcal{J})} < 2, \tag{3.23}$$

$\mathbf{W}$ is a contraction on $B_\delta(\mathbf{u})$. Furthermore, the iterates

$$\mathbf{u}^{n+1} = \mathbf{u}^n - \alpha D\mathbf{R}(\mathbf{u}^0)^T\mathbf{R}(\mathbf{u}^n), \quad n = 0, 1, \ldots, \tag{3.24}$$

stay in $B_\delta(\mathbf{u})$. In fact, as above,

$$\begin{aligned}\mathbf{u}^{n+1} - \mathbf{u} &= \mathbf{u}^n - \mathbf{u} - \alpha D\mathbf{R}(\mathbf{u}^0)^T(\mathbf{R}(\mathbf{u}^n) - \mathbf{R}(\mathbf{u}))\\ &= (\mathbf{I} - \alpha D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{u}^0))(\mathbf{u}^n - \mathbf{u}) + \mathrm{o}(\|\mathbf{u}^n - \mathbf{u}\|_{\ell_2(\mathcal{J})})\\ &\qquad + \mathrm{O}(\epsilon(\delta)\|\mathbf{u}^n - \mathbf{u}\|_{\ell_2(\mathcal{J})}).\end{aligned}$$

Hence, for α as above and δ sufficiently small, i.e., $\|\mathbf{I}-\alpha D\mathbf{R}(\mathbf{u}^0)^T D\mathbf{R}(\mathbf{u}^0)\|_{\ell_2(\mathcal{J})\to\ell_2(\mathcal{J})} =: b < 1$ and $\mathrm{o}(1) + \mathrm{O}(\epsilon(\delta)) < 1 - b$, one has $\|\mathbf{u}^{n+1} - \mathbf{u}\|_{\ell_2(\mathcal{J})} < \delta$. We can summarize these observations as follows.

Remark 3.4. Under the above assumptions there exist a $\delta_0 > 0$ and a positive α such that for any $\delta \le \delta_0$ and $\mathbf{u}^0 \in B_\delta(\mathbf{u})$ the iteration (3.24) converges to the locally unique solution $\mathbf{u}$ of (2.8). Moreover, there exists some $\rho < 1$ such that

$$\|\mathbf{u}^n - \mathbf{u}\|_{\ell_2(\mathcal{J})} \le \rho\|\mathbf{u}^{n-1} - \mathbf{u}\|_{\ell_2(\mathcal{J})}, \quad n = 1, 2, \ldots. \tag{3.25}$$

4. A perturbed first order iteration scheme. We shall now turn to step (n4) under the assumption that (2.11) gives rise to a fixed error reduction ρ per iteration step. Recall that by (3.17) and (3.25), this is indeed already the case for (L), (SL), and (GNL) for the corresponding stationary choices of $\mathbf{B}_n = \mathbf{B}$. In order to minimize technicalities we shall consider only this case in connection with such first order schemes. In order to arrive at computable versions of these schemes, we have to *approximate* the weighted residuals $\mathbf{BR}(\mathbf{u}^n)$ in each step. Already in the linear case (L), this requires approximating the application of an infinite matrix to a finitely supported vector and approximating the given data $\mathbf{f}$. In the nonlinear cases (SL), (GNL), the additional difficulty is to approximately evaluate the *nonlinear* expressions $\mathbf{R}(\mathbf{u}^j)$.

Our strategy can be outlined as follows. In the present section we shall address only issue (a) from section 1.2, namely, How accurate must these approximations be to be chosen at a given stage of the iteration so as to guarantee convergence to the correct solution? We shall do so at this point under the *assumption* that a subroutine for approximating the weighted residuals $\mathbf{BR}(\mathbf{v})$ with desired accuracy is at our disposal. Once (a) has been clarified for the general scope of problems, we shall in subsequent sections then narrow down step by step the specific requirements on the basic subroutine, develop concrete realizations for the various problem types (L), (SL), and (GNL), and analyze their complexity.

Thus for the time being we assume now that for $\mathbf{R}(\cdot) = \mathbf{F}(\cdot) - \mathbf{f}$ a routine with the following property is given.

$\mathbf{RES}\,[\eta, \mathbf{B}, \mathbf{F}, \mathbf{f}, \mathbf{v}] \to \mathbf{w}_\eta$ *determines for any positive tolerance* η *and any finitely supported input* $\mathbf{v}$ *a finitely supported* $\mathbf{w}_\eta$ *satisfying*

$$\|\mathbf{BR}(\mathbf{v}) - \mathbf{w}_\eta\|_{\ell_2(\mathcal{J})} \le \eta. \tag{4.1}$$

The need for the following further ingredient is at this point less obvious. It will be applied after a certain finite number of perturbed iterations based on the application of **RES**. It will be seen later that this is crucial for controlling the complexity of the scheme.

$\mathbf{CCOARSE}\,[\eta, \mathbf{v}] \to \mathbf{w}_\eta$ *determines for any positive tolerance* η *and any finitely supported input vector* $\mathbf{v}$ *a finitely supported output vector* $\mathbf{w}_\eta$ *such that*

$$\|\mathbf{v} - \mathbf{w}_\eta\|_{\ell_2(\mathcal{J})} \le \eta, \tag{4.2}$$

while the support of $\mathbf{w}_\eta$ *is minimized subject to certain constraints on the distribution of its entries.*

The constraints mentioned in **CCOARSE** will depend on the particular application and will be specified later. A perturbed iteration based on these ingredients requires specifying a suitable initialization.

Initialization. We distinguish the following three cases for the choice of the initial guess.

(L) In the linear case $\mathbf{R}(\mathbf{v}) = \mathbf{A}\mathbf{v} - \mathbf{f}$, we can set $\mathbf{u}^0 := \mathbf{0}$ so that an initial error bound is given, directly in view of (3.8), by $\|\mathbf{u} - \mathbf{u}^0\|_{\ell_2(\mathcal{J})} = \|\mathbf{u}\|_{\ell_2(\mathcal{J})} \le c_A^{-1}\|\mathbf{f}\|_{\ell_2(\mathcal{J})} =: \epsilon_0$. Moreover, in the positive definite case, any fixed $\alpha < 2/C_A$ in $\mathbf{B} = \alpha\mathbf{I}$ and $\alpha < 2/C_A^2$ in $\mathbf{B} = \alpha\mathbf{A}^T$ for the general least squares formulation ensure that $\mathbf{I} - \mathbf{BA}$ is a contraction on $B = \ell_2(\mathcal{J})$.

(SL) In the case of semilinear elliptic problems (3.7), (3.4), we recall from (3.12) that for $\mathbf{u}^0 = \mathbf{0}$ the initial error is bounded by

$$\|\mathbf{u}\|_{\ell_2(\mathcal{J})} \le c_A^{-1}\big(\|\mathbf{G}(\mathbf{0})\|_{\ell_2(\mathcal{J})} + \|\mathbf{f}\|_{\ell_2(\mathcal{J})}\big) =: \epsilon_0. \tag{4.3}$$

We choose $B = B_{2\epsilon_0}(\mathbf{u})$ and $\mathbf{B} := \alpha\mathbf{I}$ for a fixed $\alpha < 2/(C_A + \hat{C}(2\epsilon_0))$, $\alpha \leq 1$, so that (3.16) holds for $\delta_0 = 2\epsilon_0$ and $\rho = \rho(\alpha) < 1$, defined in (3.15).

(GNL) For the locally convergent scheme, we adhere to the assumptions made in section 3.2. For any fixed $\delta < \delta_0$ (the parameter from Remark 3.4) which satisfies $(1+\alpha)\delta < \delta_0$, where α is the constant from (3.23), we choose $\mathbf{u}^0$ according to (3.20). In this case, we have $\mathbf{B} = \alpha D\mathbf{R}(\mathbf{u}^0)^T$, and $\epsilon_0 := \delta$ is a valid initial error bound which ensures that for $\mathbf{v} \in B := B_\delta(\mathbf{u})$ the matrix $\mathbf{I} - \mathbf{B}D\mathbf{R}(\mathbf{v})$ is a contraction.

Thus in all cases (L), (SL), and (GNL) one has under the above premises

$$\|\mathbf{u} - \mathbf{u}^0\|_{\ell_2(\mathcal{J})} \leq \epsilon_0. \tag{4.4}$$

In order to control the perturbations caused by applications of **RES**, it will be convenient to extract the following fact from the above considerations.

Remark 4.1. For each of the above choices of $\mathbf{B}$ in (L), (SL), and (GNL) and the respective neighborhoods B of the exact solution $\mathbf{u}$ specified in the initialization, one has

$$\|(\mathbf{v} - \mathbf{z}) - \mathbf{B}(\mathbf{R}(\mathbf{v}) - \mathbf{R}(\mathbf{z}))\|_{\ell_2(\mathcal{J})} \leq \rho\|\mathbf{v} - \mathbf{z}\|_{\ell_2(\mathcal{J})}, \quad \mathbf{v}, \mathbf{z} \in B, \tag{4.5}$$

where $\rho < 1$ is the respective error reduction rate in (3.17) for the iteration (2.11).

Proof. The linear case (L) is obvious.

In the case (SL) of the semilinear elliptic problem (3.4), respectively, (3.7), one has for $\mathbf{B} = \alpha\mathbf{I}$ (with α specified in the initialization), by the same reasoning used in (3.11),

$$\mathbf{v} - \mathbf{z} - \alpha(\mathbf{R}(\mathbf{v}) - \mathbf{R}(\mathbf{z})) = \left(\mathbf{I} - \alpha\left(\mathbf{A} + \int_0^1 D\mathbf{G}(\mathbf{z} + s(\mathbf{v} - \mathbf{z}))ds\right)\right)(\mathbf{v} - \mathbf{z}).$$

The assertion follows then from (3.16).

Finally, for (GNL) (see section 3.2), the claim follows from (3.22) for $\mathbf{B} = \alpha D\mathbf{R}(\mathbf{u}^0)^T$ and α satisfying (3.23) with $B = B_\delta(\mathbf{u})$. □

The following last prerequisite will allow us to control the number of calls of **RES** before applying a coarsening step.

Remark 4.2. For each of the above choices of $\mathbf{B}$ in (L), (SL), and (GNL) and for the respective neighborhoods B of the exact solution $\mathbf{u}$, there exists a positive finite constant β such that

$$\|\mathbf{u} - \mathbf{v}\|_{\ell_2(\mathcal{J})} \leq \beta\|\mathbf{B}\mathbf{R}(\mathbf{v})\|_{\ell_2(\mathcal{J})}, \quad \mathbf{v} \in B. \tag{4.6}$$

Proof. Of course, in principle, this follows from (4.5) by the triangle inequality. However, β then depends on ρ for which only a poor estimate may be available. For (L) and (SL) one obtains better bounds as follows. From (3.7) and (3.9) we infer that

$$\begin{aligned}\|\mathbf{R}(\mathbf{v})\|_{\ell_2(\mathcal{J})} &= \sup_{\mathbf{z}\neq\mathbf{0}} \frac{\mathbf{z}^T(\mathbf{A}(\mathbf{v} - \mathbf{u}) + \mathbf{G}(\mathbf{v}) - \mathbf{G}(\mathbf{u}))}{\|\mathbf{z}\|_{\ell_2(\mathcal{J})}} \geq \frac{(\mathbf{v} - \mathbf{u})^T\mathbf{A}(\mathbf{v} - \mathbf{u})}{\|\mathbf{v} - \mathbf{u}\|_{\ell_2(\mathcal{J})}} \\ &\geq c_A\|\mathbf{v} - \mathbf{u}\|_{\ell_2(\mathcal{J})}.\end{aligned}$$

Thus (4.6) holds with $\beta = 1/(\alpha c_A)$. Similarly $\beta = 1/(\alpha c_A^2)$ works for the least squares formulation (3.19). For (GNL) we have by our assumptions that $\|\mathbf{B}(\mathbf{R}(\mathbf{v}) - D\mathbf{R}(\mathbf{v}))(\mathbf{v} - \mathbf{u})\|_{\ell_2(\mathcal{J})} \leq o(\|\mathbf{v} - \mathbf{u}\|_{\ell_2(\mathcal{J})})$ so that in a sufficiently small neighborhood of $\mathbf{u}$ (4.6) follows from the well-posedness relation (2.10). □

We can now describe our computable analogue of (2.11). For this we choose any fixed summable sequence $(\omega_j)_{j\in\mathbb{N}_0}$, which, for convenience, we arrange to sum to one $\sum_{j=0}^{\infty}\omega_j = 1$, and a fixed constant C^* which depends on the specific realization of the routine **CCOARSE**; see sections 5.2 and 6.2.

```
SOLVE $[\epsilon, \mathbf{R}, \mathbf{u}^0] \to \bar{\mathbf{u}}(\epsilon)$
  (i) Choose some $\bar{\rho} \in (0,1)$. Set $\bar{\mathbf{u}}^0 = \mathbf{u}^0$ and the corresponding initial bound $\epsilon_0$
      according to the above initialization, and define $j = 0$;
  (ii) If $\epsilon_j \le \epsilon$, stop and output $\bar{\mathbf{u}}(\epsilon) := \bar{\mathbf{u}}^j$; else set $\mathbf{v}^0 := \bar{\mathbf{u}}^j$ and $k = 0$
    (ii.1) Set $\eta_k := \omega_k \bar{\rho}^k \epsilon_j$ and compute
           $$\mathbf{r}^k = \mathbf{RES}\,[\eta_k, \mathbf{B}, \mathbf{F}, \mathbf{f}, \mathbf{v}^k], \qquad \mathbf{v}^{k+1} = \mathbf{v}^k - \mathbf{r}^k.$$
    (ii.2) If
           $$\beta\big(\eta_k + \|\mathbf{r}^k\|_{\ell_2(\mathcal{J})}\big) \le \epsilon_j/(2(1+2C^*)), \tag{4.7}$$
           set $\tilde{\mathbf{v}} := \mathbf{v}^k$ and go to (iii). Else set $k+1 \to k$ and go to (ii.1).
  (iii) CCOARSE $[\frac{2C^*\epsilon_j}{2(1+2C^*)}, \tilde{\mathbf{v}}] \to \bar{\mathbf{u}}^{j+1}$, $\epsilon_{j+1} = \epsilon_j/2$, $j+1 \to j$, go to (ii).
```

Let us confirm first that the choice of accuracy tolerances in **SOLVE** implies convergence.

PROPOSITION 4.3. *The iterates* $\bar{\mathbf{u}}^j$ *produced by the scheme* **SOLVE** *satisfy*

$$\|\mathbf{u} - \bar{\mathbf{u}}^j\|_{\ell_2(\mathcal{J})} \le \epsilon_j \tag{4.8}$$

so that, in particular, $\|\mathbf{u} - \bar{\mathbf{u}}(\epsilon)\|_{\ell_2(\mathcal{J})} \le \epsilon$. *By* (2.5)*, this means*

$$\Bigg\| u - \sum_{\lambda\in\Lambda(\epsilon)} \bar{u}(\epsilon)_\lambda \psi_\lambda \Bigg\|_{\mathcal{H}} \le C_1\epsilon, \tag{4.9}$$

where C_1 *is the constant from* (2.5) *and* $\Lambda(\epsilon) := \operatorname{supp}\mathbf{u}(\epsilon)$.

Moreover, the number of updates in step (ii.1) *prior to a coarsening step is uniformly bounded by some fixed* $K \in N$, *independent of* ϵ *and the data.*

Proof. We assume the above initialization and employ a simple perturbation argument using induction on j. We fix a value of j and let $\mathbf{u}^k := \mathbf{u}^k(\mathbf{v}^0)$ be the exact iterates $\mathbf{u}^{k+1} = \mathbf{u}^k - \mathbf{B}\mathbf{R}(\mathbf{u}^k)$ with initial guess $\mathbf{u}^0 = \mathbf{v}^0 = \bar{\mathbf{u}}^j$. Hence

$$\begin{aligned} \mathbf{v}^{k+1} - \mathbf{u}^{k+1} &= \mathbf{v}^k - \mathbf{u}^k - (\mathbf{r}^k - \mathbf{B}\mathbf{R}(\mathbf{u}^k)) \\ &= \mathbf{v}^k - \mathbf{u}^k - \mathbf{B}(\mathbf{R}(\mathbf{v}^k) - \mathbf{R}(\mathbf{u}^k)) + (\mathbf{B}\mathbf{R}(\mathbf{v}^k) - \mathbf{r}^k). \end{aligned} \tag{4.10}$$

Next we wish to invoke (4.5). To do this we need to make sure that the iterates $\mathbf{v}^k, \mathbf{u}^k$ stay in the neighborhood B mentioned in Remark 4.1. In the linear case (L) there is no constraint, i.e., $B = \ell_2(\mathcal{J})$. Let us look at the semilinear case (SL) next. By the induction assumption we know that $\|\mathbf{u} - \bar{\mathbf{u}}^j\|_{\ell_2(\mathcal{J})} \le \epsilon_j \le \epsilon_0$. Therefore, $\|\mathbf{u} - \mathbf{u}^k\|_{\ell_2(\mathcal{J})} \le \rho^k\|\mathbf{u} - \mathbf{u}^0\|_{\ell_2(\mathcal{J})} \le \rho^k\|\mathbf{u} - \bar{\mathbf{u}}^j\|_{\ell_2(\mathcal{J})} \le \rho^k\epsilon_j$. So $\mathbf{u}^k \in B$ for all $k \le K$. Also $\mathbf{v}^0 = \bar{\mathbf{u}}^j \in B$. Thus suppose that $\mathbf{v}^k$ is in B. We wish to show that then also $\mathbf{v}^{k+1} \in B$. To this end, let ρ_* be the true reduction rate in (2.11) (for which $\rho(\alpha)$ from (3.15) might be a poor estimate) and set $\hat{\rho} := \max\{\rho_*, \bar{\rho}\}$. Then we infer from (4.5), (4.10), and the definition of $\mathbf{r}^k$ in step (ii) that

$$\begin{aligned} \|\mathbf{v}^{k+1} - \mathbf{u}^{k+1}\|_{\ell_2(\mathcal{J})} &\le \rho_*\|\mathbf{v}^k - \mathbf{u}^k\|_{\ell_2(\mathcal{J})} + \omega_k\bar{\rho}^k\epsilon_j \\ &\le \left(\sum_{l=0}^{k} \rho_*^{k-l}\omega_l\bar{\rho}^l\right)\epsilon_j \le \hat{\rho}^k\epsilon_j, \end{aligned} \tag{4.11}$$

where we have used that $\mathbf{u}^0 = \mathbf{v}^0$. Moreover, since

$$\|\mathbf{v}^{k+1} - \mathbf{u}\|_{\ell_2(\mathcal{J})} \leq \hat{\rho}^k \epsilon_j + \|\mathbf{u}^{k+1} - \mathbf{u}\|_{\ell_2(\mathcal{J})} \leq 2\hat{\rho}^k \epsilon_j, \tag{4.12}$$

we see that $\mathbf{v}^{k+1} \in B = B_{2\epsilon_0}(\mathbf{u})$ so that the iteration can be advanced.

For the locally convergent scheme (GNL) with $\mathbf{B} = \alpha \mathbf{R}(\mathbf{u}^0)^T$, the reasoning is analogous. The choice of the initial guess ensures that $(\rho + \alpha)\epsilon_j \leq (\rho + \alpha)\epsilon_0 \leq (1 + \alpha)\epsilon_0 \leq \delta_0$. Then the above arguments for (SL) yield again (4.15) so that all iterates stay in $B = B_{\delta_0}(\mathbf{u})$.

Now note that by (4.12),

$$\|\mathbf{r}^k\|_{\ell_2(\mathcal{J})} \leq \|\mathbf{v}^{k+1} - \mathbf{u}\|_{\ell_2(\mathcal{J})} + \|\mathbf{v}^k - \mathbf{u}\|_{\ell_2(\mathcal{J})} \leq 4\hat{\rho}^{k-1}\epsilon_j$$

so that

$$\beta(\eta_k + \|\mathbf{r}^k\|_{\ell_2(\mathcal{J})}) \leq \beta\epsilon_j(\omega_k\hat{\rho} + 4)\hat{\rho}^{k-1}. \tag{4.13}$$

Hence, choosing

$$K := \min\{k \in \mathbb{N} : \beta(\omega_k\hat{\rho} + 4)\hat{\rho}^{k-1} \leq 1/(2(1 + 2C^*))\}, \tag{4.14}$$

we see that (4.7) is met after at most K steps. Moreover, (4.6) says that

$$\|\mathbf{u} - \tilde{\mathbf{v}}\|_{\ell_2(\mathcal{J})} \leq \frac{\epsilon_j}{2(1 + 2C^*)}. \tag{4.15}$$

Thus in all cases the estimate (4.8) follows now immediately from step (iii) in **SOLVE**, the definition of **CCOARSE**, and (4.2). Finally, (4.9) is an immediate consequence of the norm equivalence (2.5) and (4.8). □

Thus, for an idealized infinite dimensional scheme of order one in (n3), we know how to choose the tolerances in the routines **RES** and **CCOARSE** so as to guarantee convergence. Moreover, the true error reduction rate need not be known, and one can use any (possibly too optimistic) guess $\bar{\rho}$. Of course, choosing $\bar{\rho}$ too small, the intermediate tolerances get perhaps unnecessarily small.

Our paradigm for solving nonlinear problems is built on the availability of numerical algorithms such as **CCOARSE** and **RES**. The remainder of this paper shows how to construct concrete practical realizations of these algorithms in various settings and then shows how, under suitable controls on the computations in these algorithms, we can give complexity estimates for the entire numerical scheme **SOLVE**. More precisely, we wish to determine its *work/accuracy balance*, i.e., given any target accuracy ϵ, how many degrees of freedom $N = N(\epsilon) := \#\Lambda(\epsilon)$, where $\Lambda(\epsilon) := \operatorname{supp} \bar{\mathbf{u}}(\epsilon)$, are needed to achieve it, and what is the associated (asymptotic) computational work. Of course, one hopes to keep the latter quantity proportional to $N(\epsilon)$ so that the number of degrees of freedom is a reasonable complexity measure. In the following section we shall address these issues first for the linear case (3.18). We review quickly the relevant facts from [8, 9] tailored somewhat to the present situation. On one hand, they will serve as building blocks for the general nonlinear case. On the other hand, they also help to bring out some conceptual distinctions.

5. Realization and complexity analysis in the linear case (L). Recall from (3.10) that in the linear case, $\mathbf{BR}(\mathbf{v}) = \alpha(\mathbf{Av} - \mathbf{f})$ (or $\alpha\mathbf{A}^T(\mathbf{Av} - \mathbf{f})$). Thus one part of approximating the residual is to approximate given data, here in the form of the right-hand side $\mathbf{f}$, which, in general, is an infinite sequence.

5.1. Coarsening and best N-term approximation. We will also assume in what follows that all coefficients of $\mathbf{f}$ are *known* and thus in principle accessible. In practice this may require a preprocessing step that computes for some overall target accuracy $\bar{\epsilon}$ (depending on the desired solution accuracy) an approximation $\mathbf{f}_{\bar{\epsilon}}$ satisfying $\|\mathbf{f} - \mathbf{f}_{\bar{\epsilon}}\|_{\ell_2(\mathcal{J})} \leq \bar{\epsilon}$ and then orders the entries by size. Once this has been done, any coarser approximations needed in the course of the iteration process can be produced by the following simplest version of **CCOARSE**, introduced and analyzed in [8].

COARSE $[\eta, \mathbf{v}] \to \mathbf{v}_\eta$ *associates with any finitely supported input* $\mathbf{v}$ *a vector* $\mathbf{v}_\eta$ *such that*

$$\|\mathbf{v} - \mathbf{v}_\eta\|_{\ell_2(\mathcal{J})} \leq \eta, \quad \#\mathrm{supp}\,\mathbf{w} \geq \#\mathrm{supp}\,\mathbf{v}_\eta, \text{ whenever } \|\mathbf{v} - \mathbf{w}\|_{\ell_2(\mathcal{J})} \leq \eta. \tag{5.1}$$

Thus **COARSE** determines for a given finitely supported vector a new vector with the smallest possible support deviating no more than a prescribed tolerance from the input. There is no constraint on the distribution of active indices in this case. Ordering the entries of $\mathbf{v}$ sizewise, this can be realized by summing entries in increasing order until the sum of their squares reaches η^2. For a detailed description of this routine, see [8]. In fact, a strict ordering is not necessary. The same effect is realized by collecting the entries in binary bins, which avoids a log factor at the expense of a fixed factor in the accuracy tolerance [1].

The routine **COARSE** can be used to approximate the data $\mathbf{f}$ as follows:

$$\mathbf{RHS}\,[\eta, \mathbf{f}] := \mathbf{COARSE}\,[\eta - \bar{\epsilon}, \mathbf{f}_{\bar{\epsilon}}], \tag{5.2}$$

whenever $\eta > \bar{\epsilon}$.

Note that **COARSE** is a *nonlinear* process that realizes a given accuracy tolerance at the expense of a minimal number of degrees of freedom. It is therefore a version of *best N-term approximation* in $\ell_2(\mathcal{J})$. In fact, defining

$$\sigma_{N,\ell_2(\mathcal{J})}(\mathbf{u}) := \min_{\#\mathrm{supp}\,\mathbf{v} \leq N} \|\mathbf{u} - \mathbf{v}\|_{\ell_2(\mathcal{J})}, \tag{5.3}$$

one has for any $\mathbf{v} \in \ell_2(\mathcal{J})$

$$\sigma_{N,\ell_2(\mathcal{J})}(\mathbf{v}) = \|\mathbf{v} - \mathbf{v}_N\|_{\ell_2(\mathcal{J})} = \left(\sum_{n>N} |v_n^*|^2\right)^{1/2}, \tag{5.4}$$

where $(v_n^*)_{n\in\mathbb{N}}$ is the *nonincreasing rearrangement* of $\mathbf{v}$. Thus $\mathbf{v}_N$ is obtained by retaining the N largest (in modulus) terms of $\mathbf{v}$ and setting all other entries to zero. Depending on the context, $\mathbf{v}_N$ will be viewed as a sequence in $\ell_2(\mathcal{J})$ or a vector in $\mathbb{R}^N$.

The best N-term approximation sets a lower bound for the complexity that could ever be achieved by a scheme like **SOLVE**. In fact, it will serve as our benchmark in the case of linear variational problems of the form (3.18). In order to make this precise, we introduce the corresponding *approximation classes*

$$\mathcal{A}^s := \{\mathbf{v} \in \ell_2(\mathcal{J}) : \sigma_{N,\ell_2(\mathcal{J})}(\mathbf{v}) \lesssim N^{-s}\},$$

which we endow with the quasi norm $\|\mathbf{v}\|_{\mathcal{A}^s} := \sup_{N\in\mathbb{N}} N^s \sigma_{N,\ell_2(\mathcal{J})}(\mathbf{v})$. Clearly, every $\mathbf{v}$ with finite support belongs to $\mathcal{A}^s$ for any $s > 0$. The question is, Does **SOLVE** produce for any target accuracy ϵ an approximate solution within that tolerance at a computational expense that stays bounded by $C\epsilon^{-1/s}$ whenever the exact solution belongs to $\mathcal{A}^s$, at least for some range of $s > 0$?

5.2. Adaptive application of compressible matrices. It remains to approximate the action of $\mathbf{A}$ on a finitely supported vector $\mathbf{v}$. While the treatment of the right-hand side data has been already seen to comply with best N-term approximation complexity, the question arises whether $\mathbf{Av}$ can be approximated with a similar efficiency. This has been answered affirmatively in [8], and we briefly recall the relevant facts from there.

Due to the *vanishing moment* property of wavelets, the wavelet representation of many operators turns out to be *quasi-sparse.* The following quantification of sparsity is appropriate [8].

We shall use the notation $(\alpha_j)_{j=1}^{\infty}$ to denote a summable sequence of positive numbers: $\sum_{j=1}^{\infty} \alpha_j < \infty$. A matrix $\mathbf{C}$ is said to be s^*-compressible, $\mathbf{C} \in \mathcal{C}_{s^*}$, if for any $0 < s < s^*$ and every $j \in \mathbb{N}$ there exists a matrix $\mathbf{C}_j$ with the following properties: For some summable sequence $(\alpha_j)_{j=1}^{\infty}$, $\mathbf{C}_j$ is obtained by replacing all but the order of $\alpha_j 2^j$ entries per row and column in $\mathbf{C}$ by zero and satisfies

$$\|\mathbf{C} - \mathbf{C}_j\|_{\ell_2(\mathcal{J}) \to \ell_2(\mathcal{J})} \leq C \alpha_j 2^{-js}, \quad j \in \mathbb{N}. \tag{5.5}$$

Specifically, wavelet representations of differential (and also certain singular integral) operators fall into this category. One typically has then estimates of the type

$$|a(\psi_\lambda, \psi_\mu)| \lesssim 2^{-\sigma ||\lambda| - |\mu||}, \tag{5.6}$$

where $\sigma > d/2$ depends on the *regularity* of the wavelets.

In order to describe the essence of an approximate application scheme for compressible matrices, we abbreviate for any finitely supported $\mathbf{v}$ the best 2^j-term approximations by $\mathbf{v}_{[j]} := \mathbf{v}_{2^j}$ and define

$$\mathbf{w}_j := \mathbf{A}_j \mathbf{v}_{[0]} + \mathbf{A}_{j-1}(\mathbf{v}_{[1]} - \mathbf{v}_{[0]}) + \cdots + \mathbf{A}_0(\mathbf{v}_{[j]} - \mathbf{v}_{[j-1]}) \tag{5.7}$$

as an approximation to $\mathbf{Av}$. Obviously this scheme is *adaptive* in that it exploits directly information on $\mathbf{v}$. In fact, if $\mathbf{A} \in \mathcal{C}_{s^*}$, then the triangle inequality together with the above compression estimates yield for any fixed $s < s^*$

$$\|\mathbf{Av} - \mathbf{w}_j\|_{\ell_2(\mathcal{J})} \leq c \left(\underbrace{\|\mathbf{v} - \mathbf{v}_{[j]}\|_{\ell_2(\mathcal{J})}}_{\sigma_{2^j, \ell_2(\mathcal{J})}(\mathbf{v})} + \sum_{l=0}^{j} \alpha_l 2^{-ls} \underbrace{\|\mathbf{v}_{[j-l]} - \mathbf{v}_{[j-l-1]}\|_{\ell_2(\mathcal{J})}}_{\lesssim\ \sigma_{2^{j-l-1}, \ell_2(\mathcal{J})}(\mathbf{v})} \right), \tag{5.8}$$

where $\mathbf{v}_{[-1]} := \mathbf{0}$. One can now exploit the a posteriori information offered by the quantities $\sigma_{2^{j-l-1}, \ell_2(\mathcal{J})}(\mathbf{v})$ to choose the smallest j for which the right-hand side of (5.8) is smaller than a given target accuracy η and set $\mathbf{w}_\eta := \mathbf{w}_j$. Since the sum is finite for each finitely supported input $\mathbf{v}$, such a j does indeed exist. This leads to a concrete multiplication scheme (see [8, 2] for a detailed description, analysis, and implementation) which we summarize as follows.

APPLY $[\eta, \mathbf{A}, \mathbf{v}] \to \mathbf{w}_\eta$ *determines for any finitely supported input* $\mathbf{v}$ *a finitely supported output* $\mathbf{w}_\eta$ *such that*

$$\|\mathbf{Av} - \mathbf{w}_\eta\|_{\ell_2(\mathcal{J})} \leq \eta. \tag{5.9}$$

The complexity of this scheme would be asymptotically optimal if the size of $\operatorname{supp}(\mathbf{w}_\eta)$ and the corresponding work count remain bounded by $C(N_\eta + \#\operatorname{supp}(\mathbf{v}))$, where N_η is the smallest N such that $\sigma_{N,\ell_2(\mathcal{J})}(\mathbf{Av}) \le \eta$. We shall see that this is indeed the case for a certain range of decay rates of $\sigma_{N,\ell_2(\mathcal{J})}(\mathbf{v})$.

The main result concerning **APPLY** can be formulated as follows [8].

THEOREM 5.1. *Suppose that* $\mathbf{C} \in \mathcal{C}_{s^*}$ *and that* $0 < s < s^*$. *Then, in addition to* (5.9)*, for any input vector* $\mathbf{v}$ *with finite support,* $\mathbf{w}_\eta = \mathbf{APPLY}\,[\eta, \mathbf{C}, \mathbf{v}]$ *satisfies*

(i) $\|\mathbf{w}_\eta\|_{\mathcal{A}^s} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s}$*,*

(ii) $\#\mathrm{supp}\,\mathbf{w}_\eta \lesssim \|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\eta^{-1/s}$ *and* $\#\mathrm{flops} \lesssim \#\mathrm{supp}\,\mathbf{v} + \|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\eta^{-1/s}$*,*

where the constants in these estimates depend only on s *when* s *is small. Moreover, any* $\mathbf{C} \in \mathcal{C}_{s^*}$ *is bounded on* $\mathcal{A}^s$ *as long as* $s < s^*$*.*

Thus, when dealing with linear problems (3.18), an approximation within the tolerance $\eta > 0$ to the weighted residual $\mathbf{BR}(\mathbf{v}) = \alpha(\mathbf{Av} - \mathbf{f})$ for any finitely supported input $\mathbf{v}$ can be computed as

$$\mathbf{RES}_{\mathrm{lin}}[\eta, \alpha\mathbf{I}, \mathbf{A}, \mathbf{f}, \mathbf{v}] := \alpha\left(\mathbf{APPLY}\left[\frac{\eta}{2\alpha}, \mathbf{A}, \mathbf{v}\right] - \mathbf{RHS}\left[\frac{\eta}{2\alpha}, \mathbf{f}\right]\right), \tag{5.10}$$

where **RHS** is given by (5.2). The same ideas can be used in the least squares case (3.19), where again **RHS** can be composed of **COARSE** and **APPLY**; see [9] for details.

Remark 5.1. Since by Theorem 5.1 $\mathbf{f} \in \mathcal{A}^s$, whenever the solution $\mathbf{u}$ belongs to $\mathcal{A}^s$, the above considerations and analogous facts about **COARSE** from [8] show that the output $\mathbf{f}_\eta$ of $\mathbf{RHS}\,[\eta, \mathbf{f}]$ satisfies $\|\mathbf{f}_\eta\|_{\mathcal{A}^s} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s}$ and $\#\mathrm{supp}\,\mathbf{f}_\eta \lesssim \eta^{-1/s}\|\mathbf{u}\|_{\mathcal{A}^s}^{1/s}$.

These observations provide the following result.

PROPOSITION 5.2. *If the sequence of wavelet coefficients* $\mathbf{u}$ *of the exact solution* u *of* (3.18) *belongs to* $\mathcal{A}^s$ *and if* $\mathbf{A}$ *belongs to* $\mathcal{C}_{s^*}$ *with* $s^* > s$*, then, for any finitely supported input* $\mathbf{v}$*, the output* $\mathbf{w}_\eta$ *of the scheme* $\mathbf{RES}_{\mathrm{lin}}\,[\eta, \alpha\mathbf{I}, \mathbf{A}, \mathbf{f}, \mathbf{v}]$ *satisfies*

$$\begin{aligned} \|\mathbf{w}_\eta\|_{\mathcal{A}^s} &\lesssim (\|\mathbf{v}\|_{\mathcal{A}^s} + \|\mathbf{u}\|_{\mathcal{A}^s}), \\ \#\,\mathrm{supp}\,\mathbf{w}_\eta &\lesssim \eta^{-1/s}\left(\|\mathbf{u}\|_{\mathcal{A}^s}^{1/s} + \|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\right), \quad \eta > 0, \end{aligned} \tag{5.11}$$

where the constants in these estimates depend only on s*.*

Proposition 5.2 controls the complexity within each iteration block (ii) of perturbed iterations where, however, the constants may build up. To avoid this is exactly the role of step (iii) in **SOLVE**, which is based on the following "coarsening lemma" from [8]. (The following version can be found in [7].)

PROPOSITION 5.3. *Let* a *be some fixed number strictly larger than* 1*. If* $\mathbf{v} \in \mathcal{A}^s$ *and* $\|\mathbf{v} - \mathbf{w}\|_{\ell_2(\mathcal{J})} \le \eta$ *with* $\#\mathrm{supp}\,\mathbf{w} < \infty$*, then* $\bar{\mathbf{w}}_\eta := \mathbf{COARSE}\,[a\eta, \mathbf{w}]$ *satisfies* $\|\mathbf{v} - \bar{\mathbf{w}}_\eta\|_{\ell_2(\mathcal{J})} \le (1 + a)\eta$ *and*

$$\#\mathrm{supp}\,\bar{\mathbf{w}}_\eta \lesssim \|\mathbf{v}\|_{\mathcal{A}^s}^{1/s}\eta^{-1/s}, \quad \|\bar{\mathbf{w}}_\eta\|_{\mathcal{A}^s} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s}, \tag{5.12}$$

where the constants in these estimates depend only on s *when* s *becomes small.*

By Proposition 5.3, the coarsening step (iii), with the above algorithm **COARSE** used as **CCOARSE**, pulls a current approximation to the unknown $\mathbf{u}$ toward its best N-term approximation and controls the $\mathcal{A}^s$-norms of the approximations, *independently* of the possible increase of these norms caused by several preceding applications of **RES**, provided that $2C^* > 1$. Thus, in connection with **COARSE**, one can take any fixed $C^* > 1/2$ in (4.7) and step (iii) of **SOLVE**.

Let us denote by $\mathbf{SOLVE}_{\mathrm{lin}}$ the specification of **SOLVE** obtained by using $\mathbf{RES}_{\mathrm{lin}}$ and **COARSE** in place of **RES**, respectively, **CCOARSE**. We emphasize that adaptivity enters the scheme $\mathbf{SOLVE}_{\mathrm{lin}}$ solely through the adaptive application of $\mathbf{A}$ and the residual check (4.7).

Under the above premises, Propositions 5.2 and 5.3 allow one to show that $\mathbf{SOLVE}_{\rm lin}$ exhibits optimal complexity in the sense that it realizes the Meta-Theorem from section 1.1 with (unconstrained) best N-term approximation as a benchmark.

Remark 5.4. We conclude this section by recalling that $\mathbf{u} \in \mathcal{A}^s$ is, for instance, implied by a certain Besov regularity of u. In fact, when $\mathcal{H} = H^t$ (a Sobolev space of smoothness t), $u \in B_\tau^{t+ds}(L_\tau)$, with $\tau^{-1} = s + 1/2$, implies $\mathbf{u} \in \mathcal{A}^s$. This can be used to identify circumstances under which the adaptive scheme performs asymptotically better than a scheme based on uniform refinements. Recall that $B_\tau^{t+ds}(L_\tau)$ is the "largest" space of smoothness $t + sd$ embedded in H^t.

6. The nonlinear case.

In view of the fact that **SOLVE** has the same structure, regardless of whether the involved operators are linear or nonlinear, our strategy will be to follow closely the above lines also when the variational problem (2.2) is nonlinear. In principle, this will prove successful, although some important modifications of the ingredients will be encountered. The main distinction lies in the sparsity measure in that the role of best (unrestricted) N-term approximation will be replaced by *best tree approximation*. This constraint on the distribution of active coefficients arises naturally when analyzing the approximate evaluation of nonlinear expressions $\mathbf{R}(\mathbf{v})$. Moreover, index sets with tree structure are analogous to locally refined meshes in adaptive finite element methods.

6.1. Tree approximation and coarsening.

Let us explain first what we mean by a tree structure associated to the set of wavelet indices. In the simplest case of a one dimensional basis $\psi_\lambda = \psi_{j,k} = 2^{j/2}\psi(2^j \cdot -k)$, this structure is obvious: each index (j, k) has two children $(j + 1, 2k)$ and $(j + 1, 2k + 1)$. A similar tree structure can be associated to all available constructions of wavelet basis on a multidimensional domain: to each index λ one can assign $m(\lambda) \geq 2$ children μ such that $|\mu| = |\lambda| + 1$, where $m(\lambda)$ might vary from one index to another but is uniformly bounded by some fixed M. We shall use the notation $\mu \prec \lambda$ ($\mu \preceq \lambda$) in order to express that μ is a descendent of λ (or equals λ) in the tree. We also have the property

$$\mu \prec \lambda \Rightarrow S_\mu \subset S_\lambda, \tag{6.1}$$

where we recall that $S_\lambda := \operatorname{supp} \psi_\lambda$. A set $\mathcal{T} \subset \mathcal{J}$ is called a *tree* if $\lambda \in \mathcal{T}$ implies $\mu \in \mathcal{T}$ whenever $\lambda \prec \mu$.

If the tree $\mathcal{T} \subset \mathcal{J}$ is finite, we define the set $\mathcal{L} = \mathcal{L}(\mathcal{T})$ of *outer leaves* as the set of those indices outside the tree whose parent belongs to the tree

$$\mathcal{L} := \{\lambda \in \mathcal{J} : \lambda \notin \mathcal{T},\ \lambda \prec \mu \implies \mu \in \mathcal{T}\}. \tag{6.2}$$

We shall make use of the easily verifiable relation

$$\#\mathcal{T} \sim \#\mathcal{L}(\mathcal{T}), \tag{6.3}$$

where the constants depend only on the number M of children.

Note that $\mathcal{L}(\mathcal{T})$ plays the role of a (locally refined) mesh. Associating to any sequence $\mathbf{v} = (v_\lambda)$ in $\ell_2(\mathcal{J})$, another sequence $\tilde{\mathbf{v}} = (\tilde{v}_\lambda)$ whose entries are defined by

$$\tilde{v}_\lambda := \left(\sum_{\mu \preceq \lambda} |v_\mu|^2 \right)^{1/2}, \tag{6.4}$$

one readily confirms that $\mu \prec \lambda$ implies $\tilde{v}_\lambda \geq \tilde{v}_\mu$ and

$$\|\mathbf{v} - \mathbf{v}|_{\mathcal{T}}\|^2_{\ell_2(\mathcal{J})} = \sum_{\lambda \in \mathcal{L}(\mathcal{T})} \tilde{v}^2_\lambda. \tag{6.5}$$

Recall that in the linear case we have been able to compare the performance of **SOLVE** with the *best (unconstrained) N-term approximation.* We want now to develop sparsity measures that respect tree structure. Once a suitable measure has been identified, one can follow conceptually the lines of section 3. The counterpart for the spaces $\mathcal{A}^s$ are now the analogous spaces defined via *best tree N-term approximation* where the distribution of active coefficients in an approximant has a tree structure; see [10]. In fact, let

$$\sigma^{\text{tree}}_{N,\ell_2(\mathcal{J})}(\mathbf{v}) := \min\{\|\mathbf{v} - \mathbf{w}\|_{\ell_2(\mathcal{J})} :\ \mathcal{T} := \operatorname{supp} \mathbf{w} \ \text{ is a tree and } \ \#\mathcal{T} \leq N\}. \tag{6.6}$$

Any minimizing tree will be called $\mathcal{T}_N(\mathbf{v})$. We define now

$$\mathcal{A}^s_{\text{tree}} := \{\mathbf{v} \in \ell_2(\mathcal{J}) : \sigma^{\text{tree}}_{N,\ell_2(\mathcal{J})}(\mathbf{v}) \ \lesssim \ N^{-s}\}, \tag{6.7}$$

which again becomes a quasi-normed space under the quasi norm

$$\|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}} := \sup_{n \in \mathbb{N}} N^s \sigma^{\text{tree}}_{N,\ell_2(\mathcal{J})}(\mathbf{v}). \tag{6.8}$$

One can again relate the membership of $\mathbf{v}$ to $\mathcal{A}^s_{\text{tree}}$ to the regularity of the corresponding expansion v [10].

Remark 6.1. Let $\mathcal{H} = H^t$ for some $t > 0$. If the wavelet expansion v with coefficient sequence $\mathbf{v}$ belongs to $B^{t+sd}_{\tau'}(L_{\tau'})$ for some τ' satisfying $\tau' > (s + 1/2)^{-1}$, then $\mathbf{v} \in \mathcal{A}^s_{\text{tree}}$. Thus, in terms of regularity, $\mathcal{A}^s_{\text{tree}}$ differs from $\mathcal{A}^s$ by a little additional regularity imposed on the respective expansions, due to the stronger metric $L_{\tau'}$, $\tau' > \tau$. Thus a tree approximation rate N^{-s} can still be achieved for much larger spaces than H^{t+sd}, which governs the corresponding rate for uniform refinements.

6.2. Tree coarsening. We shall specify next a coarsening routine **CCOARSE** that preserves *tree structures* and, as before, applies to finitely supported sequences. It will be referred to as **TCOARSE**. Its definition requires some preparation. Given $\mathbf{w}$, a tree $\mathcal{T} = \mathcal{T}^*(\eta, \mathbf{w})$ is called η-best for $\mathbf{w}$ if

$$\|\mathbf{w} - \mathbf{w}|_{\mathcal{T}}\|_{\ell_2(\mathcal{J})} \leq \eta \ \text{ and } \ \#\mathcal{T} = \min\{\#\mathcal{T}' : \|\mathbf{w} - \mathbf{w}|_{\mathcal{T}'}\|_{\ell_2(\mathcal{J})} \leq \eta,\ \mathcal{T}' \text{ a tree}\}.$$

Requiring best trees will be too stringent from a practical point of view. Therefore, we shall be content with the following relaxed version. A tree $\mathcal{T} = \mathcal{T}(\eta, \mathbf{w})$ is called (η, C)-*near best* (or briefly near best when the parameters are clear from the context) if

$$\|\mathbf{w} - \mathbf{w}|_{\mathcal{T}}\|_{\ell_2(\mathcal{J})} \leq \eta \ \text{ and } \ \#\mathcal{T} \leq C\#\mathcal{T}^*(\eta/C, \mathbf{w}).$$

The action of **TCOARSE** can now be described as follows.

TCOARSE $[\eta, \mathbf{w}] \to \bar{\mathbf{w}}_\eta$ *determines for a fixed constant $C^* \geq 1$, any finitely supported input* $\mathbf{w}$*, and any tolerance $\eta > 0$ an (η, C^*)-near best tree $\mathcal{T}(\eta, \mathbf{w})$ and sets* $\bar{\mathbf{w}}_\eta := \mathbf{w}|_{\mathcal{T}(\eta,\mathbf{w})}$.

The realization of this routine can be based on either one of the two algorithms for generating near best tree approximations developed in [3]. To apply the results from [3] in the present situation, the role of the partition P associated in [3] to a tree $\mathcal{T}$ is played here by the set $\mathcal{L}(\mathcal{T})$ of outer leaves; recall (6.5). Moreover, for $\lambda \in \mathcal{L}(\mathcal{T})$, the local error terms for a given $\mathbf{v} \in \ell_2(\mathcal{J})$ are here given by $e(\lambda) := \tilde{v}_\lambda^2$. Obviously, the $e(\lambda)$ are subadditive in the sense of [3]. Hence the results from [3] apply. To use the algorithm from [3], we need to know the values $\tilde{w}_\lambda$, $\lambda \in \mathcal{T}(\operatorname{supp}\mathbf{w})$, the smallest tree containing the support of $\mathbf{w}$. Summing the squares of the entries of $\mathbf{w}$ starting from the leaves of $\mathcal{T}(\operatorname{supp}\mathbf{w})$ and working toward the roots provide these quantities at an expense of $\#\mathcal{T}(\operatorname{supp}\mathbf{w})$ operations. Combining this with Theorem 5.2 from [3] establishes the following fact.

Proposition 6.2. *For any given finitely supported input* $\mathbf{w}$*, the computational cost of the output* $\bar{\mathbf{w}}_\eta$ *produced by* **TCOARSE** $[\eta, \mathbf{w}]$ *remains proportional to* $\#\mathcal{T}(\operatorname{supp}$ $\mathbf{w})$. *The underlying tree* $\mathcal{T}(\eta, \mathbf{w})$ *is* (η, C^*)*-near best, where* C^* *is the constant appearing in the estimate* (5.8) *in Theorem* 5.2 *of* [3].

The routine **TCOARSE** will be used as **CCOARSE** in step (iii) of **SOLVE**. The constant C^* appears in the stopping criterion in step (ii.2) of **SOLVE** and in the coarsening step (iii). In analogy to the linear case, its purpose is to control the $\mathcal{A}^s_{\text{tree}}$-norms of the approximants. This is made precise by the following counterpart to Proposition 5.3.

Proposition 6.3. *If* $\mathbf{v} \in \mathcal{A}^s_{\text{tree}}$ *and* $\|\mathbf{v} - \mathbf{w}\|_{\ell_2(\mathcal{J})} \le \eta$ *with* $\#\operatorname{supp}\mathbf{w} < \infty$*, then* $\bar{\mathbf{w}}_\eta :=$ **TCOARSE** $[2C^*\eta, \mathbf{w}]$ *satisfies*

$$\#\operatorname{supp}\bar{\mathbf{w}}_\eta \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\eta^{-1/s}, \quad \|\mathbf{v} - \bar{\mathbf{w}}_\eta\|_{\ell_2(\mathcal{J})} \le (1+2C^*)\eta, \tag{6.9}$$

and

$$\|\bar{\mathbf{w}}_\eta\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}, \tag{6.10}$$

where the constants depend only on s *when* $s \to 0$ *and on* C^* *in* **TCOARSE**.

Proof. The second estimate in (6.9) follows from the triangle inequality. As for the first estimate in (6.9), assume that $\mathbf{v} \in \mathcal{A}^s_{\text{tree}}$ and consider the best N-term tree $\mathcal{T}_N(\mathbf{v})$ for $\mathbf{v}$ defined by (6.6). We first note that

$$\begin{aligned} \|\mathbf{w} - \mathbf{w}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} &\le \|(\mathbf{w} - \mathbf{v})|_{\mathcal{J}\setminus\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} + \|\mathbf{v} - \mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} \\ &\le \eta + \|\mathbf{v} - \mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})}. \end{aligned} \tag{6.11}$$

According to the definition of the norm $\|\cdot\|_{\mathcal{A}^s_{\text{tree}}}$ by (6.8), we have $\|\mathbf{v} - \mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} \le \eta$ for some $N \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\eta^{-1/s}$. Therefore, $\|\mathbf{w} - \mathbf{w}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} \le 2\eta$ so that by the definition of the $(2C^*\eta, C^*)$-near best tree $\mathcal{T}(2C^*\eta, \mathbf{w})$, we have

$$\#\mathcal{T}(2C^*\eta, \mathbf{w}) \le C^*\#\mathcal{T}^*(2\eta, \mathbf{w}) \le C^*\#\mathcal{T}_N(\mathbf{v}) \le C^*N \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\eta^{-1/s}, \tag{6.12}$$

which proves the first estimate in (6.9). It remains to prove (6.10). We wish to show that for each $\delta > 0$ there exists a tree $\mathcal{T}_\delta$ such that

$$\|\bar{\mathbf{w}}_\eta - \bar{\mathbf{w}}_\eta|_{\mathcal{T}_\delta}\|_{\ell_2(\mathcal{J})} \le \delta \quad \text{and} \quad \#(\mathcal{T}_\delta) \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\delta^{-1/s}. \tag{6.13}$$

The existence of such a tree has been already established for $\delta = \eta$. Now consider first the case $\delta \le 2(1+2C^*)\eta$. In this case, we take $\mathcal{T}_\delta := \operatorname{supp}\bar{\mathbf{w}}_\eta = \mathcal{T}(2C^*\eta, \mathbf{w})$. In fact, since then $\|\bar{\mathbf{w}}_\eta - \bar{\mathbf{w}}_\eta|_{\mathcal{T}_\delta}\|_{\ell_2(\mathcal{J})} = 0$, the first relation in (6.13) holds trivially. Moreover, since $\#(\mathcal{T}_\delta) = \#(\mathcal{T}(2C^*\eta, \mathbf{w})) \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\eta^{-1/s} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}^{1/s}\delta^{-1/s}$, the second estimate in (6.13) is also valid.

Now consider the case $\delta > 2(1+2C^*)\eta$. Let $\mathcal{T}_\delta := \mathcal{T}_N(\mathbf{v})$ be a best N-term tree for $\mathbf{v}$, where N will be chosen in a moment. Note that

$$\begin{aligned} \|\bar{\mathbf{w}}_\eta - \bar{\mathbf{w}}_\eta|_{\mathcal{T}_\delta}\|_{\ell_2(\mathcal{J})} &\le \|(\bar{\mathbf{w}}_\eta - \mathbf{v})|_{\mathcal{J}\setminus\mathcal{T}_\delta}\|_{\ell_2(\mathcal{J})} + \|\mathbf{v} - \mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} \\ &\le (1+2C^*)\eta + \|\mathbf{v} - \mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})} \le \delta, \end{aligned} \tag{6.14}$$

provided that $\delta-(1+2C^*)\eta \ge \|\mathbf{v}-\mathbf{v}|_{\mathcal{T}_N(\mathbf{v})}\|_{\ell_2(\mathcal{J})}$. This holds for some $N \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\rm tree}}^{1/s}(\delta-(1+2C^*)\eta)^{-1/s} \le 2^{1/s}\|\mathbf{v}\|_{\mathcal{A}^s_{\rm tree}}^{1/s}\delta^{-1/s}$, which confirms (6.13) also in the case $\delta > 2(1+2C^*)\eta$. This finishes the proof. □

6.3. The key requirement. Up to this point, we have not imposed any conditions on the subroutine **RES**, which is used to approximate the residual at each iteration. In later realizations of the routine **RES**, the support of its output will have tree structure which we will therefore assume to hold from now on without further mention. We will now introduce a condition, called s^*-sparsity, motivated by the analysis of the previous section for the linear case; see Proposition 5.2. We will then show that whenever **RES** is s^*-sparse, the algorithm **SOLVE** is optimal in its rate/complexity for the range of error decay rates $\sigma^{\rm tree}_{N,\ell_2(\mathcal{J})}(\mathbf{u}) \lesssim N^{-s}$ with $s < s^*$. The subsequent section will then show how to construct s^*-sparse routines for nonlinear problems.

We say that the scheme **RES** used to approximate residuals is *s^*-sparse* if, in addition to (4.1), the following property holds.

***s^**-sparsity.** *Whenever the exact solution* $\mathbf{u}$ *of* (2.8) *belongs to* $\mathcal{A}^s_{\rm tree}$ *for some* $s < s^*$*, then one has for any finitely supported input* $\mathbf{v}$ *and any tolerance* $\eta > 0$ *that the output* $\mathbf{w}_\eta := \mathbf{RES}\,[\eta, \mathbf{B}, \mathbf{F}, \mathbf{f}, \mathbf{v}]$ *satisfies*

$$\begin{aligned} \#\mathrm{supp}\,\mathbf{w}_\eta &\le C\eta^{-1/s}(\|\mathbf{v}\|_{\mathcal{A}^s_{\rm tree}}^{1/s} + \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}^{1/s} + 1), \\ \|\mathbf{w}_\eta\|_{\mathcal{A}^s_{\rm tree}} &\le C\left(\|\mathbf{v}\|_{\mathcal{A}^s_{\rm tree}} + \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}} + 1\right), \end{aligned} \tag{6.15}$$

where C *depends only on* s *when* $s \to s^*$*. Moreover, the number of operations needed to compute* $\mathbf{w}_\eta$ *stays proportional to* $C(\eta^{-1/s}(\|\mathbf{v}\|_{\mathcal{A}^s_{\rm tree}}^{1/s} + \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}^{1/s} + 1) + \#\mathcal{T}(\mathrm{supp}\,\mathbf{v}))$*, where again* $\mathcal{T}(\mathrm{supp}\,\mathbf{v})$ *denotes the smallest tree containing* $\mathrm{supp}\,\mathbf{v}$.

The occurrence of $\|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}$ in the above estimates is already plausible from the linear case, as explained in Remark 5.1.

It will be understood in what follows that **TCOARSE** is used as **CCOARSE** and that a proper initialization is used that complies if necessary with the requirements on the quality of the initial guess (see section 5) so that, in particular, the respective variant of the iteration (2.11) satisfies (3.17).

Under these premises we now show that s^*-sparsity implies asymptotically optimal complexity of the scheme **SOLVE**.

THEOREM 6.1. *Assume that the scheme* **RES** *is* s^**-sparse for some* $s^* > 0$*. If the exact solution* $\mathbf{u}$ *of* (2.8) *belongs to* $\mathcal{A}^s_{\rm tree}$ *for some* $s < s^*$*, then the approximations* $\bar{\mathbf{u}}(\epsilon)$ *satisfy for every target accuracy* $\epsilon > 0$

$$\|\mathbf{u} - \bar{\mathbf{u}}(\epsilon)\|_{\ell_2(\mathcal{J})} \le \epsilon, \tag{6.16}$$

while

$$\#\mathrm{supp}\,\bar{\mathbf{u}}(\epsilon) \le C\epsilon^{-1/s}\|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}^{1/s}, \quad \|\bar{\mathbf{u}}(\epsilon)\|_{\mathcal{A}^s_{\rm tree}} \le C\|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}, \tag{6.17}$$

where the constant C *depends only on* s *when* $s \to s^*$*. Moreover, the number of operations needed to compute* $\bar{\mathbf{u}}(\epsilon)$ *remains bounded by* $C\epsilon^{-1/s}\|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}^{1/s}$.

Proof. The first part follows directly from Proposition 4.3. From (4.15) we know that the result $\tilde{\mathbf{v}}$ after at most K perturbed iterations in the $(j+1)$st block of step (ii) in **SOLVE** satisfies $\|\mathbf{u}-\tilde{\mathbf{v}}\|_{\ell_2(\mathcal{J})} \le \epsilon_j/(2(1+2C^*))$. Now Proposition 6.3 ensures that then

$$\|\bar{\mathbf{u}}^{j+1}\|_{\mathcal{A}^s_{\text{tree}}} \le C\|\mathbf{u}\|_{\mathcal{A}^s_{\text{tree}}}, \quad \#\text{supp}\,\bar{\mathbf{u}}^{j+1} \le C\epsilon_j^{-1/s}\|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}}. \tag{6.18}$$

Moreover, the computational work required by the routine **TCOARSE** stays, by Proposition 6.2, proportional to the support size of $\tilde{\mathbf{v}}$, since the support of $\tilde{\mathbf{v}}$, as an output of **RES**, has tree structure. Here it is important to note that the constant C is *independent* of the input $\tilde{\mathbf{v}}$ of **TCOARSE**. Thus for $j > 0$ the input of the first application of **RES** in step (ii) of **SOLVE** satisfies (6.18). Since there are only at most a uniformly bounded number K of applications of **RES** in each iteration block, $\tilde{\mathbf{v}}$ also satisfies (6.18) with a constant depending now on the number of updates (ii.1) bounded by K; see (4.14). (Here we have tacitly assumed that the initial guess has been subjected to a **TCOARSE** so that it also satisfies (6.18). Otherwise, we would have to add $\#\text{supp}\,\mathbf{u}^0$ to the above estimates.) The estimate in (6.17) now follows from these estimates for the terminal value of j. This also shows that the number of operations remains proportional to $\#\text{supp}\,\bar{\mathbf{u}}(\epsilon)$. □

We shall discuss below how to obtain schemes **RES** that are s^*-sparse for certain $s^* > 0$ and what limits the value of s^*.

7. Nonlinear evaluation schemes.

Just as the efficient application of compressible matrices $\mathbf{A}$ was pivotal for the adaptive solution in the linear case (L), we need efficient evaluation schemes for $\mathbf{F}(\mathbf{v})$ that allow us to realize the residual approximation in **RES**. Such a scheme has been already proposed in [10] for a class of nonlinearities F that will be described next.

7.1. A class of nonlinear mappings.

We shall be concerned with nonlinear operators of the form

$$V = (v_1, \ldots, v_n) \mapsto w = F(D^{\alpha_1}v_1, \ldots, D^{\alpha_n}v_n), \tag{7.1}$$

acting from $\mathcal{H} \times \cdots \times \mathcal{H}$ to the dual $\mathcal{H}'$. (Here $\alpha_i = (\alpha_{i,1}, \ldots, \alpha_{i,d})$ are multi-indices.) This clearly covers our previous example of a single argument $n = 1$ but also further important cases like the nonlinearity appearing in the Navier–Stokes equations. Although we shall not address variational problems involving nonlinearities of several arguments in this paper, we shall present the evaluation schemes in this somewhat greater generality because they are important for such applications and because we shall apply the case of two arguments later in connection with Newton's scheme.

We shall first describe our requirements on F in the wavelet coordinate domain and point out later circumstances under which these requirements are met.

Denoting by $\mathbf{v}_i = (v_{i,\lambda})$ the arrays of the wavelet coefficients of the function v_i, setting $\mathbf{V} = (\mathbf{v}_1, \ldots, \mathbf{v}_n)$, and defining the corresponding discrete mapping $\mathbf{F}$ by

$$\mathbf{F}(\mathbf{V}) := (\langle \psi_\lambda, F(D^{\alpha_1}v_1, \ldots, D^{\alpha_n}v_n)\rangle)_{\lambda \in \mathcal{J}}, \tag{7.2}$$

we make the following basic assumptions.

Assumption 1. $\mathbf{F}$ *is a Lipschitz map from* $(\ell_2(\mathcal{J}))^n$ *into* $\ell_2(\mathcal{J})$,

$$\|\mathbf{F}(\mathbf{U}) - \mathbf{F}(\mathbf{V})\|_{\ell_2(\mathcal{J})} \le C\sum_{i=1}^{n}\|\mathbf{u}_i - \mathbf{v}_i\|_{\ell_2(\mathcal{J})}, \tag{7.3}$$

with $C = C(\max_i\{\|\mathbf{u}_i\|_{\ell_2(\mathcal{J})}, \|\mathbf{v}_i\|_{\ell_2(\mathcal{J})}\})$*, where* $x \mapsto C(x)$ *is a positive nondecreasing function.*

Bearing the norm equivalences (2.5), (2.6) in mind, we see that property P1 from section 3.1 is a special case of Assumption 1 for $n = 1$.

Assumption 2. *There exists a constant* $\gamma > d/2$ *such that, for any finitely supported* $\mathbf{V}$ *(i.e., with all* $\mathbf{v}_i$ *finitely supported) and* $\mathbf{w} = \mathbf{F}(\mathbf{V})$*, we have for* $\lambda \in \mathcal{J}_\psi$ *the estimate*

$$|w_\lambda| \le C \sup_{\mu\,:\,S_\lambda \cap S_\mu \neq \emptyset} \left(\sum_{i=1}^n |v_{i,\mu}|\right) 2^{-\gamma(|\lambda|-|\mu|)}, \tag{7.4}$$

where $C = C(\max_i \|\mathbf{v}_i\|_{\ell_2(\mathcal{J})})$ *and* $x \mapsto C(x)$ *is a positive nondecreasing function.*

The parameter γ plays a similar role as the compressibility range s^* for the wavelet representation of linear operators.

Nonlinear mappings that satisfy the above assumptions are, for instance, those with polynomial growth. In the special case of a single argument, a typical condition reads

$$|F^{(k)}(v)| \lesssim (1+|v|)^{(p-k)_+}, \quad k = 0, \dots, n^*, \qquad \text{for some} \;\; n^* \ge 1, \tag{7.5}$$

where $a_+ := \max\{0, a\}$.

Remark 7.1. Suppose that $\mathcal{H} = H^t$ is a Sobolev space of smoothness order $t > 0$ (or a closed subspace determined by, e.g., homogeneous boundary conditions). One can show that, for the special case $n = 1$, (7.5) implies Assumptions 1 and 2 and, in particular, property P1, with no condition on p when $t \ge d/2$ and otherwise provided that

$$1 \le p < p^* := \frac{d+2t}{d-2t}; \tag{7.6}$$

see [10].

In the general case, when the nonlinear map F has the form $F(D^{\alpha_1}u_1, \dots, D^{\alpha_n}u_n)$, we impose the growth condition

$$|D^\beta F(x_1, \dots, x_n)| \le C \prod_{i=1}^n (1+|x_i|)^{[p_i-\beta_i]_+}, \;\; |\beta| = 0, 1, \dots, n^*, \tag{7.7}$$

for some $p_i \ge 0$ and n^* a positive integer. The following fact (covering Remark 7.1) has been proven in [10].

Theorem 7.1. *Suppose that* $\mathcal{H} = H^t$ *is a closed subspace (determined by, e.g., homogeneous boundary conditions) of* $H^t(\Omega)$ *for some* $t \ge 0$*. Assume that the growth assumptions* (7.7) *hold at least with* $n^* = 0$*. Then* F *maps* $\mathcal{H} \times \cdots \times \mathcal{H}$ *to* $\mathcal{H}'$ *whenever* $t \ge 0$ *satisfies*

$$\left(\frac{1}{2} - \frac{t}{d}\right)_+ + \sum_{i=1}^n p_i \left(\frac{1}{2} - \frac{t}{d} + \frac{|\alpha_i|}{d}\right)_+ < 1. \tag{7.8}$$

If in addition $n^* = 1$*, then we also have under the same restriction*

$$\|F(u) - F(v)\|_{\mathcal{H}'} \le C \sum_{i=1}^n \|u_i - v_i\|_{\mathcal{H}}, \tag{7.9}$$

where $C = C(\max_i\{\|u_i\|_{\mathcal{H}}, \|v_i\|_{\mathcal{H}}\})$ *and* $x \to C(x)$ *is nondecreasing, and therefore, on account of* (2.5)*, Assumption* 1 *holds.*

For the verification of Assumption 2, we treat separately the polynomial case for which we have the growth condition

$$(7.10) \qquad |D^\beta F(x_1,\dots,x_n)| \le C\prod_{i=1}^{n}(1+|x_i|)^{p_i-\beta_i}, \ \ \beta_i \le p_i,$$

and $D^\beta F = 0$ if $\beta_i > p_i$ for some i, where the p_i are positive integers. We recall the following result from [10].

Theorem 7.2. *Assume that the wavelets belong to* C^m *and have vanishing moments of order* m *(i.e., are orthogonal to* $\mathbb{P}_{m-1}$ *the space of polynomials of total degree at most* $m-1$*) for some positive integer* m*. Then Assumption* 2 *holds for* $\gamma = r + t + d/2$ *with the following values of* r*:*

(i) *If* F *satisfies* (7.7) *with* p *such that* $\sum_{i=1}^{n} p_i(d/2 - t + |\alpha_i|)_+ < d/2 + t$*, then* $r = \lceil \min\{m, n^*, p^*\}\rceil$*, where* $p^* = \min\{p_i \ : \ i \text{ s.t. } d/2 - t + |\alpha_i| > 0\}$.

(ii) *If* F *satisfies* (7.10) *with* p *such that* $\sum_{i=1}^{n} p_i(d/2 - t + |\alpha_i|)_+ < d/2 + t$*, then* $r = m$.

7.2. An adaptive evaluation scheme. The schemes for approximating $\mathbf{F}(\mathbf{V})$ consist of two conceptual steps: (i) the prediction of a possibly small set of indices that covers the significant coefficients of $\mathbf{F}(\mathbf{V})$ using only knowledge of the indices of the significant coefficients of the input $\mathbf{V}$; (ii) a sufficiently accurate computation of those coefficients of $\mathbf{F}(\mathbf{V})$ that correspond to the predicted index set. Once the predicted sets are known, one can invoke the techniques developed in [16] to tackle the latter task. A more detailed treatment of this issue will be given elsewhere. Motivated by the results in [16], we shall work in what follows with the following assumption.

Assumption E. *The entries* $w_\lambda = \mathbf{F}(\mathbf{v})_\lambda$ *can be computed (with sufficient accuracy) on average at unit cost.*

Therefore, we shall concentrate here only on task (i) under the assumption that the computation can be done in linear time; see the discussion of this issue in [16]. We recall now briefly the construction from [10] of good predictions for mappings satisfying Assumptions 1 and 2. For $j = 0, 1, \dots,$ and each component $\mathbf{v}_i$ of $\mathbf{V}$ we define the near best trees introduced in section 6.2

$$(7.11) \qquad \mathcal{T}_{i,j} := \mathcal{T}\left(\frac{2^j\epsilon}{1+j}, \mathbf{v}_i\right),$$

by invoking the thresholding algorithm from [3]. Moreover, it can be shown that for any tree $\mathcal{T}$ there exists an expansion $\tilde{\mathcal{T}}$ such that for some constant C one has $\#\tilde{\mathcal{T}} \le C\#\mathcal{T}$, while for any $\lambda \in \mathcal{L}(\tilde{\mathcal{T}})$ the number of $\mu \in \mathcal{L}(\tilde{\mathcal{T}})$ such that $S_\lambda \cap S_\mu \ne \emptyset$ is bounded by C; see Lemma 3.1 in [10]. We denote these expansions of $\mathcal{T}_{i,j}$ by $\tilde{\mathcal{T}}_{i,j}$ and set

$$(7.12) \qquad \tilde{\mathcal{T}}_j := \bigcup_{i=0}^{n} \tilde{\mathcal{T}}_{i,j} \ \text{ and } \ \Delta_j := \tilde{\mathcal{T}}_j \setminus \tilde{\mathcal{T}}_{j+1}.$$

In order to build a tree which will be adapted to $\mathbf{w} = \mathbf{F}(\mathbf{V})$, we introduce

$$(7.13) \qquad \alpha := \frac{2}{2\gamma - d} > 0,$$

where γ is the constant in (7.4), and for each $\mu \in \Delta_j$, we define the *influence set*

$$\Lambda_{\epsilon,\mu} := \{\lambda \ : \ S_\lambda \cap S_\mu \neq \emptyset \text{ and } |\lambda| \leq |\mu| + \alpha j\}. \tag{7.14}$$

We then define $\mathcal{T}$ by

$$\mathcal{T}_\epsilon(\mathbf{F}, \mathbf{V}) = \mathcal{T} := \mathcal{J}_\phi \cup \left(\cup_{\mu \in \tilde{\mathcal{T}}_0} \Lambda_{\epsilon,\mu} \right). \tag{7.15}$$

The following fact has been shown in [10, Theorem 5.1].

Theorem 7.3. *Assume that F satisfies Assumptions* 1 *and* 2. *Given any $\mathbf{V} \in (\ell_2(\mathcal{J}))^n$, we have the error estimate*

$$\|\mathbf{F}(\mathbf{V}) - \mathbf{F}(\mathbf{V})|_{\mathcal{T}}\|_{\ell_2(\mathcal{J})} \ \lesssim \ \epsilon. \tag{7.16}$$

Moreover, if $\mathbf{V} \in (\mathcal{A}^s_{\rm tree})^n$ for some $s \in \left(0, \frac{2\gamma - d}{2d}\right)$, we have the estimate

$$\#(\mathcal{T}) \ \lesssim \ \|\mathbf{V}\|^{1/s}_{(\mathcal{A}^s_{\rm tree})^n} \epsilon^{-1/s} + \#(\mathcal{J}_\phi). \tag{7.17}$$

We therefore have $\mathbf{F}(\mathbf{V}) \in \mathcal{A}^s_{\rm tree}$ and

$$\|\mathbf{F}(\mathbf{V})\|_{\mathcal{A}^s_{\rm tree}} \ \lesssim \ 1 + \|\mathbf{V}\|_{(\mathcal{A}^s_{\rm tree})^n}. \tag{7.18}$$

The constants in these above inequalities depend only on $\|\mathbf{V}\|_{\ell_2(\mathcal{J})}$, the space dimension d, and the parameter s.

This suggests the following routine for approximating $\mathbf{F}(\mathbf{V})$ for any finitely supported vector $\mathbf{V}$:

EV $[\epsilon, \mathbf{F}, \mathbf{V}] \to \mathbf{w}_\epsilon$. *Given the inputs $\epsilon > 0$ and $\mathbf{V}$ with finite support do:*

Step 1: *Invoke* **TCOARSE** $[2^j\epsilon/(1+j), \mathbf{v}_i]$, $i = 1, \dots, n$, *to compute the trees*

$$\mathcal{T}_{i,j} := \mathcal{T}\left(\frac{2^j \epsilon}{C_0(j+1)}, \mathbf{v}_i \right), \tag{7.19}$$

where $C_0 = C_0(\|\mathbf{v}\|)$ is the constant involved in (7.16) *for $j = 0, \dots, J$, and stop for the smallest J such that $\mathcal{T}_J$ is empty (we always have $J \ \lesssim \ \log_2(\|\mathbf{V}\|_{\ell_2(\mathcal{J})}/\epsilon)$).*

Step 2: *Derive the expanded trees $\tilde{\mathcal{T}}_{i,j}$, the layers Δ_j, and the outcome tree $\mathcal{T} = \mathcal{T}_\epsilon(\mathbf{F}, \mathbf{V})$ according to* (7.15).

Step 3: *Compute the coefficients $\mathbf{F}(\mathbf{V})_\lambda$, $\lambda \in \mathcal{T}$; see* [16].

A more detailed discussion of this scheme can be found in [10].

We can now formulate concrete realizations of the scheme **SOLVE** that are suitable for nonlinear problems. We shall use **TCOARSE** as our version of **CCOARSE**. Moreover, for the semilinear elliptic problem (3.4) we can take

$$\begin{aligned} \mathbf{RES}_{\rm ell}[\eta, \alpha\mathbf{I}, \mathbf{A}, \mathbf{G}, \mathbf{f}, \mathbf{v}] := \alpha\,(&\mathbf{APPLY}\,[\eta/3, \mathbf{A}, \mathbf{v}] \\ &+ \mathbf{EV}\,[\eta/3, \mathbf{G}, \mathbf{v}] - \mathbf{RHS}\,[\eta/3, \mathbf{f}]), \end{aligned} \tag{7.20}$$

where **RHS** is defined here as in (5.2) but with **COARSE** replaced by **TCOARSE**.

For the general nonlinear problem (GNL), we shall now devise a residual approximation for the scheme from section 3.2 with $\mathbf{B}_n := \mathbf{B}$. Suppose that $\|\mathbf{B}\|_{\ell_2(\mathcal{J}) \to \ell_2(\mathcal{J})} \leq C_B$, and set

$$\begin{aligned} \mathbf{RES}_{\rm lc}[\eta, \mathbf{B}, \mathbf{F}, \mathbf{f}, \mathbf{v}] := \mathbf{APPLY}\ \big[&\eta/2, \mathbf{B}, \big(\mathbf{EV}\ [\eta/4C_B, \mathbf{F}, \mathbf{v}] \\ &-\mathbf{RHS}\,[\eta/4C_B, \mathbf{f}]\big)\big]. \end{aligned} \tag{7.21}$$

Of course, we have assumed here that the matrix $\mathbf{B}$ is compressible. In particular, for the stationary choice $\mathbf{B} = D\mathbf{R}(\mathbf{u}^0)$ this might be expected to be the case. We shall return to this issue later.

7.3. Complexity estimates. We have just explained how to obtain concrete realizations of the scheme **SOLVE** in each of the three cases (L), (SL), (GNL). The remainder of this section will be devoted to giving a complexity analysis of these schemes. The following theorem summarizes the properties of Algorithm **EV**; see [10, Theorem 3.4].

THEOREM 7.4. *Given the inputs $\epsilon > 0$, a nonlinear function F such that $\mathbf{F}$ satisfies Assumptions* 1 *and* 2*, and a finitely supported vector $\mathbf{V}$, then the output tree $\mathcal{T}$ has the following properties:*

P1. $\|\mathbf{F}(\mathbf{V}) - \mathbf{F}(\mathbf{V})|_{\mathcal{T}}\| \leq \epsilon$.

P2. *For any $0 < s < \frac{2\gamma-d}{2d}$ (see Theorem* 7.3*),*

$$\#(\mathcal{T}) \leq C\|\mathbf{V}\|^{1/s}_{(\mathcal{A}^s_{\text{tree}})^n}\epsilon^{-1/s} + \#(\mathcal{J}_\phi) =: N_\epsilon \tag{7.22}$$

with C a constant depending only on the constants appearing in Theorem 7.3*.*

P3. *Moreover, the number of computations needed to find $\mathcal{T}$ is bounded by $C(N_\epsilon + \#\mathcal{T}(\mathbf{V}))$, where N_ϵ is the right-hand side of* (7.22) *and $\mathcal{T}(\mathbf{V})$ is the smallest tree containing* $\operatorname{supp}\mathbf{v}$*.*

Recall that in the case of semilinear equations, $\mathbf{R}$ involves a linear and a nonlinear operator as in (3.2) or (3.4). Also recall from Theorem 5.1 that when the wavelet representation $\mathbf{A}$ of the linear operator $\mathcal{A}$ defined by

$$\langle w, \mathcal{A}v\rangle = a(v,w), \quad v,w \in \mathcal{H} = H^t,$$

belongs to $\mathcal{C}_{s^*}$, then $\mathbf{A}$ is bounded on $\mathcal{A}^s$ with $s < s^*$. However, when nonlinear operators are also involved, Theorem 6.1 tells us that the spaces $\mathcal{A}^s_{\text{tree}}$ should now play the role of $\mathcal{A}^s$. Thus we shall prove in Proposition 7.4 below the boundedness of $\mathbf{A}$ with respect to this slightly stronger norm.

To prepare for Proposition 7.4, we make some remarks.

Remark 7.2. It has been shown in [12] that when $\mathcal{A}$ is a local operator, i.e., $\langle v, \mathcal{A}w\rangle = 0$ whenever $|\operatorname{supp} v \cap \operatorname{supp} w| = 0$, and when $\mathcal{A}$ is still bounded as a mapping from H^{t+a} to H^{-t+a} for $a \leq m + d/2$, where m is less than or equal to the order of differentiability and vanishing moments of the wavelets ψ_λ, then one has

$$|a(\psi_\lambda, \psi_\nu)| \lesssim 2^{-\sigma||\lambda|-|\nu||}, \quad \sigma = t + m + d/2. \tag{7.23}$$

Moreover, we know from Proposition 3.4 in [8] that in this case $\mathbf{A}$ belongs to $\mathcal{C}_{s^*}$ with

$$s^* = \frac{t+m}{d} = \frac{2\sigma - d}{2d}. \tag{7.24}$$

Note that σ agrees with the value of γ in Assumption 2 or at least depends in an analogous way on the spatial dimension, the order of the operator, and the order of the vanishing moments and the smoothness of the wavelets; see Theorem 7.2 (ii). Moreover, the condition $s < s^*$ with s^* from (7.24) agrees with the constraint on s from Theorem 7.3 formulated in terms of γ.

Remark 7.3. One can show that for piecewise polynomial wavelets, s^* can be chosen larger than in (7.24); see [2].

By definition one has $\mathcal{A}^s_{\text{tree}} \subset \mathcal{A}^s$. We shall need the following refinement of Theorem 5.1.

PROPOSITION 7.4. *Under the assumptions from Remark* 7.2 *on the linear part $\mathcal{A}$, let*

$$\sigma = m + t + d/2. \tag{7.25}$$

Then one has for $s < \frac{2\sigma - d}{2d}$

$$\|\mathbf{A}\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}, \quad \mathbf{v} \in \mathcal{A}^s_{\text{tree}}; \tag{7.26}$$

that is, $\mathbf{A}$ *maps* $\mathcal{A}^s_{\text{tree}}$ *boundedly into itself.*

Proof. By assumption (3.1), $\mathcal{A}$ is a topological isomorphism from $\mathcal{H}$ onto $\mathcal{H}'$ and obviously satisfies Assumption 1. We need to show that Assumption 2 holds for all $\gamma' < \sigma$, defined by (7.25). To this end, note that (7.23) provides

$$\begin{aligned} |(\mathbf{A}\mathbf{v})_\lambda| &\le \sum_{\substack{|\nu| \le |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} |v_\nu| 2^{-\sigma(|\lambda|-|\nu|)} + \sum_{\substack{|\nu| > |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} |v_\nu| 2^{-\sigma(|\lambda|-|\nu|)} 2^{-2\sigma(|\nu|-|\lambda|)} \\ &\le \sup_{\substack{|\nu| \le |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} 2^{-\gamma'(|\lambda|-|\nu|)} |v_\nu| \sum_{\substack{|\nu| \le |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} 2^{-(\sigma-\gamma')(|\lambda|-|\nu|)} \\ &\quad + \sup_{\substack{|\nu| > |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} |v_\nu| 2^{-\sigma(|\lambda|-|\nu|)} \sum_{\substack{|\nu| > |\lambda|, \\ S_\nu \cap S_\lambda \ne \emptyset}} 2^{-2\sigma(|\nu|-|\lambda|)}. \end{aligned}$$

We now check that both sums appearing on the right-hand side are bounded independently of λ provided that $\gamma' < \sigma$. Indeed, in the first sum, for any $k > |\lambda|$, there is a bounded number C_0 of indices ν with $|\nu| = k$ such that $S_\nu \cap S_\lambda \ne \emptyset$. Hence this sum is bounded by $C_0 \sum_{j=0}^{\infty} 2^{-j(\sigma-\gamma')}$. For the second sum, note that for $|\nu| = |\lambda| + k$, there are at most $C_0 2^{kd}$ indices ν for which $S_\nu \cap S_\lambda \ne \emptyset$. Since, by (7.25), $2\sigma > d$, this sum can also be bounded by a geometric series. We have thus verified Assumption 2 for all $\gamma' < \sigma$. The assertion now follows from Theorem 7.3 and the restriction on s given in Theorem 7.3. However, in contrast to the general nonlinear case, we can dispense here with the constant term in the right-hand side of (7.26); see Remark 3.2 in [10]. □

Note that the support of the output of the scheme **APPLY** from section 5.2 generally does not have tree structure. In order to ensure that the output of **RES** complies with our previous assumption that its support has tree structure, we shall employ the following modification of **APPLY** while keeping the notation unchanged. First, the original version of **APPLY** is carried out with target accuracy $\eta/2$. We then apply **TCOARSE** to the output with target accuracy $\eta/2$ so that (5.9) is still valid.

We shall make use of the following consequence of Proposition 7.4.

COROLLARY 7.5. *Under the same assumptions as in Proposition* 7.4 *let* $s < s^*$. *Then* $\mathbf{w}_\eta = \mathbf{APPLY}\,[\eta, \mathbf{A}, \mathbf{v}]$ *satisfies*

(i) $\#\text{flops} \lesssim \#\mathcal{T}(\operatorname{supp}\mathbf{v}) + \|\mathbf{v}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}} \eta^{-1/s}$, $\#\operatorname{supp}\mathbf{w}_\eta \lesssim \|\mathbf{v}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}} \eta^{-1/s}$;

(ii) $\|\mathbf{w}_\eta\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}$.

Proof. Let $\hat{\mathbf{w}}$ denote the output of the original version of **APPLY** with target accuracy $\eta/2$. The first estimate in (i) for $\hat{\mathbf{w}}$ follows directly from Theorem 5.1 (ii) and the fact that $\|\cdot\|_{\mathcal{A}^s} \lesssim \|\cdot\|_{\mathcal{A}^s_{\text{tree}}}$ even with $\#\mathcal{T}(\operatorname{supp}\mathbf{v})$ replaced by $\operatorname{supp}\mathbf{v}$. Now the cost of the subsequent application of **TCOARSE** with target accuracy $\eta/2$, yielding $\mathbf{w}_\eta$, is, by Proposition 6.2, proportional to $\#\mathcal{T}(\operatorname{supp}\mathbf{v})$. This confirms the first estimate in (i). Next note that, since the chunks $(\mathbf{v}_{[j]} - \mathbf{v}_{[j-1]})$ have disjoint supports, for each j the vector $\mathbf{w}_j$, defined by (5.7), can be interpreted as $\mathbf{w}_j = \mathbf{C}^{(j)}\mathbf{v}$, where the matrix $\mathbf{C}^{(j)}$ is a compressed version of $\mathbf{A}$ defined as follows. All columns with indices outside $\operatorname{supp}\mathbf{v}_{[j]}$ are zero. The columns of $\mathbf{C}^{(j)}$ whose indices belong to $\operatorname{supp}(\mathbf{v}_{[k]} - \mathbf{v}_{[k-1]})$, $k \le j$, agree with the corresponding columns in the matrix

$\mathbf{A}_{j-k}$. Therefore, since the $\mathbf{A}_j$ are derived from $\mathbf{A}$ by replacing certain entries by zero, we conclude that $\mathbf{C}^{(j)}$ is obtained by replacing certain entries in $\mathbf{A}$ by zero. Thus the $\mathbf{C}^{(j)}$ still satisfy (7.23) uniformly in j. Assumptions 1 and 2 also remain valid. Thus Proposition 7.4 can be applied to $\mathbf{C}^{(j)}$ with constants independent of j, which provides $\|\hat{\mathbf{w}}\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}$. Therefore, one also has $\|\mathbf{w}_\eta\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}}$, which is (ii). Since **TCOARSE** produces a near best tree approximation, we conclude that $\#\operatorname{supp}\mathbf{w}_\eta \lesssim \|\hat{\mathbf{w}}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}}\eta^{-1/s}$, which, in view of the previous remark, confirms the second estimate in (i) and finishes the proof. □

We have now collected all the ingredients needed to confirm s^*-sparsity of the residual approximations defined before. We start with (7.20) for the case (SL).

Corollary 7.6. *Let γ be the parameter given in Theorem* 7.2 *for the respective nonlinear mapping G. Suppose that σ, defined by* (7.25), *satisfies $\sigma \geq \gamma$. Then* $\mathbf{RES}_{\text{ell}}$, *defined by* (7.20), *is s^*-sparse with $s^* := \frac{2\gamma-d}{2d}$.*

Proof. We have to verify the validity of (6.15) for $s < s^*$. If $\mathbf{u} \in \mathcal{A}^s_{\text{tree}}$ for some $s < s^*$, then Proposition 7.4 and Theorem 7.4 imply that $\mathbf{f} \in \mathcal{A}^s_{\text{tree}}$ and $\|\mathbf{f}\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s_{\text{tree}}}$. Hence, since **TCOARSE** satisfies completely analogous properties with regard to $\mathcal{A}^s_{\text{tree}}$ as **COARSE** with respect to $\mathcal{A}^s$ (see [8]), we conclude that the output $\mathbf{f}_\eta$ of $\mathbf{RHS}\,[\eta, \mathbf{f}]$ satisfies

$$\#\operatorname{supp}\mathbf{f}_\eta \lesssim \eta^{-1/s}\|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}}, \quad \|\mathbf{f}_\eta\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s_{\text{tree}}}. \tag{7.27}$$

Furthermore, Corollary 7.5 says that the output of **APPLY** remains bounded in $\mathcal{A}^s_{\text{tree}}$, while Theorem 7.4 ensures that the same is true for the output of **EV**. Hence, by (7.20), one has for $\mathbf{w}_\eta := \mathbf{RES}_{\text{ell}}[\eta, \alpha\mathbf{I}, \mathbf{A}, \mathbf{G}, \mathbf{f}, \mathbf{v}]$

$$\|\mathbf{w}_\eta\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \left(\|\mathbf{v}\|_{\mathcal{A}^s_{\text{tree}}} + \|\mathbf{u}\|_{\mathcal{A}^s_{\text{tree}}} + 1\right), \tag{7.28}$$

which is the second estimate in (6.15). The first estimate in (6.15) follows also from (7.27), Theorem 7.4, and Corollary 7.5 (i). Since the supports of the outputs of $\mathbf{RES}_{\text{ell}}$ and **TCOARSE** have tree structure, the required bounds for the operations count follow (under Assumption E) from P3 in Theorem 7.4 and Corollary 7.5 (i). This completes the proof. □

Combining Corollary 7.6 with Theorem 6.1 yields the first main result of this paper.

Theorem 7.5. *Under the same assumptions as in Corollary* 7.6, *suppose that the solution $u = \sum_{\lambda\in\mathcal{J}} u_\lambda\psi_\lambda$ satisfies $\mathbf{u} \in \mathcal{A}^s_{\text{tree}}$ for some $s < s^* := (2\gamma - d)/(2d)$. Then the approximate solution $u(\epsilon) = \sum_{\lambda\in\Lambda(\epsilon)} \bar{u}(\epsilon)_\lambda\psi_\lambda$ produced by* **SOLVE** *(with the initialization for the semilinear problem) after finitely many steps satisfies*

$$\|u - u(\epsilon)\|_{\mathcal{H}} \leq C_1\epsilon.$$

Moreover,

$$\#(\text{flops}),\ \#(\Lambda(\epsilon)) \lesssim \epsilon^{-1/s}\big(1 + \|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\text{tree}}}\big), \tag{7.29}$$

and

$$\|\bar{\mathbf{u}}(\epsilon)\|_{\mathcal{A}^s_{\text{tree}}} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s_{\text{tree}}}, \tag{7.30}$$

where the constants depend only on $\|\mathbf{u}\|_{\ell_2(\mathcal{J})}$, on the constants in (2.5), (3.8), (3.3), *and on s when $s \to s^*$ or $s \to 0$.*

Let us briefly discuss now the locally convergent scheme from section 2.3. We shall assume that for the general problem (2.2) the nonlinear map in (2.1) satisfies Assumptions 1 and 2. Moreover, we assume that a sufficiently good initial guess $\mathbf{u}^0$ is given so that the error reduction (3.25) holds and that **SOLVE** is initialized accordingly; see section 5.

Corollary 7.7. *Let γ be the parameter given in Theorem* 7.2 *for the respective nonlinear mapping F. Moreover, assume that the matrix $\mathbf{B} = \mathbf{B}_n$ appearing in* (2.11) *satisfies decay estimates like* (7.23) *for some $\sigma \geq \gamma$. Then the scheme $\mathbf{RES}_{\rm lc}$ defined by* (7.21) *is s^*-sparse for $s^* := (2\gamma - d)/(2d)$.*

Proof. The assertion follows again from Proposition 7.4 and Theorem 7.4. □

Corollary 7.8. *Under the assumptions of Corollary* 7.7, *the assertion of Theorem* 7.5 *remains valid for the locally convergent scheme based on $\mathbf{RES}_{\rm lc}$.*

We end this section with analyzing the compressibility of the special choice $\mathbf{B} = D\mathbf{R}(\mathbf{u}^0)^T$. We consider $\mathcal{H} = H^t$ and only nonlinear maps of a single argument $n = 1$ and the subcritical case $t < d/2$, $p < p^*$; recall (7.6). Recall from (2.9) that the entries of $D\mathbf{R}(\mathbf{u}^0)^T = D\mathbf{R}(\mathbf{u}^0)$ have the form $w_{\lambda,\nu} := \langle \psi_\lambda, \psi_\nu R'(u^0)\rangle$. Since, in view of the $\mathcal{H} = H^t$-normalization of the ψ_λ, one has $\|\psi_\lambda\|_{L_\infty} \sim 2^{(\frac{d}{2}-t)|\lambda|}$, the same arguments as used in the proof of Theorem 4.2 in [10] yield

$$|w_{\lambda,\nu}| \;\lesssim\; \|\psi_\lambda\|_{L_\infty} \inf_{P\in\mathbb{P}_r} \|P - \psi_\nu R'(u^0)\|_{L_1(S_\lambda)} \;\lesssim\; 2^{-(r+\frac{d}{2}+t)|\lambda|} |\psi_\nu R'(u^0)|_{W^r(L_\infty(S_\lambda))},$$

where we assume without loss of generality that $|\lambda| \geq |\nu|$. Moreover, we obtain

$$|\psi_\nu R'(u^0)|_{W^r(L_\infty(S_\lambda)} \;\lesssim\; \max_{l\leq r} |\psi_\nu|_{W^{r-l}(L_\infty(S_\lambda))} |R'(u^0)|_{W^l(L_\infty(S_\lambda))}.$$

Abbreviating as before $\sigma = r + \frac{d}{2} + t$, we can estimate the first factor by

$$2^{(\frac{d}{2}-t)|\nu|} 2^{(r-l)|\nu|} = 2^{\sigma|\nu|} 2^{-(2t+l)|\nu|}, \tag{7.31}$$

while the second factor can be estimated along the lines of the proof of Theorem 4.2 in [10] as

$$\begin{aligned} |R'(u^0)|_{W^l(L_\infty(S_\lambda))} \;&\lesssim\; \max_{k=1,\dots,l} \|\mathbf{u}^0\|_{\ell_2(\mathcal{J})}^{m+k-1} \\ &\times \sup_{\mu: S_\mu\cap S_\lambda\cap S_\nu\neq\emptyset} |u^0_\mu| 2^{(l+(p-1)\epsilon)|\mu|} 2^{(p-1)(\frac{d}{2}-t)|\mu|}, \end{aligned} \tag{7.32}$$

where $\epsilon > 0$, $j_i \in \mathbb{N}$, and

$$m := \begin{cases} (p-l-1)_+ & \text{if} \quad \|\mathbf{u}^0\|_{\ell_2(\mathcal{J})} \geq 1, \\ 0 & \text{if} \quad \|\mathbf{u}^0\|_{\ell_2(\mathcal{J})} < 1. \end{cases}$$

As in [10], we can choose ϵ so that

$$2^{(l+(p-1)\epsilon)|\mu|} 2^{(p-1)(\frac{d}{2}-t)|\mu|} \;\lesssim\; 2^{(l+\frac{d}{2}+t)|\mu|} 2^{-\epsilon|\mu|} 2^{-(\frac{d}{2}-t)|\mu|} = 2^{-\epsilon|\mu|} 2^{(l+2t)|\mu|}.$$

Thus, combining (7.31) and (7.32), we obtain

$$|w_{\lambda,\nu}| \;\lesssim\; C(\|\mathbf{u}^0\|_{\ell_2(\mathcal{J})}) 2^{-\sigma||\lambda|-|\nu||} \sup_{\mu: S_\mu\cap S_\lambda\cap S_\nu\neq\emptyset} |u^0_\mu| 2^{-\epsilon|\mu|} 2^{(r+2t)(|\mu|-|\nu|)}. \tag{7.33}$$

Note that the first factor $C(\|\mathbf{u}^0\|_{\ell_2(\mathcal{J})}) 2^{-\sigma||\lambda|-|\nu||}$ represents the same scalewise decay of the entries as in the matrix $\mathbf{A}$ in (7.23). This ensures that $D\mathbf{R}(\mathbf{u}^0)$ belongs to $\mathcal{C}_{s^*}$

with s^* given by (7.24). However, the entries are weighted by additional u^0-dependent factors that could, in principle, become rather large when the finite expansion u^0 contains basis functions from high scales overlapping S_λ. Nevertheless, these factors depend only on u^0 (and hence on the accuracy δ of the initial guess) but not on the accuracy by which $D\mathbf{R}(\mathbf{u}^0)$ is applied through the scheme **APPLY**. Therefore, in principle, one obtains asymptotically optimal complexity, however, with possibly poor quantitative behavior.

8. Newton's method. In concrete cases, the error reduction ρ obtained in (3.25) or (3.17) may be so close to one that the number K of necessary updates in the perturbed scheme **SOLVE** may become fairly large. So, in spite of its asymptotic optimality, the quantitative performance may be poor. We shall therefore address Newton's method, corresponding to $\mathbf{B}_n = (D\mathbf{R}(\mathbf{u}^n))^{-1}$ in (2.11), as an example where the ideal scheme permits a faster error decay. The adaptive realization of Newton's method, applied to the infinite dimensional problem (2.2) or, better yet, (2.8), does not quite fit into the format of **SOLVE**, explaining its separate treatment in this section.

Note that, for $\mathbf{B}_n = (D\mathbf{R}(\mathbf{u}^n))^{-1}$, (2.11) can be reformulated as follows. Given an initial guess $\mathbf{u}^n$, the next iterate $\mathbf{u}^{n+1}$ is determined by solving

$$D\mathbf{R}(\mathbf{u}^n)\mathbf{w}^n = -\mathbf{R}(\mathbf{u}^n) \tag{8.1}$$

and setting

$$\mathbf{u}^{n+1} := \mathbf{u}^n + \mathbf{w}^n. \tag{8.2}$$

We are not interested here in the weakest assumptions under which the iterative scheme (8.2) converges to a locally unique solution. We are instead content here with the following setting: Recall that the mapping R in the variational problem (2.2) has the form

$$R(v) = F(v) - f, \tag{8.3}$$

where throughout this section we shall confine the discussion again to nonlinear maps F of a single argument satisfying the growth condition (7.5) for some $n^* \geq 1$. (Of course, F can have a linear part as in (3.4).) Therefore, we have, in particular, that R and F have the same Frechét derivative $DR(v) = DF(v)$. Moreover, we assume that for some open ball $\mathcal{U} \subset \mathcal{H}$ one has the following:

(N1) The Frechét derivative $DR(v) : w \mapsto DR(v)w$ is an isomorphism from $\mathcal{H}$ to $\mathcal{H}'$ (see (2.4)), and there exists $\omega > 0$ such that for all $v \in \mathcal{U}$ and y such that $v + y \in \mathcal{U}$, we have

$$\|(DR(v))^{-1}(DR(v+y) - DR(v))y\|_{\mathcal{H}} \leq \omega\|y\|_{\mathcal{H}}^2. \tag{8.4}$$

(N2) There exists a solution $u \in \mathcal{U}$ and an initial guess u^0 in $\mathcal{U}$ such that

$$\|u - u^0\|_{\mathcal{H}} \leq \delta < 2/\omega \quad \text{and} \quad B_\delta(u) \subseteq \mathcal{U} \tag{8.5}$$

with ω from (N1).

Given the validity of (N1) and (N2), standard arguments can be employed to prove that all iterates

$$u^{n+1} = u^n - DR(u^n)^{-1}R(u^n), \tag{8.6}$$

arising from Newton's method formulated in $\mathcal{H}$, remain in $\mathcal{U}$ and satisfy

$$\|u-u^n\|_{\mathcal{H}}<\delta \quad \text{for} \quad n\in\mathbb{N} \quad \text{and} \quad \lim_{n\to\infty}\|u-u^n\|_{\mathcal{H}}=0. \tag{8.7}$$

In fact, one has quadratic convergence

$$\|u-u^{n+1}\|_{\mathcal{H}}\le \frac{\omega}{2}\|u-u^n\|_{\mathcal{H}}^2, \quad n=0,1,2,\dots; \tag{8.8}$$

see, e.g., [18, 19]. Finally, note that, by (2.5), the corresponding iterates in wavelet coordinates satisfy

$$\|\mathbf{u}-\mathbf{u}^{n+1}\|_{\ell_2(\mathcal{J})}\le\tilde{\omega}\|\mathbf{u}-\mathbf{u}^n\|_{\ell_2(\mathcal{J})}^2, \quad n\in\mathbb{N}_0, \quad \tilde{\omega}:=\frac{C_1^2\omega}{2c_1}. \tag{8.9}$$

Let us check that (N1) holds, for instance, in the semilinear case (SL) when F is defined by (3.4) with monotone (scalar valued) G which satisfies (7.5) with $n^*\ge 2$. We have already seen (see Remark 3.1) that $DR(v)=DF(v)$ is an isomorphism from $\mathcal{H}$ to $\mathcal{H}'$. In order to verify (8.4), it therefore suffices to show that

$$\|(G'(v+y)-G'(v))y\|_{\mathcal{H}'}\le\omega\|y\|_{\mathcal{H}}^2. \tag{8.10}$$

For this, we remark that

$$\|(G'(v+y)-G'(v))y\|_{\mathcal{H}'}\le\max_{t\in[0,1]}\|G''(v+ty)y^2\|_{\mathcal{H}'}=\|y\|_{\mathcal{H}}^2\max_{z\in\mathcal{U},\|w\|_{\mathcal{H}}\le 1}\|T(z,w,w)\|_{\mathcal{H}'}$$

with the mapping T defined by

$$T(v,w,z)=G''(v)wz. \tag{8.11}$$

Now, it is easy to check that if G satisfies (7.5) for some p and $n^*\ge 2$, then T satisfies (7.7) with $p_1=[p-2]_+$, $p_2=p_3=1$, and n^* replaced by n^*-2, and therefore, according to Theorem 7.1,

$$\omega:=\max_{z\in\mathcal{U},\|w\|_{\mathcal{H}}\le 1}\|T(z,w,w)\|<\infty, \tag{8.12}$$

as desired. The purpose of this section is to show how the approximate solution of the linear problem (8.1) can be performed again by an iterative scheme along the lines of [9]. By our assumption (N1), we know that $DR(z)$ is an isomorphism from $\mathcal{H}$ to $\mathcal{H}'$ provided that $z\in\mathcal{U}$ and hence $DR(z)$ satisfies (2.10). Given this mapping property (2.10), the adaptive scheme from [9] can actually be applied under fairly general assumptions on the linear isomorphism. For the sake of simplicity, we shall assume that $D\mathbf{R}(\mathbf{z})$ is symmetric positive definite. This is true, for example, in the case (SL) when G is monotone. Recall from Remark 3.3 that one can then find a parameter $\alpha>0$ such that $\mathbf{I}-\alpha D\mathbf{R}(\mathbf{v})$ is a contraction.

The heart of the envisaged adaptive Newton scheme will be to solve the linear problem (8.1) approximately with the aid of a variant, which will be called $\mathbf{SOLVE}_{\mathrm{N}}$, of the scheme $\mathbf{SOLVE}_{\mathrm{lin}}$ discussed in section 3. Before we describe the ingredients of $\mathbf{SOLVE}_{\mathrm{N}}$, let us point out two issues to be addressed when designing these ingredients and analyzing their complexity.

(a) The first point concerns the application of the Jacobian. Approximating at each stage the Jacobian $D\mathbf{R}(\mathbf{u}^n)$ in order to use the **APPLY** scheme based on

(5.7) might be computationally very expensive. (b) The second point concerns the complexity of approximately solving the linear problem (8.1). Recall from Theorem 6.1 that the logic of complexity estimates is to infer from a certain compressibility (or regularity) of the solution a corresponding convergence rate of the adaptive scheme. In the context of the Newton iteration, such a property will be assumed about the solution $\mathbf{u}$ of the original nonlinear problem (2.8) which, however, does not necessarily imply the same property for the solutions of the subproblems (8.1). So it is initially not clear how to derive complexity estimates for the resolution of these subproblems. It will be seen though that the solutions to these subproblems become increasingly closer to elements having the necessary properties, a fact that, as it turns out, can be exploited as long as the subproblems are not solved too accurately. In particular, the question then arises whether the quadratic convergence of the Newton scheme can be preserved.

We now turn to collecting the ingredients of the adaptive Newton scheme. First, the coarsening will be again done by **TCOARSE** even though the problem is linear. More importantly, the **RES** scheme will be of the form $\mathbf{RES}_{\mathrm{lin}}$ from (5.10) but with different schemes playing the roles of **APPLY** and **RHS**.

In view of the above issue (a), we shall pursue here the following approach. Recall from (2.9) that for any $\mathbf{v}, \mathbf{z} \in \ell_2(\mathcal{J})$ and corresponding $v = \sum_{\lambda\in\mathcal{J}} v_\lambda \psi_\lambda$, $z = \sum_{\lambda\in\mathcal{J}} z_\lambda \psi_\lambda \in \mathcal{H}$,

$$D\mathbf{R}(\mathbf{z})\mathbf{v} = (\langle \psi_\lambda, DR(z)v\rangle : \lambda \in \mathcal{J}), \tag{8.13}$$

where $DR(z)$ is the Frechét derivative of R at z. This suggests employing the scheme $\mathbf{EV}[\epsilon, \mathbf{Q}, \mathbf{V}]$ with $\mathbf{V} := (\mathbf{z}, \mathbf{v})$ and $\mathbf{Q}(\mathbf{V}) := D\mathbf{R}(\mathbf{z})\mathbf{v} = D\mathbf{F}(\mathbf{z})\mathbf{v}$. We have seen that this scheme has the optimal complexity provided that $\mathbf{Q}$ fulfills Assumptions 1 and 2.

For F defined by (3.4), the mapping $\mathbf{Q}$ has the form

$$\mathbf{Q}(\mathbf{z}, \mathbf{v}) := (\mathbf{A} + D\mathbf{G}(\mathbf{z}))\mathbf{v}. \tag{8.14}$$

The $\mathbf{A}$ part obviously satisfies Assumption 1. We also have seen that it fulfills Assumption 2 under the hypothesis from Remark 7.2. It remains to verify these assumptions for the part

$$D\mathbf{G}(\mathbf{z})\mathbf{v} = (\langle \psi_\lambda, G'(z)v\rangle : \lambda \in \mathcal{J}). \tag{8.15}$$

For this, we simply remark that if G satisfies (7.5) for some p and $n^* \geq 1$, the mapping $(z, v) \mapsto G'(z)v$ satisfies (7.7) with $p_1 = [p-1]_+$, $p_2 = 1$, and n^* replaced by $n^* - 1$. Hence Theorems 7.1 and 7.2 ensure that the mapping $(\mathbf{z}, \mathbf{v}) \mapsto D\mathbf{G}(\mathbf{z})\mathbf{v}$ satisfies Assumptions 1 and 2 in section 7.1.

This suggests the following routine.

$\mathbf{APPLY}_{\mathrm{N}}[\eta, D\mathbf{R}(\mathbf{z}), \mathbf{v}] \to \mathbf{w}_\eta$ *determines for any tolerance* $\eta > 0$ *and any finitely supported input vectors* $\mathbf{v}$ *and* $\mathbf{z}$ *a finitely supported output vector* $\mathbf{w}_\eta$ *such that*

$$\|D\mathbf{R}(\mathbf{z})\mathbf{v} - \mathbf{w}_\eta\|_{\ell_2(\mathcal{J})} \leq \eta, \tag{8.16}$$

through

$$\mathbf{APPLY}_{\mathrm{N}}[\eta, D\mathbf{R}(\mathbf{z}), \mathbf{v}] := \mathbf{EV}[\eta, \mathbf{Q}, (\mathbf{z}, \mathbf{v})], \tag{8.17}$$

where the routine **EV** *was introduced in section* 7.2.

It remains to specify the routine **RHS**. Here it is issue (b) that calls for some further preparations. The main point is that if the current right-hand sides in (8.1) are not approximated too accurately, then one actually approximates a nearby right-hand side of a problem whose solution is known to be sufficiently sparse and thus can be approximated efficiently by a linear version of **SOLVE**.

Remark 8.1. Suppose that R is twice Frechét differentiable and that $\mathbf{u}$ is the exact solution of (2.8). Then there exists a constant $\hat{C}$ such that, for any $\mathbf{z}$ such that $z = \sum_{\lambda\in\mathcal{J}} z_\lambda \psi_\lambda \in \mathcal{U}$,

$$\|D\mathbf{R}(\mathbf{z})(\mathbf{u}-\mathbf{z}) + \mathbf{R}(\mathbf{z})\|_{\ell_2(\mathcal{J})} \leq \hat{C}\|\mathbf{u}-\mathbf{z}\|^2_{\ell_2(\mathcal{J})}. \tag{8.18}$$

Proof. One has

$$-\mathbf{R}(\mathbf{z}) = \mathbf{R}(\mathbf{u}) - \mathbf{R}(\mathbf{z}) = D\mathbf{R}(\mathbf{z})(\mathbf{u}-\mathbf{z}) + \mathcal{O}\left(\|\mathbf{u}-\mathbf{z}\|^2_{\ell_2(\mathcal{J})}\right),$$

which confirms the claim. □

We shall employ the following routine in which $\hat{C}$ is the constant of Remark 8.1.

$\mathbf{RHS}_{\mathrm{N}}[\eta, \mathbf{R}, \mathbf{z}] \to \mathbf{r}_\eta(\mathbf{z})$ *is defined for any finitely supported* $\mathbf{z}$ *with* $z \in \mathcal{U}$ *such that* $\|\mathbf{u}-\mathbf{z}\|_{\ell_2(\mathcal{J})} \leq \xi$ *and for any* $\eta/2 > \hat{C}\xi^2$ *by*

$$\mathbf{RHS}_{\mathrm{N}}\,[\eta, \mathbf{R}, \mathbf{z}] := -\left(\mathbf{EV}\left[\frac{\eta}{2} - \hat{C}\xi^2, \mathbf{F}, \mathbf{z}\right] - \mathbf{RHS}\,[\eta/2, \mathbf{f}]\right), \tag{8.19}$$

where **RHS** *is defined by* (5.2) *but with* **TCOARSE** *used as* **CCOARSE**.

The role of the above conditions on $\mathbf{z}$ and η will become clear later.

We are now prepared to describe the version of **SOLVE** to be used for the approximate solution of the Newton systems (8.1) as follows.

$\mathbf{SOLVE}_{\mathrm{N}}[\eta, \mathbf{R}, \mathbf{z}] \to \mathbf{w}_\eta$ *determines for a given* $\mathbf{z} \in \ell_2(\mathcal{J})$*, such that* $z \in \mathcal{U}$*, an approximate solution* $\mathbf{w}_\eta$ *of the system* $D\mathbf{R}(\mathbf{z})\mathbf{w} = -\mathbf{R}(\mathbf{z})$ *satisfying*

$$\|\mathbf{w} - \mathbf{w}_\eta\|_{\ell_2(\mathcal{J})} \leq \eta, \tag{8.20}$$

by invoking $\mathbf{SOLVE}_{\mathrm{lin}}[\eta, D\mathbf{R}(\mathbf{z}), -\mathbf{R}(\mathbf{z})] \to \mathbf{w}_\eta$*, where, under the above assumptions on* $\mathbf{z}$ *and* η*, in step* (ii) *of* **SOLVE** *the residual approximation*

$$\begin{aligned}&\mathbf{RES}_{\mathrm{N}}[\eta, \alpha\mathbf{I}, D\mathbf{R}(\mathbf{z}), -\mathbf{R}(\mathbf{z}), \mathbf{v}]\\ &\qquad := \alpha\left(\mathbf{APPLY}_{\mathrm{N}}\left[\frac{\eta}{2\alpha}, D\mathbf{R}(\mathbf{z}), \mathbf{v}\right] - \mathbf{RHS}_{\mathrm{N}}\left[\frac{\eta}{2\alpha}, \mathbf{R}, \mathbf{z}\right]\right),\end{aligned} \tag{8.21}$$

and in step (iii) **TCOARSE** *is used.*

Note that, in view of (8.3), the evaluation of $\mathbf{R}$ also requires the approximation of the data $\mathbf{f}$ as stated explicitly in (8.19). From Theorems 7.3 and 7.4 and Proposition 6.3 we infer, as in Remark 5.1, that $\mathbf{u} \in \mathcal{A}^s_{\mathrm{tree}}$ implies $\mathbf{f} \in \mathcal{A}^s_{\mathrm{tree}}$, and its η-accurate tree approximation satisfies estimates of the form $\#\mathrm{supp}\,\mathbf{f}_\eta \lesssim \eta^{-1/s}\|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\mathrm{tree}}}$, $\|\mathbf{f}_\eta\|_{\mathcal{A}^s_{\mathrm{tree}}} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s_{\mathrm{tree}}}$.

Moreover, whenever $\mathbf{Q}(\mathbf{z}, \mathbf{v}) := D\mathbf{R}(\mathbf{z})\mathbf{v}$ satisfies Assumptions 1 and 2, we can apply Theorems 7.3 and 7.4 to conclude that the output $\mathbf{w}_\eta$ of $\mathbf{APPLY}_{\mathrm{N}}\,[\eta, D\mathbf{R}(\mathbf{z}), \mathbf{v}]$ satisfies

$$\begin{aligned}\#\mathrm{supp}\,\mathbf{w}_\eta &\lesssim \eta^{-1/s}\left(1 + \|\mathbf{z}\|^{1/s}_{\mathcal{A}^s_{\mathrm{tree}}} + \|\mathbf{v}\|^{1/s}_{\mathcal{A}^s_{\mathrm{tree}}} + \|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\mathrm{tree}}}\right),\\ \|\mathbf{w}_\eta\|_{\mathcal{A}^s_{\mathrm{tree}}} &\lesssim 1 + \|\mathbf{z}\|_{\mathcal{A}^s_{\mathrm{tree}}} + \|\mathbf{v}\|_{\mathcal{A}^s_{\mathrm{tree}}} + \|\mathbf{u}\|_{\mathcal{A}^s_{\mathrm{tree}}}.\end{aligned} \tag{8.22}$$

Likewise, the output $\mathbf{r}_\eta(\mathbf{z})$ of $\mathbf{RHS}_{\rm N}\,[\eta, \mathbf{R}, \mathbf{z}]$ satisfies

$$\begin{array}{rcl}\#\mathrm{supp}\,\mathbf{r}_\eta(\mathbf{z}) & \lesssim & \eta^{-1/s}\left(1 + \|\mathbf{z}\|^{1/s}_{\mathcal{A}^s_{\rm tree}}\right), \\ \|\mathbf{r}_\eta(\mathbf{z})\|_{\mathcal{A}^s_{\rm tree}} & \lesssim & 1 + \|\mathbf{z}\|_{\mathcal{A}^s_{\rm tree}}.\end{array} \tag{8.23}$$

Recalling from (6.15) the definition of s^*-sparsity, we can infer from (8.22) the following consequence.

Remark 8.2. Let $s^* := (2\gamma - d)/(2d)$, where γ is the parameter associated with F by Theorem 7.2. Then the scheme $\mathbf{RES}_{\rm N}$, defined by (8.21), is s^*-sparse whenever $\|\mathbf{z}\|_{\mathcal{A}^s_{\rm tree}} \lesssim 1$.

We can now formulate an adaptive Newton iteration as follows.

$\mathbf{NEWTON}\,[\epsilon, R, \bar{\mathbf{u}}^0] \to \bar{\mathbf{u}}(\epsilon)$ *determines, for any finitely supported initial guess* $\bar{\mathbf{u}}^0$ *whose corresponding expansion* u_0 *satisfies* (8.5), *an approximate solution* $\bar{\mathbf{u}}(\epsilon)$ *satisfying*

$$\|\mathbf{u} - \bar{\mathbf{u}}(\epsilon)\|_{\ell_2(\mathcal{J})} \le \epsilon, \tag{8.24}$$

by the following steps:

(i) *Set* $\epsilon_0 := c_1^{-1}\delta$, $j = 0$.

(ii) *If* $\epsilon_j \le \epsilon$, *stop and output* $\bar{\mathbf{u}}(\epsilon) := \bar{\mathbf{u}}^j$. *Otherwise, choose some* $\eta_j > 0$ *(see* (8.27) *below), and perform*

$$\mathbf{SOLVE}_{\rm N}\,[\eta_j, \mathbf{R}, \bar{\mathbf{u}}^j, \mathbf{0}] \to \bar{\mathbf{w}}^j.$$

(iii) *Let (see* (8.9)*)*

$$\hat{\mathbf{u}} := \bar{\mathbf{u}}^j + \bar{\mathbf{w}}^j, \quad \hat{\eta}_j := \tilde{\omega}\epsilon_j^2 + \eta_j, \quad \bar{\mathbf{u}}^{j+1} := \mathbf{TCOARSE}\,[2C^*\hat{\eta}_j, \hat{\mathbf{u}}]$$

(where C^* *is the constant from section* 6.2*), and set* $\epsilon_{j+1} := (1 + 2C^*)\hat{\eta}_j$, $j + 1 \to j$, *and go to* (ii).

The choice of the dynamic tolerance η_j in step (ii) is yet to be specified. The first requirement is to keep the iterates $\bar{\mathbf{u}}^j$ in the right neighborhood of the solution, which means that the corresponding expansions $\bar{u}^j$ lie in $B_\delta(u)$. For this we shall use the following lemma.

LEMMA 8.1. *Fix a positive number* $\beta < 1$, *and assume that* $\delta > 0$ *is chosen sufficiently small to ensure that, in addition to* (8.5),

$$\delta < \frac{c_1^3}{(1 + 2C^*)C_1^3\omega} \tag{8.25}$$

and

$$\frac{(1 + 2C^*)\tilde{\omega}\delta}{c_1} < \beta. \tag{8.26}$$

Then the condition $\eta_j \le \eta_0 < \delta/(2(1 + 2C^*)C_1)$ *implies that* $\bar{u}_j \in B_\delta(u)$ *for all subsequent approximate iterates. Moreover, if*

$$\eta_j \le \frac{\epsilon_j\,(\beta - (1 + 2C^*)\tilde{\omega}\epsilon_j)}{1 + 2C^*}, \quad j = 0, 1, \ldots, \tag{8.27}$$

one has for $\hat{\eta}_j$ *defined in step* (iii) *of* **NEWTON**

$$\epsilon_{j+1} = (1 + 2C^*)\hat{\eta}_j \le \beta\epsilon_j, \quad j = 0, 1, \ldots. \tag{8.28}$$

Proof. Denoting by $\mathbf{u}^1$ the exact solution of $D\mathbf{R}(\bar{\mathbf{u}}^0)\mathbf{u}^1 = -\mathbf{R}(\bar{\mathbf{u}}^0)$ and recalling from step (i) that $\|\mathbf{u}-\bar{\mathbf{u}}^0\|_{\ell_2(\mathcal{J})} \le c_1^{-1}\delta = \epsilon_0$, the vector $\hat{\mathbf{u}}$ produced in steps (ii) and (iii) satisfies, by (8.9) and (8.20),

$$\|\mathbf{u}-\hat{\mathbf{u}}\|_{\ell_2(\mathcal{J})} \le \|\mathbf{u}-\mathbf{u}^1\|_{\ell_2(\mathcal{J})} + \|\mathbf{u}^1-\hat{\mathbf{u}}\|_{\ell_2(\mathcal{J})} \le \tilde{\omega}c_1^{-2}\delta^2 + \eta_0.$$

Thus, taking the coarsening step into account, we infer from (2.5) and (8.9) that

$$\begin{aligned}\|u-\bar{u}^1\|_{\mathcal{H}} &\le C_1\|\mathbf{u}-\bar{\mathbf{u}}^1\|_{\ell_2(\mathcal{J})} \le (1+2C^*)C_1(\tilde{\omega}c_1^{-2}\delta^2+\eta_0)\\ &= \frac{(1+2C^*)C_1^3\omega\delta^2}{2c_1^3} + (1+2C^*)C_1\eta_0.\end{aligned}$$

Thus when, e.g., $\frac{(1+2C^*)C_1^3\omega\delta^2}{2c_1^3} < \delta/2$, which is (8.25), it suffices to take $\eta_0 < \delta/(2(1+2C^*)C_1)$ at the initial stage $j=0$ to ensure that

$$\|\bar{u}^1 - u\|_{\mathcal{H}} < \|u-u^0\|_{\mathcal{H}},$$

which verifies that $\bar{u}^1 \in B_\delta(u)$. We can now iterate this result; e.g., using $\bar{u}^1$ in place of $\bar{u}^0$, we obtain that $\bar{u}^2 \in B_\delta(u)$, and so on. Now when (8.26) holds, we have $\beta > (1+2C^*)\tilde{\omega}\epsilon_0$ so that the condition (8.27) on η_j is feasible for $j=0$. Moreover, (8.27) implies that $\epsilon_{j+1} = (1+2C^*)\hat{\eta}_j \le \beta\epsilon_j$, which is (8.28). This ensures that the error bounds ϵ_j decay to zero so that (8.27) remains feasible for all j. This completes the proof. □

Proposition 8.3. *Assume that δ and η_j satisfy* (8.25), (8.26)*, and* (8.27)*, respectively. Then the scheme* **NEWTON** *terminates after finitely many steps and produces a finitely supported vector $\bar{\mathbf{u}}(\epsilon)$ satisfying*

$$\|\mathbf{u}-\bar{\mathbf{u}}(\epsilon)\|_{\ell_2(\mathcal{J})} \le \epsilon. \tag{8.29}$$

Thus, by (2.5)*,*

$$\left\| u - \sum_{\lambda\in\operatorname{supp}\bar{\mathbf{u}}(\epsilon)} u(\epsilon)_\lambda \psi_\lambda \right\|_{\mathcal{H}} \le C_1\epsilon.$$

Proof. We employ a simple perturbation argument as in the proof of Lemma 8.1. Let $\mathbf{u}^{j+1}$ denote the exact Newton iteration $\mathbf{u}^{j+1} = \bar{\mathbf{u}}^j - D\mathbf{R}(\bar{\mathbf{u}}^j)^{-1}\mathbf{R}(\bar{\mathbf{u}}^j)$. By step (i) we know that $\|\mathbf{u}-\bar{\mathbf{u}}^0\|_{\ell_2(\mathcal{J})} \le \epsilon_0$. Then, supposing that $\|\mathbf{u}-\bar{\mathbf{u}}^j\|_{\ell_2(\mathcal{J})} \le \epsilon_j$, we infer from (8.9) that

$$\|\mathbf{u}-\mathbf{u}^{j+1}\|_{\ell_2(\mathcal{J})} \le \tilde{\omega}\epsilon_j^2. \tag{8.30}$$

Hence, denoting by $\mathbf{w}^j := \mathbf{u}^{j+1} - \bar{\mathbf{u}}^j$ the exact solution of $D\mathbf{R}(\bar{\mathbf{u}}^j)\mathbf{w} = -\mathbf{R}(\bar{\mathbf{u}}^j)$, we obtain, according to step (iii),

$$\begin{aligned}\|\mathbf{u}-\bar{\mathbf{u}}^{j+1}\|_{\ell_2(\mathcal{J})} &\le \|\mathbf{u}-\mathbf{u}^{j+1}\|_{\ell_2(\mathcal{J})} + \|\mathbf{u}^{j+1}-\hat{\mathbf{u}}\|_{\ell_2(\mathcal{J})} + \|\hat{\mathbf{u}}-\bar{\mathbf{u}}^{j+1}\|_{\ell_2(\mathcal{J})}\\ &\le \tilde{\omega}\epsilon_j^2 + \|\mathbf{w}^j - \bar{\mathbf{w}}^j\|_{\ell_2(\mathcal{J})} + 3\hat{\eta}_j \le \tilde{\omega}\epsilon_j^2 + \eta_j + 2C^*\hat{\eta}_j\\ &= (1+2C^*)\hat{\eta}_j = \epsilon_{j+1},\end{aligned} \tag{8.31}$$

which advances the induction assumption. By (8.28), this finishes the proof. □

It remains to analyze the work/accuracy rate of **NEWTON**. So far the only condition on the tolerances η_j in step (ii) of **NEWTON** is (8.27), which ensures only that the error bounds ϵ_j decay to zero. This would allow us to keep η_j proportional to ϵ_j, which would result in an overall first order error reduction rate. On the other hand, choosing η_j proportional to ϵ_j^2, the error bounds ϵ_j decay, by step (iii), quadratically. However, according to the earlier discussion of issue (b), the subproblem (8.1) should not be resolved too accurately, as reflected by the above right-hand side scheme $\mathbf{RHS}_{\rm N}$; see (8.19). The following main result of this section says that within these constraints on the tolerances η_j one can still realize an outer convergence rate, ranging from first to second order, in such a way that the overall scheme exhibits optimal rate/complexity.

THEOREM 8.2. *Suppose that* (N1), (N2), *and the above hypotheses on* F *hold. Assume that* δ *satisfies* (8.25) *and* (8.26) *for some fixed* $\beta < 1$. *Moreover, assume that at the* j*th stage of* **NEWTON** *the tolerance* η_j *is in addition to* (8.27) *subjected to the condition*

$$\eta_j \rho^K \geq \zeta \hat{C} \epsilon_j^2 \quad \textit{for some fixed} \;\; \zeta > 1, \tag{8.32}$$

where ρ, K *are the constants from* (3.17) *and* (4.14). *Then, for any target accuracy* $\epsilon > 0$, **NEWTON** *outputs after finitely many steps a finitely supported vector* $\bar{\mathbf{u}}(\epsilon)$ *satisfying* $\|\mathbf{u} - \bar{\mathbf{u}}(\epsilon)\|_{\ell_2(\mathcal{J})}$, *and hence*

$$\left\| u - \sum_{\lambda \in \operatorname{supp} \bar{\mathbf{u}}(\epsilon)} \bar{u}(\epsilon)_\lambda \psi_\lambda \right\|_{\mathcal{H}} \leq C_1 \epsilon.$$

Moreover, if $\mathbf{Q}(\mathbf{z}, \mathbf{v}) = D\mathbf{R}(\mathbf{z})\mathbf{v}$ *fulfills Assumptions* 1 *and* 2, *and if the solution* $\mathbf{u}$ *of* (2.8) *belongs to* $\mathcal{A}^s_{\rm tree}$ *for some* $s < s^* = (2\gamma - d)/(2d)$, *the output* $\mathbf{u}(\epsilon)$ *of* **NEWTON** *has the following properties:*

$$\|\mathbf{u}(\epsilon)\|_{\mathcal{A}^s_{\rm tree}} \;\lesssim\; \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}, \qquad \#\operatorname{supp} \mathbf{u}(\epsilon) \;\lesssim\; \|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\rm tree}} \epsilon^{-1/s}. \tag{8.33}$$

Under Assumption E the number of floating point operations needed to compute $\bar{\mathbf{u}}(\epsilon)$ *remains proportional to* $\#\operatorname{supp} \mathbf{u}(\epsilon)$.

It is understood that in the final step η_j is chosen within the above constraints as large as possible so as to attain the target accuracy. Note that, as indicated before, within the above constraints on η_j (see (8.27), (8.32)) the convergence rate of the outer inexact Newton iteration can be chosen to vary between linear and quadratic convergence.

Proof of Theorem 8.2. First, observe that in step (iii) one has at the jth stage, by the first part of (8.31),

$$\|\mathbf{u} - \hat{\mathbf{u}}\|_{\ell_2(\mathcal{J})} \leq \|\mathbf{u} - \mathbf{u}^{j+1}\|_{\ell_2(\mathcal{J})} + \|\mathbf{u}^{j+1} - \hat{\mathbf{u}}\|_{\ell_2(\mathcal{J})} \leq \tilde{\omega} \epsilon_j^2 + \eta_j = \hat{\eta}_j. \tag{8.34}$$

Hence, by Proposition 6.3 and step (iii), we obtain

$$\|\bar{\mathbf{u}}^{j+1}\|_{\mathcal{A}^s_{\rm tree}} \;\lesssim\; \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}, \quad \#\operatorname{supp} \bar{\mathbf{u}}^{j+1} \;\lesssim\; \|\mathbf{u}\|^{1/s} \epsilon_{j+1}^{-1/s}. \tag{8.35}$$

Moreover, by Proposition 6.2, the computational work required by the application of **TCOARSE** remains proportional to $\#\operatorname{supp} \hat{\mathbf{u}}$ since the support of $\hat{\mathbf{u}}$ already has tree structure.

Now let us discuss the computational complexity in step (ii) encountered between the coarsening steps. Here it is important that the Newton updates (8.1) are, in view of (8.32), not computed too accurately. In fact, under this constraint the approximation of $\mathbf{R}(\bar{\mathbf{u}}^j)$, computed in $\mathbf{SOLVE}_{\rm N}$, is incidentally also a sufficiently accurate approximation to $\mathbf{G}(\bar{\mathbf{u}}^j)$; see Remark 8.1. To explain this, recall (8.19) and set

$$\mathbf{Y}^j := \mathbf{EV}\,[\eta_j - \hat{C}\epsilon_j^2, -\mathbf{R}(\bar{\mathbf{u}}^j)].$$

Then one has, by Remark 8.1,

$$\begin{aligned}\|\mathbf{G}(\bar{\mathbf{u}}^j) - \mathbf{Y}^j\|_{\ell_2(\mathcal{J})} &\le \|\mathbf{G}(\bar{\mathbf{u}}^j) + \mathbf{R}(\bar{\mathbf{u}}^j)\|_{\ell_2(\mathcal{J})} + \|\mathbf{R}(\bar{\mathbf{u}}^j) + \mathbf{Y}^j\|_{\ell_2(\mathcal{J})}\\ &\le \hat{C}\epsilon_j^2 + \eta_j - \hat{C}\epsilon_j^2 = \eta_j.\end{aligned}$$

Thus, within the accuracy range permitted by (8.32), the routine $\mathbf{RHS}_{\rm N}$ invoked by $\mathbf{SOLVE}_{\rm N}$ satisfies the accuracy requirements for the perturbed equation $D\mathbf{R}(\bar{\mathbf{u}}^j)\hat{\mathbf{w}} = \mathbf{G}(\bar{\mathbf{u}}^j)$, whose solution is, by definition of $\mathbf{G}(\bar{\mathbf{u}}^j)$, just $\hat{\mathbf{w}}^j = \mathbf{u} - \bar{\mathbf{u}}^j$. Now we infer from Remark 8.2, Theorem 6.1, and (8.35) that

$$\#\mathrm{supp}\,\bar{\mathbf{w}}^j \;\lesssim\; \eta_j^{-1/s}\|\mathbf{u} - \bar{\mathbf{u}}^j\|^{1/s}_{\mathcal{A}^s_{\rm tree}} \;\lesssim\; \eta_j^{-1/s}\|\mathbf{u}\|^{1/s}_{\mathcal{A}^s_{\rm tree}},$$

that the computational complexity has the same bound, and that $\|\bar{\mathbf{w}}^j\|_{\mathcal{A}^s_{\rm tree}} \lesssim \|\mathbf{u}\|_{\mathcal{A}^s_{\rm tree}}$. The same bounds hold for $\hat{\mathbf{u}}$. By definition of η_j, the computational complexity of step (ii) in **NEWTON** and, by the previous remarks, also of **TCOARSE** in step (iii) therefore remains bounded by $C\|\mathbf{u}\|^{1/s}\epsilon_{j+1}^{-1/s}$, which completes the proof. □

DISCRETE ABSORBING BOUNDARY CONDITIONS FOR SCHRÖDINGER-TYPE EQUATIONS. CONSTRUCTION AND ERROR ANALYSIS[*]

ISAÍAS ALONSO-MALLO[†] AND NURIA REGUERA[‡]

Abstract. When a partial differential equation in an unbounded domain is solved numerically, it is necessary to introduce artificial boundary conditions. In this paper, a general class of absorbing boundary conditions is constructed for one-dimensional Schrödinger-type equations discretized in space by finite differences. For this, rational approximations to the transparent boundary conditions are used. We study the simplest case in detail, obtaining an estimate for the full discrete error and showing that the discrete problem is weakly unstable. Moreover, we show numerically that the discrete problems associated to higher order absorbing boundary conditions are more unstable. Several numerical experiments confirm the results previously obtained.

Key words. Schrödinger equation, transparent boundary conditions, absorbing boundary conditions

1. Introduction.

Let us consider the initial value problem for a Schrödinger-type equation given by

$$\begin{cases} \partial_t u(x,t) = \dfrac{-i}{c}\left(\partial_{xx}u(x,t) + Vu(x,t)\right), \quad x \in \mathbf{R}, \quad t \geq 0, \\ u(x,0) = u_0(x), \quad x \in \mathbf{R}, \end{cases} \tag{1.1}$$

where c is a real constant. (In this paper, we suppose without loss of generality that $c > 0$; the case $c < 0$ is analogous.) Moreover, we suppose that the potential V is constant, and we assume that when $x \notin (x_l, x_r)$, the initial value $u_0(x)$ vanishes. We remark that, to obtain the transparent boundary conditions (TBCs) below, it suffices that V is constant when $x \notin (x_l, x_r)$. The study of (1.1) arises in a wide variety of applications. Two well-known cases are the one-dimensional time dependent Schrödinger equation for a particle with mass m [15],

$$i\hbar\partial_t\Psi = -\frac{\hbar^2}{2m}\partial_x^2\Psi + V\Psi,$$

and the Fresnel equation for the evolution of a paraxial electrical field E along the z-direction in a Cartesian coordinate system [12, 21],

$$2in_0k_0\partial_z E = \partial_x^2 E + (n^2 - n_0^2)k_0^2 E. \tag{1.2}$$

For practical purposes, the numerical approximation is computed only in a finite subdomain. Therefore, it is necessary to introduce suitable boundary conditions. For

example, if *transparent*, i.e., reflection-free, boundary conditions are used, then the solution in the finite subdomain is exactly the original solution. However, such conditions are nonlocal in time for Schrödinger-type equations [5, 23], and therefore their computational cost is high. An interesting idea is to consider fast evaluations of these TBCs [4, 14]. Another possibility is to use local *absorbing* boundary conditions (ABCs), allowing only small reflections. These ABCs have been studied in several contributions [2, 6, 7] for (1.1). We have proved in [2] that the spatial semidiscretizations of the problems obtained with these ABCs may be weakly ill-posed and that they are worse-posed for higher order ABCs.

As an alternative, in the literature we can find some works where TBCs or ABCs are obtained for a semidiscrete or fully discrete problem [9, 14, 22, 23]. These approaches are specific for the chosen discretization, but a better absorption is usually obtained.

In this paper, we are going to consider ABCs for the semidiscrete problem in space [1] (we will call them SABCs). This way, we obtain much more absorption than with the ABCs proposed in [2] with the same value of the spatial stepsize. Our idea is similar to the one proposed by Halpern in [9], where a systematic method to obtain ABCs for the one-dimensional wave equation semidiscretized in space with finite differences is explained. We have also considered finite differences for the discretization in space of (1.1), and we have obtained the TBCs for this problem. As they are nonlocal, we construct a class of local ABCs by using interpolatory rational approximations to the Fourier symbol of the TBCs. Our first result is that the discrete problems obtained with these SABCs are weakly unstable in a similar way to those with ABCs in [2], with an instability that can only be compensated when the absorption is high. It seems that this instability may probably appear if other ABCs for Schrödinger-type equations are obtained in a similar way.

In the literature, several implementations for ABCs similar to the one considered in this paper have been used for other equations. For instance, Higdon [11] proposes, in the case of the dispersive wave equation, to choose the interpolatory nodes for the ABCs in a manual and approximated way. On the other hand, Trefethen and Halpern [25], for the wave equation, and Halpern and Rauch [10], for diffusion equations, propose to use several fixed nodes so that the rational approximation is optimal in a certain norm. Nevertheless, none of these implementations are useful in this case for the Schrödinger equation due to the instability (see [3]).

In this paper, we study one of the simplest cases of SABCs in detail, and we make a complete analysis of the error of the full discrete problem with these SABCs. We remark that, to our best knowledge, the study of the full discrete error has not been done in other works of the literature on ABCs for Schrödinger-type equations. For example, this study of the error is an important difference from [2, 6, 7]. There are three different terms in this error. When the spatial discretization is refined, the first term, which depends only on the spatial discretization, decreases. However, the second and third term may grow. The growth of the third term, associated to the discretization in time, is due to the instability and can be compensated for by taking smaller stepsizes or by using integrators in time of higher order. Finally, the second term is associated to the capacity of absorption of the SABCs, and it may be a small value only when the SABC is suitable for the absorption of the solution of (1.1). When this term is not small enough, it is possible to use SABCs with a higher order of absorption. However, it is necessary to take into account that, in this way, we increase the instability, and the third term of the error may behave worst.

The paper is organized as follows. The TBCs for the semidiscrete problem are obtained in section 2. In section 3, we construct one of the simplest SABCs for this problem. In section 4, we prove that the discrete problem is unstable. The reflection coefficient for these SABCs is studied in section 5. In section 6, we obtain an expression for the full discrete error. In section 7, other SABCs are constructed and studied numerically, showing a similar behavior, although the discrete problems are more unstable. Finally, in section 8, we present several numerical experiments showing the results previously obtained.

2. TBCs for the problem semidiscretized in space. Let us express the initial value problem (1.1) in an abstract way. Let us consider the space $X = L^2(\mathbf{R})$ and the dense subspace $D(A) = H^2(\mathbf{R})$. Let us define the linear operator $A : D(A) \subset X \to X$ by

$$Au = -\frac{i}{c}(u_{xx} + Vu), \quad u \in D(A).$$

PROPOSITION 2.1. *The initial value problem* (1.1) *may be written in an abstract way as*

$$\begin{cases} u'(t) = Au(t), \\ u(0) = u_0 \in X, \end{cases} \tag{2.1}$$

and its generalized solution $u(t) := \exp(tA)u_0$ *satisfies*

$$\|u(t)\| = \|u_0\|, \quad t \geq 0. \tag{2.2}$$

Proof. Since iA is linear and self-adjoint, we deduce from Stone's theorem [16] that A is the infinitesimal generator of a C_0-group of unitary operators, $\exp(tA)$, on X. Therefore, (2.1) is well-posed, its generalized solution is $u(t) = \exp(tA)u_0$, and (2.2) is satisfied. □

Let us consider now the spatial discretization of the initial value problem (1.1). Let $(x^j)_{j\in\mathbf{Z}}$ be a uniform mesh of $\mathbf{R}$, with $x^j = x_l + jh$, and denote by $u^j(t)$ an approximation of $u(x^j, t)$. For the discretization of (1.1), we have used finite differences:

$$\begin{cases} \dfrac{d}{dt}u^j = \dfrac{-i}{c}\left(\dfrac{u^{j+1} - 2u^j + u^{j-1}}{h^2} + Vu^j\right), \quad j \in \mathbf{Z}, \quad t \geq 0, \\ u^j(0) = u_0(x^j), \quad j \in \mathbf{Z}. \end{cases} \tag{2.3}$$

Let us consider the space

$$X_h = l^2(\mathbf{Z}) = \left\{ u_h = (u^j)_{j\in\mathbf{Z}} \,:\, \|u_h\|_h = \left(h \sum_{j\in\mathbf{Z}} |u^j|^2 \right)^{1/2} < \infty \right\}.$$

The spaces X and X_h are related through the linear operators

$$\begin{array}{rcl} r_h : Z \subset X & \to & X_h, \\ u & \to & r_h u = (u(x^j))_{j\in\mathbf{Z}}, \end{array} \tag{2.4}$$

where Z is a subspace such that, for $u \in Z$, we have $r_h u \in X_h$. Notice that this condition is clearly satisfied when we consider the initial value u_0 in (1.1) because $u_0(x)$ vanishes for $x \notin (x_l, x_r)$.

The operator A is approximated by the operators

$$A_h : X_h \to X_h,$$
$$u_h = (u^j)_{j\in\mathbf{Z}} \to A_h u_h = \left(\frac{-i}{c}\left(\frac{u^{j+1} - 2u^j + u^{j-1}}{h^2} + Vu^j\right)\right)_{j\in\mathbf{Z}}.$$

Since for each h fixed, A_h is a linear and bounded operator and iA_h is self-adjoint, we obtain the following result with a proof similar to that of Proposition 2.1.

PROPOSITION 2.2. *Suppose that $u_0 \in X$ is such that $r_h u_0 \in X_h$. Then the initial value problem* (2.3) *may be written in an abstract way as*

$$\text{(2.5)} \qquad \begin{cases} u_h'(t) = A_h u_h(t), \\ u_h(0) = r_h u_0 \in X_h, \end{cases}$$

and its solution $u_h(t) := \exp(tA_h)u_h(0)$ satisfies

$$\|u_h(t)\|_h = \|r_h u_0\|_h, \quad t \geq 0.$$

Let us see now what the dispersion relation of this semidiscrete problem is. Let us consider a wave solution $(u^j(t))_{j\in\mathbf{Z}} = (\exp(i(\eta j - \omega(\eta)t)))_{j\in\mathbf{Z}}$ of the problem discretized in space. Then $\omega(\eta)$ should satisfy the dispersion relation

$$\text{(2.6)} \qquad \omega(\eta) = \frac{2}{ch^2}(\cos(\eta) - 1) + \frac{V}{c}.$$

In practice, we are not going to solve (2.3) for $j \in \mathbf{Z}$ but for $0 \leq j \leq N$ with $h = L/N$, where $L = x_r - x_l$, so $(x_l, x_r) = (x^0, x^N)$. Let us obtain the TBC for this problem.

Let us define the operators $A_{h,0} : X_{h,0} \to X_{h,0}$, where

$$X_{h,0} = l^2(N, \infty) = \left\{ u_h = (u^N, u^{N+1}, \dots) : \|u_h\|_h^2 = h \sum_{j=N}^{\infty} |u^j|_h^2 < \infty \right\},$$

by

$$(A_{h,0}u_h)^N = \frac{-i}{c}\left(\frac{-2u^N + u^{N+1}}{h^2} + Vu^N\right),$$
$$(A_{h,0}u_h)^{N-1+j} = \frac{-i}{c}\left(\frac{u^{N-2+j} - 2u^{N-1+j} + u^{N+j}}{h^2} + Vu^{N-1+j}\right), \quad j \geq 2.$$

PROPOSITION 2.3. *Let us consider the problem*

$$\text{(2.7)} \qquad \begin{cases} \dfrac{d}{dt}u_{h,b}(t) = A_{h,0}u_{h,b}(t) + \phi_h(t), \\ u_{h,b}(0) = 0, \end{cases}$$

where $\phi_h(t) = [-i\phi(t)/(ch^2), 0, 0, \dots]$ and $\phi(t) \in L^1_{\text{loc}}(0, \infty)$. Then the solution of (2.7) *is*

$$\text{(2.8)} \qquad u_{h,b}(t) = \int_0^t \exp((t-s)A_{h,0})\phi_h(s)ds.$$

Moreover, the Laplace transform $\tilde{u}_{h,b}(i\omega) = \int_0^\infty \exp(-i\omega t) u_{h,b}(t)dt$, *with* $\Im(\omega) < 0$, *satisfies*

$$r_+^j(V + c\omega, h)\tilde{u}_b^{N-1+j}(i\omega) = \tilde{\phi}(i\omega), \quad j \geq 1, \tag{2.9}$$

with

$$r_+(\eta, h) = 1 - \frac{h^2}{2}\eta + i\sqrt{\frac{h^2}{2}\eta\left(2 - \frac{h^2}{2}\eta\right)},$$

where $\sqrt{}$ *denotes the squared root with positive real part. Finally,* (2.9) *can be analytically extended to* $\mathbf{C} - \{\omega \in \mathbf{C} : \Im(\omega) > 0, \Re(\omega) = -V/c, \Re(\omega) = -V/c + 4/ch^2\}$ *and, when* $\omega \in \mathbf{R}$,

$$r^j(V + c\omega, h)\tilde{u}_b^{N-1+j}(i\omega) = \tilde{\phi}(i\omega), \quad j \geq 1, \tag{2.10}$$

where

$$r(\eta, h) = \begin{cases} 1 - \frac{h^2}{2}\eta + \sqrt{\frac{h^2}{2}\eta\left(\frac{h^2}{2}\eta - 2\right)} & \text{if} \quad \frac{h^2}{2}\eta < 0, \\ 1 - \frac{h^2}{2}\eta + i\sqrt{\frac{h^2}{2}\eta\left(2 - \frac{h^2}{2}\eta\right)} & \text{if} \quad 0 \leq \frac{h^2}{2}\eta \leq 2, \\ 1 - \frac{h^2}{2}\eta - \sqrt{\frac{h^2}{2}\eta\left(\frac{h^2}{2}\eta - 2\right)} & \text{if} \quad \frac{h^2}{2}\eta > 2. \end{cases} \tag{2.11}$$

Proof. Since $A_{h,0}$ is a linear and bounded operator, the solution of (2.7) is (2.8). Moreover, $iA_{h,0}$ is self-adjoint, and we deduce that $\exp(tA_{h,0})$ is a group of unitary operators. Therefore, the type of $\exp(tA_{h,0})$ is 0. Taking the Laplace transform of (2.8) with $\Im(\omega) < 0$, we have $\tilde{u}_{h,b}(i\omega) = (i\omega - A_{h,0})^{-1}\tilde{\phi}_h(i\omega)$, and then

$$(A_{h,0} - i\omega)\tilde{u}_{h,b}(i\omega) = -\tilde{\phi}_h(i\omega).$$

This way, we can obtain the values $(\tilde{u}_b^{N-1+j})_{j\geq 1}$ from the solution of the recurrence relation

$$\begin{cases} \frac{-i}{c}\left(\frac{\tilde{u}_b^{N-2+j} - 2\tilde{u}_b^{N-1+j} + \tilde{u}_b^{N+j}}{h^2} + (V + c\omega)\tilde{u}_b^{N-1+j}\right) = 0, \ j \geq 1, \\ \tilde{u}_b^{N-1} = \tilde{\phi}, \end{cases} \tag{2.12}$$

with $\lim_{j\to\infty} \tilde{u}^{N-1+j} = 0$. The characteristic polynomial of the previous equation is

$$r^2 - 2\left(1 - \frac{h^2}{2}\eta\right)r + 1,$$

with $\eta = V + c\omega$. The roots of this polynomial are

$$r_\pm(\eta, h) = 1 - \frac{h^2}{2}\eta \pm i\sqrt{\frac{h^2}{2}\eta\left(2 - \frac{h^2}{2}\eta\right)},$$

and then the solution of (2.12) is

$$\tilde{u}_b^{N-1+j} = A_1 r_-^j + A_2 r_+^j, \quad j \geq 0.$$

We have that $|r_+| > 1$ and $|r_-| < 1$, and then, since $\tilde{u}_b^{N-1+j}$ goes to 0 as j goes to ∞, $A_2 = 0$. Therefore, $\tilde{u}_b^{N-1+j} = A_1 r_-^j$ and since for $j = 0$, $A_1 = \tilde{u}_b^{N-1} = \tilde{\phi}$, we have that

$$\tilde{u}_b^{N-1+j} = \tilde{\phi} r_-^j,$$

which is equivalent to (2.9).

Now, $r_+^j(V + c\omega, h)$ has two singularities at $\omega = -V/c$ and $\omega = -V/c + 4/ch^2$, and we obtain that (2.10) holds with $r(\eta, h)$ given by (2.11). □

Next, we use that $u^j(t)$, $j \in \mathbf{Z}$, is a tempered distribution in order to obtain an expression of the TBC in terms of its Fourier transform. For this, let us denote by $u_h(0) = (u^j(0))_{j\in\mathbf{Z}} \in l^2(-\infty, \infty)$ the initial condition of problem (2.3), and let us consider the function given by the Fourier series

$$U(\eta) = \sum_{j=-\infty}^{\infty} u^j(0) \exp(-ij\eta) \in L^2(-\pi, \pi).$$

In fact, we have supposed that $u^j(0) = 0$ for $j \notin [0, N]$, and therefore, $U(\eta) = \sum_{j=0}^{N} u^j(0) \exp(-ij\eta)$ is an analytic function of $\eta \in [-\pi, \pi]$. From $U(\eta)$ we can obtain $(u^j(0))_{j\in\mathbf{Z}}$ by means of

$$u^j(0) = \frac{1}{2\pi} \int_{-\pi}^{\pi} U(\eta) \exp(ij\eta) d\eta.$$

Proposition 2.4. *Keeping the above notation, let $(u^j(t))_{j\in\mathbf{Z}}$ be the solution of* (2.3). *Then, in the sense of the distributions,*

$$u^j(t) = \frac{1}{2\pi} \int_{\omega_1}^{\omega_2} \hat{u}^j(\omega) \exp(i\omega t) d\omega, \tag{2.13}$$

where $\omega_1 = -V/c$, $\omega_2 = 4/(ch^2) - V/c$, and $\hat{u}^j(\omega)$ is the Fourier transform of the tempered distribution $u^j(t)$.

Proof. We consider the solution of (2.3) expressed as

$$u^j(t) = \frac{1}{2\pi} \int_{-\pi}^{\pi} U(\eta) \exp(i(j\eta - \omega(\eta)t)) d\eta, \quad j \in \mathbf{Z},$$

where $\omega(\eta)$ is given by (2.6). This way we have that $u^j(t) = (I_1 + I_2)/(2\pi)$, where

$$I_1 = \int_{-\pi}^{0} U(\eta) \exp(i(j\eta - \omega(\eta)t)) d\eta, \quad I_2 = \int_{0}^{\pi} U(\eta) \exp(i(j\eta - \omega(\eta)t)) d\eta.$$

Let us make the change of variable $\omega = -\omega(\eta)$ in I_1; that is,

$$\eta = \arccos\left(1 - \frac{h^2}{2}(V + c\omega)\right) \in (-\pi, 0). \tag{2.14}$$

Then we have that

$$I_1 = \int_{\omega_1}^{\omega_2} \exp(i\omega t)\hat{u}_1(\omega) d\omega,$$

where

$$\hat{u}_1(\omega) = U(\arccos(\varphi(\omega))) \exp(ij \arccos(\varphi(\omega))) \frac{ch^2}{2\sqrt{1-\varphi(\omega)^2}},$$

with $\varphi(\omega) = 1 - h^2(V + c\omega)/2$. Similarly, $I_2 = \int_{\omega_1}^{\omega_2} \exp(i\omega t)\hat{u}_2(\omega) d\omega$, where $\hat{u}_2$ has the same expression as $\hat{u}_1$ with $\arccos(\theta) \in (0, \pi)$. Therefore, we get (2.13) with $\hat{u}^j(\omega) = \hat{u}_1(\omega) + \hat{u}_2(\omega)$. That is, the extension by zero to $\mathbf{R}$ of $\hat{u}^j(\omega)$ is the Fourier transform of $u^j(t)$ (also extended by zero for $t < 0$) for $\omega \in \mathbf{R}$. □

THEOREM 2.5 (TBCs). *Let $u_h(t)$ be the solution of* (2.3)*, and assume that $u_0(x)$, the initial value of* (1.1)*, vanishes when $x \notin (x_l, x_r) = (x^0, x^N)$, and V is constant. Then, when $h^2(V + c\omega)/2 \notin (0, 2)$, $\hat{u}^j(\omega) = 0$, $j \in \mathbf{Z}$, and when $h^2(V + c\omega)/2 \in (0, 2)$, the TBCs are given by*

$$\hat{u}^{N-1}(\omega) = r(V + c\omega, h)\hat{u}^N(\omega), \tag{2.15}$$

$$\hat{u}^1(\omega) = r(V + c\omega, h)\hat{u}^0(\omega), \tag{2.16}$$

where

$$r(\eta, h) = 1 - \frac{h^2}{2}\eta + i\sqrt{\frac{h^2}{2}\eta\left(2 - \frac{h^2}{2}\eta\right)}. \tag{2.17}$$

Proof. Let us obtain the right TBC (2.15). (The proof for the left TBC is similar.) We take $\phi(t) = u^{N-1}(t)$ in Proposition 2.3. Then $(u^j(t))_{j \geq N}$, the restriction of the solution of (2.3), is the solution of (2.7). The result is a straightforward consequence of Proposition 2.4. □

3. The simplest ABC. As we have already mentioned, the TBCs (2.15) and (2.16) are nonlocal, and thus, for practical purposes, we are going to obtain local ABCs. For this, we will consider different approximations to $r(s, h)$ which, under the conditions of Proposition 2.4, is given by (2.17).

Similarly to what we did in [2] for the continuous problem, we are going to consider approximations

$$r(V + c\omega, h) \approx q(V + c\omega, h), \tag{3.1}$$

where $q(s, h)$ is a rational function in s that interpolates $r(s, h)$. We will use the notation SABC(j_1, j_2) for the ABCs obtained when we consider $q = p_1/p_2$, with p_1 and p_2 relatively prime polynomials in s with degrees j_1 and j_2, respectively. Following the notation in [2], ABC(j_1, j_2) denotes the ABCs obtained there for the continuous problem. Moreover, we also call order of absorption the number $j_1 + j_2 + 1$.

Let us study now which should be the choice for the interpolatory nodes. Let us consider a wave solution $(u^j(t))_{j\in\mathbf{Z}} = (\exp(i(\eta j - \omega(\eta)t)))_{j\in\mathbf{Z}}$, where $\omega(\eta)$ is given by the dispersion relation (2.6). We are considering the SABCs obtained by using the approximation (3.1), and therefore we should choose the interpolatory nodes in such a way that $r(V + c\omega, h) - q(V + c\omega, h)$ is small when $\omega = -\omega(\eta)$, that is, when

$V + c\omega = (2/h^2)(1-\cos\eta)$. Therefore, the approximation should be good when at least one of the interpolatory nodes is

$$s_1 = \frac{2}{h^2}(1-\cos\eta). \tag{3.2}$$

Moreover, when the velocity of the solution is a unique known value, it is reasonable to take all the interpolatory nodes as equal.

Let us examine in more detail SABC(1,0), one of the simplest choices for the approximation (3.1). Let us take $q(s,h) = \alpha_0 + \alpha_1 s$, the polynomial that interpolates (2.17) at the points s_1 and s_2, with $s_1, s_2 \in (0, 4/h^2)$, where

$$\alpha_0 = 1 + i\frac{s_2c_1 - s_1c_2}{s_2 - s_1}, \qquad \alpha_1 = \frac{-h^2}{2} - i\frac{c_1 - c_2}{s_2 - s_1},$$

with

$$c_j = h\sqrt{s_j\left(1 - \frac{h^2}{4}s_j\right)}, \quad j = 1, 2.$$

(We omit the dependence on s_1, s_2, and h of the coefficients.) Since $h^2 \leq 4/s_j$ for $j = 1, 2$, $c_j \in \mathbf{R}$. Notice that if we take the limit when s_1 and s_2 go to a unique positive number b, the approximation we are considering is the Taylor expansion of first order of $r(s,h)$ at $s = b$.

Considering this approximation in (2.15) and taking the inverse Fourier transform, we obtain

$$\frac{d}{dt}v^N(t) = \widetilde{\alpha}v^N(t) + \widetilde{\beta}v^{N-1}(t),$$

where

$$\widetilde{\alpha} = \frac{\left(1 - \dfrac{h^2V}{2}\right)(s_1 - s_2) + ic_1(V - s_2) - ic_2(V - s_1)}{c(c_2 - c_1) - \dfrac{ich^2}{2}(s_1 - s_2)},$$

$$\widetilde{\beta} = \frac{s_2 - s_1}{c(c_2 - c_1) - \dfrac{ich^2}{2}(s_1 - s_2)}.$$

Similarly for the left boundary, we have

$$\frac{d}{dt}v^0(t) = \widetilde{\alpha}v^0(t) + \widetilde{\beta}v^1(t).$$

This way we have obtained a first order ordinary differential system

$$v_h'(t) = M(h)v_h(t), \tag{3.3}$$

where $v_h(t) = [v^0(t), v^1(t), \ldots, v^{N-1}(t), v^N(t)]^T$ and

$$M(h) = \begin{bmatrix} \widetilde{\alpha} & \widetilde{\beta} & 0 & 0 & \cdots & 0 \\ \widetilde{m}_1 & \widetilde{m}_2 & \widetilde{m}_1 & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & \widetilde{m}_1 & \widetilde{m}_2 & \widetilde{m}_1 \\ 0 & \cdots & 0 & 0 & \widetilde{\beta} & \widetilde{\alpha} \end{bmatrix} \in \mathcal{M}_{(N+1)\times(N+1)}, \tag{3.4}$$

with $\widetilde{m}_1 = -i/ch^2$ and $\widetilde{m}_2 = i(2 - Vh^2)/ch^2$. We have omitted in the notation the dependence on h and on the interpolatory nodes of the elements of $M(h)$.

4. The full discrete problem with SABC(1,0). We are going to study the system (3.3) obtained when SABC(1,0) is considered. In order to add these SABCs, recall that we suppose that the initial value has a support included in the finite interval $(x_l, x_r) = (x^0, x^N)$, where $N \in \mathbf{N}$. Therefore, we take the norm

$$\|(u^j)_{j=0}^N\|_{[x^0,x^N],h} = \left(h \sum_{j=0}^{N} |u^j|^2 \right)^{1/2}. \tag{4.1}$$

In section 2, we have considered the abstract problem (2.1), which is approximated by (2.5). We take $Y_h = \mathbf{C}^{N+1}$ with the norm (4.1) and denote by P_h the projection operator

$$\begin{array}{rccl} P_h : & X_h & \rightarrow & Y_h, \\ & u_h = (u^j)_{j\in\mathbf{Z}} & \rightarrow & P_h u_h = (u^j)_{0\le j\le N}. \end{array} \tag{4.2}$$

Notice that

$$\|P_h u_h\|_{[x^0,x^N],h} \le \|u_h\|_h, \quad u_h \in X_h.$$

Then we use SABC(1,0) and approximate the solution of (2.5) through the solution of the ordinary differential system

$$\begin{cases} v_h'(t) = M(h)v_h(t), \\ v_h(0) = P_h r_h u_0 \in Y_h, \end{cases} \tag{4.3}$$

where we have used the notation of section 3 for the matrix of coefficients $M(h)$. The solution of (4.3) is

$$v_h(t) = \exp(tM(h))P_h r_h u_0, \quad 0 \le t \le T.$$

The last step is the time discretization of (4.3). Since (4.3) is stiff and has very large eigenvalues close to the imaginary axis, it is necessary to consider an A-stable time integration method. In this paper, we use A-stable implicit Runge–Kutta methods (cf. [2]).

Let us take a time stepsize $k > 0$, and let $t_n = kn$ for $n > 0$. We consider a Runge–Kutta method of order p whose stability function is given by $s(z)$. Then the integration in time of (4.3) is given by

$$\begin{cases} v_{h,n+1} = s(kM(h))v_{h,n}, \\ \quad v_{h,0} = P_h r_h u_0 \in Y_h, \end{cases} \tag{4.4}$$

which provides the numerical approximations

$$v_{h,n} = s(kM(h))v_{h,n-1} = s^n(kM(h))P_h r_h u_0, \quad 0 \le t_n \le T,$$

to the values $v_h(t_n)$. Now, we are interested in the boundedness of $\|s^n(kM(h))\|_{[x_0,x_N],h}$ for $n \in \mathbb{N}$, that is, in the stability analysis of this time approximation.

We denote by $\mu_2(M(h))$ the logarithmic norm of $M(h)$ (see [8]). From a well-known result (see, e.g., [8, Theorem IV.11.2]), if $\mu_2(M(h)) \leq 0$ and the Runge–Kutta method is A-stable, then

$$\|s^n(kM(h))\|_{[x_0,x_N],h} \leq 1 \quad \text{for } n \in \mathbb{N}.$$

However, this result of stability is not applicable. A straightforward calculation shows that $\mu_2(M(h)) = 1/(2ch^2) + O(h^{-1})$, and we cannot reject a possible exponential instability of the discrete L^2 norm of the solution when h goes to 0. This catastrophic behavior is not observed in the numerical experiments of section 8 because $M(h)$ is nonnormal and the estimate provided by the logarithmic norm is not suitable.

If $M(h)$ has a complete eigensystem, then we can study the stability applying the scalar case (see, e.g., [13]). For this, a necessary condition is given by the fact that the matrices $M(h)$ are stable, i.e., its eigenvalues have negative real part. Of course, this fact does not imply the stability of (4.4), but it will allow us to obtain a more realistic estimate. This result is similar to the situation studied in [2], where we proved that an analogous problem to (3.3) is only weakly unstable. The following theorem is a straightforward consequence of Theorem 4.3 of [2] (see also [17]).

THEOREM 4.1. *Let us consider the matrix*

(4.5)
$$M_N(h) = \begin{bmatrix} \alpha(h) & \beta(h) & 0 & 0 & \cdots & 0 \\ -i & i(2-\delta(h)) & -i & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \ddots & \vdots \\ 0 & \cdots & 0 & -i & i(2-\delta(h)) & -i \\ 0 & \cdots & 0 & 0 & \beta(h) & \alpha(h) \end{bmatrix} \in \mathcal{M}_{(N+1)\times(N+1)},$$

whose coefficients satisfy

$$\alpha(h) = h\alpha_0 + h^2\alpha_1(h), \quad \textit{where} \quad \alpha_0 < 0, \quad \alpha_1(0) = ia_1, \tag{4.6}$$

$$\beta(h) = -h\alpha_0 + h^2\beta_1(h), \quad \textit{where} \quad \beta_1(0) = ib_1, \tag{4.7}$$

$$\delta(h) = h^2\delta_1(h) \in \mathbf{R}, \quad \textit{where} \quad \delta_1(0) = d_1, \tag{4.8}$$

$$0 > a_1 + b_1 + d_1, \tag{4.9}$$

$$0 > \alpha_0(1-N)(a_1+b_1+d_1) + 2\Re(\alpha_1'(0) + \beta_1'(0)). \tag{4.10}$$

We shall use the notation $\alpha_r(h) = \Re(\alpha(h))$, $\alpha_i(h) = \Im(\alpha(h))$, $\beta_r(h) = \Re(\beta(h)) \neq 0$, $\beta_i(h) = \Im(\beta(h)) \neq 0$, *where these coefficients satisfy one of the following properties for* $0 < h < h_0$*:*

$$|\beta(h)| \leq |\alpha_r(h)| \quad \textit{or} \tag{4.11}$$

$$|\beta(h)| > |\alpha_r(h)| \quad \textit{and} \tag{4.12}$$

$$\sqrt{|\beta(h)|^2 - \alpha_r(h)^2} < \delta(h) + \alpha_i(h) < 4 - \sqrt{|\beta(h)|^2 - \alpha_r^2(h)}. \tag{4.13}$$

We will suppose that for $0 < h < h_0$,

$$\delta(h) + \alpha_i(h) < \frac{\alpha_r(h)\beta_i(h)}{\beta_r(h)}, \tag{4.14}$$

$$(\delta(h) + \alpha_i(h))(2 + \beta_i(h)) < -\alpha_r(h)\beta_r(h) - 2\beta_i(h), \tag{4.15}$$

where $\gamma(h) = 2 - \delta(h) - \alpha_i(h)$.

Then, for every $h \in (0, h_0)$, all the eigenvalues of $M_N(h)$ have negative real part.

Making use of Theorem 4.1, we are going to prove the stability of the matrix $M(h)$, given by (3.4).

Theorem 4.2. *We suppose that $s_1 = s_2 = b > 0$ is fixed. Let $h_0 = \sqrt{2/b}$. Then all the eigenvalues of the matrix* (3.4) *have negative real part for $0 < h < h_0$.*

Proof. Notice that since $c > 0$, it suffices to prove that all the eigenvalues of $ch^2M(h)$ have negative real part. The matrix $ch^2M(h)$ is $M_N(h)$ with

$$\alpha(h) = -2\sqrt{1-a^2} + i(b-V)h^2, \quad \beta(h) = 2\sqrt{1-a^2}(a - i\sqrt{1-a^2}),$$

where $a = 1 - h^2b/2$. Then, hypotheses (4.6)–(4.8) are satisfied for

$$\alpha_0 = -2\sqrt{b} < 0, \quad a_1 = b - V \in \mathbf{R}, \quad b_1 = -2b \in \mathbf{R}, \quad d_1 = V.$$

We also have

$$\alpha_1'(0) = \frac{b^{3/2}}{4}, \quad \beta_1'(0) = \frac{-5b^{3/2}}{4}.$$

Therefore, hypotheses (4.9) and (4.10) are satisfied, since

$$a_1 + b_1 + d_1 = -b < 0,$$

$$\alpha_0(1-N)(a_1+b_1+d_1) + 2\Re(\alpha_1'(0) + \beta_1'(0)) = -2Nb^{3/2} < 0.$$

On the other hand, since $h < 2/\sqrt{b}$,

$$\alpha_r(h) = -2\sqrt{1-a(h)^2}, \quad \alpha_i(h) = (b-V)h^2,$$

$$\beta_r(h) = 2a(h)\sqrt{1-a(h)^2}, \quad \beta_i(h) = -2(1-a(h)^2).$$

We have then $|\beta| = |\alpha_r|$, so (4.11) is satisfied.

Because we are assuming that $h < \sqrt{2/b}$,

$$\delta(h) + \alpha_i(h) - \frac{\alpha_r(h)\beta_i(h)}{\beta_r(h)} = \frac{2bh^2}{-2+bh^2} < 0,$$

$$(\delta(h) + \alpha_i(h))(2 + \beta_i(h)) + \alpha_r(h)\beta_r(h) + 2\beta_i(h) = 2bh^2(-3 + bh^2) < 0,$$

so hypotheses (4.14) and (4.15) of Theorem 4.1 are satisfied.

Therefore, from Theorem 4.1 we can conclude that for $h \in (0, h_0)$ (with $h_0 = \sqrt{2/b}$), all the eigenvalues of $M(h)$ have negative real part. □

In a similar way, we have obtained the following more general result (see [17, 20]).

Theorem 4.3. *Let us consider the semidiscrete problem obtained when $SABC$(1,0) is used with $s_1 \neq s_2$. Let $h_0 = 2/\sqrt{s_1 + s_2}$. Then all the eigenvalues of matrix* (3.4) *have negative real part for $0 < h < h_0$.*

We can conclude the stability from Theorem 4.2 (or Theorem 4.3) when $M(h)$ has a complete eigensystem. Nevertheless, as $M(h)$ is nonnormal, the bound of the powers of $M(h)$ depends on h in the general case, as is proved in the following proposition.

Proposition 4.4. *Let $L(h)$ be an invertible matrix such that $M(h)$=$L(h)J(h)L(h)^{-1}$, where $J(h)$ is in Jordan form. Then we have the stability bound*

$$\|s^n(kM(h))\|_{[x_0,x_N],h} \leq \kappa_h \, \|s^n(kJ(h))\|_{[x^0,x^N],h} \tag{4.16}$$

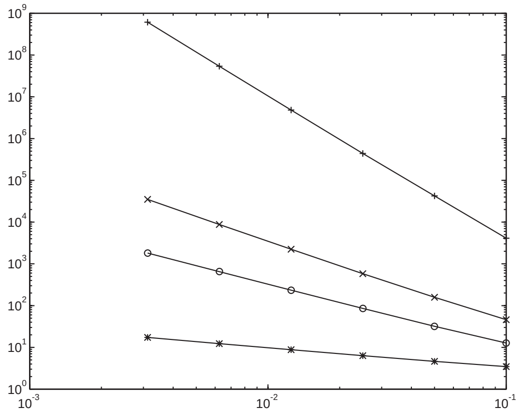

FIG. 1. *Condition number κ_h as a function of h. $*$ SABC(1,0), $\circ$ SABC(1,1), $\times$ SABC(2,1), $+$ SABC(3,2).*

for $n \in \mathbb{N}$, where κ_h is the condition number of $L(h)$. Moreover, if $M(h)$ has a complete eigensystem for $h > 0$, we have

$$\|s^n(kM(h))\|_{[x_0,x_N],h} \le \kappa_h. \tag{4.17}$$

Proof. First,

$$\begin{aligned}\|s^n(kM(h))\|_{[x^0,x^N],h} &= \left\|L(h)s^{n-j}(kJ(h))L(h)^{-1}\right\|_{[x^0,x^N],h} \\ &\le \|L(h)\|_{[x^0,x^N],h} \|s^n(kJ(h))\|_{[x^0,x^N],h} \left\|L(h)^{-1}\right\|_{[x^0,x^N],h} \\ &= \kappa_h \|s^n(kJ(h))\|_{[x^0,x^N],h},\end{aligned}$$

and we have obtained (4.16).

If $M(h)$ has a complete eigensystem, that is, $J(h)$ is the diagonal matrix of eigenvalues, then by Theorems 4.2 and 4.3, we obtain (4.17) from (4.16). □

With this stability result, we will prove in section 6 a result of convergence. Now, we are interested in the study of the behavior of the condition number κ_h. We have checked this numerically (see Figure 1), obtaining that $\kappa_h = O(h^{-1/2})$, similarly to the case of ABC(1,0) in [2]. Therefore, the possible instability of SABC(1,0) is mild, although the absorption for this SABC is not very high.

To study this weak instability, it is also possible to make an analysis of the ε-pseudoeigenvalues of $M(h)$ [24]. The ε-pseudospectrum may be calculated using random perturbations of the matrix $M(h)$. We have computed, for an example of section 8, the spectrum of $M(h) + E$ (with $h = 1/80$), where E is a random matrix of norm ϵ. In the second column of Table 1, we can see the maximum of the real part of the eigenvalues computed this way. We observe that the nonnormality of $M(h)$ is mild for SABC(1,0) because this maximum varies slowly with ϵ.

Finally, we remark that the instability arising when SABC(1,0) are used is very weak, and we have not been able to obtain numerical evidence. However, the instability may be clearly observed when other SABCs with higher orders of absorption are used because the discrete problems are more stable (see sections 7 and 8).

TABLE 1
Maximum of the real part of the ϵ-pseudoeigenvalues.

ϵ	SABC(1,0)	SABC(1,1)	SABC(2,1)	SABC(3,2)

1.0d−12	−5.6126d−4	−8.7427d−4	−1.1225d−3	−3.8832d−3

5. Reflection coefficient.

As we have remarked in section 3, the absorption of SABCs depends strongly on the choice of the interpolatory nodes. There exists a suitable node to absorb the component of the solution traveling with a given group velocity. Therefore, the absorption depends on the initial data, as is well displayed in the numerical experiments of section 8. In this section we are going to measure the absorption of SABC(1,0) by means of the reflection coefficient in a similar way to the study in [9]. The analytical results obtained confirm the previous remark.

We will consider only the case $s_1 = s_2 = b \in (0, 4/h^2)$, and we will use the notation $x = h^2(V + c\omega)/2$, $x^* = h^2 b/2$, so that to obtain SABC(1,0) we have considered the approximation (3.1) with

$$q(V + c\omega, h) = \alpha_0 + \alpha_1(x - x^*), \tag{5.1}$$

where

$$\alpha_0 = 1 - x^* + i\sqrt{1 - (1 - x^*)^2}, \quad \alpha_1 = -1 + \frac{i(1 - x^*)}{\sqrt{1 - (1 - x^*)^2}}.$$

5.1. One boundary.

First, we will study the problem with just one boundary at x^N. This case is used later to analyze the more practical case of two artificial boundary conditions. We remark that this case can also be used if the original problem is semi-infinite with a unique known boundary, for example, Dirichlet or Neumann.

Recall that $u_h(t) = (u^j(t))_{j\in\mathbf{Z}}$ is the solution of the semidiscretized problem in space (2.3) with an initial condition whose support is included in (x^J, x^L) with $L < N$. This solution satisfies the TBC (2.15). In Fourier variables,

$$\hat{u}^{j+1}(\omega) - 2\left(1 - \frac{h^2}{2}(V + c\omega)\right)\hat{u}^j(\omega) + \hat{u}^{j-1}(\omega) = 0, \quad j \in \mathbf{Z},$$

$$r(V + c\omega, h)\hat{u}^N(\omega) - \hat{u}^{N-1}(\omega) = 0.$$

On the other hand, let $v_h(t) = (v^j(t))_{j\le N}$ be the solution of the semidiscretized problem, defined for $j \le N$, with the same initial condition as for the previous problem and the SABC at x^N obtained when considering the approximation (3.1). Its Fourier transform $(\hat{v}^j(\omega))_{j\le N}$ satisfies

$$\hat{v}^{j+1}(\omega) - 2\left(1 - \frac{h^2}{2}(V + c\omega)\right)\hat{v}^j(\omega) + \hat{v}^{j-1}(\omega) = 0, \quad j \le N,$$

$$q(V + c\omega, h)\hat{v}^N(\omega) - \hat{v}^{N-1}(\omega) = 0.$$

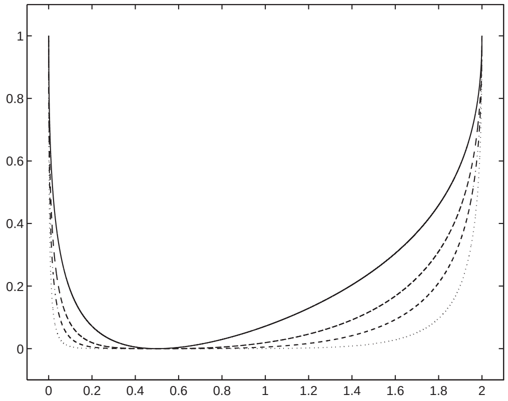

FIG. 2. *Reflection coefficient* $|R|$ *for one boundary as a function of* $x = h^2(V + c\omega)/2$ *when* $x^* = 0.5$. – *SABC*(1,0), – – *SABC*(1,1), – · *SABC*(2,1), · · · *SABC*(3,2).

Finally, let us define $w^j = v^j - u^j$, $j \leq N$, the reflected part of the solution caused by the ABC. Its Laplace transform $(\tilde{w}^j)_{j\leq N}$ satisfies

$$\hat{w}^{j+1}(\omega) - 2\left(1 - \frac{h^2}{2}(V + c\omega)\right)\hat{w}^j(\omega) + \hat{w}^{j-1}(\omega) = 0, \quad j \leq N,$$

$$q(V + c\omega, h)\hat{w}^N(\omega) - \hat{w}^{N-1}(\omega) + q(V + c\omega, h)\hat{u}^N(\omega) - \hat{u}^{N-1}(\omega) = 0.$$

For each ω and h, the reflection coefficient is defined as

$$\hat{w}^N(\omega) = R(V + c\omega, h)\hat{u}^N(\omega). \tag{5.2}$$

Note that it is enough to consider $R(V + c\omega, h)$ for $0 \leq h^2(V + c\omega)/2 \leq 2$ because of the result in Proposition 2.4.

The ideal situation is $R \equiv 0$, which leads to $\hat{w}^N(\omega) \equiv 0$. That is, there is no reflection, and the boundary condition is transparent. However, $R \not\equiv 0$ when we use ABCs, and the size of R measures the capacity of absorption of the ABCs. In Figure 2, we can observe the reflection coefficient when $x^* = 0.5$.

Since the initial value vanishes for $x = x^j$, $j > L$, and by using the TBCs (2.15) and (2.16), we have

$$\hat{u}^j(\omega) = r^{L-j}(V + c\omega, h)\hat{u}^L(\omega) \quad \text{for} \quad j > L. \tag{5.3}$$

Similarly, since the reflection vanishes for $x = x^j$, $j < N$,

$$\hat{w}^j(\omega) = r^{j-N}(V + c\omega, h)\hat{w}^N(\omega) \quad \text{for} \quad j < N. \tag{5.4}$$

Taking into account these relations,

$$(q - r^{-1})\hat{w}^N = q\hat{w}^N - \hat{w}^{N-1} = -q\hat{u}^N + \hat{u}^{N-1} = (r-q)\hat{u}^N,$$

where we have omitted the dependence on ω and h. Therefore, (5.2) is satisfied with

$$R(V + c\omega, h) = \frac{r(V + c\omega, h) - q(V + c\omega, h)}{q(V + c\omega, h) - r^{-1}(V + c\omega, h)}. \tag{5.5}$$

THEOREM 5.1. *Keeping the above notation, let $R(V + c\omega, h)$ be the reflection coefficient when SABC(1,0) with $s_1 = s_2 = b \in (0, 4/h^2)$ is considered. Then, we have*

$$|R(V + c\omega, h)| \leq \min\left(1, \frac{(x - x^*)^2}{\min((x^*)^2, (2 - x^*)^2)}\right)$$

for $0 \leq x \leq 2$, where $x = h^2(V + c\omega)/2$ and $x^* = h^2 b/2 \in (0, 2)$.

Proof. In this case q is given by (5.1). We will use the notation $\alpha_j^r = \mathrm{Re}(\alpha_j)$, $\alpha_j^i = \mathrm{Im}(\alpha_j)$. Taking into account (2.17),

$$|R| = \frac{|\alpha_0^i + \alpha_1^i(x - x^*) - \sqrt{x(2-x)}|}{|\alpha_0^i + \alpha_1^i(x - x^*) + \sqrt{x(2-x)}|} = \frac{\left|\frac{x(1-x^*)+x^*}{\sqrt{x^*(2-x^*)}} - \sqrt{x(2-x)}\right|}{\left|\frac{x(1-x^*)+x^*}{\sqrt{x^*(2-x^*)}} + \sqrt{x(2-x)}\right|}.$$

With a straightforward calculus, we have

$$|R| = \frac{\frac{x(1-x^*)+x^*}{\sqrt{x^*(2-x^*)}} - \sqrt{x(2-x)}}{\frac{x(1-x^*)+x^*}{\sqrt{x^*(2-x^*)}} + \sqrt{x(2-x)}} \leq 1$$

for $x \in [0, 2]$, having the identity only for $x = 0, 2$. Let us see now

$$|R(V + c\omega, h)| \leq (x - x^*)^2 / \min((x^*)^2, (2 - x^*)^2).$$

This bound is a consequence of

$$|R(V + c\omega, h)| \leq (x - x^*)^2/(x^*)^2$$

for $0 < x^* \leq 1$ and

$$|R(V + c\omega, h)| \leq (x - x^*)^2/(2 - x^*)^2$$

for $1 < x^* < 2$. Both estimates are easily obtained with a straightforward calculation. □

5.2. Two boundaries. In practice we do not have only one boundary as considered previously but two, and then, the reflected part of the solution caused by the SABCs will have two components, one traveling to the left and another one to the right.

As we prove below, the reflection coefficient has in this case two singularities, when the spatial parameter goes to 0, at the values $x = 0$ and $x = 2$. (A similar situation arises in the case of the wave equation [9].) These values correspond to the values of the Fourier components of the solution with group velocity very small or very high because of the aliasing brought about by the spatial discretization.

In a practical situation, the components of the solution with a very small velocity take a long time to arrive at the boundary and, on the other hand, the components with a very large velocity are usually small. As a consequence, in many practical cases these singularities are not important. However, when we obtain an estimate of the error in section 6 using the bound of the reflection coefficient, these singularities bring about a poor estimate of the part of error depending on the absorption.

Let us consider $u_h(t) = (u^j(t))_{j\in\mathbf{Z}}$ as in the previous section. It satisfies both TBCs

$$r(V + c\omega, h)\tilde{u}^0(i\omega) - \tilde{u}^1(i\omega) = 0,$$

$$r(V + c\omega, h)\tilde{u}^N(i\omega) - \tilde{u}^{N-1}(i\omega) = 0.$$

Let $v_h(t) = (v^j(t))_{0\le j\le N}$ be the solution of the semidiscretized problem with the same initial condition and SABCs in both boundaries; then

$$\hat{v}^{j+1}(\omega) - 2\left(1 - \frac{h^2}{2}(V + c\omega)\right)\hat{v}^j(\omega) + \hat{v}^{j-1}(i\omega) = 0, \quad 0 \le j \le N,$$

$$q(V + c\omega, h)\hat{v}^0(\omega) - \hat{v}^1(\omega) = 0,$$

$$q(V + c\omega, h)\hat{v}^N(\omega) - \hat{v}^{N-1}(\omega) = 0,$$

where we have omitted the dependence on ω and h of q and v^j. As in the previous section, $w^j(t) = v^j(t) - u^j(t)$, $0 \le j \le N$, will denote the reflected part of the solution caused by both SABCs. Therefore, omitting the dependence on ω and h,

$$\hat{w}^{j+1} - 2\left(1 - \frac{h^2}{2}(V + c\omega)\right)\hat{w}^j + \hat{w}^{j-1} = 0, \quad 0 \le j \le N, \tag{5.6}$$

$$q\hat{w}^0 - \hat{w}^1 = -q\hat{u}^0 + \hat{u}^1, \tag{5.7}$$

$$q\hat{w}^N - \hat{w}^{N-1} = -q\hat{u}^N + \hat{u}^{N-1}. \tag{5.8}$$

Solving this difference equation, we have

$$\hat{w}^j = A_1 r^{-j} + A_2 r^{j-N} \quad \text{for} \quad 0 \le j \le N, \tag{5.9}$$

and due to the TBC (2.15) and (2.16),

$$\hat{u}^j = r^{L-j}\hat{u}^L \quad \text{for} \quad j > L, \quad \text{and} \quad \hat{u}^j = r^{j-J}\hat{u}^J \quad \text{for} \quad j < J. \tag{5.10}$$

From (5.9) for $j = 0, N$, we get

$$\hat{w}^0 = A_1 + A_2 r^{-N}, \quad \hat{w}^N = A_1 r^{-N} + A_2,$$

and solving this system for A_1 and A_2, we obtain

$$A_1 = \beta\hat{w}^0 + \gamma\hat{w}^N, \quad A_2 = \gamma\hat{w}^0 + \beta\hat{w}^N, \tag{5.11}$$

with $\beta = 1/(1 - r^{-2N})$, $\gamma = -r^{-N}/(1 - r^{-2N})$. On the other hand, taking into account (5.9) and (5.10) in relations (5.7) and (5.8), we get

$$q\hat{w}^0 - A_1 r^{-1} - A_2 r^{1-N} = (r - q)\hat{u}^0,$$

$$q\hat{w}^N - A_1 r^{1-N} - A_2 r^{-1} = (r - q)\hat{u}^N.$$

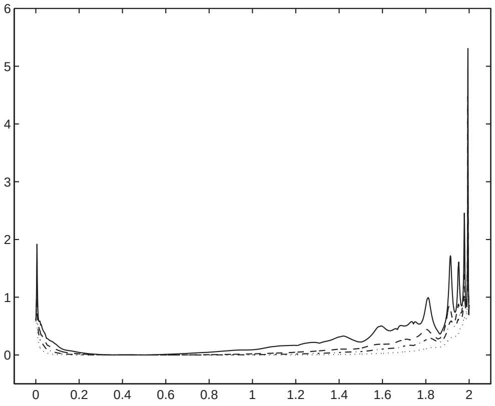

FIG. 3. *Reflection coefficients* $\max(|K_1(12)|, |K_2(12)|)$ *for two boundaries as a function of* $x = h^2(V + c\omega)/2$ *when* $x^* = 0.5$, $N = 30$, $L = 20$, $J = 10$. – *SABC*(1,0), – – *SABC*(1,1), – · *SABC*(2,1), · · · *SABC*(3,2).

Taking into account (5.11), we obtain expressions for $\hat{w}^0$, $\hat{w}^N$ in terms of $\hat{u}^0$, $\hat{u}^N$, and finally, from (5.9), we have

$$\hat{w}^j = K_1(j)\hat{u}^{L+j} + K_2(j)\hat{u}^{J-j},$$

where the reflection coefficients

$$K_1(j) = \frac{-r^L R(R + r^{2j})}{R^2 - r^{2N}}, \quad K_2(j) = \frac{-r^{-J} R(Rr^{2j} + r^{2N})}{R^2 - r^{2N}} \tag{5.12}$$

also depend on $V + c\omega$ and h, but this dependence is not displayed in the notation.

In Figure 3 we can observe $\max(|K_1(12)|, |K_2(12)|)$ when $N = 30$, $L = 20$, $J = 10$, and $x^* = 0.5$. As we have previously mentioned, we can see two possible singularities at $x = 0$ and $x = 2$. Let us analyze $|K_1(j)|$ and $|K_2(j)|$ in more detail.

THEOREM 5.2. *Let us consider* $x^* \in (0, 2)$ *and let* $K_1(j)$, $K_2(j)$ *be the reflection coefficients given by* (5.12) *when using SABC*(1,0) *with* $s_1 = s_2 = b \in (0, 4/h^2)$. *Then, for* $x = h^2(V + c\omega)/2 \in (0, 2)$ *and* $j = 0, \ldots N$,

$$\max(|K_1(j)|, |K_2(j)|) \le (N + 1)\frac{(x - x^*)^2}{\min((x^*)^2, (2 - x^*)^2)}. \tag{5.13}$$

Proof. We will suppose that $x^* \in (0, 1)$. (The proof for $1 \le x^* < 2$ is similar.) First, let us study $|K_1(j)|$. Recall that $R = -q_2(x, x^*)/q_1(x, x^*) < 0$, where

$$q_{1,2}(x, x^*) = x(1 - x^*) + x^* \pm \sqrt{x(2 - x)x^*(2 - x^*)}. \tag{5.14}$$

Taking into account that for $x \in (0, 2)$, $|r| = 1$ and $|R| < 1$, we get

$$|K_1(j)| = \frac{|R||R + r^{2j}|}{|R^2 - r^{2N}|} \le \frac{|R||R + r^{2j}|}{1 - |R|^2}.$$

Using now again that $|r| = 1$ and that R is real and negative,

$$|R + r^{2j}|^2 = (R + \Re(r^{2j}))^2 + \Im(r^{2j})^2 = (1 - |R|)^2 + 2R(\Re(r^{2j}) - 1).$$

Thus we have that

$$|K_1(j)|^2 \leq \frac{|R|^2}{(1+|R|)^2}\left(1+\frac{2|R|(1-\Re(r^{2j}))}{(1-|R|)^2}\right),$$

and using that $|R|<1$,

$$|K_1(j)|^2 \leq |R|^2\left(1+\frac{f(x)q_1(x,x^*)^2}{2x^*(2-x^*)}\right),$$

where $q_1(x,x^*)$ is given by (5.14) and

$$f(x)=\frac{1-\Re(r^{2j})}{x(2-x)}.$$

Finally, taking into account Lemmas 5.3 and 5.4 below, we get

$$|K_1(j)| \leq |R|\left(1+\frac{j^2 q_1(x,x^*)^2}{x^*(2-x^*)}\right)^{1/2} \leq (j+1)\frac{(x-x^*)^2}{(x^*)^2}.$$

Similarly, for $K_2(j)$ we obtain

$$|K_2(j)| \leq (N-j+1)\frac{(x-x^*)^2}{(x^*)^2},$$

and we deduce (5.13). □

In the proof of Theorem 5.2, we have used the following technical lemmas, whose proof can be found in [17].

Lemma 5.3. *Let*

$$f(x)=\frac{1-\Re(r^{2j})}{x(2-x)},\quad x\in(0,2),\quad j\in\mathbf{N}.$$

Then $f(x)\leq 2j^2$.

Lemma 5.4. *Let* $x^*\in(0,1)$ *and* R *the reflection coefficient for only one boundary* (5.5) *when considering SABC*(1,0) *with* $s_1=s_2=b$. *Then*

$$|R|^2\left(1+\frac{j^2 q_1(x,x^*)^2}{x^*(2-x^*)}\right) \leq (j+1)^2\frac{(x-x^*)^4}{(x^*)^4}, \tag{5.15}$$

where $q_1(x,x^*)$ *is given by* (5.14).

6. Error analysis.

In this section, our goal is to obtain an expression for the error of the full discretization with SABC(1,0). This error is given in the following definition.

Definition 6.1. *The full discrete global error is given by*

$$e_{h,n}=P_h r_h u(t_n)-v_{h,n},\quad 0\leq t_n\leq T, \tag{6.1}$$

where $v_{h,n}$ *is the solution of* (4.4), $u(t)$ *is the solution of* (2.1), r_h *is defined in* (2.4), *and* P_h *is defined in* (4.2).

The full discrete problem with SABC(1,0) has been obtained with three consecutive steps associated with three kinds of error. First, we discretize (2.1) in space obtaining the problem (2.5). The error made in this step is given by the spatial error

$$e^1_{h,n}=P_h r_h u(t_n)-P_h u_h(t_n),\quad 0\leq t_n\leq T, \tag{6.2}$$

where $u_h(t)$ is the solution of (2.5).

In the second step, we add the SABC(1,0) and we obtain (4.3). The error is now given by the error of absorption

$$e^2_{h,n} = P_h u_h(t_n) - v_h(t_n), \quad 0 \leq t_n \leq T, \tag{6.3}$$

where $v_h(t)$ is the solution of (4.3).

Finally, we use the time discretization introduced in section 4, and the error is the time global truncation error defined as

$$e^3_{h,n} = v_h(t_n) - v_{h,n}, \quad 0 \leq t_n \leq T, \tag{6.4}$$

where $v_{h,n}$ is the solution of (4.4).

The estimate of the error obtained in Theorem 6.2 is separated into three terms given by $e^i_{h,n}$, $i = 1, 2, 3$. The error may grow when h goes to zero due to two of these terms which behave as $e^3_{h,n} = O(k^p \kappa_h)$ and $\|e^2_{h,n}\|_{[x^0,x^N],h} \leq \epsilon h^{-2}$. This is a crucial difference from the wave equation (cf. [9]).

Nevertheless, notice that the growth is compensated for, in the case of $e^3_{h,n}$, by the presence of the factor k^p, which decreases when k decreases, or when p, the order of the integrator in time, grows, as is well displayed in the numerical experiments of section 8. Therefore, the use of methods of high order for the integration in time is crucial when we use SABCs with high orders of absorption, and the behavior of κ_h is worse, as we will see in section 7.

On the other hand, $\|e^2_{h,n}\|_{[x^0,x^N],h} \leq \epsilon h^{-2}$, where ϵ measures the capacity of absorption at the boundary and depends only on the solution of the semidiscrete problem. Nevertheless, we will see at the end of this section that ϵ can overestimate the error due to the absorption, and we will analyze better bounds for our numerical experiments. If the SABCs are suitable to absorb the solution arriving at the boundary, the numerical experiments indicate that the absorption is very high and the error absorption is small. If this is not the case, the alternative is to consider the higher order SABCs that are studied in next section. However, the instability is increased with these higher order SABCs and the term $e^3_{h,n}$ may grow. Moreover, due to the bad absorption of solutions traveling with a velocity distinct to the one associated with the interpolatory nodes, it is necessary to consider a distinct implementation (see [3]). Finally, we remark that the factor h^{-2} is, at least partially, a consequence of the singularities observed in the reflection coefficient in section 5, affecting components of the solution traveling with velocities very small or very large.

Then, we have the following result.

Theorem 6.2. *We assume that in the initial value problem* (2.1)*, the initial value* $u_0 \in D(A^2) = H^4(\mathbf{R})$*, and that the hypotheses of Propositions* 2.4 *and* 4.4 *are satisfied. Then the full discrete global error defined in* (6.1) *can be expressed as*

$$e_{h,n} = e^1_{h,n} + e^2_{h,n} + e^3_{h,n},$$

where $e^1_{h,n}$*, defined in* (6.2)*, satisfies*

$$\|e^1_{h,n}\|_{[x^0,x^N],h} = O(h^2) \tag{6.5}$$

and depends only on the spatial discretization. Moreover, for a fixed spatial discretization, the term $e^2_{h,n}$*, defined in* (6.3)*, depends only on SABC*(1,0)*, and, if* $s_1 = s_2 = b$*,*

$$\|e^2_{h,n}\|_{[x^0,x^N],h} \leq \epsilon h^{-2}, \tag{6.6}$$

where ϵ measures the capacity of absorption of the solution. Finally, the term $e^3_{h,n}$, defined in (6.4)*, depends only on the discretization in time and*

$$\|e^3_{h,n}\|_{[x^0,x^N],h} = O(k^p \kappa_h). \tag{6.7}$$

Proof. With the definition (6.1)

$$\begin{aligned} e_{h,n} &= P_h r_h u(t_n) - v_{h,n} \\ &= P_h r_h u(t_n) - P_h u_h(t_n) + P_h u_h(t_n) - v_h(t_n) + v_h(t_n) - v_{h,n} \\ &= e^1_{h,n} + e^2_{h,n} + e^3_{h,n}. \end{aligned}$$

The value $e^3_{h,n} = v_h(t_n) - v_{h,n}$ is the global truncation error arisen when the problem (4.3) is time discretized with an A-stable Runge–Kutta method. Then the proof the estimate (6.7) is very similar to the one used in section 5 of [2].

On the other hand, the proof of (6.5) is a classical result. Finally, we prove the estimate (6.6) in Lemma 6.3. □

LEMMA 6.3. *With the hypotheses and notation of Theorem* 6.2, (6.7) *is satisfied.*

Proof. Notice that $P_h u_h(t_n)$ is the restriction of the solution of (2.5) to $[x^0, x^N]$, that is, with TBCs, and that $v_h(t_n)$ is the approximation obtained when we use SABC(1,0). Therefore, $e^2_{h,n} = v_h(t_n) - P_h u_h(t_n)$ depends only on the absorption of the solution of (2.5) with SABC(1,0).

Let us suppose that $0 < h^2 b/2 \le 1$. (The proof for $1 < h^2 b/2 < 2$ is similar.) With the notation of section 5, we have

$$\|e^2_{h,n}\|_{[x^0,x^N],h} = \left(h \sum_{j=0}^{N} |w^j(t_n)|^2 \right)^{1/2}.$$

By Proposition 2.4,

$$w^j(t) = \frac{1}{2\pi} \int_{\omega_1}^{\omega_2} \exp(i\omega t) \hat{w}^j(\omega) d\omega,$$

where $\omega_1 = -V/c$, and $\omega_2 = -V/c + 4/(ch^2)$, and we deduce that

$$\begin{aligned} |w^j(t)|^2 &\le \frac{1}{ch^2\pi^2} \int_{\omega_1}^{\omega_2} |\hat{w}^j(\omega)|^2 d\omega \\ &= \frac{1}{ch^2\pi^2} \int_{\omega_1}^{\omega_2} |K_1(j)\hat{u}^{L+j}(\omega) + K_2(j)\hat{u}^{J-j}(\omega)|^2 d\omega. \end{aligned} \tag{6.8}$$

Using now (5.13),

$$|w^j(t)|^2 \le \frac{2(N+1)^2 c^3}{h^2 b^4 \pi^2} \int_{\omega_1}^{\omega_2} \left(|(\omega-\omega^*)^2 \hat{u}^{L+j}(\omega)|^2 + |(\omega-\omega^*)^2 \hat{u}^{J-j}(\omega)|^2 \right) d\omega.$$

Making now the change of variable $\tau = \omega - \omega^*$ and taking into account that $N = O(h^{-1})$,

$$\begin{aligned} |w^j(t)|^2 &\le \frac{2(N+1)^2 c^3}{h^2 b^4 \pi^2} \int_{\omega_1-\omega^*}^{\omega_2-\omega^*} \left(|\tau^2 \hat{u}^{L+j}(\tau+\omega^*)|^2 + |\tau^2 \hat{u}^{J-j}(\tau+\omega^*)|^2 \right) d\tau \\ &= \frac{C^2}{h^4 b^4} \int_{\omega_1-\omega^*}^{\omega_2-\omega^*} \left(|\tau^2 \hat{u}^{L+j}_{\omega^*}(\tau)|^2 + |\tau^2 \hat{u}^{J-j}_{\omega^*}(\tau)|^2 \right) d\tau, \end{aligned}$$

Table 2
Value of $\tilde{\epsilon}$.

SABC(1,0)	SABC(1,1)	SABC(2,1)	SABC(3,2)
1.2300d−2	5.5623d−4	3.0115d−5	1.3161d−7

where $\hat{u}^j_{\omega^*}(\tau) = \hat{u}^j(\tau + \omega^*)$. Finally, taking into account that $J < L$, we obtain (6.6) with

$$\epsilon = \frac{C}{b^2}\left(h\sum_{j=0}^{N}\int_{\omega_1-\omega^*}^{\omega_2-\omega^*}\left(|\tau^2\hat{u}^{L+j}_{\omega^*}(\tau)|^2 + |\tau^2\hat{u}^{J-j}_{\omega^*}(\tau)|^2\right)d\tau\right)^{1/2}. \qquad \square$$

We also note that it is possible, although only numerically, to obtain an estimate of the absorption using the last term of (6.8) from which we deduce a bound

$$\|e^2_{h,n}\|_{[x^0,x^N],h} \le \tilde{\epsilon}h^{-1},$$

where $\tilde{\epsilon}$ is given in terms of the reflection coefficients $K_1(j)$, $K_2(j)$. This bound obviously will be smaller than the previous one and has the advantage that we can use it for other SABCs of higher order. We have calculated numerically the value for $\tilde{\epsilon}$ for the experiment considered in section 8 for the initial datum with $\alpha = 20°$, $\sigma = 10$ (as in Figure 4), $L = 100$, $t_n = 500$, and $h = 0.1$, obtaining the results of Table 2. It is plain that these values are small pointing out that the absorption is high. Moreover, the value of $\tilde{\epsilon}$ decreases when the order of absorption increases.

7. Other ABCs. In section 3 we studied the procurement of SABC(1,0). Let us consider now other different choices for the approximation (3.1).

SABC(0,0). Let $q = \alpha_0$ be the function that interpolates $r(s,h)$ at s_1. The SABC obtained this way is

$$v^{N-1}(t) = \alpha_0 v^N(t).$$

In this case, we obtain a system $v_h' = Mv_h$ with $v_h = [v^1,\dots,v^{N-1}]^T$ and $M \in \mathcal{M}_{(N-1)\times(N-1)}$ such that $\mu_2(M) < 0$. Therefore, the problem is stable. Nevertheless, as the absorption of these SABCs is too small, we will not consider them for the numerical experiments of section 8.

SABC(1,1). Let $q(s,h) = (\alpha_0 + \alpha_1 s)/(1 + \alpha_2 s)$ be a rational function that interpolates $r(s,h)$ at s_1, s_2, and s_3. An approximation of (2.15) is then

$$(1 + \alpha_2(V + c\omega))\hat{v}^{N-1}(\omega) = (\alpha_0 + \alpha_1(V + c\omega))\hat{v}^N(\omega),$$

obtaining this way

$$\beta_0 v^{N-1}(t) + \beta_1\frac{d}{dt}v^{N-1}(t) = \beta_2 v^N(t) + \beta_3\frac{d}{dt}v^N(t)$$

for certain coefficients β_j depending on s_1, s_2, and s_3. Finally, taking into account the spatial discretization (2.3) we are considering for dv^{N-1}/dt, we obtain

$$\frac{d}{dt}v^N(t) = \gamma_0 v^N(t) + \gamma_1 v^{N-1}(t) + \gamma_2 v^{N-2}(t).$$

A similar expression is obtained for the left boundary.

Notice that in the limit case when $s_1 = s_2 = s_3 = b$, the approximation we are considering in (3.1) is the Padé (1,1) expansion of $r(V + c\omega, h)$ at $\omega = \omega^*$, with $\omega^* = (b - V)/c$.

This way, we have reduced the problem to the resolution of a system $v_h' = Mv_h$ with $v_h = [v^0, v^1, \dots, v^{N-1}, v^N]^T$ and $M \in \mathcal{M}_{(N+1)\times(N+1)}$.

SABC(2,1). Continuing this approach, let $q(s, h) = (\alpha_0 + \alpha_1 s + \alpha_2 s^2)/(1 + \alpha_3 s)$ be a rational function that interpolates $r(s, h)$ at s_1, s_2, s_3, and s_4. This gives rise to

$$\beta_0 v^{N-1} + \beta_1 \frac{d}{dt} v^{N-1} = \beta_2 v^N + \beta_3 \frac{d}{dt} v^N + \beta_4 \frac{d^2}{dt^2} v^N.$$

Let us define now the new function $z^N(t) = dv^N(t)/dt$. If in the previous expression, we also take into account (2.3) for $j = N - 1$, we get

$$\frac{d}{dt} z^N = \gamma_0 z^N + \gamma_1 v^N + \gamma_2 v^{N-1} + \gamma_3 v^{N-2}$$

for certain coefficients γ_j depending on s_1, s_2, s_3, and s_4. Therefore, we have obtained a system $v_h' = Mv_h$ with $v_h = [z^0, v^0, \dots, v^N, z^N]^T$ and $M \in \mathcal{M}_{(N+2)\times(N+2)}$.

SABC(3,2). Let us consider now the rational function $q = p_1/q_1$ with p_1 and q_1 polynomials of degree 3 and 2 in s, respectively, that interpolates $r(s, h)$ at s_j, $j = 1, \dots, 6$. We obtain this way the following ABC for the right boundary:

$$\beta_0 v^{N-1} + \beta_1 \frac{d}{dt} v^{N-1} + \beta_2 \frac{d^2}{dt^2} v^{N-1} = \beta_3 v^N + \beta_4 \frac{d}{dt} v^N + \beta_5 \frac{d^2}{dt^2} v^N + \beta_6 \frac{d^3}{dt^3} v^N. \tag{7.1}$$

Taking (2.3) into account for $j = N - 1$ and taking the derivative with respect to t, we get

$$\frac{d^2}{dt^2} v^{N-1} = \widetilde{m}_1 \frac{d}{dt} v^N + \widetilde{m}_1 \widetilde{m}_2 v^N + (\widetilde{m}_1^2 + \widetilde{m}_2^2) v^{N-1} + 2\widetilde{m}_1 \widetilde{m}_2 v^{N-2} + \widetilde{m}_1^2 v^{N-3}.$$

On the other hand, let us define the functions $z^N(t) = dv^N(t)/dt$ and $w^N(t) = d^2 v^N(t)/dt^2$. In this way, (7.1) gives rise to

$$\frac{d}{dt} w^N = \gamma_0 w^N + \gamma_1 z^N + \gamma_2 v^N + \gamma_3 v^{N-1} + \gamma_4 v^{N-2} + \gamma_5 v^{N-3}$$

for certain coefficients γ_j depending on the points of interpolation. In this case, we have obtained a system $v_h' = Mv_h$ with $v_h = [w^0, z^0, v^0, \dots, v^N, z^N, w^N]^T$ and $M \in \mathcal{M}_{(N+3)\times(N+3)}$.

Regarding the stability, the case of SABC(1,1) has been studied in [18, 19], where it is proved that the eigenvalues of the matrices of the associated discrete problems have a negative real part when the three interpolatory are equal.

In the other cases, we have checked numerically that all the eigenvalues of the matrices associated to the previous SABCs have negative real part. All of them are nonnormal and a study of the ϵ-pseudospectra shows that the rate of nonnormality is higher for the most ABCs. In this way, Table 1 shows, for an example of what is discussed in section 8, the maximum of the real part of the eigenvalues of $M + E$, where E is a random matrix of norm ϵ and M is the matrix associated to the indicated SABC.

In Figure 1 we can see the behavior of the condition number κ_h for the different SABCs. It is $O(h^{-3/2})$ for SABC(1,1), $O(h^{-2})$ for SABC(2,1), and $O(h^{-7/2})$ for

SABC(3,2). Therefore, for the same stepsize k, the behavior of the error term $e^1_{h,n}$ (6.7) is worse for higher order ABCs.

On the other hand, we have checked numerically (see Figure 2) that in the case $s_1 = s_2 = s_3 = b$, the reflection coefficient for one boundary satisfies

$$|R(V + c\omega, h)| \leq \min\left(1, \frac{(x - x^*)^m}{\min((x^*)^m, (2 - x^*)^m)}\right),$$

where m is the order of the ABCs used. We have also checked the following bound for the reflection coefficients in the case of two boundaries (see Figure 3):

$$\max\left(|K_1(j)|, |K_2(j)|\right) \leq (N + 1)\frac{(x - x^*)^m}{\min((x^*)^m, (2 - x^*)^m)}.$$

This way we see that for a fixed value of h, the higher the order of the ABCs is, the better the reflection coefficient behaves.

The numerical experiments of section 8 confirm the previous estimates.

SABC(2,0). Finally, if we consider the polynomial of order two that interpolates $r(s, h)$ at the points s_1, s_2, and s_3, we obtain a system $v'_h = Mv_h$ with $M \in \mathcal{M}_{(N+1)\times(N+1)}$. Nevertheless, we have checked numerically that this matrix has eigenvalues with positive real part, giving rise to an unstable problem. This result is similar to the one obtained in [2] for ABC(2,0).

8. Numerical experiments.

We are going to consider the Fresnel equation (1.2) with $n = 1$, $n_0 = \cos(21.8°)$, $\lambda = 0.832$, and $k_0 = 2\pi/\lambda$. The experiments we are going to present in this section are similar to those in [2] for the continuous case. We will consider, as in [2, 7, 22, 23], the following kind of initial conditions for the experiments:

$$u_0(x) = \exp\left(-\left(\frac{\bar{x}}{\sigma}\right)^2\right)\exp(i\tau\bar{x}), \quad x \in [0, L], \tag{8.1}$$

with $\bar{x} = x - L/2$ and $\tau = -n_0 k_0 \tan(\alpha)$. This initial condition, which is discretized by taking $r_h u_0(x) = (u_0(jh))_{j\in\mathbf{Z}}$, will give rise to a solution traveling with a velocity $\tan\alpha$. In fact, the exact solution can be calculated explicitly and is given by

$$u(x, t) = \left(1 - \frac{4it}{c\sigma^2}\right)^{-1/2} \exp\left(\frac{i}{c}(\tau^2 - V)t\right)\exp\left(i\tau\bar{x} - \frac{\left(\bar{x} + \frac{2\tau t}{c}\right)^2}{\sigma^2 - \frac{4it}{c}}\right). \tag{8.2}$$

The dispersion relation for the numerical solution is given by

$$\omega(\tau h) = \frac{2}{ch^2}(\cos(\tau h) - 1) + \frac{V}{c}. \tag{8.3}$$

Notice that, although this value is a good approximation to the dispersion relation of the theoretical solution when h is small, in general they are different.

We are going to study numerically the behavior of the SABCs obtained in this paper and compare them with the ABCs previously obtained in [2]. The interpolatory nodes s_j are considered equal to a unique positive number b. We draw in each case the relative L^2 norm error of the numerical solution with respect to the analytical solution given by (8.2), that is,

$$\frac{\|v_{h,n} - P_h r_h u(t_n)\|_{[x^0,x^N],h}}{\|P_h r_h u_0\|_{[x^0,x^N],h}} = \frac{\|v_{h,n} - P_h r_h u(t_n)\|_{[x^0,x^N],h}}{\|r_h u(t_n)\|_h}.$$

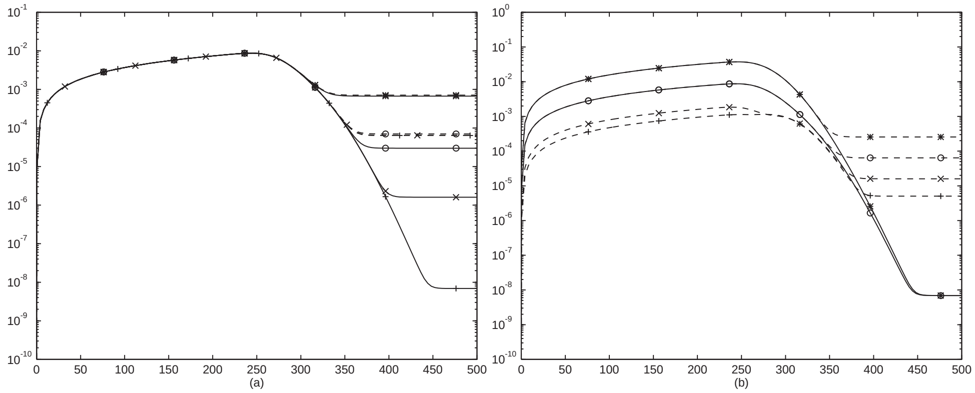

FIG. 4. *Error as a function of time.* (a) – –$*$ *ABC*(1,0), – –$\circ$ *ABC*(1,1), – –$\times$ *ABC*(2,1), – – + *ABC*(3,2), –$*$ *SABC*(1,0), –$\circ$ *SABC*(1,1), –$\times$ *SABC*(2,1), –+ *SABC*(3,2). (b) *ABC*(3,2)*:* – –$*$ $N = 8000$, – –$\circ$ $N = 16000$, – –$\times$ $N = 32000$, – –+ $N = 64000$*; SABC*(3,2)*:* –$*$ $N = 8000$, –$\circ$ $N = 16000$.

Let us consider the Fresnel equation along with the initial condition (8.1) with $\alpha = 20°$, $\sigma = 10$, and $L = 200$. Notice that, numerically, this initial condition is 0 at the boundary. (This assumption is made in the deduction of the TBC in section 2.) We have chosen the optimal value for b given by (3.2) with $\eta = \tau h$, obtained by using the discrete dispersion relation (8.3) and a spatial stepsize $h = .0125$. We have carried out the integration in time with the implicit mid-point rule (IMPR) with a stepsize $k = 0.2$. In Figure 4(a) we can observe the results in terms of relative error for the SABCs previously obtained in this paper (SABC(j_1,j_2)) and for the ABCs obtained in [2] for the continuous problem (ABC(j_1,j_2)). We can observe that the error for $t \leq 300$ is approximately the same for every ABC. This is due to the fact that until that time, the solution is traveling through the interior domain and it has not arrived to the boundary. Therefore, until that time, the error is caused by the discretization in the interior domain, which is the same for every ABC. In this paper, we are interested in the error caused by the different ABCs when the solution reaches the boundary, which for the example of Figure 4(a) happens for $t > 300$ approximately. We see that in every case the results obtained with the SABCs are better than the ones for the ABCs of the same order. This difference is bigger when the order of the boundary condition is higher. Notice that the reflections for ABC(1,1), ABC(2,1), and ABC(3,2) are almost the same. This does not happen for the SABCs for the semidiscrete problem. Let us try to explain this fact.

The ABC(j_1,j_2) has been built as an approximation to the TBC for the continuous problem and not for the problem semidiscretized in space. In this way, the reflection caused by the ABC(j_1,j_2) depends not only on the order of absorption ($j_1 + j_2 + 1$) but also on the difference between the TBC for the continuous problem and that for the semidiscretized one. Thus it is expected that in Figure 4(a), the reflection for ABC(j_1,j_2) will be smaller if h decreases. This can be seen in Figure 4(b) for ABC(3,2) and SABC(3,2). We have considered the same initial condition and the same stepsize k as in Figure 4(a), but now we have taken different spatial stepsizes. We observe that while for SABC(3,2) the reflection does not change with h, for ABC(3,2) the results are better the smaller h is. This way, in order to obtain with ABC(3,2) a similar result to that of SABC(3,2) with $N = 8000, 16000$, we should consider a much

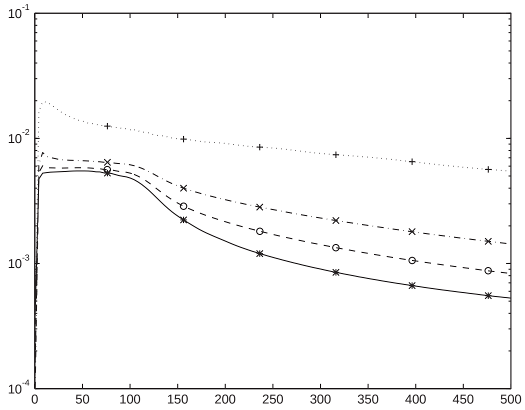

Fig. 5. *Error as a function of time.* –∗ *SABC*(1,0), – –○ *SABC*(1,1), – · –× *SABC*(2,1), · · · + *SABC*(3,2).

smaller value for h. Therefore, the use of the SABCs for the semidiscretized problem allows us to use bigger values of h.

In Figure 4(a) we also observe that the results obtained for the SABC(j_1,j_2) are due to the order of the different SABCs. We have shown in section 4 that the discrete problems associated to these SABC(j_1,j_2) are weakly unstable; nevertheless, this is not visible in Figure 4(a). This is due to the kind of initial condition we are considering, which is zero at the boundary and gives rise to a solution traveling with a fixed velocity. Since we are taking the optimal choice for the interpolatory nodes, there is a great absorption when the solution reaches the boundary. This cancels the bad behavior due to the weak instability of these problems.

It is essential that the initial condition is zero at the boundary as we can see in Figure 5, where we have taken the same initial condition as in the previous experiments but with $L = 40$. Now the value of the initial condition at the boundary is approximately 0.018. Of course, we are breaking a basic hypothesis used in section 2 for the construction of SABCs. We have considered the same stepsizes as in Figure 4(a) and the optimal value for b. The results now are quite different from those observed in Figure 4(a). The instability of the discrete problems is now visible, and we can observe a large initial growth of the error. Moreover, the higher the order of absorption of SABC is, the bigger the growth is. As a consequence, the absorption is worse for higher order SABCs. Similar experiments can be done considering initial conditions that are not regular, obtaining similar results to those in [2].

In Theorem 6.2, we have seen that there exist two elements of the error that can grow when h goes to zero. These terms measure the capacity of absorption of the SABC and the error of the discretization in time. This behavior can be observed by taking a value for b different from the optimal so that these elements are big enough. Let us consider the initial condition (8.1) with $\alpha = 30°$, $\sigma = 3$, and $L = 36$. (Notice it is zero at the boundary.) In Figure 6 we observe the results obtained when we use SABC(3,2), the worst case of instability studied in this paper, with a value for b very different from the optimal. The integration in time is carried out with the IMPR with $k = 0.1$ and values of h decreasing. We see that for $h = 36/80000$, the smaller value considered, the error grows.

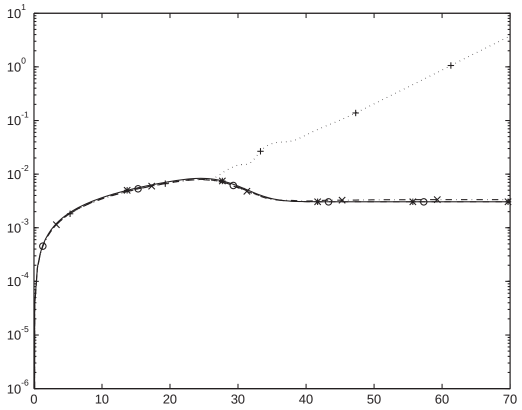

FIG. 6. *Error as a function of time. SABC*(3,2) *IMPR.* $k = 0.1$, $-*$ $N = 10000$, $--\circ$ $N = 20000$, $-\cdot-\times$ $N = 40000$, $\cdots+$ $N = 80000$.

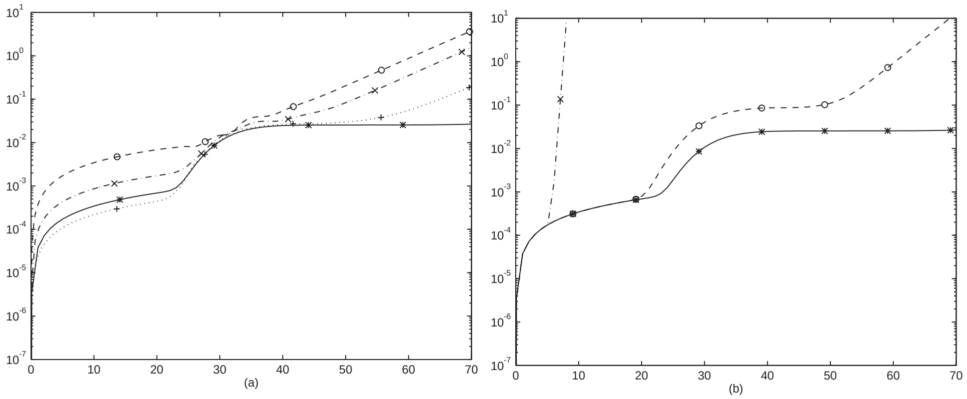

FIG. 7. *Error as a function of time. SABC*(3,2) (a) $N = 80000$*;* $-*$ *DIRK*3 $k = 0.1$*; IMPR:* $-\circ$ $k = 0.1$, $-\cdot-\times$ $k = 0.05$, $\cdots+$ $k = 0.025$. (b) *DIRK*3 $k = 0.1$*;* $-*$ $N = 80000$, $--\circ$ $N = 1600000$, $-\cdot-\times$ $N = 1320000$.

This behavior can be lessened by decreasing k or by increasing the order of the integrator in time. This is seen in Figure 7(a), where we have carried out the integration in time first with a diagonally implicit Runge–Kutta method (DIRK3) of order 3 with $h = 36/80000$, $k = 0.1$, and second with the IMPR for decreasing values of k. With this experiment, the influence of the error term, which is $O(\kappa_h k^p)$ (see section 6), is checked numerically. Nevertheless, we emphasize that the use of an integrator of high order in time will only improve the behavior of this term, but the problem is still unstable. This is observed in Figure 7(b), where we have used DIRK3 with $k = 0.1$ and where we have considered smaller values for h than in Figure 7(a). As expected, the unstable behavior again arises. On the other hand, we remark that the error of absorption is quite large because the value for b is very distinct from the optimal.

The previous experiments have been carried out considering initial conditions that give rise to solutions traveling with a quite small velocity. We have obtained similar conclusions with other numerical experiments made with higher velocities.

ERROR EXPANSION FOR AN UPWIND SCHEME APPLIED TO A TWO-DIMENSIONAL CONVECTION-DIFFUSION PROBLEM*

NATALIA KOPTEVA[†]

Abstract. We consider a singularly perturbed convection-diffusion problem in a rectangular domain. It is solved numerically using a first-order upwind finite-difference scheme on a tensor-product piecewise-uniform Shishkin mesh with $O(N)$ mesh points in each coordinate direction. It is known [G. I. Shishkin, *Grid Approximations of Singularly Perturbed Elliptic and Parabolic Equations*, Russian Academy of Sciences, Ural Branch, Ekaterinburg, Russia, 1992 (in Russian)] that the error is almost-first-order accurate in the maximum norm. We decompose the error into a sum of continuous almost-first-order terms and the almost-second-order residual under the assumption $\varepsilon \le CN^{-1}$, where ε is the singular perturbation parameter and C is a constant. This error expansion is applied to obtain maximum-norm error estimates for the Richardson extrapolation technique and derive bounds on the errors in approximating the derivatives of the true solution by divided differences of the computed solution. The analysis uses a decomposition of the true solution requiring fewer compatibility conditions than in earlier publications. Numerical results are presented that support our theoretical results.

Key words. convection-diffusion, upwind scheme, singular perturbation, error expansion, Richardson extrapolation, approximation of derivatives, Shishkin mesh

1. Introduction.

The main result of this paper is a certain error expansion for the singularly perturbed two-dimensional convection-diffusion problem

$$(1.1)\qquad \begin{aligned} Lu := -\varepsilon\triangle u + b_1u_x + b_2u_y + cu &= f \qquad \text{in } \Omega = (0,1)\times(0,1),\\ u &= 0 \qquad \text{on } \partial\Omega. \end{aligned}$$

Here ε is a small parameter that satisfies $0 < \varepsilon \ll 1$, while $b_1(x,y)$, $b_2(x,y)$, $c(x,y)$ are smooth functions with

$$(1.2a)\qquad b_1(x,y) > \beta_1 > 0, \quad b_2(x,y) > \beta_2 > 0, \quad c(x,y) \ge 0 \quad \text{for all } (x,y) \in \bar\Omega,$$

where β_1, β_2 are positive constants. To simplify the presentation we assume that

$$(1.2b)\qquad \beta_1 = \beta_2 = \beta > 0.$$

Note that all the results of this paper also hold true for the general case (1.2a); see Remarks 1.1 and 4.5.

The solution of problem (1.1) has exponential layers at the outflow boundaries $x = 1$ and $y = 1$ (see [8, 10]). We are interested in ε-uniform numerical methods that resolve the boundary layers. One approach is using layer-adapted highly nonuniform meshes.

Problem (1.1) is discretized using the standard first-order upwind scheme

$$(1.3)\qquad \begin{aligned} L^Nu^N := \big(-\varepsilon(\delta_x^2+\delta_y^2) + b_{1,ij}D_x^- + b_{2,ij}D_y^- + c_{ij}\big)u_{ij}^N &= f_{ij} \qquad \text{in } \Omega^N,\\ u_{ij}^N &= 0 \qquad \text{on } \partial\Omega^N. \end{aligned}$$

[†]Faculty of Computational Mathematics and Cybernetics, Lomonosov Moscow State University, Vorob'evy gory, RU-119992 Moscow, Russia (kopteva@cs.msu.su).

Here δ_x^2, δ_y^2, D_x^-, D_y^- are the standard finite-difference differentiation operators; see notation (2.1). Note from [11, 8, 10] that this scheme satisfies the maximum principle.

We discretize on the mesh $\bar\Omega^N = \bar\omega_{\sigma,N} \times \bar\omega_{\sigma,N} = \{(x_i, y_j) \in \bar\Omega :\ i, j = 0, \dots, N\}$ that is the tensor-product of two equal piecewise-uniform meshes. Each of these one-dimensional meshes $\bar\omega_{\sigma,N}$ is constructed by dividing each of the subintervals $[0, 1-\sigma]$ and $[1-\sigma, 1]$ into $N/2$ equal subintervals of width H and h, respectively:

$$x_i = y_i = \begin{cases} iH & \text{for} \quad i = 0, \dots, N/2, \quad \text{where} \quad H = 2(1-\sigma)/N, \\ (1-2\sigma) + ih & \text{for} \quad i = N/2, \dots, N, \quad \text{where} \quad h = 2\sigma/N. \end{cases} \tag{1.4}$$

Shishkin [13] was the first to suggest such piecewise-uniform meshes for problems like (1.1) with the mesh transition parameter $\sigma := \min\{(2/\beta)\,\varepsilon \ln N,\, 1/2\}$. For simplicity we assume that

$$\varepsilon \le CN^{-1}, \tag{1.5}$$

which is not a restriction in practical situations. This assumption implies that

$$\sigma = \frac{2}{\beta}\,\varepsilon \ln N. \tag{1.6}$$

Note also that $N^{-1} < H < 2N^{-1}$ and

$$\frac{h}{\varepsilon} = \frac{4}{\beta} N^{-1} \ln N, \qquad e^{-\beta(1-x_{N/2})/\varepsilon} = e^{-\beta(1-y_{N/2})/\varepsilon} = e^{-\beta\sigma/\varepsilon} = N^{-2}. \tag{1.7}$$

Further, let $\partial\Omega^N$ be the set of mesh points on the boundary, i.e., $\partial\Omega^N = \bar\Omega^N \cap \partial\Omega$, while $\Omega^N = \bar\Omega^N \backslash \partial\Omega^N$ is the set of the internal mesh points.

Thus the domain $\bar\Omega$ is dissected by the transition lines $x = 1-\sigma$ and $y = 1-\sigma$ into four parts

$$\begin{aligned} \Omega_2 &:= [0, 1-\sigma] \times (1-\sigma, 1], & \Omega_{12} &:= (1-\sigma, 1] \times (1-\sigma, 1], \\ \bar\Omega_0 &:= [0, 1-\sigma] \times [0, 1-\sigma], & \Omega_1 &:= (1-\sigma, 1] \times [0, 1-\sigma]. \end{aligned}$$

The restriction of the mesh $\bar\Omega^N$ to each of them is a rectangular uniform mesh.

Remark 1.1. The analogue of $\bar\Omega^N$ for $\beta_1 \ne \beta_2$ is the tensor-product rectangular mesh $\bar\omega_{\sigma_1,N} \times \bar\omega_{\sigma_2,N}$, where σ_k, H_k, h_k, $\bar\omega_{\sigma_k,N}$, for $k = 1, 2$, are defined similarly to σ, H, h, $\bar\omega_{\sigma,N}$ with β_k used instead of β; see, e.g., [8, p. 101].

The paper is organized as follows. Most of the notation is collected in section 2. In section 3 we analyze a decomposition of the true solution into an asymptotic expansion of order one and its residual. This decomposition and our estimates of its components require fewer compatibility conditions than in earlier publications [13, 7].

In section 4 we present a certain error expansion for the upwind scheme (1.3) on the Shishkin mesh (1.4). Shishkin [13] gave an ε-uniform almost-first-order estimate of the error in the discrete maximum norm, which was slightly improved in [5, Remark 3.3] to

$$\|u_{ij}^N - u(x_i, y_j)\| \le CN^{-1} \ln N.$$

We decompose the error into a sum of continuous almost-first-order terms and the almost-second-order residual (Theorem 4.1). This error expansion is applied in subsection 4.1 to obtain maximum-norm error estimates for the Richardson extrapolation technique, and in subsection 4.2 to derive bounds on the errors in approximating the derivatives. Section 5 is devoted to the proof of Theorem 4.1.

Similar error expansions were constructed in [9, 4] for one-dimensional convection-diffusion problems. These error expansions were used there to analyze the Richardson extrapolation technique. We mainly follow the analysis in [9], extending it to the two-dimensional problem. In subsection 4.2 we obtain a two-dimensional analogue of the one-dimensional estimates [1, 3, 4]. We follow the approach of [4], where, to analyze a defect correction method, the error expansion was also used to obtain bounds on the differences of the error in two adjoining nodes.

Richardson extrapolation applied to singularly perturbed problems was also studied in earlier publications of Shishkin [12, 14], where ε-uniform maximum-norm error estimates were obtained for a one-dimensional parabolic problem and a two-dimensional elliptic problem in an infinite strip.

Numerical results supporting our theory are presented in section 6.

2. Notation. Throughout the paper we use the following notation. Let k be a nonnegative integer and $\alpha \in (0,1]$. The standard notation $C^k(\bar\Omega)$ is used for the space of functions whose derivatives up to order k are continuous on $\bar\Omega$, with the norm

$$\|v\|_k = \sum_{0\le l\le k}\sum_{i+j=l}\max_{(x,y)\in\bar\Omega}\left|\frac{\partial^{i+j}}{\partial x^i\partial y^j}v(x,y)\right|.$$

As usual, we simply write $C(\bar\Omega)$ and $\|v\|$ when $k=0$. The notation $C^{k,\alpha}(\bar\Omega)$ is used for the space of Hölder continuous functions with the norm

$$\|v\|_{0,\alpha} = \sup_{x,x'\in\bar\Omega,\ x\neq x'}\frac{|v(x)-v(x')|}{\|x-x'\|_e^\alpha}, \qquad \|v\|_{k,\alpha} = \|v\|_k + \sum_{i+j=k}\left\|\frac{\partial^{i+j}}{\partial x^i\partial y^j}v\right\|_{0,\alpha},$$

where $\|\cdot\|_e$ is the Euclidean norm in R^2. Further, we shall use the notation $C^{1,1}(\bar\Omega)$ when $\alpha=1$, and $C^{1,\alpha}(\bar\Omega)$ only when $\alpha\in(0,1)$.

Let v be a discrete function defined on $\tilde\Omega^N\subset\bar\Omega^N$. By $\|v\|_{\tilde\Omega^N} = \max_{\tilde\Omega^N}|v_{ij}|$ we denote the discrete maximum norm of v on $\tilde\Omega^N$. Sometimes we shall simply write $\|v\|$ when $\tilde\Omega^N=\bar\Omega^N$.

The finite-difference operators are defined in a standard manner by

$$\begin{aligned} &h_i := x_i - x_{i-1}, \qquad D_x^- v_{ij} := \frac{v_{ij}-v_{i-1,j}}{h_i}, \qquad \delta_x^2 v_{ij} := \frac{D_x^- v_{i+1,j} - D_x^- v_{ij}}{(h_i+h_{i+1})/2},\\ &h_j := y_j - y_{j-1}, \qquad D_y^- v_{ij} := \frac{v_{ij}-v_{i,j-1}}{h_j}, \qquad \delta_y^2 v_{ij} := \frac{D_y^- v_{i,j+1} - D_y^- v_{ij}}{(h_j+h_{j+1})/2}.\end{aligned} \tag{2.1}$$

Here v_{ij} is any discrete function. Note that when it is clear that $v(x,y)$ is a continuous function, we shall sometimes use the notation $v_{ij} := v(x_i,y_j)$, while when it is clear that v_{ij} is a discrete function, we shall sometimes use the notation $v(x_i,y_j) := v_{ij}$.

For an arbitrary $\tilde\Omega\subset\bar\Omega$ and arbitrary constants a, b on $\bar\Omega^N$ define the function

$$\mathcal{E}_{ij}(a,\tilde\Omega;\ b) = \begin{cases} a & \text{for } (x_i,y_j)\in\tilde\Omega,\\ b & \text{for } (x_i,y_j)\in\bar\Omega^N\backslash\tilde\Omega.\end{cases}$$

We shall also use other similar notation, e.g., $\mathcal{E}_{ij}(a, i\le N/2;\ b)$.

Throughout the paper, C, sometimes subscripted, denotes a generic positive constant that is independent of ε and any mesh used.

3. Decomposition of the solution. In this section we decompose the solution into an asymptotic expansion of order one and its residual. We estimate the components of this decomposition and their derivatives.

THEOREM 3.1. *Let $\alpha \in (0,1)$, and β be from* (1.2). *Suppose that $f \in C^{3,1}(\bar{\Omega})$ and satisfies the compatibility conditions*

$$f(0,0) = f(0,1) = f(1,1) = f(1,0) = 0, \tag{3.1a}$$

$$\left(\frac{f}{b_1}\right)_y (0,0) = \left(\frac{f}{b_2}\right)_x (0,0), \tag{3.1b}$$

$$\left(\frac{1}{b_1}\left(b_1\frac{\partial}{\partial x} - b_2\frac{\partial}{\partial y} - c\right)\left[\frac{f}{b_1}\right]\right)_y (0,0) = \left(\frac{f}{b_2}\right)_{xx} (0,0). \tag{3.1c}$$

Then the boundary-value problem (1.1) *has a classical solution $u \in C^{3,\alpha}(\bar{\Omega})$, and this solution can be decomposed as*

$$u = (u_0 + v_0 + w_0 + z_0) + \varepsilon(u_1 + v_1 + w_1 + z_1) + \varepsilon^2 R,$$

where $u_0 \in C^{3,1}(\bar{\Omega})$, $u_1 \in C^{1,1}(\bar{\Omega})$, $\frac{\partial^k}{\partial x^k}v_1$, $\frac{\partial^k}{\partial y^k}w_1 \in C^{1,1}(\bar{\Omega})$ for $k \geq 0$, $z_1 \in C^3(\bar{\Omega})$, $R \in C^{1,1}(\bar{\Omega})$, and

$$\|u_0\|_{3,1} + \|u_1\|_{1,1} \leq C, \quad u_0(x,0) = u_0(0,y) = 0, \quad u_{0,xx}(0,0) = u_{0,yy}(0,0) = 0, \tag{3.2}$$

$$\begin{aligned} &v_0(x,y) = -u_0(1,y)e^{-b_1(1,y)(1-x)/\varepsilon}, \qquad w_0(x,y) = -u_0(x,1)e^{-b_2(x,1)(1-y)/\varepsilon}, \\ &z_0(x,y) = u_0(1,1)e^{-b_1(1,1)(1-x)/\varepsilon - b_2(1,1)(1-y)/\varepsilon}, \end{aligned} \tag{3.3}$$

$$\begin{aligned} &\left\|\frac{\partial^k}{\partial x^k}v_1(x,\cdot)\right\|_{1,1,[0,1]} \leq C\varepsilon^{-k}e^{-\beta(1-x)/\varepsilon}, \\ &\left\|\frac{\partial^k}{\partial y^k}w_1(\cdot,y)\right\|_{1,1,[0,1]} \leq C\varepsilon^{-k}e^{-\beta(1-y)/\varepsilon} \qquad \textit{for } \ 0 \leq k \leq 3, \end{aligned} \tag{3.4a}$$

$$\left|\frac{\partial^{k+m}}{\partial x^k \partial y^m} z_1(x,y)\right| \leq C\varepsilon^{-(k+m)}e^{-\beta((1-x)+(1-y))/\varepsilon} \qquad \textit{for } \ 0 \leq k+m \leq 3, \tag{3.4b}$$

$$\|R\| \leq C, \qquad |LR(x,y)| \leq C\big(1 + \varepsilon^{-1}e^{-\beta(1-x)/\varepsilon} + \varepsilon^{-1}e^{-\beta(1-y)/\varepsilon}\big). \tag{3.5}$$

Remark 3.1. In (3.4a) by $\|\frac{\partial^k}{\partial x^k}v_1(x,\cdot)\|_{1,1,[0,1]}$ we denote the norm of the function $\frac{\partial^k}{\partial x^k}v_1(x,y)$ as a function of the variable y in the space $C^{1,1}[0,1]$ of Hölder continuous functions. The second line in (3.4a) should be understood similarly.

Remark 3.2. Note that $C^{1,1}(\bar{\Omega}) = W^{2,\infty}(\Omega)$, and for any function in $C^{1,1}(\bar{\Omega})$ its second partial derivatives exist almost everywhere [2, pp. 151, 154]. Hence, since $R \in C^{1,1}(\bar{\Omega})$, in (3.5) the second inequality is to be understood in the sense that it holds true almost everywhere.

Remark 3.3. Shishkin [13, Theorem III.2.1] decomposed the solution into a smooth part and a layer part so that the layer part lay in the null space of L. A similar decomposition was constructed by Linß and Stynes [7]. They presented a full analysis and the explicit compatibility conditions. The solution was decomposed into an asymptotic expansion of order one and its residual. Then the residual was combined with the smooth part of the solution so that the layer part "almost" lay in the null space of L. Note that the hypotheses of our theorem are weaker than those of [7, Theorem 5.1]. In particular, since we do not combine the smooth part with the residual $\varepsilon^2 R$ and do not estimate the derivatives of the latter, our decomposition is useful only for small values of ε, e.g., under our assumption (1.5), but we require *fewer compatibility conditions* at the corner $(0,0)$.

Proof. We mainly follow the proof and the notation of [7, Theorem 5.1], but omit certain parts of this proof that are unnecessary for our decomposition, and combine certain terms in a different manner.

By [7, Lemma 2.1], the compatibility conditions (3.1a) combined with $f \in C^{3,1}(\bar{\Omega})$ imply that $u \in C^{3,\alpha}(\bar{\Omega})$.

We decompose u as in [7]. Thus, u_0 and u_1 are the solutions of the reduced problems [7, (5.2)]. Note that the boundary conditions $u_0(x,0) = u_0(0,y) = 0$ for u_0 yield $u_{0,xx}(0,0) = u_{0,yy}(0,0) = 0$ in (3.2), while the first estimate in (3.2) is obtained applying [7, Theorem 4.1] twice. First, $u_0 \in C^{3,1}(\bar{\Omega})$ since $f \in C^{3,1}(\bar{\Omega})$, while (3.1) implies the compatibility conditions [7, (4.8a), (4.8b), (4.8c)]. Second, $u_1 \in C^{1,1}(\bar{\Omega})$ since $\triangle u_0 \in C^{1,1}(\bar{\Omega})$, while the compatibility condition $\triangle u_0(0,0) = 0$ corresponds to [7, (4.8a)].

Furthermore, v_1 and w_1 are given explicitly by [7, (5.11b), (5.15b)], while z_1 is the solution of the problem [7, (5.17b), (5.17c)]. By [7, Lemma 5.2], the compatibility condition $f(1,1) = 0$ implies that there exists $z_1 \in C^3(\bar{\Omega})$ satisfying (3.4b).

Estimates (3.5) are derived similarly to [7, (5.31)] and the argument that follows it. Note that in [7] $R \in C^{2,\alpha}(\bar{\Omega})$, while we have $R \in C^{1,1}(\bar{\Omega})$; see Remark 3.2. The first estimate in (3.5) follows from the second by the maximum/comparison principle extended to functions in the Sobolev space $W^{1,2}(\Omega)$ (see [2, section 8.1]). □

4. Error expansion and its applications. In this section we present an expansion of the error of the upwind scheme (1.3) on the Shishkin mesh (1.4), (1.6) into a sum of continuous first-order terms and the second-order residual. This error expansion is applied in subsection 4.1 to obtain ε-uniform maximum-norm error estimates for the Richardson extrapolation technique, and in subsection 4.2 to derive bounds on the errors in approximating the derivatives.

THEOREM 4.1. *Suppose that* (1.5) *and the conditions of Theorem* 3.1 *are satisfied. Let u^N be the solution of the discrete problem* (1.3) *on the mesh* (1.4), (1.6). *Then*

$$u_{ij}^N - u(x_i, y_j) = H\Phi(x_i, y_j) + \left(\frac{h}{\varepsilon}\right)\Psi(x_i, y_j) + \mathcal{R}_{ij}^N, \tag{4.1}$$

where $\Phi(x,y)$ and $\Psi(x,y)$ are defined in terms of u_0, v_0, w_0, and z_0 from Theorem 3.1, *and $\varphi(x,y) \in C^{1,1}(\bar{\Omega})$ such that*

$$\|\varphi\|_{1,1} \le C, \tag{4.2}$$

as follows:

$$\begin{aligned}\Phi(x,y) = \varphi(x,y) &- \varphi(1,y)e^{-b_1(1,y)(1-x)/\varepsilon} - \varphi(x,1)e^{-b_2(x,1)(1-y)/\varepsilon} \\ &+ \varphi(1,1)e^{-b_1(1,1)(1-x)/\varepsilon - b_2(1,1)(1-y)/\varepsilon},\end{aligned} \tag{4.3}$$

$$\begin{aligned}\Psi(x,y) = &\ \varepsilon^{-1}(1-x)\frac{\big(b_1^2(1,y)v_0 + b_1^2(1,1)z_0\big)}{2} \\ &+ \varepsilon^{-1}(1-y)\frac{\big(b_2^2(x,1)w_0 + b_2^2(1,1)z_0\big)}{2},\end{aligned} \tag{4.4}$$

while the residual $\mathcal{R}^N_{ij}$ *satisfies*

$$|\mathcal{R}^N_{ij}| \le CN^{-2}\,\mathcal{E}_{ij}(1,\bar{\Omega}^N_0;\,\ln^2 N). \tag{4.5}$$

Proof. The whole of section 5 is devoted to the proof of this theorem; see also Remark 4.1. □

Remark 4.1. A careful inspection of the proof of Theorem 4.1 shows that

$$L^N(u^N-u) = H\frac{(b_1u_{0,xx}+b_2u_{0,yy})}{2} + \left(\frac{h}{\varepsilon}\right)\left[\frac{\varepsilon b_1(v_{0,xx}+z_{0,xx})}{2}+\frac{\varepsilon b_2(w_{0,yy}+z_{0,yy})}{2}\right]+\dots,$$

where ... denotes the terms whose contribution to the error is of almost-second order; see (5.1), (5.2), (5.7), (5.16), (5.18). The standard approach is to define the auxiliary continuous problems

$$L\bar{\Phi} = \frac{(b_1u_{0,xx}+b_2u_{0,yy})}{2} \text{ in } \Omega, \qquad \bar{\Phi} = 0 \text{ on } \partial\Omega, \tag{4.6a}$$

$$L\bar{\Psi}_1 = \frac{\varepsilon b_1(v_{0,xx}+z_{0,xx})}{2} \text{ in } \Omega, \qquad \bar{\Psi}_1 = 0 \text{ on } \partial\Omega, \tag{4.6b}$$

$$L\bar{\Psi}_2 = \frac{\varepsilon b_2(w_{0,yy}+z_{0,yy})}{2} \text{ in } \Omega, \qquad \bar{\Psi}_2 = 0 \text{ on } \partial\Omega, \tag{4.6c}$$

and derive the error expansion

$$u^N_{ij}-u(x_i,y_j) = H\bar{\Phi}(x_i,y_j) + \left(\frac{h}{\varepsilon}\right)[\bar{\Psi}_1(x_i,y_j)+\bar{\Psi}_2(x_i,y_j)]+\cdots,$$

where ... denotes almost-second-order terms; see, e.g., [9] for the one-dimensional case. Our proof mainly follows the analysis of [9], extending it to the two-dimensional case, but, as we shall see, the solutions of the two-dimensional auxiliary problems (4.6) are only in $C^{1,\alpha}(\bar{\Omega})$ since the first-order compatibility conditions are violated. Since the solutions of (4.6) do not exhibit enough smoothness for our analysis, our error expansion (4.1) uses their asymptotic expansions of order zero; see Remarks 4.2–4.4.

Remark 4.2. $\varphi(x,y)$ used in Theorem 4.1 is the solution of the reduced problem

$$b_1\varphi_x + b_2\varphi_y + c\varphi = \frac{\big(b_1u_{0,xx}+b_2u_{0,yy}\big)}{2} \text{ in } \Omega, \qquad \varphi(x,y)=0 \text{ if } x=0 \text{ or } y=0, \tag{4.7}$$

where u_0 is from Theorem 3.1.

Remark 4.3. $\Phi(x,y)$ in (4.3) is an asymptotic expansion of order zero for the solution $\bar{\Phi}(x,y)$ of problem (4.6a). We chose to use $\Phi(x,y)$ instead of $\bar{\Phi}(x,y)$ since, as we shall prove in Lemma 5.7, $\Phi(x,y) \in C^{1,1}(\bar{\Omega})$, while by [7, Lemma 2.1], we have $\bar{\Phi}(x,y) \in C^{1,\alpha}(\bar{\Omega})$ for $\alpha \in (0,1)$. Note that generally $\bar{\Phi}(x,y) \notin C^{2,\alpha}(\bar{\Omega})$ for any $\alpha \in (0,1)$, since the right-hand side $(b_1u_{0,xx}+b_2u_{0,yy})/2$ does not generally vanish at $(1,1)$ and thus does not satisfy one of the compatibility conditions.

Remark 4.4. Decompose $\Psi(x,y)$ in (4.4) as $\Psi = (\Psi_1+\tilde{\Psi}_1)+(\Psi_2+\tilde{\Psi}_2)$; see (5.8) for details. Note that $\Psi_1(x,y)+\tilde{\Psi}_1(x,y)$ and $\Psi_2(x,y)+\tilde{\Psi}_2(x,y)$ are asymptotic expansions of order zero for the solutions $\bar{\Psi}_1(x,y)$ and $\bar{\Psi}_2(x,y)$ of problems (4.6b), (4.6c). By (3.3), one can easily check that Ψ_1, $\tilde{\Psi}_1$, Ψ_2, and $\tilde{\Psi}_2$ are chosen so that

$$-\varepsilon\Psi_{1,xx}+b_1(1,y)\Psi_{1,x} = \frac{b_1(1,y)\varepsilon v_{0,xx}}{2}, \qquad -\varepsilon\tilde{\Psi}_{1,xx}+b_1(1,1)\tilde{\Psi}_{1,x} = \frac{b_1(1,1)\varepsilon z_{0,xx}}{2},$$

$$-\varepsilon\Psi_{2,yy}+b_2(x,1)\Psi_{2,y} = \frac{b_2(x,1)\varepsilon v_{0,yy}}{2}, \qquad -\varepsilon\tilde{\Psi}_{2,yy}+b_2(1,1)\tilde{\Psi}_{2,y} = \frac{b_1(1,1)\varepsilon z_{0,yy}}{2}.$$

Remark 4.5. If $\beta_1 \neq \beta_2$ and the mesh $\bar\omega_{\sigma_1,N} \times \bar\omega_{\sigma_2,N}$ described in Remark 1.1 is used, then we have a slightly different error expansion:

$$\begin{aligned}u_{ij}^N - u(x_i, y_j) &= H_1\Phi_1(x_i, y_j) + H_2\Phi_2(x_i, y_j)\\ &\quad + \left(\frac{h_1}{\varepsilon}\right)[\Psi_1 + \tilde\Psi_1](x_i, y_j) + \left(\frac{h_2}{\varepsilon}\right)[\Psi_2 + \tilde\Psi_2](x_i, y_j) + \mathcal{R}_{ij}^N.\end{aligned}$$

Here $\Psi_1 + \tilde\Psi_1$ and $\Psi_2 + \tilde\Psi_2$ are the first and the second terms on the right-hand side in (4.4)—see Remark 4.4 and (5.8)—while Φ_1 and Φ_2 are defined by (4.3) with Φ and φ replaced by Φ_k and φ_k for $k = 1, 2$. These functions φ_1 and φ_2 are the solutions of the reduced problem (4.7) with the right-hand side $(b_1 u_{0,xx} + b_2 u_{0,yy})/2$ replaced by $b_1 u_{0,xx}/2$ and $b_2 u_{0,yy}/2$, respectively.

4.1. Richardson extrapolation. Now we shall see that the error expansion given by Theorem 4.1 immediately implies ε-uniform maximum-norm error estimates for the Richardson extrapolation technique.

In this subsection for the mesh $\bar\Omega^N$ we shall use the slightly different notation $\bar\Omega_{\sigma,N} := \bar\Omega^N = \bar\omega_{\sigma,N} \times \bar\omega_{\sigma,N}$. We shall also use the tensor-product rectangular mesh $\bar\Omega_{\sigma,2N} := \bar\omega_{\sigma,2N} \times \bar\omega_{\sigma,2N} = \{(\tilde x_i, \tilde y_j) \in \bar\Omega :\ i, j = 0, \ldots, 2N\}$. Here $\bar\omega_{\sigma,2N}$ is a piecewise-uniform mesh with the meshsizes $h/2$ and $H/2$ obtained uniformly bisecting the original mesh $\bar\omega_{\sigma,N}$. Note that $\bar\omega_{\sigma,2N}$ is also described by (1.4) with the same mesh transition parameter σ (1.6) and N replaced by $2N$. The two rectangular meshes are nested; i.e., $\Omega_{\sigma,N} = \{(x_i, y_j)\} \subset \Omega_{\sigma,2N} = \{(\tilde x_i, \tilde y_j)\}$, and $(x_i, y_j) = (\tilde x_{2i}, \tilde y_{2j})$.

Let $\tilde u_{ij}^{2N} = \tilde u^{2N}(\tilde x_i, \tilde y_j)$ be the solution of the discrete problem (1.3) on the mesh $\Omega_{\sigma,2N}$. Then under the conditions of Theorem 4.1, in addition to (4.1) we have

$$\tilde u^{2N}(\tilde x_i, \tilde y_j) - u(\tilde x_i, \tilde y_j) = \frac{1}{2} H\Phi(\tilde x_i, \tilde y_j)\frac{1}{2}\left(\frac{h}{\varepsilon}\right)\Psi(\tilde x_i, \tilde y_j) + \tilde{\mathcal{R}}^{2N}(\tilde x_i, \tilde y_j).$$

Hence

$$[\, 2\tilde u^{2N}(x_i, y_j) - u_{ij}^N\,] - u(x_i, y_j) = 2\tilde{\mathcal{R}}^{2N}(x_i, y_j) - \mathcal{R}_{ij}^N,$$

and we arrive at the following.

COROLLARY 4.2. *Under the conditions of Theorem* 4.1, *we have*

$$\begin{aligned}\left|[\, 2\tilde u^{2N}(x_i, y_j) - u_{ij}^N\,] - u(x_i, y_j)\right| &\leq CN^{-2}\,\mathcal{E}_{ij}(1, \bar\Omega_0; \ln^2 N)\\ &= C\begin{cases} N^{-2} & \text{in } \bar\Omega^N \cap \bar\Omega_0,\\ N^{-2}\ln^2 N & \text{in } \bar\Omega^N \backslash \bar\Omega_0.\end{cases}\end{aligned}$$

Thus, while the two computed solutions u_{ij}^N and $\tilde u_{ij}^{2N}$ are almost-first-order accurate, their linear combination $[2\tilde u^{2N}(x_i, y_j) - u_{ij}^N]$ is almost-second-order accurate ε-uniformly.

4.2. Approximation of derivatives. In this subsection we apply the error expansion given by Theorem 4.1 to derive bounds on the errors in approximating the derivatives of the true solution by divided differences of the computed solution.

COROLLARY 4.3. *Under the conditions of Theorem* 4.1, *we have*

$$\text{(4.8a)}\quad \left|D_x^- e_{ij}^N\right| + \left|D_x^- u_{ij}^N - u_x(x_{i-1/2}, y_j)\right| \leq C\begin{cases} N^{-1} & \text{in } \bar\Omega^N \cap \bar\Omega_0,\\ N^{-1}\ln^2 N & \text{in } \bar\Omega^N \cap \Omega_2,\\ N^{-1}\ln N/\varepsilon & \text{in } \bar\Omega^N \cap (\Omega_1 \cup \Omega_{12}),\end{cases}$$

$$\text{(4.8b)}\quad \left|D_y^- e_{ij}^N\right| + \left|D_y^- u_{ij}^N - u_y(x_i, y_{j-1/2})\right| \le C \begin{cases} N^{-1} & \textit{in } \bar{\Omega}^N \cap \bar{\Omega}_0, \\ N^{-1}\ln^2 N & \textit{in } \bar{\Omega}^N \cap \Omega_1, \\ N^{-1}\ln N/\varepsilon & \textit{in } \bar{\Omega}^N \cap (\Omega_2 \cup \Omega_{12}), \end{cases}$$

where $e_{ij}^N = u_{ij}^N - u(x_i, y_j)$ *is the error, while* $x_{i-1/2}$ *and* $y_{j-1/2}$ *are the midpoints of the segments* $[x_{i-1}, x_i]$ *and* $[y_{j-1}, y_j]$.

Proof. Since (4.8a) and (4.8b) are similar, we shall prove only bound (4.8a). By Theorem 3.1 and (1.5), (2.1), (1.4), the second inequality (4.8a) follows from the bound on $|D_x^- e_{ij}^N|$, so we need prove only the first bound (4.8a).

By Theorem 4.1, we have

$$\text{(4.9)}\qquad D_x^- e_{ij}^N = H D_x^- \Phi(x_i, y_j) + \left(\frac{h}{\varepsilon}\right) D_x^- \Psi(x_i, y_j) + D_x^- \mathcal{R}_{ij}^N.$$

First, using (4.5), (2.1), (1.4), we get estimate (4.8a) for $|D_x^- \mathcal{R}_{ij}^N|$.

Further in this proof and later throughout the paper, we shall use the inequalities

$$\text{(4.10)}\qquad \begin{aligned} \varepsilon^{-1}(1-x)e^{-b_1(1,y)(1-x)/\varepsilon} &\le Ce^{-\beta(1-x)/\varepsilon}, \\ \varepsilon^{-1}(1-y)e^{-b_2(x,1)(1-y)/\varepsilon} &\le Ce^{-\beta(1-y)/\varepsilon}. \end{aligned}$$

Define

$$\hat{\Phi}(x,y) = \varphi(x,y) - \varphi(x,1)e^{-b_2(x,1)(1-y)/\varepsilon}, \qquad \hat{\Psi}(x,y) = \frac{\varepsilon^{-1}(1-y)b_2^2(x,1)w_0(x,y)}{2}.$$

Since $|D_x^- \tilde{\Phi}_{ij}| \le \max_{\bar{\Omega}} |\hat{\Phi}_x|$, then by (4.2) we have $|D_x^- \hat{\Phi}_{ij}| \le C$. This implies estimate (4.8a) also for $|H D_x^- \hat{\Phi}_{ij}|$.

Similarly, we get $|D_x^- \hat{\Psi}_{ij}| \le C$. Note that in $\bar{\Omega}_0 \cup \Omega_1$ we have the sharper estimate $|D_x^- \hat{\Psi}_{ij}| \le CN^{-2}$, since (3.3) and (1.7) imply that $\max_{\bar{\Omega}_0 \cup \Omega_1} |\hat{\Psi}_x| \le CN^{-2}$. Hence, $|(h/\varepsilon) D_x^- \hat{\Phi}_{ij}|$ also satisfies inequality (4.8a).

We proceed similarly with $D_x^-(\Phi - \hat{\Phi})_{ij}$ and $D_x^-(\Psi - \hat{\Psi})_{ij}$. Using (4.3), (4.4), (3.3), we obtain $|D_x^-(\Phi - \hat{\Phi})_{ij}| + |D_x^-(\Psi - \hat{\Psi})_{ij}| \le 1/\varepsilon$. However, in $\bar{\Omega}_0 \cup \Omega_2$ we need sharper estimates. By (2.1), we have $|D_x^-(\Phi - \hat{\Phi})_{ij}| \le (2/H) \max_{\bar{\Omega}_0 \cup \Omega_2} |\Phi - \hat{\Phi}|$. Combining this with (3.3), (1.7), we get $|D_x^-(\Phi - \hat{\Phi})_{ij}| \le CN^{-1}$ in $\bar{\Omega}_0 \cup \Omega_2$. Similarly, $|D_x^-(\Psi - \hat{\Psi})_{ij}| \le CN^{-1}$ in $\bar{\Omega}_0 \cup \Omega_2$. Hence, $|H D_x^-(\Phi - \hat{\Phi})_{ij}|$ and $|(h/\varepsilon) D_x^-(\Psi - \hat{\Psi})_{ij}|$ also satisfy inequality (4.8a).

Combining the estimates that we derived for the right-hand terms in (4.9), we obtain the first bound (4.8a). This completes the proof. □

5. Proof of Theorem 4.1.

5.1. Discrete maximum/comparison principle and its corollaries. In this subsection we state the comparison lemmas that will be used to prove Theorem 4.1.

It is well known that the upwind scheme (1.3) satisfies the *discrete maximum/comparison principle*, which implies the following comparison lemma.

Lemma 5.1. *Let* $\tilde{\Omega}^N$ *be a connected submesh of* Ω^N.

(i) *If* $|L^N v_{ij}| \le L^N B_{ij}$ *in* $\tilde{\Omega}^N$ *and* $|v_{ij}| \le B_{ij}$ *on* $\partial\tilde{\Omega}^N$, *then* $|v_{ij}| \le B_{ij}$ *in* $\tilde{\Omega}^N$.

(ii) *If* $v_{ij} = 0$ *on* $\partial\tilde{\Omega}^N$, *then* $\|v\|_{\tilde{\Omega}^N} \le \beta^{-1}\|L^N v\|_{\tilde{\Omega}^N}$.

(iii) *If* $L^N v_{ij} = 0$ *in* $\tilde{\Omega}^N$, *then* $\|v\|_{\tilde{\Omega}^N} \le \|v\|_{\partial\tilde{\Omega}^N}$.

Proof. See [11, Chapter IV] and [8, Chapter 13]. □

The following three lemmas follow from Lemma 5.1(i). We defer their proofs to Appendix A.

LEMMA 5.2. *If $L^N v_{ij} = 0$ in Ω^N and $|v_{ij}| \le e^{-\beta(1-x_i)/\varepsilon}$ on $\partial\Omega^N$, then $|v_{ij}| \le CN^{-2}$ for $i \le N/2$.*

LEMMA 5.3. (i) *If $|L^N v_{ij}| \le e^{-\beta(1-x_i)/\varepsilon}$ in Ω^N and $v_{ij} = 0$ on $\partial\Omega^N$, then $|v_{ij}| \le CN^{-1}$ in $\bar\Omega^N$, and $|v_{ij}| \le CN^{-2}$ for $i \le N/2$.*

(ii) *If $|L^N v_{ij}| \le \mathcal{E}_{ij}(\varepsilon^{-1}e^{-\beta(1-x_i)/\varepsilon}, i > N/2;\ 0)$ in Ω^N and $v_{ij} = 0$ on $\partial\Omega^N$, then $|v_{ij}| \le C\mathcal{E}_{ij}(N^{-1}, i \le N/2;\ 1)$.*

(iii) *Let $|L^N v_{ij}| \le \varepsilon^{-1}e^{-\beta(1-x_i)/\varepsilon}$ for $i > N/2$, where v_{ij} is defined for $i = N/2, \dots, N$, $j = 0, \dots, N$, and $v_{ij} = 0$ on the boundary of this submesh, i.e., if $i = N/2, N$ or $j = 0, N$. Then $|v_{ij}| \le C$ for $i \ge N/2$.*

Remark 5.1. Clearly, the analogues of Lemmas 5.2 and 5.3, with x, i replaced by y, j, also hold true.

LEMMA 5.4. *If $|L^N v_{ij}| \le \mathcal{E}_{ij}(0, \bar\Omega_0;\ 1)$ and $v_{ij} = 0$ on $\partial\Omega^N$, then $|v_{ij}| \le C\varepsilon\, \mathcal{E}_{ij}(1, \bar\Omega_0;\ \ln N) \le CN^{-1}\, \mathcal{E}_{ij}(1, \bar\Omega_0;\ \ln N)$.*

5.2. Error and truncation error. We shall derive a representation of the error

$$e_{ij}^N := u_{ij}^N - u(x_i, y_j).$$

One can easily check that $L^N e_{ij}^N = -L^N u_{ij} + (Lu)_{ij} =: r_{ij}[u]$. Here for the truncation error we have used the notation

$$r_{ij}[v] := -L^N v_{ij} + (Lv)_{ij}. \tag{5.1}$$

Recalling the decomposition of u given by Theorem 3.1, we have

$$L^N e^N = r[u_0 + v_0 + w_0 + z_0] + \varepsilon r[u_1 + v_1 + w_1 + z_1] + \varepsilon^2 r[R]. \tag{5.2}$$

Furthermore, we study the contributions to the error of each of the right-hand side terms separately.

In this section and the related appendices we shall use the *notation*

$$\begin{aligned} L_1 v &:= -\varepsilon v_{xx} + b_1(x,y)v_x, & L_2 v &:= -\varepsilon v_{yy} + b_2(x,y)v_y,\\ L_1^N v &:= -\varepsilon\delta_x^2 v + b_1(x,y)D_x^- v, & L_2^N v &:= -\varepsilon\delta_y^2 v + b_2(x,y)D_y^- v, \end{aligned} \tag{5.3}$$

$$r_{1,ij}[v] := -L_1^N v_{ij} + (L_1 v)_{ij}, \qquad r_{2,ij}[v] := -L_2^N v_{ij} + (L_2 v)_{ij}, \tag{5.4}$$

so that $L = L_1 + L_2 + c$, $L^N = L_1^N + L_2^N + c$, and $r[v] = r_1[v] + r_2[v]$.

5.3. Contribution of $\varepsilon^2 r[R]$ in the maximum norm. The contribution to the error of this component of the right-hand side in (5.2) is described by the following result.

LEMMA 5.5. *If $L^N w_{ij} = r_{ij}[R]$ in Ω^N, where R is from (3.5), and $w_{ij} = 0$ on $\partial\Omega^N$, then $\|w\| \le C\varepsilon^{-1}N^{-1}$.*

Proof. Obviously,

$$\|w\| \le \|w + R\| + \|R\|. \tag{5.5}$$

Since $r_{ij}[R] = -L^N R_{ij} + (LR)_{ij}$, we have $L^N[w + R]_{ij} = (LR)_{ij}$. Recalling (3.5) and applying Lemmas 5.1(ii), 5.3(i), and 5.1(iii), we get

$$\|w + R\| \le C(1 + \varepsilon^{-1}N^{-1}) + \max_{\partial\Omega^N} |R_{ij}|.$$

Combining this with (5.5), (3.5) and observing that (1.5) implies $1 \le C\varepsilon^{-1}N^{-1}$, we complete the proof. $\square$

Remark 5.2. The proof of this lemma does not use any estimates of the derivatives of R and thus allows us to use a decomposition of the solution requiring fewer compatibility conditions; see Remark 3.3.

Now, by (1.5), we have the following.

COROLLARY 5.6. *If $L^N v_{ij} = \varepsilon^2 r_{ij}[R]$ in Ω^N, where R is from* (3.5), *and $v_{ij} = 0$ on $\partial\Omega^N$, then $|v| \le CN^{-2}$.*

5.4. Contribution of $r[u_0]$. The contribution to the error of this component of the right-hand side in (5.2) is described by the following two lemmas.

LEMMA 5.7. (i) *The reduced problem* (4.7) *has a solution $\varphi(x,y) \in C^{1,1}(\bar\Omega)$ such that $\|\varphi\|_{1,1} \le C$, and thus $\Phi(x,y)$ from* (4.3) *using this function φ is also in $C^{1,1}(\bar\Omega)$.*

(ii) *If w satisfies*

$$L^N w_{ij} = \frac{\big(b_1 u_{0,xx} + b_2 u_{0,yy}\big)_{ij}}{2} \text{ in } \Omega^N, \quad w_{ij} = 0 \quad \text{on } \partial\Omega^N, \tag{5.6}$$

then

$$|w_{ij} - \Phi(x_i, y_j)| \le CN^{-1}\, \mathcal{E}_{ij}(1, \bar\Omega_0;\ \ln N).$$

Proof. (i) Note that φ is the solution of the reduced problem (4.7) with the right-hand side $\big(b_1 u_{0,xx} + b_2 u_{0,yy}\big)/2$, which, by (3.2), is in $C^{1,1}(\bar\Omega)$ and vanishes at the corner $(0,0)$, i.e., satisfies the compatibility condition [7, (4.8a)]. Hence, applying [7, Theorem 4.1], we have $\varphi(x,y) \in C^{1,1}(\bar\Omega)$. This implies that $\Phi(x,y) \in C^{1,1}(\bar\Omega)$.

(ii) This part of the proof is given in Appendix B. $\square$

LEMMA 5.8. *If $L^N v_{ij} = r_{ij}[u_0]$ in Ω^N, where u_0 is from Theorem* 3.1, *and $v_{ij} = 0$ on $\partial\Omega^N$, then*

$$|v_{ij} - H\Phi(x_i, y_j)| \le CN^{-2}\, \mathcal{E}_{ij}(1, \bar\Omega_0;\ \ln N).$$

Proof. Recalling (5.1) and using Taylor series expansions and (3.2), we obtain

$$\big|r_{ij}[u_0] - (h_i b_1 u_{0,xx} + h_j b_2 u_{0,yy})_{ij}/2\big| \le C(\varepsilon N^{-1} + N^{-2})\|u_0\|_3 \le CN^{-2}.$$

Furthermore, since $h_i = h_j = H$ for $(x_i, y_j) \in \bar\Omega_0$, we have

$$\big|r_{ij}[u_0] - H\,(b_1 u_{0,xx} + b_2 u_{0,yy})_{ij}\big| \le C[N^{-1}\, \mathcal{E}_{ij}(0, \bar\Omega_0;\ 1) + N^{-2}]. \tag{5.7}$$

Combining this with $L^N(v_{ij} - Hw_{ij}) = r_{ij}[u_0] - H(b_1 u_{0,xx} + b_2 u_{0,yy})_{ij}$, where w_{ij} is from Lemma 5.7, we get

$$\big|L^N(v_{ij} - Hw_{ij})\big| \le C[N^{-1}\, \mathcal{E}_{ij}(0, \bar\Omega_0;\ 1) + N^{-2}].$$

Now, applying Lemmas 5.4 and 5.1(ii), we have

$$|v_{ij} - Hw_{ij}| \le CN^{-2}\, \mathcal{E}_{ij}(1, \bar\Omega_0;\ \ln N).$$

By Lemma 5.7, this yields the statement of the lemma. $\square$

5.5. Contribution of $r[v_0 + w_0 + z_0]$. Now we shall study the contribution to the error of the component $r[v_0 + w_0 + z_0]$ of the right-hand side in (5.2).

The main result of this subsection is the following.

LEMMA 5.9. *If $L^N v_{ij} = r_{ij}[v_0 + w_0 + z_0]$ in Ω^N, where v_0, w_0, z_0 are from Theorem* 3.1 *and $v_{ij} = 0$ on $\partial\Omega^N$, then*

$$\left|v_{ij} - \left(\frac{h}{\varepsilon}\right) \Psi(x_i, y_j)\right| \leq CN^{-2}\, \mathcal{E}_{ij}(1, \bar{\Omega}_0;\ \ln^2 N),$$

where Ψ is from (4.4).

The whole subsection is devoted to the *proof* of this lemma.

Decompose Ψ from (4.4) as $\Psi = \Psi_1 + \Psi_2 + \tilde{\Psi}_1 + \tilde{\Psi}_2$, where

$$\begin{aligned} \Psi_1(x,y) &:= \frac{\varepsilon^{-1}(1-x)b_1^2(1,y)v_0}{2}, & \tilde{\Psi}_1(x,y) &:= \frac{\varepsilon^{-1}(1-x)b_1^2(1,1)z_0}{2}, \\ \Psi_2(x,y) &:= \frac{\varepsilon^{-1}(1-y)b_2^2(x,1)w_0}{2}, & \tilde{\Psi}_2(x,y) &:= \frac{\varepsilon^{-1}(1-y)b_2^2(1,1)z_0}{2}. \end{aligned} \tag{5.8}$$

Regarding the components of this decomposition, see Remark 4.4.

Now decompose v from Lemma 5.9 as $v_{ij} = V_{ij} + W_{ij} + Z_{ij}$, where

$$L^N V = r[v_0] \text{ in } \Omega^N, \qquad \left|V - \left(\frac{h}{\varepsilon}\right)\Psi_1\right| \leq CN^{-2} \text{ on } \partial\Omega^N, \tag{5.9a}$$

$$L^N W = r[w_0] \text{ in } \Omega^N, \qquad \left|W - \left(\frac{h}{\varepsilon}\right)\Psi_2\right| \leq CN^{-2} \text{ on } \partial\Omega^N, \tag{5.9b}$$

$$L^N Z = r[z_0] \text{ in } \Omega^N, \qquad \left|Z - \left(\frac{h}{\varepsilon}\right)(\tilde{\Psi}_1 + \tilde{\Psi}_2)\right| \leq CN^{-2} \text{ on } \partial\Omega^N. \tag{5.9c}$$

Note that such a decomposition of the boundary condition $v_{ij} = 0$ on $\partial\Omega^N$ is possible. Indeed, if $x = 1$ or $y = 1$, we have $\Psi_1(x,y) + \tilde{\Psi}_1(x,y) = \Psi_2(x,y) + \tilde{\Psi}_2(x,y) = 0$, while if $x = 0$ or $y = 0$, we have $|\Psi_1| + |\Psi_2| + |\tilde{\Psi}_1| + |\tilde{\Psi}_2| \leq C\varepsilon^{-2} \leq CN^{-2}$. Hence, $|\Psi_1 + \Psi_2 + \tilde{\Psi}_1 + \tilde{\Psi}_2| \leq CN^{-2}$ on $\partial\Omega^N$.

Since $(x_i, y_j) \in \bar{\Omega}_0$ if both $i, j \leq N/2$, Lemma 5.9 follows from (5.10):

$$\left|V_{ij} - \left(\frac{h}{\varepsilon}\right)\Psi_1(x_i, y_j)\right| \leq CN^{-2}\, \mathcal{E}_{ij}\left(\ln^2 N, i > \frac{N}{2};\ 1\right), \tag{5.10a}$$

$$\left|W_{ij} - \left(\frac{h}{\varepsilon}\right)\Psi_2(x_i, y_j)\right| \leq CN^{-2}\, \mathcal{E}_{ij}\left(\ln^2 N, j > \frac{N}{2};\ 1\right), \tag{5.10b}$$

$$\left|Z_{ij} - \left(\frac{h}{\varepsilon}\right)[\tilde{\Psi}_1(x_i, y_j) + \tilde{\Psi}_2(x_i, y_j)]\right| \leq CN^{-2}\, \mathcal{E}_{ij}]\left(\ln^2 N,\ i, j > \frac{N}{2};\ 1\right). \tag{5.10c}$$

Further, we shall prove that (5.10) follows from the following two lemmas.

LEMMA 5.10. *For V, W, Z from* (5.9) *we have*

$$|V_{ij}| \leq CN^{-2} \quad \textit{for } i \leq \frac{N}{2}, \tag{5.11a}$$

$$|W_{ij}| \leq CN^{-2} \quad \textit{for } j \leq \frac{N}{2}, \tag{5.11b}$$

$$|Z_{ij}| \leq CN^{-2} \quad \textit{if} \quad i \leq \frac{N}{2} \quad \textit{or} \quad j \leq \frac{N}{2}. \tag{5.11c}$$

Proof. We defer the proof of this lemma to Appendix C. □

Define the auxiliary discrete functions $\psi_{1,ij}$ for $i = N/2,\dots,N$, $j = 0,\dots,N$; $\psi_{2,ij}$ for $i = 0,\dots,N$, $j = N/2,\dots,N$; and $\tilde\psi_{1,ij}$, $\tilde\psi_{2,ij}$ for $i, j = N/2,\dots,N$ as follows. Let them satisfy the discrete equations

$$(5.12a)\qquad (L^N\psi_1)_{ij} = \frac{\varepsilon(b_1 v_{0,xx})_{ij}}{2} \quad \text{for } i = \frac{N}{2}+1,\dots,N-1,\ j = 1,\dots,N-1,$$

$$(5.12b)\qquad (L^N\psi_2)_{ij} = \frac{\varepsilon(b_2 w_{0,yy})_{ij}}{2} \quad \text{for } i = 1,\dots,N-1,\ j = \frac{N}{2}+1,\dots,N-1,$$

$$(5.12c)\qquad (L^N\tilde\psi_1)_{ij} = \frac{\varepsilon(b_1 z_{0,xx})_{ij}}{2} \quad \text{for } i,j = \frac{N}{2}+1,\dots,N-1,$$

$$(5.12d)\qquad (L^N\tilde\psi_2)_{ij} = \frac{\varepsilon(b_2 z_{0,yy})_{ij}}{2} \quad \text{for } i,j = \frac{N}{2}+1,\dots,N-1,$$

and the following conditions on the boundaries of the submeshes, where they are defined:

$$(5.13a)\qquad \psi_{1,ij} = \Psi_1(x_i,y_j) \quad \text{if } \ i = \frac{N}{2},\, N \quad \text{or } j = 0,\, N,$$

$$(5.13b)\qquad \psi_{2,ij} = \Psi_2(x_i,y_j) \quad \text{if } \ i = 0,\, N \quad \text{or } j = \frac{N}{2},\, N,$$

$$(5.13c)\qquad \tilde\psi_{k,ij} = \tilde\Psi_k(x_i,y_j) \quad \text{if } \ i = \frac{N}{2},\, N \quad \text{or } j = \frac{N}{2},\, N, \qquad k = 1,2.$$

Lemma 5.11. *For ψ_1, ψ_2, $\tilde\psi_1$, $\tilde\psi_1$ defined by* (5.12), (5.13) *and Ψ_1, Ψ_2, $\tilde\Psi_1$, $\tilde\Psi_1$ from* (5.8) *we have*

$$(5.14a)\qquad |\psi_{1,ij} - \Psi_1(x_i,y_j)| \le C\left(\frac{h}{\varepsilon}\right) \quad \textit{for } i = \frac{N}{2}+1,\dots,N,$$

$$(5.14b)\qquad |\psi_{2,ij} - \Psi_2(x_i,y_j)| \le C\left(\frac{h}{\varepsilon}\right) \quad \textit{for } j = \frac{N}{2}+1,\dots,N,$$

$$(5.14c)\qquad |\tilde\psi_{k,ij} - \tilde\Psi_k(x_i,y_j)| \le C\left(\frac{h}{\varepsilon}\right) \quad \textit{for } i,j = \frac{N}{2}+1,\dots,N, \quad k = 1,2.$$

Proof. This lemma is proved in Appendix C. □

Lemma 5.12. *Estimates* (5.10) *follow from Lemmas* 5.10 *and* 5.11.

Proof. To get the statement of this Lemma, it suffices to prove that

(a) estimate (5.10a) follows from (5.11a) and (5.14a),

(b) estimate (5.10b) follows from (5.11b) and (5.14b),

(c) estimate (5.10c) follows from (5.11c) and (5.14c).

(a) By (5.8), (3.3), (4.10), (1.7), we have $|\Psi_1(x_i,y_j)| \le CN^{-2}$ for $i \le N/2$. Combining this with (5.11a), we get (5.10a) for $i \le N/2$. Since we have (5.14a), then to obtain (5.10a) for $i > N/2$, it suffices to prove that

$$(5.15)\qquad \left|V_{ij} - \left(\frac{h}{\varepsilon}\right)\psi_{1,ij}\right| \le C\left(\frac{h}{\varepsilon}\right)^2 \quad \text{for } i > \frac{N}{2},$$

where ψ_1 is defined by (5.12a), (5.13a). Recalling the notation (5.4) and using Taylor series expansions and (3.2), (3.3), for $i > N/2$ we get

$$\left| r_{1,ij}[v_0] - \frac{h(b_1 v_{0,xx})_{ij}}{2} \right| \le Ch^2 \varepsilon^{-3} e^{-\beta(1-x_{i+1})/\varepsilon}, \tag{5.16}$$

$$\big| r_{2,ij}[v_0] \big| \le (2\varepsilon + b_{2,ij} N^{-1}) \max_{y\in[0,1]} |v_{0,yy}(x_i, y)| \le CN^{-1} e^{-\beta(1-x_i)/\varepsilon}.$$

Note that, by (1.7), (1.5), we have $N^{-1} \le Ch^2\varepsilon^{-3}$ and $e^{-\beta(1-x_{i+1})/\varepsilon} \le Ce^{-\beta(1-x_i)/\varepsilon}$, while $L^N[V - (h/\varepsilon)\psi_1] = r_1[v_0] + r_2[v_0] - hb_1 v_{0,xx}/2$. Hence,

$$\left| L^N \left[V_{ij} - \left(\frac{h}{\varepsilon}\right) \psi_{1,ij} \right] \right| \le C \left(\frac{h}{\varepsilon}\right)^2 \varepsilon^{-1} e^{-\beta(1-x_i)/\varepsilon} \quad \text{for } i > \frac{N}{2}.$$

Note that (5.9a), (5.13a) imply $|V - (h/\varepsilon)\psi_1| \le CN^{-2}$ on $\partial\Omega^N$, while (5.10a), (5.13a) imply $|V_{ij} - (h/\varepsilon)\psi_{1,ij}| = |V_{ij} - (h/\varepsilon)\Psi_1(x_i, y_j)| \le CN^{-2}$ for $i = N/2$. Now, applying Lemmas 5.3(iii) and 5.1(iii), we obtain (5.15). This completes part (a) of the proof.

(b) This part of the proof is analogous to part (a).

(c) Since this part of the proof is similar to part (a), we skip certain details. By (5.8), (3.3), (4.10), (1.7), we have $|\tilde\Psi_1(x_i, y_j)| + |\tilde\Psi_2(x_i, y_j)| \le CN^{-2}$ if $i \le N/2$ or $j \le N/2$. Combining this with (5.11c), we get (5.10c) if $i \le N/2$ or $j \le N/2$. Since we have (5.14c), then, to obtain (5.10c) for $i, j > N/2$, it suffices to prove that

$$\left| Z_{ij} - \left(\frac{h}{\varepsilon}\right) (\tilde\psi_{1,ij} + \tilde\psi_{2,ij}) \right| \le C \left(\frac{h}{\varepsilon}\right)^2 \quad \text{for } i, j > \frac{N}{2}. \tag{5.17}$$

Note that $L^N[Z - (h/\varepsilon)(\tilde\psi_1 + \tilde\psi_2)] = (r_1[z_0] - hb_1 z_{0,xx}/2) + (r_2[z_0] - hb_2 z_{0,yy}/2)$. Hence, using Taylor series expansions and (3.2), (3.3), for $i, j > N/2$ we get

$$\left| \left(r_1[z_0] - \frac{hb_1 z_{0,xx}}{2} + r_2[z_0] - \frac{hb_2 z_{0,yy}}{2} \right)_{ij} \right| \le Ch^2 \varepsilon^{-3} (e^{-\beta(1-x_i)/\varepsilon} + e^{-\beta(1-y_j)/\varepsilon}), \tag{5.18}$$

which yields

$$\left| L^N \left[Z_{ij} - \left(\frac{h}{\varepsilon}\right) (\tilde\psi_{1,ij} + \tilde\psi_{2,ij}) \right] \right| \le C \left(\frac{h}{\varepsilon}\right)^2 \varepsilon^{-1} (e^{-\beta(1-x_i)/\varepsilon} + e^{-\beta(1-y_j)/\varepsilon}).$$

Combining this with the boundary conditions from (5.9c), (5.10c), (5.13c) and applying Lemmas 5.3(iii) and 5.1(iii), we obtain (5.17). This completes the proof. □

Proof of Lemma 5.9. By Lemmas 5.10, 5.11, and 5.12, we have (5.10), which yields the statement of Lemma 5.9. □

5.6. Contribution of $\varepsilon r[u_1 + v_1 + w_1 + z_1]$.

The contribution to the error of this component of the right-hand side in (5.2) is described by the following lemma.

LEMMA 5.13. *If* $L^N v_{ij} = \varepsilon r_{ij}[u_1 + v_1 + w_1 + z_1]$ *in* Ω^N, *where* u_1, v_1, w_1, z_1 *are from Theorem* 3.1, *and* $v_{ij} = 0$ *on* $\partial\Omega^N$, *then*

$$|v_{ij}| \le CN^{-2}\, \mathcal{E}_{ij}(1, \bar\Omega_0;\, \ln N).$$

Proof. Since this result is very close to the well-known theorem by Shishkin [13, Theorem 2.3], [8, Theorem 13.2], while the argument is standard, we shall only sketch the proof. Note that it simplifies the argument that the truncation error in the right-hand side is multiplied by ε. By (3.2), (1.5), we have $|\varepsilon r[u_1]| \le C\varepsilon N^{-1} \le CN^{-2}$. By (3.4), (1.7), we get $|\varepsilon r_{1,ij}[v_1 + z_1]| \le C(h/\varepsilon)e^{-\beta(1-x_i)/\varepsilon}$ for $i > N/2$, and $|\varepsilon r_{1,ij}[v_1 + z_1]| \le Ce^{-\beta(1-x_{i+1})/\varepsilon} \le CN^{-2}$ for $i \le N/2$. The term $\varepsilon r_2[w_1 + z_1]$ is estimated similarly. We have to be careful with Taylor series expansions of v_1 and w_1 since $\frac{\partial^k}{\partial x^k}v_1$ and $\frac{\partial^k}{\partial y^k}w_1$ are generally in $C^{1,1}(\bar{\Omega})$. By (3.4a) and Remark 3.1, we estimate as follows:

$$\begin{aligned}
\big|r_{2,ij}[v_1]\big| &\le C\big\|v_1(x_i,\cdot)\big\|_{1,1,[0,1]} \le Ce^{-\beta(1-x_i)/\varepsilon},\\
\big|r_{1,ij}[w_1]\big| &\le C\big\|w_1(\cdot,y_j)\big\|_{1,1,[0,1]} \le Ce^{-\beta(1-y_j)/\varepsilon}.
\end{aligned}$$

Combining our estimates of all the components of the right-hand side and applying Lemmas 5.1(ii) and 5.3(i),(ii), we get the statement of the lemma. □

5.7. Proof of Theorem 4.1. The statement of the theorem is obtained by recalling (5.1), (5.2) and combining Corollary 5.6 and Lemmas 5.8, 5.9, 5.13. □

6. Numerical results. In this section we present numerical results illustrating our estimates for the Richardson extrapolation technique (Corollary 4.2) and on the errors in approximating the derivatives (Corollary 4.3).

We study the performance of the upwind scheme and the Richardson extrapolation technique when applied to the test problem from [6] in which $b_1 = 2$, $b_2 = 3$, $c = 1$,

$$u(x,y) = 2\sin x\,(1 - e^{-2(1-x)/\varepsilon})\,y^2(1 - e^{-3(1-y)/\varepsilon}),$$

and the right-hand side f is chosen so that (1.1) is satisfied. This problem was solved numerically using the upwind scheme (1.3) on the tensor-product piecewise-uniform Shishkin mesh from Remark 1.1 with $\beta_1 = 1.9$, $\beta_2 = 2.9$.

In Table 6.1 we present the errors before and after the Richardson extrapolation. The odd rows contain the maximum nodal errors $e^N := \|u^N_{ij} - u(x_i, y_j)\|$ in the specified subdomains of $\bar{\Omega}$, while the even rows contain the rates of convergence computed by the standard formula $r(e^N) = \log_2(e^N/e^{2N})$. Clearly, the Richardson extrapolation technique decreases the nodal errors and increases the rates of convergence. Note that the errors are very similar for $\varepsilon = 10^{-6}$ and $\varepsilon = 10^{-8}$, which confirms that our estimates are ε-uniform. The rates of convergence are slightly worse than predicted by Corollary 4.2. However, since our rates of convergence are consistent with those for the analogous one-dimensional problems [9, 4], we expect the rates of convergence to increase as N increases, similarly to [9, 4].

Tables 6.2 and 6.3 are clear illustrations of Corollary 4.2. In these tables we present the maximum nodal errors in approximating the derivatives and their rates of convergence computed as in Table 6.1.

In summary, our numerical results confirm our theoretical results.

Appendix A. Proof of Lemmas 5.2, 5.3, and 5.4 from subsection 5.1. If the conditions of Lemma 5.1(i) are satisfied, we say that B_{ij} is a *barrier function* for v_{ij}. Define the auxiliary discrete functions

$$B_i := \begin{cases} 2\left(1+\dfrac{\alpha h}{\varepsilon}\right)^{-N/2}\left(1+\dfrac{\alpha H}{\varepsilon}\right)^{-(N/2-i)}, & i = 0,\dots,\dfrac{N}{2}, \\ \left(1+\dfrac{\alpha h}{\varepsilon}\right)^{-(N-i)} + \left(1+\dfrac{\alpha h}{\varepsilon}\right)^{-N/2}, & i = \dfrac{N}{2},\dots,N, \end{cases} \tag{A.1}$$

$$\bar B_i := \begin{cases} 2\left(\dfrac{\varepsilon}{\beta}\right)\left(1+\dfrac{\beta H}{\varepsilon}\right)^{-(N/2-i)}, & i = 0,\dots,\dfrac{N}{2}, \\ 2\left(\dfrac{\varepsilon}{\beta}\right) + \sigma - (N-i)h, & i = \dfrac{N}{2},\dots,N. \end{cases} \tag{A.2}$$

It is assumed here that $\{x_i\}_{i=0}^N$ are the nodes of the mesh (1.4), (1.6). Furthermore, we shall use B_i and $\bar B_i$ normalized in different manners as discrete barrier functions.

Lemma A.1. *For any positive α the discrete function B_i from* (A.1) *is such that* $e^{-\alpha(1-x_i)/\varepsilon} < B_i \le C\mathcal{E}(N^{-2\alpha/\beta}, i \le N/2;\ 1)$ *and* $(-\varepsilon\delta_x^2 + \alpha D_x^-)B_i \ge 0$.

Proof. The lower bound for B_i follows from the inequality $e^{-t} \le (1+t)^{-1}$, which holds true for $t \ge 0$, with $t := \alpha h_i/\varepsilon$. The upper bound for B_i is obvious for $i > N/2$. For $i \le N/2$, it follows from $(1+t)^{-1} \le e^{-t+t^2}$, which we have for $t > 0$. Setting $t := \alpha h/\varepsilon$, we get $B_i \le 2(1+\alpha h/\varepsilon)^{-N/2} \le 2e^{-\alpha\sigma/\varepsilon + (\alpha h/\varepsilon)^2 N/2}$. Further, (1.7) implies $e^{-\alpha\sigma/\varepsilon} \le N^{-2\alpha/\beta}$ and $e^{(\alpha h/\varepsilon)^2 N/2} \le e$. This proves the upper bound for B_i.

The second inequality is checked using (1.4) and (2.1). In fact, $(-\varepsilon\delta_x^2+\alpha D_x^-)B_i = 0$ for $i \neq N/2$ and $(-\varepsilon\delta_x^2+\alpha D_x^-)B_i > 0$ for $i = N/2$. ∎

Proof of Lemma 5.2. Use B_i from Lemma A.1 with $\alpha := \beta$ as a barrier function for v_{ij}. Note that $L^N B_i \geq (b_{1,ij} - \beta)D_x^- B_i \geq 0$. ∎

Lemma A.2. *The discrete function B_i from* (A.1) *with $\alpha := \beta/2$ is such that $B_i \leq C\mathcal{E}(N^{-1}, i \leq N/2;\ 1)$ and $L^N B_i \geq Ce^{-\beta(1-x_i)/\varepsilon}\mathcal{E}(N, i \leq N/2;\ \varepsilon^{-1})$.*

Proof. This lemma follows from Lemma A.1. The first property is obvious. To prove the second, note that $L^N B_i \geq (b_{1,ij} - \beta/2)D_x^- B_i \geq (\beta/2)D_x^- B_i$. By (2.1), (1.5), (1.4), calculations show that $D_x^- B_i = (h_i + 2\varepsilon/\beta)^{-1}B_i$ and $(h_i + 2\varepsilon/\beta)^{-1} \geq C\mathcal{E}(N, i \leq N/2;\ \varepsilon^{-1})$. Recalling that $B_i > e^{-(\beta/2)(1-x_i/\varepsilon)} \geq e^{-\beta(1-x_i/\varepsilon)}$, we complete the proof. ∎

Proof of Lemma 5.3. This lemma follows from Lemma A.2.

(i) By (1.5), use $CN^{-1}B_i$ as a barrier function for v_{ij}.

(ii), (iii) Use CB_i as a barrier function for v_{ij}. ∎

Proof of Lemma 5.4. By (1.4), (1.6), for the discrete function $\bar{B}_i$ defined in (A.2) we have $0 < \bar{B}_i \leq C\varepsilon\ \mathcal{E}_{ij}(1, i \leq N/2;\ \ln N)$. Combining this with the analogous estimate for $\bar{B}_j$ and (1.5), we get

$$0 < \bar{B}_i + \bar{B}_j \leq C\varepsilon\ \mathcal{E}_{ij}(1, \bar{\Omega}_0;\ \ln N) \leq CN^{-1}\ \mathcal{E}_{ij}(1, \bar{\Omega}_0;\ \ln N).$$

By (2.1), (1.4), calculations show that $D_x^-\bar{B}_i = 1$ for $i > N/2$, while $D_x^-\bar{B}_i \geq 0$ for $i \leq N/2$. In particular, $D_x^-\bar{B}_{N/2} = 2(1 + \beta H/\varepsilon)^{-1}$. Further, $L^N\bar{B}_i \geq b_{1,ij} \geq \beta$ for $i > N/2$, while $L^N\bar{B}_i \geq (-\varepsilon\delta_x^2 + \beta D_x^-)\bar{B}_i = 0$ for $i < N/2$. For $i = N/2$ we also have $L^N\bar{B}_i \geq 0$, which follows from

$$L^N\bar{B}_i \geq \big(-\varepsilon\delta_x^2 + \beta D_x^-\big)\bar{B}_i = \big[\beta + 2\varepsilon(h+H)^{-1}\big]D_x^-\bar{B}_i - \big[2\varepsilon(h+H)^{-1}\big]D_x^-\bar{B}_{i+1},$$

where $i = N/2$. These imply that $L^N\bar{B}_i \geq \beta\ \mathcal{E}_{ij}\,(0, i \leq N/2;\ 1)$. Combining this estimate with its analogue for $L^N\bar{B}_j$, we obtain

$$L^N(\bar{B}_i + \bar{B}_j) \geq \beta\ \mathcal{E}_{ij}(0, \bar{\Omega}_0;\ 1).$$

Hence, $(B_i + B_j)/\beta$ is a barrier function for v_{ij}. ∎

Appendix B. Proof of Lemma 5.7(ii).

Proof. Note that (4.3) implies that $\Phi(x,y) = 0$ if $x = 1$ or $y = 1$. Further, $|\Phi(x,y)| \leq C\varepsilon \leq CN^{-1}$ on $\partial\Omega$. Hence,

$$|w_{ij} - \Phi_{ij}| \leq CN^{-1} \quad \text{on } \partial\Omega^N. \tag{B.1}$$

To study $L^N(w-\Phi)$, note that, by (4.7), (5.6), we have $L^N w_{ij} = (b_1\varphi_x + b_2\varphi_y + c\varphi)_{ij}$. Hence

$$L^N(w - \Phi) = (b_1\varphi_x + b_2\varphi_y + c\varphi - L^N\varphi) + L^N(\varphi - \Phi). \tag{B.2}$$

Using Taylor series expansions, (1.5), and (4.2), which was proved in Lemma 5.7(i), we obtain for the first term on the right-hand side that

$$|(b_1\varphi_x + b_2\varphi_y + c\varphi)_{ij} - L^N\varphi_{ij}| \leq C(N^{-1} + \varepsilon)\|\varphi\|_{1,1} \leq CN^{-1}. \tag{B.3}$$

To estimate $L^N(\varphi - \Phi)$, we define

$$\Phi_1(x,y) := \varphi(1,y)e^{-b_1(1,y)(1-x)/\varepsilon}, \qquad \Phi_2(x,y) := \varphi(x,1)e^{-b_2(x,1)(1-y)/\varepsilon},$$
$$\Phi_{12}(x,y) := \varphi(1,1)e^{-b_1(1,1)(1-x)/\varepsilon - b_2(1,1)(1-y)/\varepsilon},$$

so that $\varphi - \Phi = \Phi_1 + \Phi_2 - \Phi_{12}$. Thus, recalling the notation (5.3), we have

$$L^N(\varphi - \Phi) = L_1^N(\Phi_1 - \Phi_{12}) + L_2^N(\Phi_2 - \Phi_{12}) + L_2^N\Phi_1 + L_1^N\Phi_2 + c(\Phi_1 + \Phi_2 - \Phi_{12}). \tag{B.4}$$

For $i \le N/2$, using (1.3), (2.1), (1.4), and (1.7), we obtain

$$|L_1^N(\Phi_1 - \Phi_{12})_{ij}| \le CNe^{-\beta(1-x_{i+1})/\varepsilon} \le CNe^{-\beta(\sigma-h)/\varepsilon} \le CN^{-1}. \tag{B.5}$$

Consider $i > N/2$. First note that

$$-\varepsilon\Phi_{1,xx} + b_1(1,y)\Phi_{1,x} = 0, \qquad -\varepsilon\Phi_{12,xx} + b_1(1,1)\Phi_{12,x} = 0,$$

while the left-hand sides here are slightly different from $L_1\Phi_1$ and $L_1\Phi_{12}$. Hence,

$$L_1^N(\Phi_1 - \Phi_{12})_{ij} = (L_1^N - L_1)(\Phi_1 - \Phi_{12})_{ij} + [b_1(x_i, y_j) - b_1(1, y_j)]\Phi_{1,x}(x_i, y_j) - [b_1(x_i, y_j) - b_1(1,1)]\Phi_{12,x}(x_i, y_j).$$

Using Taylor series expansions to estimate the first term on the right-hand side, and the inequalities $|b_1(x,y) - b_1(1,y)| \le C(1-x)$ and $|b_1(x,y) - b_1(1,1)| \le C[(1-x) + (1-y)]$ combined with (4.10) to estimate the other terms, we obtain

$$|L_1^N(\Phi_1 - \Phi_{12})| \le C(h\varepsilon^{-2}e^{-\beta(1-x_{i+1})/\varepsilon} + e^{-\beta(1-x_i)/\varepsilon}) \le C(h\varepsilon^{-2}e^{\beta h/\varepsilon} + 1)e^{-\beta(1-x_i)/\varepsilon}.$$

Combining this with (B.5) and noting that, by (1.7), (1.5), $h\,\varepsilon^{-2} \ge C$ and $e^{\beta h/\varepsilon} \le C$, we get

$$|L_1^N(\Phi_1 - \Phi_{12})_{ij}| \le C\left[\left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}\left(\varepsilon^{-1}e^{-\beta(1-x_i)/\varepsilon}, i > \frac{N}{2};\ 0\right) + N^{-1}\right]. \tag{B.6}$$

Furthermore, one can easily see that

$$|L_2^N\Phi_{1,ij}| \le C\|\varphi\|_{1,1}e^{-\beta(1-x_i)/\varepsilon} \le Ce^{-\beta(1-x_i)/\varepsilon}. \tag{B.7}$$

Combining (B.4) with (B.6), (B.7), and their analogues for $L_2^N(\Phi_2 - \Phi_{12})$ and $L_1^N\Phi_2$, and then with (B.2), (B.3), we finally get the estimate

$$\begin{aligned}|L^N(w - \Phi)_{ij}| \le C\Bigg[&\left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}\left(\varepsilon^{-1}e^{-\beta(1-x_i)/\varepsilon}, i > \frac{N}{2};\ 0\right)\\ &+ \left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}\left(\varepsilon^{-1}e^{-\beta(1-y_j)/\varepsilon}, j > \frac{N}{2};\ 0\right)\\ &+ e^{-\beta(1-x_i)/\varepsilon} + e^{-\beta(1-y_j)/\varepsilon} + N^{-1}\Bigg].\end{aligned}$$

Combining this with (B.1) and applying Lemmas 5.1(ii),(iii) and 5.3(i),(ii), we obtain

$$\begin{aligned}|w_{ij} - \Phi_{ij}| &\le C\left[\left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}\left(N^{-1}, i \le \frac{N}{2};\ 1\right) + \left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}\left(N^{-1}, j \le \frac{N}{2};\ 1\right) + N^{-1}\right]\\ &\le C\left[\left(\frac{h}{\varepsilon}\right)\mathcal{E}_{ij}(N^{-1}, \bar{\Omega}_0;\ 1) + N^{-1}\right].\end{aligned}$$

By (1.7), this yields the statement of Lemma 5.7(ii). □

Appendix C. Proof of Lemmas 5.10 and 5.11.

Proof of Lemma 5.10. (a) Obviously,

$$|V| \le |V+v_0| + |v_0|, \tag{C.1}$$

where v_0 is defined in (3.3). Since $r[v_0] = -L^N v_0 + Lv_0$, we have $L^N[V+v_0] = Lv_0$. One can easily check that $-\varepsilon v_{0,xx} + b_1(1,y)v_{0,x} = 0$ holds true and implies that $L_1 v_0 = [b_1(x,y) - b_1(1,y)]v_{0,x}$. Combining this with $|b_1(x,y) - b_1(1,y)| \le C(1-x)$ and (4.10), we get $|L_1 v_0| \le Ce^{-\beta(1-x)/\varepsilon}$, while $|(L_2+c)v_0| \le Ce^{-\beta(1-x)/\varepsilon}$. Hence, $|Lv_0| \le Ce^{-\beta(1-x)/\varepsilon}$, which yields

$$\left|L^N[V+v_0]_{ij}\right| \le Ce^{-\beta(1-x_i)/\varepsilon} \quad \text{in } \Omega^N.$$

Combining this with the boundary condition

$$|(V+v_0)_{ij}| \le \left(\frac{h}{\varepsilon}\right)|\Psi_{1,ij}| + CN^{-2} + |v_{0,ij}| \le C(e^{-\beta(1-x_i)/\varepsilon} + N^{-2}) \quad \text{on } \partial\Omega^N,$$

and applying Lemmas 5.1(ii), 5.2, 5.3(i), we get $|(V+v_0)_{ij}| \le CN^{-2}$ for $i \le N/2$. Combining this with (C.1), (3.3), and (1.7), we complete part (a) of the proof.

(b) This part of the proof is analogous to part (a).

(c) Since this part of the proof is similar to part (a), we skip certain details. Again, we have $|Z| \le |Z+z_0| + |z_0|$, where z_0 is defined in (3.3), which implies $L^N[Z+z_0] = Lz_0$. Further, $-\varepsilon z_{0,xx} + b_1(1,1)z_{0,x} = 0$ and $-\varepsilon z_{0,yy} + b_2(1,1)z_0 = 0$ imply $Lz_0 = [b_1(x,y) - b_1(1,1)]z_{0,x} + [b_2(x,y) - b_2(1,1)]z_{0,y} + cz_0$. By (3.3), this yields $|Lz_0| \le Ce^{-\beta[(1-x)+(1-y)]/\varepsilon}$. Hence, $\left|L^N[Z+z_0]_{ij}\right| \le Ce^{-\beta[(1-x_i)+(1-y_j)]/\varepsilon}$ in Ω^N, while $|(Z+z_0)_{ij}| \le C(e^{-\beta[(1-x_i)+(1-y_j)]/\varepsilon} + N^{-2})$ on $\partial\Omega^N$. Applying Lemmas 5.1(ii), 5.2, 5.3(i), we get $|(Z+z_0)_{ij}| \le CN^{-2}$ for $i \le N/2$, and $|(Z+z_0)_{ij}| \le CN^{-2}$ for $j \le N/2$. Combining these two estimates, we proceed similarly to part (a). ∎

Proof of Lemma 5.11. (a) By (5.13a), we have $\psi_1 - \Psi_1 = 0$ on the boundary of the submesh $\{(x_i, y_j) : i = N/2, \dots, N,\ j = 0, \dots, N\}$ where ψ_1 is defined.

In this part of the proof we consider only $i > N/2$. Recalling the notation (5.3), we introduce the following decomposition:

$$L^N(\psi_1 - \Psi_1) = (L^N\psi_1 - L_1\Psi_1) - (L_1^N\Psi_1 - L_1\Psi_1) - (L_2^N + c)\Psi_1.$$

Using Taylor series expansions and (5.8), (3.3), (4.10), we have

$$|L_1^N\Psi_1 - L_1\Psi_1| \le Ch\,\varepsilon^{-2}e^{-\beta(1-x_{i+1})/\varepsilon}, \qquad |(L_2^N + c)\Psi_1| \le Ce^{-\beta(1-x_i)/\varepsilon}.$$

In addition, we claim that

$$|L^N\psi_{1,ij} - (L_1\Psi_1)_{ij}| \le Ce^{-\beta(1-x_i)/\varepsilon}. \tag{C.2}$$

Since (1.5), (1.7) imply that $h\,\varepsilon^{-2} \ge C$ and $e^{-\beta(1-x_{i+1})/\varepsilon} \le Ce^{-\beta(1-x_i)/\varepsilon}$, we have

$$|L^N(\psi_1 - \Psi_1)_{ij}| \le C(h/\varepsilon)\,\varepsilon^{-1}e^{-\beta(1-x_i)/\varepsilon}.$$

Further, by Lemmas 5.1(iii) and 5.3(iii), we get $|\psi_{1,ij} - \Psi_1(x_i, y_j)| \le C(h/\varepsilon + N^{-2})$, which yields statement (a) of the lemma.

To prove our claim (C.2), it suffices to check that

$$\left|\frac{b_1(x,y)\varepsilon v_{0,xx}}{2} - L_1\Psi_1\right| \le Ce^{-\beta(1-x)/\varepsilon}. \tag{C.3}$$

By Remark 4.4, we have $-\varepsilon\Psi_{1,xx} + b_1(1,y)\Psi_{1,x} = b_1(1,y)\varepsilon v_{0,xx}/2$, which implies

$$L_1\Psi_1 = \frac{b_1(x,y)\varepsilon v_{0,xx}}{2} + [b_1(x,y) - b_1(1,y)]\left(\frac{\varepsilon v_{0,xx}}{2} - v_{0,x}\right).$$

Furthermore, using (3.3), (4.10), and $|b_1(x,y) - b_1(1,y)| \le C(1-x)$, we obtain (C.3) and thus complete part (a) of the proof.

(c) This part of the proof is slightly different from part (a); namely, we have to estimate $L_2^N\tilde{\Psi}_1$ more carefully. Note that we consider only $i,j > N/2$ in part (c). Using the notation (5.4), we have $L_2^N\tilde{\Psi}_1 = -r_2[\tilde{\Psi}_1] - L_2\tilde{\Psi}_1$. Further, (5.8), (3.3), (4.10) imply that $|L_2\tilde{\Psi}_1| \le Ce^{-\beta(1-x)/\varepsilon}$ and $|r_{2,ij}[\tilde{\Psi}_1]| \le Ch\,\varepsilon^{-2}e^{-\beta(1-y_{j+1})/\varepsilon}$. Combining these two estimates, we proceed as in part (a).

(b), (d) These parts of the proof are analogous to parts (a) and (c), respectively. ∎

TRUNCATED QUADRATURE RULES OVER $(0, \infty)$ AND NYSTRÖM-TYPE METHODS*

G. MASTROIANNI† AND G. MONEGATO‡

Abstract. We propose replacing the classical Gauss–Laguerre quadrature formula by a truncated version of it, obtained by ignoring the last part of its nodes. This has the effect of obtaining optimal orders of convergence. Corresponding quadrature rules with kernels are then considered and optimal error estimates are derived also for them. These rules are finally used to define stable Nyström-type interpolants for a second kind of integral equation on the real semiaxis whose solutions decay exponentially at ∞.

Key words. Gauss–Laguerre rules, integral equations, Nyström interpolants

AMS subject classifications. 65D30, 65R20

DOI. 10.1137/S0036142901391475

1. Introduction.

Consider the classical Gauss–Laguerre quadrature formula

$$\int_0^\infty w_\alpha(x) f(x) dx = \sum_{i=1}^{m} \lambda_{mi}^\alpha f(x_{mi}^\alpha) + R_m(f), \tag{1}$$

where we have set $w_\alpha(x) = x^\alpha e^{-x}$, $\alpha > -1$, and $x_{m1}^\alpha < x_{m2}^\alpha < \cdots < x_{mm}^\alpha$. Then, associate with it the "truncated" rule

$$\int_0^\infty w_\alpha(x) f(x) dx = \sum_{0 < x_{mi}^\alpha \le 4\theta m} \lambda_{mi}^\alpha f(x_{mi}^\alpha) + R_m^\theta(f), \tag{2}$$

where $0 < \theta < 1$ is arbitrarily chosen. For notational convenience, in the following we will set $\lambda_i := \lambda_{mi}^\alpha$ and $x_i := x_{mi}^\alpha$.

Let us denote by $AC = AC(\mathbb{R}^+)$ the set of all real functions which are absolutely continuous on any bounded subinterval of $(0, \infty)$. In [13] we have shown that for functions $f \in W_r^1(w_\alpha)$, with

$$W_r^1(w_\alpha) = W_r^1 = \{f^{(r-1)} \in AC : \|f^{(r)} \varphi^r w_\alpha\|_{L^1} < \infty\},$$

$r \ge 1$ an integer, and $\varphi(x) = \sqrt{x}$, the following estimate holds:

$$|R_m^\theta(f)| \le c \left(\frac{\|f^{(r)} \varphi^r w_\alpha\|_{L^1}}{m^{r/2}} + e^{-am} \|f w_\alpha\|_{L^1} \right), \tag{3}$$

where the constants c and a are independent of f and m.

Thus we can expect to obtain the same accuracy given by (1) using only a fraction of its nodes. For instance, in the examples considered in [13], using (2) with $\theta = \frac{1}{4}$ and

‡Dipartimento di Matematica, Politecnico di Torino, 10129 Torino, Italy (monegato@polito.it).

$m = 4, 8, 16, 32, 64, 128$, i.e., taking only the first 2,5,10,19,39,78 nodes, respectively, we had the same accuracy which was given by the complete rule (1).

In section 2 we obtain, using a simpler proof, a new error estimate more convenient than (3) (see Theorem 2.7), which includes (3) as a particular case. Both these estimates, apart from an $O(e^{-an})$ term, a being a positive constant, are of the same order of the best L^1-polynomial approximation of functions in $W^1_r(w_\alpha)$. Further, we show that an error estimate of this quasi-optimal order cannot hold for the (nontruncated) Gauss–Laguerre rule (1).

In the same section we introduce a special sequence of (truncated) Lagrange interpolation operators, based on a fraction of the Gauss–Laguerre nodes. As a major result, we prove the uniform boundedness of this sequence in proper subspaces of $L^2_{w_\alpha}$ and derive an optimal interpolation error estimate. As a consequence of this estimate we also obtain a new bound for $R^\theta_m(f)$, which does not require the absolute continuity of the function f. Thus our truncation procedure combines an optimal error bound with an $O(m)$ function evaluation saving.

Our new error bounds are needed in section 3 to derive a similar error estimate for corresponding product-type rules for integrals of the form

$$\int_0^\infty w_\alpha(x)k(x,y)f(x)dx,$$

with kernels $k(x, y)$ which may have weak singularities.

Then, in section 4, we use the above truncated product rules to define Nyström-type interpolants for a class of integral equations whose solutions decay exponentially to a constant at ∞ and prove stability and convergence estimates for them. These latter results hold under weaker conditions than those required in [12]. Nevertheless, these new conditions are not satisfied yet, for example, by the well-known linear transport equation considered in [12]. For the latter, to prove stability we are forced to modify the interpolant in a neighborhood of infinity, where anyway we know that the solution is practically constant.

The numerical results we present in section 4 confirm the benefits given by the truncated rule. Furthermore, truncation greatly reduces the magnitude of the condition number associated with the linear system generated by the Nyström method.

2. Truncated Lagrange interpolation and Gauss–Laguerre rules.

To prove the results of this section we introduce some notation and recall some well-known results.

We denote by L^2 the set of all real measurable functions in $\mathbb{R}^+ = (0,\infty)$ which are square integrable and by $\|f\|_{L^2} = (\int_0^\infty f^2(x)dx)^{1/2}$ its usual norm. Having set $w_\alpha(x) = x^\alpha e^{-x}$, $x > 0$, $\alpha > -1$, we shall write $f \in L^2_{w_\alpha}$ if $f\sqrt{w_\alpha} \in L^2$ and $\|f\|_{L^2_{w_\alpha}} = \|f\sqrt{w_\alpha}\|_{L^2}$. For each $f \in L^2_{w_\alpha}$, the polynomial $S_m(f;x) = \sum_{k=0}^{m-1} c_k(f)p_k(x)$, of degree $m-1$, is the mth Fourier sum of f associated with the system of orthonormal Laguerre polynomials $\{p_m\}$ and $c_k(f) = \int_0^\infty w(x)p_k(x)f(x)dx$.

For notational convenience, here and in the following we omit in the representation of p_k, c_k, S_m the dependence upon w_α.

Finally, we denote by $E_m(f)_{L^2_{w_\alpha}} = \|f - S_m(f)\|_{L^2_{w_\alpha}}$ the error of the best polynomial approximation in $L^2_{w_\alpha}$.

Next we introduce the scale of subspaces [12]

$$L^2_{w_\alpha,s} = \{f \in L^2_{w_\alpha} : \|f\|_{L^2_{w_\alpha,s}} < \infty\}, \quad s \geq 0 \quad \text{real},$$

where $\|f\|_{L^2_{w_\alpha,s}} = \left(\sum_{i=0}^{\infty}(i+1)^s c_i^2(f)\right)^{1/2}$. Moreover, we recall the following estimate [3]:

$$E_m(f)_{L^2_{w_\alpha}} \le c\omega_\varphi^r\left(f, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}}, \ r < m, \tag{4}$$

where the positive constant c is independent of f and m,

$$\begin{aligned}\omega_\varphi^r(f,t)_{L^2_{w_\alpha}} = \Omega_\varphi^r(f,t)_{L^2_{w_\alpha}} &+ \inf_{p\in\mathbb{P}_{r-1}} \|f-p\|_{L^2_{w_\alpha}(0,4r^2t^2)} \\ &+ \inf_{p\in\mathbb{P}_{r-1}} \|f-p\|_{L^2_{w_\alpha}\left(\frac{1}{t^2},\infty\right)}\end{aligned}$$

with $4r^2t^4 < 1$,

$$\Omega_\varphi^r(f,t)_{L^2_{w_\alpha}} = \sup_{0<h\le t} \|\Delta_{h\varphi}^r f\|_{L^2_{w_\alpha}(I_h)}, \ \varphi(x) = \sqrt{x}, \ I_h = [4r^2h^2, 1/h^2],$$

and

$$\Delta_{h\varphi}^r f(x) = \sum_{k=0}^{r}(-1)^k \begin{pmatrix} r \\ k \end{pmatrix} f\left(x + \frac{h\sqrt{x}}{2}(r-2k)\right).$$

By using the previous modulus of continuity we have the equivalence

$$\|f\|_{L^2_{w_\alpha,s}} \sim \|f\|_{L^2_{w_\alpha}} + \left(\int_0^1 \left[\frac{\Omega_\varphi^r(f,t)_{L^2_{w_\alpha}}}{t^{s+1/2}}\right]^2 dt\right)^{1/2}, \tag{5}$$

which is true for $r \ge s \in \mathbb{R}^+$ (see [3]). We recall that $A \sim B$ means that $c^{-1} \le A/B \le c$ for some constant c independent of the parameters A and B.

Finally, we recall that (see [12]) $L^2_{w_\alpha,0} = L^2_{w_\alpha}$ and, for a positive integer s, we have

$$L^2_{w_\alpha,s} = W_s^2 := \{f \in L^2_{w_\alpha} : f^{(s-1)} \in AC \text{ and } \|f^{(s)}\varphi^s\|_{L^2_{w_\alpha}} < \infty\}$$

and

$$\|f\|_{L^2_{w_\alpha,s}} \sim \|f\|_{W_s^2} = \|f\|_{L^2_{w_\alpha}} + \|f^{(s)}\varphi^s\|_{L^2_{w_\alpha}},$$

where the equality between the spaces of functions is in the sense of the norm equivalence. In [12] a criteria for detecting an estimate of the real s, such that $f \in L^2_{w_\alpha,s}$, has been given.

If $f \in C^0(A)$, $A = [a, a+\delta]$, $\delta > 0$, and $\omega^k(f,t)_{L^2(A)}$ denotes the ordinary modulus of continuity of order k in $L^2(A)$ defined in [21], then we have (see [8])

$$\sqrt{\delta}\max_{x\in A}|f(x)| \le c\left[\|f\|_{L^2(A)} + \sqrt{\delta}\int_0^\delta \frac{\omega^k(f,t)_{L^2(A)}}{t^{3/2}}dt\right]. \tag{6}$$

Here and in the following c, c_1, c_2 denote constants which may take different values on different occurrences. Incidentally we notice that when $f \in C^0(A)$, the exponent 3/2 in (6) cannot be replaced by a smaller number [8].

Another estimate that we shall need is the following one (see [3]):

$$\left(\int_{2m\frac{(1+\delta)}{\lambda}}^{\infty} |P_m(x)x^{\beta}e^{-\lambda x}|^p dx\right)^{1/p} \le c_1 e^{-c_2 m}\left(\int_0^{\infty} |P_m(x)x^{\beta}e^{-\lambda x}|^p dx\right)^{1/p}, \tag{7}$$

which holds for any polynomial $P_m(x)$ of degree m and real $p, \delta, \lambda > 0, \beta > -1/p$, with constants c_1 and c_2 independent of m and P_m and depending only on δ.

Taking for example $\delta = \frac{1}{4}, \lambda = \frac{1}{2}, p = 2$, and $\beta = \frac{\alpha}{2}$ in (7), we also have

$$\begin{aligned} \|f\sqrt{w_\alpha}\|_{L^2(5m,\infty)} &\le \|(f - S_m(f))\sqrt{w_\alpha}\|_{L^2(5m,\infty)} + \|S_m(f)\sqrt{w_\alpha}\|_{L^2(5m,\infty)} \\ &\le E_m(f)_{L^2_{w_\alpha}} + c_1 e^{-c_2 m}\|S_m(f)\|_{L^2_{w_\alpha}} \\ &\le E_m(f)_{L^2_{w_\alpha}} + c_1 e^{-c_2 m}\|f\|_{L^2_{w_\alpha}}. \end{aligned} \tag{8}$$

Using (8), we further obtain

$$\|f\|_{L^2_{w_\alpha}} \le \frac{1}{1 - c_1 e^{-c_2 m}}[\|f\sqrt{w_\alpha}\|_{L^2(0,5m)} + E_m(f)_{L^2_{w_\alpha}}]. \tag{9}$$

From (9) we conclude that, in order to approximate a function $f \in L^2_{w_\alpha}$ by using polynomials, it is sufficient to approximate a "finite-section" of f, say, f_j, that is equal to f in a "large" interval containing the origin, is equal to zero otherwise, and has the same smoothness of f.

By using the zeros $x_1 < \cdots < x_m$ of the Laguerre polynomial $p_m(x)$, the construction of an f_j is described next. We recall that all these zeros are contained in the interval $(0, 4m)$ and that $x_m \sim 4m - m^{\frac{1}{3}}$ (see [20]).

Choosing a real $0 < \theta < 1$ and m sufficiently large, we define the integer $j = j(m)$ as

$$x_j := \min_k\{x_k : x_k \ge 4\theta m\}.$$

We take a nondecreasing function $\psi \in C^\infty(\mathbb{R})$, with $\psi(x) = 0$ when $x \le 0$ and $\psi(x) = 1$ for $x \ge 1$, and define

$$\psi_{j(m)}(x) = \psi_j(x) = \psi\left(\frac{x - x_j}{x_{j+1} - x_j}\right).$$

Finally, we consider the function

$$f_{j(m)} = f_j = f - \psi_j f, \tag{10}$$

which has the same degree of smoothness of f. Notice that $f_j(x) = f(x)$ for $x \le x_j$ and $f_j(x) = 0$ for $x \ge x_{j+1}$.

Then, by using (7) with $\lambda = \frac{1}{2}$, $p = 2$, and $\beta = \frac{\alpha}{2}$, it is simple to prove that, if we set $M = \lfloor \frac{\theta}{1+\delta} m \rfloor \sim m$,

$$\left.\begin{array}{c} \|f - f_j\|_{L^2_{w_\alpha}} \\ E_m(f_j)_{L^2_{w_\alpha}} \\ \|f_j - S_M(f)\|_{L^2_{w_\alpha}} \end{array}\right\} \le c_1[E_M(f)_{L^2_{w_\alpha}} + e^{-c_2 m}\|f\|_{L^2_{w_\alpha}}], \tag{11}$$

where the constants c_1, c_2 are independent of f and m.

Remark 2.1. Bounds very similar to (11) hold also when the space $L^2_{w_\alpha}$ is replaced by $L^p_w, 1 \leq p \leq \infty$, with weight $w(x) = \sqrt{w_\alpha(x)}x^a(1+x)^b \in L^p$, norm $\|fw\|_{L^p}$, and $\lim_{x\to 0,\infty}(fw)(x) = 0$ when $p = \infty$.

By $L_m(f)$ we denote the Lagrange polynomial based on the zeros of $p_m(x)$ and associated with the function f. Thus we consider

$$L_m(f_j;x) = \sum_{k=1}^{j} l_k(x)f(x_k),$$

where $\{l_k(x)\}$ denotes the fundamental Lagrange polynomials. The following result then holds.

LEMMA 2.2. *Whenever $f \in C^0(\mathbb{R}^+)$ satisfies the condition*

$$\int_0^1 \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}}dt < \infty,$$

for some $r \geq 1$, we have

$$\|L_m(f_j)\|_{L^2_{w_\alpha}} \leq c\left[\|f\|_{L^2_{w_\alpha}} + \frac{1}{\sqrt[4]{m}}\int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}}dt\right], \tag{12}$$

where the constant c is independent of m and f.

Proof. We start from the equality

$$\|L_m(w_\alpha,f_j)\|^2_{L^2_{w_\alpha}} = \sum_{k=1}^{j}\lambda_k f^2(x_k).$$

Using (6) with $\delta = \Delta x_k = x_k - x_{k-1},\ a = x_{k-1},\ x_0 = 0$, and $A = [x_{k-1}, x_k] \equiv I_k, k = 1, 2, \ldots, j$, we have

$$\sqrt{w_\alpha(x_k)}|f(x_k)|\Delta x_k \leq c\left[\|f\|_{L^2(I_k)} + \sqrt{\Delta x_k}\int_0^{\Delta x_k}\frac{\omega^r(f,t)_{L^2(I_k)}}{t^{3/2}}dt\right]\sqrt{w_\alpha(x_k)}.$$

Further,

$$\sqrt{w_\alpha(x_k)}\|f\|_{L^2(I_k)} \leq c\|f\sqrt{w_\alpha}\|_{L^2(I_k)}$$

and

$$\sqrt{w_\alpha(x_k)}\omega^r(f,t)_{L^2(I_k)} = \sqrt{w_\alpha(x_k)}\sup_{h\leq t}\left(\int_{x_{k-1}}^{x_k}[\Delta^r_h f(x)]^2dx\right)^{\frac{1}{2}}$$

$$\leq c\sup_{h\leq t}\left(\int_{x_{k-1}}^{x_k}w_\alpha(x)[\Delta^r_h f(x)]^2dx\right)^{\frac{1}{2}} =: c\tilde{\omega}^r(f,t)_{L^2_{w_\alpha}(I_k)}.$$

Thus we have

$$\sqrt{w_\alpha(x_k)}|f(x_k)|\sqrt{\Delta x_k} \leq c\left[\|f\sqrt{w_\alpha}\|_{L^2(I_k)} + \sqrt{\Delta x_k}\int_0^{\Delta x_k}\frac{\tilde{\omega}^r(f,t)_{L^2_{w_\alpha}(I_k)}}{t^{3/2}}dt\right]. \tag{13}$$

Recalling (see [14]) that

$$\lambda_k \sim w_\alpha(x_k)\Delta x_k,$$

taking the square of (13) and summing the corresponding terms for $k = 1, 2, \ldots, j$, we obtain

$$\sum_{k=1}^{j} \lambda_k f^2(x_k) \le c\left[\|f\|^2_{L^2_{w_\alpha}} + \sum_{k=1}^{j}\left(\sqrt{\Delta x_k}\int_0^{\Delta x_k} \frac{\tilde\omega^r(f,t)_{L^2_{w_\alpha}(I_k)}}{t^{3/2}}dt\right)^2\right]. \tag{14}$$

To estimate the last sum, we remark first that (see [14]) $\Delta x_k \sim \sqrt{\frac{x_k}{m}}, k = 1, \ldots, j$, uniformly with respect to m and k. Then we replace t by $\sqrt{x_k}t$ in the integral. The kth element of this sum is then dominated by

$$\frac{1}{\sqrt{m}}\left[\int_0^{1/\sqrt{m}} \frac{\tilde\omega^r(f,\sqrt{x_k}t)_{L^2_{w_\alpha}(I_k)}}{t^{3/2}}dt\right]^2.$$

For $t \le m^{-1/2}$ let $\Gamma(x) = \Gamma_t(x)$ such that $\Gamma^{(r-1)} \in AC$ and

$$\begin{gathered}\|(\Gamma - f)\sqrt{w_\alpha}\|_{L^2} + t^r\|\Gamma^{(r)}\varphi^r\sqrt{w_\alpha}\|_{L^2}\\ \le 2\inf_g\{\|(f-g)\sqrt{w_\alpha}\|_{L^2} + t^r\|g^{(r)}\varphi^r\sqrt{w_\alpha}\|_{L^2}\}\\ =: 2K_\varphi(f,t^r)_{L^2_{w_\alpha}} \le c\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}.\end{gathered}$$

The last bound is obtained using Theorem 2.1 in [3].

Then, setting $I_{kr} = [x_{k-1}, x_k + r\Delta x_k]$,

$$\begin{aligned}\tilde\omega^r(f,\sqrt{x_k}t)_{L^2_{w_\alpha}(I_k)} &\le \tilde\omega^r(f-\Gamma,\sqrt{x_k}t)_{L^2_{w_\alpha}(I_k)} + \tilde\omega^r(\Gamma,\sqrt{x_k}t)_{L^2_{w_\alpha}(I_k)}\\ &\le c(\|(f-\Gamma)\sqrt{w_\alpha}\|_{L^2(I_{kr})} + (\sqrt{x_k}t)^r\|\Gamma^{(r)}\sqrt{w_\alpha}\|_{L^2(I_{kr})})\\ &\le c(\|(f-\Gamma)\sqrt{w_\alpha}\|_{L^2(I_{kr})} + t^r\|\Gamma^{(r)}\varphi^r\sqrt{w_\alpha}\|_{L^2(I_{kr})}) =: \tilde K_\varphi(f,t)_{L^2_{w_\alpha}(I_{kr})}.\end{aligned}$$

Using the Minkovski inequality (see (6.13.8) in [7]), from (14) we have

$$\begin{aligned}&\|L_m(f_j)\sqrt{w_\alpha}\|_{L^2}\\ &\le c\left(\|f\sqrt{w_\alpha}\|_{L^2} + \tfrac{1}{\sqrt[4]{m}}\int_0^{1/\sqrt{m}}\left[\sum_{k=1}^{j}\tilde K_\varphi(f,t)^2_{L^2_{w_\alpha}(I_k)}\right]^{1/2} t^{-3/2}dt\right)\\ &\le c\left(\|f\|_{L^2_{w_\alpha}} + \tfrac{1}{\sqrt[4]{m}}\left[\int_0^{1/\sqrt{m}}\frac{K_\varphi(f,t^r)_{L^2_{w_\alpha}}}{t^{3/2}}dt\right]^2\right);\end{aligned} \tag{15}$$

hence (12) follows. □

THEOREM 2.3. *Under the same assumptions of Lemma* 2.2 *we have*

$$\|f - L_m(f_j)\|_{L^2_{w_\alpha}} \le c_1\left[\frac{1}{m^{1/4}}\int_0^{1/\sqrt{m}}\frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}}dt + e^{-c_2 m}\|f\|_{L^2_{w_\alpha}}\right], \tag{16}$$

where c_1 and c_2 are two positive constants independent of m and f.

Moreover, if $f \in L^2_{w_\alpha,s}$ with $s > \frac{1}{2}$, then

$$\|f - L_m(f_j)\|_{L^2_{w_\alpha}} \le \frac{c}{n^{s/2}} \|f\|_{L^2_{w_\alpha,s}}. \tag{17}$$

Proof. Having set $P_M = S_M(f)$, $M = \lfloor \frac{\theta}{1+\delta} m \rfloor < m$, we can write

$$\|f - L_m(f_j)\|_{L^2_{w_\alpha}} \le \|f - f_j\|_{L^2_{w_\alpha}} + \|f_j - P_M\|_{L^2_{w_\alpha}}$$

$$+\|L_m((f - P_M)_j)\|_{L^2_{w_\alpha}} + \|L_m(\psi_j P_M)\|_{L^2_{w_\alpha}}, \tag{18}$$

where

$$P_{M_j} = P_M - \psi_j P_M.$$

By (11) the sum of first two terms is dominated by

$$c_1[E_M(f)_{L^2_{w_\alpha}} + e^{-c_2 m}\|f\|_{L^2_{w_\alpha}}] \le c_1 \omega^r_\varphi\left(f, \frac{1}{\sqrt{m}}\right) + e^{-c_2 m}\|f\|_{L^2_{w_\alpha}}$$
$$\le \frac{c}{m^{1/4}} \int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}} dt + e^{-cm}\|f\|_{L^2_{w_\alpha}}.$$

About the third term, by using Lemma 2.2 and recalling the property

$$\omega^r_\varphi(f + g, t) \le c[\omega^r_\varphi(f,t) + \omega^r_\varphi(g,t)],$$

which follows directly from the definition of ω^r_φ, we have

$$\|L_m((f - P_M)_j)\|_{L^2_{w_\alpha}} \le \frac{c}{m^{1/4}} \int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f - P_M, t)_{L^2_{w_\alpha}}}{t^{3/2}} dt$$
$$+ c\|f - P_M\|_{L^2_{w_\alpha}} \le \frac{c}{m^{1/4}} \int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}} dt + \frac{c}{(\sqrt{m})^r} \|P^{(r)}_M \varphi^r w_\alpha\|_2$$
$$+ c\|f - P_m\|_{L^2_{w_\alpha}} \le \frac{c}{m^{1/4}} \int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}} dt + c\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}.$$

The last bound is obtained by using Theorem 3.7 in [3]. Therefore,

$$\|L_m((f - P_M)_j)\|_{L^2_{w_\alpha}} \le \frac{c}{m^{1/4}} \int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}} dt.$$

Finally,

$$\|L_m(\psi_j P_M)\|^2_{L^2_{w_\alpha}} = \sum_{k=j+1}^{m} \lambda_k P^2_M(x_k) \sim \sum_{k=j+1}^{m} w_\alpha(x_k) \Delta x_k P^2_M(x_k).$$

By (13) with $f = P_M$ and $r = 1$, we get

$$w_\alpha(x_k) P^2_M(x_k) \Delta x_k \le c(\|P_M \sqrt{w_\alpha}\|^2_{L^2(I_k)} + (\Delta x_k)^2 \|P'_M \sqrt{w_\alpha}\|^2)$$
$$\le c\left(\|P_M\|^2_{L^2_{w_\alpha}(I_k)} + \frac{m^{2/3}}{\sqrt{m}} \|P'_M \varphi\|^2_{L^2_{w_\alpha}(I_k)}\right)$$

since for $k > j$ we have $\Delta x_k \le cm^{1/3}\sqrt{\frac{x_k}{m}}$ (see [14]).

Summing on $k > j$, it follows that

$$\|L_m(\psi_j P_M)\|_{L^2_{w_\alpha}} \le c\|P_M w_\alpha\|_{L^2(4\theta m,\infty)} + \frac{m^{1/3}}{\sqrt{m}}\|P'_M \varphi w_\alpha\|_{L^2(4\theta m,\infty)}.$$

Now we apply (7) and then the Bernstein inequality (see [3, Theorem 3.2]), and we obtain

$$\|L_m(\psi_j P_M)\|_{L^2_{w_\alpha}} \le c_1 e^{-c_2 m}\|P_M\|_{L^2_{w_\alpha}} \le c_1 e^{-c_2 m}\|f\|_{L^2_{w_\alpha}},$$

and the proof is completed.

If $f \in L^2_{w_\alpha,s}$ with $r > s > \frac{1}{2}$, then we also have

$$\frac{1}{m^{1/4}}\int_0^{1/\sqrt{m}} \frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{3/2}}dt = \frac{1}{m^{1/4}}\int_0^{1/\sqrt{m}} \frac{t^{s-1}\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{s+1/2}}dt$$

$$\le \frac{1}{\sqrt{2s-1}}\frac{1}{m^{s/2}}\left(\int_0^{1/\sqrt{m}}\left[\frac{\omega^r_\varphi(f,t)_{L^2_{w_\alpha}}}{t^{s+1/2}}\right]^2 dt\right)^{1/2} \le \frac{c}{m^{s/2}}\|f\|_{L^2_{w_\alpha,s}}.$$

Bound (17) then follows from (16). □

Remark 2.4. Proceeding as in [15, p. 285], it can be shown that when $f \in L^2_{w_\alpha,s}$, $s > \frac{1}{2}$, for any real $0 \le t \le s$ we have

$$\|f - L_m(f_j)\|_{L^2_{w_\alpha,t}} \le \frac{c}{m^{\frac{s-t}{2}}}\|f\|_{L^2_{w_\alpha,s}}. \tag{19}$$

From this it follows that the operator

$$L^{w_\alpha}_m : f \to L_m(f_j)$$

is uniformly bounded in $L^2_{w_\alpha,s}$, $s > \frac{1}{2}$, in the sense that

$$\sup_m \|L^{w_\alpha}_m\|_{L^2_{w_\alpha,s}\to L^2_{w_\alpha,s}} < \infty. \tag{20}$$

COROLLARY 2.5. *If in* (2) $f \in L^2_{w_\alpha,s}$ *with* $s > \frac{1}{2}$, *then*

$$|R^\theta_m(f)| \le \frac{c}{m^{s/2}}\|f\|_{L^2_{w_\alpha,s}}. \tag{21}$$

Proof. The bound follows immediately from (17) and Schwarz's inequality. □

Remark 2.6. Bounds (16) and (20) are of the same order as that of the best polynomial approximation error in $L^2_{w_\alpha,s}$ (see [12]). Moreover, (20) holds also when f is not absolutely continuous.

As stated by (19), the new operator $L^{w_\alpha}_m$ is uniformly bounded in $L^2_{w_\alpha,s}$.

Finally, we remark that bounds (19) and (20) have been obtained by assuming $f \in L^2_{w_\alpha,s}$, where $w_\alpha(x) = x^\alpha e^{-x}$. In [12], where the function f is interpolated by $L_m(f)$, similar upper bounds were derived by assuming $f \in L^2_{w^q_\alpha,s}$, with $w^q_\alpha = x^\alpha e^{-qx}, 0 < q < 1$.

As mentioned in the introduction, in [13] a corresponding estimate, given in terms of weighted L^1 norm, were obtained. This can, however, be derived with a much simpler proof, as we shall do in the next theorem, where we consider functions $f \in W_1^1(w_\alpha)$.

In the following we define

$$L_w^1 = \left\{ f : \int_0^\infty w(x)|f(x)|dx < \infty \right\}.$$

THEOREM 2.7. *For any $f \in W_1^1(w_\alpha)$ we have*

$$\left|R_m^\theta(f)\right| \le c_1 \left[\frac{E_{M-1}(f')_{L^1_{\varphi w_\alpha}}}{\sqrt{m}} + e^{-c_2 m} \|f\|_{L^1_{w_\alpha}} \right],$$

where c_1 and c_2 are independent of m and f.

Proof. First, we recall that the estimates in (11) are true also in $L^1_{w_\alpha}$.

Taking $f_j = f - \psi_j f$ as in (10), we have

$$\begin{aligned} R_m^\theta(f) &= \int_0^\infty [f(x) - f_j(x)] w_\alpha(x) dx \\ &\quad + \int_0^\infty f_j(x) w_\alpha(x) dx - \sum_{k=1}^m \lambda_k(w_\alpha) f_j(x_k) = F_m(f) + R_m(f_j), \end{aligned}$$

where $R_m(f)$ is the remainder term of the Gauss–Laguerre rule (1). By (11) and Favard's theorem (see [3, Theorem 3.3]) we have

$$\begin{aligned} |F_m(f)| &\le \int_{4\theta m}^\infty |f(x) w_\alpha(x)| dx \\ &\le E_M(f)_{L^1_{w_\alpha}} + c_1 e^{-c_2 m} \|f w_\alpha\|_{L^1} \\ &\le \frac{c}{\sqrt{m}} E_{M-1}(f')_{L^1_{w_\alpha \varphi}} + c_1 e^{-c_2 m} \|f w_\alpha\|_{L^1}. \end{aligned} \tag{22}$$

For $R_m(f_j)$ we use Peano's theorem (see [2]) and write

$$R_m(f_j) = \int_0^\infty R_m((\cdot - t)_+^0) f_j'(t) dt, \quad (x - t)_+^0 = \begin{cases} 1, & t < x, \\ 0, & t \ge x. \end{cases}$$

For $0 \le t \le x_{m,1}$,

$$\begin{aligned} |R_m((\cdot - t)_+^0)| &= \left| \int_0^\infty (x - t)_+^0 w_\alpha(x) dx - \sum_{k=1}^m \lambda_k(w_\alpha)(x_k - t_0)_+^0 \right| \\ &= \left| - \int_0^t w_\alpha(x) dx \right| \le c \sqrt{\frac{t}{m}} w_\alpha(t), \end{aligned}$$

while for $t > x_{m,1}$, using the result given in [5, p. 105], we have

$$|R_m((\cdot - t)_+^0)| \le \lambda_m(w_\alpha, t).$$

Therefore,

$$|R_m(f_j)| \le \int_0^{x_{j+1}} |R_m((\cdot - t))| |f_j'(t)| dt.$$

However, when $t \le x_{j+1}$ we also have $\lambda_m(w_\alpha, t) \le c\sqrt{\frac{t}{m}}w_\alpha(t)$ and

$$\begin{aligned}|R_m(f_j)| &\le \frac{c}{\sqrt{m}}\int_0^{x_{j+1}} |f_j'(x)\varphi(x)w_\alpha(x)|dx\\ &\le c\left(\frac{1}{\sqrt{m}}\|f'\varphi w_\alpha\|_{L^1} + \|fw_\alpha\|_{L^1(4\theta m,\infty)}\right),\end{aligned}$$

since $\psi_j'(x) = 0$ if $x \le x_j$ and $\psi_j'(x) \le (\Delta x_j)^{-1}\|\psi'\|_\infty \sim \frac{\sqrt{m}}{\varphi(x_j)}$ for $x \in (x_j, x_{j+1})$.

Thus, for each polynomial Q of degree $M = \lfloor \frac{\theta m}{1+\theta} \rfloor \sim m$ such that

$$\|(f-Q)w_\alpha\|_{L^1} \le cE_M(f)_{w_\alpha,1},$$

we also have

$$|R_m((f-Q)_j)| \le c\left(\frac{\|(f-Q)'\varphi w_\alpha\|_{L^1}}{\sqrt{m}} + \|(f-Q)w_\alpha\|_{L^1(4\theta m,\infty)}\right).$$

Here and in the next lines the constant c is independent of f and m.

From the inequality (see [3])

$$\|(f-Q)'\varphi w_\alpha\|_{L^1} \le c(\sqrt{m}\|(f-Q)w_\alpha\|_{L^1} + E_{M-1}(f')_{L^2_{\varphi w_\alpha,1}}),$$

using the Favard theorem we obtain the bound

$$|R_m((f-Q)_j)| \le \frac{c}{\sqrt{m}}E_{M-1}(f')_{L^2_{\varphi w_\alpha,1}}.$$

Since

$$|R_m(f_j)| = |R_m(f_j - Q)| \le |R_m((f-Q)_j)| + |R_m(\psi_j Q)|$$

and

$$|R_m(\psi_j Q)| \le \int_{4\theta m}^\infty |Q(x)|w_\alpha(x)dx + \sum_{k=j+1}^m \lambda_k|Q(x_k)|,$$

using (7) and proceeding as in the proof of Theorem 2.3 we have

$$|R_m(\psi_j Q)| \le ce^{-Am}\|fw_\alpha\|_{L^1},$$

where c and A are independent of f and m. The theorem then easily follows. □

We remark that from this estimate, using the Favard theorem we easily obtain (3). The same estimate can also be applied to wider classes of functions—for example, to Besov spaces (see [3]).

We also notice that while the remainder of the truncated rule satisfies the bound given in Theorem 2.7, the full Gauss–Laguerre rule (1) can only satisfy an error estimate of type

$$|R_m(f)| \le \frac{c}{m^{1/6}}\|f'\varphi w_\alpha\|_{L^1}, \tag{23}$$

which has been derived in [13]. That is, the exponent 1/6 of m in (23) is optimal. This is confirmed by the following result, which we prove in the case $\alpha = 0$.

THEOREM 2.8. *For any integer $m \geq 2$ there exists a function $f_m(x)$ such that $f_m \in AC$, with $\|f_m' \varphi w_0\|_{L^1} < \infty$, and*

$$R_m(f_m) \sim \frac{c}{m^{1/6}} \|f_m' \varphi w_0\|_{L^1}, \tag{24}$$

where the constant c is independent of m and f_m.

Proof. Set $a_m = x_m - 2$ and notice that for $m \geq 2$ we have $x_{m-1} < a_m < x_m$. Then define the function

$$f_m(x) = \begin{cases} 0 & \text{in } [0, a_m), \\ x - a_m & \text{in } [a_m, x_m), \\ 2 & \text{in } [x_m, \infty). \end{cases}$$

Obviously $f_m \in AC$ and $\|f_m' \varphi w_0\|_{L^1} < \infty$. Recalling Peano's error representation

$$R_m(f) = \int_0^\infty \left[\int_0^\infty (x-t)_+^0 w_0(x) dx - \sum_{i=1}^m \lambda_i (x_i - t)_+^0 \right] f'(t) dt \tag{25}$$

and replacing f by f_m defined above, we have

$$R_m(f_m) = \int_{a_m}^{x_m} [e^{-t} - \lambda_m] f_m'(t) dt. \tag{26}$$

Further,

$$\sqrt{m} R_m(f_m) = \sqrt{m} \int_{a_m}^{x_m} f_m'(t) e^{-t} dt - \sqrt{m} \lambda_m \int_{a_m}^{x_m} f_m'(t) dt =: A_m - B_m.$$

For the first term A_m we have

$$A_m = \sqrt{m} \int_{a_m}^{x_m} \frac{1}{\sqrt{t}} f_m'(t) \sqrt{t} e^{-t} dt \sim \|f_m' \varphi w_0\|_{L^1}.$$

For the second one,

$$B_m = \sqrt{m} \lambda_m \int_{a_m}^{x_m} f_m'(t) \sqrt{t} e^{-t} (t^{-\frac{1}{2}} e^t) dt,$$

after noticing that

$$e^{-2} \frac{e^{x_m}}{\sqrt{x_m - 2}} \leq \frac{e^t}{\sqrt{t}} \leq \frac{e^{x_m}}{\sqrt{x_m}}$$

and (see [9])

$$\lambda_m \sim c m^{\frac{1}{3}} e^{-x_m},$$

we have

$$B_m \sim m^{\frac{1}{3}} \|f_m' \varphi w_0\|_{L^1}.$$

Estimate (24) then follows. □

3. Error bounds for the truncated product rule. In this section we apply the truncation, previously defined for the Gauss–Laguerre formulas, to product integration rules for integrals which exhibit a kernel $k_y(x) = k(x,y)$. This is in view of the construction of Nyström-type interpolants for the numerical solution of corresponding integral equations. This application will be considered in the final section.

The product rules we consider have the form

$$\int_0^\infty w_\alpha(x)k(x,y)f(x)dx = \sum_{i=1}^m w_i(y)f(x_i) + R_m(k_y;f), \tag{27}$$

with

$$w_i(y) = w_i(k;y) = \int_0^\infty w_\alpha(x)k(x,y)l_i(x)dx = \lambda_i S_m(k_y;x_i).$$

They are of interpolatory type; that is, they are obtained by replacing $f(x)$ by its Lagrange interpolation polynomial $L_m(f;x)$ associated with the zeros $\{x_i\}$ of the Laguerre polynomial $p_m(x)$. For the construction of the coefficients $w_i(y)$ of these rules and convergence properties, see [11], [12].

As in the case of (1), we associate with (27) its "truncation"

$$\int_0^\infty w_\alpha(x)k(x,y)f(x)dx = \sum_{0<x_i\le 4\theta m} w_i(y)f(x_i) + R_m^\theta(k_y;f), \tag{28}$$

where $0<\theta<1$ is arbitrarily chosen.

For this rule we derive some estimates which are fundamental for proving stability and convergence properties for our Nyström interpolants.

As for the remainder of (2), using (17) it is straightforward to derive the following bound for the remainder term $R_m^\theta(k_y;f)$ in (28).

Theorem 3.1. *If for a given y we have $\|k_y\|_{L^2_{w_\alpha}} < \infty$ and $f \in L^2_{w_\alpha,s}$, $s>\frac{1}{2}$, then*

$$|R_m^\theta(k_y;f)| \le \frac{c\|k_y\|_{L^2_{w_\alpha}}}{m^{s/2}}\|f\|_{L^2_{w_\alpha,s}},$$

where the constant c is independent of $m, f,$ and k_y.

By making a weaker assumption on the kernel $k_y(x)$, we are also able to derive a bound for $R_m^\theta(k_y;f)$ given in terms of a weighted L^∞ norm of f. The function f could not be in $L^2_{w_\alpha}$. Although this bound will not be used in section 4, we think that it is of interest on its own and could have some applications.

Let $u(x) = \sqrt{w_\alpha(x)}(\frac{x}{1+x})^a(1+x)^b$, $v(x) = \sqrt{w_\alpha(x)}(\frac{x}{1+x})^A(1+x)^B$, and $W(g;x) = 1+\log^+ x+\log^+|g(x)|$. Moreover, let the real constants a, b, A, B satisfy the conditions $A \le a$, $a > -1+\max\left(-\frac{\alpha}{2},\frac{1}{4}\right)$, $A \le \min\left(\frac{\alpha}{2},-\frac{1}{4}\right)$, $b<-1/4$, $B \ge -7/12$, and $B \ge b+1/6$. Then (see [17]) the following bound holds:

$$\int_0^\infty |S_m(F;x)u(x)|dx \le c\left[1+\int_0^\infty |F(x)|v(x)W(F;x)dx\right], \tag{29}$$

where the constant c is independent of m and F.

The next result then follows.

Lemma 3.2. *Let $b < -1/4$, and assume the conditions*

$$\|f\sqrt{w_\alpha(x)}(1+\cdot)^{-b}\|_\infty < \infty \text{ and}$$

$$B(k_y) := \sup_{y\geq 0}\int_0^\infty e^{-\frac{x}{2}}x^\gamma(1+x)^{-A}|k_y(x)|W(k_y;x)dx < \infty, \tag{30}$$

$$\gamma = \frac{\alpha}{2} + \min\left(\frac{\alpha}{2}, -\frac{1}{4}\right).$$

Then

$$\int_0^\infty |L_m(f_j;x)k(x,y)w_\alpha(x)|dx \leq c(1+B(k_y))\|f\sqrt{w_\alpha}(1+\cdot)^{-b}\|_\infty, \tag{31}$$

where the constant c is independent of m and f.

Proof. Set $g_m(x) = \text{sgn } L_m(f_j;x)$. Then

$$\Delta = \int_0^\infty |L_m(f_j;x)k(x,y)w_\alpha(x)|dx = \sum_{i=1}^m \lambda_i S_m(k_y g_m;x_i)f_j(x_i)$$
$$= \sum_{i=1}^j \lambda_i S_m(k_y g_m;x_i)f(x_i)(1+x_i)^{-b}(1+x_i)^b;$$

hence, recalling (13),

$$\Delta \leq c\|f\sqrt{w_\alpha}(1+\cdot)^{-b}\|_\infty \sum_{i=1}^j \sqrt{w_\alpha(x_i)}(1+x_i)^b\Delta x_i|P(x_i)|,$$

where $P = S_m(k_y g_m)$.

At this point it is sufficient to show that the last sum is uniformly bounded with respect to m. To this end, notice that, because of (13) with $f = P$ and $r = 1$,

$$\sqrt{w_\alpha(x_i)}(1+x_i)^b\Delta x_i|P(x_i)| \leq c\int_{x_{i-1}}^{x_i}|P(x)w_\alpha(x)(1+x)^b|dx$$
$$+\frac{c}{\sqrt{m}}\int_{x_{i-1}}^{x_i}|P'(x)|\sqrt{x}w_\alpha(x)(1+x)^b|dx,$$

since $\Delta x_i \leq c\sqrt{\frac{x_i}{m}}$. Therefore,

$$\Delta \leq c\|f_j\sqrt{w_\alpha}(1+\cdot)^{-b}\|_\infty\left[\int_0^{x_j}|P(x)\sqrt{w_\alpha(x)}(1+x)^b|dx\right.$$
$$\left.+\frac{1}{\sqrt{m}}\int_0^{x_j}|P'(x)\sqrt{x}\sqrt{w_\alpha(x)}(1+x)^b|dx\right].$$

By applying a Bernstein inequality (see [16]) to the last integral, we obtain

$$\Delta \leq c\|f_j\sqrt{w_\alpha}(1+\cdot)^{-b}\|_\infty\int_0^\infty|S_m(k_y g_m,x)\sqrt{w_\alpha(x)}(1+x)^b|dx. \tag{32}$$

Now we recall (29) with $A = \min(\frac{\alpha}{2}, -\frac{1}{4}), a = 0$, and $B = 0$. The integral in (32) is dominated by the corresponding bound given by (31).

The proof is then completed. □

Further, by considering the quantity

$$\sum_{i=1}^{j} \lambda_i S_m(k_y; x_i) f(x_i)$$

and proceeding as we have done to bound Δ, we obtain

$$\sup_m \sum_{i=1}^{j} \lambda_i \frac{|S_m(k_y, x_i)|}{\sqrt{w_\alpha(x_i)}(1+x_i)^{-b}} \leq c < \infty. \tag{33}$$

Theorem 3.3. *Under the same assumptions of Lemma* 3.2 *we have*

$$\sup_{y\geq 0} |R_m^\theta(k_y; f)| \leq c_1[E_{M-1}(f)_{L^\infty_\sigma} + e^{-c_2 m}\|f\|_{L^\infty_\sigma}], \quad \sigma(x) = \sqrt{w_\alpha(x)}(1+x)^{-b}, \tag{34}$$

where the constant c is independent of m and f.

Proof. Write

$$R_m^\theta(k_y; f) = \int_0^\infty [f(x) - f_j(x)] k(x,y) w_\alpha(x) dx \tag{35}$$

$$+ \left[\int_0^\infty f_j(x) k(x,y) w_\alpha(x) dx - \sum_{i=1}^{m} w_i(y) f_j(x_i) \right].$$

For the first term on the right-hand side of (35) we have

$$\Gamma := \left| \int_0^\infty (f(x) - f_j(x)) k(x,y) w_\alpha(x) dx \right| = \left| \int_{x_j}^\infty \psi_j(x) f(x) k(x,y) w_\alpha(x) dx \right|.$$

Thus

$$\begin{aligned} \Gamma &\leq \int_{4\theta m}^\infty |f(x)\sqrt{w_\alpha(x)}(1+x)^{-b} k(x,y)\sqrt{w_\alpha(x)}(1+x)^{b}| dx \\ &\leq \left\{ \sup_{[4\theta m,\infty)} |f(x)\sqrt{w_\alpha(x)}(1+x)^{-b}| \right\} \int_{4\theta m}^\infty |k(x,y)| \sqrt{w_\alpha(x)} dx \quad (b<0) \\ &\leq c_1[E_M(f)_{L^\infty_\sigma} + e^{-c_2 m}\|f\|_{L^\infty_\sigma}] \sup_{y\geq 0} E_M(k_y)_{L^1_{\sqrt{w_\alpha}}}, \end{aligned}$$

that is,

$$\Gamma \leq c_1[E_{M-1}(f)_{L^\infty_\sigma} + e^{-c_2 m}\|f\|_{L^\infty_\sigma}],$$

since

$$E_M(f)_{L^\infty_\sigma} \leq E_{M-1}(f)_{L^\infty_\sigma}$$

and

$$\sup_{y\geq 0} E_M(K_y)_{L^1_{\sqrt{w_\alpha}}} \leq B(k).$$

The second term in (35) is dominated by

$$\int_0^\infty |f_j - q_{m-1}|(x)|k(x,y)|w_\alpha(x)dx + \sum_{i=1}^m \lambda_i |S_m(k_y;x_i)||f_j(x_i) - q_{m-1}(x_i)| \\ =: A_1 + A_2$$

for each $q_{m-1} \in \mathbb{P}_{m-1}$. Moreover,

$$A_1 \leq \left(\int_0^\infty |k(x,y)|\sqrt{w_\alpha(x)}(1+x)^b dx \right) \|(f_j - q_{m-1})\sigma\|_\infty, \\ A_2 \leq c\|(f_j - q_{m-1})\sigma\|_\infty.$$

The bound of A_2 follows from (33). Taking the infimum over q_{m-1} and the sup over y, it follows that

$$A_1 + A_2 \leq cE_{m-1}(f_j)_{L^\infty_\sigma} \leq c_1[E_{M-1}(f)_{L^\infty_\sigma} + e^{-c_2 m}\|f\|_{L^\infty_\sigma}];$$

hence (34) follows. □

In the next section, to prove the stability of our Nyström interpolants, we shall need to consider the so-called (see [19]) companion rule, associated with (28), that is, obtained by taking in (28) the absolute values of $k_y(x)$ and $w_i(y)$. This is

$$(36) \qquad \int_0^\infty w_\alpha(x)|k_y(x)|h(x)dx = \sum_{0<x_i\leq 4\theta m} |w_i(y)|h(x_i) + R_m^{c,\theta}(k_y;h).$$

In particular, we shall need to prove its convergence, as $m \to \infty$, for a certain class of functions $h(x)$. To this end, Theorem 3.4 and Proposition 3.5 are of importance.

THEOREM 3.4. *If for a given y we have $\|k_y\|_{L^2_{w_\alpha}} < \infty$ and $h \in L^2_{w_\alpha,1}$, then*

$$|R_m^{c,\theta}(k_y;h)| \leq c\|h\|_{L^2_{w_\alpha,1}} \left[\omega_\varphi\left(k_y, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}} + \frac{1}{\sqrt{m}}\|k_y\|_{L^2_{w_\alpha}} \right],$$

where the constant c is independent of k_y and m.

Proof. Writing

$$|R_m^{c,\theta}(k_y;h)| = \left| \int_0^\infty |k_y(x)|h(x)w_\alpha(x)dx - \sum_{i=1}^j \lambda_i|S_m(k_y;x_i)|h(x_i) \right|$$

$$\leq \int_0^\infty |k_y(x) - S_m(k_y;x)|h(x)w_\alpha(x)dx \quad (=: A_1)$$

$$+ \left| \int_0^\infty |S_m(k_y;x)|h(x)w_\alpha(x)dx - \sum_{i=1}^j \lambda_i|S_m(k_y;x_i)|h(x_i) \right| \quad (=: A_2)$$

and recalling (4), for A_1 we have

$$A_1 \leq \|h\|_{L^2_{w_\alpha}}\|k_y - S_m(k_y)\|_{L^2_{w_\alpha}} \leq c\|h\|_{L^2_{w_\alpha}}\omega_\varphi\left(k_y, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}}.$$

Moreover, if in Theorem 2.7 we take $f(x) = |S_m|h(x) = |S_m(k_y;x)|h(x)$ and recall that

$$E_{M-1}(f')_{L^1_{\varphi w_\alpha}} \le \|f'\varphi w_\alpha\|_{L^1},$$

then we have

$$A_2 = |R^\theta_m(|S_m|h)| \le c_1 \left[e^{-c_2 m}\|S_m h w_\alpha\|_{L^1} + \frac{\|(S_m h)'\varphi w_\alpha\|_{L^1}}{\sqrt{m}} \right].$$

By applying Cauchy's inequality we further have

$$\begin{aligned} A_2 &\le c_1\|h\|_{L^2_{w_\alpha,1}} \left[\left(\frac{1}{\sqrt{m}} + e^{-c_2 m} \right) \|S_m - k_y + k_y\|_{L^2_{w_\alpha}} + \frac{1}{\sqrt{m}}\|S'_m\varphi\|_{L^2_{w_\alpha}} \right] \\ &\le c\|h\|_{L^2_{w_\alpha,1}} \left[E_m(k_y)_{L^2_{w_\alpha}} + \frac{1}{\sqrt{m}}\|S'_m\varphi\|_{L^2_{w_\alpha}} + \frac{1}{\sqrt{m}}\|k_y\|_{L^2_{w_\alpha}} \right]. \end{aligned}$$

Because of Theorem 3.7 in [3], the sum of the first two terms in the last line is bounded by $\omega_\varphi(k_y, \frac{1}{\sqrt{m}})$. Thus the bound for $|R^{c,\theta}_m(k_y;h)|$ is proved. □

The next result is needed to define the final behavior of the remainder terms $R^{c,\theta}_m(k_y;h)$ as $m \to \infty$.

Proposition 3.5. *If* $\sup_{y\ge 0}\rho(y)\|k_y\|_{L^2_{w_\alpha}} < \infty$ *for a bounded nonnegative weight function* $\rho(y)$, *then*

$$\lim_{m\to\infty}\sup_{y\ge 0}\rho(y)\omega^r_\varphi\left(k_y, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}} = 0 \qquad \textit{with } r \ge 1.$$

Proof. Setting $d_k = \int_0^\infty k_y(x)p_k(x)w_\alpha(x)dx$, from the assumption made it follows that

$$\sup_{y\ge 0}\rho(y)\sum_{k=0}^{\infty} d^2_k(k_y) = \sup_{y\ge 0}\rho(y)\|k_y\|_{L^2_{w_\alpha}} < \infty;$$

hence

$$\lim_{m\to\infty}\sup_{y\ge 0}\rho(y)\sum_{k>m} d^2_k(k_y) = 0, \qquad \text{that is,} \qquad \lim_{m\to\infty}\sup_{y\ge 0}\rho(y)E_m(k_y)_{L^2_{w_\alpha}} = 0.$$

However (see [3]),

$$\begin{aligned} \rho(y)\omega^r_\varphi\left(k_y, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}} &\le \frac{c_r}{(\sqrt{m})^r}\sum_{k=0}^{m}(1+k)^{\frac{r}{2}-1}\rho(y)E_k(k_y)_{L^2_{w_\alpha}} \\ &\sim \frac{\sum_{k=0}^{m}(1+k)^{\frac{r}{2}-1}\rho(y)E_k(k_y)_{L^2_{w_\alpha}}}{\sum_{k=0}^{m}(1+k)^{\frac{r}{2}-1}}. \end{aligned}$$

Since the latter expression tends to zero as $m \to \infty$, uniformly with respect to y, we have

$$\lim_{m\to\infty}\sup_{y\ge 0}\rho(y)\omega^r_\varphi\left(k_y, \frac{1}{\sqrt{m}}\right)_{L^2_{w_\alpha}} = 0. \qquad □$$

Remark 3.6. If in (36) we take $h \equiv 1$ and consider the full sum, i.e., $i = 1, \dots, m$, then, using arguments similar to those of Theorem 3.4, it is possible to show, assuming $\sup_{y \geq 0} \|k_y\|_{L^2_{w_\alpha}} < \infty$, that the corresponding quadrature remainder term tends to zero, as $m \to \infty$. This in turn implies that $\sup_{y \geq 0} \sum_{i=1}^m |w_i(y)| < \infty$. In [12] this property was proved under the stronger assumption that $\sup_{y \geq 0} \|k_y\|_{L^2_{w_\alpha,s}} < \infty$ for some $s > 1/3$.

4. A Nyström-type interpolant. As in [12], here we consider integral equations of the form

$$u(y) - \mu \int_0^\infty k(x,y)u(x)dx = f(y), \tag{37}$$

whose solutions decay at least as $e^{-\beta x}, \beta = \frac{1}{2} + \epsilon,\ \epsilon > 0$, for $x \to \infty$, to a finite value $u(\infty)$.

A class of integral equations of this type arises naturally from the equations of Mellin type defined on a finite interval (see [18]). Thus consider

$$u(s) - \mu \int_0^1 k\left(\frac{t}{s}\right) \frac{u(t)}{t} dt = f(s),\ 0 < s \leq 1, \tag{38}$$

and set $t = e^{-x},\ s = e^{-y}$; we have

$$v(y) - \mu \int_0^\infty k(e^{-(y-x)})v(x)dx = f(e^{-y}), \tag{39}$$

with

$$v(x) = u(e^{-x}).$$

We recall (see [4]) that often $u(t) \sim t^\sigma, \sigma > \frac{1}{2}$, near the origin, so that the (weakly) singular behavior at $t = 0$ is transformed, by the above change of variable, into the exponential decay $e^{-\sigma x}$. Thus the method we examine in this section could be used to solve the above Mellin equations.

A test equation of type (37) we have considered in [11], [12] is

$$u(y) - \frac{1}{4} \int_0^\infty E_1(|x-y|)u(x)dx = \frac{1}{2}, \tag{40}$$

where $E_1(x) = \int_x^\infty \frac{e^{-t}}{t} dt$ is the well-known exponential integral. This equation arises, for example, in the modeling of the neutron transfer in an infinite slab. The solution $u(x)$ has the behavior $1 + o(e^{-\beta x})$ as $x \to \infty$, with $\beta = 0.9575$, and has a weak singularity at the origin, of the form $\frac{\sqrt{2}}{2} + O(x^\epsilon)$ with $\epsilon > 0$ as small as we like (see, for example, [6]).

The Nyström interpolant we propose requires us to preliminarily rewrite (37) in the form

$$v(y) - \mu e^y \int_0^\infty e^{-x} k(x,y)v(x)dx = g(y),$$

where

$$v(x) = e^x[u(x) - u(\infty)]$$

and

$$g(y) = e^y \left\{ f(y) - u(\infty) \left[1 - \mu \int_0^\infty k(x,y)dx \right] \right\},$$

that is,

$$(I - \mu K)v = g. \tag{41}$$

To do this one needs to know a priori the value $u(\infty)$, which is, however, often the case. This assumption is also made, for example, in the product integration method proposed in [6]. Then, using the corresponding truncated product rule of form (26), we obtain

$$(I - \mu K_m)v_m = g \tag{42}$$

with

$$K_m v_m(y) = \sum_{i=1}^{j} \bar{w}_i(y) v_m(x_i), \qquad \bar{w}_i(y) = e^y w_i(y),$$

that is,

$$v_m(y) = g(y) + \mu K_m v_m(y). \tag{43}$$

Notice that applying our truncated quadrature rule does not mean performing a finite section of (41).

Both (41) and (42) will be examined in the weighted space

$$X := \{v \in L^\infty(0,\infty) : \|v\|_X := \|\rho(x)v(x)\|_\infty < \infty\},$$

where $\rho(x) = e^{(-\frac{1}{2}+\epsilon_1)x}$, with some $0 < \epsilon_1 \leq \epsilon$.

The values $\{v_m(x_i)\}$ are obtained by solving the linear system (hopefully nonsingular)

$$v_m(x_l) - \mu K_m v_m(x_l) = g(x_l), \ l = 1, \ldots, j. \tag{44}$$

Recalling Remark 3.6, it is now possible to claim that the method is indeed stable in X, whenever the kernel $k(x,y)$ satisfies certain assumptions.

Lemma 4.1. *If*

$$\|K\|_{X\to X} = \sup_{y\geq 0} \rho(y) \|\bar{k}_y \rho^{-1}\|_{L^1_{w_0}} < \infty, \ \bar{k}_y = e^y k(x,y), \tag{45}$$

and

$$\sup_{y\geq 0} \rho(y) \|\bar{k}_y\|_{L^2_{w_0}} < \infty, \tag{46}$$

then

$$\overline{\lim}_{m\to\infty} \|K_m\|_{X\to X} \leq \|K\|_{X\to X}. \tag{47}$$

Proof. In the case of assumption (46), property (47) follows immediately from Theorem 3.4 and Proposition 3.5, since

$$\|K_m\|_{X\to X} \leq \sup_{y\geq 0} \rho(y) \sum_{i=1}^{j} |\bar{w}_i(y)|\rho^{-1}(x_i). \qquad \square$$

Notice that to prove this lemma we have used Theorem 3.4, which requires $h(x) \equiv \rho^{-1}(x) \in L^2_{w_\alpha,1}$.

If the operator K in (41) satisfies the condition

$$\|K\|_{X\to X} < |\mu|^{-1}, \tag{48}$$

standard analysis (see [1]) and Theorem 3.1 give the following main result.

THEOREM 4.2. *If conditions* (46) *and* (48) *are verified, then for all m sufficiently large the operator $I - \mu K_m$ is invertible and*

$$\|(I-\mu K_m)^{-1}\|_{X\to X} \leq c.$$

Moreover,

$$\|v - v_m\|_X \leq c\|(K-K_m)v\|_X \leq c\frac{\|v\|_{L^2_{w_0,s}}}{m^{\frac{s}{2}}} \tag{49}$$

whenever $v \in L^2_{w_0,s}$, $s > \frac{1}{2}$.

Notice that if we define $u_m(x) = e^{-x}v_m(x) + u(\infty)$, then

$$\|v - v_m\|_X = \sup_{x\geq 0} |e^{(\frac{1}{2}+\epsilon_1)x}[u(x) - u_m(x)]|.$$

Unfortunately, it is possible for condition (46) to be not satisfied by the kernel of the integral equation one has to solve. If, for example, we consider (40) and rewrite it in the form (see [11])

$$v(y) - \frac{1}{4}e^y \int_0^\infty e^{-x}k(x,y)v(x)dx = -\frac{1}{4}e^y[e^{-y} - yE_1(y)], \tag{50}$$

where

$$k(x,y) = E_1(|x-y|), \quad v(x) = e^x[u(x) - 1], \tag{51}$$

and (see [12]) $v \in L^2_{w_0,s}$ with s not smaller than $\frac{3}{2} - \delta, \delta > 0$, as close as we like to 0, then it is not difficult to verify, by direct calculation, that assumption (46) of Lemma 4.1 does not hold because of the factor $e^{\epsilon_1 y}$ in $\rho(y)$, while condition (48) is satisfied. Incidentally, we notice that if the kernel were $e^{-\epsilon y}E_1(|x-y|)$, with $\epsilon > 0$ as small as we like, then also condition (46) would be satisfied.

On the other hand, in the weight $\rho(y)$ we have taken $\epsilon_1 > 0$ to be allowed to apply Theorem 3.4. This happens also if in (37) we take the Picard kernel $k(x,y) = e^{-|x-y|}$. Therefore, for these two equations we cannot apply Theorem 4.2 and hence claim stability, although practical computation shows that our interpolants are indeed stable. In our opinion this is due to the (weighted) L^2 estimates we have used to prove Theorem 3.4. A proof of stability using more general tools is needed. Ours is based on the use of the companion rule (36) and Theorem 3.4, and this seems to be a bit restrictive. However, at present this question remains unanswered.

To be able to prove stability in the latter two cases, we need to modify our interpolant when $y > C$, C being a positive constant arbitrarily large. In particular, for simplicity we define the trivially modified operator

$$\bar{K}_m v(y) = \begin{cases} K_m v(y) & \text{if } 0 \leq y \leq \log A, \\ K v(y) & \text{if } y > \log A, \end{cases} \tag{52}$$

where A is a positive constant that can be chosen as large as one likes. Of course this is not satisfactory from a theoretical point of view: when $y > \log A$, we should modify $K_m v(y)$ by introducing a discrete operator which can be explicitly evaluated. However, for simplicity and because the constant A can be chosen arbitrarily large, we have made the choice (52). We recall that the solution of our equation decays exponentially at infinity, to a constant we assume to know a priori.

In this case we have

$$\|\bar{K}_m\|_{X\to X} \leq \max\left\{ \sup_{0\leq y\leq \log A} \rho(y) \sum_{i=1}^{j} |\bar{w}_i(y)|\rho^{-1}(x_i), \|K\|_{X\to X} \right\},$$

that is,

$$\lim_{m\to\infty} \|\bar{K}_m\|_{X\to X} \leq \|K\|_{X\to X}.$$

Thus, if $\|K\|_{X\to X} < |\mu|^{-1}$, then also $\|\bar{K}_m\|_{X\to X} < |\mu|^{-1}$ for all m sufficiently large. However, this implies stability and the convergence estimate (49).

Instead of applying our method to an artificial equation constructed in order to satisfy the conditions required by Theorem 4.2, we have preferred to consider a case of practical interest, taken by many authors, such as (40). For this equation, the modified version of the method described above is stable and convergent with order not smaller than $O(m^{-3/2+\epsilon})$ (see [12]). In the case of (37) with the Picard kernel, $\mu = 1/4$ and $f(y) = 1/2$, whose solution is $u(x) = 1 - (1 - 2^{-\frac{1}{2}})e^{-\frac{x}{\sqrt{2}}}$, the order of convergence is higher than any negative power of m.

In [12] the Nyström interpolant based on the nontruncated rule (27) has been examined from the numerical point of view and compared with a product integration method proposed in [6]. In particular, numerical evidence on the efficiency of the first method was given. Since in [12] this method has already shown to be competitive, here we do not present any further comparisons. We simply show the improvement that the truncation we propose generates with respect to the nontruncated version.

In the following tables we report some numerical results obtained by applying our unmodified Nyström interpolant (43) to the test equation (40), after having rewritten it in the form (41). In particular, in Table 1 we report a sample of relative errors $\{e_m(t_l)\}$ obtained by using the nontruncated product rule, i.e., choosing $j = m$ in (42). In the following three tables we list the corresponding relative errors generated by our truncated rule, applied with $\theta = 1/8, 1/16, 1/32$. These errors are very similar. The choice $\theta = 1/32$ allows to obtain an accuracy similar to that given by the complete rule, using about 1/5 of its abscissas.

While it is known that $u(0) = \frac{\sqrt{2}}{2}$, to compute the relative errors at the other points, we have taken, as reference values, those obtained with $m = 180$ in Table 1 and with $m = 512$ in Tables 2, 3, and 4. The integer $m = 180$ could not be increased because of overflow problems due to the Matlab exponential function. All computation has been performed on a PC using Matlab.

256		1.76E43	3.56E18	3.16E05

Truncation also reduces significantly the magnitude of the condition numbers of the final linear systems (see Table 5).

However, we have also noticed that in all cases considered, in spite of the values of the condition numbers, no error propagation has shown up. Actually, following the idea suggested in [10], we could replace, for example, the linear system generated by the nontruncated rule by the equivalent (preconditioned) one

$$\lambda_l^{1/2} e^{x_l} \sum_{i=1}^{m} a_i \left[\lambda_i^{-1/2} e^{-x_i} \delta_{il} - \frac{\lambda_i^{-1/2}}{4} w_i(x_l) \right] = \lambda_l^{1/2} g(x_l), \quad l = 1, \ldots, m, \tag{53}$$

where $a_i = \lambda_i^{1/2} v_m(x_i)$ and $g(x) = -\frac{e^x}{4}[e^{-x} - xE_1(x)]$, which turns out to be perfectly conditioned. The corresponding results however are very similar to those produced by the original system.

Aknowledgments. The authors are grateful to Dr. C. Frammartino for performing all the numerical computations reported in section 4. They are also indebted to the two referees for their valuable comments.

A NEW LOOK AT PROPER ORTHOGONAL DECOMPOSITION[*]

MURUHAN RATHINAM[†] AND LINDA R. PETZOLD[‡]

Abstract. We investigate some basic properties of the proper orthogonal decomposition (POD) method as it is applied to data compression and model reduction of finite dimensional nonlinear systems. First we provide an analysis of the errors involved in solving a nonlinear ODE initial value problem using a POD reduced order model. Then we study the effects of small perturbations in the ensemble of data from which the POD reduced order model is constructed on the reduced order model. We explain why in some applications this sensitivity is a concern while in others it is not. We also provide an analysis of computational complexity of solving an ODE initial value problem and study the computational savings obtained by using a POD reduced order model. We provide several examples to illustrate our theoretical results.

1. Introduction.

1.1. Background on proper orthogonal decomposition.

Proper orthogonal decomposition (POD), also known as Karhunen–Loève decomposition or principal component analysis, provides a technique for analyzing multidimensional data. This method essentially provides an orthonormal basis for representing the given data in a certain least squares optimal sense. The POD method may be applied to infinite dimensional data such as fluid flow patterns as well. Truncation of the optimal basis provides a way to find optimal lower dimensional approximations of the given data.

In addition to being optimal in a least squares sense, POD has the property that it uses a modal decomposition that is completely data dependent and does not assume any prior knowledge of the process that generates the data. This property is advantageous in situations where a priori knowledge of the underlying process is insufficient to warrant a certain choice of basis. It also helps in exploring patterns in data that may reveal some insight into the underlying process that generates it.

Combined with the Galerkin projection procedure, POD provides a powerful method for generating lower dimensional models of dynamical systems that have a very large or even infinite dimensional phase space. The fact that this approach always looks for linear (or affine) subspaces instead of curved submanifolds makes it computationally tractable. However, it must be noted that POD does not neglect the nonlinearities of the original vector-field. This is so because if the original dynamical system is nonlinear, then the resulting POD reduced order model will also typically be nonlinear.

These properties of POD are the reason for its wide application in data analysis, data compression, and model reduction in various fields of engineering and science.

Applications of POD include image processing [22], data compression, signal analysis [2], modeling and control of chemical reaction systems [12, 25, 26], turbulence models [14], coherent structures in fluids [14], control of fluids [10], electrical power grids [21, 20, 18], and wind engineering to name a few.

Extensions and modifications to POD have been proposed by various researchers to accommodate properties of the applications at hand. For instance, instead of time averaging, arclength-based averaging has been found to be useful in capturing dynamics involving “intermittent” attractors in [12]. The predefined POD method has been studied in [8], where modes are selected not only on the basis of energy of the data but also on some prior knowledge of the system. Structure preserving model reduction based on POD for mechanical systems with Lagrangian structure has been developed in [15].

Systems with symmetry deserve special attention. Several authors have made important contributions. Expanding the data set using symmetry was proposed in [27, 28, 29], and later works have shown that it is an essential step in capturing the correct dynamics [3, 4]. Methods for combining reduction theory with POD have been developed in [23].

1.2. Contributions of this work.

In this paper we study some basic questions about POD. We focus on finite dimensional systems and follow a deterministic approach. The contributions of this paper include a study of the errors involved in solving an initial value problem using a POD reduced order model of a dynamical system, the sensitivity of the results of POD to perturbations in the data that is used to form the reduced model, as well as computational efficiency gained in using POD in model reduction applications. Even though these are some fundamental questions relating to POD, we believe that they have not been given sufficient attention in the literature.

1.3. Outline of the paper.

The rest of the paper is organized as follows. In section 2, we review the POD method as it is applied in data representation as well as in model reduction. In section 3, we present some mathematical preliminaries on the manifold of projection matrices and finite time solution norms of linear time invariant systems. The former is relevant in the sensitivity analysis, and the latter will be useful since throughout this paper we derive particular results for linear time invariant systems. In section 4, we provide an error analysis of the POD method of model reduction as applied to a general nonlinear system. An example is provided to illustrate the various factors affecting the errors. In section 5, we study the sensitivity of the POD projection matrix P (Proposition 5.4), the projected data $\tilde{y}$, and the reduced model solution $\hat{y}$ to perturbations in the data x that is used to form the reduced model. We also study the particular case $y = x$, where the particular data/solution y for which the reduced model is applied is the same as the ensemble of data x from which the reduced model is constructed. Two examples are provided to illustrate the sensitivity results, one focusing on the $y = x$ case. In section 6, we present an estimate of the computational complexity involved in integrating a system of ODEs with and without the use of POD reduced order models. We also provide two examples to illustrate the various factors affecting the computational savings. Finally, in section 7, we make concluding remarks.

2. Proper orthogonal decomposition (POD).

POD provides a method for finding the best approximating subspace to a given set of data. Originally POD was used as a data representation technique. For model reduction of dynamical systems, POD may be used on data points obtained from system trajectories obtained via experiments, numerical simulations, or analytical derivations. Additional information may be found in [14, 19, 17, 16].

2.1. POD in data representation.

We shall assume that the *data points* lie in $\mathbb{R}^n$. In the case of a dynamical system this is the phase space. A *data set* is a collection $x^\alpha \in \mathbb{R}^n$, where $\alpha \in \mathcal{I}$. The *index set* $\mathcal{I}$ may be a finite set $\{1, \ldots, N\}$, or a time interval $[0, T]$, or more generally of the form $\mathcal{I} = [0, T] \times \{1, \ldots, N\}$. The latter corresponds to a collection of trajectories. For example, in an image coding problem $\mathcal{I}$ is a finite discrete set. In model reduction of dynamical systems, $\mathcal{I}$ could be of the more general form above. We define an inner product between sets of data x_1 and x_2 with the same index set $\mathcal{I}$ in the obvious way. For example, if x_1 and x_2 are each a collection of N trajectories in the common interval $[0, T]$, i.e., $x_i^\alpha : [0, T] \to \mathbb{R}^n$ for $\alpha = 1, \ldots, N$ and $i = 1, 2$, then

$$(x_1, x_2) = \sum_{\alpha=1}^{N} \int_0^T (x_1^\alpha(t))^T x_2^\alpha(t) dt.$$

The corresponding norm is denoted $\|.\|$.

Remark 2.1. Note that we are using the inner product in our data space ($\mathbb{R}^n$) to induce an inner product in the space of data sets with the same index set.

We shall explain the POD method using the index set $\mathcal{I} = [0, T] \times \{1, \ldots, N\}$. Given a data set x, POD seeks a subspace $S \subset \mathbb{R}^n$ so that the total square distance

$$\|x - \rho_S x\|^2 = \sum_{\alpha=1}^{N} \int_0^T \|x^\alpha(t) - \rho_S x^\alpha(t)\|^2 dt$$

is minimized. Here ρ_S is the orthogonal projection onto the subspace S and $\rho_S x$ is the projected data set. The solution to this problem requires the construction of the *correlation matrix* defined by

$$R = \sum_{\alpha=1}^{N} \int_0^T x^\alpha(t)(x^\alpha(t))^T dt.$$

Note that R is symmetric positive semidefinite. Let $\lambda_1 \geq \lambda_2 \cdots \geq \lambda_N \geq 0$ be the ordered eigenvalues of R. Then the minimum value of $\|x - \rho_S x\|^2$ over all $k (\leq n)$ dimensional subspaces S is given by $\sum_{j=k+1}^{n} \lambda_j$ [14]. In addition the minimizing S is the invariant subspace corresponding to the eigenvalues $\lambda_1, \ldots, \lambda_k$.

Often it may be best to find an affine subspace as opposed to a linear subspace. This requires us first to find the mean value of the data points

$$\bar{x} = \frac{1}{NT} \sum_{\alpha=1}^{N} \int_0^T x^\alpha(t) dt$$

and then construct the *covariance matrix* $\bar{R}$ given by

$$\bar{R} = \sum_{\alpha=1}^{N} \int_0^T (x^\alpha(t) - \bar{x})(x^\alpha(t) - \bar{x})^T dt.$$

Let S_0 be the invariant subspace of the largest k eigenvalues of $\bar{R}$. Then the best approximating affine subspace S passes through $\bar{x}$ and is obtained by shifting S_0 by $\bar{x}$. Algebraically the projection onto the subspace S is given by

$$z = \rho(x - \bar{x}), \tag{2.1}$$

where $z \in \mathbb{R}^k$ are coordinates in the subspace S, $x \in \mathbb{R}^n$ are coordinates in the original coordinate system in $\mathbb{R}^n$, and the matrix ρ of the projection consists of row vectors ϕ_i^T $(i = 1, \ldots, k)$, where ϕ_i are the unit eigenvectors corresponding to the largest k eigenvalues of $\bar{R}$. Note that given any point $p \in S$ with coordinates $z \in \mathbb{R}^k$, the coordinates $x \in \mathbb{R}^n$ of the same point in the original coordinate system are given by

$$x = \rho^T z + \bar{x}.$$

The affine projection $\tilde{x} \subset S$ of a point $x \in \mathbb{R}^n$ in the original coordinates is given by

$$\tilde{x} = P(x - \bar{x}) + \bar{x},$$

where $P = \rho^T \rho \in \mathbb{R}^{n \times n}$ is the matrix of the (linear) projection expressed in the original coordinate system in $\mathbb{R}^n$.

Remark 2.2. Note that the reduced subspace is uniquely characterized by the pair $(\bar{x}, P)$. Different data sets may lead to the same pair $(\bar{x}, P)$, and the detailed information about the data x is lost.

2.2. POD in model reduction. The POD method may also be used in obtaining a lower dimensional model of a dynamical system. In this case, having found the approximating subspace for our system data, the next task is to construct a vector-field on this subspace that represents the reduced order model. The procedure we describe is known as Galerkin projection and has been widely used in reducing PDEs to ODEs by projecting onto appropriate basis functions that describe the spatial variations in the solution. The procedure is applicable to any subspace; the subspace need not be obtained from the POD method. See [14] for more details.

Suppose the original dynamical system in $\mathbb{R}^n$ is given by a vector-field f,

$$\dot{x} = f(x, t).$$

Let $S \subset \mathbb{R}^n$ be the best k dimensional approximating affine subspace with projection given by (2.1). A vector-field f_a in the subspace S is constructed by the following rule: for any point $p \in S$ compute the vector-field $f(p, t)$ and take the projection $\rho f(p, t)$ onto the subspace S to be the value of $f_a(p, t)$. If z are the subspace coordinates of p, then $f_a(z, t) = \rho f(\rho^T z + \bar{x}, t)$. Thus we obtain the following reduced model:

$$\dot{z} = f_a(z, t) = \rho f(\rho^T z + \bar{x}, t). \tag{2.2}$$

If we are solving an initial value problem with $x(0) = x_0$, then in the reduced model one has the initial condition $z(0) = z_0$, where

$$z_0 = \rho(x_0 - \bar{x}).$$

Hence the approximating solution $\hat{x}(t)$ in the original coordinates in $\mathbb{R}^n$ is given by

$$\hat{x}(t) = \rho^T z(t) + \bar{x}.$$

From the above it is easy to see that the approximating solution $\hat{x}(t)$ is the solution to the following initial value problem:

$$\dot{\hat{x}} = Pf(\hat{x}, t); \quad \hat{x}(0) = \hat{x}_0 = P(x_0 - \bar{x}) + \bar{x}. \tag{2.3}$$

Note that $\hat{x}_0$ is just the projection of x_0 onto the affine subspace S.

3. Mathematical preliminaries.

3.1. Manifold of projection matrices.

Let $\mathcal{P} \subset \mathbb{R}^{n\times n}$ be the manifold of all rank $k(< n)$ (orthogonal) projection matrices. ($\mathcal{P}$ is known in the literature as the Grassmannian [6].) For a general introduction to manifolds, tangent spaces, and differentiation on manifolds, see [1, 6]. Since we will be dealing with variations E of projections $P \in \mathcal{P}$ in our POD sensitivity analysis, we need a characterization of the tangent space $T_P\mathcal{P}$ to $\mathcal{P}$ at a given point $P \in \mathcal{P}$. The variation $E \in T_P\mathcal{P}$ cannot be any arbitrary matrix. In fact, the dimension of $\mathcal{P}$ and hence that of $T_P\mathcal{P}$ for any P is $k(n-k)$.

Without loss of generality, we can induce an orthonormal change of coordinates in $\mathbb{R}^n$ such that a given projection P becomes the canonical projection (P_0) in these coordinates, i.e.,

$$P_0 = \begin{bmatrix} I_{k\times k} & 0_{k\times n-k} \\ 0_{n-k\times k} & 0_{n-k\times n-k} \end{bmatrix}.$$

In many places in our analysis we shall assume the use of these canonical coordinates.

Let $V = T_{P_0}\mathcal{P}$, i.e., the tangent space to $\mathcal{P}$ at the canonical projection P_0. Using the relations $P^2 = P$ and $P^T = P$ (symmetric) and letting $P = P_0$, it is easy to see that V consists of matrices of the form

$$\begin{bmatrix} 0_{k\times k} & X_{k\times n-k} \\ X^T_{n-k\times k} & 0_{n-k\times n-k} \end{bmatrix},$$

where X is arbitrary. We will use the Frobenius norm for projection matrices P and their variations E in our analysis. We consider the basis $\{E^{ij} \ : \ i = 1, \dots, k; j = 1, \dots, n-k\}$ for V, where

$$E^{ij} = \begin{bmatrix} 0 & X_{ij} \\ X^T_{ij} & 0 \end{bmatrix}$$

and X_{ij} is the $k \times (n-k)$ matrix with all zeros except for a 1 in the (i, j)th element. Clearly $\|E^{ij}\| = \sqrt{2}$.

Remark 3.1. It may be noted that E^{ij} corresponds to an infinitesimal rotation of the subspace S (onto which P_0 projects) in the plane of the coordinates x_i and x_{j+k}. Consider the family of subspaces $S(\theta)$ which are spanned by

$$\{e_1, \dots, e_{i-1}, \cos\theta e_i + \sin\theta e_{j+k}, e_{i+1}, \dots, e_k\},$$

where $e_1, \dots, e_n$ are the canonical basis vectors in $\mathbb{R}^n$. Note that when $\theta = 0$, S corresponds to the image of P_0. Computing the corresponding family of projection matrices $P(\theta)$, we can see that $E^{ij} = \frac{dP}{d\theta}(\theta = 0)$.

3.2. Finite time response of a linear time invariant system with time varying input.

Some of the analysis in this paper requires estimating the norm of the trajectory of a linear time invariant system in a finite interval in response to a forcing input term.

Consider the system

$$\dot{x} = Ax + u$$

(where $x \in \mathbb{R}^n$) with input $u(t) \in \mathbb{R}^n$ and initial condition $x(0) = x_0$ in the interval $[0, T]$. The solution is

$$x(t) = \int_0^t e^{A(t-\tau)} u(\tau) d\tau + e^{At} x_0.$$

This may be written in the form

$$x = F(T; A)u + G(T; A)x_0, \tag{3.1}$$

where $F(T; A) : \mathcal{L}_2([0, T], \mathbb{R}^n) \to \mathcal{L}_2([0, T], \mathbb{R}^n)$ and $G(T; A) : \mathbb{R}^n \to \mathcal{L}_2([0, T], \mathbb{R}^n)$ are linear operators. It is in general very difficult to obtain sharp estimates for the norms of $F(T; A)$ and $G(T; A)$, and in fact this basically reduces to the problem of estimating the norm of the matrix exponential. As such we shall not provide an estimate, but we remark that these norms grow exponentially with T at a rate that is determined by the largest real part of any eigenvalue of A and in addition depend on the nonnormality of A. See [11] for an estimate of matrix exponential. In our analysis we shall estimate $\|x\|$ as

$$\|x\| \leq \|F(T; A)\| \|u\| + \|G(T; A)\| \|x_0\|, \tag{3.2}$$

expressing the results in terms of $\|F(T; A)\|$ and $\|G(T; A)\|$.

4. Error analysis of the POD method of model reduction. Consider solving the initial value problem $\dot{x} = f(x, t)$, $x(0) = x_0$, using a POD reduced order model in the interval $[0, T]$. Then in effect we are solving the initial value problem (2.3). We shall derive an estimate for the error $e(t) = \hat{x}(t) - x(t)$. Denote the component of $e(t)$ orthogonal to the subspace S by $e_o(t)$ and the component parallel to S by $e_i(t)$. Thus $e_o(t)$ and $e_i(t)$ are orthogonal vectors. Hence by definition $Pe_o(t) = 0$ and $Pe_i(t) = e_i(t)$. It is important to observe that $e_o(t)$ comes from the first part of the method, i.e., the subspace approximation. It is the error between $x(t)$ and its projection onto the subspace S. If one is considering a data compression problem, then $e_o(t) = e(t)$. But since we form a reduced order model by projecting the vector-field onto S, we make further approximations resulting in the additional error $e_i(t)$.

Remark 4.1. Note that for any function $g : [0, T] \to \mathbb{R}^n$, $\|g(t)\|$ is a norm in $\mathbb{R}^n$ which shall be the 2-norm throughout this paper. The function norm will be denoted by $\|g\|$, and unless explicitly stated otherwise it will be assumed to be the 2-norm.

We can derive an error estimate for $e_i(t)$ in terms of $e_o(t)$. Differentiating $e_o(t) + e_i(t) = \hat{x}(t) - x(t)$ and substituting into the ODEs for $\hat{x}$ and x, we get

$$\dot{e}_o + \dot{e}_i = Pf(\hat{x}, t) - f(x, t).$$

Multiplying on the left by P and using $P^2 = P$, we obtain the initial value problem for $e_i(t)$:

$$\dot{e}_i = P(f(x(t) + e_o(t) + e_i, t) - f(x(t), t)); \quad e_i(0) = 0. \tag{4.1}$$

Note that $e_i(0) = 0$ since the starting point $\hat{x}_0$ is the projection of x_0 onto S. Thus the error e_i is governed by (4.1), where we may regard $x(t)$ and $e_o(t)$ as forcing terms. See Figure 4.1, where x is the true solution, $\tilde{x}$ the projected solution, and $\hat{x}$ the solution of the reduced model. The errors e_i and e_o are also shown.

In the case of a linear time invariant system $\dot{x} = Ax$, (4.1) takes a simple form:

$$\dot{e}_i = PAe_i + PAe_o(t); \quad e_i(0) = 0. \tag{4.2}$$

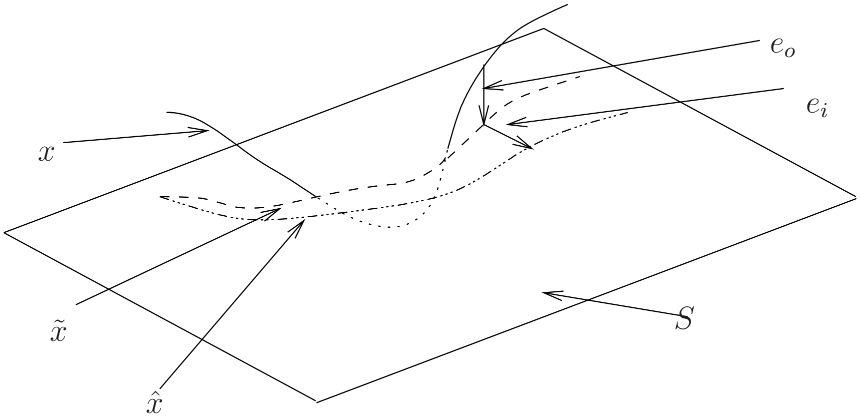

FIG. 4.1. *POD error.*

Applying the notation of (3.1), we get the estimate

$$\|e_i\|_2 \leq \|F(T;\hat{A})\|\|\tilde{A}\|\epsilon.$$

Hence the total error is

$$\|e\|_2 \leq \left(\|F(T;\hat{A})\|\|\tilde{A}\| + 1\right)\epsilon. \tag{4.3}$$

Here $\hat{A} = \rho A \rho^T$ and $\tilde{A} = \rho A \rho_c^T$, where ρ is the projection in subspace coordinates ($P = \rho^T \rho$), and ρ_c is the orthogonal complement to ρ. ϵ is the 2-norm of e_o (i.e., $\|e_o\|_2 = \epsilon$).

Before we state a proposition for the general nonlinear case, recall the definition of a *logarithmic norm related to a* 2*-norm* of a square matrix $A \in \mathbb{R}^{k\times k}$ denoted by $\mu(A)$:

$$\mu(A) = \lim_{h\to 0, h>0} \frac{\|I + hA\|_2 - 1}{h},$$

where I is the identity matrix [13].

PROPOSITION 4.2. *Consider solving the initial value problem $\dot{x} = f(x,t)$, $x(0) = x_0$, using the POD reduced order model in the interval $[0,T]$. Let $\rho \in \mathbb{R}^{k\times n}$ be the relevant projection matrix, and let S denote the affine subspace onto which POD projects. Write the solution (of the full model) $x(t)$ and the solution $\hat{x}(t)$ of the reduced model as*

$$x(t) = \rho^T u(t) + \rho_c^T v(t) + \bar{x}$$

and

$$\hat{x}(t) = \rho^T u(t) + \rho^T w(t) + \bar{x}$$

so that the errors $e_o(t)$ and $e_i(t)$ and the projected solution $\tilde{x}(t)$ are given by

$$e_o(t) = -\rho_c^T v(t),$$

$$e_i(t) = \rho^T w(t),$$

and

$$\tilde{x}(t) = \rho^T u(t) + \bar{x}.$$

Note that $u(t) \in \mathbb{R}^k$, $w(t) \in \mathbb{R}^k$, and $v(t) \in \mathbb{R}^{n-k}$. Let $\gamma \geq 0$ be the Lipschitz constant of $\rho f(x,t)$ in the directions orthogonal to S in a region containing $x(t)$ and $\tilde{x}(t)$. To be precise, suppose

$$\|\rho f(\tilde{x}(t) + \rho_c^T v, t) - \rho f(\tilde{x}(t), t)\| \leq \gamma \|v\|$$

for all $(v,t) \in D \subset \mathbb{R}^{n-k} \times [0,T]$, where the region D is such that the associated region $\tilde{D} = \{(\tilde{x}(t) + \rho_c^T v, t) \ : \ (v,t) \in D\} \subset \mathbb{R}^n \times [0,T]$ contains $(\tilde{x}(t), t)$ and $(x(t), t)$ for all $t \in [0,T]$. Let $\mu(\rho \frac{\partial f}{\partial x}(\bar{x} + \rho^T z, t)\rho^T) \leq \bar{\mu}$ for $(z,t) \in V \subset \mathbb{R}^k \times [0,T]$, where the region V is such that it contains $(u(t), t)$ and $(u(t) + w(t), t)$ for all $t \in [0,T]$ and μ denotes the logarithmic norm related to the 2-norm. Let $\epsilon = \|e_o\|_2$. Then the error e_i in the ∞-norm satisfies

$$\|e_i\|_\infty \leq \epsilon \frac{\gamma}{\sqrt{2\bar{\mu}}} \sqrt{e^{2\bar{\mu}T} - 1}, \tag{4.4}$$

and the 2-norm of the total error satisfies

$$\|e\|_2 \leq \epsilon \sqrt{1 + \frac{\gamma^2}{4\bar{\mu}^2}(e^{2\bar{\mu}T} - 1 - 2\bar{\mu}T)}. \tag{4.5}$$

Proof. We shall closely follow the ideas in [13, pp. 54–60]. Since

$$\dot{w}(t) = \rho f(\bar{x} + \rho^T u(t) + \rho^T w(t), t) - \rho f(\bar{x} + \rho^T u(t) + \rho_c^T v(t), t),$$

for $h > 0$ using Taylor expansion we have

$$\begin{aligned} \|w(t+h)\| &= \|w(t) + h\rho f(\bar{x} + \rho^T u(t) + \rho^T w(t), t) - h\rho f(\bar{x} + \rho^T u(t) + \rho_c^T v(t), t)\| \\ &\quad + O(h^2) \\ &\leq \|w(t) + h\rho f(\bar{x} + \rho^T u(t) + \rho^T w(t), t) - h\rho f(\bar{x} + \rho^T u(t), t)\| \\ &\quad + h\|\rho f(\bar{x} + \rho^T u(t) + \rho_c^T v(t), t) - \rho f(\bar{x} + \rho^T u(t), t)\| + O(h^2). \end{aligned}$$

Applying the mean value theorem to $\eta \mapsto \eta + h\rho f(\bar{x} + \rho^T \eta, t)$, we get

$$\begin{aligned} &\|w(t) + h\rho f(\bar{x} + \rho^T u(t) + \rho^T w(t), t) - h\rho f(\bar{x} + \rho^T u(t), t)\| \\ &\qquad \leq \left(\max_{\eta \in [u(t), u(t)+w(t)]} \left\| I + h\rho \frac{\partial f}{\partial x}(\bar{x} + \rho^T \eta, t)\rho^T \right\| \right) \|w(t)\|, \end{aligned}$$

where for any two vectors η_1, η_2 in $\mathbb{R}^k$, $[\eta_1, \eta_2]$ denotes the line segment joining the two. It follows that

$$\frac{\|w(t+h)\| - \|w(t)\|}{h} \leq \bar{\mu}\|w(t)\| + \gamma\|v(t)\| + O(h),$$

where the $O(h)$ term may be uniformly bounded independent of $w(t)$ [13]. Then it follows from Theorem 10.3 of [13] (also see Theorem 10.6 in [13]) that

$$\|e_i(t)\| = \|w(t)\| \leq \gamma \int_0^t e^{\bar{\mu}(t-\tau)} \|v(t)\| d\tau,$$

since $e_i(t) = \rho^T w(t)$. After applying the Cauchy–Schwarz inequality on the right side, we get

$$\|e_i(t)\| \leq \frac{\gamma}{\sqrt{2\bar{\mu}}} \sqrt{e^{2\bar{\mu}t} - 1} \sqrt{\int_0^t \|e_o(\tau)\|^2 d\tau}. \tag{4.6}$$

From this we readily obtain (4.4). Also bounding $\sqrt{\int_0^t \|e_o(\tau)\|^2 d\tau}$ by ϵ and integrating (4.6), we obtain an upper bound for $\|e_i\|_2$ which can be combined with $\|e_o\|_2$ to get (4.5). □

Remark 4.3. This analysis separates the two different errors and provides a bound for the total error in terms of the projection error ϵ of the true solution $x(t)$. The value of ϵ depends only on the true solution $x(t)$ and on the pair $(P, \bar{x})$ which determines the reduced order model (but not directly on f). If P and $\bar{x}$ were computed from the true solution $x(t)$ in the interval $[0, T]$ (this is somewhat an ideal situation), then $\epsilon = \sqrt{\sum_{j=k+1}^n \lambda_j}$, where λ_i are the eigenvalues of the covariance matrix. However, if the reduced model was computed from some other trajectories as often is the case in applications of model reduction methods, then ϵ would depend on how close $x(t)$ was to the trajectories used as data in addition to the quantity $\sum_{j=k+1}^n \lambda_j$ (typically the fractional error $\frac{\epsilon}{\|x\|_2}$ will be larger than $\frac{\sum_{j=k+1}^n \lambda_j}{\sum_{j=1}^n \lambda_j}$). For instance, in hybrid systems such as power systems where discrete events abruptly change some system parameters, data obtained from trajectories before the event results in a reduced order model with a large ϵ for simulations after the event [7].

Example 1. This example serves to illustrate the various factors that affect e_i given the same projection error e_o. We shall consider a linear time invariant system $\dot{x} = Ax$; $x(0) = x_0$. Assume A has distinct eigenvalues and that it possesses some fast decaying modes (eigenvalues with large negative real parts). Let $S \subset \mathbb{R}^n$ be the invariant subspace corresponding to the rest of the eigenvalues, where S is $k(< n)$ dimensional. If we have sufficiently many trajectories that have initial conditions symmetrically placed with respect to S, then the POD method will pick S as the subspace to project onto. We shall assume this to be the case. Performing an orthonormal change of coordinates if needed, we may assume that S corresponds to the last $n - k$ coordinates being zero. In these coordinates, the A matrix has the form

$$A = \begin{bmatrix} A_1 & A_{12} \\ 0 & A_2 \end{bmatrix},$$

where $A_1 \in \mathbb{R}^{k \times k}$, $A_{12} \in \mathbb{R}^{k \times (n-k)}$, and $A_2 \in \mathbb{R}^{(n-k)\times(n-k)}$. In fact the real Schur decomposition of A will put it in the above form. We shall say A is "block normal" if the off diagonal block $A_{12} = 0$.

Also note that

$$\rho = \begin{bmatrix} I_{k\times k} & 0_{k\times(n-k)} \end{bmatrix}$$

and

$$\rho_c = \begin{bmatrix} 0_{(n-k)\times k} & I_{(n-k)\times(n-k)} \end{bmatrix}.$$

Hence $\bar{\mu} = \mu(A_1)$ and $\gamma = \|A_{12}\|$.

For a given initial condition and time interval, the error e_o relates to the last three components of the solution and does not change if A_2 is unchanged. We can independently change $\bar{\mu}$ and γ by changing A_1 and A_{12}, respectively. We kept A_2 unchanged, thus keeping $\epsilon = \|e_o\|_2$ unchanged, and studied the effects of changing A_1 (and hence $\bar{\mu}$) and A_{12} (and hence γ) independently on the POD error. First we chose

$$A_1 = \begin{bmatrix} -0.1000 & 0 & 0 \\ 0 & -0.1732 & 2.0 \\ 0 & -2.0 & -0.1732 \end{bmatrix},$$

$$A_{12} = \begin{bmatrix} 0.3893 & 0.5179 & -1.543 \\ 1.390 & 1.300 & 0.8841 \\ 0.06293 & -0.9078 & -1.184 \end{bmatrix},$$

and

$$A_2 = \begin{bmatrix} -1.0 & 0 & 0 \\ 0 & -1.226 & -0.7080 \\ 0 & 0.7080 & -1.226 \end{bmatrix}.$$

Note that the eigenvalues of A_2 have large negative real parts compared to the eigenvalues of A_1, and the eigenvalues of A are the union of these two sets. The corresponding $\bar{\mu} = -1$ and $\gamma = 2.4419$. We randomly chose an initial condition and computed $x(t)$, $\tilde{x}(t)$, and $\hat{x}(t)$ in the interval $[0, 5]$. Note that the reduced model has dimension 3 and that the last three components of both $\tilde{x}(t)$ and $\hat{x}(t)$ are zero. Similarly, the first three components of $e_i(t)$ and $e_o(t)$ are zero. See Figure 4.2, where only the nonzero components are plotted. The computed value of the projection error was $\epsilon = \|e_o\|_2 = 1.4575$. The sup-norm and the 2-norm of the error in the subspace S were also computed and found to be $\|e_i\|_\infty = 1.5589$ and $\|e_i\|_2 = 2.5733$. The bounds provided by the theory were $\|e_i\|_\infty \leq 6.3271$ and $\|e_i\|_2 \leq 10.7930$.

The second choice was to keep A_1 and A_2 the same but scale A_{12} down by a factor of 2. We kept the same initial condition and time interval. This results in the same $\bar{\mu}$, but $\gamma = 1.2209$. In fact, according to (4.2), the effect of scaling A_{12} affects the error e_i linearly, and we expect $e_i(t)$ to be scaled down by the same factor of 2. Figure 4.3 shows a plot of $e_i(t)$ for both cases. This highlights how the rate of change of S components of the vector-field in the directions orthogonal to S affect the error. In the extreme case when $A_{12} = 0$ (i.e., A is "block normal"), the components of the vector-field parallel to S are invariant in the directions perpendicular to S, and the error e_i is zero. Thus the error e_i is zero for a matrix that is "block normal" (with respect to a decomposition of the space based on "fast decay" and the rest of the eigenmodes) if the POD indeed captures the attracting subspace S correctly.

The error e_i is more influenced by $\bar{\mu}$ than γ (as long as $\gamma > 0$), and $\bar{\mu}$ is supposed to capture the growth or decay of solutions of the vector-field of the reduced model. Keeping A_2 and A_{12} the same, we changed A_1 so that

$$A_1 = \begin{bmatrix} -0.1000 & 0 & 1.0 \\ 0 & -0.1732 & 2.0 \\ 0 & -2.0 & -0.1732 \end{bmatrix}.$$

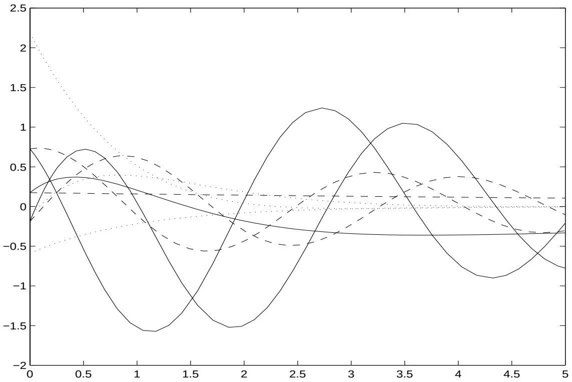

FIG. 4.2. *Example* 1 *on POD error. Solid: Projected solution $\tilde{x}(t)$. Dashed: Reduced model solution $\hat{x}(t)$. Dotted: Projection error $e_o(t)$. Only the three nonzero components $\tilde{x}_1, \tilde{x}_2, \tilde{x}_3$, $\hat{x}_1, \hat{x}_2, \hat{x}_3$ and e_{o4}, e_{o5}, e_{o6} are plotted.*

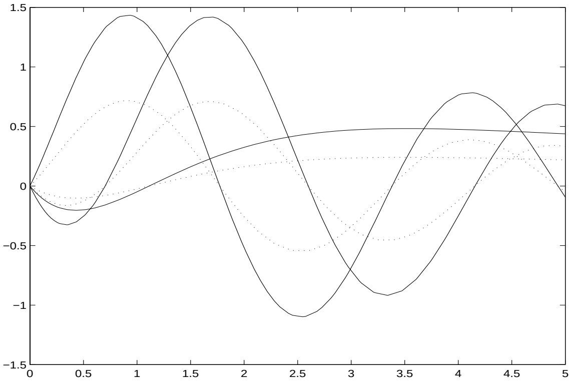

FIG. 4.3. *Example* 1 *on POD error. The effect of scaling A_{12} on the error e_i in the subspace S. Solid: e_i for unscaled A_{12}. Dotted: e_i for scaled down A_{12}. Only the three nonzero components are plotted.*

The corresponding $\bar{\mu} = 0.3647$. Note that this does not change the eigenvalues of A_1, but it does change its normality. This choice of A_1 is no longer normal, and even though the eigenvalues remain the same, the short term behavior of $e_i(t)$ is changed. In fact, $e_i(t)$ does not decay as much as in the normal case. This results in $\|e_i\|_\infty = 2.2088$ and $\|e_i\|_2 = 3.4565$. The bounds provided by the theory are $\|e_i\|_\infty \leq 25.4739$ and $\|e_i\|_2 \leq 28.3330$.

5. Sensitivity of POD to perturbations in data. Given a data set x, POD constructs a projection $P(x)$ onto a subspace which may then be used to approximate some other data set y. If POD is applied to model reduction to compute the approximation $\hat{y}$ to the true solution y of some ODE initial value problem, then the projection $P(x)$ will influence $\hat{y}$. Typically in POD applications the data set x comes from experimental measurement or numerical computations. Hence the data x has some error associated with it. Therefore, it is important to study the effect of these errors on the outcome of the POD model reduction procedure. In this section, we shall theoretically investigate the effect of infinitesimal perturbations of x on $P(x)$, $\tilde{y}$, and $\hat{y}$. We also look at the special case when $y = x$.

5.1. POD sensitivity factor. Let x be a data set, and let $P(x)$ be the corresponding POD projection. In this section, we analyze the sensitivities of the POD projection matrix $P(x)$, with respect to variations in the data x. Our analysis applies to any data set x taking values in $\mathbb{R}^n$, but for simplicity of exposition we assume x to be a single trajectory ($x : [0, T] \to \mathbb{R}^n$) whenever we need to be concrete.

Shifting the origin in data space if necessary, we may assume the mean data values $\bar{x} = 0$. In addition, we can find an orthonormal change of coordinates such that the covariance matrix of x is diagonal. We shall call this a *canonical coordinate system* for data set x. Assuming the use of these canonical coordinates, let

$$x = \sum_{\alpha=1}^{n} x_\alpha e_\alpha, \tag{5.1}$$

where e_α are the standard basis vectors in $\mathbb{R}^n$. Then it can be shown that the scalar data sets x_α are orthogonal. More specifically,

$$(x_\alpha, x_\beta) = \lambda_\alpha \delta_{\alpha,\beta}.$$

Here $\lambda_1, \lambda_2, \dots, \lambda_n$ are the eigenvalues of the covariance matrix of x. If, in addition, we permute the coordinates such that $\lambda_1 \geq \lambda_2 \cdots \geq \lambda_n \geq 0$ are the ordered eigenvalues, then we call this an *ordered canonical coordinate system.* Throughout the rest of the analysis, we shall assume that, after ordering, $\lambda_k > \lambda_{k+1}$ unless stated otherwise.

The POD projection matrix $P \in \mathcal{P} \subset \mathbb{R}^{n \times n}$ is defined as the minimizer of the function

$$e(P, x) = (Px - x, Px - x).$$

Differentiating with respect to P in the direction of E, we obtain

$$\frac{\partial e}{\partial P}(E) = 2(Px - x, Ex).$$

Thus stationary points P of e are given by the condition

$$(Px - x, Ex) = 0, \quad E \in T_P\mathcal{P}.$$

Performing an orthonormal change of coordinates if necessary, we may assume $P = P_0$ (canonical projection) is a stationary point. Then all variations $E \in V = T_{P_0}\mathcal{P}$. Requiring $(P_0 x - x, E^{ij} x) = 0$ for all E^{ij} gives us the conditions that $(x_i, x_{j+k}) = 0$ for all $1 \leq i \leq k$ and $1 \leq j \leq n - k$. This shows that all the stationary points of e are given by P that project onto any of the k dimensional invariant subspaces of the covariance matrix of x. A solution P to the above equation will be a strong local minimum if and only if the second derivative $\frac{\partial^2 e}{\partial P^2}$ is positive definite and this may be shown to be equivalent to $\lambda_k > \lambda_{k+1}$. Under this assumption, P is also a well-defined function of x locally.

Lemma 5.1. *Without loss of generality, let $P = P_0$ be a stationary point in some canonical coordinate system (this may not be ordered). Let $E \in V$ and $\tilde{E} \in V$ be given by*

$$E = \begin{bmatrix} 0_{k \times k} & X_{k \times n-k} \\ X^T_{n-k \times k} & 0_{n-k \times n-k} \end{bmatrix}$$

and

$$\tilde{E} = \begin{bmatrix} 0_{k\times k} & \tilde{X}^T_{k\times n-k} \\ \tilde{X}_{n-k\times k} & 0_{n-k\times n-k} \end{bmatrix}.$$

Then the Hessian satisfies

$$\frac{\partial^2 e}{\partial P^2}(E)(\tilde{E}) = 2(X^T x_1, \tilde{X}^T x_1) - 2(X x_2, \tilde{X} x_2). \tag{5.2}$$

Proof. Since e is a function on the manifold $\mathcal{P}$, one could introduce local coordinates on $\mathcal{P}$ to compute the Hessian of e at a stationary point. However, we shall use a coordinate independent method which allows us to work with matrices and keep the algebra simple. It may be shown that if $P(t,s)$ is a smooth mapping from $\mathbb{R}^2$ into $\mathcal{P}$ such that $P(0,0) = P_0$, $P_t(0,0) = E \in V$ and $P_s(0,0) = \tilde{E} \in V$ and if $\frac{\partial e}{\partial P}(P_0) = 0$, then the Hessian at $P = P_0$ is given by

$$\frac{\partial^2 e}{\partial P^2}(E)(\tilde{E}) = e_{ts}(0,0),$$

where P and e are regarded as functions of t and s and subscripts denote partial derivatives.

Differentiating $e = 2(Px - x, Px - x)$ with respect to t, we get

$$e_t = 2(P_t x, Px - x),$$

and differentiating again with respect to s, we get

$$e_{ts} = 2(P_{ts} x, Px - x) + 2(P_t x, P_s x). \tag{5.3}$$

Suppose

$$P_{ts}(0,0) = \begin{bmatrix} W_1 & W_2 \\ W_3 & W_4 \end{bmatrix}.$$

The matrices W_1, W_2, W_3, and W_4 are not arbitrary but satisfy some relations. These are obtained by differentiating the relation $P^2 = P$ twice. In fact, we get

$$P_{ts}P + P_t P_s + P_s P_t + P P_{ts} = P_{ts},$$

and after substituting expressions for P, P_t, P_s, and P_{ts} (at $(t,s) = (0,0)$) in the above and using the fact that P_{ts} is symmetric, we obtain that $W_1 = -\tilde{X}X^T - X\tilde{X}^T, W_4 = \tilde{X}^T X + X^T \tilde{X}, W_3^T = W_2$, where W_2 is an arbitrary $k \times (n-k)$ matrix. It then follows that $P_{ts}(0,0) = F + W$, where

$$F = \begin{bmatrix} -\tilde{X}X^T - X\tilde{X}^T & 0 \\ 0 & \tilde{X}^T X + X^T \tilde{X} \end{bmatrix}$$

and

$$W = \begin{bmatrix} 0 & W_2 \\ W_2^T & 0 \end{bmatrix},$$

and hence $W \in V$. Hence from (5.3) we obtain

$$e_{ts}(0,0) = 2(Fx, P_0 x - x) + 2(Wx, P_0 x - x) + 2(Ex, \tilde{E}x).$$

Since $\frac{\partial e}{\partial P} = 0$ at $P(0,0) = P_0$ by assumption and $W \in V$, it follows that $(Wx, P_0 x - x) = 0$. Let $x = (x_1, x_2)$, where $x_1(t) \in \mathbb{R}^k$ and $x_2(t) \in \mathbb{R}^{n-k}$. It is easy to see that

$$(Ex, \tilde{E}x) = (Xx_2, \tilde{X}x_2) + (X^T x_1, \tilde{X}^T x_1),$$

where the inner products on the right-hand side are in the appropriate function spaces. Since $(Fx, P_0 x - x) = ((P_0 - 1)Fx, x)$, after computing $(P_0 - 1)F$ it can be shown that

$$(Fx, P_0 x - x) = -(\tilde{X}^T X x_2 + X^T \tilde{X} x_2, x_2) = -2(Xx_2, \tilde{X}x_2).$$

Equation (5.2) follows from this. □

Remark 5.2. From (5.2) it may be shown that the Hessian $\frac{\partial^2 e}{\partial P^2}$ has E^{ij} as its eigenvectors with corresponding eigenvalues $2(\lambda_i - \lambda_{j+k})$ for $1 \le i \le k$ and $1 \le j \le n-k$ (note that we did not order the eigenvalues). Thus the stationary point $P = P_0$ is a strong minimum (maximum) if and only if the first k eigenvalues are strictly greater (smaller) than the rest. It is clear that if, after ordering, $\lambda_k > \lambda_{k+1}$, then there is a unique strong minimum and a unique strong maximum. The rest of the stationary points are saddle points.

The sensitivity of P to variations in data x is given by $\frac{dP}{dx}(\delta x)$, the directional derivative of P with respect to x in the direction δx, where $\delta x : [0,T] \to \mathbb{R}^n$ is assumed to be a unit-norm variation of x ($\|\delta x\| = 1$). It suffices to consider zero mean variations. This is because one may decompose any variation $\delta x \in \mathcal{L}_2([0,T] \to \mathbb{R}^n)$ into a constant function plus a zero mean function, and it is easy to see that the constant function part affects only the mean value $\bar{x}$ of the data while the zero mean function part affects only the projection P.

Remark 5.3. Variations of variables are denoted by prefix δ except for variations of P, which are denoted by E (or $\tilde{E}$, etc.). We will use the 2-norm for functions and the Frobenius norm for matrices P and E.

The norm $\|\frac{dP}{dx}\|$ is defined by

$$\left\| \frac{dP}{dx} \right\| = \sup_{\|\delta x\|=1} \left\| \frac{dP}{dx}(\delta x) \right\|$$

and measures the worst-case sensitivity of P to unit-norm variations of x. However, it makes more sense to consider the nondimensional quantity defined by

$$S_k(x) = \left\| \frac{dP}{dx} \right\| \|x - \bar{x}\|, \tag{5.4}$$

which we shall call the *POD sensitivity factor*. It is the worst-case ratio (in the limit of zero perturbation) of the perturbation of P to the fractional perturbation $\frac{\delta(x-\bar{x})}{\|x-\bar{x}\|}$. We use $x - \bar{x}$ instead of x because P depends only on $x - \bar{x}$. If we scale the data set x by a constant $c \in \mathbb{R}$, then both $\bar{x}$ and $x - \bar{x}$ also scale by c, but P remains unchanged ($P(cx) = P(x)$). The definition of S_k takes care of this scaling symmetry. In fact, we get $S_k(x) = S_k(cx)$. Note that the suffix k stands for the dimension of the reduced subspace $S \subset \mathbb{R}^n$ in which the projected data lives.

Proposition 5.4. *Consider applying POD to a data set x to find the best approximating $k(< n)$ dimensional subspace. Let the ordered eigenvalues of the covariance matrix of the data x be given by $\lambda_1 \ge \cdots \ge \lambda_n$. Suppose $\lambda_k > \lambda_{k+1}$, which ensures* *that $P(x)$ is well defined. Then*

$$S_k(x) = \max_{i\leq k,\, j\leq n-k} \sqrt{2}\frac{\sqrt{\lambda_i+\lambda_{j+k}}}{\lambda_i-\lambda_{j+k}}\sqrt{\lambda_1+\cdots+\lambda_n} \geq \sqrt{2}. \tag{5.5}$$

Furthermore, in the ordered canonical coordinates corresponding to data x, the unit-norm variation δx that causes the maximal variation in P is given by

$$\delta x = \frac{E^{\tilde{i},\tilde{j}}(x-\bar{x})}{\sqrt{\lambda_{\tilde{i}}+\lambda_{\tilde{j}+k}}}, \tag{5.6}$$

where $i=\tilde{i}$ and $j=\tilde{j}$ maximize the right-hand side of (5.5).

Proof. In this proof we will use ordered canonical coordinates. Differentiating $\frac{\partial e}{\partial P}(E)=0$ totally with respect to x in the δx direction, we get

$$\frac{\partial^2 e}{\partial P^2}(E)\left(\frac{dP}{dx}(\delta x)\right) + \frac{\partial^2 e}{\partial P \partial x}(E)(\delta x) = 0 \quad \forall E \in V. \tag{5.7}$$

Hence $\frac{dP}{dx}(\delta x)$ is implicitly defined through the above equation.

The mixed partial $\frac{\partial^2 e}{\partial P\partial x}$ is given by

$$\begin{aligned}\frac{\partial^2 e}{\partial P\partial x}(E)(\delta x) &= 2(Ex,(P-1)\delta x) + 2(E\delta x,(P-1)x)\\ &= 2((PE-E)x,\delta x) + 2((EP-E)x,\delta x)\\ &= -2(Ex,\delta x),\end{aligned} \tag{5.8}$$

where in the first step we used the fact that $E^T=E$ and $P^T=P$, and in the second step we used the fact that $PE+EP=E$ (which comes from $P^2=P$). Note that if $\bar{x}\neq 0$, then $e=(P(x-\bar{x})-(x-\bar{x}),P(x-\bar{x})-(x-\bar{x}))$. Even though we assumed without loss of generality that $\bar{x}=0$, when we take variations of x we need to consider the corresponding variations of $\bar{x}$. However, since we care only about zero mean variations δx, for those the corresponding variation $\delta\bar{x}=0$. Hence we are justified in neglecting the term $\bar{x}$.

It is instructive to examine the finite dimensional space U of $\mathbb{R}^n$-valued functions defined by

$$U = \operatorname{span}\{E'(x-\bar{x}) \ : \ E' \in V\}. \tag{5.9}$$

From (5.8) (note that we assumed $\bar{x}=0$) it can be seen that if δx is orthogonal to U, then $\frac{\partial^2 e}{\partial P\partial x}=0$, and hence by (5.7) $\frac{dP}{dx}(\delta x)=0$. Since we are only interested in variations δx that introduce nonzero variations in P, we shall assume $\delta x\in U$. It can be shown that the map $E'\in V\to E'(x-\bar{x})\in U$ is an isomorphism. This is readily seen by evaluating this map on the basis E^{ij} and showing that $E^{ij}(x-\bar{x})=E^{ij}x$ form an independent set. In fact,

$$E^{ij}x = x_i e_{j+k} + x_{j+k}e_i,$$

and hence

$$\begin{aligned}(E^{ij}x,E^{lm}x) &= \lambda_i+\lambda_{j+k}, \quad l=i, j=m,\\ &= 0 \quad \text{otherwise.}\end{aligned} \tag{5.10}$$

Hence $\{E^{ij}x \ : \ i = 1, \dots, k; j = 1, \dots, n-k\}$ is an orthogonal set (and is clearly independent as well).

Substitute (5.2) and (5.8) into the implicit equation (5.7) for $\frac{dP}{dx}$, and let

$$\frac{dP}{dx}(\delta x) = \begin{bmatrix} 0 & \tilde{X} \\ \tilde{X}^T & 0 \end{bmatrix}$$

and $\delta x = (\delta x_1, \delta x_2)$, where $\delta x_1(t) \in \mathbb{R}^k$ and $\delta x_2(t) \in \mathbb{R}^{n-k}$. Then we obtain an equation for $\tilde{X}$:

$$(5.11)\quad (X^T x_1, \tilde{X}^T x_1) - (X x_2, \tilde{X} x_2) = (X x_2, \delta x_1) + (X^T x_1, \delta x_2) \quad \forall X \in \mathbb{R}^{k \times (n-k)}.$$

Let $\delta x = E' x \in U$, where

$$E' = \sum_{l,m} \alpha_{lm} \frac{E^{lm}}{\sqrt{\lambda_l + \lambda_{m+k}}},$$

and let $\tilde{X} = \sum_{l,m} \beta_{lm} X_{lm}$. Substituting these into (5.11) for $X = X_{ij}$, we get

$$\beta_{ij} = \alpha_{ij} \frac{\sqrt{\lambda_i + \lambda_{j+k}}}{\lambda_i - \lambda_{j+k}}.$$

Hence it follows that

$$(5.12)\qquad \frac{dP}{dx}(\delta x) = \sum_{i,j} \alpha_{ij} \frac{\sqrt{\lambda_i + \lambda_{j+k}}}{\lambda_i - \lambda_{j+k}} E^{ij}.$$

The requirement that $\|\delta x\| = 1$ is equivalent to $\sum_{i,j} \alpha_{ij}^2 = 1$. Since $\|E^{ij}\| = \sqrt{2}$, it follows that

$$(5.13)\qquad \left\| \frac{dP}{dx} \right\| = \max_{i \le k,\ j \le n-k} \sqrt{2} \frac{\sqrt{\lambda_i + \lambda_{j+k}}}{\lambda_i - \lambda_{j+k}},$$

with the maximizing unit-norm variation δx given by (5.6). (Note that we need to replace x by $x - \bar{x}$, since we assumed for simplicity that $\bar{x} = 0$.) The equation in (5.5) follows from this. The inequality in (5.5) follows because

$$\max_{i \le k, j \le n-k} \frac{\sqrt{\lambda_i + \lambda_{j+k}}}{\lambda_i - \lambda_{j+k}} \sqrt{\lambda_1 + \cdots + \lambda_n} \ge \max_{i \le k, j \le n-k} \frac{\lambda_i + \lambda_{j+k}}{\lambda_i - \lambda_{j+k}} \ge 1. \qquad \square$$

The following corollary is obvious from the above proof.

COROLLARY 5.5. *Assuming $\lambda_k > \lambda_{k+1}$ as before and the use of ordered canonical coordinates, the linear map $\delta x \in U \mapsto E(x - \bar{x}) \in U$, where $E = \frac{dP}{dx}(\delta x)$, is self-adjoint and has as its eigenvectors the orthonormal basis of U given by $\{u_{ij}\}$ for $i = 1, \dots, k$ and $j = 1, \dots, n-k$, which are defined by*

$$u_{ij} = E^{ij}(x - \bar{x}) = \frac{x_i e_{j+k} + x_{j+k} e_i}{\sqrt{\lambda_i + \lambda_{j+k}}}.$$

The corresponding eigenvalues are $\frac{\lambda_i + \lambda_{j+k}}{\lambda_i - \lambda_{j+k}}$. Hence the induced 2-norm of this operator is $\frac{\lambda_k + \lambda_{k+1}}{\lambda_k - \lambda_{k+1}}$.

$$\begin{tikzcd}

 & & \begin{array}{c}\tilde{x} + \delta\tilde{x}_1\\ \xi + \delta\xi_1 = \|\tilde{x} + \delta\tilde{x}_1 - x\|^2\end{array} \\
 & & \begin{array}{c}\tilde{x} + \delta\tilde{x}_2\\ \xi + \delta\xi_2 = \|\tilde{x} + \delta\tilde{x}_2 - x\|^2\end{array} \\
x + \delta x \arrow[r] \arrow[uurr, dashed] \arrow[drr, dashed] & (\bar{x} + \delta\bar{x},\ P(x + \delta x) = P + E) \arrow[ur, dotted] \arrow[dr, dotted] & \\
 & & \begin{array}{c}\tilde{x} + \delta\tilde{x}\\ \xi + \delta\xi = \|\tilde{x} + \delta\tilde{x} - x\|^2\end{array}
\end{tikzcd}$$

FIG. 5.1. *POD sensitivity for y near x: This shows the four different possibilities of using the reduced models computed from x and $y = x + \delta x$ to approximate these data sets. The solid arrows indicate the construction of a POD reduced model from a data set. A pair of dashed and dotted arrows together show the reduced model being applied to a data set to obtain a reduced and approximate data set. The approximate data obtained and its square error with respect to x are shown on the far right.*

Remark 5.6. Proposition 5.4 was concerned with the POD method of finding the best approximating affine subspace using the mean and the covariance matrix of the data x. Instead, if we considered the POD method of finding the best approximating linear subspace using the correlation matrix, then we get the same equations and the same final expression (5.5) for $S_k(x)$ (in the definition of the space U, $(x - \bar{x})$ needs to be replaced by x). However, x, the perturbation δx, and the worst-case perturbation of δx as well as functions in the space U are no longer necessarily zero mean.

5.2. Sensitivity of the projected data $\tilde{y} = P(x)(y - \bar{x}) + \bar{x}$ and the error $\|\tilde{y} - y\|^2$ when $y = x$ and/or $y = x + \delta x$. In some applications the POD reduced model $(\bar{x}, P(x))$ constructed from a data set x may be used to approximate x itself ($y = x$ situation) or some nearby data $y = x + \delta x$. For instance, consider coding a 512×512 grey scale image by dividing it into subimages of size 8×8 to provide an ensemble of $4096 (= 64 \times 64)$ points in the 64 dimensional subimage space. Suppose that by applying POD to this ensemble we find a subspace of dimension 6 that captures 99.9% of the energy. We could then apply the POD projection to the subimages and code the entire image using 4096×6 grey scale values. This is the $y = x$ situation. If we have a sequence of nearby images (such as in video), then we can use the same reduced model $(\bar{x}, P(x))$ for the nearby images $y = x + \delta x$.

From a theoretical point of view, several different sensitivities may be of interest. These are shown in Figure 5.1. The sensitivities $\delta\tilde{x}_1$ and $\delta\xi_1$ correspond to the situation where the same reduced model $(\bar{x}, P(x))$ (obtained from x) is applied to both x and to a nearby $y = x + \delta x$. The quantity $\delta\tilde{x}_1$ is the perturbation of the approximate data, and $\delta\xi_1$ is the perturbation of the square error $\xi = \|\tilde{x} - x\|^2$. Thus

$$\delta\tilde{x}_1 = (P(x)(x + \delta x - \bar{x}) + \bar{x}) - \tilde{x}$$

and

$$\delta\xi_1 = \|(\tilde{x} + \delta\tilde{x}_1) - (x + \delta x)\|^2 - \xi,$$

where $\tilde{x} = P(x)(x - \bar{x}) + \bar{x}$. This is the most common kind of sensitivity one is interested in in practice. Note that the reason for considering the square of the error rather than the error $\|\tilde{x} - x\|$ itself is because the square root is not smooth when its argument is zero.

The sensitivities $\delta\tilde{x}_2$ and $\delta\xi_2$ correspond to the situation where two nearby reduced models $(\bar{x}, P(x))$ and $(\bar{x} + \delta\bar{x}, P(x + \delta x)$ are applied to the same data x. Thus

$$\delta\tilde{x}_2 = (P(x + \delta x)(x - (\bar{x} + \delta\bar{x})) + (\bar{x} + \delta\bar{x})) - \tilde{x}$$

and

$$\delta\xi_2 = \|(\tilde{x} + \delta\tilde{x}_2) - x\|^2 - \xi.$$

The sensitivities $\delta\tilde{x}$ and $\delta\xi$ correspond to the situation where two nearby reduced models $(\bar{x}, P(x))$ and $(\bar{x} + \delta\bar{x}, P(x + \delta x))$ are applied to the respective data sets x and $x + \delta x$ from which they were constructed. Thus

$$\delta\tilde{x} = (P(x + \delta x)((x + \delta x) - (\bar{x} + \delta\bar{x})) + (\bar{x} + \delta\bar{x})) - \tilde{x}$$

and

$$\delta\xi = \|(\tilde{x} + \delta\tilde{x}) - (x + \delta x)\|^2 - \xi.$$

We provide a useful and easy-to-prove lemma stated without proof.

Lemma 5.7. *Let $L : H \to H$ be a linear operator in the Hilbert space H. Let $K \subset H$ be a closed linear subspace of H. Then we can write $H = K \oplus K^\perp$. Furthermore, suppose $L(K) \subset K$ and $L(K^\perp) \subset K^\perp$ and that the restrictions $L|_K$ and $L|_{K^\perp}$ are bounded operators. Then $\|L\|_2 = \max\{\|L|_K\|_2, \|L|_{K^\perp}\|_2\}$.*

Proposition 5.8. *Consider applying POD to a data set x to find the best approximating $k(< n)$ dimensional subspace. Let the ordered eigenvalues of the covariance matrix of the data x be given by $\lambda_1 \geq \cdots \geq \lambda_n$. Suppose $\lambda_k > \lambda_{k+1}$, which ensures that $P(x)$ is well defined. Consider the sensitivities depicted in Figure* 5.1. *For unit-norm (infinitesimal) variations δx of x, the worst-case variations are given by*

$$\|\delta\tilde{x}_1\| = \|\delta x\|, \tag{5.14}$$

$$\|\delta\tilde{x}_2\| = \frac{\lambda_k + \lambda_{k+1}}{\lambda_k - \lambda_{k+1}} > 1, \tag{5.15}$$

$$\|\delta\tilde{x}\| = \frac{\lambda_k + \sqrt{\lambda_k\lambda_{k+1}}}{\lambda_k - \lambda_{k+1}} > 1, \tag{5.16}$$

$$|\delta\xi_1| = |\delta\xi| = 2\|\tilde{x} - x\| = 2\sqrt{\xi}, \tag{5.17}$$

$$\delta\xi_2 = 0. \tag{5.18}$$

(All norms are 2*-norms.)*

Proof. We shall use the ordered canonical coordinate system whenever necessary.

We define some relevant subspaces. As before we shall consider the data x to be a single trajectory $x : [0,T] \to \mathbb{R}^n$ for simplicity of exposition. However, the results will hold for more general types of data. We shall assume $x \in \mathcal{L}_2([0,T],\mathbb{R}^n)$, the space of all square integrable $\mathbb{R}^n$-valued functions in $[0,T]$. Let $Z \subset \mathcal{L}_2([0,T],\mathbb{R}^n)$ denote the (closed) subspace of all zero mean functions:

$$Z = \left\{ x \in \mathcal{L}_2([0,T],\mathbb{R}^n) \ : \ \int_0^T x dt = 0 \right\}.$$

Its orthogonal complement $Z^\perp$ is finite dimensional and consists of functions that are constant-valued (almost everywhere) in $[0,T]$. We shall further decompose Z into the orthogonal sum $Z = W \oplus Y$, where

$$W = \operatorname{span}\left\{ \frac{x_\alpha}{\sqrt{\lambda_\alpha}} e_\beta \ : \ \alpha = 1,\dots,\tilde{n},\ \beta = 1,\dots,n \right\}. \tag{5.19}$$

Here $\tilde{n}$ is the number of nonzero eigenvalues of the covariance matrix associated with trajectory x (thus W depends on x), and x_α are its components in the ordered canonical coordinate system. Since Y is the orthogonal complement of W in Z, it is closed. The $n\tilde{n}$ dimensional W is further decomposed into the orthogonal sum $W = U \oplus U_2 \oplus V_1 \oplus V_2$, where

$$\begin{aligned}
U &= \operatorname{span}\left\{ u_{ij} = \frac{x_i e_{j+k} + x_{j+k} e_i}{\sqrt{\lambda_i + \lambda_{j+k}}} \ : \ i = 1,\dots,k;\ j = 1,\dots,n-k \right\},\\
U_2 &= \operatorname{span}\left\{ u_{ij}^2 = \frac{\lambda_{j+k} x_i e_{j+k} - \lambda_i x_{j+k} e_i}{\sqrt{\lambda_i \lambda_{j+k} (\lambda_i + \lambda_{j+k})}} \ : \ i = 1,\dots,k;\ j = 1,\dots,\tilde{n}-k \right\},\\
V_1 &= \operatorname{span}\left\{ \frac{x_i e_\alpha}{\sqrt{\lambda_i}} \ : \ i = 1,\dots,k;\ \alpha = 1,\dots,k \right\},\\
V_2 &= \operatorname{span}\left\{ \frac{x_{j+k} e_{\beta+k}}{\sqrt{\lambda_{j+k}}} \ : \ j = 1,\dots,\tilde{n}-k;\ \beta = 1,\dots,n-k \right\}.
\end{aligned}$$

It should be noted that the spanning elements above form orthonormal bases for the respective subspaces. Furthermore, define $\widetilde{U} = U \oplus U_2$ and $V = V_1 \oplus V_2$. Also note that U defined above is the same as in (5.9).

The perturbation $\delta\tilde{x}_1$ is given by

$$\delta\tilde{x}_1 = P(x)(x + \delta x - \bar{x}) + \bar{x} - P(x)(x - \bar{x}) - \bar{x}$$

and simplifies to $\delta\tilde{x}_1 = P(x)\delta x$. Hence the worst perturbation δx is in the image of $P(x)$, resulting in $\delta\tilde{x}_1 = \delta x$. Note that this holds for finite as well as infinitesimal perturbations.

The variation $\delta\tilde{x}_2$ is given by

$$\delta\tilde{x}_2 = E(x - \bar{x}) + (1 - P(x))\delta\bar{x},$$

where $E = \frac{dP}{dx}(\delta x)$. Note that $\delta x \in Z^\perp$ implies that $E = 0$ and hence that $\delta\tilde{x}_2 = (1 - P)\delta\bar{x} \in Z^\perp$. Also note that $\delta x \in Z$ implies $\delta\tilde{x}_2 \in Z$. Furthermore, if $\delta x \in Z$ and $\delta x \perp U$, then $\delta\tilde{x}_2 = 0$. If $\delta x \in U$, then $\delta\tilde{x}_2 = E(x - \bar{x}) \in U \subset Z$. From Corollary

5.5 and Lemma 5.7 it is clear that the worst-case variation $\|\delta\tilde{x}_2\| = \frac{\lambda_k+\lambda_{k+1}}{\lambda_k-\lambda_{k+1}} > 1$ and that it corresponds to $\delta x = \frac{x_k e_{k+1} + x_{k+1} e_k}{\sqrt{\lambda_k+\lambda_{k+1}}}$.

The variation $\delta\tilde{x}$ is given by

$$\delta\tilde{x} = E(x-\bar{x}) + P\delta x - P\delta\bar{x} + \delta\bar{x}.$$

Denote by L the operator that maps δx to $\delta\tilde{x}$. The following are easy to establish: $L(Z) \subset Z$, $L(Z^\perp) \subset Z^\perp$, $L(W) \subset W$, $L(Y) \subset Y$, $L(V) \subset V$, and $L(\tilde{U}) \subset \tilde{U}$. If $\delta x \in Z^\perp$, then $\delta\tilde{x} = \delta x = \delta\bar{x}$, so $\|L|_{Z^\perp}\| = 1$. If $\delta x \in Z$ and $\delta x \perp \tilde{U}$, it follows that $\delta\tilde{x} = P\delta x$. Hence by Lemma 5.7

$$\|L\| = \max\{\|L|_{\tilde{U}}\|, 1\}.$$

It can be verified that the following orthonormal basis of $\tilde{U}$ are eigenvectors of the finite dimensional operator $L|_{\tilde{U}} : \tilde{U} \to \tilde{U}$:

$$\left\{ \frac{x_i e_{j+k}}{\sqrt{2\lambda_i}} + \frac{x_{j+k} e_i}{\sqrt{2\lambda_{j+k}}}, \frac{x_i e_{j+k}}{\sqrt{2\lambda_i}} - \frac{x_{j+k} e_i}{\sqrt{2\lambda_{j+k}}}, \frac{x_i e_{\tilde{j}+k}}{\sqrt{2\lambda_i}} \ : i = 1,\dots,k;\ j = 1,\dots,\tilde{n}-k; \right.$$
$$\left. \tilde{j} = \tilde{n}-k+1,\dots,n-k \right\}.$$

The eigenvectors $\{\frac{x_i e_{\tilde{j}+k}}{\sqrt{2\lambda_i}}\}$ all have eigenvalue 1. The eigenvectors $\{\frac{x_i e_{j+k}}{\sqrt{2\lambda_i}} + \frac{x_{j+k} e_i}{\sqrt{2\lambda_{j+k}}}\}$ have corresponding eigenvalues $\frac{\lambda_i + \sqrt{\lambda_i\lambda_{j+k}}}{\lambda_i - \lambda_{j+k}} > 1$. The eigenvectors $\{\frac{x_i e_{j+k}}{\sqrt{2\lambda_i}} - \frac{x_{j+k} e_i}{\sqrt{2\lambda_{j+k}}}\}$ have corresponding (positive) eigenvalues $\frac{\lambda_i - \sqrt{\lambda_i\lambda_{j+k}}}{\lambda_i - \lambda_{j+k}} < 1$. Hence the norm $\|L|_{\tilde{U}}\|$ is given by the largest eigenvalue $\frac{\lambda_k + \sqrt{\lambda_k\lambda_{k+1}}}{\lambda_k - \lambda_{k+1}} > 1$. Hence $\|L\| = \frac{\lambda_k + \sqrt{\lambda_k\lambda_{k+1}}}{\lambda_k - \lambda_{k+1}}$.

The (infinitesimal) variation $\delta\xi_1$ is given by

$$\delta\xi_1 = 2(\tilde{x} - x, \delta\tilde{x}_1 - \delta x) = (\tilde{x} - x, (P-1)\delta x),$$

and hence the worst case is when $\delta x = \pm\frac{\tilde{x}-x}{\|\tilde{x}-x\|}$ and results in $|\delta\xi_1| = 2\|\tilde{x} - x\|$.

The variation $\delta\xi$ is given by

$$\begin{aligned}\delta\xi &= 2(\tilde{x} - x, \delta\tilde{x} - \delta x) \\ &= 2(\tilde{x} - x, E(x-\bar{x})) + 2(\tilde{x} - x, (1-P)\delta\bar{x}) + 2(\tilde{x} - x, (1-P)\delta x) \\ &= 2(\tilde{x} - x, (1-P)\delta x).\end{aligned}$$

As before, the worst-case variation is given by $\delta x = \pm\frac{\tilde{x}-x}{\|\tilde{x}-x\|}$ and results in $|\delta\xi| = 2\|\tilde{x} - x\|$.

The variation $\delta\xi_2$ is given by

$$\begin{aligned}\delta\xi_2 &= 2(\tilde{x} - x, \delta\tilde{x}_2) \\ &= 2(\tilde{x} - x, E(x-\bar{x})) + 2(\tilde{x} - x, (1-P)\delta\bar{x}).\end{aligned}$$

Since $\tilde{x} - x \in V_2$, $E(x-\bar{x}) \in U$, and $(1-P)\delta\bar{x} \in Z^\perp$, it follows that $\delta\xi_2 = 0$. □

Remark 5.9. The above proposition shows that the projected data $\tilde{x}$ may become extremely sensitive to perturbations in the data set when $\lambda_k \approx \lambda_{k+1}$. However, the (square of the) error itself does not show this sensitivity. This is related to the fact that when $\lambda_k = \lambda_{k+1}$ there are infinitely many choices for $P(x)$ and thus for $\tilde{x}$, and these different choices for $\tilde{x}$ may be quite different from each other. However, they all have exactly the same error $\sqrt{\lambda_{k+1} + \cdots + \lambda_n}$. It should also be noted that our sensitivity results hold for infinitesimal variations, and finite perturbations are likely not to be as sensitive as the first derivative may suggest.

Example 2. This example illustrates a situation where the reduced model solution is very sensitive to perturbations of the trajectory x used as POD data. We consider a dissipative ODE example which has a periodic orbit which is a global attractor. Consider the ODE

$$\dot{x} = A(x - f(t)) + f'(t), \quad x \in \mathbb{R}^n,$$

where $f : \mathbb{R} \to \mathbb{R}^n$ is smooth. Observe that for any choice of A and f, $x = f(t)$ is a trajectory of this system. We exploit this fact to independently choose $f(t)$ and A to create an interesting example which highlights some of the potential problems with the POD procedure.

We chose $f(t)$ to be periodic and A to be a constant matrix with all of its eigenvalues in the complex left half plane. Thus $x = f(t)$ will be a global attractor of this system. Specifically we chose $f(t)$ to be of the form

$$f(t) = \left(\sqrt{a_1} \sin\left(\frac{2\pi t}{25}\right),\ \sqrt{a_2} \cos\left(\frac{2\pi t}{25}\right),\ \sqrt{a_3} \sin\left(\frac{4\pi t}{25}\right),\ \sqrt{a_4} \cos\left(\frac{4\pi t}{25}\right) \right)^T,$$

where a_i are real nonnegative constants. This trajectory has period 25. If we use this trajectory in the interval $[0, 50]$ (two periods) as POD data, we will get a reduced model with $\bar{x} = 0$ and a diagonal covariance matrix R with $R_{ii} = 25a_i$. This is because the component functions of $f(t)$ in the interval $[0, 50]$ form an orthogonal set. If we choose $a_4 = 0$ (or very small), then the POD procedure based on this trajectory will give a reduced model ODE by projecting onto the first three components in $\mathbb{R}^4$. This projection will preserve all (or almost all) of the energy of the POD data trajectory. Now consider a matrix A that has all of its eigenvalues in the complex left half plane, but its submatrix consisting of the first three rows and columns (i.e., the projection of A onto the first three components in $\mathbb{R}^4$) has an eigenvalue in the complex right half plane. Such a choice of A will lead to a reduced model which is unstable. If $a_4 = 0$, the global attractor $x = f(t)$ will still be a trajectory of the reduced model but it will not be an attractor. Thus the qualitative behavior of the reduced model will be quite different even though the POD procedure is based on a global attractor of a dissipative system.

In order to find such an A, we first chose A to be diagonalizable with eigenvalues

$$\lambda(A) = \{-0.7 + 0.4i, -0.7 - 0.4i, -0.2, -0.1\}.$$

Then by trial and error, applying random similarity transformations, we found an A with the above canonical form such that its submatrix consisting of the first three rows and columns had an eigenvalue of about 1.8 in the complex right half plane.

If we choose $a_4 = 0$, then with $k = 3$ we do not expect high sensitivity to perturbations in the data. However, we get an interesting example where doing POD on a lower dimensional global attractor still leads to a reduced model which is unstable and qualitatively different. Since we were interested in studying the effects of perturbations in the POD data on the final outcome of a POD reduced model solution, instead of choosing $a_4 = 0$, we chose the following values for a_i:

$$a_1 = 5,\ a_2 = 0.5,\ a_3 = 0.011,\ a_4 = 0.01,$$

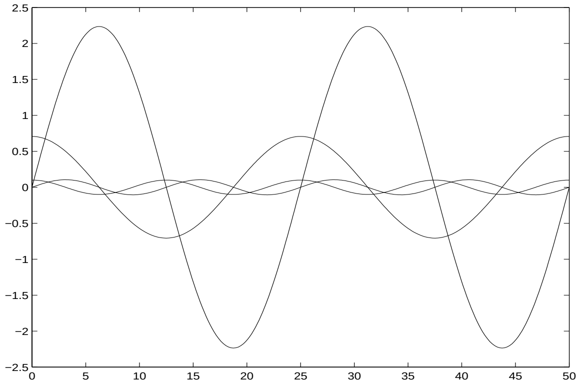

FIG. 5.2. *Example* 2: *True solution* $x(t)$.

where $a_3 \approx a_4$. With this choice, a reduced model of dimension $k = 3$ will capture most of the energy, but we will expect high sensitivity to small perturbations in the POD data. We chose the initial value problem with $x(0) = f(0)$ and time interval $[0, 50]$. Thus the solution trajectory is $x = f(t)$ and consists of two periods. In order to incoorporate the effects of numerical errors, we computed the solution using the MATLAB solver `ode45` and then computed the POD reduced model of dimension $k = 3$ numerically. We also numerically computed the projected trajectory $\tilde{x}$ as well as the solution $\hat{x}$ of the reduced ODE model. We found that the POD procedure preserved 99.8% of the energy and that the sensitivity factor was $S_k = 480$. We found $\|x\| = 11.75$ and $\|\tilde{x}\| = 11.74$. The reduced model solution was highly unstable and $\|\hat{x}\| = 1.25 \times 10^{38}$. The eigenvalues of the reduced model matrix were $\{1.80, -0.281 + 0.217i, -0.281 - 0.217i\}$.

Then we perturbed the trajectory x by δx in the direction given by (5.6) that creates the worst perturbation in P. We chose $\|\delta x\| = 0.1$. We then computed the POD reduced model corresponding to $x + \delta x$ and also computed the perturbed projected trajectory $\tilde{x} + \delta \tilde{x}$ as well as the perturbed reduced model solution $\hat{x} + \delta \hat{x}$. Figure 5.2 shows a plot of the numerically computed true solution $x(t)$ (i.e., the full model solution). Figures 5.3 and 5.4 show how a small perturbation in x leads to a larger perturbation in $\tilde{x}$, and Figure 5.5 shows an even larger perturbation in $\hat{x}$. We also observed that while the unperturbed reduced model projected almost onto the first three components in $\mathbb{R}^4$, the perturbed reduced model was projecting onto a subspace that consisted of the span of $\{e_1, e_2\}$ and a combination of e_3 and e_4, and this subspace was rotated from the span of $\{e_1, e_2, e_3\}$ by an angle of about 41° (e_i being the standard basis vectors in $\mathbb{R}^4$). It was also observed that the eigenvalues of the perturbed reduced model matrix were $\{2.89, -0.337, -0.166\}$, which correspond to a larger instability and a qualitatively different nonoscillatory behavior from that of the unperturbed reduced model.

This example illustrates two potential inadequacies of the POD method. One is that even capturing 100% of the energy of a globally attracting low dimensional trajectory may still lead to a POD reduced model with the wrong dynamics. Second, it also illustrates how POD sensitivity to the data trajectory may lead to qualitatively different reduced models.

The first problem is related to two factors. One is that a single trajectory (even a global attractor) or a set of trajectories alone does not carry all the information

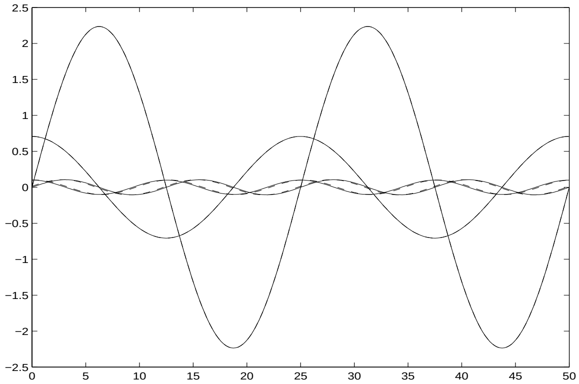

FIG. 5.3. *Example* 2. *Perturbation of x: Solid: x; dashed: $x+\delta x$. The perturbation is so small* ($\frac{\|\delta x\|}{\|x\|} = 0.0085$) *that the two trajectories are barely distinguishable. Note that all four components are plotted for both x and $x+\delta x$. The perturbation is only noticeable in the two smaller components.*

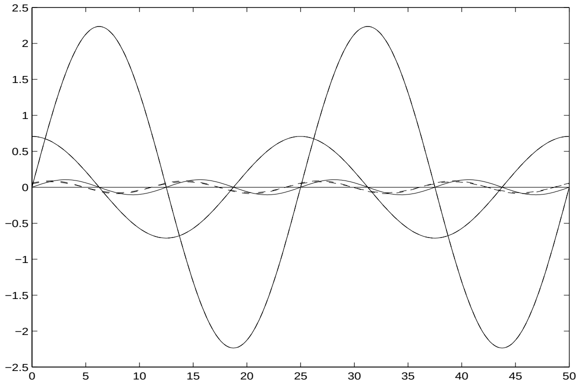

FIG. 5.4. *Example* 2. *Perturbation of $\tilde{x}$: Solid: $\tilde{x}$; dashed: $\tilde{x}+\delta\tilde{x}$. The perturbation is larger than that of x but still not noticeable for the two large components.*

about the dynamics. Second, the projection of a vector-field onto a given subspace does not preserve its stability characteristics. Our example has these characteristics and in addition has a high sensitivity factor.

5.3. Effect of POD sensitivity in data representation and model reduction. Consider the reduced model $(\bar{x}, P(x))$ obtained from a data set x. Suppose we apply this reduced model to represent another data set y and obtain $\tilde{y} = P(x)(y-\bar{x})+\bar{x}$. The previous subsection was concerned with the special situation where $y = x$. In general situations, the data set y is different from x. The variation $\delta\tilde{y}$ due to a variation δx is given by

$$\delta\tilde{y} = E(y-\bar{x}) + \delta\bar{x} - P\delta\bar{x},$$

where E is the corresponding variation of P. Since $\|E\| \leq S_k \frac{\|\delta(x-\bar{x})\|}{\|x-\bar{x}\|}$ (assuming $\|x-\bar{x}\| \neq 0$), we obtain

$$\|\delta\tilde{y}\| \leq S_k \frac{\|y-\bar{x}\|}{\|x-\bar{x}\|} \|\delta(x-\bar{x})\| + \|\delta\bar{x}\|.$$

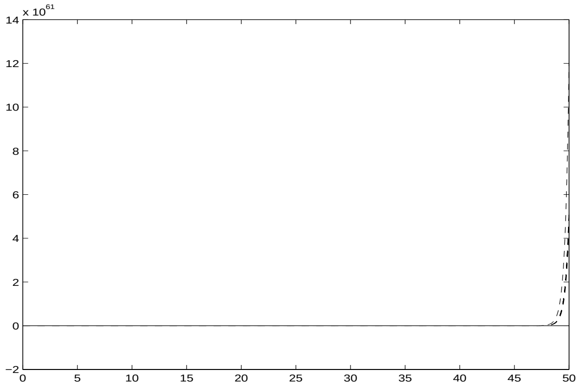

FIG. 5.5. *Example* 2. *Perturbation of $\hat{x}$: Solid: $\hat{x}$; dashed: $\hat{x}+\delta\hat{x}$. Note that $\hat{x}$ appears to be zero since it is of the order* 10^{38}*, while $\hat{x}+\delta\hat{x}$ is of the order* 10^{61}.

Assuming further that $\|y\| \neq 0$, we obtain the following fractional sensitivity relation:

$$\frac{\|\delta\tilde{y}\|}{\|y\|} \leq S_k \frac{\|y-\bar{x}\|}{\|y\|}\frac{\|\delta(x-\bar{x})\|}{\|x-\bar{x}\|} + \frac{\|\delta\bar{x}\|}{\|y\|}. \tag{5.20}$$

Now let us consider the case where we use the reduced model $(\bar{x}, P(x))$ to compute the solution of an ODE initial value problem for a linear time invariant system $\dot{y} = Ay$, with initial condition $y(0) = y_0$ in the interval $[0, T]$. Let y denote the true solution and $\hat{y}$ denote the reduced model solution. Then $\hat{y}$ satisfies the initial value problem $\dot{\hat{y}} = PA\hat{y}$, $\hat{y}(0) = P(y_0 - \bar{x}) + \bar{x}$. Taking variations, we get

$$\delta\dot{\hat{y}} = PA\delta\hat{y} + EA\hat{y},$$

with initial condition $\delta\hat{y}(0) = E(y_0 - \bar{x}) - P\delta\bar{x} + \delta\bar{x}$. Hence applying the estimate (3.2), we get

$$\|\delta\hat{y}\| \leq \|F(T;PA)\|\|E\|\|A\|\|\hat{y}\| + \|G(T;PA)\|\|E\|\|y_0-\bar{x}\| + \|G(T;PA)\|\|\delta\bar{x}\|,$$

where F and G are defined by (3.1). Since $\|E\| \leq S_k \frac{\|\delta(x-\bar{x})\|}{\|x-\bar{x}\|}$, it follows that

$$\begin{aligned}\frac{\|\delta\hat{y}\|}{\|\hat{y}\|} \leq & \left(\|F(T;PA)\|\|A\| + \|G(T;PA)\|\frac{\|y_0-\bar{x}\|}{\|\hat{y}\|}\right) S_k \frac{\|\delta(x-\bar{x})\|}{\|x-\bar{x}\|} \\ & + \|G(T;PA)\|\frac{\|\delta\bar{x}\|}{\|x-\bar{x}\|}.\end{aligned} \tag{5.21}$$

Example 3. We considered the same initial value problem of Example 2 in the same interval. However, instead of using the true solution as POD data, we used the set of eight trajectories x obtained by solving the system in the same interval with the symmetrically placed initial conditions $x(0) = e_i$ and $x(0) = -e_i$ for $i = 1, \ldots, 4$, where $e_i \in \mathbb{R}^4$ are the standard basis vectors as POD data, and computed the rank 3 projection matrix $P(x)$. The sensitivity factor was $S_k = 10.140$. We then perturbed this data set x in the direction given by (5.6) (this gives the worst perturbation in P) by an amount $\|\delta x\| = 0.5$. The norm of the data set was $\|x\| = 54.070$, and $\|x - \bar{x}\| = 52.90$. Thus we had the fractional change $\|\delta x\|/\|x - \bar{x}\| = 0.0095$. We also

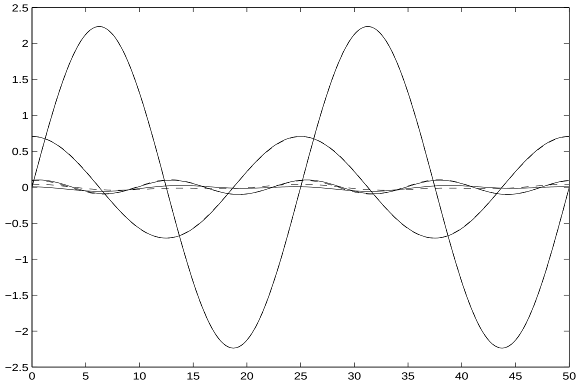

FIG. 5.6. *Example* 3. *Perturbation of $\tilde{y}$: Solid: $\tilde{y}$; dashed: $\tilde{y} + \delta\tilde{y}$.*

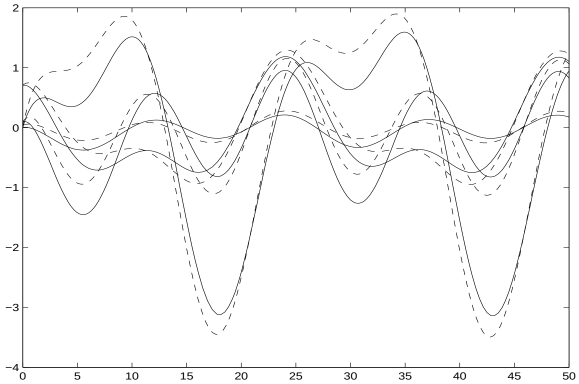

FIG. 5.7. *Example* 3. *Perturbation of $\hat{y}$: Solid: $\hat{y}$; dashed: $\hat{y} + \delta\hat{y}$.*

computed the projections $P(x)$ and $P(x + \delta x)$ corresponding to the data sets x and $x + \delta x$.

Denote by y the true solution of the initial value problem. (This is the same as $x(t)$ of Example 2 in Figure 5.2.) We applied both reduced models $P(x)$ and $P(x+\delta x)$ to compute $\tilde{y} = P(x)(y - \bar{x}) + \bar{x}$ and $\tilde{y} + \delta\tilde{y} = P(x + \delta x)(y - \bar{x} - \delta\bar{x}) + \bar{x} + \delta\bar{x}$, the projected solutions. Figure 5.6 shows the two different projected solutions.

We then computed the reduced model solutions $\hat{y}$ and $\hat{y}+\delta\hat{y}$ corresponding to $P(x)$ and $P(x + \delta x)$, respectively. These are plotted in Figure 5.7. This again illustrates how a small perturbation in the POD data set may cause a large perturbation in the reduced model solution.

Remark 5.10. In this section we basically saw how POD results may be very sensitive to slight perturbations in the data when $\lambda_k \approx \lambda_{k+1}$. However, one needs to be careful in interpreting these results. This raises the question of whether one should consider the sensitivity factor S_k (in addition to the projection error $\sqrt{\lambda_{k+1} + \cdots + \lambda_n}$) as an important factor in choosing an appropriate dimension k for the reduced model. Sometimes the distribution of eigenvalues may be such that seeking higher accuracy may lead to a high sensitivity factor S_k. The importance of S_k depends on the nature of the application. It must also be noted that our sensitivity analysis holds only for infinitesimal perturbations; the sensitivity for finite perturbations is likely to be different. For instance, infinitesimal analysis predicts that in the limit $\lambda_k \to \lambda_{k+1}$ the sensitivity of P with respect to x grows indefinitely. However, since projection matrices live on a compact set ($\|P\| = 1$), the finite perturbations of P cannot grow indefinitely. As mentioned in Remark 5.9, when $y \approx x$, for data compression type problems we have already argued that the sensitivity factor is not a serious issue. However, in reduced order models for ODEs, Examples 2 and 3 show how a small perturbation in the POD data may lead to very large perturbations in the reduced model solutions.

In addition, we would like to note that in iterative methods based on POD such as the DIRM method [20, 21], the convergence of the iterations will depend on the sensitivity factor. This has been theoretically and numerically demonstrated in [20].

6. Computational complexity of POD reduced order models. Since the POD method of model reduction results in a smaller dimensional system of ODEs, one might expect computational savings when integrating the resulting system. However, this may not be so in practice. In this section we shall take a close look at the complexity of computation for integrating a system of ODEs (initial value problems) and evaluate the savings if any in using the POD method.

To be precise, by complexity we shall mean the asymptotic behavior of the number of floating point operations (flops—addition, multiplication, and elementary functions each count as one flop) involved per integration step as the system size n (k for reduced models) becomes very large. Table 6.1 shows the complexity of various basic operations that are used in integration of ODEs. All matrices are $n \times n$ and vectors are n dimensional. Banded matrices are assumed to have $b+1$ nonzero entries symmetrically placed around the diagonal. See [11] for details on complexity of linear algebraic operations. We slightly abuse the notation and denote by $f(n)$ the number of flops involved in computing a nonlinear vector-field $f(x,t)$, where $f : \mathbb{R}^n \times \mathbb{R} \to \mathbb{R}^n$. Computing the reduced order vector-field $\rho f(\rho^T z + \bar{x}, t)$ could potentially be more expensive than $f(n)$. If this is naively treated as a composition of functions, then the complexity is $f(n) + 4nk$ (two matrix-vector multiplications should be included). Depending on the form of f, one may not be able to improve on this. However, often the analytical formula $\rho f(\rho^T z + \bar{x}, t)$ may be simplified, especially if f is a polynomial in x. We shall denote the complexity of this term by $\hat{f}(k,n)$. This may be bounded as follows:

$$\hat{f}(k,n) \leq f(n) + 4nk.$$

For Jacobian evaluations we have assumed the use of centered finite differences. See [9] for efficient numerical evaluation of banded Jacobians by finite difference approximation. Throughout the rest of this section we will assume that $f(n)$ and $\hat{f}(k,n)$ are of order greater than or equal to n and k, respectively. Under this assumption we can ignore the subtractions and divisions involved in computing the finite differences. If analytical Jacobians are used, the corresponding complexity is likely to be similar [5]. It must be noted that even if the original Jacobian is banded, the reduced model Jacobian is not likely to be.

First we shall consider a linear time invariant system $\dot{x} = Ax$. Table 6.2 shows the asymptotic complexities for various cases. The explicit method considered is forward Euler, and the implicit method considered is backward Euler. The explicit case ($x_n = x_{n-1} + h_n A x_{n-1}$) involves basically a matrix-vector product. The implicit case involves solving the equation $(I - h_n A)x_n = x_{n-1}$ at each time step. We assumed that this is done by Gaussian elimination, first doing an LU decomposition and then two

Table 6.1

Nonlinear Jacobian evaluation (reduced model)	$2k\hat{f}(k,n)$	$2k\hat{f}(k,n)$

Table 6.2

Asymptotic complexity for linear systems.

	Full model explicit	Reduced model explicit	Full model implicit	Reduced model implicit
Dense	$2n^2$	$2k^2$	$\frac{n^3}{15}$	$\frac{k^3}{15}$
Banded	$2bn$	$2k^2$	$(\frac{b^2}{20}+3b+2)n$	$\frac{k^3}{15}$

triangular system solves (one forward and one backward). Usually the LU decomposition needs to be computed only whenever the time step h_n changes. Throughout this section we shall assume that on average, the LU decomposition needs to be computed only once every 10 time steps. Thus we obtain a complexity of $\frac{n^3}{15}+2n^2+\frac{n^2}{10}+\frac{n}{10}\sim\frac{n^3}{15}$ for a dense matrix A and $(\frac{b^2}{20}+3b+2)n$ for a banded matrix A (the quantity b is held constant). If a POD reduced order model of dimension $k(<n)$ is used, then we replace n by k in most of the expressions except for that for banded A (the reduced model matrix $\rho A\rho^T$ is not likely to be banded, and we shall assume it to be dense). It must be noted that in several examples when $n\to\infty$, the adequate size k of a reduced model remains constant after an initial growth. This is especially true in discretized PDE systems, since a finite number of empirical modes are adequate to capture any given percentage of the energy. As a result the asymptotic formulae for $k\to\infty$ are often not applicable.

For nonlinear systems $\dot{x}=f(x,t)$, the explicit method (forward Euler) involves evaluating $x_n=x_{n-1}+h_nf(x_{n-1},t_{n-1})$; hence the complexity is $f(n)+2n\sim f(n)$. If the reduced model is used, then one needs to evaluate $\rho f(\rho^Tz_{n-1}+\bar{x},t_{n-1})$, and the corresponding complexity is $\hat{f}(k,n)+2k\sim\hat{f}(k,n)$.

For the implicit case one needs to solve the nonlinear system of equations

$$F(x_n)\triangleq x_n-x_{n-1}-h_nf(x_n,t_n)=0$$

for x_n. This is done typically by Newton iteration

$$\left[I-h_n\frac{\partial f}{\partial x}\right]\delta_n^{(m)}=x_{n-1}-x_n^{(m-1)}+h_nf(x_n^{(m-1)},t_n), \tag{6.1}$$

where $\delta_n^{(m)}=x_n^{(m)}-x_n^{(m-1)}$ is the correction. Ideally

$$\frac{\partial f}{\partial x}=\frac{\partial f}{\partial x}(x_n^{(m-1)},t_n);$$

Table 6.3
Asymptotic complexity for nonlinear systems.

	Full model explicit	Reduced model explicit	Full model implicit	Reduced model implicit
Dense	$f(n)$	$\hat{f}(k,n)$	$\frac{nf(n)}{5}+\frac{n^3}{15}$	$\frac{k\hat{f}(k,n)}{5}+\frac{k^3}{15}$
Banded	$f(n)$	$\hat{f}(k,n)$	$\frac{bf(n)}{5}+\frac{b^2n}{20}$	$\frac{k\hat{f}(k,n)}{5}+\frac{k^3}{15}$

hence the Jacobian should be evaluated at every Newton iteration inside a given time step. In practice it has been observed that one could get away with keeping the Jacobian unchanged not only during the Newton iteration but also for a few time steps, without severely compromising the accuracy. We assumed that the Jacobian update and the LU decomposition typically need to be done only once every 10 time steps. Note that the right-hand side of (6.1), however, needs to be computed at every Newton iteration. The evaluation of the right-hand side alone requires an asymptotic complexity of $f(n)$ at every Newton iteration for the full model. For the model reduced system one needs to evaluate $\rho f(\rho^T z_n + \bar{x}, t_n)$, which involves an asymptotic complexity of $\hat{f}(k,n)$. It is reasonable to assume that the number of Newton iterations per time step is on average a number independent of system size n (or k for the reduced model). Often in practice this could be about 2. Thus asymptotically the complexity of the Jacobian evaluations dominates over the complexity of evaluating the right-hand side of (6.1). Under these assumptions we get the asymptotic complexities shown in Table 6.3.

For nonlinear systems with explicit solver the asymptotic savings depend solely on the complexity of the nonlinear function evaluations $f(n)$ and $\hat{f}(k,n)$. Hence savings can be expected only if $\rho f(\rho^T z + \bar{x}, t)$ can be analytically simplified.

For nonlinear systems with implicit solver the complexity has two components: one from the nonlinear function evaluations and the other from the linear algebra. Depending on the complexity of f (or $\hat{f}$ for reduced models), one of these terms may be dominant. Asymptotic savings achieved depend on several factors including complexity of $f(n)$ and $\hat{f}(k,n)$ as well as the assumptions on asymptotic behavior of k as $n \to \infty$.

In our complexity analysis we have made several assumptions which are not always valid in practice. Even though most of these assumptions are reasonable, the combined error in our estimate of computational savings can sometimes be wrong by more than a factor of 10. For instance, we looked at complexity per time step. This is useful only if both the full model and the reduced model took more or less the same number of time steps. In the two examples here, the number of time steps did not vary by more than a factor of 2, except for the case of the explicit solver applied to the nonlinear PDE example with reduced model dimension $k = 6$. The asymptotic formulae may not be very applicable for the reduced models because of their smaller size. In addition we ignored computations associated with adaptive stepsize control, which seem to be a significant percentage, for the banded Jacobian case.

It must also be noted that we assumed that we care only about the solution value at the final time (or perhaps only at a few different points in the time interval), and this allowed us to ignore the cost of computing $\hat{x} = \rho^T z + \bar{x}$. The next two examples illustrate how various complex factors can affect the computational savings achieved by the use of POD reduced order models.

Example 4 (RC circuit—dense Jacobian). We considered the example of an electric circuit with resistors and capacitors. By connecting each node to every other node, we obtain a dense Jacobian. One of the nodes is considered the ground (has zero voltage). Such a circuit with n nodes other than ground is described by a first order system of n linear ODEs. The current i_{jk} from the jth node to the k node is given by

$$i_{jk} = g_{jk}(v_j - v_k) + c_{jk}(\dot{v}_j - \dot{v}_k),$$

where g_{jk} and c_{jk} are the appropriate conductances and the capacitances, and $v \in \mathbb{R}^n$ is the vector of node voltages. We may add a nonlinearity to the resistors to obtain

$$i_{jk} = g_{jk}(v_j - v_k) + h_{jk}(v_j - v_k)^3 + c_{jk}(\dot{v}_j - \dot{v}_k).$$

These equations when combined with Kirchoff's current law give rise to an equation $\dot{v} = f(v)$.

We chose the parameter values somewhat ad hoc so that the resulting linearized system had a reasonable range of eigenvalues. We chose a system with $n = 500$. A random initial condition was chosen, and the time interval was chosen to be $[0, 2]$. Both linear and nonlinear versions were simulated, with both explicit and implicit solvers `ode45` and `ode15s` from MATLAB. Reduced order models were computed from the resulting trajectories and applied to both the linear and nonlinear systems. A reduced order model of size $k = 50$ was used, even though a size of $k = 2$ would have preserved more than 99% of the energy. The reason for using $k = 50$ is that $k = 2$ is too small for the asymptotic formulae to be valid. The number of floating point operations as counted in MATLAB are shown in Table 6.4.

The asymptotic complexity of function evaluations for this example are given by

$$f(n) = Cn^2,$$

where $C = 13$ for the nonlinear (cubic) case and $C = 2$ for the linear case. The complexity for the nonlinear reduced model is

$$\hat{f}(k, n) = Cn^2 + 4nk,$$

when $\rho f(\rho^T z + \bar{x})$ is not analytically simplified. Since $f(x)$ is cubic for the nonlinear case, it is possible to analytically simplify $\rho f(\rho^T z + \bar{x})$. This will improve the savings achieved by the reduced order model. In fact assuming that we get a cubic polynomial (in z) with all the possible monomials (dense cubic), we can estimate the complexity of $\hat{f}$. Table 6.5 compares the complexities of $\hat{f}$ after analytical simplification (assuming a dense cubic) for different values of k with that of $f(n)$. It is clear that for values of $k = 15$ or $k = 8$ we can expect significant savings.

We can see from Table 6.6 that the savings predicted by our theory is within an order of magnitude of the actual savings. It must be noted that our theory is only valid asymptotically as n and k get arbitrarily large and that our theory was based on forward and backward Euler methods, while the example used a Runge–Kutta method for the explicit case and a numerical differentiation formula (NDF) for the implicit case [24]. The discrepancies are due to several other factors as well. One is that the reduced model size $k = 50$ is not large enough to use the asymptotic formula. This is an important factor in the linear implicit case but not in the explicit case. Another reason is that the number of steps taken were different for the full model and the reduced model. Furthermore, there are computations associated with

Table 6.4

adaptive stepsize control which were not accounted for by our theory. The latter was a significant factor in the explicit case. We found that the computations associated with adaptive stepsize control grew linearly with system dimension. Furthermore, we found that the Jacobian evaluations were done much less often than the LU decomposition, contrary to our initial assumption. In fact there was only one Jacobian evaluation for the whole simulation in all of the implicit solvers.

Example 5 (reaction-diffusion PDE in one dimension—banded Jacobian). We considered the one dimensional reaction diffusion equation

$$x_t = 0.1x_{ss} - cx^3$$

in the spatial interval $s \in [0, 6]$ with zero boundary conditions. We discretized the spatial dimension on a uniform grid of n interior points using centered differences for both first and second derivatives. This yields a system of ODEs: $\dot{x} = f(x)$ with $x \in \mathbb{R}^n$. We chose two values $c = 0$ and $c = 1$. The first gives rise to a linear system and the second to a nonlinear system, both being dissipative. In both cases the Jacobian is a tridiagonal matrix (hence is banded with $b = 2$). We chose a system of size $n = 499$ and used a reduced order model of size $k = 50$. The following smooth initial condition was chosen:

$$x(0, s) = \exp\left(-\frac{(s-3)^2}{9}\right)\sin^2(\frac{\pi s}{2}), \quad s \in [0, 6].$$

The time interval of simulation was $[0, 5]$. We simulated the systems with two different MATLAB solvers: `ode23` (explicit) and `ode15s` (implicit). The cost of the computation is shown in Table 6.7.

The asymptotic complexity of function evaluations for this example is given by

$$f(n) = Cn,$$

Table 6.7

Computational cost in 10^3 flops: One dimensional PDE example, full model and unsimplified reduced model with $k = 50$.

where the constant $C = 2(b + 1) = 6$ for the linear case and $C = 10$ for the nonlinear case. The complexity of the nonlinear reduced model function evaluations is

$$\hat{f}(k, n) = Cn + 4nk,$$

when $\rho f(\rho^T z + \bar{x})$ is not analytically simplified.

The computational savings achieved and the theoretical asymptotic values are compared in Table 6.8. With the exception of the nonlinear implicit case, the asymptotic theory is within an order of magnitude of the observed values. For the same reasons as in the dense Jacobian case, one cannot expect the theory to be very accurate. In addition, in the banded Jacobian case there are other factors. Since the costs associated with overhead such as stepsize control as well as the rest of the computational costs grow linearly with system size for the unreduced systems, it is no longer valid to neglect the cost of such overhead even asymptotically. Hence the theory underestimates the cost for the unreduced case. This basically explains why the savings were better than predicted by theory. Another reason for the observed discrepancies is that MATLAB (version 5) does not take advantage of the banded structure of the Jacobian. It uses only the sparsity pattern. As a result, the cost of LU decomposition and triangular system solves is greater than that predicted by the theory.

It must be noted that one reason why there are no computational savings is due to the fact that the cost of function evaluation is significantly worse for the reduced model in the nonlinear case: $\hat{f} \approx 10n + 4nk = 210n \gg 10n \approx f(n)$. This was with no expression simplification applied to $\rho f(\rho^T z + \bar{x})$. If we simplify the expression and treat it as a dense cubic, the cost of evaluation (for the $k = 50$ case) is $\hat{f} = 2342500 \gg 104790 = 217n$, which is even worse. This is because the cubic nonlinearity in f is diagonal in the original x coordinates, while the simplified expression for $\hat{f}(z)$ is (typically) a dense cubic. The cost of evaluating a dense cubic $\mathbb{R}^k \to \mathbb{R}^k$ is of order $\frac{k^4}{3}$ and can be prohibitively large if k is not sufficiently small. However, if we use a smaller reduced order model of size $k = 6$, which in this example preserves all of the energy of the solution trajectory up to eight digit accuracy, we indeed get significant computational savings. For $k = 6$, the cost of function evaluation (assuming a dense cubic) is only ≈ 996 flops. Table 6.9 shows the savings factor for $k = 6$ when the simplified expression for nonlinear $\hat{f}$ is used and compares this with the theoretical asymptotic values. The theoretical values are within an order of magnitude

Table 6.9
Computational savings factor: One dimensional PDE example, $k = 6$, simplified nonlinear $\hat{f}$.

	Observed savings	Asymptotic theoretical savings
Nonlinear explicit	860	105
Nonlinear implicit	10.9	1.75

of the observed values. The discrepancies are again due to various factors.

This example illustrates how a multitude of factors affects the computational costs of using a POD reduced model in place of the full original model.

7. Conclusions. We investigated some basic properties of the POD method in finite dimensions. We provided an analysis of the errors involved in computing the solution of a nonlinear ODE initial value problem using a POD reduced order model. In addition to providing quantitatively reasonable error estimates, the analysis also explains the various factors that affect the error.

We also provided a sensitivity analysis of the POD method. We introduced the POD sensitivity factor which was a nondimensional measure of the sensitivity of the resulting projection with respect to perturbations in the data. We studied the effect of data perturbation on the projected data as well as the reduced model solution of the POD method. The POD sensitivity factor is relevant in some applications of POD while it is not in some other applications. We provided a discussion of this issue.

In addition to the error and sensitivity analysis, we also provided an analysis of computational complexity in using the POD reduced model in computing the solution to an ODE initial value problem. Our analysis showed that the computational savings achieved by POD depend on several factors and that the complexity of the nonlinear function evaluations can significantly affect the savings that might be gained by the use of a POD reduced model. Our examples suggest that combining expression simplification with reduced order models (for the class of polynomial vector-fields) may achieve significant savings if the reduced models are small enough.

Acknowledgment. We would like to thank the reviewers for their constructive comments.

CONSERVATIVE FRONT TRACKING WITH IMPROVED ACCURACY*

JAMES GLIMM[†][‡], XIAOLIN LI[†], YINGJIE LIU[†], ZHILIANG XU[†], AND NING ZHAO[§]

Abstract. We propose a fully conservative front tracking algorithm for systems of nonlinear conservation laws. The algorithm improves by one order in its convergence rate over most finite difference schemes. Near tracked discontinuities in the solution, the proposed algorithm has $\mathcal{O}(\Delta x)$ errors, improving over $\mathcal{O}(1)$ errors commonly found near a discontinuity. Numerical experiments which confirm these assertions are presented.

Key words. front tracking, conservation, contact discontinuity

1. Introduction.

We propose and demonstrate a tracking finite difference algorithm for the problem of nonlinear conservation laws which is (a) fully conservative and (b) improves the local error by one power of Δx near tracked discontinuities. The one dimensional (1D) version of these ideas was presented in [9], and a preliminary (but different) two dimensional (2D) algorithm with the same properties was given in [8], while the results were announced in [10].

Discontinuities in the solution of systems of nonlinear hyperbolic conservation laws are a primary difficulty for numerical simulation. These equations have both linear and nonlinear discontinuities, and (perhaps counterintuitively) the former are more difficult. Nonlinear discontinuities are self-focusing, and their numerical solution does not grow in width with time. The linear discontinuities in contrast do grow and may typically occupy 4 to 10 mesh cells in width.

Front tracking was introduced to give special treatment to discontinuities. A robust validated code has been developed and used in production simulation of fluid instabilities [5, 7, 6, 4]. See also the URL http://www.ams.sunysb.edu/∼shock/FTdoc/FTmain.html.

In this paper, we address an algorithmic issue—formulation of a conservative tracking algorithm. In its original formulation, conservation was enforced only in regular grid cells, those not cut by the tracked front. The missing points of the computational stencil, in the case of a front cutting through the stencil, are filled in as ghost cells, with the state values obtained by extrapolation from nearby front

states of the same component. Thus the state values are double-valued near the front, with the left-component states extending by extrapolation for a small distance into the right component, and vice versa. The use of ghost cell states was introduced into front tracking in 1980 [11]. With the ghost states thus defined, the interior solver follows a conventional finite difference algorithm.

The algorithm proposed in the present study is conservative for all grid cells, including the irregular ones cut by the front. This algorithm presented is related to earlier work of Swartz and Wendroff [18], Harten and Hyman [14], Chern and Colella [2], and Pember et al. [16] but differs from these works in several ways. Chern and Colella and Pember et al. redistribute mass from small cells to nearby large ones to preserve stability and conservation. This issue is addressed here by merging small cells. Swartz and Wendroff discussed only the 1D algorithm. Pember et al. [16] reviews these earlier works in 1995. We emphasize here tracking of a contact rather than the shock tracking of [2].

2. Conservative tracking. Consider the 1D system of conservation laws

$$\frac{\partial u}{\partial t} + \bigtriangledown \cdot f(u) = 0. \tag{1}$$

Weak or discontinuous solutions of this equation are not unique, and the equation must be supplemented by an entropy condition [17]. In the case of discontinuities, the partial derivatives in (1) are not defined, and Rankine–Hugoniot conditions

$$n \cdot ([f] - v[u]) = 0 \tag{2}$$

apply. Here $[A] = A_+ - A_-$ is the jump in the quantity across the interface, v is the velocity of the interface, and n is a unit normal to the interface. In fact, (2) results from (1) if the derivatives in (1) are interpreted in the sense of distributions. Representing (1) in integral form, for a moving discontinuity surface S bounding a time-dependent volume V, we have

$$\frac{\partial}{\partial t}\int_V u dV + \int_S n \cdot (f(u) - vu) dS = 0. \tag{3}$$

Thus $n \cdot (f - vu)$ is the dynamic flux, which replaces the usual flux f for the time-independent surface.

The essence of the new algorithm introduced here is to track the front in space and time, based on the following three steps:

1. Construction of the space-time interface to follow the moving solution discontinuity. This will follow the grid-based construction [7] and extend it to space-time.
2. Construction of space-time finite volume cells, starting as a partition of a regular space-time cell. The cells cut by the space-time interface are defined as irregular. To ensure an adequate Courant–Friedrichs–Lewy (CFL) restriction, portions of such irregular cells with too small a top (at t_{n+1}) or no top at all are merged with neighbor cells.
3. Godunov-type finite volume differencing with limiters to ensure continuity of the dynamic flux (3), so that the algorithm is conservative on a cell by cell basis.

To explain these steps at a more detailed but still simple level, we consider in one dimension an interface whose position at time t is $\sigma_e(t)$, and we assume a linear approximation $\sigma(t)$ to $\sigma_e(t)$ on $[t_n, t_{n+1}]$. The 1D algorithm is divided into two cases. We consider only the first case, in which the cell merger from step 2 above is not required. We assume that the approximate interface does not cross a mesh cell center within the time interval $[t_n, t_{n+1}]$. Thus for some mesh index i, $x_i \leq \sigma(t_n), \sigma(t_{n+1}) \leq x_{i+1}$. We displace the cell boundary located at $x_{1+1/2}$ to the interface location. This change results in a redefinition of the cell average quantity, to yield

$$U_i^m = (\Delta_{i,e}^m)^{-1} \int_{x_{i-1/2}}^{\sigma_e(t_m)} u(x, t_m) dx, \tag{4}$$

$$U_{i+1}^m = (\Delta_{i+1,e}^m)^{-1} \int_{\sigma_e(t_m)}^{x_{i+3/2}} u(x, t_m) dx \tag{5}$$

for $m = n, n+1$, where $\Delta_{j,e}^m$ is the interval over which U_j^m is averaged.

Denote by $\mathcal{U}_i^m$ on $[x_{i-1/2}, \sigma(t_m)]$ and $\mathcal{U}_{i+1}^m$ on $[\sigma(t_m), x_{i+3/2}]$ the numerical approximations of U_i^m and U_{i+1}^m, respectively, and let Δ_j^m be the interval over which $\mathcal{U}_j^m$ is averaged. Integrating the hyperbolic system over the two trapezoidal regions $[x_{i-1/2}, \sigma(t)] \times [t_n, t_{n+1}]$ and $[\sigma(t), x_{i+3/2}] \times [t_n, t_{n+1}]$, the finite difference equation for irregular cells is replaced by

$$\Delta_i^{n+1} \mathcal{U}_i^{n+1} = \Delta_i^n \mathcal{U}_i^n - \Delta t \{\mathcal{F}_{\text{int}}^{n+1/2} - \mathcal{F}_{i-1/2}^{n+1/2}\}, \tag{6}$$

$$\Delta_{i+1}^{n+1} \mathcal{U}_{i+1}^{n+1} = \Delta_{i+1}^n \mathcal{U}_{i+1}^n - \Delta t \{\mathcal{F}_{i+3/2}^{n+1/2} - \mathcal{F}_{\text{int}}^{n+1/2}\}, \tag{7}$$

where $\mathcal{F}_{\text{int}}^{n+1/2}$ is the numerical approximation to the flux

$$F_{\text{int}}^{n+1/2} = \frac{1}{\Delta t} \int_{t_n}^{t_{n+1}} \left(f(u(\sigma_e(t), t)) - s_e u(\sigma_e(t), t) \right) dt \tag{8}$$

across the exact interface. Here $\sigma_e(t)$ and $s_e = d\sigma_e/dt$. The definition (8) gives equal values when evaluated on either side of the interface due to the Rankine–Hugoniot condition (2).

Let $s(t) = d\sigma/dt$ be the speed of the numerically tracked interface $\sigma(t)$. The choice of the numerical shock speed is discussed in [3]. Assume a smooth solution in the interior region excluding the tracked waves. Also we assume that the Riemann solution associated with (1) depends Lipschitz-continuously on the left and right states which define the Riemann problem. Using a second order monotonic upstream-centered scheme for conservation law (MUSCL) reconstruction, we first reconstruct a piecewise linear function on each cell out of the cell averages at $t = t_n$ to yield the approximate left and right states $\mathcal{U}_l^n, \mathcal{U}_r^n$ at $\sigma_e(t_n)$ so that $\mathcal{U}_l^n - u(\sigma_e(t_n)-, t_n) = \mathcal{O}(\Delta x^2)$ and $\mathcal{U}_r^n - u(\sigma_e(t_n)+, t_n) = \mathcal{O}(\Delta x^2)$. Solving the Riemann problem with the above two approximate states, we obtain a shock speed s^n which satisfies $s^n - s_e(t_n) = \mathcal{O}(\Delta x^2)$. Therefore, the approximate tracked interface position at $t = t_n + \frac{1}{2}\Delta t$ is

$$\sigma^{n+1/2} = \sigma(t_n) + \frac{1}{2}\Delta t \cdot s^n = \sigma_e(t_{n+1/2}) + \mathcal{O}(\Delta t^2).$$

Using a Taylor expansion, we reconstruct the approximate left and right states $\mathcal{U}_l^{n+1/2}$, $\mathcal{U}_r^{n+1/2}$ at $(\sigma^{n+1/2}, t_{n+1/2})$ from the MUSCL reconstruction so that

$$\mathcal{U}_l^{n+1/2} - u(\sigma_e(t_{n+1/2})-, t_{n+1/2}) = \mathcal{O}(\Delta x^2) \tag{9}$$

and

$$\mathcal{U}_r^{n+1/2} - u(\sigma_e(t_{n+1/2})+, t_{n+1/2}) = \mathcal{O}(\Delta x^2). \tag{10}$$

Finally, solving a Riemann problem with the left and right states $\mathcal{U}_l^{n+1/2}$ and $\mathcal{U}_r^{n+1/2}$, we obtain the half time step shock speed $s^{n+1/2} = s_e(t_{n+1/2}) + \mathcal{O}(\Delta t^2)$, and the new two sides states $\mathcal{U}_{l1}^{n+1/2}$ and $\mathcal{U}_{r1}^{n+1/2}$ across the interface we want to track. Since the exact solution is smooth near the interface, the new states still satisfy (9) and (10). This construction gives a local error $\mathcal{O}(\Delta x^3)$ for the propagated shock position

$$\sigma_e^{n+1} = \sigma^n + s^{n+1/2}\Delta t + \mathcal{O}(\Delta t^3).$$

In fact,

$$\begin{aligned} \sigma_e^{n+1} - \sigma^n &= \int_{t_n}^{t_{n+1}} s_e(t)dt \\ &= \int_{t_n}^{t_{n+1}} [s_e(t_{n+1/2}) + s_e'(t_{n+1/2})(t - t_{n+1/2}) + \mathcal{O}(\Delta t^2)]dt \\ &= s_e(t_{n+1/2})\Delta t + \mathcal{O}(\Delta t^3) \end{aligned} \tag{11}$$

to give the desired accuracy. Let the numerical flux across the tracked front associated with the Riemann problem defined by these two states be

$$\mathcal{F}_i^{n+1/2} = f(\mathcal{U}_{l1}^{n+1/2}, t_{n+1/2}) - s^{n+1/2}\mathcal{U}_{l1}^{n+1/2}.$$

This flux satisfies

$$\mathcal{F}_i^{n+1/2} = F_i^{n+1/2} + \mathcal{O}(\Delta x^2)$$

and is continuous when evaluated from either side of the discontinuity.

The proof that this algorithm is conservative and (for one dimension only) improves its convergence rate near the tracked discontinuity by $\mathcal{O}(\Delta x^2)$ is given in [9].

3. The 2D algorithm. Consider the two space dimensional system of conservation laws

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} + \frac{\partial g(u)}{\partial y} = 0, \tag{12}$$

defined in a spatial domain Ω. The discontinuities of u, assumed to lie on curves, are organized to form an *INTERFACE*, which is propagated from one time level to the next.

In the present study, we require at each time level that the *INTERFACE*s are topologically equivalent to a union of nonintersecting line segments or circles [13]. Thus we postulate that triple or multiple *CURVE* intersection points do not occur. Each *CURVE* is assigned an orientation which remains unchanged during the propagation of the *INTERFACE.* The discretized *CURVE* is piecewise linear and connected and composed of *BOND*s. Each *BOND* is a pair of *INTERFACE POINT*s or *POINT*s and (conceptually) the straight line segment joining them. Assume a decomposition of the plane by a rectangular grid with mesh spacing Δx, and assume the boundary $\partial\Omega$ of Ω lies on grid lines. If the *POINT*s are all on the interior of cell edges with at most one *POINT* occurring on the interior of any given grid cell edge, then the *INTERFACE* is called grid-based [7].

The front *POINT*s are propagated through the Riemann solutions in the normal direction followed by a tangential sweep to update the states on the front. Propagation [5, 7, 6, 4] of the *POINT*s of a grid-based *INTERFACE* will yield a general *INTERFACE*, not grid-based, as there is no reason for a propagated *POINT* to lie on a grid cell edge just because it starts on one. The general idea of the grid-based construction is as follows: we consider this propagated *INTERFACE* as a collection of polygonal *CURVE*s in $\Re^2$. Crossing points of the *CURVE* with grid cell edges are inserted as new *POINT*s. The propagated old *POINT*s (named images of propagation in this sense) will be deleted. The *CURVE* is then reconstructed as straight line segments joining these new *POINT*s. In this process, the *CURVE* is displaced by an amount $\mathcal{O}(\Delta x^2)$, assuming that the *CURVE* is smooth, so that all angles between neighboring *BOND*s are $\mathcal{O}(\Delta x)$. See also [15, 7, 6] for detailed discussions of the grid-based INTERFACE construction.

Let B_i^n be a *BOND* on the grid-based *INTERFACE* $\mathcal{I}^n$ at the old time step t^n, and let $\bar{B}_i^{n+1}$ be the image *BOND* after the propagation of the end *POINT*s of B_i^n. A new grid-based *INTERFACE* $\mathcal{I}^{n+1}$ is reconstructed through the new *POINT*s which are produced by the intersection of the image *BOND*s and the gridline segments. Therefore, each new *POINT* P_i^{n+1} corresponds to an old *BOND* B_i^n, but the inverse is not true, because some bonds will not intersect with any gridline segment. On the other hand, since an image *BOND* may have several intersections with different gridline segments, several new *POINT*s may correspond to a single *BOND* B_i^n.

The finite difference method presented here for (12) is an explicit finite volume integration scheme. The spatial domain Ω has two dimensions. The solution of u evolves with respect to time, and we treat the temporal dimension as the third dimension. We join the spatial *INTERFACE*s at two consecutive time steps to form a space-time interface. Assume we have a space-time discretization $\{\mathcal{V}_i\}$ which conforms to the space-time interface as u evolves in one time step from time t_n to t_{n+1}. We solve (12) explicitly in this region. Treating each $\mathcal{V}_i$ as a control volume, we integrate (12) over $\mathcal{V}_i$. By the divergence theorem, we have

$$|\mathcal{V}_i(t_{n+1})|\bar{u}\mid_{t_{n+1}}= |\mathcal{V}_i(t_n)|\bar{u}\mid_{t_n} - \int_{\partial\mathcal{V}_i}(u, f(u), g(u))\cdot ndS, \tag{13}$$

where $\bar{u}\mid_{t_{n+1}}= \frac{1}{|\mathcal{V}_i(t_{n+1})|}\int_{|\mathcal{V}_i(t_{n+1})|} u(x, y, t_{n+1})dxdy$ is defined as a cell average, $|\mathcal{V}_i(t_{n+1})|$ is the face area of $\mathcal{V}_i(t_{n+1})$ at time t_{n+1}, and n is the outward normal to the space-time surfaces of $\mathcal{V}_i$. We wish to calculate $\bar{u}\mid_{t_{n+1}}$, the solution to (12) at time t_{n+1}.

The major issues in designing the conservative algorithm are (1) to obtain the space-time *INTERFACE*, (2) to determine the discretization $\{\mathcal{V}_i\}$, and (3) to calculate the fluxes defined on the space-time surfaces of $\mathcal{V}_i$.

To construct a finite volume decomposition which respects the space-time interface, we identify the crossings of the approximate space-time interface with the space-time hexahedron. We split the space-time hexahedron whose interior is cut by the space-time interface into parts, each of which belongs to only one side of the space time interface. For the purpose of maintaining numerical stability (the CFL time step restriction), we merge those cells with small top area to form a polyhedron with top area bigger than $0.5\Delta x^2$.

3.1. Construction of the space-time interface. In the current section, we solve the following problem: given two piecewise linear spatial grid-based *INTERFACE*s (*CURVE*s) which are separated in time by a step $\triangle t$, construct (triangulate) a surface joining them. We call this joining surface the space-time interface. The space-time interface thus formed is also grid-based, as a three-dimensional (3D) interface (two spatial and one temporal dimensions). The local configurations within a single grid cell for such a 3D grid-based interface have been discussed in [6]. We introduce two hypotheses regarding the old and new spatial interfaces. These hypotheses limit the local complexity of the interface. More complicated topological structures will not be included in the scope of this paper.

Hypothesis 1. *The INTERFACE is assumed to be grid-based. There is no topological change of the INTERFACE during the time interval of computation. Each CURVE is topologically equivalent to a line segment with its two end points on the boundary, or a circle contained in the interior of* Ω. *No CURVE is totally contained within a square of side* $2\Delta x$ *made up of four cells.*

Hypothesis 2. *The CFL number is less than* $\frac{1}{2}$ *so that each POINT of the INTERFACE is propagated a distance less than* $\frac{1}{2}\Delta x$ *within a single time step.*

Assume Hypothesis 1. For a grid-based *INTERFACE* $\mathcal{I}^n$, each *POINT* on $\mathcal{I}^n$ is a crossing *POINT*; there exists at most one crossing *POINT* on each grid cell edge. No crossing is deleted during the reconstruction of the grid-based *INTERFACE*, as such deletion would indicate a change of topology. Propagation of $\mathcal{I}^n$ *POINT*s at one single time step gives a new *INTERFACE* $\mathcal{I}_0^{n+1}$. The new grid-based *INTERFACE* $\mathcal{I}^{n+1}$ is reconstructed from $\mathcal{I}_0^{n+1}$ through the algorithm discussed above.

After the reconstruction of $\mathcal{I}_0^{n+1}$, the order of *POINT*s on the reconstructed *INTERFACE* $\mathcal{I}^{n+1}$ agrees with the natural order of the *POINT*s on $\mathcal{I}^n$ in the following sense: Let B_1^n be an $\mathcal{I}^n$ *BOND* connecting adjacent *POINT*s P_1 and P_2. Let B_2^n be an $\mathcal{I}^n$ *BOND* following B_1^n, connecting adjacent *POINT*s P_2 and P_3. After propagation, B_1^n is mapped onto an $\mathcal{I}_0^{n+1}$ linear segment B_1^{n+1} with a left end point M_1 as the image of P_1 and a right end point M_2 as the image of P_2; similarly, B_2^n is mapped onto B_2^{n+1} of $\mathcal{I}_0^{n+1}$ with a left end point M_2 and a right end point M_3 as the image of P_3. The reconstruction first inserts into $\mathcal{I}_0^{n+1}$ the crossing points of $\mathcal{I}_0^{n+1}$ with grid lines as new *POINT*s. The insertion of new *POINT*s does not change the orientation or order of the polygon $B_1^{n+1}\bigcup B_2^{n+1}$, which preserves its order from the polygon $B_1^n\bigcup B_2^n$. Similarly, the removal of *POINT*s, with the deformation of the polygon to connect with the remaining *POINT*s by linear segment, is order-preserving. Thus grid-based $\mathcal{I}^{n+1}$ reconstructed from $\mathcal{I}_0^{n+1}$ by connecting the new *POINT*s as above described preserves the *POINT* order.

For the grid-based method, every *INTERFACE POINT* lies on a cell edge. A *POINT P* is assigned on index (i,j) if it is located within a half grid size $(0.5\Delta x)$ away from the grid node (i,j). The proximity *Prox P* of *P* includes nine dual grid cells centered at grid node ($i-1$ to $i+1$, $j-1$ to $j+1$).

Assume P_1 and P_2 are the start and end *POINT*s of *BOND* B^{n+1} on $\mathcal{I}^{n+1}$; the (i,j) indices of these two *POINT*s can be identical, adjacent, or diagonally adjacent. The proximity *Prox B* of *BOND* B^{n+1} is defined as *Prox* $P_1 \cap$ *Prox* P_2. Therefore, the following hold.

(1) If (i,j) indices of P_1 and P_2 are identical, say, both are (i,j), *Prox B* is the nine dual grid cells centered at nodes ($i-1$ to $i+1$, $j-1$ to $j+1$).

(2) If (i,j) indices of P_1 and P_2 are adjacent, say, (i,j) for P_1 and $(i+1,j)$ for P_2, then *Prox B* includes the six dual grid cells centered at nodes (i to $i+1$, $j-1$ to $j+1$). *Prox B* for the case in which the second index of P_1 and P_2 differs by 1 is similarly defined.

(3) If (i,j) indices of P_1 and P_2 are diagonally adjacent, say, (i,j) for P_1 and $(i+1,j+1)$ for P_2, *Prox B* includes the four dual grid cells centered at nodes (i to $i+1$, j to $j+1$).

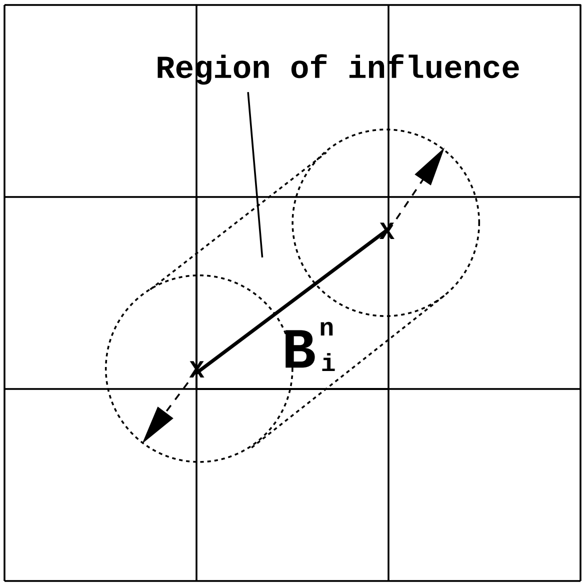

FIG. 1. *Region of influence of a bond B_i^n.*

A *POINT* of $\mathcal{I}^n$ which is located inside the proximity of B^{n+1} is called a *spatially nearest POINT* of B^{n+1} on $\mathcal{I}^n$. If a *BOND* B^{n+1} of $\mathcal{I}^{n+1}$ is the result of propagation followed by the grid-based reconstruction of a single *BOND* B^n on $\mathcal{I}^n$, then B^n is called the *parent BOND* and B^{n+1} is the *child BOND*. In this case, B^{n+1} is formed by the insertion of crossing *POINT*s into the propagated image of B^n. The *region of influence* of any *BOND* in Figure 1 is the region within $0.5\Delta x$ of the points on the *BOND*.

PROPOSITION 1. *Assume Hypotheses* 1, 2*. Let* P_1 *and* P_2 *be two adjacent POINTs connected by a reconstructed grid-based bond* B^{n+1} *of* $\mathcal{I}^{n+1}$*. If* P_1 *is produced (through propagation and intersection of a bond with a gridline segment) by* B_1^n *of* $\mathcal{I}^n$*,* P_2 *is produced by* B_2^n *of* $\mathcal{I}^n$*, and the curve on* $\mathcal{I}^n$ *is oriented so that* B_2^n *follows* B_1^n*, then there exists at least one POINT between the start of* B_1^n *and the end of* B_2^n *which lies within the proximity of* B^{n+1}*.*

Proof. Let C with corner nodes (i, j), $(i+1, j)$, $(i, j+1)$, and $(i+1, j+1)$ be the cell containing B^{n+1}. Assume $B_1^n \neq B_2^n$. In this case, to produce B^{n+1}, all the propagated *POINT*s between (including) the end of B_1^n and the start of B_2^n must lie in the cell C at the new time step t^{n+1}. By Hypothesis 2, all the corresponding old points must be in the proximity defined by P_1 and P_2, because the shortest distance from the boundary of the cell C to the boundary of the proximity is at least $0.5\Delta x$.

Next we assume $B_1^n = B_2^n$. In this case, B_1^n is the *parent BOND* of B^{n+1} and the entire B^{n+1} must be within the *region of influence* of B_1^n. Since the proximity of B^{n+1} is the intersection of the proximities of the two *POINT*s P_1 and P_2, it is the smallest when the indices of P_1 and P_2 are diagonally adjacent, a property we now assume. The proximity is the rectangle *ABCD* in Figure 2. We want to prove that at least one *POINT* of B_1^n is located within the rectangle *ABCD*. To prove this, we show that the parent *BOND* B_1^n cannot have both *POINT*s outside the proximity.

We now draw the boundary of the *region of influence* of all the grid-based bonds with both end *POINT*s outside the proximity of B^{n+1}. The inner boundary of this

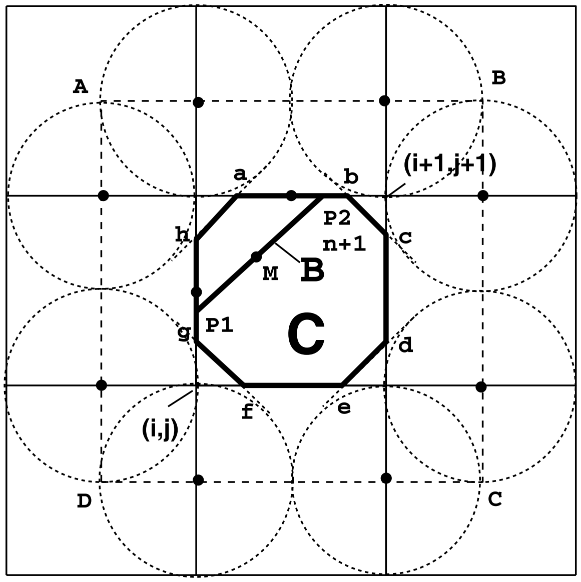

Fig. 2. *Region of influence of all bonds completely outside the proximity of B^{n+1} of which the (i,j) indices of B^{n+1} end points P_1 and P_2 are diagonally adjacent.*

region is the polygon **abcdefgh** as in Figure 2. If the parent *BOND* B_1^n has both end points outside the proximity, then B^{n+1}, lying in its region of influence, should be completely outside the polygon **abcdefgh**. Thus it must lie in one of the four small regions near one corner of the cell C. Since the polygon cuts the edges of the cell C at a distance $0.5(\sqrt{2}-1)\Delta x \approx 0.207\Delta x$ from the four cell corners, the mesh indices of the end *POINT*s of B^{n+1} cannot be diagonally adjacent. Therefore, no bond with both end *POINT*s outside the proximity $ABCD$ can be the *parent* bond of B^{n+1}. Therefore, at least one end point of B^n must be located within the proximity $ABCD$.

The other two cases, when the indices of P_1 and P_2 are identical or adjacent, have a larger proximity for B_1^n. Similar but easier arguments prove Proposition 1 in these cases. This completes the proof.

Proposition 2. *Assume Hypotheses* 1, 2. *Let B_1^{n+1} with end points P_1 and P_2, and B_2^{n+1} with end point P_2 and P_3 be two adjacent BONDs on $\mathcal{I}^{n+1}$ in their natural order. Let B_1^n, B_2^n, and B_3^n be the bonds on $\mathcal{I}^n$ which produce P_1, P_2, and P_3. Denote the spatially nearest POINTs to B_1^{n+1} on $\mathcal{I}^n$ as group* 1 *and the spatially nearest POINTs to B_2^{n+1} on $\mathcal{I}^n$ as group* 2. *There exist a POINT M_1 in group* 1 *and a POINT M_2 in group* 2 *such that* (1) *M_1 is a POINT between (including) the start of B_1^n and the end of B_2^n, and M_2 is a POINT between (including) the start of B_2^n and the end of B_3^n;* (2) *M_1 precedes or equals M_2 in the orientation of $\mathcal{I}^n$.*

Proof. If B_1^n, B_2^n, and B_3^n are three distinct bonds, we take M_1 as any *POINT* between (including) the end of B_1^n and the start of B_2^n and M_2 as any *POINT* between (including) the end of B_2^n and the start of B_3^n. This choice satisfies Proposition 2 in view of Proposition 1.

Next we consider the case $B_1^n = B_2^n \neq B_3^n$. We select M_1 as one of the end *POINT*s of B_1^n which is in group 1. Such a *POINT* exists by Proposition 1. M_2 can be selected between (including) the end of B_2^n to the start of B_3^n. M_1 and M_2 satisfy Proposition 2. The case $B_1^n \neq B_2^n = B_3^n$ is similar.

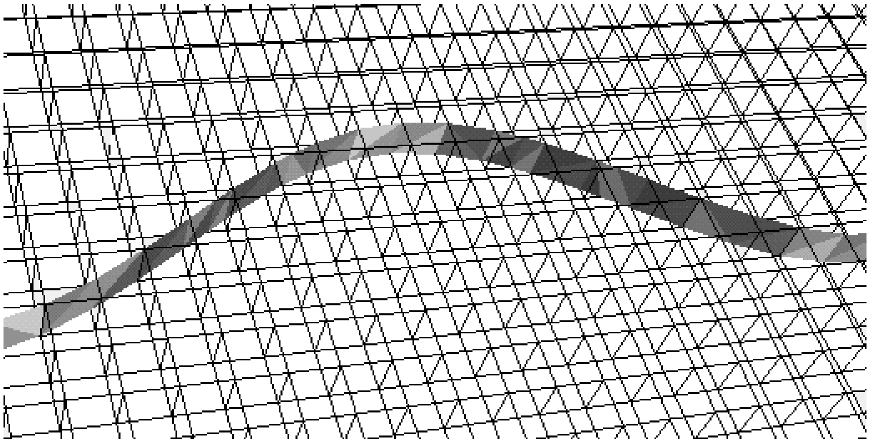

FIG. 3. *The triangulated space-time interface.*

Finally, we consider $B_1^n = B_2^n = B_3^n$. In this case, P_1, P_2, and P_3 lie on a straight line. It is obvious that Proposition 2 holds for the following three cases: (1) the start of B_1^n in both $Prox\ B_1^{n+1}$ and $Prox\ B_2^{n+1}$; (2) the end of B_1^n in both $Prox\ B_1^{n+1}$ and $Prox\ B_2^{n+1}$; and (3) the start of B_1^n in $Prox\ B_1^{n+1}$ and the end of B_1^n in $Prox\ B_2^{n+1}$.

We now prove that it is impossible to have the end of B_1^n in $Prox\ B_1^{n+1} \setminus Prox\ B_2^{n+1}$ and the start of B_1^n in $B_2^{n+1} \setminus Prox\ B_1^{n+1}$. For this to occur, the propagation of both the start and the end points of B_1^n must completely pass through the region of $Prox\ B_1^{n+1} \cap Prox\ B_2^{n+1}$. It is easy to verify that the widths of the intersection in both the x and y directions are at least Δx. However, the maximum propagation distance in one time step is $0.5\Delta x$. The proof is complete.

The surface triangles in space-time are formed by joining the *POINTs* of $\mathcal{I}^{n+1}$ and $\mathcal{I}^n$. Each triangle has a side taken from a single linear segment ($BOND$) of either $\mathcal{I}^{n+1}$ or $\mathcal{I}^n$ and an opposite $POINT$ from the other. We denote a space-time interface triangle which is composed of a $BOND$ at time t_{n+1} and an opposite $POINT$ from $\mathcal{I}^n$ as an upper triangle, and a triangle which is composed of a $BOND$ at time t_n and an opposite $POINT$ from $\mathcal{I}^{n+1}$ as a lower triangle. The space-time interface triangulation is organized into the following two steps:

1. We first form the upper triangles of the space-time interface. For each $\mathcal{I}^{n+1}$ $BOND\ B_m^{n+1}$ whose start and end *POINT*s are P_m and P_{m+1}, we find by Proposition 1 the spatially nearest *POINT*s on $\mathcal{I}^n$. Denote these *POINT*s as group m. Select one $POINT\ M_m$ from each group m to form the list $[M_1, M_2, M_3, \dots]$ with the same orientation as $\mathcal{I}^n$ (due to Proposition 2); M_i and M_{i+1} are not necessarily distinct. Connect each M_m to P_m and P_{m+1} to form upper triangles.
2. The gap on the space-time interface left by step 1 is filled by lower triangles. Each $BOND\ B_k^n$ on the $\mathcal{I}^n$ is located between a pair of distinct *POINT*s M_k and M_{k+1}. M_k and M_{k+1} are connected to a common $POINT$ on $\mathcal{I}^{n+1}$ during the construction of the upper triangles. Connect this common $POINT$ to the start and end *POINT*s of B_k^n to form a lower triangle. This completes the space-time interface triangulation.

Figure 3 shows the triangulated space-time interface. Each triangle is distinguished from its neighbors by contrasting grey shades.

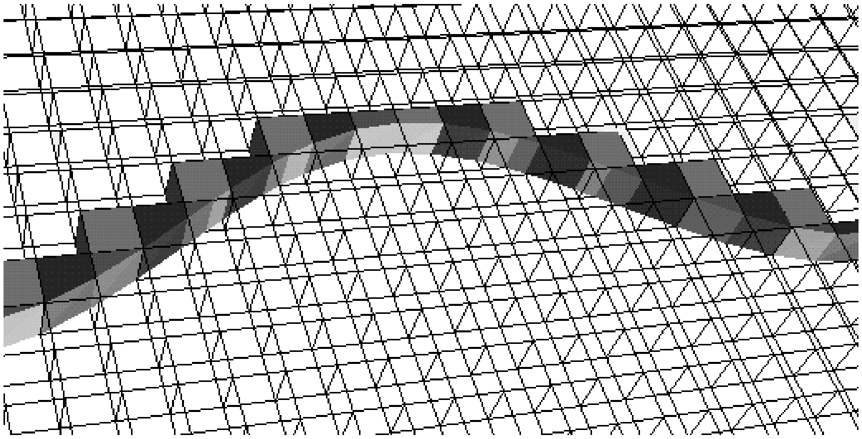

FIG. 4. *Hexahedra and partial polyhedra before volume merging.*

3.2. Construction of the space-time hexahedra. We connect the nodes of a cell D_i^n at time $t = t_n$ to the nodes of the corresponding cell D_i^{n+1} at time $t = t_{n+1}$ to form a space-time hexahedron. We call D_i^{n+1} the top of the hexahedron and D_i^n the bottom. We call a hexahedron *mixed* if the interface passes through its interior, otherwise, it is *pure*. The *mixed* hexahedra are divided into *pure partial* hexahedra, and if necessary, these are combined with neighbors to form a finite volume space-time grid suitable for construction of a conservative difference algorithm in section 3.3. They are adjacent if they share a nontrivial surface which does not meet the space-time interface. Two space-time polyhedra are neighboring if they share a nontrivial vertical line segment which is part of the grid line connecting two corresponding grid nodes at the time levels t_n and t_{n+1} (denoted by a vertical grid line) that does not cross the space-time interface. It is easy to see that two adjacent or neighboring polyhedra must be on the same side of the space-time interface.

The *mixed* hexahedron is separated by the space-time interface into several parts, each of which lies on one side of the space-time interface. These parts are called *pure partial* hexahedra or, in short, *partial* hexahedra. We can similarly define a cell to be *pure*, *mixed*, or *partial*. Any *partial* hexahedron with a trivial or small top will be merged with an adjacent *pure* hexahedron or *partial* hexahedron having a top of minimal size.

Figure 4 shows the control volumes constructed on one side of the space-time interface. Adjacent hexahedra or pure partial polyhedra are represented by contrasting grey shades. Only the volumes near the space-time interface are displayed.

Recalling that two adjacent hexahedra are on the same side of the interface, the following lemma [8] ensures the eventual success of the merging algorithm.

LEMMA 1. *Assume Hypothesis* 1. *If a space-time polyhedron is constructed by merging any number of adjacent partial hexahedra with no top, then the polyhedron will be adjacent to a pure or partial hexahedron on the same side of the space-time interface.*

Proof. At least one nontrivial piece of the side surface of the polyhedron is not on the boundary or the space-time interface; otherwise, the topological structure of the *INTERFACE* changes during this time step and Hypothesis 1 is violated. The proof is complete.

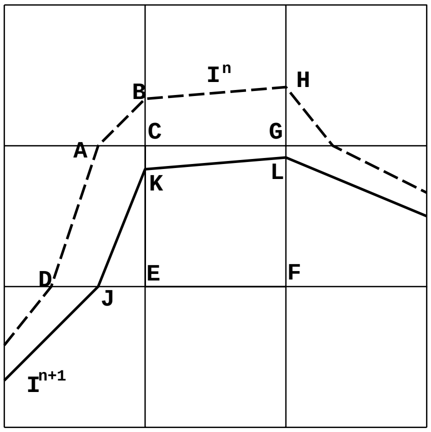

Fig. 5. *A top view of the polyhedra merging process. The solid line represents $\mathcal{I}^{n+1}$, and the dashed line represents $\mathcal{I}^n$. There are four polyhedra in the four upper left mesh blocks: polyhedron* 1 *with bottom ABC and no top, polyhedron* 2 *with bottom face $BHGC$ and no top, polyhedron* 3 *with bottom face $ACED$ and the triangular top KEJ, and polyhedron* 4 *with a square bottom $CGFE$ and the trapezoidal top $KLFE$. They will be merged into one polyhedron with bottom $ACBHGFED$ and top $KLFEJ$.*

Hypotheses 1 and 2 and Lemma 1 ensure that each partial hexahedron with no top and away from the boundary is adjacent to or neighboring one with a nontrivial top. However, for a partial hexahedron with no top and at the boundary, Hypothesis 2 may not be sufficient if the interface intersects the boundary at a small angle. We need to adjust the CFL number so that the intersection point between the *INTERFACE* and the boundary moves a distance less than Δx along the boundary during the time step in order to reach the same property.

We require a hypothesis to limit the local geometric complexity of the *INTERFACE*. To simplify the proof that the merging algorithm converges (rapidly), we state it in a stronger than necessary form. See section 3.4 for a discussion of this issue.

Hypothesis 3. *Each partial hexahedron having top area smaller than $\frac{1}{2}\Delta x^2$ is adjacent to or neighboring one with top area greater than or equal to $\frac{1}{2}\Delta x^2$.*

Because the flux exchange among control volumes is through the shared space-time surfaces, we merge only adjacent *partial* hexahedra on the same side of the space-time interface and not neighboring ones. For this reason, merger is accomplished in stages, i.e., recursively. The merging process then is stated as follows.

Assume Hypothesis 3. *Recursively merge every pure or partial hexahedron having a top area greater than or equal to $\frac{1}{2}\Delta x^2$ with adjacent partial hexahedra having no top or top area smaller than $\frac{1}{2}\Delta x^2$ which have not been merged elsewhere until none of the partial hexahedron having no top or top area smaller than $\frac{1}{2}\Delta x^2$ is left. Denote the resulting space-time polyhedra the big hexahedra. The merging process then is complete. Partial polyhedra generated at each merging stage are called intermediate hexahedra.*

As illustrated in Figure 5, polyhedron 4 with a square bottom face $CGFE$ and top face area $KLFE$ greater than $\frac{1}{2}\Delta x^2$ forms the center of merging. The merged polyhedra include polyhedron 3 with bottom face $ACED$ and a small triangular top KEJ, polyhedron 2 with bottom face $BHGC$ and no top, and polyhedron 1 with bottom face ABC and no top. Polyhedra 2 and 3 are adjacent to 4, while polyhedron

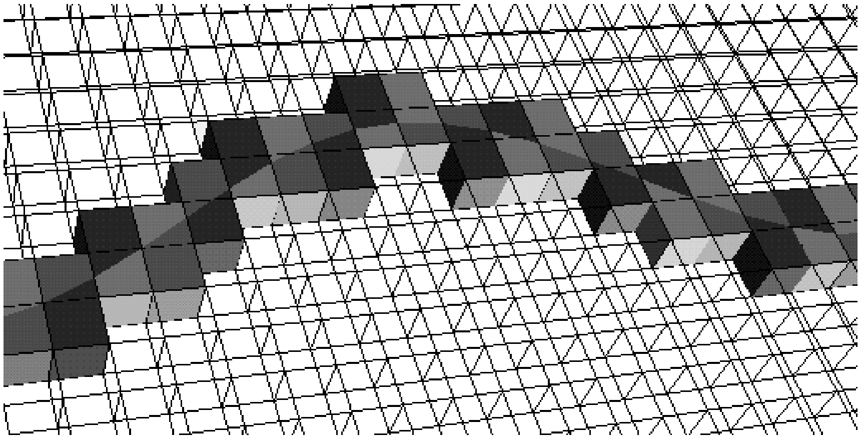

FIG. 6. *Control volumes after merging.*

1 is diagonally adjacent to 4. In the merging process, polyhedra 2 and 3 are absorbed by polyhedron 4 first. A *intermediate* hexahedron with bottom face $ACBHGFED$ is formed. Polyhedron 1 is adjacent to it. Finally, this *intermediate* hexahedron absorbs polyhedron 1, resulting in a *big* hexahedron with bottom face $ABHGFED$ and top face $KLFEJ$.

Determined by Lemma 1 and Hypothesis 3, it is easy to see that a *big* hexahedron contains no more than a fixed number of *pure* or *partial* hexahedra so that the merging process stops rapidly. Actually in most cases the merging process yields *big* hexahedra consisting of two *pure* or *partial* hexahedra. The number of *pure* or *partial* hexahedra in the *big* hexahedron could become larger if the radius of curvature of the moving *CURVE* is small. In fact, we have the following observation.

Assume Hypothesis 3. Let a *pure* or *pure partial* hexahedron $\mathcal{H}$ with top area greater than $\frac{1}{2}\Delta x^2$ be contained inside a space-time cell with cell index (i, j). If $\mathcal{H}$ forms a *big* hexahedron by absorbing *pure partial* hexahedra during the merging process, the bottom faces of these *pure partial* hexahedra which merge with $\mathcal{H}$ are located inside a square, centered at (i, j), with side $3\Delta x$.

Figure 6 shows the control volumes on two sides of the space-time interface after the merging process. Only the volumes near the space-time interface are displayed.

THEOREM 1. *Assume Hypotheses* 1–3*. After the merging algorithm, every partial hexahedron having no top or top area smaller than* $\frac{1}{2}\Delta x^2$ *will be merged into a big hexahedron having top area greater than or equal to* $\frac{1}{2}\Delta x^2$ *on the same side of the interface. The interior of each big hexahedron is connected.*

3.3. The reconstruction, limiter, and numerical scheme. Suppose at the time level $t = t_n$ we know the approximate state averages on each cell, *regular*, *irregular*, or *partial*. We want to reconstruct a piecewise linear state function on these cells with second order accuracy. The reconstruction of the piecewise linear state function on *irregular* cells follows [1], with modifications to the limiter and some simplification. Let D_i^n be a *pure* cell, *regular*, *irregular*, or *partial*, with approximate state average $\mathcal{U}_i$ and cell center (centroid) Y_i, surrounded by any of the types of cells $D_j^n, D_k^n, D_l^n, D_m^n$ with approximate state averages $\mathcal{U}_j^n, \mathcal{U}_k^n, \mathcal{U}_l^n, \mathcal{U}_m^n$ and cell centers Y_j, Y_k, Y_l, Y_m, respectively, on the same side of the *INTERFACE* . Let $\tilde{\mathcal{U}}_i = \mathcal{U}_i + (a, b) \cdot$

$(X - Y_i)$ be the second order accurate linear state function on D_i^n, where a, b are two constants. Choose any two surrounding cells, say, D_j^n, D_k^n so that Y_i, Y_j, Y_k are not colinear. We can determine a, b by solving the following equation:

$$\begin{aligned} \tilde{\mathcal{U}}_i(Y_j) &= \mathcal{U}_j^n, \\ \tilde{\mathcal{U}}_i(Y_k) &= \mathcal{U}_k^n. \end{aligned} \tag{14}$$

Further, for the solution of the above equation to be well conditioned, we require the angle θ formed by line segments $\overline{Y_iY_j}$ and $\overline{Y_iY_k}$ to satisfy $0 < \theta_1 < \theta < \theta_2 < \pi$, where θ_1, θ_2 are two constants. We repeat the above procedure until we find all possible solutions, say, a_i, b_i, for all $0 \leq i \leq I$, where $I \leq 4$. Then we set $a = \text{minmod}\{a_1, \ldots, a_I\}$ and $b = \text{minmod}\{b_1, \ldots, b_I\}$. When there are not enough surrounding cells on the same side of the *INTERFACE*, we choose $a, b = 0$ so that the reconstruction becomes first order.

When D_i^n is a *regular* cell surrounded by *regular* cells, the reconstruction process is simpler. Let the cell center of D_i^n be $(i_1\Delta x, i_2\Delta y)$ with neighboring cell centers $\{((i_1 + k_1)\Delta x, (i_2 + k_2)\Delta y) | k_1, k_2 = -1, 0, 1\}$. Let

$$\begin{aligned} \text{xslope}_\text{i} = \ & \text{minmod}\{[\mathcal{U}((i_1 + k_1)\Delta x, (i_2 + k_2)\Delta y) \\ & -\mathcal{U}((i_1 + k_1 - 1)\Delta x, (i_2 + k_2)\Delta y)]/\Delta x \mid \\ & k_1 = 0, 1; k_2 = -1, 0, 1\}, \end{aligned} \tag{15}$$

and

$$\begin{aligned} \text{yslope}_\text{i} = \ & \text{minmod}\{[\mathcal{U}((i_1 + k_1)\Delta x, (i_2 + k_2)\Delta y) \\ & -\mathcal{U}((i_1 + k_1)\Delta x, (i_2 + k_2 - 1)\Delta y)]/\Delta y \mid \\ & k_1 = -1, 0, 1; k_2 = 0, 1\}, \end{aligned} \tag{16}$$

and define

$$\tilde{\mathcal{U}}_i = \mathcal{U}_i + \text{xslope}_\text{i} \cdot (x - i_1\Delta x) + \text{yslope}_\text{i} \cdot (y - i_2\Delta y).$$

This second order reconstruction is better suited in multiple dimensions than in the operator splitting single line reconstruction (or limiter) for a uniform rectangular grid because, for example, an untracked discontinuity in two dimensions may be in the form of a strip of width between $2\Delta x$ and $3\Delta x$. When the strip is almost parallel to and fully covers the line in which the single line reconstruction occurs, one cannot expect the limiter to choose any smooth solutions nearby.

Next we apply the technique of section 3.2 to generate space-time hexahedra between time levels t^n and t^{n+1}. Let H be a big hexahedron with top D^{n+1}, bottom D^n, and triangle sides $\{S_i\}$ with a unit outer normal n_i and centroid Z_i. Notice that some elements of the $\{S_i\}$ may be on the approximate space-time interface. Integrating (12) over H, we obtain

$$|D^{n+1}| \ U^{n+1} = |D^n| \ U^n - \sum_i \int_{S_i} (u, f, g) \cdot n_i ds. \tag{17}$$

Here $|D^n|$ represents the area of D^n, and similarly $|S_i|$ is the area of S_i.

The numerical scheme can be written as

$$|D^{n+1}|\mathcal{U}^{n+1} = |D^n|\mathcal{U}^n - \sum_i |S_i|(\tilde{\mathcal{U}}_{i,m}, f(\tilde{\mathcal{U}}_{i,m}), g(\tilde{\mathcal{U}}_{i,m})) \cdot n_i. \tag{18}$$

The fluxes through triangle sides $\{S_i\}$ can be calculated by a higher order Godunov-type algorithm.

We first calculate $\tilde{\mathcal{U}}_{i,m}$ as follows: First use a Cauchy–Kowalewski procedure on the reconstructed state function on each side of S_i to get second order approximate states at Z_i on the respective sides of S_i, say, $\mathcal{U}_{i,l}$ and $\mathcal{U}_{i,r}$. If S_i is not on the tracked space-time interface, we can simply use a Riemann solver, say, R, to get the middle state on S_i, i.e.,

$$\tilde{\mathcal{U}}_{i,m} = R(\mathcal{U}_{i,l},\ \mathcal{U}_{i,r}).$$

If S_i is on the tracked space-time interface, we use the Riemann solver to get the left and the right side states $\tilde{\mathcal{U}}_{i,l}$ and $\tilde{\mathcal{U}}_{i,r}$ on the wave we are supposed to track and the wave speed ν_i. Then $\tilde{\mathcal{U}}_{i,m}$ in (18) can be replaced by either $\tilde{\mathcal{U}}_{i,l}$ or $\tilde{\mathcal{U}}_{i,r}$, depending on whether l or r is located within H or not. Also, the n_i in (18) should be replaced by $\tilde{n}_i/|\tilde{n}_i|$, where $\tilde{n}_i = (-\nu_i\sqrt{n_{ix}^2 + n_{iy}^2}, n_{ix}, n_{iy})$, $n_i = (n_{it}, n_{ix}, n_{iy})$. Note that $\tilde{n}_i$ is normal direction of the tracked space-time wave from the Riemann solver; therefore, this modification ensures that the Rankine–Hugoniot condition is satisfied.

The finite volume difference algorithm constitutes a flux through each boundary of the full, *partial*, and *big* hexahedron. Since the flux through a boundary face of the hexahedron is identical when viewed from either side of the face, we have the following theorem.

THEOREM 2. $\sum_{cells} |D^n|\mathcal{U}^n$ *in the finite volume difference scheme is conserved so that its increment over any time interval is equal to the net influx at the boundary.*

Away from the *INTERFACE* the scheme is clearly a second order scheme. For the cells along the *INTERFACE*, its local error is one order lower than in the 1D case since we use a piecewise linear approximation to the smooth *INTERFACE* and the local displacement error of this approximation is $\mathcal{O}(\Delta x^2)$. The scheme is one order better than untracked schemes, which typically have $\mathcal{O}(1)$ local error at the untracked fronts.

THEOREM 3. *Suppose the exact space-time interface and the solution on either side of it are smooth. Then the L_∞ error is $\mathcal{O}(\Delta x)$ for cells adjacent to the INTERFACE.*

Proof. Let the *INTERFACE* at t_n be exact, and let H be a big hexahedron adjacent to the approximate space-time interface. We apply the finite volume scheme to obtain the approximate state average $\mathcal{U}_i^{n+1}$ at the time level t_{n+1}, with top T and bottom B and side boundaries $\{S_i\}$, where each S_i is a triangle. The *INTERFACE* at time t_{n+1} has an $\mathcal{O}(\Delta x^2)$ displacement from the exact interface. The exact space-time interface will cut H into two pieces. Let H_1 be the piece on the same side of the interface as H. Let T_1, B_1, and S^1 be the top, bottom, and side boundaries of H_1, respectively. Let $U_{T_1}^{n+1}, U_{B_1}^n$ be the exact state averages over T_1 and B_1, respectively. Choosing $\mathcal{U}_B^n = U_{B_1}^n$, we want to show that $U_{T_1}^{n+1} - \mathcal{U}_T^{n+1} = \mathcal{O}(\Delta x)$. In fact, from (18),

$$|T|\mathcal{U}_T^{n+1} = |B|\mathcal{U}_B^n - \sum_i |S_i|(\tilde{\mathcal{U}}_{i,m}, f(\tilde{\mathcal{U}}_{i,m}), g(\tilde{\mathcal{U}}_{i,m})) \cdot n_i. \tag{19}$$

The exact solution satisfies

$$|T_1|U_{T_1}^{n+1} = |B_1|U_{B_1}^n - \int_{S^1} (u, f(u), g(u)) \cdot n ds. \tag{20}$$

Note that $|B|\mathcal{U}_B^n = |B_1|U_{B_1}^n$. Also, the numerical flux in (19) approximates the exact flux in (20) to at least $\mathcal{O}(\Delta x^3)$. In fact, when S_i is not on the approximate space-time interface, this is easily seen since $\int_{S_i}(u,f,g)\cdot n_i ds = |S_i|(u,f,g)(Z_i)\cdot n_i + \mathcal{O}(\Delta x^4)$.

Next suppose that S_i is on the approximate space-time interface. Because of the smoothness of the exact space-time interface, it has an $\mathcal{O}(\Delta x^2)$ displacement error to the exact one. The difference between their respective areas is of $\mathcal{O}(\Delta x^3)$. The area of $\bigcup S_i$ is $\mathcal{O}(\Delta x^2)$. Also, the choices of $\tilde{\mathcal{U}}_{i,m}$ and n_i in (19) ensure that $(\tilde{\mathcal{U}}_{i,m}, f(\tilde{\mathcal{U}}_{i,m}), g(\tilde{\mathcal{U}}_{i,m}))\cdot n_i$ in (19) is a first order approximation to the integrand in (20) at any point within an $\mathcal{O}(\Delta x)$ distance from the centroid Z_i of S_i. Thus $\int_{S_i}(u,f,g)\cdot n_i ds = |S_i|(u,f,g)(Z_i)\cdot n_i + \mathcal{O}(\Delta x^3)$ in the case that S_i is on the approximate space-time interface. Therefore, we have

$$\begin{aligned} U_{T_1}^{n+1} - \mathcal{U}_T^{n+1} &= (|T_1|U_{T_1}^{n+1} - |T|\mathcal{U}_T^{n+1})/|T| + U_{T_1}^{n+1}((|T| - |T_1|)/|T|) \\ &= (\mathcal{O}(\Delta x^4) + \mathcal{O}(\Delta x^3))/\mathcal{O}(\Delta x^2) + \mathcal{O}(\Delta x^3)/\mathcal{O}(\Delta x^2) \\ &= \mathcal{O}(\Delta x), \end{aligned} \tag{21}$$

where $\mathcal{O}(\Delta x^4)$ and $\mathcal{O}(\Delta x^3)$ in the first bracket follow from the local error of the numerical approximation of the flux defined on the non space-time interface and space-time interface, respectively. The proof is complete.

3.4. Cell level complexity and interface topological change. Because the dynamic evolution of the $INTERFACE$ often leads to geometrically complex situations, Hypothesis 3 might fail. For example, the Richtmyer–Meshkov (RM) instability develops very long and thin structures at the tips of bubbles and spikes at late time; see Figure 7 for an illustration.

The narrow structures and approximate or actual bifurcations will degrade the algorithm. Excessive cell merging to ensure CFL stability will degrade accuracy, and in any case actual bifurcations are (presently) excluded. We require a robust algorithm to solve problems for which any of the above occurs. We propose that these situations

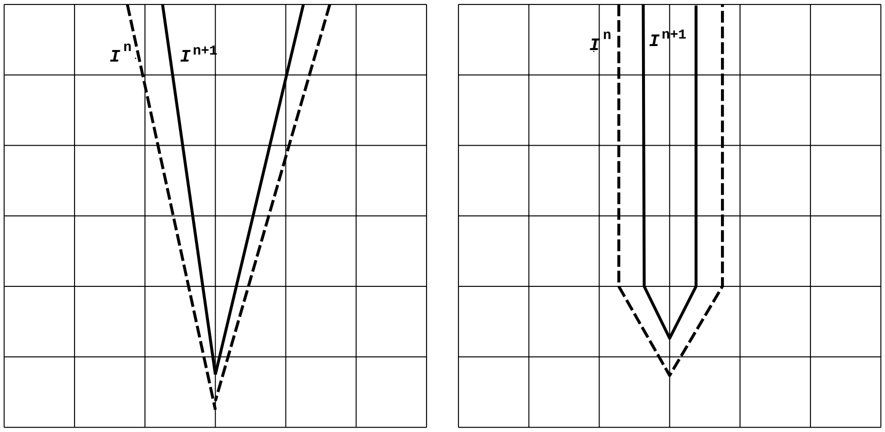

FIG. 7. *Limits on the merging process. $\mathcal{I}^n$ is represented by the dashed line and $\mathcal{I}^{n+1}$ by the solid line. At the time t^{n+1} level, in the first frame, the triangular cell at the tip is adjacent to a triangular cell and quadrilateral only; all of these cells form partial hexahedra having top area smaller than $\frac{1}{2}\Delta x^2$ and thus require further merger. In the second frame, the two branches of the curve near the tip of $\mathcal{I}^n$ and $\mathcal{I}^{n+1}$ are close and parallel to each other (forming a thin wall), thus forming a set of neighboring polyhedra with top area smaller than $\frac{1}{2}\Delta x^2$.*

Table 1
Comparison of error analysis for the test problem (22) *for Burgers' equation.*

Method	N	L_1 error	L_1 order	$\Sigma U_i \Delta x_i$

	120	2.11e-3	1.74	1.733
	240	6.04e-4	1.80	1.733

should be resolved by locally nonconservative tracking using the ghost cell algorithm of the authors [12]. Since these events will often occur on a lower dimensional space-time manifold, they will not impact the formal order of accuracy of the algorithm.

4. Numerical examples.

In this section we present numerical examples showing the convergence and conservation properties of the conservative front tracking scheme.

4.1. Burgers' equation.

Consider Burgers' equation $\frac{\partial u}{\partial t} + \frac{\partial}{\partial x}(\frac{1}{2}u^2) = 0$ on $[0, 6] \times [0, T]$, with initial conditions

$$u(x,0) = \begin{cases} 0.2 * (x-1)^2 + 0.2, & x \in [1,3], \\ 0.2, & \text{elsewhere.} \end{cases} \tag{22}$$

In Table 1 we present numerical results at ($T = 3.2$) using three different methods: the untracked MUSCL scheme, the nonconservatively (shock) tracked scheme with an MUSCL interior solver, and the conservatively (shock) tracked scheme with an MUSCL interior solver. Here the column labeled L_1 error indicates the L_1 norm of $u - \tilde{U}$, where u is the exact solution and $\tilde{U}$ is the second order approximate solution reconstructed from the piecewise constant numerical solution U at time T. Figure 8 displays the comparison of the numerical results obtained with $N = 30$ cells. For all of section 4, the CFL number is equal to 0.4.

4.2. 1D Euler equations.

Next we conduct a convergence test for the 1D Euler equations for a gamma law gas, $\gamma = 1.4$. We consider a tracked shock wave interacting with C^∞ data (a rarefaction wave with smooth edges). The computational domain is $[0, 4]$ with flow-through boundary conditions. At time $T = 0$ there is a right facing rarefaction wave in $(1, 2)$ and a left moving shock at $x = 3$. The left facing shock interacts with the rarefaction wave by the final time $T = 1$. We first define the initial states V_0 as follows: on $[0, 1]$, the density, pressure, and velocity are $2.0, 0.5$, and -1.0, respectively. On $[1, 2]$, V_0 has a centered rarefaction wave, ending at a pressure 1.5. On $[2, 3]$, the state is constant. On $[3, 4]$, the velocity is -1.5. Since the first

derivatives of V_0 have jumps at the rarefaction wave edges, we smooth the initial data V_0 so that

$$U_0(x) := \begin{cases} V_0(1)(2-\beta(x)) + V_0(2)(\beta(x)-1), & x \in (1,2), \\ V_0(x), & \text{elsewhere}, \end{cases}$$

where $\beta(x) = \frac{1}{2}(\sin \pi(x - \frac{3}{2})+3)$. We conduct the convergence test with the smoothed initial states U_0. The interior scheme is the second order MUSCL scheme with the shock wave tracked conservatively in one case and nonconservatively in the other. It is compared with a very fine ($N = 12800$, conservatively tracked) numerical solution to calculate the error in the L_1 norm. The comparison of the L_1 errors is shown in Table 2; the shock position errors $\sigma_e - \sigma_n$ are compared in Table 3, where σ_e

denotes the exact shock position and σ_n denotes the numerical shock position. The conservatively tracked scheme is second order accurate.

4.3. 2D advection. We conduct a horizontal advection conservation test for the Euler equations to compare the fully conservative tracking scheme to the nonconservative tracking scheme. The numerical experiments were performed on a rectangular 1×2 domain with a 40×80 grid, displacing the interface horizontally half the domain width in 337 time steps. For the lower and upper boundaries of the domain, we use flow-through boundary conditions on which the states are normally extrapolated from the interior, and periodic conditions on the side boundaries. We use a polytropic gas, with polytropic exponent $\gamma = 1.4$. The contact discontinuity separating distinct gas states is tracked. The interface is sinusoidally perturbed with frequency 2.0 and amplitude 0.3. The initial configuration and the one-quarter width displaced configuration are shown in Figure 9. Excellent preservation of the sine wave is evident.

Table 4
Conservation error.

Conservation Error		
	Conservative tracking	Nonconservative tracking

x-mom	0.0	0.21%
Energy	0.0	0.21%

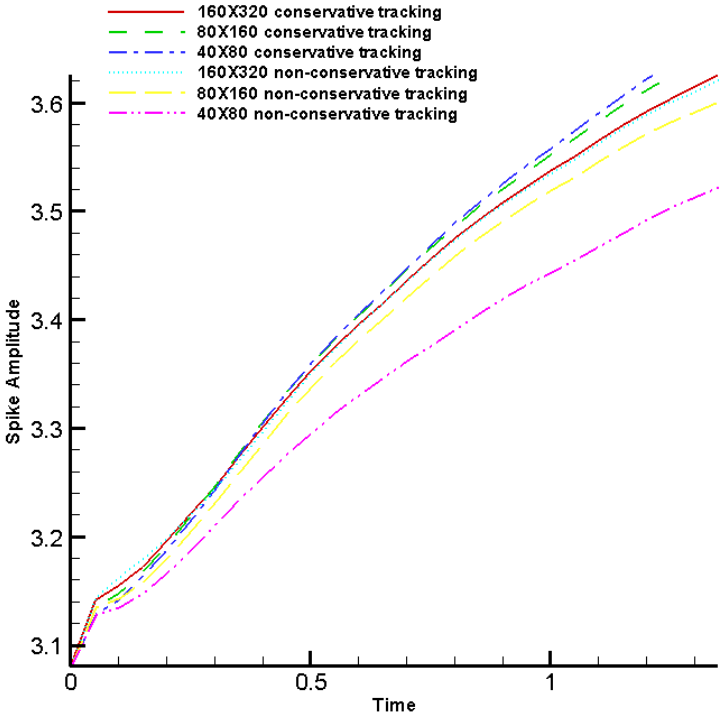

Fig. 10. *Spike amplitude in the RM instability simulations, as functions of time. The conservative tracked amplitude for a coarse grid is in approximate agreement with the nonconservative tracked amplitude for a fine grid.*

In Table 4, we compare the total conservation for the two methods, which is defined for the mass as

$$\text{(final mass} - \text{initial mass} + \text{boundary mass flux)}/\text{(initial mass)}, \tag{23}$$

with similar definitions for other conserved quantities. The conservative quantities refer to the lower gas in Figure 9. The total mass, momentum, and energy in the computational domain for the conservative tracking scheme show essentially perfect conservation, while the nonconserved tracking shows conservation errors of 0.21%.

4.4. Richtmyer–Meshkov instability. A Richtmyer–Meshkov (RM) instability is generated when a shock wave refracts through a perturbed interface which

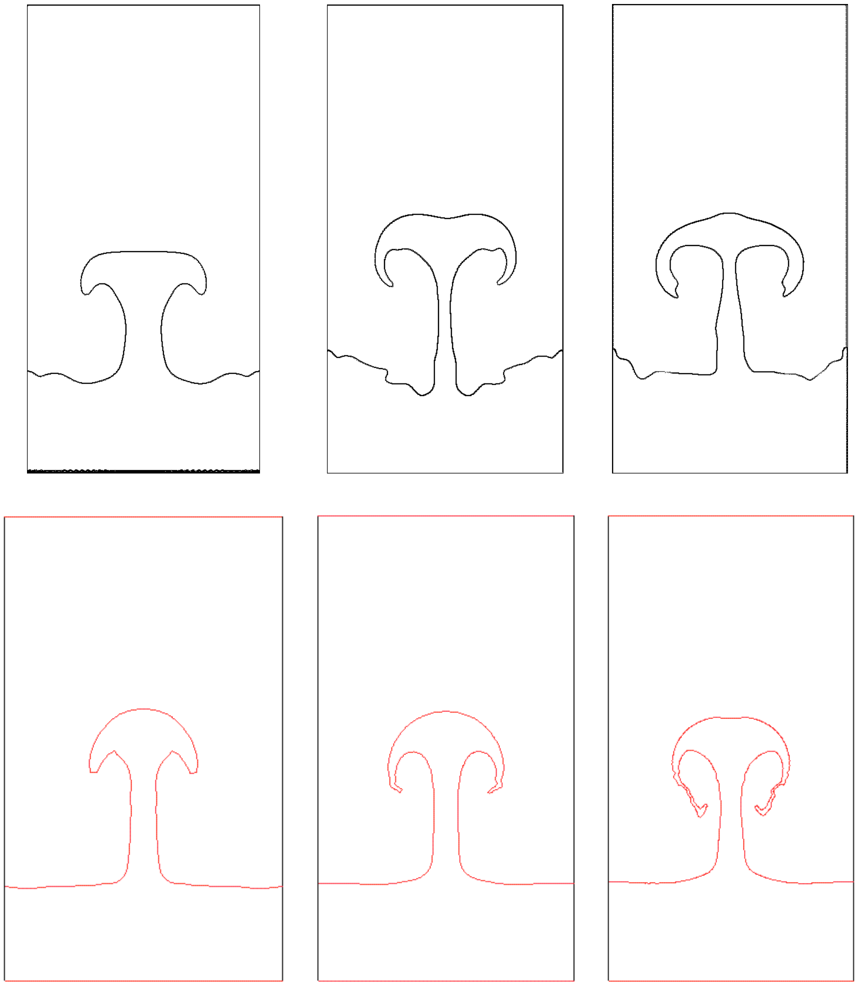

FIG. 11. *Front plot for the RM instability simulations. The upper row shows the plots of nonconservatively tracked interface at time* = 1.38. *The lower row shows the plots of conservatively tracked interface at the same time. For both rows, from left to right, are* 40×80, 80×160 *and* 160×320 *grids, respectively.*

separates fluids of differing densities. We compare simulations produced by the conservative and the nonconservative tracking schemes.

The numerical experiments were performed on a rectangular 1×2 domain, with a 40×80 grid, the lower and upper boundaries with flow-through boundary conditions, and periodic conditions for the side boundaries.

The initial configuration consists of a Mach 5.0 shock in a polytropic gas (with unshocked density 1.0) striking an interface separating two polytropic gases (both have polytropic exponent $\gamma = 1.40$). The preshock contact density ratio is $1 : 5$. The interface is sinusoidally perturbed with wavelength 1.0 and amplitude 0.1. Figure 11 shows the interface evolution of the RM instability; the initial configuration is shown as the left column. We also performed refined nonconservatively tracked simulations with 80×160 and 160×320 grids. The results indicate the convergence of the growth rate with nonconservative simulation to that of the conservative simulation when the computational mesh of the nonconservative simulation is refined. The 40×80 conservatively tracked solution appears to be comparable to both the finest (160×320) nonconservatively and conservatively tracked solutions, while the nonconservatively coarse grid run (40×80) tends to have a smaller growth rate. See Figures 10 and 11.

5. Conclusions.

We have proposed a new fully conservative front tracking algorithm. The algorithm is derived from an integral formulation of the PDEs. The 1D version of the algorithm is fully second order accurate away from the intersection of tracked waves. This has been determined by both the formal derivation and numerical experiments. In two dimensions, we provided the formal derivation that the scheme should be second order in the interior region and first order near the front. The convergence of bubble growth rate in the simulation of the RM instability seems to support this claim. Numerical tests in one and two dimensions demonstrate the improved conservation and convergence properties of the algorithm. The stability of the algorithm is verified by numerical experiments.

Conservative tracking is fundamentally an exercise in computational geometry to define the space-time interface. The finite volume differencing defined by the geometry follows standard algorithms. Further study of the space-time interface construction is called for. A robust algorithm may include nonconservative tracking for regions of greater local complexity than the conservative space-time interface construction will support.

RIGOROUS SHADOWING OF NUMERICAL SOLUTIONS OF ORDINARY DIFFERENTIAL EQUATIONS BY CONTAINMENT[*]

WAYNE B. HAYES[†] AND KENNETH R. JACKSON[†]

Abstract. An exact trajectory of a dynamical system lying close to a numerical trajectory is called a *shadow*. We present a general-purpose method for proving the existence of finite-time shadows of numerical ODE integrations of arbitrary dimension in which some measure of hyperbolicity is present and there are either 0 or 1 expanding modes, or 0 or 1 contracting modes. Much of the rigor is provided automatically by interval arithmetic and validated ODE integration software that is freely available. The method is a generalization of a previously published *containment* process that was applicable only to two-dimensional maps. We extend it to handle maps of arbitrary dimension with the above restrictions, and finally to ODEs. The method involves building n-cubes around each point of the discrete numerical trajectory through which the shadow is guaranteed to pass at appropriate times. The proof consists of two steps: first, the rigorous computational verification of a simple geometric property, which we call the *inductive containment property*, and second, a simple geometric argument showing that this property implies the existence of a shadow. The computational step is almost entirely automated and easily adaptable to any ODE problem. The method allows for the rescaling of time, which is a necessary ingredient for successfully shadowing ODEs. Finally, the method is local, in the sense that it builds the shadow inductively, requiring information only from the most recent integration step, rather than more global information typical of several other methods. The method produces shadows of comparable length and distance to all currently published results. Finally, we conjecture that the inductive containment property implies the existence of a shadow without restriction on the number of expanding and contracting modes, although proof currently eludes us.

1. Introduction.

Consider the *initial value problem* (IVP) for an autonomous *ordinary differential equation* (ODE)

$$\mathbf{y}'(t) = \mathbf{f}(\mathbf{y}(t)), \tag{1.1}$$

$$\mathbf{y}(t_0) = \mathbf{y}_0, \tag{1.2}$$

where the ODE (1.1) is called the *defining equation*, (1.2) is called the *initial condition*, $\mathbf{y}$ is an n-dimensional vector, and f is an n-dimensional vector-valued function. Standard forward error analysis (e.g., Dahlquist and Björck (1974) or Kahaner, Moler, and Nash (1989)) tells us that, for a large class of ODEs, it is impossible in fixed-precision arithmetic to produce a numerical solution to an IVP which remains uniformly close to the exact solution for a long time. As a result, forward error bounds are impractical in such cases. However, one can often guarantee that a numerical solution remains uniformly close not to the solution starting at the initial condition specified, but instead to the exact solution to the ODE (1.1) starting at a nearby initial condition. In other words, if one allows the initial condition to have a nonzero error, just as one is satisfied with a nonzero error at all other times (Murdock (1995)), then it may be possible to guarantee that the numerical solution remains uniformly close to *some* exact

solution for a long time. Such an exact solution is called a *shadow* of the numerical solution.

Backward error analysis is a general term applied to methods of error analysis that relate a numerical solution to the exact solution of a "nearby" problem (Corless (1994), for example). In the context of IVPs for ODEs, "nearby" has at least two interpretations: we can either perturb the defining equation, or we can perturb the initial condition. Defect-based and other backward error analyses allow a time-dependent perturbation to the defining equation while leaving the initial condition untouched. In contrast, shadowing perturbs only the initial condition. For many physical systems which are modelled using ODEs, the governing equations are well defined, and virtually all error is introduced by imprecise knowledge of initial conditions and/or by numerical error in the computation of the solution. In these contexts, shadowing may a be more appropriate method of error analysis than defect-based methods. On the other hand, rigorous shadowing as presented in this paper and elsewhere is extremely expensive. Whereas nonrigorous defect-controlled methods are of roughly equal expense compared to more traditional integration methods, rigorous shadowing requires validated ODE integration, which at present tends to be several orders of magnitude more expensive in both time and memory than nonvalidated methods, even for low-dimensional problems. Thus, the goal of shadowing should not be to validate every numerical solution computed, but instead to study under what conditions we can expect a numerical solution to have a shadow.

Procedures for finding shadows usually involve some sort of fixed-point method. These include nonrigorous numerical methods akin to Newton's method (Grebogi et al. (1990); Quinlan and Tremaine (1992); Hayes (1995)) and methods that employ a theorem to prove the existence of a shadow, usually relying on Brouwer's fixed-point theorem or the Newton–Kantorovich theorem (Sauer and Yorke 1991; Chow and Palmer 1991, 1992; Chow and Van Vleck 1994).

An important advance has been the realization that ODEs differ fundamentally from maps in that they have errors in *time* as well as in space. By employing a *rescaling of time*, shadow lengths for ODEs can be increased by several orders of magnitude (Coomes, Koçak, and Palmer (1994b), (1995a), (1995b); Van Vleck 1995), even allowing the proof of existence of periodic trajectories near periodic pseudotrajectories (Coomes, Koçak, and Palmer (1994a); Coomes, Koçak, and Palmer (1997)). Shadowing has also been used to demonstrate that conservative integrations that approximately satisfy a first integral can have shadows that exactly satisfy it (Coomes (1997)), and that more explicit control of the numerical error in the stable versus unstable subspaces can lead to better shadowing results (Van Vleck (2000)). An interesting application has been to prove that a chaotic trajectory exists near an apparently chaotic pseudotrajectory (Stoffer and Palmer 1999). Hayes (2001) provides a more detailed survey of ODE shadowing results.

This paper extends the work of Grebogi, Hammel, Yorke, and Sauer (1990)(hereafter GHYS), who introduced an elegant geometrical method called *containment* for proving the existence of shadows. Their proof is valid for iterated maps in two dimensions, and is also practical for two-dimensional ODE problems that do not require a rescaling of time. We extend their results to maps of arbitrary dimension in which some measure of hyperbolicity is present and there are either 0 or 1 expanding modes, or 0 or 1 contracting modes. Although we firmly believe that containment can work with an arbitrary number of expanding and contracting directions, proving the general case is a work in progress. We also introduce a new method complementary to containment that facilitates a rescaling of time. In contrast to the above methods that use a fixed-point result, containment, including our new rescaling of time, uses an entirely geometrical argument. We rigorously verify the conditions of our theorems using validated ODE integration (Nedialkov (1999); Nedialkov, Jackson, and Corliss (1999)) and demonstrate that containment is capable of proving the existence of shadows of IVPs for ODEs that are of comparable quality to any currently in the literature. We also demonstrate how containment can reproduce the proof of chaos given by Stoffer and Palmer (1999).

The outline of the paper is as follows. Section 2 presents the ideas for the proofs of containment in an informal, geometrical setting. We present the actual proofs in section 3. Formally, these proofs break into two steps. First, we must prove that the numerical trajectory satisfies a certain property called the *inductive containment property* (ICP, for short). The ICP can be proven computationally to hold, using a validated ODE integrator; we defer discussion of how this is done until section 4. Second, we must show that a numerical trajectory that satisfies the ICP has a shadow. We prove this for maps in n dimensions for the cases in which there is either one expanding or one contracting direction while all the others do the opposite (3.1), or all directions either expand or contract (3.2). The method to rescale time is presented in section 5. Section 6 presents experimental results and comparisons with previous work, followed in section 7 by our conclusions.

2. Informal description of containment.

Although containment was the first method introduced for proving the existence of finite-time shadows of numerical orbits, it has not, to our knowledge, been pursued beyond its initial conception. In this paper we demonstrate that, at least in the restricted cases discussed, containment is about as strong as any method currently in the literature.

2.1. Definitions.

In this paper, an *orbit* is a discrete sequence of points, a *solution* is a continuous curve, and a trajectory more generally refers to either an orbit or a solution, depending upon the context. The prefix *pseudo-* will be used to denote an approximate orbit, solution, or trajectory, although sometimes it will be omitted if the meaning is clear from the context.

Shadowing of numerical orbits was first applied to iterated maps.

DEFINITION 2.1. *An* orbit *of an* iterated map *consists of a sequence of points* $\mathbf{x}_i$ *generated by the recurrence* $\mathbf{x}_{i+1} = \varphi(\mathbf{x}_i)$ *for some map* φ*.*

DEFINITION 2.2. *A* homeomorphism *is a map which is continuous, one-to-one, and onto.*

For our purposes, we restrict φ to being a homeomorphism.

DEFINITION 2.3. *A* pseudo-orbit*, or* noisy *orbit, for* φ *satisfies* $\mathbf{y}_{i+1} = \varphi(\mathbf{y}_i) + \delta_i$*, where* δ_i *is the noise introduced at step* i*. If* $\|\delta_i\| < \delta$ *for all* i*, then it is called a* δ-pseudo-orbit *for* φ*.*

DEFINITION 2.4. *The exact orbit* $\{\mathbf{x}_i\}_{i=0}^N$ *is an* ε*-shadow of the pseudo-orbit* $\{\mathbf{y}_i\}_{i=0}^N$ *if* $\|\mathbf{y}_i - \mathbf{x}_i\| < \varepsilon$ *for* $i = 0, \ldots, N$*.*

Numerical solutions to ODEs can often be viewed as iterated maps by defining $\mathbf{x}_{i+1} = \varphi_{h_i}(\mathbf{x}_i)$, where φ_{h_i} is the *time-*h_i solution operator for the IVP (1.1), (1.2). The time-h_i solution operator is a homeomorphism as long as $\mathbf{f}$ in (1.1) is bounded and Lipschitz continuous over the domain of interest (Ascher, Mattheij, and Russell (1988)). For small h_i, a *one-step numerical method* approximates φ_{h_i} by $\tilde{\varphi}_{h_i}$ and then computes a sequence of discrete points $\mathbf{y}_{i+1} = \tilde{\varphi}_{h_i}(\mathbf{y}_i)$ representing approximations to $\mathbf{y}(t_{i+1})$, where $t_{i+1} = t_i + h_i$. We will term such a discrete sequence of points a *pseudotrajectory.* If the pseudotrajectory satisfies a *local error tolerance* of δ such that

$\|\mathbf{y}_{i+1} - \varphi_{h_i}(\mathbf{y}_i)\| \leq \delta$, then we call it a *$\delta$-pseudotrajectory.* If h_i is constant, we can drop it as a subscript and treat the pseudotrajectory as a pseudo-orbit of the iterated map $\varphi \equiv \varphi_h$.

2.1.1. Hyperbolicity and pseudohyperbolicity. One of the most important concepts in shadowing is that of *hyperbolicity.* Essentially, a system of ODEs is hyperbolic if the variational equation along a solution $\mathbf{y}(t)$ displays *exponential dichotomy* (Palmer 1988). This means that a perturbation δ to the solution $\mathbf{y}(t)$ at time $t = t_0$, $\mathbf{z}(t_0) = \mathbf{y}(t_0) + \delta$ produces a new solution $\mathbf{z}(t)$ with one of two properties: if δ lies in the *stable subspace* of $\mathbf{y}(t)$, then $\mathbf{z}(t)$ converges exponentially to $\mathbf{y}(t)$ as t increases; if δ lies in the *unstable subspace*, then $\mathbf{z}(t)$ diverges exponentially away from $\mathbf{y}(t)$ as t increases. More details can be found in Hayes (2001) or Palmer (1988). If a system is hyperbolic, then the angle between the stable and unstable subspaces is always bounded away from 0 (see GHYS).

This paper deals not with hyperbolic systems, but with systems whose pseudotrajectories are shadowable for finite but nontrivial lengths of time even though they are not hyperbolic. For this to occur, a system must display pseudohyperbolicity. We say that a system is *pseudohyperbolic* if a small perturbation to a trajectory $\mathbf{y}(t)$ produces a new solution $\mathbf{z}(t)$ which falls into one of two classes: those which *tend to* diverge exponentially away from $\mathbf{y}(t)$ as t increases, and those that *tend to* converge exponentially towards $\mathbf{y}(t)$ as t increases. In addition, $\mathbf{z}(t)$ should behave in this manner over nontrivial periods of time. In short, a pseudohyperbolic system should "mimic" the behavior of a hyperbolic system over finite but nontrivial periods of time. This notion could be quantified by, for example, attempting to find the stable and unstable subspaces using *refinement* (GHYS; Quinlan and Tremaine (1992); Hayes (1995), (2001)), and then performing least-squares fits to exponential curves of the growth and decay of these subspaces.

2.2. Containment in two dimensions. The first studies of shadows of pseudohyperbolic systems with both expanding and contracting directions appear to be Beyn (1987) and Hammel, Yorke, and Grebogi (1987). Hammel, Yorke, and Grebogi (1988) and GHYS provide the first proof of the existence of a shadow for a nonhyperbolic system over a nontrivial length of time. Their method consists of two steps. First, they *refine* a noisy trajectory using an iterative method that produces a nearby trajectory with less noise. When refinement converges to the point that the noise is of the order of the machine precision, they invoke *containment*, which can prove the existence of a nearby exact trajectory. Their containment method, which we now describe, is directly applicable only to two-dimensional maps.

Let $\{\mathbf{y}_i\}_{i=0}^{N} \subset \mathbf{R}^2$ be a two-dimensional δ-pseudo-orbit of φ. As i increases, orbits separated from each other by a small distance along the expanding direction diverge on average away from each other, while orbits separated by a small distance along the contracting direction approach each other on average. The containment process consists of building a parallelogram M_i around each point $\mathbf{y}_i$ of the pseudo-orbit such that two sides $C_i^{\pm 1}$ are approximately normal to, and separated from each other along, the contracting direction, while the other two sides $E_i^{\pm 1}$ are approximately normal to, and separated from each other along, the expanding direction.[1] The diameter of

[1] Note that this naming convention is exactly opposite to that of GHYS, because in two dimensions they emphasized the direction to which the sides of M_i were *parallel.* In higher dimensions, the faces of an n-cube are not parallel to a unique direction, and it is the direction along which a face is separated from the center of the n-cube that matters. We change the naming convention now to avoid confusion later.

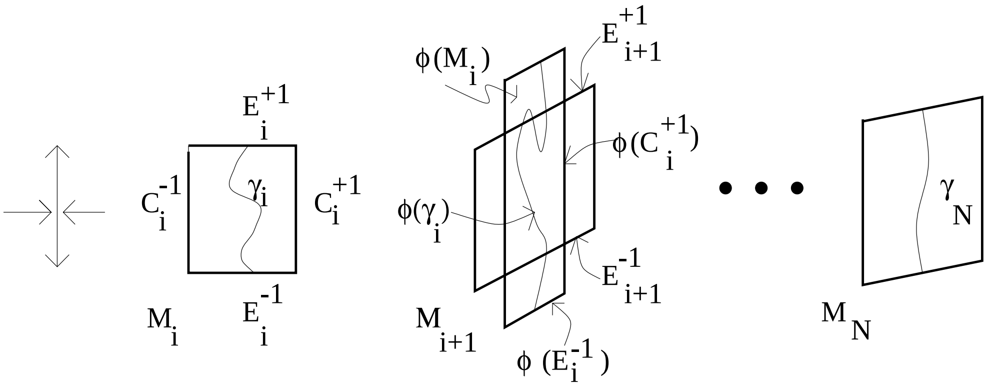

FIG. 2.1. *Containment in two dimensions, reproduced from GHYS. The horizontal direction is contracting, and the vertical direction is expanding.*

M_i will bound the distance from the pseudo-orbit to the shadow. In order to prove the existence of a shadow, the image of M_i under φ must intersect M_{i+1} such that $\varphi(M_i)$ makes a "plus sign" with M_{i+1} (Figure 2.1). To ensure that this property holds, GHYS require a bound on the second derivative of φ, and the amounts of expansion and contraction need to be resolvable to within the machine precision. The proof of the existence of an exact orbit then relies on the following argument. For any $i \in \{0, 1, \ldots, N-1\}$ let γ_i be a continuous curve in M_i connecting the expanding sides E_i^{-1} and E_i^{+1}. Its image $\varphi(\gamma_i)$ is then stretched such that there is a section of $\varphi(\gamma_i)$ lying wholly within M_{i+1}, and in particular $\varphi(\gamma_i)$ leaves M_{i+1} through the expanding sides $E_{i+1}^{\pm 1}$ at both ends. Let γ_{i+1} be a continuous subsection of $\varphi(\gamma_i)$ lying wholly within M_{i+1} connecting the expanding sides $E_{i+1}^{\pm 1}$. Repeating this process along the orbit produces γ_N lying wholly within the final parallelogram M_N. Then any point $\mathbf{x}_N \in \gamma_N$ traced backwards via φ^{-1} yields a point $\mathbf{x}_i \in \gamma_i \subset M_i$, $i = N-1, \ldots, 1, 0$. Note that $\{\mathbf{x}_i\}_{i=0}^N$ is an exact orbit. Moreover, since $\mathbf{x}_i, \mathbf{y}_i \in M_i$, we infer that $\|\mathbf{x}_i - \mathbf{y}_i\| \leq \varepsilon$, where ε bounds the diameter of M_i, $i = 0, \ldots, N$. Thus, $\{\mathbf{x}_i\}_{i=0}^N$ is an ε-shadow of $\{\mathbf{y}_i\}_{i=0}^N$. We make the intuitive argument described here rigorous in section 3.

With this picture in mind, there is a nice geometric interpretation of the requirement that the angle between the stable and unstable directions be bounded away from 0: if the angle gets too small, then the parallelogram essentially loses a dimension, and $\varphi(M_i)$ can not make a "plus sign" with M_{i+1}. Practically speaking, this occurs when the angle becomes comparable to the noise amplitude of the pseudo-orbit. Hence, the more accurate the orbit, the longer it can be shadowed (GHYS, Quinlan and Tremaine (1992)).

2.3. Containment in three dimensions. The process described by GHYS is not directly applicable to systems with more than two dimensions, and GHYS provided no indication of how it could be extended beyond two dimensions. We describe how the method can be extended to three dimensions, in which there are precisely two interesting cases:

(i) One expanding direction and two contracting (Figure 2.2). Assume that the z direction is expanding, while the x and y directions are contracting. (We assume, for simplicity of exposition and for ease of drawing, that these three directions are roughly orthogonal, although in practice they need only

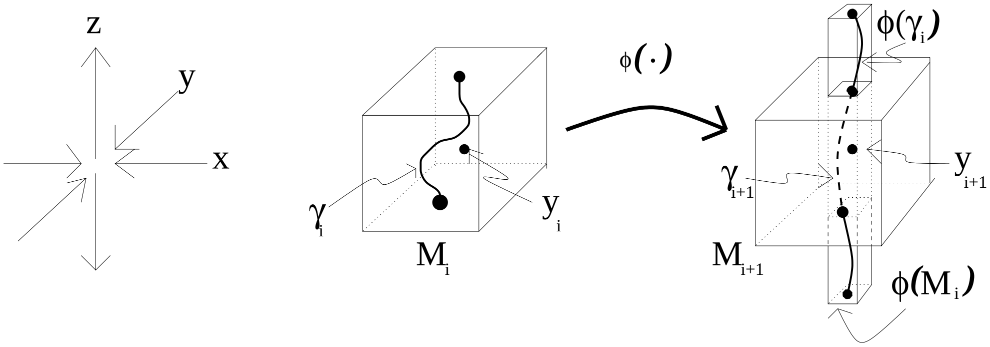

FIG. 2.2. *Containment in three-dimensions, case* (i)*: one expanding direction and two contracting.*

be resolvable from each other.) Then, analogously to the two-dimensional argument, assume we can draw a *cube* M_i of diameter no larger than ε around each noisy point $\mathbf{y}_i$, and, for $i = 0, 1, \ldots, N-1$, assume we can verify that $\varphi(M_i)$ maps over M_{i+1} so that φ stretches M_i into a long, thin tube, a segment of which lies wholly in M_{i+1}. Then, precisely as in the two-dimensional case, we can prove that an ε-shadow of $\{\mathbf{y}_i\}_{i=0}^N$ exists as follows. We introduce a curve γ_i that runs approximately along the expanding (vertical) direction from any point on the top of M_i to its bottom. If $\varphi(M_i)$ maps over M_{i+1} as in Figure 2.2, then we are guaranteed that a contiguous section of $\varphi(\gamma_i)$ lies inside M_{i+1}, connecting its top and bottom along the expanding direction. This segment of $\varphi(\gamma_i)$ becomes γ_{i+1}. Any point $\mathbf{x}_N \in \gamma_N \subset M_N$ can be traced backwards via φ^{-1} to a point $\mathbf{x}_i \in \gamma_i \subset M_i$ for $i = 0, 1, \ldots, N-1$. As in the two-dimensional case, $\{\mathbf{x}_i\}_{i=0}^N$ is an ε-shadow of $\{\mathbf{y}_i\}_{i=0}^N$.

(ii) Two expanding and one contracting direction. We note that if time is reversed in such a system, then expanding and contracting directions reverse their roles. Thus, we simply look at the pseudotrajectory in reverse and apply the above argument. That is, we set $\mathbf{z}_i = \mathbf{y}_{N-i}, i = 0, \ldots, N$, and apply the above argument to the noisy trajectory $\{\mathbf{z}_i\}_{i=0}^N$.

3. Containment theorems and proofs.

3.1. Containment in *n* dimensions with one expanding direction. Here we provide a proof of what we call the $(n, 1)$-inductive containment theorem: the n-dimensional case in which precisely one direction is expanding, while all the others contract. Previous proofs of containment required explicit a priori bounds on spatial derivatives, whereas our proof requires no such bounds.[2]

Let M_i be a parallelepiped in $\mathbf{R}^n$ with faces F_i^j, for $i = 0, \ldots, N$ and $j = \pm 1, \ldots, \pm n$, with opposite signs in the superscript representing opposite faces of a parallelepiped (see Figure 3.1). Without loss of generality, we assume that the first direction is the "expanding" one. We will denote the union of a set of faces by listing all of them in the superscript; for example, $F_i^{\pm 2, \ldots, \pm n}$ represents the set of all the faces of M_i except F_i^{-1} and F_i^{+1}. Let $\partial_E M_i \equiv F_i^{-1} \cup F_i^{+1} \equiv F_i^{\pm 1}$ and $\partial_C M_i \equiv \bigcup_{j=2}^n F_i^{-j} \cup F_i^{+j} \equiv F_i^{\pm 2, \ldots, \pm n}$. Let $\varphi : \mathbf{R}^n \to \mathbf{R}^n$ be a homeomorphism. Let

[2] Of course, our validated ODE integration (Nedialkov (1999)) must compute bounds on derivatives in order to compute enclosures, but these bounds are not a priori; they are computed on-the-fly, and if a bounds check fails, we can always try a smaller timestep to compensate.

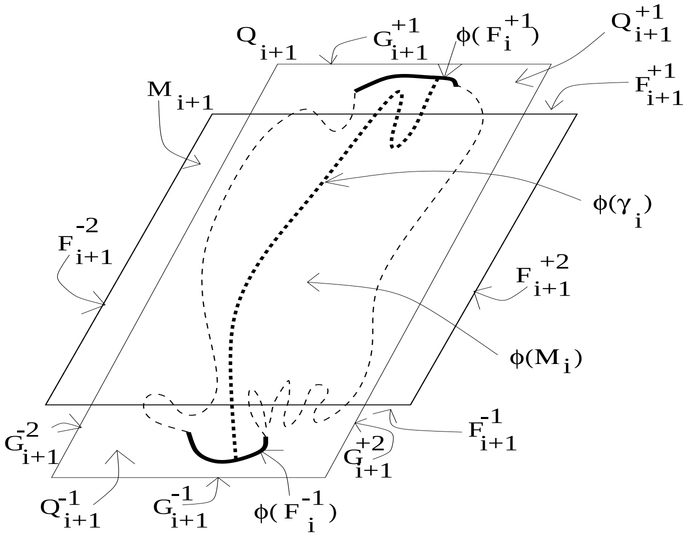

FIG. 3.1. *The image $\varphi(M_i)$ and M_{i+1} for two dimensions. The dark curves at the bottom and top are $\varphi(F_i^{\pm 1})$. The dashed curves at the left and right are $\varphi(F_i^{\pm 2})$.*

int X represent the interior of X. Then M_i and M_{i+1} satisfy the $(n,1)$-ICP if

(1) $\varphi(F_i^{\pm 1}) \cap M_{i+1} = \emptyset$, and $\varphi(F_i^{-1})$ and $\varphi(F_i^{+1})$ are on opposite sides of the infinite slab between the two hyperplanes containing F_{i+1}^{-1} and F_{i+1}^{+1}.

(2) $\exists Q_{i+1}$, a parallelepiped in $\mathbf{R}^n$ with each face G_{i+1}^j parallel to the corresponding face F_{i+1}^j of M_{i+1} for $j = \pm 1, \dots, \pm n$, such that
   (a) $\varphi(M_i) \subset \text{int } Q_{i+1}$,
   (b) $F_{i+1}^{\pm 2,\dots,\pm n} \cap Q_{i+1} = \emptyset$, and $\forall j \in \{2,\dots,n\}$, F_{i+1}^{-j} and F_{i+1}^{+j} are on opposite sides of the infinite slab between the two hyperplanes containing G_{i+1}^{-j} and G_{i+1}^{+j}.

Let $\gamma_0 \subset M_0$ be a simple curve joining F_0^{-1} to F_0^{+1}, but otherwise remaining in the interior of M_0. That is,

$$\gamma_0 \cap F_0^{-1} \neq \emptyset \quad \wedge \quad \gamma_0 \cap F_0^{+1} \neq \emptyset \quad \wedge \quad \text{int } \gamma_0 \subset \text{int } M_0.$$

THEOREM 3.1 ($(n,1)$-inductive containment theorem). *If M_i and M_{i+1} satisfy the $(n,1)$-ICP $\forall i = 0, \dots, N-1$, then $\forall i = 0, \dots, N$*

$$\exists \text{ simple curve } \gamma_i \subseteq \varphi^i(\gamma_0) \text{ s.t. } \gamma_i \cap F_i^{-1} \neq \emptyset \ \wedge \ \gamma_i \cap F_i^{+1} \neq \emptyset \ \wedge \ \text{int } \gamma_i \subset \text{int } M_i. \tag{3.1}$$

That is, γ_i touches the boundary of M_i in precisely two places, connecting F_i^{-1} to F_i^{+1}, but otherwise remains entirely inside M_i.

Proof. We proceed by induction on i. The proof of the base case $i = 0$ is immediate, by the definition of γ_0. For the inductive case, assume $\exists$ a simple curve $\gamma_i \subseteq \varphi^i(\gamma_0)$ such that $\gamma_i \cap F_i^{-1} \neq \emptyset \ \wedge \ \gamma_i \cap F_i^{+1} \neq \emptyset \ \wedge \ \text{int } \gamma_i \subset \text{int } M_i$. From ICP(1), $\varphi(F_i^{\pm 1}) \subset Q_{i+1}$, and the fact that Q_{i+1} is convex, we know that Q_{i+1} intersects both F_{i+1}^{-1} and F_{i+1}^{+1}; and from ICP(2(b)), Q_{i+1} does not intersect $F_{i+1}^{\pm 2,\dots,\pm n}$. Thus, since Q_{i+1} is convex, $Q_{i+1} - M_{i+1}$ is disconnected by the slab defined in ICP(1) into two

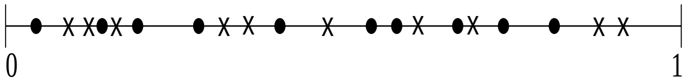

FIG. 3.2. *Schematic representation of the sets $\gamma^{-1}(s^{-1})$ (dots) and $\gamma^{-1}(s^{+1})$ ($\times$'s).*

disjoint components,[3] say Q^{-1}_{i+1} and Q^{+1}_{i+1}, each containing one of $\varphi(F^{\pm 1}_i)$, by ICP(1). Without loss of generality, assume $\varphi(F^j_i) \subset Q^j_{i+1}$, $j = \pm 1$. Now, consider one of the components, say Q^{-1}_{i+1}. It contains one of the two endpoints of $\varphi(\gamma_i)$, since one endpoint is in $\varphi(F^{-1}_i) \subset Q^{-1}_{i+1}$, while the other endpoint of $\varphi(\gamma_i)$ is in $\varphi(F^{+1}_i) \subset Q^{+1}_{i+1}$. Since γ_i is a simple curve and φ is a homeomorphism, $\varphi(\gamma_i)$ is a simple curve. Now, $Q^{-1}_{i+1} \cap Q^{+1}_{i+1} = \emptyset$, and $\varphi(\gamma_i)$ connects the two. Thus, $\varphi(\gamma_i)$ must cross the boundary of Q^{-1}_{i+1}. This boundary consists of exactly two mutually exclusive patches, one of which is a subset of ∂Q_{i+1}, the other a subset of F^{-1}_{i+1}. Since $\varphi(\gamma_i) \subset \varphi(M_i) \subset \text{int } Q_{i+1}$, we infer that $\varphi(\gamma_i) \cap \partial Q_{i+1} = \emptyset$, and so $\varphi(\gamma_i)$ leaves Q^{-1}_{i+1} through F^{-1}_{i+1}. A similar argument shows that $\varphi(\gamma_i)$ leaves Q^{+1}_{i+1} through F^{+1}_{i+1}. Thus, $\varphi(\gamma_i) \cap F^j_{i+1} \neq \emptyset$, $j = \pm 1$. It remains to show that there exists a segment γ_{i+1} of $\varphi(\gamma_i)$ which is a simple curve and maintains the property defined in (3.1).

Since $\varphi(\gamma_i)$ is a simple curve, there exists a parameterization $\gamma(t)$ for $t \in [0,1]$ such that $\gamma([0,1]) = \varphi(\gamma_i)$ and $\gamma(t)$ is a homeomorphism (Munkres (1975)). Let $s^j = \varphi(\gamma_i) \cap F^j_{i+1}$, $j = \pm 1$. Now, s^{-1} and s^{+1} are disjoint sets since $F^{-1}_{i+1} \cap F^{+1}_{i+1} = \emptyset$, and they are compact because (1) F^j_{i+1} for $j = \pm 1$ are compact; (2) γ_i is compact, φ is a homeomorphism, and so $\varphi(\gamma_i)$ is compact; and (3) the intersection of two compact sets in $\mathbf{R}^n$ is compact. Finally, $\gamma^{-1}(s^{\pm 1})$ are compact because γ is a homeomorphism. To prove that there exists a simple curve $\gamma_{i+1} \subset \varphi(\gamma_i)$ such that $\gamma_{i+1} \cap F^{-1}_{i+1} \neq \emptyset$, $\gamma_{i+1} \cap F^{+1}_{i+1} \neq \emptyset$, and $\text{int } \gamma_{i+1} \subset \text{int } M_{i+1}$, we need to show that there exist two points in $[0,1]$, one each from $\gamma^{-1}(s^{-1})$ and $\gamma^{-1}(s^{+1})$, such that no points from either set are between them (see Figure 3.2). This will prove that there exists a simple curve, which is a section of $\varphi(\gamma_i)$, that connects F^{-1}_{i+1} to F^{+1}_{i+1} without otherwise intersecting ∂M_{i+1}. To this end, let $G = \gamma^{-1}(s^{-1})$ and $R = \gamma^{-1}(s^{+1})$, and note that G and R are compact, disjoint, nonempty subsets of $[0,1]$. The following lemma completes the proof. □

LEMMA 3.2. *Let G and R be (possibly infinite) disjoint, compact, nonempty subsets of $[0,1]$. Then $\exists g \in G,\ r \in R$ such that $(g,r) \cap (G \cup R) = \emptyset$, where we have assumed without loss of generality than $g < r$.*

Proof. Consider the function $f(x,y) = |x-y|$ over the subset $G \times R$ of the plane. Since f is continuous and $G \times R$ is compact, f attains its minimum at some point $(g,r) \in G \times R$. That is, $|g-r| \leq |g'-r'|$ for any other $g' \in G$, $r' \in R$. Thus, there is no element of either set G or R between g and r, and so the open interval (g,r) is disjoint from $G \cup R$. □

THEOREM 3.3 (shadowing containment theorem). *Let φ be a homeomorphism. Let $\{M_i\}_{i=0}^N$ be a sequence of parallelepipeds enclosing a pseudotrajectory $\{\mathbf{y}_i\}_{i=0}^N$. Let ε be the maximum diameter of M_i for $i = 0, 1, \ldots, N$. Let $\gamma_i \subset M_i, \gamma_i \neq \emptyset$, $i = 0, \ldots, N$, and let $\gamma_{i+1} \subseteq \varphi(\gamma_i)$, $i = 0, \ldots, N-1$. Then $\exists$ an ε-shadow $\{\mathbf{x}_i\}_{i=0}^N$ of $\{\mathbf{y}_i\}_{i=0}^N$. That is, there is an exact trajectory $\{\mathbf{x}_i\}_{i=0}^N$ of φ such that $\|\mathbf{x}_i - \mathbf{y}_i\| < \varepsilon$, $i = 0, \ldots, N$.*

[3] This is because F^{-1}_{i+1} and F^{+1}_{i+1} are each patches of an $(n-1)$-dimensional hyperplane residing in n dimensions, and so they each disconnect any convex set they intersect, as long as that convex set does not intersect their boundaries ∂F^{-1}_{i+1} and ∂F^{+1}_{i+1}, respectively.

Proof. Since φ is a homeomorphism, φ^{-1} is a well-defined function. Pick any point $\mathbf{x}_N \in \gamma_N$, and recursively define $\mathbf{x}_i = \varphi^{-1}(\mathbf{x}_{i+1}),\ i = N-1, N-2, \ldots, 0$. Since $\gamma_{i+1} \subseteq \varphi(\gamma_i)$, $\varphi^{-1}(\gamma_{i+1}) \subseteq \gamma_i$, and so by induction $\mathbf{x}_i \in \gamma_i$ for $i = N, N-1, \ldots, 0$. Since $\mathbf{y}_i \in M_i$ and $\mathbf{x}_i \in \gamma_i \subset M_i$, $\|\mathbf{y}_i - \mathbf{x}_i\| \leq \operatorname{diam}(M_i) \leq \varepsilon,\ i = 0, \ldots, N$. □

Thus, applying Theorem 3.3 to an orbit satisfying the $(n,1)$-ICP implies the existence of a shadow.

Remark 3.1. Note that Theorem 3.3 is independent of the number of dimensions n, and of the number of expanding and contracting directions, because the only parts of the inductive containment theorem that are used are the conclusions that $\gamma_{i+1} \subseteq \varphi(\gamma_i)$ for $i = 0, 1, \ldots, N-1$ and $\emptyset \neq \gamma_i \subset M_i$ for $i = 0, \ldots, N$. The 0-expanding and 0-contracting directions are handled separately. We conjecture that the general (n,k)-inductive containment theorem (work in progress) will also assert this property, so that the above shadowing containment theorem is applicable to the general (n,k) case, in which k directions are expanding and $n-k$ are contracting.

As mentioned previously, the case with one *contracting* dimension while the other $n-1$ directions expand can be handled simply by reversing the arrow of time and applying the above argument. We call this the $(n, n-1)$ case. Another proof, which is more likely to be generalizable to an arbitrary number of expanding and contracting directions, is presented in Hayes (2001).

3.2. Containment with zero contracting or zero expanding directions. For completeness, we mention the trivial cases in which all directions are contracting, or all directions are expanding. We call these the $(n,0)$ and (n,n) cases, respectively. The former case is entirely trivial, because the problem is stable: if $\varphi(M_i) \subset M_{i+1}$ for all i, then clearly any exact solution starting in M_0 will be in M_i for all $i > 0$. Similarly, if all directions are expanding, then we apply the same argument in the reverse direction: if $\varphi^{-1}(M_{i+1}) \subset M_i$ for all i, then any exact solution *finishing* in M_N, traced backwards, lies in M_i for $i = N-1, N-2, \ldots, 0$.

3.3. Discussion. The four cases $(n,0), (n,1), (n,n-1)$, and (n,n) cover *all* cases for $n = 1, 2, 3$. That is, the theorems in this paper can prove the existence of shadows for any n-dimensional system, $n \leq 3$, in which some measure of pseudohyperbolicity is present. Furthermore, although the proofs, for simplicity, deal only with a single function φ, the induction argument could just as easily use a *different* function φ_i at each step. In particular, φ_i could be the ODE time-h_i solution operator φ_{h_i}. Thus, modulo a rescaling of time (which we discuss below), the above proofs can be used to find shadows of noisy trajectories of ODE systems, as well as maps, with up to three dependent variables. They can also be used in the case of n dependent variables, with the restriction that solutions have either one expanding and $n-1$ contracting directions, or one contracting and $n-1$ expanding directions.

Finally, we believe that a generalized (n,k)-ICP implies the existence of a shadow (work in progress; more discussion in Hayes (2001)).

3.4. Proving the existence of chaotic orbits. Following the analysis of Stoffer and Palmer (1999), we describe how to use containment to prove the existence of chaotic orbits. We quote directly from their introduction.

> The idea is to construct two periodic pseudo-orbits which happen to be close to each other at some point. We call this the branching point. Then it is possible to construct an infinite number of pseudo-orbits as follows. You follow one or the other of the periodic pseudo-orbits. When you reach the branching point, you either stay on your periodic orbit for at least one more loop, or else you switch to the other periodic orbit. Each time you

> arrive at the branching point you can again choose to stay or to switch, ad infinitum. Assume that for each such pseudo-orbit there is a unique *orbit* of the system which is close to the pseudo-orbit. Then the dynamical system indeed behaves chaotically, at least in a certain neighbourhood of the two periodic pseudo-orbits. (Stoffer and Palmer 1999)

To use this approach together with containment to prove the existence of a chaotic orbit, assume that the first orbit has a sequence of N parallelepipeds M_i satisfying the (n, k)-ICP with $M_N = M_0$. Then the (n, k)-inductive containment theorem can be invoked ad infinitum around this periodic pseudo-orbit and proves the existence of infinitely long exact orbits that remain in the vicinity of this pseudo-orbit.[4] Similarly, assume that the second orbit has a sequence of P parallelepipeds Q_i satisfying the (n, k)-ICP with $Q_P = Q_0$. Assume further that $M_i = Q_j$ for some i, j. Then $M_i = Q_j$ is the branching point, the (n, k)-inductive containment theorem can be invoked ad infinitum around *both* of these pseudo-orbits, and each time we pass $M_i = Q_j$ we can choose which pseudo-orbit to follow. The (n, k)-inductive containment theorem proves that a shadow follows us as we go.

4. Verifying the inductive containment property.

We present one method of verifying that the general (n, k)-ICP holds for a given pseudotrajectory derived from the numerical solution of an ODE. (Three more methods for verifying the ICP are presented in Hayes (2001).) We note in passing that this scheme (as well as the other three discussed in Hayes (2001)) could easily be adapted to the simpler problem of maps. We require the use of validated interval arithmetic, or a validated ODE integrator if φ derives from an ODE. The validated ODE integrator that we use is called VNODE (Nedialkov (1999); Nedialkov, Jackson, and Corliss (1999)). VNODE works with n-dimensional parallelepipeds and satisfies the following property: given an n-dimensional parallelepiped A and a timestep h, VNODE will return an n-dimensional parallelepiped B such that $\varphi_h(A) \subset B$, where φ_h is the time-h solution operator. For the purposes of this description, we will denote the output B by $\bar{\varphi}_h(A)$. Thus,

$$\varphi_h(A) \subset \bar{\varphi}_h(A).$$

We will usually omit the timestep parameter h; we will talk only of φ, keeping in mind that, in the induction, φ can be different for each step.

We verify the ICP using an iterative method that we have found empirically to require about 3–4 validated integrations per step on average, independent of n. This method rigorously verifies the ICP in the cases for which we have proven the inductive containment theorem and is the method we actually used to produce our numerical results. Three noniterative, deterministic methods are presented in Hayes (2001); however, we found this method to be the most efficient with the validated ODE solver we used (Nedialkov (1999)).

We first look at the simple two-dimensional case in which one of the directions is expanding, while the other is contracting. To begin, assume that the only information provided by our validated ODE integration is an outer bound $\bar{\varphi}(M_i)$ on $\varphi(M_i)$. Then, it is *not* possible to verify the $(2, 1)$-ICP with only one validated integration, because this information can only prove contraction, not expansion, as shown in Figure 4.1. In both Figures 4.1(a) and 4.1(b), $\bar{\varphi}(M_i)$ is a valid enclosure of $\varphi(M_i)$. In both figures, $\bar{\varphi}(M_i)$ can be used to prove that $\varphi(M_i)$ has contracted in the horizontal

[4] Slightly more is required to prove the existence of periodic orbits or to prove uniqueness.

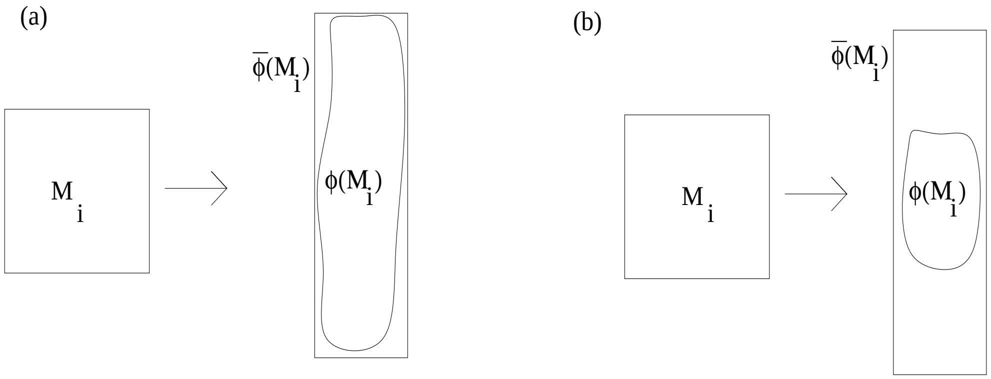

FIG. 4.1. *Enclosure methods can prove contraction but not expansion.*

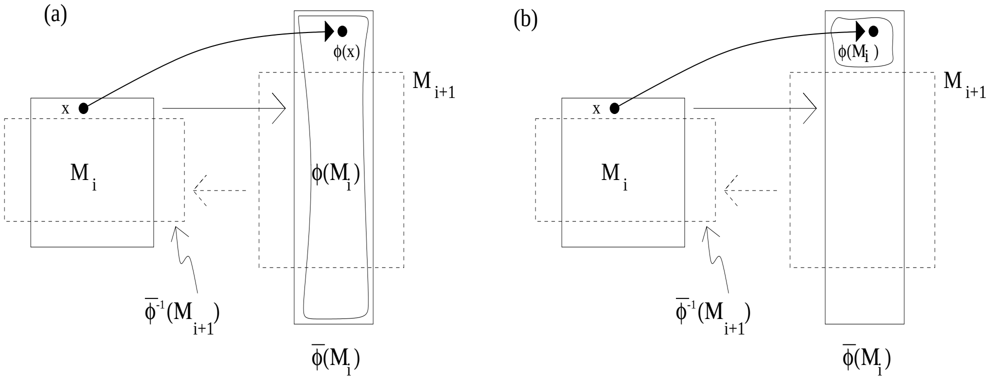

FIG. 4.2. (a) *The two validated integrations required to prove the* $(2,1)$*-ICP.* (b) *A potential problem, which is solved by doing a (cheap) point integration of one point on each expanding face, to verify that there are points of* $\varphi(M_i)$ *on both side of* M_{i+1}*.*

direction. However, enclosure methods cannot directly prove expansion, as Figure 4.1(b) illustrates: although $\bar{\varphi}(M_i)$ is a valid enclosure of $\varphi(M_i)$, it is not a very good one, because the actual image $\varphi(M_i)$ of M_i has not expanded in any direction. To solve this problem, we perform two validated integrations; refer to Figure 4.2(a). The first integration (solid rectangles) is a forward integration that provides $\bar{\varphi}(M_i)$, which in turn gives us a bound on the size of $\varphi(M_i)$ in the contracting directions (depicted as the horizontal direction in the figure). Now, assume we can find an M_{i+1} which satisfies the ICP not with $\varphi(M_i)$, but with $\bar{\varphi}(M_i)$. (If we cannot find such an M_{i+1}, then our method fails and we cannot prove the existence of a shadow beyond step i.) A validated integration *backwards* (dashed rectangles) is then performed on M_{i+1}, giving $\bar{\varphi}^{-1}(M_{i+1})$. If $\bar{\varphi}^{-1}(M_{i+1})$ proves that *contraction* has occurred in the nominally expanding directions when moving back from M_{i+1} to M_i, then we argue that expansion in forward time has occurred, as follows. Choose any $\mathbf{x} \in M_i - \bar{\varphi}^{-1}(M_{i+1})$. Since $\mathbf{x} \notin \bar{\varphi}^{-1}(M_{i+1}) \supset \varphi^{-1}(M_{i+1})$, this implies $\varphi(\mathbf{x}) \in \varphi(M_i) - M_{i+1}$. Since $F_i^{\pm 1} \subset M_i - \bar{\varphi}^{-1}(M_{i+1})$, this tells us that $\varphi(F_i^{\pm 1}) \cap M_{i+1} = \emptyset$. This is insufficient to prove ICP(1), as illustrated in Figure 4.2(b): perhaps $\bar{\varphi}(M_i)$ is a loose enclosure of $\varphi(M_i)$, and all of $\varphi(M_i)$ is actually on one side of M_{i+1}. To verify that this is not the case, we pick one point on each of F_i^{+1} and F_i^{-1} and perform a validated point

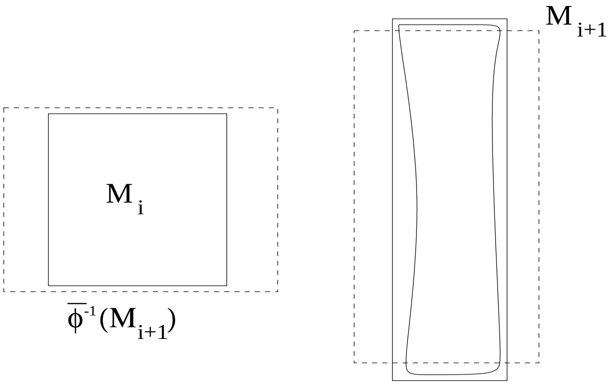

FIG. 4.3. *Shortcomings of the two-integration method: sometimes it can not prove expansion even if the M_{i+1} is valid.*

integration of each (which can be done cheaply) to verify that they land on opposite sides of M_{i+1}.[5] Since there is exactly one expanding direction, M_{i+1} cuts $\bar{\varphi}(M_i)$ into two disjoint sets, and a simple continuity argument shows that the two faces in their entirety land on opposite sides of M_{i+1}, thus verifying ICP(1). A similar argument in reverse time shows that the chosen M_{i+1} also verifies ICP(2(b)).

The argument of the previous paragraph clearly applies just as well in n dimensions when there is one expanding direction and $n-1$ contracting directions, for the same reasons that the two-dimensional proof of containment is easily transformed into Theorem 3.1 (Hayes (2001)). To prove that it also works when there is one contracting direction and $n-1$ expanding directions, note that there is a precise symmetry between the two cases (one expanding vs. one contracting): if we simultaneously reverse the order of $\{M_i\}_{i=0}^N$, giving $L_i = M_{N-i}$, and let $\psi = \varphi^{-1}$, then the above argument applies to the sequence $\{L_i\}_{i=0}^N$ using ψ as the homeomorphism. Thus, by symmetry, this method is also rigorous in the case when there is one contracting direction and $n-1$ expanding ones.

Figure 4.3 illustrates that it is possible to choose an M_{i+1} that satisfies the ICP but for which we cannot *verify* that the ICP holds. This occurs when M_{i+1} is chosen to be "almost as large" as $\bar{\varphi}(M_i)$ in the expanding directions; then, the excess when computing $\bar{\varphi}^{-1}(M_{i+1})$ swamps the contraction that occurs when integrating the expanding direction backwards in time. We solve this problem by iteratively shrinking M_{i+1} in the nominally expanding directions until $\bar{\varphi}^{-1}(M_{i+1})$ fits inside M_i in those directions. If we shrink M_{i+1} to size zero in the expanding direction without being able to integrate it backwards to fit inside M_i, then the method fails, and we cannot prove the existence of a shadow beyond step i. We have found empirically that, when the algorithm is succeeding, no more than 2 to 3 backwards integrations are usually required, independent of n. The number of backwards integrations is occasionally significantly larger, when the system encounters areas of nonhyperbolicity.

If the system were hyperbolic, then the nominally expanding directions would always expand, and the nominally contracting directions would always contract. However, in systems that are only pseudohyperbolic, the nominally expanding directions

[5] We have found empirically that this problem must be very rare, because it has not happened even once during our experiments. We suspect that it may be possible to prove the ICP without this extra point integration, but we have not devoted much thought to this matter.

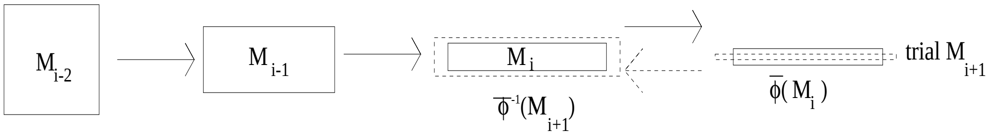

FIG. 4.4. *Example of the nominally expanding direction contracting too much for our integrator to prove contraction in the backwards direction.*

may expand most of the time, but not always, and vice versa for the contracting directions. One of the reasons our shadowing method can fail is if a nominally expanding direction contracts too much or for too long a time (Figure 4.4). Then, the expanding dimensions of M_i can become so small that no backwards integration from M_{i+1} can fit inside M_i in the nominally expanding directions.

4.1. Implementation issues and discussion. In the original paper that described containment, Grebogi et al. (GHYS) appear to have used boxes M_i of fixed size and found that smaller boxes seemed to work better. In contrast, our method dynamically grows and shrinks the M_i as i progresses, in an effort to maintain the ICP. In fact, we find it advantageous to choose the expanding dimension of M_i to be fairly large, to allow us to "absorb" possible future nonexpansion, in an effort to avoid the situation depicted in Figure 4.4. Similarly, we choose the contracting dimensions to be relatively small, to avoid the opposite effect (allowing us to "absorb" noncontraction without the nominal contracting dimensions becoming too large). Practically, we find that our "boxes" can be extremely long and thin: typically, they are of length 10^{-3} to 10^{-6} in the expanding dimensions, and as small as 10^{-12} to 10^{-14} in the contracting dimensions.

Referring once again to Figure 4.4, we note that when containment fails, the "expanding" dimension of M_i has often shrunk to almost the same size as the contracting dimension, and both can be quite small (say, 10^{-12}), whereas when containment is "working," the expanding dimension of M_i can be several orders of magnitude larger than the contracting dimension. It is interesting to note that this implies that the hardest parts of an orbit to shadow are the places where our bounds on the distance between the noisy and shadow orbits are *smallest*, i.e., where we can prove that they are unusually close together. This appears counterintuitive but may be related to the one-dimensional result of Chow and Palmer (1991), in which they proved that shadows must maintain a minimum distance from the noisy orbit.

5. Rescaling time.

5.1. Informal description. Containment as presented thus far has put no restrictions on φ other than that it is a homeomorphism. As has also been mentioned, all of our theorems and proofs have been based on a single application of φ, and there is no explicit connection between the φ used at one step and the one used on the next. Thus, everything said thus far is also applicable if we allow φ to change between steps. In particular, at each step we could use the time-h_i solution operator φ_{h_i}, with h_i being the length of the ODE integration timestep taken at step i. The resulting method for shadowing numerical ODE integrations has been dubbed the *map method* by Coomes, Koçak, and Palmer (1994b), (1995a), (1995b). However, ODE integrations suffer from errors in time. For systems in which the $\mathbf{y}'$ direction lacks even pseudohyperbolicity, errors in time (which manifest themselves in phase space as errors in the $\mathbf{y}'$ direction) can lead to short shadowing times that can be dramatically increased if time is *rescaled.* In this section, we describe how containment can be augmented to allow for the rescaling of time.

Our idea for rescaling time in containment was inspired in part by the rescaling of time developed by Coomes, Koçak, and Palmer (1994b), (1995a) (although our proofs are very different from theirs), and partly by the idea of the *Poincaré section*, also known as a *Poincaré map* or *return map.* There are several variations on this idea, but the one that concerns us is the following. Assume that the solution to an ODE is "almost periodic," in the sense that the solution passes through some fixed neighborhood of a given plane $\mathcal{H}$ approximately every T time units, where $\mathcal{H}$ is approximately perpendicular to the trajectory at the point where it crosses the plane. The Poincaré map generates the sequence of points at which the trajectory intersects $\mathcal{H}$. To accomplish the general rescaling of time, we modify this idea to remove the almost-periodic requirement of the orbit, and simply place a plane $\mathcal{H}_i$ in the vicinity of the solution at time t_i, placed so that $\mathcal{H}_i$ is approximately perpendicular to $\mathbf{y}'(t_i)$. Note that we do not compute $\mathcal{H}_i$; we only prove that it exists.

To facilitate containment, we must extend the idea of the Poincaré section to encompass a small ensemble of solutions. To that effect, we wish to take a set $M_{i-1} \subset \mathcal{H}_{i-1}$, where the diameter of M_{i-1} is small, and place an $(n-1)$-dimensional hyperplane $\mathcal{H}_i$ approximately normal to the flow in the vicinity of $\varphi_{h_{i-1}}(M_{i-1})$. Then we define the Poincaré section of the set $\varphi_{h_{i-1}}(M_{i-1})$ pointwise as follows. Let Δh_{i-1} bound the time interval over which the ensemble $\varphi_{h_{i-1}}(M_{i-1})$ crosses $\mathcal{H}_i$:

$$\forall \mathbf{x} \in M_{i-1} \quad \exists h \in [h_{i-1} - \Delta h_{i-1}/2, h_{i-1} + \Delta h_{i-1}/2] \quad \text{ s.t. } \varphi_h(\mathbf{x}) \in \mathcal{H}_i,$$

where we assume that, for each $\mathbf{x}$, the h chosen is unique. That is, we take the point-by-point Poincaré section of the points in M_{i-1} with respect to the plane $\mathcal{H}_i$. We call this a *splash* operation, because we imagine that the points in M_{i-1}, evolving via φ_h for $h \in [h_{i-1} - \Delta h_{i-1}/2, h_{i-1} + \Delta h_{i-1}/2]$, "splash" through $\mathcal{H}_i$ approximately simultaneously, and we assume that each trajectory intersects $\mathcal{H}_i$ precisely once during that interval; see Figure 5.1.

Our intent is to build $(n-1)$-dimensional parallelepipeds M_i inside $\mathcal{H}_i$ and then show that the point-by-point Poincaré section at $\mathcal{H}_i$—the splash operation—is a homeomorphism. We can then directly apply the previously proven containment theorems to the $(n-1)$-dimensional M_i's, which are each contained in the $(n-1)$-dimensional hyperplane $\mathcal{H}_i$, for an ODE system of n equations.

We note that since rescaling time via the splash operation effectively deletes one dimension from the problem, and since our map containment theorems are rigorous in three dimensions, this means that the methods presented in this paper are capable of rigorously shadowing ODE solutions of up to four dimensions, as long as a rescaling of time is applied.

5.2. Theorem: Splash is a homeomorphism. Refer to Figure 5.2. Let Q_i be an n-dimensional parallelepiped. Let $F_i^{\pm 1}$ be the two opposing faces of Q_i that are approximately normal to $\mathbf{y}'$ inside Q_i, and let $\mathbf{v}_i$ be the unit normal vector to these two faces, with $\mathbf{v}_i$ pointing from F_i^{-1} to F_i^{+1}. That is, $\mathbf{v}_i$ is approximately parallel to $\mathbf{y}'$ inside Q_i. Let D be the distance between F_i^{-1} and F_i^{+1} along $\mathbf{v}_i$. Let the infinite hyperplanes containing F_i^{-1} and F_i^{+1} be H_i^{-1} and H_i^{+1}, respectively, and let Z_i be the closed infinite slab between them. Let B_i be a parallelepiped with faces parallel to Q_i satisfying $Q_i \subset B_i \subset Z_i$, with two of the faces of B_i contained in $H_i^{\pm 1}$. Let $\{\mathbf{f}(\mathbf{x}) \cdot \mathbf{v}_i \mid \mathbf{x} \in B_i\} \subset [v_0, v_1]$, and assume $0 < v_0 \le v_1$.

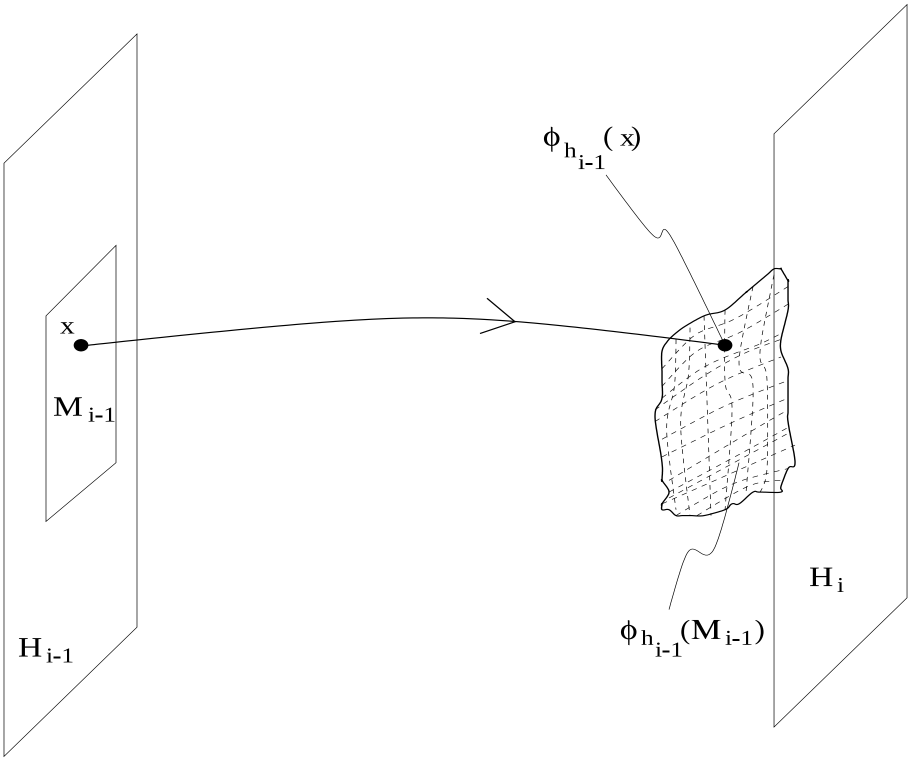

FIG. 5.1. *The "splash" operation depicted for a two-dimensional ensemble evolving in a three-dimensional configuration space. M_{i-1} is embedded in the plane $\mathcal{H}_{i-1}$ and evolves through one timestep to $\varphi_{h_{i-1}}(M_{i-1})$. As depicted, the ensemble is about to splash through $\mathcal{H}_i$.*

LEMMA 5.1. *If a trajectory remains in B_i while it is in Z_i, then it remains in Z_i for at least time $\underline{\varepsilon}_i^t \equiv D/v_1$ and at most $\bar{\varepsilon}_i^t \equiv D/v_0$.*

Proof. Let $\mathbf{y}(t)$ be a trajectory that remains in B_i while it is in Z_i. Let $z(t) = \mathbf{y}(t) \cdot \mathbf{v}_i$. Since $0 < v_0 \leq z'(t) \leq v_1$ and the width of B_i in the $\mathbf{v}_i$ direction is D, the maximum time to cross B_i is D/v_0, while the minimum time to cross is D/v_1. □

Let $\bar{\mathbf{f}}(B_i)$ be an enclosure of $\{\mathbf{f}(\mathbf{x}) \mid \mathbf{x} \in B_i\}$. Let S_i be a parallelepiped enclosure of $\{Z_i \cap (Q_i + h\bar{\mathbf{f}}(B_i)) \mid h \in [-\bar{\varepsilon}_i^t, \bar{\varepsilon}_i^t]\}$, and assume $S_i \subseteq B_i$.

Remark 5.1. S_i is intended to enclose the distance that a trajectory can drift from Q_i along the direction approximately perpendicular to $\mathbf{y}'$ as it travels across Z_i. This is required because a point in Q_i may not remain in Q_i when it is "splashed" onto $\mathcal{H}_i$. The following lemma formalizes this statement.

LEMMA 5.2. *Any trajectory intersecting Q_i remains in S_i while in Z_i, and thus remains in B_i as well.*

Proof. Since $S_i \subseteq B_i$, $\bar{\mathbf{f}}(B_i)$ bounds $\mathbf{y}' \equiv \mathbf{f}$ inside S_i. Since a trajectory remaining in B_i as it crosses Z_i does so in time $\leq \bar{\varepsilon}_i^t$, and since $S_i \subset B_i$, $\{h\bar{\mathbf{f}}(B_i) \mid h \in [-\bar{\varepsilon}_i^t, \bar{\varepsilon}_i^t]\}$ encloses the maximum possible distance from Q_i that a trajectory can travel in time $|\bar{\varepsilon}_i^t|$ while it remains in B_i. Thus, since $Q_i \subset S_i \subseteq B_i$, $\{Q_i + h\bar{\mathbf{f}}(B_i) \mid h \in [-\bar{\varepsilon}_i^t, \bar{\varepsilon}_i^t]\}$ encloses the position of any trajectory $\mathbf{y}(t)$ that is within time $\bar{\varepsilon}_i^t$ of intersecting Q_i, unless $\mathbf{y}(t)$ leaves Z_i during that time. Intersecting with Z_i completes the proof. □

Let $\mathcal{H}_i$ be any plane perpendicular to $\mathbf{v}_i$ which intersects the interior of Q_i. That

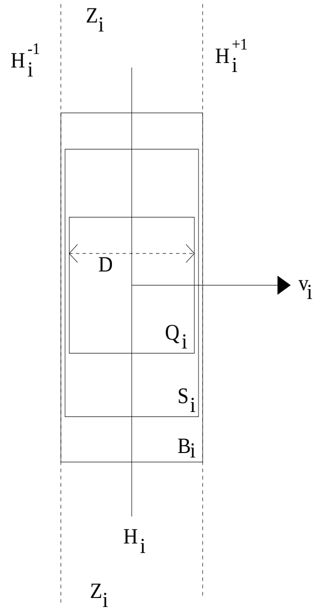

FIG. 5.2. *The objects used in Lemmas* 5.1–5.4. *Note that the left and right sides of* Q_i, S_i, B_i, *and* Z_i *are all in the planes* H_i^{-1}, H_i^{+1}, *respectively; they have been drawn as distinct for illustrative purposes only.*

is, $\mathcal{H}_i$ lies strictly between H_i^{-1} and H_i^{+1}.

LEMMA 5.3. *Every trajectory intersecting* Q_i *intersects* $\mathcal{H}_i$ *at precisely one point while it crosses* Z_i.

Proof. Let $\mathbf{y}(t)$ be a trajectory that intersects Q_i. By Lemma 5.2, $\mathbf{y}(t)$ remains in $S_i \subseteq B_i$ while it crosses Z_i. Let $z(t) = \mathbf{y}(t) \cdot \mathbf{v}_i$. Let the z coordinates of $H_i^{-1}, \mathcal{H}_i, H_i^{+1}$ be z_{-1}, z_0, z_{+1}, respectively. While the trajectory remains in $S_i \subseteq B_i$, $z'(t) \geq v_0 > 0$, and, since $z(t)$ is continuous, it increases monotonically while $\mathbf{y}(t)$ remains in S_i, taking on each value between z_{-1} and z_{+1} precisely once, by the intermediate value theorem. In particular, it takes on the value z_0 precisely once and thus crosses $\mathcal{H}_i$ precisely once. □

Assume that Q_i is an enclosure of $\varphi_{h_{i-1}}(M_{i-1})$. For a point $\mathbf{x} \in M_{i-1}$, let $\varphi_{i-1}(\mathbf{x})$ be the unique point in $\mathcal{H}_i$ defined by Lemma 5.3. Let $\bar{M}_i = S_i \cap \mathcal{H}_i$. Clearly, $\bar{M}_i$ is an enclosure of $\varphi_{i-1}(M_{i-1})$. To show that φ_{i-1} applied to M_{i-1} is a homeomorphism, we need to show that it is continuous and one-to-one. We first prove it is one-to-one.

Let $\varepsilon^t > 0$ be given. Recall $\bar{\varepsilon}_i^t$ as defined in Lemma 5.1.

Assumption 1. Assume $\bar{\varepsilon}_i^t < \varepsilon^t$ and $\nexists$ distinct $\mathbf{x}, \mathbf{y} \in M_{i-1}$ such that $\mathbf{y} = \varphi_t(\mathbf{x})$ for $|t| < \varepsilon^t$.

Each of the assumptions introduced in this section is assumed to hold throughout the remainder of section, once it is introduced.

LEMMA 5.4. *Each point in* $\varphi_{i-1}(M_{i-1})$ *comes from only one point in* M_{i-1}.

Proof. Assume to the contrary that there exist distinct $\mathbf{x}, \mathbf{y} \in M_{i-1}$ such that $\varphi_{i-1}(\mathbf{x}) = \varphi_{i-1}(\mathbf{y}) = \mathbf{z} \in \bar{M}_i$. Since $\varphi_{h_{i-1}}(\mathbf{x}), \varphi_{h_{i-1}}(\mathbf{y})$ both splash to $\mathbf{z}$, they are on the same trajectory, and since they are both in Q_i, the time-shift between them is $\leq \bar{\varepsilon}_i^t$. Thus, $\exists t_1, t_2$ such that $\varphi_{t_1}(\mathbf{x}) = \mathbf{z} = \varphi_{t_2}(\mathbf{y})$ with $|t_1 - t_2| \leq \bar{\varepsilon}_i^t$. Then $\mathbf{y} = \varphi_{t_1 - t_2}(\mathbf{x})$, contradicting Assumption 1. □

THEOREM 5.5. *φ_{i-1} applied to M_{i-1} is one-to-one.*

Proof. Lemma 5.3 proves that $\varphi_{i-1}(M_{i-1})$ is many-to-one, and Lemma 5.4 proves it is one-to-many. Thus, it is one-to-one. □

We now prove that $\varphi_{i-1}(\mathbf{x})$ is continuous for all $\mathbf{x} \in M_{i-1}$.

Assumption 2. $\varphi_t(\mathbf{x})$ exists and is continuous in both t and $\mathbf{x}$ $\forall \mathbf{x} \in M_{i-1}$ and $\forall t$ such that $\varphi_t(\mathbf{x}) \in B_i$. Note that this is true as long as $\mathbf{f}$ is Lipschitz continuous (Stuart and Humphries (1996, Theorem 2.1.12)).

We will need the following theorem.

THEOREM 5.6. *If $\mathbf{y}$ and $\mathbf{z}$ each satisfy the differential equation $\mathbf{y}'(t) = \mathbf{f}(\mathbf{y}(t))$ on the interval $[t_0, t_1]$, and if $\mathbf{f}$ is Lipschitz continuous with constant L, then $\forall t \in [t_0, t_1]$,*

$$\|\mathbf{y}(t) - \mathbf{z}(t)\| \leq \|\mathbf{y}(t_0) - \mathbf{z}(t_0)\| e^{L(t-t_0)}.$$

Proof. See Theorem 112J of Butcher (1987). □

For a point $\mathbf{x} \in M_{i-1}$, let $h_{i-1}(\mathbf{x})$ be that unique timestep defined by $\varphi_{h_{i-1}(\mathbf{x})}(\mathbf{x}) \in \mathcal{H}_i$. That is, $\varphi_{i-1}(\mathbf{x})$ specifies *where* $\mathbf{x}$ goes, and $h_{i-1}(\mathbf{x})$ specifies *how long* it takes to get there.

LEMMA 5.7. *If $\mathbf{f}$ is Lipschitz continuous, then $\forall \mathbf{x}_0 \in M_{i-1}$, $h_{i-1}(\mathbf{x})$ is continuous at $\mathbf{x} = \mathbf{x}_0$.*

Proof. For simplicity, we will drop the subscript from $h_{i-1}(\mathbf{x})$ during this proof.

Let L be the Lipschitz constant for $\mathbf{f}$. Then by Theorem 5.6, for any $\mathbf{x}_0, \mathbf{x}$,

$$\|\varphi_{h(\mathbf{x}_0)}(\mathbf{x}) - \varphi_{h(\mathbf{x}_0)}(\mathbf{x}_0)\| \leq \|\mathbf{x} - \mathbf{x}_0\| e^{Lh(\mathbf{x}_0)} \equiv \delta_3(\mathbf{x}, \mathbf{x}_0).$$

Since we are interested only in the behavior of $h(\mathbf{x})$ in a neighborhood of $\mathbf{x}_0$, choose $\mathbf{x} \in M_{i-1}$ close enough to $\mathbf{x}_0$ so that $\varphi_{h(\mathbf{x}_0)}(\mathbf{x}) \in B_i$. Now, since $\varphi_{h(\mathbf{x}_0)}(\mathbf{x}_0) \in \mathcal{H}_i$, the distance from $\varphi_{h(\mathbf{x}_0)}(\mathbf{x})$ to $\mathcal{H}_i$ is also bounded above by $\delta_3(\mathbf{x}, \mathbf{x}_0)$. Since $\varphi_{h(\mathbf{x}_0)}(\mathbf{x}) \in B_i$, the maximum time to intersect $\mathcal{H}_i$ is $\delta_3(\mathbf{x}, \mathbf{x}_0)/v_0$. Thus, $h(\mathbf{x}) \in [h(\mathbf{x}_0) - \delta_3(\mathbf{x}, \mathbf{x}_0)/v_0, h(\mathbf{x}_0) + \delta_3(\mathbf{x}, \mathbf{x}_0)/v_0]$. The continuity of $h(\mathbf{x})$ at $\mathbf{x}_0$ follows by letting $\mathbf{x} \to \mathbf{x}_0$. □

LEMMA 5.8. *$\varphi_{i-1}(\mathbf{x})$ is continuous $\forall \mathbf{x} \in M_{i-1}$.*

Proof. By definition, $\varphi_{i-1}(\mathbf{x}) = \varphi_{h_{i-1}(\mathbf{x})}(\mathbf{x})$, and by construction, $\varphi_{h_{i-1}(\mathbf{x})}(\mathbf{x}) \in S_i \subseteq B_i$. Since the composition of two continuous functions is continuous and Lemma 5.7 asserts that $h_{i-1}(\mathbf{x})$ is continuous, Assumption 2 directly implies that $\varphi_{i-1}(\mathbf{x})$ is continuous. □

Thus, $\varphi_{i-1}(\mathbf{x}) \equiv \varphi_{h_{i-1}(\mathbf{x})}(\mathbf{x})$ is the unique splash point of $\mathbf{x}$ in $\mathcal{H}_i$.

Finally, the second part of Assumption 1 cannot be taken for granted. The following lemma is applied at step i to give us the second part of Assumption 1 at step $i+1$.

Let W_i be an infinite slab with width $E > D$ in the $\mathbf{v}_i$ direction, parallel to Z_i such that $Z_i \subset W_i$. Let C_i be a parallelepiped with sides parallel to Q_i, also with a width of E in the $\mathbf{v}_i$ direction, satisfying $M_i \subset C_i \subset W_i$, where M_i is built inside $\mathcal{H}_i$ to satisfy the ICP with M_{i-1} under φ_{i-1}. Let $E_{+1} > 0$ be the distance from $\mathcal{H}_i$ in the $\mathbf{v}_i$ direction to the face of W_i, and let $E_{-1} > 0$ be the distance to the opposite face of W_i. Note that $E_{-1} + E_{+1} = E$. Let $\{\mathbf{f}(\mathbf{x}) \cdot \mathbf{v}_i \mid \mathbf{x} \in C_i\} \subset [u_0, u_1]$, and assume $0 < u_0 \leq u_1$. Let $\bar{\mathbf{f}}(C_i)$ be an enclosure of $\{\mathbf{f}(\mathbf{x}) \mid \mathbf{x} \in C_i\}$. Let T_i be a parallelepiped enclosure of $\{W_i \cap (M_i + h\bar{\mathbf{f}}(C_i)) \mid h \in [-\varepsilon^t, \varepsilon^t]\}$, and assume $T_i \subseteq C_i$.

Assumption 3. Assume $E/u_1 > \varepsilon^t$. That is, the minimum crossing time of C_i is greater than ε^t.

LEMMA 5.9. *$\nexists$ distinct $\mathbf{x}, \mathbf{y} \in M_i$ such that $\mathbf{y} = \varphi_t(\mathbf{x})$ for $|t| < \varepsilon^t$.*

Proof. Substituting M_i for Q_i, W_i for Z_i, T_i for S_i, and C_i for B_i in Lemmas 5.1–5.3, we see that

(1) If a trajectory remains in C_i while it is in W_i, then it remains in W_i for at least time E/u_1 and at most E/u_0. By a similar argument, the minimum and maximum times between such a trajectory's entering C_i and intersecting $\mathcal{H}_i$ are E_{-1}/u_1 and E_{-1}/u_0, respectively, and the corresponding times between such a trajectory's intersecting $\mathcal{H}_i$ and exiting C_i are E_{+1}/u_1 and E_{+1}/u_0.

(2) Any trajectory intersecting M_i remains in T_i while it is in W_i, and thus it remains in C_i.

(3) Every trajectory intersecting M_i intersects $\mathcal{H}_i$ at precisely one point while it remains in W_i, where $\mathcal{H}_i \subset W_i$ and $\mathcal{H}_i$ is parallel to the planes enclosing W_i.

Thus, by point (3), to intersect $\mathcal{H}_i$ more than once inside M_i, a trajectory must, at least, first traverse the distance from $\mathcal{H}_i$ to ∂C_i, exit and then reenter C_i, and traverse the distance from ∂C_i back to $\mathcal{H}_i$. By point (1), it takes time at least $E_{-1}/u_1 + E_{+1}/u_1 = E/u_1$ to do so. By Assumption 3, $E/u_1 > \varepsilon^t$. Thus, no trajectory can intersect M_i, exit T_i, and then reenter T_i to again intersect M_i in time less than ε^t. □

Remark 5.2. The base case of the induction is produced by substituting M_0 for M_i in Lemma 5.9, after building suitable W_0, C_0, and T_0.

5.3. Algorithmic details. Algorithmic verification of the requirements for the above theorems and lemmas is fairly straightforward: Q_i is simply the enclosure of $\varphi_{h_{i-1}}(M_{i-1})$ given to us by VNODE; the size of B_i is computed heuristically in an effort to ensure that $S_i \subseteq B_i$, and if our first guess is incorrect, we simply increase its size until $S_i \subseteq B_i$, or fail if increasing the size of B_i results in $0 \in \{\mathbf{f}(\mathbf{x}) \cdot \mathbf{v}_i \mid \mathbf{x} \in B_i\}$; ε^t, which is an upper bound on the time error introduced at each step by the rescaling of time, must currently be prechosen by trial and error, although we believe that good, simple heuristics for choosing it probably exist. The sole complication is in maintaining the property that Q_i has a pair of faces approximately normal to $\mathbf{y}'$ inside Q_i. Note that VNODE maintains a rotation matrix A_i, which represents the orientation of the parallelepiped Q_i. Let the columns of A_i be $\mathbf{a}_i^j, j = 1, \ldots, n$. We simply assign $\mathbf{a}_i^1$ to be parallel to our best estimate of $\mathbf{y}'(t_i)$. VNODE then ensures that $\mathbf{a}_{i+1}^1$ evolves via the variational equation to be approximately parallel to $\mathbf{y}'(t_{i+1})$. To account for the slow buildup of error that would allow $\mathbf{a}_i^1$ to drift away from $\mathbf{y}'(t_i)$, we reset $\mathbf{a}_i^1$ to be parallel to the computed $\mathbf{y}'(t_i)$ at each timestep. This corresponds to rotating Q_i about its center by a small angle θ, computed by solving

$$\cos(\theta) = \frac{\mathbf{a}_i^1 \cdot \mathbf{y}'(t_i)}{\|\mathbf{a}_i^1\| \, \|\mathbf{y}'(t_i)\|},$$

where $\mathbf{a}_i^1$ is the vector computed via evolution of the ODE from the previous timestep, and $\mathbf{y}'(t_i)$ is the value of $\mathbf{y}'$ computed directly from the right-hand side of the ODE at the current timestep. The largest distance a point in Q_i will move as a result of this rotation is $r\theta$, where r is the distance of the furthest corner in Q_i from its center. Thus, after rotating Q_i by θ, we increase its size by $r\theta$ in all directions, thus ensuring that it still encloses $\varphi_{h_{i-1}}(M_{i-1})$.

A simple variable stepsize algorithm was used: whenever containment of a particular step succeeds, we increase the stepsize by a small factor; whenever it fails, we decrease the stepsize by a factor of 2. We do not explicitly fail due to small stepsize, because too small a stepsize results in failures in other parts of the method, for example, as depicted in Figure 4.4.

6. Results and discussion. In this section, we present results of our containment method for ODEs, compare our results to those of others, discuss some of the

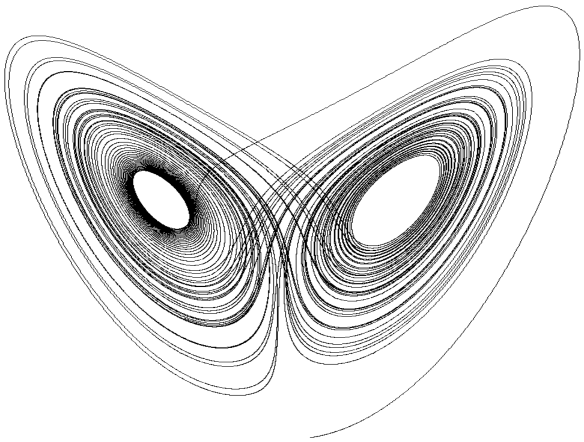

FIG. 6.1. *The "Lorenz butterfly."*

interesting implementation details of our method, and comment on observations of the behavior of our method, including how it sometimes fails.

6.1. Quantitative comparisons with other methods.

6.1.1. The Lorenz system of equations. The Lorenz equations (Lorenz (1963)),

$$\begin{pmatrix} x' \\ y' \\ z' \end{pmatrix} = \begin{pmatrix} \sigma(y-x) \\ \rho x - y - xz \\ xy - \beta z \end{pmatrix}, \tag{6.1}$$

define a dissipative dynamical system (i.e., energy is not conserved), which was originally constructed to be a very simplified weather model. It can be shown (Coomes, Koçak, and Palmer (1995a)) that, under the Lorenz equations, the set

$$U = \{(x,y,z) : \rho x^2 + \sigma y^2 + \sigma(z-2\rho)^2 \le \sigma\rho^2\beta^2/(\beta-1)\}$$

is *forward invariant:* any solution that is in U at time t_0 remains in U for all time $t \ge t_0$. All the methods discussed in this section solve the Lorenz equations with the classical parameter values $\sigma = 10, \rho = 28, \beta = 8/3$ (Lorenz (1963)). It is easy to show that, for these parameter values, the cube $[0,15]^3$ lies in U, and so for our experiments we chose initial conditions randomly inside this cube. A set of initial conditions in this cube will invariably produce a solution whose three-dimensional shape has been dubbed the "Lorenz butterfly" (Figure 6.1). Schematically, the Lorenz butterfly consists of two two-dimensional disks in three-space with a "bridge" between them. The two disks together are termed a "chaotic attractor," because solutions tend to remain in the disks but jump chaotically from one to the other and back again. Solutions lack pseudohyperbolicity in the direction of the flow (Van Vleck (1995); Coomes, Koçak, and Palmer (1994b), (1995a)), and so a rescaling of time is required to shadow them effectively. As should be clear from Figure 6.1 and the above description, in addition to the $\mathbf{y}'$ direction, at any given point a solution has one contracting direction, which is perpendicular to the disk currently housing the solution, and one expanding direction, directed radially from the center of the disk. Provided a rescaling of time is employed, solutions to the Lorenz equations display

Table 6.1

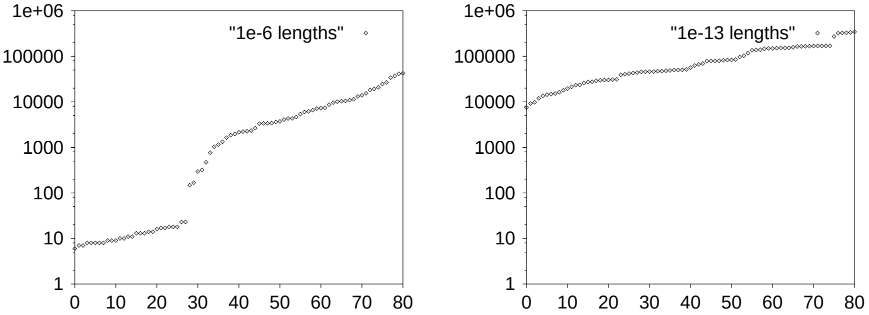

Fig. 6.2. *Distribution of shadow lengths computed by containment with a rescaling of time. Each panel shows a sorted list of shadow lengths for* 80 *simulations of the Lorenz equations. The horizontal axis is simply a label for each shadow; the vertical axis is its length. The magnitude of the noise (i.e., the local error) in the noisy orbits is about* 10^{-6} *in the left graph and* 10^{-13} *in the right.*

remarkable pseudohyperbolicity for extremely long periods of time. Thus, this system is a prime first candidate for testing shadowing methods.

We will compare our results to the only other published results on shadowing the Lorenz equations using a rescaling of time: Van Vleck (1995), whose results could be made rigorous but currently are not; and Coomes, Koçak, and Palmer (1994b), (1995a), whose results are completely rigorous.

First, with *no* rescaling of time (the "map method"), Van Vleck gives two examples of shadows with a local error[6] of about 10^{-5} lasting 1.04 and 1.38 time units; Coomes, Koçak, and Palmer have six examples with local error of about 10^{-13} lasting 9.7, 9.8, 9.9, 9.9, 86, and 126 time units. For this paper, we have simulated hundreds of shadows with various local errors. We have found that with local errors of about 10^{-5}, containment finds shadows that last between 1 and 30 time units, with a median and mean of about 20. With local errors of 10^{-13}, we find shadows lasting between 10 and 1000 time units, again with a mean and median about halfway through that range. Thus, it appears that, without a rescaling of time, the containment method is capable of finding shadows that are about an order of magnitude longer than other existing methods.

With a rescaling of time, Van Vleck gives many examples of shadows (with a local error of about 10^{-6}) ranging from 10^2 to 10^4 time units. Coomes, Koçak, and Palmer (with a local error of 10^{-13}) give six examples of shadows lasting at least 10^5 time units; they do not attempt to find longer shadows, so in fact their method

[6] The local errors used in the current paper were normalized to have comparable size per-unit-step to other methods, even though variable stepsize methods were used both for the validated ODE integration (Nedialkov (1999)) and for choosing the size of shadow steps.

may be capable of finding shadows longer than 10^5. The corresponding numbers for containment are 10^2 to 10^5 for local errors of 10^{-6}, and 10^2 to almost 10^6 for local errors of 10^{-13}. The results are summarized in Table 6.1.[7] It is clear that containment is at least as powerful as the other existing methods. It is worth noting that our results for local errors of 10^{-13} were produced using only a 17th-order Taylor series, whereas Coomes, Koçak, and Palmer used a Taylor series of 31st order.

Figure 6.2 shows two sets of results of shadow lengths, including the rescaling of time. The first is for eighty solutions with local error of approximately 10^{-6}, and the second for eighty solutions with local error of approximately 10^{-13}. The sharp increase in shadow lengths occurring just left of center in the first figure is probably due to the fact that, other than choosing $\mathbf{v}_0$ (cf. Figure 5.2 on page 1963) to be parallel to $\mathbf{y}'(t_0)$, the directions of the faces of M_0 are currently chosen at random. As a result, we sometimes choose nominally expanding and contracting directions that are not sufficiently close to the actual expanding and contracting directions. Thus, many shadows fail early due to this problem. However, if our nominally chosen directions are (by luck) close enough to the actual ones, then we get over this hump to find much longer shadows. There is probably a more clever way to choose the initial M_0, but we have not yet studied this problem closely. This problem becomes less pronounced as the local error decreases and is virtually absent in the right figure, which has local error $\delta = 10^{-13}$.

In addition, our shadowing distances (i.e., the maximum distance between the shadow and the numerical trajectory) are comparable to the methods of the above authors: for orbits with noise 10^{-6} and 10^{-13}, our method and those of Van Vleck and Coomes, Koçak, and Palmer find shadowing distances of approximately 10^{-5} and 10^{-9}, respectively. For containment, these sizes are based on ε^t and the maximum size of M_i over all i, which are at least in part user-controlled. For Van Vleck and Coomes, Koçak, and Palmer the shadowing distances are computed analytically based upon global bounds of various computed quantities.

6.1.2. Other systems of equations. We have reproduced the shadowing experiments of several other authors, usually getting comparable results, as illustrated in Table 6.2. We discussed results for the Lorenz system in the previous section. In this section, we provide results for three other problems.

Forced damped pendulum. We first compare our results for the forced damped pendulum problem,

$$y'' + ay' + \sin y = b \cos t,$$

to those of GHYS, Sauer and Yorke (1991), and Chow and Van Vleck (1994). These authors use the values $a = 0.2, b = 2.4$ and $a = 1, b = 2.4$, with initial conditions $(y, y') = (0, 0)$, and mention that they get similar results with other pairs of values of a, b and initial conditions. We used the above two pairs of values for a, b and various random initial conditions in the unit square $[0, 1]^2$. We convert the second-order equation to two first-order equations by assigning $y_1 = y,\ y_2 = y'$, giving

$$y_1' = y_2,$$

[7] Our attempts to find the longest possible shadows for the latter case have been repeatedly confounded by having either workstation or disk crashes (independent of our code) while our simulations were running. The longest shadow we have observed is thus 7.7×10^5, even though, had our machines not crashed, the shadows might have been longer.

Table 6.2

Comparison of shadow lengths for four systems. For our results, the lengths shown are typical results after attempting many trials with the given local and global errors; the results of others are taken from their respective publications. Legend: δ = local error; ε = global space error; ε_t = global time error (if none is listed for our method, then we did not rescale time); L = shadow length; CKP = Coomes, Koçak, and Palmer (1994b), (1995a)*; SY = Sauer and Yorke* (1991)*; CVV = Chow and Van Vleck* (1994a)*; VV = Van Vleck* (1995)*; NR = not rigorous.*

$$y_2' = b\cos t - \sin y_1 - ay_2.$$

GHYS and Sauer and Yorke (1991) use extended precision arithmetic with a machine epsilon of 10^{-29} to generate a trajectory with local truncation error rigorously bounded by 10^{-18} per step, which allows them to find a shadow of length 3×10^4 and rigorous maximum distance 10^{-9} from their noisy trajectory. In comparison, we use standard IEEE754 floating-point numbers and arithmetic and obtain a local truncation error of about 10^{-15} at best, so our shadow distances are significantly less stringent at 10^{-6}, and tend to be shorter, although in a few instances we successfully found shadows of length $\sim 3\times10^4$. Given that Sauer and Yorke used higher precision, we are not surprised that our shadows tend to be shorter and not as close as theirs. Comparing our results to Chow and Van Vleck (1994), we see our method is capable of rigorously proving the existence of a shadow which is closer, but lasts for a shorter time, than their method does; on the other hand, our result is rigorous, whereas theirs is not, because they do not rigorously bound numerical errors before applying their theorem.

The primary problem with shadowing this system appears to be that it is nonautonomous. We currently handle a nonautonomous system by converting it to an autonomous system with one component of our solution, y_0, representing time: $y_0(0) = t_0,\ \ y_0'(t) = 1$. This has several drawbacks: (1) the new component is decidedly nonhyperbolic; (2) assuming we can solve the linear system $y' = 1$ exactly, the interval representing y_0 then accumulates roundoff error, and as time progresses, the error in

y_0 grows; (3) this is exacerbated by the minimum absolute error in y_0 increasing as $\varepsilon_{mach}t$, where ε_{mach} is the machine precision; (4) finally, the error in the computation of $\cos(y_0)$ adds to the error. These drawbacks, however, do not seem to adequately explain our poor shadowing results for this system. Perhaps the difficulties would vanish if a native procedure for validated integration of nonautonomous systems were used, or if we used higher precision, as did Sauer and Yorke (1991).

Forced van der Pol. The forced van der Pol equation,

$$x'' + \alpha(x^2 - 1)x' + x = \beta\cos(\omega t),$$

is studied by Van Vleck (1995). He defines the parameters implicitly with $\alpha = k = \sigma = 2/5$, where $k = \beta/(2\alpha)$ and $\sigma = (1 - \omega^2)/\alpha$, and uses the initial conditions $(x, x') = (0, 0)$. We try this initial condition, as well as others chosen randomly in the unit square $[0, 1]^2$, and we convert the second-order equation to two first-order equations by assigning $y_1 = x,\ y_2 = x'$, giving

$$y_1' = y_2,$$

$$y_2' = \beta\cos(\omega t) - (y_1^2 - 1)\alpha y_2 - y_1.$$

This equation has a hyperbolic periodic attractor, which all solutions approach asymptotically, and so this system is easy to shadow. With a local truncation error of 10^{-6}, Van Vleck found numerical shadows of length 10^4 and distance 10^{-4}, while we went significantly further, finding rigorous shadows lasting 10^5 and longer with a distance of 10^{-6}. Since solutions asymptotically approach a periodic solution that is hyperbolic, we conjecture that containment could be maintained indefinitely.

Logistic equation. Finally, the logistic equation,

$$y' = y(1 - y), \quad y(0) = \zeta,\ 0 < \zeta \ll 1,$$

was studied by Chow and Van Vleck (1994). In this problem, there is an unstable fixed point at $y = 0$ and a stable fixed point at $y = 1$. Chow and Van Vleck attempt shadowing two solutions, both starting at $y(0) = \zeta$ and integrating until $y(T) \approx 1 - \zeta$. If $\zeta = 10^{-2}$, then $T \approx 9.22$, and if $\zeta = 10^{-4}$, then $T \approx 18.46$. In both cases, we use a local truncation error of $\delta = 10^{-7}$. We find that we easily match their results, noting again that ours are rigorous, while theirs are not. In fact, we find that we can prove the existence of these shadows for $\varepsilon \approx 10\delta$ for δ down to about 10^{-14}.

6.2. Qualitative comparisons with other methods. First and foremost, our method has only been proven to work in a limited number of special cases. Generalizing the (n, k)-ICP to arbitrary (n, k) is straightforward Hayes (2001). Proving that it implies the existence of a shadow is more difficult, and is in progress. See Hayes (2001) for more discussion.

Although containment is rigorous, it appears to be less robust than nonrigorous methods. For example, in two examples out of three, the nonrigorous results of Chow and Van Vleck (1994) produced shadows that were about an order of magnitude longer than we could produce using containment. In addition, Hayes (1995) presented convincing evidence that the gravitational n-body problem is shadowable, and yet containment could prove the existence of shadows lasting only 1% as long as those found nonrigorously in Hayes (1995). Even worse, the VNODE package (Nedialkov (1999)) is capable of providing a validated enclosure of an IVP for the n-body problem which is about ten times as long as the containment-produced shadow! Clearly, if an enclosure of an IVP exists, then a shadow exists for the associated point solution for at least as long. Thus, at least for some problems, our implementation of containment is incapable of finding shadows even though they exist. This does not necessarily imply that the theorems proved in section 2.2 are deficient; it probably means that our implementation for verifying that the ICP holds can be improved, for example by reducing the excess of the validated numerical integrator.

Our method requires some a priori guesses; for example, the maximum and minimum sizes of the M_i, and the maximum time rescaling ε^t, need to be chosen before the algorithm runs. We typically had to choose these numbers by trial and error for each problem; if a certain ε^t did not work, for example, we often found that increasing it or decreasing the maximum size of M_i would allow us to find longer or closer shadows, respectively. Van Vleck's (1995) method also requires some a priori guesswork to make a rescaling of time work. Although Coomes, Koçak, and Palmer do not discuss their choice of parameters, it is likely that they require significant guesswork to find parameters that satisfy their theorems as well. Finally, *all* shadowing methods currently in the literature appear to require guesswork to discover the number of expanding and contracting dimensions and to choose a local error δ which is stringent enough to satisfy their respective theorems.

It is also not trivial to see how containment could be parallelized, since each M_i depends on M_{i-1}. Possibly an iterative method that guesses all the $\{M_i\}_{i=0}^N$ and then iteratively refines them in parallel could be constructed; this may also be related to two-point boundary value problems (Ascher, Mattheij, and Russell (1988)).

On the other hand, containment appears to have several advantages over other methods.

- We use an off-the-shelf validated integrator (Nedialkov (1999)) to verify that ICP holds; this integrator is almost as easy to use as any standard integrator, and thus getting the code "up and running" on a new problem usually takes only a few minutes. Another advantage of this simplicity is that it requires the user to have no deeper understanding of the system than knowing the defining equations.[8]
- Although the success of containment may depend, of course, upon global properties of the system, the method itself is local. By that we mean that it requires information only from the previous step to extend the length of the shadow. Several other methods require computing, storing, and updating global information such as the extent of nonhyperbolicity (cf. Chow and Palmer's p parameter 1991, 1992).

7. Conclusions.

We have extended the simple and elegant *containment* method of producing shadows from two-dimensional maps to maps of arbitrary dimension in which some measure of hyperbolicity is present and there is either 0 or 1 expanding modes, or 0 or 1 contracting modes, and added a rescaling of time to allow containment to work better for ODEs. We have demonstrated that this new method produces shadows of ODE integrations that are of comparable quality and length to any currently in the literature, and noted how it can be used to prove the existence of chaos.

[8] Some may consider this a disadvantage.

LEAST SQUARES METHODS FOR THE COUPLING OF FEM AND BEM*

GABRIEL N. GATICA[†], HELMUT HARBRECHT[‡], AND REINHOLD SCHNEIDER[‡]

Abstract. In the present paper we propose least squares formulations for the numerical solution of exterior boundary value problems. The partial differential equation is a first order system in a bounded subdomain, and the unbounded subdomain is treated by means of boundary integral equations. The first order system is derived from a strongly elliptic second order system. The analysis of the present least squares formulations is reduced to the analysis of the Galerkin method for the coupling of finite element and boundary element methods (FEM and BEM) of the second order problem. The least squares approach requires no stability condition. However, it requires the computation of negative as well as of half integer Sobolev norms. The arising linear systems can be preconditioned to have condition numbers ~ 1. The present methods benefit strongly from the use of biorthogonal wavelets on the coupling boundary and the computation of corresponding equivalent norms in Sobolev spaces. In particular, the application of Green's formula leads to an efficient discretization of least squares formulations.

1. Introduction.

The combined use of the finite element method (FEM) and the boundary element method (BEM), also called coupling of FEM and BEM, is already known as a very powerful tool to solve a large class of transmission problems in physics and engineering sciences (see, e.g., [13], [22], [27], [31], [33], [37], and the references therein). In addition, the interest in using mixed FEMs instead of the usual FEM has been increasing during the last few years. Indeed, the combination of mixed finite elements with either boundary integral equations or Dirichlet-to-Neumann mappings has been recently used to solve several interior and exterior boundary value problems appearing in potential theory and elasticity (see, e.g., [2], [8], [20], [23], [25], and [34]).

The reasons for this new interest arise mainly from structural mechanics, where the use of mixed FEMs allows us to compute stresses more accurately than displacements, whereas the utilization of boundary elements or Dirichlet-to-Neumann mappings is more appropriate for linear homogeneous materials in bounded and unbounded domains. In the framework of dual-mixed methods, the recent papers [8] and [34], dealing with an exterior problem from potential theory and the linear elasticity problem, respectively, are the first ones on the subject that consider the $H(\mathrm{div};\Omega)$ spaces in the finite element domain, and the two boundary integral equations approach from [13] and [27] in the boundary element region. Now, the method from [8] and [34]

was extended in [20], [25], and [2], where a suitable combination of dual-mixed FEM with either BEM or Dirichlet-to-Neumann mappings was applied to some nonlinear transmission problems. However, this extension has not been completely successful since the derivation of explicit finite element subspaces satisfying the corresponding discrete inf-sup conditions is still an open problem. As a first attempt to overcome this difficulty, we examined in [3] the use of a primal-mixed FEM. More recently, we obtained quite satisfactory results, at both the continuous and discrete levels, by applying what we called a dual-dual mixed variational formulation (see [4], [21], and [24]). This latter approach requires an extension of the usual Babuska–Brezzi theory to a special class of nonlinear variational problems with constraints, which was derived with full details in [19].

On the other hand, a possibility that has not been fully investigated yet is the utilization of least squares methods. As is well known, this approach avoids the necessity of inf-sup conditions, and hence it becomes attractive to use it jointly with mixed finite element formulations. One of the main methods, introduced in [1], uses the general theory of elliptic boundary value problems of Agmon–Douglis–Nirenberg and reduces the system to the minimization of a least squares functional that consists of a weighted sum of the residuals occurring in the equations and the boundary conditions. This is a generalization of both the method of Jespersen [32] and the method of Wendland [39]. Another approach, mostly used for second order elliptic problems written as first order systems, introduces a least squares functional and studies the resulting minimization problem by proving that the hypotheses of the Lax–Milgram lemma are satisfied on appropriate spaces (see, e.g., [9] and [35]). More recently, a least squares functional involving a discrete inner product related to the inner product in the Sobolev space of order -1 was introduced in [5], and an approach more closely coupled to the Galerkin method was studied by the same authors in [6].

Following the approach of [5], [6], the design of the least squares method requires the use of some negative and half integer Sobolev norms, such as the norms of $H^{-1}(\Omega)$ and $H^{-1/2}(\Gamma)$, which seem to be difficult to compute in practice. However, due to recent results in multilevel preconditioning [7] and multiscale methods or wavelet approximations (see [14], [16], [36]), these norms are computable in suitable finite dimensional subspaces. Moreover, in the framework of multiscale methods or biorthogonal wavelets, these computations are fairly simple and can be carried out within optimal complexity. We would like to mention that these approaches give rise to positive definite system matrices that can be easily preconditioned. In particular, using multilevel methods, one can reduce the condition numbers to $\mathcal{O}(1)$.

In the present paper we will discuss various least squares formulations. Most of them follow obviously from the underlying equations. The first approach requires the flux to be in $H(\mathrm{div};\Omega)$ and minimizes the equilibrium equation in the $L^2(\Omega)$-norm (see [9]), whereas the other ones perform the minimization in the $H^{-1}(\Omega)$-norm. Although this and similar approaches lead to some difficulties when developing a functional analytical setting, it turns out from our investigations that one can avoid these problems completely by using the functional $\mathbf{J}_3$ (see section 3 below). This functional is based on partial integration, i.e., Green's formula, and requires no restrictions concerning $H(\mathrm{div};\Omega)$ spaces. In fact, it is easy to implement and needs no further attention, compared to the other schemes, when computing discrete Sobolev norms. The approach of [15] provides an abstract setting considering an invertible operator $\mathcal{L} = (\mathcal{L}_{i,j}) : \prod_i H_i \to \prod_i H_i'$ mapping the product of Sobolev spaces $\prod_i H_i$ into its dual $\prod_i H_i'$. We would like to emphasize that $\mathbf{J}_3$ is the only functional that can be cast into this abstract framework.

For the computation of the discrete Sobolev norms in the bounded subdomain Ω, there are mainly two possibilities, the use of wavelet bases (see [15], [17]) or, alternatively, the utilization of suitable preconditioners (see [5], [6]), which are applicable to standard multigrid finite element discretizations. For the computation of the Sobolev norms along the boundary, we recommend wavelet bases. Obviously, the stability of least squares methods is guaranteed under weak assumptions, e.g., invertibility of the operators. However, it is worth mentioning that the negative and half integer Sobolev norms can be computed only on finite dimensional test spaces. This requires an additional truncation or projection to get a computable discrete formulation. Therefore, stability is not automatically guaranteed by the continuous formulation but must be proven. Our present proofs are completely based on the theory for the Galerkin scheme of the second order problem. From these results, we conclude the stability of the present methods. Only in the case of the functional $\mathbf{J}_4$ (see section 3 below) do we have to enlarge the test spaces slightly. An important feature of the present approaches is that, for the least squares discretizations of the boundary integral operators, we need only the coefficients of the Galerkin matrices of the layer potentials and not of compositions of layer potentials (see section 7). Finally, it is worth mentioning that in the framework of multiscale methods these matrices are sparse and that there are already several techniques available to precondition them (see, e.g., [36], [38]).

Consequently, the purpose of the present work is to examine the use of least squares formulations for the coupling of mixed FEM and BEM, as applied to linear exterior boundary value problems. This must be considered as the first step toward the future extension to nonlinear exterior transmission problems. The rest of the paper is organized as follows. In section 2 we describe the exterior second order model problem and apply the boundary integral equation method to reduce it to an equivalent nonlocal boundary value problem in a bounded annular domain. Then, after setting the flux as a new unknown, the nonlocal problem is rewritten as a first order system, which yields the underlying equations for the discretization. Various continuous least squares formulations, induced by this first order system, are introduced in section 3. Although existence and uniqueness for the least squares minimization problems can be easily deduced from the mapping properties of the underlying operators, we provide explicit proofs by using coercivity estimates of the usual variational formulation for the coupling procedure, since the method of these proofs can be used for the validation of the corresponding results for the discrete least squares formulations in section 5. Next, in section 4 we define the finite dimensional subspaces. The discrete least squares formulations and the corresponding error analysis are studied in section 5. In section 6 we give a brief description of the equivalence of norms based on wavelet bases and indicate the utilization of these functions for the present least squares approach. In addition, we remark how to use the wavelet bases provided by [17] for the treatment of three dimensional problems. In the last section we consider a numerical example and demonstrate how to set up the discrete matrices related to the minimization of $\mathbf{J}_3$.

2. The exterior boundary value problem.

Let G be a bounded and simply connected domain in $\mathbb{R}^2$ with Lipschitz-continuous boundary ∂G, and let Γ_D and Γ_N be two disjoint subsets of ∂G such that $|\Gamma_D| \neq 0$ and $\partial G = \overline{\Gamma}_D \cup \overline{\Gamma}_N$. In addition, let Ω be the annular domain bounded by ∂G and a second Lipschitz-continuous curve Γ whose interior region contains G. We denote $\Omega_e := \mathbb{R}^2 - (\overline{G} \cup \overline{\Omega})$. Then, given $f \in L^2(\Omega)$ and a matrix valued function $\mathbf{a}(\cdot) := (a_{ij}(\cdot))_{2\times 2}$, we consider the following exterior boundary value problem: *Find* $u \in H^1_{loc}(\mathbb{R}^2 - \overline{G})$ *such that*

$$
\begin{gathered}
u \,=\, 0 \quad on \quad \Gamma_D \quad and \quad (\mathbf{a}\,\nabla u)\cdot\mathbf{n} \,=\, 0 \quad on \quad \Gamma_N\,,\\
-\operatorname{div}(\mathbf{a}\,\nabla u) \,=\, f \quad in \quad \Omega\,,\\
\lim_{\substack{x\to x_0\\ x\in\Omega}} u(x) = \lim_{\substack{x\to x_0\\ x\in\Omega_e}} u(x) \quad \forall\, x_0\in\Gamma\,,\\
\lim_{\substack{x\to x_0\\ x\in\Omega}} \mathbf{a}(x)\nabla u(x)\cdot\mathbf{n}(x_0) \,=\, \lim_{\substack{x\to x_0\\ x\in\Omega_e}} \nabla u(x)\cdot\mathbf{n}(x_0) \quad \forall\, x_0\in\Gamma\,,\\
-\,\Delta\, u \,=\, 0 \quad in \quad \Omega_e \quad , \quad u(x) \,=\, O(1) \quad as \quad \|x\|\to+\infty\,,
\end{gathered}
\tag{2.1}
$$

where $\mathbf{n}$ *(resp.,* $\mathbf{n}(x_0)$*) denotes the unit outward normal to* $\partial\Omega$ *(to* $x_0\in\partial\Omega$*).* Here, we assume that $a_{ij}\in L^\infty(\Omega)$ and that there exists $\alpha>0$ such that

$$
\alpha\,\|z\|^2 \,\le\, z^T\,\mathbf{a}(x)\,z \qquad \forall\, z\in\mathbb{R}^2 \quad \text{and for almost all } x\in\Omega\,. \tag{2.2}
$$

We observe that the fourth and fifth equations of (2.1) constitute the usual transmission conditions along the interface Γ.

In what follows, we use the boundary integral equation method in the region Ω_e and reduce the problem (2.1) to a nonlocal boundary value problem on the bounded domain Ω. To this end, we let

$$
E(x,y) \,:=\, -\frac{1}{2\pi}\,\log\,\|x-y\|
$$

be the fundamental solution of the Laplacian and recall that the Green representation formula in Ω_e becomes

$$
u(x) \,=\, \int_\Gamma \left\{ \frac{\partial}{\partial\mathbf{n}(y)}\,E(x,y)\,u(y) - E(x,y)\,\frac{\partial u}{\partial\mathbf{n}}(y)\right\} ds_y - \lambda \quad \forall\, x\in\Omega_e,
$$

where λ is an unknown constant.

Then, according to the well-known jump conditions of the layer potentials, and using the transmission conditions from (2.1), we obtain the integral equations

$$
\begin{aligned}
0 \;&=\; \left(\frac{1}{2}\mathbf{I}\,-\,\mathbf{K}\right)u + \mathbf{V}\sigma + \lambda \quad && \text{on } \Gamma\,,\\
\sigma \;&=\; -\,\mathbf{W}u \,+\, \left(\frac{1}{2}\mathbf{I} - \mathbf{K}'\right)\sigma && \text{on } \Gamma\,,
\end{aligned}
\tag{2.3}
$$

where we have introduced the new unknown $\sigma := (\mathbf{a}\,\nabla u)\cdot\mathbf{n}$ on Γ, and $\mathbf{V}$, $\mathbf{K}$, $\mathbf{K}'$, and $\mathbf{W}$ are the boundary integral operators of the simple, double, adjoint of the double, and hypersingular layer potentials, respectively.

Now, the condition at infinity of u implies that σ satisfies

$$
\int_\Gamma \sigma\,ds = \int_\Gamma (\mathbf{a}\,\nabla u)\cdot\mathbf{n}\,ds = 0\,,
$$

which means that $\sigma\in H_0^{-1/2}(\Gamma)$, where $H_0^{-1/2}(\Gamma) := \{\tau\in H^{-1/2}(\Gamma) : \langle\tau,1\rangle = 0\}$, and, hereafter, $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $H^{-1/2}(\Gamma)$ and $H^{1/2}(\Gamma)$ with respect to the $L^2(\Gamma)$-inner product.

In this way, the original exterior boundary value problem (2.1) reduces to the following nonlocal boundary value problem in Ω: *Find* $(u,\sigma,\lambda) \in H^1(\Omega)\times H_0^{-1/2}(\Gamma)\times \mathbb{R}$ *such that*

$$(2.4)\qquad \begin{aligned} u \,=\, 0 \quad \textit{on} \quad \Gamma_D \quad \textit{and} \quad (\mathbf{a}\,\nabla u)\cdot \mathbf{n} \,=\, 0 \quad \textit{on} \quad \Gamma_N\,,\\ -\operatorname{div}(\mathbf{a}\,\nabla u) \,=\, f \quad \textit{in} \quad \Omega\,,\\ \sigma \,=\, (\mathbf{a}\nabla u)\cdot \mathbf{n} \quad \textit{on} \quad \Gamma\,,\\ \sigma = -\,\mathbf{W}u \,+\, \left(\frac{1}{2}\mathbf{I} - \mathbf{K}'\right)\sigma \quad \textit{on} \quad \Gamma\,,\\ 0 = \left(\frac{1}{2}\mathbf{I} \,-\, \mathbf{K}\right)u + \mathbf{V}\sigma + \lambda \quad \textit{on} \quad \Gamma\,. \end{aligned}$$

We now introduce the flux $\boldsymbol{\theta} := \mathbf{a}\,\nabla u$. Since $\sigma \in H_0^{-1/2}(\Gamma)$ and $\boldsymbol{\theta}\cdot\mathbf{n} = \sigma$ on Γ, we note that the unknown $\boldsymbol{\theta}$ must belong to $H_0(\mathrm{div};\Omega)$, where

$$H_0(\mathrm{div};\Omega) := \left\{\,\boldsymbol{\zeta} \in H(\mathrm{div};\Omega):\quad \boldsymbol{\zeta}\cdot\mathbf{n} = 0 \quad \text{on} \quad \Gamma_N \quad \text{and} \quad \langle \boldsymbol{\zeta}\cdot\mathbf{n}, 1\rangle = 0\,\right\}.$$

As usual, $H(\mathrm{div};\Omega)$ is the space of functions $\boldsymbol{\zeta} \in [L^2(\Omega)]^2$ such that $\operatorname{div}\boldsymbol{\zeta} \in L^2(\Omega)$. Provided with the inner product

$$(\boldsymbol{\theta},\boldsymbol{\zeta})_{H(\mathrm{div};\Omega)} := (\boldsymbol{\theta},\boldsymbol{\zeta})_{[L^2(\Omega)]^2} \,+\, (\operatorname{div}\boldsymbol{\theta}, \operatorname{div}\boldsymbol{\zeta})_{L^2(\Omega)}\,,$$

$H(\mathrm{div};\Omega)$ is a Hilbert space. Here, $(\cdot,\cdot)_{[L^2(\Omega)]^2}$ and $(\cdot,\cdot)_{L^2(\Omega)}$ denote the inner products of the spaces indicated. Moreover, for all $\boldsymbol{\zeta} \in H(\mathrm{div};\Omega)$, $\boldsymbol{\zeta}\cdot\mathbf{n} \in H^{-1/2}(\Gamma)$ and there holds $\|\boldsymbol{\zeta}\cdot\mathbf{n}\|_{H^{-1/2}(\Gamma)} \le \|\boldsymbol{\zeta}\|_{H(\mathrm{div};\Omega)}$ (see [26] for the proof of these results).

Consequently, our problem (2.4) can be rewritten as the following equivalent first order system: *Find* $(\boldsymbol{\theta},u,\sigma,\lambda) \in H_0(\mathrm{div};\Omega)\times H^1(\Omega)\times H_0^{-1/2}(\Gamma)\times\mathbb{R}$ *such that*

$$(2.5)\qquad \begin{aligned} u \,=\, 0 \quad \textit{on} \quad \Gamma_D\,,\\ \boldsymbol{\theta} \,-\, \mathbf{a}\,\nabla\,u \,=\, 0 \quad \textit{and} \quad -\operatorname{div}\boldsymbol{\theta} \,=\, f \quad \textit{in} \quad \Omega\,,\\ \sigma \,=\, \boldsymbol{\theta}\cdot\mathbf{n} \quad \textit{on} \quad \Gamma\,,\\ \sigma = -\,\mathbf{W}u \,+\, \left(\frac{1}{2}\mathbf{I} - \mathbf{K}'\right)\sigma \quad \textit{on} \quad \Gamma\,,\\ 0 = \left(\frac{1}{2}\mathbf{I} \,-\, \mathbf{K}\right)u + \mathbf{V}\sigma + \lambda \quad \textit{on} \quad \Gamma\,. \end{aligned}$$

This system is the starting point for the least squares formulations that we propose below in section 3.

Before ending the present section, we recall that the boundary integral operators used above are formally defined by

$$(\mathbf{V}\tau)(x) := \int_\Gamma E(x,y)\,\tau(y)\,ds_y \quad \forall\,\tau \in H^{-1/2}(\Gamma)\,, \quad \forall\,x\in\Gamma\,,$$

$$(\mathbf{K}\mu)(x) := \int_\Gamma \frac{\partial}{\partial\mathbf{n}(y)}E(x,y)\,\mu(y)\,ds_y \quad \forall\,\mu \in H^{1/2}(\Gamma)\,, \quad \forall\,x\in\Gamma\,,$$

$$(\mathbf{K}'\tau)(x) := \int_\Gamma \frac{\partial}{\partial \mathbf{n}(x)} E(x,y)\,\tau(y)\,ds_y \quad \forall\,\tau \in H^{-1/2}(\Gamma)\,, \quad \forall\, x \in \Gamma\,,$$

$$(\mathbf{W}\mu)(x) := -\,\frac{\partial}{\partial \mathbf{n}(x)} \int_\Gamma \frac{\partial}{\partial \mathbf{n}(y)} E(x,y)\,\mu(y)\,ds_y \quad \forall\,\mu \in H^{1/2}(\Gamma)\,, \quad \forall\, x \in \Gamma\,.$$

Moreover, their main mapping properties are collected in the following lemma.

Lemma 2.1. *Let Γ be a Lipschitz boundary. The operators*

$$\mathbf{V} : H^{-1/2+s}(\Gamma) \longrightarrow H^{1/2+s}(\Gamma), \qquad \mathbf{K} : H^{1/2+s}(\Gamma) \longrightarrow H^{1/2+s}(\Gamma),$$

$$\mathbf{K}' : H^{-1/2+s}(\Gamma) \longrightarrow H^{-1/2+s}(\Gamma), \quad \mathbf{W} : H^{1/2+s}(\Gamma) \longrightarrow H^{-1/2+s}(\Gamma)$$

are continuous for all $s \in [-1/2,\, 1/2]$. Furthermore, there exist positive constants α_1, α_2 such that

$$\langle \tau, \mathbf{V}\tau \rangle \;\geq\; \alpha_1\, \|\tau\|^2_{H^{-1/2}(\Gamma)} \quad \forall\,\tau \in H_0^{-1/2}(\Gamma)$$

and

$$\langle \mathbf{W}\mu, \mu \rangle \;\geq\; \alpha_2\, \|\mu\|^2_{H^{1/2}(\Gamma)} \quad \forall\,\mu \in H_0^{1/2}(\Gamma)\,,$$

where

$$H_0^{1/2}(\Gamma) := \{\mu \in H^{1/2}(\Gamma) : \quad \langle 1, \mu \rangle = 0\}\,.$$

Proof. See [12]. □

3. The continuous least squares formulations. According to the system (2.5), and taking into account the least squares formulations already described in section 1, we consider here four different approaches.

First, we introduce the operator $\mathbf{P}_0 : H^{1/2}(\Gamma) \to H_0^{1/2}(\Gamma)$, where

$$\mathbf{P}_0\,\mu \;:=\; \mu \,-\, \frac{1}{|\Gamma|}\,\langle 1, \mu\rangle \quad \forall\,\mu \in H^{1/2}(\Gamma)\,. \tag{3.1}$$

Note that $\mathbf{P}_0\,\mu \equiv 0$ for all constant μ on Γ and that there exists $C > 0$, depending only on Γ, such that

$$\|\mathbf{P}_0\,\mu\|_{H^{1/2}(\Gamma)} \;\leq\; C\,\|\mu\|_{H^{1/2}(\Gamma)} \quad \forall\,\mu \in H^{1/2}(\Gamma)\,. \tag{3.2}$$

Then, we define the space

$$H^1_{\Gamma_D}(\Omega) := \{\, v \in H^1(\Omega) : \quad v = 0 \quad \text{on} \quad \Gamma_D\}$$

and consider the following minimization problem: *Find $(\boldsymbol{\theta}, u, \sigma) \in \mathbf{X}_1 := H_0(\mathrm{div};\Omega) \times H^1_{\Gamma_D}(\Omega) \times H_0^{-1/2}(\Gamma)$ such that*

$$\mathbf{J}_1(\boldsymbol{\theta}, u, \sigma) \;=\; \min_{(\boldsymbol{\zeta}, v, \tau) \in \mathbf{X}_1} \mathbf{J}_1(\boldsymbol{\zeta}, v, \tau)\,, \tag{3.3}$$

where $\mathbf{J}_1$ is the quadratic functional defined by

$$\begin{aligned} \mathbf{J}_1(\boldsymbol{\zeta}, v, \tau) \;:=\;& \|\mathbf{a}\nabla v - \boldsymbol{\zeta}\|^2_{[L^2(\Omega)]^2} \;+\; \|\mathrm{div}\,\boldsymbol{\zeta} + f\|^2_{L^2(\Omega)} \\ &+\; \left\|\mathbf{W}v + \boldsymbol{\zeta}\cdot\mathbf{n} - \left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}'\right)\tau\right\|^2_{H^{-1/2}(\Gamma)} \;+\; \left\|\mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}\tau\right]\right\|^2_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{3.4}$$

In what follows, let $H^{-1}(\Omega)$ denote the dual of $H^1_{\Gamma_D}(\Omega)$. Then, since the fourth equation from (2.5) must be understood at least in the distributional sense, it suffices to assume that the data f belongs to $H^{-1}(\Omega)$ and that the unknown $\boldsymbol{\theta}$ is sought in the space

$$H \;:=\; \left\{ \boldsymbol{\zeta} \in [L^2(\Omega)]^2 : \quad \boldsymbol{\zeta}\cdot\mathbf{n} = 0 \quad \text{on} \quad \Gamma_N \quad \text{and} \quad \boldsymbol{\zeta}\cdot\mathbf{n} \in H_0^{-1/2}(\Gamma) \right\},$$

which is endowed with the norm of $[L^2(\Omega)]^2$.

The above remark leads us to the following minimization problem: *Find* $(\boldsymbol{\theta}, u, \sigma) \in \mathbf{X}_2 := H \times H^1_{\Gamma_D}(\Omega) \times H_0^{-1/2}(\Gamma)$ *such that*

$$\mathbf{J}_2(\boldsymbol{\theta}, u, \sigma) \;=\; \min_{(\boldsymbol{\zeta}, v, \tau)\in\mathbf{X}_2} \mathbf{J}_2(\boldsymbol{\zeta}, v, \tau)\,, \tag{3.5}$$

where $\mathbf{J}_2$ *is the quadratic functional defined by*

$$\begin{aligned} \mathbf{J}_2(\boldsymbol{\zeta}, v, \tau) \;&:=\; \|\mathbf{a}\nabla v - \boldsymbol{\zeta}\|^2_{[L^2(\Omega)]^2} \;+\; \|\operatorname{div}\boldsymbol{\zeta} + f\|^2_{H^{-1}(\Omega)} \\ &+\; \left\|\mathbf{W}v + \boldsymbol{\zeta}\cdot\mathbf{n} - \left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}'\right)\tau\right\|^2_{H^{-1/2}(\Gamma)} \;+\; \left\|\mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}\tau\right]\right\|^2_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{3.6}$$

We remark that the only differences between (3.3)–(3.4) and (3.5)–(3.6) lie in the norm that measures the error arising from the equilibrium equation $(\operatorname{div}\boldsymbol{\zeta} + f) = 0$, and on the space in which the unknown $\boldsymbol{\theta}$ lives. In any case, it is easy to see that the minimum of both $\mathbf{J}_1$ and $\mathbf{J}_2$ is attained for any solution $(\boldsymbol{\theta}, u, \sigma)$ of problem (2.5). Also, it is important to mention that, instead of the first term in the definitions of $\mathbf{J}_1$ and $\mathbf{J}_2$, one may use the weighted norm $\|\mathbf{a}^{-1/2}\,(\mathbf{a}\nabla v - \boldsymbol{\zeta})\|^2_{[L^2(\Omega)]^2}$, which leads to a better conditioning of the corresponding discrete problems (see [15] for details).

The use of norms is motivated by the proper functional analytical setting $\mathcal{L} : \mathbf{X} \to \mathbf{X}'$. The paper [15] provides a general framework for least squares methods based on variational formulations. In contrast to Galerkin methods, the least square methods are stable if and only if $\mathcal{L}$ is normally solvable, i.e., if $\operatorname{Im}\mathcal{L} \subset \mathbf{X}'$ is a closed subset of $\mathbf{X}'$. However, the previous formulations do not fit exactly into the framework of [15]. Nevertheless, there is a slight modification of the functional $\mathbf{J}_2$ fitting into this setting which can be derived from the variational formulation of the second order problem. This realization facilitates the implementation; see section 7. Taking the equation $-\operatorname{div}\boldsymbol{\zeta} = f$ in its weak form, we can apply Green's theorem

$$\big((\operatorname{div} - \delta_\Gamma \otimes \;\cdot\mathbf{n})\boldsymbol{\zeta}, v\big)_{L^2(\Omega)} \;:=\; (\operatorname{div}\boldsymbol{\zeta}, v)_{L^2(\Omega)} \;-\; \langle\boldsymbol{\zeta}\cdot\mathbf{n}, v\rangle \;=\; -\,(\boldsymbol{\zeta}, \nabla v)_{[L^2(\Omega)]^2}$$

for all $v \in H^1_{\Gamma_D}(\Omega)$. Here $\delta_\Gamma \otimes \tau$ is a distribution in $H^{-1}(\Omega)$ which is supported on the interface boundary Γ. We remark that by duality and the trace theorem we find

$$\|\delta_\Gamma \otimes \tau\|_{H^{-1}(\Omega)} \;\lesssim\; \|\tau\|_{H^{-1/2}(\Gamma)} \quad \forall\,\tau \in H^{-1/2}(\Gamma).$$

Hence we derive

$$\begin{aligned} |(\operatorname{div}\boldsymbol{\zeta} - \delta_\Gamma \otimes \boldsymbol{\zeta}\cdot\mathbf{n}, v)_{L^2(\Omega)}| \;&=\; |(\operatorname{div}\boldsymbol{\zeta}, v)_{L^2(\Omega)} \;-\; (\boldsymbol{\zeta}\cdot\mathbf{n}, v)_{L^2(\Gamma)}| \;=\; |(\boldsymbol{\zeta}, \nabla v)_{L^2(\Omega)}| \\ &\le\; \|\boldsymbol{\zeta}\|_{[L^2(\Omega)]^2}\|v\|_{H^1_{\Gamma_D}(\Omega)}. \end{aligned}$$

According to the abstract setting in [15], we consider the operator

$$\mathcal{L} \;=\; \begin{bmatrix} \mathcal{L}_{1,1} & \mathcal{L}_{1,2} & \mathcal{L}_{1,3} \\ \mathcal{L}_{2,1} & \mathcal{L}_{2,2} & \mathcal{L}_{2,3} \\ \mathcal{L}_{3,1} & \mathcal{L}_{3,2} & \mathcal{L}_{3,3} \end{bmatrix} : \begin{bmatrix} [L^2(\Omega)]^2 \\ H^1_{\Gamma_D}(\Omega) \\ H_0^{-1/2}(\Gamma) \end{bmatrix} \;\to\; \begin{bmatrix} [L^2(\Omega)]^2 \\ H^{-1}(\Omega) \\ H_0^{1/2}(\Gamma) \end{bmatrix}$$

given by

$$\mathcal{L} \;=\; \begin{bmatrix} -\mathbf{I} & a\nabla & 0 \\ \operatorname{div} - \delta_\Gamma \otimes \;\cdot\mathbf{n} & -\delta_\Gamma \otimes \mathbf{W}\gamma & \delta_\Gamma \otimes \left(\frac{1}{2}\mathbf{I} - \mathbf{K}'\right) \\ 0 & \mathbf{P}_0\left(\frac{1}{2}\mathbf{I} - \mathbf{K}\right)\gamma & \mathbf{P}_0\mathbf{V} \end{bmatrix}\,,$$

where γ denotes the trace operator $\gamma : H^1_{\Gamma_D}(\Omega) \to H^{1/2}(\Gamma)$. For the sake of brevity, we use the notation $\mathbf{W}v = \mathbf{W}\gamma v$. Consequently, following [15], we introduce the Hilbert space $\mathbf{X}_3 := [L^2(\Omega)]^2 \times H^1_{\Gamma_D}(\Omega) \times H_0^{-1/2}(\Gamma)$ and $\mathbf{X}_3'$ as the dual space of $\mathbf{X}_3$ with respect to the canonical L^2-inner product. This yields the following least squares minimization problem: *Find* $(\boldsymbol{\theta}, u, \sigma) \in \mathbf{X}_3$ *such that*

$$\mathbf{J}_3(\boldsymbol{\theta}, u, \sigma) \;=\; \min_{(\boldsymbol{\zeta}, v, \tau)\in\mathbf{X}_3} \mathbf{J}_3(\boldsymbol{\zeta}, v, \tau)\,, \tag{3.7}$$

where $\mathbf{J}_3$ *is the quadratic functional defined by*

$$\begin{aligned} \mathbf{J}_3(\boldsymbol{\zeta}, v, \tau) \;:=\; & \|\mathbf{a}\nabla v - \boldsymbol{\zeta}\|^2_{[L^2(\Omega)]^2} \;+\; \left\|\mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}\tau\right]\right\|^2_{H^{1/2}(\Gamma)} \\ & + \left\|\operatorname{div}\boldsymbol{\zeta} + f - \delta_\Gamma \otimes \left(\mathbf{W}v + \boldsymbol{\zeta}\cdot\mathbf{n} - \left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}'\right)\tau\right)\right\|^2_{H^{-1}(\Omega)}\,. \end{aligned} \tag{3.8}$$

Though this minimization problem looks unusual, it is relatively simple to implement. One advantage of this formulation is that the flux can be chosen simply in $[L^2(\Omega)]^2$. Let us notice that this approach is the only one which does not assume that $\boldsymbol{\zeta} \in H$ or $\boldsymbol{\zeta}\cdot\mathbf{n} \in H_0^{-1/2}(\Gamma)$, which in turn requires $\boldsymbol{\zeta} \in H(\operatorname{div};\Omega)$. Therefore, it is the only least squares formulation which can be cast in the abstract setting of [15].

For the sake of completeness, we mention that there is another more simplified version which is obtained by inserting the transmission condition $\boldsymbol{\theta}\cdot\mathbf{n} = \sigma$ directly into the above formulation. Then, the trace norms $\|\cdot\|_{H^{1/2}(\Gamma)}$ and $\|\cdot\|_{H^{-1/2}(\Gamma)}$ in (3.6) are redundant, and we can derive a simpler minimization problem: *Find* $(\boldsymbol{\theta}, u) \in \mathbf{X}_4 := H \times H^1_{\Gamma_D}(\Omega)$ *such that*

$$\mathbf{J}_4(\boldsymbol{\theta}, u) \;=\; \min_{(\boldsymbol{\zeta}, v)\in\mathbf{X}_4} \mathbf{J}_4(\boldsymbol{\zeta}, v)\,, \tag{3.9}$$

where $\mathbf{J}_4$ *is the quadratic functional defined by*

$$\begin{aligned} \mathbf{J}_4(\boldsymbol{\zeta}, v) \;:=\; & \|\mathbf{a}\nabla v - \boldsymbol{\zeta}\|^2_{[L^2(\Omega)]^2} \;+\; \|\operatorname{div}\boldsymbol{\zeta} + f\|^2_{H^{-1}(\Omega)} \\ & + \left\|\mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}(\boldsymbol{\zeta}\cdot\mathbf{n})\right]\right\|^2_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{3.10}$$

Since $H^{-1}(\Omega)$, $H^{1/2}(\Gamma)$, and $H^{-1/2}(\Gamma)$ are Hilbert spaces, the norms are defined by the corresponding inner products $(\cdot,\cdot)_{H^{-1}(\Omega)}$, $\langle\cdot,\cdot\rangle_{H^{-1/2}(\Gamma)}$, and $\langle\cdot,\cdot\rangle_{H^{1/2}(\Gamma)}$. For example, the quadratic functional $\mathbf{J}_4$ can be rewritten by

$$\begin{aligned} \mathbf{J}_4(\boldsymbol{\zeta}, v) \;:=\; & (\mathbf{a}\nabla v - \boldsymbol{\zeta}, \mathbf{a}\nabla v - \boldsymbol{\zeta})_{[L^2(\Omega)]^2} \;+\; (\operatorname{div}\boldsymbol{\zeta} + f, \operatorname{div}\boldsymbol{\zeta} + f)_{H^{-1}(\Omega)} \\ & + \left\langle \mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}(\boldsymbol{\zeta}\cdot\mathbf{n})\right], \mathbf{P}_0\left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right)v + \mathbf{V}(\boldsymbol{\zeta}\cdot\mathbf{n})\right]\right\rangle_{H^{1/2}(\Gamma)}\,. \end{aligned}$$

In what follows, we develop the necessary tools to study the solvability and discrete approximations of our least squares formulations. However, the second, third, and fourth formulation are sharper than the first one. In fact, the resulting convergence rate is higher, and the system matrices can be preconditioned quite well. In the third and fourth formulations, the $H^{-1/2}$-norm is avoided. Moreover, in the third formulation, the flux is computed by means of Green's theorem; see section 7. This means that we need neither $\boldsymbol{\zeta}\cdot\mathbf{n}$ nor the assumption $\boldsymbol{\zeta}\cdot\mathbf{n}\in H^{-1/2}(\Gamma)$ explicitly. In our opinion, it is the most favorable approach. The fourth formulation looks most simple, and it avoids the computation of the hypersingular operator $\mathbf{W}$. However, its discretization requires some kind of stabilization, which will be discussed below in section 5. Therefore, throughout the rest of the paper, we will just concentrate on the problems (3.5)–(3.6), (3.7)–(3.8), and (3.9)–(3.10). Since the computation of the $L^2(\Omega)$-inner product offers no difficulties, the corresponding extension to (3.3)–(3.4) will be straightforward.

Now, following the general setting from [15], we find that (3.3), (3.5), and (3.7) are equivalent to

$$\mathbf{J}_i(\boldsymbol{\theta},u,\sigma) \;=\; \min_{(\boldsymbol{\zeta},v,\tau)\in\mathbf{X}_i}\mathbf{J}_i(\boldsymbol{\zeta},v,\tau)\,, \tag{3.11}$$

with

$$\mathbf{J}_i(\boldsymbol{\zeta},v,\tau) \;=\; \frac{1}{2}\,B_i\big((\boldsymbol{\zeta},v,\tau),(\boldsymbol{\zeta},v,\tau)\big) \;-\; \mathbf{G}_i(\boldsymbol{\zeta},v,\tau) \;+\; \text{const}, \tag{3.12}$$

$i=1,2,3$, with corresponding bilinear forms $B_i:\mathbf{X}_i\times\mathbf{X}_i\to\mathbb{R}$, and linear functionals $\mathbf{G}_i:\mathbf{X}_i\to\mathbb{R}$. An analogous setting holds for (3.10). Then, the minimization problems are equivalent to the following linear equations: *Find* $(\boldsymbol{\theta},u,\sigma)\in\mathbf{X}_i$ *such that*

$$B_i\big((\boldsymbol{\theta},u,\sigma),(\boldsymbol{\zeta},v,\tau)\big) \;=\; \mathbf{G}_i(\boldsymbol{\zeta},v,\tau) \tag{3.13}$$

for all $(\boldsymbol{\zeta},v,\tau)\in\mathbf{X}_i$. This equation is solved approximatively on a finite dimensional subspace in $\mathbf{X}_i$. Therein, the major difficulty is the computation of the underlying bilinear and linear forms. However, this can be done only approximatively, which means B_i is replaced by some discrete bilinear form B_i^h.

4. Coercivity estimates. It is easy to prove, using the mapping properties of the boundary integral operators (cf. Lemma 2.1) and (3.2), that B_2, B_3, and B_4 are symmetric and bounded in the corresponding energy norms. In addition, $\mathbf{G}_2$, $\mathbf{G}_3$, and $\mathbf{G}_4$ are also bounded. Therefore, in order to conclude the unique solvability of our least squares formulations (3.5)–(3.6), (3.7)–(3.8), and (3.9)–(3.10), it remains to show that B_2, B_3, and B_4 are strongly coercive in $\mathbf{X}_2$, $\mathbf{X}_3$, and $\mathbf{X}_4$, respectively. Usually, coercivity estimates for least squares formulations are valid under much weaker conditions than for Galerkin formulations since only the normal solvability of the operator is required. Since the Sobolev norms cannot be computed exactly (see below), we need to apply a more sophisticated tool for the investigation of the present discrete least squares methods. For this purpose, we have to state some previous results concerning the Galerkin scheme of the original second order nonlocal boundary value problem (2.4).

First, proceeding in the usual way (see, e.g. [13], [22], [27]), we find that the weak formulation of (2.4) reduces to the following: *Find* $(u,\sigma)\in\mathbf{H}:=H^1_{\Gamma_D}(\Omega)\times H_0^{-1/2}(\Gamma)$ *such that*

$$A\big((u,\sigma),(v,\tau)\big) \;=\; \mathbf{F}(v,\tau) \quad \forall\,(v,\tau)\in\mathbf{H}\,, \tag{4.1}$$

where $A:\mathbf{H}\times\mathbf{H}\to\mathbb{R}$ *is the bounded bilinear form defined by*

$$\begin{aligned} A\big((u,\sigma),(v,\tau)\big) \;:=\;& (\mathbf{a}\,\nabla u,\nabla v)_{[L^2(\Omega)]^2} \;+\; \langle\mathbf{W}u,v\rangle \;-\; \langle\big(\tfrac{1}{2}\mathbf{I}-\mathbf{K}'\big)\,\sigma,v\rangle \\ &+\; \langle\tau,\mathbf{V}\sigma\rangle \;+\; \langle\tau,\big(\tfrac{1}{2}\mathbf{I}-\mathbf{K}\big)\,u\rangle \end{aligned} \tag{4.2}$$

for all (u,σ), $(v,\tau) \in \mathbf{H}$, *and* $\mathbf{F} \in \mathbf{H}'$ *is given by*

$$\mathbf{F}(v,\tau) \,:=\, \int_\Omega f\,v\,dx \quad \forall\,(v,\tau) \in \mathbf{H}\,. \tag{4.3}$$

The product space $\mathbf{H}$ is endowed with the corresponding norm, that is,

$$\|(v,\tau)\|_{\mathbf{H}} \,:=\, \left\{\, \|v\|^2_{H^1(\Omega)} \,+\, \|\tau\|^2_{H^{-1/2}(\Gamma)} \,\right\}^{1/2}.$$

In what follows, given two expressions a and b, the relation $a \lesssim b$ means that a is bounded by some constant times b uniformly in all parameters upon which a and b may depend. An analogous definition holds for the relation $a \gtrsim b$. Also, $a \sim b$ means that $a \lesssim b$ and $a \gtrsim b$.

LEMMA 4.1. *The bilinear form A is strongly coercive in* $\mathbf{H}$, *that is,*

$$A\big((v,\tau),(v,\tau)\big) \,\gtrsim\, \|(v,\tau)\|^2_{\mathbf{H}} \quad \forall\,(v,\tau) \in \mathbf{H}\,.$$

Proof. Using that $\mathbf{K}'$ is the adjoint of $\mathbf{K}$, we obtain from (4.2) that

$$A\big((v,\tau),(v,\tau)\big) \,=\, (\mathbf{a}\,\nabla v, \nabla v)_{[L^2(\Omega)]^2} \,+\, \langle \mathbf{W}v, v\rangle \,+\, \langle \tau, \mathbf{V}\tau\rangle\,.$$

Since $|\Gamma_D| \neq 0$, Poincaré's inequality yields the equivalence between the norm and the seminorm of $H^1(\Omega)$ in the subspace $H^1_{\Gamma_D}(\Omega)$, which, together with (2.2), implies that

$$(\mathbf{a}\,\nabla v, \nabla v)_{[L^2(\Omega)]^2} \,\gtrsim\, \|v\|^2_{H^1(\Omega)} \quad \forall\, v \in H^1_{\Gamma_D}(\Omega)\,.$$

Then, the above inequality and the coerciveness properties of $\mathbf{V}$ and $\mathbf{W}$ given in Lemma 2.1 complete the proof. □

For the sake of completeness, we also provide the following consequence of the previous lemma.

THEOREM 4.2. *There exists a unique solution* $(u,\sigma) \in \mathbf{H}$ *of the variational formulation* (4.1). *Moreover, there holds the a priori estimate* $\|(u,\sigma)\|_{\mathbf{H}} \lesssim \|\mathbf{F}\|_{\mathbf{H}'}$.

Proof. The proof is a straightforward application of the Lax–Milgram lemma. □

The following lemma reveals a well-known fact about boundary integral operators.

LEMMA 4.3. *For* $u \in H_0^{1/2}(\Gamma)$ *and* $\sigma \in H_0^{-1/2}(\Gamma)$, *the following holds:*

$$\left\|\mathbf{W}u + (\tfrac{1}{2}\mathbf{I} + \mathbf{K}')\sigma\right\|_{H^{-1/2}(\Gamma)} \,\sim\, \left\|\mathbf{P}_0\left[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\right]\right\|_{H^{1/2}(\Gamma)}\,. \tag{4.4}$$

Proof. The proof follows easily from the equality $\mathbf{W} = -(\frac{1}{2}\mathbf{I} + \mathbf{K}')\mathbf{V}^{-1}(\frac{1}{2}\mathbf{I} - \mathbf{K})$ together with the mapping properties of the double layer potential operators in the spaces $H^{\pm 1/2}(\Gamma)$. □

THEOREM 4.4. *For all functions* $(\boldsymbol{\theta}, u, \sigma) \in \mathbf{X}_2 := H \times H^1_{\Gamma_D}(\Omega) \times H_0^{-1/2}(\Gamma)$, *the following a priori estimate is valid:*

$$\begin{aligned} &\|u\|_{H^1(\Omega)} + \|\boldsymbol{\theta}\|_{[L^2(\Omega)]^2} + \|\sigma\|_{H^{-1/2}(\Gamma)} \,\lesssim\, \|\mathbf{a}\,\nabla u - \boldsymbol{\theta}\|_{[L^2(\Omega)]^2} + \|\mathrm{div}\,\boldsymbol{\theta}\|_{H^{-1}(\Omega)} \\ &\quad + \left\|\mathbf{W}u + \boldsymbol{\theta}\cdot\mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma\right\|_{H^{-1/2}(\Gamma)} + \left\|\mathbf{P}_0\left[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\right]\right\|_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{4.5}$$

Moreover, for all $(\boldsymbol{\theta}, u, \sigma) \in \mathbf{X}_3 := [L^2(\Omega)]^2 \times H^1_{\Gamma_D}(\Omega) \times H_0^{-1/2}(\Gamma)$ *there holds*

$$\begin{aligned}\|u\|_{H^1(\Omega)} + \|\boldsymbol{\theta}\|_{[L^2(\Omega)]^2} + \|\sigma\|_{H^{-1/2}(\Gamma)} \;&\lesssim\; \|\mathbf{a}\,\nabla u - \boldsymbol{\theta}\|_{[L^2(\Omega)]^2} \\ &+ \left\|\operatorname{div}\boldsymbol{\theta} - \delta_\Gamma \otimes \left[\mathbf{W}u + \boldsymbol{\theta}\cdot\mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma\right]\right\|_{H^{-1}(\Omega)} \\ &+ \left\|\mathbf{P}_0\left[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\right]\right\|_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{4.6}$$

In addition, for any $(\boldsymbol{\theta}, u) \in \mathbf{X}_4 := H \times H^1_{\Gamma_D}(\Omega)$ *there holds the a priori estimate*

$$\begin{aligned}\|u\|_{H^1(\Omega)} + \|\boldsymbol{\theta}\|_{[L^2(\Omega)]^2} + \|\boldsymbol{\theta}\cdot\mathbf{n}\|_{H^{-1/2}(\Gamma)} \;&\lesssim\; \|\mathbf{a}\,\nabla u - \boldsymbol{\theta}\|_{[L^2(\Omega)]^2} \\ &+ \|\operatorname{div}\boldsymbol{\theta}\|_{H^{-1}(\Omega)} + \left\|\mathbf{P}_0\left[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}(\boldsymbol{\theta}\cdot\mathbf{n})\right]\right\|_{H^{1/2}(\Gamma)}\,. \end{aligned} \tag{4.7}$$

Proof. We provide a particular proof of this result because we need this reasoning below to prove the main theorem, Theorem 5.1. By virtue of Theorem 4.2 we estimate

$$\begin{aligned}\|u\|_{H^1(\Omega)} + \|\sigma\|_{H^{-1/2}(\Gamma)} \;&\lesssim\; \sup_{\delta\in H_0^{-1/2}(\Gamma)} \frac{1}{\|\delta\|_{H^{-1/2}(\Gamma)}} \left\{\langle \delta, (\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\rangle\right\} \\ &+ \sup_{v\in H^1_{\Gamma_D}(\Omega)} \frac{1}{\|v\|_{H^1(\Omega)}} \left\{(\mathbf{a}\nabla u, \nabla v)_{[L^2(\Omega)]^2} + \langle \mathbf{W}u - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma, v\rangle\right\} \\ &\lesssim \sup_{\delta\in H_0^{-1/2}(\Gamma)} \frac{1}{\|\delta\|_{H^{-1/2}(\Gamma)}} \left\{\langle \delta, (\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\rangle\right\} \\ &+ \sup_{v\in H^1_{\Gamma_D}(\Omega)} \frac{1}{\|v\|_{H^1(\Omega)}} \Big\{ (\mathbf{a}\nabla u - \boldsymbol{\theta}, \nabla v)_{[L^2(\Omega)]^2} + (\boldsymbol{\theta}, \nabla v)_{[L^2(\Omega)]^2} \\ &\qquad + \langle \mathbf{W}u - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma, v\rangle \Big\}\,. \end{aligned}$$

Next, we apply the divergence theorem and use that $\boldsymbol{\theta}\cdot\mathbf{n} = 0$ on Γ_N, whence

$$\begin{aligned}\|u\|_{H^1(\Omega)} + \|\sigma\|_{H^{-1/2}(\Gamma)} \;&\lesssim\; \sup_{\delta\in H_0^{-1/2}(\Gamma)} \frac{1}{\|\delta\|_{H^{-1/2}(\Gamma)}} \left\{\langle \delta, (\tfrac{1}{2}\mathbf{I} - \mathbf{K})u + \mathbf{V}\sigma\rangle\right\} \\ &+ \sup_{v\in H^1_{\Gamma_D}(\Omega)} \frac{1}{\|v\|_{H^1(\Omega)}} \Big\{(\mathbf{a}\nabla u - \boldsymbol{\theta}, \nabla v)_{[L^2(\Omega)]^2} - (\operatorname{div}\boldsymbol{\theta}, v)_{[L^2(\Omega)]^2} \\ &\qquad + \langle \mathbf{W}u + \boldsymbol{\theta}\cdot\mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma, v\rangle\Big\}\,, \end{aligned}$$

which implies both estimates, (4.5) and (4.6), immediately. We remark that we have used the trace theorem $\|v\|_{H^{1/2}(\Gamma)} \lesssim \|v\|_{H^1(\Omega)}$ and the fact that $v|_{\Gamma_D} = 0$ for all $v \in H^1_{\Gamma_D}(\Omega)$. To prove (4.7) we choose $\sigma = \boldsymbol{\theta}\cdot\mathbf{n}$ in (4.5) and apply the result of Lemma 4.3. □

5. Finite element approximations. For the definition of the Ritz and Galerkin methods for (3.11)–(3.12), we consider finite dimensional subspaces $\mathbf{X}_i^h := X_h^i \times V_h \times S_h$ of $\mathbf{X}_i$ and assume the following.

- *Approximation property of* V_h. There exists $d := d_V > 1$ such that for all $s < \min\{\frac{3}{2}, d\}$ and for all $u \in H^d(\Omega)$

$$\inf_{v_h\in V_h} \|u - v_h\|_{H^s(\Omega)} \;\lesssim\; h^{d-s}\|u\|_{H^d(\Omega)}\,.$$

- *Inverse property* of V_h. For all $v_h \in V_h$ and for all $t < s < \frac{3}{2}$ there holds

$$\|v_h\|_{H^s(\Omega)} \;\lesssim\; h^{t-s}\|v_h\|_{H^t(\Omega)}\,.$$

Similar properties are also assumed for X_h^i and S_h with constants d_X and d_S, respectively.

Typical candidates for these spaces are finite element spaces V_h, subordinated to a triangulation $\mathcal{T}_h = \{\tau_k\}$ of Ω consisting of triangles or quadrilaterals τ_k with diameter h_k. The above properties are valid for shape regular quasi-uniform triangulations. The results for (3.11)–(3.12) remain valid also for nonuniform triangulations. The results with respect to $\mathbf{J}_4$ seem to be also true on nonuniform grids. (Perhaps the proof becomes rather technical.)

Here d denotes polynomial degree on each triangle. Since $V_h \subset H^1_{\Gamma_D}(\Omega)$, the functions $v_h \in V_h$ are assumed to be continuous on Ω. For a consistent discretization it is sufficient to choose $d_X = d_V - 1 = d - 1$. The spaces S_h are defined analogously on the boundary, and they should be exact at least of order $d_S = d - 1$.

The $H^{-1}(\Omega)$-norm on V_h can be computed by introducing the operator $\mathbf{T}_h : H^{-1}(\Omega) \to V_h$, where for each $f \in H^{-1}(\Omega)$ the function $w_h := \mathbf{T}_h f$ is the unique function in V_h satisfying

$$(\nabla w_h, \nabla v_h)_{[L^2(\Omega)]^2} = (f, v_h)_{L^2(\Omega)} \quad \forall\, v_h \in V_h\,. \tag{5.1}$$

The computation of the operator $\mathbf{T}_h$ requires the solution of a Neumann problem which is relatively expensive. For an efficient computation it is much more feasible to use a symmetric preconditioner $\mathbf{B}_h : V_h^* \to V_h$ instead of $\mathbf{T}_h$ satisfying

$$\|\mathbf{B}_h f_h\|_{H^1_{\Gamma_D}(\Omega)} \sim \|f_h\|_{H^{-1}(\Omega)} \qquad \forall\, f_h \in V_h^* \tag{5.2}$$

or, equivalently,

$$(\mathbf{T}_h f_h, f_h)_{L^2(\Omega)} \sim (\mathbf{B}_h f_h, f_h)_{L^2(\Omega)} \quad \forall\, f_h \in V_h^*\,, \tag{5.3}$$

where $V_h^* \subset H^{-1}(\Omega)$ is a suitable finite dimensional subspace. Such preconditioners are available from multigrid or multilevel algorithms [5], [6], in which case one can choose $V_h^* = V_h$, as well as from wavelet bases [15], where the space V_h^* is generated by the dual wavelet basis.

Now, in order to compute the inner products $\langle\cdot,\cdot\rangle_{H^{\pm 1/2}(\Gamma)}$, one can use, according to Lemma 2.1, that $\langle\lambda,\lambda\rangle_{H^{1/2}(\Gamma)} \sim \langle\mathbf{W}\lambda,\lambda\rangle$ for all $\lambda \in H_0^{1/2}(\Gamma)$ and that $\langle\sigma,\sigma\rangle_{H^{-1/2}(\Gamma)} \sim \langle\sigma,\mathbf{V}\sigma\rangle$ for all $\sigma \in H_0^{-1/2}(\Gamma)$, which, however, are not accessible for numerical computations. Again we have to consider only $H^{\pm 1/2}(\Gamma)$-norms and $\langle\cdot,\cdot\rangle_{H^{\pm 1/2}(\Gamma)}$-inner products on finite dimensional subspaces. However, one can apply a preconditioner $\mathbf{D}_h$ for $\mathbf{W}$ in the same way as described above; see, e.g., [30] and [36]. It is computable on a finite dimensional subspace $\tilde{V}_h(\Gamma)$ of $H_0^{1/2}(\Gamma)$ and satisfies

$$\langle\mathbf{W}\lambda_h,\lambda_h\rangle \sim \langle\mathbf{D}_h\lambda_h,\lambda_h\rangle \quad \forall\, \lambda_h \in \tilde{V}_h(\Gamma)\,. \tag{5.4}$$

Similarly, we introduce an operator $\mathbf{C}_h$ as a preconditioner for $\mathbf{V}$ satisfying

$$\langle\sigma_h,\mathbf{V}\sigma_h\rangle \sim \langle\sigma_h,\mathbf{C}_h\sigma_h\rangle \quad \forall\, \sigma_h \in \tilde{S}_h\,, \tag{5.5}$$

where $\tilde{S}_h$ is a finite dimensional subspace of $H_0^{-1/2}(\Gamma)$. In the case in which one is dealing only with traditional boundary elements, we simply have $\tilde{V}_h = V_h|_\Gamma$ and $\tilde{S}_h = S_h$. For a wavelet preconditioner we refer to the subsequent section.

Since these operators are symmetric and coercive, we define for notation's convenience the square roots $\mathbf{B}_h^{1/2}$ by $(\mathbf{B}_h^{1/2})^*\mathbf{B}_h^{1/2} = \mathbf{B}_h$, and we set up $\mathbf{C}_h^{1/2}$ and $\mathbf{D}_h^{1/2}$

similarly. In addition, we define $V_h(\Gamma) := V_h|_\Gamma \cap H_0^{1/2}(\Gamma)$ and let $P_h : H^1_{\Gamma_D}(\Omega) \to V_h$, $\mathbb{Q}_h : H^{1/2}(\Gamma) \to S_h$, and $Q_h : H^{-1/2}(\Gamma) \to V_h(\Gamma)$ be bounded projectors with *adjoint* operators $P_h^* : H^{-1}(\Omega) \to V_h^*$, $\mathbb{Q}_h^* : H^{-1/2}(\Gamma) \to \tilde{S}_h$ and $Q_h^* : H^{1/2}(\Gamma) \to \tilde{V}_h(\Gamma)$, respectively. Then, according to (5.2), (5.4), and (5.5), we deduce that

$$\begin{aligned} (\mathbf{B}_h P_h^* f, P_h^* f)_{L^2(\Omega)} &\sim \|P_h^* f\|^2_{V_h^*} && \forall\, f \in H^{-1}(\Omega)\,, \\ \langle \mathbf{D}_h Q_h^* \lambda, Q_h^* \lambda\rangle &\sim \|Q_h^* \lambda\|^2_{H^{1/2}(\Gamma)} && \forall\, \lambda \in H_0^{1/2}(\Gamma)\,, \\ \langle\, \mathbb{Q}_h^* \sigma, \mathbf{C}_h\, \mathbb{Q}_h^* \sigma\rangle &\sim \|\,\mathbb{Q}_h^* \sigma\|^2_{H^{-1/2}(\Gamma)} && \forall\, \sigma \in H_0^{-1/2}(\Gamma)\,. \end{aligned} \tag{5.6}$$

The above means that we will use truncated bilinear forms instead of the original ones for the computation of the Galerkin solutions. Certainly, this truncation may influence the stability of the methods. Hence we prove next that stability is not violated by this procedure.

THEOREM 5.1. *For arbitrary functions $(\boldsymbol{\theta}_h, u_h, \sigma_h) \in \mathbf{X}_2^h$, the following a priori estimate holds:*

$$\begin{aligned} \|u_h\|_{H^1(\Omega)} + \|\boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} + \|\sigma_h\|_{H^{-1/2}(\Gamma)} &\lesssim \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \\ + \|\mathbf{B}_h^{1/2} P_h^* \operatorname{div} \boldsymbol{\theta}_h\|_{L^2(\Omega)} &+ \big\|\mathbf{C}_h^{1/2}\, \mathbb{Q}_h^* \big[\mathbf{W} u_h + \boldsymbol{\theta}_h \cdot \mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma_h\big]\big\|_{L^2(\Gamma)} \\ &+ \big\|\mathbf{D}_h^{1/2} Q_h^* \,\mathbf{P}_0 \big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K}) u_h + \mathbf{V}\sigma_h\big]\big\|_{L^2(\Gamma)}\,, \end{aligned} \tag{5.7}$$

and for $(\boldsymbol{\theta}_h, u_h, \sigma_h) \in \mathbf{X}_3^h$ we find

$$\begin{aligned} \|u_h\|_{H^1(\Omega)} + \|\boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} + \|\sigma_h\|_{H^{-1/2}(\Gamma)} &\lesssim \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \\ + \big\|\mathbf{B}_h^{1/2} P_h^* \big(\operatorname{div} \boldsymbol{\theta}_h - \delta_\Gamma \otimes \big[\mathbf{W} u_h &+ \boldsymbol{\theta}_h \cdot \mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma_h\big]\big)\big\|_{L^2(\Omega)} \\ &+ \big\|\mathbf{D}_h^{1/2} Q_h^* \,\mathbf{P}_0 \big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K}) u_h + \mathbf{V}\sigma_h\big]\big\|_{L^2(\Gamma)}\,. \end{aligned} \tag{5.8}$$

Proof. We estimate the expression in the same fashion as in the proof of Theorem 4.4. First we observe that the stability of the Galerkin scheme implies the estimate

$$\begin{aligned} \|u_h\|_{H^1(\Omega)} + \|\sigma_h\|_{H^{-1/2}(\Gamma)} &\lesssim \sup_{\delta_h \in S_h} \frac{1}{\|\delta_h\|_{H^{-1/2}(\Gamma)}} \big\{\langle \delta_h, (\tfrac{1}{2}\mathbf{I} - \mathbf{K}) u_h + \mathbf{V}\sigma_h\rangle\big\} \\ &+ \sup_{v_h \in V_h} \frac{1}{\|v_h\|_{H^1(\Omega)}} \big\{(\mathbf{a}\nabla u_h, \nabla v_h)_{[L^2(\Omega)]^2} + \langle \mathbf{W} u_h - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma_h, v_h\rangle\big\} \\ &\lesssim \big\|Q_h^* \,\mathbf{P}_0 \big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K}) u_h + \mathbf{V}\sigma_h\big]\big\|_{H^{1/2}(\Gamma)} + \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \\ &+ \big\|P_h^* \big(\operatorname{div} \boldsymbol{\theta}_h - \delta_\Gamma \otimes \big[\mathbf{W} u_h + \boldsymbol{\theta}_h \cdot \mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma_h\big]\big)\big\|_{H^{-1}(\Omega)} \\ &\lesssim \big\|\mathbf{D}_h^{1/2} Q_h^* \,\mathbf{P}_0 \big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K}) u_h + \mathbf{V}\sigma_h\big]\big\|_{L^2(\Gamma)} + \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \\ &+ \big\|\mathbf{B}_h^{1/2} P_h^* \big(\operatorname{div} \boldsymbol{\theta}_h - \delta_\Gamma \otimes \big[\mathbf{W} u_h + \boldsymbol{\theta}_h \cdot \mathbf{n} - (\tfrac{1}{2}\mathbf{I} - \mathbf{K}')\sigma_h\big]\big)\big\|_{L^2(\Omega)}\,, \end{aligned}$$

where we have used the properties of the operators $\mathbf{B}_h$ and $\mathbf{D}_h$. From this estimate the assertion (5.8) follows immediately. One can prove the estimate (5.7) similarly. □

This suggests that one has to solve the linear problem

$$B_i^h\big((\boldsymbol{\theta}_h, u_h, \sigma_h), (\boldsymbol{\zeta}_h, v_h, \tau_h)\big) \;=\; \mathbf{G}_i^h(\boldsymbol{\zeta}_h, v_h, \tau_h)\,, \quad i = 2, 3\,, \tag{5.9}$$

with the truncated bilinear forms $B_i^h : \mathbf{X}_i^h \times \mathbf{X}_i^h \to \mathbb{R}$ and the functionals $\mathbf{G}_i^h : \mathbf{X}_i^h \to \mathbb{R}$. The computation of the bilinear forms B_1^h, B_2^h, and B_4^h requires the computation of $\operatorname{div} \boldsymbol{\zeta}$, which is possible, e.g., if $\boldsymbol{\zeta} \in H(\operatorname{div}; \Omega)$ or $X_h \subset H$, despite the fact that the energy space using B_2^h or B_4^h is $[L^2(\Omega)]^2$. The differentiation of $\boldsymbol{\zeta}$ can be avoided with the aid of Green's theorem. This is used in the third formulation using B_3^h, which requires only that $\boldsymbol{\zeta} \in [L^2(\Omega)]^2$, i.e., $X_h \subset [L^2(\Omega)]^2$.

It turns out that, for the fourth formulation, the truncation must be performed on a finer grid to preserve the stability. Here, the bilinear form $B_4^h : \mathbf{X}_4^h \times \mathbf{X}_4^h \to \mathbb{R}$ is defined by

$$\begin{aligned} B_4^h\big((\boldsymbol{\theta}_h, u_h), (\boldsymbol{\zeta}_h, v_h)\big) \;:=\; & (\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h, \mathbf{a}\nabla v_h - \boldsymbol{\zeta}_h)_{[L^2(\Omega)]^2} \\ & + (\mathbf{B}_h P_h^* \operatorname{div} \boldsymbol{\theta}_h, P_h^* \operatorname{div} \boldsymbol{\zeta}_h)_{L^2(\Omega)} \\ + \langle \mathbf{D}_{h'} Q_{h'}^*\, \mathbf{P}_0 \left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right) u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\right], & \, Q_{h'}^*\, \mathbf{P}_0 \left[\left(\tfrac{1}{2}\mathbf{I} - \mathbf{K}\right) v_h + \mathbf{V}(\boldsymbol{\zeta}_h \cdot \mathbf{n})\right] \rangle_{L^2(\Gamma)}\,, \end{aligned}$$

where the positive parameter h' has to be chosen such that $h' \lesssim h$, that is, $h' \le c\,h$ for a sufficiently small constant c. In fact, we have the following result.

Theorem 5.2. *Assume that $\boldsymbol{\theta}_h \cdot \mathbf{n} \in S_h$ for all $\boldsymbol{\theta}_h \in X_h$. Then there exists a mesh size $h' \lesssim h$ such that for $u_h \in V_h$ and $\boldsymbol{\theta}_h \in X_h$ there holds the a priori estimate*

$$\begin{aligned} \|u_h\|_{H^1(\Omega)} \;+\; \|\boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \;+\; \|\boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2}(\Gamma)} \;\lesssim\; \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega)]^2} \\ + \big\|\mathbf{B}_h^{1/2} P_h^* \operatorname{div} \boldsymbol{\theta}_h\big\|_{L^2(\Omega)} \;+\; \big\|\mathbf{D}_{h'}^{1/2} Q_{h'}^*\, \mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{L^2(\Gamma)}\,. \end{aligned}$$

Proof. Given $(\boldsymbol{\theta}_h, u_h) \in X_h \times V_h$, we take $\sigma_h := \boldsymbol{\theta}_h \cdot \mathbf{n}$ in the estimate (5.7) and then apply Lemma 4.3 to obtain

$$\begin{aligned} \|u_h\|_{H^1(\Omega)} \;+\; \|\boldsymbol{\theta}_h\|_{[L^2(\Omega]^2} \;+\; \|\boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2}(\Gamma)} \;&\lesssim\; \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega]^2} \\ + \big\|\mathbf{B}_h^{1/2} P_h^* \operatorname{div} \boldsymbol{\theta}_h\big\|_{L^2(\Omega)} + \big\|\mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + &\mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{H^{1/2}(\Gamma)} \\ \lesssim\; \|\mathbf{a}\nabla u_h - \boldsymbol{\theta}_h\|_{[L^2(\Omega]^2} \;+\; \|\mathbf{B}_h^{1/2} P_h^* \operatorname{div} \boldsymbol{\theta}_h\|_{L^2(\Omega)} & \\ + \big\|Q_{h'}^*\, \mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{H^{1/2}(\Gamma)} & \\ + \big\|(I - Q_{h'}^*)\mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{H^{1/2}(\Gamma)}\,. & \end{aligned} \tag{5.10}$$

Next, using the approximation and inverse properties of the subspaces involved, we get

$$\begin{aligned} & \big\|(I - Q_{h'}^*)\mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{H^{1/2}(\Gamma)} \\ & \lesssim\; (h')^{\alpha} \big\|\mathbf{P}_0\big[(\tfrac{1}{2}\mathbf{I} - \mathbf{K})u_h + \mathbf{V}(\boldsymbol{\theta}_h \cdot \mathbf{n})\big]\big\|_{H^{1/2+\alpha}(\Gamma)} \\ & \lesssim\; (h')^{\alpha} \left\{\|u_h\|_{H^{1/2+\alpha}(\Gamma)} + \|\boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2+\alpha}(\Gamma)}\right\} \\ & \lesssim\; (h')^{\alpha} h^{-\alpha} \left\{\|u_h\|_{H^1(\Omega)} + \|\boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2}(\Gamma)}\right\}\,. \end{aligned} \tag{5.11}$$

Therefore, replacing (5.11) back into (5.10), choosing $h' \lesssim h$, and using (5.6), we conclude the proof. □

The error analysis of both methods then is a standard application of the well-known second Strang lemma.

Theorem 5.3. *The bilinear forms B_i^h, $i = 2, 3$, satisfy*

$$B_i^h\big((\boldsymbol{\theta}_h, u_h, \sigma_h), (\boldsymbol{\theta}_h, u_h, \sigma_h)\big) \ \sim \ \|(\boldsymbol{\theta}_h, u_h, \sigma_h)\|_{\mathbf{X}_i}^2 \,,$$

and the following convergence estimate holds in both cases:

$$\|u - u_h\|_{H^1(\Omega)} \ + \ \|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_{L^2(\Omega)} \ + \ \|\sigma - \sigma_h\|_{H^{-1/2}(\Gamma)} \ \lesssim \ h^{d-1}\|u\|_{H^d(\Omega)} \,.$$

In addition, there exists $h' \lesssim h$ such that the bilinear form B_4^h satisfies

$$B_4^h\big((\boldsymbol{\theta}_h, u_h), (\boldsymbol{\theta}_h, u_h)\big) \ \gtrsim \ \|u_h\|_{H^1(\Omega)}^2 \ + \ \|\boldsymbol{\theta}_h\|_{L^2(\Omega)}^2 \ + \ \|\boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2}(\Gamma)}^2 \,,$$

and the following convergence estimate holds:

$$\|u - u_h\|_{H^1(\Omega)} \ + \ \|\boldsymbol{\theta} - \boldsymbol{\theta}_h\|_{L^2(\Omega)} \ + \ \|\boldsymbol{\theta} \cdot \mathbf{n} - \boldsymbol{\theta}_h \cdot \mathbf{n}\|_{H^{-1/2}(\Gamma)} \ \lesssim \ h^{d-1}\|u\|_{H^d(\Omega)} \,.$$

6. Wavelet bases and related matrices. In the framework of the present least squares methods, we would like to recommend the use of wavelet bases at least for the discretization of the boundary integral operators. Wavelet bases facilitate the computation of the Sobolev norms. In fact, one can exploit several features simultaneously, namely, the computation of the half integer Sobolev norms [15], the preconditioning [14], [36], together with a sparse discretization by matrix compression [16], [36], [38], and the use of wavelet bases for an adaptive approximation [11]. The matrix compression accelerates computation with the boundary element matrices enormously. In fact, it reduces the quadratic complexity dealing with full matrices of size N to order N or $N \log^a N$; cf. [36]. This might be not a major concern for two dimensional problems, since the finite element part already has N^2 unknowns. However, for three dimensional problems the complexity of the boundary element part would dominate that of the finite element part. Therefore, fast methods for boundary integral equations become necessary when dealing with very large systems of integral equations [28].

Wavelet bases, and, in particular, wavelet bases for boundary integral equations, is by now a well-studied subject. There are many excellent accounts about wavelets in general, and for boundary integral equations we refer the reader to the survey paper [14] and the references therein. Here we focus only on those aspects which are important for the present purpose. Particularly, more information about wavelet least squares methods is contained in [15].

In general, a multiresolution analysis consists of a nested family of finite dimensional subspaces

$$S_0 \subset \cdots \subset S_j \subset S_{j+1} \subset \cdots \,,$$

where, e.g., $\bigcup_{j \geq 0} S_j$ is supposed dense in $L^2(\Gamma)$. For example, we may consider $S_j = S_h$ with $h \sim 2^{-j}$ and where $\bigcup_{j \geq 0} S_j$ is dense in $H^{-1/2}(\Gamma)$.

Each space S_j is defined by a single-scale basis, i.e., $S_j = \operatorname{span}\{\varphi_k^j : k \in \Delta_j\}$, where Δ_j denotes a suitable index set with cardinality $\#\Delta_j \sim 2^{nj}$. These basis functions might be classical piecewise constant or piecewise linear basis functions for boundary element methods. The wavelets $\Psi^j = \{\psi_k^j : k \in \nabla_j = \Delta_{j+1} \setminus \Delta_j\}$ are the bases of complementary spaces $W_j = \operatorname{span}\{\psi_k^j : k \in \nabla_j\}$ of S_j in S_{j+1}, i.e.,

$$S_{j+1} \,=\, S_j \,\oplus\, W_j, \qquad S_j \,\cap\, W_j \,=\, \{0\}\,.$$

In what follows, we adhere to the following shorthand notation. We write $\psi_k^{-1} := \varphi_k^0$ and $\nabla_{-1} := \Delta_0$. By Ψ_j we denote the (column-) vector $\Psi_j = (\psi_k^l)_{k\in\nabla_l,-1\le l<j}$. For a given vector $\mathbf{v} \in \mathbb{R}^{\#\Delta_j}$, we write simply

$$\Psi_j^T\mathbf{v} \,=\, \mathbf{v}^T\Psi_j \,=\, \sum_{l=-1}^{j-1}\sum_{k\in\nabla_l} v_{l,k}\psi_k^l\,.$$

It is supposed that the collection Ψ_j builds a uniformly stable basis of S_{j+1} and a Riesz-basis in L^2. This property is guaranteed if there exists a biorthogonal, or dual, collection $\tilde\Psi = \{\tilde\psi_k^l : k \in \nabla_l,\ l \ge -1\}$ generating spaces $\tilde S_0 \subset \cdots \subset \tilde S_j \subset \cdots$ such that $\langle\tilde\psi_k^j, \psi_l^i\rangle = \delta_{k,l}\delta_{i,j}$. In this case, every $v \in L^2(\Gamma)$ has the representations

$$v \,=\, \langle v, \tilde\Psi\rangle^T\Psi\,, \qquad v \,=\, \langle v, \Psi\rangle^T\tilde\Psi\,. \tag{6.1}$$

Then the projectors Q_j and Q_j^* are given by

$$Q_jv \,=\, \langle v, \tilde\Psi_j\rangle^T\Psi_j, \qquad Q_j^*v \,=\, \langle v, \Psi_j\rangle^T\tilde\Psi_j\,.$$

In addition, the wavelets are supposed to be local on the corresponding scale. We refer to [14], [17], and [36] for further details.

Let $\gamma := \sup\{s \in \mathbb{R} : S_j \subset H^s(\Gamma)\}$ and $\tilde\gamma$ be defined analogously. Then, for a given function v, the following norm equivalences hold:

$$\|v\|_{H^s(\Gamma)}^2 \sim \sum_{l\ge-1} 2^{-2ls}\,\|\langle v, \tilde\Psi^l\rangle\|^2, \qquad \|v\|_{H^{-s}(\Gamma)}^2 \sim \sum_{l\ge-1} 2^{2ls}\,\|\langle v, \Psi^l\rangle\|^2, \tag{6.2}$$

where $-\tilde\gamma < s < \gamma$. It is important to remark that one does not need the dual basis for the computation of the norm.

To describe the application of these norm equivalences, let us take a single operator and consider $h' \le h$, for example. Let $\Phi_{j'}$ be a wavelet basis for the traces of $V_{h'}$ on the boundary Γ. Then, we define the matrix $\mathbf{V}_{h',h} := \langle\mathbf{P}_0(\mathbf{V}\Psi_j), \Phi_{j'}\rangle$, where $h' = 2^{-j'}$ and $h = 2^{-j}$, which is nothing but a part of the Galerkin matrix for the operator $\mathbf{V}$ together with the diagonal matrix $\mathbf{D}_{h',h'}^{-2s} = \operatorname{diag}(2^{-2ls})$. For instance, we compute the $H^{1/2}(\Gamma)$-norm by setting $s = 1/2$ and obtain

$$\|Q_j\mathbf{P}_0(\mathbf{V}\Psi_j)\|_{H^{1/2}(\Gamma)}^2 \sim \mathbf{c}_j^T\mathbf{V}_{h',h}^T\mathbf{D}_{h',h'}^{-1}\mathbf{V}_{h',h}\mathbf{c}_j\,.$$

This means that the preconditioner defined in the previous section is of the form $\mathbf{D}_hu = \Psi_j\mathbf{D}_{h,h}^{-1}\langle\Psi_j, u\rangle$. The other parts of the system matrices are derived similarly. For the combination of finite element spaces and the use of the Bramble–Pasciak–Xu (BPX) preconditioner for the computation of the $H^{-1}(\Omega)$-inner products and wavelet bases on the boundary we need to apply the wavelet transform (we refer to [28] and [29] for further details). We would like to remark that the size of the matrix $\mathbf{V}_{h',h}^T\mathbf{D}_{h',h'}^{-1}\mathbf{V}_{h',h}$ is already $\sim 2^{jn} \times 2^{jn}$ and can be sparsified by wavelet matrix compression.

Remark. Wavelets on surfaces are defined in, e.g., [17] and [18]. The first construction in [17] seems to be simpler than the final one in [18]. Since in [17] the duality is based on a modified inner product $\langle\cdot,\cdot\rangle$ defined via the local parametrizations, a comment about the use of this construction is required for the correct utilization of these bases computing $H^{1/2}(\Gamma)$-inner products according to (6.2). Instead of using the inner products $\langle f,\psi_k^j\rangle$, one has to use the modified inner product $\langle\cdot,\cdot\rangle$, whereas for the computation of the $H^{-1/2}(\Gamma)$-inner products one has to use the canonical inner product $\langle\cdot,\cdot\rangle$.

Remark. A major restriction of the present approach is that the traces along the boundary Γ of the spaces V_h must also admit a multiresolution analysis. This restriction can be removed by introducing an additional unknown $\mu\in H^{1/2}(\Gamma)$ for the traces of u along Γ like in [10]. Here μ will be discretized by wavelet bases. This means that the coupling is defined by a slightly weaker condition; see [10]. The generalization of the present method to this case is rather straightforward.

7. Numerical results. In this section, we show how to compute the corresponding system matrices and right-hand sides for the minimization of the functional $\mathbf{J}_3$ and present some numerical results. The energy space of $\mathbf{J}_3$ is $\mathbf{X}_3=[L^2(\Omega)]^2\times H^1_{\Gamma_D}(\Omega)\times H_0^{-1/2}(\Gamma)$. For a conforming discretization this requires only $\boldsymbol{\zeta}_h\in X_h\subset[L^2(\Omega)]^2$, which, for instance, allows the functions in X_h to be discontinuous. In our tests we use both piecewise constant functions and continuous piecewise linear functions subordinated to the triangulation $\mathcal{T}_h$. The trial functions $u_h\in V_h\subset H^1_{\Gamma_D}(\Omega)$ are chosen piecewise linear and continuous, and $\sigma_h\in S_h\subset H^{-1/2}(\Gamma)$ consists of piecewise constant functions.

It is worthwhile describing in more detail the present realization of that least squares method. Abbreviating

$$g(\boldsymbol{\theta}_h,u_h,\sigma_h)\;:=\;\operatorname{div}\boldsymbol{\theta}_h-\delta_\Gamma\otimes(\boldsymbol{\theta}_h\cdot\mathbf{n})-\left(\delta_\Gamma\otimes\left[\mathbf{W}u_h-(\tfrac12\mathbf{I}-\mathbf{K}')\sigma_h\right]\right),$$

the discrete bilinear form $B_3^h:\mathbf{X}_3^h\times\mathbf{X}_3^h\to\mathbb{R}$ is defined by

$$\begin{aligned}B_3^h\big((\boldsymbol{\theta}_h,u_h,\sigma_h),(\boldsymbol{\zeta}_h,v_h,\tau_h)\big)\;&:=\;(\mathbf{a}\nabla u_h-\boldsymbol{\theta}_h,\mathbf{a}\nabla v_h-\boldsymbol{\zeta}_h)_{[L^2(\Omega)]^2}\\&+\big(\mathbf{B}_hP_h^*\,g(\boldsymbol{\theta}_h,u_h,\sigma_h),P_h^*\,g(\boldsymbol{\zeta}_h,v_h,\tau_h)\big)_{L^2(\Omega)}\\+\langle\mathbf{D}_hQ_h^*\,\mathbf{P}_0\left[\left(\tfrac12\mathbf{I}-\mathbf{K}\right)u_h+\mathbf{V}(\boldsymbol{\theta}_h\cdot\mathbf{n})\right],&\,Q_h^*\,\mathbf{P}_0\left[\left(\tfrac12\mathbf{I}-\mathbf{K}\right)v_h+\mathbf{V}(\boldsymbol{\zeta}_h\cdot\mathbf{n})\right]\rangle_{L^2(\Gamma)},\end{aligned}$$

and the linear functional $\mathbf{G}_3^h:\mathbf{X}_3^h\to\mathbb{R}$ is given by

$$\mathbf{G}_3^h(\boldsymbol{\zeta}_h,v_h,\tau_h)\;:=\;\big(P_h^*\,f,P_h^*\,g(\boldsymbol{\zeta}_h,v_h,\tau_h)\big)_{L^2(\Omega)}.$$

Let us denote by Φ_h the vector of basis functions $\phi_k^h\in V_h$, Θ_h consists of the basis functions in X_h, and Λ_h indicates the vector of basis functions in S_h. To build up the system matrix and the right-hand side for the corresponding least squares method, we require the matrices and vectors

$$\begin{aligned}\mathbf{A}_h\;&:=\;(\mathbf{a}\nabla\Phi_h,\nabla\Phi_h)_{[L^2(\Omega)]^2}, &\mathbf{F}_h\;&:=\;(\nabla\Phi_h,\Theta_h)_{[L^2(\Omega)]^2},\\\mathbf{G}_h\;&:=\;(\Theta_h,\Theta_h)_{[L^2(\Omega)]^2}, &\mathbf{f}_h\;&:=\;(f,\Phi_h)_{[L^2(\Omega)]^2},\end{aligned}$$

together with the matrices of basis functions belonging to the interface boundary

$$\begin{aligned}\mathbf{V}_h\;&:=\;\langle\mathbf{V}\Lambda_h,\Lambda_h\rangle, &\mathbf{K}_h\;&:=\;\langle\mathbf{K}\Phi_h,\Lambda_h\rangle,\\\mathbf{W}_h\;&:=\;\langle\mathbf{W}\Phi_h,\Phi_h\rangle, &\mathbf{I}_h\;&:=\;\langle\Phi_h,\Lambda_h\rangle.\end{aligned}$$

We use the matrices $\mathbf{C}_h$ to define the inner product in $H^{-1/2}(\Gamma)$ and $\mathbf{B}_h$ for the computation of the inner product in $H^{-1}(\Omega)$. We choose $\mathbf{B}_h$ as a BPX preconditioner [7] and $\mathbf{C}_h := (\operatorname{diag}\mathbf{V}_h)^{-1}$, where $\mathbf{V}_h = \langle \mathbf{V}\Psi_h, \Psi_h\rangle$, is given with respect to a wavelet basis Ψ_h of S_h. Then, the corresponding linear system for the present least squares method can be written in the following form:

$$\begin{aligned}&\left\{\begin{bmatrix}\mathbf{G}_h & -\mathbf{F}_h^T & \mathbf{0}\\ -\mathbf{F}_h & \mathbf{A}_h & \mathbf{0}\\ \mathbf{0} & \mathbf{0} & \mathbf{0}\end{bmatrix} + \begin{bmatrix}\mathbf{F}_h^T\\ \mathbf{W}_h\\ (\mathbf{K}_h - \frac{1}{2}\mathbf{I}_h)\end{bmatrix}\mathbf{B}_h\begin{bmatrix}\mathbf{F}_h & \mathbf{W}_h & (\mathbf{K}_h - \frac{1}{2}\mathbf{I}_h)^T\end{bmatrix}\right.\\ &\quad\left. + \begin{bmatrix}\mathbf{0}\\ (\frac{1}{2}\mathbf{I}_h - \mathbf{K}_h)^T\\ \mathbf{V}_h\end{bmatrix}\mathbf{C}_h\begin{bmatrix}\mathbf{0} & (\frac{1}{2}\mathbf{I}_h - \mathbf{K}_h) & \mathbf{V}_h\end{bmatrix}\right\}\begin{bmatrix}\boldsymbol{\theta}_h\\ \mathbf{u}_h\\ \boldsymbol{\sigma}_h\end{bmatrix} = -\begin{bmatrix}\mathbf{F}_h\\ \mathbf{W}_h\\ (\mathbf{K}_h - \frac{1}{2}\mathbf{I}_h)\end{bmatrix}\mathbf{B}_h\mathbf{f}_h.\end{aligned}$$

This system is preconditioned by the operator $\operatorname{diag}(\mathbf{Id}, \mathbf{B}_h, \mathbf{C}_h)$. We remark that $P_h^*\big(\operatorname{div}\boldsymbol{\zeta}_h - \delta_\Gamma \otimes (\boldsymbol{\zeta}_h \cdot \mathbf{n})\big)$ is computed from the inner products

$$\big(\operatorname{div}\boldsymbol{\zeta}_h - \delta_\Gamma \otimes (\boldsymbol{\zeta}_h \cdot \mathbf{n}), v_h\big)_{L^2(\Omega)} = -\,(\boldsymbol{\zeta}_h, \nabla v_h)_{[L^2(\Omega)]^2} \quad \forall\, v_h \in V_h\,.$$

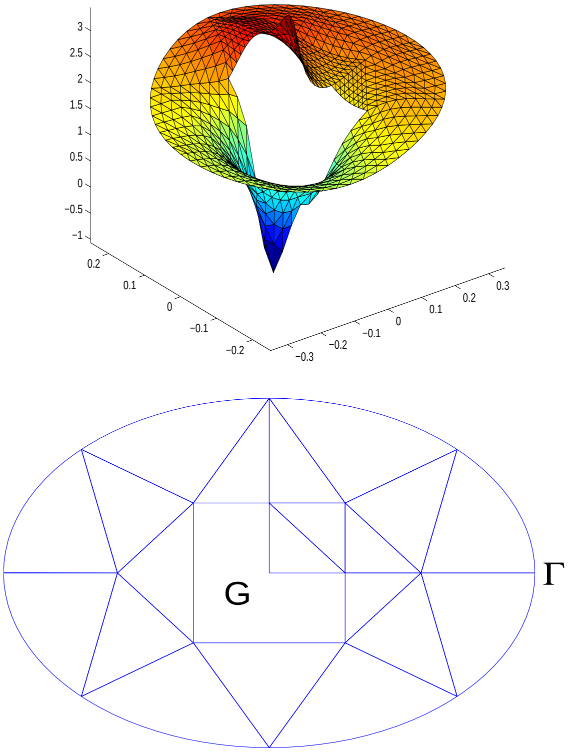

FIG. 7.1. *The solution u and the initial triangulation of Ω.*

For the numerical tests we choose G as the annulus outside the two dimensional L-shape $\left[-\frac{1}{10}, \frac{1}{10}\right]^2 \setminus \left[0, \frac{1}{10}\right]^2$ and inside an ellipse. Similarly to [29], we consider a

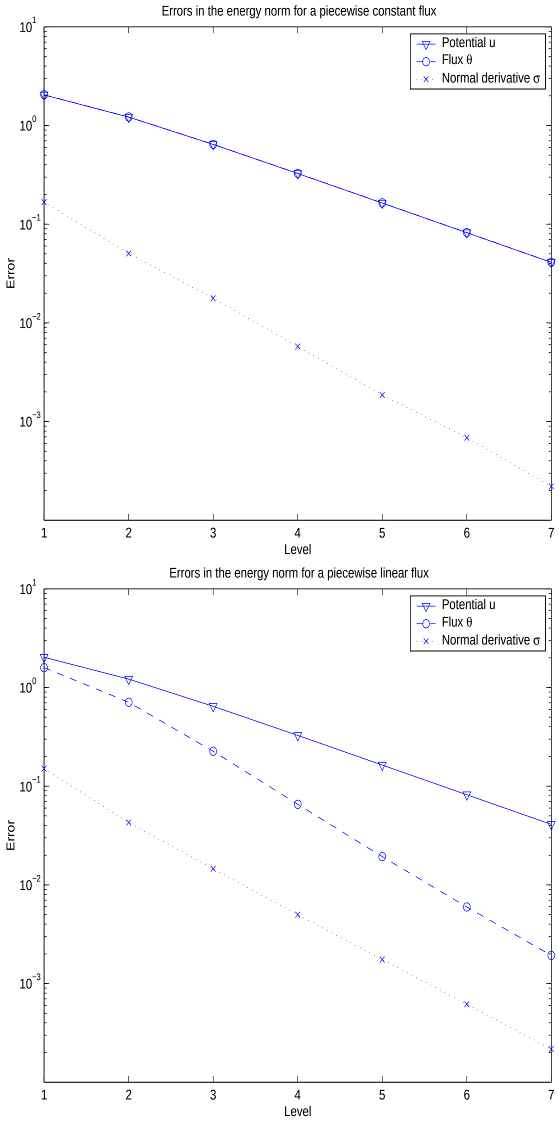

FIG. 7.2. *Error in the energy norm.*

problem for which an analytical solution is known. We split

$$u(x,y) \;=\; u_1(x,y) \;+\; u_2(x,y) \;\in\; C^2\big(\mathbb{R}^2 \setminus \left[\begin{smallmatrix}-1/20\\ 0\end{smallmatrix}\right]\big)$$

with the harmonic function

$$u_1(x,y) \;=\; \frac{1}{100}\cdot\frac{(x+\frac{1}{20})+y}{(x+\frac{1}{20})^2+y^2} \;\in\; C^\infty\big(\mathbb{R}^2 \setminus \left[\begin{smallmatrix}-1/20\\ 0\end{smallmatrix}\right]\big)$$

and the nonharmonic function $u_2 \in C^2(\mathbb{R}^2)$ defined by

$$u_2(x,y) \;=\; 2 + \begin{cases} \left(\frac{x^2}{0.3^2}+\frac{y^2}{0.2^2}-1\right)^3 & \text{if } \frac{x^2}{0.3^2}+\frac{y^2}{0.2^2} \le 1,\\ 0 & \text{if } \frac{x^2}{0.3^2}+\frac{y^2}{0.2^2} > 1. \end{cases}$$

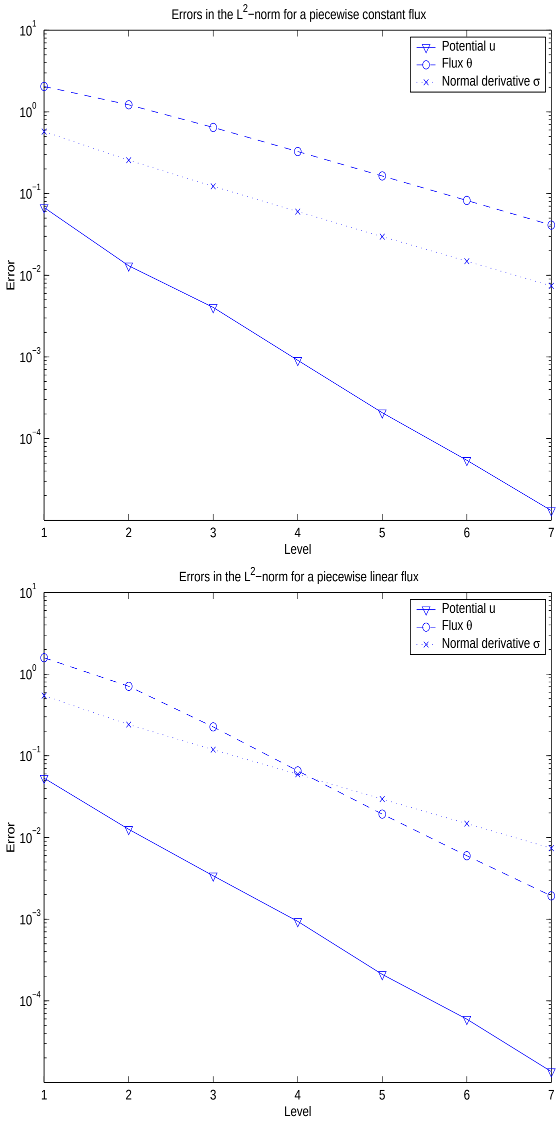

FIG. 7.3. *Error in L^2-norms.*

The function $f := -\triangle u_2 \in C^1(\mathbb{R})$ is supported in the ellipse with semiaxes 0.3 and 0.2. Thus, setting $g := u|_{\partial G}$, we obtain a boundary value problem with nonhomogeneous Dirichlet data at the boundary $\Gamma_D = \partial G$. The interface boundary Γ is chosen as the boundary of the ellipse with semiaxes 0.35 and 0.25. The solution u and the initial triangulation using curved triangles is shown in Figure 7.1.

We depict in Figure 7.2 the errors with respect to the energy norm using piecewise constant and continuous piecewise linear functions, respectively, for the approximation of the flux $\boldsymbol{\theta}_h$. In Figure 7.3 one finds the corresponding errors with respect to the L^2-norms. Note that we use double logarithmic scales.

In the previous sections, we have already proved convergence estimates with respect to the energy norm. The numerical experiments confirm the claimed convergence rate $\mathcal{O}(h)$. This does not include L^2-estimates for the potential u. However, it can be observed that the potential u converges in L^2 with the order h^2, which is optimal for piecewise linear functions. The measured convergence rate for flux in L^2 is h^1 for the piecewise constant approximation. With respect to continuous piecewise linear functions, it seems to be between $h^{3/2}$ and h^2. However, we have not proved these types of convergence rates. But we mention that the application of the Aubin–Nitzsche trick is limited due to the concave vertices of Ω. Obviously, we observe a better approximation of the flux when using piecewise linear functions.

It is confirmed by our experience that the expenses for the boundary integral part is small compared to the finite element part if the integral equations are treated by fast methods. Therefore, the efficiency of the present algorithm is comparable to the efficiency of corresponding finite element least squares methods for interior boundary value problems. Wavelet methods are proved to be an efficient tool for the treatment of boundary integral operators in the coupling. Our approach requires the same boundary element matrices as the FEM-BEM coupling for the second order system.

A FINITE VOLUME SCHEME FOR A NONCOERCIVE ELLIPTIC EQUATION WITH MEASURE DATA*

JÉRÔME DRONIOU[†], THIERRY GALLOUËT[‡], AND RAPHAÈLE HERBIN[‡]

Abstract. We show here the convergence of the finite volume approximate solutions of a convection-diffusion equation to a weak solution, without the usual coercitivity assumption on the elliptic operator and with weak regularity assumptions on the data. Numerical experiments are performed to obtain some rates of convergence in two and three space dimensions.

Key words. noncoercive elliptic equations, measure data, finite volume

1. Introduction.

The scope of this work is the discretization by the cell-centered finite volume method of convection-diffusion problems on general structured or nonstructured grids. Let Ω be a polygonal (or polyhedral) open subset of $\mathbb{R}^d$ ($d = 2$ or 3); the problem under study can be written as

$$\left\{\begin{array}{ll} -\Delta u + \operatorname{div}(\mathbf{v}u) + bu = \mu & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{array}\right. \tag{1}$$

with the following hypotheses on the data:

$$\begin{gathered} \mathbf{v} \in (C(\overline{\Omega}))^d, \\ b \in L^2(\Omega),\ b \geq 0 \quad \text{a.e. on } \Omega, \\ \mu \in M(\overline{\Omega}), \end{gathered} \tag{2}$$

where $M(\overline{\Omega}) = (C(\overline{\Omega}))'$ is the dual space of $C(\overline{\Omega})$, which may also be identified with the set of bounded measures on $\overline{\Omega}$. In what follows, we shall consider the usual infinity norm on $C(\overline{\Omega})$, and we shall denote by $||\cdot||_{M(\overline{\Omega})}$ its dual norm on $M(\overline{\Omega})$.

Our purpose is to prove the convergence of the cell-centered finite volume scheme for the discretization of problem (1). Cell-centered schemes for convection-diffusion equations using rectangular, triangular, or Voronoï grids have been analyzed in a number of papers, including [27], [18], [23], [26], [29], and [8]. The analysis which we develop here uses some of the tools which were developed in [14], [20], [15], and [19]. In [15], a convergence result without any assumption of regularity of the solution is proved. An approximate gradient is constructed in [7]. Noncoercive elliptic equations with regular H^{-1} right-hand sides were also recently studied [12]. Finally, a thorough study of finite volume schemes for linear or nonlinear elliptic, parabolic, and hyperbolic equations may be found in [14], to which we refer for further details. The discretization grids which are considered here and in these latter works consist of

polygonal (or polyhedral) control volumes satisfying adequate geometrical conditions (which are stated in what follows) and not necessarily ordered in a Cartesian grid.

Let us remark that the analysis which is developed here still holds for equations of the type

$$-\mathrm{div}\big(k(x)\nabla u(x)\big)+\mathrm{div}\big(\mathbf{v}(x)\,u(x)\big)+b(x)u(x)=f(x),\quad x\in\Omega, \tag{3}$$

with the following hypotheses on k:

$$\begin{aligned}&k \text{ is a piecewise } C^1 \text{ function from } \overline{\Omega} \text{ to } \mathbb{R};\\&\text{there exists } k_0\in\mathbb{R}_+^* \text{ such that } k(x)\geq k_0 \text{ for almost every } x\in\Omega.\end{aligned}\tag{4}$$

For the sake of the simplicity of notation, we prefer to deal with the Laplace operator here, but we shall point out the modifications which are required if the operator div$(k\nabla.)$ is considered instead: see Remarks 2.2, 2.4, and 2.6. If now k is a tensor satisfying the hypotheses

$$\begin{aligned}&k \text{ is a piecewise } C^1 \text{ function from } \overline{\Omega} \text{ to } \mathbb{R}^{d\times d},\\&\text{for all } x\in\overline{\Omega},\ k(x) \text{ is a symmetric matrix},\\&\text{there exists } k_0\in\mathbb{R}_+^* \text{ such that } k(x)\xi\cdot\xi\geq k_0\\&\qquad\text{for almost every } x\in\Omega \text{ and for all } \xi\in\mathbb{R}^d,\end{aligned}\tag{5}$$

then one may still write the finite volume scheme and obtain some error estimates in the regular case, but the assumptions on the mesh have to be modified; see [20], [24], [25], and [8]. However, if the mesh is Cartesian and if for all $x\in\overline{\Omega}$ the matrix $k(x)$ is diagonal, then the mesh is "aligned" with the grid, and the analysis is similar to the (nonconstant) scalar case of (3).

The originality of the present work with respect to the above-cited works is threefold: first, the elliptic operator associated with the convection-diffusion equation is not assumed to be coercive; second, the convection velocity $\mathbf{v}$ is assumed only to be continuous (it was assumed to be C^1 in previous works); third, the right-hand side μ is supposed only to be a Radon measure.

In the next section, the finite volume scheme for the discretization of (1) is presented, along with the admissible meshes. We then state the main convergence theorem of this paper (Theorem 2.1), along with some preliminary technical results similar to those used in [14], [20], [15], the proof of which is given in an appendix. Section 3 is devoted to a priori estimates on the approximate solutions (existence is not proved at this stage), which will be needed in order to obtain compactness results, and which also yield the existence and uniqueness of the approximate solution. The proof of Theorem 2.1, that is, the proof of the convergence of the approximate solutions to the weak solution of (1), is then given in section 4. Section 5 presents a modified finite volume scheme, where the measure data whose support is on the edges of the mesh are taken into account through a jump of the flux between two neighboring cells; comparing this scheme to the scheme of section 2, the convergence result is easy to obtain. Finally, in section 6 we present some numerical results in two and three space dimensions, using Cartesian or unstructured triangular meshes (in two dimensions), and a spherical mesh in the case of a spherical geometry. These results allow us to derive some rates of convergence of the method, even though no error estimate is known theoretically.

FIG. 1. *Notations for an admissible mesh.*

2. Conservative finite volume discretization and convergence result.

DEFINITION 2.1. *An admissible mesh of Ω, denoted by $\mathcal{M}$, is given by a finite partition $\mathcal{T}$ of Ω in polygonal (or polyhedral) convex sets (the "control volumes"), by a finite family $\mathcal{E}$ of disjoint subsets of $\overline{\Omega}$ contained in affine hyperplanes (the "edges"), and by a family $\mathcal{P} = (x_K)_{K\in\mathcal{T}}$ of points in Ω such that*

(i) *each $\sigma \in \mathcal{E}$ is a nonempty open subset of ∂K for some $K \in \mathcal{T}$;*

(ii) *by denoting $\mathcal{E}_K = \{\sigma \in \mathcal{E} \mid \sigma \subset \partial K\}$, one has $\partial K = \cup_{\sigma\in\mathcal{E}_K} \overline{\sigma}$ for all $K \in \mathcal{T}$;*

(iii) *for all $K \neq L$ in $\mathcal{T}$, either the $(d-1)$-dimensional measure of $\overline{K} \cap \overline{L}$ is null, or $\overline{K} \cap \overline{L} = \overline{\sigma}$ for some $\sigma \in \mathcal{E}$, which we denote then by $\sigma = K|L$;*

(iv) *for all $K \in \mathcal{T}$, x_K is in the interior of K;*

(v) *for all $\sigma = K|L \in \mathcal{E}$, the line (x_K, x_L) intersects and is orthogonal to σ;*

(vi) *for all $\sigma \in \mathcal{E}$, $\sigma \subset \partial\Omega \cap \partial K$, the line which is orthogonal to σ and going through x_K, intersects σ.*

Remark 2.1 (other admissible meshes). Note that property (v) in the above definition is required in order to obtain a consistent discretization of the normal fluxes over the boundary of the control domains when using the two-point finite difference scheme to discretize the normal flux. In fact, the above definition of an admissible mesh may be extended to geometries of Ω other than a polygon or a polyhedron. For instance, if $\Omega = \{x \in \mathbb{R}^d;\ |x| \leq r\}$ is a spherical ball of radius r, then a natural mesh is defined by the control volumes $K_0 = \{x \in \mathbb{R}^d;\ |x| \leq r_{1/2}\}$ and, for $i = 1, N$, $K_i = \{x \in \mathbb{R}^d;\ r_{i-1/2} \leq |x| \leq r_{i+1/2}\}$, where $(r_{i+1/2})_{i=1,N} \subset (0, r]$ is a given increasing sequence such that $r_{N+1/2} = r$. Let $x_0 = 0$ and, for $i = 1, \ldots, N$, $r_i \in (r_{i-1/2}, r_{i+1/2})$; then a discretization of the normal diffusive flux $\nabla u \cdot \mathbf{n}$ (where $\mathbf{n}$ is the outward normal unit vector) over the sphere $\{x \in \mathbb{R}^d;\ |x| = r_{i+1/2}\}$ by the two-point scheme $\frac{u_{i+1}-u_i}{r_{i+1}-r_i}$ is clearly consistent if the solution u to (1) depends only on r. Moreover, if $r_{i+1/2} = \frac{1}{2}(r_{i+1} - r_i)$, it is consistent of order 2. Hence this class of spherical discretizations is clearly admissible for the analysis that follows.

The size of the mesh is then defined by $\mathrm{size}(\mathcal{M}) = \sup_{K\in\mathcal{T}} \mathrm{diam}(K)$. We denote by $\mathrm{meas}(K)$ the Lebesgue measure of $K \in \mathcal{T}$. The unit normal to $\sigma \in \mathcal{E}_K$ outward to K is denoted by $\mathbf{n}_{K,\sigma}$. An example of interior neighboring cells and of a boundary cell is given in Figure 1, along with notation.

We define $\mathcal{E}_{\rm int} = \{\sigma \in \mathcal{E} \mid \sigma \not\subset \partial\Omega\}$ and $\mathcal{E}_{\rm ext} = \mathcal{E} \backslash \mathcal{E}_{\rm int}$. If $\sigma \in \mathcal{E}$, $\mathrm{meas}(\sigma)$ is the

$(d-1)$-dimensional measure of σ; if $\sigma = K|L \in \mathcal{E}_{\text{int}}$, d_σ is the distance between the points (x_K, x_L), and $d_{K,\sigma}$ denotes the distance between x_K and σ; if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$, $d_\sigma = d_{K,\sigma}$ is the distance between x_K and σ. The transmissivity through an edge σ is

$$\tau_\sigma = \frac{\text{meas}(\sigma)}{d_\sigma}.$$

Within the integrals, the letter λ (resp., γ) stands for the d- (resp., $(d-1)$)-dimensional measure on the domain Ω (resp., on the edges of the mesh). Note that both measures are denoted by "meas" when applied to a control volume or an edge.

We shall naturally identify the set $\mathbb{R}^{\text{Card}(\mathcal{T})}$ with the set $X(\mathcal{T})$ of functions defined a.e. on Ω and constant on each control volume $K \in \mathcal{T}$.

Remark 2.2. In the case of the operator $\text{div}(k\nabla.)$, which is considered in (3), where k is a function from $\overline{\Omega}$ to $\mathbb{R}$ or $\mathbb{R}^{d\times d}$ which satisfies (4) or (5), admissible meshes must satisfy the following additional condition:

(vii) For any $K \in \mathcal{T}$, the restriction $k|_K$ of the function k to any given control volume K belongs to $C^1(\overline{K})$.

Furthermore if k is a piecewise C^1 function from $\overline{\Omega}$ to $\mathbb{R}^{d\times d}$, the orthogonality conditions (iv) and (v) have to be modified into the following:

(iv)$'$ For any $K \in \mathcal{T}$, let k_K denote the mean value of k on K, that is,

$$k_K = \frac{1}{\text{meas}(K)} \int_K k d\lambda. \tag{6}$$

The set $\mathcal{T}$ is such that there exists a family of points

$$\mathcal{P} = (x_K)_{K\in\mathcal{T}} \quad \text{such that} \quad x_K = \cap_{\sigma\in\mathcal{E}_K} \mathcal{D}_{K,\sigma,k} \in \overline{K},$$

where $\mathcal{D}_{K,\sigma,k}$ is a straight line perpendicular to σ with respect to the scalar product induced by k_K^{-1} such that $\mathcal{D}_{K,\sigma,k} \cap \sigma = \mathcal{D}_{L,\sigma,k} \cap \sigma \neq \emptyset$ if $\sigma = K|L$. Furthermore, if $\sigma = K|L$, let $y_\sigma = \mathcal{D}_{K,\sigma,k} \cap \sigma$ $(= \mathcal{D}_{L,\sigma,k} \cap \sigma)$ and assume that $x_K \neq x_L$.

(v)$'$ For any $\sigma \in \mathcal{E}_{\text{ext}}$, let K be the control volume such that $\sigma \in \mathcal{E}_K$, and let $\mathcal{D}_{K,\sigma,k}$ be the straight line going through x_K and orthogonal to σ with respect to the scalar product induced by k_K^{-1}; then there exists $y_\sigma \in \sigma \cap \mathcal{D}_{K,\sigma,k}$.

If $\mathcal{M}$ is an admissible mesh, and under hypothesis (2), we can define the finite volume discretization of (1).

By denoting, for $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$,

$$b_K = \frac{1}{\text{meas}(K)} \int_K b d\lambda \quad \text{and} \quad v_{K,\sigma} = \int_\sigma \mathbf{v}\cdot\mathbf{n}_{K,\sigma}\, d\gamma, \tag{7}$$

the scheme is defined by

$$\text{for all } \ K \in \mathcal{T}, \ \sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} + \sum_{\sigma\in\mathcal{E}_K} v_{K,\sigma} u_{\sigma,+} + \text{meas}(K) b_K u_K = \mu(K), \tag{8}$$

$$\begin{aligned} &\text{for all } \ \sigma = K|L \in \mathcal{E}_{\text{int}}, \quad F_{K,\sigma} = -\tau_\sigma(u_L - u_K), \\ &\text{for all } \ \sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K, \qquad F_{K,\sigma} = \tau_\sigma u_K, \end{aligned} \tag{9}$$

$$\begin{aligned} &\text{for all } \ \sigma = K|L \in \mathcal{E}_{\text{int}}\,, \quad u_{\sigma,+} = u_K \ \text{ if } \ v_{K,\sigma} \geq 0, \quad u_{\sigma,+} = u_L \ \text{ otherwise}, \\ &\text{for all } \ \sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K\,, \quad\ u_{\sigma,+} = u_K \ \text{ if } \ v_{K,\sigma} \geq 0, \quad u_{\sigma,+} = 0 \ \text{ otherwise}. \end{aligned} \tag{10}$$

Equations (8)–(10) form a linear system in $(u_K)_{K\in\mathcal{T}}$ of size $\mathrm{Card}(\mathcal{T})$. Notice that this scheme is conservative in the sense that if $\sigma = K|L$, then $F_{K,\sigma} = -F_{L,\sigma}$ and $v_{K,\sigma} = -v_{L,\sigma}$.

Remark 2.3. The approximation (10) of the convective flux is the classical upwind scheme, which we choose here because it ensures both the existence of a solution to the scheme and the maximum principle without any condition on the size of the mesh. If, instead of the upwind scheme, we used the central difference scheme, then we would need a condition on the size of the mesh in order to have the existence of a solution to the scheme and in order for the maximum principle to hold. However, when the size of the mesh tends to 0, the centered scheme may also be shown to converge. The upwind scheme is often preferred in applications because of its robustness on coarse meshes.

Also note that if $v_{K,\sigma} = 0$, for some $\sigma = K|L$, for example, then (10) does not determine $u_{\sigma,+}$ uniquely since one may take either $u_{\sigma,+} = u_K$ (since $v_{K,\sigma} \geq 0$) or $u_{\sigma,+} = u_L$ (since $v_{L,\sigma} = -v_{K,\sigma} = 0 \geq 0$). However, this is no real problem since $u_{\sigma,+}$ always appears multiplied by $v_{K,\sigma}$ or $v_{L,\sigma}$ and thus, if $v_{K,\sigma} = 0$, the value of $u_{\sigma,+}$ does not matter. (One can, for example, reduce the second sum of (8) to the $\sigma \in \mathcal{E}_K$ such that $v_{K,\sigma} \neq 0$.)

Remark 2.4. In the case of a nonconstant diffusion coefficient as in (3), where k is a function from Ω to $\mathbb{R}$ satisfying (4) or from Ω to $\mathbb{R}^{d\times d}$ satisfying (5), one considers admissible meshes satisfying (vii) of Remark 2.2 and, in the tensor case, also (iv)′ and (v)′ instead of (iv) and (v). For $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$, let

$$k_{K,\sigma} = \left| \frac{1}{\mathrm{meas}(K)} \int_K k\, d\lambda\, \mathbf{n}_{K,\sigma} \right| \tag{11}$$

(where $|\cdot|$ denotes the Euclidean norm). Note that, in the scalar case, this yields in fact $k_{K,\sigma} = \frac{1}{\mathrm{meas}(K)} \int_K k d\lambda$. The exact diffusion fluxes $k(x)\nabla u \cdot \mathbf{n}_{K,\sigma}$ on an edge σ of the mesh may then be approximated in a consistent way (see [14] and [24]) by replacing the formulae in (9) by

- internal edges:

$$F_{K,\sigma} = -\tau_\sigma(u_L - u_K) \quad \text{if } \sigma \in \mathcal{E}_{\mathrm{int}},\ \sigma = K|L, \tag{12}$$

where

$$\tau_\sigma = \mathrm{meas}(\sigma) \frac{k_{K,\sigma} k_{L,\sigma}}{k_{K,\sigma} d_{L,\sigma} + k_{L,\sigma} d_{K,\sigma}};$$

- boundary edges:

$$F_{K,\sigma} = -\tau_\sigma(u_\sigma - u_K) \quad \text{if } \sigma \in \mathcal{E}_{\mathrm{ext}} \text{ and } x_K \notin \sigma, \tag{13}$$

where

$$\tau_\sigma = \mathrm{meas}(\sigma) \frac{k_{K,\sigma}}{d_{K,\sigma}}\cdot$$

Let us now state our main result, which we shall prove in the following sections.

THEOREM 2.1. *If $\mathcal{M}$ is an admissible mesh, then there exists a unique solution to* (8)–(10). *Moreover, if $(\mathcal{M}_n)_{n\geq 1}$ is a sequence of admissible meshes such that there exists $\zeta > 0$ satisfying*

$$\textit{for all } n \geq 1, \textit{ for all } K \in \mathcal{T}_n, \textit{ for all } \sigma \in \mathcal{E}_K, \quad d_{K,\sigma} \geq \zeta d_\sigma,$$

and such that $\mathrm{size}(\mathcal{M}_n) \to 0$, *then, defining* $u_n \in X(\mathcal{T}_n)$ *as the solution of* (8)–(10) *for* $\mathcal{M} = \mathcal{M}_n$, $(u_n)_{n\geq 1}$ *converges to* u *in* $L^p(\Omega)$ *for all* $p \in [1, \frac{d}{d-2})$, *where* u *is the unique solution to* (1) *in the sense*

$$(14)\quad \left\{ \begin{array}{l} u \in \displaystyle\bigcap_{q<\frac{d}{d-1}} W_0^{1,q}(\Omega), \\ \displaystyle\int_\Omega \nabla u \cdot \nabla \varphi d\lambda - \int_\Omega u\mathbf{v} \cdot \nabla \varphi d\lambda + \int_\Omega bu\varphi d\lambda = \int_\Omega \varphi\, d\mu,\ \forall \varphi \in \bigcup_{s>d} W_0^{1,s}(\Omega), \end{array} \right.$$

where $\int_\Omega \varphi\, d\mu = \langle \mu, \varphi \rangle_{(C(\bar\Omega))', C(\bar\Omega)}$. *(We recall that* $W^{1,q}(\Omega)$ *is the set of functions which belong to* $L^q(\Omega)$ *and such that their derivatives are also in* $L^q(\Omega)$ *and* $W_0^{1,q}(\Omega) = \overline{C_c^\infty(\Omega)}^{W^{1,q}(\Omega)}$. *We also recall that* $W_0^{1,s}(\Omega) \subset C_0(\bar\Omega)$ *for* $s > d$.*)*

Remark 2.5. Notice that we do not suppose the existence and uniqueness of a solution to (14); we will prove both.

Remark 2.6. A convergence result still holds if a nonconstant piecewise C^1 diffusion scalar coefficient is considered, i.e., if k satisfies (4) and if (3) is discretized by the scheme (7), (8), (11)–(13). In fact, in the two-dimensional case, the proof follows the one given below in the case $k = Id$. In the three-dimensional case, however, the regularity of the solution to the dual problem (47), which is used in the proof of the uniqueness of a solution to (14) (see section 4) is not so clear. Hence in the 3D case, uniqueness of a solution to (14) is not known, and the convergence result of Theorem 2.1 still holds, but only up to a subsequence.

If one now considers the general tensor case, then some more restrictive assumptions are needed on the mesh in order to obtain consistency of the fluxes; see [14] and [24].

The proof of the existence and uniqueness of a solution to (8)–(10) is based on a priori estimates on the solutions to this problem, which are obtained with the discrete $W_0^{1,q}$ norm defined as follows.

Definition 2.2 (discrete $W^{1,q}$ norm). *If* $\mathcal{M}$ *is an admissible mesh,* $v_\mathcal{T} = (v_K)_{K\in\mathcal{T}} \in \mathbb{R}^{\mathrm{Card}(\mathcal{T})}$, *and* $1 \leq q < \infty$, *we define*

$$||v_\mathcal{T}||_{1,q,\mathcal{M}} = \left(\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma \left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma} \right)^q \right)^{\frac{1}{q}},$$

where $D_\sigma v_\mathcal{T} = |v_K - v_L|$ *if* $\sigma = K|L \in \mathcal{E}_{\mathrm{int}}$, *and* $D_\sigma v_\mathcal{T} = |v_K|$ *if* $\sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}_K$.

Let us now state the main a priori estimate, which will be proved in section 3. This estimate is crucial to proving the existence of a solution to (8)–(10), and also to obtaining the compactness properties on approximate solutions which will eventually yield the convergence result.

Theorem 2.2. *Let* $\mathcal{M}$ *be an admissible mesh and* $\zeta > 0$ *satisfy*

$$(15)\qquad \text{for all } K \in \mathcal{T} \text{ and all } \sigma \in \mathcal{E}_K, \quad d_{K,\sigma} \geq \zeta d_\sigma.$$

Then for all $q \in [1, \frac{d}{d-1})$ *there exists* $C > 0$ *depending only on* $(\Omega, \mathbf{v}, q, \zeta)$ *such that, if* $u_\mathcal{T} \in X(\mathcal{T})$ *is a solution to* (8)–(10), *then* $||u_\mathcal{T}||_{1,q,\mathcal{M}} \leq C||\mu||_{M(\overline{\Omega})}$.

In what follows, we shall use the following properties of the discrete $W_0^{1,q}$ norm.

Proposition 2.1 (discrete Poincaré inequality). *If* $1 \leq q \leq 2$, $\mathcal{M}$ *is an admissible mesh, and* $v_\mathcal{T} \in X(\mathcal{T})$, *then*

$$(16)\qquad ||v_\mathcal{T}||_{L^q(\Omega)} \leq \mathrm{diam}(\Omega)||v_\mathcal{T}||_{1,q,\mathcal{M}}.$$

PROPOSITION 2.2 (discrete Sobolev inequality). *Let $1 \le q \le 2$, $\mathcal{M}$ be an admissible mesh, and $\zeta > 0$ satisfy* (15). *Then, with $q^* = \frac{dq}{d-q}$ if $q < d$ and $q^* < \infty$ if $q = d = 2$, there exists $C > 0$ depending only on (Ω, q, q^*, ζ) such that, for all $v_{\mathcal{T}} \in X(\mathcal{T})$,*

$$||v_{\mathcal{T}}||_{L^{q^*}(\Omega)} \le C||v_{\mathcal{T}}||_{1,q,\mathcal{M}}.$$

In fact, it is easily seen that the above inequality also holds for any $r \le q^*$, that is,

$$||v_{\mathcal{T}}||_{L^r(\Omega)} \le C||v_{\mathcal{T}}||_{1,q,\mathcal{M}} \quad \text{for any } r \le q^*.$$

PROPOSITION 2.3 (discrete Rellich theorem). *Let $1 \le q \le 2$ and $\mathcal{M}$ be an admissible mesh. Then there exists $C > 0$ depending only on (Ω, q) such that, for all $h \in \mathbb{R}^d$ and all $v_{\mathcal{T}} \in X(\mathcal{T})$, denoting as $w_{\mathcal{T}}$ the extension of $v_{\mathcal{T}}$ to $\mathbb{R}^d$ by 0 outside Ω, we have*

$$\int_{\mathbb{R}^d} |w_{\mathcal{T}}(x+h) - w_{\mathcal{T}}(x)|^q \, d\lambda(x) \le |h|(|h| + C\text{size}(\mathcal{M}))^{q-1}||v_{\mathcal{T}}||^q_{1,q,\mathcal{M}}. \tag{17}$$

In particular, if $(\mathcal{M}_n)_{n\ge1}$ is a sequence of admissible meshes and $v_n \in X(\mathcal{T}_n)$ is such that $(||v_n||_{1,q,\mathcal{M}_n})_{n\ge1}$ is bounded, then $(v_n)_{n\ge1}$ is relatively compact in $L^q(\Omega)$.

PROPOSITION 2.4 (regularity of the limit). *Let $q \in (1, 2]$ and $(\mathcal{M}_n)_{n\ge1}$ be a sequence of admissible meshes such that* size$(\mathcal{M}_n) \to 0$. *If $v_n \in X(\mathcal{T}_n)$, $(||v_n||_{1,q,\mathcal{M}_n})_{n\ge1}$ is bounded, and $v_n \to v$ in $L^q(\Omega)$, then $v \in W_0^{1,q}(\Omega)$.*

These propositions are easy adaptations of similar results in [14] for the case $q = 2$ (see also [6] for Proposition 2.2 and [19] for Proposition 2.3). We sketch the proofs of these propositions in the appendix for the sake of completeness.

3. A priori estimates.

The aim of this section is to prove the discrete $W^{1,q}$ a priori estimate of Theorem 2.2, which is crucial in the proof of existence of the scheme and also in obtaining a compactness result which will allow us to prove the convergence of a sequence of approximate solutions (Theorem 2.1 and its proof in section 4).

Such a priori estimates were already used for the study of the finite volume approximation of nonlinear elliptic or parabolic equations; see, e.g., [15], [16]. However, in those previous works, the estimates were obtained in a discrete H^1 norm, in accord with the regularity of the solution of the continuous problem.

We prove here some a priori estimates on the solution to (8)–(10) in a discrete $W^{1,q}$ norm, since the solution to the continuous problem is in $W^{1,q}$. As in the continuous case, it is difficult to obtain an estimate on $u_{\mathcal{T}}$ itself. (Note that, in the continuous case, u is not allowed as a test function in (14).) Hence, as in [19], we shall obtain estimates on truncations of the approximate solutions, that is, the functions $T_k(u_{\mathcal{T}})$, where T_k is defined in Figure 2. However, in [19], we dealt only with the Laplace operator, whereas here we allow noncoercive convection-diffusion operators. Because of this noncoercivity, we shall need to start with some weaker estimates, namely, an estimate on $\ln(1 + |u_{\mathcal{T}}|)$, as was done in [9] in the continuous case (see also [13]). In order to obtain this estimate, we shall obtain some estimates on $S_k(u_{\mathcal{T}})$, where $S_k = Id - T_k$ is also defined in Figure 2 and section 3.2. Note that, in the diffusion dominated case, the operator becomes coercive, and the discrete $W^{1,q}$ estimate may be directly obtained from the estimates on $T_k(u_{\mathcal{T}})$, as in [19].

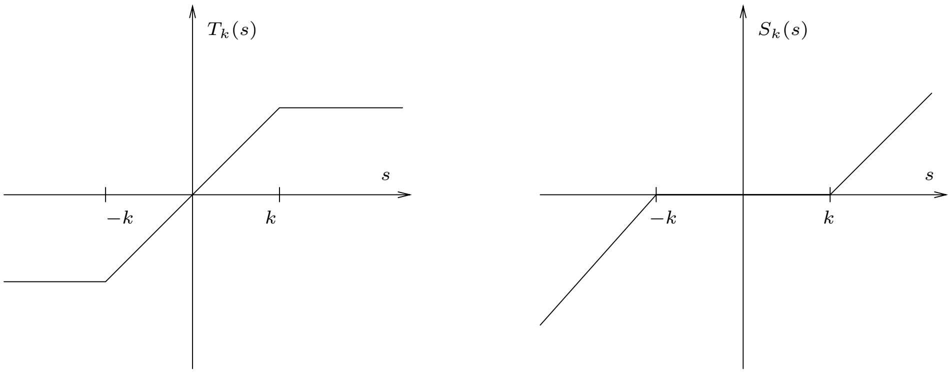

FIG. 2. *The functions T_k and S_k.*

Since the function T_k is bounded, the estimate on $T_k(u_{\mathcal{T}})$ is easy to obtain. The estimate on $S_k(u_{\mathcal{T}})$ is more tricky. The convective term is controlled through a bound of meas(E_k), where $E_k = \{|u_{\mathcal{T}}| > k\}$ (see Corollary 3.1), which is a consequence of an estimate on $\ln(1 + |u_{\mathcal{T}}|)$ (see Proposition 3.1).

Each of the estimates we present here has a continuous counterpart; see, for example, [2], [3] for estimates on nonlinear elliptic equations with measure data and [9], [10] for estimates on linear and nonlinear noncoercive variational elliptic problems. Mixing the techniques of [3] and [9] (or [10]), we can prove estimates (and an existence result) on solutions to linear or nonlinear noncoercive elliptic equations with measure data.

To obtain the estimates on the solutions to (8)–(10), we adapt to the discrete setting this mix of techniques of [3] and [9]. Thus, to make the following proofs easier to understand, we sketch, for each of the discrete estimates, the proof of the corresponding continuous estimate.

3.1. Estimate on $\ln(1 + |u_{\mathcal{T}}|)$.

PROPOSITION 3.1. *Let $\mathcal{M}$ be an admissible mesh. If $u_{\mathcal{T}} = (u_K)_{K\in\mathcal{T}}$ is a solution to* (8)–(10)*, then*

$$||\ln(1 + |u_{\mathcal{T}}|)||_{1,2,\mathcal{T}}^2 \leq 2||\mu||_{M(\overline{\Omega})} + d\text{meas}(\Omega)\,||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}^2 \tag{18}$$

(where $|\mathbf{v}|$ denotes the Euclidean norm of $\mathbf{v}$ in $\mathbb{R}^d$).

Before we prove Proposition 3.1, let us state an easy corollary, which is used in the proof of the estimate of Proposition 3.2.

COROLLARY 3.1. *Let $\mathcal{M}$ be an admissible mesh. If $u_{\mathcal{T}} = (u_K)_{K\in\mathcal{T}}$ is a solution to* (8)–(10) *and, for $k > 0$, $E_k = \{|u_{\mathcal{T}}| > k\}$, then there exists $C \in \mathbb{R}_+^*$ depending only on $(\Omega, \mathbf{v})$ such that*

$$\text{meas}(E_k) \leq \frac{C(1 + ||\mu||_{M(\overline{\Omega})})}{(\ln(1 + k))^2}.$$

Proof of Corollary 3.1. By Proposition 3.1, we get that

$$||\ln(1 + |u_{\mathcal{T}}|)||_{1,2,\mathcal{T}}^2 \leq (2 + d\text{meas}(\Omega)\,||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}^2)(1 + ||\mu||_{M(\overline{\Omega})}).$$

Therefore, using the discrete Poincaré inequality (Proposition 2.1), we get that there exists $C \in \mathbb{R}_+^*$ depending only on $(\Omega, \mathbf{v})$ such that

$$||\ln(1 + |u_{\mathcal{T}}|)||_{L^2(\Omega)}^2 \leq C(1 + ||\mu||_{M(\overline{\Omega})}).$$

Finally, since $\text{meas}(E_k) = \text{meas}(\{\ln(1+|u_{\mathcal{T}}|) \geq \ln(1+k)\})$, the Chebyshev inequality yields that $\text{meas}(E_k) \leq \frac{C(1+||\mu||_{M(\overline{\Omega})})}{(\ln(1+k))^2}$. □

Proof of Proposition 3.1. *Step* 0: Sketch of the proof in the continuous case. Let $\varphi(s) = \int_0^s \frac{dt}{(1+|t|)^2}$. Suppose that $\mu \in H^{-1}(\Omega) \cap L^1(\Omega)$, and let $u \in H_0^1(\Omega)$ be a variational solution of (1). Using $\varphi(u)$ as a test function in the equation satisfied by u, and since φ is bounded by 1, we find

$$\int_\Omega \nabla u \cdot \frac{\nabla u}{(1+|u|)^2}\,d\lambda + \int_\Omega bu\varphi(u)\,d\lambda \leq ||\mu||_{L^1(\Omega)} + ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \int_\Omega |u|\frac{|\nabla u|}{(1+|u|)^2}\,d\lambda$$
$$\leq C + C\int_\Omega \frac{|\nabla u|}{(1+|u|)}\,d\lambda,$$

where C depends only on $||\mu||_{L^1(\Omega)}$ and $\mathbf{v}$. Since $\nabla(\ln(1+|u|)) = \text{sgn}(u)\frac{\nabla u}{(1+|u|)}$ and $bu\varphi(u) \geq 0$ (b is nonnegative and $\varphi(s)$ has the same sign as s), we deduce that

$$||\,|\nabla(\ln(1+|u|))|\,||^2_{L^2(\Omega)} \leq C + C\text{meas}(\Omega)^{1/2}||\,|\nabla(\ln(1+|u|))|\,||_{L^2(\Omega)},$$

which gives an estimate on $||\,|\nabla(\ln(1+|u|))|\,||_{L^2(\Omega)}$ (and thus, by the Poincaré inequality, also on $||\ln(1+|u|)||_{L^2(\Omega)}$).

Step 1: Proof of a first discrete estimate. Let $\varphi(s) = \int_0^s \frac{dt}{(1+|t|)^2}$. Multiplying each equality of (8) by $\varphi(u_K)$ and summing on $K \in \mathcal{T}$, we have

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}\varphi(u_K) + \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} v_{K,\sigma}u_{\sigma,+}\varphi(u_K) + \sum_{K\in\mathcal{T}}\text{meas}(K)b_Ku_K\varphi(u_K)$$
$$= \sum_{K\in\mathcal{T}}\mu(K)\varphi(u_K). \tag{19}$$

Gathering by edges and using (9), we can write

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}\varphi(u_K) = \sum_{\sigma\in\mathcal{E}}\tau_\sigma(u_K-u_L)(\varphi(u_K)-\varphi(u_L)), \tag{20}$$

where we let $\sigma = K|L$ if $\sigma \in \mathcal{E}_{\text{int}}$, and $u_L = 0$ if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$.

By the conservativity of the fluxes, still gathering by edges, we find

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} v_{K,\sigma}u_{\sigma,+}\varphi(u_K) = \sum_{\sigma\in\mathcal{E}} u_{\sigma,+}v_{K,\sigma}(\varphi(u_K)-\varphi(u_L))$$

(recall that $u_L = 0$—so that $\varphi(u_L) = 0$—if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$). If $\sigma \in \mathcal{E}$, we denote $v_\sigma = |v_{K,\sigma}|$ for a $K \in \mathcal{T}$ such that $\sigma \in \mathcal{E}_K$ (the definition of v_σ does not depend on the choice of such a K) and $u_{\sigma,-}$ the downstream choice of u; i.e., $u_{\sigma,-}$ is such that $\{u_{\sigma,+}, u_{\sigma,-}\} = \{u_K, u_L\}$ (where $\sigma = K|L$ if $\sigma \in \mathcal{E}_{\text{int}}$ and $u_L = 0$ if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$).

Let $\sigma \in \mathcal{E}$; if $v_{K,\sigma} \geq 0$, then $u_{\sigma,+} = u_K$ and $u_{\sigma,-} = u_L$ so that $v_{K,\sigma}(\varphi(u_K) - \varphi(u_L)) = v_\sigma(\varphi(u_{\sigma,+}) - \varphi(u_{\sigma,-}))$; if $v_{K,\sigma} < 0$, then $u_{\sigma,+} = u_L$ and $u_{\sigma,-} = u_K$, which gives $v_{K,\sigma}(\varphi(u_K)-\varphi(u_L)) = -v_\sigma(\varphi(u_{\sigma,-})-\varphi(u_{\sigma,+})) = v_\sigma(\varphi(u_{\sigma,+})-\varphi(u_{\sigma,-}))$. Thus,

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} v_{K,\sigma}u_{\sigma,+}\varphi(u_K) = \sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,+})-\varphi(u_{\sigma,-})). \tag{21}$$

Since b is nonnegative and $\varphi(s)$ has the same sign as s,

$$\sum_{K\in\mathcal{T}}\text{meas}(K)b_Ku_K\varphi(u_K) \geq 0. \tag{22}$$

Since φ is bounded by 1 and $\mathcal{T}$ is a partition of Ω,

$$\left|\sum_{K\in\mathcal{T}} \mu(K)\varphi(u_K)\right| \le \sum_{K\in\mathcal{T}} |\mu(K)| \le |\mu|(\Omega) = ||\mu||_{M(\overline{\Omega})}. \tag{23}$$

Using (20), (21), (22), and (23) in (19), we get

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma(u_K - u_L)(\varphi(u_K) - \varphi(u_L)) \le ||\mu||_{M(\overline{\Omega})} + \sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})). \tag{24}$$

We now study each term of the last sum a little more precisely. We use the fact that φ is nondecreasing.

- If $u_{\sigma,+} \ge u_{\sigma,-}$ and $u_{\sigma,+} \ge 0$, then $\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}) \le 0$ and $u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})) \le 0$.
- If $u_{\sigma,+} \ge u_{\sigma,-}$ and $u_{\sigma,+} < 0$, then $0 > u_{\sigma,+} \ge u_{\sigma,-}$, so that $(u_{\sigma,+}, u_{\sigma,-})$ have the same sign and $|u_{\sigma,+}| \le |u_{\sigma,-}|$.
- If $u_{\sigma,+} < u_{\sigma,-}$ and $u_{\sigma,+} \ge 0$, then $0 \le u_{\sigma,+} < u_{\sigma,-}$, so that $(u_{\sigma,+}, u_{\sigma,-})$ have the same sign and $|u_{\sigma,+}| \le |u_{\sigma,-}|$.
- If $u_{\sigma,+} < u_{\sigma,-}$ and $u_{\sigma,+} < 0$, then $\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}) \ge 0$ and $u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})) \le 0$.

By defining $\mathcal{A} = \{\sigma \in \mathcal{E} \mid u_{\sigma,+} \ge u_{\sigma,-},\ u_{\sigma,+} < 0\} \cup \{\sigma \in \mathcal{E} \mid u_{\sigma,+} < u_{\sigma,-},\ u_{\sigma,+} \ge 0\}$, we notice that, for all $\sigma \in \mathcal{E}\backslash\mathcal{A}$, $v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})) \le 0$. This gives

$$\sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})) \le \sum_{\sigma\in\mathcal{A}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})).$$

As $v_\sigma \le \mathrm{meas}(\sigma)||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}$, we deduce, using the Cauchy–Schwarz inequality, that

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}))\\
&\le ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)|u_{\sigma,+}||\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})|\\
&\le ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \left(\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma) d_\sigma\right)^{\frac{1}{2}} \left(\sum_{\sigma\in\mathcal{A}} \tau_\sigma u_{\sigma,+}^2(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}))^2\right)^{\frac{1}{2}}.
\end{aligned}$$

However, $\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)d_\sigma \le \sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma)d_\sigma = d\mathrm{meas}(\Omega)$ and, if $\sigma \in \mathcal{A}$, $(u_{\sigma,+}, u_{\sigma,-})$ have the same sign and $|u_{\sigma,+}| \le |u_{\sigma,-}|$; thus, by Lemma 3.1 below and Young's inequality,

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}))\\
&\le (d\mathrm{meas}(\Omega))^{\frac{1}{2}}||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \left(\sum_{\sigma\in\mathcal{A}} \tau_\sigma(u_{\sigma,-} - u_{\sigma,+})(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+}))\right)^{\frac{1}{2}}\\
&\le \frac{1}{2} d\mathrm{meas}(\Omega)\,||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}^2 + \frac{1}{2}\sum_{\sigma\in\mathcal{E}} \tau_\sigma(u_{\sigma,-} - u_{\sigma,+})(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})).
\end{aligned}$$

For all $\sigma \in \mathcal{E}$, we have $\{u_{\sigma,+}, u_{\sigma,-}\} = \{u_K, u_L\}$, so that $(u_{\sigma,-} - u_{\sigma,+})(\varphi(u_{\sigma,-}) - \varphi(u_{\sigma,+})) = (u_K - u_L)(\varphi(u_K) - \varphi(u_L))$. Coming back to (24), we obtain

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma (u_K - u_L)(\varphi(u_K) - \varphi(u_L)) \le 2||\mu||_{M(\overline{\Omega})} + d\mathrm{meas}(\Omega)\, ||\, |\mathbf{v}|\, ||^2_{L^\infty(\Omega)}\,, \tag{25}$$

which concludes this step.

Step 2: Estimate on $\ln(1 + |u_\mathcal{T}|)$. We notice that, for all $s \in \mathbb{R}$, $\ln(1 + |s|) = \int_0^s \frac{\mathrm{sgn}(t)\,dt}{1+|t|}$. Thus, for all $(x, y) \in \mathbb{R}^2$, by the Cauchy–Schwarz inequality and since φ is nondecreasing,

$$\begin{aligned}(\ln(1 + |x|) - \ln(1 + |y|))^2 = \left(\int_y^x \frac{\mathrm{sgn}(t)\,dt}{1 + |t|}\right)^2 &\le |x - y| \left|\int_y^x \frac{dt}{(1 + |t|)^2}\right| \\ &= |x - y||\varphi(x) - \varphi(y)| = (x - y)(\varphi(x) - \varphi(y)).\end{aligned}$$

Using this upper bound and (25), we deduce the result of the proposition. □

Let us now state and prove the technical result that was used in Step 1 of the above proof.

Lemma 3.1. *Let* $\varphi(s) = \int_0^s \frac{dt}{(1+|t|)^2}$. *If* $(x, y) \in \mathbb{R}^2$ *have the same sign and* $|x| \le |y|$, *then*

$$x^2(\varphi(y) - \varphi(x))^2 \le (y - x)(\varphi(y) - \varphi(x)). \tag{26}$$

Proof of Lemma 3.1. Since φ is C^1-continuous on $\mathbb{R}$, there exists $\theta \in [x, y]$ such that $\varphi(y) - \varphi(x) = \varphi'(\theta)(y - x)$, so that, since φ is nondecreasing,

$$\begin{aligned}x^2(\varphi(y) - \varphi(x))^2 &\le \frac{x^2}{(1 + |\theta|)^2}|y - x|\,|\varphi(y) - \varphi(x)| \\ &\le \frac{x^2}{(1 + |\theta|)^2}(y - x)(\varphi(y) - \varphi(x)).\end{aligned}$$

But $|x| \le |y|$ and x and y have the same sign, so that, since $\theta \in [x, y]$, we have $|\theta| \ge |x|$, and (26) is thus a consequence of the previous inequality. □

3.2. Estimate on $||u_\mathcal{T}||_{1,q,\mathcal{M}}$.

We denote, for $k > 0$, $T_k(s) = \max(-k, \min(s, k))$ and $S_k(s) = s - T_k(s)$ (see Figure 2).

Proposition 3.2. *Let* $\mathcal{M}$ *be an admissible mesh and let* $\zeta > 0$ *be defined by* (15). *We suppose that* μ *satisfies* $||\mu||_{M(\overline{\Omega})} \le 1$. *Then there exists* $k_0 > 0$ *depending only on* $(\Omega, \mathbf{v}, \zeta)$ *and, for all* $m \in (1, 2)$, $C > 0$ *depending only on* $(\Omega, \mathbf{v}, m, \zeta)$ *such that, if* $u_\mathcal{T}$ *is a solution to* (8)–(10) *and* $\varphi_m(s) = \int_0^s \frac{dt}{(1+|t|)^m}$, *we have*

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma (S_{k_0}(u_K) - S_{k_0}(u_L))(\varphi_m(S_{k_0}(u_K)) - \varphi_m(S_{k_0}(u_L))) \le C \tag{27}$$

and

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma (T_{k_0}(u_K) - T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L))) \le C, \tag{28}$$

where we let $\sigma = K|L$ *if* $\sigma \in \mathcal{E}_{\mathrm{int}}$ *and* $u_L = 0$ *if* $\sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}_K$.

Remark 3.1. Problem (8)–(10) being linear, there is no loss of generality in the estimate if we consider measures of norm less than 1, as we will see in Theorem 2.2.

Proof of Proposition 3.2. *Step* 0: Sketch of the estimate in the continuous case. Suppose that $u \in H_0^1(\Omega)$ is a variational solution of (1) with $\mu \in H^{-1}(\Omega) \cap L^1(\Omega)$ satisfying $||\mu||_{L^1(\Omega)} \leq 1$, and take $\varphi_m(S_k(u))$ as a test function in (14). Using the fact that $bu\varphi_m(S_k(u)) \geq 0$ (b is nonnegative and $\varphi_m(s)$ and $S_k(s)$ have the same sign as s), that $\nabla(S_k(u)) = \nabla u$, where $\nabla(S_k(u)) \neq 0$, and that φ_m is bounded by $1/(m-1)$, we have

$$\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda \leq \frac{1}{m-1} + ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \int_\Omega |u| \frac{|\nabla(S_k(u))|}{(1+|S_k(u)|)^m}\,d\lambda.$$

However, $|u| \leq k + |S_k(u)|$ and $(1+|S_k(u)|)^{2m} \geq (1+|S_k(u)|)^m$, so that, by the Cauchy–Schwarz inequality,

$$\begin{aligned}\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda &\leq \frac{1}{m-1} + C_1 k \left(\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^{2m}}\,d\lambda\right)^{\frac{1}{2}}\\ &\quad + C_1 \int_\Omega \frac{|S_k(u)|}{(1+|S_k(u)|)^{\frac{m}{2}}} \frac{|\nabla(S_k(u))|}{(1+|S_k(u)|)^{\frac{m}{2}}}\,d\lambda\\ &\leq \frac{1}{m-1} + C_1 k \left(\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^{m}}\,d\lambda\right)^{\frac{1}{2}}\\ &\quad + C_1 ||\psi(S_k(u))||_{L^2(\Omega)} \left(\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^{m}}\,d\lambda\right)^{\frac{1}{2}},\end{aligned}\tag{29}$$

where C_1 depends only on $(\Omega, \mathbf{v})$ and $\psi(s) = \frac{|s|}{(1+|s|)^{\frac{m}{2}}}$.

Now, by the Hölder inequality and the Sobolev injection, and since $\psi(S_k(u)) = 0$ outside $E_k = \{|u| > k\}$, there exists $r > 2$ depending only on d, and C_2 depending only on (Ω, r) (notice that a dependence on Ω takes into account a dependence on d), such that

$$\begin{aligned}||\psi(S_k(u))||_{L^2(\Omega)} &\leq \mathrm{meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} ||\psi(S_k(u))||_{L^r(\Omega)}\\ &\leq C_2 \mathrm{meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} ||\,|\nabla(\psi(S_k(u)))|\,||_{L^2(\Omega)}.\end{aligned}\tag{30}$$

Since $|\psi'(s)| \leq \frac{1+\frac{m}{2}}{(1+|s|)^{\frac{m}{2}}} \leq \frac{2}{(1+|s|)^{\frac{m}{2}}}$, one has

$$||\,|\nabla(\psi(S_k(u)))|\,||_{L^2(\Omega)} \leq 2 \left(\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda\right)^{\frac{1}{2}}.\tag{31}$$

Gathering (29), (30), and (31), we find C_3 depending only on $(\Omega, \mathbf{v})$ such that

$$\begin{aligned}\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda &\leq \frac{C_1}{m-1} + C_1 k \left(\int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda\right)^{\frac{1}{2}}\\ &\quad + C_3 \mathrm{meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} \int_\Omega \frac{|\nabla(S_k(u))|^2}{(1+|S_k(u)|)^m}\,d\lambda.\end{aligned}\tag{32}$$

Thanks to a continuous equivalent of Corollary 3.1, there exists C_4 depending only on $(\Omega, \mathbf{v})$ such that $\mathrm{meas}(E_k) \leq \frac{C_4}{(\ln(1+k))^2}$. Thus, there exists $k_0 > 0$ depending only on

(C_4, C_3, r) (i.e., on $(\Omega, \mathbf{v})$) such that $C_3\text{meas}(E_{k_0})^{\frac{1}{2}-\frac{1}{r}} \le \frac{1}{2}$. Applying (32) to this k_0 gives

$$\int_\Omega \frac{|\nabla(S_{k_0}(u))|^2}{(1+|S_{k_0}(u)|)^m}\,d\lambda \le C_5,$$

where C_5 depends only on $(\Omega, \mathbf{v}, m)$, which is the continuous equivalent of (27).

The estimate on $T_{k_0}(u)$ is quite simple and well known (see [2]). Take $\varphi_m(T_{k_0}(u))$ as a test function in the equation satisfied by u; since $\nabla(T_{k_0}(u)) = 0$ outside $\{|u| \le k_0\}$ and $(1+|T_{k_0}(u)|)^{2m} \ge (1+|T_{k_0}(u)|)^m$, we find

$$\begin{aligned}\int_\Omega \frac{|\nabla(T_{k_0}(u))|^2}{(1+|T_{k_0}(u)|)^m}\,d\lambda &\le \frac{1}{m-1} + ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \int_{\{|u|\le k_0\}} |u| \frac{|\nabla(T_{k_0}(u))|}{(1+|T_{k_0}(u)|)^m}\,d\lambda \\ &\le \frac{1}{m-1} + ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} k_0 \text{meas}(\Omega)^{\frac{1}{2}} \left(\int_\Omega \frac{|\nabla(T_{k_0}(u))|^2}{(1+|T_{k_0}(u)|)^m}\,d\lambda\right)^{\frac{1}{2}}.\end{aligned}$$

This gives an estimate on $T_{k_0}(u)$ which is the continuous equivalent of (28).

Step 1: Estimate on $S_k(u_\mathcal{T})$. Let $\mathcal{M}$ be an admissible mesh, and take $u_\mathcal{T}$ as a solution of (8)–(10). Multiplying each equation of (8) by $\varphi_m(S_k(u_K))$, summing on $K \in \mathcal{T}$, and gathering by edges, we find

$$\begin{aligned}&\sum_{\sigma\in\mathcal{E}} \tau_\sigma(u_K - u_L)(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L))) + \sum_{K\in\mathcal{T}} \text{meas}(K) b_K u_K \varphi_m(S_k(u_K)) \\ &\quad = \sum_{K\in\mathcal{T}} \mu(K)\varphi_m(S_k(u_K)) - \sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L))).\end{aligned} \tag{33}$$

(Recall that if $\sigma \in \mathcal{E}_{\text{int}}$, we use the notation $\sigma = K|L$, and if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$, we set $u_L = 0$.)

The function φ_m is bounded by $\frac{1}{m-1}$, and $\mathcal{T}$ is a partition of Ω, so that

$$\left|\sum_{K\in\mathcal{T}} \mu(K)\varphi_m(S_k(u_K))\right| \le \frac{1}{m-1}\sum_{K\in\mathcal{T}} |\mu(K)| \le \frac{||\mu||_{M(\overline{\Omega})}}{m-1} \le \frac{1}{m-1}. \tag{34}$$

We again denote by $u_{\sigma,-}$ the downstream choice of u_σ (i.e., $u_{\sigma,-} = u_L$ if $v_{K,\sigma} \ge 0$ and $u_{\sigma,-} = u_K$ otherwise), and $v_\sigma = |v_{K,\sigma}|$ (for a $K \in \mathcal{T}$ such that $\sigma \in \mathcal{E}_K$); we then have
