
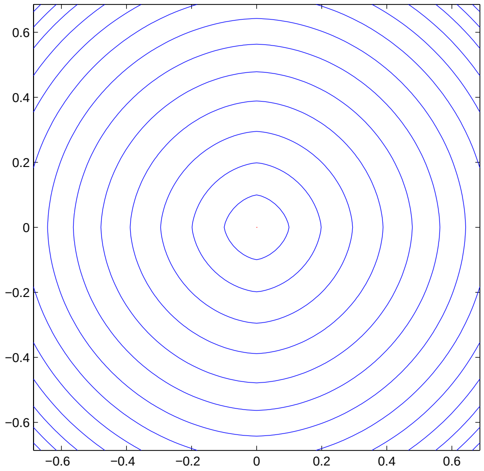

FIG. 8. *This is an example of the distance on a half-sphere. The sweeping algorithm was applied to the graph of $f(x, y) = \sqrt{1.0 - (x^2 + y^2)}$, with $\phi(0, 0) = 0$ as boundary condition, on a 100×100 grid.*

respectively. Figures 10, 11, and 12 show similar computation results applied to somewhat more oscillatory manifolds. As we expected, more sweeping iterations are required for convergence.

4.3. Grid effects. We first perform a rotation of the coordinate system. We represent this by

$$(x, y) \mapsto (\tilde{x}, \tilde{y})$$

and let

$$(a, b, c) \mapsto (\tilde{a}, \tilde{b}, \tilde{c}).$$

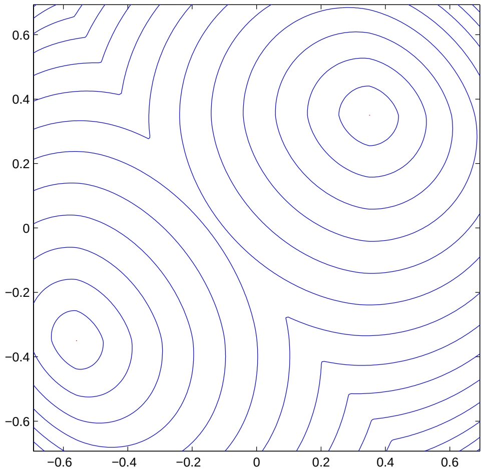

FIG. 9. *This is an example of the distance on a half-sphere. The sweeping algorithm was applied to the graph of* $f(x, y) = \sqrt{1.0 - (x^2 + y^2)}$, *with two seed points. Convergence is reached after* 2 *sweeping iterations.*

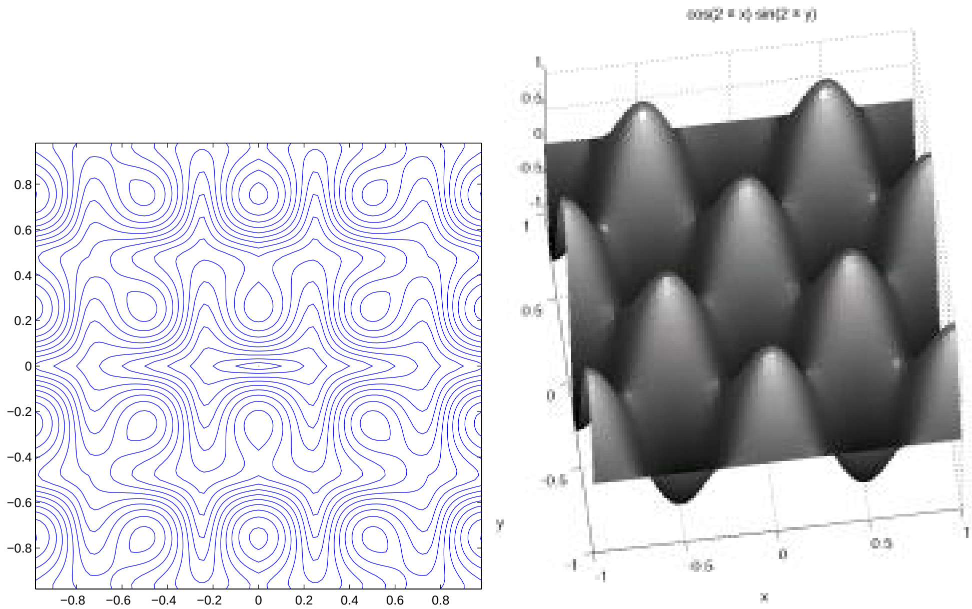

FIG. 10. *The distance contour from the seed point* $(0, 0)$ *on the graph of* $f(x, y) = \cos(2\pi x)\sin(2\pi y)$, *on a* 100×100 *grid. Convergence occurs after* 9 *iterations.*

To study the grid effects of our sweeping algorithm, we set $u = 0$ on a rotated square whose sides do not align with the grid lines. Comparing the results, shown in Figure 13, we see that the second picture, concentrating especially on the diamond-shaped contour in the middle, indeed shows grid effects compared to the first picture. However, with further grid refinement, as shown in the third picture, grid effects become unnoticeable, and the solution from our sweeping algorithm accurately ap-

proximates the exact solution.

4.4. Comparison with the time marching solutions. We use the first order Runge–Kutta–Lax–Friedrichs method [18] to discretize the following equation and march to steady state:

$$\tilde{\phi}_t+\operatorname{sgn}(\phi(x,y))(H(x,y,\tilde{\phi}_x,\tilde{\phi}_y)-r(x,y))=0, \tag{4.1}$$

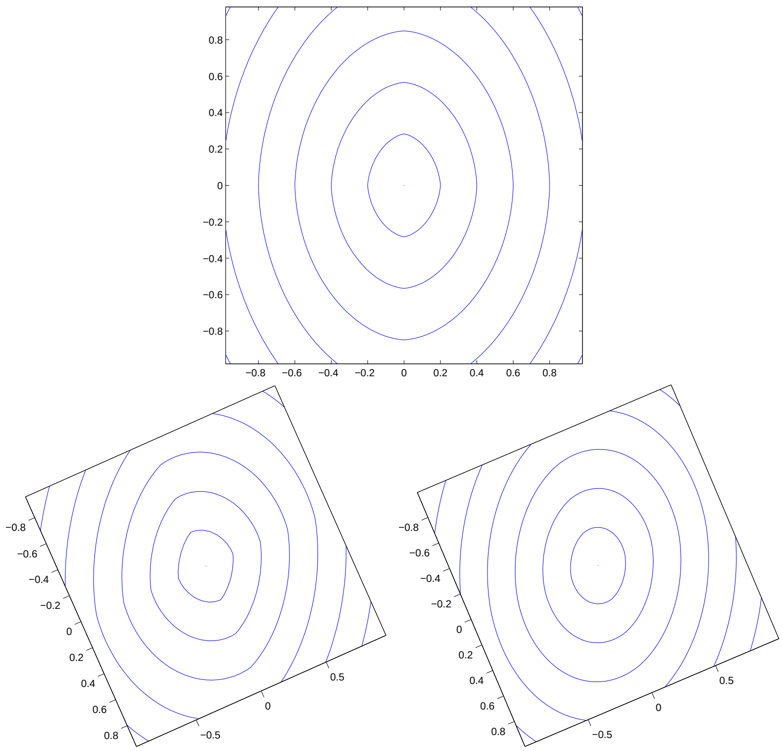

Fig. 13. *Anisotropic case with a point source at* $(0,0)$. $a = 1, b = 1, c = 0.9$ *and* $\tilde{a} = 1.70365$ $\tilde{b} = 0.296352$, *and* $\tilde{c} = -0.561141$, *on* 50×50 *and* 100×100 *grids. Convergence occurs after* 2 *iterations.*

Table 1

Comparison of the time marching and sweeping solutions to the example shown in Figure 12.

	$dx = 2/50$	2/100	2/200	2/400	2/800
$\|\|\phi - \tilde{\phi}\|\|_{L_1}$	2.85423	1.83377	1.04008	0.56206	0.295738
$\|\|\phi - \tilde{\phi}\|\|_\infty$	1.03825	0.708986	0.436469	0.246439	0.133858

where $\tilde{\phi}(x, y, t = 0) = \phi(x, y) = 0$ for $(x, y) \in \Gamma$ and ϕ is the solution obtained from the sweeping algorithm.

We remark that solving (4.1) is by no means a practical method for solving the steady state equation. Thousands of iterations are required for steady state, even if we take ϕ as the initial Cauchy data. We use it only to verify the validity of our algorithm. Secondly, the solutions of (4.1) suffer from excessive smearing due to the numerical viscosity introduced by the Lax–Friedrichs method. As a consequence, $\tilde{\phi}$ does not match well with ϕ on coarse grids. The reader can compare Figure 14 with Figure 12, for example. However, we do see that $||\phi - \tilde{\phi}||$ decreases with the refinement of the grid size; see Table 1 and Figure 14. We remark that higher order approximation schemes such as RK3-WENO5 will greatly reduce the numerical viscosity; the reader is referred to [18]. Our purpose here is only to show that the sweeping approximations converge to the viscosity solution.

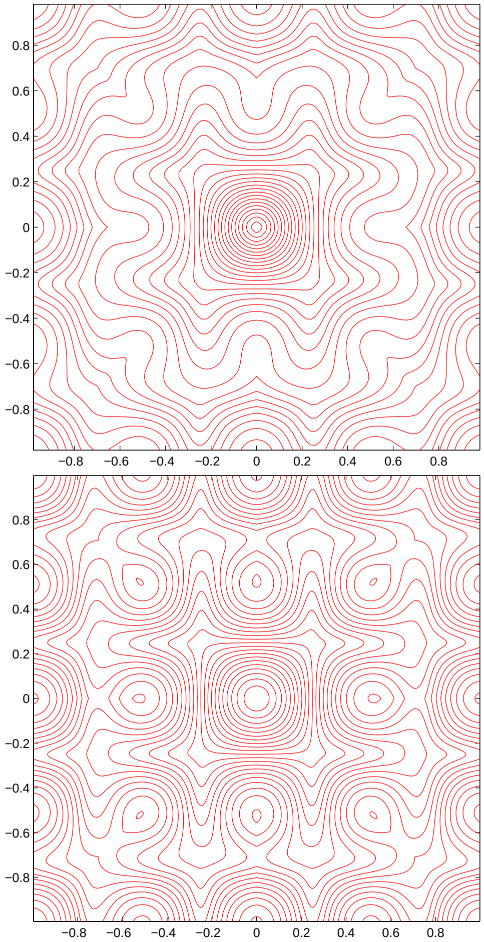

Fig. 14. *Steady state of the time marching on a* 100×100 *and* 800×800 *grid.*

Table 2
A numerical convergence study of the sweeping algorithm applied to the graph of $f(x, y) = \sqrt{1.0 - (x^2 + y^2)}$, *with* $\phi(0, 0) = 0$ *as boundary condition on the domain* $[-0.7, 0.7] \times [-0.7, 0.7]$.

	$dx = 1.4/200$	1.4/400	1.4/800	1.4/1600
$\|\|\phi - \tilde{\phi}\|\|_{L_1}$	0.0138803	0.0079927	0.00453004	0.00253513
rate		0.796	0.819	0.84

4.5. Numerical convergence. Since we can easily compute the geodesic distance on a sphere, we will use it as an example to show numerical convergence of our algorithm. A distance contour plot is shown in Figure 8. Table 2 shows a numerical convergence of order 1. We have also noticed that the number of iterations needed for the L_1 difference of the approximations in each successive iteration to decrease below the given tolerance seems to be bounded independently of the grid size. This number seems to depend on the anisotropy (c^2/ab), the forcing function r, and the configuration of the interface Γ.

5. Conclusion.

In this article, we studied a fast method for solving a class of time independent HJ equations with Dirichlet boundary conditions. The Hamiltonians of interest are homogeneous and convex. This fast method combines the idea of tracing the characteristics with Godunov construction and Gauss–Seidel iterations with smart choices of different updating sequences. In particular, we discussed some important properties of the Hamiltonian $H = \sqrt{ap^2 + bq^2 - 2cpq}$, $c^2 < ab$, and the corresponding HJ equations. By the simple structure of the convexity, we derived a compact expression for the Godunov Hamiltonian that involves taking extrema of the Hamiltonian in relation to the evaluations of the derivatives of the solution. With our compact Godunov flux, the complexity of evaluating the Godunov Hamiltonian is reduced to only eight cases in two space dimensions. We then incorporated the expression into a simple Gauss–Seidel-type iteration procedure. We have produced some computational results using this algorithm. In particular, we have applied our algorithm to compute geodesic distances on graphs of functions. This is of some importance since people are interested in finding the geodesics on terrain-like manifolds.

We also remark that this Godunov-flux sweeping approach can be extended to higher dimensional cases. We are currently preparing another paper on this subject.

Our experience shows that the number of iterations needed depends on the amount of anisotropy and the nature of the forcing function. Under normal nondegenerate circumstances, experience shows an $\mathcal{O}(N)$ complexity for convergence, where N is the number of grid points. Recently, in [26], the author provided some theoretical evidence on the bound of the number of iterations for isotropic, homogeneous eikonal equations. This points out a future research direction of bounding the number of sweeping iterations needed for convergence in relation to the anisotropy.

6. Appendix.

6.1. Derivation of the flux for homogeneous convex Hamiltonians.

To obtain the formula used earlier in this paper, we simply verify its equivalence to the following cases, which rely only on the convexity of H:

$p_- < p_+$, and $q_- < q_+$:

$$H_G = \min_{p\in[p_-,p_+]} \min_{q\in[q_-,q_+]} H(p,q).$$

- If $q_\sigma \in [q_-, q_+]$,
  - $p_\sigma < p_- < p_+$, $H(p_-, q_\sigma)$,
  - $p_- < p_+ < p_\sigma$, $H(p_+, q_\sigma)$,
  - $p_- < p_\sigma < p_+$, $H(p_\sigma, q_\sigma)$.
- If $q_\sigma < q_-$,
  - $p_\sigma < p_- < p_+$, $H(p_-, q_-)$,
  - $p_- < p_+ < p_\sigma$, $H(p_+, q_-)$,
  - $p_- < p_\sigma < p_+$, $H(p_\sigma, q_-)$.
- If $q_\sigma > q_+$,
  - $p_\sigma < p_- < p_+$, $H(p_-, q_+)$,
  - $p_- < p_+ < p_\sigma$, $H(p_+, q_+)$,
  - $p_- < p_\sigma < p_+$, $H(p_\sigma, q_+)$.

$p_- < p_+$, and $q_- > q_+$:

$$H_G = \min_{p\in[p_-,p_+]} \max_{q\in[q_+,q_-]} H(p,q) = \min_{p\in[p_-,p_+]} \max\{H(p,q_-), H(p,q_+)\}.$$

- If $q_\sigma < q_+$,
  - $p_\sigma < p_- < p_+$, $H(p_-, q_-)$,
  - $p_- < p_+ < p_\sigma$, $H(p_+, q_-)$,
  - $p_- < p_\sigma < p_+$, $H(p_\sigma, q_-)$.
- If $q_\sigma > q_-$,
  - $p_\sigma < p_- < p_+$, $H(p_-, q_+)$,
  - $p_- < p_+ < p_\sigma$, $H(p_+, q_+)$,
  - $p_- < p_\sigma < p_+$, $H(p_\sigma, q_+)$.
- If $q_+ < q_\sigma < q_-$,
  - $(q_\sigma - q_+) > (q_- - q_\sigma)$, $H(\cdot, q_+)$,
  - $(q_\sigma - q_+) \leq (q_- - q_\sigma)$, $H(\cdot, q_-)$.

$p_- > p_+$, and $q_- > q_+$:

$$H_G = \max_{p \in [p_+, p_-]} \max_{q \in [q_+, q_-]} H(p, q).$$

- If $q_\sigma > q_-$,
  - $p_\sigma > p_-$, $H(p_+, q_+)$,
  - $p_\sigma < p_+$, $H(p_-, q_+)$.
- If $q_\sigma < q_+$,
  - $p_\sigma > p_-$, $H(p_+, q_-)$,
  - $p_\sigma < p_+$, $H(p_-, q_-)$.
- If $q_+ < q_\sigma < q_-$
  - $(q_\sigma - q_+) > (q_- - q_\sigma)$, $H(\cdot, q_+)$,
  - $(q_\sigma - q_+) \leq (q_- - q_\sigma)$, $H(\cdot, q_-)$.

$p_- > p_+$, and $q_- < q_+$:

$$H_G = \max_{p \in [p_+, p_-]} \min_{q \in [q_-, q_+]} H(p, q).$$

- If $q_\sigma \in [q_-, q_+]$,
  - $p_\sigma > p_-$, $H(p_+, q_\sigma)$,
  - $p_\sigma < p_+$, $H(p_-, q_\sigma)$.
- If $q_\sigma < q_-$,
  - $p_\sigma > p_-$, $H(p_+, q_-)$,
  - $p_\sigma < p_+$, $H(p_-, q_-)$.
- If $q_\sigma > q_+$,
  - $p_\sigma > p_-$, $H(p_+, q_+)$,
  - $p_\sigma < p_+$, $H(p_-, q_+)$.

THE POSTPROCESSING GALERKIN AND NONLINEAR GALERKIN METHODS—A TRUNCATION ANALYSIS POINT OF VIEW[*]

LEN G. MARGOLIN[†], EDRISS S. TITI[‡], AND SHANNON WYNNE[§]

Abstract. We revisit the postprocessing algorithm and give a justification from a classical truncation analysis point of view. We assume a perturbation expansion for the high frequency mode component of solutions to the underlying equation. Keeping terms to certain orders, we then generate approximate systems which correspond to numerical schemes. We show that the first two leading order methods are in fact the postprocessed Galerkin and postprocessed nonlinear Galerkin methods, respectively. Hence postprocessed Galerkin is a natural leading order method, more natural than the standard Galerkin method, for approximating solutions of parabolic dissipative PDEs. The analysis is presented in the framework of the two-dimensional Navier–Stokes equation (NSE); however, similar analysis may be done for any parabolic, dissipative nonlinear PDE.

The truncation analysis is based on asymptotic estimates (in time) for the low and high mode components. We also introduce and investigate an alternative postprocessing scheme, which we call the dynamic postprocessing method, for the case in which the asymptotic estimates (in time) do not hold (i.e., in the situation of long transients, nonsmooth initial data, or highly oscillatory time-dependent solutions).

Key words. dissipative equations, spectral methods, approximate inertial manifolds, nonlinear Galerkin methods, postprocessing algorithm, multigrid

1. Introduction.

We revisit the postprocessing algorithm for the Galerkin and nonlinear Galerkin methods. Postprocessing methods first evolved from the theory of approximate inertial manifolds (AIMs) (see, e.g., [3], [5], [6], [7], [15], [19], and [21]) and take advantage of the observation that, for dissipative evolution equations, the Galerkin and nonlinear Galerkin methods do better approximating the low modes of the exact solution u than approximating the solution itself. AIMs are used to "post-process" the low modes in order to obtain a more accurate approximation for the high modes. For a variety of applications, the postprocessed Galerkin has been shown to be a very efficient algorithm for improving the accuracy of Galerkin/nonlinear Galerkin methods with very little extra computational cost (see, for example, [8], [10], [11], [12], and [17]). However, postprocessing is not simply a technique for improving efficiency. In this paper we show that postprocessing methods arise in a very natural way through a classical truncation analysis of the dissipative evolution equation. More specifically, we will show that, to leading order, the correct approximative scheme is

actually the postprocessed Galerkin method, and not the standard Galerkin method as is commonly believed.

We present this work in the context of the two-dimensional Navier–Stokes equations (NSE) in Ω, an open bounded set of $\mathbb{R}^2$, with smooth boundary $\partial\Omega$,

$$\begin{aligned} \frac{\partial u}{\partial t} - \nu\Delta u + (u\cdot\nabla)u + \nabla\pi &= f, \\ \nabla\cdot u &= 0, \\ u(0,x) &= u_0(x), \end{aligned} \tag{1.1}$$

where the unknowns are the vector velocity u and the scalar pressure π; $f(x,t)$ is a given body forcing, and $\nu > 0$ is the kinematic constant viscosity. The equations are subject to either nonslip Dirichlet boundary conditions for $\partial\Omega$ smooth enough, or periodic boundary conditions when Ω is a square. To this end, we define the Hilbert space H as

$$H = \{u \in L^2(\Omega)^2, \nabla\cdot u = 0, u\cdot\vec{n} = 0 \text{ on } \partial\Omega\}$$

in the case of nonslip Dirichlet boundary conditions, where $\vec{n}$ denotes the outward normal unit vector to $\partial\Omega$, or

$$H = \left\{u \in L^2_{\text{per}}(\Omega)^2, \nabla\cdot u = 0, \int_\Omega u\ dx = 0\right\}$$

in the case of periodic boundary conditions. The space H is a closed subspace of $L^2(\Omega)^2$ and is endowed with the scalar product and norm from $L^2(\Omega)^2$, denoted by $(\cdot,\cdot)$ and $\|\cdot\|$, respectively. We also define the Hilbert space V as $V = \{u \in H^1_0(\Omega)^2, \nabla\cdot u = 0\}$ or $V = \{u \in H^1_{\text{per}}(\Omega)^2, \nabla\cdot u = 0, \int_\Omega u\ dx = 0\}$, depending on the boundary conditions. Let P be the Leray orthogonal projection from $L^2(\Omega)^2$ onto H. Then (1.1) projected onto H may be written as an abstract functional differential equation of the form

$$\begin{aligned} \frac{du}{dt} + \nu Au + B(u,u) &= f, \\ u(0) &= u_0; \end{aligned} \tag{1.2}$$

see, e.g., [2] or [20].

The Stokes operator A is defined as $-P\Delta$ with the appropriate boundary conditions. The domain of A in H, denoted $D(A)$, is either $H^2(\Omega)^2 \cap V$ or $H^2_{\text{per}}(\Omega)^2 \cap V$, depending on the boundary conditions. The nonlinear term is $B(u,u)$ and is defined in general as $B(u,v) = P[(u\cdot\nabla)v]$. Finally, f (or $f = Pf$) is the forcing term and is assumed to be at least in H. The operator A is a positive, self-adjoint, densely defined, unbounded operator with compact inverse. The eigenfunctions of A, $\{\omega_1, \omega_2, \ldots\}$, form a complete orthonormal basis for the space H. The associated eigenvalues $\{\lambda_1, \lambda_2, \ldots\}$ satisfy $0 < \lambda_1 \le \lambda_2 \le \cdots$ and the asymptotic formula $\lambda_j \sim j$. Properties of the spaces H, $V = D(A^{1/2})$, and $D(A)$ may be found in [2], [18], or [20].

We decompose the solution u into low mode and high mode components by letting $H_N = \text{span}\{\omega_1, \omega_2, \ldots, \omega_N\}$, the span of the first N eigenfunctions of the Stokes operator A. Let P_N be the orthogonal projection of H onto H_N, and $Q_N = I - P_N$ be the projection onto the orthogonal complement space $H_N^\perp$. Then, for any $u \in H$, we can uniquely decompose $u = p + q$, where $p = P_N u$ and $q = Q_N u$. Projecting (1.2) onto H_N and $H_N^{\perp}$, we get an equivalent system for the NSE

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p,p) + B(p,q) + B(q,p) + B(q,q)\right] = P_N f, \tag{1.3}$$

$$\frac{dq}{dt} + \nu Aq + Q_N\left[B(p,p) + B(p,q) + B(q,p) + B(q,q)\right] = Q_N f, \tag{1.4}$$

$$p(0) = P_N u_0 \quad \text{and} \quad q(0) = Q_N u_0.$$

The truncation analysis is accomplished by using estimates for the low modes p and high modes q of a solution u. We present the truncation analysis for the two-dimensional NSE; however, similar analysis may be done for general nonlinear parabolic evolution or elliptic equations, such as reaction-diffusion systems, the Bénard convection problem, etc. The key to the analysis is understanding the interaction of the low and high modes, and estimating the nonlinear term.

The truncation analysis is based on asymptotic (in time) estimates for the low and high mode components, as was done in [10] and [11] when developing the postprocessing algorithm. These asymptotic estimates hold when solutions of the NSE are on, or near, the attractor, i.e., for the case of autonomous systems (f time-independent) and provided that t is large enough. However, these estimates may not hold, for example, in the case of nonsmooth initial data, long transients, or nonautonomous systems with highly oscillatory (in time) forcing. In [15] the authors showed that, for a highly oscillatory time-dependent forcing function, the dominant balance in (1.4) is between the dq/dt term and the forcing term; hence the dq/dt term should not be dropped in the AIM construction. This case leads to and justifies an alternate/reform postprocessing method, proposed in [24] for integrating along transients, which we call here *dynamic postprocessing*.

Let us emphasize again that there is a basic difference between the nonlinear Galerkin methods and the postprocessing Galerkin method. Specifically, unlike the usual multigrid (in this case two-grid) and the nonlinear Galerkin methods, in the postprocessing Galerkin methods the evolution/integration on the coarse mesh, i.e., low frequencies, does not use at all the information on the fine mesh (small scales or high frequencies). Only at the end of the calculations does one use the solution on the coarse mesh to refine the solution. On the other hand, in standard two-grid methods, including the nonlinear Galerkin methods and their variants, one uses cycles in which one has to compute the solution on the fine mesh in order to update the time step integration on the coarse mesh and vice versa. In fact, this occasional updating of the solutions on the fine mesh is the major source of computational disadvantage of the nonlinear Galerkin method in comparison to the Galerkin method, as was demonstrated computationally in, for instance, [10] and [11].

In this paper we first present a classical truncation analysis of the NSE using established asymptotic (in time) estimates. In section 2 we present several approximate systems of varying orders of accuracy based on the truncation analysis results. We introduce a more general postprocessing algorithm in section 3 for the case in which the asymptotic estimates no longer hold (i.e., in the presence of long transients, nonsmooth initial data, or highly oscillatory forcing). In section 4 we analyze the accuracy of the various postprocessing methods for the case of a highly time-oscillatory solution. In section 5 we present some numerical experiments to support the analysis of sections 2, 3, and 4 and compare the computational efficiency of the standard and the more general postprocessing methods. Finally, we give some concluding remarks in section 6. Preliminary results of this study were reported in [23].

2. Near-attractor truncation analysis. We first present the truncation analysis based on asymptotic estimates for u, p, and q. It is well known (see, e.g., [2] or [18]) that for $f \in H$ and independent of time, (1.2) is dissipative in the spaces H, V, and $D(A)$. This means that any solution $u(t)$ of (1.2) will, after a certain time, enter and remain in a ball in H centered at 0 with radius ρ_0. The same is true for a ball in V of radius ρ_1, and a ball in $D(A)$ of radius ρ_2. The radii ρ_0, ρ_1, and ρ_2 depend on $\|f\|$, ν, and λ_1. Therefore, we will assume that for $t \geq T_0$, for some positive T_0 that depends on ν, $\|f\|$, λ_1, and the initial data $\|u_0\|$, we have

$$\|u(t)\| \leq \rho_0, \qquad \|A^{1/2}u(t)\| \leq \rho_1, \qquad \|Au(t)\| \leq \rho_2. \tag{2.1}$$

Notice that the global attractor for (1.2) is contained in these balls. For solutions on the attractor, $T_0 = 0$ and the uniform bounds apply for all time $t \in \mathbb{R}$, since the global attractor is invariant (see, e.g., [2] and [18]).

From the above bounds for u, we have that q is also bounded in H, $D(A^{1/2})$, and $D(A)$ for $t > T_0$. Using the bound $\|Aq\| \leq \rho_2$ and the fact that $\|A^{\alpha}q\| \leq \lambda_{N+1}^{-\alpha}\|q\|$, we quickly obtain estimates for q in terms of λ_{N+1}. We denote $\epsilon = (\lambda_1/\lambda_{N+1})^{1/2}$. Then for $t > T_0$ the following estimates for q and dq/dt are at hand:

$$\begin{gathered}\|q\| \leq \lambda_{N+1}^{-1}\|Aq\| \leq \lambda_{N+1}^{-1}\rho_2 = O(\epsilon^2), \\ \|A^{1/2}q\| \leq \lambda_{N+1}^{-1/2}\|Aq\| \leq \lambda_{N+1}^{-1/2}\rho_2 = O(\epsilon), \\ \|Aq\| \leq \|Au\| \leq \rho_2 = O(1)\end{gathered} \tag{2.2}$$

as $\epsilon \to 0$. Using the fact that the solutions are analytic in time (see, e.g., [2] and [20]), one can apply the Cauchy formula for the derivatives of complex analytic functions to obtain an estimate for $\|dq/dt\|$ of the same order as $\|q\|$ (again, see, e.g., [2], [5], and [20]). We have

$$\left\|\frac{dq}{dt}\right\| = O(\epsilon^2) \quad \text{as } \epsilon \to 0. \tag{2.3}$$

Let us stress that the constant ρ_2, which depends on the physical parameters but not on N, is quite large in comparison with the constants ρ_0 or ρ_1 for small values of the viscosity ν or large values of $\|f\|$. It is preferable to avoid using the ρ_2 bound and to derive more delicate estimates for $\|q\|$, $\|dq/dt\|$, and $\|A^{1/2}q\|$ of the same orders as above involving only ρ_0 and ρ_1. Indeed, the authors of [5] derive bounds of the type given in (2.2) and (2.3) involving ρ_0 and ρ_1 but not ρ_2. However, this is done at the expense of adding a term of the order $|\log \epsilon|$. In practice, this is a more reasonable bound, since the best available bound for ρ_2 is many orders of magnitude larger than those for ρ_0 and ρ_1. Moreover, for practical computations, $|\log \epsilon|$ will be of order 1 even if ϵ is very small.

For the low mode component, we have only that p is bounded in H, $D(A^{1/2})$, and $D(A)$ for $t > T_0$. Hence, we set

$$\|p\|,\ \|A^{1/2}p\|,\ \|Ap\| = O(1) \quad \text{as } \epsilon \to 0. \tag{2.4}$$

For the truncation analysis we consider a perturbation expansion for q of the form

$$q = q_1 + q_2 + q_3 + q_4 + \cdots. \tag{2.5}$$

To leading order, we have estimates (2.2) and (2.3) for q. Hence, the corresponding estimates for the first expansion term q_1 are as follows:

$$\begin{aligned} \|q_1\|,\ \left\|\frac{dq_1}{dt}\right\| &= O(\epsilon^2), \\ \|A^{1/2}q_1\| &= O(\epsilon), \\ \|Aq_1\| &= O(1) \quad \text{as } \epsilon \to 0. \end{aligned} \tag{2.6}$$

Each successive term q_j is assumed to be of higher order in ϵ, i.e., $\|dq_j/dt\|, \|q_j\| = O(\epsilon^{j+1})$, $\|A^{1/2}q_j\| = O(\epsilon^j)$, and $\|Aq_j\| = O(\epsilon^{j-1})$, for $j = 1, 2, \ldots$. In principle, the initial value u_0 should also be decomposed accordingly, i.e., $u_0 = P_N u_0 + Q_N u_0$, with $Q_N u_0 = q_1^0 + q_2^0 + \cdots$ such that $O(q_j^0) = \epsilon O(q_{j-1}^0)$. In particular, for solutions on or near the attractor, we should have $\|q_j^0\| = O(\epsilon^{j+1})$, $\|A^{1/2}q_j^0\| = O(\epsilon^j)$, and $\|Aq_j^0\| = O(\epsilon^{j-1})$, for $j = 1, 2, \ldots$.

We substitute expansion (2.5) into system (1.3)–(1.4) above and estimate the order of each term in the system. By keeping terms up to order $\epsilon^{1/2}$, $\epsilon^{3/2}$, and so on, we generate approximate systems for NSEs of increasing orders of accuracy. The challenge comes with estimating the nonlinear terms. Substituting expansion (2.5) into the nonlinear terms results in the following:

$$\begin{aligned} B(p,q) = {} & B(p, q_1 + q_2 + q_3 + \cdots) \\ = {} & B(p,q_1) + B(p,q_2) + B(p,q_3) + \cdots, \\ B(q,p) = {} & B(q_1 + q_2 + q_3 + \cdots, p) \\ = {} & B(q_1,p) + B(q_2,p) + B(q_3,p) + \cdots, \\ B(q,q) = {} & B(q_1 + q_2 + q_3 + \cdots, q_1 + q_2 + q_3 + \cdots) \\ = {} & B(q_1,q_1) + B(q_1,q_2) + B(q_1,q_3) + \cdots \\ & + B(q_2,q_1) + B(q_2,q_2) + B(q_2,q_3) + \cdots \\ & + B(q_3,q_1) + B(q_3,q_2) + B(q_3,q_3) + \cdots \\ & + \cdots. \end{aligned}$$

We majorize each term using inequalities for the nonlinear term given, for instance, in [2], [20], or [22] for inequalities (2.9) and (2.10). For convenience we recall the two-dimensional version of these inequalities. For any $u, v \in D(A)$,

$$\|B(u,v)\| \le c_1 \|u\|^{1/2} \|A^{1/2}u\|^{1/2} \|A^{1/2}v\|^{1/2} \|Av\|^{1/2} \tag{2.7}$$

$$\le c_2 \|u\|^{1/2} \|Au\|^{1/2} \|A^{1/2}v\| \tag{2.8}$$

$$\le c_3 \|A^{1/2}u\| \|A^{1/2}v\| \left(1 + \log \frac{\|Au\|^2}{\lambda_1 \|A^{1/2}u\|^2}\right)^{1/2} \tag{2.9}$$

and

$$\|B(u,v)\| \le c_4 \|u\|\, \|Av\| \left(1 + \log \frac{\|A^{3/2}v\|^2}{\lambda_1 \|Av\|^2}\right)^{1/2} \tag{2.10}$$

for $u \in D(A)$ and $v \in D(A^{3/2})$. The constants c_1–c_4 are independent of u, v, and the size of Ω, but might depend on its shape. For each nonlinear term we choose the inequality that results in the highest order of ϵ. Using estimates (2.4) for p and (2.6) for q_1, we obtain $\|B(p,p)\| = O(1)$, $\|B(p,q_1)\| = O(\epsilon)$, and $\|B(q_1,q_1)\| = O(\epsilon^2)$. For the $B(q_1,p)$ term, inequality (2.7) gives $\|B(q_1,p)\| = O(\epsilon^{3/2})$, and inequality (2.10) gives $\|B(q_1, p)\| = O(\epsilon^2 L_\epsilon^{1/2})$, where $L_\epsilon = (1 + 2|\log \epsilon|)$. The $O(\epsilon^2 L_\epsilon^{1/2})$ estimate is "closer" to being of the order $O(\epsilon^2)$ than $O(\epsilon)$. However, in either case, the term is definitely of the order $O(\epsilon^{3/2})$. For simplicity of ordering the various terms, we will consider this term to be $O(\epsilon^{3/2})$.

2.1. Near-attractor approximate systems. To produce approximate schemes for the Navier–Stokes system, we keep only terms in (1.3)–(1.4) to certain orders in ϵ. Below, we list the approximate systems produced by keeping terms to order $\epsilon^{1/2}$ and $\epsilon^{3/2}$. We will set nonlinear terms of the order $O(\epsilon^2 L_\epsilon^{1/2})$ and $O(\epsilon^3 L_\epsilon^{1/2})$ to be of the order $O(\epsilon^{3/2})$ and $O(\epsilon^{5/2})$, respectively.

$\boxed{O(\epsilon^{1/2}):}$

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p,p)\right] \approx P_N f, \tag{2.11}$$

$$\nu Aq_1 + Q_N\left[B(p,p)\right] \approx Q_N f, \tag{2.12}$$

$$p(0) = P_N u_0. \tag{2.13}$$

Equation (2.11) is an evolution equation for the low mode component p. Equation (2.12) is coupled to (2.11); it defines q_1, the leading order approximation term of the high modes, in terms of the low modes and is therefore a postprocessing step. From (2.12) one can verify that $\|Aq_1\| = O(1)$, which is consistent with our assumptions.

$\boxed{O(\epsilon^{3/2}):}$

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p,p) + B(p,q_1) + B(q_1,p)\right] \approx P_N f, \tag{2.14}$$

$$\nu A(q_1 + q_2) + Q_N\left[B(p,p) + B(p,q_1) + B(q_1,p)\right] \approx Q_N f, \tag{2.15}$$

$$\nu Aq_2 + Q_N\left[B(p,q_1) + B(q_1,p)\right] \approx 0, \tag{2.16}$$

$$p(0) = P_N u_0. \tag{2.17}$$

Equation (2.14) is the evolution equation for p with q_1 in the nonlinear term defined by (2.12); it is a nonlinear Galerkin method as defined in [5], [13], [14], and [16]. Equation (2.15) defines $q_1 + q_2$, which is a higher order approximation of the high modes. Equation (2.16) defines q_2; it is derived from (2.15) and the definition of q_1 given in (2.12). From (2.16) one can show that $\|Aq_2\| \leq \|B(p,q_1)\| + \|B(q_1,p)\| = O(\epsilon)$. Hence $\|q_2\| = O(\epsilon^2)$, which is consistent with our assumptions.

Similarly, we may obtain an approximate system for the NSE valid to order $O(\epsilon^{5/2})$, $O(\epsilon^{7/2})$, and in general, valid to order $O(\epsilon^{j+1/2})$. In the general case, the low mode equation is evolved with linear combinations of q_1 through q_j in the nonlinear term; the high mode equation involves linear combinations of q_1 through q_{j+1}, where $(q_1 + q_2 + \cdots + q_{j+1})$ is used to approximate q. Thus the high modes of the solution u should be approximated to one order higher in ϵ than the order of the high mode terms used in the low mode equation. The term q_{j+1} is not used to evolve the low modes; it needs to be evaluated only once, at some final time T, and may therefore be considered a postprocessing step. The approximate systems above, produced with a classical truncation analysis, demonstrate that the postprocessing step is a very natural and significant part of approximating the original system.

2.2. Standard (near-attractor) postprocessing schemes. For each approximate system from the previous section, we may generate a postprocessed Galerkin or nonlinear Galerkin scheme of increasing order of accuracy. From the truncation analysis we know that, to approximate the low and high modes of a solution u to the same order in ϵ, we must include the postprocessing step. In general the solution of the evolution equation is sought as an approximation of the low modes of the exact solution u, and the solution of the high mode equation is sought as an approximation of the high modes of the solution u. The goal for each $\epsilon^{j+1/2}$ postprocessing scheme is to produce a more accurate approximation of the low and high modes as j increases.

From system (2.11)–(2.12), i.e., keeping terms to order $O(\epsilon^{1/2})$, we obtain the postprocessed standard Galerkin method

$$\frac{du_N}{dt} + \nu A u_N + P_N\left[B(u_N, u_N)\right] = P_N f, \tag{2.18}$$

$$\nu A \phi_1 + Q_N\left[B(u_N, u_N)\right] = Q_N f, \tag{2.19}$$

$$u_N(0) = P_N u_0, \tag{2.20}$$

where $u_N \in H_N$ is the solution of the evolution equation and is an approximation of the low modes p, and $\phi_1 \in Q_N H$ is an approximation of the high modes q (i.e., $\phi_1 \approx q_1$). Note that $\phi_1(t) = \Phi^1(u_N(t))$, where Φ^1 is exactly the Foias–Manley–Temam (FMT) AIM first introduced in [5]. This is the same postprocessed Galerkin method originally defined in [10] and [11]. Solving for $u_N(t)$ does not depend on ϕ_1, and hence one does not need to evaluate $\phi_1(t) = \Phi^1(u_N(t))$ at all times, but only when an approximate solution is needed. This is typically done once at some final time T. It is therefore a postprocessing step. The approximate solution at time T is then $u_N(T) + \phi_1(T) = u_N(T) + \Phi^1(u_N(T))$, and not $u_N(T)$ as is traditionally used with the standard Galerkin method. This scheme indicates that, to leading order in ϵ, the correct approximation method is the postprocessed Galerkin method.

The approximation properties of the postprocessed Galerkin method ($j = 0$) are well understood. We know, for instance, that Φ_1 is Lipschitz continuous, $\|\phi_1(t)\| = O(\epsilon^2)$, $\|q(t) - \phi_1(t)\| = O(\epsilon^3)$, and $\|p(t) - u_N(t)\| = O(\epsilon^3)$. Proofs of the first three properties may be found, for example, in [4] and [5]. The fourth property is proven in [11], specifically for the two-dimensional NSE.

In general, keeping terms of order $\epsilon^{j+1/2}$ for $j \geq 1$, we obtain a postprocessed nonlinear Galerkin scheme with successively more accurate approximation properties as j increases. In particular, for the scheme generated from system (2.14)–(2.16), i.e., the case $j = 1$, we can show that the low and high mode approximation errors are of the order $O(\epsilon^4)$ using the techniques as in [11] and [17]. Though more accurate, the $O(\epsilon^{j+1/2})$ systems are not computationally competitive for $j \geq 1$. We know from numerical experiments presented in [10], [11], and [17] that the more computationally efficient schemes are the postprocessed Galerkin method (2.18)–(2.19) and variants thereof, such as the postprocessed filtered Galerkin method. Hence, for the purposes of this paper, we will concentrate on the postprocessed Galerkin method, system (2.18)–(2.20).

3. A more general truncation analysis.

The standard postprocessing scheme and systems in the previous section were generated based on asymptotic (in time) estimates for the low and high mode components. These estimates hold for autonomous systems when solutions of the NSE are on or near the attractor, i.e., for t large enough. However, these estimates may no longer hold, for instance, in the case of nonsmooth initial data, long transients, or nonautonomous systems with highly oscillatory time-dependent forcing. For these cases, the leading order approximation for system (1.3)–(1.4) is no longer clear. In particular, the dq/dt term may no longer be small in comparison with the other terms in (1.4). For instance, in the case of a highly oscillatory time-dependent force, the authors of [15] presented an analytic example showing that the dominant balance in (1.4) is between the dq/dt term and the forcing term, and not between the dissipative term and the forcing and nonlinear terms. In this case they concluded that the dq/dt term should not be dropped in the AIM construction. In this section we consider the special case in which the forcing f is a highly oscillatory time-dependent function.

We start with the nonautonomous Navier–Stokes system (1.3)–(1.4) with highly oscillatory forcing. We assume that the force remains bounded (i.e., $f \in L^\infty((0,\infty);H)$ but oscillatory in time (defined later in Theorem 4.4). Furthermore, we assume that the solution $u(t)$ is bounded in $D(A)$ for $t \geq 0$ and that the initial condition is smooth, i.e., $u_0 \in D(A)$. As before, we observe that $\|Au(t)\| = O(1)$ since $\|Au(t)\|$ is bounded uniformly. Then for all $t \geq 0$ we have

$$\|p(t)\|, \|A^{1/2}p(t)\|, \|Ap(t)\| = O(1) \qquad \text{and} \qquad \|Aq(t)\| = O(1).$$

Again using the fact that $\|q\| \leq \lambda_{N+1}^{-\alpha}\|A^\alpha q\|$, we obtain that $\|q(t)\| = O(\epsilon^2)$ and $\|A^{1/2}q(t)\| = O(\epsilon)$ as before. Since the forcing is highly oscillatory in time, we cannot assume that the time derivative of the solution u, and hence q, is necessarily small. In this situation we will suppose that $\|dq/dt\| = O(1)$, the same order as the $\|Aq(t)\|$ term or larger. We have the following bounds for q,

$$\begin{aligned} \|q(t)\| &= O(\epsilon^2), \\ \|A^{1/2}q(t)\| &= O(\epsilon), \\ \|Aq(t)\|, \|dq/dt\| &= O(1). \end{aligned} \tag{3.1}$$

Without assuming that the forcing term is real analytic in time with values in H, one could not show that the solution $u(t)$ is real analytic in time with values in $D(A)$. Therefore, it would not be possible to employ the techniques used in [5] to get tight estimates on the constants involved in the bounds given in (3.1).

3.1. More general approximate systems. For the truncation analysis, we again assume a perturbation expansion for q of the form $q = (q_1 + q_2 + q_3 + \cdots)$. Since q_1 is the leading order approximation for q, the above estimates hold for q_1 as well. We then substitute the perturbation expansion for q into system (1.3)–(1.4) and estimate the orders of the various terms as before. The only differences are the orders of the $d(q_1 + q_2 + \cdots)/dt$ terms.

Keeping terms up to order $\epsilon^{1/2}$, we have the following leading order approximate system:

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p,p)\right] \approx P_N f, \tag{3.2}$$

$$\frac{dq_1}{dt} + \nu Aq_1 + Q_N\left[B(p,p)\right] \approx Q_N f, \tag{3.3}$$

$$p(0) = P_N u_0, \tag{3.4}$$

$$q_1(0) = Q_N u_0. \tag{3.5}$$

Equation (3.2) is the usual evolution equation for the low mode component; it is the standard Galerkin method. Equation (3.3) is used to define q_1, the leading order approximation of the high modes, only now it is an evolution equation. Here q_1 is not needed for the evolution of the low modes; hence (3.3) may be considered a postprocessing step. This is the same postprocessing step introduced in [24] for the case of nonsmooth initial data and long transients, and justifies the postprocessing method given therein. It is worth noting that one can think about the above system (3.2)–(3.5) as a two-level multigrid method, where one integrates (3.2) on the coarse mesh and then postprocesses on the fine mesh using (3.3).

Keeping terms up to order $\epsilon^{3/2}$, we have the following approximate system:

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p, p+q_1) + B(q_1, p)\right] \approx P_N f, \tag{3.6}$$

$$\frac{d(q_1+q_2)}{dt} + \nu A(q_1+q_2) + Q_N\left[B(p, p+q_1) + B(q_1, p)\right] \approx Q_N f, \tag{3.7}$$

$$p(0) = P_N u_0, \tag{3.8}$$

$$(q_1+q_2)(0) = Q_N u_0. \tag{3.9}$$

Equation (3.6) is the same evolution equation for p as in (2.14), but with q_1 now defined by (3.3). It is a nonlinear Galerkin method. Equation (3.7) defines q_1+q_2, the high mode approximation. From (3.3), (3.6), and (3.7) one concludes

$$\frac{dp}{dt} + \nu Ap + P_N\left[B(p, p+q_1) + B(q_1, p)\right] \approx P_N f, \tag{3.10}$$

$$\frac{dq_1}{dt} + \nu Aq_1 + Q_N\left[B(p, p)\right] \approx Q_N f, \tag{3.11}$$

$$\frac{dq_2}{dt} + \nu Aq_2 + Q_N\left[B(p, q_1) + B(q_1, p)\right] \approx 0, \tag{3.12}$$

$$p(0) = P_N u_0, \tag{3.13}$$

$$q_1(0) = q_1^0, \tag{3.14}$$

$$q_2(0) = q_2^0. \tag{3.15}$$

Equation (3.12) is a postprocessing step since q_2 is not used in the evolution equation for the low mode component p. Here again one can think about the above scheme as a two-level multigrid method.

We may continue this process as before, keeping terms to higher and higher orders in ϵ to generate a general postprocessing scheme. However, for computational efficiency, we are interested only in the leading order postprocessing algorithms.

3.2. A dynamic postprocessing scheme.

Motivated by the approximate system (3.2)–(3.5), we introduce the *dynamic postprocessing scheme*

$$\frac{du_N}{dt} + \nu Au_N + P_N\left[B(u_N, u_N)\right] = P_N f, \tag{3.16}$$

$$\frac{d\tilde{\phi}_1}{dt} + \nu A\tilde{\phi}_1 + Q_N\left[B(u_N, u_N)\right] = Q_N f, \tag{3.17}$$

$$u_N(0) = P_N u_0, \tag{3.18}$$

$$\tilde{\phi}_1(0) = Q_N u_0, \tag{3.19}$$

where the approximation for the high modes $\tilde{\phi}_1$ is obtained as the solution of evolution equation (3.17). Notice that $\tilde{\phi}_1 = \tilde{\phi}_1(t; u_N(t))$.

4. Error analysis.

In the following, we will compare the accuracy of the standard postprocessing method, system (2.18)–(2.20), with the dynamic postprocessing method, system (3.16)–(3.19), in the case of a highly oscillatory forcing function.

Since the approximation for the low mode component is exactly the same in each case, namely the Galerkin approximation, we will compare only the postprocessing approximation of the high mode component.

For comparison purposes we will use the uniform bounds

$$\|Au(t)\| \leq \rho_2, \qquad \|Au_N(t)\| \leq \rho_2^*, \qquad t \geq 0, \tag{4.1}$$

where ρ_2 and ρ_2^* are constants which depend on the data of the problem (i.e., ν, f, $\|u_0\|$, and λ_1) but are independent of N. Let us observe that usually $\rho_2^* = \rho_2$. We will also utilize a low mode accuracy estimate, which we restate below without proof (see [11], Theorem 1).

THEOREM 4.1. *Let $T > 0$ be fixed. Let $u = p + q$ be the solution of* (1.2) *on $[0, T]$ such that the bounds in* (3.1) *and* (4.1) *hold. Then, there exists a constant $C = C(T, \rho_1, \rho_2)$ such that for any $t \in [0, T]$ the solution $u_N(t)$ of* (2.18) *and* (2.20) *satisfies*

$$\|p(t) - u_N(t)\| \leq C \frac{L_\epsilon^2}{\lambda_{N+1}^{3/2}} = O(\epsilon^3 L_\epsilon^2), \tag{4.2}$$

where $L_\epsilon = 1 + 2|\log \epsilon| = 1 + \log(\lambda_{N+1}/\lambda_1)$.

The theorem is proven in the case of f time-independent. However (see [11, Remark 2]), f plays no role in the estimates, and hence the result is valid for $f = f(t)$ as well.

We first work with the leading order postprocessing method presented in section 2, whose corresponding scheme is given by (2.18)–(2.19). Here u_N is the Galerkin low mode approximation. The high mode approximation is given by $\phi_1 = \Phi^1(u_N)$, where Φ^1 is the FMT AIM introduced in [5] and is defined in general as

$$\Phi^1(v) = (\nu A)^{-1}(Q_N f - Q_N B(v, v)), \qquad v \in H_N.$$

A common approach for estimating the error $\|q(t) - \Phi^1(u_N(t))\|$ is to first bound $\|q - \Phi^1(p)\|$ using asymptotic estimates for p, q, and dq/dt, where $u(t) = p(t) + q(t)$ is the exact solution. Since we no longer assume that $\|dq/dt\|$ is small, we first reexamine the $\|q - \Phi^1(p)\|$ estimate in the case of a highly oscillatory forcing function. We have the following theorem.

THEOREM 4.2. *Let $f(t) \in L^\infty((0, \infty); H)$ and $u_0 \in D(A)$. Then for any solution $u(t) = p(t) + q(t)$ of* (1.2), *and $u_N(t)$ the solution of* (2.18) *and* (2.20) *such that estimates* (3.1) *and* (4.1) *hold, we have*

$$\|q(t) - \Phi^1(p(t))\| \leq \frac{C}{\nu \lambda_{N+1}} \left(\left\| \frac{dq}{dt} \right\| + \lambda_{N+1}^{-1/2} \|Aq\| \right), \tag{4.3}$$

$$\|q(t) - \Phi^1(u_N(t))\| \leq L\|p(t) - u_N(t)\| + \frac{C}{\nu \lambda_{N+1}} \left(\left\| \frac{dq}{dt} \right\| + \lambda_{N+1}^{-1/2} \|Aq\| \right) \tag{4.4}$$

for every $t \geq 0$. Here L is the Lipschitz constant for Φ^1, which is known to be of the order $o(1)$ as $\lambda_{N+1} \to \infty$ (see, e.g., [4], [5], *and* [21]*).*

Proof. Let $t \geq 0$. Subtracting (2.11) from (1.4) and taking the L^2 norm, we obtain

$$\|\nu A(q(t) - \Phi^1(p(t)))\| \leq \left\| \frac{dq}{dt} \right\| + \|B(p, q)\| + \|B(q, p)\| + \|B(q, q)\|.$$

Using inequalities (2.7)–(2.10) to bound the nonlinear terms, we have

$$\|\nu A(q-\Phi^1(p))\| \leq \left\|\frac{dq}{dt}\right\| + \frac{c_1\|Ap\|}{\lambda_{N+1}^{1/2}}\|Aq\| + \frac{c_1\|Ap\|}{\lambda_{N+1}^{3/4}}\|Aq\| + \frac{c_1}{\lambda_{N+1}}\|Aq\|^2,$$

and hence

$$\|q-\Phi^1(p)\| \leq (\nu\lambda_{N+1})^{-1}\left(\left\|\frac{dq}{dt}\right\| + \frac{C}{\lambda_{N+1}^{1/2}}\|Aq\|\right), \tag{4.5}$$

where $C = C(c_1, \rho_1, \rho_2)$. This proves estimate (4.3). To obtain estimate (4.4), first apply the triangle inequality,

$$\|q(t)-\Phi^1(u_N(t))\| \leq \|q(t)-\Phi^1(p(t))\| + \|\Phi^1(p(t))-\Phi^1(u_N(t))\|.$$

Then use the Lipschitz continuity of Φ^1 (see [5]) and estimate (4.3). □

In this section we assume that $\|dq/dt\|, \|Aq\| = O(1)$, and thus $\|q-\Phi^1(p)\| = O(\epsilon^2)$, rather than of the order $O(\epsilon^3) = O(\lambda_{N+1}^{-3/2})$ for the solutions on or near the attractor in the case of autonomous systems. Different asymptotic estimates for the q and dq/dt terms result in different accuracy estimates for $\|q-\Phi^1(p)\|$ and for the total accuracy estimate of the standard postprocessing algorithm. In particular, using Theorem 4.1 to bound the $\|p(t)-u_N(t)\|$ term, the bounds for $\|dq/dt\|$ and $\|Aq\|$ dominate the error in estimate (4.4). The accuracy estimate for the high mode approximation using the standard postprocessing method is given below.

COROLLARY 4.3. *Let $f(t) \in L^\infty((0,\infty); H)$, $u_0 \in D(A)$, and $T > 0$. Then for any solution $u(t) = p(t) + q(t)$ of* (1.2)*, and $u_N(t)$ the solution of* (2.18) *and* (2.20) *such that the estimates* (3.1) *and* (4.1) *hold, we have*

$$\|q(t)-\Phi^1(u_N(t))\| = O(\epsilon^2) \tag{4.6}$$

for $t \geq 0$.

Note that, without a better estimate for the $\|dq/dt\|$ term, we could easily have obtained the same estimate for $\|q-\Phi^1(p)\|$ by first applying the triangle inequality to get

$$\|q-\Phi^1(p)\| \leq \|q\| + \|\Phi^1(p)\|.$$

Then, under the assumptions of Theorem 4.2, one can show that $\|\Phi^1(p)\| = O(\lambda_{N+1}^{-1}) = O(\epsilon^2)$. Since $\|q\| = O(\epsilon^2)$ as well, we obtain $\|q-\Phi^1(p)\| = O(\epsilon^2)$. Hence, Corollary 4.3 only indicates that q and $\Phi^1(p)$ are of the same order.

With additional assumptions on $f(t)$, the above estimate for $\|q-\Phi^1(p)\|$ may be improved. In particular, in [15] the authors show that $\|q-\Phi^1(p)\| = O(\epsilon^{1+2\theta})$ for f Hölder continuous in time (with exponent θ), with values in H for N large enough. For convenience we restate the theorem.

THEOREM 4.4. *Let $f(t)$ be Hölder continuous (i.e., $\|f(t_1)-f(t_2)\| \leq L_1|t_1 - t_2|^\theta$) and satisfy $\sup_{t\geq 0}|f(t)| \leq f_\infty < \infty$. Furthermore, impose sufficient conditions on $f(t)$ so that $\|Au\|$ is uniformly bounded and, hence, the solution $p(t)$ of* (1.3) *is uniformly Lipschitz in time, (i.e., $\|p(t_1)-p(t_2)\| \leq L_2|t_2-t_1|$, where L_2 depends on ν, f_∞, and λ_1). Let $\|q(0)-\Phi^1(p(0))\| = O(\lambda_{N+1}^{(1/2+\theta)})$. Then, for N sufficiently large and $t \geq 0$, any solution $u(t) = p(t)+q(t)$ of* (1.2) *satisfies*

$$\|q(t)-\Phi^1(p(t))\| \leq \frac{4\alpha_5}{\lambda_{N+1}^{1/2+\theta}},$$

where $\alpha_5 = \alpha_4(1+(1+e)^{-1})$, $\alpha_4 = \lambda_{N+1}^{-1/2} 2\nu^{-1}(\alpha_3 L_2 \lambda_N^{1/2} + L_1) + \alpha_2 L_2 + \nu^{-1} L_1 \lambda_{N+1}^{-1/2}$, L_1 *is the Hölder constant for* f, *and* L_2 *is the Lipschitz constant for* p.

Proof. We refer the reader to [15, Theorem 5.11] for specific conditions on N, definitions of α_2, α_3, α_4, and the proof of the above theorem. □

If $\theta > 1/2$, then Theorem 4.4 represents an improvement from the previous $O(\epsilon^2)$ estimate for $\|q - \Phi^1(p)\|$, where f was only assumed to be bounded. Using the Lipschitz continuity of Φ^1 and Theorem 4.1, we have an improved estimate for $\|q - \Phi^1(u_N)\|$ in the case in which f is Hölder continuous.

COROLLARY 4.5. *Let* $f(t)$ *satisfy the conditions of Theorem* 4.4, $u_0 \in D(A)$, $T > 0$, *and* N *sufficiently large. Then for any solution* $u(t) = p(t) + q(t)$ *of* (1.2), *and* $u_N(t)$ *the solution of* (2.18) *and* (2.20) *such that estimates* (3.1) *and* (4.1) *hold, we have*

$$\|q(t) - \Phi^1(u_N(t))\| \leq L\|p(t) - u_N(t)\| + \frac{4\alpha_5}{\lambda_{N+1}^{1/2+\theta}} = O(\epsilon^{2+2(\theta-1/2)}) \tag{4.7}$$

for $t \in [0,T]$. *Here* $L = o(1)$ *is the Lipschitz constant for* Φ^1.

We now examine the dynamic postprocessing method, system (3.16)–(3.19), and obtain an estimate for $\|q(t) - \tilde{\phi}_1(t; u_N(t))\|$.

THEOREM 4.6. *Let* $f(t) \in L^\infty((0,\infty); H)$, $u_0 \in D(A)$, *and* $T > 0$. *Let* $u(t) = p(t) + q(t)$ *be a solution of* (1.2), *and* $u_N(t)$ *and* $\tilde{\phi}_1(t; u_N(t))$ *be a solution of system* (3.16)–(3.19) *such that estimates* (3.1) *and* (4.1) *hold. Then, for* $t \in [0,T]$, *we have*

$$\|q(t) - \tilde{\phi}_1(t; u_N(t))\| \leq \frac{C}{\nu\lambda_{N+1}^{1/2}} \left(\max_{s\in[0,T]} \|p(s) - u_N(s)\| + \lambda_{N+1}^{-1} \max_{s\in[0,T]} \|Aq(s)\| \right), \tag{4.8}$$

where $C = C(\rho_2, \rho_2^*)$; ρ_2 *and* ρ_2^* *are defined in* (2.1) *and* (4.1), *respectively.*

Proof. We subtract (3.17) from (1.4). Letting $\Delta(t) = q(t) - \tilde{\phi}_1(t; u_N(t))$, we have

$$\frac{d\Delta}{dt} + \nu A\Delta = Q_N \left[B(p+q,q) + B(q,p) + B(p, p-u_N) + B(p-u_N, u_N) \right].$$

Taking the inner product of Δ and the above equation, we obtain

$$\begin{aligned} \frac{1}{2}\frac{d}{dt}\|\Delta\|^2 + \nu\|A^{1/2}\Delta\|^2 \leq{}& |(B(p+q,q),\Delta)| + |(B(q,p),\Delta)| \\ &+ |(B(p,p-u_N),\Delta)| + |(B(p-u_N,u_N),\Delta)|. \end{aligned}$$

We apply the Cauchy–Schwarz inequality and Young's inequality to get a factor of $\nu\|A^{1/2}\Delta\|$ from each term on the right-hand side. Combining all $\|A^{1/2}\Delta\|$ terms with the left-hand side of the inequality and using the fact that $\lambda_{N+1}^{1/2}\|\Delta\| \leq \|A^{1/2}\Delta\|$, we have

$$\begin{aligned} \frac{d}{dt}\|\Delta\|^2 + \nu\lambda_{N+1}\|\Delta\|^2 \leq{}& \frac{5}{\nu\lambda_{N+1}} \left(\|B(p,q)\|^2 + \|B(q,p)\|^2 + \|B(q,q)\|^2 \right. \\ &\left. + \|B(p,p-u_N)\|^2 + \|B(p-u_N,u_N)\|^2 \right). \end{aligned}$$

Estimating the nonlinear terms using estimates (2.7)–(2.10) as before,

$$
\begin{aligned}
\frac{d}{dt}\|\Delta\|^2 + \nu\lambda_{N+1}\|\Delta\|^2 &\le \frac{5}{\nu\lambda_{N+1}}\Big(c_2^2\|p\|\|Ap\|\|A^{1/2}q\|^2 \\
&\quad + c_4^2(1+\log(\lambda_N/\lambda_1))\|Ap\|^2\|q\|^2 + c_2^2\|q\|\|A^{1/2}q\|^2\|Aq\| \\
&\quad + c_2^2\|p\|\|Ap\|\|A^{1/2}(p-u_N)\|^2 + c_4^2(1+\log(\lambda_N/\lambda_1))\|Au_N\|^2\|p-u_N\|^2\Big) \\
&\le \frac{5}{\nu\lambda_{N+1}}\left(\frac{c_2^2\|Ap\|^2}{\lambda_{N+1}}\|Aq\|^2 + \frac{c_4^2L_\epsilon\|Ap\|^2}{\lambda_{N+1}^2}\|Aq\|^2 + \frac{c_2^2\|Aq\|^2}{\lambda_{N+1}^2}\|Aq\|^2\right. \\
&\qquad\left. + \lambda_N c_2^2\|p\|\|Ap\|\|p-u_N\|^2 + c_4^2L_\epsilon\|Au_N\|^2\|p-u_N\|^2\right) \\
&\le \frac{C}{\nu}\left(\|p-u_N\|^2 + \lambda_{N+1}^{-2}\|Aq\|^2\right),
\end{aligned}
$$

where $C = C(c_2, c_3, c_4, \rho_2, \rho_2^*)$. We then apply Gronwall's inequality to obtain

$$
\|\Delta(t)\|^2 \le \|\Delta(0)\|^2 e^{-\nu\lambda_{N+1}t} + \frac{C}{\nu^2\lambda_{N+1}}\left(\max_{[0,T]}\|p-u_N\|^2 + \lambda_{N+1}^{-2}\max_{[0,T]}\|Aq\|^2\right)
$$

for $t \in [0,T]$. Finally, by initializing $\tilde{\phi}_1(0;u_N) = Q_N u_0 = q(0)$, we have estimate (4.8). □

COROLLARY 4.7. *Let $f(t) \in L^\infty((0,\infty);H)$, $u_0 \in D(A)$, and $T > 0$. Let $u(t) = p(t) + q(t)$ be a solution of* (1.2), *and $u_N(t)$ and $\tilde{\phi}_1(t;u_N(t))$ be a solution of system* (3.16)–(3.19) *such that estimates* (3.1) *and* (4.1) *hold. Then, for $t \in [0,T]$, we have*

$$
\|q(t) - \tilde{\phi}_1(t;u_N(t))\| = O(\epsilon^3). \tag{4.9}
$$

Proof. Since $\|Aq\| = O(1)$ and $\|p(t) - u_N(t)\| = O(\epsilon^3)$ from Theorem 4.1, the $\|Aq\|$ term dominates the right-hand side of (4.8). Thus $\|q - \tilde{\phi}_1(t;u_N(t))\| = O(\epsilon^3)$ as $\epsilon \to 0$. □

In this case, the dynamic postprocessing method produces a more accurate high mode approximation. In particular, the dynamic postprocessing method produces a high mode approximation of the same order as the low mode approximation.

5. Numerical experiments.

In this section we present some numerical experiments to support the above accuracy analysis and compare the efficiency of the two leading order methods. Opting for a one-dimensional calculation, we integrated Burgers equation with homogeneous Dirichlet boundary conditions on the interval $[0,\pi]$. That is, we used the equation

$$
\begin{aligned}
\frac{\partial u}{\partial t} - \nu\frac{\partial^2 u}{\partial x^2} + u\frac{\partial u}{\partial x} &= f(x,t), \\
u(0,t) = u(\pi,t) &= 0, \\
u(x,0) &= u_0(x).
\end{aligned}
$$

Using notation similar to the NSE, the above equation is equivalent to the functional differential equation

$$
\frac{du}{dt} + \nu Au + B(u,u) = f,
$$

where, in this case, $A = -\frac{\partial^2}{\partial x^2}$ with domain $D(A) = H^2(0,\pi) \cap H_0^1(0,\pi)$. The eigenfunctions of A are $\omega_k = \sqrt{2/\pi}\sin(kx)$, with corresponding eigenvalues $\lambda_k = k^2$, for $k = 1, 2, \ldots$. The bilinear term $B(u,u)$ is defined by $B(u,v) = \frac{2}{3}uv_x + \frac{1}{3}u_x v$ for every u, $v \in H_0^1(0,\pi)$. In particular, we have $B(u,u) = uu_x$ for every $u \in H_0^1(0,\pi)$.

We chose an exact solution $u_e(x,t)$ and then computed the "highly oscillatory" time-dependent forcing term from the exact solution. In this way we checked errors without computing a large Galerkin approximation as an "exact" solution. We chose $u_e(x,t)$ as follows,

$$(5.1) \quad u_e(x,t) = \sum_{k=1}^{\infty} \frac{a_k(t)}{k^3} \sin kx, \qquad a_k(t) = \begin{cases} 1 + \gamma \sin k^2 t, & 1 \geq k \geq 100, \\ 1, & k > 100, \end{cases}$$

and then calculated the forcing function as $f(x,t) := du_e/dt + \nu A u_e + B(u_e, u_e)$. The exact solution u_e is in $D(A)$ for $t \geq 0$ as assumed above in section 3. Actually, we can compute sharper estimates for $\|Aq\|$ and $\|dq/dt\|$ using expression (5.1) to obtain $\|Aq\| \leq \sqrt{2}/\lambda_N^{1/4} = O(\epsilon^{1/2})$, and similarly $\|dq/dt\| \leq \sqrt{\gamma}/\lambda_N^{1/4} = \gamma O(\epsilon^{1/2})$. Note that the $\|Aq\|$ and $\|dq/dt\|$ terms are of the same order, depending on the magnitude of γ. We then obtain $\|q\| = O(\epsilon^{5/2})$ and $\|A^{1/2}q\| = O(\epsilon^{3/2})$. These estimates are of slightly higher order in ϵ than those assumed in the theoretical section. However, using these estimates for the truncation analysis and keeping terms up to order ϵ, we obtain the same leading order approximate system as in system (3.2)–(3.3).

The experiments in this section were run on a Sun Ultra 5. The time integrator used was the VODE code [1] with computed diagonal Jacobians (VODE option MF=23). This code is a reliable and efficient tool for the time integration of systems of ODEs, especially for stiff problems like those arising from the spatial discretizations of dissipative PDEs. VODE consists of a backward differentiation formula (BDF) implemented with variable time step and variable order. Specifically, in the algorithm the time levels are unevenly spaced and the step sizes are produced by the code as the integration proceeds. Also, formulas of different orders (up to order six) are used, the order of the formula being selected by the code at every time step. For problems similar to those in this section, the superior efficiency of codes like VODE with respect to other frequently used time integrators was experimentally checked in [9].

For each value of N we sought the Galerkin approximation, the standard postprocessed Galerkin approximation (standard PP) from system (2.18)–(2.20), and the dynamic postprocessed Galerkin approximation (dynamic PP) from system (3.16)–(3.19). Each experiment was carried out with decreasing values of the time-integration tolerance (an input parameter to VODE) until additional reduction did not improve the accuracy of the solution any further. This means that the time discretization error is negligible in comparison with the spatial error that we are interested in examining.

Figure 5.1 shows the total errors for each of the approximations at time $t = 2.0$ units, with $\gamma = 0.1$ and $\nu = 1$. The initial condition was the projection of $u_e(x,0)$. The solid line represents errors from the Galerkin method, (2.18) and (2.20); dashed lines represent errors from the standard postprocessing method, system (2.18)–(2.20); and dotted lines represent errors from the dynamic postprocessing method, system (3.16)–(3.19). It is clear from Figure 5.1 that the dynamic postprocessing method achieves the best rate of convergence as indicated by the most negative slope. The improvement of the standard postprocessing method over the Galerkin method is only algebraic, and not a significant improvement in the rate of convergence. Thus, the addition of the dq_1/dt term in the high mode equation is beneficial in this case, at least in terms of accuracy. The low mode errors for each of the three methods are essentially the same. The high mode errors are very similar to the total errors shown in Figure 5.1, since the high mode error dominates the total Galerkin and standard postprocessing error. Only the dynamic postprocessing method produces high mode errors (and rate of convergence) that are approximately of the same order as those for the low mode errors. In the case being studied, i.e., highly oscillatory solutions, the dynamic postprocessing method is the most accurate.

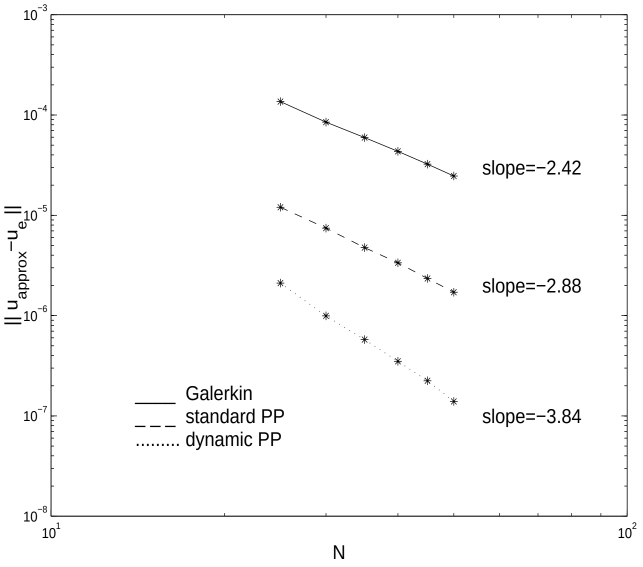

FIG. 5.1. *Total errors* $\|u_{approx} - u_e\|$.

The dynamic postprocessing method requires a numerical integration to obtain the high modes, rather than evaluating the high modes once at some final time, as with the standard postprocessing method [8], [10], [11], [17]. We next looked at the efficiency of the dynamic postprocessing method in the case of highly time-oscillatory solutions to determine whether the error improvement justifies any additional computational cost (CPU).

We again integrated Burgers equation with homogeneous Dirichlet boundary conditions on the interval $[0, \pi]$ as in section 5. However, this time we provided the forcing function defined by

$$f(x,t) = \sum_{k=1}^{\infty} \left(\frac{\dot{a}_k(t)}{k^3} + \frac{a_k(t)}{k} \right) \sin kx, \quad a_k(t) = \left\{ \begin{array}{ll} 1 + \gamma \sin k^2 t, & 1 \geq k \geq 100, \\ 1, & k > 100, \end{array} \right. \tag{5.2}$$

and used a large Galerkin run as an “exact” solution for computing errors. This way we did not accumulate the cost of computing the forcing function from an exact solution at each time step. The experiments in this section were run on an SGI Origin 2000 with $\gamma = 0.1$, $\nu = 1$, and initial condition $u_0(x) = \sum k^{-3} \sin kx$.

We first verified that we obtain accuracy results with this forcing function similar to those in the previous numerical experiment. Figure 5.2 shows the total error estimates at $t = 2.0$ units using the VODE time integrator. The rates of convergence are similar to those in Figure 5.1; the dynamic postprocessing method is again the most accurate method. In Figure 5.3 we plot the total errors $\|u_{approx} - u_e\|$ from Figure 5.2 versus the amount of computing time (in seconds) needed by each method to achieve those errors. We added results from larger mode standard postprocessing runs to better indicate any overlap. A horizontal line across the plot indicates, for a particular error, the CPU time needed by each method. Again, the solid line represents errors from the Galerkin method, dashed lines represent errors from the standard postprocessing method, and dotted lines represent errors from the dynamic

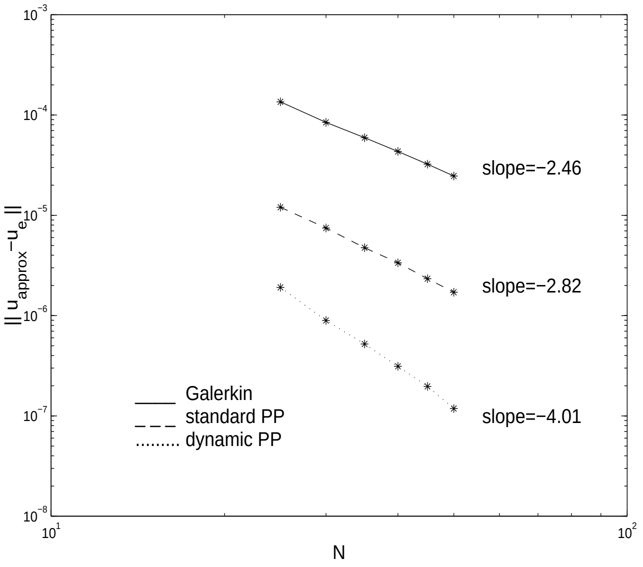

FIG. 5.2. *Total errors* $\|u_{approx} - u_e\|$.

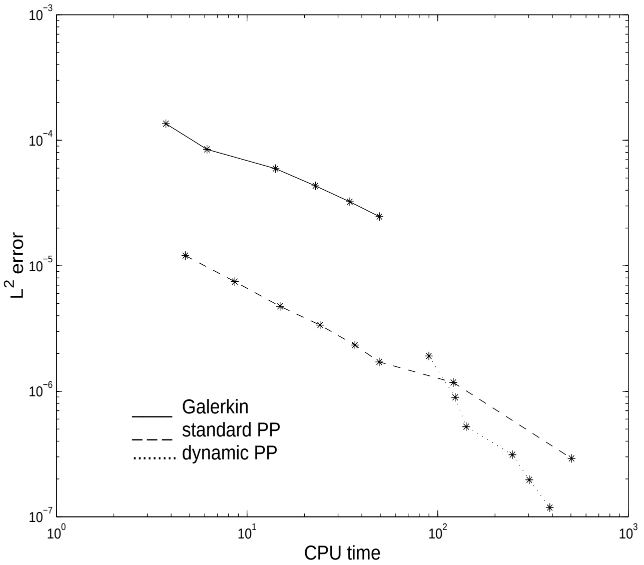

FIG. 5.3. *Error vs. CPU: VODE.*

postprocessing method. For the larger mode runs, the dynamic postprocessing method is slightly more efficient than the standard postprocessing method.

We also sought to take advantage of using a larger time step to integrate the high modes, subcycling the low mode integration within the high mode integration. For this experiment we used a semi-implicit backward Euler scheme. The low modes were integrated using the scheme

$$p^{n+1} - p^n + \Delta t \left(Ap^{n+1} + P_N B(p^n, p^n) \right) = \Delta t P_N f^n,$$

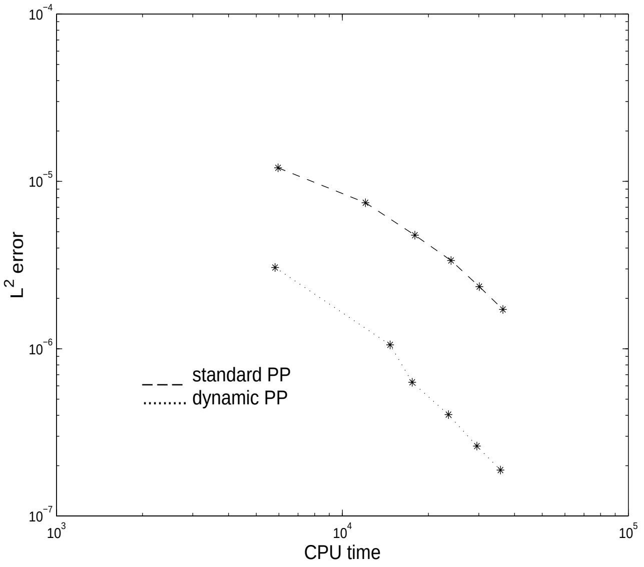

FIG. 5.4. *Error vs. CPU: backward Euler.*

and the high modes were integrated, in the dynamic postprocessing method, using

$$q^{n+1} - q^n + \Delta t \left(Aq^{n+1} + Q_N B(p^n, p^n) \right) = \Delta t Q_N f^n.$$

Otherwise, the experimental setup was the same as with the VODE time integrator, i.e., we computed the errors at time $t = 2$ units with $\nu = 1$, $\gamma = 0.1$, and initial condition $u_0(x) = \sum k^{-3} \sin kx$. In each experiment we set Δt small enough so that the low mode error ($\|p - u_N\|$) was equivalent to the low mode errors from the VODE experiments. The effect of subcycling was to slightly increase the error with little improvement in CPU time. This is because the cost of evaluating the high modes at each time step is minimal compared to the cost of evaluating the nonlinear term within each subcycle in order to integrate the low modes. The CPU comparison for the semi-implicit backward Euler experiments without subcycling is given in Figure 5.4. We plot error versus CPU time for the standard and dynamic postprocessing methods. Again the dynamic postprocessing method is the more efficient method for the case of a *highly oscillatory* (in time) solution due to a highly oscillatory (in time) forcing function.

Performing the same experiments with a less time-oscillatory forcing function, we obtained different accuracy and CPU comparisons. In this final set of experiments, we used the forcing function

$$f(x,t) = \sum_{k=1}^{\infty} \left(\frac{\dot{a}_k(t)}{k^3} + \frac{a_k(t)}{k} \right) \sin kx, \quad a_k(t) = \begin{cases} 1 + \gamma \sin t, & 1 \geq k \geq 100, \\ 1, & k > 100. \end{cases} \tag{5.3}$$

In this case we expect the solution to be less oscillatory, and hence the $\|dq/dt\|$ term should be of a smaller order, and the standard postprocessing method should be as accurate as the dynamic postprocessing method. Figure 5.5 shows the total errors for the Galerkin, standard postprocessing, and dynamic postprocessing approximations using the VODE time integrator at time $t = 3.0$ units, again with $\gamma = 0.1$, $\nu = 1.0$, and $u_0(x) = \sum k^{-3} \sin kx$. Note that the standard and dynamic postprocessing methods

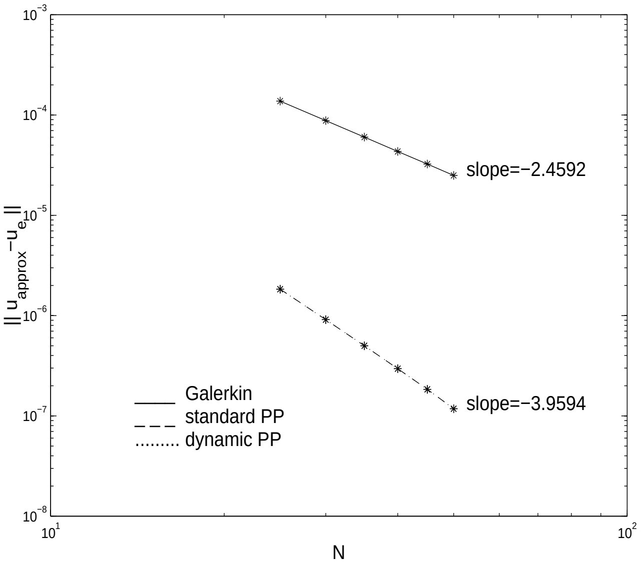

FIG. 5.5. *Total errors: f slowly oscillating in time.*

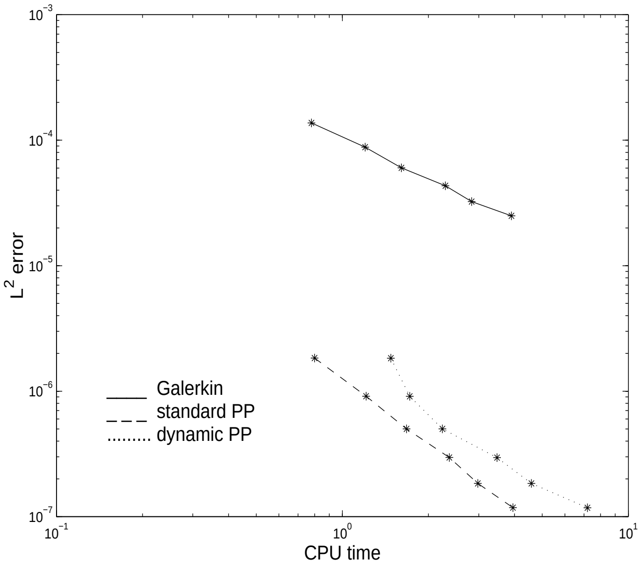

FIG. 5.6. *Error vs. CPU: VODE and f slowly oscillating in time.*

have the same rate of convergence, and there is no improvement with the dynamic postprocessing method.

In Figure 5.6 we plot the total error versus CPU time for the case of the slowly oscillating (in time) forcing function when using the VODE time integrator; the standard postprocessing method proves to be more efficient. Results using the backward Euler scheme are similar, though the differences are less pronounced.

6. Concluding remarks. Through a classical truncation analysis we have shown that postprocessing appears as a natural part of approximate systems and corresponding schemes for numerically integrating the two-dimensional NSE. For autonomous systems, we generated a family of approximate systems (and schemes) of increasing orders of approximation using the asymptotic (in time) estimates from [5] for $\|Aq\|$ and $\|dq/dt\|$. Each system included a postprocessing step that resulted in a high mode approximation of the same order as the low mode approximation. We found that the leading order system is the standard Galerkin method with postprocessing as introduced in [11]. The standard Galerkin method alone uses a less accurate approximation for the high modes than for the low modes. Hence, the accuracy of the high mode approximation, or lack thereof, dominates the error.

By assuming different asymptotic (in time) estimates for $\|Aq\|$ and $\|dq/dt\|$, we obtained the *dynamic postprocessing* method as the leading order method. This was done for the case of a highly oscillatory (in time) solution; the algorithm applies to the case of nonsmooth initial data as well [24]. In the case of a highly oscillatory solution, the dynamic postprocessing method was more accurate and efficient than the standard postprocessing method. For nonautonomous systems with solutions that are not so oscillatory, both methods obtained the same accuracy; however, the standard postprocessing method was more efficient in this case.

The method of using truncation analysis with asymptotic estimates for the low and high modes may easily be extended to general nonlinear parabolic evolution or elliptic equations to obtain postprocessing systems and schemes which approximate the low and high modes to the same order of accuracy.

7. Acknowledgments. We would like to thank Bosco Garcı́a-Archilla and Julia Novo for the stimulating and inspiring discussions. This work was initiated when E. S. T. and S. W. were visiting the Institute of Geophysical and Planetary Physics (IGPP) at the Los Alamos National Laboratory, while E. S. T. was the Orson Anderson Scholar from 1997–1998.

FIRST-ORDER SYSTEM LEAST SQUARES FOR THE STRESS-DISPLACEMENT FORMULATION: LINEAR ELASTICITY[*]

ZHIQIANG CAI[†] AND GERHARD STARKE[‡]

Abstract. This paper develops a least-squares finite element method for linear elasticity in both two and three dimensions. The least-squares functional is based on the stress-displacement formulation with the symmetry condition of the stress tensor imposed in the first-order system. For the respective displacement and stress, using the Crouzeix–Raviart and Raviart–Thomas finite element spaces, our least-squares finite element method is shown to be optimal in the (broken) H^1 and $H(\mathrm{div})$ norms uniform in the incompressible limit.

Key words. least-squares finite element method, linear elasticity, incompressible limit

1. Introduction.

The practical need of the stress tensor has motivated extensive studies of mixed finite element methods in the stress-displacement formulation (see [1, 4, 2, 3, 5, 11, 14, 20]). Unlike mixed methods for second-order scalar elliptic boundary value problems, stress-displacement finite elements are extremely difficult to construct. This is due to the fact that the stress tensor is symmetric. A beautiful finite element space had not been constructed until recently by Arnold and Winther [5]. Their space is a natural extension of the Raviart–Thomas space of $H(\mathrm{div})$. The minimum degree of freedom on each triangle of Arnold and Winther space for the symmetric stress tensor in two dimensions is 24, which is very expensive. Previous works impose the symmetry condition weakly via a Lagrange multiplier (see [1, 2, 20]). Like scalar elliptic problems, mixed methods lead to saddle-point problems, and mixed finite elements are subject to the inf-sup condition. Many solution methods which work well for symmetric positive definite problems cannot be applied directly. Although substantial progress in solution methods for saddle-point problems has been achieved, these problems may still be difficult and expensive to solve.

Finite element methods of least-squares type have been the object of many studies recently (see, e.g., the survey [7] and the monograph [18]). Least-squares finite element methods have also been applied to first-order system formulations of linear elasticity, for example, in [13], where displacement gradients are used as additional degrees of freedom. Recently, a displacement-stress-rotation least-squares formulation has been investigated in [19] (see also the references therein for some other least-squares approaches in the engineering literature). Our aim is to present a least-squares formulation that computes approximations for the stress and displacement only. These are

the quantities of interest in many practical applications including coupling of elastic deformation with fluid flow models. The least-squares formulation presented in this paper also has some advantages for the extension to geometrically nonlinear elasticity computations, as will be considered in a companion paper.

The purpose of this paper is to develop a least-squares finite element method based on the stress-displacement formulation. To circumvent the numerical difficulty on the symmetry of the stress tensor, we impose such a symmetry condition in the first-order system and then apply the least-squares principle to this overdetermined, but consistent, system. The least-squares functional uses the L^2 norm, and it is shown that the homogeneous functional is equivalent to the energy norm involving the Lamé constant for the displacement and the standard $H(\mathrm{div})$ norm for the stress. This implies that our least-squares finite element method using the respective Crouzeix–Raviart and Raviart–Thomas spaces for the displacement and stress yields optimal error estimates uniformly in the incompressible limit. The algebraic system resulting in this discretization may be efficiently solved by multigrid methods, which will be considered in a forthcoming paper. Additionally, we consider an inverse norm least-squares functional and show that its homogeneous form is equivalent to the energy norm for the displacement and the L^2 norm for the stress. This functional can be used to develop a discrete inverse norm least-squares method (see, e.g., [9]).

An outline of the paper is as follows. The linear elasticity system is introduced in section 2, along with some notations. Section 3 develops the least-squares functionals based on the extended first-order system of the stress and displacement and establishes their ellipticity and continuity. Section 4 discusses the finite element approximation. Finally, section 5 establishes an inequality in the stress tensor space, used in section 3, through a Helmholtz decomposition.

2. Linear elasticity and preliminaries.

We consider an isotropic elastic material in the configuration space $\Omega \subset \Re^d$ ($d = 2$ or 3). Assume that Ω is a bounded, open, connected domain with Lipschitz boundary $\partial\Omega$. Let $\mathbf{u} = (u_1, \dots, u_d)^t$ be the displacement and $\mathbf{f} = (f_1, \dots, f_d)^t$ be the body force. The constituent law expresses a linear relation between the stress tensor $\boldsymbol{\sigma}(\mathbf{u}) = (\sigma_{ij}(\mathbf{u}))_{d\times d}$ and the linearized strain tensor $\boldsymbol{\epsilon}(\mathbf{u}) = (\epsilon_{ij}(\mathbf{u}))_{d\times d}$, with $\epsilon_{ij}(\mathbf{u}) = \frac{1}{2}(\partial_j u_i + \partial_i u_j)$:

$$\sigma_{ij}(\mathbf{u}) = \lambda \mathrm{tr}\,\big(\boldsymbol{\epsilon}(\mathbf{u})\big)\delta_{ij} + 2\mu\epsilon_{ij}(\mathbf{u}), \tag{2.1}$$

where tr stands for the trace operator (i.e., $\mathrm{tr}\,(\boldsymbol{\epsilon}(\mathbf{u})) = \sum_{j=1}^d \epsilon_{jj}(\mathbf{u}) = \nabla\cdot\mathbf{u}$), δ_{ij} is the Kronecker tensor, and the positive constants λ and μ are the Lamé constants such that $\mu \in [\mu_1, \mu_2]$ with $0 < \mu_1 < \mu_2$ and $\lambda \in (0, \infty)$. We have the equilibrium equation

$$\sum_{i=1}^d \frac{\partial\sigma_{ij}(\mathbf{u})}{\partial x_i} + f_j = 0 \quad \text{for } j = 1, \dots, d. \tag{2.2}$$

Let Γ_D and Γ_N be a partition of the boundary of Ω such that $\partial\Omega = \bar{\Gamma}_D \cup \bar{\Gamma}_N$ and $\Gamma_D \cap \Gamma_N = \emptyset$. Let $\mathbf{n} = (n_1, \dots, n_d)^t$ be the outward unit vector normal to the boundary. We impose the homogeneous displacement and traction boundary conditions

$$\left\{\begin{aligned} \mathbf{u} = \mathbf{0} \ \text{ on } \ \Gamma_D,& \\ \sum_{i=1}^d \sigma_{ij}(\mathbf{u})n_i = 0 \ \text{ on } \ \Gamma_N& \quad \text{for } j = 1, \dots, d. \end{aligned}\right. \tag{2.3}$$

For simplicity, we assume that Γ_D is not empty (i.e., $\operatorname{mes}(\Gamma_D) \neq 0$). For the pure traction problem ($\Gamma_D = \emptyset$), our approach may be easily extended to the space of infinitesimal rigid motions.

We use the standard notation and definition for the Sobolev spaces $H^s(\Omega)$ for $s \geq 0$, the associated inner products are denoted by $(\cdot,\, \cdot)_{s,\,\Omega}$, and their norms by $\|\cdot\|_{s,\,\Omega}$. (We will omit Ω from the inner product and norm designation when there is no risk of confusion.) For $s = 0$, $H^s(\Omega)$ coincides with $L^2(\Omega)$. In this case, the norm and inner product will be denoted by $\|\cdot\|$ and $(\cdot,\, \cdot)$, respectively. Let

$$H_D^1(\Omega) = \{v \in H^1(\Omega) \,:\, v = 0 \text{ on } \Gamma_D\} \quad \text{and} \quad H_N^1(\Omega) = \{v \in H^1(\Omega) \,:\, v = 0 \text{ on } \Gamma_N\}.$$

We use $H_D^{-1}(\Omega)$ to denote the dual of $H_D^1(\Omega)$ with the norm defined by

$$\|\phi\|_{-1,\,D} = \sup_{0 \neq \psi \in H_D^1(\Omega)} \frac{(\phi,\, \psi)}{\|\psi\|_1}$$

(see [6, section 6.2]). Let

$$H(\operatorname{div};\Omega) = \{\mathbf{q} \in L^2(\Omega)^d \,:\, \nabla\cdot\mathbf{q} \in L^2(\Omega)\}$$

and

$$H(\mathbf{curl};\, \Omega) = \{\mathbf{q} \in L^2(\Omega)^d \,:\, \nabla\times\mathbf{q} \in L^2(\Omega)^{2d-3}\},$$

which are Hilbert spaces under the respective norms

$$\|\mathbf{q}\|_{H(\operatorname{div};\,\Omega)} = \left(\|\mathbf{q}\|^2 + \|\nabla\cdot\mathbf{q}\|^2\right)^{\frac{1}{2}} \quad \text{and} \quad \|\mathbf{q}\|_{H(\mathbf{curl};\,\Omega)} = \left(\|\mathbf{q}\|^2 + \|\nabla\times\mathbf{q}\|^2\right)^{\frac{1}{2}}.$$

Define the subspaces

$$H_N(\operatorname{div};\, \Omega) = \{\mathbf{q} \in H(\operatorname{div};\, \Omega) \,:\, \mathbf{n}\cdot\mathbf{q} = 0 \ \text{ on } \ \Gamma_N\}$$

and

$$H_D(\mathbf{curl};\, \Omega) = \{\mathbf{q} \in H(\mathbf{curl};\, \Omega) \,:\, \mathbf{n}\times\mathbf{q} = \mathbf{0} \ \text{ on } \ \Gamma_D\}.$$

Finally, define the product spaces

$$H_D^{-1}(\Omega)^d = \prod_{i=1}^d H_D^{-1}(\Omega)\,, \quad H_N(\operatorname{div};\Omega)^d = \prod_{i=1}^d H_N(\operatorname{div};\Omega),$$
$$\text{and} \quad H_D(\mathbf{curl};\Omega)^d = \prod_{i=1}^d H_D(\mathbf{curl};\Omega)$$

with standard product norms. We also use the notations

$$\boldsymbol{\sigma} : \boldsymbol{\tau} = \sum_{i,j=1}^d \sigma_{ij}\tau_{ij} \quad \text{and} \quad |\boldsymbol{\tau}| = \sqrt{\boldsymbol{\tau} : \boldsymbol{\tau}}.$$

The weak form of boundary value problem for the displacement in (2.2) and (2.3) has a unique solution $\mathbf{u} \in H_D^1(\Omega)^d$ for every $\mathbf{f} \in H_D^{-1}(\Omega)^d$. Moreover, the solution $\mathbf{u}$ satisfies the following H^1 regularity estimate:

$$\|\mathbf{u}\|_1 + \lambda\|\nabla\cdot\mathbf{u}\| \leq C\,\|\mathbf{f}\|_{-1}. \tag{2.4}$$

If the domain Ω is convex or its boundary is $C^{1,1}$, then the H^2 regularity estimate holds:

$$\|\mathbf{u}\|_2 + \lambda \|\nabla \cdot \mathbf{u}\|_1 \le C\,\|\mathbf{f}\| \tag{2.5}$$

for the pure displacement or pure traction problems (see, e.g., [10]). We use C with or without subscripts to denote a generic positive constant, possibly different at different occurrences, which is independent of the Lamé constant λ and the mesh size h introduced in the subsequent section but may depend on the Lamé constant μ and the domain Ω. We will frequently use the term *uniform* in reference to a relation to mean that it holds independent of λ and h.

3. First-order system least squares.

Let $\mathcal{C} = \lambda \mathbf{b}\mathbf{b}^t + 2\mu I$ be a $d^2 \times d^2$ matrix, where

$$\mathbf{b} = \begin{cases} (1,\,0,\,0,\,1)^t, & d = 2, \\ (1,\,0,\,0,\,0,\,1,\,0,\,0,\,0,\,1)^t, & d = 3. \end{cases}$$

It is easy to see that $\mathcal{C}$ is symmetric and positive definite and that its inverse has the form of

$$\mathcal{C}^{-1} = \frac{1}{2\mu}\left(I - \frac{\lambda}{d\lambda + 2\mu}\mathbf{b}\mathbf{b}^t \right).$$

It is convenient to view $d \times d$-matrices as d^2-vectors, e.g., $(\sigma_{ij})_{d\times d}$ as $(\boldsymbol{\sigma}_1, \ldots, \boldsymbol{\sigma}_d)^t$, where $\boldsymbol{\sigma}_j = (\sigma_{1j}, \ldots, \sigma_{dj})^t$ is the jth column of $(\sigma_{ij})_{d\times d}$ for $j = 1, \ldots, d$. Thus,

$$\operatorname{tr} \boldsymbol{\sigma} = \operatorname{tr}\,(\sigma_{ij})_{d\times d} = \sum_{i=1}^{d} \sigma_{ii} = \mathbf{b}^t \begin{pmatrix} \boldsymbol{\sigma}_1 \\ \vdots \\ \boldsymbol{\sigma}_d \end{pmatrix} = \mathbf{b}^t \boldsymbol{\sigma}.$$

Now, the constituent law may be rewritten in terms of the matrix $\mathcal{C}$:

$$\boldsymbol{\sigma}(\mathbf{u}) = \mathcal{C}\boldsymbol{\epsilon}(\mathbf{u}). \tag{3.1}$$

By treating the stress tensor as independent variables, we then have the following first-order system:

$$\begin{cases} \boldsymbol{\sigma} - \mathcal{C}\boldsymbol{\epsilon}(\mathbf{u}) & = & \mathbf{0} & \text{in} & \Omega, \\ \nabla \cdot \boldsymbol{\sigma} + \mathbf{f} & = & \mathbf{0} & \text{in} & \Omega, \end{cases} \tag{3.2}$$

with boundary conditions

$$\mathbf{u} = \mathbf{0} \text{ on } \Gamma_D \quad \text{and} \quad \mathbf{n} \cdot \boldsymbol{\sigma} = \mathbf{0} \text{ on } \Gamma_N. \tag{3.3}$$

Here, the respective divergence and normal operators $\nabla\cdot$ and $\mathbf{n}\cdot$ (and other operators encountered in the subsequent section) are extended componentwise:

$$\nabla \cdot \boldsymbol{\sigma} = \begin{pmatrix} \nabla \cdot \boldsymbol{\sigma}_1 \\ \vdots \\ \nabla \cdot \boldsymbol{\sigma}_d \end{pmatrix} \quad \text{and} \quad \mathbf{n} \cdot \boldsymbol{\sigma} = \begin{pmatrix} \mathbf{n} \cdot \boldsymbol{\sigma}_1 \\ \vdots \\ \mathbf{n} \cdot \boldsymbol{\sigma}_d \end{pmatrix}.$$

Note that the stress tensor is symmetric; that is,

$$\boldsymbol{\sigma} = \boldsymbol{\sigma}^t \quad \text{in } \Omega. \tag{3.4}$$

(Here, $\boldsymbol{\sigma}^t$ denotes the transpose of $\boldsymbol{\sigma}$ as a $d \times d$ matrix.) One can impose such symmetry in the solution space as in [5]. By doing so, it complicates the construction and increases the dimension of the finite element space. The construction of a piecewise linear $H(\mathrm{div})$-conforming finite element space for the stress field would necessarily be of the form

$$\boldsymbol{\sigma}|_T = \begin{pmatrix} \alpha_T + \gamma_T x_1 & \beta_T + \gamma_T x_2 \\ \rho_T + \delta_T x_1 & \sigma_T + \delta_T x_2 \end{pmatrix}$$

with $\alpha_T, \beta_T, \gamma_T, \delta_T, \rho_T, \sigma_T \in \Re$. The symmetry condition would imply $\gamma_T = \delta_T = 0$, leaving us with nothing but constants and therefore with $\operatorname{div} \boldsymbol{\sigma} = \mathbf{0}$. This does certainly not lead to an acceptable approximation property in the $H(\mathrm{div})$ norm, and therefore, piecewise linear finite element spaces are not admissible in this context. Instead of using higher-order polynomials, we choose to impose the symmetry condition in the system. To this end, an equivalent extended system for (3.2) is

$$\text{(3.5)} \qquad \left\{ \begin{array}{rcll} \mathcal{C}^{-\frac{1}{2}}\boldsymbol{\sigma} - \mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u}) & = & \mathbf{0} & \text{in} \quad \Omega, \\ \nabla \cdot \boldsymbol{\sigma} + \mathbf{f} & = & \mathbf{0} & \text{in} \quad \Omega, \\ \frac{1}{2}\left(\boldsymbol{\sigma} - \boldsymbol{\sigma}^t\right) & = & \mathbf{0} & \text{in} \quad \Omega. \end{array} \right.$$

Applying the trace operator to (3.1) gives

$$\text{(3.6)} \qquad \operatorname{tr} \boldsymbol{\sigma} = \operatorname{tr} \mathcal{C}\boldsymbol{\epsilon}(\mathbf{u}) = (d\lambda + 2\mu)\nabla \cdot \mathbf{u} \quad \text{in} \quad \Omega.$$

If $\Gamma_N = \emptyset$, then $\int_\Omega \nabla \cdot \mathbf{u}\, dx = \int_{\partial\Omega} \mathbf{n} \cdot \mathbf{u}\, ds = 0$, which implies $\int_\Omega \operatorname{tr} \boldsymbol{\sigma}\, dx = 0$. Therefore, we are at liberty to impose such a condition for $\boldsymbol{\sigma}$. Let $\mathbf{X}$ denote $H_N(\mathrm{div};\, \Omega)^d$ if $\Gamma_N \neq \emptyset$, and its subspace $\{\boldsymbol{\tau} \in H_N(\mathrm{div};\, \Omega)^d : \int_\Omega \operatorname{tr} \boldsymbol{\tau}\, dx = 0\}$ otherwise. For $\mathbf{f} \in L^2(\Omega)^d$, we define the following least-squares functionals:

$$\text{(3.7)} \qquad G_{-1}(\mathbf{u},\, \boldsymbol{\sigma};\, \mathbf{f}) = \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\sigma} - \mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla \cdot \boldsymbol{\sigma} + \mathbf{f}\|^2_{-1,D} + \left\| \frac{1}{2}\left(\boldsymbol{\sigma} - \boldsymbol{\sigma}^t\right) \right\|^2$$

and

$$\text{(3.8)} \qquad G(\mathbf{u},\, \boldsymbol{\sigma};\, \mathbf{f}) = \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\sigma} - \mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u})\|^2 + \|\nabla \cdot \boldsymbol{\sigma} + \mathbf{f}\|^2 + \left\| \frac{1}{2}\left(\boldsymbol{\sigma} - \boldsymbol{\sigma}^t\right) \right\|^2$$

for $(\mathbf{u},\, \boldsymbol{\sigma}) \in \mathbf{H} \equiv H^1_D(\Omega)^d \times \mathbf{X}$. We first establish uniform boundedness and ellipticity (i.e., equivalence) of the homogeneous functionals $G_{-1}(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0})$ and $G(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0})$ in terms of the respective functionals $M_{-1}(\mathbf{v},\, \boldsymbol{\tau})$ and $M(\mathbf{v},\, \boldsymbol{\tau})$ defined on $\mathbf{H}$ by

$$M_{-1}(\mathbf{v},\, \boldsymbol{\tau}) = \|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2 + \|\nabla \cdot \boldsymbol{\tau}\|^2_{-1,D}$$

and

$$M(\mathbf{v},\, \boldsymbol{\tau}) = \|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2 + \|\nabla \cdot \boldsymbol{\tau}\|^2.$$

THEOREM 3.1. *There exist positive constants C_1 and C_2, independent of λ, such that*

$$\text{(3.9)} \qquad \frac{1}{C_1} M_{-1}(\mathbf{v},\, \boldsymbol{\tau}) \le G_{-1}(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0}) \le C_1 M_{-1}(\mathbf{v},\, \boldsymbol{\tau})$$

and that

$$\frac{1}{C_2} M(\mathbf{v},\, \boldsymbol{\tau}) \le G(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0}) \le C_2 M(\mathbf{v},\, \boldsymbol{\tau}) \tag{3.10}$$

hold for all $(\mathbf{v},\, \boldsymbol{\tau}) \in H_D^1(\Omega)^d \times H_N(\mathrm{div};\, \Omega)^d$.

Proof. Decomposing the tensor $\boldsymbol{\tau}$ into symmetric and skew-symmetric parts

$$\boldsymbol{\tau} = \frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2} + \frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2},$$

we then have

$$\mathcal{C}^{-1}\boldsymbol{\tau} = \mathcal{C}^{-1}\left(\frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2}\right) + \frac{1}{2\mu}\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}.$$

Note that $A : B = 0$ if A and B are symmetric and skew-symmetric tensors, respectively. Hence,

$$\|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2 = \left\|\mathcal{C}^{-\frac{1}{2}}\frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2}\right\|^2 + \left\|\mathcal{C}^{-\frac{1}{2}}\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}\right\|^2 = \left\|\mathcal{C}^{-\frac{1}{2}}\frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2}\right\|^2 + \frac{1}{2\mu}\left\|\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}\right\|^2.$$

Now, the upper bounds in both (3.9) and (3.10) follow from the triangle inequality. To show the validity of the lower bound in (3.9), note first that $\boldsymbol{\epsilon}(\mathbf{v}) = \frac{1}{2}(\nabla\mathbf{v} + (\nabla\mathbf{v})^t)$ is the symmetric part of the gradient, and hence, using integration by parts,

$$\begin{aligned}(\boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v})) &= \left(\frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2},\, \boldsymbol{\epsilon}(\mathbf{v})\right) = \left(\frac{\boldsymbol{\tau} + \boldsymbol{\tau}^t}{2},\, \nabla\mathbf{v}\right) \\ &= (\boldsymbol{\tau},\, \nabla\mathbf{v}) - \left(\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2},\, \nabla\mathbf{v}\right) = -(\nabla\cdot\boldsymbol{\tau},\, \mathbf{v}) - \left(\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2},\, \nabla\mathbf{v}\right). \end{aligned} \tag{3.11}$$

Using the Cauchy–Schwarz and Korn inequalities, we then have that

$$\begin{aligned}\|\mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\|^2 &= (\mathcal{C}\boldsymbol{\epsilon}(\mathbf{v}),\, \boldsymbol{\epsilon}(\mathbf{v})) = (\mathcal{C}\boldsymbol{\epsilon}(\mathbf{v}) - \boldsymbol{\tau},\, \boldsymbol{\epsilon}(\mathbf{v})) + (\boldsymbol{\tau}, \boldsymbol{\epsilon}(\mathbf{v})) \\ &\le \|\mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\|\, \|\mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D}\, \|\mathbf{v}\| + \left\|\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}\right\|\, \|\nabla\mathbf{v}\| \\ &\le C\left(\|\mathcal{C}^{-1/2}\boldsymbol{\tau} - \mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D} + \left\|\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}\right\|\right)\|\mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\|\,, \end{aligned} \tag{3.12}$$

which implies that

$$\|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2 \le C\left(\|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau} - \mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D} + \left\|\frac{\boldsymbol{\tau} - \boldsymbol{\tau}^t}{2}\right\|\right)^2 \le C\, G_{-1}(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0}).$$

Together with the triangle inequality, it is easy to see that $\|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2$ is also bounded above by the homogeneous functional. This completes the proof of the lower bound in (3.9). Since $G_{-1}(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0}) \le G(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0})$ and $\|\nabla\cdot\boldsymbol{\tau}\|^2 \le G(\mathbf{v},\, \boldsymbol{\tau};\, \mathbf{0})$, the lower bound in (3.10) follows from that in (3.9). The proof of the theorem is therefore finished. □

Note that

$$\|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2 = 2\mu\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 + \lambda\|\nabla\cdot\mathbf{v}\|^2.$$

Hence, Korn's inequality (see, e.g., Braess [8, section VI.3]),

$$\|\mathbf{v}\|_1^2 \le C\,\|\boldsymbol{\epsilon}(\mathbf{v})\|^2 \quad \forall\ \mathbf{v}\in H^1_D(\Omega)^d,$$

implies the uniform equivalence of $\|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2$ and

$$|||\mathbf{v}||| \equiv \|\mathbf{v}\|_1^2 + \lambda\|\nabla\cdot\mathbf{v}\|^2;$$

i.e., there exists a positive constant C independent of λ such that

$$\frac{1}{C}\left(\|\mathbf{v}\|_1^2 + \lambda\|\nabla\cdot\mathbf{v}\|^2\right) \le \|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|^2 \le C\,\left(\|\mathbf{v}\|_1^2 + \lambda\|\nabla\cdot\mathbf{v}\|^2\right) \tag{3.13}$$

holds for all $\mathbf{v}\in H^1_D(\Omega)^d$. It is easy to see that

$$\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 = \frac{1}{2\mu}\left(\|\boldsymbol{\tau}\|^2 - \frac{\lambda}{d\lambda+2\mu}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2\right).$$

We may split $\mathcal{C}^{-1}$ into its deviatoric and volumetric parts as

$$\mathcal{C}^{-1}\boldsymbol{\tau} = \frac{1}{2\mu}\left(I - \frac{1}{d}\mathbf{b}\mathbf{b}^t\right)\boldsymbol{\tau} + \frac{1}{d(d\lambda+2\mu)}\mathbf{b}\mathbf{b}^t\boldsymbol{\tau} = \frac{1}{2\mu}\mathbf{dev}\,\boldsymbol{\tau} + \frac{1}{d(d\lambda+2\mu)}\mathrm{tr}\,\boldsymbol{\tau}\,I,$$

which implies

$$\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 = \frac{1}{2\mu}\|\mathbf{dev}\,\boldsymbol{\tau}\|^2 + \frac{1}{d(d\lambda+2\mu)}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2\,. \tag{3.14}$$

This means that the nondeviatoric part of the stress is unweighted in the incompressible limit. Particularly, in two dimensions one has

$$\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 = \frac{1}{2\mu}\|\tau_{12}\|^2 + \frac{1}{2\mu}\|\tau_{21}\|^2 + \frac{1}{4\mu}\|\tau_{11}-\tau_{22}\|^2 + \frac{1}{4(\lambda+\mu)}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2\,. \tag{3.15}$$

LEMMA 3.2. *For any $\boldsymbol{\tau}\in\mathbf{X}$, there exists a positive constant C independent of λ such that*

$$\|\boldsymbol{\tau}\| \le C\,(\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D}). \tag{3.16}$$

Proof. The validity of (3.16) follows from Lemmas 5.3 and 5.4 (see section 5) and the fact that

$$\|\boldsymbol{\tau}\|^2 = 2\mu\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \frac{\lambda}{d\lambda+2\mu}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2 \le 2\mu\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \frac{1}{d}\|\mathrm{tr}\,\boldsymbol{\tau}\|^2.$$

This completes the proof of the lemma. □

Since, for all $\boldsymbol{\tau}\in\mathbf{X}$,

$$\|\nabla\cdot\boldsymbol{\tau}\|_{-1,D} \le \|\boldsymbol{\tau}\| \quad \text{and} \quad \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D} \le \|\nabla\cdot\boldsymbol{\tau}\|\,,$$

it is then easy to see that there exist positive constants C_1 and C_2 such that

$$\frac{1}{C_1}\|\boldsymbol{\tau}\|^2 \le \|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2_{-1,D} \le C_1\|\boldsymbol{\tau}\|^2 \tag{3.17}$$

and that

$$\frac{1}{C_2}\|\boldsymbol{\tau}\|^2_{H(\mathrm{div};\Omega)} \le \|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2 \le C_2\|\boldsymbol{\tau}\|^2_{H(\mathrm{div};\Omega)}. \tag{3.18}$$

THEOREM 3.3. *There exist positive constants C_1 and C_2, independent of λ, such that*

$$\frac{1}{C_1}\left(|||\mathbf{v}|||^2 + \|\boldsymbol{\tau}\|^2\right) \le G_{-1}(\mathbf{v},\,\boldsymbol{\tau};\,\mathbf{0}) \le C_1\left(|||\mathbf{v}|||^2 + \|\boldsymbol{\tau}\|^2\right) \tag{3.19}$$

and that

$$\frac{1}{C_2}(|||\mathbf{v}|||^2 + \|\boldsymbol{\tau}\|^2_{H(\mathrm{div};\Omega)}) \le G(\mathbf{v},\,\boldsymbol{\tau};\,\mathbf{0}) \le C_2(|||\mathbf{v}|||^2 + \|\boldsymbol{\tau}\|^2_{H(\mathrm{div};\Omega)}) \tag{3.20}$$

hold for all $(\mathbf{v},\,\boldsymbol{\tau}) \in H^1_D(\Omega)^d \times \mathbf{X}$.

Proof. The theorem is a direct consequence of Theorem 3.1, (3.13), (3.17), and (3.18). □

4. Finite element approximation. For the finite element approximation of the system (3.5), the least-squares functional in (3.8) is minimized with respect to appropriate finite-dimensional spaces. For the stress approximation, the standard $H(\mathrm{div};\Omega)$-conforming Raviart–Thomas elements may be used. Due to the special structure of $\mathcal{C}^{-1}$, we have proved the uniform equivalence of $M(0,\boldsymbol{\tau})$ and the $H(\mathrm{div};\Omega)$ norm in (3.18). Therefore, [11, Proposition 3.9] gives approximation properties which are uniform in λ with respect to $M(0,\,\cdot)$. However, the situation is more complicated for the displacement approximation. In order to get approximation properties with respect to

$$\|\mathbf{v}\|_1^2 + \lambda\|\nabla\cdot\mathbf{v}\|^2\;,$$

standard continuous piecewise polynomial elements are not sufficient. Following [11, section VI.3] we may use nonconforming finite element spaces; see also [10, section 9.4] for the case of Crouzeix–Raviart elements.

To this end, let $\mathcal{T}_h$ be a regular triangulation of the domain Ω with elements of size $O(h)$ (see [14]). The minimization is then carried out for the discrete least-squares functional

$$G_h(\mathbf{u}_h,\boldsymbol{\sigma}_h;\mathbf{f}) = \sum_{K\in\mathcal{T}_h}\|\mathcal{C}^{-\frac12}\boldsymbol{\sigma}_h - \mathcal{C}^{\frac12}\boldsymbol{\epsilon}(\mathbf{u}_h)\|^2_{0,K} + \|\nabla\cdot\boldsymbol{\sigma}_h + \mathbf{f}\|^2 + \left\|\frac12\left(\boldsymbol{\sigma}_h - \boldsymbol{\sigma}_h^t\right)\right\|^2 \tag{4.1}$$

over a finite dimensional space $\mathbf{V}_h \times \mathbf{X}_h$. If we define the associated bilinear form

$$\begin{aligned}\mathcal{B}_h(\mathbf{u},\boldsymbol{\sigma};\mathbf{v},\boldsymbol{\tau}) = \sum_{K\in\mathcal{T}_h}&(\mathcal{C}^{-\frac12}\boldsymbol{\sigma} - \mathcal{C}^{\frac12}\boldsymbol{\epsilon}(\mathbf{u}),\mathcal{C}^{-\frac12}\boldsymbol{\tau} - \mathcal{C}^{\frac12}\boldsymbol{\epsilon}(\mathbf{v}))_{0,K}\\ &+ (\nabla\cdot\boldsymbol{\sigma},\nabla\cdot\boldsymbol{\tau}) + \frac14(\boldsymbol{\sigma}-\boldsymbol{\sigma}^t,\boldsymbol{\tau}-\boldsymbol{\tau}^t)\;,\end{aligned}$$

then the minimum $(\mathbf{u}_h,\boldsymbol{\sigma}_h) \in \mathbf{V}_h\times\mathbf{X}_h$ of the least-squares functional in (4.1) satisfies

$$\mathcal{B}_h(\mathbf{u}_h,\boldsymbol{\sigma}_h;\mathbf{v},\boldsymbol{\tau}) = -(f,\nabla\cdot\boldsymbol{\tau}) \tag{4.2}$$

for all $(\mathbf{v},\boldsymbol{\tau}) \in \mathbf{V}_h \times \mathbf{X}_h$.

For simplicity, we restrict ourselves to triangular elements in two dimensions. Specifically, for $k \geq 1$,

$$\begin{aligned}\mathbf{V}_h = \{&\mathbf{v} \in L^2(\Omega)^2 \,:\, \mathbf{v}|_T \text{ is a polynomial of degree } k \text{ for each } K \in \mathcal{T}_h\,,\\ &\text{such that } \mathbf{v} \text{ is continuous at the } k \text{ Gauss points on interior edges}\,,\\ &\text{and } \mathbf{v} = \mathbf{0} \text{ at the } k \text{ Gauss points of edges in } \Gamma_D\}\end{aligned}$$

and

$$\begin{aligned}\mathbf{X}_h = \{&\boldsymbol{\tau}_h \subset \mathbf{X} \,:\, \mathbf{v}|_T \text{ is a polynomial of degree } k \text{ for each } K \in \mathcal{T}_h\,,\\ &\text{such that } \mathbf{n}\cdot\boldsymbol{\tau}_h \text{ is a polynomial of degree } k-1 \text{ along edges}\}\,.\end{aligned}$$

In order to establish approximation properties for this approach, we need to modify the result of Theorem 3.1 for the discrete least-squares functional in (4.1). To this end, we define a discrete norm by

$$|||(\mathbf{v},\boldsymbol{\tau})|||_h \equiv \left(\sum_{K\in\mathcal{T}_h} \|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{v})\|_{0,K}^2 + \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2 + \|\nabla\cdot\boldsymbol{\tau}\|^2\right)^{\frac{1}{2}} \tag{4.3}$$

and show its equivalence with respect to the discrete least-squares functional.

THEOREM 4.1. *There exist positive constants C_E and C_C, independent of λ, such that*

$$\begin{aligned}&G_h(\mathbf{v},\boldsymbol{\tau};\mathbf{0}) \geq C_E|||(\mathbf{v},\boldsymbol{\tau})|||_h^2\\ &\qquad\qquad \forall\,(\mathbf{v},\boldsymbol{\tau}) \in \mathbf{V}_h \times \mathbf{X}_h\,,\\ &G_h(\mathbf{v},\boldsymbol{\tau};\mathbf{0}) \leq C_C|||(\mathbf{v},\boldsymbol{\tau})|||_h^2\\ &\qquad\qquad \forall\,(\mathbf{v},\boldsymbol{\tau}) \in (H_D^1(\Omega) + \mathbf{V}_h) \times H_N(\mathrm{div};\Omega).\end{aligned} \tag{4.4}$$

Proof. We proceed similarly to the proof of Theorem 3.1. As in (3.11), we obtain

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} (\boldsymbol{\tau},\boldsymbol{\epsilon}(\mathbf{v}))_{0,K} &= \sum_{K\in\mathcal{T}_h}\left[(\boldsymbol{\tau},\nabla\mathbf{v})_{0,K} - \left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\nabla\mathbf{v}\right)_{0,K}\right]\\ &= \sum_{K\in\mathcal{T}_h} (\mathbf{n}\cdot\boldsymbol{\tau},\mathbf{v})_{0,\partial K} - \sum_{K\in\mathcal{T}_h} (\nabla\cdot\boldsymbol{\tau},\mathbf{v})_{0,K} - \sum_{K\in\mathcal{T}_h}\left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\nabla\mathbf{v}\right)_{0,K}.\end{aligned}$$

The first sum on the right-hand side can be written as a sum over all edges

$$\sum_{\mathcal{E}_h\ni E\subseteq\Gamma_N} (\mathbf{n}\cdot\boldsymbol{\tau},\mathbf{v})_{0,E} + \sum_{\mathcal{E}_h\ni E\subseteq\Gamma_D} (\mathbf{n}\cdot\boldsymbol{\tau},\mathbf{v})_{0,E} + \sum_{\mathcal{E}_h\ni E\not\subseteq\partial\Omega} (\mathbf{n}\cdot\boldsymbol{\tau},[\mathbf{v}])_{0,E}\,, \tag{4.5}$$

where $\mathcal{E}_h$ is the collection of all edges of the triangulation $\mathcal{T}_h$, and $[\mathbf{v}]$ denotes the jump of $\mathbf{v}$ on E. For $(\mathbf{v},\boldsymbol{\tau}) \in \mathbf{V}_h \times \mathbf{X}_h$, the first term above vanishes since $\mathbf{n}\cdot\boldsymbol{\tau} = \mathbf{0}$ on Γ_N. For the remaining two terms, we see that $\mathbf{n}\cdot\boldsymbol{\tau}$ is a polynomial of degree $k-1$, and $\mathbf{v}$ or $[\mathbf{v}]$, respectively, is a polynomial of degree k which vanishes at the Gauss points. In both cases, the integrand is therefore a polynomial of degree $2k-1$, which is zero at the k Gauss points, implying that the second and third terms in (4.5) also vanish. We therefore have in analogy to (3.12)

$$\sum_{K\in\mathcal{T}_h}(\boldsymbol{\tau},\boldsymbol{\epsilon}(\mathbf{v}))_{0,K}=-(\nabla\cdot\boldsymbol{\tau},\mathbf{v})-\sum_{K\in\mathcal{T}_h}\left(\frac{\boldsymbol{\tau}-\boldsymbol{\tau}^t}{2},\nabla\mathbf{v}\right)_{0,K}. \tag{4.6}$$

The rest of the proof is completely analogous to that of Theorem 3.1. □

Remark. Theorem 4.1 is also valid if nonconforming elements of degree k for the displacement are combined with Raviart–Thomas elements of lower degree for the stress. For example, quadratic nonconforming elements may be combined with the lowest-order Raviart–Thomas spaces.

The quasioptimality of the least-squares finite element approximation follows from the coercivity result in Theorem 4.1 in the usual way.

COROLLARY 4.2. *Let* $(\mathbf{u},\boldsymbol{\sigma})$ *be the solution of* (3.5) *with boundary conditions* (3.3)*, and let* $(\mathbf{u}_h,\boldsymbol{\sigma}_h)\in\mathbf{V}_h\times\mathbf{X}_h$ *be the solution of* (4.2)*. Then*

$$|||(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)|||_h\le C\inf_{(\mathbf{v}_h,\boldsymbol{\tau}_h)\in\mathbf{V}_h\times\mathbf{X}_h}|||(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h)|||_h\,. \tag{4.7}$$

Proof. The triangle inequality and the first inequality in (4.4) give

$$\begin{aligned}|||(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)|||_h&\le|||(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h)|||_h+|||(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h)|||_h\\&\le|||(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h)|||_h+C_E^{-1/2}G_h(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h;0)^{1/2}\end{aligned}$$

for all $(\mathbf{v}_h,\boldsymbol{\tau}_h)\in\mathbf{V}_h\times\mathbf{X}_h$. The following orthogonality property is the consequence of (3.5) and (4.2):

$$\mathcal{B}_h(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\sigma}-\boldsymbol{\sigma}_h;\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h)=0.$$

Hence,

$$\begin{aligned}G_h(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h;0)&=\mathcal{B}_h(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h;\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h)\\&=\mathcal{B}_h(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h;\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h)\\&\le G_h(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h;0)^{1/2}G_h(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h;0)^{1/2}\,,\end{aligned}$$

which, combined with the second inequality in (4.4), implies

$$G_h(\mathbf{u}_h-\mathbf{v}_h,\boldsymbol{\sigma}_h-\boldsymbol{\tau}_h;0)\le G_h(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h;0)\le C_C|||(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h)|||_h^2\,.$$

We have therefore proved

$$|||(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)|||_h\le\left(1+\left(\frac{C_C}{C_E}\right)^{1/2}\right)|||(\mathbf{u}-\mathbf{v}_h,\boldsymbol{\sigma}-\boldsymbol{\tau}_h)|||_h \tag{4.8}$$

for all $(\mathbf{v}_h,\boldsymbol{\tau}_h)\in\mathbf{V}_h\times\mathbf{X}_h$. □

THEOREM 4.3. *Assume that* $\mathbf{f}\in L^2(\Omega)^2$ *and that the regularity estimate in* (2.5) *holds. Then, for* $k=1$*, i.e., for* $\mathbf{V}_h$ *the Crouzeix–Raviart elements and* $\mathbf{Q}_h$ *the lowest-order Raviart–Thomas elements, we have the error estimate*

$$|||(\mathbf{u}-\mathbf{u}_h,\boldsymbol{\sigma}-\boldsymbol{\sigma}_h)|||_h\le C\,h\,\|\mathbf{f}\|\,. \tag{4.9}$$

Proof. The definition of the discrete norm in (4.3) implies that it is sufficient to bound the two terms

$$\left(\sum_{K\in\mathcal{T}_h} \|\mathcal{C}^{\frac{1}{2}}\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{v}_h)\|_{0,K}^2\right)^{1/2} \qquad \text{and} \qquad \left(\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\boldsymbol{\tau}_h)\|^2+\|\nabla\cdot(\boldsymbol{\sigma}-\boldsymbol{\tau}_h)\|^2\right)^{1/2}$$

separately. For the first term we conclude in analogy to [10, section 9.4] that there is a mapping $\mathcal{I}_h : H_D^1(\Omega)^2 \to \mathbf{V}_h$ such that

$$\begin{aligned}\left(\sum_{K\in\mathcal{T}_h} \|\mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{u}-\mathcal{I}_h\mathbf{u})\|_{0,K}^2\right)^{1/2} &\\ = \left(\sum_{K\in\mathcal{T}_h}\left(2\mu\|\boldsymbol{\epsilon}(\mathbf{u}-\mathcal{I}_h\mathbf{u})\|_{0,K}^2+\lambda\|\nabla\cdot(\mathbf{u}-\mathcal{I}_h\mathbf{u})\|_{0,K}^2\right)\right)^{1/2} &\\ \le\ C\,h\ (\|\mathbf{u}\|_2+\lambda\|\nabla\cdot\mathbf{u}\|_1)&\end{aligned}$$

uniformly as $\lambda\to\infty$. For the second term we know that there exists a projection $\mathcal{R}_h : H_N(\text{div};\Omega)^2 \to \mathbf{X}_h$ such that

$$\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\mathcal{R}_h\boldsymbol{\sigma})\| \le \frac{1}{2\mu}\|\boldsymbol{\sigma}-\mathcal{R}_h\boldsymbol{\sigma}\| \le C\,h\ (\|\boldsymbol{\sigma}\|_1+\|\nabla\cdot\boldsymbol{\sigma}\|_1)\,,$$

$$\|\nabla\cdot(\boldsymbol{\sigma}-\mathcal{R}_h\boldsymbol{\sigma})\| \le C\,h\,\|\nabla\cdot\boldsymbol{\sigma}\|_1$$

uniformly in λ (cf. [11, Proposition III.3.9]). The proof is concluded using the regularity estimate (2.5) and the quasioptimality result in Corollary 4.2. □

Due to (3.14), the norm $|||(\,\cdot\,,\,\cdot\,)|||_h$ in Theorem 4.2 degenerates for the trace part as $\lambda\to\infty$. With Lemma 3.2 we get the following stronger result.

COROLLARY 4.4. *Under the same assumptions as in Theorem* 4.3 *we have the error estimate*

$$\left(\sum_{K\in\mathcal{T}_h} \|\mathcal{C}^{1/2}\boldsymbol{\epsilon}(\mathbf{u}-\mathbf{u}_h)\|_{0,K}^2+\|\boldsymbol{\sigma}-\boldsymbol{\sigma}_h\|_{H(\text{div};\Omega)}^2\right)^{1/2} \le C\,h\,\|\mathbf{f}\|. \tag{4.10}$$

Remark. The approximation results (4.9) and (4.10) are also valid for the case $k=2$. For the quadratic nonconforming elements $\mathbf{V}_h$, the existence of an interpolation operator $\mathcal{I}_h : H_D^1(\Omega)^2 \to \mathbf{V}_h$ with the desired properties follows along the same lines as in [10, section 9.4]. The crucial ingredient in the proof there is the property

$$\text{div}\,\mathbf{u}=0 \implies \text{div}\,(\mathcal{I}_h\mathbf{u})|_T=0\ \forall T\in\mathcal{T}_h,$$

which is shown in [17, pp. 513 and 514]. The interpolation result for the quadratic Raviart–Thomas elements also follows from [11, Proposition III.3.9].

Remark. The definition of $|||(\,\cdot\,,\,\cdot\,)|||_h$ involves the term

$$\sum_{K\in\mathcal{T}_h} \|C^{1/2}\boldsymbol{\epsilon}(\mathbf{v})\|_{0,K}^2.$$

For our approximation results (4.9) and (4.10) to be meaningful, we need to show that this defines a norm on $H_D^1(\Omega)+\mathbf{V}_h$. If $\Gamma_N\ne\emptyset$, this is not true for linear Crouzeix–Raviart elements, in general (cf. [11, section VI.3]). For nonconforming finite element spaces of higher degree, however, a discrete Korn's inequality can be shown (see [16]), giving us the desired result.

5. A Helmholtz decomposition. We establish a Helmholtz decomposition for any $\boldsymbol{\tau} \in \mathbf{X}$. To this end, define $\mathbf{q} \in H_D^1(\Omega)^d$ satisfying

$$\left\{ \begin{array}{rll} \nabla \cdot \big(\mathcal{C}\nabla \mathbf{q}\big) = \nabla \cdot \boldsymbol{\tau} & \text{in} & \Omega, \\ \mathbf{q} = \mathbf{0} & \text{on} & \Gamma_D, \\ \mathbf{n} \cdot \big(\mathcal{C}\nabla \mathbf{q}\big) = \mathbf{0} & \text{on} & \Gamma_N. \end{array} \right. \tag{5.1}$$

Its weak form is to find $\mathbf{q} \in H_D^1(\Omega)^d$ such that

$$\lambda(\nabla \cdot \mathbf{q},\, \nabla \cdot \boldsymbol{\xi}) + (\nabla \mathbf{q},\, \nabla \boldsymbol{\xi}) = (\nabla \cdot \boldsymbol{\tau},\, \boldsymbol{\xi}) \quad \forall\, \boldsymbol{\xi} \in H_D^1(\Omega)^d. \tag{5.2}$$

Let $L_D^2(\Omega)$ denote $L_0^2(\Omega) = \{v \in L^2(\Omega) \,:\, \int_\Omega v\, dx = 0\}$ if $\Gamma_N = \emptyset$, or $L^2(\Omega)$ otherwise. We will make use of the following lemma (see, e.g., [15]).

LEMMA 5.1. *For any $p \in L_D^2(\Omega)$, one has*

$$\|p\| \le C \sup_{\mathbf{v} \in H_D^1(\Omega)^d} \frac{(p, \nabla \cdot \mathbf{v})}{\|\mathbf{v}\|_1}. \tag{5.3}$$

LEMMA 5.2. *The solution of* (5.2) *satisfies the following regularity estimate:*

$$\lambda \|\nabla \cdot \mathbf{q}\| + \|\mathbf{q}\|_1 \le C\, \|\nabla \cdot \boldsymbol{\tau}\|_{-1,D}. \tag{5.4}$$

Proof. Taking $\boldsymbol{\xi} = \mathbf{q}$ in (5.2) and using the Poincaré inequality, one has

$$\lambda \|\nabla \cdot \mathbf{q}\|^2 + \|\mathbf{q}\|_1^2 \le C\, \|\nabla \cdot \boldsymbol{\tau}\|_{-1,D}^2. \tag{5.5}$$

It follows from Lemma 5.1 that

$$\lambda \|\nabla \cdot \mathbf{q}\| \le C \sup_{\mathbf{v} \in H_D^1(\Omega)^d} \frac{(\lambda \nabla \cdot \mathbf{q},\, \nabla \cdot \mathbf{v})}{\|\mathbf{v}\|_1} = C \sup_{\mathbf{v} \in H_D^1(\Omega)^d} \frac{(\nabla \cdot \boldsymbol{\tau},\, \mathbf{v}) - (\nabla \mathbf{q},\, \nabla \mathbf{v})}{\|\mathbf{v}\|_1},$$

which, together with the Cauchy–Schwarz inequality and (5.5), implies (5.4). □

First, let us consider the case in which $d = 2$. We use standard curl notation for two dimensions by identifying $\Re^2$ with the (x, y)-plane in $\Re^3$. Thus, the curl of $\mathbf{v} = (v_1,\, v_2)^t$ means the scalar function

$$\nabla \times \mathbf{v} = \partial_1 v_2 - \partial_2 v_1,$$

and $\nabla^\perp$ denotes its formal adjoint:

$$\nabla^\perp v = \begin{pmatrix} \partial_2 v \\ -\partial_1 v \end{pmatrix}.$$

Since $\boldsymbol{\tau} - \mathcal{C}\nabla \mathbf{q}$ is divergence-free, there exists $\boldsymbol{\phi} \in H_N^1(\Omega)^2$ such that

$$\boldsymbol{\tau} = \mathcal{C}\nabla \mathbf{q} + \nabla^\perp \boldsymbol{\phi},$$

where $\boldsymbol{\phi}$ satisfies that

$$\left\{ \begin{array}{rll} \nabla \times \big(\mathcal{C}^{-1}\nabla^\perp \boldsymbol{\phi}\big) = \nabla \times \big(\mathcal{C}^{-1}\boldsymbol{\tau}\big) & \text{in} & \Omega, \\ \mathbf{n} \times \big(\mathcal{C}^{-1}\nabla^\perp \boldsymbol{\phi}\big) = \mathbf{n} \times \big(\mathcal{C}^{-1}\boldsymbol{\tau}\big) & \text{on} & \Gamma_D, \\ \boldsymbol{\phi} = \mathbf{0} & \text{on} & \Gamma_N. \end{array} \right. \tag{5.6}$$

It is easy to see that

$$(\mathcal{C}^{-1}\nabla^\perp \boldsymbol{\phi},\, \nabla^\perp \boldsymbol{\phi}) = (\mathcal{C}^{-1}\boldsymbol{\tau},\, \nabla^\perp \boldsymbol{\phi}) \le \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|\, \|\mathcal{C}^{-\frac{1}{2}}\nabla^\perp \boldsymbol{\phi}\|,$$

which implies that

$$\frac{1}{2\mu}\left(\|\nabla^\perp \boldsymbol{\phi}\|^2 - \frac{\lambda}{2(\lambda+\mu)}\|\nabla\times\boldsymbol{\phi}\|^2\right) = (\mathcal{C}^{-1}\nabla^\perp \boldsymbol{\phi},\, \nabla^\perp \boldsymbol{\phi}) \le \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2. \tag{5.7}$$

LEMMA 5.3. *For any $\boldsymbol{\tau}\in\mathbf{X}$ and $d=2$, we have the following decomposition:*

$$\boldsymbol{\tau} = \mathcal{C}\nabla\mathbf{q} + \nabla^\perp\boldsymbol{\phi}, \tag{5.8}$$

where $\mathbf{q}\in H^1_D(\Omega)^2$ and $\boldsymbol{\phi}\in H^1_N(\Omega)^2$ satisfy (5.1) *and* (5.6)*, respectively. Moreover, we have that*

$$\|\mathrm{tr}\,\boldsymbol{\tau}\| \le C\left(\|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\| + \|\nabla\cdot\boldsymbol{\tau}\|_{-1,D}\right). \tag{5.9}$$

Proof. Since

$$\mathbf{b}^t\nabla\mathbf{q} = \nabla\cdot\mathbf{q} \quad\text{and}\quad \mathbf{b}^t\nabla^\perp\boldsymbol{\phi} = -\nabla\times\boldsymbol{\phi},$$

applying the trace operator to (5.8) gives that

$$\mathrm{tr}\,\boldsymbol{\tau} = 2(\lambda+\mu)\nabla\cdot\mathbf{q} - \nabla\times\boldsymbol{\phi}.$$

By Lemma 5.2, (5.7), and the fact that $\frac{\lambda}{\lambda+\mu} < 1$, to show the validity of (5.9), it then suffices to prove that

$$\|\nabla\times\boldsymbol{\phi}\| \le C\left(\|\nabla^\perp\boldsymbol{\phi}\|^2 - \frac{1}{2}\|\nabla\times\boldsymbol{\phi}\|^2\right)^{\frac{1}{2}}. \tag{5.10}$$

If $\Gamma_N = \emptyset$, then $\nabla\times\boldsymbol{\phi}\in L^2_0(\Omega)$ since

$$\int_\Omega \nabla\times\boldsymbol{\phi}\,dx = 2(\lambda+\mu)\int_\Omega \nabla\cdot\mathbf{q}\,dx - \int_\Omega \mathrm{tr}\,\boldsymbol{\tau}\,dx = 0,$$

where we have used the divergence theorem and $\mathbf{q}=\mathbf{0}$ on $\partial\Omega$ for the first integral, $\boldsymbol{\tau}\in\mathbf{X}$ for the second. Since $(\nabla^\perp\boldsymbol{\phi},\,\nabla\mathbf{v}) = 0$ for all $\mathbf{v}\in H^1_D(\Omega)^2$, it follows from the Cauchy–Schwarz inequality that for any $\mathbf{v}\in H^1_D(\Omega)^2$

$$\begin{aligned}(\nabla\times\boldsymbol{\phi},\,\nabla\cdot\mathbf{v}) &= \big((\nabla\times\boldsymbol{\phi})\mathbf{b},\,\nabla\mathbf{v}\big) = \big((\nabla\times\boldsymbol{\phi})\mathbf{b} + 2\nabla^\perp\boldsymbol{\phi},\,\nabla\mathbf{v}\big)\\ &\le \|(\nabla\times\boldsymbol{\phi})\mathbf{b} + 2\nabla^\perp\boldsymbol{\phi}\|\,\|\nabla\mathbf{v}\| = 2\left(\|\nabla^\perp\boldsymbol{\phi}\|^2 - \frac{1}{2}\|\nabla\times\boldsymbol{\phi}\|^2\right)^{\frac{1}{2}}\|\nabla\mathbf{v}\|.\end{aligned}$$

Hence, by Lemma 5.1, we have

$$\|\nabla\times\boldsymbol{\phi}\| \le C\sup_{\mathbf{v}\in H^1_D(\Omega)^d}\frac{(\nabla\times\boldsymbol{\phi},\nabla\cdot\mathbf{v})}{\|\mathbf{v}\|_1} \le C\left(\|\nabla^\perp\boldsymbol{\phi}\|^2 - \frac{1}{2}\|\nabla\times\boldsymbol{\phi}\|^2\right)^{\frac{1}{2}}.$$

This completes the proof of (5.10) and, hence, the lemma. □

In the case that $d = 3$, since $\boldsymbol{\tau} - \mathcal{C}\nabla\mathbf{q}$ is divergence-free, there exists $\boldsymbol{\Phi} = (\boldsymbol{\phi}_1, \boldsymbol{\phi}_2, \boldsymbol{\phi}_3) \in H(\mathbf{curl};\,\Omega)^3$ such that

$$\boldsymbol{\tau} = \mathcal{C}\nabla\mathbf{q} + \nabla\times\boldsymbol{\Phi},$$

where $\boldsymbol{\Phi}$ satisfies that

$$(5.11)\qquad \left\{\begin{array}{cl} \nabla\times\left(\mathcal{C}^{-1}\nabla\times\boldsymbol{\Phi}\right) = \nabla\times\left(\mathcal{C}^{-1}\boldsymbol{\tau}\right) & \text{in } \Omega, \\ \nabla\cdot\boldsymbol{\Phi} = \mathbf{0} & \text{in } \Omega, \\ \mathbf{n}\times\left(\mathcal{C}^{-1}\nabla^{\perp}\boldsymbol{\Phi}\right) = \mathbf{n}\times\left(\mathcal{C}^{-1}\boldsymbol{\tau}\right) & \text{on } \Gamma_D, \\ \mathbf{n}\times\boldsymbol{\Phi} = \mathbf{0} & \text{on } \Gamma_N. \end{array}\right.$$

An argument similar to that for $d = 2$ gives that

$$(5.12)\qquad \frac{1}{2\mu}\left(\|\nabla\times\boldsymbol{\Phi}\|^2 - \frac{\lambda}{3\lambda+2\mu}\|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\|^2\right) = (\mathcal{C}^{-1}\nabla\times\boldsymbol{\Phi},\,\nabla\times\boldsymbol{\Phi}) \le \|\mathcal{C}^{-\frac{1}{2}}\boldsymbol{\tau}\|^2\,.$$

LEMMA 5.4. *For any $\boldsymbol{\tau} \in \mathbf{X}$ and $d = 3$, we have the following decomposition:*

$$(5.13)\qquad \boldsymbol{\tau} = \mathcal{C}\nabla\mathbf{q} + \nabla\times\boldsymbol{\Phi},$$

where $\mathbf{q} \in H^1_D(\Omega)^2$ and $\boldsymbol{\Phi} \in H(\mathbf{curl};\,\Omega)^3$ satisfy (5.1) *and* (5.11)*, respectively. Moreover, the estimate in* (5.9) *is valid.*

Proof. Again, it suffices to show that

$$(5.14)\qquad \|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\| \le C\left(\|\nabla\times\boldsymbol{\Phi}\|^2 - \frac{1}{3}\|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\|^2\right)^{\frac{1}{2}}.$$

An argument similar to that in the proof of Lemma 5.3 implies that

$$\mathbf{b}^t\nabla\times\boldsymbol{\Phi} \in L^2_D(\Omega) \quad\text{and}\quad (\nabla\times\boldsymbol{\Phi},\,\nabla\mathbf{v}) = 0 \quad \forall\ \mathbf{v}\in H^1_D(\Omega)^3.$$

Since

$$\|(\mathbf{b}^t\nabla\times\boldsymbol{\Phi})\mathbf{b} - 3\nabla\times\boldsymbol{\Phi}\| = 3\left(\|\nabla\times\boldsymbol{\Phi}\|^2 - \frac{1}{3}\|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\|^2\right)^{\frac{1}{2}},$$

it then follows from Lemma 5.3 that

$$\begin{aligned}\|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\| &\le C\sup_{\mathbf{v}\in H^1_D(\Omega)^d}\frac{(\mathbf{b}^t\nabla\times\boldsymbol{\Phi},\nabla\cdot\mathbf{v})}{\|\mathbf{v}\|_1} \le C\,\|(\mathbf{b}^t\nabla\times\boldsymbol{\Phi})\mathbf{b} - 3\nabla\times\boldsymbol{\Phi}\| \\ &\le C\left(\|\nabla\times\boldsymbol{\Phi}\|^2 - \frac{1}{3}\|\mathbf{b}^t\nabla\times\boldsymbol{\Phi}\|^2\right)^{\frac{1}{2}}.\end{aligned}$$

This completes the proof of (5.10) and, hence, the lemma. □

6. A numerical example. We conclude this paper with a simple numerical example. On the unit square $\Omega = (-1,1)\times(-1,1)$, we consider the system (3.2), (3.3) with

$$\Gamma_D = [-1,1]\times\{-1\}, \qquad \Gamma_N = ([-1,1]\times\{1\})\cup\{-1,1\}\times[-1,1]$$

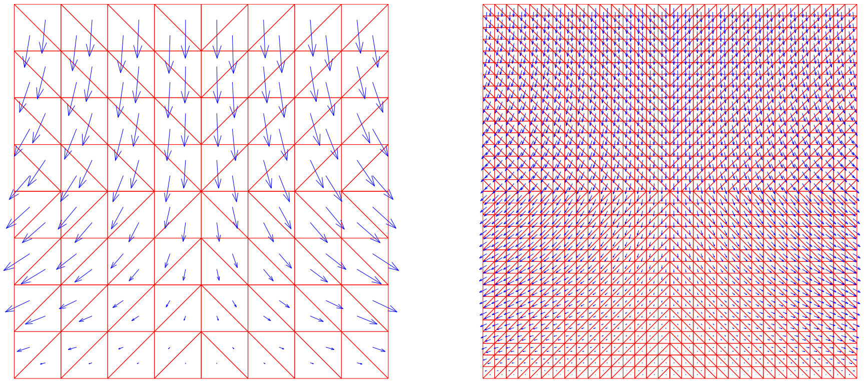

Fig. 6.1. *Displacement field on a uniform triangulation.*

and with $\mathbf{f} = (0, -1)$, i.e., a unit volume force pointing downward. The Lamé parameter μ is always 1 in this example. We compute the least-squares finite element approximation for a sequence of triangulations resulting from uniform refinement. The displacement field for $\lambda = 1000$ is shown in Figure 6.1 (for $h = 1/4$ on the left and for $h = 1/16$ on the right).

Table 6.1 shows the least-squares functional for different mesh sizes h and different values of the Lamé parameters λ. Obviously, the convergence is uniform as $\lambda \to \infty$, as indicated by the theory. Also shown is the number of triangles and the total number of degrees of freedom (for displacement and stress) in the system.

More numerical results including more sophisticated test examples will be presented in a companion paper [12], which focusses on adaptive refinement strategies.

Acknowledgment. We thank Travis Austin for helpful discussions.

CONDITIONING OF HIERARCHIC p-VERSION NÉDÉLEC ELEMENTS ON MESHES OF CURVILINEAR QUADRILATERALS AND HEXAHEDRA[*]

MARK AINSWORTH[†] AND JOE COYLE[†]

Abstract. The conditioning of a set of hierarchic basis functions for p-version edge element approximation of the space $H(\mathbf{curl})$ is studied. Theoretical bounds are obtained on the location of the eigenvalues and on the growth of the condition numbers for the mass, curl-curl, and stiffness matrices that naturally arise from Galerkin approximation of Maxwell's equations. The theory is applicable to meshes of curvilinear quadrilaterals or hexahedra in two and three dimensions, respectively, including the case in which the local order of approximation is nonuniform. Throughout, the theory is illustrated with numerical examples that show that the theoretical asymptotic bounds are sharp and are attained within the range of practical computation.

Key words. eigenvalue bounds, hierarchic basis, edge finite elements, Maxwell equations

1. Introduction.

The p-version of the finite element method is an established tool for the numerical approximation of problems arising in mechanics. The use of higher order *edge* finite elements for problems in electromagnetic applications such as approximation of Maxwell's equations, though less well established, has witnessed a steadily increasing interest since the early works of Nédélec [16] and Bossavit [3, 4, 5]. Let $H(\mathbf{curl};\Omega)$ denote the space

$$H(\mathbf{curl};\Omega) = \left\{ \boldsymbol{u} \in \boldsymbol{L}^2(\Omega) : \mathbf{curl}\, \boldsymbol{u} \in \boldsymbol{L}^2(\Omega) \right\},$$

where Ω is a bounded, curvilinear polyhedral domain in $\mathbb{R}^d$, $d = 2, 3$. The space $H(\mathbf{curl};\Omega)$ arises naturally in many physical models, such as Maxwell's equations. While the traces of the tangential components of functions belonging to $H(\mathbf{curl};\Omega)$ are continuous across any interface, the normal components may be discontinuous. Consequently, the space $H(\mathbf{curl};\Omega)$ is a proper subspace of $\boldsymbol{H}^1(\Omega)$. It is vital that any Galerkin approximation should be based on a finite dimensional subspace that matches these continuity properties. For instance, a standard conforming finite element approximation of the space $\boldsymbol{H}^1(\Omega)$ is known to lead to spurious solutions in quite commonly occurring situations [7]. A finite dimensional subspace of $H(\mathbf{curl};\Omega)$ suitable for the Galerkin approximation of Maxwell's equations may be constructed using the p-version of the finite element method based on Nédélec, or edge, finite elements [16].

Higher order edge elements are employed in the engineering literature [19, 20], where the degree of element is typically fixed in the range $p = 2, 3, 4$ and convergence is sought through mesh refinement. However, the p-version means, at least in principle, that the mesh is fixed and that the degree of approximation p tends to infinity. The mathematical analysis of the p-version edge finite elements was considered by

Monk [14, 15], while significant contributions to the practical implementation of p- and hp-version edge finite elements were made by Demkowicz and coworkers [8, 18].

The improved accuracy and rate of convergence obtained using p-version procedures comes at a price. An efficient practical implementation of higher order methods requires the use of hierarchic basis functions. Generally, it is found that the conditioning of the matrices that arise from discretization using higher order elements degenerates quite rapidly in comparison with those of h-version procedures. The conditioning of the stiffness and mass matrices on a tensor product reference element using a particular hierarchic basis for H^1 conforming p-version approximation was studied by Maitre and Pourquier [13]. Subsequently, Olsen and Douglas [17] studied the conditioning of hierarchic bases on tensor product elements in general and conjectured that, regardless of the choice of basis, the condition numbers grow as $\mathcal{O}(p^{4d})$ or faster in d space dimensions. Hu, Guo, and Katz [11] disproved this conjecture by exhibiting a hierarchical basis where the condition number of the stiffness matrix grows as $\mathcal{O}(p^{4(d-1)})$.

Comparatively little is known concerning the conditioning of the matrices arising from p-version edge element approximation of Maxwell's equations. The hierarchic basis presented by Rachowicz and Demkowicz was studied numerically in [1], where it was observed that the condition number degrades exponentially fast with increasing polynomial order, even in two spatial dimensions. An alternative hierarchic basis presented in [1] was observed numerically to have superior conditioning properties. Nevertheless, there has been no theoretical analysis of the conditioning of hierarchic p-version edge elements.

The aim of the present work is to address this problem directly and to study the conditioning theoretically and establish bounds on the growth explicitly in terms of the polynomial degree. The situation for Maxwell's equations is rather different from the cases considered in the works mentioned above. For instance, the underlying space is $H(\mathbf{curl})$ rather than H^1, meaning that the basis functions are vectorial in nature and possess only continuity of traces in the tangential components. One implication of this is that the basis functions on the physical elements are constructed using a covariant transformation from the reference element, rather than a standard pull-back construction employed in the H^1-conforming situation. Furthermore, the operators involved in the Maxwell equations are different and naturally lead [12] to the *mass*

$$M(\boldsymbol{E},\boldsymbol{F}) = \int_\Omega \varepsilon \boldsymbol{E}\cdot\boldsymbol{F}\,\mathrm{d}V \tag{1}$$

and *curl-curl*

$$S(\boldsymbol{E},\boldsymbol{F}) = \int_\Omega \mu^{-1}\,\mathbf{curl}\,\boldsymbol{E}\cdot\mathbf{curl}\,\boldsymbol{F}\,\mathrm{d}V \tag{2}$$

bilinear forms. Here, the permeability μ and permittivity ε are real, scalar-valued functions that are assumed to be bounded above and below in Ω; i.e., there exist positive constants c_1 and C_1 such that

$$c_1 \le \mu(\boldsymbol{x}), \varepsilon(\boldsymbol{x}) \le C_1 \qquad \text{for all } \boldsymbol{x}\in\Omega. \tag{3}$$

Moreover, for transient simulations, a difference approximation of the time derivatives would typically lead to the need to invert a *stiffness* matrix given by

$$\boldsymbol{A} = \boldsymbol{S} + \omega^2\boldsymbol{M}, \tag{4}$$

where ω would be inversely proportional to the time step Δt. The exponential rate of convergence of the p-version spatial discretization means that the order p will generally be modest in comparison with the choice of the time step, i.e., $\Delta t^{-1} \gg p$.

We derive bounds on the asymptotic behavior of the eigenvalues and on the growth of the condition numbers for each of the above matrices for the family of hierarchic basis functions presented in [1]. The theory is applicable to meshes of curvilinear quadrilaterals or hexahedra in two and three dimensions, respectively, and allows for nonuniform local order of approximation. By analogy with the results obtained by Hu, Guo, and Katz [11], it is shown that the condition number of the mass and curl-curl matrices grows as $\mathcal{O}(p^{4(d-1)})$ and $\mathcal{O}(p^{2(d-1)})$, respectively, in d spatial dimensions. The diagonally scaled stiffness matrix has a condition number that grows as

$$C \max\left(1, \frac{p}{\omega}\right)^2 p^{2(d-1)}$$

so that, in the typical case where $\omega \propto \Delta t^{-1} \gg p$, the condition number grows as $\mathcal{O}(p^{2(d-1)})$. Throughout, the theory is illustrated with numerical examples that show that the theoretical asymptotic bounds are sharp and are attained within the range of practical computation.

2. Statement of the results. Let $\mathcal{M}$ be a partitioning of Ω into curvilinear quadrilaterals or hexahedra [6] such that the nonempty intersection of distinct elements is either a single common face, edge, or vertex of both elements. Each element $K \in \mathcal{M}$ is the image of a reference element $\widehat{K} = (-1,1)^d$ under a differentiable bijection $\boldsymbol{F}_K : \widehat{K} \to K$. It is assumed that positive constants exist such that the Jacobian matrix $\boldsymbol{J}_K$ of the mapping satisfies

$$c_{2,K} \leq \det \boldsymbol{J}_K(\boldsymbol{\xi}) \leq C_{2,K} \tag{5}$$

and

$$\sigma\left(\boldsymbol{J}_K^{-1}\boldsymbol{J}_K^{-\top}\right) \subset [c_{3,K}, C_{3,K}] \tag{6}$$

for all $\boldsymbol{\xi} \in \widehat{K}$, where $\sigma(\boldsymbol{A})$ denotes the spectrum [10] of the matrix $\boldsymbol{A}$.

A finite element in the sense of Ciarlet [6] is represented by a triple $(\mathcal{P}, K, \Sigma)$. The space $\widehat{\mathcal{P}}$ associated with the Nédélec element of order p on the reference element is given by

$$\widehat{\mathcal{P}} = \begin{cases} \mathbb{Q}_{p,p+1} \times \mathbb{Q}_{p+1,p}, & d = 2, \\ \mathbb{Q}_{p,p+1,p+1} \times \mathbb{Q}_{p+1,p,p+1} \times \mathbb{Q}_{p+1,p+1,p}, & d = 3, \end{cases}$$

where

$$\mathbb{Q}_{p,q} = \left\{x^i y^j : 0 \leq i \leq p, 0 \leq j \leq q\right\}$$

and

$$\mathbb{Q}_{p,q,r} = \left\{x^i y^j z^k : 0 \leq i \leq p, 0 \leq j \leq q, 0 \leq k \leq r\right\}.$$

The set of degrees of freedom $\widehat{\Sigma}$ is specified implicitly by the choice of basis. Let $\{L_i\}_{i=0}^{p}$ denote normalized Legendre polynomials, so that $\|L_i\|_{(-1,1)} = 1$, and define the set $\{\ell_i\}_{i=0}^{p+1}$ as follows:

$$\ell_0(s) = \frac{1}{2}(1-s), \quad \ell_1(s) = \frac{1}{2}(1+s)$$

and

$$\ell_i(s) = \int_{-1}^{s} L_{i-1}(t)\,\mathrm{d}t, \quad i = 2, \dots, p+1.$$

The basis functions on the quadrilateral reference element $\widehat{K} = (-1,1)^2$ are chosen to be

$$\left.\begin{aligned} &L_i(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 \\ &\ell_j(\xi_1)L_i(\xi_2)\boldsymbol{e}_2 \end{aligned}\right\} \quad i = 0, \dots, p,\ j = 0, \dots, p+1, \tag{7}$$

while for the hexahedral reference element $\widehat{K} = (-1,1)^3$ the basis functions are given by

$$\left.\begin{aligned} &L_i(\xi_1)\ell_j(\xi_2)\ell_k(\xi_3)\boldsymbol{e}_1 \\ &\ell_j(\xi_1)L_i(\xi_2)\ell_k(\xi_3)\boldsymbol{e}_2 \\ &\ell_j(\xi_1)\ell_k(\xi_2)L_i(\xi_3)\boldsymbol{e}_3 \end{aligned}\right\} \quad i = 0, \dots, p,\ j, k = 0, \dots, p+1, \tag{8}$$

where $\boldsymbol{e}_1, \dots, \boldsymbol{e}_3$ denote the unit Cartesian vectors. The dimensions of $\widehat{\mathcal{P}}$ are given by $d(p+1)(p+2)^{d-1}$ for $d = 2, 3$.

The Nédélec element $(\mathcal{P}, K, \Sigma)$ on a physical domain K is constructed from the reference element as follows. First, observe that the electric field $\widehat{\boldsymbol{E}}$ on a reference element is related to the field $\boldsymbol{E}$ on the physical element by the *covariant* transformation [12],

$$\boldsymbol{E}(\boldsymbol{x})|_K = \boldsymbol{J}_K^{-\top}\widehat{\boldsymbol{E}}(\boldsymbol{\xi}), \quad \boldsymbol{x} = \boldsymbol{F}_K(\boldsymbol{\xi}). \tag{9}$$

Consequently, the global basis function $\boldsymbol{\phi}$ corresponding to the local basis function $\widehat{\boldsymbol{\phi}}$ on the reference element is defined by

$$\boldsymbol{\phi}(\boldsymbol{x})|_K = \boldsymbol{J}_K^{-\top}\widehat{\boldsymbol{\phi}}(\boldsymbol{\xi}). \tag{10}$$

The degrees of freedom Σ on the global element are implicit in the choice of basis. The degrees of freedom shared by more than one element may be shown to correspond to tangential moments of the field on the edges and faces of the element similar to the degrees of freedom employed by Nédélec [16] in the case of uniform order approximation. However, some care must be exercised if the use of a nonuniform polynomial order of approximation p_K on each element K in the partition $\mathcal{M}$ is permitted. The continuity properties of the space $H(\mathbf{curl};\Omega)$ mean that the order of approximation must be appropriately restrained at common interfaces and edges between neighboring elements. This is accomplished by applying the *minimum rule*, whereby the order of approximation on the element of higher local order is reduced to match that of the neighboring elements. We refer to [2] for a discussion of the minimum rule in the context of $\boldsymbol{H}^1(\Omega)$ conforming approximation, and to [8] for the $H(\mathbf{curl};\Omega)$ situation. The polynomial orders are collected into a degree vector $\boldsymbol{p} = \{p_K : K \in \mathcal{P}\}$, with the maximum order of approximation denoted by $p_{\max}$.

One feature of the basis presented above that is important for efficient practical implementation is that it is *hierarchical.* An alternative hierarchical basis will be found in [18]. However, numerical evidence presented in [1] indicates that the latter choice leads to extremely poorly conditioned matrices. In fact, numerical evidence suggests that the condition number degenerates exponentially fast with the polynomial order p. The conditioning of the basis described above is the subject of Theorem 1.

The spectral condition number $\kappa(\boldsymbol{A})$ of a square matrix $\boldsymbol{A}$ is defined by

$$\kappa(\boldsymbol{A}) = \frac{\lambda_{\max}(\boldsymbol{A})}{\lambda_{\min}(\boldsymbol{A})}. \tag{11}$$

Many numerical algorithms work, either explicitly or implicitly, with the diagonally scaled matrix $\widetilde{\boldsymbol{A}}$ defined by

$$\widetilde{\boldsymbol{A}} = \boldsymbol{D}^{-1/2}\boldsymbol{A}\boldsymbol{D}^{-1/2},$$

where $\boldsymbol{D}$ denotes the diagonal of $\boldsymbol{A}$. The next result presents bounds on the growth of the spectral condition number of various matrices that arise in the Galerkin approximation of Maxwell's equations. The mass matrix $\boldsymbol{M}$ is real, symmetric, and positive definite and therefore has positive eigenvalues. However, the curl-curl matrix $\boldsymbol{S}$ is semidefinite, and in this case, we bound the ratio $\kappa'(\boldsymbol{S})$ of the largest eigenvalue to the smallest nonzero eigenvalue.

THEOREM 1. *Let $\mathcal{M}$ be a partition with variable order of approximation given by $\boldsymbol{p}$, and with maximum order $p_{\max}$. Then, there exist positive constants $C^*_{\mathcal{M},\boldsymbol{M}}, C^*_{\mathcal{M},\boldsymbol{S}}$, and $C^*_{\mathcal{M},\boldsymbol{A}}$, depending on the constants defined in* (5)–(6) *but independent of the polynomial order, such that*

(1) *for the global mass matrix,*

$$\left.\begin{aligned} \kappa\big(\boldsymbol{M}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{M}} p_{\max}^{4(d-1)} \\ \kappa\big(\widetilde{\boldsymbol{M}}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{M}} p_{\max}^{2(d-1)} \end{aligned}\right\} \quad d = 2, 3; \tag{12}$$

(2) *for the global curl-curl matrix,*

$$\left.\begin{aligned} \kappa'\big(\boldsymbol{S}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{S}} p_{\max}^{4(d-2)} \\ \kappa'\big(\widetilde{\boldsymbol{S}}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{S}} p_{\max}^{2(d-2)} \end{aligned}\right\} \quad d = 2, 3; \tag{13}$$

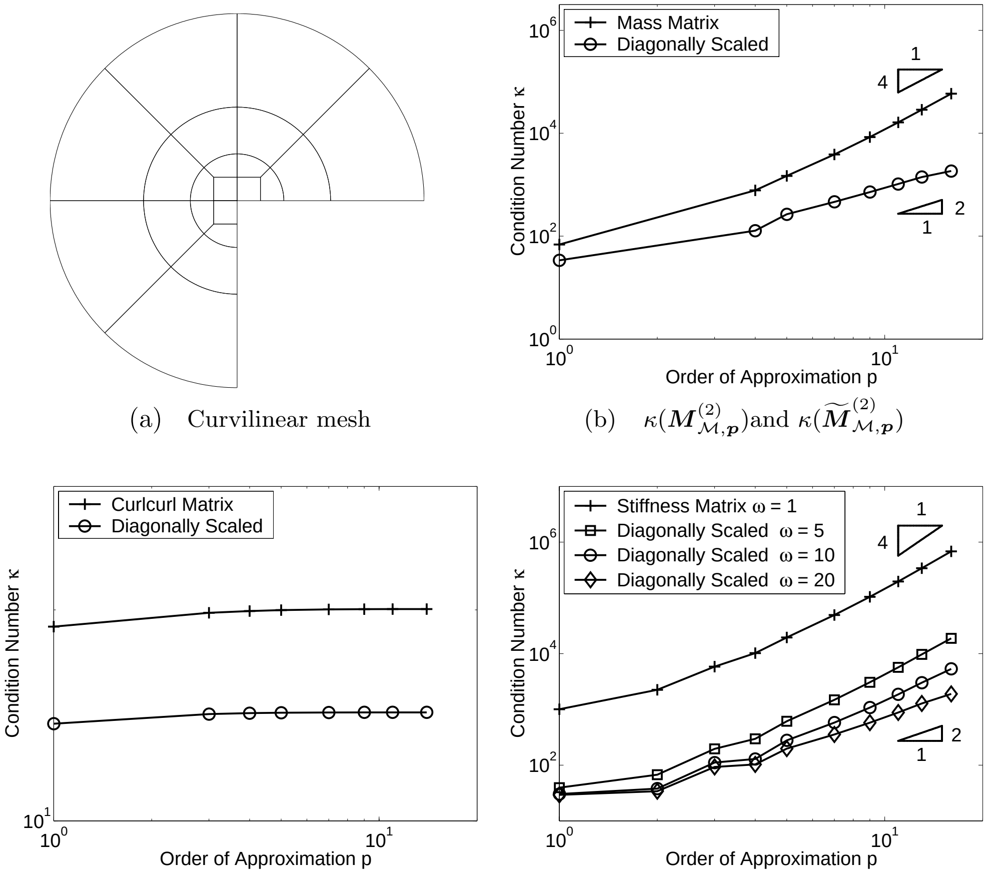
(3) *and for the global stiffness matrix,*

$$\left.\begin{aligned} \kappa\big(\boldsymbol{A}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{A}} p_{\max}^{4(d-1)} \\ \kappa\big(\widetilde{\boldsymbol{A}}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) &\le C^*_{\mathcal{M},\boldsymbol{A}} \max\left(1, \frac{p_{\max}}{\omega}\right)^2 p_{\max}^{2(d-1)} \end{aligned}\right\} \quad d = 2, 3. \tag{14}$$

The proof of this result is deferred until the next section. First, we present a simple example to illustrate the results in the case of uniform polynomial degree approximation, i.e., $p_K = p$ for all $K \in \mathcal{M}$, using the mesh shown in Figure 1(a). This mesh is typical of the type of geometrically graded meshes needed to achieve exponential rates of convergence. The permittivity and permeability are chosen to be unity throughout the domain. The numerical results agree with theoretical predictions. In particular, the theorem predicts a transition from growth of order $\mathcal{O}(p^4)$ to $\mathcal{O}(p^2)$ in the condition number of the diagonally scaled stiffness matrix $\widetilde{\boldsymbol{A}}^{(d)}_{\mathcal{M},\boldsymbol{p}}$ as the value of ω is increased. This behavior is also observed in practice, as seen in Figure 1(d).

3. Proofs of the results.

This section is organized as follows. First, bounds are established for the eigenvalues and condition numbers of the mass, curl-curl, and stiffness matrices on a single reference element. Theorem 1 is then deduced from these results.



(a) Curvilinear mesh

(b) $\kappa(\boldsymbol{M}^{(2)}_{\mathcal{M},\boldsymbol{p}})$and $\kappa(\widetilde{\boldsymbol{M}}^{(2)}_{\mathcal{M},\boldsymbol{p}})$

(c) $\kappa(\boldsymbol{S}^{(2)}_{\mathcal{M},\boldsymbol{p}})$ and $\kappa(\widetilde{\boldsymbol{S}}^{(2)}_{\mathcal{M},\boldsymbol{p}})$

(d) $\kappa(\boldsymbol{A}^{(2)}_{\mathcal{M},\boldsymbol{p}})$ and $\kappa(\widetilde{\boldsymbol{A}}^{(2)}_{\mathcal{M},\boldsymbol{p}})$

FIG. 1. *Mesh used to illustrate the results in* (12)–(14) *of Theorem* 1 *in two dimensions. The variation of the condition numbers versus the order of approximation using the mesh in* (a) *for uniform polynomial order $p = 0, \dots, 15$ is given for* (b) *the global mass and diagonally scaled global mass matrices,* (c) *the global curl-curl and diagonally scaled global curl-curl matrices, and* (d) *the global stiffness and diagonally scaled global stiffness matrices. The theoretical rates predicted in Theorem* 1 *are also indicated.*

3.1. Analysis of the mass matrix. The first result concerns the mass matrix.

LEMMA 2. *Let $\boldsymbol{M}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}$ denote the mass and diagonally scaled mass matrices in d spatial dimensions with order p approximation. Then there exist positive constants $c_{\widehat{K},\boldsymbol{M}}$ and $C_{\widehat{K},\boldsymbol{M}}$ independent of p such that*

$$\lambda_{\min}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{M}}p^{-4(d-1)}, \quad \lambda_{\max}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{M}} \tag{15}$$

and

$$\lambda_{\min}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{M}}p^{-2(d-1)}, \quad \lambda_{\max}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{M}}. \tag{16}$$

Therefore, there exists a positive constant $C^*_{\widehat{K},\boldsymbol{M}}$ independent of p such that

$$\kappa\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big) \leq C^*_{\widehat{K},\boldsymbol{M}}p^{4(d-1)} \tag{17}$$

and

$$\kappa\big(\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}\big) \le C^{*}_{\widehat{K},\boldsymbol{M}} p^{2(d-1)}. \tag{18}$$

Proof. The bounds (17) and (18) on the condition numbers are immediate consequences of (15) and (16), thanks to (11) and setting $C^{*}_{\widehat{K},\boldsymbol{M}} = C_{\widehat{K},\boldsymbol{M}}/c_{\widehat{K},\boldsymbol{M}}$. It remains to prove (15) and (16). The basis functions in (7) and (8) are multiples of the Cartesian vectors. As a result, the mass matrix can be written in block diagonal form:

$$\boldsymbol{M}^{(2)}_{\widehat{K},p} = \operatorname{blockdiag}\big(\boldsymbol{M}^{(2)}_{1,p}, \boldsymbol{M}^{(2)}_{2,p}\big) \tag{19}$$

and

$$\boldsymbol{M}^{(3)}_{\widehat{K},p} = \operatorname{blockdiag}\big(\boldsymbol{M}^{(3)}_{1,p}, \boldsymbol{M}^{(3)}_{2,p}, \boldsymbol{M}^{(3)}_{3,p}\big), \tag{20}$$

where $\boldsymbol{M}^{(d)}_{i,p}$ represents the coupling between the basis functions that are multiples of the ith Cartesian vectors. In the case of $d = 2$, order the basis functions as follows:

$$\left.\begin{aligned} \boldsymbol{\psi}^1_{j+1+i(p+2)} &= L_i(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 \\ \boldsymbol{\psi}^2_{i+1+j(p+1)} &= \ell_j(\xi_1)L_i(\xi_2)\boldsymbol{e}_2 \end{aligned}\right\} \quad i = 0,\dots,p,\ j = 0,\dots,p+1. \tag{21}$$

That is to say, we order the functions by looping over the index corresponding to the ξ_2 variable first. The block matrices in (19) can then be rewritten by observing that

$$\big(\boldsymbol{M}^{(2)}_{1,p}\big)_{j+1+i(p+2),n+1+m(p+2)} = \delta_{im} \int_{-1}^{1} \ell_j(\xi_2)\ell_n(\xi_2)\,\mathrm{d}\xi_2$$

and

$$\big(\boldsymbol{M}^{(2)}_{2,p}\big)_{i+1+j(p+1),m+1+n(p+1)} = \delta_{im} \int_{-1}^{1} \ell_j(\xi_1)\ell_n(\xi_1)\,\mathrm{d}\xi_1$$

for $i, m = 0,\dots,p$ and $j, n = 0,\dots,p+1$, where δ_{im} is the Kronecker symbol. Hence,

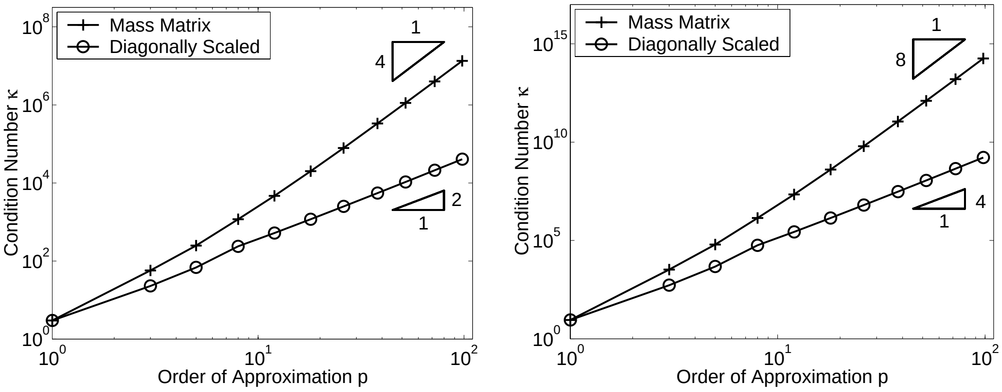
$$\boldsymbol{M}^{(2)}_{1,p} = \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}_{p+1} \quad \text{and} \quad \boldsymbol{M}^{(2)}_{2,p} = \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1},$$

where $\otimes$ denotes the Kronecker product [10], $\boldsymbol{I}_{p+1}$ is the $p+1$ by $p+1$ identity matrix, and $\boldsymbol{\ell}_{p+1}$ is the mass matrix in one dimension with entries given by

$$(\boldsymbol{\ell}_{p+1})_{ij} = \int_{-1}^{1} \ell_i(s)\ell_j(s)\,\mathrm{d}s, \quad i, j = 0,\dots,p+1.$$

Likewise, for $d = 3$, we order the basis functions by first looping over the indices corresponding to the ξ_3 variable and then over the indices corresponding to the ξ_2 variable. The block matrices in (20) take the form

$$\begin{aligned} \boldsymbol{M}^{(3)}_{1,p} &= \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{\ell}_{p+1}, \\ \boldsymbol{M}^{(3)}_{2,p} &= \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}_{p+1}, \\ \boldsymbol{M}^{(3)}_{3,p} &= \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1}. \end{aligned}$$



(a) $\kappa(\boldsymbol{M}^{(2)}_{\widehat{K},p})$ and $\kappa(\widetilde{\boldsymbol{M}}^{(2)}_{\widehat{K},p})$ (b) $\kappa(\boldsymbol{M}^{(3)}_{\widehat{K},p})$ and $\kappa(\widetilde{\boldsymbol{M}}^{(3)}_{\widehat{K},p})$

FIG. 2. *Variation of the condition numbers versus the order of approximation of the mass and diagonally scaled mass matrices for* (a) *two and* (b) *three dimensions on the reference element. These results agree with those predicted by* (17) *and* (18) *for* $d = 2$ *and* $d = 3$*, respectively.*

By Theorem 4.2.12 of [10], the spectrum of each block matrix is given by

$$\sigma\big(\boldsymbol{M}^{(d)}_{i,p}\big) = \sigma\left(\boldsymbol{I}_{p+1}\right) \otimes \overbrace{\sigma(\boldsymbol{\ell}_{p+1}) \otimes \cdots \otimes \sigma(\boldsymbol{\ell}_{p+1})}^{d-1},$$

and since $\sigma(\boldsymbol{I}_{p+1}) = \{1\}$, we obtain

$$\lambda_{\min}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big) = \lambda_{\min}\big(\boldsymbol{\ell}_{p+1}\big)^{d-1} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big) = \lambda_{\max}\left(\boldsymbol{\ell}_{p+1}\right)^{d-1}. \tag{22}$$

The bounds (15) then follow by recalling (see [13]) that there exist positive constants c and C independent of p such that

$$\lambda_{\min}\left(\boldsymbol{\ell}_{p+1}\right) \geq cp^{-4} \quad \text{and} \quad \lambda_{\max}\left(\boldsymbol{\ell}_{p+1}\right) \leq C. \tag{23}$$

Similar arguments show that for the diagonally scaled mass matrix,

$$\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p} = \operatorname{diag}\big(\widetilde{\boldsymbol{M}}^{(d)}_{1,p}, \ldots, \widetilde{\boldsymbol{M}}^{(d)}_{d,p}\big), \quad d = 2, 3,$$

and hence,

$$\lambda_{\min}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}\big) = \lambda_{\min}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big)^{d-1} \quad \text{and} \quad \lambda_{\max}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}\big) = \lambda_{\max}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big)^{d-1}.$$

The bounds (16) follow by recalling (see [13]) that

$$\lambda_{\min}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big) \geq cp^{-2} \quad \text{and} \quad \lambda_{\max}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big) \leq C \tag{24}$$

for the diagonally scaled one dimensional mass matrix. The result follows as claimed by choosing $c_{\widehat{K},\boldsymbol{M}} = \min\left(c, c^2\right)$ and $C_{\widehat{K},\boldsymbol{M}} = \max\left(C, C^2\right)$. □

In Figure 2 the variation of the condition numbers of $\boldsymbol{M}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{M}}^{(d)}_{\widehat{K},p}$ versus order of approximation for $p = 0, \ldots, 100$ is shown for $d = 2$ in (a) and $d = 3$ in (b). It will be observed that the estimates in Lemma 2 are sharp.

3.2. Analysis of the curl-curl matrix. The next result gives bounds for the nontrivial eigenvalues of the curl-curl matrix on a single reference element.

LEMMA 3. *Let $\boldsymbol{S}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{S}}^{(d)}_{\widehat{K},p}$ denote the curl-curl and diagonally scaled curl-curl matrices in d spatial dimensions with order p approximation. Then there exist positive constants $c_{\widehat{K},\boldsymbol{S}}$ and $C_{\widehat{K},\boldsymbol{S}}$ independent of p such that*

$$\lambda'_{\min}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{S}}\, p^{-4(d-2)}, \quad \lambda_{\max}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{S}} \tag{25}$$

and

$$\lambda'_{\min}\big(\widetilde{\boldsymbol{S}}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{S}}\, p^{-2(d-2)}, \quad \lambda_{\max}\big(\widetilde{\boldsymbol{S}}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{S}}, \tag{26}$$

where $\lambda'_{\min}$ denotes the smallest nonzero eigenvalue. Therefore, there exists a positive constant $C^{*}_{\widehat{K},\boldsymbol{S}}$ independent of p such that

$$\kappa'\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) \leq C^{*}_{\widehat{K},\boldsymbol{S}}\, p^{4(d-2)} \tag{27}$$

and

$$\kappa'\big(\widetilde{\boldsymbol{S}}^{(d)}_{\widehat{K},p}\big) \leq C^{*}_{\widehat{K},\boldsymbol{S}}\, p^{2(d-2)}, \tag{28}$$

where κ' denotes the ratio of $\lambda_{\max}$ to $\lambda'_{\min}$.

Proof. As before, it suffices to prove (25) and (26). We begin by considering the two dimensional case. The curl-curl matrix is less straightforward to analyze than the mass matrix. Nevertheless, the basis functions given in (7) may be partitioned into four sets that are mutually orthogonal with respect to the $H(\mathbf{curl})$ semi-inner product, as follows:

$$\begin{aligned}
S_1 &= \operatorname{span}\{L_0(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 : j \in \{0,1\}\} \\
&\quad \oplus \operatorname{span}\{\ell_j(\xi_1)L_0(\xi_2)\boldsymbol{e}_2 : j \in \{0,1\}\}, \\
S_2 &= \operatorname{span}\{L_i(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 : i \in \{1,\dots,p\}; j \in \{0,1\}\} \\
&\quad \oplus \operatorname{span}\{\ell_j(\xi_1)L_0(\xi_2)\boldsymbol{e}_2 : j \in \{2,\dots,p+1\}\}, \\
S_3 &= \operatorname{span}\{L_0(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 : j \in \{2,\dots,p+1\}\} \\
&\quad \oplus \operatorname{span}\{\ell_j(\xi_1)L_i(\xi_2)\boldsymbol{e}_2 : i \in \{1,\dots,p\}; j \in \{0,1\}\}, \\
S_4 &= \operatorname{span}\{L_i(\xi_1)\ell_j(\xi_2)\boldsymbol{e}_1 : i \in \{1,\dots,p\}; j \in \{2,\dots,p+1\}\} \\
&\quad \oplus \operatorname{span}\{\ell_j(\xi_1)L_i(\xi_2)\boldsymbol{e}_2 : i \in \{1,\dots,p\}; j \in \{2,\dots,p+1\}\}.
\end{aligned}$$

Hence

$$\boldsymbol{S}^{(2)}_{\widehat{K},p} = \operatorname{blockdiag}(\boldsymbol{S}_1, \boldsymbol{S}_2, \boldsymbol{S}_3, \boldsymbol{S}_4),$$

where $\boldsymbol{S}_i$ is the curl-curl matrix corresponding to the nonzero coupling between basis functions in S_i. Simple computation reveals that

$$\begin{aligned}
\boldsymbol{S}_1 &= \frac{1}{2}\begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \otimes \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix}, \\
\boldsymbol{S}_2 &= \frac{1}{2}\begin{bmatrix} 1 & -1 & \sqrt{2} \\ -1 & 1 & -\sqrt{2} \\ \sqrt{2} & -\sqrt{2} & 2 \end{bmatrix} \otimes \boldsymbol{I}_p, \\
\boldsymbol{S}_3 &= \boldsymbol{I}_p \otimes \frac{1}{2}\begin{bmatrix} 1 & -1 & \sqrt{2} \\ -1 & 1 & -\sqrt{2} \\ \sqrt{2} & -\sqrt{2} & 2 \end{bmatrix}, \\
\boldsymbol{S}_4 &= \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \otimes (\boldsymbol{I}_p \otimes \boldsymbol{I}_p).
\end{aligned}$$

The spectra of these matrices are found, again using Theorem 4.2.12 of [10], to be

$$\begin{aligned}
&\sigma\left(\boldsymbol{S}_1\right) = \{2, 0, 0, 0\}, \\
&\sigma\left(\boldsymbol{S}_2\right) = \{2, 0\} \qquad \text{(multiplicity of } p \text{ and } 2p\text{, respectively)}, \\
&\sigma\left(\boldsymbol{S}_3\right) = \sigma(\boldsymbol{S}_2), \\
&\sigma\left(\boldsymbol{S}_4\right) = \{2, 0\} \qquad \text{(multiplicity of } p^2 \text{ for each)}.
\end{aligned}$$

Hence, the nonzero eigenvalues satisfy

$$\lambda'_{\min}\big(\boldsymbol{S}^{(2)}_{\widehat{K},p}\big) = 2 \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{S}^{(2)}_{\widehat{K},p}\big) = 2. \tag{29}$$

The same arguments apply equally well to the case when diagonal scaling is applied. In particular, the matrices $\widetilde{\boldsymbol{S}}_2, \dots, \widetilde{\boldsymbol{S}}_4$ agree with $\boldsymbol{S}_2, \dots, \boldsymbol{S}_4$, while $\widetilde{\boldsymbol{S}}_1 = 2\boldsymbol{S}_1$. The eigenvalues of $\widetilde{\boldsymbol{S}}_1$ are therefore given by $\{4, 0, 0, 0\}$, so that

$$\lambda'_{\min}\big(\widetilde{\boldsymbol{S}}^{(2)}_{\widehat{K},p}\big) = 2 \quad \text{and} \quad \lambda_{\max}\big(\widetilde{\boldsymbol{S}}^{(2)}_{\widehat{K},p}\big) = 4. \tag{30}$$

Together, these results give (25) and (26) in the case $d = 2$. Before proceeding with the case $d = 3$, it is useful to note that maintaining the *same* ordering of the degrees of freedom as described in (21) yields the alternative form

$$\boldsymbol{S}^{(2)}_{\widehat{K},p} = \begin{bmatrix} \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}'_{p+1} & -\widetilde{\boldsymbol{L}}_p \otimes \widetilde{\boldsymbol{L}}_p^{\top} \\ -\widetilde{\boldsymbol{L}}_p^{\top} \otimes \widetilde{\boldsymbol{L}}_p & \boldsymbol{\ell}'_{p+1} \otimes \boldsymbol{I}_{p+1} \end{bmatrix}, \tag{31}$$

where $\widetilde{\boldsymbol{L}_p}$ is the matrix with entries given by

$$(\widetilde{\boldsymbol{L}_p})_{ij} = \int_{-1}^{1} L_i(s)\ell_j(s)\,\mathrm{d}s, \quad i = 0, \dots, p,\ j = 0, \dots, p+1,$$

and $\boldsymbol{\ell}'_{p+1}$ is the one dimensional stiffness matrix

$$(\boldsymbol{\ell}'_{p+1})_{ij} = \int_{-1}^{1} \ell'_i(s)\ell'_j(s)\,\mathrm{d}s, \quad i, j = 0, \dots, p+1.$$

Adopting the ordering of the basis functions used in the proof of Lemma 2 for the three dimensional mass matrix, the three dimensional curl-curl matrix takes the form

$$\boldsymbol{S}^{(3)}_{\widehat{K},p} = \boldsymbol{S}_{\mathbf{1}} + \boldsymbol{S}_2 + \boldsymbol{S}_3, \tag{32}$$

where

$$\boldsymbol{S}_1 = \begin{bmatrix} \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}'_{p+1} \otimes \boldsymbol{\ell}_{p+1} & -\widetilde{\boldsymbol{L}}_p \otimes \widetilde{\boldsymbol{L}}_p^{\top} \otimes \boldsymbol{\ell}_{p+1} & \mathbf{0} \\ -\widetilde{\boldsymbol{L}}_p^{\top} \otimes \widetilde{\boldsymbol{L}}_p \otimes \boldsymbol{\ell}_{p+1} & \boldsymbol{\ell}'_{p+1} \otimes \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}_{p+1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \end{bmatrix},$$

$$\boldsymbol{S}_2 = \begin{bmatrix} \mathbf{0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}'_{p+1} & -\boldsymbol{\ell}_{p+1} \otimes \widetilde{\boldsymbol{L}}_p \otimes \widetilde{\boldsymbol{L}}_p^{\top} \\ \mathbf{0} & -\boldsymbol{\ell}_{p+1} \otimes \widetilde{\boldsymbol{L}}_p^{\top} \otimes \widetilde{\boldsymbol{L}}_p & \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}'_{p+1} \end{bmatrix},$$

and

$$\boldsymbol{S}_3 = \begin{bmatrix} \boldsymbol{I}_{p+1} \otimes \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{\ell}'_{p+1} & \mathbf{0} & -\widetilde{\boldsymbol{L}}_p \otimes \boldsymbol{\ell}_{p+1} \otimes \widetilde{\boldsymbol{L}}_p^{\top} \\ \mathbf{0} & \mathbf{0} & \mathbf{0} \\ -\widetilde{\boldsymbol{L}}_p^{\top} \otimes \boldsymbol{l}_{p+1} \otimes \widetilde{\boldsymbol{L}}_p & \mathbf{0} & \boldsymbol{\ell}'_{p+1} \otimes \boldsymbol{\ell}_{p+1} \otimes \boldsymbol{I}_{p+1} \end{bmatrix}.$$

Observe, in particular, that $\boldsymbol{S}_1$ is related to the two dimensional curl-curl matrix $\boldsymbol{S}^{(2)}_{\widehat{K},p}$ defined in (31) by the rule

$$\boldsymbol{S}_1 = \boldsymbol{S}^{(2)}_{\widehat{K},p} \otimes \boldsymbol{\ell}_{p+1}. \tag{33}$$

By symmetry, the same expression holds for $\boldsymbol{S}_2$ and $\boldsymbol{S}_3$, and hence, by Theorem 4.2.12 of [10],

$$\sigma\left(\boldsymbol{S}_i\right) = \sigma\bigl(\boldsymbol{S}^{(2)}_{\widehat{K},p}\bigr) \otimes \sigma\left(\boldsymbol{\ell}_{p+1}\right), \quad i = 1, \dots, 3. \tag{34}$$

Let $\vec{\alpha} = (\vec{\alpha}_1, \vec{\alpha}_2, \vec{\alpha}_3) \in \mathbb{R}^{3(p+1)(p+2)^2}$ denote the values of the degrees of freedom in the approximation on the reference element. Decompose

$$\vec{\alpha} = \frac{1}{2}\bigl(\vec{\beta}_1 + \vec{\beta}_2 + \vec{\beta}_3\bigr), \tag{35}$$

where

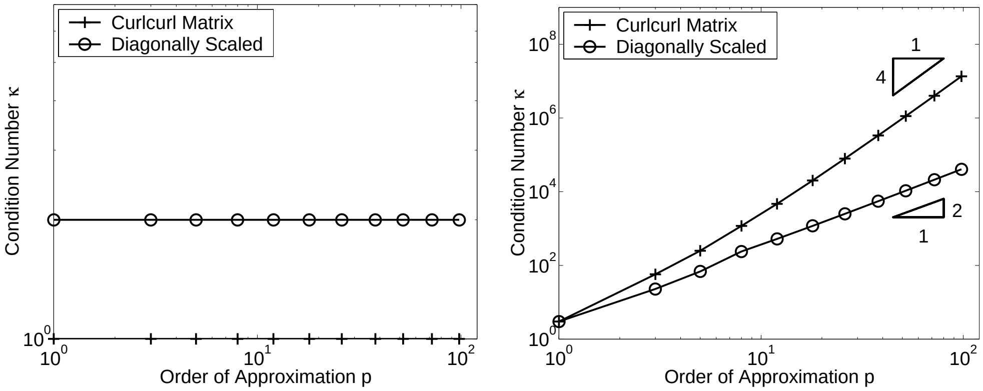
$$\vec{\beta}_1 = \begin{pmatrix} \vec{\alpha}_1 \\ \vec{\alpha}_2 \\ 0 \end{pmatrix}, \quad \vec{\beta}_2 = \begin{pmatrix} 0 \\ \vec{\alpha}_2 \\ \vec{\alpha}_3 \end{pmatrix}, \text{ and } \vec{\beta}_3 = \begin{pmatrix} \vec{\alpha}_1 \\ 0 \\ \vec{\alpha}_3 \end{pmatrix}.$$

Observing that

$$\vec{\alpha}^{\top} S_i \vec{\alpha} = \vec{\beta}_i^{\top} S_i \vec{\beta}_i, \quad i = 1, \dots, 3, \tag{36}$$

we deduce from (34) that

$$\vec{\alpha}^{\top} \boldsymbol{S}_i \vec{\alpha} \geq \lambda_{\min}\left(\boldsymbol{\ell}_{p+1}\right) \lambda_{\min}\bigl(\boldsymbol{S}^{(2)}_{\widehat{K},p}\bigr) |\vec{\beta}_i|^2 = 2\lambda_{\min}\left(\boldsymbol{\ell}_{p+1}\right) |\vec{\beta}_i|^2$$



(a) $\kappa'(\boldsymbol{S}^{(2)}_{\widehat{K},p})$ and $\kappa'(\widetilde{\boldsymbol{S}}^{(2)}_{\widehat{K},p})$ (b) $\kappa'(\boldsymbol{S}^{(3)}_{\widehat{K},p})$ and $\kappa'(\widetilde{\boldsymbol{S}}^{(3)}_{\widehat{K},p})$

FIG. 3. *Variation of the condition numbers versus the order of approximation of the curl-curl and diagonally scaled curl-curl matrices for* (a) *two and* (b) *three dimensions on the reference element. These results agree with those predicted by* (27) *and* (28) *for* $d = 2$ *and* $d = 3$*, respectively.*

and

$$\vec{\alpha}^\top \boldsymbol{S}_i \vec{\alpha} \leq \lambda_{\max}\left(\boldsymbol{\ell}_{p+1}\right) \lambda_{\max}\big(\boldsymbol{S}^{(2)}_{\widehat{K},p}\big) |\vec{\beta}_i|^2 = 2\lambda_{\max}\left(\boldsymbol{\ell}_{p+1}\right) |\vec{\beta}_i|^2.$$

Thus, using (32), (36) and the fact that $\sum_{i=1}^3 |\vec{\beta}_i|^2 = 2\sum_{i=1}^3 |\vec{\alpha}_i|^2$, we obtain

$$\vec{\alpha}^\top \boldsymbol{S}^{(3)}_{\widehat{K},p} \vec{\alpha} \geq 2\lambda_{\min}\left(\boldsymbol{\ell}_{p+1}\right) \sum_{i=1}^{3} |\vec{\beta}_i|^2 = 4\lambda_{\min}(\boldsymbol{\ell}_{p+1})|\vec{\alpha}|^2 \tag{37}$$

and

$$\vec{\alpha}^\top \boldsymbol{S}^{(3)}_{\widehat{K},p} \vec{\alpha} \leq 2\lambda_{\max}\left(\boldsymbol{\ell}_{p+1}\right) \sum_{i=1}^{3} |\vec{\beta}_i|^2 = 4\lambda_{\max}\left(\boldsymbol{l}_{p+1}\right) |\vec{\alpha}|^2. \tag{38}$$

Analogous arguments may be used in the case of diagonal scaling to obtain

$$\vec{\alpha}^\top \widetilde{\boldsymbol{S}}^{(3)}_{\widehat{K},p} \vec{\alpha} \geq 4\lambda_{\min}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big)|\vec{\alpha}|^2 \quad \text{and} \quad \vec{\alpha}^\top \widetilde{\boldsymbol{S}}^{(3)}_{\widehat{K},p} \vec{\alpha} \leq 8\lambda_{\max}\big(\widetilde{\boldsymbol{\ell}}_{p+1}\big)|\vec{\alpha}|^2. \tag{39}$$

Thus, for the nonzero eigenvalues, using (23) and (24) in conjunction with (37)–(39) yields

$$\lambda'_{\min}\big(\boldsymbol{S}^{(3)}_{\widehat{K},p}\big) \geq 4cp^{-4}, \qquad \lambda_{\max}\big(\boldsymbol{S}^{(3)}_{\widehat{K},p}\big) \leq 4C \tag{40}$$

and

$$\lambda'_{\min}\big(\widetilde{\boldsymbol{S}}^{(3)}_{\widehat{K},p}\big) \geq 4cp^{-2}, \qquad \lambda_{\max}\big(\widetilde{\boldsymbol{S}}^{(3)}_{\widehat{K},p}\big) \leq 8C. \tag{41}$$

Setting $c_{\widehat{K},\boldsymbol{S}} = 4c$ and $C_{\widetilde{K},\boldsymbol{S}} = 8C$ establishes (25) and (26) for $d = 2, 3$, and the lemma is proved. □

In Figure 3 the condition numbers of $\boldsymbol{S}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{S}}^{(d)}_{\widehat{K},p}$ versus order of approximation for $p = 0, \ldots, 100$ are shown for $d = 2$ in (a) and $d = 3$ in (b). Once again, it will be observed that the results in Lemma 3 are sharp.

3.3. Analysis of the stiffness matrix. Finally, we present bounds for the eigenvalues of the stiffness matrix on a single reference element.

LEMMA 4. *Let $\boldsymbol{A}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}$ denote the stiffness and diagonally scaled stiffness matrices in d spatial dimensions with order p approximation. Then there exist positive constants $c_{\widehat{K},\boldsymbol{A}}$ and $C_{\widehat{K},\boldsymbol{A}}$ independent of p such that*

$$\lambda_{\min}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{A}}p^{-4(d-1)}, \quad \lambda_{\max}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{A}} \tag{42}$$

and

$$\lambda_{\min}\big(\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}\big) \geq c_{\widehat{K},\boldsymbol{A}} \min\left(1, \frac{\omega}{p}\right)^2 p^{-2(d-1)}, \quad \lambda_{\max}\big(\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}\big) \leq C_{\widehat{K},\boldsymbol{A}}. \tag{43}$$

Therefore, there exists a positive constant $C^*_{K,\boldsymbol{A}}$ independent of p such that

$$\kappa\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big) \leq C^*_{\widehat{K},\boldsymbol{A}} \frac{p^{4(d-1)}}{\omega^2} \tag{44}$$

and

$$\kappa\big(\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}\big) \leq C^*_{\widehat{K},\boldsymbol{A}} \max\left(1, \frac{p}{\omega}\right)^2 p^{2(d-1)}. \tag{45}$$

Proof. Once again, it suffices to prove (42) and (43). We obtain upper bounds for the maximum eigenvalues by applying the results in Lemmas 2 and 3 for the maximum eigenvalues of the mass and curl-curl matrices to deduce

$$\vec{\alpha}^\top \boldsymbol{A}^{(d)}_{\widehat{K},p}\vec{\alpha} = \vec{\alpha}^\top \boldsymbol{S}^{(d)}_{\widehat{K},p}\vec{\alpha} + \omega^2\vec{\alpha}^\top \boldsymbol{M}^{(d)}_{\widehat{K},p}\vec{\alpha} \leq 2\max\big(C_{\widehat{K},\boldsymbol{S}}, \omega^2 C_{\widehat{K},\boldsymbol{M}}\big)|\vec{\alpha}|^2 \tag{46}$$

and hence

$$\lambda_{\max}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big) \leq 2\max\big(C_{\widehat{K},\boldsymbol{S}}, \omega^2 C_{\widehat{K},\boldsymbol{M}}\big).$$

Equally well, using the bounds in Lemmas 2 and 3 for the maximum eigenvalues of the diagonally scaled matrices gives

$$\begin{aligned}
\vec{\alpha}^\top \boldsymbol{A}^{(d)}_{\widehat{K},p}\vec{\alpha} &= \vec{\alpha}^\top \left[\boldsymbol{S}^{(d)}_{\widehat{K},p} + \omega^2 \boldsymbol{M}^{(d)}_{\widehat{K},p}\right]\vec{\alpha} \\
&\leq \vec{\alpha}^\top \left[C_{\widehat{K},\boldsymbol{S}}\mathrm{diag}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) + \omega^2 C_{\widehat{K},\boldsymbol{M}}\mathrm{diag}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\right]\vec{\alpha} \\
&\leq \max\big(C_{\widehat{K},\boldsymbol{S}}, C_{\widehat{K},\boldsymbol{M}}\big)\vec{\alpha}^\top \mathrm{diag}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big)\vec{\alpha} \qquad (47)
\end{aligned}$$

and hence

$$\lambda_{\max}\big(\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}\big) \leq \max\big(C_{\widehat{K},\boldsymbol{S}}, C_{\widehat{K},\boldsymbol{M}}\big).$$

The minimum eigenvalue of the stiffness matrix is bounded using the result in (15) for the minimum eigenvalue as follows,

$$\vec{\alpha}^\top \boldsymbol{A}^{(d)}_{\widehat{K},p}\vec{\alpha} \geq \omega^2\vec{\alpha}^\top \boldsymbol{M}^{(d)}_{\widehat{K},p}\vec{\alpha} \geq \omega^2 c_{\widehat{K},\boldsymbol{M}}p^{-4(d-1)}|\vec{\alpha}|^2,$$

and hence

$$\lambda_{\min}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big) \geq \omega^2 c_{\widehat{K},\boldsymbol{M}} p^{-4(d-1)}.$$

It remains to derive the lower bound on the minimum eigenvalue of the diagonally scaled stiffness matrix. The bound in Lemma 2 for the minimum eigenvalue of the diagonally scaled mass matrix gives

$$\vec{\alpha}^\top \boldsymbol{M}^{(d)}_{\widehat{K},p}\vec{\alpha} \geq cp^{-2(d-1)}\vec{\alpha}^\top \mathrm{diag}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\vec{\alpha}. \tag{48}$$

A direct computation using standard properties of Legendre polynomials reveals that if $\boldsymbol{\phi}$ is any of the basis functions defined in (7) or (8), then

$$\|\mathbf{curl}\,\boldsymbol{\phi}\|^2_{L_2(\widehat{K})} \leq Cp^2 \|\boldsymbol{\phi}\|^2_{L_2(\widehat{K})},$$

or, expressed in terms of matrices,

$$\vec{\alpha}^\top \mathrm{diag}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big)\vec{\alpha} \leq Cp^2\vec{\alpha}^\top \mathrm{diag}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\vec{\alpha}.$$

With the aid of (48) we deduce that

$$\vec{\alpha}^\top \boldsymbol{M}^{(d)}_{\widehat{K},p}\vec{\alpha} \geq cp^{-2d}\vec{\alpha}^\top \mathrm{diag}\left(\boldsymbol{S}^{(d)}_{\widehat{K},p}\right)\vec{\alpha}. \tag{49}$$

The bounds (48) and (49) are used to obtain the lower bound on the eigenvalue as follows,

$$\begin{aligned}
\vec{\alpha}^\top \boldsymbol{A}^{(d)}_{\widehat{K},p}\vec{\alpha} &\geq \omega^2\vec{\alpha}^\top \boldsymbol{M}^{(d)}_{\widehat{K},p}\vec{\alpha} \\
&\geq cp^{-2(d-1)}\vec{\alpha}^\top\left[\frac{\omega^2}{p^2}\,\mathrm{diag}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) + \omega^2\mathrm{diag}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\right]\vec{\alpha} \\
&\geq cp^{-2(d-1)}\min\left(1,\frac{\omega}{p}\right)^2\vec{\alpha}^\top\mathrm{diag}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p} + \omega^2\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\vec{\alpha} \\
&= cp^{-2(d-1)}\min\left(1,\frac{\omega}{p}\right)^2\vec{\alpha}^\top\mathrm{diag}\big(\boldsymbol{A}^{(d)}_{\widehat{K},p}\big)\vec{\alpha}, \qquad (50)
\end{aligned}$$

and the result follows as claimed. □

Figures 4 and 5 show the computed condition numbers of $\boldsymbol{A}^{(d)}_{\widehat{K},p}$ and $\widetilde{\boldsymbol{A}}^{(d)}_{\widehat{K},p}$ versus order of approximation on the reference element for $p = 0,\dots,80$, for $d = 2$ and $d = 3$, respectively. As before, the bounds are seen to be sharp. Observe the change in asymptotic behavior with increasing values of the coefficient ω from $\mathcal{O}(p^4)$ to $\mathcal{O}(p^2)$ in Figure 4, and from $\mathcal{O}(p^6)$ to $\mathcal{O}(p^4)$ in Figure 5, as predicted in (45).

3.4. Proof of Theorem 1. (1) Let $\boldsymbol{M}^{(d)}_{K,p}$ denote the mass matrix over a physical element $K \in \mathcal{M}$ corresponding to order of approximation p. Then, for a discrete electric field $\boldsymbol{E}$ on the physical element, relation (9) implies that

$$\boldsymbol{M}_K(\boldsymbol{E},\boldsymbol{E}) = \int_K \varepsilon|\boldsymbol{E}|^2\,\mathrm{d}\boldsymbol{x} = \int_{\widehat{K}} \varepsilon|\boldsymbol{J}_K^{-\top}\widehat{\boldsymbol{E}}|^2|\det(\boldsymbol{J}_K)|\,\mathrm{d}\boldsymbol{\xi}.$$

Applying the bounds in (3) and (5)–(6) leads to the conclusion

$$c_1c_{2,K}c_{3,K}\lambda_{\min}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\boldsymbol{I} \leq \boldsymbol{M}^{(d)}_{K,p} \leq C_1C_{2,K}C_{3,K}\lambda_{\max}\big(\boldsymbol{M}^{(d)}_{\widehat{K},p}\big)\boldsymbol{I}. \tag{51}$$

Lemma 2 implies that

$$\lambda_{\min}\big(\boldsymbol{M}^{(d)}_{K,p}\big) \geq c_{K,\boldsymbol{M}} p^{-4(d-1)} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{M}^{(d)}_{K,p}\big) \leq C_{K,\boldsymbol{M}}, \tag{52}$$

where

$$c_{K,\boldsymbol{M}} = c_1 c_{2,K} c_{3,K} c_{\widehat{K},\boldsymbol{M}} \quad \text{and} \quad C_{K,\boldsymbol{M}} = C_1 C_{2,K} C_{3,K} C_{\widehat{K},\boldsymbol{M}}.$$

As a consequence of (52),

$$\kappa\big(\boldsymbol{M}^{(d)}_{K,p}\big) \leq C^*_{K,M} p^{4(d-1)}, \tag{53}$$

where $C^*_{K,M} = C_{K,\boldsymbol{M}}/c_{K,\boldsymbol{M}}$. The same argument may be applied in the case of diagonal scaling to deduce that

$$\lambda_{\min}\big(\widetilde{\boldsymbol{M}}^{(d)}_{K,p}\big) \geq c_{K,\boldsymbol{M}}p^{-2(d-1)}, \qquad \lambda_{\max}\big(\widetilde{\boldsymbol{M}}^{(d)}_{K,p}\big) \leq C_{K,\boldsymbol{M}} \tag{54}$$

and

$$\kappa\big(\widetilde{\boldsymbol{M}}^{(d)}_{K,p}\big) \leq C^*_{K,M}p^{2(d-1)}. \tag{55}$$

Let $\vec{\alpha}_{\boldsymbol{p}} \in \mathbb{R}^N$ denote the values of the global degrees of freedom for the nonuniform order of approximation $\boldsymbol{p}$ over $\mathcal{M}$ with maximum order $p = p_{\max}$, and let $\vec{\alpha}_p \in \mathbb{R}^{N'}$ denote the value of the global degrees of freedom for the uniform order of approximation p over $\mathcal{M}$. The global mass matrix $\boldsymbol{M}^{(d)}_{\mathcal{M},p}$, corresponding to the uniform order approximation p over the entire mesh, satisfies

$$\vec{\alpha}_p^\top \boldsymbol{M}^{(d)}_{\mathcal{M},p}\vec{\alpha}_p = \vec{\alpha}_p^\top \left(\sum_{K\in\mathcal{M}} \Lambda_K \boldsymbol{M}^{(d)}_{K,p}\Lambda_K^\top\right)\vec{\alpha}_p = \sum_{K\in\mathcal{M}} \vec{\beta}^\top_{K,p}\boldsymbol{M}^{(d)}_{K,p}\vec{\beta}_{K,p},$$

where $\vec{\beta}_{K,p} = \Lambda_K^\top\vec{\alpha}_p$ and the Λ_K is the usual connectivity matrix representing the mapping from the local to the global degrees of freedom for each element $K \in \mathcal{M}$. In particular, this implies that there are positive constants c_6 and C_6 such that

$$c_6|\vec{\alpha}_p|^2 \leq \sum_{K\in\mathcal{M}} |\vec{\beta}_{K,p}|^2 \leq C_6|\vec{\alpha}_p|^2. \tag{56}$$

Using (52), it follows that

$$\vec{\alpha}_p^\top \boldsymbol{M}^{(d)}_{\mathcal{M},p}\vec{\alpha}_p \leq \sum_{K\in\mathcal{M}} \lambda_{\max}\left(\boldsymbol{M}^{(d)}_{K,p}\right)|\vec{\beta}_{K,p}|^2 \leq \left(\max_{K\in\mathcal{M}} C_{K,\boldsymbol{M}}\right)\sum_{K\in\mathcal{M}}|\vec{\beta}_{K,p}|^2$$

and

$$\vec{\alpha}_p^\top \boldsymbol{M}^{(d)}_{\mathcal{M},p}\vec{\alpha}_p \geq \sum_{K\in\mathcal{M}} \lambda_{\min}\left(\boldsymbol{M}^{(d)}_{K,p}\right)|\vec{\beta}_{K,p}|^2 \geq \left(\min_{K\in\mathcal{M}} c_{K,\boldsymbol{M}}\right)p^{-4(d-1)}\sum_{K\in\mathcal{M}}|\vec{\beta}_{K,p}|^2.$$

We use (56) to deduce

$$c_6p^{-4(d-1)}\left(\min_{K\in\mathcal{M}} c_{K,\boldsymbol{M}}\right)|\vec{\alpha}_p|^2 \leq \vec{\alpha}_p^\top\boldsymbol{M}_{\mathcal{M},p}\vec{\alpha}_p \leq C_6\left(\max_{K\in\mathcal{M}} C_{K,\boldsymbol{M}}\right)|\vec{\alpha}_p|^2,$$

which implies

$$\lambda_{\min}\big(\boldsymbol{M}^{(d)}_{\mathcal{M},p}\big) \geq c'_{\mathcal{M},\boldsymbol{M}}p^{-4(d-1)} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{M}^{(d)}_{\mathcal{M},p}\big) \leq C'_{\mathcal{M},\boldsymbol{M}},$$

where $c'_{\mathcal{M},\boldsymbol{M}} = c_6\min_{K\in\mathcal{M}} c_{K,\boldsymbol{M}}$ and $C'_{\mathcal{M},\boldsymbol{M}} = C_6\max_{K\in\mathcal{M}} C_{K,\boldsymbol{M}}$. The result for diagonal scaling

$$\lambda_{\min}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\mathcal{M},p}\big) \geq c'_{\mathcal{M},\boldsymbol{M}}p^{-2(d-1)} \quad \text{and} \quad \lambda_{\max}\big(\widetilde{\boldsymbol{M}}^{(d)}_{\mathcal{M},p}\big) \leq C'_{\mathcal{M},\boldsymbol{M}}$$

is established in the same way.

The eigenvalues of the global mass matrix corresponding to the nonuniform order approximation $\boldsymbol{p}$ over $\mathcal{M}$ satisfy

$$\lambda_{\max}\left(\boldsymbol{M}^{d}_{\mathcal{M},\boldsymbol{p}}\right) = \max_{\vec{\alpha}_{\boldsymbol{p}}\in\mathbb{R}^{N}} \frac{\vec{\alpha}_{\boldsymbol{p}}^{\top}\boldsymbol{M}^{(d)}_{\mathcal{M},\boldsymbol{p}}\vec{\alpha}_{\boldsymbol{p}}}{|\vec{\alpha}_{\boldsymbol{p}}|^{2}} \le \max_{\vec{\alpha}_{p}\in\mathbb{R}^{N'}} \frac{\vec{\alpha}_{p}^{\top}\boldsymbol{M}^{(d)}_{\mathcal{M},p}\vec{\alpha}_{p}}{|\vec{\alpha}_{p}|^{2}} \le C'_{\mathcal{M},\boldsymbol{M}} \tag{57}$$

and

$$\begin{aligned}\lambda_{\min}\left(\boldsymbol{M}^{d}_{\mathcal{M},\boldsymbol{p}}\right) = \min_{\vec{\alpha}_{\boldsymbol{p}}\in\mathbb{R}^{N}} \frac{\vec{\alpha}_{\boldsymbol{p}}^{\top}\boldsymbol{M}^{(d)}_{\mathcal{M},\boldsymbol{p}}\vec{\alpha}_{\boldsymbol{p}}}{|\vec{\alpha}_{\boldsymbol{p}}|^{2}} &\ge \min_{\vec{\alpha}_{p}\in\mathbb{R}^{N'}} \frac{\vec{\alpha}_{p}^{\top}\boldsymbol{M}^{(d)}_{\mathcal{M},p}\vec{\alpha}_{p}}{|\vec{\alpha}_{p}|^{2}}\\ &\ge p^{-4(d-1)}c'_{\mathcal{M},\boldsymbol{M}},\end{aligned} \tag{58}$$

and hence the first part of (12) holds with $C^{*}_{\mathcal{M},\boldsymbol{M}} = C'_{\mathcal{M},\boldsymbol{M}}/c'_{\mathcal{M},\boldsymbol{M}}$. The second part of (12) is proved using (54) in the same fashion.

(2) Define the following skew-symmetric form (see [16]), using the discrete electric field $\widehat{\boldsymbol{E}}$ on the reference element:

$$\boldsymbol{C}(\widehat{\boldsymbol{E}}) = \begin{bmatrix} 0 & \widehat{E}_{1,2} & \widehat{E}_{1,3} \\ -\widehat{E}_{1,2} & 0 & \widehat{E}_{2,3} \\ -\widehat{E}_{1,3} & -\widehat{E}_{2,3} & 0 \end{bmatrix}, \tag{59}$$

where

$$\widehat{\boldsymbol{E}} = (\widehat{E}_1, \widehat{E}_2, \widehat{E}_3)^{\top} \quad \text{and} \quad \widehat{E}_{i,j} = \frac{\partial \widehat{E}_j}{\partial \xi_i} - \frac{\partial \widehat{E}_i}{\partial \xi_j}.$$

Straightforward calculations reveal that

$$|\mathbf{curl}\, \widehat{\boldsymbol{E}}|^2 = \frac{1}{2}\|\boldsymbol{C}(\widehat{\boldsymbol{E}})\|_F^2,$$

where $\|\cdot\|_F$ denotes the Frobenius norm (see [9]). Furthermore, using (9), it follows that

$$\boldsymbol{C}(\boldsymbol{E}) = \boldsymbol{J}_K^{-\top}\boldsymbol{C}(\widehat{\boldsymbol{E}})\boldsymbol{J}_K^{-1}$$

for the discrete electric field $\boldsymbol{E}$ on the physical element $K \in \mathcal{M}$, and hence,

$$|\mathbf{curl}\, \boldsymbol{E}|^2 = \frac{1}{2}\|\boldsymbol{J}_K^{-\top}\boldsymbol{C}(\widehat{\boldsymbol{E}})\boldsymbol{J}_K^{-1}\|_F^2. \tag{60}$$

Using the inequality (see, e.g., problem 23, section 5.6 of [9])

$$\frac{1}{d^2}\|\boldsymbol{J}_K^{T}\|_2^{-2}\|\boldsymbol{C}(\widehat{\boldsymbol{E}})\|_F^2\|\boldsymbol{J}_K\|_2^{-2} \le \|\boldsymbol{J}_K^{-\top}\boldsymbol{C}(\widehat{\boldsymbol{E}})\boldsymbol{J}_K^{-1}\|_F^2 \le d^2\|\boldsymbol{J}_K^{-\top}\|_2^2\|\boldsymbol{C}(\widehat{\boldsymbol{E}})\|_F^2\|\boldsymbol{J}_K^{-1}\|_2^2,$$

where $\|\cdot\|_2$ denotes the spectral norm (see [9]), establishes that

$$\frac{c_3^2}{d^2}|\mathbf{curl}\, \widehat{\boldsymbol{E}}|^2 \le \frac{1}{2}\|\boldsymbol{J}_K^{-\top}\boldsymbol{C}(\widehat{\boldsymbol{E}})\boldsymbol{J}_K^{-1}\|_F^2 \le d^2C_3^2|\mathbf{curl}\, \widehat{\boldsymbol{E}}|^2 \tag{61}$$

using (5)–(6). By integrating over the physical element K, we deduce

$$S_K(\boldsymbol{E},\boldsymbol{E}) = \int_K \mu^{-1}|\mathbf{curl}\, \boldsymbol{E}|^2\,\mathrm{d}\boldsymbol{x} = \frac{1}{2}\int_{\widehat{K}} \mu^{-1}\|\boldsymbol{J}_K^{-\top}\boldsymbol{C}(\widehat{\boldsymbol{E}})\boldsymbol{J}_K^{-1}\|_F^2\ |\det(\boldsymbol{J}_K)|\,\mathrm{d}\boldsymbol{\xi},$$

and applying (3) and (61) yields

$$\lambda_{\max}\big(\boldsymbol{S}^{(d)}_{K,p}\big) \leq d^2 C_1 C_{2,K} C_{3,K}^2 \lambda_{\max}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big) \tag{62}$$

and

$$\lambda_{\min}\big(\boldsymbol{S}^{(d)}_{K,p}\big) \geq \frac{c_1 c_{2,K} c_{3,K}^2}{d^2} \lambda_{\min}\big(\boldsymbol{S}^{(d)}_{\widehat{K},p}\big).$$

As a result of (25),

$$\lambda_{\min}\big(\boldsymbol{S}^{(d)}_{K,p}\big) \geq c_{K,\boldsymbol{S}} p^{-4(d-2)} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{S}^{(d)}_{K,p}\big) \leq C_{K,\boldsymbol{S}}, \tag{63}$$

where

$$c_{K,\boldsymbol{S}} = \frac{1}{9} c_1 c_{2,K} c_{3,K}^2 c_{\widehat{K},\boldsymbol{S}} \quad \text{and} \quad C_{K,\boldsymbol{S}} = 9 C_1 C_{2,K} C_{3,K}^2 C_{\widehat{K},\boldsymbol{S}}.$$

Hence

$$\kappa\big(\boldsymbol{S}^{(d)}_{K,p}\big) \leq C^*_{K,\boldsymbol{S}} p^{4(d-2)}, \tag{64}$$

where $C^*_{K,\boldsymbol{M}} = C_{K,\boldsymbol{S}}/c_{K,\boldsymbol{S}}$. The same argument may be applied in the case of diagonal scaling:

$$\lambda_{\min}\big(\widetilde{\boldsymbol{S}}^{(d)}_{K,p}\big) \geq c_{K,\boldsymbol{S}} p^{-2(d-2)}, \qquad \lambda_{\max}\big(\widetilde{\boldsymbol{S}}^{(d)}_{K,p}\big) \leq C_{K,\boldsymbol{S}} \tag{65}$$

and

$$\kappa\big(\widetilde{\boldsymbol{S}}^{(d)}_{K,p}\big) \leq C^*_{K,\boldsymbol{S}} p^{2(d-2)}. \tag{66}$$

The global curl-curl matrix $\boldsymbol{S}^{(d)}_{\mathcal{M},p}$ corresponding to the uniform order approximation p over $\mathcal{M}$ satisfies

$$\left(\min_{K\in\mathcal{M}} c_{K,\boldsymbol{S}}\right) \sum_{K\in\mathcal{M}} |\vec{\beta}_{K,p}|^2 \leq \vec{\alpha}_p^\top \boldsymbol{S}^{(d)}_{\mathcal{M},p} \vec{\alpha}_p \leq \left(\max_{K\in\mathcal{M}} C_{K,\boldsymbol{S}}\right) \sum_{K\in\mathcal{M}} |\vec{\beta}_{K,p}|^2.$$

Thus, using (56) results in

$$c_6 p^{-4(d-2)} \left(\min_{K\in\mathcal{M}} c_{K,\boldsymbol{S}}\right) |\vec{\alpha}_p|^2 \leq \vec{\alpha}_p^\top \boldsymbol{S}^{(d)}_{\mathcal{M},p} \vec{\alpha}_p \leq C_6 \left(\max_{K\in\mathcal{M}} C_{K,\boldsymbol{S}}\right) |\vec{\alpha}_p|^2,$$

which leads to

$$\lambda_{\min}\big(\boldsymbol{S}^{(d)}_{\mathcal{M},p}\big) \geq c'_{\mathcal{M},\boldsymbol{S}} p^{-4(d-2)} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{S}^{(d)}_{\mathcal{M},p}\big) \leq C'_{\mathcal{M},\boldsymbol{S}},$$

where $c'_{\mathcal{M},\boldsymbol{S}} = c_4 \min_{K\in\mathcal{M}} c_{K,\boldsymbol{S}}$ and $C'_{\mathcal{M},\boldsymbol{S}} = C_4 \max_{K\in\mathcal{M}} C_{K,\boldsymbol{S}}$.

Applying arguments similar to those used in (57) and (58), the global curl-curl matrix corresponding to the nonuniform order approximation $\boldsymbol{p}$ over $\mathcal{M}$ satisfies

$$\lambda_{\min}\big(\boldsymbol{S}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) \geq c'_{\mathcal{M},\boldsymbol{S}} p^{-4(d-2)} \quad \text{and} \quad \lambda_{\max}\big(\boldsymbol{S}^{(d)}_{\mathcal{M},\boldsymbol{p}}\big) \leq C'_{\mathcal{M},\boldsymbol{S}},$$

and the first part of (13) holds with $C^*_{\mathcal{M},\boldsymbol{S}} = C'_{\mathcal{M},\boldsymbol{S}}/c'_{\mathcal{M},\boldsymbol{S}}$. The second part is proved using (65) in the same manner.

(3) Let $\vec{\alpha}_{K,p}$ denote the values of the degrees of freedom in the approximation over $K \in \mathcal{M}$. Retracing the steps in deriving (46) and using the estimates (52) and (63) yields

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{A}_{K,p}^{(d)}\vec{\alpha}_{K,p} \leq 2\max(C_{K,\boldsymbol{S}}, \omega^2 C_{K,\boldsymbol{M}})|\vec{\alpha}_{K,p}|^2,$$

while following the steps leading to (47) using the estimates (54) and (65) yields

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{A}_{K,p}^{(d)}\vec{\alpha}_{K,p} \leq \max(C_{K,\boldsymbol{S}}, C_{K,\boldsymbol{M}})\vec{\alpha}_{K,p}^{\top}\mathrm{diag}\big(\boldsymbol{A}_{K,p}^{(d)}\big)\vec{\alpha}_{K,p},$$

which implies that

$$\lambda_{\max}\big(\boldsymbol{A}_{K,p}^{(d)}\big) \leq C_{K,\boldsymbol{A}} \quad \text{and} \quad \lambda_{\max}\big(\widetilde{\boldsymbol{A}}_{K,p}^{(d)}\big) \leq C_{K,\boldsymbol{A}}.$$

Similarly, using (52) gives a bound for the minimum eigenvalue of the stiffness matrix

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{A}_{K,p}^{(d)}\vec{\alpha}_{K,p} \geq \omega^2\vec{\alpha}_{K,p}^{\top}\boldsymbol{M}_{K,p}^{(d)}\vec{\alpha}_{K,p} \geq \omega^2 c_{K,\boldsymbol{M}}p^{-4(d-1)}|\vec{\alpha}_{K,p}|^2.$$

The arguments used to obtain (48) and (49) may be modified to deduce that

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{M}_{K,p}^{(d)}\vec{\alpha}_{K,p} \geq cp^{-2(d-1)}\vec{\alpha}_{K,p}^{\top}\mathrm{diag}\big(\boldsymbol{M}_{K,p}^{(d)}\big)\vec{\alpha}_{K,p}$$

and

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{M}_{K,p}^{(d)}\vec{\alpha}_{K,p} \geq cp^{-2d}\vec{\alpha}_{K,p}^{\top}\mathrm{diag}\big(\boldsymbol{S}_{K,p}^{(d)}\big)\vec{\alpha}_{K,p}.$$

Then, following the steps in (50), we obtain

$$\vec{\alpha}_{K,p}^{\top}\boldsymbol{A}_{K,p}^{(d)}\vec{\alpha}_{K,p} \geq cp^{-2(d-1)}\min\left(1, \frac{\omega}{p}\right)^2\vec{\alpha}_{K,p}^{\top}\mathrm{diag}\left(\boldsymbol{A}_{K,p}^{(d)}\right)\vec{\alpha}_{K,p},$$

which leads to a bound on the smallest eigenvalue of the diagonally scaled stiffness matrix.

The above bounds for the eigenvalues of matrices on a single element are used to obtain bounds for the global matrices corresponding to uniform order of approximation p by summing element contributions as before. Then, arguments analogous to (57) and (58) are used to deduce bounds for nonuniform order of approximation $\boldsymbol{p}$.

This completes the proof of Theorem 1.

POLYNOMIAL INTERPOLATION ON THE UNIT SPHERE*

YUAN XU†

Abstract. The problem of interpolation at $(n+1)^2$ points on the unit sphere S^2 by spherical polynomials of degree at most n is studied. Many sets of points that admit unique interpolation are given explicitly. The proof is based on a method of factorization of polynomials. A related problem of interpolation by trigonometric polynomials is also solved.

Key words. interpolation, spherical polynomials, unit sphere

1. Introduction.

The purpose of this paper is to study polynomial interpolation on the unit sphere $S^2 = \{x : \|x\| = 1\}$ of $\mathbb{R}^3$, where $\|x\|$ is the Euclidean norm of $\mathbb{R}^3$. Let Π_n^2 denote the space of polynomials of degree at most n in 2 variables, and let $\mathcal{P}_n^3$ denote the space of homogeneous polynomials of degree n in 3 variables. The notation $\Pi_n(S^2)$ denotes the space of spherical polynomials of 3 variables, that is, the restriction of polynomials of 3 variables in Π_n^3 on S^2. It is known that

$$\dim \Pi_n(S^2) = (n+1)^2, \qquad n \geq 0.$$

We study the following polynomial interpolation problem on S^2:

Problem 1. Let $X = \{\mathbf{a}_i : 1 \leq i \leq (n+1)^2\}$ be a set of distinct points on S^2. Find conditions on X such that there is a unique polynomial $T \in \Pi_n(S^2)$ satisfying

$$T(\mathbf{a}_i) = f_i, \qquad \mathbf{a}_i \in X, \quad 1 \leq i \leq (n+1)^2,$$

for any given data $\{f_i\}$.

If there is a *unique* solution to the interpolation problem, we say that the problem is *poised* and that X solves Problem 1. In terms of a basis of $\Pi_n(S^2)$, the interpolation conditions give linear equations for the coefficients of T. It follows that the problem has a unique solution if and only if $T(\mathbf{a}_i) = 0$ for all $\mathbf{a}_i \in X$ implies $T = 0$, which holds if and only if the determinant of the linear system of equations is nonzero. The determinant is a polynomial of the interpolation points; hence it is nonzero for almost all choices of interpolation points. In other words, Problem 1 is poised for almost all choices of X. On the other hand, given a set of points, it is often difficult to determine if it leads to unique interpolation. The question is related to several other problems; see the discussion below. In many applications, one would like to have poised sets of points explicitly given. The main result of this paper provides families of such points that admit unique interpolation by $\Pi_n(S^2)$ for all n.

We need some basic facts about spherical harmonics (see [3, 10], for example). The harmonic polynomials are homogeneous polynomials Y in $\mathcal{P}_n^3$ that satisfy $\Delta Y = 0$, where Δ is the usual Laplace operator, and $\Delta = \partial_1^2 + \partial_2^2 + \partial_3^2$ with $\partial_i = \partial^2/\partial x_i^2$. The

spherical harmonics are the restriction of the harmonic polynomials on S^2. Let $\mathcal{H}_n^3$ denote the space of spherical harmonics of degree n in three variables. It is known that

$$\dim \mathcal{H}_n^3 = 2n+1, \qquad n \ge 0.$$

Let $\{S_{k,n} : 1 \le k \le 2n+1\}$ be an orthonormal basis of $\mathcal{H}_n^3$. The reproducing kernel $Y_n(\mathbf{x},\mathbf{y})$ of $\mathcal{H}_n^3$ is defined by

$$Y_n(\mathbf{x},\mathbf{y}) = \sum_{k=1}^{2n+1} S_{k,n}(\mathbf{x}) S_{k,n}(\mathbf{y}), \qquad \mathbf{x},\mathbf{y} \in S^2.$$

In particular, for each fixed $\mathbf{y} \in S^2$, $Y_n(\mathbf{x},\mathbf{y})$ is a spherical harmonic, the so-called zonal harmonic of degree n. Let $C_n^\lambda(t)$ be the Gegenbauer polynomial of degree n normalized so that $C_n^\lambda(1) = \binom{n+2\lambda-1}{n}$. Then Y_n satisfies

$$Y_n(\mathbf{x},\mathbf{y}) = (2n+1) C_n^{1/2}(\langle \mathbf{x},\mathbf{y}\rangle), \qquad \mathbf{x},\mathbf{y} \in S^2.$$

In $L^2(S^2)$, the space $\Pi_n(S^2)$ admits a unique orthogonal decomposition $\Pi_n(S^2) = \bigoplus_{k=0}^n \mathcal{H}_k^3$ in terms of the spaces of spherical harmonics. The reproducing kernel of $\Pi_n(S^2)$ in $L^2(S^2)$ is given by

$$K_n(\mathbf{x},\mathbf{y}) = \sum_{k=0}^n Y_k(\mathbf{x},\mathbf{y}) = \sum_{k=0}^n (2k+1) C_k^{1/2}(\langle \mathbf{x},\mathbf{y}\rangle).$$

For each fixed $\mathbf{y} \in S^2$, $K_n(\mathbf{x},\mathbf{y})$ is a polynomial in $\Pi_n(S^2)$ that depends only on $\langle \mathbf{x},\mathbf{y}\rangle$.

Apart from its own interest, the interpolation problem is related to other problems concerning spherical polynomials. As an example, let $X = \{\mathbf{a}_i : 1 \le i \le (n+1)^2\}$ be a set of distinct points on S^2; one can ask the question of when $\{K_n(\mathbf{x},\mathbf{a}_i), 1 \le i \le (n+1)^2\}$ is a basis of $\Pi_n(S^2)$. It turns out that this problem is equivalent to Problem 1. The following proposition is folklore and can be proved easily using the formulae for K_n and Y_n given above.

Proposition 1.1. *Let $X = \{\mathbf{a}_i : 1 \le i \le (n+1)^2\}$ be a set of distinct points. Then X is a solution of Problem* 1 *if and only if $\{K_n(\mathbf{x},\mathbf{a}_i), 1 \le i \le (n+1)^2\}$ forms a basis of $\Pi_n(S^2)$.*

The problem of $\{K_n(\mathbf{x},\mathbf{a}_i)\}$ being a basis has been considered recently in [4] for possible application in wavelets, since such a basis is better localized than the usual orthonormal basis. The interpolation problem is also closely related to constructing cubature formulae on the sphere (see section 3), and there have been considerable efforts computing good interpolation points for that purpose; see [12] and the references therein. Recently, the polynomial interpolation has also been studied in [6] in connection with radial basis interpolation on the sphere and in [11] in connection with scattered data interpolation on the sphere. In [15], we showed that there is a close relation between interpolation on S^d and on the unit ball B^d of $\mathbb{R}^d$. In particular, it shows that many sets of points that allow unique polynomial interpolation on $B^2 = \{(x,y) : x^2+y^2 \le 1\}$ can be used to generate symmetric points on S^2 that solve Problem 1, where symmetry means that the points are symmetric with respect to a coordinate plane. The interpolation on B^2 has been studied in [1, 2] recently. The result in [1] leads to a set of symmetric points on S^2 in which points are equidistant points on parallel circles, and each circle has the same number of points. However, the more general result in [2] cannot be used to give points on S^2, since the correspondence between points on B^2 and on S^2 requires that there are $n+1$ points on the boundary circle of B^2.

In the following section, we present a theorem that gives many sets of points that solve Problem 1. The $(n+1)^2$ points all lie on $n+1$ distinct latitudes (parallel circles on S^2), and on each latitude there are an odd number of equidistant points. The number of points need not be the same on each latitude, and there is no restriction on the distribution of latitudes. The proof relies on a method of factorization, which is closely related to the method used for polynomial interpolation on the unit ball B^2 in [2, 7]. The use of equidistant points allows us to reduce the problem of interpolation on the sphere to an interpolation problem by a family of special trigonometric polynomials, which turns out to be equivalent to a Hermite–Birkhoff interpolation by trigonometric polynomials.

As far as we know, apart from a result that is a simple consequence of Bezout's theorem (see Proposition 2.1 below), these families of points are first examples of poised interpolation points that are given explicitly for all n.

The paper is organized as follows. We prove the factorization theorem in the following section. The main result and various examples are given in section 3, which also includes a result on cubature formulae. The related trigonometric Hermite–Birkhoff interpolation is discussed in section 4.

2. Preliminary and results on factorization of polynomials. On S^2 it is more convenient to work with spherical coordinates:

$$x = \sin\theta\sin\phi, \quad y = \sin\theta\cos\phi, \quad z = \cos\theta, \qquad 0 \le \phi \le 2\pi, \quad 0 \le \theta \le \pi.$$

For a polynomial $T \in \Pi(S^2)$ we introduce the notation $\widetilde{T}$ defined by

$$\widetilde{T}_n(\theta,\phi) = T_n(\sin\theta\sin\phi, \sin\theta\cos\phi, \cos\theta), \quad 0 \le \phi \le 2\pi, \quad 0 \le \theta \le \pi.$$

If $X = \{(x_i, y_i, z_i) : 1 \le i \le M\}$ is a set of points on S^2, we also use the notation $\widetilde{X} = \{(\theta_i, \phi_i) : 1 \le i \le M\}$ for the corresponding set in spherical coordinates.

The notation $S^2(a) := \{(x,y,z) : (x,y,z) \in S^2,\ z = a\}$, $-1 < a < 1$, denotes the circle on S^2 resulting from the intersection of S^2 with the plane $z = a$ (called the latitude at $z = a$).

An orthogonal basis of $\mathcal{H}_n^3$ can be given in terms of the Gegenbauer polynomials. In spherical coordinates, define

$$\begin{aligned} Y_{k,n}^{(1)}(x,y,z) &= C_{n-k}^{k+1/2}(\cos\theta)(\sin\theta)^k\cos k\phi, \qquad 0 \le k \le n, \\ Y_{k,n}^{(2)}(x,y,z) &= C_{n-k}^{k+1/2}(\cos\theta)(\sin\theta)^k\sin k\phi, \qquad 1 \le k \le n. \end{aligned}$$

Then $\mathcal{H}_n^3 = \operatorname{span}\{Y_{k,n}^{(1)},\ 0 \le k \le n, \text{ and } Y_{k,n}^{(2)},\ 1 \le k \le n\}$. Since $\Pi_n(S^2) = \bigoplus_{k=0}^n \mathcal{H}_k^3$, every polynomial $T_n \in \Pi_n(S^2)$ can be written as

$$T_n(x,y,z) = \sum_{j=0}^{n}\sum_{k=0}^{j} C_{j-k}^{k+1/2}(\cos\theta)(\sin\theta)^k(a_{k,j}\cos k\phi + b_{k,j}\sin k\phi).$$

Changing the order of sums in the above expression, we see that

$$\widetilde{T}_n(\theta,\phi) = a_0(\cos\theta) + \sum_{k=1}^{n}[a_k(\cos\theta)(\sin\theta)^k\cos k\phi + b_k(\cos\theta)(\sin\theta)^k\sin k\phi], \tag{2.1}$$

where $a_k(t)$ and $b_k(t)$ are polynomials of degree $n-k$ in one variable,

$$a_k(\cos\theta) = \sum_{j=0}^{n-k} a_{k,k+j} C_j^{k+1/2}(\cos\theta), \quad \text{and} \quad b_k(\cos\theta) = \sum_{j=0}^{n-k} b_{k,k+j} C_j^{k+1/2}(\cos\theta).$$

Since C_j^λ is a polynomial of degree exactly j, a_k and b_k are generic polynomials of degree $n-k$. Notice that for a fixed θ, the polynomial $\widetilde{T}(\theta,\phi)$ is a trigonometric polynomial of degree n in ϕ. We will use the fact that the interpolation on $2n+1$ distinct points inside $[0,2\pi)$ by trigonometric polynomials of degree n is unique.

The proof of our main result is based on a factorization of the polynomial that vanishes on the interpolation points. In the simplest case, an analogue of such a factorization is akin to the Bezout theorem for algebraic curves. That Bezout's theorem can be used to establish the uniqueness of the interpolation is folklore (see, for example, [5]). For interpolation on the sphere, we use it to give a proof of the following proposition (see [6]), which gives a prelude of the factorization method that leads to our main result.

Proposition 2.1. *Let $z_0, z_1, \ldots, z_n$ be $n+1$ distinct elements in $(-1,1)$. If X consists of $2k+1$ distinct points on the latitude $S^2(z_k)$ for $0 \le k \le n$, then X solves Problem 1 in $\Pi_n(S^2)$.*

Proof. It is sufficient to prove that if $T_n \in \Pi_n(S^2)$ vanishes on X, then T_n is identically zero. Using the expression of $\widetilde{T}_n$ in (2.1) and the fact that T_n vanishes on $2n+1$ points of $S^2(z_n)$, it follows from the uniqueness of the trigonometric interpolation that $a_k(z_n) = 0$ and $b_k(z_n) = 0$, $0 \le k \le n$. Consequently, $a_n(z) = b_n(z) = 0$ and $a_k(z) = (z - z_n)a_k^*(z)$ and $b_k(z) = (z - z_n)b_k^*(z)$ for $0 \le k \le n-1$ so that T_n satisfies a factorization $T_n(x,y,z) = (z - z_n)T_{n-1}(x,y,z)$, where $T_{n-1} \in \Pi_{n-1}(S^2)$. Evidently, we can continue this process for $z_{n-1}, \ldots, z_0$ and conclude that $T_n(x,y,z) = (z - z_n)\ldots(z - z_0)T^*(x,y,z)$. However T_n is a polynomial of degree n so that $T_n \equiv 0$. □

The analogue of this proposition holds for higher dimensional spheres, as shown in [6]. The points in the above proposition have little symmetry on S^2, since no two latitudes have the same number of points. It is worthwhile to emphasize that the position of the points on each latitude is completely arbitrary. In our result below, the points on each latitude are equidistant points. In essence, our main result is based on a more general factorization that holds, however, only for equidistant points.

Let $\Theta_{\alpha,m}$ denote a set of $2m+1$ equidistant points,

$$\Theta_{\alpha,m} = \{\theta_j^\alpha : \theta_j^\alpha = (2j+\alpha)\pi/(2m+1), \quad j = 0,1,\ldots,2m, \quad 0 \le \alpha < 2\}. \tag{2.2}$$

Under the mapping $\phi \mapsto e^{i\phi}$, these points can be considered as points on the unit circle. The presence of the number α means that the equidistant points are defined up to a rotation. The following simple fact plays an important role in the development below.

Lemma 2.2. *Let $n = 2m$ or $n = 2m-1$. For $\phi \in \Theta_{\alpha,m}$,*

$$\widetilde{T}_n(\theta,\phi) = a_0(\cos\theta) + \sum_{k=1}^{m} \left[\left(a_k(\cos\theta)(\sin\theta)^k + u_{2m-k+1}(\cos\theta)(\sin\theta)^{2m-k+1}\right)\cos k\phi \right.$$
$$\left. + \left(b_k(\cos\theta)(\sin\theta)^k + v_{2m-k+1}(\cos\theta)(\sin\theta)^{2m-k+1}\right)\sin k\phi\right],$$

where

$$\begin{aligned} u_{2m-k+1}(\cos\theta) \ &= a_{2m-k+1}(\cos\theta)\cos\alpha\pi + b_{2m-k+1}(\cos\theta)\sin\alpha\pi, \\ v_{2m-k+1}(\cos\theta) \ &= a_{2m-k+1}(\cos\theta)\sin\alpha\pi - b_{2m-k+1}(\cos\theta)\cos\alpha\pi, \end{aligned}$$

and we assume that $a_{2m}(t) = b_{2m}(t) = 0$ *if* $n = 2m - 1$.

Proof. The proof amounts to using the fact that

$$\begin{aligned} \cos(2m-k+1)\phi \ &= \cos(\alpha\pi - k\phi) = \cos\alpha\pi\cos k\phi + \sin\alpha\pi\sin k\phi, \\ \sin(2m-k+1)\phi \ &= \sin(\alpha\pi - k\phi) = \sin\alpha\pi\cos k\phi - \cos\alpha\pi\sin k\phi \end{aligned}$$

for $\phi \in \Theta_{\alpha,m}$, and we rewrite $\widetilde{T}(\theta,\phi)$ accordingly. $\square$

In particular, using the uniqueness of trigonometric interpolation, this shows that if $\widetilde{T}_n(\theta_j,\phi_i) = 0$ for $\phi_i \in \Theta_{\alpha,m}$, $0 \le i \le 2m$, then $a_0(\theta_j) = 0$ and

$$\begin{aligned} &a_k(\cos\theta_j)(\sin\theta_j)^k + u_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1} = 0, \\ &b_k(\cos\theta_j)(\sin\theta_j)^k + v_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1} = 0. \end{aligned} \tag{2.3}$$

Hence, we need to consider the poisedness of interpolation by trigonometric polynomials of the form

$$p(\cos\theta)(\sin\theta)^k + q(\cos\theta)(\sin\theta)^{2m-k+1},$$

where $p(t)$ and $q(t)$ are polynomials of degree $n-k$ and $n-2m+k-1$, respectively. For this purpose, we need a lemma which is elementary but somewhat unexpected. It contains the following elementary formula as its simplest case:

$$\frac{d^5}{dt^5}\Big[(1-t^2)^{3/2}(at+b)\Big] = 45\frac{a+bt}{(1-t^2)^{7/2}}.$$

It is this simple formula, stumbled upon using a computer algebra system, that leads to the lemma below. We will use the Pochhammer symbol $(a)_n = a(a+1)\dots(a+n-1)$.

LEMMA 2.3. *Let* m *and* k *be positive integers, and let* $1 \le k \le 2m$. *Let* $q_{k-1}(t)$ *be an algebraic polynomial of degree* $k-1$. *Then*

$$(1-t^2)^{m+1/2}\Big(\frac{d}{dt}\Big)^{2m-k+1}\Big((1-t^2)^{m-k+1/2}q_{k-1}(t)\Big) = q^*_{k-1}(t),$$

where q^*_{k-1} *is a polynomial of degree* $k-1$ *such that* $q_{k-1}(t) = 0$ *if and only if* $q^*_{k-1}(t) = 0$. *In fact, if* $q_{k-1}(t) = \sum_{l=0}^{k-1} a_l(1-t)^l$, *then* q^*_{k-1} *is given by*

$$q^*_{k-1}(t) = (-1)^{k-1}2^{2m-k+1}\sum_{l=0}^{k-1}(-m+l+1/2)_{2m-k+1}\, a_l\, s_l(t),$$

where s_l *are polynomials of degree* $k-1$ *that are defined by*

$$s_l(t) = (1-t)^l\sum_{j=0}^{k-l-1}\frac{(-k+l+1)_j(k-2m-1)_j}{(-m+l+1/2)_j j!}\Big(\frac{1-t}{2}\Big)^j.$$

Proof. We need to recall the definition of Jacobi polynomials. Let α and β be two arbitrary real numbers. Then the Jacobi polynomial $P_n^{(\alpha,\beta)}$ is given by Rodrigue's formula [14, p. 67, (4.3.1)],

$$P_n^{(\alpha,\beta)}(t) = \frac{(-1)^n}{n!2^n}(1-t)^{-\alpha}(1+t)^{-\beta}\Big(\frac{d}{dt}\Big)^n\left[(1-t)^{n+\alpha}(1+t)^{n+\beta}\right].$$

Let $q_{k-1}(t) = \sum_{l=0}^{k-1} a_l(1-t)^l$. It follows that

$$\begin{aligned}\phi(t) :=&(1-t^2)^{m+1/2}\Big(\frac{d}{dt}\Big)^{2m-k+1}\Big((1-t^2)^{m-k+1/2}q_{k-1}(t)\Big)\\ =&\sum_{l=0}^{k-1} a_l(1-t^2)^{m+1/2}\Big(\frac{d}{dt}\Big)^{2m-k+1}\Big((1-t)^{m-k+l+1/2}(1+t)^{m-k+1/2}\Big).\end{aligned}$$

Using Rodrigue's formula with $n = 2m-k+1$, $\alpha = -m+l-1/2$, and $\beta = -m-1/2$, we get

$$\phi(t) = \sum_{l=0}^{k-1} a_l(-1)^{k-1}2^{2m-k+1}(2m-k+1)!(1-t)^l P_{2m-k+1}^{(-m-1/2+l,-m-1/2)}(t).$$

It is known that the Jacobi polynomials with negative parameters satisfy the following relation [14, p. 64, (4.22.3)]:

$$\binom{n}{j-1}P_n^{(\alpha,\beta)}(t) = \binom{n+\alpha}{n-j+1}P_{j-1}^{(\alpha,\beta)}(t) \qquad \text{if} \quad n+\alpha+\beta+j=0,$$

which shows that $P_n^{(\alpha,\beta)}(t)$ is in fact a polynomial of degree $j-1$ with $j=-n-\alpha-\beta$. The condition $n+\alpha+\beta+j=0$ is satisfied in our case with n,α,β as defined above and $j=k-l$. Consequently, we conclude that

$$\begin{aligned}\phi(t) = \sum_{l=0}^{k-1} a_l(-1)^{k-1}2^{2m-k+1}(k-l-1)!&\frac{(-m+l+1/2)_{2m-k+1}}{(-m+l+1/2)_{k-l-1}}\\ &\times(1-t)^l P_{k-l-1}^{(-m-1/2+l,-m-1/2)}(t),\end{aligned}$$

after some simplification of the constants. This shows that ϕ is indeed a polynomial of degree $k-1$, which we called q_{k-1}^* in the statement. The explicit formula of q_{k-1}^* is derived from the explicit formula of $P_n^{(\alpha,\beta)}(t)$ [14, p. 62, (4.21.2)],

$$P_n^{(\alpha,\beta)}(t) = \binom{n+\alpha}{n}{}_2F_1\left(-n, n+\alpha+\beta+1;\alpha+1;\frac{1-t}{2}\right),$$

where ${}_2F_1$ is the hypergeometric function defined by

$${}_2F_1(a,b;c;z) = \sum_{k=0}^{\infty}\frac{(a)_k(b)_k}{(c)_k k!}z^k, \qquad |z|<1.$$

Finally, let $s_l(t)$ be the polynomials in the statement. Writing $s_0(t), s_1(t), \ldots, s_{k-1}(t)$ in terms of $1, (1-t), \ldots, (1-t)^{k-1}$, the transition matrix is triangular with nonzero diagonal elements. Hence, the polynomials $s_0, s_1, \ldots, s_{k-1}$ are linearly independent. Consequently, $q_{k-1}^*(t) = 0$ if and only if $q_{k-1}(t) = 0$. $\square$

Lemma 2.4. *Let k and m be positive integers, and let $k \leq 2m$. Let p_{2m-k} be a polynomial of degree $2m-k$, and let q_{k-1} be a polynomial of degree $k-1$. If $\phi(t) = p_{2m-k}(t) + (1-t^2)^{m-k+1/2} q_{k-1}(t)$ vanishes on $2m+1$ distinct points in $[-1,1]$, then $\phi(t) \equiv 0$.*

Proof. Since ϕ has $2m+1$ zeros, Rolle's theorem implies that $\phi^{(2m-k+1)}(t)$ has at least k zeros inside $(-1,1)$. Using the previous lemma,

$$\phi^{(2m-k+1)}(t) = \left(\frac{d}{dt}\right)^{2m-k+1} \left[(1-t^2)^{m-k+1/2} q_{k-1}(t)\right] = (1-t^2)^{-m-1/2} q^*_{k-1}(t)$$

so that $q^*_{k-1}(t)$ has k zeros inside $(-1,1)$. Since q^*_{k-1} is a polynomial of degree $k-1$, we have $q^*_{k-1}(t) \equiv 0$. Consequently, $q_{k-1}(t) \equiv 0$ by the previous lemma. Therefore, $\phi(t) = p_{2m-k}(t)$, which must be zero since it is a polynomial of degree $2m-k$ and it vanishes on $2m+1$ points. □

Corollary 2.5. *Let k and m be positive integers, and let $k \leq 2m$. Let p_{2m-k} be a polynomial of degree $2m-k$, and let q_{k-1} be a polynomial of degree $k-1$. If*

$$\psi(\theta) = p_{2m-k}(\cos\theta)(\sin\theta)^k + (\sin\theta)^{2m-k+1} q_{k-1}(\cos\theta)$$

vanishes on $2m+1$ distinct points in $(0,\pi)$, then $\psi(\theta) \equiv 0$.

Proof. Using the fact that $\sin\theta$ is positive on $(0,\pi)$, the stated result follows from the previous proposition with $\phi(t) = \psi(\theta)/(\sin\theta)^k$ and $t = \cos\theta$. □

There is another way to state the result in Corollary 2.5. A system of functions $\{g_1, \dots, g_n\}$ is called a Chebyshev system on the interval $(a,b) \subset \mathbb{R}$ if for any set of nonzero real numbers $c_1, \dots, c_n$ the function $c_1 g_1 + \cdots + c_n g_n$ has at most $n-1$ zeros in (a,b).

Corollary 2.6. *Let k and m be integers, and let $k \leq 2m$. The system of functions*

$$(\sin\theta)^k\{1, \cos\theta, \dots, \cos(2m-k)\theta\} \cup (\sin\theta)^{2m-k+1}\{1, \cos\theta, \dots, \cos(k-1)\theta\}$$

is a Chebyshev system on $(0,\pi)$. Equivalently, the system of functions

$$\{1, t, \dots, t^{2m-k}\} \cup (1-t^2)^{2m-2k+1}\{1, t, \dots, t^{k-1}\}$$

is a Chebyshev system on $(0,1)$.

Even in the case of $k=1$, which states that $\{1, \cos\theta, \dots, \cos(2m-1)\theta, (\sin\theta)^{2m-1}\}$ is a Chebyshev system on $(0,\pi)$, this corollary is not obvious.

The following factorization theorem holds the key to our main result.

Theorem 2.7. *Let m be an integer, let $m \leq s \leq 2m+1$, and let $n = 2m$ or $n = 2m-1$. Let $\theta_0, \theta_1, \dots, \theta_{2\lambda}$ be distinct numbers in $(0,\pi)$, where $\lambda = s-m$. If $T \in \Pi_s(S^2)$ satisfies*

$$\widetilde{T}(\theta_j, \phi_i) = 0, \qquad 0 \leq j \leq 2\lambda, \quad 0 \leq i \leq 2m, \quad \phi_i \in \Theta_{\alpha,m},$$

where α is a number in $[0,2)$, then there is a spherical polynomial $T^* \in \Pi_{n-2\lambda-1}(S^2)$ such that

$$T(x,y,z) = \prod_{j=0}^{2\lambda} (z - \cos\theta_j) T^*(x,y,z).$$

In particular, $T^*(x,y,z) = 0$ if $s = 2m$ or $s = 2m-1$.

Proof. Using the formula (2.1), we write

$$\widetilde{T}(\theta,\phi) = a_0(\cos\theta) + \sum_{k=1}^{s} \left[a_k(\cos\theta)(\sin\theta)^k \cos k\phi + b_k(\cos\theta)(\sin\theta)^k \sin k\phi\right],$$

where a_k and b_k are polynomials of degree $s-k$. By Lemma 2.2, for $\phi_i \in \Theta_{\alpha,m}$,

$$\begin{aligned}\widetilde{T}(\theta_j,\phi_i) = a_0(\cos\theta_j) &+ \sum_{k=1}^{m} (\sin\theta_j)^k \left(a_k(\cos\theta_j)\cos k\phi_i + b_k(\cos\theta_j)\sin k\phi_i\right) \\ &+ \sum_{k=2m+1-s}^{m} \big(u_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1}\cos k\phi_i \\ &\qquad + v_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1}\sin k\phi_i\big)\end{aligned}$$

for $0 \le i \le 2m$ and $0 \le j \le 2\lambda$. For each fixed j, $\widetilde{T}(\theta_j,\phi_i) = 0$ shows that the trigonometric polynomial $\widetilde{T}(\theta_j,\cdot)$ of degree m vanishes on $2m+1$ points; the uniqueness of the trigonometric interpolation implies the following two cases.

Case 1: $0 \le k \le 2m-s$.

$$a_k(\cos\theta_i)(\sin\theta_j)^k = 0, \quad b_k(\cos\theta_j)(\sin\theta_j)^k = 0, \qquad 0 \le j \le 2\lambda,$$

where we assume $b_0(\cos\theta) = 0$. Since $\theta_j \in (0,\pi)$, this shows that $a_k(\cos\theta_j) = 0$ and $b_k(\sin\theta_j) = 0$. Consequently, there exist polynomials $a_k^*(t)$ and $b_k^*(t)$, both of degree $n-k-(2\lambda+1)$, such that $a_k(t) = \prod_{j=0}^{2\lambda}(t-\cos\theta_j)a_k^*(t)$ and $b_k(t) = \prod_{j=0}^{2\lambda}(t-\cos\theta_j)b_k^*(t)$.

Case 2: $2m-s+1 \le k \le m$.

$$\begin{aligned} a_k(\cos\theta_j)(\sin\theta_j)^k + u_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1} &= 0, \\ b_k(\cos\theta_j)(\sin\theta_j)^k + u_{2m-k+1}(\cos\theta_j)(\sin\theta_j)^{2m-k+1} &= 0, \end{aligned} \qquad 0 \le j \le 2\lambda.$$

By Corollary 2.5, this shows that $a_k(t) = b_k(t) = 0$ and $u_{2m-k+1}(t) = v_{2m-k+1}(t) = 0$. The definition of u_{2m-k+1} and v_{2m-k+1} then shows

$$\begin{aligned} a_{2m-k+1}(\cos\theta)\cos\alpha\pi + b_{2m-k+1}(\cos\theta)\sin\alpha\pi &= 0, \\ a_{2m-k+1}(\cos\theta)\sin\alpha\pi - b_{2m-k+1}(\cos\theta)\cos\alpha\pi &= 0, \end{aligned}$$

which implies that $a_{2m-k+1}(t) = b_{2m-k+1}(t) = 0$.

Together these two cases show that we have the following factorization:

$$\begin{aligned}\widetilde{T}(\theta,\phi) &= \prod_{j=0}^{2\lambda}(\cos\theta - \cos\theta_j) \\ &\quad \times \left(a_0^*(\cos\theta) + \sum_{j=1}^{2m-s} \left[a_k^*(\cos\theta)(\sin\theta)^k\cos k\phi + b_k^*(\cos\theta)(\sin\theta)^k \sin k\phi\right]\right),\end{aligned}$$

which completes the proof. □

The fact that the interpolation points are equidistant on the circle is essential in this theorem. One important property of the factorization is that it allows us to repeat the argument to get a complete factorization of the polynomial.

THEOREM 2.8. *Let n and σ be positive integers. Let $\lambda_1, \dots, \lambda_\sigma$ be nonnegative integers. Define $n_k = n_{k-1} - (2\lambda_k + 1)$ for $1 \le k \le \sigma$ with $n_0 = n$. Assume that $n_k \ge 0$ for $1 \le k \le \sigma - 1$. If $T \in \Pi_n(S^2)$ satisfies*

$$\widetilde{T}(\theta_{j,k}, \phi_{i,k}) = 0, \quad 0 \le j \le 2\lambda_k,\ 0 \le i \le 2(n_{k-1} - \lambda_k),\ 1 \le k \le \sigma,$$

where $\theta_{j,k}$, $0 \le j \le 2\lambda_k$ and $1 \le k \le \sigma$, are distinct numbers in $(0, \pi)$ and $\phi_{i,k} \in \Theta_{\alpha_k, n_{k-1}-\lambda_k}$ with $\alpha_k \in [0, 2)$, then there exists a polynomial $T^* \in \Pi_{n_\sigma}(S^2)$ such that

$$T(x, y, z) = \prod_{k=1}^{\sigma} \prod_{j=0}^{2\lambda_k} (z - \cos\theta_{j,k}) T^*(x, y, z).$$

In particular, $T(x, y, z) \equiv 0$ if $n_\sigma < 0$.

Proof. We apply the factorization in the theorem repeatedly with $s = n_{k-1}$, $m = n_{k-1} - \lambda_k$, and $\lambda = \lambda_k$ for $k = 1, 2, \dots, \sigma$. □

We note that the interpolation points in the corollary are located on σ groups of latitudes $\{S^2(z_{j,k}) : 0 \le j \le 2\lambda_k\}$, $1 \le k \le \sigma$ and $z_{j,k} = \cos\theta_{j,k}$, and latitudes in different groups contain different number of nodes. More precisely, each of the latitudes in the kth group, $S^2(z_{0,k}), S^2(z_{1,k}), \dots, S^2(z_{2\lambda_k,k})$, contains $2(n_{k-1} - \lambda_k) + 1$ equidistant points.

3. Interpolation on the unit sphere. Our main result on interpolation follows from the result on factorization. The following formula is used to show that the interpolation condition matches the dimension of the polynomial space:

$$\dim \Pi_s(S^2) = \dim \Pi_{s-2\lambda-1}(S^2) + (2\lambda + 1)(2s - 2\lambda + 1). \tag{3.1}$$

THEOREM 3.1. *Let n and σ be positive integers such that $n + 1 - \sigma$ is an even integer and $\sigma \le n + 1$. Let $\lambda_1, \dots, \lambda_\sigma$ be nonnegative integers such that*

$$\lambda_1 + \cdots + \lambda_\sigma = \frac{n + 1 - \sigma}{2}. \tag{3.2}$$

Define $n_k = n_{k-1} - (2\lambda_k + 1)$ for $1 \le k \le \sigma - 1$ with $n_0 = n$. Let

$$\widetilde{X} = \{(\theta_{j,k}, \phi_{i,k}) : 0 \le j \le 2\lambda_k,\ 0 \le i \le 2(n_{k-1} - \lambda_k),\ 1 \le k \le \sigma\},$$

where $\theta_{j,k}$, $0 \le j \le 2\lambda_k$ and $1 \le k \le \sigma$, are distinct numbers in $(0, \pi)$ and $\phi_{i,k} \in \Theta_{\alpha_k, n_{k-1}-\lambda_k}$ with $\alpha_k \in [0, 2)$. Then the set X solves Problem 1 in $\Pi_n(S^2)$.

Proof. Again it is sufficient to prove that the dimension of $\Pi_n(S^2)$ matches the interpolation conditions, and if $T \in \Pi_n(S^2)$ vanishes on X, then $T(x, y, z) \equiv 0$. Under the condition (3.2), it follows that

$$n_\sigma := n_{\sigma-1} - (2\lambda_\sigma + 1) = n - (2\lambda_1 + 1) - \cdots - (2\lambda_\sigma + 1) = -1 < 0.$$

Hence, the factorization theorem in Theorem 2.8 shows that $T(x, y, z) \equiv 0$. Moreover, it follows from (3.1) that

$$\dim \Pi_n(S^2) = (n + 1)^2 = \sum_{k=1}^{\sigma} (2\lambda_k + 1)(2n_{k-1} - 2\lambda_k + 1)$$

so that the interpolation condition matches the dimension of $\Pi_n(S^2)$. □

For a fixed n this theorem contains a number of different interpolation processes. In fact, for each positive integer n, the number of sets X contained in Theorem 3.1 depends on the number of nonnegative integer solutions of (3.2), where σ is also a variable which satisfies the condition that $n+1-\sigma$ is a nonnegative even integer. Every such solution of (3.2) leads to a set of interpolation points that solves Problem 1. The number of solutions of such an equation grows exponentially as n goes to infinity. Moreover, the order of $\lambda_1, \ldots, \lambda_\sigma$ matters; that is, different permutations of a solution $\lambda_1, \ldots, \lambda_\sigma$ of (3.2) give different sets of interpolation points.

Among the solutions of (3.2), one extreme case is $\sigma = n+1$, for which the equation has only one solution, $\lambda_1 = \cdots = \lambda_{n+1} = 0$. In this case, $n_k = n-k$, and the interpolation points are located on $n+1$ latitudes $S^2(z_0)$, $S^2(z_1), \ldots, S^2(z_n)$ and the latitude $S^2(z_k)$ contains $2k+1$ points. Hence, this is just a special case of Proposition 2.1.

The other extreme case is $\sigma = 1$. In this case, n needs to be even to keep $n+1-\sigma$ even. Assume $n = 2m$. There is only one solution of the equation, which is $\lambda_1 = (n-\sigma+1)/2 = m$. We state this case as a corollary.

Corollary 3.2. *Let m be a positive integer. Let $\theta_0, \theta_1, \ldots, \theta_{2m}$ be $2m+1$ distinct numbers in $(0,\pi)$. Let X be defined by*

$$\widetilde{X} = \{(\theta_i, \phi_i) : 0 \le j \le 2m,\ 0 \le i \le 2m\},$$

where $\phi_i \in \Theta_{\alpha,m}$ with $\alpha \in [0, 2\pi)$. Then X solves Problem 1 in $\Pi_{2m}(S^2)$.

In this case, the interpolation points are located on $2m+1$ latitudes $S^2(z_i)$ with $z_i = \cos\theta_i$; each latitude has $2m+1$ equidistant points. In the special case that $\{\theta_0, \ldots, \theta_{2m}\}$ are symmetric (that is, $\theta_{2m-i} = \pi - \theta_i$), the corollary has been established in [15] using the fact that the uniqueness of the interpolation on S^2 of the symmetric set can be related to the interpolation on the unit disc B^2 of $\mathbb{R}^2$, which allows us to use the result in [1] for interpolation on B^2. The first nontrivial case of this corollary is $m = 1$, for which there are 3 latitudes, each with 3 points.

To illustrate the main result, we list all sets of interpolation points contained in Theorem 3.1 for small n. For $n = 1$, there is only one set, for which points are located on 2 latitudes with 3 points and 1 point, respectively, which is a special case of Proposition 2.1. The case $n = 2$ contains two cases, $\sigma = 1$ and $\sigma = 3$; the case $\sigma = 1$ is a special case of Corollary 3.2 with 3 latitudes and each with 3 points; the case $\sigma = 3$ is a special case of Proposition 2.1 of 3 latitudes with 5, 3, and 1 points, respectively. In general, for each σ there can be multiple solutions of (3.2) and the order matters. The cases of $n = 3$ and $n = 4$ are given below.

Example 3.3. $n = 3$. *That $n+1-\sigma$ is even implies that σ can be either 2 or 4. The set X contains 16 points.*

1. $\sigma = 2$: $\lambda_1 + \lambda_2 = 1$ *has two solutions (order matters).*
   (a) $\lambda_1 = 1, \lambda_2 = 0$: 3 *latitudes each with* 5 *points and* 1 *latitude with* 1 *point;*
   (b) $\lambda_1 = 0, \lambda_2 = 1$: 1 *latitude with* 7 *points and* 3 *latitudes each with* 3 *points.*
2. $\sigma = 4$: $\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 = 0$ *has only one solution, $\lambda_i = 0$. This is the special case of Proposition* 2.1 *of* 4 *latitudes with* 7, 5, 3, *and* 1 *points, respectively.*

Example 3.4. $n = 4$. *That $n+1-\sigma$ is even implies that σ can be either* 1, 3, *or* 5. *Here X contains* 25 *points.*

1. $\sigma = 1$: $\lambda_1 = 5$ *is a special case of Corollary* 3.2; 5 *latitudes each with* 5 *points.*
2. $\sigma = 3$: $\lambda_1 + \lambda_2 + \lambda_3 = 1$ *has three solutions.*

(a) $\lambda_1 = 1, \lambda_2 = 0, \lambda_3 = 0$: 3 *latitudes each with* 7 *points,* 1 *latitude with* 3 *points, and* 1 *latitude with* 1 *point;*
(b) $\lambda_1 = 0, \lambda_2 = 1, \lambda_3 = 0$: 1 *latitude with* 9 *points,* 3 *latitudes each with* 5 *points, and* 1 *latitude with* 1 *point;*
(c) $\lambda_1 = 0, \lambda_2 = 0, \lambda_3 = 1$: 1 *latitude with* 9 *points,* 1 *latitude with* 7 *points, and* 3 *latitudes each with* 3 *points;*

3. $\sigma = 5$: $\lambda_1 + \lambda_2 + \lambda_3 + \lambda_4 + \lambda_5 = 0$ *has only one solution,* $\lambda_i = 0$. *This is the special case of Proposition* 2.1 *of* 5 *latitudes with* 9, 7, 5, 3, *and* 1 *points, respectively.*

Thus, for $n = 3$, Theorem 3.1 contains 3 sets of 16 points that solve Problem 1, and for $n = 4$ it contains 5 sets of 25 points. In the next two cases, $n = 5$ gives 8 sets of 36 points and $n = 6$ gives 13 sets of 49 points. In general, the number of different sets for each degree is a Fibonacci sequence. (I thank a referee for pointing out this fact.)

PROPOSITION 3.5. *Let* γ_n *denote the number of different sets in Theorem* 3.1 *that solves Problem* 1 *in* $\Pi_n(S^2)$. *Then* $\{\gamma_n\}$ *is a Fibonacci sequence:* $\lambda_n = \lambda_{n-1} + \lambda_{n-2}$, $\lambda_1 = 1$, *and* $\lambda_2 = 2$.

Proof. Denote by Ω_n the set of solutions of the equation $\lambda_1 + \cdots + \lambda_\sigma = (n + 1 - \sigma)/2$, where $\lambda_i \in \mathbb{N}_0$, $\sigma \in \mathbb{N}_0$ and $n + 1 - \sigma$ is even. Let $(\lambda_1, \ldots, \lambda_\sigma) \in \Omega_n$. If $\lambda_\sigma = 0$, then $\lambda_1 + \cdots + \lambda_{\sigma-1} = (n - 1 + 1 - (\sigma - 1))/2$ so that $(\lambda_1, \ldots, \lambda_{\sigma-1}) \in \Omega_{n-1}$, and this defines a one-to-one mapping from Ω_n to Ω_{n-1}. If $\lambda_\sigma > 0$, then $\lambda_1 + \cdots + \lambda_{\sigma-1} + (\lambda_\sigma - 1) = (n - 2 + 1 - \sigma)/2$ so that $(\lambda_1, \ldots, \lambda_{\sigma-1}, \lambda_\sigma - 1) \in \Omega_{n-2}$. Again this defines a one-to-one mapping from Ω_n to Ω_{n-2}. Since $\gamma_n = \#\Omega_n$, this shows that $\lambda_n = \lambda_{n-1} + \lambda_{n-2}$. □

Let us consider the interpolation process in Corollary 3.2 again. In this case, the interpolation points are on $2m + 1$ latitudes and each latitude has $2m + 1$ points. This seems to indicate that the interpolation polynomial should be a product type, that is, a product of two interpolation polynomials of one variable. However, since polynomials in $\Pi_n^2(S^2)$ have to have the form of (2.1), this is not the case. To find the formula for the interpolation polynomials, we need to find a formula for interpolation using the Chebyshev system in Corollary 2.6.

If we integrate an interpolation polynomial in Theorem 3.1 over the sphere, we get a cubature formula that is exact for polynomials of degree n; that is, the cubature formula is of degree n. In the case where points are those in Corollary 3.2, the formula takes a particularly simple form and can be explicitly given.

PROPOSITION 3.6. *Let* m *be a positive integer. Let* $\theta_0, \ldots, \theta_{2m}$ *be distinct numbers in* $(0, \pi)$, *and let* α *be a number in* $[0, 2)$. *Then for all* $f \in \Pi_{2m}(S^2)$,

$$\int_{S^2} f(x, y, z) d\omega = \sum_{j=0}^{2m} \frac{\lambda_j}{2m + 1} \sum_{i=0}^{2m} \widetilde{f}(\theta_j, \phi_i), \qquad \phi_i = \frac{(2i + \alpha)\pi}{2m + 1},$$

where λ_j *are given by*

$$\lambda_j = \int_{-1}^{1} \prod_{i=0, i \neq j}^{2m} \frac{t - \cos\theta_i}{\cos\theta_j - \cos\theta_i} dt.$$

Proof. Let the interpolation polynomial T_{2m} be of the form (2.1). We use the quadrature formula

$$\frac{1}{2\pi}\int_0^{2\pi}\tau(t)dt=\frac{1}{2m+1}\sum_{j=0}^{2m}\tau(\theta_j^\alpha),\qquad \theta_j^\alpha=\frac{(2j+\alpha)\pi}{2m+1}, \tag{3.3}$$

which is known to hold for every trigonometric polynomial of degree $2m$. For $\alpha=0$ this is the classical result in [16, Vol. 2, p. 8], and for $\alpha\neq 0$ it follows from

$$\int_0^{2\pi}\tau(\theta+t)dt=\int_0^{2\pi}\tau(t)dt,$$

which holds for every θ and for every trigonometric polynomial τ. Using the formula (3.3) and the interpolation property of T_{2m}, it follows that

$$a_0(\cos\theta_j)=\frac{1}{2\pi}\int_0^{2\pi}\widetilde{T}_{2m}(\theta_j,\phi)d\phi=\frac{1}{2m+1}\sum_{i=0}^{2m}\widetilde{f}(\theta_j,\phi_i),\qquad \phi_i=\frac{(2i+\alpha)\pi}{2m+1},$$

for every θ_j, $0\le j\le 2m$. Consequently, a_0 is uniquely determined by these interpolation conditions. It follows that

$$a_0(t)=\sum_{j=0}^{2m}\left(\frac{1}{2m+1}\sum_{i=0}^{2m}\widetilde{f}(\theta_j,\phi_i)\right)\ell_j(t),\qquad \ell_j(t)=\prod_{i=0,i\neq j}^{2m}\frac{t-\cos\theta_i}{\cos\theta_j-\cos\theta_i}.$$

Using the change of variable formula

$$\int_{S^2}f(x,y,z)d\omega=\int_0^\pi\int_0^{2\pi}\widetilde{f}(\theta,\phi)\sin\theta d\theta d\phi,$$

the integral of T_{2m} over the surface of the sphere is equal to

$$\int_{S^2}T_{2m}(x,y,z)d\omega=2\pi\int_0^\pi a_0(\cos\theta)\sin\theta d\theta=2\pi\int_{-1}^1 a_0(t)dt.$$

The stated formula follows from the formula of $a_0(t)$ derived above. □

In particular, if $\cos\theta_j$ are chosen so that λ_j are nonnegative, then the formula is a nonnegative cubature formula. For example, this holds if $\cos\theta_j$ are the zeros of the Legendre polynomial P_{2m+1} of degree $2m+1$ or the zeros of quasi-Legendre orthogonal polynomial $P_{2m+1}+\alpha P_{2m}$ with mild conditions imposed on $\alpha\in\mathbb{R}$. The nodes of such a formula are located on circles, just as the usual product-type formula. However, these cubature formulae are different from the usual product formulae. As it is well-known [13] that the usual way of deriving the product formula is to treat it as the product of Gaussian quadrature for trigonometric polynomials and the Gaussian quadrature formula for the unit weight on $[-1,1]$, the result works for all linear combinations of $\cos j\theta(a_k\cos k\phi+b_k\sin k\phi)$ of degree $2m+1$, which contains the spherical polynomials of degree $2m+1$ as a subset. In our case, the cubature formula is derived by interpolation, and it holds for spherical polynomials of degree up to $2m$, which are trigonometric polynomials that are of the special form (2.1). Our formula uses twice as many nodes as the usual product formula, but we still have the freedom of choosing the latitudes (that is, θ_j) on which the interpolation points lie and, in the case of several groups of latitudes, the rotations (that is, α_k) of points on the latitudes for different groups. A proper choice of θ_j and α_k may lead to some cubature formula of higher degree. Furthermore, every set of interpolation points in Theorem 3.1 leads to a cubature formula of degree n, and one can ask the question of how to find a cubature formula of the highest degree by choosing proper θ_j and α_k.

4. Trigonometric interpolation. In order to construct a formula for the interpolation polynomial in Theorem 3.1, we need to understand the interpolation by trigonometric polynomials in Corollary 2.6. It turns out that this interpolation is closely related to a nontrivial Hermite–Birkhoff interpolation problem by trigonometric polynomials, which we discuss in this section.

Let $\mathcal{T}_n$ denote the space of trigonometric polynomials of degree n,

$$\mathcal{T}_n = \operatorname{span}\left\{ a_0 + \sum_{k=1}^{n} (a_k \cos\theta + b_k \sin\theta) : a_k, b_k \in \mathbb{R} \right\}.$$

A Birkhoff interpolation problem is usually described using the notion of *incidence matrices*, which are matrices whose entries are 0 and 1. Let $E = (e_{l,j})$ be such a matrix with s rows $l = 1, 2, \ldots, s$ and n columns with $j = 0, 1, \ldots, n-1$. Then

$$T^{(j)}(t_l) = f_{l,j} \qquad \text{if} \quad e_{l,j} = 1, \quad T \in \mathcal{T}_n,$$

describes an interpolation process on the points $t_1, \ldots, t_s$. An incidence matrix E of $s \times n$ is said to satisfy the Pólya condition if

$$\sum_{k=1}^{j} \sum_{l=1}^{s} e_{l,k} \geq j+1, \qquad j = 0, 1, \ldots, n.$$

A sequence in an incidence matrix is a sequence of consecutive 1's in a row of E, say the lth row with $e_{l,k} = 1$ for $k = i+1, \ldots, i+j$, $e_{l,i} = 0$, and $e_{l,i+j+1} = 0$, and it is an odd sequence if j is odd. A supported sequence is a sequence such that there are nonzero elements of E in both its upper and lower left sides; that is, there are $e_{i_1,j_1} = 1$ and $e_{i_2,j_2} = 1$ with $i_1 < l$, $i_2 > l$, $j_1 \leq i$, and $j_2 \leq i$. For example, the matrix

$$E = \begin{bmatrix} 1 & 0 & 1 & 1 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 1 \\ 1 & 0 & 0 & 1 & 1 & 0 \end{bmatrix}$$

has, in its second row, two supported odd sequences of length 3 and 1, respectively. Since the trigonometric polynomials are periodic, the interpolation matrix should be considered periodic: Its last row should precede the first row; that is, the points in Θ are considered to be circular in the sense that the last point θ_s is in front of the first point θ_1. For example, if the matrix E in the above example is an incidence matrix for trigonometric interpolation, then its first row contains an odd supported sequence. Thus, for the interpolation by trigonometric polynomials, the supported sequence is a sequence that does not start from the first row, assuming that the matrix satisfies the Pólya condition. Although taking derivatives does not reduce the degree of a trigonometric polynomial, the analogue of the Atkinson–Sharma theorem ([8] or [9, p. 23]) still holds, giving the above understanding of the support sequence. The theorem states that a Birkhoff interpolation is poised if all its odd supported sequences begin in column 0 and E satisfies the Pólya condition.

We consider the following Hermite–Birkhoff interpolation problem.

Problem 2. Let m be a positive integer. Let $\Theta = \{\theta_i : 1 \leq i \leq 2m+1\}$ be a set of distinct points in $(0, \pi)$. Let k be an integer such that $1 \leq k \leq 2m$. Find conditions on Θ such that the interpolation problem

$$\begin{aligned} &T(\theta_i) = f_i, \qquad i = 1, 2, \dots 2m+1, \\ &T^{(j)}(0) = g_{0,j}, \quad T^{(j)}(\pi) = g_{\pi,j}, \quad j = 0, 1, \dots, k-2, k-1 \quad \text{and} \\ &\qquad\qquad\qquad\qquad\qquad\qquad j = k+1, k+3, \dots, 2m-k-1, \end{aligned}$$

has a unique solution in $\mathcal{T}_{2m}$ for any data f_i, $g_{0,j}$, and $g_{\pi,j}$.

Let Θ be the set as above. Assume that $0 < \theta_1 < \theta_2 < \cdots < \theta_{2m+1} < \pi$, and define $\theta_0 = 0$ and $\theta_{2m+2} = \pi$. Then the above problem is described by the incidence matrix E with $2m+3$ rows, whose elements $e_{l,j}$ are defined by

$$e_{0,j} = e_{2m+2,j} = 1, \qquad 0 \le j \le k-1 \ \text{ and } \ j = k+1, k+3, \dots, 2m-k-1,$$

and $e_{l,0} = 1$ for $l = 1, 2, \dots, 2m+1$; all other $e_{l,j}$ are 0. By the definition, there are exactly $2(2m)+1$ interpolation conditions, which is the same as the dimension of $\mathcal{T}_{2m}$. Clearly, the matrix E for this interpolation satisfies the Pólya condition. This matrix, however, has many odd supported sequences that do not begin in column 0; the analogue of the Atkinson–Sharma theorem does not apply. It turns out that Corollary 2.5 can be used to show that it is poised if Θ is a subset of $(0, \pi)$. The key ingredient is the following lemma.

LEMMA 4.1. *Let m be a positive integer. The trigonometric polynomial $T \in \mathcal{T}_{2m}$ satisfies the conditions*

$$\begin{aligned} T^{(j)}(0) = T^{(j)}(\pi) = 0, \quad & j = 0, 1, \dots, k-2, k-1 \quad \textit{and} \\ & j = k+1, k+3, \dots, 2m-k-1, \end{aligned}$$

for a fixed integer k, $0 \le k \le 2m$, if and only if T takes the form

$$T(\theta) = (\sin\theta)^k p(\cos\theta) + (\sin\theta)^{2m-k+1} q(\cos\theta), \tag{4.1}$$

where p is a polynomial of degree $2m-k$ and q is a polynomial of $k-1$.

Proof. First assume that T is of the special form (4.1). Let $T_1(\theta) = (\sin\theta)^k p(\cos\theta)$ and $T_2(\theta) = (\sin\theta)^{2m-k+1} q(\cos\theta)$. Since T_1 is an odd function if k is odd and an even function if k is even, and an odd trigonometric polynomial vanishes at 0 and π, it follows from taking derivatives that

$$T_1^{(j)}(0) = T_1^{(j)}(\pi) = 0, \quad 0 \le j \le k-1 \ \text{ and } \ j = k+1, k+3, k+5, \dots .$$

Similarly, since T_2 is odd if k is odd and even if k is even, it follows that

$$T_2^{(j)}(0) = T_2^{(j)}(\pi) = 0, \quad 0 \le j \le 2m-k \ \text{ and } \ j = 2m-k+2, 2m-k+4, \dots .$$

Since $T = T_1 + T_2$ and $0 \le k \le m$, the stated result follows from the above two displayed equations.

On the other hand, the conditions $T^{(j)}(0) = T^{(j)}(\pi) = 0$ for $0 \le j \le k-1$ imply that

$$T(\theta) = (\sin\theta)^k S(\theta), \qquad S \in T_{2m-k}.$$

This can be considered as a simple consequence of the fact that the Hermite interpolation problem is unique for the trigonometric interpolation (consider the Hermite interpolation conditions on 0 and π, together with Lagrange interpolation on $2(2m-k)+1$

distinct points). Applying the Leibniz rule to T implies that

$$T^{(k+2l-1)}(\theta) = \sum_{j=0}^{k+2l-1} \binom{k+2l-1}{j} S^{(j)}(\theta) \frac{d^{k+2l-1-j}}{d\theta^{k+2l-1-j}} (\sin\theta)^k.$$

Since $(d^{k+2l-1-j}/d\theta^{k+2l-1-j})(\sin\theta)^k$ is even if j is odd and odd if j is even, it follows that these terms are nonzero at $\theta = 0$ or $\theta = \pi$ only if $j = 1, 3, 5, \ldots, 2l-1$, where $l = 1, 2, 3, \ldots, m-k$. Consequently, using induction on l shows that the conditions $T^{(j)}(0) = T^{(j)}(\pi) = 0$ for $j = k+1, k+3, \ldots, 2m-k-1$ are equivalent to the following conditions on S:

$$S^{(2l-1)}(0) = S^{(2l-1)}(\pi) = 0, \qquad l = 1, 2, 3, \ldots, m-k. \tag{4.2}$$

Since $S \in T_{2m-k}$, we can write $S(\theta) = a_0 + \sum_{j=1}^{2m-k}(a_j \cos j\theta + b_j \sin j\theta)$. Because the conditions (4.2) involve only odd derivatives, it applies only to the odd part of S. Hence, we need only to show that if $S_o(\theta) := \sum_{j=1}^{2m-k} b_j \sin j\theta$ satisfies (4.2), then $S_o(\theta) = (\sin\theta)^{2m-2k+1} q(\cos\theta)$. Since S_o automatically satisfies $S_o^{(2j)}(0) = S_o^{(2j)}(\pi) = 0$ for all j, it follows that it satisfies the Hermite interpolation conditions $S_o^{(j)}(0) = S_o^{(j)}(\pi) = 0$ for $0 \le j \le 2m-2k$. Consequently, it follows that $S_o(\theta) = (\sin\theta)^{2m-2k} R(\theta)$, $R \in \mathcal{T}_{k+2m}$. However, S_o is odd, so it must be R. Consequently, we can write $R(\theta) = \sin\theta q(\cos\theta)$ so that $S(\theta) = p(\cos\theta) + (\sin\theta)^{m-2k+1} q(\theta)$, which completes the proof. □

THEOREM 4.2. *Let m be a positive integer. Let $\theta_1 < \theta_2 < \cdots < \theta_{2m+1}$ be a set of distinct points in $(0, \pi)$. Then Problem 2 has a unique solution in $\mathcal{T}_{2m}$.*

Proof. Let T be a polynomial that satisfies $T^{(j)}(x_i) = 0$ for $e_{i,j} = 1$. The above lemma shows that T is of the form (4.2), and the problem reduces to showing that if

$$T(\theta) = (\sin\theta)^k p(\cos\theta) + (\sin\theta)^{2m-k+1} q(\cos\theta)$$

vanishes on $\theta_1, \ldots, \theta_{2m+1}$, then $T(\theta) \equiv 0$. This, however, is a consequence of Corollary 2.6. □

Acknowledgment. The author thanks the referees for their careful review and valuable comments.

SEMICIRCULANT PRECONDITIONING OF ELLIPTIC OPERATORS*

SANG DONG KIM† AND SEYMOUR V. PARTER‡

Abstract. In this work we consider the semicirculant preconditioning of elliptic differential operators of the form

$$Lu := -\epsilon \Delta u + a u_x + b u_y + c u$$

in two cases: $0 < \epsilon \ll 1$ and $\epsilon \equiv 1$. The paper [*Numer. Math.*, 81 (1998), pp. 211–249] provided extremely interesting and useful results in the first case. On the other hand, those appear to contradict basic results on preconditioning given in [*SIAM J. Numer. Anal.*, 27 (1990), pp. 656–694]. We reobtain the results of [*Numer. Math.*, 81 (1998), pp. 211–249] by a new approach which we believe to be more transparent. We also clarify the situation regarding the apparent contradiction with [*SIAM J. Numer. Anal.*, 27 (1990), pp. 656–694]. Finally, we describe the distribution of the preconditioned eigenvalues in the uniformly elliptic case, $\epsilon \equiv 1$.

Key words. preconditioning, difference equations, limiting operator, convection-diffusion equation

1. Introduction.

This work was motivated by the paper [LH], which discussed the semicirculant preconditioning of two-dimensional convection diffusion equations. The results on the distribution of the eigenvalues of the preconditioned system are extremely interesting. On the other hand, these results seemed to contradict a fundamental principle enunciated in [MP]. The basic results of [MP] imply that if one preconditions a discrete elliptic operator L_h with Dirichlet boundary conditions by another discrete elliptic operator B_h and one has results such as those of [LH], then B_h must also impose Dirichlet boundary conditions. However, it would appear that the semicirculant preconditioner has some Dirichlet boundary conditions and some periodic boundary conditions. Finally, since part of the attraction of the semicirculant preconditioner is the fact that this preconditioner is easily inverted, one is led to a study of semicirculant preconditioners for the uniformly elliptic case.

In this paper we clarify the apparent contradiction between the results of [LH] and [MP]. Simply put, the limiting operator of the difference schemes is *not* elliptic. It is the limiting hyperbolic operator when ϵ, the singular perturbation parameter, goes to zero. Since the solution of the elliptic convection-diffusion equation converges to the solution of this hyperbolic equation, the method and the preconditioning approach are reasonable. Of course, there is a boundary layer in both the solution of the differential equation and the solution of the difference equation. This method does not capture the correct boundary layer. However, that is a small point.

While this clarification is both scientifically important and satisfying, it is not the main thrust of our work. Our major effort is directed at the development and exposition of a method for studying these problems which we believe is both more transparent and elementary. Using this approach we both reobtain the results of [LH] and describe the distribution of the eigenvalues of the semicirculant preconditioned system in the uniformly elliptic case. As we might expect from the results of [CC] for the full circulant preconditioner, roughly $(\frac{1}{h})$ of these eigenvalues grow like $O(\frac{1}{h})$. Still, as we shall see, for many of those eigenvalues the coefficients of the growth are quite small. Thus, given the ease of inverting the preconditioner semicirculant, preconditioning may be a useful approach for some problems. While this work focuses on the distributions of the eigenvalues, we are well aware that in these nonsymmetric problems eigenvalues do not tell the whole story as compared with the effectiveness of the preconditioning strategy; see [G].

Let $f \in C(\overline{\Omega})$, and consider the equations

$$Lu = -\epsilon\Delta u + au_x + bu_y + du = f \quad \text{in} \quad \Omega, \tag{1.1}$$

$$u = 0 \quad \text{on} \quad \partial\Omega. \tag{1.2}$$

Here Ω is the unit square $[0,1] \times [0,1]$ and the coefficients a, b, d, and ϵ are constant. Moreover,

$$d \geq 0, \quad \epsilon > 0. \tag{1.3}$$

Let m_1, m_2 be positive integers, and set

$$h_1 = \frac{1}{m_1+1}, \quad h_2 = \frac{1}{m_2+1}, \quad \varphi = \frac{h_2}{h_1}. \tag{1.4}$$

The usual centered second order finite-difference scheme which approximates (1.1) is given by

$$\begin{aligned} -\frac{\epsilon}{h_2^2}\{\, & Cu_{k-1,j} + Au_{k,j} + Bu_{k+1,j} + \gamma u_{k,j-1} \\ & +\alpha u_{k,j} + \beta u_{k,j+1}\,\} = f_{k,j}, \quad 1 \leq k \leq m_1,\ 1 \leq j \leq m_2, \end{aligned} \tag{1.5}$$

where

$$A = -2\varphi^2, \tag{1.6}$$

$$B = \varphi^2\left(1 - \frac{ah_1}{2\epsilon}\right), \quad C = \varphi^2\left(1 + \frac{ah_1}{2\epsilon}\right), \tag{1.7}$$

$$\alpha = -2 - \frac{dh_2^2}{\epsilon}, \tag{1.8}$$

$$\beta = 1 - \frac{bh_2}{2\epsilon}, \quad \gamma = 1 + \frac{bh_2}{2\epsilon}. \tag{1.9}$$

Here $u_{k,j}$ is the value of the approximant at the point (x_k, y_j) and

$$f_{k,j} = f(x_k, y_j). \tag{1.10}$$

Throughout this paper we assume the mesh Peclet number condition

$$\left|\frac{bh_2}{2\epsilon}\right| < 1, \quad \left|\frac{ah_1}{2\epsilon}\right| < 1. \tag{1.11}$$

The difference operator L_h on the left-hand side of (1.5) is easily described as

$$L_h := -\frac{\epsilon}{h_2^2}\{T_2 \otimes I_{m_1} + I_{m_2} \otimes T_1\}, \tag{1.12}$$

where I_{m_k} are the appropriate identity matrices, and T_1 and T_2 are tridiagonal matrices of order m_1 and m_2, respectively. In particular,

$$T_1 = \begin{bmatrix} A & B & & & \\ C & A & B & & \\ & \ddots & \ddots & \ddots & \\ & & & & B \\ & & & C & A \end{bmatrix} \tag{1.13}$$

and

$$T_2 = \begin{bmatrix} \alpha & \beta & & & \\ \gamma & \alpha & \beta & & \\ & \ddots & \ddots & \ddots & \\ & & & & \beta \\ & & & \gamma & \alpha \end{bmatrix}. \tag{1.14}$$

The semicircular preconditioner is given by

$$S := -\frac{\epsilon}{h_2^2}\{\overline{C} \otimes I_{m_1} + I_{m_2} \otimes T_1\}, \tag{1.15}$$

where $\overline{C}$ is the circulant

$$\overline{C} = \begin{bmatrix} \alpha & \beta & & & \gamma \\ \gamma & \alpha & \beta & & \\ & \ddots & \ddots & \ddots & \\ & & & & \beta \\ \beta & & & \gamma & \alpha \end{bmatrix} = T_2 + \begin{bmatrix} 0 & \cdots & 0 & \gamma \\ 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \cdots & 0 \\ \beta & 0 & \cdots & 0 \end{bmatrix}. \tag{1.16}$$

Our basic problem is the study of the eigenvalues λ which satisfy

$$\lambda S U = (S - Q \otimes I_{m_1})U, \tag{1.17}$$

where

$$Q := -\frac{\epsilon}{h_2^2}\begin{bmatrix} 0 & \cdots & 0 & \gamma \\ 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \cdots & 0 \\ \beta & 0 & \cdots & 0 \end{bmatrix}. \tag{1.18}$$

The reader familiar with [LH] will realize that we interchanged the roles of x and y. That small change leads to this form of the error term Q, which appears to be simpler than the corresponding term in [LH].

Of course, we can ignore the $(-\epsilon/h_2^2)$ term and deal with the eigenvalue problem

$$\lambda S_0 U = (S_0 - Q_0 \otimes I_{m_1})U, \tag{1.19}$$

where

$$S_0 = \{\overline{C} \otimes I_{m_1} + I_{m_2} \otimes T_1\} \tag{1.20}$$

and

$$Q_0 = \begin{bmatrix} 0 & \cdots & 0 & \gamma \\ 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \cdots & 0 \\ \beta & 0 & \cdots & 0 \end{bmatrix}. \tag{1.21}$$

Since Q_0 is of rank 2, it is clear that there will be $m_1m_2 - 2m_1$ eigenvalues λ which are exactly equal to one. We then focus on the remaining $2m_1$ eigenvalues.

In our approach we reduce the problem to m_1 problems of the form

$$\lambda C_0 u = T_0 u, \tag{1.22}$$

where T_0 is a particular $m_2 \times m_2$ tridiagonal matrix and C_0 is a related $m_2 \times m_2$ circulant. This is done as follows. We rewrite (1.17) as

$$\lambda\{\overline{C} \otimes I_{m_1} + I_{m_2} \otimes T_1\}U = \{T_2 \otimes I_{m_1} + I_{m_2} \otimes T_1\}U. \tag{1.23}$$

Assume that (τ, F) is an eigenpair for T_1. That is,

$$T_1 F = \tau F. \tag{1.24}$$

We seek an eigenvector of (1.23) in the form $u \otimes F$. We obtain

$$\lambda[(\overline{C} + \tau I_{m_2})u \otimes F] = (T_2 + \tau I_{m_2})u \otimes F. \tag{1.25}$$

Thus, we set

$$C_0 = \overline{C} + \tau I_{m_2},$$
$$T_0 = T_2 + \tau I_{m_2}.$$

Since T_1 has m_1 distinct eigenvalues, and hence m_1 linearly independent eigenvectors, we have indeed found m_1 such simpler (one-dimensional) problems.

In dealing with these problems we consider two distinct cases.

Case 1. $0 < E \ll 1$. This is the case considered in [LH]. In this work, as in [LH], we assume

$$\frac{h_s}{\epsilon} = G_s, \quad \text{a constant}, \quad s = 1, 2. \tag{1.26}$$

In this case the eigenvalues of (1.23) fall into three groups. There are exactly $m_1 m_2 - 2m_1$ eigenvalues equal to one. And, as $h_1, h_2 \to 0$, m_1 of the remaining eigenvalues cluster about an interval (a_1, b_1) with

$$\frac{1}{2} \leq a_1 < b_1 < 1$$

while the other m_1 eigenvalues cluster about a finite interval (c_1, d_1) with

$$1 < c_1 < d_1 < \infty.$$

These are exactly the results of [LH].

In this case the difference approximation is a poor approximation to the elliptic convection-diffusion equation [F], [WH]. On the other hand, if we imagine a sequence (or family) of computations in which (1.26) holds and $h_1 \to 0$, $h_2 \to 0$, the solutions of the difference equations converge—in every subdomain away from the edges which have the boundary layers—to an appropriate solution of the reduced hyperbolic equation

$$au_x + bu_z + du = f. \tag{1.27}$$

We will prove this in the appendix. However, it is important to point out that while that proof can be extended from the constant coefficient case to some problems with variable coefficients there are many important cases for which it cannot be extended. An example of such a case is the case of an interior "stagnation point," i.e., a point $(\overline{x}, \overline{y})$ at which

$$a(\overline{x}, \overline{y}) = b(\overline{x}, \overline{y}) = 0.$$

Case 2. $\epsilon = 1$. In this case we are dealing with a uniformly elliptic problem and simply let $h_1 \to 0$, $h_2 \to 0$.

In this case there are exactly $m_2 m_1 - 2m_1$ eigenvalues which are equal to one. There are m_1 eigenvalues in the interval $(.38, 1)$. We believe the correct interval is $(.5, 1)$, but we cannot prove this sharper result. There are m_1 eigenvalues greater than one. The larger of these grows like cm_2. However, many of the coefficients of growth are small. Indeed, $[m_1/2]$ of these eigenvalues are in the interval $[1, 1 + \frac{1+\sqrt{2}}{2\varphi^2}]$. These results are important for most regular problems. In addition, they are relevant for convection-diffusion equations where (1.26) does not hold. For example, the paper [LW] draws its inspiration and motivation from [LH]. However, we believe our results are equally relevant to those computations.

Analytically, the distinction between the two cases is that in Case 1 the limiting operator is *not* elliptic while in Case 2 the limiting operator is elliptic. Algebraically, the distinction concerns the eigenvalues τ. As we shall see in section 5, the eigenvalues in Case 1 satisfy

$$0 < 2\varphi^2(1 - \delta) \leq |\tau_j| \leq 2\varphi^2(1 + \delta),$$

where

$$\delta = \sqrt{1 - \left(\frac{aG_1}{2}\right)^2}.$$

On the other hand, in Case 2 the eigenvalues τ_j range from $O(h^2)$ to $O(1)$. It is the small eigenvalues τ_j which lead to the large eigenvalues λ.

In section 2 we develop the basic theory for finding the eigenvalues of $C_0^{-1}T_0$. In section 3 we use the elementary theory of one-dimensional difference equations to further extend the theory and obtain the required asymptotic estimates needed to deal with the reaction-diffusion equations. In section 4 we turn to an analysis of the problem in the case $\epsilon = 1$, i.e., the uniformly elliptic case. In section 5 we apply the results of sections 2, 3, and 4 to resolve the two-dimensional problems in both cases. In section 6 we discuss some computational results.

2. The basic theory.

In this section we turn to the study of (1.22) and develop the theory for finding the eigenvalues λ of the matrix $C_0^{-1}T_0$. With this in mind we replace α by

$$\hat{\alpha} = -2(1 + D_0). \tag{2.1}$$

We are interested in a wide range of values of D_0, not necessarily small. The matrix T_0 is the $m_2 \times m_2$ tridiagonal matrix given by

$$T_0 = \begin{bmatrix} \hat{\alpha} & \beta & & & \\ \gamma & \hat{\alpha} & \beta & & \\ & \ddots & \ddots & \ddots & \\ & & & & \beta \\ & & & \gamma & \hat{\alpha} \end{bmatrix} \tag{2.2}$$

and C_0 is the circulant

$$C_0 = T_0 + Q_0. \tag{2.3}$$

Thus, we are concerned with the eigenvalues λ of

$$\lambda C_0 U = TU = (C_0 - Q_0)U \tag{2.4}$$

or

$$\lambda U = (I - C_0^{-1} Q_0)U. \tag{2.5}$$

Therefore (m_2-2) eigenvalues are exactly one and there are two nontrivial eigenvalues which are of the form

$$\lambda = 1 - \rho, \tag{2.6}$$

where ρ is a nonzero eigenvalue of the problem

$$\rho C_0 U = Q_0 U. \tag{2.7}$$

We begin our discussion with the following problem: find two m_2 vectors v and w such that

$$C_0 v = \begin{bmatrix} \sigma \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{bmatrix}, \quad C_0 w = \begin{bmatrix} 0 \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ \sigma \end{bmatrix}, \tag{2.8}$$

where σ will be determined later.

LEMMA 2.1. *Consider the (m_2+1) vector $\hat{v}$ of the form*

$$\hat{v} = \begin{bmatrix} 1 \\ v_1 \\ v_2 \\ \cdot \\ \cdot \\ \cdot \\ v_{m_2-1} \\ 1 \end{bmatrix} = \begin{bmatrix} v_0 \\ v_1 \\ v_2 \\ \cdot \\ \cdot \\ \cdot \\ v_{m_2-1} \\ v_{m_2} \end{bmatrix} \tag{2.9}$$

which satisfies the (m_2-1) equations

$$\gamma v_{k-1} + \hat{\alpha} v_k + \beta v_{k+1} = 0, \quad k = 1, 2, \ldots, (m_2-1). \tag{2.10}$$

Let

$$v = \begin{bmatrix} 1 \\ v_1 \\ v_2 \\ \cdot \\ \cdot \\ \cdot \\ v_{m_2-1} \end{bmatrix}, \quad w = \begin{bmatrix} v_1 \\ v_2 \\ \cdot \\ \cdot \\ \cdot \\ v_{m_2-1} \\ 1 \end{bmatrix}. \tag{2.11}$$

Then

$$C_0 v = \begin{bmatrix} \sigma \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \end{bmatrix}, \quad C_0 w = \begin{bmatrix} 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \\ \sigma \end{bmatrix}, \tag{2.12}$$

where

$$\sigma = \hat{\alpha} + \beta v_1 + \gamma v_{m_2-1}. \tag{2.13}$$

Moreover,

$$0 < v_j \leq 1. \tag{2.14}$$

Proof. Direct verification yields (2.12) and (2.13). Since the Peclet condition (1.11) holds and β, γ are positive, the bound (2.14) follows from a standard maximum principle (convexity) argument. □

We seek an eigenvector U of (2.7) of the form

$$U = xv + yw. \tag{2.15}$$

Then

$$C_0(xv + yw) = \begin{bmatrix} x\sigma \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \\ y\sigma \end{bmatrix} \tag{2.16}$$

and

$$Q_0(xv+yw) = \begin{bmatrix} (\gamma v_{m_2-1})x & + & \gamma y \\ & 0 & \\ & \cdot & \\ & \cdot & \\ & \cdot & \\ & 0 & \\ \beta x & + & (\beta v_1)y \end{bmatrix}. \tag{2.17}$$

LEMMA 2.2. *Let M be the matrix*

$$M = \begin{bmatrix} \gamma v_{m_2-1} & 0 & \cdots & 0 & \gamma \\ 0 & \cdots & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & \cdots & \cdots & 0 \\ \beta & 0 & \cdots & 0 & \beta v_1 \end{bmatrix}. \tag{2.18}$$

Let $[x, 0, \ldots, 0, y]^T$ be an eigenvector of M with associated nonzero eigenvalues μ. Then

$$U = (xv + yw) \tag{2.19}$$

satisfies

$$\left(\frac{\mu}{\sigma}\right) C_0(xv+yw) = \frac{\mu}{\sigma} C_0 U = Q_0 U. \tag{2.20}$$

Thus, U is an eigenvector and $\mu/\sigma = \rho$ is an eigenvalue of the eigenvalue problem (2.7).

Proof. From (2.16) and (2.17) we have

$$\frac{\mu}{\sigma} C_0(xv+yw) = \mu \begin{bmatrix} x \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \\ y \end{bmatrix} \tag{2.21}$$

and

$$Q_0(xv+yw) = M \begin{bmatrix} x \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \\ y \end{bmatrix} = \mu \begin{bmatrix} x \\ 0 \\ \cdot \\ \cdot \\ \cdot \\ 0 \\ y \end{bmatrix}. \tag{2.22}$$

Therefore the lemma is proven. ☐

THEOREM 2.3. *Let*

$$R = (\gamma v_{m_2-1} + \beta v_1). \tag{2.23}$$

Then the nonzero eigenvalues of M are given by

$$\mu = \frac{R \pm \sqrt{R^2 + 4\gamma\beta(1 - v_1 v_{m_2-1})}}{2} \tag{2.24}$$

and the eigenvalues ρ of (2.7) *are given by*

$$\rho = \frac{R \pm \sqrt{R^2 + 4\gamma\beta(1 - v_1 v_{m_2-1})}}{2(-2 + R - 2D_0)} \tag{2.25}$$

and the value "0" $(m_2 - 2)$ times.

Proof. The theorem is proven by a direct computation. □

LEMMA 2.4. *Let D_0 be a number of order* 1. *Consider ρ_+ given by*

$$\rho_+ = \frac{R + \sqrt{R^2 + 4\gamma\beta(1 - v_1 v_{m_2-1})}}{2(-2 + R - 2D_0)}. \tag{2.26}$$

Then $\rho_+ < 0$ and

$$|\rho_+| \leq \frac{1 + \sqrt{2}}{2D_0}. \tag{2.27}$$

Proof. The lemma is proven by observing the following:

$$0 \leq R \leq 2, \quad 0 \leq 4\gamma\beta(1 - v_1 v_{m_2-1}) \leq 4,$$

and

$$| - 2 + R - 2D_0| \geq 2D_0. \qquad \square$$

3. The difference equations. In this section we study the eigenvalues ρ_+ and ρ_- and their dependence on the parameter D_0. This involves a rather technical discussion of the properties of the vector $\hat{v}$ described by (2.9) and (2.10). This discussion uses differentiation with respect to $(2D_0)$.

As before, we assume (1.11). Since h_2 and ϵ are always positive, we have

$$\frac{|b|h_2}{2\epsilon} < 1. \tag{3.1}$$

As is well known [H] the $\{v_j; j = 1, 2, \ldots, (m_2 - 1)\}$ are linear combinations of the roots S_1, S_2 of the quadratic equation

$$\beta S^2 + \hat{\alpha} S + \gamma = 0. \tag{3.2}$$

LEMMA 3.1. *Under the assumption* (1.11) *the roots of* (3.2)

$$S_1 = \frac{-\hat{\alpha} + \sqrt{\hat{\alpha}^2 - 4\gamma\beta}}{2\beta}, \quad S_2 = \frac{-\hat{\alpha} - \sqrt{\hat{\alpha}^2 - 4\gamma\beta}}{2\beta} \tag{3.3}$$

are both positive. If $D_0 > 0$, then

$$0 < S_2 < 1 < S_1. \tag{3.4}$$

Finally, the solution of (2.10) *subject to the boundary condition* $v_0 = v_{m_2} = 1$ *is given by*

$$v_k = \frac{(S_1^{m_2} - 1)S_2^k + (1 - S_2^{m_2})S_1^k}{S_1^{m_2} - S_2^{m_2}}. \tag{3.5}$$

Proof. The formulae (3.3) are elementary. Since

$$\hat{\alpha}^2 - 4\gamma\beta > 4 - 4\left(1 - \frac{(bh_2)^2}{4\epsilon^2}\right) = \left(\frac{bh_2}{\epsilon}\right)^2 \geq 0,$$

the roots S_1 and S_2 are distinct and positive. Furthermore,

$$S_1 \geq \frac{2(1 + D_0) + |\frac{bh_2}{\epsilon}|}{2 + |\frac{bh_2}{\epsilon}|} \geq 1 \tag{3.6}$$

and strictly greater than one if $D_0 > 0$.

If $b \leq 0$, then

$$S_1 S_2 = \frac{\gamma}{\beta} = \frac{1 - |\frac{bh_2}{2\epsilon}|}{1 + |\frac{bh_2}{2\epsilon}|} \leq 1. \tag{3.7}$$

Since $S_1 > 1$, we see that $S_2 < 1$.

On the other hand, if $b > 0$, we observe that

$$\theta_1 = \frac{1}{S_2}, \quad \theta_2 = \frac{1}{S_1} \tag{3.8}$$

are the roots of the equation $\gamma\theta^2 + \hat{\alpha}\theta + \beta = 0$. The previous argument shows that

$$\theta_1 = \frac{1}{S_2} > 1, \quad \theta_2 = \frac{1}{S_1} < 1.$$

Thus, we have established (3.4). Finally, the formula (3.5) is verified by evaluation of v_0 and v_{m_2}. □

Let "·" represent differentiation with respect to $(2D_0)$. That is, for any quantity m,

$$\frac{\partial}{\partial(2D_0)} m := \dot{m}. \tag{3.9}$$

LEMMA 3.2. *For* $D_0 > 0$ *we have*

$$\dot{S}_1 = \left[1 + \frac{-\hat{\alpha}}{\sqrt{\hat{\alpha}^2 - 4\gamma\beta}}\right] / 2\beta = \left[\frac{S_1}{\sqrt{\hat{\alpha}^2 - 4\gamma\beta}}\right] > 0, \tag{3.10}$$

$$\dot{S}_2 = \left[1 - \frac{-\hat{\alpha}}{\sqrt{\hat{\alpha}^2 - 4\gamma\beta}}\right] / 2\beta = \left[-\frac{S_2}{\sqrt{\hat{\alpha}^2 - 4\gamma\beta}}\right] < 0. \tag{3.11}$$

Moreover,

$$\dot{v}_1 < 0, \quad \dot{v}_{m_2 - 1} < 0. \tag{3.12}$$

Proof. The formulae (3.10), (3.11) are established by a simple computation.

Let us consider $v_1 = v_1(D_0)$. We have

$$v_1 = \frac{(S_1^{m_2} - 1)S_2 + (1 - S_2^{m_2})S_1}{S_1^{m_2} - S_2^{m_2}}. \tag{3.13}$$

A computation yields

$$\dot{v}_1 = Z_1 + Z_2, \tag{3.14}$$

where

$$Z_1 = \frac{\dot{S}_1(1 - S_2^{m_2})\{(S_1^{m_2} - S_2^{m_2}) - m_2(S_1 - S_2)S_1^{m_2-1}\}}{(S_1^{m_2} - S_2^{m_2})^2}, \tag{3.15}$$

$$Z_2 = \frac{\dot{S}_2(S_1^{m_2} - 1)\{(S_1^{m_2} - S_2^{m_2}) - m_2(S_1 - S_2)S_2^{m_2-1}\}}{(S_1^{m_2} - S_2^{m_2})^2}. \tag{3.16}$$

We have

$$S_1^{m_2} - S_2^{m_2} = S_1^{m_2}\left(1 - \frac{S_2}{S_1}\right)\sum_{k=0}^{m_2-1}\left(\frac{S_2}{S_1}\right)^k.$$

Thus,

$$(S_1^{m_2} - S_2^{m_2}) < m_2(S_1 - S_2)S_1^{m_2-1}.$$

Since $\dot{S}_1 > 0$ and $0 < S_2 < 1$, we see that

$$Z_1 < 0. \tag{3.17}$$

As for Z_2, we have

$$S_1^{m_2} - S_2^{m_2} = S_2^{m_2-1}(S_1 - S_2)\sum_{k=0}^{m_2-1}\left(\frac{S_1}{S_2}\right)^k.$$

Thus,

$$(S_1^{m_2} - S_2^{m_2}) > m_2 S_2^{m_2-1}(S_1 - S_2).$$

Since $\dot{S}_2 < 0$ and $S_1 > 1$, we see that

$$Z_2 < 0. \tag{3.18}$$

Therefore we have

$$\dot{v}_1 < 0. \tag{3.19}$$

The proof that $\dot{v}_{m_2-1} < 0$ follows from the observation that

$$v_{m_2-1} = \frac{(\theta_1^{m_2} - 1)\theta_2 + (1 - \theta_2^{m_2})\theta_1}{\theta_1^{m_2} - \theta_2^{m_2}},$$

$$\theta_1 = \frac{-\hat{\alpha} + \sqrt{\hat{\alpha}^2 - 4\gamma\beta}}{2\gamma} = \frac{1}{S_2},$$

$$\theta_2 = \frac{-\hat{\alpha} - \sqrt{\hat{\alpha}^2 - 4\gamma\beta}}{2\gamma} = \frac{1}{S_1},$$

and the previous argument applies. □

Lemma 3.3. *Let R and ρ_+ be defined as in the previous section. Then*

$$\dot{R} < 0, \quad -\dot{\rho}_+ < 0. \tag{3.20}$$

Proof. We have $\dot{R} < 0$ because of Lemma 3.2. And after some algebra we see that

$$-\dot{\rho}_+ \leq \frac{2[2R\dot{R} - 2\gamma\beta(\dot{v}_1 v_{m_2-1} + v_1\dot{v}_{m_2-1})][2+2D_0-R]}{[2(2+2D_0-R)]^2\sqrt{R^2+4\gamma\beta(1-v_1v_{m_2-1})}} \tag{3.21}$$
$$- 2\frac{(1-\dot{R})[R+\sqrt{R^2+4\gamma\beta(1-v_1v_{m_2-1})}]}{[2(2+2D_0-R)]^2}.$$

The second term of (3.21) is negative. Hence we need prove only that

$$2R\dot{R} - 2\gamma\beta(\dot{v}_1 v_{m_2-1} + v_1\dot{v}_{m_2-1}) < 0.$$

However, after some algebra we see that this reduces to

$$2(\gamma^2 v_{m_2-1}\dot{v}_{m_2-1} + \beta^2 v_1\dot{v}_1) < 0. \qquad \square \tag{3.22}$$

Remark 3.4. Since $\rho_+ < 0$, this implies that

$$|\rho_+| \text{ decreases as } D_0 \text{ increases.} \tag{3.23}$$

We believe that

$$|\rho_-| \text{ decreases as } D_0 \text{ increases,}$$

but we cannot prove it.

Remark 3.5. This lemma, and (3.23) in particular, enables us to study the largest eigenvalues in Case 2 by studying the smallest eigenvalues τ_j which are $O(h^2)$. In those cases we can estimate v_1 and v_{m_2-1} by studying a particular boundary value problem for an ordinary differential equation. We shall see this in section 4.

While the next theorem is valid in both cases, it is used primarily in Case 1, where it yields the asymptotic distribution of the eigenvalues.

Theorem 3.6. *Assume that*

$$D_0 = D_0(h_2) \geq D_1 > 0, \tag{3.24}$$

where D_1 is a constant. Further assume that

$$D_0(h_2) \to \overline{D}_0 \quad as \quad h_2 \to 0. \tag{3.25}$$

Observe that as $h_2 \to 0$ the quantities γ and β have limits γ^∞, β^∞. In Case 1*, where* (1.26) *holds, we have*

$$\beta \equiv 1 - \frac{b}{2}G_2 = \beta^\infty, \quad \gamma \equiv 1 + \frac{h}{2}G_2 = \gamma^\infty. \tag{3.26}$$

In Case 2*, where $\epsilon \equiv 1$, we have*

$$\beta \to 1 = \beta^\infty, \quad \gamma \to 1 = \gamma^\infty \quad as \;\; h_1, h_2 \to 0. \tag{3.27}$$

Furthermore,

$$S_1 \to S_1^\infty = \frac{(1+\overline{D}_0) + \sqrt{(1+\overline{D}_0)^2 - \gamma^\infty \beta^\infty}}{\beta^\infty}, \tag{3.28}$$

$$S_2 \to S_2^\infty = \frac{(1+\overline{D}_0) - \sqrt{(1+\overline{D}_0)^2 - \gamma^\infty \beta^\infty}}{\beta^\infty}. \tag{3.29}$$

Then as $m_2 \to \infty$ *(i.e.,* $h_2 \to 0$*) we have*

$$-\rho_+ = |\rho_+| \to -\rho_+^\infty = \frac{(1+\overline{D}_0) + \sqrt{\gamma^\infty \beta^\infty} - Z}{2Z}, \tag{3.30}$$

$$\rho_- = |\rho_-| \to \rho_-^\infty = \frac{Z + \sqrt{\gamma^\infty \beta^\infty} - (1+\overline{D}_0)}{2Z}, \tag{3.31}$$

where

$$Z = \sqrt{(1+\overline{D}_0)^2 - \gamma^\infty \beta^\infty}. \tag{3.32}$$

Proof. Under the hypotheses (3.24) and (3.25) the remarks before (3.30) and (3.31) are obvious. We proceed to prove (3.30), (3.31).

Since

$$v_1 = \frac{(S_1^{m_2} - 1)S_2 + (1 - S_2^{m_2})S_1}{S_1^{m_2} - S_2^{m_2}} \tag{3.33}$$

and

$$v_{m_2-1} = \frac{(1 - S_1^{-m_2})S_2^{m_2-1} + (1 - S_2^{m_2})S_1^{-1}}{1 - \left(\frac{S_2}{S_1}\right)^{m_2}}, \tag{3.34}$$

we see that as $m_2 \to \infty$ ($h_2 \to 0$) we have

$$v_1 \to v_1^\infty = S_2^\infty, \tag{3.35}$$

$$v_{m_2-1} \to v_{m_2-1}^\infty = \frac{1}{S_1^\infty}. \tag{3.36}$$

Hence

$$R \to R^\infty = \frac{\gamma^\infty}{S_1^\infty} + \beta^\infty S_2^\infty. \tag{3.37}$$

However,

$$\frac{\gamma^\infty}{S_1^\infty} = \beta^\infty S_2^\infty. \tag{3.38}$$

Hence

$$-\rho_+^\infty = \frac{R^\infty + 2\sqrt{\gamma^\infty \beta^\infty}}{2[2(1 - \beta^\infty S_2^\infty) + 2\overline{D}_0]}, \tag{3.39}$$

$$\rho_-^\infty = \frac{2\sqrt{\gamma^\infty \beta^\infty} - R^\infty}{2[2(1-\rho^\infty S_2^\infty) + 2\overline{D}_0]}. \tag{3.40}$$

The theorem now follows from algebraic manipulation using the fact that

$$\beta^\infty S_2^\infty = (1+\overline{D}_0) - \sqrt{(1+\overline{D}_0)^2 - \gamma^\infty \beta^\infty}. \qquad \square$$

Corollary 3.7.

$$-\dot{\rho}_+^\infty < 0, \quad \dot{\rho}_-^\infty < 0, \tag{3.41}$$

and

$$\rho_-^\infty \leq 1/2. \tag{3.42}$$

4. The case $\epsilon = 1$ in one dimension. In this section we consider the case $\epsilon \equiv 1$ and $h_2 = \frac{1}{m_2+1} \to 0$. At first we consider the case where

$$2D_0 = \hat{d} h_2^2$$

and $\hat{d}$ is a fixed constant of modest size. In this case the solutions of the equations

$$\frac{1}{h_2^2}[\gamma v_{k-1} + \hat{\alpha} v_k + \beta v_{k+1}] = 0, \quad k = 1, 2, \ldots, (m_2 - 1), \tag{4.1}$$

$$v_0 = v_{m_2} = 1 \tag{4.2}$$

approximate the function $u_h(x)$ which satisfies

$$-u_h'' + b u_h' + \hat{d} u_h = 0, \quad 0 \leq x \leq 1 - h_2, \tag{4.3}$$

$$u_h(0) = u_h(1-h_2) = 1. \tag{4.4}$$

We use this fact to obtain reasonable estimates for ρ_+, ρ_-, and

$$\lambda_+ = 1 - \rho_-, \quad \lambda_- = 1 - \rho_+. \tag{4.5}$$

The solution of (4.3) and (4.4) is

$$u_h(x) = \frac{(e^{M_1(1-h_2)} - 1)e^{M_2 x} + (1 - e^{M_2(1-h_2)})e^{M_1 x}}{e^{M_1(1-h_2)} - e^{M_2(1-h_2)}}, \tag{4.6}$$

where

$$M_1 = \frac{b + \sqrt{b^2 + 4\hat{d}}}{2}, \quad M_2 = \frac{b - \sqrt{b^2 + 4\hat{d}}}{2}. \tag{4.7}$$

Therefore

$$u_h'(0) = \frac{M_2(e^{M_1(1-h_2)} - 1) + M_1(1 - e^{M_2(1-h_2)})}{e^{M_1(1-h_2)} - e^{M_2(1-h_2)}} \tag{4.8}$$

and

$$u_h'(1-h_2) = \frac{M_2(e^{M_1(1-h_2)}-1)e^{M_2(1-h_2)} + M_1(1-e^{M_2(1-h_2)})e^{M_1(1-h_2)}}{e^{M_1(1-h_2)} - e^{M_2(1-h_2)}}. \tag{4.9}$$

We observe that

$$u_h'(0) < 0, \quad u_h'(1-h_2) > 0.$$

Moreover, there is a d_0 and an $H > 0$ such that for $\hat{d} \geq d_0$ and $0 < h_2 < H$ we have

$$|u'(0)| > \frac{|b|}{2}, \quad |u'(1)| > \frac{|b|}{2}.$$

Hence, for $\hat{d} \geq d_0$ we have

$$\beta v_1 \approx \left(1 - \frac{bh_2}{2}\right)(1 + u_h'(0)h_2) < 1 \tag{4.10}$$

and

$$\gamma v_{m_2-1} \approx \left(1 + \frac{bh_2}{2}\right)(1 - u_h'(1-h_2)h_2) < 1. \tag{4.11}$$

Since v_1 and v_{m_2-1} decrease with increasing D_0, once (4.10) and (4.11) hold for some $D_0 > 0$, they hold for all larger D_0. These inequalities will be important in the latter part of this section, where we discuss the case of large D_0 and we cannot use (4.6) to approximate v_1 and v_{m_2-1}.

We recall that

$$\sigma = \hat{\alpha} + \beta v_1 + \gamma v_{m_2-1}.$$

Since

$$v_1 = u_h(h_2) + O(h_2^3), \quad v_{m_2-1} = u_h(1-2h_2) + O(h_2^3), \tag{4.12}$$

we see that

$$\begin{aligned} \sigma = &\left[\beta u_h(h_2) - \left[1 + \frac{\hat{d}h_2^2}{2}\right] u_h(0)\right] \\ &+ \left[\gamma u_h(1-2h_2) - \left[1 + \frac{\hat{d}h_2^2}{2}\right] u_h(1-h_2)\right] + O(h_2^3). \end{aligned} \tag{4.13}$$

A careful computation using the differential equation shows that

$$\sigma = s_h h_2 + O(h_2^3), \tag{4.14}$$

where

$$s_h = u_h'(0) - u_h'(1-h_2). \tag{4.15}$$

Therefore, after a lengthy computation we see that

$$s_h = s_0\,[1 + K_0 h_2 + K_1 h_2], \tag{4.16}$$

where

$$s_0 = -\frac{e^{M_1} + e^{M_2} - 1 - e^b}{e^{M_1} - e^{M_2}} \sqrt{b^2 + 4\hat{d}} = u_0'(0) - u_0'(1), \tag{4.17}$$

$$K_0 = \frac{be^b - (M_1 e^{M_1} + M_2 e^{M_2})}{(e^{M_1} - 1)(1 - e^{M_2})}, \tag{4.18}$$

and

$$K_1 = \frac{M_1 e^{M_1} - M_2 e^{M_2}}{e^{M_1} - e^{M_2}}. \tag{4.19}$$

We also require the quantity

$$W = [u_0'(0) + u_0'(1)]^2 - 2b[u_0'(0) + u_0'(1)]. \tag{4.20}$$

We are now prepared to state and prove the main theorem for this case.

Theorem 4.1. *For $2D_0 = \hat{d}h_2^2$ and h_2 small we have*

$$\rho_+ = \frac{1}{2} + \frac{2}{\sigma} + O(h_2) \tag{4.21}$$

and

$$\rho_- = \frac{1}{2} + O(h_2). \tag{4.22}$$

Therefore

$$\lambda_+ = 1 - \rho_+ = \frac{1}{2} + \frac{2}{|s_h| h_2} + O(h_2), \tag{4.23}$$

or

$$\lambda_+ = \frac{1}{2} + \frac{2(K_0 + K_1)}{s_0} + \frac{2}{|s_0| h_2} + O(h_2), \tag{4.24}$$

and

$$\lambda_- = 1 - \rho_- = \frac{1}{2} + \frac{h_2^2}{|s_h|}\Big(\frac{\hat{d}}{2} - \frac{W}{8}\Big) + O(h_2) = \frac{1}{2} + O(h_2). \tag{4.25}$$

Proof. Since (see (2.26))

$$|\rho_+| = \frac{R + \sqrt{(\beta v_1 + \gamma v_{m_2-1})^2 + 4\gamma\beta(1 - v_1 v_{m_2-1})}}{2|\sigma|},$$

therefore

$$|\rho_+| = \frac{R + \sqrt{(\beta v_1 - \gamma v_{m_2-1})^2 + 4 - (bh_2)^2}}{2|\sigma|}. \tag{4.26}$$

Straightforward computations yield

$$R = 2 + \sigma + \hat{d}h_2^2 \tag{4.27}$$

and

$$(\beta v_1 - \gamma v_{m_2-1})^2 = h_2^2\{W + b^2\} + O(h_2^2). \tag{4.28}$$

Hence

$$\rho_+ \approx \frac{2 + \sigma + \hat{d}h_2^2 + \sqrt{4 + Wh_2^2 + O(h_2^2)}}{2\sigma}.$$

Thus,

$$\rho_+ \approx \frac{2}{\sigma} + \frac{1}{2} + O\Big(\frac{h_2^2}{\sigma}\Big). \tag{4.29}$$

Hence we have proven (4.21). A similar calculation yields (4.22). Finally, (4.24) follows from (4.29), (4.14), and (4.16). □

We now turn to those cases where $2D_0$ is not necessarily small. We recall that for $d \geq d_0$ we have (4.10) and (4.11).

THEOREM 4.2. *Let*

$$\gamma v_{m_2-1} < 1, \quad \beta v_1 < 1. \tag{4.30}$$

Consider ρ_- *given by*

$$\rho_- = \frac{R - \sqrt{R^2 + 4\gamma\beta(1 - v_1 v_{m_2-1})}}{2(-2 + R - 2D_0)}. \tag{4.31}$$

Then

$$|\rho_-| \leq \frac{\sqrt{5} - 1}{2} \approx .618. \tag{4.32}$$

Proof. Let

$$1 - \gamma v_{m_2-1} = p, \quad 1 - \beta v_1 = r. \tag{4.33}$$

Observe that

$$R^2 + 4\gamma\beta(1 - v_1 v_{m_2-1}) = (\gamma v_{m_2-1} - \beta v_1)^2 + 4\gamma\beta \tag{4.34}$$

and

$$\gamma v_{m_2-1} - \beta v_1 = r - p. \tag{4.35}$$

Let

$$\theta = \frac{\sqrt{5} - 1}{2}. \tag{4.36}$$

The assertion (4.32) is equivalent to the assertion

$$\frac{\sqrt{(r-p)^2 + 4\gamma\beta} - R}{2[(2 - R) + 2D_0]} \leq \theta.$$

Now $2 - R = (p + r)$, so this assertion is equivalent to the statement

$$\sqrt{(r-p)^2 + 4\gamma\beta} \leq 2\theta[2 - R + 2D_0] + R$$

or

$$\sqrt{(r-p)^2+4\gamma\beta} \le (2\theta-1)(p+q)+2(1+2\theta D_0).$$

Since both sides of this inequality are positive, this inequality is equivalent to

$$(r-p)^2+4\gamma\beta = (2\theta-1)^2(p+r)^2+4(2\theta-1)(1+2\theta D_0)(p+r) \\ +4(1+2\theta D_0)^2.$$

This inequality is equivalent to

$$4\gamma\beta \le [(2\theta-1)^2-1](p^2+r^2)+2[(2\theta-1)^2+1]pr \\ +4(2\theta-1)(1+2\theta D_0)(p+r)+4(1+2\theta D_0)^2.$$

Since $|p|$ and $|r|$ are each less than one and $4\gamma\beta \le 4$, it is sufficient to prove that

$$4 \le [(2\theta-1)^2+4(2\theta-1)-1][p^2+r^2]+4.$$

However, $2\theta-1=(\sqrt{5}-2)$ is a root of

$$m^2+4m-1.$$

Hence the inequality is proven. □

Remark 4.3. Notice that while this estimate is sufficient for our purposes, we have made no effort to make a sharp estimate.

5. Two dimensions. We now return to the basic eigenvalue problem (1.23). From the discussion following (1.22) we must determine the eigenvalues τ_j of T_1. However, these are known. We have the following lemma.

LEMMA 5.1. *Consider the matrix T_1 given by* (1.13) *with A,B,C given by* (1.6) *and* (1.7). *The eigenvalues of T_1 are*

(5.1) $$\tau_j = A+2\sqrt{BC}\cos \pi j h_1.$$

Proof. This is a well-known result; see [P]. □

Our first basic theorem is for the case of the convection-diffusion equation studied in [LH]. However, we must remark that due to differences in notation we have not attempted to show the exact equivalence of these formulae and those of [LH].

Unfortunately, the description of these eigenvalues requires quite a bit of notation. Our basic result is the following theorem.

THEOREM 5.2. *Let $|a|>0$. Let $0<\epsilon \ll 1$, and let*

(5.2) $$\delta = \sqrt{1-\left(\frac{aG_1}{2}\right)^2} = \varphi^2\sqrt{BC},$$

(5.3) $$D_m = \varphi^2(1-\delta),$$

(5.4) $$D_M = \varphi^2(1+\delta),$$

(5.5) $$X_m = 1+D_m,$$

$$X_M = 1 + D_M, \tag{5.6}$$

$$\delta_1 = \sqrt{1 - \left(\frac{bG_2}{2}\right)^2}, \tag{5.7}$$

$$Y_m = \sqrt{X_m^2 - \delta_1^2}, \tag{5.8}$$

$$Y_M = \sqrt{X_M^2 - \delta_1^2}, \tag{5.9}$$

$$c_1 = 1 + \frac{X_M + \delta_1 - Y_M}{2Y_M}, \tag{5.10}$$

$$d_1 = 1 + \frac{X_m + \delta_1 - Y_m}{2Y_m}, \tag{5.11}$$

$$a_1 = 1 - \frac{Y_M + \delta_1 - X_M}{2Y_M}, \tag{5.12}$$

$$b_1 = 1 - \frac{Y_m + \delta_1 - X_m}{2Y_m}. \tag{5.13}$$

Then the eigenvalues λ_j of (1.23) *subject to the conditions* (1.26) *fall into three groups:* (i) *There are $m_1m_2 - 2m_1$ eigenvalues which are exactly one.* (ii) *There are m_1 eigenvalues which lie in an interval $(\overline{a}_1(h), \overline{b}_1(h))$ and*

$$\overline{a}_1(h) \to a_1 \geq \frac{1}{2} \quad as \ \ h_1, h_2 \to 0 \tag{5.14}$$

and

$$\overline{b}_1(h) \to b_1 \leq 1 \quad as \ \ h_1, h_2 \to 0. \tag{5.15}$$

(iii) *Finally, there are m_1 eigenvalues which lie in a finite interval $(\overline{c}_1(h), \overline{d}_1(h))$ and*

$$\overline{c}_1(h) \to c_1 \geq 1 \quad as \ \ h_1, h_2 \to 0 \tag{5.16}$$

and

$$\overline{d}_1(h) \to d_1 < \infty \quad \text{as} \ \ h_1, h_2 \to 0. \tag{5.17}$$

Proof. In this case the eigenvalues τ_j are given by

$$\tau_j = 2\varphi^2(1 - \delta \cos \pi j h_1). \tag{5.18}$$

Therefore the argument in the introduction shows that we are led to study the problems of sections 2 and 3 with

$$D_0 = D_0(j) = \varphi^2(1 - \delta \cos \pi j h_1) + \frac{dh_2^2}{2\epsilon}.$$

And for all $j = 1, 2, \ldots, m_1$ we have

$$D_m \leq D_0(j) \leq D_M. \tag{5.19}$$

We now apply Theorem 3.6 with $D_0 = D_m$ and $D_0 = D_m$, together with (3.41) and (3.42), to see that the limiting eigenvalues all fall within the indicated intervals. □

We now turn to the uniformly elliptic case with $\epsilon \equiv 1$.

THEOREM 5.3. *Let $\epsilon \equiv 1$. Let j be a fixed integer, and set*

$$\hat{d}(j) = d - \frac{\tau_j}{h_2^2}. \tag{5.20}$$

Let

$$M_1 = M_1(j) = \frac{b + \sqrt{b^2 + 4\hat{d}(j)}}{2}, \quad M_2 = M_2(j) = \frac{b - \sqrt{b^2 + 4\hat{d}(j)}}{2} \tag{5.21}$$

and

$$K_0(j) = \frac{be^b - [M_1(j)e^{M_1(j)} + M_2(j)e^{M_2(j)}]}{(e^{M_1(j)} - 1)(1 - e^{M_2(j)})}, \tag{5.22}$$

$$K_1(j) = \frac{M_1(j)e^{M_1(j)} - M_2(j)e^{M_2(j)}}{e^{M_1(j)} - e^{M_2(j)}}. \tag{5.23}$$

Let

$$\overline{s} = \overline{s}(j) = -\frac{e^{M_1} + e^{M_2} - 1 - e^b}{e^{M_1} - e^{M_2}}\sqrt{b + 4\hat{d}(j)}. \tag{5.24}$$

Let

$$\lambda_1 > \lambda_2 > \cdots > \lambda_{m_1}$$

be the m_1 largest eigenvalues of (1.23). *Then as $h_1, h_2 \to 0$ we have*

$$\lambda_j \approx \frac{1}{2} + \frac{2[K_0(j) + K_1(j)]}{\overline{s}(j)} + \frac{1}{h_2}\frac{2}{|s(j)|}. \tag{5.25}$$

Furthermore, for $1 \leq j < s \leq m_1$ we have

$$1 \leq \lambda_s \leq \lambda_j. \tag{5.26}$$

Finally, for $m_1/2 \leq j \leq m_1$ we have

$$1 \leq \lambda_j \leq 1 + \frac{1 + \sqrt{2}}{2\varphi^2}. \tag{5.27}$$

Proof. For each j we have the situation described in Theorem 4.1 with $\hat{d}$ given by $\hat{d}(j)$ in (5.20). Hence (5.25) follows from Theorem 4.1. The estimate (5.26) follows from Lemma 3.3. Finally, the estimate (5.27) follows from the fact that

$$|\tau_j| \geq 2\varphi^2, \quad \frac{m_1}{2} < j \leq m_1,$$

and from (2.27). □

Remark 5.4. We note that

$$\frac{\tau_j}{h_2^2} \to -\left(\frac{a^2}{4} + (\pi j)^2\right) = -\mu_j. \tag{5.28}$$

And the quantity μ_j is precisely the jth eigenvalue of the operator

$$L_a := -\left(\frac{d}{du}\right)^2 + a\frac{d}{du}.$$

Furthermore, for very large j

$$\overline{s}(j) \to \sqrt{b^2 + 4\mu_j} \approx 2(j\pi).$$

Hence

$$\lambda_j \approx K_2 + \frac{1}{h_2}\frac{1}{(j\pi)},$$

where K_2 is a constant. Thus, for j modestly large the coefficient of $\frac{1}{h_2}$ is quite small. And (5.26) and (5.27) assure us that it is even smaller for larger values of j.

THEOREM 5.5. *There are m_1 eigenvalues $\lambda(h)$ of* (1.23) *which satisfy*

$$.38 < \frac{3-\sqrt{5}}{2} \leq \lambda \leq 1 \tag{5.29}$$

as $h_1, h_2 \to 0$.

Proof. For any fixed j we have the results of Theorem 4.2 which yields

$$\lambda_- \approx \frac{1}{2} - h_2\overline{S},$$

where $\overline{S}$ is a constant depending on b and j.

On the other hand, if j is fixed and so large that (4.30) holds, we have (4.32) which implies that (5.29) holds for all j. □

6. Numerical tests. In this section we provide a series of numerical examples to illustrate the theories developed in the previous sections. For this, we take the following examples by recalling (1.4) and (1.11).

Example 1. Consider

$$-\epsilon\Delta u + 2u_x + u_y.$$

We fix $\frac{h}{\epsilon} = \frac{3}{4}$, where $h = h_1 = h_2$ so that $\epsilon = \frac{4}{3}h$. The non-one eigenvalues are in either $[0.7136, .84762]$ or $[1.2186, 1.67316]$, which can be predicted by Theorem 5.2. The two groups of eigenvalues are listed in Tables 6.1 and 6.2.

Example 2. Consider

$$-\epsilon\Delta u + 3u_x + 3u_y + u.$$

We fix

$$\frac{h}{\epsilon} = \frac{1}{6}, \quad \text{where} \quad h = h_1 = h_2$$

TABLE 6.1
Two groups of eigenvalues for $-\epsilon\Delta u + 2u_x + u_y$.

Mesh size	Eigenvalues	Eigenvalues

so that

$$\epsilon = 6h.$$

The non-one eigenvalues are in either $[0.58861, .8563394]$ or $[1.2014, 3.23054]$, which can be predicted by Theorem 5.2. The two groups of eigenvalues are listed in Tables 6.3 and 6.4.

Example 3. Consider

$$-\Delta u + u.$$

The two groups of extreme eigenvalues are listed in Table 6.5. The range of these non-one eigenvalues can be predicted by Theorems 5.3 and 5.5.

Example 4. Consider

$$-\Delta u + 2u_x + u_y.$$

Table 6.3

TABLE 6.7
Growth rates of the first five largest eigenvalues for $-\Delta u + 2u_x + u_y$.

jth largest eigenvalue	1st	2nd	3rd	4th	5th
Computed rates	0.32682	0.15929	0.10821	0.08313	0.06857
	0.32743	0.16004	0.10925	0.08444	0.07012
	0.32756	0.16023	0.10952	0.08478	0.07053
Predicted rate	0.3276	0.1603	0.1096	0.0849	0.0707

We list a sequence of eigenvalues in Table 6.6. We also list several of the predicted growth rates of the first five largest eigenvalues with their computed growth rates in Table 6.7 when $h_1 = \frac{1}{10}$ and h_2 takes $\frac{1}{20}$, $\frac{1}{40}$, $\frac{1}{80}$, and $\frac{1}{160}$. These predictions are based on (4.24), and the computed rates are calculated using Table 6.6. For example, for $h_1 = \frac{1}{10}$ fixed we assume these larger eigenvalues can be written as

$$X_j + Y_j \frac{1}{h_2} = \lambda(j, h_2).$$

Then, a first approximation to Y_j is given by

$$Y_j = \frac{\lambda(j, \frac{1}{40}) - \lambda(j, \frac{1}{20})}{20}.$$

Appendix. Consider the case where $0 < \epsilon \ll 1$ and

$$h_1/\epsilon = G_1, \quad h_2/\epsilon = G_2. \tag{A.1}$$

For definitiveness we assume that

$$a < 0, \quad b < 0. \tag{A.2}$$

Thus the boundary layers in (1.1) occur on $\partial\Omega_b$ given by

$$\partial\Omega_b := \{(x,0); 0 < x < 1\} \cup \{(0,y); 0 < y < 1\}. \tag{A.3}$$

Let $\partial\Omega_H = \partial\Omega \backslash \partial\Omega_b$ be the hyperbolic boundary, i.e.,

$$\partial\Omega_H = \{(x,1); 0 < x < 1\} \cup \{(1,y); 0 < y < 1\}. \tag{A.4}$$

Let $u = \{u_{k,j}\}$ be the solution of (1.5) with zero Dirichlet boundary values. Let $\Phi(x,y)$ be the solution of

$$a\Phi_x + b\Phi_y = f \tag{A.5}$$

with boundary condition

$$\Phi = 0 \ \text{ on } \ \partial\Omega_H. \tag{A.6}$$

The basic result of this appendix is the following theorem.

THEOREM A.1. *Let* $0 < \delta < 1$. *Let*

$$\Omega_\delta := \{(x,y) : \delta < x, y < 1\}. \tag{A.7}$$

Then, for every such δ, *if* $(x_k, y_j) \in \Omega_\delta$, *then*

$$\text{Max } |u_{k,j} - \Phi(x_k, y_j)| \to 0 \ \text{ as } \ h_1, h_2 \to 0. \tag{A.8}$$

The proof follows from the argument below.

Let

$$u = u^I + u^{II}, \tag{A.9}$$

where

$$L_h u^I = f \ \text{ in } \ \Omega, \tag{A.10}$$

$$u^I = \Phi \ \text{ on } \ \partial\Omega, \tag{A.11}$$

and

$$L_h u^{II} = 0 \ \text{ in } \ \Omega, \tag{A.12}$$

$$u^{II} = -\Phi \quad \text{on} \quad \partial\Omega. \tag{A.13}$$

We observe that (A.13) means

$$u^{II} = 0 \quad \text{on} \quad \partial\Omega_H, \quad u^{II} = -\Phi \quad \text{on} \quad \partial\Omega_b. \tag{A.14}$$

LEMMA A.2. *There is a constant $K_3 > 0$, depending only on a, such that*

$$\|u\|_\infty \le K_3 \|f\|_\infty. \tag{A.15}$$

Proof. Let

$$\theta = 1 + \frac{h_1}{a} \approx e^{-\frac{h_1}{|a|}}, \tag{A.16}$$

and set

$$u_{k,j} = \theta^k v_{k,j}. \tag{A.17}$$

Then $v = \{v_{k,j}\}$ satisfies the equation

$$\begin{aligned} -\frac{\epsilon}{h_2^2}\Big\{\frac{C}{\theta} v_{k-1,j} - 2\varphi^2 v_{k,j} + B\theta v_{k+1,j} + \gamma v_{k,j-1} \\ +\ \alpha v_{k,j} + \beta v_{k,j+1}\Big\} = \theta^{-k} f_{k,j}. \end{aligned} \tag{A.18}$$

We approximate $\frac{1}{\theta}$ by $1 - \frac{h_1}{a}$. Let

$$C_1 = C/\theta, \quad B_1 = B\theta, \tag{A.19}$$

$$g = \left(1 - \frac{h_1^2}{2\epsilon}\right) = 1 - \frac{1}{2} G_1 h_1, \tag{A.20}$$

$$P = \left(\frac{a h_1}{2\epsilon} - \frac{h_1}{a}\right)/g = \left(\frac{a G_1}{2} - \frac{h_1}{a}\right)/g. \tag{A.21}$$

Then an algebraic computation shows that

$$C_1 = \varphi^2 g(1 + P), \quad B_1 = \varphi^2 g(1 - P), \tag{A.22}$$

$$-2\varphi^2 = -2\varphi^2 g - \frac{h_1^2}{\epsilon}\varphi^2. \tag{A.23}$$

Since

$$\frac{h_1^2}{\epsilon}\varphi^2 = \frac{h_2^2}{\epsilon},$$

we see that v satisfies

$$\begin{aligned} -\frac{\epsilon}{h_2^2}\{\varphi^2 g[(1+P)v_{k-1,j} - 2v_{k,j} + (1-P)v_{k+1,j}] \\ +\ [\gamma v_{k,j-1} + \alpha v_{k,j} + \beta v_{k,j+1}]\} + v_{k,j} = \theta^{-k} f_{k,j}. \end{aligned} \tag{A.24}$$

An easy application of maximum principle arguments shows that

$$\|v\|_\infty \le \theta^{-m_1}\|f\|_\infty \approx e^{\frac{1}{|a|}}\|f\|_\infty. \tag{A.25}$$

From (A.17) we see that

$$\|u\|_\infty \le \|v\|_\infty \le K_3\|f\|_\infty, \tag{A.26}$$

and the lemma is proven. □

LEMMA A.3. *Let $W > 0$ be a constant. Let $w = \{w_{k,j}\}$ satisfy*

$$L_h w = 0, \tag{A.27}$$

$$w = 0 \ \ on \ \ \partial\Omega_H, \tag{A.28}$$

$$|w| \le W \ \ on \ \ \partial\Omega_b. \tag{A.29}$$

Let

$$\theta_1 = \sqrt{C/B}, \quad \theta_2 = \sqrt{\gamma/\beta}. \tag{A.30}$$

Note. Since $a < 0, b < 0$, we have

$$\theta_1 < 1, \quad \theta_2 < 1. \tag{A.31}$$

Then

$$|w_{k,j}| \le \theta_1^k\theta_2^j|W|. \tag{A.32}$$

Proof. Let

$$w_{k,j} = \theta_1^k\theta_2^j v_{k,j}. \tag{A.33}$$

Then v satisfies

$$-\frac{\epsilon}{h_2^2}\{\overline{C}v_{k-1,j} - 2\varphi^2 v_{k,j} + \overline{C}v_{k+1,j} \ \ \overline{\gamma}v_{k,j-1} + \alpha v_{k,j} + \overline{\gamma}v_{k,j+1}\} = 0. \tag{A.34}$$

And, since $w = 0$ on $\partial\Omega_H$, we have

$$v = w \ \ \text{on} \ \ \partial\Omega. \tag{A.35}$$

Here

$$\overline{C} = \sqrt{CB} = \varphi^2\sqrt{1 - \left(\frac{aG_1}{2}\right)^2} \le \varphi^2, \tag{A.36}$$

$$\overline{\gamma} = \sqrt{\gamma\beta} = \sqrt{1 - \left(\frac{bG_2}{2}\right)^2} \le 1. \tag{A.37}$$

An application of the maximum principle now shows that v takes on its maximum on $\partial\Omega$. Hence

$$\|v\|_\infty \le W$$

and

$$|w_{k,j}| \leq \theta_1^k \theta_2^j W. \quad \square \tag{A.38}$$

Proof of Theorem A.1. To complete the proof of Theorem A.1 we must show that

$$\|u^I - \Phi\|_\infty \to \quad \text{as} \quad h_1, h_2 \to 0. \tag{A.39}$$

For the sake of completeness we consider two cases. First we deal with the easy case where

$$\Phi \in C^4(\overline{\Omega}).$$

Then we deal with the general case.

THEOREM A.4. *Let* $\Phi \in C^4(\overline{\Omega})$. *Then there is a constant* K *such that*

$$\|u^I - \Phi\|_\infty \leq K[h_1^2 + h_2^2]. \tag{A.40}$$

Proof. In this case we see that

$$\|L_h u^I - L_h \Phi\|_\infty \leq K(h_1^2 + h_2^2).$$

Hence the theorem follows from Lemma A.2. $\square$

THEOREM A.5. *Let* $f \in (C\overline{\Omega})$. *Then*

$$\|\Phi - u^I\|_\infty \to 0 \quad \textit{as} \quad h_2 = \epsilon / G_2 \to 0. \tag{A.41}$$

Proof. Since $f \in C(\overline{\Omega})$, we know that $\Phi \in C^1(\overline{\Omega})$. Standard "mollifier" arguments (see [N]) show that for each ϵ, h_1, h_2 with $\epsilon / h_s = G_s$, a fixed number, there exists a function $\Phi_\epsilon(x, y)$ and a number $\eta_\epsilon > 0$ such that

$$\|\Delta \Phi_\epsilon\| \leq \epsilon^{-1/2}, \tag{A.42}$$

$$\|\Phi - \Phi_\epsilon\|_\infty + \left\| \frac{\partial}{\partial x}[\Phi - \Phi_\epsilon] \right\|_\infty + \left\| \frac{\partial}{\partial y}[\Phi - \Phi_\epsilon] \right\|_\infty \leq \eta_\epsilon, \tag{A.43}$$

$$\eta_\epsilon \to 0 \quad \text{as} \quad \epsilon \to 0. \tag{A.44}$$

Therefore

$$L_h \Phi_\epsilon = f_\epsilon, \tag{A.45}$$

where

$$\|f - f_\epsilon\|_\infty \leq [|a| + |b| + |c|]\eta_\epsilon + \epsilon^{1/2}. \tag{A.46}$$

Hence, since

$$\|L_h(u^I - \Phi_\epsilon)\|_\infty \leq \|f - f_\epsilon\|,$$

Lemma A.2 yields

$$\|u^I - \Phi_\epsilon\|_\infty \leq K[(|a| + |b| + |c|)\eta_\epsilon + \epsilon^{1/2}]. \tag{A.47}$$

Finally,

$$\|u^I - \Phi\|_\infty \leq \|u^I - \Phi_\epsilon\|_\infty + \|\Phi_\epsilon - \Phi\|_\infty .$$

Therefore

$$\|u^I - \Phi\|_\infty \leq K[|a| + |b| + |c|]\eta_\epsilon + \eta_\epsilon + \epsilon^{1/2},$$

and the theorem is proven. □

CORRIGENDUM: FOURIER SPECTRAL APPROXIMATION TO A DISSIPATIVE SYSTEM MODELING THE FLOW OF LIQUID CRYSTALS*

QIANG DU†, BENYU GUO‡, AND JIE SHEN§

PII. S003614290241653X

The purpose of this note is to correct an error in the proof of Proposition 2.4 in [1]. The inequality $||g(d_M)||_1 \leq c||d_M||^2_{L^4}|d_M|_1$ on line 18 of page 741 in [1] is not correct. We now revise the proof and the result of Proposition 2.4 as follows. Indeed,

$$||g(d_M)||_1^2 \leq c\int_\Omega |d_M|^4(\nabla d_M)^2dx.$$

By integration by parts, the Cauchy inequality, and (2.10) in [1], we obtain

$$||g(d_M)||_1^2 \leq c||d_M||^5_{L^{10}}|d_M|_2 \leq c||d_M||^5_{\frac{2n}{5}}|d_M|_2 \leq cM^{2n-5}||d_M||_1^5|d_M|_2.$$

Thus, by (2.18) of [1], we have

$$||(P_M-I)g(d_M)|| \leq cM^{\frac{2n-7}{2}}||d_M||_1^{\frac{5}{2}}|d_M|_2^{\frac{1}{2}}.$$

Next, by virtue of the imbedding inequality and (2.10) of [1],

$$\begin{aligned}2\lambda|G| &\leq 2\lambda||u_M||_{L^3}||\nabla d_M||_{L^6}||(P_M-I)g(d_M)|| \leq c\lambda M^{\frac{2n-7}{2}}||u_M||_{\frac{n}{6}}||d_M||_1^{\frac{5}{2}}||d_M||_2^{\frac{3}{2}}\\ &\leq c\lambda M^{\frac{2n-7}{2}}||u_M||^{\frac{3}{4}}_{\frac{n}{6}}||u_M||_1^{\frac{1}{4}}||d_M||_1^{\frac{5}{2}}||d_M||_2^{\frac{3}{2}}\\ &\leq c\lambda M^{\frac{9n-28}{8}}||u_M||^{\frac{3}{4}}||u_M||_1^{\frac{1}{4}}||d_M||_1^{\frac{5}{2}}||d_M||_2^{\frac{3}{2}}\\ &\leq c\lambda M^{\frac{9n-28}{40}}||u_M||_1^{\frac{1}{4}}\cdot M^{\frac{3(9n-28)}{80}}||d_M||_2^{\frac{3}{2}}\cdot M^{\frac{3(9n-28)}{160}}||u_M||^{\frac{3}{4}}\cdot M^{\frac{9n-28}{16}}||d_M||_1^{\frac{5}{2}}\\ &\leq c\lambda(M^{\frac{9n-28}{5}}||u_M||_1^2+M^{\frac{9n-28}{20}}||d_M||_2^2+M^{\frac{3(9n-28)}{10}}||u_M||^{12}\cdot M^{9n-28}||d_M||_1^{40}).\end{aligned}$$

On the other hand, we have

$$\begin{aligned}2\lambda\int_\Omega F(d_M)dx &\geq \frac{\lambda}{2\varepsilon^2}(||d_M||^4_{L^4}-2||d_M||^2+(2\pi)^n)\\ &\geq \frac{\lambda}{2\varepsilon^2}\left(\frac{1}{(2\pi)^n}||d_M||^4-2||d_M||^2+(2\pi)^n\right)\\ &\geq \frac{\lambda}{2\varepsilon^2(2\pi)^n}(||d_M||^2-(2\pi)^n(1+\varepsilon^2))^2+\lambda||d_M||^2-\frac{\lambda(2\pi)^n}{2}(2+\varepsilon^2)\\ &\geq \lambda||d_M||^2-\tfrac{\lambda}{2}(2\pi)^n(2+\varepsilon^2).\end{aligned}$$

§Department of Mathematics, Purdue University, West Lafayette, IN 47907 (shen@math.purdue.edu).

Moreover, by (2.23) of [1],

$$\lambda\gamma||\Delta d_M - P_M f(d_M)||^2 = \lambda\gamma\left(|d_M|_2^2 + ||P_M f(d_M)||^2 - \frac{2}{\varepsilon^2}|d_M|_1^2\right) \geq \lambda\gamma|d_M|_2^2 - \frac{2\lambda\gamma}{\varepsilon^2}|d_M|_1^2.$$

Substituting the above three estimates into (2.17) of [1] and integrating the resulting inequality with respect to t, we find that for $n \leq 3$ and M sufficiently large

(1)
$$\begin{aligned}\widetilde{E}(t) &\equiv E(t) + \int_0^t \left(\frac{\nu}{4}|u_M(s)|_1^2 + \lambda\gamma||\Delta d_M(s) - P_M f(d_M(s))||^2\right) ds \\ &\leq \sigma_0 + \int_0^t \left(\frac{2\lambda\gamma}{\varepsilon^2}||d_M(s)||_1^2 + c_4 M^{\frac{3}{10}(9n-28)}||u_M(s)||^{12} + c_4 M^{9n-28}||d_M(s)||_1^{40}\right) ds,\end{aligned}$$

where

$$\begin{aligned}&E(t) = ||u_M(t)||^2 + \lambda||d_M(t)||_1^2, \\ &\sigma_0 = ||u_0||^2 + \lambda|d_0|_1^2 + 3\lambda\int_\Omega F(d_0)dx + \lambda(2\pi)^n(\varepsilon^2 + 1 + \varepsilon\sqrt{\varepsilon^2+1}).\end{aligned} \tag{2}$$

Finally, we apply Lemma 2.3 of [1] to the above inequality to obtain for $n \leq 3$

$$\widetilde{E}(t) \leq \sigma_0 e^{\left(\frac{2\lambda\gamma}{\epsilon^2} + c_4 M^{-\frac{3}{10}}\right)t}. \tag{3}$$

In fact, we can derive improved results for Proposition 2.4 in the two-dimensional case (i.e., $n = 2$). Indeed, using the imbedding theory and (2.9) and (2.10) in [1], we obtain for any $\delta > 0$

$$||g(d_M)||_1 \leq c||d_M||_{L^\infty}^2|d_M|_1 \leq c||d_M||_{1+\frac{\delta}{2}}^2|d_M|_1 \leq cM^{\frac{\delta}{2}}||d_M||_1^3.$$

Thus, by (2.18) of [1],

$$||(P_M - I)g(d_M)|| \leq cM^{\frac{\delta-2}{2}}||d_M||_1^3.$$

By virtue of imbedding theory and the Cauchy inequality,

$$\begin{aligned}2\lambda|G| &\leq ||u_M||_{L^\infty}||d_M||_1||(P_M - I)g(d_M)|| \leq cM^{\delta-1}||u_M||_1||d_M||_1^4 \\ &\leq \frac{\nu}{2}|u_M|_1^2 + c_4M^{\frac{1}{2}(\delta-1)}||u_M||^2 + c_4M^{\frac{3}{2}(\delta-1)}||d_M||_1^8.\end{aligned}$$

Using the above estimate instead of (2.19) in [1] and repeating the same procedure as in the proof of Proposition 2.4, we obtain the following revised result.

Proposition 2.4 (revised). *Let $\widetilde{E}(t)$, $E(t)$, and σ_0 be defined in (1)–(2). Then, for $n = 3$, we have*

$$\widetilde{E}(t) \leq \sigma_0 e^{\left(\frac{2\lambda\gamma}{\epsilon^2} + c_4 M^{-\frac{3}{10}}\right)t};$$

for $n = 2$, we have for any small $\delta > 0$,

$$\begin{aligned}&E(t) + \int_0^t \left(\frac{\nu}{2}|u_M(s)|_1^2 + 2\lambda\gamma||\Delta d_M(s) - P_M f(d_M(s))||^2\right) ds \leq \sigma_0 e^{c_4 M^{\frac{1}{2}(\delta-1)}t}, \\ &E(t) + \int_0^t \left(\frac{\nu}{2}|u(s)|_1^2 + 2\lambda\gamma|d_M(s)|_2^2\right) ds \leq \left(1 + \frac{4\gamma}{\varepsilon^2}\right)\sigma_0 e^{c_4 M^{\frac{1}{2}(\delta-1)}t}.\end{aligned}$$

Remark 1. The revised result improves the result of Proposition 2.4 in [1] when $n = 2$. We can use the revised Proposition 2.4 to prove directly the existence of a global solution for (2.3) when $n = 2$, and of a local solution for (2.3) when $n = 3$. We can also use the same techniques as in [2] to prove the existence of a global solution for (2.3) when $n = 3$.

Remark 2. There is a similar error in the proof of Theorem 3.1: the estimate (3.20) is not correct. However, we can revise the proof for Theorem 3.1 as above and show that the result of Theorem 3.1 still holds.

AN ADAPTIVE FINITE ELEMENT METHOD WITH PERFECTLY MATCHED ABSORBING LAYERS FOR THE WAVE SCATTERING BY PERIODIC STRUCTURES*

ZHIMING CHEN[†] AND HAIJUN WU[†]

Abstract. We develop a finite element adaptive strategy with error control for the wave scattering by periodic structures. The unbounded computational domain is truncated to a bounded one by an extension of the perfectly matched layer (PML) technique, which attenuates both the outgoing and evanescent waves in the PML region. PML parameters such as the thickness of the layer and the medium property are determined through sharp a posteriori error estimates. Numerical experiments are included to illustrate the competitive behavior of the proposed adaptive method.

1. Introduction.

We consider the prediction of the scattered modes that arise when an electromagnetic wave is incident on some periodic structure. The media are assumed to be nonmagnetic, and the magnetic permeability μ is constant everywhere. Then the electromagnetic fields in the whole space are governed by the following time harmonic (time dependence $e^{-\mathbf{i}\omega t}$) Maxwell equations:

$$\nabla \times \mathbf{E} - \mathbf{i}\omega\mu\mathbf{H} = 0, \tag{1.1}$$

$$\nabla \times \mathbf{H} + \mathbf{i}\omega\varepsilon\mathbf{E} = 0. \tag{1.2}$$

Here $\mathbf{E}$ and $\mathbf{H}$ are the electric and the magnetic field vectors, respectively. The physical structure is described by the dielectric coefficient $\varepsilon(x)$, $x = (x_1, x_2, x_3)$. In this paper we restrict ourselves to the two-dimensional setting (a one-dimensional (1D) grating problem); the medium and the grating surface are assumed to be constant in the x_2 direction. The more complicated biperiodic diffraction (three-dimensional) problems will be considered in a separate work. We assume that the dielectric coefficient $\varepsilon(x) = \varepsilon(x_1, x_3)$ is periodic in the x_1 direction with period $L > 0$:

$$\varepsilon(x_1 + nL, x_3) = \varepsilon(x_1, x_3) \qquad \forall\, x_1, x_3 \in \mathbf{R},\ \ n \text{ integer}.$$

The dielectric coefficient $\varepsilon(x)$ may be complex. We assume $\operatorname{Im}\varepsilon(x) \geq 0$ and $\operatorname{Re}\varepsilon(x) > 0$ whenever $\operatorname{Im}\varepsilon(x) = 0$. It is natural to assume that ε is constant away from a region $\{(x_1, x_3) : b_2 < x_3 < b_1\}$ that includes the structure; that is, there exist constants ε_1 and ε_2 such that

$$\begin{aligned} \varepsilon(x_1, x_3) &= \varepsilon_1 \quad \text{in } \ \Omega_1 = \{(x_1, x_3) : x_3 \geq b_1\}, \\ \varepsilon(x_1, x_3) &= \varepsilon_2 \quad \text{in } \ \Omega_2 = \{(x_1, x_3) : x_3 \leq b_2\}. \end{aligned}$$

In practical applications, we have $\varepsilon_1 > 0$, but ε_2 may be complex according to the substrate material used in Ω_2. Depending on the direction and polarization of the

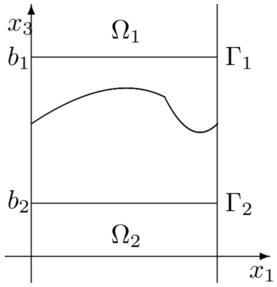

FIG. 1.1. *Geometry of the grating problem.*

incident plane wave, the Maxwell equations can be simplified by considering the two fundamental polarizations: the transverse electric (TE) polarization and the transverse magnetic (TM) polarization. In the TE case, the electric field $\mathbf{E}$ is parallel to the x_2 axis: $\mathbf{E} = (0, u, 0)^T \in \mathbf{R}^3$, where $u = u(x_1, x_3)$ satisfies the Helmholtz equation

$$\Delta u + k^2(x)u = 0 \quad \text{in} \quad \mathbf{R}^2. \tag{1.3}$$

Here $k^2(x) = \omega^2\varepsilon(x)\mu$ is the magnitude of the wave vector. Similarly, in the TM case, the magnetic field $\mathbf{H}$ is parallel to the x_2 axis: $\mathbf{H} = (0, u, 0)^T \in \mathbf{R}^3$, where $u = u(x_1, x_3)$ satisfies the equation

$$\operatorname{div}\left(\frac{1}{k^2(x)}\nabla u\right) + u = 0 \quad \text{in} \quad \mathbf{R}^2. \tag{1.4}$$

Scattering theory in periodic structures, which has many important applications in microoptics, has recently received considerable attention in the applied mathematical community. We refer to Dobson and Friedman [14], Abboud [1], Dobson [13], Bao, Dobson, and Cox [4], Bao [5], and Bao, Cao, and Yang [7] for the existence, uniqueness, and numerical approximations of solutions to grating problems. A good introduction to the problem of electromagnetic diffraction through periodic structures can be found in Petit [19]. More recent review on the diffractive optics technology and its mathematical modeling can be found in Bao, Cowsar, and Masters [6].

The purpose of this paper is to develop efficient numerical methods for solving the 1D grating problem for both the TE (1.3) and the TM (1.4) polarizations. In doing so, the first difficulty is to truncate the domain into a bounded computational domain. The finite element method studied in [4] and [7] is based on variational formulation on the bounded domain Ω, with periodic condition in the x_1 direction and the transparent boundary condition on the top and bottom boundaries Γ_1 and Γ_2 (see Figure 1.1). The transparent boundary condition is obtained by insisting that the solution u of (1.3) or (1.4) be composed of bounded outgoing plane waves in Ω_1 and Ω_2 plus the incident wave u_{I} in Ω_1. The derived transparent boundary condition is represented as a quasi-differential operator and is nonlocal. In practical computations, the infinite series in the definition of the quasi-differential operator must be truncated. The second difficulty is the singularity of the solutions. Usually, the grating surface is piecewise smooth, and across the surface the dielectric coefficient $\varepsilon(x)$ is discontinuous. Thus the solution of (1.4) will have singularities which slow down the finite element convergence when using uniform mesh refinements. Even in the TE case (1.3), when there are lossy materials beneath the grating surface, the transmitted waves decay exponentially. This makes uniform mesh refinements uneconomical.

The purpose of this paper is twofold: First we explore the possibility of applying the recently introduced perfectly matched layer (PML) technique to deal with the first difficulty in truncating the unbounded domain. Second we explore the possibility of using an a posteriori error analysis to design an efficient adaptive method with error control which adaptively determines the finite element meshes and the PML parameters such as the thickness of the PML region and the medium property inside the region. We hope the ideas developed in this paper will be useful for solving other scattering problems on unbounded domains.

A posteriori error estimates are quantities computable in terms of the discrete solution and data, and they measure the actual discrete errors without knowledge of the limit solutions. They are essential in designing algorithms for mesh modifications, which equidistribute the computational effort and optimize the computation. Ever since the pioneering work of Babuška and Rheinboldt [3], the adaptive finite element methods based on a posteriori error estimates have become crucial in scientific and engineering computations. The ability to control error and the asymptotically optimal approximation property (see, e.g., Morin, Nochetto, and Siebert [18], Chen and Dai [10]) make the adaptive finite element method attractive for complicated physical and industrial processes (cf., e.g., Chen and Dai [9], Chen, Nochetto, and Schmidt [11]). For efforts to solve scattering problems using adaptive methods based on a posteriori error estimates, we refer to the recent work of Monk [16] and Monk and Süli [17].

Under the assumption that the exterior solution is composed of outgoing waves only, the basic idea of the PML technique is to surround the computational domain with a finite thickness layer of a specially designed model medium, which would either slow down or attenuate all the waves that propagate from inside the computational domain. Since the work of Berenger [8], which proposed a PML for use with the time dependent Maxwell equations, various constructions of PML absorbing layers have been proposed and studied in the literature. We refer to Turkel and Yefet [22] for a review on various proposed models, and Lassas and Somersalo [15] for the study of mathematical properties of the PML equations. In practical applications involving the PML method, there is a judicial compromise between a thin layer, which requires a rapid variation of the artificial material property, and a thick layer, which requires more grid points and hence more computer time and more storage (see, e.g., Collino and Monk [12]). In this paper, we propose to use an a posteriori error estimate to determine the PML parameters. Moreover, the derived a posteriori error estimate has the nice feature of exponentially decaying in terms of the distance to the computational domain. This property leads to coarse mesh size away from the computational domain and thus makes the total computational cost insensitive to the thickness of the PML absorbing layer.

The layout of the paper is as follows. In section 2 we first recall the transparent boundary condition for 1D grating problems and introduce our PML formulation, which extends the standard PML condition for Helmholtz equations, in that our PML condition attenuates both the outgoing plane waves and the evanescent waves. This extension allows us to reduce the computational domain and thus reduce the computational cost. Existence, uniqueness, and convergence of the PML formulation are considered. In section 3 we introduce the finite element discretization. In section 4 we derive a sharp a posteriori error estimate, which lays down the basis of the adaptive method. In section 5 we present parallel results for the case in which $\operatorname{Im}\varepsilon_2 > 0$. Finally, in section 6 we discuss the implementation of the adaptive method and present several numerical examples to illustrate the competitive behavior of the method.

2. The PML formulation. In this section we shall introduce variational formulations for the 1D grating problem (1.3) and (1.4) using the PML technique, which are suitable for further finite element approximations. As the discussions for the TE polarization and TM polarization are parallel, we shall concentrate on the TE polarization first, and state the corresponding results on the TM polarization without proof. In sections 2–4, we consider the case in which $\operatorname{Im}\varepsilon_2 = 0$, and thus $k_j = \omega\sqrt{\varepsilon_j\mu}$ is real, for $j = 1, 2$. The parallel results for the case in which $\operatorname{Im}\varepsilon_2 > 0$ will be presented in section 5.

2.1. TE polarization. We start by recalling the variational formulation with transparent boundary condition in [4], which is the basis of the analysis in this paper. Let $u_{\mathrm{I}} = e^{\mathbf{i}\alpha x_1 - \mathbf{i}\beta x_3}$ be the incoming plane wave that is incident upon the grating surface from the top, where $\alpha = k_1 \sin\theta, \beta = k_1\cos\theta$, and $-\pi/2 < \theta < \pi/2$ is the incident angle. We are interested in quasi-periodic solutions u, that is, solutions u of (1.3) such that $u_\alpha = ue^{-\mathbf{i}\alpha x_1}$ are periodic in x_1 with period $L > 0$.

Define $\Gamma_j = \{(x_1, x_3) : 0 < x_1 < L, x_3 = b_j\}, j = 1, 2$. We wish to reduce the problem to the bounded domain

$$\Omega = \{(x_1, x_3) : 0 < x_1 < L \text{ and } b_2 < x_3 < b_1\}.$$

The radiation condition for the diffraction problem insists that u is composed of bounded outgoing plane waves in Ω_1 and Ω_2, plus the incident wave u_{I} in Ω_1.

For each integer n, let $\alpha_n = 2\pi n/L$; since u_α is periodic in the x_1 direction with period $L > 0$, it has a Fourier series expansion

$$u_\alpha(x_1, x_3) = \sum_{n\in Z} u_\alpha^{(n)}(x_3)e^{\mathbf{i}\alpha_n x_1}, \qquad u_\alpha^{(n)}(x_3) = \frac{1}{L}\int_0^L u_\alpha e^{-\mathbf{i}\alpha_n x_1}dx_1.$$

Thus we have the expansion

$$u(x_1, x_3) = u_\alpha e^{\mathbf{i}\alpha x_1} = \sum_{n\in Z} u_\alpha^{(n)}(x_3)e^{\mathbf{i}(\alpha_n+\alpha)x_1}. \tag{2.1}$$

Since u satisfies the Helmholtz equation $\Delta u + k_1^2 u = 0$ in Ω_1, we deduce that

$$\sum_{n\in Z}\left[\left(k_1^2 - (\alpha_n+\alpha)^2\right)u_\alpha^{(n)}(x_3) + \frac{d^2}{dx_3^2}u_\alpha^{(n)}(x_3)\right]e^{\mathbf{i}(\alpha_n+\alpha)x_1} = 0,$$

which yields

$$\left(k_1^2 - (\alpha_n+\alpha)^2\right)u_\alpha^{(n)}(x_3) + \frac{d^2}{dx_3^2}u_\alpha^{(n)}(x_3) = 0 \quad \text{for} \quad x_3 \geq b_1. \tag{2.2}$$

For any integer $n \in Z$ and $j = 1, 2$, we define

$$\beta_j^n = \beta_j^n(\alpha) = \begin{cases} \left(k_j^2 - (\alpha_n+\alpha)^2\right)^{1/2} & \text{if } k_j^2 \geq (\alpha_n+\alpha)^2, \\ \mathbf{i}\left((\alpha_n+\alpha)^2 - k_j^2\right)^{1/2} & \text{if } k_j^2 < (\alpha_n+\alpha)^2. \end{cases} \tag{2.3}$$

Note that $\beta_1^0 = \beta$ by definition. We assume that $k_j^2 \neq (\alpha_n+\alpha)^2$ for all $n \in Z, j = 1, 2$. This condition excludes "resonance." All the solutions of the ODE (2.2) can then be written as

$$u_\alpha^{(n)}(x_3) = A_1^n e^{\mathbf{i}\beta_1^n x_3} + B_1^n e^{-\mathbf{i}\beta_1^n x_3},$$

with complex constants A_1^n and B_1^n. The assumption that only bounded outgoing plane waves except $u_{\rm I}$ exist in Ω_1 implies $B_1^n = 0$ for $n \neq 0$. Thus we deduce from (2.1) the following Rayleigh expansion in Ω_1:

$$u = u_{\rm I} + \sum_{n\in Z} A_1^n e^{\mathbf{i}(\alpha_n+\alpha)x_1+\mathbf{i}\beta_1^n x_3}, \qquad x \in \Omega_1. \tag{2.4}$$

Similarly, we have the following Rayleigh expansion in Ω_2:

$$u = \sum_{n\in Z} A_2^n e^{\mathbf{i}(\alpha_n+\alpha)x_1-\mathbf{i}\beta_2^n x_3}, \qquad x \in \Omega_2. \tag{2.5}$$

For any quasi-periodic function f which has the expansion $f = \sum_{n\in Z} f^{(n)}\ e^{\mathbf{i}(\alpha_n+\alpha)x_1}$, the following Dirichlet to Neumann operator T_j is introduced in [4]:

$$(T_j f)(x_1) = \sum_{n\in Z} \mathbf{i}\beta_j^n f^{(n)} e^{\mathbf{i}(\alpha_n+\alpha)x_1}, \quad 0 < x_1 < L\ ,\ j = 1, 2. \tag{2.6}$$

With this notation in mind, simple calculation shows that the Rayleigh expansion u in $\Omega_j, j = 1, 2$, defined in (2.4) and (2.5) satisfies, respectively, the following relations:

$$\frac{\partial(u-u_{\rm I})}{\partial\nu} - T_1(u-u_{\rm I}) = 0 \quad \text{on} \quad \Gamma_1, \qquad \frac{\partial u}{\partial \nu} - T_2 u = 0 \quad \text{on} \quad \Gamma_2, \tag{2.7}$$

where ν stands for the unit outer normal to $\partial\Omega$. These are the transparent boundary conditions used in [4]. To define a variational formulation for the 1D grating problem (1.3) using the boundary conditions (2.7), we first introduce the following subspace of $H^1(\Omega)$, which includes all the quasi-periodic functions:

$$X(\Omega) = \{w \in H^1(\Omega) : w(0, x_3) = e^{-\mathbf{i}\alpha L} w(L, x_3) \ \text{ for } b_2 < x_3 < b_1\}.$$

Define the sesquilinear form $b : X(\Omega) \times X(\Omega) \to \mathbf{C}$ as follows:

$$b(\varphi, \psi) = \int_\Omega \left(\nabla\varphi\nabla\bar\psi - k^2(x)\varphi\bar\psi\right) dx - \sum_{j=1}^{2} \int_{\Gamma_j} (T_j\varphi)\bar\psi dx_1. \tag{2.8}$$

Note that $\frac{\partial u_{\rm I}}{\partial\nu} - T_1 u_{\rm I} = -2\mathbf{i}\beta u_{\rm I}$ on Γ_1; the weak formulation of the 1D grating problem in the TE polarization then reads as follows: Given incoming plane wave $u_{\rm I} = e^{\mathbf{i}\alpha x_1 - \mathbf{i}\beta x_3}$, seek $u \in X(\Omega)$ such that

$$b(u, \psi) = -\int_{\Gamma_1} 2\mathbf{i}\beta u_{\rm I}\bar\psi dx_1 \quad \forall\ \psi \in X(\Omega). \tag{2.9}$$

Recall that $k^2(x) = \omega^2\varepsilon(x)\mu$. The existence of a unique solution u to (2.9) is proved for all but a sequence of countable frequencies ω_j with $|\omega_j| \to +\infty$. Further uniqueness results can be obtained for any frequency ω if the dielectric coefficient $\varepsilon(x)$ has nonzero imaginary part in some subdomains in Ω. In this paper, we shall not elaborate on this issue, and we assume in the following that the variational problem (2.9) has a unique solution. Then the general theory in Babuška and Aziz [2, Chapter 5] implies that there exists a constant $\gamma > 0$ such that the following inf-sup condition holds:

$$\sup_{0\neq\psi\in H^1(\Omega)} \frac{|b(\varphi,\psi)|}{\|\,\psi\,\|_{H^1(\Omega)}} \geq \gamma\ \|\,\varphi\,\|_{H^1(\Omega)} \quad \forall\ \varphi \in X(\Omega). \tag{2.10}$$

Now we turn to the introduction of absorbing PML layers. We surround our computational domain Ω with two PML layers of thickness δ_1 and δ_2 in Ω_1 and Ω_2, respectively. The specially designed model medium in the PML layers should basically be chosen so that either the wave never reaches its external boundary or the amplitude of the reflected wave is so small that it does not essentially contaminate the solution in Ω. Let $s(x_3) = s_1(x_3) + \mathbf{i}s_2(x_3)$ be the model medium property which satisfies

$$s_1, s_2 \in C(\mathbf{R}), \quad s_1 \geq 1, s_2 \geq 0, \quad \text{and } s(x_3) = 1 \text{ for } b_2 \leq x_3 \leq b_1. \tag{2.11}$$

Here we remark that, in contrast to the original PML condition which takes $s_1 \equiv 1$ in the PML region, we allow a variable s_1 in order to attenuate both the outgoing and evanescent waves there. The advantage of this extension makes our method insensitive to the distance of the PML region from the structure. Following the general idea in designing PML absorbing layers, we introduce the PML regions

$$\begin{aligned}\Omega_1^{\mathrm{PML}} &= \{(x_1, x_3) : 0 < x_1 < L \text{ and } b_1 < x_3 < b_1 + \delta_1\},\\ \Omega_2^{\mathrm{PML}} &= \{(x_1, x_3) : 0 < x_1 < L \text{ and } b_2 - \delta_2 < x_3 < b_2\},\end{aligned}$$

and the PML differential operator

$$\mathcal{L} := \frac{\partial}{\partial x_1}\left(s(x_3)\frac{\partial}{\partial x_1}\right) + \frac{\partial}{\partial x_3}\left(\frac{1}{s(x_3)}\frac{\partial}{\partial x_3}\right) + k^2(x)s(x_3).$$

The PML equations in the PML region are

$$\mathcal{L}(\hat{u} - u_{\mathrm{I}}) = 0 \quad \text{in } \Omega_1^{\mathrm{PML}}, \tag{2.12}$$

$$\mathcal{L}\hat{u} = 0 \quad \text{in } \Omega_2^{\mathrm{PML}}. \tag{2.13}$$

The equation satisfied by the PML solution $\hat{u}$ in the domain Ω is the original Helmholtz equation $\Delta\hat{u} + k^2(x)\hat{u} = 0$. Let $D = \{(x_1, x_3) : 0 < x_1 < L, b_2 - \delta_2 < x_3 < b_1 + \delta_1\}$. Due to the assumption (2.11), we can now formulate the PML model which we are going to solve in this paper:

$$\mathcal{L}\hat{u} = -g \quad \text{in} \quad D, \tag{2.14}$$

with the quasi-periodic boundary condition $\hat{u}(0, x_3) = e^{-\mathbf{i}\alpha L}\hat{u}(L, x_3)$ for $b_2 - \delta_2 < x_3 < b_1 + \delta_1$, and the Dirichlet condition $\hat{u} = u_{\mathrm{I}}$ on $\Gamma_1^{\mathrm{PML}} = \{(x_1, x_3) : 0 < x_1 < L, x_3 = b_1 + \delta_1\}$, $\hat{u} = 0$ on $\Gamma_2^{\mathrm{PML}} = \{(x_1, x_3) : 0 < x_1 < L, x_3 = b_2 - \delta_2\}$. Here the source function is

$$g = \begin{cases} -\mathcal{L}u_{\mathrm{I}} & \text{in } \Omega_1^{\mathrm{PML}},\\ 0 & \text{elsewhere.}\end{cases}$$

For any $G \subset D$, define

$$X(G) = \{w \in H^1(G) : w_\alpha = we^{-\mathbf{i}\alpha x_1} \text{ is periodic in } x_1 \text{ with period } L\},$$

and introduce the sesquilinear form $a_G : X(G) \times X(G) \to \mathbf{C}$ as

$$a_G(\varphi, \psi) = \int_G \left(s(x_3)\frac{\partial\varphi}{\partial x_1}\frac{\partial\bar{\psi}}{\partial x_1} + \frac{1}{s(x_3)}\frac{\partial\varphi}{\partial x_3}\frac{\partial\bar{\psi}}{\partial x_3} - k^2(x)s(x_3)\varphi\bar{\psi}\right)dx.$$

Define $\overset{\circ}{X}(D) = \{w \in X(D), w = 0 \text{ on } \Gamma_1^{\mathrm{PML}} \cup \Gamma_2^{\mathrm{PML}}\}$. Then the weak formulation of the PML model reads as follows: Find $\hat{u} \in X(D)$ such that $\hat{u} = u_{\mathrm{I}}$ on $\Gamma_1^{\mathrm{PML}}, \hat{u} = 0$ on Γ_2^{PML}, and

$$a_{D}(\hat{u}, \psi) = \int_D g\bar{\psi}dx \qquad \forall\, \psi \in \overset{\circ}{X}(D). \tag{2.15}$$

Our next objective is to prove the existence and uniqueness of the above problem and derive an error estimate between $\hat{u}$ and u, the solution of the original 1D grating problem (2.9). To achieve the goal, we first find an equivalent formulation of (2.15) in the domain Ω. Similar to the argument leading to the Rayleigh expansion (2.4), we deduce from (2.12) that

$$\hat{u} = u_{\mathrm{I}} + \sum_{n \in Z} \left(A_1^n e^{\mathbf{i}\beta_1^n \int_{b_1}^{x_3} s(\tau)d\tau} + B_1^n e^{-\mathbf{i}\beta_1^n \int_{b_1}^{x_3} s(\tau)d\tau} \right) e^{\mathbf{i}(\alpha_n+\alpha)x_1} \quad \text{in } \Omega_1^{\mathrm{PML}}. \tag{2.16}$$

If we write $\hat{u}(x_1, b_1) = u_{\mathrm{I}}(x_1, b_1) + \sum_{n\in Z} \hat{u}_{\alpha}^{(n)}(b_1)e^{\mathbf{i}(\alpha_n+\alpha)x_1}$ on Γ_1, then the constants A_1^n, B_1^n can be uniquely determined by the additional boundary condition $\hat{u} = u_{\mathrm{I}}$ on Γ_1^{PML} through following equations:

$$\begin{aligned} &A_1^n + B_1^n = \hat{u}_{\alpha}^n(b_1), \\ &A_1^n e^{\mathbf{i}\beta_1^n \int_{b_1}^{b_1+\delta_1} s(\tau)d\tau} + B_1^n e^{-\mathbf{i}\beta_1^n \int_{b_1}^{b_1+\delta_1} s(\tau)d\tau} = 0. \end{aligned}$$

Thus we conclude from (2.16) that

$$\hat{u} = u_{\mathrm{I}} + \sum_{n\in Z} \frac{\zeta_1^n(x_3)}{\zeta_1^n(b_1)} \hat{u}_{\alpha}^{(n)}(b_1) e^{\mathbf{i}(\alpha_n+\alpha)x_1} \quad \text{in} \quad \Omega_1^{\mathrm{PML}}, \tag{2.17}$$

where $\zeta_1^n(x_3) = e^{-\mathbf{i}\beta_1^n \int_{x_3}^{b_1+\delta_1} s(\tau)d\tau} - e^{\mathbf{i}\beta_1^n \int_{x_3}^{b_1+\delta_1} s(\tau)d\tau}$. Similarly, we deduce from (2.13) that

$$\hat{u} = \sum_{n\in Z} \frac{\zeta_2^n(x_3)}{\zeta_2^n(b_2)} \hat{u}_{\alpha}^{(n)}(b_2) e^{\mathbf{i}(\alpha_n+\alpha)x_1} \quad \text{in} \quad \Omega_2^{\mathrm{PML}}, \tag{2.18}$$

where $\zeta_2^n(x_3) = e^{-\mathbf{i}\beta_2^n \int_{b_2-\delta_2}^{x_3} s(\tau)d\tau} - e^{\mathbf{i}\beta_2^n \int_{b_2-\delta_2}^{x_3} s(\tau)d\tau}$. Similar to (2.6), for any quasi-periodic function f which has the expansion $f = \sum_{n\in Z} f^{(n)}e^{\mathbf{i}(\alpha_n+\alpha)x_1}$, we define the following Dirichlet to Neumann operator T_j^{PML}:

$$\left(T_j^{\mathrm{PML}} f\right)(x_1) = \sum_{n\in Z} \mathbf{i}\beta_j^n \coth(-\mathbf{i}\beta_j^n \sigma_j) f^{(n)} e^{\mathbf{i}(\alpha_n+\alpha)x_1}, \tag{2.19}$$

where $\coth(\tau) = \frac{e^{\tau}+e^{-\tau}}{e^{\tau}-e^{-\tau}}$ and

$$\sigma_1 = \int_{b_1}^{b_1+\delta_1} s(\tau)d\tau, \qquad \sigma_2 = \int_{b_2-\delta_2}^{b_2} s(\tau)d\tau. \tag{2.20}$$

Then we know easily from (2.17), (2.18) that

$$\frac{\partial(\hat{u} - u_{\mathrm{I}})}{\partial\nu} - T_1^{\mathrm{PML}}(\hat{u} - u_{\mathrm{I}}) = 0 \quad \text{on} \quad \Gamma_1, \qquad \frac{\partial \hat{u}}{\partial \nu} - T_2^{\mathrm{PML}}\hat{u} = 0 \quad \text{on} \quad \Gamma_2. \tag{2.21}$$

This motivates us to introduce the sesquilinear form $b^{\text{PML}} : X(\Omega) \times X(\Omega) \to \mathbf{C}$,

$$b^{\text{PML}}(\varphi, \psi) = \int_\Omega (\nabla\varphi\nabla\bar{\psi} - k^2(x)\varphi\bar{\psi})dx - \sum_{j=1}^{2}\int_{\Gamma_j}(T_j^{\text{PML}}\varphi)\bar{\psi}dx_1, \tag{2.22}$$

and introduce the following variational problem: Find $\vartheta \in X(\Omega)$ such that

$$b^{\text{PML}}(\vartheta, \psi) = -\int_{\Gamma_1} \mathbf{i}\beta(1 + \coth(-\mathbf{i}\beta\sigma_1))u_{\text{I}}\bar{\psi}dx_1 \qquad \forall\, \psi \in X(\Omega), \tag{2.23}$$

where we have used the fact that $\frac{\partial u_{\text{I}}}{\partial \nu} - T_1^{\text{PML}}u_{\text{I}} = -\mathbf{i}\beta(1 + \coth(-\mathbf{i}\beta\sigma_1))u_{\text{I}}$ on Γ_1. The following lemma establishes the relation of this variational problem to the PML model problem (2.15).

Lemma 2.1. *Any solution $\hat{u}$ of the problem* (2.15) *restricted to Ω is a solution of* (2.23)*. Conversely, any solution ϑ of the problem* (2.23) *can be uniquely extended to the whole domain D to be a solution of* (2.15)*.*

Proof. This proof is standard based on the constructions given in (2.17) and (2.18). We omit the details. □

Let $\Delta_j^n = |k_j^2 - (\alpha_n + \alpha)^2|^{1/2}$ and $U_j = \{n : k_j^2 > (\alpha_n + \alpha)^2\}$, $j = 1, 2$. Then we have $\beta_j^n = \Delta_j^n$ for $n \in U_j$, and $\beta_j^n = \mathbf{i}\Delta_j^n$ for $n \notin U_j$. Let

$$\Delta_j^- = \min\{\Delta_j^n : n \in U_j\}, \qquad \Delta_j^+ = \min\{\Delta_j^n : n \notin U_j\}. \tag{2.24}$$

The following lemma plays a key role in the subsequent analysis.

Lemma 2.2. *For any $\varphi, \psi \in X(\Omega)$, we have*

$$\left|\int_{\Gamma_j}(T_j\varphi - T_j^{\text{PML}}\varphi)\bar{\psi}dx_1\right| \le M_j\|\,\varphi\,\|_{L^2(\Gamma_j)}\|\,\psi\,\|_{L^2(\Gamma_j)},$$

where

$$M_j = \max\left(\frac{2\Delta_j^-}{e^{2\sigma_j^I\Delta_j^-} - 1}, \frac{2\Delta_j^+}{e^{2\sigma_j^R\Delta_j^+} - 1}\right)$$

and σ_j^R, σ_j^I are the real and imaginary parts of σ_j defined in (2.20)*, that is, $\sigma_j = \sigma_j^R + \mathbf{i}\sigma_j^I$.*

Proof. For any $\varphi, \psi \in X(\Omega)$, their traces on Γ_j have the following expansions:

$$\varphi(x_1, b_j) = \sum_{n\in Z}\varphi_\alpha^{(n)}(b_j)e^{\mathbf{i}(\alpha_n+\alpha)x_1}, \qquad \psi(x_1, b_j) = \sum_{n\in Z}\psi_\alpha^{(n)}(b_j)e^{\mathbf{i}(\alpha_n+\alpha)x_1}.$$

The $\varphi_\alpha^{(n)}$ and $\psi_\alpha^{(n)}$ are the Fourier coefficients of periodic functions $\varphi_\alpha(x_1, b_j) = \varphi(x_1, b_j)e^{-\mathbf{i}\alpha x_1}$ and $\psi_\alpha(x_1, b_j) = \psi(x_1, b_j)e^{-\mathbf{i}\alpha x_1}$. The orthogonality property of Fourier series yields

$$\|\varphi\|^2_{L^2(\Gamma_j)} = \|\varphi_\alpha\|^2_{L^2(\Gamma_j)} = L\sum_{n\in Z}|\varphi_\alpha^{(n)}(b_j)|^2,$$

$$\|\psi\|^2_{L^2(\Gamma_j)} = \|\psi_\alpha\|^2_{L^2(\Gamma_j)} = L\sum_{n\in Z}|\psi_\alpha^{(n)}(b_j)|^2.$$

By the orthogonality of Fourier series, we also have

$$(2.25)\qquad \int_{\Gamma_j}(T_j\varphi - T_j^{\mathrm{PML}}\varphi)\bar{\psi}dx = L\sum_{n\in Z}\mathbf{i}\beta_j^n(1-\coth(-\mathbf{i}\beta_j^n\sigma_j))\varphi_\alpha^{(n)}(b_j)\bar{\psi}_\alpha^{(n)}(b_j).$$

For $n\in U_j$, we have $\beta_j^n = \Delta_j^n > 0$; thus

$$\begin{aligned}|\mathbf{i}\beta_j^n(1-\coth(-\mathbf{i}\beta_j^n\sigma_j))| &= \left|\frac{2\beta_j^n}{1-e^{-2\mathbf{i}\beta_j^n\sigma_j}}\right| = \frac{2\Delta_j^n}{|e^{2\mathbf{i}\Delta_j^n\sigma_j^R} - e^{2\Delta_j^n\sigma_j^I}|}\\ &\le \frac{2\Delta_j^n}{e^{2\Delta_j^n\sigma_j^I}-1} \le \frac{2\Delta_j^-}{e^{2\Delta_j^-\sigma_j^I}-1} \le M_j,\end{aligned}$$

where we have used the facts that $\Delta_j^n \ge \Delta_j^-$ for $n\in U_j$ and that the function $\xi(\tau) = 2\tau/(e^{2\tau}-1)$ is decreasing for $\tau > 0$. A similar argument shows that, for $n\notin U_j$,

$$\left|\mathbf{i}\beta_j^n(1-\coth(-\mathbf{i}\beta_j^n\sigma_j))\right| \le \frac{2\Delta_j^+}{e^{2\Delta_j^+\sigma_j^R}-1} \le M_j.$$

This completes the proof upon using the Cauchy inequality in (2.25). □

Now let us take a closer look at the structure of constant M_j, which controls the modeling error of the PML equation towards the original 1D grating problem (see Theorems 2.4 and 2.5 below). Once the incoming plane wave $u_{\mathrm{I}} = e^{\mathbf{i}\alpha x_1 - \mathbf{i}\beta x_3}$ is fixed, the numbers Δ_j^-, Δ_j^+ are fixed according to (2.24). Thus the constant M_j approaches zero exponentially as the PML parameters σ_j^R, σ_j^I tend to infinity. From the definition (2.20) we know that σ_j^R, σ_j^I can be calculated by the medium property $s(x_3)$, which is usually taken as a power function:

$$s(x_3) = \begin{cases} 1+\sigma_1^m\Big(\dfrac{x_3-b_1}{\delta_1}\Big)^m & \text{if } x_3\ge b_1,\\ 1+\sigma_2^m\Big(\dfrac{b_2-x_3}{\delta_2}\Big)^m & \text{if } x_3\le b_2,\end{cases}\qquad m\ge 1.$$

Thus we have

$$(2.26)\qquad \sigma_j^R = \left(1+\frac{\operatorname{Re}\sigma_j^m}{m+1}\right)\delta_j,\qquad \sigma_j^I = \frac{\operatorname{Im}\sigma_j^m}{m+1}\,\delta_j.$$

It is obvious that either enlarging the thickness δ_j of the PML layers or enlarging the medium parameters $\operatorname{Re}\sigma_j^m$ and $\operatorname{Im}\sigma_j^m$ will reduce the PML approximation error.

LEMMA 2.3. *For any $\psi\in X(\Omega)$, we have*

$$\|\,\psi\,\|_{L^2(\Gamma_j)} \le \|\,\psi\,\|_{H^{1/2}(\Gamma_j)} \le \hat{C}\|\,\psi\,\|_{H^1(\Omega)},$$

with $\hat{C} = \sqrt{1+(b_2-b_1)^{-1}}$. Here if $\psi(x_1,b_j) = \sum_{n\in Z}\psi_\alpha^{(n)}(b_j)e^{\mathbf{i}(\alpha_n+\alpha)x_1}$ on Γ_j,

$$\|\,\psi\,\|_{H^{1/2}(\Gamma_j)} = \left(L\sum_{n\in Z}(1+|\alpha_n+\alpha|^2)^{1/2}|\psi_\alpha^{(n)}(b_j)|^2\right)^{1/2}.$$

Proof. Since $\psi\in X(\Omega)$, we have the expansion

$$\psi(x_1,x_3) = \sum_{n\in Z}\psi_\alpha^{(n)}(x_3)e^{\mathbf{i}(\alpha_n+\alpha)x_1}\quad\text{in}\quad\Omega.$$

Thus

$$\|\psi\|^2_{H^1(\Omega)} = L\sum_{n\in Z}\int_{b_2}^{b_1}\left((1+|\alpha_n+\alpha|^2)|\psi_\alpha^{(n)}(x_3)|^2 + \left|\frac{d}{dx_3}\psi_\alpha^{(n)}(x_3)\right|^2\right)dx_3.$$

Now the proof follows from the identity

$$|\psi_\alpha^{(n)}(b_j)|^2 = |\psi_\alpha^{(n)}(x_3)|^2 + \int_{b_j}^{x_3}\frac{d}{dx_3}|\psi_\alpha^{(n)}(\tau)|^2 d\tau, \quad b_2 \le x_3 \le b_1,$$

and the Cauchy inequality. This completes the proof. □

THEOREM 2.4. *Let $\gamma > 0$ be the constant in the* inf-sup *condition* (2.10) *and* $(M_1 + M_2)\hat{C}^2 < \gamma$. *Then the PML variational problem has a unique solution* $\hat{u}$. *Moreover, we have the following error estimate:*

$$\begin{aligned} |\!|\!|u-\hat{u}|\!|\!|_\Omega &:= \sup_{0\ne\psi\in H^1(\Omega)}\frac{|b(u-\hat{u},\psi)|}{\|\,\psi\,\|_{H^1(\Omega)}} \\ &\le \hat{C}M_1\|\,\hat{u}-u_{\rm I}\,\|_{L^2(\Gamma_1)} + \hat{C}M_2\|\,\hat{u}\,\|_{L^2(\Gamma_2)}. \end{aligned} \tag{2.27}$$

Proof. By Lemma 2.1 we need to show only that the variational problem (2.23) has a unique solution. We resort to the general existence and uniqueness result for sesquilinear forms in [2, Chapter 5]. The key point is to show the inf-sup condition for the sesquilinear form $b^{\rm PML} : X(\Omega)\times X(\Omega)\to \mathbf{C}$ defined in (2.22). Thanks to Lemmas 2.2 and 2.3 and the assumption $(M_1+M_2)\hat{C}^2 < \gamma$, this is now obvious:

$$\begin{aligned} |b^{\rm PML}(\varphi,\psi)| &\ge |b(\varphi,\psi)| - \sum_{j=1}^2\left|\int_{\Gamma_j}(T_j\varphi - T_j^{\rm PML}\varphi)\bar\psi dx_1\right| \\ &\ge |b(\varphi,\psi)| - (M_1+M_2)\hat{C}^2\|\,\varphi\,\|_{H^1(\Omega)}\|\,\psi\,\|_{H^1(\Omega)} \qquad \forall\varphi,\psi\in X(\Omega). \end{aligned}$$

It remains to prove the estimate (2.27). By (2.8), (2.9), (2.22), (2.23), and Lemma 2.1 we conclude that

$$\begin{aligned} b(u-\hat{u},\psi) &= -\int_{\Gamma_1}2\mathbf{i}\beta u_{\rm I}\bar\psi dx_1 + \int_{\Gamma_1}\mathbf{i}\beta(1+\coth(-\mathbf{i}\beta\sigma_1))u_{\rm I}\bar\psi dx_1 \\ &\qquad + b^{\rm PML}(\hat{u},\psi) - b(\hat{u},\psi) \\ &= \int_{\Gamma_1}(T_1 - T_1^{\rm PML})(\hat{u}-u_{\rm I})\bar\psi dx_1 \\ &\qquad + \int_{\Gamma_2}(T_2 - T_2^{\rm PML})\hat{u}\bar\psi dx_1 \qquad \forall\psi\in X(\Omega). \end{aligned} \tag{2.28}$$

This completes the proof of the theorem upon using Lemmas 2.2 and 2.3. □

To conclude, we remark that the error estimate (2.27) is a posteriori in nature as it depends on the PML solution $\hat{u}$. This makes a posteriori error control possible (see section 3 for details).

2.2. TM polarization. In this subsection we state the parallel results for the grating problem (1.4). First we introduce the sesquilinear form $b_{\rm TM} : X(\Omega)\times X(\Omega)\to \mathbf{C}$ as follows:

$$b_{\rm TM}(\varphi,\psi) = \int_\Omega\left(\frac{1}{k^2(x)}\nabla\varphi\nabla\bar\psi - \varphi\bar\psi\right)dx - \sum_{j=1}^2\int_{\Gamma_j}\frac{1}{k_j^2}(T_j\varphi)\bar\psi dx_1. \tag{2.29}$$

The variational form for the 1D grating problem in the TM polarization then reads as follows: Given incoming plane wave $u_{\rm I} = e^{\mathbf{i}\alpha x_1 - \mathbf{i}\beta x_3}$, seek $u^{\rm TM} \in X(\Omega)$ such that

$$b_{\rm TM}(u^{\rm TM}, \psi) = -\int_{\Gamma_1} \frac{2\mathbf{i}\beta}{k_1^2} u_{\rm I}\bar{\psi}dx_1 \qquad \forall\, \psi \in X(\Omega). \tag{2.30}$$

We again assume the above variational problem has a unique solution, and thus there exists a constant $\gamma_{\rm TM} > 0$ such that

$$\sup_{0\neq\psi\in H^1(\Omega)} \frac{|b_{\rm TM}(\varphi,\psi)|}{\|\,\psi\,\|_{H^1(\Omega)}} \geq \gamma_{\rm TM}\|\,\varphi\,\|_{H^1(\Omega)} \qquad \forall\, \varphi \in X(\Omega). \tag{2.31}$$

The sesquilinear form $a_{\rm TM} : X(D) \times X(D) \to \mathbf{C}$ associated with the PML problem is

$$a_{\rm TM}(\varphi,\psi) = \int_\Omega \left(\frac{1}{k^2(x)} s(x_3) \frac{\partial\varphi}{\partial x_1}\frac{\partial\bar{\psi}}{\partial x_1} + \frac{1}{k^2(x)}\frac{1}{s(x_3)}\frac{\partial\varphi}{\partial x_3}\frac{\partial\bar{\psi}}{\partial x_3} - s(x_3)\varphi\bar{\psi} \right) dx,$$

and the weak formulation of the PML problem reads as the following: Find $\hat{u}^{\rm TM} \in X(D)$ such that $\hat{u}^{\rm TM} = u_{\rm I}$ on $\Gamma_1^{\rm PML}$, $\hat{u}^{\rm TM} = 0$ on $\Gamma_2^{\rm PML}$, and

$$a_{\rm TM}(\hat{u}^{\rm TM}, \psi) = \int_D g_{\rm TM}\bar{\psi}dx \quad \forall\, \psi \in \overset{\circ}{X}(D), \tag{2.32}$$

where $g_{\rm TM} = g/k_1^2$. The following theorem is an analogue of Theorem 2.4.

THEOREM 2.5. *Assume that* $\sum_{j=1}^2 M_j\hat{C}^2/k_j^2 < \gamma_{\rm TM}$. *Then the PML variational problem* (2.32) *has a unique solution* $\hat{u}^{\rm TM}$. *Moreover, we have the following error estimate:*

$$\begin{aligned} |||u^{\rm TM} - \hat{u}^{\rm TM}|||_\Omega^{\rm TM} &= \sup_{0\neq\psi\in H^1(\Omega)} \frac{|b_{\rm TM}(u^{\rm TM} - \hat{u}^{\rm TM}, \psi)|}{\|\,\psi\,\|_{H^1(\Omega)}} \\ &\leq \left(\frac{M_1\hat{C}}{k_1^2}\right)\|\,\hat{u}^{\rm TM} - u_{\rm I}\,\|_{L^2(\Gamma_1)} + \left(\frac{M_2\hat{C}}{k_2^2}\right)\|\,\hat{u}^{\rm TM}\,\|_{L^2(\Gamma_2)}. \end{aligned}$$

3. The discrete problem.

In this section we introduce the finite element approximations of the PML problems (2.15) and (2.32). Let $\mathcal{M}_h$ be a regular triangulation of the domain D. Remember that any triangle $T \in \mathcal{M}_h$ is considered as closed. We assume that any element T must be completely included in $\overline{\Omega_1^{\rm PML}}$, $\overline{\Omega_2^{\rm PML}}$, or $\overline{\Omega}$. To define a finite element space whose functions are quasi-periodic in the x_1 direction, we also require that if $(0, z)$ is a node on the left boundary, then (L, z) also be a node on the right boundary, and vice versa. Let $V_h(D) \subset X(D)$ be the conforming linear finite element space and $\overset{\circ}{V}_h(D) = V_h(D) \bigcap \overset{\circ}{X}(D)$. Denote by $I_h : C(\bar{D}) \to V_h(D)$ the standard finite element interpolation operator.

The finite element approximation to the PML problem (2.15) reads as follows: Find $\hat{u}_h \in V_h(D)$ such that $\hat{u}_h = I_h u_{\rm I}$ on $\Gamma_1^{\rm PML}$, $\hat{u}_h = 0$ on $\Gamma_2^{\rm PML}$, and

$$a_D(\hat{u}_h, \psi_h) = \int_D g\bar{\psi}_h dx \qquad \forall\, \psi_h \in \overset{\circ}{V}_h(D). \tag{3.1}$$

Following the general theory in [2, Chapter 5], the existence of a unique solution of the discrete problem (3.1) and the finite element convergence analysis depend on the following discrete inf-sup condition:

$$\sup_{0\neq\psi_h\in\overset{\circ}{V}_h(D)} \frac{|a_D(\varphi_h,\psi_h)|}{\|\,\psi_h\,\|_{H^1(D)}} \geq \gamma_D\ \|\,\varphi_h\,\|_{H^1(D)} \quad \forall\, \varphi_h \in \overset{\circ}{V}_h(D), \tag{3.2}$$

where the constant $\gamma_{_D} > 0$ is independent of the finite element mesh size. Since the continuous problem (2.15) has a unique solution by Theorem 2.4, the sesquilinear form $a_{_D} : X(D) \times X(D) \to \mathbf{C}$ satisfies the continuous inf-sup condition. Then a general argument of Schatz [20] implies that (3.2) is valid for sufficiently small mesh size $h < h^*$. Based on (3.2), an appropriate a priori error estimate can also be derived that depends on the regularity of the PML solution $\hat{u}$. In this paper, we are interested in a posteriori error estimates and the associated adaptive algorithm. Thus in the following we simply assume that the discrete problem (3.1) has a unique solution $\hat{u}_h \in V_h(D)$.

Let

$$A(x) = \begin{pmatrix} A_{11} & 0 \\ 0 & A_{22} \end{pmatrix} = \begin{pmatrix} s(x_3) & 0 \\ 0 & 1/s(x_3) \end{pmatrix}, \qquad B(x) = k^2(x)s(x_3).$$

Then the definitions of $\mathcal{L}$ and $a_{_D}$ can be rewritten as

$$\mathcal{L} = \text{div}\ (A(x)\nabla) + B(x),$$
$$a_{_D}(\varphi, \psi) = \int_D \left(A(x)\nabla\varphi\nabla\bar{\psi} - B(x)\varphi\bar{\psi}\right) dx.$$

For any $T \in \mathcal{M}_h$, we denote by h_T its diameter. Let $\mathcal{B}_h$ denote the set of all sides that do not lie on Γ_j^{PML}, $j = 1, 2$. For any $e \in \mathcal{B}_h$, h_e stands for its length. For any $T \in \mathcal{M}_h$, we introduce the residual

$$R_T := \mathcal{L}\hat{u}_h|_T + g|_T = \begin{cases} \mathcal{L}(\hat{u}_h|_T - u_{\text{I}}|_T) & \text{if } T \subset \overline{\Omega_1^{\text{PML}}}, \\ \mathcal{L}\hat{u}_h|_T & \text{otherwise.} \end{cases} \tag{3.3}$$

For any interior side $e \in \mathcal{B}_h$ which is the common side of T_1 and $T_2 \in \mathcal{M}_h$, we define the jump residual across e as

$$J_e = (A\nabla\hat{u}_h|_{T_1} - A\nabla\hat{u}_h|_{T_2}) \cdot \nu_e, \tag{3.4}$$

using the convention that the unit normal vector ν_e to e points from T_2 to T_1. Define $\Gamma_{\text{left}} = \{(x_1, x_3) : x_1 = 0, b_2 - \delta_2 < x_3 < b_1 + \delta_1\}$ and $\Gamma_{\text{right}} = \{(x_1, x_3) : x_1 = L, b_2 - \delta_2 < x_3 < b_1 + \delta_1\}$. If $e = \Gamma_{\text{left}} \cap \partial T$ for some element $T \in \mathcal{M}_h$ and e' the corresponding side on Γ_{right} which is also a side of some element T', then we define the jump residual as

$$\begin{aligned} J_e &= A_{11}\left[\frac{\partial}{\partial x_1}(\hat{u}_h|_T) - e^{-\mathbf{i}\alpha L} \cdot \frac{\partial}{\partial x_1}(\hat{u}_h|_{T'})\right], \\ J_{e'} &= A_{11}\left[e^{\mathbf{i}\alpha L} \cdot \frac{\partial}{\partial x_1}(\hat{u}_h|_T) - \frac{\partial}{\partial x_1}(\hat{u}_h|_{T'})\right]. \end{aligned} \tag{3.5}$$

For any $T \in \mathcal{M}_h$, denote by $\eta_{_T}$ the local error estimator, which is defined as follows:

$$\eta_{_T} = \max_{x \in \tilde{T}} \rho(x_3) \cdot \left[h_T\|R_T\|_{L^2(T)} + \left(\frac{1}{2}\sum_{e \subset T} h_e\|\, J_e \,\|_{L^2(e)}^2\right)^{1/2}\right], \tag{3.6}$$

where $\tilde{T}$ is the union of all elements having nonempty intersection with T and

$$\rho(x_3) = \begin{cases} |s(x_3)|e^{-R_j(x_3)} & \text{if } x \in \overline{\Omega_j^{\text{PML}}}, \\ 1 & \text{if } x \in \Omega, \end{cases}$$

with $R_j(x_3)$, $j=1,2$, being defined in (4.5)–(4.6) below.

The following theorem is the main result in this paper.

THEOREM 3.1. *There exists a constant $C>0$, depending only on the minimum angle of the mesh $\mathcal{M}_h$, such that the following a posteriori error estimate is valid:*

$$|||u-\hat{u}_h|||_\Omega \le \hat{C}M_1\|\hat{u}_h-u_{\rm I}\|_{L^2(\Gamma_1)}+\hat{C}M_2\|\hat{u}_h\|_{L^2(\Gamma_2)} + \hat{C}M_3\|\, I_h u_{\rm I}-u_{\rm I}\,\|_{L^2(\Gamma_1^{\rm PML})}+C(1+C_1+C_2)\left(\sum_{T\in\mathcal{M}_h}\eta_T^2\right)^{1/2},$$

where the constants $M_j (j=1,2)$, $\hat{C}$, C_j, and M_3 are defined in Lemmas 2.2, 2.3, 4.3, *and* 4.4, *respectively.*

The proof of this theorem will be given in section 4. We notice that when the PML parameters σ_j^R and σ_j^I tend to infinity, the constants M_j decay exponentially and the constants C_j remain bounded. The important exponential decay factors $e^{-R_j(x_3)}$ in the PML region $\Omega_j^{\rm PML}$ allow us to take thicker PML layers without introducing unnecessary fine meshes away from the computational domain. Recall that thicker PML layers allow a smaller PML medium property, which enhances numerical stability.

To conclude this section, we state the parallel results for the TM polarization. The finite element approximation to the TM polarization problem (2.32) reads as follows: Find $\hat{u}_h^{\rm TM}\in V_h(D)$ such that $\hat{u}_h^{\rm TM}=I_h u_{\rm I}$ on $\Gamma_1^{\rm PML}$, $\hat{u}_h^{\rm TM}=0$ on $\Gamma_2^{\rm PML}$, and

$$a_{\rm TM}(\hat{u}_h^{\rm TM},\psi_h)=\int_D g_{\rm TM}\bar{\psi}_h dx \quad \forall\, \psi_h\in \overset{\circ}{V}_h(D). \tag{3.7}$$

Let $A_{\rm TM}(x)=A(x)/k^2(x)$, $B_{\rm TM}(x)=B(x)/k^2(x)$, and $\mathcal{L}_{\rm TM}={\rm div}\,(A_{\rm TM}(x)\nabla)+B_{\rm TM}(x)$. Then we have the following theorem, parallel to Theorem 3.1, whose proof is omitted.

THEOREM 3.2. *There exists a constant $C>0$, depending only on the minimum angle of the mesh $\mathcal{M}_h$, such that the following a posteriori error estimate is valid:*

$$|||u^{\rm TM}-\hat{u}_h^{\rm TM}|||_\Omega^{\rm TM} \le \left(\frac{\hat{C}M_1}{k_1^2}\right)\|\hat{u}_h^{\rm TM}-u_{\rm I}\|_{L^2(\Gamma_1)}+\left(\frac{\hat{C}M_2}{k_2^2}\right)\|\hat{u}_h^{\rm TM}\|_{L^2(\Gamma_2)} + \left(\frac{\hat{C}M_3}{k_1^2}\right)\|\, I_h u_{\rm I}-u_{\rm I}\,\|_{L^2(\Gamma_1^{\rm PML})}+C(1+C_1+C_2)\left(\sum_{T\in\mathcal{M}_h}\eta_T^2\right)^{1/2},$$

where the constants $M_j(j=1,2)$, $\hat{C}$, C_j, and M_3 are defined in Lemmas 2.2, 2.3, 4.3, *and* 4.4, *respectively. Here η_T is defined as in* (3.6), *with $A,\mathcal{L},g$, and $\hat{u}_h$ being replaced by $A_{\rm TM},\mathcal{L}_{\rm TM},g_{\rm TM}$, and $\hat{u}_h^{\rm TM}$, respectively.*

4. A posteriori error analysis.

In this section we prove the a posteriori error estimates in Theorem 3.1.

4.1. Error representation formula.

For any $\psi\in X(\Omega)$, we extend it to be a function in $X(D)$ denoted by $\tilde{\psi}$ as follows:

$$\tilde{\psi}(x_1,x_3)=\sum_{n\in Z}\frac{\bar{\zeta}_j^n(x_3)}{\bar{\zeta}_j^n(b_j)}\psi_\alpha^{(n)}(b_j)e^{\mathbf{i}(\alpha_n+\alpha)x_1} \qquad \text{in } \Omega_j^{\rm PML},\ j=1,2, \tag{4.1}$$

where $\zeta_j^n(x_3)$ are defined in (2.17) and (2.18), and $\psi_\alpha^{(n)}(b_j)$ are the Fourier coefficients of the function $\psi_\alpha = \psi e^{-\mathbf{i}\alpha x_1}$ on Γ_j; that is,

$$\psi(x_1, b_j) = \sum_{n\in Z} \psi_\alpha^{(n)}(b_j) e^{\mathbf{i}(\alpha_n+\alpha)x_1}. \tag{4.2}$$

It is easy to see that $\tilde{\psi} = \psi$ on Γ_j and $\mathcal{L}\bar{\tilde{\psi}} = 0$ in $\Omega_j^{\rm PML}$.

Lemma 4.1. *Let ν_j be the unit outer normal to $\Omega_j^{\rm PML}$. Then for any $\varphi, \psi \in X(\Omega)$ we have*

$$\int_{\Gamma_j} T_j^{\rm PML}\varphi\bar{\psi}dx_1 = -\int_{\Gamma_j}\varphi\frac{\partial\bar{\tilde{\psi}}}{\partial\nu_j}dx_1. \tag{4.3}$$

Proof. Define

$$\varphi(x_1, b_j) = \sum_{n\in Z}\varphi_\alpha^{(n)}(b_j)e^{\mathbf{i}(\alpha_n+\alpha)x_1}.$$

Then, by the definition of $T_j^{\rm PML}$ in (2.19) and the orthogonality property of Fourier series, we have

$$\int_{\Gamma_j} T_j^{\rm PML}\varphi\bar{\psi}dx_j = L\sum_{n\in Z}\mathbf{i}\beta_j^n\coth(-\mathbf{i}\beta_j^n\sigma_j)\varphi_\alpha^{(n)}(b_j)\bar{\psi}_\alpha^{(n)}(b_j).$$

On the other hand, by direct calculation from (4.1), we have

$$\begin{aligned}
-\int_{\Gamma_j}\varphi\frac{\partial\bar{\tilde{\psi}}}{\partial\nu_j}dx_1 &= (-1)^{j-1}\int_{\Gamma_j}\varphi\frac{\partial\bar{\tilde{\psi}}}{\partial x_3}dx_1\\
&= (-1)^{j-1}L\sum_{n\in Z}\frac{d}{dx_3}\left(\frac{\zeta_j^n(x_3)}{\zeta_j^n(b_j)}\right)\Bigg|_{x_3=b_j}\varphi_\alpha^{(n)}(b_j)\bar{\psi}_\alpha^{(n)}(b_j)\\
&= L\sum_{n\in Z}\mathbf{i}\beta_j^n\coth(-\mathbf{i}\beta_j^n\sigma_j)\varphi_\alpha^{(n)}(b_j)\bar{\psi}_\alpha^{(n)}(b_j).
\end{aligned}$$

This completes the proof. □

Whenever no confusion of the notation is incurred, we shall write $\tilde{\psi}$ as ψ in $\Omega_j^{\rm PML}$ in what follows.

Lemma 4.2 (error representational formula). *For any $\psi \in X(\Omega)$, which is extended to be a function in $X(D)$ according to* (4.1), *and $\psi_h \in \mathring{V}_h(D)$, we have*

$$\begin{aligned}
b(u-\hat{u}_h, \psi) &= \int_D g(\overline{\psi-\psi_h})dx - a_D(\hat{u}_h, \psi-\psi_h)\\
&\quad + \int_{\Gamma_1}(T_1 - T_1^{\rm PML})(\hat{u}_h - u_{\rm I})\bar{\psi}dx_1 + \int_{\Gamma_2}(T_2 - T_2^{\rm PML})\hat{u}_h\bar{\psi}dx_1\\
&\quad + \int_{\Gamma_1^{\rm PML}}\frac{1}{s(x_3)}\frac{\partial\bar{\psi}}{\partial x_3}(I_h u_{\rm I} - u_{\rm I})dx_1.
\end{aligned} \tag{4.4}$$

Proof. First by (2.28), (2.22), and (2.8) we have

$$\begin{aligned}
b(u-\hat{u}_h,\psi) &= b(u-\hat{u},\psi)+b(\hat{u}-\hat{u}_h,\psi)\\
&= \int_{\Gamma_1}(T_1-T_1^{\rm PML})(\hat{u}-u_{\rm I})\bar{\psi}dx_1+\int_{\Gamma_2}(T_2-T_2^{\rm PML})\hat{u}\bar{\psi}dx_1\\
&\quad + b^{\rm PML}(\hat{u}-\hat{u}_h,\psi)-\sum_{j=1}^{2}\int_{\Gamma_j}(T_j-T_j^{\rm PML})(\hat{u}-\hat{u}_h)\bar{\psi}dx_1\\
&= \int_{\Gamma_1}(T_1-T_1^{\rm PML})(\hat{u}_h-u_{\rm I})\bar{\psi}dx_1+\int_{\Gamma_2}(T_2-T_2^{\rm PML})\hat{u}_h\bar{\psi}dx_1\\
&\quad + b^{\rm PML}(\hat{u}-\hat{u}_h,\psi).
\end{aligned}$$

Next, by (2.22) and Lemma 4.1, we obtain

$$\begin{aligned}
b^{\rm PML}(\hat{u}-\hat{u}_h,\psi) &= a_{\Omega}(\hat{u}-\hat{u}_h,\psi)-\sum_{j=1}^{2}\int_{\Gamma_j}T_j^{\rm PML}(\hat{u}-\hat{u}_h)\bar{\psi}dx_1\\
&= a_{\Omega}(\hat{u}-\hat{u}_h,\psi)+\sum_{j=1}^{2}\int_{\Gamma_j}(\hat{u}-\hat{u}_h)\frac{\partial\bar{\psi}}{\partial\nu_j}dx_1.
\end{aligned}$$

Recall that ν_j is the unit outer normal to $\partial\Omega_j^{\rm PML}$. Since $\mathcal{L}\bar{\psi}=0$ in $\Omega_j^{\rm PML}$, we deduce by the Green formula that

$$a_{\Omega_j^{\rm PML}}(\hat{u}-\hat{u}_h,\psi)=\int_{\Gamma_j}(\hat{u}-\hat{u}_h)\frac{\partial\bar{\psi}}{\partial\nu_j}dx_1+\int_{\Gamma_j^{\rm PML}}\frac{1}{s(x_3)}\frac{\partial\bar{\psi}}{\partial\nu_j}(\hat{u}-\hat{u}_h)dx_1.$$

Thus, by using (2.15) and (3.1), we conclude that

$$\begin{aligned}
b^{\rm PML}(\hat{u}-\hat{u}_h,\psi) &= a_D(\hat{u}-\hat{u}_h,\psi)-\int_{\Gamma_j^{\rm PML}}\frac{1}{s(x_3)}\frac{\partial\bar{\psi}}{\partial\nu_j}(\hat{u}-\hat{u}_h)dx_1\\
&= \int_D g(\overline{\psi-\psi_h})dx-a_D(\hat{u}_h,\psi-\psi_h)-\int_{\Gamma_1^{\rm PML}}\frac{1}{s(x_3)}\frac{\partial\bar{\psi}}{\partial x_3}(\hat{u}-\hat{u}_h)dx_1,
\end{aligned}$$

where we have used the fact that $\hat{u}=\hat{u}_h=0$ on $\Gamma_2^{\rm PML}$. This completes the proof. □

We remark that evaluating the various terms in the error representation formula in suitable Sobolev norms would yield the desired a posteriori error estimate in Theorem 3.1. To achieve the goal, we need to prove stability estimates for the extension (4.1) of the function ψ in $\Omega_j^{\rm PML}$.

4.2. Estimates for the extension. We begin by introducing the notation

$$R_1(x_3)=\min\left(\Delta_1^-\int_{b_1}^{x_3}s_2(\tau)d\tau,\Delta_1^+\int_{b_1}^{x_3}s_1(\tau)d\tau\right),\quad x_3\ge b_1, \tag{4.5}$$

$$R_2(x_3)=\min\left(\Delta_2^-\int_{x_3}^{b_2}s_2(\tau)d\tau,\Delta_2^+\int_{x_3}^{b_2}s_1(\tau)d\tau\right),\quad x_3\le b_2. \tag{4.6}$$

The objective of this section is to prove the following two lemmas.

LEMMA 4.3. *For any $\psi \in X(\Omega)$, let ψ be extended to the whole domain D according to* (4.1). *Then we have the following estimates, for $j = 1, 2$:*

$$\| s^{-1} e^{R_j} \nabla \psi \|_{L^2(\Omega_j^{\mathrm{PML}})} \le C_j \| \psi \|_{H^1(\Omega)},$$

where

$$C_j = \hat{C} \max\left(\frac{2k_j \delta_j^{1/2}}{1 - e^{-2\Delta_j^- \sigma_j^I}}, \quad \frac{2(1 + 2\delta_j(\Delta_j^+ + k_j))^{1/2}}{1 - e^{-2\Delta_j^+ \sigma_j^R}} \right).$$

Proof. We define

$$r_1(x_3) = \int_{x_3}^{b_1+\delta_1} s(\tau) d\tau, \qquad r_2(x_3) = \int_{b_2-\delta_2}^{x_3} s(\tau) d\tau.$$

Then we have $\zeta_j^n(x_3) = e^{-\mathbf{i}\beta_j^n r_j(x_3)} - e^{\mathbf{i}\beta_j^n r_j(x_3)}$ and consequently

$$\frac{d\bar{\zeta}_j^n}{dx_3} = \mathbf{i}\bar{\beta}_j^n (-1)^j \bar{s}(x_3) \left[e^{\mathbf{i}\bar{\beta}_j^n \bar{r}_j(x_3)} + e^{-\mathbf{i}\bar{\beta}_j^n \bar{r}_j(x_3)} \right].$$

By direct calculation, we deduce from (4.1) that

$$\begin{aligned} \int_0^L |\nabla \psi|^2 dx_1 = L \sum_{n \in Z} |\alpha_n + \alpha|^2 |e^{-\mathbf{i}\beta_j^n r_j(x_3)} - e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 |\zeta_j^n(b_j)|^{-2} |\psi_\alpha^{(n)}(b_j)|^2 \\ + L \sum_{n \in Z} |\beta_j^n|^2 |s(x_3)|^2 |e^{-\mathbf{i}\beta_j^n r_j(x_3)} + e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 |\zeta_j^n(b_j)|^{-2} |\psi_\alpha^{(n)}(b_j)|^2. \end{aligned} \tag{4.7}$$

Since $\mathrm{Re}\,\beta_j^n \ge 0$ and $\mathrm{Im}\,\beta_j^n \ge 0$, we have

$$\mathrm{Re}\,(-\mathbf{i}\beta_j^n r_j(x_3)) = \mathrm{Im}\,(\beta_j^n) r_j^R(x_3) + \mathrm{Re}\,(\beta_j^n) r_j^I(x_3) \ge 0.$$

Thus

$$\begin{aligned} &|e^{-\mathbf{i}\beta_j^n r_j(x_3)} \pm e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 \\ &\quad = |e^{2\mathbf{i}\mathrm{Im}\,(-\mathbf{i}\beta_j^n r_j(x_3))} \pm e^{-2\mathrm{Re}\,(-\mathbf{i}\beta_j^n r_j(x_3))}|^2 e^{2\mathrm{Re}\,(-\mathbf{i}\beta_j^n r_j(x_3))} \\ &\quad \le 4 e^{2(\mathrm{Im}\,(\beta_j^n) r_j^R(x_3) + \mathrm{Re}\,(\beta_j^n) r_j^I(s_3))}. \end{aligned}$$

Similarly, we have

$$\begin{aligned} |\zeta_j^n(b_j)|^2 &= |e^{-\mathbf{i}\beta_j^n \sigma_j} - e^{\mathbf{i}\beta_j^n \sigma_j}|^2 \\ &= |e^{2\mathbf{i}\mathrm{Im}\,(-\mathbf{i}\beta_j^n \sigma_j)} - e^{-2\mathrm{Re}\,(-\mathbf{i}\beta_j^n \sigma_j)}|^2 e^{2\mathrm{Re}\,(-\mathbf{i}\beta_j^n \sigma_j)} \\ &\ge e^{2(\sigma_j^R \mathrm{Im}\,\beta_j^n + \sigma_j^I \mathrm{Re}\,\beta_j^n)} |1 - e^{-2(\sigma_j^R \mathrm{Im}\,\beta_j^n + \sigma_j^I \mathrm{Re}\,\beta_j^n)}|^2. \end{aligned}$$

Therefore, by $r_j(b_j) = \sigma_j$, we have

$$\begin{aligned} &|e^{-\mathbf{i}\beta_j^n r_j(x_3)} \pm e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 |\zeta_j^n(b_j)|^{-2} \\ &\quad \le 4 e^{-2(\mathrm{Im}\,\beta_j^n |\int_{b_j}^{x_3} s_1(\tau) d\tau| + \mathrm{Re}\,\beta_j^n |\int_{b_j}^{x_3} s_2(\tau) d\tau|)} (1 - e^{-2(\sigma_j^R \mathrm{Im}\,\beta_j^n + \sigma_j^I \mathrm{Re}\,\beta_j^n)})^{-2}. \end{aligned} \tag{4.8}$$

For $n \in U_j$, we have $\mathrm{Re}\,\beta_j^n = \Delta_j^n \ge \Delta_j^-$, $\mathrm{Im}\,\beta_j^n = 0$, and thus

$$|e^{-\mathbf{i}\beta_j^n r_j(x_3)} \pm e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 |\zeta_j^n(b_j)|^{-2} \le 4 e^{-2R_j(x)} (1 - e^{-2\Delta_j^- \sigma_j^I})^{-2}.$$

Similarly, for $n \notin U_j$, we have $\operatorname{Re}\beta_j^n = 0, \operatorname{Im}\beta_j^n = \Delta_j^n \geq \Delta_j^+$, and thus

$$\begin{aligned}
&|e^{-\mathbf{i}\beta_j^n r_j(x_3)} \pm e^{\mathbf{i}\beta_j^n r_j(x_3)}|^2 |\zeta_j^n(b_j)|^{-2} \\
&\qquad \leq 4e^{-2(\Delta_j^n-\Delta_j^+)|\int_{b_j}^{x_3} s_1(\tau)d\tau|} e^{-2R_j(x_3)}(1-e^{-2\Delta_j^+\sigma_j^R})^{-2} \\
&\qquad \leq 4e^{-2R_j(x_3)} e^{-2(\Delta_j^n-\Delta_j^+)|x_3-b_j|}(1-e^{-2\Delta_j^+\sigma_j^R})^{-2},
\end{aligned}$$

where we have used the fact $s_1(\tau) \geq 1$ (see (2.11)). Define $I_1 = (b_1, b_1+\delta_1)$ and $I_2 = (b_2-\delta_2, b_2)$. It is easy to see that

$$\int_{I_j} e^{-2(\Delta_j^n-\Delta_j^+)|x_3-b_j|} dx_3 \leq \min\left(\delta_j, \frac{1}{2(\Delta_j^n-\Delta_j^+)}\right).$$

Then, by substituting the above estimates into (4.7), we obtain that

$$\begin{aligned}
&\|s^{-1}e^{R_j}\nabla\psi\|^2_{L^2(\Omega_j^{\mathrm{PML}})} = \int_{I_j} |s(x_3)|^{-2} e^{2R_j(x_3)} \int_0^L |\nabla\psi(x_1,x_3)|^2 dx_1 dx_3 \\
&\quad \leq 4L\delta_j \sum_{n\in U_j} \frac{|\alpha_n+\alpha|^2+|\beta_j^n|^2}{(1-e^{-2\Delta_j^-\sigma_j^I})^2} |\psi_\alpha^{(n)}(b_j)|^2 \\
&\qquad + 4L \sum_{n\notin U_j} \frac{|\alpha_n+\alpha|^2+|\beta_j^n|^2}{(1-e^{-2\Delta_j^+\sigma_j^R})^2} |\psi_\alpha^{(n)}(b_j)|^2 \min\left(\delta_j, \frac{1}{2(\Delta_j^n-\Delta_j^+)}\right) := \mathrm{I} + \mathrm{II}.
\end{aligned}$$

If $n \in U_j$, then $|\alpha_n+\alpha|^2 + |\beta_j^n|^2 = k_j^2$ and we get

$$\mathrm{I} \leq C_j^2 \hat{C}^{-2} L \sum_{n\in U_j} |\psi_\alpha^{(n)}(b_j)|^2.$$

If $n \notin U_j$, then $|\alpha_n+\alpha|^2 - k_j^2 = |\beta_j^n|^2 = |\Delta_j^n|^2$ and we have $|\alpha_n+\alpha|^2 + |\beta_j^n|^2 \leq k_j^2 + 2|\Delta_j^n|^2 \leq 2(k_j+\Delta_j^n)^2$ and $|\alpha_n+\alpha|^2 + |\beta_j^n|^2 \leq 2|\alpha_n+\alpha|^2$. Hence

$$|\alpha_n+\alpha|^2 + |\beta_j^n|^2 \leq 2|\alpha_n+\alpha|(k_j+\Delta_j^n).$$

Therefore

$$(|\alpha_n+\alpha|^2 + |\beta_j^n|^2) \min\left(\delta_j, \frac{1}{2(\Delta_j^n-\Delta_j^+)}\right) \leq |\alpha_n+\alpha|(1+2\delta_j(\Delta_j^+ + k_j)),$$

which yields

$$\mathrm{II} \leq C_j^2 \hat{C}^{-2} L \sum_{n\notin U_j} |\alpha_n+\alpha| |\psi_\alpha^{(n)}(b_j)|^2.$$

This completes the proof upon using Lemma 2.3. □

LEMMA 4.4. *For any $\psi \in X(\Omega)$, let ψ be extended to the whole domain D according to* (4.1). *Then we have the following estimate:*

$$\left\| s^{-1}\frac{\partial\psi}{\partial x_3} \right\|_{L^2(\Gamma_1^{\mathrm{PML}})} \leq \hat{C} M_3 \|\, \psi \,\|_{H^1(\Omega)},$$

where

$$M_3 = \max\left(\frac{2\Delta_1^- e^{-\Delta_1^- \sigma_1^I}}{1 - e^{-2\Delta_1^- \sigma_1^I}},\ \ \frac{2\Delta_1^+ e^{-\Delta_1^+ \sigma_1^R}}{1 - e^{-2\Delta_1^+ \sigma_1^R}}\right).$$

Proof. From (4.1) we deduce easily that

$$\frac{\partial \psi}{\partial x_3}(x_1, b_1 + \delta_1) = -2 \sum_{n \in Z} \mathbf{i}\bar{\beta}_1^n \bar{s}(b_1 + \delta_1)\bar{\zeta}_1^n(b_1)^{-1} \psi_\alpha^{(n)}(b_1) e^{\mathbf{i}(\alpha_n + \alpha)x_1}.$$

Thus

$$\left\| s^{-1} \frac{\partial \psi}{\partial x_3} \right\|_{L^2(\Gamma_1^{\mathrm{PML}})} = 2\left(\sum_{n \in Z} |\beta_1^n|^2 |\zeta_1^n(b_1)|^{-2} |\psi_\alpha^{(n)}(b_1)|^2\right)^{1/2}.$$

Moreover,

$$|\beta_1^n||\zeta_1^n(b_1)|^{-1} = \left|\frac{\beta_1^n e^{\mathbf{i}\beta_1^n \sigma_1}}{1 - e^{2\mathbf{i}\beta_1^n \sigma_1}}\right|.$$

The proof now follows by using an argument similar to that used in Lemma 2.2 and using Lemma 2.3. □

4.3. Proof of Theorem 3.1. Since we are going to interpolate nonsmooth functions satisfying quasi-periodic boundary conditions, we resort to an interpolation operator $\Pi_h : \overset{\circ}{X}(D) \to \overset{\circ}{V}_h(D)$ of Scott and Zhang [21]. Let $N_h = \{a_i\}_{i=1}^N$ be the set of all nodes of $\mathcal{M}_h$, and $\{\phi_i\}_{i=1}^N$ be the corresponding nodal basis of $V_h(D)$. For any node a_i that is interior to D, we take $\sigma_i = e$, any side in $\mathcal{B}_h$ having a_i as one of its vertices. For any node a_i that is in the interior of the left boundary, that is, $a_i = (0, z_i)$ for some $z_i \in (b_2 - \delta_2, b_1 + \delta_1)$, we take σ_i as any side on the left boundary with one vertex a_i. Now for the corresponding node $a_k = (L, z_i)$ on the right boundary, we choose σ_k as the corresponding side of σ_i on the right boundary. For the nodes a_i lying on $\overline{\Gamma_1^{\mathrm{PML}}} \cup \overline{\Gamma_2^{\mathrm{PML}}}$, we can choose σ_i as any side on $\overline{\Gamma_1^{\mathrm{PML}}}$ or $\overline{\Gamma_2^{\mathrm{PML}}}$ which has a_i as one vertex. Let $a_{i,1} = a_i$, and let $\{a_{i,j}\}_{j=1}^2$ be the set of nodal points in σ_i with nodal basis $\{\phi_{i,j}\}_{j=1}^2$. Define $\{\psi_{i,j}\}_{j=1}^2$ as the $L^2(\sigma_i)$ dual basis:

$$\int_{\sigma_i} \psi_{i,j}(x)\phi_{i,k}(x)ds = \delta_{jk}, \quad j, k = 1, 2,$$

where δ_{jk} is the Kronecker delta. We let $\psi_i = \psi_{i,1}$. Then the interpolation operator $\Pi_h : H^1(D) \to W_h(D)$, the conforming linear finite element space, is defined by

$$\Pi_h v(x) = \sum_{i=1}^N \phi_i(x) \int_{\sigma_i} \psi_i(x) v(x) ds.$$

This operator enjoys the following interpolation estimates (see [21]):

$$(4.9)\quad \| v - \Pi_h v \|_{L^2(T)} \le C h_T \| \nabla v \|_{L^2(\tilde{T})}, \qquad \| v - \Pi_h v \|_{L^2(e)} \le C h_e^{1/2} \| \nabla v \|_{L^2(\tilde{e})},$$

where $\tilde{T}$ and $\tilde{e}$ are the union of all elements in $\mathcal{M}_h$ having nonempty intersection with $T \in \mathcal{M}_h$ and the side e, respectively.

It remains to check whether Π_h keeps the boundary condition. It is clear that $\Pi_h v = 0$ on $\Gamma_1^{\rm PML}\cup\Gamma_2^{\rm PML}$ since for any $a_i \in \overline{\Gamma_1^{\rm PML}\cup\Gamma_2^{\rm PML}}, \sigma_i \subset \overline{\Gamma_1^{\rm PML}}$ or $\overline{\Gamma_2^{\rm PML}}$ and $v=0$ on $\Gamma_1^{\rm PML}\cup\Gamma_2^{\rm PML}$. Now let $a_i=(0,z_i)\in\Gamma_{\rm left}$ and $a_k=(L,z_i)\in\Gamma_{\rm right}$. Without loss of generality, we assume $\sigma_i=\{x\in\mathbf{R}^2 : x_1=0, z_i\le x_3\le z_{i+1}\}$. Then by construction we have $\sigma_k=\{x\in\mathbf{R}^2 : x_1=L, z_i\le x_3\le z_{i+1}\}$. The nodal basis $\phi_{i,1}=(z_{i+1}-x_3)/(z_{i+1}-z_i)$, $\phi_{i,2}=(x_3-z_i)/(z_{i+1}-z_i)$ in σ_i, and simple calculation yields the dual basis

$$\psi_{i,1}=\frac{4}{d_i}\phi_{i,1}-\frac{2}{d_i}\phi_{i,2},\qquad \psi_{i,2}=-\frac{2}{d_i}\phi_{i,1}+\frac{4}{d_i}\phi_{i,2}\quad\text{in}\quad\sigma_i,$$

where $d_i=z_{i+1}-z_i$. Similar computation implies that

$$\psi_k(L,x_3)=\psi_i(0,x_3)=\frac{4}{d_i}\phi_{i,1}(x_3)-\frac{2}{d_i}\phi_{i,2}(x_3).$$

Thus for any $v\in X(D)$, that is, $v(0,x_3)=e^{-\mathbf{i}\alpha L}v(L,x_3)$, we have

$$\Pi_h v(a_i)=\int_{\sigma_i}\psi_i(0,x_3)v(0,x_3)dx_3=e^{-\mathbf{i}\alpha L}\int_{\sigma_k}\psi_k(L,x_3)v(L,x_3)dx_3=e^{-\mathbf{i}\alpha L}\Pi_h v(a_k).$$

This shows that $\Pi_h v\in\overset{\circ}{V}_h(D)$ if $v\in\overset{\circ}{X}(D)$.

Now we take $\psi_h=\Pi_h\psi\in\overset{\circ}{V}_h(D)$ in the error representation formula (4.4) to get

$$\begin{aligned}b(u-\hat u_h,\psi) &= \int_D g(\overline{\psi-\Pi_h\psi})dx - a_{_D}(\hat u_h,\psi-\Pi_h\psi)\\ &\quad+\int_{\Gamma_1}(T_1-T_1^{\rm PML})(\hat u_h-u_{\rm I})\bar\psi dx_1+\int_{\Gamma_2}(T_2-T_2^{\rm PML})\hat u_h\bar\psi dx_1\\ &\quad+\int_{\Gamma_1^{\rm PML}}\frac{1}{s(x_3)}\frac{\partial\bar\psi}{\partial x_3}(I_h u_{\rm I}-u_{\rm I})dx_1\\ &:= {\rm III}+\cdots+{\rm VII}.\end{aligned}\tag{4.10}$$

We observe that, by integration by parts and using (3.3)–(3.5),

$${\rm III}+{\rm IV}=\sum_{T\in\mathcal{M}_h}\left(\int_T R_T(\overline{\psi-\Pi_h\psi})dx+\sum_{e\subset\partial T}\frac{1}{2}\int_e J_e(\overline{\psi-\Pi_h\psi})ds\right).$$

Standard argument in the a posteriori error analysis using (4.9) and Lemma 4.3 implies

$$\begin{aligned}|{\rm III}+{\rm IV}| &\le C\sum_{T\in\mathcal{M}_h}\eta_{_T}\|\,\rho^{-1}\nabla\psi\,\|_{L^2(\tilde T)}\\ &\le C(1+C_1+C_2)\left(\sum_{T\in\mathcal{M}_h}\eta_{_T}^2\right)^{1/2}\|\,\psi\,\|_{H^1(\Omega)}.\end{aligned}\tag{4.11}$$

By Lemmas 2.2 and 2.3, we obtain

$$\begin{aligned}|{\rm V}+{\rm VI}| &\le M_1\|\,\hat u_h-u_{\rm I}\,\|_{L^2(\Gamma_1)}\|\,\psi\,\|_{L^2(\Gamma_1)}+M_2\|\,\hat u_h\,\|_{L^2(\Gamma_2)}\|\,\psi\,\|_{L^2(\Gamma_2)}\\ &\le(\hat C M_1\|\,\hat u_h-u_{\rm I}\,\|_{L^2(\Gamma_1)}+\hat C M_2\|\,\hat u_h\,\|_{L^2(\Gamma_2)})\|\,\psi\,\|_{H^1(\Omega)}.\end{aligned}\tag{4.12}$$

Finally, by Lemmas 4.4 and 2.3, we get

$$\begin{aligned}|{\rm VII}| &\le M_3\|\,I_h u_{\rm I}-u_{\rm I}\,\|_{L^2(\Gamma_1^{\rm PML})}\|\,\psi\,\|_{L^2(\Gamma_1)}\\ &\le\hat C M_3\|\,I_h u_{\rm I}-u_{\rm I}\,\|_{L^2(\Gamma_1^{\rm PML})}\|\,\psi\,\|_{H^1(\Omega)}.\end{aligned}\tag{4.13}$$

Combining (4.10)–(4.13), we obtain the desired estimate. □

5. The $\mathrm{Im}\,\varepsilon_2 > 0$ case. In this section we consider briefly the case in which $\mathrm{Im}\,\varepsilon_2 > 0$. Let $k_2^2 = \omega^2\varepsilon_2\mu$ satisfy $\mathrm{Im}\,k_2 > 0$. The constants β_2^n in the Rayleigh expansion (2.5) in Ω_2 satisfy

$$(\beta_2^n)^2 = k_2^2 - (\alpha_n + \alpha)^2, \qquad \mathrm{Im}\,\beta_2^n \geq 0.$$

Define

$$\xi_n = \frac{1}{2}(\mathrm{Re}\,(k_2^2) - (\alpha_n + \alpha)^2), \qquad \eta = \frac{1}{2}\mathrm{Im}\,(k_2^2);$$

then $(\beta_2^n)^2 = 2(\xi_n + \mathbf{i}\eta)$. Since $\mathrm{Im}\,(k_2^2) = \omega^2\mathrm{Im}\,(\varepsilon_2)\mu > 0$, we obtain that

$$\mathrm{Re}\,\beta_2^n = (\sqrt{\xi_n^2 + \eta^2} + \xi_n)^{1/2}, \qquad \mathrm{Im}\,\beta_2^n = (\sqrt{\xi_n^2 + \eta^2} - \xi_n)^{1/2}. \tag{5.1}$$

Thus $\mathrm{Re}\,(-2\mathbf{i}\beta_2^n\sigma_2) = 2(\sigma_2^R\mathrm{Im}\,\beta_2^n + \sigma_2^I\mathrm{Re}\,\beta_2^n) \geq 2\sigma_2^R\mathrm{Im}\,\beta_2^n$, which yields

$$\begin{aligned}|\mathbf{i}\beta_2^n(1 - \coth(-\mathbf{i}\beta_2^n\sigma_2))| = \left|\frac{2\beta_2^n}{e^{-2\mathbf{i}\beta_2^n\sigma_2} - 1}\right| &\leq \frac{2|\beta_2^n|}{e^{2\sigma_2^R\mathrm{Im}\,\beta_2^n} - 1} \\ &= \frac{2\sqrt{2}(\xi_n^2 + \eta^2)^{1/4}}{e^{2\sigma_2^R(\sqrt{\xi_n^2+\eta^2}-\xi_n)^{1/2}} - 1}.\end{aligned}$$

Simple but tedious calculation shows that the function on the right-hand side is increasing with respect to $\xi_n \in \mathbf{R}$. Since $\xi_n \leq \frac{1}{2}\mathrm{Re}\,(k_2^2)$, we deduce after some algebraic manipulations that

$$|\mathbf{i}\beta_2^n(1 - \coth(-\mathbf{i}\beta_2^n\sigma_2))| \leq \mathcal{M}_2 := \frac{2|k_2|}{e^{2\sigma_2^R\mathrm{Im}\,k_2} - 1}.$$

Therefore, we conclude that Lemma 2.2 and thus Theorems 2.4 and 2.5 are also valid in the case $\mathrm{Im}\,\varepsilon_2 > 0$, with the definition of M_2 being replaced by $M_2 = \mathcal{M}_2$.

Moreover, we deduce from (4.8) that

$$|e^{-\mathbf{i}\beta_2^n r_2(x_3)} \pm e^{\mathbf{i}\beta_2^n r_2(x_3)}|^2|\zeta_2^n(b_2)|^{-2} \leq 4e^{-2\mathrm{Im}\,\beta_2^n\int_{x_3}^{b_2} s_1(\tau)d\tau}(1 - e^{-2\sigma_2^R\mathrm{Im}\,\beta_2^n})^{-2}.$$

Since $\xi_n \leq \frac{1}{2}\mathrm{Re}\,(k_2^2)$, we see easily from (5.1) that $\mathrm{Im}\,\beta_2^n \geq \mathrm{Im}\,k_2$. Now the argument in the proof of Lemma 4.3 implies that

$$\|\, s^{-1}e^{\mathcal{R}_2}\nabla\psi\,\|_{L^2(\Omega_2^{\mathrm{PML}})} \leq \mathcal{C}_2\|\,\psi\,\|_{H^1(\Omega)},$$

with $\mathcal{R}_2(x_3) = \mathrm{Im}\,(k_2)\int_{x_3}^{b_2} s_1(\tau)d\tau$ and

$$\mathcal{C}_2 = \hat{C}\frac{2[\max(1,|k_2|)(1 + 2\delta_2(\mathrm{Im}\,k_2 + |k_2|))]^{1/2}}{1 - e^{-2\sigma_2^R\mathrm{Im}\,k_2}}.$$

Therefore, we know that Theorems 3.1 and 3.2 are also valid, with the definitions of $R_2(x_3)$, C_2, and M_2 being replaced by $R_2 = \mathcal{R}_2(x_3)$, $C_2 = \mathcal{C}_2$, and $M_2 = \mathcal{M}_2$, respectively.

6. Implementation and numerical examples. The implementation of the adaptive algorithm in this section is based on the PDE toolbox of MATLAB. We use the a posteriori error estimate from Theorem 3.1 in the TE case and from Theorem 3.2 in the TM case to determine the PML parameters. According to the discussion in section 2, we choose the PML medium property as the power function, and thus we need to specify only the thickness δ_j of the layers and the medium parameters σ_j^m (see (2.26)). Recall from Theorem 3.1 that the a posteriori error estimate consists of two parts: the PML error $\mathcal{E}_{\mathrm{PML}}$ and the finite element discretization error $\mathcal{E}_{\mathrm{FEM}}$, where

$$\mathcal{E}_{\mathrm{PML}} = M_1\| \hat{u}_h - u_{\mathrm{I}} \|_{L^2(\Gamma_1)} + M_2\| \hat{u}_h \|_{L^2(\Gamma_2)}, \tag{6.1}$$

$$\mathcal{E}_{\mathrm{FEM}} = M_3\| \hat{u}_h - u_{\mathrm{I}} \|_{L^2(\Gamma_1^{\mathrm{PML}})} + \left(\sum_{T\in\mathcal{M}_h} \eta_T^2 \right)^{1/2}. \tag{6.2}$$

$\mathcal{E}_{\mathrm{PML}}$ and $\mathcal{E}_{\mathrm{FEM}}$ should be changed accordingly in the TM case. In our implementation we first choose δ_j and σ_j^m such that $M_j L^{1/2} \le 10^{-8}$, which makes the PML error negligible compared with the finite element discretization errors. Once the PML region and the medium property are fixed, we use the standard finite element adaptive strategy to modify the mesh according to the a posteriori error estimate (6.2). For any $T \in \mathcal{M}_h$, we define the local a posteriori error estimator as follows:

$$\tilde{\eta}_T = \eta_T + M_3\| I_h u_{\mathrm{I}} - u_{\mathrm{I}} \|_{L^2(\Gamma_1^{\mathrm{PML}}\cap\partial T)}.$$

Now we describe the adaptive algorithm we have used in this paper.

ALGORITHM 6.1. Given tolerance TOL > 0. Let $m = 2$, $\delta_1 = \delta_2 = \delta$.

```
• Choose $\delta$ and $\sigma_j^m$ such that $M_j L^{1/2} \le 10^{-8}$ for $j = 1, 2$;
• Set the computational domain $D = \Omega_2^{\mathrm{PML}} \cup \Gamma_2 \cup \Omega \cup \Gamma_1 \cup \Omega_1^{\mathrm{PML}}$ and generate
  an initial mesh $\mathcal{M}_h$ over $D$;
• While $\mathcal{E}_{\mathrm{FEM}} >$ TOL do
    – refine the mesh $\mathcal{M}_h$ according to the strategy
          if $\tilde{\eta}_T > \frac{1}{2}\max_{T\in\mathcal{M}_h} \tilde{\eta}_T$, refine the element $T \in \mathcal{M}_h$,
    – solve the discrete problem (3.1) or (3.7) on $\mathcal{M}_h$,
    – compute error estimators on $\mathcal{M}_h$,
  end while.
```

In the following, we report several numerical examples to demonstrate the competitive behavior of the proposed algorithm. In all the experiments we document only the value δ of the thickness of the PML layers. The medium parameters σ_j^m are determined accordingly through the relation $M_j L^{1/2} \le 10^{-8}$ for $j = 1, 2$. We normalize the space variables so that $\mu = 1$. We also scale the error estimator by a factor of 0.15 as in the PDE toolbox of MATLAB.

Example 1. We consider the simplest grating structure, a straight line. Assume that a plane wave $u_{\mathrm{I}} = e^{\mathbf{i}\alpha x_1 - \mathbf{i}\beta x_3}$ is incident on the straight line $\{x_3 = 0\}$, which separates two homogeneous media whose dielectric coefficients are ε_1 and ε_2, respectively. The exact solution is known (see [7]):

$$u = \begin{cases} u_{\mathrm{I}} + r e^{\mathbf{i}\alpha x_1 + \mathbf{i}\beta x_3} & \text{if } x_3 > 0, \\ t e^{\mathbf{i}\alpha x_1 - \mathbf{i}\hat{\beta} x_3} & \text{if } x_3 < 0, \end{cases}$$

Table 6.1

Comparison of numerical results using adaptive and uniform mesh refinements. N_k is the number of nodal points of mesh $\mathcal{M}_k$. $\mathcal{E}_k = (\sum_{T\in\mathcal{M}_k} \tilde{\eta}_T^2)^{1/2}$ and $e_k = \|\nabla(u-\hat{u}_k)\|_{L^2(\Omega)}$.

11	3379	0.3503	1.1864	8	9359	0.3549	1.1812

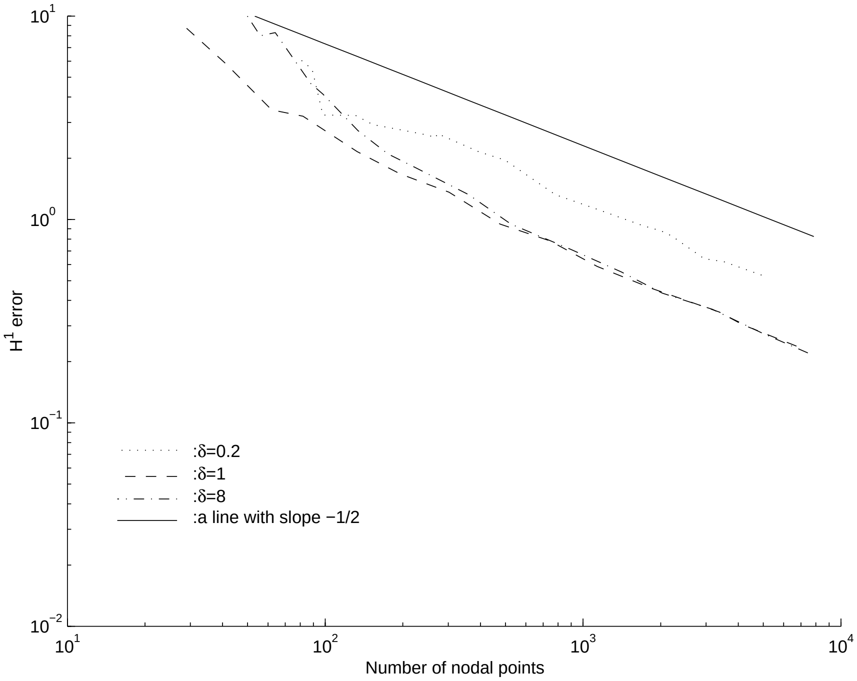

Fig. 6.1. *Quasioptimality of the adaptive mesh refinements.*

where $\hat{\beta} = (k_2^2 - \alpha^2)^{1/2}$, $t = 2\beta/(\beta+\hat{\beta})$, and $r = (\beta-\hat{\beta})/(\beta+\hat{\beta})$. The domain $\Omega = (0,L)\times(-b,b)$, $b>0$.

In our experiment, the parameters are chosen as $\varepsilon_1 = 1$, $\varepsilon_2 = (0.22+6.71\mathbf{i})^2$, $\theta = \pi/6$, $\omega = \pi$, and $L = 2$. Table 6.1 compares the results using adaptive and uniform mesh refinements when $b = \delta = 1$. It clearly shows the advantage of using adaptive mesh refinements. Moreover, our a posteriori error estimate $\mathcal{E}_k = (\sum_{T\in\mathcal{M}_k}\tilde{\eta}_T^2)^{1/2}$ provides a rather good estimate of the interested error $e_k = \|\nabla(u-\hat{u}_k)\|_{L^2(\Omega)}$.

Figure 6.1 shows the curves of $\log N_k$ versus $\log\|\nabla(u-\hat{u}_k)\|_{L^2(\Omega)}$, where N_k is the number of nodes of the mesh $\mathcal{M}_k$. It indicates that for the proposed method,

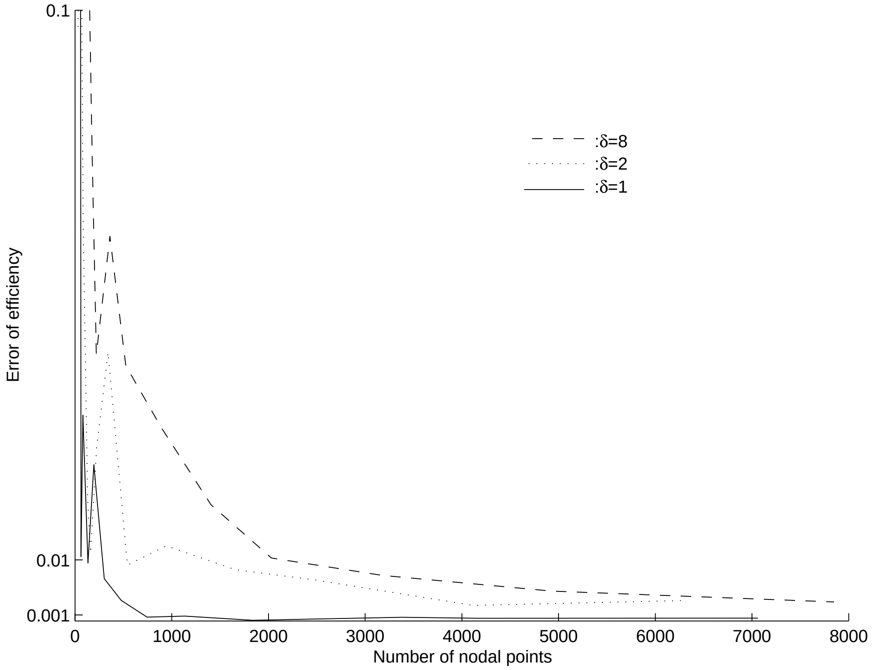

FIG. 6.2. *Robustness of the grating efficiency with respect to the thickness of PML layers.*

the meshes and the associated numerical complexity are quasi-optimal: $\| \nabla(u - \hat{u}_k) \|_{L^2(\Omega)} = CN_k^{-1/2}$ is valid asymptotically.

Figure 6.2 shows the robustness of the proposed method with respect to the choice of the thickness of PML layers: The error of the grating efficiency is insensitive to the thickness δ. The definition of the grating efficiency can be found, for example, in [7]. The reason for this robustness is the exponential decay factor in our a posteriori error estimator in the PML region. Our experiences indicate that the choice of δ in the range of $0.5L$ to $1.5L$ usually produces satisfactory results.

The parameter b determines the position of the PML layers, which, in the traditional PML technique, should be sufficiently far away from the grating surface to allow the evanescent waves to be sufficiently decayed. Figure 6.3 shows the robustness of our method with respect to the position of the PML layers, which is the purpose of our extended PML technique for attenuating both the outgoing and evanescent waves.

Example 2. This example concerns the TM polarization on a grating surface with a sharp angle, indicated in Figure 6.4. The parameters are the same as those in Example 1. There are two reflected outgoing waves. The grating efficiency of the reflected waves as well as the total grating efficiency are displayed in Figure 6.5. Figure 6.6 shows the mesh and the amplitude of the associated solution after 10 adaptive iterations when the grating efficiency is stabilized. The mesh has 3585 nodes, and the a posteriori error estimate over the mesh is 0.6468. The initial a posteriori error estimate is 3.7838. This example shows clearly the ability of the proposed method to capture the singularities of the problem. The meshes near the upper PML boundary are rather coarse, as a result of the exponential decay factor in our a posteriori error estimator.

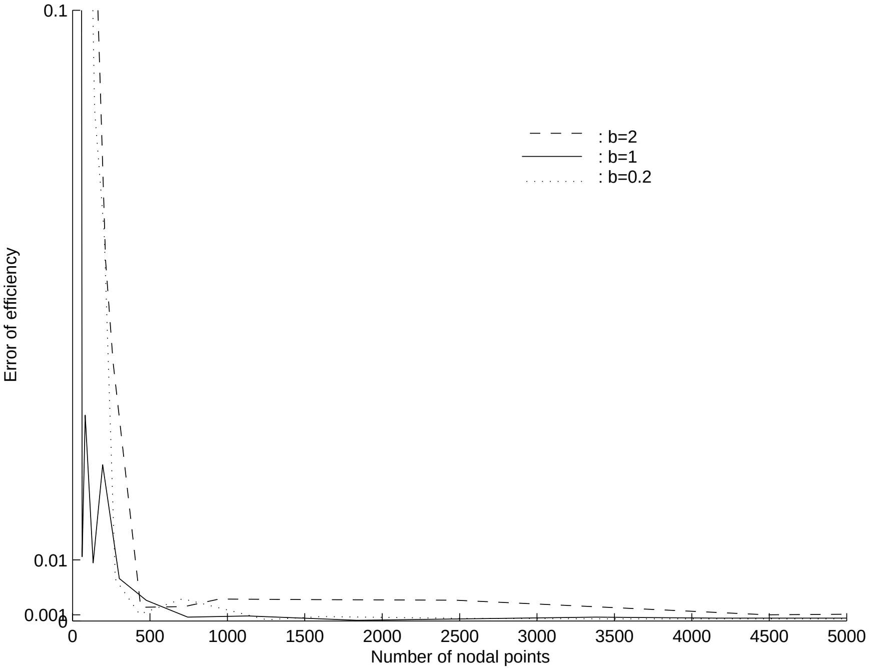

FIG. 6.3. *Robustness of the grating efficiency with respect to the position of PML layers.*

structure has applications in optical filters and guided mode resonance devices. The parameters are taken as follows: $\varepsilon_1 = 1$, $\varepsilon_2 = 2.31$, $\varepsilon_3 = 4.4$, $\varepsilon_4 = 3.6$, $\theta = \pi/4$, $L = 0.3$, and $\omega = 2\pi/0.526$. The thickness of the PML layers $\delta = 0.4$. There are two transmitted waves and one reflected outgoing wave. The grating efficiency of the reflected and transmitted waves as well as the total grating efficiency are displayed in Figure 6.8. Figure 6.9 shows the mesh and the amplitude of the associated solution after 7 adaptive iterations when the grating efficiency is stabilized. The mesh has 1480 nodes, and the a posteriori error estimate over the mesh is 0.8189. The initial a posteriori error estimate is 3.0701. Again the meshes near the upper PML boundary are rather coarse, as a result of the exponential decay factor in our a posteriori error estimator.

Acknowledgment. The authors wish to thank Gang Bao for many inspiring discussions on the physical background and mathematical modeling of the grating problems.

COMPUTING THE ZEROS AND TURNING POINTS OF SOLUTIONS OF SECOND ORDER HOMOGENEOUS LINEAR ODES*

AMPARO GIL† AND JAVIER SEGURA‡

Abstract. Algorithms to compute the zeros and turning points of the solutions of second order ODEs $y'' + B(x)y' + A(x)y = 0$ are developed. Two fixed point methods are introduced. The first method consists of fixed point iterations that are built from the first order differential system relating the problem function with a contrast function w; the contrast function w has zeros interlaced with those of y, and it is a solution of a different second order ODE. This method, which generalizes previous findings [J. Segura, *SIAM J. Numer. Anal.*, 40 (2002), pp. 114–133], requires the evaluation of the ratio of functions y/w. The second method is based on fixed point iterations stemming from the second order ODE; it requires the computation of the logarithmic derivative y'/y. Both are quadratically convergent methods; error bounds are provided. The particular case of second order ODEs depending on one parameter, $y_n'' + B_n(x)y_n' + A_n(x)y_n(x) = 0$, with applications to the computation of the zeros and turning points of special functions, is discussed in detail. The combination of both methods provides algorithms for the efficient computation of the zeros and turning points of a broad family of special functions, including hypergeometric and confluent hypergeometric functions of real parameters and variables (Jacobi, Laguerre, and Hermite polynomials are particular cases), Bessel, Airy, Coulomb, and conical functions, among others. We provide numerical examples showing the efficiency of the methods.

1. Introduction.

The study of the properties of zeros and turning points of special functions and orthogonal polynomials has become an active field in applied mathematics, which is not surprising, because of the importance of these topics in approximation theory, the theory of differential equations, and in many fields of physics and engineering.

In [1] a method of computation of zeros of special functions was presented whose applicability was illustrated for first kind Bessel functions and regular Coulomb wave functions. This article applies matrix eigenvalue methods, first put forward by Grad and Zakrajsek [10] and later enhanced by Ikebe and colleagues [11, 12, 15], who also applied the method for regular Bessel and Coulomb functions.

In [22] a fixed point method was introduced which covers the problems solved by matrix methods and can be applied to more general situations like, for instance, evaluating the zeros of *any* cylinder (Bessel) function or of *any* Coulomb function, and not necessarily the regular solutions. This method generalizes previous findings regarding Bessel functions [19, 21], and the fixed point iterations improve the convergence rate of the global Newton method considered in [19, 20]. The case of second order ODEs depending on one parameter, $y_n'' + B(x)y_n' + A_n(x)y_n(x) = 0$ (B not depending on n),

was described in detail. The global convergence of the resulting fixed point iteration was proved, and algorithms to compute with certainty the zeros inside an interval were given.

In this paper, the fixed point method described in [22], based on the first order systems associated with a set of second order ODEs, is established in its most general form (including the case of dependence of both A and B on the parameter n). In the particular case of hypergeometric functions, these fixed point methods can be directly applied for the computation of both the zeros and turning points (TPs). However, cases will be described for which these methods are difficult to apply to the computation of TPs, the main difficulty being that the change of variables is not analytically invertible. An alternative method for the computation of TPs is built. It is based on fixed point iterations stemming from the second order ODE. These methods require that an algorithm to evaluate the logarithmic derivative of the function be available. An explicit algorithm for the method based on the second order ODE is provided (section 3.3); this algorithm, combined with those described in [22], can be applied to the computation of the zeros and TPs of a broad family of special functions including hypergeometric and confluent hypergeometric functions of real parameters and variables (which includes classical orthogonal polynomials: Jacobi, Laguerre, Hermite), Bessel and Airy functions, Coulomb wave functions, and conical functions, among others.

Both methods are quadratically convergent, and error bounds are given. The methods are illustrated with three examples that combine both methods (Bessel, Coulomb, and conical functions). These examples show the efficiency of the proposed computational schemes. Comparison with other methods is also provided.

2. Method I: Fixed point methods based on first order systems.

In [22] a method for the computation of the zeros of the solutions of second order ODEs

$$y'' + B_y(x)y' + A_y(x)y = 0, \tag{2.1}$$

with continuous coefficients B_y and A_y in an interval I, was described. This method can be applied when contrast functions w exist which are solutions of a differential equation with continuous coefficients in I,

$$w'' + B_w(x)w' + A_w(x)w = 0,$$

such that, given two fundamental systems of solutions of these ODEs, $\{y^{(1)}, y^{(2)}\}$ and $\{w^{(1)}, w^{(2)}\}$, the functions y and w (twice continuously differentiable) are related by a first order system

$$\begin{aligned} y' &= \alpha(x)y + \delta(x)w, \\ w' &= \beta(x)w + \gamma(x)y \end{aligned} \tag{2.2}$$

both for $\{y^{(1)}, w^{(1)}\}$ and $\{y^{(2)}, w^{(2)}\}$, with continuous coefficients α, β, δ, γ in I. Such coefficients exist and are unique [14, Theorem 1], and therefore the restriction in the contrast function is given by the continuity of the coefficients. We restrict the analysis to real intervals I where all the coefficients are continuous and the solutions are twice continuously differentiable, which implies the differentiability of the coefficients in (2.2).

In [22], the case of uniparametric families of differential equations ($B_w = B_{n-1}$, $A_w = A_{n-1}$, $B_y = B_n$, $A_y = A_n$, with n a parameter) was considered; however, the theory applies to more general situations. Also, the restriction $B_y = B_w$ was considered; as remarked in this same reference, this is not an essential restriction because the B_y and B_w terms can be eliminated by proper changes of the dependent variable.

An essential property is the fact that the δ and γ coefficients are different from zero for any x in I [22, Lemma 2.1]; this is so because the first order system is simultaneously satisfied by $\{y^{(1)}, w^{(1)}\}$ and $\{y^{(2)}, w^{(2)}\}$ and, therefore, the first equation in (2.2) implies $\delta(x) = W[y^{(1)}, y^{(2)}]/Z(x)$, where W is the Wronskian of two independent solutions of a second order ODE (and therefore never vanishes) and

$$Z(x) = \begin{vmatrix} y^{(1)} & w^{(1)} \\ y^{(2)} & w^{(2)} \end{vmatrix}. \tag{2.3}$$

$Z(x)$ is never zero in I because we are assuming that the coefficients of the first order system are continuous in I.

Another essential ingredient of the method is the fact that $\delta(x)\gamma(x) < 0 \ \forall x \in I$ if there is a solution y of the original ODE or w of the contrast ODE with at least two zeros in I [22, Lemma 2.1].

2.1. First order systems in normal form and oscillating functions. Let us briefly summarize the transformations which must be performed over the system (2.2) in order to build global fixed point iterations to compute the zeros of $y(x)$. First, a change of the dependent functions is considered

$$y(x) = \lambda_y(x)\bar{y}(x), \qquad w(x) = \lambda_w(x)\bar{w}(x), \tag{2.4}$$

with $\lambda_y(x) \neq 0$, $\lambda_w(x) \neq 0 \ \forall x \in I$ in such a way that $\bar{y}$ and $\bar{w}$ satisfy

$$\begin{aligned} \bar{y}' &= \bar{\alpha}\,\bar{y} + \bar{\delta}\,\bar{w}, \\ \bar{w}' &= \bar{\beta}\,\bar{w} + \bar{\gamma}\,\bar{y} \end{aligned} \tag{2.5}$$

with $\bar{\delta} > 0$ and $\bar{\delta} = -\bar{\gamma}$. This is accomplished by choosing

$$\lambda_y = \operatorname{sign}(\delta)\lambda_w\sqrt{-\frac{\delta}{\gamma}}, \tag{2.6}$$

and the argument of the square root is positive if y and/or w have at least two zeros in I. The new functions $\bar{y}$ and $\bar{w}$ obviously have the same zeros as y and w; it is easy to verify that $\bar{y}$ and $\bar{w}$ satisfy second order ODEs with the same B-coefficient accompanying the first derivative term. This is the situation described in more detail in [22].

Considering now a change of variables

$$z(x) = \int \bar{\delta}(x)dx, \tag{2.7}$$

the system reads

$$\begin{aligned} \dot{\bar{y}} &= \bar{a}\,\bar{y} + \bar{w}, \\ \dot{\bar{w}} &= \bar{b}\,\bar{w} - \bar{y}, \end{aligned} \qquad \text{where } \bar{a} = \frac{\bar{\alpha}}{\bar{\delta}} \text{ and } \bar{b} = \frac{\bar{\beta}}{\bar{\delta}}, \tag{2.8}$$

where dots mean derivatives with respect to z.

From (2.8) we see that the ratio $H(z) = \bar{y}/\bar{w}$ satisfies the first order nonlinear ODE

$$\dot{H} = 1 + H^2 - 2\eta H, \qquad \text{where } \eta = \frac{\bar{b} - \bar{a}}{2}, \tag{2.9}$$

which resembles the behavior of the tangent function, at least for small η. The zeros and singularities of H are interlaced, as happens with the tangent function; this is a consequence of the continuity of the coefficients in (2.2).

For later convenience, let us consider an additional change of the dependent variables; namely, we can take $\bar{y}(z) = \nu(z)\widetilde{y}(z)$ and $\bar{w}(z) = \nu(z)\widetilde{w}(z)$, with $\nu(z) = \exp\left(\int \frac{1}{2}(\bar{a} + \bar{b})dz\right)$. Then, we have

$$\begin{aligned} \dot{\widetilde{y}} &= -\eta\,\widetilde{y} + \widetilde{w}, \\ \dot{\widetilde{w}} &= \eta\,\widetilde{w} - \widetilde{y}, \end{aligned} \tag{2.10}$$

and $\widetilde{y}$ and $\widetilde{w}$ satisfy second order ODEs in normal form; for instance,

$$\ddot{\widetilde{y}} + \widetilde{A}(z)\widetilde{y} = 0 \qquad \text{with } \widetilde{A}(z) = 1 + \dot{\eta} - \eta^2, \tag{2.11}$$

and similarly for w with $\widetilde{A}(z) = 1 - \dot{\eta} - \eta^2$.

We will say that the system (2.10) is in normal form. The function η, together with an initial value $H(z_0)$, determines the location of the zeros; η measures the deviation of $H(z)$ from a tangent function. Generally, we will have $|\eta(x)| < 1$ ($\eta(x) = \eta(z(x))$) in the interval I where our problem function oscillates. (This is an important feature when we later analyze the rate of convergence of the method.) This is so because of the following.

THEOREM 2.1. *If $|\eta| > 1$ in an interval I, then $H(z(x))$ has at most one zero and one singularity in this interval*

Proof. If $|\eta| > 1$, then (2.9) implies that $\dot{H} < 0$ for $|H - \eta| < \sqrt{\eta^2 - 1}$. Taking into account that H is differentiable except at its singularities, that the singularities and zeros are interlaced, and that H is increasing at their zeros, then if z_s is a singularity of H in I, necessarily $\lim_{z \to z_s^+} H(z) = -\infty$ and there cannot be any other singularity $z_{s'} > z_s$ (such that $\lim_{z \to z_{s'}^-} H(z) = +\infty$) because $H(z)$ becomes decreasing in a band-shaped region (above the z axis for $\eta > 0$ and below for $\eta < 0$). On the other hand, due to interlacing, if there can be no more than one singularity in I, then there can be no more than one zero in I. □

Therefore, we expect that $|\eta| < 1$ in an interval where the problem function oscillates and has several zeros. A related result is the following sufficient condition for the existence of infinitely many real zeros.

THEOREM 2.2. *If $\int_{z_0}^{+\infty}(1 - \eta(z)^2)dz = +\infty$ with η bounded in $[z_0, +\infty)$, then $H(z)$ has infinitely many interlaced zeros and singularities for $z > z_0$.*

Proof. This is a direct consequence of a well known result: the solutions of an equation in normal form $\ddot{y}(z) + A(z)y(z) = 0$ that satisfies $\int_{z_0}^{+\infty} A(z)dz = +\infty$ have infinitely many zeros for $z > z_0$. Considering (2.11), we see that $H(z) = \widetilde{y}/\widetilde{w}$ has infinitely many zeros because $\widetilde{y}$ satisfies $\ddot{\widetilde{y}} + \widetilde{A}(z)\widetilde{y} = 0$ with $\widetilde{A}(z) = 1 + \dot{\eta}(z) - \eta(z)^2$ and

$$\int_{z_0}^{+\infty} \left[1 + \dot{\eta} - \eta^2\right] dz = \lim_{z \to +\infty} \left[\eta(z) - \eta(z_0) + \int_{z_0}^{z} (1 - \eta(z)^2) dz\right] = +\infty,$$

and because the zeros and singularities are interlaced, there is also an infinite number of singularities. □

COROLLARY 2.3. *If $|\eta(x)| < 1-\epsilon$, $0<\epsilon<1$, $\forall x \geq x_0$, then $H(z(x))$ has infinitely many interlaced zeros and singularities for $x > x_0$.*

2.2. Fixed point methods for first order systems. In [22], it was shown that, given the ratio $H(z)$, with zeros and singularities interlaced and satisfying the first order nonlinear ODE (2.9), the fixed point iteration

$$T(z) = z - \arctan(H(z)) \tag{2.12}$$

is globally convergent to the zeros of the problem function $y(x(z))$ in intervals where η does not change sign. More specifically, denoting the zeros of the problem function $y(x(z))$ by $z_y^{(j)}$ (zeros of $H(z)$) and those of the contrast function by $z_w^{(j)}$ (singularities of $H(z)$), j being integer numbers such that

$$\cdots < z_w^{(j)} < z_y^{(j)} < z_w^{(j+1)} < z_y^{(j+1)} < \cdots, \tag{2.13}$$

then

$$\lim_{n\to\infty} T^{(n)}(z_0) = z_y^{(j)} \qquad \forall z_0 \in (z_w^{(j)}, z_w^{(j+1)}) \tag{2.14}$$

and the convergence to $z_y^{(j)}$ is monotonic if $\eta < 0$ and $z_0 \in (z_w^{(j)}, z_y^{(j)})$ or $\eta > 0$ and $z_0 \in (z_y^{(j)}, z_w^{(j+1)})$.

Global bounds for the distance between the zeros and singularities of $H(z)$ when η does not change sign can be established (see [22, Corollary 4.4]):

$$z_y^{(j)} - z_w^{(j)} > \frac{\pi}{2} \quad \text{and} \quad z_w^{(j+1)} - z_y^{(j)} < \frac{\pi}{2} \qquad \text{for} \;\; \eta < 0, \tag{2.15}$$

and the contrary if $\eta > 0$.

These global bounds stem from the fact that, when $\eta < 0$, the graph of $H(z)$ lies above the graph of $\tan(z - z_y^{(j)})$ around $z_y^{(j)}$; this feature also explains the global convergence of the method (see [22]). Using these global bounds, iterative schemes to compute with certainty all the zeros inside a given interval I were developed; for instance, when $\eta < 0$, we have that $z_w^{(j+1)} < z_y^{(j)} + \pi/2 < z_y^{(j+1)} < z_w^{(j+1)}$ and therefore

$$z_y^{(j+1)} = \lim_{n\to\infty} T^{(n)}(z_y^{(j)} + \Delta z^{(j)}) \qquad \text{with} \;\; \Delta z^{(j)} = \frac{\pi}{2}, \tag{2.16}$$

and the iteration converges monotonically. Hence, the successive zeros inside I can be found by using this forward iterative scheme. Obviously, when $\eta > 0$, a backward scheme is the option:

$$z_y^{(j-1)} = \lim_{n\to\infty} T^{(n)}(z_y^{(j)} + \Delta z^{(j)}) \qquad \text{with} \;\; \Delta z^{(j)} = -\frac{\pi}{2}. \tag{2.17}$$

When η changes sign, forward and backward sweeps can be combined. For the usual situation in which η changes sign only once, at $z = z_\eta$, explicit algorithms were described in [22]. These algorithms, depending on the sign of $S = (z - z_\eta)\eta$, compute zeros by an expansive sweep when $S \leq 0$ (forward sweep for $z > z_\eta$ and backward sweep for $z < z_\eta$) or by a contractive sweep when $S \geq 0$.

2.3. Improvement of the iteration step. The iteration steps $\Delta z^{(j)} = \pm\pi/2$ can be improved under certain monotonicity conditions of the $\widetilde{A}(z)$ coefficient in (2.11). For instance, when $\eta < 0$ in I, a forward sweep (2.16) can be used to compute the zeros of $y(x(z))$ in I, the convergence to each zero being monotonic because $z_y^{(j)} + \pi/2 \in (z_w^{(j+1)}, z_y^{(j+1)})$. (See [22], where the intervals $(z_w^{(j+1)}, z_y^{(j)})$ are called subintervals of monotonic convergence, or SMCs.) In this case ($\eta < 0$), the step $\Delta z^{(j)} = \pi/2$ can be improved when $\widetilde{A}(z)$ is a decreasing function; indeed, this means that $\widetilde{y}(z)$ (which has the same zeros as the problem function $y(x(z))$) oscillates more slowly as z increases, and therefore $z_y^{(j+1)} - z_y^{(j)} > z_y^{(j)} - z_y^{(j-1)}$. Hence $z_y^{(j)} + [z_y^{(j)} - z_y^{(j-1)}] < z_y^{(j+1)}$. On the other hand, because of the global bounds between zeros and singularities, $\widetilde{\Delta} z^{(j)} \equiv z_y^{(j)} - z_y^{(j-1)} > \pi/2$, and therefore

$$z_w^{(j+1)} < z_y^{(j)} + \frac{\pi}{2} < z_y^{(j)} + \widetilde{\Delta} z^{(j)} < z_y^{(j+1)}.$$

Hence, the starting value $z_y^{(j)} + \widetilde{\Delta} z^{(j)}$ guarantees (monotonic) convergence to $z_y^{(j+1)}$, and it is a better iteration step than $\Delta z^{(j)}$ because $z_y^{(j)} + \widetilde{\Delta} z^{(j)}$ lies closer to $z_y^{(j+1)}$ than $z_y^{(j)} + \Delta z^{(j)}$ (the convergence being monotonic in both cases).

In other words, when $\widetilde{A}(z)$ is decreasing and η is negative, the difference between the two previously evaluated zeros ($z_y^{(j)}$ and $z_y^{(j-1)}$) can be used as the iteration step to generate a starting value to compute the next zero ($z_y^{(j+1)}$). Obviously, a similar scheme can be devised for the case $\eta > 0$ when $\widetilde{A}(z)$ is increasing. These arguments lead to the following result.

THEOREM 2.4. *If* $\eta(z)\dot{\widetilde{A}}(z) > 0$ *in* $(z_y^{(j-1)}, z_y^{(j+1)})$*, then*

$$z_y^{(j\pm1)} = \lim_{n\to\infty} T^{(n)}(z_y^{(j)} + \Delta z^{(j)}) \qquad \textit{with } \Delta z^{(j)} = z_y^{(j)} - z_y^{(j\mp1)},$$

where the upper sign is for the case $\eta < 0$*, and the lower sign for* $\eta > 0$*. The convergence is monotonic.*

These iteration steps, as mentioned, improve the steps $\Delta z^{(j)} = \pm\pi/2$. Notice, however, that the improvement cannot be considered until two zeros have been evaluated. (The step $\Delta z^{(j)} = \pi/2$ must be considered in order to compute the second zero.)

As we will discuss next, the condition $\eta\dot{\widetilde{A}} > 0$ can be achieved with great generality for the case of families of second order ODEs depending continuously on one parameter (typical case of special functions).

2.3.1. Difference-differential equations and three term recurrence relations. Let us consider now the case, described in [22], of second order ODEs depending continuously on one parameter k,

$$y_k''(x) + B_k(x)y_k'(x) + A_k(x)y_k(x) = 0, \tag{2.18}$$

with general difference-differential equations (DDEs)

$$\begin{aligned} y_k'(x) &= a_k(x)y_k(x) + d_k(x)y_{k-1}(x), \\ y_{k-1}'(x) &= b_k(x)y_{k-1}(x) + e_k(x)y_k(x) \end{aligned} \tag{2.19}$$

satisfied by two families of independent solutions $\{y_k^{(1)}\}$ and $\{y_k^{(2)}\}$; we take integer differences of k. These general DDEs will allow us, if permitted by the range of k, to consider two different contrast functions (y_{n-1} or y_{n+1}) in order to compute the zeros of a problem function y_n; in other words, both equations in (2.19), taking $k = n$ and $k = n+1$, can be used to build the fixed point iterations to compute the zeros of y_n.

Explicitly and following the steps described in section 2.1, the following two fixed point iterations can be built:

$$T_i(z) = z - \arctan(H_i(z)), \qquad i = \pm 1, \tag{2.20}$$

where

$$H_i(z) = -i\,\mathrm{sign}(d_{n_i}) K_i \frac{y_n(x(z))}{y_{n+i}(x(z))}, \qquad n_i = \begin{cases} n, & i = -1, \\ n+1, & i = +1, \end{cases} \tag{2.21}$$

and

$$z(x) = \int \sqrt{-d_{n_i} e_{n_i}}\, dx, \qquad K_i = \left(-\frac{d_{n_i}}{e_{n_i}}\right)^{i/2}, \tag{2.22}$$

and $x(z)$ is the inverse function of $z(x)$.

The functions $H_i(z)$ satisfy $\dot{H}_i = 1 + H_i^2 - 2\eta H_i$, where the function η is given by $\eta_i(z) = \eta_i(x(z))$ and

$$\eta_i(x) = i \frac{1}{2\sqrt{-d_{n_i} e_{n_i}}} \left(a_{n_i} - b_{n_i} + \frac{1}{2}\left(\frac{e'_{n_i}}{e_{n_i}} - \frac{d'_{n_i}}{d_{n_i}} \right) \right). \tag{2.23}$$

It is interesting to note that η_{+1} is equal to η_{-1} with reversed sign and with the substitution $n \to n+1$. Therefore, quite generally, η_{-1} and η_{+1} have opposite signs. This means, as described above, that two different types of sweep are possible for computing the zeros of y_n: forward and backward when the η functions do not change sign, and expansive and contractive when the η functions change sign once. This is an important feature for improving the iteration step $\Delta z^{(j)} = \pm\pi/2$ by $\widetilde{\Delta} z^{(j)} = z_y^{(j)} - z_y^{(j\mp 1)}$ as described in the previous section, given that the sign of η can be chosen in such a way that the hypothesis of Theorem 2.4 is met.

On the other hand, (2.19), satisfied by two independent sets of solutions ($\{y_k^{(1)}\}$ and $\{y_k^{(2)}\}$), implies the existence of a three term recurrence relation between the functions $Y_k = \alpha y_k^{(1)} + \beta y_k^{(2)}$ for any α, β, namely,

$$Y_{n+1} = r_n\, Y_n + s_n\, Y_{n-1} \qquad \text{with} \quad r_n = \frac{a_n - b_{n+1}}{e_{n+1}}, \quad s_n = \frac{d_n}{e_{n+1}}, \tag{2.24}$$

with $s_n \neq 0\, \forall x \in I$.

Given that, by hypothesis, the coefficients of the DDEs are continuous in I, then $\{y_k^{(1)}\}$ and $\{y_k^{(2)}\}$ are necessarily independent solutions of the three term recurrence relation because the determinant $Z(x)$ of (2.3) (with $y \equiv y_n^{(k)}$, $k = 1, 2$, and $w = y_{n-1}^{(k)}$ or $w = y_{n+1}^{(k)}$) can never vanish in I. This is an important fact from a computational point of view because recurrence relations are useful tools for computing the ratios $y_n/y_{n\pm 1}$, which are at the heart of the fixed point method. In section 4, we will discuss these recursive computations.

2.4. Order of convergence of the method. The fixed point iteration $T(z) = z - \arctan(H(z))$ with $H(z)$ satisfying (2.9) is, as shown in [22], a globally convergent iteration. Next, we will show that the order of convergence is 2, and the speed of convergence increases as $|\eta|$ is smaller. As discussed before, generally $|\eta| < 1$ in the region where the problem function y oscillates.

Defining $\epsilon_n = z^{(n)} - z_y^{(j)}$, where $z^{(n)} = T^{(n)}(z_0)$, $z_0 \in (z_w^{(j)}, z_w^{(j+1)})$, we have, expanding in Taylor series, that

$$\epsilon_{n+1} = T(z_y^{(j)} + \epsilon_n) - z_y^{(j)} = \eta(z_y^{(j)})\epsilon_n^2 + \mathcal{O}(\epsilon_n^3)$$

because $\dot{T}(z) = 1 - \dot{H}(z)/(1 + H(z)^2) = 2\eta H(z)/(1 + H(z)^2)$ and then $\dot{T}(z_y^{(j)}) = 0$, $\ddot{T}(z_y^{(j)}) = 2\eta(z_y^{(j)})$.

Therefore the fixed point iteration is quadratically convergent. The convergence will be faster as η is smaller.

The error after the nth iteration can be bounded by standard methods when $|\dot{T}(z)| \leq M < 1$. It is well known that in this case $|\epsilon_n| \leq |z^{(1)} - z^{(0)}| M^n/(1-M)$, and given that $|\dot{T}(z)| = \left|2\eta H/(1 + H^2)\right| \leq |\eta(z)|$, the absolute error in the computation of $z_y^{(j)}$ after the nth iteration can be bounded by

$$|\epsilon_n| \leq \frac{M_\eta^n}{1 - M_\eta} |\arctan(H(z^{(0)}))| \leq \frac{\pi}{2} \frac{M_\eta^n}{1 - M_\eta}, \tag{2.25}$$

where $|\eta| \leq M_\eta < 1$ in $(z_w^{(j)}, z_w^{(j+1)})$.

As we know from Theorem 2.1 and Corollary 2.3, we can expect that $|\eta| < 1$ in the oscillating region I, while $|\eta|$ is expected to become larger than 1 outside this region. This is, for instance, the case of Bessel functions: as $x \to 0$ the oscillations end and $|\eta|$ becomes larger than one. According to (2.25) we can expect that the convergence will improve as larger zeros are considered since $|\eta|$ decreases with increasing x. (For Bessel functions the associated change of variables is trivial $z(x) = x$.) Later, we will illustrate this behavior with numerical examples.

2.5. Examples of application: Hypergeometric functions and Bessel functions. The method described will be particularly indicated for those systems for which the associated change of variables (2.7) is a simple transformation which can be analytically inverted; otherwise, we would need to develop an additional root finding scheme to invert the function $z(x)$ in order to obtain the zeros of the problem function $y(x)$.

In the particular case of the hypergeometric and confluent hypergeometric equations of real parameters and real variables, it is easy to build global fixed point iterations with simple changes of variables. On the other hand, the method described can also be applied to compute the TPs of these functions, or, more generally, the zeros of any derivative, given that the derivatives of (confluent) hypergeometric functions are (confluent) hypergeometric functions. This is an important category of functions, which, as a subset, includes classical orthogonal polynomials (Hermite, Laguerre, Jacobi).

We will illustrate the method for (confluent) hypergeometric functions. For imaginary arguments (Bessel functions), we will see how difficulties arise in the computation of the TPs, which suggest the development of an alternative method, to be developed in section 3. This alternative method will also be the method of choice for computing the turning points of other functions related to hypergeometric functions of complex parameters or variables (Coulomb and conical functions).

2.5.1. Hypergeometric functions. Let us consider the confluent hypergeometric equation

$$xy'' + (\beta - n - x)y' + ny = 0, \tag{2.26}$$

with n and β real numbers. One of the solutions of this ODE is Kummer's function ${}_1\mathrm{F}_1(-n;\beta-n;x)$. (We modify the standard notation for the parameters ${}_1\mathrm{F}_1(a;b;x)$.) We denote by y_n our problem function, which is a solution of (2.26). Taking the derivative of (2.26), we observe that y_n' satisfies the same equation with n replaced by $n-1$; we define $y_{n-1} \equiv y_n'$ and, considering (2.26), we can write the first order system relating these functions:

$$\begin{aligned} y_n' &= y_{n-1}, \\ y_{n-1}' &= \left(1 - \frac{\beta - n}{x}\right) y_{n-1} - \frac{n}{x} y_n. \end{aligned} \tag{2.27}$$

For instance, in the case of Kummer functions, $y_{n-1} = y_n' = \frac{n}{n-\beta}\, {}_1\mathrm{F}_1(-n+1;\beta-n+1;x)$; we can also take as a contrast function a confluent hypergeometric function y_{n+1} such that $y_{n+1}' = y_n$; in terms of the Kummer function we could choose $y_{n+1} = \frac{n+1-\beta}{n+1}\, {}_1\mathrm{F}_1(-n-1,\beta-n-1,x)$. In fact, it is not difficult to see that the selection of y_{n+1} as our contrast function is more appropriate since improved iteration steps (Theorem 2.4) can be implemented for this selection (contrary to the case when y_{n-1} is the contrast function).

Similarly one can build fixed point iterations for hypergeometric functions starting with the differential equation

$$x(1-x)y'' + [c - (a+b+1)x]y' - aby = 0; \tag{2.28}$$

as before, the derivative of a solution y is also a solution of the hypergeometric equation with the parameters a, b, c incremented by one. Taking y' as the contrast function for y, we have that the associated change of variables is $z(x) = \int \sqrt{ab}/\sqrt{x(1-x)}dx$. Considering, for instance, the case $I = (0,1)$, we see that, if y has at least two zeros in I, then $ab > 0$ and the change of variables is $z(x) = \sqrt{ab}\arcsin(2x-1)$. The change of variables is simple and analytically invertible, and we can proceed similarly to confluent hypergeometric functions.

As for confluent hypergeometric functions, the first order system built from the differential equation is equivalent to the first order DDEs for uniparametric families of functions with parameters $a = -n$, $b = \beta - n$, $c = \gamma - n$; this means that to compute the zeros of a solution $y(a,b;c;x)$ of (2.28), we choose as contrast functions $y(a\pm1, b\pm1; c\pm1; x)$. This is not the only possibility since, for instance, we could also choose $y(a\pm1, b; c; x)$ (and for the confluent case, $y(a\pm1; b; x)$); this was the choice considered in [22] for the case of Legendre, Hermite, and Laguerre polynomials. The selection of the most appropriate contrast functions depending on the ranges of the parameters and the dependent variables lies outside the scope of the present work [7].

As mentioned before, for (confluent) hypergeometric functions, the same methods apply for the computation of the TPs, and because the derivatives of (confluent) hypergeometric functions are (confluent) hypergeometric functions, also satisfy the (confluent) hypergeometric equation. These methods therefore enable us to compute the zeros of classical orthogonal polynomials (Hermite, Laguerre, Legendre, Jacobi, Gegenbauer) and their derivatives, or the zeros and TPs of any other solution of the same differential equation.

2.5.2. Bessel functions. Bessel functions are Kummer functions of imaginary variable [25]; they are a simple example of an important type of function for which the method described above can be used to compute the zeros [21]; however, it is not so simple to employ the same methods for the computation of their turning points. Let us consider Ricatti–Bessel functions y_n (Bessel functions multiplied by $\sqrt{x}$), which satisfy second order ODEs in normal form,

$$y_n'' + A_n(x)y_n = 0, \qquad \text{where } A_n(x) = 1 - \frac{n^2 - 1/4}{x^2}, \tag{2.29}$$

and first order DDEs in normal form

$$\begin{aligned} y_n' &= -\eta y_n + y_{n-1}, \\ y_{n-1}' &= \eta y_{n-1} - y_n, \end{aligned} \qquad \text{with } \eta = \frac{n - 1/2}{x}, \tag{2.30}$$

which can be used to build the corresponding fixed point methods. In this case, the transformations considered in section 2.1 are not required because both the ODE and the DDEs are in normal form; therefore, the change of variables is trivial $z(x) = x$. Since $\eta(x)A_n'(x) > 0$ for $n > 0$, these DDEs are suitable for applying improved iteration steps (Theorem 2.4) for positive orders. (Positive and negative orders are related by reflection formulas; (see [19, equation (24)]).)

Let us notice that we could have considered the first order system associated with the second order ODE (as we did for hypergeometric functions of real variables); however, the associated change of variables

$$z(x) = \int \sqrt{A_n(x)}dx \tag{2.31}$$

is not simple enough to allow for an analytical inversion. For this reason, the first order DDEs (2.30) are preferred. A second essential difference with respect to hypergeometric functions of real variables and parameters is that the computation of TPs is not so simple as the computation of the zeros through (2.30); the derivatives of Bessel functions (or Ricatti–Bessel functions) are not Bessel functions, and they do not satisfy the same type of DDEs. We could consider the first order system associated to the second order ODE to compute the zeros of y_n' using as a contrast function the same y_n; however, as commented, we are faced with the numerical inversion of the change of variables (2.31). Also, the possibility of considering y_n' as the problem function with contrast function y_{n-1}' (as we can do for hypergeometric functions) is also possible, but the associated change of variables is even more involved than (2.31) and is related to elliptic integrals.

In the next section, we propose an alternative method, which is based on the direct use of second order ODEs in normal form.

3. Method II: Fixed point methods based on second order ODEs in normal form.

Much as did the method based on first order systems, the method that we are next describing converges with certainty. Also, as we will show, the method is quadratically convergent. It can be used to compute zeros and TPs of any solution of a given second order ODE in normal form,

$$y''(x) + A(x)y(x) = 0, \tag{3.1}$$

where we assume that $A(x)$ is continuous and that $y(x)$ has continuous second derivative (and is not a trivial solution).

Differently from Method I, Method II does not provide iteration steps in order to find with certainty all the zeros (or TPs) of a solution of the second order ODE in a given interval I. However, we can use this method to compute bracketed zeros or TPs.

In particular, we will describe the computation of TPs of solutions of second order ODEs in normal form, which are bracketed by the zeros of these solutions. This new method will solve a considerable number of cases for which Method I, based on first order systems, failed to provide a simple solution.

This method can also be efficiently applied to second order ODEs, which can be transformed to normal form by a simple (analytically invertible) change of variables. It is important to realize that for calculating the TPs of solutions of a second order ODE

$$y'' + \tilde{B}(x)y' + \tilde{A}(x)y = 0 \tag{3.2}$$

we cannot consider changes of the dependent variable in order to write down an equation in normal form, because the extrema of $\nu(x)y(x)$ are not the extrema of $y(x)$. However, considering a change of variable $z = z(x)$, we arrive at

$$(z')^2\ddot{y} + [z'' + \tilde{B}z']\dot{y} + \tilde{A}y = 0, \tag{3.3}$$

where dots mean derivatives with respect to z, and the primes are derivatives with respect to x. And, choosing

$$z(x) = \int \exp\left(-\int \tilde{B}dx\right)dx, \tag{3.4}$$

we have

$$\ddot{y}(z) + A(z)y(z) = 0, \quad A(z) = A(x(z))\dot{x}^2. \tag{3.5}$$

The TPs of $y(x)$ will be $z^{-1}(z_{y'}^{(j)})$, with $z_{y'}^{(j)}$ being the turning points of $y(x(z))$. Thus, the problem of finding the TPs of any second order ODE with continuous coefficients $\widetilde{B}(x)$, $\widetilde{A}(x)$ can be reduced to the problem of finding the turning points of a second order ODE in normal form. We will require that this change of the independent variable be a simple change (i.e., analytically invertible in terms of elementary functions).

Of course, similarly to Method I, Method II can be applied in general, regardless of whether the change of variable is elementary. However, the cases when the change is simple are the most indicated for the method. Combining Methods I and II, the spectrum of functions whose zeros and TPs can be easily computed (with simple changes of variable) becomes very wide. As we know, the zeros and TPs of (confluent) hypergeometric functions of real parameters and variables can be obtained with Method I. Combining Methods I and II, we can add to the list of satisfactorily solved problems, among others, the computation of the zeros and TPs of Airy, Bessel ($\mathcal{C}_\nu = \cos\alpha J_\nu(x) - \sin\alpha Y_\nu(x)$), and Coulomb wave functions; Whittaker functions of real parameters; associated Legendre functions (ALFs) of real parameters and conical functions (ALFs of complex degrees); and the zeros of Bessel-related functions like $x^\alpha C_\nu(x)$. Both Methods I and II deal with any solution of the corresponding second order ODE (and not only the regular solution or the polynomial solutions, as is the case of matrix methods [1]).

3.1. Construction of the method for ODEs in normal form. In what follows, we consider that the zeros of a function $y(x)$ inside an interval $[x_1, x_2]$ have already been evaluated by using Method I (or any other method) and that this function satisfies a second order ODE in normal form (3.1). We further assume that $A(x)$ has no more than one zero in the interval of interest $[x_1, x_2]$. If this were not so, we would subdivide the search for TPs for different subintervals where this property holds.

If there is a value $x_a \in [x_1, x_2]$ for which $A(x_a) = 0$, we will take $A(x) < 0$ in $[x_1, x_a)$ and $A(x) > 0 \in (x_a, x_2]$, making the change of independent variable $x \to -x$, if necessary.

It is straightforward to prove that y can have no more than one zero in $[x_1, x_a)$; this is so because $y''y \geq 0$ in $[x_1, x_a]$. It is also a simple matter to check that the zeros of y and y' are interlaced in $(x_a, x_2]$; see the following.

LEMMA 3.1. *The zeros of y and y' are interlaced in $(x_a, x_2]$.*

Proof. y and $v \equiv y'$ can not vanish simultaneously, given that we assume that y is not a trivial solution. Interlacing is an immediate consequence of the fact that the Wronskian of y and v is always different from zero. Indeed, $W[y, v] = y'v - yv' = (y')^2 - y''y = (y')^2 + A(x)(y)^2 > 0$. □

The first step towards an algorithm to evaluate the TPs of y is computing each TP between two consecutive zeros of y in $(x_a, x_2]$. For this, given that the TPs are bracketed by the zeros of y (because they are interlaced) except for one possible exception (see the discussion after Lemma 3.12), one can, for instance, use bisection. Instead, we introduce fixed point iterations which are quadratically convergent.

Given the interlacing of the zeros of y and y', it is expected that the logarithmic derivative of y will behave roughly like the tangent function, which can be used to set globally convergent fixed point iterations. Namely, defining

$$h(x) = -\frac{y'(x)}{y(x)}, \tag{3.6}$$

taking the derivative, and using $y''(x) + A(x)y(x) = 0$, we get

$$h' = A + h^2; \tag{3.7}$$

thus h is monotonically increasing when $A(x) > 0$ except at the zeros of y. This equation is the starting point of the method. In order to implement the method we require only that an algorithm to evaluate the logarithmic derivative be available. Assuming that the function $y \equiv y_n$ satisfies relations of the form (2.19), we need only to evaluate ratios y_n/y_{n-1} (or y_n/y_{n+1}) for computing both the zeros (Method I) and TPs (Method II).

Let us first discuss the calculation of TPs when $A(x) > 0$, that is, for $x > x_a$. The next theorem provides globally convergent fixed point iterations on subintervals $(x^{(j)}, x^{(j+1)})$, with $x^{(k)}$ being the zeros of $y(x)$.

THEOREM 3.2. *Let D be the logarithmic derivative of y. Let $x^{(j)}$, $x^{(j+1)}$ be two consecutive zeros of y, and $x' \in (\bar{x}_1, \bar{x}_2) \subseteq (x^{(j)}, x^{(j+1)})$ a turning point of y. If $0 < A(x) < K$ $\forall x \in (\bar{x}_1, \bar{x}_2)$, then*

$$\lim_{p \to \infty} T^{(p)}(x) = x' \qquad \forall x \in (\bar{x}_1, \bar{x}_2),$$

where

$$T(x) = x + \frac{1}{\sqrt{K}} \arctan\left(\frac{D}{\sqrt{K}}\right) \tag{3.8}$$

and the convergence is monotonic.

Proof. Let $h = -D = -\frac{y'}{y}$; then $h' < K + h^2$, that is, $\frac{h'}{K+h^2} - 1 < 0$, and then

$$\operatorname{sign}(x - x') \int_{x'}^{x} \left[\frac{h'}{K + h^2} - 1 \right] < 0.$$

Performing the integral and taking into account that $h(x') = 0$, we get

$$\operatorname{sign}(x - x') \left[\frac{1}{\sqrt{K}} \arctan\left(\frac{h}{\sqrt{K}} \right) - (x - x') \right] < 0. \tag{3.9}$$

Then, if $x > x'$ $(x \in (\bar{x}_1, \bar{x}_2))$,

$$x' < x - \frac{1}{\sqrt{K}} \arctan\left(\frac{h}{\sqrt{K}} \right) \equiv T(x)\,,$$

and given that $h' > 0$ in $(x_a, x_2]$, then $h > 0$ in $(x', \bar{x}_2)$ (and $h < 0$ in $(\bar{x}_1, x')$). Therefore

$$x' < T(x) = x + \frac{1}{\sqrt{K}} \arctan\left(\frac{D}{\sqrt{K}} \right) < x. \tag{3.10}$$

Similarly, if $x < x'$,

$$x' > T(x) > x, \tag{3.11}$$

and given that x' is the only fixed point of $T(x)$ in $(\bar{x}_1, \bar{x}_2)$ and considering that, according to (3.10) and (3.11), the successive iterations of T form monotonic sequences, we have that

$$\lim_{p\to\infty} T^{(p)}(x) = x' \qquad \forall x \in (\bar{x}_1, \bar{x}_2)$$

and convergence is monotonic. □

Corollary 3.3. *If x is a zero adjacent to a turning point x' of y and $0 < A < K$ between x and x', then $|x - x'| > \pi/(2\sqrt{K})$.*

Proof. Take x in (3.9) to be a zero of y adjacent to x'. □

An immediate consequence of this corollary is the following.

Corollary 3.4. *If $x^{(j)}$, $x^{(j+1)}$ are two consecutive zeros of y and $0 < A < K$ between $x^{(j)}$ and $x^{(j+1)}$, then $|x^{(j+1)} - x^{(j)}| > \pi/\sqrt{K}$.*

This is nothing but the classical result from Sturm's comparison theorem [25].

Similarly, it is easy to prove the following result.

Proposition 3.5. *If x is a zero adjacent to a turning point x' of y and $0 < k < A$ between x and x', then $|x - x'| < \pi/(2\sqrt{k})$.*

Corollary 3.6. *Similarly, if $x^{(j)}$, $x^{(j+1)}$ are two consecutive zeros of y and $0 < k < A$ between $x^{(j)}$ and $x^{(j+1)}$, then $|x^{(j+1)} - x^{(j)}| < \pi/\sqrt{k}$.*

Corollaries 3.4 and 3.6 also apply to consecutive turning points of y.

The bounds from Corollary 3.3 and Proposition 3.5 can be sufficient when A varies slowly to obtain accurate values for the turning points, as in the following.

Proposition 3.7. *Let x' be a turning point between two consecutive zeros of y such that $x' \in (x^{(j)}, x^{(j+1)})$, and let $0 < k < A(x) < K$ in $(x^{(j)}, x^{(j+1)})$. Then $x' \in J \equiv (x_m - \lambda, x_m + \lambda)$ with $x_m = (x^{(j)} + x^{(j+1)})/2$ and $\lambda = \left[k^{-1/2} - K^{-1/2}\right]\pi/4$. Also, $J \subset (x^{(j)}, x^{(j+1)})$ if $K/k < 9$.*

Then, if the upper and lower bounds of A are similar, x_m will be a good approximation to x' with relative accuracy better than λ/x_m. Even if x_m is not a good enough approximation, we can use it as a starting value to evaluate x' by means of the fixed point iteration previously discussed.

When the function $A(x)$ is monotonic in some interval, the speed of convergence of the fixed point iteration can be improved by adjusting the upper bound K in each iteration. For instance, if $A(x)$ is positive and increasing inside an interval $\bar{I} = (\bar{x}_1, \bar{x}_2)$ which contains a TP of $y(x)$, x', and $y(x) \neq 0 \ \forall x \in \bar{I}$, then $x' < T(x) < x$ for any $x \in \bar{I}$ such that $h(x) > 0$. $T(x)$ is the fixed point iteration of (3.8) with K the upper bound of $A(x)$ in $\bar{I}$. But, because $x' < T(x) < x$, the same holds if K is replaced by the upper bound of $A(x)$ in $(x', x]$, which is $A(x)$. Therefore we have the following.

THEOREM 3.8. *Let D be the logarithmic derivative of y. Let $\bar{I} = (\bar{x}_1, \bar{x}_2)$ be an interval such that $A(x) > 0$ in $\bar{I}$ and $y(x) \neq 0 \, \forall x \in \bar{I}$; let $x' \in \bar{I}$ be a turning point of $y(x)$. If A is monotonic in $\bar{I}$ and $x_0 \in \bar{I}$ is such that $A'(x_0)h(x_0) \geq 0$, then*

$$\lim_{p \to \infty} T^{(p)}(x_0) = x',$$

where

$$T(x) = x + \frac{1}{\sqrt{A(x)}} \arctan\left(\frac{D(x)}{\sqrt{A(x)}}\right) \tag{3.12}$$

and the convergence is monotonic.

Later we will show that the fixed point method of the previous theorem is quadratically convergent.

If $A(x)$ is monotonic, we can find a guideline for choosing a starting value for which Theorem 3.8 holds. Although $x_m = (x^{(j)} + x^{(j+1)})/2$ could be a good estimation, it is not the best choice, given that for this initial value one can not apply Theorem 3.8, as the next result shows.

PROPOSITION 3.9. *Let $A(x)$ be positive ($x > x_a$) and x' the turning point of y in $(x^{(j)}, x^{(j+1)})$.*

1. *If $A(x)$ is increasing in $(x^{(j)}, x^{(j+1)})$, then $x_m \equiv (x^{(j)} + x^{(j+1)})/2 < x'$ and $h_m(x_m) < 0$.*
2. *If $A(x)$ is decreasing in $(x^{(j)}, x^{(j+1)})$, then $x_m \equiv (x^{(j)} + x^{(j+1)})/2 > x'$ and $h(x_m) > 0$.*

Proof.

1. $A(x') \equiv k$ is the upper bound of A in $(x^{(j)}, x']$, and then $x' - x^{(j)} > \pi/(2\sqrt{k})$ (Corollary 3.3). On the other hand, k is the lower bound of A in $[x', x^{(j+1)})$, and then $x^{(j+1)} - x' < \pi/(2\sqrt{k})$ (Proposition 3.5). Then $x_m < x'$ and $h(x_m) < 0$ because h is monotonically increasing for $x > x_a$.
2. This is shown similarly as in 1. □

However, Proposition 3.7 gives a recipe for choosing a starting value for which Theorem 3.8 will hold, whenever A does not show very strong variations and $K/k < 9$.

(a) If A is increasing in $(x^{(j)}, x^{(j+1)})$, take as a starting value $x_m + \lambda$.

(b) If A is decreasing in $(x^{(j)}, x^{(j+1)})$, take as a starting value $x_m - \lambda$.

If $K/k > 9$, we could, for instance, choose x_m as a starting value and apply Theorem 3.2. (We have never encountered such a situation in the examples we will later discuss.) An alternative, which is generally more efficient, is locating a value of x for which Theorem 3.8 applies; this can be done by applying one or two bisection steps. This possibility is generally better because, as mentioned, the fixed point iteration of Theorem 3.8 is quadratically convergent.

If $A(x)$ has a turning point in $(x^{(j)}, x^{(j+1)})$, the previous two rules are substituted with the following:

(c) If $A(x)$ has a maximum in $x_{Max} \in (x^{(j)}, x^{(j+1)})$, take x_{Max} as a starting value;

(d) If $A(x)$ has a minimum in $x_{Min} \in (x^{(j)}, x^{(j+1)})$, take $x_{Min} - \operatorname{sign}(h(x_{Min}))\lambda$ (provided $K/k < 9$).

Of course, in principle several extrema of $A(x)$ could be located between two consecutive zeros of y. However, rules (a), (c), and (d) will suffice in most circumstances. With this choice of starting values the improved iteration in Theorem 3.8 converges monotonically.

We have all the ingredients for computing the TPs between two consecutive zeros which are greater than x_a. The only thing left is the TPs in $[x_1, x^{(a+)})$, with $x^{(a+)}$ being the smallest zero larger than x_a (in the case that $x_1 < x_a$). First, it is important to note the following results.

Lemma 3.10. *If x_a is a TP, x_a is a double root of $y' = 0$ and there are no other TPs in $[x_1, x^{(a+)})$.*

Lemma 3.11. *If there are no TPs in $(x_a, x^{(a+)})$, then there are no TPs in $[x_1, x_a)$.*

Lemma 3.12. *If there is a zero of y in $[x_1, x_a]$, then there are no TPs in $[x_1, x_a]$.*

Lemmas 3.11 and 3.12 are consequences of the different convexity properties of y for $x > x_a$ and $x < x_a$ and the continuity of y''.

One should always test the existence of a TP in $[x_a, x^{(a+)})$ and compute it when it exists. If $h(x_a) = 0$, there is a turning point at x_a and no more TPs in $[x_1, x_a)$ (Lemma 3.10). If this is not so and there are no TPs in $(x_a, x^{(a+)})$, then there are no TPs in $[x_1, x_a]$ (Lemma 3.11). On the contrary, we must compute the TP in $(x_a, x^{(a+)})$ and later check the existence of a TP in (x_1, x_a) in case there is no zero of y in this subinterval (Lemma 3.12).

To compute the possible TP in $(x_a, x^{(a+)})$, bisection can be used; the convergence is accelerated by using the iteration of Theorem 3.8 when $A(x)$ is monotonic or has at most one extremum in $(x_a, x^{(a+)})$. If this is not so, Theorem 3.2 can be applied.

For finding the possible TP in (x_1, x_a) one cannot use the fixed point iterations discussed so far. Bisection is a safe choice but not the fastest method. We can use a fixed point iteration, which converges for values close enough to the TP, in order to "polish" the roots as follows.

Theorem 3.13. *Let x' be a TP in $[x_1, x_a]$ and let $-C < A(x) < 0$ in an interval I such that $x' \in I \subseteq [x_1, x_a)$, with C a positive constant; then*

$$\lim_{p\to\infty} \bar{T}^{(p)}(x) = x' \qquad \forall x \in I \textit{ such that } h^2 < C \textit{ between } x \textit{ and } x',$$

where

$$\bar{T}(x) = x - \frac{1}{\sqrt{C}} \tanh^{-1}\left(\frac{D}{\sqrt{C}}\right). \tag{3.13}$$

Proof. $h' = A + h^2 > -C + h^2$, but $h^2 < C$ and therefore $\frac{h'}{-C+h^2} - 1 < 0$. Integrating, we get

$$\operatorname{sign}(x - x') \int_{x'}^{x} \left(\frac{h'}{-C + h^2} - 1\right) dx < 0$$

and

$$\operatorname{sign}(x - x')[R(x) - (x - x')] < 0, \tag{3.14}$$

where

$$R(x) = \frac{1}{2\sqrt{C}} \log \frac{\sqrt{C} - h}{\sqrt{C} + h} = \frac{1}{\sqrt{C}} \tanh^{-1}\left(\frac{D}{\sqrt{C}}\right),$$

and similarly as in Theorem 3.2, monotonic convergence holds from (3.14). □

In the common case in which A is increasing in $[x_1, x_a]$, the following alternative to Theorem 3.13 can be considered, with the advantage that the iteration is quadratically convergent.

THEOREM 3.14. *Let x' be a TP in $[x_1, x_a)$ and let $A(x)$ be increasing in $[x_1, x_a)$. Let $x_0 < x'$ such that $0 < h(x_0) < \sqrt{-A(x_0)}$; then*

$$\lim_{p\to\infty} \bar{T}^{(p)}(x_0) = x',$$

where

$$\bar{T}(x) = x - \frac{1}{\sqrt{-A(x)}} \tanh^{-1}\left(\frac{D}{\sqrt{-A(x)}}\right), \tag{3.15}$$

and the convergence is monotonic.

If $A(x)$ may become negative on two subintervals $I_1 = [x_1, x_a)$ and $I_2 = (x_b, x_2]$ contained in the interval of interest $[x_1, x_2]$, the following Corollary can be applied to compute the possible TPs in I_1 (case of Theorem 3.14) and I_2.

COROLLARY 3.15. *Let x' be a TP inside an interval B where $A(x) < 0$, $A(x)$ being monotonic in B. Let $x_0 \in B$ such that $0 < h(x_0)\mathrm{sign}(A(x_0)) < \sqrt{-A(x_0)}$; then $\lim_{p\to\infty} \bar{T}^{(p)}(x_0) = x'$ with $T(x)$ as in Theorem 3.14. The convergence is monotonic.*

3.2. Order of convergence of the method. A good reason to consider the improved iterations from Theorems 3.8 and Corollary 3.15 instead of the iterations from Theorems 3.2 and 3.13 is that the first two iterations are quadratically convergent. Given that we can easily choose starting values such that the hypothesis of Theorems 3.8 and Corollary 3.15 are met, our algorithms (see the next section) will be based on these fixed point iterations.

It is straightforward to check that the fixed point iterations (3.12) and (3.15) are quadratically convergent. For instance, taking the derivative of the iteration (3.12) and considering the second order ODE (2.1), we have

$$T'(x) = -\frac{A'}{2A}\left[\frac{y'/y}{A + (y'/y)^2} + \frac{1}{\sqrt{A}} \arctan\left(\frac{y'/y}{\sqrt{A}}\right)\right]. \tag{3.16}$$

Therefore, if x' is a turning point of y for $x > x_a$ (a fixed point of $T(x)$), we have that $T'(x') = 0$ and then the convergence is quadratical.

Besides, we see that for $x > x_a$, $|T'(x)| \leq \frac{|A'(x)|}{4A^{3/2}(x)}\pi = |\frac{\pi}{2}\frac{d}{dx}A^{-1/2}(x)|$, which, similarly as for Method I, can be used to bound the absolute error after n iterations. The convergence is faster as $A^{-1/2}(x)$ varies more slowly.

A similar analysis can be made with the iteration (3.15).

3.3. Algorithm for the computation of TPs. Let us now describe the algorithm (using a FORTRAN-like style) for the computation of the TPs of a function $y(x)$ in an interval $I = [x_1, x_2]$. As noted in the beginning of section 3.1, we need to consider only the evaluation of TPs in an interval $I = [x_1, x_2]$, where $A(x)$ changes sign at most once, at x_a, and $A(x) < 0$ if $x < x_a$, $A(x) > 0$ if $x > x_a$. However, we have also considered the possibility that $A(x)$ may have two zeros $x_a^{(-1)}$ and $x_a^{(+1)}$ ($A(x)$ being positive in $(x_a^{(-1)}, x_a^{(+1)})$), which is an easy-to-carry generalization; we consider only the possibility of $A(x)$ having one maximum in I or $A(x)$ being monotonic in I; this is enough for a vast number of special functions.

The algorithm consists of the implementation of Theorem 3.8 for the computation of TPs for $x \in (x_a^{(-1)}, x_a^{(+1)})$ and Theorem 3.14 for $x < x_a^{(-1)}$ (which should be replaced by Theorem 3.13 if $A(x)$ is not increasing in $(x_1, x_a^{(-1)})$). When $x > x_a^{(+1)}$, according to the fact that we consider that $A(x)$ has at most one maximum, we suppose that $A(x)$ is decreasing. For the computation of the possible TP in this interval, we apply Corollary 3.15.

Algorithm: Computation of Turning Points.

Let $I \equiv [x_1, x_2]$ be the interval for the computation of TPs of $y(x)$, which is the solution of a second order ODE $y'' + A(x)y = 0$. $A(x)$ is a differentiable function with at most one extremum ($x = x_e$) in I, such possible extremum being a maximum.

Let L be such that $-L < x_1$, $L > x_2$. We define the quantities $x_a^{(-1)}$ and $x_a^{(+1)}$ as follows: $x_a^{(s)} \in I$ are such that $A(x_a^{(s)}) = 0$ and $A'(x_a^{(s)}) * s < 0$; if a value $x_a^{(s)}$ does not exist, we set $x_a^{(s)} = s * L$.

x_e is the maximum of $A(x)$. We set $x_e = -L$ if $A'(x_1) \leq 0$, and $x_e = L$ if $A'(x_2) \geq 0$. (There can be no maximum in these cases.)

Let $x^{(j)}$ be the zeros of $y(x)$, $x^{(n)} \in I$ being the smallest zero in I greater than $x_a^{(-1)}$, and $x^{(m)}$ ($m \geq n$) the largest zero in I smaller than $x_a^{(+1)}$.

Also, we will use the function $h(x) = -y'(x)/y(x)$ and, finally, given three real values x_l, x_u ($x_l < x_u$) and x_p, we define

$$\mathrm{isg}(x_l, x_u, x_p) = \begin{cases} -1 & \text{if } x_p \leq x_l, \\ 0 & \text{if } x_p \in]x_l, x_u[, \\ +1 & \text{if } x_p \geq x_u. \end{cases}$$

Then, the following algorithm computes with certainty all the zeros of $y'(x)$ in I.

Input: x_1; x_2; $x_a^{(\pm 1)}$; x_e, $x^{(n)} \dots x^{(m)}$; $\epsilon \equiv$ relative precision
Output: $x'(j)$: turning points in I. $j = ((n-2), n-1), n, \dots, m-1, (m, (m+1))$
Common parameters and functions for the routines: x_e, ϵ, $A(x)$, $h(x)$

The structure of the algorithm is as follows.

1. Lines (1)–(23) are the main program.
    (i) (1)–(12). The TPs of y, which are bracketed by their zeros (inside the interval where $A(x)$ is positive), are computed. Line (4) implements rule

(c) (one maximum of $A(x)$ between the two consecutive zeros). In line (5) the rules (a) or (b) (after Proposition 3.9) to obtain the starting values are implemented (case of monotonic $A(x)$), in the case when the upper (K) and lower bounds (k) for $A(x)$ verify $K/k < 9$; if this condition is not met, rules (a) or (b) cannot be applied. Then, the program calls SX, which computes a starting value (using a few bisection steps) for which the conditions of Theorem 3.8 are met. Then, the subroutine FP, which implements this theorem (as well as Corollary 3.15), is applied.

(ii) (13)–(17). The TPs in $[x_a^{(-1)}, x^{(n)})$ and $[x_1, x_a^{(-1)})$ are computed; if they exist, they are stored in the positions: $n-1$ and $n-2$ (respectively) of the array x'. Such computation is performed by the routine EXTR with first parameter -1.

(iii) (17)–(21). Same as before, but for the intervals $(x^{(m)}, x_a^{(+1)}]$ and $(x_a^{(-1)}, x_2]$. The TPs, if they exist, are stored in the positions m and $m+1$. Such computation is performed by the routine EXTR with first parameter $+1$.

2. Lines $(1)_1$–$(15)_1$. As described above, the routine SX performs a few bisection steps until either Theorem 3.8 or Corollary 3.15 can be applied.
3. Lines $(1)_2$–$(11)_2$. The fixed point iterations of Theorem 3.8 (line $(5)_2$) and Corollary 3.15 (line $(7)_2$) are implemented.
4. Lines $(1)_3$–$(13)_3$. This routine checks the existence of extreme TPs (those described above in items 1(ii) and 1(iii)). If they exist, starting values are computed which guarantee that Theorem 3.8 and/or Corollary 3.15 can be applied.
5. Lines $(1)_4$–$(2)_4$. Auxiliary routine called by EXTR (lines $(1)_3$–$(13)_3$).

4. Computation of the ratios y/w and the logarithmic derivatives y'/y.

In the methods described in the two previous sections, it is assumed that algorithms are available to compute the ratio between the problem function and the contrast function y/w for Method I and the logarithmic derivative for Method II. Although the numerical analysis of the computation of these ratios lies beyond the scope of the present paper, we give here some hints for the computation of ratios for functions satisfying three term recurrence relations (TTRRs).

We consider the particular case of functions which are solutions of a uniparametric family of second order ODEs, as described in section 2.3.1; this is the case of a great number of special functions. In this case, the ratios for both methods are related. The contrast function for the computation of the zeros of y_n (Method I) will be y_{n-1} or y_{n+1}. Using (2.19), we have that the logarithmic derivative for the problem function can be written as $y_n'/y_n = d_n(x) + a_n(x)y_n(x)/y_{n-1}(x)$; on the other hand, the ratio y_n/y_{n+1} is related to y_n/y_{n-1} through the TTRR (2.24), which can be used to compute the ratios $R_n = y_n/y_{n-1}$ from recursion:

$$\begin{aligned} R_n &= r_{n-1} + \frac{s_{n-1}}{R_{n-1}} \qquad \text{(forward recurrence)}, \\ R_n &= \frac{s_n}{R_{n+1} - r_n} \qquad \text{(backward recurrence)}. \end{aligned} \tag{4.1}$$

The problem of computing ratios of special functions of consecutive orders, $R_n = y_n/y_{n-1}$, satisfying a TTRR has been broadly studied in the literature. A classical reference for condition and stability issues is the article by Gautschi [6]; see also [30, 4].

Important results are Perron's and Pincherle's theorems. Perron's theorem is a classical result for determining when a TTRR admits a minimal solution $y_n^{\downarrow}$ (see [6] and [25]) and what its asymptotic behavior is as $n \to \infty$. A solution $y_n^{\downarrow}$ of a TTRR is said to be minimal if, for any other solution $y_n^{\uparrow}$ (dominant solution), we have that $\lim_{n\to\infty} y_n^{\downarrow}/y_n^{\uparrow} = 0$. (Of course, the minimal solution, if it exists, is unique.) Perron's theorem does not always provide an answer to the problem of the existence of a minimal solution; there are cases which need to be analyzed by other means. Of course, there is also the possibility that a TTRR has no minimal solution (and hence no dominant ones).

When a solution $y_n^{\uparrow}$ is known to be dominant, forward recursion is well conditioned, and the first equation in (4.1) can be safely iterated to compute the values of $R_n = y_n^{\uparrow}/y_{n-1}^{\uparrow}$ starting from a ratio $y_k^{\uparrow}/y_{k-1}^{\uparrow}$ $(k < n)$; for a minimal solution the same happens for the backward recursion (that is, starting from $k > n$ and using the second equation in (4.1)). A related result is Pincherle's theorem, which guarantees the convergence of the infinite continued fraction for the ratio of consecutive minimal solutions $y_n^{\downarrow}/y_{n-1}^{\downarrow}$ obtained by iterating infinitely many times the second recurrence of (4.1).

Then, if the function under consideration is a minimal solution of the corresponding TTRR, an infinite continued fraction can be used to compute the ratios $y_n^{\downarrow}/y_{n\pm1}^{\downarrow}$. It should be noted that only the coefficients r_n and s_n of the TTRR are needed for such a computation. In order to compute the continued fraction, the use of the Lentz–Thompson algorithm [2, 26, 17] has the great advantage that overflow problems caused by cancellation of the denominators are under control; this is an important feature when computing ratios of functions both having zeros in the interval under consideration. Minimal solutions are, for instance, the Bessel functions J_ν, the conical functions $P_{-1/2+i\tau}^{m}$, and the regular Coulomb functions $F_{L,\rho}(x)$. Of course, depending on the range of the parameters and the variables, the continued fraction will converge at different speeds. For instance, for the case of first kind Bessel functions $J_\nu(x)$ that we will later describe, the convergence of the continued fraction slows down as x increases. The same is true for regular Coulomb wave functions and for conical functions.

Apart from the condition issues previously described, it is impossible to provide a general recipe for the computation of these ratios of special functions. For instance, for dominant solutions (or more generally nonminimal solutions), even if the forward recurrence relation can be used to compute the ratios y_n/y_{n-1} starting from, say, y_1/y_0, the difficulty in the computation of this initial ratio is strongly dependent on the function under consideration: it is trivial to compute for orthogonal polynomials (understanding that n is the degree of the polynomial), but it is not so for irregular Coulomb wave functions, among other examples. (For more trivial and nontrivial examples, see, for instance, [18].) In fact, for the case of Coulomb functions that we will later analyze, the computation of the zeros for the regular Coulomb wave function can be made by using its continued fraction representation, while for any other solution combining the regular and the irregular solutions, we will directly compute the numerator and the denominator using Barnett's code [2].

We will not insist on the analysis of the computation of special function values. For the theory of the computation through TTRRs, see [4, 6, 25, 30]; numerical details on the computation of special function ratios can be found, for instance, in [2, 21, 20].

As previously noted, there are a great number of functions for which stable methods to compute the ratios are available. This has enabled the authors to develop algorithms which are able to compute the zeros and TPs of the classical orthogonal polynomials and of several important special functions: Jacobi and related polynomials (Gegenbauer, Legendre), Laguerre polynomials, Hermite polynomials, Bessel functions, Airy functions, and Coulomb wave functions.

5. Numerical examples.

In order to illustrate the performance of the methods developed, we will consider three different examples for which Methods I and II are combined to compute the zeros and TPs: Bessel functions, Coulomb wave functions, and conical functions. Of these three examples, the cases of the zeros of Bessel functions [1, 10, 12] and Coulomb wave functions [1, 11, 12] have been also considered as illustrations of the matrix methods.

5.1. Bessel functions.

The Bessel equation reads

$$y_n'' + \frac{1}{x} y_n' + \left(1 - \frac{n^2}{x^2}\right) y_n = 0 \tag{5.1}$$

with real n. The zeros and TPs of the regular Bessel function can be computed by means of matrix eigenvalue methods [1, 10, 12] (being the minimal solution of a TTRR). The zeros and TPs of irregular solutions $Y_n(x)$ can not be computed using these methods, but methods based on asymptotics [24] or more general-purpose methods [13, 27, 28] have been used. The methods discussed here cover not only these cases but also general cylinder functions $\mathcal{C}_n \equiv \cos\alpha J_n - \sin\alpha Y_n$ (and thus, for instance, also the case of Airy functions).

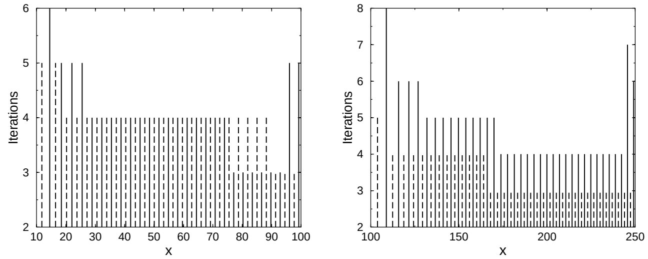
Ricatti–Bessel functions are the solutions of the second order ODE

$$y_n'' + \left(1 - \frac{n^2 - 1/4}{x^2}\right) y_n = 0, \tag{5.2}$$

with solutions related to Bessel functions by $y_n(x) = \sqrt{x}\mathcal{C}_n(x)$. Their zeros, of course, coincide with the zeros of Bessel functions but not their TPs. We discuss the evaluation of the zeros and TPs of Bessel and Ricatti–Bessel functions (appearing, for instance, in quantum electromagnetism [3]) and, in general, of TPs of $x^\alpha \mathcal{C}_n(x)$, that is, of zeros of $\alpha\mathcal{C}_n(x) + x\mathcal{C}_n'(x)$.

The evaluation of the zeros of Bessel or Ricatti–Bessel functions is performed as discussed in section 2.5.2. Figure 1 shows the performance of the fixed point method (Method I) for the evaluation of the zeros of Bessel functions (backward sweep). FORTRAN language was used, and the ratios J_n/J_{n-1} were computed using the continued fraction representation. The number of iterations needed to achieve a double precision ($\sim$ 15 digits) computation for each zero is shown. Notice that the number of iterations needed for the evaluation of the smallest zero increases with increasing order. This is as expected since the function $|\eta(x)|$ increases with decreasing x, which means that the convergence of the fixed point method must be slower for low x; besides, the spacing between the first zeros becomes larger as the order increases. However, the number of iterations increases mildly. Notice also that the two largest zeros evaluated need more iterations than the immediately smaller zeros; this is so because we need to compute two zeros before improved iteration steps can be considered. This figure thus illustrates the effect of improving the iteration step.

We have also implemented the algorithm in Maple, with the advantage that one can select almost arbitrarily the number of digits for the computation. The description of a Maple procedure to compute zeros of special functions using Method I can be found in [8]. With this, one can check that with few additional iterations the achieved



(a) (b)

FIG. 1. *Number of iterations needed for the evaluation of the zeros of the first kind Bessel function $J_n(x)$ and its derivative, plotted as a function of the values of the zeros of J_n and its derivative. Results for two different orders are shown:* (a) $n = 10$ *and* (b) $n = 100$. *The solid vertical bars correspond to the number of iterations needed in order to compute the zeros with* 15 *exact digits; the dashed lines represent the number of iterations for the computation of TPs.*

accuracy can be greatly improved. For instance, in order to achieve 10^{-100} accuracy only two or three additional iterations of the function $T(z)$ are needed for $n = 10$ and similarly for $n = 100$.

Regarding the TPs, the zeros of the derivative of Bessel–Ricatti functions can be computed directly using Theorem 3.8, given that these functions satisfy a second order ODE in normal form. For the case of Bessel functions, defined by (5.1), we have to consider a change of variables to transform the equation into normal form (section 3):

$$z(x) = \int \exp\left(-\int B dx\right) dx, \qquad B(x) = \frac{1}{x} \to z(x) = \ln x. \tag{5.3}$$

In the new variable z the differential equation reads

$$\ddot{y}_n + [e^{2z} - n^2] y_n = 0, \tag{5.4}$$

and $\tilde{A}(z) = e^{2z} - n^2$ ($\tilde{A}(z(x)) = x^2 - n^2$) is increasing. After this change of variables, one can apply the methods described in sections 3.1 and 3.3. Notice that the x variable in these sections corresponds to the z variable of (5.4). We can undo this change in the fixed point iteration, first rewriting the logarithmic derivative as

$$D(z(x)) = \frac{\dot{y}_n(x(z))}{y_n(x(z))} = x\frac{y_n'(x)}{y_n(x)}. \tag{5.5}$$

With this, the fixed point iteration of Theorem 3.12 reads

$$T(z) = z + \frac{1}{\sqrt{x^2 - n}} \arctan\left(\frac{x y_n'(x)}{y_n(x)\sqrt{x^2 - n}}\right), \qquad x = e^z. \tag{5.6}$$

For seeking the TPs inside intervals $(x_n^{(j)}, x_n^{(j+1)})$ the previous iteration is used, taking as a starting value $z_0 = z_m + \lambda$, with

$$z_m = \frac{\ln(x_n^{(j)}) + \ln(x_n^{(j+1)})}{2} = \ln\left(\sqrt{x_n^{(j)} x_n^{(j+1)}}\right) \tag{5.7}$$

and

$$\lambda = \frac{\pi}{4}\left(k_n^{-1/2} - K_n^{-1/2}\right), \quad k_n = (x_n^{(j)})^2 - n^2, \quad K_n = (x_n^{(j+1)})^2 - n^2. \tag{5.8}$$

Here z_0 is larger than $z(x'_n)$ and lies inside $(z(x_n^{(j)}), z(x_n^{(j+1)}))$ whenever $K_n/k_n < 9$. The corresponding starting value x_0 is therefore $x_0 = \exp(\lambda)\sqrt{x_n^{(j)} x_n^{(j+1)}}$.

For TPs outside intervals $(x_n^{(j)}, x_n^{(j+1)})$ (or in the rare situations for which $K_n/k_n \geq 9$) we proceed as discussed in sections 3.1 and 3.3.

With this, it turns out that the computation of the TPs is very efficient and that typically 3-4 iterations are enough to attain double precision values (15 digits) for the turning points (Figure 1). Similarly, as happens with the computation of the zeros, only two additional iterations are required when the accuracy demanded is 10^{-100}.

As a spin-off of the method, it is interesting to note that the fact that $z_m = z(x_m) < z(x'_n)$ leads to the inequality $\sqrt{x_n^{(j)} x_n^{(j+1)}} < x'_n$ relating two consecutive zeros of a cylinder function and the zero of the derivative between such zeros. This is a general inequality for the solutions of Bessel equations which proves a conjecture by Elbert [5, 23].

THEOREM 5.1. *Let $j_{\nu,\kappa}$ and $j_{\nu,\kappa+1}$ be two consecutive zeros of a solution of Bessel differential equations and $j'_{\nu,\kappa}$ the TP between them; then*

$$j'_{\nu,\kappa} > \sqrt{j_{\nu,\kappa} j_{\nu,\kappa+1}}.$$

Similar methods can be used to compute the zeros of other functions related to Bessel functions. For instance, the turning points of $x^\alpha \mathcal{C}_n(x)$ are the roots of

$$\alpha \mathcal{C}_n(x) + x\mathcal{C}'_n(x) = 0, \tag{5.9}$$

which are important roots in many applications. Using (5.1), the differential equation satisfied by the functions $y_n = x^\alpha \mathcal{C}_n(x)$ is

$$y''_n + \frac{1-2\alpha}{x} y'_n + \left(1 - \frac{n^2 - \alpha^2}{x^2}\right) y_n = 0, \tag{5.10}$$

which is transformed into the normal form by the change of variables $z(x) = x^{2\alpha}/2\alpha$ ($\alpha \neq 0$, which is the case previously discussed). After changing variables, we have that the coefficient of the second order ODE in normal form reads

$$A(z(x)) = (x^2 - (n^2 - \alpha^2))x^{-4\alpha}, \tag{5.11}$$

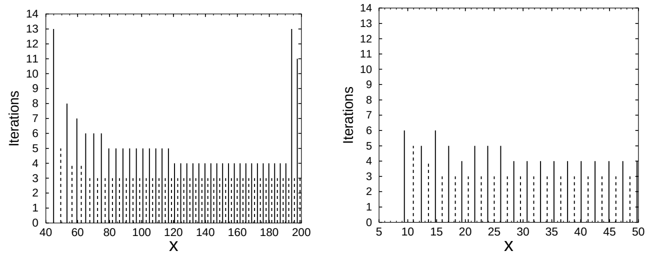
and the interlacing between the zeros of $\mathcal{C}_n$ and $\alpha\mathcal{C}_n(x) + x\mathcal{C}'_n(x)$ for $x > \sqrt{n^2 - \alpha^2}$ follows immediately. Methods similar to those used before can therefore be applied. Additional properties of the zeros of $x^\alpha \mathcal{C}_\nu(x)$ have been explored in [23] using these ideas.

5.2. Coulomb wave functions.

Coulomb functions are the solutions of the second order ODE

$$y''_n + A_n(x) y_n = 0, \qquad A_n(x) = 1 - \frac{2\gamma}{x} - \frac{n(n+1)}{x^2} \tag{5.12}$$

and satisfy the DDEs (2.19) with coefficients $a_n = -b_n = -(n^2/x + \gamma)/n$, $d_n = -e_n = \sqrt{n^2 + \gamma^2}/n$. Ricatti–Bessel functions are Coulomb functions with $\gamma = 0$.



(a) (b)

FIG. 2. *Number of iterations needed for the evaluation of the zeros and TPs with* 15 *exact digits for two different values of n and the parameter γ:* (a) $n = 10$*,* $\gamma = 20$ *and* (b) $n = 20$*,* $\gamma = -20$*. The zeros and TPs correspond to the combination of regular* (F) *and irregular* (G) *solutions* $0.5F - \sqrt{3}G/2$*.*

The main distinction of Coulomb functions with respect to Bessel functions is that $A_n(x)$ is not a monotonic function when $\gamma < 0$, which results in new phenomena with respect to the evaluation of zeros and TPs. Similarly to Bessel functions, the change of variables is trivial in this case (a factor times x). We will consider the evaluation of the positive zeros. (The negative zeros are the positive zeros of a Coulomb function with the opposite sign of γ.)

The functions η_i (see (2.23)) which determine the type of sweep to be applied are $\eta_i(x) = -i(\gamma + n_i^2/x)/\sqrt{n_i^2+\gamma^2}$, where $i = \pm 1$ and $n_{+1} = n + 1$, $n_{-1} = n$. The iteration corresponding to $i = -1$ is the most appropriate since the improved iteration step (Theorem 2.4) can be considered; indeed, $A'(x)\eta_{-1}(x) > 0$ except when $\gamma < 0$ and $x \in [x_{\eta_{-1}}, x_{Max}]$, where $x_{Max} = -n(n+1)/\gamma$ is the maximum of $A(x)$ and $\eta_{-1}(x_{\eta_{-1}}) = 0$ ($x_{\eta_{-1}} = -n^2/\gamma$). In that interval, one could always use the iteration step without improvement ($\Delta z = \pm\pi/2$). For $\gamma \geq 0$, $A(x)$ is always increasing, and the method of computation of zeros is a backward sweep ($\eta_{-1} > 0$). For $\gamma < 0$, as remarked, $A_n(x)$ has a maximum, and the zeros are computed by an expansive sweep starting from $x_{\eta_{-1}}$ (see [22]).

The monotonicity properties of $A_n(x)$ also have consequences for the evaluation of TPs. For instance, for TPs inside intervals $(x_n^{(j)}, x_n^{(j+1)})$, when $A_n(x)$ is increasing we should use starting values $x_0 = x_m + \lambda$, while we must use $x_0 = x_m - \lambda$ when $A_n(x)$ is decreasing; in this way, Theorem 3.8 can be applied. In the interval $(x_n^{(j)}, x_n^{(j+1)})$ where x_m lies we can also use Theorem 3.8 by proceeding as described after Proposition 3.9.

Figure 2 shows the performance of the method for the following choice of parameters: $n = 10$, $\gamma = 20$ (Figure 2(a)) and $n = 20$, $\gamma = -20$ (Figure 2(b)). The improved iteration step is used for computing the zeros. We use Barnett's code [2] for computing the F and G functions and obtaining the ratios appearing in the fixed point iterations.

The Maple implementation of the algorithms (for the computation of zeros of F by means of the continued fraction representation for the ratios) shows that two or three extra iterations are required to compute the zeros (and the TPs) for an accuracy of 10^{-100} (in addition to those required for 10^{-15} accuracy).

5.3. Conical functions. Conical functions are Legendre functions of degrees $-1/2 + i\tau$ with real τ ($y_n \equiv P^n_{-1/2+i\tau}(x)$ or $y_n \equiv Q^n_{-1/2+i\tau}(x)$). They satisfy general

DDEs (see (2.19)) with coefficients

$$\begin{aligned} &y_n''(x) + B(x)y_n'(x) + A_n(x)y_n(x) = 0, \\ &B(x) = \frac{2x}{x^2-1}, \qquad A_n(x) = \frac{1/4 + \tau^2 - n^2/(x^2-1)}{x^2-1}. \end{aligned} \tag{5.13}$$

We consider $n > 0$ (the differential equation is invariant under the replacement $n \to -n$), and we restrict our study to $x > 1$ (where the functions oscillate).

The DDEs (2.19) have the coefficients

$$a_n = \frac{-nx}{x^2-1}, \quad b_n = \frac{(n-1)x}{x^2-1}, \quad d_n = -\frac{\lambda_n^2}{\sqrt{x^2-1}}, \quad e_n = \frac{1}{\sqrt{x^2-1}}. \tag{5.14}$$

The η_i functions are (see (2.23)) $\eta_i(x) = i(-n_i + 1/2)x/(\lambda_{n_i}\sqrt{x^2-1})$, where, as usual, $n_{+1} = n+1$ and $n_{-1} = n$. With this, we see that $i = -1$ is the appropriate iteration in order to apply the improved iteration. Indeed, choosing $i = -1$, the associated change of variables (see (2.22)) is

$$z(x) = \lambda_n \cosh^{-1} x, \tag{5.15}$$

with $\lambda_n = \sqrt{(n-1/2)^2 + \tau^2}$, and the coefficient $\tilde{A}(z)$ of the equation in normal form (see (2.11)) is

$$\tilde{A}(z) = 1 + \dot{\eta}_{-1} - \eta_{-1}^2 = \frac{1}{\lambda_n^2}\left[\tau^2 - \frac{n^2 - 1/4}{\sinh^2(z/\lambda_n)}\right] \tag{5.16}$$

so that $\dot{\tilde{A}}(z)\eta_{-1}(z) > 0$ for $n > 0$, and therefore Theorem 2.4 can always be applied. The computation of zeros will be performed in the backward direction for $n > 1/2$ and in the forward direction of $n < 1/2$ because $\text{sign}(\eta_{-1}) = \text{sign}(n - 1/2)$.

Notice that from the expressions for both η_{-1} (Theorem 2.2 and Corollary 2.3) and $A(z)$ one deduces the following.

THEOREM 5.2. *Conical functions have infinitely many zeros for $x > 1$ and $\tau \neq 0$.*

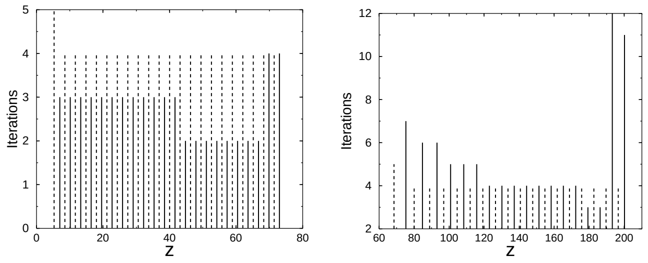
Conical functions illustrate how the change of variables associated to the DDE tends to make uniform the distribution of zeros. In fact, we see that $\tilde{A}(z) \to (\tau/\lambda_n)^2$ as $z \to +\infty$, which means that the difference between zeros in the z variable for large z tends to

$$z_y^{(j+1)} - z_y^{(j)} = \pi\sqrt{1 + \left(\frac{n-1/2}{\tau}\right)^2}, \qquad j \to +\infty.$$

In fact, for the particular case $n = 1/2$ we observe that the zeros are equally spaced in the z variable.

Regarding the TPs and going back to (5.13), the equation can be transformed to the normal form by taking a change of variables so that $dz/dx = \exp(-\int B dx)$. Let us again insist (as we did for Bessel functions) that the z variable here corresponds to the x variable in sections 3.1–3.2 and that this z variable is unrelated to (5.15). With this,

$$z(x) = -\tanh^{-1}\left(\frac{1}{x}\right), \qquad D(z) = \frac{\dot{y}_n(z)}{y_n(z)} = (x^2-1)\frac{y_n'(x)}{y_n(x)}, \tag{5.17}$$



(a) (b)

FIG. 3. *Number of iterations required for the computation of the zeros of* $P^n_{-1/2+i\tau}$ *(solid bars) and those of its derivative (dashed bars) with* 15 *exact digits as a function of its location (in the z variable of* (5.15)*). The left figure is for* $\tau = 20$*,* $n = 1$ *while the figure on the right corresponds to* $\tau = 20$*,* $n = 40$.

and the coefficient $\tilde{A}_n(z)$ appearing in the ODE in normal form (see (3.5)) is

$$\tilde{A}_n(x(z)) = (x(z)^2 - 1)A_n(x(z)) = \left(\frac{1}{4} + \tau^2\right)(x(z)^2 - 1) - n^2, \tag{5.18}$$

which is increasing in x. A method similar to the one applied for Bessel functions is the choice for conical functions.

Figure 3 shows the number of iterations required for the computation of the zeros and TPs with 15 exact digits. The effect of the improved iteration step becomes apparent from Figure 3(b), where the two largest zeros are computed by the plain iterative sweep (with $\Delta z = \pi/2$) and require more iterations than for the computation of the rest of zeros, which profit from the improved iteration step. This effect is also observed in Figure 3(a), but the improvement is not so noticeable.

6. Comparison with other methods. Other methods for computing the real zeros of special functions are the general-purpose methods described, for instance, in [13, 27, 28] (which have been applied to Bessel and Airy functions), or the most specialized methods which are based on previous approximations to the roots, mainly asymptotic approximations [16, 24]. Of course, when accurate a priori approximations to the roots are available, one can build efficient codes which use these approximations as starting points of, for instance, a Newton method; the algorithm presented in [24] is an example of an efficient algorithm based on asymptotic approximations.

Differently from these specific methods, the fixed point methods that we have described are general for a considerable number of special functions. Generally speaking, and starting from the least general to the most general methods (attending to the number of cases that they cover), the least general (but very efficient) methods are those based on specific approximations [16, 24], followed by matrix methods [1, 10, 11], our fixed point methods and the more general purpose methods [13, 27, 28].

Our computational scheme can be considered to be more general than matrix methods for the computation of real zeros in the sense that, given a second order ODE to which we can apply our methods, they are valid for any solution of the differential equation. In contrast, matrix methods can be applied only to minimal solutions with respect to a TTRR or to orthogonal polynomials (Golub–Welsch algorithm [9], [29, Problem 9, p. 80]). For example, matrix methods apply to the zeros of the regular Bessel function $J_\nu(x)$ and the regular Coulomb wave functions $F_L(\eta, \rho)$, while fixed point methods apply to any solution of the Bessel equation $\mathcal{C}_\nu = \cos\alpha J_\nu(x) -$

Table 1

Timing comparison for the evaluation of the zeros of Bessel functions $J_\nu(x)$ between the matrix method and the fixed point method (FPM) for 15 *exact digits. The first column represents the order of the function; the first row is the number of computed zeros. In each entry of the table the first number is the ratio between the time spent by the fixed point method and the time spent by the matrix diagonalization (if smaller than one FPM is faster) and the second number is the ratio between the size of the truncated matrix and the number of zeros N.*

50	2.1|3.7	1.4|2.8	0.85|2.2	0.66|2.0

$\sin\alpha Y_\nu(x)$ or any solution of the Coulomb equation. On the other hand, matrix methods can also be applied to compute complex zeros. There are other advantages of fixed point methods with respect to matrix methods, as discussed in [22], like, for instance the fact that the interval $[x_1, x_2]$ for computing the zeros can be freely chosen (while for matrix methods one has to choose to compute a given number of zeros in increasing order). Besides, our methods can be mixed with more specific methods using a priori approximations to the roots; this can be used to improve the performance.

For the case of orthogonal polynomials, the matrix eigenvalue methods are exact in the sense that the N zeros of an orthogonal polynomial of degree N can be obtained by diagonalizing a real symmetric matrix of size N. However, for the case of functions with infinitely many zeros, of course this is not so; in this case, if the function is the minimal solution of a TTRR, the problem of computing the first N zeros can be approximated by the problem of diagonalizing a truncated matrix, the exact problem being the diagonalization of a matrix of infinite size. The size of the matrix must be greater than the number of zeros that are needed to a prescribed accuracy. The main difficulty consists in estimating the size of the truncated matrix, which is function- and parameter dependent. (See [12] for estimations for the regular Bessel function, and [15] for the regular Coulomb wave function.)

Regarding the efficiency of the different methods, the most general methods tend to be slower than the most specific ones; however, fixed point methods are an exception to this rule. Indeed, the fixed point methods, though being applicable to a wider set of functions than matrix methods, are not slower. On the other hand, the comparison between our method and the more general purpose method [27] based on the concept of topological degree favors the fixed point method: in [20] such a method was compared against a global Newton method which proved to be faster and, as shown in [22], the fixed point method developed here converges faster than the Newton method [20].

In Table 1, we show the relative comparison of CPU times spent by Method I and matrix methods to compute a given number of zeros of Bessel functions for different orders. The comparison in Table 1 is performed in the following way: we compute the first N zeros of the Bessel function with our method for a relative precision better than 10^{-15}. Then we select the size of the matrix to be diagonalized by testing that the N zeros are computed with a relative precision better than 10^{-15}. We use an efficient algorithm for tridiagonal matrices [17]. The comparison in Table 1 is rather unfair because we are selecting the optimal size of the matrix for a given precision and number of zeros by comparing with our method; a stand-alone algorithm based on matrix methods should provide its own estimations of the size of the matrix, which are function dependent and not so easy to compute (see [12, 15]). As mentioned before, the truncation problem is one of the main limitations of the matrix methods for functions with infinitely many zeros.

Our methods admit simple improvements when accurate a priori approximations are available. For instance, for the particular case of Bessel functions, the performance for low numbers of zeros and high orders can be improved by considering the asymptotic approximations of [24] for high orders. And when a high number of zeros is demanded, asymptotic approximations for large zeros are also available. In any case, it is apparent that the fixed point methods are efficient methods by themselves.

7. Conclusions. Two methods for the computation of zeros and turning points of solutions of second order homogeneous linear ODEs have been presented. They are based on fixed point methods which compute with certainty all the zeros and TPs; these procedures have been applied to the computation of zeros and TPs of ODEs depending on one parameter n (like, for instance, hypergeometric functions and Bessel functions). These methods require that algorithms for the computation of ratios of solutions y_n/y_{n-1} be available. For minimal solutions of the corresponding TTRR, this ratio can be computed by using the continued fraction associated with this recurrence; the coefficients of the recurrences are then the only information necessary for computing the zeros and TPs (as happens with matrix methods [1, 11]). This is the case of the Bessel function $J_\nu(x)$, the regular Coulomb wave function $F_L(\eta, \rho)$, and the conical function $P^n_{-1/2+i\tau}(x)$, among others. Differently from matrix methods, the fixed point methods here presented can be applied to general solutions of the second order ODE; it is not required that the solutions be minimal with respect to a three-term recurrence.

The fixed point methods prove to be efficient schemes of computation, as illustrated with Bessel, Coulomb, and conical functions, and they can be systematically and easily implemented. The analytical steps prior to the application of the method are simple to perform and can be made automatic by using symbolic computation packages such as Maple or Mathematica. The methods here presented lead to efficient and portable algorithms for the computation of zeros and TPs of special functions. A Maple algorithm to compute the zeros and the TPs of the three families of functions discussed in detail in this article (Bessel, Coulomb, and conical functions) is available upon request to the authors; in the near future, the Maple algorithm will be expanded to include, among others, the cases of hypergeometric and confluent hypergeometric functions of real parameters and variables (which, as a subset, include classical orthogonal polynomials).

A LEIBNIZ FORMULA FOR MULTIVARIATE DIVIDED DIFFERENCES*

CARL DE BOOR[†]

Abstract. The Leibniz formula, for the divided difference of a product, and Opitz's formula, for the divided difference table of a function as the result of evaluating that function at a certain matrix, are shown to be special cases of a formula available for the coefficients, with respect to any basis, of an "ideal" or "Hermite" polynomial interpolant, in any number of variables.

Key words. polynomials, interpolation, ideal, multivariate, Opitz formula

1. Introduction.

The so-called Leibniz formula

$$\Delta(x_i,\dots,x_j)(fg)=\sum_{k=i}^{j}\Delta(x_i,\dots,x_k)f\ \Delta(x_k,\dots,x_j)g, \tag{1.1}$$

for the divided difference of a product in terms of the divided differences of the factors, has played a major role in the development of spline theory; it was an essential tool in the derivation of the B-spline recurrence relations. My earliest reference for it now is Popoviciu [16, p. 12], who refers, for the case of uniform spacing, to [9] where, on page 105, that special case of the formula is referred to as "bekannt". Nevertheless, the formula is generally credited (see, e.g., [15]) to Steffensen, because of his paper [20].

In this paper, the algebraic background of the Leibniz formula is explored, showing the formula to be equivalent to the Opitz formula (from [15]; see (2.1) below) that gives the divided difference table of any polynomial as the result of applying that polynomial to a certain matrix. This, in turn, is shown to be a particular consequence of the fact that, in G. Birkhoff's [2] terminology, polynomial interpolation is an "ideal" interpolation scheme. This insight is used to explore Leibniz (and Opitz) formulas for certain *multivariate* polynomial interpolation schemes and their associated divided differences.

The paper is laid out as follows. In section 2, the connection between the Leibniz formula and the Opitz formula is recalled, along with Opitz's way of deriving them. The next section brings a brief discussion of the basic features of "ideal" interpolation, i.e., linear projectors on the space of polynomials (in one or several variables, real or complex) whose kernel is a polynomial ideal. Section 4 provides the Opitz formula in the general setting of "ideal" interpolation, and the truncated Taylor series serves as a trivial illustration. The nontrivial details for both the Opitz and the Leibniz formulas are fully worked out for Chung–Yao interpolation in section 6. Such formulas for other divided differences are outlined in section 7. The final section points out that this paper's restriction to interpolation to polynomials is easily removed.

For ready reference, here is the (mostly, but not entirely, standard) notation used in this paper. $\alpha \in \mathbb{Z}_+^d$ denotes a **multi-index** or, more precisely, a d-index, i.e., a d-vector with nonnegative integer entries; $|\alpha| := \sum_j \alpha(j)$ is its **length** (or "**degree**"); also, $\alpha! := \prod_j \alpha(j)!$. There being no standard notation for it, I use

$$()^\alpha : \mathbb{F}^d \to \mathbb{F} : x \mapsto x^\alpha := \prod_j x(j)^{\alpha(j)}$$

for the monomial of **multidegree** α. Here, $\mathbb{F}$ is either $\mathbb{R}$ or $\mathbb{C}$, though usually it is $\mathbb{C}$. With this,

$$\Pi_{\mathbb{I}} := \operatorname{span}(()^\alpha : \alpha \in \mathbb{I}), \quad \mathbb{I} \subset \mathbb{Z}_+^d,$$

with the special cases

$$\Pi := \Pi(\mathbb{F}^d) := \Pi_{\mathbb{Z}_+^d}, \quad \Pi_k := \operatorname{span}(()^\alpha : |\alpha| \le k).$$

The *ad hoc* abbreviation

$$\widehat{p}(\alpha) := (D^\alpha p)(0)/\alpha!, \qquad p \in \Pi,\ \alpha \in \mathbb{Z}_+^d,$$

with

$$D^\alpha := \prod_j D_j^{\alpha(j)}$$

and D_j differentiation with respect to the jth argument, is convenient. Analogously,

$$()_j : x \mapsto x(j), \quad j = 1{:}d,$$

while

$$()_0 : x \mapsto 1.$$

In the dual, Π', of Π, *evaluation at some point* $v \in \mathbb{F}^d$ is singled out; i.e., the linear functional

$$\epsilon_v : \Pi \to \mathbb{F} : p \mapsto p(v),$$

and, more generally, $\epsilon_v q(D) : p \mapsto (q(D)p)(v)$ for $q \in \Pi$, with

$$q(D) := \sum_\alpha \widehat{q}(\alpha) D^\alpha.$$

Also,

$$Q(D) := \{q(D) : q \in Q\}, \qquad Q \subset \Pi,$$

and

$$\Lambda_\perp := \ker \Lambda := \bigcap_{\lambda \in \Lambda} \ker \lambda, \qquad \Lambda \subset \Pi'.$$

2. The Opitz formula. In his short note [15], describing a talk submitted but not given, Opitz introduces “Steigungsmatrizen” (literally “divided difference matrices”) as matrices of the form

$$S[f;X] := f(A_X),$$

with f a (univariate) polynomial or rational function or, more generally, a suitable limit of such functions, and, correspondingly, $f(A_X)$ the “value” of f at the matrix A_X, with

$$A_X := \begin{bmatrix} x_1 & 1 & & & \\ & x_2 & 1 & & \\ & & x_3 & \ddots & \\ & & & \ddots & 1 \\ & & & & x_n \end{bmatrix},$$

and with $X := (x_1, \ldots, x_n)$ a sequence of pairwise distinct complex numbers. Using the (obvious) eigenstructure of A_X, Opitz readily concludes that, for each i, j,

$$S[f;X](i,j) = \Delta(x_i, \ldots, x_j)f, \tag{2.1}$$

i.e., the divided difference of f at $(x_i, \ldots, x_j)$ (in W. Kahan’s felicitous notation[1]), and hence the name “Steigungsmatrix”. Here, as is customary, $\Delta(x_i, \ldots, x_j) := 0$ for $i > j$.

In other words, $f(A_X)$ is (or, the upper triangular part of $f(A_X)$ provides) the divided difference table for f with respect to the sequence X, and, as Opitz points out, its calculation in this fashion from A_X is less affected by loss of significance than is the direct construction of the divided difference table by the repeated formation of divided differences. In fact, it can be used for the symbolic calculation of divided differences; see, e.g., [10], and, most recently, [18].

Further, Opitz observes that the map

$$f \mapsto S[f;X]$$

is linear as well as multiplicative, and hence a ring homomorphism, from the ring of functions under pointwise addition and multiplication into the ring of matrices of order n. In particular,

$$(fg)(A_X) = f(A_X)g(A_X).$$

Because of (2.1), this is equivalent to the Leibniz formula, (1.1), i.e., to

$$\Delta(x_i, \ldots, x_j)(fg) = \sum_{k=i}^{j} \Delta(x_i, \ldots, x_k)f \ \Delta(x_k, \ldots, x_j)g.$$

Further, if we take (2.1) as the *definition* of $S[f;X]$, then the Leibniz formula implies that $f \mapsto S[f;X]$ is a ring homomorphism and so, in particular, $S[f;X] = f(A_X)$.

[1] I am using here Kahan’s notation not only because it is quite literal, but because the standard notation, $[x_i, \ldots, x_j]$, has already other uses, e.g., the matrix with columns $x_i, \ldots, x_j$ or, in the case $j = i + 1$, the closed interval with endpoints x_i, x_j.

3. Ideal interpolation. If P is a linear projector of finite rank on the linear space F with algebraic dual F', then we can think of P as providing a *linear interpolation scheme* on F: For each $g \in F$, $f = Pg$ is the unique element of $\operatorname{ran} P := P(F)$ for which

$$\lambda f = \lambda g, \quad \lambda \in \operatorname{ran} P' = \{\lambda \in F' : \lambda P = \lambda\}$$

(with $P' : F' \to F' : \lambda \mapsto \lambda P$ the dual of P). In other words, given that $\ker P = \operatorname{ran}(\mathrm{id} - P)$, we have

$$\operatorname{ran} P' = (\ker P)^{\perp} := \{\lambda \in F' : \ker P \subset \ker \lambda\}.$$

In this way, $\operatorname{ran} P'$ provides the *interpolation conditions* matched by P. Not surprisingly, there are exactly as many independent conditions as there are degrees of freedom, i.e.,

$$\dim \operatorname{ran} P = \dim \operatorname{ran} P'.$$

Now we take

$$F = \Pi,$$

the ring of polynomials in d (complex) variables. In [2], Birkhoff defined *ideal interpolation* as any linear projector P on Π whose nullspace or kernel is an ideal. In the interest of brevity, and without passing judgement, we will call such a projector **ideal**. However, Birkhoff seemed not to have been aware of the fact that such projectors had already been looked at carefully before that, by Möller in [12], who called them "Hermite interpolation", for the following reason.

As is well known (and, in this formulation, probably due to Gröbner; see [8, p. 176]), a nonempty subset I of Π is an ideal of finite codimension if and only if

$$I = \bigcap_{v \in \mathcal{V}} \ker(\epsilon_v Q_v(D))$$

for some finite subset $\mathcal{V}$ of $\mathbb{C}^d$ (necessarily the ideal's variety) and some nontrivial D-invariant finite-dimensional polynomial subspaces Q_v, necessarily given by

$$Q_v := \{q \in \Pi : ((D^{\alpha} q)(D)p)(v) = 0, \alpha \in \mathbb{Z}_+^d, p \in I\}.$$

In other words, as Möller rightly stresses, ideal interpolation is characterized by the fact that its interpolation conditions involve values and, possibly, also derivatives at certain sites, subject only to the condition that if the linear functional $\epsilon_v q(D)$ is matched, then so are all "lower" derivatives, i.e., every $\epsilon_v (D^{\alpha} q)(D)$ for $\alpha \in \mathbb{Z}_+^d$.

Since an ideal projector is, in a sense, aware of the multiplicative structure of Π, we would expect insights from considering its interaction with multiplication. The following lemma gives this interaction a handy formulation.

LEMMA 3.1. *A linear projector P on Π is ideal if and only if*

$$P(pq) = P(pPq), \quad p, q \in \Pi. \tag{3.1}$$

Proof. The condition (3.1) is equivalent to having

$$P(\Pi(\mathrm{id} - P)(\Pi)) = \{0\},$$

and, since P is a linear projector, and hence $(\mathrm{id}-P)(\Pi)=\ker P$, this is equivalent to

$$\Pi \ker P \subset \ker P,$$

and hence, given that $\ker P$ is a linear subspace, to $\ker P$ being an ideal. □

It is standard in algebraic geometry (see, e.g., [7, pp. 51ff.]) to consider, on the quotient ring

$$\Pi/\mathcal{I} := \{f+\mathcal{I} : f \in \Pi\}$$

of the polynomials over the ideal $\mathcal{I}$ and for an arbitrary polynomial p, the map

$$\Pi/\mathcal{I} \to \Pi/\mathcal{I} : f+\mathcal{I} \mapsto pf+\mathcal{I}.$$

In our context, it is more convenient to consider, equivalently, the map

$$M_p : \operatorname{ran} P \to \operatorname{ran} P : f \mapsto P(pf). \tag{3.2}$$

Evidently,

$$M_p \in L(\operatorname{ran} P);$$

i.e., M_p is a linear map on $\operatorname{ran} P$. Further, (3.1) implies that, for arbitrary $p, q \in \Pi$ and $f \in \operatorname{ran} P$,

$$M_q M_p f - M_{qp} f = P(qP(pf)) - P(qpf) = 0.$$

It follows that the map

$$m : \Pi \to L(\operatorname{ran} P) : p \mapsto M_p \tag{3.3}$$

is a ring homomorphism onto the commutative algebra generated by the specific linear maps

$$M_j : \operatorname{ran} P \to \operatorname{ran} P : f \mapsto P(()_j f), \quad j = 0{:}d,$$

in terms of which

$$M_p = p(M) := \sum_\alpha \widehat{p}(\alpha)\, M^\alpha, \quad p \in \Pi,$$

with

$$M^\alpha := \prod_j (M_j)^{\alpha(j)} = M_{()^\alpha}$$

independent of the order in which this product is formed from its factors.

It follows, directly from (3.1), that

$$p(M)P()_0 = P(p\,P()_0) = Pp, \quad p \in \Pi. \tag{3.4}$$

Such a formula plays a major role in Mourrain's intriguing paper [14], though it is proved there, consistent with that paper's setting, only for P whose range, $B := \operatorname{ran} P$, is **connected to** 1, meaning that each $b \in B$ can be written in the form $\sum_{j=0}^d ()_j b_j$ with each b_j in $B \cap \Pi_{<\deg b}$; hence, in particular, $()_0 \in B$, and (3.4) simplifies to $p(M)()_0 = Pp$.

(3.4) implies that $\ker m \subset \ker P$, while, if $p \in \ker P$, then $p(M)f = P(pf) = P(fPp) = P0 = 0$ for all $f \in \operatorname{dom} p(M) = \operatorname{ran} P$, i.e., $p(M) = 0$. Thus, altogether,

$$\ker m = \ker P. \tag{3.5}$$

4. A general Opitz formula. If now

$$V : \mathbb{F}^n \to \operatorname{ran} P : a \mapsto \sum_j v_j a(j) =: [v_1, \ldots, v_n]a$$

is any basis for $\operatorname{ran} P$, i.e., $V = [v_1, \ldots, v_n]$ is an invertible linear map, then the matrix representation for $M_p = p(M)$ with respect to this basis is

$$\widehat{M_p} = V^{-1} M_p V = p(\widehat{M}), \tag{4.1}$$

with

$$\widehat{M_j} = V^{-1} M_j V, \quad j = 1{:}d.$$

Consequently,

$$P(pv_j) = p(M)v_j = Vp(\widehat{M})(:, j), \quad p \in \Pi. \tag{4.2}$$

In particular,

$$Pp = p(M)P()_0 = Vp(\widehat{M})a_0, \quad p \in \Pi,$$

with $a_0 := V^{-1}P()_0$ the coordinates of $P()_0$ with respect to V.

(4.1), (4.2) is the promised generalization of the Opitz formula.

To make the connection with (2.1), take, in particular, $d = 1$, and let $P = P_n$ be the linear projector of interpolation from polynomials of degree $< n$ to data at the distinct sites $x_1, \ldots, x_n$. Choosing, specifically, for V the Newton basis

$$v_j := \prod_{j<k\le n} (\cdot - x_k), \quad j = 1{:}n,$$

we compute the jth column of $\widehat{M} := \widehat{M_1}$ as the coordinates, with respect to V, of

$$M_1 v_j = P_n(()_1 v_j) = P_n(x_j v_j + (\cdot - x_j)v_j) = x_j v_j + P_n v_{j-1} = x_j v_j + \begin{cases} v_{j-1}, & j > 1; \\ 0, & j = 1, \end{cases}$$

and hence

$$\widehat{M} = \begin{bmatrix} x_1 & 1 & & & \\ & x_2 & 1 & & \\ & & x_3 & \ddots & \\ & & & \ddots & 1 \\ & & & & x_n \end{bmatrix} = A_X.$$

Consider now $p(M)v_j = P_n(pv_j)$. Certainly, $(P_j p)v_j$ is in $\operatorname{ran} P_n$ and matches pv_j at all the x_i, and hence must equal $P_n(pv_j)$. Therefore,

$$p(M)v_j = \left(\sum_{k=1}^{j} \prod_{k<h\le j} (\cdot - x_h) \ \Delta(x_k, \ldots, x_j)p \right) v_j = \sum_{k=1}^{j} v_k \Delta(x_k, \ldots, x_j)p.$$

Consequently,

$$p(\widehat{M})(k, j) = \Delta(x_k, \ldots, x_j)p, \qquad k, j = 1{:}n.$$

Since Opitz [15] bases his derivations on the eigenstructure of the matrix A_X, it seems appropriate to point out that it is standard in algebraic geometry (see, e.g., [7, pp. 54ff.]) to consider the eigenstructure of the linear maps M_p (defined in (3.2)). To be sure, it is their dual, more precisely the matrix $\mathcal{M}_p$, called a **multiplication table** and defined implicitly by

$$\langle ()^\alpha p\rangle =: \sum_{\beta\in\mathbb{I}} \mathcal{M}_p(\alpha,\beta)\langle ()^\beta\rangle, \qquad \alpha\in\mathbb{I}$$

(with $\langle f\rangle := f+\mathcal{I}$ and $\mathbb{I}$ the set of multidegrees that do not occur among the multidegrees of elements of the ideal), whose eigenstructure is given, by Stetter and his collaborators, a major role in the solving of polynomial systems; see, e.g., [1], [13]. But I find it more convenient to deal with the linear maps M_p.

The bare facts are these: For each v in the variety $\mathcal{V} := \mathcal{V}(\ker P)$ of the ideal $\ker P$, $\epsilon_v \in \operatorname{ran} P'$, and hence, for every $f\in B := \operatorname{ran} P$,

$$\epsilon_v M_p f = \epsilon_v P(pf) = \epsilon_v(pf) = p(v)\epsilon_v f,$$

and this shows ϵ_v (or, more precisely, $\epsilon_v|_B$) to be a left eigenvector of M_p, with corresponding eigenvalue $p(v)$. Hence, if we are dealing with Lagrange interpolation (as is the case in [15] at the outset), i.e., if $(\epsilon_v : v\in\mathcal{V})$ spans $\operatorname{ran} P'$, then M_p is diagonalizable, and $\{p(v) : v\in\mathcal{V}\}$ is its spectrum. In that case, a right eigenbasis for M_p is the basis $(\ell_v : v\in\mathcal{V})$ of $\operatorname{ran} P$ dual to $(\epsilon_v : v\in\mathcal{V})$, i.e., $\ell_v(w) = \delta_{vw}$, the Lagrange basis. Further, $\{p(v) : v\in\mathcal{V}\}$ is also the spectrum of M_p in the general case, with each $q\in Q_v$ that is not in $\sum_{j=1}^d D_j Q_v$ giving rise to a (right) eigenvector of M_p for the eigenvalue $p(v)$.

5. An example: The truncated Taylor series. As a first (and trivial) d-variate example with $d>1$, consider $P = T_k$, the linear map on Π that associates with $p\in\Pi$ its Taylor expansion

$$T_k p := \sum_{|\alpha|<k} ()^\alpha D^\alpha p(0)/\alpha!$$

of order k. Evidently,

$$\operatorname{ran} T_k' = \epsilon_0 \Pi_{<k}(D);$$

thus

$$\ker T_k = \operatorname{ideal}(()^\alpha : |\alpha| = k).$$

In particular, with

$$V_{<k} := [()^\alpha : |\alpha| < k]$$

the power basis for $\Pi_{<k} = \operatorname{ran} T_k$, we find $()_j()^\alpha \in \operatorname{ran} T_k$ if and only if $|\alpha| < k-1$, while, for $|\alpha| = k-1$, $P(()_j()^\alpha) = 0$. Hence, with $\iota_j := (\delta_{ij} : i = 1{:}d)$,

$$\widehat{M_j}(\alpha,\beta) = \delta_{\beta+\iota_j-\alpha}, \qquad |\alpha|, |\beta| < k,$$

a strictly lower triangular matrix in any total ordering of $\mathbb{Z}_+^d$ that respects "degree", i.e., for which $|\alpha| < |\beta| \Longrightarrow \alpha < \beta$. It reflects the evident fact that the action of $\widehat{M_j}$ is to shift the coefficient function

$$\widehat{p} : \alpha \to \widehat{p}(\alpha) = D^\alpha p(0)/\alpha!$$

by ι_j, i.e.,

$$\widehat{M_j p} = \widehat{p}(\cdot - \iota_j),$$

dropping off those terms that are, thereby, pushed outside the relevant index set, $\{\alpha : |\alpha| < k\}$.

Correspondingly (or directly by (4.2)), the αth column of $p(\widehat{M})$ is obtained from $\widehat{p}$ by a shift of $\widehat{p}$ by α, again dropping off those terms that are, thereby, pushed outside $\{\alpha : |\alpha| < k\}$, i.e.,

$$p(\widehat{M})(:, \alpha) = \widehat{p}(\cdot - \alpha).$$

In particular, for any $p, q \in \Pi$,

$$\widehat{(pq)}(\alpha) = (pq)(\widehat{M})(\alpha, 0) = p(\widehat{M})q(\widehat{M})(\alpha, 0) = \sum_{\beta \le \alpha} \widehat{p}(\alpha - \beta)\widehat{q}(\beta),$$

the familiar Leibniz formula for the derivative of a product.

6. An example: Chung–Yao interpolation. In [6], Chung and Yao introduced the eponymous multivariate polynomial interpolation scheme. This scheme provides interpolation from Π_k to data at the sites

$$\Theta_{\mathbb{H}} := \{\theta_H : H \in \tbinom{\mathbb{H}}{d}\},$$

with $\mathbb{H}$ a set of $d + k$ hyperplanes in $\mathbb{R}^d$ in general position and θ_H the unique point common to the d hyperplanes in such an $H \in \tbinom{\mathbb{H}}{d}$. Chung and Yao [6] show that such interpolation is possible, and uniquely so, by exhibiting the interpolant $P_{\mathbb{H}}g$ to g in Lagrange form.

[3] (see [4] for details) provides the following Newton form for $P_{\mathbb{H}}g$:

$$P_{\mathbb{H}}g = \sum_{j=0}^{k} \sum_{K \in \tbinom{\mathbb{H}_{j-1}}{d-1}} p_{j-1,K}\, [\Theta_{\mathbb{H}_j,K} \mid n_K, \ldots, n_K]g, \tag{6.1}$$

with the various terms occurring here defined as follows:

$$\mathbb{H}_{-1} \subset \cdots \subset \mathbb{H}_k := \mathbb{H}$$

is any increasing sequence of subsets of $\mathbb{H}$ with $\#\mathbb{H}_j = d + j$, all j. Further,

$$p_{j,K} := \prod_{h \in \mathbb{H}_j \setminus K} \frac{h}{h_\uparrow(n_K)},$$

with h denoting a hyperplane as well as a particular linear polynomial whose zero set coincides with that hyperplane, and $h_\uparrow$ its **leading term**, i.e., its linear homogeneous part. Also,

$$\Theta_{\mathbb{K},K} := \Theta_{\mathbb{K}} \cap l_K,$$

with

$$l_K := \bigcap_{h \in K} h$$

the straight line common to the $d-1$ hyperplanes in K, while

$$n_K$$

is an arbitrary nontrivial vector parallel to that line. Last, but certainly not least,

$$[X \mid \Xi]g := \int_{[X]} D_\Xi g$$

is the multivariate divided difference (notation) introduced in [3]. In this formula, $X = (x_0, \ldots, x_n)$ and $\Xi = (\xi_1, \ldots, \xi_n)$ are arbitrary sequences in $\mathbb{R}^d$, the first one having one more entry than the second, $D_\Xi := D_{\xi_1} \cdots D_{\xi_n}$ is the composition of directional derivatives $D_\xi := \sum_j \xi(j) D_j$, and

$$f \mapsto \int_{[x_0,\ldots,x_n]} f := \int_0^1 \int_0^{s_1} \cdots \int_0^{s_{n-1}} f(x_0 + s_1 \nabla x_1 + \cdots + s_n \nabla x_n)\, \mathrm{d}s_n \cdots \mathrm{d}s_1 \tag{6.2}$$

(with $\nabla x_j := x_j - x_{j-1}$) is termed, by Micchelli in [11], the **divided difference functional on** $\mathbb{R}^d$ and is familiar from the Genocchi–Hermite formula for the univariate divided difference. $[X \mid \Xi]$ is symmetric in the "sites" $x \in X$, is linear and symmetric in the "directions" $\xi \in \Xi$, and satisfies the recurrence

$$[X \mid \Xi][X', \cdot \mid \Xi'] = [X, X' \mid \Xi, \Xi'].$$

Let now

$$V := [p_{j,K} : (j,K) \in \mathbb{I}], \qquad \text{with } \mathbb{I} := \{(j,K) : K \in \tbinom{\mathbb{H}_j}{d-1}, j = -1{:}(k-1)\},$$

be the corresponding "Newton" basis for $\operatorname{ran} P = \Pi_k$. For $j = 0{:}k$, let h_j be the sole element of $\mathbb{H}_j \backslash \mathbb{H}_{j-1}$, pick $K \in \tbinom{\mathbb{H}_{j-1}}{d-1}$, and let $H := K \cup h_j$. Then

$$(x - \theta_H) = \sum_{h \in H} n_{H \backslash h} \frac{h(x)}{h_\uparrow(n_{H\backslash h})}.$$

This implies that

$$\begin{aligned} x p_{j-1,K}(x) &= (\theta_H \ + \ (x - \theta_H)) p_{j-1,K}(x) \\ &= \theta_H p_{j-1,K}(x) + \sum_{h \in H} n_{H\backslash h} \left(\prod_{h' \in \mathbb{H}_j \backslash H} \frac{h'_\uparrow(n_{H\backslash h})}{h'_\uparrow(n_K)} \right) p_{j,H\backslash h}(x). \end{aligned}$$

Notice that each of the $p_{j,H\backslash h}$ in the sum over H vanishes on $\Theta_{\mathbb{H}_j}$. In particular, for $j = k$, the sum over H vanishes for every $x \in \Theta_{\mathbb{H}}$. It follows that, for $i = 1{:}d$, the matrix representation $\widehat{M_i}$ for $M_i : f \mapsto P(()_i f)$ with respect to the "Newton" basis V is "lower triangular" and quite sparse, with the column corresponding to $p_{j-1,K}$ having nonzero entries only on the diagonal, where it has the value $\theta_{h_j \cup K}(i)$, and at the entries, if any, corresponding to $p_{j,h_j \cup K\backslash h}$ for $h \in h_j \cup K$.

Now, what about $f(\widehat{M})$ for arbitrary $f \in \Pi$? The polynomial $f p_{j-1,K}$ vanishes on $\Theta_{\mathbb{H}_{j-1}}$, and hence depends only on f restricted to $\Theta_{\mathbb{H}} \backslash \Theta_{\mathbb{H}_{j-1}}$. However, this dependence is hardly simple. Formally, we have

$$f(\widehat{M})((j,K),(j',K')) = [\Theta_{\mathbb{H}_{j+1},K} \mid n_K, \ldots, n_K](f p_{j',K'}), \quad (j,K),(j',K') \in \mathbb{I}.$$

The fact that $f(\widehat{M})$ is lower triangular, in any ordering of the index set $\mathbb{I}$ that refines the natural partial ordering provided by the first components, is evident.

With this, from the fact that $(fg)(\widehat{M}) = f(\widehat{M})g(\widehat{M})$, we get the following "Leibniz formula":

$$\begin{aligned}&[\Theta_{\mathbb{H}_j,K} \mid n_K,\ldots,n_K](fg)\\ &\quad= \sum_{(j',K')\in\mathbb{I};j'<j} [\Theta_{\mathbb{H}_j,K} \mid n_K,\ldots,n_K](fp_{j',K'})\,[\Theta_{\mathbb{H}_{j'+1},K'} \mid n_{K'},\ldots,n_{K'}]g.\end{aligned} \tag{6.3}$$

Note that the second factor depends only on g on the sites in $\Theta_{\mathbb{H}_{j'+1}}$, while the first factor depends only on f on the sites in $\Theta_{\mathbb{H}_j}\backslash\Theta_{\mathbb{H}_{j'}}$. In particular, the first factor is trivially zero when $j' \geq j$, and hence the sum's restriction to $j' < j$.

Note also, by way of a check, that, for $d = 1$, $\mathbb{H}$ consists of pairwise distinct points, with $\mathbb{H}_j$ containing $j+1$ points, $h_0,\ldots,h_j$, say. Further, $K = \emptyset$ is the sole element of $\binom{\mathbb{H}_j}{d-1}$, and $l_\emptyset = \mathbb{R}$, and hence we may choose ι_1 for $n_\emptyset$ and, with that,

$$[\Theta_{\mathbb{H}_j,K} \mid n_K,\ldots,n_K] = \Delta(h_0,\ldots,h_j),$$

by the Genocchi–Hermite formula, while, as observed earlier,

$$\Delta(h_0,\ldots,h_j)\left(\prod_{i<j'}(\cdot - h_i)f\right) = \Delta(h_{j'},\ldots,h_j)f.$$

This verifies that, indeed, (6.3) reduces to (1.1) when $d = 1$.

7. Other divided differences. Let T be an arbitrary finite subset of $\mathbb{C}^d$, and assume that the polynomial subspace B is correct for it in the sense that

$$\Lambda_{\mathrm{T}}^{\mathrm{t}} : B \to \mathbb{C}^{\mathrm{T}} : b \mapsto b|_{\mathrm{T}}$$

is one-to-one and onto. Then, with

$$W : \mathbb{C}^W \to B : a \mapsto \sum_{w\in W} a(w)w$$

an arbitrary basis for B (using W to denote both the basis and the associated basis map), the Gram matrix

$$\Lambda_{\mathrm{T}}^{\mathrm{t}} W = (w(\tau) : \tau \in \mathrm{T}, w \in W)$$

is invertible; hence, for any particular ordering of the basis W, there is some ordering of T so that

$$\Lambda_{\mathrm{T}}^{\mathrm{t}} W = LU,$$

with L lower triangular and U unit upper triangular (in the chosen orderings of T and W). Then one is free to call

$$\lambda(\tau_1,\ldots,\tau_i) := \sum_k L^{-1}(i,k)\epsilon_{\tau_k} = \sum_{k\leq j} L^{-1}(i,k)\epsilon_{\tau_k}$$

the "divided difference" at the sequence $(\tau_1,\dots,\tau_i)$, and to call, correspondingly, the polynomials

$$v_j := \sum_k w_k U^{-1}(k,j) = \sum_{k\le j} w_k U^{-1}(k,j)$$

"Newton polynomials", and to call

$$\sum_j v_j\; \lambda(\tau_1,\dots,\tau_j)f$$

the "Newton form" of the interpolant from B to f at T. Assuming that B contains the constant function and that, in fact, $v_1 = ()_0$, it then follows that

$$\lambda(\tau_1,\dots,\tau_j)(fg) = \sum_{k=1}^{j} \lambda(\tau_1,\dots,\tau_j)(fv_k)\, \lambda(\tau_1,\dots,\tau_k)g,$$

with $\lambda(\tau_1,\dots,\tau_j)(fv_k)$ depending only on f at $\tau_k,\dots,\tau_j$. The role reversal of f and g here as compared to (1.1) is due to the fact that the "Newton" basis here is ordered differently than there.

It is in this manner, or, perhaps, in a more relaxed block-triangular way, that one could provide some kind of Leibniz formula and even an Opitz formula in the context of more general schemes of multivariate polynomial interpolation, e.g., the least interpolant of [5] or the Sauer–Xu formulation [19].

The divided difference introduced by Rabut in [17] does not quite fit this pattern. While Rabut does define divided differences as the coefficients of the interpolating polynomial, he sticks to the power basis

$$V_k := [()^\alpha : |\alpha| \le k]$$

rather than some kind of multivariate Newton basis. Precisely, with T some pointset in $\mathbb{R}^d$ correct for interpolation from Π_k, and hence

$$P := V_k(\Lambda_\mathrm{T}^\mathrm{t} V_k)^{-1}\Lambda_\mathrm{T}^\mathrm{t}$$

well-defined, he denotes the (T,α)**-divided difference of** f by

$$f[\mathrm{T}]^\alpha$$

and defines it implicitly by

$$Pf =: \sum_\alpha ()^\alpha f[\mathrm{T}]^\alpha.$$

With this definition, it follows from (4.2) that

$$(p[\mathrm{T}]^\alpha : |\alpha| \le k) = p(\widehat{M})(:,0), \quad p \in \Pi,$$

and hence that

$$(pq)[\mathrm{T}]^\alpha = \sum_\beta (p()^\beta)[\mathrm{T}]^\alpha\, q[\mathrm{T}]^\beta = \sum_{\beta\le\alpha} (p()^\beta)[\mathrm{T}]^\alpha\, q[\mathrm{T}]^\beta.$$

However, since $f[\mathrm{T}]^\alpha$ depends on f on all of T, the first factor in each summand still depends, offhand, on p on all of T.

In Rabut's setting, the matrix representation $\widehat{M_j}$ of

$$M_j : \Pi_k \to \Pi_k : p \mapsto P(()_j p)$$

is, in principle, not that hard to work out. For $|\alpha| \le k$, we have $()_j()^\alpha \in \Pi_k$ if and only if $|\alpha| < k$. Therefore

$$\widehat{M_j}(\alpha,\beta) = \begin{cases} \delta_{\beta+\iota_j-\alpha}, & |\beta| < k; \\ ()^{\beta+\iota_j}[\mathrm{T}]^\alpha, & |\beta| = k. \end{cases}$$

However, this still leaves the particular details of the specific divided differences $()^{\beta+\iota_j}[\mathrm{T}]^\alpha$ for $|\beta| = k$ to be supplied. At this point, I do not know whether it would be worthwhile to make that effort.

8. Extensions. In contrast to the standard literature on polynomial interpolation and divided differences, I have restricted here attention to interpolation to polynomials. However, since a polynomial interpolant depends only on the values at the interpolation sites of the function being interpolated, interpolation extends immediately to any function having values at least at the interpolation sites, and this leads to a natural extension, to such functions, of whatever divided difference notion or polynomial interpolation scheme is used.

In the univariate setting, if the interpolation involves "repeated" sites, i.e., matching of certain "consecutive" derivatives, then, correspondingly, the interpolation scheme and the divided differences extend to functions suitably differentiable at the interpolation sites. The same holds for multivariate ideal interpolation, except that, at present, it is not known whether every such Hermite interpolation scheme can be viewed as the limit of suitable Lagrange interpolation schemes, i.e., whether in this sense multivariate Hermite interpolation can be viewed as interpolation involving "repeated" sites.

Acknowledgements. I am grateful to H. Michael Möller for various discussions concerning the algebraic geometry literature and, in particular, for pointing me toward Hans J. Stetter, and to the latter for pointing out to me B. Mourrain's paper. I also thank the two referees for their most careful reading of the manuscript which further strengthened my belief that it is impossible to get anything right.

THE SEMIDISCRETE FILTERED BACKPROJECTION ALGORITHM IS OPTIMAL FOR TOMOGRAPHIC INVERSION*

ANDREAS RIEDER† AND ADEL FARIDANI‡

Abstract. The filtered backprojection algorithm is probably the most often used reconstruction algorithm in two-dimensional computerized tomography. For a semidiscrete version in the parallel scanning geometry we prove optimal L^2-convergence rates for density distributions in Sobolev spaces. Additionally we show L^2-convergence without rates when the density distribution is only in L^2. The key to success is a new representation of the filtered backprojection which enables us to apply techniques from approximation theory. Our analysis provides further a modification of the Shepp–Logan reconstruction filter with an improved convergence behavior. Numerical experiments in the fully discrete setting reproduce the theoretical predictions.

Key words. Radon transform, tomography, filtered backprojection algorithm, reconstruction filter

1. Filters in tomography.

Tomographic reconstruction means finding a density distribution f from all its line integrals $g = \mathbf{R}f$. Here, $\mathbf{R}$ denotes the *Radon transform*,

$$\mathbf{R}f(s,\vartheta) := \int_{L(s,\vartheta)\cap\Omega} f(x)\,\mathrm{d}\sigma(x),$$

mapping a function to its integrals over the lines $L(s,\vartheta) = \{\tau\,\omega^{\perp}(\vartheta) + s\,\omega(\vartheta) \mid \tau \in \mathbb{R}\}$, where $s \in \mathbb{R}$, $\omega(\vartheta) = (\cos\vartheta, \sin\vartheta)^t$, and $\omega^{\perp}(\vartheta) = (-\sin\vartheta, \cos\vartheta)^t$ for $\vartheta \in]0,\pi[$. This parameterization of lines gives rise to the *parallel scanning geometry.* The Radon transform $\mathbf{R}$ maps $L^2(\Omega)$ boundedly to $L^2(Z)$, where Ω is the unit ball in $\mathbb{R}^2$ centered about the origin and Z is the rectangle $Z =]-1,1[\times]0,\pi[$.

Analytically, tomographic reconstruction is represented by the inversion formula

$$f = (2\pi)^{-1}\,\mathbf{R}^*\,\Lambda\,g, \tag{1.1}$$

where the *backprojection operator* $\mathbf{R}^* : L^2(Z) \to L^2(\Omega)$ is the adjoint to $\mathbf{R}$,

$$\mathbf{R}^*\Phi(x) := \int_0^{\pi} \Phi(x^t\,\omega(\vartheta),\vartheta)\,\mathrm{d}\vartheta.$$

Formally, Λ is the square root of the one-dimensional Laplacian $-\Delta$: $\Lambda = (-\Delta)^{1/2}$. In (1.1), Λ acts on the variable s of g. For a proof of (1.1) see, e.g., Natterer [14].

Due to the compactness of $\mathbf{R}$ the reconstruction of f from noisy Radon data g by (1.1) is unstable (Λ amplifies high frequencies). A stable algorithm of tomographic reconstruction is therefore based on

$$f \star e_\gamma = \mathbf{R}^*(\upsilon_\gamma \star_s g), \quad e_\gamma = \mathbf{R}^*\upsilon_\gamma, \tag{1.2}$$

where $\star$ denotes convolution and $\star_s$ denotes convolution with respect to the variable s. In (1.2), $e_\gamma(x) = e(x/\gamma)/\gamma^2$, $\gamma > 0$, and $e = e_1$ is a *mollifier*, that is, a smooth function with normalized mean value. Thus, $f \star e_\gamma$ is a smoothed or mollified approximation to f. The function $\upsilon = \upsilon_1$ is called the *reconstruction kernel* or *reconstruction filter* which is independent of the angle ϑ for radially symmetric mollifiers (which we assume in what follows). Note that $\upsilon_\gamma(s) = \upsilon(s/\gamma)/\gamma^2$. By the inversion formula (1.1) we can compute the reconstruction kernel from a mollifier e:

$$\upsilon = \frac{1}{2\pi}\,\Lambda\mathbf{R}e. \tag{1.3}$$

The convolution $\upsilon_\gamma \star_s g$ realizes a low pass filtered version of $\Lambda g/(2\pi)$.

A straightforward discretization of (1.2) together with an interpolation step yields the *filtered backprojection algorithm* (FBA) which is the most frequently used algorithm in computerized tomography; see, e.g., Natterer [14, Chap. V]. In what follows let f be a density distribution compactly supported in Ω. If we assume to know the discrete Radon data $g_{k,j} := \mathbf{R}f(s_k, \vartheta_j)$ for $s_k = k/q$, $k = -q, \dots, q$, and $\vartheta_j = j\,\pi/p$, $j = 0, \dots, p-1$, then the FBA reconstructs f_{FB} by

$$f_{\mathrm{FB}}(x) := \mathbf{R}_p^*\mathrm{I}_h(w \star_q g)(x). \tag{1.4}$$

In the FBA, first the discrete convolution

$$(w \star_q g)_{\ell,j} := \frac{1}{q}\sum_{k\in\mathbb{Z}} w_{\ell-k}\, g_{k,j} \approx \big(\upsilon_\gamma \star_s g(\cdot, \vartheta_j)\big)(s_\ell) \tag{1.5}$$

is performed, where $\{w_k\}$ is a weight sequence associated with the chosen kernel υ_γ. In the second step, an interpolation operator I_h is applied (with respect to ℓ). Finally, the discrete backprojection operator

$$\mathbf{R}_p^*\Phi(x) := \frac{\pi}{p}\sum_{j=0}^{p-1}\Phi(x^t\,\omega(\vartheta_j), \vartheta_j) \tag{1.6}$$

is evaluated.

Except for the interpolation process, the discrete convolution (1.5) is the most delicate step in the FBA: the discrete convolution kernel $\{w_k\}$ has to be chosen carefully from the continuous kernel υ_γ. For instance, a common choice is

$$w_k = \upsilon_\gamma(s_k). \tag{1.7}$$

Here γ has to be adjusted to the *discretization step size* $h = 1/q$. The sensitivity of the reconstructed image to γ has been noticed probably for the first time by Smith in [22, p. 20]. Rules for selecting γ have been suggested by Smith and Keinert [23, Sect. VI], Natterer [14], and Rieder [16]. For local tomography, see Faridani [8] and Rieder, Dietz, and Schuster [17].

Smith [22, pp. 18–19] propagated a different way to define the w_k's. He intended the discrete convolution (1.5) to be exact for a large class of functions. Let $E_h u$ be an approximation to the function u given as the superposition of translated and scaled versions of a function B; that is,

$$E_h u(s) = \sum_{k\in\mathbb{Z}} u(s_k)\, B_h(s - s_k), \qquad \text{where } B_h(s) = B(s/h). \tag{1.8}$$

For instance, E_h could be an interpolation operator. Defining

$$w_k \;:=\; \frac{1}{h}\int \upsilon_\gamma(s)\; B_h(s_k - s)\;\mathrm{d}s \;=\; \frac{1}{h}\,\upsilon_\gamma \star B_h(s_k), \quad k\in\mathbb{Z}, \tag{1.9}$$

we have that

$$(w \star_q u)_\ell \;=\; \upsilon_\gamma \star_s E_h u(s_\ell), \quad \ell\in\mathbb{Z}.$$

Moreover, if E_h is interpolating, then

$$(w \star_q E_h u)_\ell \;=\; \upsilon_\gamma \star_s E_h u(s_\ell), \quad \ell\in\mathbb{Z};$$

that is, the discrete convolution (1.5) is exact for $E_h u$. Numerical as well as theoretical considerations (see [16, 22]) showed that the reconstructed images f_{FB} are less sensitive to changes in γ when working with (1.9) rather than working with (1.7). Indeed, we will show in the next section that the discrete filter $\{w_k\}$ from (1.9) converges for $\gamma \to 0$ and that its limit $\{w_k^\infty\}$ is again a reconstruction filter belonging to a compactly supported mollifier. This limit filter has an interesting feature: computing $\Lambda E_h u(s_\ell)/(2\pi)$ can now be realized by the discrete convolution

$$\frac{1}{2\pi}\;\Lambda E_h u(s_\ell) \;=\; (w^\infty \star_q u)_\ell.$$

The latter equation is the starting point in section 3 for a reformulation of the FBA leading to optimal L^2-convergence rates in a semidiscrete setting (Theorem 3.7) where in (1.4) the discrete backprojection operator $\mathbf{R}_p^*$ is replaced by the continuous one $\mathbf{R}^*$. We see how the reconstruction filter, the interpolation process (I_h in (1.4)), and the Sobolev regularity of the density distribution f influence the convergence rate. As a by-product of our analysis we discover a new reconstruction filter (Example 4.1) with an improved convergence behavior compared to the widely used Shepp–Logan filter [21] (sections 4 and 5). Indeed, our modified Shepp–Logan filter yields optimal convergence for Sobolev orders up to 5/2, whereas the convergence order of the original Shepp–Logan filter saturates at 2 (Example 5.1). Numerical experiments in the fully discrete setting of (1.4) agree completely with our theoretical predictions and are presented in section 6. Auxiliary but new approximation properties of (quasi-) interpolation operators, which we need for the analysis, are proved in several appendices.

2. The limit. We will now investigate the convergence in Sobolev spaces of $\upsilon_\gamma \star B$ as γ tends to zero. We define the Sobolev spaces $H^\alpha(\mathbb{R}^d)$, $\alpha\in\mathbb{R}$, to be the closure of $L^2(\mathbb{R}^d)$ with respect to the norm

$$\|f\|_\alpha^2 \;:=\; \int_{\mathbb{R}^d} \left(1+\|\xi\|^2\right)^\alpha\; |\widehat{f}(\xi)|^2\;\mathrm{d}\xi,$$

where $\widehat{f}(\xi) \;:=\; (2\pi)^{-d/2}\int_{\mathbb{R}^d} f(x)\,\mathrm{e}^{-\imath\,\xi^t x}\,\mathrm{d}x$ is the Fourier transform of a function f in $L^1(\mathbb{R}^d)\cap L^2(\mathbb{R}^d)$. The Fourier transform can be extended to L^2-functions and tempered distributions by continuity and duality, respectively. The Λ-operator,

$$\widehat{\Lambda f}(\xi) \;:=\; \|\xi\|\;\widehat{f}(\xi),$$

maps $H^\alpha(\mathbb{R}^d)$ boundedly to $H^{\alpha-1}(\mathbb{R}^d)$.

The latter mapping property of Λ together with a smoothing effect of $\mathbf{R}$ (see [14, Chap. II, Thm. 5.1]) and the Sobolev embedding theorem shows that υ from (1.3) is continuous whenever e is a radially symmetric compactly supported mollifier in $H^\alpha(\mathbb{R}^2)$, $\alpha > 1$. Furthermore, $\upsilon \in L^1(\mathbb{R})$; see [16, Lem. 3.1]. Thus, $\upsilon_\gamma \star B$ is well defined in $H^t(\mathbb{R})$ for $B \in H^t(\mathbb{R})$, $t \in \mathbb{R}$; see, e.g., Aubin [1, Prop. 9.3.2].

Lemma 2.1. *Let $e \in H^\alpha(\mathbb{R}^2)$, $\alpha > 1$, be a radially symmetric compactly supported mollifier, and let υ be the corresponding reconstruction kernel* (1.3). *Then,*

$$\lim_{\gamma\to 0} \Big\| \upsilon_\gamma - \frac{1}{2\pi}\,\Lambda\delta \Big\|_{-\beta} \;=\; 0 \quad \textit{for any } \beta > 3/2, \tag{2.1}$$

where δ denotes the Dirac generalized function. Moreover, if $B \in H^t(\mathbb{R})$, $t \in \mathbb{R}$, then

$$\lim_{\gamma\to 0} \Big\| \upsilon_\gamma \star B - \frac{1}{2\pi}\,\Lambda B \Big\|_{t-1} \;=\; 0. \tag{2.2}$$

For values of s such that ΛB is continuous near s we have

$$\lim_{\gamma\to 0} \upsilon_\gamma \star B(s) \;=\; \frac{1}{2\pi}\;\Lambda B(s).$$

Proof. We prove (2.2) which then implies (2.1) when setting $B = \delta$ and recalling that $\delta \in H^t(\mathbb{R})$ for $t < -1/2$. With

$$I(\xi,\gamma) \;=\; (1+|\xi|^2)^{t-1}\,\left|\sqrt{2\pi}\;\widehat{\upsilon_\gamma}(\xi)\;\widehat{B}(\xi) - |\xi|\;\widehat{B}(\xi)/(2\pi)\right|^2$$

we obtain that

$$\Big\| \upsilon_\gamma \star B - \frac{1}{2\pi}\,\Lambda B \Big\|_{t-1}^2 \;=\; \int_{\mathbb{R}} I(\xi,\gamma)\;\mathrm{d}\xi.$$

By the projection slice theorem (see, e.g., Natterer [14, Chap. II, Thm. 1.1]) we find (e is a radially symmetric function)

$$\widehat{\upsilon_\gamma}(\xi) \;=\; \frac{1}{2\pi}\;|\xi|\;\widehat{\mathbf{R}e_\gamma}(\xi) \;=\; \frac{1}{\sqrt{2\pi}}\;|\xi|\;\widehat{e_\gamma}(\xi,0) \;=\; \frac{1}{\sqrt{2\pi}}\;|\xi|\;\widehat{e}(\gamma\,\xi,0),$$

which yields

$$I(\xi,\gamma) \;\le\; (1+|\xi|^2)^t\;\big|\widehat{B}(\xi)\big|^2\;\big|\widehat{e}(\gamma\,\xi,0) - 1/(2\pi)\big|^2.$$

The stated convergence follows now from $\widehat{e}(0,0) \,=\, 1/(2\pi)$, the Riemann–Lebesgue lemma, and the dominated convergence theorem. □

Let us look at an example. For χ being the indicator function of the interval $[-1/2, 1/2]$ we are able to compute $\Lambda\chi$ by

$$\Lambda\chi(s) = -\frac{1}{\pi}\int_{\mathbb{R}} |s-t|^{-2}\;\chi(t)\;\mathrm{d}t, \quad |s| > 1/2; \tag{2.3}$$

see Faridani et al. [9, Form. (2.1)]. Evaluating the integral gives

$$\Lambda\chi(s) \;=\; \frac{4}{\pi}\;\frac{1}{1-4\,s^2}. \tag{2.4}$$

The above formula holds for all $s \in \mathbb{R} \setminus \{-1/2, 1/2\}$. This can be verified using the relation $\Lambda(1-\chi) = -\Lambda\chi$ and applying formula (2.1) of [9] to $1-\chi$, the indicator function of $\mathbb{R} \setminus [-1/2, 1/2]$. So we have that

$$\lim_{\gamma\to 0} \upsilon_\gamma \star \chi(s) \;=\; \frac{2}{\pi^2}\,\frac{1}{1-4\,s^2}, \quad |s| \neq 1/2.$$

In weaker Sobolev norms we can even give convergence rates. For formulating the respective result and later in the paper we use the following convenient notation: $A \lesssim B$ indicates the existence of a generic constant c such that $A \le c\,B$ holds uniformly with respect to all parameters A and B may depend on.

COROLLARY 2.2. *Let* $0 \le s \le 2$. *Under the assumptions of Lemma* 2.1 *we have that*

$$\Big\|\upsilon_\gamma \star B - \frac{1}{2\pi}\,\Lambda B\Big\|_{t-1-s} \lesssim \gamma^s\;\|B\|_t.$$

Proof. As in the proof of Lemma 2.1 we obtain that

$$\Big\|\upsilon_\gamma \star B - \frac{1}{2\pi}\,\Lambda B\Big\|^2_{t-1-s} \;\le\; \int_{\mathbb{R}} (1+|\xi|^2)^{t-s}\;\big|\widehat{B}(\xi)\big|^2\;M(\gamma\,\xi, 0)\;\mathrm{d}\xi,$$

where $M(z) := |\widehat{e}(z) - 1/(2\pi)|^2$, $z \in \mathbb{R}^2$. Since e is an even function all its first order moments vanish. Therefore, all first order derivatives of $\widehat{e}$ are zero at the origin. Thus the Taylor expansion of $\widehat{e}$ about the origin becomes

$$\widehat{e}(z) \;=\; \frac{1}{2\pi} + \sum_{\substack{\nu\in\mathbb{N}_0^2\\ \nu_1+\nu_2=2}} \frac{D^\nu \widehat{e}(\tau_z\,z)}{\nu!}\;z^\nu \quad \text{for a } \tau_z \in [0,1],$$

which yields $M(z) \lesssim \|z\|^4$. Now let $s \in [0,2]$. Then,

$$\begin{aligned}\Big\|\upsilon_\gamma \star B - \frac{1}{2\pi}\,\Lambda B\Big\|^2_{t-1-s} &\lesssim \int_{|\xi|\le 1/\gamma} \big|\widehat{B}(\xi)\big|^2\;(1+|\xi|^2)^{t-s}\;M(\gamma\,\xi,0)\;\mathrm{d}\xi\\ &\qquad + \int_{|\xi|>1/\gamma} \big|\widehat{B}(\xi)\big|^2\;(1+|\xi|^2)^{t-s}\;\mathrm{d}\xi\\ &\lesssim \gamma^4 \int_{|\xi|\le 1/\gamma} \big|\widehat{B}(\xi)\big|^2\;(1+|\xi|^2)^{t}\;|\xi|^{4-2s}\;\mathrm{d}\xi\\ &\qquad + \int_{|\xi|>1/\gamma} \big|\widehat{B}(\xi)\big|^2\;(1+|\xi|^2)^{t}\;|\xi|^{-2s}\;\mathrm{d}\xi.\end{aligned}$$

Both latter terms can be bounded by $\gamma^{2s}\;\|B\|_t^2$. □

Remark 2.3. The generalization of Corollary 2.2 to reconstruction kernels υ belonging to mollifiers with higher order vanishing moments is obvious.

3. The FBA is optimal.

We will reformulate the FBA (1.4) for the limit filters considered in the former section; see (3.2) below. This new representation of the FBA allows us to introduce a novel error analysis which shows that the FBA is optimal for tomographic inversion.

3.1. A new representation of the FBA. We start with the following simple observation.

Lemma 3.1. *Let B be in $H^t(\mathbb{R})$ for a $t \in \mathbb{R}$ such that $\Lambda B(s)$ is continuous near integer values of s. For $\psi(s) = \sum_{k\in\mathbb{Z}} c_k\, B_h(s - h\,k)$, where $\{c_k\}$ is a finite sequence and h is positive, we have*

$$\Lambda\psi(h\,\ell) \;=\; h^{-1} \sum_{k\in\mathbb{Z}} c_k \;\Lambda B(\ell - k), \quad \ell \in \mathbb{Z}.$$

Proof. The statement follows directly from the relations $\Lambda B_h(s) = \Lambda B(s/h)/h$ and $\Lambda T^a = T^a \Lambda$, where T^a is the translation operator $T^a u(s) = u(s - a)$. □

Remark 3.2. Relying on Lemma 3.1 we easily derive that

$$\frac{2}{\pi}\;\frac{1}{q + 1/2} \;=\; \sum_{k=-q}^{q} \Lambda\chi(k) \quad \text{for any } q \in \mathbb{N}_0,$$

where χ is as in (2.3). To prove the above identity we mention only that $\sum_{k=-q}^{q} \chi(\cdot - k)$ is the characteristic function of the interval $[-q - 1/2, q + 1/2]$.

Let the operator E_h be given by (1.8) with B as in Lemma 3.1. Define the discrete reconstruction kernel $\{w_k^\infty\}$ by

$$w_k^\infty \;=\; \frac{1}{2\pi\, h^2}\;\Lambda B(k) \;=\; v_h^\infty(h\,k), \tag{3.1}$$

where $v_h^\infty(s) = v^\infty(s/h)/h^2$ and $v^\infty(s) := \Lambda B(s)/(2\pi)$. Then, the discrete convolution (1.5) can be written as the Λ-operator applied *exactly* to a function approximating g from discrete values:

$$(w^\infty \star_q g)_{\ell,j} \;=\; \frac{1}{2\pi}\,\big(\Lambda E_h g(\cdot, \vartheta_j)\big)(h\,\ell), \quad \ell \in \mathbb{Z}.$$

Thus, the reconstructed image f_{FB} may be rewritten as

$$f_{\mathrm{FB}}(x) \;=\; \frac{1}{2\pi}\;\mathbf{R}_p^* \mathrm{I}_h \Lambda E_h g(x); \tag{3.2}$$

see (1.4). Please observe that the three operators E_h, Λ, and I_h act on the first variable of the data $g = \mathbf{R}f$.

Example 3.3. Let $B = \chi$ be the characteristic function of $[-1/2, 1/2]$. Then, the reconstruction kernel w^∞ used for evaluating (3.2) is

$$w_k^\infty \;=\; \frac{2}{\pi^2\, h^2}\;\frac{1}{1 - 4\,k^2},$$

which follows from (2.4) and (3.1). Here, w^∞ is the discrete Shepp–Logan reconstruction filter [21].

Remark 3.4. Let the discrete reconstruction kernel $\{w_k\}$ be given by (1.9). Due to Lemma 2.1 we obtain $\lim_{\gamma\to 0} w_k = w_k^\infty$, implying that

$$\lim_{\gamma\to 0}\,(w \star_q g)_{\ell,j} \;=\; \frac{1}{2\pi}\,\big(\Lambda E_h g(\cdot, \vartheta_j)\big)(h\,\ell), \quad \ell \in \mathbb{Z}.$$

We next ask the question, Which mollifier e^∞ belongs to the reconstruction kernel v^∞ (3.1)? By (1.3) and the projection slice theorem we find that

$$\widehat{e^\infty}(\xi) \;=\; \widehat{B}(\|\xi\|)/\sqrt{2\pi}, \quad \xi \in \mathbb{R}^2, \tag{3.3}$$

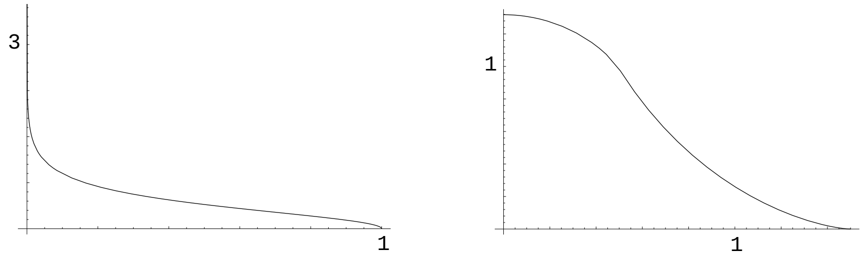

FIG. 1. *Radial part of limit mollifier* e^∞ (3.4) *where* B *is the linear (left) and the quadratic (right) B-spline, respectively.*

which yields (J_0 denoting the Bessel function of the first kind of order 0)

$$e^\infty(x) \,=\, \frac{1}{\sqrt{2\pi}} \int_0^\infty r\ \widehat{B}(r)\ \mathrm{J}_0(\|x\|\, r)\ \mathrm{d}r. \tag{3.4}$$

In view of (3.3) the mollifier e^∞ is in $L^2(\mathbb{R}^2)$ if $\lim_{r\to\infty} r\,|\widehat{B}(r)| = 0$. Further, a compact support of B implies a compact support of e^∞. More precisely, let B be *even* with $\operatorname{supp} B \subset [-R, R]$; then $\operatorname{supp} e^\infty \subset \{x \in \mathbb{R}^2 \mid \|x\| \le R\}$. The latter statement is a consequence from the Paley–Wiener theorems; see, e.g., Rudin [19, Chap. 7].

Example 3.5. Let $B = \chi$ be the characteristic function of the interval $[-1/2, 1/2]$. By formula 6.671.7 from [11] we find that

$$e^\infty(x) \,=\, \begin{cases} \frac{2}{\pi}\ \frac{1}{\sqrt{1-4\,\|x\|^2}} & : \ \ \|x\| < 1/2, \\ \qquad 0 & : \ \ \text{otherwise}, \end{cases}$$

which is the mollifier belonging to $v^\infty(s) = \frac{1}{2\pi}\Lambda\chi(s) = \frac{2}{\pi^2}(1 - 4\,s^2)^{-1}$; see (2.4). The graphs of the radial parts of e^∞ with respect to the linear and quadratic B-splines are plotted in Figure 1.

3.2. A novel error estimate. The new representation (3.2) of the FBA gives us the freedom to provide a novel error analysis based on principles from approximation theory. Indeed, we will be able to prove L^2-convergence of the FBA with optimal rates.

In contrast, the error estimates based on Fourier analysis (see Natterer [14, Chap. V] and Faridani and Ritman [10]) are of qualitative nature in terms of essentially band-limited functions. Since the main tool used is the Poisson summation formula the considered density distributions are required to be continuous functions at least ($\widehat{f} \in L^1$). Convergence has been shown before: Popov [15] established pointwise convergence restricted to a small class of functions (piecewise $\mathcal{C}^\infty$ with jumps across smooth curves). The approach of Rieder and Schuster [18] leads to L^2-convergence for $f \in H_0^\alpha(\Omega)$, $\alpha > 1/2$, however, with suboptimal rates.

In our analysis below we will not take into account the error introduced by discretizing the backprojection $\mathbf{R}^*$; that is, our model of the FBA reconstructs $\widetilde{f}_{\mathrm{FB}}$ by

$$\widetilde{f}_{\mathrm{FB}}(x) \,:=\, \frac{1}{2\pi}\ \mathbf{R}^* \mathrm{I}_h \Lambda E_h \mathbf{R} f(x); \tag{3.5}$$

compare (3.2).

Before bounding the reconstruction error of $\widetilde{f}_{\mathrm{FB}}$ we generalize both operators E_h and I_h. For $u \in H^\alpha(\mathbb{R})$, $\alpha \in \mathbb{R}$, we define

$$E_h u(s) := h^{-1} \sum_{k\in\mathbb{Z}} \big\langle u, \epsilon_h(\cdot - s_k)\big\rangle \, B_h(s - s_k), \tag{3.6}$$

where $\epsilon_h(s) = \epsilon(s/h)$ with $\epsilon \in H^{-\alpha}(\mathbb{R})$ being even and $\widehat{\epsilon}(0) = 1/\sqrt{2\pi}$. Further, $\langle\cdot,\cdot\rangle$ denotes the duality pairing in $H^\alpha(\mathbb{R}) \times H^{-\alpha}(\mathbb{R})$. For $u \in H^\alpha(\mathbb{R})$, $\alpha > 1/2$, we may choose $\epsilon = \delta$ (Dirac distribution). Thus, $h^{-1}\langle u, \epsilon_h(\cdot - s_k)\rangle = u(s_k)$, and the general form (3.6) of E_h coincides with its former definition (1.8). We extended the domain of definition of E_h to cover (generalized) functions in $H^\alpha(\mathbb{R})$ with $\alpha \le 1/2$.

The redefinition of E_h was necessary because we apply E_h to $\mathbf{R}f(\cdot,\vartheta)$ (see (3.5)), and we have only that $\mathbf{R}f(\cdot,\vartheta) \in H_0^{1/2}(-1,1)$ for $f \in L^2(\Omega)$ and almost all ϑ. Moreover, our new model allows for finite width of the rays and detector inhomogeneities in the observed semidiscrete Radon data; see Natterer [14, Chap. V.5.1]. Indeed, for ϵ being a nonnegative function compactly supported in $[-1/2, 1/2]$ with a normalized mean value we obtain

$$h^{-1} \big\langle \mathbf{R}f(\cdot,\vartheta), \epsilon_h(\cdot - s_k)\big\rangle = h^{-1} \int_{s_k - h/2}^{s_k + h/2} \mathbf{R}f(s,\vartheta)\, \epsilon_h(s - s_k)\, \mathrm{d}s. \tag{3.7}$$

Hence, ϵ can be seen as the *sensitivity profile* of the X-ray detectors.

In a very similar way we define I_h by

$$\mathrm{I}_h u(s) := h^{-1} \sum_{k\in\mathbb{Z}} \big\langle u, \eta_h(\cdot - s_k)\big\rangle \, A_h(s - s_k), \tag{3.8}$$

where η and A are like ϵ and B from (3.6), respectively.

Our modifications of E_h and I_h have no effect on the efficient computation of $\mathrm{I}_h \Lambda E_h \mathbf{R}f(\cdot,\vartheta)/(2\pi)$ by discrete convolution. A straightforward calculation reveals that

$$\frac{1}{2\pi}\,\big(\mathrm{I}_h \Lambda E_h \mathbf{R}f(\cdot,\vartheta)\big)(s) = \sum_{\ell\in\mathbb{Z}} \big(w \star_q g^\epsilon(\cdot,\vartheta)\big)_\ell \, A_h(s - s_\ell),$$

where $g^\epsilon(s,\vartheta) = \big(\mathbf{R}f(\cdot,\vartheta) \star_s \epsilon_h\big)(s)/h$ (see (3.7)), and the discrete reconstruction kernel w is given by

$$\begin{aligned} &w_r = v(r)/h^2, \quad r \in \mathbb{Z},\\ &\text{with } v(s) := \frac{1}{\pi} \int_0^\infty \sigma\, \widehat{B}(\sigma)\, \widehat{\eta}(\sigma)\, \cos(s\,\sigma)\, \mathrm{d}\sigma. \end{aligned} \tag{3.9}$$

The above integral exists as a duality pairing whenever $B \in H^t(\mathbb{R})$ and $\eta \in H^{1-t}(\mathbb{R})$.

Example 3.6. We will give the Shepp–Logan reconstruction filter a new interpretation. To this end, let $B(s) = \mathrm{sinc}(\pi\, s)$ be the interpolating function used to define E_h. In I_h let η be the characteristic function of the interval $[-1/2, 1/2]$. We obtain $\widehat{B} = \chi_{[-\pi,\pi]}/\sqrt{2\pi}$ (χ_D characteristic function of interval D) and $\widehat{\eta}(\sigma) = \mathrm{sinc}(\sigma/2)/\sqrt{2\pi}$. Hence,

$$v(s) = \frac{2}{\pi^2}\, \frac{2\,s\,\sin(\pi\,s) - 1}{4\,s^2 - 1} \quad \text{and} \quad w_k = v(k)/h^2 = \frac{2}{\pi^2\,h^2}\, \frac{1}{1 - 4\,k^2};$$

see Example 3.3 and compare formula (1.22) on page 111 in [14].

In estimating the reconstruction error below we will need that the inversion formula (1.1) holds true for functions in $L^2(\Omega)$; that is,

$$f \;=\; (2\pi)^{-1}\,\mathbf{R}^*\,\Lambda\mathbf{R}f \quad \text{for any } f\in L^2(\Omega). \tag{3.10}$$

As far as we know, the most general version of (1.1) is due to Smith, Solomon, and Wagner [24, p. 1257] requiring a compactly supported $f\in H^\alpha(\mathbb{R}^2)$ with $\alpha\ge 1/2$. To verify (3.10) we recall the following mapping property of the Radon transform:

$$\mathbf{R}: H_0^\alpha(\Omega)\to H^{(\alpha+1/2,0)} \quad \text{is bounded for any } \alpha\ge 0, \tag{3.11}$$

which is due to Louis and Natterer [13, Thm. 3.1]; see also [14, Thm. II.5.1]. Above, $H_0^\alpha(\Omega)$ is the closure of $\mathcal{C}_0^\infty(\Omega)$, the space of infinitely differentiable functions compactly supported in Ω, with respect to the norm $\|\cdot\|_\alpha$. Further, $H^{(\beta,0)}$ is the tensor product space $H^\beta(\mathbb{R})\widehat{\otimes}L^2(0,\pi)$.

Now the validity of (3.10) can be seen from the following three facts: 1. The operator $\mathbf{R}^*\,\Lambda\mathbf{R}: L^2(\Omega)\to L^2(\Omega)$ is bounded since all three mappings $\mathbf{R}: L^2(\Omega)\to H^{(1/2,0)}$, $\Lambda : H^{(1/2,0)}\to H^{(-1/2,0)}$, and $\mathbf{R}^* : H^{(-1/2,0)}\to L^2(\Omega)$ are bounded.[1] 2. Formula (3.10) applies to all $f\in\mathcal{C}_0^\infty(\Omega)$; see, e.g., Natterer [14, Thm. II.2.1]. 3. The space $\mathcal{C}_0^\infty(\Omega)$ is dense in $L^2(\Omega)$.

After these preparations we concentrate on the reconstruction error for f in $H_0^\alpha(\Omega)$, $\alpha\ge 0$. Relying on (3.10) we begin with

$$\begin{aligned}\big\|\widetilde{f}_{\mathrm{FB}}-f\big\|_{L^2(\Omega)} &= \frac{1}{2\pi}\,\big\|\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}f-\mathbf{R}^*\Lambda\mathbf{R}f\big\|_{L^2(\Omega)}\\ &\le \big\|\big(\mathbf{R}^*\mathrm{I}_h-\mathbf{R}^*\big)\Lambda E_h\mathbf{R}f\big\|_{L^2(\Omega)}\\ &\qquad\qquad + \big\|\mathbf{R}^*\Lambda\big(E_h\mathbf{R}f-\mathbf{R}f\big)\big\|_{L^2(\Omega)}\end{aligned}$$

and proceed by estimating both norms on the right-hand side.

We saw above that $\mathbf{R}^*\Lambda$ maps $H^{(1/2,0)}$ boundedly to $L^2(\Omega)$. Hence,

$$\big\|\mathbf{R}^*\Lambda\big(E_h\mathbf{R}f-\mathbf{R}f\big)\big\|_{L^2(\Omega)} \lesssim \big\|E_h\mathbf{R}f-\mathbf{R}f\big\|_{H^{(1/2,0)}}.$$

Now we need an approximation property of E_h. Therefore, we assume there are nonnegative constants $\tau_{\max}$ and $\beta_{\min}\le\beta_{\max}$ such that

$$\big\|E_h u-u\big\|_\tau \lesssim h^{\beta-\tau}\,\|u\|_\beta \quad \text{as } h\to 0 \tag{3.12a}$$

$$\text{for } \beta_{\min}\le\beta\le\beta_{\max},\ 0\le\tau\le\beta,\ \ \tau\le\tau_{\max},\ u\in H_0^\beta(-1,1). \tag{3.12b}$$

For instance, if E_h represents piecewise linear interpolation[2], then (3.12) holds with $\beta_{\max}=2$, $\beta_{\min}>1/2$, and $\tau_{\max}<3/2$. For piecewise linear interpolation the approximation property (3.12) is a classical result when $\tau\in\{0,1\}$ and $\beta=2$; see, e.g., Strang and Fix [25, Thm. 1.3]. Also band-limited interpolation[3] yields (3.12) with $\beta_{\min}>1/2$ and any $\beta_{\max}=\tau_{\max}<\infty$. In Appendices A and B we prove (3.12) for more general interpolation-like operators E_h where $\beta_{\min}=0$.

[1] The continuity of $\mathbf{R}^* : H^{(-1/2,0)}\to L^2(\Omega)$ follows from (3.11) by duality.

[2] ϵ is the Dirac distribution and B is the linear B-spline.

[3] ϵ is the Dirac distribution and $B(x)=\mathrm{sinc}(\pi x)$.

Estimates of terms from above by powers of h (like (3.12)) are in what follows always understood asymptotically in the sense of $h \to 0$.

Assume (3.12) to hold with $\beta_{\max} \geq 1/2$ and $\tau_{\max} \geq 1/2$. If $\max\{0, \beta_{\min} - 1/2\} \leq \alpha \leq \beta_{\max} - 1/2$, then

$$\big\|\mathbf{R}^*\Lambda\big(E_h\mathbf{R}f - \mathbf{R}f\big)\big\|_{L^2(\Omega)} \lesssim h^\alpha\ \|\mathbf{R}f\|_{H^{(1/2+\alpha,0)}} \overset{(3.11)}{\lesssim} h^\alpha\ \|f\|_\alpha.$$

Now we turn to $\|(\mathbf{R}^*\mathrm{I}_h - \mathbf{R}^*)\Lambda E_h\mathbf{R}f\|_{L^2(\Omega)}$ which we estimate according to

$$\begin{aligned}\big\|\mathbf{R}^*\big(\mathrm{I}_h - I\big)\Lambda E_h\mathbf{R}f\big\|_{L^2(\Omega)} \\ \leq \|\mathbf{R}^*\|_{H^{(-1/2,0)}\to L^2(\Omega)}\ \|\mathrm{I}_h - I\|_{H^{\alpha-1/2}(\mathbb{R})\to H^{-1/2}(\mathbb{R})} \\ \times\ \|\Lambda\|_{H^{\alpha+1/2}(\mathbb{R})\to H^{\alpha-1/2}(\mathbb{R})}\ \|E_h\mathbf{R}f\|_{H^{(1/2+\alpha,0)}},\end{aligned}$$

where $I : H^{\alpha-1/2}(\mathbb{R}) \hookrightarrow H^{-1/2}(\mathbb{R})$ is the canonical inclusion. Observe that (3.12) implies the boundedness of $E_h : H_0^{1/2+\alpha}(-1,1) \to H^{1/2+\alpha}(\mathbb{R})$ uniformly in h for $0 \leq \alpha \leq \min\{\beta_{\max}, \tau_{\max}\} - 1/2$. Thus,

$$\|E_h\mathbf{R}f\|_{H^{(1/2+\alpha,0)}} \lesssim \|\mathbf{R}f\|_{H^{(1/2+\alpha,0)}} \overset{(3.11)}{\lesssim} \|f\|_\alpha.$$

For the operator I_h we require that

$$\|\mathrm{I}_h - I\|_{H^{\alpha-1/2}(\mathbb{R})\to H^{-1/2}(\mathbb{R})} \lesssim h^\alpha \quad \text{as } h \to 0 \text{ for } 0 \leq \alpha \leq \alpha_{\mathrm{I}}. \tag{3.13}$$

which yields that

$$\big\|\big(\mathbf{R}^*\mathrm{I}_h - \mathbf{R}^*\big)\Lambda E_h\mathbf{R}f\big\|_{L^2(\Omega)} \lesssim h^\alpha\ \|f\|_\alpha.$$

Thus, we have proven the following theorem.

THEOREM 3.7. *Assume* (3.12) *to hold with* $\beta_{\max} \geq 1/2$ *and* $\tau_{\max} \geq 1/2$. *Further, let there exist an* $\alpha_{\mathrm{I}} > 0$ *such that* (3.13) *holds true.*

If $\max\{0, \beta_{\min} - 1/2\} \leq \alpha \leq \min\big\{\alpha_{\mathrm{I}}, \beta_{\max} - 1/2, \tau_{\max} - 1/2\big\}$ *and* $f \in H_0^\alpha(\Omega)$, *then*

$$\Big\|f - \frac{1}{2\pi}\,\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}f\Big\|_{L^2(\Omega)} \lesssim h^\alpha\ \|f\|_\alpha \quad \textit{as } h \to 0. \tag{3.14}$$

The best possible L^2-convergence rate for the reconstruction of $f \in H_0^\alpha(\Omega)$ from Radon data sampled at distance h is h^α as $h \to 0$; see Natterer [14, Chap. IV, Thm. 2.2]. So we just proved that the FBA with an "averaged" limit kernel (3.9) is an optimal reconstruction algorithm (at least for semidiscrete data). The range of Sobolev orders yielding optimal convergence depends on the chosen filter and the used interpolation procedure.

Theorem 3.7 looks similar to Theorem V.1.2 of Natterer [14]. The main difference is that our theorem takes the discretization of the convolution into account. On the other hand, the main result of Popov [15, Thm. 3, p. 35] investigates pointwise convergence utilizing an approach based on asymptotic expansions. It does consider the fully discrete algorithm but is applicable to a smaller class of functions (piecewise $\mathcal{C}^\infty$ with jumps across smooth curves), is stated without a detailed proof, and is not always easily applied to concrete examples.

Example 3.8. Here we provide a simple example for (3.13) which results in a convergence proof of the FBA with the Shepp–Logan filter and nearest-neighbor interpolation.

To this end let both η and A be first order B-splines; that is, $\eta = A = \chi_{[-1/2,1/2[}$. In this situation (3.13) applies with $\alpha_{\mathrm{I}} = 3/2$ as we will demonstrate now. By Theorem A.2,

$$\|\mathrm{I}_h u - u\|_\tau \lesssim h^{\beta-\tau}\, \|u\|_\beta \tag{3.15}$$

for $0 \le \tau \le \beta \le 1$ and $\tau < 1/2$. To estimate $\|\mathrm{I}_h u - u\|_{-1/2}$ we use a duality argument and the symmetry $\mathrm{I}_h = \mathrm{I}_h^*$, where I_h^* is the L^2-adjoint of I_h. We find that, for $0 \le \alpha \le 1/2$,

$$\begin{aligned}\|\mathrm{I}_h u - u\|_{-1/2} &= \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\langle \mathrm{I}_h u - u, v\rangle}{\|v\|_{1/2}} = \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\langle u, \mathrm{I}_h v - v\rangle}{\|v\|_{1/2}}\\ &\le \|u\|_{\alpha-1/2} \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\|\mathrm{I}_h v - v\|_{1/2-\alpha}}{\|v\|_{1/2}} \overset{(3.15)}{\lesssim} h^\alpha\, \|u\|_{\alpha-1/2}.\end{aligned} \tag{3.16}$$

For $1/2 < \alpha \le 3/2$ we estimate similarly, relying on $\mathrm{I}_h^2 = \mathrm{I}_h$,

$$\begin{aligned}\|\mathrm{I}_h u - u\|_{-1/2} &= \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\langle (\mathrm{I}_h - I)^2 u, v\rangle}{\|v\|_{1/2}} = \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\langle \mathrm{I}_h u - u, \mathrm{I}_h v - v\rangle}{\|v\|_{1/2}}\\ &\le \|\mathrm{I}_h u - u\|_{L^2(\mathbb{R})} \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\|\mathrm{I}_h v - v\|_{L^2(\mathbb{R})}}{\|v\|_{1/2}}\\ &\overset{(3.15)}{\lesssim} h^{\alpha-1/2}\, \|u\|_{\alpha-1/2}\, h^{1/2}.\end{aligned} \tag{3.17}$$

Hence, (3.13) holds for $\alpha_{\mathrm{I}} = 3/2$.

Recalling Example 3.6 we observe that the FBA with the Shepp–Logan filter and nearest-neighbor interpolation is represented by $B(s) = \operatorname{sinc}(\pi\, s)$ and $\eta = A = \chi_{[-1/2,1/2[}$ in our framework (3.5). Therefore, our results from Appendix B give that

$$\left\| \widetilde{f}_{\mathrm{FB}} - f \right\|_{L^2(\Omega)} \lesssim h^{\min\{3/2,\,\alpha\}}\, \|f\|_\alpha \quad \text{for } f \in H_0^\alpha(\Omega),\ \alpha > 0,$$

as long as ϵ is either an even, compactly supported, and normalized L^2-function (Theorem B.2) or the Dirac distribution (Theorem B.4).

In the next section we will generalize the above example, covering especially piecewise linear interpolation in I_h.

So far we have not shown L^2-convergence of the FBA when the density distribution f is only in $L^2(\Omega)$. However, we possess all the tools to do this.

COROLLARY 3.9. *Assume* (3.12) *to hold with* $\beta_{\min} \le 1/2$, $\beta_{\max} > 1/2$, *and* $\tau_{\max} > 1/2$. *Further, let there exist an* $\alpha_{\mathrm{I}} > 0$ *such that* (3.13) *holds true. Then,*

$$\lim_{h\to 0} \left\| f - \frac{1}{2\pi}\, \mathbf{R}^* \mathrm{I}_h \Lambda E_h \mathbf{R} f \right\|_{L^2(\Omega)} = 0 \quad \textit{for any } f \in L^2(\Omega). \tag{3.18}$$

Proof. We will use that $\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R} : L^2(\Omega) \to L^2(\Omega)$ is uniformly bounded in $h > 0$. This follows by setting $\alpha = 0$ in (3.14) which is allowed since $\beta_{\min} \le 1/2$. Thus, $\|\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}\|_{L^2(\Omega)\to L^2(\Omega)} \lesssim 1$.

Fix an α with $0 < \alpha \le \min\{\alpha_{\mathrm{I}}, \beta_{\max} - 1/2, \tau_{\max} - 1/2\}$. By assumption the upper bound on α is positive. Since $H_0^\alpha(\Omega)$ is dense in $L^2(\Omega)$ there exists a family $\{f_\lambda\}_{\lambda>0} \subset H_0^\alpha(\Omega)$ which converges to f in $L^2(\Omega)$ as $\lambda \to 0$. Without loss of generality we may assume that f is *not* an element of $H_0^\beta(\Omega)$ for any $\beta > 0$ (otherwise we apply Theorem 3.7 to obtain (3.18)). Therefore, the function $\rho(\lambda) := \|f_\lambda\|_\alpha$ explodes: $\rho(\lambda) \to \infty$ as $\lambda \to 0$. Now we choose a family $\{\lambda_h\}_{h>0}$ satisfying

$$\lim_{h\to 0} \lambda_h \;=\; 0 \quad \text{as well as} \quad \lim_{h\to 0} h^\alpha\, \rho(\lambda_h) \;=\; 0.$$

We proceed with

$$\begin{aligned}\Big\| f - \frac{1}{2\pi}\,\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}f\Big\|_{L^2(\Omega)} &\le \|f - f_{\lambda_h}\|_{L^2(\Omega)} \\ &\quad + \Big\| f_{\lambda_h} - \frac{1}{2\pi}\,\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}f_{\lambda_h}\Big\|_{L^2(\Omega)} \\ &\quad + \|\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}(f_{\lambda_h} - f)\|_{L^2(\Omega)} \\ &\lesssim \|f - f_{\lambda_h}\|_{L^2(\Omega)} + h^\alpha\,\rho(\lambda_h),\end{aligned}$$

where we applied Theorem 3.7 in the last step. Finally, the limit $h \to 0$ implies (3.18). □

Example 3.10. We reconsider Example 3.8 in light of Corollary 3.9. The convergence (3.18) holds true when using the Shepp–Logan filter with nearest-neighbor interpolation for I_h and band-limited quasi interpolation for E_h; that is, $\eta = A = \chi_{[-1/2,1/2[}$, $B(s) = \mathrm{sinc}(\pi\, s)$, and ϵ is an even, compactly supported, and normalized L^2-function (Theorem B.2). Please note that band-limited interpolation for E_h (ϵ is the Dirac distribution), which requires $\beta_{\min} > 1/2$, is not covered by Corollary 3.9.

4. Verifying (3.13) for interpolation-like operators $\mathbf{I}_h$ based on orthogonalized B-splines. We consider a special choice for I_h (3.8): let $\widetilde{\eta}$ and A be the B-splines of order $M \ge 1$ and $N \ge 1$, respectively. Define η by

$$\widehat{\eta}(\sigma) \;:=\; \frac{\widehat{\widetilde{\eta}}(\sigma)}{\mathbf{a}(\sigma)} \;=\; \frac{1}{\sqrt{2\pi}}\;\frac{\mathrm{sinc}^M(\sigma/2)}{\mathbf{a}(\sigma)}, \tag{4.1}$$

where

$$\mathbf{a}(\sigma) \;=\; \sum_{\ell\in\mathbb{Z}} a_\ell\; \mathrm{e}^{-\imath\,\ell\sigma} \quad \text{with } a_\ell \;=\; \int_{\mathbb{R}} \widetilde{\eta}(s)\; A(\ell - s)\;\mathrm{d}s. \tag{4.2}$$

Note that $\mathbf{a}$ is a positive even real trigonometric polynomial with $\mathbf{a}(0) = 1$; see Appendix C.1. Further, η and A are dual functions; that is,

$$\big\langle \eta(\cdot - k),\, A(\cdot)\big\rangle \;=\; \delta_{k,0}; \tag{4.3}$$

see Appendix C.2. Especially,

$$(I - \mathrm{I}_h)\,(I - \widetilde{\mathrm{I}}_h) \;=\; I - \mathrm{I}_h, \tag{4.4}$$

where $\widetilde{\mathrm{I}}_h u(s) := h^{-1}\sum_{k\in\mathbb{Z}} \langle u, \widetilde{\eta}_h(\cdot - s_k)\rangle\, A_h(s - s_k)$.

As in (3.16) we obtain

$$\|\mathrm{I}_h u - u\|_{-1/2} \;\le\; \|u\|_{\alpha-1/2} \sup_{v\in H^{1/2}(\mathbb{R})} \frac{\|\mathrm{I}_h^* v - v\|_{1/2-\alpha}}{\|v\|_{1/2}}, \quad 0 \le \alpha \le 1/2.$$

Accordingly, we have to investigate the approximation power of the L^2-adjoint operator $\mathrm{I}_h^* u(s) = h^{-1}\sum_{k\in\mathbb{Z}}\langle u, A_h(\cdot - s_k)\rangle\, \eta_h(s - s_k)$ which is done in Appendix C.3. By (C.3),

$$\|\mathrm{I}_h u - u\|_{-1/2} \;\lesssim\; h^\alpha\; \|u\|_{\alpha-1/2}, \quad 0 \le \alpha \le 1/2.$$

The range $\alpha > 1/2$ we approach as in (3.18) with the help of (4.4):

$$\|\mathrm{I}_h u - u\|_{-1/2} \;\lesssim\; h^{1/2}\; \|\widetilde{\mathrm{I}}_h u - u\|_{L^2(\mathbb{R})}.$$

Applying Theorem A.2 to the above right-hand side implies (3.13) with

$$\alpha_{\mathrm{I}} \;=\; \begin{cases} 3/2 & : \quad N = 1, \\ 5/2 & : \quad N \ge 2. \end{cases}$$

The reconstruction filter belonging to I_h considered in this section is

$$\upsilon(s) \;=\; \frac{1}{\pi\,\sqrt{2\pi}} \int_0^\infty \sigma\; \frac{\mathrm{sinc}^M(\sigma/2)}{\mathbf{a}(\sigma)}\; \widehat{B}(\sigma)\; \cos(s\,\sigma)\; \mathrm{d}\sigma.$$

To find an explicit representation of $\mathbf{a}$ poses no problem since $a_\ell = \mathcal{B}(\ell)$, where $\mathcal{B}$ is the B-spline of order $M + N$. So, $a_\ell \in \mathbb{Q}$ can be found by the B-spline recursion or explicit representations of B-splines. Nevertheless, υ cannot be evaluated explicitly in general. However, the needed values of υ at integers can be computed numerically to any desired accuracy.

Example 4.1. Let $M = 1$, $N = 2$, and $B(s) = \mathrm{sinc}(\pi\, s)$. Then, $\mathbf{a}(\sigma) = \frac{3}{4} + \frac{1}{4}\cos(\sigma)$ and

$$\upsilon(s) \;=\; \frac{4}{\pi^2} \int_0^\pi \frac{\sin(\sigma/2)\,\cos(s\,\sigma)}{3 + \cos(\sigma)}\; \mathrm{d}\sigma.$$

Using this filter in the FBA together with piecewise linear interpolation in I_h yields

$$\big\|\widetilde{f}_{\mathrm{FB}} - f\big\|_{L^2(\Omega)} \;\lesssim\; h^{\min\{5/2,\,\alpha\}}\; \|f\|_\alpha \quad \text{for } f \in H_0^\alpha(\Omega),\; \alpha > 0,$$

since band-limited interpolation (B.4) is considered for E_h ($\beta_{\max} = \tau_{\max} > 3$).

Remark 4.2. The biorthogonalization procedure (4.1) is the same procedure used in the construction of orthogonal spline wavelets; see Lemarié [12]. The connection between wavelets and reconstruction filters can even be extended to increase α_{I}. Choosing A to be a B-spline of order N and η to be a suitable compactly supported dual scaling function (see Cohen, Daubechies, and Feauveau [4]) yields an operator I_h with an α_{I} increasing with N. The needed approximation properties of I_h and $\mathrm{I}_h^\star$ are reported, for instance, by Dahmen [5, Prop. 5.1].

5. Verifying (3.13) for interpolation-like operators $\mathbf{I}_h$ based on B-splines. Our analysis presented so far does not cover operators I_h where η and A are B-splines of order M and N, respectively. We will now investigate this situation.

Let E_h and I_h be defined as earlier with respect to ϵ, B, η, and A. Moreover, let $\mathbf{a}$ be given as in (4.2); however, $\widetilde{\eta}$ is replaced by η. Further, define the operator $\mathbf{A}_h : L^2(\mathbb{R}) \to L^2(\mathbb{R})$, $h > 0$, by $\widehat{\mathbf{A}_h u}(\sigma) := \mathbf{a}(h\,\sigma)\,\widehat{u}(\sigma)$. Note that $\widehat{\mathbf{A}_h^{-1}u}(\sigma) = \widehat{u}(\sigma)/\mathbf{a}(h\,\sigma)$. Now the key observation is that

$$\widetilde{f}_{\mathrm{FB}} = \frac{1}{2\pi}\,\mathbf{R}^*\mathrm{I}_h\Lambda E_h\mathbf{R}f = \frac{1}{2\pi}\,\mathbf{R}^*\mathrm{I}_h\mathbf{A}_h^{-1}\Lambda\mathbf{A}_hE_h\mathbf{R}f.$$

Consequently, we have to study the approximation powers of the products $\mathbf{A}_hE_h$ and $\mathrm{I}_h\mathbf{A}_h^{-1}$. The latter product is exactly the operator I_h studied in the former section. Hence,

$$\|\mathrm{I}_h\mathbf{A}_h^{-1} - I\|_{H^{\alpha-1/2}(\mathbb{R})\to H^{-1/2}(\mathbb{R})} \lesssim h^\alpha, \quad 0 \le \alpha \le \alpha_{\mathrm{I}} = \begin{cases} 3/2 \;:\; N = 1, \\ 5/2 \;:\; N \ge 2. \end{cases}$$

The product $\mathbf{A}_hE_h$ requires a little bit more attention. We begin with

$$\|\mathbf{A}_hE_hu - u\|_\tau \lesssim \|E_hu - u\|_\tau + \|\mathbf{A}_hu - u\|_\tau.$$

In view of (3.12) and (C.2) we obtain

$$\|\mathbf{A}_hE_hu - u\|_\tau \lesssim h^{\beta-\tau}\|u\|_\beta, \quad u \in H_0^\beta(-1,1),$$

for $\beta_{\min} \le \beta \le \min\{\beta_{\max}, 2+\tau\}$, $0 \le \tau \le \beta$, $\tau \le \tau_{\max}$. The parameters $\beta_{\min}$, $\beta_{\max}$, and $\tau_{\max}$ correspond to E_h.

Theorem 3.7 holds accordingly, however, with the following restrictions on α:

$$\max\{0, \beta_{\min} - 1/2\} < \alpha \le \min\big\{\alpha_{\mathrm{I}},\, 2,\, \beta_{\max} - 1/2,\, \tau_{\max} - 1/2\big\};$$

that is, the maximal convergence order cannot exceed 2 which is a tribute to the operator $\mathbf{A}_h$ in front of E_h.

Example 5.1. Using the Shepp–Logan filter ($\eta = \chi_{[-1/2,1/2[}$, $B(s) = \mathrm{sinc}(\pi\,s)$) in the FBA together with piecewise linear interpolation in I_h (A is the linear B-spline) yields

$$\big\|\widetilde{f}_{\mathrm{FB}} - f\big\|_{L^2(\Omega)} \lesssim h^{\min\{2,\,\alpha\}}\,\|f\|_\alpha \quad \text{for } f \in H_0^\alpha(\Omega),\ \alpha > 0,$$

when ϵ is either an even, compactly supported, and normalized L^2-function (Theorem B.2) or the Dirac distribution (Theorem B.4).

6. Numerical illustrations. We provide numerical experiments to illustrate the convergence results proved in the former sections. Especially, we will see that the convergence rates saturate indeed at the given bounds.

To this end we need an $f \in L^2(\Omega)$ with a prescribed Sobolev order and with an analytically computable Radon transform. We favor the following construction. Let p_n be defined by $p_n(x) = (1 - \|x\|^2)^n$, $\|x\| \le 1$, and $p_n(x) = 0$, otherwise. We have that $p_n \in H_0^\alpha(\Omega)$ for any $\alpha < n + 1/2$. The function f for the first numerical experiment is then given by

$$f(x) := \sum_{k=1}^{3} d_k\; p_3\big(U_k(x - b_k)\big) \in H_0^\alpha(\Omega) \text{ for any } \alpha < 7/2, \tag{6.1}$$

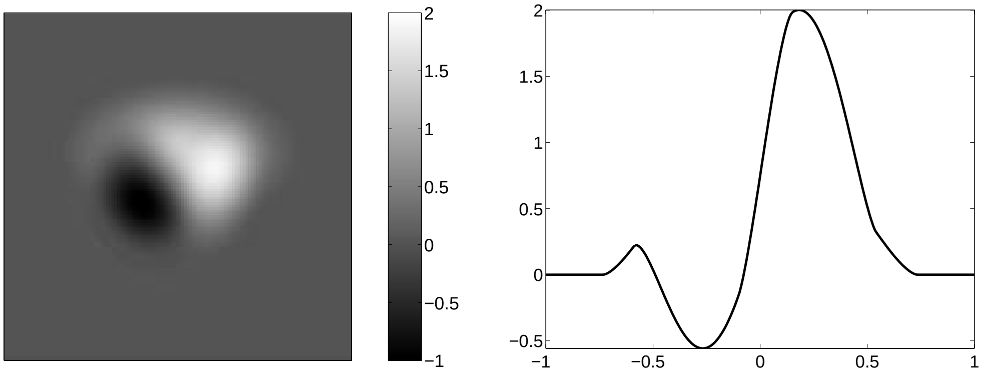

Fig. 2. *The function f from* (6.1) *(left) and its cross section $f(\cdot, 0)$ (right).*

where $d_1 = 1$, $d_2 = -1.5$, $d_3 = 1.5$, and $b_1 = (0.22, 0)^t$, $b_2 = (-0.22, 0)^t$, $b_3 = (0, 0.2)^t$. Further, $U_k = U(\varphi_k, \delta_k, \gamma_k)$, $k = 1, 2, 3$, with

$$U(\varphi, \delta, \gamma) := \begin{pmatrix} \cos(\varphi)/\delta & \sin(\varphi)/\delta \\ -\sin(\varphi)/\gamma & \cos(\varphi)/\gamma \end{pmatrix} \tag{6.2}$$

and

$$\begin{aligned} &\delta_1 = 0.51, && \gamma_1 = 0.31, && \varphi_1 = 72\pi/180, \\ &\delta_2 = 0.51, && \gamma_2 = 0.36, && \varphi_2 = 108\pi/180, \\ &\delta_3 = 0.5, && \gamma_3 = 0.8, && \varphi_3 = \pi/2. \end{aligned}$$

See Figure 2 for a graphical representation of f. We reconstructed f on the grid $\mathfrak{X}_q := \Omega \cap \{(i/q, j/q) \mid -q \leq i, j \leq q\}$ by

$$f_{\mathrm{FB},q}(x) := \frac{1}{2\pi}\, \mathbf{R}^*_{3q} \mathrm{I}_{1/q} \Lambda E_{1/q} \mathbf{R} f(x), \quad x \in \mathfrak{X}_q,$$

where $\mathbf{R}^*_p$ is defined in (1.6). We have chosen the number of directions ($3q$) close to its optimal value; see, e.g., Natterer [14, p. 84].

Now we define the relative ℓ^2-reconstruction error e by

$$e(q) := \Big(\sum_{x \in \mathfrak{X}_q} \big(f_{\mathrm{FB},q}(x) - f(x)\big)^2 \Big/ \sum_{x \in \mathfrak{X}_q} f(x)^2 \Big)^{1/2}. \tag{6.3}$$

In Figure 3 we plotted e as the function of $q \in \{25, 50, 75, 100, 125, 150, 175, 200\}$ on a double logarithmic scale with respect to three different settings in the FBA:

- The Shepp–Logan filter with nearest-neighbor interpolation (Example 3.8). Here, the expected and observed convergence rate is $e(q) \sim q^{-3/2}$; see the dot-dashed line marked with □.
- The Shepp–Logan filter with piecewise linear interpolation (Example 5.1). Here, the expected and observed convergence rate is $e(q) \sim q^{-2}$; see the dashed line marked with △.
- The modified Shepp–Logan filter with piecewise linear interpolation (Example 4.1). Here, the expected and observed convergence rate is $e(q) \sim q^{-5/2}$; see the solid line marked with ○. We also plotted an auxiliary curve decaying exactly like $q^{-5/2}$ (solid line in light gray).

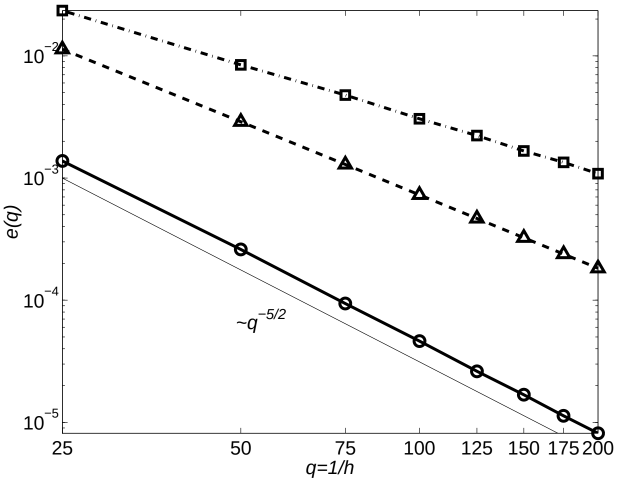

FIG. 3. *The relative ℓ^2-errors e (6.3) for reconstructing f (6.1) by the FBA using the Shepp–Logan filter with nearest-neighbor interpolation (dot-dashed with □), the Shepp–Logan filter with piecewise linear interpolation (dashed with △), and the modified Shepp–Logan filter with piecewise linear interpolation (solid with ○). The auxiliary solid line indicates exact decay $q^{-5/2}$.*

In light of the computational experiments we may conclude that our bounds for the maximal convergence orders cannot be improved (at least for the settings underlying the experiments).

Next, we present the relative ℓ^2-errors in reconstructing the Shepp–Logan head phantom; see Figure 4. The Shepp–Logan head phantom f^{SL} simulates the geometry and the density relations in a human skull. It consists of superimposed indicator functions of ellipses. Hence, $f^{\mathrm{SL}} \in H_0^\alpha(\Omega)$ for any $\alpha < 1/2$.[4] We therefore expect and observe $e(q) \sim q^{-1/2}$ for all three settings from above.

Both experiments agree completely with our theoretical results, although a discretization of the backprojection operator was not investigated. With our last experiment we justify this simplification once more by considering a setting which *might* cause trouble in a convergence analysis including the discrete backprojection operator.

The function to be reconstructed consists of indicator functions of two rectangles $\mathcal{R}_1$ and $\mathcal{R}_2$:

$$f(x) := \chi_{\mathcal{R}_1}(x) + 0.5\,\chi_{\mathcal{R}_2}(x) \tag{6.4}$$

with

$$\mathcal{R}_1 := [-2/5, 2/5] \times [-3/5, 3/5]$$

and (U as in (6.2))

$$\mathcal{R}_2 := \left\{x \in \mathbb{R}^2 \,\middle|\, U(\pi/3, 0.7, 0.4)(x-b) \in [-1,1]^2\right\}, \quad b = (-0.1, -0.1)^t;$$

see Figure 5 (left). Note that f is in $H_0^\alpha(\Omega)$ for any $\alpha < 1/2$. So what is the difference to the Shepp–Logan head phantom? While the fact that $\mathbf{R}f$ as a function

[4] In general, picture densities in medical imaging can be considered elements in $H_0^\alpha(\Omega)$ with $\alpha < 1/2$ but close to 1/2; see Natterer [14, pp. 92ff.].

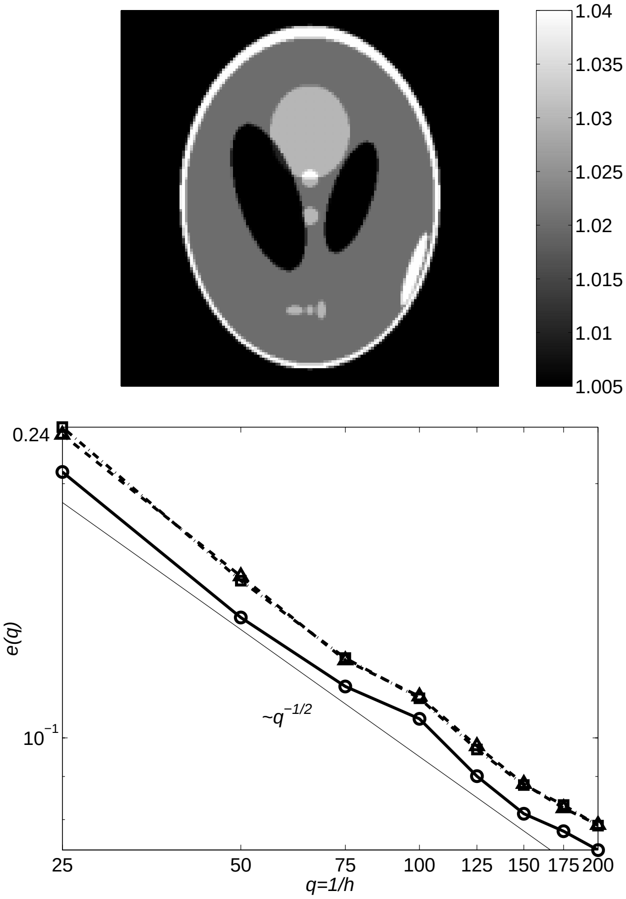

FIG. 4. *Top: head phantom due to Shepp–Logan* [21]*. Bottom: the relative ℓ^2-errors e* (6.3) *for reconstructing the Shepp–Logan phantom by the FBA using the Shepp–Logan filter with nearest-neighbor interpolation (dot-dashed with □), the Shepp–Logan filter with piecewise linear interpolation (dashed with △), and the modified Shepp–Logan filter with piecewise linear interpolation (solid with ○). The auxiliary solid line indicates exact decay $q^{-1/2}$.*

of two variables lies in $H_0^\beta(-1,1)\widehat{\otimes}L^2(0,\pi)$ implies that the functions of one variable $\mathbf{R}f(\cdot,\vartheta)$ lie in $H_0^\beta(-1,1)$ for almost all ϑ, there may be a null set of exceptional angles ϑ, where $\mathbf{R}f(\cdot,\vartheta)$ has less Sobolev regularity. For f given in (6.4) we have that $\mathbf{R}f$ is in $H_0^\beta(-1,1)\widehat{\otimes}L^2(0,\pi)$ for any $\beta<1$, but there exist four angles ϑ, where $\mathbf{R}f(\cdot,\vartheta)$ is less smooth. Indeed,

$$\mathbf{R}f(\cdot,\vartheta)\in H_0^\alpha(-1,1),\ \alpha<1/2,\quad \text{for } \vartheta\in\{0,\pi/3,\pi/2,5\pi/6\};$$

see Figure 5 (right). The bound on α is maximal (there are no such pathological angles for the Shepp–Logan head phantom; however, one expects such angles in real measurements from medical imaging).

In Figure 6 we plotted the relative reconstruction error (6.3) for the same q-values as before. Please note that the discrete Radon data for all q contain integrals over lines which run along the boundary of $\mathcal{R}_1$. Further, all used reconstruction grids $\mathcal{X}_q$ have sufficiently many points on the boundary of $\mathcal{R}_1$; indeed, the cardinality of

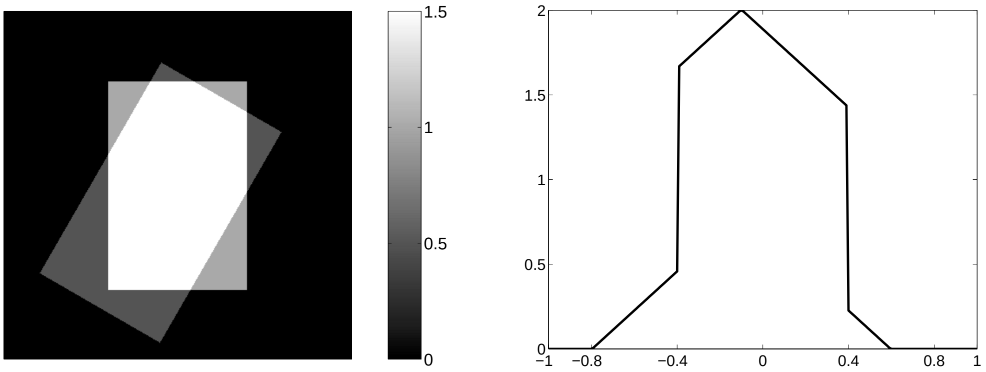

FIG. 5. *The function f from* (6.4) *(left) and its projection* $\mathbf{R}f(\cdot,0)$ *(right). The jumps of* $\mathbf{R}f(\cdot,0)$ *in* $\pm 2/5$ *are clearly visible.*

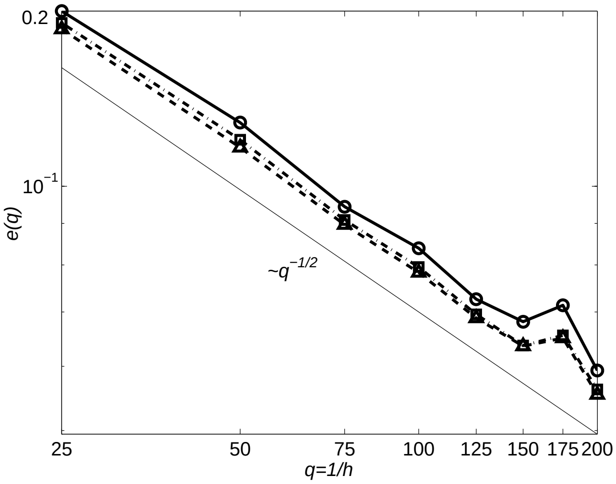

FIG. 6. *The relative ℓ^2-errors e* (6.3) *for reconstructing f* (6.4) *by the FBA using the Shepp–Logan filter with nearest-neighbor interpolation (dot-dashed with □), the Shepp–Logan filter with piecewise linear interpolation (dashed with △), and the modified Shepp–Logan filter with piecewise linear interpolation (solid with ○). The auxiliary solid line indicates exact decay $q^{-1/2}$.*

$\mathcal{X}_q \cap \partial\mathcal{R}_1$ increases like $\mathrm{O}(q)$.

We observe that even “pathological” projections do not deteriorate the convergence rate obtained by using the continuous backprojection operator for the analysis.

Appendix A. Proof of (3.12) for interpolation-like operators $\boldsymbol{E_h}$ based on B-splines. We consider E_h as defined in (3.6) where B is the cardinal B-spline of order $N \geq 1$; that is, B is the N-fold convolution of $\chi_{[-1/2,1/2]}$ with itself. The functional $\epsilon \in H_0^{-\beta_{\min}}(\mathbb{R})$, $\beta_{\min} \geq 0$, is supposed to be even, compactly supported in $\square = [-a, a]$, $a > 0$, and normalized by $\langle 1, \epsilon\rangle = 1$ where $\langle\cdot,\cdot\rangle$ denotes the duality pairing in $H^{\beta_{\min}}(\square) \times H_0^{-\beta_{\min}}(\square)$.

The techniques we use below are standard in approximation theory, yet we are not aware of any reference suitable for our setting; however, see Aubin [1, sect. 8.6].

First, we show that E_h reproduces affine linear functions if $N \geq 2$.

Lemma A.1. *If $N \geq 2$, then $E_h p = p$ for any $p \in \Pi_1$. For $N = 1$ E_h reproduces only constants.*

Proof. Note that the action of E_h on p is well defined since ϵ has compact support. Constants are preserved by $\langle 1, \epsilon(\cdot - k)\rangle = 1$ and $\sum_{k\in\mathbb{Z}} B(s-k) = 1$; see, e.g., Schoenberg [20, p. 16]. Let $p(s) = s$; then $\langle p(\cdot), \epsilon(\cdot - k)\rangle = k$ due to the evenness of ϵ. By $s = \sum_{k\in\mathbb{Z}} k\, B(s-k)$, $N \geq 2$ (see, e.g., Schoenberg [20, p. 16]), we are done. $\square$

Theorem A.2. *Let $\beta_{\min} \leq \beta \leq \min\{2, N\}$, $\tau < N - 1/2$, and $0 \leq \tau \leq \beta$. Then,*

$$\|E_h u - u\|_\tau \lesssim h^{\beta-\tau}\, \|u\|_\beta \quad \textit{as } h \to 0.$$

Proof. We restrict the proof to $N \geq 2$, and we show first a local version of the approximation property. Therefore, let $\square_{h,k} := h\,(\square + 2a\,k)$ for $k \in \mathbb{Z}$. We will rely on the Bramble–Hilbert-like estimate (A.1): there is an affine linear function $P = P(u)$ such that

$$\|u - P\|_{H^\tau(\square_{h,k})} \lesssim h^{\beta-\tau}\, \|u\|_{H^\beta(\square_{h,k})}, \quad 0 \leq \tau \leq \beta \leq 2. \tag{A.1}$$

For $\tau = 0$, (A.1) reduces to the original estimate by Bramble and Hilbert [2]. For positive real τ, see Dupont and Scott [7, Thm. 6.1] or Brenner and Scott [3, Lem. 4.3.8]. By Lemma A.1 and (A.1) we have

$$\|E_h u - u\|_{H^\tau(\square_{h,k})} \lesssim \|E_h(u-p)\|_{H^\tau(\square_{h,k})} + h^{\beta-\tau}\, \|u\|_{H^\beta(\square_{h,k})}.$$

Let $\mathfrak{J}_{h,k} := \{r \in \mathbb{Z} \mid \operatorname{supp} B_h(\cdot - s_r) \cap \square_{h,k} \neq \emptyset\}$. The cardinality of $\mathfrak{J}_{h,k}$ neither depends on h nor on k. We proceed with

$$\begin{aligned}
\|E_h(u-p)\|_{H^\tau(\square_{h,k})} &\lesssim \sum_{r\in\mathfrak{J}_{h,k}} h^{-1}\, \bigl|\bigl\langle u - P, \epsilon_h(\cdot - s_r)\bigr\rangle\bigr|\, \|B_h(\cdot - s_r)\|_{H^\tau(\mathbb{R})} \\
&\lesssim h^{-\tau} \sum_{r\in\mathfrak{J}_{h,k}} h^{-1/2}\, \bigl|\bigl\langle u - P, \epsilon_h(\cdot - s_r)\bigr\rangle\bigr|.
\end{aligned}$$

From the proof of Lemma 5.2 by Dahmen, Prössdorf, and Schneider [6] we know that

$$\bigl|\bigl\langle u - P, h^{-1/2}\, \epsilon_h(\cdot - s_r)\bigr\rangle\bigr|^2 \lesssim \|u - P\|^2_{L^2(\square_{h,r})} + h^{2\,\beta_{\min}}\, \|u - P\|^2_{H^{\beta_{\min}}(\square_{h,r})},$$

which, by (A.1), gives

$$\begin{aligned}
\|E_h u - u\|_{H^\tau(\square_{h,k})} &\lesssim h^{\beta-\tau} \sum_{r\in\mathfrak{J}_{h,k}} \|u\|_{H^\beta(\square_{h,r})} \lesssim h^{\beta-\tau} \Bigl(\sum_{r\in\mathfrak{J}_{h,k}} \|u\|^2_{H^\beta(\square_{h,r})}\Bigr)^{1/2} \\
&\lesssim h^{\beta-\tau}\, \|u\|_{H^\beta(\widetilde{\square}_{h,k})},
\end{aligned}$$

where $\widetilde{\square}_{h,k} := \bigcup_{r\in\mathfrak{J}_{h,k}} \square_{h,r}$. Thus,

$$\|E_h u - u\|_{H^\tau(\square_{h,k})} \lesssim h^{\beta-\tau}\, \|u\|_{H^\beta(\widetilde{\square}_{h,k})}.$$

Squaring both sides of the latter local approximation property and summing over $k \in \mathbb{Z}$ yield finally the stated global approximation property. $\square$

Summary. The above theorem covers especially the cases $\epsilon = \delta$ (Dirac distribution), where $\beta_{\min} > 1/2$, and $\epsilon \in L^2(\square)$ being even with $\int_\square \epsilon(s)\,\mathrm{d}s = 1$, where $\beta_{\min} = 0$. Hence, for both latter cases (3.12) holds with $\beta_{\max} = 2$ and $\tau_{\max} < N - 1/2$.

Appendix B. Proof of (3.12) for interpolation-like operators E_h based on the sinc-function. We consider E_h as defined in (3.6) where B is the *sinus cardinalis*; that is, $B(x) := \operatorname{sinc}(\pi x)$, where $\operatorname{sinc}(x) = \sin(x)/x$, $x \neq 0$, and $\operatorname{sinc}(0) = 1$. Further, $\epsilon \in L^1(\mathbb{R}) \cap L^2(\mathbb{R})$ is an even function with compact support and a normalized mean value, $\int \epsilon(x)\,\mathrm{d}x = 1$. Here, $\langle\cdot,\cdot\rangle$ denotes the $L^2(\mathbb{R})$-inner product.

First we bound E_h uniformly in h.

Lemma B.1. (a) *The operators $E_h : L^2(\mathbb{R}) \to L^2(\mathbb{R})$, $h > 0$, are uniformly bounded in h.*

(b) *Let w be in $L^2(\mathbb{R})$ with* $\operatorname{supp} \widehat{w} \subset [-\pi/h, \pi/h]$. *Then, we have the inverse estimate $\|w\|_\alpha \leq 2^{\alpha/2}\,\pi^\alpha\, h^{-\alpha}\, \|w\|_{L^2(\mathbb{R})}$ for $0 < h \leq \pi$ and any $\alpha \geq 0$.*

Proof. (a) Set $\square_{h,k} = h\,(\operatorname{supp}\epsilon + k)$. The $L^2(\mathbb{R})$-orthogonality of $\{B_h(\cdot - s_k)\}_{k\in\mathbb{Z}}$ gives

$$\|E_h u\|^2_{L^2(\mathbb{R})} = h^{-1}\sum_{k\in\mathbb{Z}} |\langle u, \epsilon_h(\cdot - s_k)\rangle|^2 \leq \sum_{k\in\mathbb{Z}} \|u\|^2_{L^2(\square_{h,k})}\|\epsilon\|^2_{L^2(\mathbb{R})} \lesssim \|u\|^2_{L^2(\mathbb{R})}.$$

(b) The inverse estimate results from a straightforward estimate of $\|w\|^2_\alpha$ taking into account the compact support of $\widehat{w}$. □

After the above preparatory results we are able to prove the claimed convergence estimate.

Theorem B.2. *Let $0 \leq \tau \leq \beta$, $\beta - \tau \leq 2$. Under the assumptions from above we have that*

$$\|E_h u - u\|_\tau \lesssim h^{\beta-\tau}\ \|u\|_\beta \quad \textit{as } h \to 0.$$

Proof. Define an auxiliary operator $P_h : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ by

$$\widehat{P_h w}(\xi) := \chi_{\square_h}(\xi)\ \widehat{w}(\xi).\,^5 \tag{B.1}$$

It is an easy exercise to obtain

$$\|P_h u - u\|_\tau \lesssim h^{\beta-\tau}\ \|u\|_\beta \quad \text{for } 0 \leq \tau \leq \beta < \infty \tag{B.2}$$

whenever the right-hand side is finite.

In a first step we consider $\|E_h P_h u - P_h u\|_\tau$. We have

$$\widehat{E_h P_h u}(\xi) = \frac{1}{\sqrt{2\pi}}\ \chi_{\square_h}(\xi) \sum_{k\in\mathbb{Z}} \langle P_h u,\, \epsilon_h(\cdot - s_k)\rangle\ \mathrm{e}^{-\imath\, hk\xi}$$

and

$$\begin{aligned} h^{1/2}\ \langle P_h u,\, \epsilon_h(\cdot - s_k)\rangle &= h^{1/2}\int_{\square_h} \widehat{P_h u}(\xi)\ \widehat{\epsilon_h}(\xi)\ \mathrm{e}^{\imath\, hk\xi}\ \mathrm{d}\xi \\ &= \Big(\frac{h}{2\pi}\Big)^{1/2} \int_{\square_h} \widehat{P_h u \star \epsilon_h}(\xi)\ \mathrm{e}^{\imath\, hk\xi}\ \mathrm{d}\xi, \end{aligned}$$

which is the kth Fourier coefficient of $\widehat{P_h u \star \epsilon_h}$. Hence,

$$\widehat{E_h P_h u}(\xi) = h^{-1}\ \chi_{\square_h}(\xi)\ \widehat{P_h u \star \epsilon_h}(\xi).$$

[5] Actually, P_h is the orthogonal projector onto the closed subspace of band-limited functions with band-width π/h.

Therefore,

$$\begin{aligned}\|E_h P_h u - P_h u\|_\tau^2 \;&=\; \int_{\square_h} (1+\xi^2)^\tau \,\left|h^{-1}\; \widehat{P_h u \star \epsilon_h}(\xi) - \widehat{P_h u}(\xi)\right|^2 \mathrm{d}\xi \\ &\lesssim\; \int_{\square_h} (1+\xi^2)^\tau \,\left|\widehat{u}(\xi)\right|^2\, M(h\xi)\;\mathrm{d}\xi,\end{aligned}$$

where $M(z) = |\widehat{\epsilon}(z) - 1/\sqrt{2\pi}|^2$, $z \in \mathbb{R}$. As in the proof of Corollary 2.2 one shows that $M(z) \lesssim z^4$ using a Taylor expansion of $\widehat{\epsilon}$ about the origin. Now let $0 \le \beta - \tau \le 2$. Then,

$$\|E_h P_h u - P_h u\|_\tau^2 \lesssim h^4 \int_{\square_h} (1+\xi^2)^\beta \,\left|\widehat{u}(\xi)\right|^2\, \xi^{4-2(\beta-\tau)}\;\mathrm{d}\xi \tag{B.3a}$$

$$\lesssim h^{2(\beta-\tau)}\;\|u\|_\beta^2. \tag{B.3b}$$

In the final step we use both statements from Lemma B.1 as well as (B.2) and (B.3):

$$\begin{aligned}\|E_h u - u\|_\tau \;&\le\; \|E_h u - E_h P_h u\|_\tau \;+\; \|E_h P_h u - P_h u\|_\tau \\ &\qquad + \|P_h u - u\|_\tau \\ &\lesssim\; h^{-\tau}\;\|u - P_h u\|_{L^2(\mathbb{R})} \;+\; h^{\beta-\tau}\;\|u\|_\beta.\end{aligned}$$

Applying (B.2) again we conclude with the proof of Theorem B.2. □

Remark B.3. The upper bound 2 on $\beta - \tau$ in Theorem B.2 may be relaxed by imposing higher order vanishing moments on ϵ.

Now we investigate band-limited interpolation; that is, E_h is defined by

$$E_h u(s) \;=\; \sum_{k\in\mathbb{Z}} u(s_k)\;\mathrm{sinc}\Big(\frac{\pi}{h}(s - s_k)\Big). \tag{B.4}$$

THEOREM B.4. *Let $\beta_{\max} \in \mathbb{N}$. Then, for $1/2 < \beta < \infty$, $0 \le \tau \le \beta$ with $\beta - \tau \le \beta_{\max}$, we have that*

$$\|E_h u - u\|_\tau \;\lesssim\; h^{\beta-\tau}\;\|u\|_\beta \quad \textit{as } h \to 0$$

whenever $u \in H^\beta(\mathbb{R})$ is compactly supported. The constant in the above estimate may *depend on $\beta_{\max}$.*

Proof. Band-limited interpolation is well defined under the assumptions on u. We introduce an auxiliary operator $E_h^{(m)}$. To this end let $\epsilon \in L^2(\mathbb{R})$ be compactly supported with normalized mean value ($\int \epsilon(x)\,\mathrm{d}x = 1$) and vanishing moments up to order $\beta_{\max}$ ($\int x^k\,\epsilon(x)\,\mathrm{d}x = 1$, $k = 1, \dots, \beta_{\max}$). Thus, $\widehat{\epsilon}(0) = 1/\sqrt{2\pi}$ and $\widehat{\epsilon}^{(\nu)}(0) = 0$, $\nu = 1, \dots, \beta_{\max}$. Define $\epsilon^{(m)}(s) := m\,\epsilon(m\,s)$, $m \in \mathbb{N}$, and

$$E_h^{(m)} u(s) \;:=\; h^{-1} \sum_{k\in\mathbb{Z}} \big\langle u, \epsilon_h^{(m)}(\cdot - s_k)\big\rangle\;\mathrm{sinc}\Big(\frac{\pi}{h}(s - s_k)\Big).$$

Observe that $E_h^{(m)} : L^2(\mathbb{R}) \to L^2(\mathbb{R})$ is uniformly bounded in h *and* m; see the proof of Lemma B.1. Hence, we may apply Theorem B.2 to obtain

$$\|E_h^{(m)} u - u\|_\tau \;\lesssim\; h^{\beta-\tau}\;\|u\|_\beta, \tag{B.5}$$

where the constant is bounded in m, as a careful inspection of the proof of Theorem B.2 shows. Moreover, the upper bound on $\beta-\tau$ in (B.5) is $\beta_{\max}$ since all derivatives of $\widehat{\epsilon}$ up to order $\beta_{\max}$ vanish about 0; see Remark B.3. By (B.5),

$$\|E_h u - u\|_\tau \lesssim \|E_h u - E_h^{(m)} u\|_\tau + h^{\beta-\tau}\,\|u\|_\beta. \tag{B.6}$$

Further,

$$\|E_h u - E_h^{(m)} u\|_\tau \le \|\mathrm{sinc}_{h/\pi}\|_\tau \sum_{k\in\mathcal{J}_{m,h}(u)} \bigl|u(s_k) - \bigl\langle u, h^{-1}\epsilon_h^{(m)}(\cdot - s_k)\bigr\rangle\bigr|$$

with $\mathcal{J}_{m,h}(u) = \{k\in\mathbb{Z} \mid s_k \in \operatorname{supp} u\} \cup \{k\in\mathbb{Z} \mid \operatorname{supp}\, u \cap h(m^{-1}\operatorname{supp}\epsilon + k)\}$. The set $\mathcal{J}_{m,h}(u)$ is finite and its cardinality is bounded in m. So we have that $\lim_{m\to\infty}\|E_h u - E_h^{(m)} u\|_\tau = 0$, and the stated estimate is readily seen from (B.6). □

SUMMARY. The band-limited interpolation-like operators considered in Theorem B.2 satisfy (3.12) with $\beta_{\min}=0$, $\beta_{\max}=2+\tau$, and any $\tau_{\max}<\infty$. For the band-limited interpolation (B.4) we have (3.12) with $\beta_{\min}>1/2$ and any positive $\tau_{\max}$ and any fixed $\beta_{\max}>1/2$.

Appendix C. Complement to section 4.

This appendix is devoted to the proof of various auxiliary results from section 4. Throughout this appendix let $\widetilde{\eta}$ and A be B-splines of order $M\ge 1$ and $N\ge 1$, respectively. Further, let η be defined by (4.1).

C.1. The trigonometric polynomial a.

Recall that

$$\mathbf{a}(\sigma) = \sum_{\ell\in\mathbb{Z}} a_\ell\, \mathrm{e}^{-\imath\,\ell\sigma} \quad \text{with } a_\ell = \int_{\mathbb{R}} \widetilde{\eta}(s)\; A(\ell - s)\;\mathrm{d}s.$$

Since $\widetilde{\eta}$ and A are even, so are $\{a_\ell\}_{\ell\in\mathbb{Z}}$ and $\mathbf{a}$. By $\sum_{\ell\in\mathbb{Z}} A(\cdot-\ell)=1$ and $\int\widetilde{\eta}(s)\mathrm{d}s = 1$ (see, e.g., Schoenberg [20, p. 16 and p. 2]), we have that $\mathbf{a}(0)=1$. In the remainder of this appendix we verify that $\mathbf{a}$ has no zeros. Then we have established all properties of $\mathbf{a}$ claimed and needed in section 4.

Straightforward calculations reveal that the a_ℓ's are the Fourier coefficients of the 2π-periodic function $2\pi\sum_{k\in\mathbb{Z}}\widehat{\widetilde{\eta}}(\sigma+2\pi\,k)\,\widehat{A}(\sigma+2\pi\,k)$. Hence,

$$\mathbf{a}(\sigma) = 2\pi\sum_{k\in\mathbb{Z}}\widehat{\widetilde{\eta}}(\sigma+2\pi\,k)\;\widehat{A}(\sigma+2\pi\,k) = \sum_{k\in\mathbb{Z}}\mathrm{sinc}^{M+N}(\sigma/2+\pi\,k). \tag{C.1}$$

If $M+N$ is even, $\mathbf{a}$ clearly has no zeros because there is no σ such that $\mathrm{sinc}^{M+N}(\sigma/2+\pi\,k)=0$ for all $k\in\mathbb{Z}$. It remains to investigate the odd case $M+N=2L+1$, $L\in\mathbb{N}$. We factorize $\mathbf{a}$ according to

$$\mathbf{a}(\sigma) = \sin^{2L}(\sigma/2)\;\mathbf{\Sigma}_{2L+1}(\sigma) \quad \text{with } \mathbf{\Sigma}_{2L+1}(\sigma) := \sum_{k\in\mathbb{Z}}\frac{(-1)^k}{(\sigma/2+\pi\,k)^{2L+1}}.$$

As multiples of 2π are not zeros of $\mathbf{a}$ it suffices to show that $\mathbf{\Sigma}_{2L+1}$ has no zeros in $]0,2\pi[$. Separating even from odd indices we find

$$\mathbf{\Sigma}_{2L+1}(\sigma) = 2^{-(2L+1)}\bigl(S_{2L+1}(\sigma/4) - S_{2L+1}(\sigma/4+\pi/2)\bigr),$$

where $S_l(\sigma) := \sum_{k\in\mathbb{Z}}(\sigma+\pi\,k)^{-l}$, $l\ge 2$. Observe that $S_{2l}(\sigma)>0$, $l\in\mathbb{N}$. Now,

$$\frac{\mathrm{d}}{\mathrm{d}\sigma}S_{2L+1}(\sigma) = -(2L+1)\;S_{2L+2}(\sigma) < 0, \quad \sigma\in]0,2\pi[.$$

Therefore S_{2L+1} is strongly decreasing in $]0,2\pi[$ which gives $\mathbf{\Sigma}_{2L+1}>0$ in $]0,2\pi[$.

C.2. Biorthogonality (4.3). By (4.1) and (C.1) we obtain

$$\begin{aligned}\big\langle \eta(\cdot-k),\, A(\cdot)\big\rangle &= \int_{\mathbb{R}} \widehat{\eta}(\sigma)\ \widehat{A}(\sigma)\ \mathrm{e}^{\imath\, k\sigma}\ \mathrm{d}\sigma\\ &= \int_0^{2\pi} \sum_{n\in\mathbb{Z}} \widehat{\eta}(\sigma+2\pi\, n)\ \widehat{A}(\sigma+2\pi\, n)\ \mathrm{e}^{\imath\, k\sigma}\ \mathrm{d}\sigma\\ &= \int_0^{2\pi} \frac{1}{\mathbf{a}(\sigma)} \ \sum_{n\in\mathbb{Z}} \widehat{\widetilde{\eta}}(\sigma+2\pi\, n)\ \widehat{A}(\sigma+2\pi\, n)\ \mathrm{e}^{\imath\, k\sigma}\ \mathrm{d}\sigma \ = \int_0^{2\pi} \frac{\mathrm{e}^{\imath\, k\sigma}}{2\pi}\ \mathrm{d}\sigma,\end{aligned}$$

which is (4.3).

C.3. Approximation power of $\mathbf{I}_h^*$. We are not able to apply Theorem A.2 directly to I_h^* as η from (4.1) does not have compact support in general. Nevertheless, we will show that the approximation power of $\widetilde{\mathrm{I}}_h^*$ carries over to I_h^* (for the notation see section 4). Since

$$\widehat{\mathrm{I}_h^* u}(\sigma) = \widehat{\widetilde{\mathrm{I}}_h^* u}(\sigma)/\mathbf{a}(h\,\sigma)$$

we have that

$$\|u-\mathrm{I}_h^* u\|_\tau^2 \lesssim \int_{\mathbb{R}} (1+\sigma^2)^\tau\ \big|\mathbf{a}(h\,\sigma)\,\widehat{u}(\sigma) - \widehat{\widetilde{\mathrm{I}}_h^* u}(\sigma)\big|^2\ \mathrm{d}\sigma.$$

Thus,

$$\|u-\mathrm{I}_h^* u\|_\tau \lesssim \|\mathbf{A}_h u - \widetilde{\mathrm{I}}_h^*\mathbf{A}_h u\|_\tau + \|\widetilde{\mathrm{I}}_h^*\mathbf{A}_h u - \widetilde{\mathrm{I}}_h^* u\|_\tau,$$

where $\widehat{\mathbf{A}_h u}(\sigma) = \mathbf{a}(h\,\sigma)\,\widehat{u}(\sigma)$. Theorem A.2 provides

$$\|\mathbf{A}_h u - \widetilde{\mathrm{I}}_h^*\mathbf{A}_h u\|_\tau \lesssim h^{\beta-\tau}\ \|\mathbf{A}_h u\|_\beta \lesssim h^{\beta-\tau}\ \|u\|_\beta$$

for $0\le\beta\le\min\{2,M\}$, $\tau<M-1/2$, and $0\le\tau\le\beta$. Further, also by Theorem A.2,

$$\|\widetilde{\mathrm{I}}_h^*\mathbf{A}_h u - \widetilde{\mathrm{I}}_h^* u\|_\tau \lesssim \|\mathbf{A}_h u - u\|_\tau$$

whenever $0\le\tau<M-1/2$, for $M\le 2$, and $0\le\tau\le 2$, otherwise. A Taylor expansion of $\mathbf{a}$ about 0 proves that $|\mathbf{a}(\sigma)-1|\lesssim\sigma^2$. Now we may copy the proof of Corollary 2.2 to obtain

$$\|\mathbf{A}_h u - u\|_\tau \lesssim h^{\min\{2,\beta-\tau\}}\ \|u\|_\beta, \quad 0\le\tau\le\beta. \tag{C.2}$$

Collecting the pieces we find

$$\|u-\mathrm{I}_h^* u\|_\tau \lesssim h^{\beta-\tau}\ \|u\|_\beta \quad \text{as } h\to 0 \tag{C.3}$$

for $0\le\beta\le\min\{2,M\}$, $\tau<\min\{2,M-1/2\}$, and $0\le\tau\le\beta$.

h-BOX METHODS FOR THE APPROXIMATION OF HYPERBOLIC CONSERVATION LAWS ON IRREGULAR GRIDS*

MARSHA J. BERGER[†], CHRISTIANE HELZEL[†], AND RANDALL J. LEVEQUE[‡]

Abstract. We study generalizations of the high-resolution wave propagation algorithm for the approximation of hyperbolic conservation laws on irregular grids that have a time step restriction based on a reference grid cell length that can be orders of magnitude larger than the smallest grid cell arising in the discretization. This Godunov-type scheme calculates fluxes at cell interfaces by solving Riemann problems defined over boxes of a reference grid cell length h.

We discuss stability and accuracy of the resulting so-called h-box methods for one-dimensional systems of conservation laws. An extension of the method for the two-dimensional case, which is based on the multidimensional wave propagation algorithm, is also described.

Key words. finite volume methods, conservation laws, nonuniform grids, stability, accuracy

1. Introduction.

We consider the numerical approximation of hyperbolic systems of conservation laws using finite volume schemes on irregular grids. We mainly restrict our considerations to the case of one spatial dimension, although an extension to the two-dimensional case will also be considered. Under appropriate smoothness assumptions the equations can be formulated in the differential form

$$\frac{\partial}{\partial t}q(x,t) + \frac{\partial}{\partial x}f(q(x,t)) = 0, \tag{1.1}$$

where $q(x,t)$ is a vector of conserved quantities and $f(q(x,t))$ is a vector of flux functions. For the numerical approximation we want to use a finite volume method. On an unstructured grid such a scheme can be written in the general form

$$Q_i^{n+1} = Q_i^n - \frac{\triangle t}{\triangle x_i}\left(F_{i+\frac{1}{2}} - F_{i-\frac{1}{2}}\right), \tag{1.2}$$

where Q_i^n is an approximation of the cell average of the conserved quantity over the grid cell $[x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}]$ at time $t = t^n$. The vector valued quantities $F_{i-\frac{1}{2}}$ and $F_{i+\frac{1}{2}}$ are the numerical flux functions at the cell interfaces. We denote the time step by $\triangle t$ and the length of the ith grid cell by $\triangle x_i = x_{i+\frac{1}{2}} - x_{i-\frac{1}{2}}$.

We are particularly interested in the construction of high-resolution schemes for a grid which contains one small grid cell, while all other grid cells have the same length, which will be denoted by $h = \triangle x$. This situation is motivated by a two-dimensional application, namely the construction of Cartesian grid methods with embedded irregular geometry. Away from the boundary one may want to use a

regular Cartesian grid. Near the boundary one then obtains irregular cut cells, which may be orders of magnitude smaller than the regular grid cells. Our aim in such a situation is to construct a scheme that is stable based on time steps adequate for the regular grid. Such methods were developed by Berger and LeVeque in [4], [5], [6]. The basic idea of these so-called h-box methods is to approximate the numerical fluxes at the interfaces of a small cell based on initial values specified over regions of length h, i.e., of the length of a regular grid cell. If this is done in an appropriate way, then the resulting method remains stable for time steps based on a CFL number appropriate for the regular part of the grid. See also [8], [9], [10], [23], [21], and [25] for other embedded boundary Cartesian grid methods that have this same stability property.

Besides this two-dimensional application, h-box schemes can also offer interesting alternatives to existing irregular grid methods. An extension of h-box methods to a completely irregular grid was considered by Berger, LeVeque, and Stern [7]; see also Stern [28]. We will consider such calculations in section 5. In section 7, we construct a multidimensional h-box method. Other potential applications are the construction of moving mesh or front-tracking algorithms. Stern [28] used an h-box method to construct a conservative finite volume algorithm for a Cartesian grid with an embedded curvilinear grid.

Unsurprisingly, the accuracy of an h-box method depends strongly on the definition of the h-box values. In this paper we develop a one-dimensional as well as a two-dimensional high-resolution h-box method. Our goal here is a systematic study of h-box methods in a relatively simple context to provide fundamental understanding for the more complex applications mentioned above. For the advection equation we show that the one-dimensional scheme leads to a second order accurate approximation of smooth solutions on nonuniform grids (without any restrictions on the grid). We also verify that the resulting method leads to high-resolution approximations for the Euler equations on nonuniform meshes. The approximation of transonic rarefaction waves turns out to require a special treatment. Throughout this paper we will discuss the construction of h-box methods based on LeVeque's high-resolution wave propagation algorithm [18]. This method is implemented in the CLAWPACK software package [13], which provided the basic tool for our test calculations.

The large time step Godunov method of LeVeque described in [14], [15], [16] is related to the h-box method. This scheme allows larger time steps in the approximation of nonlinear systems of conservation laws by increasing the domain of influence of the numerical scheme. This is done in a wave propagation approach, in which waves are allowed to move through more than one mesh cell. The interaction of waves is approximated by linear superposition. At a reflecting boundary this method becomes more difficult than an h-box method, especially in higher dimensions, since the reflection of waves at the boundary has to be considered for waves generated by Riemann problems away from the boundary; see [3]. In [22, Lemma 3.5], Morton showed that high-resolution versions of such a large time step method lead to a second order accurate approximation of the one-dimensional advection equation on a nonuniform grid only if the grid varies smoothly. The high-resolution h-box method described in this paper does not require this smoothness assumption.

2. The wave propagation algorithm.

In this section we describe the basic concept of the high-resolution wave propagation algorithm applied to irregular Cartesian grids; a more general description can be found in LeVeque [18] or [19]. The numerical method for solving (1.1) is a Godunov-type method; i.e., the fluxes at cell interfaces are calculated by solving Riemann problems defined from cell averages of the conserved quantities. This is done by calculating waves that are moving into each grid cell. The first order update of the wave propagation algorithm has the form

$$Q_i^{n+1} = Q_i^n - \frac{\triangle t}{\triangle x_i}\left(\mathcal{A}^+\triangle Q_{i-\frac{1}{2}} + \mathcal{A}^-\triangle Q_{i+\frac{1}{2}}\right).$$

Here the change of the conserved quantities is calculated by taking all waves into account that are moving into the grid cell from the left (respectively, right) cell interface. The solution of Riemann problems at cell interfaces provides a decomposition of the jump $Q_{i+1}^n - Q_i^n$ into waves $\mathcal{W}_{i+\frac{1}{2}}^p$ that are moving with speed $s_{i+\frac{1}{2}}^p$ for $1 \le p \le M_w$,

$$\triangle Q_{i+\frac{1}{2}}^n = Q_{i+1}^n - Q_i^n = \sum_{p=1}^{M_w} \mathcal{W}_{i+\frac{1}{2}}^p.$$

The left- and right-going fluctuations are calculated as

$$\mathcal{A}^+\triangle Q_{i-\frac{1}{2}} = \sum_{p=1}^{M_w} \max(s_{i-\frac{1}{2}}^p, 0)\mathcal{W}_{i-\frac{1}{2}}^p, \quad \mathcal{A}^-\triangle Q_{i+\frac{1}{2}} = \sum_{p=1}^{M_w} \min(s_{i+\frac{1}{2}}^p, 0)\mathcal{W}_{i+\frac{1}{2}}^p.$$

This can be written as a finite volume scheme of the form (1.2) using the relations

$$F_{i+\frac{1}{2}} = f(Q_i) + \mathcal{A}^-\triangle Q_{i+\frac{1}{2}}, \tag{2.1}$$

$$F_{i-\frac{1}{2}} = f(Q_i) - \mathcal{A}^+\triangle Q_{i-\frac{1}{2}}. \tag{2.2}$$

Appropriate waves and speeds for systems of conservation laws can sometimes be calculated by using an exact Riemann solver, but more often an approximative Riemann solver, for instance a Roe–Riemann solver [26], is used.

In the wave propagation algorithm second order correction terms are included by extending the first order method into the form

$$Q_i^{n+1} = Q_i^n - \frac{\triangle t}{\triangle x_i}\left(\mathcal{A}^+\triangle Q_{i-\frac{1}{2}} + \mathcal{A}^-\triangle Q_{i+\frac{1}{2}}\right) - \frac{\triangle t}{\triangle x_i}\left(\tilde{F}_{i+\frac{1}{2}}^2 - \tilde{F}_{i-\frac{1}{2}}^2\right). \tag{2.3}$$

On an irregular grid, the second order correction terms have the form

$$\tilde{F}_{i+\frac{1}{2}}^2 = \frac{1}{2}\sum_{p=1}^{M_w} |s_{i+\frac{1}{2}}^p| \left(\frac{\triangle x_i}{(\triangle x_i + \triangle x_{i+1})/2} - \frac{\triangle t}{(\triangle x_i + \triangle x_{i+1})/2}|s_{i+\frac{1}{2}}^p|\right)\tilde{\mathcal{W}}_{i+\frac{1}{2}}^p. \tag{2.4}$$

In (2.4) the waves $\tilde{\mathcal{W}}^p$ are limited waves—this limiting is necessary in order to avoid oscillations near discontinuities.

The resulting scheme is stable for the approximation of systems of conservation laws (1.1) as long as time steps are restricted such that waves move through at most one mesh cell, which means the Courant number is no larger than one, i.e.,

$$\text{CFL} = \triangle t \max_i \left(\frac{\max(\max_p(s_{i-\frac{1}{2}}^p, 0), |\min_p(s_{i+\frac{1}{2}}^p, 0)|)}{\triangle x_i}\right) \le 1. \tag{2.5}$$

The *h*-box method changes this time step restriction by replacing $\triangle x_i$ in the denominator of (2.5) by h, the width of a reference grid cell. We will use the notation CFL_h if we want to indicate that the Courant number is based on grid cells of width h.

We want to note that some care is necessary in the construction of second order accurate algorithms for irregular grids. There exist versions of the one-dimensional Lax–Wendroff method which lead to second order accurate approximations of the advection equation only if the grid is sufficiently smooth, i.e., if $\triangle x_i/\triangle x_{i-1} = 1 + \mathcal{O}(h)$, where $h = \max_i \triangle x_i$; see, for instance, Wendroff and White [30], [31] and Pike [24]. See also Morton [22] for convergence results of finite volume methods for the approximation of the advection equation on nonuniform grids.

3. The one-dimensional *h*-box method.

First we want to approximate (1.1) on an almost uniform grid that contains one small grid cell in the middle. This example allows simple analytical studies. However, we will show that the results obtained for this simple test case can be extended to more general applications.

We denote the length of a regular grid cell by $h = \triangle x$. The small cell has the length αh, with $0 < \alpha \le 1$. For the small cell the numerical method has to be modified in order to obtain a stable scheme for time steps $\triangle t$ that satisfy the stability condition in the regular part of the grid. The h-box method introduced by Berger and LeVeque [5] defines new left and right states at the edges of the small cell that represent the conserved quantities at these interfaces over boxes of length h; see Figure 1. This guarantees that the domain of dependence of the numerical solution has the size of a regular mesh cell, which is a necessary stability condition.

3.1. First order accurate *h*-box methods.

As a first step we compare the performance of two different h-box schemes applied to the advection equation $q_t(x,t) + aq_x(x,t) = 0$. We will assume that $a > 0$, although analogous considerations can of course be made for the case $a < 0$. In the following we assume that k is the index of the small cell. In order to calculate numerical fluxes at the small cell interfaces new values of the conserved quantity q that represent piecewise constant initial values over boxes of length h will be defined. For the left cell interface of the small cell, these values are denoted by $Q^L_{k-\frac{1}{2}}$ and $Q^R_{k-\frac{1}{2}}$. At the right cell interface of the small cell we have to define values $Q^L_{k+\frac{1}{2}}$ and $Q^R_{k+\frac{1}{2}}$. This is indicated by the shaded boxes at each interface in Figure 1.

The most obvious choice is to define the h-box values via cell averaging over the piecewise constant initial values. (To keep the notation simple we sometimes suppress the time index if it is clear that we mean the values at time t^n.) We obtain

$$\begin{aligned} Q^L_{k-\frac{1}{2}} &= Q_{k-1}, & Q^R_{k-\frac{1}{2}} &= \alpha Q_k + (1-\alpha)Q_{k+1}, \\ Q^L_{k+\frac{1}{2}} &= \alpha Q_k + (1-\alpha)Q_{k-1}, & Q^R_{k+\frac{1}{2}} &= Q_{k+1}. \end{aligned} \tag{3.1}$$

Such h-box values were used in Berger and LeVeque [5] as well as by Forrer and Jeltsch [10]. For the advection equation the update of the small cell value can now be calculated using the upwind method. We obtain

$$\begin{aligned} Q^{n+1}_k &= Q^n_k - \frac{\triangle t}{\alpha h}\left(aQ^L_{k+\frac{1}{2}} - aQ^L_{k-\frac{1}{2}}\right) \\ &= Q^n_k - \frac{a\triangle t}{\alpha h}\left(\alpha Q^n_k + (1-\alpha)Q^n_{k-1} - Q^n_{k-1}\right) \\ &= Q^n_k - \frac{a\triangle t}{h}(Q^n_k - Q^n_{k-1}). \end{aligned} \tag{3.2}$$

Note that the small denominator (that may cause a stability problem) has been removed. One can indeed show TVD stability for this method assuming $\text{CFL}_h \le 1$;

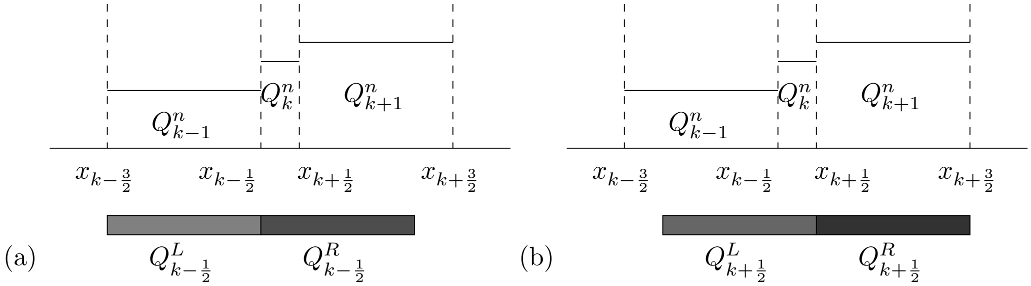

FIG. 1. *Schematic description of h-box values assigned to the left small cell interface (see* (a)*) (respectively, the right small cell interface (see* (b)*)).*

see section 4. However, it is clear that this cannot be a very accurate formula. The truncation error of the scheme (3.2) has the form

$$\begin{aligned} Lq &= \frac{q_k^{n+1} - q_k^n}{\triangle t} + a\frac{q_k^n - q_{k-1}^n}{h} \\ &= q_t(x_k, t^n) + \frac{a}{2}(\alpha + 1)q_x(x_k, t^n) + \mathcal{O}(\triangle t, h) \\ &= \frac{a}{2}(\alpha - 1)q_x(x_k, t^n) + \mathcal{O}(\triangle t, h). \end{aligned}$$

Only for $\alpha = 1$ is the truncation error in cell k of the order $\mathcal{O}(\triangle t, h)$. Note that grid functions for the exact solution q are expressed with lower-case letters, whereas numerical approximations are written in capital letters.

In spite of the apparent inconsistency of the scheme, numerical tests suggest that this h-box method converges with first order. For the advection equation we can indeed prove that under appropriate smoothness assumptions the scheme is first order accurate in the small cell. This so-called *supraconvergence property* can be shown using an idea developed for conservation laws by Wendroff and White [30], [31]. See also [12], [20], where these ideas were introduced for boundary value problems for ODEs.

PROPOSITION 1. *We consider the approximation of the advection equation on an almost uniform grid with mesh width h that contains one small mesh cell of length αh, with $\alpha \leq 1$. The one-dimensional h-box method* (3.2), *based on an upwind discretization with h-box values calculated by averaging over piecewise constant cell average values, leads to a first order accurate approximation for sufficiently smooth solutions of the advection equation, in spite of the fact that the truncation error indicates inconsistency.*

Proof. The basic step of the proof is to calculate the local truncation error for a grid function w, which must be an accurate enough approximation of the grid function of the exact solution q. We want to show that the truncation error for w is first order, i.e., $Lw = \mathcal{O}(h)$. In order to do this we specify the grid function to have the form

$$w_i^n = q_i^n + \frac{1}{2}(1 - \alpha_i)hq_x(x_i, t^n).$$

Here we assume that $\triangle x_i = \alpha_i h$, i.e., $\alpha_i = 1$ for $i \neq k$ and $\alpha_k = \alpha$. The distance between x_k and x_{k-1} is $\frac{1}{2}h(1+\alpha)$. In the simple situation of only one small grid cell we have $w_i^n = q_i^n$ for $i \neq k$ and $w_k^n = q_k^n + \frac{1}{2}(1-\alpha)hq_x(x_k, t^n)$. The truncation error of the grid function w for the scheme (3.2) has in the small cell the form

$$\begin{aligned} Lw &= \frac{w_k^{n+1} - w_k^n}{\triangle t} + a\frac{w_k^n - w_{k-1}^n}{h} \\ &= \frac{q_k^{n+1} + \frac{1}{2}(1-\alpha)hq_x(x_k, t^{n+1}) - q_k^n - \frac{1}{2}(1-\alpha)hq_x(x_k, t^n)}{\triangle t} \\ &\quad + \ a\frac{q_k^n + \frac{1}{2}(1-\alpha)hq_x(x_k, t^n) - q_{k-1}^n}{h} + \mathcal{O}(\triangle t, h) \\ &= \frac{q_k^n + \triangle t q_t(x_k, t^n) + \frac{1}{2}(1-\alpha)hq_x(x_k, t^n) - q_k^n - \frac{1}{2}(1-\alpha)hq_x(x_k, t^n)}{\triangle t} \\ &\quad + \ a\ \frac{q_k^n + \frac{1}{2}(1-\alpha)hq_x(x_k, t^n) - q_k^n + \frac{1}{2}(1+\alpha)hq_x(x_k, t^n)}{h} + \mathcal{O}(\triangle t, h) \\ &= q_t(x_k, t^n) + aq_x(x_k, t^n) + \mathcal{O}(\triangle t, h) \ = \ \mathcal{O}(\triangle t, h). \end{aligned}$$

From the truncation error of w and the stability of the method for $\mathrm{CFL}_h \leq 1$ it follows that $|w_k - Q_k| = \mathcal{O}(\triangle t, h)$. Since $w = q + \mathcal{O}(h)$ we obtain the estimate

$$|q_k - Q_k| = \mathcal{O}(h);$$

i.e., the h-box method (3.2) leads to a first order accurate approximation of the advection equation in the small cell k, in spite of the fact that the scheme is inconsistent in the small cell. Using the same grid function w one can also show that the truncation error Lw in cell $k+1$ is of the order $\mathcal{O}(h)$. In all other regularly spaced grid cells, the method agrees with the upwind scheme for which the truncation error is also $\mathcal{O}(h)$. Therefore, we obtain first order convergence in the whole domain. □

In order to obtain a more accurate small cell scheme, we will now consider the construction of h-box values based on linear interpolation using again grid cell values that are overlapped by the h-boxes. Such h-box values have the general form

$$\begin{aligned} Q^L_{k-\frac{1}{2}} &= Q_{k-1}, & Q^R_{k-\frac{1}{2}} &= \lambda Q_k + (1-\lambda)Q_{k+1}, \\ Q^L_{k+\frac{1}{2}} &= \lambda Q_k + (1-\lambda)Q_{k-1}, & Q^R_{k+\frac{1}{2}} &= Q_{k+1}. \end{aligned}$$

We want to determine λ so that we obtain a consistent h-box scheme, i.e., for which $Lq = \mathcal{O}(h, \triangle t)$. By again using Taylor series expansion we find that only $\lambda = \frac{2\alpha}{1+\alpha}$ leads to an upwind method that satisfies this condition. This suggests that the h-box values should have the form

$$\begin{aligned} Q^L_{k-\frac{1}{2}} &= Q_{k-1}, & Q^R_{k-\frac{1}{2}} &= \frac{2\ \alpha\ Q_k + (1-\alpha)\ Q_{k+1}}{1+\alpha}, \\ Q^L_{k+\frac{1}{2}} &= \frac{2\ \alpha\ Q_k + (1-\alpha)\ Q_{k-1}}{1+\alpha}, & Q^R_{k+\frac{1}{2}} &= Q_{k+1}. \end{aligned} \tag{3.3}$$

Note that this interpolation formula was already given in [4] but not further investigated there. In [7], [28] h-box values were defined in a similar way, and the resulting scheme was shown to give good results for advection and Burgers's equation.

One time step of the h-box method based on the interpolation formula (3.3) again for $a > 0$ has in the small cell the form

$$Q_k^{n+1} = Q_k^n - \frac{a\triangle t}{h} \cdot \frac{Q_k^n - Q_{k-1}^n}{(1+\alpha)/2}. \tag{3.4}$$

We can derive the same method as a finite difference scheme by replacing $q_x(x_k, t^n)$ in the Taylor series expansion of

$$\begin{aligned} q(x_k, t^n + \triangle t) &= q(x_k, t^n) + \triangle t q_t(x_k, t^n) + \mathcal{O}(\triangle t^2) \\ &= q(x_k, t^n) - \triangle t \cdot a\ q_x(x_k, t^n) + \mathcal{O}(\triangle t^2) \end{aligned} \tag{3.5}$$

by an appropriate first order accurate finite difference formula. The *h*-box method (3.4) can be interpreted as a finite difference scheme that approximates the $q_x(x_k)$ terms by one-sided finite differences. This *h*-box method leads to a first order accurate method that approximates linear functions exactly. One can also show that an upwind scheme based on the *h*-box values (3.3) also leads to a consistent first order accurate update in the two neighboring grid cells of the small cell.

If we use the wave propagation algorithm, then the first order update in the small cell can be written in the form

$$Q_k^{n+1} = Q_k^n - \frac{\triangle t}{\alpha h}\left(\mathcal{A}^+\triangle\hat{Q}_{k-\frac{1}{2}} - f(Q^R_{k-\frac{1}{2}}) + \mathcal{A}^-\triangle\hat{Q}_{k+\frac{1}{2}} + f(Q^L_{k+\frac{1}{2}})\right), \tag{3.6}$$

with $\triangle\hat{Q}_{k-\frac{1}{2}} = Q^R_{k-\frac{1}{2}} - Q^L_{k-\frac{1}{2}}$ and $\triangle\hat{Q}_{k+\frac{1}{2}} = Q^R_{k+\frac{1}{2}} - Q^L_{k+\frac{1}{2}}$. In the limit case $\alpha = 1$ we have $Q^R_{k-\frac{1}{2}} = Q^L_{k+\frac{1}{2}}$, and (3.6) reduces to the first order accurate wave propagation algorithm that is valid in the regular parts of the grid. This formula remains valid for nonlinear equations as well as systems of conservation laws, assuming we have a Riemann solver that provides us a decomposition of $Q^R - Q^L$, as described in section 2. We indicate quantities that are calculated from *h*-box values by the "ˆ" symbol.

Numerical results shown in section 5 will demonstrate the superior properties of an *h*-box method with *h*-boxes obtained by linear interpolation.

3.2. A second order accurate *h*-box method. In order to obtain a high-resolution scheme we want to include second order correction terms. This means we want to obtain an update of the small cell that can be written as

$$\begin{aligned} Q_k^{n+1} = Q_k^n &- \frac{\triangle t}{\alpha h}\left(\mathcal{A}^+\triangle\hat{Q}_{k-\frac{1}{2}} - f(Q^R_{k-\frac{1}{2}}) + \mathcal{A}^-\triangle\hat{Q}_{k+\frac{1}{2}} + f(Q^L_{k+\frac{1}{2}})\right) \\ &- \frac{\triangle t}{\alpha h}\left(\hat{F}^2_{k+\frac{1}{2}} - \hat{F}^2_{k-\frac{1}{2}}\right), \end{aligned}$$

where $\hat{F}^2$ denotes the second order correction terms that are implemented in flux differencing form. By analogy to the standard wave propagation algorithm, these second order correction terms should also be calculated by using the waves and speeds obtained from solving Riemann problems at the cell interfaces. For the small cell we again use the waves and speeds from Riemann problems defined by the same *h*-box values used to obtain the first order update. We will restrict our consideration to *h*-box values that are calculated using the interpolation formula (3.3).

The formula (2.4) for the second order correction flux on irregular grids suggests using correction terms of the form

$$\hat{F}^2_{i+\frac{1}{2}} = \frac{1}{2}\sum_{p=1}^{M_w}\left(\frac{1}{(1+\alpha)/2} - \frac{\triangle t}{(1+\alpha)h/2}|\hat{s}^p_{i+\frac{1}{2}}|\right)\cdot|\hat{s}^p_{i+\frac{1}{2}}|\cdot\hat{\mathcal{W}}^p_{i+\frac{1}{2}} \qquad (i = k-1,\ k) \tag{3.7}$$

in the small cell. The waves $\hat{\mathcal{W}}^p_{i+\frac{1}{2}}$ and the speeds $\hat{s}^p_{i+\frac{1}{2}}$ can be obtained by solving Riemann problems defined by the *h*-box values at the small cell interfaces. One can show that the truncation error in the small cell that results from such a high-resolution wave propagation scheme is $Lq_k = \mathcal{O}(h^2, \triangle t^2)$; i.e., assuming the scheme is stable we would obtain a second order accurate approximation in the small cell. However, numerical tests showed that such an approach is not stable for time steps satisfying $\mathrm{CFL}_h \leq 1$.

Instead we use second order correction terms of the form

$$\hat{F}^2_{i+\frac{1}{2}} = \frac{1}{2}\sum_{p=1}^{M_w}\left(1 - \frac{\triangle t}{h}|\hat{s}^p_{i+\frac{1}{2}}|\right) \cdot |\hat{s}^p_{i+\frac{1}{2}}|\hat{\mathcal{W}}^p_{i+\frac{1}{2}} \qquad (i = k-1,\ k). \tag{3.8}$$

The waves are again calculated from Riemann problems defined by the h-box values. The difference from (3.7) is that we do not take the size of the small cell into account in the calculation of the correction fluxes. This reflects the general concept of the h-box method where fluxes are calculated from values defined over regions of length h.

Although the truncation error for the grid cell k now contains first order terms which do not cancel out, the numerical results are very satisfying and indicate second order convergence as well as stability for $\mathrm{CFL}_h \leq 1$. Assuming that the solution is sufficiently smooth we can indeed prove that the resulting method leads to a second order accurate approximation for the advection equation.

PROPOSITION 2. *We consider the approximation of the advection equation on an almost uniform grid with mesh width h that contains one small mesh cell of length αh, with $\alpha \leq 1$. The h-box method consisting of the first order update* (3.4) *and the second order correction terms* (3.8) *(without limiters) leads to a second order accurate approximation for sufficiently smooth solutions of the advection equation.*

Proof. We again use the idea of Wendroff and White and consider the truncation error Lw for a grid function of the form $w^n_i = q^n_i + \frac{1}{8}h^2(\alpha_i+1)(\alpha_i-1)q_{xx}(x_i, t^n)$. Here we assume that $\triangle x_i = \alpha_i h$. We have $\alpha_i = 1$ for $i \neq k$ and $\alpha_k = \alpha$. In regular grid cells $i \neq k$ the grid function w agrees with the exact solution. We want to show only second order convergence in the small cell as well as in the two neighboring cells $k-1$ and $k+1$, since the method reduces to the high-resolution wave propagation algorithm in the other regular grid cells. In the case considered here, the wave propagation algorithm on the regular part of the grid is equivalent to the Lax–Wendroff scheme.

The truncation error for the grid function w has the form

$$\begin{aligned} Lw &= \frac{w^{n+1}_k - w^n_k}{\triangle t} + 2a\frac{w^n_k - w^n_{k-1}}{h(1+\alpha)} + \left(1 - a\frac{\triangle t}{h}\right)a\frac{w^n_{k+1} - 2w^n_k + w^n_{k-1}}{h(1+\alpha)} \\ &= q_t(x_k, t^n) + \frac{\triangle t}{2}q_{tt}(x_k, t^n) + aq_x(x_k, t^n) + \frac{1}{4}h(\alpha - 1)aq_{xx}(x_k, t^n) \\ &\quad - \frac{1}{4}h(1+\alpha)aq_{xx}(x_k, t^n) \\ &\quad + \left(1 - a\frac{\triangle t}{h}\right)a\frac{\frac{1}{4}h^2(1+\alpha)^2 q_{xx}(x_k, t^n) - \frac{1}{4}h^2(\alpha^2 - 1)q_{xx}(x_k, t^n)}{h(1+\alpha)} + \mathcal{O}(\triangle t^2, h^2). \end{aligned}$$

Here we use $h_{k+\frac{1}{2}} = h_{k-\frac{1}{2}} = \frac{1}{2}h(1+\alpha)$ for the distance from the cell center of the small cell k to the cell centers of the neighboring cells. By using the relations $q_t(x_k, t^n) = -aq_x(x_k, t^n)$ and $q_{tt}(x_k, t^n) = a^2 q_{xx}(x_k, t^n)$ all lower order terms in the above equation cancel and we obtain $Lw = \mathcal{O}(\triangle t^2, h^2)$. This shows that $|w_k - Q_k| = \mathcal{O}(\triangle t^2, h^2)$. Since the grid function was chosen to satisfy $w = q + \mathcal{O}(h^2)$, we conclude that

$$|q_k - Q_k| = \mathcal{O}(\triangle t^2, h^2).$$

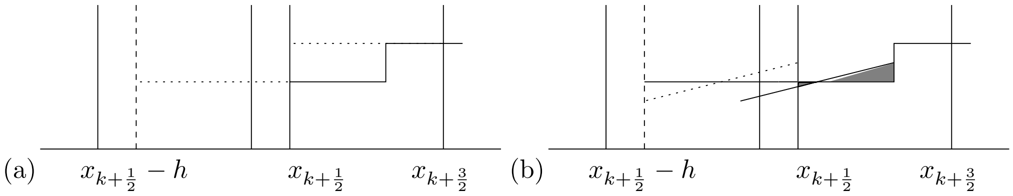

FIG. 2. *h-box values at the interface $x_{k+\frac{1}{2}}$; dotted lines depict the initial values, solid lines the solution after one time step.* (a) *first order update by h-box method;* (b) *second order correction wave of $Q^L_{i+\frac{1}{2}}$.*

Stability of this second order accurate scheme will be shown in the appendix.

Using the same grid function w, one can also show that $Lw = \mathcal{O}(\triangle t^2, h^2)$ in the neighboring grid cells $k-1$ and $k+1$. Therefore, the numerical solution converges with second order accuracy in the whole domain. □

Figure 2 shows a schematic description of the first order update and the high-resolution correction for cell $k+1$. The dotted lines depict the initial values, i.e., $Q^L_{k+\frac{1}{2}}$ and $Q^R_{k+\frac{1}{2}} = Q_{k+1}$. In a first step the piecewise constant values are propagated over a distance $a\triangle t$, as shown in Figure 2(a). In order to increase the accuracy, the piecewise constant initial values are replaced by piecewise linear functions. In Figure 2(b), we show the piecewise linear reconstructed function $Q^L_{k+1}(x, t^n)$ that has the slope $\sigma = (Q^R_{k+\frac{1}{2}} - Q^L_{k+\frac{1}{2}})/h$. Since we already calculated the first order update, the second order correction terms, calculated by propagating piecewise linear initial values $Q^L_{k+\frac{1}{2}}(x, t^n)$ instead of the piecewise constant value $Q^L_{k+\frac{1}{2}}$, take only the shaded region shown in Figure 2(b) into account. Compare with LeVeque [17], where such second order correction terms were described for the approximation of the advection equation on a uniform grid.

3.3. Limiters for the h-box method. In order to have control over unphysical oscillations near discontinuities some kind of limiters must be used in the second order correction terms (2.4). In the wave propagation algorithm this is done by using *wave limiters* that modify the magnitude of the waves $\mathcal{W}^p$ $(p = 1, \dots, M_w)$ in the fluxes that model the second order correction terms. A limited p-wave $\mathcal{W}^p_{i+\frac{1}{2}}$ is obtained by comparison of this wave with the neighboring p-waves $\mathcal{W}^p_{i-\frac{1}{2}}$ or $\mathcal{W}^p_{i+\frac{3}{2}}$, depending on the direction of flow; see LeVeque [18] or [19] for details.

In our high-resolution h-box method we can use the same limiting process in order to obtain limited versions of the waves that were calculated from h-box values. These limited waves can then be used in the second order correction fluxes (3.8). In order to obtain the limiter for waves at a small cell interface, we compare those waves with waves arising from Riemann problems at a distance h away from the cell interface. This can be done by constructing two additional h-boxes at the small cell interface. The waves resulting from the solution of Riemann problems defined by these new h-box values to the left- and right-hand side of a small cell interface can then be used in order to estimate the wave limiter for the waves at the small cell interface. This requires the solution of two additional Riemann problems for each small cell interface; see Figure 3. We used such a limiting process in order to approximate a shock wave solution on an irregular grid shown in section 5.

In addition to the wave limiting process we also include a limiter into the approximation of the h-box values. Note that the h-box values (3.3) can also be obtained by

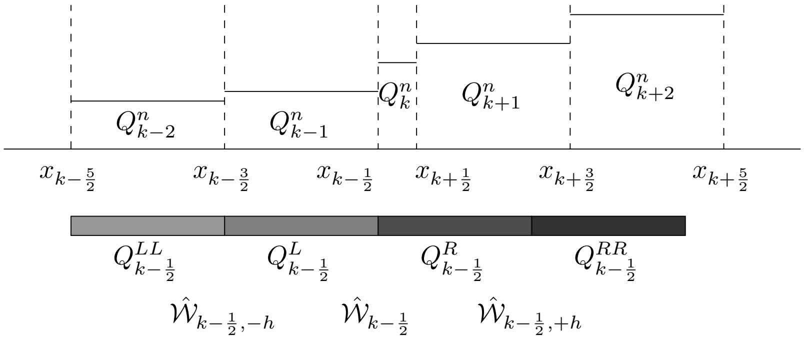

FIG. 3. *Schematic description of h-box values assigned to the left small cell interface. Two additional h-box values are needed to estimate the wave limiter for the second order correction terms.*

reconstructing a piecewise linear function $\overline{Q}(x)$ from the cell averages Q_i for all i and calculating the average value of this piecewise linear function over the same boxes of length h, as indicated in Figure 1. If the reconstructed function has the form

$$\overline{Q}_{k-1}(x) = Q_{k-1} + \frac{Q_k - Q_{k-1}}{\frac{1}{2}h(1+\alpha)}(x - x_{k-1}) \quad \text{for} \quad x \in [x_{k-\frac{3}{2}}, x_{k-\frac{1}{2}}), \tag{3.9}$$

$$\overline{Q}_{k+1}(x) = Q_{k+1} + \frac{Q_{k+1} - Q_k}{\frac{1}{2}h(1+\alpha)}(x - x_{k+1}) \quad \text{for} \quad x \in [x_{k+\frac{1}{2}}, x_{k+\frac{3}{2}}), \tag{3.10}$$

then averaging over boxes of length h leads to h-box values that have the form (3.3). The slopes of the piecewise linear initial values are

$$\sigma_{k-1} = \frac{Q_k - Q_{k-1}}{h(1+\alpha)/2} \quad \text{and} \quad \sigma_{k+1} = \frac{Q_{k+1} - Q_k}{h(1+\alpha)/2}.$$

Near discontinuities such piecewise linear values may not represent a good approximation of the solution. We can use standard *slope limiters* in order to obtain better approximations there. We can, for instance, use a slope limiter proposed by van Leer [29]. Here the slopes are replaced by limited versions that have the form $\hat{\sigma}_i = \sigma_i \phi_i$ for $i \in \{k-1, k+1\}$. For our application the limiter has the form

$$\phi_i(\theta_i) = \min\left(1, \frac{|\theta_i| + \theta_i}{1 + |\theta_i|}\right)$$

with

$$\theta_{k-1} = \frac{Q_{k-1} - Q_{k-2}}{Q_k - Q_{k-1}} \quad \text{and} \quad \theta_{k+1} = \frac{Q_{k+2} - Q_{k+1}}{Q_{k+1} - Q_k}.$$

It may be replaced by other limiter functions. Note that we do not want to use a steeper slope than σ_{k-1} (respectively, σ_{k+1}) for the construction of h-box values, because only those values lead to a second order approximation in smooth regions. However, near discontinuities we want to limit these slopes. The resulting limited h-box values can be calculated using the formulas

$$Q^L_{k+\frac{1}{2}} = \alpha Q_k + (1-\alpha)\left(Q_{k-1} + \frac{\alpha}{1+\alpha}(Q_k - Q_{k-1})\phi_{k-1}\right),$$

$$Q^R_{k-\frac{1}{2}} = \alpha Q_k + (1-\alpha)\left(Q_{k+1} + \frac{\alpha}{1+\alpha}(Q_k - Q_{k+1})\phi_{k+1}\right).$$

4. On the stability of the *h*-box method. The h-box method retains stability by constructing a finite volume scheme for which the flux difference is of the order of the size of the grid cell. For a small grid cell this requires $F_{k+\frac{1}{2}} - F_{k-\frac{1}{2}} = \mathcal{O}(\alpha h)$. In this case the term αh arising in the denominator of the finite volume scheme should not cause a stability problem. In regions where the solution of the conservation law is smooth, the h-box values are constructed to satisfy an analogous property, namely $Q^{L,R}_{k+\frac{1}{2}} - Q^{L,R}_{k-\frac{1}{2}} = \mathcal{O}(\alpha h)$. Since in our applications the flux function is a Lipschitz continuous function of Q^L and Q^R, the flux difference has the required cancellation property; see [5].

For the advection equation Stern [28] proved that the first order accurate h-box methods are TVD. Here we will briefly outline this proof which follows the general concept described above. The first order h-box method can (for $a > 0$) be rewritten in the form

$$\begin{aligned} Q_i^{n+1} &= Q_i^n - \frac{a\triangle t}{\alpha_i h}(Q^L_{i+\frac{1}{2}} - Q^L_{i-\frac{1}{2}}) \\ &= Q_i^n - \frac{a\triangle t}{\alpha_i h}\left(\alpha_i Q_i^n - \alpha_i \underbrace{\frac{1}{\alpha_i h}\int_{x_{i-\frac{1}{2}}-h}^{x_{i-\frac{1}{2}}-h+\alpha_i h} \overline{Q}^n_{i-1}(x)dx}_{\tilde{Q}_i^n}\right). \end{aligned}$$

Here we assume that each grid cell has the size $h_i = \alpha_i h$, with $0 < \alpha_i \leq 1$. $\overline{Q}^n_{i-1}(x)$ is the piecewise linear reconstructed function (3.9). The stability result also holds on an irregular grid with more than one small cell. See also section 5 for a slightly different generalization of the piecewise linear function that has to be used in the construction of h-box values for a completely irregular grid.

Using this notation we now consider the difference $|Q^{n+1}_{i+1} - Q^{n+1}_i|$ and sum over all grid cells. This sum can be estimated as

$$\begin{aligned} TV(Q^{n+1}) &= \sum_i |Q^{n+1}_{i+1} - Q^{n+1}_i| \\ &\leq \left(1 - \frac{a\triangle t}{h}\right)\sum_i |Q^n_{i+1} - Q^n_i| + \frac{a\triangle t}{h}\sum_i |\tilde{Q}^n_{i+1} - \tilde{Q}^n_i|. \end{aligned}$$

We obtain the TVD property $TV(Q^{n+1}) \leq TV(Q^n)$ for time steps $\text{CFL}_h \leq 1$ if

$$\sum_i |\tilde{Q}^n_{i+1} - \tilde{Q}^n_i| \leq TV(Q^n). \tag{4.1}$$

For the h-box method (3.2) using h-box values that were calculated by averaging over piecewise constant values, (4.1) is always satisfied, since $\tilde{Q}_i^n = Q_i^n$. For the more accurate first order h-box method (3.4), the TVD property can be shown if a TVD slope limiter is used in the construction of the h-box values, as discussed in section 3.3.

Note that for the approximation of the advection equation, the first order h-box method based on h-box values (3.1), i.e., defined by averaging over piecewise constant values of the conserved quantities, is also monotone. This property does not carry over to the first order h-box method with h-box values calculated by the interpolation formula (3.3). Note also that none of these two first order accurate h-box methods applied to Burgers's equation leads to a monotone method.

In the appendix we show stability for the second order accurate h-box method applied to the advection equation. This proof is based on the stability theory of Gustafsson, Kreiss, and Sundström [11].

5. Irregular grid calculation. In order to demonstrate the robustness of the high-resolution h-box method we now apply the scheme to a completely arbitrary grid; see Figure 4. By again assigning values to boxes of length h, we obtain a scheme that remains stable for time steps appropriate for a uniform grid with grid cells of length h. In this more general situation more than two grid cells may be overlapped by an h-box. We assume that grid cells have the length $h_i = \alpha_i h$, with $\alpha_i \leq 1$ for all indices i. We will show that a generalization of the h-box method based on averaging over piecewise linear values of the conserved quantities gives accurate results also in this more difficult situation. We will need to use piecewise linear reconstructed values

$$\overline{Q}_i(x) = Q_i + \frac{Q_{i+1} - Q_i}{h(\alpha_i + \alpha_{i+1})/2}(x - x_i) \quad \text{for } x \in [x_{i-\frac{1}{2}}, x_{i+\frac{1}{2}}), \quad i \in \{m, l\}, \tag{5.1}$$

$$\overline{Q}_j(x) = Q_j + \frac{Q_j - Q_{j-1}}{h(\alpha_j + \alpha_{j-1})/2}(x - x_j) \quad \text{for } x \in [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}), \quad j \in \{s, t\}. \tag{5.2}$$

The indices m, l and s, t indicate the grid cells that are only partly covered by the left- (respectively, right-) going h-boxes that are constructed at the cell interfaces of grid cell k. Slopes are needed only in these four cells because averaging over an entire cell gives a value that is independent of the slope. Averaging over these piecewise linear functions leads to the h-box values

$$\begin{aligned}
Q^L_{k-\frac{1}{2}} &= \sum_{i=m+1}^{k-1} \alpha_i Q_i + \Big(1 - \sum_{i=m+1}^{k-1} \alpha_i\Big) \cdot \Big[Q_m + \frac{Q_{m+1} - Q_m}{\alpha_m + \alpha_{m+1}} \Big(\sum_{i=m}^{k-1} \alpha_i - 1\Big)\Big], \\
Q^R_{k-\frac{1}{2}} &= \sum_{i=k}^{s-1} \alpha_i Q_i + \Big(1 - \sum_{i=k}^{s-1} \alpha_i\Big) \cdot \Big[Q_s + \frac{Q_s - Q_{s-1}}{\alpha_s + \alpha_{s-1}} \Big(1 - \sum_{i=k}^{s} \alpha_i\Big)\Big], \\
Q^L_{k+\frac{1}{2}} &= \sum_{i=l+1}^{k} \alpha_i Q_i + \Big(1 - \sum_{i=l+1}^{k} \alpha_i\Big) \cdot \Big[Q_l + \frac{Q_{l+1} - Q_l}{\alpha_l + \alpha_{l+1}} \Big(\sum_{i=l}^{k} \alpha_i - 1\Big)\Big], \\
Q^R_{k+\frac{1}{2}} &= \sum_{i=k+1}^{t-1} \alpha_i Q_i + \Big(1 - \sum_{i=k+1}^{t-1} \alpha_i\Big) \cdot \Big[Q_t + \frac{Q_t - Q_{t-1}}{\alpha_t + \alpha_{t-1}} \Big(1 - \sum_{i=k+1}^{t} \alpha_i\Big)\Big].
\end{aligned} \tag{5.3}$$

5.1. Approximation of the advection equation on irregular grids. We can show that these h-box values used in an upwind scheme (which is equivalent to the first order wave propagation algorithm) lead to a consistent approximation of the advection equation.

PROPOSITION 3. *The h-box method $Q_i^{n+1} = Q_i^n - a\frac{\triangle t}{\alpha_i h}(Q^L_{i+\frac{1}{2}} - Q^L_{i-\frac{1}{2}})$ with h-box values defined by* (5.3) *leads to a first order accurate approximation of the advection equation (with advection speed $a > 0$) on an irregular grid.*

The proof is based on Taylor series expansion and may be found in the preprint version of this paper [2]. Together with the stability result mentioned in section 4, we obtain first order convergence of this h-box method on irregular grids using time steps that satisfy $\text{CFL}_h \leq 1$.

Once the h-box values are defined we can apply the same second order correction terms (3.8) at the cell interfaces of a completely irregular grid. With such an approach

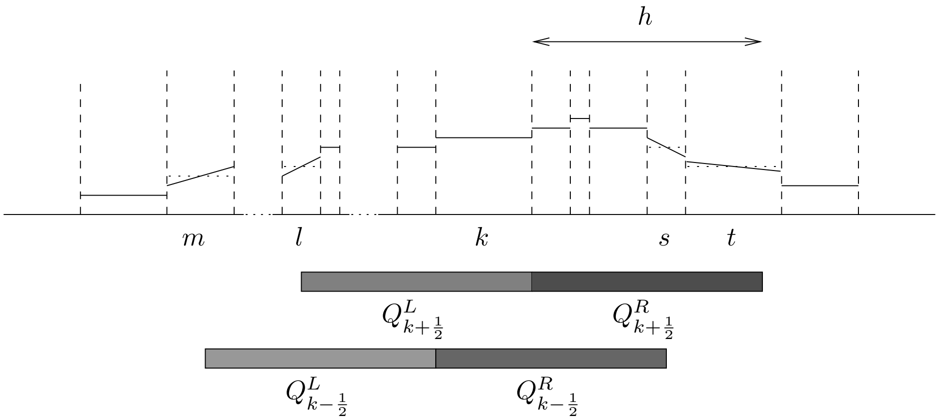

FIG. 4. *Schematic description of the h-box method on a completely irregular grid.*

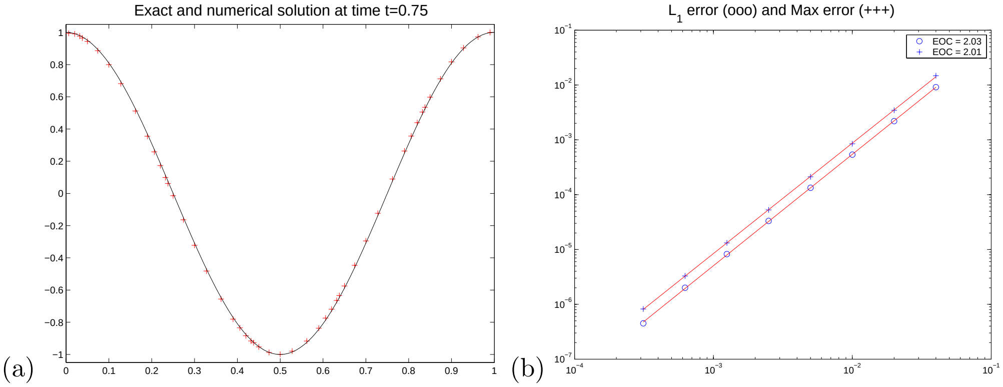

FIG. 5. *Approximation of the advection equation on an irregular grid using the high-resolution h-box method with h-box values calculated by linear interpolation.* (a) *numerical results on an irregular grid with $h = 0.04$;* (b) *log-log-plot of h versus L_1-norm error as well as maximum-norm error shows second order convergence.*

we can expect second order convergence. Figure 5 shows numerical results for the approximation of the advection equation on a sequence of irregular grids. The initial values are set to $q(x, 0) = \sin(2\pi x)$ on the interval $[0, 1]$. Periodic boundary conditions are imposed. A convergence study shows that our new high-resolution h-box method converges with second order accuracy both in the L_1-norm as well as the maximum norm. The accuracy of this calculation compares well with the accuracy of the standard wave propagation algorithm that was briefly described in section 2. However, here we could use much larger time steps. In Figure 6, we show results for the same test case, but here the h-box values were constructed by averaging over piecewise constant values of the conserved quantity, i.e., the formally inconsistent method described in section 3.1. Although we add second order correction terms (which increases the accuracy) the resulting method is only first order accurate. This is analogous to our analytical results for the simpler situation with only one small cell.

5.2. Approximation of the Euler equations on irregular grids. In this section we study the performance of the high-resolution h-box method for one-dimensional

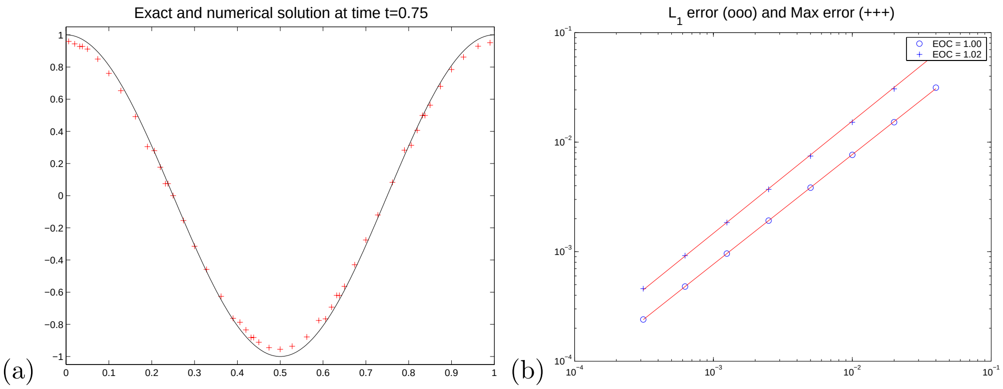

FIG. 6. *Approximation of the advection equation on an irregular grid using an h-box method with second order correction terms, where h-box values are calculated by averaging over piecewise constant values of the conserved quantity.* (a) *numerical results on an irregular grid with $h = 0.04$;* (b) *log-log-plot of h versus L_1-norm error as well as maximum-norm error shows first order convergence.*

Euler equations. The equations can be written in the form (1.1) with

$$q = (\rho, \rho u, E), \quad f(q) = (\rho u, \rho u^2 + p, u(E + p)),$$

where $\rho, p, E,$ and u describe the density, pressure, total energy, and the velocity, respectively. The equation of state has the form

$$E = \frac{p}{\gamma - 1} + \frac{1}{2}\rho u^2.$$

First we consider the approximation of a test problem defined in Example 5.1 on an irregular grid.

Example 5.1. We consider the numerical approximation of the one-dimensional Euler equations on an irregular grid. The grid cells vary in size between $h/10$ and h. The initial values are sufficiently smooth so that the solution does not develop shocks over the time interval considered. Reflecting boundary conditions are imposed on the left and right boundary. The computational domain is the interval $[0, 1]$. Our initial values are

$$\rho(x, 0) = 1 + 0.4 \sin\left(\frac{\pi}{2} + x\pi\right), \quad u(x, 0) = 0.25 - (x - 0.5)^2, \quad p(x, 0) = 1.$$

The ratio of specific heats is set to $\gamma = 1.4$.

In Figure 7 we show numerical results for the approximation of Example 5.1 using our new high-resolution h-box method. A convergence study for density at different time steps is shown in Table 5.1. Here we compare the numerical solution for density on a sequence of irregular grids to a highly resolved reference solution that was calculated on a regular spaced grid. We show results for both the unlimited second order h-box method and a version using the minmod limiter. Next we consider the approximation of a shock wave with the Euler equations.

Example 5.2. We consider the one-dimensional Euler equations with initial values on the interval $[0, 1]$ that have constant density $\rho = 1$ and constant pressure $p = 1$. The velocity is set to $u = 1$ for $x < 0.5$ and $u = -1$ for $x > 0.5$. The ratio of specific heats is $\gamma = 1.05$. The exact solution of this problem consists of two symmetric

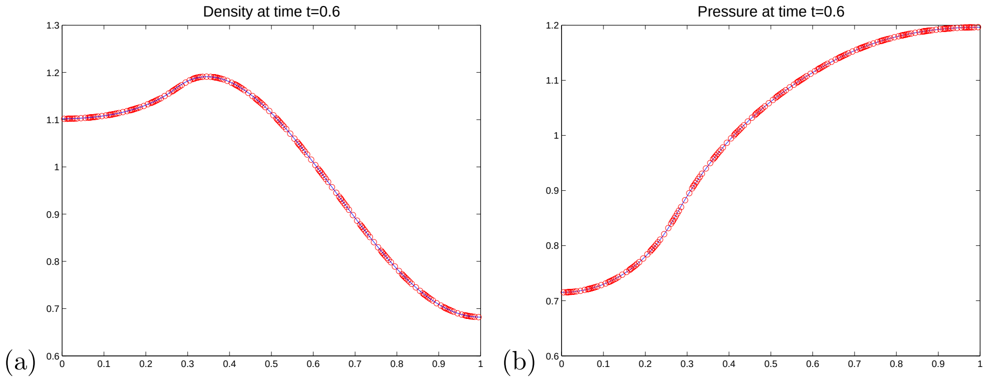

FIG. 7. *Numerical results of density and pressure for Example* 5.1 *on an irregular grid* ($h = 0.02$). *The solid line shows a highly resolved reference solution calculated on a regular grid.*

TABLE 5.1

shock waves that are propagating outwards. We use an irregular grid with grid cells that may be smaller than $h = 0.01$ on the left half of the interval. For $x > 0.5$ the grid is regular with mesh length $\triangle x = 0.01$. We use time steps that correspond to $\mathrm{CFL}_h \approx 0.9$.

Figure 8 shows numerical results of Example 5.2 for the high-resolution *h*-box method based on the linear interpolation formula. Our numerical results in Figure 8(a) show that the limiters described in section 3.3 can suppress spurious oscillations near the discontinuity. The approximation of the shock wave that is moving into the region of the irregular grid is in good agreement with the symmetric shock wave that is moving into the regular part of the grid. On the irregular grid the shock is smeared out over more grid cells than on the regular grid. The reason for this more smeared out shock profile is that a jump in the conserved quantities can influence several *h*-box values. In Figure 8(b) we show the results obtained by the second order method without limiters.

6. Approximation of transonic rarefaction waves. In this section we point out that *h*-box methods can cause numerical difficulties in the approximation of tran-

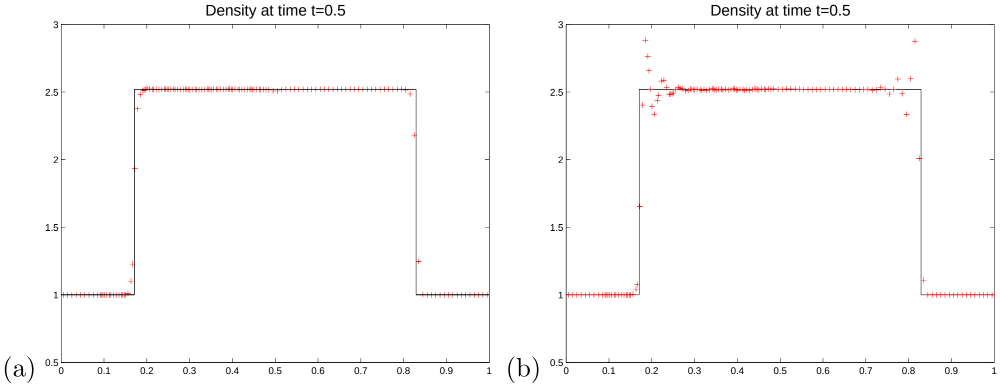

FIG. 8. *Approximation of Example* 5.2 *on a grid that is irregular for $x < 0.5$ and regular for $x > 0.5$.* (a) *plot of density with limiters;* (b) *plot of density without limiters. The solid line indicates the exact solution.*

sonic rarefaction waves that do not appear for standard Godunov-type methods on regular or irregular spaced grids. To see this we first consider the approximation of Burgers's equation $q_t + (q^2/2)_x = 0$ with initial values $q(x, 0) = -0.5$ for $x \leq 0.5$ and $q(x, 0) = 0.5$ for $x > 0.5$ on an irregular grid. The first order accurate fluxes at the cell interface $x_{i-\frac{1}{2}}$ can be calculated by using the exact formula, i.e.,

$$F_{i-\frac{1}{2}} = \begin{cases} \min_{Q^L_{i-\frac{1}{2}} \leq q \leq Q^R_{i-\frac{1}{2}}} f(q) & : \quad Q^L_{i-\frac{1}{2}} \leq Q^R_{i-\frac{1}{2}}, \\ \max_{Q^R_{i-\frac{1}{2}} \leq q \leq Q^L_{i-\frac{1}{2}}} f(q) & : \quad Q^R_{i-\frac{1}{2}} \leq Q^L_{i-\frac{1}{2}}, \end{cases}$$

with the flux $f(q) = \frac{1}{2}q^2$. Figure 9(a) demonstrates that this method produces unphysical oscillations around the sonic point. Note that in this section we use only first order accurate methods to isolate this phenomenon from the flux limiting procedure. The numerical problem can be avoided by using the Lax–Friedrichs flux, which has at the interface $x_{i-\frac{1}{2}}$ the form

$$F_{i-\frac{1}{2}} = \frac{1}{2}\big(f(Q^L_{i-\frac{1}{2}}) + f(Q^R_{i-\frac{1}{2}})\big) + \frac{h}{2\triangle t}\big(Q^L_{i-\frac{1}{2}} - Q^R_{i-\frac{1}{2}}\big).$$

See Figure 9(b) for numerical results.

The same effect can also be observed in the approximation of a transonic rarefaction wave for the Euler equations. To see this we consider a shock tube problem for which the solution consists of a right-moving shock wave, a contact discontinuity, and a left-moving transonic rarefaction wave. The initial values are $\rho = 1$, $u = 0.75$, $p = 1$ for $x \leq 0.3$ and $\rho = 0.125$, $u = 0$, $p = 0.1$ for $x > 0.3$. The ratio of specific heats is $\gamma = 1.4$. For the numerical approximation we used a Roe–Riemann solver with standard entropy fix for transonic rarefaction waves. The results of this calculation are shown in Figure 10. The numerical solution shows some oscillations around the sonic point; see Figure 10(b) for a closer view of the region around the sonic point. If the fluxes at the cell interfaces are again calculated by the Lax–Friedrichs method this numerical problem does not arise; see Figure 11.

In the preprint [2] of this paper, we studied the entropy consistency of the h-box method for the approximation of Burgers's equation. For the h-box method with Godunov flux, we showed that a discrete entropy inequality is satisfied away from sonic

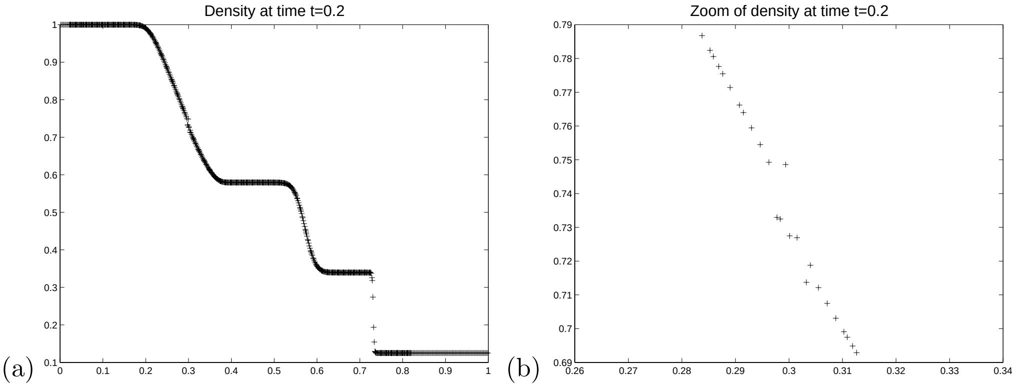

FIG. 10. *Approximation of a shock tube problem for the Euler equations.* (a) *plot of density obtained by first order Roe solver with entropy fix;* (b) *zoom of density around sonic point.*

points. This implies that the numerical solution converges to the entropy consistent weak solution of the conservation law. We showed that this discrete entropy inequality can be violated at a sonic point. While this does not give us any prediction whether or not the method is entropy consistent at the sonic point, it is interesting to note that this is exactly the case where the *h*-box method leads to numerical difficulties. We plan to further investigate the entropy consistency of *h*-box methods in order to develop an entropy fix that is less dissipative than the Lax–Friedrichs method and that can be extended to a high-resolution method.

7. Higher-dimensional irregular grid calculations. Now we will consider two-dimensional systems of conservation laws in the form

$$\frac{\partial}{\partial t}q(x,y,t)+\frac{\partial}{\partial x}f(q(x,y,t))+\frac{\partial}{\partial y}g(q(x,y,t))=0. \tag{7.1}$$

The simplest way to extend a one-dimensional method for conservation laws to multidimensional problems is to use dimension splitting. Equation (7.1) would be approximated by solving one-dimensional subproblems in an alternating way. The high-resolution one-dimensional *h*-box method could be used in each substep.

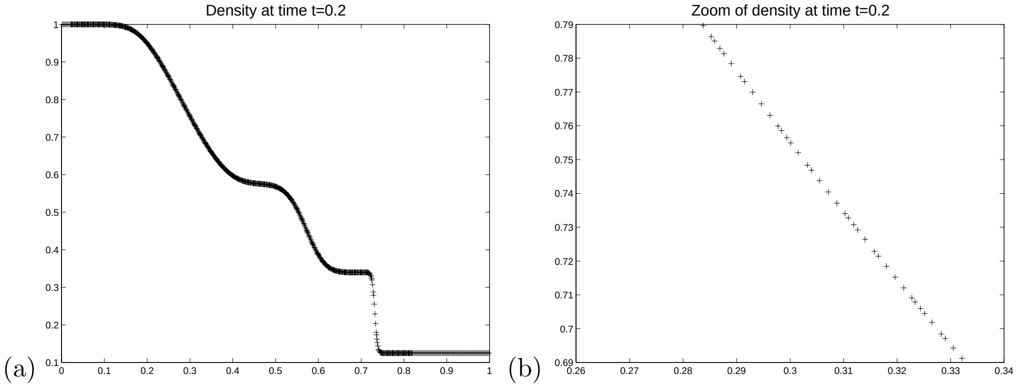

FIG. 11. *Approximation of a shock tube problem for the Euler equations.* (a) *plot of density obtained by Lax–Friedrichs method;* (b) *zoom of density around sonic point.*

Instead of using a dimensional splitting approach, we will here develop a two-dimensional h-box method that is based on the multidimensional wave propagation algorithm [17], [18]. We assume that the reader is familiar with the two-dimensional wave propagation algorithm and with the notation used below. As a first step in this approach we solve one-dimensional Riemann problems normal to each cell interface. Based on formula (3.6), which describes the one-dimensional h-box method, we obtain

$$\begin{aligned} Q_{ij}^{n+1} &= Q_{ij}^n + \triangle_{ij}^{up} \\ &= Q_{ij}^n - \frac{\triangle t}{\triangle x_i}\left(\mathcal{A}^+\triangle\hat{Q}_{i-\frac{1}{2},j} + \mathcal{A}^-\triangle\hat{Q}_{i+\frac{1}{2},j} + f(Q_{i+\frac{1}{2},j}^L) - f(Q_{i-\frac{1}{2},j}^R)\right) \\ &\quad - \frac{\triangle t}{\triangle y_j}\left(\mathcal{B}^+\triangle\hat{Q}_{i,j-\frac{1}{2}} + \mathcal{B}^-\triangle\hat{Q}_{i,j+\frac{1}{2}} + g(Q_{i,j+\frac{1}{2}}^L) - g(Q_{i,j-\frac{1}{2}}^R)\right). \end{aligned} \tag{7.2}$$

The method (7.2) is stable for time steps that satisfy $\text{CFL}_h \leq \frac{1}{2}$. Second order correction terms of the form (3.8) can be included in x as well as in y direction, which leads to a method of the form

$$Q_{ij}^{n+1} = Q_{ij}^n + \triangle_{ij}^{up} - \frac{\triangle t}{\triangle x_i}\left(\hat{F}_{i+\frac{1}{2},j}^2 - \hat{F}_{i-\frac{1}{2},j}^2\right) + \frac{\triangle t}{\triangle y_j}\left(\hat{G}_{i,j+\frac{1}{2}}^2 - \hat{G}_{i,j-\frac{1}{2}}^2\right). \tag{7.3}$$

The second order correction terms are again obtained by using the waves and speeds calculated from solving Riemann problems defined by h-box values. Limiters are used in exactly the same form as described earlier for the one-dimensional case.

In addition to fluxes in the normal direction, the multidimensional wave propagation algorithm also calculates waves that are moving in a transverse direction. For the usual wave propagation scheme one has $Q_{i+\frac{1}{2},j}^L = Q_{i-\frac{1}{2},j}^R$ and $Q_{i,j+\frac{1}{2}}^L = Q_{i,j-\frac{1}{2}}^R$. In this case the transverse propagation of waves can be obtained by a decomposition of the flux differences $\mathcal{A}^\pm\triangle Q$, $\mathcal{B}^\pm\triangle Q$ into transverse fluctuations. For the h-box method this transverse propagation has to be modified. In order to explain the transverse propagation we consider the two-dimensional advection equation

$$\frac{\partial}{\partial t}q(x,y,t) + a\frac{\partial}{\partial x}q(x,y,t) + b\frac{\partial}{\partial y}q(x,y,t) = 0, \qquad a, b > 0.$$

Assuming first that $\triangle x_i = h$ and $\triangle y_j \leq h$, the change of the cell average of the conserved quantity q in grid cell (i,j) due to the first order update in the x-direction

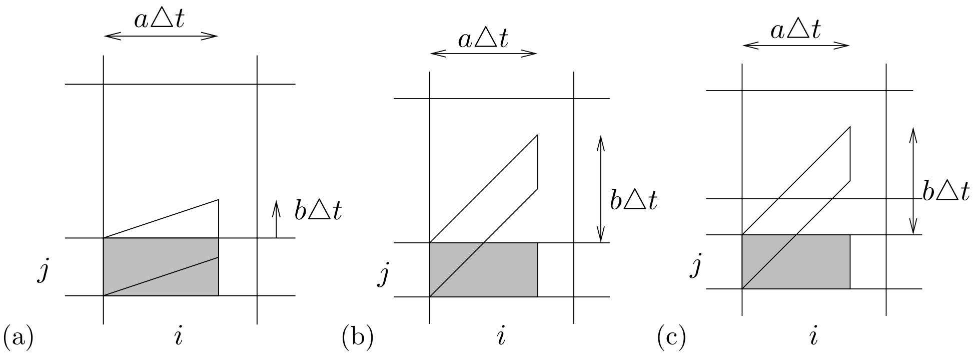

FIG. 12. *Different possibilities for transverse propagation of a right-moving wave for the advection equation on a nonuniform Cartesian grid.*

has the form

$$-\frac{\triangle t}{\triangle x_i}\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j} = -\frac{\triangle t}{h}a(Q^n_{i,j} - Q^n_{i-1,j}). \tag{7.4}$$

Since we assume that the advection speed a in the x-direction is positive, there is no wave that moves into this cell from the right cell interface. Furthermore, the difference $f(Q^L_{i+\frac{1}{2},j}) - f(Q^R_{i-\frac{1}{2},j})$ vanishes in the case $\triangle x_i = h$. In the two-dimensional case a part of the right-moving flux difference $\mathcal{A}^+\triangle Q$ should affect other grid cells. This is indicated in Figure 12. The shaded regions indicate the influence of the jump $Q_{ij} - Q_{i-1,j}$ (initially located at the left cell interface) due to the solution of the Riemann problem in the normal direction. In a multidimensional method the solution of the Riemann problem at the interface $x_{i-\frac{1}{2}}$ should not affect only the cell average of the conserved quantities in the grid cell $(i-1,j)$ and (i,j). It should also have an effect on grid cells in the tangential direction. In the situation shown in Figure 12(a), the triangular portion of the wave describes the fraction that should affect the grid cell $(i,j+1)$. The transverse propagation of the wave considered in Figure 12(a) should change the cell average of the conserved quantity in grid cell (i,j) by the amount

$$\frac{(\triangle t)^2}{\triangle x_i \triangle y_j}\frac{1}{2}b\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j} = \frac{(\triangle t)^2}{\triangle x_i \triangle y_j}\frac{1}{2}\mathcal{B}^+\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j}.$$

The change of the cell average of the conserved quantity in cell $(i,j+1)$ due to the transverse propagation of this wave has the form

$$-\frac{(\triangle t)^2}{\triangle x_i \triangle y_{j+1}}\frac{1}{2}\mathcal{B}^+\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j}.$$

The notation $\mathcal{B}^\pm\mathcal{A}^\pm\triangle Q$ was introduced in [18] to describe transverse propagations of left- and right-moving flux differences. For the wave propagation algorithm with time step restriction CFL ≤ 1 the transverse propagation has always the triangular form depicted in Figure 12(a), even if the grid is irregular. Since the transverse propagation approximates terms that are needed in order to obtain second order accuracy, we include those terms into the second order correction terms used in (7.3). The up-going flux difference $\mathcal{B}^+\mathcal{A}^+\triangle Q_{i-\frac{1}{2}}$ contributes to the $\tilde{G}$ term in the form of an update

$$\hat{G}^2_{i,j+\frac{1}{2}} := \hat{G}^2_{i,j+\frac{1}{2}} - \frac{1}{2}\frac{\triangle t}{\triangle x_i}\mathcal{B}^+\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j}.$$

For our h-box method we have to extend the transverse propagation to allow also wave propagation of other forms, for instance those shown in Figures 12(b) or (c). For the situation shown in Figure 12(b) the update of the flux $\tilde{G}$ due to the transverse propagation has the form

$$\hat{G}^2_{i,j+\frac{1}{2}} := \hat{G}^2_{i,j+\frac{1}{2}} - \frac{\triangle t - \frac{1}{2}\triangle y_j/b}{b\triangle t\triangle x_i}\triangle y_j \mathcal{B}^+\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j}.$$

In the situation shown in Figure 12(c), the transverse propagation of $\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j}$ leads to an update of $\hat{G}^2_{i,j+\frac{1}{2}}$ as well as $\hat{G}^2_{i,j+\frac{3}{2}}$, depending on the fraction of the wave considered. As demonstrated in these examples, simple geometric routines can be used to calculate the fraction of the waves that determine the change of the cell average of the conserved quantity due to the transverse propagation. Note that the wave speed in the normal direction (i.e., a in our example) is present in the fluctuations $\mathcal{A}^\pm\triangle Q$. In order to calculate the transverse propagations no other information from the structure of the Riemann problem in the normal direction is needed. Therefore, even for a system of conservation laws, we have only to decompose the left- and right-moving flux differences, instead of decomposing each wave resulting from the Riemann problem in the normal direction separately.

So far we have assumed that $\triangle x_i = h$. If $\triangle x_i < h$, we want to use the one-dimensional h-box method in order to calculate the fluxes in the normal direction. The transverse propagation will take a very similar form as discussed above. Now we could interpret the grid cells (i,j), $(i,j+1)$ shown in Figure 12 as h-boxes constructed at the interface $x_{i-\frac{1}{2}}$. The transverse propagation of waves should again depend on the fraction of the wave that moves through the h-box considered. This can be calculated in exactly the same way as described above for the case $\triangle x_i = h$. In order to obtain the correct cancellation property needed for a stable update, we have to include the terms $f(Q^L_{i+\frac{1}{2},j})$ and $f(Q^R_{i-\frac{1}{2},j})$ that arise in (7.2) into our transverse propagation. Motivated by (2.1), (2.2) we do this by applying an update of the form

$$\begin{aligned}\mathcal{A}^+\triangle Q_{i-\frac{1}{2},j} &:= \mathcal{A}^+\triangle Q_{i-\frac{1}{2},j} - f(Q^R_{i-\frac{1}{2}}),\\ \mathcal{A}^-\triangle Q_{i-\frac{1}{2},j} &:= \mathcal{A}^-\triangle Q_{i-\frac{1}{2},j} + f(Q^L_{i-\frac{1}{2}})\end{aligned}$$

before we calculate the change of the fluxes $\hat{G}^2$. For our example of the advection equation with positive advection speeds, this update of $\mathcal{A}^\pm\triangle Q$ has the effect that $\mathcal{A}^-\triangle Q$ is no longer equal to zero. Moreover, the fraction of the wave that is propagated in the transverse direction depends only on the size of the grid cells and the speed b. Therefore, our transverse propagation has the effect that a fraction of the update used in (7.3) is propagated in the transverse direction. The update, which describes the wave propagation in the x-direction was already constructed to be of the order $\mathcal{O}(\triangle x)$ with $\triangle x \le h$. Our transverse propagation allows that at most a fraction of magnitude $\mathcal{O}(\triangle y)$ $(\triangle y \le h)$ is propagated in the transverse direction. (See, for instance, Figure 12(c).) Therefore, our transverse propagation satisfies the cancellation property. The transverse propagation of $\mathcal{B}^+\triangle Q$ also has to be included in an analogous way. By including the transverse propagation into our two-dimensional h-box method, we obtain stability for time steps that satisfy the condition $\text{CFL}_h \le 1$.

A transverse propagation of the second order correction (3.8) can be included into the transverse propagation in the same form as it was discussed for the wave propagation algorithm in [18]. This further increases the accuracy of the method. It was used in our test calculations below.

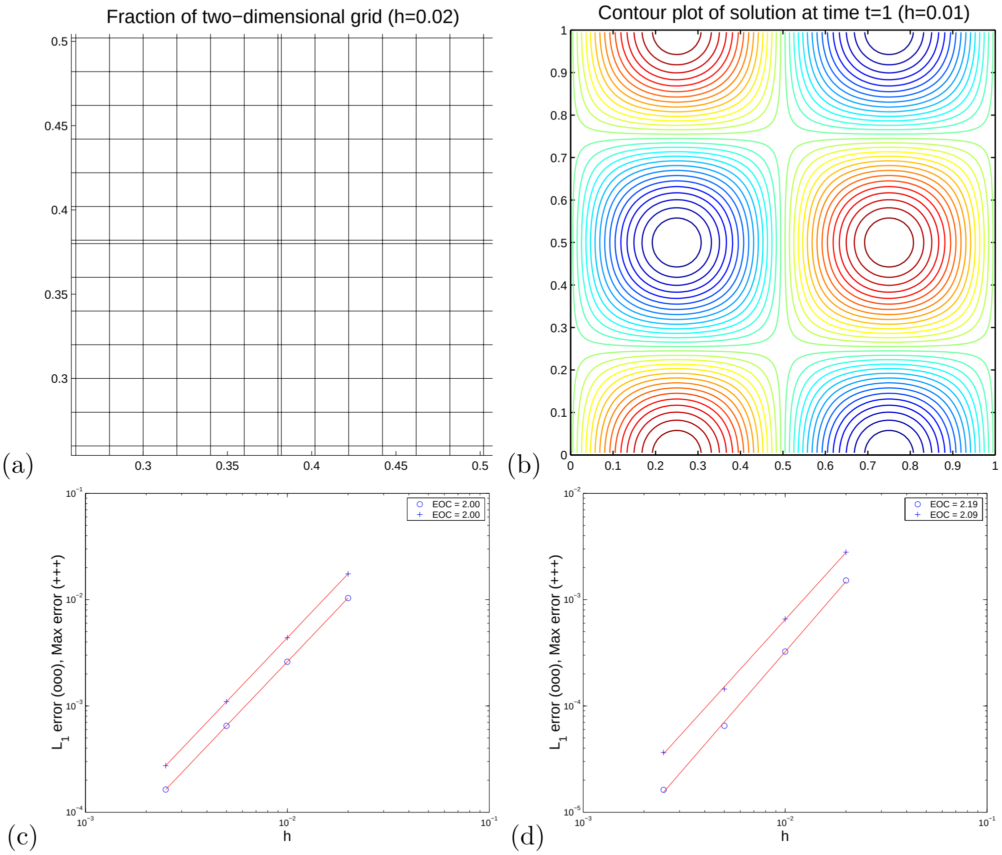

FIG. 13. *Approximation of Example* 7.1. (a) *The grid for a discretization with* $h = 0.02$; (b) *contour plot of the solution using the two-dimensional* h*-box approach with* $h = 0.01$ *and* $CFL_h \approx 0.9$; (c) *convergence study for irregular grid* CLAWPACK *algorithm,* $CFL \approx 0.9$; (d) *convergence study for* h*-box method,* $CFL_h \approx 0.9$ (o*-symbol: error in* L_1*-norm;* $+$*-symbol: error in maximum norm).*

We now demonstrate the performance of our two-dimensional high-resolution h-box method for the approximation of the advection equation. We will compare the numerical results obtained for this h-box scheme with results obtained using the standard high-resolution CLAWPACK algorithm for irregular grid calculations. The latter method requires the time step restriction CFL ≤ 1, while the h-box method is stable for time steps that satisfy $\text{CFL}_h \leq 1$. We first study the accuracy for the two-dimensional advection equation.

Example 7.1. We consider the approximation of the advection equation $q_t + q_x + q_y = 0$, with initial values $q(x, y, 0) = \sin(2\pi x)\cos(2\pi y)$ on the domain $[0, 1] \times [0, 1]$. We impose periodic boundary conditions. The grid contains two lines as well as two columns of grid cells with height (respectively, width) $0.1h$ and $0.9h$. All other grid cells have the size $h \times h$. See Figure 13(a) for a plot of a fraction of the grid.

Test calculations for Example 7.1 confirm that the h-box method leads to second order accurate approximations also in this multidimensional application. In Figure 13(d) we document the experimental order of convergence of the h-box method in both the L_1-norm (depicted by o-symbols) as well as in the maximum norm (+-symbols). For this grid, inaccuracies near the small cells would be displayed in the

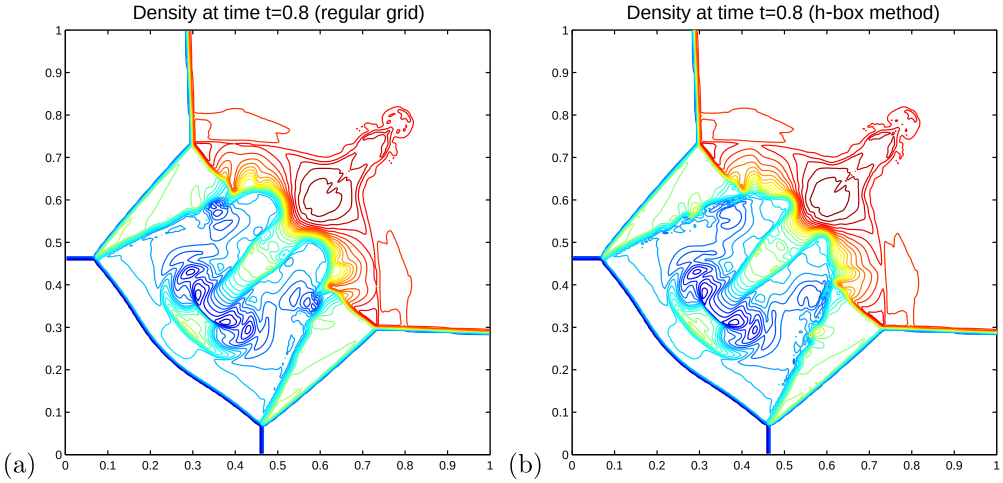

FIG. 14. (a) *Contour plot of density obtained by the high-resolution wave propagation algorithm on a uniform grid with* $h = 0.005$*;* (b) *contour plot of density obtained with high-resolution h-box method,* $h = 0.005$*. We used the monotonized centered limiter.*

maximum norm rather than in the L_1-norm. However, in both norms the experimental order of convergence is about 2. The results for the h-box method compare well with numerical results obtained with the standard wave propagation algorithm with appropriate modifications that allow the approximation on a nonuniform grid. Both schemes converge with second order, but the error is slightly smaller if we use the h-box method. This is due to the numerical viscosity, since the time step restriction CFL ≈ 0.9 for the wave propagation algorithm leads away from the small cell to time steps that correspond to CFL ≤ 0.1.

Our two-dimensional h-box method can be extended to systems of conservation laws in the same way as the standard wave propagation algorithm. The modifications described above now have to be applied to each wave resulting from the decomposition of the left- (respectively, right-) going flux differences into up- and down-going waves. In our last example we consider the approximation of a two-dimensional Riemann problem for the Euler equations, as studied in [27]. This same example was considered in [18], where results of CLAWPACK calculations on a uniform grid are shown. The initial values are piecewise constant in four quadrants, and the solution of each single Riemann problem is a shock wave. Due to the interaction a complex solution structure is obtained. For this calculation we have, in addition to the regular grid cells of the size $h \times h$, 10 lines and 10 columns with height (respectively, width) varying between $0.1h$ and $0.9h$. Our solution on a nonuniform grid calculated by the high-resolution h-box method with $h = 0.005$ compares well with those obtained on a regular grid; see Figure 14. The shock waves are equally well approximated with both methods. Slight differences are visible only at the unstable contact lines, which are very sensitive to the numerical method; see also [18], where it was shown that different limiters have quite a large impact on the approximation.

8. Conclusions. We studied high-resolution h-box methods for the approximation of hyperbolic systems of conservation laws on irregular grids and showed that the definition of the h-box values is important in order to construct accurate schemes. In forthcoming work we will use this to construct a new two-dimensional high-resolution

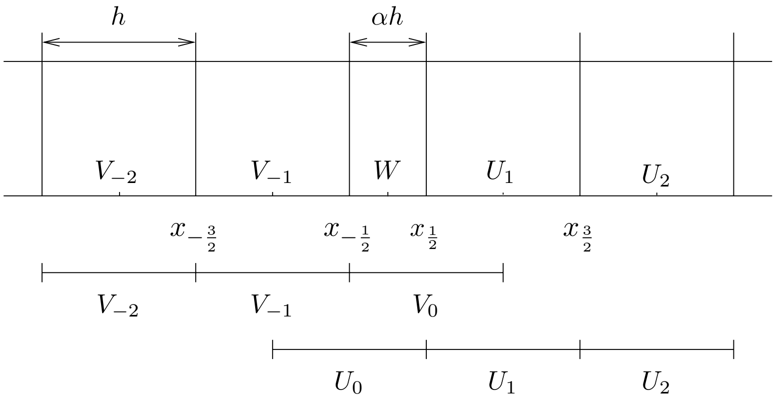

FIG. 15. *Notation for GKS stability, with one small cell in the middle.*

h-box scheme for the approximation of conservation laws with embedded irregular boundaries. So far there is no Cartesian grid embedded boundary method that leads to a second order accurate approximation at boundary cells. Further work will also concentrate on the entropy consistency of *h*-box methods and the approximation of transonic rarefaction waves.

Appendix A. Stability of the second order *h*-box method. In this appendix we prove the stability of the second order *h*-box scheme for $q_t = q_x$ using linear interpolation according to the theory of Gustafsson, Kreiss, and Sundström [11] (henceforth GKS). We treat the small cell with mesh width αh as a boundary condition for the Lax–Wendroff scheme applied on either side of the small cell, using the notation of Figure 15. Here the conserved quantity assigned to the right *h*-box at the interface $x_{-\frac{1}{2}}$ is denoted by V_0. The left *h*-box value at the interface $x_{\frac{1}{2}}$ is U_0. The derivation of the stability condition for the update of the small cell is similar to those used in Berger [1], where stability for schemes with local grid refinement was analyzed.

Both U and V are computed using the second order Lax–Wendroff scheme,

$$\text{(A.1)}\qquad \begin{aligned} U_j^{n+1} &= U_j^n + \lambda/2(U_{j+1}^n - U_{j-1}^n) + \lambda^2/2(U_{j+1}^n - 2U_j^n + U_{j-1}^n), \qquad j \geq 1,\\ V_j^{n+1} &= V_j^n + \lambda/2(V_{j+1}^n - V_{j-1}^n) + \lambda^2/2(V_{j+1}^n - 2V_j^n + V_{j-1}^n), \qquad j \leq -1, \end{aligned}$$

with $\lambda = \frac{\triangle t}{h}$. Using the approach of [1], we look for solutions of the form

$$\text{(A.2)}\qquad \begin{aligned} U_j^n &= \rho\kappa^j z^n, |\kappa| \leq 1, \qquad j = 1, 2, \dots,\\ V_j^n &= \sigma\tau^j z^n, |\tau| \geq 1, \qquad j = -1, -2, \dots. \end{aligned}$$

With this numbering, for l_2 solutions the root κ of the characteristic equation for U on the right side has magnitude less than 1, and τ has magnitude greater than 1. Roughly speaking, the scheme is unstable if and only if there are l_2 solutions satisfying the interpolation conditions with growth in time $|z| > 1$.

The linear interpolation conditions (3.3) give us

$$\text{(A.3)}\qquad U_0 = \frac{1-\alpha}{1+\alpha}V_{-1} + \frac{2\alpha}{1+\alpha}W, \qquad V_0 = \frac{1-\alpha}{1+\alpha}U_1 + \frac{2\alpha}{1+\alpha}W,$$

where the small cell, labeled W above, satisfies the "small cell" version of Lax–Wendroff,

$$W^{n+1} = W^n + \frac{\Delta t}{\alpha h}\left[\frac{U_0+U_1}{2} + \frac{\Delta t}{2h}(U_1 - U_0) - \frac{V_0+V_{-1}}{2} - \frac{\Delta t}{2h}(V_0 - V_{-1})\right]. \tag{A.4}$$

The characteristic equation for W is $W^n = \hat{w}z^n$. We normalize the equations and take $\hat{w} = 1$. Substituting the characteristic roots for U, V into the interpolation conditions (A.3) gives

$$\rho = \frac{1-\alpha}{1+\alpha}\sigma\tau^{-1} + \frac{2\alpha}{1+\alpha}, \qquad \sigma = \frac{1-\alpha}{1+\alpha}\rho\kappa + \frac{2\alpha}{1+\alpha}. \tag{A.5}$$

Equation (A.5) is easily solved for ρ and σ, giving

$$\rho = \frac{2\alpha\left(1+\alpha+(1-\alpha)\tau^{-1}\right)}{(1+\alpha)^2 - (1-\alpha)^2\kappa\tau^{-1}}, \qquad \sigma = \frac{2\alpha\left(1+\alpha+(1-\alpha)\kappa\right)}{(1+\alpha)^2 - (1-\alpha)^2\kappa\tau^{-1}}. \tag{A.6}$$

Substitution of the resolvent equations for U and V into (A.4) gives

$$z = 1 + \frac{\lambda}{2\alpha}\left[\rho(1+\kappa) + \lambda\rho(\kappa-1) - \sigma(1+\tau^{-1}) - \lambda\sigma(1-\tau^{-1})\right]. \tag{A.7}$$

We use (A.5) to replace ρ and σ in terms of $\sigma\tau^{-1}$ and $\rho\kappa$. Also, for a given mesh width h on both the left and right, it is easily seen that the product of the roots κ and τ are $\kappa\tau = \frac{\lambda-1}{\lambda+1}$, so τ^{-1} can be replaced using κ. Thus, (A.7) simplifies to

$$z = 1 - \frac{2\lambda^2}{1+\alpha} + \frac{\lambda(1+\lambda)}{1+\alpha}\kappa(\rho+\sigma). \tag{A.8}$$

We call this *root condition* for the stability of the small cell scheme with Lax–Wendroff. If there are roots z with $|z| > 1$ and κ, τ^{-1} with magnitude less than or equal to 1, satisfying (A.8), then by the GKS theory the scheme is unstable. Conversely, if there are no such roots, the scheme is stable. As in [1], we will use the maximum principle to reduce the range of values we need to check for stability.

To see that the maximum principle applies, we will show that the right-hand side of (A.8), call it $f(z)$, has no singularities for $|z| \geq 1$ and is bounded as $z \to \infty$. First note that $f(z) = (1 - \frac{2\lambda^2}{1+\alpha}) + \frac{\lambda(1+\lambda)}{1+\alpha}\kappa(\rho+\sigma)$ has no branch points for $|z| \geq 1$. This is because the roots κ, τ satisfy the Lax–Wendroff characteristic equation for (A.1),

$$z = 1 + \frac{\lambda}{2}(\eta - \eta^{-1}) + \frac{\lambda^2}{2}(\eta - 2 + \eta^{-1}), \tag{A.9}$$

which lead to a quadratic equation for η with roots

$$\eta_{1,2} = \frac{z - 1 + \lambda^2 \pm \sqrt{(z-1)^2 + \lambda^2(2z-1)}}{\lambda(\lambda+1)}. \tag{A.10}$$

One of the roots is always inside the unit circle, and the other one is outside the unit circle; see [11, Lemma 6.1]. The root inside the unit circle is the root we call κ above, and τ is the root that is outside the unit circle.

The square root term of (A.10) is zero only for $z = 1 - \lambda$, which being inside the unit circle is outside the region of interest, so there are no branch points for $|z| > 1$.

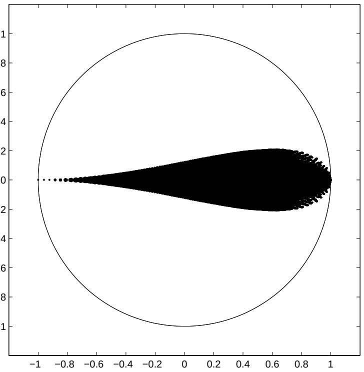

FIG. 16. *Locus of values of $f(z)$ for $|z| = 1$; all values lie inside or on the unit circle.*

Also, note from (A.10) that as $z \to \infty$, the root τ grows like $\frac{2z}{\lambda^2+\lambda}$, so the root κ grows like $\frac{\lambda(\lambda-1)}{2z}$, which is clearly bounded for large z. So the maximum principle applies.

Thus $f(z)$ attains its maximum value on the circle $|z| = 1$. The next step then is to examine the magnitude of $f(z)$ for values of z on the unit circle. Since we can show only analytically that $f(z) \leq 1$ for $\lambda > 0.5$, we instead evaluate $f(z)$ numerically, for $0 \leq \alpha \leq 1$, and $0 < \lambda \leq 1$, on the unit circle for $z = e^{i\theta}, 0 \leq \theta \leq 2\pi$. Figure 16 shows the locus of values of $f(z)$, where the unit circle is also drawn. As the figure and some algebra shows, only for $z = 1, \lambda = 0$, and $z = -1, \lambda = 1$, does $z = f(z)$.

Examining the first value $z = 1 = f(z)$, we have $\lambda = 0$, or equivalently $\Delta t = 0$, so $Q^{n+1} = Q^n$ (with $Q \in \{U, V, W\}$), which is clearly a stable solution. For the other case, we have $z = -1 = f(z)$, whose only solution (again using some numerical evaluation and some algebra) is $\lambda = 1, \alpha = 0$. But $\alpha = 0$ corresponds to the usual Lax–Wendroff scheme without the small cell, and $\lambda = 1$ for this case is straight copying of the solution ($\kappa = 0, \tau = -1$). Again this is stable.

Since Lax–Wendroff is a second order method, the use of linear interpolation with $O(h^2)$ error on a lower-dimensional set of points is reasonable. However, one might consider the use of quadratic interpolation for U_0, V_0. The next question is what stencil to use for the quadratic interpolant. Using the notation of Figure 15, one might consider using the same interpolant based on V_{-1}, W, and U_1 to get both U_0 and V_0. However, this choice reduces the stability region to $\lambda < .5$. If instead the interpolant for U_0 uses the surrounding points V_{-1} and W, and the third point is always the upwind point V_{-2}, full stability for a Courant number of $\lambda \leq 1$ is retained for all small cells with $0 < \alpha < 1$.

COUPLING OF FINITE ELEMENTS AND BOUNDARY ELEMENTS IN ELECTROMAGNETIC SCATTERING[*]

R. HIPTMAIR[†]

Abstract. We consider the scattering of monochromatic electromagnetic waves at a dielectric object with a rough surface. We investigate the coupling of a weak formulation of Maxwell's equations inside the scatterer with boundary integral equations that arise from the homogeneous problem in the unbounded region outside the scatterer. The symmetric coupling approach based on the full Calderón projector for Maxwell's equations is employed. By splitting both the electric field inside the scatterer and the surface currents into components of predominantly electric and magnetic nature, we can establish coercivity of the coupled variational problem, provided that the frequency is away from resonant frequencies.

Discretization relies on both **curl**-conforming edge elements inside the scatterer and div_Γ-conforming boundary elements for the surface currents. The splitting idea, adjusted to the discrete setting, permits us to show uniform stability of the discretized problem. We exploit it to come up with a priori convergence estimates.

Key words. electromagnetic scattering, Helmholtz decomposition, Hodge decomposition, Calderón projector, symmetric coupling, edge elements, discrete coercivity

1. Introduction.

The simulation of electromagnetic scattering is mainly concerned with approximately solving the homogeneous Maxwell equations in $\mathbb{R}^3$, subject to excitation by some monochromatic incident wave. Outside a bounded object, which is called the scatterer and occupies the bounded domain $\Omega_s \subset \mathbb{R}^3$, the electromagnetic material coefficients ϵ and μ assume the constant values $\epsilon_0 > 0$ and $\mu_0 > 0$, respectively. Inside Ω_s they may display some spatial variation. Commonly faced in applications are scatterers with piecewise smooth, Lipschitz-continuous boundary. For simplicity, we suppose that the surface $\Gamma := \partial\Omega_s$ of the scatterer is connected, but, with slight alterations, all considerations of this article carry over to more general situations.

Let $\mathbf{E}$ denote the complex amplitude of the scattered electric field in $\Omega' := \mathbb{R}^3 \setminus \bar{\Omega}_s$ and the total electric field inside Ω_s. It emerges as the solution of the transmission problem (cf. [45, sect. 5.6.3])

$$
\begin{array}{rcll}
\mathbf{curl}\,\mathbf{curl}\,\mathbf{E} - \kappa^2\mathbf{E} & = & 0 & \text{in } \Omega', \\
\mathbf{curl}\,\mu_r^{-1}\,\mathbf{curl}\,\mathbf{E} - \kappa^2\epsilon_r\mathbf{E} & = & 0 & \text{in } \Omega_s, \\
[\gamma_{\mathbf{t}}\mathbf{E}]_\Gamma = \gamma_{\mathbf{t}}\mathbf{E}_{\mathrm{inc}}, \quad \left[\frac{1}{\mu_r}\gamma_N\mathbf{E}\right]_\Gamma & = & \gamma_N\mathbf{E}_{\mathrm{inc}} & \text{on } \Gamma, \\
\lim\limits_{|\mathbf{x}|\to\infty} \mathbf{curl}\,\mathbf{E}\times\mathbf{x} - i\kappa|\mathbf{x}|\mathbf{E} & = & 0. &
\end{array}
\tag{1.1}
$$

Here, $\kappa := \omega\sqrt{\epsilon_0\mu_0}L$ (with $\omega > 0$ the fixed angular frequency of the excitation, L the characteristic length of the scatterer) stands for the normalized wave number. In what

follows, it should be regarded as merely a nonzero real parameter. $\mathbf{E}_{\text{inc}}$ stands for the complex amplitude of the electric field associated with the incident wave. In addition, we write $\gamma_{\mathbf{t}}\mathbf{E}$ for the tangential components of $\mathbf{E}$ on Γ, and $\gamma_N\mathbf{E}$ for the "magnetic trace" $\mathbf{curl}\,\mathbf{E} \times \mathbf{n}$ on Γ. The exterior unit normal vectorfield $\mathbf{n} \in L^\infty(\Gamma)$ is directed from Ω_s into Ω'. Finally, $[\gamma\phi]_\Gamma$ designates the jump $\gamma\phi_{|\Omega'} - \gamma\phi_{|\Omega_s}$ of some trace γ of a function ϕ across Γ. We remark that a similar, entirely equivalent formulation in terms of the magnetic field $\mathbf{H} := \frac{1}{i\omega\mu_r}\,\mathbf{curl}\,\mathbf{E}$ exists.

Using Rellich's lemma and unique continuation techniques, the following result can be established (cf. [35, Thm. 3.1]).

THEOREM 1.1. *Provided that the relative material parameters μ_r and $\epsilon_r > 0$ are piecewise smooth and bounded away from zero everywhere in Ω_s, the problem* (1.1) *has a unique solution.*

Boundary element methods (BEM) offer the most flexible way to deal with the homogeneous problem in the unbounded exterior domain Ω'. They are based on boundary integral operator equations (BIE) on Γ. Owing to potentially nonconstant material parameters, the field problem inside Ω_s may not be amenable to a treatment by means of boundary elements. Finite element schemes (FEM) founded on a weak variational formulation of the electric wave equation have to be used there. Thus, the topic of the paper comes into focus, namely, how to derive and discretize a suitable coupled problem, and how to analyze the resulting FEM-BEM formulation.

Coupling entails expressing the Dirichlet-to-Neumann map of the exterior problem through boundary equations linking the Cauchy data $\gamma_{\mathbf{t}}\mathbf{E}$ and $\gamma_N\mathbf{E}$ for the electric field. There is a wealth of integral formulations for the exterior electromagnetic boundary value problem. A comprehensive survey is given in Nédélec's recent monograph [45]. In principle, all these methods furnish the Dirichlet-to-Neumann map. However, in many cases, in particular with so-called indirect formulations, the resulting operator lacks structural properties of the Dirichlet-to-Neumann map. This is blatantly obvious in the case of second order elliptic problems [40]. If structure is not preserved, then the linear systems of equations obtained through Galerkin boundary element discretization are adversely affected.

For second order elliptic problems Costabel [23] discovered that the so-called direct boundary integral equations provide a remedy. The key concept is that of the Calderón projector acting on the Cauchy data of the problem. For details and theoretical examinations we refer to [17, sect. 4.5] and [29]. In short, the Calderón projector supplies two sets of boundary integral equations. Judiciously combining them yields a version of the Dirichlet-to-Neumann map that perfectly lends itself to a Galerkin discretization. The realization of Costabel's idea is called the "symmetric coupling approach" to marrying finite elements and boundary elements. It has been applied to a wide range of (strongly elliptic) problems; see, among many others, [15, 37, 41].

Unsurprisingly, the Calderón projector for the Maxwell system has been amply studied (cf. [16, sect. 1.3.2], [32], [45, sect. 5.5], and [39, sect. 3]). The idea of symmetric coupling for the transmission problem was theoretically probed in [1, 2, 3], and in [6] for a related problem involving impedance boundary conditions. All these theoretical results employ compactness arguments and the Fredholm alternative. To this end, most authors have meticulously studied the integral operators on Γ. They have completely succeeded on smooth boundaries, but all efforts to adjust the approach to nonsmooth boundaries have been in vain.

It was fundamental new insights about the trace spaces of electromagnetic fields, presented in [8, 10, 11, 13], that cleared the road to further progress. That progress could finally be achieved by remembering a highly effective policy in the modern treatment of boundary integral equations: The guideline is to stay off the boundary as far as possible by studying variational problems instead of the boundary integral operators directly. This policy has demonstrated its efficacy in the work of Costabel [24]. The recent textbook [43] discusses all nuances of this approach for strongly elliptic boundary value problems. Moving off the boundary helps steer clear of its awkward geometric features. Thus, the foundation for a theory of electromagnetic boundary integral operators on nonsmooth boundaries could be laid in [14].

In addition, in order to harness compactness arguments, we have to employ decompositions of surface vectorfields, on whose components the boundary integral operators will be considered. The classical decomposition is the so-called Hodge decomposition [32], which remains a very effective tool on piecewise smooth boundaries (see [12, 38] and, in particular, [14]). Its counterpart on domains is the Helmholtz decomposition. It is important to realize that there is some leeway in choosing the decomposition, because the exact orthogonality featured by Hodge and Helmholtz decompositions is of minor importance. Instead, we prefer to use related, but simpler, splittings.

All BIE for the exterior Dirichlet problem in electromagnetic scattering and acoustics are haunted by the presence of "forbidden frequencies" [14, 12, 18], for which the equations fail to have a unique solution. Those agree with interior Dirichlet eigenvalues. The symmetrically coupled problem investigated in this paper exhibits the same drawback. Therefore we have to resign ourselves to making the following assumption about the uniqueness of the solutions of the interior Dirichlet problem with constant coefficients.

Assumption 1. If $\mathbf{curl}\,\mathbf{curl}\,\mathbf{U} - \kappa^2\mathbf{U} = 0$ in Ω_s and $\gamma_{\mathbf{t}}\mathbf{U} = 0$ on Γ, then necessarily $\mathbf{U} = 0$.

To discretize the symmetrically coupled problem, we rely on discrete differential forms (edge elements, face elements) on triangulations of both Ω_s and Γ. The Galerkin approach is straightforward, and yet, in the discrete setting another challenge arises, because the continuous decompositions do not directly carry over to the discrete spaces. For pure indirect boundary element formulations (Rumsey's principle) remedies have been explored in [18] and [38]. Direct BIE were successfully tackled in [14]. All these approaches exploit the fact that appropriate discrete splittings can approximate their continuous counterparts reasonably well. In this paper we adapt the ideas pioneered in [14] to the symmetrically coupled FEM-BEM problem. At the heart of the developments will be symmetry and compactness properties of the Calderón projector, which were first established in [14]. We will use variants of these results that do not rely on any sophisticated results on elliptic regularity.

The plan of the paper is as follows. In the next section we discuss the rationale behind the use of decompositions. Then, the theory of tangential traces is reviewed in section 3. After that we introduce the potentials that supply the building blocks for the Stratton–Chu representation formula. These potentials spawn integral operators that are examined in section 5. The coupled variational formulation of the entire scattering problem is derived in section 6. In section 7 we construct decompositions of fields in Ω_s and on Γ. These decompositions give rise to a split variational problem that is shown to be coercive in section 8. Up to this point everything is aimed at the analysis of the continuous variational problem. Then, section 9 is devoted to the spaces of finite elements and boundary elements used for the Galerkin discretization of the coupled problem. Discrete counterparts of the continuous decompositions are presented in section 10. Abstract conditions that the discrete decompositions have to meet are put forth in section 11, which is also devoted to their verification for the concrete decompositions. Finally, in section 12, we give quantitative a priori convergence estimates.

2. Electromagnetic versus acoustic scattering. What is the point of this paper in light of the fairly general theory of symmetric coupling for strongly elliptic boundary value problems? To elucidate this, let us consider the apparently similar problem of time-harmonic acoustic scattering governed by the Helmholtz equation

$$-\Delta\rho - \kappa^2\rho = 0 \quad \text{in } \Omega'.$$

This is a showcase example for the application of the general theory. What accounts for the fundamental difference between electromagnetism and acoustics? Both phenomena, from a physical point of view, are marked by an incessant conversion of energies. In acoustics, potential and kinetic energy of the fluid are converted into each other; in electromagnetism, the same roles are played by the electric and magnetic energy. In acoustics the kinetic energy (with respect to a bounded control volume Ω) is a compact perturbation of the potential energy. Just remember that those are associated with the squared $L^2(\Omega)$- and $H^1(\Omega)$-norms, respectively. Therefore we can clearly single out the Laplacian as the principal part of the Helmholtz operator. This paves the way for proofs of coercivity based on "ignoring" the kinetic energy altogether.

Conversely, for the electric wave equation, the electric energy described by $\|\mathbf{E}\|^2_{\boldsymbol{L}^2(\Omega)}$ is by no means a compact perturbation of the magnetic energy, which is measured by $\|\mathbf{curl}\,\mathbf{E}\|^2_{\boldsymbol{L}^2(\Omega)}$. Both energies are completely symmetric, and none can be given preference at the expense of the other: No term in the differential operator $\mathbf{curl}\,\mathbf{curl}\,\mathbf{E} - \kappa^2\mathbf{E}$ plays the role of a principal part. Formally speaking, the operator of the electric wave equation lacks the essential property of strong ellipticity. However, this is what is required by standard arguments involving compact perturbations.

There is a way to promote one type of energy to dominate the other. This is called *regularization* and is usually done by imposing some constraint on the divergence of the electric field [35, 6, 28]. Regularization is problematic, because $\boldsymbol{H}(\mathbf{curl};\Omega)\cap\boldsymbol{H}(\mathrm{div};\Omega)$ is still not compactly embedded in $\boldsymbol{L}^2(\Omega)$ [4, Prop. 2.7]. In [35] this forces a separation of the surface on which the integral operators are defined and the surface on which they are evaluated in order to salvage coercivity. An alternative consists of tampering with the transmission conditions as in [6, 28, 25], but equivalence to the original problem holds only for smooth Γ.

The superior alternative to regularization is the *splitting* of the fields into two components. One set of components, called the electric, will feature dominant electric energy. With the other set, the magnetic quantities, the situation is reversed. This will promote either **curl curl** or Id to the role of a principal part. As a consequence, on each component the electric wave equation should be amenable to a treatment along the lines of the classical theory.

To find a suitable splitting, we can take our cue from a stationary situation. There, we find that valid electric fields are irrotational. In a nonstationary situation, magnetic induction generates another solenoidal contribution to $\mathbf{E}$. Thus, we have arrived at a Helmholtz decomposition

$$\mathbf{E} = \mathbf{grad}\,\varphi + \mathbf{curl}\,\mathbf{A}$$

of the electric field. The first term has an "electric nature," and the second can be labeled "magnetic." The reader should not be misled by the symbol $\mathbf{E}$ and the parlance "electric field": For positive wave numbers both $\mathbf{E}$ and $\mathbf{H}$ have a twin electric and magnetic nature.

Similar considerations apply to the Cauchy data $\gamma_{\mathbf{t}}\mathbf{E}$ and $\gamma_N\mathbf{E}$. A splitting of $\gamma_{\mathbf{t}}\mathbf{E}$ is instantly induced by the Helmholtz decomposition, and the electric and magnetic parts are also clear from it. In the case of $\gamma_N\mathbf{E}$, which is a rotated tangential trace of the magnetic field, we remember that it is commonly viewed as a "surface current." Hence, its divergence-free components are currents not accompanied by surface charges; they qualify as "magnetic quantities." Currents in a complement space inevitably generate surface charges. Thus, they can be regarded as "electric." This suggests that we start out from the *Hodge decomposition*

$$\gamma_N\mathbf{E} = \mathbf{curl}_\Gamma\varphi + \mathbf{grad}_\Gamma\,\psi$$

of the surface currents, in order to deal with the BIE.

3. Traces and spaces. The natural Hilbert space setting for the analysis of the transmission problem (1.1) is provided by the spaces

$$\boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl};\Omega) := \{\mathbf{V} \in \boldsymbol{L}^2_{\mathrm{loc}}(\Omega),\, \mathbf{curl}\,\mathbf{V} \in \boldsymbol{L}^2_{\mathrm{loc}}(\Omega)\}.$$

Here and in what follows, Ω is a "generic domain," which can either be Ω_s or Ω'. For a thorough examination of these spaces and notations, we refer to [33, Chap. 1].

The Sobolev spaces of scalar functions and related functionals, $H^s(\Gamma)$ and $H^{-s}(\Gamma)$, can be defined invariantly for $0 \le s \le 1$ [34, Sect. 1.3.3]. In addition, we write $\gamma : H^s_{\mathrm{loc}}(\Omega) \mapsto H^{s-\frac{1}{2}}(\Gamma)$, $\frac{1}{2} < s < \frac{3}{2}$, for the usual trace operator [43, Thm. 3.38]. Superscripts $-$ and $+$ will be attached to the trace operators, when it is important whether they act from Ω_s or Ω', respectively.

If Γ is a curvilinear Lipschitz polyhedron (cf. the introduction of [26]) with smooth components Γ_j, $j = 1, \dots, N_\Gamma$, we set

$$\begin{aligned} H^s(\Gamma) :=& \{u \in H^1(\Gamma),\, u_{|\Gamma_j} \in H^s(\Gamma_j),\, j = 1\dots, N_\Gamma\} \quad \text{for } s > 1,\\ \boldsymbol{H}^s_{\mathbf{t}}(\Gamma) :=& \{\mathbf{u} \in \boldsymbol{L}^2_{\mathbf{t}}(\Gamma),\, \mathbf{u}_{|\Gamma_j} \in \boldsymbol{H}^s(\Gamma_j),\, j = 1, \dots, N_\Gamma\} \quad \text{for } s \ge 0, \end{aligned}$$

where $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma) := \{\mathbf{u} \in (L^2(\Gamma))^3, \mathbf{u}\cdot\mathbf{n} = 0\}$. All these spaces are equipped with the natural graph norms.

The tangential components trace $\gamma_{\mathbf{t}}$ and the twisted tangential trace $\gamma_\times$, for $\mathbf{U} \in \boldsymbol{C}^\infty(\bar{\Omega})$ defined by $\gamma_{\mathbf{t}}\mathbf{U}(\mathbf{x}) := \mathbf{n}(\mathbf{x}) \times (\mathbf{U}(\mathbf{x}) \times \mathbf{n}(\mathbf{x}))$ and $\gamma_\times\mathbf{U}(\mathbf{x}) := \mathbf{U}(\mathbf{x}) \times \mathbf{n}(\mathbf{x})$ a.e. on Γ, play a central role in the mathematical treatment of the Maxwell transmission problem. Their extension to $\boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl};\Omega)$ was accomplished for piecewise smooth boundaries in [10, 8] and for Lipschitz domains in [13]. These articles and section 2 of [12] supply the main references for the current section.

THEOREM 3.1. *There are intrinsically defined spaces* $\boldsymbol{H}^{1/2}_{||}(\Gamma), \boldsymbol{H}^{1/2}_{\perp}(\Gamma) \subset \boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ *such that the tangential trace mappings* $\gamma_{\mathbf{t}}{}^{\pm}/\gamma^{\pm}_{\times} : \boldsymbol{H}^1_{\mathrm{loc}}(\Omega) \mapsto \boldsymbol{H}^{1/2}_{||}(\Gamma)/\boldsymbol{H}^{1/2}_{\perp}(\Gamma)$, $\Omega = \Omega', \Omega_s$, *are continuous, surjective and possess continuous right inverses.*

Proof. See Proposition 1.7 in [10] and [13, sect. 2]. □

The associated dual spaces will be denoted by $\boldsymbol{H}^{-1/2}_{||}(\Gamma)$ and $\boldsymbol{H}^{-1/2}_{\perp}(\Gamma)$, respectively, where the sesqui-linear duality pairings $\langle\cdot,\cdot\rangle_{\frac{1}{2},||,\Gamma} : \boldsymbol{H}^{-1/2}_{||}(\Gamma) \times \boldsymbol{H}^{1/2}_{||}(\Gamma) \mapsto \mathbb{C}$,

$\langle\cdot,\cdot\rangle_{\frac{1}{2},\perp,\Gamma} : \boldsymbol{H}_{\perp}^{-1/2}(\Gamma) \times \boldsymbol{H}_{\perp}^{1/2}(\Gamma) \mapsto \mathbb{C}$ are taken with $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ as pivot space.

The classical Rellich theorem can also be applied to the tangential trace spaces as follows.

Lemma 3.2. *The embeddings* $\boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma), \boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma) \hookrightarrow \boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ *are compact.*

Based on surface differential operators (cf. section 3 of [13]) we can define

$$\begin{aligned}\boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma) =&\{\mathbf{v} \in \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma),\ \mathrm{curl}_{\Gamma}\,\mathbf{v} \in H^{-\frac{1}{2}}(\Gamma)\},\\ \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) =&\{\boldsymbol{\zeta} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma),\ \mathrm{div}_{\Gamma}\boldsymbol{\zeta} \in H^{-\frac{1}{2}}(\Gamma)\}.\end{aligned}$$

These spaces are endowed with natural graph norms. They are important as suitable trace spaces for vectorfields in $\boldsymbol{H}(\mathbf{curl};\Omega)$ (see [10, Thms. 2.7, 2.8], [11, Thm. 4.5], [8], [13, sect. 4]).

Theorem 3.3. *The trace mappings* $\gamma_{\mathbf{t}}{}^{+} : \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl};\Omega') \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma)$, $\gamma_{\mathbf{t}}{}^{-} : \boldsymbol{H}(\mathbf{curl};\Omega_s) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma)$ *and* $\gamma_{\times}^{+} : \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl};\Omega') \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$, $\gamma_{\times}^{-} : \boldsymbol{H}(\mathbf{curl};\Omega_s) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ *are continuous and surjective with continuous right inverses* $\mathsf{F}^{\pm}_{\mathbf{t}}, \mathsf{F}^{\pm}_{\times}$.

We learn that $\boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma)$ is exactly the right space for the Dirichlet data $\gamma_{\mathbf{t}}{}^{\pm}\mathbf{E}$ in (1.1). Hence, we adopt the alternative notation γ_D for $\gamma_{\mathbf{t}}$ to stress that this is the right "Dirichlet trace." As demonstrated in [11, sect. 4], $\boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma)$ and $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ can be put in duality when $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ is used as pivot space. More precisely, the usual $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$-inner product can be extended to a sesqui-linear duality pairing

$$\langle\cdot,\cdot\rangle_{\boldsymbol{\tau}} : \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma) \times \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma) \mapsto \mathbb{C}$$

by means of Green's formula ("+" for $\Omega = \Omega_s$)

$$\mp \int_{\Omega} \overline{\mathbf{U}} \cdot \mathbf{curl}\,\mathbf{V} - \mathbf{curl}\,\overline{\mathbf{U}} \cdot \mathbf{V}\, d\mathbf{x} = \left\langle \gamma_{\times}^{\pm}\mathbf{V}, \gamma_{\mathbf{t}}{}^{\pm}\mathbf{U}\right\rangle_{\boldsymbol{\tau}} \quad \forall \mathbf{U},\mathbf{V} \in \boldsymbol{H}(\mathbf{curl};\Omega)\ .$$

An overbar designates complex conjugation.[1] A ubiquitous device is the surface twist operator R, for continuous tangential vectorfields given by $(\mathsf{R}\mathbf{u})(\mathbf{x}) := (\mathbf{n}\times\mathbf{u})(\mathbf{x})$ for almost all $\mathbf{x} \in \Gamma$. It gives rise to an isometric mapping $\mathsf{R} : \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_{\Gamma},\Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$.

We will also need the normal components trace $\gamma_{\mathbf{n}}$ with $\gamma_{\mathbf{n}}\mathbf{U}(\mathbf{x}) = \mathbf{n}(\mathbf{x})\cdot\mathbf{U}(\mathbf{x})$ for almost all $\mathbf{x} \in \Gamma$ and $\mathbf{U} \in C^{\infty}(\bar{\Omega})$. It can be extended to a continuous and surjective mapping $\gamma_{\mathbf{n}} : \boldsymbol{H}(\mathrm{div};\Omega) \mapsto H^{-\frac{1}{2}}(\Gamma)$ [33, Thm. 2.5].

Beside the Dirichlet trace γ_D, the transmission conditions of (1.1) feature a second trace γ_N, aptly called a Neumann trace. It has to be introduced in a weak sense: For

$$\mathbf{U} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2,\Omega) := \{\mathbf{V} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl};\Omega),\ \mathbf{curl}\,\mathbf{curl}(\mathbf{v}) \in \boldsymbol{L}^2_{\mathrm{loc}}(\Omega)\}$$

we define $\gamma_N^{\pm}\mathbf{U} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_{\Gamma},\Gamma)$ by

$$\mp \int_{\Omega} \mathbf{curl}\,\mathbf{U} \cdot \mathbf{curl}\,\overline{\mathbf{V}} - \mathbf{curl}\,\mathbf{curl}\,\mathbf{U} \cdot \overline{\mathbf{V}}\, d\mathbf{x} = \left\langle \gamma_N^{\pm}\mathbf{U}, \gamma_D^{\pm}\mathbf{V}\right\rangle_{\boldsymbol{\tau}}$$

[1] We adopt the following convention: Surface vectorfields in $\boldsymbol{H}^{-1/2}(\mathbf{curl}_{\Gamma},\Gamma)$ will be written in small bold Roman print, those in $\boldsymbol{H}^{-1/2}(\mathrm{div}_{\Gamma},\Gamma)$ in small bold Greek characters. Capital bold Roman symbols are used for vectorfields in Ω_s or Ω'. Regular print marks scalar quantities.

for all compactly supported $\mathbf{V} \in \boldsymbol{H}(\mathbf{curl};\Omega)$, where "+" applies to $\Omega = \Omega_s$. Obviously, for smooth fields we recover $\gamma_N \mathbf{U} = \gamma_\times(\mathbf{curl}\,\mathbf{U}) = \mathbf{curl}\,\mathbf{U} \times \mathbf{n}$.

Lemma 3.4 (see [37, Lem. 3.3]). *The traces* $\gamma_N^\pm$ *furnish continuous mappings* $\gamma_N^+ : \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega') \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ *and* $\gamma_N^- : \boldsymbol{H}(\mathbf{curl}^2, \Omega_s) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$.

4. Potentials.

In [12, sect. 3], in [16, Chap. 3, sect. 1.3.2], and in [45, sect. 5.5] the *Stratton–Chu representation formula* is derived. It states that any distribution $\mathbf{U} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega')$ that satisfies

$$\mathbf{curl}\,\mathbf{curl}\,\mathbf{U} - \kappa^2 \mathbf{U} = 0 \quad \text{in } \Omega' \tag{4.1}$$

and the Silver–Müller radiation conditions can be written as

$$\mathbf{U} = \boldsymbol{\Psi}_{\mathbf{M}}^\kappa(\gamma_D^+\mathbf{U}) - \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\gamma_N^+\mathbf{U}) - \mathbf{grad}\,\Psi_V^\kappa(\gamma_{\mathbf{n}}^+\mathbf{U}) \quad \text{in } \Omega'. \tag{4.2}$$

Here, $\boldsymbol{\Psi}_{\mathbf{M}}^\kappa(\cdot)$, $\boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\cdot)$, and $\Psi_V^\kappa(\cdot)$ are *potentials*, i.e, in our parlance, mappings of boundary data to functions defined everywhere off the boundary. In detail, based on the Helmholtz kernel $E_\kappa(\mathbf{x}, \mathbf{y}) := \exp(i\kappa|\mathbf{x} - \mathbf{y}|)/4\pi|\mathbf{x} - \mathbf{y}|$, $\mathbf{x} \neq \mathbf{y}$, Ψ_V^κ is the scalar single layer potential, given by

$$\Psi_V^\kappa(\phi)(\mathbf{x}) := \int_\Gamma E_\kappa(\mathbf{x}, \mathbf{y})\phi(\mathbf{y})\, dS(\mathbf{y}), \quad \mathbf{x} \notin \Gamma, \tag{4.3}$$

and $\boldsymbol{\Psi}_{\mathbf{A}}^\kappa$ its cousin, the vectorial single layer potential

$$\boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\mu})(\mathbf{x}) := \int_\Gamma E_\kappa(\mathbf{x}, \mathbf{y})\boldsymbol{\mu}(\mathbf{y})\, dS(\mathbf{y}), \quad \mathbf{x} \notin \Gamma. \tag{4.4}$$

They are joined by the Maxwell double layer potential

$$\boldsymbol{\Psi}_{\mathbf{M}}^\kappa(\mathbf{u})(\mathbf{x}) := \mathbf{curl}_{\mathbf{x}}\, \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\mathsf{R}\mathbf{u})(\mathbf{x}), \quad \mathbf{x} \notin \Gamma.$$

A simplification of (4.2) is possible by observing that (cf. [13, eq. (26)])

$$\mathrm{div}_\Gamma(\gamma_N^+\mathbf{U}) = \gamma_{\mathbf{n}}^+(\mathbf{curl}\,\mathbf{curl}\,\mathbf{U}) = \kappa^2(\gamma_{\mathbf{n}}^+\mathbf{U}) \quad \text{in } H^{-\frac{1}{2}}(\Gamma) \tag{4.5}$$

for all $\mathbf{U} \in \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega')$ satisfying (4.1). This enables us to get rid of the normal components trace in (4.2). We end up with

$$\mathbf{U} = \boldsymbol{\Psi}_{\mathbf{M}}^\kappa(\gamma_D^+\mathbf{U}) - \boldsymbol{\Psi}_{\mathbf{S}}^\kappa(\gamma_N^+\mathbf{U}) \quad \text{in } \Omega', \tag{4.6}$$

where we introduced the Maxwell single layer potential according to

$$\boldsymbol{\Psi}_{\mathbf{S}}^\kappa(\boldsymbol{\mu})(\mathbf{x}) := \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\mu})(\mathbf{x}) + \frac{1}{\kappa^2}\mathbf{grad}_{\mathbf{x}}\, \Psi_V^\kappa(\mathrm{div}_\Gamma\boldsymbol{\mu})(\mathbf{x}). \tag{4.7}$$

Lemma 4.1 (see [24], [37, Thm. 5.1]). *The single layer potentials* $\boldsymbol{\Psi}_{\mathbf{A}}^\kappa$ *and* Ψ_V^κ *give rise to continuous mappings* $\Psi_V^\kappa : H^{-1/2}(\Gamma) \mapsto H^1_{\mathrm{loc}}(\mathbb{R}^3)$, $\boldsymbol{\Psi}_{\mathbf{A}}^\kappa : \boldsymbol{H}_{||}^{-1/2}(\Gamma) \mapsto \boldsymbol{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$.

Lemma 4.2 (see [42, Lem. 2.3]). *For* $\mathbf{u} \in \boldsymbol{H}^{-1/2}(\mathrm{div}_\Gamma, \Gamma)$ *we have* $\mathrm{div}\, \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\mathbf{u}) = \Psi_V^\kappa(\mathrm{div}_\Gamma\mathbf{u})$ *in* $\boldsymbol{L}^2(\mathbb{R}^3)$.

From this we get the identities

$$(\mathbf{curl}\,\mathbf{curl} - \kappa^2 Id)\boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\mu}) = \mathbf{grad}\,\Psi_V^\kappa(\mathrm{div}_\Gamma\boldsymbol{\mu}) \quad \forall \boldsymbol{\mu} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma), \tag{4.8}$$

$$(\mathbf{curl}\,\mathbf{curl} - \kappa^2 Id)\boldsymbol{\Psi}_{\mathbf{M}}^\kappa(\mathbf{u}) = 0 \qquad \forall \mathbf{u} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma), \tag{4.9}$$

off the boundary Γ in the pointwise sense and, globally, in $\boldsymbol{L}^2_{\mathrm{loc}}(\mathbb{R}^3)$. Summing up, both $\boldsymbol{\Psi}^\kappa_{\mathbf{M}}$ and $\boldsymbol{\Psi}^\kappa_{\mathbf{S}}$ are radiating solutions of the homogeneous electric wave equation in $\Omega_s \cup \Omega'$.

From these relationships and Lemma 4.1 we infer the following continuity properties.

Theorem 4.3. *The mappings* $\boldsymbol{\Psi}^\kappa_{\mathbf{S}} : \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega_s \cup \Omega')$ *and* $\boldsymbol{\Psi}^\kappa_{\mathbf{M}} : \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{\mathrm{loc}}(\mathbf{curl}^2, \Omega_s \cup \Omega')$ *are continuous.*

The potentials also satisfy fundamental *jump relations* (cf. [22, Thm. 6.11], [45, Thm. 5.5.1], [37, sect. 5]).

Theorem 4.4. *The interior and exterior Dirichlet and Neumann traces of the potentials* $\boldsymbol{\Psi}^\kappa_{\mathbf{S}}$ *and* $\boldsymbol{\Psi}^\kappa_{\mathbf{M}}$ *are well defined and fulfill for* $\boldsymbol{\mu} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$, $\mathbf{u} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma)$,

$$[\gamma_D \boldsymbol{\Psi}^\kappa_{\mathbf{S}}(\boldsymbol{\mu})]_\Gamma = 0, \quad [\gamma_N \boldsymbol{\Psi}^\kappa_{\mathbf{S}}(\boldsymbol{\mu})]_\Gamma = -\boldsymbol{\mu}, \quad [\gamma_D \boldsymbol{\Psi}^\kappa_{\mathbf{M}}(\mathbf{u})]_\Gamma = \mathbf{u}, \quad [\gamma_N \boldsymbol{\Psi}^\kappa_{\mathbf{M}}(\mathbf{u})]_\Gamma = 0.$$

This theorem in conjunction with Lemma 4.2 and $\boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\mathsf{R}\mathbf{u}) \in \boldsymbol{H}^1_{\mathrm{loc}}(\mathbb{R}^3)$ supplies further jump relations:

$$[\gamma_{\mathbf{n}} \boldsymbol{\Psi}^\kappa_{\mathbf{M}}(\mathbf{u})]_\Gamma = 0, \qquad [\gamma \,\mathrm{div}\, \boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\boldsymbol{\mu})]_\Gamma = 0. \tag{4.10}$$

5. Integral operators. In the usual fashion, we obtain the relevant boundary integral operators by applying Dirichlet and Neumann trace operators to the potentials of the representation formula.

Lemma 5.1. *The integral operators* $\mathbf{A}_\kappa := \gamma_D \boldsymbol{\Psi}^\kappa_{\mathbf{A}} : \boldsymbol{H}^{-1/2}_{||}(\Gamma) \mapsto \boldsymbol{H}^{1/2}_{||}(\Gamma)$, $\tilde{\mathbf{A}}_\kappa := \gamma_\times \boldsymbol{\Psi}^\kappa_{\mathbf{A}} \circ \mathsf{R} : \boldsymbol{H}^{-1/2}_{\perp}(\Gamma) \mapsto \boldsymbol{H}^{1/2}_{\perp}(\Gamma)$, *and* $V_\kappa := \gamma \Psi^\kappa_V : H^{-1/2}(\Gamma) \mapsto H^{1/2}(\Gamma)$ *are continuous.*

Proof. The assertion is immediate by combining Theorem 4.3 with Theorem 3.1 and properties of the standard trace γ. □

Theorem 5.2. *The following integral operators are continuous:*

$$\begin{aligned}
\mathbf{S}_\kappa &:= \gamma_D \boldsymbol{\Psi}^\kappa_{\mathbf{S}} &&: \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma),\\
\mathbf{B}_\kappa &:= \frac{1}{2}(\gamma_N^+ + \gamma_N^-) \boldsymbol{\Psi}^\kappa_{\mathbf{A}} &&: \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma),\\
\mathbf{C}_\kappa &:= \frac{1}{2}(\gamma_D^+ + \gamma_D^-) \boldsymbol{\Psi}^\kappa_{\mathbf{M}} &&: \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma),\\
\mathbf{N}_\kappa &:= \gamma_N \boldsymbol{\Psi}^\kappa_{\mathbf{M}} &&: \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma).
\end{aligned}$$

Proof. The continuity properties instantly follow from those of the potentials stated in Theorem 4.3, and the continuity of the trace operators from Theorem 3.3 and Lemma 3.4. □

Beyond continuity, the integral operators possess numerous important properties. In particular, they are closely related as expressed in the next two lemmas.

Lemma 5.3 (see [21, eq. (3.86)]). *The identity* $\mathbf{N}_\kappa = \mathsf{R}^* \circ \mathbf{S}_\kappa \circ \mathsf{R}$ *holds true.*

Lemma 5.4. *There is a compact linear operator* $T_\kappa : \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ *such that*

$$\langle \mathbf{B}_\kappa \boldsymbol{\zeta}, \mathbf{q} \rangle_{\boldsymbol{\tau}} = \langle \boldsymbol{\zeta}, \mathbf{C}_\kappa \mathbf{q} \rangle_{\boldsymbol{\tau}} - \langle T_\kappa \boldsymbol{\zeta}, \mathbf{q} \rangle_{\boldsymbol{\tau}} \quad \forall \boldsymbol{\zeta} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma),\ \mathbf{q} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma).$$

Proof. The proof follows that of [14, Thm. 3.9]. We fix $\rho > 0$ such that $\bar{\Omega}_s$ is contained in the ball $B_\rho := \{\mathbf{x} \in \mathbb{R}^3, |\mathbf{x}| < \rho\}$. Traces onto ∂B_ρ bear a $\widehat{\ }$. Set $\mathbf{U} := \boldsymbol{\Psi}^\kappa_{\mathbf{A}}(\boldsymbol{\zeta})$, $\mathbf{V} := \boldsymbol{\Psi}^\kappa_{\mathbf{M}}(\mathbf{q})$, and observe that (4.9) involves

$$\begin{aligned}\left\langle \gamma_N^+ \mathbf{V}, \gamma_D^+ \mathbf{U} \right\rangle_{\boldsymbol{\tau}} &= -\int_{\Omega^\rho} \mathbf{curl}\,\mathbf{V} \cdot \mathbf{curl}\,\overline{\mathbf{U}} - \mathbf{curl}\,\mathbf{curl}\,\mathbf{V} \cdot \overline{\mathbf{U}}\,d\mathbf{x} + \langle \widehat{\gamma}_N \mathbf{V}, \widehat{\gamma}_D \mathbf{U} \rangle_{\boldsymbol{\tau},\partial B_\rho} \\ &= -\int_{\Omega^\rho} \mathbf{curl}\,\mathbf{V} \cdot \mathbf{curl}\,\overline{\mathbf{U}}\,d\mathbf{x} + \int_{\Omega^\rho} \kappa^2 \mathbf{V} \cdot \overline{\mathbf{U}}\,d\mathbf{x} + \langle \widehat{\gamma}_N \mathbf{V}, \widehat{\gamma}_D \mathbf{U} \rangle_{\boldsymbol{\tau},\partial B_\rho}, \\ \left\langle \gamma_N^- \mathbf{V}, \gamma_D^- \mathbf{U} \right\rangle_{\boldsymbol{\tau}} &= \int_{\Omega_s} \mathbf{curl}\,\mathbf{V} \cdot \mathbf{curl}\,\overline{\mathbf{U}} - \kappa^2 \mathbf{V} \cdot \overline{\mathbf{U}}\,d\mathbf{x}.\end{aligned}$$

The jump relations of Theorem 4.4 reveal that both expressions agree. Moreover, since $\operatorname{div}\mathbf{V} = 0$ in $\Omega_s \cup \Omega'$,

$$\begin{aligned}\left\langle \gamma_N^- \mathbf{U}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} &= \int_{\Omega_s} \mathbf{curl}\,\mathbf{U} \cdot \mathbf{curl}\,\overline{\mathbf{V}} - \mathbf{curl}\,\mathbf{curl}\,\mathbf{U} \cdot \overline{\mathbf{V}}\,d\mathbf{x} \\ &= \int_{\Omega_s} \mathbf{curl}\,\mathbf{U} \cdot \mathbf{curl}\,\overline{\mathbf{V}} - \left(\kappa^2 \mathbf{U} + \mathbf{grad}\,\Psi_V^\kappa(\operatorname{div}_\Gamma \boldsymbol{\zeta})\right) \overline{\mathbf{V}}\,d\mathbf{x} \\ &= \overline{\left\langle \gamma_N^- \mathbf{V}, \gamma_D^- \mathbf{U} \right\rangle_{\boldsymbol{\tau}}} - \overline{\left\langle \gamma_{\mathbf{n}}^- \mathbf{V}, \gamma^- \Psi_V^\kappa(\operatorname{div}_\Gamma \boldsymbol{\zeta}) \right\rangle_{\frac{1}{2},\Gamma}}\end{aligned}$$

and

$$\begin{aligned}\left\langle \gamma_N^+ \mathbf{U}, \gamma_D^+ \mathbf{V} \right\rangle_{\boldsymbol{\tau}} &= -\int_{\Omega^\rho} \mathbf{curl}\,\mathbf{U} \cdot \mathbf{curl}\,\overline{\mathbf{V}} - \mathbf{curl}\,\mathbf{curl}\,\mathbf{U} \cdot \overline{\mathbf{V}}\,d\mathbf{x} + \langle \widehat{\gamma}_N \mathbf{U}, \widehat{\gamma}_D \mathbf{V} \rangle_{\boldsymbol{\tau}} \\ &= -\int_{\Omega^\rho} \mathbf{curl}\,\mathbf{U} \cdot \mathbf{curl}\,\overline{\mathbf{V}}\,d\mathbf{x} + \int_{\Omega^\rho} \left(\kappa^2 \mathbf{U} + \mathbf{grad}\,\Psi_V^\kappa(\operatorname{div}_\Gamma \boldsymbol{\zeta})\right) \overline{\mathbf{V}}\,d\mathbf{x} + \langle \widehat{\gamma}_N \mathbf{U}, \widehat{\gamma}_D \mathbf{V} \rangle_{\boldsymbol{\tau}} \\ &= \overline{\left\langle \gamma_N^+ \mathbf{V}, \gamma_D^+ \mathbf{U} \right\rangle_{\boldsymbol{\tau}}} - \overline{\left\langle \gamma_{\mathbf{n}}^+ \mathbf{V}, \gamma^+ \Psi_V^\kappa(\operatorname{div}_\Gamma \boldsymbol{\zeta}) \right\rangle_{\frac{1}{2},\Gamma}} + \overline{\langle \widehat{\gamma}_{\mathbf{n}} \mathbf{V}, \widehat{\gamma} \Psi_V^\kappa(\operatorname{div}_\Gamma \boldsymbol{\zeta}) \rangle_{1/2,\partial B_\rho}} \\ &\qquad - \overline{\langle \widehat{\gamma}_N \mathbf{V}, \widehat{\gamma}_D \mathbf{U} \rangle_{\boldsymbol{\tau}}} + \langle \widehat{\gamma}_N \mathbf{U}, \widehat{\gamma}_D \mathbf{V} \rangle_{\boldsymbol{\tau}}.\end{aligned}$$

From the extra jump relation (4.10) we infer

$$\left\langle \gamma_N^- \mathbf{U}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \quad = \quad \left\langle \gamma_N^+ \mathbf{U}, \gamma_D^+ \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \quad + \quad \{\text{Potentials evaluated on } \partial B_\rho\}. \tag{5.1}$$

The potentials, when restricted to domains off the boundary Γ, are C^∞-smoothing (cf. the proof of Theorem 7.6 in [43]). Thus their evaluations on ∂B_ρ will lead to compact operators. Plugging in the definitions of the boundary integral operators, (5.1) gives the assertion. □

Since, ultimately, we aim to resort to a Fredholm alternative argument, compactness properties of the boundary integral operators deserve special attention. It will be crucial that we are able to switch to the "Laplace kernel" E_0 by a compact perturbation only.

LEMMA 5.5 (see [14, Thm. 3.12], [38, Lem. 3.2]). *The following integral operators are compact:*

$$\begin{aligned}\delta\mathbf{A}_\kappa &:= \mathbf{A}_\kappa - \mathbf{A}_0 &&: \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_{||}^{\frac{1}{2}}(\Gamma), \\ \delta\tilde{\mathbf{A}}_\kappa &:= \tilde{\mathbf{A}}_\kappa - \tilde{\mathbf{A}}_0 &&: \boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}_{\perp}^{\frac{1}{2}}(\Gamma), \\ \delta V_\kappa &:= V_\kappa - V_0 &&: H^{-\frac{1}{2}}(\Gamma) \mapsto H^{\frac{1}{2}}(\Gamma), \\ \delta\mathbf{N}_\kappa &:= \mathbf{N}_\kappa - \mathbf{N}_0 &&: \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma, \Gamma) \mapsto \boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma, \Gamma).\end{aligned}$$

The significance of the case $\kappa = 0$ is highlighted by the following result (cf. [43, Cor. 8.13], [31, Vol. IV, Chap. XI, sect. 2, Thm. 3], [12, Prop. 4.1]).

LEMMA 5.6 (see [14, Thm. 3.8]). *The operators V_0, $\tilde{\mathbf{A}}_0$, and $\mathbf{A}_0$ are continuous, self-adjoint and fulfill*

$$\begin{aligned}
\langle \mu, V_0\mu\rangle_{\frac{1}{2},\Gamma} &\geq C\,\|\mu\|^2_{H^{-\frac{1}{2}}(\Gamma)} && \forall \mu \in H^{-\frac{1}{2}}(\Gamma),\\
\langle \boldsymbol{\mu}, \mathbf{A}_0\boldsymbol{\mu}\rangle_{\frac{1}{2},\|,\Gamma} &\geq C\,\|\boldsymbol{\mu}\|^2_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} && \forall \boldsymbol{\mu} \in \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma),\ \mathrm{div}_\Gamma\boldsymbol{\mu} = 0,\\
\langle \mathbf{v}, \tilde{\mathbf{A}}_0\mathbf{v}\rangle_{\frac{1}{2},\perp,\Gamma} &\geq C\,\|\mathbf{v}\|^2_{\boldsymbol{H}_{\perp}^{-\frac{1}{2}}(\Gamma)} && \forall \mathbf{v} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma,\Gamma),\ \mathbf{curl}_\Gamma\mathbf{v} = 0,
\end{aligned}$$

with constants[2] *$C > 0$ depending only on Γ.*

6. Coupled problem. Applying Green's formula to the electric wave equation in Ω_s results in the variational formulation: Seek $\mathbf{E} \in \boldsymbol{H}(\mathbf{curl};\Omega_s)$ such that

$$(6.1)\qquad \left(\mu_r^{-1}\,\mathbf{curl}\,\mathbf{E}, \mathbf{curl}\,\mathbf{V}\right)_{0;\Omega_s} - \kappa^2\left(\epsilon_r\mathbf{E},\mathbf{V}\right)_{0;\Omega_s} - \left\langle \frac{1}{\mu_r}\gamma_N^-\mathbf{E}, \gamma_D^-\mathbf{V}\right\rangle_{\boldsymbol{\tau}} = 0$$

for all $\mathbf{V} \in \boldsymbol{H}(\mathbf{curl};\Omega_s)$. The coupling to the exterior domain is taken into account through the transmission conditions from (1.1):

$$(6.2)\qquad \frac{1}{\mu_r}\gamma_N^-\mathbf{E} = \gamma_N^+\mathbf{E} + \gamma_N\mathbf{E}_{\mathrm{inc}}, \quad \gamma_D^-\mathbf{E} = \gamma_D^+\mathbf{E} + \gamma_D\mathbf{E}_{\mathrm{inc}}.$$

In addition, some realization of the exterior Dirichlet-to-Neumann map has to be provided. It is furnished by the *exterior Calderón projector*, which arises from applying both the exterior Dirichlet and Neumann traces to the representation formula (4.6) (cf. [32, eq. (29)], [45, sect. 5.5], [14, sect. 3.3], [39, eq. (24)]). The resulting identity reads in variational form: For all $\boldsymbol{\mu} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$, $\mathbf{v} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathbf{curl}_\Gamma,\Gamma)$ the following must hold:

$$(6.3)\qquad \begin{aligned}
\langle \boldsymbol{\mu}, \gamma_D^+\mathbf{E}\rangle_{\boldsymbol{\tau}} &= \left\langle \boldsymbol{\mu}, \left(\frac{1}{2}Id + \mathbf{C}_\kappa\right)(\gamma_D^+\mathbf{E})\right\rangle_{\boldsymbol{\tau}} - \langle \boldsymbol{\mu}, \mathbf{S}_\kappa(\gamma_N^+\mathbf{E})\rangle_{\boldsymbol{\tau}},\\
\langle \gamma_N^+\mathbf{E}, \mathbf{v}\rangle_{\boldsymbol{\tau}} &= \langle \mathbf{N}_\kappa(\gamma_D^+\mathbf{E}), \mathbf{v}\rangle_{\boldsymbol{\tau}} + \left\langle \left(\frac{1}{2}Id - \mathbf{B}_\kappa\right)(\gamma_N^+\mathbf{E}), \mathbf{v}\right\rangle_{\boldsymbol{\tau}}.
\end{aligned}$$

Now we can use the transmission conditions (6.2) and the second equation of the Calderón projector in order to replace the boundary term in (6.1). The trick underlying the symmetric coupling according to Costabel [23] is to retain the first equation of (6.3) in addition (cf. [32, sect. 4] for Maxwell's equations). Adopting the abbreviation $\boldsymbol{\lambda} := \gamma_N^+\mathbf{E}$, we arrive at the formulation: Seek $\mathbf{E} \in \boldsymbol{H}(\mathbf{curl};\Omega_s)$, $\boldsymbol{\lambda} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ such that for all $\mathbf{V} \in \boldsymbol{H}(\mathbf{curl};\Omega_s)$, $\boldsymbol{\mu} \in \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$

$$(6.4)\qquad \begin{aligned}
q_\kappa(\mathbf{E},\mathbf{V}) - \langle \mathbf{N}_\kappa\gamma_D^-\mathbf{E}, \gamma_D^-\mathbf{V}\rangle_{\boldsymbol{\tau}} + \left\langle \left(-\frac{1}{2}Id + \mathbf{B}_\kappa\right)\boldsymbol{\lambda}, \gamma_D^-\mathbf{V}\right\rangle_{\boldsymbol{\tau}} &= f(\mathbf{V}),\\
-\left\langle \boldsymbol{\mu}, \left(-\frac{1}{2}Id + \mathbf{C}_\kappa\right)(\gamma_D^-\mathbf{E})\right\rangle_{\boldsymbol{\tau}} + \langle \boldsymbol{\mu}, \mathbf{S}_\kappa\boldsymbol{\lambda}\rangle_{\boldsymbol{\tau}} &= g(\boldsymbol{\mu}),
\end{aligned}$$

[2] We use C to designate generic constants that may depend only on "fixed quantities" as Γ, κ, and the material parameters ϵ_r, μ_r. Their values might vary between different occurrences.

with right-hand sides $f(\mathbf{V}) := \left\langle \gamma_N \mathbf{E}_{\mathrm{inc}}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} - \left\langle \mathbf{N}_\kappa(\gamma_D \mathbf{E}_{\mathrm{inc}}), \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}}$, $g(\boldsymbol{\mu}) = -\left\langle \boldsymbol{\mu}, (\frac{1}{2} Id + \mathbf{C}_\kappa) \gamma_D \mathbf{E}_{\mathrm{inc}} \right\rangle_{\boldsymbol{\tau}}$, and $q_\kappa(\cdot,\cdot)$ representing the interior sesqui-linear form, that is, $q_\kappa(\mathbf{E},\mathbf{V}) := \left(\mu_r^{-1} \mathbf{curl}\, \mathbf{E}, \mathbf{curl}\, \mathbf{V}\right)_{0;\Omega_s} - \kappa^2 \left(\epsilon_r \mathbf{E}, \mathbf{V}\right)_{0;\Omega_s}$.

LEMMA 6.1. *Provided that Assumption* 1 *holds, a solution of* (6.4) *provides a solution of* (1.1) *by retaining* $\mathbf{E}$ *in* Ω_s *and using the representation formula* (4.6) *for the Cauchy data* $(\gamma_D^- \mathbf{E} + \gamma_D \mathbf{E}_{\mathrm{inc}}, \boldsymbol{\lambda})$ *in* Ω'.

Proof. Our approach is based on [49, sect. 4.3] and [14, sect. 5]. Testing with $\mathbf{V}$ that is compactly supported in Ω_s confirms that $\mathbf{E}$ satisfies (1.1) in Ω_s. We conclude (6.1) for any admissible $\mathbf{V}$. This renders (6.4) equivalent to

$$\begin{aligned} \left\langle \boldsymbol{\xi}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} - \left\langle \mathbf{N}_\kappa \mathbf{u}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} &+ \left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa \right) \boldsymbol{\lambda}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} = 0, \\ \left\langle \boldsymbol{\mu}, \left(-\frac{1}{2} Id + \mathbf{C}_\kappa \right) \mathbf{u} \right\rangle_{\boldsymbol{\tau}} &- \left\langle \boldsymbol{\mu}, \mathbf{S}_\kappa \boldsymbol{\lambda} \right\rangle_{\boldsymbol{\tau}} = 0, \end{aligned}$$

with $\boldsymbol{\xi} := \frac{1}{\mu_r} \gamma_N^- \mathbf{E} - \gamma_N \mathbf{E}_{\mathrm{inc}}$, $\mathbf{u} := \gamma_D^- \mathbf{E} - \gamma_D \mathbf{E}_{\mathrm{inc}}$. In operator notation this means

$$\begin{aligned} -\mathbf{N}_\kappa \mathbf{u} &+ \left(\frac{1}{2} Id + \mathbf{B}_\kappa \right) \boldsymbol{\lambda} = \boldsymbol{\lambda} - \boldsymbol{\xi}, \\ \left(\frac{1}{2} Id - \mathbf{C}_\kappa \right) \mathbf{u} &+ \mathbf{S}_\kappa \boldsymbol{\lambda} = 0. \end{aligned} \tag{6.5}$$

We recognize the operator in (6.5) as an *interior Calderon projector* [14, sect. 3.3]. Its range comprises valid Cauchy data for boundary value problems for $\mathbf{curl}\,\mathbf{curl}\,\mathbf{U} - \kappa^2 \mathbf{U} = 0$ in Ω_s. In particular, $\boldsymbol{\lambda} - \boldsymbol{\xi}$ are seen to be Neumann boundary values of interior Dirichlet eigensolutions. According to Assumption 1 these are trivial, which implies $\boldsymbol{\xi} = \boldsymbol{\lambda}$.

From this we immediately conclude that $(\mathbf{u}, \boldsymbol{\lambda})$ must belong to the range of the exterior Calderon projector. Hence, $(\mathbf{u}, \boldsymbol{\lambda})$ are valid Cauchy data for the exterior field problem. By definition, $(\mathbf{u} + \gamma_D \mathbf{E}_{\mathrm{inc}}, \boldsymbol{\xi})$ are valid Cauchy data for the interior field problem. Taken together with $\boldsymbol{\xi} = \boldsymbol{\lambda}$, this finishes the proof. □

Remark 6.1. If κ^2 coincides with an interior Dirichlet eigenvalue, then the solution of (6.4) is unique only up to a contribution $(0, \boldsymbol{\eta})$, where $\boldsymbol{\eta}$ lies in the span of Neumann data belonging to interior Dirichlet eigensolutions. In particular, $\gamma_D^- \mathbf{E}$ is unique.

To keep notations short, we set $\boldsymbol{\mathcal{V}} := \boldsymbol{H}(\mathbf{curl}; \Omega_s) \times \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ and write $a_\kappa : \boldsymbol{\mathcal{V}} \times \boldsymbol{\mathcal{V}} \mapsto \mathbb{C}$ for the sesqui-linear form associated with the variational problem (6.4). Then the latter can be stated as follows: Seek $(\mathbf{E}, \boldsymbol{\lambda}) \in \boldsymbol{\mathcal{V}}$ such that

$$a_\kappa((\mathbf{E}, \boldsymbol{\lambda}), (\mathbf{V}, \boldsymbol{\mu})) = f(\mathbf{V}) + g(\boldsymbol{\mu}) \quad \forall (\mathbf{V}, \boldsymbol{\mu}) \in \boldsymbol{\mathcal{V}}. \tag{6.6}$$

At first glance, the resulting variational problem much resembles those we get in the case of strongly elliptic second order elliptic problems, as they are encountered, for instance, in models for acoustic scattering (cf. section 2). Now, $\mathbf{S}_\kappa$ seems to play the role of a single layer potential V_κ, $\mathbf{B}_\kappa$ and $\mathbf{C}_\kappa$ act as double layer boundary integral operators, and $\mathbf{N}_\kappa$ substitutes for the hypersingular operator D_κ. A closer scrutiny reveals that appearances are deceptive: The key feature of V_κ and D_κ is that they are strongly elliptic operators of order -1 and 1, respectively. Conversely, as is immediate from the formula (4.7) and Lemma 5.3, neither $\mathbf{S}_\kappa$ nor $\mathbf{N}_\kappa$ can be assigned orders, let alone different orders. They both comprise two terms of order 1 and -1, respectively, neither of which can be identified as the principal part. This mirrors the characteristics of the electric wave operator, as discussed in section 2.

7. Decompositions. The considerations of section 2 suggest that we study $\boldsymbol{L}^2(\Omega_s)$-orthogonal Helmholtz decomposition of the electric field into an irrotational component and some complement. However, it turns out that only the energetic stability of the splitting is essential, not its exact orthogonality. Hence, we decided to trade orthogonality for regularity of the magnetic component.

In the case of $\boldsymbol{H}(\mathbf{curl};\Omega_s)$, the construction of such a *Helmholtz-type decomposition* hinges on the existence of vector potentials in $\boldsymbol{H}^1(\Omega_s)$.

LEMMA 7.1 (see [4, Lem. 3.5]). *There is a linear continuous lifting operator* $\mathsf{L} : \boldsymbol{H}(\operatorname{div} 0;\Omega_s) := \{\mathbf{V} \in \boldsymbol{L}^2(\Omega_s), \operatorname{div}\mathbf{V} = 0\} \mapsto \boldsymbol{H}^1(\Omega_s)$ *that satisfies* $\operatorname{div}(\mathsf{L}\mathbf{U}) = 0$ *and* $\mathbf{curl}(\mathsf{L}\mathbf{U}) = \mathbf{U}$ *for all* $\mathbf{U} \in \boldsymbol{H}(\operatorname{div} 0;\Omega_s)$.

Using this device, we introduce the operator

$$\mathsf{P} : \boldsymbol{H}(\mathbf{curl};\Omega_s) \mapsto \boldsymbol{H}^1(\Omega_s), \qquad \mathsf{P}\mathbf{U} := \mathsf{L}(\mathbf{curl}\,\mathbf{U}).$$

From the properties of L we immediately conclude numerous features of P as follows.

LEMMA 7.2. *The operator* P *is a continuous projection that preserves the* $\mathbf{curl}$ *and satisfies* $\operatorname{Ker}(\mathsf{P}) = \operatorname{Ker}(\mathbf{curl}) \cap \boldsymbol{H}(\mathbf{curl};\Omega_s)$.

As $\operatorname{Ker}(\mathsf{P}) = \operatorname{Ker}(\mathbf{curl}) \cap \boldsymbol{H}(\mathbf{curl};\Omega_s)$, it has become evident that the closed subspaces

$$\mathbf{X}(\mathbf{curl},\Omega_s) := \mathsf{P}(\boldsymbol{H}(\mathbf{curl};\Omega_s)) \quad \text{and} \quad \mathbf{N}(\mathbf{curl},\Omega_s) := \operatorname{Ker}(\mathbf{curl}) \subset \boldsymbol{H}(\mathbf{curl};\Omega_s)$$

provide a stable and direct Helmholtz-type splitting

$$\boldsymbol{H}(\mathbf{curl};\Omega_s) = \mathbf{X}(\mathbf{curl},\Omega_s) \oplus \mathbf{N}(\mathbf{curl},\Omega_s). \tag{7.1}$$

For both components we retain the $\boldsymbol{H}(\mathbf{curl};\Omega_s)$-norm. Keeping in mind the discussion of the components of the Helmholtz decomposition in section 2, we easily identify $\mathbf{X}(\mathbf{curl},\Omega_s)$ as the space of "magnetic components" and $\mathbf{N}(\mathbf{curl},\Omega_s)$ as "electric" space. For later compactness arguments the extra regularity of the $\mathbf{X}(\mathbf{curl},\Omega_s)$-component, which is contained in $\boldsymbol{H}^1(\Omega_s)$, is pivotal, since it immediately yields the following compact embedding.

COROLLARY 7.3. *The embedding* $\mathbf{X}(\mathbf{curl},\Omega_s) \hookrightarrow \boldsymbol{L}^2(\Omega_s)$ *is compact.*

In addition, we need splittings of the Neumann trace space $\boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma)$. Here we could use an $\boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$-orthogonal Hodge decomposition as in [14]. However, as before, we waive orthogonality in favor of enhanced regularity of an algebraic complement of $\operatorname{Ker}(\operatorname{div}_\Gamma)$. The construction is largely parallel to that of $\mathbf{X}(\mathbf{curl},\Omega_s)$: Pick any $\boldsymbol{\lambda} \in \boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma)$ and set $\omega := \operatorname{div}_\Gamma\boldsymbol{\lambda} \in H^{-\frac{1}{2}}(\Gamma)$. Solve the Neumann problem

$$\Psi \in H^1(\Omega_s)/\mathbb{R} : \quad \Delta\Psi = 0 \quad \text{in } \Omega_s, \quad \gamma_{\mathbf{n}}^{-}\,\mathbf{grad}\,\Psi = w \quad \text{on } \Gamma.$$

We find that $\mathbf{W} := \mathbf{grad}\,\Psi \in \boldsymbol{H}(\operatorname{div} 0;\Omega_s)$ belongs to the domain of the lifting L. Hence, it makes sense to introduce the operator $\mathsf{J} : H^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}^1(\Omega_s)$ by $\mathsf{J}\omega := \mathsf{L}\mathbf{W}$. Its continuity is elementary and, thanks to Theorem 3.1, inherited by the mapping $\mathsf{P}^\Gamma := \gamma_\times \circ \mathsf{J} \circ \operatorname{div}_\Gamma : \boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}^{\frac{1}{2}}_{\perp}(\Gamma)$. Properties of P^Γ matching those of P can be easily established.

LEMMA 7.4. *The operator* $\mathsf{P}^\Gamma : \boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma) \mapsto \boldsymbol{H}^{\frac{1}{2}}_{\perp}(\Gamma)$ *is a continuous projection and preserves* $\operatorname{div}_\Gamma$*, and* $\operatorname{Ker}(\mathsf{P}^\Gamma) = \operatorname{Ker}(\operatorname{div}_\Gamma) \cap \boldsymbol{H}^{-\frac{1}{2}}(\operatorname{div}_\Gamma,\Gamma)$.

Through the components

$$\mathbf{X}(\mathrm{div}_\Gamma,\Gamma) := \mathsf{P}^\Gamma(\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)), \quad \mathbf{N}(\mathrm{div}_\Gamma,\Gamma) := \mathrm{Ker}(\mathrm{div}_\Gamma) \cap \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma),$$

we arrive at a stable direct decomposition of the space of magnetic traces:

$$\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) := \mathbf{X}(\mathrm{div}_\Gamma,\Gamma) \oplus \mathbf{N}(\mathrm{div}_\Gamma,\Gamma). \tag{7.2}$$

In light of the remarks in section 2, and recalling that the space $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ contains twisted tangential traces of magnetic fields, the two components in the splitting (7.2) correspond to *electric* and *magnetic* field components, respectively.

As before, the extra regularity of $\mathbf{X}(\mathrm{div}_\Gamma,\Gamma)$ rewards us with a valuable compact embedding analogous to [14, Thm. 3.4].

COROLLARY 7.5. *The embedding* $\mathbf{X}(\mathrm{div}_\Gamma,\Gamma) \hookrightarrow \boldsymbol{L}^2_{\mathbf{t}}(\Gamma)$ *is compact.*

8. Coercivity. We decompose the trial and test functions in the variational problem (6.4) according to the splittings provided in the previous section:

$$\begin{aligned}
\mathbf{E} &= \mathbf{E}^\perp + \mathbf{E}^0, \quad \mathbf{E}^\perp \in \mathbf{X}(\mathbf{curl},\Omega_s),\ \mathbf{E}^0 \in \mathbf{N}(\mathbf{curl},\Omega_s),\\
\mathbf{V} &= \mathbf{V}^\perp + \mathbf{V}^0, \quad \mathbf{V}^\perp \in \mathbf{X}(\mathbf{curl},\Omega_s),\ \mathbf{V}^0 \in \mathbf{N}(\mathbf{curl},\Omega_s),\\
\boldsymbol{\lambda} &= \boldsymbol{\lambda}^0 + \boldsymbol{\lambda}^\perp, \quad \boldsymbol{\lambda}^0 \in \mathbf{N}(\mathrm{div}_\Gamma,\Gamma),\ \boldsymbol{\lambda}^\perp \in \mathbf{X}(\mathrm{div}_\Gamma,\Gamma),\\
\boldsymbol{\mu} &= \boldsymbol{\mu}^0 + \boldsymbol{\mu}^\perp, \quad \boldsymbol{\mu}^0 \in \mathbf{N}(\mathrm{div}_\Gamma,\Gamma),\ \boldsymbol{\mu}^\perp \in \mathbf{X}(\mathrm{div}_\Gamma,\Gamma).
\end{aligned}$$

In addition, we sort the unknowns according to their "electric" or "magnetic" nature, grouping them as $(\boldsymbol{\lambda}^\perp, \mathbf{E}^0)$ (electric), $(\boldsymbol{\lambda}^0, \mathbf{E}^\perp)$ (magnetic). Thus we arrive at a variational problem with a distinct block structure. After flipping the signs of the first two equations, it reads: Find $\boldsymbol{\lambda}^\perp \in \mathbf{X}(\mathrm{div}_\Gamma,\Gamma)$, $\mathbf{E}^0 \in \mathbf{N}(\mathbf{curl},\Omega_s)$, $\boldsymbol{\lambda}^0 \in \mathbf{N}(\mathrm{div}_\Gamma,\Gamma)$, $\mathbf{E}^\perp \in \mathbf{X}(\mathbf{curl},\Omega_s)$ such that

$$\begin{array}{ccccccl}
\ast_{11} & + & \ast_{12} & = & g(\boldsymbol{\mu}^\perp) & \forall \boldsymbol{\mu}^\perp \in \mathbf{X}(\mathrm{div}_\Gamma,\Gamma), \\
 & + & & = & f(\mathbf{V}^0) & \forall \mathbf{V}^0 \in \mathbf{N}(\mathbf{curl},\Omega_s), \\
\ast_{21} & + & \ast_{22} & = & g(\boldsymbol{\mu}^0) & \forall \boldsymbol{\mu}^0 \in \mathbf{N}(\mathrm{div}_\Gamma,\Gamma), \\
 & + & & = & f(\mathbf{V}^\perp) & \forall \mathbf{V}^\perp \in \mathbf{X}(\mathbf{curl},\Omega_s),
\end{array} \tag{8.1}$$

where

$$\ast_{11} := \begin{array}{ccc}
\left\langle \boldsymbol{\mu}^\perp, \mathbf{S}_\kappa \boldsymbol{\lambda}^\perp \right\rangle_{\boldsymbol{\tau}} & + & \left\langle \boldsymbol{\mu}^\perp, \left(-\frac{1}{2}Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{E}^0 \right\rangle_{\boldsymbol{\tau}}, \\
\left\langle \left(\frac{1}{2}Id - \mathbf{B}_\kappa\right) \boldsymbol{\lambda}^\perp, \gamma_D^- \mathbf{V}^0 \right\rangle_{\boldsymbol{\tau}} & + & \kappa^2 \left\langle \gamma_D^- \mathbf{V}^0, \tilde{\mathbf{A}}_\kappa \gamma_D^- \mathbf{E}^0 \right\rangle_{\frac{1}{2},\perp,\Gamma} + \kappa^2 \left(\epsilon_r \mathbf{E}^0, \mathbf{V}^0\right)_{0;\Omega_s},
\end{array}$$

$$\ast_{12} := \begin{array}{ccc}
-\left\langle \boldsymbol{\mu}^\perp, \mathbf{A}_\kappa \boldsymbol{\lambda}^0 \right\rangle_{\frac{1}{2},\|,\Gamma} & + & \left\langle \boldsymbol{\mu}^\perp, \left(-\frac{1}{2}Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{E}^\perp \right\rangle_{\boldsymbol{\tau}}, \\
\left\langle \left(\frac{1}{2}Id - \mathbf{B}_\kappa\right) \boldsymbol{\lambda}^0, \gamma_D^- \mathbf{V}^0 \right\rangle_{\boldsymbol{\tau}} & + & \kappa^2 \left\langle \gamma_D^- \mathbf{E}^\perp, \tilde{\mathbf{A}}_\kappa \gamma_D^- \mathbf{V}^0 \right\rangle_{\frac{1}{2},\perp,\Gamma} + \kappa^2 \left(\epsilon_r \mathbf{E}^\perp, \mathbf{V}^0\right)_{0;\Omega^-},
\end{array}$$

$$\ast_{21} := \begin{array}{ccc}
\left\langle \boldsymbol{\mu}^0, \mathbf{A}_\kappa \boldsymbol{\lambda}^\perp \right\rangle_{\frac{1}{2},\|,\Gamma} & - & \left\langle \boldsymbol{\mu}^0, \left(-\frac{1}{2}Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{E}^0 \right\rangle_{\boldsymbol{\tau}}, \\
\left\langle \left(-\frac{1}{2}Id + \mathbf{B}_\kappa\right) \boldsymbol{\lambda}^\perp, \gamma_D^- \mathbf{V}^\perp \right\rangle_{\boldsymbol{\tau}} & - & \kappa^2 \left\langle \gamma_D^- \mathbf{E}^0, \tilde{\mathbf{A}}_\kappa \gamma_D^- \mathbf{V}^\perp \right\rangle_{\frac{1}{2},\perp,\Gamma} - \kappa^2 \left(\epsilon \mathbf{E}^0, \mathbf{V}^\perp\right)_{0;\Omega^-},
\end{array}$$

$$\boldsymbol{\ast}_{22} := \begin{array}{ccc} \left\langle \boldsymbol{\mu}^0, \mathbf{A}_\kappa \boldsymbol{\lambda}^0 \right\rangle_{\frac{1}{2},\|,\Gamma} & - & \left\langle \boldsymbol{\mu}^0, \left(-\frac{1}{2} Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{E}^\perp \right\rangle_{\boldsymbol{\tau}}, \\ \left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) \boldsymbol{\lambda}^0, \gamma_D^- \mathbf{V}^\perp \right\rangle_{\boldsymbol{\tau}} & - & \left\langle \mathbf{N}_\kappa \gamma_D^- \mathbf{E}^\perp, \gamma_D^- \mathbf{V}^\perp \right\rangle_{\boldsymbol{\tau}} + q(\mathbf{E}^\perp, \mathbf{V}^\perp) \; . \end{array}$$

Here, we have used that the first order parts of the operators $\mathbf{S}_\kappa$ and $\mathbf{N}_\kappa$ disappear when those are applied to functions in $\mathbf{N}(\mathrm{div}_\Gamma, \Gamma)$ and $\gamma_D^- \mathbf{N}(\mathbf{curl}, \Omega_s)$, respectively. Evidently, (8.1) and (6.4) produce exactly the same solutions for $\boldsymbol{\lambda} = \boldsymbol{\lambda}^\perp + \boldsymbol{\lambda}^0$ and $\mathbf{E} = \mathbf{E}^\perp + \mathbf{E}^0$, provided that a unique solution exists. It is also clear that (6.4) can be written as a variational problem for a continuous sesqui-linear form $\widehat{a}_\kappa$ on the Hilbert space $\boldsymbol{\mathcal{G}} := \mathbf{X}(\mathrm{div}_\Gamma, \Gamma) \times \mathbf{N}(\mathbf{curl}, \Omega_s) \times \mathbf{N}(\mathrm{div}_\Gamma, \Gamma) \times \mathbf{X}(\mathbf{curl}, \Omega_s)$ that is endowed with the natural graph norm. Also, $\widehat{a}_\kappa$ is given by

$$\begin{aligned} (8.2) \qquad & \widehat{a}_\kappa((\boldsymbol{\zeta}^\perp, \mathbf{U}^0, \boldsymbol{\zeta}^0, \mathbf{U}^\perp), (\boldsymbol{\mu}^\perp, \mathbf{V}^0, \boldsymbol{\mu}^0, \mathbf{V}^\perp)) \\ & \qquad = a_\kappa((\mathbf{U}^\perp + \mathbf{U}^0, \boldsymbol{\zeta}^\perp + \boldsymbol{\zeta}^0), (\mathbf{V}^\perp - \mathbf{V}^0, -\boldsymbol{\mu}^\perp + \boldsymbol{\mu}^0)). \end{aligned}$$

The goal is to resort to compact perturbations and achieve a block structure with elliptic diagonal blocks and off-diagonal blocks that fit a skew-symmetric pattern. To this end we have to identify operators in the above variational problem that can be neglected because they are compact.

LEMMA 8.1. *The operators*

$$(\gamma_D^-)^* \circ \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) : \mathbf{N}(\mathrm{div}_\Gamma, \Gamma) \mapsto \mathbf{N}(\mathbf{curl}, \Omega_s)',$$

$$\left(-\frac{1}{2} Id + \mathbf{C}_\kappa\right) \circ \gamma_D^- : \mathbf{N}(\mathbf{curl}, \Omega_s) \mapsto \mathbf{N}(\mathrm{div}_\Gamma, \Gamma)'$$

are compact.

Proof. The proof closely follows that of [14, Prop. 3.13]. Pick $\boldsymbol{\zeta} \in \mathbf{N}(\mathrm{div}_\Gamma, \Gamma)$, $\mathbf{V} \in \mathbf{N}(\mathbf{curl}, \Omega_s)$, and set $\mathbf{v} := \gamma_D^- \mathbf{V}$. Note that there is a direct splitting $\mathbf{N}(\mathrm{div}_\Gamma, \Gamma) = \mathbf{curl}_\Gamma H^{\frac{1}{2}}(\Gamma) \oplus \boldsymbol{\mathcal{H}}_1(\Gamma)$, where $\boldsymbol{\mathcal{H}}_1(\Gamma)$ is some cohomology space of Γ, whose dimension is finite and agrees with the first Betti number $\beta_1(\Gamma)$ (cf. [8]). Hence, we can write

$$\boldsymbol{\zeta} = \mathbf{curl}_\Gamma \phi(\boldsymbol{\zeta}) + \boldsymbol{\eta}(\boldsymbol{\zeta}), \quad \phi(\boldsymbol{\zeta}) \in H^{\frac{1}{2}}(\Gamma), \quad \boldsymbol{\eta}(\boldsymbol{\zeta}) \in \boldsymbol{\mathcal{H}}_1(\Gamma).$$

Further, let $\Phi \in H^1(\Omega_s)$ be some extension of ϕ. The key to the proof is the observation

$$\langle \boldsymbol{\zeta}, \mathbf{v} \rangle_{\boldsymbol{\tau}} = \int_\Gamma \mathbf{curl}\, \mathbf{V} \cdot \overline{\mathbf{grad}\, \Phi} - \mathbf{V} \cdot \mathbf{curl}\, \overline{\mathbf{grad}\, \Phi} \, d\mathbf{x} + \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} = \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} \, .$$

By the jump relations, the identity (4.8), and the weak definition of the Neumann trace γ_N^-,

$$\begin{aligned} \left\langle \gamma_N^+ \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}), \mathbf{v} \right\rangle_{\boldsymbol{\tau}} &= \left\langle -\boldsymbol{\zeta} + \gamma_N^- \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}), \mathbf{v} \right\rangle_{\boldsymbol{\tau}} = \left\langle \gamma_N^- \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}), \mathbf{v} \right\rangle_{\boldsymbol{\tau}} - \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} \\ &= \int_{\Omega_s} \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}) \cdot \mathbf{curl}\, \overline{\mathbf{V}} - \mathbf{curl}\, \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}) \cdot \overline{\mathbf{V}} \, d\mathbf{x} - \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} \\ &= \int_{\Omega_s} \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}) \cdot \mathbf{curl}\, \overline{\mathbf{V}} - \mathbf{grad}\, \Psi_V^\kappa(\mathrm{div}_\Gamma \boldsymbol{\zeta}) \cdot \overline{\mathbf{V}} - \kappa^2 \boldsymbol{\Psi}_{\mathbf{A}}^\kappa(\boldsymbol{\zeta}) \cdot \overline{\mathbf{V}} \, d\mathbf{x} - \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} \, . \end{aligned}$$

The first two terms can be dropped as $\mathbf{V}$ and $\boldsymbol{\zeta}$ are **curl**-free and div_Γ-free, respectively. This leaves us with

$$|\left\langle \gamma_N^+ \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}), \mathbf{v} \right\rangle_{\boldsymbol{\tau}} + \langle \boldsymbol{\eta}(\boldsymbol{\zeta}), \mathbf{v} \rangle_{\boldsymbol{\tau}} | \leq \kappa^2 \left\| \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \right\|_{\boldsymbol{L}^2(\Omega_s)} \|\mathbf{V}\|_{\boldsymbol{L}^2(\Omega_s)} .$$

As $\dim \boldsymbol{\mathcal{H}}_1(\Gamma) < \infty$, the mapping $\mathbf{N}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{\mathcal{H}}_1(\Gamma)$, $\boldsymbol{\zeta} \mapsto \boldsymbol{\eta}(\boldsymbol{\zeta})$, is compact. Since $\boldsymbol{\Psi}_{\mathbf{A}}^{\kappa} : \boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma) \mapsto \boldsymbol{H}^1(\Omega_s)$ is continuous, the compact embedding $\boldsymbol{H}^1(\Omega_s) \hookrightarrow \boldsymbol{L}^2(\Omega_s)$ confirms the first assertion of the theorem. Thanks to Lemma 5.4, the second is then immediate. $\square$

LEMMA 8.2. *The operators*

$$(\gamma_D^-)^* \circ \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) : \mathbf{X}(\mathrm{div}_\Gamma, \Gamma) \mapsto \mathbf{X}(\mathbf{curl}, \Omega_s)',$$

$$\left(-\frac{1}{2} Id + \mathbf{C}_\kappa\right) \circ \gamma_D^- : \mathbf{X}(\mathbf{curl}, \Omega_s) \mapsto \mathbf{X}(\mathrm{div}_\Gamma, \Gamma)'$$

are compact.

Proof. The proof runs parallel to that of [14, Prop. 3.13]. Choose any $\boldsymbol{\zeta} \in \mathbf{X}(\mathrm{div}_\Gamma, \Gamma)$, $\mathbf{V} \in \mathbf{X}(\mathbf{curl}, \Omega_s)$, and recall the definition of $\mathbf{B}_\kappa$ along with the jump conditions

$$\begin{aligned}
&\left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) \boldsymbol{\zeta}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} = \left\langle \gamma_N^- \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}), \gamma_D^+ \mathbf{V} \right\rangle_{\boldsymbol{\tau}} - \left\langle \boldsymbol{\zeta}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \\
&\quad = \int_{\Omega_s} \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \cdot \mathbf{curl}\, \overline{\mathbf{V}} - \mathbf{curl}\, \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \cdot \overline{\mathbf{V}}\, d\mathbf{x} - \left\langle \boldsymbol{\zeta}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \\
&\quad = \int_{\Omega_s} \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \cdot \mathbf{curl}\, \overline{\mathbf{V}} - \mathbf{grad}\, \Psi_V^{\kappa}(\mathrm{div}_\Gamma \boldsymbol{\zeta}) \cdot \overline{\mathbf{V}} - \kappa^2 \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \overline{\mathbf{V}}\, d\mathbf{x} - \left\langle \boldsymbol{\zeta}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \\
&\quad = \int_{\Omega_s} \mathbf{curl}\, \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \cdot \mathbf{curl}\, \overline{\mathbf{V}} - \kappa^2 \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \overline{\mathbf{V}}\, d\mathbf{x} - \overline{\left\langle \gamma_{\mathbf{n}}^- \mathbf{V}, V_\kappa(\mathrm{div}_\Gamma \boldsymbol{\zeta}) \right\rangle_{\frac{1}{2}, \Gamma}} - \left\langle \boldsymbol{\zeta}, \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} .
\end{aligned}$$

Owing to the construction of $\mathbf{X}(\mathbf{curl}, \Omega_s)$, this means

$$\begin{aligned}
&\left| \left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) (\boldsymbol{\zeta}), \gamma_D^- \mathbf{V} \right\rangle_{\boldsymbol{\tau}} \right| \\
&\leq |\boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta})|_{\boldsymbol{H}^1(\Omega_s)} \|\mathbf{curl}\, \mathbf{V}\|_{\boldsymbol{L}^2(\Omega_s)} + \kappa^2 \left\| \boldsymbol{\Psi}_{\mathbf{A}}^{\kappa}(\boldsymbol{\zeta}) \right\|_{\boldsymbol{L}^2(\Omega_s)} \|\mathbf{V}\|_{\boldsymbol{L}^2(\Omega_s)} \\
&\qquad + \|V_\kappa(\mathrm{div}_\Gamma \boldsymbol{\zeta})\|_{L^2(\Gamma)} \left\| \gamma_{\mathbf{n}}^- \mathbf{V} \right\|_{L^2(\Gamma)} + \|\boldsymbol{\zeta}\|_{\boldsymbol{L}^2(\Gamma)} \left\| \gamma_D^- \mathbf{V} \right\|_{\boldsymbol{L}^2(\Gamma)} \\
&\leq C \left(\|\boldsymbol{\zeta}\|_{\boldsymbol{H}_{||}^{-\frac{1}{2}}(\Gamma)} + \|V_\kappa(\mathrm{div}_\Gamma \boldsymbol{\zeta})\|_{L^2(\Gamma)} + \|\widehat{\gamma} \Psi_V^{\kappa}(\mathrm{div}_\Gamma \boldsymbol{\zeta})\|_{L^2(\widehat{\Gamma})} + \|\boldsymbol{\zeta}\|_{\boldsymbol{L}^2(\Gamma)} \right) \|\mathbf{V}\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} ,
\end{aligned}$$

with some $C = C(\Omega_s) > 0$. It goes without saying that the operators $V_\kappa : H^{-\frac{1}{2}}(\Gamma) \mapsto L^2(\Gamma)$ and $\widehat{\gamma} \Psi_V^{\kappa} : H^{-\frac{1}{2}}(\Gamma) \mapsto L^2(\widehat{\Gamma})$ are compact. Then, the compact embedding of $\mathbf{X}(\mathrm{div}_\Gamma, \Gamma)$ in $\boldsymbol{L}_{\mathbf{t}}^2(\Gamma)$ according to Corollary 7.5 finishes the proof. $\square$

The previous two lemmas reveal that the bilinear forms associated with both $*_{12}$ and $*_{21}$ from (8.1) are compact. This means that the off-diagonal blocks in (8.1) do *not* contribute to the principal part of $\widehat{a}_\kappa$. Rather, in the principal part electric and magnetic field quantities are *completely decoupled*.

To strip compact perturbations off of $*_{11}$ and $*_{22}$, we first deduce from Corollary 7.5, combined with the continuity properties from Theorem 5.3, that the operators $\mathbf{A}_\kappa : \mathbf{X}(\mathrm{div}_\Gamma, \Gamma) \mapsto \boldsymbol{H}_{||}^{1/2}(\Gamma)$ and $\tilde{\mathbf{A}}_\kappa \circ \gamma_D^- : \mathbf{X}(\mathbf{curl}, \Omega_s) \mapsto \boldsymbol{H}_{\perp}^{1/2}(\Gamma)$ are compact. Next, we recall Theorem 5.5 and obtain the following bilinear form through a compact perturbation of $\widehat{a}_\kappa$:

$$\begin{aligned}
&\widehat{b}_\kappa((\boldsymbol{\zeta}^\perp, \mathbf{U}^0, \boldsymbol{\zeta}^0, \mathbf{U}^\perp), (\boldsymbol{\mu}^\perp, \mathbf{V}^0, \boldsymbol{\mu}^0, \mathbf{V}^\perp)) \\
&\qquad = \frac{1}{\kappa^2} \left\langle \mathrm{div}_\Gamma \boldsymbol{\mu}^\perp, V_0 \mathrm{div}_\Gamma \boldsymbol{\zeta}^\perp \right\rangle_{\frac{1}{2},\Gamma} \\
&\qquad + \left\langle \boldsymbol{\mu}^\perp, \left(-\frac{1}{2} Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{U}^0 \right\rangle_{\boldsymbol{\tau}} - \left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) \boldsymbol{\zeta}^\perp, \gamma_D^- \mathbf{V}^0 \right\rangle_{\boldsymbol{\tau}} \\
&\qquad + \kappa^2 \left\langle \gamma_D^- \mathbf{V}^0, \tilde{\mathbf{A}}_0 \gamma_D^- \mathbf{U}^0 \right\rangle_{\frac{1}{2},\perp,\Gamma} + \kappa^2 \left(\epsilon_r \mathbf{U}^0, \mathbf{V}^0\right)_{0;\Omega_s} + \left\langle \boldsymbol{\mu}^0, \mathbf{A}_0 \boldsymbol{\zeta}^0 \right\rangle_{\frac{1}{2},||,\Gamma} \\
&\qquad - \left\langle \boldsymbol{\mu}^0, \left(-\frac{1}{2} Id + \mathbf{C}_\kappa\right) \gamma_D^- \mathbf{U}^\perp \right\rangle_{\boldsymbol{\tau}} + \left\langle \left(-\frac{1}{2} Id + \mathbf{B}_\kappa\right) \boldsymbol{\zeta}^0, \gamma_D^- \mathbf{V}^\perp \right\rangle_{\boldsymbol{\tau}} \\
&\qquad + \left\langle \mathrm{curl}_\Gamma \, \gamma_D^- \mathbf{V}^\perp, V_0 \, \mathrm{curl}_\Gamma \, \gamma_D^- \mathbf{U}^\perp \right\rangle_{\frac{1}{2},\Gamma} + \left(\frac{1}{\mu_r} \mathbf{curl}\, \mathbf{U}^\perp, \mathbf{curl}\, \mathbf{V}^\perp\right)_{0;\Omega_s} .
\end{aligned}$$

Obviously, due to Lemma 5.4, cancellation weeds out all terms that cannot be controlled by compactness. Then the following main result, corresponding to [14, Thm. 3.12], is straightforward.

THEOREM 8.3. *The sesqui-linear form $\widehat{a}_\kappa$ related to the variational problem* (6.4) *is coercive on $\boldsymbol{\mathcal{G}}$; that is, it can be written as a sum $\widehat{a}_\kappa = \widehat{d}_\kappa + \widehat{k}_\kappa$ of a $\boldsymbol{\mathcal{G}}$-elliptic sesqui-linear form $\widehat{d}_\kappa$ and a compact sesqui-linear form $\widehat{k}_\kappa : \boldsymbol{\mathcal{G}} \times \boldsymbol{\mathcal{G}} \mapsto \mathbb{C}$.*

Proof. By the above reasoning, $\widehat{a}_\kappa - \widehat{b}_\kappa$ is compact. Using Lemma 5.4 and the compact operator T_κ introduced there, we readily see that $\widehat{d}_\kappa := \widehat{b}_\kappa - \langle T_\kappa \cdot, \cdot \rangle_{\boldsymbol{\tau}} + \langle T_\kappa \cdot, \cdot \rangle_{\boldsymbol{\tau}}$ is $\boldsymbol{\mathcal{G}}$-elliptic. ∎

Any solution of the scattering problem (1.1) will ultimately turn out to be a solution of (6.6). Consequently, given Assumption 1, Lemma 6.1 combined with Theorem 1.1 guarantees the injectivity of the operator associated with (6.6). Thus, the Fredholm alternative (cf. [43, Thm. 2.33]) instantly vindicates that (6.6) always has a unique solution $(\mathbf{E}, \boldsymbol{\lambda}) \in \boldsymbol{H}(\mathbf{curl}; \Omega_s) \times \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$. Uniqueness carries over to the split variational problem (8.1). From this we infer the continuous inf-sup condition

$$\sup_{\mathfrak{v} \in \boldsymbol{\mathcal{G}}} \frac{|\widehat{a}_\kappa(\mathfrak{u}, \mathfrak{v})|}{\|\mathfrak{v}\|_{\boldsymbol{\mathcal{G}}}} \geq C \, \|\mathfrak{u}\|_{\boldsymbol{\mathcal{G}}} \quad \forall \mathfrak{u} \in \boldsymbol{\mathcal{G}}. \tag{8.3}$$

9. Finite element spaces. We equip (the curvilinear polyhedron) Ω_s with a family of shape-regular, tetrahedral triangulations $(\Omega_h)_h$. The parameter h designates the meshwidth, that is, the length of the longest edge. Let $\mathbb{H}$ stand for the collection of meshwidths occurring in $(\Omega_h)_h$ and, moreover, assume that $\mathbb{H} \subset \mathbb{R}^+$ forms a decreasing sequence tending to zero. The set $\mathcal{T}_h$ will include all triangles of Ω_h. Restricting Ω_h, $h \in \mathbb{H}$, to Γ gives a sequence $(\Gamma_h)_h$ of surface meshes. They inherit shape-regularity from $(\Omega_h)_h$. We suppose that all Γ_h are aligned with edges of Γ.

Discrete electric fields should be modelled by discrete 1-forms (edge elements). They can be represented by piecewise polynomial vectorfields: For a *fixed* polynomial degree ν, $\nu \in \mathbb{N}_0$, and any tetrahedron $T \in \mathcal{T}_h$ the local spaces are given by (cf. [44])

$$\boldsymbol{\mathcal{E}}^1_{\nu+1}(T) := \{\mathbf{V} \in (\mathcal{P}_{\nu+1}(T))^3,\ \mathbf{V}(\mathbf{x}) \cdot \mathbf{x} = 0\ \forall \mathbf{x} \in T\},$$

where $\mathcal{P}_\iota$ is the space of multivariate polynomials of total degree ν on T. This gives rise to the global finite element space

$$\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) := \{\mathbf{U} \in \boldsymbol{H}(\mathbf{curl}; \Omega_s),\ \mathbf{U}_{|T} \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(T)\ \forall T \in \mathcal{T}_h\}.$$

The condition $\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) \subset \boldsymbol{H}(\mathbf{curl}; \Omega_s)$ is equivalent to the continuity of tangential components across interelement faces. This renders degrees of freedom based on moments of (tangential components) on edges, faces, and the elements themselves well defined. See [44] and [36] for details and proofs of unisolvence. The discrete 1-forms on $\{\Omega_h\}_h$ form an affine family of finite elements in the sense of [19] with respect to the pullback of 1-forms. Based on the degrees of freedom, we can introduce nodal interpolation operators Π^1_h onto $\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$. To begin with, those are declared for continuous vectorfields. It turns out that this is not enough and that we badly need to apply Π^1_h to less regular vectorfields. The extent to which this is possible is revealed by the following interpolation error estimate.

LEMMA 9.1 (see [20, Lems. 3.2, 3.3]). *If $s > \frac{1}{2}$, then for all $\mathbf{U} \in \boldsymbol{H}^s(\Omega_s)$ such that $\mathbf{curl}\,\mathbf{U} \in \boldsymbol{H}^s(\Omega_s)$*

$$\begin{aligned}\left\|\mathbf{U} - \Pi^1_h\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} &\leq \tilde{C} h^{\min\{\nu+1,s\}}(|\mathbf{U}|_{\boldsymbol{H}^s(\Omega_s)} + |\mathbf{curl}\,\mathbf{U}|_{\boldsymbol{H}^s(\Omega_s)}),\\ \left\|\mathbf{curl}(\mathbf{U} - \Pi^1_h\mathbf{U})\right\|_{\boldsymbol{L}^2(\Omega_s)} &\leq \tilde{C} h^{\min\{\nu+1,s\}}\,|\mathbf{curl}\,\mathbf{U}|_{\boldsymbol{H}^s(\Omega_s)},\end{aligned}$$

with constants[3] *$\tilde{C} > 0$ depending only on Ω_s, ν, s, and the shape-regularity of the meshes.*

The reader might be wondering why we want to use the nodal interpolation operator even though it fails to be defined on the entire space $\boldsymbol{H}(\mathbf{curl}; \Omega_s)$. The reason is its exceptional algebraic properties. To explain them, we have to introduce the $\boldsymbol{H}(\mathrm{div}; \Omega_s)$-conforming finite element spaces $\boldsymbol{\mathcal{F}}^1_\nu(\Omega_h)$ of discrete 2-forms of degree ν, also known as Raviart–Thomas elements [7, Chap. 3], [44]. Suitable degrees of freedom for this space are supplied by moments of "face fluxes" and weighted integrals over elements. They induce the nodal interpolation operators Π^2_h onto $\boldsymbol{\mathcal{F}}^1_\nu(\Omega_h)$. Application of the Stokes theorem (cf. [36]) confirms the *commuting diagram property*

$$\mathbf{curl} \circ \Pi^1_h = \Pi^2_h \circ \mathbf{curl}, \tag{9.1}$$

valid for vectorfields in the domain $\mathrm{Dom}(\Pi^1_h)$ of Π^1_h. The relationship (9.1) teaches that Π^1_h leaves the kernel of $\mathbf{curl}$ invariant. This accounts for the pivotal role of the nodal interpolation operator.

To pick a suitable discrete trial space for $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ we also adopt the perspective of differential forms. Be aware that $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ is the trace space for magnetic fields, and keep in mind that those can also be described by 1-forms. This suggests that $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$ should be approximated by traces of discrete 1-forms on the surface. In other words, as $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma, \Gamma)$-conforming boundary element space we chose $\gamma_\times \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$. Elementary computations reveal that the procedure generates exactly

[3] A $\tilde{}$ tag for a generic constant indicates that it may also depend on ν and the shape-regularity of the family of meshes.

the two-dimensional Raviart–Thomas elements $\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$ [46] on the surface mesh. The degrees of freedom are also inherited from $\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$. By construction, the induced nodal interpolation operator Π^Γ_h satisfies

$$\Pi^\Gamma_h \circ \gamma_\times = \gamma_\times \circ \Pi^1_h, \tag{9.2}$$

which, due to (9.1), implies another commuting diagram property,

$$\mathrm{div}_\Gamma \circ \Pi^\Gamma_h = \mathsf{Q}^\Gamma_h \circ \mathrm{div}_\Gamma, \tag{9.3}$$

for sufficiently smooth tangential surface vectorfields. Here, Q^Γ_h is the plain $L^2(\Gamma)$-orthogonal projection onto the space $\mathcal{Q}_\nu(\Gamma_h)$ of discontinuous, piecewise polynomials (of degree ν) on Γ_h. Invariance of $\mathrm{Ker}(\mathrm{div}_\Gamma) \cap \mathrm{Dom}(\Pi^\Gamma_h)$ under Π^Γ_h is immediate.

From the results of [46] and [38, sect. 5] we harvest the following interpolation error estimates.

Lemma 9.2. *If $\boldsymbol{\mu} \in \boldsymbol{H}^s_{\mathbf{t}}(\Gamma)$, $\mathrm{div}_\Gamma \boldsymbol{\mu} \in H^s(\Gamma)$ for some $s > 0$, then*

$$\begin{aligned} \left\| \boldsymbol{\mu} - \Pi^\Gamma_h \boldsymbol{\mu} \right\|_{\boldsymbol{L}^2(\Gamma)} &\leq \tilde{C} h^{\min\{s,\nu+1\}} \left(|\boldsymbol{\mu}|_{\boldsymbol{H}^s_{\mathbf{t}}(\Gamma)} + |\mathrm{div}_\Gamma \boldsymbol{\mu}|_{H^s(\Gamma)} \right), \\ \left\| \mathrm{div}_\Gamma (\boldsymbol{\mu} - \Pi^\Gamma_h \boldsymbol{\mu}) \right\|_{L^2(\Gamma)} &\leq \tilde{C} h^{\min\{s,\nu+1\}} \, |\mathrm{div}_\Gamma \boldsymbol{\mu}|_{H^s(\Gamma)} . \end{aligned}$$

Armed with conforming finite element spaces, the Galerkin discretization of the variational problem (6.4), (6.6) is straightforward. Seek $(\mathbf{E}_h, \boldsymbol{\lambda}_h) \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) \times \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$ such that

$$a_\kappa((\mathbf{E}_h, \boldsymbol{\lambda}_h), (\mathbf{V}_h, \boldsymbol{\mu}_h)) = f(\mathbf{V}_h) + g(\boldsymbol{\mu}_h) \tag{9.4}$$

for all $(\mathbf{V}_h, \boldsymbol{\mu}_h) \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) \times \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$.

10. Discrete decompositions. The highly effective splitting idea of the continuous setting also has to be adopted for the analysis of the discretized problem (9.4). We follow a simple guideline, which boils down to applying nodal interpolation to the Helmholtz-type splittings of finite element functions. The approach to both $\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$ and $\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$ is completely parallel.

First, we construct a discrete counterpart of $\mathbf{X}(\mathbf{curl}, \Omega_s)$. As in section 7, we rely on a projector. According to the recipe outlined above, it is formally defined as $\mathsf{P}_h := \Pi^1_h \circ \mathsf{P}$. However, even on $\mathsf{P}(\boldsymbol{H}(\mathbf{curl}; \Omega_s)) \subset \boldsymbol{H}^1(\Omega_s)$ the nodal interpolation Π^1_h is not bounded, because the smoothness of the **curl**s is not controlled. Nonetheless, we aim to apply P_h to finite element functions only, which saves the idea.

Lemma 10.1. *If $\mathbf{U} \in \boldsymbol{H}^1(\Omega_s)$ and $\mathbf{curl}\,\mathbf{U} \in \boldsymbol{\mathcal{F}}^1_\nu(\Omega_h)$, then $\mathbf{U} \in \mathrm{Dom}(\Pi^1_h)$ and*

$$\left\| \mathbf{U} - \Pi^1_h \mathbf{U} \right\|_{\boldsymbol{L}^2(\Omega_s)} \leq \tilde{C} h^{\min\{\nu+1,s\}} \, |\mathbf{U}|_{\boldsymbol{H}^s(\Omega_s)} ,$$

with $\tilde{C} > 0$ depending only on Ω_s, ν, and the shape regularity of Ω_h.

Since, by (9.1), $\mathbf{curl}\,\mathsf{P}\mathbf{U}_h \in \boldsymbol{\mathcal{F}}^1_\nu(\Omega_h)$ for $\mathbf{U}_h \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$, the same arguments as in the case of P, along with the properties of the latter, give us information on P_h.

Lemma 10.2. *The operator $\mathsf{P}_h : \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) \mapsto \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$ is an h-uniformly continuous projection and preserves the* **curl**, *and* $\mathrm{Ker}(\mathsf{P}_h) = \mathrm{Ker}(\mathbf{curl}) \cap \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$.

Setting

$$\mathbf{X}_h(\mathbf{curl}, \Omega_h) := \mathsf{P}_h(\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)), \quad \mathbf{N}_h(\mathbf{curl}, \Omega_h) := \mathrm{Ker}(\mathbf{curl}) \cap \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h),$$

we instantly get an h-uniformly $\boldsymbol{H}(\mathbf{curl};\Omega_s)$-stable direct splitting

$$\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) = \mathbf{X}_h(\mathbf{curl},\Omega_h) \oplus \mathbf{N}_h(\mathbf{curl},\Omega_h). \tag{10.1}$$

The following result makes it possible to pursue the same strategy in the case of $\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$.

LEMMA 10.3 (see [38, Lem. 6.2]). *If $\boldsymbol{\lambda} \in \boldsymbol{H}^{\frac{1}{2}}_{\mathbf{t}}(\Gamma)$ and it has its surface divergence in $\mathcal{Q}_\nu(\Gamma_h)$, then $\boldsymbol{\lambda} \in \mathrm{Dom}(\Pi^\Gamma_h)$ and*

$$\left\|\boldsymbol{\lambda} - \Pi^\Gamma_h \boldsymbol{\lambda}\right\|_{\boldsymbol{L}^2(\Gamma)} \leq \tilde{C} h^{\min\{\nu+1,s\}} \left\|\boldsymbol{\lambda}\right\|_{\boldsymbol{H}^s_{\mathbf{t}}(\Gamma)},$$

with $\tilde{C} > 0$ independent of $\boldsymbol{\lambda}$ and the meshwidth h.

Thus, we can define

$$\mathsf{P}^\Gamma_h : \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h) \mapsto \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h), \qquad \mathsf{P}^\Gamma_h := \Pi^\Gamma_h \circ \mathsf{P}^\Gamma$$

and find properties corresponding to those of P_h as follows.

LEMMA 10.4. *The mapping P^Γ_h is an h-uniformly continuous projector, which preserves* div_Γ *and fulfills* $\mathrm{Ker}(\mathsf{P}^\Gamma_h) = \mathrm{Ker}(\mathrm{div}_\Gamma) \cap \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$.

The projector furnishes the desired h-uniformly $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$-stable splitting of the discrete space of Neumann traces

$$\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h) = \mathbf{X}_h(\mathrm{div}_\Gamma,\Gamma_h) \oplus \mathbf{N}_h(\mathrm{div}_\Gamma,\Gamma_h), \tag{10.2}$$

with

$$\mathbf{X}_h(\mathrm{div}_\Gamma,\Gamma_h) := \mathsf{P}^\Gamma_h(\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)), \quad \mathbf{N}_h(\mathrm{div}_\Gamma,\Gamma_h) := \mathrm{Ker}(\mathbf{curl}) \cap \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h).$$

We claimed that we were searching for discrete "counterparts" of $\mathbf{X}(\mathbf{curl},\Omega_s)$ and $\mathbf{X}(\mathrm{div}_\Gamma,\Gamma)$. If we had set out to find discrete *subspaces*, the above constructions would not have been at our disposal. Just notice that, in general, the vectorfields in $\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)$ are by no means continuous. Conversely, any piecewise polynomial vectorfield in $\mathbf{X}(\mathbf{curl},\Omega_s) \subset \boldsymbol{H}^1(\Omega_s)$ must possess continuous components. Similarly, there are elements in $\mathbf{X}_h(\mathrm{div}_\Gamma,\Gamma_h)$ that cannot occur as twisted tangential traces of continuous vectorfields. In short,

$$\mathbf{X}_h(\mathbf{curl},\Omega_h) \not\subset \mathbf{X}(\mathbf{curl},\Omega_s), \qquad \mathbf{X}_h(\mathrm{div}_\Gamma,\Gamma_h) \not\subset \mathbf{X}(\mathrm{div}_\Gamma,\Gamma).$$

This means that, introducing

$$\boldsymbol{\mathcal{G}}_h := \mathbf{X}_h(\mathrm{div}_\Gamma,\Gamma_h) \times \mathbf{N}(\mathbf{curl},\Omega_s) \times \mathbf{N}_h(\mathrm{div}_\Gamma,\Gamma_h) \times \mathbf{X}_h(\mathbf{curl},\Omega_h)$$

as a discrete approximation space for $\boldsymbol{\mathcal{G}}$, we have made a *nonconforming* choice, as $\boldsymbol{\mathcal{G}}_h \not\subset \boldsymbol{\mathcal{G}}$. This is a special kind of nonconformity, as it is not caused by the choice of finite element spaces, but by the manner in which they are split. Actually, we do not commit any "variational crime" when considering the (split) bilinear form $\widehat{a}_\kappa$ on $\boldsymbol{\mathcal{G}}_h$. However, coercivity of $\widehat{a}_\kappa$ was established only with respect to the split space $\boldsymbol{\mathcal{G}}$. This prevents us from directly applying the known results about the convergence of conforming Galerkin approximations of coercive variational problems [47]. Therefore, coercivity in the discrete setting must be established by a separate argument.

11. Bridge mappings. We recall a variant of the main result from section 4.1 of [14] (also cf. [9, 18]) as follows.

THEOREM 11.1 (see [38, sect. 7]). *Let $a : V \times V \mapsto \mathbb{C}$ be a continuous sesqui-linear form on a Banach space V, whose restriction to a closed subspace $W \subset V$ satisfies the inf-sup condition*

$$\sup_{v \in W} \frac{|a(u,v)|}{\|v\|_V} \geq \underline{c}\, \|u\|_V \quad \forall u \in W.$$

We can write $a := d - k$ with a continuous sesqui-linear form d that is V-elliptic on W, and a compact sesqui-linear form $k : W \times W \mapsto \mathbb{C}$. The family of closed subspaces $W_h \subset V$, $h \in \mathbb{H}$, is to be linked to V by two bridge mappings*: We assume the existence of families of linear, continuous operators $\mathsf{H}_h : W_h \mapsto W$ and $\mathsf{F}_h : W \mapsto W_h$, $h \in \mathbb{H}$, that satisfy*

$$\|Id - \mathsf{H}_h\|_{W_h \to V} \to 0 \quad \forall \mathfrak{u} \in W : \; \|\mathfrak{u} - \mathsf{F}_h \mathfrak{u}\|_V \to 0 \quad \textit{as } h \to 0.$$

Then, there is $h_* > 0$ and a constant $C > 0$ such that

$$\sup_{u_h \in W_h} \frac{|a(v_h, u_h)|}{\|u_h\|_V} \geq C\, \|v_h\|_V \quad \forall v_h \in W_h,\ h < h_*. \tag{11.1}$$

The assumptions of the abstract theory that seem to be most critical concern the existence of appropriate *bridge mappings* $\mathsf{H}_h : \boldsymbol{\mathcal{G}}_h \mapsto \boldsymbol{\mathcal{G}}$ and $\mathsf{F}_h : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}_h$. For their construction the components of $\boldsymbol{\mathcal{G}}$ will be targeted separately. It turns out that the same tools used in the definition of the decomposition are also very useful for building bridge mappings. We remark that existence of appropriate bridge mappings is equivalent to the assumptions (A1) and (A2) in [14, sect. 4.1].

First, we define $\mathsf{H}_h^\Omega : \mathbf{X}_h(\mathbf{curl}, \Omega_h) \mapsto \mathbf{X}(\mathbf{curl}, \Omega_s)$ by $\mathsf{H}_h^\Omega \mathbf{U}_h := \mathsf{P}\mathbf{U}_h$, $\mathbf{U}_h \in \mathbf{X}_h(\mathbf{curl}, \Omega_h)$. The projection property stated in Lemma 10.2 shows

$$\Pi_h^1 \mathsf{H}_h^\Omega \mathbf{U}_h = \Pi_h^1 \mathsf{P}\mathbf{U}_h = \mathsf{P}_h \mathbf{U}_h = \mathbf{U}_h \quad \forall \mathbf{U}_h \in \mathbf{X}_h(\mathbf{curl}, \Omega_h).$$

As $\mathbf{curl}\, \mathsf{H}_h^\Omega \mathbf{U}_h = \mathbf{curl}\, \mathbf{U}_h \in \boldsymbol{\mathcal{F}}_\nu^1(\Omega_h)$, Lemma 10.1 permits us to estimate

$$\begin{aligned} \left\|\mathbf{U}_h - \mathsf{H}_h^\Omega \mathbf{U}_h\right\|_{\boldsymbol{L}^2(\Omega_s)} &= \left\|(\Pi_h^1 - Id)\mathsf{H}_h^\Omega \mathbf{U}_h\right\|_{\boldsymbol{L}^2(\Omega_s)} \\ &\leq \tilde{C}h \left\|\mathsf{H}_h^\Omega \mathbf{U}_h\right\|_{\boldsymbol{H}^1(\Omega_s)} \leq \tilde{C}h \left\|\mathbf{curl}\, \mathbf{U}_h\right\|_{\boldsymbol{L}^2(\Omega_s)}. \end{aligned} \tag{11.2}$$

The same construction works for $\mathbf{X}_h(\mathrm{div}_\Gamma, \Gamma_h)$. We introduce $\mathsf{H}_h^\Gamma : \mathbf{X}_h(\mathrm{div}_\Gamma, \Gamma_h) \mapsto \mathbf{X}(\mathrm{div}_\Gamma, \Gamma)$ through $\mathsf{H}_h^\Gamma \boldsymbol{\mu}_h := \mathsf{P}^\Gamma \boldsymbol{\mu}_h$, $\boldsymbol{\mu}_h \in \mathbf{X}_h(\mathrm{div}_\Gamma, \Gamma_h)$. As above, now appealing to Lemma 10.4, we get

$$\Pi_h^\Gamma \mathsf{H}_h^\Gamma \boldsymbol{\mu}_h = \Pi_h^\Gamma \mathsf{P}^\Gamma \boldsymbol{\mu}_h = \mathsf{P}_h^\Gamma \boldsymbol{\mu}_h = \boldsymbol{\mu}_h \quad \forall \boldsymbol{\mu}_h \in \mathbf{X}_h(\mathrm{div}_\Gamma, \Gamma_h).$$

Then, $\mathrm{div}_\Gamma \mathsf{H}_h^\Gamma \boldsymbol{\mu}_h = \mathrm{div}_\Gamma \boldsymbol{\mu}_h$, along with Lemma 10.3, shows

$$\begin{aligned} \left\|\boldsymbol{\mu}_h - \mathsf{H}_h^\Gamma \boldsymbol{\mu}_h\right\|_{\boldsymbol{L}^2(\Gamma)} &= \left\|(\Pi_h^\Gamma - Id)\mathsf{H}_h^\Gamma \boldsymbol{\mu}_h\right\|_{\boldsymbol{L}^2(\Gamma)} \\ &\leq \tilde{C}h^{\frac{1}{2}} \left\|\mathsf{H}_h^\Gamma \boldsymbol{\mu}_h\right\|_{\boldsymbol{H}_\perp^{\frac{1}{2}}(\Gamma)} \leq \tilde{C}h^{\frac{1}{2}} \left\|\mathrm{div}_\Gamma \boldsymbol{\mu}_h\right\|_{H^{-\frac{1}{2}}(\Gamma)}. \end{aligned} \tag{11.3}$$

The kernels pose no difficulties, as $\mathbf{N}_h(\mathbf{curl}, \Omega_h) \subset \mathbf{N}(\mathbf{curl}, \Omega_s)$ and $\mathbf{N}_h(\mathrm{div}_\Gamma, \Gamma_h) \subset \mathbf{N}(\mathrm{div}_\Gamma, \Gamma)$. Therefore, we can finally define $\mathsf{H}_h : \boldsymbol{\mathcal{G}}_h \mapsto \boldsymbol{\mathcal{G}}$ through

$$\mathsf{H}_h(\boldsymbol{\mu}_h^\perp, \mathbf{V}_h^0, \boldsymbol{\mu}_h^0, \mathbf{V}_h^\perp) := (\mathsf{H}_h^\Gamma \boldsymbol{\mu}_h^\perp, \mathbf{V}_h^0, \boldsymbol{\mu}_h^0, \mathsf{H}_h^\Omega \mathbf{V}_h^\perp).$$

After replacing W, W_h by $\boldsymbol{\mathcal{G}}$, $\boldsymbol{\mathcal{G}}_h$, the uniform convergence required for Theorem 11.1 holds true.

To define F_h we first consider the $\boldsymbol{L}^2(\Omega_s)$-orthogonal projections $\mathsf{Q}_h^0 : \boldsymbol{L}^2(\Omega_s) \mapsto \mathbf{curl}\,\boldsymbol{\mathcal{E}}_{\nu+1}^1(\Omega_h)$, $h \in \mathbb{H}$. As $\boldsymbol{C}^\infty(\bar{\Omega}_s)$ is dense in $\boldsymbol{H}(\mathbf{curl};\Omega_s)$ and

$$\begin{aligned}\left\|\mathbf{curl}\,\mathbf{U} - \mathsf{Q}_h^0\,\mathbf{curl}\,\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} &\leq \left\|\mathbf{curl}\,\mathbf{U} - \Pi_h^2\,\mathbf{curl}\,\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} \\ &= \left\|\mathbf{curl}(Id - \Pi_h^1)\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} = O(h) \quad \text{as } h \to 0\end{aligned}$$

for fixed $\mathbf{U} \in \boldsymbol{C}^\infty(\bar{\Omega}_s)$, we find

$$\lim_{h\to 0} \left\|(Id - \mathsf{Q}_h^0)\,\mathbf{curl}\,\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} = 0 \quad \forall \mathbf{U} \in \boldsymbol{H}(\mathbf{curl};\Omega_s). \tag{11.4}$$

Then we define $\mathsf{F}_h^\Omega := \Pi_h^1 \circ \mathsf{L} \circ \mathsf{Q}_h^0 \circ \mathbf{curl}$. As in section 10, taking into account

$$\mathbf{curl}\,\mathsf{F}_h^\Omega\mathbf{U} = \mathbf{curl}\,\Pi_h^1\mathsf{L}(\mathsf{Q}_h^0\,\mathbf{curl}\,\mathbf{U}) = \Pi_h^2\mathsf{Q}_h^0\,\mathbf{curl}\,\mathbf{U} = \mathsf{Q}_h^0\,\mathbf{curl}\,\mathbf{U}$$

and Lemma 10.1, we see that the definition makes sense. On top of that, setting $\mathbf{U}^* := \mathsf{L}(\mathsf{Q}_h^0\,\mathbf{curl}\,\mathbf{U}) \in \mathbf{X}(\mathbf{curl},\Omega_s)$, we get the estimate

$$\begin{aligned}\left\|\mathbf{U} - \mathsf{F}_h^\Omega\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} &\leq \|\mathbf{U} - \mathbf{U}^*\|_{\boldsymbol{L}^2(\Omega_s)} + \left\|\mathbf{U}^* - \Pi_h^1\mathbf{U}^*\right\|_{\boldsymbol{L}^2(\Omega_s)} \\ &\leq C\,\|\mathbf{curl}(\mathbf{U} - \mathbf{U}^*)\|_{\boldsymbol{L}^2(\Omega_s)} + \tilde{C}h\,\|\mathbf{U}^*\|_{\boldsymbol{H}^1(\Omega_s)} \\ &\leq C\left\|(Id - \mathsf{Q}_h^0)\,\mathbf{curl}\,\mathbf{U}\right\|_{\boldsymbol{L}^2(\Omega_s)} + \tilde{C}h\,\|\mathbf{curl}\,\mathbf{U}\|_{\boldsymbol{L}^2(\Omega_s)}\,.\end{aligned} \tag{11.5}$$

Combined with (11.4), pointwise convergence in the $\boldsymbol{H}(\mathbf{curl};\Omega_s)$-norm can be inferred.

On the surface Γ a similar policy succeeds. It is based on the $H^{-\frac{1}{2}}(\Gamma)$-orthogonal projections $\mathsf{Q}_h^{\frac{1}{2}} : H^{-\frac{1}{2}}(\Gamma) \mapsto \mathcal{Q}_\nu(\Gamma_h)$. Density of $\bigcup\{\mathcal{Q}_\nu(\Gamma_h),\ h \in \mathbb{H}\}$ in $H^{-\frac{1}{2}}(\Gamma)$ shows

$$\lim_{h\to 0} \left\|\omega - \mathsf{Q}_h^{\frac{1}{2}}\omega\right\|_{H^{-\frac{1}{2}}(\Gamma)} = 0 \quad \forall \omega \in H^{-\frac{1}{2}}(\Gamma). \tag{11.6}$$

Then, introduce $\mathsf{F}_h^\Gamma := \Pi_h^\Gamma \circ \gamma_\times \circ \mathsf{J} \circ \mathsf{Q}_h^{\frac{1}{2}} \circ \mathrm{div}_\Gamma$ and observe

$$\mathrm{div}_\Gamma\mathsf{F}_h^\Gamma\boldsymbol{\lambda} = \mathsf{Q}_h^\Gamma(\mathrm{div}_\Gamma\gamma_\times\mathsf{J}(\mathsf{Q}_h^{\frac{1}{2}}\mathrm{div}_\Gamma\boldsymbol{\lambda})) = \mathsf{Q}_h^\Gamma\mathsf{Q}_h^{\frac{1}{2}}\mathrm{div}_\Gamma\boldsymbol{\lambda} = \mathsf{Q}_h^{\frac{1}{2}}\boldsymbol{\lambda}.$$

According to Lemma 10.3, the definition of F_h^Γ is meaningful, and as above we derive

$$\left\|\boldsymbol{\lambda} - \mathsf{F}_h^\Gamma\boldsymbol{\lambda}\right\|_{\boldsymbol{L}^2(\Gamma)} \leq C\|(Id - \mathsf{Q}_h^{\frac{1}{2}})\mathrm{div}_\Gamma\boldsymbol{\lambda}\|_{H^{-\frac{1}{2}}(\Gamma)} + \tilde{C}h^{\frac{1}{2}}\,\|\mathrm{div}_\Gamma\boldsymbol{\lambda}\|_{H^{-\frac{1}{2}}(\Gamma)}\,. \tag{11.7}$$

Again, pointwise convergence $\mathsf{F}_h^\Gamma\boldsymbol{\lambda} \to \boldsymbol{\lambda}$ in $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)$ follows.

The kernels are easier to deal with, because we may just use $\boldsymbol{L}^2(\Omega_s)/H^{-\frac{1}{2}}(\Gamma)$-orthogonal projections $\mathsf{N}_h^0 : \mathbf{N}(\mathbf{curl},\Omega_s) \mapsto \mathbf{N}_h(\mathbf{curl},\Omega_h)$ and $\mathsf{N}_h^{0,\Gamma} : \mathbf{N}(\mathrm{div}_\Gamma,\Gamma) \mapsto \mathbf{N}_h(\mathrm{div}_\Gamma,\Gamma_h)$, respectively. Simple density arguments establish their pointwise convergence in $\boldsymbol{L}^2(\Omega_s)$ and $H^{-\frac{1}{2}}(\Gamma)$, respectively, as $h \to 0$. Eventually, we have found that

$$\mathsf{F}_h(\boldsymbol{\mu}^\perp, \mathbf{V}^0, \boldsymbol{\mu}^0, \mathbf{V}^\perp) := (\mathsf{F}_h^\Gamma\boldsymbol{\mu}^\perp, \mathsf{N}_h^0\mathbf{V}^0, \mathsf{N}_h^{0,\Gamma}\boldsymbol{\mu}^0, \mathsf{F}_h^\Omega\mathbf{V}^\perp) \in \boldsymbol{\mathcal{G}}_h$$

is the right bridge mapping $\mathsf{F}_h : \boldsymbol{\mathcal{G}} \mapsto \boldsymbol{\mathcal{G}}_h$.

Remark 11.1. It is important to realize that the choice of both the continuous and discrete splittings is merely a theoretical tool. It does not affect the discrete problem at all, which remains given by (9.4). Therefore, different splittings may be used to investigate the *same* numerical scheme.

12. Convergence. The discovery of suitable bridge mappings paves the way for a quasi-optimal asymptotic estimate of the discretization error.

THEOREM 12.1. *Under Assumption* 1, *there exists a meshwidth* $h_* \in \mathbb{H}$, *depending only on* Ω_s, κ, ν *and on the shape-regularity of the triangulations* Ω_h, *such that for every* $h < h_*$ *the discrete problem* (9.4) *has a unique solution* $(\mathbf{E}_h, \boldsymbol{\lambda}_h) \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h) \times \boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)$, *which is quasi-optimal in the sense that*

$$\begin{aligned}\|\mathbf{E}-\mathbf{E}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} &+ \|\boldsymbol{\lambda}-\boldsymbol{\lambda}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \\ &\leq \tilde{C}\ \inf\left\{\begin{array}{l}\|\mathbf{E}-\mathbf{V}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} + \|\boldsymbol{\lambda}-\boldsymbol{\mu}_h\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)}, \\ (\mathbf{V}_h,\boldsymbol{\mu}_h) \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)\times\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h),\end{array}\right\}\end{aligned}$$

with a constant $\tilde{C} > 0$ *independent of* $(\mathbf{E}, \boldsymbol{\lambda})$ *and* $h \in \mathbb{H}$.

Proof. To begin with, we have to verify the assumptions of the abstract theory of Theorem 11.1: The role of V is now played by $\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \times \boldsymbol{H}(\mathbf{curl};\Omega_s) \times \boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma) \times \boldsymbol{H}(\mathbf{curl};\Omega_s)$. The spaces W, W_h have to be replaced by $\boldsymbol{\mathcal{G}}, \boldsymbol{\mathcal{G}}_h$. The bilinear forms $\widehat{a}_\kappa, \widehat{k}_\kappa, \widehat{d}_\kappa$ correspond to a, k, d. Continuity, compactness, and the inf-sup condition are clear from section 8 and, in particular, (8.3). Ultimately, we get h-uniform stability according to (11.1) for $\widehat{a}_\kappa$ on the family $\boldsymbol{\mathcal{G}}_h$, $h \in \mathbb{H}$, provided that h is sufficiently small.

We can now use this insight, the identity (8.2), and the following h-uniform equivalence of norms (deduced from Lemmas 10.2 and 10.4):

$$\left\|(\boldsymbol{\mu}_h^\perp, \mathbf{V}_h^0, \boldsymbol{\mu}_h^0, \mathbf{V}_h^\perp)\right\|_{\boldsymbol{\mathcal{G}}} \asymp \left\|(\mathbf{V}_h^\perp + \mathbf{V}_h^0, \boldsymbol{\mu}_h^\perp + \boldsymbol{\mu}_h^0)\right\|_{\boldsymbol{\mathcal{V}}} \quad \forall (\boldsymbol{\mu}_h^\perp, \mathbf{V}_h^0, \boldsymbol{\mu}_h^0, \mathbf{V}_h^\perp) \in \boldsymbol{\mathcal{G}}_h.$$

Taken together, these directly yield for $h < h_*$

$$\begin{aligned}(12.1)\qquad &\sup_{(\mathbf{U}_h,\boldsymbol{\zeta}_h)\in\boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)\times\boldsymbol{\mathcal{F}}^1_\nu(\Gamma_h)} \frac{|a_\kappa((\mathbf{V}_h,\boldsymbol{\mu}_h),(\mathbf{U}_h,\boldsymbol{\zeta}_h))|}{\|(\mathbf{U}_h,\boldsymbol{\zeta}_h)\|_{\boldsymbol{\mathcal{V}}}} \\ &\geq \tilde{C} \sup_{(\boldsymbol{\zeta}_h^\perp,\mathbf{U}_h^0,\boldsymbol{\zeta}_h^0,\mathbf{U}_h^\perp)\in\boldsymbol{\mathcal{G}}_h} \frac{|\widehat{a}_\kappa((\boldsymbol{\mu}_h^\perp,\mathbf{V}_h^0,\boldsymbol{\mu}_h^0,\mathbf{V}_h^\perp),(\boldsymbol{\zeta}_h^\perp,\mathbf{U}_h^0,\boldsymbol{\zeta}_h^0,\mathbf{U}_h^\perp))|}{\left\|(\boldsymbol{\zeta}_h^\perp,\mathbf{U}_h^0,\boldsymbol{\zeta}_h^0,\mathbf{U}_h^\perp)\right\|_{\boldsymbol{\mathcal{G}}}} \\ &\geq \tilde{C}\left\|(\boldsymbol{\mu}_h^\perp,\mathbf{V}_h^0,\boldsymbol{\mu}_h^0,\mathbf{V}_h^\perp)\right\|_{\boldsymbol{\mathcal{G}}} \geq \tilde{C}\,\|(\mathbf{V}_h,\boldsymbol{\mu}_h)\|_{\boldsymbol{\mathcal{V}}},\end{aligned}$$

with constants independent of the functions and $h \in \mathbb{H}$. Appealing to Babuška's theory [5], the error estimate of the theorem can be inferred. □

Prerequisite for establishing orders of convergence of best approximations in finite element spaces are assumptions on the smoothness of the continuous solutions. We will take for granted that both the electric and magnetic fields $\mathbf{E}, \mathbf{H} := \frac{1}{i\omega\mu_r}\,\mathbf{curl}\,\mathbf{E}$ belong to $\boldsymbol{H}^\sigma(\Omega_s)$ for some $\sigma > 0$. We point out that the regularity of solutions of Maxwell's equations depends on the discontinuities of the material parameters ϵ_r and μ_r [27]. The investigations in [27] show that we have to brace for very poor regularity with σ slightly larger than zero.

It is reasonable to demand that the discontinuities of μ_r and ϵ_r be resolved by the meshes Ω_h. That is, if Ω_i, $i = 1, \ldots, M$, $M \in \mathbb{M}$, are subdomains of Ω_s on which both material parameters are smooth, then $\Omega_{h|\Omega_i}$ must supply a valid triangulation of Ω_i, $i = 1, \ldots, M$. Then we can exploit $\mathbf{curl}\,\mathbf{E} = i\kappa\mu_r\mathbf{H}$ to see that $\mathbf{curl}\,\mathbf{E}$ is locally in $\boldsymbol{H}^\sigma(\Omega_i)$, $i = 1, \ldots, M$. Globally, $\mathbf{curl}\,\mathbf{E}$ is at least contained in $\boldsymbol{H}^{\min\{\sigma,\frac{1}{4}\}}(\Omega_s)$.

LEMMA 12.2. *If* $\mathbf{E}, \mathbf{H} \in \boldsymbol{H}^\sigma(\Omega_s)$ *for some* $\sigma > 0$, *and if the jumps of* ϵ_r, μ_r *are resolved by all triangulations, we find a constant* $\tilde{C} > 0$ *depending only on* ϵ_r, μ_r, Ω_s, ν, *and the shape-regularity of the meshes* Ω_h *such that*

$$\inf_{\mathbf{V}_h \in \boldsymbol{\mathcal{E}}^1_{\nu+1}(\Omega_h)} \|\mathbf{E} - \mathbf{V}_h\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} \leq \tilde{C} h^{\min\{\nu+1,\sigma\}} \left(\|\mathbf{E}\|_{\boldsymbol{H}^\sigma(\Omega_s)} + \sum_{i=1}^M \|H\|_{\boldsymbol{H}^\sigma(\Omega_i)} \right).$$

Proof. First, we restrict our attention to $\sigma > \frac{1}{2}$. Then, according to Lemma 9.1 and thanks to the strict locality of the nodal interpolation operators, we obtain

$$\left\|\mathbf{E} - \Pi^1_h \mathbf{E}\right\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} \leq \tilde{C} h^{\min\{\sigma,\nu+1\}} \left(\|\mathbf{E}\|_{\boldsymbol{H}^\sigma(\Omega_s)} + \sum_{i=1}^M \|H\|_{\boldsymbol{H}^\sigma(\Omega_i)} \right).$$

This estimate hinges on the resolution of the jumps of μ_r by the meshes.

Second, in order to cope with $\sigma \leq \frac{1}{2}$, we resort to the Helmholtz-type splitting $\mathbf{E} = \mathbf{E}^\perp + \mathbf{E}^0$ from (7.1). We start with an approximation for $\mathbf{E}^\perp \in \mathbf{X}(\mathbf{curl}, \Omega_s)$. As $\mathbf{X}(\mathbf{curl}, \Omega_s) \subset \boldsymbol{H}^1(\Omega_s)$ and $\mathbf{curl}\,\mathbf{E}^\perp \in \boldsymbol{H}^{\min\{\sigma,\frac{1}{4}\}}(\Omega_s)$, nodal interpolation is an option and it yields

$$\left\|\mathbf{E}^\perp - \Pi^1_h \mathbf{E}^\perp\right\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} \leq \tilde{C} h^\sigma \sum_{i=1}^M \|H\|_{\boldsymbol{H}^\sigma(\Omega_i)}. \tag{12.2}$$

Scalar potentials are the key to the treatment of $\mathbf{E}^0$: It is known that the irrotational vectorfield $\mathbf{E}^0$ has a representation

$$\mathbf{E}^0 = \mathbf{grad}\,\Phi + \mathbf{G}, \quad \Phi \in H^1(\Omega_s), \quad \mathbf{G} \in \boldsymbol{\mathcal{H}}(\Omega_s),$$

where $\boldsymbol{\mathcal{H}}(\Omega_s)$ is the space of harmonic Neumann vectorfields in Ω_s (see [4, sect. 3.c]). The dimension of $\boldsymbol{\mathcal{H}}(\Omega_s)$ is finite and agrees with the first Betti number $\beta_1(\Omega_s)$ of Ω_s. Moreover, a basis can be obtained from the solutions of the variational problems [4, Prop. 3.14]: Seek $\eta_j \in H^1_{[]}(\Omega_s \setminus \Sigma_j) := \{\varphi \in H^1(\Omega_s \setminus \Sigma_j), [\varphi]_{\Sigma_j} = \text{const}\}$, $j = 1, \dots, L := \beta_1(\Omega_s)$, such that

$$\int_{\Omega_s \setminus \Sigma_j} \mathbf{grad}\,\eta_j \cdot \mathbf{grad}\,\phi \, d\mathbf{x} = [\phi]_{\Sigma_j} \quad \forall \phi \in H^1_{[]}(\Omega_s \setminus \Sigma_j),$$

where Σ_j, $j = 1, \dots, \beta_1(\Omega_s)$, is a complete set of piecewise smooth Seifert surfaces for Ω_s. Hence, the η_j are fixed as solutions of Neumann problems with a jump condition across Σ_j. From them we construct $\boldsymbol{\mathcal{H}}(\Omega_s) = \text{Span}\,\{\mathbf{grad}\,\eta_1, \dots, \mathbf{grad}\,\eta_L\}$. As the exact position of the Seifert surface does not affect $\mathbf{grad}\,\eta_j$, they can always be assumed to be the union of faces of any mesh Ω_h. Besides, the regularity of $\mathbf{grad}\,\eta_j$ is determined only by the geometry of Ω_s, no matter where the Σ_j are located. More precisely, we find $\mathbf{grad}\,\eta_j \in \boldsymbol{H}^s(\Omega_s)$, where $s+1 < e_N(\Omega_s)$ and $e_N(\Omega_s)$ is the smallest singular exponent for the Neumann problem for Δ in Ω_s. This exponent depends on the angles at reentrant edges and corners of Ω_s. From [30] we know that $e_N > 3/2$ for any Lipschitz-polyhedron, and thus we can choose $s = 1/2$, at worst. At any rate, $\boldsymbol{\mathcal{H}}(\Omega_s) \subset \boldsymbol{H}^{\frac{1}{2}}(\Omega_s)$ and $\boldsymbol{\mathcal{H}}(\Omega_s) \subset \text{Dom}(\Pi^1_h)$ will hold.

To deal with the scalar potential Φ we resort to continuous quasi-interpolation operators $\mathsf{Z}_h : H^1(\Omega_s) \mapsto \mathcal{S}_{\nu+1}(\Omega_h)$ onto the space $\mathcal{S}_{\nu+1}(\Omega_h)$ of continuous, piecewise polynomial (of degree $\nu+1$) scalar functions on Ω_h. Such operators have been introduced, for instance, in [48].

With these powerful tools at our disposal, we set $\mathbf{V}_h^0 := \mathbf{grad}\,\mathsf{Z}_h\Phi + \Pi_h^1\mathbf{G}$. Please note that another commuting diagram property [44] ensures $\mathbf{grad}\,\mathcal{S}_{\nu+1}(\Omega_h) \subset \boldsymbol{\mathcal{E}}_{\nu+1}^1(\Omega_h)$. Using the interpolation properties of the Z_h and that $\mathbf{curl}\,\mathbf{G} = 0$, we end up with

$$\begin{aligned}\left\|\mathbf{E}^0 - \mathbf{V}_h^0\right\|_{\boldsymbol{L}^2(\Omega_s)} &\leq \left\|\mathbf{grad}(Id - \mathsf{Z}_h)\Phi\right\|_{\boldsymbol{L}^2(\Omega_s)} + \left\|(Id - \Pi_h^1)\mathbf{G}\right\|_{\boldsymbol{L}^2(\Omega_s)} \\ &\leq \tilde{C}h^\sigma \left\|\Phi\right\|_{\boldsymbol{H}^{\sigma+1}(\Omega_s)} + \tilde{C}h^s \left\|\mathbf{G}\right\|_{\boldsymbol{H}^s(\Omega_s)} \leq \tilde{C}h^\sigma \left\|\mathbf{E}^0\right\|_{\boldsymbol{H}^\sigma(\Omega_s)} . \qquad (12.3)\end{aligned}$$

Collecting the estimates (12.2) and (12.3), $\Pi_h^1\mathbf{E}^\perp + \mathbf{V}_h^0$ provides the desired approximation of $\mathbf{E}$ of order σ in $\boldsymbol{H}(\mathbf{curl};\Omega_s)$. □

Next, we turn to the approximation of $\boldsymbol{\lambda}$.

LEMMA 12.3. *Assume that the meshes Ω_h resolve the discontinuities of both ϵ_r and μ_r, that $\mathbf{H}, \mathbf{E} \in \boldsymbol{H}^\sigma(\Omega_s)$, $\sigma > 0$, and that $\mathbf{E}_{\mathrm{inc}}$ is smooth. Then*

$$\begin{aligned}\left\|\boldsymbol{\lambda} - \Pi_h^\Gamma\boldsymbol{\lambda}\right\|_{\boldsymbol{H}^{-\frac{1}{2}}(\mathrm{div}_\Gamma,\Gamma)} \leq \tilde{C}h^{\min\{\nu+1,\sigma\}} \Bigg(&\left\|\mathbf{H}\right\|_{\boldsymbol{H}^\sigma(\Omega_s)} + \sum_{i=1}^{M} \left\|\mathbf{E}\right\|_{\boldsymbol{H}^\sigma(\Omega_i)} \\ &+ \left\|\mathbf{E}_{\mathrm{inc}}\right\|_{\boldsymbol{H}^{\sigma+1}(\Omega_s)} \Bigg),\end{aligned}$$

where $\tilde{C} > 0$ depends neither on $\mathbf{E}, \mathbf{H}, \mathbf{E}_{\mathrm{inc}}$ nor on $h \in \mathbb{H}$.

Proof. We exploit that $\boldsymbol{\lambda} = \gamma_{\mathbf{t}}^-\mathbf{H} + \gamma_{\mathbf{t}}\mathbf{H}_{\mathrm{inc}}$. As $\mathbf{E} = i\kappa\epsilon_r\,\mathbf{curl}\,\mathbf{H}$, a complete role reversal of $\mathbf{E}$ and $\mathbf{H}$ is possible in the arguments of the previous proof. The final result is

$$\inf_{\mathbf{V}_h \in \boldsymbol{\mathcal{E}}_{\nu+1}^1(\Omega_h)} \left\|\mathbf{H} - \mathbf{V}_h\right\|_{\boldsymbol{H}(\mathbf{curl};\Omega_s)} \leq \tilde{C}h^{\min\{\nu+1,\sigma\}} \left(\left\|\mathbf{H}\right\|_{\boldsymbol{H}^\sigma(\Omega_s)} + \sum_{i=1}^{M} \left\|\mathbf{E}\right\|_{\boldsymbol{H}^\sigma(\Omega_i)} \right).$$

Then, the trace Theorem 3.3, combined with (9.2), shows the assertion of the lemma. □

Along with Theorem 12.1 this implies convergence of the Galerkin solutions in $\boldsymbol{\mathcal{E}}_{\nu+1}^1(\Omega_h) \times \boldsymbol{\mathcal{F}}_\nu^1(\Gamma_h)$ of the order $O(h^{\min\{\nu+1,\sigma\}})$ in the natural (energy) norms as $h \to 0$.

Acknowledgement. The author is grateful to Dr. A. Buffa, Prof. T. von Petersdorff, and Prof. C. Schwab from ETH Zürich for a very fruitful collaboration that much inspired the present paper.

ON MAGNUS INTEGRATORS FOR TIME-DEPENDENT SCHRÖDINGER EQUATIONS[*]

MARLIS HOCHBRUCK[†] AND CHRISTIAN LUBICH[‡]

Abstract. Numerical methods based on the Magnus expansion are an efficient class of integrators for Schrödinger equations with time-dependent Hamiltonian. Though their derivation assumes an unreasonably small time step size, as would be required for a standard explicit integrator, the methods perform well even for much larger step sizes. This favorable behavior is explained, and optimal-order error bounds are derived that require no or only mild restrictions of the step size. In contrast to standard integrators, the error does not depend on higher time derivatives of the solution, which is in general highly oscillatory.

Key words. Magnus integrators, time-dependent Schrödinger equation, commutator bounds, error bounds

1. Introduction.

We study numerical integrators for Schrödinger equations with time-dependent Hamiltonian,

$$i\,\frac{d\psi}{dt} = H(t)\psi, \qquad \psi(t_0) = \psi_0. \tag{1.1}$$

The computational Hamiltonian $H(t)$, which is a finite-dimensional Hermitian operator, is typically the sum of a discretized negative Laplacian and a time-dependent potential. As the discretization of an unbounded operator, $H(t)$ can be of arbitrarily large norm.

Magnus integrators are an interesting class of numerical methods for such problems [3, 12]. Though the error behavior of such methods is well understood in the case of moderately bounded $H(t)$ (see [6, 7]), no results are so far available when $\|H(t)\|$ becomes large. The present paper gives optimal-order estimates for situations in which the product of the time step h with $\|H(t)\|$ can be of arbitrary size. Even more interesting than the error bounds themselves are the mechanisms which lead to these bounds and which make Magnus methods perform so well for Schrödinger equations, as compared to standard explicit or implicit numerical integrators.

In section 2 we recall the concepts underlying the construction of Magnus integrators. Section 3 states the main results, which give asymptotically sharp error bounds for Magnus integrators, in a framework that applies to time-dependent Schrödinger equations requiring neither smallness nor bounds of $h\|H(t)\|$. The general procedure for obtaining such estimates is outlined in section 4 and is carried out in detail in sections 5 and 6 for methods of order 2 and 4, respectively. The extension to methods of arbitrary order is done in section 7. Numerical experiments illustrating the theoretical results are given in section 8. A basic assumption for the results of this

paper is commutator bounds; their validity for a spectral discretization is shown in the appendix.

Magnus integrators require computing a matrix exponential multiplying a vector in every time step. For the large matrices (or rather, operators of large dimension) arising from the spatial discretization of Schrödinger equations, this can be done efficiently using operator splitting or Chebyshev or Lanczos approximations. These techniques are well documented in the literature and are not considered here. Because of the stable error propagation, errors arising from the approximation of the matrix exponentials could be straightforwardly included in the error analysis.

2. Magnus integrators. For the linear differential equation

$$\dot{y} = A(t)y, \qquad y(0) = y_0, \tag{2.1}$$

with a time-dependent matrix $A(t)$, the approach of Magnus [9] aims at writing the solution as

$$y(t) = \exp(\Omega(t))y_0 \tag{2.2}$$

for a suitable matrix $\Omega(t)$. An expression for $\Omega(t)$ is obtained by using the ansatz (2.2) and differentiating. This gives

$$\dot{y}(t) = \operatorname{dexp}_{\Omega(t)}(\dot{\Omega}(t))\, y(t),$$

where the dexp operator can be expressed as

$$\operatorname{dexp}_{\Omega}(B) = \varphi(\operatorname{ad}_\Omega)(B) = \sum_{k\ge 0} \frac{1}{(k+1)!}\operatorname{ad}_\Omega^k(B), \tag{2.3}$$

with $\varphi(z) = (e^z - 1)/z$ and $\operatorname{ad}_\Omega(B) = [\Omega, B] = \Omega B - B\Omega$. Hence, (2.2) solves (2.1) if

$$A(t) = \operatorname{dexp}_{\Omega(t)}(\dot{\Omega}(t)), \qquad \Omega(0) = 0. \tag{2.4}$$

As long as $\|\Omega(t)\| < \pi$ (which is *not* the situation of interest in this article), the operator $\operatorname{dexp}_{\Omega(t)}$ is invertible, and the series

$$\operatorname{dexp}^{-1}_{\Omega(t)}(A(t)) = \sum_{k\ge 0} \frac{\beta_k}{k!}\operatorname{ad}^k_{\Omega(t)}(A(t)) \tag{2.5}$$

converges. Here β_k is the kth Bernoulli number appearing in the series $z/(e^z-1) = \sum_0^\infty (\beta_k/k!)z^k$, which converges for $|z| < 2\pi$. (Note that $\|\operatorname{ad}_\Omega(B)\| \le 2\|\Omega\|\cdot\|B\|$, which shows that (2.5) indeed converges for $\|\Omega(t)\| < \pi$.) This gives an explicit differential equation for $\Omega(t)$:

$$\dot{\Omega} = A(t) - \frac{1}{2}[\Omega, A(t)] + \frac{1}{12}[\Omega,[\Omega, A(t)]] + \cdots .$$

Picard iteration yields the *Magnus expansion*

$$\begin{aligned}\Omega(t) = \int_0^t A(\tau)d\tau &- \frac{1}{2}\int_0^t \left[\int_0^\tau A(\sigma)d\sigma, A(\tau)\right] d\tau \\ &+ \frac{1}{4}\int_0^t \left[\int_0^\tau \left[\int_0^\sigma A(\mu)d\mu, A(\sigma)\right] d\sigma, A(\tau)\right] d\tau \\ &+ \frac{1}{12}\int_0^t \left[\int_0^\tau A(\sigma)d\sigma, \left[\int_0^\tau A(\mu)d\mu, A(\tau)\right]\right] d\tau + \cdots .\end{aligned} \tag{2.6}$$

Numerical methods based on this expansion are reviewed by Iserles, et al. [6]. They are of the form

$$y_{n+1} = \exp(\Omega_n) y_n \tag{2.7}$$

to give an approximation to $y(t_{n+1})$ at $t_{n+1} = t_n + h$. Here Ω_n is a suitable approximation of $\Omega(h)$ given by (2.6), with $A(t_n + \tau)$ instead of $A(\tau)$. This approximation involves first truncating the expansion, and second approximating the integrals, e.g., by replacing $A(t)$ locally by an interpolation polynomial $\widehat{A}(t)$ for the nodes $t_n + c_j h$, so that the integrals in the Magnus expansion can be computed analytically. If Ω_n is built up in this way, then we speak of an *interpolatory Magnus integrator.* A method of order p is obtained by combining a pth order truncation of the Magnus series and interpolation of $A(t)$ at the nodes of a pth order quadrature formula. A natural choice is Gaussian quadrature.

For example, the midpoint rule yields a second-order scheme with

$$\Omega_n = hA\left(t_n + \frac{h}{2}\right). \tag{2.8}$$

The two-point Gauss quadrature rule has nodes $c_{1,2} = 1/2 \mp \sqrt{3}/6$. This yields a fourth-order scheme with

$$\Omega_n = \frac{h}{2}(A_1 + A_2) + \frac{\sqrt{3}h^2}{12}[A_2, A_1], \tag{2.9}$$

where $A_j = A(t_n + c_j h)$, $j = 1, 2$.

High-order interpolatory Magnus integrators require the computation of many commutators per step. Their number can be significantly reduced in specially constructed (noninterpolatory) Magnus integrators as given by Blanes, Casas, and Ros [2].

For the purpose of this paper, the Magnus series approach is described only for motivation, since we are interested in the case of large $\|hA(t)\|$, for which $\operatorname{dexp}_{\Omega_n}$ need not be invertible and the Magnus expansion need not converge. The known convergence proofs of the Magnus series (see [1, 10]) require that the time interval be restricted to $\int_0^t \|A(\tau)\|\, d\tau \le r$ with $r \approx 1$, and there are actually examples of matrix functions with divergent Magnus series for $\int_0^t \|A(\tau)\|\, d\tau = \pi$. (The example of [10, p. 30] is, admittedly, not of the type studied in this paper.) In any case, the question of convergence of the Magnus series is irrelevant for the problem of obtaining error bounds, much in the same way as the possible convergence or divergence of Taylor series is of no importance for finite-order error bounds elsewhere in numerical analysis. The possible noninvertibility of the dexp operator and even the nonexistence of a representation (2.2) of the exact solution would appear to be more serious obstacles, but we will show how this problem can be circumvented, using a modified differential equation satisfied by the approximate solution instead of directly estimating the difference between the Magnus expansion and its truncation.

The results of Iserles and Nørsett [7] on the order of Magnus integrators are for $\|hA(t)\| \to 0$ and are obtained by studying the remainder of the truncated Magnus series (2.6). The constants in those estimates depend on norms of commutators of $A(t)$ for different values of t, which all become large with growing $\|A(t)\|$. Therefore, results on the classical order of a method must be viewed with caution in the case of the Schrödinger equation, which involves discretizations of unbounded operators. Nevertheless, Magnus integrators work extremely well even with step sizes for which $\|hA(t)\|$ is large. The aim of the present paper is to explain this unexpectedly good behavior.

3. Statement of results.

In this section we state our assumptions and main results. Throughout the paper, $\|\cdot\|$ is the Euclidean norm or its induced matrix norm, or occasionally the L^2 norm of functions. We write

$$A(t) = -iH(t) = -i(U + V(t)). \tag{3.1}$$

We assume, once and for all, that the Hermitian matrix-valued function $V(t)$ and its time derivatives are bounded by

$$\left\| \frac{d^m}{dt^m} V(t) \right\| \le M_m, \qquad m = 0, 1, 2, \dots . \tag{3.2}$$

The matrix U is assumed to be symmetric positive definite, with $\|v\| \le \|Uv\|$ for all v, but no bound is assumed for the operator norm $\|U\|$. We set

$$D = U^{1/2}. \tag{3.3}$$

The typical situation is given by a discretization of the spatially continuous case where $U = -\Delta + I$, e.g., with periodic boundary conditions on a cube Q, and $V(t)$ is a bounded multiplication operator, i.e., $(V(t)v)(x) = V(x,t)v(x)$ for a real-valued smooth potential $V(x,t)$. In this continuous case we have

$$\|Dv\|^2 = \int_Q |\nabla v|^2 dx + \int_Q v^2 dx,$$

so that $\|Dv\|$ is the familiar H^1 Sobolev norm of v. In the spatially discretized case, $\|Dv\|$ can be viewed as a discrete Sobolev norm. For a space discretization with minimal grid spacing Δx, we note $\|U\| \sim \Delta x^{-2}$ and $\|D\| \sim \Delta x^{-1}$.

Our main assumptions are commutator bounds such as

$$\|[U, V(t)]v\| \le K_0 \|Dv\| \quad \text{and} \quad \|[U, \dot V(t)]v\| \le K_1 \|Dv\| \tag{3.4}$$

for all t and all vectors v. Condition (3.4) is easily verified in the spatially continuous case, with $U = -\Delta + I$ and a smooth potential $V(x,t)$ acting as a multiplication operator. The bound is obtained by noting that in one space dimension, with $' = d/dx$,

$$[U, V]v = -((Vv)'' - Vv'') = -(2V'v' + V''v),$$

with the obvious generalization to higher space dimensions. Hence, $[U, V]$ is a *first-order* differential operator, which yields (3.4). For a spectral discretization the bound (3.4) is shown, uniformly in the discretization parameter, in [8, Lemma 3.1].

Since $[A(\tau), A(\sigma)] = [U, V(\sigma) - V(\tau)] = \int_\tau^\sigma [U, \dot V(t)]\, dt$ (when $V(\sigma)$ and $V(\tau)$ commute), the second bound of (3.4) implies, for all vectors v,

$$\|[A(\tau), A(\sigma)]v\| \le K_1 h \, \|Dv\| \qquad \text{for } |\tau - \sigma| \le h. \tag{3.5}$$

THEOREM 3.1. *If $A(t)$ satisfies the commutator bound* (3.5), *then the error of the exponential midpoint rule* (2.7) *with* (2.8) *is bounded by*

$$\|y_n - y(t_n)\| \le Ch^2 \, t_n \max_{0 \le t \le t_n} \|Dy(t)\|.$$

The constant C depends only on M_m for $m \le 2$ and on K_1. In particular, C is independent of n, h, and $\|D\|$.

This error bound is to be contrasted with the error bound of the classical implicit midpoint rule $y_{n+1} = y_n + hA(t_{n+1/2})(y_n + y_{n+1})/2$, for which

$$\|y_n - y(t_n)\| \le Ch^2\, t_n \max_{0\le t\le t_n} \left\| \frac{d^3}{dt^3} y(t) \right\|.$$

Since solutions of Schrödinger equations are in general highly oscillatory, the appearance of higher time derivatives is unfavorable. On the other hand, $\|Dy(t)\|^2$ represents essentially the quantum kinetic energy, which is bounded a priori. We remark that a similar but weaker estimate for the exponential midpoint rule, with $\|D^2 y(t)\|$ instead of $\|Dy(t)\|$, was previously obtained in our paper [5] with a different proof. (Unfortunately, that paper also states an error bound for a third-order Magnus method, without detailed proof and involving the operator norm $\|U\|$, which is superseded by the results of the present paper.)

For methods of order p which contain commutator products of $A(t_n + c_j h)$ with r factors (in Example 2 we have $r = 2$ for order $p = 4$, and $r \le p - 1$ holds for all Magnus methods proposed in the literature), we assume that A satisfies, for all τ_j,

$$\left\| \left[A(\tau_k), \left[\dots, \left[A(\tau_1), \frac{d^m}{dt^m} V(\tau_0) \right] \right] \dots \right] v \right\| \le K\, \|D^k v\| \qquad \begin{cases} 0 \le m \le p, \\ k+1 \le rp. \end{cases} \tag{3.6}$$

Like (3.5), condition (3.6) is easily verified in the spatially continuous case. For a spectral space discretization of a time-dependent Schrödinger equation, we show in the appendix that (3.6) is indeed satisfied uniformly in the discretization parameter. Since $[A(\tau_1), A(\tau_0)] = [A(\tau_1), A(\tau_0) - A(\tau_1)] = [A(\tau_1), i\int_{\tau_0}^{\tau_1} \dot V(\tau) d\tau]$, condition (3.6) implies, whenever $|\tau_1 - \tau_0| \le h$,

$$\|[A(\tau_k), [\dots, [A(\tau_1), A(\tau_0)]] \dots] v\| \le Kh\, \|D^k v\|, \qquad k+1 \le rp. \tag{3.7}$$

Unlike the case of the exponential midpoint rule in Theorem 3.1, convergence of higher-order methods is shown only in the spatially discrete case under a step size restriction

$$h\, \|D\| \le c. \tag{3.8}$$

Note that this restriction is milder than the step size restriction for explicit integrators, such as Runge–Kutta methods, for which a more stringent condition $h\|D\|^2 \le c$ (i.e., $h\|A(t)\| \le \gamma$ for some constant γ) is required for stability. The classical error bounds for implicit integrators require smallness of $h\|D\|^2$ unless high temporal smoothness is supposed.

The following error bound holds for pth-order interpolatory Magnus integrators, i.e., those based on a pth-order truncation of the Magnus series and polynomial interpolation of $A(t)$ at the nodes of a pth-order quadrature formula (see section 2).

THEOREM 3.2. *If the commutator bounds* (3.6) *hold, then pth-order interpolatory Magnus integrators satisfy the error bound*

$$\|y_n - y(t_n)\| \le Ch^p\, t_n \max_{0\le t\le t_n} \|D^{p-1} y(t)\|$$

for time steps h restricted by (3.8). *The constant C depends only on M_m for $m \le p$, on K, c, and on p. In particular, C is independent of n, h, and $\|D\|$ as long as $h\|D\| \le c$.*

The error bound of Theorem 3.2 is valid also for noninterpolatory Magnus methods if the quadrature error satisfies, for all v,

$$\|\Omega_n v - \widetilde{\Omega}_n v\| \le C h^{p+1}\, \|D^{p-1} v\|, \tag{3.9}$$

where $\widetilde{\Omega}_n$ denotes the pth-order truncation of the Magnus series at t_n. This generalization of Theorem 3.2 follows directly from the proof below.

Condition (3.8) is not required for stability. If such a condition on the step size is not imposed, there is still pth-order convergence, though only for much smoother solutions: the error is then bounded by $C_p h^p \max \|D^{p-1} y(t)\| + C_{p+1} h^{p+1} \max \|D^p y(t)\| + \cdots + C_{pr} h^{pr} \max \|D^{pr-1} y(t)\|$.

Though Theorem 3.2 is formulated for arbitrary order p, we note that high-order error bounds are of limited value in the approximation of highly oscillatory solutions, for which (discretized) high-order derivatives $D^k y(t)$ have progressively much larger norms.

Theorems 3.1 and 3.2 are proved in the remainder of this article. In the following section we describe a general procedure for deriving error bounds. We will follow this procedure in detail for the exponential midpoint rule in section 5 and for fourth-order methods in section 6. This gives all the tools for the extension to the general case, which is treated in section 7.

4. General procedure for deriving error bounds.

The convergence analysis is done in two steps. In the first step we study the error which results from truncating the Magnus expansion; in the second step, we discuss the error resulting from approximating the integrals by quadrature. (In the estimates of this and the following sections, C is a generic constant, which assumes different values on different occurrences.)

Truncation of the Magnus expansion amounts to using a modified $\widetilde{\Omega}$ instead of Ω in (2.2), i.e.,

$$\widetilde{y}(t) = \exp(\widetilde{\Omega}(t)) y_0.$$

By differentiating, we obtain the approximate solution $\widetilde{y}(t)$ as the solution of the modified differential equation

$$\dot{\widetilde{y}}(t) = \widetilde{A}(t)\widetilde{y}(t) \qquad \text{with} \qquad \widetilde{A}(t) = \operatorname{dexp}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t)), \tag{4.1}$$

with initial value $\widetilde{y}(0) = y_0$. Note that the truncated Magnus series $\widetilde{\Omega}(t)$ and the modified operator $\widetilde{A}(t)$ are skew Hermitian if $A(t)$ is skew Hermitian. As the following lemma shows, a bound on $\widetilde{A} - A$ then immediately gives a local error bound.

LEMMA 4.1. *Let y be a solution of* (2.1) *with skew Hermitian A, $\widetilde{y}$ a solution of* (4.1). *With $E = \widetilde{A} - A$, the error satisfies*

$$\|\, \widetilde{y}(t) - y(t)\, \| \le \int_0^t \|E(\tau) y(\tau)\| d\tau.$$

Proof. We write (2.1) as $\dot{y} = A(t)y = \widetilde{A}(t)y - E(t)y$ and subtract (4.1). This shows that the error $\widetilde{\varepsilon} = \widetilde{y} - y$ satisfies

$$\dot{\widetilde{\varepsilon}} = \widetilde{A}(t)\widetilde{\varepsilon} + E(t)y, \qquad \widetilde{\varepsilon}(0) = 0.$$

Since $\widetilde{A}$ is skew Hermitian, taking the inner product with $\widetilde{\varepsilon}$ on both sides leads to

$$\langle \dot{\widetilde{\varepsilon}}, \widetilde{\varepsilon} \rangle = \langle E\, y, \widetilde{\varepsilon} \rangle \leq \|E\, y\| \, \|\widetilde{\varepsilon}\|.$$

On the other hand, $\langle \dot{\widetilde{\varepsilon}}, \widetilde{\varepsilon} \rangle = \frac{1}{2} \frac{d}{dt} \|\widetilde{\varepsilon}\|^2 = \frac{d}{dt} \|\widetilde{\varepsilon}\| \cdot \|\widetilde{\varepsilon}\|$. Integrating the inequality proves the lemma. □

A crucial step in obtaining a bound on $E = \widetilde{A} - A$ is truncating the dexp series (2.3) and providing a bound for the remainder. We define the remainder function r_p, for $p \geq 1$, via

$$\frac{e^z - 1}{z} = 1 + \frac{1}{2} z + \cdots + \frac{1}{(p-1)!}\, z^{p-2} + \frac{1}{p!}\, z^{p-1} r_p(z), \tag{4.2}$$

so that

$$\operatorname{dexp}_\Omega(B) = B + \frac{1}{2}[\Omega, B] + \cdots + \frac{1}{(p-1)!}\, \mathrm{ad}_\Omega^{p-2}(B) + \frac{1}{p!}\, r_p(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^{p-1}(B)\big). \tag{4.3}$$

For $A(t)$ of the form (3.1) satisfying the conditions of section 3, we will bound the remainder term by

$$\Big\| r_p(\mathrm{ad}_{\widetilde{\Omega}(t)})\big(\mathrm{ad}_{\widetilde{\Omega}(t)}^{p-1}\big(\dot{\widetilde{\Omega}}(t)\big)\big) v \Big\| \leq C h^p \, \|D^{p-1} v\|, \qquad 0 \leq t \leq h. \tag{4.4}$$

In the case of $p > 2$, it turns out that the bound requires time steps h with (3.8), while for $p = 2$, no restriction on h is necessary.

Next we incorporate the error resulting from approximating the integrals. In the nth time step, we take $\widetilde{\Omega}(h)$ corresponding to the truncated Magnus series for $A(t_n + t)$ instead of $A(t)$, which we denote by $\widetilde{\Omega}_n$. By the quadrature approximation, $\widetilde{\Omega}_n$ is replaced by Ω_n, with which the actual computations are done. This approximation typically satisfies

$$\|\big(\widetilde{\Omega}_n - \Omega_n\big) v\| \leq C h^{p+1} \|D^{r-1} v\|, \tag{4.5}$$

where p is the order of the quadrature rule and commutator products with r factors appear in the method. For the exponential midpoint rule ($p = 2$, $r = 1$) this bound is independent of D. For pth-order interpolatory Magnus schemes (where $r \leq p - 1$) we will show that (4.5) holds and that this leads to the local error bound

$$\|\exp(\widetilde{\Omega}_n) v - \exp(\Omega_n) v\| \leq C h^{p+1} \|D^{r-1} v\|. \tag{4.6}$$

Putting both steps together, the exact solution y of (2.1) satisfies

$$y(t_{n+1}) = \exp(\Omega_n) y(t_n) + \varepsilon_n, \tag{4.7}$$

with $\varepsilon_n = y(t_{n+1}) - \exp(\widetilde{\Omega}_n) y(t_n) + \exp(\widetilde{\Omega}_n) y(t_n) - \exp(\Omega_n) y(t_n)$. By Lemma 4.1 and (4.6), this gives

$$\|\varepsilon_n\| \leq \int_{t_n}^{t_{n+1}} \|E(\tau) y(\tau)\| d\tau + C h^{p+1} \|D^{r-1} y(t_n)\|.$$

Subtracting (2.7) from (4.7) leads to the error recursion for $e_n = y_n - y(t_n)$:

$$e_{n+1} = \exp(\Omega_n) e_n + \varepsilon_n,$$

and thus

$$\|e_n\| \le \sum_{j=0}^{n-1} \|\varepsilon_j\|. \tag{4.8}$$

In summary, error bounds for general Magnus methods are obtained as follows: we have to provide a bound on $E(t)y(t)$, which basically means proving (4.4), and we have to show that the approximation Ω_n satisfies (4.6). This program is carried out in the following sections.

5. Error bounds for the exponential midpoint rule. In this section we prove Theorem 3.1. The second-order truncation of the Magnus expansion is simply

$$\widetilde{\Omega}(t) = \int_0^t A(\tau)\, d\tau, \qquad 0 \le t \le h.$$

Following the approach described in section 4, we know that $\widetilde{y}(t) = \exp(\widetilde{\Omega}(t))y_0$ solves (4.1) with

$$\widetilde{A}(t) = \operatorname{dexp}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t)) = A(t) + \frac{1}{2} r_2(\mathrm{ad}_{\widetilde{\Omega}(t)})\big(\mathrm{ad}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t))\big) =: A(t) + E_2(t), \tag{5.1}$$

where the representation (4.3) for the dexp operator was used. The remainder r_2 was defined in (4.2).

LEMMA 5.1. *r_2 satisfies* (4.4) *with $p = 2$, where the constant C depends only on M_0 of* (3.2) *and K_1 of* (3.5).

Proof. (a) We fix an arbitrary t with $0 \le t \le h$. After an orthogonal similarity transform, we may assume that $\Omega := \widetilde{\Omega}(t)$ is diagonal, $\Omega = \mathrm{diag}(\omega_k)$ with purely imaginary eigenvalues ω_k, and we define $B = \dot{\widetilde{\Omega}}(t)$. Denoting by $\bullet$ the entrywise product of matrices, we can write

$$\mathrm{ad}_\Omega(B) = \Omega B - B\Omega = Z \bullet B,$$

where $Z = (\omega_k - \omega_\ell)_{k,\ell}$. This yields

$$r_p(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^{p-1}(B)\big)v = \big(R \bullet \mathrm{ad}_\Omega^{p-1}(B)\big)v,$$

where $R = (r_p(\omega_k - \omega_\ell))_{k,\ell}$. We now follow the proof of Lemma 2.2 of [5]. Note that for real x, $r_p(ix) = 1 + O(x)$, $x \to 0$, and $r_p(ix) = O(x^{-1})$, $|x| \to \infty$, and hence $r_p, r_p' \in L^2(i\mathbb{R})$. As can be seen, e.g., from formula (2.13) in [5], r_p has a Fourier transform $\widehat{r}_p \in L^1(\mathbb{R})$,

$$r_p(ix) = \int_{\mathbb{R}} e^{i\xi x} \widehat{r}_p(\xi)\, d\xi,$$

with $\|\widehat{r}_p\|_{L^1(\mathbb{R})} \le 2\pi \|r_p\|_{L^2(i\mathbb{R})}^{1/2} \|r_p'\|_{L^2(i\mathbb{R})}^{1/2}$. Consequently, the above expression can be written as

$$r_p(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^{p-1}(B)\big)v = \int_{\mathbb{R}} \widehat{r}_p(\xi) \exp(\xi\Omega)\, \mathrm{ad}_\Omega^{p-1}(B) \exp(-\xi\Omega)\, v\, d\xi,$$

so that

$$\Big\| r_p(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^{p-1}(B)\big)v \Big\| \le \|\widehat{r}_p\|_{L^1(\mathbb{R})} \sup_{\xi\in\mathbb{R}} \|\mathrm{ad}_\Omega^{p-1}(B) \exp(-\xi\Omega) v\|. \tag{5.2}$$

So far, this holds for general p.

(b) From now on, we set $p = 2$. Using

$$\mathrm{ad}_\Omega(B) = \mathrm{ad}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t)) = [\widetilde{\Omega}(t), \dot{\widetilde{\Omega}}(t)] = \int_0^t [A(\tau), A(t)]\, d\tau$$

and (3.5), we obtain for all vectors w

$$\|\mathrm{ad}_\Omega(B)w\| \le K_1 h^2 \|Dw\|.$$

Hence we have

$$\left\| r_p(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^{p-1}(B)\big)v \right\| \le Ch^2 \sup_{\xi\in\mathbb{R}} \|D\exp(-\xi\Omega)v\|. \tag{5.3}$$

We now use the splitting (3.1) and write

$$\frac{i}{t}\Omega = U + \frac{1}{t}\int_0^t V(\tau)d\tau =: U + \widetilde{V}.$$

We choose $\alpha \ge 0$ such that $U+\widetilde{V}+\alpha I$ is symmetric and positive definite. To keep the notation simple, we omit the constants and denote by $\sim$ equivalent norms. Because of the boundedness of $\widetilde{V}$ and (3.3), we have for all vectors w

$$\|Dw\| = \sqrt{w^* U w} \sim \sqrt{w^*(U+\widetilde{V}+\alpha I)w} = \left\| \left(\frac{i}{t}\Omega + \alpha I\right)^{1/2} w \right\|.$$

We use this norm equivalence to bound the last factor in (5.3):

$$\begin{aligned} \|D\exp(-\xi\Omega)v\| &\sim \left\| \left(\frac{i}{t}\Omega + \alpha I\right)^{1/2} \exp(-\xi\Omega)v \right\| \\ &= \left\| \exp(-\xi\Omega) \left(\frac{i}{t}\Omega + \alpha I\right)^{1/2} v \right\| \\ &= \left\| \left(\frac{i}{t}\Omega + \alpha I\right)^{1/2} v \right\| \\ &\sim \|Dv\|. \end{aligned}$$

Inserting this into (5.3) proves the lemma. □

By definition (5.1) of E_2, this immediately yields the bound

$$\|E_2(t)y(t)\| \le Ch^2\|Dy(t)\|, \qquad 0 \le t \le h.$$

Applying Lemma 4.1 gives

$$\|\widetilde{\varepsilon}(t)\| \le Ch^3 \max_{0\le\tau\le h} \|Dy(\tau)\|. \tag{5.4}$$

The midpoint rule uses the approximation

$$\widetilde{\Omega}_n = \int_0^h A(t_n+\tau)d\tau \approx hA(t_{n+1/2}) =: \Omega_n$$

in the scheme (2.7). The midpoint rule is of order 2, and since $\|\ddot{A}(t)\| \le M_2$, the quadrature error is bounded by

$$\|\widetilde{\Omega}_n - \Omega_n\| \le \frac{1}{24} M_2 h^3.$$

The identity

$$\exp(\widetilde{\Omega}_n) - \exp(\Omega_n) = \int_0^1 \exp((1-s)\Omega_n)(\widetilde{\Omega}_n - \Omega_n)\exp(s\widetilde{\Omega}_n)\, ds$$

then yields

$$\|\exp(\widetilde{\Omega}_n) - \exp(\Omega_n)\| \le \frac{1}{24} M_2 h^3. \tag{5.5}$$

Combining (5.4) and (5.5) yields for the defects ε_j of (4.7)

$$\|\varepsilon_j\| \le Ch^3 \max_{t_j \le \tau \le t_{j+1}} \|Dy(\tau)\|.$$

By (4.8), this gives

$$\|e_n\| \le Ch^2\, t_n \max_{0 \le t \le t_n} \|Dy(t)\|,$$

which is just the statement of Theorem 3.1.

6. Error bounds for fourth-order Magnus methods. This section gives the proof of Theorem 3.2 for $p = 4$. It provides all the machinery needed for treating general-order p, but still gives an explicit presentation of the appearing terms.

A Magnus method of classical order 4 is constructed by setting

$$\dot{\widetilde{\Omega}}(t) = A(t_n + t) - \frac{1}{2}\int_0^t [A(t_n+\tau), A(t_n+t)]\, d\tau, \qquad \widetilde{\Omega}(t_n) = 0, \tag{6.1}$$

for $0 \le t \le h$. To study the local error we simplify the notation and consider the case $n = 0$. Then integration yields

$$\widetilde{\Omega}(t) = \int_0^t A(\tau)\, d\tau - \frac{1}{2}\int_0^t \int_0^\tau [A(\sigma), A(\tau)]\, d\sigma d\tau, \qquad 0 \le t \le h. \tag{6.2}$$

In this case, $\widetilde{y}(t) = \exp(\widetilde{\Omega}(t))y_0$ solves (4.1) with (partly omitting the argument t)

$$\widetilde{A}(t) = \dot{\widetilde{\Omega}}(t) + \frac{1}{2}[\widetilde{\Omega}, \dot{\widetilde{\Omega}}] + \frac{1}{6}[\widetilde{\Omega}, [\widetilde{\Omega}, \dot{\widetilde{\Omega}}]] + \frac{1}{24} r_4(\mathrm{ad}_{\widetilde{\Omega}})\big(\mathrm{ad}^3_{\widetilde{\Omega}}(\dot{\widetilde{\Omega}})\big). \tag{6.3}$$

Lemma 6.1. *If $h\|D\| \le c$, then r_4 defined in (4.2) satisfies (4.4) with $p = 4$, where the constant C depends only on K, M_0, and c.*

Proof. (a) The first part of the proof is identical to part (a) of the proof of Lemma 5.1. We write again, for fixed t with $0 \le t \le h$, $\Omega = \widetilde{\Omega}(t)$ and $B = \dot{\widetilde{\Omega}}(t)$, for $\widetilde{\Omega}(t)$ of (6.2). We start with the bound (5.2) and turn to estimating $\mathrm{ad}^3_\Omega(B)w$. Using the commutator bound (3.7) (and previously the Jacobi identity, if necessary) for terms such as, e.g.,

$$\left\| \left[\int_0^t A(\tau) d\tau, \left[\int_0^t A(\tau) d\tau, \left[\int_0^t \int_0^\tau [A(\sigma), A(\tau)]\, d\sigma d\tau, A(t) \right]\right]\right] w \right\| \le Kh^5 \|D^4 w\|,$$

it is shown under the restriction $h\|D\| \le c$ that, for all w,

$$\|\mathrm{ad}_\Omega^3(B)w\| \le Ch^4\|D^3w\|, \qquad 0 \le t \le h.$$

Inserted into (5.2), this bound yields

$$r_4(\mathrm{ad}_\Omega)\big(\mathrm{ad}_\Omega^3(B)\big)v \le Ch^4 \sup_{\xi\in\mathbb{R}} \|D^3 \exp(-\xi\Omega)v\|. \tag{6.4}$$

(b) It remains to show that the supremum can be bounded by $C\|D^3v\|$. We use the splitting (3.1) and write, still for fixed t with $0 < t \le h$,

$$\frac{i}{t}\Omega = U + \frac{1}{t}\int_0^t V(\tau)d\tau - \frac{i}{2t}\int_0^t\int_0^\tau [A(\sigma), A(\tau)]\,d\sigma d\tau =: U + \widetilde{V}.$$

By the assumptions, $\widetilde{V} = V(0) + O(h)$ is a Hermitian bounded operator, and thus there exists $\alpha \ge 0$ such that $U + \widetilde{V} + \alpha I$ is positive definite. Our next aim is to show that, for all w,

$$\|D^4w\| = \|U^2w\| \sim \left\|\left(\frac{i}{t}\Omega + \alpha I\right)^2 w\right\|. \tag{6.5}$$

We have

$$(U + \widetilde{V} + \alpha I)^2 - U^2 = 2(\widetilde{V} + \alpha I)U + [U, \widetilde{V} + \alpha I] + (\widetilde{V} + \alpha I)^2.$$

The first and the last term on the right-hand side yield bounds

$$\|2(\widetilde{V} + \alpha I)Uw\| + \|(\widetilde{V} + \alpha I)^2w\| \le C\|D^2w\| + C\|w\|. \tag{6.6}$$

Bounds for the second term are obtained from assumption (3.7). By definition of $\widetilde{V}$ and writing $U = iA(\tau) - V(\tau)$, we have

$$\begin{aligned}[U, \widetilde{V}] &= \left[U, \frac{1}{t}\int_0^t V(\tau)d\tau - \frac{i}{2t}\int_0^t\int_0^\tau [A(\sigma), A(\tau)]\,d\sigma d\tau\right] \\ &= \frac{i}{t}\int_0^t [A(\tau), V(\tau)]\,d\tau \\ &\quad + \frac{1}{2t}\int_0^t\int_0^\tau [A(0), [A(\sigma), A(\tau)]]\,d\sigma d\tau \\ &\quad + \frac{i}{2t}\int_0^t\int_0^\tau [V(0), [A(\sigma), A(\tau)]]\,d\sigma d\tau.\end{aligned}$$

By the commutator bounds (3.6) and (3.7) and the Jacobi identity, we obtain for $h\|D\| \le c$

$$\|[U, \widetilde{V}]w\| \le K\|Dw\| + \frac{1}{2}Kh^2\|D^2w\| + Kh\|D^2w\| \le C\|Dw\|. \tag{6.7}$$

Together with (6.6), this proves (6.5). Moreover, the estimates (6.6) and (6.7) show that

$$\|\big((U + \widetilde{V} + \alpha I)^2 - U^2\big)U^{-1}w\| \le C\|w\|.$$

Thus we can apply Lemma 6.2 below with $\mu = 1/2$ and $\theta = 3/4$ to show that (6.5) implies

$$\|D^3 w\| = \|U^{3/2} w\| \sim \left\| \left(\frac{i}{t}\Omega + \alpha I \right)^{3/2} w \right\|.$$

As at the end of the proof of Lemma 5.1, we then obtain

$$\|D^3 \exp(-\xi\Omega) v\| \le C \|D^3 v\|,$$

with a constant independent of $\xi \in \mathbb{R}$ and t with $0 < t \le h$. Inserting this bound into (6.4) completes the proof. □

LEMMA 6.2. *Suppose S, T are Hermitian positive definite operators such that $\|(S-T)S^{-\mu}\| \le M$ holds with $0 \le \mu < 1$. If*

$$\|Sv\| \le \|Tv\| \qquad \text{for all } v,$$

then, for $0 < \theta < 1$,

$$\|S^\theta v\| \le C \|T^\theta v\| \qquad \text{for all } v,$$

where C depends only on M and μ.

Proof. This is a reformulation of Theorem 1.4.6 in [4]. □

We are now in the position to prove a bound of $\widetilde{A}(t) - A(t)$.

LEMMA 6.3. *For $\widetilde{A}(t)$ defined in (6.3) and time steps h with $h\|D\| \le c$, the error $E_4(t) := \widetilde{A}(t) - A(t)$ is bounded, for all vectors v, by*

$$\|E_4(t) v\| \le C h^4 \|D^3 v\|, \qquad 0 \le t \le h. \tag{6.8}$$

The constant C depends only on K, M_0, M_1, and c.

Proof. We insert (6.1) and (6.2) into (6.3):

$$\begin{aligned} E_4(t) = & -\frac{1}{12} \int_0^t \int_0^t \int_0^t [A(\mu), [A(\tau), [A(\sigma), A(t)]]] \, d\sigma d\tau d\mu \\ & - \frac{1}{12} \int_0^t \int_0^t \int_0^\tau [A(\mu), [[A(\sigma), A(\tau)], A(t)]] \, d\sigma d\tau d\mu \\ & + \frac{1}{24} \int_0^t \int_0^\mu \int_0^t [[A(\sigma), A(\mu)], [A(\tau), A(t)]] d\tau d\sigma d\mu + R(t) \\ & + \frac{1}{24} r_4(\mathrm{ad}_{\widetilde{\Omega}}) \big(\mathrm{ad}^3_{\widetilde{\Omega}}(\dot{\widetilde{\Omega}})\big). \end{aligned}$$

Here, $R(t)v$ contains integrals of commutators which, by (3.7), are bounded by

$$C\big(h^5 \|D^4 v\| + h^6 \|D^5 v\|\big) \le C' h^4 \|D^3 v\|$$

for $h\|D\| \le c$. The constant C depends only on K. Then, by (3.7),

$$\|E_4(t) v\| \le C h^4 \|D^3 v\| + \frac{1}{24} \left\| r_4(\mathrm{ad}_{\widetilde{\Omega}}) \big(\mathrm{ad}^3_{\widetilde{\Omega}}(\dot{\widetilde{\Omega}})\big) v \right\|.$$

The bound (6.8) now follows from Lemma 6.1. □

Lemma 4.1 shows that $\widetilde{\varepsilon} = \widetilde{y} - y$ is bounded by

$$\|\widetilde{\varepsilon}(t)\| \le Ch^5 \max_{0\le\tau\le h} \|D^3 y(\tau)\|, \qquad 0 \le t \le h.$$

Since we want to have a fourth-order scheme, we use a quadrature formula $(b_i, c_i)_{i=1}^s$ of order $p \ge 4$. In (6.2) we replace A by its interpolation polynomial $\widehat{A}$ in the nodes $t_n + c_j h$. The integrals can then be evaluated exactly. The quadrature error for $n = 0$ is given by

$$\begin{aligned}(6.9)\qquad \widetilde{\Omega}_0 - \Omega_0 &= \int_0^h A(\tau)d\tau - \int_0^h \widehat{A}(\tau)d\tau \\ &\quad - \left(\frac{1}{2}\int_0^h\int_0^\tau [A(\sigma), A(\tau)]d\sigma d\tau - \frac{1}{2}\int_0^h\int_0^\tau [\widehat{A}(\sigma), \widehat{A}(\tau)]d\sigma d\tau\right),\end{aligned}$$

and similarly for the general nth step, with $A(t_n + \tau)$ instead of $A(\tau)$.

Lemma 6.4. *The quadrature error in the nth step satisfies*

$$(6.10)\qquad \|\big(\widetilde{\Omega}_n - \Omega_n\big)v\| \le Ch^{p+1}\|Dv\|.$$

The constant C depends only on M_m for $m \le p$ and K_1.

Proof. For ease of notation, we let $n = 0$. The error of the single integral in the representation of $\widetilde{\Omega}_n - \Omega_n$ is $O(h^{p+1})$. Assume that we use a quadrature rule with s nodes. For estimating the error of the double integral we define the interpolation error

$$J(t) := A(t) - \widehat{A}(t) = h^s \int_0^1 \widehat{\kappa}_s(\theta, \vartheta) A^{(s)}(\theta h) d\theta, \qquad 0 \le t = \vartheta h \le h,$$

where $\widehat{\kappa}_s$ denotes the Peano kernel. The difficulty in the remaining proof comes from the fact that we have only $J(t) = O(h^s)$, but we need an $O(h^p)$ estimate. We use, in addition, $J(c_i h) = 0$ and $\int_0^h J(t)\,dt = O(h^{p+1})$. For the second term in (6.9) we write

$$\begin{aligned}(6.11)\qquad &\int_0^h\int_0^\tau [A(\sigma), A(\tau)]\,d\sigma d\tau - \int_0^h\int_0^\tau [\widehat{A}(\sigma), \widehat{A}(\tau)]\,d\sigma d\tau \\ &\quad = \int_0^h\int_0^\tau \Big([\widehat{A}(\sigma), J(\tau)] + [J(\sigma), \widehat{A}(\tau)] + [J(\sigma), J(\tau)]\Big)\,d\sigma d\tau.\end{aligned}$$

Approximating the outer integral with the quadrature formula, the first term becomes

$$\int_0^h\int_0^\tau [\widehat{A}(\sigma), J(\tau)]\,d\sigma d\tau = h^{p+1}\int_0^1 \kappa_p(\theta) G^{(p)}(\theta h)\,d\theta,$$

where κ_p is the Peano kernel, and

$$G(\tau) = \int_0^\tau [\widehat{A}(\sigma), J(\tau)]\,d\sigma.$$

Using Leibniz' rule, it is seen that the dominant term of $G^{(p)}(\tau)$ is $p\,[\widehat{A}(\tau), J^{(p-1)}(\tau)]$, so that by (3.6), for any vector v,

$$\|G^{(p)}(\theta h)v\| \le C\|Dv\|.$$

This yields

$$\left\| \int_0^h \int_0^\tau [\widehat{A}(\sigma), J(\tau)]\, d\sigma d\tau\ v \right\| \le Ch^{p+1}\|Dv\|. \tag{6.12}$$

For the second term, we use partial integration:

$$\int_0^h \int_0^\tau [J(\sigma), \widehat{A}(\tau)]\, d\sigma d\tau = \left[\int_0^h J(\sigma) d\sigma, \int_0^h \widehat{A}(\mu) d\mu \right] - \int_0^h \int_0^\tau [J(\tau), \widehat{A}(\sigma)]\, d\sigma d\tau.$$

Here, for the last term, the bound was already given in (6.12). Using the quadrature formula for the integral over J, we have for the first term

$$\left[\int_0^h J(\sigma) d\sigma, \int_0^h \widehat{A}(\mu) d\mu \right] = h^{p+1} \left[\int_0^1 \kappa_p(\theta) J^{(p)}(\theta h) d\theta, \int_0^h \widehat{A}(\mu) d\mu \right].$$

Noting $J^{(p)}(t) = A^{(p)}(t)$ and using (3.6), this gives the bound

$$\left\| \int_0^h \int_0^\tau [J(\sigma), \widehat{A}(\tau)]\, d\sigma d\tau\ v \right\| \le Ch^{p+1}\|Dv\|. \tag{6.13}$$

Finally, since $\|J(t)\| = O(h^s)$,

$$\left\| \int_0^h \int_0^\tau [J(\sigma), J(\tau)]\, d\sigma\, d\tau\ v \right\| \le Ch^{2s+2}\|v\| \le Ch^{p+2}\|v\|. \tag{6.14}$$

Inserting the bounds (6.12)–(6.14) into (6.11) completes the proof. □

LEMMA 6.5. *In the situation of Lemma* 6.4,

$$\| \exp(\widetilde{\Omega}_n)v - \exp(\Omega_n)v \| \le Ch^{p+1}\|Dv\|.$$

The constant C depends only on M_m for $m \le p$ and K_1.

Proof. The variation-of-constants formula yields

$$\exp\big(\widetilde{\Omega}_n\big)v - \exp(\Omega_n)v = \int_0^1 \exp\big((1-s)\Omega_n\big)\big(\widetilde{\Omega}_n - \Omega_n\big)\exp\big(s\widetilde{\Omega}_n\big)v\, ds.$$

By (6.10) we have

$$\|(\widetilde{\Omega}_n - \Omega_n)\exp(s\widetilde{\Omega}_n)v\| \le Ch^{p+1}\|D\exp(s\widetilde{\Omega}_n)v\| \le C'h^{p+1}\|Dv\|,$$

where the last inequality is obtained as in the proof of Lemma 5.1. This gives the stated bound. □

For $p \ge 4$, the local error ε_n of the scheme (2.7) thus satisfies (4.7) with

$$\|\varepsilon_n\| \le Ch^5 \max_{t_n \le t \le t_{n+1}} \|D^3 y(t)\|.$$

Hence, with (4.8), the global error is bounded by

$$\|e_n\| \le Ct_n h^4 \max_{0 \le t \le t_n} \|D^3 y(t)\|,$$

and Theorem 3.2 is proved for $p = 4$.

7. Error bounds for higher-order Magnus integrators. The arguments of the previous section can be extended rather directly to methods of arbitrary order. In the following we describe this extension, putting the emphasis on the general structure and on a few additional considerations that become necessary. Though it would have been possible to present the general proof without first discussing the second- and fourth-order cases, we believe that it is useful to have seen and understood the explicit expressions arising in the proofs for the lower-order methods before embarking on the general case.

LEMMA 7.1. *If $\|hD\| \leq c$, then r_p defined in* (4.2) *satisfies, for a pth-order truncated Magnus expansion $\widetilde{\Omega}(t)$, the bound* (4.4), *where the constant C depends only on K, M_0, c, and p.*

Proof. For the truncated Magnus series $\widetilde{\Omega}(t)$, the expression $\mathrm{ad}^{p-1}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t))$ consists (after repeated use of the Jacobi identity) of a linear combination of iterated commutators of $A(\cdot)$ integrated over all but one of the independent variables over intervals bounded by h. The appearing iterated commutators and integrals are at least $(p-1)$-fold. Together with the commutator bound (3.7) and $\|hD\| \leq c$, this yields the bound

$$\left\| \mathrm{ad}^{p-1}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t))w \right\| \leq Ch^p \, \|D^{p-1}w\|. \tag{7.1}$$

By (5.2), this implies

$$\left\| r_p(\mathrm{ad}_{\widetilde{\Omega}(t)})\mathrm{ad}^{p-1}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t))v \right\| \leq Ch^p \sup_{\xi \in \mathbb{R}} \|D^{p-1} \exp(\xi \widetilde{\Omega}(t))v\| \tag{7.2}$$

for all v. By a straightforward but tedious generalization of the argument in the proof of Lemma 6.1, the supremum is bounded by

$$\sup_{\xi \in \mathbb{R}} \|D^{p-1} \exp(\xi \widetilde{\Omega}(t))v\| \leq C \, \|D^{p-1}v\|, \tag{7.3}$$

which yields the desired bound (4.4). □

LEMMA 7.2. *For $\widetilde{A}(t)$ defined in* (4.1) *and time steps h with $h\|D\| \leq c$, the error $E_p(t) := \widetilde{A}(t) - A(t)$ is bounded, for all vectors v, by*

$$\|E_p(t)v\| \leq Ch^p \, \|D^{p-1}v\|, \qquad 0 \leq t \leq h. \tag{7.4}$$

The constant C depends only on K, M_0, M_1, c, and p.

Proof. By construction of the Magnus series, $E_p(t)$ is a linear combination of at least $(p-1)$-fold integrals of iterated commutators of $A(\cdot)$ and $r_p(\mathrm{ad}_{\widetilde{\Omega}(t)})\mathrm{ad}^{p-1}_{\widetilde{\Omega}(t)}(\dot{\widetilde{\Omega}}(t))$. The stated estimate thus follows from the commutator bound (3.7), the step size bound (3.8), and Lemma 7.1. □

Consider a quadrature formula with nodes c_i $(i = 1, \ldots, s)$ and weights b_i of order p. Let $\widehat{A}(\tau)$ be the interpolation polynomial to $A(\tau)$ in the points $c_i h$, and denote by Ω_0 the expression obtained by replacing $A(\tau)$ by $\widehat{A}(\tau)$ in the expression for $\widetilde{\Omega}_0 = \widetilde{\Omega}(h)$. Similarly, let $\widetilde{\Omega}_n$ and Ω_n denote the corresponding expressions for the nth step, with $A(t_n + \tau)$ instead of $A(\tau)$.

LEMMA 7.3. *The quadrature error in the nth step satisfies*

$$\|(\widetilde{\Omega}_n - \Omega_n)v\| \le Ch^{p+1}\|D^{p-2}v\|. \tag{7.5}$$

The constant C depends only on M_m for $m \le p$ and K_1.

Proof. The proof follows the lines of the proof of Lemma 6.4. The generalization concerns the appearance of m-fold integrals of m-fold iterated commutators, for $m \le p-2$, instead of the simple commutators studied in the proof of Lemma 6.4. These terms are treated by the same techniques; they just involve more formidable expressions. By the commutator bound (3.6), this leads to an estimate involving $\|D^{p-2}v\|$ in the general situation. □

As in Lemma 6.5, this implies

$$\|\exp(\widetilde{\Omega}_n)v - \exp(\Omega_n)v\| \le Ch^{p+1}\|D^{p-2}v\|. \tag{7.6}$$

Inserting the estimates (7.4) and (7.6) into the framework of section 4 finally yields the error bound of Theorem 3.2.

8. Numerical experiments.

To illustrate the theoretical results presented in this paper, we consider the Schrödinger equation

$$i\,\frac{\partial\psi}{\partial t} = -\frac{1}{2}\Delta\psi + b(x,t)\psi, \qquad x = (x_1,\dots,x_d) \in \mathbb{R}^d,\ t > 0, \tag{8.1}$$

with a smooth (C^∞) potential $b(x,t)$ that is 2π-periodic in every coordinate direction x_j. We impose periodic initial conditions $\psi(x,0) = \psi_0(x)$. For ease of notation only, the following discussion is for the one-dimensional case $d = 1$.

A standard space discretization is given by the pseudospectral method. Here, a trigonometric polynomial

$$\psi^N(x,t) = \sum_{k=-N/2}^{N/2-1} c_k^N(t)\, e^{ikx}$$

is determined such that the equations

$$\begin{aligned} i\dot{\psi}^N(x_\ell,t) &= -\frac{1}{2}\Delta\psi^N(x_\ell,t) + b(x_\ell,t)\psi^N(x_\ell,t),\\ \psi^N(x_\ell,0) &= \psi_0(x_\ell) \end{aligned}$$

are satisfied at the mesh-points $x_\ell = 2\pi\ell/N$, with $\ell = -N/2,\dots,N/2-1$. Setting $c^N(t) = (c_k^N(t))$ the vector of Fourier coefficients, this amounts to solving

$$i\dot{c}^N = -\frac{1}{2}\widehat{\Delta}^N c^N + B^N(t)c^N, \tag{8.2}$$

where, in the case of one space dimension,

$$\widehat{\Delta}^N = (\widehat{D}^N)^2 \qquad \text{with} \quad \widehat{D}^N = \operatorname{diag}(ik) \quad (k = -N/2,\dots,N/2-1),$$

and, with F_N denoting the discrete Fourier transform of length N,

$$B^N(t) = F_N \operatorname{diag}(b(x_\ell,t))F_N^{-1}.$$

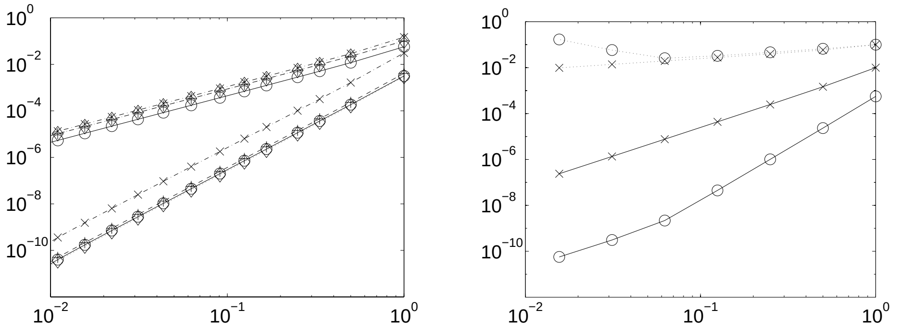

FIG. 8.1. *Error versus step sizes for the laser example: smooth and nonsmooth initial data on the left, $h\|D\| = $ const. on the right.*

We consider a one-dimensional example with data from [11], slightly modified to make the potential periodic with respect to the space interval $x \in [-\ell, \ell]$ for $\ell = 10$:

$$b(x,t) = \frac{1}{2}\frac{\pi^2}{\ell^2}\left(1 - \cos\frac{\pi x}{\ell}\right) + \sin^2(t)\frac{\pi}{\ell}\sin\frac{\pi x}{\ell}.$$

In the left-hand panel of Figure 8.1 we give precision step size diagrams at $t = 1$ for four different initial values, where we have used $N = 128$ Fourier modes for the spatial discretization. As a smooth initial value, we used the eigenstate of the unforced harmonic oscillator to the lowest energy level, $\Psi(x,0) = e^{-x^2/2}$. The convergence curves of the exponential midpoint and the fourth-order Gauss method corresponding to the smooth initial data are the solid lines marked with circles. For the other three curves, initial data of finite energy is chosen as $c^N(0) = (I - i(\widehat{D}^N)^j)^{-1}v/\rho$, $j = 1, 2, 3$, where v is a vector of normally distributed random numbers, and ρ is chosen such that $\|c^N(0)\| = 1$. For $j = 1$, the results are plotted in the dash-dotted curve marked with × symbols; for $j = 2$, we have the dashed curved marked with + symbols; and for $j = 3$, the curve is dotted marked with diamonds.

For the right-hand panel of Figure 8.1, we took the smooth initial state $\Psi(x,0) = e^{-x^2/2}$ for all curves, but varied the number of Fourier modes from $N = 32$ to $N = 2048$ and the time steps such that $Nh = 32$. This corresponds to the situation in which $\|hD\| \approx 3.5$, where $D = (-\frac{1}{2}\widehat{\Delta}^N + I)^{1/2}$. The solid line marked with the × symbols indicates the error of the midpoint rule, and the solid line marked with circles is the error for the fourth-order Gauss method. The dotted lines in the top of the picture represent the errors of the exponential midpoint and the Gauss method divided by h^2 and h^4, respectively, up to a constant factor.

9. Appendix. Commutator bounds for a spectral discretization.

We consider the pseudospectral space discretization (8.2) of the Schrödinger equation (8.1). Equation (8.2) is of the type studied in this paper, with $U = -\frac{1}{2}(\widehat{D}^N)^2 + I$ and $V(t) = B^N(t) - I$. The matrix $B^N(t)$ is circulant, with (k,l) entry equal to

$$\widehat{b}^N_{k-l}(t) = \sum_{q=-\infty}^{\infty} \widehat{b}_{k-l+qN}(t)$$

by the aliasing formula, where $\widehat{b}_j(t)$ is the jth Fourier coefficient of the 2π-periodic (in x) function $b(x,t)$. If (and only if) $b(x,t)$ is a C^∞ function of x, the Fourier coefficients $\widehat{b}_j(t)$ decay faster than any negative power of $|j|$. It then follows that the entries of the matrix $B^N(t) = (b^N_{k,l})$ are bounded by

$$|b^N_{kl}| \leq \begin{cases} \gamma_m(|k-l|+1)^{-m}, & |k-l| \leq N/2, \\ \gamma_m(N-|k-l|)^{-m}, & |k-l| > N/2, \end{cases} \tag{9.1}$$

for $k, l = -N/2, \dots, N/2-1$, with γ_m $(m = 1, 2, 3, \dots)$ independent of N.

The commutator bound (3.6) is obtained as a direct consequence of the three lemmas below, for which we need to give a further definition. We say that a sequence of matrices $\mathcal{B} = (B^N)$, with B^N of dimension $N \times N$, belongs to the class Γ^∞ if the entries satisfy estimates (9.1) with all γ_m independent of N. We denote by $\gamma(\mathcal{B}) = (\gamma_1, \gamma_2, \gamma_3, \dots)$ the sequence of smallest possible such numbers.

Lemma 9.1. *If $\mathcal{A} = (A^N)$ and $\mathcal{B} = (B^N)$ are in Γ^∞, then also $\mathcal{AB} = (A^N B^N)$ is in Γ^∞, and $\gamma(\mathcal{AB})$ is bounded in terms of $\gamma(\mathcal{A})$ and $\gamma(\mathcal{B})$.*

The proof is by direct estimation and is not given here. The following result is shown in the proof of Lemma 3.1 in [8].

Lemma 9.2. *If $\mathcal{B} = (B^N)$ is in Γ^∞, then $[\widehat{\mathcal{D}}^2, \mathcal{B}] = ([(\widehat{D}^N)^2, B^N])$ is of the form*

$$[\widehat{\mathcal{D}}^2, \mathcal{B}] = \mathcal{M}_0 + \mathcal{M}_1 \widehat{\mathcal{D}},$$

where $\mathcal{M}_0$ and $\mathcal{M}_1$ are in Γ^∞, with $\gamma(\mathcal{M}_0)$ and $\gamma(\mathcal{M}_1)$ bounded in terms of $\gamma(\mathcal{B})$.

The next lemma is proved in the same way.

Lemma 9.3. *If $\mathcal{B} = (B^N)$ is in Γ^∞, then $\widehat{\mathcal{D}}\mathcal{B} = (\widehat{D}^N B^N)$ is of the form*

$$\widehat{\mathcal{D}}\mathcal{B} = \mathcal{K}_0 + \mathcal{K}_1 \widehat{\mathcal{D}},$$

where $\mathcal{K}_0$ and $\mathcal{K}_1$ are in Γ^∞, with $\gamma(\mathcal{K}_0)$ and $\gamma(\mathcal{K}_1)$ bounded in terms of $\gamma(\mathcal{B})$.

Repeated application of these lemmas shows that

$$\left[-(\widehat{D}^N)^2 + B^N(\tau_k), \left[\dots, \left[-(\widehat{D}^N)^2 + B^N(\tau_1), \frac{d^m}{dt^m} B^N(\tau_0)\right]\right] \dots\right] = \sum_{j=0}^{k} M_j^N (\widehat{D}^N)^j,$$

with matrices M_j^N bounded independently of N and $\tau_0, \dots, \tau_k$. This gives the desired commutator bound (3.6).

Acknowledgment. We thank Katina Lorenz for stimulating discussions on commutator bounds.

AN OPTIMAL PARALLEL NONOVERLAPPING DOMAIN DECOMPOSITION ITERATIVE PROCEDURE[*]

QINGPING DENG[†]

Abstract. A nonoverlapping domain decomposition iterative procedure is developed and analyzed for second order elliptic problems in $\mathbb{R}^N$. Its convergence is proved. The method is based on a Robin-type consistency condition with two parameters, called a transmission coefficient and a penalty coefficient, as a transmission condition together with a derivative-free transmission data updating technique on the artificial interfaces. Then the method is applied to the nonconforming finite element problems. A nonoverlapping domain decomposition iterative procedure for solving the nonconforming finite element problems of second order partial differential equations is developed and analyzed, which is directly presented to the nonconforming finite element problems without introducing any Lagrange multipliers. Its convergence is demonstrated, and the convergence rate is derived. The convergence analyses imply that the convergence rate is independent of the finite element meshes size while choosing the right parameters. Furthermore, the conclusions are extended to the unstructured finite element meshes. For both continuous problems and discrete problems, the method of this paper can be applied to general multisubdomain decompositions and implemented on parallel machines with local communications naturally. The method also allows choosing subdomains very flexibly, even as small as an individual element for finite element problems.

Key words. nonoverlapping, domain decomposition, iterative, parallel, transmission data, update, transmission coefficient, penalty coefficient, Robin boundary condition, nonconforming, finite element

Introduction. Nonoverlapping domain decomposition methods have been studied extensively and have become very attractive for their parallelism and flexibility (cf. [1, 2, 3, 7, 8, 10, 11, 13, 14, 17, 18, 19, 20, 21, 22, 23] and the references therein). In nonoverlapping domain decomposition methods, the original domain is decomposed into subdomains; then the original problems are split into a number of subproblems over the subdomains. The subproblems could be solved in parallel or with greater independence. The main issues to develop nonoverlapping domain decomposition iterative procedures are what information should be transferred between subdomains (subproblems) and how the information is transferred. In other words, one issue is what the transmission data are and the other is how the transmission data are exchanged, that is, the strategy for updating the transmission data. The transmission data should guarantee that the solutions of subproblems could be pieced together into a reasonable approximation of the true solution of the original given problem. The updating strategy determines the costs and methods of the communications between subproblems.

The objective of this paper is to develop a nonoverlapping domain decomposition iterative procedure for second order elliptic partial differential problems and their nonconforming finite element problems. First, a nonoverlapping domain decomposition iterative procedure is developed and analyzed for second order elliptic problems in $\mathbb{R}^N$ $(N = 2, 3)$. Its convergence is proved by a "pseudoenergy" technique. The

method is based on a Robin-type consistency condition with two parameters, called a transmission coefficient and a penalty coefficient, as a transmission condition and a derivative-free transmission data updating technique on the artificial interfaces between two subdomains. Then the method is applied to the nonconforming finite element problems. A nonoverlapping domain decomposition iterative procedure for solving the nonconforming finite element problems of second order partial differential equations is also developed and analyzed. The method is directly presented to the nonconforming finite element problems without introducing any Lagrange multipliers. The convergence is proved, and the convergence rate of the method for the nonconforming finite element problems is derived. The convergence analyses show that the convergence rate is independent of the finite element mesh size, that is, optimal, while choosing the right parameters. Furthermore, the conclusions are extended to the unstructured finite element meshes.

For both continuous problems and discrete problems, the method can be applied to general multisubdomain decompositions and implemented on parallel machines with local simple communications naturally. The method allows choosing subdomains very flexibly, even as small as individual elements for finite element problems. For continuous problems, the transmission data and their updating techniques guarantee that all subproblems are always well-posed at every iteration if the initial subproblems are well-posed. On different iterative steps, the subproblems on the same subdomain are the same problems with the same kind of boundary condition but different boundary values, that is, which have the same differential operator. Hence, for finite element problems, the subproblems on the same subdomain, which are linear systems, have the same system matrix but different right-hand side terms at different iterations. Thus, we need to do only some simple operations of "matrix times vector" to solve the subproblems on every iterative step if decomposing the system matrix of the subproblems on every subdomain or finding its inverse matrix first. Last but not least, we would like to mention that if we assume each subproblem is solved by a direct method at every iterative step, then the method becomes a direct method in the single-subdomain case, that is, without decomposing the original domain; on the other hand, the method becomes a classic iterative method while choosing every individual element as a subdomain. Therefore, the method can be regarded as a bridge connecting direct methods and classic iterative methods under domain decomposition techniques. This implies that we might develop an optimal classic iterative method for solving the nonconforming finite element problems by using the method of this paper if every finite element is chosen as a subdomain.

The closely related works are [7, 8, 18]. In [7], a very similar nonoverlapping domain decomposition method but with a slightly different consistency condition on the artificial interfaces for partial differential problems is developed and analyzed. The method in [7] can also be regarded as a variant of the famous Lions method of [18], which uses the same kind of Robin-type transmission condition as [7] but different techniques for updating the transmission data on the interfaces. In [8], the method of [7] is applied into the nonconforming finite element problems, and the convergence analyses are considered. In particular, convergence rate estimates and numerical experiments are provided, which show that the convergence speed is dependent on the finite element mesh size and highly dependent on the transmission coefficient values. Other closely related work is [10, 11]. Després [10] applies the Lions method to the mixed hybrid finite element problems of the Helmholtz problems and Douglas et al. [12] apply the Lions method to mixed finite element problems by introducing a

Lagrange multiplier on the interfaces. We also refer to [1, 2, 3, 13, 14, 17, 18, 19, 20, 21, 22, 23] and the references therein for other nonoverlapping domain decomposition methods.

The outline of the paper is as follows. In section 1, some preliminaries are given. Transmission data and updating techniques on the artificial interfaces are discussed in section 2. In section 3, a nonoverlapping domain decomposition method for partial differential problems is developed and analyzed. Section 4 applies the method developed in section 3 for the nonconforming finite element problems. A nonoverlapping domain decomposition iterative procedure for solving the finite element problems is developed and analyzed. Then the convergence rate estimates are derived in section 5. The conclusions are extended to the unstructured finite element meshes in section 6. Finally, a short conclusion is presented.

1. Preliminaries. For the sake of simplicity in exposition, this paper considers the following second order elliptic problem:

$$\begin{cases} -\Delta u + \alpha(x)u = f & \text{in} \quad \Omega, \\ u = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{1.1}$$

where Ω is a bounded domain in $\mathbb{R}^N (N = 2, 3)$, $f \in L^2(\Omega)$, and $\alpha(x) \in L^\infty(\Omega)$, and is nonnegative. The problem (1.1) is a typical second order elliptic equation and also can model heat equations and wave equations by implicit difference discrete for time.

The weak formulation of (1.1) is to find $u \in H_0^1(\Omega)$ such that

$$a_\Omega(u, v) = (f, v)_\Omega \qquad \forall v \in H_0^1(\Omega), \tag{1.2}$$

where, and in the paper, for a domain $D \subset \mathbb{R}^N$, $(\cdot, \cdot)_D$ is an inner product of $L^2(D)$ and

$$a_D(u, v) = \int_D (\nabla u \cdot \nabla v + \alpha(x)uv)\, dx. \tag{1.3}$$

It is well known that problem (1.2) has a unique solution $u \in H_0^1(\Omega)$ (cf. [15]).

To describe finite element approximations for (1.2), we begin with the triangulation of Ω. Assume that $\mathcal{T}_h$ is a quasi-uniform and regular finite element triangulation of Ω and, for simplicity, $\overline{\Omega} = \cup_{\tau \in \mathcal{T}_h} \overline{\tau}$ (cf. [5]). Also, for the sake of simplicity in exposition, we here consider only the famous nonconforming Crouzeix–Raviart element (cf. [6]) on the n-simplex (triangle if $n = 2$, tetrahedron if $n = 3$) triangulation $\mathcal{T}_h$. However, it is not difficult to see that the analyses and conclusions of this paper can be easily extended to other nonconforming finite elements (for instance, the nonconforming finite elements for n-quadrilateral partition or n-simplex portion (cf. [12]) and the nonconforming finite elements for n-rectangle partition (cf. [16])). Let $S_h \subset L^2(\Omega)$ be the nonconforming Crouzeix–Raviart finite element space over the finite element mesh $\mathcal{T}_h$. Denoting N_h as the set of all face barycenters of $\mathcal{T}_h$'s element, i.e., n-simplex, in the interior of Ω and Γ_h as the set of all face barycenters of $\mathcal{T}_h$'s element on the boundary of $\partial\Omega$, we then define the finite element space S_h as follows (cf. [6]):

$$\begin{aligned} S_h = \{v :\ v|_\tau \in P_1(\tau),\ \tau \in \mathcal{T}_h,\ &v \textit{ continues at } p \in N_h \\ &\textit{and vanishes at } p \in \Gamma_h\}\,. \end{aligned} \tag{1.4}$$

Then the finite element approximate problem of (1.2) is to find $u \in S_h$ such that

$$a^h_\Omega(u,v) = (f,v)_\Omega \qquad \forall v \in S_h, \tag{1.5}$$

where, and in this paper, for a domain $D \subset \mathbb{R}^N$, a block (union) of elements of $\mathcal{T}_h$,

$$a^h_D(u,v) = \sum_{\tau\in\mathcal{T}_h, \tau\subset D} a_\tau(u,v). \tag{1.6}$$

It has been shown that the nonconforming finite element problem (1.5) has a unique solution, which has the optimal H^1 and L^2 errors and asymptotically optimal L^∞ error.

To develop a nonoverlapping domain decomposition method to solve the problem (1.2) and the nonconforming finite element problem (1.5), we decompose Ω into an arbitrary $m(\geq 2)$ of disjoint subdomains (open sets) $\Omega_1, \Omega_2, \dots, \Omega_m$; i.e., we assume that

$$\overline{\Omega} = \overline{\Omega}_1 \cup \overline{\Omega}_2 \cup \cdots \cup \overline{\Omega}_m = \Omega_1 \cup \Omega_2 \cup \cdots \cup \Omega_m \cup \Sigma, \tag{1.7}$$

$$\Sigma = \bigcup_{1\leq i\neq j\leq m} \gamma_{ij}, \qquad \gamma_{ij} = \partial\Omega_i \cap \partial\Omega_j, \qquad \Gamma_i = \partial\Omega_i \cap \partial\Omega. \tag{1.8}$$

Moreover, while considering the finite element problem (1.8), we also need to assume that the above nonoverlapping domain decomposition is aligned with $\mathcal{T}_h$; that is, every Ω_i is a block (union) of some elements or even an individual element of $\mathcal{T}_h$. Finally, we conclude this section by introducing the following notations G_r $(r = 1, 2, \dots)$, which are used in the convergence analyses:

$$\begin{cases} G_1 = \{\cup\Omega_k \mid \ \partial\Omega_k \cap \partial\Omega \ \text{ has positive measure}\}, \\ G_{r+1} = \{\cup\Omega_k \mid \ \partial\Omega_k \cap \overline{G_r} \ \text{ has positive measure}, \ \partial\Omega_k \cap G_l = \emptyset \ \forall l \leq r\}. \end{cases} \tag{1.9}$$

2. Transmission data and updating strategies. Let $u \in H^1_0(\Omega)$ be the solution of (1.1), and let $u_i = u\mid_{\Omega_i} \in H^1_{\Gamma_i}(\Omega_i)$, where, and in this paper, $H^1_{\Gamma_i}(\Omega_i)$ is a subspace of Sobolev space $H^1(\Omega_i)$ whose members vanish on Γ_i. Then u_i $(i = 1, 2, \dots, m)$ satisfies the following overdetermined subproblem:

$$\begin{cases} -\Delta u_i + \alpha(x)u_i = f & \text{in} \quad \Omega_i, \\ u_i = 0 & \text{on} \quad \Gamma_i, \\ u_i = u_j & \text{on} \quad \gamma_{ij}, \quad 1 \leq j \neq i \leq m, \\ \dfrac{\partial u_i}{\partial n_i} = -\dfrac{\partial u_j}{\partial n_j} & \text{on} \quad \gamma_{ij}, \quad 1 \leq j \neq i \leq m. \end{cases} \tag{2.1}$$

Conversely, let $u_i \in H^1_{\Gamma_i}(\Omega_i)$ $(i = 1, 2, \dots, m)$ be the solution of (2.1), and let u be a function defined over Ω satisfying $u\mid_{\Omega_i} = u_i$ $(i = 1, 2, \dots, m)$; then $u \in H^1_0(\Omega)$ is the solution of (1.1). This implies that a consistency condition on the artificial interface γ_{ij} of the problem (1.1) is

$$\begin{cases} u_i = u_j & \text{on} \quad \gamma_{ij}, \quad 1 \leq j \neq i \leq m, \\ \dfrac{\partial u_i}{\partial n_i} = -\dfrac{\partial u_j}{\partial n_j} & \text{on} \quad \gamma_{ij}, \quad 1 \leq j \neq i \leq m. \end{cases} \tag{2.2}$$

It is more convenient (cf. [7, 8, 10, 11, 18]) to replace (2.2) by the following Robin-type boundary condition on the artificial interface γ_{ij}:

$$\begin{cases} \dfrac{\partial u_i}{\partial n_i} + \lambda_{ij} u_i = -\dfrac{\partial u_j}{\partial n_j} + \lambda_{ij} u_j & \text{on} \quad \gamma_{ij}, \quad 1 \le j \ne i \le m, \\ \dfrac{\partial u_j}{\partial n_j} + \lambda_{ji} u_j = -\dfrac{\partial u_i}{\partial n_i} + \lambda_{ji} u_i & \text{on} \quad \gamma_{ij}, \quad 1 \le j \ne i \le m, \end{cases} \tag{2.3}$$

where $\lambda_{ij} = \lambda_{ji} > 0 \ \ (1 \le i \ne j \le m)$. Therefore, by using (2.3), a nonoverlapping domain decomposition iterative procedure is developed and analyzed (cf. [18]), which is based on the following subproblems:

$$\begin{cases} -\Delta u_i^{n+1} + \alpha(x) u_i^{n+1} = f & \text{in} \quad \Omega_i, \\ \dfrac{\partial u_i^{n+1}}{\partial n_i} + \lambda_{ij} u_i^{n+1} = -\dfrac{\partial u_j^n}{\partial n_j} + \lambda_{ij} u_j^n & \text{on} \ \ \gamma_{ij}, \ \ 1 \le j \le m, j \ne i, \\ u_i^{n+1} = 0 & \text{on} \quad \Gamma_i. \end{cases} \tag{2.4}$$

This procedure can be applied to general multisubdomain decompositions and implemented on parallel machines with local communications naturally. In the procedure, the transmission data on the interfaces are u_i^n and $\partial u_i^n / \partial n_i$, and they are updated by direct substitutions. In every iterate step, we have to find the extra data $\partial u_i^n / \partial n_i$ in order to update the transmission data, which is not easy, in particular, for discrete problems. Furthermore, this might cause ill-posed troubles of subproblems because of the regularities of the subproblems. This also makes the method difficult to apply to discrete problems (for instance, finite element problems (cf. [8, 10, 12])).

In order to avoid these disadvantages, a nonoverlapping domain decomposition iterative procedure is developed and analyzed by [7, 8], which is based on the following subproblems:

$$\begin{cases} -\Delta u_i^n + \alpha(x) u_i^n = f & \text{in} \quad \Omega_i, \\ \dfrac{\partial u_i^n}{\partial n_i} + \lambda_{ij} u_i^n = g_{ij}^n & \text{on} \ \ \gamma_{ij} \ \forall \ 1 \le j \le m, j \ne i, \\ u_i^n = 0 & \text{on} \quad \Gamma_i, \end{cases} \tag{2.5}$$

$$g_{ij}^{n+1} = 2\lambda_{ij} u_j^n - g_{ji}^n, \qquad 1 \le j \ne i \le m, \ \ \text{if } meas(\gamma_{ij}) > 0. \tag{2.6}$$

The precise meaning of (2.5) is nothing but the usual weak formulation, which is

(2.7)
$$a_{\Omega_i}(u_i^n, v) + \sum_{\substack{1 \le j \le m \\ j \ne i}} \lambda_{ij} \int_{\gamma_{ij}} u_i^n v ds = (f, v)_{\Omega_i} + \sum_{\substack{1 \le j \le m \\ j \ne i}} \int_{\gamma_{ij}} g_{ij}^n v ds \ \ \forall v \in H^1_{\Gamma_i}(\Omega_i),$$

and (2.6) is understood in $L^2(\Omega_i)$. This method also can be applied for general multisubdomain decompositions and implemented on parallel machines with local communications naturally. Like the above method, this method is also based on the consistency condition (2.3). However, the transmission data and the updating strategy of transmission data are different. In this procedure, the transmission data are g_{ij}^n, and the transmission data are updated by a derivative-free technique using the transmission data of the previous iterative step and the data obtained directly from the previous iterative step. Moreover, since there are no derivatives in (2.6) and (2.7) explicitly, we do not need to find any extra information (for instance, the first normal derivatives) in the iterative process. This guarantees that all subproblems are always well-posed in the iterative process if the initial subproblems are well-posed. This also makes the method easy to apply to the discrete problems (cf. [7, 8]). However, it follows from (2.6)–(2.7) that

$$\begin{aligned}\frac{\partial u_i^{n+1}}{\partial n_i} + \lambda_{ij} u_i^{n+1} &= g_{ij}^{n+1} \equiv 2\lambda_{ij} u_j^n - g_{ji}^n \\ &= 2\lambda_{ij} u_j^n - \left(\frac{\partial u_j^n}{\partial n_j} + \lambda_{ji} u_j^n\right) \\ &= -\frac{\partial u_j^n}{\partial n_j} + \lambda_{ij} u_j^n \qquad \text{on} \quad \gamma_{ij}.\end{aligned} \tag{2.8}$$

This means that this procedure is essentially equivalent to the above one (cf. [7, 8]). This procedure is applied to the nonconforming finite element problems and the convergence analyses, including convergence rate estimates, and numerical experiments are provided in [8]. The analyses have shown that the parameters λ_{ij}, called transmission coefficients, are highly effected on the convergence speed, but, whatever λ_{ij} are taken, it seems that the convergence speed is always dependent on the finite element mesh size in any case.

To improve this method and develop a method with the better convergence, we rewrite the consistency condition (2.2) by introducing extra parameter β_{ij}. It is not hard to check that (2.2) also can be replaced by the following condition on the artificial interfaces:

$$\begin{cases} \beta_{ij}\dfrac{\partial u_i}{\partial n_i} + \lambda_{ij} u_i = -\beta_{ij}\dfrac{\partial u_j}{\partial n_j} + \lambda_{ij} u_j \qquad \text{on} \quad \gamma_{ij}, \quad 1 \le i \ne j \le m, \\ \beta_{ji}\dfrac{\partial u_j}{\partial n_j} + \lambda_{ji} u_j = -\beta_{ji}\dfrac{\partial u_i}{\partial n_i} + \lambda_{ji} u_i \qquad \text{on} \quad \gamma_{ij} \quad 1 \le i \ne j \le m, \end{cases} \tag{2.9}$$

where

$$\begin{cases} \beta_{ij} = \beta_{ji} > 0, \quad 1 \le i \ne j \le m, \\ \lambda_{ij} = \lambda_{ji} > 0, \quad 1 \le i \ne j \le m. \end{cases} \tag{2.10}$$

By using the consistency condition (2.9), we can develop a nonoverlapping domain decomposition iterative procedure based on the following subproblems:

$$\begin{cases} -\Delta u_i^n + \alpha(x) u_i^n = f \qquad \text{in} \quad \Omega_i, \\ \beta_{ij}\dfrac{\partial u_i^n}{\partial n_i} + \lambda_{ij} u_i^n = g_{ij}^n \qquad \text{on} \quad \gamma_{ij} \ \forall\ 1 \le j \le m, j \ne i, \\ u_i^n = 0 \qquad \text{on} \quad \Gamma_i, \end{cases} \tag{2.11}$$

$$g_{ij}^{n+1} = 2\lambda_{ij} u_j^n - g_{ji}^n, \qquad 1 \le j \ne i \le m, \quad \text{if } meas(\gamma_{ij}) > 0. \tag{2.12}$$

Like (2.5)–(2.6), the subproblem (2.11) is understood as a usual weak formulation:

$$a_{\Omega_i}(u_i^n, v) + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}} u_i^n v ds = (f, v)_{\Omega_i} + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}} g_{ij}^n v ds \ \forall v \in H^1_{\Gamma_i}(\Omega_i), \tag{2.13}$$

and (2.12) is understood in $L^2(\Omega_i)$. It follows from (2.10)–(2.11) that

$$\begin{aligned}\beta_{ij}\frac{\partial u_i^{n+1}}{\partial n_i}+\lambda_{ij}u_i^{n+1} &= g_{ij}^{n+1}\equiv 2\lambda_{ij}u_j^n-g_{ji}^n\\ &= 2\lambda_{ij}u_j^n-\left(\beta_{ij}\frac{\partial u_j^n}{\partial n_j}+\lambda_{ji}u_j^n\right)\\ &= -\beta_{ij}\frac{\partial u_j^n}{\partial n_j}+\lambda_{ij}u_j^n \qquad \text{on } \gamma_{ij}.\end{aligned}\tag{2.14}$$

This means that the above method indeed implements the consistency condition (2.9) by an iterative process. Then, comparing (2.5)–(2.6) and (2.11)–(2.12), we have found that the only difference is at the second equalities of (2.5) and (2.11). That is, the second equality of (2.11) has an extra parameter β_{ij}. We call β_{ij} the penalty coefficient since it seems to introduce a penalty for artificial terms of the artificial interfaces of the weak formulation of (2.11) while comparing the weak formulation (2.7) and the weak formulation (2.13). We are going to show that this penalty coefficient can improve the convergence speed even for unstructured finite element meshes in the next sections.

3. A nonoverlapping domain decomposition method for (1.2).

Based on the discussions of the last section, we will develop and analyze a nonoverlapping domain decomposition method based on (2.11)–(2.13), that is, based on the Robin-type consistency condition (2.9) actually. The nonoverlapping domain decomposition iterative procedure is defined as follows.

Algorithm I.

(i) given $g_{ij}^0\in L^2(\gamma_{ij}),\ 1\le i\ne j\le m,\ meas(\gamma_{ij})>0$ arbitrarily;

(ii) then recursively find $u_i^n,\ \ i=1,2,\dots,m,$ by solving the subproblems

$$\begin{aligned}a_{\Omega_i}(u_i^n,v)&+\sum_{\substack{1\le j\le m\\ j\ne i}}\frac{\lambda_{ij}}{\beta_{ij}}\int_{\gamma_{ij}}u_i^n v ds\\ &= (f,v)_{\Omega_i}+\sum_{\substack{1\le j\le m\\ j\ne i}}\frac{1}{\beta_{ij}}\int_{\gamma_{ij}}g_{ij}^n v ds \quad \forall v\in H^1_{\Gamma_i}(\Omega_i);\end{aligned}\tag{3.1}$$

(iii) update the transmission condition data for $i=1,2,\dots,m,$

$$g_{ij}^{n+1}=2\lambda_{ij}u_j^n-g_{ji}^n,\qquad 1\le j\ne i\le m,\ \text{ if } meas(\gamma_{ij})>0,\tag{3.2}$$

where the penalty coefficient β_{ij} and the transmission coefficient λ_{ij} satisfy (2.10).

By similar arguments as those in (3.1)–(3.3) of [7], we now define the error at the iterative step n:

$$\varepsilon^n=(\varepsilon_i^n)_{1\le i\le m}=(u_i^n-u\,|_{\Omega_i})_{1\le i\le m}\in\prod_{i=1}^m H^1_{\Gamma_i}(\Omega_i).\tag{3.3}$$

Then we have

$$a_{\Omega_i}(\varepsilon_i^n,v)+\sum_{\substack{1\le j\le m\\ j\ne i}}\frac{\lambda_{ij}}{\beta_{ij}}\int_{\gamma_{ij}}\varepsilon_i^n v ds=\sum_{\substack{1\le j\le m\\ j\ne i}}\frac{1}{\beta_{ij}}\int_{\gamma_{ij}}g_{ij}^n v ds\quad \forall v\in H^1_{\Gamma_i}(\Omega_i),\tag{3.4}$$

$$g_{ij}^{n+1}=2\lambda_{ij}\varepsilon_j^n-g_{ji}^n\qquad \text{on }\ \gamma_{ij}\quad \forall\ \ 1\le j\le m,\ j\ne i,\tag{3.5}$$

where we have used g_{ij}^n to replace $g_{ij}^n-(\beta_{ij}\frac{\partial u}{\partial n_i}+\lambda_{ij}u)$.

LEMMA 3.1. *There then holds the following identity:*

$$|||g^{n+1}|||^2 = |||g^n|||^2 - 4\sum_{i=1}^{m} a_{\Omega_i}(\varepsilon_i^n, \varepsilon_i^n), \tag{3.6}$$

where

$$|||g^k|||^2 = \sum_{1\le i\ne j\le m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}} |g_{ij}^k|^2 ds, \quad g^k = (g_{ij}^k)_{1\le i\ne j\le m}, \ k = n, n+1. \tag{3.7}$$

Proof. It follows from (3.4)–(3.5) that

$$\begin{aligned} |||g^{n+1}|||^2 &= \sum_{1\le i\ne j\le m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}} |g_{ij}^{n+1}|^2 ds \\ &= \sum_{1\le i\ne j\le m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}} |2\lambda_{ij}\varepsilon_j^n - g_{ji}^n|^2 ds \\ &= \sum_{1\le i\ne j\le m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}} |g_{ji}^n|^2 ds - 4\sum_{j=1}^{m} \sum_{\substack{1\le i\le m \\ i\ne j}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}} (g_{ji}^n - \lambda_{ji}\varepsilon_j^n)\varepsilon_j^n ds \\ &= |||g^n|||^2 - 4\sum_{j=1}^{m} a_{\Omega_j}(\varepsilon_j^n, \varepsilon_j^n), \end{aligned}$$

where (2.10) has been used. Thus, (3.6) has been proved.

Moreover, from Lemma 3.1 and by an almost exact same argument as the proof of Theorem 3.2 of [7], we have the following convergence theorem for Algorithm I.

THEOREM 3.2. *Let* $u \in H_0^1(\Omega)$ *be the weak solution of* (1.2) *with reasonable regularities, and let* $u_i^n \in H_{\Gamma_i}^1(\Omega)$ $(i = 1, 2, \ldots, m)$ *be the weak solutions of* (3.1)–(3.2). *Then we have that, for any initial* $g_{ij}^0 \in L^2(\gamma_{ij})$,

$$\|u^n - u\|_{H^1} = \left(\sum_{i=1}^{m} \|u_i^n - u^n\|_{H^1(\Omega_i)}^2\right)^{1/2} \longrightarrow 0, \quad as \quad n \to \infty. \tag{3.8}$$

4. A nonoverlapping domain decomposition method for (1.5).

This section applies the method developed in the last section to the nonconforming finite element problem (1.5). A parallel nonoverlapping domain decomposition method for solving nonconforming finite element problem (1.5) is developed and analyzed. Following the approach to construct Algorithm I, we define the nonoverlapping domain decomposition iterative procedure over the aligned nonoverlapping domain decomposition (1.7)–(1.8) as follows.

ALGORITHM II.

(i) given $g_{ij}^0 \in S_h(\gamma_{ij}), \ 1 \le i \ne j \le m,$ if $meas(\gamma_{ij}) > 0$ arbitrarily;

(ii) then recursively find $u_i^n \in S_i \ (i = 1, 2, \ldots, m)$ by solving the subproblems

$$a_{\Omega_i}^h(u_i^n, v) + \sum_{\substack{1\le j\le m \\ j\ne i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^{*} u_i^n v ds = (f, v)_{\Omega_i} + \sum_{\substack{1\le j\le m \\ j\ne i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} g_{ij}^n v ds \ \forall v \in S_i; \tag{4.1}$$

(iii) update data of the transmission condition on the interfaces

$$g_{ij}^{n+1}(p) = \ 2\lambda_{ij}u_j^n(p) - g_{ji}^n(p), \quad \text{on} \ \ p \in \gamma_{ij} \cap N_h, \ 1 \le j \ne i \le m, \tag{4.2}$$

where the penalty and transmission coefficients, β_{ij} and λ_{ij}, satisfy (2.10), $S_i = S_h \mid_{\Omega_i}$, and

$$S_h(\gamma_{ij}) = \left\{ v \in S_h \mid \; v \; = \sum_{p \in \gamma_{ij} \cap N_h} a_p \, \varphi_p \,, \quad a_p \in \mathbb{R} \right\}, \tag{4.3}$$

$$\int_{\gamma_{ij}}^{*} uvds = \sum_{p \in \gamma_{ij} \cap N_h} u(p) \, v(p) \, meas(s_p), \tag{4.4}$$

where, and in this paper, $\{\varphi_p\}_{p \in N_h}$ is the node basis of the finite element space S_h and s_p is the element face with p as its barycenter. (4.4) implies that we have used the numerical integration in (4.1) to compute the integrations on the interfaces.

We now consider the convergence of Algorithm II. Unlike the case for partial differential boundary value problems (in detail, cf. [7, 8]), we first have to give an equivalent splitting subproblem form with respect to the nonoverlapping domain decomposition for finite element problem (1.5) in order to prove the convergence of Algorithm II.

Theorem 4.1. *Let $u \in S_h$ be the solution of the finite element problem* (1.5) *and $u_i = u \mid_{\Omega_i}$. The problem* (1.5) *can be split into an equivalent splitting subproblem form. That is, there exist $g_{ij}^{*} \in S_h(\gamma_{ij})$, $1 \le i \ne j \le m$, $meas(\gamma_{ij}) > 0$, such that $u_i \in S_i$ $(i = 1, 2, \ldots, m)$ satisfies*

$$a_{\Omega_i}^h(u_i, v) + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^{*} u_i v ds = (f, v)_{\Omega_i} + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} g_{ij}^{*} v ds \quad \forall v \in S_i. \tag{4.5}$$

Proof. Notice that $\{\varphi_p\}_{p \in N_h}$ is the node basis of the finite element space S_h. Then the problem (1.5) is equivalent to the following system:

$$a_{\Omega}^h(u, \varphi_p) = (f, \varphi_p)_{\Omega} \qquad \forall p \in N_h. \tag{4.6}$$

In particular, it follows from the small support property of $\varphi_p(x)$ that

$$a_{\Omega_i}^h(u, \varphi_p) - (f, \varphi_p)_{\Omega_i} = - \, [a_{\Omega_j}(u, \varphi_p) - (f, \varphi_p)_{\Omega_j}] \quad \forall p \in \gamma_{ij} \cap N_h. \tag{4.7}$$

For any γ_{ij}, any element face $s_p \subset \gamma_{ij}$ with p as its barycenter, we define G_{ij}^p as follows:

$$G_{ij}^p = - \frac{1}{meas(s_p)} [a_{\Omega_j}^h(u, \varphi_p) - (f, \varphi_p)_{\Omega_j}].$$

Therefore, we can construct $g_{ij}^{*} \in S_h(\gamma_{ij})$, $meas(\gamma_{ij}) > 0$ $(1 \le i \ne j \le m)$,

$$g_{ij}^{*}(x) = \sum_{p \in \gamma_{ij} \cap N_h} \left(\lambda_{ij} u(p) + \beta_{ij} G_{ij}^p \right) \, \varphi_p(x). \tag{4.8}$$

Thus, it follows from (4.7)–(4.8) that, for all $p \in \overline{\Omega}_i \cap N_h$, $u_i = u \mid_{\Omega_i}$ satisfies

$$a_{\Omega_i}^h(u_i, \varphi_p) + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^{*} u_i \varphi_p ds = (f, \varphi_p)_{\Omega_i} + \sum_{\substack{1 \le j \le m \\ j \ne i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} g_{ij}^{*} \varphi_p ds.$$

Clearly, this implies (4.5). The proof is completed.

Before discussing the convergence, we need to introduce similar notations to those in Algorithm I. Let u be the solution of the finite element problem (1.5), and let u_i^n $(1 \leq i \leq m)$ be the solutions of the subproblem (4.1) on the subdomain Ω_i at iterative step n. We then denote

$$u_i = u|_{\Omega_i}, \qquad u \ := \ (u_i)_{(1\leq i\leq m)} \in \prod_{i=1}^{m} S_i, \tag{4.9}$$

$$u^n = (u_i^n)_{(1\leq i\leq m)} \in \prod_{i=1}^{m} S_i, \qquad u^n|_{\Omega_i} \ := \ u_i^n, \tag{4.10}$$

$$e^n = (e_i^n)_{(1\leq i\leq m)} \ := \ (u_i^n - u_i) \in \prod_{i=1}^{m} S_i. \tag{4.11}$$

Clearly, e^n is indeed the error at iterative step n. Then we have

$$a_{\Omega_i}^h(e_i^n, v) + \sum_{\substack{1\leq j\leq m\\ j\neq i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^{*} e_i^n v ds = \sum_{\substack{1\leq j\leq m\\ j\neq i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} g_{ij}^n v ds \ \forall v \in S_i, \tag{4.12}$$

$$g_{ij}^{n+1}(p) = \ 2\lambda_{ij} e_j^n(p) - g_{ji}^n(p) \quad \text{on} \ \ p \in \gamma_{ij} \cap N_h, \ \ 1 \leq j \neq i \leq m, \tag{4.13}$$

where we have used g_{ij}^n to replace $g_{ij}^n - g_{ij}^*$.

LEMMA 4.2. *We then have the following identity:*

$$a_{\Omega_i}^h(e_i^n, e_i^n) = \sum_{\substack{1\leq j\leq m\\ j\neq i}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} (g_{ij}^n - \lambda_{ij} e_i^n) e_i^n ds. \tag{4.14}$$

LEMMA 4.3. *There then holds the following identity:*

$$|||g^{n+1}|||_*^2 = |||g^n|||_*^2 - 4 \sum_{i=1}^{m} a_{\Omega_i}^h(e_i^n, e_i^n), \tag{4.15}$$

where

$$|||g^k|||_*^2 = \sum_{1\leq i\neq j\leq m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^{*} |g_{ij}^k|^2 ds, \quad g^k = (g_{ij}^k)_{1\leq i\neq j\leq m}, \ \ k = n, n+1. \tag{4.16}$$

Proof. It follows from (4.13) and (4.14) that

$$\begin{aligned} |||g^{n+1}|||_*^2 &= \sum_{1\leq i\neq j\leq m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^{*} |g_{ij}^{n+1}|^2 ds \\ &= \sum_{1\leq i\neq j\leq m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^{*} |2\lambda_{ij} e_j^n - g_{ji}^n|^2 ds \\ &= \sum_{1\leq i\neq j\leq m} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^{*} |g_{ji}^n|^2 ds - 4 \sum_{j=1}^{m} \sum_{\substack{1\leq i\leq m\\ i\neq j}} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^{*} (g_{ji}^n - \lambda_{ji} e_j^n) e_j^n ds \\ &= |||g^n|||_*^2 - 4 \sum_{j=1}^{m} a_{\Omega_j}^h(e_j^n, e_j^n), \end{aligned}$$

where (2.10) has been used. Thus, (4.15) has been proved.

THEOREM 4.4. *Let $u \in S_h$ be the solution of the nonconforming finite element problem* (1.5), *and let $u_i^n \in S_i$ $(i = 1, 2, \ldots, m)$ be the solutions of subproblem* (4.1)–(4.2) *at iterative step n. Then we have*

$$\|u^n - u\|_h \equiv \left(\sum_{i=1}^{m} \sum_{\tau \in \mathcal{T}_h, \tau \subset \Omega_i} \|u_i^n - u\|_{H^1(\tau)}^2 \right)^{1/2} \longrightarrow 0, \quad \textit{as } n \to \infty. \tag{4.17}$$

Proof. Clearly, we indeed need to show that

$$\left(\sum_{i=1}^{m} \|e_i^n\|_{h(\Omega_i)}^2 \right)^{1/2} \equiv \left(\sum_{i=1}^{m} \sum_{\tau \in \mathcal{T}_h, \tau \subset \Omega_i} \|e_i^n\|_{H^1(\tau)}^2 \right)^{1/2} \longrightarrow 0, \quad \textit{as } n \to \infty. \tag{4.18}$$

By using Lemma 4.2, we have that for any positive integer M

$$\sum_{n=0}^{M} \left(\sum_{i=1}^{m} a_{\Omega_i}^h(e_i^n, e_i^n) \right) = \frac{1}{4}(|||g^0|||_*^2 - |||g^{M+1}|||_*^2) \geq 0. \tag{4.19}$$

This implies that

$$a_{\Omega_i}^h(e_i^n, e_i^n) \longrightarrow 0, \quad \textit{as} \quad n \to \infty, \qquad i = 1, 2, \ldots, m. \tag{4.20}$$

Therefore, if $\alpha(x) \geq \alpha_0 > 0$, one then obtains (4.17) from (4.20) immediately . We now consider the general case. Since e_i^n vanishes at the node points of $\partial\Gamma_i$, it is then easy to check that $(a_{\Omega_i}^h(\cdot, \cdot))^{1/2}$ is a norm on S_i for $\Omega_i \subset G_1$. It follows from equivalence of norms in S_i that

$$\|e_i^n\|_{h(\Omega_i)} \longrightarrow 0, \qquad \textit{as} \ \ n \to \infty \qquad \forall\, \Omega_i \subset G_1. \tag{4.21}$$

Clearly, (4.21) implies that

$$\int_{\gamma_{ij}}^{*} |e_i^n|^2 ds \longrightarrow 0, \quad \textit{as} \ \ n \to \infty \ \forall\, \Omega_i \subset G_1, \quad j \neq i. \tag{4.22}$$

Moreover, by using (4.12), (4.20), and (4.22), we can have that

$$\int_{\gamma_{ij}}^{*} |g_{ij}^n|^2 ds \longrightarrow 0, \quad \textit{as} \ \ n \to \infty \ \forall\, \Omega_i \subset G_1, \quad j \neq i. \tag{4.23}$$

Therefore, it follows from (4.13), (4.22), and (4.23) that

$$\int_{\gamma_{ij}}^{*} |g_{ij}^n|^2 ds \longrightarrow 0, \quad \textit{as} \ \ n \to \infty \ \forall\, \Omega_i \subset G_2, \ \Omega_j \subset G_1, \tag{4.24}$$

$$\int_{\gamma_{ij}}^{*} |e_i^n|^2 ds \longrightarrow 0, \quad \textit{as } n \to \infty \ \ \forall\, \Omega_i \subset G_2, \ \Omega_j \subset G_1. \tag{4.25}$$

Notice that, for $\Omega_i \subset G_2$,

$$\left(a_{\Omega_i}(\cdot, \cdot) + \sum_{\Omega_j \subset G_1} \int_{\gamma_{ij}}^{*} |\cdot|^2 ds \right)^{1/2} \tag{4.26}$$

is a norm on S_i. Hence, (4.20), (4.25), and (4.26) imply that

$$\|e_i^n\|_{h(\Omega_i)} \longrightarrow 0, \qquad as \;\; n \to \infty \quad \forall\, \Omega_i \subset G_2. \tag{4.27}$$

Similarly, we can show that, for $r \geq 3$,

$$\|e_i^n\|_{h(\Omega_i)} \longrightarrow 0, \quad as \;\; n \to \infty \quad \forall\, \Omega_i \subset G_r. \tag{4.28}$$

Since the number of G_r is less than m, we have proved (4.18). This finishes the proof.

5. Convergence rate estimates.

This section discusses the convergence rate of Algorithm II for quasi-uniform partition $\mathcal{T}_h$. Let

$$W = \prod_{i=1}^{m} S_i, \qquad \Lambda = \prod_{\substack{1 \leq i \neq j \leq m \\ meas(\gamma_{ij})>0}} S_h(\gamma_{ij}). \tag{5.1}$$

Also, let $A_f : W \times \Lambda \longmapsto W \times \Lambda$ be an affined mapping defined by (4.1)–(4.2) of Algorithm II. That is,

$$[u^{n+1}, g^{n+1}] = A_f[u^n, g^n], \tag{5.2}$$

where $[u^{n+1}, g^{n+1}]$ satisfies (3.1)–(3.2). We then have the following lemma.

LEMMA 5.1. *Let $u \in S_h$ be the solution of the problem* (1.5), *and let $u \equiv (u \mid_{\Omega_i}) \in W$. Then there exists $g \in \Lambda$ such that $[u, g]$ is a fixed point of A_f. Conversely, let $[u, g] \in W$ be a fixed point of A_f and $u \in L^2(\Omega)$ satisfying $u \mid_{\Omega_i} = u_i$. Then $u \in S_h$ is the solution of the problem* (1.5).

Proof. If $u \in S_h$ is the solution of (1.5), we have that, by taking $g = (g_{ij}^*) \in \Lambda$ in (4.5),

$$a_{\Omega_i}^h(u_i, v) + \sum_{\substack{1 \leq j \leq m \\ j \neq i}} \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^* u_i v ds = (f, v)_{\Omega_i} + \sum_{1 \leq j \leq m \top j \neq i} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^* g_{ij} v ds \;\; \forall v \in S_i. \tag{5.3}$$

From the definition of g_{ij}^* of Lemma 5.1, it is easy to check that

$$g_{ij}(p) = \; 2\lambda_{ij} u(p) - g_{ji}(p) \;\; \forall p \in \gamma_{ij} \cap N_h, \;\; 1 \leq j \neq i \leq m, \; meas(\gamma_{ij}) > 0. \tag{5.4}$$

Therefore, (5.3) and (5.4) immediately imply that $[u, g]$ is a fixed point of A_f.

Conversely, if $[u, g]$ is a fixed point of A_f, that is, $[u, g]$ satisfies (5.3)–(5.4), it follows from (5.3)–(5.4) that by some direct computations

$$u_i(p) = u_j(p) \quad \forall\, p \in \gamma_{ij} \cap N_h, \;\; 1 \leq j \neq i \leq m, \;\; meas(\gamma_{ij}) > 0, \tag{5.5}$$

$$\sum_{i=1}^{m} a_{\Omega_i}^h(u, v) = \sum_{i=1}^{m} (f, v)_{\Omega_i} \;\; \forall\, v \in S_h. \tag{5.6}$$

It is not difficult to see from (5.5) and (5.6) that $u \in S_h$, and u is the solution of (1.5). The proof is completed.

Furthermore, if we let $A = A_f \mid_{f=0}$, $F = A_f(0, 0)$, then A is a linear mapping, indeed, which is the iterator (iterative matrix) of Algorithm II, and satisfies

$$A_f[u, g] = A[u, g] + F, \tag{5.7}$$

$$[e_i^{n+1}, g^{n+1}] = A[e_i^n, g^n]. \tag{5.8}$$

THEOREM 5.2. *Let $\rho(A)$ be the spectral radius of A. Then we have*

$$\rho(A) < 1. \tag{5.9}$$

Proof. Let μ be an eigenvalue of A, and let $[e, g] \neq [0, 0]$ be its corresponding eigenvector. Then we have that $A[e, g] = \mu[e, g]$, that is,

$$a^h_{\Omega_i}(e_i, v) + \sum_{\substack{1\le j\le m\\ j\ne i}} \frac{\lambda_{ij}}{\beta_{ij}} \int^*_{\gamma_{ij}} e_i v ds = \sum_{\substack{1\le j\le m\\ j\ne i}} \frac{1}{\beta_{ij}} \int^*_{\gamma_{ij}} g_{ij} v ds \quad \forall v \in S_i, \tag{5.10}$$

$$\mu g_{ij}(p) = \ 2\lambda_{ij} e_j(p) - g_{ji}(p) \quad \forall\ p \in \gamma_{ij} \cap N_h, \quad 1 \le j \neq i \le m. \tag{5.11}$$

Therefore, these, together with Theorem 4.1, imply that

$$\mu^2 |||g|||^2_* = |||g|||^2_* - 4 \sum_{i=1}^m a^h_{\Omega_i}(e_i, e_i). \tag{5.12}$$

This means that $|\mu| \le 1$ and $|\mu| = 1$ if and only if

$$a^h_{\Omega_i}(e_i, e_i) = 0 \qquad \forall\ i = 1, 2, \ldots, m. \tag{5.13}$$

We next show that $|\mu| < 1$, that is, $|\mu| \neq 1$. If $|\mu| = 1$, then (4.13) implies that each e_i is a constant over Ω_i. We then have that since e_i vanishes at nodal points on $\partial\Omega_i \cap \partial\Omega$

$$e_i = 0 \qquad \text{in } \ \Omega_i \qquad \forall\ \Omega_i \subset G_1. \tag{5.14}$$

Moreover, from (5.10) and (5.11), we can obtain

$$g_{ij} = 0 \qquad \text{on} \quad \gamma_{ij} \qquad \forall\ \Omega_i \subset G_1,\ j \neq i, \tag{5.15}$$

$$g_{ij} = 0 \qquad \text{on} \quad \gamma_{ij} \qquad \forall\ \Omega_i \subset G_1,\ \Omega_j \subset G_2, \tag{5.16}$$

$$e_i = 0 \qquad \text{on} \quad \gamma_{ij} \qquad \forall\ \Omega_i \subset G_1,\ \Omega_j \subset G_2. \tag{5.17}$$

Then (5.13)–(5.16) imply that

$$e_i = 0 \qquad \text{in } \ \Omega_i \qquad \forall\ \Omega_i \subset G_2. \tag{5.18}$$

Similarly, we can consider other $\Omega_i \subset G_r (r \ge 3)$. Therefore, we have shown that

$$e_i = 0 \qquad \text{in } \ \Omega_i \quad \forall\ i = 1, 2, \ldots, m, \tag{5.19}$$

$$g_{ij} = 0 \qquad \text{on } \ \gamma_{ij} \quad \forall\ 1 \le i \neq j \le m,\ meas(\gamma_{ij}) > 0, \tag{5.20}$$

that is, $[e, g] = [0, 0]$. This is a contradiction. Hence, $|\mu| < 1$. Therefore, (5.9) is proved.

THEOREM 5.3. *Assume that $\alpha(x) \ge \alpha_0 > 0$, and*

$$\begin{cases} \beta_{ij} = \beta_{ji} = \beta > 0 & \forall\ 1 \le i \neq j \le m,\ meas(\gamma_{ij}) > 0, \\ \lambda_{ij} = \lambda_{ji} = \lambda > 0 & \forall\ 1 \le i \neq j \le m,\ meas(\gamma_{ij}) > 0. \end{cases} \tag{5.21}$$

We then have the following convergence rate estimates for Algorithm II:

$$|||g^{n+1}|||_* \le \left(1 - \frac{4}{Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2}\right)^{1/2} |||g^n|||_*, \tag{5.22}$$

$$\|u^n - u\|_h \le C(\alpha) \left(1 - \frac{4}{Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2}\right)^{n/2} |||g^0|||_*, \tag{5.23}$$

where C is a constant independent of finite element mesh size h.

Proof. It follows from (4.9)–(4.14) and (5.21) that

$$\begin{aligned}
&\sum_{j\neq i} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^* |g_{ij}^n|^2 ds \\
&= \sum_{j\neq i} \frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^* |(g_{ij}^n - \lambda_{ij}e_i^n) + \lambda_{ij}e_i^n|^2 ds \\
&= \sum_{j\neq i} \left(\frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^* |g_{ij}^n - \lambda_{ij}e_i^n|^2 ds + \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^* |e_i^n|^2 ds \right. \\
&\qquad \left. + \frac{2}{\beta_{ij}} \int_{\gamma_{ij}}^* (g_{ij}^n - \lambda_{ij}e_i^n) e_i^n ds \right) \\
&= \sum_{j\neq i} \left(\frac{1}{\beta_{ij}\lambda_{ij}} \int_{\gamma_{ij}}^* |g_{ij}^n - \lambda_{ij}e_i^n|^2 ds + \frac{\lambda_{ij}}{\beta_{ij}} \int_{\gamma_{ij}}^* |e_i^n|^2 ds \right) \\
&\qquad + 2\, a_{\Omega_i}^h(e_i^n, e_i^n).
\end{aligned} \tag{5.24}$$

Taking $v \in S_i$ such that

$$v(p) = \begin{cases} g_{ij}^n(p) - \lambda_{ij}e_i^n(p) & \text{at } \; p \in \gamma_{ij} \cap N_h, \; j \neq i, \\ 0 & \text{at } \; p \in N_h \backslash \gamma_{ij}, \; j \neq i, \end{cases}$$

and plugging v into (4.9), we have

$$\begin{aligned}
&\sum_{j\neq i} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^* |g_{ij}^n - \lambda_{ij}e_i^n|^2 ds = \sum_{j\neq i} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^* (g_{ij}^n - \lambda_{ij}e_i^n) v ds \\
&\quad = a_{\Omega_i}^h(e_i^n, v) \le \left(a_{\Omega_i}^h(e_i^n, e_i^n)\right)^{1/2} \left(a_{\Omega_i}^h(v, v)\right)^{1/2}.
\end{aligned}$$

On the other hand, it follows from some direct calculations that

$$a_{\Omega_i}^h(v, v) \le Ch^{-1} \sum_{j\neq i} \int_{\gamma_{ij}}^* |v|^2 ds. \tag{5.25}$$

Then we have that

$$\sum_{j\neq i} \frac{1}{\beta_{ij}} \int_{\gamma_{ij}}^* |g_{ij}^n - \lambda_{ij}e_i^n|^2 ds \le Ch^{-1} a_{\Omega_i}^h(e_i^n, e_i^n). \tag{5.26}$$

It also follows from $\alpha(x) > \alpha_0 > 0$ and some direct calculations that

$$\sum_{j\neq i}\int_{\gamma_{ij}}^{*} |e_i^n|^2 ds \leq Ch^{-1}(e_i^n, e_i^n)_{\Omega_i} \leq Ch^{-1}a_{\Omega_i}^h(e_i^n, e_i^n). \tag{5.27}$$

Therefore, using (5.21) and (5.24)–(5.27) and summing for $i = 1, 2, \ldots, m,$ we have

$$|||g_{ij}^n|||_*^2 \leq (Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2)\sum_{i=1}^{m} a_{\Omega_i}^h(e_i^n, e_i^n). \tag{5.28}$$

Thus, from (5.28) and Lemma 4.2, we have

$$|||g_{ij}^{n+1}|||_*^2 \leq \left(1 - \frac{4}{Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2}\right)|||g_{ij}^n|||_*^2, \tag{5.29}$$

$$\begin{aligned} \|u^n - u\|_h^2 &\leq (1 + \|\alpha\|_{L^\infty(\Omega)})\sum_{i=1}^{m} a_{\Omega_i}^h(e_i^n, e_i^n) \\ &\leq \frac{1}{4}(1 + \|\alpha\|_{L^\infty(\Omega)})|||g_{ij}^n|||_*^2. \end{aligned} \tag{5.30}$$

Finally, (5.29) and (5.30) imply (5.22) and (5.23) immediately. The proof is completed.

COROLLARY 5.4. *With the assumption of Theorems* 5.2 *and* 5.3*, we then have*

$$\rho(A) \leq \left(1 - \frac{4}{Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2}\right)^{1/2}. \tag{5.31}$$

From (5.22)–(5.23) of Theorem 5.3 and (5.31) of Corollary 5.4, it is not hard to see that if we take

$$\lambda = O(h^{-1}) \qquad \text{and} \qquad \beta = O(h^{-2}), \tag{5.32}$$

then there exists a positive constant δ independent of h such that

$$\left(1 - \frac{4}{Ch^{-1}(\lambda^{-1} + \beta^{-1}\lambda) + 2}\right)^{1/2} \leq 1 - \delta. \tag{5.33}$$

This means that the method has an optimal convergence rate if (5.32) holds.

COROLLARY 5.5. *With the assumption of Theorems* 5.2 *and* 5.3*, if* (5.32) *holds, there then exists a positive constant* δ *independent of finite element mesh size* h *such that*

$$|||g^{n+1}|||_* \leq (1 - \delta)\,|||g^n|||_*, \tag{5.34}$$

$$\|u^n - u\|_h \leq C(\alpha)\,(1 - \delta)^n\,|||g^0|||_*, \tag{5.35}$$

$$\rho(A) \leq (1 - \delta)\,. \tag{5.36}$$

Notice that Algorithm II can become a classic iterative method of linear systems if every individual element of $\mathcal{T}_h$ is chosen as a subdomain. Therefore, Corollary 5.5 implies that Algorithm II indeed constructs a classic iterative method with a contracted number independent of finite element mesh size h for solving the nonconforming finite element problem (1.5). That is, an optimal iterative method can be constructed by Algorithm II.

6. Notes on unstructured finite element meshes. This section extends the conclusions of Algorithm II developed in the last two sections to the unstructured finite element meshes (cf. [4, 9]). This means that the finite element triangulation $\mathcal{T}_h$ is not a quasi-uniform finite element partition. First, we consider Theorem 4.4 and Theorem 5.2, which are about the convergence of Algorithm II. It is not hard to check that the quasi-uniform and regular properties of the finite element partition $\mathcal{T}_h$ have never been used in the proof of Theorem 4.4 and Theorem 5.2. This means that Theorem 4.4 and Theorem 5.2 still hold even for $\mathcal{T}_h$ without either quasi-uniform or regular properties.

THEOREM 6.1. *Assume that the finite element partition $\mathcal{T}_h$ is not required to be either a quasi-uniform or a regular property. Then the conclusions of Theorem* 4.4 *and Theorem* 5.2 *still hold. That is,*

$$\|u^n - u\|_h \equiv \left(\sum_{i=1}^{m} \sum_{\tau \in \mathcal{T}_h, \tau \subset \Omega_i} \|u_i^n - u\|_{H^1(\tau)}^2 \right)^{1/2} \longrightarrow 0, \quad \textit{as } n \to \infty, \tag{6.1}$$

$$\rho(A) < 1, \tag{6.2}$$

where all of the undefined notations are the same as those in Theorem 4.4 *and Theorem* 5.2.

We then consider the conclusions of the convergence rates, which include Theorem 5.3, Corollary 5.4, and Corollary 5.5. After carefully checking their proofs, we have found that the quasi-uniform and regular properties of the finite element partition $\mathcal{T}_h$ have been used in three formulas (5.25)–(5.27). In fact, not the global quasi-uniform and regular properties of $\mathcal{T}_h$ but only the local quasi-uniform and regular properties on the subdomain Ω_i have been used in (5.25)–(5.27).

Let $\mathcal{T}_{h_i}$ be the subpartition of $\mathcal{T}_h$ on Ω_i, where h_i is the mesh size of $\mathcal{T}_{h_i}$. In other words, $\mathcal{T}_{h_i}$ is the restriction of $\mathcal{T}_h$ on Ω_i. Furthermore, we assume that every subpartition $\mathcal{T}_{h_i}$ is quasi-uniform. Therefore, we have that (5.25)–(5.27) still hold. Hence, we have that

$$\sum_{j \neq i} \int_{\gamma_{ij}}^{*} |g_{ij}^n - \lambda_{ij} e_i^n|^2 ds \le C h_i^{-1} a_{\Omega_i}^h(e_i^n, e_i^n), \tag{6.3}$$

$$\sum_{j \neq i} \int_{\gamma_{ij}}^{*} |e_i^n|^2 ds \le C h^{-1} (e_i^n, e_i^n)_{\Omega_i} \le C h_i^{-1} a_{\Omega_i}^h(e_i^n, e_i^n). \tag{6.4}$$

Therefore,

$$|||g_{ij}^n|||_*^2 \le \max_{1 \le i \neq j \le m} \left[C h_i^{-1} (\lambda_{ij}^{-1} + \beta_{ij}^{-1} \lambda_{ij}) + 2 \right] \sum_{i=1}^{m} a_{\Omega_i}^h(e_i^n, e_i^n). \tag{6.5}$$

Assume that f_{ij} is any fixed element face on the interface γ_{ij} with $meas(\gamma_{ij}) > 0$. Let

$$\begin{cases} \lambda_{ij} = \lambda_{ji} = O((m(fi_{ij}))^{-1}), & 1 \le i \neq j \le m, \\ \beta_{ij} = \beta_{ji} = O((m(f_{ij}))^{-2}), & 1 \le i \neq j \le m, \end{cases} \tag{6.6}$$

where

$$m(f_{ij}) = \begin{cases} meas(f_{ij}) & \text{if } N = 2, \\ \sqrt{meas(f_{ij})} & \text{if } N = 3. \end{cases} \tag{6.7}$$

Notice that the sub-partition $\mathcal{T}_{h_i}$ is quasi-uniform. Then, $\lambda_{ij} = O(h_i^{-1})$ and $\beta_{ij} = O(h_i^{-2})$. Thus, if (6.6) holds, there then is a positive constant δ_0 independent of h_i such that

$$4 < Ch_i^{-1}(\lambda_{ij}^{-1} + \beta_{ij}^{-1}\lambda_{ij}) + 2 < \delta_0, \quad 1 \le i \ne j \le m.$$

This implies that there is a positive constant δ independent of h_i such that

$$\left(1 - \frac{4}{\max_{1\le i\ne j\le m}[(Ch_i^{-1}(\lambda_{ij}^{-1} + \beta_{ij}^{-1}\lambda_{ij}) + 2]}\right)^{1/2} \le 1 - \delta. \tag{6.8}$$

Therefore, in view of the proof of Theorem 4.4 and (6.3)–(6.8), we have the following convergence rate estimates for the unstructured finite element mesh $\mathcal{T}_h$.

THEOREM 6.2. *Assume that the finite element partition $\mathcal{T}_h$ is piecewise quasi-uniform. This means that $\mathcal{T}_h$ is an unstructured mesh, but each of its subpartitions $\mathcal{T}_{h_i}$ is a quasi-uniform mesh. Let β_{ij} and λ_{ij} satisfy* (6.6). *Then there is a positive constant δ independent of h_i $(i = 1, 2, \dots, m)$ such that*

$$|||g^{n+1}|||_* \le (1-\delta)\, |||g^n|||_*, \tag{6.9}$$

$$\|u^n - u\|_h \le C(\alpha)\,(1-\delta)^n\, |||g^0|||_*, \tag{6.10}$$

$$\rho(A) \le (1-\delta)\,, \tag{6.11}$$

where all of the undefined notations are the same as those in Corollary 5.5.

Finally, we consider a very special case, in which every individual element of $\mathcal{T}_h$ is chosen as a subdomain. For this special case, in the last section we mentioned that Algorithm II indeed produces a classic iterative method with optimal convergence if $\mathcal{T}_h$ is quasi-uniform. We now show that this conclusion is still true even for the unstructured finite element mesh $\mathcal{T}_h$, which is not quasi-uniform but regular. It is not very difficult to see that (5.25)–(5.27) hold with the same constant C for all of the subdomain Ω_i that is an individual element of $\mathcal{T}_h$ if $\mathcal{T}_h$ is regular. Also, notice that, in this special case, the element face f_{ij} of (6.6) is just the interface γ_{ij}. Thus, (6.7) can be rewritten as

$$\begin{cases} \lambda_{ij} = \lambda_{ji} = O((m(\gamma_{ij}))^{-1}), & 1 \le i \ne j \le m, \\ \beta_{ij} = \beta_{ji} = O((m(\gamma_{ij}))^{-2}), & 1 \le i \ne j \le m, \end{cases} \tag{6.12}$$

where $m(\gamma_{ij})$ is defined as $m(f_{ij})$ in (6.6). Therefore, (6.8) still holds if λ_{ij} and β_{ij} satisfy (6.12). Thus, we have the following theorem.

THEOREM 6.3. *Let $\mathcal{T}_h$ be not a quasi-uniform but a regular finite element triangulation. Assume that every individual element of $\mathcal{T}_h$ is chosen as a subdomain. If β_{ij} and λ_{ij} satisfy* (6.12), *then Algorithm* II *produces a classic iterative method with the optimal convergence rate for the linear system* (1.5). *That is, there is a positive constant δ independent of the mesh size of $\mathcal{T}_h$ such that*

$$\rho(A) \le (1-\delta)\,, \tag{6.13}$$

where, as in Corollary 5.5, *A is the iterative matrix and $\rho(A)$ is the spectral radius of A.*

7. Conclusion. In this paper, a parallel nonoverlapping domain decomposition iterative procedure based on a Robin-type consistency condition on the artificial interfaces is developed and analyzed. The key difference between the method of this paper and other similar methods is that an extra parameter β_{ij}, called penalty coefficient, is introduced. For partial differential problems, it can be regarded as a variant of the famous Lions method of [18] as well as the method of [7, 8]. However, unlike the Lions method, it does not have the regularity trouble of subproblems. For finite element problems, the weak formulation of this method can be formally derived from the weak formulation of the method in [7, 8] by introducing a penalty coefficient β_{ij} into the terms of artificial interfaces. Hence, as explained in the introduction, this method, like the method of [7, 8], can be regarded as a bridge connecting direct methods and iterative methods of linear systems in the sense of parallel algorithms. More importantly, because of introducing the penalty coefficient β_{ij}, this method could reach the optimal convergence rate even for unstructured meshes while choosing the right parameters, but the method of [7, 8] could not. Furthermore, the idea of this paper can be extended and applied to other problems and other discrete methods (for instance, mixed finite element methods, nonsymmetric and noncoercive scalar wave problems, etc.). We will consider some of these topics as well as the numerical experiments and analyses including comparisons to the other similar methods in future work. Finally, we conclude this paper with the following table of the results of two simple examples with $\Omega = [0, 1]^2$ and exact solution $u = \sin(\pi\, x)\, \sin(\pi\, y)$. The numerical experiments are implemented on a group of Sun Workstations (440 MHz CPU) by using MPI to implement the communications. In the numerical experiments, $\mathcal{T}_h$ is a three-fixed direction uniform triangulation with mesh size (leg's length) h; the domain decomposition is a uniform decomposition, in which all subdomains are congruent small squares; each subdomain (subproblem) is assigned to its own processor (machine), and no processor (machine) takes care of more than one subdomain (subproblem); the stop criterion is 10^{-5}; $\lambda_{ij} = h^{-1}$ and $\beta_{ij} = h^{-2}$.

A LOCAL CONVERGENCE PROOF FOR THE MINVAR ALGORITHM FOR COMPUTING CONTINUOUS PIECEWISE LINEAR APPROXIMATIONS*

RICHARD E. GROFF†, PRAMOD P. KHARGONEKAR†‡, AND DANIEL E. KODITSCHEK†

Abstract. The class of continuous piecewise linear (PL) functions represents a useful family of approximants because invertibility can be readily imposed, and if a PL function is invertible, then it can be inverted in closed form. Many applications, arising, for example, in control systems and robotics, involve the simultaneous construction of a forward and inverse system model from data. Most approximation techniques require that separate forward and inverse models be trained, whereas an invertible continuous PL affords, simultaneously, the forward and inverse system model in a single representation. The `minvar` algorithm computes a continuous PL approximation to data. Local convergence of `minvar` is proven for the case when the data generating function is itself a PL function and available directly rather than through data.

Key words. piecewise linear, invertible approximation, moving mesh, triangulation

1. Introduction.

In this paper, we present `minvar`, a novel algorithm for computing continuous multidimensional piecewise linear (PL) approximations to data. The algorithm takes advantage of the structure of PL functions to provide a computationally effective approximation technique. This paper provides a local convergence proof for the special case when the data generating function is itself PL and is available directly rather than through discrete data.

Our interest in the PL family is driven by applications that require approximation of both forward and inverse functions from data. In xerography, for example, the print engine's color space transformation is required to stabilize color reproduction, while its inverse is required to generate printer specific color mixture commands in response to inputs expressed in device independent color coordinates [21, 23]. The field of robotics is rife with examples where changes of coordinates play a key role: in mobile robot navigation [27, 32, 33]; in the representation of gaits [31, 34]; in sensor based manipulation [8]; as well as in calibration [42]. Since a change of coordinates is a continuous and continuously invertible function, building a custom change of coordinates amounts to a search for the appropriate forward and inverse function. Representations of scalar invertible functions are required for certain machine tool calibration problems [24], for certain automobile fuel control settings [17], as well as for probability density estimation [15]. In all such settings, most approximation techniques require the construction of distinct forward and inverse representations, because the approximations are not invertible in closed form. In addition to doubling the effective training effort, accuracy suffers since the approximation of the inverse is not exactly the inverse of the forward approximation. In contrast, invertibility of PL

functions can be verified and even imposed geometrically, that is, by well characterized and computationally effective techniques arising from geometric insights. Moreover, if a PL function is invertible, it can be inverted in closed form. Thus a single PL approximation is ideal for applications requiring the approximation of a function and its inverse.

A substantial amount of mathematical literature on real function approximation (see, for example, [6, 9, 29]), largely concerned with linear-in-parameters techniques, deals extensively with algorithms, fundamental limits, convergence rates, and families of bases in approximating functions. Recent activity has been spurred by evidence that nonlinear-in-parameters function families offer improved approximation rates in higher dimensions as compared to linear-in-parameters representations [3]. Recently, approximation methods that employ collections of local approximations have received increasing attention [1, 16, 38]. However, very little of this linear- or nonlinear-in-parameters literature addresses the problem of function approximation under the constraint of invertibility.

PL functions have been addressed in a number of different settings. Algebraic topologists used PL homeomorphisms to classify topological spaces [36] but did not address computational considerations. The study of splines, piecewise polynomials with continuity and smoothness constraints, includes PL functions [7, 10, 35]. Splines are typically extended to multiple dimensions by means of tensor products. The domain partition is then a tensor product of partitions of the individual dimensions and the approximant is the sum of tensor products of scalar spline functions. A multidimensional linear spline is then multilinear, that is, linear in each variable separately, rather than truly linear. General splines enjoy no invertibility properties. Moreover, most of the spline literature assumes the domain partition to be fixed, in which case approximation of the best L_2 spline is a linear-in-parameters problem. Allowing the partition to change introduces a nonlinear-in-parameters problem. The multivariate adaptive regression spline (MARS) literature admits a limited nonlinear parameterization by allowing the basis to adapt but does not allow general motion of the domain partition [16, 38]. The piecewise polynomial literature addresses the problem of finding (possibly discontinuous) piecewise polynomial approximations to an explicitly known scalar function. In this setting, the domain partition is considered as part of the approximation's parameterization. For scalar functions, there are results for the existence of a best approximation by possibly discontinuous piecewise polynomials under certain generalized convexity conditions [4, 18]. Algorithms similar in flavor to the scalar specialization of `minvar` were introduced in [2, 25, 26]. A treatment of discontinuous piecewise polynomial approximations on two-dimensional triangulations is provided in [39]. Also, [40] provides an algorithm for a moving mesh finite element solution to variational problems. A specialization of this moving mesh algorithm is finding the best L^p, p finite and even, continuous piecewise polynomial approximation to a function. Both of these algorithms [39, 40], as well as the piecewise polynomial literature in general [2, 25, 26], assume that the function to be approximated is available directly, and the algorithms entail steps, such as root finding, that incorporate the function intrinsically. In contrast, the `minvar` algorithm is defined for arbitrary (finite) dimension and can either use a finite set of data or directly use the function to be approximated.

Motivated by applications that require the approximation of invertible functions, we have developed the `minvar` algorithm for computing PL approximations to a set of discrete data. In the context of these applications, PL approximations offer the substantial benefit of closed form invertibility. When the domain partition is fixed, computing the best PL approximation is a linear-in-parameters problem that can be solved using classical techniques. Treating the partition as a component of the approximation's parameterization gives a much more powerful approximant, at the cost of entering the nonlinear-in-parameters problem domain. In nonlinear-in-parameters problems, one can generally expect only local, as opposed to global, convergence properties. Moving the domain partition of a PL function, or triangulation, as formally defined in the next section, has an added difficulty. A triangulation has both continuous and combinatorial parameters that interact in complex ways. Not all combinations of continuous and combinatorial parameters yield a proper triangulation. Triangulations in two and three dimensions have been studied extensively in the computational geometry literature [13, 30], but results for general dimension are more scarce, notwithstanding significant recent progress [5, 14, 28]. The price of using a family of finitely parameterized homeomorphisms, the PL approximations, is the cost of managing the combinatorial complexities of PL functions.

This paper is divided into five main sections. Section 2 provides a careful definition of the concept of a triangulation, relating it to the parameterization of PL functions. Section 3 introduces and defines the `minvar` algorithm. Section 4 provides a local convergence proof for the `minvar` algorithm when the data generating function is piecewise linear. Section 5 presents a numerical example.

2. Triangulations and PL functions.

The ability to check invertibility of a PL function, and to invert it in closed form, derives from the interplay between the PL function's combinatorial and continuous parameters. This interplay provides much power but also creates potential pitfalls. For example, changing the continuous parameters inappropriately with respect to the combinatorial structure can cause "tangles" in the domain partition. Triangulations in general dimension, the key concept in understanding PL functions, are still an area of active research in computational geometry. While the `minvar` algorithm can be stated using only an intuitive notion of triangulation, further analytical insight, such as the local convergence proof provided in section 4, is limited without a much more careful definition. This section provides definitions of triangulations and PL functions to facilitate the exposition. For further background, see [41] for an introduction to concepts in convexity and [13] for an introduction to the geometric concept of triangulations.

2.1. Simplices.

An *affine subspace* $V \subseteq \mathbb{R}^d$ is a linear subspace $L \subseteq \mathbb{R}^d$ translated by some $x_o \in \mathbb{R}^d$, i.e., $V = L + x_o$. The dimension of V is $\dim(V) := \dim(L)$. The *affine hull* of a set $\mathcal{U} \subseteq \mathbb{R}^d$, $\mathrm{aff}(\mathcal{U})$, is the smallest affine subspace containing $\mathcal{U}$. A finite set of points $\mathcal{U} \subseteq \mathbb{R}^d$ is *affinely independent* if for $i = 1, \dots, d$, no affine subspace of dimension i contains more than $i+1$ points from $\mathcal{U}$. The *convex hull* of a set $\mathcal{U} \subseteq \mathbb{R}^d$, $\mathrm{conv}(\mathcal{U})$, is the smallest convex set containing $\mathcal{U}$. A *simplex*, s, is the convex hull of a (finite) set $\mathcal{V} \subseteq \mathbb{R}^d$ of affinely independent points, $s = \mathrm{conv}(\mathcal{V})$. The set of the extreme points, or *vertices*, of s, $\mathcal{V} = \mathrm{vert}(s)$, uniquely defines s.[1] The dimension of s is $l = \dim(s) = \dim(\mathrm{aff}(s)) = \mathrm{card}\,(\mathcal{V}) - 1$, where $\mathrm{card}\,(\mathcal{V})$ is the cardinality of $\mathcal{V}$, and s is called an l-simplex. There can be at most $d+1$ affinely independent points in $\mathbb{R}^d$, and thus there are simplices of dimension $-1, 0, 1, \dots, d$, where by convention $\emptyset$ is

[1] vert is a pseudoinverse of conv, not a true inverse, since if $\mathcal{U} \subseteq s$, then $s = \mathrm{conv}(\mathcal{U} \cup \mathrm{vert}(s))$. The concept of vertices of a simplex is a special case of the more general notion of extreme points of a convex body. The Krein–Milman theorem [41] states that any convex compact set in $\mathbb{R}^d$ is the convex hull of its extreme points.

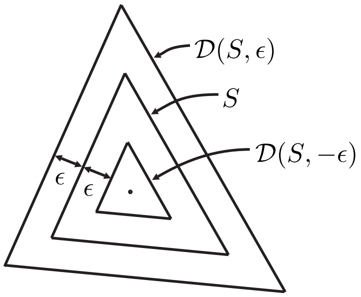

FIG. 2.1. *The* 2*-simplex* S *with its* ϵ *and* $-\epsilon$ *dilations. The point at the center is where dilation degenerates to a single point.*

considered a simplex with $\dim(\emptyset) := -1$. We may apply a partial order to simplices. Given two simplices s_1, s_2, we say that $s_1 \leq s_2$ if and only if $\operatorname{vert}(s_1) \subseteq \operatorname{vert}(s_2)$, in which case we call s_1 a face of s_2. If $\dim(s_2) = d$ and $\dim(s_1) = d-1$, then we also call s_1 a *facet* of s_2. In this paper we will predominantly be interested in d-simplices, so we adopt the convention that a capital S indicates a d-simplex, while a lowercase s denotes a simplex of any dimension.

Let S be a d-simplex with $\operatorname{vert}(S) = \{p_1, \ldots, p_{d+1}\}$. The ϵ dilation of S, written $\mathcal{D}(S,\epsilon)$, is defined as

$$\mathcal{D}(S,\epsilon) := \left\{ x = \sum_{j=1}^{d+1} \alpha_j p_j \,\middle|\, \sum_{j=1}^{d+1} \alpha_j = 1 \ \forall j, \alpha_j \geq \frac{-\epsilon}{\delta(p_j, \operatorname{aff}(\operatorname{vert}(S) - \{p_j\}))} \right\}, \tag{2.1}$$

where $\delta(p,\mathcal{U})$ is the distance from point p to the nonempty set $\mathcal{U}$. Figure 2.1 illustrates the dilation of a 2-simplex. $\mathcal{D}(S,\epsilon)$ is well defined for

$$\epsilon \geq -\left(\sum_{j=1}^{d+1} 1/\delta(p_j, \operatorname{aff}(\operatorname{vert}(S) - \{p_j\})) \right)^{-1}.$$

When equality holds, $\mathcal{D}(S,\epsilon)$ is a single point; otherwise it is a d-simplex with facets parallel to S_i, but distance $|\epsilon|$ away, with $S \subseteq \mathcal{D}(S,\epsilon)$ for $\epsilon > 0$, and $\mathcal{D}(S,\epsilon) \subseteq S$ for $\epsilon < 0$. (See Claim 3 in Appendix A for the dilation's properties.)

2.2. Triangulation. An *abstract simplicial complex* is a collection of finite sets $\mathcal{S}$ satisfying the following: if $\alpha \in \mathcal{S}$ and $\beta \subseteq \alpha$, then $\beta \in \mathcal{S}$. The *vertex set* of an abstract simplicial complex is the set $\{x \mid x \in \alpha, \alpha \in \mathcal{S}\}$.

A *geometric simplicial complex* is a collection $\mathcal{K}$ of simplices in $\mathbb{R}^d$ satisfying

1. $s_1 \in \mathcal{K}$ and $s_2 \leq s_1 \implies s_2 \in \mathcal{K}$,
2. $s_1, s_2 \in \mathcal{K} \implies s_1 \cap s_2 \leq s_1, s_2$.

The *vertex set* of a geometric simplicial complex is $\operatorname{vert}(\mathcal{K}) := \bigcup_{s \in \mathcal{K}} \operatorname{vert}(s)$. The *underlying space* of a geometric simplicial complex is $|\mathcal{K}| := \bigcup_{s \in \mathcal{K}} s$.

A *subcomplex* is a subset of a simplicial complex that is itself a simplicial complex. The *closure* of a subset $\mathcal{L} \subseteq \mathcal{K}$ is the smallest subcomplex that contains $\mathcal{L}$,

$$\operatorname{Cl} \mathcal{L} := \{\alpha \in \mathcal{K} \mid \alpha \leq \beta, \beta \in \mathcal{L}\}.$$

The *star* of a simplex s is the set of all simplices that contain s,

$$\operatorname{St} s := \{s' \in \mathcal{K} \mid s \leq s'\}.$$

The star is not in general a subcomplex.

We can parameterize[2] a geometric simplicial complex $\mathcal{K}$ in $\mathbb{R}^d$ by the pair $(P, \mathcal{S})$, where P is an indexed set of n unique points in $\mathbb{R}^d$,

$$P = \left\{ p_1, \quad p_2, \quad \dots, \quad p_n \right\},$$

and $\mathcal{S}$ is an abstract simplicial complex with vertex set $\{1, 2, \dots, n\}$. Let[3]

$$\mathcal{K}(P, \mathcal{S}) = \left\{ \operatorname{conv}(P(\alpha)) \middle| \alpha \in \mathcal{S} \right\}.$$

$\mathcal{K}(P, \mathcal{S})$ is a geometric simplicial complex if

1. for all $\alpha \in \mathcal{S}$, the points in $P(\alpha)$ are affinely independent,
2. $s_1, s_2 \in \mathcal{K}(P, \mathcal{S}) \implies s_1 \cap s_2 \leq s_1, s_2$,

and, moreover, if these properties hold, then $\operatorname{vert}(\mathcal{K}(P, \mathcal{S})) = P$. Proofs of these properties are provided in [20].

A *triangulation*[4] $\mathcal{T}$ is a geometric simplicial complex in $\mathbb{R}^d$ for which the underlying space is a k-manifold with boundary. Since a triangulation is a type of geometric simplicial complex, it can be parameterized in the same manner. We write $\mathcal{T}(P, \mathcal{S}) := \mathcal{K}(P, \mathcal{S})$ to indicate that the resulting geometric simplicial complex generated by the pair $(P, \mathcal{S})$ is a triangulation.

In this paper, we will deal only with triangulations which are d-manifolds with boundary that have a simply connected underlying space.

For notational convenience, we assume that the triangulation $\mathcal{T} = \mathcal{K}(P, \mathcal{S})$ has N d-simplices that have been indexed and named S_i, $i = 1, \dots, N$. Let $S_i, S_j \in \mathcal{T}$. We then define

$$d_{i,j} := \dim(S_i \cap S_j) = \operatorname{card}\left(\operatorname{vert}(S_i \cap S_j)\right) - 1,$$

the dimension of the face shared by S_i and S_j. Let N_i be the number of d-simplices in $\operatorname{St}\{p_i\}$,

$$N_i = \sum_{S_j \in \operatorname{St} p_i} 1.$$

2.3. PL functions.

A continuous PL function $f_{\mathcal{P}} : D \subseteq \mathbb{R}^d \to \mathbb{R}^d$ is parameterized by a triplet $\mathcal{P} = (P, Q, \mathcal{S})$. P is an indexed set of n points in the domain and Q is an indexed set of n points in the codomain,

$$P = \left\{ p_1, \quad p_2, \quad \dots, \quad p_n \right\}, \qquad Q = \left\{ q_1, \quad q_2, \quad \dots, \quad q_n \right\}.$$

[2] This is not formally a parameterization, because there are some pairs $(P, \mathcal{S})$ for which $\mathcal{K}(P, \mathcal{S})$ is not a geometric simplicial complex. However, for any geometric simplicial complex $\mathcal{K}$, we can write down a pair $(P, \mathcal{S})$ such that $\mathcal{K} = \mathcal{K}(P, \mathcal{S})$.

[3] Formally, an indexed set P of n points in $\mathbb{R}^d$ is a map $P : \{1, 2, \dots, n\} \to \mathbb{R}^d$. The ith member of P is $P(i)$, which we generally write as p_i for notational convenience. Here we extend the notion of P sets. Let $\alpha \subseteq \{1, 2, \dots, n\}$; then $P(\alpha) := \left\{ P(i) \middle| i \in \alpha \right\}$.

[4] There is no formal definition of triangulation in geometry [13]. The definition of triangulation used here is slightly more general than the one used in [14], which requires that the underlying space be the convex hull of the vertex set. A triangulation as defined here which has a simply connected underlying space may be transformed to a triangulation as defined in [14] by a PL homeomorphism. The key concept in our definition is that a triangulation has good local volume properties everywhere. The underlying space has no "thin" spots. In topology, a triangulation of a topological space $\mathcal{X}$ is formally defined as a geometric simplicial complex $\mathcal{K}$ coupled with a homeomorphism between $|\mathcal{K}|$ and $\mathcal{X}$. The definition of triangulation used in this paper is more narrow than the topological notion.

$\mathcal{S}$ is an abstract simplicial complex of indices with $\operatorname{vert}(\mathcal{S}) = \{1, \ldots, n\}$ such that $\mathcal{T}(P, \mathcal{S})$ is a triangulation and $|\mathcal{T}(P, \mathcal{S})| = D$. This defines a continuous PL function $f_{\mathcal{P}}$ such that $f_{\mathcal{P}}(p_i) = q_i$, and for any $S \in \mathcal{T}(P, \mathcal{S})$, $f_{\mathcal{P}}(x)$ is affine on S. For a d-simplex $S_i \in \mathcal{T}(P, \mathcal{S})$ with $\operatorname{vert}(S_i) = \{p_{i_1}, p_{i_2}, \ldots, p_{i_{d+1}}\}$, the PL function $f_{\mathcal{P}}(x)$ for $x \in S_i$ is given by

$$f_{\mathcal{P}}\big|_{S_i}(x) = \begin{bmatrix} q_{i_1} & q_{i_2} & \cdots & q_{i_{d+1}} \end{bmatrix} \begin{bmatrix} p_{i_1} & p_{i_2} & \cdots & p_{i_{d+1}} \\ 1 & 1 & & 1 \end{bmatrix}^{-1} \begin{bmatrix} x \\ 1 \end{bmatrix}. \tag{2.2}$$

Equation (2.2) uses a homogeneous representation for the rightmost two factors, though $f_{\mathcal{P}}|_{S_i}$ can be equivalently expressed in the more typical form as $A_i x + b_i$. The d-simplices of $\mathcal{T}(P, \mathcal{S})$ are a cover for D. If $S_i \cap S_j \neq \emptyset$, and $f_{\mathcal{P}}\big|_{S_i}(x) = A_i x + b_i$ and $f_{\mathcal{P}}\big|_{S_j}(x) = A_j x + b_j$, then $A_i x + b_i = A_j x + b_j$ for $x \in S_i \cap S_j$. This follows from Claim 5 in Appendix A, which states that $(A_i - A_j)$ has a null space of dimension $d_{i,j}$ parallel to $\operatorname{aff}(S_i \cap S_j)$.

One of the most compelling properties of PL functions is the ability to check invertibility and invert in closed form. Let $f_{\mathcal{P}}$ be a PL function parameterized by $\mathcal{P} = (P, Q, \mathcal{S})$. If $\mathcal{T}(Q, \mathcal{S})$ is a triangulation, then the PL function is invertible, and the inverse $f_{\mathcal{P}}{}^{-1}$ is a PL function parameterized by $\mathcal{P}^{-1} = (Q, P, \mathcal{S})$. This is proven in Claim 7 in Appendix A.

Another important fact applied in proving the main result of section 4 is the continuity of a PL function in its continuous parameters. This claim, stated formally in Claim 6 in Appendix A, establishes that two PL functions with the same combinatorial structure are close in the L_∞ sense if their vertices are close in the Euclidean sense.

We call a PL function $f_{\mathcal{P}}$ parameterized by $\mathcal{P} = (P, Q, \mathcal{S})$ *nondegenerate* if for all $p_i \in P$ such that $p_i \notin \partial\, |\mathcal{T}(P, \mathcal{S})|$ the matrix H_i is full rank, where

$$H_i = \left(\frac{1}{N_i} \sum_{S_j \in \operatorname{St}\{p_i\}} A_j{}^{\mathrm{T}} A_j \right) - \overline{A^i}^{\mathrm{T}} \overline{A^i}, \qquad \text{where } \overline{A^i} = \frac{1}{N_i} \sum_{S_j \in \operatorname{St}\{p_i\}} A_j.$$

Intuitively, nondegeneracy of $f_{\mathcal{P}}$ requires that for any $p_i \notin \partial\, |\mathcal{T}(P, \mathcal{S})|$ not all of the affine functions that $f_{\mathcal{P}}$ takes in the surrounding d-simplices are parallel.

3. The minvar algorithm.

The `minvar` algorithm is an iterative scheme to generate a locally good PL approximation to data. Similar to algorithms proposed in the possibly discontinuous piecewise polynomial approximation literature [2, 25, 26, 39], `minvar` takes advantage of the structure of PL functions. Let $\mathcal{Z} = \{(x_i, y_i)\}_{i=1}^{N_s}$, where $x_i \in D \subseteq \mathbb{R}^d$ and $y_i \in \mathbb{R}^d$, be the set of input-output data to be approximated. The `minvar` algorithm iteratively improves a PL approximation to the data, $f_{\mathcal{P}}^{(k)}$, parameterized by $\mathcal{P}^{(k)} = (P^{(k)}, Q^{(k)}, \mathcal{S})$, such that $\left|\mathcal{T}(P^{(k)}, \mathcal{S})\right| = D$. (The superscript in parentheses indicates the iteration number.) The algorithm breaks down into two stages. The first stage partitions the data according to the d-simplices of $\mathcal{T}(P^{(k)}, \mathcal{S})$ and computes the least squares linear approximations for each subset of the data. This set of linear approximations is the optimal possibly discontinuous PL approximation on the partition $\mathcal{T}(P^{(k)}, \mathcal{S})$. The second stage chooses $(P^{(k+1)}, Q^{(k+1)})$ to make $f_{\mathcal{P}}^{(k+1)}$, a continuous PL function, be "close" to the discontinuous approximation from the first stage. The stages are then iterated.

Recall from the previous section that the domain of a PL function is $|\mathcal{T}(P, \mathcal{S})|$, so moving a vertex $p_i \in \partial\, |\mathcal{T}(P, \mathcal{S})|$ will change the domain of definition of the PL function. Since we desire a fixed domain for the PL function, the present exposition considers vertices on the domain boundary to be fixed. This can be relaxed to allow boundary vertices that are not extreme points to move in appropriately chosen affine subspaces using a constrained version of the cost function from step 3 of the `minvar` algorithm. Computational details of constrained motion will be presented in a subsequent paper on engineering applications of `minvar`.

From an initial parameterization $\mathcal{P}^{(0)} = (P^{(0)}, Q^{(0)}, \mathcal{S})$, the `minvar` algorithm generates a sequence of parameterizations, $\mathcal{P}^{(k)} = (P^{(k)}, Q^{(k)}, \mathcal{S})$, as follows:

1. Partition the data set $\mathcal{Z}$ into subsets $\mathcal{Z}_j$ corresponding to the d-simplices, $S_1, \ldots, S_N$ of $\mathcal{T}(P^{(k)}, \mathcal{S})$, breaking multiple memberships (data points that lie on the boundary between d-simplices) systematically.
2. Compute the least squares affine approximation, $L_j(x)$, for each subset $\mathcal{Z}_j$.
3. Update the vertex locations,

$$(3.1)\quad p_i^{(k+1)} = \arg\min_{x\in\mathbb{R}^d} \operatorname{var} L^i(x) + \lambda \left\| x - p_i^{(k)} \right\|^2 \qquad \forall\, p_i^{(k)} \notin \partial \left| \mathcal{T}(P^{(k)}, \mathcal{S}) \right|,$$

$$(3.2)\quad p_i^{(k+1)} = p_i^{(k)} \qquad \text{otherwise,}$$

$$(3.3)\quad q_i^{(k+1)} = \frac{1}{N_i} \sum_{S_j \in \mathrm{St}\{p_i\}} L^i\left(p_i^{(k+1)}\right) \qquad \forall\, i,$$

where $L_j(x) = A_j x + b_j$ and

$$\operatorname{var} L^i(x) = \sum_{S_j \in \mathrm{St}\{p_i\}} \left(L_j(x) - \frac{1}{N_i} \sum_{S_k \in \mathrm{St}\{p_i\}} L_k(x) \right)^2 .$$

4. If the vertices are not converged, then $k \leftarrow k+1$, go to 1.

Notice that (3.1) is a positive definite quadratic function of x, and thus can be minimized in closed form by "completing the square," with the solution given by

$$p_i^{(k+1)} = -{H_i}^{-1} h_i, \tag{3.4}$$

where

$$H_i = \left[\frac{1}{N_i} \sum_{S_j \in \mathrm{St}\{p_i\}} {A_j}^{\mathrm{T}} A_j \right] - \overline{A^i}^{\mathrm{T}} \overline{A^i} + \lambda I,$$

$$h_i = \left[\frac{1}{N_i} \sum_{S_j \in \mathrm{St}\{p_i\}} {A_j}^{\mathrm{T}} b_j \right] - \overline{A^i}^{\mathrm{T}} \overline{b^i} - \lambda p_i^{(k)},$$

$$\overline{A^i} = \frac{1}{N_i} \sum_{S_j \in \mathrm{St}\{p_i\}} A_j \qquad \overline{b^i} = \frac{1}{N_i} \sum_{S_j \in \mathrm{St}\{p_i\}} b_j .$$

The nonnegative quantity $\operatorname{var} L^i(x)$ measures, as a function of location in the domain x, how tightly clustered the range values generated from the least squares approximations on d-simplices in $\mathrm{St}\{p_i\}$ are. In the case of a scalar domain, an interior vertex p_i is in at most two 1-simplices. Thus, if the least squares approximations are not parallel, then $\operatorname{var} L^i(x_c) = 0$ at and only at x_c, the domain value of the point at which the least squares approximations intersect. In the scalar case, the `minvar` algorithm with $\lambda = 0$ moves the domain and codomain vertices to the intersection point of the least squares approximations. We called our initial scalar algorithm the "Graph Intersection" algorithm [22] due to this fact. For dimensions higher than 1, there is generically no unique intersection point for the least squares approximations surrounding p_i, due to the geometry of triangulations. Rather than the intersection point, `minvar` with $\lambda = 0$ picks the point where the range values are most tightly clustered.

The λ term in (3.1) is a regularization. It guarantees that (3.1) will have a unique minimum, even if all the least squared approximations are parallel. More importantly, in the implementation of `minvar` the λ parameter can be tuned to prevent a vertex from jumping long distances and creating a "tangle" in the domain triangulation of the approximation. A tangle is when movement of the vertices causes $\mathcal{T}(P, \mathcal{S})$ to no longer be a geometric simplicial complex. That is, either a simplex has been "flattened" or there are simplices whose intersection is not another simplex from the complex. This generally occurs when a domain vertex moves through one of its opposing faces. Methods for detecting and correcting triangulation tangles will be covered in a subsequent paper on using `minvar` in engineering applications.

In this exposition, `minvar` does not modify the combinatorial structure, $\mathcal{S}$, of the PL approximation. Heuristics for adapting the domain triangulation of a two-dimensional PL function are presented in [12, 11] for interpolation and [39] for approximation. These heuristics flip edges in the domain triangulation to improve a local goodness criterion, similar to a method for computing the planar Delaunay triangulation. Generalizing these heuristics to higher dimensions is difficult because local topological changes of the triangulation in dimensions greater than two are more complex than edge flipping [28, 14]. Nonetheless, we find that adaptation of the combinatorial parameters of the PL function via topological flipping provides significant benefit in practice. Techniques for adapting the combinatorial structure will be presented in a subsequent paper on engineering applications of `minvar`.

4. A local convergence proof for the `minvar` algorithm.

We turn now to the central result: a local convergence proof for the `minvar` algorithm. The result is for the "approximation," as opposed to "estimation," version of the `minvar` algorithm. That is, the data generating function is considered to be directly available in closed form, rather than through a set of discrete data. In this case, the least squares approximations from step 2 become L_2 orthogonal projections of $f^*_{\mathcal{P}}|_{S_i}$, the data generating function restricted to S_i, to the space of affine functions. Since the data or data generating function only appear in step 2, the approximation version may be viewed as the limit behavior of the estimation version when provided with an unbounded quantity of uniformly distributed data.

Theorem 4.1 shows that, if the data generating function is a nondegenerate PL function and the approximation is initialized "close enough" to the data generating function, then the `minvar` algorithm with $\lambda = 0$ will cause the approximation to converge to the data generating function in the L_∞ sense. In this case, "close enough" means that the initial approximation shares the same combinatorial structure as the data generating function, and the vertices of the approximation start close to the corresponding vertices of the data generating function. Examining `minvar` when $\lambda = 0$ admits a simpler proof while capturing the essence of the algorithm. Similar results could be obtained for $\lambda > 0$, though the convergence rate would be slower. An additional technical condition, that the data generating function be nondegenerate, is required when $\lambda = 0$ in order to guarantee existence of a unique solution to (3.1), whereas for $\lambda > 0$ the regularized variance minimization in (3.1) is guaranteed to have a unique solution.

In this paper, unless otherwise noted, vector norms are the standard Euclidean norm and matrix norms are the induced two norm.

THEOREM 4.1. *Let $f^*_{\mathcal{P}}$ be a nondegenerate PL data generating function parameterized by $\mathcal{P}^* = (P^*, Q^*, \mathcal{S}^*)$. Let $\epsilon_0 = \epsilon_0(\mathcal{P}^*)$ be given by* (4.7)*. Let the initial approximation $f^{(0)}_{\mathcal{P}}$ be parameterized by $(P^{(0)}, Q^{(0)}, \mathcal{S}^*)$, satisfying for some $\epsilon < \epsilon_0$, $\|p^{(0)}_i - p^*_i\| < \epsilon$, for all i. Then application of the* `minvar` *algorithm with $\lambda = 0$ yields a sequence of approximations satisfying*

$$\lim_{j\to\infty} \left\| f^{(j)}_{\mathcal{P}} - f^*_{\mathcal{P}} \right\|_\infty = 0.$$

Proof. Proposition 4.5 shows that iteration of the `minvar` algorithm causes the vertices of the approximation to converge to the vertices of the data generating function. By Claim 6 in Appendix A, a PL function is continuous in its vertices. The theorem follows directly. □

The theorem follows readily from Proposition 4.5, which likewise follows readily from Proposition 4.4. The statements and proofs of the propositions and lemmas follow in the next subsections, but first we offer a short sketch of the structure of the proof. The essence of Proposition 4.4 is that when the distances between the vertices of the approximation and the corresponding vertices of the data generating function are bounded by ϵ, then after one iteration of the `minvar` algorithm the distances will be bounded by a constant times ϵ^2. This result is established by applying two lemmas corresponding to the two stages of the algorithm. Lemma 4.2 proves that if the distances between corresponding vertices are bounded by ϵ, then the perturbation of the least squares affine map over a given simplex of the approximation from the affine map in the corresponding simplex of the data generating function is bounded by a constant times ϵ^2. Lemma 4.3 proves that if the perturbation of the least squares affine map over a simplex of the approximation from the affine map in the corresponding simplex of the data generating function is bounded by Δ, then the variance minimization will place the new vertices of the approximation such that the distance between them and the corresponding vertices of the data generating function are bounded by a constant times Δ. The combination of Lemmas 4.2 and 4.3 provides Proposition 4.4.

The quadratic rate of convergence in Proposition 4.4 arises from the hypothesis that the data generating function is piecewise linear and close to the initial approximation. Without this assumption, Lemma 4.2 would fail to provide an ϵ^2 perturbation in the least squares affine approximations. In this case, we suspect the convergence rate of the algorithm to be linear. Convergence may be slower on fine triangulations, but since this algorithm is intended primarily for use with a discrete set of data, the fineness of the triangulation is inherently limited by the amount of data provided. In applications, `minvar` can run triangulations of practical size in a few minutes.

4.1. Lemmas and propositions. This section states the lemmas and propositions, while the proofs are provided in the following section. First, we introduce several reoccurring constants. These constants may be interpreted geometrically as minima or maxima of different measures of the "radii" of d-simplices in the triangulation $\mathcal{T}(P^*, \mathcal{S}^*)$ of the data generating function. The first measures the maximum inter-vertex distance between "connected" vertices,

$$r_1 := \max_{\substack{S^* \in \mathcal{T}(P^*, \mathcal{S}^*) \\ p_i^*, p_j^* \in S^*}} \left\| p_i^* - p_j^* \right\| . \tag{4.1}$$

The second measures the minimum distance of a vertex to its opposing hyperplanes,

$$r_2 := \min_{\substack{S^* \in \mathcal{T}(P^*, \mathcal{S}^*) \\ p^* \in \mathrm{vert}(S^*)}} \delta(p^*, \mathrm{aff}(\mathrm{vert}(S^*) - \{p^*\})) . \tag{4.2}$$

The third measures the d-simplex which can be dilated the least before it intersects simplices outside its immediate neighborhood.

$$r_3 := \min_{S^* \in \mathcal{T}(P^*, \mathcal{S}^*)} \sup \left\{ \epsilon \middle| \mathcal{D}(S^*, \epsilon) \subseteq |\mathrm{Cl}\,\mathrm{St} S^*| \right\} . \tag{4.3}$$

The first lemma shows that if the domain vertices of the approximation are close to the domain vertices of the data generating function, then least squares affine fit in a simplex S_i is a perturbation away from the affine function that the data generating function takes in S_i^*. Moreover, the perturbation is quadratic in the bound on the distance between the approximation and data generating function's domain vertices. We write $\Pi(f)$ to denote the L_2 orthogonal projection of the function f onto the space of affine functions.

LEMMA 4.2. *Let $f_{\mathcal{P}}^*$ be a PL data generating function parameterized by $\mathcal{P}^* = (P^*, Q^*, \mathcal{S}^*)$. Consider a PL approximation $f_{\mathcal{P}}$ parameterized by $\mathcal{P} = (P, Q, \mathcal{S}^*)$. Let $\epsilon < \epsilon_c$, where*

$$\epsilon_c := \min \left\{ \tfrac{1}{2(d+1)} r_2, \quad r_3, \quad 1 \right\} . \tag{4.4}$$

Consider the simplices S_i^* and S_i. Let $x_c \in S_i^*$. Let $f_{\mathcal{P}}^*|_{S_i^*}(x) = A_i^*(x - x_c) + b_i^*$. If $\left\| p_j - p_j^* \right\| < \epsilon$ for all $p_j^* \in S_i^*$, then the least squares approximation to $f_{\mathcal{P}}^*$ on S_i, $\Pi(f_{\mathcal{P}}^*|_{S_i})(x) = \hat{A}_i(x - x_c) + \hat{b}_i$, satisfies the property

$$\left\| \begin{bmatrix} \hat{A}_i{}^{\mathrm{T}} - A_i^{*\mathrm{T}} \\ \hat{b}_i{}^{\mathrm{T}} - b_i^{*\mathrm{T}} \end{bmatrix} \right\|_2 < c_{1,i} \epsilon^2, \tag{4.5}$$

where $c_{1,i} = c_{1,i}(\mathcal{P}^*)$ is given by (4.18).

The second lemma considers one set of affine functions that all intersect at a common point and another set of affine functions which are perturbations of the first set of functions. It is shown that performing the variance minimization, equivalent to (3.1) with $\lambda = 0$, on the second set of functions generates a point whose distance from the intersection point is linear in the norm of the perturbations.

LEMMA 4.3. *Let L^* be a set of N affine maps, $L_1^*, \ldots L_N^*$, such that all intersect at (p^*, q^*) and are written as $L_i^*(x) = A_i^*(x - p^*) + q^*$, and such that H^*, given by* (4.20)*, is full rank. Let L be a set of perturbed affine maps, $L_1, \ldots L_N$, expressed as $L_i(x) = \hat{A}_i(x - p^*) + \hat{q}_i$, which satisfy the property*

$$\left\| \begin{bmatrix} \hat{A}_i{}^{\mathrm{T}} - A_i^{*\mathrm{T}} \\ \hat{q}_i{}^{\mathrm{T}} - q^{*\mathrm{T}} \end{bmatrix} \right\| < \Delta \tag{4.6}$$

for $\Delta < \Delta_0$, where $\Delta_0 = \Delta_0(A_i^*, p^*, q^*)$ is given by (4.19)*. Let p' and q' be given by*

$$p' = \arg\min_x \quad \operatorname{var} L(x),$$
$$q' = \frac{1}{N}\sum_{i=1}^{N} L(p').$$

Then p' and q' satisfy

$$\|p' - p^*\| < c_2\Delta,$$
$$\|q' - q^*\| < c_3\Delta,$$

where $c_2 = c_2(A_i^*, p^*, q^*)$ and $c_3 = c_3(A_i^*, p^*, q^*)$ are given by (4.23) *and* (4.24)*.*

The first proposition brings the two lemmas together to show that a single step of the `minvar` algorithm induces a quadratic change in the distance of the approximation vertices to the data generating function vertices.

Proposition 4.4. *Let $f^*_{\mathcal{P}}$ be a nondegenerate PL data generating function parameterized by $\mathcal{P}^* = (P^*, Q^*, \mathcal{S}^*)$. Let $\epsilon < \epsilon_d$,*

$$\epsilon_d := \min\left\{\epsilon_c, \quad \sqrt{\frac{\Delta_0^m}{c_1}}\right\},$$

where $\epsilon_c = \epsilon_c(\mathcal{P}^*)$ is given by (4.4)*, $\Delta_0^m = \Delta_0^m(\mathcal{P}^*)$ by* (4.25)*, and $c_1 = c_1(\mathcal{P}^*)$ by* (4.27)*.*

If the PL approximation $f_{\mathcal{P}}$ parameterized by $(P, Q, \mathcal{S}^*)$ satisfies $\|p_i - p_i^*\| < \epsilon$ for all i, then one iteration of the `minvar` *algorithm with $\lambda = 0$ gives the new approximation f'_P parameterized by $(P', Q', \mathcal{S}^*)$, which satisfies*

$$\|p'_i - p_i^*\| < c_4\epsilon^2,$$
$$\|q'_i - q_i^*\| < c_5\epsilon^2,$$

for all i, where $c_4 = c_4(\mathcal{P}^*)$ and $c_5 = c_5(\mathcal{P}^*)$ are given by (4.31) *and* (4.32)*.*

The second proposition applies the first proposition to show that iteration of the `minvar` algorithm causes convergence of the vertices of the approximation to the vertices of the data generating function.

Proposition 4.5. *Let $f^*_{\mathcal{P}}$ be a nondegenerate PL data generating function parameterized by $(P^*, Q^*, \mathcal{S}^*)$. Let*

$$\epsilon_0 = \min\left\{\epsilon_d, \ \frac{1}{c_4}\right\}, \tag{4.7}$$

where ϵ_d and c_4 are given in Proposition 4.4*. If for some $0 < \epsilon < \epsilon_0$ the initial PL approximation $f_P^{(0)}$ with parameterization $(P^{(0)}, Q^{(0)}, \mathcal{S}^*)$ satisfies $\|p_i^{(0)} - p_i^*\| < \epsilon$ for all i, then iteration of the* `minvar` *algorithm with $\lambda = 0$ gives a sequence of approximations $f_P^{(k)}$ satisfying*

$$\lim_{k\to\infty} \left\|p_i^{(k)} - p_i^*\right\| = 0,$$
$$\lim_{k\to\infty} \left\|q_i^{(k)} - q_i^*\right\| = 0$$

for all i.

4.2. Proofs of lemmas and propositions. This section presents proofs of the lemmas and propositions stated in the previous section.

Proof of Lemma 4.2. Let $\varphi_i(x) := A_i^*(x - x_c) + b_i^*$, the extension of $f_{\mathcal{P}}^*|_{S_i^*}$ to the entire domain. Let $\psi_i(x) := f_{\mathcal{P}}^*(x) - \varphi_i(x)$.

The orthogonal projection Π is a linear operator, and, moreover, for g affine, $\Pi(g) = g$. It follows that

$$\begin{aligned} \Pi(f_{\mathcal{P}}^*|_{S_i}) &= \Pi(\varphi_i|_{S_i}) + \Pi(\psi_i|_{S_i}) \\ &= \varphi_i + \Pi(\psi_i|_{S_i}). \end{aligned} \tag{4.8}$$

Let $\hat{A}_i$ and $\hat{b}_i$ be such that $\Pi(f_{\mathcal{P}}^*|_{S_i})(x) = \hat{A}_i(x - x_c) + \hat{b}_i$. Then from (4.8) it follows that $\Pi(\psi_i|_{S_i}) = (\hat{A}_i - A_i^*)(x - x_c) + (\hat{b}_i - b_i^*)$. Moreover, since $\Pi(\psi_i|_{S_i}) = \Pi(f_{\mathcal{P}}^*|_{S_i} - \varphi_i|_{S_i})$, we can compute $(\hat{A}_i - A_i^*)$ and $(\hat{b}_i - b_i^*)$ using the formula for the L_2 orthogonal projection of $f_{\mathcal{P}}^*|_{S_i} - \varphi_i|_{S_i}$,

$$\begin{bmatrix} (\hat{A}_i - A_i^*)^{\mathrm{T}} \\ (\hat{b}_i - b_i^*)^{\mathrm{T}} \end{bmatrix} = {S_{xx,i}}^{-1} S_{xy,i},$$

$$S_{xx,i} = \int_{S_i} \begin{bmatrix} x - x_c \\ 1 \end{bmatrix} \begin{bmatrix} x^{\mathrm{T}} - {x_c}^{\mathrm{T}} & 1 \end{bmatrix} dx, \qquad S_{xy,i} = \int_{S_i} \begin{bmatrix} x - x_c \\ 1 \end{bmatrix} (f_{\mathcal{P}}^*(x) - \varphi_i(x))^{\mathrm{T}} dx.$$

The submultiplicative property holds for the induced two norm,

$$\left\| \begin{bmatrix} (\hat{A}_i - A_i^*)^{\mathrm{T}} \\ (\hat{b}_i - b_i^*)^{\mathrm{T}} \end{bmatrix} \right\| \leq \left\| {S_{xx,i}}^{-1} \right\| \left\| S_{xy,i} \right\|,$$

so we can independently establish bounds on $\left\| {S_{xx,i}}^{-1} \right\|$ and $\| S_{xy,i} \|$. We will proceed to bound $\left\| {S_{xx,i}}^{-1} \right\|$. Since S_i is a d-simplex, it follows from calculus and the definition of $S_{xx,i}$ that $S_{xx,i}$ is a positive definite matrix. Let M_i^* be given by

$$M_i^* := \int_{\mathcal{D}(S_i^*, -\epsilon_c)} \begin{bmatrix} x - x_c \\ 1 \end{bmatrix} \begin{bmatrix} x^{\mathrm{T}} - {x_c}^{\mathrm{T}} & 1 \end{bmatrix} dx.$$

Since $0 < \epsilon < \epsilon_c$ by hypothesis and $\epsilon_c \leq \frac{1}{2(d+1)} r_2$ by definition, it follows from Claim 3 in Appendix A that $\mathcal{D}(S_i^*, -\epsilon_c)$ is a d-simplex. Thus M_i^* is also positive definite, and hence invertible. Since $\epsilon < \epsilon_c$ and the vertices or S_i are all less than ϵ away from the vertices of S_i^*, it follows that $\mathcal{D}(S_i^*, -\epsilon_c) \subseteq S_i$. Thus, $x^{\mathrm{T}} M_i^* x < x^{\mathrm{T}} S_{xx,i} x$ for all x, which implies that $\lambda_{\min}(M) < \lambda_{\min}(S_{xx,i})$. This provides the bound on $\left\| {S_{xx,i}}^{-1} \right\|$,

$$\left\| {S_{xx,i}}^{-1} \right\| < \left\| {M_i^*}^{-1} \right\|.$$

Now we proceed to $\| S_{xy,i} \|$. By the properties of norms,

$$\| S_{xy,i} \| \leq \int_{S_i} \left\| \begin{bmatrix} x - x_c \\ 1 \end{bmatrix} \right\| \| \psi_i(x) \| \, dx. \tag{4.9}$$

Let $\mathcal{C}(S_i, \epsilon) = \{ x \in \mathbb{R}^d | \delta(x, S_i) \leq \epsilon \}$. By hypothesis, the vertices of S_i are less than ϵ away from the vertices of S_i^*, so $\operatorname{vert} S_i \subseteq \mathcal{C}(S_i^*, \epsilon)$. Moreover, since both S_i and

$\mathcal{C}(S_i^*, \epsilon)$ are convex, $S_i \subseteq \mathcal{D}(S_i^*, \epsilon)$. The integrand in (4.9) is nonnegative definite, so (4.9) is bounded by

$$\leq \int_{\mathcal{C}(S_i^*,\epsilon)} \left\| \begin{bmatrix} x - x_c \\ 1 \end{bmatrix} \right\| \|(\psi_i(x))\| \, dx.$$

By hypothesis $x_c \in S_i^*$. By the definition of r_1 and since $\epsilon < \epsilon_c$, it follows that for all $x \in \mathcal{C}(S_i^*, \epsilon)$, $\|x - x_c\| \leq \bar{r} := r_1 + 2\epsilon_c$. Thus, the integral above is further bounded by

$$\leq \sqrt{1 + \bar{r}^2} \int_{\mathcal{C}(S_i^*,\epsilon)} \|(\psi_i(x))\| \, dx. \tag{4.10}$$

Once again the integrand is nonnegative definite, so (4.10) can be bounded by integrating over $\mathcal{D}(S_i^*, \epsilon)$, since $\mathcal{C}(S_i^*, \epsilon) \subseteq \mathcal{D}(S_i^*, \epsilon)$,

$$\leq \sqrt{1 + \bar{r}^2} \int_{\mathcal{D}(S_i^*,\epsilon)} \|(\psi_i(x))\| \, dx \tag{4.11}$$

$$= \sqrt{1 + \bar{r}^2} \sum_{j=1}^{N} \int_{U_j} \|(\psi_i(x))\| \, dx, \tag{4.12}$$

where $U_j = \mathcal{D}(S_i^*, \epsilon) \cap S_j^*$ and N is the total number of d-simplices in the domain triangulation. Since $\psi_i(x) = 0$ on S_i^*, the term corresponding to $j = i$ in (4.12) is 0. By hypothesis $\epsilon < \epsilon_c \leq r_3$, so then following from the definition of r_3, $S_j^* \cap \mathcal{D}(S_i^*, \epsilon) \neq \emptyset$ if and only if $S_j^* \in \operatorname{St} S_i^*$. Thus the terms in (4.12) are only nonzero for j such that S_j^* is incident to S_i^*. Consider such a term,

$$\int_{U_j} \|\psi_i(x)\| \, dx = \int_{U_j} \left\| \left(A_j^* - A_i^*\right)(x - x_c) + b_j^* - b_i^* \right\| dx,$$

where $f_{\mathcal{P}}^*|_{S_j^*}(x) = A_j^*(x - x_c) + b_j^*$. By Claim 5 in Appendix A, there exists $x_O \in S_j^* \cap S_i^* \subseteq U_j$ such that $\left(A_j^* - A_i^*\right)(x_O - x_c) + b_j^* - b_i^* = 0$. Applying the change of coordinates $y = x - x_O$ gives

$$\int_{U_j} \|\psi_i(x)\| \, dx = \int_{U_j - x_O} \left\| \left(A_j^* - A_i^*\right) y \right\| \, dy. \tag{4.13}$$

Let L be the linear subspace parallel to $\operatorname{aff}(S_i^* \cap S_j^*)$. Recall that $\dim L = \dim S_i^* \cap S_j^* := d_{i,j}$. By Claim 5 in Appendix A, $L \subseteq \mathcal{N}(\left(A_j^* - A_i^*\right))$. Let $v_1, \ldots, v_{d_{i,j}}$ be an orthonormal basis for L. Let $v_{d_{i,j}+1}, \ldots, v_d$ be an orthonormal basis for $L^{\perp}$. Then $P = \begin{bmatrix} v_1 & v_2 & \cdots & v_d \end{bmatrix}$ is an orthogonal matrix. Rewrite (4.13) under the change of coordinates $z = P^{\mathrm{T}} y$,

$$= \int_{P^{\mathrm{T}}(U_j - x_O)} \left\| \left(A_j^* - A_i^*\right) P z \right\| \, dz. \tag{4.14}$$

Since the integrand is a nonnegative definite function, we may bound (4.14) by increasing the volume over which the integrand is integrated. By Claim 4 in Appendix A, there exists $\kappa_{i,j}$ such that for all $x \in U_j$, $\delta\big(x, \operatorname{aff}(S_i^* \cap S_j^*)\big) < \kappa_{i,j}\epsilon$. Equivalently $\delta(y, L) < \kappa_{i,j}\epsilon$ for any $y \in U_j - x_O$, from which it follows that the projection of y onto $L^{\perp}$ must have magnitude less than $\kappa_{i,j}\epsilon$. Moreover, by the definition of $\bar{r}$, the projection of y onto L must have magnitude less than $\bar{r}$. It follows that $P^{\mathrm{T}}(U_j - x_O) \subseteq [-\bar{r}, \bar{r}]^{d_{i,j}} \times B_{\bar{d}_{i,j}}(\kappa_{i,j}\epsilon)$, where $\bar{d}_{i,j} = d - d_{i,j}$ and $B_{\bar{d}_{i,j}}(\kappa_{i,j}\epsilon)$ is the $\bar{d}_{i,j}$-dimensional ball of radius $\kappa_{i,j}\epsilon$. Then (4.14) is bounded by

$$\leq \int_{[-\bar{r},\bar{r}]^{d_{i,j}} \times B_{\bar{d}_{i,j}}(\kappa_{i,j}\epsilon)} \left\| \left(A_j^* - A_i^*\right) P z \right\| \; dz. \tag{4.15}$$

The first $d_{i,j}$ columns of $\left(A_j^* - A_i^*\right) P$ are zero, since the first $d_{i,j}$ columns of P are in the nullspace of $\left(A_j^* - A_i^*\right)$. Thus, the integrand in (4.15) has no dependence on $z_1, z_2, \ldots, z_{d_{i,j}}$, so we can integrate through for $z_1, \ldots, z_{d_{i,j}}$, giving

$$= (2\bar{r})^{d_{i,j}} \int_{B_{\bar{d}_{i,j}}(\kappa_{i,j}\epsilon)} \left\| \left(A_j^* - A_i^*\right) P \begin{bmatrix} I \\ 0 \end{bmatrix} \bar{z}_1 \right\| \; dz_{d_{i,i}+1} \ldots dz_d, \tag{4.16}$$

where ${\bar{z}_1}^{\mathrm{T}} = \begin{bmatrix} z_{d_{i,j}+1} & \cdots & z_d \end{bmatrix}^{\mathrm{T}}$. Since the first $d_{i,j}$ columns of $\left(A_j^* - A_i^*\right) P$ are zero and P is orthogonal, it follows that $\|\left(A_j^* - A_i^*\right) P \begin{bmatrix} I & 0 \end{bmatrix}^{\mathrm{T}}\| \leq \|A_j^* - A_i^*\|$. Thus, (4.16) can be further bound by

$$\leq (2\bar{r})^{d_{i,j}} \left\| A_j^* - A_i^* \right\| \int_{B_{\bar{d}_{i,j}}(\kappa_{i,j}\epsilon)} \|\bar{z}_1\| \; d\bar{z}_1. \tag{4.17}$$

From calculus (see, for example, [37]) it can be shown that[5]

$$\int_{B_k(\epsilon)} \|w\| \; dw = \frac{k}{k+1} \frac{\pi^{k/2}}{\Gamma(k/2)} \epsilon^{k+1}.$$

Applying this with (4.17) to (4.12), and then simplifying using the fact that $\epsilon^m \leq \epsilon^2$ for $m \geq 2$ since $\epsilon < \epsilon_c \leq 1$, gives

$$\|S_{xy,i}\| \leq \sqrt{1 + \bar{r}^2} \; l_i \max_{\substack{j \text{ s.t. } j \neq i, \\ S_j^* \in \mathrm{St} S_i^*}} \left((2\bar{r})^{d_{i,j}} \left\| A_j^* - A_i^* \right\| {\kappa_{i,j}}^{1+\bar{d}_{i,j}} \frac{\bar{d}_{i,j}}{\bar{d}_{i,j}+1} \frac{\pi^{(\bar{d}_{i,j})/2}}{\Gamma((\bar{d}_{i,j})/2)} \right) \epsilon^2,$$

where $l_i = \sum_{S_j^* \in \mathrm{St} S_i^*} 1$. Then

$$\begin{aligned} \left\| \begin{bmatrix} {\hat{A}_i}^{\mathrm{T}} - A_i^{*\mathrm{T}} \\ {\hat{b}_i}^{\mathrm{T}} - b_i^{*\mathrm{T}} \end{bmatrix} \right\| &\leq \left\| {S_{xx,i}}^{-1} \right\| \|S_{xy,i}\| \\ &< c_{1,i} \epsilon^2, \end{aligned}$$

where

(4.18)

$$c_{1,i} := \left\| M_i^{*-1} \right\| \sqrt{1 + \bar{r}^2} \; l_i \max_{\substack{j \text{ s.t. } j \neq i, \\ S_j^* \in \mathrm{St} S_i^*}} \left((2\bar{r})^{d_{i,j}} \left\| A_j^* - A_i^* \right\| {\kappa_{i,j}}^{1+\bar{d}_{i,j}} \frac{\bar{d}_{i,j}}{\bar{d}_{i,j}+1} \frac{\pi^{(\bar{d}_{i,j})/2}}{\Gamma((\bar{d}_{i,j})/2)} \right)$$

[5] For even k, $\Gamma(k/2) = (k/2)!$. For odd k, let $k' = \frac{1}{2}(k-1)$; then $\Gamma(k/2) = \Gamma(\frac{1}{2} + k') = \sqrt{\pi} \frac{(2k'+2)!}{(k+1)! 4^{k'+1}}$.

and $\bar{d}_{i,j} = d - d_{i,j}$, $l_i = \sum_{S_j^* \in \mathrm{St} S_i^*} 1$, and $\bar{r} = r_1 + 2\epsilon_c$. □

Proof of Lemma 4.3. Let the constant Δ_0 from the statement of the lemma be given by

$$\Delta_0 := \min \left\{ \frac{1}{N} \sum_{j=1}^{N} \|A_j^*\| \quad , \quad \left(\frac{12}{N} \|H^{*-1}\| \sum_{j=1}^{N} \|A_j^*\| \right)^{-1} \right\}, \tag{4.19}$$

where H^* is given by (4.20).

Solving $p' = \arg\min_x \operatorname{var} \; L(x)$ is equivalent to solving (3.1) with $\lambda = 0$. As with (3.1), a closed form expression for p' can be found by "completing the square." Specifically, $p' = H^{-1}h$,

$$H := \left(\frac{1}{N} \sum_{j=1}^{N} \hat{A}_j{}^{\mathrm{T}} \hat{A}_j \right) - \overline{\hat{A}}^{\mathrm{T}} \overline{\hat{A}},$$

$$h := \left(\frac{1}{N} \sum_{j=1}^{N} \hat{A}_j{}^{\mathrm{T}} (\hat{q}_j - \hat{A}_j p^*) \right) - \overline{\hat{A}}^{\mathrm{T}} \overline{\hat{b}},$$

where $\overline{\hat{A}} = \frac{1}{N} \sum_{j=1}^{N} \hat{A}_j$ and $\overline{\hat{b}} = \frac{1}{N} \sum_{j=1}^{N} (\hat{q}_j - \hat{A}_j p^*)$. Let $\tilde{A}_j = \hat{A}_j - A_j^*$ and $\tilde{q}_j = \hat{q}_j - q^*$. Then $H = H^* + \tilde{H}$ and $h = h^* + \tilde{h}$, with

$$H^* := \left(\frac{1}{N} \sum_{j=1}^{N} A_j^{*\mathrm{T}} A_j^* \right) - \overline{A^*}^{\mathrm{T}} \overline{A^*}, \tag{4.20}$$

$$h^* := \left(\frac{1}{N} \sum_{j=1}^{N} A_j^{*\mathrm{T}} (q^* - A_j^* p^*) \right) - \overline{A^*}^{\mathrm{T}},$$

$$\tilde{H} = \frac{1}{N} \left[\sum_{j=1}^{N} (A_j^* + \tilde{A}_j)^{\mathrm{T}} \tilde{A}_j + \sum_{j=1}^{N} \tilde{A}_j{}^{\mathrm{T}} A_j^* \right] - \overline{A^*}^{\mathrm{T}} \overline{\tilde{A}} - \overline{\tilde{A}}^{\mathrm{T}} \overline{A^*} - \overline{\tilde{A}}^{\mathrm{T}} \overline{\tilde{A}},$$

$$\tilde{h} = \frac{1}{N} \left[\sum_{j=1}^{N} (A_j^* + \tilde{A}_j)^{\mathrm{T}} (\tilde{q}_j - \tilde{A}_j p^*) + \sum_{j=1}^{N} \tilde{A}_j{}^{\mathrm{T}} (q^* - A_j^* p^*) \right] - \overline{A^*}^{\mathrm{T}} \overline{\tilde{b}} - \overline{\tilde{A}}^{\mathrm{T}} \overline{b^*} - \overline{\tilde{A}}^{\mathrm{T}} \overline{\tilde{b}},$$

where

$$\overline{A^*} = \frac{1}{N} \sum_{j=1}^{N} A_j^*, \qquad \overline{b^*} = \frac{1}{N} \sum_{j=1}^{N} (q^* - A_j^* p^*),$$

$$\overline{\tilde{A}} = \frac{1}{N} \sum_{j=1}^{N} \tilde{A}_j, \qquad \overline{\tilde{b}} = \frac{1}{N} \sum_{j=1}^{N} (\tilde{q}_j - \tilde{A}_j p^*).$$

Notice that H^* and h^* depend only on A_j^*, p^*, and q^*. Moreover, since all functions in L^* go through (p^*, q^*), it must be that $p^* = \arg\min_x \operatorname{var} \; L^*(x)$, and thus $p^* =$

${H^*}^{-1}h^*$. Rewriting $p' = H^{-1}h$, gives $(H^* + \tilde{H})\,(p^* + (p' - p^*)) = h^* + \tilde{h}$. Applying $H^*p^* = h^*$ and solving for $p' - p^*$ yields

$$p' - p^* = \left(H^* + \tilde{H}\right)^{-1}\left(\tilde{h} - \tilde{H}p^*\right).$$

From the hypothesis it follows that $\|\tilde{A}_j\| < \Delta$ and $\|\tilde{q}_j\| < \Delta$. Applying these bounds and the properties of norms, it follows after some computation that

$$\begin{aligned}\left\|\tilde{H}\right\| &\le 2\Delta^2 + \frac{4\Delta}{N}\sum_{j=1}^{N}\left\|A_j^*\right\|,\\ \left\|\tilde{h}\right\| &\le 2\left(1 + \|p^*\|\right)\Delta^2 + \frac{2\Delta}{N}\sum_{j=1}^{N}\left[\left\|A_j^*\right\|\left(1 + \|p^*\|\right) + \|q^*\| + \left\|A_j^*\right\|\|p^*\|\right].\end{aligned}$$

Since $\Delta < \Delta_0$ and by definition $\Delta_0 \le \frac{1}{N}\sum_{j=1}^{N}\left\|A_j^*\right\|$, the above bounds may be further simplified to

$$\left\|\tilde{H}\right\| < \left(\frac{6}{N}\sum_{j=1}^{N}\left\|A_j^*\right\|\right)\Delta, \tag{4.21}$$

$$\left\|\tilde{h}\right\| < \left(\frac{2}{N}\sum_{j=1}^{N}\left[2\left\|A_j^*\right\|\left(1 + \|p^*\|\right) + \|q^*\| + \left\|A_j^*\right\|\|p^*\|\right]\right)\Delta. \tag{4.22}$$

Also by definition $\Delta_0 \le (\frac{12}{N}\|{H^*}^{-1}\|\sum_{j=1}^{N}\|A_j^*\|)^{-1}$, so the bound in (4.21) can be simplified to $\|\tilde{H}\| < \frac{1}{2\|{H^*}^{-1}\|}$, and thus $\|{H^*}^{-1}\tilde{H}\| < \frac{1}{2}$. From [19], if $M \in \mathbb{R}^{n\times n}$ and $\|M\| < 1$, then $I - M$ is nonsingular and $\|(I - M)^{-1}\| \le \frac{1}{1-\|M\|}$. Some computation using this fact and the bound on $\|{H^*}^{-1}\tilde{H}\|$ provides

$$\left\|(H^* + \tilde{H})^{-1}\right\| < 2\left\|{H^*}^{-1}\right\|.$$

So then

$$\begin{aligned}\|p' - p^*\| &\le \left\|\left(H^* + \tilde{H}\right)^{-1}\right\|\left\|\tilde{h} - \tilde{H}p^*\right\|\\ &\le 2\left\|{H^*}^{-1}\right\|\left(\left\|\tilde{h}\right\| + \left\|\tilde{H}\right\|\|p^*\|\right)\\ &< c_2\Delta,\end{aligned}$$

$$\text{where} \qquad c_2 := \frac{4\left\|{H^*}^{-1}\right\|}{N}\sum_{j=1}^{N}\left(6\left\|A_j^*\right\|\|p^*\| + 2\left\|A_j^*\right\| + \|q^*\|\right), \tag{4.23}$$

which is the first part of the desired result. Applying this bound and the definition of q', we find after some computation that

$$\|q' - q^*\| < c_3\Delta,$$

$$\text{where} \quad c_3 := 1 + \frac{2c_2}{N} \sum_{j=1}^{N} \left\| A_j^* \right\| \tag{4.24}$$

which completes the desired result. □

Proof of Proposition 4.4. Let

$$\Delta_0^m = \min_{\substack{i \text{ s.t.} \\ p_i^* \in P^*}} \left\{ \frac{1}{N_i} \sum_{j=1}^{N_i} \left\| A_{i_j}^* \right\| \quad , \quad \left(\frac{12}{N_i} \left\| H_i^{*-1} \right\| \sum_{j=1}^{N_i} \left\| A_{i_j}^* \right\| \right)^{-1} \right\}, \tag{4.25}$$

where $S_{i_1}^*, \dots, S_{i_{N_i}}^*$ are the N_i d-simplices in $\mathrm{St}\{p_i^*\}$, and

$$H_i^* = \left(\frac{1}{N_i} \sum_{j=1}^{N_i} A_{i_j}^{*\,\mathrm{T}} A_{i_j}^* \right) - \left(\frac{1}{N_i} \sum_{j=1}^{N_i} A_{i_j}^* \right)^{\mathrm{T}} \left(\frac{1}{N_i} \sum_{j=1}^{N_i} A_{i_j}^* \right).$$

We will examine the effect of a single iteration of the `minvar` algorithm on $p_i \in P$, $q_i \in Q$. The results will hold independently of i, giving the desired result.

The first stage of the `minvar` algorithm calculates the least squares projection $\Pi(f_{\mathcal{P}}^*|_{S_i})$ in each d-simplex S_i of the approximation (step 2 of the algorithm; since this proposition addresses the approximation version of the problem, there is no partitioning of data to be performed in step 1). Let $S_{i_1}, \dots, S_{i_{N_i}}$ be the d-simplices in $\mathrm{St}\{p_i\}$. Since $f_{\mathcal{P}}^*$ and $f_{\mathcal{P}}$ are parameterized with the same abstract simplicial complex $\mathcal{S}^*$, $S_{i_1}^*, \dots, S_{i_{N_i}}^*$ are the d-simplices in $\mathrm{St}\{p_i^*\}$. Let $f_{\mathcal{P}}^*|_{S_{i_j}^*}(x) = A_{i_j}^*(x - p_i^*) + q_i^*$ and $\Pi(f_{\mathcal{P}}^*|_{S_i}) = \hat{A}_{i_j}(x - p_i^*) + \hat{q}_{i_j}$. Since $\epsilon < \epsilon_d \leq \epsilon_c$, it follows from Lemma 4.2 that for each $j = 1, \dots, N_i$,

$$\left\| \begin{bmatrix} \hat{A}_{i_j}{}^{\mathrm{T}} - A_{i_j}^{*\,\mathrm{T}} \\ \hat{q}_{i_j}{}^{\mathrm{T}} - q_i^{*\,\mathrm{T}} \end{bmatrix} \right\| < c_{1,i_j} \epsilon^2, \tag{4.26}$$

where c_{1,i_j} is given by (4.18). Let

$$c_1 = \max_{i=1,..,N} c_{1,i}, \tag{4.27}$$

where N is the total number of d-simplices in $\mathcal{T}(P, \mathcal{S}^*)$. Then for $j = 1 \dots, N_i$,

$$\left\| \begin{bmatrix} \hat{A}_{i_j}{}^{\mathrm{T}} - A_{i_j}^{*\,\mathrm{T}} \\ \hat{b}_{i_j}{}^{\mathrm{T}} - b_{i_j}^{*\,\mathrm{T}} \end{bmatrix} \right\| < c_1 \epsilon^2. \tag{4.28}$$

Step 3 of `minvar` moves the knots taking $(p_i, q_i) \to (p_i', q_i')$. Since $\epsilon < \epsilon_d \leq \sqrt{\Delta_0^m / c_1}$ by hypothesis, it follows that $c_1 \epsilon^2 < \Delta_0^m$. Thus, (4.28) implies that the bound in (4.6) is satisfied, permitting application of Lemma 4.3, which gives

$$\| p_i' - p_i^* \| < c_{2,i} c_1 \epsilon^2,$$
$$\| q_i' - q_i^* \| < c_{3,i} c_1 \epsilon^2,$$

where

$$c_{2,i} := \frac{4 \left\| H_i^{*-1} \right\|}{N_i} \sum_{j=1}^{N_i} \left(6 \left\| A_{i_j}^* \right\| \| p_i^* \| + 2 \left\| A_{i_j}^* \right\| + \| q_i^* \| \right), \tag{4.29}$$

$$c_{3,i} := 1 + \frac{2c_{2,i}}{N_i} \sum_{j=1}^{N_i} \left\| A_{i_j}^* \right\|. \tag{4.30}$$

For each p_i, q_i we can compute such bounds. Let

$$c_4 := c_1 \max_i c_{2,i}, \tag{4.31}$$

$$c_5 := c_1 \max_i c_{3,i}. \tag{4.32}$$

Then, for all i, p_i' and q_i' satisfy

$$\|p_i' - p_i^*\| < c_4\epsilon^2, \tag{4.33}$$

$$\|q_i' - q_i^*\| < c_5\epsilon^2, \tag{4.34}$$

which is the desired result. □

Proof of Proposition 4.5. First we establish by induction that for $k \geq 1$,

$$\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k} < \epsilon_d, \tag{4.35}$$

$$\left\|p_i^{(k)} - p_i^*\right\| < \frac{1}{c_4}\left(c_4\epsilon\right)^{2^k}, \tag{4.36}$$

$$\left\|q_i^{(k)} - q_i^*\right\| < \frac{c_5}{c_4}\left(c_4\epsilon\right)^{2^k}. \tag{4.37}$$

For $k = 1$, $c_4\epsilon^2 < \epsilon_d$ since $\epsilon < \epsilon_0 \leq \sqrt{\epsilon_d/c_4}$. For $k > 1$, $\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k} < \epsilon_d$ by the induction hypothesis. Moreover, $c_4\epsilon < 1$ since $\epsilon < \epsilon_0 \leq \frac{1}{c_4}$. Then $\frac{1}{c_4}(c_4\epsilon)^{2^{(k+1)}} = (\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k})\left(c_4\epsilon\right)^{2^k} < \epsilon_d$. This establishes (4.35). Since $\epsilon < \epsilon_0 \leq \epsilon_d$, it follows that for $k = 1$, after a single iteration of the `minvar` algorithm, (4.36) and (4.37) will hold by Proposition 4.4. For $k > 1$, for all i, $\|p_i^{(k)} - p_i^*\| < \frac{1}{c_4}\left(c_4\epsilon\right)^{2^k}$ by the induction hypothesis. From (4.35), proven above, $\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k} < \epsilon_d$. Since for all i, $\|p_i^{(k)} - p_i^*\| < \epsilon_d$, it follows from Proposition 4.4 that

$$\left\|p_i^{(k+1)} - p_i^*\right\| < c_4\left(\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k}\right)^2 = \frac{1}{c_4}\left(c_4\epsilon\right)^{2^{(k+1)}},$$

$$\left\|q_i^{(k+1)} - q_i^*\right\| < c_5\left(\frac{1}{c_4}\left(c_4\epsilon\right)^{2^k}\right)^2 = \frac{c_5}{c_4}\left(c_4\epsilon\right)^{2^{(k+1)}},$$

which establishes (4.36) and (4.37). Since $c_4\epsilon < 1$, as argued above, it follows that (4.36) and (4.37) go to 0 as k goes to infinity. □

5. Numerical example. This section presents an example of the `minvar` algorithm's performance on a "test function," $f : [0,1]^2 \to \mathbb{R}^2$, given by

$$f(x) = \begin{bmatrix} \tanh\frac{5}{8}\left(2x_1 - 4{x_2}^4 + 3{x_2}^2 - 1\right) \\ \tanh\frac{5}{8}\left(2{x_1}^2 - \ \ {x_1}^4 + 2x_2 - 1\right) \end{bmatrix}, \tag{5.1}$$

which is invertible over the domain $D = [0,1]^2$. The implementation of `minvar` constructs an approximation to a discrete set of data and includes constrained motion of boundary vertices as well as data dependent retriangulation. Since the test function is neither piecewise linear nor directly available, Theorem 4.1 provides no performance guarantees, but good performance under these circumstances suggests `minvar`'s broader applicability. Two sets of numerical studies are presented. The first

test function

Fig. 5.1. *Visualizations of the test function (lower right) and a series of PL approximations to the test function. In each subfigure, the domain is displayed on the left and the range on the right. Note that the approximations are invertible, since there are no tangles in the range triangulations.*

examines the effects of varying the number of vertices in the PL approximation, and the second examines how data set size affects approximations with a fixed number of vertices.

The first set of experiments fits PL approximations of differing sizes to a single data set. The data set was generated by sampling the test function on an 80×80 uniform grid over the domain. For each $n = 2, \dots, 13$, three different PL approximations with n^2 vertices were computed: (i) the least squares continuous PL approximation on a fixed uniform triangulation of the domain (referred to as "uniform LS"), (ii) `minvar`, initialized on a uniform triangulation of the domain (referred to as "`minvar`"), and (iii) the least squares continuous PL approximation on the final triangulation from `minvar` (referred to as "`minvar` LS"). Recall that when the domain triangulation is fixed, the least squares continuous PL approximation problem becomes linear-in-parameters and the solution can be computed directly [7, 35]. Figure 5.1 shows the test function and several exemplars of the `minvar` approximations. Table 5.1 and

Table 5.1

(a) (b)

Fig. 5.2. *RMSE performance of* `minvar` *compared to a least squares continuous PL approximation on a uniform triangulation.* (a) *Vertices in approximation vs. RMSE for approximations to the* 80×80 *data set.* (b) *Density of training data set vs. RMSE on validation data for approximations with* 6^2 *vertices.*

Figure 5.2(a) show the root mean square error (RMSE) of the approximations as a function of the number of vertices. For 2^2 domain vertices, all of them are on the corners of the domain and must remain fixed, so `minvar` can change only the range vertices. Since `minvar` is not guaranteed to give the least squares continuous PL approximation for a given triangulation, it is not surprising that the uniform LS approximation's RMSE is slightly lower than `minvar`'s in this case. The RMSE difference between `minvar` and `minvar` LS approximations is less than 2%. Least squares could be applied as a post processing step to `minvar`, but since the differences are relatively small, this might not be necessary in application settings. From the triangulations of the `minvar` approximations in Figure 5.1, the domain triangulations move farther for lower numbers of vertices. As the number of vertices increases, the triangulations visually seem to deviate less from the initial uniform triangulation. The RMSE performance of `minvar` reflects this, giving the biggest reductions in RMSE as compared to uniform LS for triangulations with 3^2 to 6^2 vertices. Since this study uses initial conditions in which the vertices are on a uniform grid, approximations with large numbers of vertices may be getting caught in local minima near their initial conditions. In this case, performance could be improved by refining converged less dense approximations to create initial conditions for the dense approximations [39].

In the second set of experiments, PL approximations with 6^2 vertices were trained using data sets of varying size. The PL approximations were chosen to have 6^2 vertices because, as mentioned above, this is in the region of sizes where the performance gains from `minvar` are greatest. The data sets were generated by sampling the test function on a uniform $n \times n$ grid, $n = 25, 30, 35, \dots, 100$. The approximations were compared using a validation data set generated by evaluating the test function at 1000 points sampled from a uniform probability distribution over the domain. Figure 5.2(b) shows the validation set RMSE for `minvar` and uniform LS. With a 20×20 data set, `minvar` fails to run with a 6^2 vertex approximation, because as the vertices move, several simplices shrink to the point that they do not contain enough data to make the linear least squares approximation unique. Data sparsity is a serious issue in this type of local approximation.

From this example, `minvar` shows marked benefit when the approximation has relatively few vertices compared to the complexity of the test function. We expect that `minvar`'s performance on higher order (more vertices) approximations could be improved by seeding initial conditions based on lower order approximations. The algorithm produces a consistent approximation to variously sized data sets, so long as there is enough data for it to run.

6. Conclusion.

Numerous applications require the simultaneous approximation of a function and its inverse from a set of discrete data. While there is a substantial literature on function approximation, very little of it addresses the constraint of invertibility. The inverse of a continuous PL function can be computed in closed form, which is ideal for applications requiring the approximation of a function and its inverse. In the PL literature, the partition is often fixed, in which case the minimum squared error approximation problem is linear-in-parameters. The problem becomes nonlinear-in-parameters when the domain partition is allowed to move.

The `minvar` algorithm is a novel method for computing continuous PL approximations to data. Rather than using gradient descent on the parameters, `minvar` takes advantage of the structure of PL functions, iteratively moving the vertices of the approximation based on local least squares fits. The `minvar` algorithm is proven to converge locally in the special case when the data generating function is itself PL and available directly rather than through discrete data. While this result seems very natural, complexity in the proof arises from the interaction of the domain triangulations of the data generating function and its approximation. Indeed, many difficulties in constructing PL approximations, such as triangulation tangles, arise primarily from the combinatorial properties of PL functions. For general approximation problems, this added complexity may cause PL approximation to appear less attractive than other nonlinear-in-parameters approximation techniques, but for an important subset of applications the PL function's closed form invertibility makes the combinatorial complexity cost effective.

The present work can be extended in several directions. The analysis here addresses the approximation rather than the estimation version of the problem. A formal connection between the approximation and estimation versions could be constructed in the appropriate statistical framework. Similarly, there is no study of the effects of noise on the convergence properties of `minvar`. Since data from the data generating function are used only for computing the least squares approximations, and least squares has good noise properties, the authors expect that the `minvar` algorithm will also have good noise properties. The present analytical work considers only PL data generating functions. A desirable extension would be to show that the algorithm converges to the locally best PL approximation, given that one exists. For scalar functions there are generalized convexity conditions that characterize existence and uniqueness of (possibly discontinuous) PL approximations [4, 18, 26], but the authors are unaware of similar results for dimensions greater than one or with continuous piecewise approximations. Numerical experience suggests that `minvar` does have good convergence properties on other types of functions. Practical application of `minvar` raises a number of challenging issues such as constrained motion of vertices on the boundary of the domain, methods to avoid and correct triangulation tangling, and retriangulation or adaptation of the combinatorial parameters of the PL approximation. Due to space limitations, these topics will be addressed in detail in a subsequent paper on the use of `minvar` in engineering applications.

Appendix A. Geometric properties of simplices and triangulations. Proving properties of the `minvar` algorithms requires some insight into the underlying geometric structures upon which PL functions are constructed. This appendix presents a number of geometry facts used in the proof of convergence. Proofs of these facts are available in [20].

A.1. Barycentric coordinates as distances. It is often convenient to represent points in $\mathbb{R}^d$ using barycentric coordinates with respect to the vertices of some d-simplex. Let $p_1, \ldots, p_{d+1}$ be affinely independent points in $\mathbb{R}^d$. Let $x \in \mathbb{R}^d$ and let $\bar{\alpha} = \begin{bmatrix}\alpha_1 & \cdots & \alpha_{d+1}\end{bmatrix}^{\mathrm{T}}$ be such that $x = \sum_{i=1}^{d+1} \alpha_i p_i$ and $\sum_{i=1}^{d+1} \alpha_i = 1$. $\bar{\alpha}$ are called the *barycentric coordinates* of x with respect to $p_1, \ldots, p_{d+1}$. If $\bar{\alpha} \in \Delta_{d+1} := \{\bar{\alpha} \in \mathbb{R}^{d+1} | \alpha_i \geq 0, \sum_{i=1}^{d+1} \alpha_i = 1\}$, then $x \in \operatorname{conv}(p_1, \ldots, p_{d+1})$, and Δ_d is called the standard d-simplex.

The distance between a point $x \in \mathbb{R}^d$ and a nonempty set $A \subseteq \mathbb{R}^d$ is well defined [41] and written as $\delta(x, A) := \inf_{z \in A} \|x - z\|$. Let $H_i = \operatorname{aff}(\{p_1, \ldots, p_{d+1}\} - \{p_i\})$, the hyperplane opposing p_i. Let (a_i, c_i) be an implicit representation for H_i, that is, $H_i = \left\{z \in \mathbb{R}^d | {a_i}^{\mathrm{T}} z + c_i = 0\right\}$. The distance of a point $x \in \mathbb{R}^d$ to H_i is given by

$$\delta(x, H_i) = \frac{\left|{a_i}^{\mathrm{T}} x + c_i\right|}{\|a_i\|}.$$

We define $\delta_s(x, H_i)$ as the *signed distance* of x from H_i. That is, $|\delta_s(x, H_i)| = \delta(x, H_i)$, and $\delta_s(x, H_i) > 0$ for x on the same side of H_i as p_i, and $\delta_s(x, H_i) < 0$ for x on the opposite side of H_i as p_i.

By the following claim, the barycentric coordinates of x can be interpreted as the scaled distances of x from hyperplanes $H_1, \ldots, H_{d+1}$.

Claim 1. *Let $x \in \mathbb{R}^d$. Let $\bar{\alpha} = \begin{bmatrix}\alpha_1 & \cdots & \alpha_{d+1}\end{bmatrix}^{\mathrm{T}}$ be the barycentric coordinates of x with respect to the affinely independent points $p_1, \ldots, p_{d+1} \in \mathbb{R}^d$. Then $\delta_s(x, H_i) = \alpha_i \delta(p_i, H_i)$.*

Similarly, the barycentric coordinates of x can be used to measure the distance to an affine subspace that is the intersection of two or more of $H_1, \ldots, H_{d+1}$.

Claim 2. *Let $x \in \mathbb{R}^d$. Let $\bar{\alpha} = \begin{bmatrix}\alpha_1 & \cdots & \alpha_{d+1}\end{bmatrix}^{\mathrm{T}}$ be barycentric coordinates of x with respect to the affinely independent points $p_1, \ldots, p_{d+1}$. The distance from x to the affine subspace $A = \operatorname{aff}(\{p_1, \ldots p_k\})$ is given by $\delta(x, A) = {\bar{\alpha}_s}^{\mathrm{T}} G \bar{\alpha}_s$, where $\bar{\alpha}_s = \begin{bmatrix}\alpha_{k+1} & \alpha_{k+2} & \cdots & \alpha_{d+1}\end{bmatrix}^{\mathrm{T}}$ and $G \in \mathbb{R}^{(d-k+1) \times (d-k+1)}$ is a positive definite matrix whose entries depend only on $p_1, \ldots, p_k$.*

The explicit form for G, which derives from the Gram determinants used in the proof, is provided in [20].

A.2. Properties of the dilation. The dilation arises in Lemma 4.2 in measuring how the approximation's mismatched triangulation affects the least squares affine approximations. The first claim establishes the general properties of the dilation, and the second claim establishes a relationship between incident d-simplices that is required for the proof of Lemma 4.2.

CLAIM 3. *Let $S \subseteq \mathbb{R}^d$ be a d-simplex with vertices $p_1, \ldots, p_{d+1}$. Let*

$$\epsilon_{\min} = -\left(\sum_{i=1}^{d+1} 1/\delta(p_i, H_i)\right)^{-1}, \tag{A.1}$$

where H_i is the opposing hyperplane to p_i, as defined above. $\mathcal{D}(S, \epsilon_{\min})$ is a single point. For $\epsilon > \epsilon_{\min}$, $\mathcal{D}(S, \epsilon)$ is a d-simplex, with faces parallel to and translated distance $|\epsilon|$ away from the faces of S. For $\epsilon_{\min} \leq \epsilon \leq 0$, $\mathcal{D}(S, \epsilon) \subseteq S$, while for $\epsilon \geq 0$, $S \subseteq \mathcal{D}(S, \epsilon)$.

CLAIM 4. *Let $S_a, S_b \subseteq \mathbb{R}^d$ be incident d-simplices, that is, $S_a \cap S_b = s_{ab}$, where $s_{ab} \leq S_a, S_b$ is a $(k-1)$-simplex, $1 \leq k < d-1$. Let $\operatorname{vert} S_a = \{p_1, \ldots, p_{d+1}\}$, $\operatorname{vert} S_b = \{p_1, \ldots, p_k, q_{k+1}, \ldots, q_{d+1}\}$, and $\operatorname{vert} s_{ab} = \{p_1, \ldots, p_k\}$. Let $A = \operatorname{aff} s_{ab}$. Then $\exists \kappa_{a,b} > 0$ such that for all $\epsilon > 0$, if $x \in \mathcal{D}(S_a, \epsilon) \cap S_b$, then $\delta(x, A) < \kappa_{a,b}\epsilon$.*

A.3. Properties of PL functions. Claims pertaining to the parameterization, continuity, and invertibility of PL functions are provided below.

CLAIM 5. *Let $f_{\mathcal{P}}$ be a continuous PL function parameterized by $(P, Q, \mathcal{S})$. Let $S_i, S_j \in \mathcal{T}(P, \mathcal{S})$ be such that $S_i \cap S_j \neq \emptyset$. Let $S_i \cap S_j$ be a $(k-1)$-simplex, so then S_i and S_j share k vertices in common. Let $\operatorname{vert} S_i = \{p_{i_1}, \ldots, p_{i_{d+1}}\}$, $\operatorname{vert} S_j = \{p_{i_1}, \ldots, p_{i_k}, p_{j_{k+1}}, \ldots, p_{j_{d+1}}\}$, and $\operatorname{vert} S_i \cap S_j = \{p_{i_1}, \ldots, p_{i_k}\}$. Then,*

1. *$f_{\mathcal{P}}$ in S_i and S_j is given by*

$$f_{\mathcal{P}}\big|_{S_i}(x) = U_i V_i^{-1} \begin{bmatrix} x^{\mathrm{T}} & 1 \end{bmatrix}^{\mathrm{T}}, \qquad f_{\mathcal{P}}\big|_{S_j}(x) = U_j V_j^{-1} \begin{bmatrix} x^{\mathrm{T}} & 1 \end{bmatrix}^{\mathrm{T}},$$
$$U_i = \begin{bmatrix} q_{i_1} & \cdots & q_{i_{d+1}} \end{bmatrix}, \qquad U_j = \begin{bmatrix} q_{i_1} & \cdots & q_{i_k} & q_{j_{k+1}} & \cdots & q_{j_{d+1}} \end{bmatrix},$$
$$V_i = \begin{bmatrix} p_{i_1} & \cdots & p_{i_{d+1}} \\ 1 & & 1 \end{bmatrix}, \qquad V_j = \begin{bmatrix} p_{i_1} & \cdots & p_{i_k} & p_{j_{k+1}} & \cdots & p_{j_{d+1}} \\ 1 & & 1 & 1 & & 1 \end{bmatrix}.$$

Then $U_i V_i^{-1} \begin{bmatrix} x^{\mathrm{T}} & 1 \end{bmatrix}^{\mathrm{T}} = U_j V_j^{-1} \begin{bmatrix} x^{\mathrm{T}} & 1 \end{bmatrix}^{\mathrm{T}}$ for $x \in \operatorname{aff}(S_i \cap S_j)$.

2. *In nonhomogeneous form, let $f_{\mathcal{P}}\big|_{S_i}(x) = A_i x + b_i$ and $f_{\mathcal{P}}\big|_{S_j}(x) = A_j x + b_j$. Let L be the linear subspace parallel to $\operatorname{aff}(S_i \cap S_j)$. Then $L \subseteq \mathcal{N}(A_i - A_j)$.*

CLAIM 6 (continuity in vertices). *Consider two continuous PL functions, $f_{\mathcal{P}}^*$ parameterized by $\mathcal{P}^* = (P^*, Q^*, \mathcal{S}^*)$ and $f_{\mathcal{P}}$ parameterized by $(P, Q, \mathcal{S}^*)$, such that $|\mathcal{T}(P, \mathcal{S}^*)| = |\mathcal{T}(P^*, \mathcal{S}^*)|$. Let $c > 0$. There exists $c' = c'(\mathcal{P}^*, c)$ such that, for $0 < \epsilon < r_3$, where*

$$r_3 = \min_{S^* \in \mathcal{T}(P^*, \mathcal{S}^*)} \sup \left\{ \epsilon \,\middle|\, \mathcal{D}(S^*, \epsilon) \subseteq |\operatorname{Cl} \operatorname{St} S^*| \right\}. \tag{A.2}$$

If $\|p_i - p_i^*\| < \epsilon$ and $\|q_i - q_i^*\| < c\epsilon$ for all i, then

$$\|f_{\mathcal{P}} - f_{\mathcal{P}}^*\|_\infty < c'\epsilon.$$

That is, a continuous PL function is continuous in its vertices.

The explicit form for c' is provided in [20].

CLAIM 7. *Let $f_{\mathcal{P}}$ be a PL function parameterized by $\mathcal{P} = (P, Q, \mathcal{S})$. If $\mathcal{T}(Q, \mathcal{S})$ is also a triangulation, then the PL function is invertible on its range, and the inverse, ${f_{\mathcal{P}}}^{-1}$, is parameterized by $\mathcal{P}^{-1} = (Q, P, \mathcal{S})$.*

CONSISTENCY OF GENERALIZED FINITE DIFFERENCE SCHEMES FOR THE STOCHASTIC HJB EQUATION*

J. FRÉDÉRIC BONNANS† AND HOUSNAA ZIDANI‡

Abstract. We analyze a class of numerical schemes for solving the HJB equation for stochastic control problems, which enters the framework of Markov chain approximations and generalizes the usual finite difference method. The latter is known to be monotonic, and hence valid, only if the scaled covariance matrix is dominant diagonal. We generalize this result by, given the set of neighboring points allowed to enter the scheme, showing how to compute effectively the class of covariance matrices that is consistent with this set of points. We perform this computation for several cases in dimensions 2, 3, and 4.

Key words. stochastic control, finite differences, viscosity solutions, consistency, HJB equation

1. Motivation.

This paper is devoted to the discussion of numerical algorithms for solving stochastic optimal control problems. In order to simplify the presentation of the main ideas, consider the following model problem (Fleming and Rishel [4] and Lions and Bensoussan [7]):

$$(P_x) \qquad \begin{cases} \operatorname{Min} W(x,u) = \mathbb{E}\int_0^\infty \ell(y_{x,u}(t), u(t))e^{-\lambda t}\mathrm{d}t; \\ \begin{cases} \mathrm{d}y_{x,u}(t) = f(y_{x,u}(t), u(t))\mathrm{d}t + \sigma(y_{x,u}(t), u(t))\mathrm{d}w(t), \\ y_{x,u}(0) = x, \end{cases} \\ u(t) \in U, \quad t \in [0, \infty[. \end{cases}$$

Here $y_{x,u}(t) \in \mathbb{R}^n$ is the state variable, $u(t) \in \mathbb{R}^m$ is the control variable that for almost all t must belong to the set $U \subset \mathbb{R}^m$, $\lambda > 0$ is the discounting factor, $\ell : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}$ is a distributed cost, $f : \mathbb{R}^n \times \mathbb{R}^m \to \mathbb{R}^n$ is a deterministic dynamics, $\sigma(\cdot,\cdot)$ is a mapping from $\mathbb{R}^n \times \mathbb{R}^m$ into the space of $n \times r$ matrices, and w is a standard r dimensional Brownian motion. We are assuming full observation of the state, and we are looking for a control in the class of feedback controls. In what follows we assume f, σ, and ℓ to be Lipschitz and bounded. Then the solution to the stochastic differential equation and the associated cost are well defined (see, e.g., Fleming and Soner [5]). The covariance matrix is defined as

$$a(x,u) := \sigma(x,u)\sigma(x,u)^\top \quad \forall \ (x,u) \in \mathbb{R}^n \times \mathbb{R}^m, \tag{1.1}$$

where by $\top$ we denote the transposition operator. It is known (see Lions [8] and Fleming and Soner [5]) that the value function V of problem (P_x), defined by $V(x) =$

$\inf_u W(x,u)$, is the unique bounded viscosity solution of the Hamilton–Jacobi–Bellman (HJB) equation

$$\lambda V(x) \quad = \quad \mathcal{H}(x, V_x(x), V_{xx}(x)) \quad \forall\, x \in \mathbb{R}^n, \tag{1.2}$$

the Hamiltonian $\mathcal{H}$ being defined as

$$\mathcal{H}(x,p,Q) := \inf_{u\in U} \left\{ \ell(x,u) + f(x,u)\cdot p + \tfrac{1}{2} \sum_{i,j=1}^{n} a_{ij}(x,u)\, Q_{ij} \right\}, \tag{1.3}$$

where $x \in \mathbb{R}^n$, $p \in \mathbb{R}^n$, and Q is an $n\times n$ symmetric matrix. A basic idea for discretizing this problem is as follows (an up-to-date synthesis of this approach is given in Kushner and Dupuis [6]). Consider a regular grid G^h of discretization of the state space $\mathbb{R}^n$, with discretization steps $h = (h_1, \ldots, h_n)$. With the coordinate $k = (k_1, \ldots, k_n)$ in $\mathbb{Z}^n$ is associated the point $x_k \in \mathbb{R}^n$ of the form

$$x_k := (k_1 h_1, \ldots, k_n h_n). \tag{1.4}$$

Of course the real computations should be performed on a finite grid. However, we will not discuss this point, and we rather analyze the result of computations on this infinite grid. Let us consider an optimal control problem for a Markov chain on the grid G^h. Let $\{X^h_q, q \geq 0\}$ be the states of the Markov chain at time q, with transition probabilities denoted $p^h(x,y\,|\,u)$, where $u \in U$ is the canonical control value. Let Δt^h be an *interpolation interval* satisfying $\Delta t^h \to 0$ as $h \to 0$, and let $\mathbb{E}^{h,u}_{k,q}$ be the conditional expectation of X^h_{q+1}, given that $\{X^h_q = x_k\}$, and the control value u. Suppose that the chain obeys the following *local consistency* conditions:

$$\mathbb{E}^{h,u}_{k,q}\left[X^h_{q+1} - x_k\right] = \Delta t^h f(x_k,u) + o(\Delta t^h), \tag{1.5a}$$

$$\mathrm{Cov}^{h,u}_{k,q}\left[X^h_{q+1} - x_k\right] = \Delta t^h a(x_k,u) + o(\Delta t^h), \tag{1.5b}$$

$$\sup_q \left|X^h_{q+1} - X^h_q\right| \to 0. \tag{1.5c}$$

A possible adaptation for the cost function to this Markov chain is the following:

$$W^h(x,u^h) = \Delta t^h \mathbb{E}\left[\sum_{q\geq 0} \ell(X^h_q, u^h_q)(1+\lambda\Delta t^h)^{-q-1}\right], \tag{1.6}$$

where $u^h = (u^h_q)$, and $u^h_q \in U$ denote the random variable which represents the control action for the chain at discrete time q. Then the dynamic programming equation for the controlled chain $\{X^h_q, q\geq 0\}$ and the cost (1.6) is

$$V^h(x_k) = (1+\lambda\Delta t^h)^{-1} \operatorname*{Min}_{u\in U} \left[\Delta t^h \ell(x_k,u) + \sum_{y\in G^h} p(x_k, y \mid u) V^h(y)\right] \tag{1.7}$$

for $x_k \in G^h$. It is known that the function V^h converges uniformly over compact sets to the value function V for the original problem, as $h \to 0$, whenever the “local consistency” conditions (1.5) are satisfied, the interpolation interval possibly depending on (x,u); see Kushner and Dupuis [6].

Now the Markov chain approximation method consists of finding a chain $\{X_q^h\}$ satisfying the "local consistency" (1.5). A standard way for the construction of such an approximating chain is to use the finite difference approximations. However, this works only if the matrix a has a dominant diagonal (see section 3 for details), whereas this matrix may be an arbitrary semidefinite positive matrix. In some cases it is possible to make a change of variables in the state space in order for this hypothesis to be satisfied; see, e.g., Kushner and Dupuis [6, section 5.4]. However, when the control enters the matrix σ, and hence also in a, this is no longer possible in general. By contrast, the Markov chain approximation method is, in principle, able to handle the case when the covariance matrix is not dominant diagonal. In fact, relation (1.5) essentially gives linear relations (to be satisfied approximately) on the transition probabilities, while the latter have to be nonnegative and of sum equal to 1. Several questions then arise. First of all, since the Markov chain represents the discretization of a partial differential equation, it is highly desirable to limit the transitions from one point of the grid to other points that are not too far away. Also, for computational complexity reasons, the number of transitions should be as small as possible.

We are led then to the following question. Given a point in the grid with coordinate k and a control, choose a set of other points in the grid to which transitions are allowed. For instance we may allow transitions to points for which the coordinates k' are such that $|k'_i - k_i| \leq 1$ for all i. More generally, we choose a set of neighbors defined by constraints on the difference of coordinates $k' - k$. Is it possible then to compute consistent transition probabilities? In other words, what is the class of covariance matrices that is compatible with such a choice of possible transitions? And then what is the cost of computing the transition probabilities themselves? Finally, on what basis should we choose the neighbors?

These are several delicate questions. The paper is essentially devoted to the first of them, i.e., how to check the consistency condition. Note that our results apply also to finite horizon problems, in which the value function depends on time and space, since the analysis of consistency for these problems leads basically to questions of the same nature. Similarly, we discuss only explicit schemes, but implicit schemes (in connection to the policy iteration methods; see Kushner and Dupuis [6, section 6.2]) also lead to the same questions, and our results apply also to this case. Note that in the case of a covariance matrix that is a smooth function of the state only, it is possible to state a consistent approximation using finite elements; see Chung, Hanson, and Xu [3]. However, it is not easy to extend this idea to the case when the covariance matrix either is not differentiable or depends also on the control.

2. Generalized finite differences.

Let us present a generalization of the usual finite difference schemes; we will see later that these generalized finite differences are in fact a particular case of Markov chain approximation. Let $\varphi = \{\varphi_k\}$ be a real valued function over $\mathbb{Z}^n$. With $\xi \in \mathbb{Z}^n$, associate the *shift* operator δ_ξ defined by $\delta_\xi \varphi_k := \varphi_{\xi+k}$. Consider the finite difference operator $\Delta_\xi = \delta_\xi + \delta_{-\xi} - 2\delta_0$; in other words,

$$\Delta_\xi \varphi_k := \varphi_{k+\xi} + \varphi_{k-\xi} - 2\varphi_k = \varphi_{k+\xi} - \varphi_k - (\varphi_k - \varphi_{k-\xi}). \tag{2.1}$$

If Φ is a C^2 (twice continuously differentiable) function over $\mathbb{R}^n$, and $\varphi_k = \Phi(x_k)$ for all k, then by a standard Taylor expansion we have that

$$\Delta_\xi \varphi_k := \sum_{i,j=1}^{n} h_i h_j \xi_i \xi_j \Phi_{x_i x_j} + o(\|h\|^2). \tag{2.2}$$

For instance, when ξ is equal to e_i (the ith element of the natural basis of $\mathbb{R}^n$) and $e_i \pm e_j$, respectively, we obtain

$$\left\{ \begin{array}{lcl} \Delta_{e_i}\varphi_k & = & (h_i)^2\Phi_{x_ix_i} + o(\|h\|^2), \\ \Delta_{e_i \pm e_j}\varphi_k & = & (h_i)^2\Phi_{x_ix_i} + (h_j)^2\Phi_{x_jx_j} \pm 2h_ih_j\Phi_{x_ix_j} + o(\|h\|^2). \end{array} \right. \tag{2.3}$$

Denote v_k the approximation of the value function V at x_k. Let $D_k^u v_k$ be a notation for the upwind spatial finite difference

$$(D_k^u v_k)_i = \frac{v_{k+e_i} - v_k}{h_i} \quad \text{if} \quad f(x_k,u)_i \geq 0, \quad \frac{v_k - v_{k-e_i}}{h_i} \quad \text{if not.} \tag{2.4}$$

Now let $\mathcal{S}$ be a finite set of $\mathbb{Z}^n \setminus \{0\}$ containing $\{e_1, \dots, e_n\}$. We consider explicit schemes based on the difference operators that we just discussed, namely

$$\lambda v_k \quad = \quad \inf_{u \in U} \left\{ \ell(x_k,u) + f(x_k,u) \cdot D_k^u v_k + \sum_{\xi \in \mathcal{S}} \alpha_{k,\xi}^u \Delta_\xi v_k \right\} \tag{2.5}$$

for all $k \in \mathbb{Z}^n$. We will see soon how to choose the coefficients $\alpha_{k,\xi}^u$ in order to have a convergent approximation. Note that, since $\Delta_\xi = \Delta_{-\xi}$, we may assume without loss of generality that either $\alpha_{k,\xi}^u$ or $\alpha_{k,-\xi}^u$ is zero for all ξ. In particular, we may assume that $\alpha_{k,-e_i}^u$ is zero for all i. Note that there are possibilities other than (2.4) for discretizing the first-order term. For instance, it may be useful to consider centered differences in order to obtain (if the solution is smooth enough) higher orders of accuracy. However, since the difficulty for obtaining consistency lies in the discretization of the second-order term in the HJB equation, we will not elaborate on this.

Let $\Delta t^h > 0$ denote a *fictitious* time step (fictitious in the sense that the discrete scheme involves space, but not time, so that this time step has no influence on the solution). Multiplying (2.5) by Δt^h and adding v_k on both sides, we get

$$\begin{array}{l} v_k := (1 + \lambda\Delta t^h)^{-1}, \\ \displaystyle\inf_{u \in U} \left\{ v_k + \Delta t^h\, \ell(x_k,u) + \Delta t^h\, f(x_k,u) \cdot D_k^u v_k + \Delta t^h \sum_{\xi \in \mathcal{S}} \alpha_{k,\xi}^u \Delta_\xi v_k \right\}. \end{array} \tag{2.6}$$

With straightforward calculations, we can remark that the approximation (2.6) can be written in the form of (1.7), with the following transition probabilities:

$$\begin{aligned} & p^h(x_k, x_k \mid u) = 1 - \Delta t^h \sum_{i=1}^n \left(\frac{|f_i(x_k,u)|}{h_i} + 2\sum_{\xi \in \mathcal{S}} \alpha_{k,\xi}^u \right), \\ & p^h(x_k, x_{k \pm e_i} \mid u) = \Delta t^h \left(\frac{f_i^{\pm}(x_k,u)}{h_i} + \alpha_{k,e_i}^u \right), \\ & p^h(x_k, x_{k \pm \xi} \mid u) = \Delta t^h\, \alpha_{k,\xi}^u \qquad \text{for } \xi \in \mathcal{S}, \xi \neq e_i, \\ & p^h(x_k, y) = 0 \qquad \text{for } y \notin x_{k+\mathcal{S}}, \end{aligned}$$

where $f_i^+(x_k,u) = \max(f_i(x_k,u),0)$ and $f_i^-(x_k,u) = -\min(f_i(x_k,u),0)$.

Note that the sum of transition probabilities is, whatever the choice of coefficients $\alpha_{k,\xi}^u$, equal to one. However, that these transition probabilities are nonnegative adds the following condition on $\alpha^u_{k,\xi}$:

$$\alpha^u_{k,\xi} \geq 0 \ \ \forall\, (\xi, k, u) \in \mathcal{S} \times \mathbb{Z}^n \times U, \tag{2.7a}$$

$$\sum_{i=1}^{n} \frac{|f_i(x_k, u)|}{h_i} + 2\sum_{\xi\in\mathcal{S}} \alpha^u_{k,\xi} \leq \left(\Delta t^h\right)^{-1} \ \ \forall\, (k, u) \in \mathbb{Z}^n \times U. \tag{2.7b}$$

The second condition (2.7b) is always satisfied, when Δt^h is small enough, if the left-hand side of (2.7b) is uniformly bounded. We obtain in (2.16) such a bound. Here again we could take the more general point of view of having a time step depending on (x, u). Again, we prefer not to be general in order to concentrate on the main difficulties.

Assume (2.7) to be satisfied (we will see that (2.7b) is satisfied as soon as the time step is small enough) so that the scheme is a Markov chain approximation (of a specific type), since transition probabilities to points of the form $x_{k\pm\xi}$ are equal if $\xi \neq e_i$ for some i. We therefore concentrate on the local consistency condition (1.5). Since the terms multiplied by each coefficient $\alpha^u_{k,\xi}$ have a mean equal to x_k, we have that

$$\mathbb{E}^{h,u}_{k,q}\left[X^h_{q+1} - x_k\right] = \Delta t^h \sum_i f^+_i(x_k, u)e_i - \Delta t^h \sum_i f^-_i(x_k, u)e_i = \Delta t^h f(x_k, u) \tag{2.8}$$

so that condition (1.5a) is always satisfied. This in turn implies, denoting $\hat{x} := x_k + \Delta t^h f(x_k, u)$,

$$\mathrm{Cov}^{h,u}_{k,q}\left[X^h_{q+1} - x_k\right] = \mathbb{E}^{h,u}_{k,q}\left[(X^h_{q+1} - \hat{x}_k)(X^h_{q+1} - \hat{x}_k)^\top\right] + o(\Delta t^h) \tag{2.9}$$

and, therefore,

$$\mathrm{Cov}^{h,u}_{k,q}\left[X^h_{q+1} - x_k\right] = \Delta t^h \sum_{\xi\in\mathcal{S}} \sum_{i,j} h_i h_j \xi_i \xi_j \alpha^u_{k,\xi} e_i e_j^\top + o(\Delta t^h). \tag{2.10}$$

In view of (2.10), and since $\Delta t^h \to 0$ as $h \to 0$, local consistency holds iff we have

$$\sum_{\xi\in\mathcal{S}} \sum_{i,j} h_i h_j \xi_i \xi_j \alpha^u_{k,\xi} e_i e_j^\top = a(x_k, u) + o(1). \tag{2.11}$$

In what follows, we discuss the *strong consistency* property

$$\sum_{i,j} h_i h_j \xi_i \xi_j \alpha^u_{k,\xi} e_i e_j^\top = a(x_k, u) \quad \forall\ k \in \mathbb{Z}^n. \tag{2.12}$$

Let a^h denote the scaled covariance matrix $\{a_{ij}/h_i h_j\}$. Then a condition equivalent to (2.12) is

$$\sum_{\xi\in\mathcal{S}} \alpha^u_{k,\xi} \xi \xi^\top = a^h(x_k, u) \quad \forall\ k \in \mathbb{Z}^n. \tag{2.13}$$

Since every $\alpha^u_{k,\xi}$ is nonnegative, strong consistency means that the symmetric matrix $a^h(x_k, u)$ belongs, for all k and u, to the cone generated by the set $\{\xi\xi^\top; \xi \in \mathcal{S}\}$ that we denote

$$\mathcal{C}(\mathcal{S}) := \left\{ \sum_{\xi\in\mathcal{S}} \alpha_\xi \xi \xi^\top; \alpha \in \mathbb{R}^{|\mathcal{S}|}_+ \right\}. \tag{2.14}$$

Note that strong consistency implies a bound on the coefficients $\alpha^u_{k,\xi}$, which in turn allows us to obtain an estimate of the fictitious time step.

LEMMA 2.1. *Assume that the strong consistency condition holds. Then*

$$\sum_{\xi\in\mathcal{S}} \alpha^u_{k,\xi} \leq \operatorname{trace} a^h(x_k,u), \tag{2.15}$$

and hence condition (2.7b) *for the fictitious time step is satisfied whenever*

$$\sum_{i=1}^{n} \frac{\|f_i\|_\infty}{h_i} + 2\|\operatorname{trace} a^h\|_\infty \leq \left(\Delta t^h\right)^{-1}. \tag{2.16}$$

Proof. Taking the trace of both sides of (2.13), and since the trace of $\xi\xi^\top$ is greater than or equal to 1, obtain (2.15). The second part of the lemma is immediate. □

It follows from this lemma that, when $h \downarrow 0$, we may take Δt^h of order $O(\min_i h_i^2)$, as expected.

Now we can summarize the results of this section in the following theorem.

THEOREM 2.2. *Let $\mathcal{S}$ be a fixed finite set of $\mathbb{Z}^n \setminus \{0\}$ containing $\{e_1,\dots,e_n\}$, and let h be a fixed step size. Assume that, for every $k \in \mathbb{Z}^n$ and every $u \in U$, the scaled covariance matrix $a^h(x_k,u)$ belongs to the cone $\mathcal{C}(\mathcal{S})$. Then the scheme* (2.6) *is a consistent Markov chain approximation whenever the coefficients $(\alpha^u_{k,\xi})$ are nonnegative and satisfy condition* (2.13)*, the time step being such that* (2.16) *is satisfied.*

As said before, condition (2.16) is not really restrictive since Δt^h is just a fictitious time step. Note that implicit schemes can be used, as already mentioned, in connection with the policy iteration algorithm, and in that case it is easily seen that one can take a time step of order $O(\min_i h_i)$. Similar results hold in the finite horizon case. The most important condition in the above theorem is that the scaled matrix might belong to the cone $\mathcal{C}(\mathcal{S})$. Before going on the characterization of $\mathcal{C}(\mathcal{S})$, we will first compare our scheme to the classical finite differences approximations.

Remark 2.1. The results of this section are close to the analysis in section 5.4.4 of [6], where consistency for an arbitrary set of transition to neighbors is discussed. The point of view of this paper is rather to fix the set $\mathcal{S}$ of the neighbors allowed to enter the scheme and then to characterize the class of covariance matrices for which consistency holds. We will see in sections 4 and 5 (and this is the main novelty of the paper) how to obtain an effective characterization.

Remark 2.2. It is possible to study consistency taking the point of view of the discretization of the HJB equation (1.2), the solution being defined in the sense of viscosity. Barles and Souganidis [2] give a systematic way of obtaining convergent approximation schemes for second-order partial differential equations whose solution satisfies some strong uniqueness property. Their approach applies to (1.2) and leads to the same conditions as those of Theorem 2.2.

3. Classical finite differences approximations.

Let us show that the generalized finite difference algorithm, given in the above section, is indeed a generalization of the classical finite differences approximations that we recall now. Let Φ be a C^2 function over $\mathbb{R}^n$, and let $\varphi_k := \Phi(x_k)$ for all k. Given any $\xi \in \mathbb{Z}^n$, we can approximate the second-order derivatives of Φ by the following finite differences:

$$\frac{\delta_{\xi+e_i+e_j} - \delta_{\xi+e_i} - \delta_{\xi+e_j} + \delta_\xi}{h_i h_j}\varphi_k = \Phi_{x_i x_j}(x_k) + o(1). \tag{3.1}$$

Denote the corresponding operators as follows:

$$d_{ij}^{\xi} := \frac{\delta_{\xi+e_i+e_j} - \delta_{\xi+e_i} - \delta_{\xi+e_j} + \delta_{\xi}}{h_i h_j}. \tag{3.2}$$

Viewing i (resp., j) as the first (resp., second) coordinate, when $\xi = 0$, we call this operator d_{ij}^{ξ} the right upper approximation of $\Phi_{x_i x_j}$. We can similarly define left upper, right lower, and left lower approximations of $\Phi_{x_i x_j}$ by taking ξ equal to $-e_i$, $-e_j$, and $-e_i - e_j$, respectively. By combining these amounts, we can define centered approximations; the corresponding operators are along the main and second diagonals:

$$D_{ij}^{+} := \tfrac{1}{2}(d_{ij}^{0} + d_{ij}^{-e_i-e_j}), \qquad D_{ij}^{-} := \tfrac{1}{2}(d_{ij}^{-e_i} + d_{ij}^{-e_j}). \tag{3.3}$$

In other words,

$$\begin{aligned} D_{ij}^{+} &= \frac{1}{2h_i h_j}(\delta_{e_i+e_j} + \delta_{-e_i-e_j} + 2\delta_0 - \delta_{e_i} - \delta_{-e_i} - \delta_{e_j} - \delta_{-e_j}), \\ D_{ij}^{-} &= \frac{1}{2h_i h_j}(\delta_{e_i} + \delta_{-e_i} + \delta_{e_j} + \delta_{-e_j} - \delta_{e_i-e_j} - \delta_{e_j-e_i} - 2\delta_0). \end{aligned} \tag{3.4}$$

In addition, for the approximation of diagonal second-order derivatives we take the standard centered formula

$$D_{ii} := \frac{\delta_{e_i} + \delta_{-e_i} - 2\delta_0}{h_i h_i}. \tag{3.5}$$

The classical finite differences approximation of (1.2) is

$$\begin{aligned} \lambda v_k &= \inf_{u \in U} \left(\ell(x_k,u) + f(x_k,u) \cdot D_k^u v_k + \tfrac{1}{2} \sum_{i,j=1}^{n} a_{ij}(x_k,u) D_{ij}^{\pm} v_k \right) \\ &\quad \forall\ k \in \mathbb{Z}^n,\ \ q \in \mathbb{N}, \\ y_k^0 &= 0 \quad \forall\ k \in \mathbb{Z}^n, \end{aligned} \tag{3.6}$$

where if $i \neq j$, $D_{ij}^{\pm}$ is equal either to D_{ij}^{+} or D_{ij}^{-} and D_k^u is the upwind spatial finite difference defined in (2.4). The above scheme is equivalent to the following one:

$$\begin{aligned} &v_k := (1+\lambda \Delta t^h)^{-1}, \\ &\qquad \inf_{u \in U} \left\{ v_k + \Delta t^h \ell(x_k,u) + \Delta t^h f(x_k,u) \cdot D_k^u v_k + \tfrac{1}{2}\Delta t^h \sum_{i,j=1}^{n} a_{ij}(x_k,u) D_{ij}^{\pm} v_k. \right\}. \end{aligned} \tag{3.7}$$

It is known that this scheme is a consistent Markov chain approximation under restrictive assumptions that we make explicit now (this is a reformulation of known results; see, e.g., [6] or [9]).

Lemma 3.1. *The classical finite differences approximation scheme can be interpreted as a consistent Markov chain approximation iff the following three conditions hold:*

(i) *If $i \neq j$ is such that $a_{ij}(x_k,u) \neq 0$, then $D_{ij}^{\pm} = D_{ij}^{+}$ if $a_{ij}(x_k,u) > 0$ and $D_{ij}^{\pm} = D_{ij}^{-}$ if $a_{ij}(x_k,u) < 0$;*

(ii) *The matrix* $a^h(x_k,u)$ *is dominant diagonal or, equivalently,*

$$\frac{a_{ii}(x_k,u)}{h_i} \geq \sum_{j\neq i} \frac{|a_{ij}(x_k,u)|}{h_j} \quad \forall \ i=1,\dots,n; \tag{3.8}$$

(iii) *The time step* Δt^h *satisfies the following condition:*

$$\sum_{i=1}^{n} \frac{|f(x_k,u)_i|}{h_i} + \sum_{i=1}^{n} \left(2\frac{a_{ii}(x_k,u)}{h_i^2} - \sum_{j\neq i} \frac{|a_{ij}(x_k,u)|}{h_i h_j} \right) \leq \left(\Delta t^h\right)^{-1}. \tag{3.9}$$

We now make explicit the link between the two approaches by expressing the classical finite differences approximation scheme as a Markov chain approximation scheme. If the conditions of the above lemma are satisfied, then we can write the approximation of second-order terms as

$$\begin{aligned} \sum_{i,j=1}^{n} a_{ij}(x_k,u) D_{ij}^{\pm} &= \sum_{\substack{i\neq j \\ a_{ij}>0}} \frac{a_{ij}}{h_i h_j} \Delta_{e_i+e_j} - \sum_{\substack{i\neq j \\ a_{ij}<0}} \frac{a_{ij}}{h_i h_j} \Delta_{e_i-e_j} \\ &\quad + \sum_{i} \left(\frac{a_{ii}}{(h_i)^2} - \sum_{j\neq i} \frac{|a_{ij}|}{h_i h_j} \right) \Delta_{e_i}. \end{aligned} \tag{3.10}$$

The weights of the transitions are nonnegative iff condition (ii) of Lemma 3.1 is satisfied. It follows that the classical finite difference scheme is equivalent to the generalized finite difference scheme where the set $\mathcal{S}$ is equal to

$$\hat{\mathcal{S}} := \{e_1,\dots,e_n\} \cup \{e_i \pm e_j, 1 \leq i \neq j \leq n\}.$$

We have that $\mathcal{C}(\hat{\mathcal{S}})$ is precisely the cone of dominant diagonal matrices.

4. Characterization of finitely generated cones. Let us come back to the analysis of the generalized finite difference method. In what follows we will concentrate on characterizations of the strong consistency condition, with special attention to the case when $\mathcal{S}$ is the set $\mathcal{S}^q$ of neighboring points of order q, defined by

$$\mathcal{S}^q := \{\xi \in \mathbb{Z}^n; |\xi_i| \leq q, \ i=1,\dots,n\}. \tag{4.1}$$

Characterizing a finitely generated cone happens to be a classical problem of convex analysis and polyhedral combinatorics, and it can be solved using the notion of polar cone. Let us recall these classical results; an excellent reference on this subject is Pulleyblank [10].

Let $\mathcal{C}$ be a nonempty closed convex cone in $\mathbb{R}^p$. The associated (positively) polar cone is

$$\mathcal{C}^* = \{x^* \in X^* \ ; \ \langle x^*, x\rangle \geq 0 \quad \forall x \in \mathcal{C}\}.$$

It is known that $(\mathcal{C}^*)^* = \mathcal{C}$. Let $\mathcal{C}$ be finitely generated, say, by $g_1,\dots,g_q$. Then $\mathcal{C}^* = \bigcap_i \{x^* \in X^* \ ; \ \langle x^*, g_i\rangle \geq 0\}$. It happens that the set $\mathcal{C}^*$ is also finitely generated, say, by $g_1^*,\dots,g_r^*$; this dual generator can be computed by a certain recursion. Since $\mathcal{C} = (\mathcal{C}^*)^*$, it follows that

$$\mathcal{C} = \{x; \ \langle g_i^*, x\rangle \geq 0, \ i=1,\dots,r\}.$$

This means that the cone $\mathcal{C}$ is characterized by a finite number of linear inequalities whose coefficients can be computed.

Let us specialize this result to the case of the cone $\mathcal{C}(\mathcal{S})$. Let $\mathcal{M}$ be the set of symmetric matrices, and let $\mathcal{M}_+$ be the set of symmetric definite positive matrices. Using the Frobenius scalar product $A \cdot B = \sum_{i,j} A_{ij} B_{ij}$, for which $B \cdot \xi\xi^\top = \xi^\top B \xi$, for all square $n \times n$ symmetric matrices B and n dimensional vectors ξ, we have that the polar cone is

$$\mathcal{C}(\mathcal{S}^q)^* = \left\{ B \in \mathcal{M}\ ;\ \xi^\top B \xi \geq 0 \quad \forall \xi \in \mathcal{S} \right\}. \tag{4.2}$$

Consider the example when $\mathcal{S} = \mathcal{S}^q$ is defined in (4.1). Using the fact that $\mathcal{C}(\mathcal{S}^q)$ is strictly increasing with q and is a subset of the cone $\mathcal{M}_+$, and $(\mathcal{M}_+)^* = \mathcal{M}_+$, we have the infinite chain of strict inclusions

$$\mathcal{C}(\mathcal{S}^1) \subset \mathcal{C}(\mathcal{S}^2) \cdots \subset \mathcal{M}_+ \subset \cdots \mathcal{C}(\mathcal{S}^2)^* \subset \mathcal{C}(\mathcal{S}^1)^*. \tag{4.3}$$

It can be noticed that, since the cone $\mathcal{C}(\mathcal{S}^q)$ contains every nonnegative diagonal matrix, each element of its dual has a nonnegative diagonal.

An important observation is that $\mathcal{S}^q$, and therefore also $\mathcal{C}(\mathcal{S}^q)$, are invariant through the linear transformations in $\mathbb{R}^n$ that correspond to a permutation of coordinates and also correspond to the change of sign of coordinates. The permutation of coordinates i and j of $\xi \in \mathbb{R}^n$ result in the permutation of elements of $\xi\xi^\top$ of coordinates (i,k) and (j,k), and (k,i) and (k,j), for all k, while changing the sign of ξ_i results in changing the sign of elements of $\xi\xi^\top$ of coordinates (i,j) for $j \neq i$. Since these transformations are self-adjoint, for each $B \in \mathcal{C}(\mathcal{S}^q)^*$, the matrices obtained by the same (adjoint) transformations (so that the scalar product with B remains invariant) also belong to $\mathcal{C}(\mathcal{S}^q)^*$. In particular, a generator of $\mathcal{C}(\mathcal{S}^q)^*$ can be partitioned into classes of equivalence corresponding to the above mentioned transformations. This allows us to give a compact description of the set of generators.

5. Specific examples.

We have performed the computation of generators of dual cones using the Qhull algorithm by Barber, Dobkin, and Huhdanpaa [1]. The latter computes, given a finite set in $\mathbb{R}^m$, a minimal set of linear inequalities characterizing its convex hull. This computation is made using the floating-point arithmetic of the C language. However, the risk of numerical errors due to the floating-point arithmetic is limited, since we were able to compute a scaling of the data for which all coefficients are small integers, up to an absolute precision of 10^{-10}.

The link between the convex hull of a finite set and the generator of a dual cone is as follows. Consider a generator $g_1, \dots, g_n$, and set $g_0 := 0$. Then compute a minimal characterization of the convex hull of $g_0, \dots, g_n$ of the form $\langle g_i^*, \cdot \rangle \geq b_i$, $i = 1, \dots, r$. A minimal generator of the dual cone is given by the homogeneous inequalities; i.e., the dual cone is

$$\{ g \in \mathbb{R}^m;\ \ \langle g_i^*, g \rangle \geq b_i, \ \ i \in I \}$$

with $I := \{1 \leq i \leq r;\ \ b_i = 0\}$.

Our actual computations deal with spaces of symmetric matrices of size n. Each of them can be represented by its upper triangular part, and thus is viewed as an element of $\mathbb{R}^m$, $m = \frac{1}{2}n(n+1)$; in particular, $m = 3$, 6, and 10 for $n = 2$, 3, and 4, respectively.

Once a generator of the dual cone has been obtained, it remains to identify the classes of equivalence (defined in the previous section) in order to obtain compact expression. This was done by sorting the elements following the (ordered) weights of diagonal elements (the latter being, as we already know, nonnegative). It appears that this suffices for identifying the equivalence classes, as can be checked by generating them using the formulas given below and comparing both sets.

Dimension 2. In the case $n = 2$, we computed characterizations of the sets $\mathcal{C}(\mathcal{S}^q)$, $q = 1$ to 10. We display detailed results for $q = 1$ to 7. The set $\mathcal{C}(\mathcal{S}^1)$ is characterized by 4 constraints and 1 equivalence class:

$$a_{ii} \geq |a_{ij}|, \quad 1 \leq i \neq j \leq 2.$$

The set $\mathcal{C}(\mathcal{S}^2)$ is characterized by 8 constraints and 2 equivalence classes:

$$\begin{cases} 2a_{ii} \geq |a_{ij}|, \\ 2a_{ii} + a_{jj} \geq 3|a_{ij}| \end{cases}$$

for $1 \leq i \neq j \leq 2$. The set $\mathcal{C}(\mathcal{S}^3)$ is characterized by 16 constraints and 4 equivalence classes:

$$\begin{cases} 3a_{ii} \geq |a_{ij}|, \\ 3a_{ii} + 2a_{jj} \geq 5|a_{ij}|, \\ 6a_{ii} + a_{jj} \geq 5|a_{ij}|, \\ 6a_{ii} + 2a_{jj} \geq 7|a_{ij}| \end{cases}$$

for $1 \leq i \neq j \leq 2$. The set $\mathcal{C}(\mathcal{S}^4)$ is characterized by 24 constraints and 6 equivalence classes:

$$\begin{cases} 4a_{ii} \geq |a_{ij}|, \\ 4a_{ii} + 3a_{jj} \geq 7|a_{ij}|, \\ 6a_{ii} + a_{jj} \geq 5|a_{ij}|, \\ 6a_{ii} + 2a_{jj} \geq 7|a_{ij}|, \\ 12a_{ii} + a_{jj} \geq 7|a_{ij}|, \\ 12a_{ii} + 6a_{jj} \geq 17|a_{ij}| \end{cases}$$

for $1 \leq i \neq j \leq 2$. The set $\mathcal{C}(\mathcal{S}^5)$ is characterized by 40 constraints and 10 equivalence classes:

$$\begin{cases} 5a_{ii} \geq |a_{ij}|, \\ 5a_{ii} + 4a_{jj} \geq 9|a_{ij}|, \\ 10a_{ii} + 2a_{jj} \geq 9|a_{ij}|, \\ 10a_{ii} + 3a_{jj} \geq 11|a_{ij}|, \\ 12a_{ii} + a_{jj} \geq 7|a_{ij}|, \\ 12a_{ii} + 6a_{jj} \geq 17|a_{ij}|, \\ 15a_{ii} + 2a_{jj} \geq 11|a_{ij}|, \\ 15a_{ii} + 6a_{jj} \geq 19|a_{ij}|, \\ 20a_{ii} + a_{jj} \geq 9|a_{ij}|, \\ 20a_{ii} + 12a_{jj} \geq 31|a_{ij}| \end{cases}$$

for $1 \leq i \neq j \leq 2$. The set $\mathcal{C}(\mathcal{S}^6)$ is characterized by 48 constraints and 12 equivalence classes:

$$\begin{cases} 6_{ii} \geq |a_{ij}|, \\ 6a_{ii} + 5a_{jj} \geq 11|a_{ij}|, \\ 10a_{ii} + 2a_{jj} \geq 9|a_{ij}|, \\ 10a_{ii} + 3a_{jj} \geq 11|a_{ij}|, \\ 12a_{ii} + a_{jj} \geq 7|a_{ij}|, \\ 12a_{ii} + 6a_{jj} \geq 17|a_{ij}|, \\ 15a_{ii} + 2a_{jj} \geq 11|a_{ij}|, \\ 15a_{ii} + 6a_{jj} \geq 19|a_{ij}|, \\ 20a_{ii} + a_{jj} \geq 9|a_{ij}|, \\ 20a_{ii} + 12a_{jj} \geq 31|a_{ij}|, \\ 30a_{ii} + a_{jj} \geq 11|a_{ij}|, \\ 30a_{ii} + 20a_{jj} \geq 49|a_{ij}| \end{cases}$$

for $1 \leq i \neq j \leq 2$. The set $\mathcal{C}(\mathcal{S}^7)$ is characterized by 72 constraints and 18 equivalence classes:

$$\begin{cases} 7a_{ii} \geq |a_{ij}|, \\ 7a_{ii} + 6a_{jj} \geq 13|a_{ij}|, \\ 14a_{ii} + 3a_{jj} \geq 13|a_{ij}|, \\ 14a_{ii} + 4a_{jj} \geq 15|a_{ij}|, \\ 15a_{ii} + 2a_{jj} \geq 11|a_{ij}|, \\ 15a_{ii} + 6a_{jj} \geq 19|a_{ij}|, \\ 20a_{ii} + a_{jj} \geq 9|a_{ij}|, \\ 20a_{ii} + 12a_{jj} \geq 31|a_{ij}|, \\ 21a_{ii} + 2a_{jj} \geq 13|a_{ij}|, \\ 21a_{ii} + 10a_{jj} \geq 29|a_{ij}|, \\ 28a_{ii} + 2a_{jj} \geq 15|a_{ij}|, \\ 28a_{ii} + 15a_{jj} \geq 41|a_{ij}|, \\ 30a_{ii} + a_{jj} \geq 11|a_{ij}|, \\ 30a_{ii} + 20a_{jj} \geq 49|a_{ij}|, \\ 35a_{ii} + 6a_{jj} \geq 29|a_{ij}|, \\ 35a_{ii} + 12a_{jj} \geq 41|a_{ij}|, \\ 42a_{ii} + a_{jj} \geq 13|a_{ij}|, \\ 42a_{ii} + 30a_{jj} \geq 71|a_{ij}|. \end{cases}$$

Dimension 3. When $n = 3$, we computed characterizations of the sets $\mathcal{C}(\mathcal{S}^q)$, $q = 1$ to 2. The set $\mathcal{C}(\mathcal{S}^1)$ is characterized by

$$\begin{cases} a_{ii} \geq |a_{ij}|, \\ a_{ii} + a_{jj} \geq (-1)^p a_{ik} + (-1)^q a_{jk} + 2(-1)^{p+q+1} a_{ij} \end{cases}$$

for $i \neq j \neq k$ and $p, q \in \{1, 2\}$. As was expected, this cone is larger than the cone of dominant diagonal matrices. The set $\mathcal{C}(\mathcal{S}^2)$ is characterized by

$$\begin{cases}
2a_{ii} \geq |a_{ij}|,\\
2a_{ii} + a_{jj} \geq 3|a_{ij}|,\\
2a_{ii} + 2a_{jj} \geq 4(-1)^p a_{ij} + (-1)^q a_{jk} - (-1)^{p+q} a_{ik},\\
2a_{ii} + 2a_{jj} + a_{kk} \geq 4(-1)^p a_{ij} + 3(-1)^q a_{jk} - 3(-1)^{p+q} a_{ik},\\
3a_{ii} + 2a_{jj} + 2a_{kk} \geq 5(-1)^p a_{ij} + 4(-1)^q a_{jk} - 5(-1)^{p+q} a_{ik},\\
6a_{ii} + a_{jj} + a_{kk} \geq 5(-1)^p a_{ij} + 2(-1)^q a_{jk} - 5(-1)^{p+q} a_{ik},\\
6a_{ii} + 2a_{jj} + a_{kk} \geq 7(-1)^p a_{ij} + 3(-1)^q a_{jk} - 5(-1)^{p+q} a_{ik},\\
6a_{ii} + 2a_{jj} + 2a_{kk} \geq 7(-1)^p a_{ij} + 4(-1)^q a_{jk} - 7(-1)^{p+q} a_{ik},\\
8a_{ii} + 2a_{jj} \geq 8(-1)^p a_{ij} + (-1)^q a_{jk} - 2(-1)^{p+q} a_{ik},\\
8a_{ii} + 2a_{jj} + a_{kk} \geq 8(-1)^p a_{ij} + 3(-1)^q a_{jk} - 6(-1)^{p+q} a_{ik},\\
8a_{ii} + 3a_{jj} + 2a_{kk} \geq 10(-1)^p a_{ij} + 5(-1)^q a_{jk} - 8(-1)^{p+q} a_{ik},\\
8a_{ii} + 6a_{jj} + 2a_{kk} \geq 14(-1)^p a_{ij} + 7(-1)^q a_{jk} - 8(-1)^{p+q} a_{ik},\\
12a_{ii} + 2a_{jj} + a_{kk} \geq 10(-1)^p a_{ij} + 3(-1)^q a_{jk} - 7(-1)^{p+q} a_{ik},\\
12a_{ii} + 4a_{jj} + a_{kk} \geq 14(-1)^p a_{ij} + 4(-1)^q a_{jk} - 7(-1)^{p+q} a_{ik},\\
12a_{ii} + 6a_{jj} + 2a_{kk} \geq 17(-1)^p a_{ij} + 7(-1)^q a_{jk} - 10(-1)^{p+q} a_{ik},\\
12a_{ii} + 6a_{jj} + 4a_{kk} \geq 17(-1)^p a_{ij} + 10(-1)^q a_{jk} - 14(-1)^{p+q} a_{ik},\\
18a_{ii} + 2a_{jj} + a_{kk} \geq 12(-1)^p a_{ij} + 3(-1)^q a_{jk} - 9(-1)^{p+q} a_{ik},\\
18a_{ii} + 8a_{jj} + a_{kk} \geq 24(-1)^p a_{ij} + 6(-1)^q a_{jk} - 9(-1)^{p+q} a_{ik},\\
18a_{ii} + 10a_{jj} + 2a_{kk} \geq 27(-1)^p a_{ij} + 9(-1)^q a_{jk} - 12(-1)^{p+q} a_{ik}.
\end{cases}$$

Dimension 4. When $n = 4$, the set $\mathcal{C}(\mathcal{S}^1)$ is characterized by

$$\left\{\begin{array}{ll}
a_{ii} & \geq |a_{ij}|,\\
a_{ii} + a_{jj} & \geq (-1)^p a_{ik} + (-1)^q a_{jk} - 2(-1)^{p+q} a_{ij},\\
a_{ii} + a_{jj} + a_{kk} & \geq (-1)^p a_{il} + (-1)^q a_{jl} + (-1)^r a_{kl}\\
 & -2(-1)^{p+q} a_{ij} - 2(-1)^{p+r} a_{ik} - 2(-1)^{q+r} a_{jk},\\
2a_{ii} + a_{jj} + a_{kk} + a_{ll} & \geq 3(-1)^p a_{ij} + 3(-1)^q a_{ik} + 3(-1)^r a_{il}\\
 & -2(-1)^{p+q} a_{jk} - 2(-1)^{p+r} a_{jl} - 2(-1)^{q+r} a_{kl},\\
4a_{ii} + a_{jj} + a_{kk} & \geq 2(-1)^p a_{il} + (-1)^q a_{jl} + (-1)^r a_{kl}\\
 & -4(-1)^{p+q} a_{ij} - 4(-1)^{p+r} a_{ik} - 2(-1)^{q+r} a_{jk},\\
4a_{ii} + 2a_{jj} + a_{kk} + a_{ll} & \geq 6(-1)^p a_{ij} + 4(-1)^q a_{ik} + 4(-1)^r a_{il}\\
 & -3(-1)^{p+q} a_{jk} - 3(-1)^{p+r} a_{jl} - 2(-1)^{q+r} a_{kl}
\end{array}\right.$$

for $i \neq j \neq k \neq l$ and $p, q, r \in \{1, 2\}$.

Summary of results. The following table summarizes the various steps of our calculation and highlights the importance of reduction of constraints using the classes of equivalence.

Here $\mathcal{S}^*$ is the set of matrices in $\mathcal{S}$ of trace not greater than 1.

n	q	Size of generator of primal cone	# of constraints defining $\mathcal{S}^*$	# of constraints defining $\mathcal{C}$	# of classes of equivalence
2	1	4	6	4	1
2	2	8	13	8	2
2	3	16	27	16	4
2	4	24	39	24	6
2	5	40	67	40	10
2	6	48	87	48	12
2	7	72	123	72	18
2	8	88	159	88	22
2	9	112	203	112	28

3	2	49	563	372	19
4	1	40	476	328	6

6. Discussion of results. In this paper we have worked in the framework of "Markov chain approximations" discussed in Kushner and Dupuis [6]. Our main result is a method for computing a characterization of the class of covariance matrices that are strongly consistent with an a priori choice of neighboring points to which transitions are allowed. In the computation and display of the results, we use in an essential way the property of invariance of these cones with respect to some transformations. Although we are looking for linear inequalities with integer coefficients, the computations were made in floating-point arithmetic. However, once properly scaled, the results are up to a precision of 10^{-10} equal to very small integers, as may be seen in the table above, and hence it seems that these results are exact, despite the fact that our method is not a mathematical proof (we tried an exact approach based on computer algebra, but without success, since many singularities were encountered). So, we have performed the computations, giving explicit results, for dimensions of the state space between 2 and 4, and when only a limited number of neighboring points are allowed (which is a highly desirable feature). This said, it seems that we have performed the computations for essentially all cases for which the numerical resolution of the stochastic HJB equation is of reasonable complexity. Indeed, when the number of linear inequalities characterizing strongly consistent matrices is large, we may expect that computing the coefficient of the algorithm will be expensive.

On the other hand, our results are only a preliminary step towards an efficient numerical algorithm. There are two main difficulties. The first is designing fast algorithms for computing the coefficients $\alpha_{k,\xi}^u$. The latter are, by definition, solutions of a linear programming problem, but using a linear programming solver for each control at each point of the grid would be inefficient. The second difficulty is dealing with the case when consistency does not hold, e.g., by approximating the matrix $a(x_k, u)$ by a consistent matrix and then performing an error analysis. We are now pursuing some research in these directions.

Acknowledgment. We thank the three anonymous referees for their useful remarks.

SCALED PIVOTS AND SCALED PARTIAL PIVOTING STRATEGIES*

J. M. PEÑA[†]

Abstract. Scaled pivots for Gaussian elimination of an $n \times n$ matrix are introduced. They are used to obtain bounds for the Skeel condition number of the resulting upper triangular matrix and for a growth factor which has been introduced by Amodio and Mazzia [*BIT*, 39 (1999), pp. 385–402]. A bound of this growth factor for row scaled partial pivoting strategies is also included. It is proved that the Skeel condition number of an $n \times n$ upper triangular matrix which is strictly diagonally dominant by rows is bounded above by a number which is independent of n. It is also shown that the calculation of the n scaled pivots associated with a pivoting strategy presenting nice properties when applied to nonsingular $n \times n$ M-matrices adds $\mathcal{O}(n)$ elementary operations to the complete cost of this pivoting strategy.

Key words. growth factor, Gaussian elimination, scaled partial pivoting, Skeel condition number

1. Introduction and basic notations.

The growth factor is an indicator of the stability of Gaussian elimination. The classical growth factor of an $n \times n$ matrix $A = (a_{ij})_{1 \le i,j \le n}$ is the number

$$\rho^W(A) := \frac{\max_{i,j,k} |a_{ij}^{(k)}|}{\max_{i,j} |a_{ij}|}. \tag{1.1}$$

On p. 398 of [1], Amodio and Mazzia have introduced the growth factor

$$\rho(A) := \frac{\max_k \|A^{(k)}\|_\infty}{\|A\|_\infty} \tag{1.2}$$

and have shown its nice behavior for the error analysis of Gaussian elimination. Conditioning is another important concept to be considered in such error analysis. The traditional condition number of a matrix A with respect to the norm $\| \cdot \|_\infty$ is given by $\kappa(A) := \|A\|_\infty \, \|A^{-1}\|_\infty$. Given a matrix $B = (b_{ij})_{1 \le i,j \le n}$, we shall denote $|B|$ the matrix of absolute values of the entries of B. If we write $A \le B$, it means $a_{ij} \le b_{ij}$ for all i, j. The Skeel condition number (cf. [9]) of a matrix A is defined as

$$\mathrm{Cond}(A) = \| \, |A^{-1}| \, |A| \, \|_\infty.$$

Let us mention two nice properties of $\mathrm{Cond}(A)$. The Skeel condition number of a matrix A is less than or equal to $\kappa(A)$, and it can be much smaller. In contrast with $\kappa(A)$, $\mathrm{Cond}(A)$ is invariant under row scaling.

The first topic considered in this paper is the introduction of the scaled pivots associated with the performance of Gaussian elimination of a nonsingular $n \times n$ matrix

with any given pivoting strategy. A scaled pivot is the quotient between the absolute value of the pivot and the norm of the corresponding row. The computational cost of calculating all possible scaled pivots is $\mathcal{O}(n^2)$ elementary operations per step of Gaussian elimination. If we have obtained n pivots after the complete performance of a given pivoting strategy, the additional cost of calculating the corresponding n scaled pivots is $\mathcal{O}(n^2)$ elementary operations. In section 2 the scaled pivots are used to obtain bounds for the growth factor (1.2). In section 3 we apply them to derive bounds for the Skeel condition number of the upper triangular matrix U resulting after Gaussian elimination. As a consequence of these bounds we prove in Corollary 3.3 that the Skeel condition number of an $n \times n$ upper triangular matrix which is strictly diagonally dominant by rows is bounded above by a number which is independent of n.

The second main topic of this paper is related to scaled partial pivoting strategies, that is, strategies which incorporate row scaling *implicitly.* In [5] some properties of these strategies with respect to the Skeel condition number of the upper triangular matrix U resulting after Gaussian elimination were analyzed. We also proved that if there exists a permutation matrix P such that the LU-factorization of the matrix $B = PA$ satisfies $|LU| = |L|\,|U|$ (the property which can be used to derive small componentwise backward errors), then P is associated with the row scaled partial pivoting for any strictly monotone vector norm. In contrast with the usual growth factor (1.1), in section 4 we get specific bounds for the growth factor (1.2) in the case of row scaled partial pivoting. A disadvantage of scaled partial pivoting strategies is their high computational cost: $\mathcal{O}(n^3)$ elementary operations for the complete factorization. However, we shall see in section 5 that, for important classes of matrices, these strategies can be implemented without computational cost or with less computational cost than partial pivoting, and they present better stability properties than partial pivoting. On the other hand, we also show in section 5 that the calculation of the n scaled pivots associated with a pivoting strategy presenting nice properties when applied to nonsingular $n \times n$ M-matrices adds $\mathcal{O}(n)$ elementary operations to the complete cost of this strategy.

2. Scaled pivots and the growth factor.

Given $k \in \{1, 2, \ldots, n\}$, let α, β be two increasing sequence of k positive integers less than or equal to n. Then we denote $A[\alpha|\beta]$ the $k \times k$ submatrix of A containing rows numbered by α and columns numbered by β. Gaussian elimination with a given pivoting strategy, for nonsingular matrices $A = (a_{ij})_{1 \le i,j \le n}$, consists of a succession of at most $n-1$ major steps resulting in a sequence of matrices as follows:

$$A = A^{(1)} \longrightarrow \tilde{A}^{(1)} \longrightarrow A^{(2)} \longrightarrow \tilde{A}^{(2)} \longrightarrow \cdots \longrightarrow A^{(n)} = \tilde{A}^{(n)} = U, \tag{2.1}$$

where $A^{(t)} = (a_{ij}^{(t)})_{1 \le i,j \le n}$ has zeros below its main diagonal in the first $t-1$ columns. The matrix $\tilde{A}^{(t)} = (\tilde{a}_{ij}^{(t)})_{1 \le i,j \le n}$ is obtained from the matrix $A^{(t)}$ by reordering the rows and/or columns $t, t+1, \ldots, n$ of $A^{(t)}$ according to the given pivoting strategy and satisfying $\tilde{a}_{tt}^{(t)} \neq 0$. To obtain $A^{(t+1)}$ from $\tilde{A}^{(t)}$ we produce zeros in column t below the *pivot element* $\tilde{a}_{tt}^{(t)}$ by subtracting multiples of row t from the rows beneath it. If P and/or Q are permutation matrices such that the Gaussian elimination of $B = PAQ$ can be performed without row exchanges, then the first row of $\tilde{A}^{(t)}[t, \ldots, n]$ coincides with the first row of $B^{(t)}[t, \ldots, n]$, and the other rows coincide up to the order. If $B = P^T AP$, we say that we have performed *symmetric pivoting.* Let $r_i^{(t)}$ (resp., $\tilde{r}_i^{(t)}$) denote the ith row ($t \le i \le n$) of the submatrix $A^{(t)}[1, \ldots, n|t, t+1, \ldots, n]$ (resp., $\tilde{A}^{(t)}[1, \ldots, n|t, t+1, \ldots, n]$).

Given a pivoting strategy which has produced the pivots $\tilde{a}_{11}^{(1)}, \dots, \tilde{a}_{nn}^{(n)}$, let us define the kth *scaled pivot* as

$$p_k := \frac{|\tilde{a}_{kk}^{(k)}|}{\|\tilde{r}_k^{(k)}\|_1} \tag{2.2}$$

for each $k = 1, \dots, n$. Calculating the n scaled pivots $p_1, \dots, p_n$ associated with the pivoting strategy adds $\mathcal{O}(n^2)$ elementary operations to the complete cost of the strategy. Obviously, $p_k \le 1$ for all k and, if A is an $n \times n$ matrix, $p_n = 1$. We shall see that these numbers provide information on the growth factor ρ and on the Skeel condition number of the upper triangular matrix U.

A *row* (resp., *symmetric*) *scaled partial pivoting* strategy for the norm $\|\cdot\|_1$ consists of an implicit scaling by the norm $\|\cdot\|_1$ followed by partial (resp., symmetric and partial) pivoting. For each t $(1 \le t \le n-1)$, these strategies look for an integer $\hat{i}_t$ $(t \le \hat{i}_t \le n)$ such that

$$p_t = \frac{|a_{\hat{i}_t t}^{(t)}|}{\|r_{\hat{i}_t}^{(t)}\|_1} = \max_{t \le i \le n} \frac{|a_{it}^{(t)}|}{\|r_i^{(t)}\|_1} \tag{2.3}$$

(resp., $p_t = \frac{|a_{\hat{i}_t \hat{i}_t}^{(t)}|}{\|r_{\hat{i}_t}^{(t)}\|_1} = \max_{t \le i \le n} \frac{|a_{ii}^{(t)}|}{\|r_i^{(t)}\|_1}$). Observe that the scaled pivots p_k of a row (resp., symmetric) scaled partial pivoting strategy satisfy for each $i = k, k+1, \dots, n$

$$p_k \ge \frac{|\tilde{a}_{ik}^{(k)}|}{\|\tilde{r}_i^{(k)}\|_1} \tag{2.4}$$

and, respectively,

$$p_k \ge \frac{|\tilde{a}_{ii}^{(k)}|}{\|\tilde{r}_i^{(k)}\|_1}. \tag{2.5}$$

The scaled pivots can be calculated after performing *any* pivoting strategy. As we have commented above, the calculation of the n scaled pivots associated with a pivoting strategy adds $\mathcal{O}(n^2)$ elementary operations to the complete cost of the strategy.

The following result will be applied to show the usefulness of the scaled pivots in order to estimate the growth factor.

PROPOSITION 2.1. *If $A^{(k+1)}$ is obtained from $\tilde{A}^{(k)}$ in the kth step of Gaussian elimination with a given pivoting strategy, then one has for all $i = k+1, \dots, n$,*

$$\|r_i^{(k+1)}\|_1 \le \|\tilde{r}_i^{(k)}\|_1 + \left(\frac{1}{p_k} - 2\right) |\tilde{a}_{ik}^{(k)}|, \tag{2.6}$$

where p_k is the scaled pivot given by (2.2), *and the equality in* (2.6) *can be achieved.*

Proof. For $i = k+1, \dots, n$, $j = k+1, \dots, n$, we have

$$|a_{ij}^{(k+1)}| = \left| \tilde{a}_{ij}^{(k)} - \frac{\tilde{a}_{ik}^{(k)}}{\tilde{a}_{kk}^{(k)}} \tilde{a}_{kj}^{(k)} \right| \le |\tilde{a}_{ij}^{(k)}| + \left| \frac{\tilde{a}_{kj}^{(k)}}{\tilde{a}_{kk}^{(k)}} \right| |\tilde{a}_{ik}^{(k)}|. \tag{2.7}$$

Therefore

$$\|r_i^{(k+1)}\|_1 \le \sum_{j=k+1}^{n} \left(|\tilde{a}_{ij}^{(k)}| + \left| \frac{\tilde{a}_{kj}^{(k)}}{\tilde{a}_{kk}^{(k)}} \right| |\tilde{a}_{ik}^{(k)}| \right)$$

and so

$$\|r_i^{(k+1)}\|_1 \le (\|\tilde{r}_i^{(k)}\|_1 - |\tilde{a}_{ik}^{(k)}|) + |\tilde{a}_{ik}^{(k)}| \sum_{j=k+1}^{n} \frac{|\tilde{a}_{kj}^{(k)}|}{|\tilde{a}_{kk}^{(k)}|},$$

which can be written as

$$\|r_i^{(k+1)}\|_1 \le (\|\tilde{r}_i^{(k)}\|_1 - |\tilde{a}_{ik}^{(k)}|) + |\tilde{a}_{ik}^{(k)}| \frac{\|\tilde{r}_k^{(k)}\|_1 - |\tilde{a}_{kk}^{(k)}|}{|\tilde{a}_{kk}^{(k)}|}.$$

Hence, (2.6) follows.

We can observe that inequalities (2.7) can become equalities, depending on the sign of the elements of $\tilde{A}^{(k)}$. If (2.7) holds as an equality for each $i = k+1, \dots, n$, $j = k+1, \dots, n$, then the following inequalities become equalities and (2.6) also holds as an equality. □

Observe that the row (resp., symmetric) scaled partial pivoting chooses the maximal scaled pivots among all pivoting strategies interchanging rows (resp., the same rows and columns). From Proposition 2.1 we see that maximizing the scaled pivots is related to minimizing the quotients

$$\|r_i^{(k+1)}\|_1 / \|\tilde{r}_i^{(k)}\|_1.$$

Hence, we can say that the scaled partial pivoting strategies satisfy a "local optimality" property in the sense that the growth of row norms at a single step of Gaussian elimination is minimized.

We now can derive from Proposition 2.1 the following consequences on the growth factor ρ in terms of the scaled pivots.

COROLLARY 2.2. *Let $p_{i_1}, \dots, p_{i_r}$ be the scaled pivots less than $1/2$, and let ρ be the growth factor* (1.2) *of Gaussian elimination with a given pivoting strategy. Then $\rho = 1$ if $r = 0$ and $1 \le \rho \le \prod_{1 \le k \le r}((1 - p_{i_k})/p_{i_k})$ if $r > 0$.*

Proof. If $i \in \{1, \dots, k\}$, then $\|r_i^{(k+1)}\|_1 = \|\tilde{r}_i^{(k)}\|_1$. Let us assume that $i \in \{k+1, \dots, n\}$. If $p_k \ge 1/2$, then $\frac{1}{p_k} - 2 \le 0$ and we deduce from (2.6) that $\|r_i^{(k+1)}\|_1 \le \|\tilde{r}_i^{(k)}\|_1$. If $p_k < 1/2$, it is sufficient to apply (2.6) and observe that $(\frac{1}{p_k} - 2)|\tilde{a}_{ik}^{(k)}| \le (\frac{1}{p_k} - 2)\|\tilde{r}_i^{(k)}\|_1$ in order to derive $\|r_i^{(k+1)}\|_1 \le \frac{1-p_k}{p_k}\|\tilde{r}_i^{(k)}\|_1$. Iterating the previous arguments, we can deduce the result. □

Although the bound of Corollary 2.2 is not as sharp as the bound of Proposition 2.1, it can be useful in some cases. The case $r = 0$ in the previous corollary corresponds to $p_k \ge 1/2$ for all $k = 1, \dots, n-1$, which holds if and only if the upper triangular matrix obtained after Gaussian elimination is diagonally dominant. In this case, $\rho = 1$ (let us recall that, in this case, we proved in [7] that the usual growth factor satisfies $\rho^W \le n - 1$). On the other hand, Corollary 2.2 can be useful if we compare it with the estimate $\|A\|/\|U\|$ used in LAPACK [2, p. 241] for the inverse of the growth factor. Although LAPACK uses only this estimate for Gaussian elimination with row exchanges, if it is used without row exchanges it can be unreliable. For instance, if we consider the matrix

$$A = A^{(1)} = \begin{pmatrix} \varepsilon & 1 & 0 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{pmatrix}$$

and apply Gaussian elimination without row exchanges, we obtain the matrices

$$A^{(2)} = \begin{pmatrix} \varepsilon & 1 & 0 \\ 0 & 1 & 0 \\ 0 & -\frac{1}{\varepsilon} & 1 \end{pmatrix}, \quad A^{(3)} = U = \begin{pmatrix} \varepsilon & 1 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$

Then $\|U\|/\|A\| = 1$ and it does not show the growth corresponding to the matrix $A^{(2)}$: in fact, $\rho(A) = 1/\varepsilon$. The bound provided by Corollary 2.2 is also $1/\varepsilon$.

3. Scaled pivots and the condition number. Let us recall that Cond(A) represents the Skeel condition number of a matrix A. Given the scaled pivots p_k (2.6) of a nonsingular matrix, let us consider the *minimal scaled pivot* p

$$p := \min_{1 \le k \le n} p_k. \tag{3.1}$$

Let us observe that $0 < p \le 1$.

The following result provides a bound for the Skeel condition number of the triangular matrix resulting after Gaussian elimination in terms of the minimal scaled pivot.

THEOREM 3.1. *Let $U = (u_{ij})_{1\le i,j\le n}$ be the upper triangular matrix obtained after performing Gaussian elimination on a nonsingular matrix A with a pivoting strategy with minimal scaled pivot p (see (3.1)). Then Cond$(U) \le \frac{2-2p}{1-2p}\left(\frac{1-p}{p}\right)^{n-1} - \frac{1}{1-2p}$ if $p \ne \frac{1}{2}$ and Cond$(U) \le 2n-1$ if $p = \frac{1}{2}$.*

Proof. Let $V := D^{-1}U$, where D is the diagonal matrix whose (i,i)-entry is u_{ii} for all i. Then Cond$(U) =$ Cond(V), and $V = (V_{ij})_{1\le i,j\le n}$ is upper triangular with $V_{ii} = 1$ and

$$\sum_{j=i+1}^{n} |V_{ij}| = \sum_{j=i+1}^{n} \frac{|u_{ij}|}{|u_{ii}|} = \frac{\sum_{j=i}^{n} |u_{ij}| - |u_{ii}|}{|u_{ii}|} = \frac{1}{p_i} - 1 = \frac{1-p_i}{p_i} \le \frac{1-p}{p} \tag{3.2}$$

for all i.

If we compute V^{-1} by Gauss–Jordan, starting from the last column, we can easily obtain the following bound for the absolute value of $(V^{-1})_{ij}$ for any $i \in \{1,\dots,n\}$ and $j \ge i$:

(3.3)
$$|(V^{-1})_{ij}| \le |V_{ij}| + |V_{i,j-1}|\,|(V^{-1})_{j-1,j}| + |V_{i,j-2}|\,|(V^{-1})_{j-2,j}| + \cdots + |V_{i,i+1}|\,|(V^{-1})_{i+1,j}|.$$

Let us see by induction on $j-i$ that $|(V^{-1})_{ij}| \le \left(\frac{1-p}{p}\right)^{j-i}$. It holds when $j-i=0$ because $|(V^{-1})_{ii}| = 1$ and when $j-i=1$ because $|(V^{-1})_{i,i+1}| = |V_{i,i+1}| \le \frac{1-p}{p}$ by (3.2). Let us assume that it holds when $j-i \le k$, and let us prove it when $j-i = k+1$. In this case, if we apply (3.2) and the induction hypothesis to (3.3) we derive

$$|(V^{-1})_{ij}| \le \left(\frac{1-p}{p}\right)^{k} \sum_{j\ne i} |V_{ij}| \le \left(\frac{1-p}{p}\right)^{k+1} = \left(\frac{1-p}{p}\right)^{j-i}.$$

Let $W := |V^{-1}|\,|V|$. Then, taking into account (3.2) and that, by (3.2) $\sum_{j=k}^{n} |V_{kj}| \leq \frac{1}{p}$, we have for each $i \in \{1, \dots, n\}$ that

(3.4)

$$\sum_{j=i}^{n} |w_{ij}| = \sum_{j=i}^{n} \sum_{k=i}^{j} |(V^{-1})_{ik}||V_{kj}| = \sum_{k=i}^{n} \sum_{j=k}^{n} |(V^{-1})_{ik}||V_{kj}|$$
$$= \left(\sum_{k=i}^{n-1} \left(\sum_{j=k}^{n} |(V^{-1})_{ik}||V_{kj}| \right) \right) + |(V^{-1})_{in}||V_{nn}| \leq \sum_{k=i}^{n-1} \frac{1}{p} \left(\frac{1-p}{p} \right)^{k-i} + \left(\frac{1-p}{p} \right)^{n-i}.$$

If $p = 1/2$, then we obtain from (3.4)

$$\sum_{j=i}^{n} |w_{ij}| \leq 2n - 2i + 1. \tag{3.5}$$

If $p \neq 1/2$, then we can deduce from (3.4)

(3.6)

$$\sum_{j=i}^{n} |w_{ij}| \leq \frac{1}{p} \frac{((1-p)/p)^{n-i} - 1}{((1-p)/p) - 1} + \left(\frac{1-p}{p} \right)^{n-i} = \left(\frac{1}{1-2p} + 1 \right) \left(\frac{1-p}{p} \right)^{n-i} - \frac{1}{1-2p}$$
$$= \left(\frac{2-2p}{1-2p} \right) \left(\frac{1-p}{p} \right)^{n-i} - \frac{1}{1-2p},$$

and the result follows. □

Remark 3.2. The proof of the previous result can be applied to any nonsingular upper triangular matrix $U = (u_{ij})_{1 \leq i,j \leq n}$ such that $(|u_{ii}| / \sum_{j=i}^{n} |u_{ij}|) \geq p$ for all i. An analogous result to Theorem 3.1 also can be deduced for any nonsingular lower triangular matrix $L = (l_{ij})_{1 \leq i,j \leq n}$ such that $(|l_{ii}| / \sum_{j=1}^{i} |l_{ij}|) \geq p$ for all i. When $p = 1/2$ the matrices are diagonally dominant by rows and the bound of Theorem 3.1 for their Skeel condition number coincides with that obtained in Proposition 2.1 of [7]. The case $p > 1/2$ corresponds to the case of $n \times n$ matrices which are *strictly* diagonally dominant by rows. In this case $1 - 2p < 0$ and so we can derive the following result from Theorem 3.1, which provides a bound for the Skeel condition number which does not depend on n.

COROLLARY 3.3. *Let $U = (u_{ij})_{1 \leq i,j \leq n}$ be an upper triangular matrix which is strictly diagonally dominant by rows, and let $p := \min_{1 \leq i \leq n} \{|u_{ii}| / \sum_{j=i}^{n} |u_{ij}|\}$. Then Cond$(U) \leq \frac{1}{2p-1}$.*

In order to illustrate the use of the bound provided by Theorem 3.1, let us consider the matrices

$$A = \begin{pmatrix} 2 & -1 & 0 & 0 \\ -1 & 2 & -1 & 0 \\ 0 & -1 & 2 & -1 \\ 0 & 0 & -1 & 2 \end{pmatrix}, \quad U = \begin{pmatrix} 2 & -1 & 0 & 0 \\ 0 & \frac{3}{2} & -1 & 0 \\ 0 & 0 & \frac{4}{3} & -1 \\ 0 & 0 & 0 & \frac{5}{4} \end{pmatrix}.$$

Matrices with the structure of A often appear when applying the finite difference method for a boundary value problem. If we perform Gaussian elimination without row exchanges to A, we obtain the matrix U. Since U is strictly diagonally dominant by rows, we can apply Corollary 3.3 and obtain $\mathrm{Cond}(U) \leq 7$ ($p = 4/7$). However, if we apply the bound of Theorem 3.1, we get $\mathrm{Cond}(U) \leq 4.46875$. In this case, $\mathrm{Cond}(U) = 10/3$.

In section 5 we shall include examples where we also deal with $\kappa(U)$. On the other hand, the relationship of the row scaled partial pivoting and the Skeel condition number of U was analyzed in [5]. In the next section we provide some properties of the row scaled partial pivoting with respect to the growth factor ρ (1.2).

4. Row scaled partial pivoting strategies.

In this section, we obtain bounds for the growth factor ρ of row scaled partial pivoting strategies.

The usual growth factor ρ^W (1.1) of row scaled partial pivoting cannot be bounded above by the bound 2^{n-1} of partial pivoting (see [4, p. 192]). In Theorem 5.1 of [1] it was proved that the growth factor ρ (1.2) of partial pivoting is also bounded above by 2^{n-1}. The following result provides an upper bound for ρ when using row scaled partial pivoting, which is lower than that obtained from applying Corollary 2.2.

THEOREM 4.1. *Let $p_{i_1}, \ldots, p_{i_r}$ be the scaled pivots less than $1/2$ of the row scaled partial pivoting strategy for $\|\cdot\|_1$ for a nonsingular $n \times n$ matrix A. Then the growth factor ρ (1.2) for this strategy satisfies*

$$1 \leq \rho \leq 2^r \prod_{1 \leq k \leq r} (1 - p_{i_k}).$$

Proof. If $i \in \{1, \ldots, k\}$, then $\|r_i^{(k+1)}\|_1 = \|\tilde{r}_i^{(k)}\|_1$. Let us assume that $i \in \{k+1, \ldots, n\}$. If $p_k \geq 1/2$, then $\frac{1}{p_k} - 2 \leq 0$ and we deduce from (2.6) that $\|r_i^{(k+1)}\|_1 \leq \|\tilde{r}_i^{(k)}\|_1$. Let us assume that $p_k < 1/2$. Then $\frac{1}{p_k} - 2 > 0$ and so $1 - 2p_k > 0$.

Now, from (2.6) and (2.2) we deduce that for $i = k+1, \ldots, n$

$$\|r_i^{(k+1)}\|_1 \leq \|\tilde{r}_i^{(k)}\|_1 + (1 - 2p_k)|\tilde{a}_{ik}^{(k)}| \frac{\|\tilde{r}_k^{(k)}\|_1}{|\tilde{a}_{kk}^{(k)}|}$$

or, equivalently,

$$\|r_i^{(k+1)}\|_1 \leq \|\tilde{r}_i^{(k)}\|_1 + (1 - 2p_k)\|\tilde{r}_i^{(k)}\|_1 \frac{|\tilde{a}_{ik}^{(k)}|}{\|\tilde{r}_i^{(k)}\|_1} \frac{\|\tilde{r}_k^{(k)}\|_1}{|\tilde{a}_{kk}^{(k)}|}.$$

Taking into account (2.4) and $1 - 2p_k > 0$, we can derive

$$\|r_i^{(k+1)}\|_1 \leq \|\tilde{r}_i^{(k)}\|_1 + (1 - 2p_k)\|\tilde{r}_i^{(k)}\|_1 = 2(1 - p_k)\|\tilde{r}_i^{(k)}\|_1.$$

Iterating the previous arguments, we can deduce the result. □

Let us observe that, in contrast with section 2, in the following result we do not have to assume a bound for the scaled pivots in order to obtain a bound for the growth factor ρ. The proof in the case that there are scaled pivots less than $1/2$ is a consequence of Theorem 4.1 and the fact that $p_n = 1$. Otherwise, $\rho = 1$ by Corollary 2.2.

COROLLARY 4.2. *The growth factor ρ (1.2) of the row scaled partial pivoting strategy for the norm $\|\cdot\|_1$ for a nonsingular $n \times n$ matrix A satisfies*

$$1 \leq \rho \leq 2^{n-1}.$$

5. Examples. This section includes some examples where the results of this paper can be applied.

The stability of Gaussian elimination without pivoting when the coefficient matrix is diagonally dominant is well known (see pp. 288–289 of [11] and [10, pp. 122–123]). In Theorem 5.2 of [2] it was proved that for such matrices the growth factor $\rho = 1$. In previous sections, we have obtained nice bounds in the case that all scaled pivots are greater than or equal to $1/2$ or, equivalently, when the upper triangular matrix obtained after Gaussian elimination with a pivoting strategy is diagonally dominant by rows. In this case, we have proved that, for an $n \times n$ matrix, the growth factor $\rho = 1$ and the Skeel condition number $\mathrm{Cond}(U) \leq 2n-1$. Let us now present some classes of matrices and pivoting strategies satisfying the previous properties. A nonsingular matrix A is an *M-matrix* if it has positive diagonal entries and nonpositive off-diagonal entries, and A^{-1} is nonnegative. M-matrices have very important applications, for instance, in iterative methods in numerical analysis, in the analysis of dynamical systems, in economics, and in mathematical programming. Inverses of M-matrices arise, for instance, in the solution of certain integral equations and in certain physical problems. Given a matrix $A = (a_{ij})_{1\leq i,j\leq n}$, the *comparison matrix* $\mathcal{M}(A) = (m_{ij})_{1\leq i,j\leq n}$ is defined by $m_{ii} := |a_{ii}|$ and $m_{ij} := -|a_{ij}|$ if $i \neq j$. Finally, A is an *H-matrix* if its comparison matrix is an M-matrix. The following pivoting strategies were introduced in [7]. A row (resp., symmetric) *maximal relative diagonal dominance* (m.r.d.d.) pivoting is a pivoting (resp., symmetric pivoting) which chooses as pivot at the tth step $(1 \leq t \leq n-1)$ a row i_t satisfying $\frac{|a_{i_t t}^{(t)}|}{\sum_{j>t} |a_{i_t j}^{(t)}|} = \max_{t\leq i\leq n}\{\frac{|a_{it}^{(t)}|}{\sum_{j>t} |a_{ij}^{(t)}|}\}$ (resp., $\frac{|a_{i_t i_t}^{(t)}|}{\sum_{j\geq t, j\neq i_t} |a_{i_t j}^{(t)}|} = \max_{t\leq i\leq n}\{\frac{|a_{ii}^{(t)}|}{\sum_{j\geq t, j\neq i} |a_{ij}^{(t)}|}\}$). By Proposition 4.5 of [7], the symmetric m.r.d.d. pivoting strategy coincides with the symmetric scaled partial pivoting strategy for $\|\cdot\|_1$. A row (resp., symmetric) *maximal absolute diagonal dominance* (m.a.d.d.) pivoting is a row (resp., symmetric) pivoting which chooses as pivot at the tth step $(1 \leq t \leq n-1)$ a row i_t satisfying $|a_{i_t t}^{(t)}| - \sum_{j>t} |a_{i_t j}^{(t)}| = \max_{t\leq i\leq n}\{|a_{it}^{(t)}| - \sum_{j>t} |a_{ij}^{(t)}|\}$ (resp., $|a_{i_t i_t}^{(t)}| - \sum_{j\geq t, j\neq i_t} |a_{i_t j}^{(t)}| = \max_{t\leq i\leq n}\{|a_{ii}^{(t)}| - \sum_{j\geq t, j\neq i} |a_{ij}^{(t)}|\}$).

In Proposition 4.3 of [7] it was proved that if A is a nonsingular H-matrix, then any symmetric diagonally dominant pivoting strategy leads to an upper triangular matrix U which is diagonally dominant by rows. If A is a nonsingular M-matrix, then it is known (see, for instance, the proof of Theorem 4.4 of [7]) that the matrix U is in fact strictly diagonally dominant by rows. In this case, all scaled pivots are greater that $1/2$. If p is the minimal scaled pivot (3.1), then $\mathrm{Cond}(U) \leq (1/(2p-1))$, which is a bound independent of n (see Remark 3.2 and Corollary 3.3).

Given a nonsingular H-matrix A and any symmetric diagonally dominant pivoting strategy, since $\rho = 1$, we also have $\|U\|_\infty \leq \|A\|_\infty$. If A is an M-matrix, then, taking into account that the triangular matrices L and U associated with the strategies are also M-matrices, we can extend the arguments provided in [8] to any such strategy in order to prove that $\kappa(U) \leq \kappa(A)$ (see also [1]).

As shown in Remark 4.6 and Proposition 4.7 of [7], if A is a nonsingular $n \times n$ M-matrix, the symmetric m.a.d.d. pivoting strategy consists of choosing as pivot row in each step the row whose elements give a maximal sum, and it adds $\mathcal{O}(n^2)$ elementary operations to the computational cost of complete Gaussian elimination. Following the notations of Proposition 4.7 of [7], let $e := (1,\dots,1)^T$ and $b_1 := Ae$. The symmetric m.a.d.d. pivoting strategy produces the sequence of matrices (2.1) and the corresponding sequence of vectors:

$$b_1 = b_1^{(1)} \longrightarrow \tilde{b_1}^{(1)} \longrightarrow b_1^{(2)} \longrightarrow \tilde{b_1}^{(2)} \longrightarrow \cdots \longrightarrow b_1^{(n)} = \tilde{b_1}^{(n)} = c.$$

Taking into account that each component c_k of c gives the sum of the elements of the corresponding kth row of $U = (u_{ij})_{1 \le i,j \le n}$, that U is also a nonsingular M-matrix and so it has positive diagonal entries and nonpositive off-diagonal entries, and that $\tilde{a}_{kk}^{(k)} = u_k$, we can deduce from (2.2) that each scaled pivot p_k satisfies

$$p_k = \frac{u_{kk}}{2u_{kk} - c_k}. \tag{5.1}$$

Therefore, the calculation of each scaled pivot p_k requires one multiplication, one subtraction, and one division and so the calculation of the n scaled pivots associated with the symmetric m.a.d.d. pivoting strategy adds $\mathcal{O}(n)$ elementary operations to the complete computational cost of this strategy.

In addition to the good properties of row scaled partial pivoting strategies presented in section 4, let us recall that in [5] it was proved that, given a nonsingular matrix A, if there exists a permutation matrix P such that the LU-factorization of the matrix $B = PA$ satisfies $|LU| = |L|\,|U|$, then P is associated with the row scaled partial pivoting for any strictly monotone vector norm. This can be used to derive nice backward error bounds (see also [3] and section 9.2 of [4]). These strategies satisfy the following property.

PROPOSITION 5.1. *Let $B = (b_{ij})_{1 \le i,j \le n}$ be a nonsingular matrix. If the LU-factorization of B satisfies $|LU| = |L|\,|U|$, then $|b_{ij}^{(k)}| \le |b_{ij}|$ for all i, j, k.*

Proof. It is easy to deduce the equation

$$B^{(k)}[k, \dots, n] = L[k, \dots, n]U[k, \dots, n]. \tag{5.2}$$

Clearly,

$$|L[k, \dots, n]U[k, \dots, n]| \le |L|\,|U|. \tag{5.3}$$

The result follows from (5.2), (5.3), and the hypothesis. ☐

As a consequence of the previous result, the corresponding strategies satisfy $\rho = 1$ and $\rho^W = 1$. Let us mention some classes of matrices for which the associated pivoting strategies satisfy Proposition 5.1. *Totally positive* matrices are matrices with all their minors nonnegative. Totally positive matrices arise naturally in many areas of mathematics, statistics, and economics. Inverses of totally positive matrices appear, for instance, in difference approximations of boundary value problems of fourth order ordinary differential equations. For the following classes of matrices the row scaled partial pivoting for any strictly monotone vector norm produces no row exchanges and satisfies the hypothesis of Proposition 5.1 (see [5]): nonsingular totally positive matrices, inverses of totally positive matrices, inverses of M-matrices, tridiagonal symmetric positive definite matrices, and tridiagonal M-matrices.

Let us finish with an example in which $B = PA$ satisfies Proposition 5.1 for a permutation matrix P different from the identity. A class of matrices containing totally positive matrices is given by the sign-regular matrices. An $n \times m$ matrix A is *sign-regular* if, for each k ($1 \le k \le \min\{n, m\}$), all $k \times k$ submatrices of A have a determinant with the same nonstrict sign. In [6] there was introduced a pivoting strategy for sign-regular matrices which was called *first-last pivoting* due to the fact that we choose as pivot row at each step of Gaussian elimination either the first or the last row among all possible rows. If A is a nonsingular $n \times n$ sign-regular matrix, the first-last pivoting strategy adds at most $2n-2$ subtractions and $4n-4$ multiplications to the computational cost of complete Gaussian elimination. By Corollary 3.7 of [6], the matrix $B = PA$ (where P is the permutation matrix associated with the first-last pivoting strategy) satisfies the hypothesis of Proposition 5.1. Therefore, the first-last pivoting produces for nonsingular sign-regular matrices the same row exchanges as any row scaled partial pivoting for a strictly monotone vector norm.

SHARP CFL, DISCRETE KINETIC FORMULATION, AND ENTROPIC SCHEMES FOR SCALAR CONSERVATION LAWS*

CHARALAMBOS MAKRIDAKIS† and BENOÎT PERTHAME‡

Abstract. We consider semidiscrete and fully discrete conservative finite volume schemes approximating the solution to one-dimensional scalar conservation law. We show that all E-schemes are associated with a discrete kinetic formulation with a nonnegative kinetic defect measure. This construction provides an alternative proof of the discrete local entropy inequalities with simple expressions of the discrete entropy fluxes. In contrast to the known results, which are restricted to CFL of the form $\lambda Q \leq 1/2$, our proof holds under "sharp" CFL conditions.

Key words. scalar conservation laws, kinetic formulations, finite volume methods, CFL condition

1. Introduction.

We consider conservative schemes approximating the scalar conservation law

$$\frac{\partial}{\partial t}u + \frac{\partial}{\partial x}A(u) = 0, \tag{1.1}$$

$$u(t=0,x) = u^0(x) \in L^1 \cap L^\infty(\mathbb{R}). \tag{1.2}$$

We assume and denote

$$A(0) = 0, \qquad a(\cdot) = A'(\cdot).$$

As usual [6], [17], [18], (1.1) is completed by the family of entropy inequalities; for any convex function S, there holds

$$\frac{\partial}{\partial t}S(u) + \frac{\partial}{\partial x}\eta^S(u) \leq 0, \tag{1.3}$$

with $\eta^S(u) = \int_0^u S'(\xi)\, a(\xi)\, d\xi$.

The purpose of this paper is to give new proofs under improved CFL conditions for discrete local entropy inequalities for a wide class of conservative entropic schemes for (1.1), the E-schemes (see [14]), and to investigate the connection between these schemes and the discretization of the kinetic formulation of the conservation law as introduced in [13], [12]. In fact, the proofs of the local entropy inequalities follow (as in the continuous case) from the positiveness of the defect measure appearing in the discrete kinetic formulation of the schemes.

In order to describe our results we introduce the following notation for the discretization. For simplicity we take a uniform mesh, but the analysis covers the nonuniform case with appropriate modifications; cf. Remark 3.6.

- $h > 0$ is the uniform mesh size,
- $x_{i+1/2} = (i + 1/2)h$, $i \in \mathbb{Z}$, are the cell interfaces,
- C_i denotes the cell $(x_{i-1/2}, x_{i+1/2})$,
- Δt is the time step, $t^n = n\Delta t$,
- $v_i(t)$ (resp., v_i^n) denotes the solution to the numerical scheme,
- $\lambda = \frac{\Delta t}{h}$.

The principle of the finite volume method consists of conservation approximations of the solution cell-averages

$$u_i(t) = \frac{1}{h_i}\int_{C_i} u(t,x)\,dx \qquad \text{(semidiscrete case)},$$

$$u_i^n = \frac{1}{h_i}\int_{C_i} u(t^n,x)\,dx \qquad \text{(fully discrete case)}.$$

We study both semidiscrete and fully discrete conservative schemes based on a two point numerical flux $\mathcal{A} = \mathcal{A}(u,v)$. It is chosen so that the numerical fluxes, called below $A_{i+1/2}(t)$, approximate the exact fluxes $A(u(t, x_{i+1/2}))$. We thus require the numerical fluxes to be *consistent*, i.e., $\mathcal{A}(u,u) = A(u)$ [8], [9], [10], [11]. The semidiscrete scheme is defined by

$$\begin{aligned} h\frac{d}{dt}v_i(t) + A_{i+1/2}(t) - A_{i-1/2}(t) &= 0, \qquad i \in \mathbb{Z}, \\ v_i(t=0) = v_i^0 &\in l^1(\mathbb{Z}) \quad \text{given}, \\ A_{i+1/2}(t) &= \mathcal{A}(v_i(t), v_{i+1}(t)). \end{aligned} \tag{1.4}$$

The corresponding fully discrete scheme that we consider is

$$\begin{aligned} v_i^{n+1} - v_i^n + \lambda\big(A_{i+1/2}^n - A_{i-1/2}^n\big) &= 0, \qquad i \in \mathbb{Z}, \\ v_i(t=0) = v_i^0 &\in l^1(\mathbb{Z}) \quad \text{given}, \\ A_{i+1/2}^n &= \mathcal{A}(v_i^n, v_{i+1}^n), \end{aligned} \tag{1.5}$$

where $\mathcal{A}$ is the same numerical flux.

Local entropy inequalities. It is well known that a key property that guarantees the convergence of the schemes to the unique entropy solution of the conservation law is to satisfy a discrete version of the entropy inequalities associated with (1.1). Namely, we are interested in schemes (1.4) for which in-cell entropy inequalities hold; i.e., for any convex function S, there holds

$$\begin{aligned} h\frac{d}{dt}S(v_i(t)) + \eta_{i+1/2} - \eta_{i-1/2} &\le 0, \\ \eta_{i+1/2} &= \eta(S; v_i(t), v_{i+1}(t)) \end{aligned} \tag{1.6}$$

for some appropriate entropy discrete flux function $\eta(S\,; u, v)$. For fully discrete schemes we require

$$S(v_i^{n+1}) - S(v_i^n) + \lambda\big(\eta_{i+1/2}^n - \eta_{i-1/2}^n\big) \le 0, \qquad i \in \mathbb{Z}. \tag{1.7}$$

A related class of schemes are the *E-schemes* introduced by Osher [14] in the semidiscrete case. These are the schemes for which the Lipschitz continuous function $\mathcal{A}(u,v)$ satisfies

$$\begin{aligned} &\mathcal{A}(u,v) \le A(\xi) \qquad \text{for } u \le \xi \le v, \\ &\mathcal{A}(u,v) \ge A(\xi) \qquad \text{for } v \le \xi \le u. \end{aligned} \tag{1.8}$$

In Osher [14], it was shown that (1.6) follows from the E-property for the flux. In the fully discrete case, Tadmor [19] showed that, under certain CFL limitations, E-schemes satisfy (1.7). Tadmor's seminal approach requires writing (1.5) in its viscosity form

$$\begin{aligned} v_i^{n+1} = v_i^n &- \frac{\lambda}{2}\big(A(v_{i+1}^n) - A(v_{i-1}^n) \big) \\ &+ Q_{i+1/2}\big(v_{i+1}^n - v_i^n\big) - Q_{i-1/2}\big(v_i^n - v_{i-1}^n\big), \end{aligned} \tag{1.9}$$

where the *viscosity coefficient* $Q_{i+1/2}$ is

$$\begin{aligned} &Q_{i+1/2} = Q(v_i^n, v_{i+1}^n), \\ &Q(u,v) = \lambda \, \frac{A(u) + A(v) - 2\mathcal{A}(u,v)}{v-u}\,. \end{aligned} \tag{1.10}$$

In [19] was shown that if $\mathcal{A}(u,v)$ satisfies the E-property and the CFL conditions

$$\begin{aligned} &Q_{i+1/2} \le \frac{1}{2}, \\ &\lambda \max_\xi |a(\xi)| \le \frac{1}{2} \end{aligned} \tag{1.11}$$

are met, then the fully discrete scheme (1.5) satisfies the in-cell entropy inequalities (1.7). Later this proof was extended to the multidimensional finite volume setting in [5], [1]; see also [15] for an improved version. As it was already noticed in [19], (1.11) are stronger than one would like them to be. Indeed, consider the two limiting cases for Q that correspond to Godunov and Lax–Friedrichs schemes (denote Q^G and Q^{LF} their numerical viscosity coefficients). Then one can check that for all E-schemes [14], [19], $Q^G \le Q$, but Godunov's scheme is known to satisfy (1.7) under the following sharp CFL: $\lambda \max_\xi |a(\xi)| \le 1$. In addition, $Q^{LF} \equiv 1$, i.e., (1.11), is also restrictive. The reason behind this restricted CFL is the method of proof in [19] which splits the numerical cell into two half subcells and reduces the numerical viscosity of any E-scheme in a convex combination of Godunov and modified Lax–Friedrichs schemes. This splitting into two subcells avoids analyzing the interaction of waves but leads to the restricted CFL.

In what follows we show that indeed (1.11) can be relaxed to the "sharp" conditions

$$\begin{aligned} &Q_{i+1/2} \le 1, \\ &\lambda \max_\xi |a(\xi)| \le 1\,. \end{aligned} \tag{1.12}$$

Our proofs do not rely on the above comparison with Godunov and modified Lax–Friedrichs; rather it is based on the kinetic formulation of E-schemes that we present in what follows.

Kinetic formulation. To each one of the schemes considered we will associate a discrete kinetic scheme. To do that we first consider the kinetic formulation of the conservation law (1.1) introduced in [13] (see also [16]):

$$\frac{\partial}{\partial t}f(x,t,\xi)+a(\xi)\frac{\partial}{\partial x}f(x,t,\xi)=\frac{\partial}{\partial \xi}m(x,t,\xi)\,. \tag{1.13}$$

Then $f(x,t,\xi)=\chi(\xi,u(x,t))$, and m is a nonnegative bounded measure with compact support with respect to ξ if and only if

$$u(x,t)=\int_{\mathbb{R}}f(x,t,\xi)d\xi$$

is the unique entropy solution of the conservation law (1.1). The kinetic equation has incorporated all the entropy inequalities (1.3). We use the standard notation for the signed characteristic function, $a\in\mathbb{R}$,

$$\chi(\xi,a)=\begin{cases}1, & 0<\xi\le a,\\ -1, & a\le\xi<0,\\ 0 & \text{otherwise}\,.\end{cases} \tag{1.14}$$

For later reference note the following key property of χ that allows us to derive (1.3) integrating (1.13) against $S'(\xi)\,d\xi$; for all the continuous functions S

$$\int\chi(\xi,a)S'(\xi)d\xi=S(a)-S(0)\quad\text{for all } a\in\mathbb{R}. \tag{1.15}$$

One of the results of this paper is that, for any E-flux, an appropriate upwind discretization of the linear transport part of (1.13) provides a discrete kinetic formulation. In other words, when $v_i(t)$, $i\in\mathbb{Z}$, is given through (1.4), then there also holds

$$\begin{aligned}(1.16)\quad &h\,\frac{\partial}{\partial t}\chi(\xi,v_i(t))+\big[a_+(\xi,v_i,v_{i+1})\chi(\xi,v_i(t))-a_-(\xi,v_i,v_{i+1})\chi(\xi,v_{i+1}(t))\big]\\ &\qquad-\big[a_+(\xi,v_{i-1},v_i)\chi(\xi,v_{i-1}(t))-a_-(\xi,v_{i-1},v_i)\chi(\xi,v_i(t))\big]=\frac{\partial}{\partial\xi}m_i(t,\xi),\end{aligned}$$

where the functions in the right-hand side—called the kinetic defect measures—satisfy

$$\begin{aligned}&m_i(t,\xi)=m_-(\xi,v_{i-1},v_i)+m_+(\xi,v_i,v_{i+1}),\quad m_\pm(\cdot,u,v)\ge 0,\\ &m_\pm(\cdot,u,v)\text{ vanish outside of the nonordered interval }(u,v),\end{aligned} \tag{1.17}$$

and the numerical speeds $a_\pm$, bounded by quantities of order $\frac{\partial}{\partial u}\mathcal{A}$, $\frac{\partial}{\partial v}\mathcal{A}$, or $a(\xi)$, satisfy

$$\begin{aligned}&a_\pm(\xi,u,v)\ge 0,\\ &a_+(\xi,u,v)=\max(0,a(\xi)),\quad a_-(\xi,u,v)=\max(0,-a(\xi))\quad\text{for }\xi\notin(u,v),\\ &\mathcal{A}(u,v)=\int_{\mathbb{R}}a_+(\xi,u,v)\,\chi(\xi,u)\,d\xi-\int_{\mathbb{R}}a_-(\xi,u,v)\,\chi(\xi,v)\,d\xi\,.\end{aligned} \tag{1.18}$$

Therefore a simple ξ integration shows that from a formula (1.16) one derives a semidiscrete scheme (1.4), and the entropy flux in (1.6) follows by integrating (1.16) against $S'(\xi)$:

$$\eta(S;u,v) = \int_{\mathbb{R}} a_+(\xi,u,v)\, S'(\xi)\, \chi(\xi,u)\, d\xi - \int_{\mathbb{R}} a_-(\xi,u,v)\, S'(\xi)\, \chi(\xi,v)\, d\xi\,. \tag{1.19}$$

At this level one can observe that, for an E-scheme, the S-linear entropy flux is not unique and several choices of a_+, a_- are possible that lead to different discrete entropy fluxes.

Notice that the most natural and simple example from this point of view is the Engquist–Osher scheme [7], where (1.16) holds with

$$\begin{aligned} &a_+(\xi) = \max(0, a(\xi)), \quad a_-(\xi) = \max(0, -a(\xi)),\\ &\mathcal{A}_{EO}(u,v) = A_+(u) + A_-(v),\\ &A_+(u) = \int_0^u a_+(\xi)\, d\xi, \qquad A_-(u) = \int_0^u a_-(\xi)\, d\xi. \end{aligned} \tag{1.20}$$

This case has the remarkable property that the discrete kinetic formulation (1.16) is a linear equation on χ, a fundamental property in the continuous formulation (1.13) which allows, for instance, a convergence proof of the Engquist–Osher scheme based on merely L^∞ bounds (see [2]). This simple case is also a model for kinetic schemes for systems of conservation laws [3], [20], [16] and allows us to give another convergence proof [21]. An alternative proof based on the framework of [13] and a kinetic formulation of Godunov's finite volume scheme was given in [22].

To recover fully discrete schemes (1.5) by a kinetic formulation is more intricate and therefore we may have to introduce more general discretizations of the linear transport part of (1.13). We thus define the following.

Definition 1.1. *The function $a(\xi,u,v)$, which is integrable and has compact support with respect to ξ, is called a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$ if*

$$\begin{aligned} &\int_{\mathbb{R}} a(\xi,u,v) d\xi = \mathcal{A}(u,v)\,,\\ &a(\xi,u,u) = a(\xi)\chi(\xi,u) = A'(\xi)\chi(\xi,u)\,. \end{aligned} \tag{1.21}$$

In the semidiscrete case our choice can be, e.g., $a(\xi,u,v) = a_+(\xi,u,v)\,\chi(\xi,u) + a_-(\xi,u,v)\,\chi(\xi,v)$, but in the fully discrete case we have to consider more general representation formulas.

In section 2 we investigate the semidiscrete scheme (1.4), and we prove in Theorem 2.1 that E-schemes are characterized by the existence of a semidiscrete kinetic formulation (1.16). In fact, we show first that the existence of a more general discrete kinetic formulation (cf. (2.1)) is equivalent to the fact that $\mathcal{A}(u,v)$ is an E-flux. Towards this goal a crucial step is that the integrand of the discrete kinetic flux, defined in (2.8), should satisfy the requirements provided by Lemma 2.5 and further by Proposition 2.7.

In section 3 we investigate the fully discrete scheme (1.5) and the existence of a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$, $a(\xi,u,v)$ such that

$$\begin{aligned} \chi(\xi,v_i^{n+1}) - \chi(\xi,v_i^n) + \lambda[a(\xi,v_i^n,v_{i+1}^n) - a(\xi,v_{i-1}^n,v_i^n)]&\\ = \frac{\partial}{\partial \xi} m_i^n(\xi),& \end{aligned} \tag{1.22}$$

with m_i^n a nonnegative function as in (1.17). Our main result is that if $\mathcal{A}(u,v)$ is an E-flux and the CFL conditions (1.12) are met, then we can construct $a(\xi,u,v) = a_\lambda(\xi,u,v)$ such that (1.22) is a kinetic formulation of (1.5) with m_i^n nonnegative, Theorem 3.1. Then the in-cell entropy inequalities (1.7) follow with entropy flux $\eta_{i+1/2} = \eta(\lambda, S\,;\,u,v) = \int_{\mathbb{R}} S'(\xi)a_\lambda(\xi,u,v)\,d\xi$. The proof is constructive, and the conditions on $a(\xi,u,v)$ derived in section 2 for the semidiscrete problem are particularly useful in the analysis.

In section 4 we give the construction, and additional explicit formulas, for the Engquist–Osher scheme. This section can be viewed as a model for the generic construction in section 2.

2. Semidiscrete schemes.

In this section we investigate general three point semidiscrete scheme (1.4) with consistent flux $\mathcal{A}(u,v)$. We prove the equivalence between three properties; the E-property, the possibility of writing a kinetic discretization as (1.16), and the existence of discrete entropy fluxes in (1.6).

Namely, the main result of this section is the following theorem.

THEOREM 2.1. *Consider the semidiscrete scheme* (1.4) *with a consistent discrete flux $\mathcal{A}(u,v)$. The following three properties are equivalent:*

(i) *$\mathcal{A}(u,v)$ is an E-flux as defined in* (1.8);

(ii) *all the in-cell entropy inequalities* (1.6), *i.e., for any convex function S, are satisfied;*

(iii) *there exists a discrete kinetic flux $a(\xi,u,v)$ corresponding to $\mathcal{A}(u,v)$, and nonnegative functions m_i satisfying* (1.17), *such that the kinetic formulation of* (1.4) *holds:*

$$h\,\frac{\partial}{\partial t}\chi(\xi,v_i(t)) + [a(\xi,v_i,v_{i+1}) - a(\xi,v_{i-1},v_i)] = \frac{\partial}{\partial \xi}m_i(t,\xi). \tag{2.1}$$

The entropy fluxes in (1.6), *as well as $a(\xi,u,v)$, are not unique, and a possible relation is*

$$\eta(S;u,v) = \int_{\mathbb{R}} S'(\xi)\,a(\xi,u,v)\,d\xi.$$

In addition, $a(\xi,u,v)$ admits an "upwind" splitting of the form (1.18).

We first recall the equivalence between properties (i) and (ii) for the sake of completeness. The property (iii) is then derived in several steps. We conclude this section with an explicit construction of discrete kinetic fluxes like (1.18).

Proof of Theorem 2.1. (i) ⇔ (ii). We depart from (ii). Multiplying (1.4) by $S'(v_i(t))$, we obtain that the in-cell entropy inequality is equivalent to the existence of $\eta(S,\cdot,\cdot)$ such that, for all values v_i, $v_{i\pm1}$ and all convex S, we have

$$\eta(S;v_i,v_{i+1}) - \eta(S;v_{i-1},v_i) \le S'(v_i)[\mathcal{A}(v_i,v_{i+1}) - \mathcal{A}(v_{i-1},v_i)],$$

which is equivalent to

$$\begin{cases}\eta(S;v_i,v_{i+1}) - \eta(S;v_i,v_i) \le S'(v_i)[\mathcal{A}(v_i,v_{i+1}) - A(v_i)],\\ \eta(S;v_i,v_i) - \eta(S;v_{i-1},v_i) \le S'(v_i)[A(v_i) - \mathcal{A}(v_{i-1},v_i)],\end{cases}$$

which is again equivalent, for all u, v, and S convex, to the existence of a function $\eta(S,\cdot,\cdot)$ such that

$$\eta(S;v,v) - S'(v)[A(v) - \mathcal{A}(u,v)] \le \eta(S;u,v) \le S'(u)[\mathcal{A}(u,v) - A(u)] + \eta(S;u,u).$$

Denoting $\eta(S;v)=\eta(S;v,v)$, the above inequality is obviously equivalent to (and then the choice of $\eta(S;u,v)$ is anything in between)

$$\eta(S;v)-S'(v)[A(v)-\mathcal{A}(u,v)]\le S'(u)[\mathcal{A}(u,v)-A(u)]+\eta(S;u),$$

or, in other words,

$$\eta(S;v)-\eta(S;u)\le S'(v)A(v)-S'(u)A(u)-\mathcal{A}(u,v)[S'(v)-S'(u)],$$

which is equivalent to

$$\begin{cases}\dfrac{\partial}{\partial u}\eta(S;u)=S'(u)a(u),\\ \displaystyle\int_v^u S''(\zeta)A(\zeta)d\zeta\le\mathcal{A}(u,v)[S'(u)-S'(v)],\end{cases}$$

and it remains to choose, as a generating family for S convex, the family $S''(\zeta)=\delta(\zeta-\xi)$ to recover the equivalence with the E-property (1.8).

We would like to conclude with noticing that the entropy fluxes are automatically consistent; i.e., the relation $\frac{\partial}{\partial u}\eta(S;u,u)=S'(u)a(u)$ is derived from (ii). □

We now introduce some steps towards the semidiscrete kinetic formulation (iii). We start with the following lemma.

LEMMA 2.2. *Let $a(\xi,u,v)$ be a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$; then we have*

$$m_i(t,\xi)=m_+(\xi;v_i,v_{i+1})+m_-(\xi;v_{i-1},v_i), \tag{2.2}$$

with

$$\begin{aligned}m_+(\xi;u,v)&=\int_{-\infty}^{\xi}\delta(\zeta-u)[A(u)-\mathcal{A}(u,v)]\,d\zeta+\int_{-\infty}^{\xi}[\,a(\zeta,u,v)-a(\zeta)\chi(\zeta,u)]\,d\zeta,\\ m_-(\xi;u,v)&=-\int_{-\infty}^{\xi}\delta(\zeta-v)[A(v)-\mathcal{A}(u,v)]\,d\zeta-\int_{-\infty}^{\xi}[\,a(\zeta,u,v)-a(\zeta)\chi(\zeta,v)\,]\,d\zeta\,.\end{aligned} \tag{2.3}$$

Moreover, m_i is nonnegative for any value of its arguments if and only if both m_+ and m_- are nonnegative for any value of their arguments.

Proof. It is a simple matter to check that

$$\frac{\partial}{\partial t}\chi(\xi,v_i(t))=\delta(\xi-v_i(t))\,\frac{d}{dt}v_i(t)\,.$$

Then using the above formula and (1.4) in (2.1), we get

$$\begin{aligned}-\delta(\xi-v_i(t))\,[A_{i+1/2}-A_{i-1/2}]+[a(\xi,v_i(t),v_{i+1}(t))-a(\xi,v_{i-1}(t),v_i(t))]\\ =\frac{\partial}{\partial\xi}m_i(\xi,t)\end{aligned}$$

or, equivalently,

$$\begin{aligned}\frac{\partial}{\partial\xi}m_i(\xi,t)=\delta(\xi-v_i(t))\,[\,(A(v_i(t))-A_{i+1/2})-(A(v_i(t))-A_{i-1/2})\,]\\ +[a(\xi,v_i(t),v_{i+1}(t))-a(\xi)\chi(\xi,v_i(t))]\\ -[a(\xi,v_{i-1}(t),v_i(t))-a(\xi)\chi(\xi,v_i(t))\,]\,.\end{aligned}$$

Since we want m_i to have bounded support, we can integrate to obtain

$$\begin{aligned} m_i(\xi,t) = &\int_{-\infty}^{\xi} \delta(\zeta - v_i(t))\,[\,(A(v_i(t)) - A_{i+1/2}) - (A(v_i(t)) - A_{i-1/2})\,]\,d\zeta \\ &+ \int_{-\infty}^{\xi} [a(\zeta, v_i(t), v_{i+1}(t)) - a(\zeta)\chi(\zeta, v_i(t))] d\zeta \\ &- \int_{-\infty}^{\xi} [a(\zeta, v_{i-1}(t), v_i(t)) - a(\zeta)\chi(\zeta, v_i(t))\,]\,d\zeta \\ = &\; m_+(\xi, v_i(t), v_{i+1}(t)) + m_-(\xi, v_{i-1}(t), v_i(t)). \end{aligned}$$

By the definition of the discrete kinetic fluxes (Definition 1.1) and the consistency of the flux $\mathcal{A}(u,v)$ we see that

$$m_+(\xi, v, v) = 0, \qquad m_-(\xi, v, v) = 0;$$

thus m is nonnegative if and only if both m_+ and m_- are nonnegative. □

Remark 2.3. Since $m_\pm(+\infty; u, v) = m_\pm(-\infty; u, v) = 0$ we can see that (2.3) takes the form

$$\begin{aligned} m_+(\xi; u, v) &= \int_{-\infty}^{\xi} [\,a(\zeta, u, v) - a(\zeta)\chi(\zeta, u)\,]\,d\zeta \quad \text{for} \quad \xi < u, \\ m_+(\xi; u, v) &= -\int_{\xi}^{+\infty} [\,a(\zeta, u, v) - a(\zeta)\chi(\zeta, u)\,]\,d\zeta \quad \text{for} \quad u < \xi, \\ m_-(\xi; u, v) &= -\int_{-\infty}^{\xi} [\,a(\zeta, u, v) - a(\zeta)\chi(\zeta, v)\,]\,d\zeta \quad \text{for} \quad \xi < v, \\ m_-(\xi; u, v) &= \int_{\xi}^{+\infty} [\,a(\zeta, u, v) - a(\zeta)\chi(\zeta, v)\,]\,d\zeta \quad \text{for} \quad v < \xi. \end{aligned} \tag{2.4}$$

We proceed by further reducing the form of m_i. We need some more notation. For $u, v \in \mathbb{R}$ we denote $I_{u,v}$ the interval that they define. Also,

$$I_{u,v} = [m, M], \quad \text{where } m = \min\{u, v\} \text{ and } M = \max\{u, v\}\,. \tag{2.5}$$

We then notice the identity

$$\chi(\xi, u) = \chi(\xi, v) \quad \text{for } \xi \in \mathbb{R} \setminus I_{u,v}\,. \tag{2.6}$$

Then one may check the following lemma.

LEMMA 2.4. *Assume that $a(\xi, u, v)$ is a discrete kinetic flux corresponding to $\mathcal{A}(u, v)$. If m_+ and m_- are both nonnegative, then $a(\xi, u, v)$ satisfies the consistency condition outside the interval $I_{u,v}$:*

$$a(\xi, u, v) = a(\xi)\chi(\xi, u) = a(\xi)\chi(\xi, v), \quad \xi \in \mathbb{R} \setminus I_{u,v}\,. \tag{2.7}$$

Conversely, if (2.7) *is satisfied, then m_+ and m_- vanish (and therefore are nonnegative) outside the interval $I_{u,v}$.*

Proof. Assume first that $\xi < m < 0$; then $\chi(\xi, u) = \chi(\xi, v) = 0$. In addition, both m_+ and m_- are nonnegative; therefore (2.4) implies that

$$\int_{-\infty}^{\xi} a(\zeta, u, v)\,d\zeta = 0.$$

Since ξ is arbitrary, $a(\xi,u,v)=0$ for $\xi<m<0$. Similarly, if $\xi>M>0$, $a(\xi,u,v)=0$. In the case where $M<0$ and $M<\xi$, again by (2.4) we have

$$\int_{\xi}^{+\infty}[\,a(\zeta,u,v)-a(\zeta)\chi(\zeta,u)\,]\,d\zeta=0.$$

Since $M<\xi$ is arbitrary, we conclude that $a(\xi,u,v)=a(\xi)\chi(\xi,u)=a(\xi)\chi(\xi,v)$. The proof is similar in the case $\xi<m$, $m>0$. □

In view of Lemma 2.4 we are able to define a function $\mathcal{A}(\xi,u,v)$ of three variables as

$$\mathcal{A}(\xi,u,v)=\int_{-\infty}^{\xi}a(\zeta,u,v)\,d\zeta\,. \tag{2.8}$$

It is to be noted that $\mathcal{A}(\xi,u,v)$ should not be confused with the discrete flux $\mathcal{A}(u,v)$, although they are of course related depending on the values of ξ since by Definition 1.1

$$\mathcal{A}(+\infty,u,v)=\mathcal{A}(u,v).$$

In the next lemma we derive conditions for the discrete kinetic flux in $I_{u,v}$ by using its integrand $\mathcal{A}(\xi,u,v)$.

Lemma 2.5. *Assume that $a(\xi,u,v)$ is a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$, and that $\mathcal{A}(\xi,u,v)$ is defined by* (2.8)*. Let m_+ and m_- both be nonnegative. Then the following conditions are satisfied in the interval $I_{u,v}$:*

$$u\le\xi\le v\qquad\begin{cases}A(\xi)\ge\mathcal{A}(\xi,u,v)\ge\mathcal{A}(u,v) & \textit{when}\ \ \xi\ge 0,\\ 0\ge\mathcal{A}(\xi,u,v)\ge\mathcal{A}(u,v)-A(\xi) & \textit{when}\ \ \xi<0\end{cases} \tag{2.9}$$

and

$$v\le\xi\le u\qquad\begin{cases}\mathcal{A}(u,v)\ge\mathcal{A}(\xi,u,v)\ge A(\xi) & \textit{when}\ \ \xi\ge 0,\\ \mathcal{A}(u,v)-A(\xi)\ge\mathcal{A}(\xi,u,v)\ge 0 & \textit{when}\ \ \xi<0.\end{cases} \tag{2.10}$$

Conversely, if (2.9), (2.10) *are satisfied, then m_+ and m_- are nonnegative in the interval $I_{u,v}$.*

Proof. We treat only the case $u<\xi<v$ since the other is similar. Then equations (2.3) imply that

$$m_+(\xi,u,v)=A(u)-\mathcal{A}(u,v)+\mathcal{A}(\xi,u,v)-\int_{-\infty}^{\xi}a(\zeta)\chi(\zeta,u)\,d\zeta\,, \tag{2.11}$$

$$m_-(\xi,u,v)=-\mathcal{A}(\xi,u,v)+\int_{-\infty}^{\xi}a(\zeta)\chi(\zeta,v)\,d\zeta\,. \tag{2.12}$$

But then it is easy to check that

$$-\int_{-\infty}^{\xi}a(\zeta)\chi(\zeta,u)\,d\zeta=A(\xi)\mathbf{I}_{\{\xi<0\}}-A(u) \tag{2.13}$$

and

$$\int_{-\infty}^{\xi}a(\zeta)\chi(\zeta,v)\,d\zeta=A(\xi)\mathbf{I}_{\{\xi>0\}}. \tag{2.14}$$

Since both m_+ and m_- should be nonnegative, (2.9) follows. The converse is also immediate by using the above identities. ∎

Remark 2.6. From Lemma 2.4 we deduce that both m_+ and m_- are supported in $I_{u,v}$. Further, by the proof of the Lemma 2.5 we have the following formulas:

$$u \le \xi \le v: \quad \begin{aligned} &m_+(\xi;u,v) = \mathcal{A}(\xi,u,v) - \mathcal{A}(u,v) + A(\xi)\mathbf{1}_{\{\xi<0\}},\\ &m_-(\xi;u,v) = A(\xi)\mathbf{1}_{\{\xi>0\}} - \mathcal{A}(\xi,u,v)\end{aligned} \tag{2.15}$$

and

$$v \le \xi \le u: \quad \begin{aligned} &m_+(\xi;u,v) = \mathcal{A}(\xi,u,v) - A(\xi)\mathbf{1}_{\{\xi>0\}},\\ &m_-(\xi;u,v) = \mathcal{A}(u,v) - \mathcal{A}(\xi,u,v) - A(\xi)\mathbf{1}_{\{\xi<0\}}.\end{aligned} \tag{2.16}$$

We have now the following result.

PROPOSITION 2.7. *Assume that we have at our disposal a Lipschitz function $\mathcal{A}(\xi,u,v)$ which satisfies* (2.9) *and* (2.10) *and the endpoint values*

$$\textit{for } u \le v \quad \begin{cases} \mathcal{A}(u,u,v) = A(u)\mathbf{1}_{\{u>0\}},\\ \mathcal{A}(v,u,v) = \mathcal{A}(u,v) - A(v)\mathbf{1}_{\{v<0\}} \end{cases} \tag{2.17}$$

and

$$\textit{for } v \le u \quad \begin{cases} \mathcal{A}(u,u,v) = \mathcal{A}(u,v) - A(u)\mathbf{1}_{\{u<0\}},\\ \mathcal{A}(v,u,v) = A(v)\mathbf{1}_{\{v>0\}}. \end{cases} \tag{2.18}$$

Then $a(\xi,u,v)$ is well defined by

$$\begin{aligned} &a(\xi,u,v) = \frac{\partial}{\partial\xi}\mathcal{A}(\xi,u,v)\,, \quad \xi \in I_{u,v},\\ &a(\xi,u,v) = a(\xi)\chi(\xi,u) = a(\xi)\chi(\xi,v), \quad \xi \in \mathbb{R}\setminus I_{u,v}. \end{aligned} \tag{2.19}$$

In addition, $a(\xi,u,v)$ is a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$ and (2.1) *is a kinetic formulation of* (1.4) *with m_i nonnegative.*

Proof. Having (2.8) and (2.6) in mind, we first extend $\mathcal{A}(\xi,u,v)$ outside the interval $I_{u,v}$ by letting

$$\mathcal{A}(\xi,u,v) = \int_{-\infty}^{\xi} a(\zeta)\chi(\zeta,u)d\zeta, \quad \xi \le m,$$

and

$$\mathcal{A}(\xi,u,v) = \int_{-\infty}^{m} a(\zeta)\chi(\zeta,u)d\zeta + A(M,u,v) - A(m,u,v) + \int_{M}^{\xi} a(\zeta)\chi(\zeta,u)d\zeta, \quad \xi \ge M.$$

Then the function $\mathcal{A}(\cdot,u,v)$ is a well defined, continuous function and $a(\xi,u,v)$ is the derivative of $\mathcal{A}(\xi,u,v)$, $\xi \in \mathbb{R}$. Then it is easy to see that since $\mathcal{A}(\xi,u,v)$ satisfies (2.9) and (2.10) with equalities at the endpoints of the interval $I_{u,v}$,

$$\mathcal{A}(+\infty,u,v) = \int_{\mathbb{R}} a(\xi,u,v)d\xi = A(u,v)\,;$$

i.e., $a(\xi,u,v)$ is a discrete kinetic flux corresponding to $\mathcal{A}(u,v)$. The proof is complete in view of Lemmas 2.4 and 2.5. □

We are now ready to complete the proof of the last equivalence in Theorem 2.1.

Proof of Theorem 2.1. (i) ⇔ (iii). Assume first (i), i.e., that $\mathcal{A}(u,v)$ is an E-flux. Then one can construct a discrete kinetic flux as in Lemma 2.5 and Proposition 2.7. Indeed, one choice of $\mathcal{A}(\xi,u,v)$ in $I_{u,v}$ is

$$\text{for } u \le \xi \le v: \quad \mathcal{A}(\xi,u,v) = \max\{\mathcal{A}(u,\xi)\,,\, \mathcal{A}(u,v)\} - A(\xi)\mathbf{1}_{\{\xi<0\}} \tag{2.20}$$

and

$$\text{for } v \le \xi \le u: \quad \mathcal{A}(\xi,u,v) = \min\{\mathcal{A}(\xi,v)\,,\, \mathcal{A}(u,v)\} - A(\xi)\mathbf{1}_{\{\xi<0\}}. \tag{2.21}$$

Then since $\mathcal{A}$ is an E-flux, it is straightforward to verify that $\mathcal{A}(\xi,u,v)$ satisfies (2.9) and (2.10) with equalities at the endpoints of the interval $I_{u,v}$. Therefore Proposition 2.7 implies that (iii) holds.

Conversely, if (iii) holds with m nonnegative, then $\mathcal{A}(\xi,u,v)$ defined in (2.8) should satisfy (2.9) and (2.10). But then necessarily $\mathcal{A}(u,v)$ satisfies

$$\begin{aligned} &\text{if } u \le \xi \le v: \quad A(\xi) \ge \mathcal{A}(u,v)\,,\\ &\text{if } v \le \xi \le u: \quad \mathcal{A}(u,v) \ge A(\xi)\,; \end{aligned}$$

i.e., $\mathcal{A}(u,v)$ is an E-flux and (i) is proved. □

End of the proof of Theorem 2.1. It remains to consider another choice in Lemma 2.5 and Proposition 2.7 in order to obtain the refined kinetic formulation (1.16) with signed speeds. We built an admissible (i.e., that satisfies (2.9), (2.10), (2.17), (2.18)) Lipschitz function $\mathcal{A}(\xi,u,v)$ which is nonincreasing in ξ for $u<v$ and increasing in ξ for $v<u$. We give the formula and skip the tedious but easy proof:

$$u \le \xi \le v\colon \quad \mathcal{A}(\xi,u,v) = \begin{cases} \max\left\{\mathcal{A}(u,v)\,,\, \min\limits_{\max(0,u)\le\zeta\le\xi} \mathcal{A}(u,\zeta)\right\} & \text{when } \xi \ge 0,\\ \max\limits_{\xi\le\zeta\le\min(0,v)} \{\max(\mathcal{A}(u,v)\,,\, \mathcal{A}(u,\zeta)) - A(\zeta)\} & \text{when } \xi < 0, \end{cases} \tag{2.22}$$

$$v \le \xi \le u\colon \quad \mathcal{A}(\xi,u,v) = \begin{cases} \min\left\{\mathcal{A}(u,v)\,,\, \max\limits_{\max(0,v)\le\zeta\le\xi} \mathcal{A}(\zeta,v)\right\} & \text{when } \xi \ge 0,\\ \min\limits_{\xi\le\zeta\le\min(0,u)} \{\min(\mathcal{A}(u,v), \mathcal{A}(\zeta,v)) - A(\zeta)\} & \text{when } \xi < 0. \end{cases} \tag{2.23}$$

Thanks to the monotonicity of $\mathcal{A}(\xi,u,v)$, one readily checks that indeed (1.16) holds with

$$a_\pm(\xi,u,v) = \left|\frac{\partial}{\partial\xi}\mathcal{A}(\xi,u,v)\right| \quad \text{for } \xi \in I_{u,v},$$

$$a_\pm(\xi,u,v) = a_\pm(\xi) \quad \text{for } \xi \in \mathbb{R}\setminus I_{u,v}. \qquad □$$

3. Fully discrete schemes. For a given fully discrete scheme (1.5) we will associate a discrete kinetic formulation as follows. Assume that we are given approximations at level $n : v_i^n,\ i \in \mathbb{Z}$. Define then the approximations at the next level as

$$\begin{aligned} f_i^{n+1} &= \chi(\xi, v_i^n) - \lambda[a(\xi, v_i^n, v_{i+1}^n) - a(\xi, v_{i-1}^n, v_i^n)] \quad \text{and} \\ v_i^{n+1} &= \int f_i^{n+1}(\xi) d\xi. \end{aligned} \tag{3.1}$$

We call (3.1) *a kinetic formulation* of the difference scheme (1.5) if $a(\xi, u, v)$ is a discrete kinetic flux corresponding to $\mathcal{A}(u, v)$ and there exist measures with compact support with respect to ξ, m_i^n such that

$$\chi(\xi, v_i^{n+1}) - f_i^{n+1} = \frac{\partial}{\partial \xi} m_i^n(\xi)\,. \tag{3.2}$$

Then integrating (3.2) with respect to ξ we recover the scheme (1.5). In such a case the discrete kinetic scheme can be written in a compact form as

$$\begin{aligned} \chi(\xi, v_i^{n+1}) - \chi(\xi, v_i^n) + \lambda[a(\xi, v_i^n, v_{i+1}^n) - a(\xi, v_{i-1}^n, v_i^n)] \\ = \frac{\partial}{\partial \xi} m_i^n(\xi)\,. \end{aligned} \tag{3.3}$$

In this section we will investigate under what conditions on $\mathcal{A}(u, v)$ and $a(\xi, u, v)$ the scheme (3.1) is a kinetic formulation of (1.5) with nonnegative $m_i^n(\xi)$, i.e., under what conditions (3.3) holds with $m_i^n(\xi)$ nonnegative. This will imply that the scheme satisfies all local discrete entropy inequalities.

THEOREM 3.1. *Consider a conservative scheme* (1.5) *with a consistent discrete flux* $\mathcal{A} = \mathcal{A}(u, v)$. *Assume the following:*

(i) $\mathcal{A}(u, v)$ *is an E-flux;*

(ii) *the CFL condition* (1.12) *is satisfied.*

Then there exists a discrete kinetic flux corresponding to $\mathcal{A}(u, v)$, $a = a_\lambda(\xi, u, v)$, *and a nonnegative measure* m *such that* (3.3) *is a kinetic formulation of* (1.5). *Consequently, all the in-cell entropy inequalities, i.e., for any convex function* S, *hold true:*

$$S\Big(v_i^{n+1}\Big) - S\Big(v_i^n\Big) + \lambda\Big[\,\eta_{i+1/2}^n - \eta_{i-1/2}^n\,\Big] \le 0,$$

with discrete entropy flux

$$\eta_{i+1/2}^n = \eta(S; v_i^n, v_{i+1}^n), \qquad \eta(S; u, v) = \int_{\mathbb{R}} S'(\xi)\, a(\xi, u, v)\, d\xi.$$

Remark 3.2. In our construction, the discrete kinetic flux depends on λ. We especially do not answer the open question to know whether, for E-schemes and under the CFL condition (1.12), there are in-cell entropy inequalities with $\eta(S)$ independent of λ. Because of this difference, it seems that a reverse theorem is wrong; the existence of a fully discrete kinetic formulation with a_λ, or of in-cell entropy inequalities with $\eta_\lambda(S)$, does not imply the E-property. Note that still in the construction of [19] the discrete entropy flux depends on λ. We recall that a weaker property, called “ordered schemes” (restrict the E-property to $\xi = u$ or v) is enough to have a TVD scheme; see [16].

As in the previous section, for $u, v \in \mathbb{R}$ we denote $I_{u,v}$ the interval that they define. We will need the following lemmas.

LEMMA 3.3. *Let $a(\xi, u, v)$ be a discrete kinetic flux corresponding to $\mathcal{A}(u, v)$, and assume that* (3.3) *is a kinetic formulation of* (1.5). *Setting*

$$I_{v_i^n, v_i^{n+1}} = [m, M], \qquad \text{where } m = \min\{v_i^n, v_i^{n+1}\} \text{ and } M = \max\{v_i^n, v_i^{n+1}\}\,, \tag{3.4}$$

we have for $\xi \in \mathbb{R} \setminus I_{v_i^n, v_i^{n+1}}$

(3.5)
$$m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n) = \lambda \int_{-\infty}^{\xi} [\, a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)]\, d\zeta \quad \text{for} \quad \xi < m,$$
$$m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n) = -\lambda \int_{\xi}^{+\infty} [\, a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)]\, d\zeta \quad \text{for} \quad M < \xi.$$

Proof. Assume first that $\xi < m < 0$; then $\chi(\xi, v_i^{n+1}) = \chi(\xi, v_i^n) = 0$. Also if $\xi < m$ and $m > 0$, then for $\xi < 0$, $\chi(\xi, v_i^{n+1}) = \chi(\xi, v_i^n) = 0$ and for $\xi > 0$, $\chi(\xi, v_i^{n+1}) = \chi(\xi, v_i^n) = 1$. Therefore

$$\int_{-\infty}^{\xi} \chi(\zeta, v_i^{n+1}) - \chi(\zeta, v_i^n)\, d\zeta = 0 \qquad \text{for } \xi < m\,.$$

Similarly, we show that

$$\int_{-\infty}^{\xi} \chi(\zeta, v_i^{n+1}) - \chi(\zeta, v_i^n)\, d\zeta = v_i^{n+1}) - v_i^n \qquad \text{for } \xi > M\,,$$

and therefore (3.5) follows in view of (1.5) and Definition 1.1. □

LEMMA 3.4. *Under the assumptions of Lemma* 3.3 *we have for $\xi \in I_{v_i^n, v_i^{n+1}}$*

(3.6)
$$m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n) = \xi - v_i^n + \lambda \int_{-\infty}^{\xi} [a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)] d\zeta \quad \text{for} \quad v_i^n < \xi,$$
$$m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n) = v_i^n - \xi - \lambda \int_{\xi}^{+\infty} [a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)] d\zeta \quad \text{for} \quad \xi < v_i^n.$$

Proof. Assume first that $v_i^n < \xi < v_i^{n+1}$. Then one can verify that

$$\int_{-\infty}^{\xi} \chi(\zeta, v_i^{n+1}) - \chi(\zeta, v_i^n)\, d\zeta = \xi - v_i^n\,,$$

which implies the first equality of (3.6). Similarly, there holds

$$\int_{-\infty}^{\xi} \chi(\zeta, v_i^{n+1}) - \chi(\zeta, v_i^n)\, d\zeta = v_i^{n+1} - \xi \qquad \text{for } v_i^{n+1} < \xi < v_i^n\,,$$

and in this case (3.6) follows again in view of (1.5) and Definition 1.1. □

We are ready now to prove the main result in this section.

Proof of Theorem 3.1. For the given discrete flux $\mathcal{A}(u, v)$ we first observe that if $a(\xi, u, v)$ is a function that is constructed according to Proposition 2.7, i.e., if $a(\xi, u, v)$

is a kinetic flux for the semidiscrete scheme, then $m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n)$ in Lemma 3.3 are nonnegative. Indeed, if $\xi < m$, then $\xi < v_i^n$ and

$$m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n) = m_+(\xi; v_i^n, v_{i+1}^n) + m_-(\xi; v_{i-1}^n, v_i^n)\,,$$

where m_+ and m_- are defined in (2.4) for $\xi < v_i^n$. A similar relation holds for $\xi > M$. The same reasoning implies that

$$\int_{-\infty}^{z} [\,a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)]\, d\zeta \geq 0 \quad \text{for all} \quad z < v_i^n$$

and

$$-\int_{z}^{+\infty} [\,a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)]\, d\zeta \geq 0 \quad \text{for all} \quad v_i^n < z\,.$$

Therefore, in such a case, $m(\xi; v_{i-1}^n, v_i^n, v_{i+1}^n)$ in Lemma 3.4 will be nonnegative if we are able to show that

$$\begin{aligned} &\xi - v_i^n + \lambda \int_{v_i^n}^{\xi} [\,a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)] d\zeta \geq 0 \quad \text{for} \quad v_i^n < \xi < v_i^{n+1},\\ &v_i^n - \xi - \lambda \int_{\xi}^{v_i^n} [\,a(\zeta, v_i^n, v_{i+1}^n) - a(\zeta, v_{i-1}^n, v_i^n)]\, d\zeta \geq 0 \quad \text{for} \quad v_i^{n+1} < \xi < v_i^n. \end{aligned} \tag{3.7}$$

Next, for $u, \overline{v}, \underline{v} \in \mathbb{R}$, let

$$\overline{u} = u - \lambda\big(\mathcal{A}(u, \overline{v}) - \mathcal{A}(\underline{v}, u)\,\big)\,. \tag{3.8}$$

The proof of the theorem is therefore reduced on finding a discrete kinetic flux $a(\xi, u, v)$ such that

(a) $a(\xi, u, v)$ satisfies the requirements of Proposition 2.7;

(b) for any $u, \overline{v}, \underline{v} \in \mathbb{R}$

$$\begin{aligned} M(\underline{v}, u, \overline{v}) &= \xi - u + \lambda \int_{u}^{\xi} [\,a(\zeta, u, \overline{v}) - a(\zeta, \underline{v}, u)] d\zeta \geq 0 \quad \text{for} \quad u < \xi < \overline{u},\\ M(\underline{v}, u, \overline{v}) &= u - \xi - \lambda \int_{\xi}^{u} [\,a(\zeta, u, \overline{v}) - a(\zeta, \underline{v}, u)]\, d\zeta \geq 0 \quad \text{for} \quad \overline{u} < \xi < u. \end{aligned}$$

In what follows we show that a discrete kinetic flux that satisfies (a) and (b) indeed exists. To motivate our construction we will consider first the cases

(I) $u < \xi < \overline{u},\ \ \xi < \{\overline{v}, \underline{v}\}$,

(II) $\overline{u} < \xi < u,\ \ \{\overline{v}, \underline{v}\} < \xi$.

In case (I) we have ($\mathcal{A}(\xi, u, v)$ is defined in (2.8))

$$\begin{aligned} M(\underline{v}, u, \overline{v}) &= \xi - u + \lambda\Big(\mathcal{A}(\xi, u, \overline{v}) - \mathcal{A}(u, u, \overline{v}) - \mathcal{A}(\xi, \underline{v}, u) + \mathcal{A}(u, \underline{v}, u)\Big)\\ &= \xi - u + \lambda\Big(\mathcal{A}(\xi, u, \overline{v}) - \mathcal{A}(\xi, \underline{v}, u)\Big)\\ &= \frac{1}{2}(\xi - u) + \lambda\mathcal{A}(\xi, u, \overline{v}) - \frac{\lambda}{2}\Big[A(u) + A(\xi)\Big]\\ &\quad + \frac{1}{2}(\xi - u) - \lambda\mathcal{A}(\xi, \underline{v}, u) + \frac{\lambda}{2}\Big[A(u) + A(\xi)\Big]\,, \end{aligned}$$

where we have used that (cf. Proposition 2.7)

$$\mathcal{A}(u,u,\overline{v}) = \mathcal{A}(u,\underline{v},u) = \int_{-\infty}^{u} a(\zeta)\chi(\zeta,u)\,d\zeta\,.$$

Assume for a moment that $\xi > 0$. Then $M(\underline{v},u,\overline{v})$ is nonnegative if

$$\begin{aligned} &\frac{1}{2}(u-\xi) + \frac{\lambda}{2}\Big[A(u)+A(\xi)\Big] \le \lambda\mathcal{A}(\xi,u,\overline{v}),\\ &\lambda\mathcal{A}(\xi,\underline{v},u) \le \frac{1}{2}(\xi-u) + \frac{\lambda}{2}\Big[A(u)+A(\xi)\Big]\,. \end{aligned} \tag{3.9}$$

Similarly, in case (II) we have

$$\begin{aligned} M(\underline{v},u,\overline{v}) &= u-\xi-\lambda\mathcal{A}(u,u,\overline{v})+\lambda\mathcal{A}(\xi,u,\overline{v})+\lambda\mathcal{A}(u,\underline{v},u)-\lambda\mathcal{A}(\xi,\underline{v},u)\\ &= u-\xi-\lambda\mathcal{A}(u,\overline{v})+\lambda\mathcal{A}(\xi,u,\overline{v})+\lambda\mathcal{A}(\underline{v},u)-\lambda\mathcal{A}(\xi,\underline{v},u)\\ &= \frac{1}{2}(u-\xi)-\lambda\mathcal{A}(u,\overline{v})+\lambda\mathcal{A}(\xi,u,\overline{v})+\frac{\lambda}{2}\Big[A(u)-A(\xi)\Big]\\ &\quad+\frac{1}{2}(u-\xi)+\lambda\mathcal{A}(\underline{v},u)-\lambda\mathcal{A}(\xi,\underline{v},u)-\frac{\lambda}{2}\Big[A(u)-A(\xi)\Big]\,, \end{aligned}$$

where we have used that (cf. Proposition 2.7)

$$\mathcal{A}(u,u,\overline{v}) = \mathcal{A}(u,\overline{v}) - \int_{u}^{+\infty} a(\zeta)\chi(\zeta,u)\,d\zeta\,,$$

and the similar relation for $\mathcal{A}(u,\underline{v},u)$. Still assuming $\xi > 0$, then $M(\underline{v},u,\overline{v})$ will be nonnegative if

$$\begin{aligned} &\frac{1}{2}(\xi-u)+\lambda\mathcal{A}(u,\overline{v})-\frac{\lambda}{2}\Big[A(u)-A(\xi)\Big] \le \lambda\mathcal{A}(\xi,u,\overline{v}),\\ &\lambda\mathcal{A}(\xi,\underline{v},u) \le \frac{1}{2}(u-\xi)+\lambda\mathcal{A}(\underline{v},u)-\frac{\lambda}{2}\Big[A(u)-A(\xi)\Big]\,. \end{aligned} \tag{3.10}$$

Relations (3.9) and (3.10) suggest the following:

$$\begin{aligned} \text{for } u\le\xi\le v: \quad &\frac{1}{2}(u-\xi)+\frac{\lambda}{2}\Big[A(u)+A(\xi)\Big]\\ &\le \lambda\mathcal{A}(\xi,u,v) \le \frac{1}{2}(v-\xi)+\lambda\mathcal{A}(u,v)-\frac{\lambda}{2}\Big[A(v)-A(\xi)\Big] \end{aligned} \tag{3.11}$$

and

$$\begin{aligned} \text{for } v\le\xi\le u: \quad &\frac{1}{2}(\xi-u)+\lambda\mathcal{A}(u,v)-\frac{\lambda}{2}\Big[A(u)-A(\xi)\Big]\\ &\le \lambda\mathcal{A}(\xi,u,v) \le \frac{1}{2}(\xi-v)+\frac{\lambda}{2}\Big[A(v)+A(\xi)\Big]\,. \end{aligned} \tag{3.12}$$

It will be convenient to introduce the following notation:

$$\begin{aligned} \lambda\overline{A}_{v>u}(\xi) &= \frac{1}{2}(v-\xi)+\lambda\mathcal{A}(u,v)-\frac{\lambda}{2}\Big[A(v)-A(\xi)\Big],\\ \lambda\underline{A}_{v>u}(\xi) &= \frac{1}{2}(u-\xi)+\frac{\lambda}{2}\Big[A(u)+A(\xi)\Big] \end{aligned} \tag{3.13}$$

and

$$\begin{aligned}\lambda\overline{A}_{u>v}(\xi) &= \frac{1}{2}(\xi - v) + \frac{\lambda}{2}\Big[A(v) + A(\xi)\Big],\\ \lambda\underline{A}_{u>v}(\xi) &= \frac{1}{2}(\xi - u) + \lambda\mathcal{A}(u,v) - \frac{\lambda}{2}\Big[A(u) - A(\xi)\Big]\,.\end{aligned}\tag{3.14}$$

A crucial fact is that, despite the E-property, we have indeed

$$\underline{A}_{v>u} \le \overline{A}_{v>u} \quad \text{and} \quad \underline{A}_{u>v} \le \overline{A}_{u>v}\,.$$

This is because by (1.12),

$$\lambda\overline{A}_{v>u} - \lambda\underline{A}_{v>u} = \frac{1}{2}(v-u) + \lambda\mathcal{A}(u,v) - \frac{\lambda}{2}\big[A(v)+A(u)\big] = \frac{1}{2}(v-u)\,\big[1-Q(u,v)\big] \ge 0$$

and

$$\lambda\overline{A}_{u>v} - \lambda\underline{A}_{u>v} = \frac{1}{2}(u-v) - \lambda\mathcal{A}(u,v) + \frac{\lambda}{2}\big[A(v)+A(u)\big] = \frac{1}{2}(u-v)\,\big[1-Q(u,v)\big] \ge 0.$$

Next, since we are looking for a flux that will satisfy (2.9) and (2.10), it is useful for what follows to notice that (1.12) implies that for $\xi \in I_{u,v}$

$$\overline{A}_{v>u}(\xi) \ge \mathcal{A}(u,v), \qquad \underline{A}_{v>u}(\xi) \le A(\xi)\tag{3.15}$$

and

$$\overline{A}_{u>v}(\xi) \ge A(\xi), \qquad \underline{A}_{u>v}(\xi) \le \mathcal{A}(u,v)\,.\tag{3.16}$$

We are ready now to define

$$\begin{aligned}B_{v>u}(\xi) &= \min\{\overline{A}_{v>u}(\xi), A(\xi)\} \quad \text{for } u \le \xi \le v,\\ B_{u>v}(\xi) &= \min\{\overline{A}_{u>v}(\xi), \mathcal{A}(u,v)\} \quad \text{for } v \le \xi \le u\,.\end{aligned}\tag{3.17}$$

Then, since $\mathcal{A}(u,v)$ is an E-flux the above relationships imply that

$$\mathcal{A}(u,v) \le B_{v>u}(\xi) \le A(\xi) \quad \text{and} \quad \underline{A}_{v>u}(\xi) \le B_{v>u}(\xi) \le \overline{A}_{v>u}(\xi)\,.\tag{3.18}$$

In addition,

$$B_{v>u}(u) = \min\{\overline{A}_{v>u}(u), A(u)\} = A(u) \text{ and } B_{v>u}(v) = \min\{\mathcal{A}(u,v), A(v)\} = \mathcal{A}(u,v),\tag{3.19}$$

where in the first equality in (3.19) we used $\lambda\overline{A}_{v>u}(u) - \lambda A(u) = \frac{1}{2}(v-u)\big[1 - Q(u,v)\big] \ge 0$. Similar relations hold for $B_{u>v}$. Hence, in the cases under consideration and for $\xi > 0$, it suffices to define in $I_{u,v}$

$$A(\xi,u,v) = \begin{cases} B_{v>u}(\xi) & \text{for } u \le \xi \le v,\ \xi > 0,\\ B_{u>v}(\xi) & \text{for } v \le \xi \le u,\ \xi > 0\,.\end{cases}\tag{3.20}$$

It is clear now that the right extension of $A(\xi,u,v)$ when $\xi < 0$ is

$$A(\xi,u,v) = \begin{cases} B_{v>u}(\xi) - A(\xi) & \text{for } u \le \xi \le v,\ \xi < 0,\\ B_{u>v}(\xi) - A(\xi) & \text{for } v \le \xi \le u,\ \xi < 0\,.\end{cases}\tag{3.21}$$

It is straightforward to see that this choice satisfies (a) and (b) in cases (I) and (II) and for $\xi < 0$.

In all the other cases the above choice of $A(\xi, u, v)$ satisfies (a) and (b). Property (a) is clear in any case. Property (b) is a consequence of (3.18) (and its corresponding relation for $u > v$) and of the CFL condition $\lambda \max_\xi |a(\xi)| \leq 1$. To illustrate this we consider only the case $\overline{u} \leq \xi \leq u$, $\overline{v} < \xi < 0$, $u < \underline{v} < 0$, the other cases being similar. Indeed,

$$\begin{aligned}
M(\underline{v}, u, \overline{v}) &= u - \xi - \lambda\mathcal{A}(u, u, \overline{v}) + \lambda\mathcal{A}(\xi, u, \overline{v}) + \lambda \int_\xi^u a(\zeta)\chi(\zeta, u) d\zeta \\
&= u - \xi - \lambda\mathcal{A}(u, \overline{v}) + \lambda \int_u^{+\infty} a(\zeta)\chi(\zeta, u) d\zeta + \lambda\mathcal{A}(\xi, u, \overline{v}) \\
&\geq \frac{1}{2}(u - \xi) - \frac{\lambda}{2}\Big[A(u) - A(\xi)\Big] \\
&\quad - \lambda A(\xi) + \lambda \int_u^{+\infty} a(\zeta)\chi(\zeta, u) d\zeta \\
&= \frac{1}{2}(u - \xi) - \frac{\lambda}{2}\Big[A(u) - A(\xi)\Big] + \lambda\Big[A(u) - A(\xi)\Big] \\
&= \frac{1}{2}(u - \xi) + \frac{\lambda}{2}\Big[A(u) - A(\xi)\Big] \geq 0\,.
\end{aligned}$$

The proof of the kinetic formulation is therefore complete.

The proof of the local entropy inequalities is immediate, again after integrating (1.22) against $S'(\xi)\, d\xi$. □

Remark 3.5. It should be noted that in the proof of the previous theorem the CFL condition (1.12) was used in its local form (only specific v_i^n appear)

$$\lambda Q_{i+1/2} = \lambda Q(v_i^n, v_{i+1}^n) \leq 1.$$

Indeed, tracing back in the proof we see that $\underline{v}$, u, and $\overline{v}$ represent the values v_{i-1}^n, v_i^n, and v_{i+1}^n.

Remark 3.6. Note that in the semidiscrete case the construction of the discrete kinetic flux is local and therefore the choice of uniform mesh is done only for notational simplicity. In the fully discrete case more care is needed in the construction of the discrete kinetic flux when nonuniform mesh is considered, essentially since $a(\xi, u, v)$ depends on λ. Indeed, denoting λ' the CFL number corresponding to the next interval in the construction of the previous theorem, a modification on the choice of $B_{v>u}(\xi)$, $B_{u>v}(\xi)$ is needed depending of the sign of $1 - \lambda'/\lambda$; e.g., one may choose

$$(3.22) \quad B_{v>u}(\xi) = \begin{cases} \min\{\overline{A}_{v>u}(\xi), A(\xi)\} & \text{for } u \leq \xi \leq v, \quad \text{provided } \lambda \geq \lambda', \\ \max\{\underline{A}_{v>u}(\xi), A(u, v)\} & \text{for } u \leq \xi \leq v, \quad \text{provided } \lambda' \geq \lambda. \end{cases}$$

4. Engquist–Osher scheme.

4.1. Semidiscrete Engquist–Osher scheme. We give first a direct proof for the kinetic formulation of the Engquist–Osher scheme [7]. We also give explicit formulas for the kinetic defect measures $m_\pm$.

THEOREM 4.1. *There is a unique nonnegative function $m_i(t, \xi)$ with bounded support in ξ such that the scheme* (1.4) *with Engquist–Osher flux* (1.20) *is equivalent* *to the kinetic equation* (1.16)–(1.17), *with* $a_\pm(\xi, u, v) = a_\pm(\xi)$. *Moreover, we have the bound*

$$\sum_{i\in\mathbb{Z}} h \int_0^\infty m_i(t,\xi)\,dt \le \mathbf{I}_{\{\xi\ge 0\}} \|(v_i^0 - \xi)_+\|_{l^1} + \mathbf{I}_{\{\xi\le 0\}} \|(\xi - v^0)_+\|_{l^1} \le \|v^0\|_{l^1},$$

and the functions $m_\pm$ *are given by*

$$\begin{aligned} m_+(\xi; u, v) &= A_-(u) - A_-(\xi) \quad \text{for } u \le \xi \le v,\\ m_+(\xi; u, v) &= A_-(v) - A_-(\xi) \quad \text{for } v \le \xi \le u, \end{aligned}$$

$$\begin{aligned} m_-(\xi; u, v) &= A_+(\xi) - A_+(u) \quad \text{for } u \le \xi \le v,\\ m_-(\xi; u, v) &= A_+(\xi) - A_+(v) \quad \text{for } v \le \xi \le u. \end{aligned} \tag{4.1}$$

In other words, the Engquist–Osher scheme is nothing but a linear upwind discretization of the kinetic formulation. Also Theorem 2.1(ii) implies that the Engquist–Osher scheme satisfies all local entropy inequalities.

Proof. As in Lemma 2.2 we see that

$$m_i(t,\xi) = [m_+(\xi; v_i(t), v_{i+1}(t)) + m_-(\xi; v_{i-1}(t), v_i(t))],$$

where the functions m_+ satisfy

$$\begin{aligned} &\frac{\partial}{\partial\xi} m_+(\xi; v_i(t), v_{i+1}(t))\\ &= \delta(\xi - v_i(t))[A(v_i(t)) - A_{i+1/2}] + [a_+(\xi)\chi(\xi, v_i(t)) - a_-(\xi)\chi(\xi, v_{i+1}(t))] - a(\xi)\chi(\xi, v_i(t)) \end{aligned}$$

and

$$\begin{aligned} &\frac{\partial}{\partial\xi} m_-(\xi; v_{i-1}(t), v_i(t))\\ &= \delta(\xi - v_i(t))[-A_{i-1/2} - A(v_i(t))] - [a_+(\xi)\chi(\xi, v_{i-1}(t)) - a_-(\xi)\chi(\xi, v_i(t))] + a(\xi)\chi(\xi, v_i(t)). \end{aligned}$$

Then, with a slight change of notation,

$$\begin{aligned} &\frac{\partial}{\partial\xi} m_+(\xi; u, v)\\ &= -\delta(\xi - u)\int_{\mathbb{R}} a_-(\zeta)\,[\chi(\zeta; u) - \chi(\zeta; v)]\,d\zeta + a_-(\xi)\,[\chi(\xi; u) - \chi(\xi; v)]. \end{aligned}$$

Notice that the integral in ξ of the right-hand side of this identity vanishes. Therefore since m_+ should have compact support in ξ,

$$m_+(\xi; u, v) = 0 \qquad \text{for } \xi \notin [u, v] \quad \text{(nonordered interval)}.$$

Indeed, the brackets $[\chi(\zeta; u) - \chi(\zeta; v)]$ and $[\chi(\xi; u) - \chi(\xi; v)]$ are supported in $[u, v]$. Also, they have the same sign as $u - v$. Therefore, either $v < u$ and $\frac{\partial}{\partial\xi} m_+(\xi; u, v)$ is positive between v and u and thus $m_+(\xi; u, v)$ vanishes for $\xi \in]-\infty, v]$ or it is nonnegative for $\xi \in [v, u]$ and has a jump at $\xi = u$ and thus vanishes for $\xi > u$. Either $v > u$ and a similar argument shows that $m_+(\xi; u, v)$ is again nonnegative. The same argument as before shows that $m_-(\xi; u, v)$ is nonnegative also.

Finally, the bound on the discrete kinetic defect measure is obtained as in the continuous case. We first argue for $\xi_0 \geq 0$. We use Kruzkov's entropy $S^+_{\xi_0}(\xi) = (\xi - \xi_0)_+$, $S^{+\prime\prime}(\xi)_{\xi_0} = \delta(\xi = \xi_0)$, and we multiply (1.16) by $S^{+\prime}_{\xi_0}(\xi)$, integrate in ξ and in time, and sum up on i. Taking into account the sign in the quantity

$$\int_{\mathbb{R}} S^{+\prime}_{\xi_0}(\xi)\, \chi(\xi; v_i(t))\, d\xi \geq 0,$$

we obtain the inequality, for $\xi_0 \geq 0$,

$$\begin{aligned}\sum_{i\in\mathbb{Z}} h \int_0^\infty m_i(t,\xi_0)\, dt &\leq \sum_{i\in\mathbb{Z}} h\, \|(v_i^0 - \xi)_+\|_{l^1} \\ &\leq \|v^0\|_{l^1}.\end{aligned}$$

A similar argument for $\xi_0 \leq 0$ concludes the proof of the proposition. □

4.2. Fully discrete Engquist–Osher scheme. As in section 3, we depart from the fully discrete Engquist–Osher scheme (1.5) and define $f_i^{n+1}(\xi)$ by the formula

$$\begin{aligned} f_i^{n+1}(\xi) - \chi(\xi, v_i^n) + \lambda\big[a_+(\xi)\chi(\xi, v_i^n) - a_-(\xi)\chi(\xi, v_{i+1}^n)\big] \\ - \lambda\big[a_+(\xi)\chi(\xi, v_{i-1}^n) - a_-(\xi)\chi(\xi, v_i^n)\big] = 0, \end{aligned} \tag{4.2}$$

which can also be written under the kinetic form

$$\begin{aligned} \chi(\xi, u_i^{n+1}) - \chi(\xi, v_i^n) + \lambda\big[a_+(\xi)\chi(\xi, v_i^n) - a_-(\xi)\chi(\xi, v_{i+1}^n)\big] \\ - \lambda\big[a_+(\xi)\chi(\xi, v_{i-1}^n) - a_-(\xi)\chi(\xi, v_i^n)\big] = \frac{\partial}{\partial\xi} m_i^n(\xi), \end{aligned} \tag{4.3}$$

where $m_i^n(\xi)$ vanishes at $\pm\infty$ because

$$u_i^{n+1} = \int_{\mathbb{R}} f_i^{n+1}(\xi)\, d\xi. \tag{4.4}$$

We claim that for λ small enough this is a kinetic formulation.

Theorem 4.2. *Consider the scheme* (1.5), (1.20), *and assume the CFL condition*

$$\lambda \max_\xi |a(\xi)| \leq 1; \tag{4.5}$$

then (4.3) *holds with* $m_i^n(\xi) \geq 0$ *satisfying* (1.17), *and thus it is a kinetic formulation of the Engquist–Osher scheme.*

Proof. Using (4.4) and a variant of Brenier's lemma ([4] or [16, Chap. 2.2]), the property

$$0 \leq \operatorname{sgn}(\xi)\, f_i^{n+1}(\xi) \leq 1 \tag{4.6}$$

is enough to ensure that $m_i^n(\xi) \geq 0$, using the relation

$$\frac{\partial}{\partial\xi} m_i^n(\xi) = \chi(\xi, u_i^{n+1}) - f_i^{n+1}(\xi).$$

To check the signs in (4.6), we rewrite (4.2) as

$$\begin{aligned} f_i^{n+1}(\xi) = \chi(\xi, v_i^n)\Big(1 - \lambda\, a_+(\xi) - \lambda\, a_-(\xi)\Big) \\ + \lambda\, \chi(\xi, v_{i+1}^n) a_-(\xi) + \lambda\, \chi(\xi, v_{i+1}^n) a_+(\xi). \end{aligned} \tag{4.7}$$

To prove the property (4.6), it is enough to notice that this is a convex combination of χ's, a property which follows obviously from $a_\pm \geq 0$ and (4.5). □

Acknowledgment. The authors would like to thank the referees of this paper for their useful comments.

CONVERGENCE RATE ANALYSIS OF A MULTIPLICATIVE SCHWARZ METHOD FOR VARIATIONAL INEQUALITIES*

LORI BADEA†, XUE-CHENG TAI‡, AND JUNPING WANG§

Abstract. This paper derives a linear convergence for the Schwarz overlapping domain decomposition method when applied to constrained minimization problems. The convergence analysis is based on a minimization approach to the corresponding functional over a convex set. A general framework of convergence is established for some multiplicative Schwarz algorithm. The abstract theory is particularly applied to some obstacle problems, which yields a linear convergence for the corresponding Schwarz overlapping domain decomposition method of one and two levels. Numerical experiments are presented to confirm the convergence estimate derived in this paper.

Key words. domain decomposition, variational inequalities, finite element methods, obstacle problems

1. Introduction.

The study of domain decomposition methods was motivated by the increasing need of fast numerical solutions for problems in science and engineering. Such practical problems are often of very large scale and are extremely difficult to solve by using classical approaches. The domain decomposition method has the capability of providing new numerical algorithms which are efficient and parallelizable. The Schwarz overlapping domain decomposition method represents a typical thinking of parallelization and shall be the main focus of this paper.

The Schwarz method consists of two categories which have been traditionally classified as multiplicative and additive methods. The multiplicative Schwarz replicates the well-known Gauss–Seidel iteration for linear systems in a block fashion, while the additive Schwarz method resembles the Jacobi iteration in numerical linear algebra. Both methods have been well studied for second order elliptic problems for the last two decades. Details can be found from [2, 4, 6, 13, 14, 15, 16, 18, 20, 32] and the references cited therein. However, to the authors' knowledge, there are very few existing results which are satisfactorily developed for the Schwarz method when applied to constrained minimization problems.

The main objective of this paper is to establish a convergence rate estimate for the overlapping domain decomposition method for variational inequalities. The result is inspired by the classical analysis of [4] for linear second order elliptic problems and extends some of the new techniques for nonlinear problems of [26, 27, 29, 30]. The essential idea is to decompose the global approximating space into subspaces, which

is the key idea behind the latest convergence analysis for domain decomposition and multigrid methods. We shall first establish an abstract framework for the convergence of general minimization problems and then apply it to some obstacle problems by verifying the assumptions of the abstract theory.

A brief review of the existing work on the domain decomposition methods for variational inequalities is as follows. In [1], Badea proved a convergence of a domain decomposition algorithm which is based on minimizing quadratic functionals in a Hilbert space. A convergence rate was established there by using the maximum principle for the problem. A similar method was later proposed and analyzed in [3] as a new member of the additive Schwarz methods. Various one-level overlapping domain decomposition methods have been studied in [10, 12, 17, 19, 21, 24, 25]. A linear convergence for the one-level overlapping domain decomposition method was derived recently in [29, 22, 33] under the condition that the iterative solution increases or decreases monotonically to the true solution. It is known that we can linearize the obstacle problem first and then apply domain decomposition methods for the linearized problems; see, for example, [11]. Our approach is applied directly to the obstacle problem, and no linearization is necessary in the domain decomposition scheme.

Both the one-level and two-level domain decomposition methods are considered in this paper. As it is well known, the two-level method makes use of a coarse level, and its convergence is quite challenging in theory. In fact, the convergence for two-level algorithms has not been fully understood so far in the literature. The only ones we know are from [26, 27, 28]; see also [31] for a two-level algebraic method for the Signorini problem. The method proposed in [26, 27] relies on a decomposition of the convex set, which is different from the algorithm to be studied in the present paper. For the approach to be taken here, the subproblems can be solved in parallel or sequentially. Numerical tests and convergence rate analysis for the parallel version have been done in [28] for domain decomposition and multigrid methods. In this paper, we shall give a convergence rate estimate for the sequential method and concentrate only on the one-level and two-level domain decomposition methods. To the authors' knowledge, our result is the first that gives an explicit convergence rate estimate for this two-level Schwarz method for variational inequalities. For the one-level method, our estimate does not require any monotone property of the iterative solution. Moreover, we give an explicit relation between the convergence rate and the overlapping size. The convergence rate analysis for the multigrid method with the sequential approach is much more difficult and remains open.

This paper is organized as follows. In section 2, we present some abstract domain decomposition algorithms for general convex minimization problems over convex constraint sets. In section 3, we state an abstract result of convergence based on some assumptions for the spatial decomposition. In section 4, we apply the abstract convergence result to a specific obstacle problem by verifying all the conditions required for the abstract theory. To validate our convergence theory, we present some numerical results in section 5 for a two-sided obstacle problem. Finally, in section 6, we provide a complete proof for the main convergence estimate for constrained minimization problems.

2. Algorithm description.

Given a reflexive Banach space V and a convex functional $F : V \mapsto \mathbb{R}$, we consider the following optimization problem:

$$\min_{v \in K} F(v), \quad K \subset V, \tag{2.1}$$

where K is a closed convex subset of V. We are interested in the case where the space V can be decomposed into a sum of subspaces V_i, i.e.,

$$V = V_1 + V_2 + \cdots + V_m = \sum_{i=1}^{m} V_i \; . \tag{2.2}$$

This means that for any $v \in V$, there exists $v_i \in V_i$ such that $v = \sum_{i=1}^{m} v_i$.

With the decomposition (2.2), there are two different ways to solve the nonlinear problem (2.1). The first approach is to decompose K into a sum of $K_i \subset V_i$, $i = 1, 2, \ldots, m$, i.e.,

$$K = K_1 + K_2 + \cdots + K_m = \sum_{i=1}^{m} K_i,$$

and then to solve a minimization problem over each subset K_i in parallel or sequentially. The convergence rate analysis and numerical experiments for this approach have been conducted in [26, 27]. The approach of [26] could handle one- and two-level domain decomposition methods as well as the multigrid method. The second approach does not involve any decomposition of the convex set K and is illustrated in Algorithms 1 and 2.

Algorithm 1. *For a given $u^n \in K$ and $\rho \in (0, 1/m)$, compute $e_i^{n+1} \in V_i$ in parallel for $i = 1, 2, \ldots, m$ such that*

$$e_i^{n+1} = \arg \min_{v_i + u^n \in K, \; v_i \in V_i} G(v_i) \quad \textit{with} \quad G(v_i) = F(u^n + v_i) \tag{2.3}$$

and then update

$$u^{n+1} := u^n + \rho \sum_{i=1}^{m} e_i^{n+1}.$$

Algorithm 2. *For a given $u^n \in K$, compute $e_i^{n+1} \in V_i$ sequentially for $i = 1, 2, \ldots, m$ such that*

$$e_i^{n+1} = \arg \min_{v_i + u^{n+\frac{i-1}{m}} \in K, \; v_i \in V_i} G(v_i) \quad \textit{with} \quad G(v_i) = F(u^{n+\frac{i-1}{m}} + v_i) \tag{2.4}$$

and update

$$u^{n+\frac{i}{m}} := u^{n+\frac{i-1}{m}} + e_i^{n+1}.$$

The algorithms introduced in [1] and [3] are in the same spirit as Algorithms 1 and 2. A convergence rate analysis for Algorithm 1 has been established in [28] for domain decomposition and multigrid methods and in [3] for domain decomposition methods. The objective of this paper is to study Algorithm 2 and derive a linear convergence. The conditions for the convergence of Algorithm 2 differ from those for Algorithm 1. In addition, the analysis turns out to be more complicated than Algorithm 1. The techniques used in the analysis are extensions of those presented in [26, 29, 30].

3. An abstract theory of convergence.

Assume that the minimization functional F is Gâteaux differentiable (see [8]) and that there exists a constant $\kappa > 0$ such that

$$\langle F'(w) - F'(v), w - v\rangle \geq \kappa \|w - v\|_V^2 \quad \forall w, v \in V. \tag{3.1}$$

Here $\langle \cdot, \cdot \rangle$ is the duality pairing between V and its dual space V', i.e., the value of a linear function at an element of V. Under the condition (3.1), problem (2.1) has a unique solution; see [8, p. 35]. For some nonlinear problems, the constant κ may depend on v and w and the analysis given here is still applicable; see [30, Rem. 2.1] for more information. Our abstract convergence theory is based on the following two assumptions inspired from [1].

Assumption 1. There exists a constant $C_1 > 0$ such that for any $w, v \in K$ and $s_i \in V_i$ with $w + \sum_{j=1}^i s_j \in K$, $i = 1, \dots, m$, there exist $z_i \in V_i$ satisfying

$$\begin{cases} \text{(a) } v - w = \displaystyle\sum_{i=1}^m z_i, \qquad \text{(b) } w + \displaystyle\sum_{j=1}^{i-1} s_j + z_i \in K \quad \text{for } i = 1, \dots, m, \\ \text{(c) } \left(\displaystyle\sum_{i=1}^m \|z_i\|_V^2\right)^{\frac{1}{2}} \leq C_1 \left(\|v - w\|_V^2 + \displaystyle\sum_{j=1}^m \|s_j\|_V^2\right)^{\frac{1}{2}}. \end{cases} \tag{3.2}$$

Assumption 2. There exists a constant $C_2 > 0$ which is the least constant satisfying the following inequality for any $w_{ij} \in V, u_i \in V_i,$ and $v_j \in V_j :$

$$\sum_{i,j=1}^m |\langle F'(w_{ij} + u_i) - F'(w_{ij}), v_j\rangle| \leq C_2 \left(\sum_{i=1}^m \|u_i\|_V^2\right)^{\frac{1}{2}} \left(\sum_{j=1}^m \|v_j\|_V^2\right)^{\frac{1}{2}}. \tag{3.3}$$

Let u be the unique solution of (2.1). Our main result of the convergence estimate can be stated as follows.

THEOREM 3.1. *Assume that the space decomposition satisfies* (3.2), (3.3), *and assume that the functional F satisfies* (3.1). *Then for the iterative approximation $\{u^n\}_{n=1}^\infty$ given by Algorithm* 2, *we have*

$$\frac{|F(u^{n+1}) - F(u)|}{|F(u^n) - F(u)|} \leq 1 - \frac{1}{(\sqrt{1 + C^*} + \sqrt{C^*})^2} \tag{3.4}$$

and

$$||u^n - u|\,|_V^2 \leq \frac{2}{\kappa} \left[1 - \frac{1}{(\sqrt{1 + C^*} + \sqrt{C^*})^2}\right]^n |F(u^0) - F(u)|, \tag{3.5}$$

where

$$C^* = \left((1 + C_1)C_2 + \frac{(C_1 C_2)^2}{2\kappa}\right)\frac{2}{\kappa}. \tag{3.6}$$

In order to prove the theorem, we need to combine the special assumption (3.2) with the techniques used in [26]. The proof is tedious and rather complex, and it is postponed to section 6.

4. Application to obstacle problems.

The objective of this section is to apply the abstract convergence theory to obstacle problems and to derive a linear convergence for the corresponding domain decomposition algorithm. To this end, let $\Omega \subset \mathbb{R}^d$ be an open bounded and connected domain with a polyhedral boundary. Consider the problem that seeks an unknown function $u = u(x)$ on Ω satisfying

$$a(u, v-u) \geq f(v-u) \quad \forall v \in K, \tag{4.1}$$

where

$$\begin{aligned} a(v,w) &= \int_\Omega \nabla v \cdot \nabla w \; dx, \\ K &= \{v \in H_0^1(\Omega) | \;\; \alpha(x) \leq v(x) \leq \beta(x) \text{ a.e. in } \Omega\}, \end{aligned} \tag{4.2}$$

$\alpha(x)$ and $\beta(x)$ are two obstacle functions in $L^\infty(\Omega)$, and $f(\cdot)$ is a bounded linear functional on the Sobolev space $H_0^1(\Omega)$. It is well known that the above problem is equivalent to the following minimization problem (see [9], for instance):

$$\min_{v \in K} F(v), \quad F(v) = \frac{1}{2} a(v,v) - f(v). \tag{4.3}$$

For the obstacle problem (4.1), the reflexive Banach space is given by $V = H_0^1(\Omega)$. Correspondingly, we have $\kappa = 1$ in assumption (3.1). We point out that our algorithms and the convergence estimate presented in the previous section are valid for a general class of optimization problems in which the optimization functional F is a strongly convex functional satisfying (3.1).

We use the standard notation for Sobolev spaces $H_0^k(\Omega)$ and $W_0^{k,p}(\Omega)$ and their norms and seminorms. In particular, for a given subdomain $D \subset \Omega$ and $v \in H_0^1(D)$, we shall always extend v with zero in $\Omega \backslash D$, i.e.,

$$H_0^1(D) = \{v | \quad v \in H^1(\Omega), \quad v = 0 \text{ in } \Omega \backslash D\}.$$

Throughout the paper, C will be used to denote a generic constant that does not depend on mesh parameters of the finite element partitions introduced later.

4.1. Numerical approximation and technical tools.

The domain Ω is first partitioned into a coarse mesh denoted $\mathcal{T}_H$ with a mesh size H. Next, we refine the partition $\mathcal{T}_H$ and obtain a fine mesh partition $\mathcal{T}_h$ with a mesh size $h < H$. We assume that both the coarse and fine meshes are shape-regular (see [7]).

Let $S_H \subset W_0^{1,\infty}(\Omega)$ and $S_h \subset W_0^{1,\infty}(\Omega)$ be the continuous, piecewise linear finite element spaces associated with $\mathcal{T}_H$ and $\mathcal{T}_h$, respectively. More precisely, we have

$$S_H = \left\{ v \in W_0^{1,\infty}(\Omega) \middle| \quad v|_\tau \in P_1(\tau) \, \forall \tau \in \mathcal{T}_H \right\}$$

and

$$S_h = \left\{ v \in W_0^{1,\infty}(\Omega) \middle| \quad v|_\tau \in P_1(\tau) \, \forall \tau \in \mathcal{T}_h \right\}.$$

The obstacle problem (4.1) is approximated by a finite element function $u_h(x) \in K \cap S_h$ satisfying

$$a(u_h, v - u_h) \geq f(v - u_h) \quad \forall v \in K \cap S_h. \tag{4.4}$$

Let $\{\Omega_i\}_{i=1}^M$ be a nonoverlapping domain decomposition for Ω, and each Ω_i is the union of some coarse mesh elements. For each Ω_i, we consider an enlarged subdomain Ω_i^δ consisting of elements $\tau \in \mathcal{T}_h$ with $\operatorname{dist}(\tau, \Omega_i) \le \delta \le H$. The union of Ω_i^δ covers $\bar{\Omega}$ with overlaps of size δ. Let us denote the piecewise linear finite element space with vanishing values on the boundary $\partial\Omega_i^\delta$ as $S_h(\Omega_i^\delta)$. It is not hard to show that

$$S_h = \sum_{i=1}^{M} S_h(\Omega_i^\delta) \quad \text{and} \quad S_h = S_H + \sum_{i=1}^{M} S_h(\Omega_i^\delta)\ . \tag{4.5}$$

For the overlapping subdomains, assume that there exist m colors such that each subdomain Ω_i^δ can be marked with one color, and the subdomains with the same color will not intersect with each other. For suitable decompositions, one can choose $m = 2$ if $d = 1$, $m \le 4$ if $d = 2$, and $m \le 8$ if $d = 3$. Let Ω_i^c be the union of the subdomains with the ith color, and

$$V_i = \{v \in S_h | \quad v(x) = 0, \quad x \notin \Omega_i^c\}$$

for $i = 1, 2, \ldots, m$. By denoting $V_0 = S_H$ and $V = S_h$, we see from (4.5) that

$$\text{(a)} \quad V = \sum_{i=1}^{m} V_i \qquad \text{and} \qquad \text{(b)} \quad V = V_0 + \sum_{i=1}^{m} V_i. \tag{4.6}$$

Associated with the subdomains, we consider some functions $\theta_j^i \in C^1(\overline{\Omega})$, $i = 1, 2, \ldots, m$, $j = i, \ldots, m$, such that for any $i = 1, 2, \ldots, m$ we have

$$\operatorname{supp}(\theta_j^i) \subset \bar{\Omega}_j^c,\ 0 \le \theta_j^i \le 1 \quad \forall j = i, \ldots, m, \text{ and } \sum_{j=i}^{m} \theta_j^i = 1 \text{ in } \bigcup_{j=i}^{m} \Omega_j^c. \tag{4.7}$$

More precisely, θ_j^1 is a partition of unity with respect to the subdomains Ω_j^c, $j = 1, 2, \ldots, m$; θ_j^2 is a partition of unity with the subdomains Ω_j^c, $j = 2, \ldots, m$; i.e., the subdomains with the first color are dropped. Accordingly, θ_j^i is a partition of unity with respect to the subdomains Ω_j^c, $j = i, \ldots, m$, where the subdomains Ω_j^c, $j = 1, 2 \ldots,\ i-1$, are dropped. Due to the overlapping property, the preceding functions can be constructed to satisfy

$$|\nabla \theta_j^i| \le C/\delta. \tag{4.8}$$

In the following, I_h denotes the Lagrangian interpolation operator which uses the function values at the nodes of a given mesh $\mathcal{T}_h$ with a mesh size h. The following estimate is correct due to the special structure of the functions θ_j^i:

$$\|I_h(\theta_j^i v)\|_0 \le C\|v\|_0, \quad |I_h(\theta_j^i v)|_1 \le C\|v\|_1 + \frac{1}{\delta}\|v\|_0 \quad \forall\, i, j, \quad \forall\, v \in S_h. \tag{4.9}$$

We also need a nonlinear interpolation operator $I_H^\ominus : S_h \mapsto S_H$ introduced in [26, 27]. Denote $\mathcal{N}_H = \{x_0^i\}_{i=1}^{n_0}$ all the interior nodes for $\mathcal{T}_H$. For a given x_0^i, let ω_i be the union of the mesh elements of $\mathcal{T}_H$ having x_0^i as one of its vertices, i.e.,

$$\omega_i := \bigcup \{\tau \in \mathcal{T}_H, x_0^i \in \bar{\tau}\}.$$

Let $\{\phi_0^i\}_{i=1}^{n_0}$ be the associated nodal basis functions. It is clear that ω_i is the support of ϕ_0^i. Given a nodal point $x_0^i \in \mathcal{N}_H$ and a $v \in S_h$, let $I_i v = \min_{\omega_i} v(x)$. The interpolation function is then defined as

$$I_H^{\ominus} v := \sum_{x_0^i \in \mathcal{N}_H} (I_i v)\phi_0^i(x). \tag{4.10}$$

From the definition, it is easy to see that

$$I_H^{\ominus} v \le v \quad \forall v \in S_h, \tag{4.11}$$

$$I_H^{\ominus} v \ge 0 \quad \forall v \ge 0, v \in S_h. \tag{4.12}$$

Moreover, the interpolation for a given $v \in S_h$ on a finer mesh is always no smaller than the corresponding interpolation on a coarser mesh due to the fact that each coarser mesh element contains several finer mesh elements, i.e.,

$$I_{H_1}^{\ominus} v \le I_{H_2}^{\ominus} v \quad \forall H_1 \ge H_2 \ge h, \quad \forall v \in S_h. \tag{4.13}$$

Define

$$c_d = \begin{cases} C & \text{if} \quad d = 1, \\ C(1 + |\log(H/h)|^{\frac{1}{2}}) & \text{if} \quad d = 2, \\ C(H/h)^{\frac{1}{2}} & \text{if} \quad d = 3. \end{cases}$$

Using Lemma 2.3 in [5], it was proven in [26, 27] that the following approximation properties are correct for the nonlinear interpolation operator $I_H^{\ominus}$.

THEOREM 4.1. *For any $v, w \in S_h$, it is true that*

$$\|I_H^{\ominus} v - I_H^{\ominus} w - (v - w)\|_0 \le c_d H |v - w|_1, \tag{4.14}$$

$$\|I_H^{\ominus} v \ - \ v\|_0 \le c_d H |v|_1, \tag{4.15}$$

$$|I_H^{\ominus} v - I_H^{\ominus} w|_1 \le c_d |v - w|_1. \tag{4.16}$$

4.2. Two-level domain decomposition methods. In the two-level domain decomposition method, the coarse level space S_H is used in the iterative scheme for correction. As a result, the analysis will be based on the space decomposition as given in (4.6.b). Our goal is to verify Assumptions 1 and 2. Notice that the verification for Assumption 2 is straightforward and is essentially the same as for linear problems. We are left with the verification of Assumption 1 by finding the smallest constant C_1 which satisfies (3.2). We use V_0 to denote the coarse mesh and, correspondingly, all the summation index in Assumptions 1 and 2 will start from 0 to m.

The following lemma is stated for a general convex constraint set K defined by constraints on the function values at the fine mesh nodes, and it originates from a similar one given in [1] for the Sobolev spaces. Assume that v, w, $w + \sum_{j=0}^{i} s_j \in K$, $s_i \in V_i$, $i = 0, 1, \dots, m$, holds true for a general convex subset. Choose a $v_0 \in V_0$ such that

$$v - v_0 \in K, \qquad v_0 + w + s_0 \in K. \tag{4.17}$$

We then define z_i, $i = 0, 1, 2, \dots, m$, recursively by

$$z_0 = s_0 + v_0, \quad z_i = I_h\biggl(\theta_i^i\biggl(v - w - \sum_{j=0}^{i-1} z_j\biggr) + (1 - \theta_i^i)s_i\biggr), \quad i = 1, \dots, m. \tag{4.18}$$

LEMMA 4.2. *For a general convex subset $K \subset H_0^1(\Omega)$, assume that v, w, $w + \sum_{j=0}^{i} s_j \in K$, $s_i \in V_i$, $i = 1, \ldots, m$, and assume that v_0 satisfies* (4.17). *Then the functions z_i, $i = 1, \ldots, m$, defined in* (4.18) *satisfy*

$$z_i \in V_i, \quad z_i + w + \sum_{j=0}^{i-1} s_j \in K, \tag{4.19}$$

$$v - w - \sum_{j=0}^{i} z_j \in H_0^1\left(\bigcup_{j=i+1}^{m} \Omega_j^c\right), \tag{4.20}$$

$$v - \sum_{j=0}^{i} z_j + \sum_{j=0}^{i} s_j \in K. \tag{4.21}$$

Proof. The conclusion shall be proved by induction. For $i = 1$, we get from (4.18) that

$$z_1 = I_h(\theta_1^1(v - w - z_0) + (1 - \theta_1^1)s_1). \tag{4.22}$$

Due to the fact that $\theta_1^1 = 0$, $s_1 = 0$ in $\Omega \backslash \Omega_1^c$, it is true that $z_i = 0$ in $\Omega \backslash \Omega_1^c$ and thus $z_1 \in V_1$. Using (4.17), the assumption that $w + s_0 + s_1 \in K$, and the fact that $0 \le \theta_1^1 \le 1$, it is not hard to see that

$$z_1 + w + s_0 = I_h(\theta_1^1(v - v_0) + (1 - \theta_1^1)(w + s_0 + s_1)) \in K.$$

As $I_h(v - w - z_0) = v - w - z_0$, one gets from (4.22) that

$$v - w - z_0 - z_1 = I_h((1 - \theta_1^1)(v - w - z_0 - s_1)). \tag{4.23}$$

From (4.7), one obtains that $\theta_1^1 = 1$ in $\Omega_1^c \backslash \cup_{j=2}^{m} \Omega_j$. Combining it with the above equality we get

$$v - w - z_0 - z_1 \in H_0^1\left(\bigcup_{j=2}^{m} \Omega_j^c\right). \tag{4.24}$$

Furthermore, one gets from (4.17), the assumption that $w + s_0 + s_1 \in K$, the fact that $0 \le \theta_1^1 \le 1$, and (4.23) that

$$\begin{aligned} &v - z_0 - z_1 + s_0 + s_1 \\ &= I_h((1 - \theta_1^1)(v - z_0 + s_0) + \theta_1^1(w + s_0 + s_1)) \\ &= I_h((1 - \theta_1^1)(v - v_0) + \theta_1^1(w + s_0 + s_1)) \in K. \end{aligned}$$

In what follows, we shall assume that a z_i defined by (4.18) satisfies (4.19)–(4.21); then we shall prove that z_{i+1} also satisfies (4.19)–(4.21). From (4.18), we see that

$$z_{i+1} = I_h\left(\theta_{i+1}^{i+1}\left(v - w - \sum_{j=0}^{i} z_j\right) + (1 - \theta_{i+1}^{i+1})s_{i+1}\right). \tag{4.25}$$

Using the fact that

$$\theta_{i+1}^{i+1} \in H_0^1(\Omega_{i+1}^c), \quad s_{i+1} \in H_0^1(\Omega_{i+1}^c),$$

and from (4.20), we see that $z_{i+1} \in H_0^1(\Omega_{i+1}^c)$ and thus $z_{i+1} \in V_{i+1}$. In addition, one gets by using (4.20), (4.25), the assumption $w + \sum_{j=0}^{i} s_j \in K$, and the fact that $0 \le \theta_{i+1}^{i+1} \le 1$ that

$$\begin{aligned} z_{i+1} + w + \sum_{j=0}^{i} s_j & \\ = I_h\Bigg(\theta_{i+1}^{i+1}\Bigg(v + \sum_{j=0}^{i} s_j - \sum_{j=0}^{i} z_j\Bigg) + (1-\theta_{i+1}^{i+1})\Bigg(w + \sum_{j=0}^{i} s_j\Bigg)\Bigg) \in K. \end{aligned} \tag{4.26}$$

From (4.25), it is easy to calculate that

$$\begin{aligned} v - w - \sum_{j=0}^{i+1} z_j &= v - w - \sum_{j=0}^{i} z_j - z_{i+1} \\ &= I_h\Bigg((1-\theta_{i+1}^{i+1})\Bigg(v - w - \sum_{j=0}^{i} z_j - s_{i+1}\Bigg)\Bigg). \end{aligned} \tag{4.27}$$

Using the fact that $s_{i+1} \in H_0^1(\Omega_{i+1}^c)$, $\theta_{i+1}^{i+1} = 1$ in $\Omega_{i+1}^c \setminus \cup_{k=i+2}^m \Omega_k^c$, and from (4.20), one obtains

$$v - w - \sum_{j=0}^{i+1} z_j \in H_0^1\left(\bigcup_{j=i+2}^{m} \Omega_j^c\right).$$

To verify (4.21) for $i+1$, one gets from (4.27), (4.20), the assumption $w + \sum_{j=0}^{i+1} s_j \in K$, and the fact $0 \le \theta_{i+1}^{i+1} \le 1$ that

$$\begin{aligned} v - \sum_{j=0}^{i+1} z_j + \sum_{j=0}^{i+1} s_j & \\ = I_h\Bigg(\theta_{i+1}^{i+1}\Bigg(v - \sum_{j=0}^{i} z_j + \sum_{j=0}^{i} s_j\Bigg) + (1-\theta_{i+1}^{i+1})\Bigg(w + \sum_{j=0}^{i+1} s_j\Bigg)\Bigg) \in K. \end{aligned}$$

Thus, we have proved by induction that (4.19)–(4.21) are correct for all z_i defined as in (4.18). □

Assume from now on that the convex set K is given as in (4.2). For any $v, w+s_0 \in K$, let

$$\sigma^{\oplus} = I_h \max(0, v - w - s_0), \qquad \sigma^{\ominus} = I_h \max(0, w + s_0 - v),$$

and define

$$v_0 = I_H^{\ominus}\sigma^{\oplus} - I_H^{\ominus}\sigma^{\ominus}. \tag{4.28}$$

Due to the special structure of $\sigma^{\ominus}$ and $\sigma^{\oplus}$, it is not hard to show that

$$|\sigma^{\oplus}|_1 \le C|v - w - s_0|_1, \quad |\sigma^{\ominus}|_1 \le C|v - w - s_0|_1. \tag{4.29}$$

Thus, from (4.14)–(4.16) and the fact that $v - w - s_0 = \sigma^{\oplus} - \sigma^{\ominus}$ one obtains

$$\begin{aligned}&\|v_0 - (v - w - s_0)\|_l \\ &\leq \|I_H^{\ominus}\sigma^{\oplus} - I_H^{\ominus}\sigma^{\ominus} - (\sigma^{\oplus} - \sigma^{\ominus})\|_l \\ &\leq c_d H^{1-l}|\sigma^{\oplus}|_1 + c_d H^{1-l}|\sigma^{\ominus}|_1 \\ &\leq c_d H^{1-l}|v - w - s_0|_1, \ l = 0, 1.\end{aligned} \tag{4.30}$$

As $\alpha(x) \leq v, w + s_0 \leq \beta(x)$, there follows that

$$v - w - s_0 \leq \min(\beta - w - s_0, v - \alpha), \quad w + s_0 - v \leq \min(\beta - v, w + s_0 - \alpha).$$

Note that $\min(\beta - w - s_0, v - \alpha) \geq 0$ and $\min(\beta - v, w + s_0 - \alpha) \geq 0$. It follows from properties (4.11) and (4.12) that

$$\begin{aligned}0 \leq I_H^{\ominus}\sigma^{\oplus} \leq \min(\beta - w - s_0, v - \alpha), \\ 0 \leq I_H^{\ominus}\sigma^{\ominus} \leq \min(\beta - v, w + s_0 - \alpha),\end{aligned}$$

which implies that $v_0 = I_H^{\ominus}\sigma^{\oplus} - I_h^{\ominus}\sigma^{\ominus}$ satisfies

$$\max(v - \beta, \alpha - w - s_0) \leq v_0 \leq \min(\beta - w - s_0, v - \alpha).$$

The above inequality shows that

$$\alpha(x) \leq v_0 + w + s_0 \leq \beta(x), \qquad \alpha(x) \leq v - v_0 \leq \beta(x), \tag{4.31}$$

which means that v_0, defined in (4.28), satisfies (4.17) when K is given as in (4.2).

Lemma 4.3. *Let v_0 be given as in* (4.28). *Then the functions z_i, $i = 0, 1, 2, \ldots, m$, defined in* (4.18) *satisfy*

$$\|v - w - z_0\|_0 \leq c_d H\left(|v - w|_1 + |s_0|_1\right), \tag{4.32}$$

$$|v - w - z_0|_1 \leq c_d\left(|v - w|_1 + |s_0|_1\right), \tag{4.33}$$

$$\left\|v - w - \sum_{j=0}^{i} z_j\right\|_0 \leq c_d H\biggl(|v - w|_1 + \sum_{j=0}^{i}|s_j|_1\biggr), \quad i = 1, \ldots, m, \tag{4.34}$$

$$\left|v - w - \sum_{j=0}^{i} z_j\right|_1 \leq c_d\biggl(1 + \frac{H}{\delta}\biggr)\biggl(|v - w|_1 + \sum_{j=0}^{i}|s_j|_1\biggr), \quad i = 1, \ldots, m. \tag{4.35}$$

Proof. The estimates (4.32) and (4.33) follow from (4.30). We shall establish (4.34) and (4.35) by induction. Since $s_i \in H_0^1(\Omega_i^c)$ and Ω_i^c, $i = 1, \ldots, m$, contains many disjoint subdomains with size proportional to H, then the Friedrich–Poincaré inequality can be employed to yield

$$\|s_i\|_0 \leq CH|s_i|_1, \quad i = 1, 2, \ldots, m. \tag{4.36}$$

Now applying (4.9), (4.30), and (4.36) to (4.23) gives

$$\begin{aligned}&\|v - w - z_0 - z_1\|_0 \qquad \text{(using (4.9) and (4.23))} \\ &\leq C\|v - w - z_0 - s_1\|_0 \qquad \text{(using } z_0 = v_0 + s_0 \text{ and (4.30))} \\ &\leq c_d H|v - w - s_0|_1 + \|s_1\|_0 \qquad \text{(using (4.36))} \\ &\leq c_d H(|v - w|_1 + |s_0|_1 + |s_1|_1).\end{aligned} \tag{4.37}$$

Similarly, one arrives at

$$
\begin{aligned}
(4.38)\qquad & |v-w-z_0-z_1|_1 \\
& \le C\|v-w-v_0-s_0-s_1\|_1+\frac{C}{\delta}\|v-w-v_0-s_0-s_1\|_0 \\
& \le C\|v-w-s_0-v_0\|_1+C\|s_1\|_1 \\
& \quad +\frac{C}{\delta}\|v-w-s_0-v_0\|_0+\frac{C}{\delta}\|s_1\|_0 \\
& \le c_d\left(1+\frac{H}{\delta}\right)|v-w-s_0|_1+C\left(1+\frac{H}{\delta}\right)|s_1|_1 \\
& \le c_d\left(1+\frac{H}{\delta}\right)(|v-w|_1+|s_0|_1+|s_1|_1).
\end{aligned}
$$

Now, let us assume that (4.35) and (4.34) are correct for i, and we shall show that they are also correct for $i+1$. To this end, it follows from (4.9) and (4.27) that

$$\left\|v-w-\sum_{j=0}^{i+1}z_j\right\|_0 \le C\left(\left\|v-w-\sum_{j=0}^{i}z_j\right\|_0+\|s_{i+1}\|_0\right),$$

which, with the help of (4.36), shows that (4.34) is correct for $i+1$ if it is correct for i. Finally, using again (4.9) and (4.27), we have

$$
\begin{aligned}
\left|v-w-\sum_{j=0}^{i+1}z_j\right|_1 &\le +C\left(\left|v-w-\sum_{j=0}^{i}z_j\right|_1+|s_{i+1}|_1\right) \\
&\quad+\left(C+\frac{1}{\delta}\right)\left(\left\|v-w-\sum_{j=0}^{i}z_j\right\|_0+\|s_{i+1}\|_0\right).
\end{aligned}
$$

Thus, it follows from (4.34) and (4.36) that (4.35) is correct for $i+1$ if it is correct for the index i. This completes the proof of the lemma. □

THEOREM 4.4. *The estimate* (3.2) *in Assumption* 1 *holds true for the decomposition* (4.6.b) *with*

$$C_1=c_d\left(1+\frac{H}{\delta}\right). \tag{4.39}$$

Proof. Since $\theta_m^m\equiv 1$, then from (4.27) we conclude that

$$v-w-\sum_{j=0}^{m}z_j=0 \text{ in } \Omega,$$

which shows that (3.2.a) is valid. Condition (3.2.b) has been shown to be valid for z_0 and z_i in (4.31) and (4.19). It follows from

$$
\begin{aligned}
\|z_0\|_1 &\le \|v-w-z_0\|_1+\|v-w\|_1, \\
\|z_i\|_1 &\le \left\|v-w-\sum_{j=0}^{i}z_j\right\|_1+\left\|v-w-\sum_{j=0}^{i-1}z_j\right\|_1, \quad i=1,\ldots,m,
\end{aligned}
$$

and (4.32)–(4.35) that (3.2.c) holds true with C_1 being given in (4.39). We point out that the generic constant depends on m, which is the number of colors for the subdomains. □

The estimate (3.3) in Assumption 2 has been shown to be correct for the decomposition (4.6.b) with $C_2 = \sqrt{m+1}$ and m being the number of colors; see [30] and [20, 32] for details. Thus, all the conditions of the abstract convergence Theorem 3.1 are verified for the proposed domain decomposition method for the obstacle problem. As a consequence of Theorem 3.1, we see that the convergence rate of Algorithm 2 for the obstacle problem is given by

$$\frac{F(u^{n+1}) - F(u)}{F(u^n) - F(u)} \le 1 - \frac{1}{1 + (c_d H/\delta)^2}$$

or

$$||u^n - u||_1^2 \le \frac{2}{\kappa} \left[1 - \frac{1}{1 + (c_d H/\delta)^2}\right]^n [F(u^0) - F(u)].$$

4.3. Domain decomposition methods without coarse levels. When no coarse levels are used in the domain decomposition method, the finite element space $V = S_h$ can be decomposed into subspaces as given in (4.6.a). In this case, Algorithm 2 turns out to be the classical Schwarz alternating method for the corresponding minimization problem. We want to show that the abstract convergence Theorem 3.1 can be applied to yield a linear convergence for the Schwarz method, in which the rate of convergence depends only on the overlapping size. Furthermore, our result is more useful than those presented in [22, 29, 33] since no monotonicity is assumed on the iterative approximations.

Let $v, w \in K$ and $s_i \in V_i$ satisfy $w + \sum_{j=1}^{i} s_j \in K$. We define z_i recursively by

$$z_i = I_h\biggl(\theta_i^i\biggl(v - w - \sum_{j=1}^{i-1} v_j\biggr) + (1-\theta_i^i)s_i\biggr), \quad i = 1, \dots, m. \tag{4.40}$$

By repeating the proof as for Lemma 4.2, we obtain the following result.

LEMMA 4.5. *For a general convex subset $K \subset H_0^1(\Omega)$, assume that v, w, $w + \sum_{j=1}^{i} s_j \in K$, $s_i \in V_i$ for $i = 1, \dots, m$. Let z_i, $i = 1, \dots, m$, be defined as in* (4.40). *Then we have*

$$z_i \in V_i, \quad z_i + w + \sum_{j=1}^{i-1} s_j \in K, \tag{4.41}$$

$$v - w - \sum_{j=1}^{i} z_j = 0 \ \textit{in} \ H_0^1\left(\bigcup_{j=i+1}^{m} \Omega_j^c\right), \tag{4.42}$$

$$v - \sum_{j=1}^{i} z_j + \sum_{j=1}^{i} s_j \in K. \tag{4.43}$$

In fact, the above lemma is a consequence of Lemma 4.2 by taking $v_0 = 0$ and $s_0 = 0$. Now, using (4.9), from (4.27) in which the summation index i starts from 1, we obtain the following estimate.

Lemma 4.6. *With $z_i,\ i = 1, 2, \ldots, m$, being defined in* (4.40) *we have*

$$\left\| v - w - \sum_{j=1}^{i} z_j \right\|_0 \le C\Big(|v-w|_1 + \sum_{j=1}^{i} |s_j|_1\Big), \tag{4.44}$$

$$\left| v - w - \sum_{j=0}^{i} z_j \right|_1 \le C(1+\delta^{-1})\Big(|v-w|_1 + \sum_{j=1}^{i} |s_j|_1\Big). \tag{4.45}$$

Consequently, the following result has been proved.

Theorem 4.7. *The estimate* (3.2) *in Assumption* 1 *is valid for the decomposition* (4.6.a) *with*

$$C_1 = C(1+\delta^{-1}). \tag{4.46}$$

An application of Theorem 3.1 indicates that the one-level Schwarz method has the following convergence rate estimate for the obstacle problem:

$$\frac{F(u^{n+1}) - F(u)}{F(u^n) - F(u)} \le 1 - \frac{1}{1 + C(1+\delta^{-2})}$$

or

$$||u^n - u||_1^2 \le \frac{2}{\kappa}\left[1 - \frac{1}{1+C(1+\delta^{-2})}\right]^n [F(u^0) - F(u)].$$

5. Numerical example. To support the convergence theory developed in the previous sections, we present some numerical results here for the obstacle problem approximated by piecewise linear finite elements. To this end, consider the homogeneous problem (4.1) and (4.2) which seeks $u \in H_0^1(\Omega)$ such that

$$\alpha \le u \le \beta : \int_\Omega \nabla u \nabla (v-u) \ge 0 \quad \forall v \in H_0^1(\Omega),\ \alpha \le v \le \beta, \tag{5.1}$$

where $\alpha(x)$ and $\beta(x)$ are two obstacle functions and $\Omega = (0,4) \times (0,3)$.

The two finite element partitions $\mathcal{T}_H$ and $\mathcal{T}_h$ contain right triangles, which are obtained through a uniform refinement of Ω as illustrated in Figure 5.1. In Figure 5.1, the coarse partition $\mathcal{T}_H$ comprises 6×6 rectangles (i.e., 72 triangles) and the fine-level partition $\mathcal{T}_h$ contains 30×30 rectangles (i.e., 1800 triangles). As for the nonoverlapping structure $\{\Omega_i\}_{i=1}^M$ for Ω, we take $M = 9$, and $\{\Omega_i\}_{i=1}^9$ is obtained as a uniform partition of Ω into rectangles. The overlapping decomposition $\{\Omega_i^\delta\}_{i=1}^M$ is constructed by extending each Ω_i with a width of two triangles in $\mathcal{T}_h$. Roughly speaking, the width δ is given by $2h$.

The obstacles $\alpha(x)$ and $\beta(x)$ are shown in Figure 5.2. More precisely, we have

$$\begin{aligned} &\alpha(x,y) = 3 + \sqrt{\left(\tfrac{1}{6}\right)^2 - (x-2)^2 - (y-1.5)^2} \\ &\quad \text{if } (x-2)^2 + (y-1.5)^2 \le \left(\tfrac{1}{6}\right)^2, \text{ or else } \alpha(x,y) = 0; \\ &\beta(x,y) = 1/6 - \sqrt{\left(\tfrac{1}{6}\right)^2 - (x-\tfrac{4}{3})^2 - (y-\tfrac{3}{4})^2} \\ &\quad \text{if } (x-\tfrac{4}{3})^2 + (y-\tfrac{3}{4})^2 \le \left(\tfrac{1}{6}\right)^2, \text{ or else } \beta(x,y) = \tfrac{19}{6}. \end{aligned} \tag{5.2}$$

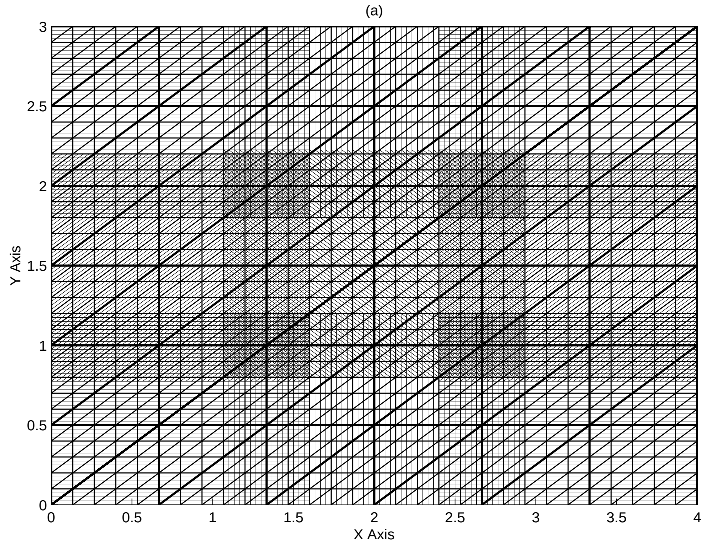

FIG. 5.1. *Meshes $\mathcal{T}_h$ and $\mathcal{T}_H$ and domain decomposition.*

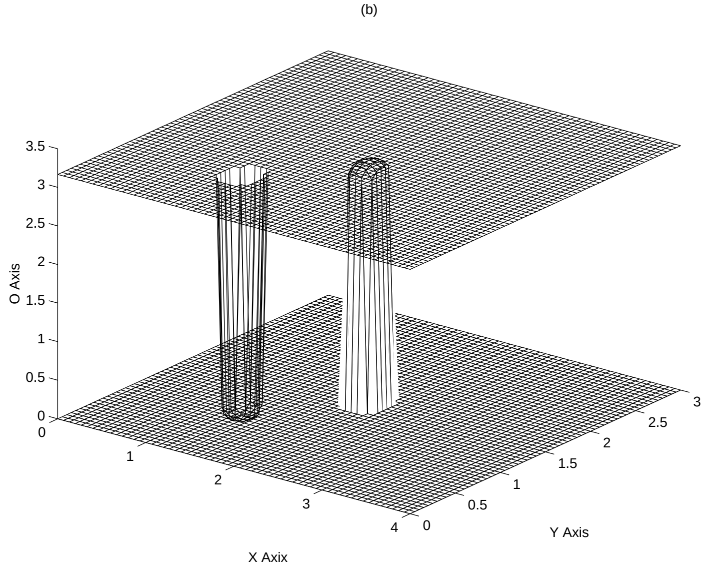

FIG. 5.2. *Obstacle functions $\alpha(x)$ (lower one) and $\beta(x)$ (upper one).*

In the numerical simulations, the obstacles are replaced by their finite element approximations. Corresponding to this obstacle, the finite element solution for (5.1) is as shown in Figure 5.3.

We have seen that the constant C_1 in the convergence estimate of Theorem 4.7 depends on δ^{-1} as given by (4.46) when one-level domain decomposition methods are considered. For two-level domain decomposition methods, the constant C_1 depends on H/h and H/δ as given in (4.39). One of the goals of this section is to numerically verify this dependence by taking various values of H, h, and δ. In all of our numerical tests

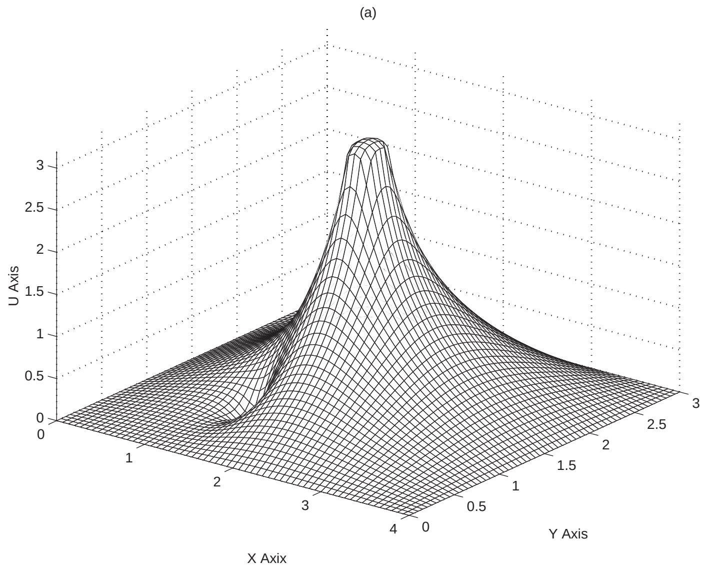

FIG. 5.3. *Solution.*

the iteration is stopped when the maximum error between two consecutive computed solutions is smaller than the tolerance $\epsilon = 0.001$. The solution for each subdomain problem is calculated by using the Gauss–Seidel iteration, which itself is a particular case of the Schwarz domain decomposition method in which each subdomain is merely the support of a nodal basis function of the finite element space. When solving subdomain problems, the calculation is terminated at a relative maximum error of $\epsilon = 10^{-5}$ at the nodes of $\mathcal{T}_h$ between two consecutive computed solutions.

For the results shown in Figure 5.4, the coarse mesh size H varies, while the ratios $H/h = 6$ and $H/\delta = 2$ stay unchanged. The plot shows the total number of iterations in the Schwarz method when the partition $\mathcal{T}_H$ has $20, 18, 16, \ldots, 2$ elements in the x- and y-directions. Starting from six elements, the number of iterations is almost constant for the two-level method, which is in concordance with the convergence theory. It can also be seen that the number of iterations is a decreasing function of H for the one-level method. Since H/δ is constant, it follows that the number of iterations is an increasing function of $1/\delta$, and this is in concordance with the estimate for C_1 in (4.46).

For the results in Figure 5.5, we have taken $H = \frac{5}{12}$, $h = \frac{5}{120}$, and $\delta = h, 2h, \ldots, 10h$. For both one- and two-level methods, the number of iterations is a decreasing function of δ. This observation is in concordance with the estimate on the constant C_1.

For the results shown in Figure 5.6, the values for H, δ are chosen as $H = \frac{5}{6}$ and $\delta = \frac{5}{12}$. The value of h assumes the mesh size of the partition $\mathcal{T}_h$ with $2 \times 6, 4 \times 6, 6 \times 6, \ldots, 20 \times 6$ elements in the x- and y-directions. For the one-level Schwarz method, the number of iterations is constant for $h \leq \frac{5}{12}$, and this confirms the observation that the constant C_1 does not depend on h for the one-level method. For the two-level method, the number of iterations is an decreasing function of h, which is in concordance with the $\log(H/h)$-dependence estimate of C_1 in (4.39).

Finally, we see from the above numerical tests that the number of iterations for the two-level method is significantly less than for the one-level method. We remark

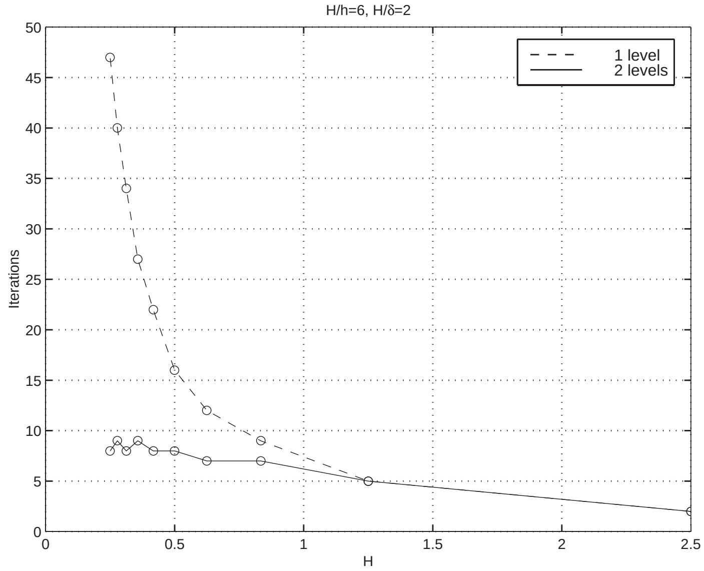

FIG. 5.4. *Number of iterations as a function of H for the Schwarz method when H/h and H/δ are fixed.*

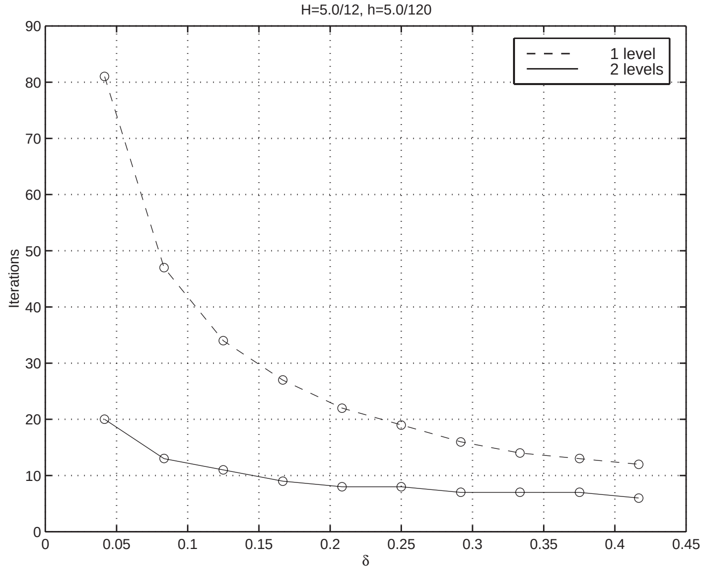

FIG. 5.5. *Number of iterations as a function of δ for the Schwarz method when H and h are fixed.*

that for one-sided obstacle problems, numerical tests using the two-level domain decomposition method have been shown in [28].

In the rest of this section, we make comments on the relaxation method that was used to solve the minimization problem on each subdomain. Notice that in the relaxation method, we have a one-dimensional minimization problem to solve on each support of the nodal basis functions. The solution of these one-dimensional problems

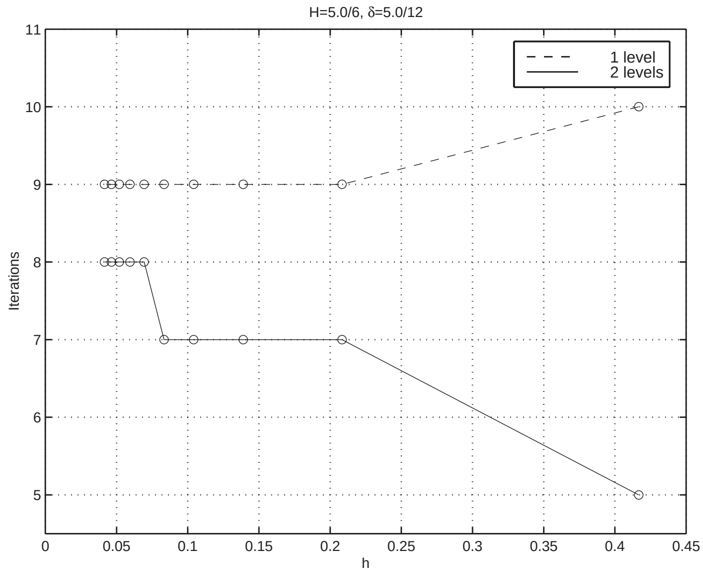

FIG. 5.6. *Number of iterations of the Schwarz method as a function of h when H and δ are fixed.*

was obtained by first solving the one-dimensional problem without constraint and then projecting it to the interval that presents the constraint for this one-dimensional problem. To be more precise, we use two vectors $u(k)$ and $e(k)$, where k runs from 1 to the number of interior nodes in $\mathcal{T}_h$ for the values of $u^{n+\frac{i-1}{m}}$ and e_i^{n+1} obtained from Algorithm 2. Naturally, we have two vectors $\alpha(k)$ and $\beta(k)$ containing the values of the two obstacles at the interior nodal points in $\mathcal{T}_h$. Assume now that we are computing the solution on the subdomain Ω_i and we are seeking the value $e(k)$ of the correction at the node k of $\mathcal{T}_h$. Let $\tilde{e}(k)$ be the value obtained from the one-dimensional problem without constraint. The projection is simply given by

$$e(k) = \min(\beta(k) - u(k),\ \max(\alpha(k) - u(k), \tilde{e}(k))). \tag{5.3}$$

For the problem associated with the coarse mesh, the minimization function (i.e., the correction value e) comes from the coarse mesh finite element space, with constraints imposed on the fine mesh. A relaxation method is employed to solve this problems in which one-dimensional problems associated with interior coarse mesh nodal basis functions $\phi_j^0(x),\ j = 1, 2, \dots, n_0$, are solved. As this is a one-dimensional minimization problem with a constraint, we can first compute the minimizer without constraint and then project this number into the interval which represents the constraint. The computation of the one-dimensional problem without constraint can be done in the same way as for the standard Schwarz method [20, 28]. The computation of the constraint interval can be done similarly as explained in [28, p. 136] for one-sided obstacle problems. To explain the idea more clearly, let us use $u^{old}(x)$ to denote the computed solution, and we need to solve the following problem to get an updated value for a coarse mesh nodal basis function $\phi_j^0(x)$:

$$e(j) = \arg \min_{\{\lambda \in R|\ \alpha(x) \le u^{old} + \lambda\phi_j^0(x) \le \beta(x) \forall x \in supp(\phi_j^0)\}} F(u^{old} + \lambda\phi_j^0), \tag{5.4}$$

where $supp(\phi_j^0)$ is the support set of the function ϕ_j^0. Let $\tilde{e}(j)$ be the minimizer of the one-dimensional unconstrained problem, i.e.,

$$\tilde{e}(j) = \arg\min_{\lambda \in R} F(u^{old} + \lambda\phi_j^0). \tag{5.5}$$

The solution $\tilde{e}(j)$ is found by solving the one-dimensional algebraic equation associated with this minimization problem. Since F is convex, $e(j)$ is the projection of $\tilde{e}(j)$ over the interval

$$[\alpha_j, \beta_j] = \{\lambda \in R \mid \alpha(x) \le u^{old} + \lambda\phi_j^0(x) \le \beta(x)\, \forall x \in supp(\phi_j^0)\},$$

where

$$\alpha_j = \sup_{x \in supp(\phi_j^0)} \frac{\alpha(x) - u^{old}(x)}{\phi_j^0(x)}, \quad \beta_j = \inf_{x \in supp(\phi_j^0)} \frac{\beta(x) - u^{old}(x)}{\phi_j^0(x)}. \tag{5.6}$$

Evidently, we have

$$e(j) = \min(\beta_j, \max(\alpha_j, \tilde{e}(j))). \tag{5.7}$$

We notice that, since $\alpha(x) \le u^{old}(x) \le \beta(x)$, we have $0 \in [\alpha_j, \beta_j]$, and, consequently, this interval is not empty. Naturally, the above $\inf_{x \in supp(\phi_j^0)}$ and $\sup_{x \in supp(\phi_j^0)}$ are calculated only for the mesh nodes of $\mathcal{T}_h$.

Similar relaxation methods have been employed in the domain decomposition for unconstrained minimization problems such as the Dirichlet problem for second order elliptic problems. For the constrained problem, the relaxation method involves an additional step which computes the lower and upper bounds α_j and β_j as given in (5.6) and the projections (5.3) and (5.7).

The projection for the two-level method is more complicated than for the one-level method. However, since the convergence of the two-level method is much faster than the one-level method, the two-level method is more preferable for practical use. For instance, for $H = 5.0/10$, $h = 5.0/60$, and $\delta = 5.0/20$, the number of iterations is 16 for the one-level method, and it is 8 for the two-level method. The computing CPU time on a PC with one processor (Intel Pentium III, 600MHz) is 5.2 minutes for the one-level method, and it is 3.7 minutes for the two-level method. The finite element discretization problem in these numerical tests involves 3481 unknowns.

We shall mention that the subproblems associated with the subdomains and the coarse mesh problem can also be solved by methods other than the relaxation method. In the numerical tests of [26] and [28], the subproblems are solved by the augmented Lagrangian method, which is also rather efficient for handling the constraints both for the subdomain and coarse mesh problems.

6. Proof of Theorem 3.1.

Since e_i^{n+1} minimizes (2.4), it satisfies (see [8])

$$\langle F'(u^{n+\frac{i-1}{m}} + e_i^{n+1}), v_i - e_i^{n+1}\rangle \ge 0 \quad \forall v_i \in V_i \text{ satisfying } v_i + u^{n+\frac{i-1}{m}} \in K. \tag{6.1}$$

Using assumption (3.1), we can prove that (see [23, Lem. 3.2])

$$F(w) - F(v) \ge \langle F'(v), w - v\rangle + \frac{\kappa}{2}\|w - v\|_V^2 \quad \forall v, w \in V. \tag{6.2}$$

Taking $v_i = 0$ in (6.1), we get from the above two inequalities that

$$F(u^{n+\frac{i-1}{m}}) - F(u^{n+\frac{i}{m}}) \ge \frac{\kappa}{2}\|e_i^{n+1}\|_V^2\ . \tag{6.3}$$

It follows from (6.3) that

$$F(u^n) - F(u^{n+1}) = \sum_{i=1}^{m} (F(u^{n+\frac{i-1}{m}}) - F(u^{n+\frac{i}{m}})) \geq \frac{\kappa}{2} \sum_{i=1}^{m} \|e_i^{n+1}\|_V^2. \tag{6.4}$$

Thus, we have

$$F(u^n) \geq F(u^{n+1}).$$

Denote, for a given n,

$$\nu_j^i = \begin{cases} u^n + \sum_{k=1}^{i} e_k^{n+1}, & j \leq i; \\ u^n + \sum_{k=1}^{j} e_k^{n+1}, & j > i. \end{cases}$$

It can be seen that ν_j^i satisfies

$$\begin{aligned} &\nu_j^i - \nu_{j-1}^i = 0, \quad j \leq i; \\ &\nu_j^i - \nu_{j-1}^i = e_j^{n+1}, \quad j > i; \\ &F'(u^{n+1}) - F'(u^{n+\frac{i}{m}}) = \sum_{j=i+1}^{m} \left(F'(\nu_j^i) - F'(\nu_{j-1}^i) \right). \end{aligned} \tag{6.5}$$

As $u,\ u^n,\ u^n + \sum_{j=1}^{i} e_j^{n+1} \in K,\ i = 1, 2, \dots, m$, we get from assumption (3.2) that there exist $z_i^n \in V_i$ such that

$$\begin{cases} \text{(a) } u - u^n = \sum_{i=1}^{m} z_i^n, \qquad \text{(b) } u^n + \sum_{j=1}^{i-1} e_j^{n+1} + z_i^n \in K,\ i = 1, \dots, m, \\ \text{(c) } \left(\sum_{i=1}^{m} \|z_i^n\|_V^2 \right)^{\frac{1}{2}} \leq C_1 \left(\|u^n - u\|_V^2 + \sum_{j=1}^{m} \|e_j^{n+1}\|_V^2 \right)^{\frac{1}{2}}. \end{cases} \tag{6.6}$$

We use (3.3), (6.6), and (6.1) to get

$$\begin{aligned} \langle F'(u^{n+1}), u^{n+1} - u \rangle &= \left\langle F'(u^{n+1}), \sum_{i=1}^{m} e_i^{n+1} + u^n - u \right\rangle \\ &= \sum_{i=1}^{m} \left\langle F'(u^{n+1}), e_i^{n+1} - z_i^n \right\rangle \qquad \text{(using (6.6.a))} \\ &\leq \sum_{i=1}^{m} \left\langle F'(u^{n+1}) - F'(u^{n+i/m}), e_i^{n+1} - z_i^n \right\rangle \\ &\qquad \text{(using (6.6.b) and (6.1))} \\ &= \sum_{i=1}^{m} \sum_{j=i+1}^{m} \left\langle F'(\nu_j^i) - F'(\nu_{j-1}^i), e_i^{n+1} - z_i^n \right\rangle \qquad \text{(using (6.5))} \end{aligned} \tag{6.7}$$

$$\leq C_2\Bigg(\sum_{j=1}^m \|e_j^{n+1}\|_V^2\Bigg)^{\frac{1}{2}}\Bigg(\sum_{i=1}^m \|e_i^{n+1}-z_i^n\|_V^2\Bigg)^{\frac{1}{2}} \qquad \text{(using (3.3))}$$

$$\leq C_2\Bigg(\sum_{j=1}^m \|e_j^{n+1}\|_V^2\Bigg)^{\frac{1}{2}}\Bigg((1+C_1)\Bigg(\sum_{i=1}^m \|e_i^{n+1}\|_V^2\Bigg)^{\frac{1}{2}} + C_1\|u^n-u\|_V\Bigg)$$

(using (6.6.c) and the triangular inequality).

The rest of the proof is the same as in [26, 27]. As u is the unique minimizer for (2.1), we use (6.2) and the optimality condition to obtain

$$F(u^n)-F(u) \geq \langle F'(u), u^n-u\rangle + \frac{\kappa}{2}\|u-u^n\|_V^2 \geq \frac{\kappa}{2}\|u-u^n\|_V^2. \tag{6.8}$$

The following estimate needs to use (6.2), (6.4), (6.7), and (6.8):

$$\begin{aligned}
&F(u^{n+1})-F(u)\\
&\leq \langle F'(u^{n+1}), u^{n+1}-u\rangle \qquad \text{(using (6.2))}\\
&\leq (1+C_1)C_2\frac{2}{\kappa}(F(u^n)-F(u^{n+1})) \qquad \text{(using (6.4) and (6.7))}\\
&\quad + C_1C_2\frac{2}{\kappa}\sqrt{F(u^n)-F(u^{n+1})}\sqrt{F(u^n)-F(u)} \qquad \text{(using (6.8) and (6.7))}.
\end{aligned}$$

Denote $d_n = F(u^n)-F(u)$ for all $n \geq 0$. Let $\mu \in (0,1)$ be a constant to be determined later. Apply the inequality $ab \leq \frac{1}{4\mu}a^2 + \mu b^2$ for all $a, b \in R$ to the last term of the above estimate to get

$$\begin{aligned}
d_{n+1} &\leq (1+C_1)\frac{2C_2}{\kappa}(d_n-d_{n+1}) + C_1C_2\frac{2}{\kappa}\sqrt{d_n-d_{n+1}}\sqrt{d_n}\\
&\leq \bigg((1+C_1)\frac{2C_2}{\kappa} + \frac{[C_1C_2]^2}{\mu\kappa^2}\bigg)(d_n-d_{n+1}) + \mu d_n\\
&\leq C^*\mu^{-1}(d_n-d_{n+1}) + \mu d_n.
\end{aligned}$$

As a consequence, we see that

$$\frac{d_{n+1}}{d_n} \leq \frac{C^*\mu^{-1}+\mu}{1+C^*\mu^{-1}} = 1 - \frac{\mu(1-\mu)}{\mu+C^*}.$$

For a given $C^* > 0$, the function $g(\mu) = \frac{\mu(1-\mu)}{\mu+C^*}$ has a unique maximizer in $[0,1]$, and the maximizer is given by $\mu^* = \sqrt{(C^*)^2+C^*} - C^* \in (0,1)$. Moreover, the maximum value is given by $g(\mu^*) = \frac{1}{(\sqrt{C^*+1}+\sqrt{C^*})^2}$. Consequently, (3.4) holds. The error estimation (3.5) is obtained using (6.8) and (3.4). This completes the proof of the theorem. ∎

ADAPTIVE SOLUTION OF OPERATOR EQUATIONS USING WAVELET FRAMES[*]

ROB STEVENSON[†]

Abstract. In "Adaptive wavelet methods II—Beyond the elliptic case" of Cohen, Dahmen, and DeVore [*Found. Comput. Math.*, 2 (2002), pp. 203–245], an adaptive method has been developed for solving general operator equations. Using a *Riesz basis* of wavelet type for the energy space, the operator equation is transformed into an equivalent matrix-vector system. This system is solved iteratively, where the application of the infinite stiffness matrix is replaced by an adaptive approximation. Assuming that the stiffness matrix is sufficiently compressible, i.e., that it can be sufficiently well approximated by sparse matrices, it was proved that the adaptive method has optimal computational complexity in the sense that it converges with the same rate as the best N-term approximation for the solution, assuming that the latter would be explicitly available. The condition concerning compressibility requires that, dependent on their order, the wavelets have sufficiently many vanishing moments, and that they be sufficiently smooth. However, except on tensor product domains, wavelets that satisfy this smoothness requirement are not easy to construct.

In this paper we write the domain or manifold on which the operator equation is posed as an *overlapping* union of subdomains, each of them being the image under a smooth parametrization of the hypercube. By lifting wavelets on the hypercube to the subdomains, we obtain a *frame* for the energy space. With this frame the operator equation is transformed into a matrix-vector system, after which this system is solved iteratively by an adaptive method similar to the one from the work of Cohen, Dahmen, and DeVore. With this approach, frame elements that have sufficiently many vanishing moments and are sufficiently smooth, something needed for the compressibility, are easily constructed. By handling additional difficulties due to the fact that a frame gives rise to an underdetermined matrix-vector system, we prove that this adaptive method has optimal computational complexity.

Key words. operator equations, adaptive methods, wavelets, frames, optimal computational complexity, best N-term approximation

1. Introduction.

For some boundedly invertible $L : H \to H'$, where H is some Hilbert space with dual H' and some $g \in H'$, we consider the problem of finding $u \in H$ such that

$$Lu = g.$$

As typical examples, we think of linear differential or integral equations in variational form. Although systems of such equations also fit into the framework, for ease of exposition in this introduction let us consider scalar equations, so that H is typically a Sobolev space H^t of some order $t \in \mathbb{R}$.

Assuming that we have a *Riesz basis* Ψ for H^t available, which we formally view as a column vector, by writing $u = \mathbf{u}^T\Psi$, the above problem becomes equivalent to finding $\mathbf{u} \in \ell_2$ satisfying the infinite matrix-vector system

$$\mathbf{M}\mathbf{u} = \mathbf{g},$$

where $\mathbf{M} := \langle \Psi, L\Psi \rangle : \ell_2 \to \ell_2$ is boundedly invertible and $\mathbf{g} := \langle \Psi, g \rangle \in \ell_2$. Here $\langle \, , \rangle$ denotes the duality product on (H^t, H^{-t}).

Let us denote by $\mathbf{u}_N$ a *best N-term approximation* for $\mathbf{u}$, i.e., a vector with at most N nonzero coefficients that has distance to $\mathbf{u}$ less than or equal to that of any vector with a support of that size. Note that $\|u - \mathbf{u}_N^T \Psi\|_{H^t} \eqsim \|\mathbf{u} - \mathbf{u}_N\|_{\ell_2}$. Considering bases Ψ of sufficiently smooth *wavelet* type, the theory of nonlinear approximation tells us [21, 4] that if both

$$0 < s < \frac{d-t}{n},$$

where d is the *order* of the wavelets and n is the space dimension, and u is in the *Besov space* $B_\tau^{sn+t}(L_\tau)$, with $\tau = (\frac{1}{2} + s)^{-1}$, then

$$\sup_{N \in \mathbb{N}} N^s \|\mathbf{u} - \mathbf{u}_N\|_{\ell_2} < \infty.$$

The condition here involving Besov regularity is much milder that the corresponding condition $u \in H^{sn+t}$ involving Sobolev regularity that would be needed to guarantee the same rate of convergence with linear approximation in the span of N wavelets corresponding to the "coarsest levels." Indeed, assuming a sufficiently smooth right-hand side, for several boundary value problems it has been proved that the solution has a much higher Besov than Sobolev regularity [13, 9]. Note that a rate higher than $\frac{d-t}{n}$ can never be expected with wavelets of order d, except when the solution u happens to be a finite linear combination of wavelets.

So far we have discussed the approximation of $\mathbf{u}$, which, however, is only implicitly given as the solution of $\mathbf{Mu} = \mathbf{g}$. Continuing earlier work in [11], in [5, 6] an iterative adaptive method for solving this system was developed that, given a tolerance $\varepsilon > 0$, yields an approximate solution $\mathbf{u}_\varepsilon$ with $\|\mathbf{u} - \mathbf{u}_\varepsilon\| \leq \varepsilon$, where the number of operations and storage locations it requires is of the same order as the length of the smallest best N-term approximation for $\mathbf{u}$ on distance ε, meaning that the method has *optimal computational complexity.*

When L and thus $\mathbf{M}$ are symmetric and positive definite, the method consists of the application of the simple damped Richardson iteration to the infinite system, where the multiplication of $\mathbf{M}$ with the current finitely supported approximation vector for $\mathbf{u}$ is replaced by an adaptive approximation. In each iteration, each column of $\mathbf{M}$ is replaced by a finitely supported approximation with a tolerance that decreases as a function of the modulus of the corresponding entry in the vector. Note that even for a differential operator the matrix $\mathbf{M}$ is not sparse due to the interaction between wavelets from different levels. A second ingredient of the method is the application after each K steps, with K being some fixed number, of a clean-up or coarsening procedure that removes the smallest entries from the current approximation in order to ensure an optimal work-accuracy balance.

For nonsymmetric or indefinite $\mathbf{M}$, one can simply apply the adaptive method to the normal equations, or alternatively one can apply more advanced iterations which may lead to quantitatively better results [6, 12, 19].

The proof of the optimality of the method requires that $\mathbf{M}$ be sufficiently *compressible*, meaning that, given some tolerance $\delta > 0$, there exists another infinite matrix on distance less than δ, which in each row and column has only a finite and sufficiently small number of nonzero entries. For large classes of differential and integral operators this property can indeed be verified when, dependent on the order d, the wavelets have *sufficiently many vanishing moments* and are *sufficiently smooth*; see [25].

The bottleneck for the application of this adaptive wavelet method is the availability of suitable wavelet bases on general nonrectangular domains or manifolds. An approach to constructing wavelet bases is to write the domain as a *nonoverlapping* union of subdomains, which are the images of the hypercube under smooth parametrizations. Wavelets, or “initial stable completions,” living on the hypercube are lifted to the subdomains. Since in general more than one subdomain is needed, there is the problem of “stitching” functions over the interfaces.

The approach from [17] yields wavelet bases that in principle satisfy all of these requirements. However, since suitable extension operators from one subdomain into neighboring subdomains enter the construction, it seems not easy to implement. The approaches from [16, 3, 8] yield wavelets that over the interfaces between subdomains are only continuous. For example, thinking of a differential equation of order 2 on a two-dimensional domain, with this restricted smoothness only for orders $d \leq 2$ sufficient compressibility of the matrix $\mathbf{M}$ can be shown. Note that it might happen that the solution is smooth everywhere exactly along one of these interfaces on which the wavelets have degenerated properties. However, with these low orders $d \leq 2$ an adaptive method can give at most a small improvement in the order of convergence compared to nonadaptive methods, which in practice might not compensate for the overhead it requires.

Again because of their lack of smoothness beyond continuity, finite element wavelets as constructed in [18, 7, 24] also seem not very well suited for the adaptive method.

The approach followed in this paper is to apply an *overlapping* decomposition of the domain or manifold into subdomains. By lifting wavelets on the hypercube to those subdomains, and by multiplying them by smooth weight functions that vanish at the internal boundaries of these subdomains, a countable set of functions is obtained, which we again denote by Ψ, which is dense in H^t and which for each $u \in H^t$ yields *some* representation $u = \mathbf{u}^T\Psi$ with $\|u\|_{H^t} \eqsim \|\mathbf{u}\|_{\ell_2}$. Such a set Ψ is called a *frame* for H^t. By writing $u = \mathbf{u}^T\Psi$, solving $Lu = g$ is again equivalent to solving $\mathbf{Mu} = \mathbf{g}$, where $\mathbf{M} = \langle \Psi, L\Psi \rangle$ and $\mathbf{g} = \langle \Psi, g \rangle$. However, due to the overlapping decomposition, the representation $u = \mathbf{u}^T\Psi$ will not be unique, and so the system $\mathbf{Mu} = \mathbf{g}$ will have more solutions, which, however, all correspond to the unique solution of $Lu = g$.

When L is symmetric and positive definite, $\mathbf{M}$ is symmetric and *semi*positive definite, and $\mathbf{Mu} = \mathbf{g}$ can be solved by the damped Richardson iteration. In each iteration the norm of the defect is reduced by a constant factor less than 1. For nonsymmetric or indefinite L, the iteration can be applied to the normal equations.

Following [6] for the Riesz basis case, in the practical algorithm the application of $\mathbf{M}$ will be replaced by the adaptive approximation. To be able to prove that the method has optimal computational complexity, it is again needed that $\mathbf{M}$ be sufficiently compressible, i.e., that, dependent on the order d, the wavelets have sufficiently many vanishing moments and be sufficiently smooth. Since its construction does not involve stitching of functions over interfaces, the advantage of this frame approach is that these conditions concerning vanishing moments and smoothness are easily satisfied.

Furthermore, because of the multiplication with the weight functions, boundary conditions at the internal boundaries of the subdomains can be chosen at one’s convenience. In particular, in the case of a closed manifold, this gives the additional advantage that all wavelet bases on the hypercube can be chosen to satisfy *periodic boundary conditions.* Such bases are the most easy to implement, and they have much better quantitative properties than available wavelet bases satisfying other boundary conditions.

A final advantage is that generally an overlapping domain decomposition is much easier to construct with simpler parametrizations than a nonoverlapping one, which might also give a favorable quantitative effect.

The use of a frame instead of a Riesz basis also gives rise to a problem: Since in the adaptive method the matrix-vector product is replaced by an adaptive approximation, each time it is invoked it gives an error that might have a component in the nontrivial kernel of $\mathbf{M}$. Also the clean-up or coarsening step may introduce such components. Just because these components are in the kernel of $\mathbf{M}$, they will not be affected by subsequent Richardson steps, meaning that in the cause of the iteration the component of the current approximation in the kernel of $\mathbf{M}$ may increase. Although this component has no influence on the obtained approximation for the solution of $Lu = g$, that is, after forming the series with the frame elements, it might be responsible for the major part of the computational costs of each iteration. Indeed, recall that in the adaptive approximation of the matrix-vector product the accuracy with which the columns of $\mathbf{M}$ are approximated is determined by the moduli of the corresponding entries in the vector.

Under some technical assumption on the frame, specifically on the projector, called $\mathbf{Q}$, onto the complement of the kernel of $\mathbf{M}$ in ℓ_2, we will prove that the above effect will not occur or only to such an extent that also in the frame case the adaptive method has optimal computational complexity. Unfortunately, although we expect it to hold more generally for our frame construction based on overlapping decompositions, so far we could only give a complete proof that this technical assumption holds in the situation that $t = 0$ and that the wavelet bases on the hypercube are L_2-orthogonal.

The above problem leads us to introduce a modified adaptive algorithm, to which a projection step is added that is applied before each coarsening step. This projector affects only the redundant representation in the overlap regions in a way that the component of the current approximation in the kernel of $\mathbf{M}$ is controlled. The projector itself, called $\mathbf{P}$, is given by an infinite matrix, and in the algorithm, as $\mathbf{M}$, it is only applied approximately using the adaptive matrix-vector product. We show that $\mathbf{P}$ is sufficiently compressible, and prove that this modified algorithm has optimal computational complexity in the general case.

This paper is organized as follows: In section 2, we recall the concept of a frame and show how it can be used to transform an operator equation into an infinite, underdetermined matrix-vector equation. We discuss iterative schemes to solve such equations. Next, we replace those ingredients of such schemes that involve infinite vectors or matrices by practical realizable approximations and show that they, together with a coarsening routine, give rise to a convergent algorithm SOLVE. In addition, we introduce a convergent modified algorithm modSOLVE that contains the inexact application of a projector $\mathbf{P}$ that explicitly controls size of the component of the current approximation in the kernel of $\mathbf{M}$.

In section 3 we study the *rate* of convergence and the computational costs of both algorithms. First we recall some theory dealing with best N-term approximation. We formulate a condition on the compressibility of the stiffness matrix $\mathbf{M}$, and for modSOLVE also of $\mathbf{P}$, that for $\mathbf{M}$ is known to be satisfied for wavelets that, dependent on their order, have sufficiently many vanishing moments and are sufficiently smooth.

Under these conditions, it is proved that both SOLVE and modSOLVE have optimal computational complexity, where for SOLVE we need the aforementioned assumption on the projector $\mathbf{Q}$.

In section 4 we outline the construction of suitable frames using overlapping domain decompositions. Having specified the construction of a frame, we now discuss the condition on $\mathbf{Q}$. Furthermore, we define a suitable $\mathbf{P}$ and show that it is sufficiently compressible.

In order to avoid the repeated use of generic but unspecified constants, in this paper by $C \lesssim D$ we mean that C can be bounded by a multiple of D, independently of parameters on which C and D may depend. Obviously, $C \gtrsim D$ is defined as $D \lesssim C$, and $C \eqsim D$ as $C \lesssim D$ and $C \gtrsim D$.

2. The basic concept.

2.1. Frames.

Let H be a separable real Hilbert space. A countable collection $\Psi \subset H$ is called a *frame* for H when there exist two positive constants A_Ψ, B_Ψ such that

$$A_\Psi \|f\|_{H'}^2 \leq \|f(\Psi)\|^2 \leq B_\Psi \|f\|_{H'}^2 \qquad (f \in H'). \tag{2.1}$$

Here with $f(\Psi)$ we mean the sequence $(f(\psi))_{\psi\in\Psi}$, with $\|f(\Psi)\|$ denoting its ℓ_2-norm. We adapted the definition of a frame given in [20, section 3] by identifying H with its dual H' via the Riesz mapping. As a consequence of (2.1), the frame operators

$$F : H' \to \ell_2 : f \mapsto f(\Psi)$$

and their dual

$$F' : \ell_2 \to H : \mathbf{c} \mapsto \mathbf{c}^T \Psi$$

are bounded with norm less than or equal to $B_\Psi^{\frac{1}{2}}$. Here we have used $\mathbf{c}^T\Psi$ as shorthand notation for $\sum_{\psi\in\Psi} c_\psi \psi$. The composition $F'F : H' \to H$ is boundedly invertible with $\|(F'F)^{-1}\|_{H'\leftarrow H} \leq A_\Psi^{-1}$. The collection $\tilde{\Psi} := (F'F)^{-1}\Psi$ is a frame for H' (the "canonical" dual frame) with frame operators

$$\tilde{F} := F(F'F)^{-1}, \qquad \tilde{F}' = (F'F)^{-1}F'$$

and frame constants B_Ψ^{-1}, A_Ψ^{-1}.

The property of Ψ being a frame for H with constants A_Ψ, B_Ψ can be shown to be equivalent to $\operatorname{clos}\operatorname{span}\Psi = H$ and

$$B_\Psi^{-1}\|u\|_H^2 \leq \inf_{\mathbf{c}\in\ell_2,\, F'\mathbf{c}=u} \|\mathbf{c}\|^2 \leq A_\Psi^{-1}\|u\|_H^2 \qquad (u \in H). \tag{2.2}$$

We have

$$\ell_2 = \operatorname{Ran} F \oplus^\perp \operatorname{Ker} F',$$

and

$$\mathbf{Q} := F(F'F)^{-1}F' : \ell_2 \to \ell_2 \tag{2.3}$$

is the orthogonal projector onto $\operatorname{Ran} F$. The frame Ψ is a Riesz basis for H if and only if $\operatorname{Ker} F' = 0$.

2.2. Transformation of an operator equation to an ℓ_2-problem. Let the linear operator $L : H \to H'$ be boundedly invertible, and let Ψ be a frame for H. Given a $g \in H'$, we consider the problem of finding $u \in H$ such that

$$Lu = g. \tag{2.4}$$

As examples, one may think of L as being a linear differential or integral operator in variational form that defines a homeomorphism between a relevant Sobolev space, or a closed subspace of that, and its dual. A possible construction of a frame will be discussed in section 4.1.

In addition to scalar equations, systems of differential and/or integral equations also fit into this framework. Examples can be found, e.g., in [6, section 3]. In this case, H is a product of relevant Sobolev spaces, and it can be equipped with a frame defined as the product of frames for the coordinate spaces.

Writing $u = F'\mathbf{u}$ for some $\mathbf{u} \in \ell_2$, $\mathbf{u}$ satisfies

$$\mathbf{M}\mathbf{u} = \mathbf{g},$$

where

$$\mathbf{M} := FLF' \quad \text{and} \quad \mathbf{g} := Fg.$$

From

$$\left.\begin{array}{l} \tilde{F}L^{-1}\tilde{F}'FLF' = \tilde{F}F' \\ FLF'\tilde{F}L^{-1}\tilde{F}' = F\tilde{F}' \end{array}\right\} = \mathbf{Q} = \mathbf{id} \quad \text{on } \operatorname{Ran} F,$$

we conclude that $\mathbf{M}|_{\operatorname{Ran} F} : \operatorname{Ran} F \to \operatorname{Ran} F$ is boundedly invertible, in particular with $\|\mathbf{M}\| \le B_\Psi \|L\|_{H' \leftarrow H}$ and $\|\mathbf{M}|_{\operatorname{Ran} F}^{-1}\| \le A_\Psi^{-1} \|L^{-1}\|_{H \leftarrow H'}$, whereas $\operatorname{Ker} \mathbf{M} = \operatorname{Ker} F'$.

2.3. Iterative schemes to solve the infinite-dimensional system $\mathbf{Mu} = \mathbf{g}$. If L is *symmetric* and *positive definite*, i.e., $L' = L$ and $\inf_{0 \ne v \in H} (Lv)(v)/\|v\|^2 > 0$, then $\mathbf{M} = \mathbf{M}^* \ge 0$. With $\lambda_{\max} := \lambda_{\max}(\mathbf{M}) = \|\mathbf{M}\|$ and $\lambda_{\min}^+ := \lambda_{\min}(\mathbf{M}|_{\operatorname{Ran} F}) = \|\mathbf{M}|_{\operatorname{Ran} F}^{-1}\|^{-1}$, for $0 < \alpha < 2/\lambda_{\max}$, we consider the *damped Richardson iteration*

$$\mathbf{u}^{(i+1)} = \mathbf{u}^{(i)} - \alpha(\mathbf{M}\mathbf{u}^{(i)} - \mathbf{g}). \tag{2.5}$$

From $\mathbf{u} - \mathbf{u}^{(i+1)} = (\mathbf{id} - \alpha\mathbf{M})(\mathbf{u} - \mathbf{u}^{(i)})$ and $\mathbf{QM} = \mathbf{MQ}$, we infer that

$$\|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i+1)})\| \le \rho \|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i)})\|, \tag{2.6}$$

where $\rho := \|(\mathbf{id} - \alpha\mathbf{M})|_{\operatorname{Ran} F}\| = \max\{\alpha\lambda_{\max} - 1, 1 - \alpha\lambda_{\min}^+\} < 1$, with minimum $\frac{\kappa-1}{\kappa+1}$ when $\alpha = 2/(\lambda_{\max} + \lambda_{\min}^+)$, where $\kappa = \lambda_{\max}/\lambda_{\min}^+$. Note that $u - F'\mathbf{u}^{(i)} = F'\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i)})$.

We will study an inexact version of (2.5) in which the application of the infinite matrix $\mathbf{M}$ is approximated. A difficulty will be that errors made in $\ker F'$ are not reduced in subsequent iterations. Although obviously these errors do not affect $F'\mathbf{u}^{(i)}$, they might hamper a cheap but sufficiently accurate matrix-vector multiplication. Under some condition on $\mathbf{Q}$, i.e., on the frame, we will prove that this is not the case, in the sense that these errors do not pile up too much.

For handling cases in which $\mathbf{Q}$ might not satisfy this condition, we consider a modified algorithm that contains the explicit application of a projector to reduce error components in $\operatorname{Ker} F'$: Let $\mathbf{P} : \ell_2 \to \ell_2$ be some bounded projector with

$$\operatorname{Ker} \mathbf{P} = \operatorname{Ker} F',$$

so that $\ell_2 = \operatorname{Ran}\mathbf{P} \oplus \operatorname{Ker} F'$ is a "stable" splitting. Let $\mathbf{u}^{(i+1)}$ denote the result of applying $\mathbf{P}$ to the result of K damped Richardson iterations starting with $\mathbf{u}^{(i)}$. Using $\mathbf{MPu} = \mathbf{g}$ and $\mathbf{P}(\mathbf{id} - \mathbf{Q}) = 0$, we arrive at

$$\mathbf{Pu} - \mathbf{u}^{(i+1)} = \mathbf{P}(\mathbf{id} - \alpha\mathbf{M})^K(\mathbf{Pu} - \mathbf{u}^{(i)}) = \mathbf{P}(\mathbf{id} - \alpha\mathbf{M})^K\mathbf{Q}(\mathbf{Pu} - \mathbf{u}^{(i)}), \tag{2.7}$$

and so

$$\|\mathbf{Pu} - \mathbf{u}^{(i+1)}\| \leq \|\mathbf{P}\|\rho^K\|\mathbf{Pu} - \mathbf{u}^{(i)}\|,$$

showing convergence when K is chosen such that $\|\mathbf{P}\|\rho^K < 1$. Note that $u - F'\mathbf{u}^{(i)} = F'(\mathbf{Pu} - \mathbf{u}^{(i)})$.

Except when the condition number κ is close to one, the Richardson iteration is known to converge relatively slowly, and quantitatively better results can be expected by more advanced iterations. However, for simplicity we confine the analysis to the easiest algorithm.

The case of L being nonsymmetric or indefinite can be treated by considering the *normal equations*

$$\mathbf{M}^*\mathbf{Mu} = \mathbf{M}^*\mathbf{g}. \tag{2.8}$$

Both $\mathbf{M}|_{\operatorname{Ran} F}$ and $\mathbf{M}^*|_{\operatorname{Ran} F}$ are boundedly invertible on $\operatorname{Ran} F$ and so is $\mathbf{M}^*\mathbf{M}|_{\operatorname{Ran} F}$, whereas $\mathbf{M}^*\mathbf{M}(\operatorname{Ker} F') = 0$. By redefining $\lambda_{\max} = \lambda_{\max}(\mathbf{M}^*\mathbf{M}) = \|\mathbf{M}\|^2$ and $\lambda_{\min}^+ = \lambda_{\min}(\mathbf{M}^*\mathbf{M}|_{\operatorname{Ran} F}) = \|\mathbf{M}|_{\operatorname{Ran} F}^{-1}\|^{-2}$, the damped Richardson iteration, possibly alternated with the projection step, can now be applied to solve (2.8).

In this paper, we confine the analysis to the symmetric positive definite (SPD) case. However, following the lines of [6, section 7], everything that will be said about the SPD case can easily be generalized to the iteration applied to (2.8).

As an alternative for saddle-point problems, in [6, 12, 19] the Uzawa algorithm or a reformulation as a positive definite system is studied, with the aim of obtaining quantitatively better algorithms by avoiding the squaring of the condition number κ. It can be expected that these methods can also be based on frames.

2.4. Approximate iterations. Obviously, since in actual computations we can neither handle the generally infinite vector $\mathbf{g}$ nor apply the infinite matrix $\mathbf{M}$, the damped Richardson iteration, possibly alternated with the projection, is not a practical algorithm. In this section, we study convergence of the iterations in which these ingredients are approximated. Following [6], we assume that we have the following routines at our disposal.

RHS$[\varepsilon, \mathbf{g}] \to \mathbf{g}_\varepsilon$. *This routine determines a finitely supported* $\mathbf{g}_\varepsilon \in \ell_2$ *satisfying*

$$\|\mathbf{g} - \mathbf{g}_\varepsilon\| \leq \varepsilon.$$

APPLY$[\varepsilon, \mathbf{N}, \mathbf{v}] \to \mathbf{w}_\varepsilon$. *This routine determines, for a finitely supported* $\mathbf{v} \in \ell_2$ *and for* $\mathbf{N} = \mathbf{M}$ *(or* $\mathbf{P}$ *or* $\mathbf{M}^*$*), a finitely supported* $\mathbf{w}_\varepsilon$ *satisfying*

$$\|\mathbf{Nv} - \mathbf{w}_\varepsilon\| \leq \varepsilon.$$

COARSE$[\varepsilon, \mathbf{v}] \to \mathbf{v}_\varepsilon$. *This routine creates, for a finitely supported* $\mathbf{v} \in \ell_2$*, a vector* $\mathbf{v}_\varepsilon$ *by replacing all but* N *coefficients of* $\mathbf{v}$ *by zeros such that*

$$\|\mathbf{v} - \mathbf{v}_\varepsilon\| \leq \varepsilon, \tag{2.9}$$

whereas N is at most a constant multiple of the minimal value of N for which (2.9) *is valid.*

In sections 3.1 and 3.2, we will discuss suitable realizations of Coarse and Apply, respectively. The routine Coarse will be necessary for obtaining an optimal work/accuracy balance. The realization of Rhs depends on the problem at hand.

Based on the above routines, we consider the following inexact version of the damped Richardson iteration.

```
    Solve$[\varepsilon, \mathbf{M}, \mathbf{g}] \to \mathbf{u}_\varepsilon$.
Let $\theta < 1/3$ and $K \in \mathbb{N}$ be fixed such that $3\rho^K < \theta$.
$i := 0$, $\mathbf{u}^{(0)} := 0$, $\varepsilon_0 := \|\mathbf{M}|_{\mathrm{Ran}\,F}^{-1}\| \, \|\mathbf{g}\|$.
While $\varepsilon_i > \varepsilon$ do
    $i := i + 1$
    $\varepsilon_i := 3\rho^K \varepsilon_{i-1}/\theta$
    $\mathbf{g}^{(i)} :=$ Rhs$[\frac{\theta\varepsilon_i}{6\alpha K}, \mathbf{g}]$
    $\mathbf{v}^{(i,0)} := \mathbf{u}^{(i-1)}$
    For $j = 1, \dots, K$ do
        $\mathbf{v}^{(i,j)} := \mathbf{v}^{(i,j-1)} - \alpha\left(\text{Apply}[\frac{\theta\varepsilon_i}{6\alpha K}, \mathbf{M}, \mathbf{v}^{(i,j-1)}] - \mathbf{g}^{(i)}\right)$
    od
    $\mathbf{u}^{(i)} :=$ Coarse$[(1-\theta)\varepsilon_i, \mathbf{v}^{(i,K)}]$
od
$\mathbf{u}_\varepsilon := \mathbf{u}^{(i)}$.
```

Proposition 2.1. *Let $\mathbf{u} \in \ell_2$ be some solution of $\mathbf{M}\mathbf{u} = \mathbf{g}$. Then the vectors $\mathbf{u}^{(i)}$, $\mathbf{v}^{(i,K)}$ produced in* Solve$[\varepsilon, \mathbf{M}, \mathbf{g}]$ *satisfy*

$$\|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i)})\| \le \varepsilon_i \qquad (i \ge 0), \tag{2.10}$$

and so, in particular, $\|\mathbf{Q}(\mathbf{u} - \mathbf{u}_\varepsilon)\| \le \varepsilon$. Furthermore,

$$\|\mathbf{Q}\mathbf{u} + (\mathbf{id} - \mathbf{Q})\mathbf{u}^{(i-1)} - \mathbf{v}^{(i,K)}\| \le \frac{2}{3}\theta\varepsilon_i \qquad (i \ge 1), \tag{2.11}$$

which will be used in section 3.3.

Proof. For $i = 0$, (2.10) follows from $\mathbf{Q}\mathbf{u} = \mathbf{M}|_{\mathrm{Ran}\,F}^{-1}\mathbf{g}$.

Now for an $i \ge 1$ let $\|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i-1)})\| \le \varepsilon_{i-1}$. Since $\mathbf{M}\mathbf{Q}\mathbf{u} = \mathbf{g}$ and $\|\mathbf{id} - \alpha\mathbf{M}\| \le 1$, we have

$$\|\mathbf{Q}\mathbf{u} - \mathbf{v}^{(i,K)} - (\mathbf{id} - \alpha\mathbf{M})^K(\mathbf{Q}\mathbf{u} - \mathbf{u}^{(i-1)})\| \le K\left(\alpha\frac{\theta\varepsilon_i}{6\alpha K} + \alpha\frac{\theta\varepsilon_i}{6\alpha K}\right) = \frac{\theta\varepsilon_i}{3}.$$

From

$$(\mathbf{id} - \alpha\mathbf{M})^K(\mathbf{Q}\mathbf{u} - \mathbf{u}^{(i-1)}) = (\mathbf{id} - \alpha\mathbf{M})^K\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i-1)}) - (\mathbf{id} - \mathbf{Q})\mathbf{u}^{(i-1)}$$

and $\|(\mathbf{id} - \alpha\mathbf{M})^K\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i-1)})\| \le \rho^K\|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i-1)})\| \le \rho^K\varepsilon_{i-1} = \frac{\theta\varepsilon_i}{3}$, we conclude (2.11). The definition of $\mathbf{u}^{(i)}$ now shows that $\|\mathbf{Q}\mathbf{u} + (\mathbf{id} - \mathbf{Q})\mathbf{u}^{(i-1)} - \mathbf{u}^{(i)}\| \le (\frac{2\theta}{3} + (1 - \theta))\varepsilon_i = (1 - \frac{\theta}{3})\varepsilon_i$, and so $\|\mathbf{Q}(\mathbf{u} - \mathbf{u}^{(i)})\| \le (1 - \frac{\theta}{3})\varepsilon_i \le \varepsilon_i$. □

Remark 2.2. Compared to the Riesz basis setting discussed in [6], we see that in Solve we have to pay for working with a frame. When going from $\mathbf{u}^{(i)}$ to $\mathbf{u}^{(i+1)}$, each of the "evaluation" errors made in the K intermediate steps, and in fact even the sum, should be less than the error that is allowed in $\mathbf{u}^{(i+1)}$. Indeed, since only $\|\mathbf{id} - \alpha\mathbf{M}\| \le 1$, these errors might not be reduced by the iteration.

The inexact version of the damped Richardson iteration, alternated with the inexact application of the projector $\mathbf{P}$, is given by the following.

```
modSOLVE$[\varepsilon, \mathbf{M}, \mathbf{g}] \to \mathbf{u}_\varepsilon$.
Let $\theta < 1/3$ and $K \in \mathbb{N}$ be fixed such that $3\rho^K \|\mathbf{P}\| < \theta$.
$i := 0$, $\mathbf{u}^{(0)} := 0$, $\varepsilon_0 := \|\mathbf{P}\| \, \|\mathbf{M}|_{\operatorname{Ran} F}^{-1}\| \, \|\mathbf{g}\|$.
While $\varepsilon_i > \varepsilon$ do
    $i := i + 1$
    $\varepsilon_i := 3\rho^K \|\mathbf{P}\| \varepsilon_{i-1}/\theta$
    $\mathbf{v}^{(i,0)} := \mathbf{u}^{(i-1)}$
    For $j = 1, \dots, K$ do
        $\mathbf{v}^{(i,j)} := \mathbf{v}^{(i,j-1)} - \alpha(\text{APPLY}[\frac{\rho^j \varepsilon_{i-1}}{2\alpha K}, \mathbf{M}, \mathbf{v}^{(i,j-1)}] - \text{RHS}[\frac{\rho^j \varepsilon_{i-1}}{2\alpha K}, \mathbf{g}])$
    od
    $\mathbf{z}^{(i)} := \text{APPLY}[\frac{\theta \varepsilon_i}{3}, \mathbf{P}, \mathbf{v}^{(i,K)}]$
    $\mathbf{u}^{(i)} := \text{COARSE}[(1-\theta)\varepsilon_i, \mathbf{z}^{(i)}]$
od
$\mathbf{u}_\varepsilon := \mathbf{u}^{(i)}$.
```

PROPOSITION 2.3. *Let $\mathbf{u} \in \ell_2$ be some solution of $\mathbf{Mu} = \mathbf{g}$. Then the vectors $\mathbf{u}^{(i)}$, $\mathbf{z}^{(i)}$ produced in* modSOLVE$[\varepsilon, \mathbf{M}, \mathbf{g}]$ *satisfy*

$$\|\mathbf{Pu} - \mathbf{u}^{(i)}\| \le \varepsilon_i \qquad (i \ge 0), \tag{2.12}$$

and so, in particular, $\|\mathbf{Pu} - \mathbf{u}_\varepsilon\| \le \varepsilon$. Furthermore,

$$\|\mathbf{Pu} - \mathbf{z}^{(i)}\| \le \theta \varepsilon_i \qquad (i \ge 1), \tag{2.13}$$

which will be used in section 3.3.

Proof. For $i = 0$, (2.12) follows from $\mathbf{Pu} = \mathbf{PM}|_{\operatorname{Ran} F}^{-1} \mathbf{g}$.

Now for an $i \ge 1$, let $\|\mathbf{Pu} - \mathbf{u}^{(i-1)}\| \le \varepsilon_{i-1}$. Since $\mathbf{MPu} = \mathbf{g}$, for $1 \le j \le K$, for some δ_j with $\|\delta_j\| \le \frac{\rho^j \varepsilon_{i-1}}{K}$, we have

$$\mathbf{Pu} - \mathbf{v}^{(i,j)} = (\mathbf{id} - \alpha \mathbf{M})(\mathbf{Pu} - \mathbf{v}^{(i,j-1)}) + \delta_j,$$

and so

$$\mathbf{Pu} - \mathbf{v}^{(i,K)} = (\mathbf{id} - \alpha \mathbf{M})^K (\mathbf{Pu} - \mathbf{u}^{(i-1)}) + \sum_{j=1}^{K} (\mathbf{id} - \alpha \mathbf{M})^{K-j} \delta_j.$$

From $(\mathbf{id} - \alpha\mathbf{M})^m = (\mathbf{id} - \alpha\mathbf{M})^m \mathbf{Q} + (\mathbf{id} - \mathbf{Q})$ and $\mathbf{P}(\mathbf{id} - \mathbf{Q}) = 0$, we obtain that $\|\mathbf{P}(\mathbf{id} - \alpha\mathbf{M})^m\| \le \|\mathbf{P}\| \rho^m$. We conclude that

$$\|\mathbf{Pu} - \mathbf{Pv}^{(i,K)}\| \le \|\mathbf{P}\| \left(\rho^K \varepsilon_{i-1} + \sum_{j=1}^{K} \rho^{K-j} \frac{\rho^j \varepsilon_{i-1}}{K} \right) = 2\rho^K \|\mathbf{P}\| \varepsilon_{i-1},$$

$$\|\mathbf{Pu} - \mathbf{z}^{(i)}\| \le 2\rho^K \|\mathbf{P}\| \varepsilon_{i-1} + \frac{\theta \varepsilon_i}{3} = \theta \varepsilon_i,$$

and finally

$$\|\mathbf{Pu} - \mathbf{u}^{(i)}\| \le \theta \varepsilon_i + (1-\theta)\varepsilon_i = \varepsilon_i. \qquad \square$$

3. Convergence rates and computational costs.

3.1. Best *N*-term approximation and COARSE**.** To assess the efficiency of SOLVE or modSOLVE, following [6], we will consider the following benchmark: Suppose that for some solution $\mathbf{u} \in \ell_2$ of $\mathbf{M}\mathbf{u} = \mathbf{g}$ we would have *all* coefficients available. Then the most economical approximation for $\mathbf{u}$ on distance less than ε would be $\mathbf{u}_N$, defined by replacing all but the N largest coefficients in modulus of $\mathbf{u}$ by zeros, with $N = N(\varepsilon, \mathbf{u})$ being the smallest integer such that

$$\|\mathbf{u} - \mathbf{u}_N\| \leq \varepsilon. \tag{3.1}$$

For $N \in \mathbb{N}$, the vector $\mathbf{u}_N$ is called the *best N-term approximation* for $\mathbf{u}$. If for some $s > 0$

$$\|\mathbf{u} - \mathbf{u}_N\| \lesssim N^{-s} \qquad (N \in \mathbb{N}), \tag{3.2}$$

then $N = N(\varepsilon, \mathbf{u})$ from (3.1) would satisfy $N(\varepsilon, \mathbf{u}) \lesssim \varepsilon^{-1/s}$.

Assuming (3.2), in section 3.3 we will prove that for $\mathbf{u}_\varepsilon$ produced by (mod)SOLVE it holds that $\#\operatorname{supp} \mathbf{u}_\varepsilon \lesssim \varepsilon^{-1/s}$, whereas the number of floating point operations to compute it is of the same order. In view of (3.2), we may conclude that (mod)SOLVE is of optimal computational complexity.

The question *whether*, and if so, *for which* s (3.2) is valid, is related to properties of the frame and the (Besov-) regularity of the solution $u \in H$ of the operator equation (2.4). This will be discussed in section 4.2.

Vectors $\mathbf{u} \in \ell_2$ that satisfy (3.2) can be characterized as follows (see [21]): Let $\gamma_n(\mathbf{u})$ denote the nth largest coefficient in modulus of $\mathbf{u}$. For $0 < \tau < 2$, the space ℓ_τ^w is defined by

$$\ell_\tau^w = \left\{ \mathbf{u} \in \ell_2 : |\mathbf{u}|_{\ell_\tau^w} := \sup_n n^{1/\tau} |\gamma_n(\mathbf{u})| < \infty \right\}.$$

It is easily verified that $\ell_\tau \hookrightarrow \ell_\tau^w \hookrightarrow \ell_{\tau+\delta}$ for any $\delta \in (0, 2-\tau]$, justifying why ℓ_τ^w is called *weak* ℓ_τ. The expression $|\mathbf{u}|_{\ell_\tau^w}$ defines only a quasinorm since it does not necessarily satisfy the triangle inequality. Yet, for each $0 < \tau < 2$, there exists a $C_1(\tau) > 0$ with

$$|\mathbf{v} + \mathbf{w}|_{\ell_\tau^w} \leq C_1(\tau) \left(|\mathbf{v}|_{\ell_\tau^w} + |\mathbf{w}|_{\ell_\tau^w} \right) \qquad (\mathbf{v}, \mathbf{w} \in \ell_\tau^w), \tag{3.3}$$

or, equivalently [2, Lemma 3.10.1], for $\mu = \mu(\tau) > 0$ sufficiently small it holds that

$$|\mathbf{v} + \mathbf{w}|_{\ell_\tau^w}^\mu \leq |\mathbf{v}|_{\ell_\tau^w}^\mu + |\mathbf{w}|_{\ell_\tau^w}^\mu \qquad (\mathbf{v}, \mathbf{w} \in \ell_\tau^w).$$

With these ℓ_τ^w-spaces at hand, it can be shown that the property (3.2) is equivalent to $\mathbf{u} \in \ell_\tau^w$, with τ related to s according to $\tau = (\frac{1}{2} + s)^{-1}$. In particular, for each $\tau \in (0, 2)$,

$$\sup_N N^s \|\mathbf{u} - \mathbf{u}_N\| \eqsim |\mathbf{u}|_{\ell_\tau^w}; \tag{3.4}$$

e.g., see [5, Proposition 3.2].

The routine $\mathbf{v}_\varepsilon = \text{COARSE}[\varepsilon, \mathbf{v}]$ might be defined by taking $\mathbf{v}_\varepsilon = \mathbf{v}_N$, with N being the smallest integer such that $\|\mathbf{v} - \mathbf{v}_N\| \leq \varepsilon$. However, since the determination of the best N-term approximation requires sorting all elements of $\mathbf{v}$ by their modulus, this algorithm cannot be implemented in linear time. It requires the order of $(\#\mathrm{supp}\,\mathbf{v}) \times \log(\#\mathrm{supp}\,\mathbf{v})$ operations, with $\#\mathrm{supp}\,\mathbf{v}$ denoting the number of nonzero coefficients of $\mathbf{v}$.

Following ideas from [1, 22], we use a routine COARSE with which this log-*factor* is avoided.

COARSE$[\varepsilon, \mathbf{v}] \to \mathbf{v}_\varepsilon$.

- $q := \lceil \log((\#\mathrm{supp}\,\mathbf{v})^{1/2}\|\mathbf{v}\|/\varepsilon)\rceil$.
- *Divide the elements of* $\mathbf{v}$ *into sets* $V_0, \ldots, V_q$, *where, for* $0 \leq i \leq q-1$, V_i *contains the elements with modulus in* $(2^{-i-1}\|\mathbf{v}\|, 2^{-i}\|\mathbf{v}\|]$, *and possible remaining elements are put into* V_q.
- *Create* $\mathbf{v}_\varepsilon$ *by extracting elements first from* V_0 *and, when it is empty, from* V_1 *and so forth, until* $\|\mathbf{v} - \mathbf{v}_\varepsilon\| \leq \varepsilon$.

The value of q is chosen such that the sum of squares of the elements in V_q is less than or equal to ε^2, meaning that the last element added to $\mathbf{v}_\varepsilon$ (assuming that this vector is nonzero) originates from V_i for some $i < q$. Since then also $\mathbf{v}_N$ with $\|\mathbf{v} - \mathbf{v}_N\| \leq \varepsilon$ must contain elements from this V_i, and since within each V_i the squared values of the elements differ by at most a factor of 4, we obtain the following result.

PROPOSITION 3.1. *For* $\mathbf{v}_\varepsilon$ *yielded by the above routine, it holds that* $\|\mathbf{v} - \mathbf{v}_\varepsilon\| \leq \varepsilon$ *and*

$$\#\mathrm{supp}\,\mathbf{v}_\varepsilon \leq 4\min\{N : \|\mathbf{v} - \mathbf{v}_N\| \leq \varepsilon\}, \tag{3.5}$$

meaning that it defines a valid procedure COARSE. *The number of operations needed for this routine is of the order*

$$\#\mathrm{supp}\,\mathbf{v} + q \lesssim \#\mathrm{supp}\,\mathbf{v} + \log(\varepsilon^{-1}\|\mathbf{v}\|). \tag{3.6}$$

Later, it will appear that the latter log-term is harmless.

Below, in Proposition 3.2, we recall a crucial result proved in [5]. It shows that, for any fixed $\theta < 1/3$, a finitely supported approximation of a target vector in ℓ_τ^w can always be coarsened such that the resulting approximation has an error that is at most $1/\theta$ times the original error, whereas the size of its support is at most some fixed multiple of that of the best N-term approximation with that error. Although this result was proved for best N-term approximations, from (3.5) it is obvious that it is also valid for the current routine COARSE.

PROPOSITION 3.2 (see [5, Corollary 5.2]). *Let* $\theta < 1/3$, $\tau \in (0,2)$, *and* $\tau = (\frac{1}{2} + s)^{-1}$. *Then for any* $\varepsilon > 0$, $\mathbf{v} \in \ell_\tau^w$, *and finitely supported* $\mathbf{w} \in \ell_2$ *with*

$$\|\mathbf{v} - \mathbf{w}\| \leq \theta\varepsilon,$$

for $\overline{\mathbf{w}} = $ COARSE$[(1-\theta)\varepsilon, \mathbf{w}]$ *it holds that*

$$\#\mathrm{supp}\,\overline{\mathbf{w}} \lesssim \varepsilon^{-1/s}|\mathbf{v}|_{\ell_\tau^w}^{1/s},$$

and obviously $\|\mathbf{v} - \overline{\mathbf{w}}\| \leq \varepsilon$.

Remark 3.3. In [5, Corollary 5.2] this result was formulated for $\theta = 1/5$. However, an inspection of the proof, and an easy generalization of [5, (5.4)] concerning thresholding, shows the result for any $\theta < 1/3$. Applying COARSE with a θ larger than 1/5 might give a quantitative improvement of (mod)SOLVE, since then it increases the error with a smaller factor. It is easily seen that in any case Proposition 3.2 can not be valid for $\theta > 1/2$.

Controlling the sizes of the supports of approximations of an ℓ_τ^w-function relative to their errors implies controlling their ℓ_τ^w-(quasi)norms. Indeed, an easy application of the next proposition shows that in the situation of Proposition 3.2, in addition we have that

$$|\overline{\mathbf{w}}|_{\ell_\tau^w} \leq C_2(\tau)|\mathbf{v}|_{\ell_\tau^w} \tag{3.7}$$

for some constant $C_2(\tau)$ independent of ε.

PROPOSITION 3.4 (see [5, Lemma 4.11]). *Let $\tau \in (0,2)$ and $\tau = (\frac{1}{2}+s)^{-1}$. Then for any $\mathbf{v} \in \ell_\tau^w$ and finitely supported $\mathbf{z} \in \ell_2$ we have*

$$|\mathbf{z}|_{\ell_\tau^w} \lesssim |\mathbf{v}|_{\ell_\tau^w} + (\#\operatorname{supp}\mathbf{z})^s \|\mathbf{v}-\mathbf{z}\|.$$

Proof. For convenience we recall the short proof. Let $N = \#\operatorname{supp}\mathbf{z}$; then

$$|\mathbf{z}|_{\ell_\tau^w} \lesssim |\mathbf{z}-\mathbf{v}_N|_{\ell_\tau^w} + |\mathbf{v}_N|_{\ell_\tau^w} \lesssim (2N)^s\|\mathbf{z}-\mathbf{v}_N\| + |\mathbf{v}|_{\ell_\tau^w},$$

where we used $\#\operatorname{supp}(\mathbf{z}-\mathbf{v}_N) \leq 2N$ and (3.4). The proof is completed by

$$\|\mathbf{z}-\mathbf{v}_N\| \leq \|\mathbf{z}-\mathbf{v}\| + \|\mathbf{v}-\mathbf{v}_N\| \leq 2\|\mathbf{z}-\mathbf{v}\|. \qquad \square$$

3.2. Requirements on the infinite-dimensional system. In order to be able to show that (mod)SOLVE has optimal computational complexity, we will have to impose some conditions on the matrix $\mathbf{M}$, and for modSOLVE also on $\mathbf{P}$, as well as on the right-hand side $\mathbf{g}$. Our treatment closely follows [5, 6], except that, following ideas from [1, 22], we avoid some log-factors in the operations count due to sorting.

DEFINITION 3.5. *Let $s^* > 0$. A bounded $\mathbf{N}: \ell_2 \to \ell_2$ is called* s^*-admissible *when for a suitable routine* APPLY, *for each $s \in (0,s^*)$, $\tau = (\frac{1}{2}+s)^{-1}$, for all $\varepsilon > 0$ and finitely supported vectors $\mathbf{v}$, with $\mathbf{w}_\varepsilon = \text{APPLY}[\varepsilon,\mathbf{N},\mathbf{v}]$ the following are valid:*

(I) $\#\operatorname{supp}\mathbf{w}_\varepsilon \lesssim \varepsilon^{-1/s}|\mathbf{v}|_{\ell_\tau^w}^{1/s}$;

(II) *the number of arithmetic operations used to compute $\mathbf{w}_\varepsilon$ is at most a fixed multiple of $\varepsilon^{-1/s}|\mathbf{v}|_{\ell_\tau^w}^{1/s} + \#\operatorname{supp}\mathbf{v}$.*

Remark 3.6. Let $\mathbf{N}$ be s^*-admissible. Then for any $s \in (0,s^*)$, with $\tau = (\frac{1}{2}+s)^{-1}$, $\mathbf{N}: \ell_\tau^w \to \ell_\tau^w$ is bounded. Indeed, let $\mathbf{v} \in \ell_\tau^w$. Part (I) from Definition 3.5 can be written as $\#\operatorname{supp}\mathbf{w}_\varepsilon \leq C\varepsilon^{-1/s}|\mathbf{v}|_{\ell_\tau^w}^{1/s}$ for some constant C. For any $N \in \mathbb{N}$, take $\varepsilon = C^s|\mathbf{v}|_{\ell_\tau^w}N^{-s}$ or, equivalently, $N = C\varepsilon^{-1/s}|\mathbf{v}|_{\ell_\tau^w}^{1/s}$. Let $(\mathbf{N}\mathbf{v})_N$ denote the best N-term approximation for $\mathbf{N}\mathbf{v}$. Then

$$N^s\|\mathbf{N}\mathbf{v}-(\mathbf{N}\mathbf{v})_N\| \leq N^s\|\mathbf{N}\mathbf{v}-\mathbf{w}_\varepsilon\| \leq N^s\varepsilon = C^s|\mathbf{v}|_{\ell_\tau^w},$$

showing $|\mathbf{N}\mathbf{v}|_{\ell_\tau^w} \lesssim |\mathbf{v}|_{\ell_\tau^w}$ by (3.4).

Next, for any $s \in (0,s^*)$ and $\tau = (\frac{1}{2}+s)^{-1}$, the mapping $\mathbf{v} \mapsto \mathbf{w}_\varepsilon := \text{APPLY}[\varepsilon,\mathbf{N},\mathbf{v}]$ is bounded on ℓ_τ^w uniformly in $\varepsilon > 0$. Indeed Proposition 3.4, Definition 3.5(I), and the boundedness of $\mathbf{N}$ demonstrated above show that

$$|\mathbf{w}_\varepsilon|_{\ell_\tau^w} \lesssim |\mathbf{N}\mathbf{v}|_{\ell_\tau^w} + (\#\operatorname{supp}\mathbf{w}_\varepsilon)^s\|\mathbf{N}\mathbf{V}-\mathbf{w}_\varepsilon\| \lesssim |\mathbf{N}\mathbf{v}|_{\ell_\tau^w} + |\mathbf{v}|_{\ell_\tau^w} \lesssim |\mathbf{v}|_{\ell_\tau^w}.$$

It will turn out that a matrix is s^*-admissible when it is s^*-compressible, a property that can be verified for the matrices at hand.

DEFINITION 3.7. *Let $s^* > 0$. A bounded $\mathbf{N}: \ell_2 \to \ell_2$ is called* s^*-compressible, *when for each $j \in \mathbb{N}$ there exist constants α_j and C_j, and an infinite matrix $\mathbf{N}_j$ having at most $\alpha_j 2^j$ nonzero entries in each column, such that*

$$\|\mathbf{N}-\mathbf{N}_j\| \leq C_j, \tag{3.8}$$

$(\alpha_j)_{j\in\mathbb{N}}$ *is summable, and, for any* $s < s^*$, $(C_j 2^{sj})_{j\in\mathbb{N}}$ *is summable.*

For s^*-compressible $\mathbf{N}$, we will make use of the following routine Apply.

Apply$[\varepsilon, \mathbf{N}, \mathbf{v}] \to \mathbf{w}_\varepsilon$.

- $q := \lceil \log((\#\mathrm{supp}\, \mathbf{v})^{1/2} \|\mathbf{v}\| \|\mathbf{N}\| 2/\varepsilon) \rceil$.
- *Divide the elements of* $\mathbf{v}$ *into sets* $V_0, \ldots, V_q$*, where, for* $0 \le i \le q-1$, V_i *contains the elements with modulus in* $(2^{-i-1}\|\mathbf{v}\|, 2^{-i}\|\mathbf{v}\|]$*, and possible remaining elements are put into* V_q.
- *For* $k = 0, 1, \ldots,$ *generate vectors* $\mathbf{v}_{[k]}$ *by subsequently extracting* $2^k - \lfloor 2^{k-1} \rfloor$ *elements from* $\cup_i V_i$*, starting from* V_0 *and when it is empty continuing with* V_1 *and so forth, until for some* $k = \ell$ *either* $\cup_i V_i$ *becomes empty or*

$$\|\mathbf{N}\| \left\| \mathbf{v} - \sum_{k=0}^{\ell} \mathbf{v}_{[k]} \right\| \le \frac{\varepsilon}{2}. \tag{3.9}$$

  In both cases $\mathbf{v}_{[\ell]}$ *may contain less than* $2^\ell - \lfloor 2^{\ell-1} \rfloor$ *elements.*
- *Compute the smallest* $j \ge \ell$ *such that*

$$\sum_{k=0}^{\ell} C_{j-k} \|\mathbf{v}_{[k]}\| \le \frac{\varepsilon}{2}. \tag{3.10}$$

- *For* $0 \le k \le \ell$*, compute the nonzero entries in the matrices* $\mathbf{N}_{j-k}$ *which have a column index in common with one of the entries of* $\mathbf{v}_{[k]}$*, and compute*

$$\mathbf{w}_\varepsilon := \sum_{k=0}^{\ell} \mathbf{N}_{j-k} \mathbf{v}_{[k]}. \tag{3.11}$$

The sizes of the entries of $\mathbf{v}$ determine the accuracy with which the corresponding columns of $\mathbf{N}$ are approximated, which justifies why we speak about an *adaptive* solution method.

Proposition 3.8. *For* $\mathbf{w}_\varepsilon$ *yielded by above routine, we have*

$$\|\mathbf{N}\mathbf{v} - \mathbf{w}_\varepsilon\| \le \varepsilon.$$

Moreover, when $\mathbf{N}$ *is* s^**-compressible, this* Apply *realizes* (I), (II) *of Definition* 3.5*, and so* $\mathbf{N}$ *is* s^**-admissible.*

Proof. From (3.9), (3.8), and (3.10), we have

$$\|\mathbf{N}\mathbf{v} - \mathbf{w}_\varepsilon\| \le \frac{\varepsilon}{2} + \sum_{k=0}^{\ell} C_{j-k} \|\mathbf{v}_{[k]}\| \le \varepsilon.$$

Let $s \in (0, s^*)$ be given and $\tau = (\frac{1}{2} + s)^{-1}$. The number of operations needed for generating the vectors $\mathbf{v}_{[k]}$ is of the order

$$\#\mathrm{supp}\, \mathbf{v} + q \lesssim \#\mathrm{supp}\, \mathbf{v} + \log(\varepsilon^{-1}\|\mathbf{v}\|) \lesssim \#\mathrm{supp}\, \mathbf{v} + \varepsilon^{-1/s} |\mathbf{v}|_{\ell^w_\tau}^{1/s}.$$

By the definition of s^*-compressibility, $\#\mathrm{supp}\, \mathbf{w}_\varepsilon$ and the number of operations needed for the evaluation of (3.11) can be bounded by $\sum_{k=0}^{\ell} \alpha_{j-k} 2^{j-k} 2^k \lesssim 2^j$, meaning that the proof will be completed once we have shown that $2^j \lesssim \varepsilon^{-1/s} |\mathbf{v}|_{\ell^w_\tau}^{1/s}$.

The value of q was chosen such that the sum of squares of elements in V_q is less than or equal to $(\varepsilon/(2\|\mathbf{N}\|))^2$, meaning that for all $k < \ell$, $\mathbf{v}_{[k]}$ contains only elements from V_i for $i < q$. Since within each of these V_i the squared values of the elements differ by at most a factor of 4, for $k \leq \ell$ we obtain that

$$\|\mathbf{v}_{[k]}\| \leq \left\| \mathbf{v} - \sum_{m=0}^{k-1} \mathbf{v}_{[m]} \right\| \leq \|\mathbf{v} - \mathbf{v}_{\lceil 2^{k-1}/4 \rceil}\| \lesssim 2^{-ks} |\mathbf{v}|_{\ell_\tau^w},$$

by (3.4).

Since ℓ is the smallest integer for which (3.9) is valid, assuming it is nonzero, we infer that

$$\frac{\varepsilon}{2} < \|\mathbf{N}\| \left\| \mathbf{v} - \sum_{k=0}^{\ell-1} \mathbf{v}_{[k]} \right\| \lesssim 2^{-\ell s} |\mathbf{v}|_{\ell_\tau^w} \|\mathbf{N}\|$$

or $2^\ell \lesssim \varepsilon^{-1/s} |\mathbf{v}|_{\ell_\tau^w}^{1/s}$.

Now assume that $j > \ell$. Since j is the smallest integer for which (3.10) is valid, we infer that

$$\frac{\varepsilon}{2} < \sum_{k=0}^{\ell} C_{j-1-k} \|\mathbf{v}_{[k]}\| \lesssim \sum_{k=0}^{\ell} C_{j-1-k} 2^{-ks} |\mathbf{v}|_{\ell_\tau^w} \lesssim 2^{-(j-1)s} |\mathbf{v}|_{\ell_\tau^w},$$

by the definition of s^*-compressibility, or $2^j \lesssim \varepsilon^{-1/s} |\mathbf{v}|_{\ell_\tau^w}^{1/s}$. □

We will consider right-hand sides $\mathbf{g}$ that satisfy the following definition.

DEFINITION 3.9. *A vector $\mathbf{g} \in \ell_2$ is called* s^*-optimal *when for a suitable routine* RHS, *for each $s \in (0, s^*)$, $\tau = (\frac{1}{2} + s)^{-1}$, and all $\varepsilon > 0$, with $\mathbf{g}_\varepsilon =$* RHS$[\varepsilon, \mathbf{g}]$ *the following are valid:*

(I) $\#\operatorname{supp} \mathbf{g}_\varepsilon \lesssim \varepsilon^{-1/s} |\mathbf{g}|_{\ell_\tau^w}^{1/s}$,

(II) *the number of arithmetic operations used to compute $\mathbf{g}_\varepsilon$ is at most a multiple of $\varepsilon^{-1/s} |\mathbf{g}|_{\ell_\tau^w}^{1/s}$.*

Remark 3.10. A direct consequence of Proposition 3.4 and Definition 3.9(I) is that

$$|\mathbf{g}_\varepsilon|_{\ell_\tau^w} \lesssim |\mathbf{g}|_{\ell_\tau^w}. \tag{3.12}$$

Implicitly, in the proof of Proposition 3.8 we assumed that each element of $\mathbf{N}_j$ can be computed at unit costs. For a discussion of the circumstances under which this, as well as $\mathbf{g}$ being s^*-optimal, can be expected, we refer to [6, section 6.2].

3.3. The complexity of (mod)SOLVE.

We show that SOLVE and modSOLVE are of optimal computational complexity. We start with modSOLVE, since for this routine the proof follows closely that given in [6] for the Riesz basis case.

THEOREM 3.11. *For some $s^* > 0$, assume that $\mathbf{M}$ and $\mathbf{P}$ are s^*-admissible, $\mathbf{g}$ is s^*-optimal, and that for some $s \in (0, s^*)$, with $\tau = (\frac{1}{2} + s)^{-1}$, $\mathbf{M}\mathbf{u} = \mathbf{g}$ has a solution $\mathbf{u} \in \ell_\tau^w$. Then for all $\varepsilon > 0$, $\mathbf{u}_\varepsilon =$* modSOLVE$[\varepsilon, \mathbf{M}, \mathbf{g}]$ *satisfies the following:*

(I) $\#\operatorname{supp} \mathbf{u}_\varepsilon \lesssim \varepsilon^{-1/s} |\mathbf{u}|_{\ell_\tau^w}^{1/s}$,

(II) *the number of arithmetic operations used to compute $\mathbf{u}_\varepsilon$ is at most a multiple of $\varepsilon^{-1/s} |\mathbf{u}|_{\ell_\tau^w}^{1/s}$.*

Further, as shown in Proposition 2.3, $\|\mathbf{P}\mathbf{u} - \mathbf{u}_\varepsilon\| \leq \varepsilon$, and so $\|u - F'\mathbf{u}_\varepsilon\|_H \leq B_\Psi^{\frac{1}{2}} \varepsilon$.

Proof. It suffices to prove the statements for any $\varepsilon = \varepsilon_i$ with $\varepsilon_i = (3\rho^K \|\mathbf{P}\|/\theta)^i \varepsilon_0$, as in the algorithm modSOLVE.

As noted in Remark 3.6, the fact that $\mathbf{P}$ is s^*-admissible implies that it is bounded on ℓ^w_τ. For any $i \geq 1$, from $\|\mathbf{P}\mathbf{u}-\mathbf{z}^{(i)}\| \leq \theta\varepsilon_i$ proved in Proposition 2.3, Proposition 3.2 and the assumption $\mathbf{u} \in \ell^w_\tau$ show that $\mathbf{u}^{(i)} := \textsc{Coarse}[(1-\theta)\varepsilon_i, \mathbf{z}^{(i)}]$ satisfies

$$\#\mathrm{supp}\,\mathbf{u}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{P}\mathbf{u}|^{1/s}_{\ell^w_\tau} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}, \tag{3.13}$$

i.e., (I), and by (3.7), also

$$|\mathbf{u}^{(i)}|_{\ell^w_\tau} \lesssim |\mathbf{P}\mathbf{u}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}. \tag{3.14}$$

Here we emphasize that both these results are valid uniformly in i.

To compute $\mathbf{u}^{(i)}$ from $\mathbf{u}^{(i-1)}$, modSolve uses one application of Rhs, K applications of Apply involving $\mathbf{M}$, $2K$ vector updates, one application of Apply involving $\mathbf{P}$, and finally an application of Coarse. From the key estimates (3.13), (3.14), and the fact that K is some *fixed constant*, in the following three paragraphs we show that these computations take not more than a multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ operations. Since $(\varepsilon_i)_i$ is a geometrically decreasing sequence, we may therefore conclude (II).

Since $\mathbf{M}$ is s^*-admissible, it is bounded on ℓ^w_τ. As a consequence, $|\mathbf{g}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$, and so the assumption of $\mathbf{g}$ being s^*-optimal gives $\#\mathrm{supp}\,\mathbf{g}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ and $|\mathbf{g}^{(i)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$ by (3.12), whereas the number of operations used to compute it is at most a multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$.

Because of $|\mathbf{g}^{(i)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$ and $|\mathbf{u}^{(i-1)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$, from the assumption that $\mathbf{M}$ is s^*-admissible we have $|\mathbf{v}^{(i,j)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$ by Remark 3.6. Again since $\mathbf{M}$ is s^*-admissible, the latter result shows that $\#\mathrm{supp}\,\mathbf{v}^{(i,j)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ for $1 \leq j \leq K$, whereas by $\#\mathrm{supp}\,\mathbf{v}^{(i,0)} \lesssim \varepsilon_{i-1}^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ (see (3.13)) and $\#\mathrm{supp}\,\mathbf{g}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$, its computation takes not more than a multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ operations.

Since $|\mathbf{v}^{(i,K)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$, $\#\mathrm{supp}\,\mathbf{v}^{(i,K)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$, and $\mathbf{P}$ is s^*-admissible, the computation of $\mathbf{z}^{(i)} := \textsc{Apply}[\theta\varepsilon_i/3, \mathbf{P}, \mathbf{v}^{(i,K)}]$ takes a number of operations that is at most a multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$, $\#\mathrm{supp}\,\mathbf{z}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$, and $|\mathbf{z}^{(i)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$. Finally, by (3.6), the latter result implies that $\textsc{Coarse}[(1-\theta)\varepsilon_i, \mathbf{z}^{(i)}]$ also needs at most a multiple of $\#\mathrm{supp}\,\mathbf{z}^{(i)} + \log(\varepsilon_i^{-1}\|\mathbf{z}^{(i)}\|) \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ operations. □

The key to the proof of Theorem 3.11 is the fact that the iterands produced by modSolve are uniformly bounded in ℓ^w_τ. Unfortunately, generally this will not be the case with Solve. Since Solve does not contain a projection onto a complement space of kerF', it is not capable of reducing errors once made in kerF'. Recall that such errors are not reduced by the Richardson steps since they are in the kernel of $\mathbf{M}$. Although, because of the geometric decrease of the tolerances, these errors are summable in ℓ_2, we cannot show this in ℓ^w_τ, and so boundedness of the iterands in ℓ^w_τ is *not* guaranteed. For example, thinking of Rhs and Apply as being performed exactly, i.e., with zero tolerances, each time $\textsc{Coarse}[(1-\theta)\varepsilon_i, \mathbf{v}^{(i,K)}]$ is invoked it gives an error, which might be completely contained in $\ker F'$, for which we can say not more than that its ℓ^w_τ-norm is less than or equal to $|\mathbf{v}^{(i,K)}|_{\ell^w_\tau}$, i.e., that it is bounded.

For $\mathbf{u}^{(i)}$, ε_i as in Solve, for some $\check{s} \in (s, s^*)$, and with $\check{\tau} = (\frac{1}{2}+\check{s})^{-1}$, in the proof of Theorem 3.12 given below we will show that

$$\varepsilon_i^{(\check{s}/s)-1}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau}, \qquad \mathrm{supp}\,\mathbf{u}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$$

and, as a consequence of these results, that the method is of optimal complexity. Note that for any $\mathbf{v}$ with finite support,

$$|\mathbf{v}|_{\ell^w_{\check{\tau}}} \le (\#\mathrm{supp}\,\mathbf{v})^{\check{s}-s}|\mathbf{v}|_{\ell^w_\tau}. \tag{3.15}$$

Thus $|\mathbf{u}^{(i)}|_{\ell^w_\tau} \lesssim 1$ and $\#\mathrm{supp}\,\mathbf{u}^{(i)} \lesssim \varepsilon_i^{-1/s}$ would give $\varepsilon_i^{(\check{s}/s)-1}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}^{(i)}|^{\check{s}/s}_{\ell^w_\tau} \lesssim 1$. However, conversely, under no condition on $\#\mathrm{supp}\,\mathbf{u}^{(i)}$, uniform boundedness of $\varepsilon_i^{(\check{s}/s)-1}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}}$ implies that of $|\mathbf{u}^{(i)}|_{\ell^w_\tau}$. In other words, it will turn out that uniform boundedness in ℓ^w_τ of the iterands is not a necessary condition for obtaining an optimal complexity result.

THEOREM 3.12. *For some $s^* > 0$, assume that $\mathbf{M}$ is s^*-admissible, $\mathbf{g}$ is s^*-optimal, and that for some $s \in (0, s^*)$, with $\tau = (\frac{1}{2}+s)^{-1}$, $\mathbf{Mu} = \mathbf{g}$ has a solution $\mathbf{u} \in \ell^w_\tau$. In addition, assume that there exists an $\check{s} \in (s, s^*)$ such that, with $\check{\tau} = (\frac{1}{2}+\check{s})^{-1}$,*

$$\mathbf{Q} \text{ is bounded on } \ell^w_{\check{\tau}}. \tag{3.16}$$

Then, if the parameter K in SOLVE *is sufficiently large—sufficient is*

$$3\rho^K < \theta \min\left\{1, \left[C_1(\check{\tau})C_2(\check{\tau})|(\mathbf{id}-\mathbf{Q})|_{\ell^w_{\check{\tau}} \leftarrow \ell^w_{\check{\tau}}}\right]^{s/(\check{s}-s)}\right\}, \tag{3.17}$$

where $C_1(\check{\tau})$, $C_2(\check{\tau})$ are the constants from (3.3), (3.7) *respectively—then for all $\varepsilon > 0$, $\mathbf{u}_\varepsilon = $* SOLVE$[\varepsilon, \mathbf{M}, \mathbf{g}]$ *satisfies the following:*

(I) $\#\mathrm{supp}\,\mathbf{u}_\varepsilon \lesssim \varepsilon^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$,

(II) *the number of arithmetic operations used to compute $\mathbf{u}_\varepsilon$ is at most a multiple of $\varepsilon^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$.*

Further, as shown in Proposition 2.1, *$\|\mathbf{Q}(\mathbf{u}-\mathbf{u}_\varepsilon)\| \le \varepsilon$, and so $\|u - F'\mathbf{u}_\varepsilon\|_H \le B_\Psi^{\frac{1}{2}}\varepsilon$.*

Proof. It suffices to prove the statements for any $\varepsilon = \varepsilon_i$ with $\varepsilon_i = (3\rho^K/\theta)^i\varepsilon_0$, as in the algorithm SOLVE.

Since $\mathbf{Q}$ is bounded on ℓ_2, and by assumption it is bounded on $\ell^w_{\check{\tau}}$, an interpolation argument (cf. [21, (4.24)]) shows that it is bounded on ℓ^w_τ as well. Let N_i be the smallest integer such that $\|\mathbf{Qu} - (\mathbf{Qu})_{N_i}\| \le \theta\varepsilon_i/3$, where $(\mathbf{Qu})_N$ denotes the best N-term approximation for $\mathbf{Qu}$. Then, using the assumption $\mathbf{u} \in \ell^w_\tau$, (3.4) shows that

$$N_i \lesssim \varepsilon_i^{-1/s}|\mathbf{Qu}|^{1/s}_{\ell^w_\tau} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau},$$

and so by (3.15),

$$\varepsilon_i^{(\check{s}/s)-1}|(\mathbf{Qu})_{N_i}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{(\check{s}/s)-1}_{\ell^w_\tau}|(\mathbf{Qu})_{N_i}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{(\check{s}/s)-1}_{\ell^w_\tau}|\mathbf{Qu}|_{\ell^w_\tau} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau}. \tag{3.18}$$

From $\|\mathbf{Qu} + (\mathbf{id}-\mathbf{Q})\mathbf{u}^{(i-1)} - \mathbf{v}^{(i,K)}\| \le 2\theta\varepsilon_i/3$ proved in Proposition 2.1, we get

$$\|(\mathbf{Qu})_{N_i} + (\mathbf{id}-\mathbf{Q})\mathbf{u}^{(i-1)} - \mathbf{v}^{(i,K)}\| \le \theta\varepsilon_i.$$

From (3.7) and then (3.3), it follows that $\mathbf{u}^{(i)} := $ COARSE$[(1-\theta)\varepsilon_i, \mathbf{v}^{(i,K)}]$ satisfies

$$\begin{aligned}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}} &\le C_2(\check{\tau})|(\mathbf{Qu})_{N_i} + (\mathbf{id}-\mathbf{Q})\mathbf{u}^{(i-1)}|_{\ell^w_{\check{\tau}}} \\ &\le C_1(\check{\tau})C_2(\check{\tau})|(\mathbf{Qu})_{N_i}|_{\ell^w_{\check{\tau}}} + C_1(\check{\tau})C_2(\check{\tau})|(\mathbf{id}-\mathbf{Q})|_{\ell^w_{\check{\tau}} \leftarrow \ell^w_{\check{\tau}}}|\mathbf{u}^{(i-1)}|_{\ell^w_{\check{\tau}}},\end{aligned}$$

and so by (3.18) and $\varepsilon_i = 3\rho^K \varepsilon_{i-1}/\theta$,

$$\begin{aligned}&\big(\varepsilon_i^{(\check{s}/s)-1}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}}\big)\\ &\qquad\qquad \le C|\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau} + C_1(\check{\tau})C_2(\check{\tau})|(\mathbf{id}-\mathbf{Q})|_{\ell^w_{\check{\tau}}\leftarrow\ell^w_{\check{\tau}}}\left(\frac{3\rho^K}{\theta}\right)^{(\check{s}/s)-1}\big(\varepsilon_{i-1}^{(\check{s}/s)-1}|\mathbf{u}^{(i-1)}|_{\ell^w_{\check{\tau}}}\big)\end{aligned}$$

for some constant $C > 0$. We may conclude that if K satisfies (3.17), then solutions of the homogeneous part of this recursion converge to zero, and so

$$\varepsilon_i^{(\check{s}/s)-1}|\mathbf{u}^{(i)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau}, \tag{3.19}$$

which, as we emphasize here, holds uniformly in i.

Knowing (3.19), Proposition 3.2 and (3.18) show that

$$\begin{aligned}\#\operatorname{supp}\mathbf{u}^{(i)} &\lesssim \varepsilon_i^{-1/\check{s}}|(\mathbf{Qu})_{N_i} + (\mathbf{id}-\mathbf{Q})\mathbf{u}^{(i-1)}|^{1/\check{s}}_{\ell^w_{\check{\tau}}}\\ &\lesssim \varepsilon_i^{-1/s}\big(\varepsilon_i^{(\check{s}/s)-1}\big[|(\mathbf{Qu})_{N_i}|_{\ell^w_{\check{\tau}}} + |\mathbf{id}-\mathbf{Q}|_{\ell^w_{\check{\tau}}\leftarrow\ell^w_{\check{\tau}}}|\mathbf{u}^{(i-1)}|_{\ell^w_{\check{\tau}}}\big]\big)^{1/\check{s}}\\ &\lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau};\end{aligned}$$

i.e., (I) is valid.

The remainder of the proof resembles that of Theorem 3.11. We have to show that the K intermediate steps that transfer $\mathbf{u}^{(i-1)}$ to $\mathbf{u}^{(i)}$ take a number of operations that is bounded by some multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$.

As in the proof of Theorem 3.11, since $\mathbf{M}$ is s^*-admissible and $\mathbf{g}$ is s^*-optimal, we have $\#\operatorname{supp}\mathbf{g}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ and $|\mathbf{g}^{(i)}|_{\ell^w_\tau} \lesssim |\mathbf{u}|_{\ell^w_\tau}$, and so, in addition, $\varepsilon_i^{(\check{s}/s)-1}|\mathbf{g}^{(i)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau}$.

Since $\mathbf{M}$ is s^*-admissible, this last result, together with $\varepsilon_{i-1}^{(\check{s}/s)-1}|\mathbf{u}^{(i-1)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau}$, shows that

$$\varepsilon_i^{(\check{s}/s)-1}|\mathbf{v}^{(i,j)}|_{\ell^w_{\check{\tau}}} \lesssim |\mathbf{u}|^{\check{s}/s}_{\ell^w_\tau} \qquad (0 \le j \le K) \tag{3.20}$$

by Remark 3.6 (use $\check{s} < s^*$).

A new element in this proof is the observation that, instead of uniform boundedness in ℓ^w_τ, (3.20) is already sufficient to guarantee that the supports have the appropriate sizes. Indeed, again since $\mathbf{M}$ is s^*-admissible (use $\check{s} < s^*$), it follows that

$$\#\operatorname{supp}\mathbf{v}^{(i,j)} \lesssim \varepsilon_i^{-1/\check{s}}|\mathbf{v}^{(i,j-1)}|^{1/\check{s}}_{\ell^w_{\check{\tau}}} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau} \qquad (1 \le j \le K), \tag{3.21}$$

whereas by $\#\operatorname{supp}\mathbf{v}^{(i,0)} \lesssim \varepsilon_{i-1}^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ (via (I)), $\#\operatorname{supp}\mathbf{g}^{(i)} \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$, and the second inequality in (3.21), its computation takes not more than a multiple of $\varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ operations.

Finally, by (3.6), the application of COARSE$[(1-\theta)\varepsilon_i, \mathbf{v}^{(i,K)}]$ needs at most a multiple of $\#\operatorname{supp}\mathbf{v}^{(i,K)} + \log(\varepsilon_i^{-1}\|\mathbf{v}^{(i,K)}\|) \lesssim \varepsilon_i^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ operations. □

Remark 3.13. The conditions imposed in Theorem 3.12 do not exclude the possibility that $\mathbf{u}_\varepsilon \in \operatorname{Ran} F$, and so $\mathbf{Qu}_\varepsilon = \mathbf{u}_\varepsilon$. Then in a manner analogous to Remark 3.6, the estimates $\|\mathbf{Q}(\mathbf{u}-\mathbf{u}_\varepsilon)\| \le \varepsilon$ and $\#\operatorname{supp}\mathbf{u}_\varepsilon \lesssim \varepsilon^{-1/s}|\mathbf{u}|^{1/s}_{\ell^w_\tau}$ *imply* that $\mathbf{Q} : \ell^w_\tau \to \ell^w_\tau$ is bounded. In this sense, the condition imposed in Theorem 3.12 that, for some $\check{\tau} < \tau$, $\mathbf{Q} : \ell^w_{\check{\tau}} \to \ell^w_{\check{\tau}}$ is bounded, is an almost necessary one.

4. Construction of frames.

Recall that $L : H \to H'$ was assumed to be a boundedly invertible operator, where we have in mind a linear differential or integral operator. When L is an operator of order $2t$, typically H is a Sobolev space of order t. We also briefly discussed the case of having systems of such equations, which, however, poses no principal additional difficulties. Thus here we restrict ourselves to scalar equations, where in addition we assume that the equation is imposed on a *domain* $\Omega \subset \mathbb{R}^n$. In particular, in connection with integral equations, it is also relevant to study the case of the equation being formulated on a manifold. However, in that case the construction of a frame may follow the same principles as in the domain case that we outline here.

4.1. Overlapping domain decompositions.

THEOREM 4.1. *For some $\Gamma^D \subset \partial\Omega$, possibly $\Gamma^D = \emptyset$, and $t \in \mathbb{R}$, let*

$$\mathcal{H}^t = \begin{cases} H^t_{0,\Gamma^D}(\Omega) & \text{when } t \geq 0, \\ (H^{-t}_{0,\Gamma^D}(\Omega))' & \text{when } t < 0, \end{cases}$$

where for $t \geq 0$

$$H^t_{0,\Gamma^D}(\Omega) = \operatorname{clos}_{H^t(\Omega)}\{u \in H^t(\Omega) \cap C^\infty(\Omega) : \operatorname{supp} u \cap \Gamma^D = \emptyset\}.$$

Let $\Omega = \cup_{i=1}^m \Omega_i$ be an open covering, by which we mean that the sets Ω_i are open and that there exists a partition of unity $\{\chi_i\}$ relative to $\{\Omega_i\}$; i.e., $\chi_i \in C^\infty(\Omega)$, $0 \leq \chi_i \leq 1$, χ_i vanishes outside Ω_i, and $\sum_i \chi_i = 1$.

With

$$\Gamma_i^D = \begin{cases} \partial\Omega_i \cap (\Omega \cup \Gamma^D) & \text{if } t \geq 0, \\ \partial\Omega_i \cap \Gamma^D & \text{if } t < 0, \end{cases}$$

let

$$\mathcal{H}_i^t = \begin{cases} H^t_{0,\Gamma_i^D}(\Omega_i) & \text{if } t \geq 0, \\ (H^{-t}_{0,\Gamma_i^D}(\Omega_i))' & \text{if } t < 0, \end{cases}$$

and let $\Psi^{(i)}$ be a Riesz basis or, more generally, a frame for $\mathcal{H}_i^t$.

Let $\{\omega_i\}_{1 \leq i \leq m}$ be a collection of nonnegative functions on Ω, with ω_i smooth on Ω_i and zero outside Ω_i, such that there exists an open covering $\Omega = \cup_{i=1}^m \hat{\Omega}_i$ with $\hat{\Omega}_i \subset \Omega_i$ and $\omega_i \eqsim 1$ on $\hat{\Omega}_i$.

Then

$$\cup_i \omega_i \Psi^{(i)} \text{ is a frame for } \mathcal{H}^t.$$

Proof. First we demonstrate that for $u \in \mathcal{H}^t$,

$$\|u\|^2_{\mathcal{H}^t} \eqsim \inf_{\omega_i^{-1} u_i \in \mathcal{H}_i^t, \sum_i u_i = u} \sum_i \|\omega_i^{-1} u_i\|^2_{\mathcal{H}_i^t}. \tag{4.1}$$

Here, by writing $\omega_i^{-1} u_i \in \mathcal{H}_i^t$, in particular we implicitly state that u_i vanishes outside $\operatorname{supp} \omega_i$.

Let $\omega_i^{-1} u_i \in \mathcal{H}_i^t$. Then, since ω_i is smooth on Ω_i, $u_i \in \mathcal{H}_i^t$. Furthermore, the spaces $\mathcal{H}_i^t$ are selected in such a way that the trivial extension with zero of a function on Ω_i extends to a bounded mapping from $\mathcal{H}_i^t \to \mathcal{H}^t$. To see this for $t < 0$, note that the restriction of a function on Ω to Ω_i, which is the adjoint of the zero extension, is a bounded mapping from $H^{-t}_{0,\Gamma_D}(\Omega)$ to $H^{-t}_{0,\partial\Omega_i\cap\Gamma^D}(\Omega_i)$. We conclude that for any $\omega_i^{-1}u_i \in \mathcal{H}_i^t$, the function $u = \sum_i u_i \in \mathcal{H}^t$, with $\|u\|^2_{\mathcal{H}^t} \lesssim \sum_i \|u_i\|^2_{\mathcal{H}_i^t} \lesssim \sum_i \|\omega_i^{-1}u_i\|^2_{\mathcal{H}_i^t}$.

Conversely, let $\{\hat{\chi}_i\}$ be a partition of unity relative to $\{\hat{\Omega}_i\}$. Then any $u \in \mathcal{H}^t$ can be written as $u = \sum_i \hat{\chi}_i u$, where, because of $\omega_i \eqsim 1$ on $\hat{\Omega}_i$, $\omega_i^{-1}\hat{\chi}_i u \in \mathcal{H}_i^t$ and $\|\omega_i^{-1}\hat{\chi}_i u\|_{\mathcal{H}_i^t} \lesssim \|\hat{\chi}_i u\|_{\mathcal{H}_i^t} \lesssim \|u\|_{\mathcal{H}^t}$, completing the proof of (4.1).

Since $\Psi^{(i)}$ is a frame for $\mathcal{H}_i^t$, for $v_i \in \mathcal{H}_i^t$ we have $\|v_i\|^2_{\mathcal{H}_i^t} \eqsim \inf_{\mathbf{c}_i\in\ell_2,\,\mathbf{c}_i^T\Psi^{(i)}=v_i} \|\mathbf{c}_i\|^2_{\ell_2}$. With v_i of the form $\omega_i^{-1}u_i$, $\mathbf{c}_i^T\Psi^{(i)} = v_i$ is equivalent to $\mathbf{c}_i^T\omega_i\Psi^{(i)} = u_i$. Now from (4.1) we conclude that, for $u \in \mathcal{H}^t$,

$$\begin{aligned}\|u\|^2_{\mathcal{H}^t} &\eqsim \inf_{\omega_i^{-1}u_i\in\mathcal{H}_i^t,\,\sum_i u_i=u} \sum_i \inf_{\mathbf{c}_i\in\ell_2,\,\mathbf{c}_i^T\omega_i\Psi^{(i)}=u_i} \|\mathbf{c}_i\|^2 \\ &= \inf_{(\mathbf{c}_1^T,\ldots,\mathbf{c}_m^T)^T\in\ell_2,\,\sum_i \mathbf{c}_i^T\omega_i\Psi^{(i)}=u} \sum_i \|\mathbf{c}_i\|^2,\end{aligned}$$

meaning that $\cup_i\omega_i\Psi^{(i)}$ is a frame for $\mathcal{H}^t$. □

Remark 4.2. If Theorem 4.1 is applied, with ω_i being the characteristic function of $\Omega_i = \hat{\Omega}_i$, then it shows that $\cup_i\Psi^{(i)}$ is a frame for $\mathcal{H}^t$.

If each ω_i is selected such that it *vanishes at* the internal boundary $\partial\Omega_i \cap \Omega$, then the above proof shows that boundary conditions on that part of $\partial\Omega_i$ can actually be chosen at one's convenience; i.e., any $\partial\Omega_i \cap \Gamma^D \subset \Gamma_i^D \subset \partial\Omega_i \cap (\Omega \cup \Gamma^D)$ will do.

To construct collections $\Psi^{(i)}$ that serve as ingredients in Theorem 4.1, we may proceed as follows: Suppose that for each $1 \leq i \leq m$ we have a sufficiently smooth regular parametrization κ_i between $(0,1)^n$, or another reference domain, and Ω_i (see Figure 1). With$\Gamma^D_{i,\square} = \kappa_i^{-1}(\Gamma_i^D)$, let $\Psi^{(i)}_\square$ be a Riesz basis for $H^t_{0,\Gamma^D_{i,\square}}(0,1)^n$ when $t \geq 0$,

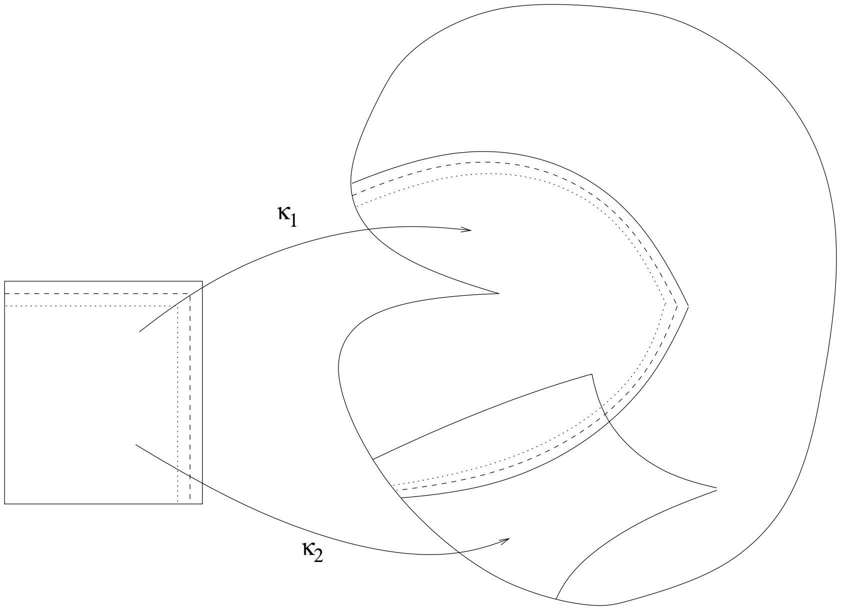

FIG. 1. *Overlapping domain decomposition. (The dashed and dotted lines will be defined in section 4.4.)*

or for $(H^{-t}_{0,\Gamma^D_{i,\square}}(0,1)^n)'$ otherwise. Then we may conclude that $\Psi^{(i)} = \Psi^{(i)}_\square \circ \kappa_i^{-1}$ is a Riesz basis for $\mathcal{H}^t_i$.

At least if the parametrizations are constructed such that the image of a face of $[0,1]^n$ either has empty intersection with Γ_D or is fully contained in Γ_D, then $\Psi^{(i)}_\square$ of wavelet type can easily be constructed by taking tensor products of wavelet bases on the interval with appropriate boundary conditions.

With the construction of spline wavelets on the interval from [15], only wavelets with supports near the endpoints depend on the boundary condition. This means that if the weights ω_i in Theorem 4.1 vanish in a sufficiently large *neighborhood of* the internal boundaries $\partial\Omega_i \cap \Omega$, then boundary conditions at these internal boundaries are irrelevant since they have no influence on the constructed frame.

Compared to the construction of wavelet *bases* for $\mathcal{H}^t$ based on a *nonoverlapping* decomposition of the domain, the frame approach seems to have the following advantages:

- It is easier to construct parametrizations corresponding to an overlapping domain decomposition; only local parametrizations of $\partial\Omega$ are needed. Having less complicated κ_i may also have a favorable quantitative effect on the frame constants A_Ψ and B_Ψ.
- Constructions of wavelet bases based on nonoverlapping domain decompositions all involve a kind of "stitching" of wavelets from different subdomains at the interfaces. The construction from [17] yields wavelets with all desired theoretical properties, but it seems not easy to implement. The constructions proposed in [16, 3, 8] yield near the interfaces wavelets that are only continuous, which restricts the values of s^* for which $\mathbf{M}$ (and $\mathbf{P}$) are s^*-compressible (see [5, Proposition 6.2.2], [25], and section 4.5).
- When a frame construction similar to that in Theorem 4.1 is applied on a *closed manifold* with weights ω_i that vanish at the internal boundaries, then the wavelet bases on $(0,1)^n$ that serve as ingredients may satisfy *periodic boundary conditions*. Not only is the implementation of such bases much easier, but also they are much better conditioned than available wavelet bases that satisfy Dirichlet or Neumann boundary conditions.

4.2. Regularity. As we have seen, under some conditions the routine Solve or modSolve exhibits an error decay of order N^{-s}, with N being the number of operations spent and coefficients stored, *in case* $\mathbf{u} \in \ell^w_\tau$ with $\tau = (\frac{1}{2}+s)^{-1}$. Recall that $\mathbf{u}$ is some solution of $\mathbf{Mu} = \mathbf{g}$; that is, $u = \mathbf{u}^T\Psi$ is the solution of $Lu = g$.

In case Ψ is a Riesz basis for $\mathcal{H}^t$ of biorthogonal wavelet type of *order* d, meaning that $d-1$ is the order of local polynomial reproduction, then it is known that for

$$0 < s < \frac{d-t}{n}$$

it holds that

$$\mathbf{u} \in \ell_\tau \quad \text{if and only if} \quad u \in B^{sn+t}_\tau(L_\tau(\Omega)), \tag{4.2}$$

at least when the wavelets are contained in $B^{sn+t}_\tau(L_\tau(\Omega))$ and $s \leq 1/2$ if $t < -n/2$ (see Figure 2). Recall that $\mathbf{u} \in \ell_\tau$ implies $\mathbf{u} \in \ell^w_\tau$. Here, for $\nu \geq 0$, $B^\nu_p(L_p(\Omega))$ is the usual Besov space, in which possible boundary conditions are incorporated, measuring "ν orders of smoothness in L_p," and for $\nu < 0$, $B^\nu_p(L_p(\Omega)) := (B^{-\nu}_{p'}(L_{p'}(\Omega))'$ with $1/p + 1/p' = 1$, and so necessarily $p \geq 1$. This latter restriction induces the afore-

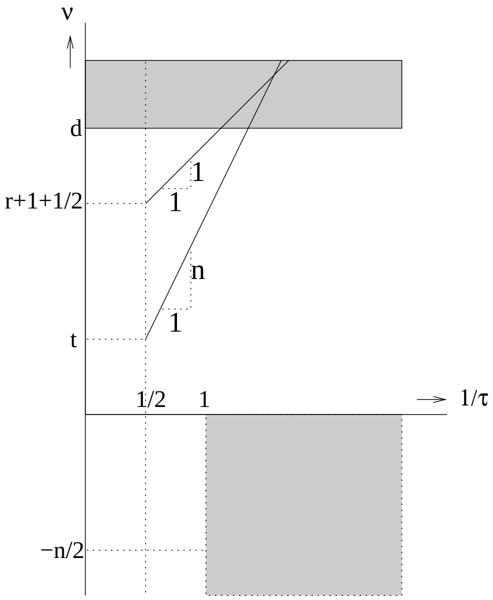

FIG. 2. $B^{\nu}_{\tau}(L_{\tau}(\Omega))$ *with the line* $\nu = sn + t$*, where* $\tau = (\frac{1}{2} + s)^{-1}$*, and the line* $\nu = r + 1 + 1/\tau$*.*

mentioned condition $s \leq 1/2$ if $t < -n/2$. For details about Besov spaces and proofs of (4.2) in various circumstances, we refer to [4].

Remark 4.3. If the wavelets are piecewise smooth globally C^r-functions for some $r \in \mathbb{N} \cup \{-1\}$, with $r = -1$ meaning that they satisfy no global smoothness requirements, then it is known that they are contained in $B^{\nu}_{\tau}(L_{\tau}(\Omega))$ when $\nu < r + 1 + 1/\tau$, whereas they are not contained in this space when $\nu > r+1+1/\tau$. So if for $s = (d-t)/n$ with $\tau = (\frac{1}{2} + s)^{-1}$ it holds that $r + 1 + 1/\tau \geq sn + t$, i.e.,

$$r \geq -\frac{3}{2} + d + \frac{t-d}{n}, \tag{4.3}$$

then smoothness of the wavelets does not limit the range for which (4.2) is valid.

With spline wavelets we have $r = d - 2$, meaning that (4.3) reads as the mild requirement $(d - t)/n \geq 1/2$.

Remark 4.4. Note that to obtain a rate N^{-s} with a linear nonadaptive method it is needed that the solution u be in $H^{sn+t}(\Omega)$, which is a much smaller space than $B^{sn+t}_{\tau}(L_{\tau}(\Omega))$. Recently, a number of regularity proofs have appeared showing that various operators have indeed a much larger regularity in the above Besov scale than in the Sobolev scale (e.g., see [13, 10]). A particular example is the operator corresponding to Poisson's equation on a two-dimensional polygonal domain, which has been shown to have infinity regularity in the Besov scale (see [9]). This means that the Besov regularity of the solution is only limited by the smoothness of the right-hand side, and thus it can be arbitrarily large.

Now let $\Psi = \cup_i \omega_i \Psi^{(i)}$ be a *frame* for $\mathcal{H}^t$, as constructed in Theorem 4.1, where the $\Psi^{(i)}$ are sufficiently smooth biorthogonal wavelet bases of order d for $\mathcal{H}^t_i$. Let $\{\hat{\chi}_i\}$ be a partition of unity relative to $\{\hat{\Omega}_i\}$. Then $u \in B^{sn+t}_{\tau}(L_{\tau}(\Omega))$ implies $\hat{\chi}_i u \in B^{sn+t}_{\tau}(L_{\tau}(\Omega_i))$ and also $\omega_i^{-1}\hat{\chi}_i u \in B^{sn+t}_{\tau}(L_{\tau}(\Omega_i))$. Thus if $0 < s < (d-t)/n$, and $s \leq 1/2$ if $t < -n/2$, then (4.2) demonstrates that each $\omega_i^{-1}\hat{\chi}_i u$ has a unique expansion $\mathbf{u}_i^T\Psi^{(i)}$, and so $\hat{\chi}_i u = \mathbf{u}_i^T\omega_i\Psi^{(i)}$, where $\mathbf{u}_i \in \ell_\tau$. We conclude that u has a representation $\sum_i \mathbf{u}_i^T\omega_i\Psi^{(i)}$ with $(\mathbf{u}_1^T,\dots,\mathbf{u}_m^T)^T \in \ell_\tau \subset \ell_\tau^w$ under the same condition on u as is needed in the Riesz basis case.

4.3. Boundedness of Q, i.e., condition (3.16). Assuming that $\mathbf{Mu} = \mathbf{g}$ has a solution $\mathbf{u} \in \ell_\tau^w$, in Theorem 3.12 the optimal computational complexity of SOLVE is proved when for some $\check{\tau} < \tau$, $\mathbf{Q}$ is bounded on $\ell_{\check{\tau}}^w$. Recall that $\mathbf{Q} = F(F'F)^{-1}F'$, where with the frame construction from Theorem 4.1 and biorthogonal wavelet bases $\Psi^{(i)}$ on the subdomains, $F' : \ell_2 \to \mathcal{H}^t : \mathbf{c} = (\mathbf{c}_1^T,\dots,\mathbf{c}_m^T)^T \mapsto \sum_i \omega_i\mathbf{c}_i^T\Psi^{(i)}$, and so $F : (\mathcal{H}^t)' \to \ell_2 : u \mapsto ((\langle u, \omega_i\Psi^{(i)}\rangle_{L_2(\Omega)})_i)^T = ((\langle \omega_i u, \Psi^{(i)}\rangle_{L_2(\Omega_i)})_i)^T$.

For wavelets that are sufficiently smooth, from (4.2) we know that $\mathbf{c}_i \mapsto \mathbf{c}_i^T\Psi_i$ is bounded from $\ell_{\check{\tau}} \to B_{\check{\tau}}^{\check{s}n+t}(L_{\check{\tau}}(\Omega_i))$ when $0 < \check{s} < (d-t)/n$ and $\check{s} \le 1/2$ if $t < -n/2$.

The mapping $v_i \mapsto \langle v_i, \Psi^{(i)}\rangle_{L_2(\Omega_i)}^T$ is the inverse of $\mathbf{d}_i \mapsto \mathbf{d}_i^T\tilde{\tilde{\Psi}}^{(i)}$, where $\tilde{\Psi}^{(i)}$ is the dual wavelet basis. When the dual wavelets are sufficiently smooth, the latter mapping is boundedly invertible from $\ell_{\check{\tau}}$ to $B_{\check{\tau}}^{\check{s}n-t}(L_{\check{\tau}}(\Omega_i))$ when $0 < \check{s} < (\tilde{d}+t)/n$, where $\tilde{d}$ is the order of the dual multiresolution analysis and $\check{s} \le 1/2$ if $-t < -n/2$.

If we now, in addition, assume that the ω_i vanish at the internal boundaries $\partial\Omega_i \cap \Omega$, and thus that these weights are globally smooth on Ω, then we may conclude that $F' : \ell_{\check{\tau}} \to B_{\check{\mathcal{T}}}^{\check{s}n+t}(L_{\check{\tau}}(\Omega))$ and $F : B_{\check{\tau}}^{\check{s}n-t}(L_{\check{\tau}}(\Omega)) \to \ell_{\check{\tau}}$ are bounded when $0 < \check{s} < \min\{(d-t)/n, (\tilde{d}+t)/n\}$ and $\check{s} \le 1/2$ if $|t| > n/2$.

Unfortunately, so far we can show boundedness of $(F'F)^{-1} : B_{\check{\tau}}^{\check{s}n+t}(L_{\check{\tau}}(\Omega)) \to B_{\check{\tau}}^{\check{s}n-t}(L_{\check{\tau}}(\Omega))$, which in combination with the above boundedness of F' and F would give the desired property of $\mathbf{Q}$, only in the particular situation that $t = 0$ and the $\Psi^{(i)}$ are $L_2(\Omega_i)$-orthonormal bases. In that case, $FF'u = \sum_i \omega_i\langle \omega_i u, \Psi^{(i)}\rangle_{L_2(\Omega_i)}\Psi^{(i)} = (\sum_i \omega_i^2)u$, and so $(FF')^{-1}u = (\sum_i \omega_i^2)^{-1}u$, meaning that, by the global smoothness of the weights, $(FF')^{-1}$ clearly has the above property for any s. Note that, on the other hand, if we do not damp the wavelets near the internal boundaries, i.e., if ω_i is just the characteristic function of Ω_i, then $(F'F)^{-1}$ will be bounded on $B_{\check{\tau}}^{\check{s}n}(L_{\check{\tau}}(\Omega))$ for $\check{s}$ in a limited range only.

Thus at least for $t = 0$ and with sufficiently smooth orthonormal $\Psi^{(i)}$ (which implies $\tilde{d} = d$) and weights ω_i that vanish at internal boundaries $\partial\Omega_i \cap \Omega$, for any τ with $0 < s = 1/\tau - 1/2 < d/n$ (which is the full range for which one may expect that $\mathbf{u} \in \ell_\tau^w$), there exists a $\check{\tau} < \tau$ such that $\mathbf{Q}$ is bounded on $\ell_{\check{\tau}}$. Since $\mathbf{Q}$ is also bounded on ℓ_2, an interpolation argument (cf. [21, (4.24)]) shows that it is bounded on $\ell_{\check{\tau}}^w$.

4.4. Construction of P. The fact that we have no general answer about whether $\mathbf{Q}$ satisfies (3.16) was the motivation to introduce the routine modSOLVE, which contains the inexact application of a suitable projector $\mathbf{P}$.

In the situation of Theorem 4.1, thus with $\{\hat{\chi}_i\}$ a partition of unity relative to $\{\hat{\Omega}_i\}$ and ω_i the weights, and where $\Psi^{(i)}$ are biorthogonal wavelet bases for $\mathcal{H}_i^t$ with duals $\tilde{\Psi}^{(i)}$, let us define $Z : u \mapsto ((\langle \hat{\chi}_i\omega_i^{-1}u, \tilde{\Psi}^{(i)}\rangle_{L_2(\Omega_i)})_i)^T$, which is a bounded mapping from $\mathcal{H}^t \to \ell_2$. It holds that $F'Zu = \sum_i \omega_i\langle \hat{\chi}_i\omega_i^{-1}u, \tilde{\Psi}^{(i)}\rangle_{L_2(\Omega_i)}\Psi^{(i)} = u$. Thus, defining

$$\mathbf{P} = ZF' : (\mathbf{c}_1^T,\dots,\mathbf{c}_m^T)^T \mapsto (((\langle \hat{\chi}_i\omega_i^{-1}{\textstyle\sum_{\breve{i}}}\omega_{\breve{i}}\mathbf{c}_{\breve{i}}^T\Psi^{(\breve{i})}, \tilde{\Psi}^{(i)}\rangle_{L_2(\Omega_i)})_i^T)^T,$$

we infer that $\mathbf{P} : \ell_2 \to \ell_2$ is a bounded projector with $\operatorname{Ker}\mathbf{P} = \operatorname{Ker}F'$, which are the basic requirements on $\mathbf{P}$ imposed in section 2.3 and which guarantee that modSOLVE is convergent, i.e., that Proposition 2.3 is valid. Note that the application of $\mathbf{P}$ may only change coefficients corresponding to wavelets for which the support or the support of the corresponding dual wavelet intersect more than one Ω_i.

To apply the above $\mathbf{P}$, we need a practical construction of the partition of unity $\{\hat{\chi}_i\}$. Apart from this, we discuss here the construction of weights in Theorem 4.1 that vanish at, or even in a neighborhood of, the internal boundaries $\partial\Omega_i \cap \Omega$. As we have seen, the application of weights that vanish at the internal boundaries seems necessary for $\mathbf{Q}$ satisfying (3.16), whereas, even when the application of $\mathbf{P}$ is necessary, such weights may have a favorable quantitative effect. Furthermore, weights that vanish even in a neighborhood of the internal boundaries allow us to ignore boundary conditions at these boundaries with the construction of wavelets on the subdomains.

Let $\Omega = \cup_i \Omega_i$ be an open covering, and $\kappa_i : (0,1)^n \to \Omega_i$ smooth regular parametrizations, where we assume that the image of a face of $[0,1]^n$ under κ_i either has empty intersection with $\partial\Omega$ or is contained in $\partial\Omega$. Then there exist $0 \leq \hat{a}_j^{(i)} \leq \check{a}_j^{(i)} < \check{b}_j^{(i)} \leq \hat{b}_j^{(i)} \leq 1$ such that $\cup_{i=1}^m \kappa_i(\prod_{j=1}^n (\check{a}_j^{(i)}, \check{b}_j^{(i)})) = \Omega$, whereas strict inequalities $0 < \hat{a}_j^{(i)} < \check{a}_j^{(i)}$ or $\check{b}_j^{(i)} < \hat{b}_j^{(i)} < 1$ hold if (and only if) the face corresponds to an internal boundary (cf. dashed and dotted boundaries in Figure 1).

Now let $\eta_i, \phi_i \in C^\infty((0,1)^n)$, with $0 \leq \eta_i, \phi_i \leq 1$, such that $\eta_i \eqsim 1$ on $\prod_j (\hat{a}_j^{(i)}, \hat{b}_j^{(i)})$, whereas it vanishes at, or even in a neighborhood of, faces of $[0,1]^n$ that correspond to internal boundaries, and $\phi_i = 1$ on $\prod_j (\check{a}_j^{(i)}, \check{b}_j^{(i)})$, whereas it vanishes at faces of $\prod_{j=1}^n (\hat{a}_j^{(i)}, \hat{b}_j^{(i)})$ that correspond to internal boundaries.

Defining $\hat{\Omega}_i = \kappa_i(\prod_j (\hat{a}_j^{(i)}, \hat{b}_j^{(i)}))$ and

$$\omega_i = \begin{cases} \eta_i \circ \kappa_i^{-1} & \text{on } \Omega_i, \\ 0 & \text{on } \Omega \backslash \Omega_i \end{cases}$$

as desired, we have that $\omega_i \in C^\infty(\Omega)$, $0 \leq \omega_i \leq 1$, $\omega_i \eqsim 1$ on $\hat{\Omega}_i$, and ω_i vanishes at or even in a neighborhood of $\partial\Omega_i \cap \Omega$.

Defining $\check{\Omega}_i = \kappa_i(\prod_j (\check{a}_j^{(i)}, \check{b}_j^{(i)}))$ and

$$\hat{\chi}_i^{(i)} = \begin{cases} \phi_i \circ \kappa_i^{-1} & \text{on } \Omega_i, \\ 0 & \text{on } \Omega \backslash \Omega_i, \end{cases}$$

we have $0 \leq \hat{\chi}_i^{(i)} \leq 1$, $\hat{\chi}_i^{(i)} = 1$ on $\check{\Omega}_i$, and $\hat{\chi}_i^{(i)}$ vanishes outside $\hat{\Omega}_i$. A partition of unity relative to $\{\hat{\Omega}_i\}$ is now given by $\{\hat{\chi}_i^{(m)} : 1 \leq i \leq m\}$, where for $2 \leq k \leq m$, $\{\hat{\chi}_i^{(k)} : 1 \leq i \leq k-1\}$ is defined by $\hat{\chi}_i^{(k)} := \hat{\chi}_i^{(k-1)}(1 - \hat{\chi}_k^{(k)})$. Indeed, an induction argument shows that $\sum_{i=1}^k \hat{\chi}_i^{(k)} = 1$ on $\cup_{i=1}^k \check{\Omega}_i$, and so in particular $\sum_{i=1}^m \hat{\chi}_i^{(m)} = 1$ on $\cup_{i=1}^m \check{\Omega}_i = \Omega$. Furthermore, $\hat{\chi}_i^{(m)} \in C^\infty(\Omega)$, $0 \leq \hat{\chi}_i^{(m)} \leq 1$, and, since $\operatorname{supp} \hat{\chi}_i^{(m)} \subset \operatorname{supp} \hat{\chi}_i^{(i)}$, $\hat{\chi}_i^{(m)}$ vanishes outside $\hat{\Omega}_i$.

4.5. Compressibility, i.e., the value of s^*. Let $\Psi = \cup_{i=1}^m \omega_i \Psi^{(i)}$ be a frame for $\mathcal{H}^t$ as constructed in Theorem 4.1, where the $\Psi^{(i)}$ are biorthogonal wavelet bases for $\mathcal{H}_i^t$ of order d, with dual bases $\tilde{\Psi}^{(i)}$ of order $\tilde{d}$.

We write $\Psi^{(i)} = \{\psi_\lambda^{(i)} : \lambda \in J^{(i)}\}$ and $\tilde{\Psi}^{(i)} = \{\tilde{\psi}_\lambda^{(i)} : \lambda \in J^{(i)}\}$, where we think of λ as consisting of two coordinates referring to scale and location, respectively. Denoting the scale associated with λ by $|\lambda| \in \mathbb{N}$, we assume that the primal wavelets are *local* in the sense that

$$\operatorname{diam}(\operatorname{supp} \psi_\lambda^{(i)}) \lesssim 2^{-|\lambda|} \quad \text{and} \quad \sup_{x \in \Omega_i, \ell \in \mathbb{N}} \#\{|\lambda| = \ell : x \in \operatorname{supp} \psi_\lambda^{(i)}\} < \infty.$$

We set

$$\gamma = \sup\{s \in \mathbb{R} : \|\psi_\lambda^{(i)}\|_{H^s(\Omega_i)} \lesssim 2^{|\lambda| s} \|\psi_\lambda^{(i)}\|_{L_2(\Omega_i)}, \lambda \in J^{(i)}, 1 \leq i \leq m\},$$

with an analogous definition of $\tilde{\gamma}$ involving dual wavelets. Necessarily, it holds that $t \in (-\tilde{\gamma}, \gamma)$. It is known that if the primal wavelets are piecewise smooth globally C^r-functions for some $r \in \mathbb{N} \cup \{-1\}$, then $\gamma = r + \frac{3}{2}$. It holds that $r \leq d - 2$, with the equality sign for spline wavelets.

Now let $L : \mathcal{H}^t \to (\mathcal{H}^t)'$ be boundedly invertible. Then $\mathbf{M} = FLF'$ is represented by an $m \times m$ blockmatrix with its $(i, \breve{\imath})$th block equal to the infinite matrix $\langle \omega_i \Psi^{(i)}, L\omega_{\breve{\imath}} \Psi^{(\breve{\imath})} \rangle_{L_2(\Omega)}$. Assuming that the weights ω_i vanish at the internal boundaries so that they are globally smooth, the analysis of the compressibility of each of these blocks can follow exactly the same lines as that of the compressibility of L with respect to a biorthogonal wavelet *basis* characterized by the same tuple $(d, \gamma, \tilde{d}, \tilde{\gamma})$.

If for some $\sigma > 0$, $L, L' : \mathcal{H}^{t+\sigma} \to \mathcal{H}^{-t+\sigma}$ are bounded, then, by substituting the estimates [14, (9.4.5), (9.4.8)] into [5, Proposition 6.6.2], we infer that $\mathbf{M}$ is s^*-compressible with

$$s^* = \frac{\min\{\sigma, \gamma - t, t + \tilde{d}\}}{n} - \frac{1}{2}, \tag{4.4}$$

at least when this value is positive. (We have used the fact that the condition $\sigma < t + \tilde{\gamma}$ imposed for [14, (9.4.8)] can actually be relaxed to $\sigma \leq t + \tilde{d}$.) The above result holds true for local operators L, i.e., $\langle v, Lw \rangle_{L_2(\Omega)} = 0$ when $\operatorname{supp} v \cap \operatorname{supp} w = \emptyset$, as well as for nonlocal L of the form

$$(Lv)(x) = \int_\Omega K(x, y) v(y) dy,$$

with a Schwarz kernel that has the Calderon–Zygmund property

$$|\partial_x^\alpha \partial_y^\beta K(x, y)| \lesssim |x - y|^{-(n+2t+|\alpha|+|\beta|)}, \qquad n + 2t + |\alpha| + |\beta| > 0.$$

The spaces $\mathcal{H}^r$ used to formulate the above continuity assumptions on L and L' are defined for $r \geq 0$ by

$$\mathcal{H}^r = \begin{cases} [L_2(\Omega), H^{|t|}_{0,\Gamma^D}(\Omega)]_{r/t}, & r \leq |t|, \\ H^{|t|}_{0,\Gamma^D}(\Omega) \cap H^r(\Omega), & r \geq |t|, \end{cases}$$

and $\mathcal{H}^{-r} = (\mathcal{H}^r)'$.

The result given in (4.4) is not completely satisfactory. Indeed, in any case when the primal wavelets are sufficiently smooth, we learned in section 4.2 that if the solution u is in $B^{sn+t}_\tau(L_\tau(\Omega))$ for some $s \in (0, \frac{d-t}{n})$, then it has a representation $u = \mathbf{u}^T \Psi$ such that the best N-term approximation for $\mathbf{u}$ converges with a rate N^{-s}. On the other hand, the convergence rate of the solutions yielded by (mod)SOLVE is bounded not only by the above value of s but also by s^*. Since s^* given in (4.4) is less than or equal to $\frac{\gamma - t}{n} - \frac{1}{2}$, and since, moreover, $\gamma < d$, on the basis of this result we may conclude only that (mod)SOLVE has optimal computational complexity for solutions *with limited regularity.*

However, in a forthcoming paper [25] it will be shown that (4.4) is actually too pessimistic and that, when $\sigma > d - t$, with suitable wavelets for local as well as for nonlocal operators, s^*-compressibility with $s^* > \frac{d-t}{n}$ can be shown.

Since the use of the projector $\mathbf{P}$ applied in modSOLVE seems restricted to the frame construction from this paper, we discuss its compressibility here. Recall that $\mathbf{P}$ is given by an $m \times m$ block matrix with its $(i, \breve{\imath})$th block being equal to the infinite matrix $\mathbf{P}^{(i,\breve{\imath})} = \langle \hat{\chi}_i \omega_i \tilde{\Psi}^{(i)}, \omega_{\breve{\imath}} \Psi^{(\breve{\imath})} \rangle_{L_2(\Omega)}$. Thus it is sufficient to investigate the compressibility of any of these blocks.

For biorthogonal wavelet bases it can be shown that for $r \in [-\tilde{d}, \gamma)$, $s < \gamma$,

$$\| \cdot \|_{\mathcal{H}^r_{\breve{i}}} \lesssim 2^{\breve{\ell}(r-s)} \| \cdot \|_{\mathcal{H}^s_{\breve{i}}} \quad \text{on} \quad W^{(\breve{i})}_{\breve{\ell}} := \operatorname{span}\{\psi^{(\breve{i})}_{\breve{\lambda}} : |\breve{\lambda}| = \breve{\ell}\}, \tag{4.5}$$

and analogously that for $r \in [-d, \tilde{\gamma})$, $s < \tilde{\gamma}$,

$$\| \cdot \|_{\mathcal{H}^r_{i}} \lesssim 2^{\ell(r-s)} \| \cdot \|_{\mathcal{H}^s_{i}} \quad \text{on} \quad \tilde{W}^{(i)}_{\ell} = \operatorname{span}\{\tilde{\psi}^{(i)}_{\lambda} : |\lambda| = \ell\}. \tag{4.6}$$

Here $\mathcal{H}^r_{\breve{i}}$ is defined as $\mathcal{H}^r$ with (Ω, Γ^D) replaced by $(\Omega_{\breve{i}}, \Gamma^D_{\breve{i}})$.

Thus, assuming that the weights vanish at the internal boundaries, for $\tilde{w}^{(i)}_{\ell} \in \tilde{W}^{(i)}_{\ell}$, $w^{(\breve{i})}_{\breve{\ell}} \in W^{(\breve{i})}_{\breve{\ell}}$, and $-d \leq s - t < \tilde{\gamma}$, $-\tilde{d} \leq t - s < \gamma$, i.e., $s \in (t - \gamma, t + \tilde{\gamma})$, we have

$$\begin{aligned} |\langle \hat{\chi}_i \omega_i^{-1} \tilde{w}^{(i)}_{\ell}, \omega_{\breve{i}} w^{(\breve{i})}_{\breve{\ell}} \rangle_{L_2(\Omega)}| &\lesssim \|\hat{\chi}_i \omega_i^{-1} \tilde{w}^{(i)}_{\ell}\|_{\mathcal{H}^{s-t}} \|\omega_{\breve{i}} w^{(\breve{i})}_{\breve{\ell}}\|_{\mathcal{H}^{t-s}} \\ &\lesssim \|\tilde{w}^{(i)}_{\ell}\|_{\mathcal{H}^{s-t}_i} \|w^{(\breve{i})}_{\breve{\ell}}\|_{\mathcal{H}^{t-s}_{\breve{i}}} \lesssim 2^{s(\ell - \breve{\ell})} \|\tilde{w}^{(i)}_{\ell}\|_{\mathcal{H}^{-t}_i} \|w^{(\breve{i})}_{\breve{\ell}}\|_{\mathcal{H}^t_{\breve{i}}}. \end{aligned}$$

Let us now define $\hat{\mathbf{P}}^{(i,\breve{i})}_j$ by removing from $\mathbf{P}^{(i,\breve{i})}$ all blocks $[\langle \hat{\chi}_i \omega_i \tilde{\psi}^{(i)}_{\lambda}, \omega_{\breve{i}} \psi^{(\breve{i})}_{\breve{\lambda}} \rangle_{L_2(\Omega)}]_{|\lambda|=\ell, |\breve{\lambda}|=\breve{\ell}}$ for which $\ell > \breve{\ell} + k_1(j,n)$ or $\breve{\ell} > \ell + \frac{\gamma - t}{\tilde{\gamma} + t} k_1(j,n)$, where $k_1(j,n)$ is an integer that will be determined below. Then, using the fact that the $\tilde{\Psi}^{(i)}$ or $\Psi^{(\breve{i})}$ are Riesz bases for $\mathcal{H}^{-t}_i$ or $\mathcal{H}^t_{\breve{i}}$, respectively, we infer that for any $0 < s < \gamma - t$

$$\|\mathbf{P}^{(i,\breve{i})} - \hat{\mathbf{P}}^{(i,\breve{i})}_j\| \lesssim 2^{-s k_1(j,n)}. \tag{4.7}$$

For the next step, we will assume also that *the dual wavelets are local.* Furthermore, we assume that the primal wavelets are *piecewise smooth.* By this we mean that that $\operatorname{supp} \psi^{(\breve{i})}_{\breve{\lambda}} \backslash \operatorname{sing\,supp} \psi^{(\breve{i})}_{\breve{\lambda}}$ is the disjoint union of m open "uniformly Lipschitz" domains $\Xi^{(\breve{i},1)}_{\breve{\lambda}}, \ldots, \Xi^{(\breve{i},k)}_{\breve{\lambda}}$, with $\cup_{q=1}^{k} \overline{\Xi^{(\breve{i},q)}_{\breve{\lambda}}} = \operatorname{supp} \psi^{(\breve{i})}_{\breve{\lambda}}$, and that $\psi^{(\breve{i})}_{\breve{\lambda}}|_{\Xi^{(\breve{i},q)}_{\breve{\lambda}}}$ is smooth with

$$\sup_{x \in \Xi^{(\breve{i},q)}_{\breve{\lambda}}} |\partial^{\beta} \psi^{(\breve{i})}_{\breve{\lambda}}(x)| \lesssim 2^{(|\beta| + \frac{n}{2} - t)|\lambda|}, \quad \beta \in \mathbb{N}^n.$$

From [23] we learn that $\psi^{(\breve{i})}_{\breve{\lambda}}|_{\Xi^{(\breve{i},q)}_{\breve{\lambda}}}$ has an extension to a smooth function $\xi^{(\breve{i},q)}_{\breve{\lambda}}$ with

$$\|\xi^{(\breve{i},q)}_{\breve{\lambda}}\|_{H^d(\mathbb{R}^n)} \lesssim 2^{|\breve{\lambda}|(d-t)} \tag{4.8}$$

(cf. also [25, Remark 4.5]).

Given $\breve{\lambda}$, $1 \leq q \leq k$, and $\ell > |\breve{\lambda}|$, let $A^{(i,\breve{i})}_{\ell,\breve{\lambda},q} = \{|\lambda| = \ell : \operatorname{supp} \tilde{\psi}^{(i)}_{\lambda} \subset \overline{\Xi^{(\breve{i},q)}_{\breve{\lambda}}}\}$. For some $k_2(j,n) \leq k_1(j,n)$ that will be determined below, we define $\mathbf{P}^{(i,\breve{i})}_j$ by removing all entries $\langle \hat{\chi}_i \omega_i \tilde{\psi}^{(i)}_{\lambda}, \omega_{\breve{i}} \psi^{\breve{i}}_{\breve{\lambda}} \rangle_{L_2(\Omega)}$ from $\hat{\mathbf{P}}^{(i,\breve{i})}_j$ when $|\lambda| - |\breve{\lambda}| > k_2(j,n)$ and $\lambda \in A^{(i,\breve{i})}_{|\lambda|,\breve{\lambda},q}$ for some $1 \leq q \leq k$. Then, by using (4.8) and (4.6) with $(r,s) = (-d,-t)$, for any

$\mathbf{c}, \mathbf{d} \in \ell_2$ we have

$$\begin{aligned}
\langle \mathbf{c}, (\hat{\mathbf{P}}_j^{(i,\breve{\imath})} - \mathbf{P}_j^{(i,\breve{\imath})})\mathbf{d}\rangle_{\ell_2} &= \left| \sum_{\ell - \breve{\ell} > k_2(j,n)} \sum_{|\breve{\lambda}| = \breve{\ell}} \mathbf{d}_{\breve{\lambda}} \left\langle \sum_{q=1}^{k} \sum_{\lambda \in A^{(i,\breve{\imath})}_{\ell,\breve{\lambda},q}} \mathbf{c}_\lambda \hat{\chi}_i \omega_i^{-1} \tilde{\psi}_\lambda^{(i)}, \omega_{\breve{\imath}} \xi_{\breve{\lambda}}^{(\breve{\imath},q)} \right\rangle \right| \\
&\lesssim \sum_{\ell - \breve{\ell} > k_2(j,n)} 2^{-(d-t)(\ell - \breve{\ell})} \sum_{|\breve{\lambda}| = \breve{\ell}} |\mathbf{d}_{\breve{\lambda}}| \sum_{q=1}^{k} \left\| \sum_{\lambda \in A^{(i,\breve{\imath})}_{\ell,\breve{\lambda},q}} \mathbf{c}_\lambda \tilde{\psi}_\lambda^{(i)} \right\|_{\mathcal{H}_i^{-t}} \\
&\lesssim \sum_{\ell - \breve{\ell} > k_2(j,n)} 2^{-(d-t)(\ell - \breve{\ell})} \sqrt{\sum_{|\breve{\lambda}| = \breve{\ell}} |\mathbf{d}_\lambda|^2} \sqrt{\sum_{|\breve{\lambda}| = \breve{\ell}} \left(\sum_{q=1}^{k} \sqrt{\sum_{\lambda \in A^{(i,\breve{\imath})}_{\ell,\breve{\lambda},q}} |\mathbf{c}_\lambda|^2} \right)^2} \\
&\lesssim \sum_{\ell - \breve{\ell} > k_2(j,n)} 2^{-(d-t)(\ell - \breve{\ell})} \sqrt{\sum_{|\breve{\lambda}| = \breve{\ell}} |\mathbf{d}_\lambda|^2} \sqrt{\sum_{|\lambda| = \ell} |\mathbf{c}_\lambda|^2} \lesssim 2^{-(d-t)k_2(j,n)} \|\mathbf{d}\| \|\mathbf{c}\|,
\end{aligned}$$

where for the last line we have used that, by the locality of the primal wavelets, each λ is contained in at most a uniformly bounded number of sets $A^{(i,\breve{\imath})}_{|\lambda|,\breve{\lambda},q}$. We conclude that

$$\|\hat{\mathbf{P}}_j^{(i,\breve{\imath})} - \mathbf{P}_j^{(i,\breve{\imath})}\| \lesssim 2^{(d-t)k_2(j,n)}. \tag{4.9}$$

By the locality of both primal and dual wavelets and the piecewise smoothness of the primal wavelets, the number of nonzeros in each *column* of $\mathbf{P}_j^{(i,\breve{\imath})}$ is of the order $2^{nk_2(j,n)} + 2^{(n-1)k_1(j,n)}$. By substituting $k_2(j,n) = \frac{j + \log(\alpha_j)}{n}$ and $k_1(j,n) = \frac{j + \log(\alpha_j)}{\max\{n-1,1\}}$ with, for example, $\alpha_j = j^{-(1+\varepsilon)}$ for some $\varepsilon > 0$, from (4.7) and (4.9) we infer that $\mathbf{P}$ is s^*-compressible with

$$s^* = \begin{cases} \min\{\frac{\gamma - t}{n-1}, \frac{d-t}{n}\} & \text{when } n > 1, \\ d - t & \text{when } n = 1. \end{cases}$$

Thus, if, when $n > 1$, $r \geq -\frac{3}{2} + d + (t-d)/n$, which was also assumed in (4.3), then $s^* = \frac{d-t}{n}$.

Acknowledgments. The author would like to thank Prof. Karsten Urban (Universität Ulm) for many inspiring discussions and for his valuable comments on an earlier version of this manuscript. Thanks also to Prof. Hans Duistermaat (Universiteit Utrecht) for suggestions that lead the author to consider frames in the first place.

A SMALL EDDY CORRECTION METHOD FOR NONLINEAR DISSIPATIVE EVOLUTIONARY EQUATIONS[*]

YANREN HOU[†] AND KAITAI LI[†]

Abstract. Considering the interaction between the large and small eddy components of solutions and using the idea of the Newton iteration, a small eddy correction method is proposed for approximating and numerically solving nonlinear dissipative PDEs of parabolic type, in particular the Navier–Stokes equations (NSE). We assume that the large eddy approximation to the solution is known. Formally applying the Newton iterative procedure to the small eddy equation, we then generate approximate systems. It is shown that the first two steps in fact lead to the standard Galerkin method (SGM) and the so-called optimum nonlinear Galerkin method (ONG), and therefore the small eddy correction method is actually a certain generalization of SGM and ONG. The boundedness and convergence analysis are presented in the framework of the two-dimensional NSE. The results show that the small eddy correction method can greatly improve the accuracy of SGM approximate solutions.

Key words. dissipative equations, spectral methods, Newton iteration, multilevel method

1. Introduction.

Considering an evolutionary dissipative nonlinear PDE system of parabolic type, for example, the Navier–Stokes equation (NSE), despite the considerable increase in the available computing power during the past few years, numerically solving this kind of system, especially the integration of evolutionary NSE on large time intervals under physically realistic situations, still remains a difficult problem whose solution is not close at hand. We thereby intend to solve dissipative evolution PDEs in dynamically nontrivial situations, i.e., when the long-term behavior is not merely convergent to a steady state. In this case, the solution to be simulated remains time dependent, and as time goes to infinity, it converges to a set, an attractor, which can be a complicated set (a fractal). Studying the complicated structure of this set, which to some extent is reflected by the long-term behavior of the solution, is of great importance to understanding the nature of turbulent phenomena. That is one of the main reasons why people are so interested in the long-term behavior of the solution and the construction of more accurate and effective numerical schemes.

We present this work in the context of the functional form of the two-dimensional NSE in divergence-free Hilbert space H defined on an open bounded domain $\Omega \subset \mathcal{R}^2$ with smooth boundary $\partial\Omega$,

$$\begin{cases} \dfrac{du}{dt} + \nu A u + B(u,u) = f, \\ u(0) = a. \end{cases} \tag{1.1}$$

Here u stands for the velocity field, f is the external force which drives the flow, $\nu > 0$ is the viscosity, and a is the initial velocity field. A and $B(\cdot,\cdot)$ are the Stokes operator and bilinear operator whose detailed definitions will be given in section 2.

For a given positive integer $m \in \mathcal{N}$, let us denote by H_m and P_m a finite-dimensional subspace of H and an associated orthogonal projection from H onto H_m, that is, $H_m = P_m H$. Then the SGM approximate system of (1.1) reads

$$\left\{\begin{array}{l} \dfrac{du_m}{dt} + \nu A u_m + P_m B(u_m, u_m) = P_m f, \\ u_m(0) = P_m a. \end{array}\right. \tag{1.2}$$

It follows from [6] that, for sufficiently large $t_0 > 0$,

$$|u(t) - u_m(t)|_{\mathcal{L}^2(\Omega)} \le c(t) L_m \lambda_{m+1}^{-1} \quad \forall t \ge t_0, \tag{1.3}$$

where $\lambda_{m+1} > 0$ is the $(m+1)$th eigenvalue of the Stokes operator A, which tends to $+\infty$ when m tends to infinity and

$$L_m \sim \left(1 + \log \frac{\lambda_m}{\lambda_1}\right)^{\frac{1}{2}}. \tag{1.4}$$

On the other hand, if we denote $Q_m = I - P_m$ and

$$u = p + q \quad \text{with} \quad p = P_m u,\ q = Q_m u,$$

we can rewrite (1.1) in the following coupled system:

$$\frac{dp}{dt} + \nu A p + P_m B(p+q, p+q) = P_m f, \tag{1.5}$$

$$\frac{dq}{dt} + \nu A q + Q_m B(p+q, p+q) = Q_m f. \tag{1.6}$$

Set

$$e = u - u_m, \quad e_p = P_m e = p - u_m, \quad e_q = Q_m e = q.$$

Simple calculation shows that

$$|e_p(t)|_{\mathcal{L}^2(\Omega)} \le c e^{ct} \sup_{0 \le s \le t} |e_q(s)|_{\mathcal{L}^2(\Omega)}. \tag{1.7}$$

That is to say that the large eddy error and thus the total error of the standard Galerkin method (SGM) can be controlled by the small eddy error. In other words, to improve the accuracy of the SGM approximation, we have only to improve the approximation of the small eddy components, which is approximated by 0 in the case of SGM. This is the basic idea of this work.

Indeed, many authors have already applied this idea to developing new methods and techniques. One of these new methods arises in connection with the concept of the approximate inertial manifold (AIM) (see [7]) and is called the nonlinear Galerkin method (NGM). For example, Marion and Temam proposed the first and the most frequently discussed NGM in [15]:

$$\left\{\begin{array}{l} \dfrac{dp_m}{dt} + \nu A p_m + P_m B(p_m + q_m, p_m + q_m) = P_m f, \\ q_m = \Phi(p_m), \end{array}\right. \tag{1.8}$$

where $\Phi : H_m \to Q_m H$ provides an approach to approximating the small eddy components, which are determined by solving the following steady Stokes problem in $Q_m H$:

$$\nu A q_m + Q_m B(p_m, p_m) = Q_m f.$$

It is shown that

$$|u(t) - (p_m(t) + \Phi(p_m(t)))|_{\mathcal{L}^2(\Omega)} \leq c(t) L_m \lambda_{m+1}^{-\frac{3}{2}} \quad \forall t \geq t_0. \tag{1.9}$$

That is, $p_m + \Phi(p_m)$ is a much better approximation to u than the SGM approximation u_m. From that point on, many authors investigated this version of the NGM (see [1], [5], [6], [14], [16], [17], [18], etc.) and its applications (see [3], [19], etc.). To improve the effectiveness of numerical schemes, Garcia-Archilla, Novo, and Titi proposed a kind of postprocessing procedure to the Galerkin method (PPGM) in [8] based on the same mapping Φ in (1.8). For any prescribed time T, they use $\Phi(u_m(T))$ to approximate $q(T)$ and show that

$$|u(T) - (u_m(T) + \Phi(u_m(T)))|_{\mathcal{L}^2(\Omega)} \leq c(T) L_m^4 \lambda_{m+1}^{-\frac{3}{2}} \quad \forall T \geq t_0. \tag{1.10}$$

Equations (1.9) and (1.10) indicate that both the NGM (1.8) and PPGM can greatly improve the accuracy of the SGM approximation and be more effective than the SGM. But there are some problems which have already been discussed in [12]. For example, they used a steady Stokes problem to approximate the small eddy equation (1.6) and overlooked the self evolution of the small eddy components. This is only valid when the small eddy part of the solution varies very slowly.

To overcome this defect of NGM (1.8), some people have already given certain modifications (see [9], [10], [11], [13], [20]). One of these modifications is the so-called optimal nonlinear Galerkin method (ONG) (see [10], [11]):

$$\frac{d\bar{p}_m}{dt} + \nu A \bar{p}_m + P_m B(\bar{p}_m + \bar{q}_m, \bar{p}_m + \bar{q}_m) = P_m f, \tag{1.11}$$

$$\frac{d\bar{q}_m}{dt} + \nu A \bar{q}_m + Q_m B(\bar{p}_m, \bar{q}_m) + Q_m B(\bar{q}_m, \bar{p}_m) = Q_m[f - B(\bar{p}_m, \bar{p}_m)], \tag{1.12}$$

where the small eddy equation in (1.8) is replaced by a generalized unsteady Stokes problem (1.12), and therefore the self evolution of the small eddy components is involved. Furthermore, it is shown in this paper that

$$|u(t) - (\bar{p}_m + \bar{q}_m)|_{\mathcal{L}^2(\Omega)} \leq c(t) L_m^4 \lambda_{m+1}^{-2} \quad \forall t \geq t_0. \tag{1.13}$$

To get a reliable long-term simulation of the NSE, we still have to consider the problem of error accumulation. Unfortunately, almost all numerical methods for the NSE in general (including the SGM, NGM, PPGM, and ONG) will lead to an exponentially increasing error, which makes the long-term simulation almost meaningless. A possible remedy is to improve the accuracy of the approximate solution without too much computational cost. Meanwhile, we have to mention that the rapid increase of available computing power in the past few years as well as the rapid development of computer networks and parallel computing techniques, which can integrate many CPUs in a system, make the large scale computation possible. If computing facilities are not a problem, we want to know whether it is possible to get a reliable simulation in a large time interval.

From the point of view of our basic idea mentioned above (the small eddy correction), the NGM, PPGM, and ONG schemes all do a small eddy correction once, and their analysis shows that they can improve the convergence rate of the SGM without too much computational cost. It seems that one cannot improve the convergence rate any more if the correction is performed only once. Then it is very natural for us to think about certain iteration methods for improving the convergence rate further. And it is also very natural for us to think about the Newton iteration because of its fast convergence speed. Based upon these considerations, we propose a small eddy correction method in this paper (see the later definition (3.1)–(3.3)). Moreover, the analysis shows that

$$|u(t) - u^l(t)|_{\mathcal{L}^2(\Omega)} \leq c(t) L_m^2 (L_m \lambda_{m+1}^{-1})^{2^l}, \tag{1.14}$$

where u^l is the small eddy correction approximation and $l \in \mathcal{N}$ is the number of iteration steps used.

This paper is arranged as follows. In section 2, the detail of a two-dimensional NSE is given. In section 3, we introduce a small eddy correction method by formally applying the Newton iteration to the small eddy equation (1.6). Then we prove that this procedure is a bounded procedure and can generate a bounded approximate solution of (1.1). In section 4, we present some error estimates of the proposed small eddy correction method and show that it can lead to a very accurate approximation of the solution of the NSE. Finally in section 5, for a one-dimensional Burger's equation and a two-dimensional NSE, we give a full discrete form of the small eddy correction scheme and then present some numerical results to check the high accuracy and high effectiveness of this method.

2. Navier–Stokes equations.

We consider the NSE on a smooth bounded domain $\Omega \in \mathcal{R}^2$:

$$\begin{cases} \dfrac{\partial u}{\partial t} - \nu \Delta u + (u \cdot \nabla) u + \nabla p = F, & (x,t) \in \Omega \times (0, +\infty), \\ \nabla \cdot u = 0, & (x,t) \in \Omega \times [0, +\infty), \\ u|_{t=0} = a(x), & x \in \Omega, \\ \text{Dirichlet or periodic boundary conditions.} \end{cases} \tag{2.1}$$

Here $u(x,t)$ and $p(x,t)$ stand for the velocity field and pressure, respectively; $F(x,t)$ the external force, which drives the flow; $a(x)$ the initial velocity, which satisfies $\nabla \cdot a = 0$; and $\nu > 0$ the kinetic viscosity.

Now, we define the Hilbert space H:

$$H = \{v \in (L^2(\Omega))^2 : \nabla \cdot v = 0,\ v \cdot n|_{\partial\Omega} = 0\}$$

in the case of the homogeneous Dirichlet boundary condition, where n denotes the unit outward normal vector to $\partial\Omega$, or

$$H = \left\{ v \in (L^2_{per}(\Omega))^2 : \nabla \cdot v = 0,\ \int_\Omega v dx = 0 \right\}$$

in the case of a periodic boundary condition. The space H is equipped with the usual L^2-inner product $(\cdot,\cdot)$ and norm $|\cdot| = (\cdot,\cdot)^{\frac{1}{2}}$ and is a closed subspace of $(L^2(\Omega))^2$.

We also define a Hilbert space

$$V = \{v \in (H_0^1(\Omega))^2 : \ \nabla \cdot v = 0\}$$

or

$$V = \left\{ v \in (H_{per}^1(\Omega))^2 : \ \nabla \cdot v = 0, \int_\Omega v dx = 0 \right\}$$

depending on the use of boundary conditions. Equipped with the usual H^1-inner product and norm, it is a Hilbert space. Let us denote by P the orthogonal projection from $(L^2(\Omega))^2$ onto H and project (2.1) onto H. Then we can get the functional form (1.1), where $A = -P\Delta$ is the Stokes operator which will be $-\Delta$ in the case of a periodical boundary condition, $B(u,u) = P[(u \cdot \nabla)u]$ and $f = PF$, which is assumed to be time independent or in $L^\infty(\mathcal{R}^+, H)$.

For the Stokes operator A, it is well known that it is a symmetric, positive definite, self-adjoint, and unbounded operator in H with compact inverse. Therefore, its eigenvalues and the associated eigenfunctions admit

$$A\phi_i = \lambda_i \phi_i, \quad 0 < \lambda_1 \le \lambda_2 \le \cdots \to +\infty,$$

and the set of eigenfunctions $\{\phi_1, \phi_2, \ldots\}$ forms a unit orthonormal basis of H. For any $\alpha \in \mathcal{R}$, the space

$$D(A^\alpha) = \left\{ v = \sum_{i=1}^\infty v_i \phi_i : \sum_{i=1}^\infty v_i^2 \lambda_i^{2\alpha} < +\infty \right\}$$

is a Hilbert space if it is equipped with the natural inner product and norm

$$(\cdot,\cdot)_{D(A^\alpha)} = (A^\alpha \cdot, A^\alpha \cdot), \qquad |\cdot|_{D(A^\alpha)} = |A^\alpha \cdot|.$$

It is known that $D(A^{\frac{1}{2}}) = V$, and $\{\phi_1, \phi_2, \ldots\}$ is also an orthonormal basis of $D(A^\alpha)$. Here and later on, we denote by $|\cdot|_s$ the $(H^s(\Omega))^2$ norm, and by $|\cdot|_\infty$ the $(L^\infty(\Omega))^2$ norm. Especially, we use $|\cdot|$ to denote $|\cdot|_0$. For the spatial periodic case, we know that $|A^\alpha \cdot|$ and $|\cdot|_{2\alpha}$ are equivalent norms for any $\alpha \in \mathcal{R}$, and this equivalence property holds for the nonslip case at least for $\alpha \le 1$.

To investigate the interaction between the large and small eddies, we define the finite-dimensional subspace H_m as in the Introduction for given $m \in \mathcal{N}$ as

$$H_m = \text{span}\{\phi_1, \phi_2, \ldots, \phi_m\},$$

and define the orthogonal projection P_m from H onto H_m as

$$u = \sum_{i=1}^\infty u_i \phi_i \in H, \quad P_m u = \sum_{i=1}^m u_i \phi_i, \quad u_i \in \mathcal{R}.$$

Also, we define $Q_m = I - P_m$. Projecting (1.1) by P_m and Q_m, we can get the coupled system (1.5)–(1.6).

For the later analysis, we recall the Agmon inequality, the Brézis–Gallouet inequality [2], and the Sobolev interpolation inequality in two dimensions: there exists a constant $c_0 > 0$ such that

$$(2.2)\quad \begin{cases} |u|_\infty \le c_0 |u|^{\frac{1}{2}}\, |Au|^{\frac{1}{2}} \ \text{ or } \ c_0 |A^{\frac{1}{4}} u|^{\frac{2}{3}} |Au|^{\frac{1}{3}} & \forall u \in D(A), \\ |u|_\infty \le c_0 |A^{\frac{1}{2}} u| \left(1 + \log \frac{|Au|}{\lambda_1^{\frac{1}{2}} |A^{\frac{1}{2}} u|}\right)^{\frac{1}{2}} & \forall u \in D(A), \\ |A^s u| \le c_0 |u|^{(m-s)/m} |A^m u|^{s/m} & \forall u \in D(A^m),\ 0 < s < m \le 1. \end{cases}$$

As a result of the Brézis–Gallouet inequality, we have

$$(2.3)\qquad |u|_\infty \le c_0 L_m |A^{\frac{1}{2}} u| \quad \forall u \in H_m,$$

where L_m is defined in (1.4). To avoid having too many symbols, we always regard c_0 as 1 in the rest of this paper, and this will not cause any significant difference.

For the projections P_m and Q_m, the following properties hold (see [4]):

$$(2.4)\quad |A^\beta P_m u| \le \lambda_m^{\beta-\mu} |A^\mu u|, \quad |A^\mu Q_m u| \le \lambda_{m+1}^{\mu-\beta} |A^\beta u| \quad \forall \mu < \beta,\ u \in D(A^\beta).$$

In what follows, we often use the following orthogonal property:

$$(2.5)\qquad |A^s(P_m u + Q_m u)|^2 = |A^s P_m u|^2 + |A^s Q_m u|^2 \quad \forall u \in D(A^s), s \in \mathcal{R}.$$

3. Small eddy correction method and its boundedness. As shown in (1.7), the large eddy error or the total error of the SGM approximation can be controlled by the small eddy error, the truncation error of u_m. This suggests that we get a more accurate approximation by paying more attention to correcting the small eddy approximation successively. In this section, we will construct a small eddy correction method to NSE (1.1) by formally applying the Newton iteration to its small eddy equation (1.6).

First of all, we define

$$F(p,q) = \frac{dq}{dt} + \nu A q + Q_m B(q,q) + Q_m B(q,p) + Q_m B(p,q) + Q_m B(p,p) - Q_m f.$$

Then (1.6) is equivalent to

$$F(p,q) = 0.$$

Suppose that the large eddy component p in the above abstract equation is known. Formally applying the Newton iteration to it, we can get the following iterative procedure: supposing the initial guess of the small eddy component $q^0 = 0$ and the kth approximation $q^k(t) \in Q_m H$ is known for some $k \in \mathcal{N}$, find the $(k+1)$th approximation $q^{k+1}(t) \in Q_m H$, which should be a more accurate approximation of $q(t)$, such that

$$D_q F(p, q^k)(q^{k+1} - q^k) = -F(p, q^k).$$

Simple calculation shows that it is the following small eddy correction procedure:

$$\begin{aligned} \frac{dq^{k+1}}{dt} &+ \nu A q^{k+1} + Q_m B(p,p) + Q_m B(p, q^{k+1}) + Q_m B(q^{k+1}, p) \\ &+ Q_m B(q^k, q^{k+1}) + Q_m B(q^{k+1}, q^k) = Q_m[f + B(q^k, q^k)]. \end{aligned}$$

Combining the above small eddy correction with the large eddy equation (1.5), we can obtain the desired small eddy correction method: with $w^0 = 0$,

$$\frac{dv}{dt} + \nu Av + P_m B(v + w^l, v + w^l) = P_m f \quad \text{for any fixed integer } l \geq 0, \tag{3.1}$$

$$\begin{aligned}\frac{dw^k}{dt} &+ \nu Aw^k + Q_m B(v, v) + Q_m B(v, w^k) + Q_m B(w^k, v) + Q_m B(w^{k-1}, w^k) \\ &+ Q_m B(w^k, w^{k-1}) = Q_m[f + B(w^{k-1}, w^{k-1})] \quad \forall 1 \leq k \leq l,\end{aligned} \tag{3.2}$$

$$v(0) = P_m a, \quad w^i(0) = Q_m a, \quad i = 1, 2, \ldots, l, \quad l \geq 1. \tag{3.3}$$

Remark 1. The small eddy correction scheme (3.1)–(3.3) can be regarded as a certain generalization of the SGM and ONG. In fact, if we take $l = 0$ in the above approximate procedure, (3.1) admits the SGM approximate equation (1.2). And if we take $l = 1$, (3.1)–(3.3) are the ONG approximate equations (1.11)–(1.12). For the sake of simplicity of expression, we give a symbol $u^l = v + w^l$ and call it the lth approximate solution to the NSE (1.1). Thus the SGM approximate solution is the 0th approximate solution, and the ONG approximate solution is the 1st approximate solution. Observing the above small eddy correction method, it is analogous to the classical Newton iteration for elliptic problems. We expect that it can have the second order convergence rate just as the usual Newton method does. Fortunately, our later analysis gives us a positive answer. It is worth mentioning that directly applying the Newton method to NSE (1.1) cannot reach such a second order convergence rate. The reason is that it does not take the advantage of the fast decay property of small eddies. For example, we refer readers to our estimates (4.11), (4.15), etc. Here (4.11) and (4.15) show that the accuracy of the small eddy approximation is always a half order higher ($\lambda_{m+1}^{-\frac{1}{2}}$) than that of the large eddy approximation, and the small eddy approximation converges very quickly, which is very important for us to derive the high order convergence rate, while the direct application of Newton iteration to NSE does not distinguish the small and large eddy components and cannot take this advantage.

In the rest of this section, we will show that the small eddy correction method (3.1)–(3.3) is a bounded procedure and can generate a bounded approximate solution. Before that, we define a trilinear form

$$b(u, v, w) = ((u \cdot \nabla)v, w) \quad \forall u, v, w \in (H^1(\Omega))^2$$

and state some properties (e.g., see [21]):

$$b(u, v, w) = -b(u, w, v) \quad \forall v, w \in (H^1(\Omega))^2,\ u \in V, \tag{3.4}$$

$$2|b(u, v, w)| \leq c_1 |u|_{s_1} |A^{\frac{1}{2}} v|_{s_2} |w|_{s_3}, \tag{3.5}$$

where $u \in (H^{s_1}(\Omega))^2$, $v \in (H^{s_2+1}(\Omega))^2$, $w \in (H^{s_3}(\Omega))^2$, and $s_1, s_2, s_3 \geq 0$, $s_1 + s_2 + s_3 \geq 1$, $(s_1, s_2, s_3) \neq (1,0,0)$,$(0,1,0)$,$(0,0,1)$, and $c_1 > 0$ is a constant independent of u, v, w. Especially, (3.5) is valid if we substitute the L^2-norm for any two of the three norms on the right-hand side and replace the rest of the norm by L^∞-norms.

Hereafter, we use $|f|$ to denote $|f|_{\mathcal{L}(\mathcal{R}^+, H)}$ and set some dimensionless constants throughout this section:

Reynold's number $\quad Re = \nu^{-1}|a| \quad$ if $\ |a| \neq 0$,
Grashof's number $\quad Gr = \lambda_1 \nu^{-2} |f|$.

Theorem 3.1. *For any given nonnegative integer l, there exist constants M_0, M_1 independent of m, l, t and a constant $M_2(T)$ (for any given $T > 0$) independent of m and l such that, if m is so large that*

$$\lambda_{m+1} \geq 128 c_1^2 \lambda_1^{-1} \nu^{-2} L_m^2 M_1^2, \tag{3.6}$$

then (3.1)–(3.3) *has a bounded solution on* $[0, +\infty)$

$$U_m(t) = (v(t), w^1(t), \ldots, w^l(t))$$

and, for any $0 \leq k \leq l$ *and* $T > 0$,

$$|v(t) + w^k(t)| \leq M_0, \quad |A^{\frac{1}{2}}(v(t) + w^k(t))| \leq M_1 \quad \forall t \geq 0,$$

$$\int_0^T |A(v(s) + w^k(s))|^2 ds \leq M_2(T),$$

where

$$M_0 = \sqrt{2\nu^2 Re^2 + 4\nu^2 Gr^2}, \qquad M_1 = 4\lambda_1^{\frac{1}{2}} \nu (Re + 2Gr) \exp(c_1^4 (2Re^2 + 5Gr^2)^2),$$

and

$$M_2(T) = 2\nu^{-1} M_1^2 (6 + c_1^4 \nu^{-3} M_0^2 M_1^2 T) + 32 \lambda_1^2 \nu^2 T Gr^2.$$

The complex form of the constant M_1 comes from the fact that we do not distinguish the types of boundary conditions. Actually, for the spatial periodic case, the corresponding M_1 will have a much simpler appearance (without the exponential factor).

Compared with NGM, PPGM, and ONG, in which the boundedness of the approximate solution is quite easy to obtain and the existence of the approximate solution is a direct result, the boundedness and the existence of the approximate solution is no longer obvious in our case, especially for $l \geq 2$.

To prove this theorem, we first consider the following Galerkin approximation of (3.1)–(3.3): for any given positive integer $M > m$, constant $T > 0$, and $k = 1, 2, \ldots, l$ find

$$v_m = \sum_{i=1}^{m} g_{im}(t) \phi_i \in H_m, \qquad w_M^k = \sum_{i=m+1}^{M} g_{im}^k(t) \phi_i \in (P_M - P_m)H \overset{\triangle}{=} P_{mM} H$$

on time interval $[0, T]$ such that for any fixed integer $l \geq 0$ and $w_M^0 = 0$

$$\frac{dv_m}{dt} + \nu A v_m + P_m B(v_m + w_M^l, v_m + w_M^l) = P_m f, \tag{3.7}$$

$$\begin{aligned} \frac{dw_M^k}{dt} &+ \nu A w_M^k + P_{mM} B(v_m, v_m) + P_{mM} B(v_m, w_M^k) \\ &+ P_{mM} B(w_M^k, v_m) + P_{mM} B(w_M^{k-1}, w_M^k) + P_{mM} B(w_M^k, w_M^{k-1}) \\ &= P_{mM}[f + B(w_M^{k-1}, w_M^{k-1})] \quad \forall 1 \leq k \leq l, \end{aligned} \tag{3.8}$$

$$v_m(0) = P_m a, \quad w_M^i(0) = P_{mM} a, \quad i = 1, 2, \ldots, l, \quad l \geq 1. \tag{3.9}$$

For simplicity of expression, we introduce the following notation for the rest of this section:

$$u_{mM}^k = v_m + w_M^k, \quad k = 0, \dots, l.$$

Noticing the orthogonal properties of $\{\phi_1, \dots, \phi_m, \dots\}$ in H and V, that is,

$$(\phi_i, \phi_j) = \delta_{ij}, \quad (A^{\frac{1}{2}}\phi_i, A^{\frac{1}{2}}\phi_j) = (A\phi_i, \phi_j) = \lambda_i \delta_{ij} \quad \forall i, j = 1, \dots, m, \dots,$$

we find that the system (3.7)–(3.9) is actually a first order ODE of $\{g_{im}(t)\}_{i=1}^m$ and $\{g_{im}^k(t)\}_{i=m+1}^M$, $k = 1, \dots, l$:

$$\begin{aligned}
&\dot{g}_{im} + \nu\lambda_i g_{im} + \sum_{j,n=1}^m \alpha_{nji} g_{jm} g_{nm} + \sum_{j=1}^m \sum_{n=m+1}^M \beta_{nji} g_{jm} g_{nm}^l \\
&\qquad + \sum_{j,n=m+1}^M \alpha_{nji} g_{jm}^l g_{nm}^l = f_i, \quad i = 1, \dots, m, \\
&\dot{g}_{im}^k + \nu\lambda_i g_{im}^k + \sum_{j,n=1}^m \alpha_{nji} g_{jm} g_{nm} + \sum_{j=1}^m \sum_{n=m+1}^M \beta_{nji} g_{jm} g_{nm}^k + \sum_{j,n=m+1}^M \beta_{nji} g_{jm}^k g_{nm}^{k-1} \\
&\qquad - \sum_{j,n=m+1}^M \alpha_{nji} g_{jm}^{k-1} g_{nm}^{k-1} = f_i \quad \forall i = m+1, \dots, M, \\
&g_{im}(0) = (a, \phi_i), \quad g_{jm}^k(0) = (a, \phi_j), \quad i = 1, \dots, m, \ j = m+1, \dots, M.
\end{aligned}$$

Here

$$\begin{cases} \alpha_{nji} = b(\phi_n, \phi_j, \phi_i), \ \beta_{nji} = b(\phi_n, \phi_j, \phi_i) + b(\phi_j, \phi_n, \phi_i), \\ f_i = (f, \phi_i), \ g_{km}^0 = 0 \ \text{ for } k = m+1, \dots, M. \end{cases}$$

Thanks to the theory of ODEs, the above nonlinear ODE has a maximal continuous solution defined on some interval $[0, T_M)$. If $T_M < T$, then $|A^{\frac{1}{2}} u_{mM}^k(t)|$, for some $0 \le k \le l$, must tend to $+\infty$ as $t \to T_M$. But we will show that this does not happen. Therefore $T_M \ge T$. Furthermore, both $|u_{mM}^k(t)|$ and $|A^{\frac{1}{2}} u_{mM}^k|$ are bounded by some constants independent of m, M, T, and l. To prove this, we need the following result.

Lemma 3.1. *For any given $t_M > 0$, suppose*

$$|A^{\frac{1}{2}} u_{mM}^k(t)| \le M_1 \quad \forall 1 \le k \le l, \ t \in [0, t_M].$$

If the condition (3.6) *is valid, we have, for $k = 1, \dots, l$,*

$$|u_{mM}^k(t)| \le M_0 \quad \forall t \in [0, t_M],$$

$$\int_t^{t+r} |A^{\frac{1}{2}} u_{mM}^k(s)|^2 ds \le \frac{4M_0^2}{\nu} + \frac{2r|f|^2}{\lambda_1 \nu^2} \qquad \textit{for any } t \ge 0, r > 0 \textit{ with } t + r \le t_M,$$

where $M_1, M_0 > 0$ are defined in Theorem 3.1.

Proof. The summation of (3.7) and (3.8) implies

$$\begin{aligned}
&\frac{du_{mM}^k}{dt} + \nu A u_{mM}^k + P_M B(v_m, v_m) + P_m[B(v_m, w_M^l) + B(w_M^l, v_m) + B(w_M^l, w_M^l)] \\
&\qquad + P_{mM}[B(v_m, w_M^k) + B(w_M^k, v_m) + B(w_M^{k-1}, w_M^k) \\
&\qquad\qquad + B(w_M^k, w_M^{k-1}) - B(w_M^{k-1}, w_M^{k-1})] = P_M f. \qquad (3.10)
\end{aligned}$$

Multiplying (3.10) by $2u_{mM}^k$, integrating it on Ω, and using the property (3.4) of the trilinear form, we get

$$\begin{aligned}\frac{d|u_{mM}^k|^2}{dt} &+ 2\nu|A^{\frac{1}{2}}u_{mM}^k|^2 \le 2|b(v_m, v_m, w_M^k)| + 2|b(v_m, w_M^l, v_m)| + 2|b(w_M^l, w_M^l, v_m)| \\ &+ 2|b(w_M^k, v_m, w_M^k)| + 2|b(w_M^k, w_M^{k-1}, w_M^k)| + 2|b(w_M^{k-1}, w_M^{k-1}, w_M^k)| + 2|(f, u_{mM}^k)|.\end{aligned}$$

Due to (2.5) and (3.6), we know $|A^{\frac{1}{2}}v_m|, |A^{\frac{1}{2}}w_M^k| \le M_1$, and $c_1M_1L_m\lambda_{m+1}^{-\frac{1}{2}} \le \frac{\nu}{10}$. By using (2.2)–(2.4) and (3.4)–(3.5), we summarize the estimates of the seven terms on the right-hand side of the above inequality as follows:

$$\begin{aligned}2|b(v_m, v_m, w_M^k)| &\le c_1|v_m|_\infty|A^{\frac{1}{2}}v_m|\,|w_M^k| \le \frac{c_1M_1L_m}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}v_m|^2 \le \frac{\nu}{10}|A^{\frac{1}{2}}v_m|^2, \\ 2|b(v_m, w_M^l, v_m)| &= 2|b(v_m, v_m, w_M^l)| \le c_1|v_m|_\infty|A^{\frac{1}{2}}v_m|\,|w_M^l| \\ &\le \frac{c_1M_1L_m}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}v_m|^2 \le \frac{\nu}{10}|A^{\frac{1}{2}}v_m|^2, \\ 2|b(w_M^l, w_M^l, v_m)| &= 2|b(w_M^l, v_m, w_M^l)| \le c_1|A^{\frac{1}{4}}w_M^l|^2|A^{\frac{1}{2}}v_m| \\ &\le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}v_m|\,|A^{\frac{1}{2}}w_M^l|^2, \\ 2|b(w_M^k, v_m, w_M^k)| &\le c_1|A^{\frac{1}{4}}w_M^k|^2|A^{\frac{1}{2}}v_m| \le \frac{c_1M_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^k|^2 \le \frac{\nu}{10}|A^{\frac{1}{2}}w_M^k|^2, \\ 2|b(w_M^k, w_M^{k-1}, w_M^k)| &\le c_1|A^{\frac{1}{4}}w_M^k|^2|A^{\frac{1}{2}}w_M^{k-1}| \le \frac{c_1M_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^k|^2 \le \frac{\nu}{10}|A^{\frac{1}{2}}w_M^k|^2, \\ 2|b(w_M^{k-1}, w_M^{k-1}, w_M^k)| &= 2|b(w_M^{k-1}, w_M^k, w_M^{k-1})| \le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^k|\,|A^{\frac{1}{2}}w_M^{k-1}|^2, \\ 2|(f, u_{mM}^k)| &\le 2|A^{-\frac{1}{2}}P_Mf|\,|A^{\frac{1}{2}}u_{mM}^k| \le \nu|A^{\frac{1}{2}}u_{mM}^k|^2 + \frac{|f|^2}{\lambda_1\nu}.\end{aligned}$$

Finally, we see that

$$\begin{aligned}\frac{d|u_{mM}^k|^2}{dt} &+ \frac{4\nu}{5}|A^{\frac{1}{2}}u_{mM}^k|^2 \\ &\le \frac{|f|^2}{\lambda_1\nu} + c_1\lambda_{m+1}^{-\frac{1}{2}}(|A^{\frac{1}{2}}w_m^k|\,|A^{\frac{1}{2}}w_M^{k-1}|^2 + |A^{\frac{1}{2}}v_m|\,|A^{\frac{1}{2}}w_M^l|^2).\end{aligned} \tag{3.11}$$

Because of $|A^{\frac{1}{2}}u_{mM}^k|^2 \ge \lambda_1|u_{mM}^k|^2$, we have

$$\begin{aligned}\frac{d|u_{mM}^k|^2}{dt} &+ \frac{11\lambda_1\nu}{20}|u_{mM}^k|^2 + \frac{\nu}{4}|A^{\frac{1}{2}}w_M^k|^2 \\ &\le \frac{|f|^2}{\lambda_1\nu} + c_1\lambda_{m+1}^{-\frac{1}{2}}(|A^{\frac{1}{2}}w_m^k|\,|A^{\frac{1}{2}}w_M^{k-1}|^2 + |A^{\frac{1}{2}}v_m|\,|A^{\frac{1}{2}}w_M^l|^2).\end{aligned}$$

Thanks to (2.5), $\max_{0\le t\le t_M}|A^{\frac{1}{2}}u_{mM}^k(t)| \le M_1$ implies

$$\max_{0\le t\le t_M}\left(\max_{1\le k\le l}|A^{\frac{1}{2}}w_M^k(t)|^2 + |A^{\frac{1}{2}}v_m(t)|^2\right) \le M_1^2.$$

Therefore

$$\max_{0\le t\le t_M}\left(\max_{1\le k\le l}|A^{\frac{1}{2}}w_M^k(t)|+|A^{\frac{1}{2}}v_m(t)|\right)\le\sqrt{2}M_1. \tag{3.12}$$

Integrating the above inequality on time interval $[0,t]$ and noticing (3.12), we obtain

$$\begin{aligned}&|u_{mM}^k(t)|^2+\frac{\nu}{4}\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^k(s)|^2ds\le|a|^2+\frac{20}{11\lambda_1^2\nu^2}|f|^2\\&\quad+\frac{\sqrt{2}c_1M_1}{\lambda_{m+1}^{\frac{1}{2}}}\max\left\{\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^{k-1}(s)|^2ds,\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^l(s)|^2ds\right\}.\end{aligned}$$

Because both terms on the left-hand side of the above inequality are positive, we have

$$\begin{aligned}&|u_{mM}^k(t)|^2\le|a|^2+\frac{20}{11\lambda_1^2\nu^2}|f|^2\\&\quad+\frac{\sqrt{2}c_1M_1}{\lambda_{m+1}^{\frac{1}{2}}}\max\left\{\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^{k-1}(s)|^2ds,\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^l(s)|^2ds\right\},\end{aligned}$$

$$\begin{aligned}&\frac{\nu}{4}\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^k(s)|^2ds\le|a|^2+\frac{20}{11\lambda_1^2\nu^2}|f|^2\\&\quad+\frac{\sqrt{2}c_1M_1}{\lambda_{m+1}^{\frac{1}{2}}}\max\left\{\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^{k-1}(s)|^2ds,\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^l(s)|^2ds\right\}.\end{aligned}$$

Taking the maximum value with respect to $1\le k\le l$ on both sides of the above two inequalities and noticing $w_M^0=0$, the summation of the results admits

$$\begin{aligned}&\max_{1\le k\le l}|u_{mM}^k(t)|^2+\frac{\nu}{4}\max_{1\le k\le l}\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^k(s)|^2ds\\&\qquad\le 2|a|^2+\frac{4}{\lambda_1^2\nu^2}|f|^2+2\sqrt{2}c_1M_1\lambda_{m+1}^{-\frac{1}{2}}\max_{1\le k\le l}\int_0^t e^{-\frac{11\lambda_1\nu}{20}(t-s)}|A^{\frac{1}{2}}w_M^k(s)|^2ds.\end{aligned} \tag{3.13}$$

Since we know $2\sqrt{2}c_1M_1\lambda_{m+1}^{-\frac{1}{2}}\le\frac{\nu}{4}$ from the condition (3.6), then (3.13) implies

$$|u_{mM}^k(t)|\le\sqrt{2|a|^2+\frac{4|f|^2}{\lambda_1^2\nu^2}}=\sqrt{2\nu^2Re^2+4\nu^2Gr^2}=M_0\quad\forall t\in[0,t_M],\ 1\le k\le l.$$

From (3.11) and the result we just obtained, we have for any $t\ge0, r>0$, and $t+r\le t_M$

$$\frac{4\nu}{5}\int_t^{t+r}|A^{\frac{1}{2}}u_{mM}^k|^2ds\le 2M_0^2+\frac{|f|^2r}{\lambda_1\nu}+2\sqrt{2}c_1M_1\lambda_{m+1}^{-\frac{1}{2}}\max_{1\le i\le l}\int_t^{t+r}|A^{\frac{1}{2}}w_M^i|^2ds.$$

Noticing that $|A^{\frac{1}{2}}w_M^k|^2\le|A^{\frac{1}{2}}u_{mM}^k|^2$ and that (3.6) guarantees $2\sqrt{2}c_1M_1\lambda_{m+1}^{-\frac{1}{2}}\le\frac{\nu}{4}$, we can easily get from the above inequality that

$$\max_{1\le k\le l}\int_t^{t+r}|A^{\frac{1}{2}}u_{mM}^k(s)|^2ds\le\frac{4M_0^2}{\nu}+\frac{2r|f|^2}{\lambda_1\nu^2}\quad\forall t\ge0,\ r>0,\ t+r\le t_M.\qquad\square$$

Now we are ready to prove that for the ODE system (3.7)–(3.9) there exists a global uniformly bounded solution.

Lemma 3.2. *For any given* $0 < T < \infty$, *if* m *is so large that the condition* (3.6) *holds, we have*

$$|A^{\frac{1}{2}}u^k_{mM}(t)| \leq M_1 \quad \forall t \in [0,T],\ 0 \leq k \leq l,$$

and

$$\int_0^T |Au^k_{mM}(s)|^2 ds \leq M_2(T), \quad k = 0, 1, \ldots, l,$$

where M_1 *and* $M_2(T)$ *are given in Theorem* 3.1.

Proof. Noticing what was mentioned before, that the ODE system (3.7)–(3.9) has a maximal continuous solution defined on some interval $[0, T_M)$, we will prove this lemma by contradiction.

Assuming that

$$T_M < T, \tag{3.14}$$

we then assert that $|A^{\frac{1}{2}}u^k_{mM}(t)|$ goes to ∞ as t tends to T_M for certain $0 \leq k \leq l$. Since $|A^{\frac{1}{2}}u^k_{mM}(t)|$ is a continuous function of t and $M_1 > |A^{\frac{1}{2}}a|$, there exists a constant $t_M < T_M$ such that

$$\max_{0\leq k\leq l} |A^{\frac{1}{2}}u^k_{mM}(t)| < M_1 \text{ on } [0, t_M) \quad \text{and} \quad \max_{0\leq k\leq l} |A^{\frac{1}{2}}u^k_{mM}(t_M)| = M_1. \tag{3.15}$$

Multiplying (3.10) by $2Au^k_{mM}$ and integrating it on Ω, we have

$$\begin{aligned}\frac{d|A^{\frac{1}{2}}u^k_{mM}|^2}{dt} + 2\nu|Au^k_{mM}|^2 &\leq 2|b(v_m, v_m, Au^k_{mM})| + 2|b(v_m, w^l_M, Av_m)| \\ &+ 2|b(w^l_M, v_m, Av_m)| + 2|b(w^l_M, w^l_M, Av_m)| + 2|b(v_m, w^k_M, Aw^k_M)| \\ &+ 2|b(w^k_M, v_m, Aw^k_M)| + 2|b(w^{k-1}_M, w^k_M, Aw^k_M)| + 2|b(w^k_M, w^{k-1}_M, Aw^k_M)| \\ &+ 2|b(w^{k-1}_M, w^{k-1}_M, Aw^k_M)| + 2|(f, Au^k_{mM})|.\end{aligned}$$

Under the conditions of (3.6) and (3.15), Lemma 3.1 asserts that $|u^k_{mM}| \leq M_0$ on $[0, t_M]$ for any $0 \leq k \leq l$. Of course, we know $|v_m|, |w^k_{mM}| \leq M_0$ from (2.5). By using (2.2)–(2.4), (3.4)–(3.5), and the result of Lemma 3.1, we have the following estimates of the ten right-hand-side terms in the above inequality on $[0, t_M]$:

$$\begin{aligned}2|b(v_m, v_m, Au^k_{mM})| &\leq c_1|v_m|_\infty|A^{\frac{1}{2}}v_m|\,|Au^k_{mM}| \leq c_1|v_m|^{\frac{1}{2}}|A^{\frac{1}{2}}v_m|\,|Au^k_{mM}|^{\frac{3}{2}} \\ &\leq \frac{3\nu}{4}|Au^k_{mM}|^2 + \frac{c_1^4M_0^2}{4\nu^3}|A^{\frac{1}{2}}v_m|^4, \\ 2|b(v_m, w^l_M, Av_m)| &\leq c_1|v_m|_\infty|A^{\frac{1}{2}}w^l_M|\,|Av_m| \leq \frac{c_1L_m}{\lambda^{\frac{1}{2}}_{m+1}}|A^{\frac{1}{2}}v_m|\,|Aw^l_M|\,|Av_m| \\ &\leq \frac{c_1L_m}{4\lambda^{\frac{1}{2}}_{m+1}}|A^{\frac{1}{2}}v_m|\,|Aw^l_M|^2 + \frac{c_1L_m}{\lambda^{\frac{1}{2}}_{m+1}}|A^{\frac{1}{2}}v_m|\,|Av_m|^2, \\ 2|b(w^l_M, v_m, Av_m)| &\leq c_1|w^l_M|\,|A^{\frac{1}{2}}v_m|_\infty|Av_m| \leq \frac{c_1L_m}{\lambda^{\frac{1}{2}}_{m+1}}|A^{\frac{1}{2}}w^l_M|\,|Av_m|^2,\end{aligned}$$

$$\begin{aligned}
2|b(w_M^l, w_M^l, Av_m)| &\le c_1|w_M^l|_\infty|A^{\frac{1}{2}}w_M^l|\,|Av_m| \\
&\le c_1|w_M^l|^{\frac{1}{2}}|Aw_M^l|^{\frac{1}{2}}|w_M^l|^{\frac{1}{2}}|Aw_M^l|^{\frac{1}{2}}|Av_m| \\
&= c_1|w_M^l|\,|Aw_M^l|\,|Av_m| \le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^l|\,|Aw_M^l|\,|Av_m| \\
&\le \frac{c_1L_m}{4\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^l|\,|Aw_M^l|^2 + \frac{c_1L_m}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^l|\,|Av_m|^2, \\
2|b(v_m, w_M^k, Aw_M^k)| &\le c_1|v_m|_\infty|A^{\frac{1}{2}}w_M^k|\,|Aw_M^k| \le \frac{c_1L_m}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}v_m|\,|Aw_M^k|^2, \\
2|b(w_M^k, v_m, Aw_M^k)| &\le c_1|w_M^k|_\infty|A^{\frac{1}{2}}v_m|\,|Aw_M^k| \le c_1|w_M^k|^{\frac{1}{2}}|Aw_M^k|^{\frac{1}{2}}|A^{\frac{1}{2}}v_m|\,|Aw_M^k| \\
&\le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}v_m|\,|Aw_M^k|^2, \\
2|b(w_M^{k-1}, w_M^k, Aw_M^k)| &\le c_1|A^{\frac{1}{4}}w_M^{k-1}|\,|A^{\frac{3}{4}}w_M^k|\,|Aw_M^k| \le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2, \\
2|b(w_M^k, w_M^{k-1}, Aw_M^k)| &\le c_1|w_M^k|_\infty|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k| \le c_1|w_M^k|^{\frac{1}{2}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^{\frac{3}{2}} \\
&\le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2, \\
2|b(w_M^{k-1}, w_M^{k-1}, Aw_M^k)| &\le c_1|w_M^{k-1}|_\infty|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k| \\
&\le c_1|w_M^{k-1}|^{\frac{1}{2}}|Aw_M^{k-1}|^{\frac{1}{2}}|w_M^{k-1}|^{\frac{1}{2}}|Aw_M^{k-1}|^{\frac{1}{2}}|Aw_M^k| \\
&= c_1|w_M^{k-1}|\,|Aw_M^{k-1}|\,|Aw_M^k| \le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^{k-1}|\,|Aw_M^k| \\
&\le \frac{c_1}{2\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2 + \frac{c_1}{2\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^{k-1}|^2, \\
2|(f, Au_{mM}^k)| &\le \frac{4}{\nu}|f|^2 + \frac{\nu}{4}|Au_{mM}^k|^2.
\end{aligned}$$

Combining the above estimates yields

$$\begin{aligned}
\frac{d|A^{\frac{1}{2}}u_{mM}^k|^2}{dt} + \nu|Au_{mM}^k|^2 \le{}& \frac{4}{\nu}|f|^2 + \frac{c_1^4M_0^2}{4\nu^3}|A^{\frac{1}{2}}v_m|^4 \\
&+ \frac{1}{4}c_1L_m\lambda_{m+1}^{-\frac{1}{2}}(|A^{\frac{1}{2}}v_m| + |A^{\frac{1}{2}}w_M^l|)|Aw_M^l|^2 \\
&+ c_1L_m\lambda_{m+1}^{-\frac{1}{2}}(|A^{\frac{1}{2}}v_m|\,|Av_m|^2 + 2|A^{\frac{1}{2}}w_M^l|\,|Av_m|^2 \\
&\qquad + 2|A^{\frac{1}{2}}v_m|\,|Aw_M^k|^2 + 2|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2) \\
&+ \frac{c_1}{2}\lambda_{m+1}^{-\frac{1}{2}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2 + \frac{c_1}{2}\lambda_{m+1}^{-\frac{1}{2}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^{k-1}|^2.
\end{aligned}$$

Noticing (3.15) and (3.12), we have for $t \in [0, t_M]$

$$\begin{aligned}
&|A^{\frac{1}{2}}v_m|\,|Av_m|^2 + |A^{\frac{1}{2}}w_M^l|\,|Av_m|^2 + |A^{\frac{1}{2}}v_m|\,|Aw_M^k|^2 + |A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|^2 \\
&\qquad \le \sqrt{2}M_1|Au_{mM}^k|^2.
\end{aligned}$$

The combination of the above estimations gives

$$\frac{d|A^{\frac{1}{2}}u^k_{mM}|^2}{dt}+\nu|Au^k_{mM}|^2\le\frac{4}{\nu}|f|^2+\frac{c_1^4M_0^2}{4\nu^3}|A^{\frac{1}{2}}v_m|^4+\frac{\sqrt{2}}{4}c_1M_1L_m\lambda_{m+1}^{-\frac{1}{2}}|Aw^l_M|^2$$
$$+\frac{2\sqrt{2}c_1M_1L_m}{\lambda_{m+1}^{\frac{1}{2}}}|Au^k_{mM}|^2+\frac{c_1M_1}{2\lambda_{m+1}^{\frac{1}{2}}}|Aw^k_M|^2+\frac{c_1M_1}{2\lambda_{m+1}^{\frac{1}{2}}}|Aw^{k-1}_M|^2.$$

Thanks to (3.6), we have $2\sqrt{2}c_1M_1L_m\lambda_{m+1}^{-\frac{1}{2}}\le\frac{\nu}{4}$. Then

$$\frac{d|A^{\frac{1}{2}}u^k_{mM}|^2}{dt}+\frac{3\nu}{4}|Au^k_{mM}|^2\le\frac{4}{\nu}|f|^2+\frac{c_1^4M_0^2}{4\nu^3}|A^{\frac{1}{2}}v_m|^4$$
$$+\frac{c_1}{2}M_1L_m\lambda_{m+1}^{-\frac{1}{2}}(|Aw^l_M|^2+|Aw^k_M|^2+|Aw^{k-1}_M|^2).$$

For any $t\ge 0$, $r>0$ satisfying $t+r\le t_M$ and $\tau\in[t,t+r]$, integrating the above inequality on $[\tau,t+r]$ shows that for all $1\le k\le l$

$$|A^{\frac{1}{2}}u^k_{mM}(t+r)|^2+\frac{3\nu}{4}\int_\tau^{t+r}|Au^k_{mM}(s)|^2ds\le\frac{4r}{\nu}|f|^2+\int_\tau^{t+r}\frac{c_1^4M_0^2}{4\nu^3}|A^{\frac{1}{2}}v_m(s)|^4ds$$
$$+\frac{c_1}{2}M_1L_m\lambda_{m+1}^{-\frac{1}{2}}\int_\tau^{t+r}[|Aw^l_M(s)|^2+|Aw^k_M(s)|^2+|Aw^{k-1}_M(s)|^2]ds+|A^{\frac{1}{2}}u^k_{mM}(\tau)|^2.$$

Now, we define

$$y(s)=\max_{1\le i\le l}|A^{\frac{1}{2}}u^i_{mM}(s)|^2.$$

By noticing that (3.6) implies $3c_1M_1L_m\lambda_{m+1}^{-\frac{1}{2}}\le\frac{\nu}{2}$ and using a similar method for deriving (3.13),

$$y(t+r)+\frac{\nu}{4}\max_{1\le i\le l}\int_\tau^{t+r}|Au^i_{mM}(s)|^2ds \tag{3.16}$$
$$\le 2y(\tau)+\frac{8r}{\nu}|f|^2+\int_\tau^{t+r}\frac{c_1^4M_0^2}{2\nu^3}y^2(s)ds.$$

Thanks to Lemma 3.1, we know

$$\int_t^{t+r}y(s)ds\le\frac{4M_0^2}{\nu}+\frac{2r|f|^2}{\lambda_1\nu^2}\triangleq a_3(r)\quad\forall t\ge 0,\ r>0,\ t+r\le t_M.$$

Also, we define

$$a_2(r)=\frac{8r}{\nu}|f|^2,\qquad a_1(r)=\frac{c_1^4M_0^2}{2\nu^3}a_3(r).$$

It is obvious that $a_1(r)$, $a_2(r)$, and $a_3(r)$ are functions of r and independent of l and M_1. Omitting the second term on the left-hand side of (3.16) and combining it with the above three inequalities, we can use the idea of the proof of the uniform Gronwall inequality (see [22]) to get

$$y(t)\le\left(\frac{2a_3(r)}{r}+a_2(r)\right)\exp(a_1(r))\triangleq B_{11}(r)\quad\forall r\le t\le t_M. \tag{3.17}$$

For $t \in [0, r]$, by using the ordinary Gronwall inequality, (3.16) implies

$$y(t) \le (2|A^{\frac{1}{2}}a|^2 + a_2(r)) \exp(a_1(r)) \overset{\triangle}{=} B_{12}(r). \tag{3.18}$$

Now let us complete the proof in two cases.

Case 1. If $t_M > \frac{1}{\lambda_1 \nu}$, we take $r = \frac{1}{\lambda_1 \nu}$ in (3.17)–(3.18). This admits

$$\max_{1 \le i \le l} |A^{\frac{1}{2}} u^i_{mM}(t)| \le \sqrt{\max\left\{ B_{11}\left(\frac{1}{\lambda_1 \nu}\right), B_{12}\left(\frac{1}{\lambda_1 \nu}\right) \right\}} \quad \forall t \in [0, t_M].$$

It is easy to verify that

$$\sqrt{\max\left\{ B_{11}\left(\frac{1}{\lambda_1 \nu}\right), B_{12}\left(\frac{1}{\lambda_1 \nu}\right) \right\}} < 4\lambda_1^{\frac{1}{2}} \nu (Re + 2Gr) \exp(c_1^4 (2Re^2 + 5Gr^2)^2) = M_1,$$

and this is a contradiction of (3.15).

Case 2. If $t_M \le \frac{1}{\lambda_1 \nu}$, it is quite easy to verify that (3.16) is still valid with $t = \tau = 0$ and any $r \le t_M$. Then we can use the ordinary Gronwall inequality on (3.16) to get

$$\max_{1 \le i \le l} |A^{\frac{1}{2}} u^i_{mM}(r)| \le \sqrt{B_{12}\left(\frac{1}{\lambda_1 \nu}\right)} < M_1 \quad \forall r \in [0, t_M].$$

In particular, $\max_{1 \le i \le l} |A^{\frac{1}{2}} u^i_{mM}(t_M)| < M_1$. This also leads to a contradiction with (3.15).

Therefore the assumption (3.14) is invalid. We can thus get $T_M \ge T$; that is, the solution of (3.7)–(3.9) will not blow up in any bounded time interval. And the proof shows that its solution is uniformly (with respect to m, M, l, and T) bounded with bound M_1.

Furthermore, from (3.16) we can get, for $k = 1, \ldots, l$,

$$\begin{aligned} \int_0^T |Au^k_{mM}(s)|^2 ds &\le 12\nu^{-1} M_1^2 + 32T\nu^{-2}|f|^2 + \frac{2c_1^4 M_0^2 M_1^4 T}{\nu^4} \\ &\le 2\nu^{-1} M_1^2 (6 + c_1^4 \nu^{-3} M_0^2 M_1^2 T) + 32\lambda_1^2 \nu^2 T Gr^2 = M_2^2(T). \qquad \square \end{aligned}$$

Proof of Theorem 3.1. By the results of Lemma 3.2, we claim that for any fixed m the sequence

$$U_{mM} \overset{\triangle}{=} \{v_m, w^1_M, \ldots, w^l_M\}, \quad M > m, \tag{3.19}$$

remains in a bounded set of $\mathcal{L}^2(0, T; \mathbf{D(A)}) \cap \mathcal{L}^\infty(0, T; \mathbf{V})$,

where $\mathbf{D(A)} = P_m D(A) \times (Q_m D(A))^l$, $\mathbf{V} = P_m V \times (Q_m V)^l$. And it is easy for us to verify that

$$U'_{mM} = \frac{dU_{mM}}{dt} \quad \text{remains in a bounded set of } \mathcal{L}^2(0, T; \mathbf{H}). \tag{3.20}$$

Here $\mathbf{H} = H_m \times (Q_m H)^l$.

Now we define $X_0 = \mathbf{D(A)}$, $X = \mathbf{V}$, $X_1 = \mathbf{H}$, and

$$\mathcal{Y} = \{U \in \mathcal{L}^2(0, T; X_0),\ U' \in \mathcal{L}^2(0, T; X_1)\}.$$

From (3.20) and the second result of Lemma 3.2, we have that the sequence $\{U_{mM}\}_{M>m}$ remains in a bounded set of $\mathcal{Y}$. Thanks to (3.19) and the compactness theorem (see Theorem 2.1 in Chapter III of [21]), we can assert the existence of an element $U_m = \{\tilde{v}_m, \tilde{w}^1, \dots, \tilde{w}^l\} \in \mathcal{L}^\infty(0,T;\mathbf{V})$ and a subsequence $\{U_{mM'}\}_{M'>m}$ such that

$$\left\{\begin{array}{l} U_{mM'} \to U_m \text{ in } \mathcal{L}^2(0,T;\mathbf{D(A)}) \text{ weakly, in} \\ \mathcal{L}^\infty(0,T;\mathbf{V}) \text{ weak star, and in} \\ \mathcal{L}^2(0,T;\mathbf{V}) \text{ strongly, as } M' \to \infty. \end{array}\right.$$

We can certainly get $U_{mM'} \to U_m$ weakly in $\mathcal{L}^2(0,T;\mathbf{V})$, weak star in $\mathcal{L}^\infty(0,T;\mathbf{H})$, and strongly in $\mathcal{L}^2(0,T;\mathbf{H})$. Noticing the continuity property of the trilinear form $b(\cdot,\cdot,\cdot)$ (see Lemma 3.2 in Chapter III of [21]), the passage to the limit shows that U_m is the solution of system (3.1)–(3.3), which shares the same bound of U_{mM}. □

In the following theorem, we will show that the small eddy components, namely $|w_M^k|$ and $|A^{\frac{1}{2}} w_M^k|$, are bounded by some small quantities. This result is very important for the error estimates in the next section.

THEOREM 3.2. *If $|A^{\frac{1}{2}} u_{mM}^k(t)| \le M_1$ for any $t \ge 0$ and $1 \le k \le l$ and m is large enough such that* (3.6) *holds, then there exists a positive constant $T_0 = T_0(a,f,\nu)$ such that*

$$|w_M^k(t)| \le \frac{K_0 L_m}{\lambda_{m+1}}, \qquad |A^{\frac{1}{2}} w_M^k(t)| \le \frac{K_1 L_m}{\lambda_{m+1}^{\frac{1}{2}}} \quad \forall t \ge T_0, 1 \le k \le l,$$

where

$$K_0 = \frac{2(c_1 M_1^2 + 2|P_{mM} f| L_m^{-1})}{\nu}, \qquad K_1 = \frac{5(c_1 M_1^2 + |P_{mM} f| L_m^{-1})}{\nu}.$$

Proof. Multiplying (3.8) with $2w_M^k$, integrating it on Ω, and using (3.4), we get

$$\begin{aligned} &\frac{d|w_M^k|^2}{dt} + 2\nu|A^{\frac{1}{2}} w_M^k|^2 + 2b(v_m, v_m, w_M^k) + 2b(w_M^k, v_m + w_M^{k-1}, w_M^k) \\ &\quad = 2(f, w_M^k) + 2b(w_M^{k-1}, w_M^{k-1}, w_M^k). \end{aligned}$$

For the trilinear forms and the force term above, using (2.2)–(2.5), (3.4)–(3.5), and the assumption $|A^{\frac{1}{2}}(v_m + w_M^k)| \le M_1$, we have

$$\begin{aligned} 2b(v_m, v_m, w_M^k) &\le c_1 |v_m|_\infty |A^{\frac{1}{2}} v_m|\,|w_M^k| \le c_1 L_m \lambda_{m+1}^{-\frac{1}{2}} |A^{\frac{1}{2}} v_m|^2 |A^{\frac{1}{2}} w_M^k| \\ &\le \frac{\nu}{4}|A^{\frac{1}{2}} w_M^k|^2 + \frac{c_1^2 L_m^2 |A^{\frac{1}{2}} v_m|^4}{\nu\lambda_{m+1}}, \\ 2b(w_M^k, v_m + w_M^{k-1}, w_M^k) &\le c_1 |A^{\frac{1}{4}} w_M^k|\,|A^{\frac{1}{2}}(v_m + w_M^{k-1})|\,|A^{\frac{1}{4}} w_M^k| \le \frac{c_1 M_1}{\lambda_{m+1}^{\frac{1}{2}}} |A^{\frac{1}{2}} w_M^k|^2, \\ 2b(w_M^{k-1}, w_M^{k-1}, w_M^k) &= -2b(w_M^{k-1}, w_M^k, w_M^{k-1}) \le c_1 |A^{\frac{1}{4}} w_M^{k-1}|\,|A^{\frac{1}{2}} w_M^k|\,|A^{\frac{1}{4}} w_M^{k-1}| \\ &\le c_1 \lambda_{m+1}^{-\frac{1}{2}} |A^{\frac{1}{2}} w_M^{k-1}|^2 |A^{\frac{1}{2}} w_M^k| \le \frac{\nu}{4}|A^{\frac{1}{2}} w_M^k|^2 + \frac{c_1^2 |A^{\frac{1}{2}} w_M^{k-1}|^4}{\nu\lambda_{m+1}}, \\ 2(f, w_M^k) &\le 2\lambda_{m+1}^{-\frac{1}{2}} |P_{mM} f|\,|A^{\frac{1}{2}} w_M^k| \le \frac{\nu}{4}|A^{\frac{1}{2}} w_M^k|^2 + \frac{4}{\nu\lambda_{m+1}}|P_{mM} f|^2. \end{aligned}$$

Thanks to (2.5), $|A^{\frac{1}{2}} v_m|^4 + |A^{\frac{1}{2}} w_M^{k-1}|^4 \le |A^{\frac{1}{2}}(v_m + w_M^{k-1})|^4 \le M_1^4$. By (3.6), we see that $c_1 M_1 \lambda_{m+1}^{-\frac{1}{2}} \le \frac{\nu}{4}$. Then

$$\frac{d|w_M^k|^2}{dt} + \nu\lambda_{m+1}|w_M^k|^2 \le \frac{c_1^2 M_1^4 L_m^2 + 4|P_{mM} f|^2}{\nu\lambda_{m+1}}.$$

Integrating the above inequality on $[0,t]$ yields

$$|w_M^k(t)| \le \frac{L_m}{\lambda_{m+1}} \cdot \frac{c_1 M_1^2 + 2|P_{mM} f| L_m^{-1}}{\nu} + e^{-\nu\lambda_{m+1}t/2}|P_{mM}a| \quad \forall t \ge 0. \tag{3.21}$$

Similarly, by using equation (3.8) again, we have

$$\begin{aligned}\frac{d|A^{\frac{1}{2}}w_M^k|^2}{dt} &+ 2\nu|Aw_M^k|^2 + 2b(v_m, v_m, Aw_M^k) + 2b(v_m + w_M^{k-1}, w_M^k, Aw_M^k)\\ &+ 2b(w_M^k, v_m + w_M^{k-1}, Aw_M^k) - 2b(w_M^{k-1}, w_M^{k-1}, Aw_M^k) = 2(f, Aw_M^k).\end{aligned}$$

Applying (2.2)–(2.5) and (3.5), the following estimates hold:

$$\begin{aligned}
2b(v_m, v_m, Aw_M^k) &\le c_1|v_m|_\infty |A^{\frac{1}{2}}v_m|\,|Aw_M^k|\\
&\le c_1 L_m |A^{\frac{1}{2}}v_m|^2 |Aw_M^k| \le \frac{\nu}{8}|Aw_M^k|^2 + \frac{4c_1^2 L_m^2 M_1^4}{\nu},\\
2b(v_m + w_M^{k-1}, w_M^k, Aw_M^k) &\le c_1|v_m|_\infty |A^{\frac{1}{2}}w_M^k|\,|Aw_M^k| + c_1|A^{\frac{1}{4}}w_M^{k-1}|\,|A^{\frac{3}{4}}w_M^k|\,|Aw_M^k|\\
&\le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}(L_m|A^{\frac{1}{2}}v_m| + |A^{\frac{1}{2}}w_M^{k-1}|)|Aw_M^k|^2\\
&\le \frac{\sqrt{2}c_1 M_1 L_m}{\lambda_{m+1}^{\frac{1}{2}}}|Aw_M^k|^2,\\
2b(w_M^k, v_m + w_M^{k-1}, Aw_M^k) &\le c_1|w_M^k|_\infty |A^{\frac{1}{2}}(v_m + w_M^{k-1})|\,|Aw_M^k|\\
&\le c_1 M_1 |w_M^k|^{\frac{1}{2}}|Aw_M^k|^{\frac{3}{2}} \le \frac{c_1 M_1}{\lambda_{m+1}^{\frac{1}{2}}}|Aw_M^k|^2,\\
2b(w_M^{k-1}, w_M^{k-1}, Aw_M^k) &\le c_1|w_M^{k-1}|_\infty |A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|\\
&\le c_1|w_M^{k-1}|^{\frac{1}{2}}|Aw_M^{k-1}|^{\frac{1}{2}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^k|\\
&\le \frac{c_1}{\lambda_{m+1}^{\frac{1}{2}}}|A^{\frac{1}{2}}w_M^{k-1}|\,|Aw_M^{k-1}|\,|Aw_M^k|\\
&\le \frac{\nu}{8}|Aw_M^k|^2 + \frac{4c_1^2 M_1^2}{\nu\lambda_{m+1}}|Aw_M^{k-1}|^2,\\
2(f, Aw_M^k) &\le 2|P_{mM}f|\,|Aw_M^k| \le \frac{\nu}{4}|Aw_M^k|^2 + \frac{4}{\nu}|P_{mM}f|^2.
\end{aligned}$$

Thanks again to (3.6), $\sqrt{2}c_1 M_1 L_m \lambda_{m+1}^{-\frac{1}{2}} \le \frac{\nu}{4}$. Then we get

$$\frac{d|A^{\frac{1}{2}}w_M^k|^2}{dt} + \nu|Aw_M^k|^2 \le \frac{4}{\nu}|P_{mM}f|^2 + \frac{4c_1^2 M_1^2}{\nu\lambda_{m+1}}|Aw_M^{k-1}|^2 + \frac{4c_1^2 M_1^4 L_m^2}{\nu}. \tag{3.22}$$

By using (2.4), we have $|Aw_M^k|^2 \ge \frac{1}{2}|Aw_M^k|^2 + \frac{\lambda_{m+1}}{2}|A^{\frac{1}{2}}w_M^k|^2$. Then it follows that

$$\begin{aligned}\frac{d|A^{\frac{1}{2}}w_M^k|^2}{dt} &+ \frac{\nu\lambda_{m+1}}{2}|A^{\frac{1}{2}}w_M^k|^2 + \frac{\nu}{2}|Aw_M^k|^2\\ &\le \frac{4}{\nu}|P_{mM}f|^2 + \frac{4c_1^2 M_1^2}{\nu\lambda_{m+1}}|Aw_M^{k-1}|^2 + \frac{4c_1^2 M_1^4 L_m^2}{\nu}.\end{aligned}$$

Integrating this inequality on $[0,t]$ admits for $1 \le k \le l$

$$|A^{\frac{1}{2}}w_M^k(t)|^2 + \frac{\nu}{2}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw_M^k(s)|^2 ds \le \frac{8(|P_{mM}f|^2 + c_1^2M_1^4L_m^2)}{\nu^2\lambda_{m+1}}$$
$$+ e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}P_{mM}a|^2 + \frac{4c_1^2M_1^2}{\nu\lambda_{m+1}}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw_M^{k-1}(s)|^2 ds.$$

By using the same method for deriving (3.15) again, we have

$$|A^{\frac{1}{2}}w_M^k(t)|^2 + \frac{\nu}{2}\max_{1\le i\le l}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw_M^i(s)|^2 ds \le \frac{16(|P_{mM}f|^2 + c_1^2M_1^4L_m^2)}{\nu^2\lambda_{m+1}}$$
$$+ 2e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}P_{mM}a|^2 + \frac{8c_1^2M_1^2}{\nu\lambda_{m+1}}\max_{1\le i\le l}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw_M^i(s)|^2 ds.$$

If m is so large that (3.6) is satisfied, we have $\frac{8c_1^2M_1^2}{\nu\lambda_{m+1}} \le \frac{\nu}{2}$. Therefore, we can obtain for $t \ge 0$

$$(3.23) \quad |A^{\frac{1}{2}}w_M^k(t)| \le \frac{L_m}{\lambda_{m+1}^{\frac{1}{2}}}\cdot\frac{4(|P_{mM}f|L_m^{-1} + c_1M_1^2)}{\nu} + \sqrt{2}e^{-\nu\lambda_{m+1}t/4}|A^{\frac{1}{2}}P_{mM}a|.$$

Taking into account (3.21) and (3.23), there must exist a constant $T_0(a,f,\nu) > 0$ such that the results of the theorem are valid. □

Comparing this result with the small eddy estimates of the NSE given in [8], we find that the small eddy components obtained in the small eddy correction method share the same properties as those of the NSE, which will be listed in the next section.

4. Convergence analysis. First of all, we recall the following property of the NSE (see [8]). There exist constants, which will be also denoted by M_0, M_1, K_0, K_1, and $T_0 = T_0(a,f,\nu)$ appearing in Theorem 3.1 and 3.2, such that for any solution $u = p + q$ of (1.1) or (1.5)–(1.6),

$$(4.1) \qquad |u(t)| \le M_0, \quad |A^{\frac{1}{2}}u(t)| \le M_1 \quad \forall t \ge 0,$$

and

$$(4.2) \qquad |q(t)| \le K_0L_m\lambda_{m+1}^{-1}, \quad |A^{\frac{1}{2}}q| \le K_1L_m\lambda_{m+1}^{-\frac{1}{2}} \quad \forall t \ge T_0.$$

LEMMA 4.1. *Under the conditions of Theorem* 3.1, *there exists a constant* $T_0' = T_0'(a,f,\nu) > 0$ *such that for any* $t \ge T_0'$

$$\nu\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw^1(s)|^2 ds \le \frac{K_1^2L_m^2}{\lambda_{m+1}},$$
$$\nu\int_0^t e^{-\nu(t-s)/2}|Aw^1(s)|^2 ds \le K_1^2L_m^2.$$

Proof. Consider $k = 1$ in (3.2). From (3.10), we can get

$$\frac{d|A^{\frac{1}{2}}w^1|^2}{dt} + \nu|Aw^1|^2 \le \frac{3}{\nu}|Q_mf|^2 + \frac{3c_1^2L_m^2M_1^4}{\nu}.$$

Since $\nu|Aw^1|^2 \ge \frac{\nu\lambda_{m+1}}{2}|A^{\frac{1}{2}}w^1|^2 + \frac{\nu}{2}|Aw^1|^2$, we have

$$(4.3) \qquad \frac{d|A^{\frac{1}{2}}w^1|^2}{dt} + \frac{\nu}{2}|Aw^1|^2 + \frac{\nu\lambda_{m+1}}{2}|A^{\frac{1}{2}}w^1|^2 \le \frac{3}{\nu}|Q_mf|^2 + \frac{3c_1^2L_m^2M_1^4}{\nu}.$$

Integrating the above inequality leads to

$$\begin{aligned}
&\nu\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|Aw^1(s)|^2ds\\
&\leq 2e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}Q_ma|^2+\frac{6|Q_mf|^2}{\nu^2\lambda_{m+1}}+\frac{6c_1^2L_m^2M_1^4}{\nu^2\lambda_{m+1}}\\
&\leq 2e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}Q_ma|^2+\frac{L_m^2}{6\lambda_{m+1}}\times\frac{36(L_m^{-2}|Q_mf|^2+c_1^2M_1^4)}{\nu^2}\\
&\leq 2e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}Q_ma|^2+\frac{L_m^2}{6\lambda_{m+1}}\left(\frac{6(L_m^{-1}|Q_mf|+c_1M_1^2)}{\nu}\right)^2\\
&= 2e^{-\nu\lambda_{m+1}t/2}|A^{\frac{1}{2}}Q_ma|^2+\frac{L_m^2}{6\lambda_{m+1}}K_1^2.
\end{aligned}$$

Not enlarging the third term on the left-hand side of (4.3) to $\frac{\nu\lambda_{m+1}}{2}|A^{\frac{1}{2}}w^1|^2$, we can use the same procedure to get

$$\nu\int_0^t e^{-\nu(t-s)/2}|Aw^1(s)|^2ds\leq 2e^{-\nu t/2}|A^{\frac{1}{2}}Q_ma|^2+\frac{L_m^2}{6}K_1^2.$$

Certainly, there is a $T_0'(a,f,\nu)>0$ such that the results are valid. □

Now, let us introduce some notation:

$$e(t)=u(t)-u^l(t),\quad \varepsilon^k(t)=w^k(t)-w^{k-1}(t),\quad |||\cdot(t)|||=\sup_{0\leq s\leq t}|\cdot(s)|.$$

In particular, $\varepsilon^1(t)=w^1(t)$.

THEOREM 4.1. *Under the condition of Theorem* 3.1*, that is, with m large enough such that* (3.6) *is valid, we assume that the results of Theorem* 3.2*,* (4.1)–(4.2)*, and Lemma* 4.1 *hold for $T_0=0$ and $T_0'=0$. Then we have for $l\geq 1$*

$$|e(t)|\leq\frac{\nu K_0L_m^2}{2^{\frac{l-4}{2}}c_1K_1}\left(\frac{2^{\frac{1}{4}}c_1K_1L_m}{\nu\lambda_{m+1}}\right)^{2^l}\exp(c_1^2M_1^2\nu^{-1}t/4)\quad\forall t\geq 0,$$

where the constants M_1, K_0, and K_1 are defined in Theorems 3.1 *and* 3.2.

Proof. Combine (3.1) and (3.2) to see that

$$\frac{du^l}{dt}+\nu Au^l+B(u^l,u^l)-Q_mB(\varepsilon^l,\varepsilon^l)=f. \tag{4.4}$$

Subtracting (4.4) from (1.1) yields

$$\frac{de}{dt}+\nu Ae+B(e,u)+B(u^l,e)+Q_mB(\varepsilon^l,\varepsilon^l)=0. \tag{4.5}$$

Next, we give a rough estimate of $|e|^2$ in terms of $|\varepsilon^l|^2$ and $|A^{\frac{1}{2}}\varepsilon^l|^2$. Multiplying (4.5) by $2e$ and integrating it on Ω, we have

$$\frac{d|e|^2}{dt}+2\nu|A^{\frac{1}{2}}e|^2\leq 2|b(e,u,e)|+2|b(\varepsilon^l,\varepsilon^l,Q_me)|.$$

For the two terms on the right-hand side of the above inequality, we have

$$\begin{aligned}2|b(e,u,e)| &\le c_1|A^{\frac14}e|^2|A^{\frac12}u| \le c_1|e|\,|A^{\frac12}e|\,|A^{\frac12}u|\\ &\le c_1M_1|e|\,|A^{\frac12}e| \le \nu|A^{\frac12}e|^2+\frac{c_1^2M_1^2}{4\nu}|e|^2,\end{aligned}$$

$$2|b(\varepsilon^l,\varepsilon^l,Q_me)| = 2|b(\varepsilon^l,Q_me,\varepsilon^l)| \le c_1|\varepsilon^l|\,|A^{\frac12}\varepsilon^l|\,|A^{\frac12}e| \le \nu|A^{\frac12}e|^2+\frac{c_1^2}{4\nu}|\varepsilon^l|^2|A^{\frac12}\varepsilon^l|^2.$$

Here we applied the Sobolev interpolation inequality (2.2) (the third equation) to the second inequality of both of the above two expressions with $s=\frac14$, $m=\frac12$. Therefore, we get

$$\frac{d|e|^2}{dt} \le \frac{c_1^2M_1^2}{4\nu}|e|^2+\frac{c_1^2}{4\nu}|\varepsilon^l|^2|A^{\frac12}\varepsilon^l|^2.$$

Integrate the above inequality on $[0,t]$ to obtain

$$|e(t)|^2 \le M_1^{-2}e^{(c_1^2M_1^2\nu^{-1}t/4)}|||\varepsilon^l(t)|||^2|||A^{\frac12}\varepsilon^l(t)|||^2. \tag{4.6}$$

To take advantage of the fast decay property of the small eddy components, we estimate the large and small eddy errors $|e_p|^2$ and $|e_q|^2$ in terms of $|\varepsilon^l|^2$ and $|A^{\frac12}\varepsilon^l|^2$ by using (4.6).

Projecting (4.5) onto H_m and Q_mH, respectively, we have

$$\frac{de_p}{dt}+\nu Ae_p+P_mB(e_p+e_q,u)+P_mB(u^l,e_p+e_q)=0, \tag{4.7}$$

$$\frac{de_q}{dt}+\nu Ae_q+Q_mB(e_p+e_q,u)+Q_mB(u^l,e_p+e_q)+Q_mB(\varepsilon^l,\varepsilon^l)=0. \tag{4.8}$$

Multiplying (4.7) by $2e_p$, integrating it on Ω, and noticing (3.4) lead to

$$\frac{d|e_p|^2}{dt}+2\nu|A^{\frac12}e_p|^2 \le 2|b(e_p,u,e_p)|+2|b(e_q,u,e_p)|+2|b(u^l,e_q,e_p)|.$$

Thanks to (2.3)–(2.4), (3.5), and Lemma 1 in [8], we know that

$$2b(u^l,e_p,e_q)=2b(P_mu^l,e_p,e_q)+2b(Q_mu^l,e_p,e_q) \le c_1M_1L_m|A^{\frac12}e_p|\,|e_q|. \tag{4.9}$$

By using (2.2)–(2.4), (3.4)–(3.5), and (4.9), we have

$$\begin{aligned}2b(e_p,u,e_p) &\le c_1M_1|e_p|\,|A^{\frac12}e_p| \le \nu|A^{\frac12}e_p|^2+\frac{c_1^2M_1^2}{4\nu}|e_p|^2,\\ 2b(e_q,u,e_p) &\le c_1M_1|e_q|\,|e_p|_\infty \le c_1M_1L_m|e_q|\,|A^{\frac12}e_p| \le \frac{\nu}{2}|A^{\frac12}e_p|^2+\frac{c_1^2M_1^2L_m^2}{2\nu}|e_q|^2,\\ 2b(u^l,e_q,e_p) &\le c_1M_1L_m|A^{\frac12}e_p|\,|e_q| \le \frac{\nu}{2}|A^{\frac12}e_p|^2+\frac{c_1^2M_1^2L_m^2}{2\nu}|e_q|^2.\end{aligned}$$

Finally, we obtain

$$\frac{d|e_p|^2}{dt} \le \frac{c_1^2M_1^2}{4\nu}|e_p|^2+\frac{c_1^2M_1^2L_m^2}{\nu}|e_q|^2.$$

Integrating the above inequality on $[0,t]$ admits

$$|e_p(t)|^2 \le 4L_m^2 \exp(c_1^2 M_1^2 \nu^{-1} t/4) |||e_q(t)|||^2. \tag{4.10}$$

Multiplying (4.8) with $2e_q$ and integrating it on Ω, we get

$$\frac{d|e_q|^2}{dt} + 2\nu |A^{\frac{1}{2}} e_q|^2 \le 2|b(e_p, u, e_q)| + 2|b(e_q, u, e_q)| + 2|b(u^l, e_p, e_q)| + 2|b(\varepsilon^l, \varepsilon^l, e_q)|.$$

For the right-hand side terms, we have

$$\begin{aligned}
2b(e_p, u, e_q) &\le c_1 M_1 |A^{\frac{1}{4}} e_p|\,|A^{\frac{1}{4}} e_q| \le c_1 M_1 |A^{\frac{1}{2}} e_q|\,|e_p| \le \frac{\nu}{4} |A^{\frac{1}{2}} e_q|^2 + \frac{c_1^2 M_1^2}{\nu} |e_p|^2, \\
2b(e_q, u, e_q) &\le c_1 M_1 |A^{\frac{1}{4}} e_q|^2 \le c_1 M_1 |A^{\frac{1}{2}} e_q|\,|e_q| \le \frac{\nu}{4} |A^{\frac{1}{2}} e_q|^2 + \frac{c_1^2 M_1^2}{\nu} |e_q|^2, \\
2b(u^l, e_p, e_q) &\le c_1 M_1 L_m |A^{\frac{1}{2}} e_p|\,|e_q| \le c_1 M_1 L_m |e_p|\,|A^{\frac{1}{2}} e_q| \\
&\le \frac{\nu}{4} |A^{\frac{1}{2}} e_q|^2 + \frac{c_1^2 M_1^2 L_m^2}{\nu} |e_p|^2, \\
2b(\varepsilon^l, \varepsilon^l, e_q) &\le c_1 |A^{\frac{1}{4}} \varepsilon^l|^2 |A^{\frac{1}{2}} e_q| \le c_1 |\varepsilon^l|\,|A^{\frac{1}{2}} \varepsilon^l|\,|A^{\frac{1}{2}} e_q| \le \frac{\nu}{4} |A^{\frac{1}{2}} e_q|^2 + \frac{c_1^2}{\nu} |\varepsilon^l|^2 |A^{\frac{1}{2}} \varepsilon^l|^2.
\end{aligned}$$

Then we derive

$$\frac{d|e_q|^2}{dt} + \nu \lambda_{m+1} |e_q|^2 \le \frac{3c_1^2 M_1^2 L_m^2}{\nu} |e_p|^2 + \frac{c_1^2}{\nu} |\varepsilon^l|^2 |A^{\frac{1}{2}} \varepsilon^l|^2.$$

Integrating this inequality on $[0,t]$ yields

$$|e_q(t)|^2 \le \frac{3c_1^2 M_1^2 L_m^2}{\nu^2 \lambda_{m+1}} |||e_p(t)|||^2 + \frac{c_1^2}{\nu^2 \lambda_{m+1}} |||\varepsilon^l(t)|||^2 |||A^{\frac{1}{2}} \varepsilon^l(t)|||^2. \tag{4.11}$$

Thanks to (4.6), we obtain

$$|e_q(t)|^2 \le \frac{4c_1^2 L_m^2 e^{(c_1^2 M_1^2 \nu^{-1} t)/4}}{\nu^2 \lambda_{m+1}} |||\varepsilon^l(t)|||^2 |||A^{\frac{1}{2}} \varepsilon^l(t)|||^2. \tag{4.12}$$

Then the combination of (4.12) and (4.10) admits

$$|e(t)|^2 \le \frac{20c_1^2 L_m^4 e^{(c_1^2 M_1^2 \nu^{-1} t)/2}}{\nu^2 \lambda_{m+1}} |||\varepsilon^l(t)|||^2 |||A^{\frac{1}{2}} \varepsilon^l(t)|||^2. \tag{4.13}$$

To complete the proof, we have to estimate the two factors on the right-hand side of (4.13) for $2 \le k \le l$. First of all, from (3.2) we find that $\varepsilon^k(t)$ satisfies

$$\begin{aligned}
&\frac{d\varepsilon^k}{dt} + \nu A \varepsilon^k + Q_m B(v, \varepsilon^k) + Q_m B(\varepsilon^k, v) + Q_m B(w^{k-1}, \varepsilon^k) \\
&\qquad + Q_m B(\varepsilon^k, w^{k-1}) + Q_m B(\varepsilon^{k-1}, \varepsilon^{k-1}) = 0 \quad \forall 2 \le k \le l.
\end{aligned} \tag{4.14}$$

Multiplying (4.14) by $2\varepsilon^k$ and integrating it on Ω gives

$$\frac{d|\varepsilon^k|^2}{dt} + 2\nu |A^{\frac{1}{2}} \varepsilon^k|^2 \le 2|b(\varepsilon^k, v, \varepsilon^k)| + 2|b(\varepsilon^k, w^{k-1}, \varepsilon^k)| + 2|b(\varepsilon^{k-1}, \varepsilon^{k-1}, \varepsilon^k)|.$$

We can summarize the estimates of the right-hand-side terms of this inequality as

$$\begin{aligned}
2|b(\varepsilon^k, v, \varepsilon^k)| &\le c_1|A^{\frac14}\varepsilon^k|^2|A^{\frac12}v| \le c_1M_1\lambda_{m+1}^{-\frac12}|A^{\frac12}\varepsilon^k|^2,\\
2|b(\varepsilon^k, w^{k-1}, \varepsilon^k)| &\le c_1|A^{\frac14}\varepsilon^k|^2|A^{\frac12}w^{k-1}| \le c_1M_1\lambda_{m+1}^{-\frac12}|A^{\frac12}\varepsilon^k|^2,\\
2|b(\varepsilon^{k-1}, \varepsilon^{k-1}, \varepsilon^k)| &\le c_1|\varepsilon^{k-1}|\,|A^{\frac12}\varepsilon^{k-1}|\,|A^{\frac12}\varepsilon^k| \le \frac{\nu}{3}|A^{\frac12}\varepsilon^k|^2 + \frac{3c_1^2}{4\nu}|\varepsilon^{k-1}|^2|A^{\frac12}\varepsilon^{k-1}|^2,
\end{aligned}$$

where, in the first inequality of the last expression above, we used the interpolation inequality in (2.2) with $s = \frac14$ and $m = \frac12$.

By choosing m large enough such that (3.6) is valid, we have

$$\frac{d|\varepsilon^k|^2}{dt} + \nu|A^{\frac12}\varepsilon^k|^2 \le \frac{3c_1^2}{4\nu}|\varepsilon^{k-1}|^2|A^{\frac12}\varepsilon^{k-1}|^2.$$

Finally, we get

$$(4.15)\qquad |\varepsilon^k(t)|^2 \le \frac{3c_1^2}{4\nu^2\lambda_{m+1}}|||\varepsilon^{k-1}(t)|||^2|||A^{\frac12}\varepsilon^{k-1}(t)|||^2 \quad \forall t \ge 0,\ 2 \le k \le l.$$

Now, let us estimate $|A^{\frac12}\varepsilon^k(t)|^2$. Multiplying (4.14) by $2A\varepsilon^k$ and integrating it on Ω, we obtain

$$\begin{aligned}
&\frac{d|A^{\frac12}\varepsilon^k|^2}{dt} + 2\nu|A\varepsilon^k|^2\\
&\qquad \le 2|b(v + w^{k-1}, \varepsilon^k, A\varepsilon^k)| + 2|b(\varepsilon^k, v + w^{k-1}, A\varepsilon^k)| + 2|b(\varepsilon^{k-1}, \varepsilon^{k-1}, A\varepsilon^k)|.
\end{aligned}$$

For the three terms on the right-hand side, we have

$$\begin{aligned}
2|b(v + w^{k-1}, \varepsilon^k, A\varepsilon^k)| &\le c_1(|v|_\infty|A^{\frac12}\varepsilon^k| + |A^{\frac14}w^{k-1}|\,|A^{\frac34}\varepsilon^k|)|A\varepsilon^k| \le \frac{c_1M_1L_m}{\lambda_{m+1}^{\frac12}}|A\varepsilon^k|^2,\\
2|b(\varepsilon^k, v + w^{k-1}, A\varepsilon^k)| &\le c_1|\varepsilon^k|_\infty|A^{\frac12}(v + w^{k-1})|\,|A\varepsilon^k| \le c_1M_1\lambda_{m+1}^{-\frac12}|A\varepsilon^k|^2,\\
2|b(\varepsilon^{k-1}, \varepsilon^{k-1}, A\varepsilon^k)| &\le c_1|\varepsilon^{k-1}|_\infty|A^{\frac12}\varepsilon^{k-1}|\,|A\varepsilon^k| \le c_1\lambda_{m+1}^{-\frac12}|A^{\frac12}\varepsilon^{k-1}|\,|A\varepsilon^{k-1}|\,|A\varepsilon^k|\\
&\le \frac{\nu}{3}|A\varepsilon^k|^2 + \frac{3c_1^2}{4\nu\lambda_{m+1}}|A^{\frac12}\varepsilon^{k-1}|^2|A\varepsilon^{k-1}|^2.
\end{aligned}$$

Thanks to (3.6) again, we derive

$$(4.16)\qquad \frac{d|A^{\frac12}\varepsilon^k|^2}{dt} + \frac{\nu\lambda_{m+1}}{2}|A^{\frac12}\varepsilon^k|^2 + \frac{\nu}{2}|A\varepsilon^k|^2 \le \frac{3c_1^2}{4\nu\lambda_{m+1}}|A^{\frac12}\varepsilon^{k-1}|^2|A\varepsilon^{k-1}|^2.$$

Integrating the above inequality on $[0, t]$ yields

$$\begin{aligned}
&|A^{\frac12}\varepsilon^k(t)|^2 + \frac{\nu}{2}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^k(s)|^2ds\\
&\quad \le e^{-\nu\lambda_{m+1}t/2}|A^{\frac12}\varepsilon^k(0)|^2 + \frac{3c_1^2|||A^{\frac12}\varepsilon^{k-1}(t)|||^2}{4\nu\lambda_{m+1}}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^{k-1}(s)|^2ds.
\end{aligned}$$

Thanks to (3.3), we have for $2 \le k \le l$

$$\left\{\begin{aligned} &|A^{\frac{1}{2}}\varepsilon^k(t)|^2 \le \frac{c_1^2 |||A^{\frac{1}{2}}\varepsilon^{k-1}(t)|||^2}{\nu\lambda_{m+1}} \int_0^t e^{-\nu\lambda_{m+1}(t-s)/2} |A\varepsilon^{k-1}(s)|^2 ds,\\ &\frac{\nu}{2}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^k(s)|^2 ds\\ &\qquad \le \frac{c_1^2 |||A^{\frac{1}{2}}\varepsilon^{k-1}(t)|||^2}{\nu\lambda_{m+1}} \int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^{k-1}(s)|^2 ds. \end{aligned}\right. \tag{4.17}$$

By (4.15) and (4.17), if we define

$$\begin{aligned} &a_k = |||\varepsilon^k|||^2, \quad b_k = |||A^{\frac{1}{2}}\varepsilon^k|||^2,\\ &c_k = \nu\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^k(s)|^2 ds, \quad \alpha = \frac{c_1^2}{\nu^2\lambda_{m+1}} < 1, \end{aligned}$$

we have for $2 \le k \le l$

$$a_k \le \alpha a_{k-1}b_{k-1}, \quad b_k \le \alpha b_{k-1}c_{k-1}, \quad c_k \le 2\alpha b_{k-1}c_{k-1}. \tag{4.18}$$

From the last two inequalities in (4.18), we see that

$$b_k c_k \le 2\alpha^2 (b_{k-1}c_{k-1})^2.$$

So we get for $2 \le k \le l$

$$b_k \le \left\{\begin{array}{ll} \alpha b_1 c_1 & (k=2)\\ \alpha\left[\prod_{i=0}^{k-3}(2\alpha^2)^{2^i}\right](b_1c_1)^{2^{k-2}} & (k \ge 3) \end{array}\right\} \le 2^{-\frac{1}{2}}(\sqrt{2}\alpha)^{2^{k-1}-1}(b_1c_1)^{2^{k-2}}. \tag{4.19}$$

The inequality for b_2 is obvious, and the one for b_k is obtained as follows: for $3 \le k \le l$

$$\begin{aligned} b_k &\le \alpha b_{k-1}c_{k-1} \le \alpha\cdot(2\alpha^2)^{2^0}(b_{k-2}c_{k-2})^{2^1} \le \alpha\cdot(2\alpha^2)^{2^0}\cdot(2\alpha^2)^{2^1}(b_{k-3}c_{k-3})^{2^2} \le \cdots\\ &\le \alpha\cdot(2\alpha^2)^{2^0+2^1+\cdots+2^{k-3}}(b_1c_1)^{2^{k-2}} = \alpha\left[\prod_{i=0}^{k-3}(2\alpha^2)^{2^i}\right](b_1c_1)^{2^{k-2}}. \end{aligned}$$

Thanks to inequality (4.18), we have for $2 \le k \le l$

$$a_k b_k \le \alpha a_{k-1}b_{k-1}b_k \le \alpha^2 a_{k-2}b_{k-2}b_{k-1}b_k \le \cdots \le \alpha^{k-1}\left[\prod_{i=2}^{k} b_i\right](a_1b_1).$$

Then by using (4.19), we can finally get

$$\begin{aligned} a_k b_k &\le \alpha^{k-1}\prod_{i=2}^{k}\left[2^{-\frac{1}{2}}(\sqrt{2}\alpha)^{2^{i-1}-1}(b_1c_1)^{2^{i-2}}\right](a_1b_1)\\ &= \alpha^{k-1}\cdot 2^{-\frac{k-1}{2}}\cdot(\sqrt{2}\alpha)^{\sum_{i=2}^{k}(2^{i-1}-1)}\\ &\quad\times(b_1c_1)^{\sum_{i=2}^{k}2^{i-2}}\cdot(a_1b_1) \le 2^{1-k}(\sqrt{2}\alpha)^{2^k-2}a_1b_1(b_1c_1)^{2^{k-1}-1}. \end{aligned} \tag{4.20}$$

From the results of Theorem 3.2 and Lemma 4.1, we can finally get the result of the theorem from (4.13) and (4.18)–(4.20) by simple calculations. ∎

For H^1-error estimates, we have the following result.

THEOREM 4.2. *Under the same conditions of Theorem* 4.1*, we have for* $l \geq 1$

$$|A^{\frac{1}{2}}e(t)| \leq 4M_1(c_1K_1L_m^5\nu^{-1})^{\frac{1}{2}}\left(\frac{2^{\frac{1}{4}}c_1K_1L_m}{\nu\lambda_{m+1}}\right)^{2^l-\frac{1}{2}}\exp{(c_3t)} \quad \forall t \geq 0,$$

where $c_3 = 2c_1^3\nu^{-2}M_1^3 + 2^{-1}\nu$ *and* M_1, K_1 *are constants defined in Theorems* 3.1 *and* 3.2.

Proof. Multiplying (4.5) by $2Ae$ and integrating it on Ω yields

$$\frac{d|A^{\frac{1}{2}}e|^2}{dt} + 2\nu|Ae|^2 \leq 2|b(e,u,Ae)| + 2|b(u^l,e,Ae)| + 2|b(\varepsilon^l,\varepsilon^l,Ae)|.$$

Thanks to (2.2), (2.4), and (3.5), we have

$$\begin{aligned}2|b(e,u,Ae)| + 2|b(u^l,e,Ae)| &\leq c_1M_1|e|_\infty|Ae| + c_1M_1|A^{\frac{1}{2}+\frac{1}{3}}e|\,|Ae|\\ &\leq 2c_1M_1|A^{\frac{1}{2}}e|^{\frac{2}{3}}|Ae|^{\frac{4}{3}} \leq \nu|Ae|^2 + \frac{2c_1^3M_1^3}{\nu^2}|A^{\frac{1}{2}}e|^2,\\ 2|b(\varepsilon^l,\varepsilon^l,Ae)| &\leq c_1|\varepsilon^l|_\infty|A^{\frac{1}{2}}\varepsilon^l|\,|Ae| \leq c_1|\varepsilon^l|^{\frac{1}{2}}|A\varepsilon^l|^{\frac{1}{2}}|A^{\frac{1}{2}}\varepsilon^l|\,|Ae|\\ &\leq c_1\lambda_{m+1}^{-\frac{1}{2}}|A^{\frac{1}{2}}\varepsilon^l|\,|A\varepsilon^l|\,|Ae| \leq \nu|Ae|^2 + \frac{c_1^2}{4\nu\lambda_{m+1}}|A^{\frac{1}{2}}\varepsilon^l|^2|A\varepsilon^l|^2.\end{aligned}$$

Therefore

$$\frac{d|A^{\frac{1}{2}}e|^2}{dt} - \frac{2c_1^3M_1^3}{\nu^2}|A^{\frac{1}{2}}e|^2 \leq \frac{c_1^2}{4\nu\lambda_{m+1}}|||A^{\frac{1}{2}}\varepsilon^l(t)|||^2|A\varepsilon^l(t)|^2.$$

Integrating the above inequality admits

$$|A^{\frac{1}{2}}e(t)|^2 \leq \frac{c_1^2|||A^{\frac{1}{2}}\varepsilon^l(t)|||^2}{4\nu\lambda_{m+1}}\int_0^t e^{\frac{2c_1^3M_1^3(t-s)}{\nu^2}}|A\varepsilon^l(s)|^2ds.$$

Defining $c_3 = 2c_1^3\nu^{-2}M_1^3 + 2^{-1}\nu$, we can deduce from the above inequality that

$$|A^{\frac{1}{2}}e(t)|^2 \leq \frac{c_1^2e^{c_3t}|||A^{\frac{1}{2}}\varepsilon^l(t)|||^2}{4\nu\lambda_{m+1}}\int_0^t e^{-\frac{\nu(t-s)}{2}}|A\varepsilon^l(s)|^2ds. \tag{4.21}$$

Similarly to the proof of Theorem 4.1, we estimate $|A^{\frac{1}{2}}e_p|^2$ and $|A^{\frac{1}{2}}e_q|^2$, respectively. Noticing (2.4) and (4.10), we have

$$\begin{aligned}|A^{\frac{1}{2}}e_p(t)|^2 \leq \lambda_{m+1}|e_p|^2 &\leq 4L_m^2\lambda_{m+1}e^{\frac{c_1^2M_1^2\nu^{-1}t}{4}}|||e_q(t)|||^2\\ &\leq 4L_m^2e^{\frac{c_1^2M_1^2\nu^{-1}t}{4}}|||A^{\frac{1}{2}}e_q(t)|||^2.\end{aligned} \tag{4.22}$$

Multiplying (4.8) with $2Ae_q$, integrating it on Ω, doing some estimates of the corresponding trilinear terms, and then integrating the final differential inequality of $|A^{\frac{1}{2}}e_q|^2$ on $[0,t]$, we can finally get

$$\begin{aligned}|A^{\frac{1}{2}}e_q|^2 \leq{}& \frac{5c_1^2L_m^2M_1^2}{\nu^2\lambda_{m+1}}|||A^{\frac{1}{2}}e_p(t)|||^2\\ &+ \frac{5c_1^2|||A^{\frac{1}{2}}\varepsilon(t)^l|||^2}{\nu\lambda_{m+1}}\int_0^t e^{-\nu\lambda_{m+1}(t-s)/2}|A\varepsilon^l(s)|^2ds.\end{aligned} \tag{4.23}$$

Combination of (4.21)–(4.23) admits

$$(4.24)\quad |A^{\frac{1}{2}}e(t)|^2 \le \frac{10c_1^4 M_1^2 L_m^4 e^{2c_3 t} |||A^{\frac{1}{2}}\varepsilon^l(t)|||^2}{\nu^3\lambda_{m+1}^2} \times \left(\int_0^t e^{-\frac{\nu(t-s)}{2}} |A\varepsilon^l(s)|^2 ds + \lambda_{m+1}\int_0^t e^{-\frac{\nu\lambda_{m+1}(t-s)}{2}} |A\varepsilon^l(s)|^2 ds \right).$$

Let us define

$$b_k = |||A^{\frac{1}{2}}\varepsilon^l(t)|||^2, \quad c_k = \nu\int_0^t e^{-\frac{\nu\lambda_{m+1}(t-s)}{2}} |A\varepsilon^k(s)|^2 ds, \quad \alpha = \frac{c_1^2}{\nu^2\lambda_{m+1}},$$

and

$$d_k = \nu\int_0^t e^{-\nu(t-s)/2} |A\varepsilon^k(s)|^2 ds.$$

We have from (4.17)–(4.18) and (4.24) that

$$|A^{\frac{1}{2}}e(t)|^2 \le 10M_1^2 L_m^4 e^{2c_3 t}\alpha^2 b_l(d_l + \lambda_{m+1}c_l),$$

$$b_k \le \alpha b_{k-1}c_{k-1}, \quad c_k \le 2\alpha b_{k-1}c_{k-1}, \quad d_k \le 2\alpha b_{k-1}d_{k-1}.$$

The last inequality is obvious if we substitute $\frac{\nu\lambda_{m+1}}{2}|A^{\frac{1}{2}}\varepsilon^k|^2$ with $\frac{\nu}{2}|A^{\frac{1}{2}}\varepsilon^k|^2$ in (4.16). From the last two inequalities we have for $l \ge 1$

$$\begin{aligned} d_l + \lambda_{m+1}c_l &\le 2\alpha b_{l-1}d_{l-1} + 2\alpha\lambda_{m+1}b_{l-1}c_{l-1} = 2\alpha b_{l-1}(d_{l-1} + \lambda_{m+1}c_{l-1}) \\ &\le (2\alpha)^2 b_{l-1}b_{l-2}(d_{l-2} + \lambda_{m+1}c_{l-2}) \le \cdots \le (2\alpha)^{l-1}\left[\prod_{i=1}^{l-1} b_i\right](d_1 + \lambda_{m+1}c_1). \end{aligned}$$

Now it is easy to get for $l \ge 1$

$$(4.25)\qquad b_l(d_l + \lambda_{m+1}c_l) \le (2\alpha)^{l-1}\left(\prod_{i=1}^{l} b_i\right)(d_1 + \lambda_{m+1}c_1).$$

Thanks to (4.19) and (4.25) we have for $l \ge 1$

$$\begin{aligned} b_l(d_l + \lambda_{m+1}c_l) &\le (2\alpha)^{l-1} b_1 \left[\prod_{i=2}^{l} 2^{-\frac{1}{2}}(\sqrt{2}\alpha)^{2^{i-1}-1}(b_1c_1)^{2^{i-2}}\right](d_1 + \lambda_{m+1}c_1) \\ &\le \sqrt{2}(2\alpha)^{l-1} b_1 (b_1c_1)^{-2^{-1}} \left[\prod_{i=1}^{l} 2^{-\frac{1}{2}}(\sqrt{2}\alpha)^{2^{i-1}-1}(b_1c_1)^{2^{i-2}}\right](d_1 + \lambda_{m+1}c_1) \\ &\le 2^{-\frac{1}{2}}(\sqrt{2}\alpha)^{2^l-2}(b_1c_1)^{2^{l-1}-\frac{1}{2}}(d_1 + \lambda_{m+1}c_1). \end{aligned}$$

Combining the above inequality with the results of Theorem 3.2, Lemma 4.1, and (4.24) leads to the result of the theorem. □

Remark 2. Compared with NGM (1.8) and PPGM (1.10), the small eddy correction method (3.1)–(3.3) involves the self evolution of the small eddy components as well as the interaction between the large and small eddies. Therefore it is suitable for approximating the NSE whenever the small eddy components change slowly or rapidly (in this case, approximating the small eddy equation with the steady Stokes equation in both NGM (1.8) and PPGM (1.10) is not suitable) and can be expected to yield a more accurate approximation. Actually, the result of Theorem 4.1 shows that u^1 can improve the L^2-accuracy of both NGM and PPGM approximations for almost half order ($\lambda_{m+1}^{-\frac{1}{2}}$).

As is said in Remark 1, u^1 is the ONG-approximate solution given in [11], in which the authors imposed some rigorous conditions on the data of the NSE, for example, $a \in D(A)$ and $f \in L^\infty(\mathcal{R}^+, V)$, and for the periodic case proved for the semidiscrete formula (3.7)–(3.9) (see (101) and (102) in [11]) that

$$|u - u_{mM}^1| \leq c(t)(\lambda_{m+1}^{-2} + \lambda_{M+1}^{-1}).$$

From the result of Theorem 4.1, it is obvious that our conditions on the data are much weaker. Indeed we demand only that $a \in V$ and $f \in L^\infty(\mathcal{R}^+, H)$. And we get almost the same estimate for both periodic and nonslip boundary conditions except for the logarithm term L_m^4, which increases very slowly as $m \to \infty$ and can be regarded as a constant in general circumstances. A more important thing is that we provide a successive correction procedure which can double the convergence rate of the previous approximate solution just as the Newton method does for elliptic problems. Of course, the larger l is, the more accurate the approximate solution is. On the other hand, Theorem 4.1 tells us that for any fixed $T > 0$ and $t \in [0, T]$

$$|u(t) - u^l(t)| \to 0 \qquad \text{as } l \to \infty.$$

That is, to ensure that $u^l(t)$ approximates $u(t)$ uniformly (with respect to certain prescribed error bound) in certain fixed time interval $[0, T]$, we have two choices: enlarge m or choose a large l.

Remark 3. In this paper, we consider only the continuous small eddy correction method. But some intermediate steps in the proofs of Theorems 4.1 and 4.2, i.e., (4.10)–(4.11) and (4.22)–(4.23), give us some suggestions for constructing its full discrete form. Actually, the four inequalities listed above show that the total error $|e|$ (or $|A^{\frac{1}{2}}e|$) of the scheme can be controlled by its small eddy error $|e_q|$ (or $|A^{\frac{1}{2}}e_q|$), and the accuracy of $|e_q|$ (or $|A^{\frac{1}{2}}e_q|$) is always a half-order higher than the large eddy error $|e_p|$ (or $|A^{\frac{1}{2}}e_p|$). To balance this kind of difference and make the full discrete algorithm more effective, one possible choice is to use different time step lengths for large eddy and small eddy equations.

5. Numerical examples. In this section, we will present some numerical examples of the small eddy correction method for dissipative evolutionary PDEs.

The small eddy correction method (3.1)–(3.3), proposed in section 3, is a time continuous scheme and is defined in an infinite-dimensional Hilbert space. In practice, we have to construct its full discrete formulations, that is, to restrict it in a finite-dimensional subspace (for example, see (3.7)–(3.9)) and do time discretization by a finite difference scheme. Of course, we have to investigate its corresponding numerical stability, error analysis, and possible multilevel scheme in time discretization, as was pointed out in Remark 3. We will address these questions elsewhere.

As the first numerical example, we integrate the following one-dimensional Burger equation with the homogeneous Dirichlet boundary condition on $[0, \pi]$. Using notation similar to that of the NSE, we have

$$\frac{du}{dt} + \nu A u + B(u, u) = f, \qquad u(0) = u_0, \tag{5.1}$$

where, in this case, $A = -\frac{\partial^2}{\partial x^2}$ with domain $D(A) = H^2(0,\pi) \cap H_0^1(0,\pi)$ and $B(u,v) = \frac{2}{3}uv_x + \frac{1}{3}u_x v$ for $u, v \in H_0^1(0,\pi)$. The eigenfunctions of A are $\phi_i = \sqrt{2/\pi}\sin(ix)$ with corresponding eigenvalues $\lambda_i = i^2$, $i = 1, 2, \dots$.

We choose an exact solution $u_e(x,t)$ and then compute the time dependent forcing term $f(x,t)$. This makes it possible to compare the numerical solutions with the exact solution without computing a large Galerkin approximation as an "exact" solution. We choose

$$u_e(x,t) = \sum_{j=1}^{\infty} \frac{a_j(t)}{j^3}\sin(jx), \quad a_j(t) = 1 + \gamma\sin(j^2 t).$$

To give a numerical implementation of the small eddy correction for (5.1), we use a spectral method for the space discretization, and the Euler backward scheme for the time discretization, with time step length $\tau > 0$. For any two positive integers $M \gg m$, we have the following two finite-dimensional subspaces:

$$\begin{aligned} H_m &= P_m H = \{\phi_1, \phi_2, \dots, \phi_m\} \quad \text{and} \\ \hat{H}_{mM} &= P_{mM} H = \{\phi_{m+1}, \phi_{m+2}, \dots, \phi_M\}. \end{aligned}$$

Then the corresponding numerical scheme for (5.1) reads: find $v_{n+1} \in H_m$ and $w_{n+1}^k \in \hat{H}_{mM}$, for $k = 1, 2, \dots, l$, such that

$$v_{n+1} - v_n + \nu\tau A v_{n+1} + \tau P_m B(v_{n+1} + w_n^l, v_{n+1} + w_n^l) = \tau P_m f((n+1)\tau), \tag{5.2}$$

$$\begin{aligned} w_{n+1}^k - w_n^k &+ \nu\tau A w_{n+1}^k + \tau P_{mM}[B(v_{n+1}, v_{n+1}) + B(v_{n+1}, w_{n+1}^k) \\ &+ B(w_{n+1}^k, v_{n+1}) + B(w_{n+1}^{k-1}, w_{n+1}^k) + B(w_{n+1}^k, w_{n+1}^{k-1})] \\ &= \tau P_{mM}[f((n+1)\tau) + B(w_{n+1}^{k-1}, w_{n+1}^{k-1})] \qquad \forall 1 \le k \le l, \end{aligned} \tag{5.3}$$

$$v_0 = P_m u_0,\ w_0^i = P_{mM} u_0,\ i = 1, 2, \dots, l,\ l \ge 1, \ \text{ and } \ w_n^0 = 0 \ \text{ for } \ n \ge 0. \tag{5.4}$$

Owing to our limited computing resources, we compute only the u^0 on H_m, u^1 and u^2 on $[H_m, H_M]$. For fixed $m = 2$, we choose a suitable $M > m$ according to the principle that the error of u^1 on $[H_m, H_M]$ will decrease no further when M increases. Here we choose $M = 254$. The time step length is $\tau = 0.001$, and it is determined in a similar manner. That is, for fixed m and M, decreasing k will not improve the accuracy of u^1 any further. Then we can regard the error as mainly determined by the space discretization. We computed the u^0, u^1, and u^2 in time interval $[0, 2]$ for $\nu = 1.0$. Furthermore, as a comparison, we also computed another u^0 on H_{m+M} in this interval. Following are the L^2-error comparison graph (Figure 5.1) and the CPU time table (Table 5.1), which indicates the CPU time used for deriving u^0, u^1, u^2 on H_m, $[H_m, H_M]$ and a large scale u^0 on H_{m+M}.

Note that the curves which represent the error of u^2 on $[H_m, H_M]$ and u^0 on H_{m+M} coincide.

As the second numerical example, we consider the following two-dimensional NSEs in the bounded domain $\Omega = [0,1] \times [0,1]$:

$$\begin{cases} \dfrac{\partial u}{\partial t} - \nu\Delta u + (u \cdot \nabla)u + \nabla p = f, \\ \text{div } u = 0, \quad u|_{t=0} = 0, \\ \text{periodic boundary condition,} \end{cases} \tag{5.5}$$

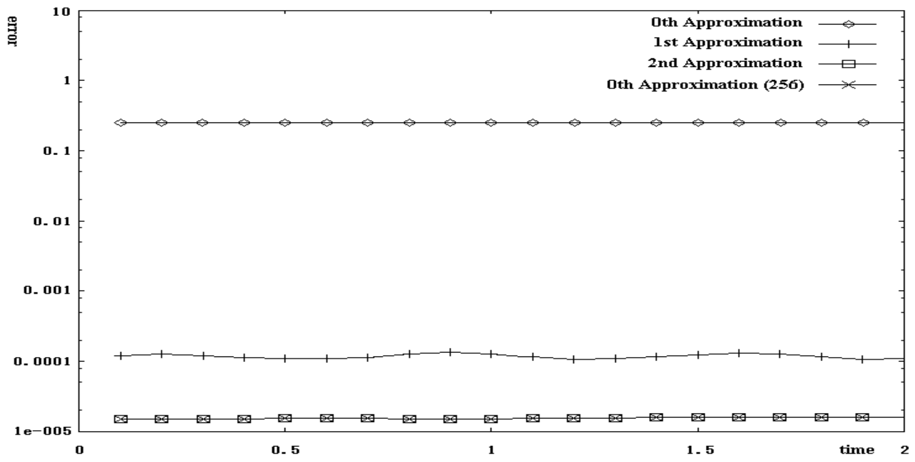

FIG. 5.1. *L^2-error comparison.*

TABLE 5.1
CPU time comparison.

u^0 on H_m	u^1 on $[H_m, H_M]$	u^2 on $[H_m, H_M]$	u^0 on H_{m+M}
0.44 sec	1328.83 sec	7469.48 sec	10054.39 sec

where $\nu = 0.01$ is the kinetic viscosity and $f(t, x, y) = f_1(x, y)(2 + \cos(t))/3$ is the density of the external forces, where $f_1(x, y) = f_1(r, \phi) = (0, f_\phi)^T$,

$$f_\phi(r,\phi) = \begin{cases} \dfrac{1}{8r_+}\displaystyle\int_0^{r_+} \rho(1+\cos(4\rho))^2 d\rho & \text{if } r_+ < \frac{1}{8}, \\ -\dfrac{1}{8r_-}\displaystyle\int_0^{r_-} \rho(1+\cos(4\rho))^2 d\rho & \text{if } r_- < \frac{1}{8}, \\ 0 & \text{otherwise,} \end{cases} \tag{5.6}$$

$r_\pm = |x + iy - (\frac{1}{2}(1+i) \pm \frac{1}{4}e^{i\theta})|$, and $\theta = 0.7$. This external force f represents stirring the fluid in opposite directions at the locations $\frac{1}{2}(1+i) \pm \frac{1}{4}e^{i\theta}$.

In this particular case, if we denote $k = (k_1, k_2)^T \in Z^2$,

$$L^2(\Omega)^2 = \left\{ \phi = \sum_{k\in Z^2, k\neq 0} c_k e^{2\pi i k\cdot x},\ c_k = \overline{c_{-k}},\ \sum_{k\in Z^2, k\neq 0} |c_k|^2 < \infty \right\},$$

$H = PL^2(\Omega)^2$, and $H_m = P_m H$, where, for any $\phi = \sum_{k\in Z^2, k\neq 0} c_k e^{2\pi i k\cdot x} \in L^2(\Omega)^2$,

$$P\phi = \sum_{k\in Z^2, k\neq 0} \left(I - \frac{k\cdot k^T}{|k|^2} \right) c_k e^{2\pi i k\cdot x} \quad \text{and} \quad P_m P\phi = \sum_{0<|k|^2\leq m} \left(I - \frac{k\cdot k^T}{|k|^2} \right) c_k e^{2\pi i k\cdot x}.$$

Projecting the above equations onto H, we can get its functional form (1.1), and its fully discrete form is completely the same as (5.2)–(5.4). Considering the computing scale, we take

$$m = 9^2, \quad M = 19^2, \quad \text{and} \quad \tau = 0.005.$$

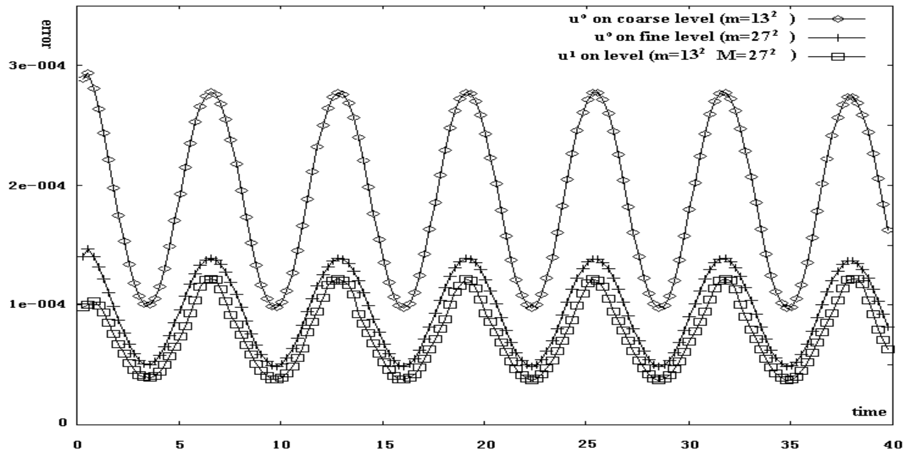

FIG. 5.2. *H^1-error comparison.*

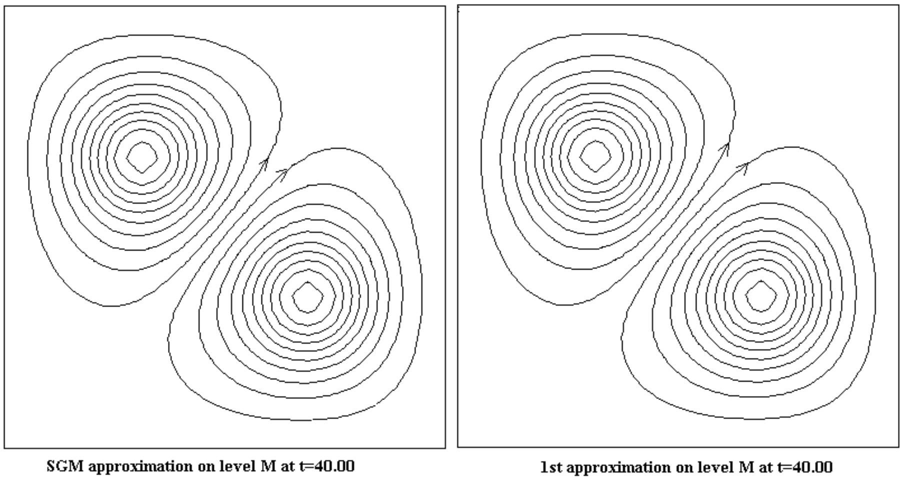

SGM approximation on level M at t=40.00

1st approximation on level M at t=40.00

FIG. 5.3. *H^1-streamline graphs.*

We compute only u^0 (with $|k_1|, |k_2| \leq \sqrt{m}$) and u^1 (with $|k_1|, |k_2| \leq \sqrt{M}$). To get the error of these numerical results, we compute another u^0 (with $|k_1|, |k_2| \leq \sqrt{\tilde{M}}$) on a larger finite-dimensional subspace $H_{\tilde{M}}$ with $\tilde{M} = 39^2$ and regard it as the "exact" solution.

In Figures 5.2 and 5.3, we give the H^1-error curves of u^0 on H_m and H_M and u^1 on $[H_m, H_M]$, and the streamline graphs of u^0 on H_M and u^1 on $[H_m, H_M]$ at $t = 40$. Here the CPU time used by u^1 on $[H_m, H_M]$ is less than one-half of the CPU time used by u^0 on H_M.

From the error comparison of Figures 5.1 and 5.2, we can easily find that both u^1 and u^2 can greatly improve the accuracy of u^0, the SGM approximation, with less CPU time than the large scale SGM approximation. If the CPU time is what we care about, we would prefer the 1st approximation u^1. However, if we care more about the accuracy of the approximate solution, we prefer a higher order approximation like u^2.

Acknowledgment. We are grateful to the two anonymous referees for their many helpful corrections, suggestions, and comments.

STABILIZED FINITE ELEMENTS ON ANISOTROPIC MESHES: A PRIORI ERROR ESTIMATES FOR THE ADVECTION-DIFFUSION AND THE STOKES PROBLEMS*

STEFANO MICHELETTI†, SIMONA PEROTTO†, AND MARCO PICASSO‡

Abstract. Stabilized finite elements on strongly anisotropic meshes are considered. The design of the stability coefficients is addressed for both the advection-diffusion and the Stokes problems when using continuous piecewise linear finite elements on triangles. Using the polar decomposition of the Jacobian of the affine mapping from the reference triangle to the current one, K, and from a priori error estimates, a new definition of the stability coefficients is proposed. Our analysis shows that these coefficients do not depend on the element diameter h_K but on a characteristic length associated with K via the polar decomposition. A numerical assessment of the theoretical analysis is carried out.

Key words. anisotropic error estimates, advection-diffusion problems, Stokes problem, stabilized finite elements

1. Introduction.

Stabilized finite elements like the Galerkin least squares (GLS) method are currently widely used in the finite element community. The goal is to employ simple finite element approximations (for instance, continuous piecewise linear) while ensuring stability of the method through extra (consistent) terms in the weak formulation.

Stabilized finite elements have been used, for instance, in [21] for solving the Stokes problem and in [16, 22, 29] for the approximation of the scalar advection-diffusion problem. Extensions to the Navier–Stokes equations have been proposed in [11, 23, 24]. Finally, stabilized finite elements have been also successfully applied to other complex problems such as viscoelastic flows [3, 6, 7], shells [12], magnetohydrodynamics [26], and semiconductors [33].

The critical issue in stabilized finite elements is the design of the so-called stability coefficients weighting the extra terms added to the weak formulation. These coefficients typically depend on some dimensionless numbers usually tuned on benchmark problems and on the local mesh size h_K, K being a mesh element. A theoretical estimation of these quantities is proposed in [25, 28] for isotropic meshes. An alternative approach consists of stabilizing via the residual-free bubble theory [9, 10, 39]. This method has the advantage of providing a self-consistent expression for the stability coefficients with no tuning parameters.

As far as we know, however, few papers have dealt with the design of the stability coefficients for strongly anisotropic meshes. In all cases, these quantities are related to some minimum size associated with each element and whose definition varying from work to work seems to be relevant for the anisotropic analysis. In [2] an anisotropic

a priori error analysis is provided for the advection–diffusion-reaction problem. It is shown that the height, say $\widetilde{h}_K$, with respect to the diameter of each element K, should be used for the design of the stability coefficient in the case of external boundary layers. The analysis is carried out for finite elements of arbitrary order but is restricted by a maximal angle condition and a coordinate system condition which may be a limitation in the framework of adaptivity. In [31] an alternative approach is proposed showing that $\widetilde{h}_K$ is again the correct choice. In this analysis, however, the interpolation constants depend on the alignment between the stretching direction of the mesh and the solution. In [40] an a posteriori error estimator for anisotropically refined grids as well as interpolation estimates are introduced, in which the minimum size of the elements parallel to the coordinate system plays a major role. In [4, 5] the authors consider the stabilization of the Stokes problem in the case of the Q_1/Q_1 pair of finite elements on anisotropic quadrilateral meshes aligned with the Cartesian coordinate axes. The stabilizing term is a variant to the one considered in the present work and takes into account both mesh spacings along the axes of the coordinate system; see section 4. Furthermore, in [36] numerical experiments show that good results can be obtained when using the minimum edge length instead of h_K.

In this paper an alternative technique is introduced based on the anisotropic interpolation error estimates derived in [18]. The maximal angle and the coordinate system conditions of [2] are avoided. Moreover, the interpolation constants depend only on the reference element (or alternatively on the reference patch), and the information about the alignment between the stretching direction of the mesh and the solution appears explicitly in the right-hand side of the estimates through some anisotropic weightings of the first or second order derivatives of the solution.

Namely, the scalar advection-diffusion and the Stokes problems are addressed with approximations based on continuous piecewise linear finite elements. Following the a priori error analysis of [20, 21, 22] and using the anisotropic interpolation estimates of [18, 19], new definitions of the stability coefficients are proposed. Numerical results confirm the theoretical predictions. Notice that the recipe derived in the present paper has already been employed in anisotropic a posteriori error analyses for both the advection-diffusion and the Stokes problem [37, 17].

The outline of the paper is as follows. In section 2 we introduce the anisotropic framework of [18]. Next, after recalling some of the results derived in [18], we prove some further anisotropic estimates upon which we develop the a priori analysis in sections 3 and 4 for the advection-diffusion and the Stokes problems, respectively. Finally, numerical results are presented in section 5.

2. Anisotropic and functional setting.

Let Ω be a polygonal domain of $\mathbb{R}^2$. For any $0 < h \leq 1$, let $\{\mathcal{T}_h\}_h$ be a family of conforming triangulations of $\overline{\Omega}$ into triangles K of diameter $h_K \leq h$. Since we are working with strongly anisotropic meshes, however, the standard regularity assumption in [13] does not hold in our analysis. Let $T_K : \widehat{K} \to K$ be the affine transformation which maps the reference triangle $\widehat{K}$ into K, where $\widehat{K}$ can be, e.g., the right triangle $(0,0), (1,0), (0,1)$ or the equilateral one $(-1/2, 0), (1/2, 0), (0, \sqrt{3}/2)$. In either case let $M_K \in \mathbb{R}^{2\times 2}$ be the Jacobian of T_K, that is,

$$\mathbf{x} = T_K(\widehat{\mathbf{x}}) = M_K \widehat{\mathbf{x}} + \mathbf{t}_K,$$

with $\mathbf{t}_K \in \mathbb{R}^2$, $\mathbf{x} = (x_1, x_2)^T \in K$, and $\widehat{\mathbf{x}} = (\widehat{x}_1, \widehat{x}_2)^T \in \widehat{K}$. Since M_K is invertible, it admits a unique polar decomposition $M_K = B_K Z_K$, where B_K and Z_K are symmetric

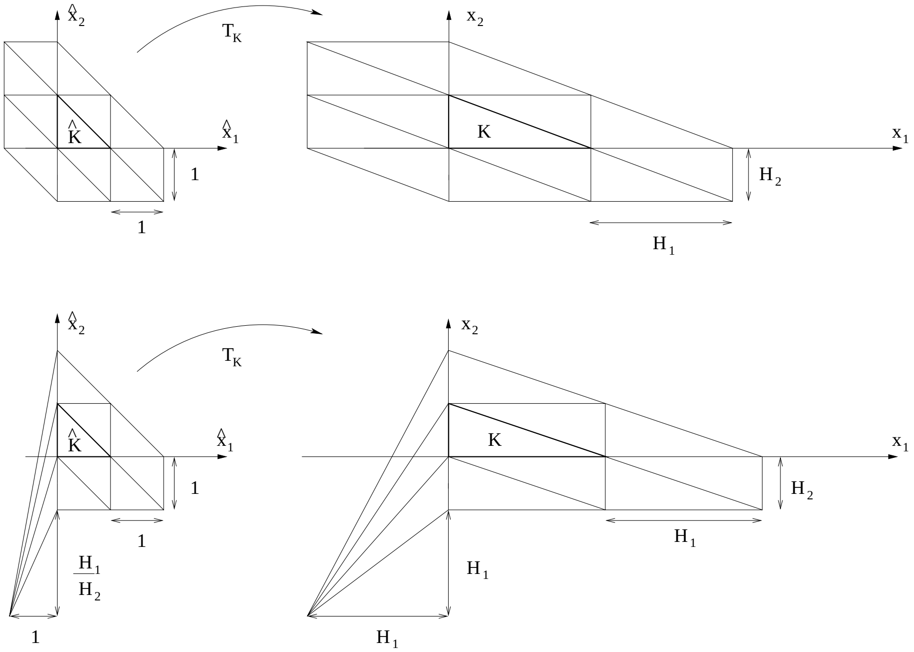

FIG. 2.1. *Example of an acceptable patch (top): the size of the reference patch $\Delta_{\widehat{K}}$ does not depend on the aspect ratio H_1/H_2. Example of a nonacceptable patch (bottom): the size of the reference patch $\Delta_{\widehat{K}}$ now depends on the aspect ratio H_1/H_2. Notice that in both cases $\mathbf{r}_{1,K} = (1,0)^T$, $\mathbf{r}_{2,K} = (0,1)^T$, $\lambda_{1,K} = H_1$, and $\lambda_{2,K} = H_2$.*

positive definite and orthogonal matrices, respectively (see, e.g., [27]). Moreover, B_K can be factorized as $B_K = R_K^T \Lambda_K R_K$, where Λ_K is diagonal with positive entries and R_K is orthogonal. Thus let

$$\Lambda_K = \begin{bmatrix} \lambda_{1,K} & 0 \\ 0 & \lambda_{2,K} \end{bmatrix} \quad \text{and} \quad R_K = \begin{bmatrix} \mathbf{r}_{1,K}^T \\ \mathbf{r}_{2,K}^T \end{bmatrix},$$

where $\lambda_{1,K}$, $\lambda_{2,K}$ (with $\lambda_{1,K} \geq \lambda_{2,K}$) and $\mathbf{r}_{1,K}$, $\mathbf{r}_{2,K}$ are the eigenvalues and the eigenvectors of B_K, respectively.

For any $K \in \mathcal{T}_h$, let us define the stretching factor $s_K = \lambda_{1,K}/\lambda_{2,K} (\geq 1)$, measuring the deformation of K with respect to $\widehat{K}$ for which $s_{\widehat{K}} = 1$, and let Δ_K be the union of all the elements sharing a vertex with K. In view of the use of Clément-type interpolation operators, we assume throughout that the cardinality of any patch Δ_K as well as the diameter of the reference patch $\Delta_{\widehat{K}} = T_K^{-1}(\Delta_K)$ are uniformly bounded independently of the geometry of the mesh; i.e., for any $K \in \mathcal{T}_h$,

$$\text{card}(\Delta_K) \leq \Gamma \quad \text{and} \quad \text{diam}(\Delta_{\widehat{K}}) \leq \widehat{C} \simeq O(1), \tag{2.1}$$

where $\widehat{C} \geq h_{\widehat{K}}$. In particular, the latter hypothesis rules out some too distorted reference patches (see Figure 2.1, where examples of acceptable and nonacceptable patches are shown).

Remark 1. Throughout we express the dependence of any constant through an explicit list. For example, $C = C(\widehat{K})$ is a constant depending only on the geometry of the reference triangle $\widehat{K}$, and $C = C(\Gamma, \widehat{C})$ is a constant taking into account the assumptions (2.1), while C is a number not depending on any geometrical quantity whatsoever. Moreover, notice that in what follows any constant C can take on different values at different occurrences.

Finally, for any function v defined on K, we let $\widehat{v}$ be the corresponding function defined on $\widehat{K}$ via the map T_K, i.e., $\widehat{v}(\widehat{\mathbf{x}}) = v(T_K(\widehat{\mathbf{x}}))$.

Let us introduce now the functional spaces used in what follows. First, let $C^k(\overline{\Omega})$, where the integer $k \geq 0$, be the space of functions with continuous derivatives in $\overline{\Omega}$ up to the kth order. We denote $L^2(\Omega)$ the space of the Lebesgue square-integrable functions with norm $\|\cdot\|_{L^2(\Omega)}$ and scalar product $(\cdot,\cdot)$. Moreover, the space $L^2_0(\Omega)$ denotes the subspace of $L^2(\Omega)$ of functions with zero average over Ω.

Let $W^{k,p}(\Omega)$ be the classical Sobolev spaces of Lebesgue-measurable functions, with k a nonnegative integer and $1 \leq p \leq \infty$ [32].

In the case of scalar valued functions, we denote $H^k(\Omega)$ the space $W^{k,2}(\Omega)$ with norm and seminorm $\|\cdot\|_{H^k(\Omega)}$ and $|\cdot|_{H^k(\Omega)}$, respectively. Then the norm of the space $W^{0,\infty}(\Omega)$, i.e., $L^\infty(\Omega)$, is denoted $\|\cdot\|_{L^\infty(\Omega)}$. When the norms or seminorms refer to some subspace S of Ω, they are written as $\|\cdot\|_{H^k(S)}$, $|\cdot|_{H^k(S)}$, $\|\cdot\|_{L^\infty(S)}$, while the scalar products are denoted $(\cdot,\cdot)_S$.

In the case of functions with values in $\mathbb{R}^2$, we use the same notation for the norms and scalar products as those for the scalar case by replacing the corresponding Sobolev spaces with $(H^k(\Omega))^2$, $(L^2(\Omega))^2$, etc.

Finally, in the case $k=1$ we let $H^1_0(\Omega)$ and $(H^1_0(\Omega))^2$ be the subspaces of $H^1(\Omega)$ and $(H^1(\Omega))^2$, respectively, satisfying homogeneous Dirichlet boundary conditions on the boundary $\partial\Omega$ of Ω.

2.1. Anisotropic interpolation estimates. This subsection provides a continuation of the analysis developed in [18], where anisotropic interpolation error estimates are derived starting from the decompositions described above. In more detail, after recalling some of the results in [18] (see Lemmas 2.1–2.4), we prove some further anisotropic inequalities in view of the convergence analysis of sections 3 and 4 (see Propositions 2.5 and 2.6 and Corollary 2.7).

The results below can be found in the proofs of Lemmas 2.2 and 2.1 in [18].

LEMMA 2.1. *For any function $v \in H^1(\Omega)$ and for any $K \in \mathcal{T}_h$, the relations*

$$|\widehat{v}|_{H^1(\widehat{K})} = \left[s_K \,\|\nabla v \cdot \mathbf{r}_{1,K}\|^2_{L^2(K)} + \frac{1}{s_K}\,\|\nabla v \cdot \mathbf{r}_{2,K}\|^2_{L^2(K)} \right]^{1/2}, \tag{2.2}$$

$$|v|_{H^1(K)} \leq s_K^{1/2} |\widehat{v}|_{H^1(\widehat{K})} \tag{2.3}$$

can be proved.

LEMMA 2.2. *For any function $v \in H^2(\Omega)$ and for any $K \in \mathcal{T}_h$, the following identity holds:*

$$\begin{aligned}|\widehat{v}|^2_{H^2(\widehat{K})} = {} & \frac{\lambda^3_{1,K}}{\lambda_{2,K}}\, L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{1,K};\, v) + \frac{\lambda^3_{2,K}}{\lambda_{1,K}}\, L_K(\mathbf{r}_{2,K},\, \mathbf{r}_{2,K};\, v) \\ & + 2\,\lambda_{1,K}\,\lambda_{2,K} L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{2,K};\, v),\end{aligned}$$

where

$$L_K(\mathbf{r}_{i,K},\, \mathbf{r}_{j,K};\, v) = \int_K \left(\mathbf{r}^T_{i,K}\, H_K(v)\, \mathbf{r}_{j,K}\right)^2 d\mathbf{x}, \quad \textit{with } i,\, j = 1,\, 2, \tag{2.4}$$

and $H_K(v)$ is the Hessian matrix associated with the function v (restricted to K)

$$H_K(v) = \begin{bmatrix} \dfrac{\partial^2 v}{\partial x_1^2} & \dfrac{\partial^2 v}{\partial x_1 \partial x_2} \\ \dfrac{\partial^2 v}{\partial x_1 \partial x_2} & \dfrac{\partial^2 v}{\partial x_2^2} \end{bmatrix}.$$

After introducing the finite element space W_h comprising continuous affine elements, let $r_h : C^0(\overline{\Omega}) \to W_h$ and $R_h : L^2(\Omega) \to W_h$ be the standard Lagrange and Clément linear interpolants, respectively, and let their restrictions to each element $K \in \mathcal{T}_h$ be denoted r_K and R_K. Then the results below can be proved (see Propositions 3.2, 3.1, and 2.1 in [18]).

LEMMA 2.3. *Let $v \in H^1(\Omega)$. Then there exists a constant $C = C(\Gamma, \widehat{C})$ such that, for any $K \in \mathcal{T}_h$,*

$$\|v - R_K(v)\|_{L^2(K)} \leq C\, [\lambda_{1,K}^2 (\mathbf{r}_{1,K}^T\, G_K(v)\, \mathbf{r}_{1,K}) + \lambda_{2,K}^2 (\mathbf{r}_{2,K}^T\, G_K(v)\, \mathbf{r}_{2,K})]^{1/2},$$

$G_K(v)$ being the symmetric positive semidefinite matrix in $\mathbb{R}^{2\times 2}$ given by

$$G_K(v) = \sum_{T\in\Delta_K} \begin{bmatrix} \displaystyle\int_T \left(\frac{\partial v}{\partial x_1}\right)^2 d\mathbf{x} & \displaystyle\int_T \frac{\partial v}{\partial x_1}\frac{\partial v}{\partial x_2}\, d\mathbf{x} \\ \displaystyle\int_T \frac{\partial v}{\partial x_1}\frac{\partial v}{\partial x_2}\, d\mathbf{x} & \displaystyle\int_T \left(\frac{\partial v}{\partial x_2}\right)^2 d\mathbf{x} \end{bmatrix}. \tag{2.5}$$

LEMMA 2.4. *Let $v \in H^2(\Omega)$. Then there exist two constants $C_1 = C_1(\widehat{K})$ and $C_2 = C_2(\widehat{K})$ such that, for any $K \in \mathcal{T}_h$,*

$$\begin{aligned} \|v - r_K(v)\|_{L^2(K)} \leq C_1\, [&\lambda_{1,K}^4\, L_K(\mathbf{r}_{1,K}, \mathbf{r}_{1,K}; v) + \lambda_{2,K}^4\, L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K}; v) \\ &+ 2\, \lambda_{1,K}^2 \lambda_{2,K}^2\, L_K(\mathbf{r}_{1,K}, \mathbf{r}_{2,K}; v)]^{1/2}, \end{aligned} \tag{2.6}$$

$$\begin{aligned} |v - r_K(v)|_{H^1(K)} \leq C_2 \Bigg[&\frac{\lambda_{1,K}^4}{\lambda_{2,K}^2}\, L_K(\mathbf{r}_{1,K}, \mathbf{r}_{1,K}; v) + \lambda_{2,K}^2\, L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K}; v) \\ &+ 2\, \lambda_{1,K}^2\, L_K(\mathbf{r}_{1,K}, \mathbf{r}_{2,K}; v)\Bigg]^{1/2}, \end{aligned} \tag{2.7}$$

the quantities $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; v)$ being defined in (2.4).

We are now ready to prove the new anisotropic results used in the convergence analysis of the advection-diffusion and the Stokes problems.

PROPOSITION 2.5. *For any $v \in H^1(\Omega)$, there exists a constant $C = C(\Gamma, \widehat{C})$ such that, for any $K \in \mathcal{T}_h$,*

$$|v - R_K(v)|_{H^1(K)} \leq C \left[\frac{\lambda_{1,K}^2}{\lambda_{2,K}^2} (\mathbf{r}_{1,K}^T\, G_K(v)\, \mathbf{r}_{1,K}) + (\mathbf{r}_{2,K}^T\, G_K(v)\, \mathbf{r}_{2,K})\right]^{1/2}, \tag{2.8}$$

$G_K(v)$ being the matrix defined in (2.5).

Proof. Applying relation (2.3) to the interpolation error $(v - R_K(v))$, we get

$$|v - R_K(v)|_{H^1(K)} \leq s_K^{1/2}\, |\widehat{v} - R_{\widehat{K}}(\widehat{v})|_{H^1(\widehat{K})}, \tag{2.9}$$

where $[R_K(v)]\hat{} = R_{\widehat{K}}(\widehat{v})$ (see [18] for a proof of this last equality). Exploiting the result

$$|v - R_T(v)|_{H^1(T)} \le C\, |v|_{H^1(\Delta_T)}, \quad \text{for any } v \in H^1(\Omega) \text{ and for any } T \in \mathcal{T}_h,$$

of the theory of Clément [14] in the right-hand side of (2.9) (identifying T with $\widehat{K}$) yields

$$|v - R_K(v)|^2_{H^1(K)} \le C\, s_K\, |\widehat{v}|^2_{H^1(\Delta_{\widehat{K}})} = C\, s_K \sum_{\widehat{T}\in\Delta_{\widehat{K}}} |\widehat{v}|^2_{H^1(\widehat{T})}. \tag{2.10}$$

By applying (2.2) to each seminorm $|\widehat{v}|_{H^1(\widehat{T})}$ in (2.10), we get

$$|v - R_K(v)|^2_{H^1(K)} \le C\, s_K \sum_{T\in\Delta_K} \left(s_K\, \|\nabla v\cdot \mathbf{r}_{1,K}\|^2_{L^2(T)} + \frac{1}{s_K}\, \|\nabla v\cdot \mathbf{r}_{2,K}\|^2_{L^2(T)} \right),$$

that is, observing that

$$\sum_{T\in\Delta_K} \|\nabla v\cdot \mathbf{r}_{i,\,K}\|^2_{L^2(T)} = \mathbf{r}^T_{i,\,K}\, G_K(v)\, \mathbf{r}_{i,\,K} \quad \text{for } i = 1,\, 2, \tag{2.11}$$

the desired inequality (2.8). □

Proposition 2.6 establishes an anisotropic relation between the H^2-seminorms of v and $\widehat{v}$ defined on K and $\widehat{K}$, respectively.

PROPOSITION 2.6. *For any function $v \in H^2(K)$ and for any $K \in \mathcal{T}_h$, the following inequalities hold:*

$$\frac{\lambda^{1/2}_{1,K}\,\lambda^{1/2}_{2,K}}{(\lambda^2_{1,K} + \lambda^2_{2,K})}\, |\widehat{v}|_{H^2(\widehat{K})} \le |v|_{H^2(K)} \le \frac{(\lambda^2_{1,K} + \lambda^2_{2,K})}{\lambda^{3/2}_{1,K}\,\lambda^{3/2}_{2,K}}\, |\widehat{v}|_{H^2(\widehat{K})}. \tag{2.12}$$

Proof. Let us begin by proving the upper bound of (2.12). Let $H_{\widehat{K}}(\widehat{v})$ and $H_K(v)$ be the Hessian matrices associated with $\widehat{v}$ and v and referred to as the elements $\widehat{K}$ and K, respectively. Then the following relation holds:

$$H_K(v) = (M_K^{-1})^T\, H_{\widehat{K}}(\widehat{v})\, M_K^{-1}.$$

Let us consider the Frobenius norm $\|\cdot\|_F$ of $H_K(v)$ while exploiting the decompositions introduced above for the matrices M_K and B_K. We get

$$\|H_K(v)\|_F = \|B_K^{-1}\, Z_K\, H_{\widehat{K}}(\widehat{v})\, Z_K^T\, B_K^{-1}\|_F = \|\Lambda_K^{-1}\, R_K\, Z_K\, H_{\widehat{K}}(\widehat{v})\, Z_K^T\, R_K^T\, \Lambda_K^{-1}\|_F,$$

as the Frobenius norm is invariant with respect to orthogonal matrices. Using the relation between the Frobenius norm of the Hessian matrix $H_K(v)$ and the H^2-seminorm of v on K yields

$$\begin{aligned} |v|^2_{H^2(K)} &= \int_K \|H_K(v)\|^2_F\, d\mathbf{x} = \int_K \|\Lambda_K^{-1}\, R_K\, Z_K\, H_{\widehat{K}}(\widehat{v})\, Z_K^T\, R_K^T\, \Lambda_K^{-1}\|_F\, d\mathbf{x} \\ &= \int_K \|\Lambda_K^{-1}\, P_K\, H_{\widehat{K}}(\widehat{v})\, P_K^T\, \Lambda_K^{-1}\|_F\, d\mathbf{x}, \end{aligned} \tag{2.13}$$

where the orthogonal matrix $P_K = R_K\, Z_K$ has been introduced in order to simplify the notation. Let us also denote Q_K the matrix

$$Q_K = \Lambda_K^{-1}\, P_K = \begin{bmatrix} \mathbf{q}_{1,K}^T \\ \mathbf{q}_{2,K}^T \end{bmatrix}, \quad \text{with } \mathbf{q}_{i,K} = \frac{1}{\lambda_{i,K}}\, \mathbf{p}_{i,K} \tag{2.14}$$

and where $\mathbf{p}_{i,K}$ are the columns of the matrix P_K, with $i = 1, 2$. Notice that, from a geometric viewpoint, matrix Q_K simply identifies a rotation followed by a rescaling of the coordinate axes. Introducing (2.14) into (2.13), the chain of equalities below may be inferred:

(2.15)

$$\begin{aligned}
|v|^2_{H^2(K)} &= \int_K \|Q_K\, H_{\widehat{K}}(\widehat{v})\, Q_K^T\|_F^2\, d\mathbf{x} \\
&= \int_K \left\{(\mathbf{q}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{q}_{1,K})^2 + (\mathbf{q}_{2,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{q}_{2,K})^2 + 2(\mathbf{q}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\mathbf{q}_{2,K})^2\right\} d\mathbf{x} \\
&= \frac{1}{\lambda_{1,K}^4} \int_K (\mathbf{p}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{1,K})^2\, d\mathbf{x} + \frac{1}{\lambda_{2,K}^4} \int_K (\mathbf{p}_{2,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{2,K})^2\, d\mathbf{x} \\
&+ \frac{2}{\lambda_{1,K}^2\, \lambda_{2,K}^2} \int_K (\mathbf{p}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{2,K})^2\, d\mathbf{x} \\
&= \frac{\lambda_{2,K}}{\lambda_{1,K}^3} \int_{\widehat{K}} (\mathbf{p}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{1,K})^2\, d\hat{\mathbf{x}} + \frac{\lambda_{1,K}}{\lambda_{2,K}^3} \int_{\widehat{K}} (\mathbf{p}_{2,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{2,K})^2\, d\hat{\mathbf{x}} \\
&+ \frac{2}{\lambda_{1,K}\, \lambda_{2,K}} \int_{\widehat{K}} (\mathbf{p}_{1,K}^T\, H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{2,K})^2\, d\hat{\mathbf{x}},
\end{aligned}$$

the last sum having been obtained by expressing the integrals over the generic element K in terms of the integrals over the reference triangle $\widehat{K}$.

Let us bound the integrals of the last sum in (2.15), suitably rewriting the terms $(\mathbf{p}_{i,K}^T H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{j,K})$ for i, $j = 1, 2$. These terms are scalar products between the vectors $\mathbf{p}_{i,K}$ and $H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{j,K}$; then we have

$$\begin{aligned}
\mathbf{p}_{i,K}^T H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{j,K} &\le \|\mathbf{p}_{i,K}\|\, \|H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{j,K}\| \\
&\le \|\mathbf{p}_{i,K}\|\, \|H_{\widehat{K}}(\widehat{v})\|_F\, \|\mathbf{p}_{j,K}\| = \|H_{\widehat{K}}(\widehat{v})\|_F,
\end{aligned} \tag{2.16}$$

where $\|\cdot\|$ is the Euclidean norm and the relations $\|\mathbf{p}_{i,K}\| = 1$ for $i = 1, 2$, together with the compatibility of the Frobenius norm with the Euclidean one, have been used. Thus, by exploiting the relation between the Frobenius norm of $H_{\widehat{K}}(\widehat{v})$ and the H^2-seminorm $|\widehat{v}|_{H^2(\widehat{K})}$ as in (2.13), we obtain

$$\int_{\widehat{K}} (\mathbf{p}_{i,K}^T H_{\widehat{K}}(\widehat{v})\, \mathbf{p}_{j,K})^2\, d\hat{\mathbf{x}} \le \int_{\widehat{K}} \|H_{\widehat{K}}(\widehat{v})\|_F^2\, d\hat{\mathbf{x}} = |\widehat{v}|^2_{H^2(\widehat{K})} \tag{2.17}$$

for i, $j = 1$, 2. Substituting this result into (2.15), we deduce that

$$|v|^2_{H^2(K)} \le \left[\frac{\lambda_{2,K}}{\lambda_{1,K}^3} + \frac{\lambda_{1,K}}{\lambda_{2,K}^3} + \frac{2}{\lambda_{1,K}\, \lambda_{2,K}}\right] |\widehat{v}|^2_{H^2(\widehat{K})} = \frac{(\lambda_{1,K}^2 + \lambda_{2,K}^2)^2}{\lambda_{1,K}^3\, \lambda_{2,K}^3}\, |\widehat{v}|^2_{H^2(\widehat{K})},$$

that is, the upper bound in (2.12).

Let us verify now the lower bound of (2.12) moving from Lemma 2.2. As the calculations in (2.16) and (2.17) can be repeated on the terms $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; v)$ (with $i, j = 1, 2$) simply by identifying $\mathbf{r}_{i,K}$ with $\mathbf{p}_{i,K}$, $H_K(v)$ with $H_{\widehat{K}}(\widehat{v})$, and K with $\widehat{K}$, we obtain

$$|\widehat{v}|^2_{H^2(\widehat{K})} \le \left[\frac{\lambda^3_{1,K}}{\lambda_{2,K}} + \frac{\lambda^3_{2,K}}{\lambda_{1,K}} + 2\lambda_{1,K}\,\lambda_{2,K}\right] |v|^2_{H^2(K)} \le \frac{(\lambda^2_{1,K} + \lambda^2_{2,K})^2}{\lambda_{1,K}\,\lambda_{2,K}}\,|v|^2_{H^2(K)},$$

which immediately provides the inequality in the left-hand side of (2.12). □

We are now in a position to bound the H^2-seminorm of a generic function $v \in H^2(K)$ in terms of the anisotropic quantities $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; v)$ defined in (2.4).

COROLLARY 2.7. *For any function $v \in H^2(K)$ and for any $K \in \mathcal{T}_h$, we have*

$$(2.18)\qquad \begin{aligned} |v|_{H^2(K)} \le (\lambda^2_{1,K} + \lambda^2_{2,K}) \Bigg[&\frac{1}{\lambda^4_{2,K}} L_K(\mathbf{r}_{1,K}, \mathbf{r}_{1,K}; v) \\ &+ \frac{1}{\lambda^4_{1,K}} L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K}; v) + \frac{2}{\lambda^2_{1,K}\,\lambda^2_{2,K}} L_K(\mathbf{r}_{1,K}, \mathbf{r}_{2,K}; v) \Bigg]^{1/2}, \end{aligned}$$

where the quantities $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; v)$ are defined in (2.4).

Proof. Let us start from the upper bound in Proposition 2.6. By adding the anisotropic information provided by Lemma 2.2, we get

$$\begin{aligned} |v|^2_{H^2(K)} \le\ & \frac{(\lambda^2_{1,K} + \lambda^2_{2,K})^2}{\lambda^4_{2,K}} L_K(\mathbf{r}_{1,K}, \mathbf{r}_{1,K}; v) + \frac{(\lambda^2_{1,K} + \lambda^2_{2,K})^2}{\lambda^4_{1,K}} L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K}; v) \\ &+ 2\,\frac{(\lambda^2_{1,K} + \lambda^2_{2,K})^2}{\lambda^2_{1,K}\,\lambda^2_{2,K}} L_K(\mathbf{r}_{1,K}, \mathbf{r}_{2,K}; v), \end{aligned}$$

which is exactly result (2.18) after simple algebraic manipulations. □

Remark 2 (anisotropic interpolation estimates for vector valued functions). All of the interpolation estimates obtained above can be easily generalized to the case when $\mathbf{v} : \Omega \to \mathbb{R}^2$. In this case, the above results still hold formally, provided that the terms $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; v)$ and $G_K(v)$ defined in (2.4) and (2.5), respectively, are replaced by the new ones, $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; \mathbf{v})$ and $G_K(\mathbf{v})$, given by

$$(2.19)\qquad L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; \mathbf{v}) = \sum_{l=1,2} \int_K \left(\mathbf{r}^T_{i,K}\, H_K(v_l)\, \mathbf{r}_{j,K}\right)^2 d\mathbf{x}, \quad \text{with } i, j = 1, 2,$$

$$\begin{aligned} G_K(\mathbf{v}) &= \sum_{l=1,2} \sum_{T \in \Delta_K} \begin{bmatrix} \displaystyle\int_T \left(\frac{\partial v_l}{\partial x_1}\right)^2 d\mathbf{x} & \displaystyle\int_T \frac{\partial v_l}{\partial x_1}\frac{\partial v_l}{\partial x_2}\, d\mathbf{x} \\ \displaystyle\int_T \frac{\partial v_l}{\partial x_1}\frac{\partial v_l}{\partial x_2}\, d\mathbf{x} & \displaystyle\int_T \left(\frac{\partial v_l}{\partial x_2}\right)^2 d\mathbf{x} \end{bmatrix} \\ &= \sum_{T \in \Delta_K} \begin{bmatrix} \displaystyle\int_T \frac{\partial \mathbf{v}}{\partial x_1} \cdot \frac{\partial \mathbf{v}}{\partial x_1}\, d\mathbf{x} & \displaystyle\int_T \frac{\partial \mathbf{v}}{\partial x_1} \cdot \frac{\partial \mathbf{v}}{\partial x_2}\, d\mathbf{x} \\ \displaystyle\int_T \frac{\partial \mathbf{v}}{\partial x_1} \cdot \frac{\partial \mathbf{v}}{\partial x_2}\, d\mathbf{x} & \displaystyle\int_T \frac{\partial \mathbf{v}}{\partial x_2} \cdot \frac{\partial \mathbf{v}}{\partial x_2}\, d\mathbf{x} \end{bmatrix}, \end{aligned}$$

where v_l, for $l = 1, 2$, are the Cartesian components of $\mathbf{v}$.

For alternative anisotropic interpolation error estimates see [1, 4, 30, 40].

3. The advection-diffusion problem.

In this section we focus our attention on the scalar advective-diffusive model. Starting from the formulation of stabilized methods presented in [22], we readdress the question of a careful design for the stability coefficients, crucial for the good performance of these methods, in the framework of anisotropic meshes.

In particular, we extend the results obtained in [22], where an expression for the stability coefficients in the whole range varying from advective to diffusive dominated flows is introduced, to the case of (possibly) highly stretched elements. In [2] an anisotropic a priori error analysis is provided for the advection–diffusion-reaction problem in the case of finite elements of arbitrary order, but the results obtained are limited by a maximal angle condition and a coordinate system condition. We consider only the case of affine finite elements so that the stabilized methods, such as GLS, SUPG [11, 29], and the method proposed in [15], do coincide with each other.

We study the convergence of the stabilized method in a mesh dependent norm, taking into account also the stability coefficients. The optimal value for these is obtained by error analysis considerations by requiring that the convergence rate, in both the advective and the diffusive dominated regimes, is of maximal order.

Theorem 3.1 is the main result of this section.

3.1. Problem statement and finite element discretization.

Let us consider the standard advection-diffusion problem for the scalar field $u = u(\mathbf{x})$

$$\begin{cases} -\mu\,\Delta u + \mathbf{a}\cdot\nabla u = f & \text{in } \Omega, \\ u = 0 & \text{on } \partial\Omega, \end{cases} \tag{3.1}$$

where $\mu = \text{const} > 0$ is the diffusivity, $\mathbf{a} = \mathbf{a}(\mathbf{x}) \in (C^1(\overline{\Omega}))^2$ is the given flow velocity with $\nabla\cdot\mathbf{a} = 0$ in Ω, and $f = f(\mathbf{x}) \in L^2(\Omega)$ is the source term.

The variational formulation of problem (3.1) reads as follows: find $u \in H_0^1(\Omega)$ which satisfies

$$B(u, v) = F(v) \quad \text{for any } v \in H_0^1(\Omega), \tag{3.2}$$

where $B(\cdot,\cdot)$ and $F(\cdot)$ define the bilinear and linear forms

$$B(u, v) = (\mu\,\nabla u,\, \nabla v) + (\mathbf{a}\cdot\nabla u,\, v) \quad \text{and} \quad F(v) = (f,\, v), \tag{3.3}$$

respectively, for any u and $v \in H_0^1(\Omega)$.

As we are interested in advection dominated problems, we discretize problem (3.2) by a stabilized finite element approach (GLS) [29]. The discrete problem thus reads as follows: find $u_h \in W_{h,0}$ such that

$$B_h(u_h,\, v_h) = F_h(v_h) \quad \text{for any } v_h \in W_{h,0}, \tag{3.4}$$

with

$$B_h(u_h,\, v_h) = B(u_h,\, v_h) + \sum_{K\in\mathcal{T}_h} (-\mu\,\Delta u_h + \mathbf{a}\cdot\nabla u_h,\, \tau_K(-\mu\,\Delta v_h + \mathbf{a}\cdot\nabla v_h))_K, \tag{3.5}$$

$$F_h(v_h) = F(v_h) + \sum_{K\in\mathcal{T}_h} (f,\, \tau_K(-\mu\,\Delta v_h + \mathbf{a}\cdot\nabla v_h))_K, \tag{3.6}$$

where we let $W_{h,0} = W_h \cap H_0^1(\Omega)$. In particular, as we are dealing with continuous affine finite elements, the terms $\Delta u_h\big|_K$ and $\Delta v_h\big|_K$ in (3.5) and (3.6) are identically equal to zero. Finally, concerning the stability coefficients τ_K, we define it as

$$\tau_K = \frac{\delta_K}{2} \, \frac{\xi(\mathrm{Pe}_K)}{\|\mathbf{a}\|_{L^\infty(K)}}, \tag{3.7}$$

where δ_K is a characteristic dimension of element K and the function $\xi(\cdot)$ is defined as

$$\xi(\mathrm{Pe}_K) = \begin{cases} \mathrm{Pe}_K & \text{if} \quad \mathrm{Pe}_K < 1, \\ 1 & \text{if} \quad \mathrm{Pe}_K \geq 1. \end{cases} \tag{3.8}$$

This choice corresponds to considering a locally advection dominated flow when the element Péclet number Pe_K, given by

$$\mathrm{Pe}_K = \delta_K \, \frac{\|\mathbf{a}\|_{L^\infty(K)}}{6\,\mu}, \tag{3.9}$$

is greater than or equal to one. Notice that recipe (3.7) generalizes the corresponding one in [22], where $\delta_K = h_K$. Nevertheless, in the case of anisotropic meshes, this choice turns out not to be the optimal one (see also, e.g., [2]). We provide in what follows an alternative determination of δ_K based on the error analysis.

3.2. Error analysis. To begin with, let us recall that the stabilized scheme (3.4) is a *consistent* method in the sense that if additional regularity is demanded for the solution u of the variational problem (3.2), that is, $u \in H^2(\Omega) \cap H^1_0(\Omega)$, then the following relation holds:

$$B_h(u, \, v_h) = F_h(v_h) \quad \text{for any } v_h \in W_{h,0}. \tag{3.10}$$

As a consequence, the well-known Galerkin orthogonality property

$$B_h(u - u_h, \, v_h) = 0 \quad \text{for any } v_h \in W_{h,0} \tag{3.11}$$

follows. In the convergence analysis provided below we endow the space $H^1_0(\Omega)$ with the discrete norm $\|\cdot\|_h$ defined, for any $w \in H^1_0(\Omega)$, by

$$\|w\|_h^2 = \mu \, \|\nabla w\|^2_{L^2(\Omega)} + \sum_{K \in \mathcal{T}_h} \|\tau_K^{1/2} \, \mathbf{a} \cdot \nabla w\|^2_{L^2(K)}. \tag{3.12}$$

We anticipate the main result of this section.

THEOREM 3.1 (convergence in norm $\|\cdot\|_h$). *Let $u \in H^2(\Omega) \cap H^1_0(\Omega)$ be the solution to (3.2), and let $u_h \in W_{h,0}$ be the solution to (3.4). Then the anisotropic definitions of the stability coefficients and of the local Péclet number are*

$$\tau_K = \frac{\lambda_{2,K}}{2} \, \frac{\xi(\mathrm{Pe}_K)}{\|\mathbf{a}\|_{L^\infty(K)}}, \tag{3.13}$$

$$\mathrm{Pe}_K = \lambda_{2,K} \, \frac{\|\mathbf{a}\|_{L^\infty(K)}}{6\,\mu}, \tag{3.14}$$

respectively, where $\xi(\cdot)$ is the same as in (3.8). Moreover, under this choice there exists a constant $C = C(\widehat{K})$ such that it holds that

$$\begin{aligned} \|u - u_h\|_h^2 \leq C \sum_{K \in \mathcal{T}_h} \Big\{ & \lambda_{2,K}^2 \Big(\lambda_{2,K} \|\mathbf{a}\|_{L^\infty(K)} \mathcal{H}(\mathrm{Pe}_K - 1) + \mu \mathcal{H}(1 - \mathrm{Pe}_K) \Big) \\ & \big[s_K^4 L_K(\mathbf{r}_{1,K}, \, \mathbf{r}_{1,K}; \, u) + L_K(\mathbf{r}_{2,K}, \, \mathbf{r}_{2,K}; \, u) + 2 s_K^2 L_K(\mathbf{r}_{1,K}, \, \mathbf{r}_{2,K}; \, u) \big] \Big\}, \end{aligned} \tag{3.15}$$

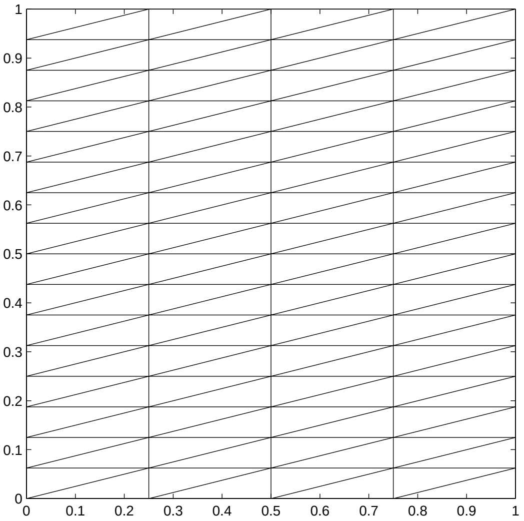

FIG. 3.1. *An example of mesh.*

where the quantities $L_K(\mathbf{r}_{i,K}, \mathbf{r}_{j,K}; u)$ *are defined by* (2.4) *and where* $\mathcal{H}(\cdot)$ *is the Heaviside function given by*

$$\mathcal{H}(s) = \begin{cases} 0 & \textit{if } s < 0, \\ 1 & \textit{if } s > 0. \end{cases} \tag{3.16}$$

Before proving Theorem 3.1, some remarks are in order. In the isotropic case when $\lambda_{1,K} \simeq \lambda_{2,K}$, (3.15) recovers Theorem 3.1 in [22] in the case of affine elements. It is interesting to observe that the interpolation error estimates in section 2.1 and in turn the convergence result (3.15) contain quantities related to the stretching factors s_K of the elements, but, as pointed out also in Remark 5.1 in [4], if the anisotropic refinement is along the correct direction, i.e., where high derivatives of the solution occur, then these terms are of smaller size than the other terms. Actually, estimate (3.15) guarantees convergence when s_K is bounded, giving a convergence rate of the order of $\lambda_{2,K}^{3/2}$ and $\lambda_{2,K}$ in the discrete norm $\|\cdot\|_h$ for the cases of $\mathrm{Pe}_K \geq 1$ and $\mathrm{Pe}_K < 1$, respectively, but convergence can be achieved even if s_K is unbounded, as we discuss in the following two examples.

Let us introduce a parameter $t < 1$, and let $\lambda_{1,K} = t$ and $\lambda_{2,K} = t^j$ (with $j > 1$) so that $s_K > 1$. In order to study convergence, we let $t \to 0$ (i.e., $s_K \to \infty$). This implies that the dominant term in the second row of (3.15) is the one of the order of $s_K^4 = t^{4(1-j)}$. Thus, the right-hand side in (3.15) behaves like $\lambda_{2,K}^3 s_K^4 = t^{4-j}$ or $\lambda_{2,K}^2 s_K^4 = t^{4-2j}$ according to whether the problem is convection dominated or not, respectively, and convergence can still be expected, provided that $1 < j < 4$ in the first case or $1 < j < 2$ in the second one. This corresponds to a "directional limit," where $\lambda_{1,K}$ and $\lambda_{2,K}$ tend to zero in a constrained manner.

Example 1. Let us provide an instance of this situation. Consider a mesh such as the one in Figure 3.1, referred to as $\Omega = (0,1)^2$, and suppose that the problem is advection dominated, i.e., $\mathrm{Pe}_K \geq 1$. Let N_x and N_y be the number of subdivisions in the x- and y-direction, respectively. Using for $\widehat{K}$ the right triangle $(0,0), (1,0), (0,1)$, it can be checked that $\lambda_{1,K} = 1/N_x$ and $\lambda_{2,K} = 1/N_y$. After introducing the parameter $t < 1$ such that $\lambda_{1,K} = t$ and $\lambda_{2,K} = t^j$, we have that $N_x = 1/t$ and $N_y = N_x^j$ for a fixed $j > 1$. Notice that the parameter t should be chosen such that $1/t$ is an integer, e.g., $t = 1/n$ with $n \in \mathbb{N}^+$.

Finally, let us introduce a family of triangulations depending on the parameter t by recalling from the above discussion that $1 < j < 4$ as the problem is convection dominated. The sequence of numerical solutions computed on this family of triangulations, as t decreases, converges at a rate $t^{2-j/2} = \lambda_{1,K}^{2-j/2}$ in the discrete norm $\|\cdot\|_h$ while s_K diverges like t^{1-j} for any $K \in \mathcal{T}_h$.

Example 2. Another case where convergence occurs while s_K may be unbounded is when $L_K(\mathbf{r}_{1,K}, \mathbf{r}_{1,K};\, u) = L_K(\mathbf{r}_{1,K}, \mathbf{r}_{2,K};\, u) = 0$ while $L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K};\, u)$ is bounded in (3.15). Starting from the same type of meshes as in Figure 3.1 and using for $\widehat{K}$ the same right triangle, it can be checked that $\mathbf{r}_{1,K} = (1,0)^T$ and $\mathbf{r}_{2,K} = (0,1)^T$, provided that the number of subdivisions $N_x < N_y$. In this case the term $L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{1,K};\, u) = \|\partial^2 u/\partial x_1^2\|^2_{L^2(K)} = 0$ and $L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{2,K};\, u) = \|\partial^2 u/\partial x_1 \partial x_2\|^2_{L^2(K)} = 0$. This implies that whenever $u = u(x_2)$ with $\|\partial^2 u/\partial x_2^2\|_{L^2(\Omega)}$ bounded, convergence is guaranteed, provided that the mesh size tends to zero in the x_2-direction while no constraint is required for the mesh size in the x_1-direction (see section 5).

To summarize, in a loose sense, if the mesh is aligned with the solution, then convergence occurs independently of the stretching factor. Otherwise, convergence may not occur. Moving from the residual-free bubble theory [9, 10, 39], we propose an alternative recipe taking into account the orientation of the convective field with respect to the mesh in [34].

In order to prove Theorem 3.1 we analyze in turn the stability and the continuity of the bilinear form $B_h(\cdot, \cdot)$ (see also [2, 22]). Let us begin with the stability result.

LEMMA 3.2 (stability in norm $\|\cdot\|_h$). *For any $v_h \in W_{h,0}$,*

$$B_h(v_h,\, v_h) = \|v_h\|_h^2. \tag{3.17}$$

Thus (3.4) *has a unique solution.*

Proof. Set $u_h = v_h$ in (3.5). □

The next result can be obtained from the anisotropic interpolation error estimates provided in section 2.1.

LEMMA 3.3. *Let us assume that the solution u to* (3.2) *satisfies $u \in H^2(\Omega) \cap H_0^1(\Omega)$. Then for any $K \in \mathcal{T}_h$*

(i) *if* $\mathrm{Pe}_K \geq 1$, *then*

(3.18)
$$\|\tau_K^{-1/2}\,(u - r_K(u))\|^2_{L^2(K)} + \mu\,\|\nabla(u - r_K(u))\|^2_{L^2(K)} + \|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u - r_K(u))\|^2_{L^2(K)}$$
$$+ \|\tau_K^{1/2}\,\mu\,\Delta(u - r_K(u))\|^2_{L^2(K)} \leq C\left[\frac{1}{\delta_K} + \frac{\delta_K}{\lambda_{2,K}^2} + \delta_K^3\,\frac{(\lambda_{1,K}^2 + \lambda_{2,K}^2)^2}{\lambda_{1,K}^4\,\lambda_{2,K}^4}\right]\|\mathbf{a}\|_{L^\infty(K)}$$
$$[\lambda_{1,K}^4\, L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{1,K};\, u) + \lambda_{2,K}^4\, L_K(\mathbf{r}_{2,K},\, \mathbf{r}_{2,K};\, u) + \, 2\lambda_{1,K}^2\,\lambda_{2,K}^2\, L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{2,K};\, u)];$$

(ii) *if* $\mathrm{Pe}_K < 1$*, then*

(3.19)
$$\|\tau_K^{-1/2}\,(u - r_K(u))\|^2_{L^2(K)} + \mu\,\|\nabla(u - r_K(u))\|^2_{L^2(K)} + \|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u - r_K(u))\|^2_{L^2(K)}$$
$$+ \|\tau_K^{1/2}\,\mu\,\Delta(u - r_K(u))\|^2_{L^2(K)} \le C\left[\frac{1}{\delta_K^2} + \frac{1}{\lambda_{2,K}^2} + \delta_K^2\,\frac{(\lambda_{1,K}^2 + \lambda_{2,K}^2)^2}{\lambda_{1,K}^4\,\lambda_{2,K}^4}\right]\mu$$
$$[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u) + \lambda_{2,K}^4\,L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)],$$

where the quantities $L_K(\mathbf{r}_{i,K},\,\mathbf{r}_{j,K};\,u)$ *are defined by* (2.4) *and* $C = C(\widehat{K})$*.*

Proof. Let us start by analyzing separately the four terms in the left-hand side of both (3.18) and (3.19), independently of the particular values of Pe_K. Concerning the first one, the inequality (2.6) in Lemma 2.4, together with the definition (3.7) of the stability coefficients τ_K, yields

$$\|\tau_K^{-1/2}\,(u - r_K(u))\|^2_{L^2(K)} \le C\,\frac{\|\mathbf{a}\|_{L^\infty(K)}}{\delta_K\,\xi(\mathrm{Pe}_K)}[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)$$
$$+ \lambda_{2,K}^4 L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)]. \tag{3.20}$$

The anisotropic estimate (2.7) in Lemma 2.4 derived for the H^1-seminorm of the interpolation error allows us to bound the second quantity. Indeed, we have

$$\begin{aligned}\mu\,\|\nabla(u - r_K(u))\|^2_{L^2(K)} &\le C\,\mu\,\left[\frac{\lambda_{1,K}^4}{\lambda_{2,K}^2}\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)\right.\\ &\qquad\left. + \lambda_{2,K}^2 L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2\lambda_{1,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)\right]\\ &= C\,\frac{\delta_K\,\|\mathbf{a}\|_{L^\infty(K)}}{\lambda_{2,K}^2\,\mathrm{Pe}_K}[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)\\ &\qquad + \lambda_{2,K}^4 L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)],\end{aligned} \tag{3.21}$$

where, thanks to (3.9), the diffusivity μ has been expressed, within a constant, in terms of the Péclet number associated with element K. Let us consider now the third term. We have

(3.22)
$$\|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u - r_K(u))\|^2_{L^2(K)} = \frac{\delta_K\,\xi(\mathrm{Pe}_K)}{2\,\|\mathbf{a}\|_{L^\infty(K)}}\int_K (\mathbf{a}\cdot\nabla(u - r_K(u)))^2\,d\mathbf{x}$$
$$\le C\,\delta_K\,\|\mathbf{a}\|_{L^\infty(K)}\xi(\mathrm{Pe}_K)\,\|\nabla(u - r_K(u))\|^2_{L^2(K)} \le C\,\frac{\delta_K\,\|\mathbf{a}\|_{L^\infty(K)}\,\xi(\mathrm{Pe}_K)}{\lambda_{2,K}^2}$$
$$[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u) + \lambda_{2,K}^4 L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)].$$

In the chain of inequalities above, the definition of the stability coefficients τ_K and the anisotropic estimate (2.7) in Lemma 2.4 have been used. Finally, let us bound suitably the last term in the left-hand side of (3.18) and (3.19), again using the expressions of τ_K and of the diffusivity μ in terms of the Péclet number Pe_K together with Corollary

2.7. Thus, it can be deduced that

(3.23)
$$\|\tau_K^{1/2}\,\mu\,\Delta(u-r_K(u))\|^2_{L^2(K)} \le \tau_K\,\mu^2\,|u|^2_{H^2(K)} \le \tau_K\,\mu^2(\lambda_{1,K}^2+\lambda_{2,K}^2)^2$$
$$\left[\frac{1}{\lambda_{2,K}^4}\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)+\frac{1}{\lambda_{1,K}^4}L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u)+\,\frac{2}{\lambda_{1,K}^2\,\lambda_{2,K}^2}\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)\right]$$
$$\le C\,\frac{\delta_K^3\,\|\mathbf{a}\|_{L^\infty(K)}\xi(\mathrm{Pe}_K)}{\mathrm{Pe}_K^2}\,\frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4\,\lambda_{2,K}^4}$$
$$[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)+\lambda_{2,K}^4L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u)+\,2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)].$$

Let us deal now with the case $\mathrm{Pe}_K \ge 1$, and consider each term (3.20)–(3.23) in turn. In the first of these terms we use definition (3.8); in the second one we use $1/\mathrm{Pe}_K \le 1$; in the third we employ definition (3.8); and in the fourth one we use again (3.8) and $1/\mathrm{Pe}_K^2 \le 1$. This allows us to further bound the left-hand side of (3.18) as

$$\|\tau_K^{-1/2}(u-r_K(u))\|^2_{L^2(K)}+\mu\,\|\nabla(u-r_K(u))\|^2_{L^2(K)}+\|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u-r_K(u))\|^2_{L^2(K)}$$
$$+\,\|\tau_K^{1/2}\,\mu\,\Delta(u-r_K(u))\|^2_{L^2(K)} \le C\left[\frac{1}{\delta_K}+\frac{\delta_K}{\lambda_{2,K}^2}+\delta_K^3\,\frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4\,\lambda_{2,K}^4}\right]\|\mathbf{a}\|_{L^\infty(K)}$$
$$[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)+\lambda_{2,K}^4\,L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u)+\,2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)].$$

Let us now consider the case $\mathrm{Pe}_K < 1$, where we follow a different path with respect to the previous case. Let us analyze the four terms (3.20)–(3.23) above in turn. We first use the definition (3.8) and then (3.9) in (3.20); on the term (3.21) we employ (3.9); in the third one we use (3.8) and then express, within a constant, the term $\|\mathbf{a}\|_{L^\infty(K)}$ as $\mu\mathrm{Pe}_K/\delta_K$ from (3.9); and finally we use $\mathrm{Pe}_K^2 < 1$. In the fourth term we employ definition (3.8) and then compute, within a constant, $\mathrm{Pe}_K/\|\mathbf{a}\|_{L^\infty(K)}$ as δ_K/μ. We can then bound the left-hand side in (3.19) as

$$\|\tau_K^{-1/2}(u-r_K(u))\|^2_{L^2(K)}+\mu\,\|\nabla(u-r_K(u))\|^2_{L^2(K)}+\|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u-r_K(u))\|^2_{L^2(K)}$$
$$+\,\|\tau_K^{1/2}\,\mu\,\Delta(u-r_K(u))\|^2_{L^2(K)} \le C\left[\frac{1}{\delta_K^2}+\frac{1}{\lambda_{2,K}^2}+\delta_K^2\frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4\lambda_{2,K}^4}\right]\mu$$
$$[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u)+\lambda_{2,K}^4\,L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u)+\,2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)],$$

and this concludes the proof. □

Let us now prove the continuity of the bilinear form $B_h(\cdot,\,\cdot)$.

LEMMA 3.4 (continuity of $B_h(\cdot,\,\cdot)$). *For any $u \in H^2(\Omega)\cap H_0^1(\Omega)$ and for any $v_h \in W_{h,0}$, there exists a constant C such that*

$$|B_h(u,v_h)| \le C\Bigg[\mu\|\nabla u\|^2_{L^2(\Omega)}+\sum_{K\in\mathcal{T}_h}\Big(\|\tau_K^{-1/2}u\|^2_{L^2(K)}$$
$$+\,\|\tau_K^{1/2}\mathbf{a}\cdot\nabla u\|^2_{L^2(K)}+\|\tau_K^{1/2}\mu\Delta u\|^2_{L^2(K)}\Big)\Bigg]^{1/2}\|v_h\|_h.$$

Proof. From the definition (3.5) of the bilinear form $B_h(\cdot,\,\cdot)$ and since $\Delta v_h\big|_K = 0$ for any $K\in\mathcal{T}_h$ and for any $v_h \in W_{h,0}$, we have

$$B_h(u,v_h) = (\mu\nabla u,\nabla v_h)+(\mathbf{a}\cdot\nabla u,v_h)+\sum_{K\in\mathcal{T}_h}(-\mu\Delta u+\mathbf{a}\cdot\nabla u,\tau_K(\mathbf{a}\cdot\nabla v_h))_K.$$

Then integrating by parts the second term and using the Cauchy–Schwarz inequality, we get

$$|B_h(u,v_h)| \leq \mu \|\nabla u\|_{L^2(\Omega)} \|\nabla v_h\|_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h} \|\tau_K^{1/2}\mathbf{a}\cdot\nabla v_h\|_{L^2(K)} \|\tau_K^{-1/2} u\|_{L^2(K)}$$
$$+ \sum_{K\in\mathcal{T}_h} \|\tau_K^{1/2}\mathbf{a}\cdot\nabla v_h\|_{L^2(K)} \Big(\|\tau_K^{1/2}\mathbf{a}\cdot\nabla u\|_{L^2(K)} + \|\tau_K^{1/2}\mu\Delta u\|_{L^2(K)} \Big).$$

Finally, thanks to the discrete Cauchy–Schwarz inequality and some simple calculations, we obtain

$$|B_h(u,v_h)| \leq C \Bigg(\mu\|\nabla u\|^2_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h} \|\tau_K^{-1/2} u\|^2_{L^2(K)}$$
$$+ \sum_{K\in\mathcal{T}_h} \Big(\|\tau_K^{1/2}\mathbf{a}\cdot\nabla u\|^2_{L^2(K)} + \|\tau_K^{1/2}\mu\Delta u\|^2_{L^2(K)} \Big) \Bigg)^{1/2}$$
$$\Bigg(\mu\|\nabla v_h\|^2_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h} \|\tau_K^{1/2}\mathbf{a}\cdot\nabla v_h\|^2_{L^2(K)} \Bigg)^{1/2},$$

that is, the desired result. □

We are now in a position to state the following anisotropic *a priori error estimate* with respect to the norm $\|\cdot\|_h$ defined in (3.12).

PROPOSITION 3.5 (a priori error estimate in norm $\|\cdot\|_h$). *Let* $u \in H^2(\Omega)\cap H^1_0(\Omega)$ *be the solution to* (3.2), *and let* $u_h \in W_{h,0}$ *be the solution to* (3.4). *Then there exists a constant* $C = C(\widehat{K})$ *such that the a priori estimate*

(3.24)
$$\|u-u_h\|_h^2 \leq C \sum_{K\in\mathcal{T}_h} \Bigg\{ \Bigg(\Bigg[\frac{1}{\delta_K} + \frac{\delta_K}{\lambda^2_{2,K}} + \delta_K^3 \frac{(\lambda^2_{1,K}+\lambda^2_{2,K})^2}{\lambda^4_{1,K}\,\lambda^4_{2,K}} \Bigg] \|\mathbf{a}\|_{L^\infty(K)}\, \mathcal{H}(\mathrm{Pe}_K - 1)$$
$$+ \Bigg[\frac{1}{\delta_K^2} + \frac{1}{\lambda^2_{2,K}} + \delta_K^2 \frac{(\lambda^2_{1,K}+\lambda^2_{2,K})^2}{\lambda^4_{1,K}\lambda^4_{2,K}} \Bigg] \mu\mathcal{H}(1-\mathrm{Pe}_K) \Bigg)$$
$$\big[\lambda^4_{1,K} L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{1,K};\, u) + \lambda^4_{2,K}\, L_K(\mathbf{r}_{2,K},\, \mathbf{r}_{2,K};\, u) + 2\lambda^2_{1,K}\,\lambda^2_{2,K}\, L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{2,K};\, u) \big] \Bigg\}$$

holds true, with $L_K(\mathbf{r}_{i,K},\, \mathbf{r}_{j,K};\, u)$ *defined in* (2.4) *and where* $\mathcal{H}(\cdot)$ *is the Heaviside function defined in* (3.16).

Proof. The stability result (3.17), combined with the Galerkin orthogonality property (3.11), yields the relations

$$\|u_h - r_h(u)\|_h^2 = B_h(u_h - r_h(u),\, u_h - r_h(u)) = B_h(u_h - u + u - r_h(u),\, u_h - r_h(u))$$
$$= B_h(u - r_h(u),\, u_h - r_h(u)) \leq |B_h(u - r_h(u),\, u_h - r_h(u))|.$$

From Lemma 3.4 we immediately get

(3.25)
$$\|u_h - r_h(u)\|_h \leq C \Bigg(\sum_{K\in\mathcal{T}_h} \Big[\|\tau_K^{-1/2}(u - r_K(u))\|^2_{L^2(K)} + \mu\|\nabla(u - r_K(u))\|^2_{L^2(K)}$$
$$+ \|\tau_K^{1/2}\mathbf{a}\cdot\nabla(u - r_K(u))\|^2_{L^2(K)} + \|\tau_K^{1/2}\mu\Delta(u - r_K(u))\|^2_{L^2(K)} \Big] \Bigg)^{1/2}.$$

Using the triangle and Young inequalities, we have

$$\|u-u_h\|_h^2 \le 2(\|u-r_h(u)\|_h^2 + \|u_h - r_h(u)\|_h^2).$$

As, trivially,

$$\begin{aligned}\|u-r_h(u)\|_h^2 \le \sum_{K\in\mathcal{T}_h} \Big[&\|\tau_K^{-1/2}\,(u-r_K(u))\|^2_{L^2(K)} + \mu\,\|\nabla(u-r_K(u))\|^2_{L^2(K)} \\ &+ \|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u-r_K(u))\|^2_{L^2(K)} + \|\tau_K^{1/2}\,\mu\,\Delta(u-r_K(u))\|^2_{L^2(K)}\Big],\end{aligned}$$

and from (3.25), it follows that

$$\begin{aligned}\|u-u_h\|_h^2 \le C \sum_{K\in\mathcal{T}_h} \Big[&\|\tau_K^{-1/2}\,(u-r_K(u))\|^2_{L^2(K)} + \mu\,\|\nabla(u-r_K(u))\|^2_{L^2(K)} \\ &+ \|\tau_K^{1/2}\,\mathbf{a}\cdot\nabla(u-r_K(u))\|^2_{L^2(K)} + \|\tau_K^{1/2}\,\mu\,\Delta(u-r_K(u))\|^2_{L^2(K)}\Big].\end{aligned} \tag{3.26}$$

Result (3.24) eventually follows by applying Lemma 3.3 to the right-hand side of (3.26). □

Proof of Theorem 3.1. Let us consider the error estimate obtained in Proposition 3.5, and, after using the definition of stretching factor, let us rewrite it as follows:

$$\begin{aligned}\|u-u_h\|_h^2 \le C \sum_{K\in\mathcal{T}_h} \Bigg\{ \Bigg(&\underbrace{\left[\frac{\lambda_{2,K}^4}{\delta_K} + \delta_K \lambda_{2,K}^2 + \delta_K^3\,\frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4}\right]}_{\text{(I)}} \|\mathbf{a}\|_{L^\infty(K)}\,\mathcal{H}(\mathrm{Pe}_K - 1) \\ &+ \underbrace{\left[\frac{\lambda_{2,K}^4}{\delta_K^2} + \lambda_{2,K}^2 + \delta_K^2 \frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4}\right]}_{\text{(II)}} \mu\mathcal{H}(1-\mathrm{Pe}_K)\Bigg) \\ &\underbrace{\left[s_K^4\, L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,u) + L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,u) + 2s_K^2\, L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,u)\right]}_{\text{(III)}}\Bigg\},\end{aligned} \tag{3.27}$$

where the term (III) is now equivalent to the H^2-norm of u on K, on recalling the definition (2.4) and that s_K is a dimensionless quantity. Moreover, $1 < \frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4} \le 4$ so that it does not play any role in the convergence analysis. Let us first deal with the isotropic case, where $\lambda_{1,K} \simeq \lambda_{2,K} \simeq h_K$. By looking at term (I) of (3.27), it turns out that the maximal order of convergence is obtained when all these terms are of the same order. This occurs when $\delta_K \simeq h_K$; i.e., we recover the recipe in [22]. In the anisotropic case, letting $\delta_K \simeq \lambda_{1,K}^m \lambda_{2,K}^n$ for some m, $n \in \mathbb{Q}$, we find these values by requiring that all the three terms in (I) be of the same order with respect to both $\lambda_{1,K}$ and $\lambda_{2,K}$. By doing so, it turns out that $m = 0$ and $n = 1$, which yields $\delta_K \simeq \lambda_{2,K}$. It also turns out that, under this choice, (I) behaves like $\lambda_{2,K}^3$.

By a similar line of reasoning, it can be checked that the same value for δ_K is obtained also for term (II). However, this behaves like $\lambda_{2,K}^2$.

Having computed the value of δ_K, relations (3.13)–(3.14) follow immediately on recalling (3.7) and (3.9). □

Notice that in the above proof the parameter δ_K is determined up to a constant. The definitions (3.13)–(3.14) are consistent with a choice of this constant equal to 1.

4. The Stokes problem.

In this section we extend the result obtained in section 3 to the case of the Stokes problem.

In the very same spirit as in the advection-diffusion case, starting from the GLS formulation presented in [20, 21], we readdress the question of a careful design for the stability coefficients in the anisotropic framework. With regard to this, in [4, 5] the authors consider the stabilization of the Stokes problem in the case of the Q_1/Q_1 pair of finite elements on anisotropic quadrilateral meshes aligned with the Cartesian coordinate axes.

In this section, we provide a possible generalization of the convergence results obtained in Theorem 3.1 in [20], in the case of continuous piecewise linear finite elements for both the velocity and the pressure, to the situation of a general anisotropic mesh. We study the convergence of the stabilized method in a mesh dependent norm, taking into account also the stability coefficients τ_K. The optimal value for this is obtained by error analysis considerations and turns out to depend on $\lambda_{2,K}$, as should be expected after the analysis leading to Theorem 3.1.

The main contribution of this section is Theorem 4.1.

4.1. Problem statement and finite element discretization.

Given the viscosity $\mu = \text{const} > 0$ and the source term $\mathbf{f} = \mathbf{f}(\mathbf{x}) \in (L^2(\Omega))^2$, we seek $\mathbf{u} = \mathbf{u}(\mathbf{x})$ and $p = p(\mathbf{x})$ such that

$$\begin{cases} -\mu\,\Delta\mathbf{u} + \nabla p = \mathbf{f} & \text{in } \Omega, \\ \nabla\cdot\mathbf{u} = 0 & \text{in } \Omega, \\ \mathbf{u} = \mathbf{0} & \text{on } \partial\Omega. \end{cases} \tag{4.1}$$

The variational formulation for the above problem consists of finding $(\mathbf{u}, p) \in V \times Q$ such that

$$B(\mathbf{u}, p; \mathbf{v}, q) = F(\mathbf{v}, q) \quad \text{for any } (\mathbf{v}, q) \in V \times Q. \tag{4.2}$$

Here $V = (H_0^1(\Omega))^2$, $Q = L_0^2(\Omega)$, while $B(\cdot\,;\cdot)$ and $F(\cdot)$ now are the symmetric bilinear and linear forms

$$B(\mathbf{u}, p; \mathbf{v}, q) = \mu(\nabla\mathbf{u}, \nabla\mathbf{v}) - (p, \nabla\cdot\mathbf{v}) - (q, \nabla\cdot\mathbf{u}) \quad \text{and} \quad F(\mathbf{v}, q) = (\mathbf{f}, \mathbf{v}),$$

respectively, for any $(\mathbf{u}, p)$, $(\mathbf{v}, q) \in V \times Q$. Let us notice that we are using the same notation to address the bilinear and linear forms $B(\cdot\,;\cdot)$ and $F(\cdot)$ for both the advection-diffusion and the Stokes problems.

As is done in the advection-diffusion case, we discretize problem (4.2) by using the GLS method with affine finite elements [20, 21]. The discrete problem is as follows: find $(\mathbf{u}_h, p_h) \in V_h \times Q_h$ such that

$$B_h(\mathbf{u}_h, p_h; \mathbf{v}_h, q_h) = F_h(\mathbf{v}_h, q_h) \quad \text{for any } (\mathbf{v}_h, q_h) \in V_h \times Q_h, \tag{4.3}$$

where $V_h \times Q_h \subset V \times Q$ is the approximation space for velocity and pressure comprising continuous affine functions over $\mathcal{T}_h$, namely $V_h = (W_{h,0})^2$ and $Q_h = W_h \cap L_0^2(\Omega)$. Here the symmetric bilinear form $B_h(\cdot\,;\cdot)$ and the linear form $F_h(\cdot)$ are defined by

$$B_h(\mathbf{u}_h, p_h; \mathbf{v}_h, q_h) = B(\mathbf{u}_h, p_h; \mathbf{v}_h, q_h) - \sum_{K\in\mathcal{T}_h} (-\mu\,\Delta\mathbf{u}_h + \nabla p_h, \tau_K(-\mu\,\Delta\mathbf{v}_h + \nabla q_h))_K,$$

(4.4)

$$F_h(\mathbf{v}_h, q_h) = F(\mathbf{v}_h, q_h) - \sum_{K\in\mathcal{T}_h} (\mathbf{f}, \tau_K(-\mu\,\Delta\mathbf{v}_h + \nabla q_h))_K,$$

with τ_K stability coefficients to be suitably chosen. The terms $\Delta \mathbf{u}_h\big|_K$ and $\Delta \mathbf{v}_h\big|_K$ in (4.4) are identically equal to zero due to the choice made for the finite element space V_h.

We point out that the technique suggested in [4, 5] is a variant with respect to the GLS method where the stabilizing term, proportional to $(\nabla p_h, \nabla q_h)_K$, is replaced by $(\nabla p_h, S\,\nabla q_h)_K$, with $S = \mathrm{diag}(h_{x_1}^2, h_{x_2}^2)$, h_{x_1}, h_{x_2} being the mesh spacings in the coordinate directions. This term is shown to produce more satisfactory numerical results in the case of anisotropic meshes among several choices of the stabilization term.

4.2. Error analysis. As in [20, 21], the GLS scheme (4.3) is said to be *consistent* in the following sense. If the solution $(\mathbf{u}, p) \in V \times Q$ of the weak formulation (4.2) is regular enough, that is, if $(\mathbf{u}, p) \in (V \cap (H^2(\Omega))^2) \times (Q \cap H^1(\Omega))$, then $(\mathbf{u}, p)$ satisfies

$$B_h(\mathbf{u}, p; \mathbf{v}_h, q_h) \;=\; F_h(\mathbf{v}_h, q_h) \quad \text{for any } (\mathbf{v}_h, q_h) \in V_h \times Q_h.$$

Consequently, if $(\mathbf{u}_h, p_h) \in V_h \times Q_h$ is the solution to (4.3), we obtain the Galerkin orthogonality property

$$B_h(\mathbf{u} - \mathbf{u}_h, p - p_h; \mathbf{v}_h, q_h) \;=\; 0 \quad \text{for any } (\mathbf{v}_h, q_h) \in V_h \times Q_h. \tag{4.5}$$

Likewise, as was done in section 3.2, we introduce the discrete norm $\|\cdot\|_h$ defined for any $(\mathbf{v}, q) \in V \times (Q \cap H^1(\Omega))$ by

$$\|(\mathbf{v}, q)\|_h^2 = \mu \|\nabla \mathbf{v}\|^2_{L^2(\Omega)} + \sum_{K \in \mathcal{T}_h} \|\tau_K^{1/2} \nabla q\|^2_{L^2(K)}. \tag{4.6}$$

We now state the main result of this section, which is an anisotropic counterpart of Theorem 3.1 in [20] restricted to the case of (continuous) affine elements for both the velocity and the pressure. Moreover, we provide estimates in a different norm, namely the discrete norm $\|\cdot\|_h$ in (4.6), while in [20] the errors $\|\mathbf{u} - \mathbf{u}_h\|_{(H^1(\Omega))^2}$, $\|\mathbf{u} - \mathbf{u}_h\|_{(L^2(\Omega))^2}$, and $\|p - p_h\|_{L^2(\Omega)}$ are considered.

THEOREM 4.1 (convergence in norm $\|\cdot\|_h$). *Let $(\mathbf{u}, p) \in (V \cap (H^2(\Omega))^2) \times (Q \cap H^1(\Omega))$ be the solution to* (4.2)*, and let $(\mathbf{u}_h, p_h) \in V_h \times Q_h$ be the solution to* (4.3)*. Then the anisotropic definition of the stability coefficients is*

$$\tau_K = \alpha \frac{\lambda_{2,K}^2}{\mu}, \tag{4.7}$$

where $\alpha \simeq O(1)$ is any positive constant. Moreover, under this choice there exists a constant $C = C(\Gamma, \widehat{C}, \widehat{K})$ such that it holds that

$$\begin{aligned}
&\|(\mathbf{u} - \mathbf{u}_h, p - p_h)\|_h^2 \le \\
&C \sum_{K \in \mathcal{T}_h} \Bigg\{ \lambda_{2,K}^2 \Bigg(\mu \Big[s_K^4\, L_K(\mathbf{r}_{1,K}, \,\mathbf{r}_{1,K}; \,\mathbf{u}) + L_K(\mathbf{r}_{2,K}, \mathbf{r}_{2,K}; \,\mathbf{u}) + 2 s_K^2 L_K(\mathbf{r}_{1,K}, \,\mathbf{r}_{2,K}; \,\mathbf{u}) \Big] \\
&\qquad + \frac{1}{\mu} \Big[s_K^2 (\mathbf{r}_{1,K}^T G_K(p)\, \mathbf{r}_{1,K}) + (\mathbf{r}_{2,K}^T G_K(p)\, \mathbf{r}_{2,K}) \Big] \Bigg) \Bigg\}.
\end{aligned} \tag{4.8}$$

Remark 3. Notice that in the case when $\lambda_{1,K} \simeq \lambda_{2,K}$, i.e., in the isotropic case, (4.8) recovers Theorem 3.1 in [20] in the case of affine elements. As far as the term depending on the velocity in (4.8) is concerned, we note that it has the same structure as the corresponding one in Theorem 3.1. Thus the same considerations discussed in the case of the advection-diffusion problem carry over to the case of the Stokes problem, provided that the contribution of the terms depending on the pressure in (4.8) are negligible. Under this assumption we may have convergence even if s_K is unbounded. Likewise, in the case when the terms depending on $\mathbf{u}$ are negligible, convergence may be achieved independently of the stretching factor, provided that $\mathbf{r}_{1,K}^T G_K(p)\,\mathbf{r}_{1,K} \simeq 0$; i.e., the gradients of the pressure in the direction $\mathbf{r}_{1,K}$ are small. Thus, as in the case of the advection-diffusion problem, roughly speaking, if the mesh is aligned with the solution, then convergence occurs independently of the stretching factor. Otherwise, convergence may not occur.

Theorem 4.1 is proved by analyzing both the stability and the continuity of the bilinear form $B_h(\cdot;\cdot)$. First let us provide the stability result.

Lemma 4.2 (stability in norm $\|\cdot\|_h$). *For any* $(\mathbf{v}_h, q_h) \in V_h \times Q_h$, *we have*

$$B_h(\mathbf{v}_h, -q_h; \mathbf{v}_h, q_h) = \|(\mathbf{v}_h, q_h)\|_h^2. \tag{4.9}$$

Therefore (4.3) *has a unique solution.*

Proof. Set $\mathbf{u}_h = \mathbf{v}_h$ and $p_h = -q_h$ in $(4.4)_1$. □

With the next lemma we analyze the continuity of the bilinear form $B_h(\cdot\,;\cdot)$.

Lemma 4.3 (continuity of $B_h(\cdot\,;\cdot)$). *For any* $(\mathbf{u}, p) \in (V \cap (H^2(\Omega))^2) \times (Q \cap H^1(\Omega))$ *and for any* $(\mathbf{v}_h, q_h) \in V_h \times Q_h$, *there exists a constant C such that*

$$|B_h(\mathbf{u}, p; \mathbf{v}_h, q_h)| \le C\Bigg[\mu\|\nabla\mathbf{u}\|_{L^2(\Omega)}^2 + \frac{1}{\mu}\|p\|_{L^2(\Omega)}^2 + \sum_{K\in\mathcal{T}_h}\Big(\|\tau_K^{-1/2}\mathbf{u}\|_{L^2(K)}^2 + \|\tau_K^{1/2}\mu\Delta\mathbf{u}\|_{L^2(K)}^2 + \|\tau_K^{1/2}\nabla p\|_{L^2(K)}^2\Big)\Bigg]^{1/2} \|(\mathbf{v}_h, q_h)\|_h.$$

Proof. From the definition of $B_h(\cdot\,;\cdot)$ we have

$$\begin{aligned} B_h(\mathbf{u}, p; \mathbf{v}_h, q_h) &= \mu(\nabla\mathbf{u}, \nabla\mathbf{v}_h) - (p, \nabla\cdot\mathbf{v}_h) - (q_h, \nabla\cdot\mathbf{u}) \\ &\quad - \sum_{K\in\mathcal{T}_h}(-\mu\,\Delta\mathbf{u} + \nabla p, \tau_K(-\mu\,\Delta\mathbf{v}_h + \nabla q_h))_K. \end{aligned}$$

Integrating by parts the third term in the right-hand side of the above equality and since $\Delta\mathbf{v}_h\big|_K = 0$ on each triangle $K \in \mathcal{T}_h$, we have

$$\begin{aligned} B_h(\mathbf{u}, p; \mathbf{v}_h, q_h) &= \mu(\nabla\mathbf{u}, \nabla\mathbf{v}_h) - (p, \nabla\cdot\mathbf{v}_h) + \sum_{K\in\mathcal{T}_h}(\mathbf{u}, \nabla q_h)_K \\ &\quad - \sum_{K\in\mathcal{T}_h}(-\mu\,\Delta\mathbf{u} + \nabla p, \tau_K\nabla q_h)_K. \end{aligned}$$

Using the Cauchy–Schwarz inequality and the straightforward relation $\|\nabla\cdot\mathbf{v}_h\|_{L^2(\Omega)} \le \sqrt{2}\|\nabla\mathbf{v}_h\|_{L^2(\Omega)}$, we obtain

$$\begin{aligned} &|B_h(\mathbf{u}, p; \mathbf{v}_h, q_h)| \le \mu\|\nabla\mathbf{u}\|_{L^2(\Omega)}\|\nabla\mathbf{v}_h\|_{L^2(\Omega)} + \sqrt{2}\,\|p\|_{L^2(\Omega)}\|\nabla\mathbf{v}_h\|_{L^2(\Omega)} \\ &+\sum_{K\in\mathcal{T}_h}\|\mathbf{u}\|_{L^2(K)}\|\nabla q_h\|_{L^2(K)} +\sum_{K\in\mathcal{T}_h}\|\tau_K^{1/2}\nabla q_h\|_{L^2(K)}\big(\|\tau_K^{1/2}\mu\Delta\mathbf{u}\|_{L^2(K)}+\|\tau_K^{1/2}\nabla p\|_{L^2(K)}\big). \end{aligned}$$

Using the discrete Cauchy–Schwarz inequality, we thus have

$$|B_h(\mathbf{u},p;\mathbf{v}_h,q_h)| \le C\biggl(\mu\|\nabla\mathbf{u}\|^2_{L^2(\Omega)} + \frac{1}{\mu}\|p\|^2_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h}\Bigl(\|\tau_K^{-1/2}\mathbf{u}\|^2_{L^2(K)} + \|\tau_K^{1/2}\mu\Delta\mathbf{u}\|^2_{L^2(K)} + \|\tau_K^{1/2}\nabla p\|^2_{L^2(K)}\Bigr)\biggr)^{1/2} \biggl(\mu\|\nabla\mathbf{v}_h\|^2_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h}\|\tau_K^{1/2}\nabla q_h\|^2_{L^2(K)}\biggr)^{1/2},$$

which yields the result. □

The proofs of Lemmas 4.2 and 4.3 allow us to derive an anisotropic *a priori error estimate* for the discretization error of both the velocity and the pressure with respect to the discrete norm $\|\cdot\|_h$ defined in (4.6).

PROPOSITION 4.4 (a priori error estimate in norm $\|\cdot\|_h$). *Let* $(\mathbf{u},p)\in(V\cap(H^2(\Omega))^2)\times(Q\cap H^1(\Omega))$ *be the solution to* (4.2), *and let* $(\mathbf{u}_h,p_h)\in V_h\times Q_h$ *be the solution to* (4.3). *Then there exists a constant* $C=C(\Gamma,\widehat{C},\widehat{K})$ *such that*

$$\|(\mathbf{u}-\mathbf{u}_h,p-p_h)\|_h^2 \le C\Biggl\{\sum_{K\in\mathcal{T}_h}\biggl[\frac{1}{\tau_K}+\frac{\mu}{\lambda_{2,K}^2}+\frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4\,\lambda_{2,K}^4}\tau_K\mu^2\biggr] \Bigl[\lambda_{1,K}^4\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{1,K};\,\mathbf{u})+\lambda_{2,K}^4\,L_K(\mathbf{r}_{2,K},\,\mathbf{r}_{2,K};\,\mathbf{u})+2\lambda_{1,K}^2\,\lambda_{2,K}^2\,L_K(\mathbf{r}_{1,K},\,\mathbf{r}_{2,K};\,\mathbf{u})\Bigr] + \sum_{K\in\mathcal{T}_h}\biggl[\frac{1}{\mu}+\frac{\tau_K}{\lambda_{2,K}^2}\biggr]\Bigl[\lambda_{1,K}^2(\mathbf{r}_{1,K}^T G_K(p)\,\mathbf{r}_{1,K})+\,\lambda_{2,K}^2(\mathbf{r}_{2,K}^T G_K(p)\,\mathbf{r}_{2,K})\Bigr]\Biggr\}, \tag{4.10}$$

where the quantities $L_K(\mathbf{r}_{i,K},\,\mathbf{r}_{j,K};\,\mathbf{u})$ *and the matrix* G_K *are defined in* (2.19) *and* (2.5)*, respectively.*

Proof. We point out that the hypothesis $(\mathbf{u},p)\in(V\cap(H^2(\Omega))^2)\times(Q\cap H^1(\Omega))$, which amounts to requiring the elliptic regularity, holds, e.g., when Ω is convex. We have

$$\|(\mathbf{u}-\mathbf{u}_h,p-p_h)\|_h \le \|(\mathbf{u}-r_h(\mathbf{u}),p-R_h(p))\|_h + \|(r_h(\mathbf{u})-\mathbf{u}_h,R_h(p)-p_h)\|_h.$$

Thanks to Lemma 4.2 and to the Galerkin orthogonality property (4.5), we have

$$\begin{aligned}\|(r_h(\mathbf{u})-\mathbf{u}_h,R_h(p)-p_h)\|_h^2 &= B_h(r_h(\mathbf{u})-\mathbf{u}_h,R_h(p)-p_h;r_h(\mathbf{u})-\mathbf{u}_h,p_h-R_h(p))\\ &= B_h(r_h(\mathbf{u})-\mathbf{u},R_h(p)-p;r_h(\mathbf{u})-\mathbf{u}_h,p_h-R_h(p)).\end{aligned}$$

With Lemma 4.3 and since $\Delta(r_h(\mathbf{u}))\big|_K=0$ on each triangle $K\in\mathcal{T}_h$, we have

$$\|(r_h(\mathbf{u})-\mathbf{u}_h,R_h(p)-p_h)\|_h \le C\biggl(\mu\|\nabla(\mathbf{u}-r_h(\mathbf{u}))\|^2_{L^2(\Omega)}+\frac{1}{\mu}\,\|p-R_h(p)\|^2_{L^2(\Omega)} + \sum_{K\in\mathcal{T}_h}\Bigl(\|\tau_K^{-1/2}(\mathbf{u}-r_K(\mathbf{u}))\|^2_{L^2(K)}+\|\tau_K^{1/2}\mu\Delta\mathbf{u}\|^2_{L^2(K)}+\|\tau_K^{1/2}\nabla(p-R_K(p))\|^2_{L^2(K)}\Bigr)\biggr)^{1/2}.$$

By the additivity of the norms, it then suffices to use the interpolation results of Lemmas 2.3 and Proposition 2.5, together with the vectorial extensions of Lemma 2.4 and Corollary 2.7 (see Remark 2), to conclude. □

Proof of Theorem 4.1. We proceed by mimicking what was done in the proof of Theorem 3.1. Thus, using in (4.10) the definition of stretching factor in the terms depending on $L_K(\mathbf{r}_{i,K},\, \mathbf{r}_{j,K};\, \mathbf{u})$ and on $\mathbf{r}_{i,K}^T G_K(p)\, \mathbf{r}_{i,K}$, we obtain

$$(4.11)\quad \|(\mathbf{u}-\mathbf{u}_h, p-p_h)\|_h^2 \le C \sum_{K\in\mathcal{T}_h} \Bigg\{ \underbrace{\left(\frac{\lambda_{2,K}^4}{\tau_K} + \mu\lambda_{2,K}^2 + \frac{(\lambda_{1,K}^2+\lambda_{2,K}^2)^2}{\lambda_{1,K}^4}\mu^2\tau_K \right)}_{\text{(I)}}$$

$$\Big[s_K^4\, L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{1,K};\, \mathbf{u}) + L_K(\mathbf{r}_{2,K},\, \mathbf{r}_{2,K};\, \mathbf{u}) + 2s_K^2 L_K(\mathbf{r}_{1,K},\, \mathbf{r}_{2,K};\, \mathbf{u}) \Big]$$

$$+ \underbrace{\left(\frac{\lambda_{2,K}^2}{\mu} + \tau_K \right)}_{\text{(II)}} \Big[s_K^2 (\mathbf{r}_{1,K}^T G_K(p)\, \mathbf{r}_{1,K}) + (\mathbf{r}_{2,K}^T G_K(p)\, \mathbf{r}_{2,K}) \Big] \Bigg\}.$$

Now, by inspecting terms (I) and (II) above, it turns out that the optimal value for τ_K is of the order of $\lambda_{2,K}^2/\mu$ in both cases; i.e., $\tau_K = \alpha\lambda_{2,K}^2/\mu$ for some $\alpha > 0$. Moreover, under this choice terms (I) and (II) behave like $\mu\lambda_{2,K}^2$ and $\lambda_{2,K}^2/\mu$, respectively. This concludes the proof. □

Remark 4. Under the same choice of the stability coefficients τ_K as obtained in the previous analysis, i.e., $\tau_K = \alpha\,\lambda_{2,K}^2/\mu$, we can further prove a convergence result with respect to the new norm $\|\cdot\|_{V\times Q}$ defined, for any $(\mathbf{v}, q) \in V \times Q$, by

$$(4.12)\qquad \|(\mathbf{v}, q)\|_{V\times Q}^2 = \mu\|\nabla\mathbf{v}\|_{L^2(\Omega)}^2 + \frac{1}{\mu}\, \frac{1}{\left(1 + \max\limits_{K\in\mathcal{T}_h} s_K^2\right)} \|q\|_{L^2(\Omega)}^2,$$

provided that the stability result in Lemma 4.2 is replaced by the new one stated in Lemma A.2 in the appendix. We remark that we have not been able to prove an optimal estimate yet with respect to the norm in (4.12), since our result still depends on the stretching factors s_K while the numerical results do not. This is the reason why we confine the proof of the new stability result to the appendix.

5. Numerical results.

In this section we first show numerically that on strongly anisotropic meshes better results are derived by using the definitions (3.13) and (4.7) of the stability coefficients τ_K when compared with the ones in [20, 21, 22]. Then we check that the convergence rate proved in Theorems 3.1 and 4.1 is confirmed by the numerical results. We also provide a numerical assessment of an adaptive anisotropic a posteriori error procedure based on standard gradient recovery techniques [37]. Two test cases for the advection-diffusion problem with parabolic internal and boundary layers, as well as with outflow boundary layers, are carried out using (3.13).

5.1. The advection-diffusion problem.

Let us consider the standard one-dimensional boundary layer problem

$$\begin{cases} -\mu\,\dfrac{d^2 v}{dx_1^2} + \dfrac{dv}{dx_1} = 1 & \text{in } \Omega \equiv (0,\,1), \\ v = 0 & \text{on } \partial\Omega, \end{cases}$$

with solution

$$v(x_1) = x_1 - \frac{1-\exp\left(\dfrac{x_1}{\mu}\right)}{1-\exp\left(\dfrac{1}{\mu}\right)}.$$

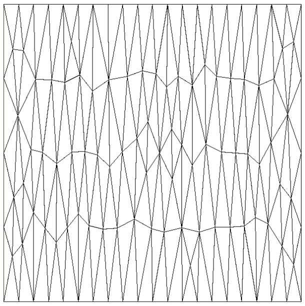

FIG. 5.1. *The advection-diffusion problem. A* 20×4 *anisotropic mesh of the domain* Ω. *All the meshes have been obtained using the* BL2D *library* [8].

To extend this test case in the two-dimensional framework, it suffices to set $\Omega = (0,1)^2$, $f = 1$, $\mathbf{a} = (1,0)^T$ in (3.1), while imposing homogeneous Dirichlet and homogeneous Neumann boundary conditions on the vertical and horizontal sides of Ω, respectively. The solution of (3.1) is thus given by $u(x_1, x_2) = v(x_1)$.

Validation of the stability coefficients. We consider the stabilized formulation (3.4), τ_K being defined, for any $K \in \mathcal{T}_h$, by

$$\tau_K = \frac{\lambda_{2,K}}{2} \frac{\xi(\mathrm{Pe}_K)}{\|\mathbf{a}\|_{L^\infty(K)}} \quad \text{with} \quad \mathrm{Pe}_K = \lambda_{2,K} \frac{\|\mathbf{a}\|_{L^\infty(K)}}{6\,\mu} \tag{5.1}$$

and

$$\tau_K = \frac{|K|^{1/2}}{2} \frac{\xi(\mathrm{Pe}_K)}{\|\mathbf{a}\|_{L^\infty(K)}} \quad \text{with} \quad \mathrm{Pe}_K = |K|^{1/2} \frac{\|\mathbf{a}\|_{L^\infty(K)}}{6\,\mu}, \tag{5.2}$$

respectively. Formula (5.2) corresponds to the stabilized method in [22] where the triangle diameter h_K is replaced by $|K|^{1/2}$, this replacement aiming at reducing the numerical dissipation. On the other hand, (5.1) represents our anisotropic design. Moreover, in all the numerical results, the reference element $\widehat{K}$ has been chosen as the right triangle $(0,0), (1,0), (0,1)$, and the values of $\lambda_{2,K}$ have been computed using a singular value decomposition routine.

In order to show that (5.1) yields better results than (5.2) in the presence of strongly anisotropic meshes, let us consider a 1000×4 anisotropic mesh of Ω of the type shown in Figure 5.1. In Figure 5.2 we have reported u_h along the bottom side of Ω for several values of the diffusivity μ. The choice (5.1) clearly turns out to be better than (5.2), with numerical diffusion being lower inside the boundary layer.

Convergence rate. In order to check the convergence rate of the GLS method with (5.1), we set $\mu = 10^{-2}$ in (3.1), select the anisotropic mesh in Figure 5.1, and refine the mesh size in the horizontal direction only. From Table 5.1 we observe that the order of convergence of the discretization error is equal to one with respect to the discrete norm $\|\cdot\|_h$ defined in (3.12). This agrees with the theoretical predictions (see Theorem 3.1). Moreover, the exact and the computed solutions along the bottom side of Ω are shown in Figure 5.3 in the presence of three different meshes.

A posteriori validation. Let us assess the behavior of recipe (5.1) on test cases characterized by two-dimensional anisotropic features (see also [34]). With this aim, we have carried out an adaptive iterative procedure based on the a posteriori analysis of [37]. With reference to (3.1), the data for the first test case (T_1) are $\mu = 10^{-4}$, $\mathbf{a} = (2,1)^T$, $f = 0$, $\Omega = (0,1)^2$, completed with Dirichlet boundary conditions, i.e.,

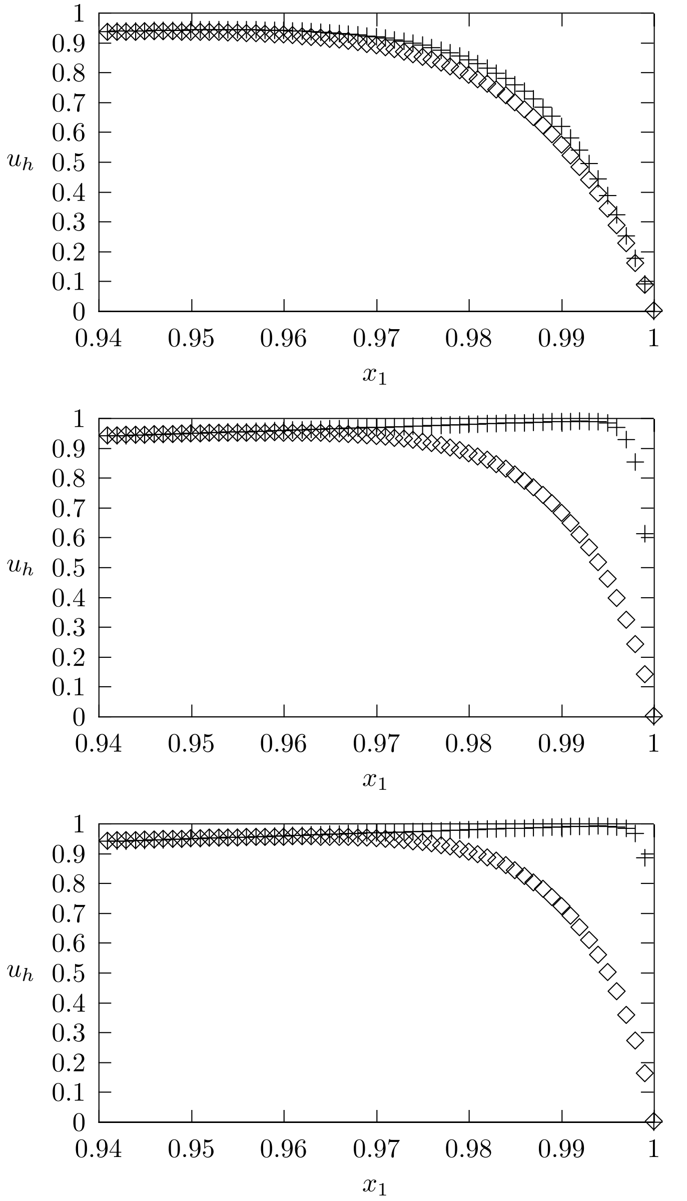

FIG. 5.2. *The advection-diffusion problem. Plots of* u_h *along the bottom side of* Ω *when using a* 1000×4 *anisotropic mesh. Only the part of the plot corresponding to* $0.94 \leq x_1 \leq 1$ *is displayed. Top:* $\mu = 10^{-2}$*; middle:* $\mu = 10^{-3}$*; bottom:* $\mu = 10^{-4}$*. $u = 1$ on the left and top sides and $u = 0$ on the remaining ones. For the second test case (T_2) we set $\mu = 10^{-4}$, $\mathbf{a} = (-1, 0)^T$, $f = 1$, $\Omega = (0,1)^2$, in addition to homogeneous Dirichlet boundary conditions on $\partial\Omega$. Notice that we expect the solutions of test cases (T_1) and (T_2) to show an internal layer and a boundary layer, and parabolic boundary layers, respectively.

Figure 5.4 shows the isolines between 0.1 and 0.9 (on the left) along with the adapted meshes (on the right) for both test cases. We remark that all the internal and boundary layers are very well captured by the adapted meshes consisting of less than 300 nodes. Moreover, it can be checked that the thickness of the internal and parabolic boundary layers is $O(\sqrt{\mu}) \simeq 10^{-2}$, while the one of the outflow boundary layers is $O(\mu) \simeq 10^{-4}$. Consequently, the aspect ratio of the two adapted meshes reaches large values of the order of 10^5.

5.2. Stokes problem. First we consider the classical Poiseuille test case in order to prove the superiority of the GLS method plus (4.7) compared with the one in [21]. Then we analyze a second test case to verify the convergence rate predicted by Theorem 4.1.

Validation of the stability coefficients. Due to the symmetry of the solution, let us choose $\Omega = (0, 0.15) \times (0, 0.03)$ (corresponding to half the physical domain) so that the Poiseuille exact solution is given by

$$\mathbf{u}(x_1, x_2) = \begin{bmatrix} (0.03 - x_2)(0.03 + x_2) \\ 0 \end{bmatrix} \quad \text{and} \quad p(x_1, x_2) = -0.02x_1 + 0.003.$$

Let us choose in (4.1) $\mathbf{f} = \mathbf{0}$ and $\mu = 10^{-2}$, while imposing Dirichlet and homogeneous Neumann boundary conditions for the velocity $\mathbf{u}$ along the left-top and bottom-right sides of Ω, respectively. Then we consider the stabilized formulation (4.3) with the

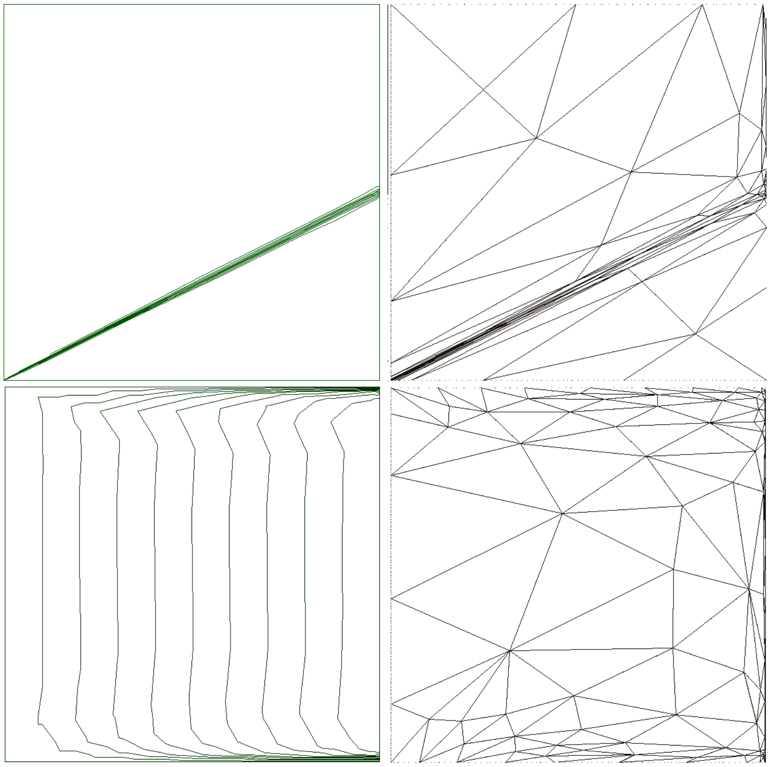

FIG. 5.4. *Isolines between* 0.1 *and* 0.9 *(left column) and adapted mesh (right column) for the test case* (T_1) *(top row) and for* (T_2) *(bottom row).*

coefficients τ_K defined, for any $K \in \mathcal{T}_h$, by

$$\tau_K = \alpha \, \frac{\lambda_{2,K}^2}{\mu} \tag{5.3}$$

and

$$\tau_K = \tilde{\alpha} \, \frac{|K|}{\mu}. \tag{5.4}$$

While (5.3) represents our design, formula (5.4) corresponds to the stabilized method of [21] with the triangle diameter h_K replaced by $|K|^{1/2}$ as was done in section 5.1. The two dimensionless coefficients α and $\tilde{\alpha}$ are tuned on the mesh of Figure 5.5 so that both computations give a reasonably precise solution.

In Figure 5.6 (top) the exact pressure profile along the bottom side of Ω is shown together with the stabilized approximate solutions with $\alpha = 0.1$ and $\tilde{\alpha} = 0.01$ in (5.3) and (5.4), respectively.

Then the same calculations are performed on the computational domain Ω stretched in the horizontal direction by a factor 10 and 100, that is, on $\Omega = (0, 1.5) \times (0, 0.03)$ and $\Omega = (0, 15) \times (0, 0.03)$. These new choices for the domain Ω allow us to preserve the total number of the elements and of the nodes of the mesh while increasing the maximal aspect ratio of the triangles (close to 1000 for the last mesh). The corresponding results are summarized in Figure 5.6 (middle and bottom). We

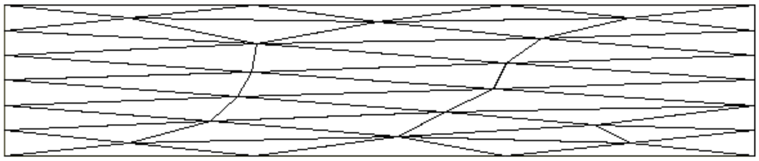

FIG. 5.5. *Stokes problem: Poiseuille test case. A* 3×6 *mesh of the domain* Ω.

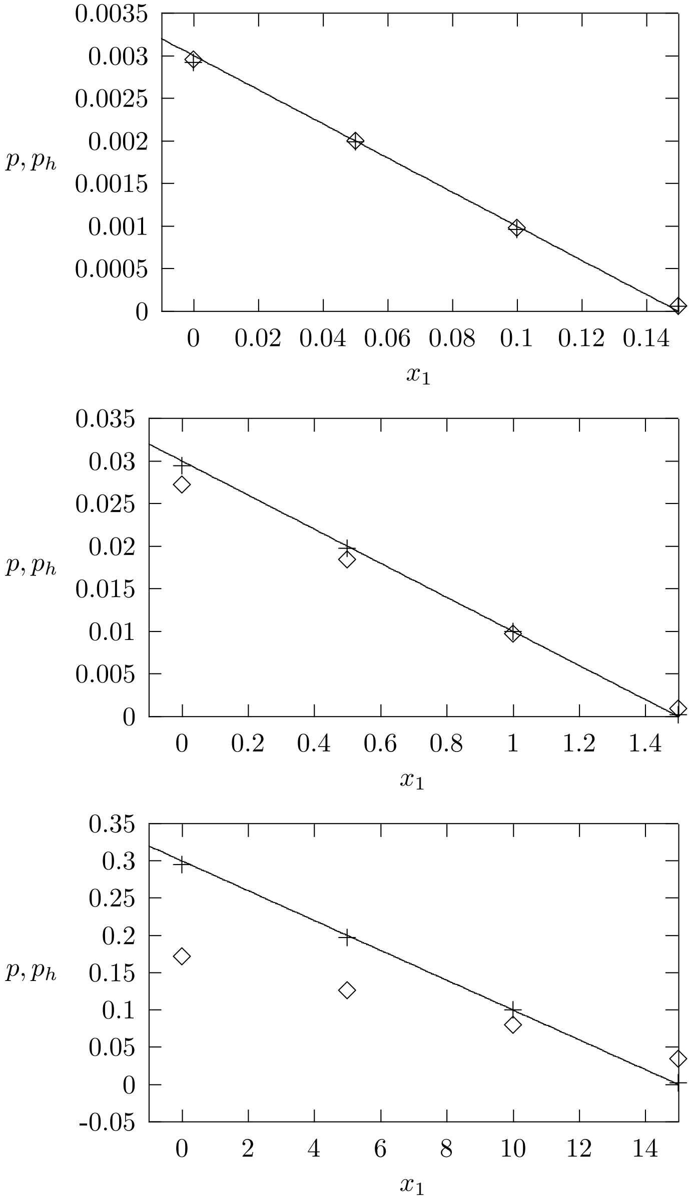

FIG. 5.6. *Stokes problem: Poiseuille test case. TABLE 5.2
Stokes problem: second test case. Errors with respect to the discrete norm (4.6) *in the presence of different anisotropic meshes and for the choice* $\mu = 10^{-2}$ *in* (4.1).

Mesh	$\|(\mathbf{u}-\mathbf{u}_h, p-p_h)\|_h$	$\|p-p_h\|_{L^2(\Omega)}$
6×30	0.83	0.9
6×60	0.31	0.37
6×120	0.15	0.18

observe that in all three cases the GLS method plus (5.3) yields better results than the GLS method plus (5.4).

Convergence rate. We consider the domain $\Omega = (0, 0.15) \times (0, 0.03)$ and choose in (4.1) $\mu = 10^{-2}$ and $\mathbf{f}$ so that the solution is given by

$$\mathbf{u}(x_1, x_2) = \left[\begin{array}{c} u_1(x_2) \\ 0 \end{array} \right] \quad \text{and} \quad p(x_1, x_2) = 0,$$

with

$$u_1(x_2) = \begin{cases} 1 & \text{if } \ 0 < x_2 \le 0.01, \\ \exp\left(\dfrac{(x_2 - 0.01)^2}{(x_2-0.01)^2 - 0.0001} \right) & \text{if } \ 0.01 < x_2 < 0.02, \\ 0 & \text{if } \ \ 0.02 \le x_2 < 0.03. \end{cases}$$

Thus the velocity is horizontal, smooth, zero, or one valued except in a region of width 0.01. We consider the same boundary conditions as in the previous example. Starting from the grid in Figure 5.7, we refine such a mesh in the vertical direction only. Then we approximate the solution of the Stokes problem by choosing as stability coefficients those defined in (5.3) with $\alpha = 0.1$. From Table 5.2 we observe that the error in the discrete norm $\| \cdot \|_h$ defined in (4.6) is of order one in agreement with the theoretical predictions (see Theorem 4.1). Moreover, it seems that the pressure error in the L^2-norm is of order one too. Finally, the exact and approximate velocity profiles computed along the vertical right side of the domain Ω are shown in Figure 5.8 in the presence of two different meshes.

We point out that the numerical results seem to show that the theory developed for homogeneous Dirichlet boundary conditions in (3.1) and (4.1) covers also the case of more general boundary conditions.

6. Conclusions. In this paper a theoretically sound design of the stability coefficients is proposed for the scalar advection-diffusion and the Stokes problems solved on strongly anisotropic meshes. Only continuous piecewise linear stabilized finite elements are considered.

Anisotropic adaptive finite elements have been developed with the present design of the stability coefficients (see [17, 37] for details). The numerical method seems to be robust since boundary layers of order 10^{-4} can be obtained with no more than

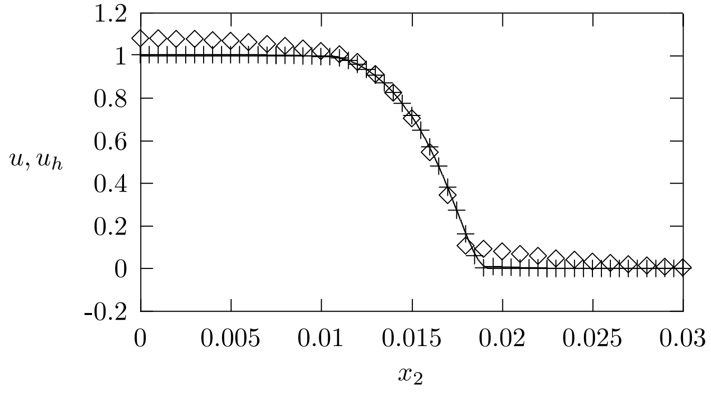

FIG. 5.8. *Stokes problem: second test case. Continuous line: profile of* $\mathbf{u}$ *along the vertical right side of* Ω *for the choice* $\mu = 10^{-2}$ *in* (4.1). *Solution obtained by GLS plus* (5.3) *on a:* 6×30 *mesh (diamonds);* 6×60 *mesh (crosses).*

300 vertices, the maximum aspect ratio being greater than 10^5. Even if the values obtained for both the aspect ratio and the number of vertices are no surprise in the literature (see, e.g., [35, 38]), we point out that our results have been obtained by a completely automatic adaptive procedure (see Figure 5.4).

Appendix. Let us assume that in the definition of the stability coefficients (4.7) $\alpha = 1$. First let us recall the standard inf-sup condition.

LEMMA A.1 (standard inf-sup condition). *There exists a constant* $\beta > 0$ *(depending only on the domain* Ω*) such that, for any* $p \in Q$*, we have*

$$\sup_{\substack{\mathbf{v}\in V\\ \mathbf{v}\neq\mathbf{0}}} \frac{-(p, \nabla\cdot\mathbf{v})}{\|\nabla\mathbf{v}\|_{L^2(\Omega)}} \geq \beta\|p\|_{L^2(\Omega)}.$$

Now we prove the stability of the bilinear form $B_h(\cdot,\cdot)$ associated with the Stokes problem with respect to the norm $\|\cdot\|_{V\times Q}$ defined in (4.12).

LEMMA A.2 (stability in norm $\|\cdot\|_{V\times Q}$). *There exists a constant* $C = C(\Gamma, \widehat{C}, \beta)$ *such that, for any* $(\mathbf{u}_h, p_h) \in V_h \times Q_h$*, we have*

$$\sup_{\substack{(\mathbf{v}_h,q_h)\in V_h\times Q_h\\ (\mathbf{v}_h,q_h)\neq(\mathbf{0},0)}} \frac{B_h(\mathbf{u}_h, p_h; \mathbf{v}_h, q_h)}{\|(\mathbf{v}_h, q_h)\|_{V\times Q}} \geq C\|(\mathbf{u}_h, p_h)\|_{V\times Q}.$$

Proof. It suffices to prove that there exist two constants $C_1 = C_1(\widehat{K}, \beta)$ and $C_2 = C_2(\widehat{K}, \beta)$ such that, for any $(\mathbf{u}_h, p_h) \in V_h \times Q_h$, there is a $(\mathbf{v}_h, q_h) \in V_h \times Q_h$ satisfying

$$\text{(A.1)}\quad B_h(\mathbf{u}_h, p_h; \mathbf{v}_h, q_h) \geq C_1\|(\mathbf{u}_h, p_h)\|^2_{V\times Q}, \quad \|(\mathbf{v}_h, q_h)\|_{V\times Q} \leq C_2\|(\mathbf{u}_h, p_h)\|_{V\times Q}.$$

We proceed as in [20] but in the frame of anisotropic meshes. The analogue of the so-called Verfürth's trick [41] is used in the presence of anisotropic meshes.

From Lemma A.1 there exists a function $\mathbf{v} \in V$ such that

$$\text{(A.2)}\qquad \|\nabla\mathbf{v}\|_{L^2(\Omega)} = \frac{1}{\mu}\|p_h\|_{L^2(\Omega)}$$

and

$$\frac{\beta}{\mu}\|p_h\|^2_{L^2(\Omega)} \leq -(p_h, \nabla\cdot\mathbf{v}). \tag{A.3}$$

Let $R_h(\mathbf{v})$ be the Clément interpolant of $\mathbf{v}$. Using the definition $(4.4)_1$ of the stabilized bilinear form $B_h(\cdot;\cdot)$ and integrating by parts we have

$$\begin{aligned} B_h(\mathbf{u}_h, p_h; R_h(\mathbf{v}), 0) &= \mu(\nabla\mathbf{u}_h, \nabla R_h(\mathbf{v})) - (p_h, \nabla\cdot R_h(\mathbf{v})) \\ &= \mu(\nabla\mathbf{u}_h, \nabla\mathbf{v}) - (p_h, \nabla\cdot\mathbf{v}) \\ &- \mu(\nabla\mathbf{u}_h, \nabla(\mathbf{v} - R_h(\mathbf{v}))) + (p_h, \nabla\cdot(\mathbf{v} - R_h(\mathbf{v}))) \\ &= \mu(\nabla\mathbf{u}_h, \nabla\mathbf{v}) - (p_h, \nabla\cdot\mathbf{v}) \\ &- \mu\sum_{K\in\mathcal{T}_h}(\nabla\mathbf{u}_h, \nabla(\mathbf{v} - R_K(\mathbf{v})))_K - \sum_{K\in\mathcal{T}_h}(\nabla p_h, \mathbf{v} - R_K(\mathbf{v}))_K. \end{aligned}$$

Notice that the stabilization term in the definition of $B_h(\cdot,\cdot)$ vanishes in this case. We now use the Cauchy–Schwarz inequality with (A.2) and (A.3) to obtain

$$\begin{aligned} B_h(\mathbf{u}_h, p_h; R_h(\mathbf{v}), 0) &\geq -\|\nabla\mathbf{u}_h\|_{L^2(\Omega)}\|p_h\|_{L^2(\Omega)} + \frac{\beta}{\mu}\|p_h\|^2_{L^2(\Omega)} \\ - \mu\sum_{K\in\mathcal{T}_h}\|\nabla\mathbf{u}_h\|_{L^2(K)}&\|\nabla(\mathbf{v} - R_K(\mathbf{v}))\|_{L^2(K)} - \sum_{K\in\mathcal{T}_h}\|\nabla p_h\|_{L^2(K)}\|\mathbf{v} - R_K(\mathbf{v})\|_{L^2(K)}. \end{aligned}$$

From the vectorial extensions of Lemma 2.3 and Proposition 2.5 (see Remark 2), there is a constant $C = C(\Gamma, \widehat{C})$ such that

$$\begin{aligned} B_h(\mathbf{u}_h, p_h; R_h(\mathbf{v}), 0) \geq &- \|\nabla\mathbf{u}_h\|_{L^2(\Omega)}\|p_h\|_{L^2(\Omega)} + \frac{\beta}{\mu}\|p_h\|^2_{L^2(\Omega)} \\ &- C\sum_{K\in\mathcal{T}_h}\left\{\left(\frac{\mu}{\lambda_{2,K}}\|\nabla\mathbf{u}_h\|_{L^2(K)} + \|\nabla p_h\|_{L^2(K)}\right)\right. \\ &\left.[\lambda^2_{1,K}(\mathbf{r}^T_{1,K}G_K(\mathbf{v})\mathbf{r}_{1,K}) + \lambda^2_{2,K}(\mathbf{r}^T_{2,K}G_K(\mathbf{v})\mathbf{r}_{2,K})]^{1/2}\right\}. \end{aligned}$$

Using Young inequality $ab \leq \frac{\gamma a^2}{2} + \frac{b^2}{2\gamma}$, with a, b and $\gamma > 0$, we then obtain

$$\begin{aligned} B_h(\mathbf{u}_h, p_h; R_h(\mathbf{v}), 0) \geq &-\frac{\mu}{2\beta}\|\nabla\mathbf{u}_h\|^2_{L^2(\Omega)} + \frac{\beta}{2\mu}\|p_h\|^2_{L^2(\Omega)} \\ &- C\,\frac{\gamma}{2}\sum_{K\in\mathcal{T}_h}\left(\mu\|\nabla\mathbf{u}_h\|^2_{L^2(K)} + \frac{\lambda^2_{2,K}}{\mu}\|\nabla p_h\|^2_{L^2(K)}\right) \\ &- C\,\frac{\mu}{\gamma}\sum_{K\in\mathcal{T}_h}\left\{\frac{1}{\lambda^2_{2,K}}[\lambda^2_{1,K}(\mathbf{r}^T_{1,K}G_K(\mathbf{v})\mathbf{r}_{1,K})\right. \\ &\left.+ \lambda^2_{2,K}(\mathbf{r}^T_{2,K}G_K(\mathbf{v})\mathbf{r}_{2,K})]\right\}, \end{aligned} \tag{A.4}$$

where γ has still to be chosen. Recalling the relation (2.11) and the hypothesis (2.1) on Δ_K and using (A.2) we have

$$\begin{aligned}\sum_{K\in\mathcal{T}_h}\left\{\frac{1}{\lambda_{2,K}^2}[\lambda_{1,K}^2(\mathbf{r}_{1,K}^T G_K(\mathbf{v})\mathbf{r}_{1,K})+\lambda_{2,K}^2(\mathbf{r}_{2,K}^T G_K(\mathbf{v})\mathbf{r}_{2,K})]\right\}&\\ \le C\left(1+\max_{K\in\mathcal{T}_h} s_K^2\right)\|\nabla\mathbf{v}\|_{L^2(\Omega)}^2 = C\left(1+\max_{K\in\mathcal{T}_h} s_K^2\right)\frac{1}{\mu^2}\|p_h\|_{L^2(\Omega)}^2,&\end{aligned}\tag{A.5}$$

with $C=C(\Gamma)$. Replacing the above estimate in (A.4) we can then choose γ so that

$$\begin{aligned}B_h(\mathbf{u}_h,p_h;R_h(\mathbf{v}),0)\ge\frac{\beta}{4\mu}\|p_h\|_{L^2(\Omega)}^2&\\ -\frac{C}{\beta}\left(1+\max_{K\in\mathcal{T}_h}s_K^2\right)\left(\mu\|\nabla\mathbf{u}_h\|_{L^2(\Omega)}^2+\sum_{K\in\mathcal{T}_h}\frac{\lambda_{2,K}^2}{\mu}\|\nabla p_h\|_{L^2(K)}^2\right),&\end{aligned}\tag{A.6}$$

where $C=C(\Gamma,\widehat{C})$. On the other hand, from Lemma 4.2 and (4.7) we know that

$$B_h(\mathbf{u}_h,p_h;\mathbf{u}_h,-p_h)=\mu\|\nabla\mathbf{u}_h\|_{L^2(\Omega)}^2+\sum_{K\in\mathcal{T}_h}\frac{\lambda_{2,K}^2}{\mu}\|\nabla p_h\|_{L^2(K)}^2.\tag{A.7}$$

Therefore, combining relations (A.6) and (A.7) we have

$$\begin{aligned}B_h(\mathbf{u}_h,p_h;\mathbf{u}_h+\delta R_h(\mathbf{v}),-p_h)\ge\delta\frac{\beta}{4\mu}\|p_h\|_{L^2(\Omega)}^2&\\ +\left(1-\delta\frac{C}{\beta}\left(1+\max_{K\in\mathcal{T}_h}s_K^2\right)\right)\left(\mu\|\nabla\mathbf{u}_h\|_{L^2(\Omega)}^2+\sum_{K\in\mathcal{T}_h}\frac{\lambda_{2,K}^2}{\mu}\|\nabla p_h\|_{L^2(K)}^2\right)&\end{aligned}$$

for any $\delta>0$. Choosing, for instance, δ such that

$$\frac{1}{2}=1-\delta\frac{C}{\beta}\left(1+\max_{K\in\mathcal{T}_h}s_K^2\right),$$

i.e.,

$$\delta=\frac{\beta}{2C\left(1+\max\limits_{K\in\mathcal{T}_h}s_K^2\right)},\tag{A.8}$$

we finally obtain

$$B_h(\mathbf{u}_h,p_h;\mathbf{u}_h+\delta R_h(\mathbf{v}),-p_h)\ge C\|(\mathbf{u}_h,p_h)\|_{V\times Q}^2,$$

with $C=C(\Gamma,\widehat{C},\beta)$. With reference to Lemma A.2, for each pair $(\mathbf{u}_h,p_h)\in V_h\times Q_h$, we can thus identify the test functions $(\mathbf{v}_h,q_h)\in V_h\times Q_h$ satisfying $(\text{A.1})_1$ as $(\mathbf{v}_h,q_h)=(\mathbf{u}_h+\delta R_h(\mathbf{v}),-p_h)$, where $\mathbf{v}\in V$ satisfies Lemma A.1 for $p=p_h$, and δ is given, e.g., by (A.8). In order to prove (A.1), it then remains to bound $\|(\mathbf{u}_h+\delta R_h(\mathbf{v}),-p_h)\|_{V\times Q}$ in terms of the norm $\|(\mathbf{u}_h,p_h)\|_{V\times Q}$. Young inequality yields

$$\begin{aligned}\|(\mathbf{u}_h+\delta R_h(\mathbf{v}),-p_h)\|_{V\times Q}^2\le 2\mu\Big(\|\nabla\mathbf{u}_h\|_{L^2(\Omega)}^2+\delta^2\|\nabla R_h(\mathbf{v})\|_{L^2(\Omega)}^2\Big)&\\ +\frac{1}{\mu}\frac{1}{\left(1+\max\limits_{K\in\mathcal{T}_h}s_K^2\right)}\|p_h\|_{L^2(\Omega)}^2.&\end{aligned}$$

Now, since

$$\|\nabla R_h(\mathbf{v})\|_{L^2(\Omega)} \leq \|\nabla \mathbf{v}\|_{L^2(\Omega)} + \|\nabla(\mathbf{v} - R_h(\mathbf{v}))\|_{L^2(\Omega)},$$

using relation (A.2), the vectorial extension of Proposition 2.5 (see Remark 2), and estimate (A.5), we obtain

$$\|\nabla R_h(\mathbf{v})\|_{L^2(\Omega)} \leq \frac{C}{\mu}\left(1 + \max_{K\in\mathcal{T}_h} s_K^2\right)^{1/2} \|p_h\|_{L^2(\Omega)},$$

where $C = C(\Gamma, \widehat{C})$. Finally, using the definition (A.8) of δ we obtain

$$\|(\mathbf{u}_h + \delta R_h(\mathbf{v}), -p_h)\|^2_{V\times Q} \leq C\|(\mathbf{u}_h, p_h)\|^2_{V\times Q},$$

with $C = C(\Gamma, \widehat{C}, \beta)$. $\square$

SURFACE PRESSURE POISSON EQUATION FORMULATION OF THE PRIMITIVE EQUATIONS: NUMERICAL SCHEMES*

ROGER SAMELSON[†], ROGER TEMAM[‡], CHENG WANG[‡], AND SHOUHONG WANG[‡]

Abstract. Numerical methods for the primitive equations (PEs) of oceanic flow are presented in this paper. First, a two-dimensional Poisson equation with a suitable boundary condition is derived to solve the surface pressure. Consequently, we derive a new formulation of the PEs in which the surface pressure Poisson equation replaces the nonlocal incompressibility constraint, which is known to be inconvenient to implement. Based on this new formulation, backward Euler and Crank–Nicolson schemes are presented. The marker and cell scheme, which gives values of physical variables on staggered mesh grid points, are chosen as spatial discretization. The convergence analysis of the fully discretized scheme is established in detail. The accuracy check for the scheme is also shown.

Key words. the primitive equations, surface pressure, staggered grid, convergence analysis

Introduction. The primary purpose of this paper is to propose and analyze numerical methods for the three-dimensional (3-D) primitive equations (PEs) of large scale oceanic flow using the surface pressure Poisson equation with a suitable boundary condition.

The hydrostatic balance results in the decomposition of the total pressure field into two parts: the integral of the density variable in the vertical direction, and the pressure field at surface level $z = 0$, i.e., the surface pressure. It was shown by Lions, Temam, and Wang [13] that the surface pressure is the Lagrange multiplier of an incompressibility constraint (namely, the vertically averaged horizontal velocity is divergence-free). Based on this remark, they introduced a new mathematical formulation of the PEs in which the surface pressure disappears by projecting the PEs onto the function space of the divergence-free averaged horizontal velocity field.

In this paper, the preoccupations are different: we want to develop numerical algorithms for the solution of the PEs. Contrary to the approach in [13], the surface pressure will play a central role in the algorithm; it is dynamically updated in the momentum equation, instead of being treated as a Lagrange multiplier. In particular, we will display a Poisson equation for the surface pressure and derive an approximate boundary condition for this Poisson equation. As a result, the surface pressure Poisson equation replaces the nonlocal constraint for the horizontal velocity field. The vertical velocity is calculated by integrating the horizontal divergence of the horizontal velocity field, due to the 3-D incompressibility.

Numerical methods are then proposed for the PEs formulated in the surface pres-

sure Poisson equation. At each time step, the surface pressure field is determined by a two-dimensional (2-D) Poisson solver after the data of the horizontal velocity field and the density field are updated by the momentum equations and the density equations. In turn, the gradient of the surface pressure is updated at the next time step. The temporal discretization is implemented by either the backward Euler or the Crank–Nicolson method. For the spatial discretization, we adopt the idea of the 3-D marker and cell (MAC) grid. Different variables in the PEs are evaluated on different staggered grids. The derivatives are replaced by second order centered-difference operators, while the integration in the vertical direction is implemented by the trapezoidal rule. Following the approach related to the development of a local vorticity boundary condition, we derive a consistent and second order accurate boundary condition for the surface pressure at the discrete level. The main advantage of the MAC scheme can be seen in the fact that the computed horizontal velocity field has exactly zero mean-divergence in a discrete level. Because of such a property, the 3-D calculated velocity field is orthogonal to the horizontal and vertical gradients of the total pressure field in a discrete L^2 space, which plays an important role in the convergence analysis. The idea is similar to that of the finite element approach, yet it dramatically simplifies the computation. To our knowledge, this is the first theoretical analysis of the PEs on the MAC grid (which is usually referred to as a "C grid" in the geophysical fluid dynamics (GFD) literature). It should be possible to use similar methods to analyze other related GFD models.

The paper is organized as follows. In section 1 we recall the formulation of the PEs and introduce the alternate formulation using the surface pressure Poisson equation. Backward Euler and Crank–Nicolson schemes (in temporal discretization) are presented in section 2. The description of the 3-D MAC scheme is given in section 3, and the detailed convergence analysis of the backward Euler method combined with the MAC staggered grid is provided in section 4. Finally, a numerical accuracy check is given in section 5, using a set of exact solutions to compare with the profiles computed by our scheme.

1. The PEs and the surface pressure Poisson equation. We start with the nondimensional PEs with proper scaling:

$$\tag{1.1} \begin{cases} \boldsymbol{v}_t + (\boldsymbol{v}\cdot\nabla)\boldsymbol{v} + w\dfrac{\partial \boldsymbol{v}}{\partial z} + \dfrac{f}{Ro}k\times\boldsymbol{v} + \dfrac{1}{Ro}\left(\displaystyle\int_z^0 \nabla\rho(x,y,s)\,ds + \nabla p_s\right) = L_1\boldsymbol{v}, \\ \rho_t + (\boldsymbol{v}\cdot\nabla)\rho + w\dfrac{\partial\rho}{\partial z} = L_2\rho, \\ \nabla\cdot\displaystyle\int_{-H_0}^0 \boldsymbol{v}\,dz = 0. \end{cases}$$

See, e.g., Pedlosky [19] and Lions, Temam, and Wang [12, 13] for a detailed derivation. In the above system, $\boldsymbol{u} = (\boldsymbol{v}, w) = (u, v, w)$ is the 3-D velocity vector field, $\boldsymbol{v} = (u, v)$ the horizontal velocity, $w = \mathcal{W}(\boldsymbol{v})$ the vertical velocity in which the operator $\mathcal{W}$ will be introduced in (1.7), ρ the density field, p_s the surface pressure, and Ro a Rossby number. The term $fk \times \boldsymbol{v}$ corresponds to the Coriolis force in its β-plane approximation, with the parameter $f = f_0 + \beta y$. The operators ∇, $\nabla\cdot$, $\triangle$ represent the gradient, divergence, and Laplacian in the (x, y)-plane, respectively. The diffusion operators are given by $L_1 = (\frac{1}{Re_1}\triangle + \frac{1}{Re_2}\partial_z^2)$ and $L_2 = (\frac{1}{Rt_1}\triangle + \frac{1}{Rt_2}\partial_z^2)$. For simplicity, we denote $\nu_1 = \frac{1}{Re_1}$, $\nu_2 = \frac{1}{Re_1}$, $\kappa_1 = \frac{1}{Rt_1}$, $\kappa_2 = \frac{1}{Rt_1}$. The computational domain is taken as $\mathcal{M} = \mathcal{M}_0 \times [-H_0, 0]$, where $\mathcal{M}_0$ is the surface part of the ocean. The boundary condition for (1.1) is given by

$$\begin{aligned} \nu_2 \frac{\partial \boldsymbol{v}}{\partial z} &= \tau_0, \quad \kappa_2 \frac{\partial \rho}{\partial z} = \rho_f \quad \text{at } z = 0, \\ \nu_2 \frac{\partial \boldsymbol{v}}{\partial z} &= 0, \quad \kappa_2 \frac{\partial \rho}{\partial z} = 0 \quad \text{at } z = -H_0, \end{aligned} \tag{1.2}$$

$$\boldsymbol{v} = 0 \quad \text{and} \quad \frac{\partial \rho}{\partial \boldsymbol{n}} = 0 \quad \text{on } \partial\mathcal{M}_0 \times [-H_0, 0], \tag{1.3}$$

in which the term τ_0 represents the wind stress force and ρ_f represents the heat flux at the surface of the ocean.

Furthermore, the PEs (1.1) are supplemented with the following initial data:

$$\boldsymbol{v}(x, y, z, 0) = \boldsymbol{v}_0(x, y, z), \quad \rho(x, y, z, 0) = \rho_0(x, y, z), \tag{1.4}$$

in which $\boldsymbol{v}_0$ satisfies the mean divergence-free property as will be stated below.

The momentum equation for the horizontal velocity $\boldsymbol{v}$ comes from its original form

$$\boldsymbol{v}_t + (\boldsymbol{v}\cdot\nabla)\boldsymbol{v} + w\frac{\partial \boldsymbol{v}}{\partial z} + \frac{1}{Ro}\Big(fk \times \boldsymbol{v} + \nabla p\Big) = \Big(\nu_1 \triangle + \nu_2 \partial_z^2\Big)\boldsymbol{v}, \tag{1.5}$$

combined with the hydrostatic balance

$$\frac{\partial p}{\partial z} = -\rho, \qquad \text{which implies} \quad p(x, y, z) = \int_z^0 \rho(x, y, s)\, ds + p_s(x, y). \tag{1.6}$$

We note that p denotes the total pressure field; the surface pressure $p_s(x, y) = p(x, y, 0)$ is a 2-D field in the horizontal plane. We refer the readers to [3, 20, 24] for other physical and numerical considerations related to surface pressure.

The representation formula for the vertical velocity w comes from the vertical integration of the continuity equation $\nabla\cdot\boldsymbol{v} + \partial_z w = 0$, using the vanishing boundary condition for w at the top ($z = 0$) and at the bottom ($z = -H_0$):

$$w(x, y, z) = -\nabla\cdot \int_{-H_0}^{z} \boldsymbol{v}(x, y, s)\, ds \equiv \mathcal{W}(\boldsymbol{v}). \tag{1.7}$$

It was first observed by Lions, Temam, and Wang in [13] that the surface pressure appears to be the Lagrange multiplier of the nonlocal constraint $\nabla\cdot\int_{-H_0}^{0} \boldsymbol{v}\, dz = 0$. For instance, in view of studying the balance of energy of the system, we multiply the first equation in (1.1) by $\boldsymbol{v}$; then the integral $\int_{\mathcal{M}} \boldsymbol{v}\cdot\nabla p_s\, d\boldsymbol{x}$ vanishes.

1.1. Determination of the surface pressure variable. A major difficulty in the numerical approximation of the PEs is the absence of a time evolution equation for the surface pressure field. The main objective in this section is to derive an alternate formulation equivalent to the usual formulation (1.1) such that the surface pressure variable p_s can be determined by the horizontal velocity field $\boldsymbol{v}$ and the density field ρ, which can be updated by the momentum equations and the density equations. Some earlier work on this issue can be found in [1, 2, 4, 5, 7, 8, 11, 14, 15, 16, 18, 21, 22, 23, 25, 26].

1.1.1. Surface pressure Poisson equation. We now derive an equation for the surface pressure function $p_s(x,y)$. The starting point is the nonlocal constraint $\nabla\cdot\int_{-H_0}^0 \boldsymbol{v}\,dz=0$. By taking the horizontal divergence of the momentum equation in (1.1), integrating over $(-H_0,\,0)$ in the z-direction, dividing by H_0, and keeping in mind that p_s is a variable in the (x,y) plane, we arrive at the following equation:

$$\begin{aligned}(\partial_t-\nu_1\triangle)\Big(\overline{\nabla\cdot\boldsymbol{v}}\Big)-\nu_2\overline{\Big(\partial_z^2(\nabla\cdot\boldsymbol{v})\Big)}+\frac{1}{H_0}\int_{-H_0}^0\nabla\cdot\Big((\boldsymbol{v}\cdot\nabla)\boldsymbol{v}+w\frac{\partial\boldsymbol{v}}{\partial z}\Big)\,dz\\ +\frac{1}{Ro}\overline{\nabla\cdot\Big(fk\times\boldsymbol{v}\Big)}+\frac{1}{H_0}\frac{1}{Ro}\int_{-H_0}^0\int_z^0\triangle\rho(x,y,s)\,ds\,dz+\frac{1}{Ro}\triangle p_s=0,\end{aligned}\tag{1.8}$$

where $\overline{f}$ represents the average of the variable f in the z-direction. The first term in (1.8) vanishes, since $\overline{\nabla\cdot\boldsymbol{v}}$ is identically 0 in the horizontal domain. The second term turns out to be

$$\nu_2\overline{\Big(\partial_z^2(\nabla\cdot\boldsymbol{v})\Big)}=\frac{\nu_2}{H_0}\int_{-H_0}^0\partial_z^2(u_x+v_y)\,dz=\frac{\nu_2}{H_0}\Big(u_{zx}+v_{zy}\Big)\Big|_{-H_0}^0.\tag{1.9}$$

The boundary condition in (1.2) indicates that $(u_{zx}+v_{zy})=\frac{1}{\nu_2}(\partial_x(\tau_0)_1+\partial_y(\tau_0)_2)$ at $z=0$ and $(u_{zx}+v_{zy})=0$ at $z=-H_0$. Inserting (1.9) into (1.8) and setting $\tau_d=\nabla\cdot\tau_0)$ at $z=0$, which is a known function, we conclude that the surface pressure p_s solves the following Poisson equation:

$$\begin{aligned}\triangle p_s=\frac{Ro}{H_0}\nabla\cdot\tau_0-\frac{Ro}{H_0}\int_{-H_0}^0\nabla\cdot\Big((\boldsymbol{v}\cdot\nabla)\boldsymbol{v}+w\frac{\partial\boldsymbol{v}}{\partial z}+\frac{1}{Ro}(fk\times\boldsymbol{v})\Big)\,dz\\ -\frac{1}{H_0}\int_{-H_0}^0\int_z^0\triangle\rho(x,y,s)\,ds\,dz.\end{aligned}\tag{1.10}$$

The Poisson equation (1.10), together with the boundary condition described below, determines the surface pressure field by the velocity field and the density field without involving time derivative profiles.

1.1.2. Boundary condition for the surface pressure. Another point we have to emphasize is that there should be a boundary condition imposed for the surface pressure Poisson equation (1.10) if the Dirichlet boundary condition (1.3) for horizontal velocity field $\boldsymbol{v}$ is imposed on the lateral boundary section $\partial\mathcal{M}_0\times[-H_0,0]$.

Integrating the momentum equation in (1.1) over $(-H_0,\,0)$ in the z-direction and dividing by H_0 gives

$$\begin{aligned}\overline{\boldsymbol{v}}_t+\overline{\Big((\boldsymbol{v}\cdot\nabla)\boldsymbol{v}+w\frac{\partial\boldsymbol{v}}{\partial z}\Big)}+\frac{1}{Ro}\overline{fk\times\boldsymbol{v}}+\frac{1}{H_0}\frac{1}{Ro}\int_{-H_0}^0\int_z^0\nabla\rho(\cdot,s)\,ds\,dz\\ +\frac{1}{Ro}\nabla p_s=\nu_1\triangle\overline{\boldsymbol{v}}+\nu_2\overline{\partial_z^2\boldsymbol{v}},\end{aligned}\tag{1.11}$$

assuming that p_s is independent of the z-variable. On the lateral boundary $\partial\mathcal{M}_0\times[-H_0,0]$, the time marching term $\overline{\boldsymbol{v}}_t$ and all the convection terms vanish because of the no-penetration, no-slip boundary condition (the term $w\frac{\partial\boldsymbol{v}}{\partial z}$ disappears since $\frac{\partial\boldsymbol{v}}{\partial z}$ is zero on the boundary). The term $\overline{\partial_z^2\boldsymbol{v}}$ also vanishes, since $\partial_z^2\boldsymbol{v}$ is also 0 on $\partial\mathcal{M}_0\times[-H_0,0]$. Therefore, by taking the inner product of (1.11) with the unit normal vector field on the boundary $\partial\mathcal{M}_0$ (of the 2-D domain $\mathcal{M}_0$), we arrive at the following boundary condition for the surface pressure:

$$\frac{\partial p_s}{\partial \boldsymbol{n}} = \nu_1\, Ro\, \triangle \overline{\boldsymbol{v}} \cdot \boldsymbol{n} \quad \text{on} \quad \partial\mathcal{M}_0. \tag{1.12}$$

1.2. Alternate formulation of the PEs. We then have the following formulation, in which the nonlocal constraint $\nabla\cdot\int_{-H_0}^{0} \boldsymbol{v}\, dz = 0$ is replaced by the surface pressure Poisson equation and a mean divergence-free boundary condition for the horizontal velocity:

$$\boldsymbol{v}_t + (\boldsymbol{v}\cdot\nabla)\boldsymbol{v} + \mathcal{W}(\boldsymbol{v})\frac{\partial \boldsymbol{v}}{\partial z} + \frac{f}{Ro}k\times\boldsymbol{v} + \frac{1}{Ro}\left(\int_z^0 \nabla\rho(x,y,s)\,ds + \nabla p_s\right) = L_1\boldsymbol{v}, \tag{1.13a}$$

$$\rho_t + (\boldsymbol{v}\cdot\nabla)\rho + \mathcal{W}(\boldsymbol{v})\frac{\partial \rho}{\partial z} = L_2\rho, \tag{1.13b}$$

$$\begin{aligned} \triangle p_s = {} & \frac{Ro}{H_0}\tau_d - \frac{Ro}{H_0}\int_{-H_0}^{0} \nabla\cdot\Big((\boldsymbol{v}\cdot\nabla)\boldsymbol{v} + \mathcal{W}(\boldsymbol{v})\frac{\partial \boldsymbol{v}}{\partial z} + \frac{1}{Ro}(fk\times\boldsymbol{v})\Big)\,dz \\ & - \frac{1}{H_0}\int_{-H_0}^{0}\int_z^0 \triangle\rho(x,y,s)\,ds\,dz, \end{aligned} \tag{1.13c}$$

$$\begin{aligned} & \frac{\partial \boldsymbol{v}}{\partial z} = \frac{\tau_0}{\nu_2} \quad \text{at} \quad z=0, \qquad \frac{\partial \boldsymbol{v}}{\partial z} = 0 \quad \text{at} \quad z=-H_0, \\ & \frac{\partial \rho}{\partial z} = \frac{\rho_f}{\kappa_2} \quad \text{at} \quad z=0, \qquad \frac{\partial \rho}{\partial z} = 0 \quad \text{at} \quad z=-H_0, \\ & \boldsymbol{v} = 0 \quad \text{and} \quad \frac{\partial \rho}{\partial \boldsymbol{n}} = 0 \quad \text{on} \quad \partial\mathcal{M}_0\times[-H_0,0], \end{aligned} \tag{1.13d}$$

$$(\overline{\nabla\cdot\boldsymbol{v}}) = 0 \quad \text{on} \quad \partial\mathcal{M}_0. \tag{1.13e}$$

PROPOSITION 1.1. *For $\boldsymbol{v},\rho \in L^\infty([0,T],H^3)$, $\partial_t\boldsymbol{v},\partial_t\rho \in L^\infty([0,T],H^1)$, the original formulation* (1.1)–(1.3) *of the PEs is equivalent to the alternate formulation* (1.13a)–(1.13e).

Proof. Assume $(\boldsymbol{v},\rho,p_s)$ is a solution of (1.1)–(1.3). We observe that p_s satisfies the Poisson equation (1.13b), which can be obtained by taking the horizontal divergence of the momentum equation in (1.1) and averaging in the vertical direction as shown in the above derivation. In addition, taking the vertical derivative of the representation formula for the vertical velocity in (1.1) indicates that the horizontal velocity $\boldsymbol{v}$ satisfies the constraint $\overline{\nabla\cdot\boldsymbol{v}} = 0$. The usage of the regularity for $\boldsymbol{v}\in L^\infty([0,T],H^3)$ shows that $\boldsymbol{v}$ satisfies the additional boundary condition (1.13e). This concludes that $(\boldsymbol{v},\rho,p_s)$ is also a solution of (1.13).

Conversely, assume $(\boldsymbol{v},\rho,p_s)$ is a solution of (1.13). We need to show that $\overline{\nabla\cdot\boldsymbol{v}} = 0$. Taking the divergence of (1.13a) and integrating in the vertical direction leads to

$$\partial_t(\overline{\nabla\cdot\boldsymbol{v}}) - \nu_1\triangle(\overline{\nabla\cdot\boldsymbol{v}}) = 0, \tag{1.14a}$$

since *all the other terms are canceled by the surface pressure Poisson equation.* Hence the heat equation (1.14a) for the scalar quantity $\overline{\nabla\cdot\boldsymbol{v}}$, together with the homogeneous initial data

$$(\overline{\nabla\cdot\boldsymbol{v}})(x,y,t=0)=0, \tag{1.14b}$$

and the additional mean divergence-free boundary condition for the horizontal velocity imposed by (1.13e),

$$(\overline{\nabla\cdot\boldsymbol{v}})=0 \quad \text{on } \partial\mathcal{M}_0, \tag{1.14c}$$

show that $(\overline{\nabla\cdot\boldsymbol{v}})=0$; namely, the third equation in (1.1) is satisfied for all $t>0$. Therefore, $(\boldsymbol{v},\rho,p_s)$ is also a solution of (1.1)–(1.3). That completes the proof of Proposition 1.1. □

Remark 1.2. The above arguments show that the system (1.13a)–(1.13e) implies the original system of PEs (1.1)–(1.3), and therefore it implies (1.12), a Neumann-type boundary condition for the surface pressure p_s, since (1.12) is derived from the momentum equation in (1.1). In other words, the boundary condition (1.12) must be satisfied by any solution of the system (1.13a)–(1.13e). For the computations, the additional boundary condition (1.13e), a mean divergence-free boundary condition for the horizontal velocity, is not convenient to use. Instead, we will replace it by (1.12), a boundary condition for the surface pressure, to solve for the Poisson equation (1.13b); note that we are not claiming that the systems are equivalent if we replace (1.13e) by (1.12), leaving (1.13a)–(1.13d) unchanged. However, as we show below, such an equivalence occurs in the case of the MAC scheme, the spatially discrete scheme that will be studied in section 3.

1.3. Analogy with the 2-D Navier–Stokes equations. It could be observed that the boundary condition (1.13e) is coupled with the surface pressure Poisson equation (1.13b) and the momentum equation (1.13a), (1.13d). In more detail, in the derived formulation (1.13), four boundary conditions are prescribed for the horizontal velocity field: $\frac{\partial\boldsymbol{v}}{\partial z}=\frac{\tau_0}{\nu_2}$ on $z=0$, $\frac{\partial\boldsymbol{v}}{\partial z}=0$ on $z=-H_0$, $\boldsymbol{v}=0$ on $\partial\mathcal{M}_0\times[-H_0,0]$, and $(\overline{\nabla\cdot\boldsymbol{v}})=0$ on $\partial\mathcal{M}_0$, while there is no boundary condition for the surface pressure p_s. This subtle fact appears in a similar way for the formulations of incompressible fluid equations, such as the Navier–Stokes equation (NSE). For example, the vorticity-stream function formulation of the 2-D NSE in a simply connected domain, which is also a derived formulation, can be written as

$$\begin{cases} \partial_t\omega+(\boldsymbol{v}\cdot\nabla)\omega=\nu\triangle\omega, \\ \triangle\psi=\omega, \\ u=-\partial_y\psi, \qquad v=\partial_x\psi, \end{cases} \tag{1.15}$$

where $\boldsymbol{v}=(u,v)$ denotes the 2-D velocity field, $\omega=\nabla\times\boldsymbol{u}=-\partial_y u+\partial_x v$ denotes the vorticity, and the no-penetration, no-slip boundary condition can be written in terms of the stream function ψ:

$$\psi=0, \quad \frac{\partial\psi}{\partial\mathbf{n}}=0 \qquad \text{on} \qquad \partial\mathcal{M}_0. \tag{1.16}$$

Similar to our derived formulation (1.13), in the coupled system (1.15) and (1.16), there are two boundary conditions for the stream function ψ (both Dirichlet and Neumann) and no explicit boundary condition for the vorticity ω. On the other hand, updating the dynamic equation in (1.15) requires the vorticity boundary values; see [6, 10, 17, 18, 27, 28] for detailed description, derivation, and analysis of vorticity boundary conditions. A similar difficulty arises in the formulation (1.13): what boundary condition should be imposed to solve surface pressure p_s? Of course, the Neumann boundary condition (1.12) is a good choice to replace (1.13e); their equivalence is not claimed at the PDE level, as noted in Remark 1.2. However, in the MAC spatial discretization with a staggered grid described in section 3, the boundary condition $(\overline{\nabla\cdot\boldsymbol{v}})\ |_{\partial\mathcal{M}_0}= 0$ is converted by a second order accurate realization into the surface pressure boundary condition. Furthermore, in such a staggered grid, the equivalence between the derived boundary condition and the nonlocal constraint on the boundary as in (1.13e) can be fully proven.

Remark 1.3. The precise approximation of the pressure field via the pressure Poisson equation is a well-known difficulty in the incompressible flow calculation if the physical boundary condition is presented. The approach for solving the 2-D and 3-D NSEs by utilizing a local pressure boundary condition was recently introduced by Johnston and Liu in [11]. Some ideas in their paper can be adapted in our work.

Remark 1.4. The PEs with general boundary conditions or noncylindric domains were investigated in earlier literatures by Lions, Temam, and Wang [12, 13, 14, 15, 16] in a PDE level. The corresponding numerical methods can be accordingly derived using finite element approaches. We hope to report that issue in a future paper.

2. Temporal discretization.

Two computational methods for the PEs in surface pressure Poisson equation formulation (1.13) are proposed in this section. The horizontal velocity field and the density field are updated by the momentum equation (1.13a) and the density equation (1.13b). The surface pressure field, which is essentially a Lagrange multiplier in a horizontal plane, is determined by a 2-D Poisson solver, using the information of the velocity field and the density field at the same time step (stage). Henceforth, the surface pressure gradient is treated as a force term in the dynamic evolution of the momentum equation in the next time step (the stage). As a result, the surface pressure term is decoupled from the diffusion term; thus the Stokes solver is avoided. That dramatically simplifies the computation.

For simplicity, we use implicit treatment of the diffusion terms in the momentum equation and the density equation, which makes the stability and convergence analysis of the numerical scheme easier to handle. The backward Euler scheme is chosen as the example of the first order method (in temporal discretization) and the Crank–Nicolson scheme as the second order version.

2.1. Backward Euler method.

Given the velocity field $\boldsymbol{u}^n$, surface pressure field p_s^n, and density field ρ^n at time t^n, we update all the profiles at the time step t^{n+1} through the following procedure.

Step 1. The semi-implicit scheme for the momentum equation and the density equation is given, leaving the convection term and the surface pressure gradient explicit:

$$\text{(2.1a)}\quad \left\{\begin{aligned} &\frac{\boldsymbol{v}^{n+1}-\boldsymbol{v}^n}{\triangle t} + (\boldsymbol{v}^n\cdot\nabla)\boldsymbol{v}^n + \mathcal{W}(\boldsymbol{v}^n)\frac{\partial \boldsymbol{v}^n}{\partial z} + \frac{f}{Ro}k\times\boldsymbol{v}^n \\ &\qquad + \frac{1}{Ro}\int_z^0 \nabla\rho^n(x,y,s)\,d + \frac{1}{Ro}\nabla p_s^n(x,y) = \Big(\nu_1\triangle + \nu_2\partial_z^2\Big)\boldsymbol{v}^{n+1}, \\ &\frac{\rho^{n+1}-\rho^n}{\triangle t} + (\boldsymbol{v}^n\cdot\nabla)\rho^n + w^n\frac{\partial\rho^n}{\partial z} = \Big(\kappa_1\triangle + \kappa_2\partial_z^2\Big)\rho^{n+1}, \end{aligned}\right.$$

which are three standard Poisson-like equations, with the boundary condition

$$\begin{aligned}
&\frac{\partial \boldsymbol{v}^{n+1}}{\partial z} = \frac{\tau_0}{\nu_2}, \quad \frac{\partial \rho^{n+1}}{\partial z} = \frac{\rho_f}{\kappa_2} \quad \text{at } z=0,\\
&\frac{\partial \boldsymbol{v}^{n+1}}{\partial z} = 0, \quad \frac{\partial \rho^{n+1}}{\partial z} = 0 \quad \text{at } z=-H_0,\\
&\boldsymbol{v}^{n+1} = 0 \quad \text{and} \quad \frac{\partial \rho^{n+1}}{\partial \boldsymbol{n}} = 0 \quad \text{on } \partial\mathcal{M}_0 \times [-H_0, 0].
\end{aligned} \tag{2.1b}$$

Step 2. With all the velocity field $\boldsymbol{v}^{n+1}$, w^{n+1} at hand, we can solve for the surface pressure field at the time step t^{n+1} by the 2-D Poisson equation

$$\begin{aligned}
\triangle p_s^{n+1} = &\frac{Ro}{H_0}\tau_d^{n+1} - \frac{1}{H_0}\int_{-H_0}^0 \int_z^0 \triangle \rho^{n+1}(x,y,s)\,ds\,dz\\
&- \frac{Ro}{H_0}\int_{-H_0}^0 \nabla\cdot\Big((\boldsymbol{v}^{n+1}\cdot\nabla)\boldsymbol{v}^{n+1} + \mathcal{W}(\boldsymbol{v}^{n+1})\frac{\partial \boldsymbol{v}^{n+1}}{\partial z} + \frac{1}{Ro}(fk\times\boldsymbol{v}^{n+1})\Big)\,dz,
\end{aligned} \tag{2.2a}$$

supplemented with the derived boundary condition (1.12), as argued in Remark 1.2 and section 1.3:

$$\frac{\partial p_s^{n+1}}{\partial \boldsymbol{n}} = \nu_1\, Ro\, \triangle \overline{\boldsymbol{v}}^{n+1}\cdot\boldsymbol{n} \quad \text{on} \quad \partial\mathcal{M}_0. \tag{2.2b}$$

2.2. Crank–Nicolson method. The updating from time step t^n to t^{n+1} is carried out by the following steps.

Step 1. Solve for the momentum equations and the density equations

$$\begin{cases}
\dfrac{\boldsymbol{v}^{n+1}-\boldsymbol{v}^n}{\triangle t} + RHS1^{n+\frac12} + \dfrac{1}{Ro}\nabla p_s^{n+\frac12} = \dfrac12\Big(\nu_1\triangle + \nu_2\partial_z^2\Big)(\boldsymbol{v}^n + \boldsymbol{v}^{n+1}),\\
\dfrac{\rho^{n+1}-\rho^n}{\triangle t} + RHS2^{n+\frac12} = \dfrac12\Big(\kappa_1\triangle + \kappa_2\partial_z^2\Big)(\rho^n + \rho^{n+1}),
\end{cases} \tag{2.3}$$

using the boundary condition (2.1b), where

$$\begin{aligned}
RHS1^{n+\frac12} &= (\boldsymbol{v}^{n+\frac12}\cdot\nabla)\boldsymbol{v}^{n+\frac12} + \mathcal{W}(\boldsymbol{v}^{n+\frac12})\frac{\partial \boldsymbol{v}^{n+\frac12}}{\partial z} + \frac{f}{Ro}k\times\boldsymbol{v}^{n+\frac12}\\
&\quad + \frac{1}{Ro}\int_z^0 \nabla\rho^{n+\frac12}(x,y,s)\,ds,\\
RHS2^{n+\frac12} &= (\boldsymbol{v}^{n+\frac12}\cdot\nabla)\rho^{n+\frac12} + \mathcal{W}(\boldsymbol{v}^{n+\frac12})\frac{\partial \rho^{n+\frac12}}{\partial z}.
\end{aligned} \tag{2.4}$$

The velocity and the density profiles $(\boldsymbol{u}, \rho) = (\boldsymbol{v}, w, \rho)$, along with the surface pressure p_s, at the time step $t^{n+\frac12}$ are evaluated by second order explicit extrapolation in time

$$\boldsymbol{u}^{n+\frac12} = \frac32\boldsymbol{u}^n - \frac12\boldsymbol{u}^{n-1}, \quad \rho^{n+\frac12} = \frac32\rho^n - \frac12\rho^{n-1}, \quad p_s^{n+\frac12} = \frac32 p_s^n - \frac12 p_s^{n-1}. \tag{2.5}$$

Note that the system (2.3) is also composed of three standard Poisson-like equations.

Step 2. The surface pressure field at the time step t^{n+1} is solved by the 2-D Poisson equation (2.2a) with the derived boundary condition (2.2b), as in the second step of the backward Euler scheme.

3. Spatial discretization: MAC scheme. We consider hereafter the oceanic basin given by $\mathcal{M}_0 = [0,1]^2$ and assume for simplicity that $\triangle x = \triangle y = \triangle z = h$. The analysis of the spatial discretization with regular grids is quite difficult. In this paper, we consider the MAC staggered grid as spatial discretization. Some well-known difficulties in the numerical simulation of NSE, such as enforcement of the incompressibility condition and lack of proper evolutionary equation for the pressure and associate boundary condition, were elegantly resolved in the celebrated MAC scheme, which was first proposed by Harlow and Welch in [9]. For the system of the PEs, the 3-D MAC staggered grid is used in the computational method.

An illustration of the MAC mesh on the section $z_k = (k+1/2)\triangle z$ is given in Figure 3.1. The surface pressure variable p_s is evaluated at the square points $(i \pm 1/2, j \pm 1/2)$, the velocity u is evaluated at the triangle points $(i, j \pm 1/2, k \pm 1/2)$, the velocity v is evaluated at the circle points $(i \pm 1/2, j, k \pm 1/2)$, and the velocity w and the density function ρ are evaluated at the dot points $(i \pm 1/2, j \pm 1/2, k)$. The advantage of such a staggered grid is the convenience to assure the divergence-free property of the numerical velocity field, which can be observed later.

The following centered differences using different stencils at different grid points is introduced to facilitate the description below:

$$\begin{aligned} &D_x g(x) = \frac{g(x+\frac{1}{2}h) - g(x-\frac{1}{2}h)}{h}, \quad \tilde{D}_x g(x) = \frac{g(x+h) - g(x-h)}{2h}, \\ &D_x^2 g(x) = \frac{g(x-h) - 2g(x) + g(x+h)}{h^2}, \end{aligned} \tag{3.1}$$

which are second order approximations to ∂_x, ∂_x^2, respectively. The corresponding operators in y- and z-directions, such as D_y, $\tilde{D}_y$, D_y^2, D_z, $\tilde{D}_z$, D_z^2, can be defined in the same fashion.

The discrete divergence of the total velocity field $\boldsymbol{u}$ is evaluated at the square points:

$$(\nabla_h \cdot \boldsymbol{u})_{i+1/2,j+1/2,k+1/2} = \Big(D_x u + D_y v + D_z w \Big)_{i+1/2,j+1/2,k+1/2}. \tag{3.2}$$

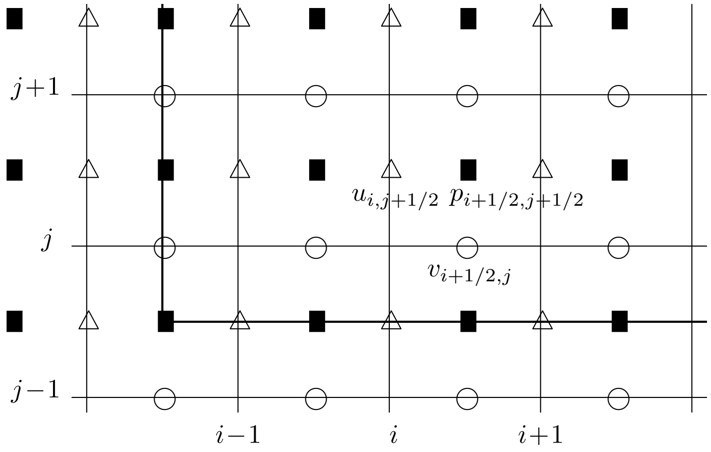

FIG. 3.1. *MAC mesh at $z_k = (k+1/2)\triangle z$; Harlow and Welch* [9].

The diffusion term for the velocity u is approximated by

$$\Big(\nu_1 \triangle + \nu_2 \partial_z^2\Big) u = \Big(\nu_1 \triangle_h + \nu_2 D_z^2\Big) u = \Big(\nu_1 (D_x^2 + D_y^2) + \nu_2 D_z^2\Big) u \tag{3.3}$$

at $(i, j+1/2, k+1/2)$. The other diffusion terms, $\triangle_h v$, $D_z^2 v$, at the mesh point $(i+1/2, j, k+1/2)$, and $\triangle_h \rho$, $D_z^2 \rho$, at the mesh point $(i+1/2, j+1/2, k)$, can be given in the same way. The gradient of density and the surface pressure appearing in the momentum equation is discretized by $(D_x\rho)_{i,j+1/2,k+1/2}$, $(D_y\rho)_{i,j+1/2,k+1/2}$ (and $(D_x p_s)_{i,j+1/2}$, $(D_y p_s)_{i+1/2,j}$), respectively.

The approximation to the nonlinear convection term $(\boldsymbol{v}\cdot\nabla)\boldsymbol{v} + w\frac{\partial \boldsymbol{v}}{\partial z}$, $(\boldsymbol{v}\cdot\nabla)\rho + w\frac{\partial \rho}{\partial z}$ at the corresponding mesh points for u, v, ρ relies on the introduction of average value of u, v, w at the staggered grid. For example, at the mesh point $(i, j+1/2, k+1/2)$ where u is located, the average v, w can be introduced as

$$\begin{aligned} \overline{\overline{v}}_{i,j+1/2,k+1/2} = \; & \frac{1}{4}(v_{i-1/2,j,k+1/2} + v_{i+1/2,j,k+1/2} \\ & + v_{i-1/2,j+1,k+1/2} + v_{i+1/2,j+1,k+1/2}), \end{aligned} \tag{3.4a}$$

$$\begin{aligned} \overline{\overline{w}}_{i,j+1/2,k+1/2} = \; & \frac{1}{4}(w_{i-1/2,j+1/2,k} + w_{i+1/2,j+1/2,k} \\ & + w_{i-1/2,j+1/2,k+1} + w_{i+1/2,j+1/2,k+1}), \end{aligned} \tag{3.4b}$$

and the corresponding convection term for u: $uu_x + vu_y + wu_z$ can be defined as

$$\mathcal{N}_h(\boldsymbol{u}, u) = u\tilde{D}_x u + \overline{\overline{v}}\tilde{D}_y u + \overline{\overline{w}}\tilde{D}_z u \qquad \text{at} \qquad (i, j+1/2, k+1/2). \tag{3.5}$$

The two other convection terms, $\mathcal{N}_h(\boldsymbol{u}, v)_{i+1/2,j,k+1/2}$, $\mathcal{N}_h(\boldsymbol{u}, \rho)_{i+1/2,j+1/2,k}$, which are approximations to $uv_x + vv_y + wv_z$, $u\rho_x + v\rho_y + w\rho_z$ at the corresponding mesh points, can be similarly defined. In addition, the Coriolis force term $fk \times \boldsymbol{v} = (-fv, fu)$ is evaluated at the mesh points for u, v, respectively, by taking the average of v and u at the required grid points as in (5.4):

$$\begin{aligned} (-fv)_{i,j+1/2,k+1/2} &= -f_{i,j+1/2}\overline{\overline{v}}_{i,j+1/2,k+1/2}, \\ (fu)_{i+1/2,j,k+1/2} &= f_{i+1/2,j}\overline{\overline{u}}_{i+1/2,j,k+1/2}. \end{aligned} \tag{3.6}$$

Clearly, the truncation errors of these approximations are of second order. The momentum equation for u is implemented at triangle points, the second momentum equation is implemented at circle points, and the density equation is implemented at the mesh points $(i+1/2, j+1/2, k)$. The discrete version of the term $\int_z^0 \nabla\rho(x,y,s)\,ds$ appearing in the momentum equation is a discrete integral of $\tilde{D}_x\rho$, $\tilde{D}_y\rho$ (which are defined at mesh points $(i, j+1/2, k)$, $(i+1/2, j, k)$, respectively, as given in (3.3)), in the z-direction. More accurately, $\mathcal{P}NRX$ is defined as the discrete version of $\int_z^0 \rho_x(x,y,s)\,ds$:

(3.7a)

$$\begin{aligned} &\mathcal{P}NRX_{i,j+1/2,N-1/2} = \frac{1}{2}\triangle z\,(D_x\rho)_{i,j+1/2,N}, \\ &\mathcal{P}NRX_{i,j+1/2,k-1/2} = \mathcal{P}NRX_{i,j+1/2,k+1/2} + \triangle z\,(D_x\rho)_{i,j+1/2,k}, \quad k \le N_z - 1, \end{aligned}$$

and $\mathcal{P}NRY$ can be given in a similar way:

(3.7b)

$$\begin{aligned} &\mathcal{P}NRY_{i+1/2,j,N-1/2} = \frac{1}{2}\triangle z\,(D_y\rho)_{i+1/2,j,N}, \\ &\mathcal{P}NRY_{i+1/2,j,k-1/2} = \mathcal{P}NRY_{i+1/2,j,k+1/2} + \triangle z\,(D_y\rho)_{i+1/2,j,k}, \quad k \le N_z - 1. \end{aligned}$$

Both formulae are second order approximation to the integral of the density gradient from z_k to 0.

The 2-D discrete Poisson equation for surface pressure p_s is implemented at square points. In more detail, we denote

$$\begin{aligned} \mathcal{F}U &= -\mathcal{N}_h(\boldsymbol{u}, u) + \frac{1}{Ro}(fv) - \frac{1}{Ro}\mathcal{P}NRX \quad \text{at } (i, j+1/2, k+1/2), \\ \mathcal{F}V &= -\mathcal{N}_h(\boldsymbol{u}, v) - \frac{1}{Ro}(fu) - \frac{1}{Ro}\mathcal{P}NRY \quad \text{at } (i+1/2, j, k+1/2) \end{aligned} \tag{3.8}$$

as the convection terms (including the Coriolis force term) for the momentum equation; therefore, the Poisson equation for surface pressure p_s can be written as

(3.9)

$$\begin{aligned} &(\triangle_h p_s)_{i+1/2,j+1/2} = \frac{Ro}{H_0}\Big(D_x\tau_{0,1} + D_y\tau_{0,2}\Big)_{i+1/2,j+1/2} + Ro\,\overline{\mathcal{F}P}_{i+1/2,j+1/2}, \text{ where} \\ &\mathcal{F}P_{i+1/2,j+1/2,k+1/2} = (D_x\mathcal{F}U)_{i+1/2,j+1/2,k+1/2} + (D_y\mathcal{F}V)_{i+1/2,j+1/2,k+1/2}, \end{aligned}$$

on the mesh points $(i+1/2, j+1/2)$ in the 2-D region $\mathcal{M}_0 = [0,1]^2$. The average of $\mathcal{F}P$, which is evaluated at the same numerical mesh grid as p, is defined as

$$\overline{\mathcal{F}P}_{i+1/2,j+1/2} = \frac{1}{H_0}\sum_{k=0}^{nz-1}(\triangle z\,\mathcal{F}P_{i+1/2,j+1/2,k+1/2}), \tag{3.10}$$

which is a second order approximation to the integral of $\mathcal{F}P$ in the z-direction. Such an evaluation of the discrete integral in the z-direction can be applied to any variable whose z-direction grid is indexed as $k \pm 1/2$.

It should be remarked that some suitable boundary condition is needed to solve the 2-D Poisson equation (3.9). Such a choice of the boundary condition assures the discrete divergence $(\nabla_h \cdot \boldsymbol{v})$ has mean zero (in the z-direction) on the boundary $\partial\mathcal{M}_0$. Details will be discussed in a later section.

On the physical boundary section $i = 0$, the no-penetration, no-slip boundary condition $\boldsymbol{v} = 0$ is translated by the reflection rule, whose application in the case of the 2-D NSE can be found in earlier work [4, 6, 7, 9],

$$u_{0,j+1/2,k+1/2} = 0, \quad v_{-1/2,j,k+1/2} + v_{1/2,j,k+1/2} = 0, \tag{3.11}$$

and the no-flux boundary condition for the density function is imposed by

$$(D_x\rho)_{0,j+1/2,k} = 0, \quad \text{which implies } \rho_{-1/2,j+1/2,k} = \rho_{1/2,j+1/2,k}. \tag{3.12}$$

Similarly, on the boundary section $j = 0$, the boundary condition $\boldsymbol{v} = 0$ is imposed by $v_{i+1/2,0,k+1/2} = 0$, $u_{i,-1/2,k+1/2} + u_{i,1/2,k+1/2} = 0$, and the boundary condition $\frac{\partial\rho}{\partial\boldsymbol{n}} = 0$ is imposed by $\rho_{i+1/2,-1/2,k} = \rho_{i+1/2,1/2,k}$.

On the bottom boundary $z = -H_0$, i.e., $k = 0$, the boundary condition $\frac{\partial \boldsymbol{v}}{\partial z} = 0$, $\frac{\partial \rho}{\partial z} = 0$ can be written as

$$\begin{aligned} &u_{i,j+1/2,-1/2} = u_{i,j+1/2,1/2}, \quad v_{i+1/2,j,-1/2} = v_{i+1/2,j,1/2}, \\ &\rho_{i+1/2,j+1/2,-1} = \rho_{i+1/2,j+1/2,1}, \end{aligned} \tag{3.13}$$

using a similar argument as in (3.12).

3.1. Boundary condition for surface pressure $\boldsymbol{p_s}$. The derived boundary condition (1.12) is needed to solve the surface pressure Poisson equation (3.9). As assumed earlier, in the case that $\mathcal{M}_0 = [0,1]^2$, we concentrate on the left boundary $x = 0$ for simplicity of presentation. The other three boundary sections $x = 1$, $y = 0, 1$ can be dealt with in the same manner. In PDE formulation, on the left boundary section $x = 0$, (1.12) indicates that

$$\frac{\partial p_s}{\partial x} = \nu_1 \, Ro \, \triangle \overline{u} = \nu_1 \, Ro \, \partial_x^2 \overline{u}, \tag{3.14}$$

where the second step is based on the fact that the velocity u vanishes; henceforth $\overline{u}$ vanishes on the boundary, too. The MAC mesh grid near the left boundary is shown in Figure 3.1.

Our methodology for approximating $\partial_x^2 \overline{u}$ as in (3.14) follows the approach taken by numerical methods for the 2-D NSE formulated in the vorticity-stream function, as given in (1.15), (1.16), based on local vorticity boundary conditions. The earliest work in this direction is due to Thom [27]. The more recent works [6], [10], [28] revived interest in the use of local formulae for vorticity on the boundary and analyzed the stability and convergence of a class of such formulae. The key point in these approaches is to convert the Neumann boundary condition for the stream function ψ, which states the no-slip velocity boundary condition, into a local vorticity boundary condition, such as Thom's formula.

A similar idea can be used in the approximation to $\partial_x^2 \overline{u}$ as in (3.14). In our scheme, the mean divergence-free boundary condition for the horizontal velocity, $(\nabla \cdot \boldsymbol{v}) \mid_{\partial \mathcal{M}_0} = 0$, can be converted into an approximation of the Neumann boundary condition for the surface pressure as derived in (1.12). In more detail, the following finite-difference method is applied on the boundary grid point $(0, j \pm 1/2)$:

$$\begin{aligned} \partial_x^2 \overline{u}_{0,j+1/2} &= \frac{\overline{u}_{-1,j+1/2} - 2\overline{u}_{0,j+1/2} + \overline{u}_{1,j+1/2}}{\triangle x^2} + O(h^2) \\ &= \frac{\overline{u}_{-1,j+1/2} + \overline{u}_{1,j+1/2}}{\triangle x^2} + O(h^2), \end{aligned} \tag{3.15}$$

where the second step is based on the fact that the velocity field $\boldsymbol{v}$ vanishes on the boundary. The second-order approximation (5.15) requires a value for $\overline{u}$ at grid point $(-1, j+1/2)$, which is a "ghost" point outside the computational domain. A consistent prescription of the value for $\overline{u}_{-1,j+1/2}$ relies on a second order centered difference of the mean divergence-free boundary condition $\overline{\nabla \cdot \boldsymbol{v}} \mid_{x=0} = 0$,

$$0 = (\partial_x \overline{u} + \partial_y \overline{v}) \mid_{x=0} = 0 + \partial_y \overline{v} \mid_{x=0} = \frac{\overline{u}_{1,j+1/2} - \overline{u}_{-1,j+1/2}}{2\triangle x} + O(h^2), \tag{3.16}$$

where the second step is due to the boundary condition $\overline{v} = 0$ on $\partial\mathcal{M}_0$. The finite-difference identity (3.16) directs us to take

$$\overline{u}_{-1,j+1/2} = \overline{u}_{1,j+1/2}, \tag{3.17}$$

whose substitution into (3.15), (3.14) gives a second order approximation of the derived Neumann boundary condition (1.12),

$$\frac{\partial p_s}{\partial \boldsymbol{n}} \mid_{0,y_{j+1/2}} = \frac{\partial p_s}{\partial x} \mid_{0,y_{j+1/2}} = Ro\,\frac{2\nu_1}{\triangle x^2}\overline{u}_{1,j+1/2}. \qquad \text{(ASPBC)} \tag{3.18}$$

The evaluation of $\frac{\partial p_s}{\partial \boldsymbol{n}}$ at three other boundary sections can be derived in the same fashion. We refer to the above formula as the accurate surface pressure boundary condition (ASPBC). A similar derivation for the local pressure boundary condition in the spatially discrete level of the incompressible NSE can be found in a recent paper of Johnston and Liu [11]. Therefore, we have the following set of boundary conditions for p_s in the discrete version:

$$\begin{aligned} (p_s)_{-1/2,j+1/2} &= (p_s)_{1/2,j+1/2} - Ro\,\frac{2\nu_1}{\triangle x}\overline{u}_{1,j+1/2}, \\ (p_s)_{i+1/2,-1/2} &= (p_s)_{i+1/2,1/2} - Ro\,\frac{2\nu_1}{\triangle y}\overline{v}_{i+1/2,1}. \end{aligned} \tag{3.19}$$

3.2. The MAC scheme for the PEs. Thus the system of MAC spatial discretization of the PEs can be written as

$$\left\{ \begin{aligned} & u_t + \mathcal{N}_h(\boldsymbol{u}, u) + \frac{1}{Ro}\Big(-f\overline{\overline{v}} + \mathcal{P}NRX + D_x p_s\Big) = L_{1,h}u \quad \text{at } \triangle, \\ & v_t + \mathcal{N}_h(\boldsymbol{u}, v) + \frac{1}{Ro}\Big(f\overline{\overline{u}} + \mathcal{P}NRY + D_y p_s\Big) = L_{1,h}v \quad \text{at } \bigcirc, \\ & D_z\boldsymbol{v} \mid_{z=-H_0} = 0, \quad D_z\boldsymbol{v} \mid_{z=0} = \frac{\tau_0}{\nu_2}, \\ & \boldsymbol{v}\cdot\boldsymbol{n} = 0, \quad \boldsymbol{v}\cdot\tau = 0 \quad \text{on } \partial\mathcal{M}_0 \times [-H_0, 0], \end{aligned} \right. \tag{3.20a}$$

$$\left\{ \begin{aligned} & (\triangle_h p_s)_{i+1/2,j+1/2} = Ro\,\overline{\mathcal{F}P}_{i+1,j+1/2}, \\ & \frac{\partial p_s}{\partial \boldsymbol{n}} = Ro\,\nu_1\,(\triangle_h \boldsymbol{v})\cdot\boldsymbol{n}, \end{aligned} \right. \tag{3.20b}$$

$$w_{i+1/2,j+1/2,k} = -\triangle z \sum_{l=0}^{k-1}\Big((D_x u)_{i+1/2,j+1/2,l+1/2} + (D_y v)_{i+1/2,j+1/2,l+1/2}\Big), \tag{3.20c}$$

$$\left\{ \begin{aligned} & \rho_t + \mathcal{N}_h(\boldsymbol{u}, \rho) = L_{2,h}\rho \quad \text{at } (i+1/2, j+1/2, k), \\ & \tilde{D}_z\rho \mid_{z=0} = \frac{\rho_f}{\kappa_2}, \quad \tilde{D}_z\rho \mid_{z=-H_0} = 0, \\ & \frac{\partial \rho}{\partial \boldsymbol{n}} = 0 \quad \text{on } \partial\mathcal{M}_0 \times [-H_0, 0]. \end{aligned} \right. \tag{3.20d}$$

Hereafter we denote $L_{1,h} = (\nu_1\triangle_h + \nu_2 D_z^2)$, $L_{2,h} = (\kappa_1\triangle_h + \kappa_2 D_z^2)$ for simplicity of presentation.

3.3. Mean divergence-free property. In this section, we argue that the numerical velocity field $\boldsymbol{v}_h$, the solution of the system (3.20), has free mean-divergence in a discrete level; i.e.,

$$D_x\overline{u} + D_y\overline{v} = 0 \quad \text{on mesh point} \quad (i+1/2, j+1/2), \tag{3.21}$$

where $\overline{u}$, $\overline{v}$ are defined in the same way as in (3.10). To see this, we use a similar argument as in (1.14a), (1.14b), and (1.14c). Taking the discrete divergence of the two momentum equations in (3.20a) at mesh points $(i+1/2, j+1/2, k+1/2)$, summing in the z-direction, and keeping in mind the discrete Poisson equation for p_s as in (3.8), (3.9), we have

$$(\overline{\nabla_h\cdot\boldsymbol{v}})_t = \nu_1\triangle_h\overline{\nabla_h\cdot\boldsymbol{v}} \quad \text{at} \quad (i+1/2, j+1/2). \tag{3.22}$$

In the derivation of (3.22), we used the fact that the composition of discrete divergence and discrete gradient (D_x, D_y) gives exactly the five-point Laplacian in the context of the MAC spatial discretization. Another important fact we used in the derivation of (3.22) is that, on MAC grids, the Laplacian operator $\triangle_h$ and the divergence operator are commutative. These two points represents a crucial advantage of the MAC grid.

The homogeneous initial data for $\overline{\nabla_h\cdot\boldsymbol{v}}$ is obvious:

$$\Big((\overline{\nabla_h\cdot\boldsymbol{v}})(\cdot, t=0)\Big)_{i+1/2,j+1/2} = 0. \tag{3.23}$$

It remains to make sure it vanishes on the lateral boundary $\partial\mathcal{M}_0$. We concentrate on the boundary section $x=0$. The discrete divergence of $\overline{\boldsymbol{v}}$ on $x=0$ can be evaluated as

$$\begin{aligned}(\overline{\nabla_h\cdot\boldsymbol{v}})_{0,j+1/2} &= \frac{1}{2}\Big((\overline{\nabla_h\cdot\boldsymbol{v}})_{-1/2,j+1/2} + (\overline{\nabla_h\cdot\boldsymbol{v}})_{1/2,j+1/2}\Big)\\ &= \frac{1}{2}\Big(\frac{\overline{u}_{0,j+1/2} - \overline{u}_{-1,j+1/2}}{\triangle x} + \frac{\overline{v}_{-1/2,j+1} - \overline{v}_{-1/2,j}}{\triangle y}\\ &\quad + \frac{\overline{u}_{1,j+1/2} - \overline{u}_{0,j+1/2}}{\triangle x} + \frac{\overline{v}_{1/2,j+1} - \overline{v}_{1/2,j}}{\triangle y}\Big),\\ &= \frac{\overline{u}_{1,j+1/2} - \overline{u}_{-1,j+1/2}}{2\triangle x} + \frac{1}{2}\Big(\frac{\overline{v}_{-1/2,j+1} - \overline{v}_{-1/2,j}}{\triangle y} + \frac{\overline{v}_{1/2,j+1} - \overline{v}_{1/2,j}}{\triangle y}\Big),\end{aligned} \tag{3.24}$$

where $\overline{u}_{-1,j+1/2}$, $\overline{v}_{-1/2,j}$ are "ghost" point computational values for $\overline{u}$, $\overline{v}$. Meanwhile, the reflection rule (3.11) (due to the no-slip boundary condition for v) gives that the last two terms in (3.12) vanish, i.e.,

$$(\overline{\nabla_h\cdot\boldsymbol{v}})_{0,j+1/2} = \frac{\overline{u}_{1,j+1/2} - \overline{u}_{-1,j+1/2}}{2\triangle x}. \tag{3.25}$$

By the identity (3.17) that $\overline{u}_{-1,j+1/2} = \overline{u}_{1,j+1/2}$, which is used for the derivation of the Neumann boundary condition for the surface pressure p_s, we conclude that the mean discrete divergence of $\boldsymbol{v}$ vanishes on the boundary $x=0$. In other words, the ASPBC (3.18) conversely indicates the choice for $\overline{u}_{-1,j+1/2}$ as in (3.17). The substitution of (3.17) into (3.25) gives

$$(\overline{\nabla_h\cdot\boldsymbol{v}})_{0,j+1/2} = 0. \tag{3.26}$$

The combination of (3.26), (3.22), (3.23) indicates (3.21), which states that the numerical solution $\boldsymbol{v}_h$ of the system (3.20) has exactly zero discrete mean-divergence. Henceforth, the formula (3.20c) for the determination of vertical velocity is consistent with the combination of divergence-free property of the numerical velocity $\boldsymbol{u}_h$:

$$\nabla_h \cdot \boldsymbol{v}_h + D_z w = 0, \tag{3.27}$$

and the boundary condition for the vertical velocity w at $z = 0$ and $z = -H_0$:

$$w_{i+1/2,j+1/2,0} = w_{i+1/2,j+1/2,N} = 0. \tag{3.28}$$

4. Convergence analysis of the fully discretized scheme using the backward Euler method combined with the MAC grid.

The MAC spatial discretization can be easily implemented in practical computations, combined with either backward Euler or Crank–Nicolson schemes as outlined in section 2. For technical simplicity, the periodic boundary condition is assumed in the horizontal (x, y)-plane so that only the top and bottom boundary sections need to be taken into consideration in the convergence analysis below. The scheme with physical lateral boundary conditions can be dealt with in a similar fashion, with more technical details involved in the consistency analysis. We skip it for the sake of brevity.

The fully discretized scheme using backward Euler temporal discretization is formulated as below. The corresponding Crank–Nicolson method can be similarly proposed and analyzed. We omit it in this article.

$$\begin{cases} \dfrac{u^{n+1} - u^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, u^n) + \dfrac{1}{Ro}\Big(-f\overline{\overline{v}}^n + \mathcal{P}NRX^n + D_x p_s^n\Big) \\ \quad = L_{1,h} u^{n+1} \quad \text{at} \ \ \triangle, \\ \dfrac{v^{n+1} - v^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, v^n) + \dfrac{1}{Ro}\Big(f\overline{\overline{u}}^n + \mathcal{P}NRY^n + D_y p_s^n\Big) \\ \quad = L_{1,h} v^{n+1} \quad \text{at} \ \ \bigcirc, \\ D_z \boldsymbol{v} \mid_{z=-H_0} = 0, \quad D_z \boldsymbol{v} \mid_{z=0} = 0, \end{cases} \tag{4.1a}$$

$$(\triangle_h p_s)^{n+1}_{i+1/2,j+1/2} = Ro\, \overline{\mathcal{F}P}^{n+1}_{i+1,j+1/2}, \tag{4.1b}$$

$$w^{n+1}_{i+1/2,j+1/2,k} = -\triangle z \sum_{l=0}^{k-1} \Big((D_x u)^{n+1}_{i+1/2,j+1/2,l+1/2} + (D_y v)^{n+1}_{i+1/2,j+1/2,l+1/2} \Big), \tag{4.1c}$$

$$\begin{cases} \dfrac{\rho^{n+1} - \rho^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, \rho^n) = L_{2,h} \rho^{n+1} \quad \text{at} \ \ \bullet, \\ \tilde{D}_z \rho \mid_{z=0} = 0, \quad \tilde{D}_z \rho \mid_{z=-H_0} = 0. \end{cases} \tag{4.1d}$$

4.1. Main theorem and some notations.

The following notations of L^2 norms in a discrete level need to be introduced.

Notation 4.1. For any pair of variables u^a, u^b which are defined at the mesh points $(i, j+1/2, k+1/2)$ (such as u, $\tilde{D}_x u$, $\tilde{D}_y u$, $\tilde{D}_z u$, etc.), the discrete L^2-inner product is given by

$$\langle u^a,\, u^b\rangle_1 = \sum_{k=0}^{N-1}\sum_{j=0}^{N-1}\sum_{i=0}^{N-1} u^a_{i,j+1/2,k+1/2}\, u^b_{i,j+1/2,k+1/2}\, h^3. \tag{4.2a}$$

For any pair of variables v^a, v^b which are defined at the mesh points $(i+1/2, j, k+1/2)$ (such as v, $\tilde{D}_x v$, $\tilde{D}_y v$, $\tilde{D}_z v$, etc.), the discrete L^2-inner product is given by

$$\langle v^a,\, v^b\rangle_2 = \sum_{k=0}^{N-1}\sum_{j=0}^{N-1}\sum_{i=0}^{N-1} v^a_{i+1/2,j,k+1/2}\, v^b_{i+1/2,j,k+1/2}\, h^3. \tag{4.2b}$$

For any pair of variables ρ^a, ρ^b defined at the mesh points $(i+1/2, j+1/2, k)$ (such as ρ, w, $\tilde{D}_x \rho$, $\tilde{D}_y \rho$, $\tilde{D}_z \rho$, etc.), the discrete L^2-inner product is given by

(4.2c)

$$\begin{aligned}\langle \rho^a,\, \rho^b\rangle_3 = \sum_{j=0}^{N-1}\sum_{i=0}^{N-1}\Big(&\sum_{k=1}^{N-1} \rho^a_{i+1/2,j+1/2,k}\, \rho^b_{i+1/2,j+1/2,k} \\ &+ \frac{1}{2}\rho^a_{i+1/2,j+1/2,0}\, \rho^b_{i+1/2,j+1/2,0} + \frac{1}{2}\rho^a_{i+1/2,j+1/2,N}\, \rho^b_{i+1/2,j+1/2,N}\Big)\, h^3.\end{aligned}$$

Finally, for any pair of variables p^a, p^b defined at the mesh points $(i+1/2, j+1/2, k+1/2)$ (such as p, $D_x u$, $D_y v$, $D_z w$), the discrete L^2-inner product is defined by

$$\langle p^a,\, p^b\rangle_4 = \sum_{k=0}^{N-1}\sum_{j=0}^{N-1}\sum_{i=0}^{N-1} p^a_{i+1/2,j+1/2,k+1/2}\, p^b_{i+1/2,j+1/2,k+1/2}\, h^3. \tag{4.2d}$$

Clearly, all the discrete L^2-inner products defined above are second order accurate. The corresponding L^2_h norms can be defined accordingly. In addition, we set a vector norm for the horizontal velocity as $\|\boldsymbol{v}\|^2_{\boldsymbol{L}^2_h} = \|u\|_1^2 + \|v\|_2^2$, where $\|u\|_1^2 = \langle u,\, u\rangle_1$, $\|v\|_2^2 = \langle v,\, v\rangle_2$.

The following is the main theorem of this paper.

THEOREM 4.1. *Let $\boldsymbol{u}_e = (\boldsymbol{v}_e, w_e)$, p_e, ρ_e be the exact solution of the PEs* (1.1), (1.2), *with periodic boundary condition in the horizontal (x, y)-plane, and let $(\boldsymbol{v}_{\triangle t,h}, w_{\triangle t,h}, \rho_{\triangle t,h})$ be the numerical solution of the backward Euler coupled with the MAC grid in* (4.1). *We assume that $\triangle t \le Ch$, in which C is an arbitrary fixed constant. Then the following convergence result holds as $\triangle t$ and h go to zero:*

$$\|\boldsymbol{v}_e - \boldsymbol{v}_{\triangle t,h}\|_{L^\infty(0,T;\boldsymbol{L}^2_h)} + \|\rho_e - \rho_{\triangle t,h}\|_{L^\infty(0,T;L^2_h)} \le C(\triangle t + h^2), \tag{4.3a}$$

where the constant C depends only on the regularity of the exact solution

(4.3b)

$$C = C\Big(\|\boldsymbol{u}_e\|_{L^\infty(0,T;C^{7,\alpha})}, \|\rho_e\|_{L^\infty(0,T;C^{7,\alpha})}, \|\boldsymbol{u}_e\|_{C^4(0,T;C^{2,\alpha})}, \|\rho_e\|_{C^4(0,T;C^{2,\alpha})}\Big).$$

The rest of the paper is devoted to the proof of Theorem 4.1. The main steps include the following: 1. The numerical horizontal velocity is shown to have vanishing averaged divergence. 2. The leading order consistency analysis, which gives a construction of approximate velocity and density profiles satisfying the numerical scheme up to an $O(\triangle t + h^2)$ error. Moreover, the constructed horizontal velocity satisfies zero mean-divergence property at the discrete level. 3. Higher order expansion, up to $O(\triangle t^3 + h^4)$ expansion, of the numerical scheme. That makes the recovery of the L^∞ a priori assumption possible, for both the horizontal and the vertical velocity fields in the full nonlinear system of the PEs, by the usage of inverse inequalities. 4. The energy estimate for the error functions. The four steps will be presented in sections 4.2–4.5 below, respectively.

4.2. Evolution for the mean divergence of $\boldsymbol{v}$. To facilitate the proof of Theorem 4.1, we show that the calculated horizontal velocity at each time step has free mean-divergence at the discrete level; i.e., (3.21) is satisfied for $\boldsymbol{v}$ at each time step. The argument is similar to the one in section 3.3. Taking the discrete divergence of the momentum equations in (4.1a) at mesh points $(i+1/2, j+1/2, k+1/2)$ and summing in the z-direction gives

$$\frac{\overline{\nabla_h \cdot \boldsymbol{v}^{n+1}} - \overline{\nabla_h \cdot \boldsymbol{v}^{n}}}{\triangle t} = \nu_1 \triangle_h (\overline{\nabla_h \cdot \boldsymbol{v}^{n+1}}) \quad \text{at} \quad (i+1/2, j+1/2), \tag{4.4a}$$

since all other terms at the time step t^n were canceled by the surface pressure Poisson equation (4.1b) at the same time step. The combination of the evolution equation in (4.4a) and the homogeneous initial data,

$$\overline{\nabla_h \cdot \boldsymbol{v}^{0}} = 0, \tag{4.4b}$$

shows that the numerical solution $\boldsymbol{v}_{h,\triangle t}$ of the scheme (4.1) has exactly zero discrete mean-divergence. As a result, the combined system (3.27), (3.28) is valid for $\boldsymbol{v}^n$, w^n at any time step t^n.

Furthermore, the numerical scheme (4.1a) for the momentum equation and the discrete Poisson equation (4.1b) can also be reformulated in a form similar to that of (1.5), (1.6) in the PDE level, for the sake of simplicity of the convergence analysis given below. We denote the total pressure variable p at mesh points $(i+1/2, j+1/2, k+1/2)$ as

$$p_{i+1/2,j+1/2,k+1/2} = \mathcal{P}R_{i+1/2,j+1/2,k+1/2} + (p_s)_{i+1/2,j+1/2}, \tag{4.5a}$$

where $\mathcal{P}R$, a discrete realization of $\int_z^0 \rho(x,y,s)\,ds$, is defined in a similar way as in (3.7):

$$\begin{aligned} &\mathcal{P}R_{i+1/2,j+1/2,N-1/2} = \frac{1}{2} \triangle z \, \rho_{i+1/2,j+1/2,N}, \\ &\mathcal{P}R_{i+1/2,j+1/2,k-1/2} = \mathcal{P}R_{i+1/2,j,k+1/2} + \triangle z \, \rho_{i+1/2,j+1/2,k}. \end{aligned} \tag{4.5b}$$

Clearly, (4.5) is a discrete version of the hydrostatic equation. One obvious fact is that

$$D_z p = \rho \qquad \text{at the mesh point } (i+1/2, j+1/2, k). \tag{4.6}$$

Therefore the scheme (4.1) can be rewritten as the following system:

$$\text{(4.7a)}\quad \begin{cases} \dfrac{u^{n+1}-u^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, u^n) + \dfrac{1}{Ro}\Big(-f\overline{\overline{v}}^n + D_x p^n\Big) = L_{1,h} u^{n+1} \quad \text{at} \;\; \triangle, \\ \dfrac{v^{n+1}-v^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, v^n) + \dfrac{1}{Ro}\Big(f\overline{\overline{u}}^n + D_y p^n\Big) = L_{1,h} v^{n+1} \quad \text{at} \;\; \bigcirc, \\ D_z \boldsymbol{v}^{n+1} \mid_{z=-H_0} = 0, \quad D_z \boldsymbol{v}^{n+1} \mid_{z=0} = 0, \end{cases}$$

$$\text{(4.7b)}\qquad D_z p^{n+1} = \rho^{n+1} \quad \text{at} \;\; (i+1/2, j+1/2, k),$$

$$\text{(4.7c)}\qquad \begin{cases} \nabla_h \cdot \boldsymbol{v}^{n+1} + D_z w^{n+1} = 0, \\ w^{n+1}_{i+1/2,j+1/2,0} = w^{n+1}_{i+1/2,j+1/2,N} = 0, \end{cases}$$

$$\text{(4.7d)}\qquad \begin{cases} \dfrac{\rho^{n+1}-\rho^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{u}^n, \rho^n) = L_{2,h}\rho^{n+1} \quad \text{at} \;\; \bullet, \\ \tilde{D}_z \rho \mid_{z=0} = 0, \quad \tilde{D}_z \rho \mid_{z=-H_0} = 0. \end{cases}$$

We remark that the mean divergence-free property for the numerical horizontal velocity field and the corresponding identities (3.27), (3.28) assure that the 3-D velocity field is orthogonal to the horizontal and vertical gradients of the total pressure field p in the staggered L^2 space introduced in (4.2), i.e.,

$$\text{(4.8)}\qquad \langle u, D_x p\rangle_1 + \langle v, D_y p\rangle_2 + \langle w, D_z p\rangle_3 = -\langle (\nabla_h \cdot \boldsymbol{v} + D_z w), p\rangle_4 = 0,$$

by usage of summing by parts in the MAC grid and of the boundary condition for the velocity field. This crucial point makes possible the convergence analysis of the whole numerical scheme using the MAC spatial discretization.

4.3. Leading order consistency analysis. Our goal is to construct approximate velocity profiles $\boldsymbol{V}^0 = (U^0, V^0)$, $\boldsymbol{W}^0$ and approximate density profile Θ^0, and to show that their combination with exact pressure profile p_e satisfies the numerical scheme (4.7) up to an $O(\triangle t + h^2)$ error. Furthermore, the constructed $\boldsymbol{V}^0$ has to be assured to have zero mean-divergence in the discrete sense, i.e.,

$$\text{(4.9)}\qquad \overline{\nabla_h \cdot \boldsymbol{V}^0} = 0 \quad \text{at} \quad (i+1/2, j+1/2),$$

so that the vertical velocity $\boldsymbol{W}^0$ can be determined by the formula in the same way as in (4.7c) consistent with its boundary condition:

$$\text{(4.10)}\qquad \boldsymbol{W}^0_{i+1/2,j+1/2,k} = -\triangle z \sum_{l=0}^{k-1} \Big((D_x U^0)_{i+1/2,j+1/2,l} + (D_y V^0)_{i+1/2,j+1/2,l} \Big).$$

In other words, the combination of (4.9) and (4.10) gives

$$\text{(4.11)}\qquad \begin{cases} \nabla_h \cdot \boldsymbol{V}^0 + D_z W^0 = 0, \\ \boldsymbol{W}^0_{i+1/2,j+1/2,0} = \boldsymbol{W}^0_{i+1/2,j+1/2,N} = 0, \end{cases}$$

which is analogous to (4.7c).

The construction of the leading term for the horizontal velocity field $\boldsymbol{V}^0$ relies on the fact that any C^1 function g in $\mathcal{M}$ can be uniquely recovered from its average in the z-direction and its derivative with respect to z by

$$g(x,y,z) = \int_{-H_0}^{z} g_z(x,y,s)\,ds + \overline{g}(x,y) - \frac{1}{H_0}\int_{-H_0}^{0}\int_{-H_0}^{z'} g_z(x,y,s)\,ds\,dz'. \tag{4.12}$$

As a result, the exact horizontal velocity field $\boldsymbol{v}_e$ can be represented as

(4.13)

$$\begin{aligned} u_e(x,y,z) &= \int_{-H_0}^{z} \partial_z u_e(x,y,s)\,ds + \overline{u_e}(x,y) - \frac{1}{H_0}\int_{-H_0}^{0}\int_{-H_0}^{z} \partial_z u_e(x,y,s)\,ds\,dz,\\ v_e(x,y,z) &= \int_{-H_0}^{z} \partial_z v_e(x,y,s)\,ds + \overline{v_e}(x,y) - \frac{1}{H_0}\int_{-H_0}^{0}\int_{-H_0}^{z} \partial_z v_e(x,y,s)\,ds\,dz. \end{aligned}$$

The discrete form of the recovery formula (4.13) applied to U^0, V^0 can be written as follows:

$$\begin{aligned} U^0_{i,j+1/2,k+1/2} &= -\mathcal{P}UZ^0_{i,j+1/2,k+1/2} + \overline{U^0}_{i,j+1/2} + \overline{PUZ}^0_{i,j+1/2},\\ V^0_{i+1/2,j,k+1/2} &= -\mathcal{P}VZ^0_{i+1/2,j,k+1/2} + \overline{V^0}_{i+1/2,j} + \overline{PVZ}^0_{i+1/2,j}, \end{aligned} \tag{4.14}$$

the construction of the mean velocity field $\overline{U}^0$, $\overline{V}^0$ will be given later, and $\mathcal{P}UZ^0$, $\mathcal{P}VZ^0$ represents the discrete integral of $\partial_z u_e$, $\partial_z v_e$ from $-H_0$ up to $z_k = (k+\frac{1}{2})\triangle z$, respectively. Keeping in mind that $\partial_z u_e$, $\partial_z v_e$ are defined on the numerical grids $(i, j \pm 1/2, k)$, $(i \pm 1/2, j, k)$, respectively, we express such integrals as

$$\begin{aligned} \mathcal{P}UZ^0_{i,j+1/2,-1/2} &= -\frac{1}{2}\triangle z\,(\partial_z u_e)_{i,j+1/2,0},\\ \mathcal{P}UZ^0_{i,j+1/2,k+1/2} &= \mathcal{P}UZ^0_{i,j+1/2,k-1/2} + \triangle z\,(\partial_z u_e)_{i,j+1/2,k}, \end{aligned} \tag{4.15a}$$

$$\begin{aligned} \mathcal{P}VZ^0_{i+1/2,j,-1/2} &= -\frac{1}{2}\triangle z\,(\partial_z v_e)_{i+1/2,j,0},\\ \mathcal{P}VZ^0_{i+1/2,j,k+1/2} &= \mathcal{P}VZ^0_{i+1/2,j,k-1/2} + \triangle z\,(\partial_z v_e)_{i+1/2,j,k}. \end{aligned} \tag{4.15b}$$

Obviously, the combination of (4.14) and (4.15) gives

$$\begin{aligned} &\sum_{k=0}^{N_z-1} (\triangle z\, U^0_{i,j+1/2,k+1/2}) = \overline{U^0}_{i,j+1/2}, \quad (D_z U^0)_{i,j+1/2,k} = (\partial_z u_e)_{i,j+1/2,k},\\ &\sum_{k=0}^{N_z-1} (\triangle z\, V^0_{i+1/2,j,k+1/2}) = \overline{V^0}_{i+1/2,j}, \quad (D_z V^0)_{i+1/2,j,k} = (\partial_z v_e)_{i+1/2,j,k}. \end{aligned} \tag{4.16}$$

We use the "mean stream function" corresponding to the exact velocity solution $\boldsymbol{v}_e$ to construct the mean velocity field $\overline{\boldsymbol{V}^0}$ appearing in the construction formula (4.14). Since the average of the exact velocity field $\overline{\boldsymbol{v}_e}$ is divergence-free in the 2-D domain $\mathcal{M}_0$, as shown in (1.4), there exists a mean stream function $\overline{\psi_e}$ such that

$$\overline{\boldsymbol{v}_e} = \nabla^{\perp}\overline{\psi_e} = (-\partial_y\overline{\psi_e}, \partial_x\overline{\psi_e}). \tag{4.17}$$

Subsequently, the average of $\boldsymbol{V}^0$ (in the z-direction) can be determined via second order finite-difference of the exact "mean stream function"

$$\begin{aligned} \overline{U^0} &= -D_y\overline{\psi_e} = -\frac{\overline{\psi_e}_{i,j+1} - \overline{\psi_e}_{i,j}}{\triangle y} \quad \text{at} \quad (i, j+1/2), \\ \overline{V^0} &= D_x\overline{\psi_e} = \frac{\overline{\psi_e}_{i+1,j} - \overline{\psi_e}_{i,j}}{\triangle x} \quad \text{at} \quad (i+1/2, j). \end{aligned} \tag{4.18}$$

It should be remarked that the mean stream function is evaluated at regular mesh points (i, j), $0 \le i, j \le N$. Obviously, (4.18) gives

$$D_x\overline{U^0} + D_y\overline{V^0} = -D_x(D_y\overline{\psi_e}) + D_y(D_x\overline{\psi_e}) = 0, \tag{4.19}$$

which along with the identity (4.16) assures that the mean divergence-free property is automatically satisfied for the constructed leading velocity field

$$\overline{\nabla_h \cdot \boldsymbol{V}^0} = 0 \quad \text{at} \quad (i+1/2, j+1/2). \tag{4.20}$$

Accordingly, the recovery formula analogous to (4.2) is used to construct the leading vertical velocity

$$\boldsymbol{W}^0_{i+1/2,j+1/2,k} = -\triangle z \sum_{l=0}^{k-1}\Big((D_xU^0)_{i+1/2,j+1/2,l+1/2} + (D_yV^0)_{i+1/2,j+1/2,l+1/2}\Big), \tag{4.21}$$

which is compatible with the boundary condition $\boldsymbol{W}^0_{i+1/2,j+1/2,0} = \boldsymbol{W}^0_{i+1/2,j+1/2,N} = 0$.

The proposition below states that the constructed leading velocity profile, together with its temporal derivative, is within $O(h^2)$ difference with the exact velocity $\boldsymbol{u}_e = (\boldsymbol{v}_e, w_e)$. Its verification is omitted in this paper for brevity and will appear elsewhere.

PROPOSITION 4.2. *The following estimates for $\boldsymbol{V}^0$, $\boldsymbol{W}^0$ hold:*

$$\|\boldsymbol{V}^0 - \boldsymbol{v}_e\|_{W^{m,\infty}(\mathcal{M})} \le Ch^2\|\boldsymbol{v}_e\|_{C^{m+3}} \quad \textit{for} \;\; m = 0, 1, 2\ldots, \tag{4.22a}$$

$$\|W^0 - w_e\|_{W^{m,\infty}(\mathcal{M})} \le Ch^2\|\boldsymbol{v}_e\|_{C^{m+4}}. \tag{4.22b}$$

Here $\|\cdot\|_{W^{m,\infty}(\mathcal{M})}$ represents the maximum value at the corresponding mesh points of the given function up to mth order finite-difference over the 3-D domain $\mathcal{M}$. Furthermore, the difference between the time derivatives of $\boldsymbol{V}^0$ and $\boldsymbol{v}_e$ can be controlled by

$$\partial_t^m\boldsymbol{V}^0 = \partial_t^m\boldsymbol{v}_e + O(h^2)\|\partial_t^m\boldsymbol{v}_e\|_{C^3} \quad \textit{for} \;\; m \ge 1. \tag{4.23}$$

In addition, we observe that $\boldsymbol{V}^0$ exactly satisfies the boundary condition in the discrete form as given in (4.7) at the top $z = 0$ and at the bottom $z = -H_0$:

$$\begin{aligned} &(D_zU^0)_{i,j+1/2,0} = 0, \quad (D_zV^0)_{i+1/2,j,0} = 0, \\ &(D_zU^0)_{i,j+1/2,N} = 0, \quad (D_zV^0)_{i+1/2,j,N} = 0, \end{aligned} \tag{4.24}$$

due to its construction in (4.15) and the fact that $\partial_z \boldsymbol{v}_e = 0$ at the two boundary sections.

The leading order density profile is composed of the exact density and a correction term

$$\Theta^0 = \rho_e + h^2 \Theta^1. \tag{4.25}$$

The addition of the $O(h^2)$ correction terms $h^2\Theta^1$ is due to the higher order consistency of the approximate profile Θ with the boundary condition given in the numerical scheme (4.7d), which is required in the error analysis presented later. The correction function Θ^1 is constructed as the solution of the Poisson equation with Neumann boundary condition

(4.26)
$$\begin{cases} \triangle \Theta^1 = C^1 \equiv \dfrac{1}{|\mathcal{M}|} \left(\displaystyle\int_{\mathcal{M}_0} \frac{1}{6} \partial_z^3 \rho_e(x,y,-H_0)\, d\boldsymbol{x} - \int_{\mathcal{M}_0} \frac{1}{6} \partial_z^3 \rho_e(x,y,0)\, d\boldsymbol{x} \right), \\ \partial_z \Theta^1(x,y,-H_0) = -\dfrac{1}{6}\, \partial_z^3 \rho_e(x,y,-H_0), \quad \partial_z \Theta^1(x,y,0) = -\dfrac{1}{6}\, \partial_z^3 \rho_e(x,y,0). \end{cases}$$

Note that the number C^1 (a function of time t) is chosen so that $\int_{\mathcal{M}} C^1 \, d\boldsymbol{x}\, dz = \int_{\partial\mathcal{M}} \frac{\partial \Theta^1}{\partial \boldsymbol{n}}\, d\boldsymbol{n}$ to maintain the consistency. The Schauder's estimate applied to the Poisson equation (4.26) gives that

$$\|\Theta^1\|_{C^{m,\alpha}} \le \|\rho_e\|_{C^{m+2,\alpha}}, \quad \|\partial_t^k \Theta^1\|_{C^{m,\alpha}} \le \|\partial_t^k \rho_e\|_{C^{m+2,\alpha}} \qquad \text{for } \ m \ge 2. \tag{4.27}$$

The choice of the boundary condition for Θ^1 in (4.26) implies that the approximated density Θ as given in the expansion (4.25) satisfies the discrete boundary condition in (4.7d) to an $O(h^5)$ order. It can be seen by local Taylor expansion for the exact density field ρ_e around the bottom boundary that

(4.28)
$$(\rho_e)_{i+1/2,j+1/2,-1} = (\rho_e)_{i+1/2,j+1/2,1} - \frac{\triangle z^3}{3}\, \partial_z^3 \rho_e(x_{i+1/2}, y_{j+1/2}, -H_0) + O(h^5) \|\rho_e\|_{C^5},$$

in which the no-flux boundary condition is used. The insertion of the boundary condition given by (4.26) into the Taylor expansion of Θ^1, along with Schauder's estimate $\|\Theta_1\|_{C^2} \le C \|\rho_e\|_{C^{5,\alpha}}$ given by (4.27), leads to

(4.29)
$$\Theta^1_{i+1/2,j+1/2,-1} = \Theta^1_{i+1/2,j+1/2,1} + \frac{\triangle z}{3}\, \partial_z^3 \rho_e(x_{i+1/2}, y_{j+1/2}, -H_0) + O(h^3) \|\rho_e\|_{C^{5,\alpha}}.$$

The combination of (4.28) and (4.29) results in the following estimate for $\Theta^0 = \rho_e + h^2\Theta^1$:

$$\Theta^0_{i+1/2,j+1/2,-1} = \Theta^0_{i+1/2,j+1/2,1} + O(h^5) \|\rho_e\|_{C^{5,\alpha}}, \tag{4.30}$$

which proves our claim. The top boundary $z = 0$ can be dealt with in the same manner.

It is straightforward to verify the following local truncation estimates:

$$
\text{(4.31a)}\quad \begin{cases} \dfrac{(U^0)^{n+1}-(U^0)^n}{\triangle t} + \mathcal{N}_h((\boldsymbol{U}^0)^n,(U^0)^n) + \dfrac{1}{Ro}\Big(-f(\overline{\overline{V^0}})^n + D_x p_e^n\Big) \\ \qquad = L_{1,h}(U^0)^{n+1} + \triangle t E_{\triangle t}^{u(0),n} + h^2 E_h^{u(0),n} \quad \text{at } \triangle, \\ \dfrac{(V^0)^{n+1}-(V^0)^n}{\triangle t} + \mathcal{N}_h((\boldsymbol{U}^0)^n,(V^0)^n) + \dfrac{1}{Ro}\Big(f(\overline{\overline{U^0}})^n + D_y p_e^n\Big) \\ \qquad = L_{1,h}(V^0)^{n+1} + \triangle t E_{\triangle t}^{v(0),n} + h^2 E_h^{v(0),n} \quad \text{at } \bigcirc, \\ (U^0)^{n+1}_{i,j+1/2,-1/2} = (U^0)^{n+1}_{i,j+1/2,1/2}, \quad (V^0)^{n+1}_{i+1/2,j,-1/2} = (V^0)^{n+1}_{i+1/2,j,1/2}, \end{cases}
$$

$$
\text{(4.31b)}\qquad D_z p_e^{n+1} = (\Theta^0)^{n+1} + h^2 E_h^{p(0),n} \quad \text{at } (i+1/2, j+1/2, k),
$$

$$
\text{(4.31c)}\qquad \begin{cases} \nabla_h \cdot (\boldsymbol{V}^0)^{n+1} + D_z(\boldsymbol{W}^0)^{n+1} = 0, \\ (\boldsymbol{W}^0)^{n+1}_{i+1/2,j+1/2,0} = (\boldsymbol{W}^0)^{n+1}_{i+1/2,j+1/2,N} = 0, \end{cases}
$$

$$
\text{(4.31d)}\qquad \begin{cases} \dfrac{(\Theta^0)^{n+1}-(\Theta^0)^n}{\triangle t} + \mathcal{N}_h((\boldsymbol{U}^0)^n,(\Theta^0)^n) \\ \qquad = L_{2,h}(\Theta^0)^{n+1} + (\triangle t + h^2) E^{\rho(0),n} \quad \text{at } \bullet, \\ (\Theta^0)^{n+1}_{i+1/2,j+1/2,-1} = (\Theta^0)^{n+1}_{i+1/2,j+1/2,1} + h^5 \boldsymbol{e}_{\rho b}, \end{cases}
$$

via high order Taylor expansion of the constructed solution $\boldsymbol{V}^0$, W^0, Θ^0, along with the usage of Proposition 4.2. The local error terms satisfy

$$
\text{(4.32)}\quad \begin{aligned} &|E^{u(0)}|, |E^{v(0)}| \le C\Big(\|\partial_t \boldsymbol{v}_e\|_{C^2} + \|\partial_t^2 \boldsymbol{v}_e\|_{C^2} + \|\boldsymbol{u}_e\|_{C^6}(1+\|\boldsymbol{u}_e\|_{C^3}) + \|p_e\|_{C^4}\Big), \\ &|E^{p(0)}| \le C\|\rho_e\|_{C^2}, \quad |E^{\rho(0)}| \le C\Big(\|\partial_t \rho_e\|_{C^2} + \|\partial_t^2 \rho_e\|_{C^2} + \|\rho_e\|_{C^5}(1+\|\boldsymbol{u}_e\|_{C^4})\Big). \end{aligned}
$$

4.4. Higher order expansion of the numerical scheme.

The consistency analysis (4.31) is not enough to recover the L^∞ a priori estimates for the approximate velocity field in the full nonlinear system of the PEs. We need to construct further fields, $(\boldsymbol{V}_h^1, \boldsymbol{W}_h^1, \Theta_h^1, P_h^1)$, $(\boldsymbol{V}_{\triangle t}^1, \boldsymbol{W}_{\triangle t}^1, \Theta_{\triangle t}^1, P_{\triangle t}^1)$, $(\boldsymbol{V}_{\triangle t}^2, \boldsymbol{W}_{\triangle t}^2, \Theta_{\triangle t}^2, P_{\triangle t}^2)$, and to introduce, for the error analysis, the fields $\boldsymbol{V}$, $\boldsymbol{W}$, Θ, P defined by

$$
\text{(4.33)}\quad \begin{aligned} &\boldsymbol{V} = \boldsymbol{V}^0 + h^2 \boldsymbol{V}_h^1 + \triangle t \boldsymbol{V}_{\triangle t}^1 + \triangle t^2 \boldsymbol{V}_{\triangle t}^2, \\ &\boldsymbol{W} = \boldsymbol{W}^0 + h^2 \boldsymbol{W}_h^1 + \triangle t \boldsymbol{W}_{\triangle t}^1 + \triangle t^2 \boldsymbol{W}_{\triangle t}^2, \\ &\Theta = \Theta^0 + h^2 \Theta_h^1 + \triangle t \Theta_{\triangle t}^1 + \triangle t^2 \Theta_{\triangle t}^2, \quad P = p_e + h^2 P_h^1 + \triangle t P_{\triangle t}^1 + \triangle t^2 P_{\triangle t}^2. \end{aligned}
$$

These new fields depend solely on $(\boldsymbol{V}^0, \boldsymbol{W}^0, \Theta^0, p_e)$, namely, on the exact solution. Their construction is straightforward but lengthy; we omit the details. The expanded profiles satisfy the backward Euler scheme combined with the MAC grid up to order $O(\triangle t^3 + h^4)$:

(4.34a)
$$\begin{cases} \dfrac{U^{n+1} - U^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{U}^n, U^n) + \dfrac{1}{Ro}\Big(-f\overline{\overline{V^n}} + D_x P^n\Big) \\ \qquad = L_{1,h} U^{n+1} + (\triangle t^3 + h^4) E^{u,n}, \\ \dfrac{V^{n+1} - V^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{U}^n, V^n) + \dfrac{1}{Ro}\Big(f\overline{\overline{U^n}} + D_y P^n\Big) \\ \qquad = L_{1,h} V^{n+1} + (\triangle t^3 + h^4) E^{v,n}, \\ U^{n+1}_{i,j+1/2,-1/2} = U^{n+1}_{i,j+1/2,1/2} + h^5 \boldsymbol{e}_{ub}, \quad V^{n+1}_{i+1/2,j,-1/2} = V^{n+1}_{i+1/2,j,1/2} + h^5 \boldsymbol{e}_{ub}, \end{cases}$$

$$D_z P^{n+1} = \Theta^{n+1} + h^4 E^{p,n}, \tag{4.34b}$$

$$\begin{cases} \nabla_h \cdot \boldsymbol{V}^{n+1} + D_z \boldsymbol{W}^{n+1} = 0, \\ \boldsymbol{W}^{n+1}_{i+1/2,j+1/2,0} = \boldsymbol{W}^{n+1}_{i+1/2,j+1/2,N} = 0, \end{cases} \tag{4.34c}$$

$$\begin{cases} \dfrac{\Theta^{n+1} - \Theta^n}{\triangle t} + \mathcal{N}_h(\boldsymbol{U}^n, \Theta^n) = L_{2,h} \Theta^{n+1} + (\triangle t^3 + h^4) E^{\rho,n}, \\ \Theta^{n+1}_{i+1/2,j+1/2,-1} = \Theta^{n+1}_{i+1/2,j+1/2,1} + h^5 \boldsymbol{e}_{\rho b}, \end{cases} \tag{4.34d}$$

in which the local truncation error and the boundary error terms are bounded in the L^∞ norm

$$|E^u|, |E^v|, |E^p|, |E^\rho||\boldsymbol{e}_{ub}|, |\boldsymbol{e}_{vb}|, |\boldsymbol{e}_{\rho b}| \le \mathcal{C}^*, \tag{4.34e}$$

with the constant $\mathcal{C}^*$ depending on the exact solution. This completes the consistency analysis.

Remark 4.3. As stated earlier, the purpose of the higher order expansion (4.33) is to obtain the L^∞ estimate of the error function via its L^2 norm in higher order accuracy by utilizing an inverse inequality in spatial discretization, which will be shown below. Such expansion is always possible under suitable regularity assumption of the exact solution. A detailed analysis shows that

$$|\boldsymbol{v}_e - \boldsymbol{V}| + |\boldsymbol{w}_e - \boldsymbol{W}| + |\rho_e - \Theta| \le C(\triangle t + h^2), \tag{4.35}$$

with C introduced in Theorem 4.1. This estimate will be used later.

Remark 4.4. We note that there is no $O(h^3)$ term in the higher order expansion (4.33). This is due to the centered difference we used in the spatial discretization, which gives local truncation errors with only even order, etc., $O(h^2)$, $O(h^4)$.

4.5. Proof of Theorem 4.1. We consider the following error functions:

$$\tilde{\boldsymbol{v}} = (\tilde{u}, \tilde{v}) = \boldsymbol{V} - \boldsymbol{v} = (U - u, V - v), \quad \tilde{w} = \boldsymbol{W} - w, \quad \tilde{p} = P - p, \quad \tilde{\rho} = \Theta - \rho. \tag{4.36}$$

Subtracting (4.7) from (4.34), we obtain the following system for the error functions:

(4.37a)
$$\begin{cases} \dfrac{\tilde{u}^{n+1} - \tilde{u}^n}{\triangle t} + \mathcal{E}NLU^n + \dfrac{1}{Ro}\Big(-f \overline{\overline{\tilde{v}}}^n + D_x \tilde{p}^n \Big) = L_{1,h} \tilde{u}^{n+1} + (\triangle t^3 + h^4) E^{u,n}, \\ \dfrac{\tilde{v}^{n+1} - \tilde{v}^n}{\triangle t} + \mathcal{E}NLV^n + \dfrac{1}{Ro}\Big(f \overline{\overline{\tilde{u}}}^n + D_y \tilde{p}^n \Big) = L_{1,h} \tilde{v}^{n+1} + (\triangle t^3 + h^4) E^{v,n}, \\ \tilde{u}^{n+1}_{i,j+1/2,-1/2} = \tilde{u}^{n+1}_{i,j+1/2,1/2} + h^5 \boldsymbol{e}_{ub}, \quad \tilde{v}^{n+1}_{i+1/2,j,-1/2} = \tilde{v}^{n+1}_{i+1/2,j,1/2} + h^5 \boldsymbol{e}_{ub}, \end{cases}$$

(4.37b)
$$D_z \tilde{p}^{n+1} = \tilde{\rho}^{n+1} + h^4 E^{p,n},$$

(4.37c)
$$\begin{cases} \nabla_h \cdot \tilde{\boldsymbol{v}}^{n+1} + \tilde{D}_z \tilde{w}^{n+1} = 0, \\ \tilde{w}^{n+1}_{i+1/2,j+1/2,0} = \tilde{w}^{n+1}_{i+1/2,j+1/2,N} = 0, \end{cases}$$

(4.37d)
$$\begin{cases} \dfrac{\tilde{\rho}^{n+1} - \tilde{\rho}^n}{\triangle t} + \mathcal{E}NLR^n = L_{2,h} \tilde{\rho}^{n+1} + (\triangle t^3 + h^4) E^{\rho,n}, \\ \tilde{\rho}^{n+1}_{i+1/2,j+1/2,-1} = \tilde{\rho}^{n+1}_{i+1/2,j+1/2,1} + h^5 \boldsymbol{e}_{\rho b}\,; \end{cases}$$

the nonlinear error terms corresponding to the convection have the following decomposition:

(4.37e)
$$\begin{aligned} \mathcal{E}NLU &= \mathcal{N}_h(\boldsymbol{U}, U) - \mathcal{N}_h(\boldsymbol{u}, u) = \mathcal{N}_h(\tilde{\boldsymbol{u}}, U) + \mathcal{N}_h(\boldsymbol{u}, \tilde{u}), \\ \mathcal{E}NLV &= \mathcal{N}_h(\boldsymbol{U}, V) - \mathcal{N}_h(\boldsymbol{u}, v) = \mathcal{N}_h(\tilde{\boldsymbol{u}}, V) + \mathcal{N}_h(\boldsymbol{u}, \tilde{v}), \\ \mathcal{E}NLR &= \mathcal{N}_h(\boldsymbol{U}, \Theta) - \mathcal{N}_h(\boldsymbol{u}, \rho) = \mathcal{N}_h(\tilde{\boldsymbol{u}}, \Theta) + \mathcal{N}_h(\boldsymbol{u}, \tilde{\rho}). \end{aligned}$$

4.5.1. Preliminary results.

The following preliminary results will be needed in the energy estimate of the system (4.37). The proofs are straightforward so that we omit the detail.

LEMMA 4.5. *We have the following:*

(i) *Inverse inequality in* 3*-D:*

(4.38a)
$$\|f\|_{L^\infty} \le \frac{C}{h^{\frac{3}{2}}} \|f\|_{L^2}.$$

(ii) *Suppose* $w_{i+1/2,j+1/2,0} = w_{i+1/2,j+1/2,N}$*; then*

(4.38b)
$$\|\overline{\overline{u}}\|_2 \le \|u\|_1, \quad \|\overline{\overline{v}}\|_1 \le \|v\|_2, \quad \|\overline{\overline{w}}\|_1 \le \|w\|_3, \quad \|\overline{\overline{w}}\|_2 \le \|w\|_3.$$

(iii) *For* $\tilde{w}$ *determined by* (4.37c), *we have*

(4.38c)
$$\|\tilde{w}\|_3 \le \|D_x^+ \tilde{u}\|_1 + \|D_y^+ \tilde{v}\|_2.$$

(iv) *Suppose* $\tilde{\boldsymbol{v}} = (\tilde{u}, \tilde{v})$ *and* $\tilde{\rho}$ *satisfy the boundary condition in* (4.37); *then*

(4.38d)
$$\begin{aligned} &\|\tilde{D}_x \tilde{u}\|_1 \le \|D_x^+ \tilde{u}\|_1, \quad \|\tilde{D}_y \tilde{u}\|_1 \le \|D_y^+ \tilde{u}\|_1, \quad \|\tilde{D}_z \tilde{u}\|_1 \le \|D_z^+ \tilde{u}\|_1 + h^4, \\ &\|\tilde{D}_y \tilde{v}\|_2 \le \|D_y^+ \tilde{v}\|_2, \quad \|\tilde{D}_x \tilde{v}\|_2 \le \|D_x^+ \tilde{v}\|_2, \quad \|\tilde{D}_z \tilde{v}\|_2 \le \|D_z^+ \tilde{v}\| + h^4, \\ &\|\tilde{D}_x \tilde{\rho}\|_3 \le \|D_x^+ \tilde{\rho}\|_3, \quad \|\tilde{D}_z \tilde{\rho}\|_3 \le \|D_z^+ \tilde{\rho}\|_3, \quad \|\tilde{D}_y \tilde{\rho}\|_3 \le \|D_y^+ \tilde{\rho}\| + h^4. \end{aligned}$$

(v) *Suppose* $w_{i+1/2,j+1/2,0} = w_{i+1/2,j+1/2,N} = 0$; *then*

$$\text{(4.38e)}\quad \langle u, \tilde{D}_x p\rangle_1 + \langle v, \tilde{D}_y p\rangle_2 + \langle w, \tilde{D}_z p\rangle_3 = -\langle(\nabla_h \cdot \boldsymbol{v} + \tilde{D}_z w), p\rangle_4.$$

4.5.2. Energy estimate for the error functions. Assume a priori that

$$\|\tilde{\boldsymbol{v}}\|_{L^\infty} + \|\tilde{w}\|_{L^\infty} \le \frac{1}{2}. \tag{4.39}$$

Such a priori assumption will be verified later using the inverse inequality (4.38a).

Taking the inner product of the first momentum error equation in (4.37a) with $\tilde{u}^{n+1}$ at the mesh point $(i, j+1/2, k+1/2)$, the second momentum error equation with $\tilde{v}^{n+1}$ at the mesh point $(i+1/2, j, k+1/2)$, the equation in (4.37b) with $\frac{\tilde{w}^{n+1}}{Ro}$ at the mesh point $(i+1/2, j+1/2, k)$, and summing up gives

(4.40)

$$\begin{aligned}
&\frac{1}{2}\cdot\frac{1}{\triangle t}\Big(\|\tilde{u}^{n+1}\|_1^2 - \|\tilde{u}^n\|_1^2 + \|\tilde{u}^{n+1} - \tilde{u}^n\|_1^2 + \|\tilde{v}^{n+1}\|_2^2 - \|\tilde{v}^n\|_2^2 + \|\tilde{v}^{n+1} - \tilde{v}^n\|_2^2\Big)\\
&+ \Big\langle \tilde{u}^{n+1}, \mathcal{E}NLU^n \Big\rangle_1 + \Big\langle \tilde{v}^{n+1}, \mathcal{E}NLV^n \Big\rangle_2 + \frac{1}{Ro}\Big(\langle \tilde{u}^{n+1}, -f\overline{\overline{\tilde{v}}}^n\rangle_1 + \langle \tilde{v}^{n+1}, f\overline{\overline{\tilde{u}}}^n\rangle_2\Big)\\
&+ \frac{1}{Ro}\Big(\langle \tilde{u}^{n+1}, D_x\tilde{p}^n\rangle_1 + \langle \tilde{v}^{n+1}, D_y\tilde{p}^n\rangle_2 + \langle \tilde{w}^{n+1}, D_z\tilde{p}^n\rangle_3\Big)\\
&- \Big\langle \tilde{u}^{n+1}, (\nu_1\triangle_h + \nu_2 D_z^2)\tilde{u}^{n+1}\Big\rangle_1 - \Big\langle \tilde{v}^{n+1}, (\nu_1\triangle_h + \nu_2 D_z^2)\tilde{v}^{n+1}\Big\rangle_2\\
&= \frac{1}{2}\cdot\frac{1}{\triangle t}\Big(\|\tilde{u}^{n+1}\|_1^2 - \|\tilde{u}^n\|_1^2 + \|\tilde{u}^{n+1} - \tilde{u}^n\|_1^2 + \|\tilde{v}^{n+1}\|_2^2 - \|\tilde{v}^n\|_2^2\\
&\qquad\qquad + \|\tilde{v}^{n+1} - \tilde{v}^n\|_2^2\Big) + I_{cu}^n + I_{cv}^n + \frac{1}{Ro}I_{cg}^n + \frac{1}{Ro}I_p^n + I_{du}^{n+1} + I_{dv}^{n+1}\\
&= \langle \tilde{u}^{n+1}, (\triangle t^3 + h^4)E^{u,n}\rangle_1 + \langle \tilde{v}^{n+1}, (\triangle t^3 + h^4)E^{v,n}\rangle_2\\
&\quad - \frac{1}{Ro}\langle \tilde{w}^{n+1}, \tilde{\rho}^n\rangle_3 + \frac{h^4}{Ro}\langle \tilde{w}^{n+1}, E^{p,n}\rangle_3.
\end{aligned}$$

A direct application of part (v) in Lemma 4.5 gives that I_p^n appearing in (4.40) vanishes indeed:

$$\begin{aligned}
I_p^n &= \langle \tilde{u}^{n+1}, D_x\tilde{p}^n\rangle_1 + \langle \tilde{v}^{n+1}, D_y\tilde{p}^n\rangle_2 + \langle \tilde{w}^{n+1}, D_z\tilde{p}^n\rangle_3\\
&= -\langle(\nabla_h \cdot \tilde{\boldsymbol{v}}^{n+1} + D_z\tilde{w}^{n+1}), \tilde{p}^n\rangle_4 = 0,
\end{aligned} \tag{4.41}$$

due to the fact that $\tilde{\boldsymbol{u}} = (\tilde{u}, \tilde{v}, \tilde{w})$ is identically divergence-free at the discrete level and the vertical velocity vanishes on the top and bottom boundaries. The identity (4.41) is analogous to (4.8), which shows that the 3-D velocity field is orthogonal to the pressure gradient in the staggered L^2 space. This represents the main advantage of the MAC grid.

The term I_{cg}^n, which corresponds to the Coriolis force, can be controlled directly by the Cauchy inequality and the application of part (ii) in Lemma 4.5:

(4.42)

$$|I_{cg}^n| = \Big|\langle \tilde{u}^{n+1}, -f\overline{\overline{\tilde{v}}}^n\rangle_1 + \langle \tilde{v}^{n+1}, f\overline{\overline{\tilde{u}}}^n\rangle_2\Big| \le \frac{f_0 + \beta}{2}\Big(\|\tilde{u}^{n+1}\|_1^2 + \|\tilde{u}^n\|_1^2 + \|\tilde{v}^{n+1}\|_2^2 + \|\tilde{v}^n\|_2^2\Big).$$

Next we consider the terms I_{du}^{n+1}, I_{dv}^{n+1} corresponding to the diffusion of $\tilde{u}$ and $\tilde{v}$. A direct calculation shows that

$$-\langle \tilde{u}^{n+1}, D_x^2 \tilde{u}^{n+1}\rangle_1 = \|D_x^+ \tilde{u}^{n+1}\|_1^2, \quad -\langle \tilde{u}^{n+1}, D_y^2 \tilde{u}^{n+1}\rangle_1 = \|D_y^+ \tilde{u}^{n+1}\|_1^2, \tag{4.43a}$$

$$\begin{aligned} &-\langle \tilde{u}^{n+1}, D_z^2 \tilde{u}^{n+1}\rangle_1 = \|D_z \tilde{u}^{n+1}\|_1^2 + \mathcal{B}_{uz}^{n+1}, \\ &\mathcal{B}_{uz}^{n+1} = h^3 \sum_{j=0}^{N-1} \sum_{i=1}^{N-1} \Big(h^3 \tilde{u}_{i,j+1/2,1/2}^{n+1} \boldsymbol{e}_{ub} + h^3 \tilde{u}_{i,j+1/2,N-1/2}^{n+1} \boldsymbol{e}_{ut} \Big), \end{aligned} \tag{4.43b}$$

by utilizing the boundary condition for $\tilde{u}^{n+1}$ given in (4.37a). The boundary error term $\mathcal{B}_{uz}^{n+1}$ can be bounded from below as follows:

(4.44)
$$\begin{aligned} \mathcal{B}_{uz}^{n+1} &\geq h^3 \sum_{j=0}^{N-1} \sum_{i=1}^{N-1} \Big(-\frac{1}{2} (\tilde{u}_{i,j+1/2,1/2}^{n+1})^2 - \frac{1}{2} h^6 \boldsymbol{e}_{ub}^2 - \frac{1}{2} (\tilde{u}_{i,j+1/2,N-1/2}^{n+1})^2 - \frac{1}{2} h^6 \boldsymbol{e}_{ut}^2 \Big) \\ &\geq -\frac{1}{2} \|\tilde{u}^{n+1}\|_1^2 - \frac{1}{2} h^9 \sum_{j=0}^{N-1} \sum_{i=1}^{N-1} (\boldsymbol{e}_{ub}^2 + \boldsymbol{e}_{ut}^2) \geq -\frac{1}{2} \|\tilde{u}^{n+1}\|_1^2 - \frac{1}{2} h^6 \,; \end{aligned}$$

in the second step we absorbed the terms $\tilde{u}_{i,j+1/2,1/2}^2$ and $\tilde{u}_{i,j+1/2,N-1/2}^2$ into $\|\tilde{u}\|_1^2$ by its definition. Then we obtain

(4.45)
$$I_{du}^{n+1} \geq \nu_0 (\|D_x^+ \tilde{u}^{n+1}\|_1^2 + \|D_y^+ \tilde{u}^{n+1}\|_1^2 + \|D_z^+ \tilde{u}^{n+1}\|_1^2) - \frac{1}{2} \nu_2 \|\tilde{u}^{n+1}\|_1^2 - \frac{1}{2} \nu_2 h^6,$$

in which $\nu_0 = \min(\nu_1, \nu_2, \kappa_1, \kappa_2)$. Similar estimates can be obtained for I_{dv}^{n+1}:

$$I_{dv}^{n+1} \geq \nu_0 (\|D_x^+ \tilde{v}^{n+1}\|_2^2 + \|D_y^+ \tilde{v}^{n+1}\|_2^2 + \|D_z^+ \tilde{v}^{n+1}\|_2^2) - \frac{1}{2} \nu_2 \|\tilde{v}^{n+1}\|_2^2 - \frac{1}{2} \nu_2 h^6. \tag{4.46}$$

It remains to estimate I_{cu}^n and I_{cv}^n corresponding to the nonlinear convection terms. Using the decomposition for $\mathcal{E}NLU$ as shown in (4.37e) yields

$$I_{cu}^n = \Big\langle \tilde{u}^{n+1}, \mathcal{E}NLU^n \Big\rangle_1 = \Big\langle \tilde{u}^{n+1}, \mathcal{N}_h(\tilde{\boldsymbol{u}}^n, U^n) \Big\rangle_1 + \Big\langle \tilde{u}^{n+1}, \mathcal{N}_h(\boldsymbol{u}^n, \tilde{u}^n) \Big\rangle_1 . \tag{4.47}$$

The application of the Cauchy inequality to the first integral appearing on the right-hand side of (4.47) indicates

(4.48)
$$-\Big\langle \tilde{u}^{n+1}, \mathcal{N}_h(\tilde{\boldsymbol{u}}^n, U^n) \Big\rangle_1 \leq \tilde{C}_1 \Big(\|\tilde{u}^{n+1}\|_1^2 + \|\tilde{u}^n\|_1^2 + \|\overline{\overline{\tilde{v}}}^n\|_1^2 \Big) + \frac{2\tilde{C}_1^2}{\nu_0} \|\tilde{u}^{n+1}\|_1^2 + \frac{1}{8} \nu_0 \|\overline{\overline{\tilde{w}}}^n\|_1^2,$$

where $\tilde{C}_1 = \|U\|_{W^{1,\infty}}$. The consistency analysis (4.35) shows that $\tilde{C}_1 \leq \|\boldsymbol{v}_e\|_{C^1} + 1$. Meanwhile, the combination of parts (ii) and (iii) in Lemma 4.5 gives

$$\|\overline{\overline{\tilde{w}}}^n\|_1^2 \leq \|\tilde{w}^n\|_3^2 \leq 2(\|D_x^+ \tilde{u}^n\|^2 + \|D_y^+ \tilde{v}^n\|^2), \quad \|\overline{\overline{\tilde{v}}}^n\|_1^2 \leq \|\tilde{v}^n\|_2^2, \tag{4.49}$$

whose insertion into (4.48) leads to

$$\begin{aligned}-\Big\langle \tilde u^{n+1}, \mathcal{N}_h(\tilde{\boldsymbol u}^n, U^n)\Big\rangle_1 &\le \frac{3\tilde C_1^2}{\nu_0}\|\tilde u^{n+1}\|_1^2 + \tilde C_1(\|\tilde u^n\|_1^2 + \|\tilde v^n\|_2^2)\\ &\quad + \frac{1}{4}\nu_0(\|D_x^+\tilde u^n\|_1^2 + \|D_y^+\tilde v^n\|_2^2).\end{aligned} \tag{4.50}$$

The second inner product appearing on the right-hand side of (4.47) can be controlled in a similar way:

$$-\Big\langle \tilde u^{n+1}, \mathcal{N}_h(\boldsymbol u^n, \tilde u^n)\Big\rangle_1 \le 2\cdot\frac{\tilde C_2^2}{\nu_0}\|\tilde u^{n+1}\|_1^2 + \frac{1}{4}\nu_0\Big(\|D_x^+\tilde u^n\|_1^2 + \|D_y^+\tilde u^n\|_1^2 + \|D_z^+\tilde u^n\|_1^2\Big), \tag{4.51}$$

where $\tilde C_2 = \|\boldsymbol u\|_{L^\infty}$. The a priori assumption (4.39) and the consistency analysis (4.35) assures that

$$\tilde C_2 \le \|\boldsymbol V\|_{L^\infty} + \|\boldsymbol W\|_{L^\infty} + \frac{1}{2} \le \|\boldsymbol u_e\|_{C^0} + C(\triangle t + h^2) + \frac{1}{2} \le \|\boldsymbol u_e\|_{C^0} + 1, \tag{4.52}$$

provided that $\triangle t$ and h are small enough. Applying part (iv) of Lemma 4.5 into (4.52) results in

$$\begin{aligned}&-\Big\langle \tilde u^{n+1}, \mathcal{N}_h(\boldsymbol u^n, \tilde u^n)\Big\rangle_1\\ &\le \frac{2\tilde C_2^2}{\nu_0}\|\tilde u^{n+1}\|_1^2 + \frac{1}{4}\nu_0\Big(\|D_x^+\tilde u^n\|_1^2 + \|D_y^+\tilde u^n\|^2 + \|D_z^+\tilde u^n\|_1^2 + 2h^6\Big).\end{aligned} \tag{4.53}$$

Thus the combination of (4.51) and (4.53) gives

$$\begin{aligned}I_{cu}^n &\ge -\Big(\frac{3\tilde C_1^2}{\nu_0} + \frac{2\tilde C_2^2}{\nu_0}\Big)\|\tilde u^{n+1}\|_1^2 - \tilde C_1(\|\tilde u^n\|_1^2 + \|\tilde v^n\|_2^2)\\ &\quad - \frac{1}{2}\nu_0\Big(\|D_x^+\tilde u^n\|_1^2 + \|D_y^+\tilde u^n\|_1^2 + \|D_z^+\tilde u^n\|_1^2\Big) - h^6,\end{aligned} \tag{4.54}$$

where $\tilde C_1 \le \|\boldsymbol v_e\|_{C^1}+1$, $\tilde C_2 \le \|\boldsymbol u_e\|_{C^0}+1$. The bound for I_{cv}^n can be similarly obtained:

$$\begin{aligned}I_{cv}^n &\ge -\Big(\frac{3\tilde C_1^2}{\nu_0} + \frac{2\tilde C_2^2}{\nu_0}\Big)\|\tilde v^{n+1}\|_2^2 - \tilde C_1(\|\tilde u^n\|_1^2 + \|\tilde v^n\|_2^2)\\ &\quad - \frac{1}{2}\nu_0\Big(\|D_x^+\tilde v^n\|_2^2 + \|D_y^+\tilde v^n\|_2^2 + \|D_z^+\tilde v^n\|_2^2\Big) - h^6.\end{aligned} \tag{4.55}$$

The four terms appearing on the right-hand side of (4.40) can be controlled by the Cauchy inequality, together with the application of part (iii) of Lemma 4.5:

$$\begin{aligned}&\langle \tilde u^{n+1}, (\triangle t^3 + h^4)E^{u,n}\rangle_1 \le \frac{1}{2}\|\tilde u^{n+1}\|_1^2 + (\triangle t^6 + h^8)\|E^{u,n}\|_1^2,\\ &\langle \tilde v^{n+1}, (\triangle t^3 + h^4)E^{v,n}\rangle_2 \le \frac{1}{2}\|\tilde v^{n+1}\|_2^2 + (\triangle t^6 + h^8)\|E^{v,n}\|_2^2,\\ &-\frac{1}{Ro}\langle \tilde w^{n+1}, \tilde\rho^n\rangle_3 \le \frac{1}{8}\nu_0(\|D_x^+\tilde u^{n+1}\|^2 + \|D_y^+\tilde v^{n+1}\|^2) + \frac{C}{\nu_0}\|\tilde\rho^n\|_3^2,\\ &\frac{h^4}{Ro}\langle \tilde w^{n+1}, E^{p,n}\rangle_3 \le \frac{1}{8}\nu_0(\|D_x^+\tilde u^{n+1}\|_1^2 + \|D_y^+\tilde v^{n+1}\|_2^2) + \frac{C}{\nu_0}h^8\,\|E^{p,n}\|_3^2.\end{aligned} \tag{4.56}$$

Substituting (4.56), (4.55), (4.54), (4.46), (4.45), (4.42), and (4.41) into (4.40), and denoting

$$\begin{aligned} \mathcal{IEV} &= \|D_x^+\tilde{u}\|_1^2 + \|D_y^+\tilde{u}\|_1^2 + \|D_z^+\tilde{u}\|_1^2 + \|D_x^+\tilde{v}\|_2^2 + \|D_y^+\tilde{v}\|_2^2 + \|D_z^+\tilde{v}\|_2^2, \\ \mathcal{IER} &= \|D_x^+\tilde{\rho}\|_3^2 + \|D_y^+\tilde{\rho}\|_3^2 + \|D_z^+\tilde{\rho}\|_3^2, \end{aligned} \tag{4.57}$$

we have the energy estimate for $\tilde{\boldsymbol{v}}$

$$\begin{aligned} &\frac{1}{2}\cdot\frac{1}{\triangle t}\Big(\|\tilde{u}^{n+1}\|_1^2 - \|\tilde{u}^n\|_1^2 + \|\tilde{v}^{n+1}\|_2^2 - \|\tilde{v}^n\|_2^2\Big) + \frac{3}{4}\nu_0\mathcal{IEV}^{n+1} \\ &\le \Big(\frac{4\tilde{C}_1^2}{\nu_0} + \frac{4\tilde{C}_2^2}{\nu_0} + C\Big)\|\tilde{\boldsymbol{v}}\|^2 + \frac{C}{\nu_0}\|\tilde{\rho}\|_3^2 + \frac{1}{2}\nu_0\mathcal{IEV}^n + \tilde{E}_u^n, \end{aligned} \tag{4.58a}$$

in which $\tilde{C}_1 \le \|\boldsymbol{v}_e\|_{C^1} + 1$, $\tilde{C}_2 \le \|\boldsymbol{u}_e\|_{C^0} + 1$, and the error term satisfies

$$\tilde{E}_u^n \le \frac{1}{2}(\triangle t^6 + h^8)\Big(\|E^{u,n}\|_1^2 + \|E^{v,n}\|_2^2) + \frac{\|E^{p,n}\|_3^2}{\nu_0}\Big) + Ch^6. \tag{4.58b}$$

The energy estimate for the density error function can be carried out in a similar way (we omit the details):

$$\begin{aligned} &\frac{1}{2}\cdot\frac{1}{\triangle t}\Big(\|\tilde{\rho}^{n+1}\|_3^2 - \|\tilde{\rho}^n\|_3^2\Big) + \frac{3}{4}\nu_0\mathcal{IER}^{n+1} \le \Big(\frac{\tilde{C}_3^2}{\nu_0} + \frac{4\tilde{C}_2^2}{\nu_0} + C\Big)\|\tilde{\rho}\|_3^2 + \frac{1}{2}\|\tilde{\boldsymbol{v}}\|^2 \\ &\quad + \frac{1}{8}\nu_0(\|D_x^+\tilde{u}^n\|_1^2 + \|D_y^+\tilde{v}^n\|_2^2) + \frac{1}{2}\nu_0\mathcal{IER}^n + C(\triangle t^6 + h^8)\,\|E^{\rho,n}\|_3^2, \end{aligned} \tag{4.59}$$

in which $\tilde{C}_3 = \|\Theta\|_{W^{1,\infty}} \le \|\rho_e\|_{C^1} + 1$. By setting $\|\tilde{\boldsymbol{v}}\|^2 = \|\tilde{u}\|_1^2 + \|\tilde{v}\|_2^2$, we arrive at

$$\begin{aligned} &\frac{1}{2}\cdot\frac{1}{\triangle t}\Big(\|\tilde{\boldsymbol{v}}^{n+1}\|^2 - \|\tilde{\boldsymbol{v}}^n\|^2 + \|\tilde{\rho}^{n+1}\|_3^2 - \|\tilde{\rho}^n\|_3^2\Big) + \frac{3}{4}\nu_0\,\mathcal{IEV}^{n+1} + \frac{3}{4}\nu_0\,\mathcal{IER}^{n+1} \\ &\le \Big(\frac{4\tilde{C}_1^2}{\nu_0} + \frac{4\tilde{C}_2^2}{\nu_0} + \frac{\tilde{C}_3^2}{\nu_0} + C\Big)(\|\tilde{\boldsymbol{v}}\|^2 + \|\tilde{\rho}\|_3^2) + \frac{5}{8}\nu_0\,\mathcal{IEV}^n + \frac{1}{2}\nu_0\,\mathcal{IER}^n + \tilde{E}^n, \text{ with} \\ &\qquad \tilde{E}^n \le C(\triangle t^6 + h^8)\Big(\|E^{u,n}\|_1^2 + \|E^{v,n}\|_2^2 + \|E^{\rho,n}\|_3^2) + \frac{\|E^{p,n}\|_3^2}{\nu_0}\Big) + Ch^6, \end{aligned} \tag{4.60}$$

since the term $(\|D_x^+\tilde{u}^n\|_1^2+\|D_y^+\tilde{v}^n\|_2^2)$ appearing on the right-hand side of (4.59) can be absorbed into $\mathcal{IEV}^n$. Summing (4.60) in time and applying the Gronwall inequality yield

$$\|\tilde{\boldsymbol{v}}^n\|^2 + \|\tilde{\rho}^n\|_3^2 \le \quad C\cdot\exp\Big(\frac{Ct}{\nu_0}\Big)\Big(\triangle t^6 + h^8\Big)(\mathcal{C}^*)^2 + CTh^6, \tag{4.61}$$

where C was given in Theorem 4.1 and $\mathcal{C}^*$ depends only on the exact solution. In the derivation of (4.61), we drop the gradient terms since the coefficients of $\mathcal{IEV}$, $\mathcal{IER}$ on the right-hand side of (4.60) are less than those on the left-hand side. The inequality (4.61) amounts to saying

$$\begin{aligned} &\|\boldsymbol{v}_{\triangle t,h} - \boldsymbol{V}\|_{L^\infty(0,T;\boldsymbol{L}_h^2)} + \|\rho_{\triangle t,h} - \Theta\|_{L^\infty(0,T;L_h^2)} \\ &\qquad \le C\mathcal{C}^*\Big(\exp\Big\{\frac{CT}{\nu_0}\Big\} + T\Big)\Big(\triangle t^3 + h^3\Big), \end{aligned} \tag{4.62}$$

whose combination with the estimate (4.35) gives the convergence result (4.3a). The inverse inequality in three dimensions as given in Lemma 4.5 shows that

$$\|\tilde{\boldsymbol{v}}\|_{L^\infty} \leq C\frac{\triangle t^3 + h^3}{h^{\frac{3}{2}}}, \tag{4.63}$$

and this is bounded by $Ch^{3/2}$, since we impose to $\triangle t$ a CFL-like condition $\triangle t \leq Ch$. Moreover, we have

$$\|\tilde{w}\|_{L^\infty} \leq \frac{C}{h}\|\tilde{\boldsymbol{v}}\|_{L^\infty} \leq Ch^{1/2}, \tag{4.64}$$

which comes from the determination identity for $\tilde{w}$ in (4.37). As a result, the a priori assumption (4.39) is satisfied if h is small enough. Thus Theorem 4.1 is proven.

Remark 4.6. The inverse inequality (4.38a) recovers the L^∞ a priori assumption (4.39) for the velocity field. This is the main advantage in the analysis of the fully discretized system. Since the vertical velocity is formulated as the integration of the divergence for the horizontal velocity, the $O(h^{\frac{5}{2}})$ estimate for the L^2 norm of $\tilde{\boldsymbol{v}}$ is required. This is the reason for the higher order consistency analysis in section 4.4.

Remark 4.7. The stability constraint in Theorem 4.1 is $\triangle t \leq Ch$. We infer from (4.62) that the backward Euler scheme is unconditionally stable for the $L^2(0, T; L^2)$ norm, as expected from a scheme with implicit treatment of the diffusion term. The stability constraint $\triangle t \leq Ch$ is introduced after (4.63), (4.64) to recover the $L^\infty([0, T] \times \mathcal{M})$ stability, and C is an arbitrary fixed constant; note that the usual CFL constraint has the same form with $C = |\boldsymbol{u}|^{-1}_{L^\infty}$, but in the present case C is arbitrary, since the CFL condition is needed only to ensure additional stability.

5. Numerical accuracy check. In this section we check the numerical accuracy of the computational scheme. The exact velocity and density are chosen to be

$$\begin{aligned} u_e(x, y, z, t) &= \frac{1}{\pi^2}\text{sin}(\pi x)\text{sin}(\pi y)\text{cos}(\pi z)\text{cos}t, \\ v_e(x, y, z, t) &= \frac{1}{\pi^2}\text{sin}(\pi x)\text{sin}(\pi y)\text{cos}(\pi z)\text{cos}t, \\ \rho_e(x, y, z, t) &= \frac{1}{\pi^2}\text{cos}(\pi x)\text{cos}(\pi y)\text{cos}(\pi z)\text{cos}t. \end{aligned} \tag{5.1}$$

The corresponding exact vertical velocity w_e and exact pressure variable p_e are determined by the incompressibility $\nabla\cdot\boldsymbol{v}_e + \partial_z w_e$ and hydrostatic balance $\frac{\partial p_e}{\partial z} = -\rho_e$, respectively:

$$\begin{aligned} w_e(x, y, z, t) &= -\frac{1}{\pi^2}\Big(\text{cos}(\pi x)\text{sin}(\pi y) + \text{sin}(\pi x)\text{cos}(\pi y)\Big)\text{sin}(\pi z)\text{cos}t, \\ p_e(x, y, z, t) &= \frac{1}{\pi^3}\text{cos}(\pi x)\text{cos}(\pi y)\Big(1 - \text{sin}(\pi z)\Big)\text{cos}t, \end{aligned} \tag{5.2}$$

in which we set the exact surface pressure as

$$p_{se}(x, y, t) = p_e(x, y, 0, t) = \frac{1}{\pi^3}\text{cos}(\pi x)\text{cos}(\pi y)\text{cos}t. \tag{5.3}$$

Then we arrive at the following system of PEs with force terms $\boldsymbol{f}$, $\boldsymbol{g}$ in the momentum equation and the density equation

(5.4a)

$$\begin{cases} \partial_t \boldsymbol{v}_e + (\boldsymbol{v}_e \cdot \nabla)\boldsymbol{v}_e + w_e \dfrac{\partial \boldsymbol{v}_e}{\partial z} + \dfrac{1}{Ro}\Big(f k \times \boldsymbol{v}_e + \nabla p_e \Big) = \Big(\nu_1 \triangle + \nu_1 \partial_z^2 \Big) \boldsymbol{v}_e + \boldsymbol{f}, \\ \dfrac{\partial p_e}{\partial z} = -\rho_e, \\ \nabla \cdot \boldsymbol{v}_e + \partial_z w_e = 0, \\ \partial_t \rho_e + (\boldsymbol{v}_e \cdot \nabla)\rho_e + w_e \dfrac{\partial \rho_e}{\partial z} = \Big(\kappa_1 \triangle + \kappa_2 \partial_z^2 \Big) \rho_e + \boldsymbol{g}, \end{cases}$$

with the boundary condition

$$\begin{aligned} &\frac{\partial \boldsymbol{v}_e}{\partial z} = 0, \quad w_e = 0, \quad \frac{\partial \rho_e}{\partial z} = 0 \quad \text{at}\, z = 0, -H_0, \\ &\boldsymbol{v}_e = 0, \quad \frac{\partial \rho_e}{\partial \boldsymbol{n}} = 0 \quad \text{on} \quad \partial \mathcal{M}_0 \times [-H_0, 0]. \end{aligned} \tag{5.4b}$$

The computational domain is chosen as $\mathcal{M} = \mathcal{M}_0 \times [-H_0, 0]$, where $\mathcal{M}_0 = [0,1]^2$, $H_0 = 1$. The viscosity parameters are given by $\nu_1 = \nu_2 = 0.005$, $\kappa_1 = \kappa_2 = 0.005$. In a usual GFD model, the Rossby number ranges from $O(1)$ to $O(10^{-3})$. We choose $Ro = 0.5$ in the numerical experiment. The Coriolis force parameter is set to be $f_0 = 0.5$, $\beta = 1$.

The system (5.4) can be formulated in the same fashion as (1.13) such that the surface pressure Poisson equation replaces the nonlocal incompressibility constraint for the horizontal velocity. Note that a force term $\nabla \cdot \boldsymbol{f}$ appears in the Poisson equation. Based on such formulation, we apply the Crank–Nicolson method, a second order numerical scheme with implicit diffusion terms, using the MAC spatial grid, to solve the PEs (5.4). The force terms $\boldsymbol{f}$, $\boldsymbol{g}$ and $\nabla \cdot \boldsymbol{f}$ are added when we update the momentum equation and the density equation and solve the surface pressure Poisson equation. The final time is taken to be $t = 1.0$. Table 5.1 lists the absolute errors between the numerical and exact solutions for velocity and density. All the error functions are measured in L^1, L^2, and L^∞ norms in a discrete level similar to that

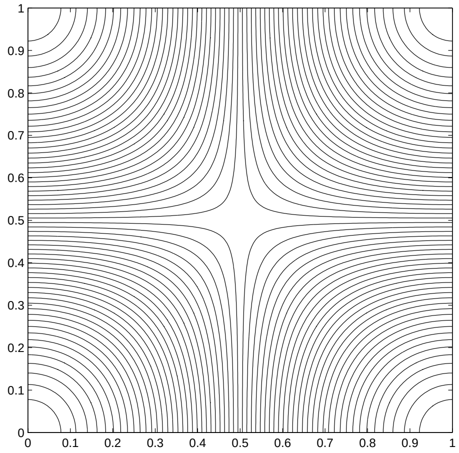

Fig. 5.1. *The contour plot of the surface pressure at $t = 1$ with $N = 128$.*

in the notation (4.2). As can be seen, exactly second order accuracy for the velocity field $\boldsymbol{v} = (u, v)$ and the density field ρ, in both L^1, L^2, and L^∞ norms, is obtained.

The contour plot of the surface pressure at the final time $t = 1.0$ (calculated by the resolution $N = 128$) is also presented in Figure 5.1, which shows a smooth numerical profile and verifies the robustness of the computational method. Such a plot gives an accurate approximation to the exact surface pressure given by (5.3).

p INTERPOLATION ERROR ESTIMATES FOR EDGE FINITE ELEMENTS OF VARIABLE ORDER IN TWO DIMENSIONS*

L. DEMKOWICZ† AND I. BABUŠKA†

Abstract. We derive optimal p interpolation error estimates for triangular edge elements of variable order.

Key words. Maxwell's equations, hp finite elements

AMS subject classifications. 65N30, 35L15

DOI. 10.1137/S0036142901387932

1. Introduction.

This paper is concerned with the finite element discretization of Maxwell's equations in two dimensions. Critical to the theory of such discretizations is the so-called de Rham diagram relating two exact sequences of spaces, on both continuous and discrete levels, and corresponding interpolation operators,

$$\begin{tikzcd}
\mathbb{R} \arrow[r] \arrow[d, "id"] & H^{1+\epsilon} \arrow[r, "\boldsymbol{\nabla}"] \arrow[d, "\Pi"] & \boldsymbol{H}^{\epsilon} \cap \boldsymbol{H}(\mathrm{curl}) \arrow[r, "\boldsymbol{\nabla}\times"] \arrow[d, "\Pi^{\mathrm{curl}}"] & L^2 \arrow[r] \arrow[d, "{P,}"] & \mathbf{0}, \\
\mathbb{R} \arrow[r] & \mathcal{P}^{p+1}_{p_e+1} \arrow[r, "\boldsymbol{\nabla}"] & \mathbf{P}^{p}_{p_e} \arrow[r, "\boldsymbol{\nabla}\times"] & \mathcal{P}^{p-1} \arrow[r] & \mathbf{0}\,.
\end{tikzcd} \tag{1.1}$$

All functional spaces are defined on the equilateral, master triangular element[1]

$$T = \left\{ (x_1, x_2) \,:\, x_2 > 0,\ x_2 < \sqrt{3}\left(x_1 + \frac{1}{2}\right),\ x_2 < -\sqrt{3}\left(x_1 - \frac{1}{2}\right) \right\} .$$

In (1.1) and throughout this paper, $\epsilon > 0$ denotes a small positive constant (always smaller than exponent r representing regularity of functions being interpolated), and all constants that appear in presented estimates depend, in general, on ϵ.

The polynomial spaces present in the diagram are defined as follows.

- $\mathcal{P}^p_{p_e}$—space of polynomials of order p, defined on the triangle, whose traces to edges e reduce to (possibly lower) order $p_e, e = 1, 2, 3$.
- $\boldsymbol{P}^p_{p_e}$—space of vector-valued polynomials of order p, defined on triangle T, with traces of their tangential components on edges e of (possibly lower) order p_e.
- $\mathcal{P}^p$—space of polynomials of order p, defined on triangle T.

In particular, $\mathcal{P}^p_{-1}$ denotes the space of polynomials of order p, vanishing on the boundary of the triangle, and $\boldsymbol{P}^p_{-1}$ stands for the space of vector-valued polynomials of order p, with the trace of the tangential component on the boundary equal

[1] We shall restrict our presentation to triangular elements only.

to zero. The assumption that edge orders p_e should not exceed polynomial order p, $p_e \leq p, e = 1, 2, 3$, is realized in practice by implementing the *minimum rule* that sets an edge order p_e to the minimum of orders p corresponding to the adjacent elements.

The three interpolation operators present in the diagram map are H^1-, $H(\text{curl})$-, and L^2-conforming operators. The last operator is simply the L^2-projection, and the first two will be discussed in detail in the next sections. The operators are constructed in such a way that, when applied elementwise to a function defined on a whole mesh, they yield a discretization that is globally conforming. Simply speaking, if u is continuous, then the union of element H^1-interpolants is continuous as well. Similarly, if field $\boldsymbol{E}$ has a continuous tangential component across every interelement boundary, the corresponding $H(\text{curl})$-conforming interpolant will have the same property.

This paper is concerned with p interpolation error estimates, with respect to order of approximation p, with minimum regularity assumptions that would yield optimal convergence rates. Such estimates are critical in proving discrete compactness property, and consequently convergence of Maxwell eigenvalues [6], which in turn implies (and it is necessary for) the stability of finite element approximations to the time-harmonic Maxwell equations. The p interpolation error estimates are also the first step towards proving exponential convergence of hp discretizations; see, e.g., [19], analysis of two-grid and multigrid algorithms, etc.

The presented H^1 interpolation error estimate derives directly from the works of Babuška and his collaborators. To the best of our knowledge, the corresponding result for the $H(\text{curl})$-conforming interpolation is new.

There are two related known results for quad edge elements. Monk [13] proved (suboptimal) p interpolation error estimates for square and hexahedral elements using the Nédélec interpolation [14, 15]. Stenberg and Suri [21] studied Brezzi–Douglas–Fortin–Marini (BDFM) elements (in two dimensions $H(\text{curl})$-conforming elements can be obtained by "rotating" $H(\text{div})$-conforming elements), and proved ϵ-optimal L^2 and $H(\text{curl})$ estimates for the original BDFM interpolation operator, generalizing and improving the earlier work of Suri [22] for Brezzi–Douglas–Marini spaces.

In both cases, the proofs were based on expansions in terms of Legendre polynomials and do not seem to be generalizable to the triangular elements.

For details on implementation of the variable order edge elements, see [17, 18].

2. Preliminaries.

Fundamental spaces and norms. We shall use a number of standard inner products and the corresponding norms.

The L^2 product on triangle T will be denoted (u, v), and the corresponding L^2 norm will be denoted $\|u\|$. The notions extend in a standard way to vector-valued functions.

The standard H^1-norm will be denoted $\|u\|_{H^1(T)}$. We shall also need the corresponding seminorm,

$$|u|_{H^1(T)} = \|\boldsymbol{\nabla} u\| \,.$$

Space $H^{\frac{1}{2}}(\partial T)$ will be defined as the space of traces of functions from $H^1(T)$ to boundary ∂T. The corresponding seminorm can be defined as

$$|u|^2_{H^{\frac{1}{2}}(\partial T)} = \inf_{U|_{\partial T} = u} |U|^2_{H^1(T)} = \|\boldsymbol{\nabla} \tilde{u}\|^2 = \left\langle \frac{\partial \tilde{u}}{\partial n}, \tilde{u} \right\rangle \,. \tag{2.1}$$

Here $\langle\cdot,\cdot\rangle$ stands for the duality pairing between $H^{-\frac{1}{2}}(\partial T)$ and $H^{\frac{1}{2}}(\partial T)$, $\tilde{u}$ is the harmonic lift of function $u \in H^{\frac{1}{2}}(\partial T)$, and the normal derivative is in the subspace of functionals with vanishing average,

$$H_0^{-\frac{1}{2}}(\partial T) = \{\phi \in H^{-\frac{1}{2}}(\partial T) \,:\, \langle \phi, 1\rangle = 0\}\,.$$

The parallelogram law allows us to learn the corresponding inner product,

$$\begin{aligned}(u,v)_{H^{\frac{1}{2}}(\partial T)} &= \frac{1}{4}\left\{|u+v|^2_{H^{\frac{1}{2}}(\partial T)} - |u-v|^2_{H^{\frac{1}{2}}(\partial T)}\right\}\\ &= \frac{1}{4}\{\|\boldsymbol{\nabla}(\tilde{u}+\tilde{v})\|^2 - \|\boldsymbol{\nabla}(\tilde{u}-\tilde{v}\|^2\}\\ &= (\boldsymbol{\nabla}\tilde{u}, \boldsymbol{\nabla}\tilde{v})\\ &= \left\langle \frac{\partial \tilde{u}}{\partial n}, \tilde{v}\right\rangle = \left\langle \frac{\partial \tilde{v}}{\partial n}, \tilde{u}\right\rangle.\end{aligned}$$

In an analogous way we can use the norm and inner product in $H^1(T)$ to introduce the corresponding norm and inner products in $H^{\frac{1}{2}}(\partial T)$. On the quotient space $H^{\frac{1}{2}}(\partial T)/\mathbb{R}$, the seminorm turns into a norm, equivalent to the standard norm for quotient spaces. Subspace $H_0^{-\frac{1}{2}}(\partial T)$ can be identified with the dual of $H^{\frac{1}{2}}(\partial T)/\mathbb{R}$.

By Riesz theorem, $\phi \in H_0^{-\frac{1}{2}}(\partial T)$ can be identified with the equivalence class of a function $u_\phi \in H^{\frac{1}{2}}(\partial T)$ such that

$$\langle \phi, v\rangle = (\boldsymbol{\nabla}\tilde{u}_\phi, \boldsymbol{\nabla}\tilde{v}) = \left\langle \frac{\partial \tilde{u}_\phi}{\partial n}, \tilde{v}\right\rangle\,.$$

Consequently,

$$\|\phi\|_{H_0^{-\frac{1}{2}}(\partial T)} = \sup_{v\in H^{\frac{1}{2}}(\partial T)} \frac{|\langle \phi, v\rangle|}{|v|_{H^{\frac{1}{2}}(\partial T)}} = \sup_{v\in H^{\frac{1}{2}}(\partial T)} \frac{(\boldsymbol{\nabla}\tilde{u}_\phi, \boldsymbol{\nabla}\tilde{v})}{|\boldsymbol{\nabla}\tilde{v}|} = |\boldsymbol{\nabla}\tilde{u}_\phi|\,, \tag{2.2}$$

and the parallelogram law again can be used to recover the scalar product,

$$(\phi,\psi)_{H_0^{-\frac{1}{2}}(\partial T)} = (\boldsymbol{\nabla}\tilde{u}_\phi, \boldsymbol{\nabla}\tilde{v}_\psi)\,.$$

Let e be one of the triangle edges. Space $H_{00}^{\frac{1}{2}}(e)$ is defined as the collection of restrictions of functions from $H^{\frac{1}{2}}(\partial T)$ vanishing along the two remaining edges,

$$H_{00}^{\frac{1}{2}}(e) = \{u|_e \,:\, u \in H^{\frac{1}{2}}(\partial T),\ u = 0 \text{ on } \partial T - e\}\,.$$

Equivalently, u is in $H_{00}^{\frac{1}{2}}(e)$ if its zero extension $\tilde{u}$ is in $H^{\frac{1}{2}}(\partial T)$. The seminorm and the corresponding product in $H^{\frac{1}{2}}(\partial T)$ define the norm and the scalar product in $H_{00}^{\frac{1}{2}}(e)$,

$$\begin{aligned}\|u\|_{H_{00}^{\frac{1}{2}}(e)} &= |\tilde{u}|_{H^{\frac{1}{2}}(\partial T)},\\ (u,v)_{H_{00}^{\frac{1}{2}}(e)} &= (\tilde{u},\tilde{v})_{H^{\frac{1}{2}}(\partial T)}.\end{aligned}$$

Sobolev spaces of fractional order. We shall need a number of technical but standard facts about fractional order spaces; see, e.g., [12, 1, 20, 2, 19, 5].

We may use Fourier transform to introduce spaces $H^r(\mathbb{R}^2)$, $r \geq 0$. Functions from $H^r(T)$, $r \geq 0$, can be identified with restrictions of functions from $H^r(\mathbb{R}^2)$. Elements of $H^r(\partial T)$, $r > 0$, can be identified with traces of functions from $H^{r+\frac{1}{2}}(T)$. Their duals define fractional boundary spaces with negative exponents $H^r(\partial T)$, $r < 0$. For $-1 < r < 1$, the boundary spaces can be defined directly using local maps, and spaces $H^r(\mathbb{R})$ can be defined through Fourier transform, and the two definitions are equivalent.

For an edge e, spaces $H^r(e)$, $r \geq 0$, can be constructed by considering restrictions from $H^r(\partial T)$. They are naturally isomorphic with space $H^r(I)$ for unit interval $I = (0,1)$, which can be obtained via restrictions of functions from $H^r(\mathbb{R})$. For $\frac{1}{2} < r < 1$, boundary spaces $H^r(\partial T)$ can be conveniently characterized:

$$H^r(\partial T) = \{u \,:\, u|_e \in H^r(e), \text{ for each edge } e, \text{ and } u \text{ is continuous at vertices}\}$$

(Notice that, for $r > \frac{1}{2}$, $H^r(e)$ is embedded in $C(\bar{e})$; see Lemma 1.)

Finally, space $H^{\frac{1}{2}}_{00}(I)$, isomorphic with $H^{\frac{1}{2}}_{00}(e)$, can be equipped with an explicit, equivalent norm,

$$\|u\|^2_{H^{\frac{1}{2}}_{00}(I)} = \|u\|^2_{H^{\frac{1}{2}}(I)} + \int_0^1 \frac{u^2}{x}\,dx + \int_0^1 \frac{u^2}{1-x}\,dx. \tag{2.3}$$

We shall need a couple of nonstandard results involving the fractional spaces.

LEMMA 1. *Let $r > \frac{1}{2}$. Subspace of $H^r(I)$, consisting of functions vanishing at the endpoints,*

$$\{u \in H^r(0,1) \,:\, u(0) = u(1) = 0\}\,,$$

is continuously embedded in $H^{\frac{1}{2}}_{00}(I)$.

Proof. Due to the existence of a continuous extension operator from $H^r(I)$ into $H^r(\mathbb{R})$, $r \geq 0$ [20], it is sufficient to consider functions from $H^r(\mathbb{R})$.

Recall first that space $H^{\frac{1}{2}+\epsilon}(\mathbb{R})$ is continuously embedded in the space of Hölder continuous functions $C^\epsilon(\mathbb{R})$; see, e.g., [1, Thm. 7.57].

We now use the explicit norm (2.3). It is sufficient to show that the last two terms can be bounded by the norm in $H^{\frac{1}{2}+\epsilon}(I)$. But this follows immediately from the embedding into the Hölder continuous functions; e.g., for the first term we have

$$\int_0^1 \frac{u^2}{x}\,dx \leq C\|u\|^2_{H^{\frac{1}{2}+\epsilon}(I)} \int_0^1 \frac{x^{2\epsilon}}{x}\,dx \leq C\|u\|^2_{H^{\frac{1}{2}+\epsilon}(I)}\,. \qquad \square$$

LEMMA 2. *With norms* (2.1) *and* (2.2), *the tangential derivative defines an isometry from $H^{\frac{1}{2}}(\partial T)/\mathbb{R}$ onto $H_0^{-\frac{1}{2}}(\partial T)$,*

$$\frac{\partial}{\partial s} \,:\, H^{\frac{1}{2}}(\partial T)/\mathbb{R} \ni u \to \frac{\partial u}{\partial s} \in H_0^{-\frac{1}{2}}(\partial T)\,.$$

The construction extends to an isomorphism between fractional spaces,

$$\frac{\partial}{\partial s} : H^{\frac{1}{2}+r}(\partial T)/\mathbb{R} \ni u \to \frac{\partial u}{\partial s} \in H^{-\frac{1}{2}+r}(\partial T)$$

for $0 < r < \frac{1}{2}$.

Proof. Let u_1 be the harmonic lift of u, and let u_2 be the harmonic function such that $\frac{\partial u_2}{\partial n} = \frac{\partial u}{\partial s}$. The first result follows from the fact that u_1 and u_2 are conjugate harmonic functions and, consequently,

$$\|\boldsymbol{\nabla} u_1\| = \|\boldsymbol{\nabla} u_2\| .$$

The second result follows by the standard interpolation argument applied to the first case and an obvious case with integer order spaces,

$$H^1(\partial T)/\mathbb{R} \ni u \to \frac{\partial u}{\partial s} \in L^2_0(T) . \qquad \square$$

3. Discrete Friedrichs inequality. The classical Friedrichs inequalities (see, e.g., [2] and the literature therein) formulated for Dirichlet and Neumann boundary conditions state that there exist positive constants C_1, C_2 such that

(3.1)
$$\|\boldsymbol{E}\| \le C_1 \|\mathrm{curl}\boldsymbol{E}\| \quad \text{for every } \boldsymbol{E} \in \boldsymbol{H}_0(\mathrm{curl}, T) \quad \text{such that } (\boldsymbol{E}, \boldsymbol{\nabla}\phi) = 0\, \forall \phi \in H^1_0(T),$$
$$\|\boldsymbol{E}\| \le C_2 \|\mathrm{curl}\boldsymbol{E}\| \quad \text{for every } \boldsymbol{E} \in \boldsymbol{H}(\mathrm{curl}, T) \quad \text{such that } (\boldsymbol{E}, \boldsymbol{\nabla}\phi) = 0\, \forall \phi \in H^1(T).$$

Here $H^1_0(T)$ stands for the subspace of all functions in $H^1(T)$, vanishing on boundary ∂T, and $\boldsymbol{H}_0(\mathrm{curl}, T)$ is the subspace of all fields in $\boldsymbol{H}(\mathrm{curl}, T)$, with the tangential component vanishing on boundary ∂T.

Both inequalities trivially extend to polynomial spaces,

(3.2)
$$\|\boldsymbol{E}\| \le C_1 \|\mathrm{curl}\boldsymbol{E}\| \quad \text{for every } \boldsymbol{E} \in \boldsymbol{P}^p_{-1} \quad \text{such that } (\boldsymbol{E}, \boldsymbol{\nabla}\phi) = 0\, \forall \phi \in \mathcal{P}^{p+1}_{-1},$$
$$\|\boldsymbol{E}\| \le C_2 \|\mathrm{curl}\boldsymbol{E}\| \quad \text{for every } \boldsymbol{E} \in \boldsymbol{P}^p \quad \text{such that } (\boldsymbol{E}, \boldsymbol{\nabla}\phi) = 0\, \forall \phi \in \mathcal{P}^{p+1}.$$

Indeed, the right-hand sides in (3.2) define equivalent norms on the involved subspace of discrete divergence-free polynomials. The question is, How do the constants C_1, C_2 depend upon order p ?

THEOREM 1 (discrete Friedrichs inequalities). *There exist* C_1, C_2 *in* (3.2) *that are independent of* p.

Proof. The first two steps are identical for both cases. We shall present the Neumann case with an obvious generalization to the Dirichlet case.

Step 1. In order to prove $(3.2)_2$, it is sufficient to show that

$$\min_{\phi \in \mathcal{P}^{p+1}} \|\boldsymbol{E} - \boldsymbol{\nabla}\phi\| \le C \|\mathrm{curl}\boldsymbol{E}\| \quad \forall \boldsymbol{E} \in \boldsymbol{P}^p . \tag{3.3}$$

Indeed, if $(\boldsymbol{E}, \boldsymbol{\nabla}\phi) = 0$, for all $\phi \in \mathcal{P}^{p+1}$, then

$$\min_{\phi \in \mathcal{P}^{p+1}} \|\boldsymbol{E} - \boldsymbol{\nabla}\phi\| = \|\boldsymbol{E}\| .$$

Step 2. In order to prove (3.3), it is sufficient to construct a *continuous* left inverse of the curl operator,

$$A \,:\, \mathcal{P}^{p-1} \ni \psi \to A\psi = \boldsymbol{E} \in \mathcal{P}^p, \quad \mathrm{curl}(A\psi) = \psi \,,$$

with the continuity constant $\|A\|$ *independent* of p. Indeed,

$$\min_{\phi\in\mathcal{P}^{p+1}} \|\boldsymbol{E}-\boldsymbol{\nabla}\phi\| \le \|\boldsymbol{E}-(\boldsymbol{E}-A(\mathrm{curl}\boldsymbol{E})\| = \|A(\mathrm{curl}\boldsymbol{E})\| \le C\|\mathrm{curl}\boldsymbol{E}\|\,.$$

Notice that $\mathrm{curl}(\boldsymbol{E}-A(\mathrm{curl}\boldsymbol{E})) = \mathrm{curl}\boldsymbol{E}-\mathrm{curl}\boldsymbol{E}=0$ and, therefore, $\boldsymbol{E}-A(\mathrm{curl}\boldsymbol{E})$ is the gradient of some polynomial of order $p+1$.

Step 3. The first two steps are identical for both the Dirichlet $(3.2)_1$ and Neumann $(3.2)_2$ versions of the discrete Friedrichs inequality. In the final step, we have to consider the two cases separately.

Case of "Neumann boundary conditions." Use Poincaré's map for operator A,

$$E_1(\boldsymbol{x}) = -\quad x_2\int_0^1 t\psi(t\boldsymbol{x})\,dt,$$

$$E_2(\boldsymbol{x}) = \quad x_1\int_0^1 t\psi(t\boldsymbol{x})\,dt.$$

The map is well defined as both E_1, E_2 are polynomials of order p, provided ψ is a polynomial of order $p-1$. *Right inverse:*

$$\begin{aligned}
\mathrm{curl}\boldsymbol{E} &= \frac{\partial E_2}{\partial x_1}-\frac{\partial E_1}{\partial x_2}\\
&= \int_0^1 t\psi(t\boldsymbol{x})\,dt + x_1\int_0^1 t\frac{\partial\psi}{\partial y_1}t\,dt + \int_0^1 t\psi(t\boldsymbol{x})\,dt + x_2\int_0^1 t\frac{\partial\psi}{\partial y_2}t\,dt\\
&= 2\int_0^1 t\psi(t\boldsymbol{x})\,dt + \int_0^1 t^2\frac{d}{dt}(\psi(t\boldsymbol{x}))\,dt\\
&= 2\int_0^1 t\psi(t\boldsymbol{x})\,dt - \int_0^1 2t\psi(t\boldsymbol{x})\,dt + t^2\psi(t\boldsymbol{x})|_0^1\\
&= \psi(\boldsymbol{x}).
\end{aligned}$$

Continuity of the operator follows from the continuity of the Poincaré map at the continuous level. It is sufficient to demonstrate it, e.g., for the right triangle,

$$T = \{(x_1,x_2)\,:\,0<x_1<1,\ 0<x_2<1-x_1\}\,.$$

We have

$$\begin{aligned}
\int_T (E_1^2+E_2^2)\,dT &= \int_T \underbrace{(x_1^2+x_2^2)}_{\le 1}\left(\int_0^1 t\psi(t\boldsymbol{x})\,dt\right)^2 dT\\
&\le \int_T\left(\int_0^1 t^2\psi^2(t\boldsymbol{x})\,dt\right)\,dT\\
&= \int_0^1 t^2\left(\int_T \psi^2(t\boldsymbol{x})\,dT\right)\,dt \qquad (\text{ use substitution } t\boldsymbol{x}=\boldsymbol{x}')\\
&= \int_0^1 \left(\int_{T'}\psi^2(\boldsymbol{x}')\right)dT'\\
&\le \int_T \psi^2(\boldsymbol{x})\,dT \qquad (\text{ image } T' \text{ is contained in } T\ ).
\end{aligned}$$

Case of "Dirichlet boundary conditions." Assume $p > 2$. Let $\psi \in \mathcal{P}^{p-1}$. We decompose ψ into a constant c and ψ_0 with zero average, $\int_T \psi_0 \, dT = 0$. Let $\boldsymbol{E}_0$ be a unique polynomial $\boldsymbol{E}_0 \in \boldsymbol{P}^2_{-1}$ such that $\operatorname{curl}\boldsymbol{E}_0 = 1$, and $(\boldsymbol{E}_0, \boldsymbol{\nabla}\phi) = 0$ for all $\phi \in \mathcal{P}^3_{-1}$. We define the map A as follows:

$$A\psi = A(c + \psi_0) = c\boldsymbol{E}_0 + A\psi_0 \, .$$

In order to define $A\psi_0$, we first evaluate the Poincaré map at ψ_0 to obtain a field $\boldsymbol{E}$ and learn that tangential component $\boldsymbol{n} \times \boldsymbol{E}$ vanishes along the horizontal and vertical edges and has a zero average along the inclined edge e_2. Consequently, there exists a polynomial ϕ of order p in space $\mathcal{P}^p_{-1}(e_2)$ such that $\frac{\partial \phi}{\partial s} = \boldsymbol{n} \times \boldsymbol{E}$. By the polynomial extension theorem of Babuška and Suri [3] and Babuška et al. [4], ψ admits a polynomial extension $\tilde{\phi}$, defined on T such that

$$\begin{aligned}(3.4)\quad \|\boldsymbol{\nabla}\tilde{\phi}\| \le C\|\phi\|_{H^{\frac{1}{2}}_{00}(e_2)} = C\left\|\frac{\partial \phi}{\partial s}\right\|_{H^{-\frac{1}{2}}(\partial T)} = C\|\boldsymbol{n} \times \boldsymbol{E}\|_{H^{-\frac{1}{2}}(\partial T)} &\le C\|\boldsymbol{E}\|_{H(\mathrm{curl},T)} \\ &\le C\|\psi_0\|.\end{aligned}$$

In the estimate above we have used Lemma 2 and the continuity of the Poincaré map. Finally, we define

$$A\psi_0 = \boldsymbol{E} - \boldsymbol{\nabla}\tilde{\phi} \, .$$

Adding the gradient does not change the curl of $A\psi_0$, and the L^2 boundedness follows from (3.4). □

Remark 1. The relevance of the Poincaré map in the construction of Nédélec's edge elements of the first type was first noticed by Hiptmair [11].

4. $\boldsymbol{H^1}$-conforming interpolation. Given a function $u \in H^{1+\epsilon}(T)$, we define the corresponding interpolant $\Pi u := u^p \in \mathcal{P}^p_{p_e}(T)$ as the sum of three components,

$$(4.1)\qquad u^p = u_1 + \underbrace{\sum_{e=1}^{3} u^p_{2,e}}_{u^p_2} + u^p_3 \, .$$

Step 1: *Linear interpolant.* We construct $u_1 \in \mathcal{P}^1(T)$ by the standard, linear interpolation at the vertices,

$$u_1 \in \mathcal{P}^1(T), \quad u_1(v) = u(v) \quad \text{for every vertex } v \, .$$

Step 2: *Edge interpolants.* For each edge e, we project trace of difference $u - u_1$ onto space $\mathcal{P}^{p_e}_{-1}(e)$ of polynomials of order p_e, vanishing at the edge endpoints, using the $H^{\frac{1}{2}}_{00}(e)$-norm:

$$\left\{\begin{array}{l} u_{2,e} \in \mathcal{P}^{p_e}_{-1}(e), \\ \|u_{2,e} - (u - u_1)|_e\|_{H^{\frac{1}{2}}_{00}(e)} \to \min \, . \end{array}\right.$$

Next, we extend $u_{2,e}$ to a polynomial $u^p_{2,e}$ from $\mathcal{P}^p_{p_e}(T)$, vanishing along the two remaining edges. The sum of edge interpolants $u^p_{2,e}$ will be denoted u^p_2.

Step 3: *Interior interpolant.* We project difference $u - u_1 - u_2^p$ onto space $\mathcal{P}^p_{-1}(T)$ of polynomials of order p, vanishing on ∂T, in the H^1-seminorm:

$$\begin{cases} u_3^p \in \mathcal{P}^p_{-1}(T), \\ |u_3^p - (u - u_1 - u_2^p)|_{H^1(T)} \to \min . \end{cases}$$

Remark 2. Notice that even though extensions $u^p_{2,e}$ are not uniquely defined, the final interpolant is unique. To ensure the uniqueness of the extensions, we could use, e.g., discrete harmonic extensions, i.e., request for the orthogonality

$$(\boldsymbol{\nabla} u^p_{2,e}, \boldsymbol{\nabla} v) = 0 \quad \forall v \in \mathcal{P}^p_{-1}(T) .$$

PROPOSITION 1. *Operator* $\Pi : H^{1+\epsilon}(T) \to H^1(T)$ *is well defined and bounded, with the norm independent of orders* p, p_e.

Proof. Step 1. It follows from the continuous embedding of $H^{1+\epsilon}(T)$ into $C(\bar{T})$ and equivalence of norms on a finite dimensional space that

$$\|u_1\|_{H^1(T)} \leq \|u_1\|_{H^{1+\epsilon}(T)} \leq C \left(\sum_{\boldsymbol{a}} |u(\boldsymbol{a})|^2 \right)^{\frac{1}{2}} \leq C \|u\|_{H^{1+\epsilon}(T)} ,$$

where $\boldsymbol{a}$ denote vertices of the triangle.

Step 2. By Lemma 1, restriction $(u - u_1)|_e$ to edge e is in $H^{\frac{1}{2}}_{00}(e)$, so the edge minimization problem is well defined and

$$\begin{aligned} \|u_{2,e}\|_{H^{\frac{1}{2}}_{00}(e)} \leq \|(u-u_1)|_e\|_{H^{\frac{1}{2}}_{00}(e)} \leq C \|(u-u_1)|_e\|_{H^{\frac{1}{2}+\epsilon}(e)} &\leq C \|u - u_1\|_{H^{1+\epsilon}(T)} \\ &\leq C \|u\|_{H^{1+\epsilon}(T)} . \end{aligned}$$

By the polynomial extension theorem of Babuška and Suri [3] and Babuška et al. [4], there exists an extension $u^{p_e}_{2,e} \in \mathcal{P}^{p_e}(T)$, vanishing along the two remaining edges, such that

$$\|u^{p_e}_{2,e}\|_{H^1(T)} \leq C \|u^p_{2,e}|_e\|_{H^{\frac{1}{2}}_{00}(e)} ,$$

with constant C *independent* of p_e.

Step 3. By Poincaré's inequality and the results of the first two steps,

$$\begin{aligned} \|u_3^p\|_{H^1(T)} &\leq C |u_3^p|_{H^1(T)} \leq C |u - (u_1 + u_2^p)|_{H^1(T)} \\ &\leq C (\|u\|_{H^1(T)} + \|u_1\|_{H^1(T)} + \|u_2^p\|_{H^1(T)}) \leq C \|u\|_{H^1(T)} . \end{aligned}$$

Applying the triangle inequality to the definition of the interpolant finishes the proof. □

THEOREM 2 (H^1-conforming interpolation error estimate). *There exists a constant* C, *dependent upon* ϵ *but independent of* p, p_e, *such that*

$$\|u - \Pi u\|_{H^1(T)} \leq C \inf_{v \in \mathcal{P}^p_{p_e}} \|u - v\|_{H^{1+\epsilon}(T)} \leq C p_{min}^{-(r-\epsilon)} \|u\|_{H^{1+r}(T)}$$

for every $r > 1$ *and* $0 < \epsilon < r$. *Here* $p_{min} = \min_e p_e$.

Proof. It is sufficient to consider "small" $\epsilon, 0 < \epsilon < \min\{r, \frac{1}{2}\}$. As the interpolation preserves polynomials ψ from $\mathcal{P}^p_{p_e}(T)$, we have

$$\|u - \Pi u\|_{H^1(T)} = \|u - \psi - \Pi(u - \psi)\|_{H^1(T)} \leq (1 + \|\Pi\|) \|u - \psi\|_{H^{1+\epsilon}(T)} ,$$

where $\|\Pi\|$ is the norm of the interpolation operator in space $\mathcal{L}(H^{1+\epsilon}(T), H^1(T))$ and ψ is an arbitrary polynomial from $\mathcal{P}^p_{p_e}(T)$. Consequently, it follows from the best approximation results for polynomial spaces (see, e.g., [4]) that

$$\|u - \Pi u\|_{H^1(T)} \leq C \inf_{\psi \in \mathcal{P}^{p_{min}}(T)} \|u - \psi\|_{H^{1+\epsilon}(T)} \leq C p_{min}^{-(r-\epsilon)} \|u\|_{H^r(T)} \,. \qquad \square$$

Remark 3.

1. The described interpolation procedure is a generalization of the *hp*-interpolation proposed in [16] and used in [9]. The original *hp*-interpolation uses stronger $H^1_0(e)$-norms along the edges and requires more regularity ($u \in H^{3/2+\epsilon}(T)$). Consequently, it does not yield optimal (up to ϵ) convergence rates.
2. According to Lemma 2, projection in the $H^{\frac{1}{2}}_{00}(e)$-norm over the edges can be reinterpreted as the projection in the $H^{-\frac{1}{2}}(\partial T)$-norm of the (tangential) derivatives,

$$\|u_{2,e} - w\|_{H^{\frac{1}{2}}_{00}(e)} = \|\tilde{u}_{2,e} - \tilde{w}\|_{H^{\frac{1}{2}}(\partial T)} = \left\| \frac{\partial}{\partial s}(\tilde{u}_{2,e} - \tilde{w}) \right\|_{H^{-\frac{1}{2}}(\partial T)} \,.$$

   Here $w = (u - u_1)|_e$, and $\tilde{u}_{2,e}, \tilde{w}$ denote zero extensions of $u_{2,e}, w$ to the whole boundary ∂T.

5. $\boldsymbol{H}$(curl)-conforming interpolation.

Given a function $\boldsymbol{E} \in \boldsymbol{H}^\epsilon \cap \boldsymbol{H}(\text{curl}, T)$, we construct interpolant $\Pi^{\text{curl}}\boldsymbol{E} := \boldsymbol{E}^p \in \boldsymbol{P}^p_{p_e}(T)$ again in three steps,

$$\boldsymbol{E}^p = \boldsymbol{E}_1 + \underbrace{\sum_{e=1}^{3} \boldsymbol{E}^p_{2,e}}_{\boldsymbol{E}^p_2} + \boldsymbol{E}^p_3 \,. \tag{5.1}$$

Step 1: *Whitney's (lowest order) interpolant.* For each edge e, let $\boldsymbol{\phi}^e \in \boldsymbol{P}^1(T)$ denote the vector-valued, linear polynomial such that

$$\phi^e_t = \boldsymbol{n} \times \boldsymbol{\phi}^e = \begin{cases} 1 \text{ along edge } e, \\ 0 \text{ along the remaining edges.} \end{cases}$$

Here $\boldsymbol{n}$ is the outward normal unit vector to ∂T, and $\phi_t = \boldsymbol{n} \times \boldsymbol{\phi} = (-n_2)\phi_1 + n_1\phi_2$ denotes the trace of the tangential component of vector-valued function $\boldsymbol{\phi}$ to boundary ∂T. The Whitney interpolant is then defined as

$$\boldsymbol{E}_1 = \sum_e \left(\int_e E_t \right) \boldsymbol{\phi}^e \,.$$

Step 2: *Edge interpolants.* It follows from the construction of the Whitney interpolant that the trace of tangential component $\boldsymbol{n} \times (\boldsymbol{E} - \boldsymbol{E}_1)$ has zero average over each edge e. Thus, we can introduce a scalar-valued function ψ, defined on boundary ∂T, such that

$$\frac{\partial \psi}{\partial s} = \boldsymbol{n} \times (\boldsymbol{E} - \boldsymbol{E}_1), \quad \psi = 0 \text{ at vertices.}$$

For each edge e then, we project restriction $\psi|_e$ in the $H^{\frac{1}{2}}_{00}$-norm onto polynomials $\mathcal{P}^{p_e+1}_{-1}(e)$,

$$\begin{cases} \psi_{2,e} \in \mathcal{P}^{p_e+1}_{-1}(e), \\ \|\psi_{2,e} - \psi|_e\|_{H^{\frac{1}{2}}_{00}(e)} \to \min \, . \end{cases}$$

We take then any polynomial extension $\psi^{p+1}_{2,e} \in \mathcal{P}^{p+1}_{p_e+1}(T)$ that vanishes along the two remaining edges and define the edge interpolant by the gradient of the extension,

$$\boldsymbol{E}^p_{2,e} = \boldsymbol{\nabla}\psi^{p+1}_{2,e} \in \boldsymbol{P}^p_{p_e}(T) \, .$$

Step 3: *Interior interpolant.* We solve the constrained minimization problem,

$$\begin{cases} \boldsymbol{E}^p_3 \in \boldsymbol{P}^p_{-1}(T), \\ \|\mathrm{curl}(\boldsymbol{E}^p_3 - (\boldsymbol{E} - \boldsymbol{E}_1 - \boldsymbol{E}^p_2))\| = \|\mathrm{curl}(\boldsymbol{E}^p_3 - (\boldsymbol{E} - \boldsymbol{E}_1))\| \to \min, \\ (\boldsymbol{E}^p_3 - (\boldsymbol{E} - \boldsymbol{E}_1 - \boldsymbol{E}^p_2), \boldsymbol{\nabla}\phi) = 0 \quad \forall\phi \in \mathcal{P}^{p+1}_{-1}(T) \, . \end{cases}$$

Remark 4.

1. Notice again that the final interpolant is uniquely defined despite the possibility of many extensions $\psi^{p+1}_{2,e}$. In fact, we can even use extensions $\boldsymbol{E}^p_{2,e}$ of tangential trace $\frac{\partial\psi 2,e}{\partial s}$ with nonzero curl.
2. The edge interpolants can again be defined directly using the projection in $H^{-\frac{1}{2}}(\partial T)$-norm; compare Remark 3.

Proposition 2. *Operator* $\Pi^{\mathrm{curl}} : \boldsymbol{H}^{\epsilon}(T) \cap \boldsymbol{H}(\mathrm{curl}, T) \to \boldsymbol{H}(\mathrm{curl}, T)$ *is well defined and bounded, with a norm independent of orders* p, p_e*.*

Proof. Step 1. Consider a test function $\phi \in H^{1-\epsilon}(T)$, $\phi = 1$ on edge e, $\phi = 0$ on the two remaining edges. It follows from the integration by parts formula

$$\int_T \mathrm{curl}\boldsymbol{E}\,\phi = \int_T \boldsymbol{E}(\boldsymbol{\nabla}\times\phi) \;+ \int_{\partial T} (\boldsymbol{n}\times\boldsymbol{E})\phi$$

$(\mathrm{curl}\boldsymbol{E} = \frac{\partial E_2}{\partial x_1} - \frac{\partial E_1}{\partial x_2},\ \boldsymbol{\nabla}\times\phi = (\frac{\partial\phi}{\partial x_2}, -\frac{\partial\phi}{\partial x_1})\ )$ that functional

$$\boldsymbol{H}^{\epsilon}(T) \cap \boldsymbol{H}(\mathrm{curl}, T) \ni \boldsymbol{E} \to \int_e E_t = \int_e \boldsymbol{n}\times\boldsymbol{E}$$

is well defined and continuous. By the finite dimensionality argument, we get

$$\|\boldsymbol{E}_1\|_{H(\mathrm{curl})} \le (\|\boldsymbol{E}_1\|^2_{H^\epsilon} + \|\mathrm{curl}\boldsymbol{E}_1\|^2)^{\frac{1}{2}} \le C(\|\boldsymbol{E}\|^2_{H^\epsilon} + \|\mathrm{curl}\boldsymbol{E}\|^2)^{\frac{1}{2}} \, .$$

In fact, one can show directly [8] that $\|\mathrm{curl}\boldsymbol{E}_1\| \le \|\mathrm{curl}\boldsymbol{E}\|$.

Step 2. From the result of Step 1 and the integration by parts,

$$\int_T \mathrm{curl}(\boldsymbol{E} - \boldsymbol{E}_1)\phi = \int_T (\boldsymbol{E} - \boldsymbol{E}_1)(\boldsymbol{\nabla}\times\phi) + \int_{\partial T} \boldsymbol{n}\times(\boldsymbol{E} - \boldsymbol{E}_1)\phi \, ,$$

it follows that $\boldsymbol{n}\times(\boldsymbol{E} - \boldsymbol{E}_1) \in H^{-\frac{1}{2}+\epsilon}(\partial T)$. From the construction of $\boldsymbol{E}_1$ it follows that $\boldsymbol{n}\times(\boldsymbol{E} - \boldsymbol{E}_1)$ has zero average,

$$\int_{\partial T} \boldsymbol{n}\times(\boldsymbol{E} - \boldsymbol{E}_1) = 0 \, .$$

Consequently, by Lemma 2, potential ψ is well defined and it lives in $H^{\frac{1}{2}+\epsilon}(\partial K)$. Repeating arguments from the proof of Proposition 1, we show that

$$\|\psi^p_{2,e}\|_{H^1(T)} \leq C\|\boldsymbol{n} \times (\boldsymbol{E} - \boldsymbol{E}_1)\|_{H^{-\frac{1}{2}+\epsilon}(\partial T)} \leq C(\|\boldsymbol{E}\|^2_{H^\epsilon(T)} + \|\mathrm{curl}\boldsymbol{E}\|^2)^{\frac{1}{2}} \ .$$

Consequently,

$$\|\boldsymbol{E}^p_2\| = \|\boldsymbol{E}^p_2\|_{H(\mathrm{curl})} \leq C(\|\boldsymbol{E}\|^2_{H^\epsilon(T)} + \|\mathrm{curl}\boldsymbol{E}\|^2)^{\frac{1}{2}} \ .$$

Step 3. We use the discrete Helmholtz decomposition,

$$\boldsymbol{E}^p_3 = \boldsymbol{E}^p_{3,0} + \boldsymbol{\nabla}\psi^{p+1} \ , \tag{5.2}$$

where $\psi \in \mathcal{P}^{p+1}_{-1}(T)$, $\boldsymbol{E}^p_{3,0} \in \boldsymbol{P}^p_{-1}$, $(\boldsymbol{E}^p_{3,0}, \boldsymbol{\nabla}\phi) = 0$ for all $\phi \in \mathcal{P}^{p+1}_{-1}(T)$.

We have

$$\|\mathrm{curl}\boldsymbol{E}^p_{3,0}\| = \|\mathrm{curl}\boldsymbol{E}^p_3\| \leq \|\mathrm{curl}(\boldsymbol{E} - \boldsymbol{E}_1)\| \leq 2\|\mathrm{curl}\boldsymbol{E}\| \ ,$$

and by the discrete Friedrichs inequality (3.2),

$$\|\boldsymbol{E}^p_{3,0}\| \leq C\|\mathrm{curl}\boldsymbol{E}^p_{3,0}\| \leq 2C\|\mathrm{curl}\boldsymbol{E}\| \ .$$

Finally, by the results of the first two steps,

$$\|\boldsymbol{\nabla}\psi^{p+1}\| \leq \|\boldsymbol{E} - \boldsymbol{E}_1 - \boldsymbol{E}^p_2\| \leq C(\|\boldsymbol{E}\|^2_{H^\epsilon} + \|\mathrm{curl}\boldsymbol{E}\|^2)^{\frac{1}{2}} \ .$$

Applying the triangle inequality to the definition of the interpolant finishes the proof. □

PROPOSITION 3. *de Rham diagram* (1.1) *commutes.*

Proof. Both horizontal sequences in the diagram are exactl; compare [9, 10].

Commutativity of the first part of the diagram is obvious; operator Π preserves constants.

Let now $\boldsymbol{E} = \boldsymbol{\nabla}\phi, \phi \in H^{1+\epsilon}(T)$. It follows from the definitions of the interpolation operators that the Whitney interpolant of $\boldsymbol{\nabla}\phi$ coincides with the gradient of linear interpolant ϕ_1 of ϕ, $\boldsymbol{E}_1 = \boldsymbol{\nabla}\phi_1$. Consequently, $\phi - \phi_1$ coincides with function ψ used to define $\boldsymbol{E}^p_2$, and extensions $\psi^{p+1}_{2,e}$ and $\phi^{p+1}_{2,e}$ may be taken to be the same. Finally, $\boldsymbol{E}^p_{3,0}$ in the Helmholtz decomposition of $\boldsymbol{E}^p_3$ is zero, and ψ^{p+1} in (5.2) coincides with ϕ^{p+1}_3.

Finally, we need to show that

$$(\mathrm{curl}(\boldsymbol{E}^p - \boldsymbol{E}), \mathrm{curl}\boldsymbol{F}) = (\mathrm{curl}(\boldsymbol{E}^p_1 + \boldsymbol{E}^p_3 - \boldsymbol{E}), \mathrm{curl}\boldsymbol{F}) = 0 \quad \forall \boldsymbol{F} \in \boldsymbol{P}^p_{p_e} \ .$$

It follows from our discussion (see also [8]) that any $\boldsymbol{F} \in \boldsymbol{P}^p_{p_e}$ can be decomposed as

$$\boldsymbol{F} = \boldsymbol{F}_1 + \boldsymbol{F}^p_2 + \boldsymbol{F}^p_3,$$

where $\boldsymbol{F}^p_2$ is a gradient. Orthogonality with $\boldsymbol{F}_1$ follows from the integration by parts and the definition of the Whitney interpolant,

$$(\mathrm{curl}(\boldsymbol{E}^p_1+\boldsymbol{E}^p_3-\boldsymbol{E}), \mathrm{curl}\boldsymbol{F}_1) = \int_{\partial T}\boldsymbol{n}\times(\boldsymbol{E}_1+\boldsymbol{E}^p_3-\boldsymbol{E})\mathrm{curl}\boldsymbol{F}_1 = \int_{\partial T}\boldsymbol{n}\times(\boldsymbol{E}_1-\boldsymbol{E})\mathrm{curl}\boldsymbol{F}_1 = 0.$$

Orthogonality with $\boldsymbol{F}^p_3$ is a consequence of the definition of $\boldsymbol{E}^p_3$. □

Best approximation result. Let $\boldsymbol{E} \in \boldsymbol{H}^r(T)$ and curl$\boldsymbol{E} \in H^r(T), 0 < r \leq 1$. Consider the Helmholtz decomposition,

$$\boldsymbol{E} = \boldsymbol{E}_0 + \boldsymbol{\nabla}\psi \quad (\boldsymbol{E}_0, \boldsymbol{\nabla}\phi) = 0 \quad \forall\phi \in H^1(T) .$$

Potential ψ is the solution of the Poisson equation,

$$\begin{cases} \psi \in H^1(T)/\mathbb{R}, \\ (\boldsymbol{\nabla}\psi, \boldsymbol{\nabla}\phi) = (\boldsymbol{E}, \boldsymbol{\nabla}\phi) \quad \forall\phi \in H^1(T) . \end{cases}$$

It follows from the regularity results of Costabel and Dauge [7] that

- $\boldsymbol{E}_0 \in \boldsymbol{H}^{1+r}(T)$ and

$$\|\boldsymbol{E}_0\|_{H^{1+r}} \leq C\|\text{curl}\boldsymbol{E}_0\|_{H^r} = \|\text{curl}\boldsymbol{E}\|_{H^r};$$

- $\psi \in H^{1+r}(T)$ and

$$\|\psi\|_{H^{1+r}} \leq C\|\boldsymbol{E}\|_{H^r} .$$

Consequently, there exists a vector-valued polynomial $\boldsymbol{E}_0^p \in \boldsymbol{P}^p(T)$ such that

$$\|\boldsymbol{E}_0 - \boldsymbol{E}_0^p\|_{H^1} \leq Cp^{-r}\|\text{curl}\boldsymbol{E}\|_{H^r}$$

and, consequently,

$$(\|\boldsymbol{E}_0 - \boldsymbol{E}_0^p\|_{H^\epsilon}^2 + \|\text{curl}(\boldsymbol{E}_0 - \boldsymbol{E}_0^p)\|^2)^{\frac{1}{2}} \leq Cp^{-r}\|\text{curl}\boldsymbol{E}\|_{H^r} .$$

Also, there exists a polynomial $\psi^{p+1} \in \mathcal{P}^{p+1}$ such that

$$\|\boldsymbol{\nabla}\psi^{p+1} - \boldsymbol{\nabla}\psi\|_{H^\epsilon} \leq Cp^{-(r-\epsilon)}\|\psi\|_{H^{1+r}(T)} .$$

Summing up $\boldsymbol{E}_0^p$ and $\boldsymbol{\nabla}\psi^{p+1}$,

$$\boldsymbol{E}^p = \boldsymbol{E}_0^p + \boldsymbol{\nabla}\psi^{p+1} ,$$

and using the triangle inequality we get

$$(\|\boldsymbol{E} - \boldsymbol{E}^p\|_{H^\epsilon}^2 + \|\text{curl}(\boldsymbol{E} - \boldsymbol{E}^p)\|^2)^{\frac{1}{2}} \leq Cp^{-(r-\epsilon)}(\|\boldsymbol{E}\|_{H^r}^2 + \|\text{curl}\boldsymbol{E}\|_{H^r}^2)^{\frac{1}{2}} .$$

Theorem 3 ($\boldsymbol{H}$(curl)-conforming interpolation error estimate). *There exists $C > 0$, dependent upon ϵ but independent of p, p_e, such that*

$$\begin{aligned} \|\boldsymbol{E} - \Pi^{\text{curl}}\boldsymbol{E}\|_{H(\text{curl},T)} &\leq C \inf_{\boldsymbol{F}\in\boldsymbol{P}_{p_e}^p} (\|\boldsymbol{E} - \boldsymbol{F}\|_{H^\epsilon}^2 + \|\text{curl}(\boldsymbol{E} - \boldsymbol{F})\|^2)^{\frac{1}{2}} \\ &\leq Cp_{min}^{-(r-\epsilon)}(\|\boldsymbol{E}\|_{H^r}^2 + \|\text{curl}\boldsymbol{E}\|_{H^r}^2)^{\frac{1}{2}} \end{aligned} \tag{5.3}$$

for every $0 < r < 1$ and $0 < \epsilon < r$. Here $p_{min} = \min_e p_e$.

Proof. Combining Proposition 2 with the best approximation error estimate, we have

$$\begin{aligned} \|\boldsymbol{E} - \Pi^{\text{curl}}\boldsymbol{E}\|_{H(\text{curl},T)} &= \|\boldsymbol{E} - \boldsymbol{F} - \Pi^{\text{curl}}(\boldsymbol{E} - \boldsymbol{F})\|_{H(\text{curl},T)} \qquad (\forall\boldsymbol{F} \in \boldsymbol{P}_{p_e}^p) \\ &\leq (1 + \|\Pi^{\text{curl}}\|) \inf_{\boldsymbol{F}\in\boldsymbol{P}_{p_e}^p} (\|\boldsymbol{E} - \boldsymbol{F}\|_{H^\epsilon}^2 + \|\text{curl}(\boldsymbol{E} - \boldsymbol{F})\|^2)^{\frac{1}{2}} \\ &C \leq p^{-(r-\epsilon)}(\|\boldsymbol{E}\|_{H^r}^2 + \|\text{curl}\boldsymbol{E}\|_{H^r}^2)^{\frac{1}{2}} . \qquad \square \end{aligned}$$

6. Final remarks.

First family of Nédélec's elements. Results concerning the $H(\text{curl})$-conforming interpolation extend automatically to the diagram corresponding to the first family of Nédélec's family of triangular elements [14]:

$$\begin{tikzcd}
H^{1+\epsilon} \arrow[r, "\boldsymbol{\nabla}"] \arrow[d, "\Pi"] & \boldsymbol{H}^{\epsilon} \cap \boldsymbol{H}(\text{curl}) \arrow[r, "\boldsymbol{\nabla}\times"] \arrow[d, "\Pi^{\text{curl}}"] & L^2, \arrow[d, "P,"] \\
\mathcal{P}^{p+1}_{p_e+1} \arrow[r, "\boldsymbol{\nabla}"] & \mathbf{P}^{p}_{p_e} \oplus \tilde{\mathbf{P}}^{p+1}_{p_e} \arrow[r, "\boldsymbol{\nabla}\times"] & \mathcal{P}^{p}\,.
\end{tikzcd} \tag{6.1}$$

Here $\tilde{\boldsymbol{P}}^{p+1}_{p_e+1}$ corresponds to the direct sum decompositions,

$$\begin{aligned}
\mathcal{P}^{p+2}_{p_e+1} &= \mathcal{P}^{p+1}_{p_e+1} \oplus \tilde{\mathcal{P}}^{p+1}_{p_e}, \\
\boldsymbol{P}^{p+1}_{p_e} &= \boldsymbol{P}^{p}_{p_e} \oplus \boldsymbol{\nabla}\tilde{\mathcal{P}}^{p+2}_{p_e+1} \oplus \tilde{\boldsymbol{P}}^{p+1}_{p_e}\,;
\end{aligned}$$

see [10] for a more detailed discussion. Contrary to the original diagram, order p may now be equal to zero, except for $p = 0$ (when $\tilde{\mathcal{P}}^2_1$ is trivial, space $\boldsymbol{P}^{p}_{p_e} \oplus \tilde{\boldsymbol{P}}^{p+1}_{p_e}$ is not uniquely defined and depends upon the choice of algebraic component $\tilde{\boldsymbol{P}}^{p+1}_{p_e}$, unless one requests additionally for orthogonality of the components [10]).

The advantage of using the first Nédélec family is that both $\boldsymbol{E}$ and curl $\boldsymbol{E}$ are now interpolated with polynomials of the same order.

Extensions. An extension to the case of square elements in two dimensions seems to be straightforward. As the interpolation takes place on the master element, the results extend automatically to the case of curvilinear, parametric elements [9]. The results extend also to three-dimensional tetrahedral elements with a minimum regularity of $H^{\frac{3}{2}+\epsilon}(T)$ for the H^1-conforming interpolation. The limitation comes from the definition of the linear, vertex interpolant. It looks like the analysis for three-dimensional elements (nD differential forms in general [11]) will require nonlocal interpolation operators. The question of how to define them so that the de Rham diagram will commute is open.

RESTRICTED ADDITIVE SCHWARZ PRECONDITIONERS WITH HARMONIC OVERLAP FOR SYMMETRIC POSITIVE DEFINITE LINEAR SYSTEMS*

XIAO-CHUAN CAI[†], MAKSYMILIAN DRYJA[‡], AND MARCUS SARKIS[§]

Abstract. A restricted additive Schwarz (RAS) preconditioning technique was introduced recently for solving general nonsymmetric sparse linear systems. In this paper, we provide one-level and two-level extensions of RAS for symmetric positive definite problems using the so-called harmonic overlaps (RASHO). Both RAS and RASHO outperform their counterparts of the classical additive Schwarz variants (AS). The design of RASHO is based on a much deeper understanding of the behavior of Schwarz-type methods in overlapping subregions and in the construction of the overlap. In RASHO, the overlap is obtained by extending the nonoverlapping subdomains only in the directions that do not cut the boundaries of other subdomains, and all functions are made harmonic in the overlapping regions. As a result, the subdomain problems in RASHO are smaller than those of AS, and the communication cost is also smaller when implemented on distributed memory computers, since the right-hand sides of discrete harmonic systems are always zero and therefore do not need to be communicated. We also show numerically that RASHO-preconditioned CG takes fewer iterations than the corresponding AS-preconditioned CG. A nearly optimal theory is included for the convergence of RASHO-preconditioned CG for solving elliptic problems discretized with a finite element method.

Key words. restricted additive Schwarz preconditioner, two-level domain decomposition, harmonic overlap, elliptic equations, finite elements

1. Introduction.

A restricted additive Schwarz (RAS) preconditioning technique was introduced recently for solving general nonsymmetric sparse linear systems [1, 5, 7, 14, 16, 17, 20]. RAS outperforms the classical additive Schwarz (AS) preconditioner [8, 24] in the sense that it requires fewer iterations, as well as lower communication and CPU time costs when implemented on distributed memory computers [1]. Unfortunately, RAS in its original form is nonsymmetric, and therefore the CG method cannot be used [15]. Although a symmetrized version was constructed in [7], our numerical experiments show that it often takes more iterations than the corresponding AS/CG. In this paper we propose another modification of RAS and show in both theory and numerical experiments that this new variant works well for symmetric positive definite sparse linear systems and is superior to AS. Recall that the basic building blocks of classical Schwarz-type algorithms are realized by solving

the linear systems of the form

$$A_i^\delta w = R_i^\delta v \tag{1.1}$$

on each extended subdomain, where A_i^δ is the extended subdomain stiffness matrix and R_i^δ is the restriction operator for the extended subdomain. (Formal definitions will be given later in the paper.) The key idea of RAS is that (1.1) is replaced by

$$A_i^\delta w = \begin{cases} v & \text{inside the unextended subdomain,} \\ 0 & \text{in the overlapping part of the subdomain.} \end{cases} \tag{1.2}$$

Note that the solution of (1.2) is discrete harmonic in the overlapping part of the subdomain and therefore carries minimum energy in some sense. Setting part of the right-hand-side vector to zero reduces the energy of the solution and also destroys the symmetry of the additive Schwarz operator. In this paper, we further explore the idea of "harmonic overlap" and at the same time keep the symmetry of the Schwarz preconditioner. We mention that other approaches can also be taken to modifying the Schwarz algorithm in the overlapping regions, such as allowing the functions to be discontinuous [4].

The algorithm to be discussed below is applicable for general symmetric positive definite problems. However, in order to provide a complete mathematical analysis, we restrict our discussion to a finite element problem [3]. We consider a simple variational problem: Find $u \in H_0^1(\Omega)$ such that

$$a(u, v) = f(v) \qquad \forall\ v \in H_0^1(\Omega), \tag{1.3}$$

where

$$a(u, v) = \int_\Omega \nabla u \cdot \nabla v \, dx \quad \text{and} \quad f(v) = \int_\Omega f v \, dx \qquad \text{for } f \in L^2(\Omega).$$

For simplicity, let Ω be a bounded polygonal region in $\Re^2$ with a diameter of size $O(1)$. The extension of the results to $\Re^3$ can be carried out easily by using the theory developed here in this paper and the well-known three-dimensional AS techniques; see [9, 10, 12]. Let $\mathcal{T}^h(\Omega)$ be a shape-regular quasi-uniform triangulation of size $O(h)$ of Ω, and $\mathcal{V} \subset H_0^1(\Omega)$ the finite element space consisting of continuous piecewise linear functions associated with the triangulation. We are interested in solving the following discrete problem associated with (1.3): Find $u^* \in \mathcal{V}$ such that

$$a(u^*, v) = f(v) \qquad \forall\ v \in \mathcal{V}. \tag{1.4}$$

Using the standard basis functions, (1.4) can be rewritten as a linear system of equations

$$Au^* = f. \tag{1.5}$$

For simplicity, we understand u^* and f both as functions and vectors, depending on the situation.

The paper is organized as follows. In section 2, we introduce notation. The new algorithm is described in section 3. Section 4 is devoted to the mathematical analysis of the new algorithm. We conclude the paper in section 5 by providing some numerical results and final remarks. Throughout this paper, C is a positive generic constant that is independent of any of the mesh parameters and the number of subdomains. All the domains and subdomains are assumed to be open; i.e., boundaries are not included in their definitions.

2. Notation. Let n be the total number of interior nodes of $\mathcal{T}^h(\Omega)$, and W the set containing all the interior nodes. We assume that a node-based partitioning has been applied and has resulted in N nonoverlapping subsets $W_i^0, i = 1, \ldots, N$, whose union is W. For each W_i^0, we define a subregion Ω_i^R to be the union of all elements of $\mathcal{T}^h(\Omega)$ that have all three vertices in $W_i^0 \cup \partial\Omega$. Note that $\cup\bar{\Omega}_i^R$ is not equal to $\bar{\Omega}$; see Figure 2.1(b). We denote by H the representative size (diameter) of the subregion Ω_i^R.

We define the overlapping partition of W as follows. Let $\{W_i^1\}$ be the one-overlap partition of W, where $W_i^1 \supset W_i^0$ is obtained by including all the immediate neighboring vertices of all vertices in W_i^0; see Figure 2.1(c). Using the idea recursively, we can define a δ-overlap partition of W,

$$W = \bigcup_{i=1}^{N} W_i^\delta.$$

Here the integer δ indicates the level of overlap with its neighboring subdomains, and δh is approximately the length of the extension. The definition of W_i^δ, as well as many other subsets, can be found in an illustrative picture, Figure 2.1.

We next define a subregion of Ω induced by a subset of nodes of $\mathcal{T}^h(\Omega)$ as follows. Let Z be a subset of W. The induced subregion, denoted by $\Omega(Z)$, is defined as the union of (1) the set Z itself, (2) the union of all the open elements (triangles) of $\mathcal{T}^h(\Omega)$ that have at least one vertex in Z, and (3) the union of the open edges of these triangles that have at least one endpoint as a vertex of Z. Note that $\Omega(Z)$ is always an open region. The extended subregion Ω_i^δ is defined as $\Omega(W_i^\delta)$, and the corresponding subspace as

$$\mathcal{V}_i^\delta \equiv \mathcal{V} \cap H_0^1(\Omega_i^\delta) \quad \text{extended by zero to } \Omega\backslash\Omega_i^\delta.$$

It is easy to verify that

$$\mathcal{V} = \mathcal{V}_1^\delta + \mathcal{V}_2^\delta + \cdots + \mathcal{V}_N^\delta.$$

This decomposition is used in defining the classical one-level AS algorithm [8]. Note that for $\delta = 0$ this decomposition is a direct sum. Let us define $P_i^\delta : \mathcal{V} \to \mathcal{V}_i^\delta$ by the following: For any $u \in \mathcal{V}$,

$$a(P_i^\delta u, v) = a(u, v) \qquad \forall v \in \mathcal{V}_i^\delta. \tag{2.1}$$

Then, the classical one-level AS operator has the form

$$P^\delta = P_1^\delta + \cdots + P_N^\delta.$$

In the classical AS as defined above, all the nodes of W_i^δ are treated equally even through some subsets of the nodes play different roles in determining the convergence rate of the AS-preconditioned CG. To further understand the issue, we classify the nodes as follows. Let $\Gamma_i^\delta = \partial\Omega_i^\delta \backslash \partial\Omega$, i.e., the part of the boundary of Ω_i^δ that does not belong to the Dirichlet part of the physical boundary $\partial\Omega$. We define the interface-overlapping boundary Γ^δ as the union of all Γ_i^δ; i.e., $\Gamma^\delta = \cup_{i=1}^N \Gamma_i^\delta$. We also need to define the following subsets of W (see, for example, Figure 2.1, where $\delta = 1$):

- $W^{\Gamma^\delta} \equiv W \bigcap \Gamma^\delta$ (interface nodes),
- $W_i^{\Gamma^\delta} \equiv W^{\Gamma^\delta} \bigcap W_i^\delta$ (local interface nodes),

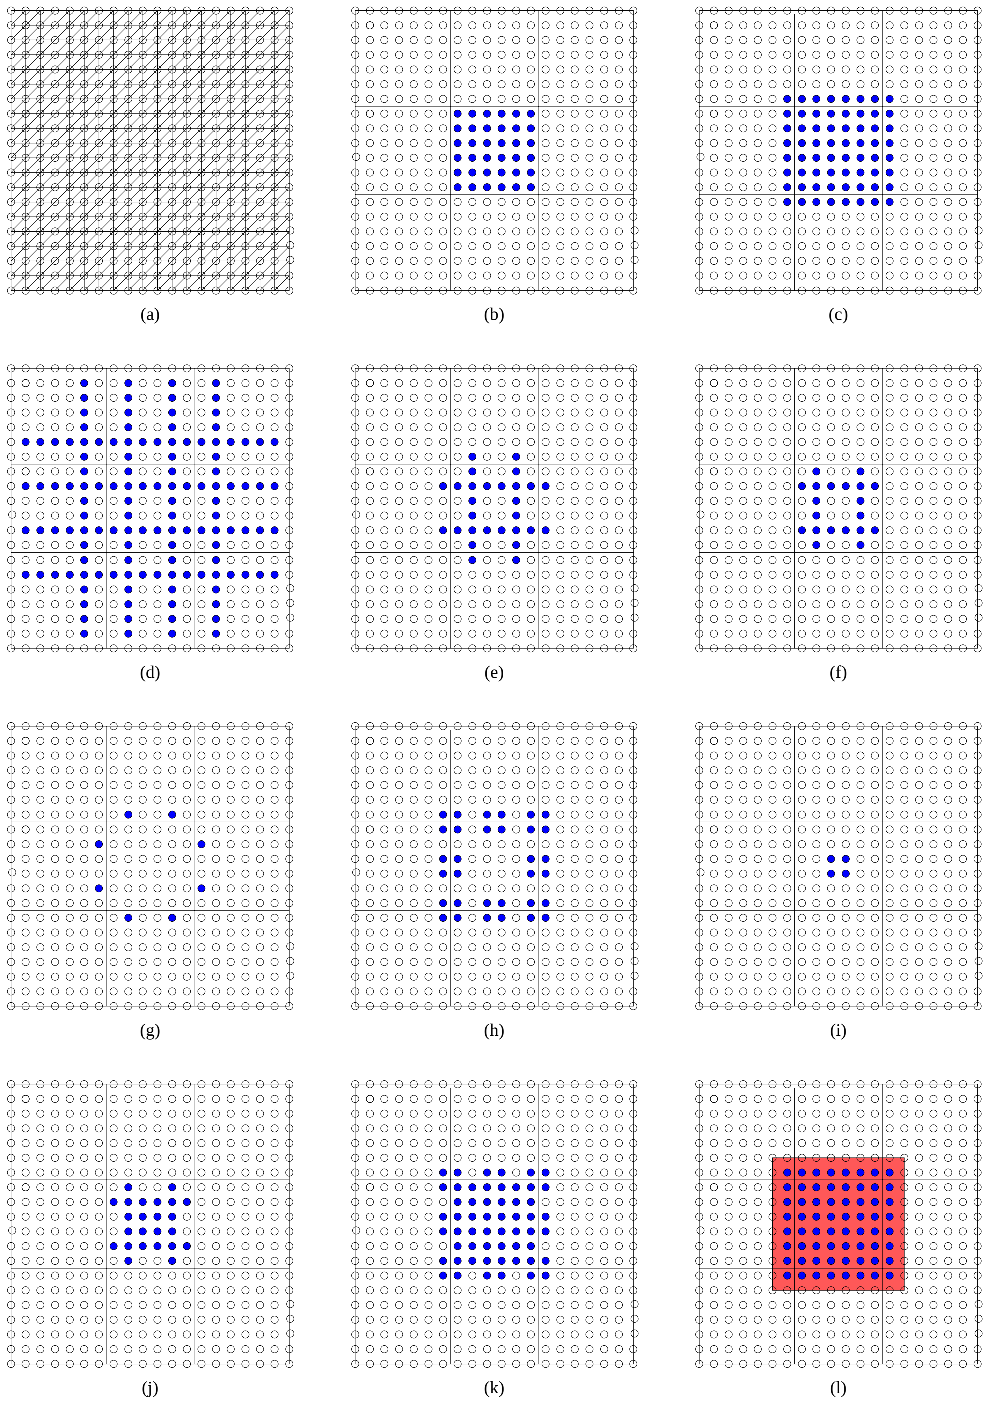

Fig. 2.1. *The partition of a finite element mesh into nine subdomains with the overlapping factor* $\delta = 1$. - $W_{i,in}^{\Gamma^\delta} \equiv W^{\Gamma^\delta} \bigcap W_i^0$ (local internal interface nodes),
- $W_{i,cut}^{\Gamma^\delta} \equiv W_i^{\Gamma^\delta} \backslash W_{i,in}^{\Gamma^\delta}$ (local cut interface nodes),
- $W_{i,ovl}^{\delta} \equiv (W_i^\delta \backslash W_i^{\Gamma^\delta}) \bigcap (\bigcup_{j \neq i} W_j^\delta)$ (local overlapping nodes),
- $W_{i,non}^{\delta} \equiv W_i^\delta \backslash (W_i^{\Gamma^\delta} \bigcup W_{i,ovl}^\delta)$ (local nonoverlapping nodes),
- $W_{i,in}^{\delta} \equiv W_{i,non}^\delta \bigcup W_{i,in}^{\Gamma^\delta}$ (internal nodes).

We note that the most northwest and the southeast nodes in Figure 2.1(c) were added to Γ_i^δ in order to make Ω_i^δ a rectangle. This is just to simplify the presentation, and it is not required in the implementation of the algorithms.

We frequently use functions that are discrete harmonic at certain nodes. Let $x_k \in W$ be a mesh point and $\phi_{x_k}(x) \in \mathcal{V}$ the finite element basis function associated with x_k; i.e., $\phi_{x_k}(x_k) = 1$, and $\phi_{x_k}(x_j) = 0, j \neq k$. We say that $u \in \mathcal{V}$ is discrete harmonic at x_k if

$$a(u, \phi_{x_k}) = 0.$$

If u is discrete harmonic at a set of nodal points Z, we say that u is discrete harmonic in $\Omega(Z)$.

Our new algorithm will be built on the subspace $\widetilde{\mathcal{V}}_i^\delta$ defined as a subspace of $\mathcal{V}_i^\delta$. $\widetilde{\mathcal{V}}_i^\delta$ consists of all functions that vanish on the cutting nodes $W_{i,cut}^{\Gamma^\delta}$ and are discrete harmonic at the nodes of $W_{i,ovl}^\delta$. Note that the degrees of freedom associated with the subspace $\widetilde{\mathcal{V}}_i^\delta$ are

$$\widetilde{W_i^\delta} \equiv W_i^\delta \backslash W_{i,cut}^{\Gamma^\delta},$$

and, since the values at the harmonic nodes are not independent, they cannot be counted toward the degrees of freedom. The dimension of $\widetilde{\mathcal{V}}_i^\delta$ is

$$\dim(\widetilde{\mathcal{V}}_i^\delta) = |W_{i,in}^\delta|.$$

Let $\Omega(\widetilde{W_i^\delta})$ be the induced domain. It is easy to see that $\Omega(\widetilde{W_i^\delta})$ is the same as Ω_i^δ but with cuts. We denote $\Omega(\widetilde{W_i^\delta})$ by $\widetilde{\Omega}_i^\delta$. We then have $\widetilde{\mathcal{V}}_i^\delta = \mathcal{V} \cap H_0^1(\widetilde{\Omega}_i^\delta)$, and hence the functions in $\widetilde{\mathcal{V}}_i^\delta$ are discrete harmonic on $\Omega(W_{i,ovl}^\delta)$. We denote $\Omega(W_{i,ovl}^\delta)$ by $\Omega_{i,ovl}^\delta$.

We define $\widetilde{\mathcal{V}}^\delta \subset \mathcal{V}^\delta$ as

$$\widetilde{\mathcal{V}}^\delta = \widetilde{\mathcal{V}}_1^\delta \oplus \cdots \oplus \widetilde{\mathcal{V}}_N^\delta,$$

which is a direct sum. We remark that functions in $\widetilde{\mathcal{V}}^\delta$ are, by definition, the sum of functions $u_i \in \widetilde{\mathcal{V}}_i^\delta$, $i = 1, \ldots, N$. Functions in $\widetilde{\mathcal{V}}^\delta$ can, in fact, be characterized easily as in the following lemma.

Lemma 2.1. *If $u \in \mathcal{V}$ and u is discrete harmonic at all the overlapping nodes, i.e., on $\cup_{i=1}^N W_{i,ovl}^\delta$, then $u \in \widetilde{\mathcal{V}}^\delta$.*

Proof. To prove that $u \in \widetilde{\mathcal{V}}^\delta$, all we need is to find a decomposition

$$u = \sum_{i=1}^N u_i, \quad \text{with } u_i \in \widetilde{\mathcal{V}}_i^\delta, \quad i = 1, \ldots, N.$$

For the given u, we define u_i piece by piece as follows. On the nodes in $W_{i,in}^\delta$ we let $u_i = u$. On the nodes in $W_{i,cut}^\delta$ we let u_i be zero. On the nodes outside W_i^δ we set u_i to zero. We now need only to define u_i on the nodes belonging to $W_{i,ovl}^\delta$. There, we extend u_i as a discrete harmonic function with boundary data given by u_i just defined. ◻

3. One-level RASHO method. Using notation introduced in the previous section, we now describe a new method, namely a RASHO.

We first define $\widetilde{P}_i^\delta : \widetilde{\mathcal{V}}^\delta \rightarrow \widetilde{\mathcal{V}}_i^\delta$ as a projection operator such that, for any $u \in \widetilde{\mathcal{V}}^\delta$,

$$a(\widetilde{P}_i^\delta u, v) = a(u, v) \qquad \forall v \in \widetilde{\mathcal{V}}_i^\delta. \tag{3.1}$$

The RASHO operator can then be defined as

$$\widetilde{P}^\delta = \widetilde{P}_1^\delta + \cdots + \widetilde{P}_N^\delta. \tag{3.2}$$

Note, however, that the solution u^* of (1.4) (see also (1.5)), is not, generally speaking, in the subspace $\widetilde{\mathcal{V}}^\delta$; therefore, the operator $\widetilde{P}^\delta$ cannot be used to solve the linear system (1.5) directly. We will need to modify the right-hand side of system (1.5). A reformulated (1.5) will be presented in Lemma 3.1 below. We will show that the elimination of the variables associated with the overlapping nodes is not needed in order to apply $\widetilde{P}^\delta$ to any given vector $v \in \widetilde{P}^\delta$.

We now introduce a matrix form of (3.2). We define the restriction operator, or a matrix, $\widetilde{R}_i^\delta$ as follows. Let $v = (v_1, \ldots, v_n)^T$ be a vector corresponding to the nodal values of a function $u \in \mathcal{V}$; namely, for any node $x_k \in W$, $v_k = u(x_k)$. For convenience, we say "v is defined on W." Its restriction on $\widetilde{W}_i^\delta$, $\widetilde{R}_i^\delta v$ is defined as

$$(\widetilde{R}_i^\delta v)(x_k) = \begin{cases} v_k & \text{if } x_k \in \widetilde{W}_i^\delta, \\ 0 & \text{otherwise.} \end{cases} \tag{3.3}$$

The matrix representation of $\widetilde{R}_i^\delta$ is given by a diagonal matrix, with 1 for nodal points in $\widetilde{W}_i^\delta$ and 0 for the remaining nodal points. We remark that, by way of definition, the operator $\widetilde{R}_i^\delta$ is symmetric; i.e., $(\widetilde{R}_i^\delta)^T = \widetilde{R}_i^\delta$. Using this restriction operator, we define the subdomain stiffness matrix as

$$\widetilde{A}_i^\delta = \widetilde{R}_i^\delta \; A \; (\widetilde{R}_i^\delta)^T,$$

which can also be obtained by the discretization of the original finite element problem on $\widetilde{W}_i^\delta$ with zero Dirichlet data on nodes $W \setminus \widetilde{W}_i^\delta$. The matrix $\widetilde{A}_i^\delta$ is block diagonal with blocks corresponding to the structure of $\widetilde{R}_i^\delta$, and its inverse is understood as an inverse of the nonzero block. A matrix representation of $\widetilde{P}_i^\delta$, denoted also by $\widetilde{P}_i^\delta$, is equal to

$$\widetilde{P}_i^\delta = (\widetilde{A}_i^\delta)^{-1} \; A$$

and

$$\widetilde{P}^\delta = ((\widetilde{A}_1^\delta)^{-1} + \cdots + (\widetilde{A}_N^\delta)^{-1}) \; A. \tag{3.4}$$

Using the matrix notations, the next lemma shows how to modify system (1.5) so that its solution belongs to $\widetilde{\mathcal{V}}^\delta$.

LEMMA 3.1. *Let u^* and f be the exact solution and the right-hand side of* (1.5)*, and*

$$w = \sum_{i=1}^{N} (\widetilde{A}_i^\delta)^{-1} \widetilde{R}_i^0 f; \tag{3.5}$$

then we have $\widetilde{u}^* = u^* - w \in \widetilde{\mathcal{V}}^\delta$*, which is the solution of the modified linear system of equations*

$$A\widetilde{u}^* = f - Aw = \widetilde{f}.$$

Proof. If we can show that

$$a(w, \phi_k) = f(\phi_k)$$

for a regular basis function associated with an arbitrary overlapping node $x_k \in W^\delta_{i,ovl}$, for some i, then we will have

$$a(u^* - w, \phi_k) = f(\phi_k) - f(\phi_k) = 0, \tag{3.6}$$

which says that $\widetilde{u}^* = u^* - w$ is discrete harmonic at the overlapping node x_k. We can then use Lemma 2.1 to conclude the proof. Let us now consider

$$w_i = (\widetilde{A}^\delta_i)^{-1}\widetilde{R}^0_i f,$$

which, by definition, is the same as

$$a(w_i, \phi_j) = (\phi_j, \widetilde{R}^0_i f) \qquad \forall x_j \in \widetilde{W}^\delta_i.$$

Here and in the rest of the proof, ϕ_j is the basis function associated with the node $x_j \in \widetilde{W}^\delta_i$. Using that $\widetilde{R}^0_i$ is symmetric and

$$(\phi_j, \widetilde{R}^0_i f) = (f, \widetilde{R}^0_i \phi_j) = a(u^*, \widetilde{R}^0_i \phi_j),$$

we get

$$a(w_i, \phi_j) = a(u^*, \widetilde{R}^0_i \phi_j). \tag{3.7}$$

Let us compute $a(w_i, \phi_k)$. Since x_k is an overlapping node, it cannot be on the boundary of $\widetilde{\Omega}^\delta_i$. This leaves us with the following two cases.

Case 1. The support of $\phi_k(x)$ belongs to the exterior of $\widetilde{\Omega}^\delta_i$. Since the supports of w_i and ϕ_k do not overlap, we have

$$a(w_i, \phi_k) = 0.$$

Case 2. The support of $\phi_k(x)$ belongs to the interior of $\widetilde{\Omega}^\delta_i$. In this case, we have

$$a(w_i, \phi_k) = a(u^*, \widetilde{R}^0_i \phi_k).$$

Taking the sum of the above equality for $i = 1, \ldots, N$, we get

$$a(w, \phi_k) = a\left(\sum_{i=1}^N w_i, \phi_k\right) = a\left(u^*, \sum_{i=1}^N \widetilde{R}^0_i \phi_k\right) = a(u^*, \phi_k),$$

which proves (3.6). Here the fact that $\sum_{i=1}^N \widetilde{R}^0_i = I$ has been used. □

There are basically two ways to compute w in practice. Suppose that subdomain problems are solved using some LU factorization–based method. One can use the same factorization of $\widetilde{A}^\delta_i$ to modify the right-hand side of the system and to solve subdomain problems in the preconditioning steps as that suggested in Lemma 3.1.

Alternatively, one can obtain w by solving several small Dirichlet problems on each subdomain with zero Dirichlet boundary conditions in the overlapping regions $\Omega^\delta_{i,ovl}$. In both strategies, the computation can be done in parallel, and no communication is needed in a distributed memory implementation. In the first approach, $\widetilde{u}^*$ is discrete harmonic in $W^\delta_{i,ovl} \cup W^\delta_{i,non}$, and in the second approach, $\widetilde{u}^*$ is discrete harmonic only in $W^\delta_{i,ovl}$. We note that the discrete harmonicity of $\widetilde{u}^*$ on $W^\delta_{i,non}$ is not required for the algorithms and for the corresponding theory developed in this paper.

Let $\widetilde{f} = f - Aw$; then $\widetilde{u}^*$ is the solution of the following linear system of equations:

$$A\widetilde{u}^* = \widetilde{f}. \tag{3.8}$$

Since $\widetilde{u}^* \in \widetilde{\mathcal{V}}^\delta$,

$$g \equiv \widetilde{P}^\delta \widetilde{u}^*$$

is well defined and can be computed without knowing $\widetilde{u}^*$ by using the following relations:

$$a(\widetilde{P}^\delta_i \widetilde{u}^*, v) = a(\widetilde{u}^*, v) = (\widetilde{f}, v) \qquad \forall v \in \widetilde{\mathcal{V}}^\delta_i \text{ and } i = 1, \dots, N.$$

More precisely, we can obtain g by solving the subdomain problems

$$a(g_i, v) = (\widetilde{f}, v) \qquad \forall v \in \widetilde{\mathcal{V}}^\delta_i$$

for $i = 1, \dots, N$ and taking $g = g_1 + \cdots + g_N$. With such a right-hand side, we introduce a new linear system

$$\widetilde{P}^\delta \widetilde{u}^* = g, \tag{3.9}$$

which is equivalent to the linear system (3.8); see Theorem 5.1. The system (3.9) is a symmetric positive definite system under the usual energy inner product and therefore can be solved using the CG method. RASHO has a few advantages over the classical AS preconditioner. Let us recall AS briefly. Let

$$\left(R^\delta_i v\right)(x_k) = \begin{cases} v_k & \text{if } x_k \in W^\delta_i, \\ 0 & \text{otherwise.} \end{cases} \tag{3.10}$$

Then the AS operator takes the following matrix form:

$$P^\delta = \left((A^\delta_1)^{-1} + \cdots + (A^\delta_N)^{-1}\right) A, \tag{3.11}$$

where $A^\delta_i = R^\delta_i A (R^\delta_i)^T$. Because of the inclusion of the cut interface nodes, the size of the matrix A^δ_i is $|W^\delta_i|$, which is slightly larger than the size of the matrix $\widetilde{A}^\delta_i$, which is $|\widetilde{W}^\delta_i|$. In a distributed memory implementation, the operation $R^\delta_i v$ involves moving data from one processor to another, but the operation $\widetilde{R}^\delta_i v$ does not involve any communication. More precisely, in RASHO, if $u \in \widetilde{\mathcal{V}}^\delta$, then it is easy to see that

$$\widetilde{R}^\delta_i A u = \widetilde{R}^\delta_{i,in} A u, \tag{3.12}$$

where $\widetilde{R}^\delta_{i,in}$ is defined as

$$(\widetilde{R}^\delta_{i,in} v)(x_k) = \begin{cases} v_k & \text{if } x_k \in W^\delta_{i,in}, \\ 0 & \text{otherwise.} \end{cases} \tag{3.13}$$

Therefore, for functions in $\widetilde{\mathcal{V}}^\delta$ we can rewrite $\widetilde{P}^\delta$, as in (3.4), in the following form:

$$\widetilde{P}^\delta = ((\widetilde{A}_1^\delta)^{-1}\widetilde{R}_{1,in}^\delta + \cdots + (\widetilde{A}_N^\delta)^{-1}\widetilde{R}_{N,in}^\delta)\, A. \tag{3.14}$$

Although the operator (3.14) does not look like a symmetric operator, it is indeed symmetric when applied to functions in the subspace $\widetilde{\mathcal{V}}^\delta$. The form (3.12) takes advantage of the fact that the operator $\widetilde{R}_{i,in}^\delta$ is communication-free in the sense that it needs only the residual associated with nodes in $W_{i,in}^\delta \subset \Omega_i^0$.

We make some further comments on how the residual Au can be calculated in a distributed memory environment for a given vector $u \in \widetilde{\mathcal{V}}^\delta$. In a typical implementation, the matrix A is constructed and stored in the form $\{\widetilde{A}_i^\delta\}$; each processor has one or several of the subdomain matrix $\widetilde{A}_i^\delta$. Similarly, u is stored in the form $\{u_i\}$, where $u_i \in \widetilde{\mathcal{V}}_i^\delta$. We note, however, that to compute the residual at nodes $W_{i,in}^{\Gamma^\delta}$ some communications are required. The processor associated with subdomain Ω_i^δ needs to obtain the local solution from the neighboring subdomains at nodes connected to $W_{i,in}^{\Gamma^\delta}$. It is important to note that the amount of communication does not depend on the size of the overlap, since only one layer of nodes is required. This shows that in terms of communication, the RASHO is superior to AS and RAS.

4. Some two-level versions. As with other domain decomposition methods, the convergence rate of the single-level method depends on the number of subdomains. To make the algorithm more scalable with respect to the number of subdomains, we next introduce two two-level versions of RASHO in this section. This includes an additive version and a hybrid version using the same coarse space.

Standard coarse spaces cannot be used since they are usually not discrete harmonic in the overlapping regions. To construct a coarse subspace $\widetilde{\mathcal{V}}_0$ of $\widetilde{\mathcal{V}}$, we introduce the coarse basis functions $\phi^i(x), i = 1, \ldots, N$, based on a partition of unity [21] on the interface nodes W^{Γ^δ}. For each subdomain, we define the nodal values of $\phi^i(x) \in \widetilde{\mathcal{V}}_i$ as follows:

$$\phi^i(x_k) = \begin{cases} 1 & \text{if } x_k \in W_{i,in}^{\Gamma^\delta}, \\ \text{discrete harmonic} & \text{if } x_k \in W_{i,ovl}^\delta \cup W_{i,non}^\delta, \\ 0 & \text{if } x_k \in W \backslash \widetilde{W}_i^\delta. \end{cases} \tag{4.1}$$

Let us denote $\Omega(W_{i,non}^\delta)$ by $\Omega_{i,non}^\delta$. Then $\phi^i(x_k) = 1$ at $x_k \in W_{i,non}^\delta$ for the case $\Omega_{i,non}^\delta \cap \partial\Omega = \emptyset$ since all the boundary nodal values of $\Omega_{i,non}^\delta$ belong to $W_{i,in}^{\Gamma^\delta}$ and therefore have nodal values equal to one. For the case $\Omega_{i,non}^\delta \cap \partial\Omega \neq \emptyset$, we have chosen to define $\phi^i(\Omega_{i,non}^\delta)$ as the discrete harmonic extension with boundary nodal values equal to one on $W_{i,in}^{\Gamma^\delta}$ and equal to zero at $\bar{\Omega}_{i,non}^\delta \cap \partial\Omega$; note, however, that we do not require that $\widetilde{\mathcal{V}}_0^\delta$ be discrete harmonic on $\Omega_{i,non}^\delta$. If we had chosen ϕ^i equal to one at all nodes of $\Omega_{i,non}^\delta$ also for the $\Omega_{i,non}^\delta \cap \partial\Omega \neq \emptyset$ case, ϕ^i would have a jump from one to zero on the neighboring elements of $\partial\Omega$. This jump would give lower bounds that depend on the factor h/H, and such bounds would be poor if the overlap were very small. Another possibility for avoiding the discrete harmonicity of ϕ^i on $\Omega_{i,non}^\delta$ in the $\Omega_{i,non}^\delta \cap \partial\Omega \neq \emptyset$ case would be the use of the boundary layer technique developed in [21]. We note, however, that the bounds of Theorem 5.1 would remain the same as well as the analysis, with some minor modifications.

The coarse space $\widetilde{\mathcal{V}}_0^\delta$ is simply the space spanned by all linear combinations of the coarse basis functions $\phi^i, i = 1, \ldots, N$. We define $\widetilde{P}_0^\delta : \mathcal{V} \to \widetilde{\mathcal{V}}_0^\delta$ as the operator such that, for any $u \in \mathcal{V}$,

$$a(\widetilde{P}_0^\delta u, v) = a(u, v) \qquad \forall v \in \widetilde{\mathcal{V}}_0^\delta.$$

A two-level additive version of RASHO can now be introduced with the operator

$$\widetilde{P}_C^\delta = \sum_{i=0}^{N} \widetilde{P}_i^\delta. \tag{4.2}$$

The convergence properties of this two-level algorithm will be studied in the next section. To describe the computational aspects of the coarse problem, we rewrite the above definitions in matrix notation. Recall that n is the total number of nodes in W, N is the total number of subdomains, and ϕ^i is the coarse basis function. We write the fine-to-coarse restriction operator as an $N \times n$ matrix

$$(\widetilde{R}_0)_{N\times n} = \left(\phi^i(x_k)\right)_{i=1,N;k=1,n}.$$

The matrix form of the coarse projection operator $\widetilde{P}_0^\delta$ is

$$\widetilde{P}_0^\delta = \widetilde{R}_0^T \widetilde{A}_0^{-1} \widetilde{R}_0 A, \tag{4.3}$$

where $\widetilde{A}_0 = \widetilde{R}_0 A \widetilde{R}_0^T$ is an $N \times N$ matrix.

We remark that $\widetilde{A}_0$ is more sparse than coarse space matrices that appear in other methods such as Neumann–Neumann or FETI-type algorithms [12, 13, 18, 23], since only connections with the neighboring subdomains appear in the stencils associated with a coarse basis function. Another feature of this coarse space problem is that the computation of the right-hand side, i.e., $\widetilde{R}_0 A u$ for some u, can be done inside each Ω_i^δ; this is a clear advantage over regular coarse spaces.

The two-level additive algorithm (4.2) is easy to code, but the performance isn't as good as expected. Some examples are given in the numerical experiments section of this paper. We next introduce another two-level algorithm—a hybrid Schwarz operator (see [19]) with the error propagation operator given by

$$\left(I - \widetilde{P}_0^\delta\right)\left(I - \sum_{i=1}^{N} \widetilde{P}_i^\delta\right)\left(I - \widetilde{P}_0^\delta\right). \tag{4.4}$$

This is a symmetric operator with which we can work essentially without any extra cost, since, when forming powers of the operator (4.4) on building the Krylov space on the PCG, we can use the fact that $I - \widetilde{P}_0^\delta$ is a projection, and therefore $(I - \widetilde{P}_0^\delta)^2 = I - \widetilde{P}_0^\delta$. Subtracting the operator (4.4) from the identity operator I, we obtain the operator

$$\widetilde{P}_{hyb}^\delta = \widetilde{P}_0^\delta + \left(I - \widetilde{P}_0^\delta\right)\left(\sum_{i=1}^{N} \widetilde{P}_i^\delta\right)\left(I - \widetilde{P}_0^\delta\right). \tag{4.5}$$

The spectral properties of $\widetilde{P}_{hyb}^\delta$ will be studied in the next section. Some numerical results obtained using the additive and the hybrid two-level methods will be presented in the numerical experiments section of the paper, and they will both be compared with the single-level method.

5. Theoretical analysis.

The algorithm presented in the previous section is applicable for general sparse, symmetric positive definite linear systems. The notions of subdomains, harmonic overlaps, the classification of the nodal points, etc. can all be defined in terms of the graph of the sparse matrix. In this section we provide a nearly optimal estimate for a Poisson equation discretized with a piecewise linear finite element method. We estimate the condition number of the RASHO operators $\widetilde{P}^\delta$ and $\widetilde{P}^\delta_C$ in terms of the fine mesh size h, the subdomain size H, and the overlapping factor δ. We shall follow the abstract AS theory [24] in what follows.

Lemma 5.1. *Suppose that the following assumptions hold:*

(i) *There exists a constant C_0 such that for any $u \in \widetilde{\mathcal{V}}^\delta$ there exists a decomposition*

$$u = \sum_{i=0}^{N} u_i,$$

where $u_i \in \widetilde{\mathcal{V}}^\delta_i$, and

$$\sum_{i=0}^{N} |u_i|^2_{H^1(\Omega)} \le C_0^2 |u|^2_{H^1(\Omega)}.$$

(ii) *There exist constants $\epsilon_{ij}, i, j = 1, \ldots, N$, such that*

$$a(u_i, u_j) \le \epsilon_{ij}\, a(u_i, u_i)^{1/2} a(u_j, u_j)^{1/2} \qquad \forall u_i \in \widetilde{\mathcal{V}}^\delta_i,\ \forall u_j \in \widetilde{\mathcal{V}}^\delta_j.$$

Then $\widetilde{P}^\delta_C$ is invertible, symmetric; i.e., $a(\widetilde{P}^\delta_C u, v) = a(u, \widetilde{P}^\delta_C v)$,

$$C_0^{-2} a(u,u) \le a(\widetilde{P}^\delta_C u, u) \le (\rho(\mathcal{E}) + 1) a(u,u) \qquad \forall u \in \widetilde{\mathcal{V}}^\delta. \tag{5.1}$$

Here $\rho(\mathcal{E})$ is the spectral radius of $\mathcal{E}$, which is an $(N) \times (N)$ matrix made of $\{\epsilon_{ij}\}$.

It is trivial to see that $\rho(\mathcal{E}) \le C$. Thus our focus in the rest of the section is on bounding C_0. For the case of the single-level RASHO, the lemma above can be modified by replacing $u = \sum_{i=0}^N u_i$, $\widetilde{P}^\delta_C$, and $(\rho(\mathcal{E}) + 1)$ with $u = \sum_{i=1}^N u_i$, $\widetilde{P}^\delta$, and $\rho(\mathcal{E})$, respectively.

To analyze the hybrid algorithm, we use a result due to Mandel [19, Lemma 3.2], which in our context is given by the following.

Lemma 5.2. *The extreme eigenvalues of $\widetilde{P}^\delta_{hyb}$, $\widetilde{P}^\delta_C$, and $\widetilde{P}^\delta$ satisfy*

$$\lambda_{min}(\widetilde{P}^\delta_{hyb}) \ge \lambda_{min}(\widetilde{P}^\delta_C) \qquad \text{and} \qquad \lambda_{max}(\widetilde{P}^\delta_{hyb}) \le \lambda_{max}(\widetilde{P}^\delta).$$

5.1. The partition of unity and a comparison function.

The construction of a partition of unity is one of the key steps in an AS analysis. Consider $\phi^i(x)$ defined in (4.1). It is easy to see that $\{\phi^i(x), i = 1, \ldots, N\}$ restricted to W^{Γ^δ} forms a partition of unity.

In addition to $\phi^i(x)$, we also need to construct a *comparison function* $\theta_i(x)$ for each subdomain Ω^δ_i. Comparison functions, or barrier functions, are very useful for many Schwarz algorithms, such as these on nonmatching grids [6]. We will show that, even though $\theta_i(x) \in \mathcal{V}^\delta_i$, and is not in $\widetilde{\mathcal{V}}^\delta_i$ as we wished, it can still be used to bound functions in $\widetilde{\mathcal{V}}^\delta_i$. Both $\theta_i(x)$ and $\phi^i(x)$ depend on the overlapping factor δ. Because $\phi^i(x)$ is discrete harmonic at $W^\delta_{i,ovl} \cup W^\delta_{i,non}$ and identical to θ_i at the remaining nodes, we have

$$a(\phi^i, \phi^i) \le a(\theta_i, \theta_i).$$

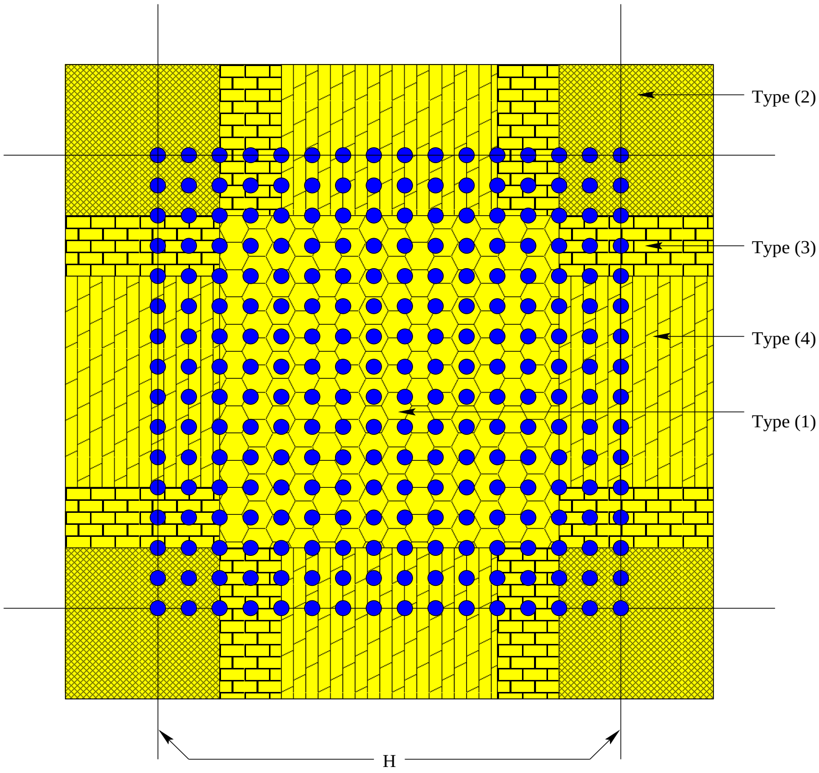

FIG. 5.1. *The partition of Ω_i^δ into the union of four types of subregions. This is a "floating" subdomain with $\delta = 2$. The collection of "$\bullet$" forms the set W_i^0.*

To construct the function $\theta_i(x)$, we first consider the case in which Ω_i^0 is a floating square subdomain. "Floating" refers to the fact that the subdomain doesn't touch the boundary $\partial\Omega$. The extension to cases in which Ω_i^δ touches the boundary is simple, and we will comment on it later. To further simplify our arguments, we assume that Ω_i^δ and its neighboring extended subdomains Ω_j^δ are squares of the same size, i.e., sides of length equal to $H + 2(\delta + 1)h$. This assumption is equivalent to claiming that Ω^R has size H and that δ levels of overlap are applied; see Figure 5.1. We also assume that the overlap is not too large; for the analysis given below, δh no larger than $H/4$ is enough. Our techniques can be modified to consider larger overlaps and more complex subdomains, although too large of an overlap has little practical value.

Roughly speaking, $\theta_i(x)$ is equal to $\phi^i(x)$ on $W \backslash W_{i,ovl}^\delta$. On the overlapping region $W_{i,ovl}^\delta$, we need to define $\theta_i(x)$ carefully so that we can control its energy in the H^1 seminorm. For this purpose, we decompose Ω_i^δ into subregions of four types (see Figure 5.1), $\Omega_{i,non}^\delta$ (Type (1)), $\Omega_i^{\delta\delta}$ (Type (2)), $\Omega_i^{\delta H}$ (Type (3)), and $\Omega_i^{\delta\tilde{\delta}}$ (Type (4)), and define $\theta_i(x)$ on each piece of the subregion separately.

Type (1). The first subregion is $\Omega_{i,non}^\delta$, which is a square with sides of size $H - 2\delta h$.

Type (2). The second subregion $\Omega_i^{\delta\delta}$ is the area in which Ω_i^δ overlaps simultaneously with three neighbors Ω_j^δ. $\Omega_i^{\delta\delta}$ therefore represents the union of the four corner pieces of Ω_i^δ, i.e., four squares with sides of size $(2\delta + 1)h$.

Types (3) and (4). The area in which Ω_i^δ overlaps only one neighbor is four rectangles of size $H-2\delta h\times(2\delta+1)h$. We further partition each of the four rectangles into three smaller rectangles; i.e., two of them are of $\Omega_i^{\delta\tilde{\delta}}$ type and one of them of $\Omega_i^{\delta H}$ type. For instance, without lost of generality, let us consider the intersection of Ω_i^{δ} with its right-hand neighbor Ω_j^{δ}, excluding the corner parts. In this case, the subregion to be partitioned is a rectangle of size $(2\delta+1)h$ in the x direction and $H-2\delta h$ in the y direction. The partition of this rectangles gives two smaller rectangles of $\Omega_i^{\delta\tilde{\delta}}$ type with dimensions $2(\delta+1)h\times\delta h$, and each one has an edge in common with a square of $\Omega_i^{\delta\delta}$ type. We define them as transition subregions because they are placed between a corner-type subregion $\Omega_i^{\delta\delta}$ and a face-type subregion $\Omega_i^{\delta H}$. The $\Omega_i^{\delta H}$ face-type subregions are the smaller rectangles that are placed between the two smaller rectangles of $\Omega_i^{\delta\tilde{\delta}}$ type. $\Omega_i^{\delta H}$ face-type regions are of size $(2\delta+1)h$ by $H-4\delta h$.

For any node x belonging to a Type (1) region $\Omega_{i,non}^{\delta}$, we define $\theta_i(x)$ to be equal to one, i.e., equal to $\phi^i(x)$. Therefore

$$|\phi^i(x)|^2_{H^1(\Omega^\delta_{i,non})}=|\theta_i(x)|^2_{H^1(\Omega^\delta_{i,non})}=0.$$

We next define $\theta_i(x)$, node by node, in $\Omega^\delta_{i,ovl}$, which is the union of corner-, transition-, and face-type regions defined above.

For a Type (2) region $\Omega_i^{\delta\delta}$, let Q be such a square with vertices $V_1=(a,b)$, $V_2=(a+(2\delta+1)h,b)$, $V_3=(a,b+(2\delta+1)h)$, and $V_4=(a+(2\delta+1)h,b+(2\delta+1)h)$. We assume that V_1,V_2, and V_4 belong to $\partial\Omega_i^\delta$. In other words, Q is located on the southeast corner of Ω_i^δ. Let us also introduce another square region $\widetilde{Q}$, with vertices $V_3=(a,b+(2\delta+1)h)$, $\widetilde{V}_1=(a,b+\delta h)$, $\widetilde{V}_2=(a+(\delta+1)h,b+\delta h)$, and $\widetilde{V}_4=(a+(\delta+1)h,b+(2\delta+1)h)$. Note that $\widetilde{Q}$ is contained in Q, with V_3 as the common vertex. To define $\theta_i(x)$ on Q, we set $\theta_i(V_3)=1$, $\theta_i(\widetilde{V}_1)=0$, $\theta_i(\widetilde{V}_2)=0$, $\theta_i(\widetilde{V}_4)=0$. At the remaining nodes x on the edges $\widetilde{V}_1\widetilde{V}_2$ and $\widetilde{V}_2\widetilde{V}_4$ we set $\theta_i(x)=0$, and on the edges $V_3\widetilde{V}_1$ and $V_3\widetilde{V}_4$ we set $\theta_i(x)=1$. For nodes on $Q\backslash\widetilde{Q}$ we set $\theta_i(x)=0$. It remains only to define $\theta_i(x)$ for nodes x in the interior of $\widetilde{Q}$. To define $\theta_i(x)$ there, we use a well-known cutoff function technique, such as the one introduced in Lemma 4.4 of [10], but for two-dimensional square regions. An illustrative picture of $\theta_i(x)$ in a typical region $\Omega_i^{\delta\delta}$ is shown in Figure 5.2. For the completeness of this paper, we include the construction below. Let C be the center of the square $\widetilde{Q}$. The construction of $\theta_i(x)$ is defined by the following steps:

(1) Define $\theta_i(V_3)=1$, $\theta_i(\widetilde{V}_2)=0$, $\theta_i(\widetilde{V}_1)=0$, and $\theta_i(\widetilde{V}_4)=0$.

(2) For a point P that belongs to the segments $V_3\widetilde{V}_4$ or $V_3\widetilde{V}_1$, define $\theta_i(P)=1$. For a point P that belongs to the segments $\widetilde{V}_4\widetilde{V}_2$ or $\widetilde{V}_1\widetilde{V}_2$, define $\theta_i(P)=0$.

(3) For a point Y that belongs to the line segment connecting C to V_3, define $\theta_i(Y)$ by linear interpolation between values $\theta_i(C)=1/2$ and $\theta_i(V_3)=1$. For a point Y that belongs to the line segment connecting C to $\widetilde{V}_2$, define $\theta_i(Y)$ by linear interpolation between values $\theta_i(C)=1/2$ and $\theta_i(\widetilde{V}_2)=0$.

(4) For a point S that belongs to a line segment connecting a point Y to a vertex $\widetilde{V}_1$ or $\widetilde{V}_4$, define $\theta_i(S)=\theta_i(Y)$.

(5) Note that the θ_i is defined everywhere on $\widetilde{Q}\cup\partial\widetilde{Q}$. θ_i is continuous everywhere except at the points $\widetilde{V}_1$ and $\widetilde{V}_4$. We redefine θ_i as the continuous piecewise linear finite element function given by the standard pointwise interpolation.

The most important observation of the construction of $\theta_i(x)$ inside $\widetilde{Q}$ is that $|\nabla\theta_i(x)|\le C/r$ near $\widetilde{V}_1$ or $\widetilde{V}_4$. Here r is the distance of x from $\widetilde{V}_1$ or $\widetilde{V}_4$. Therefore,

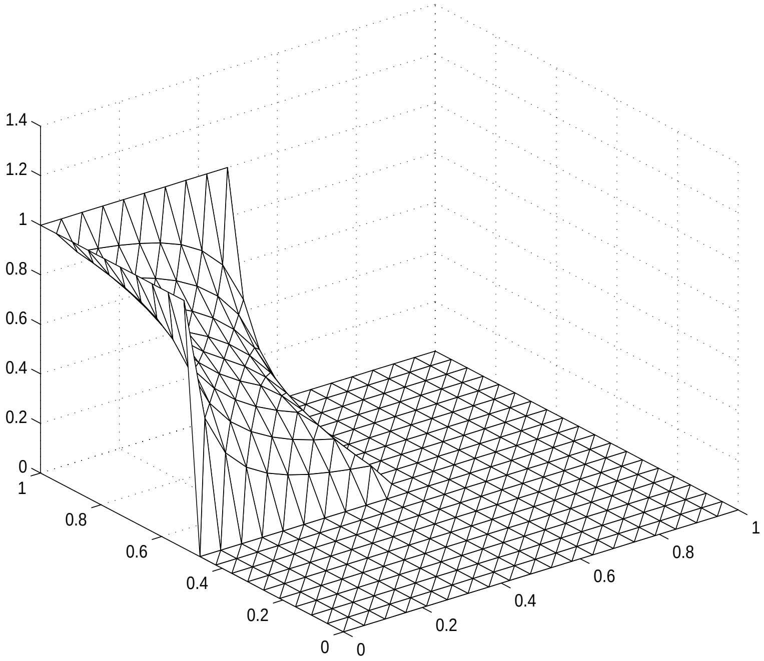

FIG. 5.2. *An illustrative picture of $\theta_i(x)$ in a typical region $\Omega_i^{\delta\delta}$.*

we obtain (see [10] and [23])

$$|\theta_i(x)|^2_{H^1(Q)} = |\theta_i(x)|^2_{H^1(\widetilde{Q})} \leq C\left(1 + \log\left(\frac{(\delta+1)h}{h}\right)\right) = C(1 + \log(\delta + 1)).$$

Since inside of Ω_i^δ there are four of those squares, we obtain

$$|\theta_i(x)|^2_{H^1(\Omega_i^{\delta\delta})} \leq C\left(1 + \log(\delta + 1)\right).$$

Type (3) regions consist of transition-type rectangles. Let us consider one of them and denote it by T, which we assume has vertices at $V_3 = (a, b + (2\delta + 1)h)$, $V_4 = (a+(2\delta+1)h, b+(2\delta+1)h)$, $V_5 = (a, b+(3\delta+1)h)$, and $V_6 = (a+(2\delta+1)h, b+(3\delta+1)h)$. Note that T stands on top of the square Q introduced above and has the common edge V_3V_4. We define $\theta_i(x)$ over the edge V_3V_4 to be equal to $\phi^i(x)$. Over the edge V_3V_5, we set $\theta_i(x) = 1$. Over the edge V_4V_6, we set $\theta_i(x) = 0$. And over the edge V_5V_6 we let $\theta_i(x)$ decrease linearly from the value 1 to 0. What remains is to define $\theta_i(x)$ inside T. Let us define the nodes $V_l = (a+\delta h, b+(2\delta+1)h)$ and $V_r = (a+(\delta+1)h, b+(2\delta+1)h)$, which is the same as the node $\widetilde{V}_4$ used in the description of Type (2) regions. The nodes V_l and V_r are exactly the places on the edge V_3V_4 where $\phi^i(x)$ jumps from 1 to 0. On the triangle $V_3V_lV_5$ we set $\theta_i(x) = 1$. On the triangle $V_rV_4V_6$ we set $\theta_i(x) = 0$. On the region $V_lV_rV_6V_5$, we let $\theta_i(x)$ decrease linearly in the x direction from the value 1 to 0. We note that next to the nodes V_lV_r, $\theta_i(x)$ has a singular behavior similar to $|\nabla\theta_i(x)| \leq C/r$, where r is the distance from x to the line $V_l\ V_r$. Similarly, we have

$$|\theta_i(x)|^2_{H^1(T)} \leq C\left(1 + \log(\delta + 1)\right).$$

Since there are eight rectangles of Type (3) inside $\Omega_i^{\delta\tilde{\delta}}$, we obtain

$$|\theta_i(x)|^2_{H^1(\Omega_i^{\delta\tilde{\delta}})} \leq C\left(1 + \log(\delta+1)\right).$$

Type (4) regions are rectangles of face type. Let R be one of them, and assume that the vertices are given by $V_5 = (a, b+(3\delta+1)h)$, $V_6 = (a+(2\delta+1)h, b+(3\delta+1)h)$, $V_7 = (a, b+H-(\delta-1)h)$, and $V_8 = (a+(2\delta+1)h, b+H-(\delta-1)h)$. Note that R is on the top of the rectangle T defined above, and its height is $H - 4\delta h$. The vertices V_6 and V_8 are the vertices that belong to $\partial\Omega_i^\delta$. We define $\theta_i(x) = 1$ if x is on the edge V_5V_7, and $\theta_i(x) = 0$ if x is on the edge V_6V_8, and $\theta_i(x)$ is linear in the horizontal direction for the remaining points. We then obtain

$$|\theta_i(x)|^2_{H^1(R)} \leq \frac{H-4\delta h}{(2\delta+1)h}.$$

Since there are four of those rectangles inside $\Omega_i^{\delta H}$, we obtain

$$|\theta_i(x)|_{H^1(\Omega_i^{\delta H})} \leq C\frac{H-4\delta h}{(2\delta+1)h} \leq C\frac{H}{(2\delta+1)h}.$$

For the cases in which Ω_i^0 touches the boundary $\partial\Omega$, the analysis needs to be modified slightly. The first modification is because the shape of the overlapping region changes slightly, i.e., the longer side is shorter; it is easy to see that we get similar bounds as before. The other modification is because ϕ^i on $\Omega_{i,non}^\delta$ is not identically equal to one and therefore the corresponding energy is not necessarily zero; for this case we can design θ_i similarly and obtain

$$|\theta_i(x)|^2_{H^1(\Omega_{i,non}^\delta)} \leq C\left(1 + \log\left(\frac{H}{h}\right)\right).$$

Putting all the pieces of $\theta_i(x)$ together, we see that $\theta_i(x) \in \mathcal{V}_i^\delta$, and it is equal to $\phi^i(x)$ on W^{Γ^δ}. Adding all the estimates on subregions of the four types, we arrive at the following lemma.

Lemma 5.3. *For $i = 1, \ldots, N$, $\theta_i(x) \in \mathcal{V}_i^\delta$, $\phi^i(x) \in \tilde{\mathcal{V}}_i^\delta$, and the following hold:*

(1) $|\phi^i|^2_{H^1(\Omega_i^\delta)} \leq |\theta_i|^2_{H^1(\Omega_i^\delta)}$.

(2)

$$|\theta_i|^2_{H^1(\Omega_i^\delta \backslash \Omega_{i,non}^\delta)} \leq C\left(1 + \log(\delta+1) + \frac{H}{(2\delta+1)h}\right).$$

(3) *If $\Omega_{i,non}^\delta \cap \partial\Omega = \emptyset$, then $|\theta_i|^2_{H^1(\Omega_{i,non}^\delta)} = 0$.*

(4) *If $\Omega_{i,non}^\delta \cap \partial\Omega \neq \emptyset$, then*

$$|\theta_i|^2_{H^1(\Omega_{i,non}^\delta)} \leq C\left(1 + \log\left(\frac{H}{h}\right)\right).$$

Here $C > 0$ is independent of the parameters h, H, and δ.

5.2. A bounded partition lemma. To obtain the parameter C_0 of assumption (i) of the abstract AS theory (see Lemma 5.1), we construct a decomposition of $\widetilde{\mathcal{V}}^\delta$ and prove its boundedness below.

Lemma 5.4. *There exists a constant $C > 0$, independent of h, H, and δ, such that for any $u \in \widetilde{\mathcal{V}}^\delta$ there exist $v_i \in \widetilde{\mathcal{V}}_i^\delta$ such that*

$$u = \sum_{i=0}^{N} v_i \tag{5.2}$$

and

$$\begin{aligned}\sum_{i=0}^{N} |v_i|_{H^1(\Omega)}^2 \le C\left(\left(\frac{H}{(2\delta+1)h}\right)\right)|u|_{H^1(\Omega)}^2 \\ + C(1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right)|u|_{H^1(\Omega)}^2.\end{aligned} \tag{5.3}$$

In addition, there exist $u_i \in \widetilde{\mathcal{V}}_i^\delta$ such that

$$u = \sum_{i=1}^{N} u_i \tag{5.4}$$

and

$$\begin{aligned}\sum_{i=1}^{N} |u_i|_{H^1(\Omega)}^2 \le C\,(1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right)|u|_{H^1(\Omega)}^2 \\ + C\frac{1}{H^2}\left(1+\log(\delta+1)+\frac{H}{(2\delta+1)h}\right)|u|_{H^1(\Omega)}^2.\end{aligned} \tag{5.5}$$

Proof. We first construct the decomposition (5.4). For any given $u \in \widetilde{\mathcal{V}}^\delta$ we define $u_i \in \widetilde{\mathcal{V}}_i^\delta$ as

$$u_i(x_k) = \begin{cases} u(x_k) & \text{if } x_k \in W_{i,in}^\delta, \\ \text{discrete harmonic} & \text{if } x_k \in W_{i,ovl}^\delta, \\ 0 & \text{if } x_k \in W \backslash \widetilde{W}_i^\delta. \end{cases}$$

It is easy to see that (5.4) holds. We next construct the decomposition (5.2). For $i = 1, \dots, N$, let us define $v_i \in \widetilde{\mathcal{V}}_i^\delta$ by

$$v_i = u_i - \bar{u}_i \phi^i \in \widetilde{\mathcal{V}}_i^\delta,$$

where

$$\bar{u}_i = \frac{1}{|\Omega_i^\delta|}\int_{\Omega_i^\delta} u dx$$

is the average of u on the extended region Ω_i^δ. Here $|\Omega_i^\delta|$ is the area of the region Ω_i^δ. We also define

$$v_0 = \sum_{i=1}^{N} \bar{u}_i \phi^i.$$

It is easy to see that (5.2) holds.

The next step is to bound $\sum_{i=1}^{N} |v_i|^2_{H^1(\Omega)}$. To bound each term $|v_i|^2_{H^1(\Omega)}, i = 1, \dots, N$, we use $\theta_i(x), i = 1, \dots, N$, introduced before. Consider $\tilde{v}_i \in \mathcal{V}_i^\delta$ defined as follows:

$$\tilde{v}_i(x) = I_h(\theta_i(x)(u(x) - \bar{u}_i)).$$

Note that $\tilde{v}_i(x)$ is equal to $v_i(x)$ on $W_i^{\Gamma^\delta}$ and on $\partial\Omega_i^\delta$. On $\Omega^\delta_{i,ovl}$, v_i is discrete harmonic. Therefore, we have

$$|v_i|^2_{H^1(\Omega^\delta_{i,ovl})} \leq |\tilde{v}_i|^2_{H^1(\Omega^\delta_{i,ovl})}.$$

In addition, $v_i(x)$ is identical to $\tilde{v}_i$ on $\Omega^\delta_{i,non}$ whenever $\Omega^\delta_{i,non}$ does not touch $\partial\Omega$. For such cases, we next devote the proof to the estimate of $|\tilde{v}_i|^2_{H^1(\Omega_i^\delta)}$ in terms of $|u|^2_{H^1(\Omega_i^\delta)}$. The estimate of $|v_i|^2_{H^1(\Omega^\delta_{i,non})}$ for the case in which $\Omega^\delta_{i,non}$ does not touch $\partial\Omega$ is done afterwards in (5.10).

Let K be an element of Ω_i^δ, and let us define $w_i = u - \bar{u}_i$; then

$$(5.6)\qquad |\tilde{v}_i|^2_{H^1(K)} = |I_h(\theta_i w_i)|^2_{H^1(K)} \leq 2|\bar{\theta}_i w_i|^2_{H^1(K)} + 2|I_h((\bar{\theta}_i - \theta_i)w_i)|^2_{H^1(K)}.$$

Here, $\bar{\theta}_i$ is the average of θ_i on K, and I_h is the standard pointwise interpolation. To estimate the first part of (5.6) we use the fact that $|\bar{\theta}_i| \leq 1$ to obtain

$$|\bar{\theta}_i w_i|^2_{H^1(K)} = |\bar{\theta}_i(u - \bar{u}_i)|^2_{H^1(K)} \leq |u - \bar{u}_i|^2_{H^1(K)} = |u|^2_{H^1(K)}.$$

The last equality comes from the fact that $\bar{u}_i$ is a constant. For the second part of (5.6), according to an inverse inequality, we have

$$(5.7)\qquad |I_h((\bar{\theta}_i - \theta_i)w_i)|^2_{H^1(K)} \leq C\frac{1}{h^2}\|I_h((\bar{\theta}_i - \theta_i)w_i)\|^2_{L^2(K)}.$$

To obtain the bound for the right-hand side of (5.7), we consider the element K in four different situations corresponding to the four types of subregions into which the the subregion Ω_i^δ is split, i.e., $\Omega^\delta_{i,non}$, $\Omega_i^{\delta H}$, $\Omega_i^{\delta\tilde{\delta}}$, and $\Omega_i^{\delta\delta}$.

The proof for the cases $K \subset \Omega_i^{\delta H}$ and $K \subset \Omega_i^{\delta\tilde{\delta}}$ are nearly the same, so we only consider one of them here. For $K \subset \Omega_i^{\delta H}$, since

$$\|\bar{\theta}_i - \theta_i\|^2_{L^\infty(K)} \leq C\left(\frac{h}{(2\delta+1)h}\right)^2,$$

we obtain

$$\frac{1}{h^2}\|I_h((\bar{\theta}_i - \theta_i)w_i)\|^2_{L^2(K)} \leq C\frac{1}{((2\delta+1)h)^2}\|w_i\|^2_{L^2(K)}.$$

Applying a technique developed in Dryja and Widlund [11], we obtain

$$(5.8)\ \frac{1}{((2\delta+1)h)^2}\|w_i\|^2_{L^2(\Omega_i^{\delta H})} \leq C\left(\frac{H}{(2\delta+1)h}|w_i|^2_{H^1(\Omega_i^\delta)} + \frac{1}{H((2\delta+1)h)}\|w_i\|^2_{L^2(\Omega_i^\delta)}\right).$$

Using the fact that $|w_i|^2_{H^1(\Omega_i^\delta)} = |u|^2_{H^1(\Omega_i^\delta)}$ and a Friedrichs inequality, we have

$$(5.9)\qquad \|w_i\|^2_{L^2(\Omega_i^\delta)} \leq CH^2|u|^2_{H^1(\Omega_i^\delta)}.$$

Combining the estimates (5.8) and (5.9), we obtain

$$\frac{1}{((2\delta+1)h)^2}\|w_i\|^2_{L^2(\Omega_i^{\delta H})} \le C\frac{H}{(2\delta+1)h}|u|^2_{H^1(\Omega_i^\delta)}.$$

For the case when $K \subset \Omega_i^{\delta\delta}$, we use similar arguments as in Dryja, Smith, and Widlund [10] to obtain

$$\sum_{K\in\Omega_i^{\delta\delta}} \frac{1}{h^2}\|I_h((\bar{\theta}_i - \theta_i)w_i)\|^2_{L^2(K)} \le \sum_{K\in\Omega_i^{\delta\delta}} C\frac{1}{r^2}\|w_i\|^2_{L^2(K)}, \tag{5.10}$$

where $ch \le r \le C((\delta+1)h)$ is the distance to those "cut pieces." We have used here that $\theta_i(x)$ has the singular behavior C/r on $\Omega_i^{\delta\delta}$. We then have

$$\sum_{K\in\Omega_i^{\delta\delta}} \frac{1}{r^2}\|w_i\|^2_{L^2(K)} \le C\int_{ch}^{C(\delta+1)h}\int_\alpha r^{-2}r\|w_i\|^2_{L^\infty(\Omega_i^{\delta\delta})}d\alpha dr \tag{5.11}$$

and

$$\|w_i\|^2_{L^\infty(\Omega_i^{\delta\delta})} \le C\left(1+\log\left(\frac{H}{h}\right)\right)|u|^2_{H^1(\Omega_i^\delta)}. \tag{5.12}$$

For the inequality (5.12), we have used a well-known result (see Bramble [2])

$$\|u-\bar{u}_i\|^2_{L^\infty(\Omega_i^{\delta\delta})} \le \|u-\bar{u}_i\|_{L^\infty(\Omega_i^{\delta})} \le C\left(1+\log\left(\frac{H}{h}\right)\right)\|u-\bar{u}_i\|^2_{H^1(\Omega_i^\delta)}$$

and that $\bar{u}_i$ is the average of u on Ω_i^δ, i.e., a Friedrichs inequality,

$$\|u-\bar{u}_i\|^2_{H^1(\Omega_i^\delta)} \le C|u|^2_{H^1(\Omega_i^\delta)}.$$

Putting (5.11) and (5.12) together, we obtain

$$\sum_{K\in\Omega_i^{\delta\delta}} \frac{1}{r^2}\|w_i\|^2_{L^2(K)} \le C\left((1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right)\right)|u|^2_{H^1(\Omega_i^\delta)}. \tag{5.13}$$

For the case $K \subset \Omega^\delta_{i,non}$, if Ω_i^0 is a floating subdomain, which is to say that $\Omega^\delta_{i,non}$ does not touch $\partial\Omega$, then $\bar{\theta}_i - \theta_i$ is zero. If $\Omega^\delta_{i,non}$ touches the boundary $\partial\Omega$, then the estimate becomes

$$\begin{aligned} |v_i|^2_{H^1(\Omega^\delta_{i,non})} &\le C\left(|u|^2_{H^1(\Omega^\delta_{i,non})} + |\bar{u}_i|^2|\phi^i|^2_{H^1(\Omega^\delta_{i,non})}\right) \\ &\le C\left(1+\log\left(\frac{H}{h}\right)\right)|u|^2_{H^1(\Omega_i^\delta)}. \end{aligned} \tag{5.14}$$

Here we have used Lemma 5.3 and that for the cases $i \in \partial\Omega$ we can use a Poincaré inequality to obtain

$$\sum_{i\in\partial\Omega}|\bar{u}_i|^2 \le C\sum_{i\in\partial\Omega}\frac{1}{H^2}\|u\|^2_{L^2(\Omega_i^\delta)} \le C\sum_{i\in\partial\Omega}|u|^2_{H^1(\Omega_i^\delta)} \le C|u|^2_{H^1(\Omega)}. \tag{5.15}$$

Here we have introduced the notation $i \in \partial\Omega$ to denote the subdomains Ω_i^0 that touch the boundary $\partial\Omega$ with a face.

Putting everything together, we have shown that

$$\sum_{i=1}^{N} |v_i|_{H^1(\Omega)}^2 \leq C\left(\left(\frac{H}{(2\delta+1)h}\right)\right)|u|_{H^1(\Omega)}^2 + C(1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right)|u|_{H^1(\Omega)}^2. \tag{5.16}$$

We remark that the bound (5.3) follows from (5.16). To see this, we use that $v_0 = u - \sum_i v_i$, the triangular inequalities, and (5.16) to obtain (5.3).

We now consider the bound for the one-level RASHO method, i.e., to bound $\sum_{i=1}^N u_i$. Note that

$$\sum_{i=1}^{N} u_i = \sum_{i=1}^{N} v_i + \sum_{i=1}^{N} \bar{u}_i \phi^i.$$

For the second sum above, we first use Lemma 5.3 to obtain

$$\sum_{i=1}^{N} |\bar{u}_i \phi^i|_{H^1(\Omega)}^2 \leq C\left(1+\log\left(\frac{H}{h}\right)\right)\sum_{i\in\partial\Omega} |\bar{u}_i|^2 + C\left(1+\log(\delta+1)+\frac{H}{(2\delta+1)h}\right)\sum_{i=1}^{N}|\bar{u}_i|^2.$$

We then use the Cauchy–Schwarz and Friedrichs inequalities to obtain

$$\begin{aligned}\sum_{i=1}^{N}|\bar{u}_i|^2 = \sum_{i=1}^{N}\left(\frac{1}{|\Omega_i^\delta|}\int_{\Omega_i^\delta} u dx\right)^2 &\leq C\sum_{i=1}^{N}\frac{1}{H^2}\|u\|_{L^2(\Omega_i^\delta)}^2 \\ &\leq C\frac{1}{H^2}\|u\|_{L^2(\Omega)}^2 \leq C\frac{1}{H^2}|u|_{H^1(\Omega)}^2.\end{aligned}$$

For the cases $i \in \partial\Omega$, we use (5.15). The inequality (5.5) then follows. □

5.3. The main theorem. We state the main theorem of this paper here. The proof follows directly from all the abstract Schwarz theory given by Lemmas 5.1, 5.2, and 5.4.

THEOREM 5.1. *The RASHO operators $\widetilde{P}^\delta$, $\widetilde{P}_C^\delta$, and $\widetilde{P}_{hyb}^\delta$ are symmetric in the inner product $a(\cdot,\cdot)$, nonsingular, and bounded from below and above:*

$$C_0^{-2}a(u,u) \leq a(\widetilde{P}_C^\delta u, u) \leq C_1 a(u,u) \qquad \forall u \in \widetilde{\mathcal{V}}^\delta,$$

$$\hat{C}_0^{-2}a(u,u) \leq a(\widetilde{P}^\delta u, u) \leq \hat{C}_1 a(u,u) \qquad \forall u \in \widetilde{\mathcal{V}}^\delta,$$

and

$$\kappa(\widetilde{P}_{hyb}^\delta) \leq \kappa(\widetilde{P}_C^\delta).$$

Here

$$C_0^2 = C\left(\frac{H}{(2\delta+1)h} + (1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right)\right)$$

and

$$\hat{C}_0^2 = C\left((1+\log(\delta+1))\left(1+\log\left(\frac{H}{h}\right)\right) + \frac{1}{H^2}\left(1+\log(\delta+1)+\frac{H}{(2\delta+1)h}\right)\right).$$

The constants $C, C_1, \hat{C}_1 > 0$ are independent of h, H, and δ.

We remark that the corresponding convergence rate estimate for the regular one-level AS methods [11], in terms of the constant $\hat{C}_0$, is

$$\hat{C}_0^2 = C\left(1+\frac{1}{H(2\delta+1)h}\right),$$

and that for the two-level additive Schwarz method is

$$C_0^2 = C\left(1+\frac{H}{\delta h}\right).$$

The lower bound $\hat{C}_0^2$ of the one-level RASHO algorithm is theoretically slightly worse than the lower bound of regular AS algorithm in the case of large overlap, but roughly the same for small overlap. For small overlap, the lower bounds of both algorithms behave like $O(H/h)$. When the overlap gets larger, the RASHO scheme starts to feel the factor $\log(H/h)$, and the performance gets worse than the additive version for large overlap. On the other hand, the upper bound C_1 of RASHO is smaller than the upper bounds of AS. We can see this since $\widetilde{\mathcal{V}}_k^\delta \subset \mathcal{V}_k^\delta \ \forall k$ implies that the positive numbers ϵ_{ij} defined in Lemma 5.1 are smaller for RASHO than the corresponding ϵ_{ij} for AS. Consequently, the spectral radius $\mathcal{E}$ of RASHO is smaller. Because C_1 of RASHO is smaller, the numerical performance of RASHO presented in the next section is better than that of AS for the practical cases. Similar considerations also apply to the two-level RASHO methods.

6. Numerical experiments. In this section, we present some numerical results for solving the Poisson equation on the unit square with zero Dirichlet boundary conditions. We compare the performance of RASHO- and AS-preconditioned CG methods in terms of the number of iterations and the condition numbers. We pay particular attention to the dependence of the performance on the number of subdomains and the size of overlap.

We first discuss a few implementation issues related to the new preconditioner. In order to apply the RASHO/CG method, it is necessary to force the solution to belong to $\widetilde{\mathcal{V}}^\delta$. To do this, a pre-CG-computation is needed, and it is done through the formula (3.5). We note that $u = u^* - w \in \widetilde{\mathcal{V}}^\delta$ (see Lemma 3.1), and therefore we can apply the regular preconditioned CG to the RASHO-preconditioned system (3.9). The AS/CG is the classical AS preconditioned CG as described in [8]. We note that in the case $\delta = 0$, i.e., $ovlp = h$, RASHO and AS are the same.

The stopping condition for the CG method is to reduce the initial residual by a factor of 10^{-6}. The exact solution of the equation is $u(x,y) = e^{5(x+y)}\sin(\pi x)\sin(\pi y)$. All subdomain problems are solved exactly. The iteration counts (iter), condition numbers (cond), maximum (max) and minimum (min) eigenvalues of the preconditioned matrix are summarized in Tables 6.1–6.5.

From Tables 6.1, 6.2, and 6.3, it is clear that for overlap not too large and for mesh not too small, which is the case of practical interest, the one-level RASHO/CG outperforms the classical one-level AS/CG in terms of the iteration counts and condition numbers. In this case of small overlap, the condition number of RASHO is

almost twofold smaller than AS. This is an important result since it is easy to modify a (parallel) one-level AS/CG code to obtain a one-level RASHO/CG implementation. Although we do not have any parallel results to report here, we confidently predict that RASHO/CG would be even better than AS/CG on a parallel computer with distributed memory, since many less communications are required. Also the local solvers in RASHO are slightly cheaper, since the local solvers have slightly smaller numbers of unknowns than for the regular AS. From Table 6.4 we see that both the two-level hybrid and additive versions of RASHO attain scalability in terms of number of iterations when the number of subdomains becomes large; the hybrid version reaches the asymptotic behavior sooner than the additive version. The hybrid version is superior to the additive version since the number of iterations is much smaller. Finally, from Table 6.5 we see that larger overlap reduces dramatically the number of iterations.

A NUMERICAL METHOD FOR AN INTEGRO-DIFFERENTIAL EQUATION WITH MEMORY IN BANACH SPACES: QUALITATIVE PROPERTIES[*]

E. CUESTA[†] and C. PALENCIA[†]

Abstract. A first order method is considered for the discretization in time of an integro-differential equation, which can be written as $D^\alpha u(t) = Au(t) + f(t)$, $1 < \alpha < 2$, where $A : D(A) \subset X \to X$ is a sectorial operator in a Banach space X. Qualitative properties of the numerical solution, such as contractivity and positivity, are studied. A numerical illustration is provided.

Key words. integro-differential equations, memory, parabolic, sectorial operator, Banach space, Euler method, fractional quadrature, positivity, contractivity

1. Introduction.

In the present paper we consider a numerical method for the time discretization of the problem

$$\left\{\begin{array}{rcl} u'(t) &=& \dfrac{1}{\Gamma(\alpha-1)}\displaystyle\int_0^t (t-s)^{\alpha-2} Au(s)\,ds + f(t), \qquad 0 \le t \le T, \\ u(0) &=& u_0 \in D(A), \end{array}\right. \tag{1}$$

where $A : D(A) \subset X \to X$ is a linear, closed operator in a complex Banach space X and $f : [0,T] \to X$. The parameter α lies in the open interval $(1,2)$. The operator A is assumed to be sectorial, and the precise hypothesis concerning A is given in section 2.

These equations with memory are of interest in connection with several applications (see [1, 12]). Formally, the equation in (1) can be viewed as (see [5, 6])

$$D^\alpha u(t) = Au(t) + D^{\alpha-1} f(t),$$

where D^α and $D^{\alpha-1}$ stand for the fractional time derivatives, defined in terms of the Riemann–Liouville operator (see [5, 7, 11, 13]). Thus, the equation in (1) is intermediate between the one with $\alpha = 1$,

$$\left\{\begin{array}{rcl} u'(t) &=& Au(t) + f(t), \\ u(0) &=& u_0, \end{array}\right.$$

and the one with $\alpha = 2$,

$$\left\{\begin{array}{rcl} u''(t) &=& Au(t) + f'(t), \\ u(0) &=& u_0, \\ u_t(0) &=& 0. \end{array}\right.$$

Numerical methods for (1) have been considered in [10, 14] in the context of self-adjoint operators in Hilbert spaces and in [3] in the context of sectorial operators in Banach spaces. Here we consider the method introduced in [10] and [14]. This scheme combines the backward Euler method with an appropriate quadrature rule for the integral (see [8]). The analysis in [10] can be extended to the present framework of sectorial operators and Banach spaces. Moreover, as remarked at the end of section 3, the convergence can also be proved from the results in [8, 9]. Because of this, we focus only on some qualitative properties of the method.

A brief review of the continuous problem (1) is given in section 2, where some new qualitative properties are also deduced. The numerical method is presented in section 3. It is shown, in section 4, that the values provided by the method can be expressed as certain averages of the continuous solution under discretization. From this representation we deduce that the numerical method inherits qualitative properties such as contractivity and positivity from the continuous solution. A numerical illustration is given in section 5.

2. Continuous problem.

In this section, for the convenience of the reader, we recall some basic facts about the solutions of (1). We also derive some new results concerning their qualitative behavior.

Notice that problem (1) is well posed (see [2, 12]) when A is sectorial and its spectral angle is small enough. To be precise, when there exist $\omega \in \mathbb{R}$, $0 < \theta < \pi(2-\alpha)/2$, and $M \geq 1$ such that, for $z \in \mathbb{C}$ outside the sector

$$\omega + S_\theta = \omega + \{\mu \in \mathbb{C} \;/\; |\arg(-\mu)| \leq \theta\},$$

the resolvent $(z-A)^{-1} : X \to X$ exists and

$$\|(z-A)^{-1}\| \leq \frac{M}{|z-\omega|}, \qquad z \notin \omega + S_\theta. \tag{2}$$

In the rest of the paper we assume that A is sectorial in this sense.

Suppose first that $f = 0$, and let $u : [0,T] \to X$ be a solution of (1). Assume that u is of exponential growth. Then taking the Laplace transform on both sides of (1) leads to (see [2, 6])

$$U(z) = z^{\alpha-1}(z^\alpha - A)^{-1}u_0, \qquad |\arg(z-\omega)| < (\pi-\theta)/\alpha, \tag{3}$$

where U stands for the Laplace transform of u. Thus, by the inversion formula, it turns out that

$$u(t) = E_\alpha(t)u_0, \qquad t \geq 0, \tag{4}$$

where $E_\alpha(t) : X \to X$, $t > 0$, is the bounded operator

$$E_\alpha(t) := \frac{1}{2\pi i}\int_\Gamma e^{tz} z^{\alpha-1}(z^\alpha - A)^{-1}\,dz,$$

Γ being a suitable path connecting $-i\infty$ with $+i\infty$.

For arbitrary $u_0 \in X$ we define the generalized solution of the corresponding Cauchy problem (1) by the expression in (4). The above discussion shows that a solution of exponential growth is necessarily the generalized solution corresponding to its initial value.

If $f \neq 0$, then it is well known that the solution is represented by means of the variation-of-constant formula

$$u(t) = E_\alpha(t)u_0 + \int_0^t E_\alpha(t-s)f(s)\,ds, \qquad t \geq 0. \tag{5}$$

For $\omega = 0$ and $t > 0$ we can take $\Gamma = \Gamma_t$ as the positive boundary of the union of S_θ and the circle $|z| = 1/t^\alpha$. Then, by (2), it is straightforward to prove that

$$\|E_\alpha(t)\| \leq CM, \tag{6}$$

where $C > 0$ stands for a constant depending only on α and θ. This estimate can also be proved by other means (see [12, Corollary 6.4]).

For $\omega < 0$ we can choose $\Gamma = \tilde{\Gamma}_t$ to be the boundary of the sector S_θ. Using again (2), this time we obtain

$$\|E_\alpha(t)\| \leq \frac{CM}{(2-\alpha)|\omega|t^\alpha}, \qquad t > 0,$$

which combined with (6) results finally in

$$\|E_\alpha(t)\| \leq \frac{CM}{1 + (2-\alpha)|\omega|t^\alpha}. \tag{7}$$

The case $\omega > 0$ is a bit more cumbersome. By arguments similar to the ones used in [2] we can establish now that

$$\|E_\alpha(t)\| \leq CM(1 + \ln^+(t\omega^{1/\alpha}))e^{t\omega^{1/\alpha}}. \tag{8}$$

In the remainder of the paper, for simplicity, we will assume that $\omega = 0$. When $\omega \neq 0$ the estimates we will derive are affected by similar factors to those appearing in (7) or (8).

It is also true that the family $E_\alpha(t)$, $t > 0$, is strongly continuous. Continuity at 0^+ holds in the case where A is densely defined.

To end this section we present some new estimates relating the qualitative behavior of $E_\beta(t)$ to the ones of $E_\alpha(t)$, $1 < \beta < \alpha < 2$.

Lemma 2.1. *For $0 < \mu < 1$, let $K_\mu : (0, +\infty) \times (0, +\infty) \to \mathbb{C}$ be the mapping defined by*

$$K_\mu(\sigma, t) := \frac{1}{2\pi i}\int_{-i\infty}^{+i\infty} e^{st - \sigma s^\mu}\,ds, \qquad \sigma > 0, \quad t > 0.$$

Then there exist constants $c = c(\mu) > 0$ and $C = C(\mu) > 0$ such that, for any $a > 0$,

$$K_\mu(\sigma, t) \leq C \min\left\{\frac{1}{t}, \frac{e^{at - ca^\mu\sigma}}{\sigma^{1/\mu}}\right\}, \qquad \sigma > 0, \quad t > 0.$$

Moreover,

$$K_\mu(\sigma, t) \geq 0, \qquad \sigma > 0, \quad t > 0.$$

Proof. The positivity of K_μ is provided by Proposition 2 in Chapter IX of [16].

On the other hand, for $a > 0$ fixed, let Γ_1 be the positive boundary of a sector S_φ with $0 < \varphi < \pi/2$ and $(\pi - \varphi)\mu \geq \pi/2$. Notice that there exists $C = C(\mu) > 0$ such that

$$|e^{st-\sigma s^\mu}| \leq Ce^{-|s|t\cos\varphi}, \qquad s \in \Gamma_1.$$

Therefore,

$$|K_\mu(\sigma, t)| \leq \frac{C}{2\pi}\int_{\Gamma_1} e^{-|s|t\cos\varphi}\,|ds| \leq \frac{C}{\pi t\cos\varphi}.$$

Besides, let us consider the path $\Gamma_2(\xi) = a + i\xi$, $-\infty < \xi < +\infty$. Now, for $s = a + i\xi \in \Gamma_2$, we have

$$|s^\mu| = (a^2 + \xi^2)^{\mu/2} \geq 2^{\mu/2-1}(a^\mu + |\xi|^\mu)$$

and $|\arg(s^\mu)| \leq \pi\mu/2$ so that

$$|e^{st-\sigma s^\mu}| \leq e^{at}e^{-ca^\mu\sigma}e^{-c|\xi|^\mu\sigma},$$

where $c = \cos(\pi\mu/2)/2^{\mu/2-1}$. Therefore,

$$|K_\mu(\sigma, t)| \leq \frac{1}{\pi}e^{at}\,e^{-ca^\mu\sigma}\int_0^{+\infty} e^{-c\sigma\xi^\mu}\,d\xi = \frac{1}{\pi}e^{at}\,e^{-ca^\mu\sigma}\frac{\Gamma(1/\mu)}{\mu(c\sigma)^{1/\mu}}. \qquad \square$$

THEOREM 2.2. *For $1/\alpha < \mu < 1$ and $t > 0$ there holds*

$$E_{\alpha\mu}(t) = \frac{1}{\Gamma(1-\mu)}\int_0^t \frac{1}{(t-\tau)^\mu}\left[\int_0^{+\infty} K_\mu(\sigma, \tau)E_\alpha(\sigma)\,d\sigma\right]d\tau. \tag{9}$$

Proof. Set $h_\mu(t) = t^{-\mu}/\Gamma(1-\mu)$ and

$$E_\alpha^\mu(t) = \int_0^{+\infty} K_\mu(\sigma, t)E_\alpha(\sigma)\,d\sigma, \qquad t > 0.$$

Since the integrand is strongly continuous and, because of the previous lemma, absolutely convergent (this is true even for $\omega \neq 0$), it turns out that the integral exists in the strong sense and that the operators $E_\alpha^\mu(t)$ are uniformly bounded in $t > 0$.

Notice that for fixed $\sigma > 0$ the Laplace transform of $t \to K_\mu(\sigma, t)$ is the mapping $s \to e^{-\sigma s^\mu}$. Therefore, the Laplace transform of $t \to E_\alpha^\mu(t)$ is

$$\mathcal{L}E_\alpha^\mu(s) = \int_0^{+\infty} e^{-\sigma s^\mu}E_\alpha(\sigma)\,d\sigma, \qquad \Re(s) > 0.$$

Recalling (3) we deduce that

$$\mathcal{L}E_\alpha^\mu(s) = s^{\mu(\alpha-1)}(s^{\alpha\mu} - A)^{-1}, \qquad \Re(s) > 0,$$

so that the Laplace transform of $h_\mu * E_\alpha^\mu$ is

$$\mathcal{L}(h_\mu * E_\alpha^\mu)(s) = s^{\mu-1}s^{\mu(\alpha-1)}(s^{\alpha\mu} - A)^{-1} = s^{\mu\alpha-1}(s^{\alpha\mu} - A)^{-1}, \qquad \Re(s) > 0,$$

which, by (3) applied to $\alpha\mu$, is the Laplace transform of $E_{\alpha\mu}$. $\square$

Corollary 2.3. *Let $u_0 \in X$, and assume that $\|E_\alpha(t)u_0\| \leq H$ for $t > 0$. Then, for $1/\alpha < \mu < 1$, there holds*

$$\|E_{\alpha\mu}(t)u_0\| \leq H, \qquad t > 0.$$

Proof. Notice that the equation in (2.2) with $A = 0$ reduces to

$$\frac{1}{\Gamma(1-\mu)} \int_0^t \frac{1}{(t-\tau)^\mu} \left[\int_0^{+\infty} K_\mu(\sigma,\tau)\, d\sigma \right] d\tau = 1.$$

Then, since $K_\mu \geq 0$, taking norms in (9) leads to

$$\|E_{\mu\alpha}(t)u_0\| \leq \frac{H}{\Gamma(1-\mu)} \int_0^t \frac{1}{(t-\tau)^\mu} \left[\int_0^{+\infty} K_\mu(\sigma,\tau)\, d\sigma \right] d\tau \leq H. \qquad \square$$

In the same way we can prove the next corollary.

Corollary 2.4. *Assume that X is an ordered Banach lattice (see* [15]*). If $u_0 \in X$ is such that*

$$E_\alpha(t)u_0 \geq 0, \qquad t > 0,$$

then, for $1/\alpha < \mu < 1$, we also have

$$E_{\alpha\mu}(t)u_0 \geq 0, \qquad t > 0.$$

It is possible to prove that Theorem 2.2 and its corollaries are valid even for $\alpha = 2$, under the hypothesis that now A generates a cosine family (see [4]). Thus, for instance, since the one-dimensional wave equation with Dirichlet conditions

$$\left\{ \begin{array}{rcll} u_{tt}(t,x) & = & u_{xx}(t,x), & 0 \leq x \leq L, \quad t \geq 0, \\ u(0,x) & = & u_0(x), & 0 \leq x \leq L, \\ u_t(0,x) & = & 0, & 0 \leq x \leq L, \\ u(t,0) & = & 0, & t \geq 0, \\ u(t,L) & = & 0, & t \geq 0, \end{array} \right.$$

is contractive with respect to the maximum norm, i.e.,

$$\|u(t,\cdot)\|_\infty \leq \|u_0\|_\infty, \qquad t \geq 0,$$

Corollary 2.3 shows that $\|E_\beta(t)\| \leq 1$, $t \geq 0$, $1 < \beta < 2$, with respect to the maximum norm, where $E_\beta(t)$ is the evolution operator corresponding to (1) and the operator $A\phi := \phi''$ acting on the domain

$$D(A) = \{\phi \in \mathcal{C}[0,L] \;/\; \phi'' \in \mathcal{C}[0,L] \text{ and } \phi(0) = \phi(L) = 0\}.$$

In the case of Neumann boundary conditions, the one-dimensional wave equation preserves positivity. Therefore, by Corollary 2.4, this property remains valid for the corresponding $E_\beta(t)$, $t > 0$, for $1 < \beta < 2$. These qualitative results extend those in [5, 6].

3. The numerical method. The numerical method we propose for (1) has already been considered in [10] and [14] in the context of Hilbert spaces and self-adjoint operators. The basic idea is to combine the classical backward Euler method with a suitable quadrature rule for approximating the integral term, which is the fractional quadrature rule generated by the rectangle rule (see [2, 8]). The resulting numerical method reads

$$\frac{U_n - U_{n-1}}{\tau} = \sum_{j=1}^{n} q_{n-j}^{(\alpha-1)} A U_j + \tau f(t_n), \qquad 0 < n \leq [T/\tau], \tag{10}$$

where $\tau > 0$ stands for the step size, $t_n = n\tau$, and $U_n \in X$ are the approximations to $u(t_n)$ we are looking for. The weights $q_n^{(\alpha-1)}$ are given by

$$\sum_{n=0}^{+\infty} q_n^{(\alpha-1)} z^n := \left(\frac{\tau}{\delta(z)} \right)^{\alpha-1},$$

where

$$\delta(z) := 1 - z.$$

Therefore, the weights turn out to be

$$q_n^{(\alpha-1)} := \tau^{\alpha-1} (-1)^n \binom{1-\alpha}{n}.$$

As starting value U_0 we can take either u_0 or an available approximation to u_0.

Notice that (10) is an implicit scheme. To obtain U_n from $U_0, U_1, \ldots, U_{n-1}$ we must solve the linear equation

$$(I - \tau^\alpha A) U_n = U_{n-1} + \tau \sum_{j=1}^{n-1} q_{n-j}^{(\alpha-1)} A U_j + \tau f(t_n), \tag{11}$$

which, since $\omega = 0$, possesses a unique solution (in general, for $\omega \neq 0$, a sufficient condition for the uniqueness and solvability of (11) is $\max\{\omega, 0\} \cdot \tau^\alpha < 1$).

For the analysis of the method it is convenient to rewrite (10) in terms of generating functions. To this end, without loss of generality, we assume that f and u are defined on $[0, +\infty)$. Thus, set

$$U(z) := \sum_{n=1}^{+\infty} U_n z^n, \qquad F(z) := \sum_{n=1}^{+\infty} f(t_n) z^n, \qquad Q(z) := \frac{\tau}{\delta(z)}.$$

Multiplying (10) by z^n and summing up in n we obtain

$$U(z) - zU(z) - zU_0 = \tau Q(z)^{\alpha-1} A U(z) + \tau F(z)$$

or

$$(I - Q(z)^\alpha A) U(z) = \frac{z}{1-z} U_0 + \frac{\tau}{1-z} F(z).$$

Therefore, since

$$I - Q(z)^\alpha A = Q(z)^\alpha \left(\frac{1}{Q(z)^\alpha} - A \right),$$

and since, for $|z| = r < 1$, we have $\Re((1-z)/\tau) > 0$, it is clear that $I - Q(z)^\alpha A$ is invertible and that

$$(I - Q(z)^\alpha A)^{-1} = \frac{1}{Q(z)^\alpha}\left(\frac{1}{Q(z)^\alpha} - A\right)^{-1}$$

is a holomorphic operator-valued mapping. Cauchy's formula shows now that

$$\frac{z}{1-z}(I - Q(z)^\alpha A)^{-1} = \sum_{n=1}^{+\infty} D_n^{(\alpha)} z^n, \qquad |z| < 1,$$

where the bounded operators $D_n^{(\alpha)} : X \to X$, $n \geq 1$, are given by

$$D_n^{(\alpha)} = \frac{1}{2\pi i}\int_{|z|=r} \frac{1}{(1-z)z^n}(I - Q(z)^\alpha A)^{-1}\, dz, \qquad 0 < r < 1.$$

Going back to (11) we obtain the following expression for the numerical approximation:

$$U_n = D_n^{(\alpha)} U_0 + \tau \sum_{j=1}^{n} D_{n+1-j}^{(\alpha)} f(t_j), \qquad n \geq 1. \tag{12}$$

The above representation shows that the numerical scheme makes sense even for starting values $u_0 \in X$ which are not in $D(A)$.

It is also of interest to connect this method with the approach in [8, 9]. Assume that $U_0 = 0$. Now, in view of (5), we have

$$u(t) = \int_0^t E_\alpha(t-s) f(s)\, ds, \qquad t \geq 0.$$

Discretizing this convolution by the method in [8, 9] leads to approximations

$$U_n = \tau \sum_{j=0}^{n} L_{n-j}^{(\alpha)} f(t_j) \simeq u(t_n), \tag{13}$$

where the operators $L_n^{(\alpha)} : X \to X$ are defined by

$$\sum_{n=0}^{+\infty} L_n^{(\alpha)} z^n := \frac{1}{\tau} F_\alpha\left(\frac{\delta(z)}{\tau}\right), \tag{14}$$

and F_α stands for the Laplace transform of E_α, i.e.,

$$F_\alpha(\xi) := \int_0^{+\infty} e^{-\xi t} E_\alpha(t)\, dt = \xi^{\alpha-1}(\xi^\alpha - A)^{-1}.$$

Since

$$\frac{1}{\tau} F_\alpha\left(\frac{\delta(z)}{\tau}\right) = \frac{1}{1-z}(I - Q(z)^\alpha A)^{-1},$$

comparison of (13) with (12) shows readily that

$$D_n^{(\alpha)} = L_{n-1}^{(\alpha)}, \qquad n \geq 1, \tag{15}$$

a useful result we use later.

Finally, notice that (15), together with the stability of the method (see the next section), allows us to prove that the method is convergent of first order just by using Theorem 3.1 in [8]. Besides, Theorem 4.1 in [8] yields an optimal estimate in the case where $u_0 \notin D(A)$.

4. Qualitative behavior of the numerical solutions. The next theorem provides a representation of the discrete evolution operators $D_n^{(\alpha)}$ as an average of the continuous ones $E_\alpha(t)$, $t > 0$. This, combined with (12), allows us to obtain several interesting properties concerning the qualitative behavior of U_n.

For fixed $\tau > 0$, we set

$$\rho_n(t) := e^{-t/\tau} \left(\frac{t}{\tau}\right)^{n-1} \frac{1}{\tau(n-1)!}, \qquad t \geq 0, \quad n \geq 1.$$

Notice that $\rho_n(t) \geq 0$ and that

$$\int_0^{+\infty} \rho_n(t)\, dt = 1.$$

Theorem 4.1. *For $n \geq 1$ there holds*

$$D_n^{(\alpha)} = \int_0^{+\infty} E_\alpha(t) \rho_n(t)\, dt.$$

Proof. By definition (14), we have

$$\sum_{n=0}^{+\infty} L_n^{(\alpha)} z^n = \frac{1}{\tau} \int_0^{+\infty} E_\alpha(t) e^{-t\delta(z)/\tau}\, dt.$$

Then, since

$$\frac{1}{\tau} e^{-t\delta(z)/\tau} = \sum_{n=0}^{+\infty} \rho_{n+1}(t) z^n, \qquad t > 0,$$

we obtain

$$L_n^{(\alpha)} = \int_0^{+\infty} \rho_{n+1}(t) E_\alpha(t)\, dt, \qquad n \geq 0,$$

and the theorem is now clear because of (15). □

From this theorem we derive several corollaries whose proofs are obvious. For simplicity, we consider only $f = 0$. Related results for nonhomogeneous problems could be obtained by using (12).

Corollary 4.2. *Let $U_0 \in X$, and assume that $\|E_\alpha(t) U_0\| \leq H$, $t > 0$. Then*

$$\|D_n^{(\alpha)} U_0\| \leq H, \qquad n \geq 1.$$

In particular, the previous corollary shows that

$$\|D_n^{(\alpha)}\| \leq \sup_{t \geq 0} \|E_\alpha(t)\|, \qquad n \geq 1,$$

i.e., that the numerical scheme is stable. Using (6), we see that the stability constant is less than or equal to CM. Finally, notice that if $E_\alpha(t)$, $t > 0$, are contractions (recall Theorem 2.2), we also have that $D_n^{(\beta)}$, $n \geq 1$, are contractions for $1 < \beta \leq \alpha$.

Corollary 4.3. *Assume that X is an ordered Banach lattice (see* [15]*) and that for some $U_0 \in X$ we have $E_\alpha(t) U_0 \geq 0$, $t \geq 0$. Then*

$$D_n^{(\alpha)} U_0 \geq 0, \qquad n \geq 1.$$

Corollary 4.3 shows in particular that if $E_\alpha(t) \geq 0$, $t \geq 0$ (i.e. the operators $E_\alpha(t)$ are order-preserving), then $D_n^{(\alpha)} \geq 0$, $n \geq 1$. To illustrate the scope of Corollary 4.3 in situations where $E_\alpha(t)$ are not order-preserving let us consider the three-dimensional wave equation. For radial initial data

$$u_0(r) = \frac{f(r)}{r}$$

the solution of

$$\begin{cases} u_{tt}(t,r) &= c^2 \Delta u(t,r), \\ u(0,r) &= u_0(r), \\ u_t(0,r) &= 0 \end{cases}$$

turns out to be

$$u(t,r) = \frac{1}{2r}\left[f(r+ct) + f(r-ct)\right].$$

Therefore, if $u_0 \geq 0$, we have that $u(r,t) \geq 0$. Then, by Theorem 2.2, we deduce that $E_\alpha(t)u_0 \geq 0$, $1 < \alpha < 2$, where $E_\alpha(t)$ is the evolution operator that corresponds to $A = \Delta$ in (1). Now Corollary 4.3 shows that $D_n^{(\alpha)} u_0 \geq 0$, $n \geq 1$.

5. Numerical illustration. Let us consider the two-dimensional problem

$$\begin{cases} u_t(t,x,y) &= \dfrac{1}{\Gamma(\alpha-1)} \displaystyle\int_0^t (t-s)^{\alpha-2} \Delta u(s,x,y)\, ds, \qquad (x,y) \in \Omega, \\ u(0,x,y) &= u_0(x,y), \qquad (x,y) \in \Omega, \end{cases}$$

in the square $\Omega = [0,1] \times [0,1]$ with homogeneous Neumann boundary condition

$$D_n u(t,x,y), \qquad (x,y) \in \partial\Omega, \quad t \geq 0.$$

As an initial condition we take the indicator mapping of the subsquare $[1/3, 1/7] \times [1/3, 1/7]$. Notice that, by the maximum principle, for $\alpha = 1$ the solution is nonnegative. This problem is fully discretized by using first centered finite differences in space, with parameter h, and then applying method (10) to the resulting semidiscrete problem with step size τ.

Let A_h be the matrix corresponding to the discrete Laplacian, and denote by $E_{\alpha,h}(t)$ the corresponding evolution operators. Since A_h is symmetric, nonpositive, and diagonally dominant, it is well known that $E_{1,h}(t) = e^{tA_h}$ preserves the positivity. For $\alpha = 1.1, h = 1/50$, and $\tau = 1/200$ it turns out that $\min U_6 = -0.1164$. Because of Theorem 4.1 we deduce that $E_{\alpha,h}(t)$ cannot be positive for $1.1 \leq \alpha < 2$. Thus, in view of Corollary 4.3, this experiment suggests that $E_\alpha(t)$ is not positive either for $1.1 \leq \alpha < 2$. It is reasonable to conjecture that, in fact, $E_\alpha(t)$ does not preserve the positivity for $1 < \alpha < 2$.

Acknowledgment. The authors wish to express their gratitude to Prof. Ch. Lubich for several remarks which greatly improved the presentation of the paper.

VARIABLE PRECONDITIONING VIA QUASI-NEWTON METHODS FOR NONLINEAR PROBLEMS IN HILBERT SPACE*

JÁNOS KARÁTSON† AND ISTVÁN FARAGÓ†

Abstract. The aim of this paper is to develop stepwise variable preconditioning for the iterative solution of monotone operator equations in Hilbert space and apply it to nonlinear elliptic problems. The paper is built up to reflect the common character of preconditioned simple iterations and quasi-Newton methods. The main feature of the results is that the preconditioners are chosen via spectral equivalence. The latter can be executed in the corresponding Sobolev space in the case of elliptic problems, which helps both the construction and convergence analysis of preconditioners. This is illustrated by an example of a preconditioner using suitable domain decomposition.

Key words. variable preconditioning, quasi-Newton methods, iterative methods in Hilbert space, nonlinear elliptic problems

1. Introduction.

The aim of this paper is to develop stepwise variable preconditioning for the iterative solution of monotone operator equations

$$F(u) = 0 \tag{1}$$

in Hilbert space and apply it to nonlinear elliptic boundary value problems.

Nonlinear elliptic problems arise in many applications in physics and other fields, for instance in elastoplasticity, magnetic potential equations, and flow problems. The most frequently used numerical methods for nonlinear elliptic problems rely on some discretized form of the problem, whose solution is obtained by an iterative method. Simple iteration is often able to yield favorable speed of global convergence if supplied with suitable preconditioning, and in these cases its usage can be justified versus Newton's method owing to the extra work of forming the Jacobians (see, e.g., [2, 5]). Hence, similarly to linear problems, preconditioning is most times a crucial element of the construction of the iterative method. The choice of preconditioners is often helped by Hilbert space background, which helps both the construction of methods and the study of convergence. A typical example of this is the Sobolev gradient technique [25, 26]. (For the authors' related results see, e.g., [6, 15, 20].) In the case of monotone operators a natural kind of preconditioning is based on spectral equivalence, in an analogous way to symmetric linear equations. Namely, preconditioners are chosen to be globally spectrally equivalent to the derivatives $F'(u)$ of the operator in each point. A Hilbert space framework has been developed for this in [21], in which preconditioners for the discretized elliptic systems are found as projections of linear operators chosen as preconditioners for the original nonlinear differential operator.

The above described simple iterations are globally preconditioned in the sense that the preconditioners are the same in each step and rely on the global behavior of

$F'(u)$. However, this may be insufficient since the global convergence quotient may be very poor, as it is, e.g., for magnetic potential equations [23]. This insufficiency demands the stepwise improvement of contractivity, which necessarily involves the local properties of the Jacobians during the iteration. The stepwise comparison to $F'(u_n)$ leads to the framework of Newton-like or inexact Newton methods.

Inexact Newton methods, coupled with damping when global convergence is required, form a class that encompasses most iterative methods. A general description of these methods is found, e.g., in [10, 12], and with applications to BVPs in [1, 14]. The scope of these methods involves two main areas. In the first case the auxiliary equations contain exactly $F'(u_n)$ and inexactness comes from solving them approximately, often by an inner iteration. The other area (quasi-Newton methods) involves approximate Jacobians when they are not known exactly or in order to reduce work. (Several related methods are discussed in [13].) The generalization of Newton's method to Hilbert spaces has long been known [19], and many inexact versions can be put through as well.

The problem of preconditioning is connected to the second (quasi-Newton or approximate Jacobian) approach of inexact Newton methods. In both cases the iterative sequences are of the form

$$u_{n+1} = u_n - B_n^{-1} F(u_n) \qquad (n \in \mathbf{N}) \tag{2}$$

(which in fact contains all reasonable one-step iterative methods for (1)). The difference in approach is that preconditioning uses B_n to improve contractivity, whereas in quasi-Newton methods B_n has to approximate $F'(u_n)$. However, for elliptic problems, B_n required by the two methods may be similar, as is suggested by the preceding considerations and will be the case in our investigations. (Concerning the one-step sequence (2), we note that CG-type multistep methods in this context are in general unable to increase the order of convergence [9].)

Our investigation concerns variable preconditioning of iterations in Hilbert space, motivated by Sobolev space methods for nonlinear elliptic problems. The main feature of our results is that the preconditioners are chosen via spectral equivalence. This construction exploits the ellipticity properties of the equation. We note that our results also reflect more directly the way in which (2) shares equally the characters of simple and Newton iterations.

The main difficulty encountered in the convergence proof is that the variable preconditioners yield natural contractivity in stepwise different norms that are unable to produce a common estimate. Hence a transition is required to norms that can be compared to a common one. This will involve background investigations of suitable energy norms.

The approximate Jacobian approach, to which our investigation belongs, is relevant in applications to elliptic problems. Although the linear elliptic operators $F'(u)$ are then known exactly, it is worth looking for suitable approximations of $F'(u_n)$ in order to have simpler auxiliary equations. The use of Sobolev space background for such preconditioners seems an efficient approach for elliptic problems. This is the main scope of application for our method, the idea being analogous to the one suggested in [21] for simple iterations. Namely, preconditioning matrices can be obtained as projections of linear preconditioning operators chosen for the BVP itself on the continuous level, i.e., in the corresponding Sobolev space. In this way the original properties of the differential operator (mostly, those of its coefficients) can be exploited before discretization, and the obtained conditioning properties are mesh independent. As a main example, the operators B_n can be close to the Laplacian regarding their structure: for this purpose one may look for them as diagonal (scalar) coefficient operators with piecewise constant coefficients. (We note that the solution of the auxiliary linear systems in the steps of the iteration can rely on efficient standard methods, since these are highly developed; see, e.g., [3, 22]. In [3, 8] there is also discussed variable preconditioning in the context of linear equations.) We note that a summary on preconditioning operators is given in the book [16].

The paper is organized as follows. In section 2, first a result on simple iterations is quoted as a starting point; then some required properties of linear operators are given. The Hilbert space results on variable preconditioning are found in sections 3 and 4. First, section 3 provides local linear convergence using fixed spectral bounds for preconditioning. Although this theorem might be essentially derived from the one to come in section 4, it is worth formulating for two reasons. First of all, it illustrates more lucidly the preconditioning role of quasi-Newton methods, the result being an exact analogue of the quoted theorem on simple iterations in section 2. Besides, technical background is clearer when developed first for this simpler case. Section 4 contains the general method: global convergence up to second order is obtained using damped iteration and variable spectral bound preconditioning. Its proof is provided using the preceding technical background in the framework of damped quasi-Newton methods. Finally, in section 5 we apply the results to nonlinear elliptic boundary value problems. First we derive a general convergence result in Sobolev space and then give the construction of piecewise constant coefficient preconditioning operators using suitable domain decomposition. A numerical example illustrates the convergence results.

2. Preliminaries.

Let H be a Hilbert space with norm $\|\,.\,\|$. The notation

$$\langle u, v\rangle_A = \langle Au, v\rangle$$

will be used for the energy inner product of a self-adjoint positive operator. The corresponding norm has the obvious notation $\|\,.\,\|_A$.

2.1. Motivation: Simple preconditioning.

The following theorem gives a linear convergence result for preconditioned simple iterations.

THEOREM 2.1. *Let H be a real Hilbert space. Let the nonlinear operator $F : H \to H$ have a Gâteaux derivative satisfying the following properties:*

(i) *For any $u \in H$ the operator $F'(u)$ is self-adjoint.*

(ii) *(Ellipticity.) There exist constants $\Lambda \geq \lambda > 0$ satisfying*

$$\lambda\|h\|^2 \leq \langle F'(u)h, h\rangle \leq \Lambda\|h\|^2 \qquad (u, h \in H).$$

Denote u^* the unique solution of equation $F(u) = 0$. Assume that B is a self-adjoint linear operator satisfying

$$m\langle Bh, h\rangle \leq \langle F'(u)h, h\rangle \leq M\langle Bh, h\rangle \qquad (u, h \in H) \tag{3}$$

with some constants $M \geq m > 0$. Then for any $u_0 \in H$, the following sequence converges linearly to u^*:

$$u_{n+1} = u_n - \frac{2}{M+m} B^{-1}F(u_n) \qquad (n \in \mathbf{N}).$$

Namely,

$$\|u_n - u^*\| \leq C \cdot \left(\frac{M-m}{M+m}\right)^n \qquad (n \in \mathbf{N}) \tag{4}$$

with some constant $C > 0$.

Proof. The theorem is a special case of Theorem 3.2 in [21], where F itself is not assumed to be Gâteaux differentiable. Incidentally, in this form it follows easily from the well-known special case (see, e.g., [17]) when $B = I$ and (3) is no more than condition (ii). Namely, $B^{-1}F$ inherits the properties of F in the energy space H_B of the operator B (i.e., w.r.t. the inner product $\langle u, v\rangle_B = \langle Bu, v\rangle$).

We note that the basis of the convergence estimate (4) is the contractivity of the operator $I - \frac{2}{M+m} B^{-1}F$ with constant $\frac{M-m}{M+m}$ w.r.t. the energy norm $\| \, . \, \|_B$, which implies (4) in the $\| \, . \, \|_B$-norm. The equivalence of the two norms then yields (4).

Theorem 2.1 can be used for the preconditioning of the iterative solution of nonlinear elliptic BVPs. The straightforward application is to consider the discretized version of the problem and use the finite dimensional case of the theorem with a suitable preconditioning matrix B. The Hilbert space setting can be applied if F is the weak form of the differential operator and B is a weak linear elliptic operator defined in $H^1_0(\Omega)$ by

$$\langle Bh, v\rangle = \int_\Omega G(x)\, \nabla h \cdot \nabla v \qquad (h, v \in H^1_0(\Omega)),$$

where the coefficient matrix $G(x)$ can be chosen following the properties of $F'(u)$. Then for any discretization of the BVP, a suitable preconditioning matrix can be obtained as the projection of B under the same discretization, and this yields a mesh independent convergence estimate. Preconditioning strategies of this kind are summarized in [21]. (We note that often $B = I$ is already suitable in $H^1_0(\Omega)$; i.e., the original operator in strong form is preconditioned by the minus Laplacian. This works, e.g., for problems in plasticity [15]. The discrete Laplacian preconditioner is connected to the Sobolev gradient idea, developed for least-squares methods [25].) In both approaches the preconditioners so obtained are favorable, provided that M/m is not very large.

However, this kind of preconditioning is insufficient if M/m is large, and the latter may be unimprovable globally. This insufficiency demands the stepwise improvement of contractivity, i.e., varying B during the iteration to produce better spectral bounds. Since this modification involves the local properties of the Jacobians during the iteration (i.e., stepwise comparison to $F'(u_n)$), it leads to the framework of quasi-Newton methods.

As mentioned in the introduction, the following difficulty is encountered in this generalization. The variable preconditioners B_n yield contractivity in the above way in the stepwise different $\| \, . \, \|_{B_n}$ norms; hence we must verify contractivity in other norms that can be compared to a common one. Some properties required for this are given in the next subsection.

2.2. Properties of spectrally equivalent operators.

We formulate two lemmas for operators in a Hilbert space H satisfying the following spectral equivalence condition:

(C1) A and B be are self-adjoint linear operators in H with positive lower bound, and there exist constants $M \geq m > 0$ such that

$$m\langle Bh, h\rangle \leq \langle Ah, h\rangle \leq M\langle Bh, h\rangle \qquad (h \in H).$$

LEMMA 2.2. *Let the operators A and B satisfy condition* (C1). *Then*

$$m\langle A^{-1}h, h\rangle \leq \langle B^{-1}h, h\rangle \leq M\langle A^{-1}h, h\rangle \qquad (h \in H). \tag{5}$$

Proof. We prove only the right side of (5); the left one is similar. Let $v \in H$. Setting $h = B^{-1/2}v$, condition (C1) yields

$$\|A^{1/2}B^{-1/2}v\|^2 = \|A^{1/2}h\|^2 \le M\|B^{1/2}h\|^2 = M\|v\|^2.$$

Using also that for arbitrary bounded linear operator C there holds

$$\|C\| = \|C^*\|$$

and setting $C = B^{-1/2}A^{1/2}$, we obtain

$$\|B^{-1/2}A^{1/2}\|^2 = \|(B^{-1/2}A^{1/2})^*\|^2 = \|A^{1/2}B^{-1/2}\|^2 \le M,$$

which implies that

$$\langle B^{-1}h, h\rangle = \|B^{-1/2}A^{1/2}A^{-1/2}h\|^2 \le M\|A^{-1/2}h\|^2 = M\langle A^{-1}h, h\rangle \qquad (h \in H).$$

Lemma 2.3. *Let the operators A and B satisfy condition* (C1). *Then*

$$\left\| I - \frac{2}{M+m}AB^{-1} \right\|_{A^{-1}} \le \frac{M-m}{M+m}, \tag{6}$$

where I is the identity operator.

Proof. Let $C = \frac{M+m}{2}B$. The operator $I - AC^{-1}$ is self-adjoint w.r.t. the energy norm of A^{-1}, since

$$\langle AC^{-1}h, v\rangle_{A^{-1}} = \langle C^{-1}h, v\rangle = \langle h, C^{-1}v\rangle = \langle h, AC^{-1}v\rangle_{A^{-1}} \qquad (h, v \in H).$$

Hence

$$\|I - AC^{-1}\|_{A^{-1}} = \sup_{h\neq 0} \frac{|\langle (I - AC^{-1})h, h\rangle_{A^{-1}}|}{\|h\|^2_{A^{-1}}} = \sup_{h\neq 0} \frac{|\langle (A^{-1} - C^{-1})h, h\rangle|}{\langle A^{-1}h, h\rangle}. \tag{7}$$

Since $C^{-1} = \frac{2}{M+m}B^{-1}$, condition (C1) and Lemma 2.2 imply

$$\frac{2m}{M+m}\langle A^{-1}h, h\rangle \le \langle C^{-1}h, h\rangle \le \frac{2M}{M+m}\langle A^{-1}h, h\rangle.$$

Hence for any $h \in H$

$$-\frac{M-m}{M+m}\langle A^{-1}h, h\rangle \le \langle (A^{-1} - C^{-1})h, h\rangle \le \frac{M-m}{M+m}\langle A^{-1}h, h\rangle;$$

i.e., the supremum in (7) is indeed at most $\frac{M-m}{M+m}$.

3. Linear convergence by variable preconditioning.

3. Linear convergence by variable preconditioning. The following theorem provides local linear convergence using fixed spectral bounds for preconditioning. The result being locally an exact analogue of Theorem 2.1, it illustrates the preconditioning role of quasi-Newton methods.

Theorem 3.1. *Let H be a real Hilbert space. Assume that the nonlinear operator $F : H \to H$ has a Gâteaux derivative satisfying the following properties:*

(i) *For any $u \in H$ the operator $F'(u)$ is self-adjoint.*

(ii) *(Ellipticity.) There exist constants $\Lambda \ge \lambda > 0$ satisfying*

$$\lambda\|h\|^2 \le \langle F'(u)h, h\rangle \le \Lambda\|h\|^2 \qquad (u, h \in H).$$

(iii) *(Lipschitz continuity.) There exists* $L > 0$ *such that*

$$\|F'(u) - F'(v)\| \le L\|u - v\| \qquad (u, v \in H).$$

Denote u^* *the unique solution of equation* $F(u) = 0$. *We fix constants* $M \ge m > 0$. *Then there exists a neighborhood* $\mathcal{V}$ *of* u^* *such that for any* $u_0 \in \mathcal{V}$, *the sequence*

$$u_{n+1} = u_n - \frac{2}{M+m} B_n^{-1} F(u_n) \qquad (n \in \mathbf{N}),$$

with self-adjoint linear operators B_n *satisfying*

$$m\langle B_n h, h\rangle \le \langle F'(u_n)h, h\rangle \le M\langle B_n h, h\rangle \qquad (n \in \mathbf{N},\ h \in H), \tag{8}$$

converges linearly to u^*. *Namely,*

$$\|u_n - u^*\| \le C \cdot \left(\frac{M-m}{M+m}\right)^n \qquad (n \in \mathbf{N}) \tag{9}$$

with some constant $C > 0$.

(We note that constructive estimates are provided in the proof for the neighborhood $\mathcal{V}$; cf. (22) and Remark 1(b), and for the constant C, cf. (25).)

The proof of Theorem 3.1 is preceded by some required properties.

Lemma 3.2. *Let conditions* (i)–(iii) *of Theorem* 3.1 *hold. Then for any* $u, v, h \in H$,

$$\langle F'(u)h, h\rangle \le \langle F'(v)h, h\rangle \left(1 + L\lambda^{-2}\|F(u) - F(v)\|\right). \tag{10}$$

Proof. Condition (ii) of Theorem 3.1 implies that $\|F(u) - F(v)\| \ge \lambda\|u - v\|$. Hence

$$\langle F'(u)h, h\rangle \le \langle F'(v)h, h\rangle + L\|u-v\|\|h\|^2 \le \langle F'(v)h, h\rangle + L\lambda^{-2}\|F(u)-F(v)\|\langle F'(v)h, h\rangle.$$

Applying Lemma 3.2 to u and u^*, we obtain the following corollary.

Corollary 3.3. *If* $F(u^*) = 0$, *then for any* $u \in H$ *there holds*

$$\frac{1}{1+\mu(u)} \le \frac{\langle F'(u^*)h, h\rangle}{\langle F'(u)h, h\rangle} \le 1 + \mu(u),$$

where $\mu(u) = L\lambda^{-2}\|F(u)\| \le L\Lambda^{1/2}\lambda^{-2}\langle F'(u^*)F(u), F(u)\rangle^{1/2}$.

We introduce the norms

$$\|h\|_u = \langle F'(u)^{-1}h, h\rangle^{1/2} \quad (u, h \in H). \tag{11}$$

Then Corollary 3.3 and Lemma 2.2 imply directly the following corollary.

Corollary 3.4. *If* $F(u^*) = 0$, *then for any* $u \in H$ *there holds*

$$\frac{1}{1+\mu(u)} \le \frac{\|h\|_{u^*}^2}{\|h\|_u^2} \le 1 + \mu(u),$$

where $\mu(u)$ *is from Corollary* 3.3.

Proof of Theorem 3.1. Assumption (ii) and Lemma 2.2 imply that $\Lambda^{-1}\|h\|^2 \le \langle F'(u)^{-1}h, h\rangle \le \lambda^{-1}\|h\|^2$ for any $u, h \in H$. Hence the norms (11) satisfy

$$\lambda^{1/2}\|h\|_u \le \|h\| \le \Lambda^{1/2}\|h\|_u \qquad (u, h \in H), \tag{12}$$

and there also holds

$$\|F'(u)^{-1/2}\| \le \lambda^{-1/2} \qquad (u \in H). \tag{13}$$

Since the assumptions imply that $\lambda M^{-1}\|h\|^2 \le \langle B_n h, h\rangle$ for any $h \in H$, we obtain similarly to (13) that

$$\|B_n^{-1/2}\| \le \lambda^{-1/2} M^{1/2}. \tag{14}$$

The following norms (special cases of (11)) will be used throughout the proof:

$$\|\,.\,\|_n = \|\,.\,\|_{u_n} \quad (n \in \mathbf{N}), \qquad \|\,.\,\|_* = \|\,.\,\|_{u^*}. \tag{15}$$

The Lipschitz continuity of F implies that

$$F(u_{n+1}) = F(u_n) + F'(u_n)(u_{n+1} - u_n) + R(u_n), \tag{16}$$

where

$$\|R(u_n)\| \le \frac{L}{2}\|u_{n+1} - u_n\|^2. \tag{17}$$

Here

$$F(u_n) + F'(u_n)(u_{n+1} - u_n) = F(u_n) - \frac{2}{M+m} F'(u_n) B_n^{-1} F(u_n);$$

hence (8) and Lemma 2.3 imply that

$$\begin{aligned} \|F(u_n) + F'(u_n)(u_{n+1} - u_n)\|_n &\le \left\| I - \frac{2}{M+m} F'(u_n) B_n^{-1} \right\|_n \|F(u_n)\|_n \\ &\le \frac{M-m}{M+m}\|F(u_n)\|_n. \end{aligned} \tag{18}$$

Further, (12) and (17) yield

$$\|R(u_n)\|_n \le \frac{2L}{\lambda^{1/2}(M+m)^2}\|B_n^{-1}F(u_n)\|^2.$$

Here, using (14), (8), and Lemma 2.2, we have

$$\begin{aligned} \|B_n^{-1}F(u_n)\|^2 &\le \|B_n^{-1/2}\|^2 \|B_n^{-1/2}F(u_n)\|^2 \le M\lambda^{-1}\langle B_n^{-1}F(u_n), F(u_n)\rangle \\ &\le M^2\lambda^{-1}\langle F'(u_n)^{-1}F(u_n), F(u_n)\rangle = M^2\lambda^{-1}\|F(u_n)\|_n^2. \end{aligned}$$

Hence

$$\|R(u_n)\|_n \le \frac{2LM^2}{\lambda^{3/2}(M+m)^2}\|F(u_n)\|_n^2. \tag{19}$$

Altogether, (16), (18), and (19) yield

$$\|F(u_{n+1})\|_n \le \left(\frac{M-m}{M+m} + \frac{2LM^2}{\lambda^{3/2}(M+m)^2}\|F(u_n)\|_n \right) \|F(u_n)\|_n\,.$$

Finally, using Corollary 3.4, we obtain

$$\|F(u_{n+1})\|_* \le (1+\mu(u_n)) \left(\frac{M-m}{M+m} + \frac{2LM^2}{\lambda^{3/2}(M+m)^2} (1+\mu(u_n))^{1/2} \|F(u_n)\|_* \right) \|F(u_n)\|_* \,,$$

where $\mu(u_n) = L\Lambda^{1/2}\lambda^{-2}\|F(u_n)\|_*$. That is,

$$\|F(u_{n+1})\|_* \le \varphi(\|F(u_n)\|_*) \, \|F(u_n)\|_* \,, \tag{20}$$

where

$$\varphi(t) = (1+\beta\Lambda^{1/2}t) \left(Q + M^2\beta\alpha^{-2}\lambda^{1/2}(t/2) \left(1+\beta\Lambda^{1/2}t\right)^{1/2} \right) \tag{21}$$

and the notations

$$\alpha = \frac{M+m}{2}, \quad \beta = \frac{L}{\lambda^2}, \quad Q = \frac{M-m}{M+m}$$

are used. Then $\varphi : \mathbf{R}^+ \to \mathbf{R}^+$ is a strictly increasing continuous function and $\varphi(0) = Q$.

Estimate (20) puts us in the position to prove the required convergence estimate (9), provided that the assumption

$$r := \varphi(\|F(u_0)\|_*) \; < \; 1 \tag{22}$$

is satisfied for the initial guess.

First, we obtain by induction that

$$\|F(u_{n+1})\|_* \le r\|F(u_n)\|_* \qquad (n \in \mathbf{N}). \tag{23}$$

Namely, $\|F(u_1)\|_* = r\|F(u_0)\|_*$. Further, the assumption $\|F(u_{k+1})\|_* \le r\|F(u_k)\|_*$ $(k = 0, \dots, n-1)$ yields $\|F(u_n)\|_* < \|F(u_0)\|_*$; hence

$$\|F(u_{n+1})\|_* \le \varphi(\|F(u_n)\|_*) \, \|F(u_n)\|_* \le \varphi(\|F(u_0)\|_*) \, \|F(u_n)\|_* = r\|F(u_n)\|_* \,.$$

Inequality (23) implies that $\|F(u_n)\|_* \le r^n\|F(u_0)\|_* \to 0$, $\varphi(\|F(u_n)\|_*) \to Q$, and hence

$$\limsup \frac{\|F(u_{n+1})\|_*}{\|F(u_n)\|_*} \le \lim \varphi(\|F(u_n)\|_*) = Q.$$

From now on we use the notation

$$e_n = \|F(u_n)\|_* \,.$$

Then (20) implies that

$$e_n \le \left(\prod_{k=0}^{n-1} \varphi(e_k) \right) e_0 = \left(\prod_{k=0}^{n-1} \frac{\varphi(e_k)}{Q} \right) Q^n e_0 \qquad (n \in \mathbf{N}). \tag{24}$$

Using (21) and the notations $c = \beta\Lambda^{1/2}$, $d = (M^2\beta\alpha^{-2}\lambda^{1/2})/2$, we have

$$\varphi(t) = (1+ct) \left(Q + dt \, (1+ct)^{1/2} \right).$$

Here

$$\frac{\varphi(e_k)}{Q} = (1+ce_k)\left(1+\frac{d}{Q}e_k\,(1+ce_k)^{1/2}\right)$$

$$\leq (1+ce_k)\left(1+\frac{d}{Q}e_k\left(1+\frac{c}{2}e_k\right)\right) = 1+\left(c+\frac{d}{Q}\right)e_k+\frac{cd}{Q}e_k^2+\frac{c^2d}{2Q}e_k^3$$

$$\leq 1+\left(c+\frac{d}{Q}\right)e_0r^k+\frac{cd}{Q}e_0^2r^{2k}+\frac{c^2d}{2Q}e_0^3r^{3k}.$$

Since for any sequence $(a_k)\subset \mathbf{R}^+$ there holds $\prod_{k=0}^{n-1}(1+a_k)\leq \prod_{k=0}^{n-1}\exp(a_k)\leq \exp(\sum_{k=0}^{\infty}a_k)$, we obtain

$$\prod_{k=0}^{n-1}\frac{\varphi(e_k)}{Q}\leq \exp\left\{\left(c+\frac{d}{Q}\right)\frac{e_0}{1-r}+\frac{cd}{Q}\frac{e_0^2}{1-r^2}+\frac{c^2d}{2Q}\frac{e_0^3}{1-r^3}\right\} =: E\,.$$

Therefore (24) yields

$$e_n \;\leq\; e_0E\cdot Q^n \qquad (n\in\mathbf{N}).$$

Finally, using condition (ii) and (12), this implies

$$\|u_n-u^*\|\leq \lambda^{-1}\|F(u_n)\|\leq\; \lambda^{-1}\Lambda^{1/2}e_0E\cdot Q^n \qquad (n\in\mathbf{N}), \tag{25}$$

which coincides with the required convergence estimate with $C=\lambda^{-1}\Lambda^{1/2}e_0E$.

Remark 1. The convergence has been proved under the sufficient condition

$$\varphi(\|F(u_0)\|_*)\;<\;1 \tag{26}$$

for the initial guess, with φ defined in (21). In connection with this we note the following:

(a) The condition (26) is satisfied if

$$K\frac{L}{\lambda^2}\|F(u_0)\|_*\;<\;1\,,$$

where $K=\Lambda^{1/2}(M/m)\max\left\{1,\,2(M-m)^{-1}(\lambda/\Lambda)^{1/2}\right\}$. (This is proved in the appendix.) Relating this to the well-known sufficient condition $\frac{L}{2\lambda^2}\|F(u_0)\|<1$ of the exact Newton iteration, we observe that the order is similar (although K is obviously somewhat larger than 1/2).

(b) The sufficient condition of convergence can be given using the original norm as follows. Since the theoretical norm $\|\,.\,\|_*$ satisfies $\|F(u_0)\|_*\leq\lambda^{-1/2}\|F(u_0)\|$ by (12), and φ increases, therefore we obtain the condition

$$\varphi(\lambda^{-1/2}\|F(u_0)\|)\;<\;1$$

to be checked for u_0.

4. Damped quasi-Newton method as variable preconditioning. We recall the following definitions of norms (see (15)), where (u_n) is an iterative sequence and u^* is the solution of $F(u) = 0$:

$$\|h\|_n = \langle F'(u_n)^{-1}h, h\rangle^{1/2} \quad (n \in \mathbf{N}), \qquad \|h\|_* = \langle F'(u^*)^{-1}h, h\rangle^{1/2}. \tag{27}$$

The following theorem generalizes Theorem 3.1. Using damped iteration and variable spectral bound preconditioning, it provides global convergence up to second order.

Theorem 4.1. *Let H be a real Hilbert space. Let the operator $F : H \to H$ have a Gâteaux derivative satisfying the properties* (i)–(iii) *of Theorem* 3.1.

Denote u^* the unique solution of equation $F(u) = 0$. For arbitrary $u_0 \in H$ let (u_n) be the sequence defined by

$$u_{n+1} = u_n - \frac{2\tau_n}{M_n + m_n} B_n^{-1} F(u_n) \qquad (n \in \mathbf{N}), \tag{28}$$

where the following conditions hold:

(iv) *$M_n \geq m_n > 0$ and the self-adjoint linear operators B_n satisfy*

$$m_n\langle B_n h, h\rangle \leq \langle F'(u_n)h, h\rangle \leq M_n\langle B_n h, h\rangle \qquad (n \in \mathbf{N},\, h \in H);$$

further, using notation $\mu(u_n) = L\lambda^{-2}\|F(u_n)\|$, there exist constants $K > 1$ and $\varepsilon > 0$ such that $M_n/m_n \leq 1 + 2/(\varepsilon + K\mu(u_n))$.

(v) *We define*

$$\tau_n = \min\left\{1, \frac{1 - Q_n}{2\rho_n}\right\}, \tag{29}$$

where $Q_n = \frac{M_n - m_n}{M_n + m_n}(1 + \mu(u_n))$, $\rho_n = 2LM_n^2\lambda^{-3/2}(M_n + m_n)^{-2}\|F(u_n)\|_n(1 + \mu(u_n))^{1/2}$, $\mu(u_n)$ is as in condition (iv), *and $\|\,.\,\|_n$ is defined in* (27). *(This value of τ_n ensures optimal contractivity in the nth step in the $\|\,.\,\|_*$-norm.)*

Then there holds

$$\|u_n - u^*\| \leq \lambda^{-1}\|F(u_n)\| \to 0;$$

namely,

$$\limsup \frac{\|F(u_{n+1})\|_*}{\|F(u_n)\|_*} \leq \limsup \frac{M_n - m_n}{M_n + m_n} < 1\,. \tag{30}$$

Moreover, if in addition we assume $M_n/m_n \leq 1 + c_1\|F(u_n)\|^\gamma$ $(n \in \mathbf{N})$ with some constants $c_1 > 0$ and $0 < \gamma \leq 1$, then

$$\|F(u_{n+1})\|_* \leq d_1\|F(u_n)\|_*^{1+\gamma} \qquad (n \in \mathbf{N}) \tag{31}$$

with some constant $d_1 > 0$.

Owing to the equivalence of the norms $\|\,.\,\|$ and $\|\,.\,\|_*$, the orders of convergence corresponding to the estimates to (30) and (31) can be formulated with the original norm.

Corollary 4.2 (rate of convergence in the original norm).

(a) *If $\limsup M_n/m_n = K > 1$, then*

$$\|u_n - u^*\| \leq \lambda^{-1}\|F(u_n)\| \leq \text{const.} \cdot \rho^n$$

with $\rho = (K-1)/(K+1)$.

(b) *In the case* $M_n/m_n \le 1 + c_1\|F(u_n)\|^\gamma$ *(with constants* $c_1 > 0,\ \ 0 < \gamma \le 1$*) there holds*

$$\|u_n - u^*\| \le \lambda^{-1}\|F(u_n)\| \le \text{const.} \cdot \rho^{(1+\gamma)^n}$$

with some constant $0 < \rho < 1$.

Proof of Theorem 4.1. Using (16) and (28), we obtain

$$F(u_{n+1}) = (1-\tau_n)F(u_n) - \tau_n\left(F(u_n) - \frac{2}{M_n+m_n}F'(u_n)B_n^{-1}F(u_n)\right) + R(u_n).$$

Hence

$$\|F(u_{n+1})\|_* \le (1-\tau_n)\|F(u_n)\|_* + \tau_n\left\|\left(I - \frac{2}{M_n+m_n}F'(u_n)B_n^{-1}\right)F(u_n)\right\|_* + \|R(u_n)\|_*\,.$$

Here, using Corollary 3.4 and Lemma 2.3,

$$\left\|\left(I - \frac{2}{M_n+m_n}F'(u_n)B_n^{-1}\right)F(u_n)\right\|_* \le\ (1+\mu(u_n))^{1/2}\frac{M_n-m_n}{M_n+m_n}\|F(u_n)\|_n$$

$$\le\ (1+\mu(u_n))\frac{M_n-m_n}{M_n+m_n}\|F(u_n)\|_*\,,$$

where $\mu(u_n) = L\lambda^{-2}\|F(u_n)\|$. Further, from (12) and (17) there follows

$$\|R(u_n)\|_* \le \frac{L}{2\lambda^{1/2}}\|u_{n+1}-u_n\|^2 = \tau_n^2\frac{2L}{\lambda^{1/2}(M+m)^2}\|B_n^{-1}F(u_n)\|^2;$$

hence, using the estimate preceding (19) and then Corollary 3.4, we obtain

$$\|R(u_n)\|_* \le \tau_n^2\frac{2LM^2}{\lambda^{3/2}(M+m)^2}\|F(u_n)\|_n^2$$

$$\le \tau_n^2(1+\mu(u_n))^{1/2}\frac{2LM^2}{\lambda^{3/2}(M+m)^2}\|F(u_n)\|_n\|F(u_n)\|_*.$$

Summing up, we obtain

$$\|F(u_{n+1})\|_* \le \Bigg(1 - \tau_n + \tau_n(1+\mu(u_n))\frac{M_n-m_n}{M_n+m_n}$$

$$+ \tau_n^2(1+\mu(u_n))^{1/2}\frac{2LM^2}{\lambda^{3/2}(M+m)^2}\|F(u_n)\|_n\Bigg)\ \|F(u_n)\|_*\,.$$

That is,

$$\|F(u_{n+1})\|_* \le \left(1 - \tau_n(1-Q_n) + \tau_n^2\rho_n\right)\ \|F(u_n)\|_*\,, \tag{32}$$

where Q_n and ρ_n are as in condition *(v)*.

There exists $\tilde{Q} < 1$ such that

$$Q_n \le \tilde{Q} \qquad (n \in \mathbf{N}). \tag{33}$$

Namely, the assumption $M_n/m_n \le 1+2/(\varepsilon+K\mu(u_n))$ with $K>1$ and $\varepsilon>0$ implies that

$$1+\varepsilon+K\mu(u_n) \le 1+\frac{2}{(M_n/m_n)-1} = \frac{M_n+m_n}{M_n-m_n};$$

hence

$$1+\mu(u_n) \le \tilde{Q}\,\frac{M_n+m_n}{M_n-m_n}$$

with $\tilde{Q} := \max\{1/K, 1/(1+\varepsilon)\} < 1$.

Let us introduce the function $p:[0,1]\to \mathbf{R}$, $p(t) := 1-(1-Q_n)t+\rho_n t^2$. Here $p'(t) = -(1-Q_n)+2\rho_n t$ yields that τ_n defined in (29) satisfies

$$p(\tau_n) = \min_{t\in[0,1]} p(t) < 1,$$

since $p'(0) = -(1-Q_n) < 0$. Hence from (32)

$$\|F(u_{n+1})\|_* \le p(\tau_n)\|F(u_n)\|_* < \|F(u_n)\|_* \,. \tag{34}$$

Moreover, if $\tau_n = 1$ (i.e., when $1 \le (1-Q_n)/2\rho_n$), then

$$p(\tau_n) = Q_n+\rho_n \le Q_n+(1-Q_n)/2 = (1+Q_n)/2 \le (1+\tilde{Q})/2 < 1.$$

In the case $\tau_n = (1-Q_n)/2\rho_n$ we have

$$p(\tau_n) = 1-(1-Q_n)^2/(4\rho_n) \le 1-(1-\tilde{Q})^2/(4\sup_n \rho_n) =: Q' < 1.$$

The latter holds since by (34) $\|F(u_n)\|_*$ is bounded, and hence

$$\rho_n = \text{const.}\cdot\|F(u_n)\|_n\,(1+\text{const.}\cdot\|F(u_n)\|)^{1/2} \tag{35}$$

is bounded, the three norms being equivalent. Altogether, from (34) we obtain

$$\|F(u_n)\|_* \le \text{const.}\cdot r^n \to 0,$$

where $r = \max\{(1+\tilde{Q})/2, Q'\}$. This also implies that $\rho_n \to 0$ and $\mu(u_n) = L\lambda^{-2}\|F(u_n)\| \to 0$. A brief calculation gives

$$p(\tau_n) = Q_n+\rho_n\left(1-(1-\tau_n)^2\right) \tag{36}$$

(for both $\tau_n = 1$ and $\tau_n < 1$); hence (34) yields

$$\limsup \frac{\|F(u_{n+1})\|_*}{\|F(u_n)\|_*} \le \limsup Q_n = \limsup \frac{M_n-m_n}{M_n+m_n}\,.$$

The bound $M_n/m_n \le 1+2/\varepsilon$ in assumption (iv) implies that

$$\limsup \frac{M_n-m_n}{M_n+m_n} \le \frac{1}{1+\varepsilon} < 1\,.$$

Finally, let $M_n/m_n \le 1+c_1\|F(u_n)\|^\gamma$ with constants $c_1>0$, $0<\gamma\le 1$. Then $M_n/m_n \le 1+c_2\|F(u_n)\|_*^\gamma$ with $c_2 = c_1\Lambda^{1/2}$; hence

$$\frac{M_n-m_n}{M_n+m_n} < \frac{M_n-m_n}{m_n} \le c_2\|F(u_n)\|_*^\gamma\,,$$

and therefore

$$Q_n \le c_3 \|F(u_n)\|_*^\gamma$$

with $c_3 = c_2(1 + \sup_n \mu(u_n))$. Also,

$$\rho_n \le c_4 \|F(u_n)\|_*$$

with some $c_4 > 0$ since $\|F(u_n)\|_*$ is bounded (cf. (35)). With the use of notation $e_n = \|F(u_n)\|_*$, we obtain from (34) and (36) that

$$e_{n+1} \le (Q_n + \rho_n)\, e_n \le (Q_n + c_4 e_n)\, e_n \le \left(c_3 e_n^\gamma + c_4 e_0 \frac{e_n}{e_0} \right) e_n$$

$$\le \left(c_3 e_n^\gamma + c_4 e_0 \left(\frac{e_n}{e_0} \right)^\gamma \right) e_n = d_1 e_n^{1+\gamma}$$

with $d_1 = c_3 + c_4 e_0^{1-\gamma}$.

Remark 2. (a) It is worth mentioning that Theorems 3.1 and 4.1 define descent methods, similarly to the simple iteration. Namely, conditions (i)–(iii) of Theorem 3.1 imply the existence of a potential $\Phi : H \to \mathbf{R}$, i.e., $\Phi'(u) = F(u) \quad (u \in H)$. Then the directions $-B_n^{-1} F(u_n)$ are descent directions, since their angle is acute with the steepest descent direction $-F(u_n)$ owing to

$$\langle B_n^{-1} F(u_n), F(u_n) \rangle > 0\,.$$

We also note that the residuals $\Phi(u_n) - \Phi(u^*)$ are equivalent to $\|u_n - u^*\|^2$ owing to the ellipticity condition (ii) of Theorem 3.1.

(b) The conditions of Theorems 3.1 and 4.1 can be relaxed. Namely, since the constructed sequences are bounded, it suffices to assume (ii) and (iii) on the corresponding ball that (u_n) runs within. Further, the proofs can be repeated with obvious modification if (iii) is replaced by Hölder continuity only. (See [1] for a related damped inexact Newton result.)

(c) The value of τ_n need not necessarily be maximized by 1 as in (29), but suitable overrelaxation is also feasible which may accelerate the convergence.

5. Sobolev space preconditioning for nonlinear elliptic problems. In this section we consider the BVP

$$\begin{cases} -\operatorname{div} f(x, \nabla u) = g(x), \\ u_{|\partial\Omega} = 0 \end{cases} \tag{37}$$

with the following conditions: $\Omega \subset \mathbf{R}^N$ is a bounded domain, $g \in L^2(\Omega)$, f is measurable and $f(x, .) \in C^1(\mathbf{R}^N, \mathbf{R}^N)$ for all $x \in \Omega$, and the Jacobians $\frac{\partial f(x,\eta)}{\partial \eta}$ are Lipschitz continuous in η, symmetric, and satisfy

$$\lambda |\xi|^2 \le \frac{\partial f(x,\eta)}{\partial \eta} \xi \cdot \xi \le \Lambda |\xi|^2, \qquad (x,\eta) \in \Omega \times \mathbf{R}^N, \xi \in \mathbf{R}^N, \tag{38}$$

with constants $\Lambda \ge \lambda > 0$ independent of (x, η).

An important special case of f is of the form $f(x,\eta) = a(|\eta|)\eta$, where $0 < \lambda \le a(r) \le (r a(r))' \le \Lambda \quad (r > 0)$. This kind of operator arises, e.g., in plasticity theory or in connection with magnetic potential (see, e.g., [23, 24]).

Owing to uniform ellipticity, problem (37) has a unique weak solution $u^* \in H_0^1(\Omega)$, and the finite element approximations converge to u^*.

Let $V_h \subset H_0^1(\Omega)$ be a finite element subspace, and denote $u_h \in V_h$ the solution of the discretized problem

$$\int_\Omega f(x, \nabla u_h) \cdot \nabla v = \int_\Omega gv \qquad (v \in V_h). \tag{39}$$

Our aim is to find preconditioners for the iterative solution of (39) based on Theorem 4.1.

5.1. Variable preconditioning operators for nonlinear elliptic problems. In order to fit in the operator framework of Theorem 4.1, we first formulate the properties of the operator corresponding to (39). Namely, let $F : V_h \to V_h$ denote the operator defined by

$$\langle F(u), v\rangle = \int_\Omega \big(f(x, \nabla u) \cdot \nabla v \ - gv\big) \qquad (u, v \in V_h), \tag{40}$$

where $\langle u, v\rangle = \int_\Omega \nabla u \cdot \nabla v$. Then F has a Gâteaux derivative satisfying properties (i)–(iii) of Theorem 3.1. Namely,

$$\langle F'(u)v, w\rangle = \int_\Omega \frac{\partial f}{\partial \eta}(x, \nabla u)\, \nabla v \cdot \nabla w \qquad (u, v, w \in V_h); \tag{41}$$

hence (38) implies that $F'(u)$ is self-adjoint and

$$\lambda \|v\|^2 \le \langle F'(u)v, v\rangle \le \Lambda \|v\|^2 \qquad (u, v \in V_h).$$

Further, (41) implies that F' inherits the Lipschitz continuity of $\frac{\partial f(x,\eta)}{\partial \eta}$ in η.

Our approach is *Sobolev space preconditioning*, which means that we will find preconditioners by considering (39) as the projection of the exact equation (with u^* and all $v \in H_0^1(\Omega)$), instead of viewing the actual form of the nonlinear algebraic system that (39) is. This means defining linear operators in weak form, spectrally equivalent to $F'(u_n)$, relying directly on the properties of the matrices $\frac{\partial f}{\partial \eta}(x, \nabla u_n)$. The required variable preconditioners are the matrices that these linear operators define in V_h. (Since these matrices are the projections of operators in $H_0^1(\Omega)$, defined by the same integral, the spectral bounds can be obtained in a mesh uniform way.)

The above idea is the analogue of the one developed in [21] for fixed preconditioners. We note that the Sobolev space framework is also useful in the context of exact Newton iterations; namely, (41) yields the Jacobians without numerical differentiation. The variable preconditioners lead to systems of possibly simpler structure than those containing exact Jacobians.

THEOREM 5.1. *Let $u_0 \in V_h$ be arbitrary, and let $(u_n) \subset V_h$ be the sequence defined as follows.*

If, for $n \in \mathbf{N}$, u_n is obtained, then we choose constants $M_n \ge m_n > 0$ and a symmetric matrix-valued function $G_n \in L^\infty(\Omega, \mathbf{R}^{N\times N})$ for which there holds

$$m_n \langle G_n(x)\xi, \xi\rangle \le \left\langle \frac{\partial f}{\partial \eta}(x, \nabla u_n(x))\xi, \xi \right\rangle \le M_n \langle G_n(x)\xi, \xi\rangle \qquad (x \in \Omega,\ \xi \in \mathbf{R}^N); \tag{42}$$

further, M_n/m_n *and* τ_n *satisfy the conditions* (iv)–(v) *in Theorem* 4.1. *We define*

$$u_{n+1} = u_n - \frac{2\tau_n}{M_n + m_n} z_n \,, \tag{43}$$

where $z_n \in V_h$ *is the solution of*

$$\int_\Omega G_n(x)\, \nabla z_n \cdot \nabla v = \int_\Omega \big(f(x, \nabla u_n) \cdot \nabla v \; - gv \big) \qquad (v \in V_h). \tag{44}$$

Then u_n *converges to* u_h *according to the estimates of Theorem* 4.1.

Proof. For any $n \in \mathbf{N}$ let $B_n : V_h \to V_h$ denote the linear operator

$$\langle B_n v, w \rangle = \int_\Omega G_n(x)\, \nabla v \cdot \nabla w \qquad (v, w \in V_h).$$

Then B_n is self-adjoint and (42) implies that

$$m_n \langle B_n v, v \rangle \le \langle F'(u_n) v, v \rangle \le M_n \langle B_n v, v \rangle \qquad (v \in V_h).$$

Since F fulfills properties (i)–(iii) of Theorem 3.1, therefore all the conditions are satisfied and the convergence results hold.

The matrices of the linear systems corresponding to problems (44) are the variable preconditioners for the problem (39). They can also be considered as the discretizations of the auxiliary linear operators

$$L_n u = -\text{div}\ (G_n(x) \nabla u)$$

(the strong form of B_n). As mentioned above, the choice of the matrices G_n requires only the properties of the matrices $\frac{\partial f}{\partial \eta}(x, \nabla u_n)$, instead of investigating the actual form of the nonlinear algebraic system (39). This means that the preconditioning for the latter is determined by that for the Jacobians of f; hence the preconditioning matrices are not difficult to compile. A further advantage, as mentioned before, is that the resulting condition numbers can be obtained in a straightforward and mesh independent way.

Remark 3. We note that preconditioning by spectral equivalence is also efficient in other contexts (e.g., by using a rougher mesh for the same operator [5]). The raison d'être for the proposed coupling of spectral equivalence with Sobolev space framework is given by the advantages mentioned above.

We also remark that the idea of Theorem 5.1 can be similarly used in the setting of multilevel iterations, i.e., when the discretization parameter h is redefined in each step n.

The systems (44) are of simpler structure than those containing exact Jacobians if the G_n are appropriately chosen. In what follows we give an appropriate construction and study the properties of the obtained method. We note that other possible choices of such preconditioners are summarized in the book [16] together with the theoretical background for preconditioning operators.

5.2. Variable preconditioning operators with piecewise constant coefficient operators. The following example illustrates an appropriate construction of variable preconditioners: the Jacobians are replaced by the discretizations of piecewise constant coefficient preconditioning operators.

These operators are constructed as follows. Let u_n be fixed. To improve the bounds in (38), the domain Ω is decomposed in subdomains Ω_i $(i = i(n) = 1, \ldots, s_n)$ such that for all i

$$\lambda_i \, |\xi|^2 \le \frac{\partial f}{\partial \eta}(x, \nabla u_n) \, \xi \cdot \xi \le \Lambda_i \, |\xi|^2 \qquad (x \in \Omega_i \, , \xi \in \mathbf{R}^N), \tag{45}$$

with $\lambda < \lambda_i \le \Lambda_i < \Lambda$. We introduce a piecewise constant weight function w_n such that

$$w_{n \, | \Omega_i} \equiv c_i \quad (i = i(n) = 1, \ldots, s_n), \tag{46}$$

where c_i is some mean of λ_i and Λ_i. Let

$$G_n(x) := \, w_n(x) \cdot I \, ,$$

where $I \in \mathbf{R}^{N \times N}$ is the identity matrix. Then G_n defines the linear operator B_n corresponding to the weight function w, i.e.,

$$\langle B_n h, v \rangle = \int_\Omega w_n \, \nabla h \cdot \nabla v \, .$$

Defining

$$m_n := \min_i \lambda_i / c_i \quad \text{and} \quad M_n := \max_i \Lambda_i / c_i \, , \tag{47}$$

the left and right sides of (45) can be estimated further by $m_n w(x) |\xi|^2$ and $M_n w(x) |\xi|^2$, respectively. This and (41) yield

$$m_n \langle B_n v, v \rangle = m_n \int_\Omega w |\nabla v|^2 \le \langle F'(u_n) v, v \rangle \le M_n \int_\Omega w |\nabla v|^2 = M_n \langle B_n v, v \rangle \tag{48}$$

for all $v \in V_h$. The obtained condition number estimate of the operator $B_n^{-1} F'(u_n)$ satisfies

$$M_n / m_n = \max_i \Lambda_i / \lambda_i ; \tag{49}$$

hence it can be decreased by the suitable refinement of decomposition.

This operator B_n was studied in [4] in the context of a standard inner-outer iteration.

The corresponding preconditioning matrix $\mathcal{B}_n$ (the discretization of the operator B_n in the subspace V_h) is the modification of the discrete Laplacian via blockwise multiplication by the corresponding constants c_i. Moreover (see [4, 7]), the matrix $\mathcal{B}_n$ can be decomposed in the product form

$$\mathcal{B}_n = \mathcal{C} \mathcal{W}_n \mathcal{C}^T \, , \tag{50}$$

where the matrices $\mathcal{C}$ and $\mathcal{C}^T$ correspond to the discretization of $-div$ and ∇, respectively, and hence are independent of n; further, $\mathcal{W}_n$ is a diagonal matrix consisting of constants c_i at the entries corresponding to the subdomains Ω_i.

Clearly, the condition number of the preconditioned system is also estimated by M_n / m_n. This bound is mesh independent in the setting of multilevel iterations, i.e., independent of the discretization parameter $h = h_n$ defined in step n.

For instance, the required decompositions are straightforward to define for the special cases of (37) of the form

$$\begin{cases} -\mathrm{div}\,(a(|\nabla u|)\nabla u) \;=\; g(x), \\ \;u_{|\partial\Omega} = 0\,, \end{cases} \tag{51}$$

where $0 < \lambda \le a(r) \le a(r) + a'(r)r \le \Lambda$. Here $f(x,\eta) = a(|\eta|)\eta$ satisfies

$$a(|\nabla u_n|)|\xi|^2 \le \frac{\partial f}{\partial \eta}(x, \nabla u_n)\,\xi\cdot\xi \le (a(|\nabla u_n|) + a'(|\nabla u_n|)|\nabla u_n|)\,|\xi|^2$$

(see, e.g., [24]); hence

$$\lambda_i \;= \inf_{\Omega_i} a(|\nabla u_n|)\,, \qquad \Lambda_i \;= \sup_{\Omega_i}\,(a(|\nabla u_n|) + a'(|\nabla u_n|)|\nabla u_n|)\;. \tag{52}$$

That is, the bounds λ_i and Λ_i are determined only by the values of $|\nabla u_n|$ (in addition to the given function $a(r)$).

The above preconditioner compensates possible sharp gradients, i.e., when Λ_i/λ_i is very large. This is the case, e.g., for magnetic potential (in stator sheets, etc.); see [23]. The construction is also suitable to follow discontinuities of the coefficients. In this case the decomposition is to be chosen such that the boundaries of subdomains fit the discontinuities of $f(x, \nabla u_n)$. A straightforward illustration of this is another special case of (37) of the form

$$\begin{cases} -\mathrm{div}\,(b(x,|\nabla u|)\nabla u) \;=\; g(x), \\ \;u_{|\partial\Omega} = 0, \end{cases}$$

where $\Omega_1 \subset \Omega$,

$$b(x,r) := \begin{cases} a(r) & \text{if } x \in \Omega_1, \\ \alpha & \text{if } x \in \Omega \setminus \Omega_1\,, \end{cases}$$

$a(r)$ is as in (51), and $\alpha > 0$ is a constant. (This nonlinearity arises, e.g., in connection with potential in H-shaped magnets [23].) Then an obviously suitable choice of the weight function w is defined as above for (51) on Ω_1 and as constant α on $\Omega \setminus \Omega_1$.

5.3. Numerical experiment. Let us consider the two-dimensional magnetic potential problem (51) with the following nonlinearity, which characterizes the reluctance of stator sheets in the cross-sections of an electrical motor in the case of isotropic media [23]:

$$a(r) = \frac{1}{\mu_0}\left(\alpha + (1-\alpha)\frac{r^8}{r^8+\beta}\right) \qquad (r \ge 0), \tag{53}$$

where $\alpha = 3\cdot 10^{-4}$ and $\beta = 1.6\cdot 10^4$; further, μ_0 is the vacuum permeability. (For simplicity we can consider $\mu_0 = 1$ since μ_0 does not affect the conditioning.) For the right-hand side we set

$$g(x) \equiv \rho = 4\cdot 10^6, \tag{54}$$

which is a realistic value for the electric current density (see also [23]). For simplicity we consider problem (51) on the unit square domain $\Omega = [0,1]\times[0,1]$.

TABLE 1
The number of iterations to achieve error 10^{-4} *and* 10^{-8} *under different numbers of node points using six subdomains.*

Node points:	2^6	2^8	2^{10}
# iterations for $\varepsilon = 10^{-4}$:	10	10	10
# iterations for $\varepsilon = 10^{-8}$:	16	16	16

We note that the function a varies in several magnitudes over the whole domain: the bounds in (38) are $\lambda = \alpha = 0.0003$ and $\Lambda = \max(a(r) + a'(r)r) = 2.5313$; hence the related condition number is $\Lambda/\lambda = 8437.7$.

We apply the variable preconditioning procedure with the above described piecewise constant coefficient preconditioning operators. For simplicity, we choose V_h as the subspace of piecewise linear elements on a uniform triangulation of Ω. Then the iteration (43)–(44) takes the form

$$u_{n+1} = u_n - \frac{2\tau_n}{M_n + m_n} z_n \tag{55}$$

with $z_n \in V_h$ being the solution of problem

$$\int_\Omega w_n(x)\,\nabla z_n \cdot \nabla v = \int_\Omega \big(a(|\nabla u_n|)\,\nabla u_n \cdot \nabla v \ - \rho v\big) \qquad (v \in V_h), \tag{56}$$

where $a(r)$ and ρ are as above, w_n is a piecewise constant weight function, and M_n and m_n are from (47). In order to define w_n, we first observe that for a given number $\kappa > 1$ satisfying $\kappa > \sup_{r>0}\,(a(r)+a'(r)r)/a(r)$, one can recursively define subintervals $J_i = [r_{i-1}, r_i) \subset [0, \infty)$ such that $r_0 = 0$ and

$$\sup_{r\in J_i}\,(a(r) + a'(r)r) \,/\, \inf_{r\in J_i}\, a(r) \ = \kappa \qquad (i \in \mathbf{N}).$$

Then the subdomains Ω_i are defined as the level sets of $|\nabla u_n|$ corresponding to J_i, and by (52) they satisfy $\Lambda_i/\lambda_i \le \kappa$ for all i; hence by (49) we have $M_n/m_n \le \kappa$. In this way one uses the minimal number of subdomains to achieve the condition number κ, and, conversely, for a given number of subdomains one can find the subdomains themselves that produce the lowest bound κ of M_n/m_n. (For details see [4], where this preconditioner was studied in the context of a standard inner-outer iteration.)

In the numerical experiment we have used a decomposition to six subdomains in each step of the iteration. In each step n we have determined the subdomains that yield the lowest value of κ for $|\nabla u_n|$ according as above using a suitable subroutine. We have chosen c_i to be the arithmetic mean of λ_i and Λ_i for all i.

The error during the iteration was measured by the weighted residual errors corresponding to (40) with the inner product with weight w_n. This error is obtained from the iteration without any extra work as the weighted norm of the actual coefficient vector w.r.t. the Gram matrix. (It is a computable approximation of the $*$-norm (27) that appears in the convergence estimates of Theorem 4.1.)

The experiment was made using 2^k node points of the mesh with $k = 6$, 8, and 10. Table 1 summarizes the number of iterations that decrease the residual error $\|F(u_n)\|$ below 10^{-4} and 10^{-8}, respectively. The results exhibit mesh independence; i.e., the number of iterations remains the same when the number of node points is increased.

We have repeated the experiment with 12 subdomains, and the results were the same (except that for 2^6 node points the number of iterations for $\varepsilon = 10^{-8}$ was only

Table 2

The sequence of errors up to eight digits, using 2^{10} node points and six subdomains.

15). This means that the smaller number of subdomains already suffices to achieve the available convergence speed.

The distribution of the errors behaved much similarly for the different runs. We give one of them below for illustration.

Finally, in order to compare the results in Table 1, we cite results from other papers where the same or a similar problem is studied. The coefficients (53) and (54) are quoted from [18] and [23], and a similar nonlinearity was first considered in the early paper [11]. In the latter, Newton's method is applied with overrelaxation for finite difference method on a square with 90 and 870 points, and requires 20 (resp., 98) iterations to achieve a residual error $\varepsilon = 10^{-6}$. Successive overrelaxation (or Kacanov's frozen coefficient method) in [11] requires 18 (resp., 58) iterations for the same error, and the variants of this method require 162 iterations for $\varepsilon = 10^{-5}$ with 384 node points in [18] (on a complicated domain) and 15 iterations for $\varepsilon = 10^{-6}$ with 1000 node points in [23], respectively. Compared even to this last fastest result, the iteration (55)–(56) is less costly. Namely, since the auxiliary systems in (56) come from a piecewise constant coefficient operator, their structure is simpler than either for Newton's method or for frozen coefficients. That is, (50) implies that the matrices of the auxiliary systems are the modifications of the discrete Laplacian such that their updating consists of updating the diagonal matrix $\mathcal{W}_n$. In fact, the latter requires only distributing the six constants c_i at the entries corresponding to the subdomains Ω_i.

5.4. Conclusions. We summarize our numerical method for the solution of the nonlinear elliptic problem (37).

Using the quasi-Newton setting in an operator framework, the Jacobians were replaced by the discretizations of suitably chosen piecewise constant coefficient elliptic operators. This has a twofold advantage. First, superlinear convergence can be preserved, and stepwise the condition number of the preconditioned system is mesh independent. Second, our method is less costly than either a Newton or a frozen coefficient iteration due to the decomposition (50), which implies that the matrices of the auxiliary systems are the modifications of the discrete Laplacian such that their updating consists of updating the diagonal factor $\mathcal{W}_n$.

Our numerical experiment has demonstrated these advantages. We have achieved convergence which is in accordance with the theoretical result: Table 2 exhibits the superlinear convergence. Table 1 also suggests mesh independence of the iterations. The convergence results are favorable in comparison with some other cited ones. Concerning computational cost, the experiment with a rather ill-conditioned problem has shown that even a coarse decomposition of the domain has been able to provide the above described favorable convergence. Namely, Tables 1 and 2 were achieved using six subdomains, in which case the matrix of the auxiliary system is very close to the discrete Laplacian. Its updating required only distributing the six constants c_i at the entries corresponding to the subdomains Ω_i, and this structure property slightly increases only the complexity of a Laplacian solver.

Appendix.

Proof of Remark 1(a). We use the notations as earlier:

$$e_0 = \|F(u_0)\|_*\,, \quad \alpha = \frac{M+m}{2}, \quad \beta = \frac{L}{\lambda^2}, \quad Q = \frac{M-m}{M+m}\,.$$

The estimate to be proved is

$$\varphi(e_0) = (1+\beta\Lambda^{1/2}e_0)\left(\tilde{Q} + M^2\beta\alpha^{-2}\lambda^{1/2}(e_0/2)\left(1+\beta\Lambda^{1/2}e_0\right)^{1/2}\right) \, < \, 1\,,$$

where $\beta = L\lambda^{-2}$, under the assumption $K\beta e_0 < 1$. We use that the estimate $(1-x)^{1/2} \le 1-(x/2) \quad (0 \le x \le 1)$ implies that

$$Q^{1/2} = \left(1 - \frac{2m}{M+m}\right)^{1/2} \le \frac{M}{M+m}, \quad Q^{-1/2} \ge \frac{M+m}{M} = 1 + \frac{m}{M}\,.$$

Then for the first term in $\varphi(e_0)$ we have

$$1+\beta\Lambda^{1/2}e_0 < 1 + \frac{\Lambda^{1/2}}{K} \le 1 + \frac{\Lambda^{1/2}}{\Lambda^{1/2}(M/m)} = 1 + \frac{m}{M} \le Q^{-1/2}.$$

From this, using $K\beta e_0 < 1$ and using that $2\alpha^2 QK \ge M\lambda^{1/2}(M+m)/m$, the second term is estimated by

$$\tilde{Q} + \frac{M^2\lambda^{1/2}}{2\alpha^2 Q^{1/2}K} \le Q^{1/2}\left(\frac{M}{M+m} + \frac{m}{M+m}\right) = Q^{1/2}.$$

Multiplying the two terms, $\varphi(e_0) < 1$ is verified.

TWO-LEVEL METHOD BASED ON FINITE ELEMENT AND CRANK–NICOLSON EXTRAPOLATION FOR THE TIME-DEPENDENT NAVIER–STOKES EQUATIONS*

YINNIAN HE[†]

Abstract. A fully discrete two-level finite element method (the two-level method) is presented for solving the two-dimensional time-dependent Navier–Stokes problem. The method requires a Crank–Nicolson extrapolation solution $(u_{H,\tau_0}, p_{H,\tau_0})$ on a spatial-time coarse grid J_{H,τ_0} and a backward Euler solution $(u^{h,\tau}, p^{h,\tau})$ on a space-time fine grid $J_{h,\tau}$. The error estimates of optimal order of the discrete solution for the two-level method are derived. Compared with the standard Crank–Nicolson extrapolation method (the one-level method) based on a space-time fine grid $J_{h,\tau}$, the two-level method is of the error estimates of the same order as the one-level method in the H^1-norm for velocity and the L^2-norm for pressure. However, the two-level method involves much less work than the one-level method.

Key words. Navier–Stokes equations, mixed finite element, two-level method, Crank–Nicolson extrapolation

DOI. 10.1137/S0036142901385659

1. Introduction.

The two-grid strategy is closely related to the finite element nonlinear Galerkin methods (see [2, 16, 26, 27]) and has been widely studied for steady semilinear elliptic equations (see the work of Xu [34, 35]), for steady Navier–Stokes equations (see, for example, the work of Layton [22], Layton and Lenferink [23], Ervin and Layton [10], Ervin, Layton, and Maubach [11], Layton and Tobiska [24], and Girault and Lions [12]), and for time-dependent Navier–Stokes equations (see the work of Girault and Lions [13] and Olshanskii [28]). Moreover, the Crank–Nicolson scheme with second-order accuracy is adapted to the time discretization of the Navier–Stokes equations by Heywood and Rannacher [18]. The well-known Crank–Nicolson extrapolation scheme with second order accuracy is applied to the time discretization of the Navier–Stokes equations by Girault and Raviart [14] and Simo and Armero [30]. Also, the Crank–Nicolson extrapolation scheme is applied to the time discretization of the nonlinear parabolic equations (see Douglas and Dupont [8], Cannon and Lin [6], and Lin [25]) and the nonlinear dynamics (see Simo, Tarnow, and Wong [31]). Other higher-order time discrete schemes are given by Baker, Dougalis, and Karakashian [3] for the time-dependent Navier–Stokes equations and Dupont, Fairweather, and Johnson [9] for the nonlinear parabolic equations.

In the case of the nonlinear evolution problem, the basic idea of the two-level method is to find an approximation u_H by solving a nonlinear problem on a coarse grid with grid size H and find an approximation u^h by solving a linearized problem about the known approximation u_H on a fine grid with grid size h. In [13], Girault and Lions consider the semidiscretization in space of the three-dimensional time-dependent Navier–Stokes equations by the two-level method, where the error

estimates are provided. If $H = O(h^{1/2})$ is chosen, then the two-level method is of the convergence rate of the same order as the standard Galerkin method. Furthermore, Olshanskii in [28] deals mainly with the full discretization in space time of the two-dimensional and three-dimensional time-dependent Navier–Stokes equations by the two-level method, where the local error estimates, stability, and convergence are proved, but the global error estimates are not provided. In fact, this scheme is global first-order accurate with respect to the time step size τ.

In this paper we want to combine this two-grid strategy with the Crank–Nicolson extrapolation scheme with second-order accuracy to solve the two-dimensional time-dependent Navier–Stokes equations. We set J_H as a coarse grid of $\bar{\Omega}$ into triangles or quadrilaterals with mesh size H, assumed to be uniformly regular in the usual sense, and τ_0 denotes a large time step size; this spatial-time grid is denoted J_{H,τ_0}. Next, a fine grid J_h can be thought of as generated from the coarse mesh J_H by a mesh refinement process, and therefore nested, and a small time step size $\tau = \frac{\tau_0}{k}$ (k is a fixed integer), and this space-time grid is denoted $J_{h,\tau}$. Here, the basic idea of our two-level method is to find an approximation $(u_{H,\tau_0}, p_{H,\tau_0})$ by solving the linearized Navier–Stokes problem on a space-time coarse grid J_{H,τ_0} and to then find an approximation $(u^{h,\tau}, p^{h,\tau})$ by solving the Stokes problem on a space-time fine grid $J_{h,\tau}$, where $h \ll H, \ \ \tau \ll \tau_0$; here our scheme is second-order accurate with respect to time discretization.

The finite element space pairs (X_H, M_H) and (X_h, M_h) are constructed based on the coarse mesh J_H and the fine mesh J_h, which possess some approximate properties and the so-called inf-sup condition stated in section 3. Now, let us consider the numerical solution $(u^{h,\tau}, p^{h,\tau})$ of the two-dimensional time-dependent Navier–Stokes equations by the two-level method. In the first step, our approximation $(u_{H,\tau_0}, p_{H,\tau_0})$ is computed on a space-time coarse grid J_{H,τ_0} using the Crank–Nicolson extrapolation scheme. In the second step, an approximation $(u^{h,\tau}, p^{h,\tau})$ is computed on a spatial-time fine grid $J_{h,\tau}$ using the backward Euler scheme "around" u_{H,τ_0}. Then under quite general circumstances, we have obtained the error estimate of optimal order for the one-level finite element solution $(u_{h,\tau}, p_{h,\tau})$:

$$\|u(t) - u_{h,\tau}(t)\|_{H_0^1} \le \kappa h + \kappa\sigma^{-1/2}(t)\tau \quad \forall 0 < t \le T, \tag{1.1}$$

$$\|p(t) - p_{h,\tau}(t)\|_{L^2} \le \kappa\sigma^{-1/2}(t)h + \kappa\sigma^{-3/2}(t)\tau \quad \forall 0 < t \le T; \tag{1.2}$$

and we have obtained the error estimate of optimal order for the two-level finite element solution $(u^{h,\tau}, p^{h,\tau})$:

$$\begin{aligned}\|u(t) - u^{h,\tau}(t)\|_{H_0^1} &\le \kappa h + \kappa H(1-t)\sigma^{-1/2}(t)(\tau + H^{3/2} + \tau_0^{3/2}) \\ &\quad + \kappa H(t-1)(\tau + H^2 + \tau_0^2) \quad \forall 0 < t \le T,\end{aligned} \tag{1.3}$$

$$\|p(t) - p^{h,\tau}(t)\|_{L^2} \le \kappa\sigma^{-1/2}(t)h + \kappa\sigma^{-3/2}(t)(\tau + \tau_0^2 + H^2) \quad \forall 0 < t \le T \tag{1.4}$$

on the fine grid $J_{h,\tau}$, where $\sigma(t) = \min\{1, t\}$, $H(t) = 1$ as $t \ge 0$, and $H(t) = 0$ as $t < 0$. Hence, if one chooses (H, τ_0) such that $\tau_0^{3/2} + H^{3/2} = O(\tau)$ for $t \in [0, 1]$ and $\tau_0^2 + H^2 = O(\tau)$ for $t \in (1, T]$, then the two-level solution $(u^{h,\tau}, p^{h,\tau})$ is of the convergence rate of the same order as the one-level solution $(u_{h,\tau}, p_{h,\tau}$; but the velocity $u^{h,\tau}$ of the two-level solution is less accurate than the velocity $u_{h,\tau}$ of the one-level solution in the L^2-norm); see Theorem 5.6 and Lemma 6.3.

Of course, the computation of $(u^{h,\tau}, p^{h,\tau})$ involves much less "work" than the direct computation of $(u_{h,\tau}, p_{h,\tau})$. In fact, to find $(u^{h,\tau}, p^{h,\tau})$ we need to solve the discrete linearized Navier–Stokes problem by using the Crank–Nicolson extrapolation scheme on a space-time coarse grid J_{H,τ_0} and solve the discrete Stokes problem by using the Euler scheme on a fine space-time grid $J_{h,\tau}$; see section 6. However, the computation of $(u_{h,\tau}, p_{h,\tau})$ needs to solve a discrete linearized Navier–Stokes problem by using the extrapolation Crank–Nicolson scheme on a space-time fine grid $J_{h,\tau}$; see section 5.

The contents of this paper are divided into sections as follows. In section 2, functional setting of the Navier–Stokes problem is given with some basic statements. Finite element Galerkin approximation is recalled in section 3. Some key technical lemmas and known results are provided in section 4. The error estimates of the one-level finite element solution $(u_{h,\tau}, p_{h,\tau})$ will be proven in section 5. The error estimates of the two-level finite element solution $(u^{h,\tau}, p^{h,\tau})$ will be derived in section 6.

2. Functional setting of the Navier–Stokes equations. Let Ω be a bounded domain in R^2 assumed to have a Lipschitz continuous boundary $\partial\Omega$ and to satisfy a further condition stated in (A1) below. We consider the time-dependent Navier–Stokes problem

$$\begin{cases} u_t - \nu\Delta u + (u\cdot\nabla)u + \nabla p = f, \ \operatorname{div} u = 0 \ \ \forall (x,t) \in \Omega\times(0,T]; \\ u(x,0) = u_0(x) \ \ \forall x\in\Omega; \quad u(x,t)|_{\partial\Omega} = 0 \ \ \forall t\in[0,T], \end{cases} \tag{2.1}$$

where $u = u(x,t) = (u_1(x,t), u_2(x,t))$ represents the velocity vector, $p = p(x,t)$ the pressure, $f = f(x,t)$ the prescribed body force, $u_0(x)$ the initial velocity, $\nu > 0$ the viscosity, and $T > 0$ a finite time. For the mathematical setting of problem (2.1), we introduce the following Hilbert spaces:

$$X = H_0^1(\Omega)^2, \quad Y = L^2(\Omega)^2, \quad M = L_0^2(\Omega) = \left\{ q\in L^2(\Omega); \int_\Omega q dx = 0 \right\}.$$

The space $L^2(\Omega)^d$, $d = 1,2,4$, is equipped with the usual L^2-scalar product $(\cdot,\cdot)$ and L^2-norm $\|\cdot\|_{L^2}$. The spaces $H_0^1(\Omega)$ and X are equipped with their usual scalar product and equivalent norm

$$((u,v)) = (\nabla u, \nabla v), \quad \|u\|_{H_0^1} = \|\nabla u\|_{L^2}.$$

Next, let the closed subset V of X be given by

$$V = \{v\in X; d(v,q) = 0 \ \ \forall q\in M\} = \{v\in X; \operatorname{div} v = 0\}$$

and denote H the closed subset of Y, i.e.,

$$H = \{v\in Y; \operatorname{div} v = 0, v\cdot n|_{\partial\Omega} = 0\}.$$

We refer the readers to [1, 15, 17, 32] for more details on these spaces. We also denote the Stokes operator by $A = -P\Delta$, where P is the L^2-orthogonal projection of Y onto H.

As mentioned above, we need a further assumption on Ω provided in [17].

(A1). Assume that Ω is smooth so that the unique solution $(v,q)\in(X,M)$ of the steady Stokes problem

$$-\nu\Delta v + \nabla q = g, \quad \operatorname{div} v = 0 \quad \text{in } \Omega, \quad v|_{\partial\Omega} = 0,$$

for any prescribed $g \in Y$ exists and satisfies

$$\|v\|_{H^2} + \|q\|_{H^1} \leq c\|g\|_{L^2},$$

where $c > 0$ is a generic constant depending on Ω and ν which may stand for different values at its different occurrences.

We remark that the validity of assumption (A1) is known (see [15, 17, 20, 32]) if $\partial\Omega$ is of C^2 or if Ω is a two-dimensional convex polygon. From assumption (A1), it is well known [1, 17, 21] that

$$\|v\|_{H^2} \leq c\|Av\|_{L^2} \quad \forall v \in D(A) = H^2(\Omega)^2 \cap V, \tag{2.2}$$

$$\|v\|_{L^2} \leq \gamma_0\|v\|_{H_0^1} \quad \forall v \in X, \quad \|v\|_{H_0^1} \leq \gamma_0\|Av\|_{L^2} \quad \forall v \in D(A), \tag{2.3}$$

where γ_0 is positive constant depending only on Ω.

We usually make the following assumptions about the prescribed data for problem (2.1).

(A2). The initial velocity $u_0(x)$ and force $f(x,t)$ satisfy that $u_0 \in D(A)$, f, f_t, $f_{tt} \in L^\infty(0,T;Y)$ with

$$\|Au_0\|_{L^2} + \sup_{t\in[0,T]}\{\|f(t)\|_{L^2} + \|f_t(t)\|_{L^2} + \|f_{tt}(t)\|_{L^2}\} \leq C$$

for some positive constant C. We also introduce the following bilinear operator:

$$B(u,v) = (u\cdot\nabla)v + \frac{1}{2}(\mathrm{div}u)v \quad \forall u,v \in X.$$

Moreover, we define the continuous bilinear forms $a(\cdot,\cdot)$ and $d(\cdot,\cdot)$ on $X \times X$ and $X \times M$, respectively, by

$$a(u,v) = \nu((u,v)) \quad \forall u,v \in X,$$

$$d(v,q) = -(v,\nabla p) = (q,\mathrm{div}v) \quad \forall v \in X, \quad q \in M,$$

and a trilinear form on $X \times X \times X$ by

$$\begin{aligned} b(u,v,w) = \langle B(u,v),w\rangle_{X',X} &= ((u\cdot\nabla)v,w) + \frac{1}{2}((\mathrm{div}u)v,w) \\ &= \frac{1}{2}((u\cdot\nabla)v,w) - \frac{1}{2}((u\cdot\nabla)w,v) \quad \forall u,v,w \in X. \end{aligned}$$

With the above notations, the variational formulation of problem (2.1) reads as follows: find $(u,p) \in (X,M)$ for all $t \in [0,T]$ such that for all $(v,q) \in (X,M)$,

$$(u_t,v) + a(u,v) - d(v,p) + d(u,q) + b(u,u,v) = (f,v), \tag{2.4}$$

$$u(0) = u_0. \tag{2.5}$$

3. Finite element Galerkin approximation. Let $h > 0$ be a real positive parameter. Finite element subspace (X_h, M_h) of (X,M) is characterized by $J_h = J_h(\Omega)$, a partitioning of $\bar{\Omega}$ into triangles K or quadrilaterals K, assumed to be uniformly regular as $h \to 0$. For further details, the reader can refer to Ciarlet [7] and Girault and Raviart [15].

We define the subspace V_h of X_h given by

$$V_h = \left\{ v_h \in X_h\,;\, d(v_h, q_h) = 0 \ \ \forall q_h \in M_h \right\}. \tag{3.1}$$

Let $P_h : Y \rightarrow V_h$ denote the L^2-orthogonal projection defined by

$$(P_h v,\ v_h) = (v, v_h) \ \ \forall v \in Y,\ v_h \in V_h.$$

We assume that the couple (X_h, M_h) satisfies the following approximation properties: for each $v \in H^2(\Omega)^2 \cap X$ and $q \in H^1(\Omega) \cap M$, there exist approximations $\pi_h v \in X_h$ and $\rho_h q \in M_h$ such that

$$\begin{cases} d(v - \pi_h v, q_h) = 0 \ \forall q_h \in M_h, \\ \|v - \pi_h v\|_{H_0^1} \le ch\|v\|_{H^2},\ \|q - \rho_h q\|_{L^2} \le ch\|q\|_{H^1}, \end{cases} \tag{3.2}$$

together with the inverse inequality

$$\|v_h\|_{H_0^1} \le ch^{-1}\|v_h\|_{L^2} \ \ \forall v_h \in X_h; \tag{3.3}$$

and we have the so-called inf-sup inequality: for each $q_h \in M_h$, there exists $v_h \in X_h, v_h \neq 0$ such that

$$d(v_h, q_h) \ge \beta\|q_h\|_{L^2}\|v_h\|_{H_0^1}\,, \tag{3.4}$$

where $\beta > 0$ is a constant depending on Ω.

The following properties are classical (see [2, 15, 17, 19]):

$$\|P_h v\|_{H_0^1} \le c\|v\|_{H_0^1} \ \ \forall v \in X, \tag{3.5}$$

$$\|v - P_h v\|_{L^2} + h\|v - P_h v\|_{H_0^1} \le ch^2\|Av\|_{L^2} \ \ \forall v \in D(A), \tag{3.6}$$

$$\|v - P_h v\|_{L^2} \le ch\|v - P_h v\|_{H_0^1} \ \ \forall v \in X. \tag{3.7}$$

The standard finite element Galerkin approximation of (2.4)–(2.5) based on (X_h, M_h) reads as follows: find $(u_h, p_h) \in (X_h, M_h)$ such that for all $0 < t \le T$ and $(v_h, q_h) \in (X_h, M_h)$,

$$(u_{ht}, v_h) + a(u_h, v_h) - d(v_h, p_h) + d(u_h, q_h) + b(u_h, u_h, v_h) = (f, v_h), \tag{3.8}$$

$$u_h(0) = u_{0h} = P_h u_0. \tag{3.9}$$

With the above statements, a discrete analogue $A_h = -P_h\Delta_h$ of the Stokes operator A is defined through the condition that $(-\Delta_h u_h, v_h) = ((u_h, v_h))$ for all $u_h, v_h \in X_h$. The restriction of A_h to V_h is invertible, with inverse denoted A_h^{-1}. Since A_h^{-1} is self-adjoint and positive definite, we may define "discrete" Sobolev norms on V_h, of any order $r \in R$, by setting

$$\|v_h\|_r = \|A_h^{r/2} v_h\|_{L^2} \ \ \forall v_h \in V_h.$$

These norms will be assumed to have various properties similar to their continuous counterparts, an assumption that implicitly imposes conditions on the structure of the spaces X_h and M_h. In particular, there holds

$$\|v_h\|_0 = \|v_h\|_{L^2}, \ \ \|v_h\|_1 = \|v_h\|_{H_0^1} \ \ \forall v_h \in V_h.$$

By the way, we derive from (2.3) that

$$\|v_h\|_0 \le c\|v_h\|_1, \quad \|v_h\|_1 \le c\|A_h v_h\|_0 \quad \forall v_h \in V_h. \tag{3.10}$$

Under the conditions above, and with some further assumptions about the structure of the spaces X_h and M_h, it has been shown in Heywood and Rannacher [17] that

$$\|u(t)-u_h(t)\|_{L^2} + h\|u(t)-u_h(t)\|_{H_0^1} + \sigma^{1/2}(t)h\|p(t)-p_h(t)\|_{L^2} \le \kappa h^2 \tag{3.11}$$

for all $t \in (0,T]$.

4. Technical preliminaries. This section considers preliminary estimates which will be very useful in the error estimates of finite element solution (u_h, p_h). Now we will provide the following estimates of the trilinear form b.

LEMMA 4.1. *The trilinear form b satisfies the following estimates:*

$$b(u_h, v_h, w_h) = -b(u_h, w_h, v_h), \tag{4.1}$$

$$|b(u_h, v_h, w_h)| + |b(w_h, v_h, u_h)| \le c\|u_h\|_0^{1/2}\|u_h\|_1^{1/2}\|v_h\|_1\|w_h\|_1 \tag{4.2}$$

for all $u_h, v_h, w_h \in X_h$ and

$$|b(u_h, v_h, w_h)| + |b(w_h, v_h, u_h)| \le c\|A_h v_h\|_0^{1/2}\|v_h\|_1^{1/2}\|u_h\|_1\|w_h\|_0, \tag{4.3}$$

$$|b(u_h, v_h, w_h)| + |b(w_h, v_h, u_h)| \le c\|u_h\|_{-1}\|A_h v_h\|_0\|A_h w_h\|_0 \tag{4.4}$$

for all $u_h, v_h, w_h \in V_h$.

Proof. It is well known [17, 18] that (4.1)–(4.3) are valid. To prove (4.4), we need some discrete Gagliardo–Nireberg estimates (see [19]):

$$\|v_h\|_{L^4} \le c\|v_h\|_0^{1/2}\|v_h\|_1^{1/2} \quad \forall v_h \in X_h, \tag{4.5}$$

$$\|\nabla v_h\|_{L^4} \le c\|v_h\|_1^{1/2}\|A_h v_h\|_0^{1/2}, \quad \|v_h\|_{L^\infty} \le c\|v_h\|_0^{1/2}\|A_h v_h\|_0^{1/2} \quad \forall v_h \in V_h, \tag{4.6}$$

the proof of which is identical to that given by Heywood and Rannacher [17, inequalities (4.37) and (4.39), p. 298]. From the definition of b, there holds the following estimate:

$$\begin{aligned}
&|b(u_h, v_h, w_h)| + |b(w_h, v_h, u_h)| \\
&\qquad \le \frac{1}{2}\|A_h^{-1/2}u_h\|_{L^2}\|A_h^{1/2}((\nabla v_h)w_h - (\nabla w_h)v_h)\|_{L^2} \\
&\qquad + \left\|A_h^{1/2}((w_h\cdot\nabla)v_h + \frac{1}{2}(\mathrm{div} w_h)v_h)\right\|_{L^2}\|A_h^{-1/2}u_h\|_{L^2} \\
&\qquad \le c\|u_h\|_{-1}(\|\nabla v_h\|_{L^4}\|\nabla w_h\|_{L^4} + \|A_h v_h\|_{L^2}\|w_h\|_{L^\infty} + \|v_h\|_{L^\infty}\|A_h w_h\|_{L^2}).
\end{aligned}$$

Combining this inequality with (4.5)–(4.6) and using (3.10) yields (4.4). □

In order to obtain our error analysis for the time discretization, we will recall the following smooth properties of (u_h, p_h) proved in [18].

Theorem 4.2. *Assume that assumptions* (A$_1$)–(A$_2$) *and* (3.2)–(3.4) *are valid. Then the finite element solution* (u_h, p_h) *satisfies the following estimates:*

$$\|u_h(t)\|_2^2 + \|p_h(t)\|_0^2 \le \kappa, \quad \sigma^r(t)\|u_{ht}(t)\|_r^2 \le \kappa, \quad r = 0, 1, 2, \tag{4.7}$$

$$\sigma^{r+2}\|u_{htt}(t)\|_r^2 \le \kappa, \quad r = -1, 0, 1, \tag{4.8}$$

$$\int_0^t \sigma^r(s)\|u_{ht}(s)\|_{r+1}^2 ds \le \kappa, \quad r = 0, 1, \tag{4.9}$$

$$\int_0^t \sigma^{r+1}(s)\|u_{htt}(s)\|_r^2 ds \le \kappa, \quad r = -1, 0, 1, \tag{4.10}$$

$$\int_0^t \sigma^{r+2}(s)\|u_{httt}(s)\|_{r-1}^2 ds \le \kappa, \quad r = -1, 0, 1 \tag{4.11}$$

for all $t \in [0, T]$.

We will frequently use a discrete version of the Gronwall lemmas used in [18] and [29].

Lemma 4.3. *Let* C, τ, *and* a_n, b_n, c_n, d_n, *for integers* $n \ge 0$, *be nonnegative numbers such that*

$$a_m + \tau\sum_{n=0}^m b_n \le \tau\sum_{n=0}^m a_n d_n + \tau\sum_{k=0}^m c_n + C \quad \forall m \ge 1. \tag{4.12}$$

Suppose that $d_n\tau < 1$, *for all* n, *and set* $\gamma_n \equiv (1 - d_n\tau)^{-1}$. *Then*

$$a_m + \Delta t\sum_{n=0}^m b_n \le \exp\left(\tau\sum_{n=0}^m \gamma_n d_n\right)\left(\tau\sum_{n=0}^m c_n + C\right) \quad \forall m \ge 1. \tag{4.13}$$

Lemma 4.4. *Let* C, τ, *and* a_n, b_n, c_n, d_n, *for integers* $n \ge 0$, *be nonnegative numbers such that*

$$a_m + \tau\sum_{n=0}^m b_n \le \tau\sum_{n=0}^{m-1} a_n d_n + \tau\sum_{n=0}^{m-1} c_n + C \quad \forall m \ge 1. \tag{4.14}$$

Then

$$a_m + \tau\sum_{n=0}^m b_n \le \exp\left(\tau\sum_{n=0}^{m-1} d_n\right)\left(\tau\sum_{n=0}^{m-1} c_n + C\right) \quad \forall m \ge 1. \tag{4.15}$$

5. One-level finite element method. In this section we consider the time discretization of the finite element Galerkin approximation (3.8)–(3.9). Let $t_n = n\tau(n = 0, 1, \ldots, N)$ be the discrete point, $\tau = \frac{T}{N}$ the time step size, and N an integer. The Crank–Nicolson extrapolation scheme on the space-time grid $J_{h,\tau}$ is to determine function pair $(u_{h,\tau}(t), p_{h,\tau}(t))$ on $[0, T]$ such that for $t \in (t_{n-1}, t_n], 1 \le n \le N$, we define one-level finite element solution $(u_{h,\tau}(t), p_{h,\tau}(t))$ as follows:

$$u_{h,\tau}(t) = u_h^{n-1} + (t - t_{n-1})d_t u_h^n, \quad p_{h,\tau}(t) = p_h^n,$$

where $u_{h,\tau}(0) = u_{0h} = u_h^0$, $\{u_h^n\}_{n=1}^N \subset V_h$, $\{p_h^n\}_{n=1}^N \subset M_h$ as the solution of the recursive linear equation:

$$(d_t u_h^n, v_h) + a(\bar{u}_h^n, v_h) - d(v_h, p_h^n) + d(\bar{u}_h^n, q_h) + b(\phi(\bar{u}_h^n), \bar{u}_h^n, v_h) = (\bar{f}(t_n), v_h) \tag{5.1}$$

for all $(v_h, q_h) \in (X_h, M_h)$. Here and after, we often use the following notations:

$$\phi(\bar{u}_h^n) = H(1-n)\bar{u}_h^n + H(n-2)\left(\frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}\right),$$

$$\bar{u}_h^n = \frac{1}{2}(u_h^n + u_h^{n-1}), \quad \bar{u}_h(t_n) = \frac{1}{2}(u_h(t_n) + u_h(t_{n-1})), \quad d_t u_h^n = \frac{u_h^n - u_h^{n-1}}{\tau}.$$

From the definition of ϕ, $(u_h^1, p_h^1) = (u_*^1, p_*^1)$ is defined by the Crank–Nicolson scheme, where the scheme is as follows: find $\{u_*^n\}_{n=1}^N \subset V_h$ and $\{p_*^n\}_{n=1}^N \subset M_h$ such that

$$(5.2)\ \ (d_t u_*^n, v_h) + a(\bar{u}_*^n, v_h) - d(v_h, p_*^n) + d(\bar{u}_*^n, q_h) + b(\bar{u}_*^n, \bar{u}_*^n, v_h) = (\bar{f}(t_n), v_h),$$

with the initial value $u_*^0 = u_{0h}$.

An error argument given in [18] shows the following error estimate results.

Theorem 5.1. *Suppose that the assumptions* (A1)–(A2) *are valid and the couple* (X_h, M_h) *satisfies the approximate properties* (3.2)–(3.4) *and* $\tau \le \tau_T$*, where* τ_T *is a finite constant which can take different values at its different occurrences. Then there hold the following error estimates:*

$$(5.3)\qquad \|u_h(t_m) - u_*^m\|_r^2 + \tau\sum_{n=1}^m \|\bar{u}_h(t_n) - \bar{u}_*^n\|_{r+1}^2 \le \kappa\tau^{2-r}, \quad r = -2, -1, 0, 1,$$

$$(5.4)\qquad \|u_h(t_m) - u_*^m\|_r^2 + \tau\sum_{n=1}^m \|d_t(u_h(t_n) - u_*^n)\|_{r-1}^2 \le \kappa\tau^{2-r}, \quad r = -1, 0, 1, 2,$$

$$(5.5)\ \ \sigma(t_m)\|u_h(t_m) - u_*^m\|_r^2 + \tau\sum_{n=1}^m \sigma(t_n)\|u_h(t_n) - u_*^n\|_{r+1}^2 \le \kappa\tau^{3-r}, \quad r = 0, 1,$$

$$(5.6)\ \ \sigma(t_m)\|u_h(t_m) - u_*^m\|_0 \le \kappa\tau^2, \quad \sigma^{3/2}(t_m)\|p_h(t_m) - p_*^m\|_{L^2} \le \kappa\tau$$

for all $1 \le m \le N$.

Again, in determining the velocity approximation, the pressure term can be eliminated by restricting the test functions in (5.1) and (5.2) to V_h. That is, the velocity can be determined from

$$(5.7)\qquad (d_t u_h^n, v_h) + a(\bar{u}_h^n, v_h) + b(\phi(\bar{u}_h^n), \bar{u}_h^n, v_h) = (\bar{f}(t_n), v_h) \quad \forall v_h \in V_h$$

or

$$(5.8)\qquad (d_t u_*^n, v_h) + a(\bar{u}_*^n, v_h) + b(\bar{u}_*^n, \bar{u}_*^n, v_h) = (\bar{f}(t_n), v_h) \quad \forall v_h \in V_h.$$

In order to analyze the discretization error $(u_h(t_n) - u_h^n, \bar{p}_h(t_n) - p_h^n)$, we will first consider the discrete error $(e_h^n, \mu_h^n) = (u_*^n - u_h^n, p_*^n - p_h^n)$ with $(e_h^1, \mu_h^1) = (0, 0)$ and then combine this with Theorem 5.1. However, this needs the following regularity of functions $\{u_*^n\}_{n=1}^N$.

Lemma 5.2. *Under the assumptions of Theorem* 5.1*, there holds*

$$(5.9)\qquad \|u_*^m\|_r^2 + \tau\sum_{n=1}^m (\|\bar{u}_*^n\|_r^2 + \|d_t u_*^n\|_{r-1}^2) \le \kappa, \quad 1 \le m \le N, \quad r = 0, 1, 2,$$

$$(5.10)\ \ \sigma(t_m)\|d_t u_*^m\|_1^2 + \tau\sum_{n=2}^m (\|d_{tt} u_*^n\|_{-1}^2 + \sigma(t_n)\|d_{tt} u_*^n\|_0^2) \le \kappa, \quad 2 \le m \le N.$$

Proof. First, we use (4.7), (4.9) and Theorem 5.1, obtaining

$$\|u_*^n\|_r^2 + \tau\sum_{n=1}^m \|\bar{u}_*^n\|_r^2 \le 2\|u_*^n - u_h(t_n)\|_r^2 + 2\|u_h(t_n)\|_r^2$$

$$+ 2\tau\sum_{n=1}^m (\|\bar{u}_*^n - \bar{u}_h(t_n)\|_r^2 + \|\bar{u}_h(t_n)\|_r^2) \le \kappa,$$

$$\tau\sum_{n=1}^m \|d_t u_*^n\|_{r-1}^2 \le 2\tau\sum_{n=1}^m (\|d_t u_*^n - d_t u_h(t_n)\|_{r-1}^2 + \|d_t u_h(t_n)\|_{r-1}^2)$$

$$\le \kappa + c\int_0^{t_m} \|u_{ht}\|_{r-1}^2 dt + c\int_0^{t_m} \sigma^2(t)\|u_{htt}\|_{r-1}^2 dt \le \kappa,$$

which yields (5.9).

Next, we derive from (5.8) that

$$(d_{tt}u_*^n, v_h) + a(d_t\bar{u}_*^n, v_h) + b(d_t\bar{u}_*^n, \bar{u}_*^n, v_h) + b(\bar{u}_*^{n-1}, d_t\bar{u}_*^n, v_h)$$

$$= \tau^{-1}\int_{t_{n-2}}^{t_n} (f_t(t), v_h)dt \quad \forall v_h \in V_h.$$

Taking $v_h = 2\tau d_{tt}u_*^n$ in the above relation, we obtain

$$2\tau\|d_{tt}u_*^n\|_0^2 + \nu(\|d_t u_*^n\|_1^2 - \|d_t u_*^{n-1}\|_1^2) + 2\tau b(d_t\bar{u}_*^n, \bar{u}_*^n, d_{tt}u_*^n)$$

$$+ 2\tau b(\bar{u}_*^{n-1}, d_t\bar{u}_*^n, d_{tt}u_*^n) \le \frac{\tau}{2}\|d_{tt}u_*^n\|_0^2 + c\int_{t_{n-2}}^{t_n} \|f_t(t)\|_{L^2}^2 dt. \tag{5.11}$$

In view of Lemma 4.1, there holds

$$2\tau|b(d_t\bar{u}_*^n, \bar{u}_*^n, d_{tt}u_*^n)| + 2\tau|b(d_t\bar{u}_*^n, \bar{u}_*^n, d_{tt}u_*^n)|$$

$$\le \frac{\tau}{2}\|d_{tt}u_*^n\|_0^2 + c\tau\|A_h\bar{u}_*^n\|_0^2\|d_t\bar{u}_*^n\|_1^2.$$

Combining this inequality with (5.11), using (5.9) with $r = 2$ and the fact that $\sigma(t_n) \le \sigma(t_{n-1}) + \tau$ yields

$$\tau\sigma(t_n)\|d_{tt}u_*^n\|_0^2 + \nu(\sigma(t_n)\|d_t u_*^n\|_1^2 - \sigma(t_{n-1})\|d_t u_*^{n-1}\|_1^2)$$

$$\le \nu\tau(\|d_t u_*^{n-1}\|_1^2 + \kappa\|d_t u_*^n\|_1^2) + c\int_{t_{n-2}}^{t_n} \|f_t(t)\|_{L^2}^2 dt. \tag{5.12}$$

Summing this inequality from $n = 2$ to $n = m$ and using (5.9), we arrive at

$$\tau\sum_{n=2}^m \sigma(t_n)\|d_{tt}u_*^n\|_0^2 + \nu\sigma(t_m)\|d_t u_*^m\|_1^2 \le \kappa, \quad 2 \le m \le N. \tag{5.13}$$

Finally, we derive from (4.10) and (5.4) with $r = -1$ that

$$\tau\sum_{n=2}^m \|d_{tt}u_*^n\|_{-1}^2 = \tau^{-1}\sum_{n=2}^m \|d_t u_*^n - d_t u_*^{n-1}\|_{-1}^2 \le c\tau^{-1}\sum_{n=2}^m (\|d_t u_*^n - d_t u_h(t_n)\|_{-1}^2$$

$$+ \|d_t u_*^{n-1} - d_t u_h(t_{n-1})\|_{-1}^2 + \|d_t u_h(t_n) - d_t u_h(t_{n-1})\|_{-1}^2)$$

$$\leq \kappa + c\tau^{-3}\sum_{n=2}^{m}\left\|\int_{t_{n-1}}^{t_n}(t_n-t)u_{htt}dt + \int_{t_{n-2}}^{t_{n-1}}(t-t_{n-2})u_{htt}dt\right\|_{-1}^2$$

$$\leq \kappa + c\int_0^{t_m}\|u_{htt}\|_{-1}^2 dt \leq \kappa,$$

which along with (5.13) gives (5.10). □

Lemma 5.3. *Under the assumptions of Theorem* 5.1*, there holds*

$$\|e_h^m\|_r^2 + \tau\sum_{n=1}^{m}\|\bar{e}_h^n\|_{r+1}^2 \leq \kappa\tau^{3-r}, \quad r=-1,0,1, \quad 1\leq m\leq N, \tag{5.14}$$

$$\|e_h^m\|_1^2 + \tau\sum_{n=1}^{m}\|d_t e_h^n\|_0^2 \leq \kappa\tau^2, \quad 1\leq m\leq N. \tag{5.15}$$

Proof. Subtracting (5.7) from (5.8), we obtain

$$\begin{aligned}&(d_t e_h^n, v_h) + a(\bar{e}_h^n, v_h) + b(\phi(\bar{e}_h^n), \bar{u}_*^n, v_h) + b(\phi(\bar{u}_*^n), \bar{e}_h^n, v_h)\\ &\quad - b(\phi(\bar{e}_h^n), \bar{e}_h^n, v_h) + \frac{1}{2}H(n-2)\tau^2 b(d_{tt}u_*^n, \bar{u}_*^n, v_h) = 0 \quad \forall v_h \in V_h.\end{aligned} \tag{5.16}$$

Taking $v_h = 2\tau\bar{e}_h^n$ in (5.16) and using (4.1), we get

$$\begin{aligned}&\|e_h^n\|_0^2 - \|e_h^{n-1}\|_0^2 + 2\nu\tau\|\bar{e}_h^n\|_1^2 + 2\tau b(\phi(\bar{e}_h^n), \bar{u}_*^n, \bar{e}_h^n)\\ &\quad + H(n-2)\tau^3 b(d_{tt}u_*^n, \bar{u}_*^n, \bar{e}_h^n) = 0.\end{aligned} \tag{5.17}$$

Using (4.3), it follows that

$$2\tau|b(\phi(\bar{e}_h^n), \bar{u}_*^n, \bar{e}_h^n)| \leq \frac{\nu\tau}{2}\|\bar{e}_h^n\|_1^2 + c\tau\|A_h\bar{u}_*^n\|_0^2\|\phi(\bar{e}_h^n)\|_0^2,$$

$$H(n-2)\tau^3|b(d_{tt}u_*^n, \bar{u}_*^n, \bar{e}_h^n)| \leq \frac{\nu\tau}{2}\|\bar{e}_h^n\|_1^2 + cH(n-2)\tau^5\|d_{tt}u_*^n\|_0^2\|A_h\bar{u}_*^n\|_0^2.$$

Combining these inequalities with (5.17) and applying Lemma 5.2 results in

$$\|e_h^n\|_0^2 - \|e_h^{n-1}\|_0^2 + \nu\tau\|\bar{e}_h^n\|_1^2 \leq \kappa\|\phi(\bar{e}_h^n)\|_0^2 + \kappa H(n-2)\tau^5\|d_{tt}u_*^n\|_0^2. \tag{5.18}$$

Summing (5.18) from $n=1$ to $n=m$ leads to the following estimate:

$$\|e_h^m\|_0^2 + \nu\tau\sum_{n=1}^{m}\|\bar{e}_h^n\|_1^2 \leq \kappa\tau\sum_{n=1}^{m-1}\|e_h^n\|_0^2 + \kappa\tau^4\sum_{n=2}^{m}\sigma(t_n)\|d_{tt}u_*^n\|_0^2.$$

Applying Lemma 4.4 and Lemma 5.2 to this inequality yields (5.14) with $r=0$.

Next, by setting $v_h = 2\tau d_t e_h^n$ in (5.16) and using (4.1), we get

$$\begin{aligned}&\nu(\|e_h^n\|_1^2 - \|e_h^{n-1}\|_1^2) + 2\tau\|d_t e_h^n\|_0^2 + 2\tau b(\phi(\bar{e}_h^n), \bar{u}_*^n, d_t e_h^n)\\ &\quad + 2\tau b(\phi(\bar{u}_*^n), e_h^{n-1}, d_t e_h^n) + 4b(\phi(\bar{e}_h^n), \bar{e}_h^n, e_h^{n-1})\\ &\quad + H(n-2)\tau^3 b(d_{tt}u_*^n, \bar{u}_*^n, d_t e_h^n) = 0.\end{aligned} \tag{5.19}$$

From Lemma 4.1 and (3.10), we get

$$
\begin{aligned}
2\tau|b(\phi(\bar{e}_h^n),\bar{u}_*^n,d_te_h^n)| &\le \frac{\tau}{4}\|d_te_h^n\|_0+c\tau\|A_h\bar{u}_*^n\|_0^2\|\phi(\bar{e}_h^n)\|_1^2,\\
2\tau|b(\phi(\bar{u}_*^n),e_h^{n-1},d_te_h^n)| &\le \frac{\tau}{4}\|d_te_h^n\|_0^2+c\tau\|A_h\phi(\bar{u}_*^n)\|_0^2\|e_h^{n-1}\|_1^2,\\
4|b(\phi(\bar{e}_h^n),\bar{e}_*^n,e_h^{n-1})| &\le c\|\phi(\bar{e}_h^n)\|_1\|\bar{e}_h^n\|_1\|e_h^{n-1}\|_1,\\
H(n-2)\tau^3|b(d_{tt}u_*^n,\bar{u}_*^n,A_h^{r-1}d_te_h^n)| &\le \frac{\tau}{4}\|d_te_h^n\|_0^2+cH(n-2)\tau^5\|d_{tt}u_*^n\|_1^2\|A_h\bar{u}_*^n\|_0^2.
\end{aligned}
$$

Combining these inequalities with (5.19) and using Lemma 5.2 and (5.14) with $r=0$, we see that

$$
\begin{aligned}
\nu(\|e_h^n\|_1^2-\|e_h^{n-1}\|_1^2)+\tau\|d_te_h^n\|_0^2 &\le \kappa\tau(\|e_h^{n-1}\|_1^2+\|\phi(\bar{e}_h^n)\|_1^2)\\
&\quad +H(n-2)\kappa\tau^3\|d_tu_*^n-d_tu_*^{n-1}\|_1^2.
\end{aligned}
$$

Summing this inequality from $n=1$ to $n=m$ and applying Lemma 5.2 results in

$$
\|e_h^m\|_1^2+\nu\tau\sum_{n=1}^{m}\|d_te_h^n\|_0^2 \le \kappa\tau\sum_{n=1}^{m-1}\|e_h^n\|_1^2+\kappa\tau^2.
$$

Applying Lemma 4.4 to this inequality yields (5.15).

Next, we take $v_h=2\tau A_h^r\bar{e}_h^n$ in (5.16) with $r=-1,1$, obtaining

$$
\begin{aligned}
&\|e_h^n\|_r^2-\|e_h^{n-1}\|_r^2+2\nu\tau\|\bar{e}_h^n\|_{r+1}^2+2\tau b(\phi(\bar{e}_h^n),\bar{u}_*^n,A_h^r\bar{e}_h^n)+2\tau b(\phi(\bar{u}_*^n),\bar{e}_h^n,A_h^r\bar{e}_h^n)\\
&\qquad +2\tau b(\phi(\bar{e}_h^n),\bar{e}_h^n,A_h^r\bar{e}_h^n)+H(n-2)\tau^3 b(d_{tt}u_*^n,\bar{u}_*^n,A_h^r\bar{e}_h^n)=0.
\end{aligned}
\tag{5.20}
$$

From Lemma 4.1, it follows that

$$
\begin{aligned}
2\tau|b(\phi(\bar{e}_h^n),\bar{u}_*^n,A_h^r\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|\bar{e}_h^n\|_{r+1}^2+c\tau\|A_h\bar{u}_*^n\|_0^2\|\phi(\bar{e}_h^n)\|_r^2,\\
2\tau|b(\phi(\bar{u}_*^n),\bar{e}_h^n,A_h^r\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|\bar{e}_h^n\|_r^2+c\tau\|A_h\phi(\bar{u}_*^n)\|_0^2\|\bar{e}_h^n\|_r^2,\\
2\tau|b(\phi(\bar{e}_h^n),\bar{e}_h^n,A_h^r\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|\bar{e}\|_{r+1}^2\\
&\quad +c\tau\|\phi(\bar{e}_h^n)\|_0^{1-r}\|\phi(\bar{e}_h^n)\|_1^{2+2r}\|\bar{e}_h^n\|^2,\\
\tau^3|b(d_{tt}u_*^n,\bar{u}_*^n,A_h^r\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|\bar{e}_h^n\|_{r+1}^2+c\tau^5\|d_{tt}u_*^n\|_r^2\|A_h\bar{u}_*^n\|_0^2.
\end{aligned}
$$

Combining these inequalities with (5.20) and applying Lemma 5.2 yields

$$
\begin{aligned}
\|e_h^n\|_r^2-\|e^{n-1}\|_r^2+\nu\tau\|\bar{e}_h^n\|_{r+1}^2 &\le c\tau(\|\phi(\bar{e}_h^n)\|_r^2+\|\bar{e}_h^n\|_r^2)\\
&\quad +c\tau\|\phi(\bar{e}_h^n)\|_0^{1-r}\|\phi(\bar{e}_h^n)\|_1^{2+2r}\|\bar{e}_h^n\|_1^2+cH(n-2)\tau^5\|d_{tt}u_*^n\|_r^2.
\end{aligned}
\tag{5.21}
$$

Summing (5.21) from $n=1$ to $n=m$ and applying Lemma 5.2, (5.15), and (5.14) with $r=0$, we obtain

$$
\|e_h^m\|_r^2+\tau\sum_{n=1}^{m}\|\bar{e}_h^n\|_{r+1}^2 \le \kappa\tau^{3-r}+\kappa\tau\sum_{n=1}^{m}\|e_h^n\|_r^2.
\tag{5.22}
$$

Applying Lemma 4.3 to this inequality with $\tau \le \tau_T$ yields (5.14) with $r = -1, 1$. □

LEMMA 5.4. *Under the assumptions of Theorem* 5.1*, there holds*

$$\sigma(t_m)\|e_h^m\|_0^2 + \tau \sum_{n=1}^{m} \sigma(t_n)\|\bar{e}_h^n\|_1^2 \le \kappa\tau^4, \quad 1 \le m \le N, \tag{5.23}$$

$$\sigma(t_m)\|d_t e_h^m\|_0^2 + \tau \sum_{n=1}^{m} \sigma(t_n)\|d_t\bar{e}_h^n\|_1^2 \le \kappa\tau^2, \quad 1 \le m \le N. \tag{5.24}$$

Proof. Multiplying (5.18) by $\sigma(t_n)$ and using Lemma 5.2 and the fact that

$$\sigma(t_n) \le \sigma(t_{n-1}) + \tau, \quad e_h^{n-1} = \bar{e}^n - \frac{\tau}{2} d_t e^n, \tag{5.25}$$

we obtain

$$\begin{aligned}\sigma(t_n)\|e_h^n\|_0^2 - \sigma(t_{n-1})\|e_h^{n-1}\|_0^2 + \nu\tau\sigma(t_n)\|\bar{e}_h^n\|_1^2 \\ \le 2\tau\|\bar{e}_h^n\|_0^2 + \tau^3\|d_t e_h^n\|_0^2 + \kappa\tau\sigma(t_n)\|\phi(\bar{e}_h^n)\|_0^2 + cH(n-2)\tau^5\sigma(t_n)\|d_{tt}u_*^n\|_0^2.\end{aligned}$$

Summing this inequality from $n = 1$ to $n = m$ and using Lemma 5.2, we obtain

$$\begin{aligned}\sigma(t_m)\|e_h^m\|_0^2 + \nu\tau \sum_{n=1}^{m} \sigma(t_n)\|\bar{e}_h^n\|_1^2 \le \kappa\tau^4 + \kappa\tau \sum_{n=0}^{m-1} \sigma(t_n)\|e_h^n\|_0^2 \\ + \tau \sum_{n=1}^{m} (2\|\bar{e}_h^n\|_0^2 + \tau^3\|d_t e_h^n\|_0^2).\end{aligned} \tag{5.26}$$

Applying Lemma 4.4 and Lemma 5.3 with $r = -1$ to this inequality yields

$$\sigma(t_m)\|e_h^m\|_0^2 + \nu\tau \sum_{n=1}^{m} \sigma(t_n)\|\bar{e}_h^n\|_1^2 \le \kappa\tau^4,$$

which gives (5.23).

Furthermore, we derive from (5.16) that

$$\begin{aligned}(d_{tt}e_h^n, v_h) + a(d_t\bar{e}_h^n, v_h) + b(\phi(d_t\bar{e}_h^n), \bar{u}_*^n, v_h) \\ + b(\phi(\bar{e}_h^{n-1}), d_t\bar{u}_*^n, v_h) + b(\phi(d_t\bar{u}_*^n), \bar{e}_h^n, v_h) \\ + b(\phi(\bar{u}_*^{n-1}), d_t\bar{e}_h^n, v_h) - b(\phi(d_t\bar{e}_h^n), \bar{e}_h^n, v_h) \\ - b(\phi(\bar{e}_h^{n-1}), d_t\bar{e}_h^n, v_h) + \frac{1}{2}H(n-2)\tau b(d_{tt}u_*^n, \bar{u}_*^n, v_h) \\ - \frac{1}{2}H(n-3)\tau b(d_{tt}u_*^{n-1}, \bar{u}_*^{n-1}, v_h) = 0\end{aligned} \tag{5.27}$$

for all $v_h \in V_h$. We take $v_h = 2\tau d_t\bar{e}_h^n$ in (5.27) and use (4.1), obtaining

$$\begin{aligned}\|d_t e_h^n\|_0^2 - \|d_t e_h^{n-1}\|_0^2 + 2\nu\tau\|d_t\bar{e}_h^n\|_1^2 + 2\tau b(\phi(d_t\bar{e}_h^n), \bar{u}_*^n, d_t\bar{e}_h^n) \\ + 2\tau b(\phi(\bar{e}_h^{n-1}), d_t\bar{u}_*^n, d_t\bar{e}_h^n) + 2\tau b(\phi(d_t\bar{u}_*^n), \bar{e}_h^n, d_t\bar{e}_h^n) \\ - 2\tau b(\phi(d_t\bar{e}_h^n), \bar{e}_h^n, d_t\bar{e}_h^n) + H(n-2)\tau^2 b(d_{tt}u_*^n, \bar{u}_*^n, d_t\bar{e}_h^n) \\ - H(n-3)\tau^2 b(d_{tt}u_*^{n-1}, \bar{u}_*^{n-1}, d_t\bar{e}_h^n) = 0.\end{aligned} \tag{5.28}$$

From Lemma 4.1, it follows that

$$\begin{aligned}
2\tau|b(\phi(d_t\bar{e}_h^n),\bar{u}_*^n,d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{8}\|d_t\bar{e}_h^n\|_1^2+c\tau\|A_h\bar{u}_*^n\|_0^2\|\phi(d_t\bar{e}_h^n)\|_0^2,\\
2\tau|b(\phi(\bar{e}_h^{n-1}),d_t\bar{u}_*^n,d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{8}\|d_t\bar{e}_h^n\|_1^2+c\tau\|d_t\bar{u}_*^n\|_1^2\|\phi(\bar{e}_h^{n-1})\|_1^2,\\
2\tau|b(\phi(d_t\bar{u}_*^n),\bar{e}_h^n,d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{8}\|d_t\bar{e}_h^n\|_1^2+c\tau^{-1}\|A_h\phi(\bar{u}_*^n)-A_h\phi(\bar{u}_*^{n-1})\|_0^2\|\bar{e}_h^n\|_0^2,\\
2\tau|b(\phi(d_t\bar{e}_h^n),\bar{e}_h^n,d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2+c\tau\|\phi(d_t\bar{e}_h^n)\|_1^2\|\bar{e}_h^n\|_1^2,\\
H(n-2)\tau^2|b(d_{tt}u_*^n,\bar{u}_*^n,d_t\bar{e}_h^n)| &+ H(n-3)\tau^2|b(d_{tt}u_*^{n-1},\bar{u}_*^{n-1},d_t\bar{e}_h^n)|\\
&\le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2+c\tau^3H(n-2)\|d_{tt}u_*^n\|_0^2\|A_h\bar{u}_*^n\|_0^2\\
&\quad+c\tau^3H(n-3)\|d_{tt}u_*^{n-1}\|_0^2\|A_h\bar{u}_*^{n-1}\|_0^2.
\end{aligned}$$

Combining these inequalities with (5.28) and using Lemma 5.2 yields

$$\begin{aligned}
\sigma(t_n)\|d_te_h^n\|_0^2 &- \sigma(t_{n-1})\|d_te_h^{n-1}\|_0^2+\nu\tau\sigma(t_n)\|d_t\bar{e}_h^n\|_1^2\\
&\le \tau\|d_te_h^{n-1}\|_0^2+c\sigma(t_n)\tau\|\phi(d_t\bar{e}_h^n)\|_0^2+c\tau\|d_t\bar{u}_*^n\|_1^2\|\bar{e}_h^n\|_1^2\\
&\quad+c\tau^{-1}\|A_h\phi(\bar{u}_*^n)-A_h\phi(\bar{u}_*^{n-1})\|_0^2\|\bar{e}_h^n\|_0^2\\
&\quad+c\tau^3(H(n-2)\sigma(t_n)\|d_{tt}u_*^n\|_0^2+H(n-3)\sigma(t_{n-1})\|d_{tt}u_*^{n-1}\|_0^2).
\end{aligned}$$

Summing this inequality from $n=1$ to $n=m$ and using Lemma 5.2 and Lemma 5.3, we obtain (5.24). □

LEMMA 5.5. *Under the assumptions of Theorem* 5.1, *there holds*

$$\|p_h^m-\bar{p}(t_m)\|_{L^2}\le\kappa\sigma^{-3/2}(t_m)\tau,\quad 1\le m\le N. \tag{5.29}$$

Proof. First, we derive from (5.1)–(5.2) that

$$\begin{aligned}
d(v_h,\mu_h^m) &= (d_te_h^m,v_h)+a(\bar{e}_h^m,v_h)+b(\phi(\bar{e}_h^m),\bar{u}_*^m,v_h)+b(\phi(\bar{u}_*^m),\bar{e}_h^m,v_h)\\
&\quad-b(\phi(\bar{e}_h^m),\bar{e}_h^m,v_h)+\frac{1}{2}H(m-2)\tau^2b(d_{tt}u_*^m,\bar{u}_*^m,v_h)\quad\forall v_h\in X_h,
\end{aligned}\tag{5.30}$$

where $\mu_h^m=p_*^m-p_h^m$. Hence, by using (3.4) and (4.2), we derive from (5.30) that

$$\begin{aligned}
\sigma(t_m)\|\mu_h^m\|_{L^2} &\le c\sigma(t_m)\|d_te_h^m\|_0+c(1+\|\phi(\bar{u}_*^m)\|_1+\|\phi(\bar{e}_h^m)\|_1)\|\bar{e}_h^m\|_1\\
&\quad+c\|\bar{u}_*^m\|_1\|\phi(\bar{e}_h^m)\|_1+\kappa\tau^2\sigma(t_m)\|d_{tt}u_*^m\|_0.
\end{aligned}$$

Using Lemmas 5.2–5.4 in the above estimate yields

$$\sigma(t_m)\|\mu_h^m\|_{L^2}\le\kappa\tau,\quad 1\le m\le N.$$

Combining this estimate with (5.6) in Theorem 5.1 yields (5.29). □

THEOREM 5.6. *Under the assumptions of Theorem* 5.1, *there holds*

$$\|u_h(t)-u_{h,\tau}(t)\|_0\le\kappa\sigma^{-1}(t)\tau^2,\|u_h(t)-u_{h,\tau}(t)\|_1\le\kappa\sigma^{-1/2}(t)\tau, \tag{5.31}$$

$$\|p_h(t)-p_{h,\tau}(t)\|_{L^2}\le\kappa\sigma^{-3/2}(t)\tau \tag{5.32}$$

for all $t \in (0, T]$.

Remark. Combining (5.31)–(5.32) with (3.11) yields (1.1)–(1.2).

Proof. First, for $t \in (0, t_1]$ there holds

$$\begin{aligned}
&\|u_{ht}(s)\|_0 + \|d_t u_h^1\|_0 \le \kappa,\\
&\left\|\int_0^t (u_{ht}(s) - d_t u_h^1) ds\right\|_1 \le \tau^{1/2}\left(\int_0^t \|u_{ht}(s)\|_1^2 ds^{1/2} + \tau^{1/2}\sigma^{1/2}(t_1)\|d_t u_h^1\|_1\right)\\
&\qquad \le \kappa\tau^{1/2}.
\end{aligned}$$

Hence, we have

$$\begin{aligned}
\sigma^{\frac{2-r}{2}}(t)\|u_h(t) - u_{h,\tau}(t)\|_r &= \sigma^{\frac{2-r}{2}}(t)\left\|\int_0^t (u_{ht}(s) - d_t u_h^1) ds\right\|_r\\
&\le \kappa\tau^{2-r}, \quad r = 0, 1. \qquad (5.33)
\end{aligned}$$

Moreover, we note that for $t \in (t_{n-1}, t_n], \quad 2 \le n \le N$, the error $u_h(t) - u_{h,\tau}(t)$ satisfies

$$\begin{aligned}
u_h(t) - u_{h,\tau}(t) &= u_h(t_{n-1}) - u_h^{n-1} + (t - t_{n-1})(d_t u_h(t_n) - d_t u_h^n)\\
&\quad + \int_{t_{n-1}}^t (u_{ht}(s) - d_t u_h(t_n)) ds. \qquad (5.34)
\end{aligned}$$

Thus,

$$\begin{aligned}
\sigma^{1-r/2}(t)\|u_h(t) - u_{h,\tau}(t)\|_r &\le \sigma^{1-r/2}(t)\|u_h(t_{n-1}) - u_h^{n-1}\|_r\\
&\quad + (t - t_{n-1})\sigma^{2-r/2}(t)\|d_t u_h(t_n) - d_t u_h^n\|_r\\
&\quad + \sigma^{1-r/2}(t)\left\|\int_{t_{n-1}}^t (u_{ht}(s) - d_t u_h(t_n)) ds\right\|_r, \quad r = 0, 1. \qquad (5.35)
\end{aligned}$$

From Theorem 4.2 and Theorem 5.1 and Lemma 5.3 and Lemma 5.4 it follows that

$$\begin{aligned}
\sigma^{1-r/2}(t)\left\|\int_{t_{n-1}}^t (u_{ht}(s) - d_t u_h(t_n)) ds\right\|_r &\le c\tau^{2-r}\sigma^{1+r/2}(t_{n-1})\|u_{htt}(\xi)\|_r\\
&\le \kappa\tau^{2-r},\\
\sigma^{1-r/2}(t)\|u_h(t_{n-1}) - u_h^{n-1}\|_r &\le \sigma^{1-r/2}(t_{n-1})(\|u_h(t_{n-1}) - u_*^{n-1}\|_r + \|e_h^{n-1}\|_r)\\
&\le \kappa\tau^{2-r},\\
\sigma(t)\|d_t u_h(t_n) - d_t u_h^n\|_0 &\le \sigma(t_n)(\|d_t u_h(t_n) - d_t u_*^n\|_0 + \|d_t e_h^n\|_0) \le \kappa\tau,\\
\sigma^{1/2}(t)\|d_t u_h(t_n) - d_t u_h^n\|_1 &\le \sigma^{1/2}(t_n)\|d_t u_h(t_n)\|_1 + \sigma^{1/2}(t_n)\|d_t u_h^n\|_1 \le \kappa.
\end{aligned}$$

Combining (5.35) with these inequalities yields

$$\sigma^{\frac{2-r}{2}}(t)\|u_h(t) - u_{h,\tau}(t)\|_r \le \kappa\tau^{2-r}, \quad r = 0, 1, \quad t \in (t_1, T], \qquad (5.36)$$

which along with (5.33) completes the proof of (5.31).

Now, we need the smoothness of p_{ht}. From (3.8) we have

$$d(v_h,p_{ht}) = (u_{htt},v_h) + a(u_{ht},v_h) + b(u_{ht},u_h,v_h) + b(u_h,u_{ht},v_h) \\ - (f_t,v_h) \quad \forall v_h \in X_h,$$

which along with (3.4), (3.10), (4.2), and (4.7)–(4.8) implies that

$$\sigma(t)\|p_{ht}(t)\|_{L^2} \le \kappa, \quad t \in (0,T]. \tag{5.37}$$

Now, we will prove (5.32). From (4.7) we derive that for $t \in (0,t_1]$,

$$\sigma^{3/2}(t)\|p_h(t) - p_{h,\tau}(t)\|_{L^2} \le \sigma^{3/2}(t)\|p_h(t) - \bar{p}_h(t_1)\|_{L^2} \\ + \sigma^{3/2}(t_1)\|\bar{p}_h(t_1) - p_h^1\|_{L^2} \le \kappa\tau. \tag{5.38}$$

Moreover, by using (5.37), we obtain that for $t \in (t_{n-1},t_n],\ 2 \le n \le N$,

$$\sigma(t)\|p_h(t) - \bar{p}_h(t_n)\|_{L^2} = \frac{1}{2}\sigma(t)\left\|\int_{t_{n-1}}^{t} p_{ht}(s)ds - \int_{t}^{t_n} p_{ht}(s)ds\right\|_{L^2} \\ \le \int_{t_{n-1}}^{t} \sigma(s)\|p_{ht}(s)\|_{L^2}ds + \frac{1}{2}\int_{t}^{t_n} \sigma(s)\|p_{ht}(s)\|_{L^2}ds \le \kappa\tau.$$

Hence, by virtue of Lemma 5.5, we obtain that for $t \in (t_{n-1},t_n],\ 2 \le n \le N$,

$$\sigma^{3/2}(t)\|p_h(t) - p_{h,\tau}(t)\|_{L^2} \le \sigma^{3/2}(t)\|p_h(t) - \bar{p}_h(t)\|_{L^2} \\ + \sigma^{3/2}(t_n)\|\bar{p}_h(t_n) - p_h^n\|_{L^2} \le \kappa\tau, \tag{5.39}$$

which along with (5.38) gives (5.32). □

THEOREM 5.7. *Under the assumptions of Theorem* 5.1*, there holds*

$$\int_0^T \|u_h(t) - u_{h,\tau}(t)\|_r^2 dt \le \kappa\tau^{3-r}, \quad r = -1,0,1, \tag{5.40}$$

$$\int_0^T \sigma^{r+1}(t)\|u_h(t) - u_{h,\tau}(t)\|_r^2 dt \le \kappa\tau^4, \quad r = 0,1. \tag{5.41}$$

Proof. First, using the integration by parts and the fact that

$$u_h(t_n) - u_h^n = \bar{u}_h(t_n) - \bar{u}_h^n + \frac{\tau}{2}(d_t u_h(t_n) - d_t u_h^n),$$

we derive

$$\int_{t_{n-1}}^{t_n} \|u_h(t) - u_{h,\tau}(t)\|_r^2 dt \le c\tau\|u_h(t_n) - u_h^n\|_r^2 + c\tau^3\|u_{ht}(t_n) - d_t u_h^n\|_r^2 \\ + c\tau^2\int_{t_{n-1}}^{t_n} (t-t_{n-1})^2\|u_{htt}(t)\|_r^2 dt \\ \le c\tau\|\bar{u}_h(t_n) - \bar{u}_*^n\|_r^2 + c\tau\|\bar{e}_h^n\|_r^2 + c\tau^3\|d_t(u_h(t_n) - u_*^n)\|_r^2 + c\tau^3\|d_t e_h^n\|_r^2 \\ + c\tau^{3-r}\int_{t_{n-1}}^{t_n} \sigma^{1+r}(t)\|u_{htt}(t)\|_r^2 dt. \tag{5.42}$$

Summing this inequality from $n = 1$ to $n = m$, we obtain

$$\int_0^T \|u_h(t) - u_{h,t}(t)\|_r^2 dt \le c\tau \sum_{n=1}^N \|\bar{u}_h(t_n) - \bar{u}_*^n\|_r^2 + c\tau^3 \sum_{n=1}^N \|d_t u_h(t_n) - d_t u_*^n\|_r^2$$

$$+ c\tau \sum_{n=1}^N \|\bar{e}_h^n\|_r^2 + c\tau^3 \sum_{n=1}^N \|d_t e_h^n\|_r^2 + c\tau^{3-r} \int_0^T \sigma^{1+r}(t)\|u_{htt}(t)\|_r^2 dt. \tag{5.43}$$

Applying Theorem 4.2 and Theorem 5.1 and Lemma 5.3 and Lemma 5.4 in (5.43), we obtain (5.40).

Moreover, we also have

$$\begin{aligned}\int_{t_{n-1}}^{t_n} \sigma^{r+1}(t)\|u_h(t) - u_{h,\tau}(t)\|_r^2 dt &\le c\tau\sigma^{r+1}(t_n)\|u_h(t_n) - u_h^n\|_r^2 \\ &+ c\tau^3\sigma^{r+1}(t_n)\|u_{ht}(t_n) - d_t u_h^n\|_r^2 \\ &+ c\tau^2 \int_{t_{n-1}}^{t_n} (t - t_{n-1})\sigma^{r+1}(t)\|u_{htt}(t)\|_r^2 dt \\ &\le c\tau\sigma^{r+1}(t_n)\|\bar{u}_h(t_n) - \bar{u}_*^n\|_r^2 + c\tau\sigma^{r+1}(t_n)\|\bar{e}_h^n\|_r^2 \\ &+ c\tau^3\sigma^{r+1}(t_n)\|d_t(u_h(t_n) - u_*^n)\|_r^2 + c\tau^3\sigma^{r+1}(t_n)\|d_t e_h^n\|_r^2 \\ &+ c\tau^4 \int_{t_{n-1}}^{t_n} \sigma^{r+1}(t)\|u_{htt}(t)\|_r^2 dt.\end{aligned} \tag{5.44}$$

Summing (5.44) from $n = 1$ to $n = m$, we obtain

$$\int_0^T \sigma^{r+1}(t)\|u_h(t) - u_{h,t}(t)\|_r^2 dt \le c\tau \sum_{n=1}^N \sigma^{r+1}(t_n)\|\bar{u}_h(t_n) - \bar{u}_*^n\|_r^2$$

$$+ c\tau^3 \sum_{n=1}^N \sigma^{r+1}(t_n)\|d_t u_h(t_n) - d_t u_*^n\|_r^2 + c\tau \sum_{n=1}^N \sigma^{r+1}(t_n)\|\bar{e}_h^n\|_r^2$$

$$+ c\tau^3 \sum_{n=1}^N \sigma^{r+1}(t_n)\|d_t e_h^n\|_r^2 + c\tau^4 \int_0^T \sigma^{r+1}(t)\|u_{htt}(t)\|_r^2 dt. \tag{5.45}$$

A further extension of some arguments provided by Heywood and Rannacher in [18] can yield the following estimates:

$$\tau \sum_{n=1}^N \sigma^{r+1}(t_n)\|\bar{u}_h(t_n) - \bar{u}_*^n\|_r^2 \le \kappa\tau^4, \tag{5.46}$$

$$\tau \sum_{n=1}^N \sigma^{r+1}(t_n)\|d_t u_h(t_n) - d_t u_*^n\|_r^2 \le \kappa\tau^2 \tag{5.47}$$

for $r = 0, 1$. Using Theorem 4.2, Lemma 5.3, Lemma 5.4, and (5.46)–(5.47) in (5.45), we obtain (5.41). □

6. Two-level finite element method.

In this section we consider a two-level finite element method for the time-dependent Navier–Stokes equations.

Given a coarse grid J_H with $H > h$ and a large time step size $\tau_0 = k\tau = \frac{T}{N_0}$ with $N_0 = \frac{N}{k}$ for some fixed integer k, the two-level finite element method applied to the finite element Galerkin approximation (3.8)–(3.9) is described as follows:

- Calculate the one-level finite element solution $u_{H,\tau_0}(t)$ on a time-spatial coarse grid J_{H,τ_0} by (5.1) with $h = H, \quad \tau = \tau_0, \quad N = N_0$.
- Given $u_{H,\tau_0}(t) \in X_H$, $t \in [0, T]$, calculate the two-level finite element solution

  $$u^{h,\tau}(t) = u^{h,n-1} + (t - t_{n-1}) d_t u^{h,n}, \;\; p^{h,\tau}(t) = p^{h,k} \;\; \forall t \in (t_{n-1}, t_n], \;\; 1 \le n \le N,$$

  on the spatial-time fine grid $J_{h,\tau}$, where $\{(u^{h,n}, p^{h,n})\}_{n=1}^N$ is mainly defined by the backward Euler scheme as follows: for all $(v_h, q_h) \in (X_h, M_h)$ with the starting value $u^{h,0} = u_{0h}$,

$$
\begin{aligned}
&(d_t u^{h,n}, v_h) + a(\bar{u}^{h,n}, v_h) - d(v_h, p^{h,n}) + d(\bar{u}^{h,n}, q_h) \\
&\quad + b(\phi(\bar{u}^{h,n}), \bar{u}_{H,\tau_0}(t_n), v_h) = (\bar{f}(t_n), v_h), \quad 1 \le n \le N,
\end{aligned}
\tag{6.1}
$$

where (6.1) is not the backward Euler scheme in the case of $n = 1$.

By using an exact similar argument as in the proof of Lemma 5.2, we can obtain the following regularity result of the finite element solutions $\{(u_h^n, p_h^n)\}_{n=1}^N$ and $\{(u^{h,n}, p^{h,n})\}_{n=1}^N$.

LEMMA 6.1. *Under the assumptions of Theorem* 5.1, *there holds*

$$\|\varphi_h^m\|_r^2 + \tau \sum_{n=1}^m (\|\bar{\varphi}_h^n\|_r^2 + \|d_t \varphi_h^n\|_{r-1}^2) \le \kappa, 1 \le m \le N, \quad r = 0, 1, 2, \tag{6.2}$$

$$\sigma(t_m)\|d_t \varphi_h^m\|^2 + \tau \sum_{n=2}^m (\|d_{tt}\varphi_h^n\|_{-1}^2 + \sigma(t_n)\|d_{tt}\varphi_h^n\|_0^2) \le \kappa, \quad 2 \le m \le N \tag{6.3}$$

for $\varphi_h^n = u_h^n, u^{h,n}$.

LEMMA 6.2. *Under the assumptions of Theorem* 5.1, *there holds*

$$\|e_h^m\|_r^2 + \tau \sum_{n=1}^m \|\bar{e}_h^n\|_{r+1}^2 \le \kappa(H^{4-r(r+1)} + \tau_0^{3-r}), \quad r = -1, 0, 1, \tag{6.4}$$

$$\|e_h^m\|_r^2 + \tau \sum_{n=1}^m \|d_t e_h^n\|_{r-1}^2 \le \kappa(H^2 + \tau_0^2)^{2-r}, \quad r = 1, 2 \tag{6.5}$$

for $1 \le m \le N$, *where* $e_h^n = u_h^n - u^{h,n}$.

Proof. Subtracting (6.1) from (5.1), we obtain

$$
\begin{aligned}
&(d_t e_h^n, v_h) + a(\bar{e}_h^n, v_h) - d(v_h, \mu_h^n) + b(\phi(\bar{e}_h^n), \bar{u}_h^n, v_h) \\
&\quad + b(\phi(\bar{u}^{h,n}), \bar{u}_{h,\tau}(t_n) - \bar{u}_{H,\tau_0}(t_n), v_h) = 0 \;\; \forall v_h \in X_h,
\end{aligned}
\tag{6.6}
$$

where $u_h^n = u_{h,\tau}(t_n)$ and $\mu_h^n = p_h^n - p^{h,n}$. We take $v_h = 2\tau A_h^r \bar{e}_h^n \in V_h$ in (6.6) with $r = -1, 0, 1$, obtaining

$$
\begin{aligned}
&\|e_h^n\|_r^2 - \|e_h^{n-1}\|_r^2 + 2\nu\tau\|\bar{e}_h^n\|_{r+1}^2 + 2\tau b(\phi(\bar{e}_h^n), \bar{u}_h^n, A_h^r \bar{e}_h^n) \\
&\quad + 2\tau b(\phi(\bar{u}^{h,n}), \bar{u}_{h,\tau}(t_n) - \bar{u}_{H,\tau_0}(t_n), A_h^r \bar{e}_h^n) = 0.
\end{aligned}
\tag{6.7}
$$

In view of Lemma 4.1, there holds

$$2\tau|b(\phi(\bar{e}_h^n),\bar{u}_h^n,A_h^r\bar{e}_h^n)|\le\frac{\nu\tau}{4}\|\bar{e}_h^n\|_{r+1}^2+c\tau\|A_h\bar{u}_h^n\|_0^2\|\phi(\bar{e}_h^n)\|_r^2,$$
$$2\tau|b(\phi(\bar{u}^{h,n}),\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t_n),A_h^r\bar{e}_h^n)|$$
$$\le\frac{\nu\tau}{4}\|\bar{e}_h^n\|_{r+1}^2+c\tau\|A_h\phi(\bar{u}^{h,n})\|_0\|\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t_n)\|_r^2.$$

Combining these inequalities with (6.7) and using Lemma 5.2 and Lemma 6.1 yields

$$\|e_h^n\|_r^2-\|e_h^{n-1}\|_r^2+\nu\tau\|\bar{e}_h^n\|_{r+1}^2\le\kappa\tau\|\phi(\bar{e}_h^n)\|_r^2+\kappa\tau\|\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t_n)\|_r^2. \tag{6.8}$$

Summing (6.8) from $n=1$ to $n=m$ yields

$$\|e_h^m\|_r^2+\nu\tau\sum_{n=1}^{m}\|\bar{e}_h^n\|_{r+1}^2\le\kappa\tau\sum_{n=1}^{N}\|\phi(\bar{e}_h^n)\|_r^2+\kappa\tau\sum_{n=1}^{N}\|\bar{u}_H(t_n)-\bar{u}_{H,\tau_0}(t_n)\|_r^2. \tag{6.9}$$

From integration by parts there holds the following formula:

$$\bar{u}_h(t_n)=\frac{1}{\tau}\int_{t_{n-1}}^{t_n}u_h(t)dt+\frac{1}{2\tau}\int_{t_{n-1}}^{t_n}(t_n-t)(t-t_{n-1})u_{htt}(t)dt. \tag{6.10}$$

Hence, we derive from Theorem 5.7 and (3.10)–(3.11) that

$$\tau\sum_{n=1}^{N}\|u_{h,\tau}(t_n)-u_{H,\tau_0}(t_n)\|_r^2\le\sum_{n=1}^{N}\int_{t_{n-1}}^{t_n}\|u_{h,\tau}(t)-u_{H,\tau_0}(t)\|_r^2dt$$
$$\le c\int_0^T(\|u_h(t)-u_{h,\tau}(t)\|_r^2+\|u_H(t)-u_{H,\tau_0}(t)\|_r^2+\|u_h(t)-u_H(t)\|_r^2)dt \tag{6.11}$$
$$\le\kappa(H^{4-r(r+1)}+\tau_0^{3-r}),$$

which along with (6.9) yields

$$\|e_h^m\|_r^2+\nu\tau\sum_{n=1}^{m}\|\bar{e}_h^n\|_{r+1}^2\le\kappa\tau\sum_{n=1}^{m}\|\phi(\bar{e}_h^n)\|_r^2+\kappa(H^{4-r(r+1)}+\tau_0^{3-r}). \tag{6.12}$$

Applying Lemma 4.3 with $m=1$ and Lemma 4.4 with $2\le m\le N$ to (6.12) yields (6.4).

Next, we take $v_h=2\tau A_h^{r-1}d_te_h^n$ in (6.6) with $r=1,2$, obtaining

$$2\tau\|d_te_h^n\|_{r-1}^2+\nu(\|e_h^n\|_r^2-\|e_h^{n-1}\|_r^2)+2\tau b(\phi(\bar{e}_h^n),\bar{u}_h^n,A_h^{r-1}d_te_h^n)$$
$$+2\tau b(\phi(\bar{u}^{h,n}),\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t),A_h^{r-1}d_te_h^n)=0. \tag{6.13}$$

In view of Lemma 4.1, there holds

$$2\tau|b(\phi(\bar{e}_h^n),\bar{u}_h^n,A_h^{r-1}d_te_h^n)|\le\frac{\tau}{4}\|d_te_h^n\|_{r-1}^2+c\tau\|A_h\bar{u}_h^n\|_0^2\|\phi(\bar{e}_h^n)\|_r^2$$
$$2\tau|b(\phi(\bar{u}^{h,n}),\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t),A_h^{r-1}d_te_h^n)|$$
$$\le\frac{\tau}{4}\|d_te_h^n\|_{r-1}^2+\kappa\tau\|A_h\phi(\bar{u}^{h,n})\|_0^2\|\bar{u}_{h,\tau}(t_n)-\bar{u}_{H,\tau_0}(t_n)\|^2.$$

Combining these inequalities with (6.13) and using Lemma 5.2 yields

$$\tau\|d_te_h^n\|_{r-1}^2+\nu(\|e_h^n\|_r^2-\|e_h^{n-1}\|_r^2)\le\kappa\tau\|\phi(\bar e_h^n)\|_r^2+\kappa\tau\|\bar u_h^n-\bar u_{H,\tau_0}(t_n)\|_r^2. \tag{6.14}$$

Summing this inequality from $n=1$ to $n=m$ and using (6.11) with $r=1$ and Lemma 6.1 with $r=2$, we obtain

$$\nu\|e_h^m\|_r^2+\tau\sum_{n=1}^m\|d_te_h^n\|_{r-1}^2\le\kappa\tau\sum_{n=1}^m\|\phi(\bar e_h^n)\|_r^2+\kappa(H^2+\tau_0^2)^{2-r}. \tag{6.15}$$

Applying Lemma 4.3 with $m=1$ and Lemma 4.4 with $2\le m\le N$ to (6.15) yields (6.5). □

LEMMA 6.3. *Under the assumptions of Theorem* 5.1*, there holds*

$$\sigma(t_m)\|e_h^m\|_0^2+\tau\sum_{n=1}^m\sigma(t_n)\|\bar e_h^n\|_1^2\le\kappa(H^4+\tau_0^4)\quad\forall 1\le m\le N. \tag{6.16}$$

Proof. For $n=1$ we derive from Lemma 6.2 that

$$\sigma(t_n)\|e_h^n\|_0^2+\tau\sigma(t_n)\|\bar e_h^n\|_1^2\le\kappa(H^4+\tau_0^4). \tag{6.17}$$

Multiplying (6.8) with $r=0$ by $\sigma(t_n)$ and noting

$$\sigma(t_n)\le\sigma(t_{n-1})+\tau,\quad e_h^{n-1}=\bar e_h^n-\frac{\tau}{2}d_te_h^n, \tag{6.18}$$

for $2\le n\le N$, we obtain

$$\begin{aligned}\sigma(t_n)\|e_h^n\|_0^2-\sigma(t_{n-1})\|e_h^{n-1}\|_0^2+2\nu\tau\|\bar e_h^n\|_1^2&\le 2\tau(\|\bar e^n\|_0^2+\tau^2\|d_te_h^n\|_0^2)\\&+\kappa\tau\sigma(t_n)\|\phi(\bar e_h^n)\|_0^2+\kappa\tau\sigma(t_n)\|\bar u_{h,\tau}(t_n)-\bar u_{H,\tau_0}(t_n)\|_0^2.\end{aligned} \tag{6.19}$$

Summing (6.19) from $n=2$ to $n=m$ and using Lemma 6.2 yields

$$\begin{aligned}&\sigma(t_m)\|e_h^m\|_0^2+\nu\tau\sum_{n=2}^m\sigma(t_n)\|\bar e_h^n\|_1^2\le\kappa\sum_{n=2}^{m-1}(\|\bar e^n\|_0^2+\tau^2\|d_te_h^n\|_0^2)\\&+\kappa\tau\sum_{n=2}^N\sigma(t_n)\|\bar u_{h,\tau}(t_n)-\bar u_{H,\tau_0}(t_n)\|_0^2+\kappa\tau\sum_{n=1}^{m-1}\sigma(t_n)\|e_h^n\|_0^2+\kappa(H^4+\tau_0^4).\end{aligned} \tag{6.20}$$

Using Theorem 5.7, we obtain

$$\begin{aligned}\tau\sum_{n=2}^N\sigma(t_n)\|u_{h,\tau}(t_n)-u_{H,\tau_0}(t_n)\|_0^2&\le\sum_{n=1}^N\int_{t_{n-1}}^{t_n}\sigma(t)\|u_{h,\tau}(t)-u_{H,\tau_0}(t)\|_0^2dt\\&\le c\int_0^T(\sigma(t)\|u_h(t)-u_{h,\tau}(t)\|_0^2+\sigma(t)\|u_H(t)-u_{H,\tau_0}(t)\|_0^2)dt\\&+\int_0^T\sigma(t)\|u_h(t)-u_{H,\tau_0}(t)\|_0^2dt\le\kappa(H^4+\tau_0^4).\end{aligned} \tag{6.21}$$

Applying Lemma 4.4 and (6.21) to (6.20) and using (6.17) yields (6.16). □

Lemma 6.4. *Under the assumptions of Theorem 5.1, there holds*

$$\sigma^i(t_m)\|e_h^m\|_1^2 + \tau\sum_{n=1}^{m}\sigma^i(t_n)\|d_te_h^n\|_0^2 \le \kappa(\tau^2 + H^{2+i} + \tau_0^{2+i}), \quad i = 1,2, \tag{6.22}$$

for all $1 \le m \le N$.

Proof. Multiplying (6.13) with $r = 1$ by $\sigma^i(t_n)$, we obtain

$$\begin{aligned}&\tau\sigma^i(t_n)\|d_te_h^n\|_0^2 + \nu(\sigma^i(t_n)\|e_h^n\|_1^2 - \sigma^i(t_{n-1})\|e_h^{n-1}\|_1^2)\\ &\le i\nu\tau\sigma^{i-1}(t_n)\|e_h^{n-1}\|_1^2 + \kappa\tau\sigma^i(t_n)\|\phi(\bar{e}_h^n)\|_1^2 + \kappa\tau\sigma^i(t_n)\|\bar{u}_h^n - \bar{u}_{H,\tau_0}(t_n)\|_1^2.\end{aligned} \tag{6.23}$$

Summing this inequality from $n = 1$ to $n = m$ and using Lemma 6.2 and Lemma 6.3, Theorem 5.7, and (6.10), we obtain

$$\begin{aligned}&\sigma^i(t_m)\|e_h^m\|_1^2 + \tau\sum_{n=1}^{m}\sigma^i(t_n)\|d_te_h^n\|_0^2\\ &\le \kappa\tau\sum_{n=1}^{m}\sigma^i(t_n)\|\phi(\bar{e}_h^n)\|_1^2 + \kappa\tau\sum_{n=1}^{m}\sigma^{i-1}(t_n)(\|\bar{e}_h^n\|_1^2 + \tau^2\|d_te_h^n\|_1^2)\\ &+ \kappa\tau\sum_{n=1}^{m}\sigma^i(t_n)\|\bar{u}_h^n - \bar{u}_{H,\tau_0}(t_n)\|_1^2 \le \kappa(\tau^2 + H^{2+i} + \tau_0^{2+i}),\end{aligned}$$

which is (6.22). □

Lemma 6.5. *Under the assumptions of Theorem* 5.1*, there holds*

$$\|\mu_h^m\|_{L^2} \le \kappa\sigma^{-3/2}(t_m)(\tau + H^2 + \tau_0^2), \quad 1 \le m \le N. \tag{6.24}$$

Proof. From (6.6) we derive

$$\begin{aligned}&(d_{tt}e_h^n, v_h) + a(d_t\bar{e}_h^n, v_h) + b(\phi(d_t\bar{e}_h^n), \bar{u}_h^n, v_h)\\ &\quad + b(\phi(d_t\bar{u}^{h,n}), \bar{u}_{h,\tau}(t_n) - u_{H,\tau_0}(t_n), v_h) + b(\phi(\bar{e}_h^{n-1}), d_t\bar{u}_h^n, v_h)\\ &\quad + b(\phi(\bar{u}_{h,n-1}), d_t\bar{u}_{h,\tau}(t_n) - d_tu_{H,\tau_0}(t_n), v_h) \quad \forall v_h \in V_h.\end{aligned} \tag{6.25}$$

Next, we take $v_h = 2\tau d_t\bar{e}_h^n$ in (6.25), obtaining

$$\begin{aligned}&\|d_te_h^n\|_0^2 - \|d_te_h^{n-1}\|_0^2 + 2\tau\nu\|d_t\bar{e}_h^n\|_1^2 + 2\tau b(\phi(d_t\bar{e}_h^n), \bar{u}_h^n, d_t\bar{e}_h^n)\\ &\quad + 2\tau b(\phi(d_t\bar{u}^{h,n}), \bar{u}_{h,\tau}(t_n) - u_{H,\tau_0}(t_n), d_t\bar{e}_h^n) + 2\tau b(\phi(\bar{e}_h^{n-1}), d_t\bar{u}_h^n, d_t\bar{e}_h^n)\\ &\quad + 2\tau b(\phi(\bar{u}^{n-1,h}), d_t\bar{u}_{h,\tau}(t_n) - d_tu_{H,\tau_0}(t_n), d_t\bar{e}_h^n) = 0.\end{aligned} \tag{6.26}$$

From Lemma 4.1, Lemma 5.2, and Lemma 6.1, we have

$$\begin{aligned}2\tau|b(\phi(d_t\bar{e}_h^n), \bar{u}_h^n, d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2 + \kappa\tau\|\phi(d_t\bar{e}_h^n)\|_0^2,\\ 2\tau|b(\phi(d_t\bar{u}^{h,n}), \bar{u}_h^n &- \bar{u}_{H,\tau_0}(t), d_t\bar{e}_h^n)|\\ &\le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2 + \kappa\tau\|d_t\bar{u}^{h,n}\|_1^2\|\bar{u}_h^n - \bar{u}_{H,\tau_0}(t_n)\|_1^2,\\ 2\tau|b(\phi(\bar{e}_h^{n-1}), d_t\bar{u}_h^n, d_t\bar{e}_h^n)| &\le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2 + c\|d_t\bar{u}_h^n\|_1^2\|\phi(\bar{e}_h^{n-1})\|_1^2,\\ 2\tau|b(\phi(\bar{u}^{h,n-1}), d_t\bar{u}_{h,\tau}(t_n) &- d_tu_{H,\tau_0}(t_n), d_t\bar{e}_h^n)| \le \frac{\nu\tau}{4}\|d_t\bar{e}_h^n\|_1^2\\ &+ c\tau\|A_h\phi(\bar{u}^{h,n-1})\|_0^2\|d_t\bar{u}_{h,\tau}(t_n) - d_t\bar{u}_{H,\tau_0}(t_n))\|_0^2.\end{aligned}$$

Combining these inequalities with (6.26) yields

$$\begin{aligned}\|d_te_h^n\|_0^2 - \|d_te_h^{n-1}\|_0^2 + \nu\tau\|d_t\bar{e}_h^n\|_1^2 \leq{}& \kappa\tau\|\phi(d_t\bar{e}_h^n)\|_0^2\\ &+ c\tau\|d_t\bar{u}_{h,\tau}(t_n) - d_t\bar{u}_{H,\tau_0}(t_n)\|_0^2 + c\tau\|\phi(\bar{e}_h^{n-1})\|_1^2\|d_t\bar{u}_h^n\|_1^2\\ &+ c\tau\|\phi(d_t\bar{u}^{h,n})\|_1^2\|\bar{u}_h^n - \bar{u}_{H,\tau_0}(t_n)\|_1^2.\end{aligned}\tag{6.27}$$

Multiplying (6.27) by $\sigma^3(t_n)$ and applying Lemma 5.2 and Lemma 6.1 yields

$$\begin{aligned}\sigma^3(t_n)\|d_te_h^n\|_0^2 - \sigma^3(t_{n-1})\|d_te_h^{n-1}\|_0^2 + \nu\tau\sigma^3(t_n)\|d_t\bar{e}_h^n\|_1^2&\\ \leq 2\tau\sigma^2(t_{n-1})\|d_te_h^{n-1}\|_0^2 + \kappa\tau\sigma^3(t_n)\|\phi(d_t\bar{e}_h^n)\|_0^2&\\ + c\tau\sigma^3(t_n)\|d_t\bar{u}_{h,\tau}(t_n) - d_t\bar{u}_{H,\tau_0}(t_n)\|_0^2 + c\tau\sigma^2(t_n)\|\phi(\bar{e}_h^{n-1})\|_1^2&\\ + c\tau\sigma^2(t_n)\|\bar{u}_{h,\tau}(t_n) - \bar{u}_{H,\tau_0}(t_n)\|_1^2.&\end{aligned}\tag{6.28}$$

Summing (6.28) from $n = 1$ to $n = m$ and applying Lemma 6.3 and Lemma 6.4 with $i = 2$ and Theorem 5.7, we obtain

$$\begin{aligned}\sigma^3(t_m)\|d_te_h^m\|_0^2 + \tau\sum_{n=1}^{m}\sigma^3(t_n)\|d_t\bar{e}_h^n\|_1^2&\\ \leq \kappa(\tau^2 + H^4 + \tau_0^4) + \kappa\tau\sum_{n=1}^{m}\sigma^3(t_n)\|\phi(d_t\bar{e}_h^n)\|_0^2.&\end{aligned}\tag{6.29}$$

Applying Lemma 4.3 with $m = 1$ and Lemma 4.4 with $2 \leq m \leq N$ to (6.29) yields

$$\sigma^3(t_m)\|d_te_h^m\|_0^2 + \tau\sum_{n=1}^{m}\sigma^3(t_n)\|d_t\bar{e}_h^n\|_1^2 \leq \kappa(\tau^2 + H^4 + \tau_0^4).\tag{6.30}$$

Finally, we derive from (3.4), (6.6), (6.30), Theorem 5.7, Lemma 6.4, and (6.30) that

$$\begin{aligned}\|\mu_h^m\|_{L^2} &\leq \kappa(\|d_te_h^m\|_0 + \|\bar{e}_h^m\|_1 + \|\bar{u}_{h,\tau}(t_m) - \bar{u}_{H,\tau_0}(t_m)\|_1 + \|\phi(\bar{e}_h^m)\|_1)\\ &\leq \sigma^{-3/2}(t_m)(\tau + H^2 + \tau_0^2), \quad 1 \leq m \leq N,\end{aligned}$$

which is (6.24). □

Theorem 6.6. *Under the assumptions of Theorem* 5.1, *the following error estimates hold:*

$$\begin{aligned}\|u_h(t) - u^{h,\tau}(t)\|_{H_0^1} \leq{}& \kappa H(1-t)\sigma^{-1/2}(t)(\tau + \tau_0^{3/2} + H^{3/2})\\ &+ \kappa H(t-1)(\tau + \tau_0^2 + H^2), \quad t \in (0, T],\end{aligned}\tag{6.31}$$

$$\|p_h(t) - p^{h,\tau}(t)\|_{L^2} \leq \kappa\sigma^{-3/2}(t)(\tau + \tau_0^2 + H^2), \quad t \in (0, T].\tag{6.32}$$

This proof can be completed by combining Theorem 5.6, Lemma 6.5, and Lemma 6.4 with $i = 1$ for $t \in (0, 1]$ and $i = 2$ for $t \in (1, T]$; it can be omitted.

Remark. Combining Theorem 6.6 with (3.11) yields (1.3)–(1.4).

Acknowledgments. The author would like to thank the editor and referees for their criticism, valuable comments, and suggestions which helped to improve the results of this paper.

STUDY OF A MAXIMAL MONOTONE MODEL WITH A DELAY TERM*

CLAUDE-HENRI LAMARQUE[†], JÉRÔME BASTIEN[‡], AND MATTHIEU HOLLAND[†]

Abstract. We present a model involving a friction term and a delay term. By using results of existence and uniqueness for maximal monotone differential inclusions, we give theoretical results for this model. An implicit Euler numerical scheme and results related to order of convergence are also provided from both a theoretical and a numerical point of view.

Key words. delay, friction, maximal monotone, numerical scheme

1. Introduction.

In this paper, we study models including maximal monotone terms and delay terms. Differential inclusions involving only maximal monotone terms have been studied in many references from the point of view of mathematics (e.g., [7, 6, 10, 13]), mathematics and mechanics (e.g., [20, 1, 22, 2, 5]), numerical analysis (e.g., [25, 2, 5]), mechanics (e.g., [27, 17, 8]), and recently with friction and impact [30]. Indeed, many applications are concerned since it could be very convenient to use set-valued force laws in order to write models for impacts, friction, or elastoplastic constitutive laws, for example. Existence and uniqueness for stochastic differential inclusions have been investigated [24, 26, 11, 12] and numerical schemes of Euler type have been considered [26, 11].

Models including smooth nonlinear terms and delay terms have been also studied (see, e.g., [19]). But models including both maximal monotone terms and delay terms have not been investigated from the mathematical or numerical point of view. This is the main topic of this paper.

Motivations for introduction of delay terms can be found in [19, 29] or occur from applications: the control of structures (see, e.g., [31] for a survey of strategies in the frame of civil engineering) may include friction forces or elastoplastic terms together with a control law depending on the state of the structure delayed applied control force. The stability of systems including delay terms is also important for applications [23].

Recently, many studies have been devoted to the analysis of the behavior of cutter-tools (see, e.g., [18, 28, 23]). In [28], hysteresis terms lead to both maximal monotone terms (of sign type) and delay terms. The present work is based on the Master's thesis of Holland [21]. The paper is organized as follows. In section 2, the models considered are described. In section 3, mathematical background and existence and uniqueness results are provided. In section 4, a numerical scheme is built, its convergence is investigated, and numerical results given for a simple example.

2. Description of the model. In the field of mechanics, one frequently considers the following differential inclusion:

$$(2.1)\qquad \begin{cases} m\ddot{x}(t) + f\big(\dot{x}(t), x(t), t\big) + g\big(\dot{x}(t-\tau), x(t-\tau), t\big) \ni 0 \quad \text{on } [0,T], \\ x_0, \dot{x}_0 \text{ given functions on } [-\tau, 0]. \end{cases}$$

In the simplest case $f\big(\dot{x}(t), x(t), t\big)$ can be written as

$$(2.2)\qquad f\big(\dot{x}(t), x(t), t\big) \in c\dot{x}(t) + kx(t) - H(t) + \alpha\sigma\big(\dot{x}(t)\big),$$

with viscous damping c, stiffness k, external force $H(t)$ (exerted on the mass m), and friction force of Coulomb type $\alpha\sigma(\dot{x}(t))$, where σ is the full graph “sign”; it is defined by (see Figure 1)

$$\sigma(x) = \begin{cases} \{-1\} & \text{if } x < 0, \\ \{+1\} & \text{if } x > 0, \\ [-1, 1] & \text{if } x = 0. \end{cases}$$

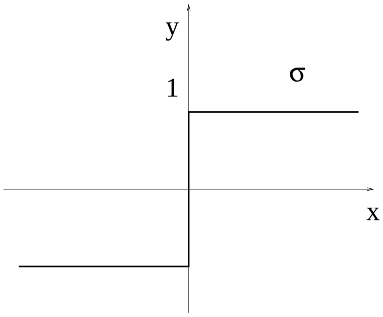

Fig. 1. *The graph σ.*

In (2.2), α depends on the normal force and Coulomb coefficient (see [4, 5]). The function g contains delay terms. In the simplest case g is given by

$$(2.3)\qquad g\big(\dot{x}(t-\tau), x(t-\tau), t\big) = \beta(t)\dot{x}(t-\tau) + \gamma(t)x(t-\tau),$$

with delay τ and smooth functions $\beta(t)$ and $\gamma(t)$. This model is represented in Figure 2.

In the general case with n dof the following models are considered for applications. They correspond to vectorial differential inclusions with several delays τ_i, $1 \le i \le N$, written as

$$\begin{cases} M\ddot{X}(t) + f\left(\dot{X}(t), X(t), t\right) + \sum_{i=1}^{N} g_i\left(\dot{X}(t-\tau_i), X(t-\tau_i), t\right) + \text{friction like forces} \ni 0, \\ X_0,\ \dot{X}_0 \text{ given vector functions on } [-\tau_N, 0], \end{cases}$$

with mass matrix M (size $n \times n$), $X(t) \in \mathbb{R}^n$, f and g_i $(1 \le i \le n)$ similar to the previous one dof case except that $f : \mathbb{R}^n \times \mathbb{R}^n \times [0, +\infty[\longrightarrow \mathbb{R}^n$ and $g : \mathbb{R}^n \times \mathbb{R}^n \times [0, +\infty[\longrightarrow \mathbb{R}^n$. For practical investigation one chooses frequently $N = 1$.

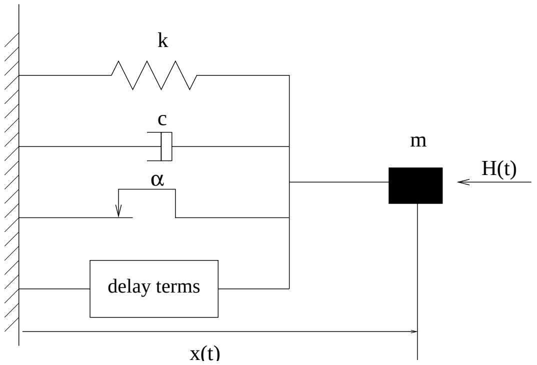

FIG. 2. *The studied mechanical model, with one dof, for f defined by* (2.2).

Let H be a separable Hilbert space equipped with a scalar product denoted $(.,.)$ and a norm denoted $|.|$, with T a strictly positive number. A is a maximal monotone multivalued operator on H, whose domain is denoted $D(A)$. In this paper, a mathematical problem of the form

$$\dot{u}(t)+A\big(u(t)\big)+B\big(t,u(t)\big)+G\big(u(t-\tau)\big)\ni 0 \text{ a.e. on }]0,T[\tag{2.4}$$

$$\forall t\in[-\tau,0],\quad u(t)=z(t), \tag{2.5}$$

is considered, where $\tau>0$, and

$$z\in W^{1,\infty}(-\tau,0;H). \tag{2.6a}$$

G a mapping from H to H whose differential is locally bounded on H, i.e.,

$$\forall R\geq 0,\quad \Psi(R)=\sup\left\{\|G'(x)\| : |x|\leq R\right\}<+\infty. \tag{2.6b}$$

B is a mapping from $[0,T]\times H$ from H, Lipschitz continuous with respect to its second argument and whose derivative maps the bounded sets of $L^2(0,T;H)$ into bounded sets of $L^2(0,T;H)$, i.e.,

$$\exists L\geq 0 :\quad \forall t\in[0,T],\quad \forall x_1,x_2\in H,\quad |B(t,x_1)-B(t,x_2)|\leq\omega\,|x_1-x_2|\,, \tag{2.6c}$$

and let us denote

$$\forall R\geq 0,\quad \Phi(R)=\sup\left\{\left\|\frac{\partial B}{\partial t}(.,v)\right\|_{L^2(0,T;H)} : \|v\|_{L^2(0,T;H)}\leq R\right\}<+\infty. \tag{2.6d}$$

The case with N delay terms would be treated in the same way. For applications, H is equal to $\mathbb{R}^n$.

For numerical simulations, we consider a class of one dof mechanical systems that can occur from a simple control problem with delayed applied control force or from a dynamic cutting process (see, e.g., [18, 28, 29, 23]) governed by (2.1), (2.2), and (2.3) with $m=1$, $\beta\equiv 0$, and $\gamma(t)=\gamma$; so we studied the system:

$$\begin{cases} \ddot{x}(t)+c\dot{x}(t)+kx(t)+\alpha\sigma\big(\dot{x}(t)\big)+\gamma x(t-\tau)\ni H(t) & \text{on } [0,T],\\ x(t)=x_0(t) & \text{on } [-\tau,0],\\ \dot{x}(t)=\dot{x}_0(t) & \text{on } [-\tau,0]. \end{cases} \tag{2.7}$$

3. Existence and uniqueness.

3.1. Summary of an existence and uniqueness result. In this section, we give an existence and uniqueness result that corresponds to the generalization of results obtained by Brezis [6] and [7]. A proof of this result can be found in [3], [2], [5], or in [15]. We proved the existence and uniqueness of the solution to a differential inclusion, as the by-product of convergence results for a numerical scheme. We were in the more general frame of a Gelfand triple $V \hookrightarrow H \hookrightarrow V'$, where we denote $\hookrightarrow$ a dense and continuous inclusion. Here, it is enough to make the identification $V = H = V'$ for the mechanical models studied. This result generalizes the result of [7] for a differential inclusion with a maximal monotone term equal to the subdifferential of the indicatrix of a nonempty closed convex set and the result of [6, Prop. 3.13, p. 107] for a maximal monotone term whose domain is not necessarily with a nonempty interior.

We assume now that f is a function from $[0,T] \times H$ to H, Lipschitz continuous with respect to its second argument and whose derivative maps the bounded sets of $L^2(0,T;H)$ into bounded sets of $L^2(0,T;H)$, i.e.,

$$\exists L \geq 0 : \quad \forall t \in [0,T], \quad \forall x_1, x_2 \in H, \quad |f(t,x_1) - f(t,x_2)| \leq L\,|x_1 - x_2| \tag{3.1}$$

and

$$\forall R \geq 0, \quad \Phi(R) = \sup\left\{ \left\| \frac{\partial f}{\partial t}(.,v) \right\|_{L^2(0,T;H)} : \|v\|_{L^2(0,T;H)} \leq R \right\} < +\infty. \tag{3.2}$$

The existence and uniqueness result is the following proposition.

Proposition 3.1. *If A is a multivalued maximal monotone operator from H and if assumptions* (3.1) *and* (3.2) *hold, then there exists a unique solution $u \in W^{1,\infty}(0,T;H)$ of the differential inclusion*

$$\dot{u}(t) + A\big(u(t)\big) \ni f\big(t, u(t)\big) \text{ a.e. on }]0,T[, \tag{3.3a}$$

$$u(0) = u_0. \tag{3.3b}$$

3.2. Existence and uniqueness results. We now apply Proposition 3.1 to a maximal monotone inclusion with a delay term.

Proposition 3.2. *Under assumptions* (2.6), *there exists a unique function $u \in W^{1,\infty}(-\tau,T;H)$ solution of the differential inclusion with delay*

$$\dot{u}(t) + A\big(u(t)\big) + B\big(t, u(t)\big) + G\big(u(t-\tau)\big) \ni 0 \text{ a.e. on }]0,T[\tag{3.4}$$

$$\forall t \in [-\tau, 0], \quad u(t) = z(t). \tag{3.5}$$

Proof. The delay term $G(u(t-\tau))$ is a smooth term and the maximal monotone inclusion (3.4) is similar to the differential inclusion:

$$\dot{u}(t) + A\big(u(t)\big) \ni \widetilde{f}\big(t, u(t)\big) \text{ a.e. on }]0,T[, \tag{3.6}$$

$$u(0) = u_0. \tag{3.7}$$

Let τ_1 be equal to $\tau_1 = \min(T, \tau)$. Define the mapping f_1 from $[0,\tau_1] \times H$ to H by

$$\forall t \in [0,\tau_1], \quad \forall x \in H, \quad f_1(t,x) = -B(t,x) - G\big(z(t-\tau)\big).$$

Over the interval $[0, \tau_1]$, problem (3.4)–(3.5) is then equivalent to the problem

$$\dot{u}(t) + A\big(u(t)\big) \ni f_1\big(t, u(t)\big) \text{ a.e. on }]0, \tau_1[, \tag{3.8}$$

$$u(0) = z(-\tau). \tag{3.9}$$

We are in the frame of Proposition 3.1. Indeed, according to assumption (2.6c), we have

$$\forall t \in [0, \tau_1], \quad \forall x_1, x_2 \in H, \quad |f_1(t, x_1) - f_1(t, x_2)| \leq \omega\, |x_1 - x_2|\,;$$

thus, assumption (3.1) holds on $[0, \tau_1]$. Otherwise, we have

$$\forall t \in [0, \tau_1], \quad \forall v \in L^2(0, \tau_1; H), \quad \frac{\partial f_1}{\partial t}(t, v) = -\frac{\partial B}{\partial t}(t, v) - \Big(G'\big(z(t-\tau)\big), \dot{z}(t-\tau)\Big),$$

and then, by integration over the interval $[0, \tau_1]$,

$$\int_0^{\tau_1} \left|\frac{\partial f_1}{\partial t}(t, v)\right|^2 dt \leq 2 \left(\int_0^{\tau_1} \left|\frac{\partial B}{\partial t}(t, v)\right|^2 dt + \int_0^{\tau_1} \left|G'\big(z(t-\tau)\big)\right|^2 |\dot{z}(t-\tau)|^2 dt\right),$$

and according to assumptions (2.6a), (2.6b), and (2.6d), if $\|v\|_{L^2(0,\tau_1;H)} \leq R$,

$$\int_0^{\tau_1} \left|\frac{\partial f_1}{\partial t}(t, v)\right|^2 dt \leq 2 \left(\Phi^2(R) + \tau_1 \|\dot{z}\|^2_{L^\infty(-\tau,0,H)} \Psi^2\left(\|z\|_{C^0([-\tau,0],H)}\right)\right).$$

Thus, assumption (3.2) holds on $[0, \tau_1]$. Then, according to Proposition 3.1, there exists a unique solution $u_1 \in W^{1,+\infty}(0, \tau_1; H)$ of (3.8)–(3.9). If $\tau_1 = T$, the proposition is proved. If $\tau_1 < T$, by setting $\tau_2 = \min(2\tau, T)$, we denote

$$\forall t \in [\tau_1, \tau_2], \quad \forall x \in H, \quad f_2(t, x) = -B(t, x) - G\big(u_1(t-\tau)\big).$$

As previously, problem (3.4)–(3.5) on $]\tau_1, \tau_2[$ is equivalent to the problem

$$\dot{u}(t) + A\big(u(t)\big) \ni f_2\big(t, u(t)\big) \text{ a.e. on }]\tau_1, \tau_2[, \tag{3.10}$$

$$u(\tau_1) = u_1(\tau_1 - 0), \tag{3.11}$$

where $u_1(\tau_1 - 0)$ is the value at time τ_1 of the continuous function u_1. So, thanks to Proposition 3.1, there exists a unique solution $u_2 \in W^{1,\infty}(\tau_1, \tau_2; H)$ of (3.10)–(3.11). Finally, we can construct by induction two sequences $(\tau_i)_{0 \leq i \leq q}$: $0 = \tau_0 < \tau_1 < \tau_2 < \cdots < \tau_q = T$ and $(u_i)_{1 \leq i \leq q}$ such that, for all $i \in \{1, \ldots, q\}$, u_i belongs to $W^{1,\infty}(\tau_{i-1}, \tau_i; H)$ and is the unique solution of

$$\dot{u}_i(t) + A\big(u_i(t)\big) + B\big(t, u_i\big) + G\big(u_{i-1}(t-\tau)\big) \ni 0 \text{ a.e. on }]\tau_{i-1}, \tau_i[, \tag{3.12}$$

$$u_i(\tau_{i-1}) = u_{i-1}(\tau_{i-1} - 0), \tag{3.13}$$

where u_0 is equal to z on $[-\tau, 0]$. We consider the unique function u from $[0, T]$ to H whose restriction to each interval $[\tau_{i-1}, \tau_i[$ is equal to u_i. It is clear that u is the unique solution of (3.4)–(3.5). Moreover, each function u_i is continuous on the interval $[\tau_{i-1}, \tau_i[$. According to (3.13), u is continuous on $[0, T]$. By construction, each function $\dot{u}_i$ belongs to $L^\infty(\tau_{i-1}, \tau_i; H)$; thus, the restriction of the function $\dot{u}$ to $[0, T]$ belongs to $L^\infty(0, T; H)$ and the restriction of the function u to $[0, T]$ belongs to $W^{1,\infty}(0, T; H)$, which concludes this proof. □

4. Numerical scheme.

4.1. Summary of results for numerical schemes. In this section, we recall two error estimates, which are generalizations of results by Lippold [25] proved in [3, 2, 5]; we proved that an implicit Euler numerical scheme for differential inclusion (3.3) is of order $1/2$ in the general case and of order one if the multivalued term is equal to the subdifferential of the indicatrix of a nonempty convex set of H.

Results of convergence can also be found in [16], [15], or [9], based on general properties of consistence. Elliot described some cases where this consistency is true (for example if the derivative of the solution possesses only a finite number of discontinuities). Our results [3], [2], or [5] are more general. In [14], a survey on numerical methods for differential inclusions can be read as follows: results for order of convergence are provided. They are obtained if the nonlinear term is compact and Lipschitz (in the sense of a one-sided Lipschitz condition). We did not assume such a condition in [3], [2], or [5]. References about the numerical point of view are given in [3] or [5].

Let N be an integer. Let $h = T/N$, and let U^p be the solution of the numerical scheme

$$\forall p \in \{0, \dots, N-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) \ni f\left(ph, U^p\right), \tag{4.1}$$

$$U^0 = u_0. \tag{4.2}$$

Denote $u_h \in C^0\left([0,T], H\right)$ the linear interpolation at times $t_p = hp$ of the U^p. The solution U^p of the numerical scheme (4.1) exists and is unique since A is maximal monotone; indeed, in this case the operator $(I + hA)^{-1}$, where I is the identity of H, is a single-valued operator defined by all the space H, and U^{p+1} is defined by

$$\forall p \in \{0, \dots, N-1\}, \quad U^{p+1} = (I + hA)^{-1}\big(hf\left(t_p, U^p\right) + U^p\big). \tag{4.3}$$

See [6]. The first result of convergence reads as the following proposition.

Proposition 4.1. *Under the assumptions* (3.1) *and* (3.2)*, the numerical scheme* (4.1)–(4.2) *is of order* $1/2$*; i.e., there exists* C *such that, for all* h*,*

$$\forall t \in [0,T], \quad |u(t) - u_h(t)| \le C\sqrt{h}, \tag{4.4}$$

where u *is the solution of* (3.3).

Let K be a closed convex nonempty subset of H, and let $\partial\psi_K$ be the subdifferential of the indicatrix of K, which is given by

$$\forall (x,y) \in K \times H, \quad y \in \partial\psi_K(x) \Longleftrightarrow \forall z \in K, \quad \langle y, x - z\rangle \ge 0, \tag{4.5}$$

and

$$\forall x \notin K, \quad \partial\psi_K(x) = \emptyset. \tag{4.6}$$

This result of convergence can be improved by the following proposition.

Proposition 4.2. *Under the assumptions* (3.1) *and* (3.2) *and if* A *is equal to* $\partial\psi_K$*, the numerical scheme* (4.1)–(4.2) *is of order one; i.e., there exists* C *such that, for all* h*,*

$$\forall t \in [0,T], \quad |u(t) - u_h(t)| \le Ch, \tag{4.7}$$

where u *is the solution of* (3.3).

For numerical results, we will need a more general result, when the initial condition of the numerical scheme is not equal to u_0.

LEMMA 4.3. *Let v_0 belong to $D(A)$, and let V^p be the solution of the numerical scheme*

$$\forall p \in \{0, \dots, N-1\}, \quad \frac{V^{p+1} - V^p}{h} + A\left(V^{p+1}\right) \ni f\left(ph, V^p\right), \tag{4.8}$$

$$V^0 = v_0. \tag{4.9}$$

Denote $v_h \in C^0([0,T], H)$ the linear interpolation at times $t_p = hp$ of the V^p. In the general case, there exists C such that, for all h,

$$\forall t \in [0,T], \quad |u(t) - v_h(t)| \le |u_0 - v_0| e^{LT} + C\sqrt{h},$$

and if A is equal to $\partial\psi_K$, there exists C such that, for all h,

$$\forall t \in [0,T], \quad |u(t) - v_h(t)| \le |u_0 - v_0| e^{LT} + Ch.$$

Proof. Since we have, by triangle inequality,

$$\forall t \in [0,T], \quad |u(t) - v_h(t)| \le |u(t) - u_h(t)| + |u_h(t) - v_h(t)|,$$

it is enough to prove, according to Propositions 4.1 and 4.2, that we have

$$\forall t \in [0,T], \quad |u_h(t) - v_h(t)| \le |u_0 - v_0| e^{LT},$$

which is true if

$$\forall p \in \{0, \dots, N\}, \quad |U^p - V^p| \le |u_0 - v_0| e^{LT}.$$

Numerical schemes (4.1) and (4.8) can be rewritten as

$$U^{p+1} + hA\left(U^{p+1}\right) \ni hf\left(t_p, U^p\right) + U^p, \tag{4.10}$$

$$V^{p+1} + hA\left(V^{p+1}\right) \ni hf\left(t_p, V^p\right) + V^p. \tag{4.11}$$

If we subtract (4.10) and (4.11), we obtain, by multiplication of $U^{p+1} - V^{p+1}$ by monotonicity of A,

$$\left|U^{p+1} - V^{p+1}\right|^2 \le h\left(f\left(t_p, U^p\right) - f\left(t_p, V^p\right), U^{p+1} - V^{p+1}\right) + \left(U^p - V^p, U^{p+1} - V^{p+1}\right),$$

which implies, thanks to the Cauchy–Schwarz inequality and assumption (3.1),

$$\left|U^{p+1} - V^{p+1}\right|^2 \le \left|U^{p+1} - V^{p+1}\right| |U^p - V^p| \left(hL + 1\right).$$

We can then infer

$$\left|U^{p+1} - V^{p+1}\right| \le |U^p - V^p| \left(hL + 1\right) \le e^{hL} |U^p - V^p|; \tag{4.12}$$

by multiplying (4.12) for $k \in \{0, \dots, p\}$, we obtain

$$\forall p \in \{0, \dots, N\}, \quad |U^p - V^p| \le \left|U^0 - V^0\right| e^{hNL} \le |u_0 - v_0| e^{TL}. \qquad \square$$

4.2. Definition and order of the numerical scheme. Let us now apply the results of Propositions 4.1 and 4.2 to differential inclusion (3.4)–(3.5). In order to simplify the presentation, we assume that

$$\tau < T \text{ and } \exists Q \in \mathbb{N}^* : \quad T = Q\tau. \tag{4.13}$$

Let N be an integer, and let

$$h = \frac{\tau}{N}. \tag{4.14}$$

So we have $T = Q\tau = QhN$. We then have

$$h = \frac{T}{M}, \text{ where } M = QN. \tag{4.15}$$

Let $(U^p)_{-N\leq p\leq M}$ be the solution of the numerical scheme

$$\forall p \in \{0, \dots, M-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) + B\left(ph, U^p\right) + G\left(U^{p-N}\right) \ni 0, \tag{4.16}$$

$$\forall p \in \{-N, \dots, 0\}, \quad U^p = z\left(ph\right). \tag{4.17}$$

Denote $u_h \in C^0\left([-\tau, T], H\right)$ the linear interpolation at times $t_p = hp$ of the U^p for $-N \leq p \leq M$. The solution U^p of the numerical scheme (4.16) is also defined by

(4.18)

$$\forall p \in \{0, \dots, M-1\}, \quad U^{p+1} = (I + hA)^{-1}\left(h\Big(-B\left(ph, U^p\right) - G\left(U^{p-N}\right)\Big) + U^p\right).$$

Proposition 4.4. *Under assumptions* (2.6)*, the numerical scheme* (4.16)*–*(4.17) *is of order* 1/2*; i.e., there exists C such that, for all h,*

$$\forall t \in [0, T], \quad |u(t) - u_h(t)| \leq C\sqrt{h}, \tag{4.19}$$

in the general case and if A is equal to $\partial\psi_K$, then it is of order one; i.e., there exists C such that, for all h,

$$\forall t \in [0, T], \quad |u(t) - u_h(t)| \leq Ch. \tag{4.20}$$

Proof. We use again the notations of the proof of Proposition 3.2: we rewrite problem (3.4)–(3.5) on the interval $[0, \tau_1] = [0, \tau]$ under the form (3.8)–(3.9), discretized by the numerical scheme

$$\forall p \in \{0, \dots, N-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) \ni f_1\left(t_p, U^p\right),$$
$$U^0 = z(0),$$

which is equivalent to

$$\forall p \in \{0, \dots, N-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) + B\left(ph, U^p\right) + G\left(U^{p-N}\right) \ni 0, \tag{4.21}$$

$$U^0 = z(0). \tag{4.22}$$

According to Propositions 4.1 and 4.2, we then have

$$\forall t \in [0, \tau_1], \quad |u(t) - u_h(t)| \leq C h^{\alpha}, \tag{4.23}$$

where $\alpha = 1/2$ in the general case and $\alpha = 1$ if $A = \partial \phi_K$. We then rewrite problem (3.4)–(3.5) on the interval $[\tau_1, \tau_2] = [\tau, \tau_2]$ under the form (3.10)–(3.11), discretized by the numerical scheme with discrete initial condition

$$\begin{aligned}&\forall p \in \{N, \dots, 2N-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) \ni f_2\left(t_p, U^p\right),\\ &U^N = u_h(\tau_1),\end{aligned}$$

which is equivalent to

$$\forall p \in \{N, \dots, 2N-1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) + B\left(ph, U^p\right) + G\left(U^{p-N}\right) \ni 0, \tag{4.24}$$

$$U^N = u_h(\tau_1). \tag{4.25}$$

According to Lemma 4.3 applied on the interval $[\tau_1, \tau_2]$ we then have

$$\forall t \in [\tau_1, \tau_2], \quad |u(t) - u_h(t)| \leq |u(\tau_1) - u_h(\tau_1)| \, e^{\tau_1 L} + C h^{\alpha},$$

where $\alpha = 1/2$ in the general case and $\alpha = 1$ if $A = \partial \phi_K$. Thanks to estimate (4.23), we obtain

$$\forall t \in [\tau_1, \tau_2], \quad |u(t) - u_h(t)| \leq C h^{\alpha} \left(1 + e^{\tau_1 L}\right).$$

By induction, we prove easily that the numerical scheme (4.16)–(4.17) is equivalent to, for all $r \in \{0, \dots, Q-1\}$,

$$\begin{aligned}&\forall p \in \{rN, \dots, (r+1)N - 1\}, \quad \frac{U^{p+1} - U^p}{h} + A\left(U^{p+1}\right) + B\left(ph, U^p\right) + G\left(U^{p-N}\right) \ni 0,\\ &U^{rN} = u_h(\tau_r),\end{aligned}$$

and according to Lemma 4.3 applied on the interval $[\tau_r, \tau_{r+1}]$ we then have

$$\forall t \in [\tau_r, \tau_{r+1}], \quad |u(t) - u_h(t)| \leq \left(e^{\tau_1 L} + e^{(\tau_2 - \tau_1) L} + \dots + e^{(T - \tau_{Q-1})}\right) C h^{\alpha},$$

which allows us to conclude this proof since this implies that there exists M not depending on h such that

$$\forall t \in [0, T], \quad |u(t) - u_h(t)| \leq M h^{\alpha}. \qquad \square$$

4.3. Numerical simulations. We study numerically system (2.7). We assume that

$$\alpha \geq 0, \quad x_0 \in W^{2,\infty}(-\tau, 0), \quad g \in H^1(0, T). \tag{4.26}$$

We consider Hilbert space $H = \mathbb{R}^2$ equipped with its canonical scalar product. We define the multivalued operator A on H by

$$\forall u = (u_1, u_2) \in \mathbb{R}^2, \quad A(u_1, u_2) = \{0\} \times \alpha \sigma\left(u_2\right).$$

Since $\alpha \geq 0$ and σ is maximal monotone on $\mathbb{R}$ (see, for example, [6]), A is maximal monotone on H. We define the functions B, G, and z by, for all $u = (u_1, u_2) \in \mathbb{R}^2$, for all $t \in [0, T]$,

$$\begin{aligned} B(t,u) &= \begin{pmatrix} -u_2 \\ ku_1 + cu_2 - H(t) \end{pmatrix}, \\ G(u) &= \begin{pmatrix} 0 \\ \gamma u_1 \end{pmatrix}, \\ z(t) &= \begin{pmatrix} x_0(t) \\ \dot{x}_0(t) \end{pmatrix}. \end{aligned}$$

By setting $u(t) = (x(t), \dot{x}(t))$, we see that system (2.7) is equivalent to systems (3.4) and (3.5). According to assumption (4.26), we prove easily that assumptions (2.6) hold. Then, thanks to Proposition 3.2, system (2.7) admits a unique solution, whose restriction to $[0, T]$ belongs to $W^{2,\infty}(0, T)$. Moreover, thanks to Proposition 4.4, the numerical scheme (4.16)–(4.17) is of order 1/2, i.e.,

$$\forall t \in [0,T], \quad |u(t) - u_h(t)|_{\mathbb{R}^2} \leq C\sqrt{h}. \tag{4.27}$$

We recall that the subdifferential of a convex proper and lower semicontinuous function ϕ from H to $]-\infty, +\infty]$ is defined by

$$\forall (x,y) \in H \times H, \quad y \in \partial\phi(x) \Longleftrightarrow \forall z \in H, \quad \phi(z) - \phi(x) \geq \langle y, z - x \rangle.$$

So we see that

$$\forall x \in \mathbb{R}, \quad \sigma(x) = \partial |x|.$$

Then

$$\forall u = (u_1, u_2) \in \mathbb{R}^2, \quad A(u_1, u_2) = \partial \left(\alpha |u_2| \right).$$

Function $\alpha|.|$ is not equal to the subdifferential of a indicatrix of a closed convex set of $\mathbb{R}^2$: we cannot conclude from Proposition 4.4 that the order of the numerical scheme is equal to 1.

We consider now the numerical scheme defined in section 4.2 and we set

$$\forall p \in \{-N, \dots, M\}, \quad U^p = (u^p, v^p).$$

After computation, we obtain, for all h,

$$\forall \left(u_1, u_2\right) \in \mathbb{R}^2, \quad \left(I + hA\right)^{-1} \left(u_1, u_2\right) = \begin{pmatrix} u_1 \\ \left(I + h\alpha\sigma\right)^{-1} \left(u_2\right) \end{pmatrix},$$

where (see Figure 3)

$$\forall x \in \mathbb{R}, \quad \left(I + h\alpha\sigma\right)^{-1}(x) = \begin{cases} x - \alpha h & \text{if } x \geq \alpha h, \\ x + \alpha h & \text{if } x \leq -\alpha h, \\ 0 & \text{if } x \in [-\alpha h, \alpha h]. \end{cases}$$

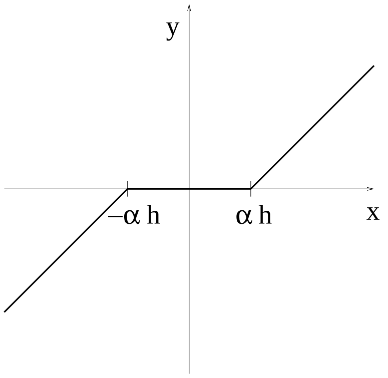

FIG. 3. *The function* $(I + h\alpha\sigma)^{-1}$.

Numerical scheme (4.16)–(4.17) is equivalent to (4.18)–(4.17) and can then be rewritten as

$$\forall p \in \{0,\dots,M-1\},\quad u^{p+1} = hv^p + u^p, \tag{4.28a}$$

$$v^{p+1} = (I+h\alpha\sigma)^{-1}\left(-chv^p - khu^p - \gamma hu^{p-N} + hH(ph) + v^p\right) \tag{4.28b}$$

$$\forall p \in \{-N,\dots,0\},\quad u^p = x_0(ph), \tag{4.28c}$$

$$v^p = \dot{x}_0(ph). \tag{4.28d}$$

We choose three values of parameters c, k, γ, α, τ and functions H and x_0:

$$c=0.1,\quad k=0.5,\quad \gamma=1.1,\quad \alpha=0.99,\quad \tau=1,\quad H(t)=\sin(t),\quad x_0(t)=0, \tag{4.29}$$

$$c=0.1,\quad k=0.5,\quad \gamma=1.1,\quad \alpha=0.10,\quad \tau=1,\quad H(t)=\sin(t),\quad x_0(t)=0, \tag{4.30}$$

$$c=0.1,\quad k=0.5,\quad \gamma=1.1,\quad \alpha=0.99,\quad \tau=1,\quad H(t)=\sin(t),\quad x_0(t)=0.5\sin(t). \tag{4.31}$$

For these three simulations, we choose

$$Q = 100,\quad N = 10^4. \tag{4.32}$$

We plot the discrete abscissa and velocity computed with numerical scheme (4.28) in Figures 4–6. In Figure 4, we observe, as in [21], a stable periodical regime after a transition; this regime is composed of statical phases (with $\dot{x} \equiv 0$) and dynamical phases (with $\operatorname{sign}(\dot{x}) \in \{-1, 1\}$). In Figures 5 and 6, the behavior seems unstable and we see only transient phases.

As in [3], we look second for an empirical order of convergence of the numerical scheme. We expect the error to be of the form

$$\|u - u_h\|_{C^0([0,T],\mathbb{R}^2)} \approx Ch^\delta, \tag{4.33}$$

and we try to identify the numbers C and δ. According to (4.13), (4.14), and (4.15), we rewrite (4.33) under the form

$$\|u - u_N\|_{C^0([0,T],\mathbb{R}^2)} \approx \frac{C}{N^\delta}. \tag{4.34}$$

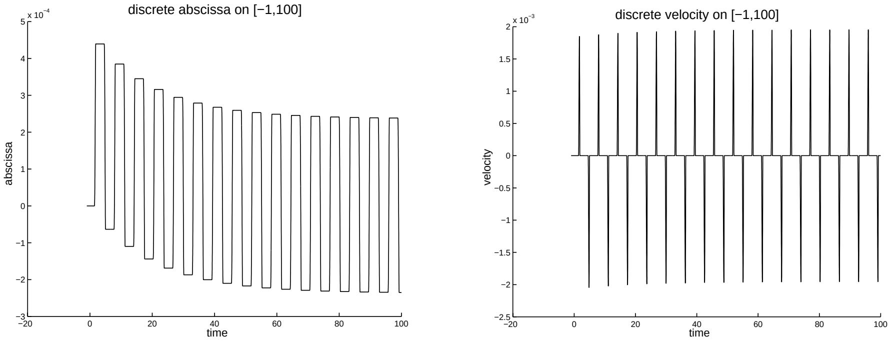

FIG. 4. *Discrete abscissa and velocity for differential inclusion* (2.7) *with* (4.29) *and* (4.32).

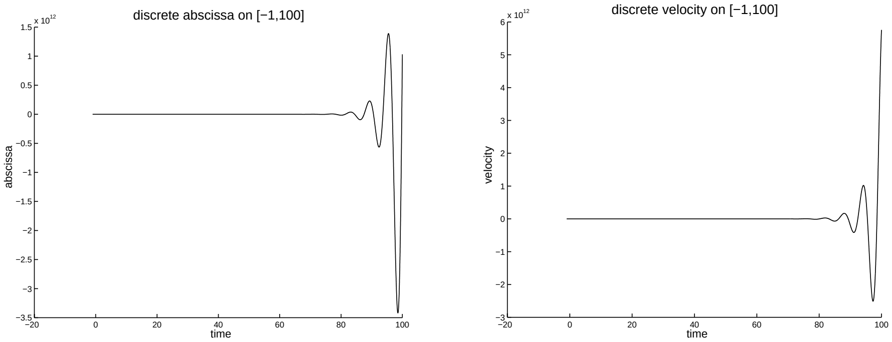

FIG. 5. *Discrete abscissa and velocity for differential inclusion* (2.7) *with* (4.30) *and* (4.32).

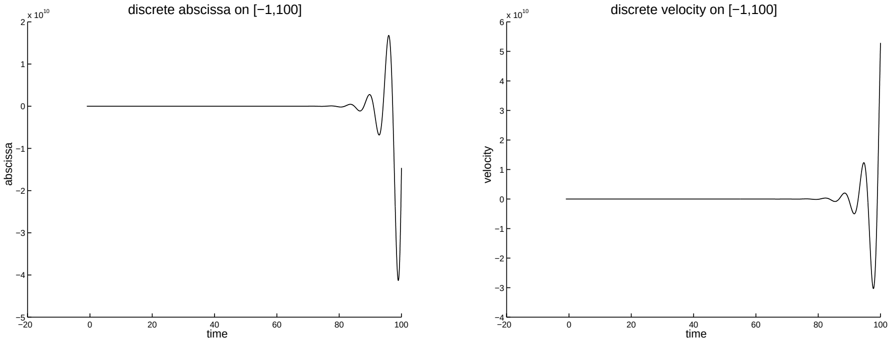

FIG. 6. *Discrete abscissa and velocity for differential inclusion* (2.7) *with* (4.31) *and* (4.32).

Define

$$\varepsilon(N) = \|u_N - u_{2N}\|_{C^0([0,T],\mathbb{R}^2)};$$

then, formally,

$$\log\left(\varepsilon(N)\right) \approx -\delta \log(N) + \log(2C).$$

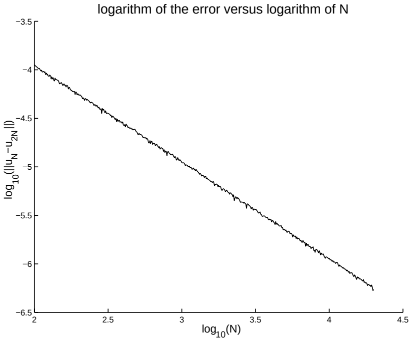

FIG. 7. *Log-log curves* $\varepsilon(N)$ *versus* N *for differential inclusion* (2.7) *with* (4.29)*,* $Q = 100$*, and* (4.35)*.*

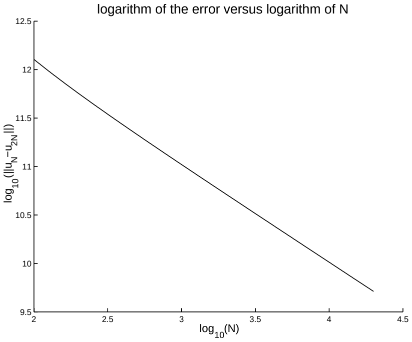

FIG. 8. *Log-log curves* $\varepsilon(N)$ *versus* N *for differential inclusion* (2.7) *with* (4.30)*,* $Q = 100$*, and* (4.35)*.*

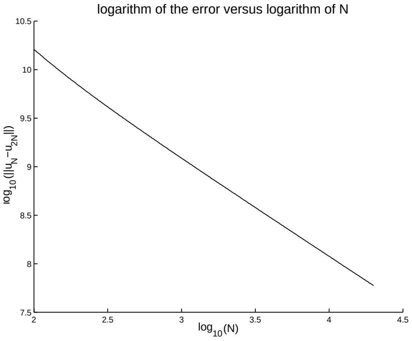

FIG. 9. *Log-log curves* $\varepsilon(N)$ *versus* N *for differential inclusion* (2.7) *with* (4.31)*,* $Q = 100$*, and* (4.35)*.*

A log-log plot of $\varepsilon(N)$ versus N gives an estimate of C and δ. We choose

(4.35)
$$p = 500, \quad N_{\min} = 100, \quad N_{\max} = 20000 \quad \forall i \in \{1, \dots, p\}, \quad N_i = N_{\min}^{\frac{p-i}{p-1}} N_{\max}^{\frac{i-1}{p-1}},$$

and the same physical parameters as above ($Q = 100$ and (4.29), (4.30), and (4.31)). Log-log curves $\varepsilon(N)$ versus N are plotted in Figures 7–9, and the values of δ and the

TABLE 1
Values δ and r for different values of parameters.

Parameter defined by	δ	r
(4.29)	0.995894134	0.999887705
(4.30)	1.0283258	0.999836087
(4.31)	1.04108214	0.999677062

correlation of set of points r are given in Table 1.

We see that the empirical order δ and the correlation r are close to one, which is more accurate than (4.27). The numerical scheme is then of order one, but in this case we proved only that the order is equal to 1/2. To prove that numerical scheme (4.1) and (4.2) is of order one for all maximal monotone graphs A (not necessarily equal to the subdifferential of the indicatrix of a closed set) is an open problem to our knowledge.

5. Conclusion. In this paper existence and uniqueness results have been provided for differential inclusions with both maximal monotone terms and delay terms. Even if in many interesting applications H has finite dimension, the results are very general ones. Based on the previous works, a numerical scheme of Euler implicit type has been proposed. This scheme has been proved to be of order 1/2 for general maximal monotone graphs and possesses order one in the case of the subdifferential of the indicatrix of a convex set. This numerical scheme has been tested in a previous work [21]: a good agreement is obtained with the exact solution known. Here it can be noticed that the numerical behavior is even better than those forecasted by theory. This is an important point for applications: the proposed scheme is the only one available in the literature with rigorous mathematical results (existence, uniqueness, convergence, and order), but 1/2 is a rather weak order. So it is useful to have indeed order one in practice. This good behavior has been observed in all our simulations. As we said, the proof of better theoretical results in the general case is an open problem.

Acknowledgment. We want to thank the reviewers for indicating a few useful references.

A FINITE VOLUME SCHEME FOR TWO-PHASE IMMISCIBLE FLOW IN POROUS MEDIA*

ANTHONY MICHEL†

Abstract. In this paper, we prove the convergence of a numerical method for solving two-phase immiscible, incompressible flow in porous media. The method combines an upwind time implicit finite volume scheme for the saturation equation (hyperbolic-parabolic type) and a centered finite volume scheme for the Chavent global pressure equation (elliptic type). The capillary pressure is not neglected, and we study the case when the diffusion term in the saturation equation is weakly degenerated. Estimates on the approximate solution are proven; then by using compactness theorems we obtain a limit when the size of the discretization goes to zero, and we prove that this limit is the unique weak solution of the problem that we study.

Key words. multiphase flow, Darcy's law, porous media, degenerate elliptic parabolic system, finite volume scheme

AMS subject classifications. 35K65, 76S05, 65M12

DOI. 10.1137/S0036142900382739

1. Introduction.

In this paper, we define and analyze a finite volume method for a mathematical model for the flow of two immiscible incompressible fluids in a porous medium:

$$u_t - \operatorname{div}(k_1(u)\nabla p) = q_1 \text{ in } \Omega \times (0,T), \tag{1}$$

$$(1-u)_t - \operatorname{div}(k_2(u)\nabla(p + p_c(u))\,) = q_2 \text{ in } \Omega \times (0,T), \tag{2}$$

where Ω is a bounded domain of $\mathbb{R}^d$ ($d = 1, 2$ or 3) modeling the reservoir, $\{u, p\}$ are the saturation and the pressure of the wetting fluid (the water in the oil recovery context), k_1 and k_2 are the reduced mobilities of the wetting and the nonwetting fluid, and $\{q_1, q_2\}$ are source terms which model injection or production wells inside the reservoir.

If we introduce the global pressure of Chavent,

$$\theta = p + \int_0^u \frac{k_2(s)}{k_1(s)+k_2(s)}\, {p_c}'(s)ds, \tag{3}$$

and the total velocity flow,

$$\mathbf{F} = -(k_1(u) + k_2(u))\nabla p - k_2(u)\nabla p_c(u), \tag{4}$$

then the system (1)–(2) is equivalent to the following system of two coupled partial differential equations for the unknowns u and θ:

$$u_t + \operatorname{div}(f(u)\mathbf{F}) - \Delta\varphi(u) = q_1, \tag{5}$$

$$\operatorname{div}(M(u)\nabla\theta) = q_1 + q_2, \tag{6}$$

$$(\mathbf{F} = -M(u)\nabla\theta), \tag{7}$$

†Institut Français du Pétrole, 1 et 4 avenue du Bois Préau, BP 311, 92852 Rueil Malmaison Cedex, France (anthony.michel@ifp.fr).

where $M = k_1 + k_2$ is the total mobility of the two phase fluid, $f = \frac{k_1}{k_1+k_2}$ is the fractional flow of the wetting fluid, and $\varphi(u) = -\int_0^u \frac{k_1(s)k_2(s)}{k_1(s)+k_2(s)} {p_c}'(s)ds$ (introduced by Arbogast in [1]) is a nonlinear function which is closely related to the capillary pressure p_c .

This model has been well known in the reservoir simulation community for more than 30 years [3], [4], [7], [26], [24], [12]. It has been studied from the theoretical point of view [1], [23], [8], and results on existence or uniqueness and some estimates on the weak solution have been proved in different cases. The interest in this problem for oil companies has resulted in early motivated investigations in numerical methods [12], [7]. In particular, numerous works [25], [2], [15], [14], [5], [13], [16] have been done on convergence and error estimates of numerical schemes using a mixed finite element method [27] to approximate the total velocity flow and the pressure. Both miscible and immiscible cases have been extensively treated where the capillary pressure is neglected (the saturation equation is then of hyperbolic type). It is only recently [25], [8] that equivalent studies have been done in the case of immiscible fluids with degenerate capillary pressure.

The aim of this paper is to show that if we discretize the two equations (5)–(6) using first order finite volume schemes (see [18], [28]), then the numerical approximate solution converges to the exact solution of problem (5)–(6). This work takes its originality from the fact that we consider a full finite volume method on a single mesh, and we allow any weak degeneracy of the function φ. The convergence proof is done without assuming any existence or regularity on the weak solution.

The paper is organized as follows. In section 2, we give some assumptions. In section 3, we present the finite volume scheme and prove a priori estimates on the discrete solution. As a corollary we obtain that the implicit scheme is well defined. In section 4.1, we use these estimates to obtain compactness properties on the corresponding piecewise constant approximate solution. In section 5, we state and prove the main result: the convergence theorem, Theorem 5.1. Then we discuss the last step of the proof which consists of passing to the limit in the weak formulation. In section 6, we present some numerical results, and we end in section 7 with some concluding remarks.

2. Assumptions.

In order to close the system (5)–(6), we prescribe the following Neumann boundary conditions:

$$\nabla\theta \cdot \mathbf{n} = 0 \text{ on } \partial\Omega \times (0,T), \tag{8}$$

$$\nabla\varphi(u) \cdot \mathbf{n} = 0 \text{ on } \partial\Omega \times (0,T); \tag{9}$$

the following initial condition:

$$u(\cdot,0) = u_0 \text{ on } \Omega; \tag{10}$$

and, since the pressure is defined only up to a constant, we prescribe the following arbitrary condition:

$$\int_\Omega \theta(x,\cdot)dx = 0 \text{ on } (0,T). \tag{11}$$

The source terms depend on the saturation u and on the injection concentration c. They are defined by

$$q_1 = c\overline{s} - u\underline{s}, \tag{12}$$

$$q_2 = (1-c)\overline{s} - (1-u)\underline{s}. \tag{13}$$

We make the following assumptions on the data:

- φ is an increasing Lipschitz continuous function on $[0,1]$, Φ will denote its Lipschitz constant, and $\varphi^* = \max_{x\in[0,1]} |\varphi(x)|$.
- f is a nondecreasing Lipschitz continuous function on $[0,1]$, $\mathbf{F}$ will denote its Lipschitz constant, $f(0)=0$, and $f(1)=1$.
- M is a continuous function on $[0,1]$ with $0 < M_* \leq M(u) \leq M^* < \infty$.
- The functions $\overline{s}$ and $\underline{s}$ belong to $L^\infty(0,T,L^2(\Omega))$. $\overline{s} \geq 0$ and $\underline{s} \geq 0$ a.e. $x \in \Omega \times (0,T)$, $\int_\Omega \overline{s}(x) - \underline{s}(x)dx = 0$ for a.e. $t \in (0,T)$.
- $u_0 \in L^\infty(\Omega)$, $0 \leq u_0(x) \leq 1$ a.e. $x \in \Omega$.
- c is a constant, $0 \leq c \leq 1$.

Remark 2.1. *The function c can also be taken in $L^\infty(Q)$ with $0 \leq c \leq 1$ without any difficulty. One needs only to replace c by an approximate in the finite volume scheme.*

3. The finite volume scheme.

Assume Ω is a polygonal bounded domain of $\mathbb{R}^d$ and $\mathcal{T}$ is a mesh of Ω consisting of convex polygons. The finite volume method (cf. [18]) consists of integrating the equations over a control volume $K \in \mathcal{T}$ and obtaining a relation between mean values over K and fluxes on the edges of K by using the Stokes formula. Thanks to the Neumann boundary conditions, the normal fluxes on the boundary $\partial\Omega$ are equal to zero, so we need only to consider the interfaces between two control volumes. For convection terms, a simple way to get stability is to compute an upwind scheme, but the results also extend to a general monotone scheme (see [6]). For diffusion terms, we have to approximate the normal derivative of $\varphi(u)$ on the interface. Without additional assumptions on the mesh, we can take into account the values of u on control volumes other than the two neighbors K and L of the interface (see, for example, the VF9 method in [21]). Here we make some assumptions (see Definition 3.1) in order to ensure that the cheap discretization of $\frac{\partial\varphi(u)}{\partial n}$ by $\frac{\varphi(U_L^{n+1})-\varphi(U_K^{n+1})}{d_{K|L}}$ is consistent.

3.1. Definitions and notations.

Definition 3.1 (admissible mesh of Ω). *An admissible mesh $\mathcal{T}$ of Ω is given by a set of open bounded polygonal convex subsets of Ω called control volumes, a family $\mathcal{E}$ of subsets of $\bar{\Omega}$ contained in hyperplanes of $\mathbb{R}^d$ with strictly positive measure, and a family of points (the "centers" of control volumes) satisfying the following properties:*

(i) *The closure of the union of all control volumes is $\bar{\Omega}$.*

(ii) *For any $(K,L) \in \mathcal{T}^2$ with $K \neq L$, either the length of $\bar{K}\cap\bar{L}$ is 0 or $\bar{K}\cap\bar{L} = \bar{\sigma}$ for some $\sigma \in \mathcal{E}$. Then we will denote $\sigma = K|L$.*

(iii) *For any $K \in \mathcal{T}$, there exists a subset $\mathcal{E}(K)$ of $\mathcal{E}$ such that $\partial K = \bar{K}\backslash K = \cup_{\sigma\in\mathcal{E}(K)}\bar{\sigma}$. Furthermore, $\mathcal{E} = \cup_{K\in\mathcal{T}}\mathcal{E}(K)$, and we will denote $\mathcal{N}(K)$ the set of boundary control volumes of K, that is, $\mathcal{N}(K) = \{L \in \mathcal{T}, K|L \in \mathcal{E}(K)\}$.*

(iv) *The family of points $(x_K)_{K\in\mathcal{T}}$ is such that $x_K \in K$ (for all $K \in \mathcal{T}$), and, if $\sigma = K|L$, it is assumed that the straight line (x_K, x_L) is orthogonal to σ.*

For a control volume $K \in \mathcal{T}$, we denote $m(K)$ its measure. If $L \in \mathcal{N}(K)$, then we denote $m(K|L)$ the measure of the interface $K|L$ in $\mathbb{R}^{d-1}$, $d_{K|L}$ the distance between the centers of the control volumes K and L, $T_{K|L} = \frac{m(K|L)}{d_{K|L}}$ the discrete transmissibility, and $\mathbf{n}_{K,L}$ the normal vector of $K|L$ outward to K. We denote $d_{K,K|L}$ the distance between the center x_K of K and the interface $K|L$, and we define the size of the mesh by

$$size(\mathcal{T}) = \max_{K\in\mathcal{T}} diam(K).$$

To prove the convergence theorem, Theorem 5.1, we need uniform regularity properties on meshes in the following sense.

DEFINITION 3.2. *An admissible mesh $\mathcal{T}$ is ξ-regular if for all $K \in \mathcal{T}$,*

$$\sum_{L\in\mathcal{N}(K)} m(K|L)d_{K|L} \le m(K)\,\xi.$$

3.2. The scheme. Let $\mathcal{T}$ be an admissible mesh, and let δt be a time step such that $T = (N+1)\delta t$ with $N \in \mathbb{N}$. We define $\overline{S}_K^{n+1}$ and $\underline{S}_K^{n+1}$ by

$$\overline{S}_K^{n+1} = \frac{1}{\delta t}\int_{n\delta t}^{(n+1)\delta t}\int_K \overline{s},$$
$$\underline{S}_K^{n+1} = \frac{1}{\delta t}\int_{n\delta t}^{(n+1)\delta t}\int_K \underline{s}.$$

With the notations previously introduced, one may define a finite volume scheme as the following set of equations for the discrete unknowns (U,Θ), where $U = (U_K^n)_{K\in\mathcal{T},n\in[\![0,N+1]\!]}$ and $\Theta = (\Theta_K^n)_{K\in\mathcal{T},n\in[\![1,N+1]\!]}$:

$\forall K \in \mathcal{T}$,

$$U_K^0 = \frac{1}{m(K)}\int_K u_0(x)dx; \tag{14}$$

$\forall K \in \mathcal{T}, \forall n \in [\![0,N]\!]$,

$$\begin{aligned}\frac{U_K^{n+1}-U_K^n}{\delta t}m(K) - \sum_{L\in\mathcal{N}(K)} T_{K|L}(\varphi(U_L^{n+1}) - \varphi(U_K^{n+1}))\\ + \sum_{L\in\mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1} f(u)_{K|L}^{n+1} = c\overline{S}_K^{n+1} - U_K^{n+1}\,\underline{S}_K^{n+1};\end{aligned} \tag{15}$$

$\forall K \in \mathcal{T}, \forall L \in \mathcal{N}(K), \forall n \in [\![0,N]\!]$,

$$\mathbf{F}_{K,L}^{n+1} = -M(u)_{K|L}^{n+1} T_{K|L}(\Theta_L^{n+1} - \Theta_K^{n+1}); \tag{16}$$

$\forall K \in \mathcal{T}, \forall n \in [\![0,N]\!]$,

$$\sum_{L\in\mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1} = \overline{S}_K^{n+1} - \underline{S}_K^{n+1}; \tag{17}$$

$\forall n \in [\![0,N]\!]$,

$$\sum_{K\in\mathcal{T}} m(K)\Theta_K^{n+1} = 0, \tag{18}$$

where $f(u)_{K|L}^{n+1}$ and $M(u)_{K|L}^{n+1}$ are, respectively, an upwind discretization of $f(u)$ and a consistent approximation of $M(u)$ on the interface $K|L$ given by

$$f(u)_{K|L}^{n+1} = \begin{cases} f(U_K^{n+1}) & \text{if} \quad \mathbf{F}_{K,L}^{n+1} > 0, \\ f(U_L^{n+1}) & \text{if} \quad \mathbf{F}_{K,L}^{n+1} < 0, \end{cases}$$

$$M(u)_{K|L}^{n+1} = \frac{d_{K|L}}{\frac{d_{K,K|L}}{M(U_K^{n+1})} + \frac{d_{L,K|L}}{M(U_L^{n+1})}}. \tag{19}$$

REMARK 3.1. *Definition* (19) *of $M(u)_{K|L}^{n+1}$ by a harmonic mean ensures consistency property in the general case when the function $M(u)$ is discontinuous on the interface $K|L$ (see* [22], [18]*). However, in our proof of convergence we need only $M(u)_{K|L}^{n+1}$ to be in the interval $[M(U_K^{n+1}), M(U_L^{n+1})]$ since the functions used are more regular.*

3.3. A priori estimates. The scheme (14)–(18) is time implicit, so the existence of a solution must be proven. We will first prove a priori estimates assuming existence of a solution and then prove the existence by using the Leray–Schauder theorem (see [11]). We also use these estimates to obtain compactness properties.

PROPOSITION 3.1. *Assume that $((U_K^n)_{K\in\mathcal{T},n\in[\![0,N+1]\!]}, (\Theta_K^{n+1})_{K\in\mathcal{T},n\in[\![0,N]\!]})$ is a solution to* (14)–(18)*; then*

$$0 \le U_K^{n+1} \le 1 \;\forall K \in \mathcal{T}, \forall n \in [\![0, N+1]\!]. \tag{20}$$

Moreover, there exist $C_1(u_0, \overline{s}, \underline{s}, \Phi) \ge 0$ and $C_2(M_*, \overline{s}, \underline{s}) > 0$ such that

$$\sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} T_{K|L}(\varphi(U_L^{n+1}) - \varphi(U_K^{n+1}))^2 \le C_1 \tag{21}$$

and

$$\sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} T_{K|L}(\Theta_L^{n+1} - \Theta_K^{n+1})^2 \le C_2 \;\forall n \in [\![0, N]\!]. \tag{22}$$

Proof. Rewriting the discrete convection flux in a nondivergence form using (19) and (17), we obtain

$\forall K \in \mathcal{T}, \forall n \in [\![0, N]\!],$

(23)
$$\sum_{L\in\mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1} f(u)_{K|L}^{n+1} = - \sum_{L\in\mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1\,-}(f(U_L^{n+1}) - f(U_K^{n+1})) + f(U_K^{n+1})(\overline{S}_K^{n+1} - \underline{S}_K^{n+1}),$$

where one denotes $x^- = \max(0, -x)$.

In order to prove the discrete maximum principle (20), we follow the continuous case. If U attains its bounds on $\Omega \times \{0\}$, i.e., at points of type $(K, 0)$, the definition of U_K^0 in (14) gives the conclusion. By contradiction, if, for example, $\max(U) > 1$, then necessarily U attains its maximum at an interior point of the parabolic domain $Q = \Omega \times [0,T)$, i.e., at a point of type $(K, n+1)$. In that case, by (23) and (16) we have

$$\begin{aligned} \frac{U_K^{n+1} - U_K^n}{\delta t} m(K) \quad &+ \sum_{L \in \mathcal{N}(K)} T_{K|L}(\varphi(U_K^{n+1}) - \varphi(U_L^{n+1})) \\ &+ \sum_{L \in \mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1^-}(f(U_K^{n+1}) - f(U_L^{n+1})) \\ &+ (f(U_K^{n+1}) - c)\overline{S}_K^{n+1} + (U_K^{n+1} - f(U_K^{n+1}))\,\underline{S}_K^{n+1} = 0, \end{aligned} \tag{24}$$

and φ and f are nondecreasing functions, so we have $U_K^n \geq U_K^{n+1}$. Consequently, also U attains its maximum at point (K, n) and by induction the maximum is attained on $\Omega \times \{0\}$, which leads to a contradiction.

Proofs of the discrete energy estimates (21) and (22) also mimic continuous ones. Multiplying (24) by $\delta t\, U_K^{n+1}$ and summing the result over $K \in \mathcal{T}$ and $n \in [\![0, N]\!]$ yields $E1 + E2 + E3 + E4 = 0$ with

$$\begin{aligned} E1 &= \sum_{n=0}^{N} \sum_{K \in \mathcal{T}} m(K)(U_K^{n+1} - U_K^n)U_K^{n+1}, \\ E2 &= \sum_{n=0}^{N} \delta t \sum_{K \in \mathcal{T}} \sum_{L \in \mathcal{N}(K)} T_{K|L}(\varphi(U_K^{n+1}) - \varphi(U_L^{n+1}))U_K^{n+1}, \\ E3 &= \sum_{n=0}^{N} \delta t \sum_{K \in \mathcal{T}} \sum_{L \in \mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1^-}(f(U_K^{n+1}) - f(U_L^{n+1}))U_K^{n+1}, \\ E4 &= \sum_{n=0}^{N} \delta t \sum_{K \in \mathcal{T}} (f(U_K^{n+1}) - c)U_K^{n+1}\overline{S}_K^{n+1} + (U_K^{n+1} - f(U_K^{n+1}))U_K^{n+1}\,\underline{S}_K^{n+1}. \end{aligned}$$

By a discrete time integration by parts, we obtain

$$\begin{aligned} E1 &= \frac{1}{2}\sum_{K \in \mathcal{T}} m(K)(U_K^{N+1})^2 - \frac{1}{2}\sum_{K \in \mathcal{T}} m(K)(U_K^0)^2 + \frac{1}{2}\sum_{n=0}^{N} \sum_{K \in \mathcal{T}} m(K)(U_K^{n+1} - U_K^n)^2 \\ &\geq -\frac{1}{2}\|u_0\|^2_{L^2(\Omega \times (0,T))}. \end{aligned}$$

Gathering by edges we get for $E2$

$$\begin{aligned} E2 &= \sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K \in \mathcal{T}} \sum_{L \in \mathcal{N}(K)} T_{K|L}(\varphi(U_K^{n+1}) - \varphi(U_L^{n+1}))(U_K^{n+1} - U_L^{n+1}) \\ &\geq \frac{1}{\Phi}\sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K \in \mathcal{T}} \sum_{L \in \mathcal{N}(K)} T_{K|L}(\varphi(U_K^{n+1}) - \varphi(U_L^{n+1}))^2. \end{aligned}$$

To deal with $E3$, we need a technical lemma which is proved, for example, in [18].

LEMMA 3.1. *Let f be a nondecreasing continuous function on $\mathbb{R}$, and define g by $g(u) = uf(u) - \int_0^u f(\tau)d\tau$. Then for every $(a, b) \in \mathbb{R}^2$,*

$$(f(a) - f(b))a \geq g(a) - g(b).$$

By using Lemma 3.1 and the local conservation property $\mathbf{F}_{K,L}^{n+1} + \mathbf{q}_{L,K}^{n+1} = 0$ we get

$$\begin{aligned} E3 &\geq \sum_{n=0}^{N} \delta t \sum_{K\in\mathcal{T}} \mathbf{F}_{K,L}^{n+1^-}(g(U_L^{n+1}) - g(U_K^{n+1})) \\ &= \sum_{K\in\mathcal{T}} g(U_K^{n+1}) \sum_{L\in\mathcal{N}(K)} \mathbf{F}_{K,L}^{n+1} \\ &= -\sum_{K\in\mathcal{T}} g(U_K^{n+1})(\overline{S}_K^{n+1} - \underline{S}_K^{n+1}). \end{aligned}$$

Hence,

$$\begin{aligned} E3 + E4 &\geq \sum_{n=0}^{N} \delta t \sum_{K\in\mathcal{T}} \overline{S}_K^{n+1}(f(U_K^{n+1})U_K^{n+1} - g(U_K^{n+1}) - cU_K^{n+1}) \\ &\quad + \sum_{n=0}^{N} \delta t \sum_{K\in\mathcal{T}} \underline{S}_K^{n+1}(g(U_K^{n+1}) - f(U_K^{n+1})U_K^{n+1} + (U_K^{n+1})^2) \\ &\geq \sum_{n=0}^{N} \delta t \sum_{K\in\mathcal{T}} -2(\overline{S}_K^{n+1} + \underline{S}_K^{n+1}) \\ &\geq -2(\|\overline{s}\|_{L^1(\Omega\times(0,T))} + \|\underline{s}\|_{L^1(\Omega\times(0,T))}). \end{aligned}$$

Collecting the previous inequalities yields exactly (21) with

$$C_1 = \Phi\left(\frac{1}{2}\|u_0\|^2_{L^2(\Omega\times(0,T))} + 2(\|\overline{s}\|_{L^1(\Omega\times(0,T))} + \|\underline{s}\|_{L^1(\Omega\times(0,T))})\right).$$

Now let us multiply (17) by Θ_K^{n+1} and sum over $K \in \mathcal{T}$. Gathering by edges, we obtain

$$\begin{aligned} \sum_{K\in\mathcal{T}} \frac{1}{2} \sum_{L\in\mathcal{N}(K)} M(u)_{K|L}^{n+1}(\Theta_K^{n+1} - \Theta_L^{n+1})^2 &= \sum_{K\in\mathcal{T}} (\overline{S}_K^{n+1} - \underline{S}_K^{n+1})\Theta_K^{n+1} \\ &\leq \|\overline{s} - \underline{s}\|_{L^\infty(0,T,L^2(\Omega))} \left(\sum_{K\in\mathcal{T}} m(K)(\Theta_K^{n+1})^2\right)^{\frac{1}{2}}. \end{aligned}$$

And by the discrete Poincaré inequality (see [10]), there exists $C(\Omega)$ such that

$$\sum_{K\in\mathcal{T}} m(K)(\Theta_K^{n+1})^2 \leq C(\Omega)^2 \sum_{K\in\mathcal{T}} \frac{1}{2} \sum_{L\in\mathcal{N}(K)} T_{K|L}(\Theta_K^{n+1} - \Theta_L^{n+1})^2.$$

This gives (22) with $C_2 = C(\Omega)\frac{1}{M_*}\|\overline{s} - \underline{s}\|^2_{L^2(\Omega\times(0,T))}$. □

3.4. Existence of the approximate solution. Let $E = \mathbb{R}^{[\![0,N+1]\!]\times\mathcal{T}}\mathbb{R}^{[\![1,N+1]\!]\times\mathcal{T}}$ and $\mathcal{G} : E \to E$ such that $\mathcal{G}(U,\theta) = (\tilde{U}, \tilde{\theta})$, where $(\tilde{U}, \tilde{\theta})$ is the solution of the following set of equations:

$\forall K \in \mathcal{T}$,

$$\tilde{U}_K^0 = \frac{1}{m(K)} \int_K u_0(x)dx;$$

$\forall K \in \mathcal{T}$ and $\forall n \in [\![0, N]\!]$,

$$\frac{\tilde{U}_K^{n+1} - \tilde{U}_K^n}{\delta t} m(K) - \sum_{\sigma \in \mathcal{E}(K)} T_{K|L}(\varphi(U_L^{n+1}) - \varphi(U_K^{n+1}))$$
$$- \sum_{\sigma \in \mathcal{E}(K)} \tilde{\mathbf{F}}_{K,L}^{n+1+} f(U_K^{n+1}) - \tilde{\mathbf{F}}_{K,L}^{n+1-} f(U_L^{n+1}) = c\overline{S}_K^{n+1} - U_K^{n+1}\,\underline{S}_K^{n+1};$$

$\forall K \in \mathcal{T}$, $\forall L \in \mathcal{N}(K)$, $\forall n \in [\![0, N]\!]$,

$$\tilde{\mathbf{F}}_{K,L}^{n+1} = -M(u)_{K|L}^{n+1} T_{K|L}(\tilde{\Theta}_L^{n+1} - \tilde{\Theta}_K^{n+1});$$

$\forall K \in \mathcal{T}, \forall n \in [\![0, N]\!]$,

$$\sum_{L \in \mathcal{N}(K)} \tilde{\mathbf{F}}_{K,L}^{n+1} = \overline{S}_K^{n+1} - \underline{S}_K^{n+1};$$

$\forall n \in [\![0, N]\!]$,

$$\sum_{K \in \mathcal{T}} m(K)\tilde{\Theta}_K^{n+1} = 0.$$

The function $\mathcal{G}$ is well defined only if there exists a unique solution to this set of equations. In fact, this system of equations can be easily solved iteratively (on the contrary to system (14)–(18)), because the diffusion term on the elliptic equation on $\tilde{\Theta}$, which is $M(u)_{K|L}^{n+1}$, is given and cannot degenerate since $M(u)_{K|L}^{n+1} \in [M(U_K^{n+1}), M(U_L^{n+1})]$ and $M(u) \geq M_* > 0$ by assumption.

By using the continuity of $U \to M(u)_{K|L}^{n+1}$, $x \to x^+$, and $x \to x^-$, we obtain in the same time that $\mathcal{G}$ is a continuous function. Now, by construction, for any $\alpha \in [0, 1]$, the problem $(U, \Theta) = \alpha\mathcal{G}(U, \Theta)$ has exactly the same solutions as the numerical scheme (14)–(18) with $\alpha\varphi$, αu_0, $\alpha\overline{s}$, and $\alpha\underline{s}$ instead of φ, u_0, $\overline{s}$, and $\underline{s}$.

But $\alpha \in [0, 1]$, so Φ is also a Lipschitz constant for $\alpha\varphi$, and we have $\|\alpha\overline{s}\| \leq \|\overline{s}\|$, $\|\alpha\underline{s}\| \leq \|\underline{s}\|$, $\|\alpha u_0\| \leq \|u_0\|$. Thus estimates given in Proposition 3.1 are uniformly satisfied for any $\alpha \in [0, 1]$ and any solution of $(U, \Theta) = \alpha\mathcal{G}(U, \Theta)$.

Now all the assumptions of the Leray–Schauder theorem are satisfied, so there exists a fixed point for $\mathcal{G}$; i.e., there exists at least a solution to the scheme (14)–(18).

4. Compactness results. Each solution $(U, \Theta)_{\mathcal{T},\delta t}$ of (14)–(18) for an admissible mesh $\mathcal{T}$ and a time step δt corresponds to an approximate solution $(u_{\mathcal{T},\delta t}, \theta_{\mathcal{T},\delta t})$ of problem (5)–(6) defined a.e. on $\Omega \times (0, T)$ by

$$u_{\mathcal{T},\delta t}(x, t) = U_K^{n+1}, x \in K, t \in (n\delta t, (n+1)\delta t),$$
$$\theta_{\mathcal{T},\delta t}(x, t) = \Theta_K^{n+1}, x \in K, t \in (n\delta t, (n+1)\delta t).$$

The first step toward the convergence theorem, Theorem 5.1, consists of the proof of compactness properties on $u_{\mathcal{T},\delta t}$ and $\theta_{\mathcal{T},\delta t}$, by using a priori estimates on the discrete solution obtained in Proposition 3.1.

4.1. Compactness of $\boldsymbol{u_{\mathcal{T},\delta t}}$. We shall prove that $\varphi(u_{\mathcal{T},\delta t})$ is relatively compact in $L^2(\Omega \times (0, T))$ for the strong topology by using Kolmogorov's theorem and that when $size(\mathcal{T}) \to 0$ and $\delta t \to 0$, the limit of each convergent sequence of approximate solutions belongs to $L^2(0,T,H^1(\Omega))$. Let us first recall Kolmogorov's compactness theorem, which is a consequence of the Ascoli compactness theorem.

THEOREM 4.1 (Fréchet–Kolmogorov). *Let $\mathcal{F}$ be a bounded subset of $L^2(\mathbb{R}^d)$, and let Ω be a bounded domain of $\mathbb{R}^d$; then $\mathcal{F}$ is relatively compact in $L^2(\Omega)$ if and only if*

$$\lim_{|\xi|\to 0}\sup_{f\in\mathcal{F}}\|f(\cdot+\xi)-f(\cdot)\|_{L^2(\mathbb{R}^d)}=0.$$

In our case, to apply this theorem on $Q=\Omega\times(0,T)$, we need to study the space and time translates of $\varphi(u_{\mathcal{T},\delta t})$. As a direct consequence of (21) (see [17], [18]) we already have the following result.

PROPOSITION 4.1 (space translates). *Let C_1 be defined in Proposition 3.1; then for all $\xi\in\mathbb{R}^d$,*

$$\int_0^T\int_{\Omega_\xi}[\varphi(u_{\mathcal{T},\delta t}(x+\xi,\cdot)-\varphi(u_{\mathcal{T},\delta t}(x,\cdot))]^2dx\le C\Phi|\xi|(2m(\mathcal{T})+|\xi|),$$

where $\Omega_\xi=\{x\in\Omega,[x,x+\xi]\subset\Omega\}$ and $|\xi|$ is the Euclidean norm on $\mathbb{R}^d$.

We can establish an analogue but with slightly different results for time translates estimates. We now adapt the method of [19], but since this method is not quite well known, we shall give the complete proof of it. Let us first state exactly the result we shall prove.

PROPOSITION 4.2 (time translates). *There exist $C'(\varepsilon,\varphi,f,\mathbf{q},u_0,\Omega,T)>0$ such that for every $s\in\mathbb{R}^+$,*

$$\int_0^{T-s}\int_\Omega(\varphi(u_{\mathcal{T},\delta t}(x,t+s))-\varphi(u_{\mathcal{T},\delta t}(x,t))\,)^2dxdt\le C's.$$

Proof. Let us define $A(t)=\int_\Omega(u_{\mathcal{T},\delta t}(x,t+s)-u_{\mathcal{T},\delta t}(x,t))(\varphi(u_{\mathcal{T},\delta t}(x,t+s)-\varphi(u_{\mathcal{T},\delta t}(x,t)))dxdt$. Then

$$\int_\Omega(\varphi(u_{\mathcal{T},\delta t}(x,t+s))-\varphi(u_{\mathcal{T},\delta t}(x,t))\,)^2dxdt\le A(t)\,\Phi.$$

If for any $t\in\mathbb{R}$ we denote $n(t)$ the integer part of $\frac{t}{\delta t}$, then for any $K\in\mathcal{T}$ and $x\in K$,

$$\begin{aligned}u_{\mathcal{T},\delta t}(x,t+s)-u_{\mathcal{T},\delta t}(x,t)&=\sum_{n=n(t)}^{n(t+s)-1}U_K^{n+1}-U_K^n\\&=\frac{1}{m(K)}\sum_{n=n(t)}^{n(t+s)-1}\delta t\sum_{L\in\mathcal{N}(K)}T_{K|L}(\varphi(U_K^{n+1})\\&\quad-\varphi(U_L^{n+1}))-\mathbf{F}_{K,L}^{n+1}f(u)_{K|L}^{n+1}.\end{aligned}$$

So $A(t)=A_1(s,t)-A_1(0,t)-A_2(s,t)+A_2(0,t)$, where for $\rho=0$ or $\rho=s$ we denote

$$A_1(\rho,t)=\sum_{n=n(t)}^{n(t+s)-1}\delta t\sum_{K\in\mathcal{T}}\sum_{L\in\mathcal{N}(K)}T_{K|L}(\varphi(U_K^{n+1})-\varphi(U_L^{n+1}))\varphi(U_K^{n(t+\rho)}),$$

$$A_2(\rho,t)=\sum_{n=n(t)}^{n(t+s)-1}\delta t\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}(K)}\mathbf{F}_{K,L}^{n+1}f(u)_{K|L}^{n+1}\varphi(U_K^{n(t+\rho)}).$$

Gathering by edges and using the local conservation of the discrete fluxes, we get

$$A_1(\rho,t)=\sum_{n=n(t)}^{n(t+s)-1}\delta t\frac{1}{2}\sum_{K\in\mathcal{T}}\sum_{L\in\mathcal{N}(K)}T_{K|L}(\varphi(U_K^{n+1})-\varphi(U_L^{n+1}))(\varphi(U_K^{n(t+\rho)})-\varphi(U_L^{n(t+\rho)})),$$
$$A_2(\rho,t)=\sum_{n=n(t)}^{n(t+s)-1}\delta t\frac{1}{2}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}(K)}\mathbf{F}_{K,L}^{n+1}f(u)_{K|L}^{n+1}(\varphi(U_K^{n(t+\rho)})-\varphi(U_L^{n(t+\rho)})).$$

Now by using the Young inequality, we have

$$|A_1(\rho,t)|\le\frac{1}{2}\sum_{n=n(t)}^{n(t+s)-1}\delta t\,(S(n)+S(n(t+\rho))),$$
$$|A_2(\rho,t)|\le\frac{1}{2}\sum_{n=n(t)}^{n(t+s)-1}\delta t\,(R(n)+S(n(t+\rho))),$$

where

$$S(n)=\sum_{n=0}^{N}\delta t\frac{1}{2}\sum_{K\in\mathcal{T}}\sum_{L\in\mathcal{N}(K)}T_{K|L}(\varphi(U_K^{n+1})-\varphi(U_L^{n+1}))^2,$$
$$R(n)=\sum_{n=0}^{N}\delta t\frac{1}{2}\sum_{K\in\mathcal{T}}\sum_{L\in\mathcal{N}(K)}\frac{1}{T_{K|L}}(\mathbf{F}_{K,L}^{n+1}f(u)_{K|L}^{n+1})^2.$$

Let us assume the following technical results.

Lemma 4.1. *Let $B:\mathbb{N}\to\mathbb{R}^+$ such that $\sum_{n=0}^{N}\delta tB(n)\le C$; then for all $s\in\mathbb{R}^+$, $\int_0^{T-s}\sum_{n=n(t)}^{n(t+s)-1}\delta tB(n)dt\le C\,s$.*

Lemma 4.2. *Let $B:\mathbb{N}\to\mathbb{R}^+$ such that $\sum_{n=0}^{N}\delta tB(n)\le C$; then for all $s\in\mathbb{R}^+$, $\int_0^{T-s}\sum_{n=n(t)}^{n(t+s)-1}\delta tB(n(t+\rho))dt\le C\,s$.*

According to estimates (21) and (22), S and R satisfy the assumptions of the two lemmas, so we obtain

$$\|A_1(\rho,t)\|\le C',$$
$$\|A_2(\rho,t)\|\le C'',$$

and collecting the previous inequalities completes the proof of Proposition 4.2. Yet, it remains only to show the two lemmas.

For Lemma 4.1, $\int_0^{T-s}\sum_{n=n(t)}^{n(t+s)-1}\delta tB(n)=\sum_{n=0}^{N}\delta tB(n)\int_0^{T-s}\mathbb{1}_{n\in[\![n(t),n(t+s)-1]\!]}dt$ and $n\in[\![n(t),n(t+s)-1]\!]$ if and only if $t\in[(n+1)\delta t-s,(n+1)\delta t)$, so $\int_0^{T-s}\mathbb{1}_{n\in[\![n(t),n(t+s)-1]\!]}dt\le s$.

For Lemma 4.2, $\int_0^{T-s}\sum_{n=n(t)}^{n(t+s)-1}\delta tB(n(t+\rho))dt=\sum_{n=0}^{N}\delta tB(n)\int_0^{T-s}(n(t+s)-n(t))\,\mathbb{1}_{n(t+\rho)=n}dt$, but $n(t+s)-n(t)$ is periodic with period δt, so $\int_0^{T-s}(n(t+s)-n(t))\,\mathbb{1}_{n(t+\rho)=n}dt\le\int_{n\delta t-\rho}^{(n+1)\delta t-\rho}(n(t+s)-n(t))dt\le\int_0^{\delta t}n(t+s)dt\le s$. □

To prove compactness of $\varphi(u_{\mathcal{T},\delta t})$ in $L^2(\Omega)$, let us check the hypothesis of Theorem 4.1. From Propositions 4.1 and 4.2 we easily deduce that if we extend $u_{\mathcal{T},\delta t}$ by zero outside of $\Omega \times (0,T)$, then for every $\xi \in \mathbb{R}^d$ and $s \in \mathbb{R}^+$ one has

$$\|\varphi(u_{\mathcal{T},\delta t}(\cdot+\xi,\cdot+s)) - \varphi(u_{\mathcal{T},\delta t}(\cdot,\cdot))\|_{L^2(\mathbb{R}^{m+1})} \leq 2C|\xi|(|\xi|+2h) + 2C's \\ + (4T|\xi|m(\partial\Omega) + 2m(\Omega)s)(\varphi^*)^2.$$

Let $u_m = u_{\mathcal{T}_m,\delta t_m}$ be a sequence of approximate solutions with $size(\mathcal{T}_m) \to 0$ when m tends to infinity, and suppose that $\varphi(u_m)$ tends to $\bar{\varphi}$ in $L^2(\Omega \times (0,T))$. It remains to show that $\bar{\varphi}$ is in $L^2(0,T,H^1(\Omega))$. In order to prove it, we shall use space translate estimates in the interior of Ω.

Let $\omega \subset\subset \Omega$. From Proposition 4.1, if $(\xi, z) \in \mathbb{R}^d \times \mathbb{R}$ satisfies $|\xi| \leq d(\omega, \mathbb{R}^d - \Omega)$ and $-1 \leq z \leq 1$,

$$\left\| \frac{\varphi(u_m(\cdot+z\xi,\cdot)) - \varphi(u_m(\cdot,\cdot))}{z} \right\|_{L^2(\omega\times(0,T))} \leq |\xi|\sqrt{C\Phi} + \sqrt{2h_m\frac{|\xi|}{|z|}}.$$

So by letting m tend to infinity, it holds that

$$\left\| \frac{\bar{\varphi}(\cdot+z\xi,\cdot) - \bar{\varphi}(\cdot,\cdot)}{z} \right\|_{L^2(\omega\times(0,T))} \leq |\xi|\sqrt{C\Phi},$$

and by letting z tend to zero we obtain finally

$$\|\nabla\bar{\varphi}\cdot\xi\|_{L^2(\omega\times(0,T))} \leq |\xi|\sqrt{C\Phi}. \tag{25}$$

By homogeneity, inequality (25) is true for every $\xi \in \mathbb{R}^d$, so $\bar{\varphi} \in L^2(0,T,H^1(\Omega))$ and $\|\nabla\bar{\varphi}\|_{L^2((0,T)\times\Omega)} \leq \sqrt{C\Phi}$. This regularity property will be useful, for example, for writing a weak formulation for the problem (5)–(6).

4.2. Compactness of $\boldsymbol{\theta_{\mathcal{T},\delta t}}$. In the same way as for $\varphi(u_{\mathcal{T},\delta t})$, we can show space translate estimates on $\theta_{\mathcal{T},\delta t}$, but since the equation satisfied by θ does not include time derivatives relative to θ, we do not have any time translate estimate. Hence we cannot apply the same method to obtain compactness on $\theta_{\mathcal{T},\delta t}$. However, by Poincaré inequality, $(\theta_{\mathcal{T},\delta t})_{\mathcal{T},\delta t}$ is bounded in $L^\infty(0,T,L^2(\Omega))$. Therefore $\theta_{\mathcal{T},\delta t}$ is sequentially weakly relatively compact in $L^2(\Omega\times(0,T))$, and by the same arguments as those used in the previous section, every possible limit when $size(\mathcal{T})$ tends to zero belongs to $L^\infty(0,T,H^1(\Omega))$. This is sufficient for convergence under the hypothesis that φ' is strictly nondecreasing, since we get in that case the strong convergence of $u_{\mathcal{T},\delta t}$ directly from the strong convergence of $\varphi(u_{\mathcal{T},\delta t})$.

5. Convergence of the scheme.

DEFINITION 5.1 (weak solution). *(u,θ) is a weak solution of problem* (5)–(6) *if $u \in L^\infty(\Omega\times(0,T))$, $0 \leq u(x,t) \leq 1$ a.e $(x,t) \in \Omega\times(0,T)$, $\varphi(u) \in L^2(0,T,H^1(\Omega))$, $\theta \in L^\infty(0,T,H^1(\Omega))$, and for any $\psi \in (\mathbb{R}^d\times[0,T))^2$ there hold*

$$\int_0^T\int_\Omega u\psi_t - \int_0^T\int_\Omega \nabla\varphi(u)\cdot\nabla\psi - \int_0^T\int_\Omega f(u)M(u)\nabla\theta\cdot\nabla\psi + \int_\Omega u_0\psi(\cdot,0) \\ = -\int_0^T\int_\Omega c\bar{s}\psi + \int_0^T\int_\Omega u\underline{s}\psi, \tag{26}$$

$$\int_0^T\int_\Omega M(u)\nabla\theta\cdot\nabla\psi = \int_0^T\int_\Omega(\bar{s}-\underline{s})\psi. \tag{27}$$

We shall now give and prove the main result of this paper.

Theorem 5.1 (the convergence theorem). *Let* $(u_m,\theta_m)=(u_{\mathcal{T}_m,\delta t_m},\theta_{\mathcal{T}_m,\delta t_m})$ *be a sequence of approximate solutions given by scheme* (14)–(18) . *Let us assume that there exists* $\xi>0$ *such that for every* $m\in\mathbb{N}$, $\mathcal{T}_m$ *is a* ξ*-regular admissible mesh. Assume also that* $size(\mathcal{T}_m)\to 0$ *and* $\delta t_m\to 0$ *when* m *tends to* ∞. *Then there exists a weak solution* (u,θ) *of problem* (5)–(6) *such that up to a subsequence,*

$$u_m\to u,\ \textit{strongly in } L^2(\Omega\times(0,T))\ \textit{as } m\to\infty,$$
$$\theta_m\to\theta,\ \textit{weakly in } L^2(\Omega\times(0,T))\ \textit{as } m\to\infty.$$

Remark 5.1. *Under the assumption that* $f(\varphi^{-1})$ *is Holder continuous with exponent* $\frac{1}{2}$ *and with the additional hypothesis* $\|\nabla\theta\|\in L^\infty(\Omega\times(0,T))$, *we can prove that the weak solution is unique (see* [9]*). So the whole sequence of approximate solutions is convergent.*

Proof. From compactness properties of u_m and θ_m, we already know that up to a subsequence $\varphi(u_m)\to\bar\varphi$ strongly in $L^2(\Omega\times(0,T))$, $\theta_m\to p$ weakly in $L^2(\Omega\times(0,T))$ as $m\to\infty$. Since $size(\mathcal{T}_m)\to 0$, $\bar\varphi\in L^2(0,T,H^1(\Omega))$ and $\theta\in L^\infty(0,T,H^1(\Omega))$. Now since φ is strictly nondecreasing, by using, for example, the dominated convergence theorem we deduce that u_m tends to $u=\varphi^{-1}(\bar\varphi)$ strongly in $L^2(\Omega\times(0,T))$. It remains to show that u is a weak solution of problem (5)–(6).

Let $(\mathcal{T},\delta t)=(\mathcal{T}_m,\delta t_m)$. We define the discretization and approximate of ψ denoted, respectively, Ψ and $\psi_{\mathcal{T},\delta t}$ by the following formulas:

$$\Psi_K^{n+1}=\psi(x_K,n\delta t),K\in\mathcal{T},n\in[\![0,N]\!], \tag{28}$$
$$\psi_{\mathcal{T}}(x,t)=\Psi_K^{n+1},x\in K,t\in(n\delta t,(n+1)\delta t). \tag{29}$$

In order to prove that (u,θ) is a weak solution, we multiply (16) and (17) by $\delta t\Psi_K^{n+1}$ and sum over $n\in[\![0,N]\!]$ and $K\in\mathcal{T}$. Then we let m tend to infinity and show that we obtain (26) and (27) when passing to the limit.

As in [19], [28], [6], by using the consistency of fluxes, we obtain at the limit the following terms:

$$\int_0^T\int_\Omega u\psi_t+\int_\Omega u_0,\int_0^T\int_\Omega\nabla\varphi(u)\cdot\nabla\psi,\int_0^T\int_\Omega c\overline{s}\psi,\int_0^T\int_\Omega u\underline{s}\psi,\ \text{and}\int_0^T\int_\Omega(\overline{s}-\underline{s})\psi.$$

But we encounter original difficulties to obtain the two remaining terms, namely

$$\int_0^T\int_\Omega f(u)M(u)\nabla\theta\ \text{and}\int_0^T\int_\Omega M(u)\nabla\theta.$$

Indeed, heuristically, we have to prove the weak convergence of $f(u_m)M(u_m)\nabla\theta_m$ and $M(u_m)\nabla\theta_m$ to $f(u)M(u)\nabla\theta$ and $M(u)\nabla\theta$, with u_m strongly converging to u and θ_m bounded in $L^2(0,T,H^1(\Omega))$ and weakly converging to θ. In the continuous case, this problem can be solved since a product of two functions, the first converging strongly and the other weakly, is weakly converging to the product of the limits. However, the gradient of discrete function is not in general a function, so we need to use a regularization argument that we shall detail.

Remark 5.2. *Our heuristic argument justifies why the strong convergence of* u_m *is crucial. Indeed, a product of weak convergent sequences of functions in general does not converge to the product of the limit, even if it has a weak limit. In our case we obtain this strong convergence by using the hypothesis that* φ' *is a strictly increasing* *function, but our method would also work in all cases where we were able to prove that $f(u_m)$ and $M(u_m)$ converge strongly.*

We will restrict ourselves to the case when $A = \int_\Omega \int_0^T f(u)M(u)\nabla\theta \cdot \nabla\psi$ because the other integral is a special case with $f = 1$. Let us first define $A_{\mathcal{T},\delta t}$ by

$$A_{\mathcal{T},\delta t} = \sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} f(u)_{K|L}^{n+1} M(u)_{K|L}^{n+1} (\Theta_L^{n+1} - \Theta_K^{n+1})(\Psi_L^{n+1} - \Psi_K^{n+1}).$$

$A_{\mathcal{T},\delta t}$ is the term corresponding to A when we multiply (16) by $\delta t \Psi_K^{n+1}$, sum over $K \in \mathcal{T}$ and $n \in [\![0, N]\!]$, and gather by edges. Assume first that $f(u)$ and $M(u)$ are in $\mathcal{D}(\Omega \times (0,T))$, and $M(U)$, $m(u_{\mathcal{T},\delta t})$ and $f(U)$, $f(u_{\mathcal{T},\delta t})$ are discretizations and approximations of $f(u)$ and $M(u)$ defined in the same way as Ψ and $\psi_{\mathcal{T},\delta t}$ by (28)–(29). By the Stokes formula,

$$A = -\int_0^T \int_\Omega \theta \ \mathrm{div}(f(u)M(u)\nabla\psi).$$

So because of the weak convergence of θ_m to θ, $A = \lim_{m\to\infty} B_{\mathcal{T}_m,\delta t_m}$, where $B_{\mathcal{T},\delta t}$ is given by

$$B_{\mathcal{T},\delta t} = \int_0^T \int_\Omega \theta_{\mathcal{T},\delta t} \mathrm{div}(f(u)M(u)\nabla\psi),$$

and by definition of the piecewise constant function $\theta_{\mathcal{T},\delta t}$ we get

$$\begin{aligned} B_{\mathcal{T},\delta t} &= -\sum_{n=0}^{N} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} \Theta_K^{n+1} \int_{n\delta t}^{(n+1)\delta t} \int_{K|L} f(u)M(u)\nabla\psi \cdot \mathbf{n}_{K,L} \\ &= \sum_{n=0}^{N} \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} (\Theta_L^{n+1} - \Theta_K^{n+1}) \int_{n\delta t}^{(n+1)\delta t} \int_{K|L} f(u)M(u)\nabla\psi \cdot \mathbf{n}_{K,L}. \end{aligned}$$

Now, let us compare $B_{\mathcal{T},\delta t}$ and $A_{\mathcal{T},\delta t}$, using the consistency of the flux on the interfaces $K|L$ for regular functions. By the Cauchy–Schwarz inequality, we have

$$\begin{aligned} &|A_{\mathcal{T},\delta t} - B_{\mathcal{T},\delta t}|^2 \\ &\leq \sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} T_{K|L} (\Theta_K^{n+1} - \Theta_L^{n+1})^2 \sum_{n=0}^{N} \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} \frac{1}{T_{K|L}} R_{K|L}^2, \end{aligned}$$

where

$$R_{K|L} = |f(u)_{K|L}^{n+1} M(u)_{K|L}^{n+1} T_{K|L} (\Psi_K^{n+1} - \Psi_L^{n+1}) - \frac{1}{\delta t} \int_{n\delta t}^{(n+1)\delta t} \int_{K|L} f(u)M(u)\nabla\psi \cdot \mathbf{n}_{K,L}|.$$

By using the regularity of $f(u)$, $M(u)$, and ψ and the orthogonality property $x_K - x_L = d_{K|L}\mathbf{n}_{K,L}$, we easily get the existence of $C_3 > 0$ depending only on $f(u)$, $M(u)$, and ψ such that $R_{K|L} \leq C_3 d_{K|L} m(\sigma)$. Then using estimate (22) we obtain $\lim_{m\to\infty} A_{\mathcal{T}_m,\delta t_m} - B_{\mathcal{T}_m,\delta t_m} = 0$ and $\lim_{m\to\infty} A_{\mathcal{T}_m,\delta t_m} = A$, in the particular case considered here. To extend the result to the general case by density, it suffices to remark the continuity of A with respect to $M(u), f(u)$ and the uniform continuity of

$A_{\mathcal{T},\delta t}$ for the $L^2(\Omega\times(0,T))$ norm. The continuity of A is clear. To show uniform continuity of $A_{\mathcal{T},\delta t}$, we use first the Cauchy–Schwarz inequality to get the following inequalities:

$$\|A_{\mathcal{T},\delta t}\|^2 \le \|\nabla\psi\|^2_{L^2(0,T,L^\infty(\Omega))} C_2 \sum \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} d_{K|L} m(K|L)(M(u)^{n+1}_{K|L})^2,$$

$$\|A_{\mathcal{T},\delta t}\|^2 \le \|\nabla\psi\|^2_{L^2(0,T,L^\infty(\Omega))} (M^*)^2 C_2 \sum \delta t \frac{1}{2} \sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} d_{K|L} m(K|L)(f(u)^{n+1}_{K|L})^2.$$

Then, since $M(u)^{n+1}_{K|L}$ belongs to the interval $[M(U^{n+1}_K), M(U^{n+1}_L)]$ and $f(u)^{n+1}_{K|L} \in [f(U^{n+1}_K), f(U^{n+1}_L)]$, we have

$$\sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} (M(u)^{n+1}_{K|L})^2 d_{K|L} m(K|L) \le 2 \sum_{K\in\mathcal{T}} M(U^{n+1}_K)^2 \left(\sum_{L\in\mathcal{N}(K)} d_{K|L} m(K|L) \right),$$

$$\sum_{K\in\mathcal{T}} \sum_{L\in\mathcal{N}(K)} (f(u)^{n+1}_{K|L})^2 d_{K|L} m(K|L) \le 2 \sum_{K\in\mathcal{T}} f(U^{n+1}_K)^2 \left(\sum_{L\in\mathcal{N}(K)} d_{K|L} m(K|L) \right).$$

By using the uniform ξ-regularity of meshes, we finally get

$$\|A_{\mathcal{T},\delta t}\| \le \sqrt{C_2\xi}\|\psi\|_{L^2(0,T,L^\infty(\Omega))}\|M(u_{\mathcal{T},\delta t})\|,$$
$$\|A_{\mathcal{T},\delta t}\| \le \sqrt{C_2\xi}\|\psi\|_{L^2(0,T,L^\infty(\Omega))} M^* \|f(u_{\mathcal{T},\delta t})\|,$$

and we use the bilinearity of $A_{\mathcal{T},\delta t}$ to conclude. This completes the proof of Theorem 5.1. □

6. Numerical results. As an example of application, we perform numerical experiments with the following data, which are realistic in the study of oil and water flow in a homogeneous porous media:

$$k_1(x) = \frac{x^3}{2}, \quad k_2(x) = \frac{(1-x)^3}{3},$$
$$p_c(x) = -0.5\sqrt{\frac{1-x}{x}}.$$

As an initial condition we take uniformly the value $u_0 = 0.5$ and prescribe $c = 0.8$. We represent in Figure 1 the behavior of k_1, k_2, M, f, and p_c. We can verify that the hypotheses that we made on the data in section 2 are satisfied.

The domain of study is the open subset $\Omega = (0,1)^2$ of $\mathbb{R}^2$. If we denote $D_1 = \{(x,y)\in\mathbb{R}^2, (x-0.5)^2+(y-0.8)^2 \le 0.01\}$, $D_2 = \{(x,y)\in\mathbb{R}^2, (x-0.2)^2+(y-0.2)^2 \le 0.01\}$, $D_3 = \{(x,y)\in\mathbb{R}^2, (x-0.8)^2+(y-0.5)^2 \le 0.01\}$, we can take sources and sinks terms as follows:

$$\overline{s}(x,y) = 10\,\mathbb{1}_{D_1}(x,y) + 20\,\mathbb{1}_{D_2}(x,y),$$
$$\underline{s}(x,y) = 30\,\mathbb{1}_{D_3}(x,y).$$

Figures 2 and 3 represent the numerical results at time $t = 2.1$ and $t = 9.1$. As we could expect, the saturation in the reservoir increases in mean because $u_0 \le c$ and

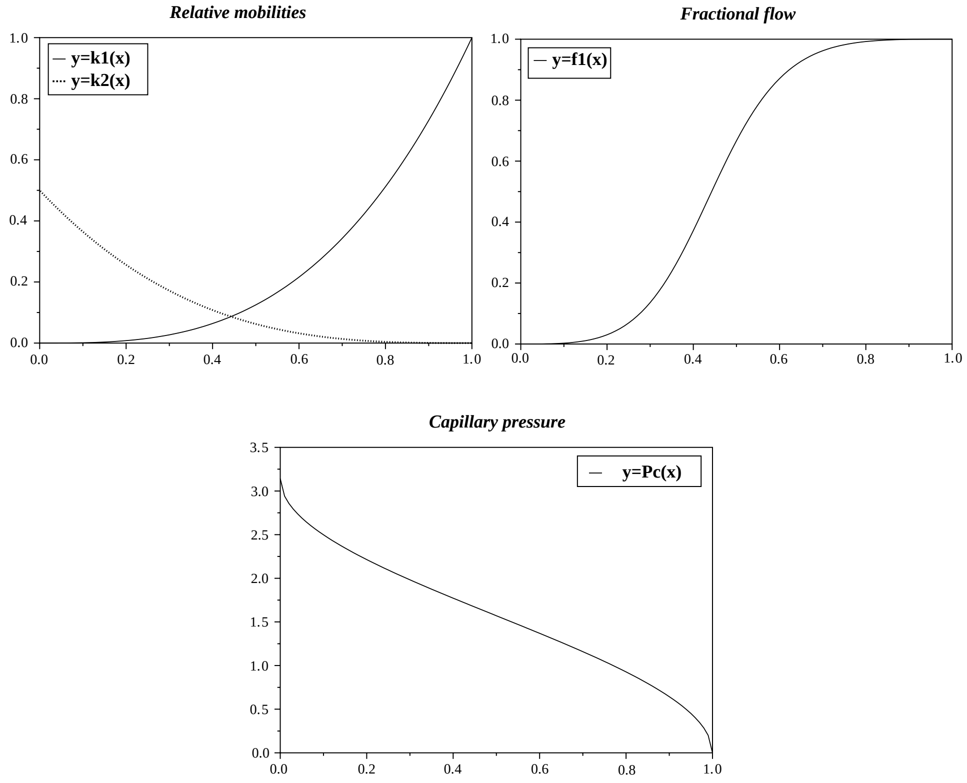

Fig. 1. *Behavior of the functions* k_1, k_2, f_1, p_c.

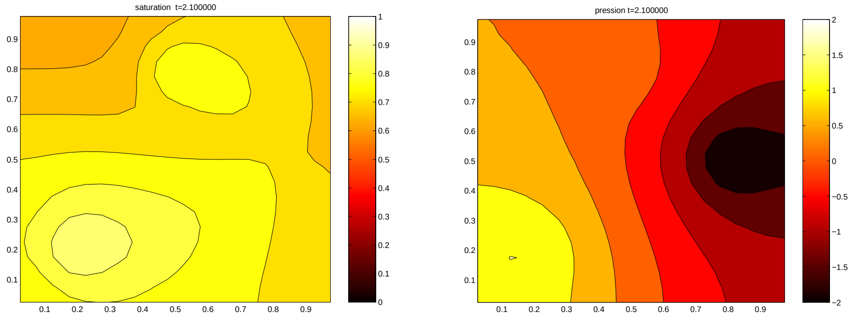

Fig. 2. *Saturation and pressure at time* $t = 2.1$.

the gradient of the pressure is oriented from the sources to the sink. The pressure is nearly stationary, which is not surprising since sources and sinks are stationary and the variations of the diffusion coefficient $M(u)$ is not very large in the interval $[0, 1]$. The flow is more important at the beginning, when the difference between the injection saturation and the mean saturation in the reservoir is the largest.

7. Concluding remarks. We have proved the convergence of an implicit fully finite volume method using the elliptic parabolic structure of the problem after a transformation due to Chavent (see [7]). We have made two-dimensional computations

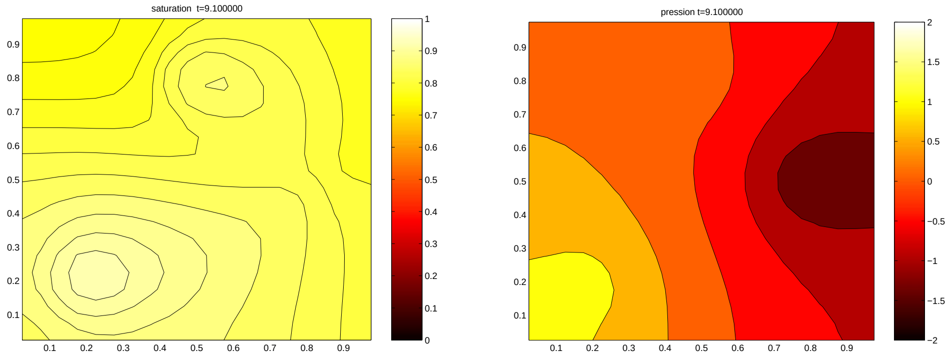

FIG. 3. *Saturation and pressure at time $t = 9.1$.*

that showed that it works well. It should be interesting to compare our method with other methods in terms of accuracy and performance. In particular, we aim to compare it to the phase by phase upwind scheme (see [20]) which consists of directly discretizing the two mass conservation equations.

Acknowledgment. I would like to thank M. Olhberger for helpful discussions.

AN INTERIOR ESTIMATE OF SUPERCONVERGENCE FOR FINITE ELEMENT SOLUTIONS FOR SECOND-ORDER ELLIPTIC PROBLEMS ON QUASI-UNIFORM MESHES BY LOCAL PROJECTIONS[*]

HONGSEN CHEN[†] AND JUNPING WANG[‡]

Abstract. This paper establishes some superconvergence estimates for finite element solutions of second-order elliptic problems by a projection method depending only on local properties of the domain and the finite element solution. The projection method is a postprocessing procedure that constructs a new approximation by using the method of least squares. In particular, some local superconvergence estimates in the L^2 and L^∞ norms are derived for the local projections of the Galerkin finite element solution. The results have two prominent features. First, they are established for any quasi-uniform meshes, which are of practical importance in scientific computation. Second, they are derived on the basis of local properties of the domain and the solution for the second-order elliptic problem. Therefore, the result of this paper can be employed to provide useful a posteriori error estimators in practical computing.

Key words. finite element method, superconvergence, local estimate, projection method, second-order elliptic equation

1. Introduction.

In this paper, we are concerned with local estimates of superconvergence for the Galerkin finite element solution of second-order elliptic equations. The Galerkin finite element method is known to provide numerical solutions for partial differential equations with superconvergence upon the use of appropriately defined postprocessing procedures which are computationally feasible. Because the superconvergence property of the finite element solution can be used to construct a new approximate solution with a higher order of accuracy, it naturally provides a posteriori error estimators in the quality assessment of the finite element approximations in scientific computing.

The research on superconvergence phenomena has been actively conducted by many numerical analysts for over 30 years. Among a large number of literatures, we mention Douglas and Dupont [5], Bramble and Schatz [2], Zlamal [38], Krizek and Neittaanmaki [10], Wahlbin [29], Zienkiewicz and Zhu [37], Ewing, Lazarov, and Wang [7], Zhu and Lin [35], Wheeler and Whiteman [32], Schatz, Sloan, and Wahlbin [24], Zhang [33], Zhu [34], and the references therein. For some technical reasons in the theoretical analysis, all the above-mentioned results on superconvergence require that the underlying finite element meshes be uniform or almost uniform or symmetric about a point. Recently, Wang [30] obtained a superconvergence for general quasi-uniform meshes by using the L^2 projection in the solution postprocessing. Although the results in [30] no longer assume any mesh uniformity or symmetry, they still rely strongly on

the smoothness of the exact solution and a certain a priori regularity of the underlying problem globally over the whole domain. In general, the required a priori regularity holds true for problems with sufficiently smooth data and domains. Consequently, the superconvergence results developed in [30] have a theoretical limitation in practical applications.

Our objective in this paper is to derive some local superconvergence error estimates for the projection method in which the L^2 projection is defined locally on subdomains. The new results require the exact solution to be only locally smooth, and no global a priori regularity of the problem is assumed. However, the local superconvergence estimate contains a pollution term which is the estimate of the error measured in some negative Sobolev norms. The superconvergence error estimates of this paper are derived in both the L^2 and the maximum norms.

A brief outline of this paper follows. In section 2 we review the Galerkin finite element method for a model second-order elliptic problem. In section 3 we derive a global superconvergence in the L^2 norm for the projection method. Section 4 contains some global estimate in the L^∞ norm. In sections 5 and 6, we establish some local superconvergence error estimates in both the L^2 and the L^∞ norms. A case discussion is made in section 7.

2. Preliminaries. Let Ω be an open bounded domain in R^2. Consider the second-order elliptic boundary value problem that seeks an unknown function $u = u(x)$ satisfying

$$\mathcal{L}u \equiv -\sum_{i,j=1}^{2} \frac{\partial}{\partial x_j}\left(a_{ij}\frac{\partial u}{\partial x_i}\right) + \sum_{i=1}^{2} b_i \frac{\partial u}{\partial x_i} + cu = f \qquad \text{in } \Omega \tag{2.1}$$

and the homogeneous Neumann boundary condition:

$$\mathcal{B} \equiv \sum_{i,j=0}^{2} a_{ij}\frac{\partial u}{\partial x_i} n_j = 0 \qquad \text{on } \partial\Omega,$$

where the coefficients a_{ij}, b_i, and c are given smooth functions and f is a prescribed function; (n_1, n_2) denotes the unit outward normal vector on $\partial\Omega$.

We use the standard notation for Sobolev spaces and norms (see, e.g., Adams [1]). For nonnegative integer k and real number $p \in [1, \infty]$ and subdomain $D \subset \Omega$, denote

$$W^{k,p}(D) = \left\{v : \ \|v\|_{W^{k,p}(D)} < \infty\right\}$$

with

$$\|v\|_{W^{k,p}(D)} = \left(\sum_{|\alpha|\le k} \int_D \left|\frac{\partial^\alpha v(x)}{\partial x^\alpha}\right|^p dx\right)^{1/p} \qquad \text{if } p < \infty,$$

$$\|v\|_{W^{k,\infty}(D)} = \max_{|\alpha|\le k} \sup_{x\in D} \left|\frac{\partial^\alpha v(x)}{\partial x^\alpha}\right| \qquad \text{if } p = \infty.$$

Let $W_0^{k,p}(D)$ be the completion of $C_0^\infty(D)$ according to the norm $\|\cdot\|_{W^{k,p}(D)}$, where $C_0^\infty(D)$ represents the space of functions with continuous derivatives of arbitrary order and compact supports in D. We adopt the usual notation:

$$H^k(D) = W^{k,2}(D), \quad H_0^k(D) = W_0^{k,2}(D), \quad L^p(D) = W^{0,p}(D).$$

Denote $(\cdot,\cdot)_D$ the standard inner product in $L^2(D)$ given by

$$(u,v)_D = \int_D uvdx.$$

When $D = \Omega$, we write $(\cdot,\cdot) = (\cdot,\cdot)_\Omega$. The negative Sobolev norm $\|\cdot\|_{H^{-k}(D)}$ is defined as follows:

$$\|v\|_{H^{-k}(D)} = \sup_{\varphi \in C_0^\infty(D)} \frac{(v,\varphi)}{\|\varphi\|_{H^k(D)}},$$

where $\langle v,\varphi\rangle$ is the value of the linear functional v at φ.

To describe a weak formulation for the problem (2.1), we introduce a bilinear form $A_D(\cdot,\cdot)$ for any $D \subset \Omega$ as follows:

$$A_D(u,v) = \int_D \left(\sum_{i,j=1}^2 a_{ij}(x) \frac{\partial u}{\partial x_i}\frac{\partial v}{\partial x_j} + \sum_{i=1}^2 b_i(x)\frac{\partial u}{\partial x_i} v + c(x)uv \right) dx,$$

and we write $A(u,v) = A_\Omega(u,v)$. The weak formulation of the problem (2.1) now seeks $u \in H^1(\Omega)$ such that

$$A(u,v) = (f,v) \quad \forall\, v \in H^1(\Omega). \tag{2.2}$$

Assume that $\mathcal{L}$ is elliptic: there is a constant $\lambda_0 > 0$ such that

$$\sum_{i,j=1}^2 a_{ij}(x)\xi_i\xi_j \geq \lambda_0 \sum_{i=1}^2 \xi_i^2 \quad \forall\, \xi = (\xi_1,\xi_2) \in R^2.$$

Furthermore, assume that the problem (2.2) has a unique solution in $H^1(\Omega)$.

For simplicity of local analysis, we assume that A is $H^1(\Omega)$-coercive: there is a constant $\lambda_1 > 0$ such that

$$A(v,v) \geq \lambda_1 \|v\|^2_{H^1(\Omega)} \quad \forall\, v \in H^1(\Omega).$$

The standard finite element method for numerically solving (2.1) is associated with the weak formulation (2.2) and a finite dimensional subspace $S_r^h \subset H^1(\Omega)$ with two parameters $h \in (0,1)$ and $r \geq 1$. The space S_r^h is associated with a prescribed finite element partition $\mathcal{T}_h$ of the domain Ω and comprises continuous piecewise polynomials of degree no more than r. The finite element approximation, denoted $u_h \in S_r^h$, for u is determined by

$$A(u_h,v) = (f,v) \quad \forall\, v \in S_r^h. \tag{2.3}$$

By (2.2) and (2.3), we have the following error equation:

$$A(u-u_h,v) = 0 \quad \forall\, v \in S_r^h, \tag{2.4}$$

which, due to the coercivity of A, implies the optimal order error estimate in H^1 (see Ciarlet [4] or Brenner and Scott [3] for details):

$$\|u-u_h\|_{H^1(\Omega)} \leq C \inf_{v \in V_h} \|u-v\|_{H^1(\Omega)}. \tag{2.5}$$

Here and throughout the paper, C stands for a generic constant independent of the functions and parameters involved.

For any subset $D \subset \Omega$, let $S_r^h(D)$ be the functional space consisting of the restrictions of functions in S_r^h on D. Furthermore, we introduce the notation

$$L^2_<(D) = \{v \in L^2(D) : \ \mathrm{dist}(\mathrm{supp}(v), \partial D \backslash \partial\Omega) > 0\},$$

where $\mathrm{supp}(v)$ denotes the support of v. The finite element space S_r^h is constructed so that the following three assumptions are satisfied:

A.1 (*approximation properties*). Let $D_1 \subset D_2 \subset \Omega$ with $\mathrm{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0 h$ for some constant $C_0 > 0$ and $0 \leq i \leq 1 \leq j \leq r+1$, $1 \leq p \leq \infty$. Then, for any $v \in W^{j,p}(D_2)$, there exists a $\chi \in S_r^h(D_2)$ such that

$$\|v - \chi\|_{W^{i,p}(D_1)} \leq C h^{j-i} \|v\|_{W^{j,p}(D_2)}.$$

Moreover, if $v \in L^2_<(D_1)$, then $\chi \in L^2_<(D_2)$. The above results also hold true in the case of $D_1 = D_2 = \Omega$.

A.2 (*inverse properties*). Let $D_1 \subset D_2 \subset \Omega$ with $\mathrm{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0 h$ for some constant $C_0 > 0$. Then, for $0 \leq i \leq j \leq 1$, $1 \leq q \leq p \leq \infty$, and any $v_h \in S_r^h(D_2)$,

$$\|v_h\|_{W^{j,p}(D_1)} \leq C h^{-(j-i)-2(1/q-1/p)} \|v_h\|_{W^{i,q}(D_2)}.$$

Furthermore, if $v_h \in S_r^h(\Omega)$, then

$$\|v_h\|_{W^{j,p}(\Omega)} \leq C h^{-(j-i)-2(1/q-1/p)} \|v_h\|_{W^{i,q}(\Omega)}.$$

A.3 (*superapproximation properties*). Let $D_1 \subset D_2 \subset D_3 \subset D_4 \subset \Omega$ with $\mathrm{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0 h$, $\mathrm{dist}(D_2, \partial D_3 \backslash \partial\Omega) \geq C_0 h$, $\mathrm{dist}(D_3, \partial D_4 \backslash \partial\Omega) \geq C_0 h$ for some constant $C_0 > 0$. Let $\omega \in L^2_<(D_3) \cap C^\infty(D_3)$ satisfy $\omega \equiv 1$ on D_2. Then, for $j = 0, 1$ and any $v_h \in S_r^h(D_4)$, there is an $\eta \in S_r^h(D_4) \cap L^2_<(D_4)$ such that

$$\|\omega v_h - \eta\|_{L^2(D_3)} \leq C h^{1+j} \|v_h\|_{H^j(D_3 \backslash D_1)}.$$

Let us now briefly review the global and local error estimates for $u - u_h$ in L^2 and L^∞ norms. Under the assumptions A.1, A.2, and A.3, one has the following optimal or suboptimal order error estimates in the L^2 and L^∞ norms for $i = 0, 1$:

$$\|u - u_h\|_{H^i(\Omega)} \leq C h^{r+1-i} \|u\|_{H^{r+1}(\Omega)} \tag{2.6}$$

and

$$\|u - u_h\|_{W^{i,\infty}(\Omega)} \leq C h^{r+1-i} |\ln h|^{\bar{r}} \|u\|_{W^{r+1,\infty}(\Omega)}, \tag{2.7}$$

where $\bar{r}$ is defined by

$$\bar{r} = \begin{cases} 1 & \text{if } r = 1 \text{ and } i = 0, \\ 0 & \text{if } r > 1 \text{ or } i = 1. \end{cases} \tag{2.8}$$

For the estimate (2.6) in L^2, see Ciarlet [4]. For the estimate (2.7) in L^∞, see Natterer [16], Nitsche [17], Scott [28], Rannacher [20], Rannacher and Scott [21], and Schatz and Wahlbin [25, 26]. The error estimates (2.6) and (2.7) require that the solution $u \in$

$H^{r+1}(\Omega)$ and $u \in W^{r+1,\infty}(\Omega)$, in order to achieve the optimal order of convergence in H^i and $W^{i,\infty}$, respectively.

It was shown in Nitsche and Schatz [18] and Schatz and Wahlbin [25] that if $\Omega_0 \subset\subset \Omega_1 \subset \Omega$, then for $i = 0$ or 1 we have the following interior estimates:

$$\|u - u_h\|_{H^i(\Omega_0)} \leq C \left(h^{r+1-i} \|u\|_{H^{r+1}(\Omega_1)} + \|u - u_h\|_{H^{-m}(\Omega)} \right),$$
$$\|u - u_h\|_{W^{i,\infty}(\Omega_0)} \leq C \left(h^{r+1-i} |\ln h|^{\bar{r}} \|u\|_{W^{r+1,\infty}(\Omega_1)} + \|u - u_h\|_{H^{-m}(\Omega)} \right).$$

Here and throughout the paper, $\Omega_0 \subset\subset \Omega_1$ means that $\operatorname{dist}(\Omega_0, \partial\Omega_1) \geq C$ and $\bar{r}$ is defined as above by (2.8). Although these estimates were established for interior regions Ω_0, they can be extended to regions up to the boundary (see Schatz and Wahlbin [26]). We also mention that more localized error estimates have been obtained recently by Schatz [22, 23].

We now turn to the superconvergence estimate. Any estimate that indicates a higher order of convergence than the optimal-order is called a superconvergence. A superconvergence is usually obtained by a postprocessing or recovery technique applied to the original finite element approximation u_h by an appropriate projection or interpolation operator. For example, if u_I is the Lagrange linear interpolation of the exact solution u and if the mesh $\mathcal{T}_h$ is uniform or almost uniform, then we have

$$\|u_I - u_h\|_{H^1(\Omega)} \leq C h^2 \|u\|_{H^3(\Omega)} \tag{2.9}$$

for piecewise linear finite element solutions. The estimate (2.9) leads to a superconvergence estimate of order $\mathcal{O}(h^2)$ for the partial derivatives of u_h by postprocessing ∇u_h via a simple local averaging technique. For details about the definition of uniform or almost uniform meshes and various postprocessing techniques, as well as superconvergence results for other finite elements or other problems, see, for example, Krizek and Neittaanmaki [9, 10], Levine [11], Lin and Wang [12], Lin and Xu [14], Zhu and Lin [35], Wahlbin [29], Wang [31], Douglas and Wang [6], Ewing, Liu, and Wang [8], Li and Zhang [13], Lin and Zhou [15], and the references therein.

To achieve a superconvergence, the exact solution u is often assumed to be more regular than what is needed in the optimal-order error estimate. For example, the superconvergence estimate (2.9) requires that $u \in H^3(\Omega)$, as opposed to $u \in H^2(\Omega)$ in the optimal-order error estimate. Interior or local superconvergence can be found in Wahlbin [29] with additional conditions imposed on the finite element partition $\mathcal{T}_h$. The result shows that one has superconvergence locally in regions where the solution is sufficiently smooth and the finite element partition is either translation invariant or symmetric.

The rest of the paper will investigate the local superconvergence of the Galerkin finite element method by the projection method proposed and studied in [30]. The projection method is essentially an L^2 projection onto a second finite element space based on a high order of polynomials on a coarser grid. This method can be considered as a generalization of the patch recovery technique of Zienkiewicz and Zhu [36, 37] by employing a global patch with smooth functions. More precisely, let $\mathcal{T}_\tau$ be a coarser partition of Ω with $\tau = h^\alpha$ for some $\alpha \in (0, 1)$, and let Q_τ be the L^2 projection operator from $L^2(\Omega)$ onto a finite element space having high order of approximation properties. It was proved in [30] that $u - Q_\tau u_h$ is superconvergent for general quasi-uniform partitions $\mathcal{T}_h$. The superconvergence of [30] requires that both the exact solution be sufficiently smooth and the underlying problem have sufficiently high order of a priori regularity. Although a local L^2 projection was employed to give a superconvergence in [30], the corresponding superconvergence estimates derived in [30] require the same a priori estimates for the global problem just as the global superconvergence does. Our main objective of this paper is to establish some local superconvergence for locally defined projections.

The following regularity on local smooth subdomains shall be assumed in the local superconvergence analysis. Let $D \subset \Omega$ be sufficiently smooth. Then, for any $\varphi \in H^k(D)$, there exists a unique $\Phi \in H^{k+2}(D)$ satisfying

$$\mathcal{L}\Phi = \varphi \quad \text{in } D, \quad \mathcal{B}\Phi = 0 \text{ on } \partial D, \tag{2.10}$$

and

$$\|\Phi\|_{H^{k+2}(D)} \leq C\|\varphi\|_{H^k(D)}, \tag{2.11}$$

where $C > 0$ is a constant independent of φ and Φ. We also assume that the above regularity holds true for the corresponding adjoint operators of $\mathcal{L}$ and $\mathcal{B}$. To be convenient, we say that a subdomain $D \subset \Omega$ is of H^ℓ, $\ell \geq 1$, regularity if (2.11) holds true for any $k \leq \ell - 2$.

We now introduce a second family of finite dimensional subspaces. Let $S^\tau_{m,s} \subset H^m(\Omega)$ be another family of finite dimensional subspaces with $m \geq 0$, $s \geq 0$, $\tau = Ch^\alpha$ for some $\alpha > 0$ to be determined later. The parameter m characterizes the regularity of the fitting space $S^\tau_{m,s}$ and is particularly reserved for this purpose in the rest of the paper. The parameter s indicates the degree of polynomials used in the construction of $S^\tau_{m,s}$. For any $D \subset \Omega$, let $S^\tau_{m,s}(D)$ again be the restriction of functions of $S^\tau_{m,s}$ in D.

Corresponding to A.1, A.2, and A.3, we assume that the following assumptions for spaces $S^\tau_{m,s}$ are satisfied.

B.1 Let $D_1 \subset D_2 \subset \Omega$ with $\text{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0\tau$ for some constant $C_0 > 0$ and $0 \leq i \leq j \leq s+1$, $1 \leq p \leq \infty$. Then, for any $v \in W^{j,p}(D_2)$, there exists a $\chi \in S^\tau_{m,s}(D_2)$ such that

$$\|v - \chi\|_{W^{i,p}(D_1)} \leq C\tau^{j-i}\|v\|_{W^{j,p}(D_2)}.$$

Moreover, if $v \in L^2_<(D_1)$, then $\chi \in L^2_<(D_2)$.

B.2 (*inverse properties*). Let $D_1 \subset D_2 \subset \Omega$ with $\text{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0\tau$ for some constant $C_0 > 0$. Then, for $0 \leq i \leq j \leq m$, $1 \leq q \leq p \leq \infty$, and any $v_\tau \in S^\tau_{m,s}(D_2)$,

$$\|v_\tau\|_{W^{j,p}(D_1)} \leq C\tau^{-(j-i)-2(1/q-1/p)}\|v_\tau\|_{W^{i,q}(D_2)}.$$

Furthermore, if $v_\tau \in S^\tau_{m,s}(\Omega)$,

$$\|v_\tau\|_{W^{j,p}(\Omega)} \leq C\tau^{-(j-i)-2(1/q-1/p)}\|v_\tau\|_{W^{i,q}(\Omega)}.$$

B.3 (*superapproximation properties*). Let $D_1 \subset D_2 \subset D_3 \subset D_4 \subset \Omega$ with $\text{dist}(D_1, \partial D_2 \backslash \partial\Omega) \geq C_0\tau$, $\text{dist}(D_2, \partial D_3 \backslash \partial\Omega) \geq C_0\tau$, $\text{dist}(D_3, \partial D_4 \backslash \partial\Omega) \geq C_0\tau$ for some constant $C_0 > 0$. Let $\omega \in L^2_<(D_3) \cap C^\infty(D_3)$ satisfy $\omega \equiv 1$ on D_2. Then, for $0 \leq j \leq \min(m, s+1)$ and any $v_\tau \in S^\tau_{m,s}(D_4)$, there is an $\eta \in S^\tau_{m,s}(D_4) \cap L^2_<(D_4)$ such that

$$\|\omega v_\tau - \eta\|_{L^2(D_4)} \leq C\tau^{1+j}\|v_\tau\|_{H^j(D_4 \backslash D_1)}.$$

Next, we introduce the notation of L^2 projection. For any $D \subset \Omega$, let

$$Q_\tau^D : \; L^2(D) \to S_{m,s}^\tau(D)$$

denote the L^2 projection operator defined by

$$(Q_\tau^D v, \varphi)_D = (v, \varphi)_D \quad \forall\, v \in L^2(D),\ \varphi \in S_{m,s}^\tau(D).$$

When $D = \Omega$, we shall ignore Ω and use the notation $Q_\tau = Q_\tau^\Omega$.

Throughout this paper, we assume that assumptions A.1, A.2, and A.3 and assumptions B.1, B.2, and B.3 are satisfied.

3. A global superconvergence in L^2. In this section we establish a global superconvergence in the L^2 norm for the general second-order elliptic problem (2.1). The following theorem can be considered as a generalization of the results of Wang [30] from Laplacian to general second-order elliptic problems.

THEOREM 3.1. *Assume that u and u_h satisfy* (2.4) *and that Ω is of H^{k+2} regularity, $k \geq 0$. If $u \in H^{1+r}(\Omega)$ when $r > s$ or $u \in H^{1+s}(\Omega)$ when $r \leq s$, then for*

$$\tau = O(h^\alpha), \qquad \text{with } \alpha = \frac{1 + r + \min(r-1, m, k)}{1 + s + \min(r-1, m, k)}, \tag{3.1}$$

we have

$$\|u - Q_\tau u_h\|_{H^i(\Omega)} \leq C h^{\frac{1+r+\min(r-1,m,k)}{1+\theta_i}} \left(\|u\|_{H^{1+r}(\Omega)} + \|u\|_{H^{1+s}(\Omega)} \right),$$

where θ_i is given by

$$\theta_i = \frac{i + \min(m, r-1, k)}{s + 1 - i}. \tag{3.2}$$

Proof. The proof follows the same line as in Wang [30]. For completeness, it is outlined as follows. Since Q_τ is the L^2 projection, we have for any $\varphi \in C_0^\infty(\Omega)$,

$$(Q_\tau(u - u_h), \varphi) = (u - u_h, Q_\tau \varphi). \tag{3.3}$$

Let $\Phi \in H^1(\Omega)$ be the unique solution of

$$A(\psi, \Phi) = (Q_\tau \varphi, \psi) \quad \forall\, \psi \in H^1(\Omega).$$

Using assumption A.1, there is an $\chi \in S_r^h$ such that

$$\|\Phi - \chi\|_{H^1(\Omega)} \leq C h^{i-1} \|\Phi\|_{H^i(\Omega)}, \quad 1 \leq i \leq 1 + r. \tag{3.4}$$

Then it follows from (3.3), Hölder's inequality, and inequality (3.4) that

$$\begin{aligned} (Q_\tau(u - u_h), \varphi) &= A(u - u_h, \Phi) = A(u - u_h, \Phi - \Pi_h \Phi) \\ &\leq C \|u - u_h\|_{H^1(\Omega)} \|\Phi - \Pi_h \Phi\|_{H^1(\Omega)} \\ &\leq C h^{1+\min(m,r-1,k)} \|u - u_h\|_{H^1(\Omega)} \|\Phi\|_{H^{2+\min(r-1,m,k)}(\Omega)}. \end{aligned} \tag{3.5}$$

An application of the a priori H^{k+2} regularity, inverse property B.2, and the stability of L^2 projection yields

$$\begin{aligned} \|\Phi\|_{H^{2+\min(r-1,m,k)}(\Omega)} &\leq C \|Q_\tau \varphi\|_{H^{\min(r-1,m,k)}(\Omega)} \\ &\leq C \tau^{-\min(r-1,m,k)} \|Q_\tau \varphi\|_{L^2(\Omega)} \\ &\leq C \tau^{-\min(r-1,m,k)} \|\varphi\|_{L^2(\Omega)}, \end{aligned}$$

which, combined with (3.5), leads us to

$$\|Q_\tau(u-u_h)\|_{L^2(\Omega)} = \sup_{\varphi\in C_0^\infty(\Omega),\varphi\neq 0} \frac{(Q_\tau(u-u_h),\varphi)}{\|\varphi\|_{L^2(\Omega)}} \tag{3.6}$$
$$\le Ch^{1+\min(r-1,m,k)}\tau^{-\min(r-1,m,k)}\|u-u_h\|_{H^1(\Omega)}.$$

Using the optimal-order error estimate for $\|u-u_h\|_{H^1(\Omega)}$ (Ciarlet [4]),

$$\|u-u_h\|_{H^1(\Omega)} \le Ch^r\|u\|_{H^{1+r}(\Omega)},$$

the best approximation property of the L^2 projection, and the approximation property B.1,

$$\|u-Q_\tau u\|_{L^2(\Omega)} \le C\inf_{\chi\in S_{m,s}^\tau}\|u-\chi\|_{L^2(\Omega)} \le C\tau^{s+1}\|u\|_{H^{1+s}(\Omega)},$$

we conclude that

$$\|u-Q_\tau u_h\|_{L^2(\Omega)} \le \|u-Q_\tau u\|_{L^2(\Omega)} + \|Q_\tau(u-u_h)\|_{L^2(\Omega)} \tag{3.7}$$
$$\le C\tau^{s+1}\|u\|_{H^{1+s}(\Omega)} + Ch^{1+r+\min(r-1,m,k)}\tau^{-\min(r-1,m,k)}\|u\|_{H^{1+r}(\Omega)}.$$

Now, choose τ so that

$$\tau^{1+s} = \mathcal{O}(h^{1+r+\min(r-1,m,k)}\tau^{-\min(r-1,m,k)});$$

then τ satisfies (3.1), and the desired estimate follows from (3.7). This completes the proof. □

4. A global superconvergence in L^∞.

This section is devoted to the derivation of a global superconvergence estimate in the L^∞ norm. A traditional and standard approach for pointwise error estimates of finite element methods will be employed here for superconvergence. This approach is based on special weighted Sobolev norms. The main result of this section is stated as follows.

THEOREM 4.1. *Assume that u and u_h satisfy (2.4) and that the domain Ω is of H^{k+2} regularity with $k \ge 0$. If τ satisfies (3.1) and $u \in W^{1+r,\infty}(\Omega)$ when $r > s$ or $u \in W^{1+s,\infty}(\Omega)$ when $r \le s$, then for $i = 0$ or 1 we have*

$$\|u-Q_\tau u_h\|_{W^{i,\infty}(\Omega)} \le Ch^{\frac{1+r+\varrho}{1+\theta_i}}|\ln h|\left(\|u\|_{W^{1+r,\infty}(\Omega)}+\|u\|_{W^{1+s,\infty}(\Omega)}\right),$$

where θ_i is defined by (3.2) and

$$\varrho = \min(r-1,m,k). \tag{4.1}$$

The proof of this theorem is based on some technical tools in weighted Sobolev norms. We shall develop the tools first and postpone the proof to the end of this section.

Let us start with the weight function definition. For any fixed $z \in \bar\Omega$, we define

$$\sigma = \sigma(x,z) = (|x-z|^2+\gamma h^2)^{1/2},$$

with $\gamma > 0$ being a constant. Associated with the function σ, we introduce the following weighted Sobolev norms:

$$\|v\|_{L^2_{\sigma^\beta}(D)} = \left(\int_D \sigma^\beta|v|^2dx\right)^{1/2},$$

$$\|v\|_{H^k_{\sigma^\beta}(D)} = \left(\sum_{|\alpha|\le k} \left\| \frac{\partial^k v}{\partial x^\alpha} \right\|^2_{L^2_{\sigma^\beta}(D)} \right)^{1/2}.$$

We now collect some well-known estimates associated with the weighted norms. The first one is an analogy of A.1 in the weighted norm.

LEMMA 4.2. *For $0 \le i \le 1 \le j \le r+1$ and any real β, $v \in H^j(\Omega)$, there exists $\chi \in S^h_r$ such that*

$$\|v - \chi\|_{H^i_{\sigma^\beta}(\Omega)} \le C h^{j-i} \|v\|_{H^j_{\sigma^\beta}(\Omega)}.$$

LEMMA 4.3. *For $0 \le i \le j$ and any $\varphi_\tau \in S^\tau_{m,s}(\Omega)$,*

$$\|\varphi_\tau\|_{H^j_{\sigma^\beta}(\Omega)} \le C \tau^{i-j} \|\varphi_\tau\|_{H^i_{\sigma^\beta}(\Omega)}.$$

A proof of Lemmas 4.2 and 4.3 can be found in Brenner and Scott [3]. The following lemma gives the a priori estimates for the differential operator $\mathcal{L}$ in the weighted norms.

LEMMA 4.4. *Suppose $\Phi \in H^{k+2}(\Omega)$ with $k \ge 0$. Then*

$$\|\Phi\|_{H^{k+2}_{\sigma^2}(\Omega)} \le C \|\mathcal{L}\Phi\|_{H^k_{\sigma^2}(\Omega)} + C \|\Phi\|_{H^{k+1}(\Omega)}.$$

Proof. Let $x = (x_1, x_2)$ and $z = (z_1, z_2)$. For any nonnegative integers k_1 and k_2 such that $k_1 + k_2 = k + 2$, we have

$$(x_1 - z_1) \frac{\partial^{k+2}\Phi}{\partial x_1^{k_1} \partial x_2^{k_2}} = \frac{\partial^{k+2}((x_1 - z_1)\Phi)}{\partial x_1^{k_1} \partial x_2^{k_2}} - k_1 \frac{\partial^{k+1}\Phi}{\partial x_1^{k_1-1} \partial x_2^{k_2}}.$$

Hence, it follows that

$$\begin{aligned}
&\int_\Omega (x_1 - z_1)^2 \left| \frac{\partial^{k+2}\Phi}{\partial x_1^{k_1} \partial x_2^{k_2}} \right|^2 dx \\
&\le C \int_\Omega \left| \frac{\partial^{k+2}((x_1 - z_1)\Phi)}{\partial x_1^{k_1} \partial x_2^{k_2}} \right|^2 dx + C \left\| \frac{\partial^{k+1}\Phi}{\partial x_1^{k_1-1} \partial x_2^{k_2}} \right\|^2_{L^2(\Omega)} \\
&\le C \|(x_1 - z_1)\Phi\|^2_{H^{k+2}(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)} \\
&\le C \|\mathcal{L}((x_1 - z_1)\Phi)\|^2_{H^k(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)} \\
&\le C \|(x_1 - z_1)\mathcal{L}\Phi\|^2_{H^k(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)} \\
&\le C \|\mathcal{L}\Phi\|^2_{H^k_{\sigma^2}(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)}.
\end{aligned}$$

Similarly, we have

$$\int_\Omega (x_2 - z_2)^2 \left| \frac{\partial^{k+2}\Phi}{\partial x_1^{k_1} \partial x_2^{k_2}} \right|^2 dx \le C \|\mathcal{L}\Phi\|^2_{H^k_{\sigma^2}(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)}.$$

Consequently,

$$\int_\Omega |x - z|^2 \left| \frac{\partial^{k+2}\Phi}{\partial x_1^{k_1} \partial x_2^{k_2}} \right|^2 dx \le C \|\mathcal{L}\Phi\|^2_{H^k_{\sigma^2}(\Omega)} + C \|\Phi\|^2_{H^{k+1}(\Omega)}. \tag{4.2}$$

Furthermore,

$$\int_\Omega \gamma h^2 \left| \frac{\partial^{k+2}\Phi}{\partial x_1^{k_1} \partial x_2^{k_2}} \right|^2 dx \le C\gamma h^2 \|\mathcal{L}\Phi\|^2_{H^k(\Omega)} \le C\|\mathcal{L}\Phi\|^2_{H^k_{\sigma^2}(\Omega)}. \tag{4.3}$$

Adding (4.2) and (4.3) completes the proof. □

For $z \in \bar\Omega$, let $D_{\tau,z} \subset \Omega$ be such that

$$z \in \bar D_{\tau,z}, \quad \operatorname{diam}(D_{\tau,z}) \le C\tau.$$

Construct $\delta_{\tau,z} \in C_0^\infty(D_{\tau,z})$ so that

$$(\delta_{\tau,z}, \varphi_\tau) = \varphi_\tau(z) \quad \forall\ \varphi_\tau \in S^\tau_{m,s}(\Omega)$$

and

$$\|\delta_{\tau,z}\|_{W^{i,\infty}(D_{\tau,z})} \le C\tau^{-2-i}.$$

(See Rannacher and Scott [21] or Brenner and Scott [3].)

Further, let $G_{\tau,z}$, $\partial_\nu G_{\tau,z} \in H^1(\Omega)$ be the solution of

$$A(\varphi, G_{\tau,z}) = (Q_\tau \delta_{\tau,z}, \varphi) \quad \forall\ \varphi \in H^1(\Omega)$$

and

$$A(\varphi, \partial_\nu G_{\tau,z}) = -(Q_\tau(\nu \cdot \nabla \delta_{\tau,z}), \varphi) \quad \forall\ \varphi \in H^1(\Omega),$$

where ν is any fixed vector. Then we have the following $W^{1,1}$ estimates for $G_{\tau,z}$, $\partial_\nu G_{\tau,z}$, and their finite element approximations.

LEMMA 4.5. *Assume that Ω is of H^{k+2} regularity for $k \ge 0$. Then there exist $\Pi_h G_{\tau,z} \in S^\tau_{m,s}$ and $\Pi_h(\partial_\nu G_{\tau,z}) \in S^\tau_{m,s}$ such that*

$$\|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{W^{1,1}(\Omega)} \le Ch^{1+\varrho}\,\tau^{-\varrho}|\ln h|, \tag{4.4}$$

$$\|\partial_\nu G_{\tau,z} - \Pi_h(\partial_\nu G_{\tau,z})\|_{W^{1,1}(\Omega)} \le Ch^{1+\varrho}\,\tau^{-1-\varrho}|\ln h|, \tag{4.5}$$

where ϱ is defined in (4.1) *and ν is any fixed vector.*

Proof. According to Lemma 4.2, there is an $\Pi_h G_{\tau,z} \in S^\tau_{m,s}$ satisfying

$$\|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{H^1_{\sigma^2}(\Omega)} \le Ch^{1+\min(r-1,m,k)}\|G_{\tau,z}\|_{H^{2+\min(r-1,m,k)}_{\sigma^2}(\Omega)},$$

which, along with Lemma 4.4, implies

$$\|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{H^1_{\sigma^2}(\Omega)} \le Ch^{1+\varrho}\left(\|\delta_{\tau,z}\|_{H^\varrho_{\sigma^2}(\Omega)} + \|G_{\tau,z}\|_{H^{1+\varrho}(\Omega)}\right). \tag{4.6}$$

If $\varrho = \min(r-1, m, k) \ge 1$, using the assumption of H^{k+2} a priori regularity and the inverse property B.2 we have

$$\begin{aligned} \|G_{\tau,z}\|_{H^{1+\varrho}(\Omega)} &\le C\|Q_\tau \delta_{\tau,z}\|_{H^{-1+\varrho}(\Omega)} \\ &\le C\tau^{1-\varrho}\|\delta_{\tau,z}\|_{L^2(\Omega)} \le C\tau^{-\varrho}. \end{aligned} \tag{4.7}$$

If $\varrho = \min(r-1, m, k) = 0$, using the coercivity of A and the definition of $G_{\tau,z}$, we get

$$\begin{aligned} \lambda_1 \|G_{\tau,z}\|^2_{H^{1+\varrho}(\Omega)} &= \lambda_1 \|G_{\tau,z}\|^2_{H^1(\Omega)} \le A(G_{\tau,z}, G_{\tau,z}) \\ &= (Q_\tau \delta_{\tau,z}, G_{\tau,z}) = Q_\tau G_{\tau,z}(z) \\ &\le \|Q_\tau G_{\tau,z}\|_{L^\infty(\Omega)} \\ &\le C|\ln \tau|^{1/2} \|Q_\tau G_{\tau,z}\|_{H^1(\Omega)}. \end{aligned} \tag{4.8}$$

Here, we have also used the following estimate:

$$\|Q_\tau G_{\tau,z}\|_{L^\infty(\Omega)} \le C|\ln \tau|^{1/2} \|Q_\tau G_{\tau,z}\|_{H^1(\Omega)},$$

which can be found, e.g., in Ciarlet [4]. With the estimates (4.7) and (4.8) and noting that

$$\|\delta_{\tau,z}\|_{H^\varrho_{\sigma^2}(\Omega)} \le C\tau^{-\varrho},$$

we conclude from (4.6) that

$$\|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{H^1_{\sigma^2}(\Omega)} \le Ch^{1+\varrho}\tau^{-\varrho}|\ln \tau|^{1/2}. \tag{4.9}$$

From Hölder's inequality, it follows that

$$\begin{aligned} \|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{W^{1,1}(\Omega)} &\le \left(\int_\Omega \sigma^{-2} dx\right)^{1/2} \|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{H^1_{\sigma^2}(\Omega)} \\ &\le C|\ln h|^{1/2} \|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{H^1_{\sigma^2}(\Omega)}. \end{aligned} \tag{4.10}$$

Since $|\ln \tau|$ is proportional to $|\ln h|$, substituting (4.9) into (4.10) yields (4.4). The estimate (4.5) can be derived in a similar way. This completes the proof. □

Now we are in a position to prove the main result of this section.

Proof of Theorem 4.1. In view of the definition of $G_{\tau,z}$ and (2.4), we have

$$\begin{aligned} Q_\tau(u-u_h)(z) &= (Q_\tau(u-u_h), \delta_{\tau,z}) = (u-u_h, Q_\tau \delta_{\tau,z}) \\ &= A(u-u_h, G_{\tau,z}) = A(u-u_h, G_{\tau,z} - \Pi_h G_{\tau,z}) \\ &\le C\|u-u_h\|_{W^{1,\infty}(\Omega)} \|G_{\tau,z} - \Pi_h G_{\tau,z}\|_{W^{1,1}(\Omega)}, \end{aligned}$$

where $\Pi_h G_{\tau,z}$ is chosen according to Lemma 4.5. Applying Lemma 4.5 and the following well-known estimate (e.g., [3], [4]),

$$\|u-u_h\|_{W^{1,\infty}(\Omega)} \le Ch^r \|u\|_{W^{1+r,\infty}(\Omega)}, \tag{4.11}$$

we see that

$$|Q_\tau(u-u_h)(z)| \le Ch^{1+r+\varrho}\tau^{-\varrho}|\ln \tau| \|u\|_{W^{1+r,\infty}(\Omega)}. \tag{4.12}$$

Hence, from the approximation property B.1 and (4.12), it follows that

$$\begin{aligned} |(u - Q_\tau u_h)(z)| &\le |(u - Q_\tau u)(z)| + |Q_\tau(u-u_h)(z)| \\ &\le C\tau^{1+s}\|u\|_{W^{1+s,\infty}(\Omega)} \\ &\quad + Ch^{1+r+\varrho}\tau^{-\varrho}|\ln \tau| \|u\|_{W^{1+r,\infty}(\Omega)}, \end{aligned} \tag{4.13}$$

which proves Theorem 4.1 for $i = 0$ according to the relationship (3.1) between h and τ. To show Theorem 4.1 for $i = 1$, we let ν be a fixed vector and note that (with possibly a minor modification of $\delta_{\tau,z}$)

$$\begin{aligned}\nu \cdot \nabla Q_\tau(u-u_h)(z) &= (\nu \cdot \nabla Q_\tau(u-u_h), \delta_{\tau,z}) = -(Q_\tau(u-u_h), \nu \cdot \nabla \delta_{\tau,z}) \\ &= -(u-u_h, Q_\tau(\nu \cdot \nabla \delta_{\tau,z})) \\ &= a(u-u_h, \partial_\nu G_{\tau,z}) = a(u-u_h, \partial_\nu G_{\tau,z} - \Pi_h(\partial_\nu G_{\tau,z})) \\ &\leq C\|u-u_h\|_{W^{1,\infty}(\Omega)} \|\partial G_{\tau,z} - \Pi_h(\partial G_{\tau,z})\|_{W^{1,1}(\Omega)},\end{aligned}$$

which, along with Lemma 4.5, yields

$$|\nu \cdot \nabla Q_\tau(u-u_h)(z)| \leq Ch^{1+\rho}\tau^{-1-\rho}\|u-u_h\|_{W^{1,\infty}(\Omega)}. \tag{4.14}$$

Using (4.14) and the well-known estimate for L^2 projection,

$$|\nu \cdot \nabla(u - Q_\tau u)(z)| \leq C\|u - Q_\tau u\|_{W^{1,\infty}(\Omega)} \leq C\tau^s \|u\|_{W^{1+s,\infty}(\Omega)},$$

and (4.11) we get

$$\begin{aligned}&|\nu \cdot \nabla(u - Q_\tau u_h)(z)| \\ &\leq |\nu \cdot \nabla(u - Q_\tau u)(z)| + |\nu \cdot \nabla Q_\tau(u-u_h)(z)| \\ &\leq C\tau^s\|u\|_{W^{1+s,\infty}(\Omega)} + Ch^{1+r+\varrho}\tau^{-1-\varrho}|\ln \tau| \|u\|_{W^{1+r,\infty}(\Omega)}.\end{aligned} \tag{4.15}$$

Thus, choosing a direction ν and a point z such that

$$\|\nabla(u - Q_\tau u_h)\|_{L^\infty(\Omega)} = |\nu \cdot \nabla(u - Q_\tau u_h)(z)|,$$

and using (4.15), we complete the proof of Theorem 4.1. □

5. A local superconvergence in L^2.

In this section, we establish a local superconvergence in the L^2 and H^1 norms. The main result is stated as follows.

THEOREM 5.1. *Suppose u and u_h satisfy* (2.4) *and the subdomain $\Omega_0 \subset \Omega_1 \subset \Omega$ satisfies dist$(\Omega_0, \partial\Omega_1 \backslash \partial\Omega) \geq C_1 h$ for sufficiently large $C_1 > 1$, and $\partial\Omega_1 \cap \partial\Omega$ is sufficiently smooth. Then for τ given by* (3.1) *and any $0 \leq q \leq m+1$,*

$$\begin{aligned}\|u - Q_\tau^{\Omega_1} u_h\|_{H^i(\Omega_0)} \leq Ch^{\frac{r+1+\min(m,k,r-1)}{1+\theta_i}} &\left(\|u\|_{H^{1+r}(\Omega_1)} + \|u\|_{H^{1+s}(\Omega_1)}\right) \\ &+ C\|u-u_h\|_{H^{-q}(\Omega_1)},\end{aligned} \tag{5.1}$$

where θ_i is given by (3.2).

Proof. Observe that

$$\|u - Q_\tau^{\Omega_1} u_h\|_{H^i(\Omega_0)} \leq \|u - Q_\tau^{\Omega_1} u\|_{H^i(\Omega_0)} + \|Q_\tau^{\Omega_1}(u-u_h)\|_{H^i(\Omega_0)}. \tag{5.2}$$

Let $\Omega_0 \subset\subset \Omega_2 \subset\subset \Omega_1$. Using Lemma 5.3 and assumption B.1, we have

$$\begin{aligned}\|u - Q_\tau^{\Omega_1} u\|_{L^2(\Omega_0)} &\leq C \inf_{\chi \in S_{m,s}^\tau} \|u - \chi\|_{L^2(\Omega_2)} + \tau^{1+s}\|u\|_{L^2(\Omega_1)} \\ &\leq C\tau^{1+s}\|u\|_{H^{1+s}(\Omega_1)}.\end{aligned} \tag{5.3}$$

Applying a well-known interior estimate in H^1 norm (Nitsche and Schatz [18])

$$\|u-u_h\|_{H^1(\Omega_2)} \leq Ch^r\|u\|_{H^{1+r}(\Omega_1)} + C\|u-u_h\|_{H^{-q}(\Omega_1)}$$

and Lemma 5.5 we obtain

$$\begin{aligned}(5.4)\qquad &\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_0)}\\ &\le Ch^{1+\min(r-1,m)}\tau^{-\min(r-1,m)}\|u-u_h\|_{H^1(\Omega_2)}+C\|u-u_h\|_{H^{-q}(\Omega_2)}\\ &\le Ch^{1+r}(h/\tau)^{\min(r-1,m)}\|u\|_{H^{1+r}(\Omega_1)}+C\|u-u_h\|_{H^{-q}(\Omega_1)}.\end{aligned}$$

The desired estimate (5.1) with $i=0$ follows from (5.3), (5.4), and (5.2). With the same procedure combined with the inverse inequality in B.2, we obtain (5.1) for $i=1$. This completes the proof. □

The proof of Theorem 5.1 is based on the result of Lemma 5.5, which will be established in the rest of this section.

LEMMA 5.2. *Let $D_1 \subset D_2 \subset\subset D_3 \subset D_4 \subset D \subset \Omega$ with $\operatorname{dist}(D_1, \partial D_2\backslash\partial\Omega) \ge C_0 h$, $\operatorname{dist}(D_2, \partial D_3\backslash\partial\Omega) \ge C_0 h$, $\operatorname{dist}(D_3, \partial D_4\backslash\partial\Omega) \ge C_0 h$, $\operatorname{dist}(D_4, \partial D\backslash\partial\Omega) \ge C_0 h$ for some constant $C_0 > 0$. Let $\omega \in C^\infty(D_3) \cap L^2_<(D_3)$ satisfy $\omega \equiv 1$ on D_2. Then, for $0 \le j \le \min(s+1, m)$ and any $v_\tau \in S^\tau_{m,s}(D_3)$, we have*

$$\|\omega v_\tau - Q_\tau^D(\omega v_\tau)\|_{L^2(D)} \le C\tau^{1+j}\|v_\tau\|_{H^j(D_4\backslash D_1)}.$$

Proof. The lemma follows immediately from assumption B.3 and the best approximation property of the L^2 projection. □

The following lemma provides a local error estimate for the L^2 projection. The result shows that the local error of a "global" L^2 projection Q_τ is bounded by the best local approximation plus a global pollution of order $\mathcal{O}(\tau^M)$ with arbitrary $M > 0$.

LEMMA 5.3. *For $D_0 \subset D_1 \subset D \subset \Omega$ satisfying dist$(D_0, \partial D_1\backslash\partial\Omega) \ge C_1 h$ with sufficiently large $C_1 > 0$, and $M > 0$, there holds*

$$\|v - Q_\tau^D v\|_{L^2(D_0)} \le \inf_{\chi\in S^\tau_{m,s}(D)} \|v-\chi\|_{L^2(D_1)} + C\tau^M\|v\|_{L^2(D)}.$$

Proof. The proof can be found in Nitsche and Schatz [19] and Schatz and Wahlbin [27]. □

We now show a local a priori estimate for the differential operator $\mathcal{L}$.

LEMMA 5.4. *Suppose $D_0 \subset D_1 \subset D \subset \Omega$ with $d = $ dist$(D_0, \partial D_1\backslash\partial\Omega) > 0$ and $\partial D_1 \cap \partial\Omega$ is sufficiently smooth. Then for $k \ge 0$ and any $w \in H^{k+2}(D_1)$ with $\mathcal{L}w \in L^1(D)$ and $\mathcal{B}w = 0$ on ∂D,*

$$\|w\|_{H^{k+2}(D_0)} \le C\left(\|\mathcal{L}w\|_{H^k(D_1)} + \|\mathcal{L}w\|_{L^1(D)}\right).$$

Proof. Let $D_0 \subset D_2 \subset D_1 \subset \Omega$ with $\operatorname{dist}(D_0, \partial D_2\backslash\partial\Omega) = \operatorname{dist}(D_2, \partial D_1\backslash\partial\Omega) = d/2$ and $\omega \in C^\infty(D_2) \cap L^2_<(D_2)$ satisfying $\omega \equiv 1$ on D_0. We assume that ∂D_2 is sufficiently smooth. Then

$$\begin{aligned}(5.5)\qquad \|w\|_{H^{k+2}(D_0)} &\le \|\omega w\|_{H^{k+2}(D_2)} \le C\|\mathcal{L}(\omega w)\|_{H^k(D_2)}\\ &\le C\|\mathcal{L}w\|_{H^k(D_2)} + C\|w\|_{H^{k+1}(D_2)}.\end{aligned}$$

Applying (5.5) for $\|w\|_{H^{k+1}(D_2)}$ and repeating the procedure, we conclude that

$$\begin{aligned}(5.6)\qquad \|w\|_{H^{k+2}(D_0)} &\le C\|\mathcal{L}w\|_{H^k(D_1)} + C\|w\|_{L^2(D_1)}\\ &\le C\|\mathcal{L}w\|_{H^k(D_1)} + C\|\mathcal{L}w\|_{L^1(D)}.\end{aligned}$$

Here, in the last step of (5.6), we have used the following estimate:

$$\|w\|_{L^2(D_1)} \le C\|w\|_{L^2(D)} \le C\|\mathcal{L}w\|_{L^1(D)},$$

which can be verified, e.g., by using the representation of w in terms of the Green's function of the differential operator $\mathcal{L}$ on domain D. This completes the proof. ∎

LEMMA 5.5. *Suppose $\Omega_0 \subset \Omega_1 \subset \Omega$ with $d = dist(\Omega_0, \partial\Omega_1 \backslash \partial\Omega) \geq C_1 h$ for some sufficiently large $C_1 > 1$; then, for any $0 \leq q \leq 1+m$, there holds*

$$(5.7) \qquad \|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_0)} \leq Ch^{1+\min(r-1,m)}\tau^{-\min(r-1,m)}\|u-u_h\|_{H^1(\Omega_1)} + C\|u-u_h\|_{H^{-q}(\Omega_1)},$$

where the constant $C > 0$ depends on d but is independent of h and u.

Proof. Let $\Omega_0 \subset \Omega_2 \subset \Omega_3 \subset \Omega_4 \subset \Omega_5 \subset \Omega_6 \subset \Omega_7 \subset \Omega_1$ satisfy

$$\begin{aligned} &\mathrm{dist}(\Omega_0, \partial\Omega_2\backslash\partial\Omega) = \mathrm{dist}(\Omega_2, \partial\Omega_3\backslash\partial\Omega) = \mathrm{dist}(\Omega_3, \partial\Omega_4\backslash\partial\Omega) = \mathrm{dist}(\Omega_4, \partial\Omega_5\backslash\partial\Omega) \\ &= \mathrm{dist}(\Omega_5, \partial\Omega_6\backslash\partial\Omega) = \mathrm{dist}(\Omega_6, \partial\Omega_7\backslash\partial\Omega) = \mathrm{dist}(\Omega_7, \partial\Omega_1\backslash\partial\Omega) = d/7 \end{aligned}$$

with sufficiently smooth $\partial\Omega_7$, and let $\omega \in C^\infty(\Omega_5) \cap L^2_<(\Omega_5)$ be a function satisfying $\omega \equiv 1$ on Ω_4. For any $\varphi \in C_0^\infty(\Omega_0)$, by some elementary manipulations we have

$$\begin{aligned} (5.8) \quad &(Q_\tau^{\Omega_1}(u-u_h), \varphi) = (\omega Q_\tau^{\Omega_1}(u-u_h), \omega\varphi) \\ &= (Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \varphi) + (\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \varphi) \\ &= (Q_\tau^{\Omega_1}(u-u_h), \omega^2 Q_\tau^{\Omega_1}\varphi) + (\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \varphi) \\ &= (\omega^2(u-u_h), Q_\tau^{\Omega_1}\varphi) + (u-u_h, Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\varphi) - \omega^2 Q_\tau^{\Omega_1}\varphi)_{\Omega_1} \\ &\quad + (\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \varphi). \end{aligned}$$

For the second term on the right-hand side of (5.8), using Lemma 5.2 we have

$$\begin{aligned} (5.9) \qquad &|(u-u_h, Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\varphi) - \omega^2 Q_\tau^{\Omega_1}\varphi)_{\Omega_1}| \\ &\leq \|u-u_h\|_{L^2(\Omega_1)}\|\omega^2 Q_\tau^{\Omega_1}\varphi - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\varphi)\|_{L^2(\Omega_1)} \\ &\leq c\tau\|u-u_h\|_{L^2(\Omega_1)}\|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_6\backslash\Omega_3)}. \end{aligned}$$

Using Lemma 5.3, we obtain

$$\begin{aligned} \|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_6\backslash\Omega_3)} &\leq \|\varphi\|_{L^2(\Omega_6\backslash\Omega_3)} + \|\varphi - Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_6\backslash\Omega_3)} \\ &\leq 0 + \|\varphi\|_{L^2(\Omega_7\backslash\Omega_2)} + C\tau^{M-1}\|\varphi\|_{L^2(\Omega_0)} \\ &\leq C\tau^{M-1}\|\varphi\|_{L^2(\Omega_0)}, \end{aligned}$$

which, along with (5.9), gives

$$|(u-u_h, Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\varphi) - \omega^2 Q_\tau^{\Omega_1}\varphi)_{\Omega_1}| \leq c\tau^M\|u-u_h\|_{L^2(\Omega_1)}\|\varphi\|_{L^2(\Omega_0)}.$$

For the third term on the right-hand side of (5.8), using Lemma 5.2 we have

$$\begin{aligned} (5.10) \qquad &|(\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \varphi)| \\ &\leq \|\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h))\|_{L^2(\Omega_0)}\|\varphi\|_{L^2(\Omega_0)} \\ &\leq C\tau\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)}\|\varphi\|_{L^2(\Omega_0)}. \end{aligned}$$

Substituting (5.9) and (5.10) into (5.8), we obtain

$$\begin{aligned} (5.11) \qquad &\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_0)} \\ &\leq \sup_{\varphi \in C_0^\infty(\Omega_0)} \frac{(\omega(u-u_h), \omega Q_\tau^{\Omega_1}\varphi)}{\|\varphi\|_{L^2(\Omega_0)}} \\ &\quad + C\tau^M\|u-u_h\|_{L^2(\Omega_1)} + C\tau\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)}. \end{aligned}$$

It remains to estimate the first term on the right-hand side of (5.11). To this end, let $\Phi \in H^1(\Omega_7)$ be the solution of the following auxiliary problem:

$$A_{\Omega_7}(\psi, \Phi) = (\omega Q_\tau^{\Omega_1}\varphi, \psi)_{\Omega_7} \quad \forall\ v \in H^1(\Omega_7).$$

Then, by (2.10), for any $0 \le k \le m$,

$$\|\Phi\|_{H^{k+2}(\Omega_7)} \le C\|\omega Q_\tau^{\Omega_1}\varphi\|_{H^k(\Omega_7)} \le C\|Q_\tau^{\Omega_1}\varphi\|_{H^k(\Omega_5)} \tag{5.12}$$

and

$$\|\Phi\|_{H^{k+2}(\Omega_5\setminus\Omega_4)} \le C\left(\|Q_\tau^{\Omega_1}\varphi\|_{H^k(\Omega_6\setminus\Omega_3)} + \|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_1)}\right). \tag{5.13}$$

Thus,

$$\begin{aligned}(\omega(u-u_h), \omega Q_\tau^{\Omega_1}\varphi_\tau) &= A_{\Omega_1}(\omega(u-u_h), \Phi) = A(\omega(u-u_h), \Phi)\\ &= A(u-u_h, \omega\Phi) + I_\omega(u-u_h, \Phi),\end{aligned} \tag{5.14}$$

where, for the Laplacian operator,

$$I_\omega(u, v) = (u\nabla\omega, \nabla v) - (\nabla u, v\nabla\omega).$$

By assumption A.1, there exists a $\chi \in S_r^h \cap L^2_<(\Omega_6)$ such that

$$\|\omega\Phi - \chi\|_{H^1(\Omega_6)} \le Ch^{i-1}\|\Phi\|_{H^i(\Omega_7)}, \quad 1 \le i \le 1+r. \tag{5.15}$$

Thus, according to (2.4), (5.15), and (5.12), we have

$$\begin{aligned}A(u-u_h, \omega\Phi) &= A(u-u_h, \omega\Phi-\chi)\\ &\le Ch^{1+\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_6)}\|\Phi\|_{H^{2+\min(m,r-1)}(\Omega_7)}\\ &\le Ch^{1+\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\|Q_\tau^{\Omega_1}\varphi\|_{H^{\min(m,r-1)}(\Omega_5)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_6)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\|\varphi\|_{L^2(\Omega_0)}.\end{aligned} \tag{5.16}$$

For the second term on the right-hand side of (5.14), we have for $0 \le q \le 1+m$

$$\begin{aligned}&|I_\omega(u-u_h, \Phi)|\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_5)}\|\Phi\|_{H^{q+1}(\Omega_5\setminus\Omega_4)}\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_1)}\left(\|Q_\tau^{\Omega_1}\varphi\|_{H^{q-1}(\Omega_6\setminus\Omega_3)} + \|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_1)}\right)\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_1)}\left(\|\varphi\|_{H^{q-1}(\Omega_7\setminus\Omega_2)} + \tau^M\|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_1)}\right.\\ &\qquad\left. + \|Q_\tau^{\Omega_1}\varphi\|_{L^2(\Omega_1)}\right)\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_1)}\|\varphi\|_{L^2(\Omega_0)}.\end{aligned} \tag{5.17}$$

Substituting (5.17) and (5.16) into (5.14), we have

$$\begin{aligned}\sup_{\varphi\in C_0^\infty(\Omega_0)} \frac{(\omega(u-u_h), \omega Q_\tau^{\Omega_1}\varphi)}{\|\varphi\|_{L^2(\Omega_0)}} &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\\ &\quad + C\|u-u_h\|_{H^{-q}(\Omega_1)},\end{aligned}$$

which, together with (5.11), implies

$$\begin{aligned}(5.18)\qquad &\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_0)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\\ &\quad + C\tau^M\|u-u_h\|_{L^2(\Omega_1)} + \|u-u_h\|_{H^{-q}(\Omega_1)}\\ &\quad + C\tau\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)}.\end{aligned}$$

A repeated use of (5.18) leads to

$$\begin{aligned}(5.19)\qquad &\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_0)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\\ &\quad + C\tau^M\|u-u_h\|_{L^2(\Omega_1)} + \|u-u_h\|_{H^{-q}(\Omega_1)}\\ &\quad + C\tau^M\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_7)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}\\ &\quad + C\tau^M\|u-u_h\|_{L^2(\Omega_1)} + \|u-u_h\|_{H^{-q}(\Omega_1)}.\end{aligned}$$

Choosing $M > 0$ sufficiently large so that

$$\tau^M\|u-u_h\|_{L^2(\Omega_1)} \le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{H^1(\Omega_1)}$$

completes the proof. □

6. A local superconvergence in L^∞.

Our objective in this section is to derive a local superconvergence estimate in the maximum norm. The result can be stated as follows.

THEOREM 6.1. *Suppose u and u_h satisfy* (2.4) *and the subdomains $\Omega_0 \subset \Omega_1 \subset \Omega$ satisfy dist$(\Omega_0, \partial\Omega_1\backslash\partial\Omega) \ge C_1 h$ for sufficiently large $C_1 > 1$. If τ satisfies* (3.1)*, then, for any $0 \le q \le m+1$ and $i = 0, 1$, we have*

$$\begin{aligned}(6.1)\qquad &\|u - Q_\tau^{\Omega_1}u_h\|_{W^{i,\infty}(\Omega_0)}\\ &\le Ch^{\frac{r+1+\min(m,r-1)}{1+\theta_i}}\left(\|u\|_{W^{1+r,\infty}(\Omega_1)} + \|u\|_{W^{1+s,\infty}(\Omega_1)}\right)\\ &\quad + C\|u-u_h\|_{H^{-q}(\Omega_1)},\end{aligned}$$

where θ_i is defined by (3.2).

Proof. Observe that from the triangle inequality we have

$$(6.2)\quad \|u - Q_\tau^{\Omega_1}u_h\|_{W^{i,\infty}(\Omega_0)} \le \|u - Q_\tau^{\Omega_1}u\|_{W^{i,\infty}(\Omega_0)} + \|Q_\tau^{\Omega_1}(u-u_h)\|_{W^{i,\infty}(\Omega_0)}.$$

The first term on the right-hand side of (6.2) can be estimated using an analogy of Lemma 5.3 in the L^∞ norm. The second term on the right-hand side of (6.2) can be handled using Lemma 6.2, which will be established in the rest of this section. The desired superconvergence is merely a combination of those results. □

The remaining portion of this section is devoted to the establishment of a result that has been used in the proof of Theorem 6.1.

LEMMA 6.2. *Suppose $\Omega_0 \subset \Omega_1 \subset \Omega$ with dist$(\Omega_0, \partial\Omega_1\backslash\partial\Omega) \ge C_1 h$ for sufficiently large $C_1 > 1$; then, for $0 \le q \le m+1$, there holds*

$$\begin{aligned}(6.3)\qquad &\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^\infty(\Omega_0)}\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}\|u-u_h\|_{W^{1,\infty}(\Omega_1)}\\ &\quad + C\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_1)} + C\|u-u_h\|_{H^{-q}(\Omega_1)}.\end{aligned}$$

Proof. Let $z \in \bar{\Omega}_0$ be such that

$$|Q_\tau(u-u_h)(z)| = \max_{x\in\Omega_0} |Q_\tau(u-u_h)(x)|.$$

Let $\Omega_0 \subset \Omega_2 \subset \Omega_3 \subset \Omega_4 \subset \Omega_5 \subset \Omega_6 \subset \Omega_7 \subset \Omega_1$ satisfy

$$\begin{aligned}&\mathrm{dist}(\Omega_0, \partial\Omega_2\backslash\partial\Omega) = \mathrm{dist}(\Omega_2, \partial\Omega_3\backslash\partial\Omega) = \mathrm{dist}(\Omega_3, \partial\Omega_4\backslash\partial\Omega) = \mathrm{dist}(\Omega_4, \partial\Omega_5\backslash\partial\Omega)\\ &= \mathrm{dist}(\Omega_5, \partial\Omega_6\backslash\partial\Omega) = \mathrm{dist}(\Omega_6, \partial\Omega_7\backslash\partial\Omega) = \mathrm{dist}(\Omega_7, \partial\Omega_1\backslash\partial\Omega) = d/7\end{aligned}$$

with sufficiently smooth $\partial\Omega_7$. Then, for $\omega \in C^\infty(\Omega_5) \cap L^2_<(\Omega_5)$ with $\omega \equiv 1$ in Ω_4,

$$\begin{aligned}(6.4)\qquad &Q_\tau^{\Omega_1}(u-u_h)(z)\\ &= (Q_\tau^{\Omega_1}(u-u_h), \delta_{\tau,z}) = (\omega Q_\tau^{\Omega_1}(u-u_h), \omega\delta_{\tau,z})\\ &= (\omega^2(u-u_h), Q_\tau^{\Omega_1}\delta_{\tau,z}) + (u-u_h, Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z}) - \omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z})\\ &\quad + (\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \delta_{\tau,z}).\end{aligned}$$

By Lemma 5.2, we have

$$\begin{aligned}(6.5)\qquad &(u-u_h, Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z}) - \omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z})_{\Omega_1}\\ &\le \|u-u_h\|_{L^2(\Omega_1)} \|\omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z} - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}\delta_{\tau,z})\|_{L^2(\Omega_1)}\\ &\le C\tau\|u-u_h\|_{L^2(\Omega_1)} \|Q_\tau^{\Omega_1}\delta_{\tau,z}\|_{L^2(\Omega_6\backslash\Omega_3)}\\ &\le C\tau^{M+1}\|u-u_h\|_{L^2(\Omega_1)} \|\delta_{\tau,z}\|_{L^2(\Omega_1)}\\ &\le C\tau^M\|u-u_h\|_{L^2(\Omega_1)}\end{aligned}$$

and

$$\begin{aligned}(6.6)\qquad &(\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)), \delta_{\tau,z})\\ &\le \|\omega^2 Q_\tau^{\Omega_1}(u-u_h) - Q_\tau^{\Omega_1}(\omega^2 Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_1)} \|\delta_{\tau,z}\|_{L^2(\Omega_1)}\\ &\le C\tau\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)} \|\delta_{\tau,z}\|_{L^2(\Omega_1)}\\ &\le C\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)}.\end{aligned}$$

It remains to estimate the first term on the right-hand side of (6.4). Let $G \in H^1(\Omega_7)$ be the solution of

$$A_{\Omega_7}(\psi, G) = (\omega Q_\tau^{\Omega_1}\delta_{\tau,z}, \psi) \quad \forall\ \psi \in H^1(\Omega_7).$$

Then, similar to (5.14), we have

$$(6.7)\qquad (\omega(u-u_h), \omega Q_\tau^{\Omega_1}\delta_{\tau,z}) = A(u-u_h, \omega G) + I_\omega(u-u_h, G).$$

Moreover, choosing $\chi \in S_r^h \cap L^2_<(\Omega_6)$ such that

$$\|\omega G - \chi\|_{W^{1,1}(\Omega_6)} \le Ch^{i-1}\|G\|_{W^{i,1}(\Omega_7)}, \quad 1 \le i \le 1+r,$$

we have

$$\begin{aligned}(6.8)\qquad &A(u-u_h, \omega G) = A(u-u_h, \omega G - \Pi_h(\omega G))\\ &\le Ch^{1+\min(m,r-1)}\|u-u_h\|_{W^{1,\infty}(\Omega_6)} \|G\|_{W^{2+\min(m,r-1),1}(\Omega_7)}.\end{aligned}$$

To estimate $\|G\|_{W^{2+\min(m,r-1),1}(\Omega_7)}$, we use Lemma 4.4:

$$\begin{aligned}(6.9)\qquad &\|G\|_{W^{2+\min(m,r-1),1}(\Omega_7)} \le C|\ln\tau|^{1/2}\|G\|_{H^{2+\min(m,r-1)}_{\sigma^2}(\Omega_7)}\\ &\le C\Big(\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)} + \|G\|_{H^{1+\min(m,r-1)}(\Omega_7)}\Big)\\ &\le C\Big(\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)} + \|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{-1+\min(m,r-1)}(\Omega_7)}\Big).\end{aligned}$$

For $\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)}$, we have

$$\begin{aligned}(6.10)\qquad &\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)}\\ &\le C\|\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)} + C\|\delta_{\tau,z} - Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{\min(m,r-1)}_{\sigma^2}(\Omega_7)}\\ &\le C\tau^{-\min(m,r-1)} + C\tau^2\|\delta_{\tau,z}\|_{H^{2+\min(m,r-1)}_{\sigma^2}(\Omega_1)}\\ &\le C\tau^{-\min(m,r-1)}.\end{aligned}$$

For $\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{-1+\min(m,r-1)}(\Omega_7)}$, we have if $\min(m,r-1)\ge 1$,

$$\begin{aligned}(6.11)\qquad \|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{-1+\min(m,r-1)}(\Omega_1)} &\le C\tau^{1-\min(m,r-1)}\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{L^2(\Omega_7)}\\ &\le C\tau^{-\min(m,r-1)},\end{aligned}$$

and if $\min(m,r-1)=0$,

$$(6.12)\qquad \|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{-1}(\Omega_7)} \le C|\ln\tau|^{1/2}.$$

Therefore, we have

$$\|G\|_{W^{2+\min(m,r-1),1}(\Omega_7)} \le C\tau^{-\min(m,r-1)}|\ln\tau|^{\bar r/2},$$

which, together with (6.8), implies

$$(6.13)\qquad A(u-u_h,\omega G) \le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}|\ln\tau|^{\bar r}.$$

Next, we estimate the second term $I_\omega(u-u_h,G)$ in (6.7). According to the formula for I_ω, we have for $0\le q\le 1+m$

$$\begin{aligned}(6.14)\qquad &I_\omega(u-u_h,G)\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_5)}\|G\|_{H^{q+1}(\Omega_5\backslash\Omega_3)}\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_1)}\left(\|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{H^{q-1}(\Omega_4\backslash\Omega_2)} + \|Q^{\Omega_1}_\tau\delta_{\tau,z}\|_{L^1(\Omega_1)}\right)\\ &\le C\|u-u_h\|_{H^{-q}(\Omega_1)},\end{aligned}$$

where we have employed Lemma 5.4 in the second inequality. Combining (6.13), (6.14), and (6.7), we obtain

$$\begin{aligned}(6.15)\qquad &(\omega(u-u_h),\omega Q^{\Omega_1}_\tau\delta_{\tau,z})\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}|\ln h|^{\bar r}\|u-u_h\|_{W^{1,\infty}(\Omega_1)}\\ &\quad + C\|u-u_h\|_{H^{-q}(\Omega_1)}.\end{aligned}$$

Therefore, (6.5), (6.6), and (6.15) conclude that

$$\begin{aligned}(6.16)\qquad &|Q_\tau^{\Omega_1}(u-u_h)(z)|\\ &\le Ch^{1+\min(m,r-1)}\tau^{-\min(m,r-1)}|\ln h|^{\bar r}\|u-u_h\|_{W^{1,\infty}(\Omega_1)}\\ &\quad + C\|u-u_h\|_{H^{-q}(\Omega_1)} + C\|Q_\tau^{\Omega_1}(u-u_h)\|_{L^2(\Omega_6)}\\ &\quad + C\tau^M\|u-u_h\|_{L^2(\Omega_1)}.\end{aligned}$$

By choosing sufficiently large values of M, we can bound the last term by the first term on the right-hand side of (6.16). This completes the proof. □

7. Case discussions. According to the results derived in the previous sections, the leading term of the global error $u-Q_\tau u_h$ or the local error $u-Q_\tau^{\Omega_1}u_h$ is of order

$$\mathcal{O}\left(h^{(1+r+\min(r-1,m,k))/(1+\theta_0)}\right).$$

Recall that the parameter m is the smoothness of the finite element projection space $S_{m,s}^\tau$, and $k+2$ is the regularity of the second-order elliptic problem defined locally on smooth subdomains. In practical applications, we have $m>\frac{1}{2}$ and $k\ge 0$. In view of the optimal-order error estimate

$$u-u_h=\mathcal{O}\left(h^{1+r}\right),$$

we see that the projected finite element approximation has superconvergence if $\min(r-1,m,k)>\theta_0(1+r)$ or, equivalently, if $r<s$ and $\min(r-1,m,k)>0$. In other words, if $\min(r-1,m,k)>0$ holds true, then any L^2 projection of the finite element solution u_h in a higher (i.e., $s>r$) order finite element space $S_{m,s}^\tau$ will produce a superconvergent new approximation.

For the gradient of the error, the leading term of the global or local errors are bounded by

$$\mathcal{O}\left(h^{(1+r+\min(r-1,m,k))/(1+\theta_1)}\right).$$

Since the optimal-order of error estimate for the gradient is $\mathcal{O}(h^r)$, we then obtain a superconvergence if $\min(r-1,m,k)>\theta_1 r-1$. Equivalently speaking, the global or local L^2 projections produce superconvergent approximations if $\min(r-1,m,k)>-1$ and $r<s$.

Notice that the error $u-u_h$ in negative norms can be shown to be of higher order than $\mathcal{O}(h^{1+r})$ for $k>0$ and of higher order than $\mathcal{O}(h^r)$ for $k>-1$. Thus, the following conclusions can be made without any proof:

1. $u-Q_\tau u_h$ and its local analogy $u-Q_\tau^{\Omega_1}u_h$ are superconvergent if $s>r\ge 2$, $m>0$, and $k>0$.
2. $\nabla(u-Q_\tau u_h)$ and its local analogy $\nabla(u-Q_\tau^{\Omega_1}u_h)$ are superconvergent if $s>r\ge 1$, $m>-1$, and $k>-1$.

A more detailed illustration on the exact order of superconvergence corresponding to different indices of r, s, m can be found in Wang [30].

HIGH-ORDER CENTRAL WENO SCHEMES FOR MULTIDIMENSIONAL HAMILTON–JACOBI EQUATIONS*

STEVE BRYSON† AND DORON LEVY‡

Abstract. We present new third- and fifth-order Godunov-type central schemes for approximating solutions of the Hamilton–Jacobi (HJ) equation in an arbitrary number of space dimensions. These are the first central schemes for approximating solutions of the HJ equations with an order of accuracy that is greater than two. In two space dimensions we present two versions for the third-order scheme: one scheme that is based on a genuinely two-dimensional central weighted ENO reconstruction, and another scheme that is based on a simpler dimension-by-dimension reconstruction. The simpler dimension-by-dimension variant is then extended to a multidimensional fifth-order scheme. Our numerical examples in one, two, and three space dimensions verify the expected order of accuracy of the schemes.

1. Introduction.

We are interested in high-order numerical approximations for the solution of multidimensional Hamilton–Jacobi (HJ) equations of the form

$$\phi_t + H(\nabla\phi) = 0, \qquad \vec{x} = (x_1, \dots, x_d) \in \mathbb{R}^d,$$

where H is the Hamiltonian, which we assume depends on $\nabla\phi$ and possibly on x and t. In recent years, the HJ equations have attracted a lot of attention from analysts and numerical analysts due to the important role that they play in applications such as optimal control theory, image processing, geometric optics, differential games, calculus of variations, etc. The main difficulty in treating these equations arises from the discontinuous derivatives that develop in finite time even when the initial data is smooth. Vanishing viscosity solutions provide a good tool for defining weak solutions when the Hamiltonian is convex [15]. The celebrated *viscosity solution* provides a suitable extension of weak solutions for more general Hamiltonians [3, 7, 8, 9, 10, 28, 29].

Given the importance of the HJ equations, there has been relatively little activity in developing numerical tools for approximating their solutions. This is surprising, given that most of the numerical ideas are based on the similarity between hyperbolic conservation laws and the HJ equations, and that the field of numerical methods for conservation laws has been flourishing in recent years.

Converging first-order approximations were introduced by Souganidis in [38]. High-order upwind methods were introduced by Osher and Sethian [34] and Osher and Shu [35]. These methods are based on Harten's essentially nonoscillatory (ENO) reconstruction [13, 37], which is evolved in time with a monotone flux. The weighted

ENO (WENO) interpolant of [18, 32, 36] was used for constructing high-order upwind methods for the HJ equations in [17], and extensions of these methods for triangular meshes were introduced in [1, 40]. We note in passing that there are other approaches for approximating solutions of HJ equations such as discontinuous Galerkin methods [14, 24] and relaxation schemes [20].

A different class of Godunov-type schemes for hyperbolic conservation laws, the so-called central schemes, has recently been applied to the HJ equations. The prototype for these schemes is the Lax–Friedrichs scheme [11]. A second-order staggered central scheme was developed for conservation laws by Nessyahu and Tadmor in [33]. The main advantage of central schemes is their simplicity. Since they do not require any (approximate) Riemann solvers, they are particularly suitable for approximating multidimensional systems of conservation laws. Lin and Tadmor applied these ideas to the HJ equations in [31]. There, first- and second-order staggered schemes versions of [2, 19, 33] were written in one and two space dimensions. An L^1 convergence of order one for this scheme was proved in [30]. After the introduction of a semidiscrete central scheme for hyperbolic conservation laws in [23], a second-order semidiscrete scheme for HJ equations was introduced by the same authors in [22]. While less dissipative, this scheme requires the estimation of the local speed of propagation at every grid-point, a task that is computationally intensive, particularly with problems of high dimensionality. By considering more precise information about the local speed of propagation, an even less dissipative scheme was generated in [21].

Recently we introduced in [5] new and efficient central schemes for multidimensional HJ equations. These nonoscillatory, nonstaggered schemes were first- and second-order accurate and were designed to scale well with an increasing dimension. Efficiency was obtained by carefully choosing the location of the evolution points and by using a one-dimensional projection step. Avoiding staggering by adding an additional projection step is an idea which we already utilized in the framework of conservation laws [16].

In this work we introduce third- and fifth-order accurate schemes for approximating solutions of multidimensional HJ equations. These are the *first* central schemes for such equations of order greater than two. This work is the HJ analogue to the corresponding works in conservation laws: an ENO-based central scheme [4] and the central WENO (CWENO) central schemes [25, 26, 27]. We announced a preliminary version of the one-dimensional results in a recent proceedings publication [6].

The structure of this paper is as follows. We start in section 2 with the derivation of our one-dimensional schemes. A third-order WENO reconstruction scheme is presented in section 2.2. This scheme requires a fourth-order reconstruction of the point-values and a third-order reconstruction of the derivatives at the evolution points. Even though the optimal location of the evolution points in one dimension is in the center of the interval, in order to prepare the grounds for the multidimensional schemes we write a reconstruction for an arbitrary location of the evolution points. A fifth-order method is then presented in section 2.3.

We turn to the multidimensional framework in section 3. Here there is flexibility in the reconstruction step. For simplicity we carry out most of the discussion in two space dimensions. Extensions to more than two space dimensions are presented in section 3.4. First, we provide a brief outline of the general structure of two-dimensional central schemes in section 3.1. The main remaining ingredient, the reconstruction step, is then described in the following two sections. For a two-dimensional third-order scheme we present in section 3.2 two ways to obtain a high-order reconstruction of the approximate solution at the evolution points. The first option in section 3.2.1 is based on a genuinely two-dimensional reconstruction. An alternative dimension-by-dimension approach is based on a sequence of one-dimensional reconstructions and is presented in section 3.2.2. Our numerical results show that both approaches are essentially equivalent. Hence, the rest of the paper deals with the dimension-by-dimension reconstruction. A fifth-order dimension-by-dimension extension of the one-dimensional scheme in section 2.3 to two dimensions is then presented in section 3.3. Since the solution at the next time step is computed at grid-points that are different from those on which the data is given, we reproject the evolved solution back onto the original grid-points. Different ways to approach this reprojection step are discussed in section 3.2.3.

We conclude in section 4 with several numerical examples in one, two, and three space dimensions that confirm the expected order of accuracy and the high-resolution nature of our scheme. We compare our results with the scheme of Jiang and Peng [17]. We also study the convergence rate after the emergence of the discontinuities in the solution.

2. One-dimensional schemes.

2.1. One-dimensional central schemes.

Consider the one-dimensional HJ equation of the form

$$\phi_t(x,t) + H\left(\phi_x\right) = 0, \qquad x \in \mathbb{R}. \tag{2.1}$$

We are interested in approximating solutions of (2.1) subject to the initial data $\phi(x, t = 0) = \phi_0(x)$. For simplicity we assume a uniform grid in space and time with mesh spacings Δx and Δt, respectively. Denote the grid-points by $x_i = i\Delta x$, $t^n = n\Delta t$, and the fixed mesh ratio by $\lambda = \Delta t/\Delta x$. Let φ_i^n denote the approximate value of $\phi\left(x_i, t^n\right)$, and $\left(\varphi_x\right)_i^n$ denote the approximate value of the derivative $\phi_x\left(x_i, t^n\right)$. We define the forward and backward differencing as $\Delta^+\varphi_i^n := \varphi_{i+1}^n - \varphi_i^n$ and $\Delta^-\varphi_i^n := \varphi_i^n - \varphi_{i-1}^n$.

Assume that the approximate solution at time t^n, φ_i^n is given. A Godunov-type scheme for approximating the solution of (2.1) starts with a continuous piecewise-polynomial $\tilde{\varphi}(x, t^n)$ that is reconstructed from the data φ_i^n:

$$\tilde{\varphi}(x,t^n) = \sum_i P_{i+\frac{1}{2}}(x,t^n)\chi_{i+\frac{1}{2}}(x). \tag{2.2}$$

Here, $\chi_{i+1/2}(x)$ is the characteristic function of the interval $[x_i, x_{i+1}]$, and $P_{i+1/2}(x, t^n)$ is a polynomial of a suitable degree that satisfies the interpolation requirements

$$P_{i+\frac{1}{2}}(x_{i+\beta}, t^n) = \varphi_{i+\beta}^n, \quad \beta = 0, 1.$$

The reconstruction (2.2) is then evolved from time t^n to time t^{n+1} according to (2.1) and is sampled at the half-integer grid-points $\{x_{i+1/2}\}$, where the reconstruction is smooth (as long as the CFL condition $\lambda\left|H'\left(\varphi_x\right)\right| \leq 1/2$ is satisfied):

$$\varphi_{i+\frac{1}{2}}^{n+1} = \varphi_{i+\frac{1}{2}}^n - \int_{t^n}^{t^{n+1}} H\left(\tilde{\varphi}_x\left(x_{i+\frac{1}{2}}, \tau\right)\right) d\tau. \tag{2.3}$$

The point-value $\varphi_{i+1/2}^n$ is obtained by sampling (2.2) at $x_{i+1/2}$; i.e., $\varphi_{i+1/2}^n = \tilde{\varphi}(x_{i+1/2}, t^n)$. Since the evolution step (2.3) is done at points where the solution is smooth, we can approximate the time integral on the right-hand side (RHS) of (2.3) using a sufficiently accurate quadrature rule. For example, for a third- and fourth-order method, this integral can be replaced by a Simpson's quadrature,

$$(2.4)\quad \int_{t^n}^{t^{n+1}} H\left(\tilde{\varphi}_x\left(x_{i+\frac{1}{2}},\tau\right)\right)d\tau \approx \frac{\Delta t}{6}\left[H\left(\varphi'^{\,n}_{i+\frac{1}{2}}\right)+4H\left(\varphi'^{\,n+\frac{1}{2}}_{i+\frac{1}{2}}\right)+H\left(\varphi'^{\,n+1}_{i+\frac{1}{2}}\right)\right].$$

The derivative at time t^n, $\varphi'^{\,n}_{i+1/2}$, is obtained by sampling the derivative of the reconstruction (2.2), i.e., $\varphi'^{\,n}_{i+1/2}=\tilde{\varphi}'(x_{i+1/2},t^n)$. The intermediate values of the derivative in time, $\varphi'^{\,n+1/2}_{i+1/2}$ and $\varphi'^{\,n+1}_{i+1/2}$, which are required in the quadrature (2.4), can be predicted using a Taylor expansion or with a Runge–Kutta (RK) method. Alternatively, (2.1) can be treated as a semidiscrete equation by replacing the spatial derivatives with their numerical approximations and integrating in time via an RK method.

The only remaining ingredient to specify is the reconstruction (2.2). Below we present two reconstructions. The first is a fourth-order reconstruction of the point-values and the derivatives, which leads to a third-order scheme, and the second is a sixth-order reconstruction that results in a fifth-order scheme.

Remarks.

1. In order to return to the original grid, we project $\varphi^{n+1}_{i+1/2}$ back onto the integer grid-points $\{x_i\}$ to end up with φ^{n+1}_i. This projection is accomplished with the same reconstruction used to approximate $\varphi^n_{i+1/2}$ from φ^n_i.

2. In order to maximize the size of the time step, the evolution points should be taken as far as possible from the singularities in the reconstructed piecewise polynomial. In one dimension the appropriate evolution point is located at $x_{i+1/2}$. In d dimensions with a uniform grid with spacing Δx, the optimal evolution points are located at $x_{i+\alpha}=x_i+\alpha\Delta x$ in each direction, where $\alpha=1/(d+\sqrt{d})$ (see [5]). One of the multidimensional schemes we present in section 3 is based on one-dimensional reconstructions. Hence, in order to prepare the grounds for the multidimensional setup, we write the one-dimensional reconstruction in this section, assuming that the evolution points are $x_{i\pm\alpha}$. The reader should keep in mind that in one dimension, $\alpha=1/2$.

3. We would like to point out that one does not need to fully reconstruct the polynomials $P_{i+1/2}(x,t^n)$. The only values that the scheme requires are the approximated point-values $\varphi^n_{i+1/2}=\tilde{\varphi}(x_{i+1/2},t^n)$ and the approximated derivatives $\varphi'_{i+1/2}=\tilde{\varphi}'(x_{i+1/2})$. Hence, in the rest of the paper whenever we refer to reconstruction steps we directly treat the recovery of these two quantities.

2.2. A third-order scheme.

A third-order scheme is generated by combining a third-order accurate ODE solver in time, for predicting the intermediate values of the derivatives in (2.4), with a sufficiently high-order reconstruction in space.

Given φ^n_i, in order to invoke (2.3), we should compute two quantities in every time step: the point-values at the evolution points, $\varphi_{i\pm\alpha}$, and the derivatives $\varphi'_{i\pm\alpha}$. In order to obtain a third-order scheme, the approximations of the point-values should be fourth-order accurate, and the approximation of the derivatives should be third-order accurate. In this scheme, the reconstruction of the point-values is done in locations that are staggered with respect to the location of the data. The reconstruction of the derivatives, which is required in every step of the ODE solver, is done at the same points where the data is given. Since we need two types of reconstructions and due to symmetry considerations, we derive a fourth-order approximation of the derivatives.

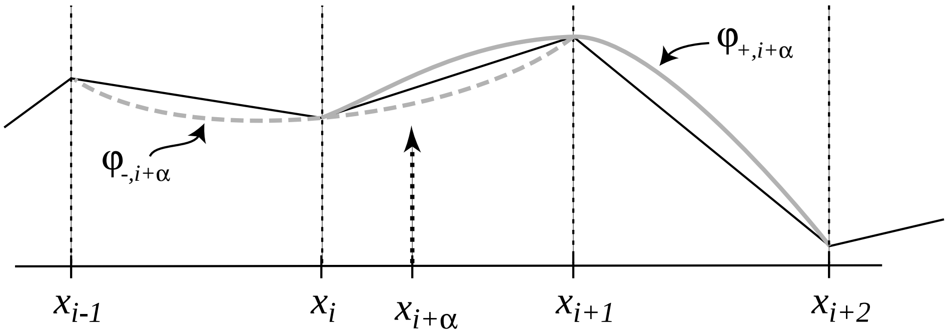

FIG. 2.1. *The two interpolants used for the third-order reconstruction at the evolution point at* $x_{i+\alpha}$.

Obviously, this more accurate reconstruction of the derivatives does not increase the order of accuracy of the scheme, but it does reduce the error.

2.2.1. The reconstruction of $\varphi_{i\pm\alpha}$ from φ_i. A fourth-order reconstruction of $\varphi_{i+\alpha}$ can be obtained by considering a convex combination of two quadratic polynomials, each of which requires the evaluation of φ on a three-point stencil. One quadratic polynomial $\varphi_-(x)$ is constructed on a stencil that is left-biased with respect to $x_{i+\alpha}$, $\{x_{i-1}, x_i, x_{i+1}\}$, while the other polynomial $\varphi_+(x)$ is constructed on a right-biased stencil, $\{x_i, x_{i+1}, x_{i+2}\}$; see Figure 2.1. We set

$$\begin{aligned} \varphi_{-,i+\alpha} &= \left(\frac{-\alpha+\alpha^2}{2}\right)\varphi_{i-1} + \left(1-\alpha^2\right)\varphi_i + \left(\frac{\alpha+\alpha^2}{2}\right)\varphi_{i+1}, \\ \varphi_{+,i+\alpha} &= \left(\frac{2-3\alpha+\alpha^2}{2}\right)\varphi_i + \left(2\alpha-\alpha^2\right)\varphi_{i+1} + \left(\frac{-\alpha+\alpha^2}{2}\right)\varphi_{i+2}. \end{aligned} \tag{2.5}$$

For smooth φ, a straightforward computation shows that $\varphi_{\pm,i+\alpha} = \varphi\left(x_{i+\alpha}\right) + O(\Delta x^3)$ and

$$\frac{1}{3}\left(2-\alpha\right)\varphi_{-,i+\alpha} + \frac{1}{3}\left(1+\alpha\right)\varphi_{+,i+\alpha} = \varphi\left(x_{i+\alpha}\right) + O\left(\Delta x^4\right).$$

Similarly, the reconstruction of $\varphi_{i-\alpha}$ is obtained using the quadratic polynomials $\varphi_-(x)$ based on the left-biased stencil enclosing $x_{i-\alpha}$, $\{x_{i-2}, x_{i-1}, x_i\}$, and $\varphi_+(x)$ based on the right-biased stencil $\{x_{i-1}, x_i, x_{i+1}\}$:

$$\begin{aligned} \varphi_{-,i-\alpha} &= \left(\frac{-\alpha+\alpha^2}{2}\right)\varphi_{i-2} + \left(2\alpha-\alpha^2\right)\varphi_{i-1} + \left(\frac{2-3\alpha+\alpha^2}{2}\right)\varphi_i, \\ \varphi_{+,i-\alpha} &= \left(\frac{\alpha+\alpha^2}{2}\right)\varphi_{i-1} + \left(1-\alpha^2\right)\varphi_i + \left(\frac{-\alpha+\alpha^2}{2}\right)\varphi_{i+1}. \end{aligned} \tag{2.6}$$

This time, $\varphi_{\pm,i-\alpha} = \varphi\left(x_{i-\alpha}\right) + O(\Delta x^3)$ and

$$\frac{1}{3}\left(1+\alpha\right)\varphi_{-,i-\alpha} + \frac{1}{3}\left(2-\alpha\right)\varphi_{+,i-\alpha} = \varphi\left(x_{i-\alpha}\right) + O\left(\Delta x^4\right).$$

A fourth-order WENO estimate of $\varphi_{i\pm\alpha}$ is therefore given by the convex combination

$$\varphi_{i\pm\alpha} = w^-_{i\pm\alpha}\varphi_{-,i\pm\alpha} + w^+_{i\pm\alpha}\varphi_{+,i\pm\alpha}, \tag{2.7}$$

where the weights satisfy $w^-_{i\pm\alpha} + w^+_{i\pm\alpha} = 1$, $w^\pm_{i\pm\alpha} \geq 0$, $\forall i$. In smooth regions we would like to satisfy $w^-_{i+\alpha} = w^+_{i-\alpha} \approx (2-\alpha)/3$ and $w^+_{i+\alpha} = w^-_{i-\alpha} \approx (1+\alpha)/3$ to attain an $O(\Delta x^4)$ error. When the stencil supporting $\varphi_{i\pm\alpha}$ contains a discontinuity, the weight of the more oscillatory polynomial should vanish. Following [18, 32], these requirements are met by setting

$$w^k_{i\pm\alpha} = \frac{\alpha^k_{i\pm\alpha}}{\sum_l \alpha^l_{i\pm\alpha}}, \qquad \alpha^k_{i\pm\alpha} = \frac{c^k_{i\pm\alpha}}{\left(\epsilon + S^k_{i\pm\alpha}\right)^p}, \tag{2.8}$$

where $k, l \in \{+,-\}$. The constants are independent of the grid index i and are given by $c^-_{i+\alpha} = c^+_{i-\alpha} = (2-\alpha)/3$, $c^+_{i+\alpha} = c^-_{i-\alpha} = (1+\alpha)/3$. We choose ϵ as 10^{-6} to prevent the denominator in (2.8) from vanishing, and set $p = 2$ (see [18]). The smoothness measures $S^\pm_i$ should be large when φ is nearly singular. Following [18], we take $S_{i\pm\alpha}$ to be the sum of the squares of the L^2-norms of the derivatives on the stencil supporting $\varphi_\pm$. If we approximate the first derivative at x_i by $\Delta^+\varphi_i/\Delta x$, the second derivative by $\Delta^+\Delta^-\varphi_i/(\Delta x)^2$, and define the smoothness measure

$$S_i\,[r,s] = \Delta x \sum_{j=r}^{s} \left(\frac{1}{\Delta x}\Delta^+\varphi_{i+j}\right)^2 + \Delta x \sum_{j=r+1}^{s} \left(\frac{1}{\Delta x^2}\Delta^+\Delta^-\varphi_{i+j}\right)^2, \tag{2.9}$$

then we have $S^-_{i+\alpha} = S_i\,[-1,0]$, $S^+_{i+\alpha} = S_i\,[0,1]$, $S^-_{i-\alpha} = S_i\,[-2,-1]$, and $S^+_{i-\alpha} = S_i\,[-1,0]$.

For future reference we label the reconstruction in this section with the procedural form

$$\varphi_{i\pm\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_3}\,(i, \pm\alpha, \varphi)\,, \tag{2.10}$$

where φ is the one-dimensional array $(\varphi_1, \ldots, \varphi_N)$. This notation will be used in the dimension-by-dimension reconstructions in section 3.

2.2.2. The reconstruction of $\varphi'_{i\pm\alpha}$ from $\varphi_{i\pm\alpha}$. The values of φ that we recovered in the previous step at the regularly spaced locations $\{x_{i\pm\alpha}\}$ can be used to recover the derivative $\varphi'_{i\pm\alpha}$ via a (noncentral) WENO reconstruction. To obtain a fourth-order WENO approximation of $\varphi'_{i\pm\alpha}$, we write a convex combination of three quadratic interpolants: $\varphi'_{-,i\pm\alpha}$ on the stencil $\{x_{i-2\pm\alpha}, x_{i-1\pm\alpha}, x_{i\pm\alpha}\}$, $\varphi'_{0,i\pm\alpha}$ on $\{x_{i-1\pm\alpha}, x_{i\pm\alpha}, x_{i+1\pm\alpha}\}$, and $\varphi'_{+,i\pm\alpha}$ on $\{x_{i\pm\alpha}, x_{i+1\pm\alpha}, x_{i+2\pm\alpha}\}$. For smooth φ,

$$\begin{aligned}
\varphi'_{-,i\pm\alpha} &= \frac{1}{2\Delta x}(\varphi_{i-2\pm\alpha} - 4\varphi_{i-1\pm\alpha} + 3\varphi_{i\pm\alpha}) = \varphi'\,(x_{i\pm\alpha}) + O\left(\Delta x^2\right), \\
\varphi'_{0,i\pm\alpha} &= \frac{1}{2\Delta x}(\varphi_{i+1\pm\alpha} - \varphi_{i-1\pm\alpha}) = \varphi'\,(x_{i\pm\alpha}) + O\left(\Delta x^2\right), \\
\varphi'_{+,i\pm\alpha} &= \frac{1}{2\Delta x}(-3\varphi_{i\pm\alpha} + 4\varphi_{i+1\pm\alpha} - \varphi_{i+2\pm\alpha}) = \varphi'\,(x_{i\pm\alpha}) + O\left(\Delta x^2\right).
\end{aligned} \tag{2.11}$$

A straightforward computation yields

$$\frac{1}{6}\varphi'_{-,i\pm\alpha} + \frac{2}{3}\varphi'_{0,i\pm\alpha} + \frac{1}{6}\varphi'_{+,i\pm\alpha} = \varphi'\,(x_{i\pm\alpha}) + O\left(\Delta x^4\right).$$

The fourth-order WENO estimate of $\varphi'_{i\pm\alpha}$ from $\varphi_{i\pm\alpha}$ is therefore

$$\varphi'_{i\pm\alpha} = w^-_{i\pm\alpha}\varphi'_{-,i\pm\alpha} + w^0_{i\pm\alpha}\varphi'_{0,i\pm\alpha} + w^+_{i\pm\alpha}\varphi'_{+,i\pm\alpha}, \tag{2.12}$$

where the weights w are of the form (2.8), with $k, l \in \{+, 0, -\}$, $c^- = c^+ = 1/6, c^0 = 2/3$, and the oscillatory indicators are $S^-_{i\pm\alpha} = S_{i\pm\alpha}[-2,-1]$, $S^0_{i\pm\alpha} = S_{i\pm\alpha}[-1,0]$, and $S^+_{i\pm\alpha} = S_{i\pm\alpha}[0,1]$.

For future reference we label the above reconstruction of $\varphi'_{i\pm\alpha}$ with the procedural form

$$\varphi'_{i\pm\alpha} = \text{reconstruct\_}\varphi'\text{\_1D\_3}\left(i, \pm\alpha, \varphi_{\pm\alpha}\right), \tag{2.13}$$

where $\varphi_{\pm\alpha}$ is the one-dimensional array $(\varphi_{1\pm\alpha}, \dots, \varphi_{N\pm\alpha})$.

We would like to summarize the one-dimensional third-order algorithm in the following, where $\text{RK}(\varphi^n_{i\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha}, \Delta t)$ is the third-order Runge–Kutta method that integrates (2.1) and is used to predict the intermediate values of the derivatives. Each internal step of the RK method will require additional reconstructions of $\varphi'_{i\pm\alpha}$ from that step's $\varphi_{i\pm\alpha}$.

ALGORITHM 2.1. *Assume that* $\{\varphi^n_i\}$ *are given.*

(a) *Reconstruct:*

$$\begin{aligned}\varphi^n_{i\pm\alpha} &= \text{reconstruct\_}\varphi\text{\_1D\_3}\left(i, \pm\alpha, \varphi^n\right),\\ \varphi'^{\,n}_{i\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_1D\_3}(i, \pm\alpha, \varphi^n_{i\pm\alpha}).\end{aligned}$$

(b) *Integrate:*

$$\begin{aligned}\varphi^{n+\frac{1}{2}}_{i\pm\alpha} &= RK\left(\varphi^n_{i\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha}, \Delta t/2\right),\\ \varphi'^{\,n+\frac{1}{2}}_{i\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_1D\_3}(i, \pm\alpha, \varphi^{n+\frac{1}{2}}_{i\pm\alpha}),\\ \varphi^{n+1}_{i\pm\alpha} &= RK\left(\varphi^n_{i\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha}, \Delta t\right),\\ \varphi'^{\,n+1}_{i\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_1D\_3}\left(i, \pm\alpha, \varphi^{n+1}_{i\pm\alpha}\right),\\ \varphi^{n+1}_{i\pm\alpha} &= \varphi^n_{i\pm\alpha} + \frac{\Delta t}{6}\left[H\left(\varphi'^{\,n}_{i\pm\alpha}\right) + 4H(\varphi'^{\,n+\frac{1}{2}}_{i\pm\alpha}) + H\left(\varphi'^{\,n+1}_{i\pm\alpha}\right)\right].\end{aligned}$$

(c) *Reproject:*

$$\varphi^{n+1}_i = \text{reconstruct\_}\varphi\text{\_1D\_3}\left(i, \mp\alpha, \varphi^{n+1}_{i\pm\alpha}\right).$$

Remark. It is possible to replace the Simpson's quadrature in the integration step with a single RK time step, $\varphi^{n+1}_{i\pm\alpha} = \text{RK}(\varphi^n_{i\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha}, \Delta t)$. Our simulations show that this choice reduces the complexity of the computation but also reduces its accuracy.

2.3. A fifth-order scheme. In order to obtain a fifth-order scheme, we need a sixth-order approximation of the point-values of φ, a fifth-order approximation of the derivative φ', and a higher-order prediction of the intermediate derivatives which appear in the quadrature formula. Due to arguments similar to those given in section 2.2, we again derive a more accurate reconstruction of the derivatives, which in this case is sixth-order.

We start with the reconstruction of $\varphi_{i+\alpha}$ from φ_i. We write sixth-order interpolants as a convex combination of three cubic interpolants, each of which requires the evaluation of φ on a four-point stencil. We use the polynomials $\varphi_-(x)$ defined on the left-biased stencil $\{x_{i-2}, x_{i-1}, x_i, x_{i+1}\}$, $\varphi_0(x)$ defined on the centered stencil $\{x_{i-1}, x_i, x_{i+1}, x_{i+2}\}$, and $\varphi_+(x)$ defined on the right-biased stencil $\{x_i, x_{i+1}, x_{i+2}, x_{i+3}\}$; see Figure 2.2. For smooth φ,

$$\begin{aligned}\varphi_{-,i+\alpha} &= a_1\varphi_{i-2} + a_2\varphi_{i-1} + a_3\varphi_i + a_4\varphi_{i+1} = \varphi\left(x_{i+\alpha}\right) + O\left(\Delta x^4\right),\\ \varphi_{0,i+\alpha} &= a_5\varphi_{i-1} + a_6\varphi_i + a_7\varphi_{i+1} + a_8\varphi_{i+2} = \varphi\left(x_{i+\alpha}\right) + O\left(\Delta x^4\right),\\ \varphi_{+,i+\alpha} &= a_9\varphi_i + a_{10}\varphi_{i+1} + a_{11}\varphi_{i+2} + a_{12}\varphi_{i+3} = \varphi\left(x_{i+\alpha}\right) + O\left(\Delta x^4\right),\end{aligned} \tag{2.14}$$

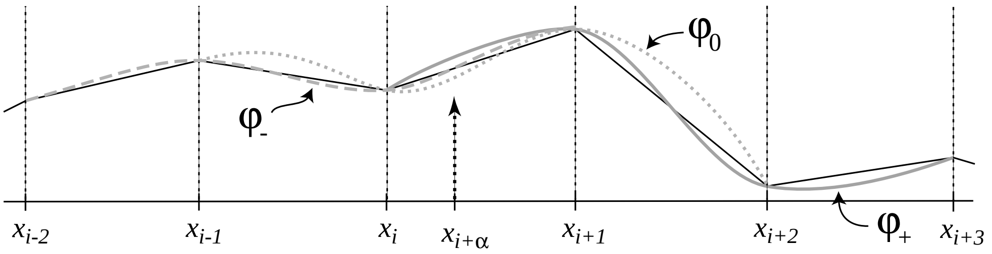

Fig. 2.2. *The three interpolants used for the fifth-order reconstruction $\varphi_{i+\alpha}$ at the evolution point at $x_{i+\alpha}$. In this example, because of the large gradient between x_{i+1} and x_{i+2}, the interpolant φ_- will have the strongest contribution to the CWENO reconstruction at $x_{i+\alpha}$.*

where the constants are given by

$$\begin{aligned}
a_1 &= \frac{1}{6}\alpha - \frac{1}{6}\alpha^3, & a_2 &= -\alpha + \frac{1}{2}\alpha^2 + \frac{1}{2}\alpha^3,\\
a_3 &= 1 + \frac{1}{2}\alpha - \alpha^2 - \frac{1}{2}\alpha^3, & a_4 &= \frac{1}{3}\alpha + \frac{1}{2}\alpha^2 + \frac{1}{6}\alpha^3,\\
a_5 &= -\frac{1}{3}\alpha + \frac{1}{2}\alpha^2 - \frac{1}{6}\alpha^3, & a_6 &= 1 - \frac{1}{2}\alpha - \alpha^2 + \frac{1}{2}\alpha^3,\\
a_7 &= \alpha + \frac{1}{2}\alpha^2 - \frac{1}{2}\alpha^3, & a_8 &= -\frac{1}{6}\alpha + \frac{1}{6}\alpha^3 = -a_1,\\
a_9 &= 1 - \frac{11}{6}\alpha + \alpha^2 - \frac{1}{6}\alpha^3, & a_{10} &= 3\alpha - \frac{5}{2}\alpha^2 + \frac{1}{2}\alpha^3,\\
a_{11} &= -\frac{3}{2}\alpha + 2\alpha^2 - \frac{1}{2}\alpha^3, & a_{12} &= \frac{1}{3}\alpha - \frac{1}{2}\alpha^2 + \frac{1}{6}\alpha^3.
\end{aligned}$$

At $x_{i-\alpha}$ we have

$$\begin{aligned}
\varphi_{-,i-\alpha} &= a_{12}\varphi_{i-3} + a_{11}\varphi_{i-2} + a_{10}\varphi_{i-1} + a_9\varphi_i = \varphi\left(x_{i-\alpha}\right) + O\left(\Delta x^4\right),\\
\varphi_{0,i-\alpha} &= a_8\varphi_{i-2} + a_7\varphi_{i-1} + a_6\varphi_i + a_5\varphi_{i+1} = \varphi\left(x_{i-\alpha}\right) + O\left(\Delta x^4\right),\\
\varphi_{+,i-\alpha} &= a_4\varphi_{i-1} + a_3\varphi_i + a_2\varphi_{i+1} + a_1\varphi_{i+2} = \varphi\left(x_{i-\alpha}\right) + O\left(\Delta x^4\right).
\end{aligned} \tag{2.15}$$

A straightforward computation yields

$$c^-_{i\pm\alpha}\varphi_{-,i\pm\alpha} + c^0_{i\pm\alpha}\varphi_{0,i\pm\alpha} + c^+_{i\pm\alpha}\varphi_{+,i\pm\alpha} = \varphi\left(x_{i\pm\alpha}\right) + O\left(\Delta x^6\right),$$

where

$$\begin{aligned}
c^-_{i+\alpha} = c^+_{i-\alpha} &= \frac{1}{20}\alpha^2 - \frac{1}{4}\alpha + \frac{3}{10},\\
c^0_{i\pm\alpha} &= -\frac{1}{10}\alpha^2 + \frac{1}{10}\alpha + \frac{3}{5},\\
c^+_{i+\alpha} = c^-_{i-\alpha} &= \frac{1}{20}\alpha^2 + \frac{3}{20}\alpha + \frac{1}{10}.
\end{aligned} \tag{2.16}$$

A sixth-order reconstruction of $\varphi_{i\pm\alpha}$ is therefore given by

$$\varphi_{i\pm\alpha} = w^-_{i\pm\alpha}\varphi_{-,i\pm\alpha} + w^0_{i\pm\alpha}\varphi_{0,i\pm\alpha} + w^+_{i\pm\alpha}\varphi_{+,i\pm\alpha}, \tag{2.17}$$

where the weights w^k are given by (2.8) with $k, l \in \{+, 0, -\}$, and the constants c^k are given by (2.16). The oscillatory indicators are given via (2.9) by $S^-_{i\pm\alpha} = S_i\,[-2, 0]$, $S^0_{i\pm\alpha} = S_i\,[-1, 1]$, and $S^+_{i\pm\alpha} = S_i\,[0, 2]$.

A sixth-order approximation of $\varphi'_{i\pm\alpha}$ from $\varphi_{i\pm\alpha}$ is written as a convex combination of four cubic interpolants. This reconstruction is similar to the third-order case and is based on a noncentral WENO reconstruction. We skip the details and summarize the result:

$$\varphi'_{i\pm\alpha} = w^1_{i\pm\alpha}\varphi'_{1,i\pm\alpha} + w^2_{i\pm\alpha}\varphi'_{2,i\pm\alpha} + w^3_{i\pm\alpha}\varphi'_{3,i\pm\alpha} + w^4_{i\pm\alpha}\varphi'_{4,i\pm\alpha}, \tag{2.18}$$

where

$$\begin{aligned}
\varphi'_{1,i\pm\alpha} &= \frac{1}{6\Delta x}(-2\varphi_{i-3\pm\alpha} + 9\varphi_{i-2\pm\alpha} - 18\varphi_{i-1\pm\alpha} + 11\varphi_{i\pm\alpha}),\\
\varphi'_{2,i\pm\alpha} &= \frac{1}{6\Delta x}(\varphi_{i-2\pm\alpha} - 6\varphi_{i-1\pm\alpha} + 3\varphi_{i\pm\alpha} + 2\varphi_{i+1\pm\alpha}),\\
\varphi'_{3,i\pm\alpha} &= \frac{1}{6\Delta x}(-2\varphi_{i-1\pm\alpha} - 3\varphi_{i\pm\alpha} + 6\varphi_{i+1\pm\alpha} - \varphi_{i+2\pm\alpha}),\\
\varphi'_{4,i\pm\alpha} &= \frac{1}{6\Delta x}(-11\varphi_{i\pm\alpha} + 18\varphi_{i+1\pm\alpha} - 9\varphi_{i+2\pm\alpha} + 2\varphi_{i+3\pm\alpha}).
\end{aligned}$$

Here the weights w^k are given by (2.8) with $c_1 = c_4 = 1/20, c_2 = c_3 = 9/20$, $S^1_{i\pm\alpha} = S_{i\pm\alpha}\,[-3, -1]$, $S^2_{i\pm\alpha} = S_{i\pm\alpha}\,[-2, 0]$, $S^3_{i\pm\alpha} = S_{i\pm\alpha}\,[-1, 1]$, and $S^4_{i\pm\alpha} = S_{i\pm\alpha}\,[0, 2]$.

Notation.

1. We label the reconstruction of the point-values, (2.17), as

$$\varphi_{i\pm\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(i, \pm\alpha, \varphi)\,, \tag{2.19}$$

where φ is the one-dimensional array $(\varphi_1, \dots, \varphi_N)$.

2. We label the reconstruction of $\varphi'_{i\pm\alpha}$, (2.18), as

$$\varphi'_{i\pm\alpha} = \text{reconstruct\_}\varphi'\text{\_1D\_5}\,(i, \pm\alpha, \varphi_{\pm\alpha})\,, \tag{2.20}$$

where $\varphi_{\pm\alpha}$ is the one-dimensional array $(\varphi_{1\pm\alpha}, \dots, \varphi_{N\pm\alpha})$.

Remarks.

1. To conclude, the fifth-order method is given by Algorithm 2.1, where the fourth-order reconstructions are replaced by the sixth-order reconstructions (2.19)–(2.20). As is, this scheme is only fourth-order in time. A higher-order method in time can be easily obtained by replacing Simpson's quadrature with a more accurate quadrature and computing the sixth-order approximations for the point-values and the derivatives at the new quadrature points.

2. We choose to predict the intermediate values of the derivatives in time using the fourth-order strong stability preserving (SSP) RK scheme of [12]. For $s \in \left\{\frac{1}{2}, 1\right\}$, the SSP-RK scheme is given by

$$\begin{aligned}
\varphi^{(1)} &= \varphi^n - \frac{1}{2}s\Delta t H\left(\varphi^n_x\right),\\
\varphi^{(2)} &= \frac{649}{1600}\varphi^n + \frac{10890423}{25193600}s\Delta t H\left(\varphi^n_x\right) + \frac{951}{1600}\varphi^{(1)} - \frac{5000}{7873}s\Delta t H(\varphi^{(1)}_x),
\end{aligned}$$

$$\begin{aligned}\varphi^{(3)} &= \frac{53989}{2500000}\varphi^{n} + \frac{102261}{5000000}s\Delta tH\left(\varphi_x^n\right) + \frac{4806213}{20000000}\varphi^{(1)}\\ &\quad + \frac{5121}{20000}s\Delta tH(\varphi_x^{(1)}) + \frac{23619}{32000}\varphi^{(2)} + \frac{7873}{10000}s\Delta tH(\varphi_x^{(2)}),\\ \varphi^{n+s} &= \frac{1}{5}\varphi^{n} - \frac{1}{10}s\Delta tH\left(\varphi_x^n\right) + \frac{6127}{30000}\varphi^{(1)} + \frac{1}{6}s\Delta tH(\varphi_x^{(1)}) + \frac{7873}{30000}\varphi^{(2)}\\ &\quad + \frac{1}{3}\varphi^{(3)} - \frac{1}{6}s\Delta tH(\varphi_x^{(3)}).\end{aligned}$$

Alternatively, the natural continuous extension of the RK method [39] can be used to produce the intermediate values $\varphi'^{\,n+\frac{1}{2}}$ and $\varphi'^{\,n+1}$ with a single RK step, though we observe that errors are somewhat larger in this case.

3. Multidimensional schemes.

3.1. Two-dimensional central schemes. Consider the two-dimensional HJ equation of the form

$$\phi_t + H(\nabla\phi) = 0, \qquad \vec{x} = (x_1, x_2) \in \mathbb{R}^2, \tag{3.1}$$

subject to the initial data $\phi(\vec{x}, t = 0) = \phi_0(\vec{x})$. Define $x_{i,j} := (x_1 + i\Delta x_1, x_2 + j\Delta x_2)$. Similarly to the one-dimensional setup, $\varphi_{i,j}$ will denote the approximation of ϕ at $x_{i,j}$. We define the two sets of grid-points, $I_+ = \{x_{i,j}, x_{i+1,j}, x_{i,j+1}\}$ and $I_- = \{x_{i,j}, x_{i-1,j}, x_{i,j-1}\}$, and denote by T_+, T_- the triangles with vertices I_+ and I_-, respectively. For simplicity we assume a uniform grid $\Delta x_1 = \Delta x_2 = \Delta x$.

Assume that the approximate solution at time t^n, $\varphi_{i,j}^n$, is given. Similarly to the one-dimensional setup in section 2.1, a Godunov-type scheme for approximating the solution of (3.1) starts with a continuous piecewise polynomial $\tilde{\varphi}(\vec{x}, t^n)$ that is reconstructed from the data $\varphi_{i,j}^n$,

$$\tilde{\varphi}(\vec{x}, t^n) = \sum_{i,j} P_{i,j}^{T_\pm}(\vec{x}, t^n)\chi_{T_\pm}(\vec{x}). \tag{3.2}$$

As usual, $\chi_{T_\pm}(\vec{x})$ is the characteristic function of the triangle $T_\pm$, and $P_{i,j}^{T_\pm}(\vec{x}, t^n)$ is a polynomial of a suitable degree that satisfies the interpolation requirements

$$P_{i,j}^{T_\pm}(\vec{x}_l, t^n) = \varphi(\vec{x}_l, t^n), \quad \vec{x}_l \in I_\pm$$

(see Figure 3.1). The reconstruction (3.2) is then evolved from time t^n to time t^{n+1} by (3.1) and sampled at the evolution points $\{x_{i\pm\alpha,j\pm\alpha}\}$. In two dimensions the choice $\alpha = 1/(2+\sqrt{2})$ guarantees that the solution remains smooth at the evolution point as long as the CFL condition $\frac{\Delta t}{\Delta x}\left|H'\left(\nabla\varphi\right)\right| < \alpha$ is satisfied. The evolved solution now reads

$$\varphi_{i\pm\alpha,j\pm\alpha}^{n+1} = \varphi_{i\pm\alpha,j\pm\alpha}^{n} - \int_{t^n}^{t^{n+1}} H\left(\nabla\tilde{\varphi}\left(x_{i\pm\alpha,j\pm\alpha}, \tau\right)\right)d\tau. \tag{3.3}$$

The point-values $\varphi_{i\pm\alpha,j\pm\alpha}^n$ are obtained by sampling (3.2) at $x_{i\pm\alpha,j\pm\alpha}$, i.e., $\varphi_{i\pm\alpha,j\pm\alpha}^n = \tilde{\varphi}(x_{i\pm\alpha,j\pm\alpha}, t^n)$. As in the one-dimensional case, the evolution points are in smooth regions, and therefore the integral on the RHS of (3.3) can be replaced with a sufficiently accurate quadrature such as the Simpson rule (2.4), which leads to a scheme that is

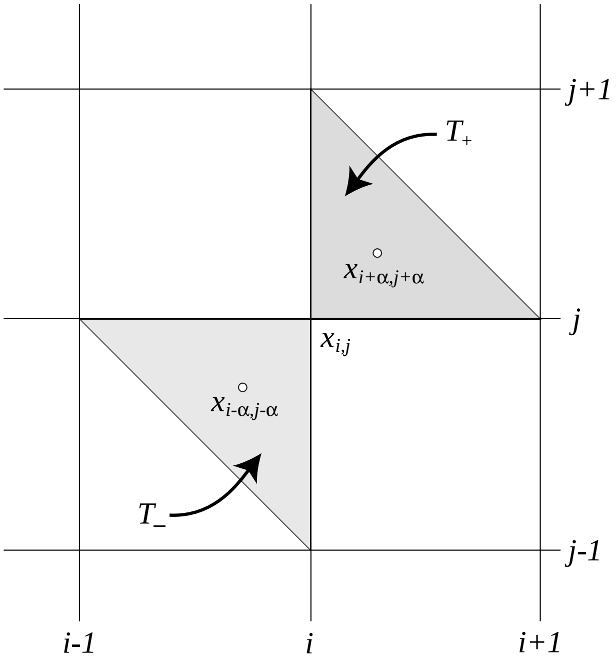

FIG. 3.1. *The location of the evolution points $x_{i\pm\alpha,j\pm\alpha}$ and the domain of definition of the interpolants $\varphi_{i\pm\alpha,j\pm\alpha}$ in two dimensions.*

fourth-order accurate in time. The derivatives at time t^n, $\varphi'^{\,n}_{i\pm\alpha,j\pm\alpha}$, are obtained by sampling the derivative of the reconstruction (3.2), i.e., $\varphi'^{\,n}_{i\pm\alpha,j\pm\alpha} = \tilde{\varphi}'(x_{i\pm\alpha,j\pm\alpha}, t^n)$. The other intermediate values of the derivative in time that are required in the quadrature can be predicted using a Taylor expansion or with a RK method in a way analogous to that for the one-dimensional case.

Remarks.

1. We present two different algorithms for constructing $\varphi_{i\pm\alpha,j\pm\alpha}$: two-dimensional interpolants defined on two-dimensional stencils and a dimension-by-dimension approach. We present both algorithms for the third-order scheme and extend the simpler dimension-by-dimension approach to fifth-order. Our numerical simulations in section 4 indicate that both reconstructions of $\varphi_{i\pm\alpha,j\pm\alpha}$ are of a comparable quality. In both approaches, the reconstruction of the derivatives $\nabla\varphi_{i\pm\alpha,j\pm\alpha}$ is done dimension-by-dimension.

2. We reproject $\varphi^{n+1}_{i+\alpha,j+\alpha}$ and $\varphi^{n+1}_{i-\alpha,j-\alpha}$ back onto the integer grid-points, obtaining $\varphi^{n+1}_{i,j}$. We present several ways to carry out this reprojection: a genuinely two-dimensional approach, a dimension-by-dimension strategy, and a reprojection along the diagonal line through $x_{i-\alpha,j-\alpha}$ and $x_{i+\alpha,j+\alpha}$.

3.2. Two-dimensional third-order schemes.

In order to obtain a third-order scheme, we need a fourth-order reconstruction of the point-values at the evolution points $x_{i\pm\alpha,j\pm\alpha}$.

3.2.1. A two-dimensional reconstruction of $\varphi_{i\pm\alpha,j\pm\alpha}$.

In this section we present a two-dimensional fourth-order reconstruction of the point-values $\varphi_{i\pm\alpha,j\pm\alpha}$. In principle, a two-dimensional cubic interpolant would provide a reconstruction with the desired accuracy. Such an interpolant is based on a ten-point stencil. As usual,

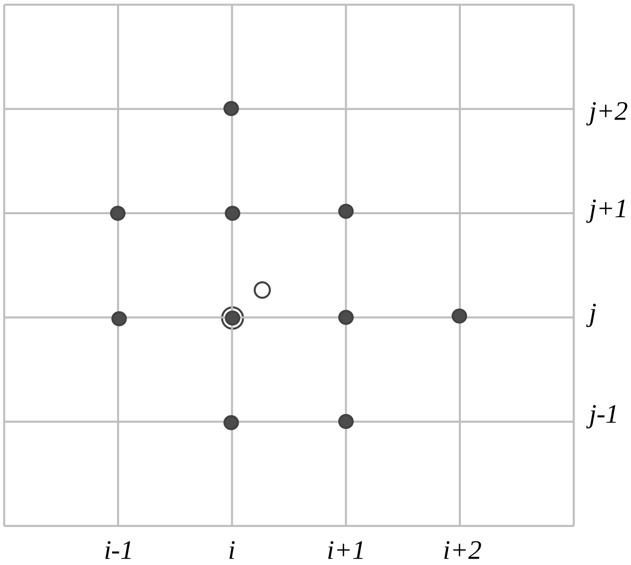

Fig. 3.2. *The ten-point stencil for the two-dimensional reconstruction of $\varphi_{i+\alpha,j+\alpha}$. The open circle shows the location of the evolution point at $x_{i+\alpha,j+\alpha}$.*

solving such a direct interpolation problem is unsatisfactory because spurious oscillations might develop as a result of the lack of smoothness in the solution. Instead, we generate a two-dimensional fourth-order reconstruction as a convex combination of four quadratic interpolants, each of which is based on a six-point stencil. We choose compact quadratic interpolants such that the union of all the six-point stencils is a compact ten-point stencil. Similarly to any WENO-type reconstruction, when singularities are present the six-point stencils containing the singularities are suppressed. In any case, we implicitly assume that the solution is sufficiently resolved such that the singularities in the solution are isolated in the sense that they do not occur along neighboring parallel cell edges. Singularities will in general occur along adjacent cell edges. There is a lot of flexibility in choosing the ten-point stencil as well as the different six-point stencils. Here, for the evolution point $x_{i+\alpha,j+\alpha}$ we choose the ten-point stencil shown in Figure 3.2. We also choose to use the four six-point stencils that are shown in Figure 3.3; obviously, the union of these stencils is the ten-point stencil in Figure 3.2. Furthermore, they all enclose the cell containing the evolution point, and they all cross different edges of the enclosing cell. A singularity along an edge will suppress two of these stencils, while a singularity in a corner will suppress three of these stencils.

Remarks.

1. The stencils for the evolution point at $x_{i-\alpha,j-\alpha}$ are obtained by a rotation of 180 degrees of the stencils in Figures 3.2–3.3.

2. We could use fewer than four stencils and still generate a scheme that will have the desired order of accuracy.

Given the four six-point stencils in Figure 3.3, a straightforward computation shows that third-order approximations for smooth φ at the evolution points $x_{i\pm\alpha,j\pm\alpha}$, $\varphi^k_{i\pm\alpha,j\pm\alpha} = \varphi\left(x_{i\pm\alpha}, y_{j\pm\alpha}\right) + O(\Delta x^3, \Delta y^3)\ \forall k \in \{1,2,3,4\}$ are obtained with

$$\varphi^1_{i\pm\alpha,j\pm\alpha} = a_1\varphi_{i,j} + a_2\varphi_{i\pm1,j} + a_2\varphi_{i,j\pm1} + a_3\varphi_{i\pm1,j\pm1} + a_4\varphi_{i\pm2,j} + a_4\varphi_{i,j\pm2}, \tag{3.4}$$

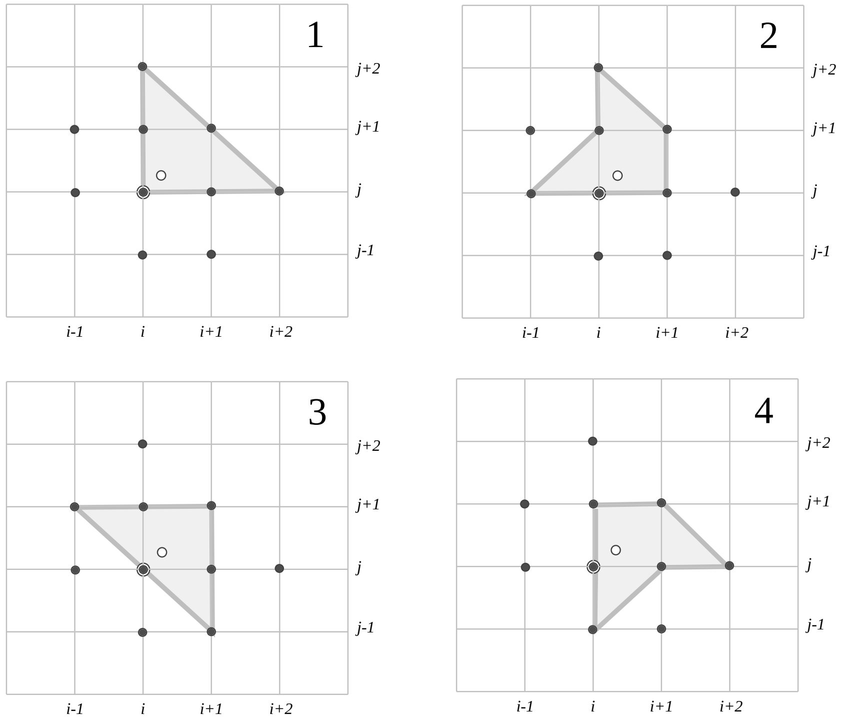

FIG. 3.3. *The four six-point stencils that cover the ten-point stencil for the two-dimensional reconstruction.*

$$\varphi^2_{i\pm\alpha,j\pm\alpha} = a_5\varphi_{i,j} + a_6\varphi_{i\pm1,j} + a_2\varphi_{i,j\pm1} + a_3\varphi_{i\pm1,j\pm1} + a_4\varphi_{i,j\pm2} + a_4\varphi_{i\mp1,j},$$
$$\varphi^3_{i\pm\alpha,j\pm\alpha} = a_7\varphi_{i,j} + a_2\varphi_{i\pm1,j} + a_2\varphi_{i,j\pm1} + a_8\varphi_{i\pm1,j\pm1} + a_4\varphi_{i\pm1,j\mp1} + a_4\varphi_{i\mp1,j\pm1},$$
$$\varphi^4_{i\pm\alpha,j\pm\alpha} = a_5\varphi_{i,j} + a_2\varphi_{i\pm1,j} + a_6\varphi_{i,j\pm1} + a_3\varphi_{i\pm1,j\pm1} + a_4\varphi_{i\pm2,j} + a_4\varphi_{i,j\mp1},$$

where

$$\begin{aligned} &a_1 = 1 - 3\alpha + 2\alpha^2, && a_2 = 2\alpha - 2\alpha^2, && a_3 = \alpha^2, \\ &a_4 = -\frac{1}{2}\alpha + \frac{1}{2}\alpha^2, && a_5 = 1 - \frac{3}{2}\alpha + \frac{1}{2}\alpha^2, && a_6 = \frac{1}{2}\alpha - \frac{1}{2}\alpha^2, \\ &a_7 = 1 - 2\alpha + \alpha^2, && a_8 = -\alpha + 2\alpha^2. \end{aligned} \tag{3.5}$$

The linear combination

$$\sum_{k=1}^{4} c_k \varphi^k_{i\pm\alpha,j\pm\alpha} = \varphi\left(x_{i\pm\alpha}, y_{j\pm\alpha}\right) + O\left(\Delta x^4, \Delta y^4\right)$$

is fourth-order accurate, provided that the constants c_i are taken as

$$c_1 = \frac{1}{3}\left(5\alpha - 1\right), \quad c_2 = c_4 = \frac{2}{3}\left(-2\alpha + 1\right), \quad c_3 = \alpha. \tag{3.6}$$

A two-dimensional CWENO reconstruction is a straightforward generalization of the one-dimensional case (compare with (2.7), (2.8)):

$$\varphi_{i\pm\alpha,j\pm\alpha} = \sum_{k=1}^{4} w^k_{i\pm\alpha,j\pm\alpha}\varphi^k_{i\pm\alpha,j\pm\alpha}.$$

Here

$$w^k_{i\pm\alpha,j\pm\alpha} = \frac{\alpha^k_{i\pm\alpha,j\pm\alpha}}{\sum_{l=1}^{4}\alpha^l_{i\pm\alpha,j\pm\alpha}}, \qquad \alpha^k_{i\pm\alpha,j\pm\alpha} = \frac{c_k}{\left(\epsilon + S^k_{i\pm\alpha,j\pm\alpha}\right)^p},$$

with the constants c_k given by (3.6). As usual, the smoothness measure for every stencil is taken as a normalized sum of the discrete L^2-norms of the derivatives. If we define the forward and backward differences $\Delta_x^+\varphi_{i,j} = \varphi_{i+1,j} - \varphi_{i,j}$, $\Delta_x^-\varphi_{i,j} = \varphi_{i,j} - \varphi_{i-1,j}$, $\Delta_y^+\varphi_{i,j} = \varphi_{i,j+1} - \varphi_{i,j}$, $\Delta_y^-\varphi_{i,j} = \varphi_{i,j} - \varphi_{i,j-1}$, then the smoothness measures for the evolution point $x_{i+\alpha,j+\alpha}$ are given by

$$\begin{aligned}
S^1_{i+\alpha,j+\alpha} &= \left(\Delta_x^+\varphi_{i,j}\right)^2 + \left(\Delta_x^+\varphi_{i+1,j}\right)^2 + \left(\Delta_x^+\varphi_{i,j+1}\right)^2 + \left(\Delta_y^+\varphi_{i,j}\right)^2 + \left(\Delta_y^+\varphi_{i,j+1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i+1,j}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i+1,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j+1}\right)^2\right], \\
S^2_{i+\alpha,j+\alpha} &= \left(\Delta_x^+\varphi_{i,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j}\right)^2 + \left(\Delta_x^+\varphi_{i,j+1}\right)^2 + \left(\Delta_y^+\varphi_{i,j}\right)^2 + \left(\Delta_y^+\varphi_{i,j+1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i+1,j}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j+1}\right)^2\right], \\
S^3_{i+\alpha,j+\alpha} &= \left(\Delta_x^+\varphi_{i,j}\right)^2 + \left(\Delta_x^+\varphi_{i,j+1}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j+1}\right)^2 + \left(\Delta_y^+\varphi_{i,j}\right)^2 + \left(\Delta_y^+\varphi_{i+1,j}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i+1,j-1}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i,j+1}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i+1,j}\right)^2\right], \\
S^4_{i+\alpha,j+\alpha} &= \left(\Delta_x^+\varphi_{i,j}\right)^2 + \left(\Delta_x^+\varphi_{i+1,j}\right)^2 + \left(\Delta_x^+\varphi_{i,j+1}\right)^2 + \left(\Delta_y^+\varphi_{i,j}\right)^2 + \left(\Delta_y^+\varphi_{i,j-1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i+1,j}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i+1,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j}\right)^2\right].
\end{aligned}$$

The smoothness measures for the evolution point $x_{i-\alpha,j-\alpha}$ are

$$\begin{aligned}
S^1_{i-\alpha,j-\alpha} &= \left(\Delta_x^+\varphi_{i-2,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j-1}\right)^2 + \left(\Delta_y^+\varphi_{i,j-2}\right)^2 + \left(\Delta_y^+\varphi_{i,j-1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i-1,j-1}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i-1,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j-1}\right)^2\right], \\
S^2_{i-\alpha,j-\alpha} &= \left(\Delta_x^+\varphi_{i,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j-1}\right)^2 + \left(\Delta_y^+\varphi_{i-1,j}\right)^2 + \left(\Delta_y^+\varphi_{i-1,j-1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i,j-2}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j-1}\right)^2\right], \\
S^3_{i-\alpha,j-\alpha} &= \left(\Delta_x^+\varphi_{i-1,j}\right)^2 + \left(\Delta_x^+\varphi_{i,j-1}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j-1}\right)^2 + \left(\Delta_y^+\varphi_{i,j-1}\right)^2 + \left(\Delta_y^+\varphi_{i-1,j}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i-1,j-1}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i,j-1}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i-1,j}\right)^2\right], \\
S^4_{i-\alpha,j-\alpha} &= \left(\Delta_x^+\varphi_{i-2,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j}\right)^2 + \left(\Delta_x^+\varphi_{i-1,j-1}\right)^2 + \left(\Delta_y^+\varphi_{i,j}\right)^2 + \left(\Delta_y^+\varphi_{i,j-1}\right)^2 \\
&\quad + \left(\Delta_y^+\varphi_{i-1,j-1}\right)^2 + \frac{1}{\Delta x^2}\left[\left(\Delta_x^+\Delta_x^-\varphi_{i-1,j}\right)^2 + \left(\Delta_y^+\Delta_y^-\varphi_{i,j}\right)^2\right].
\end{aligned}$$

FIG. 3.4. *The dimension-by-dimension reconstruction process in two dimensions. Left: the first step, where the intermediate interpolants $\varphi_{i+\alpha,j}$ at $x_{i+\alpha,j}$ (open squares) are computed using the data $\varphi_{i,j}$ (black dots). Right: the second step, where $\varphi_{i+\alpha,j}$ is interpolated in the j direction, giving $\varphi_{i+\alpha,j+\alpha}$ at $x_{i+\alpha,j+\alpha}$ (open circle).*

3.2.2. A dimension-by-dimension reconstruction of $\varphi_{i\pm\alpha,j\pm\alpha}$. A different way to obtain high-order approximations for the values of $\varphi_{i\pm\alpha,j\pm\alpha}$ is by carrying out a sequence of one-dimensional reconstructions from section 2.2. This dimension-by-dimension approach for the reconstruction step is similar in spirit to that of [17], but here, in order to generate a Godunov-type scheme (unlike [17]), we are forced to use evolution points that are not positioned in the same locations as the data $x_{i,j}$. An appropriately chosen sequence of one-dimensional reconstructions addresses this problem.

We use the subscript "$*$" to denote the full range of an array, such that $\varphi_{*,j}$ and $\varphi_{i,*}$ denote the one-dimensional arrays $\varphi_{*,j} = (\varphi_{1,j}, \dots, \varphi_{N,j})$ and $\varphi_{i,*} = (\varphi_{i,1}, \dots, \varphi_{i,N})$. With the notation for the one-dimensional third-order reconstruction, (2.10), we can express the dimension-by-dimension reconstruction at $x_{i+\alpha,j+\alpha}$ as

1. for each i, j: $\varphi_{i+\alpha,j} = \text{reconstruct\_}\varphi\text{\_1D\_3}\,(i, \alpha, \varphi_{*,j})$;
2. for each i, j: $\varphi_{i+\alpha,j+\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_3}\,(j, \alpha, \varphi_{i+\alpha,*})$.

Here, we first interpolate along the first coordinate axis and reconstruct φ at $x_{i+\alpha,j}$. The data at $x_{i+\alpha,j}$ is then interpolated along the second coordinate axis to the location $x_{i+\alpha,j+\alpha}$ to give $\varphi_{i+\alpha,j+\alpha}$ (see Figure 3.4). Obviously, the order in which the steps are performed is not important. In a similar way, a dimension-by-dimension reconstruction at $x_{i-\alpha,j-\alpha}$ is given by

1. for each i, j: $\varphi_{i-\alpha,j} = \text{reconstruct\_}\varphi\text{\_1D\_3}\,(i, -\alpha, \varphi_{*,j})$;
2. for each i, j: $\varphi_{i-\alpha,j-\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_3}\,(j, -\alpha, \varphi_{i-\alpha,*})$.

3.2.3. The reprojection step. After evolving the solution to the next time step at the evolution points $x_{i\pm\alpha,j\pm\alpha}$, we would like to reproject $\varphi^{n+1}_{i+\alpha,j+\alpha}$ back onto the integer grid-points $x_{i,j}$ to end up with $\varphi^{n+1}_{i,j}$. There are several different ways to perform this task, out of which we choose to present the following: a two-dimensional reprojection using the two-dimensional reconstruction of section 3.2.1 or the dimension-by-dimension reconstruction of section 3.2.2, and a one-dimensional projection along the diagonal.

I. *A 2D reprojection.* The evolution points at $x_{i\pm\alpha,j\pm\alpha}$ have the same geometrical relationship to $x_{i,j}$ as $x_{i,j}$ has to $x_{i-\alpha,j-\alpha}$. Hence, in order to reconstruct $\varphi^{n+1}_{i,j}$ from $\varphi_{i\pm\alpha,j\pm\alpha}$, we can directly utilize the projections from section 3.2.1 or section 3.2.2,

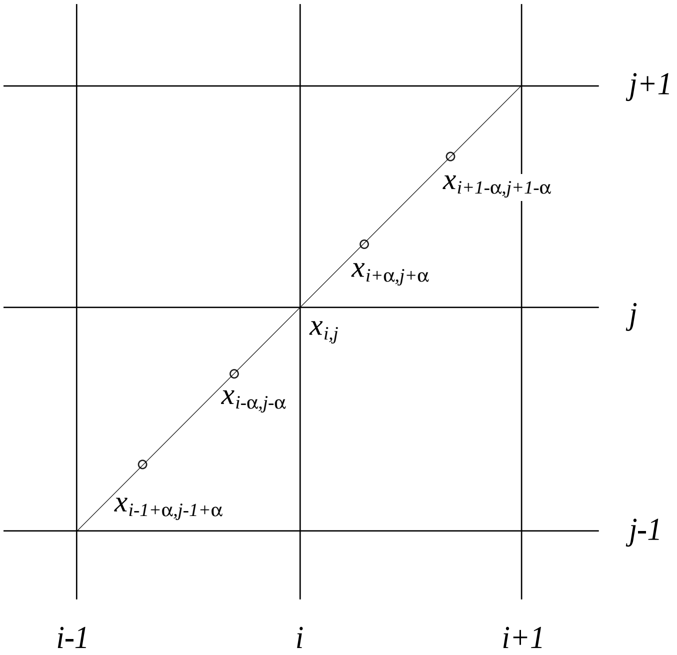

FIG. 3.5. *The evolution points used for the diagonal reconstruction of* $\varphi_{i,j}$.

taking $\varphi_{i\pm\alpha,j\pm\alpha}$ as the input data and reversing the sign of the parameter from $\pm\alpha$ to $\mp\alpha$. The final value $\varphi^{n+1}_{i,j}$ is then taken as the average of the projections of $\varphi_{i+\alpha,j+\alpha}$ and $\varphi_{i-\alpha,j-\alpha}$. Hence, if we denote either the two-dimensional or the dimension-by-dimension reconstruction described in section 3.2.1 or section 3.2.2 as

$$\varphi_{i\pm\alpha,j\pm\alpha} = \text{reconstruct\_}\varphi\text{\_2D\_3}\left(i, j, \pm\alpha, \varphi\right), \tag{3.7}$$

where φ is now the two-dimensional array $\{\varphi_{i,j}\}$, then the reprojection step is

(i) for each i, j: $\varphi^{+}_{i,j} = \text{reconstruct\_}\varphi\text{\_2D\_3}\left(i, -\alpha, \varphi_{i+\alpha,j+\alpha}\right)$;

(ii) for each i, j: $\varphi^{-}_{i,j} = \text{reconstruct\_}\varphi\text{\_2D\_3}\left(i, \alpha, \varphi_{i-\alpha,j-\alpha}\right)$;

(iii) for each i, j: $\varphi^{n+1}_{i,j} = \frac{1}{2}(\varphi^{+}_{i,j} + \varphi^{-}_{i,j})$.

II. *A diagonal reprojection.* In this case we use one-dimensional data along the diagonal, $\{\varphi_{i-1+\alpha,j-1+\alpha}, \varphi_{i-\alpha,j-\alpha}, \varphi_{i+\alpha,j+\alpha}, \varphi_{i+1-\alpha,j+1-\alpha}\}$, to construct a third-order WENO approximation of $\varphi^{n+1}_{i,j}$ (see Figure 3.5).

Define

$$\begin{aligned} \varphi^{-}_{i,j} &:= \frac{\alpha^2}{2\alpha-1}\varphi_{i-1+\alpha,j-1+\alpha} + \frac{\alpha-1}{2(2\alpha-1)}\varphi_{i-\alpha,j-\alpha} \\ &\quad + \frac{1-\alpha}{2}\varphi_{i+\alpha,j+\alpha} = \varphi\left(x_{i,j}\right) + O\left(\Delta x^3, \Delta y^3\right), \\ \varphi^{+}_{i,j} &:= \frac{1-\alpha}{2}\varphi_{i-\alpha,j-\alpha} + \frac{\alpha-1}{2(2\alpha-1)}\varphi_{i+\alpha,j+\alpha} \\ &\quad + \frac{\alpha^2}{2\alpha-1}\varphi_{i+1-\alpha,j+1-\alpha} = \varphi\left(x_{i,j}\right) + O\left(\Delta x^3, \Delta y^3\right). \end{aligned} \tag{3.8}$$

Since $(\varphi^-_{i,j} + \varphi^+_{i,j})/2 = \varphi(x_{i,j}) + O(\Delta x^4, \Delta y^4)$, we can obtain $\varphi^{n+1}_{i,j}$ as

$$\varphi^{n+1}_{i,j} = w^-_{i,j}\varphi^-_{i,j} + w^+_{i,j}\varphi^+_{i,j}, \tag{3.9}$$

where as usual $w^\pm_{i,j} = \alpha^\pm_{i,j}/(\alpha^+_{i,j} + \alpha^-_{i,j})$ and $\alpha^\pm_{i,j} = (2(\epsilon + S^\pm_{i,j})^p)^{-1}$. The smoothness measures are again taken as the sum of the discrete L^2-norm of the derivatives, which in this case is more complicated due to the uneven spacing of the data:

$$S^-_{i,j} = \frac{1}{\Delta x}\left[\left(\frac{\varphi_{i-\alpha,j-\alpha} - \varphi_{i-1+\alpha,j-1+\alpha}}{1-2\alpha}\right)^2 + \left(\frac{\varphi_{i+\alpha,j+\alpha} - \varphi_{i-\alpha,j-\alpha}}{2\alpha}\right)^2\right]$$
$$+ \frac{4}{\Delta x^3}\left(\frac{\varphi_{i-\alpha,j-\alpha} - \varphi_{i-1+\alpha,j-1+\alpha}}{1-2\alpha} - \frac{\varphi_{i+\alpha,j+\alpha} - \varphi_{i-\alpha,j-\alpha}}{2\alpha}\right)^2,$$

$$S^+_{i,j} = \frac{1}{\Delta x}\left[\left(\frac{\varphi_{i+\alpha,j+\alpha} - \varphi_{i-\alpha,j-\alpha}}{2\alpha}\right)^2 + \left(\frac{\varphi_{i+1-\alpha,j+1-\alpha} - \varphi_{i+\alpha,j+\alpha}}{1-2\alpha}\right)^2\right]$$
$$+ \frac{4}{\Delta x^3}\left(\frac{\varphi_{i+\alpha,j+\alpha} - \varphi_{i-\alpha,j-\alpha}}{2\alpha} - \frac{\varphi_{i+1-\alpha,j+1-\alpha} - \varphi_{i+\alpha,j+\alpha}}{1-2\alpha}\right)^2.$$

Remark. Our numerical simulations in section 4.3 indicate that there is little difference between the quality of the two-dimensional reconstruction and the dimension-by-dimension reconstruction of sections 3.2.1 and 3.2.2. We will use this fact when extending our methods to fifth order and higher dimensions. We note that the diagonal reprojection significantly reduces the CFL number (see section 4.4).

3.3. A two-dimensional fifth-order scheme.

Using the dimension-by-dimension approach, it is easy to extend the above scheme to fifth order: simply replace the one-dimensional third-order interpolations by the fifth-order interpolation in section 3.2.2. Using the one-dimensional notation, (2.19), we obtain a fifth-order reconstruction at $x_{i+\alpha,j+\alpha}$ as

1. for each i,j: $\varphi_{i+\alpha,j} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(i,\alpha,\varphi_{*,j})\,;$
2. for each i,j: $\varphi_{i+\alpha,j+\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(j,\alpha,\varphi_{i+\alpha,*})$.

Similarly, at $x_{i-\alpha,j-\alpha}$ we have

1. for each i,j: $\varphi_{i-\alpha,j} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(i,-\alpha,\varphi_{*,j})\,;$
2. for each i,j: $\varphi_{i-\alpha,j-\alpha} = \text{reconstruct\_}\varphi\text{\_1D\_5}\,(j,-\alpha,\varphi_{i-\alpha,*})$.

We denote this reconstruction as

$$\varphi_{i\pm\alpha,j\pm\alpha} = \text{reconstruct\_}\varphi\text{\_2D\_5}\,(i,j,\pm\alpha,\varphi)\,. \tag{3.10}$$

For the derivatives we have

1. for each i,j: $\varphi'_{i\pm\alpha,j} = \text{reconstruct\_}\varphi'\text{\_1D\_5}\,(i,\pm\alpha,\varphi_{*,j})$,
2. for each i,j: $\varphi'_{i\pm\alpha,j\pm\alpha} = \text{reconstruct\_}\varphi'\text{\_1D\_5}\,(j,\pm\alpha,\varphi_{i\pm\alpha,*})$,

which we denote as

$$\varphi'_{i\pm\alpha,j\pm\alpha} = \text{reconstruct\_}\varphi'\text{\_2D\_5}\,(i,j,\pm\alpha,\varphi)\,. \tag{3.11}$$

Reprojection onto the original grid-points $x_{i,j}$ is performed using the two-dimensional dimension-by-dimension reprojection option described in section 3.2.3.

Remarks.

1. Due to the reduced stability resulting from the use of diagonal reprojection, which is demonstrated in section 4.4, we do not develop a fifth-order analogue to the third-order diagonal reprojection.

2. It is straightforward to develop a fifth-order two-dimensional method involving two-dimensional stencils, extending section 3.2.1. Such a method would involve four interpolants defined on ten-point stencils that cover a 21-point stencil.

We summarize the two-dimensional fifth-order algorithm in the following, where $\mathrm{RK}(\varphi^n_{i\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha}, \Delta t)$ is now the fourth-order RK method which integrates (2.1). As in Algorithm 2.1, each internal step of the RK method will require additional reconstructions of $\varphi'_{i\pm\alpha}$ from that step's $\varphi_{i\pm\alpha}$.

ALGORITHM 3.1. *Let $\alpha = 1/(2+\sqrt{2})$. Assume that $\{\varphi^n_{i,j}\}$ are given.*

(a) *Reconstruct:*

$$\begin{aligned}\varphi_{i\pm\alpha,j\pm\alpha} &= \text{reconstruct\_}\varphi\text{\_2D\_5}\,(i,j,\pm\alpha,\varphi)\,,\\ \varphi'^{\,n}_{i\pm\alpha,j\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_2D\_5}\,(i,j,\pm\alpha,\varphi)\,.\end{aligned}$$

(b) *Integrate:*

$$\begin{aligned}\varphi^{n+\frac{1}{2}}_{i\pm\alpha,j\pm\alpha} &= RK\left(\varphi^n_{i\pm\alpha,j\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha,j\pm\alpha}, \Delta t/2\right),\\ \varphi'^{\,n+\frac{1}{2}}_{i\pm\alpha,j\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_2D\_5}(i,\pm\alpha,\varphi^{n+\frac{1}{2}}_{\pm\alpha,\pm\alpha}),\\ \varphi^{n+1}_{i\pm\alpha,j\pm\alpha} &= RK\left(\varphi^n_{i\pm\alpha,j\pm\alpha}, \varphi'^{\,n}_{i\pm\alpha,j\pm\alpha}, \Delta t\right),\\ \varphi'^{\,n+1}_{i\pm\alpha,j\pm\alpha} &= \text{reconstruct\_}\varphi'\text{\_2D\_5}\left(i,\pm\alpha,\varphi^{n+1}_{\pm\alpha,\pm\alpha}\right),\\ \varphi^{n+1}_{i\pm\alpha,j\pm\alpha} &= \varphi^n_{i\pm\alpha,j\pm\alpha} + \frac{\Delta t}{6}\left[H\left(\varphi'^{\,n}_{i\pm\alpha,j\pm\alpha}\right) + 4H(\varphi'^{\,n+\frac{1}{2}}_{i\pm\alpha,j\pm\alpha}) + H\left(\varphi'^{\,n+1}_{i\pm\alpha,j\pm\alpha}\right)\right].\end{aligned}$$

(c) *Reproject:*

$$\varphi^{n+1}_{i,j} = \text{reconstruct\_}\varphi\text{\_2D\_5}\left(i,j,\mp\alpha,\varphi^{n+1}_{\pm\alpha,\pm\alpha}\right).$$

3.4. Multidimensional extensions.

The extension of the dimension-by-dimension approach to more than two space dimensions is straightforward. For example, using the notation of section 3.3, a three-dimensional fifth-order reconstruction is
