BOUNDARY CONCENTRATED FINITE ELEMENT METHODS*

B. N. KHOROMSKIJ[†] AND J. M. MELENK[†]

Abstract. A method with optimal (up to logarithmic terms) complexity for solving elliptic problems is proposed. The method relies on interior regularity, but the solution may have globally low regularity due to rough boundary data or geometries. Elliptic regularity results, high order approximation results, and an efficient preconditioner are presented.

The method is utilized to realize, with linear-logarithmic complexity, an accurate and data-sparse approximation to the associated elliptic Poincaré–Steklov operators. Further applications include the treatment of exterior boundary value problems and the solution of problems in the framework of domain decomposition methods.

Key words. *hp*-finite element methods, preconditioning, data-sparse approximation to Poincaré–Steklov operator, meshes refined toward boundary

1. Introduction.

In this paper, we present the *boundary concentrated finite element method*. This method is designed to solve numerically elliptic boundary value problems with low global Sobolev regularity. The coefficients of the underlying PDE, however, are assumed to be smooth so that, owing to interior elliptic regularity, the low global Sobolev regularity is due to boundary effects such as low-regularity boundary data or geometries. The key idea of the method is to exploit this interior regularity in the framework of the *hp*-version of the finite element method (*hp*-FEM) by using low order elements on refined meshes near the boundary and high order polynomials on large elements in the interior of the domain. The combination of mesh refinement near the boundary and polynomial degree distribution proposed in this paper concentrates most degrees of freedom in a narrow neighborhood of the boundary, which explains the name boundary concentrated FEM.

Since the boundary concentrated FEM may be viewed as a generalization of the boundary element method (BEM), we illustrate its most important properties by a side-by-side comparison with the classical BEM. In the BEM (see, e.g., [18] for an introduction to the topic), an elliptic boundary value problem on a domain $\Omega \subset \mathbb{R}^d$ is reduced to a problem posed on the boundary $\partial\Omega$, thereby effecting a dimensional reduction. This dimensional reduction immediately leads to a reduction of the problem size of the discrete problems. In the present paper, we show that from the "error vs. degrees of freedom" perspective, the boundary concentrated FEM achieves the same rate of convergence as the classical, low order Galerkin h-BEMs that are formulated on quasi-uniform boundary triangulations. In this respect, therefore, the boundary concentrated FEM is comparable to the classical BEM. However, it represents a generalization of the BEM, in that it can be formulated for equations with variable (albeit piecewise analytic) coefficients, while the BEM is effectively restricted to equations with constant coefficients because explicit knowledge of a fundamental solution is required.

A second difference between the classical BEM and the boundary concentrated FEM manifests itself in the structure of the resulting linear system of equations. The boundary concentrated FEM, being an FEM, naturally leads to sparse stiffness matrices. In contrast, the stiffness matrix in BEM is in general fully populated. We mention, however, that this drawback of the classical BEM has been successfully overcome in recent years by various compression schemes, notably the panel clustering techniques [21], multipole expansions (see the survey [14] and the references therein), and wavelet compression methods [12]. A generalization of the clustering techniques are the recently introduced $\mathcal{H}$-matrices [19, 20].

A further interesting point of comparison is the cost of setting up and solving the linear system. We show in this paper that the stiffness matrix of the boundary concentrated FEM can be computed with optimal complexity $O(N)$, where N is the problem size. The classical BEM, which, as we mentioned above, achieves a comparable accuracy with the same number of degrees of freedom N, requires $O(N^2)$ operations to set up the linear system due to the fact that the stiffness matrix is fully populated. Again, only recent progress in compression schemes for the BEM has led to methods with complexity $O(N \log^q N)$ for suitable $q \in \mathbb{N}_0$.

Another important observation is that our technique leads to the accurate and data-sparse approximation of complexity $O(N \log N)$ to Poincaré–Steklov operators associated with elliptic equations with variable coefficients. This generalizes previously known methods for equations with piecewise constant coefficients in polygonal domains such as [24, 27, 28, 25].

In this paper we present a complete theory in the two-dimensional setting. Many results, however, have analogues in higher dimensions. In particular, the regularity assertion (Theorem 1.4) and *hp*-approximation results on shape-regular meshes (Theorem 2.13) can be extended in a straightforward way to three dimensions. Preconditioning techniques for *hp*-FEM/*hp*-BEM in three dimensions have recently been proposed [1, 16, 38], and we expect that these ideas can be employed for the successful development of preconditioners for the boundary concentrated FEM in three dimensions.

The paper is organized as follows. We start with a formulation of the model problem and provide analytic regularity results for the solution. In section 2, we present convergence results for the *hp*-FEM applied to the model problem and show that the method yields the same optimal convergence rate as the *h*-BEM on quasi-uniform meshes. In section 3, we address the question of efficiently solving the resulting linear system. For Dirichlet problems we show that the condition number of the linear system grows only polylogarithmically with the problem size. For Neumann problems, we exhibit a block-diagonal preconditioner such that the condition number of the preconditioned system grows again polylogarithmically. We show in section 4 how the boundary concentrated FEM can be employed to realize an application of the Poincaré–Steklov operator with linear-logarithmic complexity with respect to the boundary degrees of freedom (both in operation count and memory requirement). So far, for the sake of simplicity, our discussion has been mainly restricted to interior problems with analytic coefficients. However, the boundary concentrated FEM can also be employed for exterior problems and domain decomposition problems (piecewise smooth data with respect to a regular geometric decomposition); these applications are briefly addressed in section 5. Numerical experiments in section 6 illustrate the theoretical results of sections 2 and 3.

1.1. Notation. For a Lipschitz domain $\Omega \subset \mathbb{R}^2$, the Sobolev spaces $H^k(\Omega)$, $H^k_0(\Omega)$, $k \in \mathbb{N}_0$, are defined in the standard way. Fractional order Sobolev spaces $H^s(\Omega)$ are defined by interpolation (the real method) between integer order Sobolev spaces. Negative order spaces such as $H^{-1}(\Omega)$ are defined by duality: $H^{-s}(\Omega) = (H^s_0(\Omega))'$. Spaces on the boundary $\partial\Omega$ are defined in the usual way:

$$H^s(\partial\Omega) = \begin{cases} \{u|_{\partial\Omega} \,|\, u \in H^{s+1/2}(\Omega)\} & \text{if } s > 0, \\ L^2(\partial\Omega) & \text{if } s = 0, \\ (H^{-s}(\partial\Omega))' & \text{if } s < 0. \end{cases}$$

We mention at this point the important fact that, for *polygonal domains* Ω, the spaces $H^s(\partial\Omega)$, $|s| < 3/2$, are invariant under piecewise smooth changes of parametrization of $\partial\Omega$. In particular, the parametrization $\varphi : [0, L) \to \partial\Omega$ by arc length provides an isomorphism $u \mapsto u \circ \varphi$ from $H^s(\partial\Omega)$ to $H^s_{per}([0, L))$ for $|s| < 3/2$. Here, for $s > 0$ we set $H^s_{per}([0, L)) := \{u \in H^s(\mathbb{R}) \,|\, u \text{ is } L\text{-periodic}\}$ with the corresponding topology and $H^{-s}_{per}([0, L)) = (H^s_{per}([0, L)))'$ for $s < 0$.

Duality pairings will be denoted by $\langle \cdot, \cdot \rangle$, with subscripts indicating the spaces with respect to which the pairing is taken. Since the spaces $H^{1/2}(\partial\Omega)$, $H^{-1/2}(\partial\Omega)$ arise frequently in this paper, we abbreviate

$$Y := H^{1/2}(\partial\Omega), \qquad Y' := H^{-1/2}(\partial\Omega). \tag{1.1}$$

1.2. Problem class. For simplicity of exposition, we will restrict our attention to problems formulated on polygons, and we will not consider the case of mixed boundary conditions. That is, we consider for a *polygonal* Lipschitz domain $\Omega \subset \mathbb{R}^2$ either the Dirichlet problem

$$\mathcal{L}u = f \in L^2(\Omega) \qquad \text{in } \Omega, \tag{1.2a}$$

$$\gamma_0 u = \lambda \in H^{1/2}(\partial\Omega) \qquad \text{on } \partial\Omega, \tag{1.2b}$$

or the Neumann problem

$$\mathcal{L}u = f \in L^2(\Omega) \qquad \text{in } \Omega, \tag{1.3a}$$

$$\gamma_1 u = \psi \in H^{-1/2}(\partial\Omega) \qquad \text{on } \partial\Omega. \tag{1.3b}$$

Here, the differential operator $\mathcal{L}$ is given by

$$\mathcal{L}u := -\nabla \cdot (A\nabla u) + b \cdot \nabla u + a_0 u, \tag{1.4}$$

with uniformly (in $x \in \overline{\Omega}$) symmetric positive definite matrix $A = (a_{ij})^2_{i,j=1}$; the vector-valued function b and the scalar-valued function a_0 are assumed to be analytic on $\overline{\Omega}$. The operator γ_0 is the trace operator $\gamma_0 : H^1(\Omega) \to H^{1/2}(\partial\Omega)$, and $\gamma_1 := \sum_{i,j=1}^2 n_i a_{ij} \partial_j$ is the conormal derivative operator. We assume that the operator $\mathcal{L}$ generates an $H^1(\Omega)$-elliptic bilinear form

$$B(u, v) = \int_\Omega \sum_{i,j=1}^2 a_{ij} \partial_j u \partial_i v + \sum_{i=1}^2 b_i \partial_i u v + a_0 u v \, dx, \tag{1.5}$$

i.e.,

$$c_0 \|u\|^2_{1,\Omega} \leq B(u, u) \leq c_1 \|u\|^2_{1,\Omega} \qquad \forall u \in V, \tag{1.6}$$

where we introduced the space $V \subset H^1(\Omega)$ in the standard way as

$$V := \begin{cases} H_0^1(\Omega) & \text{if the Dirichlet problem (1.2) is considered,} \\ H^1(\Omega) & \text{if the Neumann problem (1.3) is considered.} \end{cases} \tag{1.7}$$

The boundary value problems (1.2), (1.3) are understood in the usual, variational sense. Solving (1.2) is equivalent to

$$\text{Find } u \in H^1(\Omega) \text{ with } \gamma_0 u = \lambda \text{ and } B(u,v) = \int_\Omega f\, v\, dx \qquad \forall v \in H_0^1(\Omega). \tag{1.8}$$

Solving (1.3) reads as

$$\text{Find } u \in H^1(\Omega) \text{ s.t. } B(u,v) = \int_\Omega f\, v\, dx + \langle \psi, \gamma_0 v \rangle_{Y' \times Y} \qquad \forall v \in H^1(\Omega). \tag{1.9}$$

1.3. Assumptions on the data. In this paper we make the following assumptions on the data:

$$\text{The coefficients } A,\ b,\ a_0 \text{ and the right-hand side } f \text{ are analytic on } \overline{\Omega} \text{ and the solution } u \in H^{1+\delta}(\Omega) \text{ for some } \delta \in (0,1]. \tag{1.10}$$

Such a situation arises, for example, if the boundary data λ, ψ are not smooth and/or if the domain Ω is merely a Lipschitz domain.

The problem class under consideration may be viewed as a generalization of the setting of the classical BEM in that, while the boundary input data are allowed to be rough, the coefficients of the differential equation are smooth on Ω. The particular case of constant coefficients and homogeneous right-hand side, which is the setting of the BEM, is a special case.

Remark 1.1. The boundary concentrated FEM could also be adapted to the case of piecewise analytic coefficients A, b, a_0 and right-hand side f; see also section 5.3.

Remark 1.2. Methodologically, the analysis of the present paper is closely related to the classical *hp*-FEM [40, 42]. In the classical *hp*-FEM, stronger regularity assumptions are made, namely, piecewise analyticity of the boundary $\partial\Omega$, and the boundary data λ, ψ is stipulated. These stronger regularity assumptions imply stronger regularity results for the solution u. In the classical *hp*-FEM, these stronger regularity assertions for u are exploited to design exponentially convergent methods by using meshes that are graded geometrically towards few singularities located at the boundary. Our weaker regularity assumptions (1.10) require geometric refinement towards the whole boundary and lead to algebraic rates of convergence only. Nevertheless, the algebraic rates obtained in this paper are optimal (in the sense of n-widths) for the class of problems characterized by the regularity assumptions (1.10).

Remark 1.3. Our regularity assumption (1.10) makes strong smoothness assumptions on the right-hand side f. However, the techniques presented in this paper could be employed for methods for solving

$$\mathcal{L}u = f, \qquad \gamma_1 u = \psi,$$

with $f \in H^{-1+\delta}(\Omega)$ and $u \in H^{1+\delta}(\Omega)$, $\delta \in (0,1/2)$. In that case, let $u_0 \in H_0^{1+\delta}(\Omega)$ be the particular solution of $\mathcal{L}u = f$ in Ω solving

$$B(u_0, v) = \int_\Omega f(x) v dx \qquad \forall v \in H_0^1(\Omega). \tag{1.11}$$

For the remaining $\mathcal{L}$-harmonic component of the solution $u_H = u - u_0 \in V_H$, where

$$V_H = \{v \in V : B(v,z) = 0 \quad \forall z \in H^1_0(\Omega)\}, \tag{1.12}$$

we have the equation

$$B(u_H, v) = \int_{\partial\Omega} \psi v ds + \langle \gamma_1 u_0, v\rangle_{H^{-1/2}(\partial\Omega)\times H^{1/2}(\partial\Omega)} \qquad \forall v \in H^1(\Omega) \tag{1.13}$$

and note that u_H solves an equation satisfying the regularity assumptions (1.10). For finite element discretizations, we may use different ansatz spaces to approximate the solutions to (1.11) and (1.13). The only constraint is that these spaces have to provide *the same trace space on* $\partial\Omega$. In particular, we obtain $u = u_0 + u_H$ with $u_0 \in H^{1+\delta}(\Omega)$, $u_H \in \widetilde{\mathcal{B}}^2_{1-\delta}$, where the countably normed space $\widetilde{\mathcal{B}}^2_{1-\delta}$ is defined in (1.17) below.

1.4. Regularity of the solution. The key to efficiently treating (1.2), (1.3) numerically is precise regularity assertions for their solutions. In the case analyzed in the classical *hp*-FEM (see Remark 1.2), the regularity of the solution u is best described in terms of the countably normed spaces $\mathcal{B}^2_\beta$ [4, 5]. This regularity assertion allows for a rigorous proof of exponential convergence of the *hp*-FEM on suitably chosen meshes [40]. We are interested in the case of the weakened regularity assumptions (1.10). That is, we study regularity properties of the solution u to the differential equation

$$\mathcal{L}u = f \qquad \text{on } \Omega, \tag{1.14}$$

where f is analytic on $\overline{\Omega}$; the boundary conditions—of Dirichlet, Neumann, or mixed type—however, may be rough. By standard interior regularity [35, Chapter 5], any solution u to (1.14) is analytic on Ω, but control of higher order derivatives is lost as one approaches the boundary $\partial\Omega$. Nevertheless, it is possible to measure the blow-up of higher order derivatives near the boundary in terms of weighted spaces. A very precise control, which is suitable for the *hp*-FEM error analysis below, is achieved with the countably normed space $\widetilde{\mathcal{B}}^2_\beta$ that we define as follows: For the distance function

$$r(x) := \operatorname{dist}(x, \partial\Omega) \tag{1.15}$$

and $\beta \in [0,1)$ the space $H^2_\beta(\Omega)$ is the completion of $C^\infty(\overline{\Omega})$ under the norm

$$\|u\|^2_{H^2_\beta(\Omega)} := \|u\|^2_{H^1(\Omega)} + \|r^\beta \nabla^2 u\|^2_{L^2(\Omega)}. \tag{1.16}$$

For analytic coefficients in the differential operator $\mathcal{L}$, the regularity of the solutions to (1.14) can be described in terms of countably normed spaces, akin to the spaces $\mathcal{B}^2_\beta(C,\gamma)$ introduced in [4, 5]. Specifically, for C, $\gamma > 0$, $\beta \in [0,1)$ we define $\widetilde{\mathcal{B}}^2_\beta(C,\gamma)$ by

$$\widetilde{\mathcal{B}}^2_\beta(C,\gamma) = \{u \in H^2_\beta(\Omega) \,|\, \|u\|_{H^2_\beta(\Omega)} \le C,\ \|r^{\beta+p}\nabla^{p+2}u\|_{L^2(\Omega)} \le C\gamma^p p!\ \forall p \in \mathbb{N}\}. \tag{1.17}$$

We then have the following result. (See Theorem A.1 for the proof, where in fact the assumptions on the right-hand side f are slightly weaker.)

THEOREM 1.4. *Let Ω be a Lipschitz domain. Let A, b, a_0, f be analytic on $\overline{\Omega}$, and assume that $u \in H^{1+\delta}(\Omega)$, $\delta \in (0,1]$, solves* (1.14). *Then u is analytic on Ω, and there exist C, $\gamma > 0$ depending only on Ω, A, b, a_0, δ, and $\|u\|_{H^{1+\delta}(\Omega)}$ such that*

$$u \in \widetilde{\mathcal{B}}^2_{1-\delta}(C,\gamma).$$

Remark 1.5. An analogous result can be formulated if the data A, b, c, f are piecewise analytic.

It is of interest to state conditions under which a solution u to (1.14) satisfies $u \in H^{1+\delta}(\Omega)$. For example, for a general Lipschitz domain Ω the solution u of the Dirichlet problem (1.2) satisfies the following shift theorem (see [36]):

$$\|u\|_{H^{1+\delta}(\Omega)} \leq C_\delta \left[\|f\|_{H^{-1+\delta}(\Omega)} + \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)}\right], \qquad \delta \in [0, 1/2), \tag{1.18}$$

provided that the right-hand side of (1.18) is finite. Equation (1.18) represents a shift theorem with restriction $\delta \in [0, 1/2)$. Shift theorems where one can shift further (i.e., $\delta \geq 1/2$) are known for piecewise smooth boundaries (e.g., polygons). Using the techniques of [15, 6] shows that for a polygon $\Omega \subset \mathbb{R}^2$ there exists $\delta_0 \in (1/2, 1]$ (depending on Ω and A) such that the solution u of the Dirichlet problem (1.2) satisfies

$$\|u\|_{H^{1+\delta}(\Omega)} \leq C_\delta \left[\|f\|_{H^{-1+\delta}(\Omega)} + \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)}\right], \qquad \delta \in [0, \delta_0). \tag{1.19}$$

We recall further that for convex polygons $\delta_0 = 1$.

2. Discretization by *hp*-FEM.

2.1. Abstract FEM.

2.1.1. Formulation. The FEM is obtained from the weak formulations (1.8), (1.9) by replacing the space V with a finite-dimensional space. For a space $V_N \subset H^1(\Omega)$ the FEM for the Neumann problem (1.9) reads as

$$\text{Find } u_N \in V_N \text{ s.t. } B(u_N, v) = \int_\Omega f\, v\, dx + \langle \psi, \gamma_0 v \rangle_{Y' \times Y} \quad \forall v \in V_N. \tag{2.1}$$

For the Dirichlet problem (1.2), we introduce the space

$$Y_N := V_N|_{\partial\Omega} = \{\gamma_0 v \,|\, v \in V_N\} \subset H^{1/2}(\partial\Omega). \tag{2.2}$$

For an approximation $\lambda_N \in Y_N$ to λ we can then define the FEM for (1.8) as

$$\text{Find } u_N \in V_N \text{ s.t. } u_N = \lambda_N \text{ and } B(u_N, v) = \int_\Omega f\, v\, dx \quad \forall v \in V_N \cap H^1_0(\Omega). \tag{2.3}$$

The coercivity assumption (1.6) ensures existence of the finite element approximation u_N. Furthermore, by Céa's lemma there is $C > 0$ independent of V_N such that

$$\|u - u_N\|_{H^1(\Omega)} \leq C \inf_{v \in V_N} \|u - v\|_{H^1(\Omega)} \tag{2.4}$$

for the solution u_N of (2.1) and

$$\|u - u_N\|_{H^1(\Omega)} \leq C \inf_{\substack{v \in V_N \\ \gamma_0 v = \lambda_N}} \left\{\|u - v\|_{H^1(\Omega)} + \|\lambda_N - \lambda\|_{H^{1/2}(\partial\Omega)}\right\} \tag{2.5}$$

for the solution u_N of the Dirichlet problem (2.3).

In practice, the approximations λ_N are obtained with the aid of a linear operator $P_N : H^{1/2}(\partial\Omega) \to Y_N$ by setting $\lambda_N = P_N\lambda$. In most of the present paper, we will choose this operator P_N to be the L^2-projection Q_N; i.e., for $\lambda \in L^2(\partial\Omega)$ the function $Q_N\lambda$ is defined by

$$\langle Q_N\lambda, v\rangle_{0,\partial\Omega} = \langle \lambda, v\rangle_{0,\partial\Omega} \qquad \forall v \in Y_N. \tag{2.6}$$

2.1.2. Discrete harmonic extension. In this paper, we will consider only families of approximation spaces V_N that are sufficiently large in the following sense: There exists $\widetilde{C} > 0$ such that for all $u \in H^1(\Omega)$ with $u|_{\partial\Omega} \in Y_N$

$$\inf\{\|u - v\|_{H^1(\Omega)} \,|\, v \in V_N \text{ and } v|_{\partial\Omega} = u|_{\partial\Omega}\} \leq \widetilde{C}\|u\|_{H^1(\Omega)}. \tag{2.7}$$

Remark 2.1. Condition (2.7) is satisfied for all approximation spaces considered in this paper. For the standard piecewise linear spaces, condition (2.7) may be verified with the aid of the Clément-type interpolation operator of [41]. For the high order spaces employed in the present paper, the corresponding *hp*-Clément-type interpolation operator is constructed in [34].

Condition (2.7) is required for the discrete harmonic extension to have the following stability properties.

LEMMA 2.2. *Let $\Omega \subset \mathbb{R}^2$ be a Lipschitz domain. Assume that a family of approximation spaces $V_N \subset H^1(\Omega)$ satisfies* (2.7)*. Then there exists $C > 0$ such that the discrete harmonic extension operator $E_N : Y_N \to V_N$ given by*

$$B(E_N u, v) = 0 \qquad \forall v \in V_N \cap H^1_0(\Omega) \tag{2.8}$$

is stable, i.e.,

$$\|E_N u\|_{H^1(\Omega)} \leq C\|u\|_{H^{1/2}(\partial\Omega)} \qquad \forall u \in Y_N.$$

Moreover, the Galerkin orthogonality implies

$$B(z, z) = B(z - E_N(\gamma_0 z), z - E_N(\gamma_0 z)) + B(E_N(\gamma_0 z), E_N(\gamma_0 z)) \qquad \forall z \in V_N.$$

2.2. Geometric meshes and *hp*-FEM spaces.

2.2.1. The geometric mesh. For simplicity of notation, we will restrict our attention to triangulations consisting of *affine triangles*. We emphasize, however, that an extension to quadrilateral elements is possible. The triangulation $\mathcal{T} = \{K\}$ of Ω consists of elements K. Each element K is the image $F_K(\hat{K})$ of the equilateral reference triangle

$$\hat{K} = \left\{(x, y) \,|\, 0 < x < 1,\ 0 < y < \sqrt{3}\left(\frac{1}{2} - \left|x - \frac{1}{2}\right|\right)\right\}$$

under the *affine* map F_K. We furthermore assume that the triangulation $\mathcal{T}$ is γ-*shape-regular*, i.e.,

$$h_K^{-1}\|F'_K\|_{L^\infty(T)} + h_K\|(F'_K)^{-1}\|_{L^\infty(T)} \leq \gamma \qquad \forall K \in \mathcal{T}. \tag{2.9}$$

Here, h_K denotes the diameter of the element K. Of particular importance to us will be the "geometric meshes," which are strongly refined meshes near the boundary $\partial\Omega$, defined as follows.

DEFINITION 2.3 (geometric mesh). *A γ-shape-regular (cf.* (2.9)*) mesh $\mathcal{T}$ is called a* geometric mesh *with* boundary mesh size h *if there exist c_1, $c_2 > 0$ such that for all $K \in \mathcal{T}$ the following hold:*

1. *If $\overline{K} \cap \partial\Omega \neq \emptyset$, then $h \leq h_K \leq c_2 h$;*
2. *if $\overline{K} \cap \partial\Omega = \emptyset$, then $c_1 \inf_{x\in K} \operatorname{dist}(x, \partial\Omega) \leq h_K \leq c_2 \sup_{x\in K} \operatorname{dist}(x, \partial\Omega)$.*

A typical example of a geometric mesh is depicted in Figure 2.1. Note that the restriction to the boundary $\partial\Omega$ of a geometric mesh is a quasi-uniform mesh, which justifies speaking of a "boundary mesh size h."

Remark 2.4. An important algorithmic issue is the automatic generation of geometric meshes. Such meshes can be generated with the algorithm of [39].

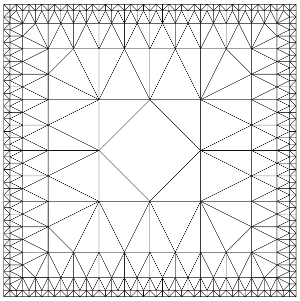

FIG. 2.1. *Example of a geometric mesh in the sense of Definition* 2.3.

2.2.2. *hp*-FEM spaces. In order to define *hp*-FEM spaces on a mesh $\mathcal{T}$, we associate a polynomial degree $p_K \in \mathbb{N}$ with each element K, collect these p_K in the polynomial degree vector $\mathbf{p} := (p_K)_{K\in\mathcal{T}}$, and set

$$S^{\mathbf{p}}(\Omega,\mathcal{T}) := \{u \in H^1(\Omega)\,|\, u\circ F_K \in \mathcal{P}_{p_K}(\hat{K}) \quad \forall K \in \mathcal{T}\}, \tag{2.10}$$

$$S^{\mathbf{p}}_0(\Omega,\mathcal{T}) := S^{\mathbf{p}}(\Omega,\mathcal{T}) \cap H^1_0(\Omega), \tag{2.11}$$

where for $p \in \mathbb{N}$ we introduced the space of all polynomials of degree p as

$$\mathcal{P}_p(\hat{K}) = \operatorname{span}\{x^i y^j \,|\, 0 \le i+j \le p\}.$$

For the approximation of solutions to (1.14) on geometric meshes (in the sense of Definition 2.3), the so-called *linear degree vector* is a particularly useful polynomial degree distribution.

DEFINITION 2.5 (linear degree vector). *Let $\mathcal{T}$ be a geometric mesh in the sense of Definition* 2.3. *A polynomial degree vector $\mathbf{p} = (p_K)_{K\in\mathcal{T}}$ is said to be a* linear degree vector with slope $\alpha > 0$ *if*

$$1 + \alpha c_1 \log\frac{h_K}{h} \le p_K \le 1 + \alpha c_2 \log\frac{h_K}{h}.$$

Here, $h := \min_{K\in\mathcal{T}}$ is a measure for the mesh size of the quasi-uniform mesh $\mathcal{T}|_{\partial\Omega}$.

Remark 2.6. Linear degree vectors $\mathbf{p}$ have the additional property that the polynomial degree varies slowly; i.e., there exists $C > 0$ such that

$$C^{-1}p_{K'} \le p_K \le Cp_{K'} \qquad \forall K, K' \in \mathcal{T} \quad \text{with } \overline{K} \cap \overline{K'} \neq \emptyset. \tag{2.12}$$

We conclude this section by showing that for geometric meshes in the sense of Definition 2.3, the number of elements of $\mathcal{T}$ is proportional to the number of elements on the boundary. Similarly, for linear degree vectors (Definition 2.5), the dimension $\dim S^{\mathbf{p}}(\Omega,\mathcal{T})$ is proportional to the number of unknowns on the boundary as is seen in the following result.

PROPOSITION 2.7. *Let $\mathcal{T}$ be a geometric mesh with boundary mesh size h. Let $\mathbf{p}$ be a linear degree vector with slope $\alpha > 0$ on $\mathcal{T}$. Then there exists $C > 0$ depending only on Ω, the shape-regularity constant γ, and the constants c_1, c_2, α of Definitions* 2.3, 2.5 *such that*

$$\sum_{K\in\mathcal{T}} 1 \le Ch^{-1},$$

$$\dim S^{\mathbf{p}}(\Omega, \mathcal{T}) \sim \sum_{K \in \mathcal{T}} p_K^2 \leq C h^{-1},$$
$$\max_{K \in \mathcal{T}} p_K \leq C |\log h|.$$

Proof. We will prove only the second estimate, as the first one is proved similarly.

$$\sum_{K \in \mathcal{T}} p_K^2 = \sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega \neq \emptyset} p_K^2 + \sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega = \emptyset} p_K^2. \tag{2.13}$$

For the first sum, we note that the assumptions on a geometric mesh $\mathcal{T}$ and the linear degree vector give that $p_K \leq C$ for all $K \in \mathcal{T}$ with $\overline{K} \cap \partial\Omega \neq \emptyset$. Thus,

$$\sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega \neq \emptyset} p_K^2 \leq C \sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega \neq \emptyset} 1 \leq C h^{-1}.$$

For the second sum in (2.13) we bound

$$\begin{aligned} \sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega = \emptyset} p_K^2 &\leq C \sum_{K \in \mathcal{T} : \overline{K} \cap \partial\Omega = \emptyset} \int_K \frac{1 + |\ln(r(x)/h)|^2}{r^2(x)}\, dx \\ &\leq C \int_{x \in \Omega, r(x) \geq ch} \frac{1 + |\ln(r(x)/h)|^2}{r^2(x)}\, dx \leq C \int_{c'h}^{\infty} \frac{1 + |\ln(z/h)|^2}{z^2}\, dz \leq C h^{-1}, \end{aligned}$$

where in the penultimate step we have locally flattened the boundary with Lipschitz maps. The integral represents the integration normal to the boundary, whereas the integration in the tangential direction was absorbed in the constant C. □

2.3. *hp*-FEM approximation on geometric meshes.

2.3.1. Approximation on the boundary $\partial\Omega$. If $\mathcal{T}$ is a geometric mesh and $V_N = S^{\mathbf{p}}(\Omega, \mathcal{T})$ with linear degree vector $\mathbf{p}$, then the space Y_N defined in (2.2) is a space of piecewise polynomials of fixed, low degree (depending on α and the constants c_1, c_2 appearing in Definition 2.5) on a quasi-uniform mesh. It can be shown (with the aid of Proposition C.3) that for $0 \leq s < 3/2$ the L^2-projector Q_N is stable on $H^s(\partial\Omega)$; in particular, therefore, $Y_N \subset H^s(\partial\Omega)$ for $0 \leq s < 3/2$. This allows us to extend the operator Q_N by duality to an operator $H^{-s}(\partial\Omega) \to Y_N$ with $0 \leq s < 3/2$ by

$$\langle Q_N u, v \rangle_{0,\partial\Omega} = \langle u, v \rangle_{H^{-s}(\partial\Omega) \times H^s(\partial\Omega)} \qquad \forall u \in H^{-s}(\partial\Omega) \quad \forall v \in Y_N. \tag{2.14}$$

By a slight abuse of notation, the extended operator is again denoted by Q_N. It has the following properties.

LEMMA 2.8. *Let Ω be a polygon, let $\mathcal{T}$ be a geometric mesh with boundary mesh size h in the sense of Definition* 2.3, *and let $\mathbf{p}$ be a linear degree vector given by Definition* 2.5. *Set $V_N := S^{\mathbf{p}}(\Omega, \mathcal{T})$, and let Y_N be defined by* (2.2), *and the L^2-projection Q_N be given by* (2.6) *and* (2.14). *Then*

$$\|Q_N u\|_{H^s(\partial\Omega)} \leq C_s \|u\|_{H^s(\partial\Omega)} \quad \forall u \in H^s(\partial\Omega), \quad 0 \leq |s| < 3/2, \tag{2.15}$$

$$\|u - Q_N u\|_{H^s(\partial\Omega)} \leq C_{s,s'} h^{s'-s} \|u\|_{H^{s'}(\partial\Omega)} \quad \forall u \in H^{s'}(\partial\Omega), \tag{2.16}$$

where $-3/2 < s \leq s' < 3/2$. The constants C_s, $C_{s,s'}$ depend only on Ω, s, s', and the constants appearing in Definitions 2.3, 2.5.

Proof. Let $\varphi : [0, L) \to \partial\Omega$ be a parametrization by arclength. The fact that Ω is a polygon together with Lemma C.1 implies that the map $u \mapsto u \circ \phi$ is an isomorphism between the Sobolev spaces $H^s(\partial\Omega)$ and $H^s_{per}([0, L))$, $0 \leq s < 3/2$. The stability result (2.15) for $s \geq 0$ now follows from Proposition C.3 and by duality for $s \in (-3/2, 0)$. For $0 \leq s$, the approximation result (2.16) follows from (2.15) and standard approximation results in the usual way. The case $s \in (-3/2, 0)$ is again obtained by duality. □

2.3.2. Approximation of $\widetilde{\mathcal{B}}^2_\beta$-functions from $S^{\mathbf{p}}(\Omega, \mathcal{T})$. Our *hp*-FEM approximation results for functions of $\widetilde{\mathcal{B}}^2_\beta$ will be based on the following lemma.

LEMMA 2.9. *Let $\hat{K}$ be the reference triangle with edges Γ_i, $i \in \{1, 2, 3\}$. Let $\hat{u}$ be analytic on $\overline{\hat{K}}$, and assume that*

$$\|\nabla^{n+2}\hat{u}\|_{L^2(\hat{K})} \leq C_u \gamma_u^n n! \qquad \forall n \in \mathbb{N}_0$$

for some C_u, $\gamma_u > 0$. Let $c \in (0, 1]$. Then for each p, p_1, p_2, $p_3 \in \mathbb{N}$ with

$$cp \leq p_i \leq p, \qquad i \in \{1, 2, 3\},$$

there exists a polynomial $\pi_p \in \mathcal{P}_p(\hat{K})$ with

1. *$\pi_p|_{\Gamma_i} = i_{p_i,\Gamma_i}(u|_{\Gamma_i})$ for $i \in \{1, 2, 3\}$. Here, i_{p_i,Γ_i} denotes the Gauss–Lobatto interpolant of degree p_i on edge Γ_i.*
2. *$\|u - \pi_p\|_{W^{1,\infty}(\hat{K})} \leq CC_u e^{-bp}$.*

The constants C, $b > 0$ depend only on c and γ_u.

Proof. The case $p_1 = p_2 = p_3 = p$ is considered in [32, Theorem 3.2.20, Proposition 3.2.21]. The extension to the present case is straightforward. □

PROPOSITION 2.10. *Let $\mathcal{T}$ be a geometric mesh with boundary mesh size h, as defined in Definition* 2.3*. Let* $\mathbf{p}$ *be a linear degree vector on $\mathcal{T}$ with slope $\alpha > 0$. Let $u \in \widetilde{\mathcal{B}}^2_\beta(C_u, \gamma_u)$ for some $\beta \in [0, 1)$, C_u, $\gamma_u > 0$. Then there exist C, $b > 0$ depending only on Ω, the shape-regularity constant γ, and the constants c_1, c_2 of Definition* 2.3 *as well as C_u, γ_u, β such that*

$$\inf\left\{\|u - v\|_{H^1(\Omega)} \,|\, v \in S^{\mathbf{p}}(\Omega, \mathcal{T})\right\} \leq Ch^{1-\beta} + Ch^{b\alpha}. \tag{2.17}$$

In terms of degrees of freedom, we have $N = \dim S^{\mathbf{p}}(\Omega, \mathcal{T}) \sim h^{-1}$.

Proof. For $u \in \widetilde{\mathcal{B}}^2_\beta(C_u, \gamma_u)$ we define

$$C_K^2 := \sum_{n=0}^{\infty} \frac{1}{(2\gamma_u)^{2n}(n!)^2} \|r^{n+\beta}\nabla^{n+2}u\|^2_{L^2(K)}.$$

The assumption $u \in \widetilde{\mathcal{B}}^2_\beta(C_u, \gamma_u)$ guarantees

$$\sum_{K\in\mathcal{T}} C_K^2 \leq \sum_{n=0}^{\infty} \frac{1}{(2\gamma_u)^{2n}(n!)^2} \|r^{n+\beta}\nabla^{n+2}u\|^2_{L^2(\Omega)} \leq C_u^2 \sum_{n=0}^{\infty} \frac{1}{2^{2n}} = \frac{4}{3}C_u^2.$$

Hence, we conclude that $u \in \widetilde{\mathcal{B}}^2_\beta(C_u, \gamma_u)$ implies

$$\|r^{n+\beta}\nabla^{n+2}u\|_{L^2(K)} \leq C_K(2\gamma_u)^n n! \qquad \forall n \in \mathbb{N}_0, \quad \forall K \in \mathcal{T}, \tag{2.18a}$$

$$\sum_{K\in\mathcal{T}} C_K^2 \leq \frac{4}{3}C_u^2. \tag{2.18b}$$

We explicitly construct an element of $S^{\mathbf{p}}(\Omega, \mathcal{T})$ with the desired approximation properties. To that end, we first assume, as we may, that $p_K = 1$ for all elements abutting $\partial\Omega$. Next, we associate with each edge e of $\mathcal{T}$ a polynomial degree $p_e := \min\{p_K \,|\, e \text{ is an edge of element } K\}$. After these preparations, we construct the approximant element by element. We distinguish the cases $\overline{K} \cap \partial\Omega \neq \emptyset$ and $\overline{K} \cap \partial\Omega = \emptyset$.

Using Theorem B.4 and a scaling argument, we obtain for all elements K abutting on $\partial\Omega$ that the linear interpolant Iu satisfies

$$\|u - Iu\|_{H^1(K)} \leq C h_K^{1-\beta} \|r^\beta \nabla^2 u\|_{L^2(K)} \leq C h^{1-\beta} C_K.$$

For the elements not abutting on $\partial\Omega$, we employ Lemma 2.9. Using (2.18a), we see that the pull-back $\hat{u} := u \circ F_K$ satisfies

$$\begin{aligned} \|\nabla^{n+2} \hat{u}\|^2_{L^2(\hat{K})} &\leq C h_K^{2(n+1)} \|\nabla^{n+2} u\|^2_{L^2(K)} \leq C h_K^{2-2\beta} \|r^{n+\beta} \nabla^{n+2} u\|^2_{L^2(K)} \\ &\leq C C_K \, h_K^{2(1-\beta)} (2\gamma_u)^{2n} (n!)^2, \end{aligned}$$

with $C > 0$ independent of n and K. The approximant Iu of Lemma 2.9 then satisfies

$$\|u - Iu\|_{H^1(K)} \leq C C_K h_K^{1-\beta} e^{-b p_K}$$

for some C, $b > 0$ independent of the element K. We note that the interpolant constructed elementwise in this fashion is indeed an element of $S^{\mathbf{p}}(\Omega, \mathcal{T})$. (The edge polynomial degrees p_i in Lemma 2.9 are taken to be the polynomial degrees p_e of the corresponding edges e.) Using $p_K \geq c\alpha \ln(h_K/h)$, we arrive at

$$\|u - Iu\|_{H^1(K)} \leq C C_K h_K^{1-\beta-\alpha b'} h^{\alpha b'}$$

for some $b' > 0$. Exploiting that $h_K \geq ch$, a simple calculation reveals that

$$h_K^{1-\beta-\alpha b'} h^{\alpha b'} \leq C h^{\min\{1-\beta, \alpha b'\}}.$$

We thus conclude in view of (2.18b) that

$$\sum_{K \in \mathcal{T}} \|u - Iu\|^2_{H^1(K)} \leq C \sum_{K \in \mathcal{T}} C_K^2 h^{\min\{1-\beta, \alpha b'\}} \leq C h^{\min\{1-\beta, \alpha b'\}},$$

which is the desired estimate. The bound for the dimension of $S^{\mathbf{p}}(\Omega, \mathcal{T})$ follows from Proposition 2.7. □

Remark 2.11. The meshes $\mathcal{T}$ considered here consist of triangles only. Likewise, the approximation result in Proposition 2.10 is formulated for triangles only. This restriction is not essential and was done for simplicity of exposition only. The approximation results can be formulated for meshes consisting of nonaffine elements (quadrilaterals, curved elements) as well. To handle this case, it is required that the element maps F_K for elements K not abutting on the boundary be analytic (with a controlled domain of analyticity; see, e.g., [32]) and that the error on elements abutting $\partial\Omega$ be $O(h^{1-\beta})$.

Proposition 2.10 is a result for unconstrained approximation in $H^1(\Omega)$. For treating Dirichlet problems, constrained approximation as in (2.5) is required. This is accomplished in the following corollary.

COROLLARY 2.12. *Assume the hypotheses of Proposition* 2.10 *and additionally* $u \in H^{2-\beta}(\Omega) \cap \widetilde{B}^2_\beta(C_u, \gamma_u)$ *for some* C_u, $\gamma_u > 0$, $\beta \in (0, 1)$. *Let* Y_N *be the restriction* *of $S^{\mathbf{p}}(\Omega, \mathcal{T})$ to $\partial\Omega$ as given by* (2.2)*. Let Q_N be the L^2-projection into Y_N (cf.* (2.6)*). Then*

$$\inf\{\|u - v\|_{H^1(\Omega)} \mid v \in S^{\mathbf{p}}(\Omega, \mathcal{T}) \text{ with } \gamma_0 v = Q_N(\gamma_0 u)\} \le C\left[h^{1-\beta} + h^{b\alpha}\right]. \tag{2.19}$$

The constants C, $b > 0$ depend only on Ω, the shape-regularity constant γ, the constants c_1, c_2 appearing in Definition 2.3*, and C_u, γ_u, β, $\|u\|_{H^{2-\beta}(\Omega)}$.*

Proof. We first observe that the trace theorem gives $\|\gamma_0 u\|_{H^{3/2-\beta}(\partial\Omega)} \le C\|u\|_{H^{2-\beta}(\Omega)}$. Lemma 2.8 and Proposition 2.10 therefore imply the existence of $v_N \in S^{\mathbf{p}}(\Omega, \mathcal{T})$ such that

$$\|u - v_N\|_{H^1(\Omega)} \le C\left[h^{1-\beta} + h^{b\alpha}\right],$$
$$\|\gamma_0 u - Q_N(\gamma_0 u)\|_{H^{1/2}(\partial\Omega)} \le Ch^{1-\beta}\|u\|_{H^{2-\beta}(\Omega)}.$$

The desired result now follows with the aid of the discrete harmonic extension operator E_N of Lemma 2.2: Since $\gamma_0 v_N - Q_N(\gamma_0 u) \in Y_N$, we get that the function $\widetilde{v}_N := v_N - E_N(\gamma_0 v_N - Q_N(\gamma_0 u)) \in V_N$ satisfies $\gamma_0 \widetilde{v}_N = Q_N(\gamma_0 u)$ and

$$\begin{aligned}\|\widetilde{v}_N - u\|_{H^1(\Omega)} &\le \|u - v_N\|_{H^1(\Omega)} + \|E_N(\gamma_0 v_N - Q_N(\gamma_0 u))\|_{H^1(\Omega)}\\ &\le \|u - v_N\|_{H^1(\Omega)} + C\|\gamma_0 v_N - Q_N(\gamma_0 u)\|_{H^{1/2}(\partial\Omega)}\\ &\le \|u - v_N\|_{H^1(\Omega)} + C\left[\|\gamma_0(v_N - u)\|_{H^{1/2}(\partial\Omega)} + \|\gamma_0 u - Q_N(\gamma_0 u)\|_{H^{1/2}(\partial\Omega)}\right].\end{aligned}$$

The result now follows. □

Corollary 2.12 allows us to finally formulate an approximation result for the *hp*-FEM on geometric meshes applied to (1.2) and (1.3) as follows.

Theorem 2.13. *Let $\mathcal{T}$ be a geometric mesh with boundary mesh size h, as defined in Definition* 2.3*. Let $\mathbf{p}$ be a linear degree vector on $\mathcal{T}$ with slope $\alpha > 0$ (cf. Definition* 2.5*). Let Q_N be the L^2-projection onto $Y_N = S^{\mathbf{p}}(\Omega, \mathcal{T})|_{\partial\Omega}$.*

Let $u \in H^{1+\delta}(\Omega)$, $\delta \in (0, 1)$, be the solution to (1.2) *(resp., the solution to* (1.3)*) with coefficients A, b, a_0, and right-hand side f analytic on $\overline{\Omega}$. Then the FE-solution u_N given by* (2.3) *(resp.,* (2.1)*) satisfies*

$$\|u - u_N\|_{H^1(\Omega)} \le C\left[h^{\delta} + h^{b\alpha}\right]. \tag{2.20}$$

The constants C, $b > 0$ depend only on the shape-regularity constant γ, the constants c_1, c_2 appearing in Definition 2.3*, and the data A, b, c, f, Ω.*

Proof. Theorem 1.4 implies that the solution $u \in H^{1+\delta}(\Omega)$ is in $\widetilde{B}^2_{1-\delta}(C_u, \gamma_u)$ for some C_u, $\gamma_u > 0$. In view of the best approximation properties (2.5), (2.4), the assertion (2.20) now follows from Corollary 2.12. □

For α sufficiently large the boundary concentrated FEM achieves the optimal rate of convergence

$$\|u - u_N\|_{H^1(\Omega)} \le Ch^{\delta} = O(N^{-\delta}).$$

3. *hp*-FEM solution procedure.

Choosing the slope α of the polynomial degree vector sufficiently large, we obtain for the FEM approximation the optimal rate $\|u - u_N\|_{H^1(\Omega)} \le CN^{-\delta}$. In the present section we discuss how the FE solution u_N can be computed with complexity $O(N \log^2 N)$. We mention in passing that, in the two-dimensional situation, a direct solver with complexity $O(N \log^8 N)$ was constructed in [26]. We consider iterative methods for solving the Dirichlet and Neumann problems

Table 3.1
Conditioning of the hp-FEM stiffness matrices: $N = \#$ elements, $p = \max_{K\in\mathcal{T}} p_K$.

Bdy. cond.	$p = p(N)$	DOF	cond (A^c)	cond $(C^{-1}A)$
Dirichlet	$O(\log N)$	N	$O(p(1+\log p))$	$O(1+\log^2 p)$
Neumann	$O(\log N)$	N	$O(Np(1+\log p))$	$O(1+\log^2 p)$

on geometric meshes in the sense of Definition 2.3. We restrict our attention to the symmetric positive definite case; i.e., in (1.4) we take

$$b_0 = 0, \quad a_0 > 0.$$

The main results of this section are collected in Table 3.1. A is the stiffness matrix, A^c stands for the statically condensed stiffness matrix (with the shape functions discussed in Example 3.1), and C stands for the preconditioners proposed here.

We focus here on the design of preconditioners for Neumann problems. The reason for our concentrating on this case can be seen in Table 3.1: While the Dirichlet problem is fairly well conditioned (the condition number without preconditioning grows only polylogarithmically in N since $p = O(\log N)$), the Neumann problem leads to at least linearly (in N) growing conditioning numbers, thus requiring preconditioning.

Our approach for the design of a preconditioner for the Neumann problem is based on the results of [3] (see also [40, section 4.7]).

3.1. Shape functions and assembling.

3.1.1. Element shape functions. In order to set up the stiffness matrix, bases of the polynomial spaces $\mathcal{P}_p$ have to be chosen. It is customary in p- and hp-FEM to split a basis of $\mathcal{P}_{p_K}$ into *vertex*, *side*, and *internal* shape functions. These three types of shape functions are characterized as follows:

1. *Vertex shape functions $\mathcal{V}$.* These are the usual linear nodal shape functions, which are equal to one in one node and vanish on the edge opposite that node. We write $\widetilde{\mathcal{V}} = \operatorname{span} \mathcal{V}$.
2. *Side shape functions $\mathcal{S} = \mathcal{S}_1 \cup \mathcal{S}_2 \cup \mathcal{S}_3$.* The side shape functions from $\mathcal{S}_i$ are associated with the edge Γ_i of $\partial\hat{K}$ and vanish on the edges Γ_j for $j \neq i$. We write $\widetilde{\mathcal{S}}_i = \operatorname{span} \mathcal{S}_i$ and $\widetilde{\mathcal{S}} := \operatorname{span}\{\mathcal{S}_1 \cup \mathcal{S}_2 \cup \mathcal{S}_3\}$.
3. *Internal shape functions $\mathcal{I}$.* The functions from $\mathcal{I}$ vanish on $\partial\hat{K}$. We write $\widetilde{\mathcal{I}} = \operatorname{span} \mathcal{I}$.

The side and internal shape functions are not uniquely defined with the above separation. An important consideration for an actual choice is the conditioning of the resulting stiffness matrix. We will discuss this point further below. One possible choice of a basis of $\mathcal{P}_p$ is based on Lagrange interpolation polynomials with respect to the Gauss–Lobatto points on the sides, which we elaborate in the following example.

Example 3.1. Denote by v_i, $i = 1, \dots, 3$, the three vertices of $\hat{K}$, and by Γ_i, $i = 1, \dots, 3$, the three edges (we assume $\Gamma_1 = \{(x, 0) \in \mathbb{R}^2 \,|\, 0 < x < 1\}$). Let $p_i \in \mathbb{N}$ be polynomial degrees associated with the edges Γ_i, and let $p \in \mathbb{N}$ be the polynomial degree of the internal shape functions. We then define vertex shape functions $\mathcal{V}$, side shape functions $\mathcal{S} = \mathcal{S}_1 \cup \mathcal{S}_2 \cup \mathcal{S}_3$, and internal shape functions $\mathcal{I}$ as follows:

$$\mathcal{V} := \text{the usual linear nodal shape functions } n_i \text{ with } n_i(v_j) = \delta_{ij},$$

$$\mathcal{S}_1 := \left\{ l_{j,p_1}(x) \frac{y - \sqrt{3}x}{x} \frac{y + \sqrt{3}(x-1)}{1-x} \,\Big|\, j = 1, \dots, p_1 - 1 \right\},$$

$$\mathcal{I} := \left\{ y(y - \sqrt{3}x)(y + \sqrt{3}(x-1))L_i(x)L_j(y) \,|\, 0 \le i + j \le \frac{(p-3)(p-2)}{2} \right\}.$$

Here, the polynomials L_i are the Legendre polynomials scaled to the interval $[0,1]$. The polynomials l_{j,p_1} are the Lagrange interpolation polynomials with respect to the $p_1 + 1$ Gauss–Lobatto points on $[0,1]$; letting $0 = x_0 < x_1 < \cdots < x_{p_1} = 1$ be the zeros of the polynomials $x \mapsto x(1-x)L'_{p_1}(x)$, the functions $l_{j,p_1}(x)$ are defined by

$$l_{j,p_1}(x) := \prod_{\substack{i=0\\ i\neq j}}^{p_1} \frac{x - x_i}{x_j - x_i}, \qquad j = 0, \dots, p_1. \tag{3.1}$$

The side shape functions $\mathcal{S}_2$, $\mathcal{S}_3$ are obtained similarly, with p_1 replaced with p_2 (resp., p_3) and a suitable coordinate transformation.

3.1.2. Global bases and assembling. The decomposition of a basis $\mathcal{B}_K$ of $\mathcal{P}_{p_K}$ facilitates the assembly process in *hp*-FEM with variable polynomial degree. For a detailed discussion of this procedure, we refer, for example, to [37, 13]. The basis of Example 3.1, however, may serve to illustrate the main point. The topological entities "edge" and "element" carry a polynomial degree: The polynomial degree associated with an element K is p_K, whereas the polynomial degree p_e associated with an edge $e = \overline{K} \cap \overline{K'}$ is $p_e := \min\{p_K, p_{K'}\}$. These edge polynomial degrees p_e then correspond to the polynomial degrees p_i, $i = 1, \dots, 3$, in Example 3.1; since the side shape functions are Lagrange interpolation polynomials on the edges, the assembly process is straightforward.

We introduce the *assembly operator* $\mathcal{A}_{K\in\mathcal{T}}$ of [23] to combine the bases $\mathcal{B}_K$ of the spaces $\mathcal{P}_{p_K}$ into a global basis $\mathcal{B}$ of the FE-space V_N:

$$\mathcal{B} = \mathop{\mathcal{A}}_{K\in\mathcal{T}} \mathcal{B}_K.$$

One can also assemble only the functions from $\mathcal{V}$, $\mathcal{S}$, or $\mathcal{I}$:

$$V_{\mathcal{V}} = \mathop{\mathcal{A}}_{K\in\mathcal{T}} \mathcal{V}_K, \qquad V_{\mathcal{S}} = \mathop{\mathcal{A}}_{K\in\mathcal{T}} \mathcal{S}_K, \qquad V_{\mathcal{I}} = \mathop{\mathcal{A}}_{K\in\mathcal{T}} \mathcal{I}_K. \tag{3.2a}$$

Of course, the functions of $V_{\mathcal{V}}$ are just the standard piecewise linear hat functions spanning the space $S^1(\Omega, \mathcal{T})$. The shape functions of $V_{\mathcal{I}}$ are supported by a single element, and the shape functions of $V_{\mathcal{S}}$ are supported by at most two adjacent elements. We can further split $V_{\mathcal{S}}$ into

$$V_{\mathcal{S}} = \oplus_{\text{edges } e} V_e, \qquad V_e = \{v \in V_{\mathcal{S}} \,|\, v_{|_{e'}} = 0 \quad \text{for all edges } e' \neq e\}. \tag{3.2b}$$

3.2. Cost of setting up the stiffness matrix and local condensation. We first show that setting up the stiffness matrix and the optional local static condensation can be performed with optimal complexity on geometric meshes with linear degree vectors. To see that, we introduce the elementwise bilinear form B_K by restricting B to the element K:

$$B_K(u, v) := \int_K (A\nabla u \cdot \nabla v + a_0 uv)\, dx.$$

Furthermore, for functions u, $v \in V_N$, we write $u_K := u|_K$, $v_K := v|_K$. With this understanding we can write

$$B(u, v) = \sum_{K\in\mathcal{T}} B_K(u_K, v_K). \tag{3.3}$$

The actual evaluation of $B_K(u_K, v_K)$ is performed by integrating on the reference element $\hat{K}$ instead of K. That is, writing $\hat{u} = u_K \circ F_K$, $\hat{v} = v_K \circ F_K$, we set $B_K(u,v) := \hat{B}_K(\hat{u},\hat{v})$, where

$$\begin{aligned}
&\hat{B}_K(\hat{u},\hat{v}) := \int_{\hat{K}} \hat{A}\nabla\hat{u}\cdot\hat{v} + \hat{a}_0\hat{u}\hat{v}\,dx,\\
&\hat{A} := \left(F_K'\right)^{-1}(A\circ F_K)\left(F_K'\right)^{-\top}|\det F_K'|, \qquad \hat{a}_0 = a_0\circ F_K\cdot|\det F_K'|.
\end{aligned}$$

In practice, the integration over $\hat{K}$ that is required for the evaluation of B_K is performed with a quadrature rule with $O(p_K^2)$ points. In a standard *hp*-FEM code, the bilinear form B_K defines the element stiffness matrix

$$A_K = \left(B_K(u,v)\right)_{u,v\in\mathcal{V}\cup\mathcal{S}\cup\mathcal{I}},$$

which is an $O(p_K)\times O(p_K)$-matrix. Finally, in the assembly the local stiffness matrices A_K are combined into the global stiffness matrix A. As in [23], we write this assembly process as $A = \mathcal{A}_{K\in\mathcal{T}} A_K$.

In *hp*-FEM it is also customary to perform local static condensation. The partitioning of the basis of $\mathcal{P}_K$ in vertex, side, and internal shape functions implies a corresponding block structure of A_K:

$$A_K = \begin{pmatrix} A_K^{\mathcal{V}\mathcal{V}} & A_K^{\mathcal{V}\mathcal{S}} & A_K^{\mathcal{V}\mathcal{I}} \\ & A_K^{\mathcal{S}\mathcal{S}} & A_K^{\mathcal{S}\mathcal{I}} \\ sym. & & A_K^{\mathcal{I}\mathcal{I}} \end{pmatrix}.$$

Since $A_K^{\mathcal{I}\mathcal{I}}$ is invertible, one can form the following Schur complement:

$$A_K^c := A_K^{\mathcal{E}\mathcal{E}} - A_K^{\mathcal{E}\mathcal{I}}\left(A_K^{\mathcal{I}\mathcal{I}}\right)^{-1}\left(A_K^{\mathcal{E}\mathcal{I}}\right)^{\top},$$

where we introduce the notion of *external shape functions*

$$\mathcal{E} := \mathcal{V}\cup\mathcal{S}. \tag{3.4}$$

The condensed global stiffness matrix A^c is obtained by assembling the condensed local matrices A_K^c:

$$A^c := \underset{K\in\mathcal{T}}{\mathcal{A}} A_K^c. \tag{3.5}$$

An important observation is that the condensed stiffness matrix A^c is the stiffness matrix corresponding to elementwise discrete harmonic external shape functions.

PROPOSITION 3.2. *Let $\mathcal{T}$ be a geometric mesh with boundary mesh size h, and let $\mathbf{p}_K$ be a linear degree vector with slope α in the sense of Definition* 2.5. *Assume that for all elements quadrature rules with $O(p_K^2)$ points are used. Then the stiffness matrix A is generated with work*

$$W(A) = O(N),$$

where $N \sim h^{-1}$. Additionally, the local static condensation, i.e., forming the Schur complement with respect to the internal shape functions, is performed with work $W(A^c) = O(N)$.

Proof. The cost of setting up the local stiffness matrix with $O(p_K^2 \times p_K^2)$ entries using numerical quadrature with $O(p_K^2)$ points is $O(p_K^6)$. Thus, the total cost to set up the global stiffness matrix is

$$W \sim \sum_{K \in \mathcal{T}} (p_K^2)^3 = O(N),$$

where the last bound is obtained by arguments similar to those in the proof of Proposition 2.7. Also computing the condensed stiffness matrix A_K^c is done with work $O((p_K^2)^3) = O(p_K^6)$. Again, summing this work estimate over all elements K of the geometric mesh, we arrive at $W(A^c) = O(N)$. □

Remark 3.3. The presence of numerical quadrature introduces variational crimes. It can be shown (see [33]) that the bilinear form $\tilde{B}$ obtained by numerical quadrature induces an inner product on V_N that is equivalent to the inner product generated by B, and the approximation result Theorem 2.13 still holds.

3.3. The Dirichlet problem. The aim of the present section is to show that the stiffness matrix resulting from the discretization of a Dirichlet problem is fairly well conditioned. We have the following result.

PROPOSITION 3.4. *Given a geometric mesh $\mathcal{T}$ with boundary mesh size h, let $\mathbf{p}$ be a polynomial degree distribution satisfying* (2.12)*, and let the element shape functions be taken as described in Example* 3.1. *Then there exists $C > 0$ independent of h and $\mathbf{p}$ such that the condensed stiffness matrix A^c corresponding to the Dirichlet problem has l^2-condition number*

$$\kappa(A^c) \leq C|\mathbf{p}|(1 + \log|\mathbf{p}|), \tag{3.6}$$

where $|\mathbf{p}| = \max_{K\in\mathcal{T}} p_K$. In the case of Neumann boundary conditions, there holds

$$\kappa(A^c) \leq Ch^{-1}\,|\mathbf{p}|(1 + \log|\mathbf{p}|). \tag{3.7}$$

Proof. For the case of Dirichlet boundary conditions, we refer to [31, Theorem 2.2]. The case of the Neumann boundary conditions is obtained by combining the results of [31] for the p-dependence with those of [7, Theorem 4.1] for the h-dependence.

We mention that the $O(1)$-condition number estimate for $p = 1$ and Dirichlet boundary conditions has already been proved in [44]. □

Applied to the case of linear degree vector $\mathbf{p}$, Proposition 3.4 yields that in the case of a Dirichlet problem the condensed stiffness matrix satisfies

$$\kappa(A^c) \leq C \log N(1 + \log\log N)$$

because $|\mathbf{p}| \leq C \log N = C|\log h|$. Thus, solving Dirichlet problems on geometric meshes can be accomplished efficiently by simple CG-iterations. We remark that the condition number $\kappa(A)$ of the full hp-FEM stiffness matrix can be shown to be $O(|\mathbf{p}|^q)$ for suitable $q \geq 1$; thus, CG-iterations again lead to linear-logarithmic complexity.

Applied to the Neumann problem on geometric meshes with linear degree vectors, Proposition 3.4 yields a bound of the form $\kappa(A^c) \leq CN \log N(1 + \log\log N)$. In this case, preconditioning seems to be desirable for the efficient solution of the resulting linear system. We propose a preconditioner in the following two subsections.

3.4. Neumann problem: Reduction to preconditioning on piecewise linear spaces. The bilinear form B is expressed in (3.3) as a sum of element contributions. The preconditioner C is also constructed elementwise:

$$C(u, v) := \sum_{K\in\mathcal{T}} C_K(u_K, v_K). \tag{3.8}$$

For the construction of the preconditioner, we use the fact that by our discussion in section 3.1.1 the space $\mathcal{P}_{p_K}$ can be written as $\mathcal{P}_{p_K} = \widetilde{\mathcal{V}} \oplus_{i=1}^{3} \widetilde{\mathcal{S}}_i \oplus \widetilde{\mathcal{I}}$, where the polynomial degrees associated with sets of side shape functions $\mathcal{S}_i$ and the internal shape functions $\mathcal{I}$ implicitly depend on K. Correspondingly, a function $u_K \in \mathcal{P}_{p_K}$ can be written as

$$u_K = u_K^{\mathcal{V}} + \sum_{i=1}^{3} u_K^{\mathcal{S}_i} + u_K^{\mathcal{I}}. \tag{3.9}$$

We then define the element contributions C_K of the preconditioner C as

$$C_K(u, v) = B_K(u_K^{\mathcal{V}}, v_K^{\mathcal{V}}) + \sum_{i=1}^{3} B_K(u_K^{\mathcal{S}_i}, v_K^{\mathcal{S}_i}) + B_K(u_K^{\mathcal{I}}, v_K^{\mathcal{I}}). \tag{3.10}$$

We mentioned in section 3.1.1 that the splitting of a basis of $\mathcal{P}_{p_K}$ into vertex, side, and internal shape functions is not unique. The following result, which is due to [3], asserts that for discrete harmonic side shape functions the preconditioner C given by (3.8) is only weakly dependent on $\mathbf{p}$ and independent of the mesh.

PROPOSITION 3.5 (see [3]). *Let $\mathcal{T}$ be a shape-regular mesh consisting of triangles. Assume that the side shape functions are discrete harmonic, i.e.,*

$$B_K(u, v) = 0 \qquad \forall u \in \widetilde{\mathcal{S}} \quad \forall v \in \widetilde{\mathcal{I}}. \tag{3.11}$$

Then there exist c_1, $c_2 > 0$ depending only on the coefficients A, a_0 and the shape-regularity constant γ such that

$$c_1 B(u, u) \le C(u, u) \le c_2 (1 + \ln |\mathbf{p}|)^2 B(u, u) \qquad \forall u \in S^{\mathbf{p}}(\Omega, \mathcal{T}),$$

where $|\mathbf{p}| = \max_{K \in \mathcal{T}} p_K$.

Remark 3.6. The condition (3.11) can be achieved by a process akin to the local static condensation described in section 3.2. By Proposition 3.2, the condition (3.11) can be enforced with work $O(N)$.

Remark 3.7. When solving the system by local static condensation as described in section 3.2, the condition (3.11) should be substituted by

$$B_K(u, v) = 0 \qquad \forall u \in \widetilde{\mathcal{E}} \quad \forall v \in \widetilde{\mathcal{I}}. \tag{3.12}$$

It is easy to see that the energy minimization property of the discrete B-harmonic functions now implies the same condition number for the preconditioner (3.10), (3.12) as in Proposition 3.5. On the other hand, the former preconditioner (3.10), (3.11) can be shown to have the same condition number as the modified one.

We now analyze the cost of applying the preconditioner C, i.e., solving

$$C(u, v) = l(v) \qquad \forall v \in V_N.$$

By the decomposition (3.2) of the basis $\mathcal{B}$ of V_N, the sought function $u \in V_N$ can be written in the form

$$u = u^{\mathcal{V}} + \sum_{\text{edges } e} u^e + \sum_{K \in \mathcal{T}} u_K^{\mathcal{I}}, \tag{3.13}$$

where $u^{\mathcal{V}} \in S^1(\Omega, \mathcal{T})$, $u_e \in \operatorname{span} V_e$, $u_K^{\mathcal{I}} \in \operatorname{span} V_{\mathcal{I}}$. Computing the components $u^{\mathcal{V}}$, u^e, $u_K^{\mathcal{I}}$ amounts to solving a global problem corresponding to a discretization with piecewise linear functions and two sets of local problems:

$$B(u^{\mathcal{V}}, v) = l(v) \qquad \forall v \in V_{\mathcal{V}}, \tag{3.14}$$

$$B(u^e, v) = l(v) \qquad \forall v \in V_e \qquad \text{for all edges } e, \tag{3.15}$$

$$B(u_K^{\mathcal{I}}, v) = l(v) \qquad \forall v \in V_{\mathcal{I}} \qquad \forall K \in \mathcal{T}. \tag{3.16}$$

Solving (3.15) and (3.16) can be accomplished with work $O(N)$ on geometric meshes with linear degree vectors as follows.

PROPOSITION 3.8. *Let $\mathcal{T}$ be a geometric mesh with boundary mesh size h and let $\mathbf{p}$ be a linear degree vector. Then the problems* (3.15) *and* (3.16) *can be solved with work $W = O(N)$, where $N \sim h^{-1}$.*

Proof. First, we note that the stiffness matrices corresponding to (3.15), (3.16) are submatrices of the global stiffness matrix; this guarantees that the problems can be set up with optimal complexity $O(N)$. For the solution step, we observe that the problems decouple into problems associated with single elements or two adjacent elements. Specifically, using Gaussian elimination for each element with cost $O(p_K^6)$, we arrive at the total cost for the solution of (3.16)

$$W \leq C \sum_{K \in \mathcal{T}} p_K^6 = O(N),$$

by a reasoning like that of the proof of Proposition 2.7. The solution of (3.15) decouples into problems associated with each edge of the mesh, and a calculation shows again that the required work is $O(N)$. □

Since $\dim S^1(\Omega, \mathcal{T}) = O(N)$, the cost for solving (3.14) is at least $O(N)$; hence, by Proposition 3.8, the total cost of applying the preconditioner C is controlled by the cost of solving (3.14).

3.5. Efficient solution of piecewise linear discretization. The analysis of the preceding section allowed us to restrict our attention to the case of piecewise linear approximation on geometric meshes $\mathcal{T}$. By the general theory of preconditioning, it suffices to find a spectrally equivalent bilinear form $\widetilde{B}$ on $S^1(\Omega, \mathcal{T}) \times S^1(\Omega, \mathcal{T})$. To that end, the space $S^1(\Omega, \mathcal{T})$ is decomposed further as

$$S^1(\Omega, \mathcal{T}) = V_{\mathcal{H}} \oplus (S^1(\Omega, \mathcal{T}) \cap H_0^1(\Omega)); \tag{3.17}$$

here, $V_{\mathcal{H}}$ is given by

$$V_{\mathcal{H}} := \operatorname{Range} E_{\mathcal{V}},$$

where $E_{\mathcal{V}}$ is the $S^1(\Omega, \mathcal{T})$-discrete harmonic extension operator

$$\begin{aligned} E_{\mathcal{V}} : \gamma_0(S^1(\Omega, \mathcal{T})) &\to S^1(\Omega, \mathcal{T}), \\ u &\mapsto E_{\mathcal{V}} u \quad \text{with} \quad B(E_{\mathcal{V}} u, v) = 0 \qquad \forall v \in S^1(\Omega, \mathcal{T}) \cap H_0^1(\Omega). \end{aligned}$$

The decomposition (3.17) also provides the B-orthogonal splitting (cf. Lemma 2.2)

$$B(u, v) = B(E_{\mathcal{V}} \gamma_0 u, E_{\mathcal{V}} \gamma_0 v) + B(u - E_{\mathcal{V}} \gamma_0 u, v - E_{\mathcal{V}} \gamma_0 v) \tag{3.18}$$

$\forall u, v \in S^1(\Omega, \mathcal{T})$. Due to Proposition 3.4, any spectrally equivalent approximation to the first term on the right-hand side of (3.18) yields the desired bilinear form $\widetilde{B}$. For simplicity of exposition, we now assume that Ω is simply connected. Following the standard construction in the domain decomposition methods, we apply a circulant preconditioning matrix. Let $F_\Omega : \widehat{C} \to \partial\Omega$ be the bi-Lipschitz mapping providing the global parametrization of $\partial\Omega$ by a 2π-periodic function. Assume that our quasi-uniform partitioning of $\mathcal{T}_{|\partial\Omega}$ is the image of the uniform grid $\mathcal{T}_{\widehat{C}}$ on $\widehat{C} := [0, 2\pi]$. Let $\Delta_{\widehat{C},h}$ be the discrete Laplacian defined on the set $\mathcal{T}_{\widehat{C}}$ and associated with the corresponding FE space of periodic piecewise linear functions $V_h(\widehat{C})$:

$$\langle -\Delta_{\widehat{C},h} u, v\rangle_{0,\widehat{C}} = \int_{\widehat{C}} \nabla u \cdot \nabla v \, ds + \int_{\widehat{C}} uv \, ds \qquad \forall\, u, v \in V_h(\widehat{C}). \tag{3.19}$$

The bilinear form $\widetilde{B}$ is then defined on $S^1(\Omega, \mathcal{T}) \times S^1(\Omega, \mathcal{T})$ by

$$\widetilde{B}(u, v) := \langle (-\Delta_{\widehat{C},h})^{1/2} (\gamma_0 u \circ F_\Omega), (\gamma_0 v \circ F_\Omega)\rangle_{0,\widehat{C}} + B(u - E_{\mathcal{V}}\gamma_0 u, v - E_{\mathcal{V}}\gamma_0 v).$$

The symmetric positive definite bilinear form $\widetilde{B}$ is spectrally equivalent to B on $S^1(\Omega, \mathcal{T})$ since

$$\langle (-\Delta)^{1/2} (\gamma_0 u \circ F_\Omega), \gamma_0 u \circ F_\Omega\rangle \sim \|\gamma_0 u\|^2_{1/2,\partial\Omega} \sim \|E_{\mathcal{V}}(\gamma_0 u)\|^2_{1,\Omega}.$$

We are thus left with the efficient solution of the problem

$$\text{Find } u \in S^1(\Omega, \mathcal{T}) \text{ s.t. } \widetilde{B}(u, v) = l(v) \qquad \forall v \in S^1(\Omega, \mathcal{T}). \tag{3.20}$$

Problem (3.20) can be solved in four steps as follows.

Algorithm 3.9 (preconditioner for piecewise (p.w.) linear discretization).

1. *Determine* $\tilde{u} \in S^1(\Omega, \mathcal{T}) \cap H^1_0(\Omega)$ *as the solution of*

$$B(\tilde{u}, v) = l(v) \qquad \forall v \in S^1(\Omega, \mathcal{T}) \cap H^1_0(\Omega). \tag{3.21}$$

This can be done efficiently by CG-iteration, because the stiffness matrix has uniformly bounded condition number.

2. *Determine* $\gamma_0 u$ *as the solution of*

$$\langle (-\Delta_{\widehat{C},h})^{1/2} (\gamma_0 u \circ F_\Omega), (\gamma_0 v \circ F_\Omega)\rangle_{0,\widehat{C}} = l(v) - B(\tilde{u}, v) \;\; \forall v \in S^1(\Omega, \mathcal{T}). \tag{3.22}$$

Note that the right-hand side in (3.22) *depends only on* $\gamma_0 v$, *which makes it possible to compute it with the test functions supported within one near-boundary grid layer. Due to the special structure of the operator* $\Delta_{\widehat{C},h}$ *on uniform meshes, solving* (3.22) *is efficiently accomplished by a forward and a backward FFT.*

3. *Compute (approximately) the discrete* B*-harmonic extension* $E_{\mathcal{V}}\gamma_0 u$. *This can be achieved with the aid of explicit extension operators* [17], *or by CG-iteration of the problem*

$$B(E_{\mathcal{V}}\gamma_0 u, v) = 0 \qquad \forall v \in S^1(\Omega, \mathcal{T}) \cap H^1_0(\Omega),$$

since the stiffness matrix corresponding to this problem has condition number bounded uniformly in N *by Proposition* 3.4.

4. *Set* $u := \tilde{u} + E_{\mathcal{V}}\gamma_0 u$.

Algorithm 3.9 has the following complexity.

PROPOSITION 3.10. *If steps* 1, 3 *in Algorithm* 3.9 *are solved iteratively with a tolerance* $\varepsilon = O(N^{-q})$, *then the solution of* (3.20) *with Algorithm* 3.9 *requires* $O(N \log N)$ *floating point operations.*

Proof. The solution of the problem in step 1 requires $O(N|\log \varepsilon|)$ work. The cost of the FFT is $O(N \log N)$. Finally, the calculation of the harmonic extension by the CG-iteration requires $O(N|\log \varepsilon|)$ arithmetic operations, where $\varepsilon > 0$ is the desired accuracy. Setting $\varepsilon = O(N^{-q})$ completes the proof. □

3.6. Remarks on implementations with static condensation. In computational practice one would likely base an iterative solution fully on local static condensation. One of the advantages of such a procedure is the reduction of the size of the problem that is solved iteratively. We recall the classical static condensation-based scheme as follows.

ALGORITHM 3.11 (solution based on local static condensation).

1. *Compute the local stiffness matrices* A_K *and the local load vectors* l_K.
2. *Compute the condensed local stiffness matrices* A_K^c *(note that this enforces* (3.12)*) and compute the condensed load vectors* l_K^c.
3. *Assemble* $A^c = \mathcal{A}_{K\in\mathcal{T}} A_K^c$ *and assemble the condensed load vectors* l^c *(see, e.g.,* [42]*).*
4. *Solve the linear system* $A^c x = l^c$ *by a preconditioned CG-iteration with the modified preconditioner of Algorithm* 3.12 *below.*
5. *Sweep through the mesh and solve for the internal degrees of freedom.*

Note that, with the exception of solving the condensed system $A^c x = l^c$, all steps of this algorithm can be accomplished with work $O(N)$. For Dirichlet problems, Proposition 3.4 shows that the condition number of the matrix A^c grows polylogarithmically with the problem size and can thus be treated efficiently by CG-iterations. For the Neumann problem, a preconditioner C^c similar to the one introduced above is required.

Static condensation on the element level can be interpreted as choosing new nodal shape functions $V_{\mathcal{V}}^c$ and side shape functions $V_{\mathcal{S}}^c$. Specifically, the mapping Z that accomplishes this transformation of shape functions is given by

$$Z : u \mapsto Zu, \qquad Zu \text{ satisfies} \left\{ \begin{array}{rl} Zu|_e = u|_e & \forall \text{ edges } e, \\ B(Zu, v) = 0 & \forall v \in V_{\mathcal{I}}. \end{array} \right. \tag{3.23}$$

The mapping Z maps the set of piecewise linears $V_{\mathcal{V}}$ and the set of side shape functions $V_{\mathcal{S}}$ onto discrete harmonic nodal shape functions $V_{\mathcal{V}}^c := ZV_{\mathcal{V}}$ and discrete harmonic side shape functions $V_{\mathcal{S}}^c := ZV_{\mathcal{S}}$, respectively. The preconditioner C^c employed for the solution of the condensed linear system can then be realized with the following algorithm.

ALGORITHM 3.12 (preconditioner C^c for a statically condensed stiffness matrix).

Output: solution $u = u_{\mathcal{V}^c} + u_{\mathcal{S}^c} \in \operatorname{span} V_{\mathcal{V}}^c \cup V_{\mathcal{S}}^c$ *such that*

$$C^c(u, v) = l(v) \qquad \forall v \in \operatorname{span} V_{\mathcal{V}}^c \cup V_{\mathcal{S}}^c.$$

1. (a) *Determine* $\widetilde{u} \in \operatorname{span} V_{\mathcal{V}}^c \cap H_0^1(\Omega)$ *as the solution to*

$$B(\tilde{u}, v) = l(v) \qquad \forall v \in \operatorname{span} V_{\mathcal{V}}^c \cap H_0^1(\Omega). \tag{3.24}$$

This can be done efficiently by a CG-iteration, as the stiffness matrix has uniformly bounded condition number (cf. [31]*). Note that the stiffness matrix corresponding to* (3.24) *is a submatrix of* A^c.

(b) *Determine* $\gamma_0 u$ *as the solution of*

$$\langle(-\Delta_{\widehat{C},h})^{1/2}(\gamma_0 u\circ F_\Omega),(\gamma_0 v\circ F_\Omega)\rangle_{0,\widehat{C}} = l(v) - B(\tilde{u},v) \qquad \forall v\in \operatorname{span} V^c_{\mathcal{V}}.$$

(c) *Find* $E^c\gamma_0 u \in \operatorname{span} V^c_{\mathcal{V}}$ *such that*

$$B(E^c\gamma_0 u, v) = 0 \qquad \forall v \in \operatorname{span} V^c_{\mathcal{V}}. \tag{3.25}$$

This could be accomplished by a CG-iteration, as the stiffness matrix corresponding to (3.25) *has uniformly bounded condition number by Proposition* 3.4. *Note again that the stiffness matrix is a submatrix of* A^c.

(d) *Set* $u_{\mathcal{V}^c} := \tilde{u} + E^c\gamma_0 u$.

2. *Introduce* $V^{c,e} := \{v \in V^c_{\mathcal{S}}\,|\, v|_{e'} = 0 \quad$ *for all edges* $e' \neq e\}$. *Then* $u_{\mathcal{S}^c} \in \operatorname{span} V^c_{\mathcal{S}}$ *is given by* $u_{\mathcal{S}^c} = \sum_{\text{edges } e} u^e$, *with* $u^e \in V^{c,e}$ *solving*

$$B(u^e, v) = l(v) \qquad \forall v \in V^{c,e}. \tag{3.26}$$

Note that the stiffness matrices for these edge-based problems are submatrices of A^c. *Solving all edge problems* (3.26) *can be achieved with work* $O(N)$ *by Gaussian elimination.*

We will not analyze the scheme consisting of Algorithms 3.11, 3.12. In view of the following lemma, however, we expect complexity estimates for this scheme as in Proposition 3.10.

LEMMA 3.13. *The mapping* Z *of* (3.23) *is an isomorphism between* $S^1(\Omega,\mathcal{T})$ *and* $ZS^1(\Omega,\mathcal{T})$; *i.e., for some* $C>0$ *there holds*

$$C^{-1}\|Zu\|_{H^1(\Omega)} \le \|u\|_{H^1(\Omega)} \le C\|Zu\|_{H^1(\Omega)} \qquad \forall u \in S^1(\Omega,\mathcal{T}). \tag{3.27}$$

Proof. The lower bound $\|Zu\|_{H^1(\Omega)} \le C\|u\|_{H^1(\Omega)}$ follows from the fact that the energy norm is equivalent to the H^1-norm and the energy minimization properties of the mapping Z. For the upper bound, we write Ω as the union of elements. For a fixed element K, we write $\widehat{u}$, $\widehat{Zu}$ for the pull-backs to the reference element $\hat{K}$ of the functions $u|_K$, $Zu|_K$. We then calculate, using the trace theorem on $\hat{K}$ and exploiting that $\widehat{u}$ is linear,

$$\|\nabla\widehat{u}\|_{L^2(\hat{K})} \sim |\widehat{u}|_{H^{1/2}(\partial\hat{K})} = |\widehat{Z}u|_{H^{1/2}(\partial\hat{K})} \le C\|\nabla\widehat{Z}u\|_{L^2(\hat{K})},$$

where the implied constant in the $\sim$ notation and the constant C are independent of the polynomial degree p_K and the element K. Scaling to the physical element K and summing over all elements yields $\|\nabla u\|_{L^2(\Omega)} \le C\|\nabla Zu\|_{L^2(\Omega)}$. Since $u = Zu$ on $\partial\Omega$, we get the upper bound $\|u\|_{H^1(\Omega)} \le C\|Zu\|_{H^1(\Omega)}$ in (3.27). □

4. Approximation to Poincaré–Steklov operators.

4.1. Poincaré–Steklov operators in elliptic problems. In some applications, the solution u to (1.2) or (1.3) is not the principal quantity of interest, but instead the missing data for a complete set of Cauchy data are sought. The Poincaré–Steklov operator T (also known as the Dirichlet-to-Neumann map) is defined as

$$\begin{array}{rcl} T : H^{1/2}(\partial\Omega) & \to & H^{-1/2}(\partial\Omega),\\ \lambda & \mapsto & \gamma_1 u, \quad u \text{ solves (1.2) with } f=0. \end{array} \tag{4.1}$$

Likewise, we define the Poincaré–Steklov operator S (also called the Neumann-to-Dirichlet map) by

$$\begin{array}{rcl} S : H^{-1/2}(\partial\Omega) & \to & H^{1/2}(\partial\Omega),\\ \psi & \mapsto & \gamma_0 u, \quad u \text{ solves (1.3) with } f=0. \end{array} \tag{4.2}$$

We note that the operators S, T are in fact inverses to each other, i.e., $S^{-1} = T$. Akin to the situations in (1.18), (1.19), the operator T admits a shift theorem. For general Lipschitz domains Ω, [10, Lemma 3.7] asserts for each $s \in [0, 1/2]$ the existence of $C_s > 0$ such that

$$\|T\lambda\|_{H^{-1/2+s}(\partial\Omega)} \leq C_s \|\lambda\|_{H^{1/2+s}(\partial\Omega)} \qquad \forall \lambda \in H^{1/2+s}(\partial\Omega). \tag{4.3}$$

For polygonal domains Ω, this shift theorem holds in a larger range. While this is closely related to (1.19), a precise reference seems to be missing, and we therefore formulate this as the following assumption.

Assumption 4.1. *There exists $\delta_0 > 1/2$ such that for each $\delta \in [0, \delta_0)$ a constant $C_\delta > 0$ can be found with*

$$\|E\lambda\|_{H^{1/2+\delta}(\partial\Omega)} + \|T\lambda\|_{H^{-1/2+\delta}(\partial\Omega)} \leq C_\delta \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)} \qquad \forall \lambda \in H^{1/2+\delta}(\partial\Omega), \tag{4.4}$$

where the extension $E\lambda \in H^1(\Omega)$ solves (1.2) *with $f = 0$.*

Remark 4.2. For the case of Laplace's equation (and thus the case of constant coefficients), Assumption 4.1 can be verified as follows. Let $\delta_0 \in (1/2, 1]$ be defined by (1.19). For general Lipschitz domains Ω, the estimate (4.3) covers the case $\delta \in [0, 1/2]$. For $\delta \in (1/2, 1)$, combining [11, Lemma 2.11] and [11, Lemma 2.7] gives

$$\|T\lambda\|_{H^{-1/2+\delta}(\partial\Omega)} \leq C\|E\lambda\|_{H^{1+\delta}(\Omega)} \leq C_\delta \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)},$$

where the second estimate follows from the regularity result (1.19).

In the case of convex polygons, we have $\delta_0 = 1$.

Remark 4.3. The case $b = 0$, $a_0 = 0$ does not fall directly into our framework because assumption (1.6) is not satisfied. The modification of considering the energy space $V = H^1(\Omega)/\mathbb{R}$, as is standard for Laplace's equation, can be carried out in the case of nonconstant matrix A as well.

4.2. *hp*-FEM approximation of Poincaré–Steklov operators *T* and *S*. We recall that the projector Q_N of (2.6) can be extended to an operator on $H^{-1/2}(\partial\Omega)$ by (2.14).

4.2.1. Approximation of the Poincaré–Steklov operator. Viewing the dual space Y_N' as a subspace of $H^{-1/2}(\partial\Omega)$, we define the approximation S_N to the Poincaré–Steklov operator S as

$$\begin{aligned} S_N : Y_N' &\to Y_N, \\ \Psi &\mapsto S_N\Psi := \gamma_0 u_N, \end{aligned}$$

where $u_N \in V_N$ solves the following discrete Neumann problem:

$$B(u_N, v) = \langle \Psi, v\rangle_{0,\partial\Omega} \qquad \forall v \in V_N.$$

The error analysis for S_N is rather straightforward.

Theorem 4.4. *Under the assumptions of Theorem* 2.13 *(with $f = 0$) there holds*

$$\|S\Psi - S_N\Psi\|_{H^{1/2}\partial\Omega} \leq C\left[h^\delta + h^{b\alpha}\right]. \tag{4.5}$$

Proof. Applying the trace theorem, we obtain

$$\|S\Psi - S_N\Psi\|_{H^{1/2}\partial\Omega} = \|\gamma_0 u - \gamma_0 u_N\|_{H^{1/2}\partial\Omega} \leq C\|u - u_N\|_{1,\Omega}.$$

Now (2.20) yields (4.5). □

4.2.2. Approximation of the Poincaré–Steklov operator. The approximation

$$
\begin{aligned}
T_N : Y_N &\to Y_N', \\
\lambda &\mapsto T_N\lambda
\end{aligned}
\tag{4.6}
$$

to the Poincaré–Steklov operator T defines an element of the dual space Y_N' via

$$\langle T_N\lambda, v\rangle_{0,\partial\Omega} = B(u_N, \widetilde{v}) \qquad \forall v \in Y_N,$$

where $\widetilde{v} \in V_N$ is an arbitrary extension of v, $\gamma_0\widetilde{v} = v$, and $u_N \in V_N$ satisfies

$$\gamma_0 u_N = \lambda \quad \text{ and } \quad B(u_N, v) = 0 \quad \forall\, v \in V_N \cap H_0^1(\Omega).$$

THEOREM 4.5. *Let Ω be a polygon, and let δ_0 be given by Assumption* 4.1. *Then for any $\delta \in [0, \delta_0) \cap [0, 3/2)$ and $\lambda \in H^{1/2+\delta}(\partial\Omega)$ there holds*

$$\|T\lambda - T_N Q_N \lambda\|_{H^{-1/2}(\partial\Omega)} \le C_\delta[h^\delta + h^{b\alpha}], \tag{4.7}$$

where C_δ, $b > 0$ and $\alpha > 0$ is the slope of the degree vector.

Proof. Using $Q_N T_N Q_N = T_N Q_N$, we write

$$T - T_N Q_N = (\mathrm{Id} - Q_N)T + Q_N T(\mathrm{Id} - Q_N) + Q_N(T - T_N)Q_N. \tag{4.8}$$

The first two terms in (4.8) lead to estimates of the form

$$\|(\mathrm{Id} - Q_N)T\lambda\|_{H^{-1/2}(\partial\Omega)} \le C_\delta h^\delta \|T\lambda\|_{H^{-1/2+\delta}(\partial\Omega)} \le C_\delta h^\delta \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)}, \tag{4.9}$$

$$\|Q_N T(\mathrm{Id} - Q_N)\lambda\|_{H^{-1/2}(\partial\Omega)} \le C\|(\mathrm{Id} - Q_N)\lambda\|_{H^{1/2}(\partial\Omega)} \le Ch^\delta \|\lambda\|_{H^{1/2+\delta}(\partial\Omega)}, \tag{4.10}$$

where we exploited the stability and approximation properties of the projector Q_N given in Lemma 2.8 and used the shift theorem for T as detailed in Assumption 4.1. For the third term in (4.8), we first introduce for the elliptic extension $E_N : Y_N \to V_N$. By a reasoning similar to that in the proof of Corollary 2.12, we get for $v \in H^{1/2}(\partial\Omega)$

$$\|E_N(Q_N v)\|_{H^1(\Omega)} \le C\|Q_N v\|_{H^{1/2}(\partial\Omega)} \le C\|v\|_{H^{1/2}(\partial\Omega)}, \tag{4.11}$$

where we used the stability result (2.15) in the last step. For the treatment of the third term in (4.8), we next let $u \in H^1(\Omega)$ be the solution to (1.2) with $f = 0$ and Dirichlet boundary conditions λ; $\tilde{u} \in H^1(\Omega)$ solves (1.2) with $f = 0$ and boundary conditions $Q_N\lambda$; and $u_N \in V_N$ is the *hp*-FEM approximation to u given by (2.3). Reasoning as in [25, Lemma 6.1], the definitions of the operators T, T_N imply

$$
\begin{aligned}
\|Q_N(T - T_N)Q_N\lambda\|_{H^{-1/2}(\partial\Omega)} &= \sup_{v \in H^{1/2}(\partial\Omega)} \frac{\langle (T - T_N)Q_N\lambda, Q_N v\rangle_{0,\partial\Omega}}{\|v\|_{H^{1/2}(\partial\Omega)}} \\
&= \sup_{v \in H^{1/2}(\partial\Omega)} \frac{B(\tilde{u} - u_N, E_N(Q_N v))}{\|v\|_{H^{1/2}(\partial\Omega)}} \\
&\le C\|\tilde{u} - u_N\|_{H^1(\Omega)} \le C\left[\|u - u_N\|_{H^1(\Omega)} + \|u - \tilde{u}\|_{H^1(\partial\Omega)}\right] \\
&\le C\left[\|u - u_N\|_{H^1(\Omega)} + \|\lambda - Q_N\lambda\|_{H^{1/2}(\partial\Omega)}\right].
\end{aligned}
$$

$\|\lambda - Q_N\lambda\|_{H^{1/2}(\partial\Omega)}$ can be bounded as required by (4.10), and Theorem 2.13 allows us to bound $\|u - u_N\|_{H^1(\Omega)}$ in the desired fashion. □

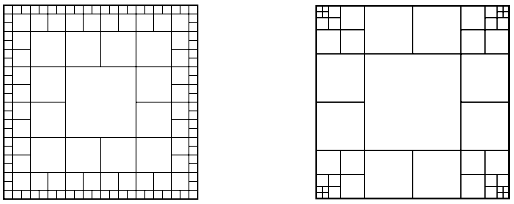

FIG. 4.1. *Refined interface corresponding to Figure* 2.1 *(left) and to Remark* 1.2 *(right).*

Remark 4.6. We employed the $L^2(\partial\Omega)$-projection Q_N in the definition of T_N. Other projections could, in principle, be used as well. Essential is that the projector P_N has the following stability and approximation properties for $\delta \in [0, \delta_0)$:

$$\begin{aligned}\|P_N u\|_{H^{-1/2}(\partial\Omega)} &\leq C\|u\|_{H^{-1/2}(\partial\Omega)},\\ \|P_N u\|_{H^{1/2+\delta}(\partial\Omega)} &\leq C_\delta\|u\|_{H^{1/2+\delta}(\partial\Omega)},\\ \|u - P_N u\|_{H^{1/2}(\partial\Omega)} &\leq C_\delta h^\delta \|u\|_{H^{1/2+\delta}(\partial\Omega)}.\end{aligned}$$

Due to the results of section 3 (see also Table 3.1), the implementation of the finite-dimensional operators S_N and T_N has the linear-logarithmic complexity $O(N \log^q N)$ with respect to $N = O(\dim Y_N)$, except in the case of Neumann boundary conditions, where we arrive at the cost $O(N^{3/2} \log^q N)$.

Remark 4.7. In the case of piecewise constant coefficients in a polygonal domain, an efficient method for matrix-vector product with the discrete Poincaré–Steklov operators was developed in [24, 27, 28, 25]. It is based on a sparse h-FEM approximation to the Schur complement matrix on a rectangle, combined with the reduction of the PDE to the *refined interface*. In this way the Schur complement matrix in each $n \times n$ rectangular subdomain is treated with $O(n \log^2 n)$ arithmetic operations using a truncated Fourier representation. In the case of symmetric and positive definite operators with piecewise constant coefficients, the spectrally equivalent multilevel interface preconditioners (see [27, 28]) lead to the complexity $O(N \log^3 N)$ and the memory requirements $O(N \log N)$ for solving the Schur complement equation on the refined interface.

An example of the refined interface is given in Figure 4.1, where nonconforming decompositions in Figure 4.1 (left) correspond to the geometric meshes in Figure 2.1. Figure 4.1 (right) corresponds to the case of composite meshes refined towards the corner points, related to the situation in Remark 1.2. An extension of this approach to the biharmonic, Stokes, and Lamé equations was discussed in [25].

In this way, the boundary concentrated hp-FEM presented in this paper extends the above-mentioned methods to the case of variable (piecewise analytic) coefficients.

5. Further applications.

5.1. Relation to boundary integral equations. Consider the case of constant coefficients. The results on the sparse approximation to the Poincaré–Steklov operators directly apply to the construction of asymptotically optimal solvers for the classical boundary integral equations involving the weakly singular, hypersingular, and double layer harmonic potential operators V, D, and K, respectively, defined by

$$Vu(x) = \int_\Gamma g(x,y)u(y)dy, \qquad Ku(x) = \int_\Gamma \frac{\partial}{\partial n_y} g(x,y)u(y)dy,$$
$$K'u(x) = \int_\Gamma \frac{\partial}{\partial n_x} g(x,y)u(y)dy, \qquad Du(x) = -\int_\Gamma \frac{\partial}{\partial n_x}\frac{\partial}{\partial n_y} g(x,y)u(y)dy\,,$$

where $g(x,y)$ denotes the fundamental solution for the corresponding elliptic operator $\mathcal{L}$, and $\Gamma = \partial\Omega$ for a Lipschitz domain $\Omega \in \mathbb{R}^2$. The idea is based on the representation of the inverse to the above-mentioned boundary integral operators in terms of interior T_1, S_1 and exterior T_2, S_2 Poincaré–Steklov mappings proposed in [24]. Given a Hilbert space H and an element $g \in H'$, we denote $H_g := \{v \in H : \langle v, g\rangle = 0\}$.

THEOREM 5.1 (see [24]). *The operator* $V^{-1} : H^{1/2}_{g_0}(\Gamma) \to H^{-1/2}_1(\Gamma)$ *has the representation* $V^{-1} = T_1 + T_2$, *where* g_0 *is the Robin potential on* Γ *satisfying* $K'g_0 = -\frac{1}{2}g_0$. *There holds* $(\frac{1}{2}I - K)^{-1}z = (I + S_2 \cdot T_1)z \;\forall\; z \in H^{1/2}(\Gamma)$, *and* $(\frac{1}{2}I + K)^{-1}z = (I + S_1 \cdot T_2)z \;\forall\; z \in H^{1/2}_{g_0}(\Gamma)$. *The operator* $D^{-1} : H^{-1/2}_1(\Gamma) \to H^{1/2}_{g_0}(\Gamma)$ *has the representation* $D^{-1} = S_1 + S_2$.

An important consequence of the above statement is that whenever some efficient discretization (say, with linear-logarithmic cost) is constructed for the operators T_i and S_i, $i = 1, 2$, we immediately obtain the corresponding efficient approximation for the inverse to the classical boundary integral operators in question. We refer to [19, 20, 8] for an alternative approach to data-sparse approximations of T and S based on modern $\mathcal{H}$-matrix arithmetic.

5.2. Application to exterior boundary value problems. BEMs are very often applied to exterior domain problems. In this subsection, we want to briefly show how the boundary concentrated FEM can be adapted to this setting.

In the exterior domain $\Omega_e := \mathbb{R}^d \setminus \Omega$, we consider the Dirichlet problem

$$\mathcal{L}_e u := -\nabla\cdot(A(x)\nabla u) + b(x)\cdot\nabla u + c(x)u = f \quad \text{in } \Omega_e, \tag{5.1a}$$
$$\gamma_0 u = \lambda \quad \text{on } \partial\Omega, \tag{5.1b}$$

with similar assumptions on the data as in section 1.3. In addition, we assume that b, a_0, and f have bounded support Ω_0 such that $\mathcal{L}_e = -\Delta$ in $\mathbb{R}^2 \setminus \Omega_0$, and that u satisfies the "radiation condition" of the form

$$|u(x)| = O(|x|^{-1}), \qquad |\nabla u| = O(|x|^{-2}), \quad |x| \to \infty. \tag{5.2}$$

(This requires a compatibility condition that suppresses the logarithmic growth at infinity typically exhibited by solutions to Laplace's equation on exterior domains.) We approximate (5.2) by imposing homogeneous Neumann conditions on the auxiliary boundary Γ_∞ with $\operatorname{dist}(\Gamma_\infty, \partial\Omega) = R = O(N^{1/2})$. As above, N denotes the number of degrees of freedom on $\partial\Omega_e$. Following [28] (see also the references therein), we use a mesh on $\operatorname{Int}(\Gamma_\infty) \setminus \Omega$ that is a geometric mesh in the sense of Definition 2.3 (see Figure 5.1). The number of levels is again estimated by $\log R = O(\log N)$. We stress that the approximation and solution schemes remain verbatim as for the interior problem.

Our arguments indicate that, in the framework of boundary concentrated *hp*-FEM, there is no essential difference between solving exterior and interior problems in the case of smooth coefficients, and we again expect complexity $O(N \log^q N)$ for the approximation of the exterior Poincaré–Steklov operators.

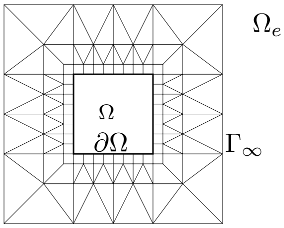

FIG. 5.1. *Geometric mesh on an exterior domain.*

5.3. Application in domain decomposition. The efficient realization of the Poincaré–Steklov operators can also be employed in the context of domain decomposition methods. Let the domain Ω consist of $M_0 \geq 1$ nonoverlapping polygons Ω_i, $\overline{\Omega} = \cup_{i=1}^{M_0}\overline{\Omega}_i$ with $\Gamma := \cup_{i=1}^{M_0}\Gamma_i \setminus \partial\Omega$, and let $f \in H^{-1}(\Omega)$ and $\psi_i \in H^{-1/2}(\Gamma_i)$. Let the bilinear form $B(\cdot,\cdot)$ be written as a sum of subdomain contributions, and consider the problem of finding $u \in H_0^1(\Omega)$ such that

$$\sum_{i=1}^{M_0} B_i(u_{|\Omega_i}, v_{|\Omega_i}) = B(u,v) = F(v) = \int_\Omega f(x)v dx + \sum_{i=1}^{M} \langle \psi_i, v\rangle_{L^2(\Gamma_i)} \qquad \forall v \in H_0^1(\Omega),$$

where the local continuous forms $B_i : V_i \times V_i \to \mathbb{R}$ are supposed to be $H_0^1(\Omega_i)$-elliptic with $V_i := H^1(\Omega_i)$. Letting $u_{0,i} \in H_0^1(\Omega_i)$ be the particular solutions in Ω_i,

$$B_i(u_{0,i}, v) = \int_{\Omega_i} f(x)v dx \qquad \forall v \in H_0^1(\Omega_i), \tag{5.3}$$

and introducing the trace space on Γ,

$$Y_\Gamma = \{u = z_{|\Gamma} : \ z \in H_0^1(\Omega)\}, \qquad \|u\|_{Y_\Gamma} = \inf_{z \in H_0^1(\Omega): z_{|\Gamma} = u} \|z\|_{H^1(\Omega)},$$

we transform the above problem into the interface equation

$$u_{|\Gamma} \in Y_\Gamma : \quad B_\Gamma(u_{|\Gamma}, v) := \sum_{i=1}^{M} \langle T_i u_i, v_i\rangle_{0,\Gamma_i} = \sum_{i=1}^{M} \langle g_i, v\rangle_{\Gamma_i} \quad \forall v \in Y_\Gamma, \tag{5.4}$$

where $g_i = \psi_i - \gamma_{1,i}u_{0,i}$ and $u_i = u_{|\Gamma_i}$, $v_i = v_{|\Gamma_i}$. The local Poincaré–Steklov operators $T_i : H^{1/2}(\Gamma_i) \to H^{-1/2}(\Gamma_i)$ are defined by the B_i-harmonic extensions; see (4.6). Since the bilinear form $B_\Gamma(\cdot,\cdot) : Y_\Gamma \times Y_\Gamma \to \mathbb{R}$ is continuous and coercive, (5.4) is uniquely solvable in Y_Γ for any $g_i \in H^{-1/2}(\Gamma_i)$ providing the trace $u_{|\Gamma}$ (see [25]). Thus, the boundary concentrated FEM can be applied on each subdomain Ω_i separately to numerically realize the operators T_i.

6. Numerics. The main goal of this section is to confirm the principal features of our method (approximation power and conditioning for both full and linear-subspace stiffness matrices) for a simple model problem. Specifically, we consider

$$-\Delta u = 0 \quad \text{on } \Omega = (0,1)^2, \qquad u|_{\partial\Omega} = \begin{cases} \sin \pi x & \text{if } y = 0, \\ 0 & \text{else,} \end{cases} \tag{6.1}$$

with the exact solution $u(x,y) = \sin \pi x \, \frac{\sinh(\pi(1-y))}{\sinh \pi}$. Our calculations are performed with the code CONCEPTS [29]. For quadrilateral elements, this general *hp*-FEM code

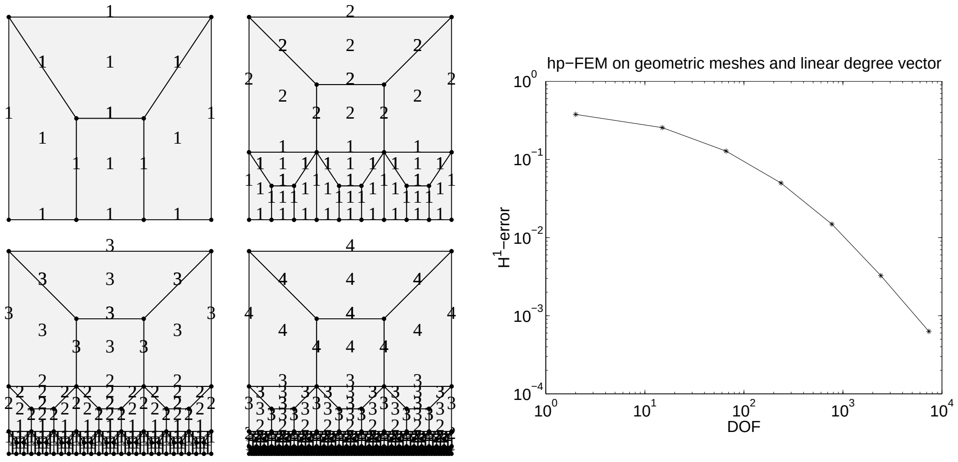

FIG. 6.1. *Geometric meshes for levels* 1–4 *and linear degree vector (left), and* H^1*-error for hp-FEM versus* N *(right).*

TABLE 6.1
Iteration count in the case $p = 1$ *with the mesh in Figure* 2.1.

Level	6	7	8	9	10	11	12
N_{it}	27	30	32	35	37	38	41
N_Γ	376	760	1528	3064	6136	12280	24568
N_Ω	665	1417	2937	5993	12121	24300	48953

employs the so-called Babuška–Szabó shape functions, which are the tensor products of the following one-dimensional shape functions defined on $(-1, 1)$ (we refer to [42, 40] for the details):

$$\varphi_1(x) = \frac{1}{2}(1-x), \quad \varphi_2(x) = \frac{1}{2}(1+x), \quad \varphi_i(x) = \frac{1}{\|L_{i-3}\|_{L^2(-1,1)}} \int_{-1}^{x} L_{i-3}(t)\,dt, \; i \geq 3.$$

Here, the polynomials L_i are the usual Legendre polynomials. First, we check the convergence result of Theorem 2.13, which asserts that for suitable linear degree vector the hp-FEM yields $\|u - u_N\|_{H^1(\Omega)} \leq Ch$. We check this assertion for the meshes and linear degree vectors depicted in Figure 6.1. The mesh size on the portion $y = 0$ of $\partial\Omega$ takes the role of the boundary mesh size h in the statement of Theorem 2.13. The convergence behavior (H^1-error versus number of degrees of freedom DOF $=$ $\dim S^{\mathbf{p}}(\mathcal{T}, \Omega)$) is given in Figure 6.1.

We now turn to our results in Proposition 3.4 concerning the conditioning of the stiffness matrix. For the present Dirichlet problem and $p = 1$, Proposition 3.4 asserts that the condition number is bounded uniformly in h for the meshes of Figure 6.1. The numerical results can be found in Figure 6.2. A second numerical example for the condition number estimates for the stiffness matrix is shown in Table 6.1. For meshes as depicted in Figure 2.1 and polynomial degree $p = 1$, we present in Table 6.1 the number of boundary nodes N_Γ, the number N_Ω of nodes in Ω, as well as the number of CG-iterations N_{it} (with diagonal preconditioning) to reach a residual with l^2-norm below 10^{-6}.

We finally consider the condition number of the full stiffness matrix on the meshes and polynomial degree distributions as depicted in Figure 6.1. From [30] and a rea-

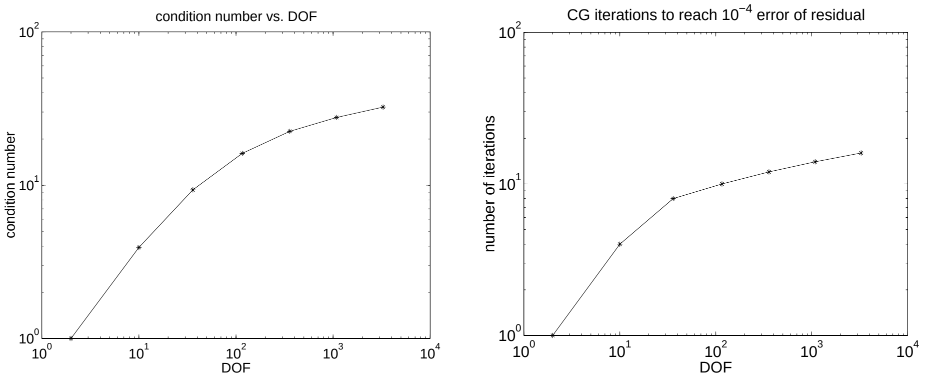

FIG. 6.2. *Condition number of stiffness matrix number of CG-iterations required for a residual of* 10^{-4} *using p.w. linear elements.*

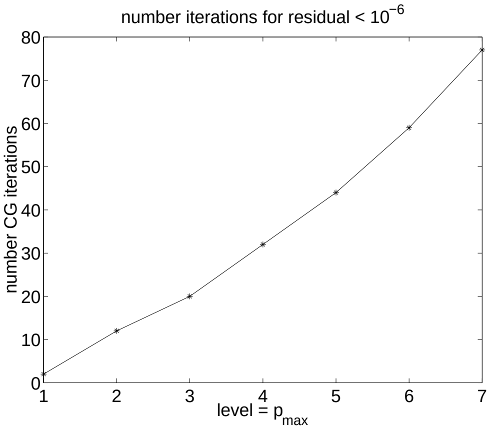

FIG. 6.3. *Iteration count for the full system versus the number of levels.*

soning as in the proof of Proposition 3.4 (see also [31]), the condition number of the full stiffness matrix is bounded by

$$\kappa(A) \leq Cp^4, \tag{6.2}$$

where C is independent of h. Figure 6.3 presents the number of CG-iterations (without preconditioning) to reach a residual of 10^{-6}. The numerical results are slightly better than the growth of $O(p^2)$ expected from (6.2).

Appendix A. Analytic regularity results. In the present section, we are interested in analytic regularity results for solutions to the equation

$$\mathcal{L}u := -\nabla \cdot (A(x)\nabla u) + b(x) \cdot \nabla u + a_0(x)u = f(x) \quad \text{on } \Omega. \tag{A.1}$$

Here, the symmetric matrix A is uniformly positive definite and b is a vector. We furthermore assume the coefficients A, b, c to be analytic; i.e., we stipulate the existence of C_d, $\gamma_d > 0$ such that

$$\|\nabla^p A\|_{L^\infty(\Omega)} + \|\nabla^p b\|_{L^\infty(\Omega)} + \|\nabla^p a_0\|_{L^\infty(\Omega)} \leq C_d \gamma_d^p p! \qquad \forall p \in \mathbb{N}_0. \tag{A.2}$$

The aim of the present section is the proof of the following analytic regularity result for the solution u of (A.1).

THEOREM A.1. *Let $\Omega \subset \mathbb{R}^2$ be a bounded Lipschitz domain with boundary $\partial\Omega$. Let the distance function r be given by* (1.15). *Let f be analytic on Ω and satisfy for some $\delta \in (0,1]$ and C_f, $\gamma_f > 0$*

$$\|r^{p+1-\delta}\nabla^p f\|_{L^2(\Omega)} \leq C_f \gamma_f^p p! \qquad \forall p \in \mathbb{N}_0. \tag{A.3}$$

Finally, let $u \in H^{1+\delta}(\Omega)$ solve (*A.1*) *with data A, b, a_0 satisfying* (*A.2*). *Then there exist C, $\gamma > 0$ depending only on Ω, C_d, C_f, γ_d, γ_f, and δ such that*

$$\|r^{p+1-\delta}\nabla^{p+2}u\|_{L^2(\Omega)} \leq C\gamma^p p! \|u\|_{H^{1+\delta}(\Omega)} \qquad \forall p \in \mathbb{N}_0.$$

Remark A.2. The restrictions on the data A, b, c are not minimal: blow-up akin to that in (A.3) is conceivable. The theorem can also be extended to the case of piecewise analytic data A, b, c.

In order to prove Theorem A.1, we start with the following lemma.

LEMMA A.3. *Let B_R be a ball of radius $R \leq 1$. Assume that A, b, c satisfy* (A.2) *with Ω replaced with B_R. Assume that f satisfies on B_R*

$$\|\nabla^p f\|_{L^2(B_R)} \leq C_f \gamma_f^p p! R^{-p-1+\delta} \qquad \forall p \in \mathbb{N}_0$$

for some C_f, $\gamma_f > 0$, $\delta \in (0,1]$. Let $u \in H^{1+\delta}(B_R)$ solve

$$-\nabla \cdot (A\nabla u) + b \cdot \nabla u + cu = f \qquad \text{on } B_R.$$

Then for every $c \in (0,1)$ there exist constants C, $\gamma > 0$ depending only on C_d, γ_d, C_f, γ_f, δ, and c such that

$$\|\nabla^{p+2}u\|_{L^2(B_{cR})} \leq CR^{-p-1+\delta}\gamma^p p! \left[\|u\|_{H^1(B_R)} + |\nabla u|_{H^\delta(B_R)}\right],$$

where $|\nabla u|_{H^\delta(B_R)}$ stands for the Aronszajn–Slobodeckij norm.

Proof. Using the techniques of [35], we have (see [32, Proposition 5.5.1] for the details)

$$R^p\|\nabla^{p+2}u\|_{L^2(B_{cR})} \leq C\gamma^p p! \left[R^{-1}\|\nabla u\|_{L^2(B_R)} + R^{-2}\|u\|_{L^2(B_R)} + C_f R^{-1+\delta}\right], \tag{A.4}$$

where C, $\gamma > 0$ depend only on γ_f, C_d, and γ_d. For an arbitrary linear function l, the function $u - l$ satisfies

$$L(u-l) = \tilde{f} := f - \mathcal{L}l.$$

From the assumptions on the data, we then conclude that for all $p \in \mathbb{N}_0$

$$\begin{aligned}\|\nabla^p \tilde{f}\|_{L^2(B_R)} &\leq C_f\gamma_f^p p! R^{-p-1+\delta} + C\gamma^p p! \|l\|_{H^1(B_R)} \\ &\leq \tilde{C}\tilde{\gamma}^p R^{-p-1+\delta}\left[C_f + R^{1-\delta}\|l\|_{H^1(B_R)}\right],\end{aligned}$$

where the constants $\tilde{C}$, $\tilde{\gamma} > 0$ depend on C_d, γ_d, and γ_f. Applying (A.4) with u replaced with $u - l$, we obtain

$$\begin{aligned}R^p\|\nabla^{p+2}u\|_{L^2(B_{cR})} \leq C\gamma^p p! [&R^{-1}\|\nabla(u-l)\|_{L^2(B_R)} \\ &+ R^{-2}\|u-l\|_{L^2(B_R)} + R^{-1+\delta}C_f + \|l\|_{H^1(B_R)}].\end{aligned} \tag{A.5}$$

The assumption $u \in H^{1+\delta}(B_R)$ implies the existence of a linear function l such that

$$\|u - l\|_{L^2(B_R)} + R\|\nabla(u - l)\|_{L^2(B_R)} \le CR^{1+\delta}|\nabla u|_{H^\delta(B_R)},$$

where $|\cdot|_{H^\delta(B_R)}$ denotes the Aronszajn–Slobodeckij seminorm. Using $R \le 1$, we get

$$R^{1-\delta+p}\|\nabla^{p+2}u\|_{L^2(B_{cR})} \le C\gamma^p p! \left[|\nabla u|_{H^\delta(B_R)} + \|u\|_{H^1(B_R)} + C_f\right]. \qquad \square$$

Proof of Theorem A.1. Using the Besicovitch covering theorem (see, e.g., [45]), we can construct a covering of Ω by a countable collection $\mathcal{B} = \{B_i \,|\, i \in \mathbb{N}\}$ of closed balls B_i with the following properties:

1. $B_i = B_{r_i}(x_i)$, where $r_i = c' \operatorname{dist}(x_i, \partial\Omega)$ for some fixed $c' \in (0, 1)$;
2. there exists $N \in \mathbb{N}$ such that for all $x \in \Omega$: $|\{i \in \mathbb{N} \,|\, x \in B_i\}| \le N$;
3. there exists $c \in (0, 1)$ such that $\Omega \subset \cup_{i\in\mathbb{N}} B_{cr_i}(x_i)$.

Set

$$C_i^2 := \sum_{p\in\mathbb{N}_0} \frac{1}{(2\gamma_f)^{2p}(p!)^2}\|r^{p+1-\delta}\nabla^p f\|^2_{L^2(B_i)}.$$

The properties of the covering $\mathcal{B}$ and the assumption (A.3) imply

$$r_i^{p+1-\delta}\|\nabla^p f\|_{L^2(B_i)} \le C_i \left(\frac{c'}{1-c'}\right)^{p+1-\delta} (2\gamma_f)^p p! \qquad \forall p \in \mathbb{N}_0,$$

$$\sum_{i\in\mathbb{N}} C_i^2 \le NC_f^2 \sum_{p\in\mathbb{N}_0} \frac{1}{(2\gamma_f)^{2p}(p!)^2}\gamma_f^{2p}(p!)^2 = \frac{4}{3}NC_f^2.$$

From Lemma A.3 we get

$$r_i^{p+1-\delta}\|\nabla^{p+2}u\|_{L^2(B_{cr_i}(x_i))} \le \gamma^p p! \left[C_i + \|u\|_{H^1(B_i)} + |\nabla u|_{H^\delta(B_i)}\right].$$

Using the fact that $\Omega \subset \cup_i B_{cr_i}(x_i)$ and the finite overlap property of the covering $\mathcal{B}$, we get by summation over all balls B_i

$$\begin{aligned}\|r^{p+1-\delta}\nabla^{p+2}u\|^2_{L^2(\Omega)} &\le \left(\frac{1+c'}{c'}\right)^{p+1-\delta} \sum_{i\in\mathbb{N}} r_i^{2(p+1-\delta)}\|\nabla^{p+2}u\|^2_{L^2(B_{cr_i}(x_i))} \\ &\le C(\gamma^p p!)^2 \sum_{i\in\mathbb{N}} C_i^2 + \|u\|^2_{H^1(B_i)} + |\nabla u|^2_{H^\delta(B_i)} \\ &\le C(\gamma^p p!)^2[C_f^2 + \|u\|^2_{H^{1+\delta}(\Omega)}]\end{aligned}$$

for suitable constants C, γ. $\square$

The restriction $\delta \in (0, 1]$ in Theorem A.1 can be removed as follows.

Corollary A.4. *Let $\Omega \subset \mathbb{R}^2$ be a bounded Lipschitz domain and r be defined by* (1.15). *Let $k = \kappa + \delta$ with $\kappa \in \mathbb{N}_0$, $\delta \in [0, 1)$ be given. Assume that $u \in H^{1+k}(\Omega)$ satisfies* (A.1), *with coefficients A, b, c satisfying* (A.2) *and f satisfying*

$$\text{(A.6)} \qquad \|f\|_{H^{\kappa-1}(\Omega)} + \|r^{p+1-\delta}\nabla^{p+\kappa}f\|_{L^2(\Omega)} \le C_f\gamma_f^p p! \qquad \forall p \in \mathbb{N}_0.$$

Then there exist C, $\gamma > 0$ such that

$$\|r^{p+1-\delta}\nabla^{p+2+\kappa}u\|_{L^2(\Omega)} \le C\gamma^p p! \left[C_f + \|u\|_{H^{1+k}(\Omega)}\right].$$

Proof. The corollary is proved by induction on $\kappa \in \mathbb{N}_0$. For $\kappa = 0$, the result holds true by Theorem A.1. Assuming that it holds for all $0 \le \kappa' < \kappa$ for some $\kappa \in \mathbb{N}$, we show that it holds for $\kappa + 1$. The induction hypothesis implies that

$$\|r^{p+1-\delta}\nabla^{p+2+\kappa'}u\|_{L^2(\Omega)} \le C[C_f + \|u\|_{H^{1+\delta+\kappa'}(\Omega)}]\gamma^p p! \qquad \forall p \in \mathbb{N}_0, \quad 0 \le \kappa' < \kappa.$$

Differentiating (A.1) κ times, it is easy to see that $D^\alpha u$ with $|\alpha| = \kappa$ satisfies a differential equation of the form

$$LD^\alpha u = f_\alpha := D^\alpha f + \tilde{u}_\alpha,$$

where $\tilde{u}_\alpha = \sum_{|\beta|\le\kappa+1} \lambda_{\alpha,\beta} D^\beta u$ for some analytic functions $\lambda_{\alpha,\beta}$. The induction hypothesis and the assumptions on f imply that

$$\|r^{p+1-\delta}\nabla^p f_\alpha\|_{L^2(\Omega)} \le C\left[C_f + \|u\|_{H^{1+\delta+\kappa}(\Omega)}\right]\gamma^p p! \qquad \forall p \in \mathbb{N}_0.$$

(See [32, Lemma 4.3.3] for a rigorous proof that products $\lambda_{\alpha,\beta}D^\beta u$ satisfy the desired bounds.) Theorem A.1 therefore allows us to conclude the induction argument. □

Appendix B. Compact embeddings. For $\delta \in (0, 1)$ and a domain $\Omega \subset \mathbb{R}^2$ we define as usual

$$\|u\|^2_{\widetilde{H}^\delta(\Omega)} := \int_\Omega \int_\Omega \frac{|u(x) - u(y)|^2}{|x - y|^{2+2\delta}}\, dxdy + \int_\Omega \frac{|u(x)|^2}{|\mathrm{dist}\,(x, \partial\Omega)|^{2\delta}}\, dx. \tag{B.1}$$

The following lemma is due to von Petersdorff [43] (see also [2] for a proof).

LEMMA B.1. *Let $\mathcal{B} = \{B_i \,|\, i \in \mathbb{N}\}$ be a covering of a domain $\Omega \subset \mathbb{R}^2$ that satisfies a* finite overlap property*; i.e., there exists $N \in \mathbb{N}$ such that*

$$\sup_{x\in\Omega} \mathrm{card}\,\{i \in \mathbb{N} \,|\, x \in B_i\} \le N. \tag{B.2}$$

Then

$$\sum_{i,j\in\mathbb{N}} \int_{B_i}\int_{B_j} \frac{|u(x) - u(y)|^2}{|x - y|^{2+2\delta}}\, dxdy \le N\left(3 + \frac{\pi}{\delta}\right) \sum_{i\in\mathbb{N}} \|u\|^2_{\widetilde{H}^\delta(B_i)}.$$

Let $\Omega \subset \mathbb{R}^2$ be a bounded Lipschitz domain, and let r be defined by (1.15). For $k \in \mathbb{N}$ and $\beta \in (0, 1)$ introduce the norm

$$\|u\|^2_{H^k_\beta(\Omega)} := \|u\|^2_{H^{k-1}(\Omega)} + \|r^\beta \nabla^k u\|^2_{L^2(\Omega)} \tag{B.3}$$

and define the spaces $H^k_\beta(\Omega)$ as the completion of $C^\infty(\overline{\Omega})$ under this norm.

LEMMA B.2. *Let $\Omega \subset \mathbb{R}^2$ be a Lipschitz domain, $\beta \in (0, 1)$. Then for each $0 \le \delta < \min\{1/2, 1 - \beta\}$ there exists $C > 0$ such that*

$$\|u\|_{H^\delta(\Omega)} \le C\|u\|_{H^1_\beta(\Omega)} \qquad \forall u \in H^1_\beta(\Omega).$$

Proof. We start with the following variant of Hardy's inequality in one dimension:

$$\int_0^\infty x^{-2\delta}|u(x)|^2\, dx \le C_\delta \left[\int_0^\infty x^{2(1-\delta)}|u'(x)|^2\, dx + \int_0^\infty |u(x)|^2\, dx\right] \tag{B.4}$$

for all functions u such that the right-hand side is finite (see, e.g., [22, Theorem 330]). In the standard way by locally flattening the boundary (note that Ω is assumed to be Lipschitz), we then obtain from (B.4) the following two-dimensional result: For every $\delta \in [0, 1/2)$ there exists $C_\delta > 0$ such that

$$\|r^{-\delta} u\|_{L^2(\Omega)} \leq C_\delta \left[\|r^{1-\delta}\nabla u\|_{L^2(\Omega)} + \|u\|_{L^2(\Omega)}\right] \qquad \forall u \in H^1_\beta(\Omega). \tag{B.5}$$

We now turn to the proof of the lemma. Let $\mathcal{B} = \{B_i \,|\, i \in \mathbb{N}\}$ be the cover of Ω by balls given in the proof of Theorem A.1. For each i, let $\hat{u}_i = u \circ F_i$, where the affine map $F_i : \hat{B} \to B_i$ maps the unit ball $\hat{B}$ onto B_i. Sobolev's embedding theorem implies

$$\|\hat{u}_i\|^2_{\widetilde{H}^\delta(\hat{B})} \leq C \left[\|\nabla \hat{u}_i\|^2_{L^2(\hat{B})} + \|\hat{u}_i\|^2_{L^2(\hat{B})}\right].$$

Here, we used the assumption $\delta < 1/2$. Scaling back to the balls B_i, we conclude

$$r_i^{-2+2\delta}\|u\|^2_{\widetilde{H}^\delta(B_i)} \leq C \left[\|\nabla u\|^2_{L^2(B_i)} + r_i^{-2}\|u\|^2_{L^2(B_i)}\right].$$

Thus, using the properties of the covering

$$\|u\|^2_{\widetilde{H}^\delta(B_i)} \leq C \left[\|r^{1-\delta}\nabla u\|^2_{L^2(B_i)} + \|r^{-\delta} u\|^2_{L^2(B_i)}\right].$$

Summing over all balls B_i of the covering and using its overlap property together with Lemma B.1, we arrive at

$$\begin{aligned}\|u\|^2_{H^\delta(\Omega)} &\leq C \sum_i \|u\|^2_{\widetilde{H}^\delta(B_i)} \leq C \left[\|r^{1-\delta}\nabla u\|^2_{L^2(\Omega)} + \|r^{-\delta} u\|^2_{L^2(\Omega)}\right] \\ &\leq C \left[\|r^{1-\delta}\nabla u\|^2_{L^2(\Omega)} + \|u\|^2_{L^2(\Omega)}\right],\end{aligned}$$

where, in the last step, we appealed to (B.5). Noting $1 - \delta > \beta$ finishes the proof. □

A consequence of Lemma B.2 is the following.

Theorem B.3. *Let $\Omega \subset \mathbb{R}^2$ be a bounded Lipschitz domain, $\beta \in (0, 1)$. Then for each $0 \leq \delta < \min\{1/2, 1 - \beta\}$ the embedding $H^2_\beta(\Omega) \subset H^{1+\delta}(\Omega)$ is compact. In particular, $H^2_\beta(\Omega) \subset C^0(\overline{\Omega})$.*

Proof. The embedding $H^2_\beta(\Omega) \subset C^0(\overline{\Omega})$ follows from $H^{1+\delta}(\Omega) \subset C^0(\overline{\Omega})$, valid for all $\delta > 0$ by Sobolev's embedding theorem. Because $H^{1+\delta}(\Omega) \subset H^{1+\delta'}(\Omega)$ is compactly embedded for $0 \leq \delta < \delta'$, it suffices to show that for each δ there exists $C > 0$ such that $\|u\|_{H^{1+\delta}(\Omega)} \leq C\|u\|_{H^2_\beta(\Omega)}$, which follows from Lemma B.2 applied to ∇u. □

Theorem B.4. *Let $\hat{K}$ be the reference square or the reference triangle. Let $r(x) = \operatorname{dist}(x, \hat{K})$, $\beta \in (0, 1)$. For $u \in H^2_\beta(\hat{K})$ let Iu be the linear (if $\hat{K} = T$) or the bilinear (if $\hat{K} = S$) interpolant of u. Then*

$$\|u - Iu\|_{H^2_\beta(\hat{K})} \leq C\|r^\beta \nabla^2 u\|_{L^2(\hat{K})}.$$

Proof. Let A_1, A_2, A_3 be three vertices of $\hat{K}$. Exploiting the compactness result of Theorem B.3 in the same way as in the proof of [40, Lemma 4.16], we obtain the existence of $C > 0$ such that

$$\|u\|^2_{H^2_\beta(\hat{K})} \leq C \left[\|r^\beta \nabla^2 u\|^2_{L^2(\hat{K})} + \sum_{i=1}^3 |u(A_i)|^2\right] \qquad \forall u \in H^2_\beta(\hat{K}).$$

As $u(A_i) = Iu(A_i)$ by construction, the result follows. □

Appendix C. Sobolev spaces on the boundary of polygons.

LEMMA C.1. *Let $I = [a, b]$, $I' = [a', b']$ be intervals. Let $\varphi : I \to I'$ be a piecewise smooth bijection. Then for $|s| < 3/2$ the map $u \mapsto u \circ \phi$ is an isomorphism between $H^s(I)$ and $H^s(I')$. The same result holds for the spaces $H^s_{per}(I)$, $H^s_{per}(I')$ of periodic functions if the piecewise smooth function ϕ satisfies additionally $\varphi(a) = \varphi(b)$.*

In particular, for a polygon Ω, let $\varphi : I \to \partial\Omega$ be the parametrization by arc length. Then the map $u \mapsto u \circ \phi$ provides an isomorphism between the spaces $H^s(\partial\Omega)$ and $H^s_{per}(I)$ for $|s| < 3/2$.

Proof. This result is due to Grisvard; see, e.g., [11, Corollary 2.8]. □

For a mesh $\mathcal{T} = \{K\}$, we define piecewise polynomial spaces $S^{p,k}(I, \mathcal{T})$, p, $k \in \mathbb{N}_0$, by

$$S^{p,k}(I, \mathcal{T}) = \{u \in H^k(I) \,|\, u|_K \text{ is a polynomial of degree } p\}.$$

LEMMA C.2. *Let $I \subset \mathbb{R}$ be an interval and $\mathcal{T}$ a quasi-uniform mesh on I with mesh size h; i.e., the nodes $x_0 < x_1 < \cdots < x_N$ of the mesh satisfy $\gamma^{-1}h \le x_{i+1} - x_i \le \gamma h$, $i = 0, \ldots, N-1$, for some $\gamma > 0$. Then for every $\varepsilon \in [0, 1/2)$ and every $p \in \mathbb{N}_0$ there exists $C_{\varepsilon,p} > 0$ such that*

$$\|u\|_{H^\varepsilon(I)} \le C_{\varepsilon,p} h^{-\varepsilon} \|u\|_{L^2(I)} \qquad \forall u \in S^{p,0}(I, \mathcal{T}), \tag{C.1}$$

$$\|u\|_{H^{1+\varepsilon}(I)} \le C_{\varepsilon,p} h^{-(1+\varepsilon)} \|u\|_{L^2(I)} \qquad \forall u \in S^{p,1}(I, \mathcal{T}). \tag{C.2}$$

Proof. We first show (C.1). Equation (C.1) is trivially valid for $\varepsilon = 0$. Let therefore $\varepsilon \in (0, 1/2)$. We characterize the norm $\|\cdot\|_{H^\varepsilon(I)}$ using the K-functional; that is, we have for all $u \in H^\varepsilon(I)$

$$\|u\|^2_{H^\varepsilon(I)} \sim \int_0^\infty t^{-2\varepsilon-1} K^2(u, t)\, dt, \qquad K^2(u, t) := \inf_{v \in H^1(I)} \|u - v\|^2_{L^2(I)} + t^2 |v'|^2_{L^2(I)}.$$

We choose v in the infimum appropriately. For $t \ge h$ we take $v \equiv 0$ and get

$$\int_h^\infty t^{-2\varepsilon-1} K^2(u, t)\, dt \le \int_h^\infty t^{-2\varepsilon-1} \|u\|^2_{L^2(I)}\, dt = \frac{1}{2\varepsilon} h^{-2\varepsilon} \|u\|^2_{L^2(I)}. \tag{C.3}$$

In the range $t \in (0, h)$ we proceed as follows. Let $\varphi \in C_0^\infty(\mathbb{R})$ be a smooth function with $0 \le \varphi(x) \le 1$ that is supported by $[-1, 1]$ and that satisfies $\varphi \equiv 1$ on $[-1/2, 1/2]$. For $\delta > 0$ we set $\varphi_\delta(x) := \varphi(x/\delta)$. For $t \in (0, h)$ we then set

$$\psi_t(x) := 1 - \sum_{i=0}^N \varphi_{t/\gamma}(x - x_i)$$

(γ is the quasiuniformity constant of the mesh $\mathcal{T}$) and choose the function v in the infimum defining $K(t, u)$ as $v(x) := \psi_t(x) u(x)$. Noting the support properties of ψ_t and standard polynomial inverse estimates, we get with the shorthand $I_i := (x_i, x_{i+1})$

$$\begin{aligned}\|u - v\|^2_{L^2(I)} = \|(1 - \psi_t) u\|^2_{L^2(I)} &\le \sum_{i=0}^{N-1} t\gamma^{-1} \|u\|^2_{L^\infty(I_i)} \le C \sum_{i=0}^{N-1} t h^{-1} \|u\|^2_{L^2(I_i)} \\ &\le C t h^{-1} \|u\|^2_{L^2(I)},\end{aligned}$$

$$\begin{aligned}\|v'\|^2_{L^2(I)} &\le \sum_{i=0}^{N-1} \|(u\psi_t)'\|^2_{L^2(I_i)} \le 2\sum_{i=0}^{N-1} \|u'\|^2_{L^2(I_i)} + \|u\|^2_{L^\infty(I_i)}\|\psi_t'\|^2_{L^2(I_i)} \\ &\le C\sum_{i=0}^{N-1} h^{-2}\|u\|^2_{L^2(I_i)} + h^{-1}t^{-1}\|u\|^2_{L^2(I_i)} \le Ch^{-2}\left(1+\frac{h}{t}\right)\|u\|^2_{L^2(I)}.\end{aligned}$$

A straightforward calculation then shows

$$\int_0^h t^{-1-2\varepsilon}K^2(t,u)\,dt \le Ch^{-2\varepsilon}\|u\|^2_{L^2(I)},$$

where the constant C depends on p, ε, I, and γ but is independent of u and h. This proves (C.1). For (C.2), we note again that the case $\varepsilon = 0$ is a standard polynomial inverse estimate. For $\varepsilon \in (0, 1/2)$, we bound

$$\|u\|_{H^{1+\varepsilon}(I)} \le C\left[\|u\|_{L^2(I)} + \|u'\|_{L^2(I)} + \|u'\|_{H^\varepsilon(I)}\right] \le Ch^{-1}\|u\|_{L^2(I)} + C\|u'\|_{H^\varepsilon(I)}.$$

Since $u' \in S^{p-1,0}(I, \mathcal{T})$, we may apply (C.1) to the second term to get

$$\|u\|_{H^{1+\varepsilon}(I)} \le Ch^{-1}\|u\|_{L^2(I)} + C_{\varepsilon,p}h^{-\varepsilon}\|u'\|_{L^2(I)} \le C_{\varepsilon,p}h^{-1-\varepsilon}\|u\|_{L^2(I)}. \qquad \square$$

PROPOSITION C.3. *Let $I \subset \mathbb{R}$ be an interval, $\mathcal{T}$ be a quasi-uniform mesh on I with quasiuniformity constant γ. Let $P : L^2(I) \to S^{p,1}(I, \mathcal{T})$ be a linear operator with*

(i) *$\|Pu\|_{L^2(I)} \le C_{stable}\|u\|_{L^2(I)}$ for all $u \in L^2(I)$;*
(ii) *$Pu = u$ for all $u \in S^{1,1}(I, \mathcal{T})$.*

Then for every $\varepsilon \in [0, 3/2)$ there exists a constant $C_\varepsilon > 0$ depending only on p, C_{stable}, γ, and ε such that

$$\|Pu\|_{H^\varepsilon(I)} \le C_\varepsilon\|u\|_{H^\varepsilon(I)}.$$

Proof. Let $u \in H^\varepsilon(I)$ be arbitrary. By simultaneous approximation in Sobolev spaces (see, e.g., [9]) there exists $C_\varepsilon > 0$ independent of h such that for every $u \in H^\varepsilon(I)$ we can find $q_u \in S^{1,1}(I, \mathcal{T})$ with

$$h^\varepsilon\|u - q_u\|_{H^\varepsilon(I)} + \|u - q_u\|_{L^2(I)} \le C_\varepsilon h^\varepsilon\|u\|_{H^\varepsilon(I)}. \tag{C.4}$$

Exploiting the reproduction assumption (ii) and the stability assumption (i), we get

$$\|u - Pu\|_{L^2(I)} \le \|u - q_u\|_{L^2(I)} + \|P(u - q_u)\|_{L^2(I)} \le (1 + C_{stable})\|u - q_u\|_{L^2(I)}. \tag{C.5}$$

We can therefore estimate with Lemma C.2

$$\begin{aligned}\|Pu\|_{H^\varepsilon(I)} &\le \|u\|_{H^\varepsilon(I)} + \|u - Pu\|_{H^\varepsilon(I)} \le \|u\|_{H^\varepsilon(I)} + \|u - q_u\|_{H^\varepsilon(I)} + \|q_u - Pu\|_{H^\varepsilon(I)} \\ &\le C_\varepsilon\|u\|_{H^\varepsilon(I)} + C_\varepsilon h^{-\varepsilon}\|q_u - Pu\|_{L^2(I)} \\ &\le C_\varepsilon\|u\|_{H^\varepsilon(I)} + C_\varepsilon h^{-\varepsilon}\left\{\|u - q_u\|_{L^2(I)} + \|u - Pu\|_{L^2(I)}\right\} \\ &\le C_\varepsilon\|u\|_{H^\varepsilon(I)} + C_\varepsilon(2 + C_{stable})h^{-\varepsilon}\|u - q_u\|_{L^2(I)} \le C\|u\|_{H^\varepsilon(I)},\end{aligned}$$

where we have used (C.5) and (C.4). This concludes the proof of the proposition. $\square$

Remark C.4. It can be checked that Proposition C.3 also holds if the linear operator P is replaced with an operator $P : H^1(I) \to S^{p,1}(I, \mathcal{T})$ that is stable in $H^1(I)$, i.e., $\|Pu\|_{H^1(I)} \le C_{stable}\|u\|_{H^1(I)}$ for all $u \in H^1(I)$, and that satisfies assumption (ii) of Proposition C.3.

It can also be checked that Proposition C.3 remains valid for periodic functions, i.e., if $P : L^2(I) \to S^{p,1}(I, \mathcal{T}) \cap H^1_{per}(I)$ satisfies $Pu = u$ for all $u \in H^s_{per}(I)$.

CONVERGENCE ANALYSIS OF A FINITE VOLUME METHOD FOR MAXWELL'S EQUATIONS IN NONHOMOGENEOUS MEDIA[*]

ERIC T. CHUNG[†], QIANG DU[‡], AND JUN ZOU[§]

Abstract. In this paper, we analyze a recently developed finite volume method for the time-dependent Maxwell's equations in a three-dimensional polyhedral domain composed of two dielectric materials with different parameter values for the electric permittivity and the magnetic permeability. Convergence and error estimates of the numerical scheme are established for general nonuniform tetrahedral triangulations of the physical domain. In the case of nonuniform rectangular grids, the scheme converges with second order accuracy in the discrete L^2-norm, despite the low regularity of the true solution over the entire domain. In particular, the finite volume method is shown to be superconvergent in the discrete $H(\text{curl};\Omega)$-norm. In addition, the explicit dependence of the error estimates on the material parameters is given.

1. Introduction.

Let Ω be a general polyhedral domain in $\mathbb{R}^3$, occupied by a material with electric permittivity ε and magnetic permeability μ. Maxwell's equations state that

$$\varepsilon\frac{\partial \mathbf{E}}{\partial t} - \mathbf{curl}\,\mathbf{H} = \mathbf{J} \quad \text{in} \quad \Omega\times(0,T), \tag{1.1}$$

$$\mu\frac{\partial \mathbf{H}}{\partial t} + \mathbf{curl}\,\mathbf{E} = \mathbf{0} \quad \text{in} \quad \Omega\times(0,T), \tag{1.2}$$

$$\text{div}(\varepsilon\mathbf{E}) = \rho \quad \text{in} \quad \Omega\times(0,T), \tag{1.3}$$

$$\text{div}(\mu\mathbf{H}) = 0 \quad \text{in} \quad \Omega\times(0,T), \tag{1.4}$$

where $\mathbf{E} = \mathbf{E}(x,t)$ and $\mathbf{H} = \mathbf{H}(x,t)$ denote the electric and magnetic fields, $\mathbf{J} = \mathbf{J}(x,t)$ denotes the applied current density, and $\rho = \rho(x,t)$ denotes the charge density. This paper is concerned with the case where the domain Ω is composed of two distinct dielectric materials. Let Ω_1 be a polyhedral subdomain strictly lying inside Ω, occupied by a material with electric permittivity ε_1 and magnetic permeability μ_1, and let $\Omega_2 = \Omega\backslash\bar{\Omega}_1$ be occupied by another material with electric permittivity ε_2 and magnetic permeability μ_2. For ease of exposition, we shall consider only the case where the parameters ε_i and μ_i are constant functions in Ω_i, $i = 1,2$, but possibly with great differences in their values. We remark that our subsequent analyses can be

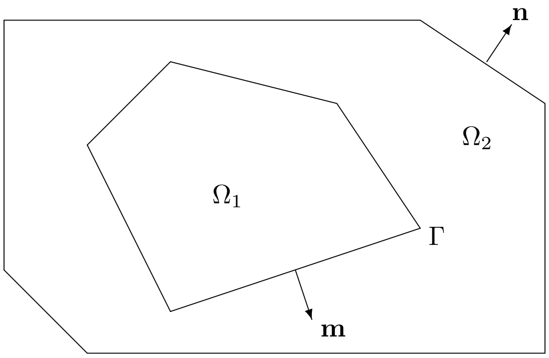

Fig. 1. *Two-dimensional cross-section of dielectric materials Ω_1, Ω_2 and their interface* Γ.

naturally extended to the case with piecewise smooth coefficients as well as multiple subdomains for which our methods have broad applications [3, 11].

Let $\Gamma = \partial\Omega_1$ be the boundary of Ω_1 with a unit outward normal vector $\mathbf{m}$, and let $\partial\Omega$ be the boundary of Ω with a unit outward normal vector $\mathbf{n}$; see Figure 1. We supplement the system (1.1)–(1.4) with the perfect conductor boundary condition and the initial condition given by

$$\mathbf{E} \times \mathbf{n} = \mathbf{0} \quad \text{on} \quad \partial\Omega \times (0,T)\ , \tag{1.5}$$

$$\mathbf{E}(x,0) = \mathbf{E}_0(x) \quad \text{and} \quad \mathbf{H}(x,0) = \mathbf{H}_0(x) \quad \forall x \in \Omega. \tag{1.6}$$

It is well known [3, 19] that the electric and magnetic fields $\mathbf{E}$ and $\mathbf{H}$ satisfy the following physical jump conditions across the interface Γ:

$$[\mathbf{E} \times \mathbf{m}] = \mathbf{0}, \quad [\varepsilon\mathbf{E} \cdot \mathbf{m}] = \rho_\Gamma, \tag{1.7}$$

$$[\mathbf{H} \times \mathbf{m}] = \mathbf{0}, \quad [\mu\mathbf{H} \cdot \mathbf{m}] = 0, \tag{1.8}$$

where $\rho_\Gamma = \rho_\Gamma(x)$ is the surface charge density and, throughout this paper, the jump of any function f across the interface Γ is defined by

$$[f] := f_2|_\Gamma - f_1|_\Gamma,$$

where $f_i = f|_{\Omega_i}$ for $i = 1, 2$.

In addition, we have the following constitutive relations:

$$\mathbf{D} = \varepsilon\mathbf{E}, \quad \mathbf{B} = \mu\mathbf{H}, \tag{1.9}$$

where $\mathbf{D}$ and $\mathbf{B}$ are the electric flux density and the magnetic flux density, respectively.

Over the past few decades, numerical methods for solving Maxwell's equations in homogeneous media have received much attention [11, 20]. The simple and popular Yee's scheme was proposed in 1966 [21], though its convergence analysis was not available until the work by Monk and Süli for nonuniform rectangular grids [14]. In order to handle domains with complicated geometry, both finite element and finite volume methods have been widely studied. For example, some fully discrete finite element methods were used to solve the decoupled time-dependent Maxwell's equations by Monk [13] and Raviart [18]. Second order convergence for the stationary case was established there, while a convergence analysis for the fully discrete time-dependent case was given by Ciarlet and Zou [7]. Chen and Yee proposed a finite volume method to solve Maxwell's equations in [4]. Convergence analyses for both semidiscrete and fully discrete schemes were given by Nicolaides and Wang [16].

For most real applications, however, one is often confronted with the solution of Maxwell's equations in nonhomogeneous media. Many of the aforementioned numerical methods either are not directly applicable or become inefficient (with lower order convergence) for these problems due to different physical characteristics reflected by the electric permittivities and magnetic permeabilities of different media, and due to the extra jump conditions the electric and magnetic fields need to satisfy on the interface; see (1.7)–(1.8). Several attempts have been made to handle the interface Maxwell's problems [4, 5, 20]. For example, Chen and Yee studied a hybrid FDTD/FVTD method for the interface problem [4], assuming that both the tangential components of the electric and magnetic fields are continuous across the interface and the electric field is tangentially piecewise constant on the interface. Chen, Du, and Zou [5] proposed an edge finite element method for solving Maxwell's system with general interface conditions and developed a general framework for its convergence analysis.

Recently, Chung and Zou presented a new finite volume method for Maxwell's equations in nonhomogeneous media [6], together with numerical experiments. In this paper, we will give the convergence analysis of the method for general tetrahedral triangulations. As in many interface problems, the regularity of the analytical solution of Maxwell's system in the entire physical domain is very low, which makes the convergence analysis very difficult. Regardless, we will show that, without making any extra regularity assumptions beyond those that are used for the case of a homogeneous medium [14, 16], the method under consideration is first order convergent for general tetrahedral triangulations and second order convergent for general nonuniform rectangular grids. Furthermore, it is shown that the proposed method has superconvergence in a discrete $H(\mathrm{curl};\Omega)$-norm, and the explicit dependence of the error estimates on the physical material parameters is given. To our knowledge, this seems to be the first rigorous work so far on the convergence of a finite volume method for Maxwell's equations with discontinuous coefficients.

We end this section with some notational conventions to be used in the subsequent analysis. For a nonnegative integer m and $1 \le p < \infty$, we use $W^{m,p}(\Omega)$ to denote the standard Sobolev space equipped with the norm [1]

$$\|u\|_{W^{m,p}(\Omega)} = \left(\sum_{0 \le |\alpha| \le m} \|D^\alpha u\|^p_{L^p(\Omega)} \right)^{1/p}$$

and the seminorm

$$|u|_{W^{m,p}(\Omega)} = \left(\sum_{|\alpha| = m} \|D^\alpha u\|^p_{L^p(\Omega)} \right)^{1/p} .$$

Here $D^\alpha u$ denotes the αth order weak derivative of u. In addition, we define [10]

$$H(\mathrm{curl};\Omega) = \{\mathbf{u} \in L^2(\Omega)^3; \quad \mathbf{curl}\ \mathbf{u} \in L^2(\Omega)^3\},$$

with its seminorm and norm given by

$$|\mathbf{u}|_{H(\mathrm{curl};\Omega)} = \|\mathbf{curl}\ \mathbf{u}\|_{L^2(\Omega)^3}; \quad \|\mathbf{u}\|_{H(\mathrm{curl};\Omega)} = \{\|\mathbf{u}\|^2_{L^2(\Omega)^3} + \|\mathbf{curl}\ \mathbf{u}\|^2_{L^2(\Omega)^3}\}^{\frac{1}{2}} ,$$

respectively. Furthermore, for some $0 < \lambda < 1$, $C^{m,\lambda}(\Omega)$ denotes the standard Hölder spaces of functions whose mth order derivatives are Hölder continuous with exponent λ. The same definitions are adopted on Ω_1 and Ω_2.

We use $L^p(0,T;\mathbf{X})$ to denote the space of all L^p integrable functions $\mathbf{u}(t,\cdot)$ from $[0,T]$ into the Banach space $\mathbf{X}$, and we also define [12]

$$W^{m,p}(0,T;\mathbf{X}) = \left\{\mathbf{u} \in L^p(0,T;\mathbf{X}); \quad \frac{\partial^\alpha \mathbf{u}}{\partial t^\alpha} \in L^p(0,T;\mathbf{X}) \quad \forall |\alpha| \le m\right\},$$

with norm

$$\|\mathbf{u}\|_{W^{m,p}(0,T;\mathbf{X})} = \left\{\sum_{0\le|\alpha|\le m} \left\|\frac{\partial^\alpha \mathbf{u}}{\partial t^\alpha}\right\|_{\mathbf{X}}^p\right\}^{1/p}.$$

When $p = 2$, we set $H^m(\Omega) = W^{m,2}(\Omega)$ and $H^m(0,T;\mathbf{X}) = W^{m,2}(0,T;\mathbf{X})$.

The rest of the paper is organized as follows. Some discrete vector fields and the finite volume method are introduced in sections 2 and 3, respectively. In section 4, we give a discussion of the discrete divergence constraints and stability. The convergence analysis for the general tetrahedral triangulation and the convergence analysis for the case of a nonuniform rectangular grid are given in section 5. Some concluding remarks are given in section 6.

2. Discrete vector fields. We now discuss the triangulation of the domain Ω. We use the Voronoi–Delaunay triangulation [9], which enjoys many elegant geometric properties that allow us to derive the numerical schemes in the subsequent sections. We adopt the notation developed by Nicolaides [15], Nicolaides and Wang [16], and Nicolaides and Wu [17], where a finite volume method was proposed for solving Maxwell's equations with smooth physical coefficients ε and μ.

We first triangulate Ω using the standard tetrahedral elements, which are called the *primal elements*. The triangulation is chosen so that the faces of the primal elements are aligned with the interface Γ. A primal element with at least one face lying on Γ is called an *interface primal element*, and a primal face (edge) lying on Γ is called an interface primal face (edge).

The *dual elements* are the Voronoi polyhedra formed by connecting the circumcenters of adjacent primal elements. Those dual elements (faces and edges) separated by the interface Γ into two parts lying in Ω_1 and Ω_2, respectively, are called the interface dual elements (faces and edges). The definitions and convergence analysis related to dual elements are much more complicated than those related to primal elements, due to the interface. From geometry, it is known that each primal edge is perpendicular to and is in one-to-one correspondence with a dual face, and each dual edge is perpendicular to and in one-to-one correspondence with a primal face.

For the subsequent convergence analysis, we assume that all dihedral angles of each tetrahedron are uniformly acute and the triangulation restricted to each subdomain satisfies

$$K_r \le \frac{h^r_{\max}}{h^r_{\min}} \le \tilde{K}_r, \qquad r = 1, 2\ , \tag{2.1}$$

where $h^r_{\max}$ and $h^r_{\min}$ are, respectively, the local maximum and minimum side lengths of adjacent primal and dual elements in Ω_r, and K_r and $\tilde{K}_r$ are two positive constants.

Let N and L be the numbers of primal and dual elements, respectively, and let F be the number of primal faces (dual edges) and M the number of primal edges (dual faces). Assume that these quantities are numbered sequentially in some order. The individual elements, faces, edges, and nodes of the primal mesh are denoted by τ_i, κ_j, σ_k, and ν_l, respectively. Those quantities related to the dual mesh are denoted by the primed forms such as τ'_i, κ'_j, σ'_k, and ν'_l. The area of κ_j is denoted by s_j, and the length of σ_k is given by h_k. A direction is assigned to each primal and dual edge by the rule that positive direction is from low to high node number. A direction is also assigned to each primal (dual) face so that it is the same as that of the corresponding dual (primal) edge. We denote by F_1 the number of interior primal faces (dual edges) and by M_1 the number of interior primal edges (dual faces). For each dual edge σ'_j of length h'_j, we define a scaled length:

$$\bar{h}'_j = \begin{cases} \frac{1}{\mu_1} h'_j & \text{if} \quad \sigma'_j \in \Omega_1, \\ \frac{1}{\mu_2} h'_j & \text{if} \quad \sigma'_j \in \Omega_2, \\ (\frac{1}{\mu_1} a_j + \frac{1}{\mu_2}(1-a_j))h'_j & \text{otherwise,} \end{cases}$$

where $0 < a_j < 1$ is the ratio of the length of the portion of σ'_j that belongs to Ω_1 over the length of σ'_j. For any u and v in $\mathbb{R}^{F_1}$, we introduce a mesh and parameter dependent inner product defined by

$$(u,v)_W := \sum_{\kappa_j \subset \Omega} u_j v_j s_j \bar{h}'_j = (Su, D'v) = (D'u, Sv), \tag{2.2}$$

where $S := \text{diag}(s_j)$ and $D' := \text{diag}(\bar{h}'_j)$ are $F_1 \times F_1$ diagonal matrices and $(\cdot,\cdot)$ denotes the standard Euclidean inner product. Similarly, for each dual face κ'_j with area s'_j, we define a scaled area:

$$\bar{s}'_j = \begin{cases} \varepsilon_1 s'_j & \text{if} \quad \kappa'_j \in \Omega_1, \\ \varepsilon_2 s'_j & \text{if} \quad \kappa'_j \in \Omega_2, \\ (\varepsilon_1 b_j + \varepsilon_2(1-b_j))s'_j & \text{otherwise,} \end{cases}$$

where $0 < b_j < 1$ is the ratio of the area of the portion of κ'_j that belongs to Ω_1 over the area of κ'_j. Also, we define a mesh and parameter dependent inner product in $\mathbb{R}^{M_1}$ by

$$(u,v)_{W'} := \sum_{\kappa'_j \subset \Omega} u_j v_j \bar{s}'_j h_j = (S'u, Dv) = (Du, S'v), \tag{2.3}$$

where $S' := \text{diag}(\bar{s}'_j)$ and $D := \text{diag}(h_j)$ are $M_1 \times M_1$ diagonal matrices.

For any $\sigma_j \in \partial\kappa_i$, we say that σ_j is oriented positively along $\partial\kappa_i$ if the direction of σ_j agrees with the one of $\partial\kappa_i$ formed by the right-hand rule with the thumb pointing in the direction of σ'_i. Otherwise, we say that σ_j is oriented negatively along $\partial\kappa_i$. For each interior primal face κ_i, we define its discrete circulation by

$$(Cu)_{\kappa_i} := \sum_{\sigma_j \subset \partial\kappa_i} u_j \tilde{h}_j, \tag{2.4}$$

where

$$\tilde{h}_j = \begin{cases} h_j & \text{if } \sigma_j \text{ is oriented positively along } \partial\kappa_i, \\ -h_j & \text{if } \sigma_j \text{ is oriented negatively along } \partial\kappa_i. \end{cases}$$

Similarly, for each interior dual face κ_i' we define its discrete circulation by

$$(C'u)_{\kappa_i'} := \sum_{\sigma_j' \subset \partial\kappa_i'} u_j \tilde{h}_j', \tag{2.5}$$

where

$$\tilde{h}_j' = \begin{cases} \bar{h}_j' & \text{if } \sigma_j' \text{ is oriented positively along } \partial\kappa_i', \\ -\bar{h}_j' & \text{if } \sigma_j' \text{ is oriented negatively along } \partial\kappa_i'. \end{cases}$$

Clearly, C and C' are two linear mappings from $\mathbb{R}^M$ to $\mathbb{R}^{F_1}$ and $\mathbb{R}^{F_1}$ to $\mathbb{R}^{M_1}$, respectively. We remark that (2.4) and (2.5) are the discrete analogues of the integrals

$$\int_{\kappa_i'} \mathbf{E} \cdot \mathbf{n}_i \, d\sigma \quad \text{and} \quad \int_{\kappa_i} \mathbf{H} \cdot \mathbf{n}_i \, d\sigma$$

by Stokes' theorem, where in what follows $\mathbf{n}_i$ represents the unit normal vector for both primal and dual faces.

For each strictly interior dual edge σ_j' with both endpoints of σ_j' lying in Ω and the ith strictly interior dual face κ_i', we define the entries of a $F_1 \times M_1$ matrix G as

$$(G)_{ji} := \begin{cases} 1 & \text{if } \sigma_j' \text{ is oriented positively along } \partial\kappa_i', \\ -1 & \text{if } \sigma_j' \text{ is oriented negatively along } \partial\kappa_i', \\ 0 & \text{if } \sigma_j' \text{ does not meet } \partial\kappa_i'. \end{cases}$$

Let $w \in \mathbb{R}^M$ be a vector whose kth component is the value assigned to the kth primal edge. Let $w_1 \in \mathbb{R}^{M_1}$ be the restriction of w to the interior primal edges. Denote by $w|_{\partial\Omega}$ the components of w that are related to the boundary. Likewise, denote by $v \in \mathbb{R}^{F_1}$ the vector whose jth component represents a value on the jth interior dual edge. Similarly to [15, 16, 17], we have the following result.

LEMMA 2.1. *Let w, w_1, and v be defined as above, and $w|_{\partial\Omega} = 0$; then we have*

$$Cw = GDw_1 \, , \qquad C'v = G^T D'v \, . \tag{2.6}$$

Proof. To see the first relation in (2.6), we note that the ith component of both sides corresponds to the primal face κ_i. By the definition (2.4) and $w|_{\partial\Omega} = 0$, we have

$$(Cw)_{\kappa_i} = \sum_{\sigma_j \subset \partial\kappa_i} w_j \tilde{h}_j = \sum_{j=1}^{M_1} c_j w_j h_j, \qquad (GDw_1)_{\kappa_i} = \sum_{j=1}^{M_1} g_j h_j w_j,$$

where

$$c_j = \begin{cases} 1 & \text{if } \sigma_j \text{ is oriented postively along } \partial\kappa_i, \\ -1 & \text{if } \sigma_j \text{ is oriented negatively along } \partial\kappa_i, \\ 0 & \text{if } \sigma_j \text{ does not meet } \partial\kappa_i \end{cases}$$

for any interior primal edge σ_j, and $g_j = (G)_{ij}$. By the orthogonality between primal and dual meshes, we conclude that c_j and g_j are the same; the first relation in (2.6) is thus proved. The second relation can be proved by a similar technique. □

Using Lemma 2.1, we can show a discrete analogue of the following Green's formula:

$$\int_\Omega \mathbf{curl}\,\mathbf{E}\cdot\mathbf{B}\,dx = \int_\Omega \mathbf{curl}\,\mathbf{B}\cdot\mathbf{E}\,dx,$$

which holds when $\mathbf{E}\times\mathbf{n}=0$ on $\partial\Omega$.

LEMMA 2.2. *With the same definitions as in Lemma* 2.1, *we have*

$$(Cw, D'v) = (C'v, Dw_1). \tag{2.7}$$

Proof. Equation (2.7) follows directly from Lemma 2.1 and (2.6):

$$(C'v, Dw_1) = (G^T D'v, Dw_1) = (D'v, GDw_1) = (D'v, Cw). \qquad \square$$

With the definition of the discrete circulation operator C, we define the following inner product:

$$(u,v)_V := \sum_{\kappa_i\subset\Omega} (Cu)_i (Cv)_i s_i^{-1}\bar{h}'_i = (S^{-1}Cu, D'Cv) = (D'Cu, S^{-1}Cu) \tag{2.8}$$

for any vectors $u, v \in \mathbb{R}^M$, and the induced norm

$$|u|_V := (u,u)_V^{\frac{1}{2}}. \tag{2.9}$$

This norm is equivalent to the discrete seminorm of $H(\text{curl};\Omega)$. We also define

$$\|u\|_V := (\|u\|_{W'}^2 + |u|_V^2)^{\frac{1}{2}}, \tag{2.10}$$

which is a discrete analogue of the norm in $H(\text{curl};\Omega)$.

Let τ_i be a primal element and $\kappa_j \in \partial\tau_i$ be a primal face. We say κ_j is oriented positively along $\partial\tau_i$ if the dual edge σ'_j on κ_j is directed towards the outside of τ_i. Otherwise, we say κ_j is oriented negatively along $\partial\tau_i$. For each primal element τ_i we define a discrete flux by

$$(\mathcal{D}u)_i := \sum_{\kappa_j\subset\partial\tau_i} u_j\tilde{s}_j \qquad \forall u\in\mathbb{R}^{F_1}\ , \tag{2.11}$$

where no components of u on the boundary faces are involved, and $\tilde{s}_j$ is given by

$$\tilde{s}_j = \begin{cases} s_j & \text{if } \kappa_j \text{ is oriented positively along } \partial\tau_i,\\ -s_j & \text{if } \kappa_j \text{ is oriented negatively along } \partial\tau_i.\end{cases}$$

The mapping $\mathcal{D}$ is the discrete version of the divergence operator by noting that

$$\int_{\tau_i} \operatorname{div}\mathbf{u}\,dx = \int_{\partial\tau_i}\mathbf{u}\cdot\mathbf{n}\,ds.$$

Similarly, for each dual element τ'_i, we define a discrete flux by

$$(\mathcal{D}'u)_i := \sum_{\kappa'_j\subset\partial\tau'_i} u_j\tilde{s}'_j \quad \forall u\in\mathbb{R}^{M_1}\ , \tag{2.12}$$

where

$$\tilde{s}'_j = \begin{cases} \bar{s}'_j & \text{if } \kappa'_j \text{ is oriented positively along } \partial\tau'_i, \\ -\bar{s}'_j & \text{if } \kappa'_j \text{ is oriented negatively along } \partial\tau'_i. \end{cases}$$

Next we present a discrete analogue of the identity div(**curl u**) = 0 for the discrete divergence operators $\mathcal{D}$ and $\mathcal{D}'$. To do so, we introduce two matrices B_1 and B'_1. B_1 is a $F_1 \times N$ matrix given by

$$(B_1)_{ji} := \begin{cases} 1 & \text{if } \kappa_j \text{ is oriented positively along } \partial\tau_i, \\ -1 & \text{if } \kappa_j \text{ is oriented negatively along } \partial\tau_i, \\ 0 & \text{if } \kappa_j \text{ does not meet } \partial\tau_i, \end{cases}$$

while B'_1 is a $M_1 \times L$ matrix given by

$$(B'_1)_{ji} := \begin{cases} 1 & \text{if } \kappa'_j \text{ is oriented positively along } \partial\tau'_i, \\ -1 & \text{if } \kappa'_j \text{ is oriented negatively along } \partial\tau'_i, \\ 0 & \text{if } \kappa'_j \text{ does not meet } \partial\tau'_i. \end{cases}$$

Then we have the following relations (cf. [6]).

Lemma 2.3. *We have*

$$\mathcal{D} = B_1^T S, \qquad \mathcal{D}' = (B'_1)^T S', \tag{2.13}$$

$$B_1^T C = \mathbf{0}, \qquad (B'_1)^T C' = \mathbf{0}. \tag{2.14}$$

3. The finite volume method. The finite volume method proposed in Chung and Zou [6] for solving the interface Maxwell's equations (1.1)–(1.8) approximates the edge average of **E** on each primal edge and the face average of **B** on each primal face. The use of the magnetic flux density **B** in the approximation, instead of the magnetic field **H** as in most existing numerical methods, is crucial for maintaining accuracy in interface problems. This observation is supported by the numerical experiments presented in [6].

We now introduce some average quantities. For the magnetic flux density **B**, we define its primal face average $B_f \in \mathbb{R}^{F_1}$ by

$$(B_f)_i := \frac{1}{s_i} \int_{\kappa_i} \mathbf{B} \cdot \mathbf{n}_i \, d\sigma$$

for each primal face κ_i and its dual edge average $B'_e \in \mathbb{R}^{F_1}$ by

$$(B'_e)_i := \frac{1}{h'_i} \int_{\sigma'_i} \mathbf{B} \cdot \mathbf{t}_i \, dl$$

for each noninterface dual edge σ'_i. Further, we let

$$\begin{aligned} (B'_e)_i &:= \alpha_i (B'_{e_1})_i + (1-\alpha_i)(B'_{e_2})_i \\ &:= \alpha_i \frac{1}{h_i^1} \int_{\sigma_i^1} \mathbf{B} \cdot \mathbf{t}_i \, dl + (1-\alpha_i) \frac{1}{h_i^2} \int_{\sigma_i^2} \mathbf{B} \cdot \mathbf{t}_i \, dl \end{aligned} \tag{3.1}$$

for each interface dual edge σ'_i. Here, for $r = 1, 2$, $\sigma_i^r = \sigma'_i \cap \Omega_r$ is the portion of σ'_i in Ω_r and $\alpha_i := \mu_r^{-1} h_i^r (\bar{h}'_i)^{-1}$ with h_i^r being the length of σ_i^r.

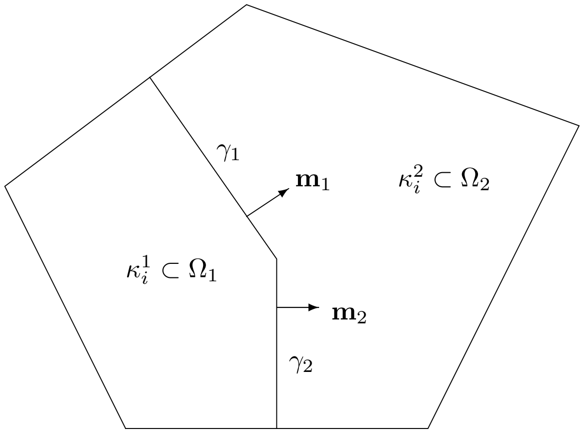

FIG. 2. *A dual face κ_i', divided by the interface into two parts κ_i^1, κ_i^2.*

For the electric field $\mathbf{E}$, we define its primal edge average $E_e \in \mathbb{R}^{M_1}$ by

$$(E_e)_i := \frac{1}{h_i}\int_{\sigma_i} \mathbf{E}\cdot\mathbf{n}_i \, dl$$

for each primal edge σ_i and its dual face average $E_f' \in \mathbb{R}^{M_1}$ by

$$(E_f')_i := \frac{1}{s_i'}\int_{\kappa_i'} \mathbf{E}\cdot\mathbf{n}_i \, d\sigma$$

for each non-interface dual face κ_i', and we let

$$\begin{aligned}(E_f')_i &:= \beta_i(E_{f_1}')_i + (1-\beta_i)(E_{f_2}')_i \\ &:= \beta_i\frac{1}{s_i^1}\int_{\kappa_i^1} \mathbf{E}\cdot\mathbf{n}_i \, d\sigma + (1-\beta_i)\frac{1}{s_i^2}\int_{\kappa_i^2} \mathbf{E}\cdot\mathbf{n}_i \, d\sigma\end{aligned} \tag{3.2}$$

for each interface dual face κ_i'; see Figure 2. Here, for $r = 1, 2$, $\kappa_i^r = \kappa_i' \cap \Omega_r$ is the portion of κ_i' in Ω_i with its area being s_i^r, and $\beta_i := \varepsilon_r s_i^r(\bar{s}_i')^{-1}$.

With the above notation, one can show that for each primal face κ_j and dual face κ_j' the true electric and magnetic fields $\mathbf{E}$ and $\mathbf{B}$ satisfy the equations [6]

$$s_j \frac{d}{dt}(B_f)_j + (CE_e)_{\kappa_j} = 0, \tag{3.3}$$

$$\bar{s}_j' \frac{d}{dt}(E_f')_j - (C'B_e')_{\kappa_j'} = \int_{\kappa_j'} \mathbf{J}\cdot\mathbf{n}_j \, d\sigma\,. \tag{3.4}$$

Let $E \in \mathbb{R}^{M_1}$ and $B \in \mathbb{R}^{F_1}$ be the approximations of the primal edge and face averages of the true solution $\mathbf{E}$ and $\mathbf{B}$ to (1.1)–(1.4), respectively. Note that each dual face (edge) average and the corresponding primal edge (face) average are approximately the same for sufficiently small h. Due to continuity of the tangential component of $\mathbf{E}$ and the normal component of $\mathbf{B}$ across the interface Γ, we naturally come to the following approximations based on (3.3) and (3.4):

Find $E \in \mathbb{R}^{M_1}$ and $B \in \mathbb{R}^{F_1}$ such that $E(0) = E_e(0)$, $B(0) = B_f(0)$, and

$$S' \frac{dE}{dt} - C'B = \tilde{J}, \tag{3.5}$$

$$S \frac{dB}{dt} + CE = \mathbf{0}, \tag{3.6}$$

where $\tilde{J} \in \mathbb{R}^{M_1}$ are defined by the right-hand sides of (3.4), while $E_e(0)$ and $B_f(0)$ are the primal edge average of $\mathbf{E}$ and primal face average of $\mathbf{B}$ at time $t = 0$.

Applying standard results concerning the well-posedness of systems of first order ordinary differential equations, we obtain the following theorem.

THEOREM 3.1. *The semi-discrete scheme* (3.5)–(3.6) *is well-posed.*

4. Discrete divergence constraints and stability. In this section, we show that the solutions E and B of the semidiscrete finite volume scheme (3.5)–(3.6) satisfy the divergence constraint conditions (1.3)–(1.4) at the discrete level.

THEOREM 4.1. *Let E and B be the solutions of* (3.5)–(3.6)*, and let B_f, E_e, and E'_f be the average vectors of* $\mathbf{B}$ *or* $\mathbf{E}$ *as defined in section* 3. *Then*

$$\mathcal{D}B(t) = \mathbf{0}, \qquad \mathcal{D}B_f(t) = \mathbf{0}, \tag{4.1}$$

$$\mathcal{D}'E(t) = \tilde{\rho}(t) + \mathcal{D}'(E_e - E'_f)(0), \qquad \mathcal{D}'E_e(t) = \tilde{\rho}(t) + \mathcal{D}'(E_e - E'_f)(t) \tag{4.2}$$

for any $0 \le t \le T$*, where*

$$\tilde{\rho}_j(t) := \int_{\tau'_j} \rho(x,t)\, dx + \int_{\tau'_j \cap \Gamma} \rho_\Gamma(x,t)\, d\sigma. \tag{4.3}$$

Furthermore, we have the following discrete charge conservation law:

$$(B'_1)^T \tilde{J} = \frac{d\tilde{\rho}(t)}{dt}. \tag{4.4}$$

Proof. Multiplying (3.3) and (3.6) by the matrix B_1^T, and using (2.14), we have

$$\mathcal{D}\frac{dB_f}{dt} = \mathbf{0}, \quad \mathcal{D}\frac{dB}{dt} = \mathbf{0}.$$

So $\mathcal{D}B(t) = \mathcal{D}B_f(t) = \mathcal{D}B_f(0)$. Now (4.1) follows directly from the divergence-free condition (1.4).

To show (4.2) and (4.4), we multiply (3.4) by the matrix $(B'_1)^T$ and then use (2.13) to get

$$\mathcal{D}'\frac{dE'_f}{dt} = (B'_1)^T \tilde{J}. \tag{4.5}$$

Integrating the divergence condition (1.3) on each dual element, we obtain

$$\mathcal{D}'E'_f(t) = \tilde{\rho}(t) \tag{4.6}$$

for any $0 \le t \le T$, which is the second relation in (4.2). Also, the discrete charge conservation law (4.4) follows readily from the two equations above.

Now we multiply (3.5) by the matrix $(B'_1)^T$ and use (4.4) to get

$$\mathcal{D}'\frac{dE}{dt} = (B'_1)^T \tilde{J} = \frac{d\tilde{\rho}(t)}{dt}\ .$$

Integrating in time, we have

$$\mathcal{D}'E(t) = \tilde{\rho}(t) + \mathcal{D}'E(0) - \tilde{\rho}(0),$$

which is the first equation in (4.2) by applying (4.6) at $t = 0$. $\square$

Next we state some stability results for the approximate solutions E and B.

Theorem 4.2. *The solution* (E, B) *to the semidiscrete scheme* (3.5)–(3.6) *satisfies the following stability inequality:*

$$\max_{0\le t\le T}\{\|B(t)\|_W^2 + \|E(t)\|_{W'}^2\} \le 2\|B(0)\|_W^2 + 2\|E(0)\|_{W'}^2 + 4T\int_0^T \|S^{'-1}\tilde{J}(t)\|_{W'}^2\, dt.$$

Proof. Multiplying (3.6) by $D'B$ and (3.5) by DE, and adding up the resulting equations and using (2.7), we obtain

$$\left(S\frac{dB}{dt}, D'B\right) + \left(S'\frac{dE}{dt}, DE\right) = (\tilde{J}, DE),$$

and consequently

$$\frac{1}{2}\frac{d}{dt}\|B(t)\|_W^2 + \frac{1}{2}\frac{d}{dt}\|B(t)\|_{W'}^2 = (\tilde{J}, DE).$$

Integrating with respect to time, we get for any $0 \le s < t$

$$\|B(s)\|_W^2 + \|E(s)\|_{W'}^2 = \|B(0)\|_W^2 + \|E(0)\|_{W'}^2 + 2\int_0^s (\tilde{J}, DE)\, dt.$$

Using the above equation, the desired bound follows from the estimate

$$\begin{aligned}2\int_0^s (\tilde{J}, DE)\, dt &\le 2\int_0^s \|S^{'-1}\tilde{J}(t)\|_{W'}\|E(t)\|_{W'}\, dt\\ &\le 2T\int_0^s \|S^{'-1}\tilde{J}(t)\|_{W'}^2\, dt + \frac{1}{2T}\int_0^s \|E(t)\|_{W'}^2\, dt. \qquad \square\end{aligned}$$

5. Error estimates for the finite volume method. We devote this section to the error analysis of the finite volume scheme (3.5)–(3.6). We will present the discrete L^2-norm error estimates for both a tetrahedral grid and a rectangular grid, where the same convergence orders can be achieved as for noninterface Maxwell's equations. Also, we will show a discrete $H(\text{curl};\Omega)$-norm error estimate, from which one can observe some superconvergence results for the finite volume method.

5.1. Discrete L^2-norm error estimate for tetrahedral grids. The purpose of this section is to develop the error analysis of the numerical scheme (3.5)–(3.6) in the discrete L^2-norms $\|\cdot\|_{W'}$ and $\|\cdot\|_W$. To do so, subtracting (3.3) from the jth component of (3.6), we obtain

$$S\frac{d}{dt}(B - B_f) + C(E - E_e) = 0\ ; \tag{5.1}$$

then subtracting (3.4) from the jth component of (3.5) gives

$$S'\frac{d}{dt}(E - E_f') - C'(B - B_e') = \mathbf{0}\ . \tag{5.2}$$

Now multiplying (5.1) by $D'(B - B'_e)$ and (5.2) by $D(E - E_e)$, and then adding the resulting equalities, we have

$$\begin{aligned}(S(\dot{B} - \dot{B}_f), D'(B - B_e)) + (S'(\dot{E} - \dot{E}'_f), D(E - E_e))\\ = (C'(B - B'_e), D(E - E_e)) - (C(E - E_e), D'(B - B'_e)),\end{aligned} \tag{5.3}$$

where the dot represents the time derivative. By the boundary condition $\mathbf{E} \times \mathbf{n} = \mathbf{0}$ on $\partial\Omega$, we know that all the components of $E - E_e$ on the boundary vanish. So by Lemma 2.2 we see that

$$(C'(B - B'_e), D(E - E_e)) - (C(E - E_e), D'(B - B'_e)) = 0,$$

and consequently we obtain from (5.3) that

$$(\dot{B} - \dot{B}_f, B - B'_e)_W + (\dot{E} - \dot{E}'_f, E - E_e)_{W'} = 0. \tag{5.4}$$

Now we rewrite (5.4) as

$$\begin{aligned}(\dot{B} - \dot{B}'_e, B - B'_e)_W + (\dot{E} - \dot{E}_e, E - E_e)_{W'}\\ = (\dot{E}'_f - \dot{E}_e, E - E_e)_{W'} + (\dot{B}_f - \dot{B}'_e, B - B'_e)_W\end{aligned}$$

or, equivalently, as

$$\frac{1}{2}\frac{d}{dt}(\|B - B'_e\|^2_W + \|E - E_e\|^2_{W'}) = (\dot{E}'_f - \dot{E}_e, E - E_e)_{W'} + (\dot{B}_f - \dot{B}'_e, B - B'_e)_W. \tag{5.5}$$

This enables us to show the following (optimal) first order convergence result for the finite volume scheme (3.5)–(3.6) for solving Maxwell's equations (1.1)–(1.4) on general tetrahedral grids.

THEOREM 5.1. *Assume that* $\mathbf{E}, \mathbf{B} \in W^{1,1}(0, T; W^{1,p}(\Omega_i)^3)$, *for* $i = 1, 2$ *and* $p > 2$, *are the solutions to Maxwell's system* (1.1)–(1.4), *while* E *and* B *are the finite volume solution of* (3.5)–(3.6). *Then the following error estimate holds for some constant* K, *independent of the mesh and the material parameters:*

$$\begin{aligned}&\max_{0\le t\le T}\{\|(E - E_e)(t)\|_{W'} + \|(B - B_f)(t)\|_W\}\\ &\le Kh\sum_{i=1}^{2}\{\|\varepsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{1,1}(0,T;W^{1,p}(\Omega_i)^3)} + \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{W^{1,1}(0,T;W^{1,p}(\Omega_i)^3)}\}.\end{aligned} \tag{5.6}$$

Proof. We prove this theorem by using (5.5). For each noninterface interior primal edge σ_i, by definition we have

$$(\dot{E}'_f - \dot{E}_e)_i = \frac{1}{s'_i}\int_{\kappa'_i}\dot{\mathbf{E}}\cdot\mathbf{n}_i\,d\sigma - \frac{1}{h_i}\int_{\sigma_i}\dot{\mathbf{E}}\cdot\mathbf{t}_i\,dl,$$

where $\mathbf{n}_i$ is the unit normal vector to the dual face κ'_i. Let τ'_{i_1} and τ'_{i_2} be the two dual elements sharing the same dual face κ'_i; then by the Sobolev embedding theorem we have, for $p > 2$,

$$W^{1,p}(\tau'_{i_1} \cup \tau'_{i_2}) \hookrightarrow L^1(\kappa'_i), \qquad W^{1,p}(\tau'_{i_1} \cup \tau'_{i_2}) \hookrightarrow L^1(\sigma_i)\,.$$

Hence, $(\dot{E}'_f - \dot{E}_e)_i$ is a bounded linear functional on $W^{1,p}(\tau'_{i_1} \cup \tau'_{i_2})^3$ and vanishes for all constant functions. By the Bramble–Hilbert lemma and a standard scaling argument, we obtain

$$|(\dot{E}'_f - \dot{E}_e)_i| \le K h^{1-\frac{3}{p}} |\dot{\mathbf{E}}|_{W^{1,p}(\tau'_{i_1} \cup \tau'_{i_2})^3} \tag{5.7}$$

for some generic constant K.

Next, for each interface primal edge σ_i corresponding to an interface dual face κ'_i, using (3.2) we get

$$\begin{aligned}(\dot{E}'_f - \dot{E}_e)_i &= (\beta_i \dot{E}'_{f_1} + (1-\beta_i)\dot{E}'_{f_2})_i - (\dot{E}_e)_i \\ &= \beta_i (\dot{E}'_{f_1} - \dot{E}_e)_i + (1-\beta_i)(\dot{E}'_{f_2} - \dot{E}_e)_i \,.\end{aligned}$$

Let $O_{i_1} = (\tau'_{i_2} \cup \tau'_{i_1}) \cap \Omega_1$ and $O_{i_2} = (\tau'_{i_2} \cup \tau'_{i_1}) \cap \Omega_2$; then the same reasoning as above shows that $(\dot{E}'_{f_1} - \dot{E}_e)_i$ and $(\dot{E}'_{f_2} - \dot{E}_e)_i$ are bounded linear functionals on $W^{1,p}(O_{i_1})^3$ and $W^{1,p}(O_{i_2})^3$, respectively, and vanish for all constant functions. Again, an application of the Bramble–Hilbert lemma and a scaling argument yield

$$|(\dot{E}'_{f_1} - \dot{E}_e)_i| \le K h^{1-\frac{3}{p}} |\dot{\mathbf{E}}|_{W^{1,p}(O_{i_1})^3}, \tag{5.8}$$

$$|(\dot{E}'_{f_2} - \dot{E}_e)_i| \le K h^{1-\frac{3}{p}} |\dot{\mathbf{E}}|_{W^{1,p}(O_{i_2})^3} \,. \tag{5.9}$$

By the definitions of $\bar{s}'_i$ and β_i, it is easy to see that $\bar{s}'_i \beta_i^2 \le \varepsilon_1 s_i^1$ and $\bar{s}'_i (1-\beta_i)^2 \le \varepsilon_2 s_i^2$. Thus we have

$$\begin{aligned}\bar{s}'_i h_i |(\dot{E}'_f - \dot{E}_e)_i|^2 &\le \bar{s}'_i h_i (2\beta_i^2 |(\dot{E}'_{f_1} - \dot{E}_e)_i|^2 + 2(1-\beta_i)^2 |(\dot{E}'_{f_2} - \dot{E}_e)_i|^2) \\ &\le 2\varepsilon_1 h_i s_i^1 |(\dot{E}'_{f_1} - \dot{E}_e)_i|^2 + 2\varepsilon_2 h_i s_i^2 |(\dot{E}'_{f_2} - \dot{E}_e)_i|^2 \,.\end{aligned}$$

This, along with the estimates (5.7)–(5.9) and the Cauchy–Schwarz inequality, leads to

$$\begin{aligned}\|\dot{E}'_f - \dot{E}_e\|^2_{W'} &= \sum_{\kappa'_i \subset \Omega_1 \cup \Omega_2} \bar{s}'_i h_i |(\dot{E}'_f - \dot{E}_e)_i|^2 + \sum_{\kappa'_i \cap \Gamma \neq \phi} \bar{s}'_i h_i |(\dot{E}'_f - \dot{E}_e)_i|^2, \\ &\le K h^{5-\frac{6}{p}} \sum_{i=1}^{M_1} \left\{ \varepsilon_1 |\dot{\mathbf{E}}|^2_{W^{1,p}(O_{i_1})^3} + \varepsilon_2 |\dot{\mathbf{E}}|^2_{W^{1,p}(O_{i_2})^3} \right\}, \\ &\le K h^{5-\frac{6}{p}} \left\{ \sum_{i=1}^{M_1} \varepsilon_1^{p/2} |\dot{\mathbf{E}}|^p_{W^{1,p}(O_{i_1})^3} + \varepsilon_2^{p/2} |\dot{\mathbf{E}}|^p_{W^{1,p}(O_{i_2})^3} \right\}^{\frac{2}{p}} \left\{ \sum_{i=1}^{M_1} 1 \right\}^{1-\frac{2}{p}} .\end{aligned}$$

Noting the fact that $h^3 \sum_{i=1}^{M_1} 1 \le K$, we conclude that

$$\|\dot{E}'_f - \dot{E}_e\|_{W'} \le K h \sum_{r=1}^{2} |\varepsilon_r^{\frac{1}{2}} \dot{\mathbf{E}}|_{W^{1,p}(\Omega_r)^3}. \tag{5.10}$$

Similarly, we have

$$\|\dot{B}_f - \dot{B}'_e\|_W \le K h \sum_{r=1}^{2} |\mu_r^{-\frac{1}{2}} \dot{\mathbf{B}}|_{W^{1,p}(\Omega_r)^3}. \tag{5.11}$$

By integrating (5.5) over $(0,t)$ and applying the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned}\|(B-B_e')(t)\|_W^2 + \|(E-E_e)(t)\|_{W'}^2 &\le 2\int_0^t (\|(B-B_e')(s)\|_W \|(\dot{B}_f-\dot{B}_e')(s)\|_W \\ &\quad + \|(E-E_e)(s)\|_{W'}\|(\dot{E}_f'-\dot{E}_e)(s)\|_{W'})\, ds, \\ &\le 2\max_{0\le t\le T}(\|(B-B_e')(t)\|_W + \|(E-E_e)(t)\|_{W'}) \\ &\quad \times \int_0^T (\|(\dot{B}_f-\dot{B}_e')(s)\|_W + \|(\dot{E}_f'-\dot{E}_e)(s)\|_{W'})\, ds.\end{aligned}$$

Then, by (5.10) and (5.11), we have

$$\begin{aligned}&\max_{0\le t\le T}(\|(E-E_e)(t)\|_{W'} + \|(B-B_e')(t)\|_W) \\ &\le Kh\sum_{i=1}^{2}(|\varepsilon_i^{\frac{1}{2}}\mathbf{E}|_{W^{1,1}(0,T;W^{1,p}(\Omega_i))^3} + |\mu_i^{-\frac{1}{2}}\mathbf{B}|_{W^{1,1}(0,T;W^{1,p}(\Omega_i))^3}).\end{aligned}$$

In order to complete the proof, we first observe that

$$\|(B-B_f)(t)\|_W \le \|(B-B_e')(t)\|_W + \|(B_e'-B_f)(t)\|_W.$$

So it remains to estimate $\|(B_e'-B_f)(t)\|_W$. Following the same argument as the one that led to (5.11), we have

$$\|B_f - B_e'\|_W \le Kh\sum_{r=1}^{2}|\mu_r^{-\frac{1}{2}}\mathbf{B}|_{W^{1,p}(\Omega_r)^3}.$$

Hence,

$$\begin{aligned}\max_{0\le t\le T}\|(B_f-B_e')(t)\|_W &\le Kh\sum_{r=1}^{2}\max_{0\le t\le T}|\mu_r^{-\frac{1}{2}}\mathbf{B}(t)|_{W^{1,p}(\Omega_r)^3} \\ &\le Kh\sum_{r=1}^{2}\|\mu_r^{-\frac{1}{2}}\mathbf{B}\|_{W^{1,1}(0,T;W^{1,p}(\Omega_r))^3}. \qquad \square\end{aligned}$$

Remark. There are very few studies in the literature concerning the regularity of the solution to the time-dependent Maxwell system (1.1)–(1.4) with discontinuous coefficients. However, for domains with smooth boundaries and interfaces, the regularity $\mathbf{B},\mathbf{E} \in L^2(0,T;W^{1,p}(\Omega_i))$ $(i=1,2)$ can be shown by slightly modifying the proof of Theorem 6.2 [8] in combination with the equivalence between the space $\{\mathbf{w} \in W^{1,p}(\Omega);\ \mathbf{w}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\}$ and the space

$$\{\mathbf{w} \in L^p(\Omega)^3;\ \mathbf{curl}\,\mathbf{w} \in L^p(\Omega)^3, \mathbf{div}\,\mathbf{w} \in L^p(\Omega)^3,\ \mathbf{w}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\}.$$

The additional time differentiability $\mathbf{B},\mathbf{E} \in W^{1,1}(0,T;W^{1,p}(\Omega_i))$ can be proved using standard arguments; see, e.g., [2].

5.2. Discrete L^2-norm error estimate for rectangular grids. The first order convergence of the finite volume scheme (3.5)–(3.6) given in the last subsection is generally optimal in terms of the regularities used. In this section, we intend to improve the convergence rate of the scheme (3.5)–(3.6) on rectangular grids by one order; namely, we establish second order convergence by making full use of the local regularities of the fields **E** and **B**. Such a second order convergence result is invalid for general tetrahedral triangulations, even in the case of the noninterface Maxwell's equations [14, 16].

Let Ω be a rectangular cuboid in R^3. Similarly to the case of a polyhedral domain in section 2, we generate the primal and dual triangulations of Ω by using smaller rectangular cuboids. Note that both the primal and dual meshes are now made up of rectangular cuboids. For simplicity, the directions of edges and faces are assigned as follows: a direction is assigned to each primal and dual edge by the rule that positive direction means that it points in the positive axis direction. The directions of primal and dual faces are the same as those of the corresponding dual and primal edges. Below, we adopt the same notations as in section 2.

Clearly, most of the arguments presented in the previous subsection remain valid for the case of rectangular domain Ω considered here. To begin, we rewrite (5.4) as

$$\begin{aligned}&(\dot{B}-\dot{B}_f, B-B_f)_W + (\dot{E}-\dot{E}_e, E-E_e)_{W'}\\ &= (\dot{B}-\dot{B}_f, B'_e-B_f)_W + (\dot{E}'_f-\dot{E}_e, E-E_e)_{W'}\end{aligned}$$

or, equivalently, as

$$\frac{1}{2}\frac{d}{dt}(\|B-B_f\|^2_W + \|E-E_e\|^2_{W'}) \tag{5.12}$$

$$= (\dot{B}-\dot{B}_f, B'_e-B_f)_W + (\dot{E}'_f-\dot{E}_e, E-E_e)_{W'}. \tag{5.13}$$

Next we estimate the terms on the right-hand side of (5.13), and this needs the following two auxiliary lemmas.

LEMMA 5.2. *There exist functions $u(t)$ and $\xi(t) \in \mathbb{R}^{F_1}$ such that all the noninterface components of $\xi(t)$ vanish, all the components of u and ξ are bounded linear functionals of* **B**, *and the following relation holds for all $\phi \in \mathbb{R}^M$ with $\phi|_{\partial\Omega} = 0$:*

$$(C\phi, D'(B_f - B'_e)) = (C\phi, D'u) + (C\phi, \xi)\,. \tag{5.14}$$

Furthermore, the following estimates hold for $u(t)$ and $\xi(t)$:

(5.15)

$$\|u\|_W \le Kh^2 \sum_{i=1}^{2} \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{H^3(\Omega_i)^3}\,, \qquad \|D^{'-1}\xi\|_W \le Kh^2 \sum_{i=1}^{2} \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{H^3(\Omega_i)^3}.$$

Proof. By definition, for any strictly interior primal face κ_j we have

$$(B_f - B'_e)_j = \frac{1}{s_j}\int_{\kappa_j} \mathbf{B}\cdot\mathbf{n}_j\, d\sigma - \frac{1}{h'_j}\int_{\sigma'_j} \mathbf{B}\cdot\mathbf{t}_j\, dl.$$

Assume that κ_j is parallel to the xy-plane, with P_1 as its center; see Figure 3. We know that the quadrature rule

$$\int_{\kappa_j} \mathbf{B}\cdot\mathbf{n}_j\, d\sigma = s_j\,(\mathbf{B}\cdot\mathbf{n}_j)(P_1)$$

is exact for linear functions.

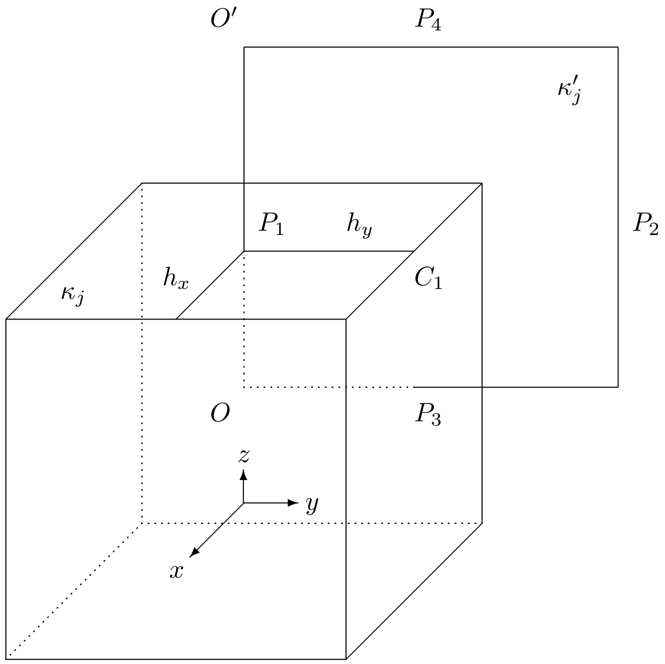

FIG. 3. *Noninterface element.*

Note that P_1 is not the center of the dual edge σ'_j. By adding a first order correction term, it is easy to see that the quadrature rule

$$\int_{\sigma'_j} \mathbf{B}\cdot\mathbf{t}_j\, dl = (\mathbf{B}\cdot\mathbf{t}_j)(P_1)h'_j + \frac{1}{2}(\overline{O'P_1}^2\mathbf{B}_{3z}(O') - \overline{OP_1}^2\mathbf{B}_{3z}(O))$$

is then exact for linear functions. Here $\overline{O'P_1}$ denotes the distance from O' to P_1 and $\mathbf{B}_{3z}$ denotes the derivative of the third component of $\mathbf{B}$ with respect to z. Similar notation will be used below. By the two relations above, we can rewrite $(B_f - B'_e)_j$ as

$$(B_f - B'_e)_j = \frac{1}{h'_j}\tilde{u}_j + u_j, \tag{5.16}$$

where u_j vanishes for linear functions and the first order correction $\tilde{u}_j$ is given by

$$\begin{aligned}\tilde{u}_j := {} & \frac{1}{2\mu_r}(\overline{OP_1}^2\mathbf{B}_{3z} + h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(O)\\ & - \frac{1}{2\mu_r}(\overline{O'P_1}^2\mathbf{B}_{3z} + h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(O').\end{aligned} \tag{5.17}$$

Here $r = 1$ or 2 is the index corresponding to the subdomain Ω_r in which κ_j lies. Moreover, notice the fact that $\mathbf{B}_{1x}(O) - \mathbf{B}_{1x}(O')$ and $\mathbf{B}_{2y}(O) - \mathbf{B}_{2y}(O')$ vanish for all linear functions, and the terms related to $\mathbf{B}_{1x}$ and $\mathbf{B}_{2y}$ are added to the above equation to make the relation more symmetric.

Next, by (3.1), for an interface primal face κ_i lying on Γ, we have

$$(B_f - B'_e)_i = \alpha_i(B_f - B'_{e_1})_i + (1-\alpha_i)(B_f - B'_{e_2})_i\ .$$

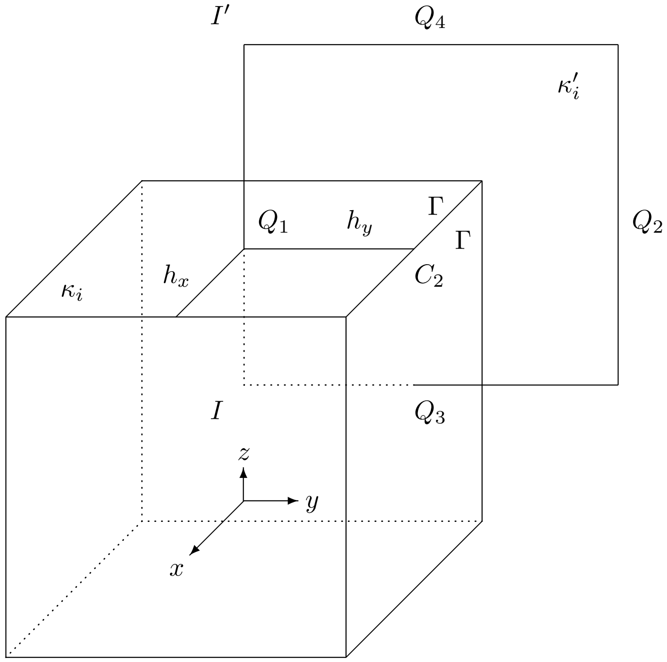

FIG. 4. *Interface element.*

Without loss of generality, we assume that κ_i is parallel to the xy-plane; see Figure 4. It is easy to verify that the quadrature rules

$$\int_{\kappa_i} \mathbf{B}\cdot\mathbf{n}_i \, d\sigma = s_i\,(\mathbf{B}\cdot\mathbf{n}_i)(Q_1)\ ,$$

$$(B'_{e_1})_i = \int_{\sigma_i^1} \mathbf{B}\cdot\mathbf{t}_i \, dl = (\mathbf{B}\cdot\mathbf{t}_i)(Q_1)h_i^1 - \frac{1}{2}\overline{IQ_1}^2\mathbf{B}_{3z}(I),$$

$$(B'_{e_2})_i = \int_{\sigma_i^2} \mathbf{B}\cdot\mathbf{t}_i \, dl = (\mathbf{B}\cdot\mathbf{t}_i)(Q_1)h_i^2 + \frac{1}{2}\overline{I'Q_1}^2\mathbf{B}_{3z}(I')$$

are all exact for linear functions. Using these relations, we can rewrite $(B_f - B'_e)_i$ as

$$(B_f - B'_e)_i = \frac{1}{\bar{h}'_i}\tilde{u}_i + \frac{1}{\bar{h}'_i}\xi_i + u_i, \tag{5.18}$$

where $u_i = \alpha_i u_i^1 + (1-\alpha_i)u_i^2$, u_i^1 and u_i^2 both vanish for linear functions, and the correction terms $\tilde{u}_i$ and ξ_i are given by

$$\begin{aligned}\tilde{u}_i := &\frac{1}{2\mu_1}(\overline{IQ_1}^2\mathbf{B}_{3z} + h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(I)\\ &- \frac{1}{2\mu_2}(\overline{I'Q_1}^2\mathbf{B}_{3z} + h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(I'),\end{aligned} \tag{5.19}$$

$$\xi_i := \frac{1}{2\mu_2}(h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(I') - \frac{1}{2\mu_1}(h_x^2\mathbf{B}_{1x} + h_y^2\mathbf{B}_{2y})(I)\ . \tag{5.20}$$

For the same reason as earlier for the noninterface face κ_i, we have also added some extra terms related to $\mathbf{B}_{1x}$ and $\mathbf{B}_{2y}$ here. Note, however, that due to the jumps across the interface, ξ_i no longer vanishes for linear functions.

By (5.17), (5.19), and the definition of B_1, we can write $\tilde{u} = B_1\tilde{\phi}$ for some $\tilde{\phi} \in \mathbb{R}^N$. Hence for any $\phi \in \mathbb{R}^M$ with $\phi|_{\partial\Omega} = 0$, we get from (5.16) and (5.18) that

$$\begin{aligned}(C\phi, D'(B_f - B_e')) &= (C\phi, \tilde{u}) + (C\phi, D'u) + (C\phi, \xi)\\ &= (C\phi, B_1\tilde{\phi}) + (C\phi, D'u) + (C\phi, \xi)\\ &= (B_1^T C\phi, \tilde{\phi}) + (C\phi, D'u) + (C\phi, \xi)\\ &= (C\phi, D'u) + (C\phi, \xi).\end{aligned}$$

This proves (5.14).

For the estimate (5.15), let u_j be a component of u corresponding to an interior primal face κ_j in Ω_r, $r = 1, 2$. We recall from (5.16) that

$$u_j = (B_f - B_e')_j - \frac{1}{\bar{h}_j'}\tilde{u}_j.$$

By the Sobolev embedding theorem, we have

$$H^3(\tau_{j_1} \cup \tau_{j_2}) \hookrightarrow C^{1,\frac{1}{2}}(\tau_{j_1} \cup \tau_{j_2}),$$

where τ_{j_1} and τ_{j_2} are two elements in Ω_r and share the face κ_j. Hence, u_j is a bounded linear functional of $\mathbf{B}$ in $H^3(\tau_{j_1} \cup \tau_{j_2})^3$ and vanishes for linear fields $\mathbf{B}$. Then, by the Bramble–Hilbert lemma, we have

$$|u_j|^2 \le K(h)\left(|\mathbf{B}|^2_{H^2(\tau_{j_1}\cup\tau_{j_2})^3} + |\mathbf{B}|^2_{H^3(\tau_{j_1}\cup\tau_{j_2})^3}\right).$$

A standard scaling argument yields

$$|u_j|^2 \le Kh\left(|\mathbf{B}|^2_{H^2(\tau_{j_1}\cup\tau_{j_2})^3} + |\mathbf{B}|^2_{H^3(\tau_{j_1}\cup\tau_{j_2})^3}\right) \le Kh\|\mathbf{B}\|^2_{H^3(\tau_{j_1}\cup\tau_{j_2})^3}. \tag{5.21}$$

Now consider a component u_i of u corresponding to an interface face κ_i, which is shared by the element τ_{i_1} in Ω_1 and τ_{i_2} in Ω_2. Recall that

$$u_i = \alpha_i u_i^1 + (1 - \alpha_i)u_i^2,$$

where

$$\begin{aligned}h_i^1 u_i^1 &:= h_i^1(B'_{e_i^1} - (B_f)_i) - \frac{1}{2}\overline{IQ_1}^2\mathbf{B}_{3z}(I)\ ,\\ h_i^2 u_i^2 &:= h_i^2(B'_{e_i^2} - (B_f)_i) + \frac{1}{2}\overline{I'Q_1}^2\mathbf{B}_{3z}(I').\end{aligned}$$

By the Sobolev embedding theorem, u_i^r is a bounded linear functional of $\mathbf{B}$ in $H^3(\tau_{i_r})^3$ and vanishes for all linear fields for $r = 1$ or 2. Hence, again by the Bramble–Hilbert lemma and a scaling argument, we have

$$|u_i^1| \le Kh^{\frac{1}{2}}\|\mathbf{B}\|_{H^3(\tau_{i_1})^3}, \qquad |u_i^2| \le Kh^{\frac{1}{2}}\|\mathbf{B}\|_{H^3(\tau_{i_2})^3}.$$

Similarly to the proof of (5.10), using the above estimates and (5.21) we obtain

$$\begin{aligned}\|u\|_W^2 &= \sum_{\sigma_i'\subset\Omega_1\cap\Omega_2} s_j\bar{h}_j'|u_j|^2 + \sum_{\sigma_i'\cap\Gamma\neq\phi} s_j\bar{h}_j'|u_j|^2\\ &\le \sum_{\sigma_i'\subset\Omega_1\cap\Omega_2} s_j\bar{h}_j'|u_j|^2 + \sum_{\sigma_j'\cap\Gamma\neq\phi} s_j\bar{h}_j'(2\alpha_j^2|u_j^1|^2 + 2(1-\alpha_j)^2|u_j^2|^2)\\ &\le Kh^4\left\{\sum_{\tau_{i_1}\subset\Omega_1}\mu_1^{-1}\|\mathbf{B}\|^2_{H^3(\tau_{i_1})^3} + \sum_{\tau_{i_2}\subset\Omega_2}\mu_2^{-1}\|\mathbf{B}\|^2_{H^3(\tau_{i_2})^3}\right\}\\ &\le Kh^4\left\{\sum_{r=1}^2\|\mu_r^{-\frac{1}{2}}\mathbf{B}\|^2_{H^3(\Omega_r)^3}\right\}^2 .\end{aligned}$$

We are now ready to estimate ξ. For each interface primal face κ_i shared by the element τ_{i_1} in Ω_1 and τ_{i_2} in Ω_2, we rewrite ξ_i using the interface condition (1.8) as

$$\begin{aligned}\xi_i := &\left\{\frac{1}{2}(h_x^2\mathbf{H}_{1x} + h_y^2\mathbf{H}_{2y})(I') - \frac{1}{2}(h_x^2\mathbf{H}_{1x} + h_y^2\mathbf{H}_{2y})(Q_1)\right\}\\ &+\left\{\frac{1}{2}(h_x^2\mathbf{H}_{1x} + h_y^2\mathbf{H}_{2y})(Q_1) - \frac{1}{2}(h_x^2\mathbf{H}_{1x} + h_y^2\mathbf{H}_{2y})(I)\right\}.\end{aligned}\tag{5.22}$$

By the Hölder continuity of $\mathbf{H}_{1x}$, we have

$$|\mathbf{H}_{1x}(I') - \mathbf{H}_{1x}(Q_1)| \le Kh^{\frac{1}{2}}\|\mathbf{H}\|_{C^{1,\frac{1}{2}}(\tau_{i_2})^3}.$$

Similar estimates hold for the other pairs in (5.22). This leads to

$$|\xi_i| \le Kh^{\frac{5}{2}}\left\{\|\mathbf{H}\|_{C^{1,\frac{1}{2}}(\tau_{i_1})^3} + \|\mathbf{H}\|_{C^{1,\frac{1}{2}}(\tau_{i_2})^3}\right\}.$$

Consequently, by the fact that $\xi_i = 0$ for any noninterface primal face, we get

$$\begin{aligned}\|D^{'-1}\xi\|_W^2 &= \sum_{i=1}^{F_1} s_i\bar{h}_i'|(\bar{h}_j')^{-1}\xi_i|^2\\ &\le Kh^6\sum_{\kappa_i\subset\Gamma}\left\{\mu_1\|\mathbf{H}\|^2_{C^{1,\frac{1}{2}}(\tau_{i_1})^3} + \mu_2\|\mathbf{H}\|^2_{C^{1,\frac{1}{2}}(\tau_{i_2})^3}\right\}\\ &\le Kh^4\sum_{r=1}^2\|\mu_r^{\frac{1}{2}}\mathbf{H}\|^2_{C^{1,\frac{1}{2}}(\Omega_r)^3}. \qquad \square\end{aligned}$$

LEMMA 5.3. *There exist functions $v(t)$, $\lambda(t) \in \mathbb{R}^{M_1}$, and $w(t) \in \mathbb{R}^{F_1}$, such that all the noninterface components of $\lambda(t)$ vanish and all the components of v, w, and λ are bounded linear functionals of $\mathbf{E}$, and the following relation holds for all $\phi \in \mathbb{R}^M$ with $\phi|_{\partial\Omega} = 0$:*

$$(\dot{E}_f' - \dot{E}_e, \phi)_{W'} = (\dot{v}, \phi)_{W'} + (D'\dot{w}, C\phi) + (S^{'-1}\dot{\lambda}, \phi)_{W'} .\tag{5.23}$$

Furthermore, we have the following estimates for $v(t)$, $\lambda(t)$, $w(t)$, and $p > 3$:

$$\|\dot{v}\|_{W'} \le Kh^2\sum_{i=1}^2\|\epsilon_i^{\frac{1}{2}}\dot{\mathbf{E}}\|_{H^3(\Omega_i)^3}\ , \qquad \|\dot{w}\|_W \le Kh^2\sum_{i=1}^2\|\epsilon_i^{\frac{1}{2}}\dot{\mathbf{E}}\|_{W^{2,p}(\Omega_i)^3},\tag{5.24}$$

$$\|S^{'-1}\dot{\lambda}\|_{W'} \ \le\ Kh^2\sum_{i=1}^2\|\epsilon_i^{\frac{1}{2}}\dot{\mathbf{E}}\|_{H^3(\Omega_i)^3}\ .\tag{5.25}$$

Proof. The proof is similar to that of Lemma 5.2. First, we consider a noninterface dual face κ'_j lying in Ω_r $(r = 1, 2)$. Recall that

$$(E'_f - E_e)_j = \frac{1}{s'_j} \int_{\kappa'_j} \mathbf{E} \cdot \mathbf{n}_j \, d\sigma - \frac{1}{h_j} \int_{\sigma_j} \mathbf{E} \cdot \mathbf{t}_j \, dl.$$

We see from Figure 3 that C_1 is the center of the primal edge σ_j, so the quadrature rule

$$\int_{\sigma_j} \mathbf{E} \cdot \mathbf{t}_j \, dl = \mathbf{E}_1(C_1) h_j$$

is exact for all linear functions. However, C_1 is not the center of the dual face κ'_j. By adding a first order correction term $\tilde{w}_j$, the quadrature rule

$$\int_{\kappa'_j} \mathbf{E} \cdot \mathbf{n}_j \, d\sigma = \mathbf{E}_1(C_1) s'_j + \tilde{w}_j$$

is then exact for all linear functions, where $\tilde{w}_j$ is given by

$$2\tilde{w}_j = [\mathbf{E}_{1y}(P_2)\overline{P_2C_1}^2 - \mathbf{E}_{1y}(P_1)\overline{P_1C_1}^2]\overline{P_3P_4} + [\mathbf{E}_{1z}(P_4)\overline{P_4C_1}^2 - \mathbf{E}_{1z}(P_3)\overline{P_3C_1}^2]\overline{P_1P_2}.$$

By direct computations, $\tilde{w}_j$ can be represented by the discrete circulation as follows:

$$\tilde{w}_j := \frac{1}{\varepsilon_r}(C'w)_j \ , \tag{5.26}$$

where the components of w corresponding to the four edges of κ'_j containing the points P_1, P_2, P_3, and P_4 are assigned, respectively, the following values:

$$\begin{aligned}
w(P_1) &:= \frac{1}{2}\varepsilon_r\mu_r(h_y^2\mathbf{E}_{1y}(P_1) - h_x^2\mathbf{E}_{2x}(P_1)),\\
w(P_2) &:= \frac{1}{2}\varepsilon_r\mu_r((\overline{P_2C_1}^2\mathbf{E}_{1y}(P_2) - h_x^2\mathbf{E}_{2x}(P_2)),\\
w(P_3) &:= \frac{1}{2}\varepsilon_r\mu_r(h_x^2\mathbf{E}_{3x}(P_3) - \overline{P_3C_1}^2\mathbf{E}_{1z}(P_3)),\\
w(P_4) &:= \frac{1}{2}\varepsilon_r\mu_r(h_x^2\mathbf{E}_{3x}(P_4) - \overline{P_4P_1}^2\mathbf{E}_{1z}(P_4)).
\end{aligned}$$

We remark that for the verification of (5.26) we have used the simple fact that $\mathbf{E}_{2x}(P_1)$ and $\mathbf{E}_{2x}(P_2)$, as well as $\mathbf{E}_{3x}(P_1)$ and $\mathbf{E}_{3x}(P_2)$, are equal, respectively, for all linear functions. Using (5.26), we can rewrite $\dot{E}'_f - \dot{E}_e$ as

$$(\dot{E}'_f - \dot{E}_e)_j = \frac{1}{\bar{s}'_j}(C'\dot{w})_j + \dot{v}_j, \tag{5.27}$$

where $\dot{v}_j$ is a functional which vanishes for all linear functions.

Now consider an interface dual face κ'_i. By the definition (3.2) we have

$$\bar{s}'_i(\dot{E}'_f - \dot{E}_e)_i = \frac{d}{dt}\{\varepsilon_1 s_i^1(E'_{f_1} - E_e)_i + \varepsilon_2 s_i^2(E'_{f_2} - E_e)_i\}.$$

Without loss of generality, we assume that κ_i' is parallel to the zy-plane and perpendicular to the interface primal face κ_i; see Figure 4. It is straightforward to verify that the three quadrature rules

$$\begin{aligned}
(E_e)_i &= \frac{1}{h_i}\int_{\sigma_i} \mathbf{E}\cdot\mathbf{t}_i\,dl = \mathbf{E}_1(C_2),\\
(E'_{f_1})_i &= \frac{1}{s_i^1}\int_{\kappa_i^1} \mathbf{E}\cdot\mathbf{n}_i\,d\sigma = \frac{1}{s_i^1}\{\mathbf{E}_1(C_2)s_i^1 + \tilde{w}_i^1\},\\
(E'_{f_2})_i &= \frac{1}{s_i^2}\int_{\kappa_i^2} \mathbf{E}\cdot\mathbf{n}_i\,d\sigma = \frac{1}{s_i^2}\{\mathbf{E}_1(C_2)s_i^2 + \tilde{w}_i^2\}
\end{aligned}$$

are all exact for linear functions, where

$$\tilde{w}_i^1 := \frac{1}{2}[-\mathbf{E}_{1y}(Q_1)\overline{Q_1C_2}^2]\overline{Q_3C_2} + \frac{1}{2}[-\mathbf{E}_{1z}(Q_3)\overline{Q_3C_2}^2]\overline{Q_1C_2}$$

and

$$\begin{aligned}
\tilde{w}_i^2 :=& \frac{1}{2}[\mathbf{E}_{1y}(Q_2)\overline{Q_2C_2}^2]\overline{Q_3Q_4} + \frac{1}{2}[-\mathbf{E}_{1y}(Q_1)\overline{Q_1C_2}^2]\overline{Q_4C_2}\\
&+ \frac{1}{2}[\mathbf{E}_{1z}(Q_4)\overline{Q_4C_2}^2]\overline{Q_1Q_2} + \frac{1}{2}[-\mathbf{E}_{1z}(Q_3)\overline{Q_3C_2}^2]\overline{Q_2C_2}.
\end{aligned}$$

Then we have

$$\bar{s}_i'(\dot{E}_f' - \dot{E}_e)_i = \frac{d}{dt}(\varepsilon_1\tilde{w}_i^1 + \varepsilon_2\tilde{w}_i^2) + \frac{d}{dt}(\varepsilon_1 s_i^1 v_i^1 + \varepsilon_2 s_i^2 v_i^2),$$

where v_i^1 and v_i^2 are linear functionals which vanish for all linear functions. We further write

$$\frac{d}{dt}(\varepsilon_1\tilde{w}_i^1 + \varepsilon_2\tilde{w}_i^2) = (C'\dot{w})_i + \dot{\lambda}_i, \tag{5.28}$$

where the components of w on the four edges of κ_i' containing the points Q_1, Q_2, Q_3, and Q_4 are assigned, respectively, the following values:

$$\begin{aligned}
w(Q_1) :=& \frac{1}{2\bar{h}'_{i_1}}(\varepsilon_1\overline{Q_3C_2}h_y^2\mathbf{E}_{1y}(Q_1) + \varepsilon_2\overline{Q_4C_2}h_y^2\mathbf{E}_{1y}(Q_1))\\
&+ \frac{1}{2\bar{h}'_{i_1}}(-\varepsilon_1\overline{Q_3C_2}h_x^2\mathbf{E}_{2x}(Q_1) - \varepsilon_2\overline{C_2Q_4}h_x^2\mathbf{E}_{2x}(Q_1)),\\
w(Q_2) :=& \frac{1}{2\bar{h}'_{i_2}}(\varepsilon_2\overline{Q_3Q_4}\,\overline{C_2Q_2}^2\mathbf{E}_{1y}(Q_2) - \varepsilon_2\overline{Q_3Q_4}h_x^2\mathbf{E}_{2x}(Q_2)),\\
w(Q_3) :=& \frac{1}{2\bar{h}'_{i_3}}(-\varepsilon_1\overline{Q_1C_2}\,\overline{Q_3C_2}^2\mathbf{E}_{1z}(Q_3) - \varepsilon_2\overline{C_2Q_2}\,\overline{Q_3C_2}^2\mathbf{E}_{1z}(Q_3))\\
&+ \frac{1}{2\bar{h}'_{i_3}}(\varepsilon_1\overline{Q_1C_2}h_x^2\mathbf{E}_{3x}(Q_3) + \varepsilon_2\overline{C_2Q_2}h_x^2\mathbf{E}_{3x}(Q_3)),\\
w(Q_4) :=& \frac{1}{2\bar{h}'_{i_4}}(-\varepsilon_2\overline{Q_1Q_2}\,\overline{C_2Q_4}^2\mathbf{E}_{1z}(Q_4) + \varepsilon_2\overline{Q_1Q_2}h_x^2\mathbf{E}_{3x}(Q_4)),
\end{aligned}$$

and λ_i is a term due to the jump in the coefficients across the interface:

$$\begin{aligned}\lambda_i =& \frac{1}{2}\{-\varepsilon_1\overline{Q_3C_2}h_x^2\mathbf{E}_{2x}(Q_1) - \varepsilon_2\overline{C_2Q_4}h_x^2\mathbf{E}_{2x}(Q_1) + \varepsilon_2\overline{Q_3Q_4}h_x^2\mathbf{E}_{2x}(Q_2)\}\\ &+ \frac{1}{2}\{-\varepsilon_1\overline{Q_1C_2}h_x^2\mathbf{E}_{3x}(Q_3) - \varepsilon_2\overline{C_2Q_2}h_x^2\mathbf{E}_{3x}(Q_3) + \varepsilon_2\overline{Q_1Q_2}h_x^2\mathbf{E}_{3x}(Q_4)\}\\ :\equiv& \frac{1}{2}\,\mathrm{I} + \frac{1}{2}\,\mathrm{II}\,.\end{aligned}$$

As above, we can write

$$(\dot{E}'_f - \dot{E}_e)_i = \frac{1}{\bar{s}'_i}(C'\dot{w})_i + \frac{1}{\bar{s}'_i}\dot{\lambda}_i + \dot{v}_i, \tag{5.29}$$

where $\dot{v}_i = (\varepsilon_1 s_i^2 \dot{v}_i^1 + \varepsilon_2 s_i^2 \dot{v}_i^2)/\bar{s}'_i$. It is easy to see by using (5.27) and (5.29) that

$$\begin{aligned}(\dot{E}'_f - \dot{E}_e, \phi)_{W'} &= (C'\dot{w}, D\phi) + (\dot{v}, \phi)_{W'} + (S^{'-1}\dot{\lambda}, \phi)_{W'}\\ &= (D'\dot{w}, C\phi) + (\dot{v}, \phi)_{W'} + (S^{'-1}\dot{\lambda}, \phi)_{W'}.\end{aligned}$$

The estimates in (5.24) can be proved similarly to those in Lemma 5.2. We show only (5.25).

First, we rewrite $\dot{\mathrm{I}}$ as $\dot{\mathrm{I}} = \dot{\delta}_1 + \dot{\delta}_2$ with

$$\begin{aligned}\dot{\delta}_1 &= -\varepsilon_2\overline{C_2Q_4}h_x^2\dot{\mathbf{E}}_{2x}(Q_1) + \varepsilon_2\overline{C_2Q_4}h_x^2\dot{\mathbf{E}}_{2x}(Q_2),\\ \dot{\delta}_2 &= -\varepsilon_1\overline{Q_3C_2}h_x^2\dot{\mathbf{E}}_{2x}(Q_1) + \varepsilon_2\overline{Q_3C_2}h_x^2\dot{\mathbf{E}}_{2x}(Q_2).\end{aligned}$$

Note that the term $\dot{\delta}_1$ clearly vanishes for any linear field $\mathbf{E}$, so it can be absorbed into the term $\dot{v}_i$. The remaining term $\dot{\delta}_2$ can be written as

$$\dot{\delta}_2 = \varepsilon_1\overline{Q_3C_2}h_x^2\{-\dot{\mathbf{E}}_{2x}(Q_1) + \dot{\mathbf{E}}_{2x}(C_2)\} - \varepsilon_2\overline{Q_3C_2}h_x^2\{\dot{\mathbf{E}}_{2x}(C_2) - \dot{\mathbf{E}}_{2x}(Q_2)\}$$

by using the interface condition (1.7) and the fact that the function ρ_Γ depends only on the spatial variables. Then, by the Hölder continuity of $\dot{\mathbf{E}}_{2x}$, we have

$$\begin{aligned}|\dot{\mathbf{E}}_{2x}(Q_1) - \dot{\mathbf{E}}_{2x}(C_2)| &\le Kh^{\frac{1}{2}}\|\dot{\mathbf{E}}\|_{C^{1,\frac{1}{2}}(\tau'_{i_1})},\\ |\dot{\mathbf{E}}_{2x}(Q_2) - \dot{\mathbf{E}}_{2x}(C_2)| &\le Kh^{\frac{1}{2}}\|\dot{\mathbf{E}}\|_{C^{1,\frac{1}{2}}(\tau'_{i_2})},\end{aligned}$$

where τ'_{i_r} is the intersection of Ω_r with the union of all dual elements sharing the dual face κ'_i $(r = 1, 2)$. Hence,

$$|\delta_2| \le Kh^{\frac{7}{2}}\left\{\epsilon_1^{\frac{1}{2}}\|\dot{\mathbf{E}}\|_{C^{1,\frac{1}{2}}(\tau'_{i_1})} + \epsilon_2^{\frac{1}{2}}\|\dot{\mathbf{E}}\|_{C^{1,\frac{1}{2}}(\tau'_{i_2})}\right\}.$$

The term II can be estimated in the same manner. The rest of the proof is the same as the proof for ξ in (5.15). □

We are now ready to give the main result of this section.

Theorem 5.4. *Assume that the following regularity hypotheses hold for the solution of the interface Maxwell system* (1.1)–(1.8):

$$\mathbf{E} \in W^{1,1}(0,T;H^3(\Omega_i)^3) \cap W^{2,1}(0,T;W^{2,p}(\Omega_i)^3), \qquad \mathbf{B} \in W^{1,1}(0,T;H^3(\Omega_i)^3)$$

for $i = 1, 2$ *and* $p > 3$*, and* $(E,\ B)$ *is the solution of* (3.5)–(3.6) *on a nonuniform rectangular grid of size* h*. Then we have*

$$\max_{0\le t\le T}\{\|(E-E_e)(t)\|_{W'} + \|(B-B_f)(t)\|_W\}$$

$$\le Kh^2\sum_{i=1}^{2}\{\|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{1,1}(0,T;H^3(\Omega_i)^3)} \tag{5.30}$$

$$+ \|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{2,1}(0,T;W^{2,p}(\Omega_i)^3)} + \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{W^{1,1}(0,T;H^3(\Omega_i)^3)}\}.$$

Proof. It follows from (5.1), (5.13), (5.14), and (5.23) that

$$\begin{aligned}
&\frac{1}{2}\frac{d}{dt}(\|B-B_f\|_W^2 + \|E-E_e\|_{W'}^2)\\
&\quad= (C(E-E_e), D'(B_f - B_e')) + (\dot v, E-E_e)_{W'}\\
&\qquad+ (D'\dot w, C(E-E_e)) + (S^{'-1}\dot\lambda, E-E_e)_{W'}\\
&\quad= (C(E-E_e), D'u) + (C(E-E_e), \xi) + (\dot v, E-E_e)_{W'}\\
&\qquad- (\dot w, \dot B - \dot B_f)_W + (S^{'-1}\dot\lambda, E-E_e)_{W'}\\
&\quad= -\,(\dot B - \dot B_f, u)_W - (\dot B - \dot B_f, D^{'-1}\xi)_W + (\dot v, E-E_e)_{W'}\\
&\qquad- (\dot w, \dot B - \dot B_f)_W + (S^{'-1}\dot\lambda, E-E_e)_{W'}\,.
\end{aligned}$$

Integrating over $(0, t_1)$, we have

$$\begin{aligned}
&\frac{1}{2}(\|B-B_f\|_W^2 + \|E-E_e\|_{W'}^2)(t_1)\\
&\quad= \int_0^{t_1}[-(\dot B - \dot B_f, u)_W - (\dot B - \dot B_f, D^{'-1}\xi)_W + (\dot v, E-E_e)_{W'}\\
&\qquad\qquad -(\dot w, \dot B - \dot B_f)_W + (S^{'-1}\dot\lambda, E-E_e)_{W'}]dt\,.
\end{aligned}$$

Then, by integration by parts,

$$\begin{aligned}
&\frac{1}{2}(\|B-B_f\|_W^2 + \|E-E_e\|_{W'}^2)(t_1)\\
&\quad= \int_0^{t_1}[(\dot v, E-E_e)_{W'} + (S^{'-1}\dot\lambda, E-E_e)_{W'}]\,dt\\
&\qquad+ \int_0^{t_1}(B-B_f, \dot u + \ddot w)_W\,dt + \int_0^{t_1}(B-B_f, D^{'-1}\dot\xi)_W\,dt\\
&\qquad- (B-B_f, \dot w + u)_W(t_1) - (B-B_f, D^{'-1}\xi)_W(t_1).
\end{aligned}$$

Now the desired estimate follows from the Cauchy–Schwarz inequality and the estimates in Lemmas 5.2 and 5.3. □

5.3. Superconvergence in the discrete $H(\mathbf{curl};\Omega)$-norm. We now show that the finite volume scheme (3.5)–(3.6) has certain superconvergence property; namely, the errors $E - E_e$ and $B - B_f$ are also second order convergent in a discrete $H(\mathrm{curl};\Omega)$-norm. To do so, we first differentiate (3.5) with respect to t to obtain

$$S'\frac{d^2E}{dt^2} - C'\frac{dB}{dt} = \frac{d\tilde J}{dt},$$

and then by (3.6) we obtain

$$S'\frac{d^2E}{dt^2}+C'S^{-1}CE=\frac{d\tilde{J}}{dt}. \tag{5.31}$$

We supplement (5.31) with the following initial conditions:

$$E(0)=E_e(0), \qquad \dot{E}(0)=\dot{E}_e(0). \tag{5.32}$$

Upon rewriting (5.31) as

$$S'\frac{d^2}{dt^2}(E-E_e)+C'S^{-1}C(E-E_e)=\frac{d\tilde{J}}{dt}-S'\frac{d^2E_e}{dt^2}-C'S^{-1}CE_e,$$

and by (3.3), we then have

$$S'\frac{d^2}{dt^2}(E-E_e)+C'S^{-1}C(E-E_e)=S'\frac{d^2}{dt^2}(E_f'-E_e)+\frac{d}{dt}(C'(B_f-B_e')). \tag{5.33}$$

This indicates that $E-E_e$ satisfies the ordinary differential equation (5.33) with the homogeneous initial conditions

$$(E-E_e)(0)=0, \qquad (\dot{E}-\dot{E}_e)(0)=0. \tag{5.34}$$

Multiplying (5.33) by $D(\dot{E}-\dot{E}_e)$, we obtain

$$\begin{aligned}&(S'(\ddot{E}-\ddot{E}_e),D(\dot{E}-\dot{E}_e))+(C'S^{-1}C(E-E_e),D(\dot{E}-\dot{E}_e))\\ &=(S'(\ddot{E}_f'-\ddot{E}_e),D(\dot{E}-\dot{E}_e))+(C'(\dot{B}_f-\dot{B}_e'),D(\dot{E}-\dot{E}_e)).\end{aligned}$$

Then, using (2.7), we get

$$\begin{aligned}&(S'(\ddot{E}-\ddot{E}_e),D(\dot{E}-\dot{E}_e))+(D'S^{-1}C(E-E_e),C(\dot{E}-\dot{E}_e))\\ &=(S'(\ddot{E}_f'-\ddot{E}_e),D(\dot{E}-\dot{E}_e))+(D'(\dot{B}_f-\dot{B}_e'),C(\dot{E}-\dot{E}_e)),\end{aligned}$$

which can be written as

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|\dot{E}-\dot{E}_e\|_{W'}^2+\frac{1}{2}\frac{d}{dt}\|E-E_e\|_V^2\\ &=(\ddot{E}_f'-\ddot{E}_e,\dot{E}-\dot{E}_e)_{W'}+(D'(\dot{B}_f-\dot{B}_e'),C(\dot{E}-\dot{E}_e)).\end{aligned} \tag{5.35}$$

The following theorem gives a superconvergence result for $E-E_e$.

Theorem 5.5. *Assume that*

$$\mathbf{E}\in W^{2,1}(0,T;H^3(\Omega_i)^3)\cap W^{3,1}(0,T;W^{2,p}(\Omega_i)^3), \qquad \mathbf{B}\in W^{2,1}(0,T;H^3(\Omega_i)^3)$$

satisfy the interface Maxwell system (1.1)–(1.8) *for* $i=1,2$ *and* $p>3$, *and* $(E,\,B)$ *is the solution of* (3.5)–(3.6) *on a nonuniform rectangular grid of size* h. *Then we have*

$$\begin{aligned}&\max_{0\le t\le T}\{\|(\dot{E}-\dot{E}_e)(t)\|_{W'}+\|(E-E_e)(t)\|_V\}\\ &\le Kh^2\sum_{i=1}^{2}\{\|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)}\\ &+\|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)}+\|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)}\}.\end{aligned} \tag{5.36}$$

Proof. By Lemma 5.3 we have

$$(\dot{E}'_f - \dot{E}_e, E - E_e)_{W'} = (\dot{v}, E - E_e)_{W'} + (D'\dot{w}, C(E - E_e)) + (S'^{-1}\dot{\lambda}, E - E_e)_{W'}.$$

A proof similar to the one for (5.23) leads to the following relations:

$$(\ddot{E}'_f - \ddot{E}_e, E - E_e)_{W'} = (\ddot{v}, E - E_e)_{W'} + (D'\ddot{w}, C(E - E_e)) + (S'^{-1}\ddot{\lambda}, E - E_e)_{W'},$$
$$(\dddot{E}'_f - \dddot{E}_e, E - E_e)_{W'} = (\dddot{v}, E - E_e)_{W'} + (D'\dddot{w}, C(E - E_e)) + (S'^{-1}\dddot{\lambda}, E - E_e)_{W'},$$

with $\ddot{v}, \dddot{v}, \ddot{w}, \dddot{w}, \ddot{\lambda}, \ \dddot{\lambda}$ obeying the same estimates as those stated in Lemma 5.3. In addition, by Lemma 5.2 and (5.1), we have

$$(C(E - E_e), D'(B_f - B'_e)) = (C(E - E_e), u) + (C(E - E_e), \xi).$$

Again, by a proof similar to the one of Lemma 5.2 we deduce that

$$(C(E - E_e), D'(\dot{B}_f - \dot{B}'_e)) = (C(E - E_e), \dot{u}) + (C(E - E_e), \dot{\xi}),$$
$$(C(E - E_e), D'(\ddot{B}_f - \ddot{B}'_e)) = (C(E - E_e), \ddot{u}) + (C(E - E_e), \ddot{\xi}),$$

with the corresponding estimates for $\dot{u}, \ddot{u}, \dot{\xi}$, and $\ddot{\xi}$ as those stated in Lemma 5.2. Now, integrating (5.35) over $[0, t_1]$, and by (5.34), we obtain

$$\begin{aligned}
&\|(\dot{E} - \dot{E}_e)(t_1)\|^2_{W'} + \|(E - E_e)(t_1)\|^2_V \\
&= 2\int_0^{t_1} (\ddot{E}'_f - \ddot{E}_e, \dot{E} - \dot{E}_e)_{W'}\, ds + 2\int_0^{t_1} (D'(\dot{B}_f - \dot{B}'_e), C(\dot{E} - \dot{E}_e))\, ds.
\end{aligned}$$

An application of integration by parts yields

$$\begin{aligned}
&\|(\dot{E} - \dot{E}_e)(t_1)\|^2_{W'} + \|(E - E_e)(t_1)\|^2_V \\
&= 2\int_0^{t_1} (\ddot{E}'_f - \ddot{E}_e, \dot{E} - \dot{E}_e)_{W'}\, ds \\
&\quad + 2(D'(\dot{B}_f - \dot{B}'_e), C(E - E_e))(t_1) - 2\int_0^{t_1} (D'(\ddot{B}_f - \ddot{B}'_e), C(E - E_e))\, ds.
\end{aligned}$$

Substituting the relations given in the beginning of the proof into the above equation, and using the Cauchy–Schwarz inequality together with the estimates in Lemmas 5.2 and 5.3, we obtain the desired estimate. $\square$

The following theorem gives a superconvergence result for $B - B_f$.

THEOREM 5.6. *Under the same assumptions as in Theorem* 5.5, *we have*

$$\begin{aligned}
&\max_{0\le t\le T}\left\{ \|(\dot{B} - \dot{B}_f)(t)\|_W + \sup_{\phi\in\mathbb{R}^{M_1}} \frac{|(C'(B - B_f), D\phi)|}{\|\phi\|_V} \right\} \\
&\quad \le Kh^2 \sum_{i=1}^{2} \{ \|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} + \|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)} \\
&\qquad + \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} \}\ .
\end{aligned}$$

Proof. By (5.1) and (5.36), we obtain

$$\begin{aligned}
&\max_{0\le t\le T} \|(\dot{B} - \dot{B}_f)(t)\|_W \\
&\quad \le\ Kh^2 \sum_{i=1}^{2} \{ \|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} +\ \|\epsilon_i^{\frac{1}{2}}\mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)} \\
&\qquad + \|\mu_i^{-\frac{1}{2}}\mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} \}.
\end{aligned}$$

By (5.2), we have

$$C'(B-B_f) = S'\frac{d}{dt}(E-E_e) - S'\frac{d}{dt}(E'_f - E_e) - C'(B_f - B'_e). \tag{5.37}$$

For any $\phi \in \mathbb{R}^{M_1}$, multiplying (5.37) by $D\phi$ and using (2.7), we obtain

$$(C'(B-B_f), D\phi) = (\dot{E} - \dot{E}_e, \phi)_{W'} - (\dot{E}'_f - \dot{E}_e, \phi)_{W'} - (D'(B_f - B'_e), C\phi).$$

First, by (5.36) we have

$$\begin{aligned} &|(\dot{E} - \dot{E}_e, \phi)_{W'}| \\ &\quad \le\ Kh^2 \|\phi\|_{W'} \sum_{i=1}^{2} \{ \|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} +\ \|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)} \\ &\qquad\qquad + \|\mu_i^{-\frac{1}{2}} \mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} \}. \end{aligned}$$

Then, using (5.23) and (5.25), we easily derive

$$|(\dot{E}'_f - \dot{E}_e, \phi)_{W'}| \le Kh^2 \|\phi\|_V \sum_{i=1}^{2} \{ \|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} + \|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)} \},$$

while using (5.14) and (5.15) we have

$$|(D'(B_f - B'_e), C\phi)| \le Kh^2 \|\phi\|_V \sum_{i=1}^{2} \|\mu_i^{-\frac{1}{2}} \mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)}.$$

Collecting the above results leads to

$$\begin{aligned} \frac{|(C'(B-B_f), C\phi)|}{\|\phi\|_V} &\le K_1 h^2 \sum_{i=1}^{2} (\|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} + \|\epsilon_i^{\frac{1}{2}} \mathbf{E}\|_{W^{3,1}(0,T;W^{2,p}(\Omega_i)^3)}) \\ &\quad + K_2 h^2 \sum_{i=1}^{2} \|\mu_i^{-\frac{1}{2}} \mathbf{B}\|_{W^{2,1}(0,T;H^3(\Omega_i)^3)} \end{aligned}$$

for any $\phi \in \mathbb{R}^{M_1}$. □

6. Conclusion. Through a detailed analysis, we have established some rigorous convergence results for a finite volume method for the time-dependent Maxwell's equations in a three-dimensional polyhedral domain. Different materials are allowed to occupy portions of the domain, and interface conditions are imposed. Our analysis does not require extra regularity assumptions on the solutions of the interface problem beyond those for the analogous convergence results for noninterface Maxwell's equations, and our estimates also exhibit the detailed dependence on the material parameters. For brevity, we have chosen the case of two subdomains in our derivations, though much of our theory can be generalized to cases involving multiple subdomains. Implementations and applications of the methods discussed here are currently underway, and the results will be reported elsewhere.

Acknowledgments. The authors would like to thank the editor and the referees whose constructive suggestions and comments significantly improved the presentation of the paper.

A MIXED SPECTRAL-DIFFERENCE METHOD FOR THE STEADY STATE BOLTZMANN–POISSON SYSTEM[*]

CHRISTIAN RINGHOFER[†]

Abstract. The approximate solution of the Boltzmann transport equation via Galerkin-type series expansion methods leads to a system of conservation laws in space and time for the expansion coefficients. In this paper, we derive discretization methods for these equations in the mean field approximation, which are based on the entropy principles of the underlying Boltzmann equation, and discuss the performance of these discretizations and the series expansion approach in nonequilibrium regimes.

1. Introduction.

This paper is concerned with the numerical solution of the steady state Boltzmann–Poisson system, describing the transport of an ensemble of electrons or holes in a crystal interacting with a phonon background under the mean field approximation. The Boltzmann–Poisson system in steady state is given by (see [14])

$$(1)\qquad \text{(a)}\quad \nabla_x \cdot [\nabla_k \varepsilon(k) f] - q\nabla_k \cdot [\nabla_x V(x) f] + \frac{1}{\lambda} Q(f) = 0,$$

$$\text{(b)}\quad -\sigma \Delta_x V + q[D^{dop}(x) - \rho] = 0, \quad \rho(x) := \int f(x,k)dk,$$

where the phase space density function $f(x,k)$ is a function of position $x \in R_x^d$ ($d =$ 1, 2, or 3) and wave vector $k \in R_k^3$. The function $\varepsilon(k)$ describes the energy band under consideration. So $\nabla_k \varepsilon$ denotes the velocity with which a particle (electron or hole) with wave vector k travels. (If more than one energy band is considered, one density function f per band would have to be computed.) The Boltzmann equation (1) arises from a many body problem under the mean field approximation. So the function $V(x)$ denotes the mean field potential and q denotes the charge of the particle ($q = -1$ for electrons, $q = 1$ for holes). $\rho(x)$, as defined in (1)(b), denotes the density of particles in physical space and σ stands for the dielectricity constant of the material. The function $D^{dop}(x)$ in (1)(b) models the doping concentration, the background density of ions due to the implantation of donor and acceptor atoms into the crystal. Equation (1) has already been brought into a scaled dimensionless form, where the parameter λ denotes scaled mean-free path, i.e., the average distance a particle travels before it undergoes a collision event. (See [14, Chap. 1] for details of the scaling.) Finally, collisions of electrons or holes with the phonon background (the vibrations of the crystal lattice)

are modeled by the integral operator Q in (1)(a). For the semiconductor Boltzmann–Poisson problem, Q is of the form

$$Q[f](x,k) = \int_{R_k^3} S(k,k')[f(x,k)e^{\varepsilon(k)} - f(x,k')e^{\varepsilon(k')}]dk', \tag{2}$$

where $S(k,k')$ denotes the scaled scattering cross section. Because of the principle of detailed balance [3], the scattering cross section S is a symmetric function ($S(k,k') = S(k',k)$), which guarantees that the charge ρ is conserved by the collision operator Q. Moreover, the above form of the collision operator guarantees that the Maxwellians of the form $f(x,k) = c(x)e^{-\varepsilon(k)}$ are in the kernel of Q. The collision operator Q models the generation and annihilation of phonons, resulting in a specified gain or loss of energy of the particles. Consequently, the function S is a distribution of the form

$$S(k,k') = \sum_{\nu=-1}^{1} s_\nu(k,k')\delta(\varepsilon(k) - \varepsilon(k') + \nu\omega), \tag{3}$$

where ω is the amount of energy gained or lost due to the collisions. Because of the symmetry of the scattering cross section,

$$s_\nu(k,k') = s_{-\nu}(k',k)$$

has to hold. The assumption of a linear collision operator of the form (2) implies that we neglect electron-electron interactions. The steady state Boltzmann–Poisson system (1) is subject to a mixed set of Dirichlet and Neumann boundary conditions which will be discussed in the context of the discretization in section 3.

The outline of this paper is as follows. We will discretize the Boltzmann equation (1)(a) by a spectral Galerkin method in the wave vector direction, obtaining a system of conservation laws in x, which is solved by a difference method. This difference method is the actual topic of this paper. The spectral Galerkin method is chosen such as to preserve the entropy properties of the Boltzmann equation. So in section 2 we briefly review the general concepts involved in entropy based series expansion methods for the Boltzmann equation. In section 3, we derive the actual difference scheme which, in more than one spatial dimension, is based on a staggered grid approach. The resulting difference equations are nonlinear due to the coupling to the Poisson equation (1)(b). In section 4, we prove the stability of the linearization of these equations. Section 5 is devoted to the actual implementation of the method in one spatial dimension and to a numerical test example. The example consists of a standard $n^+ - n - n^+$ semiconductor diode with a $50nm$ channel. We demonstrate that in this example the solution to the Boltzmann equation exhibits truly kinetic features, which cannot be modeled by fluid dynamical approximations.

2. Entropy based Galerkin methods.

This paper is concerned with the spatial discretization of first order systems of partial differential equations in physical (x-) space, which arise from employing a certain type of series expansion method for the Boltzmann equation (1) in the wave vector direction. Series expansion methods for the Boltzmann–Poisson system in the context of modeling semiconductor devices were first used effectively in [8]. The expansion methods considered in this paper make use of the entropy property of the Boltzmann equation. In this section, we briefly present the use of such entropy principles in a somewhat more general framework than is actually used in this paper. It is generally more convenient to consider entropy principles for the case of the time dependent Boltzmann equation in the absence of boundary conditions ($x \in R_x^d$, $k \in R_k^3$), which we will do in this section. So the following is a brief review of general concepts described in detail in [7] or [11]. It should be pointed out here that, for the purpose of this paper, we approach the subject from a somewhat different angle. The entropy concept is usually relevant for the transient kinetic problem in the absence of boundary conditions. As a matter of fact, it does not hold in the form described here in the presence of boundary conditions. (See [5].) However, when discretizing the steady state Boltzmann equation with boundary conditions, one still has to deal with a rather stiff system of partial differential equations due to rapid potential variation; i.e., the same problems which make the discretization of the drift-diffusion or the energy transport system non-trivial arise again. The subject of this paper is the development of discretization methods for these systems, and we will only make use of the structure of the free-space operator induced by the free-space entropy property.

Generally, an entropy is given by a function $H(f,x,k)$, satisfying the following properties.

P1. The entropy is dissipated by the collision operator, so

$$\int_{R_x^d \times R_k^3} \partial_f H(f,x,k) Q[f](x,k) dxdk > 0$$

holds.

P2. The entropy is preserved by the free streaming operator, so

$$\int_{R_x^d \times R_k^3} \partial_f H(f,x,k)[\nabla_x \cdot (\nabla_k \varepsilon(k) f) - q \nabla_k \cdot (\nabla_x V(x) f)] dxdk = 0$$

holds.

P3. For fixed x and k the function H is a strictly convex function of the variable f and the functional

$$\eta(f) = \int_{R_x^d \times R_k^3} H(f(x,k),x,k) dxdk \tag{4}$$

is a convex functional of f.

The above properties guarantee that, for the time dependent Boltzmann equation

$$\partial_t f + \nabla_x \cdot [\nabla_k \varepsilon(k) f] - q \nabla_k \cdot [\nabla_x V(x) f] + \frac{1}{\lambda} Q(f) = 0, \tag{5}$$

the functional η is nonincreasing in time. This can be easily verified by integrating (5) against $\partial_f H(f,x,k)$ over $R_x^3 \times R_k^3$. However, since this paper is concerned with the steady state problem, we will use the structure induced by the entropy functional for a stability estimate for the steady state problem. Entropy based Galerkin methods are truncated series expansions of the solution f of (1) which preserve this structure. To this end, we introduce the inverse of $\partial_f H$ with respect to the variable f by

$$g = \partial_f H(f,x,k) \quad \Longleftrightarrow \quad f = \mu(g,x,k),$$

which exists since $\partial_f H$ is a monotone function of f. To obtain an approximation which preserves the entropy property, we apply a Galerkin procedure to the Boltzmann equation (5) in the entropy variable g. Thus, after choosing some basis functions $\{\phi_m(k),\, m = 0, 1, \dots, M\}$, we set

$$g(x,k,t) = \sum_{n=0}^{M} f_n(x,t)\phi_n(k), \quad f(x,k,t) = \mu\Big(\sum_{n=0}^{M} f_n(x,t)\phi_n(k), x, k\Big)$$

and integrate the Boltzmann equation for the entropy variable g, which is of the form

$$\partial_t \mu(g,x,k) + \nabla_x \cdot [\nabla_k \varepsilon(k)\mu(g,x,k)] - q\nabla_k \cdot [\nabla_x V(x)\mu(g,x,k)] + \frac{1}{\lambda}Q(\mu(g,x,k)) = 0$$

against each of the basis functions with respect to the wave vector k. This yields a first order system of partial differential equations of the form

$$\text{(6) (a)} \quad \partial_t G(F) + \sum_{j=1}^{d}[\partial_{x_j} A^j(F) - q(\partial_{x_j} V)B^j(F)] + \frac{1}{\lambda}C(F) = 0, \quad F = (f_0, \dots, f_M)^T,$$

$$\text{(b)} \quad G_m(F,x) = \int \phi_m(k) f(x,k,t)dk, \quad A^j_m(F,x) = \int \phi_m(k)(\partial_{k_j}\varepsilon(k)) f(x,k,t)dk,$$

$$\text{(c)} \quad B^j_m(F,x) = \int \phi_m(k)\partial_{k_j} f(x,k,t)dk, \quad C_m(F,x) = \int \phi_m(k) Q[f](x,k,t)dk,$$

which, by virtue of construction, automatically satisfies the entropy estimate

$$\partial_t \eta(F) \le 0, \quad \eta(F) = \int F^T(x,t)G(F,x)dx,$$

where, for simplicity, we denote the entropy function $\eta(F)$ of the coefficient vector F with the same symbol as the entropy $\eta(f)$ in (4) evaluated at the corresponding linear combination of the basis functions. The existence of the above estimate automatically guarantees that the generally nonlinear first order system (6) is hyperbolic [11]. The actual form of the system is determined by the choice of basis function ϕ_m and the form of the entropy function H.

Choice of entropies. The classical physical entropy, which arises in the kinetic description of fluids, where the collision operator Q models particle-particle interactions and is nonlinear, is given by the natural logarithm $\partial_f H = \ln f$, $H = f(\ln f - 1)$. Since we are dealing with a greatly simplified linear operator, and also are considering a plasma driven by the field $\nabla_x V$, there is a much larger degree of freedom in the choice of entropy. A straightforward calculation gives

$$\text{(7)} \qquad \int \partial_f H(f,x,k)Q[f](x,k)dk$$

$$= \frac{1}{2}\int_{R^3_k \times R^3_k} S(k,k')[\partial_f H(f,x,k) - \partial_f H(f',x,k')][fe^{\varepsilon} - f'e^{\varepsilon'}]dkdk',$$

where the prime denotes evaluation of the corresponding function at k'. Thus, any entropy H whose derivative is a nondecreasing function of fe^{ε} (meaning $\partial_f H(f,x,k) = h_1(fe^{\varepsilon(k)}, x)$ with $\partial_u h_1(u,x) \ge 0$) will satisfy the first requirement on the entropy since the term $[h_1(fe^{\varepsilon(k)},x)-h_1(f'e^{\varepsilon(k')},x)][f(x,k)e^{\varepsilon(k)}-f(x,k')e^{\varepsilon(k')}]$ in the integrand of (7) will always be nonnegative. To satisfy the second requirement, namely, that the entropy is preserved by the free streaming operator, we note that

$$\partial_f H(f,x,k)[\nabla_x\cdot(\nabla_k\varepsilon(k)f)-q\nabla_k\cdot(\nabla_x V(x)f)] \tag{8}$$

$$=[\nabla_x\cdot(\nabla_k\varepsilon(k)H)-q\nabla_k\cdot(\nabla_x V(x)H)]-[\nabla_k\varepsilon\cdot\nabla_2 H-q\nabla_x V(x)\cdot\nabla_3 H]$$

holds, where ∇_2,∇_3 denote the derivatives with respect to the second and third variables of $H(f,x,k)$. The integral over the whole phase space of the first term on the right-hand side of (8) is zero since it represents a total derivative. So the second condition on the entropy H is satisfied if the second term on the right-hand side of (8) vanishes. The general solution of $[\nabla_k\varepsilon\cdot\nabla_2-q\nabla_x V(x)\cdot\nabla_3]H(f,x,k)=0$ is given by all functions of the total energy $\varepsilon(k)+qV(x)$. So $H(f,x,k)$, and therefore also $\partial_f H(f,x,k)$, should depend on x and k only through the total energy $\varepsilon(k)+qV(x)$. Combining this with the first requirement $\partial_f H(f,x,k)=h_1(fe^{\varepsilon(k)},x)$, we see that any function H satisfying

$$\partial_f H(f,x,k)=h(f\exp(\varepsilon(k)+qV(x)),\quad h'(u)\geq 0,$$

can be chosen as an entropy for the Boltzmann equation. The physical entropy, the logarithm, now corresponds to the choice

$$h(u)=\ln u,\quad H(f,x,k)=f[\ln f-1+\varepsilon(k)+qV(x)],\quad \mu(g,x,k)=\exp[g-\varepsilon(k)-qV(x)].$$

If this entropy is used with the basis functions $1,k,\varepsilon(k)$, we obtain the classical hydrodynamic model for semiconductors. If more terms are used in the Galerkin approximation (6), we face the problem that, because of the exponential function μ, the involved integrals will in general become infinite. This problem can be remedied by using special restricted sets of basis functions developed by Levermore [11]. However, we face the additional problem that we have to evaluate the quite complicated integrals of the collision operator Q. In the Levermore approach, as well as in the hydrodynamic models, the collision operator is usually replaced by some form of BGK approximation with fitted relaxation times. Indeed, the Galerkin approach (6) can be philosophically viewed in two different ways. One is to regard (6) as deriving extensions of the Euler equations. The other one is to regard (6) as an actual numerical method for the Boltzmann equation. The difference is that in the first approach only relatively few terms are taken which have some physical interpretation. In the second approach, arbitrarily many terms in the expansion (6) have to be generated automatically, and the physical interpretation of the high order terms is not important. In this paper, we follow the second approach. This means that we use the simplest possible entropy, namely a quadratic function.

$$\eta(u)=u,\quad H(f,x,k)=\frac{1}{2}f^2\exp[\varepsilon(k)+qV(x)],\quad \mu(g,x,k)=g\exp[-\varepsilon(k)-qV(x)]. \tag{9}$$

This choice makes the Galerkin equations (6) linear, as long as we do not couple the Boltzmann equation to the Poisson equation (1)(b), and the entropy estimate becomes an L^2 estimate with the weight function $\exp[\varepsilon+qV]$. Methods based on these basis functions have been analyzed and implemented in [17], [18], and suitable time discretization methods have been developed in [15]. All of this work was concerned with the linear time dependent Boltzmann equation for a given potential V. In this paper, we treat the steady state Boltzmann–Poisson problem instead, using the same linear entropy. So the role of the entropy will not be to provide an a priori estimate on the time dependent solution. Instead, we will make use of the effect of the entropy on the structure of the involved nonlinear operators. The convergence of Galerkin methods using the linear entropy in the linear case (i.e., for a given potential) has been analyzed in [16], [18].

3. Difference schemes. In this section, we present the spatial discretization of the Galerkin equations arising from (6) together with the Poisson equation (1)(b). When designing the spatial discretization one is confronted with two somewhat contradictory priorities. On one hand, the discretization should reflect the entropy preservation property of the free streaming operator; that is, a discrete equivalent of P3 in section 2 should hold. In the case of the quadratic entropy used in this paper, this means that the spatially discretized free streaming operator should be antisymmetric with respect to the weight function e^{qV}. This results in obviously desirable stability properties of the discretization. On the other hand, we wish to locally conserve charge. Building the zero order moment of the Boltzmann equation (1)(a) with respect to the wave vector k yields the continuity equation

$$(10) \qquad \nabla_x \cdot \langle \nabla_k \varepsilon \rangle = 0, \quad \langle \nabla_k \varepsilon \rangle := \int \nabla_k \varepsilon(k) f(x,k) dk.$$

This continuity equation should hold locally; that is, we should be able to apply a discrete version of Gauss's theorem locally over any submesh. In the context of a finite element discretization in the spatial direction, the first priority would suggest a straightforward finite element discretization using a weighted scalar product, which would automatically not be locally conservative. A similar problem exists when using difference schemes. Our approach is the following: We will split the balance equations (6)(a) into those governing the even and odd order moments of the kinetic density function f. The difference scheme for the even order moment equations will be designed in such a way that it locally conserves the appropriate momenta. The difference scheme for the odd order moment equations will then be chosen such that the whole scheme has the appropriate entropy properties outlined in the previous section. This represents a compromise between the two priorities of local conservation and entropy dissipation. This compromise is acceptable, since the collisions modeled by the operator Q are nonelastic and the odd order moments are not conserved anyway. In the steady state case, the odd order moments have to be viewed rather as constitutive relations.

First we observe that the free streaming operator L, defined by

$$L[f] = \nabla_x \cdot [\nabla_k \varepsilon(k) f] - q \nabla_k \cdot [\nabla_x V(x) f],$$

induces a natural decomposition of the function space for f. If the band energy $\varepsilon(k)$ is an even function of the wave vector k (which always can be assumed), the operator L maps even functions of k into odd functions and vice versa. So we split the density function f, as well as the Boltzmann equation, into its even and odd parts

$$(11) \qquad (a) \quad f = f^e + f^o, \quad f^e(x,k) = f^e(x,-k), \quad f^o(x,k) = -f^o(x,-k),$$

$$(b) \quad L[f^o] + Q^e[f^e + f^o] = 0, \quad (c) \quad L[f^e] + Q^o[f^e + f^o] = 0,$$

where Q^e, Q^o denote the even and odd parts of the collision operator. Next we observe that the important conservation laws (for charge and energy) are given by the even part of the Boltzmann equation. Since the given collision operator does not preserve momentum anyway, the moments of the odd part of the Boltzmann equation gives rise to constitutive relations rather than conservation laws. Consequently, we will dicretize (11)(b) conservatively and choose the discretization of (11)(c) to satisfy the entropy conservation property P2 of the operator L. After splitting into even and odd parts, the entropy property of the free streaming operator L reads

$$\int_{R^3_x \times R^3_k} e^{\varepsilon+V} f^e L[f^o] dx dk + \int_{R^3_x \times R^3_k} e^{\varepsilon+V} f^o L[f^e] dx dk = 0. \tag{12}$$

We will use (12) as a weak definition of $L[f^e]$ in terms of $L[f^o]$. Moreover, we can also assume that in general the scattering cross section $S(k,k')$ (3) is an even function of its arguments. This implies that the collision operator Q maps even functions of k into even functions and odd functions into odd functions, giving

$$Q^e[f^e + f^o] = Q[f^e], \quad Q^o[f^e + f^o] = Q[f^o].$$

In keeping with the spirit of the entropy based Galerkin approach outlined in the previous section, we expand f^e and f^o into

$$f^e(x,k) = \sum_{n=0}^{N_e} f^e_n(x) e^{-\varepsilon} \phi^e_n(k), \quad f^o(x,k) = \sum_{n=0}^{N_o} f^o_n(x) e^{-\varepsilon} \phi^o_n(k),$$

where we have absorbed the factor e^{-qV} in (9) into the coefficients $f^{e,o}_n$ for notational convenience. Integrating (11)(b) against the even basis functions ϕ^e_m and (11)(c) against the odd basis functions ϕ^o_m yields the system

$$\text{(13)} \qquad \text{(a)} \quad \sum_{\nu=1}^{d} [A^{eo}_\nu \partial_{x_\nu} F^o - q(\partial_{x_\nu} V) B^{eo}_\nu F^o] + \frac{1}{\lambda} C^e F^e = 0,$$

$$\text{(b)} \quad \sum_{\nu=1}^{d} [A^{oe}_\nu \partial_{x_\nu} F^e - q(\partial_{x_\nu} V) B^{oe}_\nu F^e] + \frac{1}{\lambda} C^o F^o = 0,$$

where $F^{e,o}(x)$ denotes the coefficient vector $(f^{e,o}_0, \dots, f^{e,o}_{N_{e,o}})$ and the matrices are defined in the obvious way by

$$\text{(14) (a)} \quad A^{eo}_\nu(m,n) = \int [\phi^e_m (\partial_{k_\nu} \varepsilon) e^{-\varepsilon} \phi^o_n] dk, \quad A^{oe}_\nu(m,n) = \int [\phi^o_m (\partial_{k_\nu} \varepsilon) e^{-\varepsilon} \phi^e_n] dk,$$

$$\text{(b)} \quad B^{eo}_\nu(m,n) = \int \phi^e_m \partial_{k_\nu} [e^{-\varepsilon} \phi^o_n] dk, \quad B^{oe}_\nu(m,n) = \int \phi^o_m \partial_{k_\nu} [e^{-\varepsilon} \phi^e_n] dk,$$

$$\text{(c)} \quad C^e(m,n) = \int \phi^e_m Q[e^{-\varepsilon} \phi^e_n] dk, \quad C^o(m,n) = \int \phi^o_m Q[e^{-\varepsilon} \phi^o_n] dk.$$

As mentioned, we will discretize the even part (13)(a) by a conservative difference method and the odd part (13)(b) in its weak form defined by the relation (12). A simple calculation gives that the relations

$$B^{eo}_\nu + (B^{oe}_\nu)^T + A^{eo}_\nu = 0, \quad \nu = 1, \dots, d, \tag{15}$$

hold. Furthermore, because of the symmetry of the scattering cross section S, the odd collision operator is given by

$$C^o(m,n) = \int \phi^o_m \sigma(k) \phi^o_n dk, \quad \sigma(k) = \int S(k,k')dk'.$$

Therefore the matrix C^o, corresponding to the odd part of the collision operator, is invertible as a consequence of the fact that the kernel of Q contains only even functions. This suggests eliminating F^o locally by inverting C^o in (13)(b) and inserting the resulting expression into (13)(a). To discretize (13) in the spatial direction, we will need difference operators which are conservative and satisfy a discrete version of Gauss's theorem. This is nontrivial in more than one spatial dimension if a general nonrectangular mesh is used, unless they do not act on the same grids. We therefore assume two separate grids for F^e and F^o and difference operators acting between them. We define the meshes

$$M^e = \{\mathbf{x}_j,\ j = 0,\dots,J_e\}, \quad M^o = \{\mathbf{y}_j,\ j = 0,\dots,J_o\}$$

and difference operators D^{eo}_ν, D^{oe}_ν, both approximating ∂_{x_ν}, acting between them

$$(D^{eo}_\nu u^o)(\mathbf{x}_j) = \sum_{s=0}^{J_o} d^{eo}_\nu(j,s) u^o(\mathbf{y}_s), \quad (D^{oe}_\nu u^e)(\mathbf{y}_j) = \sum_{s=0}^{J_e} d^{oe}_\nu(j,s) u^e(\mathbf{x}_s)$$

for grid functions u^e, u^o defined on the respective meshes. Using appropriate discrete integration operators I_e, I_o, the discrete integration by parts formula we assume takes the form

$$(16)\ \text{(a)} \quad I_e[(u^e)^T(D^{eo}_\nu u^o)] = -I_o[(u^o)^T(D^{oe}_\nu u^e)] + b^e(u^e)^T b^o(u^o), \quad \nu = 1,\dots,d,$$

$$\text{(b)} \quad I_e[u^e] = \sum_{s=0}^{J_e} \gamma_e(s) u^e(\mathbf{x}_s), \quad I_o[u^o] = \sum_{s=0}^{J_o} \gamma_o(s) u^o(\mathbf{y}_s)$$

for vector grid functions u^e, u^o with appropriate integration weights γ_e, γ_o. The boundary operators b^e, b^o correspond to evaluation of the grid function at the boundary points of the respective meshes M^e, M^o. There is one minor problem caused by the introduction of the dual meshes M^e, M^o, which is that the free streaming operator L contains derivatives of the density function as well as zero order terms, which couples the meshes. This is remedied by using an interpolation formula which is in some sense generic for the free streaming operator. In order to write the term $q(\partial_{x_\nu}V)(\partial_{k_\nu}f)$ solely in terms of spatial derivatives of f, we replace it by $\partial_{x_\nu}[qV\partial_{k_\nu}f] - qV\partial_{x_\nu}\partial_{k_\nu}f$. Thus (13)(a) is discretized by

$$(17) \quad L^{eo}F^o + \frac{1}{\lambda}C^e F^e = 0, \quad L^{eo}F^o = \sum_{\nu=1}^{d}[D^{eo}_\nu(A^{eo}_\nu F^o - qVB^{eo}_\nu F^o) + qVB^{eo}_\nu D^{eo}_\nu F^o].$$

The odd part (13)(b) of the Boltzmann equation is now discretized using the dual operator to L^{eo} as defined by (12). This gives

$$(18) \qquad \text{(a)} \quad L^{oe}F^e + \frac{1}{\lambda}C^o F^o = 0,$$

$$\text{(b)} \quad L^{oe}F^e = \sum_{\nu=1}^{d} e^{-qV}[(A^{eo}_\nu - qVB^{eo}_\nu)^T D^{oe}_\nu(e^{qV}F^e) + (B^{eo}_\nu)^T D^{oe}_\nu(qVe^{qV}F^e)].$$

This represents a consistent discretization of (13)(b) because of the relation (15) for the coefficient matrices, as can be easily verified. By virtue of construction, the discrete system (17), (18) now has the desired symmetry properties and accurately represents a discrete version of the conservation law (10). We summarize these statements in the following proposition.

PROPOSITION 1. *The discretized operators* L^{eo}, L^{oe} *in* (17), (18) *satisfy the equality*

$$I_e[e^{qV}(F^e)^T L^{eo} F^o] + I_o[e^{qV}(F^o)^T L^{oe} F^e] \tag{19}$$

$$= \sum_{\nu=1}^{d} b^e(e^{qV}F^e)^T b^o(A_\nu^{eo}F^o - qVB_\nu^{eo}F^o) + b^e(qVe^{qV}F^e)b^o(B_\nu^{eo}D_\nu^{eo}F^o)$$

for any choice of grid functions F^e, F^o, V. *Furthermore, the discrete conservation law*

$$I_e[\mathbf{e}^T L^{eo} F^o] = \sum_{\nu=1}^{d} b^e(\mathbf{e})^T b^o(A_\nu^{eo}F^o) \tag{20}$$

holds, where $\mathbf{e}$ *denotes the first unit vector in* R^{N_e}.

Proof. Equation (19) holds by virtue of construction, using the discrete integration by parts formulae (16). Equation (20) is obtained from (19) by setting $F^e = \mathbf{e}$ and observing that because of (14)(b) the first row of B_ν^{eo} vanishes. □

We now turn to coupling (17), (18) to the Poisson equation (1)(b). Using the obvious discretization induced by the difference operators D_ν^{eo}, D_ν^{oe}, the discretization of the Poisson equation reads

$$-\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} V^e + q[D^{dop} - \rho^T F^e] = 0, \quad \rho^T = (\rho_1, \dots, \rho_{N_e}), \quad \rho_n = \int e^{-\varepsilon}\phi_n^e dk.$$

Therefore, if the even coefficient vector F^e is only defined on the mesh M^e, so is the potential. The discretization of the Boltzmann equation (17), (18) requires, however, the potential on both meshes M^e and M^o, and therefore some interpolation formula is needed which computes the potential V on the mesh M^o from V^e. So, in summary, the discretized Boltzmann–Poisson system is given by

$$\text{(a)} \quad L^{eo}(F^e, F^o) + \frac{1}{\lambda}C^e F^e = 0, \quad \text{(b)} \quad L^{oe}(F^e) + \frac{1}{\lambda}C^o F^o = 0, \tag{21}$$

$$\text{(c)} \quad -\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} V^e + q[D^{dop} - \rho^T F^e] = 0, \quad V^o = S(V^e),$$

$$\text{(d)} \quad L^{eo}(F^e, F^o) = \sum_{\nu=1}^{d} [D_\nu^{eo}(A_\nu^{eo}F^o - qV^o B_\nu^{eo}F^o) + qV^e B_\nu^{eo} D_\nu^{eo} F^o],$$

$$\text{(e)} \quad L^{oe}(F^e) = \sum_{\nu=1}^{d} e^{-qV^o}[(A_\nu^{eo} - qVB_\nu^{eo})^T D_\nu^{oe}(e^{qV^e}F^e) + (B_\nu^{eo})^T D_\nu^{oe}(qV^e e^{qV^e}F^e)],$$

where V^o is somehow interpolated from V^e using the interpolation operator S. Notice that L^{eo} and L^{oe} are now nonlinear operators because the potentials V^e, V^o are given in terms of F^e through the solution of the Poisson equation (21)(c). In principle, any interpolation formula could be used which is of a high enough order as to keep the total order of accuracy of (17), (18), and the choice of interpolation formula cannot be discussed further without being more specific about the structure of the mesh and the form of the difference operators. In practice, we will take the following approach: The Galerkin approximation to the Boltzmann–Poisson system will reduce to the drift-diffusion system if only the basis functions $1, k_1, k_2, k_3$ are used with $N_e = 0$, $N_o = 2$. In this case, the matrices B^{eo}_ν and C^e vanish and the matrices A^{eo}_ν will form the rows of a multiple of the identity matrix; i.e., there will be no mixed derivatives appearing in the equations. Given a certain mesh structure and a set of difference operators, we will choose the interpolation formula to compute V^o in such a way that the resulting scheme reduces to the well-known Scharfetter–Gummel scheme on this mesh.

Boundary conditions. For practical applications, the boundary will be decomposed in two types of boundary segments, namely insulating parts at which the particle fluxes normal to the boundary vanish and parts at which particles are injected according to a Maxwellian distribution in such a way that charge neutrality in the Poisson equation is preserved (meaning $\rho = D$ in (1)(b)). The insulation property simply translates into the odd component of the density function being equal to zero. The injection of particles results in a quite complicated mixed boundary condition involving the diagonalization of the matrices A^{eo}_ν, A^{oe}_ν. (See [15] for more details.) For the solution of the transient problem, it is quite essential to capture the precise structure of the boundary conditions in order to avoid artificial reflections. For the steady state problem, it turns out the structure of the boundary conditions has actually relatively little impact on the solution as long as charge neutrality is guaranteed. As mentioned before, we will actually eliminate the odd component vector F^o for the practical implementation of the scheme and solve (21) in the form

$$\lambda L^{eo}(F^e, -\lambda(C^o)^{-1}L^{oe}(F^e)) + C^e F^e = 0.$$

In this formulation, dealing with the mixed boundary condition resulting from the particle injection is actually quite cumbersome. We therefore use the simplified set of boundary conditions

$$(22) \qquad \text{(a)} \quad b^e(F^e) = D^{dop}\mathbf{e}, \quad V^e = V^e_b \quad \text{for } \mathbf{x}_j \in \partial M^e_{Dir},$$

$$\text{(b)} \quad b^o(F^o) = 0, \quad b^o(D^{eo}V^e) = 0 \quad \text{for } \mathbf{y}_j \in \partial M^o_{Neu},$$

where the subscripts Dir, Neu denote the union of Dirichlet and Neumann segments of the boundary and b^e, b^o are the boundary operators in (16). Note that b^o is actually the discretization of the outward normal component of a vector. Also, (22)(a) tacitly assumes that $\phi^e_0 = 1$ holds and that the basis functions form an orthonormal system, which implies that the physical space density ρ is actually given by F^e_0 and therefore Maxwellians of the form $e^{-\varepsilon}$ correspond to the first unit vector $\mathbf{e}$.

4. Stability of the linearization. In this section, we prove that the linearization of the scheme defined in the previous section around the equilibrium solution is stable. This implies, among other things, that close to equilibrium Newton's method will be locally quadratically convergent when applied to the nonlinear system (21). To this end, we first reformulate (21) slightly by essentially writing it as a correction to a discretization of the drift-diffusion–Poisson equations. We assume that the Galerkin approximation (13) to the Boltzmann equation contains the balance equations for charge and momentum, i.e., that the functions $1, k$ are contained in the set of basis functions. So we set

$$\phi_0^e = 1, \quad \phi_n^o = k_n, \quad n = 1, \dots, d.$$

Next we split the system (21) into the balance equations for charge and momentum and the rest by setting

$$F^e = \begin{pmatrix} F_0^e \\ F_1^e \end{pmatrix}, \quad F^o = \begin{pmatrix} F_0^o \\ F_1^o \end{pmatrix}, \quad L^{eo} = \begin{pmatrix} L_0^{eo} \\ L_1^{eo} \end{pmatrix}, \quad L^{oe} = \begin{pmatrix} L_0^{oe} \\ L_1^{oe} \end{pmatrix},$$

where F_0^e and L_0^{eo} denote the first component of F^e, L^{eo} and F_1^e and L_1^{eo} denote the other N_e components. In the same way, F_0^o, L_0^{oe} denote the first d components of F^o, L^{oe} and F_1^o, L_1^{oe} denote the other $N_o + 1 - d$ components. Accordingly, we partition the matrices A_ν^{eo}, B_ν^{eo}, C^e, and C^o into

$$A_\nu^{eo} = \begin{pmatrix} A_\nu^{00} & A_\nu^{01} \\ A_\nu^{10} & A_\nu^{11} \end{pmatrix}, \quad B_\nu^{eo} = \begin{pmatrix} 0 & 0 \\ B_\nu^{10} & B_\nu^{11} \end{pmatrix},$$

$$C^e = \begin{pmatrix} 0 & 0 \\ 0 & C_e^{11} \end{pmatrix}, \quad C^o = \begin{pmatrix} C_o^{00} & C_o^{01} \\ C_o^{10} & C_o^{11} \end{pmatrix}.$$

Note that the first row of B^{eo} and the first row and column of C^e vanish because of the conservation properties. In this partition, the system (21) now becomes

$$\text{(23)} \qquad \text{(a)} \quad L_0^{eo}(F_0^o, F_1^o) = 0, \quad \text{(b)} \quad L_0^{oe}(F_0^e, F_1^e) + \frac{1}{\lambda}[C_o^{00} F_0^o + C_o^{01} F_1^o] = 0,$$

$$\text{(c)} \quad -\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} V^e + q[D^{dop} - F_0^e] = 0, \quad V^o = S(V^e),$$

$$\text{(d)} \quad b^e(F_0^e) = D^{dop}, \quad b^e(V^e) = V_b^e, \quad \mathbf{x}_j \in \partial M_{Dir}^e,$$

$$b^o(F_0^o) = 0, \quad b^o(D^{eo} V^e) = 0 \quad \mathbf{y}_j \in \partial M_{Neu}^o,$$

(24)

$$\text{(a)} \quad L_1^{eo}(F_0^e, F_1^e, F_0^o, F_1^o) + \frac{1}{\lambda} C_e^{11} F_1^e = 0, \quad \text{(b)} \quad L_1^{oe}(F_0^e, F_1^e) + \frac{1}{\lambda}[C_o^{10} F_0^o + C_o^{11} F_1^o] = 0,$$

$$\text{(c)} \quad b^e(F_1^e) = 0, \quad \mathbf{x}_j \in \partial M_{Dir}^e, \quad b^o(F_1^o) = 0, \quad \mathbf{y}_j \in \partial M_{Neu}^o,$$

where the involved operators are given by

$$\text{(25)} \qquad \text{(a)} \quad L_0^{eo}(F_0^o, F_1^o) = \sum_{\nu=1}^{d} D_\nu^{eo}(A_\nu^{00} F_0^o + A_\nu^{01} F_1^o),$$

$$\text{(b)} \quad L_0^{oe}(F_0^e, F_1^e)$$

$$= \sum_{\nu=1}^{d} e^{-qV^o}[(A_\nu^{00})^T D_\nu^{oe}(e^{qV^e}F_0^e) + (A_\nu^{10} - qVB_\nu^{10})^T D_\nu^{oe}(e^{qV^e}F_1^e) + (B_\nu^{10})^T D_\nu^{oe}(qV^e e^{qV^e}F_1^e)],$$

$$\text{(c)} \quad L_1^{eo}(F_0^e, F_1^e, F_0^o, F_1^o)$$

$$= \sum_{\nu=1}^{d}[D_\nu^{eo}(A_\nu^{10}F_0^o + A_\nu^{11}F_1^o - qV^o B_\nu^{10}F_0^o) - qV^o B_\nu^{11}F_1^o) + qV^e B_\nu^{10} D_\nu^{eo}F_0^o + qV^e B_\nu^{11} D_\nu^{eo}F_1^o],$$

$$\text{(d)} \quad L_1^{oe}(F_0^e, F_1^e)$$

$$= \sum_{\nu=1}^{d} e^{-qV^o}[(A_\nu^{01})^T D_\nu^{oe}(e^{qV^e}F_0^e)(A_\nu^{11} - qVB_\nu^{11})^T D_\nu^{oe}(e^{qV^e}F_1^e) + (B_\nu^{11})^T D_\nu^{oe}(qV^e e^{qV^e}F_1^e)].$$

We write the system (23), (24) as a nonlinear equation for F_1^e and F_1^o, where the remaining variables are given implicitly by (23). So write (24) as

$$(26) \qquad \text{(a)} \quad K^e(F_1^e, F_1^o) = 0, \quad K^o(F_1^e, F_1^o) = 0,$$

$$\text{(b)} \quad K^e(F_1^e, F_1^o) = L_1^{eo}(F_1^e, F_1^e, F_0^o, F_1^o) + \frac{1}{\lambda}C_e^{11}F_1^e,$$

$$\text{(c)} \quad K^o(F_1^e, F_1^o) = L_1^{oe}(F_0^e, F_1^e) + \frac{1}{\lambda}[C_o^{10}F_0^o + C_o^{11}F_1^o]$$

with V^e, V^o, F_0^o, F_0^e given in terms of F_1^e, F_1^o as the solution of the equations (23). So, in order to evaluate K^e, K^o a drift-diffusion–Poisson problem has to be solved where F_1^e, F_1^o appear as source terms. We will show that the linearization of (26) is stable around the equilibrium solution. The equilibrium solution is given by a Maxwellian in the wave vector direction multiplied by the function e^{iqV}, where the potential V is such that it satisfies the resulting nonlinear Poisson equation (1). We first confirm that this solution is an exact solution of our difference scheme by proving the following theorem.

THEOREM 1. *If the boundary potential V_b^e in* (23)(b) *is given by $V_b^e = -\frac{1}{q}\ln D^{dop}$, and the corresponding discrete Poisson problem*

$$-\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} V^e + q[D^{dop} - e^{-qV^e}] = 0$$

has a solution, the system

$$K^e(F_1^e, F_1^o) = 0, \quad K^o(F_1^e, F_1^o) = 0$$

has a solution $F_1^e = 0$, $F_1^o = 0$.

The proof is deferred to the appendix.

If we now consider the linearization around this equilibrium solution, we have the following theorem.

THEOREM 2. *Let $\delta F_1^e, \delta F_1^o$ be the solution of the linearized problem*

$$\text{(27)} \qquad \text{(a)} \quad dK^e(0,0)(\delta F_1^e, \delta F_1^o) = R_1^e, \quad dK^o(0,0)(\delta F_1^e, \delta F_1^o) = R_1^o,$$

$$\text{(b)} \quad b^e(\delta F_1^e) = 0, \quad \mathbf{x}_j \in \partial M_{Dir}^e, \quad b^o(\delta F_1^o) = 0, \quad \mathbf{y}_j \in \partial M_{Neu}^o.$$

Then there exists a constant c, dependent only on the collision matrices C^e, C^o, such that $\delta F_1^e, \delta F_1^o$ satisfy $||(\delta F_1^e, \delta F_1^o)|| \le c\lambda ||(R_1^e, R_1^o)||$, where the norm is defined by

$$||(\delta F_1^e, \delta F_1^o)|| = I_e[e^{qV^e}|\delta F_1^e|^2] + I_o[e^{qV^o}|\delta F_1^o|^2],$$

and V^e, V^o are the potentials corresponding to the equilibrium solution.

The proof is deferred to the appendix.

Two remarks should be made at this point. First, while the reformulation and partitioning of the problem seems like a formality at first sight, it does have a practical implication. The stability result of Theorem 2 guarantees, among other things, that the solution can be computed by a locally quadratically convergent Newton method of the form

$$dK^e(F_1^e, F_1^o)(\delta F_1^e, \delta F_1^o) = -K^e(F_1^e, F_1^o), \quad dK^o(F_1^e, F_1^o)(\delta F_1^e, \delta F_1^o) = -K^o(F_1^e, F_1^o).$$

However, to compute the right-hand side of the linearized equations, we have to evaluate the terms K^e, K^o, which involves solving the nonlinear problem (23) exactly, which corresponds to solving a nonlinear drift-diffusion–Poisson problem at each Newton step. While this is not really necessary in practice, the convergence of Newton's method can be improved dramatically if a few extra iterations are performed on the low-dimensional system (23) within each Newton step. Second, the above formulation tacitly assumes that K^e, K^o can be evaluated, that is, that the drift-diffusion–Poisson system can be solved by the discretization (23) for any source terms arising from F_1^e, F_1^o. This is the main reason why the interpolation operator S in (21) is chosen such that the resulting scheme reduces to the Scharfetter–Gummel scheme on the given mesh, which is a well tested and incredibly robust discretization. (See [19] for an overview.)

5. Implementation and numerical test example. In this section we present a numerical test example in one spatial dimension and outline how to actually compute the coefficient matrices C^e, C^o, corresponding to the collision operator. The computation of these matrices is not completely trivial because of the presence of the $\delta-$ functions in the integral kernel (3). (See [12], [13].) In one spatial dimension, the choice of meshes M^e and M^o and the choice of the corresponding difference operators D_1^{eo}, D_1^{oe} is quite obvious. We define the grids by

$$M^e = \{\mathbf{x}_0 < \cdots < \mathbf{x}_J\}, \quad M^o = \left\{\mathbf{y}_j : \mathbf{y}_j = \frac{1}{2}(\mathbf{x}_j + \mathbf{x}_{j+1}),\ j = 0, \ldots, J-1\right\}$$

and the difference operators by

$$(D^{oe}u^e)(\mathbf{y}_j) = \frac{u^e(\mathbf{x}_{j+1}) - u^e(\mathbf{x}_j)}{\mathbf{x}_{j+1} - \mathbf{x}_j}, \quad (D^{eo}u^o)(\mathbf{x}_j) = \frac{u^o(\mathbf{y}_j) - u^o(\mathbf{y}_{j-1})}{\mathbf{y}_j - \mathbf{y}_{j-1}}.$$

If we define the discrete integral operators I_e, I_o by

$$I_e(u^e) = \sum_{j=1}^{J-1} (\mathbf{y}_j - \mathbf{y}_{j-1}) u^e(\mathbf{x}_j), \quad I_o(u^o) = \sum_{j=0}^{J-1} (\mathbf{x}_{j+1} - \mathbf{x}_j) u^o(\mathbf{y}_j),$$

then the discrete integration by parts formula (16) holds with the boundary terms b^e, b^o given by

$$b^e(u^e) = \begin{pmatrix} -u^e(\mathbf{x}_0) \\ u^e(\mathbf{x}_J) \end{pmatrix}, \quad b^o(u^o) = \begin{pmatrix} -u^o(\mathbf{y}_0) \\ u^o(\mathbf{y}_{J-1}) \end{pmatrix}.$$

In order for the scheme to reduce to the exponentially fitted Scharfetter–Gummel scheme in one dimension, the interpolation operator S for the potential V^o is chosen such that e^{qV} is expressed as $\frac{d}{dV} e^{qV}$. So S is chosen as

$$S(V^e)(\mathbf{y}_j) = \frac{1}{q} \ln\left(\frac{\exp[qV(\mathbf{x}_{j+1})] - \exp[qV(\mathbf{x}_j)]}{qV(\mathbf{x}_{j+1}) - qV(\mathbf{x}_j)} \right).$$

For a general band energy function $\varepsilon(k)$, the matrices A^{eo}, B^{eo}, C^e, C^o will have to be computed numerically. This can be done at a considerable computational expense, since it has to be done only once for a given set of basis functions. In particular, the collision matrices C^e, C^o have to be computed exercising some care so that the conservation and dissipation properties are not destroyed by the involved numerical integration. Generally, we have to compute integrals of the form $\int \phi_m(k) Q[e^{-\varepsilon} \phi_n(k)] dk$, where ϕ_m, ϕ_n denote either the even or the odd basis functions. Using the symmetry of the collision operator, we will compute the matrix elements of the collision operator as

$$C(m,n)$$

$$= \frac{1}{2} \sum_{\nu=-1}^{1} \int_{R_k^3 \times R_{k'}^3} s_\nu(k,k') \delta(\varepsilon(k) - \varepsilon(k') + \nu\omega)[\phi_m(k) - \phi_m(k')][\phi_n(k) - \phi_n(k')] dk dk'$$

and use numerical integration formulas for the integral in this form. Note that, in this form, it is apparent that the matrix C will be symmetric and that, if either ϕ_m or ϕ_n are constants, the matrix element will be zero, corresponding to conservation of charge and the Maxwellian kernel. Thus, we just have to make sure that numerical integration is applied in the same way in the k and k' variables to preserve these properties. The presence of the $\delta-$ functions in the integration kernel suggests writing the wave vector k in polar coordinates $k = r(\cos\alpha, \sin\alpha \sin\beta, \sin\alpha \cos\beta)$ giving

$$C(m,n)$$

$$= \frac{1}{2} \sum_{\nu=-1}^{1} \int s_\nu \delta(\varepsilon - \varepsilon' + \nu\omega)[\phi_m - \phi'_m][\phi_n - \phi'_n] r^2 \sin(\alpha)(r')^2 \sin(\alpha') dr d\alpha d\beta dr' d\alpha' d\beta',$$

where the $'$ denotes evaluation at r', α', β'. We now choose as basis functions spherical harmonic functions in the angular directions and polynomials in the radial direction $r = |k|$,

$$\phi_m(r,\alpha,\beta) = P_{m_1}(r) \Gamma_{m_2}(\alpha,\beta), \quad m = (m_1, m_2).$$

To take care of the $\delta-$ function in the integral kernel, we change variables in the integral from r to ε. Thus, we need to invert the band energy function ε as a function of the radius r for fixed angles α, β:

$$\varepsilon(r,\alpha,\beta) = u \quad \Longleftrightarrow \quad r = g(\varepsilon,\alpha,\beta). \tag{28}$$

In the transformed variables, the integration with respect to ε' can now be carried out exactly using the δ function. So the matrix element $C(m,n)$ now becomes

$$C(m,n) = \frac{1}{2}\sum_{\nu=-1}^{1}\int_0^\infty d\varepsilon \int d\alpha d\beta d\alpha' d\beta' [g^2(g')^2 \frac{dg}{d\varepsilon}\frac{dg'}{d\varepsilon'}\sin(\beta)\sin(\beta')] \tag{29}$$

$$\times\, \theta(\varepsilon+\nu\omega)s_\nu[P_{m_1}\Gamma_{m_2} - P'_{m_1}\Gamma'_{m_2}][P_{n_1}\Gamma_{n_2} - P'_{n_1}\Gamma'_{n_2}],$$

where the $'$ now denotes evaluation at $r = g(\varepsilon+\nu\omega,\alpha',\beta')$ and α',β', and θ is the Heaviside function. The structure of the scattering cross sections s_ν is usually sufficiently simple, such that the integrals with respect to the angular variables can be carried out exactly, leaving only the one-dimensional integral with respect to the energy to be evaluated numerically. The procedure outlined above is applicable in principle to an arbitrary band structure. It becomes significantly simpler if the band energy is actually radially symmetric, i.e., $\varepsilon = \varepsilon(|k|)$, since in this case the inverse band energy function g depends only on the energy. A popular choice is the dispersion relation due to Kane which is of the form (see [9])

$$\varepsilon(k) = \frac{|k|^2}{1+\sqrt{1+\kappa|k|^2}}.$$

We should point out that, if the band energy is actually not radially symmetric, the solution will actually depend on how the sample is aligned with the crystal direction, which might pose a considerable technological problem.

We now present results of a numerical test on the standard $n^+ - n - n^+$ silicon diode with a channel of $50nm$ length. This means that the doping concentration D^{dop} in (1) is given by a step function of the form

$$D^{dop}(x) = \begin{pmatrix} 10^{24}m^{-3} & 0 < x < 50nm \\ 10^{21}m^{-3} & 50nm < x < 100nm \\ 10^{24}m^{-3} & 100nm < x < 150nm \end{pmatrix}.$$

For the sake of simplicity, we restrict ourselves to parabolic band structures. So (in scaled variables) $\varepsilon(k) = \frac{|k|^2}{2}$ holds, which makes the computation of the inverse function $g(\varepsilon,\alpha,\beta)$ in (28) trivial. ($g(\varepsilon,\alpha,\beta) = \sqrt{2\varepsilon}$ holds and all integrations in (29) can be carried out exactly.) Also, since the problem in one spatial dimension admits solutions which are cylindrically symmetric around the k_1 direction (i.e., $f(x,k) = f(x_1,k_1,k_2^2+k_3^2)$), we choose only spherical harmonics with this symmetry as basis functions. For scattering cross sections we choose Fermi's golden rule formula

(30)

$$\text{(a)}\quad Q[f](x,k) = \frac{\hbar 2 V_L F(\xi)^2\pi}{\Omega}\sum_{\nu=\pm1}\left(N_\xi + \frac{1+\nu}{2}\right)\delta(\varepsilon(k)-\varepsilon(k')+\nu\hbar\omega)f(x,k')dk' - \frac{f(x,k)}{\tau(k)},$$

$$\text{(b)} \quad \frac{1}{\tau(k)} = \frac{2V_L F(\xi)^2 m_*^{3/2}}{\hbar^2 \Omega} 4\pi^2 \sum_{\nu=\pm 1} \left(N_\xi + \frac{1+\nu}{2} \right) \sqrt{2(\varepsilon(k) - \nu\hbar\omega)}^+,$$

$$\text{(c)} \quad \varepsilon(k) = \frac{\hbar^2 |k|^2}{2m_*}, \quad \Omega = \ln\left(\frac{N_\xi + 1}{N_\xi} \right),$$

where $F(\xi)$ denotes the frequency of the lattice state with momentum ξ and N_ξ denotes its occupation number. V_L denotes the volume of one lattice cell. $F(\xi)$ is given according to the formula

$$F(\xi) = \sqrt{\frac{q^2 \hbar\omega}{2V_L |\xi|^2 \varepsilon_0} \left(\frac{1}{\varepsilon_\infty} - \frac{1}{\varepsilon_s} \right)}.$$

The constants are given by the following expressions:

Symbol	Value	Unit	Meaning
q	$1.602 * 10^{-19}$	C	electron charge
$\hbar$	$6.626196 * 10^{-34}$	kgm^2/sec	Planck constant
m_*	$0.063 * 0.109 * 10^{-31}$	kg	effective electron mass
$\hbar\omega$	0.036	eV	emission/absorption energy
ε_0	$8.85 * 10^{-12}$	$\frac{C}{Vm}$	dielectricity constant (vacuum)
ε_∞	10.92	1	
ε_s	12.9	1	

We take into account only one single phonon momentum vector (corresponding to a $\delta-$ function collision potential; see [2], [4], [10]), which is evaluated at equilibrium, meaning $|\xi|^2 = m_* KT$ holds at room temperature. This gives, for an occupation number N_ξ corresponding to room temperature, numerical values of

$$\frac{\hbar 2V_L F(\xi)^2 \pi}{\Omega} N_\xi = 5.9356e * 10^5 \frac{m^3}{sec^2}, \quad \frac{2V_L F(\xi)^2 m_*^{3/2}}{\hbar^2 \Omega} N_\xi 4\pi^2 = 9.6044 * 10^{23} \frac{1}{m\sqrt{kg}}$$

for the constants necessary to evaluate (30). Finally, choosing computational units of $10^{-7} m$ for x and $10^7 m^{-1}$ for k, this gives a value of $\lambda = 0.3974$ for the dimensionless parameter λ in (1) with a scaled band energy $\varepsilon = \frac{|k|^2}{2}$.

The results below were obtained by varying the applied bias (the difference of the boundary potential V_b^e between the right and the left endpoint) form $-0.1V$ to $-0.5V$. A uniform mesh with 151 gridpoints and 128 expansion terms (16 in the energy direction and 8 in the angular direction) was used. The obtained figures did not change significantly when either doubling the number of expansion terms or halving the mesh size.

Figures 1–4 depict the potential as well as the physical densities for electrons, electron velocity, and electron energy as functions of the spatial variable x. Figure 1 shows the potential distribution $V(x)$. Figure 2 shows the electron density $\langle 1 \rangle(x) = \int f(x,k)dk = \rho^T F^e$. Figure 3 shows the velocity distribution $u(x) = \frac{\langle \partial_{k_1} \varepsilon \rangle(x)}{\langle 1 \rangle(x)}$ with $\langle \partial_{k_1} \varepsilon \rangle = \int \partial_{k_1} \varepsilon(k) f(x,k)dk$. Figure 4 shows the corresponding energy densities given by $w(x) = \frac{\langle \varepsilon \rangle(x)}{\langle 1 \rangle(x)}$.

Figures 5–8 depict the kinetic density $f(x,k)$ for the bias value of $0.4V$ for various values of x. Using spherical harmonic basis functions $\phi_m(k)$ gives the kinetic density function f in spherical coordinates as $f = f^{sph}(x, r, \cos(\alpha), \beta)$ with

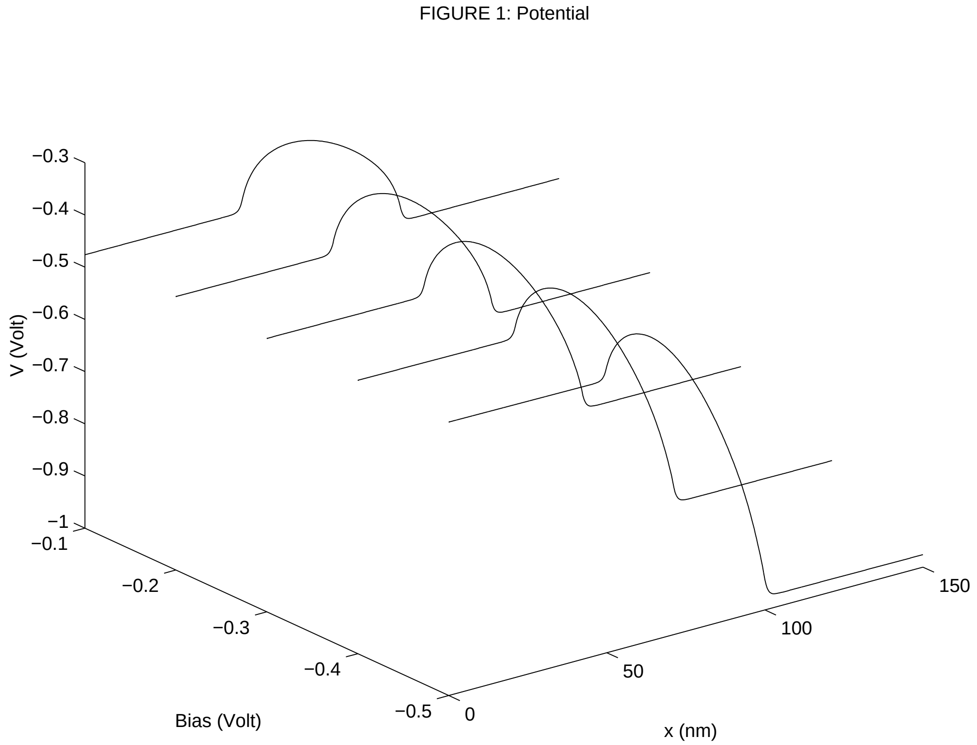

Fig. 1. *Potential.*

$k = (r\cos(\alpha), r\sin(\alpha)\sin(\beta), r\sin(\alpha)\cos(\beta))$, $\alpha \in [0,\pi]$, $\beta \in [-\pi,\pi]$. It is, however, more instructive to look at the kinetic density $f = f^{car}$ in Cartesian coordinates. In the case of one spatial dimension, the kinetic energy density will be cylindrically symmetrical around the k_1-axis. So $f^{car}(x,k) = f(x, k_1, \sqrt{k_2^2 + k_3^2})$ and $f^{sph}(x,k) = f(x, r, \cos(\alpha))$ hold. f^{car} and f^{sph} are related through $f^{car}(x, r\cos(\alpha), r\sin(\alpha)) = r^2 f^{sph}(x, r, \cos(\alpha))$, where the factor r^2 arises from the infinitesimal volume element due to the coordinate transformation. So Figures 5–8 show the function $r^2 f^{sph}(x, r, \cos(\alpha))$ for fixed values of x as a function of $k_1 = r\cos(\alpha)$ and $\sqrt{k_2^2 + k_3^2} = r\sin(\alpha)$, which is the density against which any function of Cartesian coordinates has to be integrated to compute expectations.

The purpose of these computations is to investigate how far away from the fluid dynamic regime we are. (For such a short channel and the given applied bias, we expect to see some distinctly nonequilibrium phenomena.) Figure 5 shows the distribution to the left of the channel. It is essentially given by a forward and a backward traveling Maxwellian of roughly the same amplitude. Figures 6 and 7 show the distribution at the beginning and the end of the channel. First we notice that the wave has developed a second peak in the forward as well as in the backward traveling component. Moreover, it has become definitely asymmetric in the k_1 direction at the end of the channel (in Figure 7). After the electron has left the channel in Figure 8, remnants of the second peak are still visible, but the solution has become symmetric in k_1 again. Figure 5 could have been produced by a hydrodynamic model or even by drift-diffusion equations, considering the low values of the group velocity in Figure 3 at this point. The second peak in Figure 8 (after leaving the channel) could have

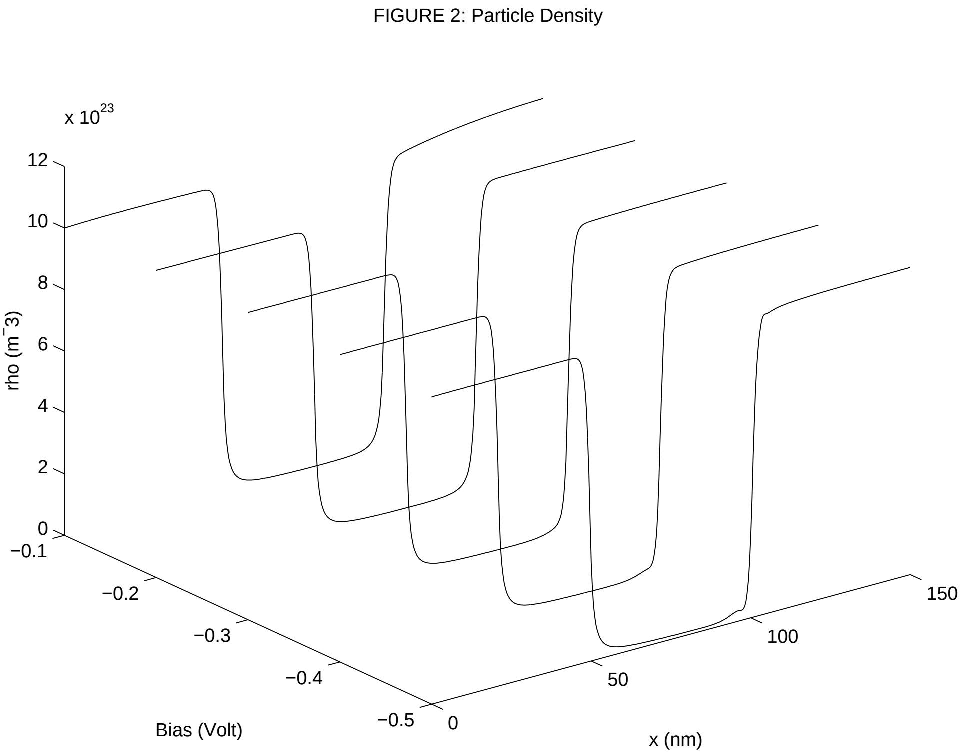

Fig. 2. *Particle density.*

been produced by a SHE-model. However, the strongly asymmetric distribution at the channel end (Figure 7) is a truly kinetic phenomenon and could not have been produced by either of the above approximations.

Concluding remarks. We conclude this section with some remarks concerning future work and the extension of this approach to two spatial dimensions. First, going to two spatial dimensions means a dramatic increase in the computational cost, since in addition to the added spatial dimension the cylindrical symmetry of the density function is lost. In the two-dimensional case, the density has to be taken of the form $f(x,k) = f(x_1, x_2, k_1, k_2, |k_3|)$, thus going effectively from a three- to a five-dimensional problem. The computations above were carried out using 16 expansion terms in the energy direction and 8 terms in the angular directions, so a system of 128 one-dimensional conservation laws was solved. Roughly estimating the cost in the two-dimensional case, allowing for a little less resolution and still exploiting the symmetry in the k_3 direction, this would translate into solving anywhere between 256 and 1024 two-dimensional conservation laws. On the other hand, we do not expect it to be necessary to solve the full kinetic problem in the whole device; i.e., for the simulation of a transistor this amount of resolution would only be necessary in a rather narrow region around the channel. Indeed, the promise of the expansion approach in two spatial dimensions is that it allows for a model hierarchy ranging from a Scharfetter–Gummel solution of the drift-diffusion equation (i.e., taking only three terms) to the full Boltzmann solution. Taking this into account, we estimate that a two-dimensional solution would involve around half a million variables. This raises, of course, the issue of the iterative solution of the involved linear system. In the one-

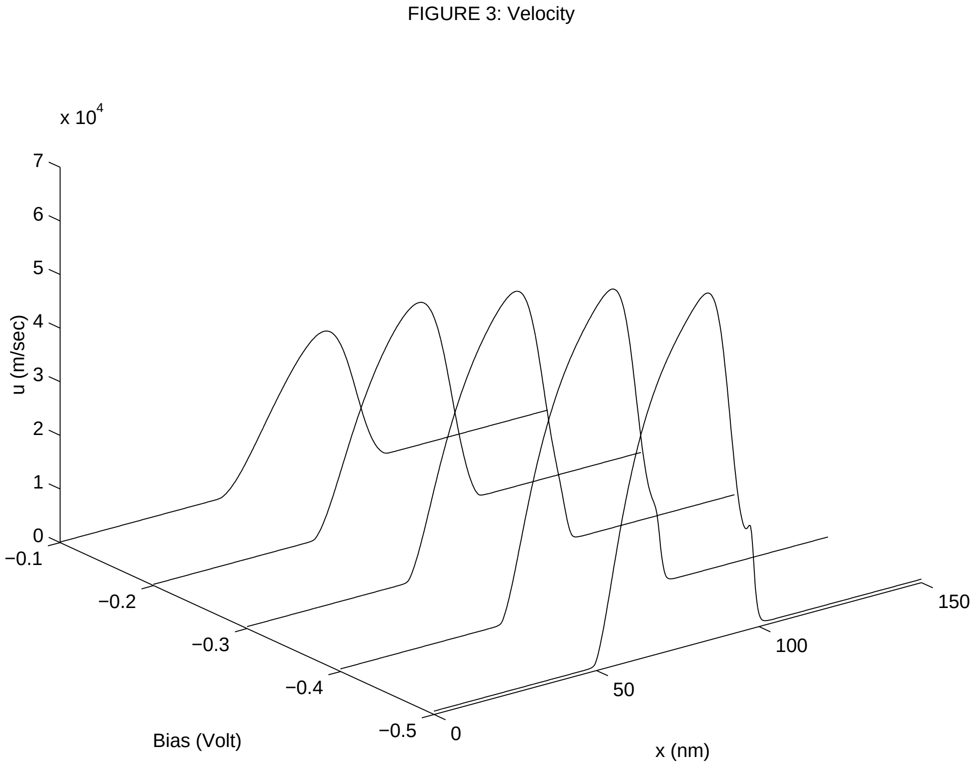

Fig. 3. *Velocity.*

dimensional case, a direct solution of the linear system was combined with a standard Gummel iteration procedure for the coupling to Poisson's equation. (See [19].) One possibility is to precondition the system by a solution of the drift-diffusion equations (i.e., by the the equations corresponding to the first three terms only). This would result in a pseudo time marching algorithm where the diffusive part of the operator is discretized implicitly in time and the hyperbolic part explicitly, as first proposed in [17] for the solution of the transient problem.

Finally, we would like to comment on the differences in the approaches to solving the steady state problem and the transient Boltzmann equation. There have been several approaches to deterministic solutions of the transient Boltzmann equation using methods designed for hyperbolic conservation laws. (See [1], [6], and references therein.) The transient solution (as well as the conservation law resulting from its Galerkin approximation in the wave vector direction) will exhibit a variety of hyperbolic and dispersive transient phenomena which would be unduly damped by the pseudo time marching algorithm suggested above. (See [15].) On the other hand, because of this fact, a pseudo time marching algorithm, based on the discretization presented here, will arrive at the correct steady state much faster, albeit with the wrong transient response, than a method designed for hyperbolic equations. So the method presented in this paper is really designed for the computation of steady states and for accurate deterministic simulations of the transient behavior it is probably preferable to use methods which take into account the hyperbolic and dispersive nature of the transient problem as given in [6] and [15].

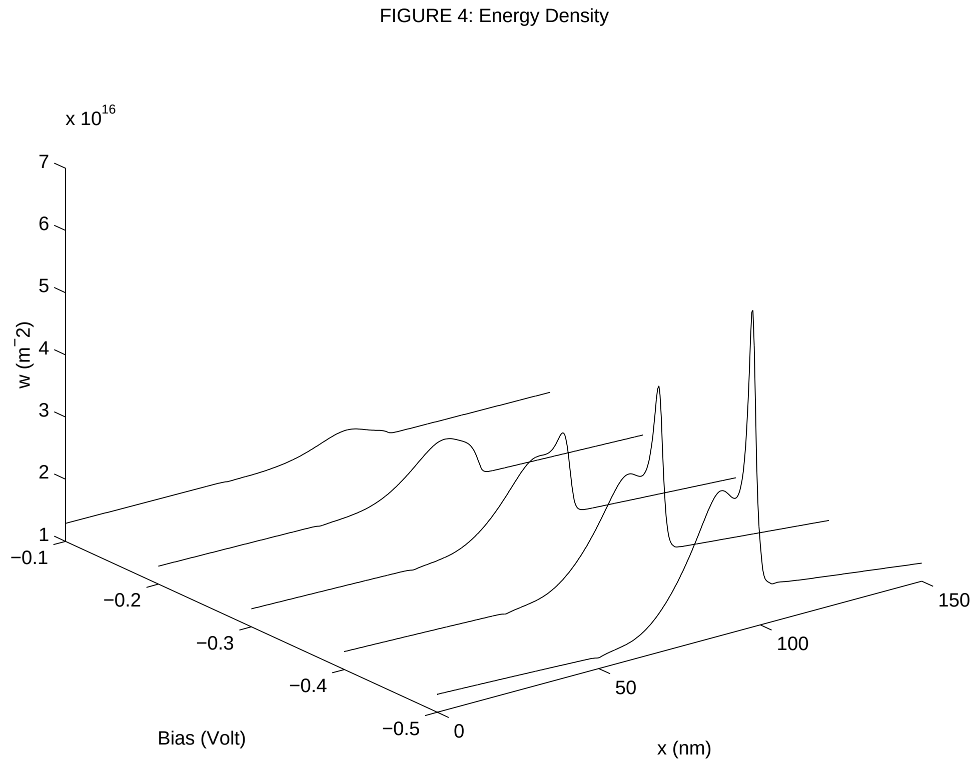

Fig. 4. *Energy density.*

6. Appendix.

Proof of Theorem 1. Setting $F_1^e = 0$, $F_1^o = 0$ in (26) gives the equations

$$\sum_{\nu=1}^{d}[D_\nu^{eo}(A_\nu^{10}F_0^o - qV^o B_\nu^{10}F_0^o)) + qV^e B_\nu^{10} D_\nu^{eo} F_0^o] = 0,$$

$$\sum_{\nu=1}^{d} e^{-qV^o}[(A_\nu^{01})^T D_\nu^{oe}(e^{qV^e}F_0^e)] + \frac{1}{\lambda}C_o^{10}F_0^o = 0,$$

which depend only on F_0^o and discrete derivatives of $e^{qV^e}F_0^e$. For $F_1^e = 0$, $F_1^o = 0$ these terms are given by (23) as the solution of

$$\sum_{\nu=1}^{d} D_\nu^{eo}(A_\nu^{00}F_0^o) = 0,$$

$$\sum_{\nu=1}^{d} e^{-qV^o}[(A_\nu^{00})^T D_\nu^{oe}(e^{qV^e}F_0^e)] + \frac{1}{\lambda}C_o^{00}F_0^o = 0,$$

$$-\sigma\sum_{\nu=1}^{d} D_\nu^{eo}D_\nu^{oe}V^e + q[D^{dop} - F_0^e] = 0,$$

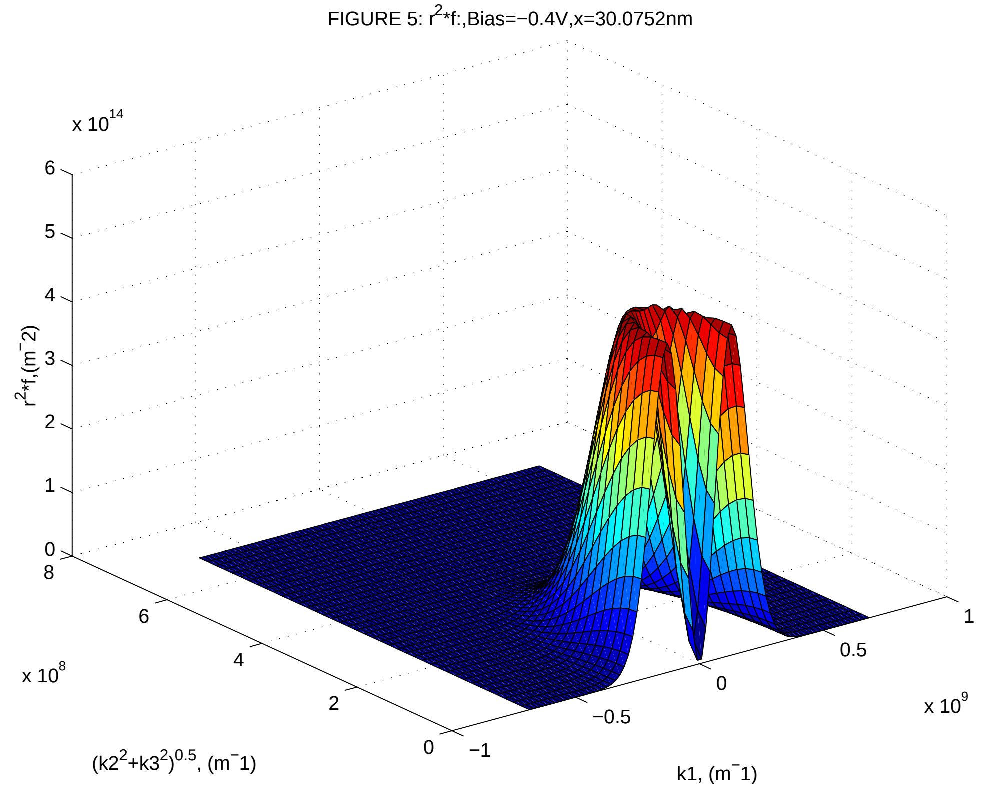

FIG. 5. $r^2 * f$: *Bias* $= -0.4V$, $x = 30.0752nm$.

and setting $F_0^o = 0$ and $F_0^e = e^{-qV}$ satisfies all of the above equations and the boundary conditions, except for the Poisson equation. Therefore V^e has to be chosen as the solution of

$$-\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} V^e + q[D^{dop} - e^{-qV^e}] = 0$$

together with the corresponding boundary conditions (23)(d) which corresponds to the equilibrium solution. $\square$

Proof of Theorem 2. The linearized problem (27) is given by the equations

$$\text{(31)} \qquad \text{(a)} \quad dL_1^{eo}(F_0^e, 0, 0, 0)(\delta F_0^e, \delta F_1^o, \delta F_0^o, \delta F_1^o) + \frac{1}{\lambda} C_e^{11} \delta F_1^e = R_1^e,$$

$$\text{(b)} \quad dL_1^{oe}(F_0^e, 0)(\delta F_0^e, \delta F_1^e) + \frac{1}{\lambda}[C_o^{10} \delta F_0^o + C_o^{11} \delta F_1^o] = R_1^o,$$

where the terms $\delta F_0^e, \delta F_0^o, \delta V^e, \delta V^o$ are given in terms of $\delta F_1^e, \delta F_1^o$ by linearizing the drift-diffusion–Poisson system (23):

$$\text{(32)} \qquad \text{(a)} \quad dL_0^{eo}(0, 0)(\delta F_0^o, \delta F_1^o) = 0,$$

$$\text{(b)} \quad dL_0^{oe}(F_0^e, 0)(\delta F_0^e, \delta F_1^e) + \frac{1}{\lambda}[C_o^{00} \delta F_0^o + C_o^{01} \delta F_1^o] = 0,$$

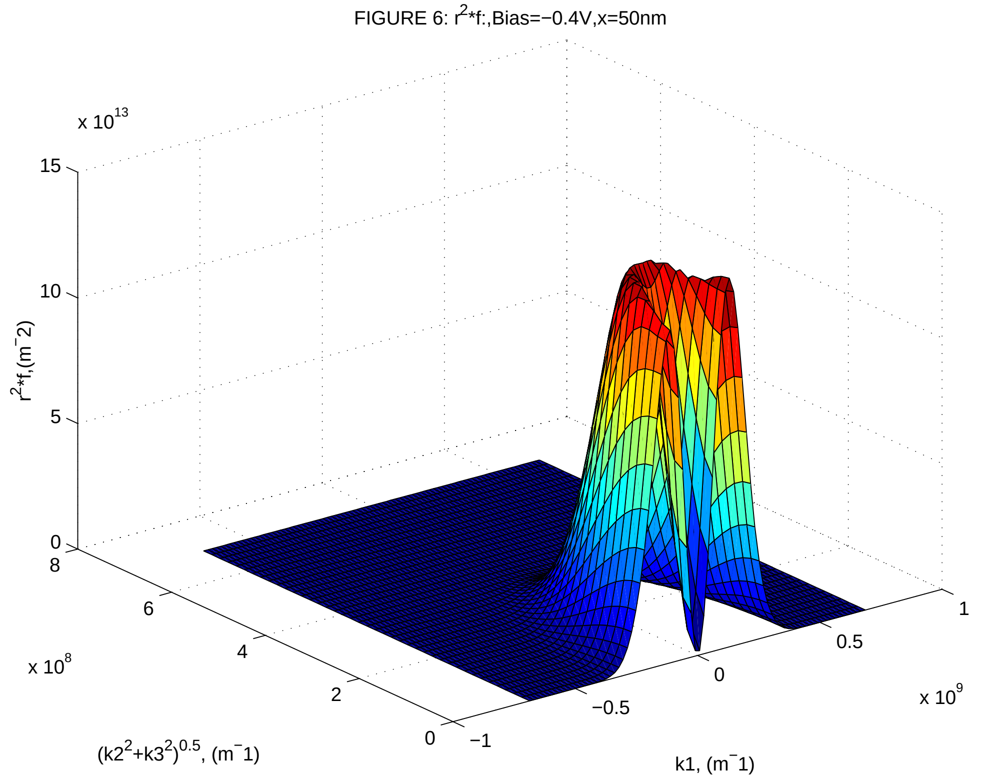

Fig. 6. $r^2 * f$: *Bias* $= -0.4V$, $x = 50nm$.

$$\text{(c)} \quad -\sigma \sum_{\nu=1}^{d} D_\nu^{eo} D_\nu^{oe} \delta V^e + q[D^{dop} - \delta F_0^e] = 0$$

together with homogeneous boundary conditions of the form (23)(d). Combining (31)(a–b) with (32)(a–b) we obtain the linearized system for the full equations

$$(33) \qquad \text{(a)} \quad dL^{eo}(F^e, 0)(\delta F^e, \delta F^o) + \frac{1}{\lambda} C^e \delta F^e = R^e,$$

$$\text{(b)} \quad dL^{oe}(F^e)(\delta F^e) + \frac{1}{\lambda} C^o \delta F^o = R^o,$$

with

$$\delta F^e = \begin{pmatrix} \delta F_0^e \\ \delta F_1^e \end{pmatrix}, \quad \delta F^o = \begin{pmatrix} \delta F_0^o \\ \delta F_1^o \end{pmatrix}, \quad F^e = \begin{pmatrix} F_0^e \\ 0 \end{pmatrix},$$

$$R^e = \begin{pmatrix} 0 \\ R_1^e \end{pmatrix}, \quad R^o = \begin{pmatrix} 0 \\ R_1^o \end{pmatrix}.$$

So we basically obtain the same linearized system as if we had linearized (21) directly, except for the crucial fact that the first component of R^e and the first three components of R^o are zero. Now, by virtue of construction of the discrete operators L^{eo}, L^{oe}

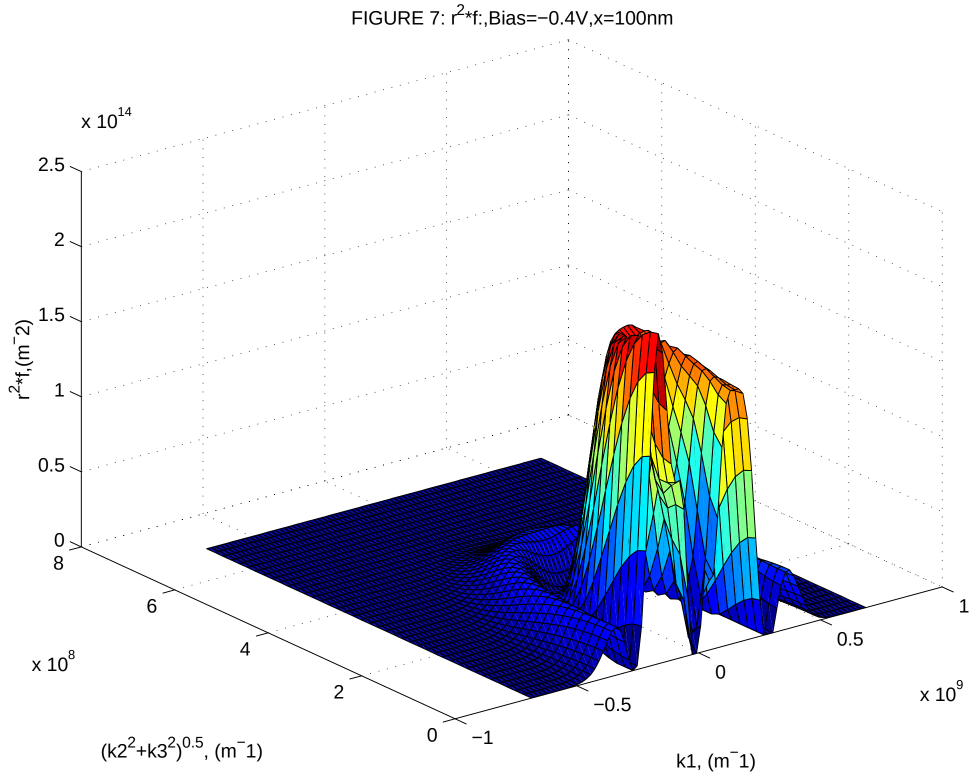

FIG. 7. $r^2 * f$: *Bias* $= -0.4V$, $x = 100nm$.

(see Proposition 1) and because of the structure of the boundary conditions, we have that

$$I_e[h^e(F^e)^T L^{eo}(F^e, F^o)] + I_o[h^o(F^e, F^o)^T L^{oe}(F^e)] = 0 \tag{34}$$

holds for any choice of F^e, F^o, where I_e, I_o denote the discrete integral operators defined in (16) and the entropies h^e, h^o are given by $h^e(F^e) = e^{qV^e} F^e$, $h^o(F^e, F^o) = e^{qV^o} F^o$ and, of course, the potentials V^e, V^o depend on F^e through the Poisson equation. Differentiating (34) twice functionally with respect to all of its arguments yields

$$\begin{aligned}
&I_e[(d^2h^e(F^e)(\delta F^e)^2)^T L^{eo}(F^e, F^o)] \\
&+ 2I_e[(dh^e(F^e)(\delta F^e))^T (dL^{eo}(F^e, F^o)(\delta F^e, \delta F^o))] \\
&+ I_e[h^e(F^e)(d^2L^{eo}(F^e, F^o)^T (\delta F^e, \delta F^o)^2)] \\
&+ I_o[(d^2h^o(F^e, F^o)(\delta F^e, \delta F^o)^2)^T L^{oe}(F^e)] \\
&+ 2I_o[(dh^o(F^e, F^o)(\delta F^e, \delta F^o))^T (dL^{oe}(F^e)(\delta F^e))] \\
&+ I_o[h^o(F^e, F^o)(d^2L^{oe}(F^e)^T (\delta F^e)^2)] = 0.
\end{aligned}$$

Inserting the equilibrium solution $F^o = 0$, $F^e = e^{-qV^e}\mathbf{e}$ into the above equations, we

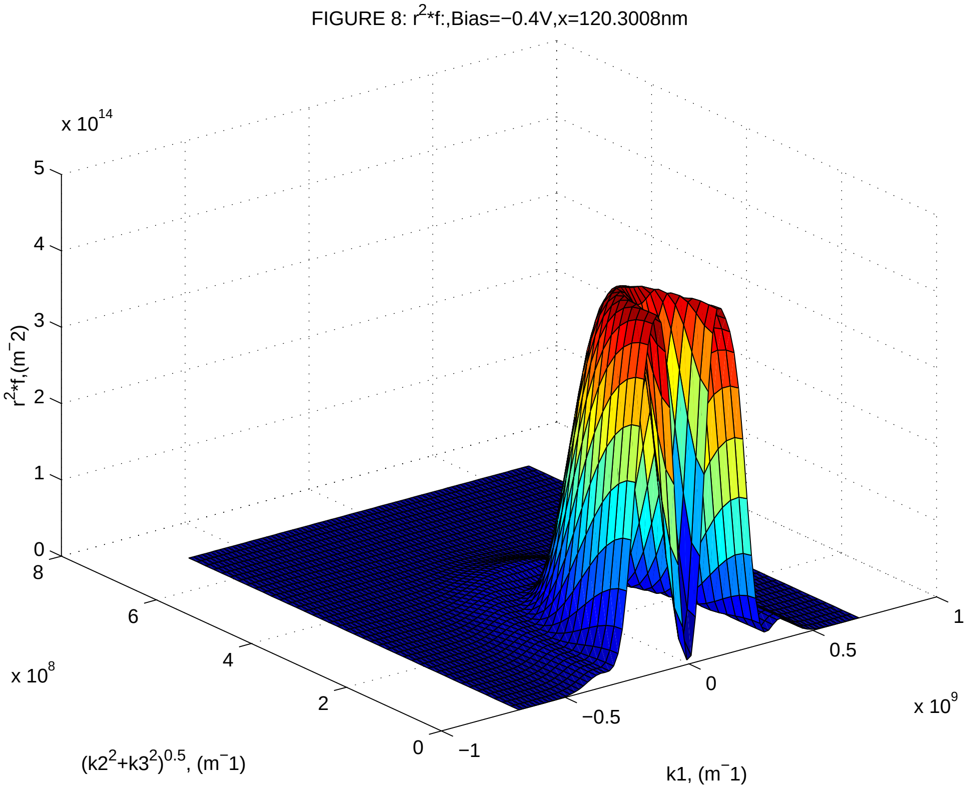

Fig. 8. $r^2 * f$: *Bias* $= -0.4V$, $x = 120.3008nm$.

see that

$$L^{eo}(F^e, F^o) = 0, \quad L^{oe}(F^e) = 0, \quad h^o(F^e, F^o) = 0, \quad h^e(F^e) = \mathbf{e}$$

holds, which eliminates three of the six terms in the above relations. Thus, we obtain

$$
\begin{aligned}
(35) \qquad & 2I_e[(dh^e(F^e)(\delta F^e))^T(dL^{eo}(F^e,F^o)(\delta F^e,\delta F^o))] \\
& + I_e[h^e(F^e)(d^2L^{eo}(F^e,F^o)^T(\delta F^e,\delta F^o)^2)] \\
& + 2I_o[(dh^o(F^e,F^o)(\delta F^e,\delta F^o))^T(dL^{oe}(F^e)(\delta F^e))] = 0,
\end{aligned}
$$

where in the second term of (35) only the first component of L^{eo} is left because of the form of h^e. However, from (25) it can be seen that L^{eo}_0 is a pure divergence operator, and therefore, because of the structure of the boundary conditions, the discrete integral over L^{eo}_0 vanishes for all arguments. Therefore the same is true for its second functional derivative, and we obtain the formula

$$
\begin{aligned}
& 2I_e[(dh^e(F^e)(\delta F^e))^T(dL^{eo}(F^e,F^o)(\delta F^e,\delta F^o))] \\
& + 2I_o[(dh^o(F^e,F^o)(\delta F^e,\delta F^o))^T(dL^{oe}(F^e)(\delta F^e))] = 0
\end{aligned}
$$

which we use to estimate the linearized equations (33). Multiplying (33)(a) by $(dh^e(F^e)(\delta F^e))^T$ and (33)(b) by $(dh^o(F^e,0)(\delta F^e,\delta F^o))^T$, and applying the discrete integral operators I_e, I_o, we obtain

$$\begin{aligned} &I_e[(dh^e(F^e)(\delta F^e))^T C^e \delta F^e] + I_o[(dh^o(F^e,0)(\delta F^e,\delta F^o))^T C^o \delta F^o] \\ &= \lambda I_e[(dh^e(F^e)(\delta F^e))^T R^e] + \lambda I_o[(dh^o(F^e,0)(\delta F^e,\delta F^o))^T R^o]. \end{aligned} \tag{36}$$

Computing the first Frechet derivatives of h^e, h^o at the equilibrium solution gives

$$dh^e(F^e)(\delta F^e) = q\delta V^e \mathbf{e} + e^{qV^e}\delta F^e, \quad dh^o(F^e,0)(\delta F^o,\delta V^o) = e^{qV^o}\delta F^o,$$

with $\delta V^e, \delta V^0$ the solutions of the linearized Poisson equation with homogeneous boundary conditions. Inserting this into (36), and using the fact that the first row and column of C^e vanishes, and that the first component of R^e, R^o is also zero, we get

$$\begin{aligned} &I_e[e^{qV^e}(\delta F_1^e)^T C_e^{11} \delta F_1^e] + I_o[e^{qV^o}(\delta F^o)^T C^o \delta F^o] \\ &= \lambda I_e[e^{qV^e}(\delta F_1^e)^T R_1^e] + \lambda I_o[e^{qV^o}(\delta F_1^o)^T R_1^o]. \end{aligned}$$

Now the matrices C_e^{11} and C^o are strictly positive definite. Using the Cauchy–Schwarz inequality gives the result. □

KRYLOV SUBSPACE ACCELERATION OF WAVEFORM RELAXATION[*]

ANDREW LUMSDAINE[†] AND DEYUN WU[‡]

Abstract. In this paper we describe and analyze Krylov subspace techniques for accelerating the convergence of waveform relaxation for solving time-dependent problems. A new class of accelerated waveform methods, convolution Krylov subspace methods, is presented. In particular, we give convolution variants of the CG algorithm and the GMRES algorithm and analyze their convergence behavior. We prove that the convolution Krylov subspace algorithms for initial value problems have the same convergence bounds as their linear algebra counterparts. Analytical examples are given to illustrate the operation of convolution Krylov subspace methods. Experimental results are presented which show the convergence behavior of traditional and convolution waveform methods applied to solving a linear initial value problem as well as the convergence behavior of static Krylov subspace methods applied to solving the associated linear algebraic equation.

Key words. convolution, dynamic iteration, Galerkin method, Krylov subspace methods, waveform relaxation

1. Introduction.

Dynamic iteration methods for initial value problems were first studied by Picard (1893) and Lindelöf (1894) in the context of existence and uniqueness of solutions to ODEs. In the early 1980's, dynamic iteration was reintroduced (with the name "waveform relaxation") as an efficient method for solving the large sparsely coupled differential equation systems generated by the simulation of integrated circuits [15, 43]. Since then, this method has been extended and applied to various other application areas [20, 24, 40]. Waveform relaxation continues to attract interest because of its natural medium-scale parallelism.

With the waveform approach, a dynamic system of equations is first decomposed spatially (i.e., at the equation level). Individual equations, or sets of equations taken together, are then solved iteratively by using values from previous iterates of other equations as input. Thus, the iterates are functions ("waveforms") rather than vectors.

Unfortunately, the convergence rate of standard waveform relaxation can be prohibitively slow for many problems of interest. As with relaxation-based approaches for linear algebra (e.g., Jacobi), application of appropriate acceleration is necessary to make the waveform approach practical. Previous approaches for accelerating the convergence of waveform relaxation include the shifted Picard iteration [34], multigrid [18, 41], SOR [23], Chebyshev acceleration [17], convolution SOR [30], $\mathbb{L}^2$ Krylov subspace methods [19], and adaptive window size selection [14].

Many of these waveform acceleration techniques are analogous to acceleration methods for iteratively solving linear systems of equations. However, in most cases, the generalizations of those approaches to waveform relaxation do not accelerate con-

vergence to the same degree as their linear algebra counterparts [23]. An analysis of why linear acceleration of waveform relaxation can, in general, be expected to be limited is given in [28].

One acceleration method for waveform relaxation that does, in fact, provide the same degree of acceleration as the analogous linear algebra method is convolution SOR, developed in [30, 31]. Inspired by convolution SOR, we use a convolution-based approach to develop an entirely new class of algorithms for accelerating the convergence of waveform relaxation, namely, convolution Krylov subspace methods. As particular exemplars of this new class of algorithms, we develop and analyze convolution GMRES (CGMRES) and biconvolution CG (BiCCG). Analysis of these methods shows that the convolution algorithms for linear differential equations and the corresponding algorithms for the associated linear algebraic equations have the same convergence rate bounds. In other words, the convolution Krylov subspace methods accelerate the convergence of waveform relaxation to the same degree as their linear algebra counterparts.

In the next two sections, we first review waveform relaxation and the $\mathbb{L}^2$ Krylov subspace techniques presented in [19]. The convolution Krylov subspace methods are then developed and analyzed. Experimental results comparing various waveform approaches are presented, and we conclude with a discussion and suggestions for further work.

2. Waveform relaxation. The mathematical description of waveform methods that we will be use throughout this paper is based on the model initial value problem:

$$\left\{ \begin{aligned} \tfrac{d}{dt}\boldsymbol{x}(t) + \boldsymbol{A}\boldsymbol{x}(t) &= \boldsymbol{f}(t), \\ \boldsymbol{x}(0) &= \boldsymbol{x}_0, \end{aligned} \right. \tag{2.1}$$

where $\boldsymbol{A} \in \mathbb{R}^{n\times n}$, $\boldsymbol{f}(t) \in \mathbb{R}^n$ is a given input, and $\boldsymbol{x}(t) \in \mathbb{R}^n$ is the unknown vector to be computed over an interval of interest $[0, T]$.

In (2.1), let $\boldsymbol{A} = \boldsymbol{M} - \boldsymbol{N}$ be a splitting of $\boldsymbol{A}$. The waveform relaxation algorithm based on this splitting is expressed in matrix form as follows.

ALGORITHM 1 (waveform relaxation for linear systems).

1. *Initialize:* Pick $\boldsymbol{x}^0$.
2. *Iterate:* For waveform iteration $k = 0, 1, \ldots$

   Solve

$$\left\{ \begin{aligned} \tfrac{d}{dt}\boldsymbol{x}^{k+1}(t) + \boldsymbol{M}\boldsymbol{x}^{k+1}(t) &= \boldsymbol{N}\boldsymbol{x}^k(t) + \boldsymbol{f}(t), \\ \boldsymbol{x}^{k+1}(0) &= \boldsymbol{x}_0 \end{aligned} \right.$$

   for $\boldsymbol{x}^{k+1}(t)$ on $[0, T]$.

Using operator notation, the waveform relaxation iteration can be expressed as

$$\boldsymbol{x}^{k+1} = \mathcal{K}\boldsymbol{x}^k + \boldsymbol{\psi}, \tag{2.2}$$

where the variables are defined on $\mathbb{L}^2([0, T], \mathbb{R}^n)$. The operator

$$\mathcal{K} : \mathbb{L}^2([0, T], \mathbb{R}^n) \to \mathbb{L}^2([0, T], \mathbb{R}^n)$$

is defined by

$$(\mathcal{K}\boldsymbol{x})(t) = \int_0^t e^{-\mathbf{M}(t-s)}\boldsymbol{N}\boldsymbol{x}(s)ds, \tag{2.3}$$

and $\boldsymbol{\psi} \in \mathbb{L}^2([0,T],\mathbb{R}^n)$ is given by

$$\boldsymbol{\psi}(t) = e^{-\mathbf{M}t}\boldsymbol{x}_0 + \int_0^t e^{-\mathbf{M}(t-s)}\boldsymbol{f}(s)ds.$$

It is obvious then that $\boldsymbol{x}$ will satisfy

$$(\boldsymbol{I} - \mathcal{K})\boldsymbol{x} = \boldsymbol{\psi}, \tag{2.4}$$

where $\boldsymbol{I}$ is the identity operator.

2.1. Properties. In this section we briefly review some relevant properties of the operator $\mathcal{K}$.

Remark. Associated with the initial value problem (2.1) is a linear algebraic problem

$$\boldsymbol{A}\boldsymbol{x} = \boldsymbol{b}. \tag{2.5}$$

Similarly, associated with the waveform relaxation equation (2.4) is a preconditioned linear system of equations

$$(\boldsymbol{I} - \boldsymbol{M}^{-1}\boldsymbol{N})\boldsymbol{x} = \boldsymbol{M}^{-1}\boldsymbol{b}. \tag{2.6}$$

In what follows, we relate properties (in particular, spectral properties) of $\boldsymbol{M}^{-1}\boldsymbol{N}$ to properties of $\mathcal{K}$ and relate the behavior of algorithms applied to (2.4) to the behavior of algorithms applied to (2.6).

LEMMA 2.1. *The operator $\mathcal{K}$ as defined in* (2.3) *is compact, has zero spectral radius, and has adjoint operator $\mathcal{K}^*$ given by*

$$(\mathcal{K}^*\boldsymbol{x})(t) = \int_t^T \left[e^{-\mathbf{M}(s-t)}\boldsymbol{N}\right]^T \boldsymbol{x}(s)ds.$$

Remark. In general, $\mathcal{K}$ is not self-adjoint with respect to the $\mathbb{L}^2$ inner product, even when $\boldsymbol{M}^{-1}\boldsymbol{N}$, the matrix for the corresponding linear system, is symmetric in $\mathbb{R}^n$ (or Hermitian in $\mathbb{C}^n$).

Since $\mathcal{K}$ is compact with zero spectral radius, a straightforward convergence result can be stated.

THEOREM 2.2. *The waveform relaxation algorithm* (2.2) *generates a sequence of iterates $\{\boldsymbol{x}^k\}$ such that $\boldsymbol{x}^k \to \boldsymbol{x}$ as $k \to \infty$.*

Although $\mathcal{K}$ has zero spectral radius, it is highly nonnormal and thus the characteristics of the operator are far from trivial. That is, the spectrum itself provides very little insight into the behavior of iterative methods involving the operator $\mathcal{K}$. One approach to understanding iterative methods involving $\mathcal{K}$ is to consider the case for $T \to \infty$, in which case spectral properties of the operator apparently do provide information about the behavior of iterative methods involving $\mathcal{K}$. A detailed analysis of waveform relaxation for the $T \to \infty$ case is given in [23].

Unfortunately, the spectrum of $\mathcal{K}$ is discontinuous as a function of T—for any finite T, the spectral radius of $\mathcal{K}$ is zero. Thus, the degree to which the results for infinite T apply to real problems (which necessarily use finite T) is problem-dependent. One tool for understanding the behavior of $\mathcal{K}$ for finite T, and one that in some sense unifies the two cases of finite and infinite T, is pseudospectral analysis [38].

Definition. Let $\mathbb{X}$ be a Banach space with norm $\|\cdot\|$. The ϵ-pseudospectrum of a densely defined closed linear operator $\mathcal{A}:\mathbb{X}\to\mathbb{X}$ is defined as

$$\Lambda_\epsilon(\mathcal{A}) \equiv \left\{\lambda\in\mathbb{C} : \|(\lambda\boldsymbol{I}-\mathcal{A})^{-1}\| \geq \epsilon^{-1}\right\},$$

where it is understood that $\|(\lambda\boldsymbol{I}-\mathcal{A})^{-1}\| = \infty$ for $\lambda\in\Lambda(\mathcal{A})$. Here $\Lambda(\mathcal{A})$ is the spectrum of $\mathcal{A}$.

The following result (the proof is given in [22]) shows that the pseudospectrum is continuous as $T\to\infty$.

THEOREM 2.3. *Let $\mathcal{K}_T$ and $\mathcal{K}_\infty$ denote the operator $\mathcal{K}$ on $\mathbb{L}^2([0,T],\mathbb{R}^n)$ and $\mathbb{L}^2([0,\infty),\mathbb{R}^n)$, respectively. Then, for $\varepsilon>0$,*

$$cl \lim_{T\to\infty}\Lambda_\varepsilon(\mathcal{K}_T) = \Lambda_\varepsilon(\mathcal{K}_\infty).$$

2.2. Example. To aid our subsequent discussion, we provide a graphical illustration of the spectrum and pseudospectrum of $\mathcal{K}$ for the model problem (2.1). We take $\boldsymbol{A}$ to be a symmetric positive definite matrix:

$$\boldsymbol{A} = \frac{1}{\Delta x^2}\begin{bmatrix} 2 & -1 & & & 0 \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ 0 & & & -1 & 2 \end{bmatrix}_{n\times n}, \tag{2.7}$$

which is obtained, e.g., from discretizing the one-dimensional heat equation with spatial discretization Δx. For this example, we use a Jacobi splitting to obtain $\boldsymbol{M}$ and $\boldsymbol{N}$ from $\boldsymbol{A}$, and we take $\Delta x = 1/16$, $n=17$, and $\varepsilon = 10^{-3}$.

Figure 2.1 shows the spectra and pseudospectra of $\mathcal{K}_T$ and $\mathcal{K}_\infty$ for $\boldsymbol{A}$ given in (2.7), where $\mathcal{K}_T$ and $\mathcal{K}_\infty$, respectively, denote the operator $\mathcal{K}$ on $\mathbb{L}^2([0,T],\mathbb{R}^n)$ and $\mathbb{L}^2([0,\infty),\mathbb{R}^n)$. Since the matrix $\boldsymbol{M}^{-1}\boldsymbol{N}$ is normal, the pseudospectrum of $\mathcal{K}_\infty$

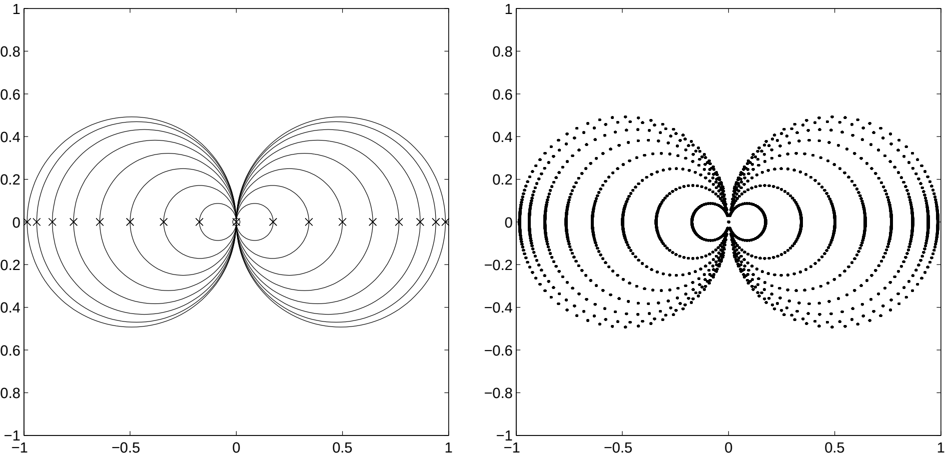

FIG. 2.1. *Spectrum and pseudospectrum of $\mathcal{K}_T$ and $\mathcal{K}_\infty$ for $\boldsymbol{A}$ given in* (2.7)*. In the left figure, $\Lambda(\mathcal{K}_\infty)$ is the union of the interiors of the circles shown, $\Lambda(\mathcal{K}_T)$ is the origin (indicated with* o*), and the eigenvalues of $\boldsymbol{M}^{-1}\boldsymbol{N}$ are indicated with* x*. In the right figure, $\Lambda_\varepsilon(\mathcal{K}_\infty)$ is the union of the interiors of the dotted circles.*

is also very close to the spectrum. The spectra and pseudospectra were plotted using the formulae given in [22]. Note that $\Lambda_\varepsilon(\mathcal{K}_T)$ does not have a known formula (only bounds are known), and so it is not plotted.

3. Hilbert space acceleration methods. For solving linear algebra problems, Krylov subspace algorithms form sequences of approximate solutions $\{\boldsymbol{x}^k\}$ with

$$\boldsymbol{x}^k = \boldsymbol{x}^0 + \sum_{i=0}^{k-1} \alpha_i \boldsymbol{A}^i \boldsymbol{r}^0,$$

where $\boldsymbol{x}^0$ is the initial estimate for $\boldsymbol{x}$ and $\boldsymbol{r}^k = \boldsymbol{b} - \boldsymbol{A}\boldsymbol{x}^k$ is the residual associated with the kth iterate. That is, each $\boldsymbol{x}^k$ is a member of the affine Krylov subspace

$$\boldsymbol{x}^k \in \boldsymbol{x}^0 + \mathbb{K}^k(\boldsymbol{A}, \boldsymbol{r}^0) = \boldsymbol{x}^0 + \operatorname{span}\{\boldsymbol{r}^0, \boldsymbol{A}\boldsymbol{r}^0, \ldots, \boldsymbol{A}^{k-1}\boldsymbol{r}^0\} \subset \mathbb{R}^n.$$

Algorithms for generating $\{\boldsymbol{x}^k\}$ typically do so by enforcing some type of Galerkin or minimal residual condition on the iterates. To enforce these conditions, it is only necessary that the underlying space has certain geometric properties, namely, that a notion of orthogonality exists. This is usually taken to mean Hilbert space, but, as we will see, it seems that Hilbert space geometry may be too strong and that weaker geometric conditions can yield effective methods (see the discussion in section 7). Thus, Krylov subspace algorithms can readily be extended from $\mathbb{R}^n$ to Hilbert space (a fact that has been known since the early development of Krylov subspace iterative methods for linear algebra [10]). By embedding (2.4) into an appropriate Hilbert space, it is a rather straightforward matter to develop Krylov subspace acceleration techniques for waveform relaxation. A natural Hilbert space for this problem is $\mathbb{L}^2([0,T], \mathbb{R}^n)$.

3.1. Waveform GMRES. By Lemma 2.1, it is obvious that $\mathcal{K}$ is not self-adjoint with respect to the $\mathbb{L}^2$ inner product. Thus, in order to accelerate waveform relaxation, we must restrict our attention to those Krylov subspace algorithms suitable for non-Hermitian linear systems. At present, the premier such algorithm is the GMRES algorithm of Saad and Schultz [33].

The waveform GMRES (WGMRES) algorithm is as follows.

```
ALGORITHM 2 (WGMRES).
  1. Start: Set $\boldsymbol{r}^0 = \boldsymbol{\psi} - (\boldsymbol{I} - \mathcal{K})\boldsymbol{x}^0$, $\boldsymbol{v}^1 = \boldsymbol{r}^0/\|\boldsymbol{r}^0\|$, $\beta = \|\boldsymbol{r}^0\|$.
  2. Iterate: For $k = 1, 2, \ldots,$ until satisfied do:
             $h_{jk} = \langle(\boldsymbol{I} - \mathcal{K})\boldsymbol{v}^k, \boldsymbol{v}^j\rangle, \ j = 1, 2, \ldots, k$
       $\widetilde{\boldsymbol{v}}^{k+1} = (\boldsymbol{I} - \mathcal{K})\boldsymbol{v}^k - \sum_{j=1}^{k} h_{jk}\boldsymbol{v}^j$
         $h_{k+1,k} = \|\widetilde{\boldsymbol{v}}^{k+1}\|$
          $\boldsymbol{v}^{k+1} = \widetilde{\boldsymbol{v}}^{k+1}/h_{k+1,k}$.
  3. Form approximate solution:
     $\boldsymbol{x}^k = \boldsymbol{x}^0 + \boldsymbol{V}^k\boldsymbol{y}^k$, where $\boldsymbol{y}^k$ minimizes $\|\beta\boldsymbol{e}_1 - \bar{\boldsymbol{H}}^k\boldsymbol{y}^k\|$,
     $\boldsymbol{V}^k = (\boldsymbol{v}^1, \boldsymbol{v}^2, \ldots, \boldsymbol{v}^k)$, $\boldsymbol{e}_1 = (1, 0, \ldots, 0)^T$, and $\bar{\boldsymbol{H}}^k = (h_{ij})_{(k+1)\times k}$.
```

Remark. Symbolically, this algorithm is identical to the GMRES algorithm on $\mathbb{R}^n$. The difference is that the vectors and vector-space operations are understood to be defined on the Hilbert space $\mathbb{L}^2([0,T], \mathbb{R}^n)$ rather than on $\mathbb{R}^n$. That is, $\boldsymbol{x}^k$, $\boldsymbol{r}^k$, $\boldsymbol{\psi}$, $\boldsymbol{v}^k$, $\widetilde{\boldsymbol{v}}^k \in \mathbb{L}^2([0,T], \mathbb{R}^n)$, $h_{jk} \in \mathbb{C}$, and $\langle\cdot,\cdot\rangle$ is the $\mathbb{L}^2$ inner product.

3.2. Analysis of WGMRES. In order to analyze WGMRES, it is useful to recall that GMRES is a Galerkin method. The use of a Galerkin method over a Krylov space generated by $(\boldsymbol{I}-\mathcal{K})$ is discussed in [25] and [29], where the approach is called the method of moments (see also [42]). The following two results can be found in [19, 21].

THEOREM 3.1. *Let $\boldsymbol{X}$ be a Hilbert space and let $\mathcal{A} : \boldsymbol{X} \to \boldsymbol{X}$ be a bounded bijective linear operator. Let $\boldsymbol{X}^k \subset \boldsymbol{X}$ be a k-dimensional subspace with $\boldsymbol{X}^k \subset \boldsymbol{X}^{k+1}$ for all $k \in \mathbb{N}$. If $\boldsymbol{x}$ is in the closure of $\mathbb{S} = \bigcup_{k=1}^{\infty} \boldsymbol{X}^k$, then the Galerkin method for the operator equation $\mathcal{A}\boldsymbol{x} = \boldsymbol{f}$ converges.*

COROLLARY 3.2. *The Galerkin method for $(\boldsymbol{I}-\mathcal{K})\boldsymbol{x} = \boldsymbol{\psi}$ converges in the space $\mathbb{L}^2([0,T],\mathbb{R}^n)$, with finite dimensional subspaces $\mathbb{K}^m(\mathcal{K},\boldsymbol{\psi}) = \{\boldsymbol{\psi},\mathcal{K}\boldsymbol{\psi},\dots,\mathcal{K}^{m-1}\boldsymbol{\psi}\}$ for all $m \in \mathbb{N}$.*

As an immediate consequence, we have that WGMRES converges.

Unfortunately, because of the nonnormality of the operator $\mathcal{K}$, nothing much can be said about the rate of convergence, particularly in relationship to the spectrum of $\boldsymbol{M}^{-1}\boldsymbol{N}$ (or, more to the point, in relationship to the behavior of GMRES applied to solving a linear system of equations based on $\boldsymbol{M}^{-1}\boldsymbol{N}$).

Although precise statements about the convergence behavior of GMRES cannot be made, certain (rather pessimistic) qualitative statements can be made. Nevanlinna considered the general case of linear acceleration of waveform relaxation in [28], with the conclusion that significant speedups (of the sort one sees for linear algebra problems) would not be achievable in general.

Intuitively, we can see that it is much more difficult for GMRES to be effective when applied to waveform relaxation. Figure 2.1 shows the spectrum and pseudospectrum of $\mathcal{K}$. For the matrix problem, the spectrum of $\boldsymbol{M}^{-1}\boldsymbol{N}$ consists of a set of distinct eigenvalues on the real axis. For the waveform problem, the pseudospectrum of $\mathcal{K}$ fills a two-dimensional region in the complex plane. Clearly, it is much more difficult to find a good minimizing polynomial for the waveform case than for the linear algebra case. In fact, by using conformal mapping techniques, it is possible to show that there is, in fact, no essential speedup possible for WGMRES for a large class of problems [37] (on the infinite interval).

However, all is not lost. Similar pessimistic results hold for waveform relaxation accelerated with SOR [23]. However, with the use of convolution techniques, Reichelt developed a variant of SOR for waveform relaxation that does for (2.4) what algebraic SOR does for (2.6) [31]. That convolution techniques can provide the desired rate of acceleration for SOR gives us hope that similar results can be achieved for Krylov subspace techniques. We develop such a class of algorithms and prove their rates of convergence in the next section.

4. Convolution methods.

The principle behind convolution SOR (CSOR), and, indeed, the convolution methods developed in this paper, is that rather than simply taking linear combinations of waveform iterates, the methods take sums weighted by a convolution kernel. The resulting algorithms thus circumvent the limitations of linear acceleration as described in [23] and [28]. In fact, CSOR and the convolution Krylov subspace algorithms developed here exhibit speedup precisely comparable to that in the associated linear algebra problem.

4.1. CSOR.

A waveform relaxation algorithm using CSOR for solving (2.1) is shown in Algorithm 3. The algorithm takes an ordinary Gauss–Seidel waveform relaxation step to obtain a value for the intermediate variable $\widehat{x}_i^{k+1}$. The iterate x_i^{k+1} is obtained by adding a correction obtained by convolving $\widehat{x}_i^{k+1} - x_i^{k+1}$ with a kernel function $\omega(t)$. This is in contrast to simple waveform SOR in which x_i^{k+1} is obtained by multiplying $\widehat{x}_i^{k+1} - x_i^{k+1}$ with a scalar parameter ω. With the convolution, the CSOR method correctly accounts for the temporal frequency-dependence of the spectrum of the Jacobi waveform relaxation operator (e.g., Jacobi waveform relaxation smoothes high frequency components of the error waveform more rapidly than low frequency components) by, in effect, using a different SOR parameter for each frequency [31].

Algorithm 3 (Gauss–Seidel waveform relaxation with CSOR acceleration).

1. *Initialize:* Pick vector waveform $\boldsymbol{x}^0(t) \in C^1([0,T],\mathbb{R}^n)$ with $\boldsymbol{x}^0(0) = \boldsymbol{x}_0$.
2. *Iterate:* For $k = 0, 1, \ldots,$ until converged,
   - *Solve* for scalar waveform $\widehat{x}_i^{k+1}(t) \in C^1([0,T],\mathbb{R})$ with $\widehat{x}_i^{k+1}(0) = x_{0i}$,

$$\left(\tfrac{d}{dt} + a_{ii}\right)\widehat{x}_i^{k+1}(t) = f_i(t) - \sum_{j=1}^{i-1} a_{ij} x_i^{k+1}(t) - \sum_{j=i+1}^{n} a_{ij} x_i^{k}(t).$$

   - *Overrelax* to generate $x_i^{k+1}(t) \in C^1([0,T],\mathbb{R})$,

$$x_i^{k+1}(t) = x_i^k(t) + \int_0^t \omega(\tau) \cdot \left[\widehat{x}_i^{k+1}(t-\tau) - x_i^k(t-\tau)\right] d\tau. \tag{4.1}$$

4.2. Convolution Krylov subspace algorithms. In this section and the next, we incorporate convolution into the Krylov subspace approach for accelerating waveform relaxation. We begin by identifying some key spaces and associated operations to be used in what follows.

Assume $f, g \in \mathbb{L}^2(\mathbb{R},\mathbb{R})$ are functions, and $\boldsymbol{x} = (x_1, \ldots, x_n)^T,\ \boldsymbol{y} = (y_1, \ldots, y_n)^T \in \mathbb{L}^2(\mathbb{R},\mathbb{R}^n)$ are vectors of functions. Define

$$\begin{aligned}
(f \star g)(t) &= \int_{-\infty}^{\infty} f(s) g(t-s) ds \in \mathbb{L}^1(\mathbb{R},\mathbb{R}),\\
(f \star \boldsymbol{x})(t) &= ((f \star x_1)(t) \ldots (f \star x_n)(t))^T \in \mathbb{L}^1(\mathbb{R},\mathbb{R}^n),\\
\langle \boldsymbol{x}, \boldsymbol{y} \rangle_\star(t) &= \sum_{i=1}^{n} (x_i \star \widetilde{y_i})(t) \in \mathbb{L}^1(\mathbb{R},\mathbb{R}),
\end{aligned}$$

where $\widetilde{f}(t) = f(-t)$, and $\widetilde{\boldsymbol{x}}(t) = \boldsymbol{x}(-t)$.

Remark. Although the above formulae are defined in general for $\mathbb{L}^2$ functions, one important subset of $\mathbb{L}^2$ that will figure prominently is $C_0([0,\infty),\mathbb{R})$, the compactly supported continuous functions, and we will be working with this space in what follows. The following technique is purely for the analysis of the algorithms, although the implementational computations are not related to it. For brevity we will indicate $\mathcal{K}_T$ by $\mathcal{K}$.

From the basic operational calculus [26, 27, 36], it is known that convolution induces a ring structure on $C_0([0,\infty),\mathbb{R})$. As with any ring structure, this ring structure, can be algebraically extended to a quotient field (in a manner similar to extending the ring of integers to the field of rational numbers). Define $\mathbb{Q}$ to be the set of ordered pairs ("fractions")

$$\mathbb{Q} = \{f/g : f, g \in C_0([0,\infty),\mathbb{R})\}.$$

By a result of Titchmarsh [36], there are no zero divisors; i.e., $f \star g = 0$ implies that either $f = 0$ or $g = 0$. The axiomatic operations required for field structure are then readily defined. An operational calculus has been developed on this basis, adding a theoretical underpinning to the operational calculus of Heaviside [26, 27].

A result of Foiaş shows that the range of convolution is dense in $\mathbb{L}^1$, a result that was later extended to the continuous case [7, 35]. More recently, a constructive proof of these results has been given by Bäumer [2]. As a direct consequence of the injectivity and dense range properties of convolution, we have the following.

LEMMA 4.1. *Let $\mathbb{Q}$ be the quotient field induced by the convolution ring $\{C_0([0,\infty),\mathbb{R}),\star\}$. For any element $f/g \in \mathbb{Q}$, there is a sequence $\{\phi_i\}$ with $\phi_i \in C_0([0,\infty),\mathbb{R})$ such that*

$$\lim_{i\to\infty} \phi_i \star g = f.$$

Remark. $\mathbb{Q}$ is, in fact, a space of generalized functions; the limit $\lim_{i\to\infty}\phi_i$ may not necessarily exist in $C_0([0,\infty),\mathbb{R})$. For example, the element in $\mathbb{Q}$ identified with f/f is the Dirac δ-distribution. In this regard, $\mathbb{Q}$ is a completion of $C_0([0,\infty),\mathbb{R})$ with respect to the convolution operator. Notice that a function $f \in C_0([0,\infty),\mathbb{R})$ can be identified with any quotient of the form $(f\star g)/g$, $g \neq 0$; i.e., $f \in C_0([0,\infty),\mathbb{R})$ implies $f \in \mathbb{Q}$.

Using this definition of convolution between elements of $\mathbb{Q}$ and continuous functions, we can readily create a vector space over the field $\mathbb{Q}$ using convolution.

PROPOSITION 4.2. *Let $\mathbb{Q}$ be the quotient field induced by the convolution ring $\{C_0([0,\infty),\mathbb{R}),\star\}$. For $q \in \mathbb{Q}$ and $\boldsymbol{x} \in C_0([0,\infty),\mathbb{R}^n)$, let $\phi_i \to q$ in the sense of Lemma* 4.1. *With the convolution operation defined by*

$$q \star \boldsymbol{x} = \lim_{i\to\infty} \phi_i \star \boldsymbol{x},$$

$C_0([0,\infty),\mathbb{R}^n)$ forms a vector space over $\mathbb{Q}$.

Definition. Assume $\mathcal{A}$ is a bounded linear operator defined on $C_0([0,\infty),\mathbb{R}^n)$ and $\boldsymbol{r}^0 \in C_0([0,\infty),\mathbb{R}^n)$ is fixed. The m-dimensional convolution Krylov subspace generated by $\mathcal{A}$ and $\boldsymbol{r}^0$ is defined to be

$$\begin{aligned}\mathbb{K}_\star^m(\mathcal{A},\boldsymbol{r}^0) &= \operatorname{span}_\star\{\boldsymbol{r}^0, \mathcal{A}\boldsymbol{r}^0, \ldots, \mathcal{A}^{m-1}\boldsymbol{r}^0\}\\ &= \left\{\sum_{i=0}^{m-1} \alpha_i \star \mathcal{A}^i\boldsymbol{r}^0 : \alpha_i \in \mathbb{Q}\right\} \subset C_0([0,\infty),\mathbb{R}^n).\end{aligned}$$

Notice that this definition of the convolution Krylov subspace differs from the usual definition of a Krylov subspace due to the convolution operator; by $\operatorname{span}_\star$ we mean combinations under convolution. However, as with methods that use the traditional definition of a Krylov subspace, we seek to find the element of $\mathbb{K}_\star^m(\mathcal{A},\boldsymbol{r}^0)$ that best satisfies (2.4).

4.3. Examples.

Using convolutions in Krylov subspace methods may seem counterintuitive. To demonstrate the general operation of convolution Krylov subspace methods, we present two examples.

Example. Consider the following initial value problem:

$$\left\{\begin{aligned} \tfrac{d}{dt}\boldsymbol{x}(t) + \boldsymbol{A}\boldsymbol{x}(t) &= \boldsymbol{0},\\ \boldsymbol{x}(0) &= (0,1)^T, \end{aligned}\right. \tag{4.2}$$

where $\boldsymbol{A}$ is a 2×2 matrix

$$\boldsymbol{A} = \begin{pmatrix} 2 & -1 \\ -1 & 2 \end{pmatrix}.$$

For splitting $\boldsymbol{A} = \boldsymbol{M} - \boldsymbol{N}$ with $\boldsymbol{M} = 2\boldsymbol{I}$, in order to solve $(\boldsymbol{I} - \mathcal{K})\boldsymbol{x} = \boldsymbol{\psi}$, we choose

$$\boldsymbol{x} = \alpha_0 \star \boldsymbol{r}^0 + \alpha_1 \star (\boldsymbol{I} - \mathcal{K})\boldsymbol{r}^0.$$

By the Galerkin conditions,

$$\langle(\boldsymbol{I} - \mathcal{K})\boldsymbol{x}, \boldsymbol{r}^0\rangle_\star = \langle\boldsymbol{\psi}, \boldsymbol{r}^0\rangle_\star,$$

$$\langle(\boldsymbol{I} - \mathcal{K})\boldsymbol{x}, (\boldsymbol{I} - \mathcal{K})\boldsymbol{r}^0\rangle_\star = \langle\boldsymbol{\psi}, (\boldsymbol{I} - \mathcal{K})\boldsymbol{r}^0\rangle_\star,$$

we can find

$$\begin{cases} \alpha_0 = \frac{2}{3}[e^{-2t} \star (-2 + e^{-2t})]/[(e^{-2t} - 1) \star (e^{-2t} - 1)], \\ \alpha_1 = -\frac{2}{3}[-1 + 2e^{-2t})]/[(e^{-2t} - 1) \star (e^{-2t} - 1)] \end{cases}$$

and

$$\begin{cases} x_1 = -(te^{-2t})/(te^{-2t} - 1) = e^{-2t}\sinh t, \\ x_2 = -(e^{-2t})/(te^{-2t} - 1) = e^{-2t}\cosh t, \end{cases}$$

which is the analytic solution for (4.2).

Example. Let us consider another initial value problem:

$$\begin{cases} \frac{d}{dt}\boldsymbol{x}(t) + \boldsymbol{A}\boldsymbol{x}(t) = \boldsymbol{0}, \\ \qquad\qquad \boldsymbol{x}(0) = (0, 1)^T, \end{cases} \tag{4.3}$$

where $\boldsymbol{A}$ is a 2×2 matrix

$$\boldsymbol{A} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}.$$

In this case, we take splitting $\boldsymbol{A} = \boldsymbol{M} - \boldsymbol{N}$ with $\boldsymbol{M} = 0$. Again choose

$$\boldsymbol{x} = \alpha_0 \star \boldsymbol{r}^0 + \alpha_1 \star (\boldsymbol{I} - \mathcal{K})\boldsymbol{r}^0.$$

As in the last example, by using the Galerkin conditions, we can find

$$\begin{cases} \alpha_0 = -(6t - t^3)/(6t + t^3), \\ \alpha_1 = 6/(6t + t^3) \end{cases}$$

and

$$\begin{cases} x_1 = t^3/(6t + t^3) = \sin t, \\ x_2 = (3t^2)/(6t + t^3) = \cos t, \end{cases}$$

which is the analytic solution for (4.3).

4.4. Fourier transform. Define the Fourier–Laplace transform on $\mathbb{L}^2(\mathbb{R},\mathbb{R})$ to be

$$\widehat{f}(z) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-izx} f(x)dx \quad \text{for } z \in \mathbb{C}.$$

It is well known that $\|\widehat{f}\|_{\mathbb{L}^2(\mathbb{R},\mathbb{R})} = \|f\|_{\mathbb{L}^2(\mathbb{R},\mathbb{R})}$.

Remarks.

1. $\langle \boldsymbol{x}, \boldsymbol{y}\rangle_\star\widehat{\ }(\xi) = \langle \widehat{\boldsymbol{x}}(\xi), \widehat{\boldsymbol{y}}(\xi)\rangle$, where $\langle\cdot,\cdot\rangle$ is the Hermitian inner product in $\mathbb{C}^n$, and $\xi \in \mathbb{R}$.
2. $\langle \boldsymbol{x}, \boldsymbol{y}\rangle_\star = \widetilde{\langle \boldsymbol{y}, \boldsymbol{x}\rangle_\star} = \langle \widetilde{\boldsymbol{y}}, \widetilde{\boldsymbol{x}}\rangle_\star$.
3. For $f, g \in C_0([0,\infty),\mathbb{R})$ $(f/g)\widehat{\ } = \frac{\widehat{f}}{\widehat{g}}$ is a meromorphic function with discrete poles [1]. (Here $\frac{\cdot}{\cdot}$ indicates normal division.)
4. Under the convolution inner product "$\langle\cdot,\cdot\rangle_\star$," the convolution adjoint operator of $\mathcal{K}$ is the same as the $\mathbb{L}^2$ adjoint operator $\mathcal{K}^*$ of $\mathcal{K}$. Thus, even with real symmetric $\boldsymbol{A}$, $\mathcal{K}$ is not self-adjoint with respect to $\langle\cdot,\cdot\rangle_\star$.

Since convolution is closely related to the Fourier transform (which is isometric on the $\mathbb{L}^2(\mathbb{R},\mathbb{R})$ space), we restrict our analysis to $\mathbb{L}^2$ spaces. In this context, we view $C_0([0,\infty),\mathbb{R}^n)$ as a subspace of $\mathbb{L}^2(\mathbb{R},\mathbb{R}^n)$ by extending elements in $C_0([0,\infty),\mathbb{R}^n)$ trivially on $(-\infty,0)$. Hence, for any $f \in C_0([0,\infty),\mathbb{R})$ we have $\|\widehat{f}\| = \|f\|$ in the $\mathbb{L}^2(\mathbb{R},\mathbb{R})$ norm.

4.5. The convolution GMRES algorithm. In this section, we introduce the convolution GMRES (CGMRES) algorithm. Analogous to GMRES for linear systems of equations, CGMRES is appropriate for operator systems where $\mathcal{A}$ is not self-adjoint with respect to the convolution inner product.

ALGORITHM 4 (CGMRES). Let $\mathcal{A} : C_0([0,\infty),\mathbb{R}^n) \to \overline{C_0([0,\infty),\mathbb{R}^n)}$ be a bounded linear operator. By Bäumer [2], $\mathcal{A}$ is extendable to $\overline{C_0([0,\infty),\mathbb{R}^n)}$, the vector-valued generalized function space, i.e., the completion of $C_0([0,\infty),\mathbb{R}^n)$ under operator $\mathcal{A}$, which is a vector space over $\mathbb{Q}$ due to the commutative of $\mathcal{A}$ and $\star$. Let $\boldsymbol{f} \in C_0([0,\infty),\mathbb{R}^n)$.

1. Pick $\boldsymbol{x}^0 \in C_0([0,\infty),\mathbb{R}^n)$ and compute $\boldsymbol{r}^0 = \boldsymbol{f} - \mathcal{A}\boldsymbol{x}^0,\ \beta = |\widehat{\boldsymbol{r}^0}|^\vee, \boldsymbol{v}^1 = \boldsymbol{r}^0/\beta$.
2. For $j = 1, \ldots,$ until converged,

$$\begin{aligned}
\boldsymbol{w}^j &= \mathcal{A}\boldsymbol{v}^j \\
h_{ij} &= \langle \boldsymbol{w}^j, \boldsymbol{v}^i\rangle_\star, i = 1,\ldots,j \\
\boldsymbol{w}^j &= \boldsymbol{w}^j - \sum_{i\le j} h_{ij} \star \boldsymbol{v}^i \\
h_{j+1,j} &= |\widehat{\boldsymbol{w}^j}|^\vee, \ \text{ if } h_{j+1,j} \equiv 0, \text{ set } m = j \text{ and go to step 3} \\
\boldsymbol{v}^{j+1} &= \boldsymbol{w}^j/h_{j+1,j}.
\end{aligned}$$

3. Compute $\boldsymbol{y}^m$, the minimizer of $\langle(\beta\star(\delta_0,0,\ldots,0)^T - \bar{\boldsymbol{H}}^m\star\boldsymbol{y}), (\beta\star(\delta_0,0,\ldots,0)^T - \bar{\boldsymbol{H}}^m \star \boldsymbol{y})\rangle_\star$ and $\boldsymbol{x}^m = \boldsymbol{x}^0 + \boldsymbol{V}^m \star \boldsymbol{y}^m$, where $\bar{\boldsymbol{H}}^m = (h_{ij})_{(m+1)\times m}$, $\boldsymbol{V}^m = (\boldsymbol{v}^1, \boldsymbol{v}^2, \ldots, \boldsymbol{v}^m)$, and δ_0 is the Dirac δ-distribution.

Remarks.

1. In the above algorithms, "$|\cdot|$" is the Euclidean norm defined in $\mathbb{C}^n$, and "$\vee$" means the inverse Fourier transform.
2. By $\boldsymbol{x}/f$ for $\boldsymbol{x} \in C_0([0,\infty),\mathbb{R}^n)$ and $f \in C_0([0,\infty),\mathbb{R})$ we mean the vector $(x_1/f, x_2/f, \ldots, x_n/f)^T \in \mathbb{Q}^n$.

3. It is not hard to see that there is a compactly supported sequence $\beta_i \in C_0(-\infty,\infty)$ such that $\beta_i \to \beta \in \mathbb{L}^2(\mathbb{R})$. Rewrite $\boldsymbol{v}^1 = \boldsymbol{r}^0/\beta = (\boldsymbol{r}^0 \star h)/(\beta \star h)$, where $h \neq 0$ is any function in $C_0([0,\infty),\mathbb{R})$. Now $\beta_i \star h \in C_0([0,\infty),\mathbb{R})$. We view $\mathcal{A}\boldsymbol{v}^1 = \lim_{i\to\infty}(\mathcal{A}\boldsymbol{r}^0 \star h)/(\beta_i \star h)$ which is well-defined on the completion vector space $\overline{C_0([0,\infty),\mathbb{R}^n)}$ over $\mathbb{Q}$.

4.6. Convergence of CGMRES. To analyze the convergence of the CGMRES algorithm we begin with the convolution Petrov–Galerkin conditions

$$\langle \boldsymbol{f} - \mathcal{A}\boldsymbol{x}, \boldsymbol{w}\rangle_\star = 0 \quad \forall \boldsymbol{w} \in \mathcal{A}\mathbb{K},$$

where for brevity $\mathbb{K}$ indicates $\mathbb{K}_\star^m(\mathcal{A}, \boldsymbol{r}^0)$. Based on these conditions, we say that $\boldsymbol{f} - \mathcal{A}\boldsymbol{x}$ is *convolutionally perpendicular* to $\mathcal{A}\mathbb{K}$. Note that $\langle \boldsymbol{x}, \boldsymbol{y}\rangle_\star = 0$ if and only if $\langle \hat{\boldsymbol{x}}(\xi), \hat{\boldsymbol{y}}(\xi)\rangle_\star = 0$ for all $\xi \in \mathbb{R}$.

Therefore, after taking Fourier transforms, the CGMRES algorithm becomes the GMRES algorithm for the linear algebraic equation

$$\boldsymbol{A}(\xi)\boldsymbol{u} = \widehat{\boldsymbol{f}}(\xi)$$

at each fixed $\xi \in \mathbb{R}$, where $\boldsymbol{A}(\xi) = (i\xi + d)^{-1}(i\xi\boldsymbol{I} + \boldsymbol{A})$.

Notice that Fourier transform is isometric on $\mathbb{L}^2$. Therefore, by Proposition 6.15 in [32], we have the following result.

THEOREM 4.3. *Assume $\boldsymbol{A} = \boldsymbol{X}\,\mathrm{diag}(\lambda_1,\dots,\lambda_n)\boldsymbol{X}^{-1}$ has a splitting $\boldsymbol{M} - \boldsymbol{N}$ with $\boldsymbol{M} = d\boldsymbol{I}$, $d > 0$. Define*

$$\epsilon^{(k)} = \max_{\xi\in\mathbb{R}} \min_{\substack{p\,\in\,\mathbb{P}_k\\ p(0)\,=\,1}} \max_{j=1,\dots,n} \left| p\left(\frac{i\xi + \lambda_j}{i\xi + d}\right)\right|.$$

Then the residual $\boldsymbol{r}^k = \boldsymbol{\psi} - (\boldsymbol{I} - \mathcal{K})\boldsymbol{x}^k$ obtained by the CGMRES algorithm satisfies

$$\|\boldsymbol{r}^k\|_{\mathbb{L}^2} \le \kappa_2(\boldsymbol{X})\epsilon^{(k)}\|\boldsymbol{r}^0\|_{\mathbb{L}^2},$$

where $\kappa_2(\boldsymbol{X}) = \|\boldsymbol{X}\|_2\|\boldsymbol{X}^{-1}\|_2$ is the condition number of $\boldsymbol{X}$ under the 2-norm.

Proof. For each fixed $\xi \in \mathbb{R}$, it is known that

$$\left|\widehat{\boldsymbol{r}^k}(\xi)\right|_2 \le \kappa_2(\boldsymbol{X}) \min_{\substack{p\,\in\,\mathbb{P}_k\\ p(0)\,=\,1}} \max_{j=1,\dots,n} \left| p\left(\frac{i\xi + \lambda_j}{i\xi + d}\right)\right| \cdot \left|\widehat{\boldsymbol{r}^0}(\xi)\right|_2.$$

The right-hand side of the above inequality is bounded by $\kappa_2(\boldsymbol{X})\epsilon^{(k)}|\hat{\boldsymbol{r}}^0(\xi)|_2$. Integrating both sides in ξ, we get the desired inequality. □

In order to estimate $\epsilon^{(k)}$, we assume that eigenvalues of $\boldsymbol{A}$ are included in an ellipse $E(c,e,a)$, centered at c, with focal distance e and semimajor axis a, which excludes the origin.

Assume a kth order polynomial p satisfies $p(0) = 1$. Then, since $d > 0$, $\xi \in \mathbb{R}$, $i\xi + d \neq 0$,

$$q_\xi(z) = p\left(\frac{i\xi + z}{i\xi + d}\right)$$

is of degree k in z and $q_\xi(-i\xi) = 1$. For fixed ξ,

$$\{q_\xi \in \mathbb{P}_k : \; q_\xi(-i\xi) = 1\} = \{q \in \mathbb{P}_k : \; q(-i\xi) = 1\}.$$

In fact, assume $q(z) = 1 + a_1(z + i\xi) + \cdots + a_k(z + i\xi)^k$. Define kth order polynomials

$$\begin{aligned} p(z) &= 1 + a_1(d + i\xi)z + \cdots + a_k(d + i\xi)^k z^k, \\ q_\xi(z) &= p\left(\frac{i\xi + z}{i\xi + d}\right), \end{aligned}$$

and then $q(z) = q_\xi(z)$. Therefore, the above two sets are equal. Hence,

$$\begin{aligned} \epsilon^{(k)} &\le \max_{\xi\in\mathbb{R}} \min_{\substack{p\,\in\,\mathbb{P}_k \\ p(0)\,=\,1}} \max_{z\in E(c,e,a)} \left| p\left(\frac{i\xi + z}{i\xi + d}\right)\right| \\ &= \max_{\xi\in\mathbb{R}} \min_{\substack{q_\xi\,\in\,\mathbb{P}_k \\ q_\xi(-i\xi)\,=\,1}} \max_{z\in E(c,e,a)} |q_\xi(z)| \\ &= \max_{\xi\in\mathbb{R}} \min_{\substack{q\,\in\,\mathbb{P}_k \\ q(-i\xi)\,=\,1}} \max_{z\in E(c,e,a)} |q(z)|. \end{aligned}$$

By an estimate in [32, p. 192],

$$\min_{q\in\mathbb{P}_k,\, q(-i\xi)=1} \max_{z\in E(c,e,a)} |q(z)| = \frac{C_k\left(\frac{a}{e}\right)}{\left|C_k\left(\frac{c+i\xi}{e}\right)\right|},$$

where C_k is the kth order Chebyshev polynomial. Hence,

$$\epsilon^{(k)} \le \max_{\xi\in\mathbb{R}} \frac{C_k\left(\frac{a}{e}\right)}{\left|C_k\left(\frac{c+i\xi}{e}\right)\right|}.$$

The following is a key lemma for analyzing the convergence of CGMRES.

LEMMA 4.4. *If c, e are real and positive, then*

$$\min_{\xi\in\mathbb{R}} \left|C_k\left(\frac{c + i\xi}{e}\right)\right| = C_k\left(\frac{c}{e}\right).$$

Proof. By the definition of the Chebyshev polynomial $C_k(z)$, or by noticing that $C_k(z)$ has real coefficients, we have $C_k(\overline{z}) = \overline{C_k(z)}$. As an immediate consequence,

$$\min_{\xi\in\mathbb{R}} \left|C_k\left(\frac{c + i\xi}{e}\right)\right| = \min_{\xi\ge 0} \left|C_k\left(\frac{c + i\xi}{e}\right)\right|.$$

In order to find the minimum, define

$$f(\xi) = \left|C_k\left(\frac{c + i\xi}{e}\right)\right|^2.$$

Let $w = \rho e^{i\theta}$ such that

$$\frac{1}{e}(c + i\xi) = \frac{1}{2}(w + w^{-1}).$$

Then

$$(\rho + \rho^{-1})\cos\theta = \frac{2c}{e}, \quad (\rho - \rho^{-1})\sin\theta = \frac{2\xi}{e}.$$

By a computation, we get

$$f'(\xi) = \frac{k}{2e\beta^2}[(\rho^{2k} - \rho^{-2k})(\rho + \rho^{-1})\sin\theta - 2(\rho - \rho^{-1})\cos\theta\sin(2k\theta)],$$

where $\beta^2 = |\rho e^{i\theta} - \rho^{-1}e^{-i\theta}|^2$.

If $\rho = 1$ or $\theta = 0$, then $\xi = 0$ and $f'(\xi) = 0$. However, in our case, since $c > e$, $\rho \neq 1$. Otherwise, $\cos\theta = \frac{c}{e} > 1$, which is impossible.

By the relation $(\rho - \rho^{-1})\sin\theta = \frac{2\xi}{e}$, if $0 < \theta < \frac{\pi}{2}$, then $\rho > 1$; if $-\frac{\pi}{2} < \theta < 0$, then $\rho < 1$. By symmetry, in order to prove that $f'(\xi) > 0$ for $\xi > 0$, it is enough to prove that

$$g(\rho, \theta) = (\rho^{2k} - \rho^{-2k})(\rho + \rho^{-1})\sin\theta - 2(\rho - \rho^{-1})\cos\theta\sin(2k\theta) > 0$$

for $0 < \theta < \frac{\pi}{2}$ and $\rho > 1$. By introduction, one can prove that $\sin(m\theta) \leq m\sin\theta$ for $0 < \theta < \frac{\pi}{2}$ and $m \in \mathbb{N}$. Also, notice that $\rho + \rho^{-1} > 2$. Hence, in order to prove $g(\rho, \theta) > 0$, it is sufficient to prove that

$$g(\rho) = \rho^{2k} - \rho^{-2k} - k(\rho^2 - \rho^{-2}) > 0$$

for $\rho > 1$. However, $g(\rho)$ is a strictly increasing function for $\rho > 1$, which implies $g(\rho) > g(1) = 0$. This proves the lemma. □

Notice that the Chebyshev polynomial $C_k(z)$ has properties $|C_k(z)| = |C_k(\overline{z})| = |C_k(-z)| = |C_k(-\overline{z})|$. Therefore, by the last lemma, we have the following consequence.

COROLLARY 4.5. *If c is a complex number and $e \neq 0$ is real, then*

$$\min_{\xi \in \mathbb{R}} \left| C_k\left(\frac{c + i\xi}{e}\right) \right| = C_k\left(\frac{|Re\, c|}{|e|}\right).$$

Finally, we have the following convergence result for CGMRES.

THEOREM 4.6. *Assume $\boldsymbol{A} = \boldsymbol{X}\Lambda\boldsymbol{X}^{-1} = \boldsymbol{M} - \boldsymbol{N}$, $\boldsymbol{M} = d\boldsymbol{I}$, $d > 0$. The spectrum of $\boldsymbol{A}$ is included in ellipse $E(c, e, a)$, centered at c, with focal distance e and semimajor axis a, which excludes origin. Then the residual $\boldsymbol{r}^k = \boldsymbol{\psi} - (\boldsymbol{I} - \mathcal{K})\boldsymbol{x}^k$ obtained by the CGMRES algorithm satisfies the estimate*

$$\|\boldsymbol{r}^k\|_{\mathbb{L}^2} \leq \kappa_2(\boldsymbol{X}) \frac{C_k\left(\frac{a}{e}\right)}{C_k\left(\frac{c}{e}\right)} \|\boldsymbol{r}^0\|_{\mathbb{L}^2}.$$

Remark. Thus, CGMRES applied to (2.4) is bounded by the same rate of convergence as GMRES applied to the associated problem (2.6).

5. Biconvolution acceleration methods. The CGMRES algorithm demonstrates that the use of convolution can accelerate waveform relaxation in a manner similar to GMRES applied to the associated linear algebra problem. However, there is still something unsatisfying about the algorithm in that even for Hermitian $\boldsymbol{A}$ one must use CGMRES. In this section, we turn our attention to a method that exploits Hermitian properties of the matrix $\boldsymbol{A}$, namely, biconvolution CG (BiCCG). The development of BiCCG will use a convolution bilinear form in place of the convolution inner product used by CGMRES.

We begin by defining the following bilinear form:

$$[\boldsymbol{x}, \boldsymbol{y}]_\star(t) = \sum_{i=1}^{n}(x_i \star y_i)(t) \in \mathbb{L}^1(\mathbb{R}, \mathbb{R}).$$

Remarks.

1. Convolution between a function and a vector of functions is the same as defined in section 4. However, the convolution bilinear form $[\cdot,\cdot]_\star$ is different from the previously defined inner product $\langle\cdot,\cdot\rangle_\star$.
2. Notice that $[\boldsymbol{x},\boldsymbol{y}]_\star\widehat{\;}(\xi) = [\widehat{\boldsymbol{x}}(\xi),\widehat{\boldsymbol{y}}(\xi)]$. Here $[\cdot,\cdot]$ is the bilinear form in $\mathbb{C}^n$ defined by
$$[\boldsymbol{z},\boldsymbol{w}] = \sum_{i=1}^{n} z_i w_i$$
for $\boldsymbol{w},\boldsymbol{z}\in\mathbb{C}^n$. Note that this is *not* the typical inner product in $\mathbb{C}^n$. It is, however, the bilinear form used in the BiCG algorithm [8], hence the name "biconvolution CG."
3. Since, by assumption, functions and vectors are compactly supported, $f\star\boldsymbol{x}$ and $[\boldsymbol{x},\boldsymbol{y}]_\star$ are in fact in $\mathbb{L}^2$.

5.1. The BiCCG algorithm. The CG algorithm is a popular and effective iterative method for solving symmetric positive definite systems of equations [11, 13]. Waveform extensions (using scalar parameters) of the CG algorithm are not well-defined, even for symmetric positive definite $\boldsymbol{A}$, since, in general, the operator $\mathcal{K}$ is not self-adjoint with respect to the $\mathbb{L}^2$ inner product. On the other hand, as we will see below, it is possible to develop a well-defined waveform extension to CG using convolution, i.e., the BiCCG algorithm.

Definition. An operator $\mathcal{A}:\ \mathbb{L}^2([0,T],\mathbb{R}^n)\to\mathbb{L}^2([0,T],\mathbb{R}^n)$ is called *convolution self-adjoint* if for any $\boldsymbol{u},\ \boldsymbol{v}\in\mathbb{L}^2([0,T],\mathbb{R}^n),\ [\mathcal{A}\boldsymbol{u},\boldsymbol{v}]_\star = [\boldsymbol{u},\mathcal{A}\boldsymbol{v}]_\star$.

Remark. If $\boldsymbol{A}$ is Hermitian, the operator $\mathcal{K}$ is convolution self-adjoint with respect to the convolution bilinear form "$[\cdot,\cdot]_\star$."

Definition. An operator $\mathcal{A}:\ \mathbb{L}^2([0,T],\mathbb{R}^n)\to\mathbb{L}^2([0,T],\mathbb{R}^n)$ is called *convolution definite* if for any nonzero $\boldsymbol{u}\in\mathbb{L}^2([0,T],\mathbb{R}^n),\ [\mathcal{A}\boldsymbol{u},\boldsymbol{u}]_\star\neq 0$ in the $\mathbb{L}^2$ sense.

Since $(s+d)^{-1}(s\boldsymbol{I}+\boldsymbol{A})$ is symmetric positive definite for positive real s and symmetric positive definite $\boldsymbol{A}$, the following lemma follows immediately from the above definitions and the equivalence (via the Fourier transform) between $(\boldsymbol{I}-\mathcal{K})$ and $(s+d)^{-1}(s\boldsymbol{I}+\boldsymbol{A})$.

LEMMA 5.1. *If $\boldsymbol{A}$ is real symmetric with splitting $\boldsymbol{M}-\boldsymbol{N},\ \boldsymbol{M}=d\boldsymbol{I},\ d>0$, then $(\boldsymbol{I}-\mathcal{K})$ is convolution self-adjoint. Furthermore, if $\boldsymbol{A}$ is positive definite, then $(\boldsymbol{I}-\mathcal{K})$ is also convolution definite.*

If $\mathcal{A}$ is convolution self-adjoint and convolution definite on $\mathbb{L}^2([0,T],\mathbb{R}^n)$, then we can define the following BiCCG algorithm (analogous to CG).

ALGORITHM 5 (BiCCG). Let $\mathcal{A}: C_0([0,\infty),\mathbb{R}^n)\to C_0([0,\infty),\mathbb{R}^n)$ be a bounded linear operator. As before, $\mathcal{A}$ is extendable to $\overline{C_0([0,\infty),\mathbb{R}^n)}$, the vector-valued generalized function space, which is again a vector space over $\mathbb{Q}$. Let $\boldsymbol{f}\in C_0([0,\infty),\mathbb{R}^n)$.

1. Pick $\boldsymbol{x}^0\in C_0([0,\infty),\mathbb{R}^n)$ and compute $\boldsymbol{r}^0=\boldsymbol{f}-\mathcal{A}\boldsymbol{x}^0,\ \boldsymbol{p}^0=\boldsymbol{r}^0$.
2. For $j=0,1,\ldots$ until converged,
$$\begin{aligned}\alpha_j &= [\boldsymbol{r}^j,\boldsymbol{r}^j]_\star/[\mathcal{A}\boldsymbol{p}^j,\boldsymbol{p}^j]_\star\\ \boldsymbol{x}^{j+1} &= \boldsymbol{x}^j+\alpha_j\star\boldsymbol{p}^j\\ \boldsymbol{r}^{j+1} &= \boldsymbol{r}^j-\alpha_j\star\mathcal{A}\boldsymbol{p}^j,\\ \beta_j &= [\boldsymbol{r}^{j+1},\boldsymbol{r}^{j+1}]_\star/[\boldsymbol{r}^j,\boldsymbol{r}^j]_\star\\ \boldsymbol{p}^{j+1} &= \boldsymbol{r}^{j+1}+\beta_j\star\boldsymbol{p}^j.\end{aligned}$$

Note that the Fourier transform of the BiCCG algorithm for $\mathcal{A}=\boldsymbol{I}-\mathcal{K}$ is the BiCG algorithm (see [6, 8, 13]) for matrix $\boldsymbol{A}(\xi)=(i\xi\boldsymbol{I}+\boldsymbol{M})^{-1}(i\xi\boldsymbol{I}+\boldsymbol{A})$. Therefore, we can view the BiCG algorithm (for a complex system) as a continuation of the CG algorithm (for a real system). Also, notice that by [5] there is a CG algorithm for matrix $\boldsymbol{A}(\xi) = (i\xi + d)^{-1}(i\xi\boldsymbol{I} + \boldsymbol{A})$.

5.2. Laplace and Fourier transforms. To analyze the convergence of the BiCCG algorithm, we first give some definitions for weighted Sobolev spaces (see [16]) and introduce some results related to Laplace and Fourier transforms.

Definition. For a real number $\lambda > 0$, $\alpha \geq 0$, define the weighted Sobolev space $\mathbb{H}^\alpha_\lambda(\mathbb{R}, \mathbb{R})$ according to

$$\mathbb{H}^\alpha_\lambda(\mathbb{R}, \mathbb{R}) = \{u \in \mathbb{L}^2(\mathbb{R}, \mathbb{R}) : \ (\lambda^2 + |\xi|^2)^{\alpha/2}|\widehat{u}(\xi)| \in \mathbb{L}^2(\mathbb{R}, \mathbb{R})\}.$$

In particular, if $\lambda = 1$, then the weighted $\mathbb{H}^\alpha_1$ space is the regular $\mathbb{H}^\alpha$ space [16]. Also notice that $\mathbb{H}^\alpha_\lambda$ can be defined by another equivalent norm as follows:

$$\mathbb{H}^\alpha_\lambda(\mathbb{R}, \mathbb{R}) = \{u \in \mathbb{L}^2(\mathbb{R}, \mathbb{R}) : \ (|\lambda| + |\xi|)^{\alpha}|\widehat{u}(\xi)| \in \mathbb{L}^2(\mathbb{R}, \mathbb{R})\}.$$

Now assume $\boldsymbol{A} = \boldsymbol{U}\,\mathrm{diag}(\lambda_1, \ldots, \lambda_n)\boldsymbol{U}^T = \boldsymbol{U}\Lambda\boldsymbol{U}^T$ is real symmetric positive definite, where $\boldsymbol{U}\boldsymbol{U}^T = \boldsymbol{I}$, and $0 < \lambda_1 \leq \cdots \leq \lambda_n$. Define a weighted $\mathbb{H}^\alpha_{\mathbf{A}}$ as follows:

$$\mathbb{H}^\alpha_{\mathbf{A}}(\mathbb{R}, \mathbb{R}^n) = \{\boldsymbol{u} = (u_1, \ldots, u_n)^T : (\lambda_j + |\xi|)^\alpha|(\boldsymbol{U}^T\widehat{u})_j(\xi)| \in \mathbb{L}^2(\mathbb{R}, \mathbb{R})\}.$$

By the definition, we can see that $\mathbb{H}^\alpha_{\mathbf{A}} = \mathbb{H}^\alpha_{\lambda_1} \times \mathbb{H}^\alpha_{\lambda_2} \times \cdots \times \mathbb{H}^\alpha_{\lambda_n}$. Also, on $\mathbb{H}^\alpha_{\mathbf{A}}$, we can define an inner product

$$\begin{aligned}(\boldsymbol{u}, \boldsymbol{v})_\alpha &= \int_{\mathbb{R}} \widehat{\boldsymbol{u}}^T(\xi)(|\xi|\boldsymbol{I} + \boldsymbol{A})^{2\alpha}\overline{\widehat{\boldsymbol{v}}(\xi)}d\xi \\ &= \int_{\mathbb{R}} \langle \widehat{\boldsymbol{u}}(\xi), \widehat{\boldsymbol{v}}(\xi)\rangle_{(|\xi|\mathbf{I}+\mathbf{A})^{\mathbf{2}\alpha}} d\xi,\end{aligned}$$

which makes $\mathbb{H}^\alpha_{\mathbf{A}}$ a Hilbert space with norm

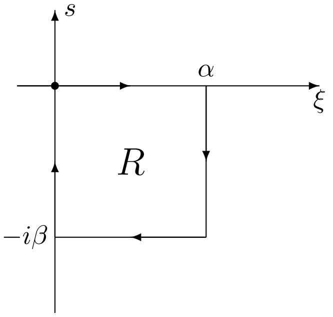
$$\|\boldsymbol{u}\|_{\mathbb{H}^\alpha_{\mathbf{A}}} = \left(\sum_{j=1}^n \int_{\mathbb{R}} (\lambda_j + |\xi|)^{2\alpha}|(\boldsymbol{U}^T\widehat{u})_j(\xi)|^2 d\xi\right)^{1/2}.$$

Now we want to study the relationship between the Laplace transform and the Fourier transform.

Since $f \in \mathbb{L}^2([0, T], \mathbb{R})$, and the trivial extension of f to $\mathbb{L}^2(\mathbb{R}, \mathbb{R})$ is compactly supported, the Fourier transform of f is therefore entire in $\mathbb{C}$. By Cauchy's theorem,

$$\int_R (\widehat{f}(z))^2 dz = 0,$$

where R is a rectangle as shown in the figure at the right. Therefore,



$$\begin{aligned}&\int_0^\alpha (\widehat{f}(\xi))^2 d\xi + \int_0^{-\beta} (\widehat{f}(\alpha + is))^2 d(is) \\ &+ \int_\alpha^0 (\widehat{f}(\xi - i\beta))^2 d\xi + \int_{-\beta}^0 (\widehat{f}(is))^2 d(is) = 0.\end{aligned}$$

For fixed β, let $\alpha \to \infty$. By a property of the Fourier transform (see [12]), $\lim_{\alpha\to\infty} \widehat{f}(\alpha + is) = 0$. Also, since $(\widehat{f}(\alpha + is))^2$ is absolutely integrable,

$$\lim_{\alpha\to\infty} \int_0^{-\beta} (\widehat{f}(\alpha + is))^2 d(is) = i \int_0^{-\beta} \lim_{\alpha\to\infty} (\widehat{f}(\alpha + is))^2 ds = 0.$$

The third term becomes $-\int_0^\infty (\widehat{f}(\xi - i\beta))^2 d\xi$. Let $\beta \to \infty$, and then by

$$\widehat{f}(\xi - i\beta) = \frac{1}{\sqrt{2\pi}} \int_0^\infty e^{-\beta x - i\xi x} f(x)dx \to 0$$

we get that

$$\lim_{\beta\to\infty} \int_0^\infty (\widehat{f}(\xi - i\beta))^2 d\xi = 0.$$

Hence, we conclude that

$$i \int_0^\infty (\widehat{f}(\xi))^2 d\xi = \int_0^\infty (\widehat{f}(-is))^2 ds \geq 0, \tag{5.1}$$

since $\widehat{f}(-is)$ is the Laplace transform and is real. We denote the Laplace transform by $\mathcal{L}f(s) = \widehat{f}(-is)$. This relationship between the Laplace and Fourier transforms plays an important role in what follows.

For subsequent analysis, we require the following definition (see [16]).

Definition.

$$\mathbb{H}_0^\alpha\left([0,\infty),\mathbb{R}\right) = \text{closure of } C_0^\infty[0,\infty) \text{ in } \mathbb{H}^\alpha\left([0,\infty),\mathbb{R}\right),$$

where $C_0^\infty[0,\infty) = \{f : f \in C^\infty[0,\infty) \text{ with compact support }\}$.

If we assume that $f \in \mathbb{H}_0^{1/2}\left([0,\infty),\mathbb{R}\right)$, then by Cauchy's theorem again,

$$\int_R z(\widehat{f}(z))^2 dz = 0,$$

so that

$$-\int_0^\infty \xi(\widehat{f}(\xi))^2 d\xi = \int_0^\infty s(\mathcal{L}f(s))^2 ds \geq 0. \tag{5.2}$$

Combining (5.1) and (5.2) yields a key lemma.

LEMMA 5.2. *For $f \in \mathbb{H}_0^{1/2}([0,\infty),\mathbb{R})$, $\lambda \in \mathbb{C}$,*

$$i \int_0^\infty (i\xi + \lambda)(\widehat{f}(\xi))^2 d\xi = \int_0^\infty (s + \lambda)(\mathcal{L}f(s))^2 ds.$$

Because of this key equality, we can give the following definitions.

Definition. Assume $\boldsymbol{f} = (f_1, \ldots, f_n)^T$, $\boldsymbol{g} = (g_1, \ldots, g_n)^T \in \mathbb{H}_0^{1/2}([0,\infty),\mathbb{R}^n)$, and real symmetric and positive definite $\boldsymbol{A} = \boldsymbol{U}\,\mathrm{diag}(\lambda_1, \ldots, \lambda_n)\boldsymbol{U}^T$ with $\boldsymbol{U}\boldsymbol{U}^T = \boldsymbol{I}$ and $0 < \lambda_1 \leq \cdots \leq \lambda_n$. Define an $\boldsymbol{A}$-weighted inner product by

$$\begin{aligned}\langle \boldsymbol{f}, \boldsymbol{g}\rangle_{\mathbf{A}} &= i \int_0^\infty \langle \hat{\boldsymbol{f}}, \hat{\boldsymbol{g}}\rangle_{i\xi\mathbf{I}+\mathbf{A}} d\xi \\ &= \sum_{j=1}^n i \int_0^\infty (i\xi + \lambda_j) \left(\widehat{\boldsymbol{U}\boldsymbol{f}}\right)_j (\xi) \left(\widehat{\boldsymbol{U}\boldsymbol{g}}\right)_j (\xi) d\xi.\end{aligned}$$

Definition. For $\boldsymbol{f} \in \mathbb{H}_0^{1/2}([0,\infty),\mathbb{R}^n)$, define a norm by

$$\|\boldsymbol{f}\|_{\mathbb{K}_{\mathbf{A}}^{1/2}} = \langle \boldsymbol{f}, \boldsymbol{f}\rangle_{\mathbf{A}}^{1/2}.$$

The new normed space is again a Hilbert space and is denoted by $\mathbb{K}_{\mathbf{A}}^{1/2}([0,\infty),\mathbb{R}^n)$.

Remarks.

1. By integration over a wedge instead of over a rectangle as in Lemma 5.2, one can see that

$$ie^{i\theta}\int_0^\infty (ire^{i\theta}+\lambda)(\widehat{f}(re^{i\theta}))^2 dr = \int_0^\infty (s+\lambda)(\mathcal{L}f(s))^2 ds.$$

   This means the integral

$$i\int_{R(\theta)} (iz+\lambda)(\widehat{f}(z))^2 dz = \int_{R(\theta+\pi/2)} (z+\lambda)(\mathcal{L}f(z))^2 dz$$

   is invariant in θ, where $R(\theta) = \{re^{i\theta} : 0 \le r < +\infty\}$ is a ray starting at the origin.
2. The $\mathbb{K}_{\mathbf{A}}^{1/2}$ norm is bounded by the $\mathbb{H}_{\mathbf{A}}^{1/2}$ norm.
3. By Theorem 11.1, Chapter 1 in [16], $\mathbb{H}_0^{1/2}(\mathbb{R}^+,\mathbb{R}^n) = \mathbb{H}^{1/2}(\mathbb{R}^+,\mathbb{R}^n)$, where $\mathbb{R}^+ = \{x \in \mathbb{R} : x > 0\}$ is the positive half ray of $\mathbb{R}$.

5.3. Convergence of the BiCCG algorithm. By using the projection properties and Chebyshev polynomials, one can prove the following well-known theorem [32] for CG applied to the linear system $\boldsymbol{Ax} = \boldsymbol{b}$.

THEOREM 5.3. *Assume matrix $\boldsymbol{A}$ is real symmetric and positive definite. Let $\{\boldsymbol{x}_m\}$ be the sequence of approximate solutions obtained by the CG algorithm and let $\boldsymbol{x}_*$ be the exact solution. Then the iterates satisfy*

$$\|\boldsymbol{x}_* - \boldsymbol{x}_m\|_{\mathbf{A}} \le 2\left[\frac{\sqrt{\kappa(\boldsymbol{A})}-1}{\sqrt{\kappa(\boldsymbol{A})}+1}\right]^m \|\boldsymbol{x}_* - \boldsymbol{x}_0\|_{\mathbf{A}},$$

where $\kappa(\boldsymbol{A}) = \frac{\lambda_{\max}}{\lambda_{\min}}$ is the condition number of the matrix $\boldsymbol{A}$.

For the BiCCG algorithm we can prove a similar convergence theorem.

THEOREM 5.4. *Let $\boldsymbol{M}-\boldsymbol{N}$ be a splitting of a real symmetric positive definite matrix $\boldsymbol{A}$ with $\boldsymbol{M} = d\boldsymbol{I}$, $d > 0$. Then the BiCCG algorithm applied to* (2.4) *generates a sequence of iterates $\{\boldsymbol{x}^m\}$ that satisfy the weighted $\frac{1}{2}$-estimates*

$$\|\boldsymbol{x}^* - \boldsymbol{x}^m\|_{\mathbb{K}_{\mathbf{A}}^{1/2}} \le 2\left[\frac{\sqrt{\kappa(\boldsymbol{A})}-1}{\sqrt{\kappa(\boldsymbol{A})}+1}\right]^m \|\boldsymbol{x}^* - \boldsymbol{x}^0\|_{\mathbb{K}_{\mathbf{A}}^{1/2}}, \tag{5.3}$$

where $\boldsymbol{x}^*$ is the exact solution.

Proof. By taking Fourier transform on the BiCCG algorithm, we can see that, for each m, $\boldsymbol{x}^* - \boldsymbol{x}^m \in \mathbb{L}^2([0,\infty),\mathbb{R}^n)$. Since $\boldsymbol{x}^* - \boldsymbol{x}^m$ is differentiable on $[0,T]$ and $(\boldsymbol{x}^* - \boldsymbol{x}^m)(0) = 0$, by Urysohn's lemma, we can assume that $\boldsymbol{x}^* - \boldsymbol{x}^m$ is also compactly supported on $[0,\infty)$. Therefore $\boldsymbol{x}^* - \boldsymbol{x}^m$ is in fact in $\mathbb{H}_0^{1/2}([0,\infty),\mathbb{R}^n)$. By taking Laplace transform on the BiCCG algorithm, we can see that $\mathcal{L}(\boldsymbol{x}^m)(s)$ is an approximate solution obtained by the CG algorithm applied to real matrix $(s+d)^{-1}(s\boldsymbol{I}+\boldsymbol{A})$. By Theorem 5.3, for each fixed $s \ge 0$,

$$\|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^m)(s)\|_{\frac{s\mathbf{I}+\mathbf{A}}{s+d}} \le 2\left[\frac{\sqrt{\kappa(s\boldsymbol{I}+\boldsymbol{A})}-1}{\sqrt{\kappa(s\boldsymbol{I}+\boldsymbol{A})}+1}\right]^m \|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^0)(s)\|_{\frac{s\mathbf{I}+\mathbf{A}}{s+d}}. \tag{5.4}$$

Since $\boldsymbol{A}$ is positive definite, there exists an unitary matrix $\boldsymbol{U}$ such that

$$\boldsymbol{A} = \boldsymbol{U}\Lambda\boldsymbol{U}^T,$$

where $\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_n)$, and $0 < \lambda_1 \leq \cdots \leq \lambda_n$. It is easy to see that

$$\kappa(s\boldsymbol{I} + \boldsymbol{A}) = \frac{s + \lambda_n}{s + \lambda_1}.$$

Notice that

$$\max_{s \in \mathbb{R}^+ \cup \{0\}} \kappa(s\boldsymbol{I} + \boldsymbol{A}) = \max_{s \in \mathbb{R}^+ \cup \{0\}} \left[\frac{s + \lambda_n}{s + \lambda_1}\right] = \kappa(\boldsymbol{A}).$$

Since $f(x) = \frac{\sqrt{x}-1}{\sqrt{x}+1}$ is an increasing function on $[0, +\infty)$, we have

$$\begin{aligned} \frac{\sqrt{\kappa(s\boldsymbol{I} + \boldsymbol{A})} - 1}{\sqrt{\kappa(s\boldsymbol{I} + \boldsymbol{A})} + 1} &\leq \frac{\sqrt{\max_{s \in \mathbb{R}^+ \cup \{0\}} \kappa(s\boldsymbol{I} + \boldsymbol{A})} - 1}{\sqrt{\max_{s \in \mathbb{R}^+ \cup \{0\}} \kappa(s\boldsymbol{I} + \boldsymbol{A})} + 1} \\ &= \frac{\sqrt{\kappa(\boldsymbol{A})} - 1}{\sqrt{\kappa(\boldsymbol{A})} + 1}. \end{aligned}$$

By (5.4) we get

$$(5.5) \qquad \|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^m)(s)\|^2_{\frac{s\mathbf{I}+\mathbf{A}}{s+d}} \leq 4 \left[\frac{\sqrt{\kappa(\boldsymbol{A})} - 1}{\sqrt{\kappa(\boldsymbol{A})} + 1}\right]^{2m} \|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^0)(s)\|^2_{\frac{s\mathbf{I}+\mathbf{A}}{s+d}}.$$

Multiplying both sides of (5.5) by $(s + d)$, we obtain

$$(5.6) \qquad \|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^m)(s)\|^2_{s\mathbf{I}+\mathbf{A}} \leq 4 \left[\frac{\sqrt{\kappa(\boldsymbol{A})} - 1}{\sqrt{\kappa(\boldsymbol{A})} + 1}\right]^{2m} \|\mathcal{L}(\boldsymbol{x}^* - \boldsymbol{x}^0)(s)\|^2_{s\mathbf{I}+\mathbf{A}}.$$

Integrating both sides of (5.6) with respect to s and taking the square root gives the desired inequality (5.3). □

Remarks.

1. Thus, under the weighted $\mathbb{K}_{\mathbf{A}}^{1/2}$ norm, BiCCG applied to (2.4) is bounded by the same rate of convergence as CG applied to the associated problem (2.6).
2. Another important point to note is that, for the Laplace transform, we have the pointwise inequality (5.4). For the Fourier transform, it is not known whether a similar pointwise inequality is true or not. Such an inequality with the Fourier transform is unnecessary, however, because, by Theorem 5.4, it is the integral of the Fourier transforms of $\boldsymbol{x}^* - \boldsymbol{x}^m$ and $\boldsymbol{x}^* - \boldsymbol{x}^0$ which must satisfy a similar inequality.

Notice that, since $((\boldsymbol{I} - \mathcal{K})^n)\hat{} = ((\boldsymbol{I} - \mathcal{K})\hat{})^n$, and the CG algorithm terminates in finite steps, we have the following result regarding finite termination.

COROLLARY 5.5. *The BiCCG algorithm applied to* (2.4) *terminates in finite steps.*

Remark. For the algebraic equation (2.5), the CG algorithm terminates in finite steps. For the differential equation (2.1), we should expect that finite termination is possible [34]. Although the finite termination property is typically not important in practice, the fact that convolution Krylov subspace methods exhibit this property is another indication that they are the "right" generalization from linear algebra problems to waveform problems. The Hilbert space methods in section 3 do not exhibit finite termination.

6. Numerical experiments. In this section, we present preliminary experimental results using convolution Krylov subspace methods. For our model problem, we take the one-dimensional heat equation with unit spatial dimension and $T = 64$ for the temporal dimension. The problem is discretized with 64 spatial points and 32 temporal points and is integrated using backward-Euler.

Two convolution Krylov subspace methods are examined: BiCCG and the convolution variant of the generalized conjugate residual algorithm [4], CGCR. The CGCR algorithm is included rather than convolution GMRES because, although it is theoretically equivalent to GMRES, it is much simpler to implement. Thus, the CGCR results should be taken to be indicative of CGMRES.

The experimental code for BiCCG was written in C++, using the CG module from the IML++ class library [3]. Although IML++ was developed for solving linear systems of equations, by using it with a waveform class and by overloading the appropriate operators, the same CG code was able to be used for both linear algebra problems and waveform problems. The code for CGCR was similarly based on a GCR module (auxiliary to the IML++ library distribution). The experimental code for CSOR and WGMRES was written in C. The convolution kernel for CSOR was obtained according to the algorithms given in [30, 31].

Elements in $\mathbb{Q}$ were applied to functions by first convolving with the numerator and then deconvolving with the denominator. The deconvolution was implemented in a variety of ways, including computation of $(\frac{\hat{f}}{\hat{g}})^{\vee}$, inversion of the convolution based recurrence, and a Newton iteration. All approaches gave similar results.

Figure 6.1 compares the convergence rates of waveform relaxation, WGMRES, CSOR, and BiCCG applied to solving the model problem. We also show the performance of CG applied to solving the corresponding linear algebra problem. For this experiment, BiCCG and CGCR have remarkably better convergence behavior than the other waveform methods and is, in fact, much better than CG itself. This be-

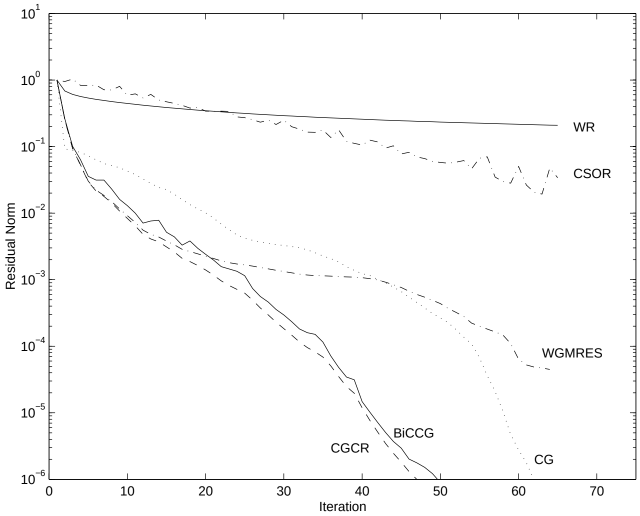


FIG. 6.1. *Convergence of waveform relaxation, WGMRES, CSOR, BiCCG, and CGCR applied to solving a model initial value problem. Also shown is the convergence of CG applied to the corresponding linear algebra problem.*

havior is typical of BiCCG and CGCR over a wide variety of experiments that we conducted (with a particular *caveat*, which we discuss below).

7. Discussion.

7.1. Deconvolution.

It is well known that, in general, deconvolution is an ill-posed problem and that therefore numerical deconvolution will be ill-conditioned. This ill-posedness arises because the "divisor" in the deconvolution may have zero values at particular frequencies.

Theoretically, the convolution Krylov subspace algorithms avoid this ill-posedness naturally because of our choice of functions (i.e., compactly supported $\mathbb{L}^2$ functions). That is, the deconvolution is well-defined in the $\mathbb{L}^2$ sense.

Practically, however, the issue becomes somewhat more delicate, because we need to be concerned not simply with possible zero divisors, but with divisors that are small in a relative numerical sense. Since the convolution Krylov algorithms can be interpreted as being simultaneous iterative processes in the frequency domain, one at each frequency, small divisors can occur during the solution process if the residual values at particular frequencies are small relative to others.

The numerical ill-conditioning can be avoided in part by ensuring that each temporal frequency is present in the initial waveform $\boldsymbol{x}^0$. In our experiments, we effected this by setting $\boldsymbol{x}^0$ to have random values as a function of $t \neq 0$. Unfortunately, for problems having a large number of timepoints, higher temporal frequencies will tend to converge at a much higher rate than the lower frequencies, and numerical instabilities due to deconvolution may appear. Practical implementations of convolution Krylov subspace algorithms (if there turn out to be such things) should be able to circumvent this difficulty via windowing (which may be attractive for memory conservation reasons at any rate) or perhaps by restarting. Alternatively, it may be possible to modify the algorithms in such a way as to equalize the rates of convergence at all frequencies, or through the incorporation of some kind of regularization procedure.

7.2. Conclusion.

As should be evident from this paper, convolution Krylov subspace methods are tremendously interesting, and we have scratched only the surface here. These methods appear to be the "right" generalization of linear algebra acceleration techniques to waveform relaxation. Moreover, they open some entirely new lines of inquiry about Krylov subspace iterations. For instance, the vector space defined by convolution with generalized function is seemingly more abstract than $\mathbb{R}^n$ or $\mathbb{L}^2$, where Krylov subspace algorithms are normally thought to be appropriate. The geometry of Hilbert space is explicitly present only in the transform domain. Finally, there have been a number of algorithms developed recently for the efficient iterative solution, large nonsymmetric linear systems of equations—QMR [9] and Bi-CGSTAB [39] to name just two. Adaptation of these and other methods to the convolution case should be relatively straightforward in terms of description and implementation (although, as with BiCCG and CGMRES, analysis may be somewhat less straightforward). However, a comprehensive experimental study of an assortment of convolution Krylov subspace methods, particularly if applied to practical application problems, would help to shed light on whether or not these methods will be practical in real life.

Acknowledgments. Convolution Krylov subspace algorithms have tantalized the authors for several years. During that time, we have had helpful discussions on this topic with Boris Bäumer, Roland Freund, Alex Himonas, Ken Jackson, Tom Manteuffel, Mark Reichelt, Stefan Vandewalle, and Jacob White and we wish to thank them. The authors also wish to thank the referees for their careful reading and helpful suggestions for strengthening this paper.

VELOCITY-CORRECTION PROJECTION METHODS FOR INCOMPRESSIBLE FLOWS*

J. L. GUERMOND† AND JIE SHEN‡

Abstract. We introduce and study a new class of projection methods—namely, the velocity-correction methods in standard form and in rotational form—for solving the unsteady incompressible Navier–Stokes equations. We show that the rotational form provides improved error estimates in terms of the H^1-norm for the velocity and of the L^2-norm for the pressure. We also show that the class of fractional-step methods introduced in [S. A. Orsag, M. Israeli, and M. Deville, *J. Sci. Comput.*, 1 (1986), pp. 75–111] and [K. E. Karniadakis, M. Israeli, and S. A. Orsag, *J. Comput. Phys.*, 97 (1991), pp. 414–443] can be interpreted as the rotational form of our velocity-correction methods. Thus, to the best of our knowledge, our results provide the first rigorous proof of stability and convergence of the methods in those papers. We also emphasize that, contrary to those of the above groups, our formulations are set in the standard L^2 setting, and consequently they can be easily implemented by means of any variational approximation techniques, in particular the finite element methods.

1. Introduction.

We consider in this paper the time discretization of the unsteady incompressible Navier–Stokes equations in primitive variables. For a given body force $f(t)$ and an initial solenoidal vector field v_0, we look for u and p such that

$$(1.1)\qquad \begin{cases} \partial_t \mathsf{u} - \nu\nabla^2\mathsf{u} + \mathsf{u}\cdot\nabla\mathsf{u} + \nabla\mathsf{p} = f \qquad \text{in } \Omega\times[0,T], \\ \nabla\cdot\mathsf{u} = 0 \qquad \text{in } \Omega\times[0,T], \\ \mathsf{u}|_\Gamma = 0, \\ \mathsf{u}|_{t=0} = v_0 \qquad \text{in } \Omega. \end{cases}$$

The boundary condition on the velocity is set to zero for the sake of simplicity. The fluid domain Ω is open and bounded in $\mathbb{R}^d$ ($d = 2$ or 3 in practical situations). The domain boundary Γ is assumed to be smooth; e.g., Γ is Lipschitzian and Ω is locally on one side of its boundary.

The goal of this paper is to present a new class of fractional-step projection methods. The original projection method was introduced by Chorin [3] and Temam [15] in the late 60s. An important class of projection methods is the so-called pressure-correction methods introduced in [5, 8]. These schemes consist of two substeps per time step: the pressure is treated explicitly in the first substep and corrected in the second substep by projecting the intermediate velocity onto the space of divergence-free

fields. These schemes are widely used in practice and have been rigorously analyzed in [4, 14, 7].

The new class of projection methods that we introduce in this paper also consist of two substeps per time step: here the viscous (velocity) term is treated explicitly in the first substep and corrected in the second one. Two versions of the method are presented: a standard form and a rotational form. We prove stability and $\mathcal{O}(\delta t^2)$ convergence in the L^2-norm of the velocity for both versions. We also prove improved error estimates for the rotational form, namely, $\mathcal{O}(\delta t^{3/2})$ convergence in the H^1-norm of the velocity and the L^2-norm of the pressure. Such estimates are new and, as indicated by our numerical results, appear to be the best possible under the general context considered in this paper. Since this class of projection methods can be viewed as the dual class of pressure-correction methods, we shall hereafter refer to them as velocity-correction methods.

An interesting aspect of the new class of projection methods is its relation to a set of schemes introduced in [10] and [9]. These schemes have never been analyzed rigorously, partly because they do not fit into any standard weak setting. As originally presented in [10] and [9], these schemes use normal traces of second derivatives of the velocity at the boundary, introducing formidable difficulties in analysis as well as in implementation. In contrast, the new schemes are set in the standard L^2 weak setting and consequently can be naturally implemented and analyzed by means of finite elements or spectral methods. In fact, the schemes in [10] and [9] are formally equivalent, in the spatial continuous case, to the rotational forms of our velocity-correction methods. Thus, to the best of our knowledge, this paper provides the first rigorous proof of stability and convergence of the methods introduced in [10] and [9].

The paper is organized as follows. In the next section, we introduce the velocity-correction method in standard form and prove error estimates for both the time continuous and the time discrete versions of the method. Then, in section 3, we introduce the rotational form of the velocity-correction method and show that this version yields better convergence rates than its standard counterpart. In section 4, we present numerical results, using a finite element method and a Legendre spectral method, which are consistent with our theoretical analysis. In section 5, we examine the relation between the splitting schemes introduced in [10] and [9] and our velocity-correction methods in rotational form. In section 6, we indicate how nonlinear terms can be treated in the velocity-correction schemes. We present concluding remarks in section 7.

We now introduce some notation. We shall use the standard Sobolev spaces $L^2(\Omega)^d$, $H^1(\Omega)^d$, $H^{-1}(\Omega)^d$, etc., whose norm will be denoted by $\|\cdot\|_{0,\Omega}$, $\|\cdot\|_{1,\Omega}$, $\|\cdot\|_{-1,\Omega}$, etc. The L^2 scalar product for scalar and vector valued functions is denoted by $(\cdot,\cdot)$. We equip $H^1_0(\Omega)^d$ with the following norm:

$$\forall\beta\in H^1_0(\Omega)^d,\qquad \|\beta\|_{1,\Omega} := (\|\nabla\cdot\beta\|^2_{0,\Omega} + \|\nabla\times\beta\|^2_{0,\Omega})^{1/2}. \tag{1.2}$$

We introduce two spaces of solenoidal vector fields

$$H = \{v\in L^2(\Omega)^d;\ \nabla\cdot v = 0;\ v\cdot n|_\Gamma = 0\}, \tag{1.3}$$

$$V = \{v\in H^1(\Omega)^d;\ \nabla\cdot v = 0;\ v|_\Gamma = 0\}, \tag{1.4}$$

and we define P_H to be the L^2 projection onto H.

We denote by d_t and ∂_t the time derivative and the partial derivative with respect to time, respectively. Let $\delta t > 0$ be a time step and set $t^k = k\delta t$ for $0 \le k \le K =$

$[T/\delta t]$. Let $\phi^0, \phi^1, \dots, \phi^K$ be some sequence of functions in some Banach space E. We shall use the following discrete norms:

$$\|\phi\|_{l^2(E)} := \left(\delta t \sum_{k=0}^{K} \|\phi^k\|_E^2\right)^{1/2}, \qquad \|\phi\|_{l^\infty(E)} := \max_{0\le k\le K}\left(\|\phi^k\|_E^2\right). \tag{1.5}$$

We denote by c a generic constant which is independent of ε and δt but possibly depends on the data and the solution, and the value of which may vary at each occurrence.

Since the nonlinear term does not contribute in any essential way to the error analysis of projection methods, we shall carry out our analysis for the linearized equations only, so as to avoid technicalities which may obscure the essential ideas in the proof. Our proofs can be adapted to account for the nonlinearity using standard techniques (cf. [16, 14, 7]).

2. Velocity-correction methods: Standard form.

2.1. Introduction of the scheme. Before introducing velocity-correction methods, let us recall the second-order pressure-correction scheme. Hereafter, we take $\nu = 1$ for simplicity and drop the nonlinear term. A second-order pressure-correction scheme is written in the following form: set $u^0 = \mathsf{u}(0)$, $p^0 = \mathsf{p}(0)$, and choose u^1 and p^1 to be reasonable approximations of $\mathsf{u}(\delta t)$ and $\mathsf{p}(\delta t)$; then for $k \ge 1$ we look for $(\tilde u^{k+1}; u^{k+1}, p^{k+1})$ such that

$$\begin{cases} \frac{1}{2\delta t}(3\tilde u^{k+1} - 4u^k + u^{k-1}) - \nabla^2 \tilde u^{k+1} + \nabla p^k = f(t^{k+1}), \\ \tilde u^{k+1}|_\Gamma = 0 \end{cases} \tag{2.1}$$

and

$$\begin{cases} \frac{3}{2\delta t}(u^{k+1} - \tilde u^{k+1}) + \nabla(p^{k+1} - p^k) = 0, \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0, \end{cases} \tag{2.2}$$

where n is the outward normal of Ω. For a rigorous analysis of this scheme and its variants, we refer to [4, 14, 7].

Now we propose to adopt a new point of view by switching the role of pressure and velocity. We first treat the viscous (velocity) term explicitly in the first substep and then correct it in the second substep. The corresponding scheme is as follows: set $\tilde u^0 = v_0$ and choose $\tilde u^1$ to be a good approximation of $\mathsf{u}(\delta t)$; then for $k \ge 1$ we look for $(u^{k+1}, p^{k+1}; \tilde u^{k+1})$ such that

$$\begin{cases} \frac{1}{2\delta t}(3u^{k+1} - 4\tilde u^k + \tilde u^{k-1}) - \nabla^2 \tilde u^k + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0 \end{cases} \tag{2.3}$$

and

$$\begin{cases} \frac{3}{2\delta t}(\tilde u^{k+1} - u^{k+1}) - \nabla^2(\tilde u^{k+1} - \tilde u^k) = 0, \\ \tilde u^{k+1}|_\Gamma = 0. \end{cases} \tag{2.4}$$

We shall hereafter refer to this scheme as the standard form of the velocity-correction method. Note that there is a strong similarity between the velocity-correction method and the pressure-correction method. In fact, our velocity-correction scheme can be regarded as the dual of the pressure-correction scheme.

Note also that (2.3) can be written as

$$u^{k+1} = P_H\left(\frac{4}{3}\tilde{u}^k - \frac{1}{3}\tilde{u}^{k-1} + \frac{2\delta t}{3}(\nabla^2\tilde{u}^k + f(t^{k+1}))\right),$$

where P_H is the L^2 projection onto H. Hence, the method defined by (2.3)–(2.4) falls into the class of the projection methods as introduced by Chorin and Temam. Since the projection step precedes the viscous step, one could also refer to these methods as "projection–diffusion" methods as in [1].

We observe from (2.4) that $\nabla^2(\tilde{u}^{k+1} - \tilde{u}^k)\cdot n|_\Gamma = 0$, which implies that

$$\nabla^2\tilde{u}^{k+1}\cdot n\big|_\Gamma = \nabla^2\tilde{u}^k\cdot n|_\Gamma = \cdots = \nabla^2\tilde{u}^0\cdot n|_\Gamma. \tag{2.5}$$

We then derive from the above and (2.3) that

$$\left.\frac{\partial p^{k+1}}{\partial n}\right|_\Gamma = (f(t^{k+1}) + \nabla^2\tilde{u}^0)\cdot n|_\Gamma. \tag{2.6}$$

This is obviously an artificial Neumann boundary condition for the pressure, which will introduce a numerical boundary layer on the pressure and limit the accuracy of the scheme, just as in the case of pressure-correction schemes.

2.2. Implementation of the standard form. When working with H^1-conformal finite elements, it is difficult to solve (2.3) as a weak Poisson problem for the pressure, for there is a second derivative in the right-hand side which cannot be tested against gradients. To avoid this difficulty, we rewrite the algorithm in an equivalent form by making algebraic substitutions.

By subtracting step (2.3) at time t^k from step (2.3) at time t^{k+1} and by substituting step (2.4) at time t^k into the resulting equation, one obtains a new equivalent form of the projection step:

$$\begin{cases} \frac{1}{2\delta t}(3u^{k+1} - 7\tilde{u}^k + 5\tilde{u}^{k-1} - \tilde{u}^{k-2}) + \nabla(p^{k+1} - p^k) = f(t^{k+1}) - f(t^k), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0. \end{cases} \tag{2.7}$$

Note that in this form the projection step can be solved easily as a weak Poisson problem as follows:

$$\begin{cases} \text{Find } p^{k+1} \text{ in } H^1(\Omega)/\mathbb{R} \text{ such that } \forall q \text{ in } H^1(\Omega)/\mathbb{R} \\ (\nabla(p^{k+1} - p^k), \nabla q) = (f(t^{k+1}) - f(t^k) + \frac{1}{2\delta t}(7\tilde{u}^k - 5\tilde{u}^{k-1} + \tilde{u}^{k-2}), \nabla q). \end{cases} \tag{2.8}$$

Once the pressure is known, the new viscous velocity $\tilde{u}^{k+1}$ is evaluated by solving

$$\begin{cases} \frac{1}{2\delta t}(3\tilde{u}^{k+1} - 4\tilde{u}^k + \tilde{u}^{k-1}) - \nabla^2\tilde{u}^{k+1} + \nabla p^{k+1} = f(t^{k+1}), \\ \tilde{u}^{k+1}|_\Gamma = 0. \end{cases} \tag{2.9}$$

Note that the projected velocity u^{k+1} has been completely eliminated from the algorithm (2.8)–(2.9); hence, it is not necessary to evaluate this quantity, i.e., $\tilde{u}^{k+1}$ is the approximate velocity to be considered in practice.

2.3. The time continuous version: A singularly perturbed PDE. Just as in the pressure-correction case (cf., e.g., [11, 14]), the behavior of the error for the velocity-correction scheme (2.7)–(2.9) is determined by the corresponding singularly perturbed system:

$$\partial_t u^\varepsilon - \nabla^2 u^\varepsilon + \nabla p^\varepsilon = f, \qquad u^\varepsilon|_\Gamma = 0, \tag{2.10}$$

$$\nabla\cdot(u^\varepsilon - \varepsilon(\nabla p_t^\varepsilon - f_t)) = 0, \qquad \left(\frac{\partial p_t^\varepsilon}{\partial n} - f_t\cdot n\right)\Big|_\Gamma = 0, \tag{2.11}$$

$$u^\varepsilon|_{t=0} = \mathsf{u}(0),\ p^\varepsilon|_{t=0} = \mathsf{p}(0). \tag{2.12}$$

Note that (2.11) is obtained by taking the divergence of (2.7) and letting $\delta t \to 0$. Its singular nature comes from the nonphysical boundary condition $(\frac{\partial p_t^\varepsilon}{\partial n} - f_t\cdot n)|_\Gamma = 0$, which introduces a numerical boundary layer for the pressure.

The following theorem characterizes the errors $\mathsf{u} - u^\varepsilon$ and $\mathsf{p} - p^\varepsilon$.

Theorem 2.1. *If the solution of* (1.1) *is sufficiently smooth, we have*

$$\|\mathsf{u} - u^\varepsilon\|_{L^2(L^2)} + \varepsilon^{\frac14}\|\mathsf{u} - u^\varepsilon\|_{L^\infty(L^2)} + \varepsilon^{\frac12}(\|\mathsf{u} - u^\varepsilon\|_{L^\infty(H^1)} + \|\mathsf{p} - p^\varepsilon\|_{L^\infty(L^2)}) \le c\varepsilon.$$

Proof. We shall first derive some a priori estimates.

We denote $e = \mathsf{u} - u^\varepsilon$ and $q = \mathsf{p} - p^\varepsilon$. Subtracting (2.10) from (1.1), we find

$$\begin{cases} e_t - \nabla^2 e + \nabla q = 0, \quad e|_\Gamma = 0, \\ \nabla\cdot e = -\varepsilon\nabla\cdot(\nabla p_t^\varepsilon - f_t) = \epsilon\nabla\cdot\nabla q_t - \epsilon\nabla\cdot(\nabla\partial_t\mathsf{p} - f_t), \quad (\frac{\partial p_t^\varepsilon}{\partial n} - f_t\cdot n)|_\Gamma = 0, \end{cases} \tag{2.13}$$

with $e(0) = 0$ and $q(0) = 0$. Taking the inner product of (2.13) with (e, q), we find

$$\begin{aligned} \frac12 d_t\|e\|_{0,\Omega}^2 + \|\nabla e\|_{0,\Omega}^2 + \frac{\varepsilon}{2} d_t\|\nabla q\|_{0,\Omega}^2 &= \varepsilon(\nabla\partial_t\mathsf{p} - f_t, \nabla q) \\ &\le \frac{\varepsilon}{2}\|\nabla\partial_t\mathsf{p} - f_t\|_{0,\Omega}^2 + \frac{\varepsilon}{2}\|\nabla q\|_{0,\Omega}^2. \end{aligned}$$

Thus, an application of the Gronwall lemma leads to

$$\|e(t)\|_{0,\Omega}^2 + \varepsilon\|\nabla q(t)\|_{0,\Omega}^2 + \int_0^t \|\nabla e\|_{0,\Omega}^2 ds \le c\varepsilon. \tag{2.14}$$

Now, noticing that $e(0) = 0$ and $q(0) = 0$ imply that $e_t(0) = 0$, we can repeat the computation above to obtain

$$\|e_t(t)\|_{0,\Omega}^2 + \varepsilon\|\nabla q_t(t)\|_{0,\Omega}^2 + \int_0^t \|\nabla e_t\|_{0,\Omega}^2 ds \le c\varepsilon, \tag{2.15}$$

which implies, in particular, that

$$\|u_t^\varepsilon\|_{L^\infty(L^2)} + \|\nabla p_t^\varepsilon\|_{L^\infty(L^2)} \le c. \tag{2.16}$$

We are now in position to derive the desired error estimates. Consider the following parabolic dual problem:

$$\begin{cases} w_t + \nabla^2 w + \nabla r = e(s), \quad s \in (0, t), \\ \nabla\cdot w = 0, \\ w|_\Gamma = 0, \quad w(t) = 0. \end{cases} \tag{2.17}$$

It is well known (and an easy matter to show) that

$$\int_0^t (\|w\|_{2,\Omega}^2 + \|\nabla r\|_{0,\Omega}^2) ds \le c \int_0^t \|e(s)\|_{0,\Omega}^2 ds. \tag{2.18}$$

Taking the inner product of (2.17) with $e(s)$ and using the error equation (2.13) and the fact that $\nabla \cdot w = 0$, we infer

$$\begin{aligned} \|e\|_{0,\Omega}^2 &= (e, w_t) + (e, \nabla^2 w) + (\nabla r, e) \\ &= d_t(e,w) - (e_t, w) + (\nabla^2 e, w) - (r, \nabla \cdot e) \\ &= d_t(e,w) - \varepsilon(\nabla r, \nabla(p_t^\varepsilon - f_t)). \end{aligned} \tag{2.19}$$

Integrating the equation above on the interval $[0,t]$, we find

$$\int_0^t \|e\|_{0,\Omega}^2 ds \le \varepsilon \left(\int_0^t \|\nabla r\|_{0,\Omega}^2 ds \right)^{\frac{1}{2}} \left(\int_0^t \|\nabla (p_t^\varepsilon - f_t)\|_{0,\Omega}^2 ds \right)^{\frac{1}{2}}.$$

Using this bound together with (2.16) and (2.18), we finally obtain

$$\|e\|_{L^2(L^2)} \le c\varepsilon.$$

Next, we consider a second parabolic dual problem:

$$\begin{cases} w_t + \nabla^2 w + \nabla r = e_t(s), \quad s \in (0,t), \\ \nabla \cdot w = 0, \\ w|_\Gamma = 0, \quad w(t) = 0. \end{cases} \tag{2.20}$$

Owing to (2.15), we have

$$\int_0^t (\|w\|_{2,\Omega}^2 + \|\nabla r\|_{0,\Omega}^2) ds \le c \int_0^t \|e_t(s)\|_{0,\Omega}^2 ds \le c\varepsilon. \tag{2.21}$$

Taking the inner product of (2.20) with $e(s)$, and proceeding in the same fashion as above, we find

$$\frac{1}{2} d_t \|e\|_{0,\Omega}^2 = d_t(e,w) - (r, \nabla \cdot e) = d_t(e,w) - \varepsilon(\nabla r, \nabla(p_t^\varepsilon - f_t)). \tag{2.22}$$

Integrating this equation in time and using (2.21), we deduce

$$\|e(t)\|_{0,\Omega}^2 \le 2\varepsilon \left(\int_0^t \|\nabla r\|_{0,\Omega}^2 ds \right)^{\frac{1}{2}} \left(\int_0^t \|\nabla (p_t^\varepsilon - f_t)\|_{0,\Omega}^2 ds \right)^{\frac{1}{2}} \le c\varepsilon^{\frac{3}{2}}.$$

To estimate $\|e\|_{L^\infty(H^1)}$, we take the inner product of the first equation in (2.13) with e_t as follows:

$$\begin{aligned} \|e_t\|_{0,\Omega}^2 + \frac{1}{2} d_t \|\nabla e\|_{0,\Omega}^2 &= (q, \nabla \cdot e_t) = \varepsilon(\nabla q, \partial_t \nabla (p_t^\varepsilon - f_t)) \\ &= \varepsilon d_t (\nabla q, \nabla(p_t^\varepsilon - f_t)) - \varepsilon(\nabla q_t, \nabla(p_t^\varepsilon - f_t)). \end{aligned} \tag{2.23}$$

Integrating this equation in time and using the a priori estimates in (2.16), we obtain

$$\|e_t\|_{L^2(L^2)}^2 + \|\nabla e\|_{L^\infty(L^2)}^2 \le C\varepsilon(\|\nabla q\|_{L^\infty(L^2)} + \|\nabla q_t\|_{L^2(L^2)}) \|\nabla(p_t^\varepsilon - f_t)\|_{L^\infty(L^2)} \le c\varepsilon.$$

Finally, using the estimate above and (2.15), we derive

$$\|q\|_{L^\infty(L^2)} \le c\varepsilon^{\frac{1}{2}}.$$

The proof is now complete. □

2.4. Error estimates for the standard velocity-correction scheme. In this section we derive error estimates for the standard velocity-correction scheme (2.3)–(2.4). Hereafter we assume that the following nonessential initialization hypothesis holds:

$$\text{(H)} \quad \begin{cases} \|\mathsf{u}(\delta t) - \tilde{u}^1\|_{0,\Omega} \le c\delta t^2, \\ \|\mathsf{u}(\delta t) - \tilde{u}^1\|_{1,\Omega} \le c\delta t^{3/2}, \\ \|\mathsf{u}(\delta t) - \tilde{u}^1\|_{2,\Omega} \le c\delta t. \end{cases}$$

Remark 2.1. We point out that this hypothesis would hold, in particular, if $(\tilde{u}^1, u^1, p^1)$ were obtained by using a first-order velocity-correction projection scheme. This would amount to replacing the second-order BDF (backward difference formula) time stepping in (2.3) with the backward Euler time stepping at the very first time step.

THEOREM 2.2. *Under the initialization hypothesis* (H) *and provided that the solution to* (1.1) *is smooth enough in time and space, the solution* $(u^k, \tilde{u}^k, p^k)$ *to* (2.3)–(2.4) *is such that*

$$\begin{aligned} \|\mathsf{u} - u\|_{l^2(L^2(\Omega)^d)} + \|\mathsf{u} - \tilde{u}\|_{l^2(L^2(\Omega)^d)} &\le c(\mathsf{u}, \mathsf{p}, T)\, \delta t^2, \\ \|\mathsf{u} - u\|_{l^\infty(L^2(\Omega)^d)} + \|\mathsf{u} - \tilde{u}\|_{l^\infty(L^2(\Omega)^d)} &\le c(\mathsf{u}, \mathsf{p}, T)\, \delta t^{\frac{3}{2}}, \\ \|\mathsf{u} - \tilde{u}\|_{l^\infty(H^1(\Omega)^d)} + \|\mathsf{p} - p\|_{l^\infty(L^2(\Omega))} &\le c(\mathsf{u}, \mathsf{p}, T)\, \delta t. \end{aligned}$$

Note that the discrete norms in the theorem above, and subsequently in later sections, are defined in (1.5). By comparing the time discrete version (2.3)–(2.4) and the time continuous version (2.10)–(2.12), one observes that ε in (2.10)–(2.12) corresponds to δt^2 in (2.3)–(2.4). Thus, the results of Theorem 2.2 are fully consistent with those of Theorem 2.1.

The proof of Theorem 2.2 follows exactly the same procedure as the proof of Theorem 2.1 but for the time discretization. The main technical difficulty comes from the treatment of the second-order BDF term, which will be treated in detail in the proof of Theorem 3.1. Thus, we omit the proof here to avoid unnecessary repetition.

3. Velocity-correction method: Rotational form.

3.1. Introduction of the scheme. The main obstacle in proving error estimates better than first-order on the velocity in the H^1-norm and the pressure in the L^2-norm comes from the fact that the algorithm enforces the nonphysical pressure Neumann boundary condition (2.6). This phenomenon is reminiscent of the numerical boundary layer induced by the nonphysical boundary condition $\partial_n p^{k+1}|_\Gamma = \cdots = \partial_n p^0|_\Gamma$ enforced by the pressure-correction method in its standard form; cf. [14, 7]. Thus, in order to obtain better approximation for the pressure, we need to correct this nonphysical boundary condition. Considering the identity $\nabla^2\tilde{u}^k = \nabla\nabla\cdot\tilde{u}^k - \nabla\times\nabla\times\tilde{u}^k$ and the fact that we are searching for divergence-free solutions, we are led to replace $-\nabla^2\tilde{u}^k$ in (2.3)–(2.4) with $\nabla\times\nabla\times\tilde{u}^k$. The new scheme is as follows:

$$(3.1) \qquad \begin{cases} \frac{1}{2\delta t}(3u^{k+1} - 4\tilde{u}^k + \tilde{u}^{k-1}) + \nabla\times\nabla\times\tilde{u}^k + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0 \end{cases}$$

and

$$\left\{\begin{array}{l}\frac{3}{2\delta t}(\tilde{u}^{k+1}-u^{k+1})-\nabla^2\tilde{u}^{k+1}-\nabla\times\nabla\times\tilde{u}^k=0,\\ \tilde{u}^{k+1}|_\Gamma=0.\end{array}\right. \tag{3.2}$$

This scheme is hereafter referred to as the rotational form of the velocity-correction algorithm.

Observing from (3.2) that $(\nabla^2\tilde{u}^{k+1}+\nabla\times\nabla\times\tilde{u}^k)\cdot n|_\Gamma=0$, we derive from (3.1) that

$$\left.\frac{\partial p^{k+1}}{\partial n}\right|_\Gamma=(f(t^{k+1})+\nabla^2\tilde{u}^{k+1})\cdot n|_\Gamma, \tag{3.3}$$

which, unlike (2.6), is a consistent Neumann boundary condition for the pressure. This is the main reason why the rotational form yields a much better pressure approximation than the standard form.

3.2. Implementation of the rotational form. As in the standard form of the method, the projection step (3.1) cannot be solved as a weak Poisson problem when working with H^1-conformal finite elements, for there is a second derivative in the right-hand side. This difficulty can be solved once more by making algebraic substitutions.

By subtracting step (3.1) at time t^k from step (3.1) at time t^{k+1} and by substituting step (3.2) at time t^k into the resulting equation, a more adequate form of the projection step is obtained:

$$\left\{\begin{array}{l}\frac{1}{2\delta t}(3u^{k+1}-7\tilde{u}^k+5\tilde{u}^{k-1}-\tilde{u}^{k-2})+\nabla(p^{k+1}-p^k+\nabla\cdot\tilde{u}^k)\\ \qquad=f(t^{k+1})-f(t^k),\\ \nabla\cdot u^{k+1}=0,\\ u^{k+1}\cdot n|_\Gamma=0.\end{array}\right. \tag{3.4}$$

The new viscous velocity $\tilde{u}^{k+1}$ is evaluated by solving

$$\left\{\begin{array}{l}\frac{1}{2\delta t}(3\tilde{u}^{k+1}-4\tilde{u}^k+\tilde{u}^{k-1})-\nabla^2\tilde{u}^{k+1}+\nabla p^{k+1}=f(t^{k+1}),\\ \tilde{u}^{k+1}|_\Gamma=0.\end{array}\right. \tag{3.5}$$

Note that the new form of the projection step is still not satisfactory since a second derivative remains in the form of the term $\nabla\nabla\cdot\tilde{u}^k$. To remove this final difficulty, we introduce an auxiliary pressure $\phi^{k+1}=p^{k+1}-p^k+\nabla\cdot\tilde{u}^k$. The final algorithm is as follows:

$$\left\{\begin{array}{l}\frac{1}{2\delta t}(3u^{k+1}-7\tilde{u}^k+5\tilde{u}^{k-1}-\tilde{u}^{k-2})+\nabla\phi^{k+1}=f(t^{k+1})-f(t^k),\\ \nabla\cdot u^{k+1}=0,\\ u^{k+1}\cdot n|_\Gamma=0,\end{array}\right. \tag{3.6}$$

$$p^{k+1}=\phi^{k+1}+p^k-\nabla\cdot\tilde{u}^k, \tag{3.7}$$

$$\left\{\begin{array}{l}\frac{1}{2\delta t}(3\tilde{u}^{k+1}-4\tilde{u}^k+\tilde{u}^{k-1})-\nabla^2\tilde{u}^{k+1}=f(t^{k+1})-\nabla p^{k+1},\\ \tilde{u}^{k+1}|_\Gamma=0.\end{array}\right. \tag{3.8}$$

In practice, the projection step is processed as follows:

$$\left\{\begin{array}{l}\text{Find } \phi^{k+1} \text{ in } H^1(\Omega)/\mathbb{R} \text{ such that } \forall q \text{ in } H^1(\Omega)/\mathbb{R},\\ (\nabla\phi^{k+1},\nabla q)=(f(t^{k+1})-f(t^k)+\frac{1}{2\delta t}(7\tilde{u}^k-5\tilde{u}^{k-1}+\tilde{u}^{k-2}),\nabla q).\end{array}\right. \tag{3.9}$$

Note once again that the projected velocity u^{k+1} has been eliminated from the algorithm.

3.3. A time continuous version. We emphasize that it is informative to study the time continuous version of the scheme, since it both reveals the behavior of the splitting error and indicates the procedure to follow for obtaining stability and convergence results on the discrete system.

By neglecting some small terms, the following can be considered an "approximate" time continuous version of the scheme (3.6)–(3.8):

$$\partial_t u^\varepsilon - \nabla^2 u^\varepsilon + \nabla p^\varepsilon = f, \qquad u^\varepsilon|_\Gamma = 0, \tag{3.10}$$

$$\nabla\cdot u^\varepsilon - \varepsilon\nabla\cdot(\nabla\phi - \varepsilon f_t) = 0, \qquad (\nabla\phi - \varepsilon f_t)\cdot n|_\Gamma = 0, \tag{3.11}$$

$$\phi = \varepsilon p_t^\varepsilon + \nabla\cdot u^\varepsilon, \tag{3.12}$$

with $u^\varepsilon(0) = \mathsf{u}(0)$ and $p^\varepsilon(0) = \mathsf{p}(0)$. Note that (3.10) and (3.12) correspond, respectively, to (3.8) and (3.7), while (3.11) corresponds to the divergence of (3.6), and $\varepsilon \sim \Delta t$.

Without going into the full details of proving the well-posedness of (3.10)–(3.12) and providing a detailed error analysis as we did for (2.10)–(2.12), we just indicate how to derive the first a priori estimate. This will guide us to prove the stability of the discrete scheme and will show that this scheme provides a better control on the divergence of the approximate velocity.

Taking the inner product of $\varepsilon u_t^\varepsilon$ with the time derivative of (3.10), we find

$$\begin{aligned}\frac{\varepsilon}{2}d_t\|u_t^\varepsilon\|_{0,\Omega}^2 + \varepsilon\|\nabla u_t^\varepsilon\|_{0,\Omega}^2 &= \varepsilon(u_t^\varepsilon, f_t) + \varepsilon(p_t^\varepsilon, \nabla\cdot u_t^\varepsilon)\\ &= \varepsilon(u_t^\varepsilon, f_t) - (\nabla\cdot u^\varepsilon - \phi, \nabla\cdot u_t^\varepsilon)\\ &= \varepsilon(u_t^\varepsilon, f_t) - \frac{1}{2}d_t\|\nabla\cdot u^\varepsilon\|_{0,\Omega}^2 + (\phi, \nabla\cdot u_t^\varepsilon).\end{aligned}$$

Noting that

$$(\phi, \nabla\cdot u_t^\varepsilon) = (\phi, \varepsilon\nabla^2\phi_t - \varepsilon^2\nabla\cdot f_t) = -\frac{\varepsilon}{2}d_t\|\nabla\phi\|_{0,\Omega}^2 + \varepsilon^2(\nabla\phi, f_t),$$

we obtain

$$\frac{\varepsilon}{2}d_t\|u_t^\varepsilon\|_{0,\Omega}^2 + \varepsilon\|\nabla u_t^\varepsilon\|_{0,\Omega}^2 + \frac{1}{2}d_t\|\nabla\cdot u^\varepsilon\|_{0,\Omega}^2 + \frac{\varepsilon}{2}d_t\|\nabla\phi\|_{0,\Omega}^2 = \varepsilon(u_t^\varepsilon, f_t) + \varepsilon^2(\nabla\phi, f_t).$$

Using the fact that the initial data are such that $u_t^\varepsilon(0) = f(0) + \nabla^2 u^\varepsilon(0) - \nabla p^\varepsilon(0) = f(0) + \nabla^2\mathsf{u}(0) - \nabla\mathsf{p}(0)$, the Gronwall lemma yields

$$\|u_t^\varepsilon(t)\|_{0,\Omega}^2 + \|\nabla\phi(t)\|_{0,\Omega}^2 + \frac{1}{\varepsilon}\|\nabla\cdot u^\varepsilon(t)\|_{0,\Omega}^2 + \int_0^t \|\nabla u_t^\varepsilon\|_{0,\Omega}^2 ds \le c, \qquad t \in [0,T].$$

Let us define $e = \mathsf{u} - u^\varepsilon$ and $\psi = \varepsilon\partial_t(\mathsf{p} - p^\varepsilon) + \nabla\cdot u^\varepsilon$. By working with the error equation, the above results become

$$\|e_t(t)\|_{0,\Omega}^2 + \|\nabla\psi(t)\|_{0,\Omega}^2 + \frac{1}{\varepsilon}\|\nabla\cdot u^\varepsilon(t)\|_{0,\Omega}^2 + \int_0^t \|\nabla e_t\|_{0,\Omega}^2 ds \le c\varepsilon^2, \qquad t \in [0,T].$$

A remarkable consequence, which is essential for obtaining improved error estimates, is that we have

$$\|\nabla\cdot u^\varepsilon\|_{L^\infty(L^2)} \leq c\varepsilon^{\frac{3}{2}}. \tag{3.13}$$

3.4. Error analysis. We now turn our attention to the error analysis of the discrete scheme (3.1)–(3.2). The main result in this section is the following.

THEOREM 3.1. *Under the initialization hypothesis* (H)*, if* (u,p)*, the solution to* (1.1)*, is smooth enough in time and space, the solution* $(u^k,\tilde{u}^k,p^k)$ *to* (3.1)–(3.2) *satisfies the estimates*

$$\|\mathsf{u}-u\|_{l^2(L^2(\Omega)^d)} + \|\mathsf{u}-\tilde{u}\|_{l^2(L^2(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^2,$$
$$\|\mathsf{u}-\tilde{u}\|_{l^2(H^1(\Omega)^d)} + \|\mathsf{p}-p\|_{l^2(L^2(\Omega))} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^{3/2}.$$

The remainder of this section is devoted to the proof of the above theorem. Let us introduce some notation. For any sequence $\phi^0,\phi^1,\dots$, we set

$$\delta_t\phi^k = \phi^k - \phi^{k-1}, \quad \delta_{tt}\phi^k = \delta_t(\delta_t\phi^k), \quad \delta_{ttt}\phi^k = \delta_t(\delta_{tt}\phi^k).$$

For any sequence of functions in $H_0^1(\Omega)^d \cap H^2(\Omega)^d$, say $\phi^0,\phi^1,\dots$, we set

$$D_t\phi^k = -\nabla^2\phi^k - \nabla\times\nabla\times\phi^{k-1}.$$

We shall make use of the following identity:

$$\forall\beta\in H_0^1(\Omega)^d, \qquad (D_t\phi^{k+1},\beta) = (\nabla\cdot\phi^{k+1},\nabla\cdot\beta) + (\nabla\times\delta_t\phi^{k+1},\nabla\times\beta). \tag{3.14}$$

Hereafter we shall make use of the following notation:

$$\left\{\begin{array}{rcl} e^k &=& \mathsf{u}(t^k) - u^k, \\ \tilde{e}^k &=& \mathsf{u}(t^k) - \tilde{u}^k, \\ \tilde{\psi}^k &=& \mathsf{u}(t^{k+1}) - \tilde{u}^k, \\ \epsilon^k &=& \mathsf{p}(t^k) - p^k. \end{array}\right. \tag{3.15}$$

The proof of Theorem 3.1 will be carried out through a sequence of estimates presented below.

3.4.1. Stability and the improved estimate on $\|\nabla\cdot\tilde{u}^k\|_{0,\Omega}$.

LEMMA 3.1. *Provided that the solution of* (1.1) *is smooth enough in space and time and satisfies the initialization hypothesis* (H)*, then we have the following error estimates:*

$$\|\nabla\cdot\tilde{u}\|_{l^\infty(L^2(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^{3/2},$$
$$\|\tilde{e}-e\|_{l^\infty(L^2(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^2,$$
$$\|\delta_t\tilde{e}-\delta_t e\|_{l^2(L^2(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^{5/2}.$$

Proof. The proof of this lemma follows the procedure set out in section 3.3 for the time continuous counterpart of the scheme. The critical step here consists of working with the time increments $\delta_t e^{k+1}$ and $\delta_t\tilde{e}^{k+1}$, which corresponds to taking the inner product of $\varepsilon\partial_t u^\varepsilon$ with the time derivative of (3.10).

Step 1: Let us first write the equations that control the time increments of the errors. By defining $R^k = \partial_t \mathsf{u}(t^k) - (3\mathsf{u}(t^k) - 4\mathsf{u}(t^{k-1}) + \mathsf{u}(t^{k-2}))/2\delta t$, we have for $k \geq 2$

$$\left\{\begin{array}{l} \frac{1}{2\delta t}(3\delta_t e^{k+1} - 4\delta_t \tilde{e}^k + \delta_t \tilde{e}^{k-1}) + D_t\tilde{\psi}^k + \nabla(\delta_t \epsilon^{k+1} + \nabla\cdot\tilde{u}^k) = \delta_t R^{k+1}, \\ \nabla\cdot\delta_t e^{k+1} = 0, \\ \delta_t e^{k+1}\cdot n|_\Gamma = 0, \end{array}\right. \tag{3.16}$$

$$\left\{\begin{array}{l} \frac{3}{2\delta t}\delta_t \tilde{e}^{k+1} + D_t\tilde{e}^{k+1} = \frac{3}{2\delta t}\delta_t e^{k+1} + D_t\tilde{\psi}^k, \\ \tilde{e}^{k+1}|_\Gamma = 0. \end{array}\right. \tag{3.17}$$

Step 2: Let us multiply (3.16) by $4\delta t\delta_t e^{k+1}$ and integrate over Ω. We obtain

$$\begin{aligned} 2(\delta_t e^{k+1}, 3\delta_t e^{k+1} - 4\delta_t \tilde{e}^k + \delta_t \tilde{e}^{k-1}) + 4\delta t(\delta_t e^{k+1}, D_t\tilde{\psi}^k) &= 4\delta t(\delta_t e^{k+1}, \delta_t R^{k+1}) \\ &\leq 4\delta t(\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|_{0,\Omega} + \|\delta_t\tilde{e}^{k+1}\|_{0,\Omega})\|\delta_t R^{k+1}\|_{0,\Omega} \\ &\leq \delta t\|\delta_t\tilde{e}^{k+1}\|^2_{1,\Omega} + \delta t\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + c\delta t^7, \end{aligned}$$

where we have used the Poincaré inequality and the fact that $\|\delta_t R^{k+1}\|_{0,\Omega} \leq c\delta t^3$. Note also that we have used the inequality $2ab \leq \gamma a^2 + b^2/\gamma$, which holds for all $\gamma > 0$. We shall repeatedly use this standard trick hereafter without mentioning it anymore.

Since the treatment of the approximate time derivative is quite involved, we show the details. Let us define

$$\begin{aligned} I &= 2(\delta_t e^{k+1}, 3\delta_t e^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}) \\ &= 6(\delta_t e^{k+1}, \delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}) + 2(\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}, 3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}) \\ &\quad + 2(\delta_t\tilde{e}^{k+1}, 3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}) \end{aligned}$$

and denote by I_1, I_2, and I_3 the three terms in the right-hand side. Owing to the standard identities

$$\begin{aligned} 2(a^{k+1}, a^{k+1} - a^k) &= |a^{k+1}|^2 + |a^{k+1} - a^k|^2 - |a^k|^2, \\ 2(a^{k+1}, 3a^{k+1} - 4a^k + a^{k-1}) &= |a^{k+1}|^2 + |2a^{k+1} - a^k|^2 + |\delta_{tt}a_{k+1}|^2 \\ &\quad - |a^k|^2 - |2a^k - a^{k-1}|^2, \end{aligned} \tag{3.18}$$

we deduce

$$\begin{aligned} I_1 &= 3\|\delta_t e^{k+1}\|^2_{0,\Omega} + 3\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} - 3\|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega}, \\ I_3 &= \|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \|2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^k\|^2_{0,\Omega} + \|\delta_{ttt}\tilde{e}^{k+1}\|^2_{0,\Omega} \\ &\quad - \|\delta_t\tilde{e}^k\|^2_{0,\Omega} - \|2\delta_t\tilde{e}^k - \delta_t\tilde{e}^{k-1}\|^2_{0,\Omega}. \end{aligned}$$

For the remaining term I_2, we make use of (3.17) as follows:

$$\frac{3}{2\delta t}I_2 = 2(D_t\tilde{e}^{k+1} - D_t\tilde{\psi}^k, 3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}).$$

Using the relation $\tilde{\psi}^k = \delta_t\mathsf{u}(t^{k+1}) + \tilde{e}^k$, we obtain

$$\begin{aligned} \frac{3}{2\delta t}I_2 &= 2(D_t\delta_t\tilde{e}^{k+1}, 3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}) \\ &\quad - 2(D_t\delta_t\mathsf{u}(t^{k+1}), 3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}). \end{aligned}$$

By denoting as I_{21} and I_{22} the two terms in the right-hand side, and by using the identities (3.14) and (3.18), we infer

$$\begin{aligned}
I_{21} &= 2(\nabla\cdot\delta_t\tilde{e}^{k+1}, \nabla\cdot(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^{k} + \delta_t\tilde{e}^{k-1}))\\
&\quad + 2(\nabla\times\delta_{tt}\tilde{e}^{k+1}, 3\nabla\times\delta_{tt}\tilde{e}^{k+1} - \nabla\times\delta_{tt}\tilde{e}^{k})\\
&= \|\nabla\cdot\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \|\nabla\cdot(2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^{k})\|^2_{0,\Omega} + \|\nabla\cdot(\delta_{ttt}\tilde{e}^{k+1})\|^2_{0,\Omega}\\
&\quad - \|\nabla\cdot\delta_t\tilde{e}^{k}\|^2_{0,\Omega} - \|\nabla\cdot(2\delta_t\tilde{e}^{k} - \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega} + 3\|\nabla\times\delta_{tt}\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&\quad + \frac{1}{3}\|\nabla\times(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^{k} + \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega} - \frac{1}{3}\|\nabla\times\delta_{tt}\tilde{e}^{k}\|^2_{0,\Omega},\\
I_{22} &= -\,2(\nabla\times\delta_{tt}\mathsf{u}(t^{k+1}), \nabla\times(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^{k} + \delta_t\tilde{e}^{k-1}))\\
&\geq -\,c\delta t^4 - \frac{1}{6}\|\nabla\times(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^{k} + \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega}.
\end{aligned}$$

By combining all the results above, we deduce the following bound:

$$\begin{aligned}
3\|\delta_t e^{k+1}\|^2_{0,\Omega} &- 3\|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + 3(1-\delta t)\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&+ \|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \|2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^{k}\|^2_{0,\Omega} + \|\delta_{ttt}\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&+ \frac{2\delta t}{3}\Big(\|\nabla\cdot\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \|\nabla\cdot(2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^{k})\|^2_{0,\Omega} + \|\nabla\cdot(\delta_{ttt}\tilde{e}^{k+1})\|^2_{0,\Omega}\\
&\qquad + 3\|\nabla\times\delta_{tt}\tilde{e}^{k+1}\|^2_{0,\Omega} + \frac{1}{6}\|\nabla\times(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^{k} + \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega}\Big)\\
&+ 4\delta t(\delta_t e^{k+1}, D_t\tilde{\psi}^k)\\
&\leq \ \delta t\|\delta_t\tilde{e}^{k+1}\|^2_{1,\Omega} + \|\delta_t\tilde{e}^{k}\|^2_{0,\Omega} + \|2\delta_t\tilde{e}^{k} - \delta_t\tilde{e}^{k-1}\|^2_{0,\Omega}\\
&+ \frac{2\delta t}{3}\left(\|\nabla\cdot\delta_t\tilde{e}^{k}\|^2_{0,\Omega} + \|\nabla\cdot(2\delta_t\tilde{e}^{k} - \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega} + \frac{1}{3}\|\nabla\times\delta_{tt}\tilde{e}^{k}\|^2_{0,\Omega}\right)\\
&+ c\delta t^5.
\end{aligned}$$

Step 3: By taking the square of (3.17), multiplying the result by $\frac{4}{3}\delta t^2$, and integrating over the domain, we have

$$\begin{aligned}
3\|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} &+ 4\delta t(\delta_t\tilde{e}^{k+1}, D_t\tilde{e}^{k+1}) + \frac{4\delta t^2}{3}\|D_t\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&= 3\|\delta_t e^{k+1}\|^2_{0,\Omega} + 4\delta t(\delta_t e^{k+1}, D_t\tilde{\psi}^k) + \frac{4\delta t^2}{3}\|D_t\tilde{\psi}^k\|^2_{0,\Omega}.
\end{aligned}$$

Owing to (3.14), we deduce

$$\begin{aligned}
3\|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} &- 3\|\delta_t e^{k+1}\|^2_{0,\Omega} + 2\delta t\|\nabla\cdot\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&+ 2\delta t\|\nabla\cdot\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + 4\delta t\|\nabla\times\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \frac{4\delta t^2}{3}\|D_t\tilde{e}^{k+1}\|^2_{0,\Omega}\\
&= 2\delta t\|\nabla\cdot\tilde{e}^{k}\|^2_{0,\Omega} + 4\delta t(\delta_t e^{k+1}, D_t\tilde{\psi}^k) + \frac{4\delta t^2}{3}\|D_t\tilde{\psi}^k\|^2_{0,\Omega}.
\end{aligned}$$

A control on $\|D_t\tilde{\psi}^k\|^2_{0,\Omega}$ is obtained as follows:

$$\begin{aligned}
\|D_t\tilde{\psi}^k\|^2_{0,\Omega} &\leq \big(\|D_t\delta_t\mathsf{u}(t^{k+1})\|_{0,\Omega} + \|D_t\tilde{e}^k\|_{0,\Omega}\big)^2\\
&\leq \big(c\delta t^2 + \|D_t\tilde{e}^k\|_{0,\Omega}\big)^2 = c^2\delta t^4 + 2\delta t c\delta t\|D_t\tilde{e}^k\|_{0,\Omega} + \|D_t\tilde{e}^k\|^2_{0,\Omega}\\
&\leq c^2\delta t^4 + \delta t\big(c^2\delta t^2 + \|D_t\tilde{e}^k\|^2_{0,\Omega}\big) + \|D_t\tilde{e}^k\|^2_{0,\Omega}\\
&\leq c\delta t^3 + (1+\delta t)\|D_t\tilde{e}^k\|^2_{0,\Omega}.
\end{aligned}$$

Note that it is at this very point that the splitting error spoils the optimality. Finally, we have

$$\begin{aligned} 3\|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} - 3\|\delta_t e^{k+1}\|^2_{0,\Omega} + 2\delta t\|\nabla\cdot\tilde{e}^{k+1}\|^2_{0,\Omega} + 2\delta t\|\delta_t\tilde{e}^{k+1}\|^2_{1,\Omega} + \frac{4\delta t^2}{3}\|D_t\tilde{e}^{k+1}\|^2_{0,\Omega} \\ \leq 2\delta t\|\nabla\cdot\tilde{e}^{k}\|^2_{0,\Omega} + 4\delta t(\delta_t e^{k+1}, D_t\tilde{\psi}^k) + \frac{4\delta t^2}{3}(1+\delta t)\|D_t\tilde{e}^{k}\|^2_{0,\Omega} + c\delta t^5. \end{aligned}$$

Step 4: By combining the bounds obtained at Steps 2 and 3, and by dropping some nonessential positive terms on the left-hand side, we finally deduce

$$\begin{aligned} \|\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} &+ \|2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^{k}\|^2_{0,\Omega} + 2\delta t\|\nabla\cdot\tilde{e}^{k+1}\|^2_{0,\Omega} + \frac{4\delta t^2}{3}\|D_t\tilde{e}^{k+1}\|^2_{0,\Omega} \\ &+ \frac{2\delta t}{3}\left(\|\nabla\cdot\delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \|\nabla\cdot(2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^{k})\|^2_{0,\Omega} + \frac{1}{3}\|\nabla\times\delta_{tt}\tilde{e}^{k+1}\|^2_{0,\Omega}\right) \\ &+ 3(1-\delta t)\|\delta_t e^{k+1} - \delta_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \delta t\|\delta_t\tilde{e}^{k+1}\|^2_{1,\Omega} \\ \leq{}& \|\delta_t\tilde{e}^{k}\|^2_{0,\Omega} + \|2\delta_t\tilde{e}^{k} - \delta_t\tilde{e}^{k-1}\|^2_{0,\Omega} + 2\delta t\|\nabla\cdot\tilde{e}^{k}\|^2_{0,\Omega} + (1+\delta t)\frac{4\delta t^2}{3}\|D_t\tilde{e}^{k}\|^2_{0,\Omega} \\ &+ \frac{2\delta t}{3}\left(\nabla\cdot\delta_t\tilde{e}^{k^2} + \|\nabla\cdot(2\delta_t\tilde{e}^{k} - \delta_t\tilde{e}^{k-1})\|^2_{0,\Omega} + \frac{1}{3}\|\nabla\times\delta_{tt}\tilde{e}^{k}\|^2_{0,\Omega}\right) \\ &+ c\delta t^5. \end{aligned}$$

By applying the discrete Gronwall lemma and using the initialization hypothesis (H), we infer

$$\begin{aligned} \delta t\|\nabla\cdot\tilde{e}^{k+1}\|^2_{0,\Omega} + \delta t^2\|D_t\tilde{e}^{k+1}\|^2_{0,\Omega} + \sum_{l=0}^{k}\|\delta_t e^l - \delta_t\tilde{e}^l\|^2_{0,\Omega} \\ \leq c(\|\tilde{e}^2\|^2_{0,\Omega} + \delta t\|\tilde{e}^2\|^2_{1,\Omega} + \delta t^2\|\tilde{e}^2\|^2_{2,\Omega} + \delta t^4). \end{aligned}$$

Thanks to (H), it is an easy matter to show directly that

$$\|\tilde{e}^2\|^2_{0,\Omega} + \delta t\|\tilde{e}^2\|^2_{1,\Omega} + \delta t^2\|\tilde{e}^2\|^2_{2,\Omega} + \delta t^4 \leq c\delta t^4.$$

Finally, noticing that

$$\begin{aligned} \frac{3}{2}\|\tilde{e}^{k+1} - e^{k+1}\|_{0,\Omega} &= \delta t\|D_t\tilde{e}^{k+1} + \nabla\times\nabla\times\delta_t \mathsf{u}(t^{k+1})\|_{0,\Omega} \\ &\leq \delta t\|D_t\tilde{e}^{k+1}\|_{0,\Omega} + c\delta t^2, \end{aligned}$$

the desired result follows from the last three inequalities. □

Remark 3.1. The first result in the above lemma, namely, $\|\nabla\cdot\tilde{u}\|_{l^\infty(L^2)} \leq c\delta t^{\frac{3}{2}}$, is the key for obtaining error estimates that improve on those from the standard velocity-correction scheme. A remarkable property of the rotational velocity-correction scheme is that even if the time stepping in (3.1)–(3.2) is replaced by the first-order backward Euler stepping, the estimate on $\nabla\cdot\tilde{u}$ still holds.

3.4.2. The inverse of the Stokes operator. In this section we recall properties of the inverse of the Stokes operator that will be useful for proving estimates in the L^2-norm. This operator, which we shall denote by $S : H^{-1}(\Omega)^d \longrightarrow V$, is defined as follows. For all v in $H^{-1}(\Omega)^d$, $S(v) \in V$ is the solution to the following problem:

$$\begin{cases} (\nabla S(v), \nabla w) - (r, \nabla\cdot w) = \langle v, w\rangle \qquad \forall w \in H^1_0(\Omega)^d, \\ (q, \nabla\cdot S(v)) = 0 \qquad \forall q \in L^2_0(\Omega), \end{cases}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing between $H^{-1}(\Omega)^d$ and $H_0^1(\Omega)^d$. Obviously, we have

$$\forall v \in H^{-1}(\Omega)^d, \qquad \|S(v)\|_{1,\Omega} + \|r\|_{0,\Omega} \leq c\|v\|_{-1,\Omega}. \tag{3.19}$$

We shall assume hereafter that the domain Ω is such that the following regularity property holds:

$$\forall v \in L^2(\Omega)^d, \qquad \|S(v)\|_{2,\Omega} + \|r\|_{1,\Omega} \leq c\|v\|_{0,\Omega}. \tag{3.20}$$

The operator S has interesting properties, as listed below.

LEMMA 3.2. *For all v in $H_0^1(\Omega)^d$ and all $0 < \gamma < 1$ we have*

$$\forall v^\star \in H, \qquad (\nabla S(v), \nabla v) \geq (1-\gamma)\|v\|_{0,\Omega}^2 - c(\gamma)\|v - v^\star\|_{0,\Omega}^2.$$

In particular,

$$\forall v \in V, \qquad (\nabla S(v), \nabla v) = \|v\|_{0,\Omega}^2.$$

Proof. Owing to the definition of $S(v)$, we have

$$\begin{aligned}
(\nabla S(v), \nabla v) &= (r, \nabla\cdot v) + \|v\|_{0,\Omega}^2 \\
&= (r, \nabla\cdot(v - v^\star)) + \|v\|_{0,\Omega}^2 && \forall v^\star \in H \\
&= -(\nabla r, v - v^\star) + \|v\|_{0,\Omega}^2 \\
&\geq -\|r\|_{1,\Omega}\|v - v^\star\|_{0,\Omega} + \|v\|_{0,\Omega}^2 \\
&\geq -c(\gamma)\|v - v^\star\|_{0,\Omega}^2 + (1-\gamma)\|v\|_{0,\Omega}^2, && \text{owing to (3.20).}
\end{aligned}$$

This completes the proof. □

LEMMA 3.3. *The bilinear form*

$$H^{-1}(\Omega)^d \times H^{-1}(\Omega)^d \ni (v,w) \longmapsto \langle S(v), w\rangle := (\nabla S(v), \nabla S(w)) \in \mathbb{R}$$

induces a seminorm on $H^{-1}(\Omega)^d$ that we denote $|\cdot|_\star$, and

$$\forall v \in H^{-1}(\Omega)^d, \qquad |v|_\star = \|\nabla S(v)\|_{0,\Omega} \leq c\|v\|_{-1,\Omega}.$$

Proof. It is clear that it is symmetric $\langle S(v), w\rangle = (\nabla S(v), \nabla S(w)) = \langle S(w), v\rangle$ and positive $\langle S(v), v\rangle = \|\nabla S(v)\|_{0,\Omega}^2$; hence, $\langle S(v), w\rangle$ induces a seminorm on $H^{-1}(\Omega)^d$. Furthermore,

$$|v|_\star^2 = \langle S(v), v\rangle = (\nabla S(v), \nabla S(v)) = \|\nabla S(v)\|_{0,\Omega}^2 \leq c\|v\|_{-1,\Omega}^2.$$

The proof is complete. □

3.4.3. Proof of the L^2-estimate on the velocity. In this subsection we prove

$$\|\mathsf{u} - u\|_{l^2(L^2(\Omega)^d)} \leq c\delta t^2.$$

Proof. We begin by reconstructing the momentum equation at time t^{k+1} by adding the projection step to the viscous step. In terms of the errors, we obtain

$$\frac{3\tilde{e}^{k+1} - 4\tilde{e}^k + \tilde{e}^{k-1}}{2\delta t} - \nabla^2\tilde{e}^{k+1} + \nabla\epsilon^{k+1} = R^{k+1}. \tag{3.21}$$

By taking the L^2 scalar product with $4\delta t S(\tilde{e}^{k+1})$, we obtain

$$|\tilde{e}^{k+1}|_\star^2 + |2\tilde{e}^{k+1} - \tilde{e}^k|_\star^2 + |\delta_{tt}\tilde{e}^{k+1}|_\star^2 + 4\delta t(\nabla S(\tilde{e}^{k+1}), \nabla \tilde{e}^{k+1}) \\ = 4\delta t(R^{k+1}, S(\tilde{e}^{k+1})) + |\tilde{e}^k|_\star^2 + |2\tilde{e}^k - \tilde{e}^{k-1}|_\star^2.$$

Owing to Lemma 3.2 and the fact that e^{k+1} is in H, we infer

$$4\delta t(\nabla S(\tilde{e}^{k+1}), \nabla \tilde{e}^{k+1}) \geq 2\delta t\|\tilde{e}^{k+1}\|_{0,\Omega}^2 - c\delta t\|\tilde{e}^{k+1} - e^{k+1}\|_{0,\Omega}^2.$$

Thanks to (3.20), we have

$$4\delta t(R^{k+1}, S(\tilde{e}^{k+1})) \leq c\delta t\|R^{k+1}\|_{0,\Omega}^2 + \delta t\|\tilde{e}^{k+1}\|_{0,\Omega}.$$

As a result, we obtain

$$|\tilde{e}^{k+1}|_\star^2 + |2\tilde{e}^{k+1} - \tilde{e}^k|_\star^2 + |\delta_{tt}\tilde{e}^{k+1}|_\star^2 + \delta t\|\tilde{e}^{k+1}\|_{0,\Omega}^2 \leq c\delta t^5 + c'\delta t\|\tilde{e}^{k+1} - e^{k+1}\|_{0,\Omega}^2 \\ + |\tilde{e}^k|_\star^2 + |2\tilde{e}^k - \tilde{e}^{k-1}|_\star^2.$$

By applying the discrete Gronwall lemma and using the initialization hypothesis, we infer

$$\|e\|_{l^2(L^2(\Omega)^d)}^2 \leq c\|\tilde{e} - e\|_{l^2(L^2(\Omega)^d)}^2 + \delta t^4.$$

The desired result is now an easy consequence of Lemma 3.1. □

3.4.4. Proof of the H^1-estimate on the velocity. First we need to prove an estimate on the approximate time derivative. For any sequence of functions $\phi^0, \phi^1, \ldots,$ we set

$$\mathcal{D}_t\phi^{k+1} = \frac{1}{2}(3\phi^{k+1} - 4\phi^k + \phi^{k-1}).$$

LEMMA 3.4. *Under the hypotheses of Theorem* 3.1 *we have the following error estimates:*

$$\|\mathcal{D}_t\tilde{e}\|_{l^2(L^2(\Omega)^d)} \leq c\delta t^{5/2}.$$

Proof. We use the same argument as for the proof of the L^2-estimate, but we use it on the time increment $\delta_t\tilde{e}^{k+1}$. For $k \geq 2$ we have

$$\frac{1}{2\delta t}(3\delta_t\tilde{e}^{k+1} - 4\delta_t\tilde{e}^k + \delta_t\tilde{e}^{k-1}) - \nabla^2\delta_t\tilde{e}^{k+1} + \nabla\delta_t\epsilon^{k+1} = \delta_t R^{k+1}.$$

By taking the L^2 scalar product with $4\delta t S(\delta_t\tilde{e}^{k+1})$ and repeating the same arguments as above, we obtain

$$|\delta_t\tilde{e}^{k+1}|_\star^2 + |2\delta_t\tilde{e}^{k+1} - \delta_t\tilde{e}^k|_\star^2 + |\delta_{ttt}\tilde{e}^{k+1}|_\star^2 + \delta t\|\delta_t\tilde{e}^{k+1}\|_{0,\Omega}^2 \\ \leq c\delta t^7 + c'\delta t\|\delta_t\tilde{e}^{k+1} - \delta_t e^{k+1}\|_{0,\Omega}^2 + |\delta_t\tilde{e}^k|_\star^2 + |2\delta_t\tilde{e}^k - \delta_t\tilde{e}^{k-1}|_\star^2.$$

Owing to this inequality, the discrete Gronwall lemma, and the initialization hypotheses, we infer

$$\|\delta_t\tilde{e}\|_{l^2(L^2(\Omega)^d)}^2 \leq c\|\delta_t\tilde{e} - \delta_t e\|_{l^2(L^2(\Omega)^d)}^2 + c\delta t^7.$$

The conclusion is an easy consequence of Lemma 3.1 together with the bound

$$\|\mathcal{D}_t\tilde{e}\|_{l^2(L^2(\Omega)^d)} \leq 2\|\delta_t\tilde{e}\|^2_{l^2(L^2(\Omega)^d)}. \qquad \square$$

Now we are in position to prove the H^1-estimate for the velocity approximation and the L^2-estimate for the pressure approximation.

Consider the error equation corresponding to (3.8):

$$\begin{cases} \frac{1}{2\delta t}(3\tilde{e}^{k+1} - 4\tilde{e}^k + \tilde{e}^{k-1}) - \nabla^2\tilde{e}^{k+1} = R^{k+1} - \nabla\epsilon^{k+1}, \\ \tilde{e}^{k+1}|_\Gamma = 0. \end{cases} \tag{3.22}$$

We rewrite the above equation and (3.2) as a nonhomogeneous Stokes system for $(\tilde{e}^{k+1}, \epsilon^{k+1})$:

$$\begin{cases} -\nabla^2\tilde{e}^{k+1} + \nabla\epsilon^{k+1} = h^{k+1}, \quad \tilde{e}^{k+1}|_\Gamma = 0, \\ \nabla\cdot\tilde{e}^{k+1} = g^{k+1}, \end{cases} \tag{3.23}$$

where we have defined

$$\begin{aligned} h^{k+1} &= R^{k+1} - \frac{3e^{k+1} - 4e^k + e^{k-1}}{2\delta t}, \\ g^{k+1} &= -\nabla\cdot\tilde{u}^{k+1}. \end{aligned} \tag{3.24}$$

Owing to Lemma 3.1, we have

$$\|g^{k+1}\|_{0,\Omega} = \|\nabla\cdot\tilde{u}^{k+1}\|_{0,\Omega} \leq c\delta t^{\frac{3}{2}} \qquad \forall k. \tag{3.25}$$

We also have

$$\begin{aligned} \|h^{k+1}\|_{-1,\Omega} &\leq \|R^{k+1}\|_{-1,\Omega} + \left\|\frac{3\tilde{e}^{k+1} - 4\tilde{e}^k + \tilde{e}^{k-1}}{2\delta t}\right\|_{-1,\Omega} \\ &= \|R^{k+1}\|_{-1,\Omega} + \frac{1}{\delta t}\|\mathcal{D}_t\tilde{e}^{k+1}\|_{-1,\Omega}. \end{aligned} \tag{3.26}$$

Now, the standard result for the nonhomogeneous Stokes system (3.23) leads to

$$\|\tilde{e}^{k+1}\|_{1,\Omega} + \|\epsilon^{k+1}\|_{0,\Omega} \leq c\|h^{k+1}\|_{-1,\Omega} + \|g^{k+1}\|_{0,\Omega}. \tag{3.27}$$

Thanks to (3.25), (3.26), and Lemma 3.4, we derive

$$\|\tilde{e}\|_{l^2(H^1(\Omega)^d)} + \|\epsilon\|_{l^2(L^2(\Omega))} \leq c\delta t^{\frac{3}{2}}.$$

Thus, all the results in Theorem 3.1 have been proved.

4. Numerical results.

To test the two versions of the velocity-correction methods described above, we make convergence tests with respect to δt with finite elements and a Legendre spectral approximation.

4.1. Convergence tests with finite elements.

We test the finite element approximation on the Stokes problem (1.1) in $\Omega =]0,1[^2$. We set the source term so that the exact solution is

$$\begin{aligned} \mathsf{p}(x,y,t) &= \cos(\pi x)\sin(\pi y)\sin t, \\ \mathsf{u}(x,y,t) &= \pi\sin(2\pi y)\sin^2(\pi x)\sin t, \\ \mathsf{u}(x,y,t) &= -\pi\sin(2\pi x)\sin^2(\pi y)\sin t. \end{aligned}$$

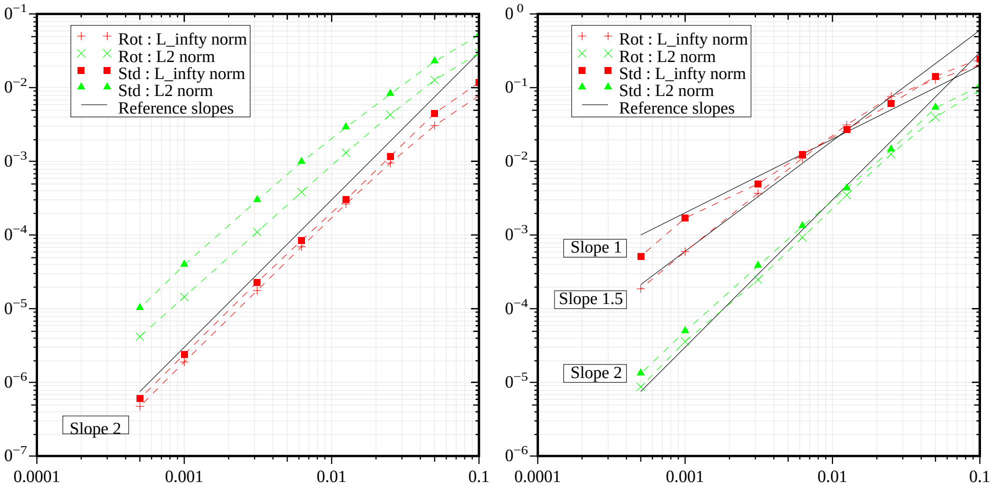

FIG. 1. *Convergence tests for the velocity-correction methods with BDF2 and finite elements. Left: velocity; right: pressure.*

We use mixed $\mathbb{P}_2/\mathbb{P}_1$ finite elements. The mesh used in the tests is composed of 3694 triangles so that the mesh size is $h \approx 1/40$. There are 1928 $\mathbb{P}_1$-nodes and 7549 $\mathbb{P}_2$-nodes. We make the tests on the range $5.10^{-4} \leq \delta t \leq 10^{-1}$ so that the approximation error in space is far smaller than the time splitting error.

We have tested the algorithms (2.3)–(2.4) and (3.1)–(3.2); the results are reported in the Figure 1. In the left panel we show the errors on the velocity in the L^∞- and L^2-norms as functions of δt. The $+$ and $\times$ symbols are for the results from the velocity-correction method in rotational form, whereas the black symbols are for the results from the standard form of the method. It is clear that for the velocity, the improvement brought by the rotational form is marginal and both schemes are second-order accurate in the L^2-norm. Note, however, that for any given δt the results from the rotational form of the algorithm are systematically more accurate than their standard counterparts. The situation is somewhat different for the pressure. The convergence results for this quantity in the L^∞- and L^2-norms are reported in the right panel of Figure 1, the $+$ and $\times$ symbols being for the rotational form of the method and the black symbols for the standard form. The behavior of the errors in the L^2-norm seems to be identical for both variants of the method with a slope slightly less than 2; however, the rotational form results are systematically better than the standard ones. For the L^∞-norm the picture is different. The results from the rotational form seem to behave like $\delta t^{3/2}$, whereas those from the standard form of the algorithm behave more or less like δt.

The difference between the standard form and the rotational form of the velocity-correction algorithm is more spectacular when looking directly at the error fields. We show in Figure 2 the error on the pressure obtained by both algorithms at time $T = 1$ with $\delta t = 0.01$, using the same scale on both graphs to emphasize the differences. It is clear from this picture that the pressure field from the standard method is polluted by a numerical boundary layer, whereas that from the rotational form is smooth.

4.2. Legendre spectral approximation. We have also implemented the second-order standard and rotational velocity-correction schemes with a Legendre–Galerkin approximation [13] using 32×32 modes. We tested the same analytical

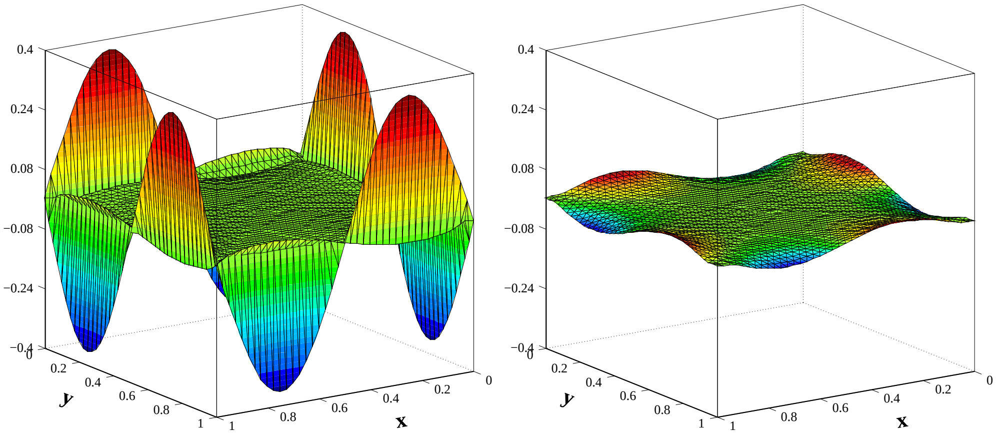

FIG. 2. *Pressure error fields at $T = 1$ with finite elements. Left: standard form; right: rotational form.*

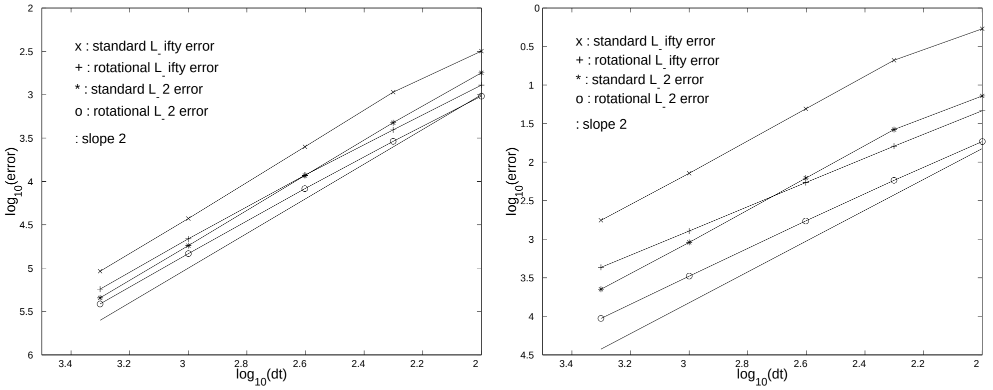

FIG. 3. *Convergence tests for the velocity-correction methods with BDF2 and the Legendre–Galerkin method. Left: velocity; right: pressure.*

solution as above but with $\Omega = \,]-1,+1[^2$. The convergence rates and the pressure error fields are presented in Figures 3 and 4. We observe that the results are similar to those obtained with the finite element approximation and are consistent with our theoretical analysis.

5. Connection with the schemes in [10, 9]. In this section we show how the schemes proposed by Orszag, Israeli, and Deville [10] and Karniadakis, Israeli, and Orszag [9] can be interpreted as the rotational form of our velocity-correction methods.

Let us denote by $\frac{1}{\delta t}(\beta_q u^{k+1} - \sum_{j=0}^{q-1} \beta_j u^{k-j})$ the qth-order BDF approximation for $\partial_t \mathsf{u}(t^{k+1})$. Then, the scheme originally proposed in [10] and [9] (with an Adams–Moulton-type scheme replacing our BDF scheme—note that this replacement is made for the convenience of our presentation only; it does not change the essential error

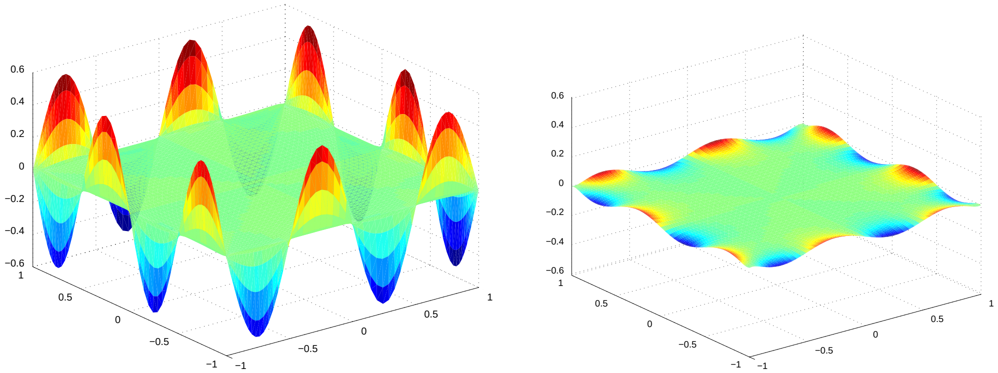

FIG. 4. *Pressure error fields at $T = 1$ with a Legendre–Galerkin approximation. Left: standard form; right: rotational form.*

behaviors) can be written as follows:

$$
(5.1) \qquad \begin{cases} \frac{1}{\delta t}(\beta_q \hat{u}^{k+1} - \sum_{j=0}^{q-1} \beta_j \tilde{u}^{k-j}) + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot \hat{u}^{k+1} = 0, \\ \hat{u}^{k+1} \cdot n|_\Gamma = -\delta t (\nabla^2 u)^{\star,k} \cdot n|_\Gamma. \end{cases}
$$

We then correct the velocity $\hat{u}^{k+1}$ by computing $\tilde{u}^{k+1}$ as follows:

$$
(5.2) \qquad \begin{cases} \frac{\beta_q}{\delta t}(\tilde{u}^{k+1} - \hat{u}^{k+1}) - \nabla^2 \tilde{u}^{k+1} = 0, \\ \tilde{u}^{k+1}|_\Gamma = 0, \end{cases}
$$

where $(\nabla^2 u)^{\star,k}$ is some approximate value of $\nabla^2 \mathsf{u}(t^{k+1})$. The authors in [10, 9] proposed the followings choices:

$$
(5.3) \qquad (\nabla^2 u)^{\star,k} = \begin{cases} 0 & \text{for } \mathcal{O}(\delta t) \text{ accuracy}, \\ -\nabla\times\nabla\times \tilde{u}^k & \text{for } \mathcal{O}(\delta t^2) \text{ accuracy}, \\ -\nabla\times\nabla\times(2\tilde{u}^k - \tilde{u}^{k-1}) & \text{for } \mathcal{O}(\delta t^3) \text{ accuracy}. \end{cases}
$$

In practice, problem (5.1) is solved as a Poisson equation with the Neumann boundary condition

$$
\partial_n p^{k+1}|_\Gamma = (f(t^{k+1}) + (\nabla^2 u)^{\star,k}) \cdot n.
$$

These methods differ from the standard pressure-correction projection methods in the sense that a consistent pressure boundary condition is enforced. Hence, in principle, these methods should achieve better convergence properties. To the best of our knowledge, no proof of stability or convergence is available in the literature for this class of methods. Furthermore, since second derivatives of the velocity are used in the Neumann boundary condition for the pressure, this class of methods cannot be applied directly with a finite element method where these derivatives are usually not available. This is the main reason why successful implementations of these methods are reported only with spectral or spectral-element approximations where the trace of the second-order derivatives of the velocity are available. On the other hand, the explicit treatment of second derivatives of the velocity leads one to suspect that this type of algorithm can be only conditionally stable, with a stability condition of type $\delta t \leq ch^2$ for finite element approximations and $\delta t \leq cN^{-4}$ for spectral or spectral element approximations.

We shall see in what follows that the boundary condition ambiguity can be removed by rewriting the algorithm in the L^2 weak framework, and that the resulting algorithm is indeed *unconditionally stable*, for it is a velocity-correction algorithm.

5.1. The weak setting. Let us now rewrite (5.1), (5.2) in L^2. Let us assume for the time being that $\nabla\cdot(\nabla^2\tilde{u})^{\star,k} = 0$. By setting $u^{k+1} = \hat{u}^{k+1} + \delta t(\nabla^2\tilde{u})^{\star,k}$ and observing that $\nabla\cdot u^{k+1} = 0$ and $u^{k+1}\cdot n|_\Gamma = 0$, the system (5.1) can be rewritten

$$\tag{5.4} \begin{cases} \frac{1}{\delta t}(\beta_q u^{k+1} - \sum_{j=0}^{q-1}\beta_j\tilde{u}^{k-j}) - (\nabla^2\tilde{u})^{\star,k} + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0. \end{cases}$$

Now, inserting the definition of u^{k+1} back into (5.2), we obtain

$$\tag{5.5} \begin{cases} \dfrac{\beta_q(\tilde{u}^{k+1} - u^{k+1})}{\delta t} - \nabla^2\tilde{u}^{k+1} + (\nabla^2\tilde{u})^{\star,k} = 0, \\ \tilde{u}^{k+1}|_\Gamma = 0. \end{cases}$$

Note that for $q = 2$ and $(\nabla^2\tilde{u})^{\star,k} = -\nabla\times\nabla\times\tilde{u}^k$, the scheme (5.4)–(5.5) is exactly the velocity-correction algorithm in rotational form (3.1)–(3.2), while the case $q = 2$ and $(\nabla^2\tilde{u})^{\star,k} = \nabla^2\tilde{u}^k$ corresponds to the velocity-correction algorithm in standard form (2.3)–(2.4).

5.2. First-order schemes. It is interesting to consider the case $q = 1$ and $(\nabla^2\tilde{u})^{\star,k} = 0$, the resulting scheme being

$$\tag{5.6} \begin{cases} \dfrac{u^{k+1} - \tilde{u}^k}{\delta t} + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n|_\Gamma = 0, \end{cases}$$

$$\tag{5.7} \begin{cases} \dfrac{\tilde{u}^{k+1} - u^{k+1}}{\delta t} - \nabla^2\tilde{u}^{k+1} = 0, \\ \tilde{u}^{k+1}|_\Gamma = 0. \end{cases}$$

In this case, the standard version and the rotational version coincide, and this method can be viewed as the dual of the original Chorin–Temam method. Of course, it suffers from the dual ailments of the Chorin–Temam algorithm, i.e., it enforces $\partial_n p^{k+1}|_\Gamma = f(t^{k+1})\cdot n$ and $\nabla^2\tilde{u}^{k+1}|_\Gamma = 0$, whereas the Chorin–Temam scheme enforces $\nabla^2\tilde{u}^{k+1}|_\Gamma = f(t^{k+1})$ and $\partial_n p^{k+1}|_\Gamma = 0$.

From the point of view of accuracy, the two algorithms are equivalent.

THEOREM 5.1. *If* (u,p)*, the solution to* (1.1)*, is smooth enough in space and time, the solution to* (5.6)–(5.7) *satisfies the following error estimates:*

$$\|\mathsf{u} - u\|_{l^\infty(L^2(\Omega)^d)} + \|\mathsf{u} - \tilde{u}\|_{l^\infty(L^2(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t,$$
$$\|\mathsf{p} - p\|_{l^\infty(L^2(\Omega))} + \|\mathsf{u} - \tilde{u}^k\|_{l^\infty(H^1(\Omega)^d)} \leq c(\mathsf{u},\mathsf{p},T)\,\delta t^{1/2}.$$

Proof. Since the proof is very similar to that of the Chorin–Temam algorithm, we refer the reader to Shen [12], Rannacher [11], Guermond [6], or to the proof of second-order accuracy in section 3.4. ◻

6. Treatment of nonlinear terms.

6.1. Semi-implicit treatment. We now describe briefly how the nonlinear terms can be properly treated. Taking the second-order rotational velocity-correction scheme as an example, one way to treat the nonlinear term semi-implicitly is as follows:

$$\tag{6.1} \begin{cases} \dfrac{3u^{k+1}-4\tilde{u}^k+\tilde{u}^{k-1}}{2\delta t} + \nu\nabla\times\nabla\times\tilde{u}^k \\ \qquad + d(2\tilde{u}^{k-1}-\tilde{u}^{k-2},\tilde{u}^k) + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n_{|\Gamma} = 0 \end{cases}$$

and

$$\tag{6.2} \begin{cases} \dfrac{3\tilde{u}^{k+1}-3u^{k+1}}{2\delta t} - \nu\nabla^2\tilde{u}^{k+1} + d(2\tilde{u}^k-\tilde{u}^{k-1},\tilde{u}^{k+1}) \\ \qquad\qquad - \nu\nabla\times\nabla\times\tilde{u}^k - d(2\tilde{u}^{k-1}-\tilde{u}^{k-2},\tilde{u}^k) = 0, \\ \tilde{u}^{k+1}_{|\Gamma} = 0, \end{cases}$$

where the bilinear form d accounts for the advection and can take various forms to ensure unconditional stability. For instance, we can use

$$\tag{6.3} d(v,w) = \begin{cases} v\cdot\nabla w + \frac{1}{2}(\nabla\cdot v)w & \text{or} \\ (\nabla\times v)\times w, \end{cases}$$

where in the second case, p^{k+1} is the total pressure, i.e., the kinetic energy has to be subtracted from p^{k+1} to get the real pressure. One can show, just as in the linear case, that the scheme (6.1)–(6.2) is unconditionally stable and that Theorem 3.1 holds.

Note that with the presence of the nonlinear term, the projection step is once again given by (3.4) in strong form or (3.9) in weak form. By adding (6.2) to (6.1), one obtains

$$\tag{6.4} \frac{3\tilde{u}^{k+1}-4\tilde{u}^k+\tilde{u}^{k-1}}{2\delta t} - \nu\nabla^2\tilde{u}^{k+1} + d(2\tilde{u}^k-\tilde{u}^{k-1},\tilde{u}^{k+1}) + \nabla p^{k+1} = f(t^{k+1}),$$

with $\tilde{u}^{k+1}_{|\Gamma} = 0$, which is a linear elliptic equation for $\tilde{u}^{k+1}$ that can be solved by standard procedures. As a result, a simple way to code the semi-implicit velocity-correction algorithm in rotational form with the projected velocity eliminated is (3.9), (3.7), (6.4).

6.2. Explicit treatment. One can also treat the nonlinear term totally explicitly as is done usually with spectral approximations [2]:

$$\tag{6.5} \begin{cases} \dfrac{3u^{k+1}-4\tilde{u}^k+\tilde{u}^{k-1}}{2\delta t} + \nu\nabla\times\nabla\times\tilde{u}^k \\ \qquad + (2d(\tilde{u}^k,\tilde{u}^k) - d(\tilde{u}^{k-1},\tilde{u}^{k-1})) + \nabla p^{k+1} = f(t^{k+1}), \\ \nabla\cdot u^{k+1} = 0, \\ u^{k+1}\cdot n_{|\Gamma} = 0 \end{cases}$$

and

$$\tag{6.6} \begin{cases} \dfrac{3\tilde{u}^{k+1}-3u^{k+1}}{2\delta t} - \nu\nabla^2\tilde{u}^{k+1} - \nu\nabla\times\nabla\times\tilde{u}^k = 0, \\ \tilde{u}^{k+1}_{|\Gamma} = 0. \end{cases}$$

In this case, the scheme is only conditionally stable with a usual CFL condition.

In practice the projected velocity can be completely eliminated from the algorithm as follows. Upon substituting $f(t^{k+1})$ into (3.9) by $f(t^{k+1}) - (2d(\tilde{u}^k, \tilde{u}^k) - d(\tilde{u}^{k-1}, \tilde{u}^{k-1}))$, the projection step is still (3.9). After updating the pressure according to (3.7), the new velocity $\tilde{u}^{k+1}$ is obtained by solving

$$\begin{aligned} &\frac{3\tilde{u}^{k+1} - 4\tilde{u}^k + \tilde{u}^{k-1}}{2\delta t} - \nu\nabla^2\tilde{u}^{k+1} + (2d(\tilde{u}^k, \tilde{u}^k) - d(\tilde{u}^{k-1}, \tilde{u}^{k-1})) + \nabla p^{k+1} \\ &\qquad = f(t^{k+1}) \end{aligned} \tag{6.7}$$

with $\tilde{u}^{k+1}_{|\Gamma} = 0$.

7. Concluding remarks. We have introduced a class of velocity-correction schemes in standard and rotational form. We proved stability and $\mathcal{O}(\delta t^2)$ convergence in the L^2-norm of the velocity for both versions. We also proved improved error estimates for the rotational form, i.e., $\mathcal{O}(\delta t^{3/2})$ convergence in the H^1-norm of the velocity and the L^2-norm of the pressure. Our numerical results indicate that these estimates appear to be the best possible under the general assumptions on Ω considered in this paper.

We have also shown that the schemes introduced in [10] and [9] are formally equivalent, in the spatial continuous case, to the velocity-correction projection methods in rotational form. Thus, our results provide the first rigorous proof of stability and convergence for these schemes. In addition, contrary to the original form of these methods which involve the normal trace of second-order derivatives of the velocity at the boundary, the new velocity-correction projection methods, being set in the standard L^2 weak setting, can be easily implemented by using any variational approximation techniques, including finite element methods.

NUMERICAL APPROXIMATIONS OF PRESSURELESS AND ISOTHERMAL GAS DYNAMICS[*]

FRANÇOIS BOUCHUT[†], SHI JIN[‡], AND XIANTAO LI[‡]

Abstract. We study several schemes of first- or second-order accuracy based on kinetic approximations to solve pressureless and isothermal gas dynamics equations. The pressureless gas system is weakly hyperbolic, giving rise to the formation of density concentrations known as delta-shocks. For the isothermal gas system, the infinite speed of expansion into vacuum leads to zero timestep in the Godunov method based on exact Riemann solver. The schemes we consider are able to bypass these difficulties. They are proved to satisfy positiveness of density and discrete entropy inequalities, to capture the delta-shocks, and to treat data with vacuum.

Key words. pressureless gas, isothermal gas, kinetic schemes, positivity preserving, delta-shock, vacuum, entropy inequalities

1. Introduction.

The purpose of this work is to study some numerical approximations of the pressureless gas and isothermal gas dynamics equations. These equations take the form

$$\begin{cases} \rho_t + \operatorname{div}(\rho u) = 0, \\ (\rho u)_t + \operatorname{div}(\rho u \otimes u + \nu^2 \rho \ \mathrm{I}) = 0, \end{cases} \tag{1}$$

where $t > 0$, $x \in \mathbb{R}^N$, $\rho(x,t) \geq 0$, $u(x,t) \in \mathbb{R}^N$, with initial data

$$\rho(x,0) = \rho^0(x), \qquad \rho(x,0)u(x,0) = \rho^0(x)u^0(x). \tag{2}$$

The momentum will also be denoted by $q \equiv \rho u$. When $\nu = 0$, (1) is referred to as the pressureless gas equations, which arise in the modeling of sticky particles to explain the formation of large scale structures in the universe [26], [24]. The pressureless system has been studied at the theoretical level by several authors; see [2], [11], [14], [7], [21], [25], [23], [22], and for related problems see [8], [6], [1]. In the pressureless gas system, the Jacobian matrix of the flux is a Jordan block, thus the system is *weakly* hyperbolic. A main feature of this weakly hyperbolic system is the development of delta-shocks and the emergence of the vacuum state. For the isothermal gas equations, $\nu > 0$, the density profile forms a concentration that turns to a delta-wave as $\nu \to 0$ [12], [13]. Vacuum state cannot form for this system, but, if we start from vacuum, an expansion occurs at infinite velocity. Thus the Godunov method based on the exact Riemann solver requires the timestep to be zero for numerical stability, resulting in the failure of the method.

Some numerical schemes were introduced in [2], [4], [5] for the pressureless gas and related equations, and this paper can be viewed as a continuation of these earlier

investigations. We consider here several first-order and second-order schemes based on kinetic approximations that are able to treat delta-waves and vacuum, and we compare their numerical performances. The maximum principle on the velocity u is also established.

In the case of isothermal gas dynamics, we introduce a kinetic scheme that reduces to the kinetic scheme for pressureless gas as $\nu \to 0$. This kinetic scheme is able to treat vacuum state since it takes the form of a flux vector splitting, giving some approximate Riemann solver that can deal with the vacuum state with nonzero timestep for numerical stability. Indeed, we establish an entropy inequality under some natural CFL condition.

Weakly hyperbolic systems also arise in mathematical modelings of multiphase geometrical optics [15, 18]. Simple and efficient numerical schemes for such problems include the Lax–Friedrichs scheme and its second-order extension [15], [17]. Compared with upwind-type schemes, including the Godunov and kinetic schemes, the central schemes offer greater simplicity and efficiency, yet they are slightly more diffusive. See more numerical experiments carried out in [16], [18].

The paper is organized as follows. In section 2, we study several schemes for the one-dimensional pressureless gas equations. In section 3, we generalize some kinetic schemes to two dimensions. In section 4, we study a kinetic scheme for an isothermal gas, and in section 5 we perform numerical tests.

2. Kinetic schemes for one-dimensional pressureless gas. As is now classical, gas dynamics equations can be solved by kinetic schemes; see [9], [19]. We refer, for example, to [3] for general properties of such schemes. For the pressureless system (1) with $\nu = 0$, a simple δ function can be taken as a Maxwellian [2], and the scheme can be written as follows in one space dimension. Starting from functions $\rho^n(x)$ and $u^n(x)$ at time t_n, one solves the transport equation

$$\left\{ \begin{array}{l} \partial_t f + \xi\, \partial_x f = 0 \qquad \text{in} \quad \mathbb{R}_x \times \mathbb{R}_\xi \times]t_n, t_{n+1}[, \\ f(x,\xi,t_n) = f^n(x,\xi) = M(\rho^n(x), u^n(x), \xi), \end{array} \right. \tag{3}$$

where the Maxwellian is defined for any $\rho \geq 0$, $u \in \mathbb{R}$, and $\xi \in \mathbb{R}$ by

$$M(\rho, u, \xi) = \rho\, \delta(\xi - u). \tag{4}$$

The transport equation has the exact solution $f(x,\xi,t) = f^n(x - \xi(t-t_n), \xi)$ for $t_n \leq t < t_{n+1}$. In the projection step, let

$$\begin{pmatrix} \rho^{n+1-}(x) \\ q^{n+1-}(x) \end{pmatrix} = \int_{\mathbb{R}} \begin{pmatrix} 1 \\ \xi \end{pmatrix} f(x,\xi,t_{n+1}-)\, d\xi. \tag{5}$$

In order to obtain discrete values over a mesh of constant size Δx, one defines the new averages ρ_j^{n+1-}, q_j^{n+1-}, with the usual definition

$$w_j^n = \frac{1}{\Delta x} \int_{x_{j-1/2}}^{x_{j+1/2}} w(x, t_n)\, dx. \tag{6}$$

It remains only to define functions $\rho^n(x)$ and $u^n(x)$ from the average values ρ_j^{n-}, q_j^{n-}. This is the reconstruction step, which needs to conserve $\rho_j^n = \rho_j^{n-}$, $q_j^n = q_j^{n-}$. For a first-order scheme, one just takes $\rho^n(x)$ and $u^n(x)$ (or, equivalently, $q^n(x)$) piecewise constant.

Notice that this algorithm keeps the nonnegativeness of the density ρ since f itself is nonnegative, and satisfies the maximum principle on the velocity u, in the following form:

$$\inf_x u^n(x) \le \frac{q^{n+1-}(x)}{\rho^{n+1-}(x)} \le \sup_x u^n(x), \tag{7}$$

which is easily seen from (5) and by the fact that from (3) and (4) the support in ξ of f lies in the range of u^n. The same inequalities (7) obviously hold also for q_j^{n+1-}/ρ_j^{n+1-}.

In order to obtain an explicit formula, one integrates the transport equation (3) over $(x_{j-1/2}, x_{j+1/2}) \times \mathbb{R}_\xi \times (t_n, t_{n+1})$, and a conservative numerical scheme is obtained as

$$\begin{aligned} \rho_j^{n+1} &= \rho_j^n - \frac{\Delta t}{\Delta x}\left(F^{(1)}_{j+1/2} - F^{(1)}_{j-1/2}\right), \\ q_j^{n+1} &= q_j^n - \frac{\Delta t}{\Delta x}\left(F^{(2)}_{j+1/2} - F^{(2)}_{j-1/2}\right), \end{aligned} \tag{8}$$

where

$$F_{j+1/2} = \begin{pmatrix} F^{(1)}_{j+1/2} \\ F^{(2)}_{j+1/2} \end{pmatrix} = \frac{1}{\Delta t}\int_{t_n}^{t_{n+1}} \int_{\mathbb{R}} \xi \begin{pmatrix} 1 \\ \xi \end{pmatrix} f(x_{j+1/2}, \xi, t)\, d\xi dt. \tag{9}$$

In addition, one can compute the integrals over $\mathbb{R}^+$ and $\mathbb{R}^-$ separately, and then the numerical flux can be written in the flux vector splitting form,

$$F_{j+1/2} = F^+_{j+1/2} + F^-_{j+1/2}, \tag{10}$$

with

$$F^\pm_{j+1/2} = \frac{1}{\Delta t}\int_{t_n}^{t_{n+1}} \int_{\pm\xi>0} \xi \begin{pmatrix} 1 \\ \xi \end{pmatrix} f^n\big(x_{j+1/2} - \xi(t-t_n), \xi, t\big)\, d\xi dt. \tag{11}$$

2.1. First-order kinetic scheme. For a first-order scheme, one uses piecewise constant data:

$$\rho(x) = \rho_j, \quad u(x) = u_j \qquad \text{for} \quad x_{j-1/2} < x < x_{j+1/2}. \tag{12}$$

Note that under the CFL condition

$$|u_j|\Delta t \le \Delta x \tag{13}$$

the integrals involved in (11) have support on at most one point. For instance, the integral for $F^+_{j+1/2}$ has support $\{\xi = u_j\}$ only if u_j is nonnegative. Therefore,

$$F^{+(1)}_{j+1/2} = \frac{1}{\Delta t}\int_{t_n}^{t_{n+1}} \int_0^\infty \xi\, \rho_j\, \delta(\xi - u_j)\, d\xi dt = \rho_j (u_j)_+. \tag{14}$$

Similarly,

$$F^{-(1)}_{j+1/2} = \rho_{j+1}(u_{j+1})_-, \;\; F^{+(2)}_{j+1/2} = \rho_j u_j (u_j)_+, \;\; F^{-(2)}_{j+1/2} = \rho_{j+1} u_{j+1} (u_{j+1})_-, \tag{15}$$

with the convention $u_+ + u_- = u$, $u_+ - u_- = |u|$. Thus the final scheme takes the form (8), (10), (14), (15), with $q_j^n = \rho_j^n u_j^n$. As is easily seen, under the CFL condition (13), this first-order kinetic scheme keeps the density ρ nonnegative and satisfies the maximum principle on the velocity u. Other properties, like entropy inequalities or the TVD property on u, can also be proved; see [2].

2.2. Godunov scheme. To compare with the kinetic scheme, we also derive the first-order Godunov scheme in this section. As was derived in [2], [23], the Riemann problem (1) with $\nu = 0$ and initial data

$$(\rho^0(x), u^0(x)) = \begin{cases} (\rho_j, u_j) & x < x_{j+1/2}, \\ (\rho_{j+1}, u_{j+1}) & x > x_{j+1/2}, \end{cases} \tag{16}$$

where $u_j \geq u_{j+1}$, has the delta-shock solution

$$(\rho(x,t), u(x,t)) = \begin{cases} (\rho_j, u_j) & x < x_{j+1/2} + u_\delta t, \\ (w(t)\,\delta(x - x_{j+1/2} - u_\delta t), u_\delta) & x = x_{j+1/2} + u_\delta t, \\ (\rho_{j+1}, u_{j+1}) & x > x_{j+1/2} + u_\delta t, \end{cases} \tag{17}$$

where

$$w(t) = \sqrt{\rho_j \rho_{j+1}}(u_j - u_{j+1})t, \quad u_\delta = \frac{\sqrt{\rho_j}u_j + \sqrt{\rho_{j+1}}u_{j+1}}{\sqrt{\rho_j} + \sqrt{\rho_{j+1}}}. \tag{18}$$

Therefore, still in the case when $u_j \geq u_{j+1}$, we obtain the Godunov flux

$$F_{j+1/2} = \begin{cases} (\rho_j u_j, \rho_j u_j^2) & \text{if } u_\delta > 0, \\ (\rho_{j+1} u_{j+1}, \rho_{j+1} u_{j+1}^2) & \text{if } u_\delta < 0, \\ ((\rho_j u_j + \rho_{j+1} u_{j+1})/2, \rho_j u_j^2 = \rho_{j+1} u_{j+1}^2) & \text{if } u_\delta = 0. \end{cases} \tag{19}$$

In the case when $u_\delta = 0$, there is a stationary delta-shock at the interface, thus the formula has to be explained a bit. We choose arbitrarily to put half of the mass to the left and the other half to the right of the line $x = x_{j+1/2}$. This means that

$$\rho_j^{n+1} = \frac{1}{\Delta x}\left(\int_{x_{j-1/2}}^{x_{j+1/2}-} \rho^{n+1-}(x)\,dx + \frac{1}{2}w(\Delta t)\right).$$

In order to see which numerical flux we get, we write down the finite difference formula

$$\rho_j^n + \frac{1}{2}\frac{\Delta t}{\Delta x}\sqrt{\rho_j \rho_{j+1}}(u_j - u_{j+1}) - \rho_j^n + \frac{\Delta t}{\Delta x}(F_{j+1/2}^{(1)} - F_{j-1/2}^{(1)}) = 0,$$

and assuming that $F_{j-1/2}^{(1)} = \rho_j u_j$ this yields by using the fact that $u_\delta = 0$:

$$F_{j+1/2}^{(1)} = \rho_j u_j - \frac{1}{2}\sqrt{\rho_j \rho_{j+1}}(u_j - u_{j+1}) = \frac{1}{2}(\rho_j u_j + \rho_{j+1} u_{j+1}).$$

On the contrary, there is no momentum on the delta-shock since $u_\delta = 0$, and a similar computation as above gives the flux $F_{j+1/2}^{(2)} = \rho_j u_j^2 = \rho_{j+1} u_{j+1}^2$.

In the case where $u_j < u_{j+1}$, the exact solution of the Riemann problem contains vacuum and is given by

$$(\rho(x,t), u(x,t)) = \begin{cases} (\rho_j, u_j) & x < x_{j+1/2} + u_j t, \\ (0, \text{undefined}) & x_{j+1/2} + u_j t < x < x_{j+1/2} + u_{j+1} t, \\ (\rho_{j+1}, u_{j+1}) & x > x_{j+1/2} + u_{j+1} t, \end{cases} \tag{20}$$

and the numerical flux takes the form

$$F_{j+1/2} = \begin{cases} (\rho_j u_j, \rho_j u_j^2) & \text{if } u_j > 0, \\ (\rho_{j+1} u_{j+1}, \rho_{j+1} u_{j+1}^2) & \text{if } u_{j+1} < 0, \\ (0, 0) & \text{otherwise.} \end{cases} \tag{21}$$

Again under the CFL condition (13), it is easy to see that the Godunov scheme (8), (19), (21), with $q_j^n = \rho_j^n u_j^n$, keeps the density ρ nonnegative and satisfies the maximum principle on the velocity u.

2.3. A second-order kinetic scheme. For a second-order scheme, one can use a piecewise linear reconstruction,

$$\left\{ \begin{array}{l} \rho(x) = \rho_j + D\rho_j(x - x_j) \\ u(x) = \overline{u}_j + Du_j(x - x_j) \end{array} \right. \qquad \text{for} \quad x_{j-1/2} < x < x_{j+1/2}, \tag{22}$$

where $\overline{u}_j$ is chosen as

$$\overline{u}_j = u_j - \frac{D\rho_j Du_j}{12\rho_j}\Delta x^2, \tag{23}$$

$$u_j = q_j/\rho_j, \tag{24}$$

in order to have the conservation property; namely, the cell average of $q(x) = \rho(x)u(x)$ must be q_j. There are several limitations on $D\rho_j$ and Du_j, which need to be computed from ρ_j and q_j in the reconstruction step. We shall collect and summarize all the restrictions at the end of this section.

Let us first explain the evolution step (3)–(6), starting from the initial data (22). We need to compute $F^+_{j+1/2}$ in (11). We use the CFL condition

$$\Delta t \sup_x |u^n(x)| \le \Delta x. \tag{25}$$

To get an explicit expression, we assume the piecewise nonovertaking condition

$$\Delta t Du^n_j > -1. \tag{26}$$

Then we can proceed with the calculation,

$$\begin{aligned} F^+_{j+1/2} &= \frac{1}{\Delta t}\int_0^{\Delta t}\int_0^\infty \xi \begin{pmatrix} 1 \\ \xi \end{pmatrix} \rho^n(x_{j+1/2} - \xi t)\,\delta(\xi - u^n(x_{j+1/2} - \xi t))\,d\xi dt \\ &= \frac{1}{\Delta t}\int_0^\infty \int_{x_{j+1/2}-\xi\Delta t}^{x_{j+1/2}} \begin{pmatrix} 1 \\ \xi \end{pmatrix} \rho^n(x)\,\delta(\xi - u^n(x))\,dx d\xi \\ &= \frac{1}{\Delta t}\int_{x_{j-1/2}}^{x_{j+1/2}} \rho^n(x) \begin{pmatrix} 1 \\ u^n(x) \end{pmatrix} \mathbb{I}_{x+\Delta t u^n(x) > x_{j+1/2}}\,dx \\ &= \frac{1}{\Delta t}\int_{x^L_{j+1/2}}^{x_{j+1/2}} \begin{pmatrix} \rho^n(x) \\ \rho^n(x)u^n(x) \end{pmatrix} dx, \end{aligned} \tag{27}$$

where

$$x^L_{j+1/2} = x_{j+1/2} - \Delta t \frac{(\overline{u}_j + \frac{\Delta x}{2}Du_j)_+}{1 + \Delta t Du_j}. \tag{28}$$

Thus we obtain

$$\begin{aligned} F^{+(1)}_{j+1/2} &= \frac{\rho^L_{j+1/2}(u^L_{j+1/2})_+}{1 + \Delta t Du_j} - \frac{\Delta t}{2} D\rho_j \frac{u^L_{j+1/2}(u^L_{j+1/2})_+}{(1 + \Delta t Du_j)^2}, \\ F^{+(2)}_{j+1/2} &= \rho^L_{j+1/2} u^L_{j+1/2}(u^L_{j+1/2})_+ \frac{1 + \frac{\Delta t}{2}Du_j}{(1 + \Delta t Du_j)^2} \\ &\qquad - \frac{\Delta t}{6} D\rho_j \frac{(u^L_{j+1/2})^2 (u^L_{j+1/2})_+}{(1 + \Delta t Du_j)^3}(3 + \Delta t Du_j), \end{aligned} \tag{29}$$

with

$$\begin{aligned}
\rho^L_{j+1/2} &= \rho_j + \tfrac{\Delta x}{2} D\rho_j,\\
\rho^R_{j+1/2} &= \rho_{j+1} - \tfrac{\Delta x}{2} D\rho_{j+1},\\
u^L_{j+1/2} &= \overline{u}_j + \tfrac{\Delta x}{2} Du_j,\\
u^R_{j+1/2} &= \overline{u}_{j+1} - \tfrac{\Delta x}{2} Du_{j+1}.
\end{aligned}\tag{30}$$

Similarly,

$$F^-_{j+1/2} = -\frac{1}{\Delta t}\int_{x_{j+1/2}}^{x^R_{j+1/2}} \begin{pmatrix} \rho^n(x) \\ \rho^n(x)u^n(x) \end{pmatrix} dx,\tag{31}$$

$$x^R_{j+1/2} = x_{j+1/2} - \Delta t \frac{(u^R_{j+1/2})_-}{1+\Delta t Du_{j+1}},\tag{32}$$

and

$$\begin{aligned}
F^{-(1)}_{j+1/2} &= \frac{\rho^R_{j+1/2}(u^R_{j+1/2})_-}{1+\Delta t Du_{j+1}} - \frac{\Delta t}{2} D\rho_{j+1} \frac{u^R_{j+1/2}(u^R_{j+1/2})_-}{(1+\Delta t Du_{j+1})^2},\\
F^{-(2)}_{j+1/2} &= \rho^R_{j+1/2} u^R_{j+1/2} (u^R_{j+1/2})_- \frac{1+\frac{\Delta t}{2} Du_{j+1}}{(1+\Delta t Du_{j+1})^2}\\
&\quad - \frac{\Delta t}{6} D\rho_{j+1} \frac{(u^R_{j+1/2})^2 (u^R_{j+1/2})_-}{(1+\Delta t Du_{j+1})^3}(3+\Delta t Du_{j+1}).
\end{aligned}\tag{33}$$

An interpretation of (27) is that we put in the flux $F^+_{j+1/2}$ the total mass and momentum of all particles located at $x \in (x_{j-1/2}, x_{j+1/2})$ at time t_n that pass through the node $x_{j+1/2}$ (in the sense of characteristics) between times t_n and t_{n+1}. Indeed, $x + (t - t_n)u^n(x) = x_{j+1/2}$ for some $t_n < t < t_{n+1}$ is equivalent to $x + \Delta t\, u^n(x) > x_{j+1/2}$. Under condition (26), these characteristics do not cross; however, this is done regardless of the trajectories of particles coming from the right.

Finally, we have to specify the reconstruction step. In order to ensure the nonnegativity of ρ, one needs that

$$|D\rho_j \Delta x/2| \le \rho_j.\tag{34}$$

To guarantee the maximum principle property on the velocity

$$m_j \le u(x) \le M_j, \qquad x \in (x_{j-1/2}, x_{j+1/2}),\tag{35}$$

where

$$m_j = \min\{u_{j-1}, u_j, u_{j+1}\}, \qquad M_j = \max\{u_{j-1}, u_j, u_{j+1}\},\tag{36}$$

we need that

$$\begin{aligned}
m_j &\le u_j + \frac{\Delta x}{2} Du_j (1 - D\rho_j \Delta x / 6\rho_j) \le M_j,\\
m_j &\le u_j - \frac{\Delta x}{2} Du_j (1 + D\rho_j \Delta x / 6\rho_j) \le M_j.
\end{aligned}\tag{37}$$

Therefore we have the restrictions on the slopes of u,

$$Du_j \le \min\left\{ \frac{M_j - u_j}{(1 - D\rho_j \Delta x/6\rho_j)\frac{\Delta x}{2}}, \frac{u_j - m_j}{(1 + D\rho_j \Delta x/6\rho_j)\frac{\Delta x}{2}} \right\} \tag{38}$$

and

$$Du_j \ge \max\left\{ \frac{m_j - u_j}{(1 - D\rho_j \Delta x/6\rho_j)\frac{\Delta x}{2}}, \frac{u_j - M_j}{(1 + D\rho_j \Delta x/6\rho_j)\frac{\Delta x}{2}} \right\}. \tag{39}$$

In practice, we can choose the following limiters to satisfy all the constraints:

$$\begin{aligned} D\rho_j &= \frac{1}{2}\Big(\operatorname{sgn}(\rho_{j+1} - \rho_j) + \operatorname{sgn}(\rho_j - \rho_{j-1})\Big) \\ &\qquad \times \min\left\{ \frac{|\rho_{j+1} - \rho_j|}{\Delta x}, \frac{|\rho_j - \rho_{j-1}|}{\Delta x}, \frac{2\rho_j}{\Delta x} \right\}, \\ Du_j &= \frac{1}{2}\Big(\operatorname{sgn}(u_{j+1} - u_j) + \operatorname{sgn}(u_j - u_{j-1})\Big) \\ &\qquad \times \min\left\{ \frac{|u_{j+1} - u_j|}{(1 - \Delta x D\rho_j/6\rho_j)\Delta x}, \frac{|u_j - u_{j-1}|}{(1 + \Delta x D\rho_j/6\rho_j)\Delta x}, \frac{1}{\Delta t} \right\}. \end{aligned} \tag{40}$$

The scheme we obtain is then second-order in space and time. The second-order accuracy in time here comes from the very special property of the system of pressureless gas, which is that (3) is indeed a kinetic formulation of (1) with $\nu = 0$, in the sense that as soon as we have smooth solutions to (1) the solution to (3) remains Maxwellian. This property was proved in [2] (see also [10]).

2.4. A simplified second-order kinetic scheme. In order to obtain an easy extension of our second-order method to two-dimensional problems, we can rather use the standard extension to second-order of the scheme we have obtained in section 2.1. It can be interpreted as using the transport-projection method (3)–(6) with initial data that are piecewise constant over half-cells,

$$\begin{aligned} \rho(x) &= \rho^R_{j-1/2}, \quad u(x) = u^R_{j-1/2} \qquad \text{for} \quad x_{j-1/2} < x < x_j, \\ \rho(x) &= \rho^L_{j+1/2}, \quad u(x) = u^L_{j+1/2} \qquad \text{for} \quad x_j < x < x_{j+1/2}, \end{aligned} \tag{41}$$

with as before

$$\begin{aligned} \rho^L_{j+1/2} &= \rho_j + D\rho_j \Delta x/2, \\ \rho^R_{j+1/2} &= \rho_{j+1} - D\rho_{j+1} \Delta x/2, \\ u^L_{j+1/2} &= \overline{u}_j + Du_j \Delta x/2, \\ u^R_{j+1/2} &= \overline{u}_{j+1} - Du_{j+1} \Delta x/2. \end{aligned} \tag{42}$$

Now, to have conservation of momentum, $\overline{u}_j$ is chosen as

$$\overline{u}_j = u_j - \frac{D\rho_j Du_j}{4\rho_j}\Delta x^2, \qquad u_j = q_j/\rho_j. \tag{43}$$

By restricting the CFL number to 1/2,

$$\Delta t \sup_x |u^n(x)| \le \Delta x/2, \tag{44}$$

we obtain the same numerical flux as in the first-order scheme,

$$
\begin{aligned}
F_{j+1/2} = \Big(& \rho^L_{j+1/2}(u^L_{j+1/2})_+ + \rho^R_{j+1/2}(u^R_{j+1/2})_-, \\
& (\rho u)^L_{j+\frac{1}{2}}(u^L_{j+1/2})_+ + (\rho u)^R_{j+1/2}(u^R_{j+\frac{1}{2}})_- \Big).
\end{aligned} \tag{45}
$$

From this construction, we obviously achieve second-order accuracy in space. Concerning time, a simple second-order Runge–Kutta method can be used,

$$
\begin{cases}
U^*_j = U^n_j - \frac{\Delta t}{\Delta x}(F^n_{j+1/2} - F^n_{j-1/2}), \\
U^{**}_j = U^*_j - \frac{\Delta t}{\Delta x}(F^*_{j+1/2} - F^*_{j-1/2}), \\
U^{n+1}_j = (U^n_j + U^{**}_j)/2.
\end{cases} \tag{46}
$$

In the reconstruction step, the restrictions on slopes are similar to the previous section,

$$
\begin{aligned}
D\rho_j = {} & \frac{1}{2}\Big(\operatorname{sgn}(\rho_{j+1} - \rho_j) + \operatorname{sgn}(\rho_j - \rho_{j-1})\Big) \\
& \times \min\left\{ \frac{|\rho_{j+1} - \rho_j|}{\Delta x}, \frac{|\rho_j - \rho_{j-1}|}{\Delta x}, \frac{2\rho_j}{\Delta x} \right\}, \\
Du_j = {} & \frac{1}{2}\Big(\operatorname{sgn}(u_{j+1} - u_j) + \operatorname{sgn}(u_j - u_{j-1})\Big) \\
& \times \min\left\{ \frac{|u_{j+1} - u_j|}{(1 - D\rho_j\Delta x/2\rho_j)\Delta x}, \frac{|u_j - u_{j-1}|}{(1 + D\rho_j\Delta x/2\rho_j)\Delta x} \right\}.
\end{aligned} \tag{47}
$$

Again, this reconstruction preserves the nonnegativity of the density and satisfies the maximum principle on the velocity. Similar properties were established in [20] for such a scheme.

2.5. An improved second-order kinetic scheme. A scheme that is even more precise than that of subsection 2.3 can be derived in the following way. We use again piecewise linear functions (22) with (23), (24) but perform a different reconstruction. By considering the mesh with half the cells of the original one, one can compute, under a half CFL condition, the new averages on half-cells $\rho^{n+1-}_{j\pm 1/4}$, $q^{n+1-}_{j\pm 1/4}$, with formulas similar to those of subsection 2.3. Then the averages are given by

$$
\rho^{n+1}_j = \frac{1}{2}\Big(\rho^{n+1-}_{j+1/4} + \rho^{n+1-}_{j-1/4}\Big), \qquad q^{n+1}_j = \frac{1}{2}\Big(q^{n+1-}_{j+1/4} + q^{n+1-}_{j-1/4}\Big). \tag{48}
$$

Formulas (23), (24) still hold for conservativity, but now the slopes are computed in a different way. Indeed, one evolves both the averages and the slopes, and therefore one has to give the value of the new slopes $D\rho^{n+1}_j$, Du^{n+1}_j from the evolution step. We use

$$
D\rho^{n+1}_j = \operatorname{sgn}\Big(\rho^{n+1-}_{j+1/4} - \rho^{n+1-}_{j-1/4}\Big)\frac{2}{\Delta x}\min\Big(\Big|\rho^{n+1-}_{j+1/4} - \rho^{n+1-}_{j-1/4}\Big|\ , \rho^{n+1}_j\Big), \tag{49}
$$

$$
\begin{aligned}
Du^{n+1}_j = {} & \operatorname{sgn}\left(\frac{q^{n+1-}_{j+1/4}}{\rho^{n+1-}_{j+1/4}} - \frac{q^{n+1-}_{j-1/4}}{\rho^{n+1-}_{j-1/4}}\right) \\
& \times \frac{2}{\Delta x}\min\left(\left|\frac{q^{n+1-}_{j+1/4}}{\rho^{n+1-}_{j+1/4}} - \frac{q^{n+1-}_{j-1/4}}{\rho^{n+1-}_{j-1/4}}\right|\ , \frac{\min(M_j - u^{n+1}_j, u^{n+1}_j - m_j)}{1 + |D\rho^{n+1}_j|\Delta x/6\rho^{n+1}_j}\right),
\end{aligned} \tag{50}
$$

where m_j and M_j are a bit less restrictive than in (36),

$$
\begin{aligned}
m_j &= \inf_{x_{j-3/2}<x<x_{j+3/2}} u^n(x) \\
&= \min\Big(\overline{u}^n_{j-1} - |Du^n_{j-1}|\frac{\Delta x}{2}, \overline{u}^n_j - |Du^n_j|\frac{\Delta x}{2}, \overline{u}^n_{j+1} - |Du^n_{j+1}|\frac{\Delta x}{2}\Big),
\end{aligned} \tag{51}
$$

$$
\begin{aligned}
M_j &= \sup_{x_{j-3/2}<x<x_{j+3/2}} u^n(x) \\
&= \max\Big(\overline{u}^n_{j-1} + |Du^n_{j-1}|\frac{\Delta x}{2}, \overline{u}^n_j + |Du^n_j|\frac{\Delta x}{2}, \overline{u}^n_{j+1} + |Du^n_{j+1}|\frac{\Delta x}{2}\Big).
\end{aligned} \tag{52}
$$

3. Two-dimensional pressureless gas. For convenience, we write the two-dimensional pressureless gas equations as

$$
\begin{cases}
\rho_t + p_x + q_y = 0, \\
p_t + (pu)_x + (pv)_y = 0, \\
q_t + (qu)_x + (qv)_y = 0,
\end{cases} \tag{53}
$$

with $p = \rho u$, $q = \rho v$. We shall use a conservative scheme

$$
U^{n+1}_{j,k} - U^n_{j,k} + \frac{\Delta t}{\Delta x}(F_{j+1/2,k} - F_{j-1/2,k}) + \frac{\Delta t}{\Delta y}(G_{j,k+1/2} - G_{j,k-1/2}) = 0, \tag{54}
$$

with $U = (\rho, p, q) = (\rho, \rho u, \rho v)$. The numerical fluxes have positive and negative contributions

$$
F_{j+1/2,k} = F^+_{j+1/2,k} + F^-_{j+1/2,k}, \qquad G_{j,k+1/2} = G^+_{j,k+1/2} + G^-_{j,k+1/2}. \tag{55}
$$

3.1. The first-order scheme. As usual, we use a piecewise constant data for $x_{j-1/2} < x < x_{j+1/2},\ y_{k-1/2} < y < y_{k+1/2}$,

$$
\begin{cases}
\rho(x,y) = \rho_{j,k}, \\
u(x,y) = u_{j,k}, \\
v(x,y) = v_{j,k}.
\end{cases} \tag{56}
$$

We use the same kinetic model (3)–(4), except that now $\xi \in \mathbb{R}^2$. The following computational lemma in one dimension will be useful.

LEMMA 3.1. *Suppose that $u(x)$ and $r(x)$ are piecewise constant functions,*

$$
u(x) = u_j,\ r(x) = r_j \quad \text{as } x \in (x_{j-1/2}, x_{j+1/2}), \tag{57}
$$

and the CFL condition is

$$
\frac{\Delta t}{\Delta x}|u| \le 1. \tag{58}
$$

Then

$$
\begin{aligned}
&\frac{1}{\Delta t}\int_0^{\Delta t} \frac{1}{\Delta x}\int_{x_{j-1/2}}^{x_{j+1/2}} \int_{-\infty}^{\infty} r(x-\xi t)\,\delta(\xi - u(x-\xi t))\,dt dx d\xi \\
&= \frac{\Delta t}{2\Delta x}\, r_{j-1}(u_{j-1})_+ + \left(1 - |u_j|\frac{\Delta t}{2\Delta x}\right) r_j - \frac{\Delta t}{2\Delta x}\, r_{j+1}(u_{j+1})_-.
\end{aligned} \tag{59}
$$

In order to get the numerical fluxes, we integrate the kinetic equation (3) over $(x_{j-1/2}, x_{j+1/2}) \times (y_{k-1/2}, y_{k+1/2}) \times \mathbb{R}^2 \times (0, \Delta t)$. Under the CFL conditions

$$\frac{\Delta t}{\Delta x}|u| \le 1, \qquad \frac{\Delta t}{\Delta y}|v| \le 1, \tag{60}$$

we find

$$\begin{aligned} F^{(1)+}_{j+1/2,k} &= \frac{1}{\Delta t \Delta y}\int_0^{\Delta t}\int_{y_{k-1/2}}^{y_{k+1/2}}\int_{\mathbb{R}} p(x_j, y-\xi_2 t)_+ \delta(\xi_2 - v(x_j, y-\xi_2 t))\, dt dy d\xi_2 \\ &= (p_{j,k})_+ + \frac{\Delta t}{2\Delta y}\Big((p_{j,k-1})_+(v_{j,k-1})_+ \\ &\qquad -(p_{j,k+1})_+(v_{j,k+1})_- - (p_{j,k})_+|v_{j,k}|\Big), \end{aligned}$$

$$\begin{aligned} F^{(1)-}_{j+1/2,k} &= \frac{1}{\Delta t \Delta y}\int_0^{\Delta t}\int_{y_{k-1/2}}^{y_{k+1/2}}\int_{\mathbb{R}} p(x_{j+1}, y-\xi_2 t)_- \delta(\xi_2 - v(x_{j+1}, y-\xi_2 t))\, dt dy d\xi_2 \\ &= (p_{j+1,k})_- + \frac{\Delta t}{2\Delta y}\Big((p_{j+1,k-1})_-(v_{j+1,k-1})_+ \\ &\qquad -(p_{j+1,k+1})_-(v_{j+1,k+1})_- - (p_{j+1,k})_-|v_{j+1,k}|\Big). \end{aligned}$$

Therefore, in compact form, the first-order kinetic scheme reads

$$\begin{aligned} F^{+}_{j+1/2,k} &= U_{j,k}(u_{j,k})_+ \\ &\quad + \frac{\Delta t}{2\Delta y}\Big(U_{j,k-1}(u_{j,k-1})_+(v_{j,k-1})_+ \\ &\qquad -U_{j,k+1}(u_{j,k+1})_+(v_{j,k+1})_- - U_{j,k}(u_{j,k})_+|v_{j,k}|\Big), \\ F^{-}_{j+1/2,k} &= U_{j+1,k}(u_{j+1,k})_- \\ &\quad + \frac{\Delta t}{2\Delta y}\Big(U_{j+1,k-1}(u_{j+1,k-1})_-(v_{j+1,k-1})_+ \\ &\qquad -U_{j+1,k+1}(u_{j+1,k+1})_-(v_{j+1,k+1})_- - U_{j+1,k}(u_{j+1,k})_-|v_{j+1,k}|\Big), \\ G^{+}_{j,k+1/2} &= U_{j,k}(v_{j,k})_+ \\ &\quad + \frac{\Delta t}{2\Delta x}\Big(U_{j-1,k}(v_{j-1,k})_+(u_{j-1,k})_+ \\ &\qquad -U_{j+1,k}(v_{j+1,k})_+(u_{j+1,k})_- - U_{j,k}(v_{j,k})_+|u_{j,k}|\Big), \\ G^{-}_{j,k+1/2} &= U_{j,k+1}(v_{j,k+1})_- \\ &\quad + \frac{\Delta t}{2\Delta x}\Big(U_{j-1,k+1}(v_{j-1,k+1})_-(u_{j-1,k+1})_+ \\ &\qquad -U_{j+1,k+1}(v_{j+1,k+1})_-(u_{j+1,k+1})_- - U_{j,k+1}(v_{j,k+1})_-|u_{j,k+1}|\Big). \end{aligned}$$

3.2. A second-order scheme. As in subsection 3.1, we use a simplified second-order scheme. Define

$$u^I_{j,k} = \overline{u}_{j,k} + \frac{\Delta x}{2} D_x u_{j,k} + \frac{\Delta y}{2} D_y u_{j,k}, \tag{61}$$

$$u^{II}_{j,k} = \overline{u}_{j,k} - \frac{\Delta x}{2} D_x u_{j,k} + \frac{\Delta y}{2} D_y u_{j,k}, \tag{62}$$

$$u^{III}_{j,k} = \overline{u}_{j,k} - \frac{\Delta x}{2} D_x u_{j,k} - \frac{\Delta y}{2} D_y u_{j,k}, \tag{63}$$

$$u^{IV}_{j,k} = \overline{u}_{j,k} + \frac{\Delta x}{2} D_x u_{j,k} - \frac{\Delta y}{2} D_y u_{j,k}, \tag{64}$$

where

$$\overline{u}_{j,k} = u_{j,k} - \frac{\Delta x^2}{4\rho_{j,k}} D_x \rho_{j,k} D_x u_{j,k} - \frac{\Delta y^2}{4\rho_{j,k}} D_y \rho_{j,k} D_y u_{j,k}. \tag{65}$$

We can define ρ and v in a similar way. Then it is easy to derive the following formulas, valid under half CFL conditions:

$$\begin{aligned}
F^{+}_{j+1/2,k} = {} & \frac{1}{2}\Big((Uu_+)^{I}_{j,k} + (Uu_+)^{IV}_{j,k}\Big) \\
& + \frac{\Delta t}{2\Delta y}\Big(-(Uu_+v_+)^{I}_{j,k} + (Uu_+v_-)^{IV}_{j,k} \\
& \qquad + (Uu_+v_+)^{I}_{j,k-1} - (Uu_+v_-)^{IV}_{j,k+1}\Big), \\
F^{-}_{j+1/2,k} = {} & \frac{1}{2}\Big((Uu_-)^{II}_{j+1,k} + (Uu_-)^{III}_{j+1,k}\Big) \\
& + \frac{\Delta t}{2\Delta y}\Big(-(Uu_-v_+)^{II}_{j+1,k} + (Uu_-v_-)^{III}_{j+1,k} \\
& \qquad + (Uu_-v_+)^{II}_{j+1,k-1} - (Uu_-v_-)^{III}_{j+1,k+1}\Big),
\end{aligned}$$

$$\begin{aligned}
G^{+}_{j,k+1/2} = {} & \frac{1}{2}\Big((Uv_+)^{I}_{j,k} + (Uv_+)^{II}_{j,k}\Big) \\
& + \frac{\Delta t}{2\Delta x}\Big(-(Uv_+u_+)^{I}_{j,k} + (Uv_+u_-)^{II}_{j,k} \\
& \qquad + (Uv_+u_+)^{I}_{j-1,k} - (Uv_+u_-)^{II}_{j+1,k}\Big), \\
G^{-}_{j,k+1/2} = {} & \frac{1}{2}\Big((Uv_-)^{IV}_{j,k+1} + (Uv_-)^{III}_{j,k+1}\Big) \\
& + \frac{\Delta t}{2\Delta x}\Big(-(Uv_-u_+)^{IV}_{j,k+1} + (Uv_-u_-)^{III}_{j,k+1} \\
& \qquad + (Uv_-u_+)^{IV}_{j-1,k+1} - (Uv_-u_-)^{III}_{j+1,k+1},\Big).
\end{aligned}$$

4. Isothermal gas dynamics. We now wish to generalize the previous schemes to the system of isothermal gas dynamics

$$\begin{cases} \partial_t \rho + \partial_x(\rho u) = 0, \\ \partial_t(\rho u) + \partial_x(\rho u^2 + \nu^2 \rho) = 0, \end{cases} \tag{66}$$

with $\rho(x,t) \geq 0$, $u(x,t) \in \mathbb{R}$, and $\nu > 0$. Features that are desirable for a numerical scheme to solve (66) are positivity preserving for the density ρ, the ability to treat data with vacuum, and a discrete entropy inequality. We shall achieve these goals in such a way that (at least for first-order), as $\nu \to 0$, the scheme reduces to the one presented in section 2.1. We recall that the physical energy

$$\eta(\rho, u) = \rho u^2/2 + \nu^2 \rho \ln \frac{\rho}{\sqrt{2\pi\nu}} \tag{67}$$

is a convex entropy for (66), with entropy flux

$$\vartheta(\rho,u)=\big(\eta(\rho,u)+\nu^2\rho\big)\,u, \tag{68}$$

i.e., $\vartheta'=\eta' F'$, where $F=(\rho u,\rho u^2+\nu^2\rho)$, and prime stands for differentiation with respect to $(\rho, q=\rho u)$.

Since second-order accuracy can be obtained as usual with a half CFL condition (as in section 2.4), we give only the first-order scheme. We shall use again a kinetic method, as described in [3], with the physical Maxwellian equilibrium

$$M(\rho,u,\xi)=\begin{pmatrix}1\\ \xi\end{pmatrix}\frac{\rho}{\sqrt{2\pi}\nu}e^{-(\xi-u)^2/2\nu^2},\qquad \rho\ge 0,\ u,\xi\in\mathbb{R}. \tag{69}$$

We can decompose the flux F of (66) as

$$F(\rho,u)\equiv(\rho u,\rho u^2+\nu^2\rho)=F^+(\rho,u)+F^-(\rho,u), \tag{70}$$

with

$$F^+(\rho,u)=\int_0^\infty \xi M(\rho,u,\xi)\,d\xi,\quad F^-(\rho,u)=\int_{-\infty}^0 \xi M(\rho,u,\xi)\,d\xi. \tag{71}$$

These half-fluxes are homogeneous of degree 1 with respect to $(\rho,\rho u)$, and this enables the scheme to treat vacuum data. The numerical scheme then takes the form

$$U_j^{n+1}-U_j^n+\frac{\Delta t}{\Delta x}(F_{j+1/2}-F_{j-1/2})=0, \tag{72}$$

with $U_j^n=(\rho_j^n,\rho_j^n u_j^n)$ and

$$F_{j+1/2}=F^+(\rho_j^n,u_j^n)+F^-(\rho_{j+1}^n,u_{j+1}^n). \tag{73}$$

Since the Maxwellian M in (69) does not have a compact support in ξ, we cannot apply the classical CFL condition $\Delta t\sup_{\xi\in\mathrm{supp}M}|\xi|\le\Delta x$ to derive positiveness of density and entropy inequalities. Therefore, we are going to use the analysis of [3] to derive explicitly a sufficient CFL condition. The scheme will satisfy the discrete entropy inequality

$$\eta(\rho_j^{n+1},u_j^{n+1})-\eta(\rho_j^n,u_j^n)+\frac{\Delta t}{\Delta x}(\vartheta_{j+1/2}-\vartheta_{j-1/2})\le 0, \tag{74}$$

with

$$\vartheta_{j+1/2}=\vartheta^+(\rho_j^n,u_j^n)+\vartheta^-(\rho_{j+1}^n,u_{j+1}^n), \tag{75}$$

and ϑ^+, ϑ^- verify $(\vartheta^+)'=\eta'(F^+)'$, $(\vartheta^-)'=\eta'(F^-)'$ and are given by

$$\vartheta^+(\rho,u)=\int_0^\infty \xi H(M(\rho,u,\xi),\xi)\,d\xi,\ \vartheta^-(\rho,u)=\int_{-\infty}^0 \xi H(M(\rho,u,\xi),\xi)\,d\xi, \tag{76}$$

where, for any $f=(f_0,f_1)$ with $f_0\ge 0$, $f_1=\xi f_0$,

$$H(f,\xi)=f_0\xi^2/2+\nu^2 f_0\ln f_0. \tag{77}$$

Let us recall the results of [3], which apply to our case.

DEFINITION 4.1. *A vector function $W(U)$ satisfying*

$$W'(U)^t\eta''(U) \quad \textit{is symmetric} \tag{78}$$

is said to be η-dissipative in a set $\mathcal{U}_{stab}$ if

$$D_\eta[W](U,V) \le 0 \quad \textit{for all } U,V \in \mathcal{U}_{stab}, \tag{79}$$

where the elementary entropy dissipation is defined by

$$D_\eta[W](U,V) = G_\eta[W](U) - G_\eta[W](V) + \eta'(U)(W(V) - W(U)), \tag{80}$$

and

$$G_\eta[W]' = \eta' W'. \tag{81}$$

PROPOSITION 4.2 (see [3]). *Let F^+, F^- be given by* (70), *and assume that*

$$F^+, \quad -F^- \quad \textit{are } \eta\textit{-dissipative in } \mathcal{U}_{stab}, \tag{82}$$

and the CFL conditions are

$$c\Delta t \le \Delta x, \tag{83}$$

$$\mathrm{Id} - (F^+ - F^-)/c \quad \textit{is } \eta\textit{-dissipative in } \mathcal{U}_{stab} \tag{84}$$

for some $c > 0$. Then the scheme (72)–(73) *satisfies the discrete entropy inequality* (74)–(75) *as soon as $U_j^n \in \mathcal{U}_{stab}$, $j \in \mathbb{Z}$, and $U_j^{n+1} \in \mathcal{U}_{stab}$, $j \in \mathbb{Z}$.*

The main result of this section is the following. We state it for positive densities, but by continuity it also holds for data with vacuum.

THEOREM 4.3. *Assume that at time t_n, $U_j^n = (\rho_j^n, \rho_j^n u_j^n)$ satisfy for some $c > 0$*

$$\rho_j^n > 0, \quad |u_j^n| + \left(\frac{4}{\sqrt{2\pi}} + \frac{\sqrt{2\pi}}{2}\right)\nu \le c \quad \textit{for } j \in \mathbb{Z}. \tag{85}$$

Define $\mathcal{U}_{stab}$ as

$$\mathcal{U}_{stab} = \left\{(\rho, \rho u)\ ;\ \rho > 0,\ |u| + \frac{4}{\sqrt{2\pi}}\nu \le c\right\}. \tag{86}$$

Then the stability requirements (82), (84) *hold, and under the CFL condition* (83) *the $(U_j^{n+1})_{j\in\mathbb{Z}}$ defined by* (72) *belong to $\mathcal{U}_{stab}$. Therefore, by Proposition* 4.2, *the entropy inequalities* (74) *hold.*

Before going into the proof of Theorem 4.3, let us first give explicit formulas for the fluxes and entropy fluxes. Let us define

$$\mathcal{M}(\xi) = \frac{e^{-\xi^2/2}}{\sqrt{2\pi}}, \tag{87}$$

$$\mathrm{erf}(y) = \int_y^\infty \mathcal{M}(\xi)\, d\xi. \tag{88}$$

Then

$$\begin{gathered}\int_y^\infty \xi\mathcal{M}(\xi)\,d\xi = \mathcal{M}(y), \quad \int_y^\infty \xi^2\mathcal{M}(\xi)\,d\xi = y\mathcal{M}(y) + \operatorname{erf}(y),\\ \int_y^\infty \xi^3\mathcal{M}(\xi)\,d\xi = (y^2+2)\mathcal{M}(y).\end{gathered}\tag{89}$$

With these formulas, one can easily check that

$$\begin{aligned}F^+(\rho,u) = \Big(&\rho u\operatorname{erf}(-u/\nu) + \rho\nu\mathcal{M}(u/\nu),\\ &(\rho u^2+\rho\nu^2)\operatorname{erf}(-u/\nu) + \nu\rho u\mathcal{M}(u/\nu)\Big).\end{aligned}\tag{90}$$

Noticing that, with $M = (M_0, M_1)$,

$$M(\rho,u,-\xi) = \Big(M_0(\rho,-u,\xi), -M_1(\rho,-u,\xi)\Big),\tag{91}$$

we get

$$F^-(\rho,u) = \Big(-F_0^+(\rho,-u), F_1^+(\rho,-u)\Big),\tag{92}$$

where $F^+ = (F_0^+, F_1^+)$, and therefore

$$\begin{aligned}F^+ - F^- = \Big(&\rho u\,(\operatorname{erf}(-u/\nu) - \operatorname{erf}(u/\nu)) + 2\nu\rho\mathcal{M}(u/\nu),\\ &(\rho u^2+\nu^2\rho)\,(\operatorname{erf}(-u/\nu) - \operatorname{erf}(u/\nu)) + 2\nu\rho u\mathcal{M}(u/\nu)\Big).\end{aligned}\tag{93}$$

For the computation of ϑ^+, we have

$$\begin{aligned}\vartheta^+(\rho,u) &= \int_0^\infty \xi H(M(\rho,u,\xi),\xi)\,d\xi\\ &= \int_0^\infty \xi\frac{\rho}{\nu}\mathcal{M}\left(\frac{\xi-u}{\nu}\right)\left(\nu^2\ln\frac{\rho}{\sqrt{2\pi}\nu} - u^2/2 + u\xi\right)d\xi\\ &= \left(\nu^2\ln\frac{\rho}{\sqrt{2\pi}\nu} - u^2/2\right)F_0^+(\rho,u) + uF_1^+(\rho,u)\end{aligned}\tag{94}$$

and

$$\vartheta^-(\rho,u) = -\vartheta^+(\rho,-u).\tag{95}$$

Proof of Theorem 4.3. Let us first prove that (82) and (84) hold. We notice that η is strictly convex, with

$$\eta' = \left(\nu^2\left(1+\ln\frac{\rho}{\sqrt{2\pi}\nu}\right) - u^2/2, u\right) \equiv (v_0, v_1),\tag{96}$$

and that $\eta'(\mathcal{U}_{stab})$ is convex. Therefore, as pointed out in [3], a function W is η-dissipative in $\mathcal{U}_{stab}$ if and only if it satisfies

$$W'(U)^t\eta''(U) \text{ is symmetric nonnegative for any } U\in\mathcal{U}_{stab}.\tag{97}$$

This is also equivalent to assert that

$$W = \nabla_{v_0,v_1}\psi_W, \qquad \psi_W \text{ convex in } \eta'(\mathcal{U}_{stab}).\tag{98}$$

We observe that

$$\nu^2 M_0(\rho,u,\xi) = \nu \frac{\rho}{\sqrt{2\pi}} e^{-(\xi-u)^2/2\nu^2} = \nu^2 e^{(v_0+v_1\xi-\xi^2/2)/\nu^2-1}, \tag{99}$$

thus

$$M(\rho,u,\xi) = \nabla_{v_0,v_1}\psi(\rho,u,\xi), \qquad \psi(\rho,u,\xi) = \nu^2 M_0(\rho,u,\xi), \tag{100}$$

and therefore $F^+ = \nabla_{v_0,v_1}\psi^+$, $F^- = \nabla_{v_0,v_1}\psi^-$, with

$$\psi^+ = \int_0^\infty \xi\psi(\rho,u,\xi)\,d\xi, \qquad \psi^- = \int_{-\infty}^0 \xi\psi(\rho,u,\xi)\,d\xi. \tag{101}$$

Since $(\rho,\rho u) = \nabla_{v_0,v_1}\eta^*(v_0,v_1)$ with $\eta^*(v_0,v_1) = \eta'\cdot U - \eta$, the dual convex function of η (here, $\eta^* = \nu^2\rho$), we have to check that ψ^+, $-\psi^-$ and $\eta^* - (\psi^+ - \psi^-)/c$ are convex with respect to $(v_0,v_1) \in \eta'(\mathcal{U}_{stab})$. In other words, we have to check the nonnegativity of $D^2_{v_0,v_1}\psi^+$, $-D^2_{v_0,v_1}\psi^-$, $(\eta'')^{-1} - D^2_{v_0,v_1}(\psi^+ - \psi^-)/c$ in $\eta'(\mathcal{U}_{stab})$.

From (101) and (99), we get

$$D^2_{v_0,v_1}\psi^+ = \int_0^\infty \xi\,\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}\frac{d\xi}{\nu^4}, \tag{102}$$

$$D^2_{v_0,v_1}\psi^- = \int_{-\infty}^0 \xi\,\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}\frac{d\xi}{\nu^4}, \tag{103}$$

and the two first properties follow. Next, since

$$\begin{aligned}(\eta'')^{-1} &= \nabla_{v_0,v_1}\begin{pmatrix} \rho \\ \rho u \end{pmatrix} = \nabla_{v_0,v_1}\int_{\mathbb{R}} M(\rho,u,\xi)\,d\xi \\ &= D^2_{v_0,v_1}\int_{\mathbb{R}}\psi(\rho,u,\xi)\,d\xi \\ &= \int_{\mathbb{R}}\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}\frac{d\xi}{\nu^4},\end{aligned} \tag{104}$$

we obtain for $(\rho,\rho u) \in \mathcal{U}_{stab}$

$$\begin{aligned}&c(\eta'')^{-1} - D^2_{v_0,v_1}(\psi^+ - \psi^-) \\ &= \frac{1}{\nu^4}\int_{\mathbb{R}}(c - |\xi|)\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}d\xi \\ &\geq \frac{1}{\nu^4}\int_{\mathbb{R}}\left(|u| + \frac{4}{\sqrt{2\pi}}\nu - |\xi|\right)\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}d\xi \\ &\geq \frac{1}{\nu^4}\int_{\mathbb{R}}\left(\frac{4}{\sqrt{2\pi}}\nu - |\xi - u|\right)\psi(\rho,u,\xi)\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}d\xi.\end{aligned} \tag{105}$$

Noticing that

$$\begin{pmatrix} 1 & \xi \\ \xi & \xi^2 \end{pmatrix}\cdot\begin{pmatrix} y_0 \\ y_1 \end{pmatrix}\cdot\begin{pmatrix} y_0 \\ y_1 \end{pmatrix} = \begin{pmatrix} 1 & (\xi-u)/\nu \\ (\xi-u)/\nu & (\xi-u)^2/\nu^2 \end{pmatrix}\cdot\begin{pmatrix} y_0' \\ y_1' \end{pmatrix}\cdot\begin{pmatrix} y_0' \\ y_1' \end{pmatrix}$$

with $y_0' = y_0 + uy_1$ and $y_1' = \nu y_1$, we observe that the positiveness of (105) is equivalent to

$$\int_{\mathbb{R}} \left(\frac{4}{\sqrt{2\pi}}\nu - |\xi - u| \right) \psi(\rho, u, \xi) \begin{pmatrix} 1 & (\xi - u)/\nu \\ (\xi - u)/\nu & (\xi - u)^2/\nu^2 \end{pmatrix} d\xi \geq 0. \tag{106}$$

This is checked easily with (89); the computation of this integral is left to the reader; and this concludes the first part of the theorem.

It now remains to prove that $U_j^{n+1} \in \mathcal{U}_{stab}$.

Lemma 4.4. *For any $\rho \geq 0$, $u \in \mathbb{R}$, we have $F_0^+(\rho, u) \geq 0$, $F_0^-(\rho, u) \leq 0$, and*

$$0 \leq F_1^+(\rho, u) \leq \left(u_+ + \nu\sqrt{2\pi}/2\right) F_0^+(\rho, u), \tag{107}$$

$$0 \leq F_1^-(\rho, u) \leq \left((-u)_+ + \nu\sqrt{2\pi}/2\right)(-F_0^-(\rho, u)). \tag{108}$$

Moreover, whenever $(\rho, \rho u) \in \mathcal{U}_{stab}$,

$$\rho - \frac{F_0^+(\rho, u) - F_0^-(\rho, u)}{c} > 0, \tag{109}$$

$$\left| \rho u - \frac{F_1^+(\rho, u) - F_1^-(\rho, u)}{c} \right| \leq \left(\rho - \frac{F_0^+(\rho, u) - F_0^-(\rho, u)}{c} \right) |u|. \tag{110}$$

Let us postpone the proof of the lemma and conclude with Theorem 4.3. Since $U \equiv U_j^n$ satisfies (85), we have $U \in \mathcal{U}_{stab}$, and by (109)–(110)

$$\left| \frac{\rho u - (F_1^+ - F_1^-)/c}{\rho - (F_0^+ - F_0^-)/c} \right| + \frac{4}{\sqrt{2\pi}}\nu \leq c. \tag{111}$$

Then, from (107), (108), and (85)

$$\frac{F_1^+}{F_0^+} + \frac{4}{\sqrt{2\pi}}\nu \leq u_+ + \frac{\sqrt{2\pi}}{2}\nu + \frac{4}{\sqrt{2\pi}}\nu \leq c, \tag{112}$$

$$\frac{F_1^-}{-F_0^-} + \frac{4}{\sqrt{2\pi}}\nu \leq (-u)_+ + \frac{\sqrt{2\pi}}{2}\nu + \frac{4}{\sqrt{2\pi}}\nu \leq c. \tag{113}$$

We deduce that

$$F^+(\rho, u)/c, \quad -F^-(\rho, u)/c, \quad U - (F^+(\rho, u) - F^-(\rho, u))/c \ \in \mathcal{U}_{stab}. \tag{114}$$

Finally, we write

$$\begin{aligned} U_j^{n+1} &= U_j^n - \frac{\Delta t}{\Delta x}\left(F^+(U_j^n) + F^-(U_{j+1}^n) - F^+(U_{j-1}^n) - F^-(U_j^n)\right) \\ &= \left(1 - \frac{c\Delta t}{\Delta x}\right) U_j^n + \frac{c\Delta t}{\Delta x}\left(U_j^n - F^+(U_j^n)/c + F^-(U_j^n)/c\right) \\ &\quad + \frac{\Delta t}{\Delta x} F^+(U_{j-1}^n) - \frac{\Delta t}{\Delta x} F^-(U_{j+1}^n), \end{aligned} \tag{115}$$

and since $\mathcal{U}_{stab}$ is a convex cone we conclude with the CFL condition (83) that $U_j^{n+1} \in \mathcal{U}_{stab}$. □

Proof of Lemma 4.4. From (69) and (71), we obviously have $F_0^+ \geq 0$, $F_1^+ \geq 0$. However, from (90),

$$F_1^+ = uF_0^+ + \nu^2 \rho \operatorname{erf}(-u/\nu). \tag{116}$$

One can check that

$$\sup_{y \geq 0} \frac{\operatorname{erf}(-y)}{y \operatorname{erf}(-y) + \mathcal{M}(y)} = \frac{\sqrt{2\pi}}{2}, \tag{117}$$

the maximum being attained at $y = 0$. Therefore,

$$\text{for all } u \geq 0, \qquad F_1^+(\rho, u) \leq \left(u + \frac{\sqrt{2\pi}}{2} \nu \right) F_0^+(\rho, u). \tag{118}$$

Then we observe that if $\rho > 0$,

$$F_0^+ = \int_0^\infty \xi e^{(v_0 + v_1 \xi - \xi^2/2)/\nu^2 - 1} \, d\xi, \tag{119}$$

with (v_0, v_1) defined in (96), thus this function is log-convex in v_1 as an integral of a log-convex function. Next,

$$F_1^+ = \int_0^\infty \xi^2 e^{(v_0 + v_1 \xi - \xi^2/2)/\nu^2 - 1} \, d\xi = \nu^2 \partial_{v_1} F_0^+. \tag{120}$$

Therefore, $F_1^+/F_0^+ = \nu^2 \partial_{v_1} (\ln F_0^+)$ is nondecreasing in v_1, and we deduce that, for $v_1 \leq 0$, F_1^+/F_0^+ is upper bounded by the value at $v_1 = 0$, that is, $\nu\sqrt{2\pi}/2$. Together with (118), we conclude that (107) holds. Obviously, (108) follows from (92). In order to prove (109)–(110), let us first establish that, for any $u \in \mathbb{R}$,

$$(u^2 + \nu^2) \frac{2}{u} \int_0^{u/\nu} \frac{e^{-\xi^2/2}}{\sqrt{2\pi}} d\xi \leq |u| + \frac{2}{\sqrt{2\pi}} \nu. \tag{121}$$

Indeed, the left-hand side is an even nonnegative function of u. On one hand, if $u \geq \nu\sqrt{2\pi}/2$, by bounding the integral by $1/2$, we can estimate the left-hand side by $(u^2 + \nu^2)/u \leq u + 2\nu/\sqrt{2\pi}$. On the other hand, if $0 < u \leq \nu\sqrt{2\pi}/2$, we can estimate the integral by $u/\sqrt{2\pi}\nu$, thus the left-hand side is less than $(u^2 + \nu^2)2/\sqrt{2\pi}\nu \leq u + 2\nu/\sqrt{2\pi}$. This proves (121).

Now we use (93) and get that

$$\rho - \frac{F_0^+ - F_0^-}{c} = \rho \left(1 - \left(2u \int_0^{u/\nu} \mathcal{M}(\xi) \, d\xi + 2\nu \mathcal{M}(u/\nu) \right) /c \right), \tag{122}$$

and using (121) and $\mathcal{M}(u/\nu) \leq 1/\sqrt{2\pi}$ we get with (86) that (122) is positive. Finally, from (93),

$$\rho u - \frac{F_1^+ - F_1^-}{c} = u \left(\rho - \frac{F_0^+ - F_0^-}{c} - \frac{\nu^2 \rho}{c} \frac{2}{u} \int_0^{u/\nu} \mathcal{M}(\xi) \, d\xi \right). \tag{123}$$

By (121) and (86) again,

$$0 \le \rho - \frac{F_0^+ - F_0^-}{c} - \frac{\nu^2\rho}{c}\frac{2}{u}\int_0^{u/\nu} \mathcal{M}(\xi)\,d\xi \le \rho - \frac{F_0^+ - F_0^-}{c}, \tag{124}$$

which yields (110). □

Remark. When using the Godunov method to solve the isothermal problem with vacuum initial data, the speed defined by the exact Riemann solution is infinity; see the third test in section 5. The kinetic scheme, which takes the form of a flux vector splitting, can be interpreted as an approximate Riemann solver with a finite speed [3], thus the timestep can be nonzero. The speed of this approximate Riemann solver is the c in Theorem 4.3, which needs to bound the eigenvalues, but *only on initial data* rather than the exact solution (which would be infinity). The counterpart is that the sound speed is increased by a factor greater than one, $4/\sqrt{2\pi} + \sqrt{2\pi}/2$ in (85). Then, at the end of the first timestep, the new velocity will be greater than its initial value, thus c needs to be recomputed at each timestep. A rough estimate of this increase is contained in the statement in Theorem 4.3 that says that U_j^{n+1} belongs to $\mathcal{U}_{stab}$. Thus the maximal velocity increases by at most a constant, $\nu\sqrt{2\pi}/2$, at each timestep (that is chosen to satisfy the CFL condition). This gives the following rough estimates:

$$\|u^n\| \approx \|u^0\| + n\nu, \qquad \Delta t_n \approx \Delta x/(\|u^0\| + n\nu)\,.$$

The sum over all n of these timesteps is infinity. This justifies that we can attain any given time T in a finite number of timesteps, roughly $\Delta x/\nu \ln(1+n\nu/\|u^0\|) = T$, thus $n = \|u^0\|(e^{T\nu/\Delta x} - 1)/\nu$. The size of the support is of the order of $n\Delta x$.

5. Numerical tests.

We now conduct several numerical tests using the numerical schemes we have derived. In the first two tests, we solve the pressureless gas system and compare the first-order kinetic scheme with the first-order Godunov scheme and the second-order kinetic schemes. In the third test, we solve the isothermal system with vacuum data by both the first- and the second-order kinetic schemes.

In the first numerical test, we take the initial data to be

$$\rho^0 = 0.5\,, \qquad u^0(x) = \begin{cases} -0.5, & x < -0.5, \\ 0.4, & -0.5 < x < 0, \\ 0.4 - x, & 0 < x < 0.8, \\ -0.4, & x > 0.8. \end{cases}$$

The exact solution at time $t = 0.5$ is

$$u(x, 0.5) = \begin{cases} -0.5, & x < -0.75, \\ \text{undefined} & -0.75 < x < -0.3, \\ 0.4, & -0.3 < x < 0.2, \\ 0.8 - 2x, & 0.2 < x < 0.6, \\ -0.4, & x > 0.6, \end{cases}$$

and

$$\rho(x, 0.5) = \begin{cases} 0, & -0.75 < x < -0.3, \\ 1, & 0.2 < x < 0.6, \\ 0.5 & \text{otherwise.} \end{cases}$$

The initial velocity jumps to a higher value at $x = -0.5$, which leads to a vacuum state, followed by a linearly decreasing part, where the mass accumulates and causes

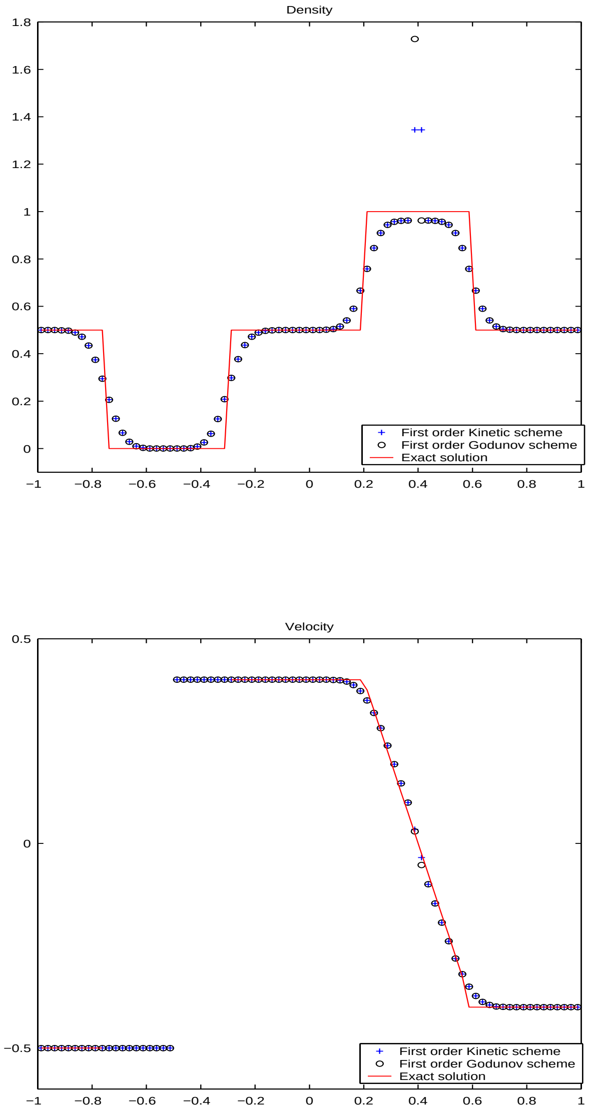

FIG. 1. *Numerical test* I. $\Delta t/\Delta x = 5/3$, $\Delta x = 0.025$.

the density to increase. In the density profile, first-order kinetic and Godunov schemes form a spike, due to some inconsistency at sonic points that was noticed in [2]. See Figure 1. This problem goes away with all second-order kinetic schemes, among which the improved scheme slightly outperforms the other two and the simplified scheme is slightly inferior to the other two, as shown by Figure 2.

A Riemann problem is solved in the second test. We take

$$(\rho^0(x), u^0(x)) = \begin{cases} (1, 0.5) & x < 0, \\ (0.25, -0.4) & x > 0. \end{cases}$$

A delta-shock immediately develops and by (18) the shock speed is 0.2. As shown in Figures 3 and 4, all the numerical schemes are able to capture the delta-shock with

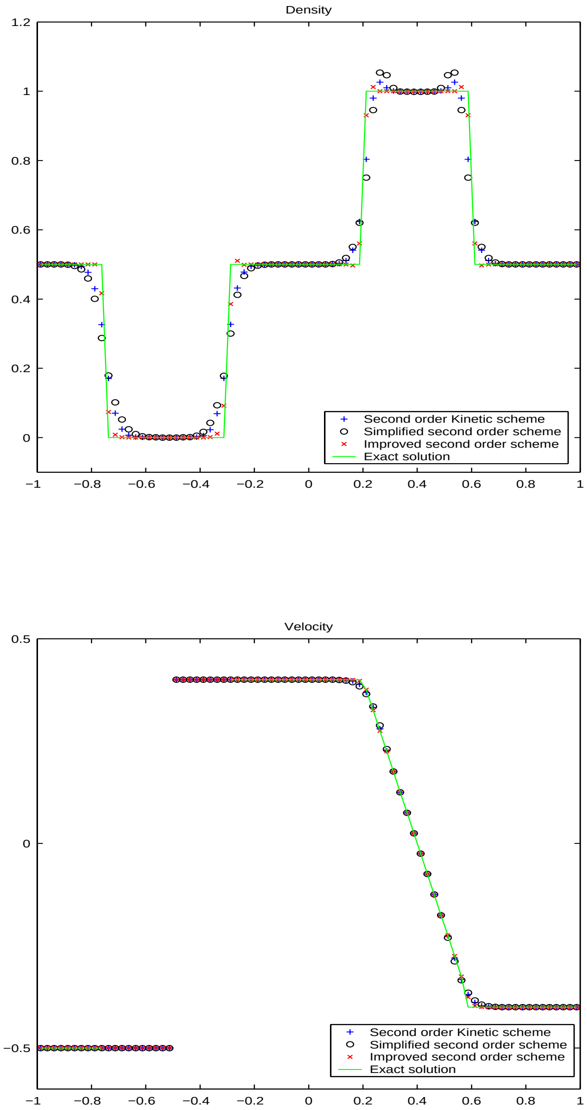

FIG. 2. *Numerical test* I. $\Delta t/\Delta x = 5/3$, $\Delta x = 0.025$.

the correct propagation speed. The numerical approximations provided by the second-order schemes give a slightly sharper profile across the velocity discontinuity.

In the third test, we solve the isothermal gas equations (66) with $\nu = 0.2$ and the vacuum initial data

$$\rho^0(x) = \begin{cases} 0 & x < 0, \\ 1 & x > 0, \end{cases} \qquad u^0(x) = 0.$$

The exact solution at time t is given by

$$(\rho(x,t), u(x,t)) = \begin{cases} (\mathrm{e}^{x/\nu t-1}, x/t - \nu) & x < \nu t, \\ (1,0) & x > \nu t. \end{cases}$$

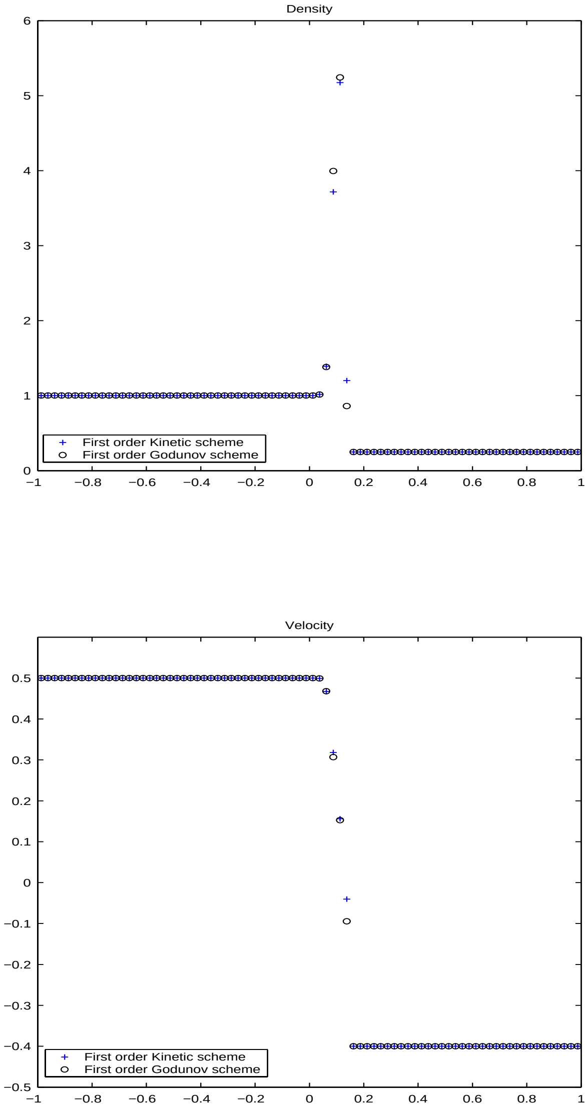

FIG. 3. *Numerical test* II. $\Delta t/\Delta x = 5/3$, $\Delta x = 0.025$.

The density decays exponentially to zero while the velocity goes to minus infinity linearly in the vacuum state. The numerical results for $t = 0.5$ are shown in Figure 5. Both first- and second-order kinetic schemes give accurate density profile, while for the velocity the second-order scheme yields more accurate velocity slope than the first-order one.

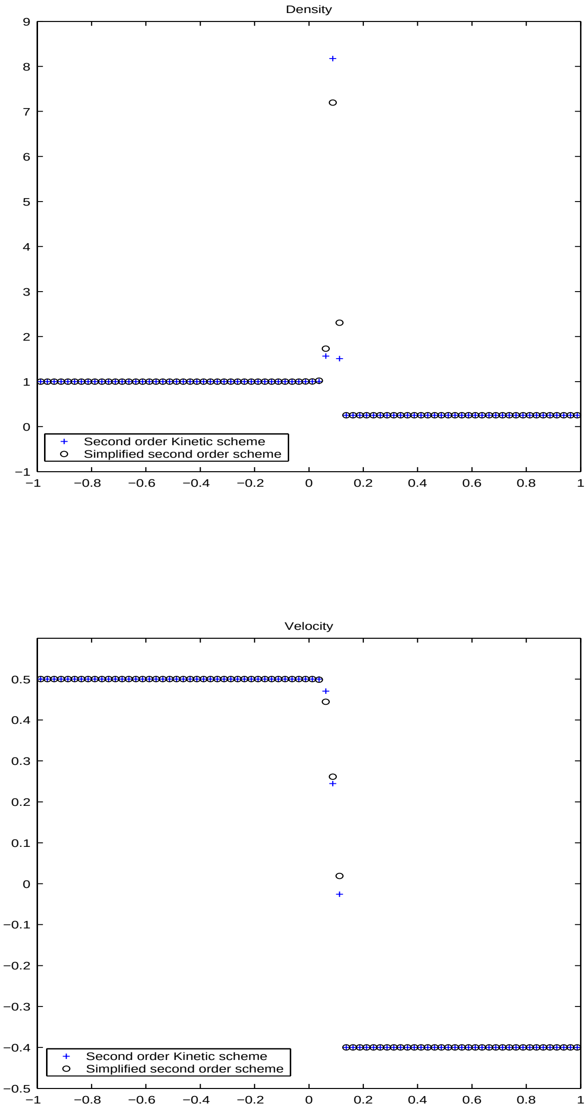

FIG. 4. *Numerical test* II. $\Delta t/\Delta x = 5/3$, $\Delta x = 0.025$.

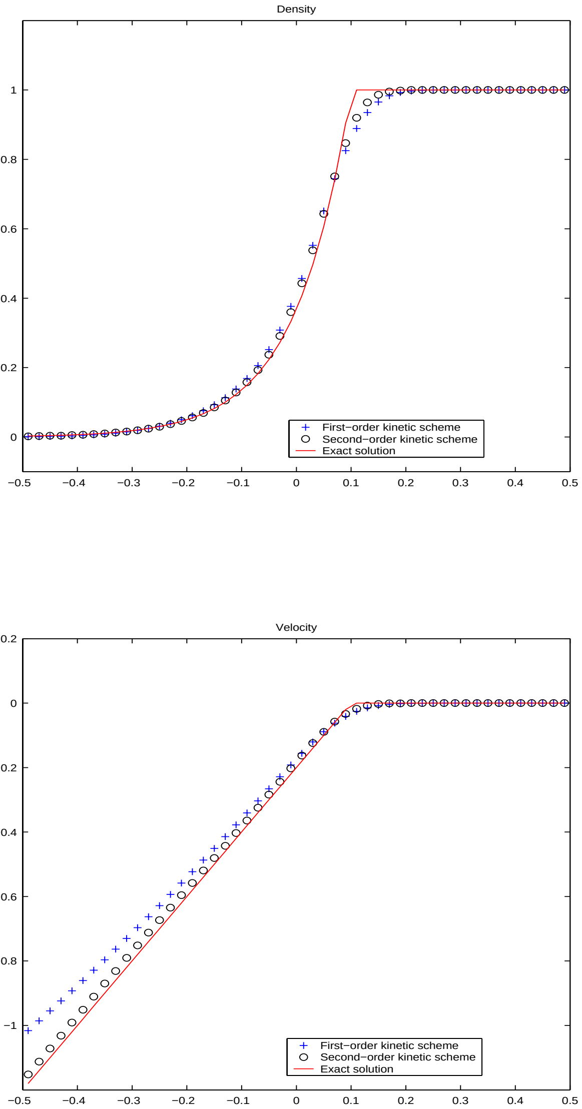

FIG. 5. *Numerical test* III. $t = 0.5$, $\Delta x = 0.02$.

WAVELET DISCRETIZATIONS OF PARABOLIC INTEGRODIFFERENTIAL EQUATIONS*

T. VON PETERSDORFF[†] AND C. SCHWAB[‡]

Abstract. We consider parabolic problems $\dot{u} + Au = f$ in $(0,T) \times \Omega$, $T < \infty$, where $\Omega \subset \mathbb{R}^d$ is a bounded domain and A is a strongly elliptic classical pseudodifferential operator of order $\rho \in [0,2]$ in $\tilde{H}^{\rho/2}(\Omega)$. We use a θ-scheme for time discretization and a Galerkin method with N degrees of freedom for space discretization. The full Galerkin matrix for A can be replaced with a sparse matrix using a wavelet basis, and the linear systems for each time step are solved approximatively with GMRES. We prove that the total cost of the algorithm for M time steps is bounded by $O(MN(\log N)^\beta)$ operations and $O(N(\log N)^\beta)$ memory. We show that the algorithm gives optimal convergence rates (up to logarithmic terms) for the computed solution with respect to L^2 in time and the energy norm in space.

1. Introduction.

Fast algorithms such as wavelets and multipole or clustering methods for the numerical solution of elliptic integrodifferential equations

$$A[u](x) = \int_\Omega k(x, x-y)u(y)dy = f, \qquad x \in \Omega, \tag{1.1}$$

with kernel function $k(x,z)$, have been introduced and analyzed in recent years (see, e.g., [3, 4, 7]). In the present paper we investigate the numerical solution of a class of parabolic integrodifferential equations

$$u_t = A[u](x) + f \quad \text{ in } (0,T) \times \Omega, \tag{1.2}$$

with suitable initial and boundary conditions. Such equations arise as Kolmogorov forward equations for Lévy processes X_t with infinitesimal generators $A[u]$. Brownian motion B_t with diffusion $\sigma(x)$ and drift $r(x)$ is a particular Lévy process. The infinitesimal generator of B_t in dimension $d = 1$ is the second order elliptic differential operator

$$A_B[u](x) = -\frac{d}{dx}\left(\sigma(x)\frac{du}{dx}(x)\right) + r(x)\frac{du}{dx}, \tag{1.3}$$

and the Kolmogorov forward equation is the diffusion equation with drift. The decomposition theorem of Lévy states that the infinitesimal generator A of any Lévy-process X_t is the sum of a differential operator A_B as in (1.3), which accounts for the diffusion

part of X_t and could possibly vanish, and a nonlocal operator A_L of the form (1.1), which corresponds to the pure jump part of the process (see, e.g., [2, 12]). The order ρ of the infinitesimal generator A of a Lévy-process always satisfies

$$0 \leq \rho \leq 2. \tag{1.4}$$

We emphasize that due to (1.4) the kernels $k(x, z)$ are not integrable near $z = 0$ and that the integral in (1.1) has to be understood as a finite part or principal value, i.e., in the sense of distributions [16]. Interpretations of the integral operators A in the distribution sense can naturally be accounted for in Galerkin discretizations.

While the initial-boundary value problems (1.2) with (1.3) and constant σ, r can be solved analytically for certain initial conditions, numerical solutions are required for nonconstant coefficients, general Lévy-processes, and free boundary problems arising with optimal stopping of X_t. In a numerical solution, $u(x, t)$ is approximated by finite differences or finite elements in x with N degrees of freedom, reducing (1.2) to a system of N ordinary differential equations for the approximation u_N which must be integrated in t by a time-stepping scheme. We consider the θ-scheme for time discretization, which includes as special cases the forward Euler method ($\theta = 0$), the backward Euler method ($\theta = 1$), and the Crank–Nicolson method ($\theta = \frac{1}{2}$). In general this leads to implicit methods where a linear system has to be solved for each time step. For the differential operator (1.3) in dimension $d = 1$, the matrices to be inverted in each time step are banded and can be factored in $O(N)$ operations. If the operator A is nonlocal, however, standard Galerkin discretizations of u with N degrees of freedom entail dense stiffness matrices and hence at least $O(N^2)$ complexity per time step for the numerical solution of (1.2). We reduce this complexity by a wavelet-based matrix compression as in [10, 11, 14, 4]. The basic idea behind this compression is to represent the Galerkin approximation u_N of (1.2) in a wavelet basis. Wavelet matrix compression exploits the fact that the generators A are often classical pseudodifferential operators, which implies special properties of their Schwartz kernel function $k(x, z)$ such as

$$\text{sing supp}(k(x, z)) \subset \{z = 0\}$$

and even analyticity of $k(x, z)$ off the origin $z = 0$. Wavelet matrix compression requires only finite differentiability of $k(x, z)$ for $z \neq 0$ and allows the generation of an approximate stiffness matrix of the nonlocal operator A in (1.1) in $O(N(\log N)^a)$ memory and operations where $a \geq 0$ is a small integer (see, e.g., [3, 4, 10, 9, 11, 14] and the references there).

The analysis of the impact of this truncation error on stability and consistency of the θ time-stepping scheme for the nonlocal parabolic initial-boundary value problems (1.1), (1.2) is the purpose of the present paper. A large body of literature on time-stepping for parabolic problems with Galerkin discretization is available; see [18] and the references there. The impact of quadrature errors on spatial semidiscretizations was also investigated early on, for example, in [13]. However, the present fully discrete setting with integral operators and wavelet matrix compression causes consistency errors which do not fit readily into existing error analyses of fully discrete schemes: For consistency errors resulting from numerical integration, one has that the difference between the energy bilinear form $a(u_h, v_h)$ and the perturbed bilinear form $\tilde{a}_h(u_h, v_h)$ goes to zero with respect to the energy norms of u_h, v_h; i.e.,

$$|a(u_h, v_h) - \tilde{a}_h(u_h, v_h)| \leq \eta(h) \|u_h\|_V \|v_h\|_V , \quad \text{with } \eta(h) \to 0 \text{ as } h \to 0.$$

For a perturbed bilinear form $\tilde{a}_h(u_h, v_h)$ resulting from wavelet compression, however, this is no longer true.

Here, we develop a framework for perturbation error analysis of the θ-scheme which accommodates consistency errors due to wavelet compression of the spatial nonlocal operator A without any loss in order. We note in passing that our framework can accommodate other matrix compression techniques, such as, e.g., multipole-based methods. Unlike wavelet-based compression, these techniques exploit the analyticity of the kernel function and yield exponentially convergent matrix approximations. We also give a stability analysis for the perturbed θ-schemes that does not require symmetry or resort to eigenfunction expansions of the spatial operator. As is well known, the stability of explicit time-stepping schemes for Galerkin discretizations for the parabolic problems (1.2), (1.4) requires a CFL condition which, as we will show, depends on the order ρ of the operator A and which takes the form

$$\Delta t \leq C(\Delta x)^{\rho}, \quad \rho \in [0, 2]. \tag{1.5}$$

For $\rho = 2$, e.g., the heat equation, we recover the classical CFL condition which forces small time steps Δt in explicit schemes when the meshwidth $h = \Delta x$ of the space discretization is reduced. If, however, the order of A is $\rho \leq 1$, condition (1.5) is of the type usually encountered in time-stepping for first order hyperbolic equations, and explicit time-stepping schemes appear competitive.

Next, we present classes of spline wavelets and a matrix compression strategy which leads to sparse approximations for the stiffness matrix of A with $O(N \log N)$ (rather than $O(N^2)$ for standard Galerkin schemes) nonvanishing entries. We prove that this compression preserves the asymptotic convergence rates of the full Galerkin scheme.

In the θ-scheme, a linear system of equations at each implicit time step must be solved. Since the compressed matrices are not banded and possibly nonsymmetric (due to the presence of a drift term or if $k(x, z)$ is asymmetric for $z \to \pm\infty$), we propose inexact equation solution by GMRES iteration. Using wavelets, we precondition the compressed matrix in dependence on the discretization parameters and the order ρ of A. We relate the GMRES stopping criterion to the discretization error of the scheme and prove that the resulting method converges still with optimal order in space and time while its complexity is essentially $O(N)$ memory and operations per (explicit or implicit) time step. This is comparable to the complexity for the heat equation using the backward Euler method in time and banded matrices in space.

We emphasize that our analysis is applicable to general kernels $k(x, z)$, translation invariant or not, of any order $\rho \geq 0$. Therefore, the θ-scheme with wavelet compression allows the numerical solution of the Kolmogorov equations (1.2) for a large class of Lévy-processes with complexity comparable to standard finite differences for the heat equation in one dimension.

The outline of the paper is as follows. In section 2, we present the class of parabolic problems and the class of spatial integrodifferential operators A admissible in our analysis. In section 3, we discuss the fully discrete θ-scheme. We describe wavelet Galerkin discretization of A and give several examples of wavelets. Section 4 is devoted to the stability analysis of the θ-scheme with compression in the "explicit" case $0 \leq \theta < \frac{1}{2}$ as well as in the implicit case $\theta > \frac{1}{2}$. In section 5, we prove our convergence estimates with particular attention to the error due to wavelet compression of the stiffness matrix $\mathbf{A}$ of A. Section 6 is devoted to the complexity estimates, the matrix preconditioning in the implicit time-stepping schemes, and the error analysis in the presence of incomplete GMRES iterations. Throughout, C will denote a generic positive constant independent of the discretization parameters taking different values in different places. If the value of C is relevant, we write also C_i.

2. Problem formulation. In the time interval $J = (0, T)$ with $T > 0$, we consider parabolic evolution problems of the form

$$\dot{u}(t) + Au(t) = g(t), \qquad t \in J, \tag{2.1}$$

$$u(0) = u_0, \tag{2.2}$$

where A is a possibly nonlocal operator of order $\rho > 0$.

For a variational formulation of this problem we introduce Sobolev spaces. Let $\Omega \subset \mathbb{R}^d$ be a bounded domain with Lipschitz boundary $\Gamma = \partial\Omega$. We denote by $H = L^2(\Omega)$ the usual square integrable functions with inner product $(.,.)$, and by $H^s(\Omega)$, $s \geq 0$, the corresponding Sobolev spaces (see, e.g., [1]). Further, for $s \geq 0$, we define the space

$$\tilde{H}^s(\Omega) = \{\, u|_\Omega \mid u \in H^s(\mathbb{R}^d),\, u|_{\mathbb{R}^d \setminus \Omega} = 0\}. \tag{2.3}$$

If $s + 1/2 \notin \mathbb{N}$, then $\tilde{H}^s(\Omega)$ coincides with $H_0^s(\Omega)$, the closure of $C_0^\infty(\Omega)$ with respect to the norm in $H^s(\Omega)$. We identify $L^2(\Omega)$ with its dual and define

$$V = \widetilde{H}^{\rho/2}(\Omega). \tag{2.4}$$

Then $V \overset{d}{\hookrightarrow} L^2(\Omega)$ with dense injection, and V^*, the dual of V, satisfies

$$V \overset{d}{\hookrightarrow} L^2(\Omega) \overset{d}{\hookrightarrow} V^*. \tag{2.5}$$

We assume that $A \in \mathcal{L}(V; V^*)$. By $(\cdot,\cdot)_{V^* \times V}$ we denote the extension of $(.,.)$ as duality pairing in $V^* \times V$, and by $\|\cdot\|$, $\|\cdot\|_V$, $\|\cdot\|_{V^*}$ the norms in $L^2(\Omega), V, V^*$, respectively. We associate with A the bilinear form $a(\cdot,\cdot)\colon V \times V \to \mathbb{C}$ via

$$a(u, v) := (Au, v)_{V^* \times V}, \qquad u, v \in V. \tag{2.6}$$

Then the form $a(\cdot,\cdot)$ is continuous,

$$\forall u, v \in V: \quad |a(u, v)| \leq \alpha \|u\|_V \|v\|_V, \tag{2.7}$$

and we assume that it is coercive in the sense that

$$\forall u \in V: \quad a(u, u) \geq \beta \|u\|_V^2 \tag{2.8}$$

for some $0 < \beta \leq \alpha < \infty$. Then $A \in \mathcal{L}(V, V^*)$ is an isomorphism and $\|A\|_{\mathcal{L}(V,V^*)} \leq \alpha$, $\|A^{-1}\|_{\mathcal{L}(V^*,V)} \leq \frac{1}{\beta}$. The time derivative $\dot{u}(t)$ in (2.1) is understood in the weak sense; i.e., for $u \in L^2(J; V)$ we have $\dot{u} \in L^2(J; V^*)$ defined by

$$\int_J (\dot{u}(t), v)_{V^* \times V}\, \varphi(t) dt = -\int_J (u(t), v)\, \dot{\varphi}(t) dt \tag{2.9}$$

for every $v \in V$, $\varphi \in C_0^\infty(J)$. The weak form of (2.1), (2.2) reads: Given

$$u_0 \in H, \qquad g \in L^2(J; H), \tag{2.10}$$

find $u \in L^2(J;V) \cap H^1(J;V^*)$ such that $u(0) = u_0$ and, for every $v \in V$, $\varphi \in C_0^\infty(J)$,

$$-\int_J (u(t),v)\,\dot{\varphi}(t)dt + \int_J a(u,v)\,\varphi(t)dt = \int_J (g(t),v)_{V^*\times V}\,\varphi(t)dt. \tag{2.11}$$

Note that the initial condition is well defined since (see [8])

$$L^2(J;V) \cap H^1(J;V^*) \subset C^0([0,T];\ H). \tag{2.12}$$

Under the assumption (2.10), problem (2.11) has a unique weak solution $u(t)$, and there holds the a priori estimate (see, e.g., [8])

$$\|u\|_{C(\overline{J};H)} + \|u\|_{L^2(J;V)} + \|\dot{u}\|_{L^2(J;V^*)} \le C(\|g\|_{L^2(J;H)} + \|u_0\|_H). \tag{2.13}$$

Remark 2.1.

(i) We do not assume A to be self-adjoint. The form $a(\cdot,\cdot)$ need not be symmetric.

(ii) Properties (2.7) and (2.8) allow us to define on V an equivalent norm by

$$\|u\|_a := (a(u,u))^{1/2} \sim \|u\|_V, \tag{2.14}$$

to which we shall refer below as the “energy-norm.”

(iii) Testing (2.1) with $u(t)$ in the $(\cdot,\cdot)$ inner product, we find with (2.6) that for almost every $t \in (0,T)$

$$(u,\dot{u}) + a(u,u) = (u,g),$$

and integrating from $t=0$ to $t=T$, we find

$$\frac{1}{2}\|u(T)\|^2 - \frac{1}{2}\|u(0)\|^2 + \int_0^T a(u(t),\,u(t))dt = \int_0^T (u,g)dt$$
$$\le \int_0^T \|u(t)\|_a \sup_{v\in V} \frac{(v,g)}{\|v\|_a}\,dt \le \frac{1}{2}\int_0^T \|u(t)\|_a^2\,dt + \frac{1}{2}\int_0^T \|g(t)\|_{V^*}^2\,dt,$$

which implies the a priori estimate

$$\|u(T)\|^2 + \int_0^T \|u(t)\|_a^2\,dt \le \|u(0)\|^2 + \int_0^T \|g(t)\|_{V^*}^2\,dt, \tag{2.15}$$

where we have set, for any $g \in V^*$,

$$\|g\|_{V^*} = \sup_{v\in V} \frac{(g,v)}{\|v\|_a}\,.$$

Some examples follow.

Example 2.2 (diffusion problem). Here $\rho = 2$ and

$$A = -\nabla\cdot\mathbf{D}(x)\nabla,\ \ V = H_0^1(\Omega) \overset{d}{\hookrightarrow} L^2(\Omega) = H, \quad a(u,v) = \int_\Omega \nabla v\cdot\mathbf{D}(x)\nabla u\,dx,$$

where $\mathbf{D} \in L^\infty(\Omega)^{d\times d}$ satisfies for some $\gamma > 0$

$$\xi^T\,\mathbf{D}(x)\xi \ge \gamma\,|\xi|^2 \qquad \forall\underline{\xi} \in \mathbb{R}^n,\ \text{a.e. } x \in \Omega\,.$$

Then (2.1), (2.2) is the Dirichlet problem for the heat equation in $\Omega \times (0,T)$.

In this example, the operators A are differential operators and, in particular, local. The nonlocal operators A of interest to us are classical pseudodifferential operators.

Example 2.3. For $0 \leq \rho \in \mathbb{R}$, $\Omega \subset \mathbb{R}^d$ open, bounded, and Lipschitz, we consider classical pseudodifferential operators of order $\rho \in [0,2]$ in Ω, i.e., $A \in \Psi^\rho(\Omega)$, which acts from $V \to V^*$, where $V = \widetilde{H}^{\frac{\rho}{2}}(\Omega)$. By the Schwartz kernel theorem (see, e.g., [16, 15]), $A \in \Psi^\rho(\Omega)$ has a representation in terms of a distributional kernel

$$k(x, x-y) \in \mathcal{D}'(\Omega \times \Omega) \tag{2.16}$$

plus a C^∞ kernel $c(x,y)$. To the singular kernel, we associate a bilinear form

$$a(u,v) = (Au, v)_{V^* \times V} = \left\langle k(x,x-y),\ v(x) \otimes u(y) \right\rangle. \tag{2.17}$$

Moreover, the singular kernel $k(x,x-y) \in C^\infty(\Omega \times \Omega \backslash \{x=y\})$ satisfies the so-called *Calderón–Zygmund estimates*: for all $\alpha, \beta \in \mathbb{N}_0^n$, $(x,y) \in \Omega \times \Omega \backslash \{x=y\}$,

$$|\partial_x^\alpha \, \partial_y^\beta \, k(x,x-y)| \leq C(\alpha,\beta)|x-y|^{-(d+\rho+|\alpha|+|\beta|)}. \tag{2.18}$$

A particular example for a nonlocal operator of order $\rho = 1$ is given by $\Omega = (-1/2, 1/2) \subset \mathbb{R}$ and, for $u \in V = \widetilde{H}^{1/2}(\Omega)$,

$$(Wu)(x) = -\text{p.f.} \int_\Omega \frac{u(y)}{|x-y|^2} \, dy, \tag{2.19}$$

where the integral is to be understood in the finite-part sense (see, e.g., [16]). For the bilinear form $a(u,v)$ corresponding to the hypersingular operator W in (2.19), integration by parts yields the representation

$$\forall u, v \in \widetilde{H}^{1/2}(\Omega): \ a(u,v) = -\int_\Omega v'(x) \int_\Omega \log(x-y)\, u'(y)\, dy\, dx, \tag{2.20}$$

and one can show that there are $\beta, \gamma > 0$ with

$$\forall u \in \widetilde{H}^{1/2}(\Omega): \ a(u,u) \geq \beta \, \|u\|^2_{\widetilde{H}^{1/2}(\Omega)}. \tag{2.21}$$

Remark 2.4. In the setting (2.17), we often do not have the coercivity (2.8), but rather a (weaker) *Gårding inequality:* There is $\gamma \geq 0$ such that

$$\forall u \in V: \ a(u,u) + \gamma \, \|u\|^2 \geq \beta \, \|u\|_V^2 \tag{2.22}$$

(where $\|u\|^2$ is, e.g., due to the C^∞ part of the kernel of A).

This case can be reduced to (2.8) by the substitution $w = \exp(-\gamma t)u$, since then (2.1) implies that w solves the problem

$$\dot{w} + (A + \gamma I)\, w = \exp(-\gamma t)\, g \ \text{ in } \ (0,T),$$

and the operator $A + \gamma I$ is, by (2.22), once again coercive.

3. Discretization. We discretize (2.1) in time using the so-called θ-scheme, and in space by a finite element method. We describe wavelet finite element bases and the compression of the stiffness matrix.

3.1. Space discretization. To discretize the parabolic problem (2.11) in space, we use an elliptic projection onto a family $\{V_h\}_h \subset V$ of finite dimensional subspaces of V, based on piecewise polynomials of degree $p \geq 0$ on a quasi-uniform family of triangulations $\{\mathcal{T}_h\}_h$ of Ω.

The semidiscrete problem reads: Given $u_0 \in H$, $g \in L^2(J; H)$, first choose an approximation $u_{0,h} \in V_h$ for the initial data u_0. Then find $u_h \in H^1(J; V_h)$ such that

$$u_h(0) = u_{0,h} \tag{3.1}$$

and

$$\frac{d}{dt}(u_h, v_h) + a(u_h, v_h) = (g(t), v_h) \qquad \forall v_h \in V_h. \tag{3.2}$$

Let $P_h \colon L^2 \to V_h$ be a projector. Then the approximation of the initial data could be chosen as $u_{0,h} = P_h u_0$ or as an interpolant of u_0.

The semidiscrete problem (3.1), (3.2) is an initial value problem for $N = \dim V_h$ ordinary differential equations

$$\mathbf{K}\frac{d}{dt}\underline{u} + \mathbf{A}\underline{u} = \underline{g}(t), \qquad \underline{u}(0) = \underline{u}_0,$$

where $\underline{u}(t)$ denotes the coefficient vector of $u_h(t)$ with respect to some basis of V_h. Likewise $\underline{u}_0$ denotes the coefficient vector of $u_{0,h}$, and $\mathbf{K}, \mathbf{A}$ denote the mass- and stiffness matrix, respectively, with respect to the basis of V_h.

In the ensuing error analysis, we need to consider functions in V which have additional regularity and introduce for this purpose the spaces $\mathcal{H}^s(\Omega)$ which are defined as

$$\mathcal{H}^s(\Omega) = \begin{cases} V = \tilde{H}^{\rho/2}(\Omega) & \text{for } s = \rho/2, \\ V \cap H^s(\Omega) & \text{for } s > \rho/2. \end{cases}$$

We assume the *approximation property*: For all $u \in \mathcal{H}^t$ with $t \geq \rho/2$ there exists a $u_h \in V_h$ such that for $0 \leq s \leq \frac{\rho}{2}$ and $\rho/2 \leq t \leq p+1$

$$\|u - u_h\|_{\tilde{H}^s(\Omega)} \leq ch^{t-s} \|u\|_{\mathcal{H}^t(\Omega)}. \tag{3.3}$$

We assume that the projector $P_h \colon V \to V_h$ satisfies (3.3) with $u_h = P_h u$.

We shall also need the *inverse property*: There is $c > 0$ independent of h such that

$$\forall u_h \in V_h \quad \|u_h\|_{\tilde{H}^s(\Omega)} \leq ch^{-s} \|u_h\|_{L^2(\Omega)}, \quad 0 \leq s \leq \frac{\rho}{2}. \tag{3.4}$$

3.2. Time discretization using the $\boldsymbol{\theta}$-scheme. For $T < \infty$ and $M \in \mathbb{N}$, define the time step

$$k = \frac{T}{M}$$

and $t^m = mk$, $m = 0, \ldots, M$. The fully discrete θ-scheme reads: Given $u_0 \in H$, find $u_h^m \in V_h$ satisfying

$$u_h^0 = u_{0,h}, \tag{3.5}$$

and, for $m = 0, 1, \dots, M-1$, find $u_h^{m+1} \in V$ such that for all $v_h \in V_h$

$$\left(\frac{u_h^{m+1} - u_h^m}{k}, v_h \right) + a\big(u_h^{m+\theta}, v_h\big) = \big(g^{m+\theta}, v_h\big) \tag{3.6}$$

holds. Here $u_h^{m+\theta} := \theta u_h^{m+1} + (1-\theta) u_h^m$ and $g^{m+\theta} := \theta g(t^{m+1}) + (1-\theta) g(t^m)$. In matrix form, (3.6) reads

$$(k^{-1}\mathbf{K} + \theta \mathbf{A}) \underline{u}^{m+1} = k^{-1}\mathbf{K}\underline{u}^m - (1-\theta)\mathbf{A}\underline{u}^m + \underline{g}^{m+\theta}, \qquad m = 0, 1, \dots, M-1,$$

where $\underline{u}^m$ is the coefficient vector of u_h^m with respect to a basis of V_h.

Remark 3.1. Even for the forward Euler method (i.e., for $\theta = 0$), we have to solve at each time step a linear system with the mass matrix. For $0 \le \rho < 1$ the spaces $H^{\rho/2}(\Omega)$ allow for the use of discontinuous multiwavelets to obtain a diagonal mass matrix. In this case, each time step requires only one matrix-vector product with the matrix $\mathbf{A}$.

3.3. Perturbation. Previous analyses of the θ-scheme (3.5) assumed that the form $a(\cdot,\cdot)\colon V_h \times V_h \to \mathbb{R}$ can be evaluated exactly, i.e., that the corresponding stiffness matrix $\mathbf{A}$ is available. In practice, this is unrealistic. Even for the heat equation, numerical integration and isoparametric boundary approximations allow one to realize only an approximation of $\mathbf{A}$. The impact of the resulting consistency error in the context of semidiscrete schemes was investigated early on [13].

Here, we are interested in wavelet compression of $\mathbf{A}$ as in, e.g., [10, 11, 14], resulting in a compressed matrix $\tilde{\mathbf{A}}$. With the compressed matrix $\tilde{\mathbf{A}}$ we associate the perturbed bilinear form $\tilde{a}(\cdot,\cdot)$. (Other perturbations, e.g., due to numerical integration or domain approximation by isoparametric elements in the context of Example 2.2, can be treated in the same way.) Using $\tilde{a}(\cdot,\cdot)$ in place of $a(\cdot,\cdot)$ in (3.6) gives *perturbed θ-schemes*

$$\widetilde{u}_h^0 = u_{0,h}, \tag{3.7a}$$

$$\left(\frac{\widetilde{u}_h^{m+1} - \widetilde{u}_h^m}{k}, v_h \right) + \widetilde{a}\big(\widetilde{u}_h^{m+\theta}, v_h\big) = \big(g^{m+\theta}, v_h\big) \tag{3.7b}$$

for $m = 0, 1, 2, \dots, M-1$ and every $v_h \in V_h$, where $\widetilde{u}_h^{m+\theta} := \theta \widetilde{u}_h^{m+1} + (1-\theta)\,\widetilde{u}_h^m$. In matrix form, (3.7b) reads

$$(k^{-1}\mathbf{K} + \theta \tilde{\mathbf{A}}) \underline{\tilde{u}}^{m+1} = k^{-1}\mathbf{K}\underline{\tilde{u}}^m - (1-\theta)\tilde{\mathbf{A}}\underline{\tilde{u}}^m + \underline{g}^{m+\theta}, \qquad m = 0, 1, \dots, M-1,$$

where $\underline{\tilde{u}}^m$ is the coefficient vector of $\tilde{u}_h^m$ with respect to a basis of V_h.

We shall assume for $\widetilde{a}(\cdot,\cdot)$ the following *consistency conditions*: There is $\delta < 1$ independent of h such that

$$|a(u_h, v_h) - \widetilde{a}(u_h, v_h)| \le \delta \, \|u_h\|_a \, \|v_h\|_a \qquad \forall u_h, v_h \in V_h, \tag{3.8}$$

and there is $C > 0$ independent of h such that

$$\begin{aligned} &|a(P_h u, v_h) - \widetilde{a}(P_h u, v_h)| \\ &\quad \le C h^{p+1-\rho/2} |\log h|^\nu \|u\|_{\mathcal{H}^{p+1}(\Omega)} \, \|v_h\|_{\tilde{H}^{\rho/2}(\Omega)} \qquad \forall u \in \mathcal{H}^{p+1}(\Omega),\ v_h \in V_h, \end{aligned} \tag{3.9}$$

with some $\nu \ge 0$.

Condition (3.8) shows that on $V_h \times V_h$ the form $\widetilde{a}(\cdot,\cdot)$ is equivalent to $a(\cdot,\cdot)$ in the following sense.

PROPOSITION 3.2. *For* $\delta < 1$ *in* (3.8), *we have for some constants* $0 < \widetilde{\beta} \leq \widetilde{\alpha} < \infty$ *independent of* h

$$\forall u_h, v_h \in V_h : \ |\widetilde{a}(u_h, v_h)| \leq \widetilde{\alpha} \, \|u_h\|_a \, \|v_h\|_a \tag{3.10}$$

and

$$\forall u_h \in V_h : \ |\widetilde{a}(u_h, u_h)| \geq \widetilde{\beta} \, \|u_h\|_a^2 \, . \tag{3.11}$$

Proof. Consider (3.11). We have for $u_h \in V_h$

$$|\tilde{a}(u_h, u_h)| \geq |a(u_h, u_h)| - |a(u_h, u_h) - \tilde{a}(u_h, u_h)| = \|u_h\|_a^2 - |a(u_h, u_h) - \tilde{a}(u_h, u_h)| \, ,$$

and, using the definition of $\|\cdot\|_a$ and the consistency condition (3.8), we get (3.11) with $\tilde{\beta} = 1 - \delta$. The continuity (3.10) is proved in the same way. □

3.4. Wavelet compression. In the context of Example 2.3, perturbed bilinear forms $\widetilde{a}$ are obtained by various matrix compression techniques which reduce the dense matrices $\mathbf{A}$ to sparse ones that can be manipulated in linear complexity. We illustrate this by the wavelet compression of operators of order $0 \leq \rho \leq 2$ in dimensions $d = 1, 2$; we present here only the main principles—for details and proofs, see [9, 14, 4]. All results carry over to dimensions $d > 2$ if a suitable wavelet basis is used.

3.4.1. Subspaces V_h. For $d = 1$ the domain Ω is an interval. For $d = 2$ we assume that Ω is a polygon. Let T_0 be a fixed coarse triangulation of the domain. We then define the triangulation T_l for $l > 0$ by bisection of each interval in T_{l-1} for $d = 1$, or by subdivision of a triangle in T_{l-1} into four congruent subtriangles for $d = 2$. We assume that the triangulation $\{\mathcal{T}_h\}$ is obtained in this way as T_L, for some $L > 0$ so that $h = C2^{-L}$.

For $0 \leq \rho < 1$ we define V_h as the space of piecewise polynomials of total degree $p \geq 0$ (without any continuity restriction) on the triangulation T_L.

For $1 \leq \rho \leq 2$ the space V_h is defined as the space of continuous piecewise polynomials of degree $p \geq 1$ on the triangulation with zero values on the boundary $\partial\Omega$.

In the same way we define the spaces V^l corresponding to the triangulation T_l, so that we have

$$V^0 \subset V^1 \subset \cdots \subset V^L = V_h.$$

Let $N^l = \dim V^l$ and $M^l := N^l - N^{l-1}$ so that $N = \dim V_h = N^L = C2^L$.

3.4.2. Wavelet basis. By choosing a suitable basis for V_h we will be able to represent the bilinear form $a(\cdot,\cdot)$ as a matrix where most elements are small and can be neglected, yielding the approximate bilinear form $\tilde{a}(\cdot,\cdot)$. The basis will also allow optimal preconditioning. We will use so-called biorthogonal wavelets. (Note that the dual wavelets described below will not be used in the computation.)

We will use a hierarchical basis of functions ψ_j^l with $j = 1, \ldots, M^l$ and $l = 0, 1, \ldots$ with the following properties:

1. $V^l = \operatorname{span}\{\psi_j^l \mid 0 \leq l \leq L, 1 \leq j \leq M^l\}$.
2. The function ψ_j^l has support $S_j^l := \operatorname{supp} \psi_j^l$ of diameter bounded by $C \, 2^{-l}$.

3. Wavelets ψ_j^l with $\bar{S}_j^l \cap \partial\Omega = \emptyset$ have vanishing moments up to order p, i.e., $(\psi_j^l, q) = 0$ for all polynomials q of total degree p or less.
4. The functions ψ_j^l for $l \geq l_0$ are obtained by scaling and translation of the functions $\psi_j^{l_0}$.
5. A function $v \in V_h$ has the representation

$$v = \sum_{l=0}^{L} \sum_{j=1}^{M^l} v_j^l \psi_j^l$$

with $v_j^l = (v, \tilde{\psi}_j^l)$, where $\tilde{\psi}_j^l$ are the so-called dual wavelets. For $v \in V$ one obtains an infinite series

$$v = \sum_{l=0}^{\infty} \sum_{j=1}^{M^l} v_j^l \psi_j^l$$

with $v_j^l = (v, \tilde{\psi}_j^l)$, which converges in $\tilde{H}^s$ for $0 \leq s \leq \rho/2$.
6. There holds the norm equivalence

$$c_1 \|v\|_{\tilde{H}^s(\Omega)}^2 \leq \sum_{l=0}^{\infty} \sum_{j=1}^{M^l} \left|v_j^l\right|^2 2^{2ls} \leq c_2 \|v\|_{\tilde{H}^s(\Omega)}^2 \tag{3.12}$$

for $0 \leq s \leq \rho/2$, and for $\rho/2 < s \leq p+1$ we have the one-sided bounds

$$\sum_{l=0}^{L} \sum_{j=1}^{M^l} \left|v_j^l\right|^2 2^{2ls} \leq c_3 L^\nu \|v\|_{\mathcal{H}^s(\Omega)}^2 ,$$

where $c_i > 0$ are independent of L, $\nu = 0$ if $s < p+1$, and $\nu = 1$ if $s = p+1$.

We now define the projection $P_h : V \to V_h$ by truncating the wavelet expansion: For $v \in V$

$$P_h v := \sum_{l=0}^{L} \sum_{j=1}^{M^l} v_j^l \psi_j^l. \tag{3.13}$$

This projection satisfies the approximation property (3.3).

3.4.3. Examples for wavelets. In the case $0 \leq \rho < 1$ a multiwavelet basis as in [11] can be used: Let $\{p_k\}$ be a basis for polynomials of total degree p or less. Then the functions ψ_j^0 are the functions which are on one element equal to a function p_k, and zero elsewhere. For $l > 1$ we choose for ψ_j^l functions in V^l that are nonzero on one element of T_{l-1} and that are orthogonal on all polynomials of total degree p or less.

In all cases $0 \leq \rho \leq 2$, so-called prewavelets can be used; these are functions in V^l with small support which are orthogonal on V^{l-1}.

Another possibility are so-called biorthogonal wavelets, which need not be orthogonal on V^{l-1}. For piecewise linears the functions ψ_j^l in the interior of the interval have values $0, \dots, 0, -1, 2, -1, 0, \dots, 0$. In the case of Neumann boundary conditions the wavelet at the left boundary has values $-2, 2, 1, 0, \dots, 0$; in the case of Dirichlet conditions the values are $0, 2, -1, 0, \dots, 0$ (and similarly at the right boundary). Note that the boundary wavelets have fewer vanishing moments in general.

In dimension $d = 2$ the construction of piecewise linear prewavelets on arbitrary polygons is described, e.g., in [5, 17].

3.4.4. Matrix compression. The bilinear form a on $V_h \times V_h$ corresponds to a matrix $\mathbf{A}$ with elements $A_{(l,j),(l',j')} = a(\psi^l_j, \psi^{l'}_{j'})$.

We assumed that the kernel of the operator satisfies the estimates (2.18). This implies a decay of the matrix elements with increasing distance of their supports.

We define the compressed matrix $\tilde{\mathbf{A}}$ and the corresponding bilinear form $\tilde{a}$ by replacing certain small matrix elements in $\mathbf{A}$ with zero:

$$\tilde{A}_{(j,l),(j',l')} := \begin{cases} A_{(j,l),(j',l')} & \text{if } \operatorname{dist}(S^l_j, S^{l'}_{j'}) \leq \delta_{l,l'} \text{ or } S^l_j \cap \partial\Omega \neq \emptyset, \\ 0 & \text{otherwise.} \end{cases} \tag{3.14}$$

Here the truncation parameters $\delta_{l,l'}$ are given by

$$\delta_{l,l'} := c \max\{2^{-L+\hat{\alpha}(2L-l-l')}, 2^{-l}, 2^{-l'}\} \tag{3.15}$$

with some parameters $c > 0$ and $\hat{\alpha} > 0$. The consistency conditions (3.8), (3.9) can be satisfied as follows (see, e.g., [9, 10, 11, 14]).

PROPOSITION 3.3. *If c in* (3.15) *is chosen sufficiently large, then for all $L > 0$ condition* (3.8) *holds. If additionally*

$$\hat{\alpha} \geq \frac{2p+2}{2p+2+\rho} \tag{3.16}$$

holds, then condition (3.9) *holds with $\nu = \frac{3}{2}$ if equality holds in* (3.16)*, and $\nu = \frac{1}{2}$ otherwise.*

The matrix compression (3.14) reduces the number of nonzero elements from N^2 to N times a logarithmic term as follows (see [9, 10, 11, 14]).

PROPOSITION 3.4. *The compressed matrix $\tilde{\mathbf{A}}$ has $O(N \log N)$ nonzero elements if $\hat{\alpha} < 1$, and $O(N(\log N)^2)$ nonzero elements if $\hat{\alpha} = 1$.*

In particular, for operators of order $\rho > 0$ we can choose $\hat{\alpha}$ such that $\nu = \frac{1}{2}$ in (3.9) *and the number of nonzero elements in $\tilde{\mathbf{A}}$ is $O(N \log N)$. In the case of order $\rho = 0$ we have to choose $\hat{\alpha} = 1$, implying $\nu = \frac{3}{2}$ in* (3.9)*, and the number of nonzero elements in $\tilde{\mathbf{A}}$ is $O(N(\log N)^2)$.*

4. Stability. The stability of the θ-scheme is well known in the context of Example 2.2, i.e., if the spatial operator is elliptic and of second order. We investigate here general operators A of order $\rho \geq 0$ that are elliptic in the sense that (2.7), (2.8) hold in $V = \widetilde{H}^{\rho/2}(\Omega)$. We prove an $L^2(J;V)$ stability estimate for the approximate solutions obtained from the θ-scheme with wavelet-compressed space operator.

In the analysis, we will use for $f \in V_h^*$ the following notation:

$$\|f\|_* := \sup_{v_h \in V_h} \frac{(f, v_h)}{\|v_h\|_a} \,. \tag{4.1}$$

We will also need λ_A defined by

$$\lambda_A := \sup_{v_h \in V_h} \frac{\|v_h\|^2}{\|v_h\|_*^2}.$$

We first address the stability of the θ-scheme with exact bilinear form $a(\cdot,\cdot)$. In the case $\frac{1}{2} \leq \theta \leq 1$, the θ-scheme is stable for any time step $k > 0$, whereas in the case $0 \leq \theta < \frac{1}{2}$, the time step k must be sufficiently small.

Proposition 4.1. *In the case of* $\frac{1}{2} \le \theta \le 1$ *assume that*

$$0 < C_1 < 2, \qquad C_2 \ge \frac{1}{2 - C_1}, \tag{4.2}$$

and in the case of $0 \le \theta < \frac{1}{2}$ *assume that*

$$\sigma := k(1 - 2\theta)\lambda_A < 2, \tag{4.3}$$

$$0 < C_1 < 2 - \sigma, \qquad C_2 \ge \frac{1 + (4 - C_1)\sigma}{2 - \sigma - C_1}. \tag{4.4}$$

Then the sequence $\{u_h^m\}_{m=0}^M$ *of solutions of the* θ*-scheme* (3.5) *satisfies the stability estimate*

$$\|u_h^M\|^2 + C_1 k \sum_{m=0}^{M-1} \|u_h^{m+\theta}\|_a^2 \le \|u_h^0\|^2 + C_2 k \sum_{m=0}^{M-1} \|g^{m+\theta}\|_*^2. \tag{4.5}$$

Proof. Let

$$X^m := \|u_h^m\|^2 - \left\|u_h^{m+1}\right\|^2 + C_2 k \left\|g^{m+\theta}\right\|_*^2 - C_1 k \left\|u_h^{m+\theta}\right\|_a^2.$$

We want to show that $X^m \ge 0$. Then adding these inequalities for $m = 0, \dots, M-1$ will obviously give (4.5).

Let $w := u_h^{m+1} - u_h^m$; then $u_h^{m+\theta} = (u_h^m + u_h^{m+1})/2 + (\theta - \frac{1}{2})w$ and

$$\left\|u_h^{m+1}\right\|^2 - \|u_h^m\|^2 = (u_h^{m+1} - u_h^m, u_h^{m+1} + u_h^m) = (w, 2u_h^{m+\theta} - (2\theta - 1)w).$$

By the definition of the θ-scheme, we have

$$\begin{aligned}(w, u_h^{m+\theta}) &= k(-Au_h^{m+\theta} + g^{m+\theta}, u_h^{m+\theta}) = k\Big[-\left\|u_h^{m+\theta}\right\|_a^2 + (g^{m+\theta}, u_h^{m+\theta})\Big] \\ &\le k\Big[-\left\|u_h^{m+\theta}\right\|_a^2 + \left\|g^{m+\theta}\right\|_* \left\|u_h^{m+\theta}\right\|_a\Big].\end{aligned}$$

This gives

$$X^m \ge (2\theta - 1)\|w\|^2 + k\Big[(2 - C_1)\left\|u_h^{m+\theta}\right\|_a^2 - 2\left\|g^{m+\theta}\right\|_* \left\|u_h^{m+\theta}\right\|_a + C_2 \left\|g^{m+\theta}\right\|_*^2\Big].$$

In the case of $\frac{1}{2} \le \theta \le 1$ we now obtain $X^m \ge 0$ if the conditions (4.2) are satisfied.

In the case $0 \le \theta < \frac{1}{2}$ we have by the definition of the θ-scheme that $(w, v_h) = k(-Au_h^{m+\theta} + g^{m+\theta}, v_h)$, yielding

$$\|w\| \le \lambda_A^{1/2} \|w\|_* \le \lambda_A^{1/2} k\Big(\left\|Au_h^{m+\theta}\right\|_* + \left\|g^{m+\theta}\right\|_*\Big) = \lambda_A^{1/2} k\Big(\left\|u_h^{m+\theta}\right\|_a + \left\|g^{m+\theta}\right\|_*\Big),$$

since $(Au_h^{m+\theta}, v_h) \le \|u_h^{m+\theta}\|_a \|v_h\|_a$ gives $\|Au_h^{m+\theta}\|_* \le \|u_h^{m+\theta}\|_a$ and choosing $v_h := u_h^{m+\theta}$ gives $\|Au_h^{m+\theta}\|_* \ge \|u_h^{m+\theta}\|_a$. Hence

$$k^{-1}X^m \ge (2 - C_1 - \sigma)\left\|u_h^{m+\theta}\right\|_a^2 - 2(1 + \sigma)\left\|g^{m+\theta}\right\|_* \left\|u_h^{m+\theta}\right\|_a + (C_2 - \sigma)\left\|g^{m+\theta}\right\|_*^2.$$

Therefore we have $X^m \ge 0$ if conditions (4.3) hold. □

Remark 4.2. The a priori estimate (4.5) is, in a sense, the discrete analogue of the a priori estimate (2.15). Note, however, that $\|g^{m+\theta}\|_*$ is not identical to $\|g^{m+\theta}\|_{V^*}$—in fact, for $g \in V^*$ we have by $V_h \subset V$ that

$$\|g^{m+\theta}\|_* \leq \|g^{m+\theta}\|_{V^*}.$$

Consider now the sequence $\{\widetilde{u}_h^m\}_{m=0}^M$ of solutions to the perturbed θ-scheme (3.7a), (3.7b). We analogously define for $v_h \in V_h$ and $f \in V_h^*$

$$\|v_h\|_{\tilde{a}} := \tilde{a}(v_h, v_h), \qquad \|f\|_{\tilde{*}} := \sup_{v_h \in V_h} \frac{(f, v_h)}{\|v_h\|_{\tilde{a}}}, \qquad \lambda_{\tilde{A}} := \sup_{v_h \in V_h} \frac{\|v_h\|^2}{\|v_h\|_{\tilde{*}}^2}. \tag{4.6}$$

Due to the norm equivalence in Proposition 3.2, we obtain in the same way as in Proposition 4.1, with $\tilde{a}(\cdot,\cdot)$ in place of $a(\cdot,\cdot)$, the following result.

PROPOSITION 4.3. *Assume that* (3.8) *holds with* $\delta < 1$. *In the case of* $\frac{1}{2} \leq \theta \leq 1$ *assume that* (4.2) *holds. In the case of* $0 \leq \theta < \frac{1}{2}$ *assume that*

$$\sigma := k(1 - 2\theta)\lambda_{\tilde{A}} < 2 \tag{4.7}$$

and that (4.4) *holds.*

Then the sequence $\{\tilde{u}_h^m\}_{m=0}^M$ *of solutions of the perturbed* θ*-scheme* (3.7a), (3.7b) *satisfies the stability estimate*

$$\|\tilde{u}_h^M\|^2 + C_1 k \sum_{m=0}^{M-1} \|\tilde{u}_h^{m+\theta}\|_{\tilde{a}}^2 \leq \|\tilde{u}_h^0\|^2 + C_2 k \sum_{m=0}^{M-1} \|g^{m+\theta}\|_{\tilde{*}}^2. \tag{4.8}$$

Remark 4.4. By the inverse estimate (3.4) and the norm equivalence (2.14) we have for $w_h \in V_h$

$$\|w_h\|_a \leq C\,\|w_h\|_{\rho/2} \leq C' h^{-\rho/2}\,\|w_h\|,$$

and therefore for $v_h \in V_h$

$$\|v_h\|_* = \sup_{w_h \in V_h} \frac{(v_h, w_h)}{\|w_h\|_a} \geq C h^{\rho/2} \sup_{w_h \in V_h} \frac{(v_h, w_h)}{\|w_h\|} = C h^{\rho/2}\,\|v_h\|, \tag{4.9}$$

$$\lambda_A^{1/2} = \sup_{v_h \in V_h} \frac{\|v_h\|}{\|v_h\|_*} \leq C h^{-\rho/2}. \tag{4.10}$$

Hence there exists a positive constant C_* independent of h and θ such that the time-step restriction

$$k \leq C_* \frac{h^\rho}{1 - 2\theta} \tag{4.11}$$

is sufficient for stability (4.3). For $\rho = 2$ and $\theta < \frac{1}{2}$ (e.g., forward Euler and the heat equation) this reduces to the well-known time-step restriction $k \leq C_\theta h^2$ for explicit schemes. For smaller values of ρ the restriction is less severe, and in the limiting case $\rho = 0$ condition (4.11) gives $k \leq C_*/(1 - 2\theta)$ with a bound independent of h.

For the perturbed scheme (3.7) we can proceed in the same way and obtain, using Proposition 3.2, that (4.11) is a sufficient condition for (4.7) (with a different value of C_*).

Remark 4.5. As θ tends to $\frac{1}{2}$ from below the bound on k in the stability condition, (4.3) tends to infinity, and for $\theta \geq \frac{1}{2}$ the stability holds with $\sigma = 0$ and C_1, C_2 as in (4.4) for *all* values of k.

5. Convergence. Based on the stability results obtained in section 4 and the consistency (3.8), (3.9) of the compressed form $\widetilde{a}(\cdot,\cdot)$, we shall now obtain optimal convergence estimates of the compressed θ-scheme (sufficient regularity of the exact solution $u(x,t)$ in space and time provided). Throughout this section, we shall set

$$u^m = u(t^m) \in V. \tag{5.1}$$

We will estimate the error

$$\widetilde{e}_h^m := u^m - \widetilde{u}_h^m\,. \tag{5.2}$$

To this end, we split $\widetilde{e}_h^m$ as follows:

$$\widetilde{e}_h^m = \underbrace{(u^m - P_h u^m)}_{\eta^m} + \underbrace{(P_h u^m - \widetilde{u}_h^m)}_{\xi_h^m} = \eta^m + \xi_h^m, \tag{5.3}$$

where $P_h : V \to V_h$ is the quasi interpolant in (3.13) (realized as a truncated wavelet expansion; see section 3.4 or [9, 3] for details).

As η^m is a best approximation error, we focus now on $\xi_h^m \in V_h$.

LEMMA 5.1. *If $u \in C^1(\overline{J}; H)$, the $\{\xi_h^m\}_m$ are solutions of the θ-scheme*

$$\xi_h^0 = P_h u_0 - \widetilde{u}_h^0$$

for $m = 0, 1, \ldots, M-1$ and every $v_h \in V_h$;

$$k^{-1}(\xi_h^{m+1} - \xi_h^m, v_h) + \widetilde{a}\left(\theta\xi_h^{m+1} + (1-\theta)\,\xi_h^m, v_h\right) = (r^m, v_h), \tag{5.4}$$

where the weak residuals r^m: $V_h \to \mathbb{R}$ are given by

$$r^m = r_1^m + r_2^m + r_3^m + r_4^m \tag{5.5}$$

with

$$\begin{aligned}
(r_1^m, v_h) &:= \left(\frac{u^{m+1} - u^m}{k} - \dot{u}^{m+\theta}, v_h\right),\\
(r_2^m, v_h) &:= \left(\frac{P_h u^{m+1} - P_h u^m}{k} - \frac{u^{m+1} - u^m}{k}\,,\ v_h\right),\\
(r_3^m, v_h) &:= \widetilde{a}\left(P_h u^{m+\theta}, v_h\right) - a\left(P_h u^{m+\theta}, v_h\right),\\
(r_4^m, v_h) &:= a\left(P_h u^{m+\theta} - u^{m+\theta}, v_h\right).
\end{aligned}$$

Proof. We note that (2.11) and $u \in C^1(\overline{J}; H)$ imply

$$(\dot{u}^{m+\theta}, v) + a(u^{m+\theta}, v) = (g^{m+\theta}, v) \qquad \forall v \in V\,. \tag{5.6}$$

Since $V_h \subset V$, we get for every $v_h \in V_h$

$$\begin{aligned}
&k^{-1}(\xi_h^{m+1} - \xi_h^m, v_h) + \widetilde{a}(\theta\xi_h^{m+1} + (1-\theta)\,\xi_h^m, v_h)\\
&\quad= \left(\frac{(P_h u^{m+1} - \widetilde{u}_h^{m+1}) - (P_h u^m - \widetilde{u}_h^m)}{k}\,,\ v_h\right) + \widetilde{a}\left(P_h u^{m+\theta}, v_h\right) - \widetilde{a}\left(\widetilde{u}_h^{m+\theta}, v_h\right)\\
&\quad= \left(\frac{P_h u^{m+1} - P_h u^m}{k}\,,\ v_h\right) + \widetilde{a}(P_h u^{m+\theta}, v_h)
\end{aligned}$$

$$
\begin{aligned}
& - \left\{ \left(\frac{\widetilde{u}_h^{m+1} - \widetilde{u}_h^{m}}{k}\,,\; v_h \right) - \widetilde{a}\,(\widetilde{u}_h^{m+\theta}, v_h) \right\} \\
&\overset{(3.7)}{=} \left(\frac{P_h u^{m+1} - P_h u^{m}}{k}\,,\; v_h \right) + \widetilde{a}\,(P_h u^{m+\theta}, v_h) - (g^{m+\theta}, v_h) \\
&\overset{(5.6)}{=} \left(\frac{P_h u^{m+1} - P_h u^{m}}{k} - \dot{u}^{m+\theta}, v_h \right) + \widetilde{a}\,(P_h u^{m+\theta}, v_h) - a\,(u^{m+\theta}, v_h) =: (r, v_h)\,.
\end{aligned}
$$

The representation (5.5) of (r, v_h) is now evident. □

Lemma 5.1 implies, together with the stability result Proposition 4.3, the following estimate for the ξ_h^m.

COROLLARY 5.2. *Under the assumptions of Proposition* 4.3 *and if* $u \in C^1(\overline{J}; H)$, *we have*

$$
\|\xi_h^M\|^2 + C_1 k \sum_{m=0}^{M-1} \left\|\xi_h^{m+\theta}\right\|_{\widetilde{a}}^2 \le \|\xi_h^0\|^2 + C_2 k \sum_{m=0}^{M-1} \left\|r^m\right\|_{\widetilde{*}}^2. \tag{5.7}
$$

Based on (5.5), we must estimate the $\|r_j^m\|_{\widetilde{*}}$, $j = 1, \dots, 4$.

Estimate of r_1^m. This value is based on a Taylor expansion in t. Noting that for any $v_h \in V_h$

$$
|(r_1^m, v_h)| \le \|k^{-1}(u^{m+1} - u^m) - \dot{u}^{m+\theta}\|_{\tilde{*}}\; \|v_h\|_{\tilde{a}}
$$

and

$$
k^{-1}\left|(u^{m+1} - u^m) - \dot{u}^{m+\theta}\right| = k^{-1}\left|\int_{t_m}^{t_{m+1}} (s - (1-\theta)t_{m+1} - \theta\, t_m)\, \ddot{u}\, ds\right|,
$$

we get

$$
\begin{aligned}
\|k^{-1}(u^{m+1} - u^m) - \dot{u}^{m+\theta}\|_{\tilde{*}} &\le k^{-1} \int_{t_m}^{t_{m+1}} |s - (1-\theta)\, t_{m+1} - \theta\, t_m|\; \|\ddot{u}\|_{\tilde{*}}\, ds \\
&\le C_\theta \int_{t_m}^{t_{m+1}} \|\ddot{u}(s)\|_{\tilde{*}}\, ds \\
&\le C_\theta\, k^{\frac{1}{2}} \left(\int_{t_m}^{t_{m+1}} \|\ddot{u}(s)\|_{\tilde{*}}^2\, ds \right)^{\frac{1}{2}}.
\end{aligned} \tag{5.8}
$$

If $\theta = \frac{1}{2}$, an integration by parts gives

$$
\left|k^{-1}(u^{m+1} - u^m) - \dot{u}^{m+\theta}\right| = \frac{1}{2k}\left|\int_{t_m}^{t_{m+1}} (t_{m+1} - s)(t_m - s)\; \dddot{u}\; (s) ds\right|,
$$

and it follows that

$$
\|k^{-1}(u^{m+1} - u^m) - \dot{u}^{m+\theta}\|_{\tilde{*}} = C\, k^{\frac{3}{2}} \left(\int_{t_m}^{t_{m+1}} \|\; \dddot{u}\; (s)\|_{\tilde{*}}^2\, ds \right)^{\frac{1}{2}}.
$$

Estimate of r_2^m. Here

$$
\begin{aligned}
|(r_2^m, v_h)| &\le C\, \|k^{-1}\, [(u^{m+1} - u^m) - P_h(u^{m+1} - u^m)]\|_{\tilde{*}}\, \|v_h\|_{\widetilde{a}} \\
&= C\, k^{-1} \left\| (I - P_h) \int_{t_m}^{t_{m+1}} \dot{u}(s)\, ds \right\|_{\tilde{*}} \|v_h\|_{\widetilde{a}} \\
&\le C\, k^{-1} \int_{t_m}^{t_{m+1}} \|(I - P_h)\, \dot{u}\|_{\tilde{*}}\, ds\, \|v_h\|_{\widetilde{a}} \\
&\le C k^{-\frac{1}{2}} h^{p+1-\rho/2} \left(\int_{t_m}^{t_{m+1}} \|\dot{u}\|^2_{\mathcal{H}^{p+1-\rho/2}(\Omega)} ds \right)^{\frac{1}{2}},
\end{aligned}
\tag{5.9}
$$

where we used $\|w\|_{\tilde{*}} \le C\, \|w\|$ and the approximation property (3.3) of P_h pointwise in t.

Estimate of r_3^m. Here we use the consistency (3.9)

$$
|(r_3^m, v_h)| \le C\, h^{p+1-\rho/2} |\log h|^{\nu} \|u^{m+\theta}\|_{\mathcal{H}^{p+1}(\Omega)} \|v_h\|_{\tilde{H}^{\rho/2}(\Omega)}\,. \tag{5.10}
$$

By (2.14) and (3.11), we get $\|v_h\|_{\tilde{H}^{\rho/2}} \le C\, \|v_h\|_{\widetilde{a}}$ and hence a bound on $\|r_3^m\|_{\widetilde{*}}$.

Estimate on r_4^m. Using (3.11) gives

$$
|(r_4^m, v_h)| \le C\, \|u^{m+\theta} - P_h u^{m+\theta}\|_a\, \|v_h\|_{\widetilde{a}},
$$

and with the approximation property (3.3) we find

$$
|(r_4^m, v_h)| \le C\, h^{p+1-\rho/2} \|u^{m+\theta}\|_{\mathcal{H}^{p+1}(\Omega)}\, \|v_h\|_{\widetilde{a}}\,. \tag{5.11}
$$

Collecting the bounds (5.8)–(5.11) gives the following result.

LEMMA 5.3. *Assume that* (3.8), (3.9) *hold. If* $u(x,t)$ *is sufficiently smooth in* $\overline{J} \times \overline{\Omega}$, *we have for* r^m *given by* (5.5)

$$
\begin{aligned}
\|r^m\|_{\widetilde{*}} \le C &\begin{cases} k^{\frac{1}{2}} \left(\int_{t_m}^{t_{m+1}} \|\ddot{u}(s)\|_*^2 ds \right)^{\frac{1}{2}} & \forall\, \theta \in [0,1], \\ k^{\frac{3}{2}} \left(\int_{t_m}^{t_{m+1}} \|\dddot{u}(s)\|_*^2 ds \right)^{\frac{1}{2}} & \forall\, \theta = \dfrac{1}{2} \end{cases} \\
&+ C k^{-\frac{1}{2}} h^{p+1-\rho/2} \left(\int_{t_m}^{t_{m+1}} \|\dot{u}\|^2_{\mathcal{H}^{p+1-\rho/2}(\Omega)} ds \right)^{\frac{1}{2}} \\
&+ C h^{p+1-\rho/2} |\log h|^{\nu} \|u^{m+\theta}\|_{\mathcal{H}^{p+1}(\Omega)}\,.
\end{aligned}
\tag{5.12}
$$

THEOREM 5.4. *Assume that the consistency conditions* (3.8), (3.9) *hold. For* $\theta \in [0, \frac{1}{2})$ *assume* (4.7). *Assume further that the approximation* $u_{0,h} \in V_h$ *of the initial data* u^0 *is quasi-optimal in* $L^2(\Omega)$. *Then the following error estimate holds for* *the perturbed θ-scheme with $\theta \in [0,1]$:*

(5.13)

$$\left\|u^M - \widetilde{u}_h^M\right\|^2 + k \sum_{m=0}^{M-1} \|u^{m+\theta} - \widetilde{u}_h^{m+\theta}\|_a^2 \leq Ch^{2(p+1-\rho/2)} |\log h|^{2\nu} \max_{0 \leq t \leq T} \|u(t)\|^2_{\mathcal{H}^{p+1}(\Omega)}$$
$$+ C \begin{cases} k^2 \displaystyle\int_0^T \|\ddot{u}(s)\|_*^2 ds & \forall\, \theta \in [0,1], \\ k^4 \displaystyle\int_0^T \|\dddot{u}(s)\|_*^2 ds & \text{for } \theta = \frac{1}{2} \end{cases}$$
$$+ Ch^{2(p+1-\rho/2)} \int_0^T \|\dot{u}(s)\|^2_{\mathcal{H}^{p+1-\rho/2}(\Omega)} ds.$$

Proof. Based on (5.3), we have for every $M \geq 1$

$$\left\|\widetilde{e}_h^M\right\|^2 + k \sum_{m=0}^{M-1} \|\widetilde{e}_h^{m+\theta}\|_a^2$$
$$\leq 2 \left\{ \left\|\eta^M\right\|^2 + k \sum_{m=0}^{M-1} \|\eta^{m+\theta}\|_a^2 \right\} + 2 \left\{ \left\|\xi_h^M\right\|^2 + k \sum_{m=0}^{M-1} \|\xi_h^{m+\theta}\|_a^2 \right\}.$$

The first term can be estimated with the approximation property (3.3). The second term is treated using (3.11) and (4.8). We get

$$\begin{aligned} \left\|\xi_h^M\right\|^2 + k \sum_{m=0}^{M-1} \|\xi_h^{m+\theta}\|_a^2 &\leq \left\|\xi_h^M\right\|^2 + k\widetilde{\beta}^{-1} \sum_{m=0}^{M-1} \left\|\xi_h^{m+\theta}\right\|_{\widetilde{a}}^2 \\ &\leq \max\left\{1, \frac{1}{(\widetilde{\beta} C_1)}\right\} \left\{ \left\|\xi_h^M\right\|^2 + C_1 k \sum_{m=0}^{M-1} \left\|\xi_h^{m+\theta}\right\|_{\widetilde{a}}^2 \right\} \\ &\leq \max\left\{1, \frac{1}{(\widetilde{\beta} C_1)}\right\} \left\{ \left\|\xi_h^0\right\|^2 + C_2 k \sum_{m=0}^{M-1} \left\|r_h^{m+\theta}\right\|_{\widetilde{*}}^2 \right\}. \end{aligned}$$

Using now the bound (5.12) for $\left\|r_h^{m+\theta}\right\|_{\widetilde{*}}$, the quasi optimality of $u_{0,h}$ and the approximation property (3.3) with $s = 0$ to estimate $\left\|\xi_h^0\right\|$ give the assertion. □

6. Approximate solution of linear equations and complexity. In order to compute the approximate solution $\tilde{u}_h^m$ in (3.7) for $m = 1, \dots, M$, we proceed as follows.

First we compute the mass matrix $\mathbf{K}$ in the wavelet basis with elements $K_{(l,j),(l',j')}$, where $O(N \log N)$ elements are nonzero. Note that for discontinuous multiwavelets (which can be used for $0 \leq \rho < 1$) the mass matrix is diagonal.

Then we compute the compressed stiffness matrix $\tilde{\mathbf{A}}$, where $O(N(\log N)^r)$ elements are nonzero and $r = 1$ if $\rho \in (0,2]$, $r = 2$ if $\rho = 0$; see Proposition 3.4. If explicit antiderivatives of the kernel function are available (as is often the case), the total cost for computing the stiffness matrix $\tilde{\mathbf{A}}$ is $O(N(\log N)^r)$ operations. In other cases, quadrature as described in [10] can be used. This preserves the consistency conditions (3.8), (3.9), and the total cost of computing $\tilde{\mathbf{A}}$ is $O(N(\log N)^{r+d})$ for $d = 1, 2$.

For each time step we have to solve (3.7b): We have to find $\tilde{w}_h^m := \tilde{u}_h^{m+1} - \tilde{u}_h^m \in V_h$ satisfying

$$k^{-1}(\tilde{w}_h^m, v_h) + \theta\tilde{a}(\tilde{w}_h^m, v_h) = (g^{m+\theta}, v_h) - \tilde{a}(\tilde{u}_h^m, v_h) \quad \forall v_h \in V_h \tag{6.1}$$

and then update $\tilde{u}_h^{m+1} := \tilde{u}_h^m + \tilde{w}_h^m$. Let $\tilde{w}^m \in \mathbb{R}^N$ denote the coefficient vectors of $\tilde{w}_h^m$ with respect to the wavelet basis, and $\mathbf{K}, \tilde{\mathbf{A}} \in \mathbb{R}^{N\times N}$ the mass and stiffness matrices corresponding to $(\cdot,\cdot)$ and $\tilde{a}(\cdot,\cdot)$ in this basis. Then we obtain for $\tilde{w}^m$ a linear system $\mathbf{B}\tilde{w}^m = \tilde{b}^m$ with the matrix $\mathbf{B} = k^{-1}\mathbf{K} + \theta\tilde{\mathbf{A}}$ and a known right-hand side vector $\tilde{b}^m$.

For a standard finite element basis, the matrix $\mathbf{B}$ has a condition number of order $h^{-\rho}$ for small h and fixed k. For the matrix $\mathbf{B}$ in the wavelet basis we can achieve a uniformly bounded condition number if we scale the rows and columns of $\mathbf{B}$ as follows: Let $\mu_l := (k^{-1} + \theta 2^{l\rho})^{1/2}$ and let $\hat{B}_{(l,j),(l',j')} := \mu_l^{-1}\mu_{l'}^{-1}B_{(l,j),(l',j')}$. A similar scaling was proposed in [4]. In what follows let $\|\cdot\|$ denote the 2-norm of a vector or the 2-norm of a matrix. We will use the GMRES method with restart every $m_0 \geq 1$ iterations, denoted by GMRES(m_0).

LEMMA 6.1. *For the linear system $\hat{\mathbf{B}}x = b$ let x_j for $j \in \mathbb{N}$ denote the iterates obtained by the restarted GMRES(m_0) method with initial guess x_0. Then there holds*

$$\|x - x_j\| \leq Cq^j \|x - x_0\|, \tag{6.2}$$

where C and $q < 1$ are independent of L, k, θ.

Proof. Throughout the proof, C_i will denote generic positive constants independent of h, k and unrelated to C_i in the main body of the text above. Let $\mathbf{D}$ denote the diagonal matrix with entries $D_{(l,j),(l,j)} = 2^{l\rho/2}$. Because of the norm equivalence (3.12), we have for all $x, y \in \mathbb{R}^N$

$$C_1 \|x\|^2 \leq x^T\mathbf{K}x, \qquad x^T\mathbf{K}y \leq C_2 \|x\| \|y\|.$$

Using the consistency conditions (3.8) of the wavelet truncation and (2.7), (2.8), we obtain

$$C_3 \|\mathbf{D}x\|^2 \leq x^T\tilde{\mathbf{A}}x, \qquad x^T\tilde{\mathbf{A}}y \leq C_4 \|\mathbf{D}x\| \|\mathbf{D}y\|.$$

The constants $C_j > 0$ are independent of L. Therefore $\mathbf{B} = k^{-1}\mathbf{K} + \theta\tilde{\mathbf{A}}$ satisfies with $C_5 := \min\{C_1, C_3\}$ and $C_6 := \max\{C_2, C_4\}$

$$C_5\, x^T(k^{-1}\mathbf{I} + \theta\mathbf{D}^2)x \leq x^T\mathbf{B}x, \tag{6.3}$$

$$\begin{aligned} x^T\mathbf{B}y &\leq C_6[k^{-1}\|x\|\|y\| + \theta\|\mathbf{D}x\|\|\mathbf{D}y\|] \\ &\leq C_6\big[x^T(k^{-1}\mathbf{I} + \theta\mathbf{D}^2)x\big]^{1/2}\big[y^T(k^{-1} + \theta\mathbf{D}^2)y\big]^{1/2} \end{aligned} \tag{6.4}$$

using the Cauchy–Schwarz inequality for the last estimate. Hence scaling with the diagonal matrix $\mathbf{S} := (k^{-1}\mathbf{I}+\theta\mathbf{D}^2)^{1/2}$ yields with $\hat{\mathbf{B}} = \mathbf{S}^{-1}\mathbf{B}\mathbf{S}^{-1}$ and $\hat{x} := \mathbf{S}x$, $\hat{y} := \mathbf{S}y$ that

$$C_5 \|\hat{x}\|^2 \leq \hat{x}^T\hat{\mathbf{B}}\hat{x}, \qquad \hat{x}^T\hat{\mathbf{B}}\hat{y} \leq C_6 \|\hat{x}\| \|\hat{y}\| \tag{6.5}$$

for all $\hat{x}, \hat{y} \in \mathbb{R}^N$, and therefore

$$\lambda_{\min}\left(\frac{(\hat{\mathbf{B}}+\hat{\mathbf{B}}^T)}{2}\right) \geq C_5, \qquad \|\hat{\mathbf{B}}\| \leq C_6.$$

According to [6], the GMRES iterates $x_{j+\nu}$ and their residuals $r_{j+\nu} := b - \hat{\mathbf{B}}x_{j+\nu}$ after a restart satisfy for $\nu = 1, \dots, m_0$

$$\|r_{j+\nu}\| \leq \left(1 - \frac{C_5^2}{C_6^2}\right)^{\nu/2} \|r_j\| .$$

Because of $C_5 \|x_j - x\|^2 \leq (x_j - x)^T \hat{\mathbf{B}}(x_j - x) \leq C_6 \|x_j - x\| \|r_j\|$, a corresponding estimate holds for the errors $\|x_j - x\|$. □

Remark 6.2. If the operator A is symmetric, we can also use the conjugate gradient method for the symmetric matrix $\hat{\mathbf{B}}$. This will in general give the bound (6.2) with a smaller constant q than the GMRES method.

Note that, for a function $v_h \in V_h$ with coefficient vector v and scaled coefficient vector $\hat{v} = \mathbf{S}v$, we have from (6.5) that with $b(u,v) := k^{-1}(u,v) + \theta\tilde{a}(u,v)$ and $\|v\|_b^2 := b(v,v)$

$$\|\hat{v}\|^2 \sim \hat{v}^T \hat{\mathbf{B}} \hat{v} = \|v_h\|_b^2 .$$

A functional $f_h \in V_h^*$ corresponds to a coefficient vector f so that $(f_h, v_h) = f^T v$, and a scaled vector $\hat{f} = \mathbf{S}^{-1} f$ so that $(f_h, v_h) = \hat{f}^T \hat{v}$. Assume that we solve a linear system $\hat{B}\hat{v}_* = \hat{f}$ using n_G steps of GMRES(m_0), starting with initial guess 0, yielding an approximation $\hat{v}$. We then have

$$\|v_{h,*} - v_h\|_b \leq C q^{n_G} \|v_{h,*}\|_b ,$$

and for the residuals $\rho_h \in V_h^*$ defined by $(\rho_h, w_h) = (f, w_h) - b(v_h, w_h)$ it holds that

$$\|\rho_h\|_{b,*} \leq C q^{n_G} \|f_h\|_{b,*} ,$$

where for $g_h \in V_h^*$ with $\hat{\mathbf{B}}_s := (\hat{\mathbf{B}} + \hat{\mathbf{B}}^T)/2$

$$\|g_h\|_{b,*} := \sup_{w_h \in V_h} \frac{(g_h, w_h)}{\|w_h\|_b} = (\hat{g}^T \hat{\mathbf{B}}_s^{-1} \hat{g})^{1/2} \sim \|\hat{g}\| .$$

We have with the inverse inequality

$$(c_1 k^{-1} h^\rho + \theta)\tilde{a}(v_h, v_h) \leq b(v_h, v_h) \leq (c_2 k^{-1} + \theta)\tilde{a}(v_h, v_h)$$

implying

$$(c_2 k^{-1} + \theta)^{-1/2} \|f_h\|_{\tilde{*}} \leq \|f_h\|_{b,*} \leq (c_1 k^{-1} h^\rho + \theta)^{-1/2} \|f_h\|_{\tilde{*}}$$

and

$$\|v_{h,*} - v_h\|_{\tilde{a}} \leq C\gamma^{1/2} q^{n_G} \|v_{h,*}\|_{\tilde{a}} , \tag{6.6}$$

$$\|\rho_h\|_{\tilde{*}} \leq C\gamma^{1/2} q^{n_G} \|f_h\|_{\tilde{*}} , \tag{6.7}$$

where

$$\gamma := \frac{c_2 k^{-1} + \theta}{c_1 k^{-1} h^{\rho} + \theta}.$$

We now define the *perturbed θ-scheme with GMRES approximation* as follows. Pick a value $m_0 \geq 1$ for the restart number, e.g., $m_0 = 1$, and a value n_G for the number of GMRES iterations. Let $\breve{u}_h^0 := u_{0,h}$. At each time step we want to find an approximation of $w_{h,*}^m$ satisfying

$$b(w_{h,*}^m, v_h) = (g^{m+\theta}, v_h) - \tilde{a}(\breve{u}_h^m, v_h) \qquad \forall\ v_h \in V_h,$$

which corresponds to a scaled linear system $\hat{\mathbf{B}}\hat{w}_*^m = \hat{b}^m$. We solve this system approximately with n_G steps of GMRES(m_0), using zero as initial guess, yielding an approximation $\hat{w}^m$ of the exact solution $\hat{w}_*^m$. We then let $\breve{u}_h^{m+1} := \breve{u}_h^m + w_h^m$, where $w_h^m \in V_h$ is the function corresponding to the scaled vector $\hat{w}^m$. Then we have the following.

THEOREM 6.3. *Assume that the consistency conditions* (3.8), (3.9) *hold. For* $\theta \in [0, \frac{1}{2})$ *assume* (4.3). *Then the solution* $\breve{u}_h^m$ *of the perturbed* θ*-scheme with GMRES approximation satisfies the same error bound as* $\tilde{u}_h^m$ *in* (5.13) *if* $n_G \geq C\,|\log h|$.

Proof. Let $\tilde{u}_h^m$ denote the solution of (3.7) (with all linear systems solved exactly), and let $\breve{u}_h^m$ denote the corresponding solution where the linear system (6.1) for each time step is solved with n_G GMRES(m_0) steps, using zero as initial guess. Let $\rho_h^m \in V_h^*$ denote the residual of the approximate GMRES solution w_h^m: For all $v_h \in V_h$

$$\begin{aligned}(\rho_h^m, v_h) &= b(w_h^m, v_h) - (g^{m+\theta}, v_h) + \tilde{a}(\breve{u}_h^m, v_h)\\ &= k^{-1}(\breve{u}_h^{m+1} - \breve{u}_h^m, v_h) + \tilde{a}(\breve{u}_h^{m+\theta}, v_h) - (g^{m+\theta}, v_h).\end{aligned}$$

Then the difference $\zeta_h^m := \breve{u}_h^m - \tilde{u}_h^m$ satisfies $\zeta_h^0 = 0$ and a θ-scheme of the same form as (3.7b),

$$k^{-1}(\zeta_h^{m+1} - \zeta_h^m, v_h) + \tilde{a}(\zeta_h^{m+\theta}, v_h) = (\rho_h^m, v_h),$$

where $\zeta_h^{m+\theta} = (1-\theta)\zeta^m + \theta\zeta^{m+1}$.

We now apply Proposition 4.3 and obtain for $l = 0, \dots, M$

$$\begin{aligned}E_l := \left\|\zeta^l\right\|^2 + C_1 k \sum_{m=0}^{l-1} \left\|\zeta_h^{m+\theta}\right\|_{\tilde{a}}^2 &\leq C_2 k \sum_{m=0}^{l-1} \|\rho_h^m\|_{\tilde{*}}^2\\ &\leq C\gamma q^{2n_G} k \sum_{m=0}^{l-1} \left\|g^{m+\theta} - \tilde{a}(\breve{u}_h^m, \cdot\,)\right\|_{\tilde{*}}^2\\ &\leq C'\gamma q^{2n_G} k \sum_{m=0}^{l-1} \Big(\left\|g^{m+\theta}\right\|_{\tilde{*}}^2 + \|\zeta_h^m\|_{\tilde{a}}^2 + \|\tilde{u}_h^m\|_{\tilde{a}}^2\Big).\end{aligned}$$

We denote the right-hand side of (4.8) by Q.

Let us first assume that $\theta = 0$ or $\theta = 1$. In this case we choose n_G large enough so that $C'\gamma q^{2n_G} \leq C_1/2$ and obtain with $l = M$

$$\left\|\zeta^M\right\|^2 + \tfrac{1}{2} C_1 k \sum_{m=0}^{M-1} \left\|\zeta_h^{m+\theta}\right\|_{\tilde{a}}^2 \leq C\gamma q^{2n_G} Q, \tag{6.8}$$

since the terms $\|\zeta_h^m\|_{\tilde{a}}^2$ occur in E_M and the terms $\|\tilde{u}_h^m\|_{\tilde{a}}^2$ occur in the left-hand side of (4.8).

In the general case $\theta \in [0,1]$ we use

$$\|\tilde{u}_h^m\|_{\tilde{a}}^2 \le Ch^{-\rho} \|\tilde{u}_h^m\|^2 \le Ch^{-\rho} Q,$$
$$\|\zeta_h^m\|_{\tilde{a}}^2 \le Ch^{-\rho} \|\zeta_h^m\|^2 \le Ch^{-\rho} E_m,$$

yielding

$$E_l \le C\gamma q^{2n_G} \left((1+h^{-\rho})Q + k \sum_{m=0}^{l-1} h^{-\rho} E_m \right).$$

Therefore we have estimates of the form

$$E_0 = 0, \qquad E_l \le \mu + \nu \sum_{m=0}^{l-1} E_m,$$

from which we easily get by induction

$$E_l \le \mu(1+\nu)^{l-1}.$$

Here we have $\nu = C\gamma q^{2n_G} h^{-\rho} T/M$. We choose n_G large enough so that $C\gamma q^{2n_G} h^{-\rho} \le 1$ and get $(1+\nu)^M \le e^T$ and

$$E_M \le C\gamma q^{2n_G}(1+h^{-\rho})Qe^T. \tag{6.9}$$

Finally we have to choose n_G large enough so that the right-hand side in (6.8) or (6.9) is less than the bound in Theorem 5.4: If $k \le 1$, we have $\gamma \le Ch^{-\rho}$, and therefore we need n_G such that

$$q^{2n_G} h^{-2\rho} \le Ch^{2(p+1-\rho/2)},$$

which is satisfied for $n_G \ge C\,|\log h|$ with $C > 0$ sufficiently large, but independent of h, k. □

Theorem 6.3 allows us to estimate the complexity of the time-stepping scheme with incomplete GMRES solution of the linear systems.

Corollary 6.4. *Given the compressed stiffness matrix $\tilde{\mathbf{A}}$, the additional work for computing $\check{u}_h^1, \dots, \check{u}_h^M$ is bounded by $CMN(\log N)^{r+1}$, where $r = 1$ for $\rho \in (0,2]$, $r = 2$ for $\rho = 0$.*

The total work of the algorithm (for computing the compressed stiffness matrix and performing M time steps) is bounded by $CMN(\log N)^{r+1}$ operations if we use exact antiderivatives, and by $CN(\log N)^{r+d} + CMN(\log N)^{r+1}$ operations if we use quadrature for $d = 1, 2$.

We remark in closing that the powers of $\log N$ in these complexity estimates could be reduced by more elaborate compression techniques; see, e.g., [14].

DOMAIN DECOMPOSITION FOR A MIXED FINITE ELEMENT METHOD IN THREE DIMENSIONS*

Z. CAI[†], R. R. PARASHKEVOV[‡], T. F. RUSSELL[§], J. D. WILSON[¶], AND X. YE[‖]

Abstract. We consider the solution of the discrete linear system resulting from a mixed finite element discretization applied to a second-order elliptic boundary value problem in three dimensions. Based on a decomposition of the velocity space, these equations can be reduced to a discrete elliptic problem by eliminating the pressure through the use of substructures of the domain. The practicality of the reduction relies on a local basis, presented here, for the divergence-free subspace of the velocity space. We consider additive and multiplicative domain decomposition methods for solving the reduced elliptic problem, and their uniform convergence is established.

Key words. divergence-free basis, domain decomposition, second-order elliptic problems, mixed finite element method

1. Introduction.

In [6], Ewing and Wang considered and analyzed a domain decomposition method for solving the discrete system of equations which result from mixed finite element approximation of second-order elliptic boundary value problems in two dimensions. The approach in [6] is first to seek a discrete velocity satisfying the discrete continuity equation through a variation of domain decomposition (static condensation), and then to apply a domain decomposition method to the reduced elliptic problem arising from elimination of the pressure in the saddle-point problem. For analogous work, see also [8], [10], and [4]. The crucial part of the approach in [6] is to characterize the divergence-free velocity subspaces. This is also the essential difference with those in [8], [10], and [4].

In this paper, we will use the domain decomposition approach in [6] for the solution of the algebraic system resulting from the mixed finite element method applied to second-order elliptic boundary value problems in three dimensions. As mentioned above, the basis of the divergence-free velocity subspace plays an essential role in the approach; hence we will construct a basis of this subspace for the lowest-order rectangular Raviart–Thomas–Nedelec velocity space [13], [12]. The construction in two dimensions (2-D) is more general and rather easier than in three dimensions (3-D) due to the fact that any divergence-free vector in 2-D can be expressed as the curl

of a scalar stream function. Extension of this work to triangular or irregular meshes and to multilevel domain decomposition will be discussed in a forthcoming paper.

This approach has several practical advantages. For an $n \times n \times n$ grid in 3-D, the number of discrete unknowns is approximately $4n^3$, essentially one pressure and three velocity components per cell. Using the divergence-free subspace, we decouple the system in such a manner that the velocity can be obtained by solving a symmetric positive definite system of order roughly $2n^3$. In contrast to some other proposed procedures, this does not require the introduction of Lagrange multipliers corresponding to pressures at cell interfaces, and it permits direct computation of the velocity, which is often the principal variable of interest, alone. If the pressure is also needed, it can be calculated inexpensively in an additional step. Furthermore, the approach deals readily with the case of full-tensor conductivity (cross-derivatives), where the mass matrix is fuller than tridiagonal and methods based on reduced integration (mass lumping) are difficult to apply. This case results, for example, from anisotropic permeabilities in flows in porous media, where highly discontinuous conductivity coefficients are also common. For such problems, mixed methods are known to produce more realistic velocities than standard techniques [11].

The outline of the remainder of this paper is as follows. In section 2, we review the mixed finite element method for elliptic problems with homogeneous Neumann boundary conditions. The domain decomposition method for the resulting algebraic system is discussed in section 3, and its uniform convergence is established in section 5. A computationally convenient, divergence-free basis with minimal support is constructed in section 4.

2. Mixed finite element method. In this section, we begin with a brief review of the mixed finite element method with lowest-order Raviart–Thomas–Nedelec [13], [12] (RTN) approximation space for second-order elliptic boundary value problems in three dimensions. For simplicity, we consider a homogeneous Neumann problem: find p such that

$$\left\{ \begin{array}{rcllc} -\nabla \cdot (k\nabla p) & = & f & \text{in} & \Omega = (0,\,1)^3, \\ (k\nabla p)\cdot \mathbf{n} & = & 0 & \text{on} & \partial\Omega, \end{array} \right. \tag{2.1}$$

where $f \in L^2(\Omega)$ satisfies the relation

$$\int_\Omega f \, dx\, dy\, dz = 0 \tag{2.2}$$

and $\mathbf{n}$ denotes the unit outward normal vector to $\partial\Omega$. The symbols $\nabla\cdot$ and ∇ stand for the divergence and gradient operators, respectively. Assume that $k = (k_{ij})_{3\times 3}$ is a given real-valued symmetric matrix function with bounded and measurable entries k_{ij} ($i,\, j = 1,\, 2,\, 3$) and satisfies the ellipticity condition; i.e., there exist positive constants α_1 and α_2 such that

$$\alpha_1 \xi^t\, \xi \le \xi^t k(x,\, y,\, z)\xi \le \alpha_2 \xi^t\, \xi \tag{2.3}$$

for all $\xi \in \mathbb{R}^3$ and almost all $(x,\, y,\, z) \in \bar{\Omega}$.

We shall use the following space to define the mixed variational problem. Let

$$H(div;\Omega) \equiv \{\mathbf{w} \in L^2(\Omega)^3 \,|\, \nabla\cdot\mathbf{w} \in L^2(\Omega)\},$$

which is a Hilbert space equipped with the norm

$$\|\mathbf{w}\|_{H(div;\Omega)} \equiv (\|\mathbf{w}\|^2_{L^2(\Omega)^3} + \|\nabla\cdot\mathbf{w}\|^2_{L^2(\Omega)})^{1/2}$$

and the associated inner product. By introducing the flux variable

$$\mathbf{v} = -k\nabla p,$$

which is of practical interest for many physical problems, we can rewrite the PDE of (2.1) as a first-order system

$$\left\{ \begin{array}{rcl} k^{-1}\mathbf{v} + \nabla p &=& 0, \\ \nabla \cdot \mathbf{v} &=& f \end{array} \right.$$

and obtain the mixed formulation of (2.1): find $(\mathbf{v},\, p) \in \mathbf{V} \times \Lambda$ such that

$$\left\{ \begin{array}{lcll} a(\mathbf{v},\, \mathbf{w}) - b(\mathbf{w},\, p) &=& 0 & \forall\, \mathbf{w} \in \mathbf{V}, \\ b(\mathbf{v},\, \lambda) &=& (f,\, \lambda) & \forall\, \lambda \in \Lambda. \end{array} \right. \tag{2.4}$$

Here $\mathbf{V} = H_0(div;\Omega) \equiv \{\mathbf{w} \in H(div;\Omega)\,|\,\mathbf{w}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\}$, Λ is the quotient space $L_0^2(\Omega) = L^2(\Omega)/\{\text{constants}\}$, the bilinear forms $a(\cdot\,,\cdot) : \mathbf{V}\times\mathbf{V} \to \mathbb{R}$ and $b(\cdot\,,\cdot) : \mathbf{V}\times\Lambda \to \mathbb{R}$ are defined by

$$a(\mathbf{w},\, \mathbf{u}) = \int_\Omega (k^{-1}\mathbf{w})\cdot\mathbf{u}\, dx\, dy\, dz \quad \text{and} \quad b(\mathbf{w},\, \lambda) = \int_\Omega (\nabla\cdot\mathbf{w})\lambda\, dx\, dy\, dz$$

for any $\mathbf{w},\, \mathbf{u} \in \mathbf{V}$ and $\lambda \in \Lambda$, respectively, and $(\cdot,\cdot)$ denotes the $L^2(\Omega)$ inner product.

To discretize the mixed formulation (2.4), we assume that we are given two finite element subspaces

$$\mathbf{V}^h \subset \mathbf{V} \quad \text{and} \quad \Lambda^h \subset \Lambda$$

defined on a uniform rectangular mesh with elements of size $O(h)$. The mixed approximation of $(\mathbf{v}\,, p)$ is defined to be the pair $(\mathbf{v}^h,\, p^h) \in \mathbf{V}^h \times \Lambda^h$ satisfying

$$\left\{ \begin{array}{lcll} a(\mathbf{v}^h,\, \mathbf{w}) - b(\mathbf{w}\,, p^h) &=& 0 & \forall\, \mathbf{w} \in \mathbf{V}^h, \\ b(\mathbf{v}^h,\, \lambda) &=& (f,\, \lambda) & \forall\, \lambda \in \Lambda^h. \end{array} \right. \tag{2.5}$$

We refer to [13] for the definition of a class of approximation subspaces $\mathbf{V}^h$ and Λ^h. In this paper, we shall consider only the lowest-order RTN space defined on a rectangular triangulation of Ω. Such a space for the velocity consists of vector functions whose ith component is continuous piecewise linear in the x_i variable and discontinuous piecewise constant in the x_j variable for $j \neq i$. The corresponding pressure space Λ^h consists of discontinuous piecewise constants with respect to the triangulation $\mathcal{T}^h$ with a fixed value on one element. Specifically, let $\mathcal{T}^h$ denote a uniform rectangular triangulation of Ω. Then the lowest-order RTN approximation space for the velocity on a rectangle $K \in \mathcal{T}^h$ is defined by

$$\mathbf{V}^h(K) = \mathcal{P}_{1,\,0,\,0} \times \mathcal{P}_{0,\,1,\,0} \times \mathcal{P}_{0,\,0,\,1}, \tag{2.6}$$

and the corresponding pressure space is

$$\Lambda^h(K) = \mathcal{P}_{0,\,0,\,0}, \tag{2.7}$$

where $\mathcal{P}_{i_1,\,i_2,\,i_3}(K)$ denotes the polynomials of degree i_j $(j = 1,\, 2,\, 3)$ with respect to x_j. It is well known that the above RTN space satisfies the Babŭska–Brezzi stability condition (cf. [13]): there exists a positive constant β independent of the mesh size h of $\mathcal{T}^h$ such that

$$\sup_{\mathbf{w}\in\mathbf{V}^h} \frac{b(\mathbf{w}\,,\lambda)}{\|\mathbf{w}\|_{H(div,\,\Omega)}} \geq \beta\|\lambda\|_{L^2(\Omega)} \quad \forall\,\lambda\in\Lambda^h. \tag{2.8}$$

Also, Raviart and Thomas in [13] demonstrated the existence of a projection operator $\mathbf{\Pi}_h : \mathbf{V} \longrightarrow \mathbf{V}^h$ such that, for any $\mathbf{v}\in\mathbf{V}$,

$$b(\mathbf{\Pi}_h\mathbf{v}\,,\lambda) = b(\mathbf{v}\,,\lambda) \quad \forall\,\lambda\in\Lambda^h, \tag{2.9}$$

$$\|\mathbf{\Pi}_h\mathbf{v}-\mathbf{v}\|_{L^2(\Omega)^3} \leq C\,h^s\|\mathbf{v}\|_{H^s(\Omega)^3}, \quad s=0,\,1. \tag{2.10}$$

3. Domain decomposition.

Problem (2.5) is clearly symmetric and indefinite. To reduce it to a symmetric positive definite problem, we need a discrete velocity $\mathbf{v}_I^h\in\mathbf{V}^h$ satisfying

$$b(\mathbf{v}_I^h,\,\lambda) = (f,\,\lambda) \quad \forall\,\lambda\in\Lambda^h. \tag{3.1}$$

Define the discretely (as opposed to pointwise) divergence-free subspace $\mathbf{D}^h$ of $\mathbf{V}^h$:

$$\mathbf{D}^h = \{\mathbf{w}\in\mathbf{V}^h \,|\, b(\mathbf{w},\lambda)=0 \quad \forall\,\lambda\in\Lambda^h\}, \tag{3.2}$$

and let

$$\mathbf{v}_D^h = \mathbf{v}^h - \mathbf{v}_I^h,$$

which is obviously in $\mathbf{D}^h$ by the second equation of (2.5) and which satisfies

$$a(\mathbf{v}_D^h,\,\mathbf{w}) = -a(\mathbf{v}_I^h,\,\mathbf{w}) \quad \forall\,\mathbf{w}\in\mathbf{D}^h, \tag{3.3}$$

by the first equation. This problem is symmetric and positive definite.

This suggests the following procedure for obtaining $\mathbf{v}^h$, the solution of (2.5): find $\mathbf{v}_I^h\in\mathbf{V}^h$ satisfying (3.1), compute the projection $\mathbf{v}_D^h\in\mathbf{D}^h$ satisfying (3.3), then set $\mathbf{v}^h=\mathbf{v}_I^h+\mathbf{v}_D^h$. This procedure will be the basis for Algorithms 3.1 and 3.2 below. Given $\mathbf{v}_I^h$, (3.3) leads to a unique $\mathbf{v}^h$, which is independent of the choice of $\mathbf{v}_I^h$. (A term added to a given $\mathbf{v}_I^h$ must be in $\mathbf{D}^h$, and it is canceled by the resulting change in $\mathbf{v}_D^h$.) For an $n\times n\times n$ grid, computing the projection $\mathbf{v}_D^h$ involves solving a system of order approximately $2n^3$. Solving for p^h is optional; if it is desired, it can be obtained from the first equation in (2.5) once $\mathbf{v}^h$ is known.

There are many discrete velocities in $\mathbf{V}^h$ satisfying (3.1), and several approaches have been discussed in the literature for seeking such a discrete velocity (e.g., [6], [8], and [10]). All of these approaches are based on a type of domain decomposition (static condensation) method applied to problem (2.5). In this paper, we will adopt the approach discussed in [6] by Ewing and Wang. This approach requires solving only a coarse-grid problem and some local problems of the form (2.5).

To compute $\mathbf{v}_I^h$ and define the domain decomposition method for problem (3.3), we start with a coarse initial rectangular triangulation $\mathcal{T}^H=\{K_j\}_{j=1}^J$ of the domain Ω (so that $\bar{\Omega}=\cup_{j=1}^J\bar{K}_j$), and a regular fine rectangular triangulation $\mathcal{T}^h$ obtained by further partitioning all of the elements in $\mathcal{T}^H$. Associated with the coarse triangulation $\mathcal{T}^H$, we construct a set of overlapping subdomains $\{\Omega_j\}_{j=1}^J$ by extending each element $K_j \in \mathcal{T}^H$ to a larger subdomain Ω_j, whose diameter is denoted by $H_j \leq C\,H$. Assume that the maximum number of subdomain overlaps is bounded, and further that the distance between the boundaries ∂K_j and $\partial\Omega_j$ is bounded below by $\zeta_1 H$ and above by $\zeta_2 H$; i.e., for all $j \in \{1, \ldots, J\}$ there exist constants $\zeta_1,\, \zeta_2 > 0$ such that

$$\zeta_1 H \leq \operatorname{dist}(\partial K_j,\, \partial\Omega_j) \leq \zeta_2 H.$$

Also assume that the boundaries of the Ω_j do not cut through any element in $\mathcal{T}^h$, i.e., they must coincide with boundaries of elements of $\mathcal{T}^h$. Thus, the restrictions of $\mathcal{T}^h$ on Ω_j and K_j provide two uniform triangulations $\mathcal{T}_j^h$ and $\tilde{\mathcal{T}}_j^h$ for Ω_j and K_j, respectively.

Let $\mathbf{V}_j \times \Lambda_j$ and $\tilde{\mathbf{V}}_j \times \tilde{\Lambda}_j$ be the lowest-order RTN approximation spaces corresponding to the triangulations $\mathcal{T}_j^h$ and $\tilde{\mathcal{T}}_j^h$, respectively. For convenience, let $\mathbf{V}^H = \mathbf{V}_0 = \tilde{\mathbf{V}}_0$ and $\Lambda^H = \Lambda_0 = \tilde{\Lambda}_0$. As in [6], let f^h and $f_0^h \equiv f^H$ be the L^2 projection of f in Λ^h and Λ^H, respectively, and $f_j^h \in \tilde{\Lambda}_j^h$ be the restriction of $f^h - f_0^h$ on K_j. Then the discrete velocity $\mathbf{v}_I^h$ satisfying (3.1) may be determined by the sum of $\mathbf{v}_j$'s which are the solutions of the following problems: find $(\mathbf{v}_j,\, p_j) \in \tilde{\mathbf{V}}_j \times \tilde{\Lambda}_j$ such that

$$\left\{ \begin{array}{lcll} (\tilde{k}\mathbf{v}_j,\, \mathbf{w}) - b(\mathbf{w},\, p_j) & = & 0 & \forall\, \mathbf{w} \in \tilde{\mathbf{V}}_j, \\ b(\mathbf{v}_j,\, \lambda) & = & (f_j^h,\, \lambda) & \forall\, \lambda \in \tilde{\Lambda}_j, \end{array} \right. \tag{3.4}$$

where $\tilde{k} \in \mathbb{R}^{3\times 3}$ is an arbitrary matrix-valued function which is symmetric positive definite and defined on Ω_j for all $j \in \{0,\, 1, \ldots, J\}$. Note that $\mathbf{v}_0$ is the solution of problem (2.5) corresponding to the coarse triangulation $\mathcal{T}^H$, and that $\mathbf{v}_j$ for $1 \leq j \leq J$ can be obtained by solving some local problems.

We shall use additive and multiplicative domain decomposition methods for approximate computation of the solution of problem (3.3). To this end, we define the family of discretely divergence-free velocity subspaces $\{\mathbf{D}_j\}_{j=0}^J$ by $\mathbf{D}_0 = \mathbf{D}^H$, and for $j \in \{1,\, 2, \ldots, J\}$,

$$\mathbf{D}_j = \{\mathbf{u} \in \mathbf{V}_j \,|\, b(\mathbf{u},\, \lambda) = 0 \quad \forall\, \lambda \in \Lambda_j\}.$$

For any $\mathbf{u} \in \mathbf{D}^h$, we define the projection operators $\mathbf{P}_j : \mathbf{D}^h \longrightarrow \mathbf{D}_j$ associated with the bilinear form $a(\cdot\,,\cdot)$ by

$$a(\mathbf{P}_j\mathbf{u},\, \mathbf{w}) = a(\mathbf{u},\, \mathbf{w}) \quad \forall\, \mathbf{w} \in \mathbf{D}_j$$

for $j \in \{0,\, 1, \ldots, J\}$.

ALGORITHM 3.1 (Additive domain decomposition).

1. *For $j = 0, 1, \ldots, J$, compute $\mathbf{v}_j \in \tilde{\mathbf{V}}_j$ by solving problems* (3.4). *Then set*

$$\mathbf{v}_I^h = \mathbf{v}_0 + \mathbf{v}_1 + \cdots + \mathbf{v}_J.$$

2. *Compute an approximation $\mathbf{v}_D$ of $\mathbf{v}_D^h \in \mathbf{D}^h$ by applying conjugate gradient iteration to*

$$\mathbf{P}\mathbf{v}_D = \mathbf{F}, \tag{3.5}$$

where $\mathbf{P} = \mathbf{P}_0 + \mathbf{P}_1 + \cdots + \mathbf{P}_J$, $\mathbf{F} = \mathbf{F}_0 + \mathbf{F}_1 + \cdots + \mathbf{F}_J$, and $\mathbf{F}_j = \mathbf{P}_j\mathbf{v}_D^h$.

3. *Set*

$$\mathbf{v}^h = \mathbf{v}_D + \mathbf{v}_I^h.$$

Remark 3.1. The right-hand side $\mathbf{F}$ in (3.5) can be computed by solving the coarse-grid problem and local subproblems. Specifically, for each $j \in \{0, 1, \ldots, J\}$, $\mathbf{F}_j$ is the solution of the following problem:

$$a(\mathbf{F}_j,\, \mathbf{w}) = a(\mathbf{P}_j \mathbf{v}_D^h,\, \mathbf{w}) = -a(\mathbf{v}_I^h,\, \mathbf{w}) \quad \forall\, \mathbf{w} \in \mathbf{D}_j. \tag{3.6}$$

For $\mathbf{F}_j$ given in (3.6), we can see as follows that (3.5) is equivalent to problem (3.3). Given (3.3), define $\mathbf{F}_j$ as in (3.6), and $\mathbf{P}$ and $\mathbf{F}$ as above. Then $a(\mathbf{F}_j, w) = a(v_D^h, w)$ $\forall w \in \mathbf{D}_j$, so that $\mathbf{F}_j = \mathbf{P}_j \mathbf{v}_D^h$, and summing on j yields $\mathbf{P}\mathbf{v}_D^h = \mathbf{F}$. To complete the equivalence, we claim that $\mathbf{v}_D^h$ is the only solution of (3.5). It suffices to show that $\mathbf{P}\mathbf{u} = \mathbf{0}$ implies that $\mathbf{u} = \mathbf{0}$ for $\mathbf{u} \in \mathbf{D}^h$. If $\mathbf{P}\mathbf{u} = \mathbf{0}$, then

$$0 = a(\mathbf{P}\mathbf{u}, \mathbf{u}) = \sum_j a(\mathbf{P}_j\mathbf{u}, \mathbf{u}) = \sum_j a(\mathbf{P}_j\mathbf{u}, \mathbf{P}_j\mathbf{u}),$$

so that $a(\mathbf{P}_j\mathbf{u}, \mathbf{P}_j\mathbf{u}) = 0$ $\forall j$; hence $\mathbf{P}_j\mathbf{u} = \mathbf{0}$ $\forall j$. In Lemma 5.1 below, we prove that $\mathbf{u}$ has a decomposition $\mathbf{u} = \mathbf{u}_0 + \mathbf{u}_1 + \cdots + \mathbf{u}_J$, where $\mathbf{u}_j \in \mathbf{D}_j$. With this,

$$a(\mathbf{u}, \mathbf{u}) = \sum_j a(\mathbf{u}_j, \mathbf{u}) = \sum_j a(\mathbf{u}_j, \mathbf{P}_j\mathbf{u}) = 0,$$

and hence $\mathbf{u} = \mathbf{0}$, as claimed.

At each iteration of the conjugate gradient method applied to (3.5), we need to compute the action of the projection operator $\mathbf{P}_j$ on a given $\mathbf{u} \in \mathbf{D}^h$, which may be obtained by solving the following problem:

$$a(\mathbf{P}_j\mathbf{u},\, \mathbf{w}) = a(\mathbf{u},\, \mathbf{w}) \quad \forall\, \mathbf{w} \in \mathbf{D}_j. \tag{3.7}$$

When analyzing the preconditioned conjugate gradient method for a system of linear equations, the crucial issue is to estimate the condition number of the preconditioned operator. In section 5, we will establish a uniform estimate of the condition number for $\mathbf{P}$ and find a basis for $\mathbf{D}^h$ that allows for efficient computations.

Algorithm 3.2 (Multiplicative domain decomposition).

1. *Compute* $\mathbf{v}_I^h$ *as in the first step of* Algorithm 3.1.
2. *Given an approximation* $\mathbf{v}_D^l \in \mathbf{D}^h$ *to the solution* $\mathbf{v}_D^h$ *of* (3.3)*, define the next approximation* $\mathbf{v}_D^{l+1} \in \mathbf{D}^h$ *as follows:*
   (a) *Set* $W_{-1} = \mathbf{v}_D^l$.
   (b) *For* $j = 0, 1, \ldots, J$ *in turn, define* W_j *by*
   $$W_j = W_{j-1} + \omega \mathbf{P}_j(\mathbf{v}_D^h - W_{j-1}),$$
   where the parameter $\omega \in (0,\, 2)$.
   (c) *Set* $\mathbf{v}_D^{l+1} = W_J$.
3. *Set*
   $$\mathbf{v}^h = \mathbf{v}_I^h + \mathbf{v}_D^L.$$

Remark 3.2. $\mathbf{P}_j(\mathbf{v}_D^h - W_{j-1})$ can be computed by solving the following problem:

$$a(\mathbf{P}_j(\mathbf{v}_D^h - W_{j-1}),\, \mathbf{w}) = -a(\mathbf{v}_I^h + W_{j-1},\, \mathbf{w}) \quad \forall\, \mathbf{w} \in \mathbf{D}_j. \tag{3.8}$$

A simple computation implies that the error propagation operator of multiplicative domain decomposition at the second step of Algorithm 3.2 has the form of

$$\mathbf{E} = (\mathbf{I} - \mathbf{P}_J)(\mathbf{I} - \mathbf{P}_{J-1}) \cdots (\mathbf{I} - \mathbf{P}_0). \tag{3.9}$$

Define a norm associated with the bilinear form $a(\cdot,\, \cdot)$ by

$$\|\mathbf{u}\|_a = a(\mathbf{u},\, \mathbf{u})^{1/2} \quad \forall\, \mathbf{u} \in \mathbf{D}^h.$$

We shall show in the last section that $\|\mathbf{E}\|_a$ is bounded by a constant which is less than one and independent of the mesh size h and the number of subdomains.

4. Construction of a divergence-free basis. Since the technique of the mixed method leads to a saddle-point problem, which causes the final system to be indefinite, many well-established efficient linear system solvers cannot be applied. As we mentioned earlier, (2.5) could be symmetric and positive definite if we discretize it in the discrete divergence-free subspace $\mathbf{D}^h$. The construction of a basis for $\mathbf{D}^h$ is essential.

In this section, we will construct a computationally convenient basis for $\mathbf{D}^h$—the divergence-free subspace of $\mathbf{V}^h$. We will do this by first constructing a vector potential space $\mathbf{U}^h$ such that

$$\mathbf{D}^h = \mathbf{curl}\,\mathbf{U}^h. \tag{4.1}$$

Next, we will find a basis for $\mathbf{U}^h$, and we will define a basis for $\mathbf{D}^h$ by simply taking the curls of the vector potential basis functions.

Denote the mesh on $\Omega = (0,1)^3$ by $0 = x_0 < \cdots < x_i < \cdots < x_n = 1$, and similarly with y_j and z_k, $0 \le j,k \le n$. The assumption of the same number n of intervals in each direction is merely for convenience and is not necessary for the construction to follow. Let

$$\phi^x_{i,j,k}(x,y,z) = \chi_i(x)\psi_j(y)\psi_k(z), \qquad 1 \le i \le n, \quad 1 \le j,k \le n-1,$$

where χ_i is the characteristic function of (x_{i-1}, x_i), ψ_j is the standard hat function supported on (y_{j-1}, y_{j+1}), and similarly ψ_k is supported on (z_{k-1}, z_{k+1}). Then $\phi^x_{i,j,k}$ is the standard bilinear nodal basis function on $(y_{j-1}, y_{j+1}) \times (z_{k-1}, z_{k+1})$, extended as a constant in the x-direction in the ith slice only, zero in the other slices. For economy of notation, write $\phi_i(y,z)$ for $\phi^x_{i,j,k}(x,y,z)$, where the single index i, $1 \le i \le n(n-1)^2$, runs through the triples (i,j,k) lexicographically (k varying most rapidly). The support of a typical $\phi_i(y,z)$ consists of a $1 \times 2 \times 2$ set of 4 cells and is shown in Figure 4.1. Similarly, let

$$\begin{aligned} \phi^y_{j,i,k}(x,y,z) &= \chi_j(y)\psi_i(x)\psi_k(z) = \phi_j(x,z), \quad 1 \le j \le n,\ 1 \le i,k \le n-1, \\ \phi^z_{k,i,j}(x,y,z) &= \chi_k(z)\psi_i(x)\psi_j(y) = \phi_k(x,y), \quad 1 \le k \le n,\ 1 \le i,j \le n-1, \end{aligned}$$

where j, k run lexicographically through (j,i,k) and (k,i,j), respectively. Finally, let $\mathbf{U}^h$ be defined as follows:

$$\mathbf{U}^h = \text{span}\left\{ \begin{pmatrix} \phi_i(y,z) \\ 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ \phi_j(x,z) \\ 0 \end{pmatrix}, \begin{pmatrix} 0 \\ 0 \\ \phi_k(x,y) \end{pmatrix} \right\}, \tag{4.2}$$

where $1 \le i \le (n-1)^2$ (thus, only the first yz-slice is included) and $1 \le j,k \le n(n-1)^2$ (all xz- and xy-slices are included). Note that the number of excluded ϕ_i's is $(n-1)^3$. If the number of intervals in the x-, y-, and z-directions were ℓ, m, and n, respectively, the number excluded would be $(\ell-1)(m-1)(n-1)$ and would be the same if all but one xz- or xy-slice were excluded instead of all but one yz-slice.

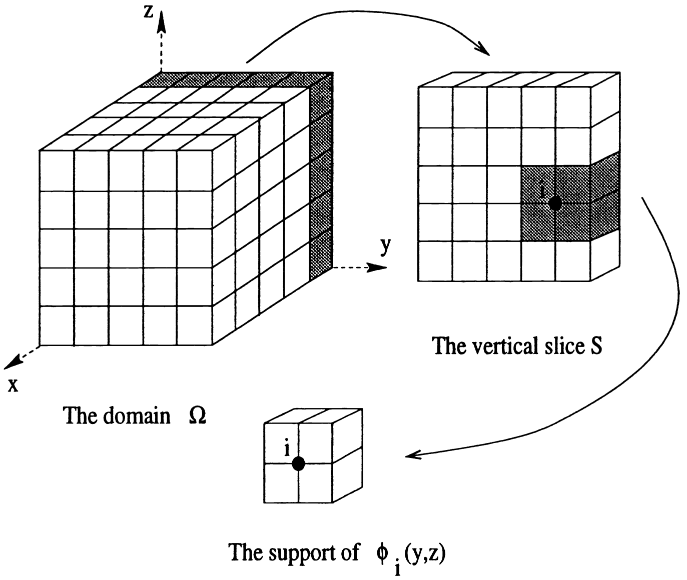

FIG. 4.1. *The support of a typical potential basis function.*

Next, we list some properties of $\mathbf{U}^h$ which follow directly from the definition of the potential space.

Remark 4.1. $\mathbf{U}^h \not\subset H(div;\Omega)$ (because, e.g., $\phi_i(y,z)$ is discontinuous in x), and hence, $\mathbf{U}^h \not\subset H^1(\Omega)^3$.

Remark 4.2. Every $\mathbf{\Phi} \in \mathbf{U}^h$ satisfies $\mathbf{\Phi} \times \mathbf{n} = \mathbf{0}$ on $\partial\Omega$ (because, e.g., $\phi_j(0,z)$ and $\phi_k(0,y)$ are identically zero).

Remark 4.3. $\mathbf{U}^h$ is locally divergence-free, i.e., $\nabla\cdot\mathbf{\Phi} = 0$ on each element $K \in \mathcal{T}^h$ for every $\mathbf{\Phi} \in \mathbf{U}^h$.

Remark 4.4. $\mathbf{U}^h \subset H(curl;\Omega)$, and hence $\mathbf{curl}\,\mathbf{U}^h \subset \mathbf{V}^h$. To see this, consider as a typical case the vector function $(\phi_i(y,z),0,0) \in \mathbf{U}^h$, whose curl is $(0, \partial\phi_i/\partial z, -\partial\phi_i/\partial y)$. Because ϕ_i is discontinuous only in the x-direction and no x-derivatives appear in the curl, we have $(\phi_i,0,0) \in H(curl;\Omega)$. Further, the y-component of $\mathbf{curl}(\phi_i,0,0)$ is $\partial\phi_i/\partial z = \chi_i(x)\psi_j(y)\psi_k'(z)$, which is continuous piecewise linear in y and discontinuous piecewise constant in x and z; similarly, the other components have the correct form to yield $\mathbf{curl}(\phi_i,0,0) \in \mathbf{V}^h$.

Since $\operatorname{div}\mathbf{curl} \equiv 0$, we have $\mathbf{curl}\,\mathbf{U}^h \subset \mathbf{D}^h$. Counting dimensions,

$$\dim \mathbf{U}^h = (2n+1)(n-1)^2 = 2n^3 - 3n^2 + 1.$$

Also, $\operatorname{div}\mathbf{V}^h$ consists of those piecewise constants with integral zero over Ω, and hence has dimension $n^3 - 1$, and we obtain

$$\dim \mathbf{D}^h = \dim \mathbf{V}^h - \dim \operatorname{div} \mathbf{V}^h = 3(n-1)n^2 - (n^3 - 1) = 2n^3 - 3n^2 + 1.$$

We claim that the curls of the vectors in (4.2) are linearly independent, so that

$$\dim \mathbf{D}^h = \dim \mathbf{curl}\,\mathbf{U}^h = \dim \mathbf{U}^h = 2n^3 - 3n^2 + 1,$$

which implies that for every divergence-free vector $\mathbf{v} \in \mathbf{D}^h$ there exists a unique potential vector $\mathbf{\Phi} \in \mathbf{U}^h$ such that

$$\mathbf{v} = \mathbf{curl}\,\mathbf{\Phi}.$$

To prove linear independence, first note that vectors in $\mathbf{V}^h$ can be characterized in terms of normal fluxes across the $3(n-1)n^2$ interior faces between elements. For example, some calculations will show that $\mathbf{curl}\,(\phi_1(y,z),0,0) = \mathbf{curl}\,(\phi^x_{1,1,1}(x,y,z),0,0)$ has y-component 1 on face $(1,3/2,1) = (x_0,x_1) \times \{y_1\} \times (z_0,z_1)$ and -1 on face $(1,3/2,2) = (x_0,x_1) \times \{y_1\} \times (z_1,z_2)$, and z-component 1 on $(1,2,3/2)$ and -1 on $(1,1,3/2)$, where the four fluxes have been scaled to unit magnitude. This is shown in Figure 4.2. We denote this particular curl by $+1(1,3/2,1)-1(1,3/2,2)+1(1,2,3/2)-1(1,1,3/2)$.

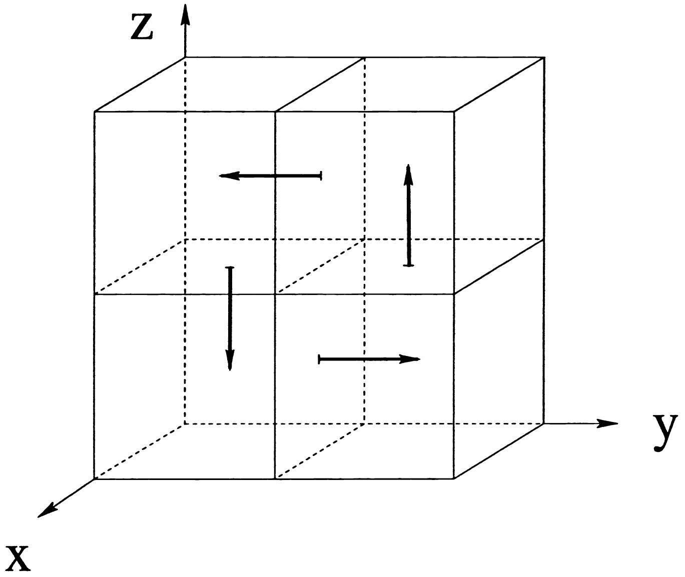

FIG. 4.2. *The curl of a typical potential basis function.*

Now consider $\mathbf{curl}\,(0,\phi_j(x,z),0)$, $1 \le j \le n(n-1)^2$. Put $\phi_j(x,z) = \phi^y_{j,i,k}(x,y,z)$ in lexicographic order, noting that $\mathbf{curl}\,(0,\phi^y_{j,i,k},0) = +1(i+1/2,j,k+1) - 1(i+1/2,j,k) + 1(i,j,k+1/2) - 1(i+1,j,k+1/2)$ and that face $(i+1/2,j,k+1)$ appears for the first time in $\mathbf{curl}\,(0,\phi^y_{j,i,k},0)$. Since each curl introduces a nonzero flux on a new face, the curls of $(0,\phi_j(x,z),0)$ are linearly independent. Next, we have $\mathbf{curl}\,(0,0,\phi_k(x,y)) = \mathbf{curl}\,(0,0,\phi^z_{k,i,j}) = +1(i+1,j+1/2,k) - 1(i,j+1/2,k) + 1(i+1/2,j,k) - 1(i+1/2,j+1,k)$, and face $(i+1,j+1/2,k)$ appears for the first time in $\mathbf{curl}\,(0,0,\phi^z_{k,i,j})$. Thus, the curls of $(0,\phi_j(x,z),0)$ and $(0,0,\phi_k(x,y))$, $1 \le j,k \le n(n-1)^2$, are all linearly independent.

Finally, consider a linear combination

$$\sum_i \alpha_i \mathbf{curl}\,(\phi_i(y,z),0,0) = \sum_{j=1}^{n-1}\sum_{k=1}^{n-1} \alpha_{jk}\mathbf{curl}\,(\phi^x_{1,j,k},0,0)$$

(terms from first yz-slice only). Because the curls of $(\phi_i,0,0)$ are linearly independent by the argument applied above to the curls of $(0,\phi_j,0)$, it suffices to show that this linear combination is independent of the curls of $(0, \phi_j, 0)$ and $(0, 0, \phi_k)$. We have $\mathbf{curl}\,(\phi^x_{1,j,k}, 0, 0) = +1(1, j + 1/2, k) - 1(1, j + 1/2, k + 1) + 1(1, j + 1, k + 1/2) - 1(1, j, k + 1/2)$. Each of these four terms occurs exactly once in the curls of $(0, \phi_j(x, z), 0)$ and $(0, 0, \phi_k(x, y))$, namely in $-\mathbf{curl}\,(0, 0, \phi^z_{k,1,j})$, $+\mathbf{curl}\,(0, 0, \phi^z_{k+1,1,j})$, $+\mathbf{curl}\,(0, \phi^y_{j+1,1,k}, 0)$, $-\mathbf{curl}\,(0, \phi^y_{j,1,k}, 0)$, respectively. Hence, a dependency relationship for $\mathbf{curl}\,(\phi^x_{1,j,k}, 0, 0)$ in terms of the preceding curls must involve these four curls, and when they are combined we get $\mathbf{curl}\,(\phi^x_{1,j,k}, 0, 0) - \mathbf{curl}\,(\phi^x_{2,j,k}, 0, 0)$. Applying this fact to each term of the linear combination, we have $\sum_{j=1}^{n-1} \sum_{k=1}^{n-1} \alpha_{jk}(\mathbf{curl}\,(\phi^x_{1,j,k}, 0, 0) - \mathbf{curl}\,(\phi^x_{2,j,k}, 0, 0))$. To cancel $\sum_{j,k} \alpha_{jk}(-\mathbf{curl}\,(\phi^x_{2,j,k}, 0, 0))$ with the preceding curls, the forced combination yields $\sum_{j,k} \alpha_{jk}(\mathbf{curl}\,(\phi^x_{2,j,k}, 0, 0) - \mathbf{curl}\,(\phi^x_{3,j,k}, 0, 0))$, and so on until $\sum_{j,k} \alpha_{jk}(-\mathbf{curl}\,(\phi^x_{n,j,k}, 0, 0))$ remains, and it is not possible to cancel it. It follows that no dependency relationship exists, so that the curls of the vectors in (4.2) are indeed linearly independent.

The vector functions in (4.2) constitute one choice of a basis for $\mathbf{U}^h$. As noted above, this choice includes all $2n(n-1)^2$ vectors of the forms $(0, \phi_j, 0)$ and $(0, 0, \phi_k)$, but only $(n-1)^2$ vectors of the type $(\phi_i, 0, 0)$ with support contained in one vertical slice S of Ω (say, the shaded one in Figure 4.1).

Remark 4.5. The above-defined basis for $\mathbf{U}^h$ (and hence for $\mathbf{D}^h$) consists of vector functions with minimal possible support. (A moment's reflection shows that a nontrivial divergence-free vector function must be supported on at least four elements, as in the pattern in Figure 4.2.)

Now we need to prove the following Poincaré-type inequality.

LEMMA 4.1. *There exists a constant $C(\Omega) > 0$, independent of the quasi-uniform mesh size h, such that for all $\mathbf{\Phi} \in \mathbf{U}^h$ we have*

$$\|\mathbf{\Phi}\|_{L^2(\Omega)^3} \le C(\Omega)\, \|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3}. \tag{4.3}$$

(Since the vector potential space $\mathbf{U}^h \not\subset H^1(\Omega)^3$, inequality (4.3) does not follow from the standard Poincaré inequality.)

Proof. Keeping in mind our choice for a basis in $\mathbf{U}^h$, we have

$$\mathbf{\Phi} = (\Phi_x, \Phi_y, \Phi_z)^T,$$

and since Φ_x vanishes outside the vertical slice S we have

$$\begin{aligned}\|\mathbf{\Phi}\|^2_{L^2(\Omega)^3} &= \|\Phi_x\|^2_{L^2(S)} + \|\Phi_y\|^2_{L^2(S)} + \|\Phi_z\|^2_{L^2(S)} \\ &\quad + \|\Phi_y\|^2_{L^2(\Omega\setminus S)} + \|\Phi_z\|^2_{L^2(\Omega\setminus S)}.\end{aligned}$$

Let us estimate the last term first. Noting that $\Phi_z(x, y, z)$ is a continuous function of x and vanishes for $x = 0$ and $x = 1$, we can write

$$\Phi_z(x, y, z) = \int_1^x \frac{\partial \Phi_z(x', y, z)}{\partial x} dx'.$$

After squaring both sides of the above identity, then using the Cauchy–Schwarz inequality on the right-hand side, and finally integrating both sides over $\Omega\setminus S$, we obtain

$$\|\Phi_z\|_{L^2(\Omega\setminus S)} \le C(\Omega)\, \|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3},$$

where we have used the fact that on $\Omega\setminus S$ we have $\mathbf{curl}\,\mathbf{\Phi} = (*, -\frac{\partial \Phi_z}{\partial x}, \frac{\partial \Phi_y}{\partial x})^T$. Exactly in the same manner we get $\|\Phi_y\|_{L^2(\Omega\setminus S)} \le C(\Omega)\, \|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3}$.

The next step of the proof will be estimating $\|\Phi_z\|_{L^2(S)}$ in terms of $\|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3}$. Since Φ_z is a piecewise constant function in the z-direction, let us denote by $\Phi_z^k(x,y)$ the restriction of Φ_z to the kth horizontal slice of Ω. Note that Φ_z^k is linear in x within S and vanishes when $x=0$. Then

$$\begin{aligned}\|\Phi_z\|^2_{L^2(S)} &= \sum_{k=1}^n h\int_0^1\int_0^h \left[\Phi_z^k(x,y)\right]^2 dx\,dy\\ &\le \sum_{k=1}^n h\int_0^1\int_0^h \left[\Phi_z^k(h,y)\right]^2 dx\,dy\\ &= h^2\sum_{k=1}^n \int_0^1 \left[\Phi_z^k(h,y)\right]^2 dy \le h^2\,C(\Omega)\,\|\mathbf{curl}\,\mathbf{\Phi}\|^2_{L^2(\Omega)^3},\end{aligned}$$

where to obtain the last inequality we have again integrated $\frac{\partial\Phi_z}{\partial x}$ over $\Omega\backslash S$. The term $\|\Phi_y\|_{L^2(S)}$ is estimated in an analogous manner.

Finally, consider the identity on S,

$$\Phi_x(y,z) = \int_0^z \left[\frac{\partial\Phi_x(y,z')}{\partial z} - \frac{\partial\Phi_z(x,y,z')}{\partial x}\right] dz' + \int_0^z \frac{\partial\Phi_z(x,y,z')}{\partial x} dz'.$$

Again, after we square both sides, apply the Cauchy–Schwarz inequality on the right-hand side, integrate both sides over S, and note that $\frac{\partial\Phi_x}{\partial z} - \frac{\partial\Phi_z}{\partial x}$ is a component of $\mathbf{curl}\,\mathbf{\Phi}$, we get

$$\|\Phi_x\|^2_{L^2(S)} \le C(\Omega)\left\{\|\mathbf{curl}\,\mathbf{\Phi}\|^2_{L^2(S)^3} + \left\|\frac{\partial\Phi_z}{\partial x}\right\|^2_{L^2(S)}\right\}.$$

Now we complete the proof by applying an inverse inequality on the last term and using the estimate for $\|\Phi_z\|^2_{L^2(S)}$ that was obtained earlier. □

COROLLARY 4.2. *The linear system* (3.3) *to be solved in* $\mathbf{D}^h$ *has a symmetric and positive definite matrix with condition number of order* $O(h^{-2})$.

5. Convergence analysis. In this section, we provide a uniform upper bound for the condition number of the preconditioned operator $\mathbf{P}$ which indicates that the conjugate gradient iteration for problem (3.5) converges uniformly with respect to the mesh size h and the number of subdomains J. We also establish the uniform convergence of the multiplicative domain decomposition proposed in the second step of Algorithm 3.2. These convergence rates do depend on the factor ζ_1 in the minimum overlap $\zeta_1 H$, where H is the coarse-grid mesh size.

Here and henceforth, we shall use C with or without a subscript to denote a generic positive constant independent of the mesh size h and the number of subdomains J. The next lemma plays an essential role in estimating the minimum eigenvalue of the preconditioned operator $\mathbf{P}$.

LEMMA 5.1. *For any* $\mathbf{v}\in\mathbf{D}^h$, *there exists a decomposition of the form*

$$\mathbf{v} = \mathbf{v}_0 + \mathbf{v}_1 + \cdots + \mathbf{v}_J \quad \textit{with} \quad \mathbf{v}_j \in \mathbf{D}_j$$

and

$$\sum_{j=0}^J a(\mathbf{v}_j,\,\mathbf{v}_j) \le C\,a(\mathbf{v},\,\mathbf{v}), \tag{5.1}$$

where the positive constant C is independent of the mesh size h and the number of subdomains J (but depends on the factor ζ_1 in the minimum overlap $\zeta_1 H$).

Proof. For any $\mathbf{v} \in \mathbf{D}^h$, there exists a vector potential (cf. [7]) $\mathbf{\Phi} \in H^1(\Omega)^3$ such that $\mathbf{v} = \mathbf{curl}\,\mathbf{\Phi}$, $\mathbf{\Phi} \times \mathbf{n} = \mathbf{0}$ on $\partial\Omega$, and

$$\|\mathbf{\Phi}\|_{L^2(\Omega)^3} \le C\,\|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3} \quad \text{and} \quad \|\nabla\mathbf{\Phi}\|_{L^2(\Omega)^3} \le C\,\|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3}. \tag{5.2}$$

Let $\mathbf{U}^H$, associated with the coarse triangulation $\mathcal{T}^H$, be defined similarly as in the previous section and $\mathbf{Q}^H$ be the standard L^2 projection operator onto $\mathbf{U}^H$. Let $\mathbf{\Psi} = \mathbf{\Phi} - \mathbf{Q}^H\mathbf{\Phi}$; then it is easy to check (see [2]) that

$$\|\mathbf{\Psi}\|_{L^2(\Omega)^3} \le C\,H\|\nabla\,\mathbf{\Phi}\|_{L^2(\Omega)^3} \quad \text{and} \quad \|\mathbf{curl}\,(\mathbf{Q}^H\mathbf{\Phi})\|_{L^2(\Omega)^3} \le C\,\|\nabla\,\mathbf{\Phi}\|_{L^2(\Omega)^3}. \tag{5.3}$$

Define $\mathbf{v}_0 = \mathbf{curl}\,(\mathbf{Q}^H\mathbf{\Phi})$; then $\mathbf{v}_0 \in \mathbf{D}_0$. By using inequalities (5.3) and (5.2), we have that

$$\begin{aligned} \|\mathbf{v}_0\|_{L^2(\Omega)^3} &= \|\mathbf{curl}\,(\mathbf{Q}^H\mathbf{\Phi})\|_{L^2(\Omega)^3} \le C\,\|\nabla\,\mathbf{\Phi}\|_{L^2(\Omega)^3} \\ &\le C\,\|\mathbf{curl}\,\mathbf{\Phi}\|_{L^2(\Omega)^3} = C\,\|\mathbf{v}\|_{L^2(\Omega)^3}. \end{aligned} \tag{5.4}$$

Now, let $\theta_j \in C_0^\infty(\Omega_j)$, $j = 1, \ldots, J$, be a partition of unity such that

$$|\nabla\theta_j| \le C\,\zeta_1^{-1}\,H^{-1}, \tag{5.5}$$

and let

$$\mathbf{v}_j = \mathbf{\Pi}_h\mathbf{curl}(\theta_j\mathbf{\Psi}) \in \mathbf{D}_j.$$

Note that $\mathbf{v} = \mathbf{curl}\,\mathbf{\Phi} = \mathbf{v}_0 + \mathbf{curl}\,\mathbf{\Psi}$ and $\mathbf{\Pi}_h\mathbf{v} = \mathbf{v}$. Then linearity of $\mathbf{\Pi}_h$ and $\mathbf{curl}$ imply that $\mathbf{v}$ has a decomposition of the form

$$\mathbf{v} = \mathbf{v}_0 + \mathbf{v}_1 + \cdots + \mathbf{v}_J.$$

Since

$$\mathbf{curl}(\theta_j\mathbf{\Psi}) = \mathbf{\Psi} \times \nabla\theta_j + \theta_j\mathbf{curl}\,\mathbf{\Psi},$$

it follows from inequalities (2.3) and (2.10), the Cauchy–Schwarz inequality, and inequality (5.5) that for $j \in \{1, 2, \ldots, J\}$

$$\begin{aligned} a(\mathbf{v}_j,\, \mathbf{v}_j) &\le C\,\|\mathbf{v}_j\|^2_{L^2(\Omega)^3} \\ &\le C\,\|\mathbf{curl}(\theta_j\mathbf{\Psi})\|^2_{L^2(\Omega)^3} \\ &\le C\int_{\Omega_j}\left(|\nabla\theta_j|^2|\mathbf{\Psi}|^2 + \theta_j^2|\mathbf{curl}\,\mathbf{\Psi}|^2\right) \\ &\le C\,\zeta_1^{-2}\,H^{-2}\int_{\Omega_j}|\mathbf{\Psi}|^2 + C\int_{\Omega_j}|\mathbf{curl}\,\mathbf{\Psi}|^2. \end{aligned}$$

By summing the above inequality over j, it follows from the fact that the maximum number of subdomain overlaps is bounded, and from inequalities (5.2), (5.3), (5.4), and (2.3), that

$$\begin{aligned} \sum_{j=0}^{J} a(\mathbf{v}_j,\, \mathbf{v}_j) &\le C\,\|\mathbf{v}_0\|^2_{L^2(\Omega)^3} + C\,\zeta_1^{-2}\,H^{-2}\int_\Omega|\mathbf{\Psi}|^2 + C\int_\Omega|\mathbf{curl}\,\mathbf{\Psi}|^2 \\ &\le C\,\|\mathbf{v}_0\|^2_{L^2(\Omega)^3} + C\,\zeta_1^{-2}\,\|\mathbf{v}\|^2_{L^2(\Omega)^3} \\ &\le C\,(1+\zeta_1^{-2})\,\|\mathbf{v}\|^2_{L^2(\Omega)^3} \\ &\le C\,a(\mathbf{v},\, \mathbf{v}). \end{aligned}$$

This completes the proof of the lemma. □

Now, the standard argument provides the condition number estimate for $\mathbf{P}$.

THEOREM 5.1. *For any vector* $\mathbf{v} \in \mathbf{D}^h$, *we have*

$$C_1 a(\mathbf{v}, \mathbf{v}) \leq a(\mathbf{P}\mathbf{v}, \mathbf{v}) \leq C_2 a(\mathbf{v}, \mathbf{v}), \tag{5.6}$$

where the constants C_1 *and* C_2 *are independent of* h *and* J. *(*C_1 *contains the factor* $(1+\zeta_1^{-2})^{-1}$.*)*

Proof. The proof of the right-hand inequality follows from the boundedness of $\mathbf{P}_j$ and the maximum number of subdomain overlaps. The left-hand inequality follows from Lemma 5.1 and Lions' lemma [9]. □

Remark 5.1. In 2-D, a special Poincaré-type lemma (see [5, Lemma 3.1]), together with a bound of $\|\nabla\phi\|$ in terms of $\|\mathbf{curl}\,\phi\|$, allows an argument from Chapter 5 of [14] to prove a condition-number bound involving $1+\zeta_1^{-1}$ instead of $1+\zeta_1^{-2}$. It is not clear whether the analogous bound holds in 3-D.

To analyze the convergence of the multiplicative domain decomposition method defined at the second step in Algorithm 3.2, we note that for any $\mathbf{w} \in \mathbf{D}$ we have by the definition of the projection operators $\mathbf{P}_j$

$$a(\omega\mathbf{P}_j\mathbf{w}, \omega\mathbf{P}_j\mathbf{w}) = \omega\, a(\omega\mathbf{P}_j\mathbf{w}, \mathbf{w}). \tag{5.7}$$

And Lemma 5.1, the Cauchy–Schwarz inequality, and the bound on the number of subdomain overlaps give that

$$\begin{aligned} a(\mathbf{v}, \mathbf{v}) &= \sum_{j=0}^{J} a(\mathbf{v}, \mathbf{v}_j) = \sum_{j=0}^{J} a(\mathbf{P}_j\mathbf{v}, \mathbf{v}_j) \\ &\leq \left(\sum_{j=0}^{J} a(\mathbf{P}_j\mathbf{v}, \mathbf{P}_j\mathbf{v})\right)^{1/2} \left(\sum_{j=0}^{J} a(\mathbf{v}_j, \mathbf{v}_j)\right)^{1/2} \\ &\leq C \left(\sum_{j=0}^{J} a(\omega\mathbf{P}_j\mathbf{v}, \omega\mathbf{P}_j\mathbf{v})\right)^{1/2} a(\mathbf{v}, \mathbf{v})^{1/2}, \end{aligned}$$

which implies that

$$a(\mathbf{v}, \mathbf{v}) \leq C \sum_{j=0}^{J} a(\omega\mathbf{P}_j\mathbf{v}, \omega\mathbf{P}_j\mathbf{v}). \tag{5.8}$$

Hence, a straightforward consequence of [1] (see also Remark 2.2 in [3]) gives the following result.

THEOREM 5.2. *The iterative method defined at the second step in Algorithm* 3.2 *is uniformly convergent; i.e.,*

$$\|\mathbf{E}\|_a \leq \gamma < 1, \tag{5.9}$$

where γ *is a constant that does not depend on the number of subdomains and the mesh size. (*γ *does depend on* ζ_1.*)*

6. Numerical results. We briefly summarize some computations [15] that will be presented in more detail elsewhere. The additive preconditioner has been implemented and run on a variety of test problems. Corollary 4.2 was confirmed, as the smallest and largest eigenvalues of the system matrix varied as $O(h)$ and $O(h^{-1})$, respectively. For coarse grids ranging from $H = 1/4$ (thus $4 \times 4 \times 4$) to $H = 1/32$, with fine grids $h = H/4$ and overlaps $\zeta_1 H = h$, the iteration counts needed to reduce the preconditioned residual by 10 orders of magnitude were 31 to 32 for constant k (Poisson's equation), 31 for $k = 10^{-5}$ in $(1/4,\ 3/4)^3$ and $k = 1$ elsewhere, and 32 to 36 for $k = 10^{-5}$ in randomly-distributed coarse-grid blocks and $k = 1$ elsewhere. These results correspond to norm reductions of 0.47 (31 iterations) to 0.52 (36 iterations) per iteration. When random heterogeneity was combined with random anisotropy (k a diagonal tensor, three random entries of 10^{-5}, 10^{-4}, $\ldots$, 10^0 in each coarse-grid block), so that there was an increasing number of random blocks on finer grids, norm reductions were significantly worse (0.79 to 0.91) and worsened on finer grids. The theory of this paper does not address the dependence of iteration counts on jumps in coefficients, but it appears that this dependence is substantial only when heterogeneity and anisotropy are intertwined.

WELL POSEDNESS OF THE INITIAL VALUE PROBLEM FOR VERTICALLY DISCRETIZED HYDROSTATIC EQUATIONS[*]

ANDREI BOURCHTEIN[†] AND VLADIMIR KADYCHNIKOV[‡]

Abstract. Vertically discretized linearized hydrostatic equations in hybrid coordinates are considered. The matrix of vertical structure, which depends on vertical discretization and determines the classification of the obtained system of time-dependent partial differential equations, is derived. The main theorem about oscillatory properties of the matrix of vertical structure is proved. This result ensures the well posedness of the initial value problem for vertically discretized primitive equations.

Key words. numerical weather prediction, initial value problems, well posedness, oscillatory matrices

1. Introduction.

Semi-implicit schemes based on Eulerian and semi-Lagrangian treatments of advection have been intensively used in numerical weather forecast models in the last three decades. These two approaches have been developed primarily by Robert [31, 32] for barotropic equations and are currently the most popular techniques in all areas of atmospheric modeling. It is sufficient to mention some hydrostatic and nonhydrostatic atmospheric models with different areas of application (e.g., mesoscale, regional and global forecasting, climate simulation, and air quality monitoring) based on finite-difference, spectral, and finite-element numerical schemes and designed for operational forecasts as well as research simulations. Numerous bibliographic sources indicated in classical books [17, 21, 27] can be completed by abundant reference lists in recent papers [14, 28, 37].

Construction and solution of the implicit coupled equations connected to linear terms of the primitive equations are important parts of all semi-implicit schemes. This implicit part depends on vertical discretization and the choice of reference temperature profile. Due to its linearity, these discretized equations can be vertically decoupled, which reduces the three-dimensional space problem to the set of two-dimensional systems in the form of shallow water equations. The classification of these two-dimensional systems is determined by the matrix of the vertical structure. The properties of this matrix have been studied and discussed in the context of design of numerical weather prediction models [6, 8, 30, 15], forecast accuracy [4, 5], normal mode initialization [38, 39], and four-dimensional data assimilation [9, 12], among many other papers and applications.

Usually, the authors' analysis of the implicit linear equations (including stability and convergence analysis) is based on the supposition that this matrix has positive distinct eigenvalues, which guarantees a complete decoupling of the primitive linearized equations and the well posedness of initial value problems for all obtained shallow water systems [6, 8, 26, 30, 33]. Although this supposition has been confirmed by numerical computations in different models, it has not been demonstrated analytically

for any numerical scheme. The goal of the present work is verifying the well posedness of the initial value problem for a family of linearized vertically discretized hydrostatic equations to provide additional theoretical justification for using the semi-implicit Eulerian and semi-Lagrangian schemes. Our analysis is for a large set of vertical grids, including, in particular, the optimal vertical grids constructed in [4, 5] to improve forecast accuracy.

This paper is divided into two main sections. In section 2, we present primitive hydrostatic equations, which we linearize and vertically discretize using one of the commonly used vertical grids. The matrix of vertical structure is derived, and its influence on vertical decoupling is discussed. Section 3 is devoted to the study of the properties of the matrix of vertical structure. The principal result consists of the proof of the oscillatory properties of the considered vertical matrix. Some concluding remarks are presented in the final section.

2. Deriving the matrix of vertical structure. We set out the continuous equations in Cartesian coordinates x, y of a conformal mapping projection and hybrid vertical coordinate $\eta(p, p_s)$, which is a monotonic function of the pressure p and also depends on the surface pressure p_s in such a way that

$$\eta\left(0, p_s\right) = 0, \qquad \eta\left(p_s, p_s\right) = 1.$$

Following Kasahara [23] and Simmons and Burridge [36], the primitive hydrostatic equations can be written as follows:

horizontal momentum equations

$$\frac{du}{dt} = -\frac{u^2+v^2}{2} m_x^2 + fv - RTP_x - \Phi_x, \tag{1}$$

$$\frac{dv}{dt} = -\frac{u^2+v^2}{2} m_y^2 - fu - RTP_y - \Phi_y, \tag{2}$$

hydrostatic equation

$$\Phi_\eta = -RTP_\eta, \tag{3}$$

thermodynamic equation

$$\frac{dT}{dt} = \frac{RT}{c_p}\frac{dP}{dt}, \tag{4}$$

continuity equation

$$\frac{dp_\eta}{dt} = -p_\eta m^2 \left(u_x + v_y\right) - p_\eta \dot{\eta}_\eta, \tag{5}$$

pressure equation

$$P_t + \dot{\eta} P_\eta = -\frac{m^2}{p}\int_0^\eta \left(up_\eta\right)_x + \left(vp_\eta\right)_y d\eta, \tag{6}$$

surface pressure equation

$$\left(P_s\right)_t = -\frac{m^2}{p_s}\int_0^1 \left(up_\eta\right)_x + \left(vp_\eta\right)_y d\eta. \tag{7}$$

The last two equations are the consequence of the continuity equation and the upper and lower boundary conditions

$$\dot{\eta} = 0 \quad \text{at} \quad \eta = 0; 1.$$

Here

$$\frac{d\varphi}{dt} = \varphi_t + m^2 \left(u\varphi_x + v\varphi_y \right) + \dot{\eta}\varphi_\eta$$

is the three-dimensional individual derivative, u and v are the horizontal projection velocity components, and the following common denotations are used: t is the time, $P = \ln p$, $P_s = \ln p_s$, m is the mapping factor, f is the Coriolis parameter, T is the temperature, $\Phi = gz$ is the geopotential, z is the height, g is the gravitational acceleration, R is the gas constant, c_p is the specific heat at constant pressure, and the subscripts t, x, y, η denote the partial derivatives with respect to the indicated variable. (Note that other subscripts do not mean differentiation.)

The first step to obtain the vertical structure matrix is linearization of this system about a state of rest:

$$u_t = fv - RT_0 P_x - \Phi_x, \tag{8}$$

$$v_t = -fu - RT_0 P_y - \Phi_y, \tag{9}$$

$$\Phi_\eta = -RT_0 P_\eta - RTS_\eta, \tag{10}$$

$$T_t = \frac{RT_0}{c_p} \cdot \left(P_t + S_\eta \dot{\eta} \right), \tag{11}$$

$$P_t + S_\eta \dot{\eta} = -\frac{1}{\sigma} \int_0^\eta \sigma_\eta D d\eta, \tag{12}$$

$$\left(P_s \right)_t = -\frac{1}{\sigma_s} \int_0^1 \sigma_\eta D d\eta. \tag{13}$$

Here $T_0 =$ const is the reference temperature profile, $p_0 = \sigma(\eta)$ is the reference pressure profile ($\sigma(\eta)$ is the positive strictly increasing function), $\sigma_s = \sigma(1)$, $S = \ln \sigma$, and $D = m^2(u_x + v_y)$ is the horizontal divergence.

Substituting the right-hand side of (12) in (11) and introducing a new unknown function $G = \Phi + RT_0 P$, the system (8)–(11), (13) can be written in the following form:

$$u_t = fv - G_x, \tag{14}$$

$$v_t = -fu - G_y, \tag{15}$$

$$G_\eta = -RTS_\eta, \tag{16}$$

$$T_t = -\frac{RT_0}{c_p \sigma} \int_0^\eta \sigma_\eta D d\eta, \tag{17}$$

$$(G_s)_t = -\frac{RT_0}{\sigma_s}\int_0^1 \sigma_\eta D d\eta. \tag{18}$$

Equation (12), which can be considered an equation for the vertical velocity component, is decoupled from the last system and has no effect upon the linear analysis of the primitive equations. Note that the analogous system (with or without Coriolis terms) can be obtained for the implicit part of semi-implicit Eulerian or semi-Lagrangian schemes [6, 8, 26, 30, 33, 34].

Of course, studying the continuous problem one can eliminate T from system (14)–(18) and, seeking separable solutions, can obtain the differential vertical structure equation [13, 18]. However, to construct the vertical structure matrix used in numerical schemes we have to follow the procedure of vertical discretization used in numerical models. Thus, the second step consists of choosing the type of vertical grid and vertical discretization. We choose a rather popular Lorenz vertical grid which carries horizontal velocities, temperature, and geopotential at the same model levels that represent model layers, while vertical velocity is carried at the interfaces of these layers (see Figure 1).

This grid divides the considered atmosphere in K vertical layers. The boundaries $\eta_{k+1/2}$, $k = 0, \ldots, K$ (solid lines) of these layers can be chosen arbitrarily, and the inner levels η_k, $k = 1, \ldots, K$ (dashed lines) satisfy the natural inequalities

$$\eta_{k-1/2} < \eta_k < \eta_{k+1/2}, \qquad k = 1, \ldots, K. \tag{19}$$

In [6, 8, 11], the values η_k are defined as midlines of the layers; that is,

$$\eta_k = \frac{\eta_{k+1/2} + \eta_{k-1/2}}{2}, \qquad k = 1, \ldots, K,$$

but it is not essential for our analysis. The restrictions $\eta_{1/2} = 0$, $\eta_{K+1/2} = 1$, and (19) are uniquely used in subsequent reasoning. Therefore, the vertical grid construction is sufficiently flexible, and it involves a wide set of grids.

This type of grid was introduced by Lorenz [25] to construct a vertically discrete balanced model, which conserves the total energy, the mean potential temperature, and the variance of the potential temperature under adiabatic and frictionless processes. Following Lorenz's approach, Arakawa and Lamb [1] and Arakawa and Suarez [2] constructed vertically discrete models based on the Lorenz grid satisfying the most integral constraints of the continuous system. Thus, the distribution of variables on the Lorenz grid is more straightforward for keeping conservation properties of the primitive equations. For this reason, it seems to be the most widespread vertical grid used for hydrostatic equation models [3]. We can mention the NASA numerical weather prediction and climate models [6, 11, 35], NCEP global and mesoscale models [7, 22], and the Pennsylvania State University MM5 model [16], among others, which use this vertical approximation.

All the variables u, v, T, G of the linearized system (14)–(18) are defined at the levels η_k. Since variable $\dot{\eta}$ is not used in linear analysis, the Lorenz grid coincides with the completely unstaggered vertical grid. Therefore, our analysis is also applied to this last grid used, for example, in [24]. Note that the reference pressure $\sigma(\eta)$ is a given function, and then it can be calculated at both boundaries and inner levels.

The approximation of the hydrostatic equation (16) is realized by formulas

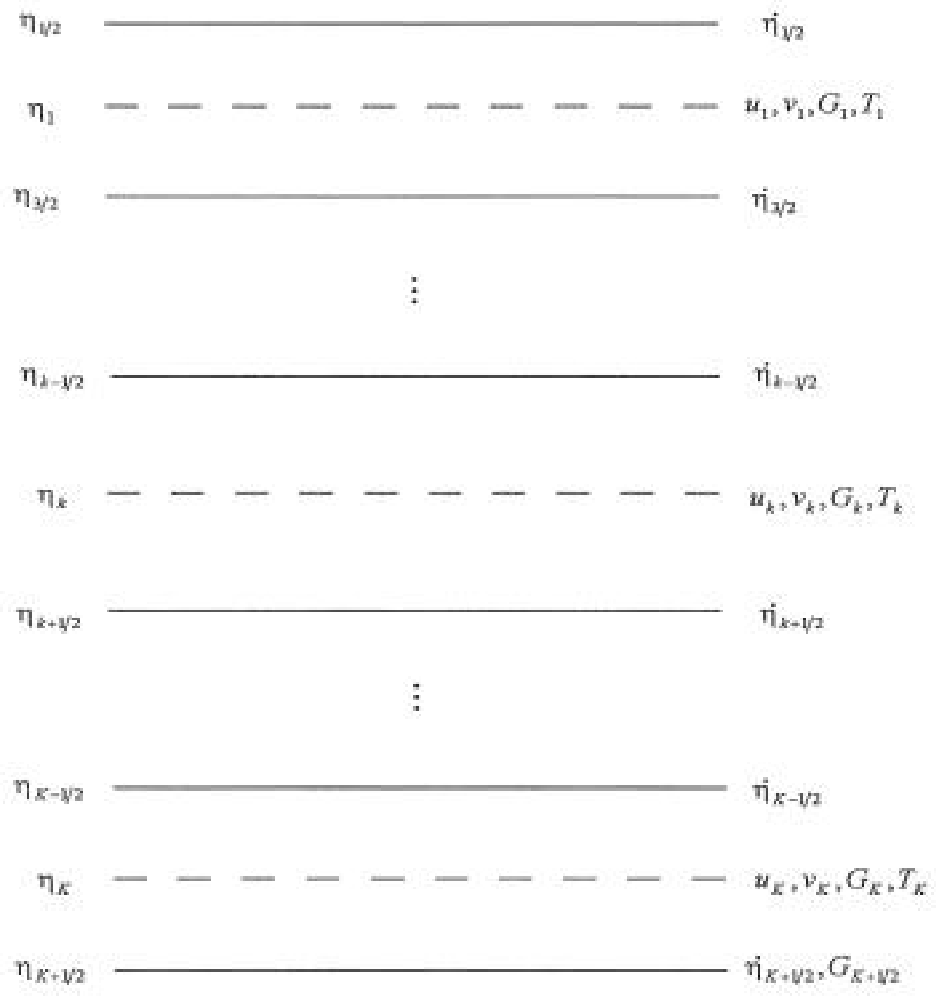

FIG. 1. *K layer Lorenz vertical grid.*

$$G_k = G_{K+1} + R\left[\sum_{i=k+1}^{K} \ln\frac{\sigma_{i+1/2}}{\sigma_{i-1/2}}\cdot T_i + \ln\frac{\sigma_{k+1/2}}{\sigma_k}\cdot T_k\right], \qquad k = 1,\dots,K,$$

$$G_{K+1} \equiv G_s.$$

The thermodynamic and continuity equations (17)–(18) are approximated as

$$T_{k_t} = -\frac{RT_0}{c_p}\cdot\left[\sum_{i=1}^{k-1}\frac{\sigma_{i+1/2}-\sigma_{i-1/2}}{\sigma_k}D_i + \frac{\sigma_{k+1/2}-\sigma_{k-1/2}}{2\sigma_k}D_k\right], \qquad k = 1,\dots,K,$$

$$(G_s)_t = -\frac{RT_0}{\sigma_{K+1/2}}\sum_{i=1}^{K}(\sigma_{i+1/2}-\sigma_{i-1/2})\,D_i.$$

In the above, a summation is defined to be zero if the lower limit of the summation index exceeds the upper limit.

Introducing vector columns

$$\mathbf{u}=(u_1,\dots,u_K)^T,\mathbf{v}=(v_1,\dots,v_K)^T,\mathbf{D}=(D_1,\dots,D_K)^T,\mathbf{G}=(G_1,\dots,G_K)^T,$$

$$\mathbf{T}=(T_1,\dots,T_K,G_s)^T,$$

we can write discrete analogues of (14)–(18) in the form

$$\mathbf{u}_t=f\mathbf{v}-\mathbf{G}_x, \tag{20}$$

$$\mathbf{v}_t=-f\mathbf{u}-\mathbf{G}_y, \tag{21}$$

$$\mathbf{G}=R\mathbf{A}_T\cdot\mathbf{T}, \tag{22}$$

$$\mathbf{T}_t=-\frac{RT_0}{c_p}\mathbf{A}_D\cdot\mathbf{D}. \tag{23}$$

Here $\mathbf{A}_T$ and $\mathbf{A}_D$ are the $K\times(K+1)$ and $(K+1)\times K$ matrices, respectively, determined as follows:

$$\mathbf{A}_T=\begin{pmatrix}
\ln\frac{\sigma_{3/2}}{\sigma_1} & \ln\frac{\sigma_{5/2}}{\sigma_{3/2}} & \cdots & \ln\frac{\sigma_{k+1/2}}{\sigma_{k-1/2}} & \cdots & \ln\frac{\sigma_{K-1/2}}{\sigma_{K-3/2}} & \ln\frac{\sigma_{K+1/2}}{\sigma_{K-1/2}} & 1\\
0 & \ln\frac{\sigma_{5/2}}{\sigma_2} & \cdots & \ln\frac{\sigma_{k+1/2}}{\sigma_{k-1/2}} & \cdots & \ln\frac{\sigma_{K-1/2}}{\sigma_{K-3/2}} & \ln\frac{\sigma_{K+1/2}}{\sigma_{K-1/2}} & 1\\
\vdots & \vdots & \ddots & \vdots & & \vdots & \vdots & \vdots\\
0 & 0 & \cdots & \ln\frac{\sigma_{k+1/2}}{\sigma_k} & \cdots & \ln\frac{\sigma_{K-1/2}}{\sigma_{K-3/2}} & \ln\frac{\sigma_{K+1/2}}{\sigma_{K-1/2}} & 1\\
\vdots & \vdots & & \vdots & \ddots & \vdots & \vdots & \vdots\\
0 & 0 & \cdots & 0 & \cdots & \ln\frac{\sigma_{K-1/2}}{\sigma_{K-1}} & \ln\frac{\sigma_{K+1/2}}{\sigma_{K-1/2}} & 1\\
0 & 0 & \cdots & 0 & \cdots & 0 & \ln\frac{\sigma_{K+1/2}}{\sigma_K} & 1
\end{pmatrix}$$

and

$$\mathbf{A}_D=$$

$$\begin{pmatrix}
\frac{\sigma_{3/2}-\sigma_{1/2}}{2\sigma_1} & 0 & \cdots & 0 & \cdots & 0 & 0\\
\frac{\sigma_{3/2}-\sigma_{1/2}}{\sigma_2} & \frac{\sigma_{5/2}-\sigma_{3/2}}{2\sigma_2} & \cdots & 0 & \cdots & 0 & 0\\
\vdots & \vdots & \ddots & \vdots & & \vdots & \vdots\\
\frac{\sigma_{3/2}-\sigma_{1/2}}{\sigma_k} & \frac{\sigma_{5/2}-\sigma_{3/2}}{\sigma_k} & \cdots & \frac{\sigma_{k+1/2}-\sigma_{k-1/2}}{2\sigma_k} & \cdots & 0 & 0\\
\vdots & \vdots & & \vdots & \ddots & \vdots & \vdots\\
\frac{\sigma_{3/2}-\sigma_{1/2}}{\sigma_{K-1}} & \frac{\sigma_{5/2}-\sigma_{3/2}}{\sigma_{K-1}} & \cdots & \frac{\sigma_{k+1/2}-\sigma_{k-1/2}}{\sigma_{K-1}} & \cdots & \frac{\sigma_{K-1/2}-\sigma_{K-3/2}}{2\sigma_{K-1}} & 0\\
\frac{\sigma_{3/2}-\sigma_{1/2}}{\sigma_K} & \frac{\sigma_{5/2}-\sigma_{3/2}}{\sigma_K} & \cdots & \frac{\sigma_{k+1/2}-\sigma_{k-1/2}}{\sigma_K} & \cdots & \frac{\sigma_{K-1/2}-\sigma_{K-3/2}}{\sigma_K} & \frac{\sigma_{K+1/2}-\sigma_{K-1/2}}{2\sigma_K}\\
\frac{\sigma_{3/2}-\sigma_{1/2}}{\sigma_{K+1/2}/c_p} & \frac{\sigma_{5/2}-\sigma_{3/2}}{\sigma_{K+1/2}/c_p} & \cdots & \frac{\sigma_{k+1/2}-\sigma_{k-1/2}}{\sigma_{K+1/2}/c_p} & \cdots & \frac{\sigma_{K-1/2}-\sigma_{K-3/2}}{\sigma_{K+1/2}/c_p} & \frac{\sigma_{K+1/2}-\sigma_{K-1/2}}{\sigma_{K+1/2}/c_p}
\end{pmatrix}.$$

Finally, differentiating hydrostatic equations with respect to t and eliminating $\mathbf{T}$, we obtain

$$\mathbf{G}_t = R\mathbf{A}_T T_t = R\mathbf{A}_T\left(-\frac{RT_0}{c_p}\mathbf{A}_D\mathbf{D}\right) = -\frac{R}{c_p}RT_0\mathbf{A}_T\mathbf{A}_D\mathbf{D} = -\frac{R}{c_p}RT_0\mathbf{A}\mathbf{D},$$

where $\mathbf{A} = \mathbf{A}_T\mathbf{A}_D$ is the $K \times K$ matrix of the vertical structure. If all eigenvalues of matrix $\mathbf{A}$ are positive and respective eigenvectors are linearly independent (that is, these form a basis in the space R^K), then the system

$$\mathbf{u}_t = f\mathbf{v} - \mathbf{G}_x, \tag{24}$$

$$\mathbf{v}_t = -f\mathbf{u} - \mathbf{G}_y, \tag{25}$$

$$\mathbf{G}_t = -\frac{R}{c_p}RT_0\mathbf{A}\mathbf{D} \tag{26}$$

can be vertically decoupled in the K linearized shallow water systems with different gravitational wave speeds. To make this, one can represent the vertical structure matrix $\mathbf{A}$ in the spectral form $\mathbf{A} = \mathbf{S}\Lambda\mathbf{S}^{-1}$, where Λ is the diagonal eigenvalue matrix and $\mathbf{S}$ is the matrix of eigenvectors (that is, vertical normal modes) of the $\mathbf{A}$, and, multiplying (24)–(26) on the left by $\mathbf{S}^{-1}$, one can obtain

$$\tilde{\mathbf{u}}_t = f\tilde{\mathbf{v}} - \tilde{\mathbf{G}}_x, \tag{27}$$

$$\tilde{\mathbf{v}}_t = -f\tilde{\mathbf{u}} - \tilde{\mathbf{G}}_y, \tag{28}$$

$$\tilde{\mathbf{G}}_t = -\frac{R}{c_p}RT_0\mathbf{\Lambda}\tilde{\mathbf{D}}, \tag{29}$$

where coefficients of vertical mode expansion are introduced by formula

$$\tilde{\varphi} = \mathbf{S}^{-1}\varphi, \qquad \varphi = \mathbf{u}, \mathbf{v}, \mathbf{G}.$$

If at least one of the eigenvalues of matrix $\mathbf{A}$ is negative, then the corresponding shallow water system in (27)–(29) is elliptic, and the initial value problem is not well posed for this system, which results in an incorrect problem for system (20)–(23) with any initial conditions. This leads to an ill posed initial value problem for vertically discretized primitive equations (1)–(7), and, therefore, their numerical solution has no meaning.

Thus, the properties of vertical structure matrix $\mathbf{A}$ are crucial for the well posedness of vertically discretized equations (20)–(23), which is a necessary condition for the well posedness of the numerical scheme. In the following section, we verify some properties of matrix $\mathbf{A}$, which guarantee the positivity of all its eigenvalues and the completeness of the set of eigenvectors.

3. Oscillatory properties of matrix A. A matrix is called totally positive if all its minors are nonnegative. A strictly totally positive matrix is a matrix whose minors are all positive. A $K \times K$ matrix is called oscillatory if it is totally positive and its certain power is strictly totally positive.

We use the following criterion for oscillatory matrices given in [19].

Theorem G1. *Matrix* $\mathbf{A}$ *is oscillatory if*

(1) $\mathbf{A}$ *is totally positive;*

(2) $\det \mathbf{A} > 0$*;*

(3) $a_{ij} > 0$ *for* $|i-j| \le 1$*; that is, all the entries on the principal diagonal, first superdiagonal, and first subdiagonal are positive.*

The following fundamental theorem is true for oscillatory matrices [19].

Theorem G2. *An oscillatory* $K \times K$ *matrix* $\mathbf{A}$ *has* K *distinct positive eigenvalues* $\lambda_1 > \lambda_2 > \cdots > \lambda_K > 0$*, and eigenvector* $\mathbf{s}_k (k = 1, \ldots, K)$*, which corresponds to eigenvalue* λ_k*, has* $k-1$ *variations of sign.*

Thus, if the oscillatoriness of matrix $\mathbf{A}$ is demonstrated, it will guarantee the well posedness of (20)–(23). According to Theorem G1, we have to show three properties of matrix $\mathbf{A}$ to guarantee its oscillatoriness. We start with the study of the total positivity of this matrix.

A direct consequence of the well-known Cauchy–Binet identity for determinants is that the product of totally positive matrices is again a totally positive matrix. Thus, to show the total positivity of matrix $\mathbf{A} = \mathbf{A}_T \mathbf{A}_D$ it is sufficient to prove that each matrix $\mathbf{A}_T$ and $\mathbf{A}_D$ is totally positive.

Let us consider matrix $\mathbf{A}_T$. We can factor it into the form

$$\mathbf{A}_T = \mathbf{B}\mathbf{C},$$

where $\mathbf{B}$ is a $K \times (K+1)$ matrix

$$\mathbf{B} = \begin{pmatrix} b_1 & 1 & \cdots & 1 & \cdots & 1 & 1 & 1 \\ 0 & b_2 & \cdots & 1 & \cdots & 1 & 1 & 1 \\ \vdots & \vdots & \ddots & \vdots & & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & b_k & \cdots & 1 & 1 & 1 \\ \vdots & \vdots & & \vdots & \ddots & \vdots & \vdots & \vdots \\ 0 & 0 & \cdots & 0 & \cdots & b_{K-1} & 1 & 1 \\ 0 & 0 & \cdots & 0 & \cdots & 0 & b_K & 1 \end{pmatrix}$$

with elements

$$b_1 = \ln \frac{\sigma_{3/2}}{\sigma_1}, \quad b_k = \frac{\ln(\sigma_{k+1/2}/\sigma_k)}{\ln(\sigma_{k+1/2}/\sigma_{k-1/2})}, \quad k = 2, \ldots, K$$

and $\mathbf{C}$ is a $(K+1) \times (K+1)$ diagonal matrix $\mathbf{C} = \mathbf{diag}[1, c_2, \ldots, c_K, 1]$ with elements

$$c_k = \ln \frac{\sigma_{k+1/2}}{\sigma_{k-1/2}}, \qquad k = 2, \ldots, K.$$

Since (19) holds and $\sigma(\eta)$ is a positive strictly increasing function, the elements b_k, $k = 1, \ldots, K$, and c_k, $k = 2, \ldots, K$, are positive and $b_k < 1$ for $k = 2, \ldots, K$.

Obviously, matrix $\mathbf{C}$ is totally positive. The principal property of matrix $\mathbf{B}$ is established in the following theorem. Although this result can be derived from the test for total positivity provided in [20], for the sake of completeness we include a direct proof.

Theorem 1. *Matrix* $\mathbf{B}$ *is totally positive.*

Proof. To prove this result we use the determinantal criterion given in [10] and [29].

Criterion C1. $\mathbf{A}$ is an $m \times n$ matrix, $n \geq m$, such that $\det \mathbf{A}[1,\dots,k|1,\dots,k] > 0$ for all $1 \leq k \leq m$. Then $\mathbf{A}$ is totally positive if and only if all minors with initial consecutive columns or initial consecutive rows are nonnegative.

Hereinafter, $\mathbf{A}[\alpha|\beta]$ denotes the $k \times l$ submatrix of $m \times n$ matrix $\mathbf{A}$ ($k \leq m$ and $l \leq n$), containing rows numbered by $\alpha = [\alpha_1,\dots,\alpha_k]$ and columns numbered by $\beta = [\beta_1,\dots,\beta_l]$, where α and β are increasing sequences of k and l natural numbers α_i, $i = 1,\dots,k$, and β_j, $j = 1,\dots,l$, respectively.

First, note that $\det \mathbf{B}[1,\dots,k|1,\dots,k] = b_1 \times \cdots \times b_k > 0$ for any $k = 1,\dots,K$. Second, $\det \mathbf{B}[\alpha|1,\dots,k] = 0$ for any $k = 1,\dots,K$ and $\alpha \neq [1,\dots,k]$. Therefore, we can simplify Criterion C1 for matrix $\mathbf{B}$ to the following form.

Criterion C2. $\mathbf{B}$ is totally positive if and only if all minors with initial consecutive rows are nonnegative; that is, $\det \mathbf{B}[1,\dots,k|\beta] \geq 0$ for any k and for any increasing set of k indices $\beta \neq [1,\dots,k]$.

Let us consider two cases.

(1) If $\beta_{k-1} > k$, then the columns with indices β_{k-1} and β_k contain all their entries above the first principal diagonal (above the diagonal with entries $b_1,\dots,b_K$). Hence, these two columns coincide and $\det \mathbf{B}[1,\dots,k|\beta] = 0$.

(2) If $\beta_{k-1} \leq k$, then, taking into account that $\beta_k > k$, we have

$$\det \mathbf{B}[1,\dots,k|\beta] = \begin{vmatrix} b_{1,\beta_1} & \dots & b_{1,\beta_{k-1}} & b_{1,\beta_k} \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-1,\beta_1} & \dots & b_{k-1,\beta_{k-1}} & b_{k-1,\beta_k} \\ b_{k,\beta_1} & \dots & b_{k,\beta_{k-1}} & b_{k,\beta_k} \end{vmatrix}$$

$$= \begin{vmatrix} b_{1,\beta_1} & \dots & b_{1,\beta_{k-1}} & 1 \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-1,\beta_1} & \dots & b_{k-1,\beta_{k-1}} & 1 \\ b_{k,\beta_1} & \dots & b_{k,\beta_{k-1}} & 1 \end{vmatrix} = \begin{vmatrix} b_{1,\beta_1} - b_{k,\beta_1} & \dots & b_{1,\beta_{k-1}} - b_{k,\beta_{k-1}} & 0 \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-1,\beta_1} - b_{k,\beta_1} & \dots & b_{k-1,\beta_{k-1}} - b_{k,\beta_{k-1}} & 0 \\ b_{k,\beta_1} & \dots & b_{k,\beta_{k-1}} & 1 \end{vmatrix}. \tag{30}$$

Expanding in cofactors along the last column and observing that $b_{k,\beta_i} = 0$ for all $i = 1,\dots,k-2$ because $\beta_i < \beta_{k-1} \leq k$, we obtain the $k-1$ order determinant

$$\det \mathbf{B}[1,\dots,k|\beta] = \begin{vmatrix} b_{1,\beta_1} & \dots & b_{1,\beta_{k-2}} & b_{1,\beta_{k-1}} - b_{k,\beta_{k-1}} \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-2,\beta_1} & \dots & b_{k-2,\beta_{k-2}} & b_{k-2,\beta_{k-1}} - b_{k,\beta_{k-1}} \\ b_{k-1,\beta_1} & \dots & b_{k-1,\beta_{k-2}} & b_{k-1,\beta_{k-1}} - b_{k,\beta_{k-1}} \end{vmatrix}. \tag{31}$$

Now two situations can occur. The first, when $\beta_{k-1} = k-1$, is the simplest. In this case, $\beta_i = i$ for $i = 1,\dots,k-2$, $b_{k,\beta_{k-1}} = 0$, and, consequently,

$$\det \mathbf{B}[1,\dots,k|\beta] = \det \mathbf{B}[1,\dots,k-1|1,\dots,k-1] = b_1 \times \cdots \times b_{k-1} > 0.$$

In the second case, $\beta_{k-1} = k$ and $b_{k,\beta_{k-1}} = b_{k,k} = b_k$, $b_{k-1,\beta_{k-1}} = b_{k-1,k} = 1$. Therefore, we simplify (31) to

$$\det \mathbf{B}[1,\dots,k|\beta] = \begin{vmatrix} b_{1,\beta_1} & \dots & b_{1,\beta_{k-2}} & 1 - b_k \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-2,\beta_1} & \dots & b_{k-2,\beta_{k-2}} & 1 - b_k \\ b_{k-1,\beta_1} & \dots & b_{k-1,\beta_{k-2}} & 1 - b_k \end{vmatrix}, \tag{32}$$

and we continue to reduce the order of determinant

$$(33)\qquad = (1-b_k)\begin{vmatrix} b_{1,\beta_1} & \dots & b_{1,\beta_{k-3}} & b_{1,\beta_{k-2}} - b_{k-1,\beta_{k-2}} \\ \vdots & \ddots & \vdots & \vdots \\ b_{k-3,\beta_1} & \dots & b_{k-3,\beta_{k-3}} & b_{k-3,\beta_{k-2}} - b_{k-1,\beta_{k-2}} \\ b_{k-2,\beta_1} & \dots & b_{k-2,\beta_{k-3}} & b_{k-2,\beta_{k-2}} - b_{k-1,\beta_{k-2}} \end{vmatrix}.$$

Obtained determinant (33) is similar to (31), but it is one order less. Again we have two choices. If $\beta_{k-2} = k-2$, then $\beta_i = i$ for $i = 1, \dots, k-3$ and $b_{k-1,\beta_{k-2}} = 0$, which gives the following result:

$$\begin{aligned} \det \mathbf{B}[1,\dots,k|\beta] &= (1-b_k)\det \mathbf{B}[1,\dots,k-2|1,\dots,k-2] \\ &= b_1 \times \cdots \times b_{k-2} \times (1-b_k) > 0. \end{aligned}$$

In the opposite case, $\beta_{k-2} = k-1$, $b_{k-1,\beta_{k-2}} = b_{k-1}$, $b_{k-2,\beta_{k-2}} = 1$, and we get the determinant in the form (32), but its order is one less than the order of (32).

We can continue this procedure until a determinant of the first order is obtained. The final result of the calculus of the determinant (30) can be represented in the form

$$\det \mathbf{B}[1,\dots,k|\beta] = d_1 \times \cdots \times d_{k-1},$$

where

$$d_i = b_i \text{ or } (1-b_{i+1}), \qquad i = 1, \dots, k-1,$$

which depends on the choice of the index set β. In either case, all $d_i > 0$, and, consequently,

$$(34)\qquad \det \mathbf{B}[1,\dots,k|\beta] = d_1 \times \cdots \times d_{k-1} > 0.$$

Since we consider the arbitrary value of k, Criterion C2 is proved. Therefore, matrix **B** is totally positive and Theorem 1 is proved.

Hence, matrix $\mathbf{A}_T$ is totally positive as the product of two totally positive matrices **B** and **C**.

To prove the total positivity of matrix $\mathbf{A}_D$ we use factorization in the form

$$\mathbf{A}_D = \mathbf{FGH},$$

where **G** is $(K+1) \times K$ matrix

$$\mathbf{G} = \begin{pmatrix} 1/2 & 0 & \cdots & 0 & \cdots & 0 & 0 \\ 1 & 1/2 & \cdots & 0 & \cdots & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & & \vdots & \vdots \\ 1 & 1 & \cdots & 1/2 & \cdots & 0 & 0 \\ \vdots & \vdots & & \vdots & \ddots & \vdots & \vdots \\ 1 & 1 & \cdots & 1 & \cdots & 1/2 & 0 \\ 1 & 1 & \cdots & 1 & \cdots & 1 & 1/2 \\ 1 & 1 & \cdots & 1 & \cdots & 1 & 1 \end{pmatrix},$$

F is $(K+1) \times (K+1)$ diagonal matrix $\mathbf{F} = \mathbf{diag}[f_1, \dots, f_K, f_{K+1}]$ with elements

$$f_k = \frac{1}{\sigma_k}, \quad k = 1, \dots, K, \quad f_{K+1} = \frac{c_p}{\sigma_{K+1/2}},$$

and $\mathbf{H}$ is $K \times K$ diagonal matrix $\mathbf{H} = \mathbf{diag}[h_1, \ldots, h_K]$ with elements

$$h_k = \sigma_{k+1/2} - \sigma_{k-1/2}, \qquad k = 1, \ldots, K.$$

It is evident that matrices $\mathbf{F}$ and $\mathbf{H}$ are totally positive. Matrix $\mathbf{G}$ is totally positive because it is a particular case of matrix $\mathbf{B}^T$. Therefore, matrix $\mathbf{A}_D$ is totally positive. Finally, due to the total positivity of matrices $\mathbf{A}_T$ and $\mathbf{A}_D$, matrix $\mathbf{A} = \mathbf{A}_T\mathbf{A}_D$ is totally positive too.

It remains to verify the second and third conditions of Theorem G1. To show the second condition we observe that evaluation (34) considered for $k = K$ means that all K order minors of matrix $\mathbf{B}$ are positive. Obviously, all K order minors of matrix $\mathbf{C}$ are nonnegative and some of these are positive. Therefore, by Cauchy–Binet formulas, all K order minors of matrix $\mathbf{A}_T$ are positive. Analogously, we can show that all K order minors of matrix $\mathbf{A}_D$ are positive. Applying the Cauchy–Binet identity to the determinant of $K \times K$ matrix $\mathbf{A}$ we demonstrate its positivity. Finally, the positivity of the elements $a_{ij} > 0$ for $|i - j| \leq 1$ follows directly from a structure of matrices $\mathbf{A}_T$ and $\mathbf{A}_D$.

Thus, all three conditions of Theorem G1 are satisfied, and, therefore, matrix $\mathbf{A}$ is oscillatory. According to Theorem G2, this implies that all eigenvalues are positive and distinct, which guarantees the strict hyperbolicity of all shallow water systems (27)–(29). Therefore, the initial value problem is well posed for discretized equations (20)–(23).

4. Conclusion. An analytical study of the vertical structure matrix of discretized hydrostatic equations is performed. The principal statement about the oscillatoriness of this matrix is proved using the determinantal criterion for total positivity and the oscillatory matrix test. The properties of the oscillatory matrix ensure that all the decoupled linearized shallow water equations are strictly hyperbolic. Therefore, the initial value problem is well posed for linearized primitive equations, which is the necessary condition for the convergence of semi-implicit schemes.

APPROXIMATION OF A THIN PLATE SPLINE SMOOTHER USING CONTINUOUS PIECEWISE POLYNOMIAL FUNCTIONS[*]

STEPHEN ROBERTS[†], MARKUS HEGLAND[‡], AND IRFAN ALTAS[§]

Abstract. A new smoothing method is proposed which can be viewed as a finite element thin plate spline. This approach combines the favorable properties of finite element surface fitting with those of thin plate splines. The method is based on first order techniques similar to mixed finite element techniques for the biharmonic equation. The existence of a solution to our smoothing problem is demonstrated, and the approximation theory for uniformly spread data is presented in the case of both exact and noisy data. This convergence analysis seems to be the first for a discrete smoothing spline with data perturbed by white noise. Numerical results are presented which verify our theoretical results and demonstrate our method on a large real life data set.

Key words. thin plate splines, finite element methods, surface smoothing

1. Introduction.

We propose a new finite element approximation of the thin plate spline for surface fitting in $\mathbb{R}^2$. We call our new smoother the TPSFEM smoother. This new approach combines the favorable properties of finite element surface fitting with those of thin plate splines. In particular, the method can deal with very large data sets consisting of tens of millions of predictor and response observations. Our smoothing function is a finite element approximation. As a consequence, the computational problem can be broken into two stages:

1. Forming the finite element matrices and vectors, which entails only a single scan of the data.
2. Solving for the finite element solution. This entails solving a sparse matrix system with size dependent on the discretization of a finite element mesh.

The size of the finite element structures can be chosen to be independent of the size of the data. This enables us to deal with very large data sets (tens of millions). For instance, in section 4 we present the results of smoothing geomagnetic data [6] with 735,700 data points.

Our method uses techniques typical of mixed finite element methods (see Brezzi and Fortin [11]) and of first order systems least squares (FOSLS) methods (see Cai, Manteuffel, and McCormick [14, 12, 13] and Cai et al. [15]). Auxiliary functions representing the gradient of the smoother are introduced to lower the order of smoothness of the resulting equations from $H^2(\Omega)$ to $H^1(\Omega)$. This allows for the use of simpler finite elements spaces and results in a better-conditioned problem.

The combined use of smoothing techniques and mixed finite element techniques provides a smoothing method which can deal with large data sets but still retains

the good smoothing properties of the thin plate spline. An initial discussion of the method can be found in [23] and [24], and a discussion of the implementation and solution of the resulting discrete equations in [16] and [17].

The rest of the paper is organized as follows. The next section provides a detailed description and motivation for our method. In section 3 we describe the main convergence result, Theorem 3.2 on page 215, which justifies our claim that the TPSFEM method has approximation properties similar to those of a discrete thin plate spline. In section 4 we describe the numerical method used to solve our smoothing problem and present some numerical results for test problems and a real life large data set. The rest of the paper involves proving various properties of our method. The TPSFEM smoothing method produces a unique solution, provided that the values of the predictor variable are not collinear. This is shown in section 5. In section 6 we provide a number of useful results that will be used in section 7 to prove convergence of our method, that is, to prove Theorem 3.2. Finally in section 8 we conclude our discussion.

2. Description of the method.

2.1. Sobolev spaces. Before proceeding, let us introduce some notation. The $L^2(\Omega)$ inner-product and norm are given, respectively, by

$$(v,w)_{L^2(\Omega)} = \int_\Omega vw\,d\mathbf{x} \quad \text{and} \quad \|v\|^2_{L^2(\Omega)} = (v,v)_{L^2(\Omega)}.$$

Standard $H^1(\Omega)$ and $H^2(\Omega)$ Sobolev semi-inner-products are given by

$$(v,w)_{H^1(\Omega)} = \int_\Omega \left(\frac{\partial v}{\partial x_1}\frac{\partial w}{\partial x_1} + \frac{\partial v}{\partial x_2}\frac{\partial w}{\partial x_2}\right) d\mathbf{x}$$

and

$$(v,w)_{H^2(\Omega)} = \int_\Omega \left(\frac{\partial^2 v}{\partial^2 x_1}\frac{\partial^2 w}{\partial^2 x_1} + 2\frac{\partial^2 v}{\partial x_1\partial x_2}\frac{\partial^2 w}{\partial x_1\partial x_2} + \frac{\partial^2 v}{\partial^2 x_2}\frac{\partial^2 w}{\partial^2 x_2}\right) d\mathbf{x}.$$

The corresponding seminorms are given by

$$|v|^2_{H^1(\Omega)} = (v,v)_{H^1(\Omega)} \quad \text{and} \quad |v|^2_{H^2(\Omega)} = (v,v)_{H^2(\Omega)},$$

and the associated norms by

$$\|v\|^2_{H^1(\Omega)} = \|v\|^2_{L^2(\Omega)} + |v|^2_{H^1(\Omega)},$$
$$\|v\|^2_{H^2(\Omega)} = \|v\|^2_{L^2(\Omega)} + |v|^2_{H^2(\Omega)}.$$

Note that we use single bars $|\cdot|$ to denote seminorms, and double bars $\|\cdot\|$ to denote norms. For vector functions $\mathbf{u} = (u_1,u_2), \mathbf{v} = (v_1,v_2) \in H^1(\Omega)^2$, we define the (semi-)inner products and (semi-)norms as follows:

$$\begin{aligned}(\mathbf{u},\mathbf{v})_{L^2(\Omega)^2} &= (u_1,v_1)_{L^2(\Omega)} + (u_2,v_2)_{L^2(\Omega)},\\ \|\mathbf{u}\|^2_{L^2(\Omega)^2} &= (\mathbf{u},\mathbf{u})_{L^2(\Omega)^2},\\ (\mathbf{u},\mathbf{v})_{H^1(\Omega)^2} &= (u_1,v_1)_{H^1(\Omega)} + (u_2,v_2)_{H^1(\Omega)},\\ |\mathbf{u}|^2_{H^1(\Omega)^2} &= (\mathbf{u},\mathbf{u})_{H^1(\Omega)^2}.\end{aligned}$$

The dual norm $H^{-1}(\Omega)$ is given by

$$\|v\|_{H^{-1}(\Omega)} = \sup_{u\in H^1_0(\Omega)} \frac{\int_\Omega v(\mathbf{x})u(\mathbf{x})\,d\mathbf{x}}{\|u\|_{H^1(\Omega)}}.$$

2.2. Overview: Thin plate spline. To describe our method we first recall the definition of the standard thin plate spline, which provides a smoother that predicts a real response variable y, given the value of a predictor variable $\mathbf{x} \in \mathbb{R}^2$. The input to the construction of this smoother is an array of response values

$$\mathbf{y} = [y^{(1)} \ \cdots \ y^{(n)}]^T \in \mathbb{R}^n$$

and a corresponding array of predictor values

$$P = [\mathbf{x}^{(1)} \ \cdots \ \mathbf{x}^{(n)}]^T \in \mathbb{R}^{n\times 2}.$$

We suppose that the predictor values all lie in a convex bounded domain $\Omega \subset \mathbb{R}^2$.

The thin plate spline is the solution of the following minimization problem.

PROBLEM 1 (Thin plate spline). *For a fixed response vector* $\mathbf{y}$, *find the minimizer* $\bar{s}_\alpha(\mathbf{y})$ *of the functional*

$$\begin{aligned}\bar{J}_\alpha(s, \mathbf{y}) &= n^{-1}\sum_{i=1}^{n}(s(\mathbf{x}^{(i)}) - y^{(i)})^2 + \alpha|s|^2_{H^2(\Omega)} \\ &= \|\boldsymbol{\rho}^n s - \mathbf{y}\|_n^2 + \alpha|s|^2_{H^2(\Omega)}\end{aligned}$$

over all $s \in H^2(\Omega)$.

Here we have introduced the notation

$$\boldsymbol{\rho}^n s = [s(\mathbf{x}^{(1)}) \ \cdots \ s(\mathbf{x}^{(n)})]^T$$

and a norm on $\mathbb{R}^n$ defined by

$$\langle \mathbf{z}, \mathbf{w}\rangle_n = n^{-1}\mathbf{z}^T\mathbf{w}, \qquad \|\mathbf{z}\|_n^2 = \langle \mathbf{z}, \mathbf{z}\rangle_n.$$

We have absorbed the n factor into the definition of this norm, so that if s is a "smooth" function, then $\|\boldsymbol{\rho}^n s\|_n$ provides an estimate of $\|s\|_{L^2(\Omega)}$. (This is quantified in Lemma 6.2.)

Note that we have defined the thin plate spline with respect to a domain Ω. Indeed it is more common to use $\mathbb{R}^2$ than Ω. In that case the smoother is rotationally invariant. We are using a finite domain since we will be using simple finite element spaces.

The functional $\bar{J}_\alpha$ also depends on a smoothing parameter α. An appropriate choice of α depends on the size of the data errors and the number of data points. In many cases an appropriate choice of α can be made automatically using generalized cross-validation (see Craven and Wahba [19] or Wahba [29, Chapter 4]). But in this paper we will generally consider α as being fixed.

It is very reasonable to assume that the predictor variables $\mathbf{x}^{(i)}$ are not collinear (i.e., they do not all lie on a line in $\mathbb{R}^2$). When the domain is $\mathbb{R}^2$, it has been shown by Duchon [20] that Problem 1 has a unique solution and that the solution has an explicit representation as a sum of radial basis functions. This approach requires the solution of a symmetric indefinite dense linear system of equations that has a size proportional to the number of data records, n. Although this initial approach was improved later [7, 8, 9, 10, 26], these techniques require complex data structures and algorithms and an $O(n)$ workspace. Thus, it is a challenge to use standard thin plate splines for applications that have very large data sets.

Standard finite element discretizations of a problem like Problem 1 involve minimizing the functional $\bar{J}_\alpha$ over finite dimensional, finite element subspaces of $H^2(\Omega)$.

An analysis of these standard methods can be found in the work of Arcangéli and his coworkers [2, 3, 4, 5, 27]. There are reasonably simple $H^2(\Omega)$ finite element spaces (for instance, the Bogner–Fox–Schmidt rectangle [18, pp. 76–77]), but these are necessarily more complicated than the simpler $H^1(\Omega)$ finite element spaces. In particular, these smoother spaces lead to more dense stiffness matrices. For instance, the Bogner–Fox–Schmidt rectangle space will lead to sparse matrices with 36 nonzeros per variable, as compared to 9 for the space of bilinear functions. In addition, the conditioning of the $H^2(\Omega)$ matrix equations is typically $O(h^{-4})$, where h is a measure of the "mesh size" of the finite element space. Hence for problems which do not need the added smoothness it is more efficient to use the method described in this paper.

2.3. The $\boldsymbol{H^1(\Omega)}$ method. Our aim is to smooth very large data sets, which often necessitates fine meshes (typically $h <$ diameter$(\Omega)/500$ in many of our applications). As such, it is convenient to concentrate on methods in which the underlying finite element space is as simple as possible. This is very similar to the philosophy of using mixed finite element methods to solve the Navier–Stokes equation in fluid mechanics. To this end we reformulate Problem 1 so that only first order derivatives occur. In this case simple finite element spaces in $H^1(\Omega)$ can be utilized to discretize the problem. The conditioning of the resulting matrix problems are $O(h^{-2})$ and are readily solved using multigrid preconditioners.

As in many mixed finite element methods (see [11]), a new vector variable $\mathbf{u} = (u_1, u_2)$ is introduced. This variable represents the gradient of the function s sought in Problem 1. Our method formulates the minimization in terms of this new variable $\mathbf{u}$.

Suppose that $\mathbf{u}$ is the gradient of s, the minimizer of Problem 1. Then

$$\boldsymbol{\nabla} s = \mathbf{u}, \tag{2.1}$$

which determines s up to a constant. This constant can be determined by noting that a necessary condition for s to be the minimizer of Problem 1 is that

$$\langle \boldsymbol{\rho}^n s, \mathbf{e}\rangle_n = \langle \mathbf{y}, \mathbf{e}\rangle_n, \tag{2.2}$$

where $\mathbf{e}$ is the vector of all ones, $\mathbf{e} = [1 \ \cdots \ 1]^T$.

On the other hand, for general $\mathbf{u}$ we cannot expect to find an s satisfying (2.1) and (2.2). But for a given $\mathbf{u} \in H^1(\Omega)^2$ it is always possible to find an $s \in H^2(\Omega)$ satisfying

$$(\boldsymbol{\nabla} s, \boldsymbol{\nabla} v)_{L^2(\Omega)^2} = (\mathbf{u}, \boldsymbol{\nabla} v)_{L^2(\Omega)^2} \tag{2.3}$$

for all $v \in H^1(\Omega)$. In fact, there will be a unique such s satisfying (2.2) and (2.3), which we denote $\Phi(\mathbf{u}, \mathbf{y})$. Observe that $\Phi : H^1(\Omega)^2 \times \mathbb{R}^n \to H^2(\Omega)$.

The function $s = \Phi(\mathbf{u}, \mathbf{y})$ also satisfies a Neumann boundary value problem

$$\begin{aligned} \Delta\, s &= \boldsymbol{\nabla} \cdot \mathbf{u} \quad \text{in } \Omega, \\ \boldsymbol{\nabla} s \cdot \mathbf{n} &= \mathbf{u} \cdot \mathbf{n} \quad \text{on } \partial\Omega, \end{aligned}$$

together with the normalization (2.2).

Now consider the associated operator $\Psi : H^1(\Omega)^2 \to H^2(\Omega)$, where $g = \Psi(\mathbf{u})$ satisfies the Neumann boundary value problem

$$\Delta\, g = \boldsymbol{\nabla} \cdot \mathbf{u} \quad \text{in } \Omega, \tag{2.4}$$

$$\boldsymbol{\nabla} g \cdot \mathbf{n} = \mathbf{u} \cdot \mathbf{n} \quad \text{on } \partial\Omega, \tag{2.5}$$

$$\langle \boldsymbol{\rho}^n g, \mathbf{e}\rangle_n = 0. \tag{2.6}$$

It is easy to see that $\Phi(\mathbf{u}, \mathbf{y})$ and $\Psi(\mathbf{u})$ differ by a constant since they satisfy the same Neumann boundary value problem, and indeed

$$\Phi(\mathbf{u}, \mathbf{y}) = \Psi(\mathbf{u}) + \langle \mathbf{y}, \mathbf{e} \rangle_n.$$

We are thus led to the following problem.

Problem 2 (H^1 smoother). *For a fixed response vector $\mathbf{y}$, find $\mathbf{u}_\alpha(\mathbf{y}) \in H^1(\Omega)^2$ which minimizes the functional*

$$J_\alpha(\mathbf{u}, \mathbf{y}) = \|\boldsymbol{\rho}^n \Phi(\mathbf{u}, \mathbf{y}) - \mathbf{y}\|_n^2 + \alpha |\mathbf{u}|_{H^1(\Omega)^2}^2$$

over all $\mathbf{u} \in H^1(\Omega)^2$. The function $\Phi(\mathbf{u}_\alpha(\mathbf{y}), \mathbf{y})$ will correspond to our H^1 smoother and will be denoted $s_\alpha(\mathbf{y})$.

Problems 1 and 2 are not equivalent. For instance, there will be $\mathbf{u}$'s which are not the gradient of any s. Indeed, to force equivalence we would have to ensure that we minimize over those $\mathbf{u}$'s which are the gradient of some function, and this can be shown to be equivalent to $\mathbf{u}$ having zero curl ($\partial u_1/\partial x_2 - \partial u_2/\partial x_1 = 0$). While this can be done, and is the subject of many methods associated with the solution of the Navier–Stokes equation (see [21]), we instead advocate that the zero curl condition be dropped completely. The resulting Problem 2 is much easier to solve than one in which a zero curl condition is enforced. In addition, it is our claim that the smoothing function provided by Problem 2 produces a fit to the data (at least near the data points) that is similar to the standard thin plate spline. The precise statement of this result is our main convergence result, Theorem 3.2. The main advantages of this new minimization problem are that we can work with simple subspaces of $H^1(\Omega)$ and the problem becomes essentially an $H^1(\Omega)$ minimization problem, for which there are efficient solvers (for example, multigrid solvers).

2.4. The TPSFEM method. To discretize our problem we can minimize J_α over any simple finite dimensional subspace of $H^1(\Omega)^2$. In particular, we use simple continuous piecewise polynomial spaces $\mathbb{V}^h \subset H^1(\Omega)$ parameterized by h, the mesh size. Associated with each finite element space $\mathbb{V}^h$ is a mesh $\mathcal{T}^h$, consisting of a set of "elements" (usually triangles or quadrilaterals) $K \in \mathcal{T}^h$. The mesh size is given by

$$h = \max_{K \in \mathcal{T}^h} \text{diameter}(K).$$

We assume that the finite element spaces $\mathbb{V}^h$, and in particular the associated meshes $\mathcal{T}^h$, satisfy the following assumption.

Assumption 1 (Quasi-uniform meshes). *We will assume that the meshes $\mathcal{T}^h$ are "quasi-uniform"; that is,*

$$\max_{K \in \mathcal{T}^h} \frac{\text{diameter}(K)}{\rho(K)}$$

and

$$\frac{\max_{K \in \mathcal{T}^h} \text{diameter}(K)}{\min_{K \in \mathcal{T}^h} \text{diameter}(K)}$$

are bounded uniformly in h. Here $\rho(K)$ is the maximum diameter of any ball contained within K. Hence the elements of $\mathcal{T}^h$ cannot get too small relative to h, and they cannot get too "long and thin."

We also assume that the family of finite element spaces $\mathbb{V}^h$ satisfies the following approximation properties.

ASSUMPTION 2 (Standard approximation). *For all $\mathbb{V}^h$ there exists a linear operator $Q^h : H^1(\Omega) \to \mathbb{V}^h$ and a constant $C > 0$ such that for all $v \in H^2(\Omega)$*

$$\begin{aligned} \|v - Q^h v\|_{L^2(\Omega)} &\le Ch^2 |v|_{H^2(\Omega)}, \\ |v - Q^h v|_{H^1(\Omega)} &\le Ch|v|_{H^2(\Omega)}, \\ \sum_{K \in \mathcal{T}^h} \|v - Q^h v\|^2_{H^2(K)} &\le C|v|^2_{H^2(\Omega)}. \end{aligned}$$

In what follows, we will also need to control the $H^{-1}(\Omega)$ norm of the finite element approximation. As such, we also assume that our family of finite element spaces satisfies the following assumption.

ASSUMPTION 3 ($H^{-1}(\Omega)$ approximation). *For all $v \in H^1(\Omega)$ the linear operator $Q^h : H^1(\Omega) \to \mathbb{V}^h$ introduced in Assumption 2 satisfies*

$$\begin{aligned} \|v - Q^h v\|_{H^{-1}(\Omega)} &\le Ch^2 |v|_{H^1(\Omega)}, \\ \|v - Q^h v\|_{L^2(\Omega)} &\le Ch|v|_{H^1(\Omega)}, \\ |v - Q^h v|_{H^1(\Omega)} &\le C|v|_{H^1(\Omega)} \end{aligned}$$

for some constant $C > 0$.

The spaces of continuous piecewise linear functions associated with quasi-uniform triangulations of Ω or quadrilateral grids with bilinear functions satisfy Assumptions 2 and 3, with Q^h given by the $L^2(\Omega)$ projection.

The evaluation of $J_\alpha(\mathbf{u}, \mathbf{y})$ involves the calculation of $\Psi(\mathbf{u})$. An approximation of $g = \Psi(\mathbf{u})$ in $\mathbb{V}^h$ is given by $g^h = \Psi^h(\mathbf{u})$, where

$$(\boldsymbol{\nabla} g^h, \boldsymbol{\nabla} v)_{L^2(\Omega)^2} = (\mathbf{u}, \boldsymbol{\nabla} v)_{L^2(\Omega)^2} \tag{2.7}$$

for all $v \in \mathbb{V}^h$, also subject to the condition (2.6). We then let

$$\Phi^h(\mathbf{u}, \mathbf{y}) = \Psi^h(\mathbf{u}) + \langle \mathbf{y}, \mathbf{e} \rangle_n.$$

Our final discrete problem becomes the following.

PROBLEM 3 (TPSFEM smoother). *For a given response vector $\mathbf{y}$, find $\mathbf{u}^h_\alpha(\mathbf{y}) \in \mathbb{V}^h \times \mathbb{V}^h$, which minimizes the functional*

$$J^h_\alpha(\mathbf{u}, \mathbf{y}) = \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}, \mathbf{y}) - \mathbf{y}\|^2_n + \alpha |\mathbf{u}|^2_{H^1(\Omega)^2}$$

over the space $\mathbb{V}^h \times \mathbb{V}^h$. The function $\Phi^h(\mathbf{u}^h_\alpha(\mathbf{y}), \mathbf{y})$ will correspond to our TPSFEM smoothing function and is denoted $s^h_\alpha(\mathbf{y})$.

3. Approximation properties of the TPSFEM smoother. To obtain some quantitative information about the approximation properties of our smoother, we follow Utreras [28] and make the following assumptions about the form of the response variable observations and the values of the predictor variables. First the response variable.

ASSUMPTION 4 (Data model). *We suppose that our response variable is modelled by a smooth function $f \in H^2(\Omega)$ plus error. That is, the value of the response variable at a data point satisfies*

$$y^{(i)} = f(\mathbf{x}^{(i)}) + \nu^{(i)},$$

where $\nu^{(i)}$ denotes measurement error. We suppose that the $\nu^{(i)}$ are independent identically distributed random variables with mean zero and variance σ^2.

We also make an assumption about the spread of the values of the predictor variable. Let

$$d = \sup_{\mathbf{x}\in\Omega} \text{distance}(\mathbf{x}, \{\mathbf{x}^{(i)}\}) \tag{3.1}$$

be the maximum distance of any point in Ω from a data point. Following the problem formulation in [28], we assume that the predictor variables are "uniformly spread" throughout Ω in the following sense.

ASSUMPTION 5 (Uniformly spread data). *We assume that d, as a function of the number of data points n, is controlled by the minimum distance between data points. That is, there exists a constant $C > 1$ such that*

$$d < C \min_{i\neq j} |\mathbf{x}^{(i)} - \mathbf{x}^{(j)}|.$$

This implies that any ball of radius, say, $2d$ contained in Ω will have at least three data points, with the number uniformly bounded above. By filling larger balls $B \subset \Omega$ with balls of radius $2d$, we conclude that the number of predictor points in a larger ball is proportional to the area of the ball. In particular we have that

$$d^2 n_B \preceq \text{area}(B) \preceq d^2 n_B. \tag{3.2}$$

Here $n_B = \text{card}\{\mathbf{x}^{(i)} : \mathbf{x}^{(i)} \in B\}$, the number of predictor points in B. We will use this notation for any set B.

REMARK 1. *Note that we have introduced the notation*

$$f(d,h,\alpha) \preceq g(d,h,\alpha),$$

which will signify that

$$f(d,h,\alpha) \leq Cg(d,h,\alpha)$$

for some constant $C > 0$ uniformly for all choices of d, h, and α over the specified range of values. This notation will be used extensively in what follows.

REMARK 2. *Since our set Ω is convex, we can assume that it satisfies an interior cone condition and so conclude that* (3.2) *holds for all balls of radius greater than* $2d$ *with center contained in Ω (i.e., the balls may extend over the boundary of Ω).*

Combining the assumptions on the data and the finite element spaces, we conclude a similar point density estimate for elements of our meshes. Namely, we claim the following.

PROPOSITION 3.1. *Provided that the finite element spaces satisfy Assumption* 1 *and the data satisfies Assumption* 5, *then there exists a constant $C_1 > 1$ such that, for any mesh $\mathcal{T}^h$ with $h > C_1 d$, the elements $K \in \bigcup_{h>C_1 d} \mathcal{T}^h$ satisfy*

$$d^2 n_K \preceq \text{area}(K) \preceq d^2 n_K. \tag{3.3}$$

Proof. Assumption 1 implies that for each $K \in \mathcal{T}^h$ there exist balls $\underline{B}_K$ and $\overline{B}_K$ such that $\underline{B}_K \subset K \subset \overline{B}_K$ and $\text{area}(\overline{B}_K) \preceq \text{area}(K) \preceq \text{area}(\underline{B}_K)$. The elements

K cannot get too long and thin. Provided the elements are large enough ($h > C_1\, d$ for some C_1), we can assume that for all elements $K \in \bigcup_{h>C_1\, d} \mathcal{T}^h$ the inscribed balls satisfy radius$(\underline{B}_K) > 2d$. Hence (3.2) implies that area$(\underline{B}_K) \preceq d^2 n_{\underline{B}_K}$ and $d^2 n_{\overline{B}_K} \preceq \text{area}(\overline{B}_K)$. Combining these estimates leads to

$$d^2 n_K \preceq d^2 n_{\overline{B}_K} \preceq \text{area}(\overline{B}_K) \preceq \text{area}(K) \preceq \text{area}(\underline{B}_K) \preceq d^2 n_{\underline{B}_K} \preceq d^2 n_K,$$

which implies (3.3). □

REMARK 3. *By summing* (3.3) *over all K in the mesh, we conclude that*

$$d^2 n \preceq \text{area}(\Omega) \preceq d^2 n. \tag{3.4}$$

Now we can state the main convergence property of our smoother when applied to data which is uniformly spread.

THEOREM 3.2 (Main convergence result). *Suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3 *and our data satisfies Assumptions* 4 *and* 5. *Then there exist constants $C_1 > 1$ and $\alpha_0 > 0$ such that for all $f \in H^2(\Omega)$ the expected errors of the TPSFEM smoother satisfy*

$$E\|s_\alpha^h(\mathbf{y}) - f\|^2_{L^2(\Omega)} \preceq (\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)} + \frac{\sigma^2}{\alpha^{1/2}} \frac{(h^4 + d^4)}{h^2}, \tag{3.5}$$

$$E|s_\alpha^h(\mathbf{y}) - f|^2_{H^1(\Omega)} \preceq \frac{1}{\alpha^{1/2}}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)} + \frac{\sigma^2}{\alpha} \frac{(h^4 + d^4)}{h^2}, \tag{3.6}$$

$$E\|\mathbf{u}_\alpha^h(\mathbf{y})\|^2_{H^1(\Omega)^2} \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)} + \frac{\sigma^2}{\alpha^{3/2}} \frac{(h^4 + d^4)}{h^2}, \tag{3.7}$$

provided that h and α satisfy $h > C_1\, d$ and $d^4 + h^4 < \alpha < \alpha_0$.

Hence, under standard assumptions on the data, our smoothing method satisfies smoothing properties very similar to those of the standard thin plate spline (see [28, Theorem 1.1]).

To help qualify the contributions of the approximations in our method, we have elected to present the convergence result with the explicit α, d, and h dependencies retained. We see that the errors naturally divide into a bias and a variance term. In the bias term, the quantity $\alpha + d^4 + h^4$ arises from the

1. smoothing error (α),
2. error in approximating $L^2(\Omega)$ norms with pointwise norms (d^4), and
3. finite element approximation error (h^4).

The variance term is essentially of the form $\sigma^2 d^2/\alpha^{1/2}$ for small h, which is the bound obtained for the standard thin plate spline. Actually we conjecture that a more sophisticated analysis will show that the variance term is of the form $\sigma^2 d^2/(\alpha^{1/2}+h^2)$, which would demonstrate the smoothing influence of coarser grids.

In section 7 we prove this theorem using an argument very similar to that found in Utreras [28]. First, in Theorem 7.3 we bound the norms of bias of the method $s_\alpha^h(\boldsymbol{\rho}^n f) - f$. Then in Theorem 7.8 the norms of the variance $s_\alpha^h(\boldsymbol{\nu})$ are shown to be bounded by the analogous bounds for the standard thin plate spline. This convergence analysis seems to be the first for a discrete smoothing spline with data perturbed by white noise. It should be possible to apply our methodology to proving convergence for the standard discrete smoothing splines.

It should be noted that, given the requirements that $h > C_1\, d$ and $d^4 + h^4 < \alpha < \alpha_0$, we can obtain the somewhat "cleaner" estimates

$$\begin{aligned} E\|s^h_\alpha(\mathbf{y}) - f\|^2_{L^2(\Omega)} &\preceq \alpha\|f\|^2_{H^2(\Omega)} + h^2\frac{\sigma^2}{\alpha^{1/2}}, \\ E|s^h_\alpha(\mathbf{y}) - f|^2_{H^1(\Omega)} &\preceq \alpha^{1/2}\|f\|^2_{H^2(\Omega)} + h^2\frac{\sigma^2}{\alpha}, \\ E\|\mathbf{u}^h_\alpha(\mathbf{y})\|^2_{H^1(\Omega)^2} &\preceq \|f\|^2_{H^2(\Omega)} + h^2\frac{\sigma^2}{\alpha^{3/2}}. \end{aligned}$$

4. The numerical method.

In this section we will outline the method we use to calculate our smoother. In subsection 4.2 we describe the generalized cross-validation method that we often use to calculate an appropriate value for the smoothing parameter α. Finally in subsection 4.3 we provide two numerical experiments to compare our method with Duchon's method and to demonstrate our method on a large data fitting problem.

4.1. The discrete equations.

The TPSFEM method provides a gradient function $\mathbf{u} = \mathbf{u}^h_\alpha(\mathbf{y})$ and an associated smoothing function $s = \Phi^h_\alpha(\mathbf{u}, \mathbf{y})$. To obtain an explicit representation of these functions in $\mathbb{V}^h$ we must calculate their expansion in terms of a basis for $\mathbb{V}^h$. As such, let

$$\mathbf{h}(\mathbf{x}) = \begin{bmatrix} h_1(\mathbf{x}) \\ \vdots \\ h_m(\mathbf{x}) \end{bmatrix}$$

denote a vector of basis functions for the finite element space $\mathbb{V}^h$. The values of the basis functions at the data points are encapsulated by the matrix

$$\boldsymbol{H}^T = \boldsymbol{\rho}^n \mathbf{h}(\mathbf{x})^T = \begin{bmatrix} h_1(\mathbf{x}^{(1)}) & \cdots & h_m(\mathbf{x}^{(1)}) \\ \vdots & \vdots & \vdots \\ h_1(\mathbf{x}^{(n)}) & \cdots & h_m(\mathbf{x}^{(n)}) \end{bmatrix}.$$

Then s and $\mathbf{u} = [u_1, u_2]^T$ will be of the form

$$s(\mathbf{x}) = \mathbf{h}(\mathbf{x})^T\mathbf{c}, \quad u_1(\mathbf{x}) = \mathbf{h}(\mathbf{x})^T\mathbf{g}_1, \quad u_2(\mathbf{x}) = \mathbf{h}(\mathbf{x})^T\mathbf{g}_2, \tag{4.1}$$

where the vectors $\mathbf{c}$, $\mathbf{g}_1$, and $\mathbf{g}_2$ represent the linear combination coefficients in the basis $\mathbf{h}$.

Relation (2.3) between s and $\mathbf{u}$ can be written as

$$\boldsymbol{L}\mathbf{c} = \boldsymbol{G}_1\mathbf{g}_1 + \boldsymbol{G}_2\mathbf{g}_2, \tag{4.2}$$

where $\boldsymbol{L} = (\boldsymbol{\nabla}\mathbf{h}, \boldsymbol{\nabla}\mathbf{h}^T)_{L^2(\Omega)}$ is a matrix approximation to the operator $-\Delta$, and $\boldsymbol{G}_1 = (\partial_{x_1}\mathbf{h}, \mathbf{h}^T)_{L^2(\Omega)}$ and $\boldsymbol{G}_2 = (\partial_{x_2}\mathbf{h}, \mathbf{h}^T)_{L^2(\Omega)}$ are matrix approximations to the operators $-\partial_{x_1}$ and $-\partial_{x_2}$, respectively. Consequently

$$\mathbf{c} = \boldsymbol{L}^+(\boldsymbol{G}_1\mathbf{g}_1 + \boldsymbol{G}_2\mathbf{g}_2),$$

where $\boldsymbol{L}^+$ is the pseudoinverse of $\boldsymbol{L}$ which satisfies $L^+ H\mathbf{e} = 0$. In our implementation all calculations involving $\boldsymbol{L}^+$ are provided by a multigrid Poisson solver.

Our discrete functional is now equivalent to

$$J^h_\alpha(\mathbf{u},\mathbf{y}) = \tilde{J}^h_\alpha(\mathbf{g},\mathbf{y}) = \|\mathcal{K}\mathbf{g} + \langle \mathbf{y},\mathbf{e}\rangle_n \mathbf{e} - \mathbf{y}\|^2_n + \alpha \mathbf{g}^T \mathcal{L}\mathbf{g}, \tag{4.3}$$

where $\mathbf{g} = [\mathbf{g}_1^T \quad \mathbf{g}_2^T]^T$, $\mathcal{K} = \boldsymbol{H}^T L^+ [\boldsymbol{G}_1 \quad \boldsymbol{G}_2]$, and

$$\mathcal{L} = \begin{bmatrix} \boldsymbol{L} & \mathbf{0} \\ \mathbf{0} & \boldsymbol{L} \end{bmatrix}.$$

Our smoothing problem consists of minimizing this functional over all vectors $\mathbf{g} \in \mathbb{R}^{2m}$.

The minimizer satisfies the equation

$$\left[\mathcal{K}^T\mathcal{K} + n\alpha\mathcal{L}\right]\mathbf{g} = \mathcal{K}^T\tilde{\mathbf{y}}, \tag{4.4}$$

where $\tilde{\mathbf{y}} = \mathbf{y} - \langle \mathbf{y},\mathbf{e}\rangle_n \mathbf{e}$. In terms of the components $\mathbf{g}_1$ and $\mathbf{g}_2$, this becomes

$$\begin{bmatrix} \boldsymbol{G}_1^T\boldsymbol{Z}\boldsymbol{G}_1 + n\alpha\boldsymbol{L} & \boldsymbol{G}_1^T\boldsymbol{Z}\boldsymbol{G}_2 \\ \boldsymbol{G}_2^T\boldsymbol{Z}\boldsymbol{G}_1 & \boldsymbol{G}_2^T\boldsymbol{Z}\boldsymbol{G}_2 + n\alpha\boldsymbol{L} \end{bmatrix} \begin{bmatrix} \mathbf{g}_1 \\ \mathbf{g}_2 \end{bmatrix} = \begin{bmatrix} \boldsymbol{G}_1^T\boldsymbol{L}^+\boldsymbol{z} \\ \boldsymbol{G}_2^T\boldsymbol{L}^+\boldsymbol{z} \end{bmatrix}, \tag{4.5}$$

where $\boldsymbol{Z} = \boldsymbol{L}^+\boldsymbol{H}\boldsymbol{H}^T\boldsymbol{L}^+$ and $\boldsymbol{z} = \boldsymbol{H}^T\tilde{\mathbf{y}}$. The matrix $\boldsymbol{H}\boldsymbol{H}^T$ and the vector $\boldsymbol{z}$ depend on the data and are evaluated by reading the data arrays from disk and computing the contribution due to each data point. This is then accumulated into global data structures. Thus, the formation of $\boldsymbol{H}\boldsymbol{H}^T$ and $\boldsymbol{z}$ is scalable with respect to the data size. These operations parallelize well because the different segments of the data can be processed independently.

The matrices $\boldsymbol{L}$, $\boldsymbol{G}_1$, and $\boldsymbol{G}_2$ depend on the specified mesh size, which in many cases can be chosen independently of the data. It can be seen that the system (4.5) is symmetric positive definite, and so we use the conjugate gradient method to solve the equation. In fact, we use the preconditioned conjugate gradient (PCG) method, with preconditioner matrix

$$\boldsymbol{Q} = \begin{bmatrix} \boldsymbol{L}^+ & \mathbf{0} \\ \mathbf{0} & \boldsymbol{L}^+ \end{bmatrix}.$$

Each iteration of our PCG solver involves four applications of $\boldsymbol{L}^+$. For smooth problems we need on the order of twenty iterations of our PCG method to reduce the residual of the equation by a factor of 10^{-10}.

4.2. Estimation of optimal $\boldsymbol{\alpha}$ and $\boldsymbol{h}$. The parameters α and h provide a measure of the smoothing effect of our method. We usually determine "optimal" values for these parameters in a two-step process. For a given h we use generalized cross-validation (GCV) to determine α. Then we decrease h until the value of α obtained by the GCV method stabilizes at a fixed value.

4.2.1. The generalized cross-validation method. For a fixed h we obtain an "optimal" value for α using the GCV method. The GCV function

$$V(\alpha) = \frac{\|(I - \mathcal{K}[\mathcal{K}^T\mathcal{K} + n\alpha\mathcal{L}]^{-1}\mathcal{K}^T)\tilde{\mathbf{y}}\|^2_n}{[tr(I - \mathcal{K}[\mathcal{K}^T\mathcal{K} + n\alpha\mathcal{L}]^{-1}\mathcal{K}^T)]^2}$$

provides a cumulative measure of the error of estimating the response value at a point by a smoother in which individual data points have been "left out." This function provides a measure of how well the smoother is fitting the data, and also how well "new" data is approximated by the smoother. The reader is referred to Wahba's book [29] for a description of cross-validation and GCV methods. In the GCV method the "optimal" smoothing parameter α is the minimizer of the GCV function [29, p. 43]. For us, the problem is how to calculate the function $V(\alpha)$ efficiently. The most difficult term is the trace term, as we do not want to assemble the full matrix $[\mathcal{K}^T\mathcal{K}+n\alpha\mathcal{L}]^{-1}$. We use an approximation due to Hutchinson [25], in which the trace term is approximated by an unbiased stochastic estimator. In particular, we use the function

$$\bar{V}(\alpha) = \frac{\|(I - \mathcal{K}[\mathcal{K}^T\mathcal{K} + n\alpha\mathcal{L}]^{-1}\mathcal{K}^T)\tilde{\mathbf{y}}\|_n^2}{[tr(I) - \mathbf{u}^T\mathcal{K}[\mathcal{K}^T\mathcal{K} + n\alpha\mathcal{L}]^{-1}\mathcal{K}^T\mathbf{u}]^2}$$

as an approximation of the standard GCV function. Here $\mathbf{u}$ is a random vector whose entries take on the values 1 and -1 with equal probability $\frac{1}{2}$. To calculate $\bar{V}(\alpha)$ for any fixed α, we must solve two smoothing problems (4.4). We have found that it is necessary to obtain the optimal α only to within an order of magnitude, and so we generally need to calculate $\bar{V}(\alpha)$ for only four to five values of α.

4.3. Numerical experiments. We now provide two numerical experiments. The first verifies that the TPSFEM method and the standard thin plate spline smoother provide similar results for a simple smoothing problem. Our second experiment demonstrates our method on a reasonably large data set.

First the comparison with the thin plate spline smoother. For clarity, we will apply our method to a small problem in order to *accentuate* the difference between the two smoothers. Our data is of the form

$$\mathbf{y} = \boldsymbol{\rho}^n f + \boldsymbol{\nu},$$

where the random variables $\boldsymbol{\nu}$ are normally distributed with expectation 0 and standard deviation 0.2. The components of the data points $\mathbf{x}^{(i)}$ are independently normally distributed with expectation 0.5 and standard deviation 0.25. For f the "peaks" function from MATLAB has been chosen. The peaks function is formed as a linear combination of several scaled and translated Gaussian distributions. The smoothing parameter is $\alpha = 10^{-6}$. In this case we use bilinear elements on a uniform 32 by 32 grid.

As can be seen from Figure 4.1, the two smoothers approximate the data well in the region of high density and show slightly different behavior on the boundary where the two smoothers satisfy different conditions and the data points are less dense. Generally the qualitative behavior is similar.

As another example of our method we present results in Figure 4.2 from smoothing a survey of magnetic field strengths known as the Ebagoola magnetic data set [6]. The survey comprises 735,700 data points consisting of latitude and longitude and magnetic field strength obtained from an aerial survey of the Ebagoola region of Cape York Peninsula in northern Australia. The region surveyed is approximately 61 by 63 kilometers. The distance between data points is very small in the direction of flight (about 10 meters), whereas the distance between adjacent flight paths is longer, on the order of 500 meters.

The smoother was obtained in 7.5 minutes using a MATLAB implementation on a 135 MHz SUN Sparc Station. Reading in and parsing the 17MB ASCII data set takes 5 minutes on the same workstation. It should be noted the TPSFEM smoother

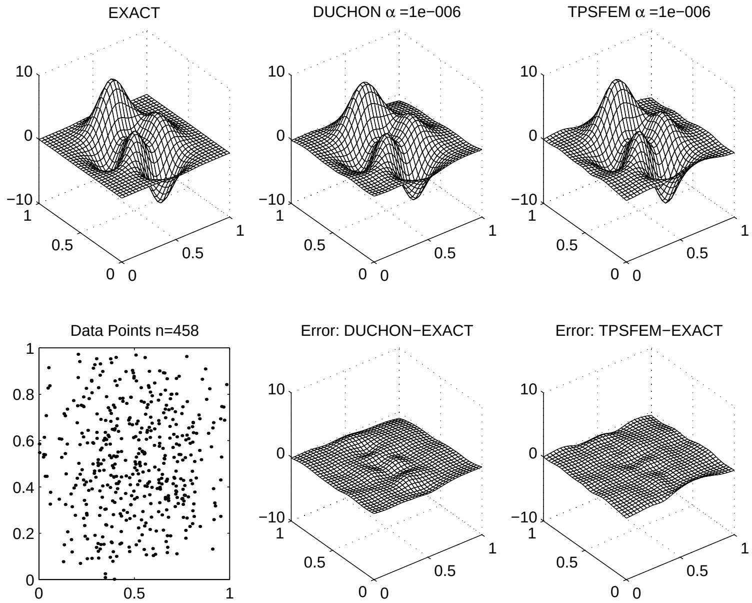

Fig. 4.1. *Comparison of standard thin plate spline (DUCHON) and the TPSFEM smoother; an example fitting data with* 458 *points. Approximation properties are similar except near the boundaries, where there are only a small number of data points.*

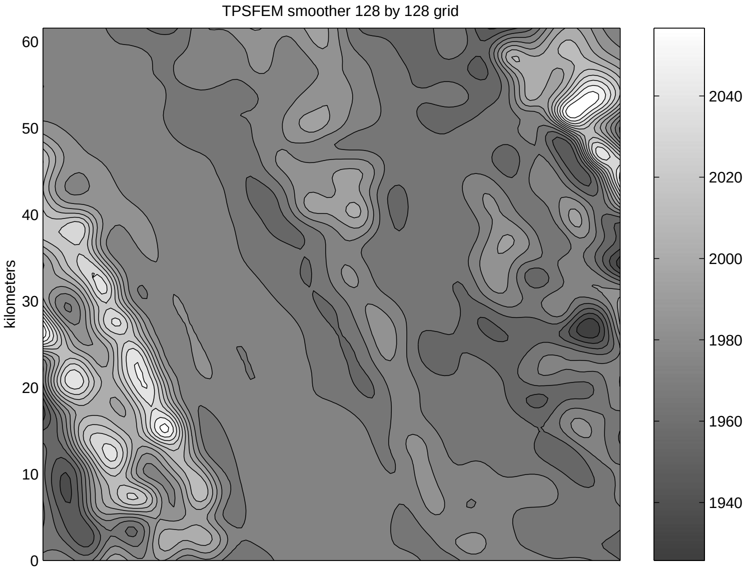

Fig. 4.2. *The TPSFEM smoother for the Ebagoola magnetic data set of* 735,700 *points with a finite element grid of* 128 *by* 128.

provides an extreme compression of the data. The grid size has been chosen to match the data spread between flight paths. This is provided by using bilinear elements on a uniform 128 by 128 grid. Even so, it not guaranteed that each element will have data points. The use of the TPSFEM provides a robust smoother which deals with the large data size and is also guaranteed to have a solution for essentially any distribution of data points (as opposed to a simple finite element least squares fit, which will fail if any finite element contains no data points).

5. Existence and uniqueness of the minimizers. We will now show that if the values of the predictor variables $\mathbf{x}^{(i)}$ are not collinear, then the unconstrained minimization problems 2 and 3 will have unique solutions. This will be shown by proving that equivalent associated variational equations satisfy standard continuity and ellipticity properties.

First we note that the thin plate spline problem, Problem 1 on page 210, is equivalent to the following variational problem.

PROBLEM 4 (Thin plate spline smoother). *For fixed* $\mathbf{y} \in \mathbb{R}^n$, *find* $\bar{s}_\alpha(\mathbf{y}) \in H^2(\Omega)$ *such that*

$$\bar{a}_\alpha(s_\alpha(\mathbf{y}), v) = \bar{F}(v, \mathbf{y}) \qquad \textit{for all } v \in H^2(\Omega), \tag{5.1}$$

where

$$\bar{a}_\alpha(w, v) = \langle \boldsymbol{\rho}^n w, \boldsymbol{\rho}^n v \rangle_n + \alpha (w, v)_{H^2(\Omega)}$$

and

$$\bar{F}(v, \mathbf{y}) = \langle \mathbf{y}, \boldsymbol{\rho}^n v \rangle_n.$$

The existence and uniqueness of the solution of this problem is provided by Duchon [20].

The H^1 smoothing problem, Problem 2 on page 212, is equivalent to the following variational problem.

PROBLEM 5 (H^1 smoother). *For fixed* $\mathbf{y} \in \mathbb{R}^n$, *find* $\mathbf{u}_\alpha(\mathbf{y}) \in H^1(\Omega)^2$ *such that*

$$a_\alpha(\mathbf{u}_\alpha(\mathbf{y}), \mathbf{v}) = F(\mathbf{v}, \mathbf{y}) \qquad \textit{for all } \mathbf{v} \in H^1(\Omega)^2, \tag{5.2}$$

where

$$a_\alpha(\mathbf{u}, \mathbf{v}) = \langle \boldsymbol{\rho}^n \Psi(\mathbf{u}), \boldsymbol{\rho}^n \Psi(\mathbf{v}) \rangle_n + \alpha (\mathbf{u}, \mathbf{v})_{H^1(\Omega)^2}$$

and

$$F(\mathbf{v}, \mathbf{y}) = \langle \mathbf{y}, \boldsymbol{\rho}^n \Psi(\mathbf{v}) \rangle_n.$$

The equivalence of Problems 2 and 5 follows from the fact that

$$\begin{aligned} J_\alpha(\mathbf{u}, \mathbf{y}) &= \|\boldsymbol{\rho}^n \Phi(\mathbf{u}, \mathbf{y}) - \mathbf{y}\|_n^2 + \alpha |\mathbf{u}|_{H^1(\Omega)^2}^2 \\ &= \|\boldsymbol{\rho}^n \Psi(\mathbf{u}) - \mathbf{y} + \langle \mathbf{y}, \mathbf{e} \rangle_n \mathbf{e}\|_n^2 + \alpha |\mathbf{u}|_{H^1(\Omega)^2}^2. \end{aligned}$$

It is elementary that the minimization problem is equivalent to the variational equation (5.2), where a_α is given above and

$$F(\mathbf{v}, \mathbf{y}) = \langle \mathbf{y} - \langle \mathbf{y}, \mathbf{e} \rangle_n \mathbf{e}, \boldsymbol{\rho}^n \Psi(\mathbf{v}) \rangle_n.$$

Now $\langle \boldsymbol{\rho}^n \Psi(\mathbf{v}), \mathbf{e}\rangle_n = 0$, and so

$$F(\mathbf{v}, \mathbf{y}) = \langle \mathbf{y}, \boldsymbol{\rho}^n \Psi(\mathbf{v})\rangle_n,$$

as required.

The TPSFEM variational problem is given by the following.

PROBLEM 6 (TPSFEM smoother). *For fixed* $\mathbf{y} \in \mathbb{R}^n$*, find* $\mathbf{u}_\alpha^h(\mathbf{y}) \in \mathbb{V}^h \times \mathbb{V}^h$ *such that*

$$a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{y}), \mathbf{v}) = F^h(\mathbf{v}, \mathbf{y}) \qquad \textit{for all } \mathbf{v} \in \mathbb{V}^h \times \mathbb{V}^h, \tag{5.3}$$

where

$$a_\alpha^h(\mathbf{u}_\alpha^h, \mathbf{v}) = \langle \boldsymbol{\rho}^n \Psi^h(\mathbf{u}), \boldsymbol{\rho}^n \Psi^h(\mathbf{v})\rangle_n + \alpha(\mathbf{u}, \mathbf{v})_{H^1(\Omega)^2}$$

and

$$F^h(\mathbf{v}, \mathbf{y}) = \langle \mathbf{y}, \boldsymbol{\rho}^n \Psi^h(\mathbf{v})\rangle_n.$$

The equivalence of Problem 3 on page 213 and Problem 6 follows in exactly the same way as the previous equivalence statement.

To prove the existence and uniqueness of solutions of these variational equations, we must show continuity and ellipticity of the operators. First we show the continuity of bilinear forms $a_\alpha(\cdot,\cdot)$ and $a_\alpha^h(\cdot,\cdot)$ and the linear functionals $F(\cdot, \mathbf{y})$ and $F^h(\cdot, \mathbf{y})$.

PROPOSITION 5.1 (Continuity). *The bilinear forms* $a_\alpha(\cdot,\cdot)$ *and* $a_\alpha^h(\cdot,\cdot)$ *and the linear forms* $F(\cdot, \mathbf{y})$ *and* $F^h(\cdot, \mathbf{y})$ *are continuous on* $H^1(\Omega)^2$*.*

Proof. The continuity of these linear operators follows from the fact that the pointwise evaluations of the functions $\Psi(\mathbf{v})$ and $\Psi^h(\mathbf{v})$ are continuous operations when $\mathbf{v} \in H^1(\Omega)^2$. Recall that the function $\Psi(\mathbf{v})$ satisfies (2.4). Now $\mathbf{v} \in H^1(\Omega)^2$, and so $\boldsymbol{\nabla} \cdot \mathbf{v} \in L^2(\Omega)$ and $\mathbf{v} \cdot \mathbf{n} \in H^{1/2}(\partial\Omega)$. The standard regularity theory for second order elliptic equations on convex domains and the trace theorem (see [22]) imply that

$$|\Psi(\mathbf{v})|_{H^1(\Omega)} + |\Psi(\mathbf{v})|_{H^2(\Omega)} \preceq \|\boldsymbol{\nabla} \cdot \mathbf{v}\|_{L^2(\Omega)} + \|\mathbf{v} \cdot \mathbf{n}\|_{H^{1/2}(\partial\Omega)} \preceq \|\mathbf{v}\|_{H^1(\Omega)^2}.$$

The condition $\langle \boldsymbol{\rho}^n \Psi(\mathbf{v}), \mathbf{e}\rangle_n = 0$ implies that a Poincaré inequality holds for $\Psi(\mathbf{v})$, namely,

$$\|\Psi(\mathbf{v})\|_{L^2(\Omega)} \preceq |\Psi(\mathbf{v})|_{H^1(\Omega)},$$

and so

$$\|\Psi(\mathbf{v})\|_{H^2(\Omega)} \preceq \|\mathbf{v}\|_{H^1(\Omega)^2}. \tag{5.4}$$

The Sobolev inequality implies that the pointwise norm $\|\cdot\|_n$ is bounded by the $H^2(\Omega)$ norm, and so we conclude that there exists a constant $C > 0$ (perhaps dependent on the data distribution) such that

$$\|\boldsymbol{\rho}^n \Psi(\mathbf{v})\|_n \leq C\|\mathbf{v}\|_{H^1(\Omega)^2}. \tag{5.5}$$

A similar estimate is necessary for $\Psi^h(\mathbf{v})$, the finite element approximation of $\Psi(\mathbf{v})$. It is useful to observe that since the finite element space $\mathbb{V}^h$ satisfies Assumption 2 on page 213, standard error estimates imply that

$$\|\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})\|^2_{L^2(\Omega)} \preceq h^4 \|\Psi(\mathbf{v})\|^2_{H^2(\Omega)}, \tag{5.6}$$

$$|\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})|^2_{H^1(\Omega)} \preceq h^2 \|\Psi(\mathbf{v})\|^2_{H^2(\Omega)}, \tag{5.7}$$

$$\sum_{K \in \mathcal{T}^h} |\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})|^2_{H^2(K)} \preceq \|\Psi(\mathbf{v})\|^2_{H^2(\Omega)}. \tag{5.8}$$

We cannot assume that $\Psi^h(\mathbf{v}) \in H^2(\Omega)$, but we can assume that $\Psi^h(\mathbf{v})$ restricted to each element $K \in \mathcal{T}^h$ is in $H^2(K)$. Hence there exists a constant $C > 0$ such that

$$\|\boldsymbol{\rho}^n \Psi^h(\mathbf{v})\|^2_n \leq C \sum_{K \in \mathcal{T}^h} \|\Psi^h(\mathbf{v})\|^2_{H^2(K)}.$$

Equation (5.8) implies that

$$\begin{aligned} &\sum_{K \in \mathcal{T}^h} \|\Psi^h(\mathbf{v})\|^2_{H^2(K)} \\ &\preceq \sum_{K \in \mathcal{T}^h} \|\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})\|^2_{H^2(K)} + \sum_{K \in \mathcal{T}^h} \|\Psi(\mathbf{v})\|^2_{H^2(K)} \preceq \|\Psi(\mathbf{v})\|^2_{H^2(\Omega)}. \end{aligned}$$

By (5.4) we conclude that there exists a constant $C > 0$ such that

$$\|\boldsymbol{\rho}^n \Psi^h(\mathbf{v})\|_n \leq C \|\mathbf{v}\|_{H^1(\Omega)^2}. \tag{5.9}$$

Equations (5.5) and (5.9) then imply that the bilinear functionals $a_\alpha(\cdot,\cdot)$ and $a^h_\alpha(\cdot,\cdot)$ and the linear functionals $F(\cdot,\mathbf{y})$ and $F^h(\cdot,\mathbf{y})$ are continuous. $\square$

PROPOSITION 5.2 (Ellipticity). *Suppose that the values of the predictor variable are not collinear. Then $a_\alpha(\cdot,\cdot)$ and $a^h_\alpha(\cdot,\cdot)$ are $H^1(\Omega)^2$-elliptic.*

Proof. First observe that for any constants c_1 and c_2

$$\Psi((c_1,c_2)) = \Psi^h((c_1,c_2)) = c_1(\mathrm{x}_1 - \langle \boldsymbol{\rho}^n \mathrm{x}_1, \mathbf{e}\rangle_n) + c_2(\mathrm{x}_2 - \langle \boldsymbol{\rho}^n \mathrm{x}_2, \mathbf{e}\rangle_n)$$

since both $H^1(\Omega)$ and $\mathbb{V}^h$ contain the linear functions. Without loss of generality we may suppose that the origin of the $\mathbf{x}$ variable has been chosen so that $\langle \boldsymbol{\rho}^n \mathrm{x}_1, \mathbf{e}\rangle_n = 0$ and $\langle \boldsymbol{\rho}^n \mathrm{x}_2, \mathbf{e}\rangle_n = 0$. In this case we have

$$\Psi((c_1,c_2)) = \Psi^h((c_1,c_2)) = c_1 \mathrm{x}_1 + c_2 \mathrm{x}_2. \tag{5.10}$$

Thus constants are mapped to linear functions via both $\Psi(\cdot)$ and $\Psi^h(\cdot)$.

For $\mathbf{v} = (v_1, v_2) \in H^1(\Omega)^2$ let $c_1 = \int_\Omega v_1 \, d\mathbf{x}$ and $c_2 = \int_\Omega v_2 \, d\mathbf{x}$. Then the Poincaré inequality implies that

$$\|\mathbf{v} - (c_1,c_2)\|^2_{L^2(\Omega)^2} \leq C|\mathbf{v}|^2_{H^1(\Omega)^2} \quad \text{and} \quad \|\mathbf{v}\|^2_{H^1(\Omega)^2} \leq C[c_1^2 + c_2^2 + |\mathbf{v}|^2_{H^1(\Omega)^2}].$$

Let $P = [\mathbf{x}^{(1)} \quad \cdots \quad \mathbf{x}^{(n)}]^T$. Since the points $\mathbf{x}^{(i)}$ are not collinear, the matrix P has full rank (of two), and the matrix $P^T P$ will be positive definite. Hence

$$c_1^2 + c_2^2 \leq C \frac{1}{n} [c_1 \ c_2] P^T P [c_1 \ c_2]^T = C \|\boldsymbol{\rho}^n \Psi((c_1,c_2))\|^2_n,$$

and so

$$\|\mathbf{v}\|^2_{H^1(\Omega)^2} \leq C[\|\boldsymbol{\rho}^n \Psi((c_1,c_2))\|^2_n + |\mathbf{v}|^2_{H^1(\Omega)^2}]$$

for some constant C (which can depend on h and n). Finally note that by the triangle inequality and the Poincaré inequality

$$\begin{aligned} \|\boldsymbol{\rho}^n\Psi((c_1,c_2))\|_n^2 &= \|\boldsymbol{\rho}^n\Psi((c_1,c_2)-\mathbf{v})+\boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2 \\ &\le 2\|\boldsymbol{\rho}^n\Psi((c_1,c_2)-\mathbf{v})\|_n^2+2\|\boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2 \\ &= 2\|(c_1,c_2)-\mathbf{v}\|_{H^1(\Omega)^2}^2+2\|\boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2 \\ &\le C[|\mathbf{v}|_{H^1(\Omega)^2}^2+\|\boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2], \end{aligned} \tag{5.11}$$

and consequently

$$\|\mathbf{v}\|_{H^1(\Omega)^2}^2 \le C[\|\boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2+\alpha|\mathbf{v}|_{H^1(\Omega)^2}^2] = Ca_\alpha(\mathbf{v},\mathbf{v}).$$

The proof for a_α^h is identical. □

The following theorem is a direct application of a standard existence/uniqueness result for abstract variation problems; see [18, pp. 2–3].

THEOREM 5.3 (Existence-uniqueness). *Suppose that the values of the predictor variable are not collinear. Then there is a unique* $\mathbf{u}\in H^1(\Omega)^2$ *which solves Problems* 2 *and* 5. *Similarly, there is a unique* $\mathbf{u}^h\in\mathbb{V}^h\times\mathbb{V}^h$ *which solves Problems* 3 *and* 6.

Hence our H^1 and TPSFEM smoothing problems have unique solutions. They are not the standard thin plate splines, but, as we will prove in section 7, they do possess smoothing properties similar to the standard smoothing splines.

6. Auxilary results. We will now quote and prove a number of results which allow us to estimate the error due to approximating $\Psi(\mathbf{v})$ with $\Psi^h(\mathbf{v})$, and estimating the $L^2(\Omega)$ norms with $\mathbb{R}^n$ norms (and visa versa).

We quote an important result which follows from Utreras [28, Theorems 3.3 and 3.4] when applied to each $K\in\mathcal{T}^h$.

LEMMA 6.1 (Element norms). *Suppose that our finite element spaces satisfy Assumption* 1 *and our data satisfies Assumption* 5. *Then there exists a constant* $C_1>1$ *such that for any* $K\in\mathcal{T}^h$ *where* $h>C_1\,d$, *and for any* $f\in H^2(K)$, *the following bounds hold:*

$$d^2\sum_{\mathbf{x}^{(i)}\in K} f(\mathbf{x}^{(i)})^2 \preceq \|f\|_{L^2(K)}^2+d^4|f|_{H^2(K)}^2$$

and

$$\|f\|_{L^2(K)}^2 \preceq d^2\sum_{\mathbf{x}^{(i)}\in K} f(\mathbf{x}^{(i)})^2+d^4|f|_{H^2(K)}^2.$$

Proof. Results of this type, where the element K is replaced by small balls of radius $2d$, are shown in Utreras [28, Theorems 3.3 and 3.4]. Just as in Proposition 3.1, we can cover each element K with balls of radius $2d$ and sum to obtain our result. □

We are working with functions in $H^1(\Omega)$, which are not in $H^2(\Omega)$ but are controlled in $H^2(K)$ for each element K of a mesh. Hence we need the following generalization of Utreras' result.

LEMMA 6.2 (Pointwise norm equivalence). *Suppose that our finite element spaces satisfy Assumption* 1 *and our data satisfies Assumption* 5. *Then there exists a constant* $C_1>1$ *such that for any* $K\in\mathcal{T}^h$ *where* $h>C_1\,d$, *and for* $f\in H^1(\Omega)$ *such that* f *restricted to each* K *has bounded* $H^2(K)$ *norm, we have that*

$$\|\boldsymbol{\rho}^n f\|_n^2 \preceq \|f\|_{L^2(\Omega)}^2+d^4\sum_{K\in\mathcal{T}^h}|f|_{H^2(K)}^2$$

and

$$\|f\|^2_{L^2(\Omega)} \preceq \|\boldsymbol{\rho}^n f\|^2_n + d^4 \sum_{K\in\mathcal{T}^h} |f|^2_{H^2(K)}.$$

Proof. This result follows by summing the inequalities from Lemma 6.1 over all $K \in \mathcal{T}^h$ and observing that, since the data points are "uniformly spread," d^2 is comparable to $1/n$. □

With this lemma we can prove the following useful results.

LEMMA 6.3 (Ψ^h consistency). *Suppose that our finite element spaces satisfy Assumption* 1 *and our data satisfies Assumption* 5. *Then there exists a constant* $C_1 > 1$ *such that for* $h > C_1\, d$ *and for* $\mathbf{v} \in H^1(\Omega)^2$

$$\|\boldsymbol{\rho}^n\Psi^h(\mathbf{v}) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n \preceq (h^4 + d^4)\|\mathbf{v}\|^2_{H^1(\Omega)^2}.$$

Proof. By Lemma 6.2

$$\begin{aligned}&\|\boldsymbol{\rho}^n\Psi^h(\mathbf{v}) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n\\ &\preceq \|\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})\|^2_{L^2(\Omega)} + d^4 \sum_{K\in\mathcal{T}^h} |\Psi^h(\mathbf{v}) - \Psi(\mathbf{v})|^2_{H^2(K)}.\end{aligned}$$

The first term is bounded by (5.6) and the second term by (5.8). Consequently

$$\|\boldsymbol{\rho}^n\Psi^h(\mathbf{v}) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n \preceq (h^4 + d^4)\|\Psi(\mathbf{v})\|^2_{H^2(\Omega)}.$$

By (5.4), $\|\Psi(\mathbf{v})\|_{H^2(\Omega)}$ is bounded by $\|\mathbf{v}\|^2_{H^1(\Omega)^2}$ so that

$$\|\boldsymbol{\rho}^n\Psi^h(\mathbf{v}) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n \preceq (h^4 + d^4)\|\mathbf{v}\|^2_{H^1(\Omega)^2}. \qquad \square$$

LEMMA 6.4 (Ψ stability). *Suppose that our finite element spaces satisfy Assumption* 1 *and our data satisfies Assumption* 5. *Then there exists a constant* $C_1 > 1$ *such that for* $h > C_1\, d$ *and for* $\mathbf{v} \in H^1(\Omega)^2$

$$\|\boldsymbol{\rho}^n\Psi(\mathbf{v}^h) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n \preceq (h^4 + d^4)\|\mathbf{v}\|^2_{H^1(\Omega)^2},$$

where $\mathbf{v}^h = Q^h\mathbf{v}$*, the projection operator referred to in Assumptions* 2 *and* 3, *has been applied to each component of* $\mathbf{v}$.

Proof. By Lemma 6.2

$$\begin{aligned}&\|\boldsymbol{\rho}^n\Psi(\mathbf{v}^h) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|^2_n\\ &\preceq \|\Psi(\mathbf{v}^h - \mathbf{v})\|^2_{L^2(\Omega)} + d^4|\Psi(\mathbf{v}^h - \mathbf{v})|^2_{H^2(\Omega)}.\end{aligned}$$

Standard regularity results for second order elliptic equations provide the bounds

$$\begin{aligned}\|\Psi(\mathbf{v}^h - \mathbf{v})\|^2_{L^2(\Omega)} &\preceq \|\mathbf{v}^h - \mathbf{v}\|^2_{H^{-1}(\Omega)^2},\\ |\Psi(\mathbf{v}^h - \mathbf{v})|^2_{H^2(\Omega)} &\preceq \|\mathbf{v}^h - \mathbf{v}\|^2_{H^1(\Omega)^2}.\end{aligned}$$

Assumption 3 on page 213 implies that

$$\begin{aligned}\|\mathbf{v}^h - \mathbf{v}\|^2_{H^{-1}(\Omega)^2} &\preceq h^4\|\mathbf{v}\|^2_{H^1(\Omega)^2},\\ \|\mathbf{v}^h - \mathbf{v}\|^2_{H^1(\Omega)^2} &\preceq \|\mathbf{v}\|^2_{H^1(\Omega)^2}.\end{aligned}$$

Consequently

$$\|\boldsymbol{\rho}^n\Psi(\mathbf{v}^h) - \boldsymbol{\rho}^n\Psi(\mathbf{v})\|_n^2 \preceq (h^4 + d^4)\|\mathbf{v}\|_{H^1(\Omega)^2}^2. \qquad \square$$

Lemma 6.5 ($H^1(\Omega)^2$ norm equivalence). *Suppose that our finite element spaces satisfy Assumption* 1 *and our data satisfies Assumption* 5. *Then there exists a constant* $C_1 > 1$ *such that for* $h > C_1\, d$ *and for* $\mathbf{v} \in H^1(\Omega)^2$

$$\|\mathbf{v}\|_{H^1(\Omega)^2}^2 \preceq \|\boldsymbol{\rho}^n\Psi^h(\mathbf{v})\|_n^2 + |\mathbf{v}|_{H^1(\Omega)^2}^2,$$

where the implied constant is independent of the data points.

Proof. In the previous section we proved this result for a fixed choice of data points. Now we want to show that the constant is independent of the data points, provided that they satisfy our "uniformly spread" assumption, Assumption 5.

We know that

$$\|\mathbf{v}\|_{H^1(\Omega)^2}^2 \preceq c_1^2 + c_2^2 + |\mathbf{v}|_{H^1(\Omega)^2}^2,$$

where $c_1 = \int_\Omega v_1 \, d\mathbf{x}$ and $c_2 = \int_\Omega v_2 \, d\mathbf{x}$. By explicit calculation,

$$c_1^2 + c_2^2 \preceq \int_\Omega (c_1\mathrm{x}_1 + c_2\mathrm{x}_2)^2 d\mathbf{x}.$$

Lemma 6.2 implies that

$$\int_\Omega (c_1\mathrm{x}_1 + c_2\mathrm{x}_2)^2 d\mathbf{x} = \|c_1\mathrm{x}_1 + c_2\mathrm{x}_2\|_{L^2(\Omega)}^2 \preceq \|\boldsymbol{\rho}^n\Psi^h((c_1, c_2))\|_n^2$$

since the function $c_1\mathrm{x}_1 + c_2\mathrm{x}_2$ is linear and so $\|c_1\mathrm{x}_1 + c_2\mathrm{x}_2\|_{H^2(\Omega)} = 0$. Using a similar argument as in (5.11), we conclude that

$$\|\boldsymbol{\rho}^n\Psi^h((c_1, c_2))\|_n^2 \preceq \|\boldsymbol{\rho}^n\Psi^h(\mathbf{v})\|_n^2 + |\mathbf{v}|_{H^1(\Omega)^2}^2.$$

Consequently

$$c_1^2 + c_2^2 \preceq \|\boldsymbol{\rho}^n\Psi^h(\mathbf{v})\|_n^2 + |\mathbf{v}|_{H^1(\Omega)^2}^2,$$

and so

$$\|\mathbf{v}\|_{H^1(\Omega)^2}^2 \preceq \|\boldsymbol{\rho}^n\Psi^h(\mathbf{v})\|_n^2 + |\mathbf{v}|_{H^1(\Omega)^2}^2. \qquad \square$$

Lemma 6.6 (Energy orthogonality). *For any* $\mathbf{y} \in \mathbb{R}^n$,

1. *For all* $s \in H^2(\Omega)$

$$\bar{J}_\alpha(s, \mathbf{y}) = \bar{J}_\alpha(\bar{s}_\alpha(\mathbf{y}), \mathbf{y}) + \bar{a}_\alpha(\bar{s}_\alpha(\mathbf{y}) - s, \bar{s}_\alpha(\mathbf{y}) - s).$$

2. *For all* $\mathbf{v} \in H^1(\Omega)^2$

$$J_\alpha(\mathbf{v}, \mathbf{y}) = J_\alpha(\mathbf{u}_\alpha(\mathbf{y}), \mathbf{y}) + a_\alpha(\mathbf{u}_\alpha(\mathbf{y}) - \mathbf{v}, \mathbf{u}_\alpha(\mathbf{y}) - \mathbf{v}).$$

3. *For all* $\mathbf{v}^h \in \mathbb{V}^h \times \mathbb{V}^h$

$$J_\alpha^h(\mathbf{v}^h, \mathbf{y}) = J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{y}), \mathbf{y}) + a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{y}) - \mathbf{v}^h, \mathbf{u}_\alpha^h(\mathbf{y}) - \mathbf{v}^h).$$

Proof. Expand $\bar{J}_\alpha(s - \bar{s}_\alpha(\mathbf{y}) + \bar{s}_\alpha(\mathbf{y}), \mathbf{y})$, $J_\alpha(\mathbf{v} - \mathbf{u}_\alpha(\mathbf{y}) + \mathbf{u}_\alpha(\mathbf{y}), \mathbf{y})$, and $J_\alpha^h(\mathbf{v}^h - \mathbf{u}_\alpha^h(\mathbf{y}) + \mathbf{u}_\alpha^h(\mathbf{y}), \mathbf{y})$, and use (5.1), (5.2), and (5.3), respectively, to eliminate cross terms. $\square$

7. Convergence of the method. In this section we will prove the main convergence result, Theorem 3.2. For a function $f \in H^2(\Omega)$, we will use the notation $\mathbf{u}_\alpha(f)$ to denote $\mathbf{u}_\alpha(\boldsymbol{\rho}^n f)$. Similarly we define $\mathbf{u}_\alpha^h(f)$, $s_\alpha(f)$, and $s_\alpha^h(f)$.

Recall that we assume that the response values satisfy Assumption 4 on page 213, namely,

$$\mathbf{y} = \boldsymbol{\rho}^n f + \boldsymbol{\nu},$$

where $\boldsymbol{\nu} = [\nu^{(1)} \ \cdots \ \nu^{(n)}]^T$ and the $\nu^{(i)}$'s are independent identically distributed random variables with zero mean and variance σ^2.

It is clear that $\mathbf{u}_\alpha^h$ and s_α^h are linear operators, and so

$$\begin{aligned} \mathbf{u}_\alpha^h(\mathbf{y}) &= \mathbf{u}_\alpha^h(f) + \mathbf{u}_\alpha^h(\boldsymbol{\nu}), \\ s_\alpha^h(\mathbf{y}) &= s_\alpha^h(f) + s_\alpha^h(\boldsymbol{\nu}). \end{aligned}$$

We want to measure how well $s_\alpha^h(\mathbf{y})$ approximates f. Using the linearity of the operators, we can separate the errors into those due to bias and those due to variance. In particular we have

$$\|s_\alpha^h(\mathbf{y}) - f\|_{L^2(\Omega)} \le \|s_\alpha^h(f) - f\|_{L^2(\Omega)} + \|s_\alpha^h(\boldsymbol{\nu})\|_{L^2(\Omega)}, \tag{7.1}$$

$$|s_\alpha^h(\mathbf{y}) - f|_{H^1(\Omega)} \le |s_\alpha^h(f) - f|_{H^1(\Omega)} + |s_\alpha^h(\boldsymbol{\nu})|_{H^1(\Omega)}, \tag{7.2}$$

$$\|\mathbf{u}_\alpha^h(\mathbf{y})\|_{H^1(\Omega)} \le \|\mathbf{u}_\alpha^h(f)\|_{H^1(\Omega)} + \|\mathbf{u}_\alpha^h(\boldsymbol{\nu})\|_{H^1(\Omega)}. \tag{7.3}$$

To produce our estimates we will use the following result proved by Utreras for the exact thin plate spline.

THEOREM 7.1 (see Utreras [28, equations (6.2) and (6.4)]). *Suppose that the data satisfies Assumptions* 4 *and* 5. *Then there exists a constant* $\alpha_0 > 0$ *such that*

$$E\bar{a}_\alpha(\bar{s}(\boldsymbol{\nu}), \bar{s}(\boldsymbol{\nu})) \preceq \sigma^2 \frac{d^2}{\alpha^{1/2}} \tag{7.4}$$

for $d^4 < \alpha < \alpha_0$.

Note that we have written the bound in terms of d instead of n by using the result $n^{-1} \preceq d^2$.

Throughout this section we will be making the same basic assumption about the allowed range of values for h and α. We quantify this assumption as follows.

ASSUMPTION 6 (Constraints on h and α). *Let* C_1 *and* α_0 *be the constants introduced in Proposition* 3.1 *and Theorem* 7.1, *respectively. We assume that* h *and* α *satisfy* $h > C_1\, d$ *and* $d^4 + h^4 < \alpha < \alpha_0$.

We can now prove convergence of our method by first looking at exact data (the bias term) and then estimating the variance.

7.1. Exact response variable data. We deal first with the error for exact data. Using an argument almost identical to that found in Utreras [28, Theorem 4.1], we will show that the value of the functional $J_\alpha^h(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f)$ can be controlled by the smoothness of the underlying model function f.

PROPOSITION 7.2 (Energy bound). *Let the finite element spaces satisfy Assumptions* 1, 2, *and* 3, *the data satisfy Assumptions* 4 *and* 5, *and* h *and* α *satisfy Assumption* 6. *Then for all* $f \in H^2(\Omega)$

$$J_\alpha^h(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) \preceq (\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}.$$

Proof. Let $\mathbf{v} = \boldsymbol{\nabla} f$. Then $f = \Phi(\mathbf{v}, \boldsymbol{\rho}^n f)$. Let $\mathbf{v}^h = Q^h \mathbf{v}$. As $\mathbf{u}_\alpha^h(f)$ is the minimizer of $J_\alpha^h(\cdot, \boldsymbol{\rho}^n f)$, we conclude that

$$J_\alpha^h(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) \le J_\alpha^h(\mathbf{v}^h, \boldsymbol{\rho}^n f).$$

Now

$$\begin{aligned} J_\alpha^h(\mathbf{v}^h, \boldsymbol{\rho}^n f) &= \|\boldsymbol{\rho}^n \Phi^h(\mathbf{v}^h, \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 + \alpha |\mathbf{v}^h|_{H^1(\Omega)^2}^2 \\ &\preceq \|\boldsymbol{\rho}^n \Phi^h(\mathbf{v}^h, \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n \Phi(\mathbf{v}, \boldsymbol{\rho}^n f)\|_n^2 \\ &\quad + \|\boldsymbol{\rho}^n \Phi(\mathbf{v}, \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 + \alpha |\mathbf{v}^h|_{H^1(\Omega)^2}^2 \\ &\preceq \|\boldsymbol{\rho}^n \Psi^h(\mathbf{v}^h) - \boldsymbol{\rho}^n \Psi(\mathbf{v})\|_n^2 \\ &\quad + \|\boldsymbol{\rho}^n \Phi(\mathbf{v}, \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 + \alpha |\mathbf{v}^h|_{H^1(\Omega)^2}^2. \end{aligned}$$

Using Lemmas 6.3 and 6.4, a simple triangle inequality argument bounds the first term, namely,

$$\begin{aligned} \|\boldsymbol{\rho}^n \Psi^h(\mathbf{v}^h) - \boldsymbol{\rho}^n \Psi(\mathbf{v})\|_n^2 &\preceq \|\boldsymbol{\rho}^n \Psi^h(\mathbf{v}^h) - \boldsymbol{\rho}^n \Psi(\mathbf{v}^h)\|_n^2 + \|\boldsymbol{\rho}^n \Psi(\mathbf{v}^h) - \boldsymbol{\rho}^n \Psi(\mathbf{v})\|_n^2 \\ &\preceq (h^4 + d^4)[\|\mathbf{v}^h\|_{H^1(\Omega)^2}^2 + \|\mathbf{v}\|_{H^1(\Omega)^2}^2] \\ &\preceq (h^4 + d^4)\|\mathbf{v}\|_{H^1(\Omega)^2}^2. \end{aligned}$$

The term $\|\boldsymbol{\rho}^n \Phi(\mathbf{v}, \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n$ is zero since $\Phi(\mathbf{v}, \boldsymbol{\rho}^n f) = f$. Taking this together, we conclude that

$$\begin{aligned} J_\alpha^h(\mathbf{v}^h, \boldsymbol{\rho}^n f) &\preceq (h^4 + d^4)\|\mathbf{v}\|_{H^1(\Omega)^2}^2 + \alpha |\mathbf{v}^h|_{H^1(\Omega)^2}^2 \\ &\preceq (\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2, \end{aligned}$$

since Assumption 2 and the triangle inequality imply that

$$\|\mathbf{v}^h\|_{H^1(\Omega)^2} \preceq \|\mathbf{v}\|_{H^1(\Omega)^2},$$

and, by the definition of $\mathbf{v}$,

$$\|\mathbf{v}\|_{H^1(\Omega)^2} = \|\boldsymbol{\nabla} f\|_{H^1(\Omega)^2} \le \|f\|_{H^2(\Omega)}. \qquad \square$$

We have proved that

$$\|\boldsymbol{\rho}^n s_\alpha^h(f) - \boldsymbol{\rho}^n f\|_n^2 + \alpha |\mathbf{u}_\alpha^h(f)|_{H^1(\Omega)^2}^2 \preceq (\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2.$$

Now we can obtain $L^2(\Omega)$ and $H^1(\Omega)$ norm estimates for the error for exact data.

THEOREM 7.3 (Convergence: exact data). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and* h *and* α *satisfy Assumption* 6. *Then for all* $f \in H^2(\Omega)$

$$\|s_\alpha^h(f) - f\|_{L^2(\Omega)}^2 \preceq (\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2, \tag{7.5}$$

$$|s_\alpha^h(f) - f|_{H^1(\Omega)}^2 \preceq \frac{1}{\alpha^{1/2}}(\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2, \tag{7.6}$$

$$\|\mathbf{u}_\alpha^h(f)\|_{H^1(\Omega)^2}^2 \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2. \tag{7.7}$$

Proof. First we prove (7.7). Proposition 7.2 implies that

$$|\mathbf{u}_\alpha^h(f)|_{H^1(\Omega)^2}^2 \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|_{H^2(\Omega)}^2 \tag{7.8}$$

and

$$\|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 \preceq (\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}. \tag{7.9}$$

Lemma 6.5, together with (7.8), provides the bound

$$\begin{aligned}\|\mathbf{u}^h_\alpha(f)\|^2_{H^1(\Omega)^2} &\preceq \|\boldsymbol{\rho}^n \Psi^h(\mathbf{u}^h(f))\|_n^2 + |\mathbf{u}^h_\alpha(f)|^2_{H^1(\Omega)^2}\\ &\preceq \|\boldsymbol{\rho}^n \Psi^h(\mathbf{u}^h(f))\|_n^2 + \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}.\end{aligned}$$

Using the bound (7.9), the Sobolev inequality (which implies that the pointwise norm $\|\boldsymbol{\rho}^n \cdot\|_n$ is bounded by the norm $\|\cdot\|_{H^2(\Omega)}$) and a triangle inequality estimate give us

$$\begin{aligned}\|\boldsymbol{\rho}^n \Psi^h(\mathbf{u}^h(f))\|_n^2 &\preceq \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}^h(f), \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f - \langle \boldsymbol{\rho}^n f, \mathbf{e}\rangle_n \mathbf{e} + \boldsymbol{\rho}^n f\|_n^2\\ &\preceq \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}^h(f), \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 + \|\langle \boldsymbol{\rho}^n f, \mathbf{e}\rangle_n \mathbf{e}\|_n^2 + \|\boldsymbol{\rho}^n f\|_n^2\\ &\preceq (\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)} + \|\boldsymbol{\rho}^n f\|_n^2 \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}.\end{aligned}$$

Consequently

$$\|\mathbf{u}^h_\alpha(f)\|^2_{H^1(\Omega)^2} \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}.$$

Equation (7.5) follows from Lemma 6.2,

$$\begin{aligned}&\|s^h_\alpha(f) - f\|^2_{L^2(\Omega)} = \|\Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f\|^2_{L^2(\Omega)}\\ &\qquad\preceq \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - \boldsymbol{\rho}^n f\|_n^2 + d^4 \sum_{K \in \mathcal{T}^h} |\Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f|^2_{H^2(K)},\end{aligned}$$

which by (7.9) and the triangle inequality implies

$$\begin{aligned}&\preceq (\alpha + h^4 + d^4)\alpha\|f\|^2_{H^2(\Omega)} + d^4 \sum_{K \in \mathcal{T}^h} \Big[|\Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f)|^2_{H^2(K)} + |f|^2_{H^2(K)}\Big]\\ &\preceq (\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)},\end{aligned}$$

since by (5.8)

$$\sum_{K \in \mathcal{T}^h} |\Psi^h(\mathbf{u}^h_\alpha(f))|^2_{H^2(K)} \preceq \|\Psi(\mathbf{u}^h_\alpha(f))\|^2_{H^2(\Omega)} \preceq \|f\|^2_{H^2(\Omega)}.$$

Finally, (7.6) will follow from an interpolation result which estimates the H^1 norm of $s^h_\alpha(f) - f$ by use of the preceding L^2 estimate and an H^2 estimate. Unfortunately $s^h_\alpha(f) = \Phi^h(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f)$ is not in $H^2(\Omega)$. On the other hand, $\Phi(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f)$ is in $H^2(\Omega)$. We will first use an interpolation result to estimate $|\Phi(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f|^2_{H^1(\Omega)}$ in terms of $\|\Phi(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f\|^2_{L^2(\Omega)}$ and $|\Phi(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f|^2_{H^2(\Omega)}$. Now

$$\begin{aligned}&\|\Phi(\mathbf{u}^h_\alpha(f), \boldsymbol{\rho}^n f) - f\|^2_{L^2(\Omega)}\\ &\preceq \|\Psi(\mathbf{u}^h_\alpha(f)) - \Psi^h(\mathbf{u}^h_\alpha(f))\|^2_{L^2(\Omega)} + \|s^h_\alpha(f) - f\|^2_{L^2(\Omega)}\\ &\preceq (\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}\end{aligned}$$

and

$$|\Phi(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) - f|^2_{H^2(\Omega)} \preceq \frac{1}{\alpha}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}.$$

An interpolation estimate (see, for example, [1, Theorem 4.14]) then implies that

$$|\Phi(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) - f|^2_{H^1(\Omega)} \preceq \frac{1}{\alpha^{1/2}}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)}.$$

Now we can estimate the quantity $|\Phi^h(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) - f|^2_{H^1(\Omega)}$. Equation (5.7), together with the previous estimate, implies that

$$\begin{aligned} |s_\alpha^h(f) - f|^2_{H^1(\Omega)} &= |\Phi^h(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) - f|^2_{H^1(\Omega)} \\ &\preceq |\Psi^h(\mathbf{u}_\alpha^h(f)) - \Psi(\mathbf{u}_\alpha^h(f))|^2_{H^1(\Omega)} + |\Phi(\mathbf{u}_\alpha^h(f), \boldsymbol{\rho}^n f) - f|^2_{H^1(\Omega)} \\ &\preceq \left(h^2 + \frac{1}{\alpha^{1/2}}(\alpha + h^4 + d^4)\right)\|f\|^2_{H^2(\Omega)} \\ &\preceq \frac{1}{\alpha^{1/2}}(\alpha + h^4 + d^4)\|f\|^2_{H^2(\Omega)} \end{aligned}$$

(since $h^2 < \alpha^{1/2}$), which provides the required $H^1(\Omega)$ seminorm estimate for $s_\alpha^h(f) - f$. □

7.2. Variance of the error. We will now bound

$$E|s^h(\mathbf{u}^h(\boldsymbol{\nu}))|^2_{L^2(\Omega)}, \quad E|s^h(\mathbf{u}^h(\boldsymbol{\nu}))|^2_{H^1(\Omega)}, \quad \text{and} \quad E|\mathbf{u}^h(\boldsymbol{\nu})|^2_{H^1(\Omega)},$$

the expected error due to the random part of the response variable data.

The idea is to use Utreras' result for the thin plate spline, namely Theorem 7.1, and in particular the bound (7.4), to bound $Ea_\alpha^h(\mathbf{u}^h(\boldsymbol{\nu}), \mathbf{u}^h(\boldsymbol{\nu}))$. Observe that $\boldsymbol{\nu} = \sum_{k=1}^n \nu^{(k)}\mathbf{e}_k$, where $\mathbf{e}_k$ is the kth coordinate vector. Using this expansion, we observe that

$$\begin{aligned} a_\alpha^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \mathbf{u}_\alpha^h(\boldsymbol{\nu})) &= a^h\left(\sum_{k=1}^n \nu^{(k)}\mathbf{u}_\alpha^h(\mathbf{e}_k), \sum_{j=1}^n \nu^{(j)}\mathbf{u}_\alpha^h(\mathbf{e}_k)\right) \\ &= \sum_{k,j=1}^n \nu^{(k)}\nu^{(j)} a^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{u}_\alpha^h(\mathbf{e}_j)). \end{aligned}$$

Hence

$$\begin{aligned} Ea_\alpha^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \mathbf{u}_\alpha^h(\boldsymbol{\nu})) &= \sum_{k,j=1}^n E(\nu^{(k)}\nu^{(j)}) a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{u}_\alpha^h(\mathbf{e}_j)) \\ &= \sum_{k=1}^n \sigma^2 a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{u}_\alpha^h(\mathbf{e}_k)) \end{aligned} \tag{7.10}$$

since the $\nu^{(k)}$ are independent random variables with zero mean and variance σ^2. Similarly the thin plate spline function $\bar{s}_\alpha(\boldsymbol{\nu})$ satisfies

$$E\bar{a}_\alpha(\bar{s}_\alpha(\boldsymbol{\nu}), \bar{s}_\alpha(\boldsymbol{\nu})) = \sum_k^n \sigma^2 \bar{a}_\alpha(\bar{s}_\alpha(\mathbf{e}_k), \bar{s}_\alpha(\mathbf{e}_k)). \tag{7.11}$$

We will bound $a^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{u}^h_\alpha(\mathbf{e}_k))$ in terms of $\bar{a}_\alpha(\bar{s}_\alpha(\mathbf{e}_k), \bar{s}_\alpha(\mathbf{e}_k))$. To do this, note that

$$\begin{aligned} \frac{1}{n} - \frac{1}{n^2} &= \|\mathbf{e}_k - \langle \mathbf{e}_k, \mathbf{e}\rangle_n \mathbf{e}\|_n^2 \\ &= \bar{J}(\bar{s}_\alpha(\mathbf{e}_k), \mathbf{e}_k) + \bar{a}_\alpha(\bar{s}_\alpha(\mathbf{e}_k), \bar{s}_\alpha(\mathbf{e}_k)) \\ &= J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) + a_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{u}_\alpha(\mathbf{e}_k)) \\ &= J^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{e}_k) + a^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{u}^h_\alpha(\mathbf{e}_k)). \end{aligned} \tag{7.12}$$

This follows from Lemma 6.6 with $s = \langle \mathbf{e}_k, \mathbf{e}\rangle_n$ and $\mathbf{v} = \mathbf{v}^h = 0$. Essentially (7.12) shows that a result like

$$a^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{u}^h_\alpha(\mathbf{e}_k)) \le \bar{a}_\alpha(\bar{s}_\alpha(\mathbf{e}_k), \bar{s}_\alpha(\mathbf{e}_k))$$

holds if an opposite inequality of the form

$$\bar{J}_\alpha(\bar{s}_\alpha(\mathbf{e}_k), \mathbf{e}_k) \le J^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{e}_k)$$

holds. In fact we will be able to prove the following slightly weaker results.

LEMMA 7.4 (Energy bound). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and h and α satisfy Assumption* 6. *Then*

$$J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) \le \left(1 + \frac{h^2}{\alpha^{1/2}}\right) J^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{e}_k) + \frac{C_1}{n\alpha^{1/2}} \frac{(h^4 + d^4)}{h^2}$$

for some constant C_1 independent of h, d, and α.

LEMMA 7.5 (Thin plate spline lower bound). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and h and α satisfy Assumption* 6. *Then there exists a constant $C_2 > 0$ such that for $\alpha' = C_2\alpha$*

$$\bar{J}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \mathbf{e}_k) \le J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k).$$

Before proving these lemmas, let us use them to show the following.

PROPOSITION 7.6 (Thin plate spline bound). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and h and α satisfy Assumption* 6. *Then there exists a constant $C_2 > 0$ such that for $\alpha' = C_2\alpha$*

$$a^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{u}^h_\alpha(\mathbf{e}_k)) \le \bar{a}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \bar{s}_{\alpha'}(\mathbf{e}_k)) + \frac{C_3}{n\alpha^{1/2}} \frac{(h^4 + d^4)}{h^2}$$

for some constant C_3.

Proof. Combining (7.12), Lemma 7.4, and Lemma 7.5, we conclude that

$$\begin{aligned} &\left(1 + \frac{h^2}{\alpha^{1/2}}\right) a^h_\alpha(\mathbf{u}^h_\alpha(\mathbf{e}_k), \mathbf{u}^h_\alpha(\mathbf{e}_k)) \\ &\le \bar{a}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \bar{s}_{\alpha'}(\mathbf{e}_k)) + \left(\frac{1}{n} - \frac{1}{n^2}\right)\left(\frac{h^2}{\alpha^{1/2}}\right) + \frac{C_1}{n\alpha^{1/2}} \frac{(h^4 + d^4)}{h^2}, \end{aligned}$$

where C_1 is defined in Lemma 7.4. Our assumption on h ensures that $h > d$. So we conclude that for $C_3 = C_1 + 1$,

$$a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{u}_\alpha^h(\mathbf{e}_k)) \leq \bar{a}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \bar{s}_{\alpha'}(\mathbf{e}_k)) + \frac{C_3}{n\alpha^{1/2}}\frac{(h^4+d^4)}{h^2},$$

as required. □

Now we can estimate $Ea_\alpha^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \mathbf{u}_\alpha^h(\boldsymbol{\nu}))$.

Theorem 7.7 (Energy norm convergence: random data). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and h and α satisfy Assumption* 6. *Then*

$$Ea_\alpha^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \mathbf{u}_\alpha^h(\boldsymbol{\nu})) \preceq \frac{\sigma^2}{\alpha^{1/2}}\frac{(h^4+d^4)}{h^2}.$$

Proof. By summing the inequalities in the statement of Proposition 7.6 over k and noting (7.10) and (7.11), we arrive at the conclusion that

$$Ea_\alpha^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \mathbf{u}_\alpha^h(\boldsymbol{\nu})) \leq E\bar{a}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \bar{s}_{\alpha'}(\mathbf{e}_k)) + \frac{C_3\sigma^2}{\alpha^{1/2}}\frac{(h^4+d^4)}{h^2}.$$

Equation (7.4) then implies that there exists a constant C_4 such that

$$E\bar{a}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \bar{s}_{\alpha'}(\mathbf{e}_k)) \leq C_4\sigma^2\frac{d^2}{\alpha'^{1/2}} \leq \frac{C_4\sigma^2}{C_2^{1/2}\alpha^{1/2}}d^2 \preceq \frac{\sigma^2}{\alpha^{1/2}}\frac{(h^4+d^4)}{h^2}.$$

Putting this together, the required result is obtained. □

Note that we have proved that

$$E(\|\boldsymbol{\rho}^n\Psi^h(\mathbf{u}_\alpha^h(\boldsymbol{\nu}))\|_n^2 + \alpha|\mathbf{u}_\alpha^h(\boldsymbol{\nu})|_{H^1(\Omega)^2}^2) \preceq \frac{\sigma^2}{\alpha^{1/2}}\frac{(h^4+d^4)}{h^2}.$$

We can now obtain $L^2(\Omega)$ and $H^1(\Omega)$ estimates of the error.

Theorem 7.8 (Convergence: random data). *We suppose that our finite element spaces satisfy Assumptions* 1, 2, *and* 3, *our data satisfies Assumptions* 4 *and* 5, *and h and α satisfy Assumption* 6. *Then*

$$\begin{aligned} E\|s_\alpha^h(\boldsymbol{\nu})\|_{L^2(\Omega)}^2 &\preceq \frac{\sigma^2}{\alpha^{1/2}}\frac{(h^4+d^4)}{h^2}, \\ E|s_\alpha^h(\boldsymbol{\nu})|_{H^1(\Omega)}^2 &\preceq \frac{\sigma^2}{\alpha}\frac{(h^4+d^4)}{h^2}, \\ E\|\mathbf{u}_\alpha^h(\boldsymbol{\nu})\|_{H^1(\Omega)^2}^2 &\preceq \frac{\sigma^2}{\alpha^{3/2}}\frac{(h^4+d^4)}{h^2}. \end{aligned}$$

Proof. Just as in the proof of Theorem 7.3, we can use Lemma 6.2 to obtain an $L^2(\Omega)$ estimate from the pointwise error provided by Theorem 7.7. The $H^1(\Omega)$ estimate of $\mathbf{u}_\alpha^h(\boldsymbol{\nu})$ also follows from Theorem 7.7. Finally the $H^1(\Omega)$ estimate of $s_\alpha^h(\boldsymbol{\nu})$ follows from an interpolation result based on the $L^2(\Omega)$ and an $H^2(\Omega)$ estimate of $s(\mathbf{u}_\alpha^h(\boldsymbol{\nu}), \boldsymbol{\nu})$. See the proof of (7.6) in Theorem 7.3 for a similar argument. □

The proof of Theorem 3.2 now follows simply from Theorems 7.3 and 7.8 and the bounds provided by (7.1), (7.2), and (7.3).

7.3. Proof of Lemma 7.4. Finally we return to the proof of Lemma 7.4, which quantifies the difference between $J_\alpha(\cdot, \mathbf{e}_k)$ and $J_\alpha^h(\cdot, \mathbf{e}_k)$ at their respective minimizers.

Now

$$\begin{aligned} J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) &\le J_\alpha(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) \\ &\le J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) + \|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 \\ &\quad - \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2. \end{aligned}$$

Elementary manipulations and the Cauchy-Schwarz inequality imply that

$$\begin{aligned} &\|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 - \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 \\ &= \|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k)\|_n^2 \\ &\quad - 2\langle \boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k), \boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\rangle_n. \end{aligned}$$

The geometric, arithmetic mean inequality implies that for any $0 < \epsilon < 1$

$$\langle \mathbf{v}, \mathbf{w}\rangle_n \le \|\mathbf{v}\|_n \|\mathbf{w}\|_n \le \frac{\epsilon^{-1}}{2}\|\mathbf{v}\|_n^2 + \frac{\epsilon}{2}\|\mathbf{w}\|_n^2.$$

Consequently

$$\begin{aligned} &\|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 - \|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 \\ &\le (1+\epsilon^{-1})\|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k)\|_n^2 \\ &\quad + \epsilon\|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2. \end{aligned}$$

Since $\|\boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|_n^2 \le J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k)$, we conclude that

$$\begin{aligned} J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) &\le (1+\epsilon) J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) \\ &\quad + (1+\epsilon^{-1})\|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) - \boldsymbol{\rho}^n \Phi^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k)\|_n^2 \\ &\le (1+\epsilon) J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) + 2\epsilon^{-1}(h^4 + d^4)\|\mathbf{u}_\alpha^h(\mathbf{e}_k)\|_{H^1(\Omega)^2}^2 \\ &\le (1+\epsilon) J_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{e}_k) + 2\epsilon^{-1}\frac{(h^4 + d^4)}{n\alpha}. \end{aligned}$$

The last inequality follows from (7.12) since

$$\alpha\|\mathbf{u}_\alpha^h(\mathbf{e}_k)\|_{H^1(\Omega)^2}^2 \le a_\alpha^h(\mathbf{u}_\alpha^h(\mathbf{e}_k), \mathbf{u}_\alpha^h(\mathbf{e}_k)) \le \frac{1}{n}.$$

Finally we choose $\epsilon = h^2/(\alpha^{1/2})$ to obtain the required estimate.

7.4. Proof of Lemma 7.5. Next we compare the functionals $\bar{J}_\alpha$ and J_α. First consider the following decomposition of a function in $H^1(\Omega)^2$. A $\mathbf{u} \in H^1(\Omega)^2$ can be decomposed into gradient and curl components via

$$\mathbf{u} = V(\mathbf{u}) + W(\mathbf{u}),$$

where $\mathbf{v} = V(\mathbf{u})$ satisfies

$$\begin{aligned} \boldsymbol{\nabla} \cdot \mathbf{v} &= \boldsymbol{\nabla} \cdot \mathbf{u} && \text{in } \Omega, \\ \boldsymbol{\nabla} \times \mathbf{v} &= 0 && \text{in } \Omega, \\ \mathbf{v} \cdot \mathbf{n} &= \mathbf{u} \cdot \mathbf{n} && \text{on } \partial\Omega, \end{aligned}$$

and $\mathbf{w} = W(\mathbf{u})$ satisfies

$$\begin{aligned} \boldsymbol{\nabla} \times \mathbf{w} &= \boldsymbol{\nabla} \times \mathbf{u} && \text{in } \Omega, \\ \boldsymbol{\nabla} \cdot \mathbf{w} &= 0 && \text{in } \Omega, \\ \mathbf{w} \cdot \mathbf{n} &= 0 && \text{on } \partial\Omega. \end{aligned}$$

It is possible to show that there exists a constant $C_2 > 0$ such that

$$|V(\mathbf{u})|^2_{H^1(\Omega)^2} + |W(\mathbf{u})|^2_{H^1(\Omega)^2} \leq \frac{1}{C_2} |\mathbf{u}|^2_{H^1(\Omega)^2}.$$

If we let $\alpha' = C_2 \alpha$, then

$$\bar{J}_{\alpha'}(\bar{s}_{\alpha'}(\mathbf{e}_k), \mathbf{e}_k) \leq J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k). \tag{7.13}$$

Let $s' = \bar{s}_{\alpha'}(\mathbf{e}_k)$ and $\mathbf{u}' = \boldsymbol{\nabla} s'$. Note that $V(\mathbf{u}') = \boldsymbol{\nabla} s'$ and $W(\mathbf{u}') = 0$ and $\Phi(\mathbf{u}', \mathbf{e}_k) = s'$. Now (7.13) follows from

$$\begin{aligned} \bar{J}_{\alpha'}(s', \mathbf{e}_k) &= \|\boldsymbol{\rho}^n s' - \mathbf{e}_k\|^2_n + \alpha' |s'|^2_{H^2(\Omega)} \\ &= \|\boldsymbol{\rho}^n \Phi(\mathbf{u}', \mathbf{e}_k) - \mathbf{e}_k\|^2_n + \alpha' |V(\mathbf{u}')|^2_{H^1(\Omega)^2} + \alpha' |W(\mathbf{u}')|^2_{H^1(\Omega)^2} \\ &\leq \|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|^2_n + \alpha' |V(\mathbf{u}_\alpha(\mathbf{e}_k))|^2_{H^1(\Omega)^2} + \alpha' |W(\mathbf{u}_\alpha(\mathbf{e}_k))|^2_{H^1(\Omega)^2} \\ &\leq \|\boldsymbol{\rho}^n \Phi(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k) - \mathbf{e}_k\|^2_n + \alpha |\mathbf{u}_\alpha(\mathbf{e}_k)|^2_{H^1(\Omega)^2} \\ &= J_\alpha(\mathbf{u}_\alpha(\mathbf{e}_k), \mathbf{e}_k). \end{aligned}$$

Here we have used the fact that $\mathbf{u}' = \boldsymbol{\nabla} s'$ will be the minimizer of the functional

$$M_{\alpha'}(\mathbf{u}, \mathbf{e}_k) = \|\boldsymbol{\rho}^n \Phi(\mathbf{u}, \mathbf{e}_k) - \mathbf{e}_k\|^2_n + \alpha' |V(\mathbf{u})|^2_{H^1(\Omega)^2} + \alpha' |W(\mathbf{u})|^2_{H^1(\Omega)^2}$$

over $H^1(\Omega)^2$.

It should be noted that the functional $M_\alpha(\cdot, \mathbf{y})$ provides an alternative method for approximating a thin plate spline, the disadvantage being the need to have an auxiliary vector function $\mathbf{w}(\mathbf{u})$ (or $\mathbf{v}(\mathbf{u})$). On the other hand, we do intend to analyze this alternative method in a future paper and compare it to the method discussed here.

8. Conclusions. We have introduced a finite element method which provides a flexible and practical tool for smoothing as well as surface fitting. It is a scalable method in the sense that the size of the data set does not affect the overall size of the system obtained from the discretization of the equations. The assembly of the finite element matrices involves only a single scan of the data set. We have demonstrated that the method can be used to provide data fits of very large data sets, providing results similar to those obtained by standard thin plate splines. Additionally, the TPSFEM method as described can easily be generalized to three dimensions.

VARIATIONAL MESH ADAPTATION METHODS FOR AXISYMMETRICAL PROBLEMS*

WEIMING CAO†, RICARDO CARRETERO-GONZÁLEZ‡, WEIZHANG HUANG§, AND ROBERT D. RUSSELL¶

Abstract. We study variational mesh adaptation for axially symmetric solutions to two-dimensional problems. The study is focused on the relationship between the mesh density distribution and the monitor function and is carried out for a traditional functional that includes several widely used variational methods as special cases and a recently proposed functional that allows for a weighting between mesh isotropy (or regularity) and global equidistribution of the monitor function. The main results are stated in Theorems 4.1 and 4.2. For axially symmetric problems, it is natural to choose axially symmetric mesh adaptation. To this end, it is reasonable to use the monitor function in the form $G = \lambda_1(r)\boldsymbol{e}_r\boldsymbol{e}_r^T + \lambda_2(r)\boldsymbol{e}_\theta\boldsymbol{e}_\theta^T$, where $\boldsymbol{e}_r$ and $\boldsymbol{e}_\theta$ are the radial and angular unit vectors.

It is shown that when higher mesh concentration at the origin is desired, a choice of λ_1 and λ_2 satisfying $\lambda_1(0) < \lambda_2(0)$ will make the mesh denser at $r = 0$ than in the surrounding area whether or not λ_1 has a maximum value at $r = 0$. The purpose can also be served by choosing λ_1 to have a local maximum at $r = 0$ when a Winslow-type monitor function with $\lambda_1(r) = \lambda_2(r)$ is employed. On the other hand, it is shown that the traditional functional provides little control over mesh concentration around a ring $r = r_\lambda > 0$ by choosing λ_1 and λ_2.

In contrast, numerical results show that the new functional provides better control of the mesh concentration through the monitor function. Two-dimensional numerical results are presented to support the analysis.

Key words. mesh adaptation, variational method, mesh regularity, equidistribution

1. Introduction.

Mesh adaptation has become an indispensable tool for use in the numerical solution of PDEs. One of the most widely used approaches for generating adaptive meshes is a variational method. With such a method, meshes are generated as images of a reference mesh through a coordinate transformation between the physical and computational (or logical) domains. The transformation is determined as the minimizer of a functional formulated to measure difficulties in the numerical approximation of the physical solution, typically through a so-called monitor function prescribed by the user to control the mesh adaptation. A variational method often results in an elliptic (PDE) mesh generation system. Such a system generates smooth meshes, allows for full specification of mesh behavior at the boundary, does not propagate boundary singularities into the domain, has less danger of producing mesh overlappings, and can be solved efficiently using many well-developed

algorithms. Moreover, the equidistribution principle, a concept which has been used successfully in one-dimensional mesh adaptation [3], can be naturally extended to multidimensions in the variational framework. Finally, many mesh features, such as orthogonality, smoothness, and concentration, can be incorporated explicitly into the mesh adaptation functional.

A number of variational methods have been developed in the past. For example, Winslow [15] proposes the variable diffusion method for which the mesh lines play the role of equipotentials of a potential problem [14]. Brackbill and Saltzman [1] develop a popular method combining mesh concentration, smoothness, and orthogonality. Several functionals are formulated by Steinberg and Roache [13] to control mesh properties such as the spacing of the points, areas or volumes of the cells, and the angles between mesh lines. Dvinsky [4] uses the energy of harmonic mappings as his mesh adaptation functional. Knupp [9, 10] and Knupp and Robidoux [11] develop functionals based on the idea of conditioning the Jacobian matrix of the coordinate transformation. A functional balancing mesh regularity and adaptivity is proposed by Huang [6].

Some theoretical work has been devoted to better understanding the existing methods. Cao, Huang, and Russell [2] study the qualitative effect of monitor functions on the resulting mesh for a general class of variational methods that includes Winslow's method [15] and the method using harmonic mappings [4] as special cases. In the recent work of Huang and Sun [8], the monitor function for the functional of [6] is defined based on interpolation error estimates, and asymptotic error bounds are obtained for interpolation on the resulting adaptive meshes satisfying the so-called isotropy and equidistribution conditions. The ability of the resulting method to generate adaptive meshes satisfying these conditions is also demonstrated numerically. Nevertheless, more work remains to be done on better understanding the existing variational methods, especially on precisely how the monitor function controls the concentration of the generated mesh.

In this paper we present such a study for two functionals, the traditional one studied in [2] and the new one proposed in [6], for the simple but important case of two-dimensional problems with axisymmetrical solutions. These types of problems arise in many practical situations, particularly for problems with blowup or quenching solutions. There has been considerable recent interest in solving higher-dimensional blowup problems such as the Schrödinger equation, and this work was motivated by the observation that the standard moving mesh procedures generally perform inadequately on such problems (e.g., see [2, 12]).

Let (x,y) be the coordinates in the physical domain Ω, and let (ξ,η) be the coordinates in the computational domain Ω_c. The traditional functional is

$$I_{trad}[\xi,\eta] = \int_{\Omega} \left(\nabla\xi^T G^{-1}\nabla\xi + \nabla\eta^T G^{-1}\nabla\eta\right) dxdy \tag{1.1}$$

and the new functional in [6] has the form

$$\begin{aligned} I_{new}[\xi,\eta] \quad &= \quad \gamma\int_{\Omega}\sqrt{g}\left(\nabla\xi^T G^{-1}\nabla\xi + \nabla\eta^T G^{-1}\nabla\eta\right)^q dxdy \\ &\quad + (1-2\gamma)2^q\int_{\Omega}\frac{\sqrt{g}}{(J\sqrt{g})^q}dxdy, \end{aligned} \tag{1.2}$$

where $J = x_\xi y_\eta - x_\eta y_\xi$ is the Jacobian of the coordinate transformation, G is the (matrix) monitor function with determinant g, and $q \geq 1$ and $\gamma \in (0, 1/2]$ are parameters. Here, $q \geq 1$ is required in order for the first integral of (1.2) to be convex. The features of these functionals and the roles of the parameters will be discussed in sections 2 and 3.

Axisymmetrical problems. For simplicity, we assume that the physical domain is $\Omega = \{(x, y) \mid x^2 + y^2 < 1\}$ and the computational domain is $\Omega_c = \{(\xi, \eta) \mid \xi^2 + \eta^2 < 1\}$. Let the polar coordinate systems for the physical and computational domains be

$$\begin{cases} x = r\cos\theta, \\ y = r\sin\theta, \end{cases} \qquad \begin{cases} \xi = R\cos\Theta, \\ \eta = R\sin\Theta. \end{cases}$$

Consider the case where the solution $u(x, y)$ is axially symmetric; i.e., u is invariant under rotation about the center $(0, 0)$. It is natural to choose an axially symmetric coordinate transformation

$$R = R(r), \qquad \Theta = \theta \tag{1.3}$$

for mesh adaptation. To this end, it is reasonable to use the monitor function in the form

$$G = \lambda_1(r)\boldsymbol{e}_r\boldsymbol{e}_r^T + \lambda_2(r)\boldsymbol{e}_\theta\boldsymbol{e}_\theta^T, \tag{1.4}$$

where $\boldsymbol{e}_r$ and $\boldsymbol{e}_\theta$ are unit vectors in the radial and angular directions, respectively. Thus, G is determined by its radial and angular components $\lambda_1 > 0$ and $\lambda_2 > 0$.

We are interested in the relationship between the monitor function and the mesh distribution. In particular, we focus on the mesh density $D(r)$. The Jacobian of the coordinate transformation J is easily seen to satisfy

$$\frac{1}{J} \equiv \det\left(\frac{\partial(\xi, \eta)}{\partial(x, y)}\right) = \frac{R}{r}\frac{dR}{dr}, \tag{1.5}$$

and thus the mesh density is given by

$$D(r) = \frac{R}{r}\frac{dR}{dr}. \tag{1.6}$$

The central aim of this paper is to gain insight into how much control one has on the mesh density $D(r)$ by appropriately choosing λ_1 and λ_2. In order for the variational method to be successful one needs that the solution to the variational problem gives a mesh distribution compatible with the chosen monitor function. For example, it is natural to choose one or more of the eigenvalues of the monitor function to have a higher value (a maximum) in the region where a physical solution needs a high concentration of mesh points; e.g., see [2]. It will become clear below that this is not always achievable and that if one is not careful in choosing the appropriate relation between λ_1 and λ_2 it is possible for the mesh density maximum to occur at a different location than that of the maximum of the eigenvalue. This can in turn lead to a large error in the numerical approximation of the physical solution.

An outline of the paper is as follows. In sections 2 and 3 basic properties of the traditional and new functionals for radially symmetric problems are presented. In section 4 we carry out an in-depth analysis on the control of the mesh density via the monitor function. In particular, we find that the relationship between the radial (λ_1) and the angular (λ_2) components of the monitor function is crucial for a good control of the mesh density. Section 5 presents some two-dimensional numerical results highlighting in part the lack of control of the mesh concentration for a wide choice of monitor functions. A brief analysis is given in section 6 for the traditional functional applied to spherically symmetric problems in three dimensions. Finally, section 7 contains conclusions and comments.

2. The traditional functional. In this section we consider the traditional functional (1.1) for axisymmetrical problems and give some of its basic properties. It is a generalization of the functionals for Winslow's method and Dvinsky's method of harmonic mappings. The monitor function G can be defined by arbitrarily choosing λ_1 and λ_2. However, it is worth pointing out that a number of commonly used monitor functions can be obtained through the interdependent relationship

$$\lambda_2 = \lambda_1^p \tag{2.1}$$

for some power p. For example, we have

$$\begin{array}{lll} \text{(HM)} & p=-1: & \text{harmonic mapping monitor function;} \\ \text{(Al)} & p=0: & \text{arclength monitor function;} \\ \text{(Ws)} & p=1: & \text{Winslow's monitor function;} \\ \text{(St)} & p=2: & \text{strong concentration monitor function.} \end{array} \tag{2.2}$$

In polar coordinates the gradient operator reads as

$$\nabla = \boldsymbol{e}_r \frac{\partial}{\partial r} + \frac{\boldsymbol{e}_\theta}{r}\frac{\partial}{\partial \theta},$$

and it follows from (1.3) and (1.4) that

$$\nabla\xi^T G^{-1}\nabla\xi + \nabla\eta^T G^{-1}\nabla\eta = \frac{1}{\lambda_1}\left(\frac{dR}{dr}\right)^2 + \frac{1}{\lambda_2}\left(\frac{R}{r}\right)^2. \tag{2.3}$$

Substituting (2.3) into (1.1) gives

$$I_{trad}[R] = 2\pi\int_0^1 \left[\frac{1}{\lambda_1}\left(\frac{dR}{dr}\right)^2 + \frac{1}{\lambda_2}\left(\frac{R}{r}\right)^2\right] rdr,$$

and its Euler–Lagrange equation is

$$-\frac{d}{dr}\left(\frac{r}{\lambda_1}\frac{dR}{dr}\right) + \frac{R}{r\lambda_2} = 0. \tag{2.4}$$

This equation is supplemented with the boundary conditions

$$R(0) = 0, \qquad R(1) = 1. \tag{2.5}$$

For a given monitor function (i.e., for given λ_1 and λ_2), solving (2.4) determines the resulting mesh transformation $R(r)$.

2.1. Nonnegativeness and mesh crossing. We have $R(r) \geq 0$ for $r \in (0,1)$. To see this, we note that the minimum of $R(r)$ occurs at the left end and/or an interior point due to the boundary conditions (2.5). If $R(0) = \min R(r)$, then we have $R(r) \geq 0$ from (2.5). If instead the minimum point is $r_0 \in (0,1)$, then $R'(r_0) = 0$ and $R''(r_0) \geq 0$. From (2.4)

$$\frac{1}{r_0\lambda_2}R(r_0) = \frac{d}{dr}\left(\frac{r}{\lambda_1}\right)\left(\frac{dR}{dr}\right)\bigg|_{r_0} + \frac{r}{\lambda_1}\frac{d^2R}{dr^2}\bigg|_{r_0} \geq 0.$$

Hence, in either case $R(r) \geq R(r_0) \geq 0$. Furthermore, (2.4) gives

$$\frac{dR}{dr} = \frac{\lambda_1}{r}\int_0^r \frac{R(x)}{x\lambda_2(x)}\,dx,$$

so it follows that $\frac{dR}{dr} > 0$ for $r \in (0,1)$; i.e., the mesh transformation is guaranteed to be nonsingular and produce no mesh crossing.

2.2. Mesh transformation for harmonic mappings. For the case of harmonic mappings ($p = -1$ or $\lambda_2 = 1/\lambda_1$) it is possible to find an analytical form for the mesh transformation $R(r)$. We explicitly construct $R(r)$ here since it then serves as the basis of study for other cases. Using the change of coordinates

$$s(r) = \int_1^r \frac{\lambda_1(x)}{x} dx, \tag{2.6}$$

(2.4) reads

$$-\frac{d^2R}{ds^2} + R = 0.$$

Its solution satisfying the boundary conditions (2.5) is $R(r) = e^s$. In section 4.1, using a transformation based on (2.6), we study more general monitor functions (including arclength and Winslow) in detail.

3. The new functional. The formulation of the new functional (1.2) is based on the so-called isotropy (or regularity) and equidistribution (or adaptation) requirements for an error distribution [6]. Specifically, the first integral term corresponds to the regularity requirement, while the second is associated with equidistribution. These two requirements are balanced by adjusting the value of the parameter γ. When $q = 1$ or $\gamma = 1/2$, the second integral becomes constant or simply vanishes, and only the isotropy plays a role. When $q = 1$ the functional gives rise to the energy functional of a harmonic mapping. The relation between the new and traditional functionals will be addressed later in section 3.3.

From (1.4) the determinant of G is $g = \det(G) = \lambda_1\lambda_2$. Let

$$\Lambda = \sqrt{\lambda_1\lambda_2}, \tag{3.1}$$

$$\mu_1(r) = \frac{\lambda_1}{\Lambda^{1/q}}, \qquad \mu_2(r) = \frac{\lambda_2}{\Lambda^{1/q}}. \tag{3.2}$$

Using the symmetry assumption, we can rewrite (1.2) as

$$I_{new}[R] = \gamma \int_0^1 \left[\frac{1}{\mu_1}\left(\frac{dR}{dr}\right)^2 + \frac{1}{\mu_2}\left(\frac{R}{r}\right)^2 \right]^q r dr + (1-2\gamma)2^q \int_0^1 \left[\frac{RR'}{r\sqrt{g}}\right]^q r\sqrt{g} dr.$$

Its Euler–Lagrange equation is given by

$$\begin{aligned} &-\frac{\gamma}{\beta^{q-1}}\frac{d}{dr}\left(\frac{r\beta^{q-1}R'}{\mu_1}\right) + \frac{\gamma R}{r\mu_2} \\ &-\frac{(1-2\gamma)2^{q-1}(q-1)R}{\beta^{q-1}}\left(\frac{RR'}{r\sqrt{g}}\right)^{q-2}\frac{d}{dr}\left(\frac{RR'}{r\sqrt{g}}\right) = 0, \end{aligned} \tag{3.3}$$

where

$$\beta = \frac{1}{\mu_1}\left(\frac{dR}{dr}\right)^2 + \frac{1}{\mu_2}\left(\frac{R}{r}\right)^2.$$

The highly nonlinear form of the new functional does not lend itself to a straightforward analytical treatment of its basic properties. Nonetheless, we devote the rest of this section to the study of several special cases of (3.3) subject to the boundary conditions (2.5). These cases are important because they help to better understand the functional and link it to the traditional one.

3.1. The exact equidistribution case ($\gamma = 0$). We first consider the case $\gamma = 0$ which corresponds to exact equidistribution. Assuming that $R(r) > 0$ for $r \in (0,1)$, (3.3) implies

$$\frac{1}{\sqrt{g}} \frac{R}{r} \frac{dR}{dr} = \alpha, \tag{3.4}$$

where α is a constant. From (1.5), this is equivalent to

$$\frac{1}{J\sqrt{g}} = \alpha,$$

which is a multidimensional generalization of the well-known equidistribution principle in one dimension. This equation guarantees that J, the Jacobian of the coordinate transformation, does not change sign in the domain.

3.2. The pure isotropy case ($\gamma = 1/2$). For $\gamma = 1/2$ the mesh equation (3.3) reduces to

$$\frac{d}{dr}\left[\frac{\beta^{q-1} r\, R'}{\mu_1}\right] = \frac{\beta^{q-1} R}{r\mu_2}.$$

As in section 2.1, it is easy to show that $R(r) \geq 0$ and $R'(r) \geq 0$. Thus, for this case the mesh is also guaranteed not to cross.

In Figure 1 we depict $R'(r)$ for the traditional functional and the new functional with $\gamma = 1/2$ and several values of q. As can be seen, the mesh transformation for the new functional with different values of q is quite similar to the traditional functional. This is not surprising since for $\gamma = 1/2$ the new functional shifts all the weight towards isotropy and thus resembles the traditional functional.

3.3. The case $q = 1$. When $q = 1$, the second integral in (1.2) becomes constant. From (3.1) the mesh equation (3.3) reduces to

$$-\frac{d}{dr}\left(\frac{\Lambda r}{\lambda_1}\frac{dR}{dr}\right) + \frac{\Lambda R}{r\lambda_2} = 0. \tag{3.5}$$

Once again it is easy to prove that mesh crossing will not occur. Note that the mesh equation (3.5) is independent of the parameter γ and very similar to (2.4) for the traditional functional. In fact, for the harmonic mapping case where $\Lambda = 1$, the mesh equations (3.5) and (2.4) are identical.

For the Winslow monitor function case ($\Lambda = \lambda_1 = \lambda_2$) the mesh equation is

$$\frac{d}{dr}\left(r\frac{dR}{dr}\right) = \frac{R}{r}. \tag{3.6}$$

The solution of (3.6) compatible with the boundary conditions is $R(r) = r$. Therefore, the case $q = 1$ of the new functional method gives a trivial coordinate transformation $R = r$ and does not allow for any control of the mesh concentration when a Winslow-type monitor function is used.

Finally, for the arclength monitor function ($\lambda_2 = 1$) the mesh equation is

$$-\frac{d}{dr}\left(\frac{r}{\sqrt{\lambda_1}}\frac{dR}{dr}\right) + \frac{R}{r\sqrt{\lambda_1}} = 0.$$

This mesh equation is equivalent to that for the traditional functional (2.4) using a Winslow-type monitor function with $\sqrt{\lambda_1}$ instead of λ_1.

In summary, except for the Winslow case, for $q = 1$ the new functional corresponds to the traditional functional with a suitable choice of the monitor function.

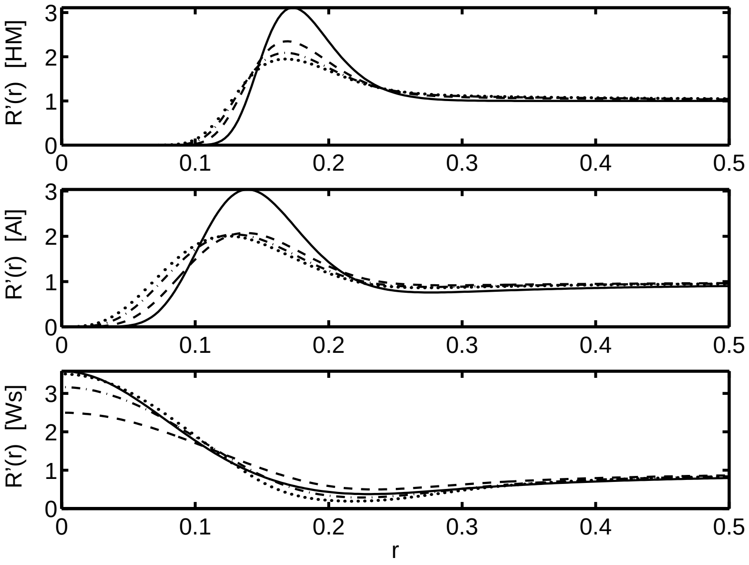

Fig. 1. *Comparison of $R'(r)$ for the traditional functional (solid line) and the new functional with $\gamma = 1/2$ ($q = 2$: dashed, $q = 3$: dotted-dashed, $q = 4$: dotted). The plots correspond to the three popular choices of monitor function (harmonic mapping, arclength, and Winslow) with $\lambda_1(r) = 1 + \exp(-r^2/a)/a$ ($a = 0.01$).*

4. Control of mesh density via $\boldsymbol{\lambda_1}$ and $\boldsymbol{\lambda_2}$.

4.1. The traditional functional. The Euler–Lagrange equation (2.4) for the traditional functional relates the coordinate transformation to the monitor function for a given choice of λ_1 and λ_2. The purpose of this section is to use this to show that precise control of the mesh density $D(r)$ cannot be achieved from the choice of λ_1 and λ_2. In fact, we prove that the maximum for the mesh concentration does not occur at the maximum of λ_1, resulting in misplacement of mesh concentration.

Let us then take (2.4) and solve for the mesh density $D(r)$ in (1.6). Motivated by the transformation (2.6) leading to the exact solution of (2.4) for the harmonic mapping monitor function ($\lambda_2 = 1/\lambda_1$), we consider the change of dependent variable

$$R(r) = e^{s(r)} \quad \text{with} \quad s(r) = \int_1^r \frac{\lambda_1(x)\, v(x)}{x} dx \tag{4.1}$$

for a to-be-determined and bounded function v. Substituting this into (2.4) yields the ODE for v

$$\frac{dv}{dr} = \frac{\lambda_1}{r}\left(\frac{1}{\Lambda^2} - v^2\right). \tag{4.2}$$

It satisfies

$$v(0) = \frac{1}{\Lambda(0)}, \tag{4.3}$$

since any other initial value (at $r = 0$) produces an unbounded solution v. The choice (4.3) is compatible with the special case of the harmonic mapping where $v(r) = 1$.

LEMMA 4.1. *$v(r) > 0$ for all $r \in [0,1]$.*

Proof. This is an immediate result of the initial condition $v(0) = 1/\Lambda(0) > 0$ and the fact that $v' > 0$ on the line $v = 0$. □

The overall behavior of v is determined by the nullcline

$$v_{\text{null}}(r) = \frac{1}{\Lambda(r)}. \tag{4.4}$$

LEMMA 4.2. *$v_{\min} \le v(r) \le v_{\max}$ for all $r \in [0,1]$, where $v_{\min} = \min_r\{1/\Lambda(r)\}$ and $v_{\max} = \max_r\{1/\Lambda(r)\}$. Thus, the solution $v(r)$ is bounded by the minimum and maximum of the nullcline.*

Proof. Note that $v' > 0$ below the nullcline and $v' < 0$ above it. Since $v_{\min} \le v_{\text{null}}(r)$, we have $v' \ge 0$. This and $v(0) = 1/\Lambda(0) \ge v_{\min}$ imply that $v(r) \ge v_{\min}$. Similarly, we have $v(r) \le v_{\max}$. □

Define r_λ as the point where λ_1 attains its maximum, i.e.,

$$\lambda_1(r_\lambda) = \max_{r\in[0,1]} \lambda_1(r).$$

We have the following lemma.

LEMMA 4.3. *Let r_λ be a strict maximum point of λ_1 (so $\lambda_1^{''}(r_\lambda) < 0$), and let $\lambda_2 = c\lambda_1^p$ for some power $p > -1$ and some constant $c > 0$. Then, $v(r_\lambda) > \frac{1}{\Lambda(r_\lambda)}$.*

Proof. For this particular choice of λ_2, we have

$$\Lambda'(r_\lambda) = 0, \quad \Lambda''(r_\lambda) \ne 0, \quad v_{\min} = \frac{1}{\Lambda(r_\lambda)}.$$

We prove the lemma by contradiction. From Lemma 4.2, we can assume only $v(r_\lambda) = 1/\Lambda(r_\lambda)$. By differentiating (4.2) twice and using the fact that $\lambda_1^{'}(r_\lambda) = 0$, we get

$$\begin{aligned} v'(r_\lambda) &= v''(r_\lambda) = 0,\\ v'''(r_\lambda) &= -\frac{2\lambda_1(r_\lambda)\Lambda''(r_\lambda)}{r_\lambda\Lambda(r_\lambda)^3} \ne 0. \end{aligned}$$

This implies that

$$\begin{aligned} v(r) &= v(r_\lambda) + \frac{(r-r_\lambda)^3}{6}v'''(r_\lambda) + O((r-r_\lambda)^4)\\ &= v_{\min} + \frac{(r-r_\lambda)^3}{6}v'''(r_\lambda) + O((r-r_\lambda)^4). \end{aligned}$$

Hence, $v(r) < v_{\min}$ at some points in the neighborhood of r_λ, which contradicts Lemma 4.2. □

Figure 2 shows a typical vector field for v.

To study the mesh density, note that in terms of s,

$$D(r) = \frac{R}{r}\frac{dR}{dr} = \frac{e^s}{r}s'e^s = \frac{s'e^{2s}}{r},$$

and its rate of change

$$\begin{aligned} \frac{dD}{dr} &= \frac{d}{dr}\left(\frac{s'e^{2s}}{r}\right)\\ &= \frac{e^{2s}}{r}\left(s'' + 2s'^2 - \frac{s'}{r}\right)\\ &= \frac{e^{2s}}{r^2}\left(\lambda_1'v + \lambda_1 v' - 2\frac{\lambda_1 v}{r} + 2\frac{\lambda_1^2 v^2}{r}\right). \end{aligned} \tag{4.5}$$

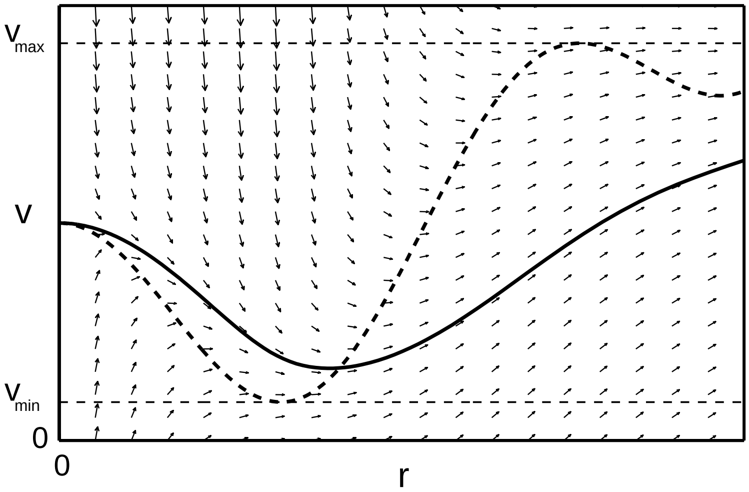

FIG. 2. *Typical vector field for* (4.2). *The total variation* $[v_{\min}, v_{\max}]$ *of the nullcline* (4.4) *(dashed line) bounds the behavior of the solution with* $v(0) = 1/\Lambda(0)$ *(solid line).*

Using (4.2) one obtains

$$\frac{dD}{dr} = \frac{e^{2s}}{r^2}\left\{\lambda_1' v + \frac{\lambda_1^2}{r}\left[\left(v - \frac{1}{\lambda_1}\right)^2 + \left(\frac{1}{\Lambda^2} - \frac{1}{\lambda_1^2}\right)\right]\right\}. \tag{4.6}$$

Equation (4.6) determines where the mesh density reaches an extremum in terms of λ_1 and λ_2. In general, it is desired that the mesh has a higher concentration of points at the maximum location of λ_1 so that the mesh concentration can be controlled by choosing λ_1. We first consider mesh concentration at the origin $r = 0$.

THEOREM 4.1. (i) *If* $\lambda_1(0) - \lambda_2(0) \neq 0$, *then* $D'(0)$ *has the same sign as* $\lambda_1(0) - \lambda_2(0)$ *whether* λ_1 *has a maximum at* $r = 0$ *or not. Specifically, if* $\lambda_1(0) > \lambda_2(0)$, *then* $D'(0) > 0$ *(i.e., the mesh at the origin is coarser than in the surrounding area), and if* $\lambda_1(0) < \lambda_2(0)$, *then* $D'(0) < 0$ *(i.e., the mesh at the origin is denser than in the surrounding area).*

(ii) *Let* $\lambda_2(r) = \lambda_1(r)$. *If* $\lambda_1^{'}(0) \neq 0$, *then* $D'(0)\lambda_1^{'}(0) > 0$. *If* $\lambda_1^{'}(0) = 0$ *but* $\lambda_1^{''}(0) \neq 0$, *then* $D'(0)\lambda_1^{''}(0) > 0$.

Proof. Let $y(r) = \lambda_1(r)v(r)$. Note that $y(0) = \lambda_1(0)/\Lambda(0) = \sqrt{\lambda_1(0)/\lambda_2(0)}$. Equation (4.5) can be rewritten as

$$\frac{dD}{dr} = \frac{e^{2s}}{r^2}\left(y' - \frac{2y}{r} + \frac{2y^2}{r}\right).$$

Expanding the bracketed terms on the right-hand side about $r = 0$, we get

$$\begin{aligned}\frac{dD}{dr} &= \frac{e^{2s}}{r^2}\left\{\frac{2}{r}y(0)\left(y(0) - 1\right) + y'(0)\left(4y(0) - 1\right) + O(r)\right\} \\ &= \frac{e^{2s}}{r^2}\left\{\frac{2}{r}\sqrt{\frac{\lambda_1(0)}{\lambda_2(0)}}\left(\sqrt{\frac{\lambda_1(0)}{\lambda_2(0)}} - 1\right) + y'(0)\left(4\sqrt{\frac{\lambda_1(0)}{\lambda_2(0)}} - 1\right) + O(r)\right\}. \qquad (4.7)\end{aligned}$$

Thus, if $\lambda_1(0) \neq \lambda_2(0)$, the first term in the bracket dominates. In this case, $D'(r)$ has the same sign as $\lambda_1(0) - \lambda_2(0)$. The result in (i) follows.

We now prove part (ii) using (4.6). This can also be done through (4.5), but higher order terms must be used. Using the assumption $\lambda_1(r) = \lambda_2(r)$ and expanding the bracketed terms of (4.6) about $r = 0$, we get

$$\frac{dD}{dr} = \frac{e^{2s}}{r^2}\{v(0)\lambda_1^{'}(0) + r[\lambda_1(0)v'(0) + \lambda_1^{'}(0)(1 + v'(0)) + \lambda_1^{''}(0)v(0)] + O(r^2)\}.$$

The results in (ii) follow since $\lambda_1^{'}(0) = 0$ implies $v'(0) = 0$. □

We now consider the case where mesh concentration away from the origin is desired, i.e., when $r_\lambda > 0$. Let

$$r_D : \qquad D(r_D) = \max_{r \in [0,1]} D(r).$$

The following theorem shows the relative positioning of r_D with respect to r_λ.

THEOREM 4.2. *Let* $r_\lambda > 0$.

(i) *If* $\lambda_1(r_\lambda) > \lambda_2(r_\lambda)$, *then* $D'(r_\lambda) > 0$ *and thus* $r_D > r_\lambda$.

(ii) *Further, if we assume that* $\lambda_2(r) = \lambda_1(r)$ *(Winslow's method) and* r_λ *is a strict maximum point of* λ_1 *(i.e.,* $\lambda_1{''}(r_\lambda) < 0$*), then* $D'(r_\lambda) > 0$ *or again* $r_D > r_\lambda$.

Proof. (i) The result is an immediate consequence of (4.6) and the assumptions.

(ii) When $\lambda_2(r) = \lambda_1(r)$, we have $\Lambda(r) = \lambda_1(r)$. Lemma 4.3, the fact that $\lambda_1(r_\lambda) = 0$, and (4.6) imply that $D'(r_\lambda) > 0$. □

We note that a result can be obtained for the general choice of λ_2 satisfying $\lambda_2(r) = \lambda_1(r)$ only at $r = r_\lambda$. Moreover, numerical experiments (see below) show that the mismatch between r_D and r_λ for the Winslow monitor function is relatively small.

The situation with $\lambda_1(r_\lambda) < \lambda_2(r_\lambda)$ is much more complex. Note that the last term in (4.6) is now negative. In order to determine the relative positions of r_D and r_λ it is necessary to compare all the terms on the right-hand side of (4.6). It is possible for r_D and r_λ to coincide. However, numerical results (see section 4.1.4) also show that for $\lambda_2 = \lambda_1^p$ with $p > 1$, r_D can be located on either side of r_λ.

It is emphasized that part (i) of both Theorems 4.1 and 4.2 requires no explicit relationship between λ_1 and λ_2, although we typically apply them to the monitor functions defined in (2.2).

4.1.1. The harmonic mapping case ($p = -1$). In this case, $\lambda_2 = 1/\lambda_1$. Assuming that $\lambda_1(r_\lambda) > 1$, we have $\lambda_1(r_\lambda) > \lambda_2(r_\lambda)$. Theorem 4.2 implies that $r_D > r_\lambda$, or the location of maximum mesh density is to the right of the maximum for λ_1.

When a (local) higher mesh concentration at the origin is desired, Theorem 4.1 implies that if (a) $\lambda_1(0) > 1$, the mesh at the origin is coarser than in the surrounding area, whether λ_1 has a maximum at $r = 0$ or not. This effect is clearly depicted in Figure 3 (left column, second plot) where $r_D > r_\lambda = 0$ implies a failure to concentrate the points at the origin. If instead (b) $0 < \lambda_1(0) \leq 1$, then $\lambda_1(0) \leq \lambda_2(0)$ and the mesh will be denser in the center than in the surrounding area.

We now consider conditions under which $r_\lambda > 0$ and r_D coincide. There is a tight restriction on the choice of λ_1 since $D' = 0$ must hold where $\lambda_1^{'} = 0$. Notice that we have $\Lambda = 1$ for the current case. Equation (4.6) implies that this can be achieved if and only if $\lambda_1(r_\lambda) = 1$. However, this cannot hold in general unless the high mesh concentration is desired only at the global maximum point and $\lambda_1(r_\lambda) = 1$ can be achieved by rescaling.

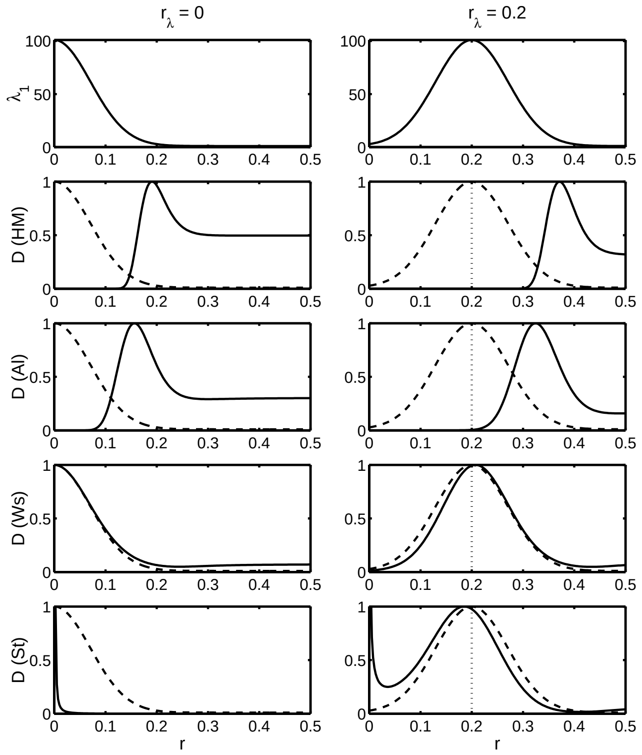

Fig. 3. *Normalized mesh densities obtained with the traditional functional for different monitor functions defined in* (2.2) *and with* $\lambda_1(r) = 1+\exp(-(r-r_\lambda)^2/a)/a$ $(a = 0.01)$ *that has its maximum located at* $r_\lambda = 0$ *(left column) and* $r_\lambda = 0.2$ *(right column). The top plot depicts* $\lambda_1(r)$*. For guidance, we plot, along with the normalized densities (solid lines), the normalized curve for* $\lambda_1(r)$ *(dashed lines).*

From the above analysis we see that if $\lambda_1(r_\lambda) > 1$, r_D will be located to the right of r_λ. This failure to place the higher concentration of points in the desired area is depicted in Figure 3 (right column, second plot).

4.1.2. The arclength case ($p = 0$). For the arclength case $\lambda_2(r) = 1$, a similar analysis as the one for the harmonic mapping case can be carried out. We assume $\lambda_1(r_\lambda) > 1$ since this is the one commonly used in the literature.

If $r_\lambda > 0$, Theorem 4.2 and $\lambda_1(r_\lambda) > 1 = \lambda_2$ imply that the maximum of the mesh density occurs at a location to the right of that of the maximum of λ_1. This mismatch is illustrated in Figure 3 (right column, third plot).

The argument for $r_\lambda = 0$ is similar, and there is again a mismatch (to the right) between the locations of the maxima of the mesh density and λ_1 (see Figure 3, left column, third plot.

4.1.3. The Winslow case ($p = 1$). If a high mesh concentration is desired at a strict maximum point $r_\lambda > 0$ of λ_1, Theorem 4.2 implies that r_D will be located to the right of r_λ. Nevertheless, as Figure 3 (right column, fourth plot) shows, the mismatch between the maxima for D and λ_1 can be very small (compared with the other cases).

On the other hand, Theorem 4.1 implies that the mesh has higher concentration

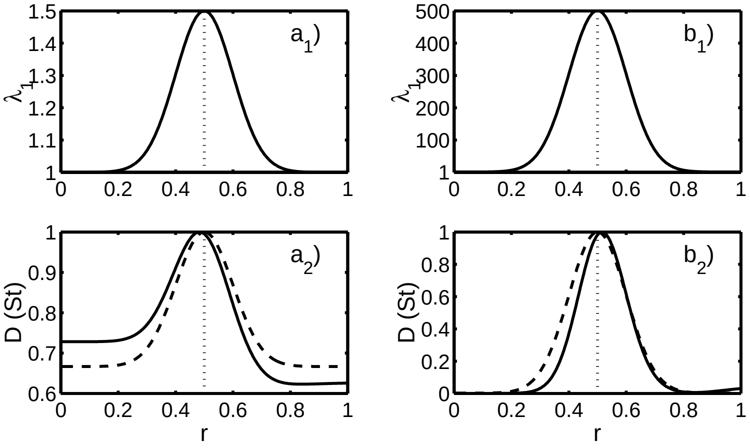

FIG. 4. *Normalized mesh densities obtained with the traditional functional for the strong concentration case ($p = 2$) with $\lambda_1(r) = 1 + A\exp(-(r - r_\lambda)^2/a)/a$ ($a = 0.02$, $r_\lambda = 0.5$) and* (a) *$A = 0.01$ and* (b) *$A = 10$. The top plots show $\lambda_1(r)$. For guidance, in a_2 and b_2 we plot the normalized curve for $\lambda_1(r)$ (dashed lines) along with the normalized densities (solid lines).*

at $r = 0$ if either $\lambda_1'(0) < 0$ or $r = 0$ is a local maximum point of λ_1. Figure 3 (left column, fourth plot) shows good agreement between the shape of λ_1 and the mesh density.

4.1.4. The strong concentration case ($p = 2$). Consider first the case where a higher mesh concentration at the origin is desired. Theorem 4.1 implies that the maximum for the mesh density is located at the origin if $\lambda_1(0) > 1$ (see the last plot in Figure 3, left column). However, the rate of change of the density may be a very large negative value—proportional to $\lim_{r\to 0} e^{2s}/r^3$. This effect is observed in Figure 3 (last plot, left column) where the mesh density is very steep at the origin, giving an overconcentration of points at $r = 0$. Incidentally, our use of the term "strong concentration" for the $p = 2$ case reflects this behavior.

For $r_\lambda > 0$, the current situation is more complex than the previous cases and Theorem 4.2 does not apply if $\lambda_1(r_\lambda) > 1$. Figure 4 shows that r_D can be located to either side of r_λ. Since in this case we have $\lambda_1(0) < \lambda_2(0)$, Theorem 4.1 implies that the mesh concentration has a maximum at the origin. Thus, it is possible for the mesh concentration to have two (or more) maxima, one near the desired location r_λ and a spurious (and steep) maximum at $r = 0$ (see the last plot in Figure 3, right column).

4.2. The new functional. The Euler–Lagrange equation (3.3) corresponding to the new functional is too complex to carry out an analysis similar to the one for the traditional functional, and we instead perform a numerical study of the relation between the monitor function (λ_1 and λ_2) and the mesh density $D(r)$. In particular, we show that by appropriate control of the weighting γ between isotropy and equidistribution it is possible to reduce the mismatch between the location of the maximum for the monitor function and that of the maximum for $D(r)$. As for the traditional functional, we concentrate our attention on monitor functions of the type (2.1) and use the same notation as in (2.2) to designate the most popular choices of p. Note that for the harmonic mapping monitor function $g = 1$, and equidistribution reads as $J =$ constant, giving no mesh control in the new functional. As a result, it is expected

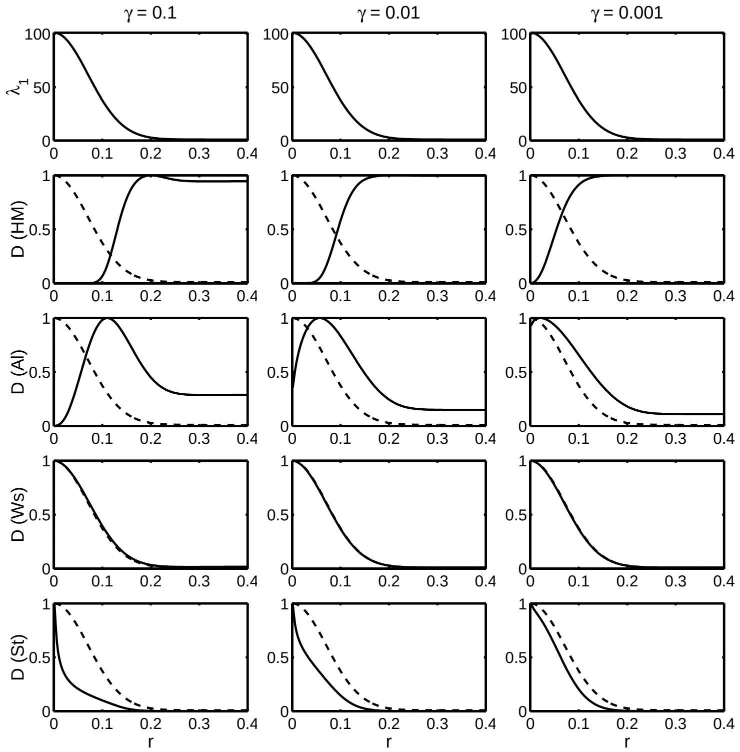

FIG. 5. *Normalized mesh densities (solid lines) obtained with the new functional for a monitor function (dashed lines) such that* $\lambda_1(r) = 1 + \exp(-(r - r_\lambda)^2/a)/a$ *(*$a = 0.01$, $r_\lambda = 0$*) for different choices of* λ_2 *and* γ *(*$q = 2$*).*

that the new functional combined with the harmonic mapping monitor function gives no better results than those with the traditional functional, even for a small value of γ.

4.2.1. Concentration at $r = 0$. For $r_\lambda = 0$, Figure 5 shows the monitor function and the mesh density for the various choices of monitor function (2.2) and weighting between isotropy and equidistribution. For large γ (close to 1/2), the new functional tends to emphasize isotropy, giving similar results to those for the traditional functional. For $\gamma = 0.1$ (first column in Figure 5), the harmonic mapping and the arclength monitor functions tend to misplace the position of the maximum for the density as before. For the Winslow and strong concentration cases, $D(r)$ achieves its maximum at $r = 0$.

Decreasing γ puts more weight on equidistribution, allowing for a better distribution of the mesh density. In fact, by decreasing γ (second and third columns in Figure 5) the maximum for the mesh density is pulled towards the correct position $r = 0$. As pointed out above, the harmonic mapping case fails to have its maximum at $r = 0$ even for very small γ. For the other cases ($p \geq 0$), as γ tends to zero, not only the mesh density has its maximum placed correctly, but its shape tends to mimic the shape of λ_1. This suggests that for small γ it is possible to control the position of the maximum mesh concentration as well as the shape of the mesh density from the choice of monitor function. Interestingly, the Winslow case provides the best control

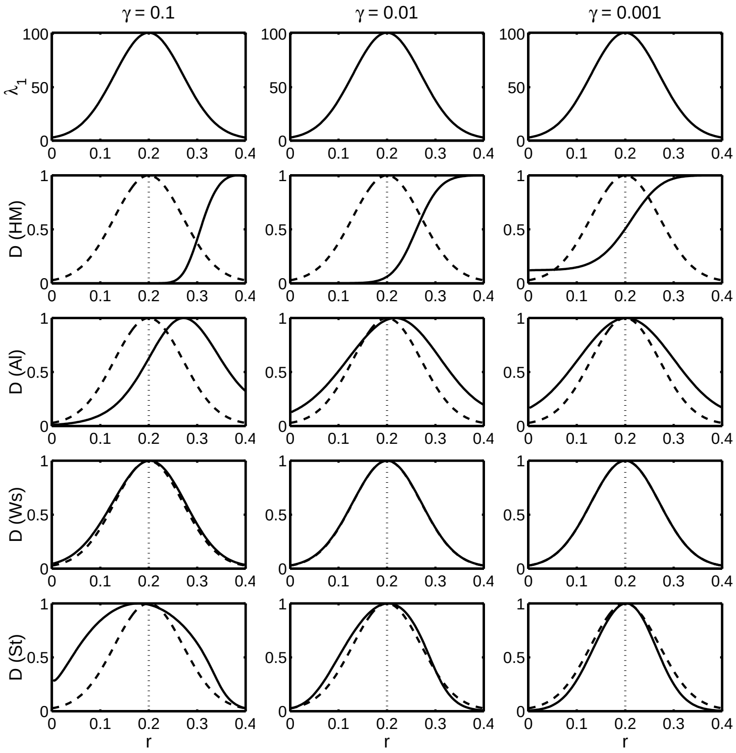

Fig. 6. *Normalized mesh densities (solid lines) obtained with the new functional for a monitor function (dashed lines) such that* $\lambda_1(r) = 1 + \exp(-(r - r_\lambda)^2/a)/a$ *(*$a = 0.001$*,* $r_\lambda = 0.2$*) for different choices of* λ_2 *and* γ *(*$q = 2$*).*

on the mesh density, and for small γ ($\gamma < 0.01$) $D(r)$ is almost indistinguishable from $\lambda_1(r)$.

4.2.2. Concentration at $r > 0$. For $r_\lambda > 0$ we obtain similar results to those for the traditional functional when using a large value of γ (see left column in Figure 6). In particular, the position of the mesh density maximum does not coincide with r_λ except in the Winslow case. As we decrease γ, the new functional weights more towards equidistribution, and the location of the maximum for $D(r)$ tends to approach r_λ, again reinforcing the observation that for small γ and $p \geq 0$ it is possible to have a good control on the mesh density (maximum and shape) from the monitor function.

5. Numerical results. In this section we present some numerical results obtained with the functionals (1.1) and (1.2). For simplicity, square physical and computational domains and structured meshes are used in the computation. As a consequence, axially symmetric meshes are not generated. Nevertheless, the numerical results are sufficient to support the analysis of the previous sections and highlight the level of control of mesh concentration through the monitor functions.

The (two-dimensional) Euler–Lagrange equations for functionals (1.1) and (1.2) are discretized with central finite differences and solved using the moving mesh PDE approach [5, 7]. With this approach, a derivative $(\partial \boldsymbol{x})/(\partial t)$ (where $\boldsymbol{x} = (x, y)^T$) with respect to pseudotime t is added to the Euler–Lagrange equation, and the resulting parabolic system is integrated using a modified backward Euler scheme with which the coefficients of terms $(\partial \boldsymbol{x})/(\partial \xi^i)$ and $(\partial^2 \boldsymbol{x})/(\partial \xi^i \partial \xi^j)$ are calculated at the previous time level. The linear algebraic system is solved using a preconditioned conjugate gradient method. The converged mesh is obtained when the root-mean-square norm of the residual is less than 10^{-4}. All computations start with a uniform mesh of size 41×41 and use a uniform boundary correspondence between Ω and Ω_c. We use $q = 2$ in all cases and, following the common practice, choose λ_1 to be greater than 1.

Example 5.1. The first example is to generate adaptive meshes for the monitor function (1.4) with

$$\lambda_1 = 1 + \frac{1}{a} e^{-(r-0.2)^2/a}, \tag{5.1}$$

where $r = \sqrt{x^2 + y^2}$ and $a = 0.01$. In the (x, y) coordinate system, G has the form

$$G = \frac{\lambda_1}{x^2 + y^2} \begin{pmatrix} x^2 & xy \\ xy & y^2 \end{pmatrix} + \frac{\lambda_2}{x^2 + y^2} \begin{pmatrix} y^2 & -xy \\ -xy & x^2 \end{pmatrix}. \tag{5.2}$$

The goal is to generate meshes with higher point concentration around the circle $x^2 + y^2 = 0.2^2$.

The meshes obtained are shown in Figures 7 and 8. The first row corresponds to the traditional functional, while the second, third, and fourth rows are for the new functional with $\gamma = 0.5$, 0.1 and 0.01, respectively. Each column is associated with a given monitor function.

The left column of Figure 7 shows that the mesh concentration is badly misplaced for both the traditional and new functionals using the harmonic mapping monitor function ($p = -1$). In this case the traditional functional gives exactly the harmonic mapping method used by Dvinsky [4]. Note that the new functional does not work well, as expected, since $g = 1$ and $J =$ constant, giving no control of mesh concentration.

For the arclength monitor function ($p = 0$, the right column of Figure 7), the traditional functional still produces the mismatched concentration. However, since $g = \lambda$ and the equidistribution becomes $J\sqrt{\lambda} =$ constant, the new functional bears the feature of equidistribution and leads to the correct concentration when a small value of γ is used.

Interestingly, with the Winslow-type monitor function, both the traditional and new functionals generate correct mesh concentration—see the left column of Figure 8. For the case of strong concentration with $p = 2$ (see the right column of Figure 8), the new functional produces the correct results, whereas the traditional one seems to overconcentrate mesh points inside the circle $x^2 + y^2 = 0.2^2$, although there is also concentration around the circle.

From these two figures one can also see that the new functional with $\gamma = 0.5$ leads to results similar to but slightly less adaptive than those obtained with the traditional functional.

Example 5.2. The second example is to generate adaptive meshes for the monitor function (1.4) with

$$\lambda_1 = 1 + \frac{1}{a} e^{-r^2/a}, \qquad a = 0.01. \tag{5.3}$$

The goal is now to generate adaptive meshes with higher point concentration at the origin.

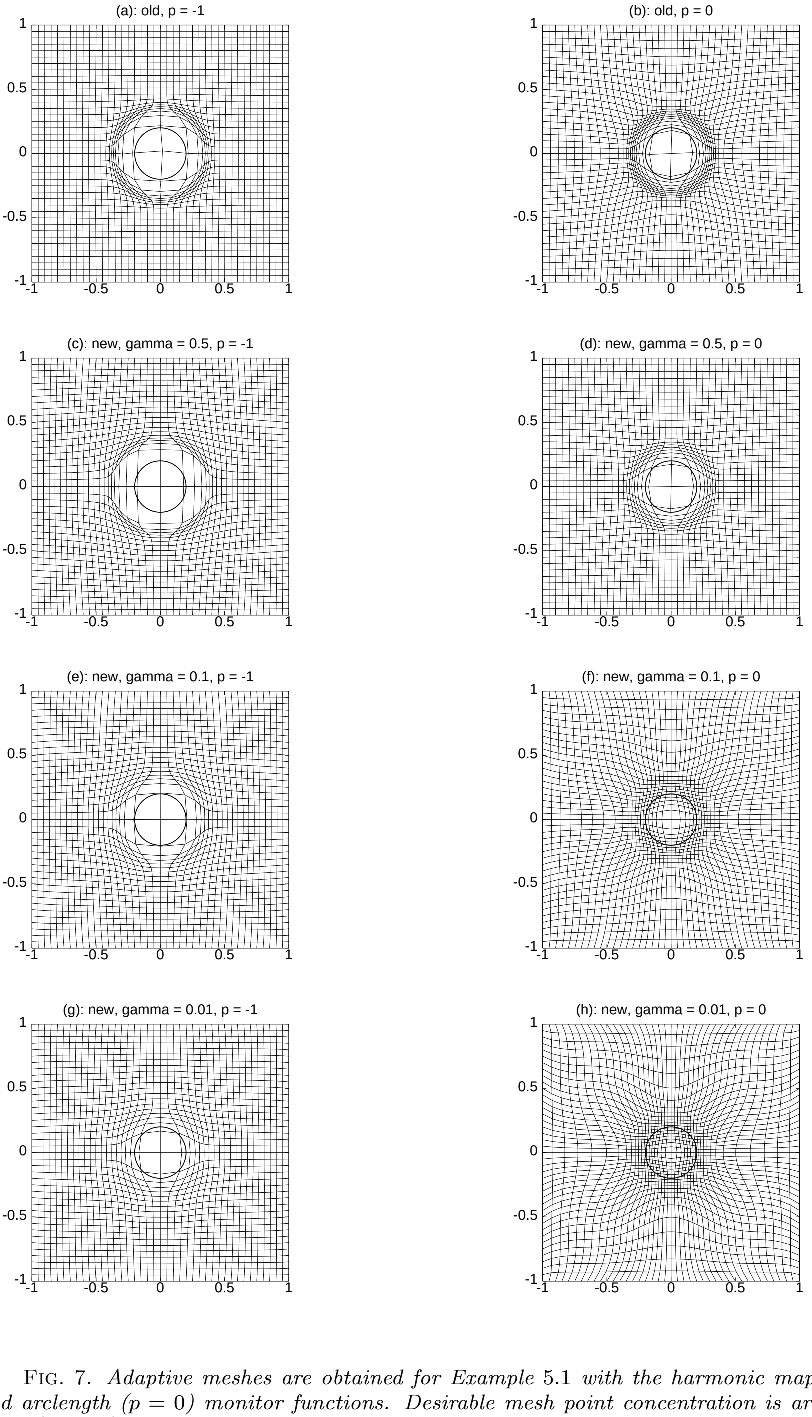

FIG. 7. *Adaptive meshes are obtained for Example* 5.1 *with the harmonic mapping* ($p = -1$) *and arclength* ($p = 0$) *monitor functions. Desirable mesh point concentration is around the circle* $x^2 + y^2 = 0.2^2$ *(the bold solid circle).*

FIG. 8. *Adaptive meshes are obtained for Example* 5.1 *with the Winslow-type* ($p = 1$) *and strong concentration* ($p = 2$) *monitor functions. Desirable mesh point concentration is around the circle* $x^2 + y^2 = 0.2^2$ *(the bold solid circle).*

The meshes obtained are shown in Figures 9 and 10. The results confirm the observations made in Example 5.1 and the analysis given in the preceding sections. That is, the traditional functional misplaces meshes for the harmonic mapping and arclength monitor functions and correctly places them for the Winslow-type and strong concentration monitor functions; the new functional with $\gamma = 0.5$ leads to meshes similar to but slightly less adaptive than those obtained with the traditional functional; and the new functional with a small value of γ leads to meshes with correct concentration when the arclength, Winslow-type, or strong concentration monitor function is used.

6. The traditional functional for spherically symmetric problems. A similar analysis can be carried out for the traditional functional applied to spherically symmetric problems in three dimensions. Consider

$$I_{trad}[\xi,\eta,\zeta] = \int_\Omega \left(\nabla\xi^T G^{-1}\nabla\xi + \nabla\eta^T G^{-1}\nabla\eta + \nabla\zeta^T G^{-1}\nabla\zeta\right) dxdydz, \tag{6.1}$$

where $\Omega = \{(x,y,z) \,|\, x^2+y^2+z^2 < 1\}$. Take $\Omega_c = \{(\xi,\eta,\zeta) \,|\, \xi^2+\eta^2+\zeta^2 < 1\}$, and let the spherical coordinates for Ω and Ω_c be

$$\begin{cases} x = r\sin(\theta)\cos(\phi), \\ y = r\sin(\theta)\sin(\phi), \\ z = r\cos(\theta), \end{cases} \qquad \begin{cases} \xi = R\sin(\Theta)\cos(\Phi), \\ \eta = R\sin(\Theta)\sin(\Phi), \\ \zeta = R\cos(\Theta). \end{cases}$$

Consider the case where the physical solution is spherically symmetric. Assume that the corresponding mesh adaptation is also spherically symmetric, i.e.,

$$R = R(r), \quad \Theta = \theta, \quad \Phi = \phi. \tag{6.2}$$

Then it is reasonable to use the monitor function in the form

$$G = \lambda_1(r)\boldsymbol{e}_r\boldsymbol{e}_r^T + \lambda_2(r)\boldsymbol{e}_\theta\boldsymbol{e}_\theta^T + \lambda_3(r)\boldsymbol{e}_\phi\boldsymbol{e}_\phi^T, \tag{6.3}$$

where $\boldsymbol{e}_r$, $\boldsymbol{e}_\theta$, and $\boldsymbol{e}_\phi$ are the unit vectors in the radial, latitudinal, and longitudinal axes. Under the symmetry assumption, (6.1) reduces to

$$I_{trad}[R] = \int_0^1 \left[\frac{1}{\lambda_1}\left(\frac{dR}{dr}\right)^2 + \frac{2}{\lambda_{23}}\left(\frac{R}{r}\right)^2\right] r^2 dr,$$

where λ_{23} is defined as

$$\frac{2}{\lambda_{23}} = \frac{1}{\lambda_2} + \frac{1}{\lambda_3}.$$

The corresponding boundary value problem is given by

$$\begin{aligned} &-\frac{d}{dr}\left(\frac{r^2}{\lambda_1}\frac{dR}{dr}\right) + \frac{2}{\lambda_{23}}R = 0, \\ &R(0) = 0, \qquad R(1) = 1. \end{aligned} \tag{6.4}$$

The transformation (4.1) can be used for analyzing (6.4). We obtain the equation for v

$$v' = \frac{\lambda_1}{r}\left(\frac{2}{\lambda_1\lambda_{23}} - \frac{v}{\lambda_1} - v^2\right) \tag{6.5}$$

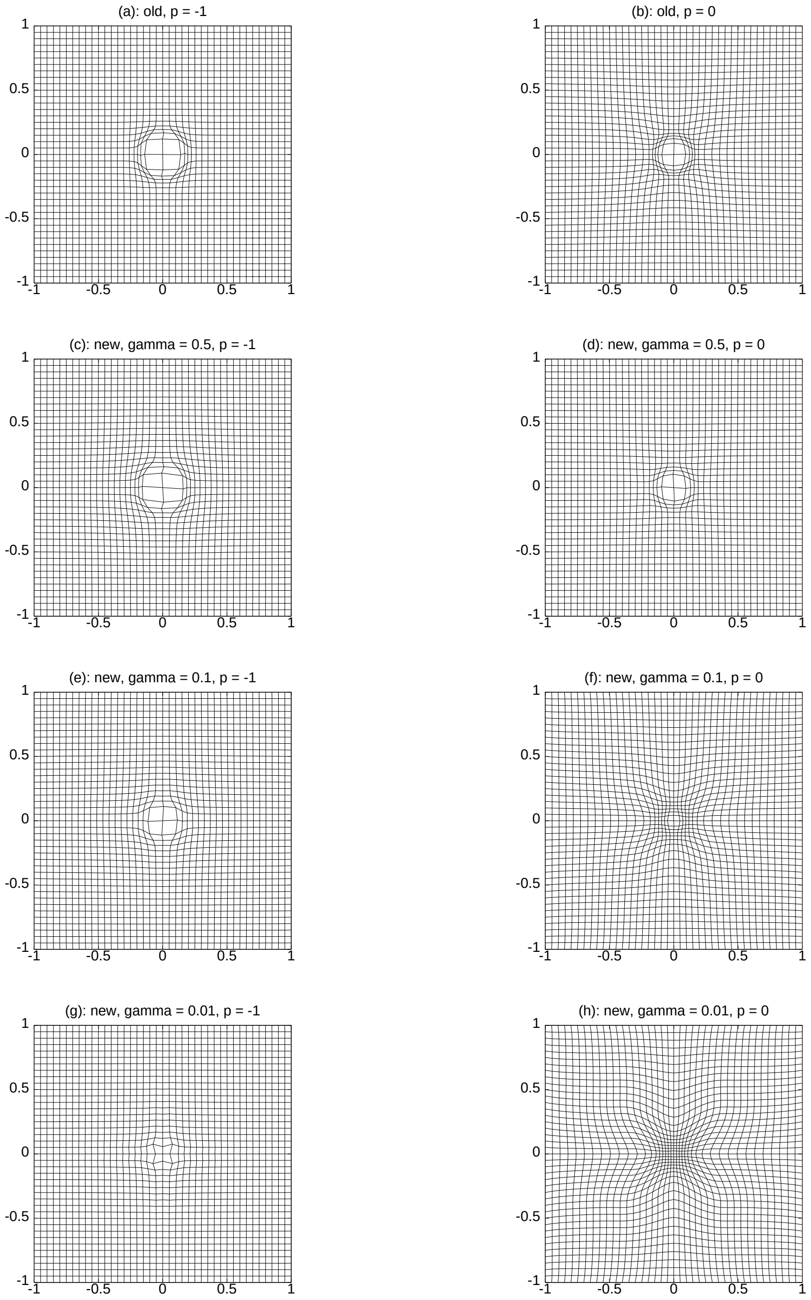

Fig. 9. *Adaptive meshes are obtained for Example* 5.2 *with the harmonic mapping* ($p = -1$) *and arclength* ($p = 0$) *monitor functions. Desirable mesh point concentration is near the origin.*

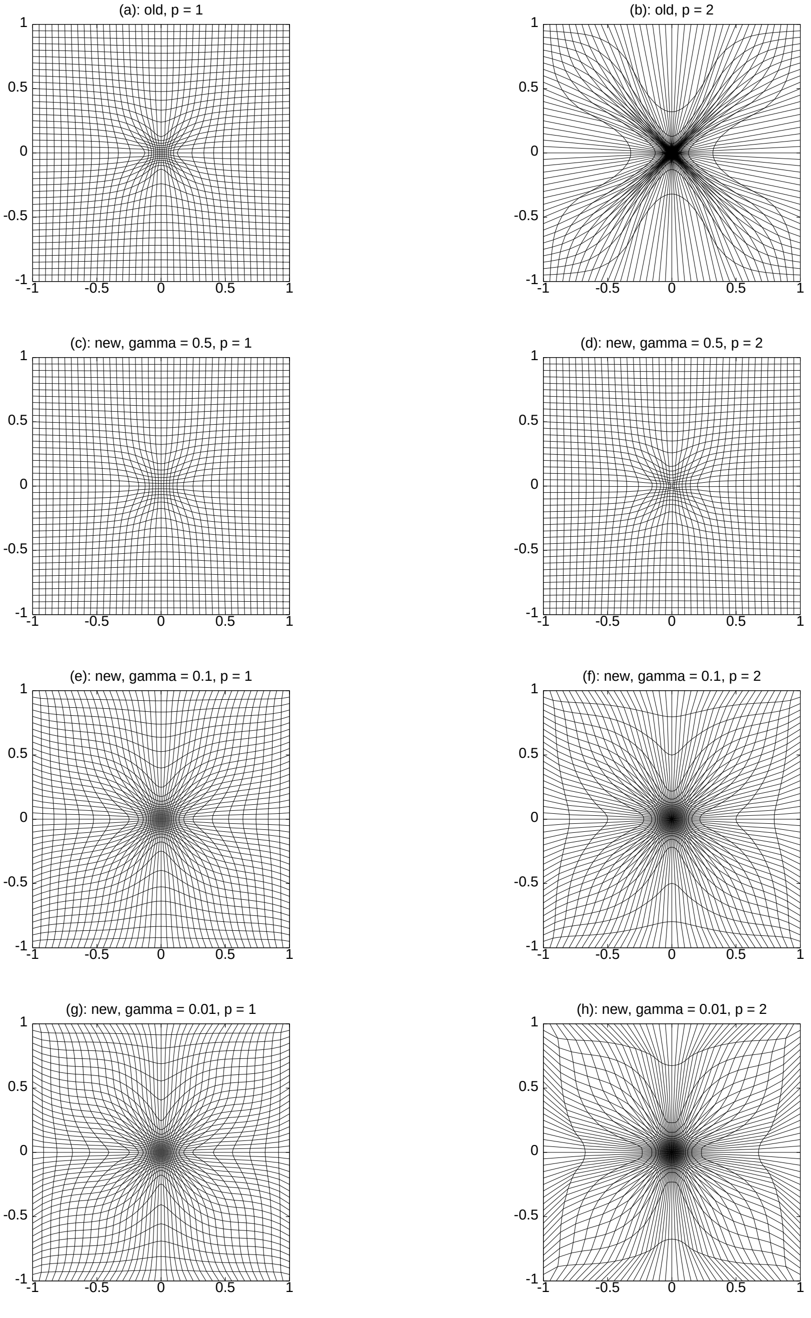

FIG. 10. *Adaptive meshes are obtained for Example* 5.2 *with the Winslow-type* ($p = 1$) *and strong concentration* ($p = 2$) *monitor functions. Desirable mesh point concentration is near the origin.*

which is subject to the initial condition

$$v(0) = \frac{1}{2}\sqrt{\frac{1}{\lambda_1(0)^2} + \frac{8}{\lambda_1(0)\lambda_{23}(0)}} - \frac{1}{2\lambda_1(0)}. \tag{6.6}$$

It is straightforward to show that the solution v of (6.5) has the properties stated in Lemmas 4.1–4.3.

In the current situation, the mesh density has the form

$$D(r) = \frac{R^2}{r^2}\frac{dR}{dr}.$$

Its rate of change reads as

$$\begin{aligned} D'(r) &= \frac{e^{3s}}{r^3}\left[(\lambda_1 v)' - \frac{3(\lambda_1 v)}{r} + \frac{3(\lambda_1 v)^2}{r}\right] \\ &= \frac{e^{3s}}{r^3}\left[\lambda_1^{'} v + \frac{2\lambda_1^2}{r}\left(\left(v - \frac{1}{\lambda_1}\right)^2 + \left(\frac{1}{\lambda_1\lambda_{23}} - \frac{1}{\lambda_1^2}\right)\right)\right]. \end{aligned} \tag{6.7}$$

We have the following theorems which are basically identical to Theorems 4.1 and 4.2. One may notice that in this three-dimensional case, the relation between λ_1 and λ_{23}, rather than those between λ_1 and each of λ_2 and λ_3, plays a role in affecting the corresponding mesh adaptation.

THEOREM 6.1. (i) *If $\lambda_1(0) - \lambda_{23}(0) \neq 0$, then $D'(0)$ has the same sign as $\lambda_1(0) - \lambda_{23}(0)$, whether $r = 0$ is a maximum point of λ_1 or not.*

(ii) *Let $\lambda_{23}(r) = \lambda_1(r)$. If $\lambda_1^{'}(0) \neq 0$, then $D'(0)\lambda_1^{'}(0) > 0$. If $\lambda_1^{'}(0) = 0$ but $\lambda_1^{''}(0) \neq 0$, then $D'(0)\lambda_1^{''}(0) > 0$.*

THEOREM 6.2. *Let $r_\lambda > 0$.*

(i) *If $\lambda_1(r_\lambda) > \lambda_2(r_\lambda)$, then $D'(r_\lambda) > 0$ and thus $r_D > r_\lambda$.*

(ii) *Further, if we assume that $\lambda_{23}(r) = \lambda_1(r)$ and r_λ is a strict maximum point of λ_1 (i.e., $\lambda_1''(r_\lambda) < 0$), then $D'(r_\lambda) > 0$ or $r_D > r_\lambda$.*

7. Conclusions and comments. The question of how variational grid generators behave when solving problems with axisymmetric solutions has been investigated. Specifically, two functionals have been analyzed in the previous sections for their abilities to precisely control the mesh concentration via monitor functions. One is the traditional functional (1.1) which includes Winslow's method and Dvinsky's method of harmonic mappings as special cases. The other is the new functional (1.2) proposed by Huang in [6] which explicitly includes the isotropy (or regularity) and equidistribution features. The analysis is primarily done for axisymmetrical problems in two dimensions. For axially symmetric mesh adaptation, it is reasonable to use a monitor function of the form in (1.4).

Theoretical results for the traditional functional are given in Theorems 4.1 and 4.2. Specifically, when higher mesh concentration at the origin is desired, a choice of the radial and angular components λ_1 and λ_2 of the monitor function satisfying $\lambda_1(0) < \lambda_2(0)$ will make the mesh denser at $r = 0$ than in the surrounding area whether or not λ_1 has a maximum value at $r = 0$. The purpose can also be served by choosing λ_1 to have a local maximum at $r = 0$ when a Winslow-type monitor function with $\lambda_1(r) = \lambda_2(r)$ is employed. Unfortunately, the choice $\lambda_2(r) = \lambda_1(r)^p$ with $p < 0$, which includes Dvinsky's method of harmonic mappings and the arclength monitor function as special cases, will not satisfy the condition $\lambda_1(0) < \lambda_2(0)$ if $\lambda_1(0) > 1$ (as commonly taken in the literature) and leads to a mesh with coarser concentration of points in the center than in the surrounding area.

On the other hand, when higher mesh concentration around a ring $r = r_\lambda > 0$ is desired, the traditional functional provides far less control by choosing λ_1 and λ_2. Indeed, Theorem 4.2 shows that there surely is a mismatch between the position r_λ of the maximum of λ_1 and the location r_D of the maximum of the mesh density if either (a) $\lambda_1(r_\lambda) > \lambda_2(r_\lambda)$ (which is the case for the harmonic mapping or the arclength monitor function with $\lambda_1(r_\lambda) > 1$) or (b) a Winslow-type monitor function is used and r_λ is a strict maximum point of λ_1. Moreover, a mismatch between r_D and r_λ is also possible for the case $\lambda_1(r_\lambda) < \lambda_2(r_\lambda)$. Indeed, the numerical results show that r_D can be located to either side of r_λ when $\lambda_1(r_\lambda) > 1$ and λ_2 is taken as $\lambda_2 = \lambda_1^p$ for $p > 1$. Nevertheless, the numerical results suggest that $|r_D - r_\lambda|$ is relatively small for the Winslow case $\lambda_2 = \lambda_1$. The analysis also shows that for the harmonic mapping case $\lambda_2 = 1/\lambda_1$, r_D can be made to agree with r_λ by rescaling λ_1 such that $\lambda_1(r_\lambda) = 1$. However, this can be done if the mesh concentration is needed only at the location of the (global) maximum of λ_1.

For axially symmetric problems, the new functional leads to a nonlinear mesh equation too complex to permit an analysis like that for the traditional functional. Nevertheless, numerical results presented in sections 4 and 5 show that the new functional offers explicit control for mesh concentration by adjusting the value of γ that weights the isotropy and equidistribution. Specifically, when using a large value of γ (close to 1/2) we obtain similar results to those for the traditional functional cases. However, as we decrease γ, the new functional weights more towards equidistribution, and both the location of the maximum and the profile of the mesh density tend to coincide with those of λ_1 for a monitor function with a nonconstant determinant. For the case of the harmonic mapping monitor function, the determinant is $g = 1$ and equidistribution becomes $J =$ constant so no control of mesh concentration is possible by choosing λ_1. Thus, as expected, the new functional does not work in this case even when a small value of γ is used.

Analysis has also been carried out for the traditional functional applied to spherically symmetric problems in three dimensions. The results are stated in Theorems 6.1 and 6.2.

In the future we intend to investigate a number of higher-dimensional axisymmetrical problems arising in physical applications and show the practicability of the methods which have performed well here.

Acknowledgment. The authors are grateful to the referees for their valuable comments.

CONVERGENCE ESTIMATES FOR THE GENERALIZED DAVIDSON METHOD FOR SYMMETRIC EIGENVALUE PROBLEMS I: THE PRECONDITIONING ASPECT*

E. OVTCHINNIKOV†

Abstract. The generalized Davidson (GD) method can be viewed as a generalization of the preconditioned steepest descent (PSD) method for solving symmetric eigenvalue problems. There are two aspects of this generalization. The most obvious one is that in the GD method the new approximation is sought in a larger subspace, namely the one that spans all the previous approximate eigenvectors, in addition to the current one and the preconditioned residual thereof. Another aspect relates to the preconditioning. Most of the available results for the PSD method are associated with the same view on preconditioning as in the case of linear systems. Consequently, they fail to detect the superlinear convergence for certain "ideal" preconditioners, such as the one corresponding to the "exact" version of the Jacobi–Davidson method—one of the most familiar instances of the GD method. Focusing on the preconditioning aspect, this paper advocates an alternative approach to measuring the quality of preconditioning for eigenvalue problems and presents corresponding nonasymptotic convergence estimates for the GD method in general and Jacobi–Davidson method in particular that correctly detect known cases of the superlinear convergence.

Key words. iterative methods for eigenvalue problems, preconditioning, generalized Davidson method, convergence estimates, superlinear convergence

1. Introduction.

This paper presents convergence estimates for a class of iterative methods for finding the smallest eigenvalue of the generalized eigenvalue problem

$$Lu = \lambda M u \tag{1}$$

or, equivalently, finding the global minimum of the Rayleigh quotient functional

$$\lambda(u) \equiv \frac{(Lu, u)}{(Mu, u)}, \tag{2}$$

where L and M are, respectively, a symmetric and a symmetric positive definite linear operator in a Euclidean space $\mathcal{E}$, and $(\cdot, \cdot)$ is the scalar product in $\mathcal{E}$. The class of methods in question embraces methods based on the following iterative scheme for calculating λ_0 numerically: *given an arbitrary nontrivial vector u^0 calculate a sequence λ^n of approximations to λ_0 using the following recurrent formula:*

$$\begin{aligned} u^n &= \arg \min_{u \in \mathcal{D}^n, (Mu,u)=1} \lambda(u), \quad \lambda^n = \lambda(u^n), \\ \mathcal{D}^{n+1} &= \operatorname{span}\{u^0, \ldots, u^n, K_n(L - \lambda^n M)u^n\}, \end{aligned} \tag{3}$$

where K_n are some linear operators in $\mathcal{E}$.

Two familiar methods based on the iterative scheme (3) are the Davidson method (see, e.g., [4, 3]) and the Jacobi–Davidson method (see, e.g., [29, 27, 9, 28] and the

[†] Harrow School of Computer Science, University of Westminster, Watford Road, London HA1 3TP, United Kingdom (eeo@wmin.ac.uk).

relevant chapters in [1]). In the former, L is a matrix, $M = I$ (the unit matrix), and $K_n = (D_L - \lambda^n I)^{-1}$, where D_L is the diagonal of L (i.e., a diagonal matrix of the same size and with the same diagonal entries as in L). In the Jacobi–Davidson method $v = K_n r$ is calculated by approximately solving the linear system

$$(1 - \pi_n)^T (L - \lambda^n M)(1 - \pi_n)v = (1 - \pi_n)^T r, \quad \pi_n v = 0, \tag{4}$$

where $\pi_n w = (Mw, u^n)u^n$ (this approach is apparently closely related to the so-called shift-and-invert technique—see, e.g., [1, 24]). The general case is sometimes referred to as the generalized Davidson (GD) method [1, 25, 22], which is the term adopted in the present paper.

Nowadays, extensive numerical evidence of the efficiency of the GD method, especially in the Jacobi–Davidson case, is available in the literature (see, e.g., the above references). The present paper is one of a few that focus on *theoretical* convergence results for the GD method. Accordingly, the GD method is presented here in an abstract mathematical form (3), which is convenient for the convergence analysis, but not for its practical implementation, which should follow, e.g., the guidelines in [1].

The GD method can be viewed as a generalization of the preconditioned steepest descent (PSD) iterations

$$u^{n+1} = u^n - \tau_n g^n, \quad g^n = K_n(L - \lambda(u^n)M)u^n, \tag{5}$$

where τ_n are suitably chosen parameters, e.g.,

$$\tau_n = \arg\min_\tau \lambda(u^n - \tau g^n), \tag{6}$$

and K_n is a symmetric positive definite operator usually referred to as *preconditioner*. Preconditioned eigensolvers based on (5) are among the oldest and best-studied to date (see, e.g., [26, 7, 5, 6, 11, 12, 17, 18, 19]; for the related historical overview, see [2, 13]). An obvious aspect of the generalization of (5)–(6) into the GD method is the minimization of $\lambda(u)$ over a larger subspace, and this aspect is addressed by Part II of this paper [23], whereas here we address a less obvious, yet important aspect of the preconditioning.

Formally speaking, both (3) and (5) can be used with the same preconditioners[1] K_n. However, the convergence results available to date for (5) (see, e.g., the references of the previous paragraph; cf. also section 3 below) are associated with essentially the same view on preconditioning as that for linear systems, which is certainly not the case with Davidson and Jacobi–Davidson methods. The "ideal" preconditioner for the (nondegenerate) linear system $Lu = f$ is obviously $K = L^{-1}$—indeed, with this preconditioner the convergence can be achieved in just one iteration. Accordingly, in the general case the quality of a preconditioner K is measured by its closeness to L^{-1}, which can be expressed quantitatively via the spectral condition number (the ratio of the largest and the smallest eigenvalue) of KL, the smaller the better. The convergence results for (5) mentioned above are formulated in terms of the same ratio (or related quantities) and thereby suggest the same "ideal" preconditioner. However, for eigenvalue problems $K = L^{-1}$ is obviously not the best choice, since it fails to deliver a superlinear convergence achievable with some other preconditioners.

It is argued in [13] (cf. also [29]) that an "ideal" preconditioner for (5) would be the pseudoinverse of $L_0 \equiv L - \lambda_0 M$. Indeed, with this preconditioner the convergence

[1] In the PSD method, K_n usually does not depend on n, but this fact is of little importance for the convergence analysis of this method.

of (5), and hence (3), is superlinear (in fact, it is cubic—cf. section 5). Accordingly, the natural measure of the quality of preconditioning for eigenvalue problems should be based rather on how far the preconditioner K_n is from the pseudoinverse of L_0. An example of a convergence estimate for (5) in such terms is an asymptotic estimate in [26], which was later reproduced for the GD method in [22]. The major disadvantage of both is that they are asymptotic, i.e., contain unknown "small enough" quantities. In the important case of a parameter-dependent problem (e.g., a discretized differential one, which involves discretization parameters), such estimates are insufficient for comprehensive analysis of the convergence of iterative methods and its dependence on the parameters of the problem. In the present paper a similar but *nonasymptotic* estimate is derived (Theorem 5.2), alongside an analogous estimate related to the Jacobi–Davidson-type preconditioning (Theorem 4.2).

The outline of the paper is as follows. After introducing the notation in section 2, we discuss in section 3 the available convergence estimates for the iterations (5) that are applicable to the GD method. It should be noted that the discussion is restricted to the most advanced results, leaving out quite a few historically important ones (cf. [2, 13, 16] for a more detailed review). In section 4 we study the convergence of the Jacobi–Davidson method. We show that the approximate solution of (4) is equivalent to the use of preconditioners K_n (in the GD method) that satisfy the assumption (22), which measures the quality of preconditioning against the "ideal" case of solving (4) exactly. Based on this assumption, we present a new convergence estimate that correctly predicts the cubic convergence in this "ideal" case. In section 5 we discuss the relation between the two "ideal" cases mentioned above and present a new nonasymptotic convergence estimate for the GD method that detects the cubic convergence in the case when K_n is the pseudoinverse of L_0.

2. Notation. In this paper we use the standard notation $A > 0$ ($A \geq 0$) to declare that a symmetric linear operator A is positive definite (resp., semidefinite). Accordingly, $A \geq B$ stands for $A - B \geq 0$, etc. For $A \geq 0$ we denote (Au, v) by $(u, v)_A$, and $\|u\|_A$ stands for $\sqrt{(u, u)_A}$.

The minimal eigenvalue of (1) is denoted λ_0, and λ_1 denotes the second smallest *distinct* eigenvalue. The invariant subspace of $M^{-1}L$ corresponding to λ_0 is denoted by $\mathcal{I}_0$, and π denotes the $(\cdot,\cdot)_M$-orthogonal projection onto $\mathcal{I}_0$. The orthogonal complement to $\mathcal{I}_0$ in $\mathcal{E}$ is denoted by $\bar{\mathcal{I}}_0$. For any projection π' we denote $\bar{\pi}' \equiv 1 - \pi'$.

The projection π has the following simple properties:

$$L\pi = \pi^T L = \lambda_0 M\pi, \quad M\pi = \pi^T M, \quad L_0 \equiv L - \lambda_0 M = L_0\bar{\pi} = \bar{\pi}^T L_0,$$

the last one implying that

$$\|\bar{\pi}u\|^2_{L_0} = \|u\|^2_{L_0} = \|u\|^2_L - \lambda_0\|u\|^2_M = (\lambda(u) - \lambda_0)\|u\|^2_M.$$

Further,

$$\begin{aligned}\lambda(u)\|u\|^2_M = \|u\|^2_L = \|\pi u\|^2_L + \|\bar{\pi}u\|^2_L = \lambda_0\|\pi u\|^2_M + \lambda(\bar{\pi}u)\|\bar{\pi}u\|^2_M \\ \geq \lambda_0\|\pi u\|^2_M + \lambda_1\|\bar{\pi}u\|^2_M = \lambda_0\|u\|^2_M + (\lambda_1 - \lambda_0)\|\bar{\pi}u\|^2_M.\end{aligned}$$

Thus, for any vector u

$$\|\bar{\pi}u\|^2_M \leq \delta(\lambda(u))\|u\|^2_M, \quad \|\bar{\pi}u\|^2_{L_0} = (\lambda(u) - \lambda_0)\|u\|^2_M, \tag{7}$$

where

$$\delta(\lambda) = \frac{\lambda - \lambda_0}{\lambda_1 - \lambda_0}.$$

3. Available convergence estimates. From the minimax principle for eigenvalues it follows that $\lambda(u_0(\mathcal{D}^{n+1})) \le \lambda(u^n - \tau g^n)$ for any τ. Hence, convergence results for any method based on (5) in terms of eigenvalues[2] apply to (3) with the same preconditioners K_n. In view of this, let us start with a brief account of (the most advanced) available convergence results for the PSD method (5), paying special attention to the assumptions on K_n.

As mentioned in the introduction, in the convergence analysis for methods based on (5) the following assumption on K_n is standard:

$$aK_n^{-1} \le L \le bK_n^{-1}, \tag{8}$$

where a and b are some positive constants, or, equivalently,

$$aL^{-1} \le K_n \le bL^{-1} \tag{9}$$

or else

$$(1-\gamma)L \le \tau_n L K_n L \le (1+\gamma)L, \tag{10}$$

where $0 \le \gamma < 1$ and $\tau_n > 0$. The equivalence between (8) and (10) is established by the following relationships:

$$\tau_n = \frac{2}{a+b}, \quad \gamma = \frac{b-a}{b+a}. \tag{11}$$

One of the best available convergence results for the preconditioned iterations (5) under the assumption (10) is given in [19] (see also [14, 15, 16] and the related results in [17, 18]):

$$\Delta(\lambda^{n+1}) \le q(\gamma)^2 \Delta(\lambda^n), \quad \Delta(\mu) = \frac{\mu - \lambda_0}{\lambda_1 - \mu}, \quad q(\gamma) = \gamma + (1-\gamma)\frac{\lambda_0}{\lambda_1}, \tag{12}$$

where $\lambda^n \equiv \lambda(u^n)$. The above estimate is sharp for iterations (5) with fixed $\tau_n = \tau$. For variable τ_n one can find in [12] an asymptotically better estimate: assuming (8) one has

$$\lambda^{n+1} - \lambda_0 \le (\tilde{\gamma} + \epsilon(\lambda^n - \lambda_0))^2 (\lambda^n - \lambda_0), \tag{13}$$

where $\epsilon(t) = \mathcal{O}(\sqrt{t})$ and

$$\tilde{\gamma} = \frac{1-\xi}{1+\xi}, \quad \xi = \frac{a}{b}\left(1 - \frac{\lambda_0}{\lambda_1}\right).$$

The same result for the corresponding variant of the GD method was obtained independently in [22].

The main disadvantage of the above results is their failure to detect cubic convergence of (5) achievable with, e.g., $K = L_0^{-1}\bar{\pi}^T$ (here and below L_0^{-1} is the inverse of the restriction of $L_0 = L - \lambda_0 M$ onto $\bar{\mathcal{I}}_0$). To overcome this limitation, which is apparently closely related to the form of the assumptions (8) and (10), [22] considers the assumption

$$(1-\gamma)L_0 \le \tau_n L_0 K_n L_0 \le (1+\gamma)L_0, \tag{14}$$

[2] It is important to emphasize that the convergence results for (5) in other terms (e.g., those in [8, 20, 30]) may not be straightforwardly applicable to (3).

leading to the following asymptotic estimate:

$$\lambda^{n+1} - \lambda_0 \le (\gamma + \epsilon_n)^2(\lambda^n - \lambda_0), \tag{15}$$

where $\epsilon_n = \mathcal{O}(\sqrt{\lambda^n - \lambda_0})$. It should be noted that [22] addresses the GD method. As far as the PSD method is concerned, the above estimate was actually available as early as in 1958 [26] and represents the first convergence result for preconditioned eigensolvers. We observe that in the "ideal" case $\gamma = 0$ the estimate (15) predicts quadratic convergence for (5) (in reality, it is cubic—cf. section 5).

As mentioned in the introduction, the main drawback of the estimate (15) is the presence of an unknown (albeit asymptotically insignificant) term ϵ_n. Furthermore, it is not clear how to apply this estimate to some practical implementations of the GD method, such as the Jacobi–Davidson method. In section 4 below we show that the approximate solution of (4) in the Jacobi–Davidson method is equivalent to using the GD method with preconditioners K_n satisfying the assumption (22). In subsequent section 5 we show how this new assumption is related to (a generalization of) (14), thereby illuminating the relevance of the latter to the Jacobi–Davidson method and, furthermore, present a nonasymptotic analogue of (15).

4. A new convergence estimate for the Jacobi–Davidson method.

Let us rewrite (4) in the following equivalent form:

$$\tilde{L}_n v = \bar{\pi}_n^T r, \tag{16}$$

where

$$\tilde{L}_n = \omega \pi_n^T M \pi_n + \bar{\pi}_n^T (L - \lambda(u^n)M)\bar{\pi}_n \tag{17}$$

and ω is a positive constant. The auxiliary result below shows that (16) is correctly posed provided that λ_0 is simple and $\lambda(u^n)$ is "close enough" to λ_0.

LEMMA 4.1. *If λ_0 is a simple eigenvalue and $\lambda^n \equiv \lambda(u^n) < (\lambda_0 + \lambda_1)/2$, then*

$$\tilde{L}_n \ge c_n M, \quad c_n = \min\{\lambda_0 + \lambda_1 - 2\lambda^n, \omega\}.$$

Proof. See Appendix A.2 (cf. also [20]). □

If (16) is solved exactly, then the Jacobi–Davidson method is known to have cubic convergence [24, 29]. If the size of the problem makes the exact solution impractical, then one has to resort to solving (16) iteratively (cf. inexact shift-and-invert iterations—see, e.g., [30]). We note that the iterative solution of (4) by the preconditioned conjugate gradient method was studied in [20]. Just like this paper, [20] focuses on the preconditioning aspect and thereby considers actually the iterations (5) (referred to as "simplified GD method" there) rather than (3). However, the convergence results in [20], unlike those below, are given in terms of residuals, and hence they do not directly apply to the GD method.[3]

Below we assume that (16) is solved by some iterative method with the error propagation operators T_i (e.g., Chebyshev semi-iterative method [10]), i.e.,

$$v^i - v = T_i(v^0 - v). \tag{18}$$

[3] A recent report [21], which was not available to the author at the time of submission, has removed this limitation.

We assume that $\tilde{L}_n T_i$ are symmetric and that we stop (18) after k iterations, where k is such that

$$-\delta_k \tilde{L}_n \le \tilde{L}_n T_k \le \delta_k \tilde{L}_n, \quad \delta_k < 1, \tag{19}$$

which implies the reduction of the $\tilde{L}_n$-norm of the error by a factor of δ_k. If we start with the zero initial guess v^0, then

$$v^k = (1 - T_k)v = (1 - T_k)\tilde{L}_n^{-1}\bar{\pi}_n^T r \equiv K_n \bar{\pi}_n^T r = K_n r \tag{20}$$

and from (19) we have

$$(1 - \delta_k)\tilde{L}_n \le \tilde{L}_n K_n \tilde{L}_n \le (1 + \delta_k)\tilde{L}_n, \tag{21}$$

which shows that in this Jacobi–Davidson implementation of the GD method K_n can be viewed as a preconditioner for $\tilde{L}_n$. Accordingly, Theorem 4.2 below presents a convergence estimate for (5) with the following assumption on K_n that generalizes (21) (cf. (9) and (10)):

$$a^0 \tilde{L}_n^{-1} \le K_n \le b^0 \tilde{L}_n^{-1}. \tag{22}$$

THEOREM 4.2. *Assume that λ_0 is a simple eigenvalue of* (1). *If $\lambda^{n_0} < \frac{\lambda_0 + \lambda_1}{2}$ for some n_0 and the preconditioner K_n satisfies* (22) *for $n \ge n_0$, then the convergence of the iterations* (5) *for $n \ge n_0$ is described by the following estimate:*

$$0 \le \lambda^{n+1} - \lambda_0 \le \tilde{q}(\kappa^0, \nu, \delta(\lambda^n))^2 (\lambda^n - \lambda_0), \tag{23}$$

where

$$\kappa^0 = \frac{b^0}{a^0}, \quad \nu = \frac{\omega}{\lambda_1 - \lambda_0},$$

$$\tilde{q}(u, v, w) = \frac{u\tilde{\rho}(v, w) - 1}{u\tilde{\rho}(v, w) + 1}, \quad \tilde{\rho}(v, w) = \frac{1}{1 - 2w} \frac{(1 + w)^2 + vw}{(1 - w)^2}.$$

Proof. See Appendix A.3. □

COROLLARY 4.3. *The convergence estimate of Theorem* 4.2 *applies to the iterations* (3).

We observe that in the above Jacobi–Davidson implementation of the GD method $a^0 = 1 - \delta_k$ and $b^0 = 1 + \delta_k$ (cf. (21)), and hence $\tilde{q}(\kappa^0, \nu, \delta(\lambda^n)) = \delta_k + \mathcal{O}(\delta(\lambda^n))$. Thus, in the "ideal" case $\delta_k = 0$ (i.e., the system (4) solved exactly) the convergence is indeed cubic.

Finally, we note that Theorem 4.2 remains valid for $\omega = 0$, provided that $\tilde{L}_n^{-1}$ in (22) is the pseudoinverse of $\tilde{L}_n$: this case obviously corresponds to solving (4) by an iterative method in the subspace of vectors orthogonal to u^n in the scalar product $(\cdot, \cdot)_M$.

5. A new convergence estimate for the GD method. The aim of this section is to present a nonasymptotic convergence estimate for the GD method that would detect cubic convergence in another "ideal" case mentioned above, namely the case when K_n is the pseudoinverse of L_0. The form of the operator in the left-hand side of (4) suggests that this case is closely related to the case of solving (4) (or, equivalently, (16)) exactly. Below we express this relationship quantitatively based on the following lemma.

Lemma 5.1. *Let P be the $(\cdot,\cdot)_M$-orthogonal projection onto a subspace of $\mathcal{E}$ of the same dimension as $\mathcal{I}_0$, and denote*

$$L_{\alpha,P} = \alpha P^T M P + \bar{P}^T (L - \lambda_P M)\bar{P}, \tag{24}$$

where $\lambda_P = \max_u \lambda(Pu)$ and $\bar{P} = 1 - P$. If $\delta_P \equiv \delta(\lambda_P) < \delta_0$, where

$$\delta_0 = \frac{\min\{\alpha, \lambda_1 - \lambda_0\}}{\alpha + \lambda_1 - \lambda_0},$$

then

$$\left(1 - 2\sqrt{\frac{\delta_P}{\delta_0}} - \frac{\delta_P}{\delta_1}\right) L_{\alpha,\pi} \le L_{\alpha,P} \le \left(1 + \sqrt{\frac{\delta_P}{\delta_0}}\right)^2 L_{\alpha,\pi}, \tag{25}$$

where

$$\delta_1 = \min\left\{1, \frac{\alpha}{\lambda_1 - \lambda_0}\right\}.$$

Proof. See Appendix A.1. □

From Lemma 5.1 it follows that if λ_0 is simple, then

$$\tilde{a}_n \tilde{L} \le \tilde{L}_n \le \tilde{b}_n \tilde{L},$$

where $\tilde{a}_n = 1 - \mathcal{O}(\sqrt{\delta(\lambda^n)})$, $\tilde{b}_n = 1 + \mathcal{O}(\sqrt{\delta(\lambda^n)})$, and $\lambda^n = \lambda(u^n)$. Therefore, the operators $\tilde{L}_n$ defined by (17) converge to the operator

$$\tilde{L} = \omega\, \pi^T M \pi + \bar{\pi}^T L_0 \bar{\pi}, \tag{26}$$

and the assumption (22) is asymptotically equivalent to

$$a^0 \tilde{L}^{-1} \le K_n \le b^0 \tilde{L}^{-1}. \tag{27}$$

In the convergence result below the above assumption is slightly weakened, for the sake of generality (and in order to cover the case when K is the pseudoinverse of L_0), to become

$$a_0 \bar{\pi} L_0^{-1} \bar{\pi}^T \le K_n \le b_0 \left(\alpha \pi M \pi^T + \bar{\pi} L_0 \bar{\pi}^T\right)^{-1}, \tag{28}$$

where a_0, b_0, and α are positive constants.[4] Apart from its relation to (22), the assumption (28) can also be viewed as a generalization of (8) in the following sense: if K_n satisfies (8), then it also satisfies (28) with

$$a_0 = a\frac{\lambda_1 - \lambda_0}{\lambda_1}, \quad b_0 = b, \quad \alpha = \lambda_0. \tag{29}$$

It is also easy to see that (28) implies (14) with

$$\tau_n = \frac{2}{a_0 + b_0}, \quad \gamma = \frac{b_0 - a_0}{b_0 + a_0}. \tag{30}$$

[4] The use of different letters indicates that (28) does not need the same constants as (22).

The main convergence result of this section combines the advantages of the results discussed in section 3 and is free from their limitations: it is nonasymptotic, it produces the same asymptotic convergence factor as in (15) (the smallest one for (5) available to date), and it adequately predicts the cubic convergence in the "ideal" case $a_0 = b_0$.

THEOREM 5.2. *Assuming that* $\lambda^{n_0} < \lambda_1$ *for some* n_0 *and that the condition* (28) *is satisfied for* $n \geq n_0$, *the convergence of the iterations* (5) *for* $n \geq n_0$ *is described by the following estimate:*

$$0 \leq \lambda^{n+1} - \lambda_0 \leq q(\kappa_0, \sigma, \delta(\lambda^n))^2 (\lambda^n - \lambda_0), \tag{31}$$

where

$$\kappa_0 = \frac{b_0}{a_0}, \quad \sigma = \frac{\lambda_1 - \lambda_0}{\alpha},$$

$$q(u, v, w) = \frac{u\rho(v, w) - 1}{u\rho(v, w) + 1}, \quad \rho(v, w) = \frac{(1 + w)^2 + vw}{(1 - w)^2}.$$

Proof. See Appendix A.4. □

COROLLARY 5.3. *If* K_n *satisfies* (8), *then* (13) *is valid with* $\epsilon(t) = \mathcal{O}(t)$.

COROLLARY 5.4. *If* K_n *satisfies* (28), *then* (15) *is valid with* $\epsilon_n = \mathcal{O}(\lambda^n - \lambda_0)$.

COROLLARY 5.5. *The convergence estimate of Theorem* 5.2 *applies to the GD method.*

We observe that $q(\kappa_0, \sigma, \delta(\lambda^n)) < 1$ for $\lambda^n < \lambda_1$, and, by Corollary 5.4, the asymptotically insignificant term in (31) is smaller than that in (15). Furthermore, in the "ideal" case $\kappa_0 = 1$ one has $q(\kappa_0, \sigma, \delta(\lambda^n)) = \mathcal{O}(\delta(\lambda^n))$ and, thus, $\delta(\lambda^{n+1}) = \mathcal{O}(\delta(\lambda^n)^3)$ (cubic convergence). The last relationship, together with the discussion at the beginning of this section, advocates the use of the assumption (28) for measuring the quality of preconditioning for eigenvalue problems, instead of the standard assumptions (8) or (10), which are certainly more simple but do not guarantee the cubic convergence for any values of a, b, and γ.

Appendix A. Proofs and auxiliary results.

LEMMA A.1. *Assuming that*

$$a_u L_0 \leq L_0 \bar{\pi}_u K \bar{\pi}_u^T L_0 \leq b_u L_0, \tag{32}$$

where $K = K^T$,

$$\pi_u v = \frac{(Mv, u)}{(Mu, u)} u,$$

and $0 \neq u \in \mathcal{E}$, *the following inequalities are valid:*

$$0 \leq \min_\tau \lambda(u - \tau K r(u)) - \lambda_0 \leq \left(\frac{b_u - a_u}{b_u + a_u} \right)^2 (\lambda(u) - \lambda_0). \tag{33}$$

Proof. We have

$$\operatorname{span}\{u, Kr(u)\} = \operatorname{span}\{u, \bar{\pi}_u K r(u)\},$$

and hence

$$\min_\tau \lambda(u - \tau K r(u)) = \min_\tau \lambda(u - \bar{\pi}_u \tau K r(u)).$$

It is easy to verify that

$$\pi_u^T M = M\pi_u = \pi_u^T M \pi_u$$

and

$$\pi_u^T r(u) = 0, \quad r(u) = \bar{\pi}_u^T r(u) = \bar{\pi}_u^T L_0 u.$$

Therefore,

$$u(\tau) \equiv u - \tau\bar{\pi}_u K r(u) = u - \tau\bar{\pi}_u K \bar{\pi}_u^T r(u) = (1 - \tau K_u L_0)u,$$

where $K_u \equiv \bar{\pi}_u K \bar{\pi}_u^T$. Since $L_0 = \bar{\pi}^T L_0 \bar{\pi}$ we have

$$\bar{\pi} u(\tau) = (1 - \tau\bar{\pi} K_u \bar{\pi}^T L_0)\bar{\pi} u \equiv T_\tau \bar{\pi} u.$$

The operator $T_\tau : \bar{\mathcal{I}}_0 \to \bar{\mathcal{I}}_0$ is symmetric in the scalar product $(\cdot,\cdot)_{L_0}$. Furthermore, from (32) it follows that for

$$\tau = \tau_{opt} \equiv \frac{2}{a_u + b_u}$$

its spectral radius $\rho(T_\tau)$ is

$$\rho(T_{\tau_{opt}}) = \rho_{opt} \equiv \frac{b_u - a_u}{b_u + a_u}.$$

Hence,

$$\|u(\tau_{opt})\|_{L_0} \le \rho_{opt} \|u\|_{L_0}.$$

Since $\|u\|_{L_0}^2 = (\lambda(u) - \lambda_0)\|u\|_M^2$, $\|u(\tau_{opt})\|_{L_0}^2 = (\lambda(u(\tau_{opt})) - \lambda_0)\|u(\tau_{opt})\|_M^2$, and $\|u(\tau_{opt})\|_M^2 \ge \|u\|_M^2$ we finally obtain

$$\min_\tau \lambda(u - \tau K r(u)) - \lambda_0 = \min_\tau (\lambda(u(\tau)) - \lambda_0) \le \rho_{opt}^2 (\lambda(u) - \lambda_0).$$

The right-hand side inequality in (33) follows from the minimax principle. □

A.1. Proof of Lemma 5.1. From (7) it follows that if $\tilde{\pi}$ is a projection in the scalar product $(\cdot,\cdot)_M$ onto a subspace $\tilde{\mathcal{I}}_0$ of the same dimension as $\mathcal{I}_0$, then

$$\|(\pi - \tilde{\pi})u\|_M^2 \le \delta(\lambda^0)\|u\|_M^2, \quad \lambda^0 = \max_{v \in \tilde{\mathcal{I}}_0} \lambda(v). \tag{34}$$

Since $L_{\alpha,\pi} \ge \alpha_0 M$, where $\alpha_0 = \min\{\alpha, \lambda_1 - \lambda_0\}$, using (34) we obtain

$$\|(P - \pi)u\|_M^2 \le \delta_P \|u\|_M^2 \le \frac{\delta_P}{\alpha_0}\|u\|_{L_{\alpha,\pi}}^2.$$

Further,

$$\|(P - \pi)u\|_{L_0}^2 = \|\bar{\pi} P u\|_{L_0}^2 \le (\lambda_P - \lambda_0)\|u\|_M^2 \le \frac{\lambda_P - \lambda_0}{\alpha_0}\|u\|_{L_{\alpha,\pi}}^2.$$

Thus, in the norm $[\cdot]$ given by $[u]^2 = \alpha\|u\|_M^2 + \|u\|_{L_0}^2$ we have

$$[(P - \pi)u]^2 \le \frac{\alpha\delta_P + \lambda_P - \lambda_0}{\alpha_0}\|u\|_{L_{\alpha,\pi}}^2 = \frac{\delta_P}{\delta_0}\|u\|_{L_{\alpha,\pi}}^2. \tag{35}$$

Since $\delta_0 \le \frac{1}{2}$, the same calculations as in the proof of Lemma 4.1 show that $L_{\alpha,P} > 0$. Further,

$$\|u\|^2_{L_{\alpha,P}} = \alpha\|Pu\|^2_M + \|\bar{P}u\|^2_{L_0} - (\lambda_P - \lambda_0)\|\bar{P}u\|^2_M.$$

Using the relationships $Pu = \pi u + (P - \pi)u$ and $\bar{P}u = \bar{\pi}u - (P - \pi)u$ we obtain

$$\begin{aligned}\alpha\|Pu\|^2_M + \|\bar{P}u\|^2_{L_0} &= \alpha(\|\pi u\|^2_M + 2(\pi u, (P-\pi)u)_M + \|(P-\pi)u\|^2_M) \\ &\quad + \|\bar{\pi}u\|^2_{L_0} - 2(\bar{\pi}u, (P-\pi)u)_{L_0} + \|(P-\pi)u\|^2_{L_0} \\ &= \|u\|^2_{L_{\alpha,\pi}} + [(P-\pi)u]^2 + 2(\alpha(\pi u, (P-\pi)u)_M - (\bar{\pi}u, (P-\pi)u)_{L_0}).\end{aligned}$$

We have

$$\begin{aligned}&|\alpha(\pi u, (P-\pi)u)_M - (\bar{\pi}u, (P-\pi)u)_{L_0}| \\ &\le \alpha\|\pi u\|_M\|(P-\pi)u\|_M + \|\bar{\pi}u\|_{L_0}\|(P-\pi)u\|_{L_0} \\ &\le \|u\|_{L_{\alpha,\pi}}[(P-\pi)u] \le \sqrt{\frac{\delta_P}{\delta_0}}\|u\|^2_{L_{\alpha,\pi}}\end{aligned}$$

and

$$(\lambda_P - \lambda_0)\|\bar{P}u\|^2_M \le (\lambda_P - \lambda_0)\|u\|^2_M \le \frac{\lambda_P - \lambda_0}{\alpha_0}\|u\|^2_{L_{\alpha,\pi}} = \frac{\delta_P}{\delta_1}\|u\|^2_{L_{\alpha,\pi}}.$$

Thus,

$$\|u\|^2_{L_{\alpha,P}} \le \left(1 + \sqrt{\frac{\delta_P}{\delta_0}}\right)^2 \|u\|^2_{L_{\alpha,\pi}}$$

and

$$\|u\|^2_{L_{\alpha,P}} \ge \left(1 - 2\sqrt{\frac{\delta_P}{\delta_0}} - \frac{\delta_P}{\delta_1}\right)\|u\|^2_{L_{\alpha,\pi}}.$$

In what follows we assume that $\|u^n\|_M = 1$, and we denote $\pi_n v \equiv \pi_{u^n}$ and $\tilde{K}_n \equiv \bar{\pi}_n K_n \bar{\pi}_n^T$.

A.2. Proof of Lemma 4.1. We have

$$\begin{aligned}(\tilde{L}_n v, v) &= ((L - \lambda^n M)\bar{\pi}_n v, \bar{\pi}_n v) + \omega\|\pi_n v\|^2_M, \\ ((L - \lambda^n M)\bar{\pi}_n v, \bar{\pi}_n v) &= \|\bar{\pi}\bar{\pi}_n v\|^2_{L-\lambda^n M} - (\lambda^n - \lambda_0)\|\pi\bar{\pi}_n v\|^2_M \\ &\ge (\lambda_1 - \lambda^n)\|\bar{\pi}\bar{\pi}_n v\|^2_M - (\lambda^n - \lambda_0)\|\pi\bar{\pi}_n v\|^2_M \\ &= (\lambda_1 - \lambda^n)(\|\bar{\pi}\bar{\pi}_n v\|^2_M - \tilde{\delta}(\lambda^n)\|\pi\bar{\pi}_n v\|^2_M),\end{aligned}$$

where

$$\tilde{\delta}(\mu) = \frac{\mu - \lambda_0}{\lambda_1 - \mu} = \frac{1}{1 - \delta(\mu)} - 1, \quad \lambda_0 \le \mu < \lambda_1.$$

From (7) it follows that

$$\|\pi\bar{\pi}_n v\|^2_M = \|(\pi - \pi_n)\bar{\pi}_n v\|^2_M \le \delta(\lambda^n)\|\bar{\pi}_n v\|^2_M$$

and, thus,

$$\|\bar\pi\bar\pi_n v\|_{M}^2 = \|\bar\pi_n v\|_{M}^2 - \|\pi\bar\pi_n v\|_{M}^2 \ge (1-\delta(\lambda^n))\|\bar\pi_n v\|_{M}^2.$$

Therefore,

$$\begin{aligned}(\tilde L_n v, v) &\ge (\lambda_1-\lambda^n)(1-\delta(\lambda^n)-\delta(\lambda^n)\tilde\delta(\lambda^n))\|\bar\pi_n v\|_{M}^2 + \omega\|\pi_n v\|_{M}^2\\ &= (\lambda_1-\lambda^n)(1-\tilde\delta(\lambda^n))\|\bar\pi_n v\|_{M}^2 + \omega\|\pi_n v\|_{M}^2\\ &= (\lambda_0+\lambda_1-2\lambda^n)\|\bar\pi_n v\|_{M}^2 + \omega\|\pi_n v\|_{M}^2\\ &\ge \min\{\lambda_0+\lambda_1-2\lambda^n, \omega\}\,\|v\|_{M}^2.\end{aligned}$$

A.3. Proof of Theorem 4.2. Denote $B_n = K_n^{-1}$ and consider an auxiliary linear system

$$B_n v = \bar\pi_n^T L_0 u. \tag{36}$$

We have

$$\bar\pi_n^T L_0 u = L_0 u - (L_0 u, u^n) M u^n.$$

Hence, multiplying (36) by $\bar\pi u$ (in the scalar product in $\mathcal{E}$) we obtain

$$\|u\|_{L_0}^2 = (Mu^n, \bar\pi u)(L_0 u, u^n) + (B_n v, \bar\pi u).$$

The first term in the right-hand side can be estimated as follows:

$$\begin{gathered}|(Mu^n, \bar\pi u)(L_0 u, u^n)| \le \|\bar\pi u^n\|_{M}\|\bar\pi u\|_{M}\|u^n\|_{L_0}\|u\|_{L_0},\\ \|\bar\pi u^n\|_{M}^2 \le \frac{\lambda^n-\lambda_0}{\lambda_1-\lambda_0}, \quad \|u^n\|_{L_0}^2 = \lambda^n-\lambda_0, \quad \|\bar\pi u\|_{M}^2 \le \frac{1}{\lambda_1-\lambda_0}\|u\|_{L_0}^2,\\ |(Mu^n, \bar\pi u)(L_0 u, u^n)| \le \delta(\lambda^n)\|u\|_{L_0}^2.\end{gathered}$$

For the second term we have

$$|(B_n v, \bar\pi u)| \le \|v\|_{B_n}\|\bar\pi u\|_{B_n}$$

and, thus,

$$(1-\delta(\lambda^n))\|u\|_{L_0}^2 \le \|v\|_{B_n}\|\bar\pi u\|_{B_n}.$$

The second factor in the right-hand side can be estimated as follows:

$$\begin{gathered}\|\bar\pi u\|_{B_n}^2 \le \frac{1}{a^0}\|\bar\pi u\|_{\tilde L_n}^2 = \frac{1}{a^0}\left(\nu(\lambda_1-\lambda_0)\|\pi_n\bar\pi u\|_{M}^2 + ((L-\lambda^n M)\bar\pi_n\bar\pi u, \bar\pi_n\bar\pi u)\right),\\ \|\pi_n\bar\pi u\|_{M}^2 = (M\bar\pi u, u^n)^2 \le \frac{\delta(\lambda^n)}{\lambda_1-\lambda_0}\|u\|_{L_0}^2,\\ ((L-\lambda^n M)\bar\pi_n\bar\pi u, \bar\pi_n\bar\pi u) \le \|\bar\pi_n\bar\pi u\|_{L_0}^2,\\ \begin{aligned}\|\bar\pi_n\bar\pi u\|_{L_0} = \|\bar\pi u - (M\bar\pi u, u^n)u^n\|_{L_0} &\le \|u\|_{L_0} + |(M\bar\pi u, u^n)|\|u^n\|_{L_0}\\ &\le (1+\delta(\lambda^n))\|u\|_{L_0},\end{aligned}\\ \|\bar\pi u\|_{B_n}^2 \le \frac{1}{a^0}\left(\nu\delta(\lambda^n) + (1+\delta(\lambda^n))^2\right)\|u\|_{L_0}^2,\end{gathered}$$

which leads to the following estimate:

$$\|u\|^2_{L_0} \le \frac{1}{a^0} \frac{\nu\delta(\lambda^n) + (1+\delta(\lambda^n))^2}{(1-\delta(\lambda^n))^2} \|v\|^2_{B_n} = \frac{1}{a^0_n} \|v\|^2_{B_n}, \tag{37}$$

where

$$a^0_n = a^0 \frac{(1-\delta(\lambda^n))^2}{(1+\delta(\lambda^n))^2 + \nu\delta(\lambda^n)}.$$

Now, multiplying (36) by v we have

$$\begin{aligned}(B_n v, v) = (L_0 u, \bar{\pi}_n v) \le \|u\|_{L_0} \|\bar{\pi}_n v\|_{L_0} &\le \frac{\lambda_1 - \lambda_0}{\lambda_1 - \lambda^n} \|u\|_{L_0} \|\bar{\pi}\bar{\pi}_n v\|_{L-\lambda^n M} \\ &= (1+\tilde{\delta}(\lambda^n)) \|u\|_{L_0} \|\bar{\pi}\bar{\pi}_n v\|_{L-\lambda^n M}.\end{aligned} \tag{38}$$

Further,

$$(\tilde{L}_n v, v) \ge ((L - \lambda^n M)\bar{\pi}_n v, \bar{\pi}_n v) \ge \|\bar{\pi}\bar{\pi}_n v\|^2_{L-\lambda^n M} - (\lambda^n - \lambda_0)\|\pi\bar{\pi}_n v\|^2_M$$

and (cf. the proof of Lemma 4.1)

$$\|\pi\bar{\pi}_n v\|^2_M \le \frac{\delta(\lambda^n)}{1-\delta(\lambda^n)} \|\bar{\pi}\bar{\pi}_n v\|^2_M = \tilde{\delta}(\lambda^n) \|\bar{\pi}\bar{\pi}_n v\|^2_M \le \frac{\tilde{\delta}(\lambda^n)}{\lambda_1 - \lambda^n} \|\bar{\pi}\bar{\pi}_n v\|^2_{L-\lambda^n M}.$$

Therefore,

$$(\tilde{L}_n v, v) \ge (1 - \tilde{\delta}(\lambda^n)^2) \|\bar{\pi}\bar{\pi}_n v\|^2_{L-\lambda^n M}$$

and we obtain from (38) the estimate

$$(B_n v, v) \le \frac{1+\tilde{\delta}(\lambda^n)}{\sqrt{1-\tilde{\delta}(\lambda^n)^2}} \|u\|_{L_0} \|v\|_{\tilde{L}_n} \le \frac{1+\tilde{\delta}(\lambda^n)}{\sqrt{1-\tilde{\delta}(\lambda^n)^2}} \sqrt{b^0} \|u\|_{L_0} \|v\|_{B_n},$$

which leads to the estimate

$$\|u\|^2_{L_0} \ge \frac{1}{b^0} \frac{1-\tilde{\delta}(\lambda^n)^2}{(1+\tilde{\delta}(\lambda^n))^2} \|v\|^2_{B_n} = \frac{1}{b^0} \frac{1-\tilde{\delta}(\lambda^n)}{1+\tilde{\delta}(\lambda^n)} \|v\|^2_{B_n} = \frac{1}{b^0_n} \|v\|^2_{B_n}, \tag{39}$$

where

$$b^0_n = b^0 \frac{1+\tilde{\delta}(\lambda^n)}{1-\tilde{\delta}(\lambda^n)} = \frac{b^0}{1-2\delta(\lambda^n)}.$$

Thus,

$$a^0_n \|u\|^2_{L_0} \le \|v\|^2_{B_n} \le b^0_n \|u\|^2_{L_0}.$$

Recalling that $v = B_n^{-1} \bar{\pi}_n^T L_0 u = K_n \bar{\pi}_n^T L_0 u$ we can rewrite the above inequalities as

$$a^0_n \|u\|^2_{L_0} \le (\tilde{K}_n L_0 u, L_0 u) \le b^0_n \|u\|^2_{L_0}.$$

To complete the proof, it remains to apply Lemma A.1.

A.4. Proof of Theorem 5.2. Since

$$(\alpha \pi^T M \pi + \bar{\pi}^T L_0 \bar{\pi})^{-1} = \alpha^{-1} \pi M^{-1} \pi^T + \bar{\pi} L_0^{-1} \bar{\pi}^T$$

from (28) we have for any $u \in \mathcal{E}$

$$a_0 \|\bar{\pi}^T u\|^2_{L_0^{-1}} \le (K_n u, u) \le b_0 \left(\alpha^{-1} \|\pi^T u\|^2_{M^{-1}} + \|\bar{\pi}^T u\|^2_{L_0^{-1}} \right). \tag{40}$$

In order to apply Lemma A.1 let us take $u = \bar{\pi}_n^T L_0 v$. We have

$$\pi^T u = \pi^T \bar{\pi}_n^T L_0 v = -\pi^T \pi_n^T L_0 v = -(L_0 v, u^n) M \pi u^n,$$

and hence

$$\begin{aligned} \alpha^{-1} \|\pi^T u\|^2_{M^{-1}} = \alpha^{-1} (L_0 v, u^n)^2 \|\pi u^n\|^2_M &\le \alpha^{-1} \|v\|^2_{L_0} \|u^n\|^2_{L_0} \\ &= \sigma \frac{\lambda^n - \lambda_0}{\lambda_1 - \lambda_0} \|v\|^2_{L_0}. \end{aligned}$$

Further,

$$\bar{\pi}^T u = \bar{\pi}^T \bar{\pi}_n^T L_0 v = \bar{\pi}^T L_0 v - \bar{\pi}^T \pi_n^T L_0 v = L_0 v - (L_0 v, u^n) \bar{\pi}^T M u^n.$$

For $w = (L_0 v, u^n) \bar{\pi}^T M u^n$ we have

$$\begin{aligned} \|w\|^2_{L_0^{-1}} &= (L_0 v, u^n)^2 \|M \bar{\pi} u^n\|^2_{L_0^{-1}} = (L_0 v, u^n)^2 \|L_0^{-1} M \bar{\pi} u^n\|^2_{L_0} \\ &\le \|v\|^2_{L_0} \|u^n\|^2_{L_0} \frac{\|u^n\|^2_{L_0}}{(\lambda_1 - \lambda_0)^2} = \left(\frac{\lambda^n - \lambda_0}{\lambda_1 - \lambda_0} \right)^2 \|v\|^2_{L_0} = \delta(\lambda^n)^2 \|v\|^2_{L_0}. \end{aligned}$$

Hence,

$$\|\bar{\pi}^T u\|_{L_0^{-1}} \le \|L_0 v\|_{L_0^{-1}} + \|w\|_{L_0^{-1}} = \|v\|_{L_0} + \|w\|_{L_0^{-1}} \le (1 + \delta(\lambda^n)) \|v\|_{L_0}$$

and

$$\|\bar{\pi}^T u\|_{L_0^{-1}} \ge \|v\|_{L_0} - \|w\|_{L_0^{-1}} \ge (1 - \delta(\lambda^n)) \|v\|_{L_0}.$$

Substituting the above estimates for $\pi^T u$ and $\bar{\pi}^T u$ into (40), we obtain

$$a_{0n} (L_0 v, v) \le (L_0 \bar{\pi}_n K_n \bar{\pi}_n^T L_0 v, v) \le b_{0n} (L_0 v, v),$$

where

$$a_{0n} = a_0 (1 - \delta(\lambda^n))^2, \quad b_{0n} = b_0 ((1 + \delta(\lambda^n))^2 + \sigma \delta(\lambda^n)). \tag{41}$$

To complete the proof it remains to apply Lemma A.1.

CONVERGENCE ESTIMATES FOR THE GENERALIZED DAVIDSON METHOD FOR SYMMETRIC EIGENVALUE PROBLEMS II: THE SUBSPACE ACCELERATION*

E. OVTCHINNIKOV†

Abstract. The generalized Davidson (GD) method can be viewed as a generalization of the preconditioned steepest descent (PSD) method for solving symmetric eigenvalue problems. In the GD method, the new approximation is sought in the subspace that spans all the previous approximate eigenvectors, in addition to the current one and the preconditioned residual thereof used in PSD. In this respect, the relation between the GD and PSD methods is similar to that between the standard steepest descent method for linear systems and methods in Krylov subspaces. This paper presents convergence estimates for the (restarted) GD method that demonstrate convergence acceleration compared to the PSD method, similar to that achieved by methods in Krylov subspaces compared to the standard steepest descent.

1. Introduction.

This paper presents convergence estimates for the generalized Davidson (GD) method [1, 17, 11] for finding the smallest eigenvalue of the generalized eigenvalue problem

$$Lu = \lambda M u, \tag{1}$$

where L and M are, respectively, a symmetric and a symmetric positive definite linear operator in a Euclidean space $\mathcal{E}$. The GD method can be formulated as follows: given an arbitrary nontrivial vector u^0 we calculate a sequence λ^n of approximations to the smallest eigenvalue λ_0 of (1) using the following recurrent formula:

$$\begin{aligned} u^n &= \arg \min_{u \in \mathcal{D}^n,\ (Mu,u)=1} \lambda(u), \quad \lambda^n = \lambda(u^n), \\ \mathcal{D}^{n+1} &= \operatorname{span}\{u^0, \dots, u^n, K_n(L - \lambda^n M)u^n\}, \end{aligned} \tag{2}$$

where K_n are some linear operators in $\mathcal{E}$, $(\cdot,\cdot)$ is the scalar product in $\mathcal{E}$, and $\lambda(u)$ is the Rayleigh quotient, i.e.,

$$\lambda(u) \equiv \frac{(Lu,u)}{(Mu,u)}. \tag{3}$$

Two familiar instances of the GD method are the Davidson method (see, e.g., [3, 2]) and the Jacobi–Davidson method (see, e.g., [19] and the relevant chapters in [1]). In the former, L is a matrix, $M = I$ (the unit matrix), and $K_n = (D_L - \lambda^n I)^{-1}$, where D_L is the diagonal of L (i.e., a diagonal matrix of the same size and with the same

*Received by the editors January 11, 2002; accepted for publication September 16, 2002; published electronically March 26, 2003.

†Harrow School of Computer Science, University of Westminster, Watford Road, London HA1 3TP, United Kingdom (eeo@wmin.ac.uk).

diagonal entries as in L). In the Jacobi–Davidson method $v = K_n r$ is calculated by approximately solving the linear system

$$(1-\pi_n)^T(L-\lambda^n M)(1-\pi_n)v = (1-\pi_n)^T r, \quad \pi_n v = 0, \tag{4}$$

where $\pi_n w = (Mw, u^n)u^n$.

It is easy to see that the number of arithmetic operations needed to perform the nth iteration (2) is asymptotically proportional to n^2. To avoid excessive computational expenses, in practical calculations the iterations (2) are restarted using the last approximation u^n as the initial one.[1] If the restart takes place every m iterations, then we arrive at the following iterative scheme:

$$\begin{aligned} u^{lm+k} &= \arg \min_{u \in \mathcal{D}^{lm,k},(Mu,u)=1} \lambda(u), \quad \lambda^{lm+k} = \lambda(u^{lm+k}), \\ \mathcal{D}^{l,k+1} &= \operatorname{span}\{u^{lm}, \dots, u^{lm+k}, K_{lm+k}(L-\lambda^{lm+k}M)u^{lm+k}\}. \end{aligned} \tag{5}$$

An alternative approach to restarting the GD method is to choose some $k > 0$ and to remove vectors $u^0,\dots,u^{n-k}$ from the definition of the subspace $\mathcal{D}^{n+1}$ for $n \geq k$, thereby bounding its dimension by $k+1$. For $k = 2$ this yields the so-called locally optimal preconditioned conjugate gradient (LOPCG) method [6]. Quite interestingly, there is numerical evidence (see [14]; cf. also [8, 9]) that the LOPCG method converges at the same rate as the GD method, despite using a smaller subspace. This remarkable phenomenon still awaits explanation (for some insights into the convergence behavior of LOPCG, see [6, 8]).

The GD method can be viewed as a generalization of the preconditioned steepest descent (PSD) iterations

$$u^{n+1} = u^n - \tau_n g^n, \quad g^n = K(L-\lambda(u^n)M)u^n, \tag{6}$$

where

$$\tau_n = \arg\min_{\tau} \lambda(u^n - \tau g^n), \tag{7}$$

and K is a symmetric positive definite operator usually referred to as *preconditioner*. Preconditioned eigensolvers based on (6) are among the oldest and best-studied to date (see, e.g., [7] and the references therein; for the comparative discussion of the latest results, see also [13, 15]). Owing to the minimax principle, any convergence estimate for (6) in terms of eigenvalues apply to (2) and (5) as well.[2] However, such estimates can only be used as preliminary ones because the GD method should obviously converge faster than the PSD method, by virtue of using larger subspaces for minimizing $\lambda(u)$. Indeed, if we take $K = L^{-1}$, then, assuming $\lambda^n < \lambda_1$, for (6) we have [5]

$$\frac{\mu_0 - \mu^n}{\mu^n - \mu_1} \leq \left(\frac{1-\xi}{1+\xi}\right)^2 \frac{\mu_0 - \mu^{n-1}}{\mu^{n-1} - \mu_1}, \tag{8}$$

where $\mu_0 = 1/\lambda_0$, $\mu^n = 1/\lambda^n$, and ξ is the relative distance between λ_0 and the second smallest distinct eigenvalue λ_1, i.e., $\xi = 1 - \lambda_0/\lambda_1$. Accordingly, if we take $K_n = L^{-1}$,

[1] A somewhat different restart strategy is suggested in [8].

[2] In fact, the only convergence estimates for the GD method that have been available so far are those for the PSD method (see [13] and the references therein).

then the subspaces $\mathcal{D}^n$ become Krylov subspaces, and (2) becomes equivalent to the Lanczos method (for finding the largest eigenvalue μ_0 of $L^{-1}M$), for which we have [5]

$$\frac{\mu_0 - \mu^n}{\mu^n - \mu_1} \le \left(T_n\left(\frac{1+\xi}{1-\xi}\right)\right)^{-2} \frac{\mu_0 - \mu^0}{\mu^0 - \mu_1}, \tag{9}$$

where $T_n(x) = \cos(n \arccos x)$ are the Chebyshev polynomials and we assume that $\mu^0 > \mu_1$. Since $T_n((1+\xi)/(1-\xi)) \ge 0.5((1+\sqrt{\xi})/(1-\sqrt{\xi}))^n$, the estimate (9) leads to the asymptotic convergence factor $((1-\sqrt{\xi})/(1+\sqrt{\xi}))^2$, which implies that (2) converges about twice as fast as (6) for a small ξ.

In the general case neither $\mathcal{D}^n$ nor $\mathcal{D}^{l,k}$ is a Krylov subspace. However, there are several Krylov subspaces that $\mathcal{D}^{l,k}$ approaches as l increases. Indeed, assuming for simplicity that $K_n = K$, we can define $\mathcal{D}^{l,k}$ equivalently as

$$\mathcal{D}^{l,k+1} = \operatorname{span}\{u^{lm}, K(L - \lambda^{lm}M)u^{lm}, \ldots, K(L - \lambda^{lm+k}M)u^{lm+k}\}$$

from which we see immediately that, as l increases, $\mathcal{D}^{l,k}$ approaches the Krylov subspace

$$\mathcal{K}_{k+1}(u^{lm}, K(L - \lambda^{lm}M)), \tag{10}$$

where

$$\mathcal{K}_n(u, A) = \operatorname{span}\{u, Au, \ldots, A^n u\}.$$

Some other Krylov subspaces that are "close" to $\mathcal{D}^{l,k}$ are discussed in section 4. We note that the subspace (10) appears in various preconditioned eigensolvers. For example, denoting by $\nu(t)$ the smallest eigenvalue of $A_t = K(L - tM)$, we can rewrite the problem (1) equivalently as $\nu(\lambda) = 0$. Applying the Newton method to solve this equation together with a method in Krylov subspaces for A_t to approximately compute $\nu(t)$, we obtain a two-level method that uses subspaces similar to (10) at the inner iteration level (see, e.g., [5]; cf. also [1, Algorithms 11.7 and 11.8]).

The present paper uses the above property of the Davidson subspaces $\mathcal{D}^{l,k}$ and the standard analysis in Krylov subspaces (cf. Lemma 4.1) to obtain convergence estimates for (5) that are similar to those for two-level methods using Krylov subspaces at the inner iteration level (cf. [5]). It should be noted that similar estimates for $m \le 2$ can be found in [6]. For $m > 2$ the estimates of the present paper are, to the best of the author's knowledge, the first estimates for the (restarted) GD method that reflect the subspace acceleration aspect of this method.

2. Notation.

In this paper we use the standard notation $A > 0$ (resp., $A \ge 0$) to declare that a symmetric linear operator A is positive definite (resp., semidefinite). Accordingly, $A \ge B$ stands for $A - B \ge 0$, etc. For $A \ge 0$ we denote (Au, v) by $(u, v)_A$, and $\|u\|_A$ stands for $\sqrt{(u,u)_A}$. By considering an auxiliary eigenvalue problem $Au = \mu Bu$ it is easy to show that $0 < A \le B$ implies $B^{-1} \le A^{-1}$, which, together with the fact that $A \le B$ implies $C^T AC \le C^T BC$ for any C, leads to the following elementary result:

$$\begin{gathered} 0 < A \le cB^{-1} \;\Rightarrow\; \|Au\|_B^2 \le c\|u\|_A^2 \le c^2\|u\|_{B^{-1}}^2, \\ \|BAu\|_A \le c\|u\|_A, \quad \|BAu\|_{B^{-1}} \le c\|u\|_{B^{-1}}. \end{gathered} \tag{11}$$

The minimal eigenvalue of (1) is denoted λ_0, and λ_1 denotes the second smallest *distinct* eigenvalue. The invariant subspace of $M^{-1}L$ corresponding to λ_0 is denoted by $\mathcal{I}_0$, and the $(\cdot,\cdot)_M$-orthogonal projection onto $\mathcal{I}_0$ is denoted by π. For any projection π' we denote $\bar{\pi}' \equiv I - \pi'$, where I is the identity operator. The projection π has the following simple properties:

$$L\pi = \pi^T L = \lambda_0 M\pi, \quad M\pi = \pi^T M, \quad L_0 \equiv L - \lambda_0 M = L_0\bar{\pi} = \bar{\pi}^T L_0,$$

and for any vector u

$$\|\bar{\pi}u\|_M^2 \le \delta(\lambda(u))\|u\|_M^2, \quad \|\bar{\pi}u\|_{L_0}^2 = (\lambda(u) - \lambda_0)\|u\|_M^2,$$

where

$$\delta(\lambda) = \frac{\lambda - \lambda_0}{\lambda_1 - \lambda_0}.$$

Finally, $r(u)$ denotes the residual $Lu - \lambda(u)Mu$, and $u_i(\mathcal{H})$ are the Ritz eigenvectors of the problem (1) in a subspace $\mathcal{H} \subset \mathcal{E}$, i.e.,

$$u_i(\mathcal{H}) \in \mathcal{H} \;:\; (r(u_i(\mathcal{H})), v) = 0 \quad \forall v \in \mathcal{H}. \tag{12}$$

We assume that $\|u_i(\mathcal{H})\|_M = 1$ and we enumerate the Ritz eigenpairs $\{\lambda_i(\mathcal{H}), u_i(\mathcal{H})\}$ in the ascending order of $\lambda_i(\mathcal{H}) = \lambda(u_i(\mathcal{H}))$.

3. Assumptions on the preconditioners. Preconditioning in the GD method has been discussed in detail in Part I of this paper [13]. Here we summarize that discussion in order to make proper assumptions on the preconditioners K_n.

The role of preconditioning in iterative methods is to improve the convergence. Accordingly, a usual assumption on a preconditioner K is

$$aK_* \le K \le bK_*, \tag{13}$$

where a and b are positive constants and K_* is some "ideal" preconditioner, i.e., the one that would lead to a very fast convergence if used. For example, in the case of a linear system $Lu = f$ with $L > 0$, taking $K = K_* = L^{-1}$ as a preconditioner in the PSD method makes it converge after just one iteration. Furthermore, convergence estimates for preconditioned algorithms for solving linear systems show that in the general case (13) (with $K_* = L^{-1}$) the ratio $\kappa = b/a$ can be used as a measure of the quality of preconditioning: the smaller, the better, the "ideal" case being $\kappa = 1$.

Many papers on preconditioned eigensolvers feature exactly the same choice for K_* despite the fact that it is no longer "ideal" in the case of eigenvalue problems, since it fails to deliver a superlinear convergence achievable with some other preconditioners. Part I of this paper considers two alternative choices $K_* = \tilde{L}^{-1}$ and $K_* = \tilde{L}_n^{-1}$, where

$$\tilde{L} = \alpha\,\pi^T M\pi + \bar{\pi}^T L_0\bar{\pi}$$

and

$$\tilde{L}_n = \omega\pi_n^T M\pi_n + \bar{\pi}_n^T(L - \lambda(u^n)M)\bar{\pi}_n$$

and α and ω are positive constants. These two choices are, in a sense, asymptotically equivalent, since $\tilde{L}_n$ with $\omega = \alpha$ converges to $\tilde{L}$ [13]. It should be noted that the first choice is not entirely new: the asymptotic estimates in [18] and [11] essentially use $K_* = \tilde{L}$ and assumption (13) in the subspace orthogonal to $\mathcal{I}_0$. The second choice is closely related to the Jacobi–Davidson method: if (4) is solved approximately using a linear iterative algorithm, then the respective Jacobi–Davidson method can be interpreted as the GD method with preconditioners satisfying (13) with $K_* = \tilde{L}_n$, $a = 1-\delta$, and $b = 1+\delta$, where δ is the accuracy in the $\tilde{L}_n$-norm to which (4) is solved [13].

The convergence estimates in [18, 11, 13] show that the suggested alternative assumptions on K are indeed more suitable for preconditioned eigensolvers than the "standard" one based on $K_* = L^{-1}$ because in the "ideal" case $a = b$ both lead to cubic convergence. In view of this, below we assume that either

$$a_0\tilde{L}^{-1} \le K_n \le b_0\tilde{L}^{-1} \tag{14}$$

or

$$a^0\tilde{L}_n^{-1} \le K_n \le b^0\tilde{L}_n^{-1}, \tag{15}$$

where a_0, b_0, a^0, and b^0 are positive constants. To simplify the proofs, we assume further that λ_0 is simple and that $K_{lm+i} = K_{lm}$ for $i = 1, \ldots, m-1$ (see [12] for a more general case).

4. Rayleigh–Ritz approximation in auxiliary Krylov subspaces. As mentioned in the introduction, the idea behind the estimates of this paper is to use the asymptotic closeness of the Davidson subspaces $\mathcal{D}^{l,k}$ to some Krylov subspaces. One such subspace is that in (10). Another one is obviously

$$\operatorname{span}\{u^{lm}, K(L-\lambda_0 M)u^{lm}, \ldots, (K(L-\lambda_0 M))^k u^{lm}\}. \tag{16}$$

In this section we introduce yet another Krylov subspace that appears to be asymptotically closer to $\mathcal{D}^{l,k}$ than (16) and provides better approximation for u_0 than (10).

Denoting $r^n \equiv r(u^n)$ and $g^n = K_n r^n$, we have

$$\mathcal{D}^{l,k+1} = \mathcal{D}^{l,k} + \operatorname{span}\{g^{lm+k}\}$$

and, therefore,

$$\begin{aligned}\mathcal{D}^{l,k+1} &= \operatorname{span}\{u^{lm}, g^{lm}, \ldots, g^{lm+k}\}\\ &= \operatorname{span}\{u^{lm}, \bar{\pi}_{lm}g^{lm}, \ldots, \bar{\pi}_{lm}g^{lm+k}\}.\end{aligned}$$

Since $(r^n, u^{lm}) = 0$ for $lm \le n \le (l+1)m$, we have $\bar{\pi}_{lm}^T r^n = r^n$ and $g^n = K_n\bar{\pi}_{lm}^T r^n = K_{lm}\bar{\pi}_{lm}^T r^n$. Therefore

$$\mathcal{D}^{l,k+1} = \operatorname{span}\{v_i^0\}_{i=-1,k},$$

where

$$v_{-1}^0 = u^{lm}, \quad v_i^0 = \bar{\pi}_{lm}K_{lm}\bar{\pi}_{lm}^T r^{lm+i} \equiv \hat{K}_{lm}r^{lm+i}, \quad i \ge 0. \tag{17}$$

Consider now the following Krylov subspaces:

$$\mathcal{K}^{l,k} = \mathcal{K}_{k+1}(u^{lm}, \hat{K}_{lm}L_0). \tag{18}$$

Using the standard technique for estimating the accuracy of the Rayleigh–Ritz approximation in Krylov subspaces (see, e.g., [5]), one easily obtains the following estimate for the smallest Ritz eigenvalue $\lambda^{l,k} = \lambda(u_0(\mathcal{K}^{l,k}))$ in $\mathcal{K}^{l,k}$.

LEMMA 4.1. *Assume that $\lambda^{l_0 m} < \lambda_1$ for some l_0 and that K_n satisfies* (14) *for $n \geq l_0 m$. Then for $l \geq l_0$ the following estimate holds for the smallest Ritz eigenvalue $\lambda^{l,k}$ in the subspace $\mathcal{K}^{l,k}$:*

$$0 \leq \lambda^{l,k} - \lambda_0 \leq \frac{\lambda^{lm} - \lambda_0}{T_k(\eta_l)^2}, \tag{19}$$

where $\eta_l = q(\kappa_0, \sigma, \delta(\lambda^{lm}))^{-1}$ and

$$\kappa_0 = \frac{b_0}{a_0}, \quad \sigma = \frac{\lambda_1 - \lambda_0}{\alpha},$$

$$q(u, v, w) = \frac{u\rho(v, w) - 1}{u\rho(v, w) + 1}, \quad \rho(v, w) = \frac{(1 + w)^2 + vw}{(1 - w)^2}.$$

Proof. Let us denote for brevity $n = lm$. We have

$$\lambda_0 \leq \lambda^{l,k} = \min_{u \in \mathcal{K}^{l,k}} \lambda(u) \leq \lambda(P_k(\hat{K}_n L_0) u^n),$$

where $P_k(x)$ is any polynomial of degree k. Let us take $P_k(x) \equiv \tilde{T}_k(x)$, where

$$\tilde{T}_k(x) = c_k T_k\left(2\frac{x - a_{0n}}{b_{0n} - a_{0n}} - 1\right), \quad c_k = T_k\left(-\frac{b_{0n} + a_{0n}}{b_{0n} - a_{0n}}\right)^{-1} = \frac{(-1)^k}{T_k(\eta_l)},$$

a_{0n} and b_{0n} are given in Lemma A.4, and $T_k(x) = \cos(k \arccos x)$ is the Chebyshev polynomial of degree k. Since $\tilde{T}_k(0) = 1$ we have

$$\tilde{T}_k(x) = 1 - \sum_{i=1}^{k} \tau_i x^i$$

and, thus,

$$v^k \equiv \tilde{T}_k(\hat{K}_n L_0) u^n = \left(1 - \sum_{i=1}^{k} \tau_i (\bar{\pi}_n K_n \bar{\pi}_n^T L_0)^i\right) u^n.$$

Since $v = v^k - u^n = \bar{\pi}_n v$ we have $(Mv, u^n) = 0$, and hence $\|v^k\|_M \geq 1$, and

$$\|v^k\|_{L_0}^2 = (\lambda(v^k) - \lambda_0)\|v^k\|_M^2 \geq \lambda(v^k) - \lambda_0 \geq \lambda^{l,k} - \lambda_0.$$

Further, since $L_0 = \bar{\pi}^T L_0 \bar{\pi}$ we have $\bar{\pi}(\hat{K}_n L_0)^i = (\bar{\pi}\hat{K}_n \bar{\pi}^T L_0)^i$, and, thus,

$$\|v^k\|_{L_0} = \|\bar{\pi}\tilde{T}_k(\hat{K}_n L_0) u^n\|_{L_0} = \|\tilde{T}_k(\bar{\pi}\hat{K}_n \bar{\pi}^T L_0) u^n\|_{L_0}.$$

The operator $\bar{\pi}\hat{K}_n \bar{\pi}^T L_0$ is symmetric in the semiscalar product $(\cdot,\cdot)_{L_0}$, and so is $\tilde{T}_k(\bar{\pi}\hat{K}_n \bar{\pi}^T L_0)$. From Lemma A.4 it follows that nonzero eigenvalues of $\bar{\pi}\hat{K}_n \bar{\pi}^T L_0$ lie in the interval $[a_{0n}, b_{0n}]$. Since $|\tilde{T}_k(x)| \le |c_k|$ for $a_{0n} \le x \le b_{0n}$, this implies that $\|v^k\|_{L_0} \le |c_k| \|u^n\|_{L_0}$, and, thus,

$$\lambda^{l,k} - \lambda_0 \le c_k^2 \|u^n\|_{L_0}^2 = c_k^2(\lambda^n - \lambda_0) = \frac{\lambda^{lm} - \lambda_0}{T_k(\eta_l)^2}. \qquad \square$$

Since $\bar{\pi}_{lm}^T M u^{lm} = 0$, we have $\hat{K}_{lm} r^{lm} = \hat{K}_{lm} L_0 u^{lm}$ and, thus, $\mathcal{D}^{l,k} = \mathcal{K}^{l,k}$ for $k = 0$ and $k = 1$. For $k > 1$, $\hat{K}_{lm} r^{lm+i} \to \hat{K}_{lm} L_0 u^{lm+i}$ as $l \to \infty$ and, thus, the subspace $\mathcal{D}^{l,k}$ approaches $\mathcal{K}^{l,k}$ as $l \to \infty$. The proof of Theorem 5.3 (see Appendix B) shows that for $0 \le i < k$ the distance between v_i^0 and $\mathcal{K}^{l,k}$ is of the order $\mathcal{O}\left(\delta(\lambda^{lm})^{3/2}\right)$ (cf. (37), (41), and (34)), whereas for (16) the author could only estimate the same distance as[3] $\mathcal{O}\left(\delta(\lambda^{lm})\right)$. Further, from Lemma 4.1 we observe that $\lambda^{l,k}$ converges to λ_0 as k increases, whereas the same is not true for the minimal Ritz eigenvalue in the Krylov subspace (10). Hence, this paper uses the subspaces $\mathcal{K}^{l,k}$ for the convergence analysis of (5), instead of those in (10) or (16).

5. Convergence estimates.

In Part I of this paper the following convergence results for the PSD method (6) were obtained.

THEOREM 5.1. *Assuming that $\lambda^{n_0} < \lambda_1$ for some n_0 and that the condition* (14) *is satisfied for $n \ge n_0$, the convergence of the iterations* (6) *for $n \ge n_0$ is described by the following estimate:*

$$0 \le \lambda^{n+1} - \lambda_0 \le q(\kappa_0, \sigma, \delta(\lambda^n))^2 (\lambda^n - \lambda_0), \tag{20}$$

where

$$\kappa_0 = \frac{b_0}{a_0}, \quad \sigma = \frac{\lambda_1 - \lambda_0}{\alpha},$$

$$q(u, v, w) = \frac{u\rho(v, w) - 1}{u\rho(v, w) + 1}, \quad \rho(v, w) = \frac{(1 + w)^2 + vw}{(1 - w)^2}.$$

THEOREM 5.2. *Assume that λ_0 is a simple eigenvalue of* (1). *If $\lambda^{n_0} < \frac{\lambda_0 + \lambda_1}{2}$ for some n_0 and the preconditioner K_n satisfies* (15) *for $n \ge n_0$, then the convergence of the iterations* (6) *for $n \ge n_0$ is described by the following estimate:*

$$0 \le \lambda^{n+1} - \lambda_0 \le \tilde{q}(\kappa^0, \nu, \delta(\lambda^n))^2 (\lambda^n - \lambda_0), \tag{21}$$

where

$$\kappa^0 = \frac{b^0}{a^0}, \quad \nu = \frac{\omega}{\lambda_1 - \lambda_0},$$

$$\tilde{q}(u, v, w) = \frac{u\tilde{\rho}(v, w) - 1}{u\tilde{\rho}(v, w) + 1}, \quad \tilde{\rho}(v, w) = \frac{1}{1 - 2w} \frac{(1 + w)^2 + vw}{(1 - w)^2}.$$

Due to the minimax principle, the above results apply to the restarted GD method as well. In this section we present respective improved estimates that reflect the acceleration of the convergence due to the increasing size of subspaces $\mathcal{D}^{l,k}$.

[3] This is still enough to obtain estimates similar to those in this paper but with somewhat larger asymptotically insignificant terms—cf. [12].

THEOREM 5.3. *Assume that λ_0 is simple, that $\lambda^{l_0 m} < \lambda_1$ for some l_0, and that K_n satisfies* (14) *for $n \geq l_0 m$. Then the convergence of the restarted generalized Davidson method* (5) *for $l \geq l_0$ is described by the following estimate:*

$$0 \leq \lambda^{lm+k} - \lambda_0 \leq q^2_{lm+k}(\lambda^{lm} - \lambda_0), \tag{22}$$

where

$$q_{lm+k} \leq \prod_{n=lm}^{lm+k-1} q(\kappa_0, \sigma, \delta(\lambda^n)) < 1 \tag{23}$$

and κ_0, σ, and $q(u,v,w)$ are given in Theorem 5.1. *Furthermore,*

$$q_{lm+k} = T_k\left(\frac{\kappa_0+1}{\kappa_0-1}\right)^{-1} + \mathcal{O}\left(\sqrt{\delta(\lambda^{lm})}\right), \quad k = 0, \dots, m-1. \tag{24}$$

Proof. The estimate (23) follows immediately from that in Theorem 5.3. The proof of the estimate (24) is rather long and technical, despite the simplicity of its main idea—the closeness between the Davidson subspaces $\mathcal{D}^{l,k}$ and the Krylov subspaces $\mathcal{K}^{l,k}$ discussed in the previous section—and it is therefore placed, together with other technicalities, in the appendix (see Appendix B). □

Remark 5.1. If K_n satisfies "standard" condition $aL^{-1} \leq K_n \leq bL^{-1}$, then $\kappa_0 = \frac{a}{b}\frac{\lambda_1}{\lambda_1-\lambda_0}$ and (24) becomes the asymptotic relationship proved earlier for $m \leq 2$ by Knyazev (see [6]).

Now, it is easy to see that

$$q(\kappa_0, \sigma, \delta(\lambda^n)) = \frac{\kappa_0-1}{\kappa_0+1} + \mathcal{O}(\delta(\lambda^n)). \tag{25}$$

Comparing the above asymptotics with (24) and recalling (8) and (9), we observe that the acceleration of convergence in Davidson subspaces is similar to that in Krylov subspaces.

Finally, using Theorem 4.2 and Lemma 5.1 from [13], we obtain from Theorem 5.3 the following convergence result for the restarted Jacobi–Davidson method.

THEOREM 5.4. *Assume that λ_0 is simple, that $\lambda^{l_0 m} < \frac{\lambda_0+\lambda_1}{2}$ for some l_0, and that K_n satisfies* (15) *for $n \geq l_0 m$. Then the convergence of the restarted generalized Davidson method* (5) *for $l \geq l_0$ is described by* (22), *where*

$$q_{lm+i} \leq \prod_{n=lm}^{lm+i-1} \tilde{q}(\kappa^0, \nu, \delta(\lambda^n)) < 1, \tag{26}$$

$$q_{lm+i} = T_i\left(\frac{\kappa^0+1}{\kappa^0-1}\right)^{-1} + \mathcal{O}\left(\sqrt{\delta(\lambda^{lm})}\right), \quad i = 0, \dots, m-1, \tag{27}$$

and κ^0, ν, and $\tilde{q}(u,v,w)$ are given in Theorem 5.2.

The above result allows one to make the following observation. Assume that $\lambda^0 < (\lambda_0+\lambda_1)/2$ and that preconditioners Z_n are available that satisfy the assumption $a\tilde{L}_n^{-1} \leq Z_n \leq b\tilde{L}_n^{-1}$. One has a choice: either to use the preconditioners Z_n in the Jacobi–Davidson method, i.e., in the iterative solution of (4), or to use them directly in the GD method. It was shown in [13] that if (4) is solved by a linear iterative method that reduces the $\tilde{L}_n$-norm of the error by a factor of $\delta < 1$, then the resulting two-level iterative method can be viewed as the GD method with preconditioners K_n satisfying (15) with $a^0 = 1 - \delta$ and $b^0 = 1 + \delta$. Assuming that j iterations of the Chebyshev semi-iterative method [4] are applied we have $\delta = T_j((b+a)/(b-a))^{-1}$, and hence by Theorem 5.4 we have

$$\begin{aligned} \lim_{l\to\infty} q_{lm+i} &= T_i(\delta^{-1})^{-1} = T_i(T_j((b+a)/(b-a)))^{-1} \\ &= T_{ij}((b+a)/(b-a))^{-1}. \end{aligned} \tag{28}$$

We observe that the above asymptotic relationship is precisely the same as that for q_{lm+ij} in the restarted GD method with $K_n = Z_n$. Thus, we may conclude that in the case at hand the use of two-level rather than one-level iterations does not accelerate the convergence of the GD method. At the same time, (28) suggests that the two-level option allows one to achieve the same asymptotic convergence rate using j times smaller Davidson subspaces, which obviously improves the performance of the GD method (cf. the introduction). The same, however, cannot be said about the LOPCG versus (the considered implementation of) the Jacobi–Davidson method. Assuming, on the basis of numerical evidence, that the estimate of Theorem 5.3 is valid for the LOPCG method (cf. [8, 14]), we observe from (28) that one should expect the latter method to have an asymptotic convergence rate similar to that of the Jacobi–Davidson method if the same preconditioners Z_n are used in both and, due to the use of a smaller subspace (of dimension three—cf. the introduction), to have better overall performance. We note that this theoretical conclusion is in agreement with the numerical comparisons in [9] between the LOPCG and two practical implementations of the Jacobi–Davidson method: JDCG by Notay [10] and JDRQ by Sleijpen (see, e.g., [1]).

Appendix A. Auxiliary results. In the convergence analysis below the following auxiliary scalar product and the associated norm in $\mathcal{E}$ are used:

$$\langle u, v\rangle = (M\pi_{lm}u, \pi_{lm}u) + (\hat{K}_{lm}^{-1}\bar{\pi}_{lm}u, \bar{\pi}_{lm}v), \quad \langle u\rangle = \sqrt{\langle u, u\rangle}, \tag{29}$$

where (and in the rest of the paper) $\hat{K}_n^{-1}$ is the inverse of the restriction of $\hat{K}_n \equiv \bar{\pi}_n K_n \bar{\pi}_n^T$ onto $\bar{\pi}_n^T\mathcal{E}$.

LEMMA A.1. *If K_n satisfies* (14)*, then*

$$\langle u\rangle^2 \le \|\pi_{lm}u\|_M^2 + \frac{1}{a_0}\|\bar{\pi}_{lm}u\|_{\tilde{L}}^2 \le \left(1 + \frac{\alpha}{a_0}\right)\|u\|_M^2 + \frac{1}{a_0}\|\bar{\pi}_{lm}u\|_{L_0}^2, \tag{30}$$

where the norm $\langle\cdot\rangle$ is given by (29).

Proof. Let us denote for brevity $n = lm$. Consider the system

$$\hat{K}_n v = \bar{\pi}_n u, \quad \pi_n^T v = 0.$$

Multiplying the first equation by $\bar{\pi}_n^T v$ and using (14) we obtain

$$a_0\|\bar{\pi}_n^T v\|_{\tilde{L}^{-1}}^2 \le (K_n\bar{\pi}_n^T v, \bar{\pi}_n^T v) = (\bar{\pi}_n u, \bar{\pi}_n^T v) \le \|\bar{\pi}_n u\|_{\tilde{L}}\|\bar{\pi}_n^T v\|_{\tilde{L}^{-1}},$$

that is, $\|\bar{\pi}_n^T v\|_{\tilde{L}^{-1}} \le a_0^{-1}\|\bar{\pi}_n u\|_{\tilde{L}}$. Therefore,

$$\begin{aligned} (\hat{K}_n^{-1}\bar{\pi}_n u, \bar{\pi}_n u) &= (v, \bar{\pi}_n u) = (\bar{\pi}_n u, \bar{\pi}_n^T v) \le \frac{1}{a_0}\|\bar{\pi}_n u\|_{\tilde{L}}^2 \\ &= \frac{\alpha}{a_0}\|\pi\bar{\pi}_n u\|_M^2 + \frac{1}{a_0}\|\bar{\pi}\bar{\pi}_n u\|_{L_0}^2 \le \frac{\alpha}{a_0}\|u\|_M^2 + \frac{1}{a_0}\|\bar{\pi}_n u\|_{L_0}^2, \end{aligned}$$

which leads to (30). □

Lemma A.2. *The vectors v_i^0 given by* (17) *are orthogonal in the scalar product $\langle\cdot,\cdot\rangle$ given by* (29).

Proof. From (29) we see that $\langle v_{-1}^0, v_i^0\rangle = 0$ for $i \geq 0$. For $0 \leq i \leq j$ we have

$$\begin{aligned} \langle v_i^0, v_j^0\rangle = \langle \hat{K}_{lm} r^{lm+i}, \hat{K}_{lm} r^{lm+j}\rangle &= (r^{lm+i}, \hat{K}_{lm} r^{lm+j}) \\ &= (r^{lm+i}, K_{lm} r^{lm+j}). \end{aligned} \tag{31}$$

Since u^{lm+i} is a Ritz vector in $\mathcal{D}^{l,i}$, we have (cf. (12))

$$(r^{lm+i}, v) = 0 \quad \forall v \in \mathcal{D}^{l,i}$$

and, thus, for $0 \leq j < i$

$$\langle v_i^0, v_j^0\rangle = (r^{lm+i}, K_{lm} r^{lm+j}) = 0$$

because $K_{lm} r^{lm+j} \in \mathcal{D}^{l,j+1} \subset \mathcal{D}^{l,i}$. □

Lemma A.3. *Let $\lambda(u^{l_0 m}) < \lambda_1$ for some l_0. Let x_i be the coordinates of u^{lm+k} in the basis $\{v_i^0\}_{i=-1,k-1}$, i.e.,*

$$u^{lm+k} = x_{-1} u^{lm} + \sum_{i=0}^{k-1} x_i v_i^0. \tag{32}$$

If K_n satisfies (14), *then $|x_i| \leq (a_0(1-\delta(\lambda^{l_0 m}))^2)^{-1}$ for $l \geq l_0$ and $i \geq 0$.*

Proof. For $i = j \geq 0$ we have from (31)

$$\begin{aligned} \langle v_i^0\rangle^2 = \|r^{lm+i}\|^2_{K_{lm}} &\geq a_0 \|\bar{\pi}^T r^{lm+i}\|^2_{L_0^{-1}} = \|(L - \lambda^{lm+i} M)\bar{\pi} u^{lm+i}\|^2_{L_0^{-1}} \\ &\geq a_0 \left(\frac{\lambda_1 - \lambda^{lm+i}}{\lambda_1 - \lambda_0}\right)^2 \|\bar{\pi} u^{lm+i}\|^2_{L_0} = a_0(1 - \delta(\lambda^{lm+i}))^2 (\lambda^{lm+i} - \lambda_0) \\ &\geq c_0^2 (\lambda^{lm+i} - \lambda_0), \end{aligned} \tag{33}$$

where $c_0 = \sqrt{a_0}(1 - \delta(\lambda^{l_0 m}))$. Multiplying (32) by v_i^0 in the scalar product $\langle\cdot,\cdot\rangle$ we obtain

$$x_i \langle v_i^0\rangle^2 = \langle u^{lm+k}, v_i^0\rangle.$$

We have

$$\begin{aligned} |\langle u^{lm+k}, v_i^0\rangle| &= |(u^{lm+k}, r^{lm+i})| = |(u^{lm+k}, (L - \lambda^{lm+i} M) u^{lm+i})| \\ &= |(\lambda^{lm+k} - \lambda^{lm+i})(M u^{lm+k}, u^{lm+i})| \leq \lambda^{lm+i} - \lambda_0 \end{aligned}$$

and, thus, $|x_i| \leq c_0^{-2} = (a_0(1 - \delta(\lambda^{l_0 m}))^2)^{-1}$. □

Lemma A.4.

$$a_{0,n} L_0 \leq L_0 \hat{K}_n L_0 \leq b_{0,n} L_0,$$

where $a_{0,n} = a_0(1 - \delta(\lambda^n))^2$, $b_{0,n} = b_0((1 + \delta(\lambda^n))^2 + \sigma\delta(\lambda^n))$, and σ is defined in Theorem 5.1.

Proof. See the proof of Theorem 5.2 of [13]. □

Appendix B. Proof of Theorem 5.3. Nonasymptotic result (23) follows immediately from Theorem 5.1. It remains to obtain the asymptotic result (24).

First, we note that if $\delta(\lambda^{lm+k_0}) \le \delta(\lambda^{lm})^3$ for some $k_0 \le m$, then $\delta(\lambda^{lm+k}) \le \delta(\lambda^{lm})^3$ for $k_0 \le k \le m$ and therefore we can take in (22)

$$q_{lm+k} = T_k\left(\frac{\kappa_0+1}{\kappa_0-1}\right)^{-1} + \delta(\lambda^{lm})^2, \quad k_0 \le k \le m.$$

Hence, in the rest of the proof we consider only the case $k < k_0$ (in other words, we assume that $\delta(\lambda^{lm+k}) > \delta(\lambda^{lm})^3$).

Let us show that the distance between the vector u^{lm+i} and the subspace $\mathcal{K}^{l,i}$ in $\|\cdot\|_{L_0}$ is $\mathcal{O}(\delta(\lambda^{lm})^{\frac{3}{2}})$. In other words, let us show that for any $0 \le i \le m$ there exists $\tilde{u}^{lm+i} \in \mathcal{K}^{l,i}$ such that

$$\|u^{lm+i} - \tilde{u}^{lm+i}\|_{L_0}^2 \le \alpha_i \delta(\lambda^{lm})^3, \tag{34}$$

where α_i are positive constants independent of l and $\delta(\lambda^{lm})$. Obviously, (34) is valid for $i = 0$ and $i = 1$. Therefore, it is enough to prove that if it is valid for $i < k$, then it is valid for $i = k$.

Let

$$\tilde{v}_{-1}^0 = u^{lm}, \quad \tilde{v}_i^0 = \hat{K}_{lm} L_0 \tilde{u}^{lm+i}, \ i \ge 0, \quad \tilde{v}_i = \langle v_i^0 \rangle^{-1} \tilde{v}_i^0,$$

$$\tilde{u}^{lm+i} = \sum_{j=-1}^{i-1} x_j^i \tilde{v}_j^0, \quad \delta u^i = \tilde{u}^{lm+i} - u^{lm+i},$$

where x_j^i are the coordinates of u^{lm+i} in the basis $\{v_j^0\}_{j=-1,i-1}$. Let us start with the estimates for $\tilde{v}_i^0 - v_i^0$ in M- and L_0-norms. We have

$$\begin{aligned}\tilde{v}_i^0 - v_i^0 &= \hat{K}_{lm}((L-\lambda_0 M)\tilde{u}^{lm+i} - (L - \lambda^{lm+i}M)u^{lm+i}) \\ &= \hat{K}_{lm} L_0 \delta u^i + (\lambda^{lm+i} - \lambda_0)\hat{K}_{lm} M u^{lm+i} \equiv \delta_1 + \delta_2.\end{aligned} \tag{35}$$

From (14) we observe that

$$K_n \le b_0 \max\left\{\frac{1}{\alpha}, \frac{1}{\lambda_1 - \lambda_0}\right\} M^{-1} \equiv b^M M^{-1}. \tag{36}$$

Hence,

$$\begin{aligned}\|\hat{K}_{lm} L_0 \delta u^i\|_M^2 &= \|\bar{\pi}_{lm} K_{lm} \bar{\pi}_{lm}^T L_0 \delta u^i\|_M^2 \le \|K_{lm}\bar{\pi}_{lm}^T L_0 \delta u^i\|_M^2 \\ &\le b^M \|\bar{\pi}_{lm}^T L_0 \delta u^i\|_{K_{lm}}^2 = b^M \|L_0 \delta u^i\|_{\hat{K}_{lm}}^2 \le b^M b_{0,lm} \|\delta u^i\|_{L_0}^2,\end{aligned}$$

where $b_{0,n}$ is given in Lemma A.4. Further,

$$\begin{aligned}\|\hat{K}_{lm} M u^{lm+i}\|_M &= \|\bar{\pi}_{lm} K_{lm} \bar{\pi}_{lm}^T M u^{lm+i}\|_M \le \|K_{lm}\bar{\pi}_{lm}^T M u^{lm+i}\|_M \\ &= \|K_{lm} M \bar{\pi}_{lm} u^{lm+i}\|_M \le b^M \|\bar{\pi}_{lm} u^{lm+i}\|_M.\end{aligned}$$

Since λ_0 is simple, we have

$$\begin{aligned}\|\bar{\pi}_{lm} u^{lm+i}\|_M &= \|(\pi_{lm+i} - \pi_{lm}) u^{lm+i}\|_M \le \|(\pi_{lm+i} - \pi) u^{lm+i}\|_M \\ &\quad + \|(\pi_{lm} - \pi) u^{lm+i}\|_M \le 2\sqrt{\delta(\lambda^{lm})},\end{aligned}$$

and hence $\|\hat{K}_{lm} M u^{lm+i}\|_{_M} < 2b^M \sqrt{\delta(\lambda^{lm})}$. Thus,

$$
\begin{aligned}
\|\tilde{v}_i^0 - v_i^0\|_{_M} &\le \sqrt{b^M b_{0,lm}} \|\delta u^i\|_{_{L_0}} + 2b^M (\lambda_1 - \lambda_0) \delta(\lambda^{lm+i})^{\frac{3}{2}} \\
&\le \sqrt{b^M (4+\sigma) b_0} \|\delta u^i\|_{_{L_0}} + 2b^M (\lambda_1 - \lambda_0) \delta(\lambda^{lm+i})^{\frac{3}{2}} \\
&\equiv b_1 \|\delta u^i\|_{_{L_0}} + b_2 \delta(\lambda^{lm+i})^{\frac{3}{2}} = (b_1 \sqrt{\alpha_i} + b_2) \delta(\lambda^{lm+i})^{\frac{3}{2}}. \qquad (37)
\end{aligned}
$$

In L_0-norm we have

$$
\|\delta_1\|_{_{L_0}} \le b_{0,lm} \|\delta u^i\|_{_{L_0}} \le (4+\sigma) b_0 \|\delta u^i\|_{_{L_0}} \equiv b_3 \|\delta u^i\|_{_{L_0}}. \qquad (38)
$$

Further, since (14) implies that $L_0 \le b_0 K_n^{-1}$, we have

$$
\begin{aligned}
\|\hat{K}_{lm} M u^{lm+i}\|_{_{L_0}} &= \|(1 - \pi_{lm}) K_{lm} M \bar{\pi}_{lm} u^{lm+i}\|_{_{L_0}} \\
&\le \|K_{lm} M \bar{\pi}_{lm} u^{lm+i}\|_{_{L_0}} + \|K_{lm} M \bar{\pi}_{lm} u^{lm+i}\|_{_M} \|u^{lm}\|_{_{L_0}} \\
&\le \left(\sqrt{b_0} + \sqrt{b^M} \sqrt{\lambda^{lm} - \lambda_0} \right) \|M \bar{\pi}_{lm} u^{lm+i}\|_{_{K_{lm}}} \\
&\le \left(\sqrt{b_0 b^M} + b^M \sqrt{\lambda^{l_0 m}} \right) \|\bar{\pi}_{lm} u^{lm+i}\|_{_M} \\
&\equiv b_4 \|\bar{\pi}_{lm} u^{lm+i}\|_{_M} = 2b_4 \sqrt{\delta(\lambda^{lm})}. \qquad (39)
\end{aligned}
$$

Thus,

$$
\|\delta_2\|_{_{L_0}} \le 2b_4 (\lambda_1 - \lambda_0) \delta(\lambda^{lm+i})^{\frac{3}{2}} \equiv b_5 \delta(\lambda^{lm+i})^{\frac{3}{2}} \qquad (40)
$$

and

$$
\|\tilde{v}_i^0 - v_i^0\|_{_{L_0}} \le b_3 \|\delta u^i\|_{_{L_0}} + b_5 \delta(\lambda^{lm+i})^{\frac{3}{2}} = (b_3 \sqrt{\alpha_i} + b_5) \delta(\lambda^{lm+i})^{\frac{3}{2}}. \qquad (41)
$$

Using Lemma A.3 together with (37) and (41) we obtain (34).

The outline of rest of the proof is as follows. First, we show that the vectors $\tilde{v}_i$ are linearly independent, by exploiting the fact that $\tilde{v}_i$ are close to v_i in the norm $\langle \cdot \rangle$, and v_i are orthogonal in the scalar product $\langle \cdot, \cdot \rangle$. Then, using $\tilde{v}_i$, $i = -1, \dots, k-1$, as a basis in $\mathcal{K}^{l,k}$ we obtain an estimate for the coordinates of the Ritz vector $v^{l,k} = u_0(\mathcal{K}^{l,k})$ in this basis. Finally, we use this estimate together with the above estimates for $\tilde{v}_i^0 - v_i^0$ in L_0-norm and Lemma 4.1 to obtain the asymptotic estimate (24).

Obviously, $\langle \tilde{v}_{-1}, \tilde{v}_i \rangle = 0$, $i \ge 0$. Let $\tilde{V}_{l,k-1}$ be the Gram matrix for $\tilde{v}_i$, $i = 0, \dots, k-1$, associated with the scalar product $\langle \cdot, \cdot \rangle$, i.e., the matrix with the entries $\langle \tilde{v}_i, \tilde{v}_j \rangle$. From (34) we have

$$
\|\delta u^i\|_{_{L_0}}^2 \le \gamma_0 \delta(\lambda^{lm})^3, \quad \gamma_0 = \max_{0 \le i < k_0} \alpha_i,
$$

and hence

$$
\langle \delta_1 \rangle^2 = (\hat{K}_{lm} L_0 \delta u^i, L_0 \delta u^i) \le b_{0,lm} \|\delta u^i\|_{_{L_0}}^2 \le b_3 \gamma_0 \delta(\lambda^{lm})^3.
$$

Further,

$$
\langle \delta_2 \rangle^2 = (\lambda^{lm+i} - \lambda_0)^2 \|M u^{lm+i}\|_{_{\hat{K}_{lm}}}^2 \le 4b^M (\lambda_1 - \lambda_0)^2 \delta(\lambda^{lm+i})^3,
$$

where δ_1 and δ_2 are from (35). Thus,

$$\langle \tilde{v}_i^0 - v_i^0 \rangle^2 \le \gamma_1^2 \delta(\lambda^{lm})^3,$$

where $\gamma_1 = \sqrt{b_3\gamma_0} + 2(\lambda_1 - \lambda_0)\sqrt{b^M}$. Denoting $v_i = \langle v_i^0 \rangle^{-1} v_i^0$ we have

$$\text{(42)} \qquad \langle \tilde{v}_i - v_i \rangle^2 = \langle v_i^0 \rangle^{-2} \langle \tilde{v}_i^0 - v_i^0 \rangle^2 \le \frac{\gamma_1^2}{c_0^2(\lambda_1 - \lambda_0)} \frac{\delta(\lambda^{lm})^3}{\delta(\lambda^{lm+i})} \equiv \gamma_2^2 \frac{\delta(\lambda^{lm})^3}{\delta(\lambda^{lm+i})},$$

where c_0 is given in the proof of Lemma A.2. From the above estimate, together with the trivial relationship

$$\langle \tilde{v}_i, \tilde{v}_j \rangle = \langle v_i, v_j \rangle + \langle \tilde{v}_i - v_i, v_j \rangle + \langle v_i, \tilde{v}_j - v_j \rangle + \langle \tilde{v}_i - v_i, \tilde{v}_j - v_j \rangle,$$

we obtain for $i > j \ge 0$

$$|\langle \tilde{v}_j \rangle^2 - 1| \le \epsilon_{l,j}, \quad |\langle \tilde{v}_i, \tilde{v}_j \rangle| \le \epsilon_{l,i},$$

where

$$\epsilon_{l,i} = \gamma_2 \left(2 + \gamma_2 \frac{\delta(\lambda^{lm})^{\frac{3}{2}}}{\sqrt{\delta(\lambda^{lm+i})}} \right) \frac{\delta(\lambda^{lm})^{\frac{3}{2}}}{\sqrt{\delta(\lambda^{lm+i})}}.$$

By the same logic as above, we may assume that $\delta(\lambda^{lm+k}) \ge \delta(\lambda^{lm})^2$ and, thus, $\epsilon_{l,i} = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}})$, and the matrix $\tilde{V}_{l,k-1}$ can be represented as $\tilde{V}_{l,k-1} = 1 - \tilde{W}_{l,k-1}$ with $\|\tilde{W}_{l,k-1}\| = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}})$. Thus, for $l \ge l_0$ we have $\|\tilde{W}_{l,k-1}\| < 1$, and hence the matrix $\tilde{V}_{l,k-1}$ is nondegenerate, which implies that the vectors $\tilde{v}_i$ are linearly independent.

Using $\tilde{v}_i$, $i = -1, \dots, k-1$, as the basis in $\mathcal{K}^{l,k}$ we have

$$\text{(43)} \qquad v^{l,k} = u_0(\mathcal{K}^{l,k}) = x_{-1}u^{lm} + \sum_{i=0}^{k-1} x_j \tilde{v}_j.$$

The last technically difficult step in the proof is to obtain for the coordinates x_i, $i \ge 0$, the estimate $x_i = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}})$. Multiplying (43) by $\tilde{v}_i$, $i = 0, \dots, k-1$, in the scalar product $\langle \cdot, \cdot \rangle$ we obtain the linear system

$$\sum_{j=0}^{k-1} x_j \langle \tilde{v}_i, \tilde{v}_j \rangle = \langle \tilde{v}_i, v^{l,k} \rangle \equiv y_i, \quad i = 0, \dots, k-1,$$

or, in matrix form,

$$\tilde{V}_{l,k-1} x = y,$$

which is equivalent to

$$\tilde{V}_{l,k-1} z = \tilde{W}_{l,k-1} y,$$

where $z = x - y$. Using the above estimates for the norm of $\tilde{W}_{l,k-1}$, we have

$$\|z\| \le \|\tilde{W}_{l,k-1}\| \, \|y\| = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}) \|y\|,$$

which shows that $\|x\| = \mathcal{O}(\|y\|)$. To estimate $\|y\|$ we observe that

$$\begin{aligned}\langle v^{l,k}, v_i^0\rangle &= (v^{l,k}, r^i) = (v^{l,k}, (L - \lambda^{lm+i}M)u^{lm+i})\\ &= (v^{l,k}, L_0 u^{lm+i}) - (\lambda^{lm+i} - \lambda_0)(Mv^{l,k}, u^{lm+i}),\end{aligned}$$

and hence

$$\begin{aligned}|\langle v^{l,k}, v_i^0\rangle| &\le \|v^{l,k}\|_{L_0}\|u^{lm+i}\|_{L_0} + |\lambda^{lm+i} - \lambda_0||(Mv^{l,k}, u^{lm+i})|\\ &\le \sqrt{\lambda^{l,k} - \lambda_0}\sqrt{\lambda^{lm+i} - \lambda_0} + \lambda^{lm+i} - \lambda_0.\end{aligned}$$

Now, if $\lambda^{lm+i} - \lambda_0 \le \lambda^{l,k} - \lambda_0$, then $\lambda^{lm+k} - \lambda_0 \le \lambda^{l,k} - \lambda_0$, and, by Lemma 4.1, we can take $q_{lm+k} = T_k(\eta_l)^{-1}$. Otherwise, we have

$$|\langle v^{l,k}, v_i^0\rangle| \le 2(\lambda^{lm+i} - \lambda_0), \quad |\langle v^{l,k}, v_i\rangle| \le \frac{2}{c_0}\sqrt{\lambda^{lm+i} - \lambda_0}.$$

Further,

$$\begin{aligned}\|\bar{\pi}_{lm} v^{l,k}\|_{L_0} &\le \|v^{l,k}\|_{L_0} + |(Mv^{l,k}, u^{lm})|\|u^{lm}\|_{L_0}\\ &\le \sqrt{\lambda^{l,k} - \lambda_0} + \sqrt{\lambda^{lm} - \lambda_0} \le 2\sqrt{\lambda^{lm} - \lambda_0},\end{aligned}$$

and hence, using Lemma A.1, we have

$$\langle v^{l,k}\rangle \le 1 + \frac{\alpha}{a_0} + 4(\lambda^{l_0 m} - \lambda_0) \equiv \gamma_3.$$

Thus,

$$\begin{aligned}|\langle v^{l,k}, \tilde{v}_i\rangle| &\le |\langle v^{l,k}, \hat{v}_i\rangle| + |\langle v^{l,k}, (\tilde{v}_i - v_i)\rangle|\\ &\le \frac{2}{c_0}\sqrt{\lambda^{lm+i} - \lambda_0} + \gamma_2\gamma_3\frac{\delta(\lambda^{lm})^{\frac{3}{2}}}{\sqrt{\delta(\lambda^{lm+i})}} = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}})\end{aligned}$$

and

$$\|x\| = \mathcal{O}(\|y\|) = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}). \tag{44}$$

The rest of the proof is fairly simple. Let us denote

$$u^{l,k} = x_{-1}u^{lm} + \sum_{i=0}^{k-1} x_j v_j.$$

From (37) and (41) we have

$$\|\tilde{v}_i - v_i\|_M = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}), \quad \|\tilde{v}_i - v_i\|_{L_0} = \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}).$$

Using the above estimates and (44), we have for $\delta v^{l,k} = v^{l,k} - u^{l,k}$

$$\|\delta v^{l,k}\|_M = \mathcal{O}(\delta(\lambda^{lm})), \quad \|\delta v^{l,k}\|_{L_0} = \mathcal{O}(\delta(\lambda^{lm})).$$

Using Lemma 4.1 we obtain

$$\begin{aligned}\|u^{l,k}\|_{L_0} \le \|v^{l,k}\|_{L_0} + \|\delta v^{l,k}\|_{L_0} &= \sqrt{\lambda^{l,k} - \lambda_0} + \mathcal{O}(\delta(\lambda^{lm}))\\ &\le T_k(\eta)^{-1}\sqrt{\lambda^{lm} - \lambda_0} + \mathcal{O}(\delta(\lambda^{lm}))\\ &= (T_k(\eta_l)^{-1} + \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}))\sqrt{\lambda^{lm} - \lambda_0}.\end{aligned}$$

Since $\|u^{l,k}\|_M \geq \|v^{l,k}\|_M - \|\delta v^{l,k}\|_M = 1 - \|\delta v^{l,k}\|_M = \mathcal{O}(1)$, we finally obtain

$$\begin{aligned}\lambda^{lm+k} - \lambda_0 \leq \lambda(u^{l,k}) - \lambda_0 &\leq (\lambda(u^{l,k}) - \lambda_0)(\|u^{l,k}\|_M + \|\delta v^{l,k}\|_M)^2 \\ &= \|u^{l,k}\|_{L_0}^2 \left(1 + \frac{\|\delta v^{l,k}\|_M}{\|u^{l,k}\|_M}\right)^2 \leq q_{lm+k}^2(\lambda^{lm} - \lambda_0),\end{aligned}$$

where

$$\begin{aligned}q_{lm+k} &= (T_k(\eta_l))^{-1} + \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}))(1 + \mathcal{O}(\delta(\lambda^{lm})) \\ &= T_k(\eta_l)^{-1} + \mathcal{O}(\delta(\lambda^{lm})^{\frac{1}{2}}).\end{aligned}$$

Abstract. A technique derived from two related methods suggested earlier by some of the authors for optimization of finite-difference grids and absorbing boundary conditions is applied to discretization of perfectly matched layer (PML) absorbing boundary conditions for wave equations in Cartesian coordinates. We formulate simple sufficient conditions for optimality and implement them. It is found that the minimal error can be achieved using pure imaginary coordinate stretching. As such, the PML discretization is algebraically equivalent to the rational approximation of the square root on $[0, 1]$ conventionally used for approximate absorbing boundary conditions. We present optimal solutions for two cost functions, with exponential (and exponential of the square root) rates of convergence with respect to the number of the discrete PML layers using a second order finite-difference scheme with optimal grids. Results of numerical calculations are presented.

Key words. absorbing boundary conditions, exponential convergence, finite differences, hyperbolic problems, perfectly matched layers, wave propagation, optimal rational approximations

1. Introduction.

This paper is a sequel to a number of papers on so-called optimal finite-difference grids or finite-difference Gaussian rules [11, 12, 3, 4, 18, 13], where exponential superconvergence of standard second order finite-difference schemes at a priori given points was obtained due to a special grid optimization procedure. This approach was successfully applied to the approximation of many nontrivial practically important problems, including elliptic PDEs for both bounded and unbounded domains. For the latter, in [18] the optimal finite-difference grid was obtained, which can be considered as the boundary condition requiring minimal arithmetic work for a given spectral interval. For hyperbolic problems, however, optimal grids were introduced only for the approximation in the interior part of the domain. Here we consider exterior hyperbolic problems. For this kind of problem a closely related method of continued fraction boundary conditions was suggested in [16], where absorbing boundary conditions were reduced to a three-term equations resembling finite-difference relations. Combining the approaches of [18] and [16] we obtain frequency independent finite-difference discretization of Berenger's perfectly matched layer (PML) absorbing boundary conditions (ABCs) [7], which produces the minimal possible impedance error for a given number of discrete layers. Similarly to the optimal grid for the Laplace equation with a solution from a Sobolev space considered in [18], the obtained discretizations show the exponential of the square root rates of convergence, though they use only the three-point stencil for second derivatives. Our solution exhibits much smaller reflection coefficients compared to examples of optimized PMLs (for the same

numbers of discrete layers) known from the literature [10]. The optimal solution represents a limiting case of PML with pure imaginary coordinate stretching that results in a different type of the equation in time domain. The drawback of the proposed method is that, unlike a conventional PML discretization, it cannot be implemented in time domain using the same time-stepping realization in the interior and the exterior parts. Nevertheless, the arithmetical cost per grid node of the new method is close to that of the conventional PML.

Let us consider a model problem for the scalar wave equation on $\mathbb{R}^2 \times [0, +\infty)$ in Cartesian coordinates

$$u_{xx} + u_{yy} - u_{tt} = 0. \tag{1.1}$$

After the Fourier transform with respect to y and t, (1.1) becomes

$$u_{xx} - \left(l^2 - \omega^2\right) u = 0, \tag{1.2}$$

where l and ω are real spatial and temporal frequencies, respectively. We here abuse notation slightly by using the same name for a function and its Fourier transform; the use of the time or frequency domain will always be clear from the context. The ratio $\sigma = l/\omega$ is the sine of the incidence angle of the wave on the plane $x = 0$; this angle is labelled θ.

We assume that only so-called propagative modes with $|\sigma| \leq 1$ are present in the spectrum of the solution and that for positive x the solution contains only waves moving to the right; i.e., we are considering solutions of the form

$$u(x) = ce^{-i\omega\sqrt{\lambda}x} \text{ if } x > 0, \tag{1.3}$$

where $\lambda = 1 - \sigma^2 = \cos^2\theta$ is positive.

The solutions of this form do not vanish at infinity, which is the origin of the notorious problem of domain truncation in the numerical solution of wave problems on unbounded domains. Functions given by (1.3) satisfy the impedance boundary condition

$$u_x\big|_{x=0} = -i\omega\sqrt{\lambda}u\big|_{x=0}. \tag{1.4}$$

With the help of this condition, the subdomain $x > 0$ can be truncated. Many approximate ABCs are based on rational approximation of $\sqrt{\lambda}$, e.g., in [14, 16]. The authors of these investigations used the fact that the approximant after the inverse Fourier transform to (y, t) coordinates becomes a solution of a PDE in (y, t) plane; i.e., it can be computed within the finite-difference time-stepping framework of the solution of (1.1).

Instead of the direct implementation of the approximate condition (1.4), one can modify (1.2) for $x > 0$ in such a way that it would be easier to solve and the new solution would approximate (1.4) well. The methods of this sort that recently received wide attention in the literature, e.g., in [7, 9, 10, 19], are Berenger's PML or sponge layer methods. These methods generate special artificial media layers that add exponential decay or attenuation to the propagative modes so that the new solution satisfies the same boundary condition at $x = 0$. Thus, the domain for the new equation can be truncated, which will produce only a small reflection for $x < 0$. For brevity we will call PML all methods from this group.

It is known that Berenger's PML can be obtained using complex coordinate stretching [9]:

$$dx = \left(\alpha + \frac{\beta}{i\omega}\right) d\bar{x} \quad \text{if } x > 0, \qquad x = \bar{x} \quad \text{otherwise,} \tag{1.5}$$

where α and β are some real nonnegative functions. The ω^{-1} dependence of the imaginary part is introduced to simplify the time-domain formulation and weaken the dependence on ω of the PML error. The new function $\bar{u}(\bar{x}) = u(x)$ is defined, and the equation is modified in the following way: the new variable $\bar{x}$ is taken to be real. This transformation does not change the solution for negative $\bar{x}$, and for positive $\bar{x}$ it transforms (1.3) to

$$\bar{u}(\bar{x}) = c \exp\left[-\sqrt{\lambda}\int_0^{\bar{x}} \beta(\xi) d\xi\right] \exp\left[-i\omega\sqrt{\lambda}\int_0^{\bar{x}} \alpha(\xi) d\xi\right];$$

i.e., the exponential attenuation is added to the resulting function. Because of this attenuation of the solution in the new coordinate, the subdomain $[0, +\infty)$ can be truncated to a finite length L, with the logarithm of the absolute value of the impedance error (or reflection coefficient) approximately proportional to

$$R = -\sqrt{\lambda}\int_0^L \beta(\xi) d\xi.$$

From this estimate one might conclude that just choosing large enough β alone would make error negligibly small, regardless of the temporal frequency. Unfortunately, this consideration cannot be applied to *discretized* PML because of the numerical dispersion, which is frequency dependent and increases with the increase of β. Conventionally, ad hoc rules or general nonlinear optimization algorithms have been used for the choice of the discrete PML parameters, e.g., in [10]. It is obvious that proper use of the analytical structure of the cost function can greatly improve the efficiency of such optimization; this is the main motivation of our investigation.

Let u^k denote the solution of (1.2) after a three-point second order finite-difference discretization of PML with k primary and k dual nodes. In this case, α and β become finite $2k$-dimensional vectors that determine the discrete transformation at the primary and dual grid nodes. We consider the following *PML optimization problem*:

- Find α, β minimizing the error functional

$$\delta_k^{\alpha,\beta} = \sup_{0\le\lambda\le1,\ 0<\omega\le\omega_{\max}} s(\lambda)\left|\sqrt{\lambda} - \frac{u_x^k}{i\omega u^k}\Big|_{x=0}\right|, \tag{1.6}$$

where u_x^k is the finite-difference derivative of the discrete solution at the boundary. Here we assume that the temporal spectrum of the solution is uniformly bounded at $(0, \omega_{\max}]$ by a positive constant, where $\omega_{\max}$ is a cutoff frequency (as we shall see, the value of $\omega_{\max}$ is unimportant for the construction of our optimal solution), and $s(\lambda)$ is a nonnegative weight, chosen depending on the distribution of the incident waves. We will consider two cases:

$$s(\lambda) = \frac{1}{\sqrt{\lambda}} \text{ if } \lambda \in [\lambda_{\min}, 1], \lambda_{\min} > 0, \qquad s(\lambda) = 0 \text{ otherwise,} \tag{1.7}$$

and

$$s(\lambda) = 1, \quad \lambda \in [0, 1]. \tag{1.8}$$

Here the first case corresponds to all possible waves with the incidence angles not exceeding $\arccos(\sqrt{\lambda_{\min}}) < \frac{\pi}{2}$; the second case assumes that the wave amplitudes are uniformly bounded for all incidence angles on $[0, \pi/2]$. The first case will be used when a priori information limiting the range of incidence angles is available; the second case will generally be used when no such information can be obtained from the geometry of the model.

Traditionally, only equidistant grids were used for the PML discretization, and the optimization was performed by adjusting the distribution of α or β. Such discretization can be equivalently presented as the one on a nonuniform grid with *complex* grid steps but with $\alpha = 1$, $\beta = 0$. So, we can apply the approach of [11, 18], which reduces the problem of the finite-difference grid optimization to rational approximation and allows us to make the following conclusions, which will be proven in the following sections:

- The minimum of $\delta_k^{\alpha,\beta}$ can be achieved with pure imaginary stretching:
$$\min_{\alpha,\beta} \delta_k^{\alpha,\beta} = \min_{\beta} \delta_k^{0,\beta},$$
though it is not clear if the condition $\alpha \equiv 0$ is necessary for optimality.
- With pure imaginary stretching the PML discretization becomes *independent* of ω and depends only on the incidence angle. In other words, the PML discretization becomes a well-studied problem of rational approximation of the $\sqrt{\lambda}$ on a nonnegative interval of real axis.

Choosing appropriate grid steps (or β) for PML with pure imaginary stretching, one can make it algebraically equivalent to known approximate ABCs of, e.g., [14, 16]. Instead, using known results of approximation theory, we give optimal solutions for the two weight functions considered here, which are efficient for wide bandwidth of the incidence angles. For a problem similar to (1.7) the optimal PML discretization is based on a closed form solution, obtained in 1877 by Zolotarjov [20]. If $0 < \lambda_{\min} \ll 1$ its error decays with the increase of k approximately as

$$O\left\{\exp\left[\frac{\pi^2 k}{\log\left(\sqrt{\lambda_{\min}}/4\right)}\right]\right\}. \tag{1.9}$$

For the case (1.8) the optimal grid was computed in the manner of [24], where optimal rational approximants of a slightly different type were computed to very high precision. For the latter case the optimal error asymptotically decays as

$$8e^{-\pi\sqrt{2k}}. \tag{1.10}$$

Both of these estimates again highlight the phenomenon of exponential superconvergence of three-point second order finite-different approximations, which has been earlier used for efficient approximation of elliptic and hyperbolic problems in [11, 3, 18, 12].

The condition $\alpha \equiv 0$ does not allow standard split time-domain PML realization; however, it makes possible a simple nonsplit realization, which is, in fact, similar to the one of [16].

2. S-fraction representation of discrete PML.

We want the propagating solution $u = ce^{-i\sqrt{\omega^2 - l^2}x}$ to become nonoscillating evanescent for $x > 0$. We consider a limiting case of transformation (1.5) with $\alpha = 0$ and $\beta = 1$:

$$\bar{x} = i\omega x \text{ if } x > 0, \qquad \bar{x} = x \text{ otherwise.}$$

Define a new function $\bar{u}(\bar{x}) = u(x)$ and again take $\bar{x}$ to be real. The equation that is satisfied by this new function can be written in divergence form as

$$\frac{d}{d\bar{x}}\left[\gamma(\bar{x})\frac{d\bar{u}(\bar{x})}{d\bar{x}}\right] - \lambda\rho(\bar{x})\bar{u}(\bar{x}) = 0, \tag{2.1}$$

where $\lambda = 1 - l^2/\omega^2 = \cos^2\theta$ and

$$\gamma = i\omega,\ \rho = i\omega \text{ if } \bar{x} > 0, \qquad \gamma = 1,\ \rho = -\omega^2 \text{ otherwise.} \tag{2.2}$$

Equation (2.1) is a standard divergence equation with discontinuous coefficients; $\bar{u}(\bar{x})$ and $\gamma(\bar{x})\frac{d\bar{u}(\bar{x})}{d\bar{x}}$ are continuous across the interface at $\bar{x} = 0$.

The transformed Helmholtz equation (2.1) becomes diffusive (absorbing) for $\bar{x} > 0$ and remains the same as the original oscillating (1.2) otherwise. Its solution vanishing at $+\infty$ can be written as

$$\bar{u} = ce^{-\sqrt{\lambda}\bar{x}} \text{ if } \bar{x} > 0, \qquad \bar{u} = ce^{-i\omega\sqrt{\lambda}\bar{x}} = u \text{ otherwise.}$$

From now on we will approximate the above solution for $\bar{x} \in \mathbb{R}$, so we will drop the bars over all the symbols. The impedance condition (1.4) is then written as

$$u_x\big|_{x=0+} = -\sqrt{\lambda}u\big|_{x=0+}, \tag{2.3}$$

and the error functional (1.6) for the discrete absorbing condition is

$$\delta_k = \max_{0\le\lambda\le1} s(\lambda)\left|\sqrt{\lambda} - \frac{u_x^k}{u^k}|_{x=0}\right|, \tag{2.4}$$

where u^k is the discrete solution of (2.1), and u_x^k stands for the finite-difference analogue of the derivative of u.

Now, using a second order finite-difference approximation of the diffusive part of (2.1) as it was done for diffusive problems in [11, 18], we obtain a formulation equivalent to the continued fraction of [16].

We want to approximate the ABC (2.3) and to get an explicit expression for the error functional (2.4) in terms of the steps of the finite-difference discretization. For this purpose we first consider (2.1) for $x \in [0, +\infty)$ with the following boundary conditions:

$$-\gamma u'(0) = 1, \qquad u(+\infty) = 0.$$

Let us approximate the solution of this problem by a staggered three-point finite-difference scheme. In a staggered scheme, the numerical solution is defined at primary nodes

$$x_j,\quad j = 1, \ldots, k+1, \qquad \text{with}\quad x_1 = 0 \quad\text{and}\quad x_{j+1} > x_j\ (1 \le j \le k),$$

and the finite-difference derivatives are defined at dual nodes

$$\hat{x}_j,\quad j = 0, \ldots, k, \qquad \text{with}\quad \hat{x}_0 = 0 \quad\text{and}\quad \hat{x}_{j+1} > \hat{x}_j\ (1 \le j \le k-1).$$

We denote the step sizes by

$$h_j = x_{j+1} - x_j \quad\text{and}\quad \hat{h}_j = \hat{x}_j - \hat{x}_{j-1}$$

and solve the following finite-difference problem:

$$\frac{1}{\hat{h}_j}\left(\hat{\gamma}_j\frac{u_{j+1}-u_j}{h_j}-\hat{\gamma}_{j-1}\frac{u_j-u_{j-1}}{h_{j-1}}\right)-\lambda\rho_j u_j=0, \qquad j=2,\dots,k, \tag{2.5}$$

with the boundary conditions

$$\frac{\hat{\gamma}_1}{\hat{h}_1}\left(\frac{u_2-u_1}{h_1}\right)-\lambda\rho_1 u_1=-\frac{1}{\hat{h}_1} \tag{2.6}$$

and

$$u_{k+1}=0. \tag{2.7}$$

Note that the first boundary condition (2.6) is consistent with the differential equation since it is the same as creating a dummy node u_0, allowing $j=1$ in (2.5) and setting

$$-\hat{\gamma}_0\frac{u_1-u_0}{h_0}=1.$$

Discrete analogues of γ and ρ equal $\hat{\gamma}_j=\rho_j=i\omega$ in accordance with the definition (2.2) of their continuous counterparts on $[0,+\infty)$.

As follows from [11, 18], $u_1=-\frac{f_k}{\gamma}$, where the so-called discrete impedance function f_k is the Stieltjes fraction or S-fraction

$$f_k(\lambda)=\cfrac{1}{\hat{h}_1\lambda+\cfrac{1}{h_1+\cfrac{1}{\hat{h}_2\lambda+\dots\cfrac{1}{h_{k-1}+\cfrac{1}{\hat{h}_k\lambda+\cfrac{1}{h_k}}}}}}. \tag{2.8}$$

It is easy to see that this S-fraction formulation is algebraically equivalent to the continued fraction formulation of [16] with a proper choice of the steps.

Overall, for the error functional we get

$$\delta_k=\max_{\lambda\in[0,1]} s(\lambda)\left|\sqrt{\lambda}-\frac{1}{\gamma u_1}\right|=\max_{\lambda\in[0,1]} s(\lambda)\left|\sqrt{\lambda}-\frac{1}{f_k(\lambda)}\right|. \tag{2.9}$$

We are now prepared to show that the proper choice of steps for the finite-difference discretization makes δ_k attain the minimum value for all $\delta_k^{\alpha,\beta}$.

3. Optimality.

Let us return to the finite-difference PML for the general case given by (1.5) and show that the problem of its optimal finite-difference approximation can be reduced (possibly not uniquely) to the problem considered in the previous section, i.e.,

$$\min_{\alpha,\beta}\delta_k^{\alpha,\beta}=\min_{\beta}\delta_k^{0,\beta}\equiv\min_{h,\hat{h}}\delta_k.$$

Fortunately, the latter is a well-studied problem of Chebyshev rational approximation.

In terms of the new variable $\bar{x}$ defined by (1.5) we obtain the same problem as (2.1) but with the following new coefficients:

$$\gamma = \frac{i\omega}{i\omega\alpha + \beta}, \quad \rho = -\omega^2 \left(\alpha + \frac{\beta}{i\omega}\right) \text{ if } \bar{x} > 0.$$

We use a finite-difference discretization similar to (2.5)–(2.7). Let us denote the discrete counterparts of α and β, respectively, by $\alpha_j, \hat{\alpha}_j$ and $\beta_j, \hat{\beta}_j$. Formally we assume that α_j, β_j and $\hat{\alpha}_j, \hat{\beta}_j$ reside at points x_j and $\hat{x}_j$, respectively. Then the PML finite-difference solution satisfies (2.5)–(2.7) but with $\hat{\gamma}_j = \rho_j = 1$ and the new grid "steps"

$$a_j = h_j \left(\hat{\alpha}_j + \frac{\hat{\beta}_j}{i\omega}\right), \qquad \hat{a}_j = -\omega^2 \hat{h}_j \left(\alpha_j + \frac{\beta_j}{i\omega}\right), \qquad j = 1, \ldots, k. \tag{3.1}$$

The general finite-difference PML solution can be defined similarly to the one from the previous section if we use the new steps (3.1) in (2.5)–(2.7). We denote by $f_k^{\alpha,\beta} = f_k^{\alpha,\beta}(\lambda, \omega)$ the discrete impedance function presented by formula (2.8) with the new steps (3.1). This function $f_k^{\alpha,\beta}$ is still a regular continued fraction but since its coefficients can be complex now, it is generally not an S-fraction anymore. We can equivalently rewrite the PML error (1.6) as

$$\delta_k^{\alpha,\beta} = \max_{\lambda \in [0,1],\ \omega \in [0, \omega_{\max}]} s(\lambda) \left| \sqrt{\lambda} - \frac{1}{i\omega f_k^{\alpha,\beta}(\lambda, \omega)} \right|. \tag{3.2}$$

It is easy to check that when $\alpha = 0$ the dependence on ω of function $f_k^{0,\beta}(\lambda, \omega)$ is such that $i\omega f_k^{0,\beta}(\lambda, \omega) = f_k^{\beta}(\lambda)$. Obviously, for every set β_j, $\hat{\beta}_j$ we can find real steps h_j, $\hat{h}_j$, so that $f_k^{\beta}(\lambda) = f_k(\lambda)$, and hence the error functional (3.2) with $\alpha = 0$ coincides with (2.9), i.e.,

$$\delta_k = \delta_k^{0,\beta}.$$

The following proposition shows that the general complex transformations cannot produce better PML approximations than their purely imaginary counterparts.

PROPOSITION 3.1. *For any α and any $\beta \neq 0$ we have $\delta_k^{\alpha,\beta} \geq \delta_k$.*

Proof. From the definitions it follows that

$$\left[i\omega f_k^{\alpha,\beta}(\lambda, \omega) \right] \Big|_{\omega=0} = i\omega f_k^{0,\beta}(\lambda, \omega) = f_k^{\beta}(\lambda);$$

therefore,

$$\delta_k^{\alpha,\beta} = \max_{\lambda \in [0,1],\ \omega \in [0, \omega_{\max}]} s(\lambda) \left| \sqrt{\lambda} - \frac{1}{i\omega f_k^{\alpha,\beta}(\lambda, \omega)} \right| \geq \max_{\lambda \in [0,1],\ \omega = 0} s(\lambda) \left| \sqrt{\lambda} - \frac{1}{i\omega f_k^{\alpha,\beta}(\lambda, \omega)} \right|$$

$$= \max_{\lambda \in [0,1]} s(\lambda) \left| \sqrt{\lambda} - \frac{1}{i\omega f_k^{0,\beta}(\lambda, \omega)} \right| = \max_{\lambda \in [0,1]} s(\lambda) \left| \sqrt{\lambda} - \frac{1}{f_k(\lambda)} \right| = \delta_k^{0,\beta} = \delta_k. \qquad \square$$

The proposition allows us to reduce minimization of $\delta_k^{\alpha,\beta}$ to minimization of δ_k, which is a well-studied problem of Chebyshev rational optimization. Using the fact that $\sqrt{\lambda}$ is hypernormal on the support $[a, b]$ of s [23], we conclude that the existence and uniqueness theorems for the Chebyshev (optimal) rational approximation, which can be found in [2, Chapter II, Theorems 33 and 34], are applicable. Since the function f_k is an S-fraction, it is a $[(k-1)/k]$ real rational function (though the opposite statement is not true in general). However, we will be looking for the optimal approximation in the form of the $[(k-1)/k]$ real rational function. Such an approximant is irreducible and has exactly $2k+1$ alternating points (set of ordered noncoinciding points λ_j, where the weighted error is equal to $(-1)^j\delta_k$) on $[a, b]$. Hence, the $[(k-1)/k]$ optimal rational approximant must have $2k$ interpolation points on (a, b), so it must be a Markov–Stieltjes function [15]. But any Markov–Stieltjes function can be presented as an S-fraction [6, Theorem 5.1.2, Corollary 2], i.e., as (2.8) with all h_j and $\hat{h}_j$ being positive. The above consideration can be summarized in the following proposition.

Proposition 3.2. *Let the support of s be a segment $[a, b] \subseteq [0, 1]$, and let s be continuous and positive on $[a, b]$. Then there exists the unique minimum of δ_k with the optimal approximant being an S-fraction* (2.8)*.*

The optimal approximant can be uniquely characterized as the one that has exactly $2k+1$ alternation points, all of which are located on $[a, b]$.

From the above proposition we obtain the following corollary.

Corollary 3.3. *The choice of parameters $\alpha_j^{opt} = \hat{\alpha}_j^{opt} = 0$, $\beta_j^{opt} = h_j$, $\hat{\beta}_j^{opt} = \hat{h}_j$, which minimize δ_k, defines a solution that minimizes the functional $\delta_k^{\alpha,\beta}$.*

Remark 3.1. Generally, there is no uniqueness in optimal approximation by complex rational functions even in approximating real functions on real intervals [25, Chapter 5]; that is why we cannot say if our optimal solution is unique. Though, obviously, β^{opt} is unique, so the remaining question is whether there exists an optimal pair $(\alpha^{\text{opt}}, \beta^{\text{opt}})$ with $\alpha^{\text{opt}} \neq 0$.

Remark 3.2. There is an important reason why we chose the L^∞ norm in our "cost" functional, instead of the L_2 norm traditionally used in the literature on PML, e.g., in [10], in addition to the fact that the former provides more reliable bounds. Even real rational approximation problems in L^p, $1 \leq p < \infty$, may have more than one optimal solution [20, section 2.3], so using the L^∞ norm at least provides us the uniqueness for β^{opt}.

Remark 3.3. An interesting question is if a high order or spectral Galerkin PML discretization can perform better than the optimal finite-difference scheme, and the answer is that it cannot. The reason is that a Galerkin (and, generally, any Galerkin–Petrov) process on any k-dimensional subspace also generates a $[(k-1)/k]$ rational impedance [13], so it cannot do better than the optimal $[(k-1)/k]$ approximation.

4. Rational approximation and optimal grids.

Perhaps the simplest way to construct a rational approximation is to compute a Padé approximant satisfying the conditions

$$\frac{d^i}{d\lambda^i}\left[f_k(\lambda) - \sqrt{\lambda}\right]\Big|_{\lambda=1} = 0, \quad i = 0, \ldots, 2k-1,$$

in which case the PML becomes algebraically equivalent to the ABC by Engquist and Majda [14]. However, such an approximation is not efficient for small λ. Better results can be achieved using a more general continued fraction ABC based on multipoint Padé approximants [16], but the double root interpolation used there does not produce the alternation of the error and thus cannot arrive at the optimal approximation.

Real optimal rational approximations in rare cases can be obtained in a closed form, and in most cases they are obtained numerically, but in all cases the algorithms are based on the alternation property which was stated in Proposition 3.2.

4.1. Zolotarjov's approximation. Consider first the case $\lambda_{\min} > 0$. The interval $[\lambda_{\min}, 1]$ can be linearly shifted onto $[1, 1/\lambda_{\min}] = [1, 1/\kappa'^2]$ with $\kappa' = \sqrt{\lambda_{\min}}$. Let $\kappa = \sqrt{1-\kappa'^2}$. Zolotarjov found a $[(k-1)/k]$ rational function $\tilde{r}$ such that

$$\left\| 1 - \sqrt{\lambda}\tilde{r}(\lambda) \right\|_{C[1,1/\kappa'^2]} = \inf_r \left\{ \left\| 1 - \sqrt{\lambda} r(\lambda) \right\|_{C[1,1/\kappa'^2]} \right\}.$$

When the error is small, this optimization problem is close to (1.6)–(1.7), in the sense that if the error of one of these approximation is equal to ε, then the error of the other is $\varepsilon + O(\varepsilon^2)$.

THEOREM 4.1 (see Zolotarjov, 1887 [20]). *The best approximant is given by*

$$\tilde{r}(\lambda) = D \frac{\prod_{l=1}^{k-1}(\lambda + c_{2l})}{\prod_{l=1}^{k}(\lambda + c_{2l-1})}, \tag{4.1}$$

where

$$c_l = \frac{\mathrm{sn}^2\,(lK/(2k);\kappa)}{\mathrm{cn}^2\,(lK/(2k);\kappa)}, \qquad l = 1, \ldots, 2k-1,$$

$K = K(\kappa)$ *is the complete elliptic integral, and the number* D *is uniquely determined by the condition*

$$\max_{C[1,1/\kappa'^2]} \left[1 - \sqrt{\lambda}\tilde{r}(\lambda) \right] = - \min_{C[1,1/\kappa'^2]} \left[1 - \sqrt{\lambda}\tilde{r}(\lambda) \right].$$

Remark 4.1. If $\lambda_{\min}$ is small, then κ is close to 1. Standard subroutines for computing elliptic functions fail at the very beginning, because they accept κ and compute $\kappa' = \sqrt{1-\kappa^2}$, losing significant digits. We recommend computing the elliptic functions by the arithmetic-geometric mean method [1, Chapters 16 and 17] in terms of $\kappa' = \sqrt{\lambda_{\min}}$.

Recall that the asymptotic convergence factor is given by formula (1.9).

In Figure 1 one can see the Chebyshev alternation of the error via λ on the optimal interval for a Zolotarjov's grid. The L^∞ norm of the error for $\lambda_{\min} = 10^{-3}$ is given in Figure 2; it is in good agreement with the estimate (1.9).

4.2. Approximation on [0, 1]. In the case $\lambda_{\min} = 0$ we numerically solved the optimization problem (1.6), (1.8). Here we followed the solution of this problem given in [24] with some minor modifications.

For small values of k we used the unconditionally converging differential correction method [20, section 2.5], the convergence of which, however, deteriorates rapidly with the increase of k. To solve the associated convex nonsmooth optimization problem, we exploited the Fortran 90 package SOLVOPT by A. Kuntsevich and F. Kappel (see http://bedvgm.kfunigraz.ac.at:8001/alex/solvopt).

For larger k the Remez method [20, section 2.5] was exploited. This algorithm converges quadratically, provided a good initial guess is given, but otherwise it may diverge. Therefore, we implemented an extrapolation procedure in the spirit of [24] to obtain good initial iterants. The Fortran 90 multiple precision package [5] was incorporated into our Fortran program realizing the Remez method.

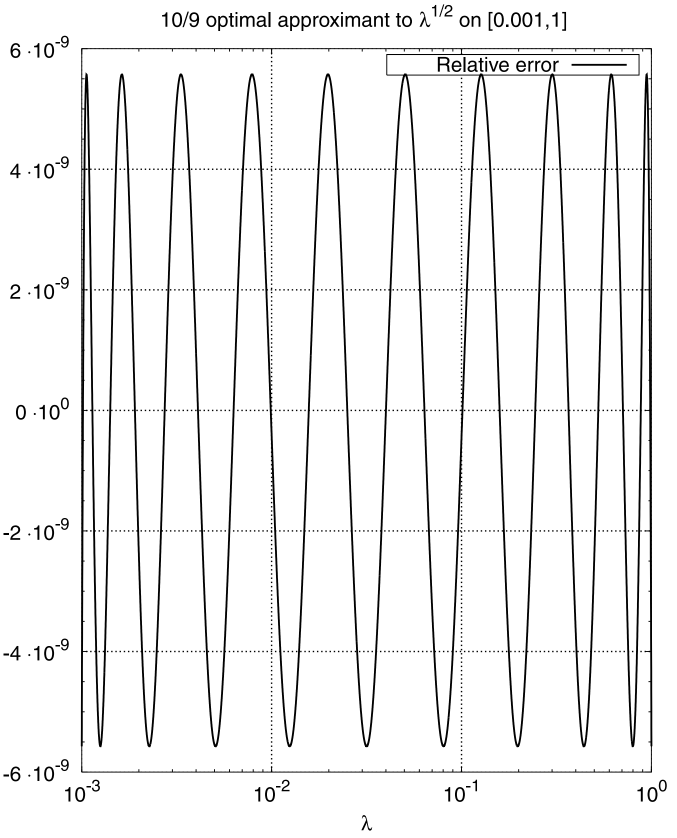

FIG. 1. *Impedance error* $\sqrt{\lambda}\tilde{r}(\lambda) - 1$ *of Zolotarjov's grid for* $\lambda_{\min} = 10^{-3}$ *and* $k = 10$ *as a function of* λ.

An error estimate is presented by formula (1.10); it follows from [21]. The actual distribution of the error for $k = 10$ is plotted in Figure 3; similarly to the Zolotarjov's error it exhibits Chebyshev alternating properties according to Proposition 3.2. The error graph in Figure 4 is in very good agreement with the error estimate (1.10).

4.3. Computation of grid steps. The optimal rational approximations obtained above can be represented in terms of poles and residues as

$$f_k(\lambda) = \sum_{i=1}^{k} \frac{y_i}{\lambda - \theta_i},$$

but to construct the finite-difference scheme we need them in the form of an S-fraction (2.8). A recursive algorithm of computing h_i and $\hat{h}_i$ from y_i and θ_i based on the Lanczos method is given in [11, subsection 3.1]. In Figure 5 we show grids for Zolotarjov approximation on $[0.001, 1]$- and $[0, 1]$-optimal approximations. Qualitatively, both the grids behave similarly to other optimal or Gaussian grids described in [11, 12, 3, 18, 13]; i.e., they exhibit gradual refinement towards the origin and alternation of primary and dual nodes. Specifically, both grids are close to geometric progressions, which corresponds well to the asymptotic property of optimal grids on spectral intervals with large condition numbers, discovered in [18]. Since the $[0, 1]$-

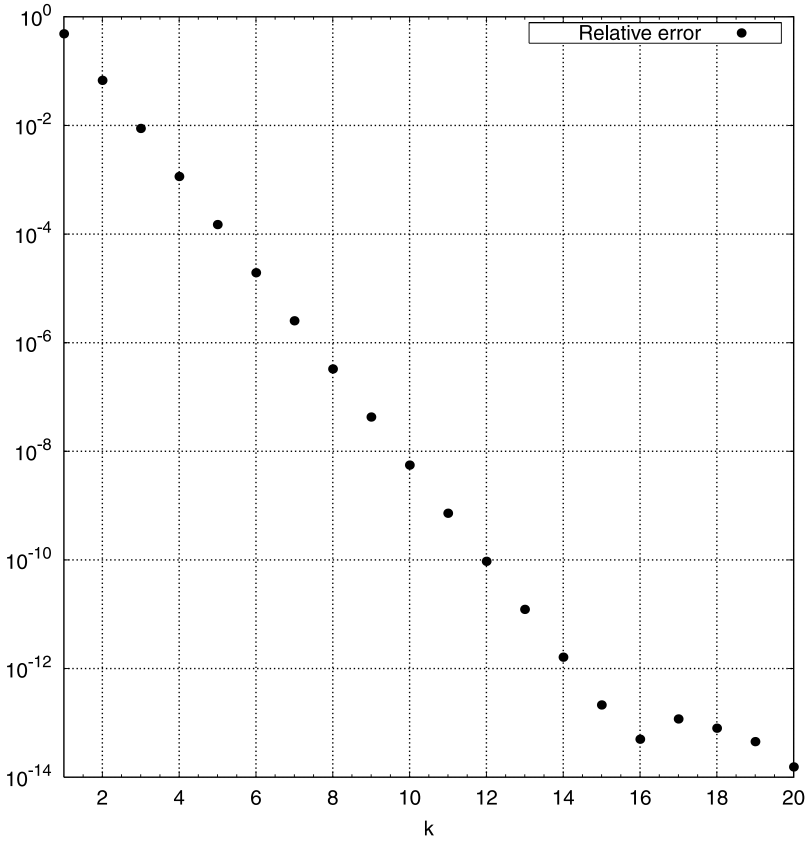

FIG. 2. *The computed impedance error of Zolotarjov's grids* $\max_{[10^{-3},1]}|\sqrt{\lambda}\tilde{r}(\lambda)-1|$.

grid is designed to absorb at all incidence angles, it requires thicker PML than the Zolotarjov grid.

4.4. Comparison with standard PML. The first advantage of the new method of implementation of PML over the standard implementation is that the errors of the newly computed meshes depend only on the incidence angle $\theta = \arccos(\sqrt{\lambda})$ and not on the frequency. The practical importance of this fact is that the user can fix the mesh only once, depending on the requirements of the accuracy and the spectral range in question. Of course, the reflection coefficient of such a mesh will also depend on the discretization of the interior domain, and thus the total error of the ABC will not be better than the error of the interior discretization.

The second important property is that these meshes give an optimal or near-optimal error for a chosen spectral interval, and no ad hoc or numerical optimization of parameters is necessary after the mesh is defined.

Previously, in the literature devoted to PML absorbing conditions, near-optimal solutions for the parameters were obtained by various numerical optimization schemes [10, 8]. Comparing the magnitudes of these errors to the errors of the new optimal PML, we conclude that the new scheme produces a much smaller error. From Figure 2 we see that a 5 point Zolotarjov's mesh gives an error of approximately 10^{-4} for all $\lambda \in [10^{-3}, 1]$, which corresponds to the incident angles $\theta \in [0, 88°]$, and a 10 point

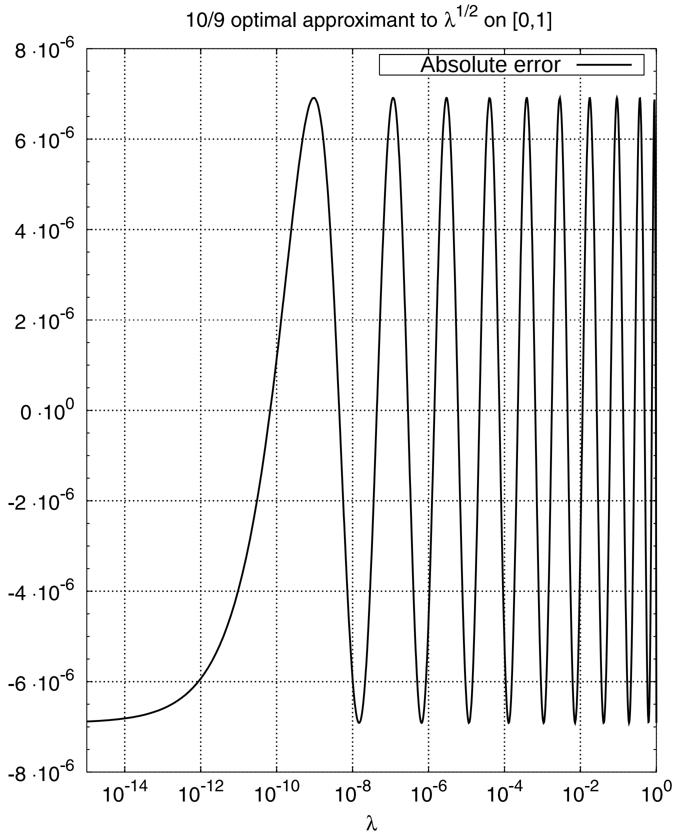

FIG. 3. *The impedance error* $\sqrt{\lambda} - \tilde{r}(\lambda)$ *of optimal grid for the segment* $[0,1]$ *and* $k = 10$ *as a function of* λ*.*

mesh gives an error of 10^{-8} for the same angles, all independent of the frequency. For comparison, the PML discretizations in [10] for approximately the same range of the angles give an error that varies (depending on the frequency) between 10^{-2} and 10^{-1} (5 point mesh), and between 10^{-3} and 10^{-2} (10 point mesh).

Among the disadvantages of the proposed method we see the nontrivial discretization of the time-domain problem.

5. Time-domain realization. The S-fraction representation of the impedance function f_k provides stability of the time-domain solution. The poles of S-fractions are real negative and their residues are real positive, which is sufficient for the absence of exponentially growing modes [22].

Unfortunately, our modification of the equation in the absorbing region makes impossible the simple variable-splitting time-domain realization that is commonly used in the PML methods. Moreover, the equation in the absorbing region becomes noncausal, and hence the discretized system has to be implicit.

We will first consider the discretization of our two-dimensional wave equation with the absorbing region in the half-space $x > 0$; the case with absorbing layers on the four edges of a square differs only by the treatment of the corners; i.e., the subdomains in which the imaginary stretching is applied to both coordinates. The treatment of the two-dimensional domains will be briefly discussed in the end of the

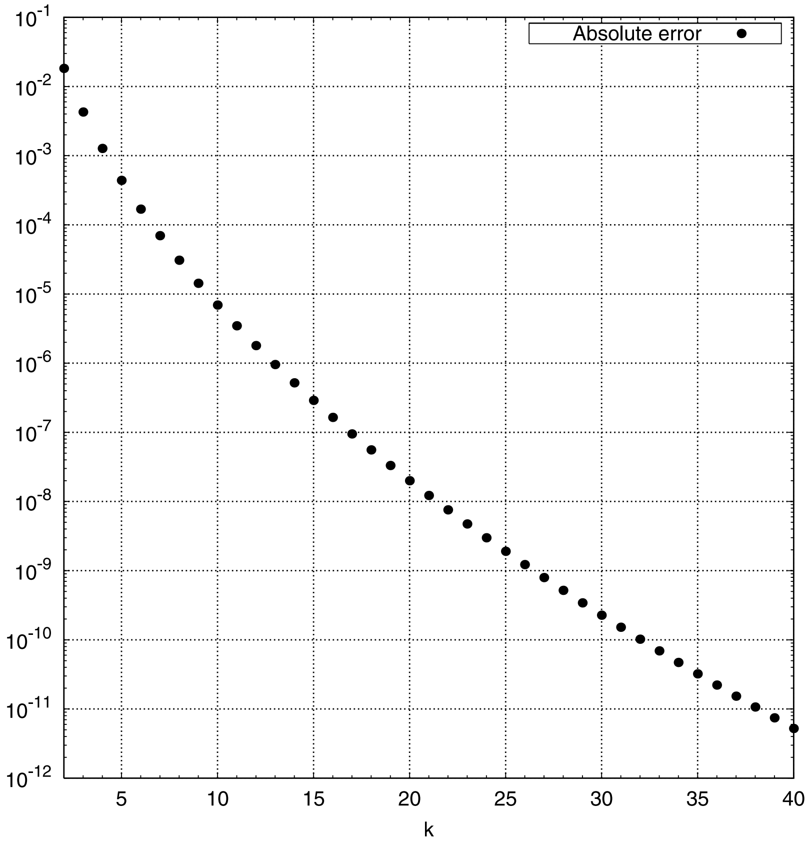

FIG. 4. *The impedance error* $\max_{[0,1]} |\sqrt{\lambda} - \tilde{r}(\lambda)|$ *for different* k.

section.

Let us first Fourier transform (2.1)–(2.2) back to the two-dimensional wave problem while again keeping the same name for the function:

$$u_{xx} + u_{yy} - u_{tt} = 0 \quad \text{if } x < 0, \qquad u_{xxtt} + u_{yy} - u_{tt} = 0 \quad \text{otherwise,}$$

with the interface conjugation conditions

$$u(0-, y, t) = u(0+, y, t), \qquad u(0-, y, t)_x = u(0+, y, t)_{xt}$$

and the boundary condition $u(+\infty, y, t) = 0$. We will demonstrate the discretization in time and in the x-direction, while leaving the problem continuous in the y-direction.

For $x < 0$ we write the discretization of the equations in the standard way:

$$\frac{d}{dt} u_j^- = \frac{V_j^- - V_{j-1}^-}{\hat{h}_j^-} + W_{j,y}^-, \qquad j = 1, \ldots, k, \tag{5.1}$$

$$\frac{d}{dt} V_j^- = \frac{u_{j+1}^- - u_j^-}{h_j^-}, \qquad u_{k+1}^- = 0, \qquad j = 1, \ldots, k, \tag{5.2}$$

$$\frac{d}{dt} W_j^- = u_{j,y}^-, \qquad j = 1, \ldots, k. \tag{5.3}$$

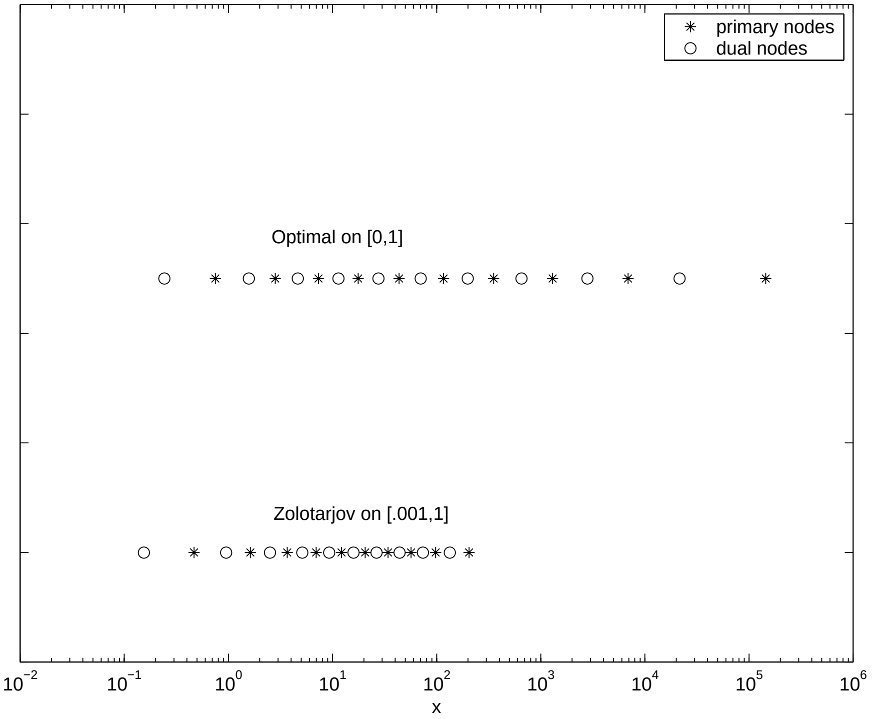

FIG. 5. *Zolotarjov and* $[0, 1]$*-optimal grids,* $k = 10$.

Here the unknowns are numbered from right to left with u_1^- and V_0^- being placed at the boundary of the PML region. We note that the right-to-left numbering of the unknowns implies that the steps h_j^-, $\hat{h}_j^-$ are negative.

The only change in the PML region, i.e., for $x > 0$, is that the steps h_j^+ and $\hat{h}_j^+$ get divided by $i\omega$, which leads to the following system in time domain:

$$\frac{d}{dt}u_j^+ = \frac{d}{dt}\frac{V_j^+ - V_{j-1}^+}{\hat{h}_j^+} + W_{j,y}^+, \qquad j = 1, \ldots, k, \tag{5.4}$$

$$\frac{d}{dt}V_j^+ = \frac{d}{dt}\frac{u_{j+1}^+ - u_j^+}{h_j^+}, \qquad u_{k+1}^+ = 0, \qquad j = 1, \ldots, k, \tag{5.5}$$

$$\frac{d}{dt}W_j^+ = u_{j,y}^+, \qquad j = 1, \ldots, k. \tag{5.6}$$

Here the numbering of the unknowns is left to right; hence the steps h_j^+, $\hat{h}_j^+$ are positive.

It is clear that to get the total number of equations equal to the total number of unknowns we need two extra equations; these are

$$u_1^- = u_1^+, \qquad V_0^- = V_0^+. \tag{5.7}$$

The time discretization follows naturally: we place variables u_j^- at time levels $n\Delta t$ and variables V_j^- and W_j^- at time levels $(n + 1/2)\Delta t$, where $\Delta t > 0$ is a time step. The system (5.1)–(5.3) is thus solved in the standard explicit "leap-frog" fashion.

For $x > 0$, however, we have to place variables u_j^+ and V_j^+ at the same time levels $n\Delta t$, and only the variables W_j^+ at time levels $(n + 1/2)\Delta t$; thus (5.4), (5.5), and the second equation in (5.7) will compose the system of equations that needs to be solved at every time step. With the use of the notation

$$[D_t f]^{m+1/2} = \frac{f^{m+1} - f^m}{\Delta t}, \qquad [A_t f]^{m+1/2} = \frac{f^{m+1} + f^m}{2},$$

where one can put $m = n$ or $m = n + 1/2$, we rewrite the scheme (5.1)–(5.7) as

$$\begin{aligned}
&[D_t u_1]^{n+1/2} = \frac{V_1^{-,n+1/2} - [A_t V_0^+]^{n+1/2}}{\hat{h}_1^-} + W_{1,y}^{-,n+1/2}, && \\
&[D_t u_j^-]^{n+1/2} = \frac{V_j^{-,n+1/2} - V_{j-1}^{-,n+1/2}}{\hat{h}_j^-} + W_{j,y}^{-,n+1/2}, && j = 2, \dots, k, \\
&[D_t V_j^-]^n = \frac{u_{j+1}^{-,n} - u_j^{-,n}}{h_j^-}, && j = 1, \dots, k, \\
&[D_t W_j^-]^n = u_{j,y}^{-,n}, && j = 1, \dots, k,
\end{aligned}$$

for $x \le 0$, and

$$\begin{aligned}
&[D_t u_j^+]^{n+1/2} = \frac{[D_t V_j^+]^{n+1/2} - [D_t V_{j-1}^+]^{n+1/2}}{\hat{h}_j^+} + W_{j,y}^{+,n+1/2}, && j = 1, \dots, k, \\
&[D_t V_j^+]^{n+1/2} = \frac{[D_t u_{j+1}^+]^{n+1/2} - [D_t u_j^+]^{n+1/2}}{h_j^-}, && j = 1, \dots, k, \\
&[D_t W_j^+]^n = u_{j,y}^{+,n}, && j = 1, \dots, k,
\end{aligned}$$

for $x > 0$. We note that variables V_j^+ with $j > 0$ can be excluded from the scheme analytically by substituting the second of the three equations above into the first. The time marching follows in an obvious fashion.

The discretization of the two-dimensional model is performed as a tensor product of the two one-dimensional discretizations. It can be seen that in the corners of a rectangular domain in this case the equation is independent of time. In fact, it turns out that the Helmholtz equation $u - u_{xx} - u_{yy} = 0$ is solved there, with the time dependent boundary conditions. For such an equation on a given mesh one can compute the Neumann-to-Dirichlet map on the boundary and include only the variables defined on the boundary in the total scheme.

It becomes clear that the computational cost of the new boundary condition amounts to solving a linear system with a tridiagonal matrix of dimension k for each point on the interface at every time step. This cost will be linear in k with the constant close to the one for the implementation of standard Berenger's PML with variable splitting. The computation of the corner regions for a two-dimensional problem requires computing at each time step a partial Neumann-to-Dirichlet map on a $k \times k$ square, which again is an operation proportional to the total number of nodes in the absorbing region.

6. Numerical experiments. We performed a series of experiments for the following elongated model: the source and the receiver, positioned on the same vertical

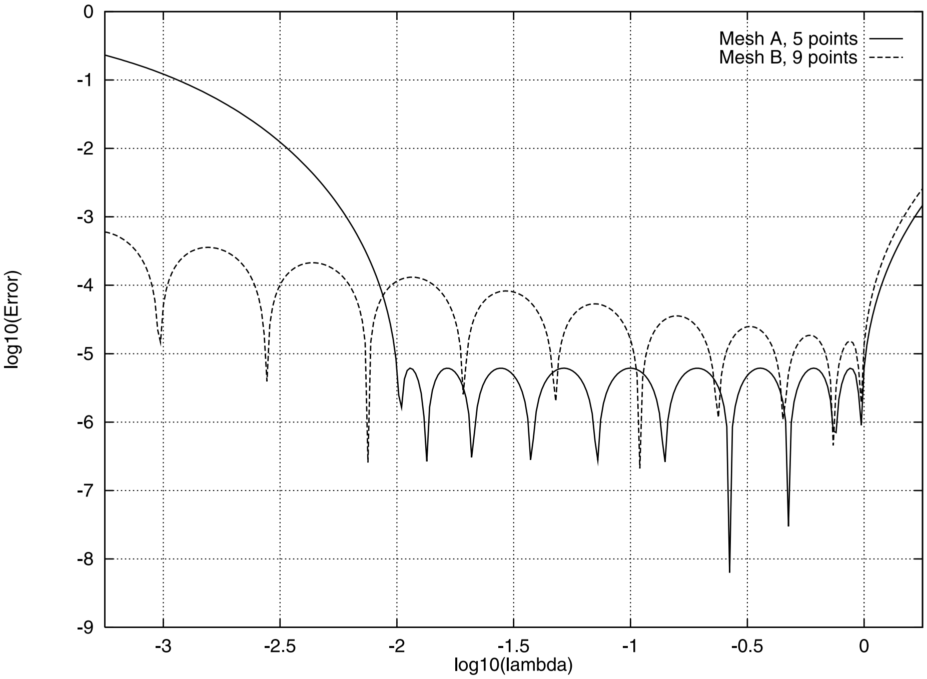

FIG. 6. *The relative error for meshes* A *and* B *of Experiment* 1.

line, are separated by 10 wavelengths with the new PML boundary conditions positioned at two wavelengths on both sides of that line, as well as below the source and above the receiver. For such an elongation the average incidence angle is $\theta = \arctan 0.2$ and the maximum incidence angle is $\theta = \arctan 0.1$; hence the minimum value of λ is approximately 10^{-2}.

We take the source wavelet as the second derivative of a Blackman–Harris pulse [17] with the maximum frequency $F_{\max} = 1$. The signal recorded at the receiver was compared with the signal recorded in the "infinite" discrete experiment, i.e., the one in which the discrete computational domain is big enough so that any reflections from the boundary do not get recorded within the assumed time frame. The error of the two signals was calculated as $L^\infty(t)$, relative to the signal of this larger computation. As this error obviously depends on the discretization of the propagative part of the computational domain, we performed the experiments using 8, 16, and 32 points per wavelength in the interior part.

The experiment was carried out using two different absorbing meshes: mesh A was taken as Zolotarjov's optimized for the interval $\lambda \in [10^{-2}, 1]$ with the total of five points, and mesh B was taken to be optimal on $\lambda \in [0, 1]$ with the total of nine points. The first mesh was chosen to take advantage of the a priori knowledge of the range of λ; the second was taken to be of approximately the same error but assuming no such knowledge. As we see, a priori knowledge of the range of incidence angles lets one decrease the amount of work required for absorption almost twice for the given tolerance.

The relative errors (i.e., with $s(\lambda)$ defined as in (1.7)—notice that mesh B was designed to provide minimum error in a different norm!) for these meshes are presented in Figure 6, and we see that these two meshes have approximately the same order of

Table 1
The $L^\infty(t)$ relative error in percent for Experiment 1.

	Mesh A, $k = 5$			Mesh B, $k = 9$		
Frequency	8 ppw.	16 ppw.	32 ppw.	8 ppw.	16 ppw.	32 ppw.
$F_{\max} = 1$	1.286	0.712	0.710	1.618	0.947	0.906
$F_{\max} = 2$	1.191	0.641	0.387	1.258	0.605	0.460
$F_{\max} = 4$	1.129	0.591	0.335	1.142	0.563	0.333

approximation on the spectral interval of interest. It is thus not surprising that the $L^\infty(t)$ errors that we obtain are similar too, as seen in the line $F_{\max} = 1$ of Table 1.

It is clear that the error is partly due to the reflection of the evanescent modes from the boundary between the interior propagative part of the domain and the absorbing part. To consider the importance of evanescent reflections, we increase the frequency of the source, thus keeping the incidence angles of the experiment unchanged, while effectively increasing the distance from the absorbing boundary to the receiver in terms of the wavelengths, and decreasing the effect of the evanescent reflections. The errors resulting from this change (with frequencies $F_{\max} = 2$ and $F_{\max} = 4$) are shown on the corresponding lines of Table 1. We note that with this change the boundary conditions become more effective for all values of the discretization of the interior for both meshes, but the effect of the decrease of the evanescent modes is especially notable for fine discretization of 32 points per wavelength, at which the boundary conditions approach the saturation error.

For the ABCs to be most effective, they need to be able to absorb not only the propagative modes of the solution but also the evanescent modes. Our proposed PML ABCs are optimal in terms of the absorption of the propagative part; however, the evanescent modes were left untreated. The obvious solution to this problem is to place this boundary condition at a distance to the closest receiver; this will ensure that the evanescent modes of the solution get absorbed. However, in the problems in which the receiver stays closer to the boundary conditions than any scatterer, the necessity of placing the boundary conditions away from the receiver clearly decreases the effectiveness of such conditions. This problem can be cured by using the regular nonabsorbing optimal meshes [3, 11, 12, etc.] in the layers between the receiver and the boundary conditions. This approach allows one to solve the problem of absorbing both the evanescent and propagative modes in an optimal way.

It can be seen from the results of these experiments that in the cases in which the spectral interval is known a priori (as above) it is reasonable to use Zolotarjov's meshes, specifically designed for such an interval. However, when such a mesh is not available, or in the case where the spectral interval is not known in advance (such as in models with multiple reflections), we expect that it will be advantageous to use the universal optimal mesh of the same type as "B" above, which satisfies the accuracy requirements.

7. Conclusions. We have shown that the optimal choice of the attenuation parameters for Berenger PML ABCs can be achieved in the limiting case of the purely imaginary coordinate stretching approach. Indeed, it was questioned by one of the reviewers if the proposed approach can and should be included in the class of PML boundary conditions, because, unlike those conditions, it leads to a diffusion-type equation in the absorbing region. However, the situation when a minimum is attained on the boundary of the closure of a set is often encountered in optimization theory, and thus our new ABC is a part of the closure of the classical PML set.

For this limiting case, the problem becomes frequency independent and can be viewed as a classical Chebyshev rational approximation of the square root function, and the parameters that need to be chosen are the steps of the grid of the resulting finite-difference scheme. We consider two different error functions and show how to obtain the optimal grid steps for them. The resulting scheme exhibits attenuative properties superior to those of the classical PML known to the authors; the goal attenuation of 1% can be achieved using as few as five points in the absorbing region. The drawback of the resulting scheme is that, unlike the classic PML, it needs to be implemented in a fashion that is different in the absorbing and the propagating regions. The details of the discretization of a two-dimensional scalar wave problem are discussed and the results of numerical experiments are presented.

POINCARÉ–FRIEDRICHS INEQUALITIES FOR PIECEWISE H^1 FUNCTIONS[*]

SUSANNE C. BRENNER[†]

Abstract. Poincaré–Friedrichs inequalities for piecewise H^1 functions are established. They can be applied to classical nonconforming finite element methods, mortar methods, and discontinuous Galerkin methods.

Key words. Poincaré–Friedrichs inequalities, piecewise H^1 functions, nonconforming finite elements, mortar methods, discontinuous Galerkin methods

AMS subject classifications. 65N30, 46E35

PII. S0036142902401311

1. Introduction.

Let Ω be a connected open polyhedral domain in $\mathbb{R}^d$ ($d = 2, 3$), and let $H^1(\Omega)$ be the Sobolev space of (real-valued) functions in $L_2(\Omega)$ whose first order distributional derivatives also belong to $L_2(\Omega)$. The Poincaré–Friedrichs inequalities (cf. [23, 29]) state that

$$\|\zeta\|_{L_2(\Omega)} \le C\left(|\zeta|_{H^1(\Omega)} + \left|\int_\Gamma \zeta\, ds\right|\right) \qquad \forall\, \zeta \in H^1(\Omega), \tag{1.1}$$

$$\|\zeta\|_{L_2(\Omega)} \le C\left(|\zeta|_{H^1(\Omega)} + \left|\int_\Omega \zeta\, dx\right|\right) \qquad \forall\, \zeta \in H^1(\Omega), \tag{1.2}$$

where

$$|\zeta|_{H^1(\Omega)} = \left(\int_\Omega |\nabla\zeta|^2\, dx\right)^{1/2},$$

Γ is a measurable subset of $\partial\Omega$ with a positive $(d-1)$-dimensional measure, and ds is the infinitesimal $(d-1)$-dimensional volume.

In this paper we establish analogues of (1.1) and (1.2) for piecewise H^1 functions with respect to a partition $\mathcal{P}$ of Ω by open polygons ($d = 2$) or polyhedra ($d = 3$), which is not necessarily a triangulation of Ω. In other words, we assume only that

$$D \cap D' = \emptyset \text{ if } D \text{ and } D' \text{ are distinct members of } \mathcal{P}, \text{ and } \overline{\Omega} = \bigcup_{D\in\mathcal{P}} \overline{D}.$$

Typical two- and three-dimensional examples of partitions are depicted in Figure 1.1, where the square is partitioned into seven subdomains and the cube is partitioned into five subdomains. The space $H^1(\Omega, \mathcal{P})$ of piecewise H^1 functions is defined by

$$H^1(\Omega, \mathcal{P}) = \{\zeta \in L_2(\Omega) : \zeta_D = \zeta\big|_D \in H^1(D) \quad \forall\, D \in \mathcal{P}\},$$

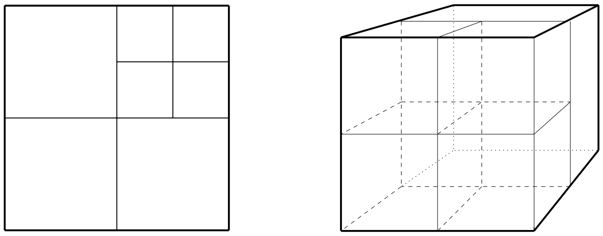

FIG. 1.1. *Examples of general partitions.*

and the seminorm $|\cdot|_{H^1(\Omega,\mathcal{P})}$ is defined by

$$|\zeta|_{H^1(\Omega,\mathcal{P})} = \left(\sum_{D\in\mathcal{P}} \int_D |\nabla\zeta|^2\,dx\right)^{1/2}.$$

We will denote by $S(\mathcal{P},\Omega)$ the set of all the (open) sides (i.e., edges ($d=2$) or faces ($d=3$)) common to two subdomains in $\mathcal{P}$. For example, there are ten such edges in the two-dimensional example in Figure 1.1 and eight such faces in the three-dimensional example. (The precise definition of $S(\mathcal{P},\Omega)$ will be given in sections 6 and 7.)

The following are analogues of the Poincaré–Friedrichs inequalities for $\zeta \in H^1(\Omega,\mathcal{P})$:

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{d/(1-d)}\left(\int_\sigma [\zeta]\,ds\right)^2 + \left(\int_\Gamma \zeta\,ds\right)^2\right], \tag{1.3}$$

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{d/(1-d)}\left(\int_\sigma [\zeta]\,ds\right)^2 + \left(\int_\Omega \zeta\,dx\right)^2\right], \tag{1.4}$$

where $|\sigma|$ is the $(d-1)$-dimensional volume of the side σ, $[\zeta]$ denotes the jump of the function ζ across a side, and the positive constant C depends only on the shape regularity of the partition $\mathcal{P}$. In particular, these inequalities are valid for partitions that are not quasi-uniform. (More details on the shape regularity assumptions are given in sections 6 and 7.)

Remark 1.1. The Poincaré–Friedrichs inequalities (1.3) and (1.4) can also be written in the following equivalent forms:

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} (\operatorname{diam}\sigma)^{-1}\|\pi_{0,\sigma}[\zeta]\|^2_{L_2(\sigma)} + \left(\int_\Gamma \zeta\,ds\right)^2\right],$$

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} (\operatorname{diam}\sigma)^{-1}\|\pi_{0,\sigma}[\zeta]\|^2_{L_2(\sigma)} + \left(\int_\Omega \zeta\,dx\right)^2\right],$$

where $\pi_{0,\sigma}$ is the orthogonal projection operator from $L_2(\sigma)$ onto $P_0(\sigma)$, the space of constant functions on σ.

The inequalities (1.3) and (1.4) imply that

$$\|\zeta\|_{L_2(\Omega)} \le C\left(|\zeta|_{H^1(\Omega,\mathcal{P})} + \left|\int_\Gamma \zeta\, ds\right|\right), \tag{1.5}$$

$$\|\zeta\|_{L_2(\Omega)} \le C\left(|\zeta|_{H^1(\Omega,\mathcal{P})} + \left|\int_\Omega \zeta\, dx\right|\right), \tag{1.6}$$

provided

$$\int_\sigma [\zeta]\, ds = 0 \qquad \forall\, \sigma \in S(\mathcal{P},\Omega)\,. \tag{1.7}$$

Thus we immediately obtain (1.5) and (1.6) for ζ belonging to many classical nonconforming finite element spaces [15, 19, 21, 18, 25, 17, 12, 11] where $\mathcal{P}$ is a triangulation of Ω, and for ζ belonging to mortar element spaces [5, 6, 26, 4, 30, 20] for a general partition $\mathcal{P}$.

The estimates (1.3) and (1.4) also imply that

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left(|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{1/(1-d)} \int_\sigma [\zeta]^2\, ds + \int_\Gamma |\zeta|^2\, ds\right), \tag{1.8}$$

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left(|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{1/(1-d)} \int_\sigma [\zeta]^2\, ds + \left(\int_\Omega \zeta\, dx\right)^2\right) \tag{1.9}$$

for all $\zeta \in H^1(\Omega,\mathcal{P})$. Such inequalities are useful for the analysis of discontinuous Galerkin methods (cf. [14, 24, 3] and the references therein). It should be pointed out that for $d = 2$ and $\Gamma = \partial\Omega$ the inequality (1.8) is slightly stronger than an earlier one obtained in [2], which has the form

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left(|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} \frac{1}{|\sigma|} \int_\sigma [\zeta]^2\, ds + \sum_{\sigma\subseteq\partial\Omega} \frac{1}{|\sigma|} \int_\sigma |\zeta|^2\, ds\right), \tag{1.10}$$

where the integrals on the edges along $\partial\Omega$ are also penalized.

Note that the classical inequalities (1.1) and (1.2) are simple consequences of the compactness of the embedding of $H^1(\Omega)$ in $L_2(\Omega)$ (cf. [23, 29]), while the proof of (1.10) in [2] relies on the much deeper regularity theory for the Laplace operator on nonsmooth domains. In contrast, the approach in this paper is based on the classical Poincaré–Friedrichs inequalities and therefore the elementary nature of (1.3) and (1.4) (and hence of (1.8) and (1.9)) is restored.

The rest of the paper is organized as follows. We will first establish (1.3) and (1.4) for the simpler case where $\mathcal{P}$ is a simplicial triangulation of Ω. The key idea is to bridge the classical estimates and the discontinuous estimates through the construction of a nonconforming P_1 interpolant and through the connections between nonconforming P_1 finite elements (in two and three dimensions) and their conforming relatives. These are carried out in sections 2 and 3. Poincaré–Friedrichs inequalities for nonconforming P_1 finite element functions are then derived in section 4, followed by Poincaré–Friedrichs inequalities for piecewise H^1 functions with respect to a simplicial triangulation of Ω in section 5. Finally, Poincaré–Friedrichs inequalities for piecewise H^1 functions with respect to general partitions are given in sections 6 and 7 for two- and three-dimensional domains, and some concluding remarks are given in section 8.

2. A nonconforming P_1 interpolant. In this and the next three sections we restrict our attention to the case where the partition is actually a simplicial triangulation $\mathcal{T}$ of Ω consisting of triangles ($d = 2$) or tetrahedra ($d = 3$); i.e., the intersection of the closures of two members of $\mathcal{T}$ is either empty, a vertex, a closed edge, or a closed face. In this case $S(\mathcal{T}, \Omega)$ is just the set of interior open edges ($d = 2$) or open faces ($d = 3$). We will also denote the set of boundary edges or faces by $S(\mathcal{T}, \partial\Omega)$ and the minimum angle of the triangles or tetrahedra in $\mathcal{T}$ by $\theta_{\mathcal{T}}$.

To avoid the proliferation of constants, we henceforth use the notation $A \lesssim B$ to represent the statement $A \le \kappa(\theta_{\mathcal{T}})B$, where the (generic) function $\kappa : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ is continuous and independent of $\mathcal{T}$. The notation $A \approx B$ is equivalent to $A \lesssim B$ and $B \lesssim A$.

The nonconforming P_1 finite element space (cf. [15]) associated with the triangulation $\mathcal{T}$ is $V_{\mathcal{T}} = \{v \in L_2(\Omega) : v_{\scriptscriptstyle T} = v\big|_T \in P_1(T)$ for any $T \in \mathcal{T}$ and v is continuous at the center of the common side of any two neighboring triangles ($d = 2$) or tetrahedra ($d = 3$)$\}$. A function in $V_{\mathcal{T}}$ is completely determined by its nodal values at the centers of the sides of the triangles or tetrahedra in $\mathcal{T}$ (cf. Figure 2.1).

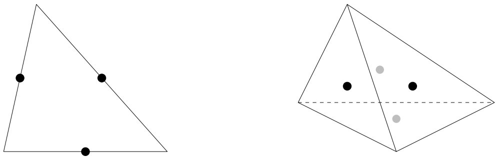

FIG. 2.1. *P_1 nonconforming finite elements.*

The interpolation operator $\mathcal{I} : H^1(\Omega, \mathcal{T}) \longrightarrow V_{\mathcal{T}}$ is defined by

$$(\mathcal{I}\zeta)(c_\sigma) = \frac{1}{|\sigma|}\int_\sigma \{\zeta\}\, ds \qquad \forall\, \sigma \in S(\mathcal{T}, \Omega) \cup S(\mathcal{T}, \partial\Omega), \tag{2.1}$$

where c_σ is the center of the side σ and $\{\zeta\}$ is the average of the traces from the two sides of σ. For $\sigma \subset \partial\Omega$, we take $\{\zeta\}$ to be ζ.

Let $\Pi_T : H^1(T) \longrightarrow P_1(T)$ be the local interpolation operator defined by

$$(\Pi_T\zeta)(c_\sigma) = \frac{1}{|\sigma|}\int_\sigma \zeta\, ds \qquad \forall\, \sigma \subset \partial T\,. \tag{2.2}$$

From (2.1) and (2.2) we see that the difference of the two interpolants on $T \in \mathcal{T}$ is given by

$$(\mathcal{I}\zeta - \Pi_T\zeta)(c_\sigma) = \begin{cases} \dfrac{1}{2|\sigma|}\displaystyle\int_\sigma [\zeta]\, ds & \text{if} \quad \sigma \subset \partial T \setminus \partial\Omega, \\ 0 & \text{if} \quad \sigma \subset \partial T \cap \partial\Omega, \end{cases} \tag{2.3}$$

where the jump $[\zeta]$ is measured by subtracting the interior trace from the exterior trace.

Using (2.3) and standard finite element estimates (cf. [13, 10]), we find

$$\begin{aligned}|\mathcal{I}\zeta-\Pi_T\zeta|^2_{H^1(T)} &\lesssim |T|^{1-(2/d)}\sum_{\sigma\subset\partial T}\big[\big(\mathcal{I}\zeta-\Pi_T\zeta\big)(c_\sigma)\big]^2\\ &\lesssim |T|^{1-(2/d)}\sum_{\sigma\subset\partial T\setminus\partial\Omega}\frac{1}{|\sigma|^2}\left(\int_\sigma[\zeta]\,ds\right)^2 \qquad (2.4)\\ &\lesssim \sum_{\sigma\subset\partial T\setminus\partial\Omega}|\sigma|^{d/(1-d)}\left(\int_\sigma[\zeta]\,ds\right)^2,\end{aligned}$$

$$\begin{aligned}\|\mathcal{I}\zeta-\Pi_T\zeta\|^2_{L_2(T)} &\lesssim |T|\sum_{\sigma\subset\partial T}\big[\big(\mathcal{I}\zeta-\Pi_T\zeta\big)(c_\sigma)\big]^2 \qquad (2.5)\\ &\lesssim \sum_{\sigma\subset\partial T\setminus\partial\Omega}|\sigma|^{(2-d)/(d-1)}\left(\int_\sigma[\zeta]\,ds\right)^2,\end{aligned}$$

where $|T|$ is the d-dimensional volume of T. Note that

$$|T|\approx|\sigma|^{d/(d-1)} \qquad \text{for} \quad \sigma\subset\partial T\,. \tag{2.6}$$

On the other hand, we also have the following well-known estimates (cf. [15]) for the local interpolation operator:

$$\|\zeta-\Pi_T\zeta\|^2_{L_2(T)}+|T|^{2/d}\,|\Pi_T\zeta|^2_{H^1(T)}\lesssim|T|^{2/d}\,|\zeta|^2_{H^1(T)}\,. \tag{2.7}$$

Combining the estimates (2.4)–(2.7) and summing over all $T\in\mathcal{T}$ we find

$$|\mathcal{I}\zeta|^2_{H^1(\Omega,\mathcal{T})}\lesssim|\zeta|^2_{H^1(\Omega,\mathcal{T})}+\sum_{\sigma\in S(\mathcal{T},\Omega)}|\sigma|^{d/(1-d)}\left(\int_\sigma[\zeta]\,ds\right)^2, \tag{2.8}$$

$$\|\zeta-\mathcal{I}\zeta\|^2_{L_2(\Omega)}\lesssim\sum_{T\in\mathcal{T}}|T|^{2/d}\,|\zeta|^2_{H^1(T)}+\sum_{\sigma\in S(\mathcal{T},\Omega)}|\sigma|^{(2-d)/(d-1)}\left(\int_\sigma[\zeta]\,ds\right)^2. \tag{2.9}$$

3. The connections between nonconforming P_1 finite elements and their conforming relatives. Let $W_{\mathcal{T}}\subset H^1(\Omega)$ be the P_2 Lagrange finite element space associated with $\mathcal{T}$ for $d=2$ and the P_3 Lagrange finite element space associated with $\mathcal{T}$ for $d=3$. The nodal variables (degrees of freedom) of these elements are depicted in Figure 3.1. We will denote the set of the centers of the sides of T by $\mathcal{C}(T)$, denote the set of the other nodes by $\mathcal{N}(T)$, and define $\mathcal{C}(\mathcal{T})=\bigcup_{T\in\mathcal{T}}\mathcal{C}(T)$ and $\mathcal{N}(\mathcal{T})=\bigcup_{T\in\mathcal{T}}\mathcal{N}(T)$.

Remark 3.1. The nonconforming P_1 finite element and the conforming P_2 (respectively, P_3) finite element in two (respectively, three) dimensions are *relatives* in

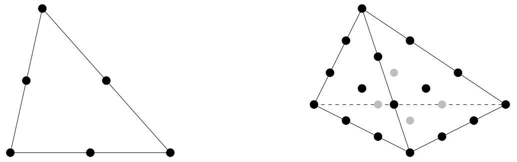

FIG. 3.1. *Two-dimensional P_2 and three-dimensional P_3 Lagrange elements.*

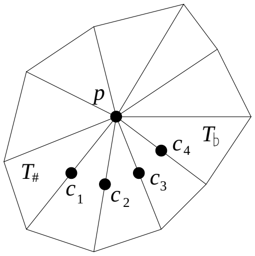

FIG. 3.2. *A sequence of c_j's connecting $T_\sharp$ and $T_\flat$.*

the sense that the shape functions of the first are also shape functions of the latter and the nodal variables of the first are also nodal variables of the latter (cf. Figures 2.1 and 3.1).

The finite element spaces $V_{\mathcal{T}}$ and $W_{\mathcal{T}}$ are connected by the operators $E : V_{\mathcal{T}} \longrightarrow W_{\mathcal{T}}$ and $F : W_{\mathcal{T}} \longrightarrow V_{\mathcal{T}}$ defined by

$$\big(Ev\big)(p) = \frac{1}{|\Xi_p|} \sum_{T \in \Xi_p} v_{_T}(p) \qquad \forall\, p \in \mathcal{N}(\mathcal{T}) \cup \mathcal{C}(\mathcal{T}), \tag{3.1}$$

$$\big(Fw\big)(p) = w(p) \qquad \forall\, p \in \mathcal{C}(\mathcal{T}), \tag{3.2}$$

where $\Xi_p = \{T \in \mathcal{T} : p \in \partial T\}$ is the set of the simplexes sharing p as a vertex and $|\Xi_p|$ is the number of elements in Ξ_p. Note that $\big(Ev\big)(p) = v(p)$ for $p \in \mathcal{C}(\mathcal{T})$ since v is continuous at the centers of the sides. For $d = 2$, these connection operators were introduced in [8, 9] and used in the analysis of domain decomposition methods and multigrid methods for nonconforming finite elements.

The following lemma contains the basic estimates for E and F.

LEMMA 3.2. *It holds that*

$$\|Ev - v\|^2_{L_2(\Omega)} \approx \sum_{T \in \mathcal{T}} |T|^{2/d} |v|^2_{H^1(T)} \qquad \forall\, v \in V_{\mathcal{T}}, \tag{3.3}$$

$$\|Fw - w\|^2_{L_2(\Omega)} \approx \sum_{T \in \mathcal{T}} |T|^{2/d} |w|^2_{H^1(T)} \qquad \forall\, w \in W_{\mathcal{T}}\,. \tag{3.4}$$

Proof. Let $p \in \mathcal{N}(\mathcal{T})$ and $T_\sharp, T_\flat \in \Xi_p$. We can find a sequence $c_1, \ldots, c_m$ in $\mathcal{C}(\mathcal{T})$ so that $c_1 \in \partial T_\sharp$, $c_m \in \partial T_\flat$, and c_j, c_{j+1} belong to the boundary of $T_j \in \Xi_p$ for $j = 1, \ldots, m-1$ (cf. Figure 3.2 for a two-dimensional example with $m = 4$). Note that $|\Xi_p|$ and hence m are bounded by a constant depending continuously on the minimum angle $\theta_{\mathcal{T}}$. Hence it follows from the Cauchy–Schwarz inequality and the mean value theorem that

$$\begin{aligned}
[v_{_{T_\sharp}}(p) - v_{_{T_\flat}}(p)]^2 &\lesssim [v_{_{T_\sharp}}(p) - v_{_{T_\sharp}}(c_1)]^2 + \sum_{j=1}^{m-1} [v_{_{T_j}}(c_j) - v_{_{T_j}}(c_{j+1})]^2 \\
&\qquad + [v_{_{T_\flat}}(c_m) - v_{_{T_\flat}}(p)]^2 \\
&\lesssim \sum_{T' \in \Xi_p} |T'|^{(2/d)-1} |v|^2_{H^1(T')}\,.
\end{aligned} \tag{3.5}$$

Using (3.1), (3.5), and the Cauchy–Schwarz inequality we find for any $T \in \Xi_p$

$$\big[\big(Ev - v_{_T}\big)(p)\big]^2 \lesssim \sum_{T' \in \Xi_p} |T'|^{(2/d)-1} |v|^2_{H^1(T')} \qquad \forall\, v \in V_{\mathcal{T}}\,. \tag{3.6}$$

Let $T \in \mathcal{T}$. We have, by (3.6),

$$\begin{aligned} \|Ev - v\|^2_{L_2(T)} &\approx |T| \sum_{p \in \mathcal{N}(T) \cup \mathcal{C}(T)} \big[\big(Ev - v_{_T}\big)(p)\big]^2 \\ &= |T| \sum_{p \in \mathcal{N}(T)} \big[\big(Ev - v_{_T}\big)(p)\big]^2 \\ &\lesssim \sum_{p \in \mathcal{N}(T)} \sum_{T' \in \Xi_p} |T'|^{2/d} |v|^2_{H^1(T')}, \end{aligned} \tag{3.7}$$

where we have also used the fact that

$$|T| \approx |T'| \qquad \text{for} \quad T' \in \Xi_p \ \text{ and } \ p \in \mathcal{N}(T)\,. \tag{3.8}$$

The estimate (3.3) then follows by summing (3.7) over all $T \in \mathcal{T}$.

Observe that, on each $T \in \mathcal{T}$, Fw is just the linear nodal interpolant of w with the nodes placed at the centers of the sides of T. It follows from standard interpolation and inverse estimates (cf. [13, 10]) that

$$\|Fw - w\|^2_{L_2(T)} \lesssim |T|^{4/d} |w|^2_{H^2(T)} \lesssim |T|^{2/d} |w|^2_{H^1(T)} \qquad \forall\, w \in W_{\mathcal{T}}\,. \tag{3.9}$$

The estimate (3.4) follows by summing (3.9) over all $T \in \mathcal{T}$. □

COROLLARY 3.3. *It holds that*

$$\|Ev\|_{L_2(\Omega)} \approx \|v\|_{L_2(\Omega)} \qquad \forall\, v \in V_{\mathcal{T}}, \tag{3.10}$$

$$|Ev|_{H^1(\Omega)} \approx |v|_{H^1(\Omega,\mathcal{T})} \qquad \forall\, v \in V_{\mathcal{T}}\,. \tag{3.11}$$

Proof. It follows from (3.3) and a standard inverse estimate (cf. [13, 10]) that

$$\begin{aligned} \|Ev\|_{L_2(\Omega)} &\le \|Ev - v\|_{L_2(\Omega)} + \|v\|_{L_2(\Omega)} \\ &\lesssim \Big(\sum_{T \in \mathcal{T}} |T|^{2/d} |v|^2_{H^1(T)}\Big)^{1/2} + \|v\|_{L_2(\Omega)} \\ &\lesssim \|v\|_{L_2(\Omega)} \qquad \forall\, v \in V_{\mathcal{T}}\,. \end{aligned} \tag{3.12}$$

Similarly from (3.4) we have

$$\|Fw\|_{L_2(\Omega)} \lesssim \|w\|_{L_2(\Omega)} \qquad \forall\, w \in W_{\mathcal{T}}\,. \tag{3.13}$$

It is clear from definitions (3.1) and (3.2) that

$$F(Ev) = v \qquad \forall\, v \in V_{\mathcal{T}}, \tag{3.14}$$

and hence, by (3.13),

$$\|v\|_{L_2(\Omega)} = \|F(Ev)\|_{L_2(\Omega)} \lesssim \|Ev\|_{L_2(\Omega)} \qquad \forall\, v \in V_{\mathcal{T}}\,. \tag{3.15}$$

The estimates (3.12) and (3.15) together yield (3.10).

By (3.3) and a standard inverse estimate, we also find

$$
\begin{aligned}
|Ev|_{H^1(\Omega)} &\le |Ev - v|_{H^1(\Omega,\mathcal{T})} + |v|_{H^1(\Omega,\mathcal{T})} \\
&\lesssim \left(\sum_{T\in\mathcal{T}} |T|^{-(2/d)} \|Ev - v\|^2_{L_2(T)} \right)^{1/2} + |v|_{H^1(\Omega,\mathcal{T})} \qquad (3.16)\\
&\lesssim |v|_{H^1(\Omega,\mathcal{T})} \qquad \forall\, v \in V_{\mathcal{T}}\,.
\end{aligned}
$$

Similarly, we derive from (3.4) that

$$
|Fw|_{H^1(\Omega,\mathcal{T})} \lesssim |w|_{H^1(\Omega)} \qquad \forall\, w \in W_{\mathcal{T}}\,. \tag{3.17}
$$

Again, the estimate (3.11) follows from (3.14), (3.16), and (3.17). □

4. Poincaré–Friedrichs inequalities for nonconforming P_1 finite element functions.

Functions in the nonconforming P_1 finite element space $V_{\mathcal{T}}$ are known to satisfy Poincaré–Friedrichs inequalities (cf. [28, 27, 16, 22]). Here we give a simple derivation of such inequalities using the connection between $V_{\mathcal{T}}$ and its conforming relative $W_{\mathcal{T}}$ developed in section 3.

Let Φ be a seminorm on $H^1(\Omega)$ with the following properties:

$$
\Phi(\phi) \le C\|\phi\|_{H^1(\Omega)} \qquad \forall\, \phi \in H^1(\Omega), \tag{4.1}
$$

where C is a positive constant, and

(4.2) for a constant function c, $\Phi(c) = 0$ if and only if $c = 0$.

Then we have the generalized Poincaré–Friedrichs inequality (cf. [23]) for $H^1(\Omega)$:

$$
\|\phi\|_{L_2(\Omega)} \le C\big[|\phi|_{H^1(\Omega)} + \Phi(\phi)\big] \qquad \forall\, \phi \in H^1(\Omega), \tag{4.3}
$$

which follows from the compactness of the embedding of $H^1(\Omega)$ in $L_2(\Omega)$.

We can derive from (4.3) a generalized Poincaré–Friedrichs inequality for nonconforming P_1 finite element functions.

THEOREM 4.1. *Let Φ be a seminorm on $H^1(\Omega,\mathcal{T})$ that satisfies* (4.1), (4.2), *and the additional condition that*

$$
\Phi(Ev - v) \lesssim |v|_{H^1(\Omega,\mathcal{T})} \qquad \forall\, v \in V_{\mathcal{T}}, \tag{4.4}
$$

where $E : V_{\mathcal{T}} \longrightarrow W_{\mathcal{T}}$ is defined by (3.1). *Then there exists a continuous function $\kappa : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$, independent of $\mathcal{T}$ such that*

$$
\|v\|_{L_2(\Omega)} \le \kappa(\theta_{\mathcal{T}})\big(|v|_{H^1(\Omega,\mathcal{T})} + \Phi(v)\big) \qquad \forall\, v \in V_{\mathcal{T}}\,. \tag{4.5}
$$

Proof. Combining (3.10), (3.11), (4.3), and (4.4), we find

$$
\begin{aligned}
\|v\|_{L_2(\Omega)} \approx \|Ev\|_{L_2(\Omega)} &\lesssim |Ev|_{H^1(\Omega)} + \Phi(Ev) \\
&\lesssim |v|_{H^1(\Omega,\mathcal{T})} + \Phi(Ev - v) + \Phi(v) \\
&\lesssim |v|_{H^1(\Omega,\mathcal{T})} + \Phi(v) \qquad \forall\, v \in V_{\mathcal{T}}\,.
\end{aligned}
$$

□

The following are examples of seminorms that satisfy (4.1), (4.2), and (4.4).

Example 4.2. Let ψ be a square integrable function on $\partial\Omega$ such that

$$\int_{\partial\Omega} \psi \, ds \neq 0,$$

and let $\Phi_1 : H^1(\Omega, \mathcal{T}) \longrightarrow \mathbb{R}$ be defined by

$$\Phi_1(\zeta) = \left| \int_{\partial\Omega} \psi\zeta \, ds \right| . \tag{4.6}$$

Then (4.2) is obvious and (4.1) follows from the trace theorem. Condition (4.4) can be established as follows:

$$\begin{aligned}
[\Phi_1(Ev - v)]^2 &\leq \|\psi\|^2_{L_2(\partial\Omega)} \|Ev - v\|^2_{L_2(\partial\Omega)} \\
&\lesssim \sum_{\sigma \in S(\mathcal{T}, \partial\Omega)} \|Ev - v\|^2_{L_2(\sigma)} \\
&\lesssim \sum_{\sigma \in S(\mathcal{T}, \partial\Omega)} |\sigma| \sum_{p \in \mathcal{N}(\sigma)} \left[(Ev - v_{T_\sigma})(p) \right]^2,
\end{aligned}$$

where $\mathcal{N}(\sigma)$ denotes the set of the nodes on $\bar{\sigma}$ excluding the center of σ, and T_σ is the member of $\mathcal{T}$ whose boundary contains σ. Combining this last estimate with (2.6), (3.6), and (3.8), we find

$$[\Phi_1(Ev - v)]^2 \lesssim \sum_{\substack{T \in \mathcal{T} \\ |\partial T \cap \partial\Omega| > 0}} |T|^{1/d} |v|^2_{H^1(T)} \lesssim |v|^2_{H^1(\Omega, \mathcal{T})} .$$

Example 4.3. Let ψ be a square integrable function on Ω such that

$$\int_{\Omega} \psi \, dx \neq 0,$$

and let $\Phi_2 : H^1(\Omega, \mathcal{T}) \longrightarrow \mathbb{R}$ be defined by

$$\Phi_2(\zeta) = \left| \int_{\Omega} \psi\zeta \, dx \right| . \tag{4.7}$$

Then (4.1) and (4.2) are trivial, and (4.4) follows from (3.3).

Remark 4.4. The Poincaré–Friedrichs inequalities (1.5) and (1.6) for P_1 nonconforming finite element functions follow immediately from Theorem 4.1 if we take ψ to be the characteristic function of Γ in (4.6) and the characteristic function of Ω in (4.7).

5. Poincaré–Friedrichs inequalities for $H^1(\Omega, \mathcal{T})$. Let $\mathcal{T}$ be a simplicial triangulation of Ω. The last ingredient for establishing a generalized Poincaré–Friedrichs inequality for $H^1(\Omega, \mathcal{T})$ is the following condition on Φ:

$$[\Phi(\mathcal{I}\zeta - \zeta)]^2 \lesssim |\zeta|^2_{H^1(\Omega, \mathcal{T})} + \sum_{\sigma \in S(\mathcal{T}, \Omega)} |\sigma|^{d/(1-d)} \left(\int_{\sigma} [\zeta] \, ds \right)^2 \tag{5.1}$$

for all $\zeta \in H^1(\Omega, \mathcal{T})$.

THEOREM 5.1. *Let Φ be a seminorm on $H^1(\Omega,\mathcal{T})$ that satisfies the conditions* (4.1), (4.2), (4.4), *and* (5.1). *Then there exists a continuous function $\kappa : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$, independent of $\mathcal{T}$, such that*

$$\|\zeta\|^2_{L_2(\Omega)} \le \kappa(\theta_{\mathcal{T}}) \left[|\zeta|^2_{H^1(\Omega,\mathcal{T})} + \sum_{\sigma\in S(\mathcal{T},\Omega)} |\sigma|^{d/(1-d)} \left(\int_\sigma [\zeta]\, ds \right)^2 + [\Phi(\zeta)]^2 \right] \tag{5.2}$$

for all $\zeta \in H^1(\Omega,\mathcal{T})$.

Proof. Combining (2.8), (2.9), (4.5), and (5.1) we have

$$\begin{aligned} \|\zeta\|^2_{L_2(\Omega)} &\lesssim \|\zeta - \mathcal{I}\zeta\|^2_{L_2(\Omega)} + \|\mathcal{I}\zeta\|^2_{L_2(\Omega)} \\ &\lesssim \|\zeta - \mathcal{I}\zeta\|^2_{L_2(\Omega)} + |\mathcal{I}\zeta|^2_{H^1(\Omega,\mathcal{T})} + [\Phi(\mathcal{I}\zeta)]^2 \\ &\lesssim \|\zeta - \mathcal{I}\zeta\|^2_{L_2(\Omega)} + |\mathcal{I}\zeta|^2_{H^1(\Omega,\mathcal{T})} + [\Phi(\mathcal{I}\zeta - \zeta)]^2 + [\Phi(\zeta)]^2 \\ &\lesssim |\zeta|^2_{H^1(\Omega,\mathcal{T})} + \sum_{\sigma\in S(\mathcal{T},\Omega)} |\sigma|^{d/(1-d)} \left(\int_\sigma [\zeta]\, ds \right)^2 + [\Phi(\zeta)]^2 . \qquad \square \end{aligned}$$

Note that condition (5.1) is satisfied by the seminorms Φ_1 (Example 4.2) and Φ_2 (Example 4.3). The case of Φ_2 follows immediately from (2.9). The case of Φ_1 can be established as follows.

First of all we have, by the Cauchy–Schwarz inequality,

$$\begin{aligned} [\Phi_1(\mathcal{I}\zeta - \zeta)]^2 &\lesssim \sum_{\substack{T\in\mathcal{T} \\ |\partial T\cap\partial\Omega|>0}} \|\mathcal{I}\zeta - \zeta\|^2_{L_2(\partial T\cap\partial\Omega)} \\ &\lesssim \sum_{T\in\mathcal{T}} \|\mathcal{I}\zeta - \Pi_T\zeta\|^2_{L_2(\partial T)} + \sum_{T\in\mathcal{T}} \|\Pi_T\zeta - \zeta\|^2_{L_2(\partial T)} . \end{aligned} \tag{5.3}$$

Using the equivalence of norms on finite-dimensional spaces and a scaling argument, we have

$$\|\mathcal{I}\zeta - \Pi_T\zeta\|^2_{L_2(\partial T)} \lesssim |T|^{-(1/d)} \|\mathcal{I}\zeta - \Pi_T\zeta\|^2_{L_2(T)} . \tag{5.4}$$

On the other hand, it follows from the trace theorem, the Bramble–Hilbert lemma (cf. [7]), and scaling that

$$\|\Pi_T\zeta - \zeta\|^2_{L_2(\partial T)} \lesssim |T|^{1/d} |\zeta|^2_{H^1(T)} \lesssim |\zeta|^2_{H^1(T)} . \tag{5.5}$$

From (2.5), (2.6), and (5.3)–(5.5) we then obtain the estimate (5.1):

$$\begin{aligned} [\Phi_1(\mathcal{I}\zeta - \zeta)]^2 &\lesssim |\zeta|^2_{H^1(\Omega,\mathcal{T})} + \sum_{T\in\mathcal{T}} \sum_{\sigma\subset\partial T\setminus\partial\Omega} |\sigma|^{-1/(d-1)} |\sigma|^{(2-d)/(d-1)} \left(\int_\sigma [\zeta]\, ds \right)^2 \\ &\lesssim |\zeta|^2_{H^1(\Omega,\mathcal{T})} + \sum_{T\in\mathcal{T}} \sum_{\sigma\subset\partial T\setminus\partial\Omega} |\sigma|^{-1} \left(\int_\sigma [\zeta]\, ds \right)^2 \\ &\lesssim |\zeta|^2_{H^1(\Omega,\mathcal{T})} + \sum_{\sigma\in S(\mathcal{T},\Omega)} |\sigma|^{d/(1-d)} \left(\int_\sigma [\zeta]\, ds \right)^2 . \end{aligned}$$

Remark 5.2. Let $\mathfrak{T}_\Omega$ be the set of all simplicial triangulations of Ω. From here on we assume that $\Phi : \bigcup_{\mathcal{T}\in\mathfrak{T}_\Omega} H^1(\Omega,\mathcal{T}) \longrightarrow \mathbb{R}$ is a seminorm for every $\mathcal{T} \in \mathfrak{T}_\Omega$ and that it satisfies the conditions (4.1), (4.2), (4.4), and (5.1) for every $\mathcal{T} \in \mathfrak{T}_\Omega$.

Remark 5.3. The Poincaré–Friedrichs inequalities (1.3) and (1.4) for $\zeta \in H^1(\Omega,\mathcal{T})$ follow immediately from Theorem 5.1 if the functions ψ in (4.6) and (4.7) are chosen as in Remark 4.4. Similar remarks also apply in the next two sections.

6. Poincaré–Friedrichs inequalities for $H^1(\Omega,\mathcal{P})$ on two-dimensional domains. Let us first give the precise definition of interior edges for a general partition $\mathcal{P}$. We define a vertex of the partition $\mathcal{P}$ to be a vertex of any of the subdomains in $\mathcal{P}$. (For example, the partition of the square in Figure 1.1 has 14 vertices.) We then define an open edge of $\mathcal{P}$ to be an open line segment on the boundary of a subdomain in $\mathcal{P}$ bounded between two of the vertices of $\mathcal{P}$. The set $S(\mathcal{P},\Omega)$ contains the open edges of $\mathcal{P}$ that are common to the boundaries of two members of $\mathcal{P}$.

Remark 6.1. The concept of an edge of a polygon $D \in \mathcal{P}$ and the concept of an edge of $\mathcal{P}$ on ∂D should be distinguished. For example, a square always has four edges, while there are five edges of the two-dimensional partition in Figure 1.1 on the boundary of the square at the lower right corner.

In order to apply Theorem 5.1 we define the set

$$\begin{aligned}(6.1)\qquad \mathfrak{T}_\mathcal{P} = \{&\mathcal{T} : \mathcal{T} \text{ is a triangulation of } \Omega \text{ by triangles and each member of}\\ &S(\mathcal{P},\Omega) \text{ is also an edge of } \mathcal{T}\}.\end{aligned}$$

(A triangulation belonging to $\mathfrak{T}_\mathcal{P}$ for the two-dimensional example in Figure 1.1 is depicted in Figure 6.1.) By definition (6.1), $H^1(\Omega,\mathcal{P})$ is a subspace of $H^1(\Omega,\mathcal{T})$ for any $\mathcal{T} \in \mathfrak{T}_\mathcal{P}$. Observing that for a function $\zeta \in H^1(\Omega,\mathcal{P})$ the jump $[\zeta]$ is zero across the edges of $\mathcal{T}$ that are not in $S(\mathcal{P},\Omega)$, we immediately deduce the following result from Theorem 5.1.

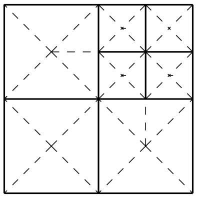

Fig. 6.1. *A triangulation in $\mathfrak{T}_\mathcal{P}$ for a partition of a square.*

Theorem 6.2. *Let Φ be as in Remark* 5.2. *Then we have*

$$(6.2)\quad \|\zeta\|^2_{L_2(\Omega)} \le \left[\inf_{\mathcal{T}\in\mathfrak{T}_\mathcal{P}} \kappa(\theta_\mathcal{T})\right]\left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{-2}\left(\int_\sigma [\zeta]\,ds\right)^2 + [\Phi(\zeta)]^2\right]$$

for all $\zeta \in H^1(\Omega,\mathcal{P})$, where $\kappa : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ is a continuous function independent of $\mathcal{P}$.

In an abstract sense the set $\{\theta_\mathcal{T} : \mathcal{T} \in \mathfrak{T}_\mathcal{P}\}$ provides a measure of the shape regularity of the partition $\mathcal{P}$ and $\inf_{\mathcal{T}\in\mathfrak{T}_\mathcal{P}} \kappa(\theta_\mathcal{T})$ is a constant depending on the shape regularity of $\mathcal{P}$.

On the other hand, we can also describe the shape regularity of $\mathcal{P}$ more concretely in terms of the shape regularity of individual subdomains and the relative positions of subdomains sharing a common edge of $\mathcal{P}$.

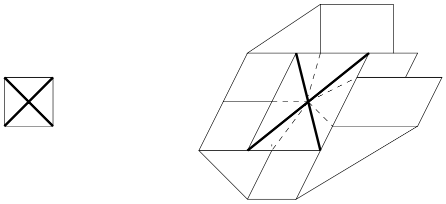

FIG. 6.2. *An example of the construction of* $\mathfrak{T}_{\mathcal{P}_i}$.

The shape regularity of a polygonal (or polyhedral) domain D can be measured by using an affine homeomorphism between D and a reference domain, and by using the aspect ratio of D defined by the quotient (diameter of D)/(diameter of the largest disc (or ball) in $\bar{D}$).

We will use the quantity

$$\rho(\mathcal{P}) = \max\{|\partial D|/|\sigma| : \sigma \in S(\mathcal{P},\Omega),\ D \in \mathcal{P} \text{ and } \sigma \subset \partial D\} \tag{6.3}$$

to measure the relative positions between subdomains sharing a common edge of $\mathcal{P}$.

We can now formulate and prove the following corollary, which gives an application of Theorem 6.2 to a fairly general class of two-dimensional partitions.

COROLLARY 6.3. *Let* Φ *be as in Remark* 5.2, *and let* $\{\mathcal{P}_i : i \in I\}$ *be a family of partitions of* Ω. *Suppose that the polygons appearing in all the partitions* $\mathcal{P}_i$ *are affine homeomorphic to a fixed finite set of reference polygons and the aspect ratios of the polygons in all the* $\mathcal{P}_i$*'s are uniformly bounded. Assume also that the set* $\{\rho(\mathcal{P}_i) : i \in I\}$ *is bounded. Then there exists a positive constant* C, *independent of* $i \in I$, *such that*

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P}_i)} + \sum_{\sigma\in S(\mathcal{P}_i,\Omega)} |\sigma|^{-2}\left(\int_\sigma [\zeta]\,ds\right)^2 + [\Phi(\zeta)]^2\right] \tag{6.4}$$

for any $\zeta \in H^1(\Omega,\mathcal{P}_i)$ *and* $i \in I$.

Proof. First we impose on each reference polygon a triangulation by triangles such that each edge of the polygon is also the edge of a triangle in the triangulation and each triangle of the triangulation has at most one edge on the boundary of the polygon.

Let $D \in \mathcal{P}_i$. We can induce a triangulation $\mathcal{T}_D$ on D using the triangulation on a reference polygon and the corresponding affine homeomorphism. Let $p \in \partial D$ be a vertex of $\mathcal{P}$ but not a vertex of D. Then p belongs to an edge of D which is a side of a triangle $T \in \mathcal{T}_D$, and we connect p to the vertex of T not on ∂D by a straight line (cf. Figure 6.2 where the construction is carried out for a square reference domain and a subdomain D which is a parallelogram). In this way we have created a triangulation $\mathcal{T}_i \in \mathfrak{T}_{\mathcal{P}_i}$.

Let $\hat{D}$ be the reference polygon affine homeomorphic to D, and let $\hat{x} \mapsto \alpha(\hat{x}) = B\hat{x}+b$ be the corresponding affine map from $\hat{D}$ to D. The uniform boundedness of the aspect ratios implies (cf. Theorem 3.1.3 in [13]) the existence of a positive constant C_*, independent of $i \in I$, such that

$$\|B\| \le C_*(\operatorname{diam} D) \text{ and } \|B^{-1}\| \le C_*(\operatorname{diam} D)^{-1}, \tag{6.5}$$

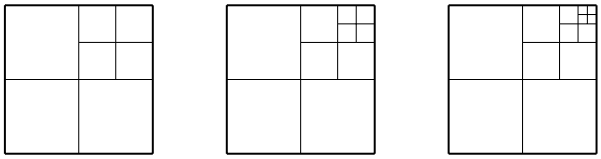

FIG. 6.3. *A family of partitions of a square.*

where $\|\cdot\|$ is the matrix 2-norm induced by the Euclidean vector norm. Hence we have

$$C_*^{-2}\frac{|\hat{x}_1-\hat{x}_2|}{|\hat{x}_3-\hat{x}_4|}\le\frac{|x_1-x_2|}{|x_3-x_4|}\le C_*^2\frac{|\hat{x}_1-\hat{x}_2|}{|\hat{x}_3-\hat{x}_4|}, \tag{6.6}$$

where $x_j=\alpha(\hat{x}_j)$, and $\hat{x}_1,\hat{x}_2,\hat{x}_3,\hat{x}_3$ are any four points such that $\hat{x}_1\neq\hat{x}_2$ and $\hat{x}_3\neq\hat{x}_4$.

We conclude from (6.6) and the boundedness of the set $\{\rho(\mathcal{P}_i): i\in I\}$ that $\theta_{\mathcal{T}_i}$ is bounded away from zero. The estimate (6.4) then follows from (6.2) if we take C to be an upper bound of the bounded set $\{\kappa(\theta_{\mathcal{T}_i}): i\in I\}$. □

Remark 6.4. If the family of partitions $\{\mathcal{P}_i: i\in I\}$ in Corollary 6.3 is actually a family of triangulations, then the condition on the boundedness of $\{\rho(\mathcal{P}_i): i\in I\}$ is redundant.

An example of a family of partitions satisfying the assumptions of Corollary 6.3 is depicted in Figure 6.3, where the partition of the square in Figure 1.1 is being refined successively towards the upper right corner.

7. Poincaré–Friedrichs inequalities for $H^1(\Omega,\mathcal{P})$ on three-dimensional domains. We first give the precise definition of interior faces for a partition $\mathcal{P}$. We define an edge of $\mathcal{P}$ to be an edge of any of the subdomains in $\mathcal{P}$. We then define an open face of $\mathcal{P}$ to be an open subset of the boundary of a member of $\mathcal{P}$ enclosed by edges of $\mathcal{P}$. The set $S(\mathcal{P},\Omega)$ contains the open faces of $\mathcal{P}$ that are common to the boundaries of two members of $\mathcal{P}$.

Remark 7.1. Again the concept of a face of a polyhedron $D\in\mathcal{P}$ and the concept of a face of $\mathcal{P}$ on ∂D should be distinguished. For example, there are always six faces on a parallelepiped, while there are nine faces of the three-dimensional partition in Figure 1.1 on the boundary of the subdomain in the back.

The situation here is more complicated than the two-dimensional case discussed in section 6, since the faces in $S(\mathcal{P},\Omega)$ may not be triangles. Accordingly, we introduce the set

$$\begin{aligned}\mathfrak{T}_{\mathcal{P}}=\{\mathcal{T}:\ &\mathcal{T}\text{ is a triangulation of }\Omega\text{ by tetrahedra such that each face in}\\ &S(\mathcal{P},\Omega)\text{ is triangulated by the (triangular) faces in }S(\mathcal{T},\Omega)\}.\end{aligned} \tag{7.1}$$

Since a face in $S(\mathcal{P},\Omega)$ may not be a face in $S(\mathcal{T},\Omega)$, we cannot immediately obtain an analogue of Theorem 6.2. In order to apply Theorem 5.1 to derive a generalized Poincaré–Friedrichs inequality for $H^1(\Omega,\mathcal{P})$, we need to introduce two more parameters related to the shape regularity of $\mathcal{P}$ besides the parameter $\rho(\mathcal{P})$ defined by (6.3).

Let $\mathcal{T}\in\mathfrak{T}_{\mathcal{P}}$. For $\sigma\in S(\mathcal{P},\Omega)$ we will denote by $\mathcal{T}_\sigma$ the triangulation of σ by faces of $S(\mathcal{T},\Omega)$, i.e.,

$$\mathcal{T}_\sigma=\{\tilde{\sigma}\in S(\mathcal{T},\Omega):\tilde{\sigma}\subseteq\sigma\},$$

and define the parameter

$$\rho(\mathcal{P},\mathcal{T}) = \max\{|\sigma|/|\tilde{\sigma}| : \sigma \in S(\mathcal{P},\Omega) \text{ and } \tilde{\sigma} \in \mathcal{T}_\sigma\}\,. \tag{7.2}$$

Note that we have the following obvious bound for $|\mathcal{T}_\sigma|$ (the number of elements in $\mathcal{T}_\sigma$):

$$|\mathcal{T}_\sigma| \le \rho(\mathcal{P},\mathcal{T}) \qquad \forall\, \sigma \in S(\mathcal{P},\Omega)\,. \tag{7.3}$$

Moreover, (6.3) and (7.2) imply that

$$\frac{|\partial D|}{|\tilde{\sigma}|} \le \rho(\mathcal{P})\rho(\mathcal{P},\mathcal{T}) \qquad \text{for} \quad D \in \mathcal{P},\ \tilde{\sigma} \in \mathcal{T}_\sigma \ \text{ and } \ \sigma \subset \partial D\,. \tag{7.4}$$

The other parameter is the smallest number $\lambda(\mathcal{P}) \ge 1$ with the property that

$$\left(\frac{1}{|\mathcal{F}|}\int_{\mathcal{F}} |\zeta - \bar{\zeta}|\, ds\right)^2 \le \frac{\lambda(\mathcal{P})}{\operatorname{diam} D} |\zeta|^2_{H^1(D)}, \tag{7.5}$$

where D is any member of $\mathcal{P}$, $\mathcal{F}$ is any face of D, ζ is any function in $H^1(D)$, and $\bar{\zeta} = |D|^{-1}\int_D \zeta\, dx$ is the mean of ζ over D. The existence of $\lambda(\mathcal{P})$ is a consequence of the trace theorem, the classical Poincaré–Friedrichs inequalities, and scaling.

Note that (7.5) implies

$$\left(\frac{1}{|G|}\int_{G} |\zeta - \bar{\zeta}|\, ds\right)^2 \le \left(\frac{1}{|G|}\int_{\mathcal{F}} |\zeta - \bar{\zeta}|\, ds\right)^2 \le \left(\frac{|\mathcal{F}|}{|G|}\right)^2 \frac{\lambda(\mathcal{P})}{\operatorname{diam} D} |\zeta|^2_{H^1(D)}, \tag{7.6}$$

where G is any measurable subset of $\mathcal{F}$ with a positive $(d-1)$-dimensional measure.

Theorem 7.2. *Let Φ be as in Remark 5.2. Then we have*

$$\begin{aligned} \|\zeta\|^2_{L_2(\Omega)} \le &\left[\inf_{\mathcal{T}\in\mathfrak{T}_\mathcal{P}} K\big(\rho(\mathcal{P}),\lambda(\mathcal{P}),\rho(\mathcal{P},\mathcal{T}),\theta_\mathcal{T}\big)\right] \\ &\times \left[|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{\sigma\in S(\mathcal{P},\Omega)} |\sigma|^{-\frac{3}{2}} \left(\int_\sigma [\zeta]\, ds\right)^2 + [\Phi(\zeta)]^2\right] \end{aligned} \tag{7.7}$$

for all $\zeta \in H^1(\Omega,\mathcal{P})$, where $K : \mathbb{R}^4_+ \longrightarrow \mathbb{R}_+$ is a continuous function independent of $\mathcal{P}$.

Proof. Since definition (7.1) implies that $H^1(\Omega,\mathcal{P})$ is a subspace of $H^1(\Omega,\mathcal{T})$ for any $\mathcal{T} \in \mathfrak{T}_\mathcal{P}$, we deduce from Theorem 5.1 the estimate

$$\begin{aligned} \|\zeta\|^2_{L_2(\Omega)} \le \kappa(\theta_\mathcal{T}) \Bigg[|\zeta|^2_{H^1(\Omega,\mathcal{P})} &+ \sum_{\sigma\in S(\mathcal{P},\Omega)} \sum_{\tilde{\sigma}\in\mathcal{T}_\sigma} |\tilde{\sigma}|^{1/2} \left(\frac{1}{|\tilde{\sigma}|}\int_{\tilde{\sigma}} [\zeta]\, ds\right)^2 \\ &+ [\Phi(\zeta)]^2 \Bigg] \end{aligned} \tag{7.8}$$

for any $\zeta \in H^1(\Omega,\mathcal{P})$ and $\mathcal{T} \in \mathfrak{T}_\mathcal{P}$, where $\kappa : \mathbb{R}_+ \longrightarrow \mathbb{R}_+$ is a continuous function.

Let $\sigma \in S(\mathcal{P},\Omega)$. Since $\mathcal{T}_\sigma$ is a triangulation of σ, it follows from the Cauchy–Schwarz inequality and (7.3) that

$$\sum_{\tilde{\sigma}\in\mathcal{T}_\sigma} |\tilde{\sigma}|^{1/2} \le |\mathcal{T}_\sigma|^{1/2} \left(\sum_{\tilde{\sigma}\in\mathcal{T}_\sigma} |\tilde{\sigma}|\right)^{1/2} \le [\rho(\mathcal{P},\mathcal{T})]^{1/2} |\sigma|^{1/2}\,. \tag{7.9}$$

Let $\mathcal{P}_\sigma$ be the set of the two polyhedra in $\mathcal{P}$ which share σ as a common face. Then we have, by the Cauchy–Schwarz inequality,

$$\left(\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}[\zeta]\,ds\right)^2 \le 3\left(\frac{1}{|\sigma|}\int_{\sigma}[\zeta]\,ds\right)^2 + 3\sum_{D\in\mathcal{P}_\sigma}\left(\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}\zeta_{_D}\,ds - \frac{1}{|\sigma|}\int_{\sigma}\zeta_{_D}\,ds\right)^2 \tag{7.10}$$

for any $\zeta\in H^1(\Omega,\mathcal{P})$.

From (6.3), (7.4), and (7.6) we have

$$\begin{aligned}&\left(\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}\zeta_{_D}\,ds - \frac{1}{|\sigma|}\int_{\sigma}\zeta_{_D}\,ds\right)^2\\ &\quad= \left(\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}(\zeta_{_D}-\bar\zeta_{_D})\,ds - \frac{1}{|\sigma|}\int_{\sigma}(\zeta_{_D}-\bar\zeta_{_D})\,ds\right)^2\\ &\quad\le 2\left[\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}|\zeta_{_D}-\bar\zeta_{_D}|\,ds\right]^2 + 2\left[\frac{1}{|\sigma|}\int_{\sigma}|\zeta_{_D}-\bar\zeta_{_D}|\,ds\right]^2\\ &\quad\le 2[\rho(\mathcal{P})]^2\big([\rho(\mathcal{P},\mathcal{T})]^2+1\big)\frac{\lambda(\mathcal{P})}{\operatorname{diam} D}|\zeta|^2_{H^1(D)}\end{aligned} \tag{7.11}$$

for $D\in\mathcal{P}_\sigma$, where $\bar\zeta_{_D} = |D|^{-1}\int_D \zeta\,dx$ is the mean of ζ over D.

Combining (7.9)–(7.11), we obtain

$$\begin{aligned}\sum_{\tilde\sigma\in\mathcal{T}_\sigma}|\tilde\sigma|^{1/2}\left(\frac{1}{|\tilde\sigma|}\int_{\tilde\sigma}[\zeta]\,ds\right)^2 &\le 3[\rho(\mathcal{P},\mathcal{T})]^{1/2}|\sigma|^{-(3/2)}\left(\int_\sigma[\zeta]\,ds\right)^2\\ &\quad+ 6[\rho(\mathcal{P},\mathcal{T})]^{1/2}[\rho(\mathcal{P})]^2\big([\rho(\mathcal{P},\mathcal{T})]^2+1\big)\lambda(\mathcal{P})\sum_{D\in\mathcal{P}_\sigma}|\zeta|^2_{H^1(D)},\end{aligned} \tag{7.12}$$

where we have used the fact that $|\sigma|^{1/2} < \operatorname{diam} D$.

Finally, we observe that the number of faces of $S(\mathcal{P},\Omega)$ on the boundary of any subdomain in $\mathcal{P}$ is less than or equal to $\rho(\mathcal{P})$, and hence

$$\sum_{\sigma\in S(\mathcal{P},\Omega)}\sum_{D\in\mathcal{P}_\sigma}|\zeta|^2_{H^1(D)} \le \rho(\mathcal{P})|\zeta|^2_{H^1(\Omega,\mathcal{P})}\,. \tag{7.13}$$

The generalized Poincaré–Friedrichs inequality (7.7) then follows from (7.8), (7.12), and (7.13), with the function K given by, for example,

$$K\big(\rho(\mathcal{P}),\lambda(\mathcal{P}),\rho(\mathcal{P},\mathcal{T}),\theta_{\mathcal{T}}\big) = 13[\rho(\mathcal{P})]^3\lambda(\mathcal{P})[\rho(\mathcal{P},\mathcal{T})]^{5/2}\kappa(\theta_{\mathcal{T}})\,. \qquad \square$$

Again in an abstract sense the set $\big\{\big(\rho(\mathcal{P}),\lambda(\mathcal{P}),\rho(\mathcal{P},\mathcal{T}),\theta_{\mathcal{T}}\big) : \mathcal{T}\in\mathfrak{T}_{\mathcal{P}}\big\}$ provides a measure of the shape regularity of the partition $\mathcal{P}$, and the number

$$\inf_{\mathcal{T}\in\mathfrak{T}_{\mathcal{P}}} K\big(\rho(\mathcal{P}),\lambda(\mathcal{P}),\rho(\mathcal{P},\mathcal{T}),\theta_{\mathcal{T}}\big)$$

is a constant depending on the shape regularity of $\mathcal{P}$. In applications one can use Theorem 7.2 to derive Poincaré–Friedrichs inequalities with a uniform constant for a family of partitions under appropriate concrete shape regularity assumptions. Since the geometry of three-dimensional partitions can be much more varied than that of two-dimensional ones, here we are content with giving only an analogue of Corollary 6.3 for partitions by *convex* polyhedra.

Note that a face of a partition of Ω by convex polyhedra is a convex polygon, and therefore it can be triangulated by connecting the center to the vertices by straight lines. Such a triangulation will be referred to as the *canonical triangulation* of the convex polygon.

COROLLARY 7.3. *Let Φ be as in Remark* 5.2, *and let $\{\mathcal{P}_i : i \in I\}$ be a family of partitions of Ω. Assume that the following conditions are satisfied:*

(i) *The polyhedra appearing in all the partitions $\mathcal{P}_i$ are affine homeomorphic to a fixed finite set of convex reference polyhedra and the aspect ratios of the polyhedra in all the $\mathcal{P}_i$'s are uniformly bounded.*

(ii) *The set $\{\rho(\mathcal{P}_i) : i \in I\}$ is bounded.*

(iii) *The angles of the triangles in the canonical triangulations of the faces of all the partitions $\mathcal{P}_i$ are bounded below by a positive constant.*

Then there exists a positive constant C, independent of $i \in I$, such that

$$\|\zeta\|^2_{L_2(\Omega)} \le C\left[|\zeta|^2_{H^1(\Omega,\mathcal{P}_i)} + \sum_{\sigma\in S(\mathcal{P}_i,\Omega)} |\sigma|^{-\frac{3}{2}}\left(\int_\sigma [\zeta]\,ds\right)^2 + [\Phi(\zeta)]^2\right] \tag{7.14}$$

for any $\zeta \in H^1(\Omega,\mathcal{P}_i)$ and $i \in I$.

Proof. Let $D \in \mathcal{P}_i$, $\hat{D}$ be a reference polyhedron affine homeomorphic to D, and let $\alpha(\hat{x}) = B\hat{x} + b$ be the corresponding affine map from $\hat{D}$ to D. Then the estimates (6.5) and (6.6) again follow from condition (i).

Let $\hat{\mathcal{F}}$ be a face of $\hat{D}$ corresponding to a face $\mathcal{F}$ of D. From the Poincaré–Friedrichs inequalities for $\hat{D}$ and the trace theorem, we have

$$\left(\frac{1}{|\hat{\mathcal{F}}|}\int_{\hat{\mathcal{F}}} |\hat{\zeta} - \bar{\hat{\zeta}}|\,d\hat{s}\right)^2 \le \lambda(\hat{D})|\hat{\zeta}|^2_{H^1(\hat{D})} \qquad \forall\,\hat{\zeta} \in H^1(\hat{D}), \tag{7.15}$$

where $\bar{\hat{\zeta}}$ is the mean of $\hat{\zeta}$ over $\hat{D}$ and $\lambda(\hat{D})$ is a positive constant depending only on $\hat{D}$. Combining (6.5) and (7.15) we find

$$\left(\frac{1}{|\mathcal{F}|}\int_{\mathcal{F}} |\zeta - \bar{\zeta}|\,ds\right)^2 = \left(\frac{1}{|\hat{\mathcal{F}}|}\int_{\hat{\mathcal{F}}} |\hat{\zeta} - \bar{\hat{\zeta}}|\,d\hat{s}\right)^2 \le C_\dagger \frac{\lambda(\hat{D})}{\operatorname{diam} D}|\zeta|^2_{H^1(D)} \tag{7.16}$$

for all $\zeta \in H^1(D)$, where $\bar{\zeta}$ is the mean of ζ over D, $\hat{\zeta} = \zeta \circ \alpha$, and $C_\dagger$ is a positive constant independent of $i \in I$. It follows from (7.16) and the finiteness of the number of reference polyhedra that the set

$$\{\lambda(\mathcal{P}_i) : i \in I\} \text{ is bounded.} \tag{7.17}$$

Let $i \in I$. We construct a triangulation $\mathcal{T}_i \in \mathfrak{T}_{\mathcal{P}_i}$ by first imposing the canonical triangulation on each face of $\mathcal{P}_i$ and then triangulating each member of $\mathcal{P}_i$ using its center and the triangles on its faces.

Since the number of edges on each face of $\mathcal{P}_i$ is limited by the number of edges appearing on the faces of the reference polyhedra, condition (iii) implies that the set

$$\{\rho(\mathcal{P}_i, \mathcal{T}_i) : i \in I\} \text{ is bounded.} \tag{7.18}$$

Moreover, it follows from conditions (ii) and (iii) that the triangulation induced by $\mathcal{T}_i$ on the boundary of any subdomain in $\mathcal{P}_i$ is quasi-uniform, which together with (6.6) implies

$$\inf\{\theta_{\mathcal{T}_i} : i \in I\} > 0\,. \tag{7.19}$$

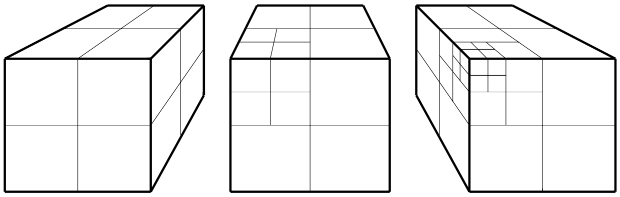

FIG. 7.1. *A family of partitions of a cube.*

Combining condition (ii) and (7.17)–(7.19), we see that the set

$$\{(\rho(\mathcal{P}_i), \lambda(\mathcal{P}_i), \rho(\mathcal{P}_i, \mathcal{T}_i), \theta_{\mathcal{T}_i}) : i \in I\}$$

is a precompact subset of $\mathbb{R}^4_+$. The estimate (7.14) then follows from (7.7) if we take C to be an upper bound of the bounded set

$$\{K(\rho(\mathcal{P}_i), \lambda(\mathcal{P}_i), \rho(\mathcal{P}_i, \mathcal{T}_i), \theta_{\mathcal{T}_i}) : i \in I\}. \qquad \square$$

Remark 7.4. If the family of partitions in Corollary 7.3 is actually a family of triangulations, then conditions (ii) and (iii) are redundant.

An example of a family of partitions satisfying the assumptions of Corollary 7.3 is depicted in Figure 7.1, where a cube is being refined successively towards the upper left corner in the front.

8. Concluding remarks. The approach to Poincaré–Friedrichs inequalities in this paper depends only on the classical Poincaré–Friedrichs inequalities which in turn depend only on the compactness of the embedding of $H^1(\Omega)$ in $L_2(\Omega)$. Since this is valid for any Ω satisfying the cone condition (cf. [1]), the results of this paper are also valid for domains with cracks.

We can, of course, also treat the one-dimensional case where Ω is an interval. In this case we can take the interpolant $\mathcal{I}\zeta \in H^1(\Omega)$ to be the piecewise linear function which takes the average value of ζ at the internal nodes of $\mathcal{P}$ and agrees with ζ at the endpoints. The resulting Poincaré–Friedrichs inequalities for $\zeta \in H^1(\Omega, \mathcal{P})$ are

$$(8.1) \qquad \|\zeta\|^2_{L_2(\Omega)} \le C \left(|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{p\in\mathcal{P}_0} \sum_{e\in\Xi_p} |e|^{-1}[\zeta(p)]^2 + |\zeta(q)|^2 \right),$$

$$(8.2) \qquad \|\zeta\|^2_{L_2(\Omega)} \le C \left(|\zeta|^2_{H^1(\Omega,\mathcal{P})} + \sum_{p\in\mathcal{P}_0} \sum_{e\in\Xi_p} |e|^{-1}[\zeta(p)]^2 + \left|\int_\Omega \zeta\, dx\right|^2 \right),$$

where $\mathcal{P}_0$ is the set of the internal nodes of the partition $\mathcal{P}$, Ξ_p is the set of the two subintervals sharing p as an endpoint, $[\zeta(p)]$ is the jump of ζ across the point p, q is an endpoint of Ω, and C is a universal positive constant.

Let $\Omega = (0, 1)$, $\mathcal{P}_n$ be the uniform partition of Ω by n subintervals, and let ζ_n be the piecewise constant function defined by

$$(8.3) \qquad \zeta_n(x) = i \qquad \text{for} \quad \frac{i}{n} < x < \frac{i+1}{n} \ \text{ and } \ 0 \le i \le n-1.$$

Then $\zeta_n \in H^1(\Omega, \mathcal{P}_n)$ and $\zeta_n(0) = |\zeta_n|_{H^1(\Omega,\mathcal{P}_n)} = 0$. A straightforward calculation shows that both sides of (8.1) (with $q = 0$) grow at the rate of n^2 for the function ζ_n, and hence the weight $|e|^{-1}$ in (8.1) cannot be improved. If we define

$$\zeta_n(x) = -\frac{n-1}{2} + i \qquad \text{for} \quad \frac{i}{n} < x < \frac{i+1}{n} \ \text{ and } \ 0 \le i \le n-1, \tag{8.4}$$

then $\int_\Omega \zeta_n dx = |\zeta_n|_{H^1(\Omega,\mathcal{P}_n)} = 0$. Again both sides of (8.2) grow at the rate of n^2 for the function ζ_n, which shows that the weight $|e|^{-1}$ in (8.2) also cannot be improved.

Similarly, we can show that the weight $|\sigma|^{d/(1-d)}$ in (1.3) and (1.4) is sharp. Indeed, let Ω be the unit square $(0,1)^2$ and $\mathcal{P}_n$ be the uniform partition of Ω by n^2 squares. Consider the piecewise constant function (an analogue of the function in (8.3)) defined by

$$\zeta_n(x_1,x_2) = i \qquad \text{for} \quad \frac{i}{n} < x_1 < \frac{i+1}{n},\ \frac{j}{n} < x_2 < \frac{j+1}{n}, \ \text{ and } \ 0 \le i,j \le n-1.$$

We have $\zeta_n \in H^1(\Omega,\mathcal{P}_n)$ and $|\zeta_n|_{H^1(\Omega,\mathcal{P}_n)} = \zeta_n\big|_\Gamma = 0$, where Γ is the side $\{(0,t) : 0 < t < 1\}$. Again both sides of (1.3) grow at the rate of n^2 for ζ_n, and hence the weight $|\sigma|^{-2}$ cannot be improved. The sharpness of $|\sigma|^{-2}$ in (1.4) is established by constructing piecewise constant functions analogous to the ones defined by (8.4), and the sharpness of the weight $|\sigma|^{-3/2}$ for three-dimensional domains can be handled by similar constructions.

Finally, we remark that the techniques of this paper can also be used to derive Poincaré–Friedrichs inequalities for piecewise W_p^1 functions and $p \neq 2$.

ORDERED UPWIND METHODS FOR STATIC HAMILTON–JACOBI EQUATIONS: THEORY AND ALGORITHMS*

JAMES A. SETHIAN† and ALEXANDER VLADIMIRSKY‡

Abstract. We develop a family of fast methods for approximating the solutions to a wide class of static Hamilton–Jacobi PDEs; these fast methods include both semi-Lagrangian and fully Eulerian versions. Numerical solutions to these problems are typically obtained by solving large systems of coupled nonlinear discretized equations. Our techniques, which we refer to as "Ordered Upwind Methods" (OUMs), use partial information about the characteristic directions to decouple these nonlinear systems, greatly reducing the computational labor. Our techniques are considered in the context of control-theoretic and front-propagation problems.

We begin by discussing existing OUMs, focusing on those designed for isotropic problems. We then introduce a new class of OUMs which decouple systems for general (anisotropic) problems. We prove convergence of one such scheme to the viscosity solution of the corresponding Hamilton–Jacobi PDE. Next, we introduce a set of finite-differences methods based on an analysis of the role played by anisotropy in the context of front propagation and optimal trajectory problems.

The performance of the methods is analyzed, and computational experiments are performed using test problems from computational geometry and seismology.

Key words. ordered upwind methods, fast marching methods, Dijkstra-like methods, anisotropic optimal control, dynamic programming, viscosity solution, anisotropic front propagation

1. Introduction.

In this paper we present a family of noniterative methods applicable to the boundary value problem for static Hamilton–Jacobi equations of the form[1]

$$(1)\qquad \begin{array}{lcll} H(\nabla u, \boldsymbol{x}) & = & 1, & \boldsymbol{x} \in \Omega \subset R^2, \\ u(\boldsymbol{x}) & = & q(\boldsymbol{x}), & \boldsymbol{x} \in \partial\Omega, \end{array}$$

where the Hamiltonian H is assumed to be Lipschitz-continuous, convex, and homogeneous of degree 1 in the first argument:

$$(2)\qquad H(\nabla u, \boldsymbol{x}) = \|\nabla u\| F\left(\boldsymbol{x}, \frac{\nabla u}{\|\nabla u\|}\right)$$

for some function F. We will further assume that the function q is also Lipschitz-continuous, and that

$$0 < F_1 \le F(\boldsymbol{x}, \boldsymbol{p}) \le F_2,$$
$$q_1 \le q(\boldsymbol{x}) \le q_2$$

[1] For the sake of notational clarity we restrict our discussion to R^2; all results can be restated for R^n and for meshes on manifolds.

for all $\boldsymbol{x} \in \Omega$ and for all the vectors of unit length $\boldsymbol{p}$.

Even for arbitrarily smooth H, q, and $\partial\Omega$, a smooth solution on Ω need not exist. In general, there are infinitely many weak Lipschitz-continuous solutions, but the unique *viscosity solution* can be defined using additional conditions on the smooth test functions (see [10, 9]).

To obtain a numerical solution, one often starts with a mesh X covering the domain Ω. Let $U_i = U(\boldsymbol{x_i})$ be the numerical solution at the mesh point $\boldsymbol{x_i} \in X$. Denote the set of mesh points adjacent to $\boldsymbol{x_i}$ as $N(\boldsymbol{x_i})$ and the set of values adjacent to U_i as $NU(\boldsymbol{x_i}) = \{U_j | \boldsymbol{x_j} \in N(\boldsymbol{x_i})\}$. Let $\overline{H}$ be a consistent discretization of H such that one can write

$$\overline{H}(U_i, NU(\boldsymbol{x_i}), \boldsymbol{x_i}) = 1. \tag{3}$$

If M is the total number of mesh points, then one needs to solve M coupled nonlinear equations simultaneously. One typical approach is to solve this nonlinear system iteratively.

Our ultimate goal is to introduce a set of "single-pass" numerical methods. By this, we mean that each U_i is recalculated at most r times, where r depends only upon the PDE (1) and the mesh structure and not upon the number of mesh points.

To construct single-pass algorithms with efficient update orderings, one can utilize the fact that the value of $u(\boldsymbol{x})$ for the first-order PDE depends only on the value of u along the characteristic(s) passing through the point $\boldsymbol{x}$. If $\boldsymbol{x_{i_1}}, \boldsymbol{x_{i_2}} \in N(\boldsymbol{x_i})$ are such that the characteristic for the mesh point $\boldsymbol{x_i}$ lies in the simplex $\boldsymbol{x_i x_{i_1} x_{i_2}}$, then it is useful to consider an *upwind* discretization of the PDE:

$$\overline{H}(U_i, U_{i_1}, U_{i_2}, \boldsymbol{x_i}) = 1. \tag{4}$$

This reduces the coupling in the system: U_i *depends* only upon U_{i_1} and U_{i_2} and not on all of the $NU(\boldsymbol{x_i})$. A recursive construction allows one to build the entire *dependency graph* for $\boldsymbol{x_i}$.

If two or more characteristics collide at the point $\boldsymbol{x}$, the solution loses smoothness. The entropy condition does not allow characteristics to be created at these collision points; hence, if $\boldsymbol{x_i}$ is far enough from these collision points, then, for a suitably chosen discretization, its dependency graph is actually a tree. If the characteristic directions of the PDE were known in advance, then the dependency-ordering of the grid points would be known as well, leading to a fully decoupled system. Formally, this construction would lead to an $O(M)$ method.

In general, characteristic directions are not known in advance due to the nonlinearity of (1). Nonetheless, single-pass methods can be devised to determine the mesh point ordering (and the characteristic directions) in the process of decoupling the system. We refer to such methods as "Ordered Upwind Methods" (OUMs) and show that they have computational complexity of $O(M \log M)$.

Since (1) can be interpreted as a description of a continuous control problem, we start in section 2 by viewing the discrete control problem and by considering Dijkstra's method as a prototype for the OUMs to be built for the continuous case.

Next, in section 3, we view the Hamilton–Jacobi PDE (1) as an anisotropic min-time optimal trajectory problem. In this control-theoretic setting, the speed of a vehicle's motion depends not only on its position, but also on the direction. The corresponding value function u is the viscosity solution of the static Hamilton–Jacobi–

Bellman equation

$$\begin{aligned} &\max_{\boldsymbol{a}\in S_1}\{(\nabla u(\boldsymbol{x})\cdot(-\boldsymbol{a}))f(\boldsymbol{x},\boldsymbol{a})\}=1, \quad && \boldsymbol{x}\in\Omega,\\ &u(\boldsymbol{x})=q(\boldsymbol{x}), && \boldsymbol{x}\in\partial\Omega. \end{aligned} \tag{5}$$

Here, $\boldsymbol{a}$ is the unit vector determining the direction of motion, $f(\boldsymbol{x},\boldsymbol{a})$ is the speed of motion in the direction $\boldsymbol{a}$ starting from the point $\boldsymbol{x}\in\Omega$, and $q(\boldsymbol{x})$ is the time-penalty for exiting the domain at the point $\boldsymbol{x}\in\partial\Omega$. The maximizer $\boldsymbol{a}$ corresponds to the characteristic direction for the point $\boldsymbol{x}$.

If the speed functions F and f depend only upon their first argument, both forms of the Hamilton–Jacobi PDE reduce to the Eikonal equation

$$\|\nabla u(\boldsymbol{x})\| = K(\boldsymbol{x}), \tag{6}$$

where $K(\boldsymbol{x})=\frac{1}{F(\boldsymbol{x})}=\frac{1}{f(\boldsymbol{x})}$. In this case, the characteristics of the PDE coincide with the gradient lines of its viscosity solution u. This property is the foundation for two single-pass methods for the Eikonal equation: Tsitsiklis' algorithm (1994) and Sethian's Fast Marching Method (1996), representing Dijkstra-like decoupling of a semi-Lagrangian and a fully Eulerian discretization of (1), respectively (section 4).

We then proceed to the central part of this paper. First, we show (in section 5) that neither of these single-pass Eikonal solvers can be directly applied in the general anisotropic case. Nonetheless, the underlying ideas can be used to build the OUMs which are applicable for much more general equations. Such methods hinge on two properties of the unique viscosity solution:

1. The viscosity solution $u(\boldsymbol{x})$ is strictly increasing along the characteristics of the PDE (1).
2. We can derive a precise upper bound on the maximum angle between the characteristic and the gradient of u.

In section 6, we introduce the first general OUM with computational complexity of $O(\frac{F_2}{F_1}M\log M)$ based on a semi-Lagrangian discretization; an announcement of this algorithm without details or proof was first made in [39]. The method's convergence to the viscosity solution is proven in section 7.

Next, in section 8, we reinterpret the Hamilton–Jacobi PDE (1), this time as describing an anisotropic front expansion (contraction) problem. In this context, $F(\boldsymbol{x},\boldsymbol{n})$ is interpreted as the speed of the front in the normal direction $\boldsymbol{n}$, and $\partial\Omega$ as the initial position of the front.

$$\begin{aligned} &\|\nabla u\|F\left(\boldsymbol{x},\tfrac{\nabla u}{\|\nabla u\|}\right)=1, \quad && \boldsymbol{x}\in\Omega,\\ &u(\boldsymbol{x})=0, && \boldsymbol{x}\in\partial\Omega. \end{aligned}$$

The anisotropy is the result of the dependence of F on $\boldsymbol{n}$. The level sets of the viscosity solution u correspond to the positions of the front at different times. We consider only those front expansion (contraction) problems in which the speed F is such that the Hamiltonian H is convex.

The fully Eulerian OUMs, introduced in section 8, use the finite-difference approximations developed as a generalization of the Fast Marching Method and are based on the analysis of the role played by anisotropy in the front propagation and optimal trajectory problems. These single-pass methods also have the same computational complexity of $O(\frac{F_2}{F_1}M\log M)$. The appendix examines the relationship between the first-order semi-Lagrangian and Eulerian OUMs.

Finally, in section 9, we analyze the efficiency of the new methods and consider several anisotropic test problems from computational geometry and seismology.

2. Dijkstra's method and discrete optimal trajectories. We begin by considering the problem of computing the shortest path on a network. (See, for example, [3] for a catalogue of available algorithms.) Computing the shortest path can be viewed as a discrete dynamic programming problem. Here, it serves as a simpler analogue for the continuous optimal trajectory problem considered in the next section.

For the case in which the network is sparsely connected and all arc-costs are positive, the heap-sort version of Dijkstra's method [12] is one of the most widely used algorithms. We will now reinterpret Dijkstra's method as a single-pass OUM since it serves as a model for building the OUMs for the continuous front propagation and optimal trajectory problems.

2.1. Shortest paths and value function. Consider a discrete network of nodes $X = \{\boldsymbol{x_1}, \dots, \boldsymbol{x_M}\}$. A vehicle starts somewhere in the network and travels from node to node until it reaches one of the *exit nodes* $\boldsymbol{x} \in Q \subset X$. A vehicle's trajectory is a sequence of nodes $(\boldsymbol{y_1}, \dots, \boldsymbol{y_r})$ such that $\boldsymbol{y_r} \in Q$ and $\boldsymbol{y_k} \notin Q$ for $k < r$. There is a *time-penalty* $K(\boldsymbol{x_i}, \boldsymbol{x_j}) = K_{ij} > 0$ for passing from $\boldsymbol{x_i}$ to $\boldsymbol{x_j}$. ($K_{ij} = +\infty$ if there is no link from $\boldsymbol{x_i}$ to $\boldsymbol{x_j}$.) For all $\boldsymbol{x} \in Q$ there is an *exit time-penalty* $q(\boldsymbol{x}) < \infty$. Thus, the total time needed for a trajectory $(\boldsymbol{y_1}, \dots, \boldsymbol{y_r})$ is

$$\text{TotalTime}(\boldsymbol{y_1}, \dots, \boldsymbol{y_r}) = \sum_{j=1}^{r} K(\boldsymbol{y_j}, \boldsymbol{y_{j+1}}) + q(\boldsymbol{y_r}). \tag{7}$$

The goal is to find the optimal trajectory for each node $\boldsymbol{x} \in X \backslash Q$.

The key idea of *dynamic programming* [5, 6] is to solve for all of the nodes at once. Instead of searching for a particular optimal trajectory, one derives an equation for the *value function* $U(\boldsymbol{x})$, defined as the minimum time to exit the network if one starts at $\boldsymbol{x}$:

$$\begin{cases} U(\boldsymbol{x}) = \min\limits_{\substack{\text{all the paths} \\ \text{starting at } \boldsymbol{x}}} \text{TotalTime}(\boldsymbol{x}, \dots), & \boldsymbol{x} \in X \backslash Q, \\ U(\boldsymbol{x}) = q(\boldsymbol{x}), & \boldsymbol{x} \in Q. \end{cases} \tag{8}$$

Bellman's optimality principle [5] shows the relationship between $U(\boldsymbol{x})$ and the values of U on the set of adjacent nodes $N(\boldsymbol{x}) = \{\boldsymbol{y} \in X \mid K(\boldsymbol{x}, \boldsymbol{y}) < \infty\}$, namely,

$$U(\boldsymbol{x}) = \min_{\boldsymbol{y} \in N(\boldsymbol{x})} \{K(\boldsymbol{x}, \boldsymbol{y}) + U(\boldsymbol{y})\} \quad \text{for all } \boldsymbol{x} \in X \backslash Q. \tag{9}$$

Equation (9) is nonlinear, and it has to hold for each node in $X \backslash Q$. Thus, if there are M such nodes, we have to solve a coupled system of M nonlinear equations.

2.2. Dijkstra's method. Dijkstra's method [12] provides a way of decoupling system (9) and is based on the following monotonicity observations.

OBSERVATION 2.1. *If* $(\boldsymbol{y_1}, \dots, \boldsymbol{y_r})$ *is an optimal trajectory for* $\boldsymbol{y_1}$, *then we have* $U(\boldsymbol{y_1}) > \dots > U(\boldsymbol{y_r})$.

OBSERVATION 2.2. *If* $N_-(\boldsymbol{x}) = \{\boldsymbol{y} \in N(\boldsymbol{x}) \mid U(\boldsymbol{y}) < U(\boldsymbol{x})\}$, *then Bellman's equation* (9) *can be rewritten as*

$$U(\boldsymbol{x}) = \min_{\boldsymbol{y} \in N_-(\boldsymbol{x})} \{K(\boldsymbol{x}, \boldsymbol{y}) + U(\boldsymbol{y})\} \quad \textit{for all } \boldsymbol{x} \in X \backslash Q. \tag{10}$$

If the nodes were somehow sorted by the value of U, one could solve equations (10) one by one, yielding a method with an overall complexity of $O(M)$. Even though this ordering on X is not known in advance, Dijkstra's method reconstructs it (one node at a time) as follows.

All the nodes are divided into three classes: *Far* (no information about the correct value of U is known), *Accepted* (the correct value of U has been computed), and *Considered* (adjacent to *Accepted*). For every *Considered* $\boldsymbol{x}$ we define the set $\mathrm{NF}(\boldsymbol{x}) = \{\boldsymbol{y} \in N(\boldsymbol{x}) \,|\boldsymbol{y} \text{ is } \textit{Accepted}\}$.

1. Start with all the nodes in *Far*.
2. Move the exit nodes ($\boldsymbol{y} \in Q$) to *Accepted* ($U(\boldsymbol{y}) = q(\boldsymbol{y})$).
3. Move all the nodes $\boldsymbol{x}$ adjacent to the boundary into *Considered* and evaluate the tentative values

$$V(\boldsymbol{x}) := \min_{\boldsymbol{y} \in \mathrm{NF}(\boldsymbol{x})} \{K(\boldsymbol{x},\boldsymbol{y}) + U(\boldsymbol{y})\}\,. \tag{11}$$

4. Find the node $\bar{\boldsymbol{x}}$ with the smallest value of V among all the *Considered*.
5. Move $\bar{\boldsymbol{x}}$ to *Accepted* ($U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}})$).
6. Move the *Far* nodes adjacent to $\bar{\boldsymbol{x}}$ into *Considered*.
7. Reevaluate V for all the *Considered* $\boldsymbol{x}$ adjacent to $\bar{\boldsymbol{x}}$

$$V(\boldsymbol{x}) := \min\{V(\boldsymbol{x}), K(\boldsymbol{x},\bar{\boldsymbol{x}}) + U(\bar{\boldsymbol{x}})\}\,. \tag{12}$$

8. If *Considered* is not empty, then go to 4.

The described algorithm has the computational complexity of $O(M\log(M))$; the factor of $\log(M)$ reflects the necessity to maintain a sorted list of the *Considered* values $V(\boldsymbol{x_i})$ to determine the next *Accepted* node.[2]

On a grid-like network, we can reinterpret Dijkstra's method as an upwind finite difference scheme. Consider a uniform Cartesian grid of grid size h, where the time-penalty $K_{ij} > 0$ is given for passing through each grid point $x_{ij} = (ih, jh)$. The minimal total time-to-exit U_{ij} starting from the node $\boldsymbol{x}_{ij}$ can be written in terms of the minimal total time-to-exit starting at its neighbors:

$$U_{ij} = \min\left(U_{i-1,j}, U_{i+1,j}, U_{i,j-1}, U_{i,j+1}\right) + K_{ij}. \tag{13}$$

As pointed out by Sethian in [36], the U_{ij} obtained through Dijkstra's method is formally a first-order approximation to the solution $u(x,y)$ of the differential equation

$$H(\nabla u(\boldsymbol{x}), u(\boldsymbol{x}), \boldsymbol{x}) = \max(|u_x|, |u_y|) = K(\boldsymbol{x}), \tag{14}$$

provided that the time-penalties are $K_{ij} = hK(\boldsymbol{x})$.

3. Continuous optimal trajectory problems and semi-Lagrangian discretization.

3.1. Statement of problem.

Consider an optimal trajectory problem for a vehicle moving inside the domain Ω, with the speed f depending upon the direction of motion and the current position of the vehicle inside the domain. The dynamics of the vehicle is defined by

$$\begin{aligned} \boldsymbol{y}'(t) &= f(\boldsymbol{y}(t), \boldsymbol{a}(t))\boldsymbol{a}(t), \\ \boldsymbol{y}(0) &= \boldsymbol{x} \ \in \Omega, \end{aligned} \tag{15}$$

[2] This variant of Dijkstra's method is often referred to as a *heap-sort Dijkstra's method* since its implementation requires the use of a binary heap, d-heap, or Fibonacci heap to maintain the ordering of the *Considered* nodes efficiently [3].

The complexity estimate for the densely connected network would be $O(M^2\log(M))$, but for our case, when X is a grid or a mesh, the precise complexity estimate is $O(rM\log(M))$, where r is the maximum number of nodes connected to a single node in X.

where $\boldsymbol{y}(t)$ is the position of the vehicle at time t, $S_1 = \{\boldsymbol{a} \in R^2 \mid \|\boldsymbol{a}\| = 1\}$ is the set of *admissible control values*, and $\mathcal{A} = \{\boldsymbol{a} : R_{+,0} \mapsto S_1 \mid \boldsymbol{a}(\cdot) \text{ is measurable}\}$ is the set of *admissible controls*. We are interested in studying $\boldsymbol{y}(t)$ only while the vehicle remains inside Ω, i.e., until the exit time

$$T(\boldsymbol{x}, \boldsymbol{a}(\cdot)) = \inf\{t \in R_{+,0} | \boldsymbol{y}(t) \in \partial\Omega\}.$$

If the function $q(\boldsymbol{x}) \geq 0$ is the *time-penalty* for exiting the domain at the point $\boldsymbol{x} \in \partial\Omega$, then a *min-time* optimal trajectory problem is the task of finding an optimal control $\boldsymbol{a}(\cdot)$ which minimizes the total time:[3]

$$\text{TotalTime}\left(\boldsymbol{x}, \boldsymbol{a}(\cdot)\right) = T\left(\boldsymbol{x}, \boldsymbol{a}(\cdot)\right) + q\left(\boldsymbol{y}\left(T(\boldsymbol{x}, \boldsymbol{a}(\cdot))\right)\right).$$

We will alternatively refer to the above quantity as a *total cost* of using the control: $\text{Cost}\left(\boldsymbol{x}, \boldsymbol{a}(\cdot)\right) = \text{TotalTime}\left(\boldsymbol{x}, \boldsymbol{a}(\cdot)\right)$.

Unless otherwise explicitly specified, we will assume that both f and q are Lipschitz-continuous and that there exist constants f_1, f_2, q_1, q_2 such that

$$\begin{aligned} 0 < f_1 \leq f(\boldsymbol{x}, \boldsymbol{a}) \leq f_2 < \infty \quad & \text{for all } \boldsymbol{x} \in \Omega \text{ and } \boldsymbol{a} \in S_1, \\ 0 < q_1 \leq q(\boldsymbol{x}) \leq q_2 < \infty \quad & \text{for all } \boldsymbol{x} \in \partial\Omega. \end{aligned} \tag{16}$$

For notational convenience, we will also define the *anisotropy coefficient* $\Upsilon = \frac{f_2}{f_1}$. Strictly speaking, since f_1 and f_2 are global bounds, the coefficient Υ reflects the measure of anisotropy only in the homogeneous domain (i.e., when $f(\boldsymbol{x}, \boldsymbol{a}) = f(\boldsymbol{a})$). We will use Υ in deriving the worst-case-scenario computational complexity of the algorithms. In section 9.2, the more accurate *local anisotropy coefficient* $\Upsilon(\boldsymbol{x})$ will be defined and used for a more detailed computational complexity analysis.

As in the discrete case, the key idea of dynamic programming [5] is to define the value function $u(\boldsymbol{x})$ such that

$$\begin{cases} u(\boldsymbol{x}) = \inf_{\boldsymbol{a}(\cdot)} \text{Cost}(\boldsymbol{x}, \boldsymbol{a}(\cdot)), & \boldsymbol{x} \in \Omega \backslash \partial\Omega, \\ u(\boldsymbol{x}) = q(\boldsymbol{x}), & \boldsymbol{x} \in \partial\Omega. \end{cases} \tag{17}$$

In general, an optimal control $\boldsymbol{a}(\cdot)$ does not have to exist; therefore, when proving properties of the value function u, one uses *ϵ-suboptimal controls* $\boldsymbol{a}(\cdot)$ such that $\text{Cost}(\boldsymbol{x}, \boldsymbol{a}(\cdot)) < u(\boldsymbol{x}) + \epsilon$. To simplify the presentation, we will somewhat loosely refer to the optimal controls and trajectories. If such optimal controls do not exist, the corresponding properties can be formulated and proven for the ϵ-suboptimal controls and trajectories.

3.2. Properties of the value function. The following lemmas enumerate several well-known properties of the value function (see proofs in [46], for example). In section 7 we will prove the similar properties of the numerical approximation constructed by the OUM.

LEMMA 3.1 (Fixed-time optimality principle). *Let $d(\boldsymbol{x})$ be the minimum distance to the boundary $\partial\Omega$. Then for every point $\boldsymbol{x} \in \Omega \backslash \partial\Omega$ and for any $\tau < d(\boldsymbol{x})$*

$$u(\boldsymbol{x}) = \tau + \inf_{\boldsymbol{a}(\cdot)} \left\{ u(\boldsymbol{y}(\tau)) \right\}, \tag{18}$$

[3] A different optimal trajectory problem can be formulated for minimizing the total cost of moving the vehicle with a unit speed, when the running cost depends upon both the vehicle's position and the direction of motion; see [45, 15], for example. It is not hard to show the equivalence of this *min-cost* problem to the *min-time* optimal trajectory problem considered here [46].

where $\boldsymbol{y}(\cdot)$ is a trajectory corresponding to a chosen control $\boldsymbol{a}(\cdot)$.

LEMMA 3.2 (Fixed-boundary optimality principle). *Consider a simple closed curve $\Gamma \subset \Omega \backslash \partial\Omega$ and an arbitrary point $\boldsymbol{x}$ inside Γ. For every control $\boldsymbol{a}(\cdot)$, we define $T_\Gamma(\boldsymbol{x}, \boldsymbol{a}(\cdot))$ to be the earliest time at which the corresponding trajectory $\boldsymbol{y}(\cdot)$ reaches the curve Γ. Then*

$$u(\boldsymbol{x}) = \inf_{\boldsymbol{a}(\cdot)} \left\{ T_\Gamma\left(\boldsymbol{x}, \boldsymbol{a}(\cdot)\right) + u\left(\boldsymbol{y}\left(T_\Gamma(\boldsymbol{x}, \boldsymbol{a}(\cdot))\right)\right) \right\}. \tag{19}$$

LEMMA 3.3. *The value function $u(\boldsymbol{x})$ is Lipschitz-continuous*[4] *and bounded on $\Omega \backslash \partial\Omega$. If $\boldsymbol{y}'(t) = \boldsymbol{a}(t)$ defines an optimal trajectory for a point $\boldsymbol{x}$ (i.e., $\boldsymbol{y}(0) = \boldsymbol{x}$ and $u(\boldsymbol{x}) = \mathrm{Cost}(\boldsymbol{x}, \boldsymbol{a}(\cdot))$), then the function $u(\boldsymbol{y}(t))$ is strictly decreasing for $t \in [0, T(\boldsymbol{x}, \boldsymbol{a}(\cdot))]$.*

The following two lemmas utilize the *fixed-time optimality principle* and provide the key motivation for constructing OUMs for this problem (sections 6 and 8).

LEMMA 3.4. *Consider a point $\bar{\boldsymbol{x}} \in \Omega \backslash \partial\Omega$. Then, for any constant C such that $q_2 \leq C \leq u(\bar{\boldsymbol{x}})$, the optimal trajectory for $\bar{\boldsymbol{x}}$ will intersect the level set $u(\boldsymbol{x}) = C$ at some point $\tilde{\boldsymbol{x}}$. If $\bar{\boldsymbol{x}}$ is distance d_1 away from that level set, then*

$$\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| \leq d_1 \Upsilon. \tag{20}$$

Proof. Let $\boldsymbol{a}(\cdot)$ be an optimal control for $\bar{\boldsymbol{x}}$. The intersection point $\tilde{\boldsymbol{x}} = \boldsymbol{y}(\tau)$ exists because of the continuity of the value function and of the optimal trajectory: $u(\bar{\boldsymbol{x}}) \geq C \geq q_2 \geq u(\boldsymbol{y}(T(\bar{\boldsymbol{x}}, \boldsymbol{a}(\cdot))))$.

Therefore,

$$u(\bar{\boldsymbol{x}}) = \tau \, + \, u(\tilde{\boldsymbol{x}}) \geq \frac{\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f_2} + C.$$

There also exists some point $\hat{\boldsymbol{x}}$ on the level set such that $\|\bar{\boldsymbol{x}} - \hat{\boldsymbol{x}}\| = d_1$. Consider a control $\boldsymbol{a_1}(t) = \frac{\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}}{d_1}$, and suppose it takes time τ_1 to reach $\hat{\boldsymbol{x}}$ along the corresponding straight-line trajectory. By the optimality principle,

$$u(\bar{\boldsymbol{x}}) \leq \tau_1 \, + \, u(\hat{\boldsymbol{x}}) \leq \frac{d_1}{f_1} + C.$$

Thus, $\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| \leq d_1 \Upsilon$. □

LEMMA 3.5. *Consider an unstructured (triangulated) mesh X of diameter h on Ω. Consider a simple closed curve $\Gamma \subset \Omega \backslash \partial\Omega$ with the property that for any point $\boldsymbol{x}$ on Γ there exists a mesh point $\hat{\boldsymbol{x}}$ inside Γ such that $\|\boldsymbol{x} - \hat{\boldsymbol{x}}\| < h$. Suppose a mesh point $\bar{\boldsymbol{x}}$ is such that $u(\bar{\boldsymbol{x}}) \leq u(\boldsymbol{x_i})$ for all the mesh points $\boldsymbol{x_i} \in X$ inside Γ. The optimal trajectory for $\bar{\boldsymbol{x}}$ will intersect Γ at some point $\tilde{\boldsymbol{x}}$ such that*

$$\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| \leq h \Upsilon. \tag{21}$$

Proof. Let $\boldsymbol{a}(\cdot)$ be an optimal control for $\bar{\boldsymbol{x}}$. The intersection point $\tilde{\boldsymbol{x}} = \boldsymbol{y}(\tau)$ exists because of the continuity of Γ and of the optimal trajectory. Therefore,

$$u(\bar{\boldsymbol{x}}) = \tau \, + \, u(\tilde{\boldsymbol{x}}) \geq \frac{\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f_2} + \, u(\tilde{\boldsymbol{x}}).$$

[4] This holds in the interior of Ω even in the presence of *state constraints*: the assumption $f_1 > 0$ is sufficient for the *local controllability* near $\partial\Omega$ (as defined in [4], for example).

Let $\hat{\boldsymbol{x}}$ be a mesh point inside Γ such that $\|\tilde{\boldsymbol{x}} - \hat{\boldsymbol{x}}\| \leq h$. Consider a control $\boldsymbol{a_1}(t) = \frac{\tilde{\boldsymbol{x}}-\hat{\boldsymbol{x}}}{\|\tilde{\boldsymbol{x}}-\hat{\boldsymbol{x}}\|}$, and let τ_1 be the time required to reach $\tilde{\boldsymbol{x}}$ from $\hat{\boldsymbol{x}}$ using $\boldsymbol{a_1}(\cdot)$. Then, by the optimality principle,

$$u(\hat{\boldsymbol{x}}) \leq \tau_1 \,+\, u(\tilde{\boldsymbol{x}}) \leq \frac{h}{f_1} \,+\, u(\tilde{\boldsymbol{x}}).$$

To complete the proof, we recall that $u(\bar{\boldsymbol{x}}) \leq u(\hat{\boldsymbol{x}})$. □

3.3. Hamilton–Jacobi–Bellman PDE. As in the discrete case, Bellman's optimality principle can be used to formally derive the local equation for $u(\boldsymbol{x})$ if the value function is smooth around $\boldsymbol{x}$:

$$\begin{aligned} \min_{\boldsymbol{a}\in S_1}\{(\nabla u(\boldsymbol{x}) \cdot \boldsymbol{a}) f(\boldsymbol{x},\boldsymbol{a})\} \,+\, 1 = 0, \quad \boldsymbol{x} \in \Omega, \\ u(\boldsymbol{x}) = q(\boldsymbol{x}), \quad \boldsymbol{x} \in \partial\Omega. \end{aligned} \tag{22}$$

The above *Hamilton–Jacobi–Bellman PDE* can be rewritten in the form $H(\nabla u, \boldsymbol{x}) = 1$, where the Hamiltonian $H = -\min_{\boldsymbol{a}\in S_1}\{(\boldsymbol{p}\cdot\boldsymbol{a}) f(\boldsymbol{x},\boldsymbol{a})\} = \max_{\boldsymbol{a}\in S_1}\{(\boldsymbol{p}\cdot(-\boldsymbol{a})) f(\boldsymbol{x},\boldsymbol{a})\}$. Moreover, this Hamiltonian is convex and homogeneous of degree one in the first argument; thus, this PDE belongs to the class of problems described in section 1. We also note that the characteristics of this PDE can be formally shown to be the optimal trajectories for the corresponding min-time control problem.

In an important case of isotropic optimal speed function ($f(\boldsymbol{x},\boldsymbol{a}) = f(\boldsymbol{x})$), equation (22) reduces to the *Eikonal equation* $\|\nabla u(\boldsymbol{x})\| = \frac{1}{f(\boldsymbol{x})}$. We particularly emphasize one property of the Eikonal equations: if ∇u is defined at the point, then the minimizer is $\boldsymbol{a} = \frac{-\nabla u}{\|\nabla u\|}$. Thus, the gradient lines of $u(\boldsymbol{x})$ coincide with the characteristics of the Eikonal PDE (i.e., the optimal trajectories for the isotropic min-time control problem). This is the main reason for the following *causality property*, a foundation for the noniterative Eikonal solvers.

PROPERTY 3.6 (Causality for the Eikonal equation). *If $\nabla u(\boldsymbol{x})$ is defined and $\boldsymbol{x}\boldsymbol{x_1}\boldsymbol{x_2}$ is a sufficiently small acute simplex, which contains the characteristic for $\boldsymbol{x}$, then $u(\boldsymbol{x}) \geq \max\{u(\boldsymbol{x_1}), u(\boldsymbol{x_2})\}$.*

Unfortunately, a smooth solution to (22) might not exist even for smooth f, q, and $\partial\Omega$. Generally, this equation has infinitely many weak Lipschitz-continuous solutions, but the unique *viscosity solution* [10] can be defined using the conditions on smooth test functions [9] as follows.

A bounded, uniformly continuous function u is the *viscosity solution* of (22) if the following holds for each smooth test function[5] $\phi \in C_c^\infty(\Omega)$:

(i) if $u - \phi$ has a local minimum at $\boldsymbol{x_0} \in \Omega$, then

$$\min_{\boldsymbol{a}\in S_1}\{(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a}) f(\boldsymbol{x_0},\boldsymbol{a})\} + 1 \leq 0; \tag{23}$$

(ii) if $u - \phi$ has a local maximum at $\boldsymbol{x_0} \in \Omega$, then

$$\min_{\boldsymbol{a}\in S_1}\{(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a}) f(\boldsymbol{x_0},\boldsymbol{a})\} + 1 \geq 0. \tag{24}$$

Moreover, the optimality principle (Lemma 3.1) can be used to demonstrate that the value function of the min-time optimal trajectory problem satisfies the inequalities

[5] The standard definition of the viscosity solution (see [9, 8], for example) uses the test functions $\phi \in C^1(\Omega)$. However, as shown in [9], the definition using the test functions $\phi \in C_c^\infty(\Omega)$ is equivalent. This second formulation enables us to use the upper bounds on the second derivatives of ϕ in the convergence proof in section 7.

(24) and (23) and thus is the viscosity solution of the Hamilton–Jacobi–Bellman PDE (see [8, 7] or [16], for example[6]).

3.4. Modified definition of the viscosity solution. Define $S_1^{\phi,\boldsymbol{x}} = \{\boldsymbol{a} \in S_1 \mid \boldsymbol{a}\cdot\nabla\phi(\boldsymbol{x}) \leq -\|\nabla\phi(\boldsymbol{x})\|\Upsilon^{-1}\}$. In [46] we demonstrate that using $S_1^{\phi,\boldsymbol{x_0}}$ instead of S_1 in the inequalities (24) and (23) yields an equivalent definition of the viscosity solution for (22).

Proof. We first observe that, since $f > f_1 > 0$, if the minimum is attained for some $\boldsymbol{a} = \boldsymbol{a_1}$, then $(\boldsymbol{a_1} \cdot \nabla\phi(\boldsymbol{x_0})) < 0$. Let $\boldsymbol{b} = \frac{-\nabla\phi(\boldsymbol{x_0})}{\|\nabla\phi(\boldsymbol{x_0})\|}$. Since $\boldsymbol{a_1}$ is the minimizer, we have

$$(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a_1}) f(\boldsymbol{x_0}, \boldsymbol{a_1}) \leq (\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{b}) f(\boldsymbol{x_0}, \boldsymbol{b}) \leq -\|\nabla\phi(\boldsymbol{x_0})\| f_1.$$

Therefore,

$$\boldsymbol{a_1} \cdot \nabla\phi(\boldsymbol{x_0}) \leq -\|\nabla\phi(\boldsymbol{x_0})\| \frac{f_1}{f(\boldsymbol{x_0}, \boldsymbol{a_1})} \leq -\|\nabla\phi(\boldsymbol{x_0})\|\Upsilon^{-1}. \qquad \square$$

Remark 3.7. We have just established a bound on the angle between the characteristic of the PDE (22) and the gradient line of its viscosity solution. If the gradient $\nabla u(\boldsymbol{x_0})$ exists, then $\nabla u(\boldsymbol{x_0}) = \nabla\phi(\boldsymbol{x_0})$. Therefore, $\boldsymbol{a_1}\cdot\nabla u(\boldsymbol{x_0}) \leq -\|\nabla u(\boldsymbol{x_0})\|\Upsilon^{-1}$. If γ is the angle between $\nabla u(\boldsymbol{x_0})$ and $(-\boldsymbol{a_1})$, then $\cos(\gamma) \geq \frac{1}{\Upsilon}$. (If the level sets of $u(\boldsymbol{x})$ were straight lines, the last inequality would trivially follow from Lemma 3.4.) We note that the above argument heavily uses the existence of a positive lower bound f_1 and, therefore, does not directly apply to more general control problems.

3.5. A semi-Lagrangian discretization for the Hamilton–Jacobi–Bellman PDE. Assume that a triangulated mesh X of diameter h is defined on Ω. For every mesh point $\boldsymbol{x} \in X$, define $S(\boldsymbol{x})$ to be a set of all the simplexes in the mesh adjacent to $\boldsymbol{x}$ (i.e., the simplexes that have $\boldsymbol{x}$ as one of their vertices). If $s \in S(\boldsymbol{x})$, we will use the notation $\boldsymbol{x_{s,1}}$ and $\boldsymbol{x_{s,2}}$ for the other vertices of the simplex s.

A simple control-theoretic discretization of (19) follows from the assumption that, as the vehicle starts to move from a mesh point $\boldsymbol{x}$ inside a simplex $s \in S(x)$, its direction of motion $\boldsymbol{a}$ does not change until the vehicle reaches the edge $\boldsymbol{x_{s,1}x_{s,2}}$ (see Figure 1). The value $u(\tilde{\boldsymbol{x}})$ at the point of intersection can be approximated[7] using the values $u(\boldsymbol{x_{s,1}})$ and $u(\boldsymbol{x_{s,2}})$.

Defining $\tau(\zeta) = \|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| = \|(\zeta\boldsymbol{x_{s,1}} + (1-\zeta)\boldsymbol{x_{s,2}}) - \boldsymbol{x}\|$ and $\boldsymbol{a}_\zeta = \frac{\tilde{\boldsymbol{x}}-\boldsymbol{x}}{\tau(\zeta)}$, we can now write the equation for the numerical approximation U:

$$\begin{aligned} U(\boldsymbol{x}) &= \min_{s\in S(\boldsymbol{x})} V_s(\boldsymbol{x}), \\ V_s(\boldsymbol{x}) &= \min_{\zeta\in[0,1]} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \boldsymbol{a}_\zeta)} + \zeta U(\boldsymbol{x_{s,1}}) + (1-\zeta)U(\boldsymbol{x_{s,2}}) \right\}. \end{aligned} \tag{25}$$

The above "naive" derivation is based on a direct application of Bellman's optimality principle rather than on discretization of the corresponding Hamilton–Jacobi–Bellman

[6] The control-theoretic problems discussed in these papers are slightly different. They consider infinite horizon or exit time problems with time-discounted running costs, e.g., $\text{Cost}(\boldsymbol{x}, \boldsymbol{a}(\cdot)) = \int_0^\infty e^{-\lambda s} K(\boldsymbol{y}(s), \boldsymbol{a}(s))ds$. Thus, the resulting PDE is also slightly different, but Kruzhkov's transform [24] can be used to obtain the mapping from one to another; see [8], [4], for example. In addition, the iterative methods in these papers are also applicable for a more general case of $f_1 = 0$.

[7] Since the interpolation has to be used to approximate the value at a non–mesh point $\tilde{\boldsymbol{x}}$, we refer to this and similar discretizations as *semi-Lagrangian*.

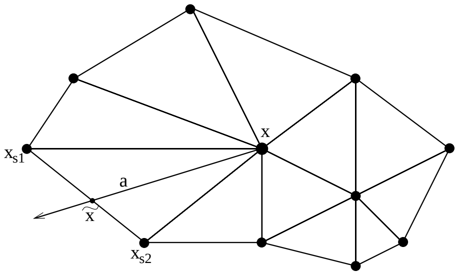

Fig. 1. *A control-theoretic discretization: each trajectory is approximated by a straight line within a simplex.*

PDE; a number of related methods, treatment of more general control problems (including the case $f_1 = 0$), and the proof of convergence can be found in [25, 26], and [18]. Similar higher-order control-theoretic numerical methods can be found in [17].

The discretized equation (25) has to be satisfied at every mesh point in X; this results in a coupled system of M nonlinear equations, which usually have to be solved simultaneously through the iterations. Due to the structure of the system, each iteration involves solving a local minimization problem for each mesh point, and even in the simplest problems the number of iterations will be proportional to the diameter of the mesh-graph. The number of iterations can be reduced using Gauss–Seidel relaxation (as in [18]), but we know of no theoretical guarantees of the rate of convergence.

4. OUMs for the isotropic case: Dijkstra-like Eikonal solvers.

Until recently, the Eikonal equation, corresponding to the isotropic optimal trajectory and front propagation problems, was the only case for which single-pass methods were available. Several fast algorithms have been introduced to solve the corresponding discretized system as efficiently as Dijkstra's method solves the shortest path problems on discrete networks. These methods are based on an observation that a particular upwind discretization possesses a *causality* property similar to that of the Eikonal equation (Property 3.6).

Property 4.1 (Causality). *If s is an acute simplex in $S(\boldsymbol{x})$ and $V_s(\boldsymbol{x})$ is a value of $U(\boldsymbol{x})$ computed under the assumption that the characteristic for $\boldsymbol{x}$ lies in s, then $V_s(\boldsymbol{x}) \geq \max\{U(\boldsymbol{x_{s,1}}), U(\boldsymbol{x_{s,2}})\}$.*

Any upwind discretization possessing this property leads to equations which can be decoupled by computing the value function at the mesh points in the increasing order. Since the ordering is not known in advance, we can structure these Dijkstra-like solvers in the spirit of section 2.2 as follows.

All the mesh points are divided into three classes: *Far* (no information about the correct value of U is known), *Accepted* (the correct value of U has been computed), and *Considered* (adjacent to *Accepted*), for which V has already been computed, but it is still unclear if $V = U$. For every *Considered* $\boldsymbol{x}$, we define the set $\mathrm{NS}(\boldsymbol{x}) = \{s \in S(\boldsymbol{x}) \mid \boldsymbol{x_{s,1}}$ and $\boldsymbol{x_{s,2}}$ are *Accepted*$\}$. We will also use a set $S(\boldsymbol{x_1}, \boldsymbol{x_2})$ to denote the simplexes adjacent to both of these mesh points.

1. Start with all the mesh points in *Far*.
2. Move the mesh points on the boundary ($\boldsymbol{y} \in \partial\Omega$) to *Accepted* ($U(\boldsymbol{y}) = q(\boldsymbol{y})$).
3. Move all the mesh points $\boldsymbol{x}$ adjacent to the boundary into *Considered* and

evaluate the tentative values

$$V(\boldsymbol{x}) := \min_{s \in NS(\boldsymbol{x})} V_s(\boldsymbol{x}). \tag{26}$$

4. Find the mesh point $\bar{\boldsymbol{x}}$ with the smallest value of V among all the *Considered*.
5. Move $\bar{\boldsymbol{x}}$ to *Accepted* ($U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}})$).
6. Move the *Far* mesh points adjacent to $\bar{\boldsymbol{x}}$ into *Considered*.
7. Reevaluate V for all the *Considered* $\boldsymbol{x}$ adjacent to $\bar{\boldsymbol{x}}$

$$V(\boldsymbol{x}) := \min \left\{ V(\boldsymbol{x}), \min_{s \in (S(\boldsymbol{x}, \bar{\boldsymbol{x}}) \bigcap \mathrm{NS}(\boldsymbol{x}))} V_s(\boldsymbol{x}) \right\}. \tag{27}$$

8. If *Considered* is not empty, then go to 4.

Such Dijkstra-like methods use heap-sort data structures to achieve Dijkstra-like efficiency of $O(M \log M)$ and compute the numerical solutions converging to the viscosity solution (due to the upwinding structure of discretization).

The first Dijkstra-like method, introduced by Tsitsiklis in 1994, evolved from studying isotropic min-cost optimal trajectory problems and was based on a direct approximation of the characteristic directions at each mesh point [44, 45]. Tsitsiklis proved that Property 4.1 holds for the particular first-order semi-Lagrangian discretization (i.e., formula (25)) of the Eikonal equation, when used on a uniform Cartesian grid in R^n. The algorithm requires solving a local minimization problem to update the solution at each mesh point; however, as shown in [45], the Kuhn–Tucker optimality conditions can be used to find a quadratic equation satisfied by the minimum value instead. In the appendix we provide a more general proof that the same causality property is possessed by the discretization (25) on an arbitrary unstructured mesh and derive the corresponding quadratic equation for the minimum value.

The family of Fast Marching Methods, introduced by Sethian in [33] and extended by Sethian and several co-authors in [35, 21, 38], evolved from studying isotropic front propagation problems (see section 8.1 for the recasting of Eikonal PDE in this context). Those discretizations were based on upwinding approximations of the gradient and were all obtained in a fully Eulerian frame of reference. Sethian proved that the causality Property 4.1 holds for a wide class of upwind finite-difference discretizations. Following that approach, upwind finite-difference operators were then used to obtain higher-order Cartesian versions [35], extensions to triangulated meshes [21], and general higher-order versions for the unstructured meshes in R^n [38]. In addition, the "lifting-to-surface" technique introduced in [38] allowed the Fast Marching Method to be used to solve a limited class of non-Eikonal (elliptically anisotropic) problems. We note that these extensions are all OUMs, relying on an upwinding criterion that establishes a monotonicity-preserving update procedure. Early applications of the Fast Marching Methods included the narrow band level set method [1], photolithography [34], a comparison of a similar algorithm with volume-of-fluid techniques [19], and a fast algorithm for image segmentation [27]. More recent applications include problems in robotic navigation [22], extension velocity computation [2], visibility evaluation [35], geophysics [32, 37], and computational geometry [23]. To produce an update for each mesh point, these methods require solving a quadratic equation, which will depend on the particular upwind finite-difference operator used. The original Fast Marching Method, as defined in [33], was based on the first-order Godunov-type discretization on a uniform Cartesian grid, and the corresponding quadratic update equation coincides with the equation derived from the Kuhn–Tucker conditions in [45].

(See the appendix for a discussion of the correspondence between the first-order semi-Lagrangian and fully Eulerian discretizations on unstructured meshes.)

Several different higher-order versions of the Fast Marching Method are available for structured and unstructured meshes, while there are currently no higher-order Dijkstra-like methods based on a semi-Lagrangian approach. The reason is the difficulty of finding the higher-order semi-Lagrangian discretization that would provably possess the causality property. Finally, when such a discretization is found, it will generally require performing a local minimization at every mesh point, since it is not obvious whether the Kuhn–Tucker conditions can be used to produce a quadratic equation in this more general case.

5. Characteristics versus gradients. In this section, we show why the Dijkstra-like methods cannot be directly applied to handle general (non-Eikonal) Hamilton–Jacobi equations. As a test problem, consider the "distance from the origin" Eikonal equation ($\|\nabla d\| = 1$, $d(0,0) = 0$), in a plane $z = c_1 x + c_2 y$ for some vector $\boldsymbol{c} = \left[\begin{smallmatrix} c_1 \\ c_2 \end{smallmatrix}\right]$. The level sets of d will be just the circles around the origin in that plane. Projecting those circles orthogonally onto the $x-y$ plane, we will see a set of concentric ellipses. As expected, the function $u(\boldsymbol{x})$, whose level sets coincide with these ellipses, may be obtained in two ways:

- *As an optimal-trajectory problem.* The function d can be considered as a value function for a vehicle moving with a unit speed in the plane $z = c_1 x + c_2 y$. As shown in [46], if one considers another vehicle which moves as a shadow of the first one in the $x-y$ plane, its value function will be the viscosity solution $u(\boldsymbol{x})$ of the Hamilton–Jacobi–Bellman equation

$$\min_{\boldsymbol{a} \in S_1} \{(\nabla u(\boldsymbol{x}) \cdot \boldsymbol{a}) f(\boldsymbol{x}, \boldsymbol{a})\} + 1 = 0, \qquad \boldsymbol{x} \in \Omega, \tag{28}$$

  and the vehicle's speed function in the direction $\boldsymbol{a} = \left[\begin{smallmatrix} a_1 \\ a_2 \end{smallmatrix}\right]$ will be given by

$$f(\boldsymbol{a}, x, y) = \left(1 + (c_1 a_1 + c_2 a_2)^2\right)^{-\frac{1}{2}}.$$

- *As a front propagation problem.* As shown in [36], this same problem can be viewed in the front propagation framework, using the speed function

$$F(\boldsymbol{x}, \boldsymbol{n}) = \sqrt{\frac{(1 + c_2^2) n_1^2 + (1 + c_1^2) n_2^2 - 2 c_2 c_1 n_1 n_2}{1 + c_1^2 + c_2^2}}.$$

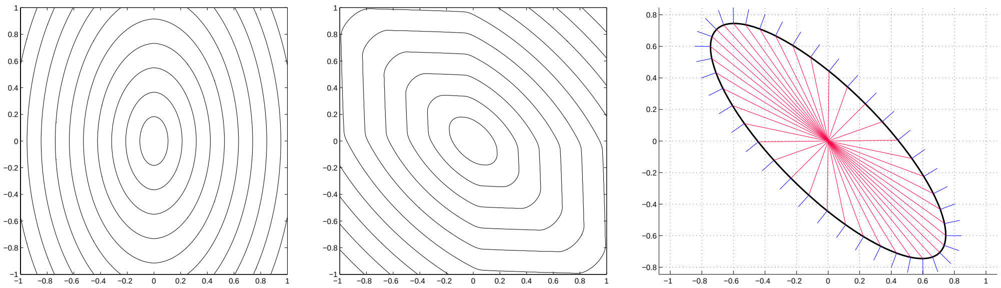
  The Hamilton–Jacobi PDE corresponding to this speed function F is

$$\sqrt{\frac{(1 + c_2^2) u_x^2(\boldsymbol{x}) + (1 + c_1^2) u_y^2(\boldsymbol{x}) - 2 c_2 c_1 u_x(\boldsymbol{x}) u_y(\boldsymbol{x})}{1 + c_1^2 + c_2^2}} = 1. \tag{29}$$

It would appear that Tsitsiklis' algorithm (defined for the isotropic case in section 4) can be applied to this anisotropic problem without any changes at all, except that the dependence of the speed f upon the direction $\boldsymbol{a}$ will now be present in the update-from-a-single-simplex formula:

$$V_s(\boldsymbol{x}) = \min_{\zeta \in [0,1]} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \boldsymbol{a}_\zeta)} + \zeta U(\boldsymbol{x}_{\boldsymbol{s},\boldsymbol{1}}) + (1 - \zeta) U(\boldsymbol{x}_{\boldsymbol{s},\boldsymbol{2}}) \right\}. \tag{30}$$

What happens when this algorithm is used to compute the expansion of the ellipse (as defined by (28))? In Figure 2 we show the level sets of the numerical solution



(a) (b) (c)

Fig. 2. (a) *and* (b) *Ellipse expansion computed by Tsitsiklis' algorithm. Both computations were performed on a* 129×129 *uniform Cartesian grid.* (c) *The characteristics and the gradient directions for the second expanding ellipse.*

U obtained by this method for two different expanding ellipses. The first contour plot corresponds to the vector $\boldsymbol{c} = \left[\begin{smallmatrix}\sqrt{2}\\0\end{smallmatrix}\right]$. The numerical solution converges to the value function $u(\boldsymbol{x})$ and is first-order accurate as the grid size tends to 0. (We will return to this example later when we discuss fast methods relying on a particular grid orientation in section 5.) The second contour plot corresponds to the vector $\boldsymbol{c} = \left[\begin{smallmatrix}1\\1\end{smallmatrix}\right]$. In this case, it is obvious that $U(\boldsymbol{x})$ does not approximate the viscosity solution very well. Nor does it improve under a grid refinement.

In order to understand what is different in the second example, we recall that all Dijkstra-like methods are fundamentally dependent on the *causality property* (3.6) of the Eikonal equation. Each of these single-pass methods is based on the observation that a certain discretization also possesses a similar *causality property*. This *causality* results from the fact that the characteristics of the Eikonal equation coincide with the gradient lines of its viscosity solution u. However, for the anisotropic problems this property does not hold. When the characteristic and gradient directions are different, the simplex $\boldsymbol{x x_j x_k}$ may contain the characteristic for the point $\boldsymbol{x}$, even if the gradient $\nabla u(\boldsymbol{x})$ is not pointing from that simplex. Thus, no matter how small that simplex is, it is still possible that $u(\boldsymbol{x}) < u(\boldsymbol{x_j})$. This is an intrinsic problem with Dijkstra-like methods in the anisotropic case: to produce the numerical solution efficiently, these methods attempt to compute $U(\boldsymbol{x})$ in the ascending order (i.e., from the simplex containing $(-\nabla u)$), whereas, in order to maintain the upwinding, $U(\boldsymbol{x})$ has to be computed from the simplex containing the characteristic. That phenomenon is also quite obvious from comparing Figures 2(b) and 2(c): the Dijkstra-like method fails exactly at those points where the gradient line and the characteristic do not lie in the same coordinate quadrant (or, more generally, in the same simplex—the quadrants are used because the numerical solution in Figure 2 is computed on a Cartesian grid).

However, it is still possible that, for a given PDE and for a chosen discretization scheme, Dijkstra-like decoupling will produce a convergent numerical solution, provided that it is used on *a specially oriented grid* (e.g., Figure 2(a)). A criterion based on this observation was introduced by Sethian in [36] as follows.

Criterion 5.1 (Applicability of the Fast Marching Method). *For a static Hamilton–Jacobi equation* $H(\nabla u, \boldsymbol{x}) = 0$*, if the convex Hamiltonian* H *is approximated on a Cartesian grid by a consistent difference operator*

$$H_{ij}(U_{i,j}, U_{i-1,j}, U_{i+1,j}, U_{i,j-1}, U_{i,j+1}, \boldsymbol{x_{i,j}}) = 0,$$

and if it is known that $U_{i,j}$ depends only on the smaller *values of U at the neighboring points, then the Fast Marching Method can be used to compute $U_{i,j}$'s efficiently.*

Remark 5.2. In the context of upwinding discretizations on unstructured meshes, the above criterion is equivalent to requiring that the characteristics and the (numerically approximated) vector $(-\nabla u)$ should always lie in the same simplex. Several sufficient conditions for a class of numerical Hamiltonians to satisfy the above criterion on Cartesian grids were presented by Osher and Fedkiw in [29]. For instance, the causality property was proven in [29] for the Godunov-type upwinding discretization H^G_{ij}, provided that the original Hamiltonian $H(\nabla u, \boldsymbol{x})$ has a special form $H(\nabla u, \boldsymbol{x}) = G(u_x^2, u_y^2)$ for some function G. We note that, even for a relatively simple elliptical front propagation (29), this condition is satisfied only in the case when c_1 or c_2 is equal to zero, i.e., only when the axes of the ellipse are exactly aligned with the grid coordinate directions. This is precisely the situation illustrated by Figure 2(a).

In general, finding discretizations which satisfy Criterion 5.1 is a difficult task. We note the following problems associated with this approach:

- *Whether or not the criterion is satisfied depends upon a particular grid/mesh-orientation.* Indeed, the two test problems in Figure 2 are actually the same (modulo a rotation by 45°), yet only one of them satisfies the criterion.
- *For any anisotropic problem, there are infinitely many grid orientations such that the criterion is not satisfied.* If an angle between the characteristic and the gradient line is not zero, then any grid line lying inside that angle will violate the criterion. Correspondingly, the bigger the *anisotropy coefficient* Υ is, the harder it is to find the grid orientation satisfying the criterion.
- *The criterion is infinitely sensitive to grid perturbations.*
- *If the criterion is not satisfied, the numerical solution does not lose stability under grid refinement.* In other words, when it does not work, it is not immediately obvious.
- *If the criterion is not satisfied even at a single grid point, the numerical solution need not converge to the viscosity solution.* Criterion 5.1 is the basis for determining the order for computing the values of U. Computing even one of them from a wrong quadrant can greatly affect the ordering of the remaining computations.
- *For many anisotropic problems, the criterion cannot be satisfied for any choice of the grid directions.* Indeed, if the angle between gradient lines and the characteristics is sufficiently wide, and if the medium is substantially inhomogeneous (i.e., if the speed $f(\boldsymbol{x}, \boldsymbol{a})$ varies significantly in different parts of Ω), then any Cartesian grid might violate Criterion 5.1 for some grid point $\boldsymbol{x} \in X$.

As a result, we have chosen to concentrate on a family of robust single-pass methods, which are independent of the grid choice[8] and applicable to a wider class of control problems. Nevertheless, for the limited class of problems in which Criterion 5.1 can be analytically demonstrated for a certain choice of grid, the original Dijkstra-like solvers will perform better than the new OUMs introduced in the next section.

[8] Of course, it is just the fact of *convergence* that is independent of the grid choice for our methods; the *speed of convergence* is certainly influenced by the choice of the grid and its alignment with the shock lines.

In fact, if the computational mesh is not fixed for some application-specific reasons, the convergence of our single-pass methods can be further improved by using the computed characteristic information to dynamically add the mesh points inside the AF, wherever the shock is suspected.

5.1. Causality in the Hamilton–Jacobi–Bellman PDE. A different (weaker) *causality property* for the more general Hamilton–Jacobi–Bellman equation results from Bellman's optimality principle (see section 3). Since the characteristics of that PDE are, in fact, the optimal trajectories of the corresponding control problem, we know that the value function u is strictly increasing along the characteristics. Our OUMs for the general anisotropic problems will be based on the fixed-boundary optimality principle (Lemma 3.2).

Let $u(\boldsymbol{x})$ be the value function for the anisotropic min-time optimal trajectory problem defined on Ω in section 3. We will use the notation $T_{\hat{\boldsymbol{x}}}(\boldsymbol{x})$ for the minimum time required to reach the point $\hat{\boldsymbol{x}}$ starting from the point $\boldsymbol{x}$. If Γ is a simple closed curve in $\Omega\backslash\partial\Omega$ and a point $\boldsymbol{x}$ is inside Γ, then Lemma 3.2 shows that

$$u(\boldsymbol{x}) = \inf_{\hat{\boldsymbol{x}} \in \Gamma} \left\{ T_{\hat{\boldsymbol{x}}}(\boldsymbol{x}) + u(\hat{\boldsymbol{x}}) \right\}.$$

Because of the properties of the speed function f and by the continuity of Γ, that infimum is actually a minimum achieved at some point $\tilde{\boldsymbol{x}}$, i.e., $u(\boldsymbol{x}) = T_{\tilde{\boldsymbol{x}}}(\boldsymbol{x}) + u(\tilde{\boldsymbol{x}})$. The point $\tilde{\boldsymbol{x}}$ can be interpreted as an intersection of the optimal trajectory for $\boldsymbol{x}$ with the curve Γ. Thus, knowing u on Γ is sufficient for evaluating u at any point inside Γ. Moreover, if Γ is a level set of $u(\boldsymbol{x})$, then, by Lemma 3.4, we know that $\|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq d_1\Upsilon$, where $\Upsilon = \frac{f_2}{f_1}$ and d_1 is the distance from $\boldsymbol{x}$ to Γ (see Figure 3). The last observation[9] necessary for constructing a computational algorithm is that, if d_1 is small relative to the size of Γ, then the optimal time $T_{\tilde{\boldsymbol{x}}}(\boldsymbol{x})$ cannot be much smaller than the time required to traverse the straight line trajectory from $\boldsymbol{x}$ to $\tilde{\boldsymbol{x}}$.

6. Control-theoretic OUM. We now describe our control-theoretic OUM, which was first discussed without convergence proof in [39]. Consider an unstructured triangulated mesh X of diameter h (i.e., if the mesh points $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ are adjacent, then $\|\boldsymbol{x_j} - \boldsymbol{x_k}\| \leq h$).

Let $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ be two adjacent mesh points. Define the upwinding approximation for $U(\boldsymbol{x})$ from a "virtual simplex" $\boldsymbol{x_j x x_k}$:

$$V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}) = \min_{\zeta\in[0,1]} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \boldsymbol{a}_\zeta)} + \zeta U(\boldsymbol{x_j}) + (1-\zeta)U(\boldsymbol{x_k}) \right\}, \tag{31}$$

where $\tau(\zeta) = \|(\zeta\boldsymbol{x_j} + (1-\zeta)\boldsymbol{x_k}) - \boldsymbol{x}\|$ and $\boldsymbol{a}_\zeta = \frac{(\zeta\boldsymbol{x_j}+(1-\zeta)\boldsymbol{x_k})-\boldsymbol{x}}{\tau(\zeta)}$.

Remark 6.1. The above update formula is basically the same as the upwind formula for simplex s given by (25). The difference is that $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ is defined even when $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ are not adjacent to $\boldsymbol{x}$.

Control-theoretic OUM for anisotropic problems. As before, mesh points are divided into three classes (*Far*, *Considered*, *Accepted*). The *AcceptedFront* is defined as a set of *Accepted* mesh points, which are adjacent to some not-yet-accepted (i.e., *Considered*) mesh points. Define the set AF of the line segments $\boldsymbol{x_j x_k}$, where $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ are adjacent mesh points on the *AcceptedFront*, such that there exists a *Considered* mesh point $\boldsymbol{x_i}$ adjacent to both $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$. For each *Considered* mesh point $\boldsymbol{x}$ we define the "near front" as the part of AF "relevant to $\boldsymbol{x}$":

$$\mathrm{NF}(\boldsymbol{x}) = \{\boldsymbol{x_j x_k} \in AF \ \mid \exists \tilde{\boldsymbol{x}} \text{ on } \boldsymbol{x_j x_k} \text{ s.t. } \|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq h\Upsilon\}.$$

[9] Since Γ generally is not a level set of u, the logic of the method is more subtle and cannot really be based on Lemma 3.4. Instead, it relies on Lemma 3.5, which provides a weaker version of this inequality, but for any Γ "well-resolved" by an underlying mesh X.

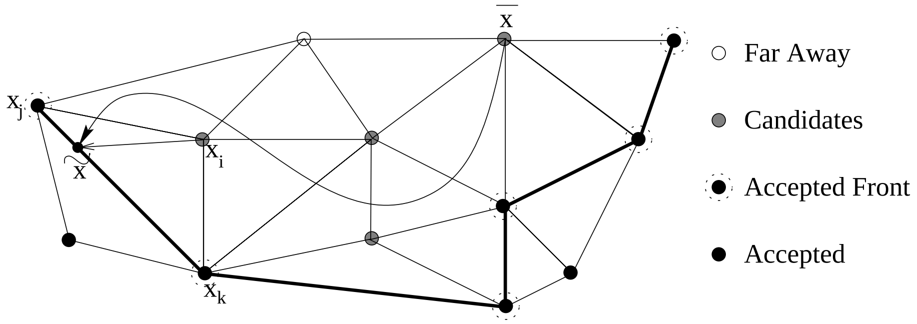


FIG. 3. *The AcceptedFront and the Considered mesh points. Segments of AF are shown in bold. The optimal trajectory for $\bar{\boldsymbol{x}}$ cannot intersect AF too far away from $\bar{\boldsymbol{x}}$, for if $\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| > h\Upsilon$, then $u(\boldsymbol{x_i}) < u(\bar{\boldsymbol{x}})$.*

1. Start with all the mesh points in *Far*.

2. Move the mesh points on the boundary ($\boldsymbol{y} \in \partial\Omega$) to *Accepted* ($U(\boldsymbol{y}) = q(\boldsymbol{y})$).

3. Move all the mesh points $\boldsymbol{x}$ adjacent to the boundary into *Considered* and evaluate the tentative values

$$V(\boldsymbol{x}) := \min_{\boldsymbol{x_j x_k} \in \mathrm{NF}(\boldsymbol{x})} V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}). \tag{32}$$

4. Find the mesh point $\bar{\boldsymbol{x}}$ with the smallest value of V among all the *Considered*.

5. Move $\bar{\boldsymbol{x}}$ to *Accepted* ($U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}})$) and update the *AcceptedFront*.

6. Move the *Far* mesh points adjacent to $\bar{\boldsymbol{x}}$ into *Considered* and compute their tentative values by (32).

7. Recompute the value for all the other *Considered* $\boldsymbol{x}$ such that $\bar{\boldsymbol{x}} \in \mathrm{NF}(\boldsymbol{x})$

$$V(\boldsymbol{x}) := \min\left\{V(\boldsymbol{x}), \min_{\bar{\boldsymbol{x}}\boldsymbol{x_i} \in \mathrm{NF}(\boldsymbol{x})} V_{\bar{\boldsymbol{x}},\boldsymbol{x_i}}(\boldsymbol{x})\right\}. \tag{33}$$

8. If *Considered* is not empty, then go to 4.

We note that the resulting algorithm

- is "single-pass," since it produces the numerical solution U in $O(\Upsilon^2 M \log(M))$ steps. This is because there are a total of M points to *Accept*, every time a mesh point is accepted there are at most Υ^2 *Considered* points to reevaluate, and we must maintain an ordering of *Considered* based on V, which contributes a factor of $\log(M)$.
- produces the numerical solution U that converges to u as the diameter of the mesh tends to zero (see the proof in section 7);
- is at most first-order accurate;
- works equally well on acute and nonacute triangulated meshes;
- is applicable for a general anisotropic optimal trajectory problem described in section 3.

An extension of this method to R^n and manifolds is straightforward, since the update formula (31) can easily be generalized for these cases. The only part of the program which needs to be modified to handle a manifold-approximating mesh is the algorithm for sorting and searching the *AcceptedFront*.

Remark 6.2 (Comments on computational complexity).

1. In the above complexity analysis, the calculation of an upwind-update-from-a-single-simplex value $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ was counted as a single operation. We note that

the optimization problem solved to compute $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ is *local* (i.e., $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ can be computed independently from any other $V_{\boldsymbol{x_i},\boldsymbol{x_m}}(\boldsymbol{x_l})$) and, thus, should not be confused with the iterations necessary to solve the coupled system of nonlinear equations (25) simultaneously. More details on algorithmic efficiency can be found in section 9.

2. As we will show in section 7, AF can be considered as an approximation for a level set of U. Thus, if the mesh diameter h is sufficiently small, then the number of $Considered$ points which have to be updated after each acceptance becomes closer to Υ, since the $Considered$ points are immediately adjacent to AF. Thus, as h decreases, the computational complexity of the method tends to $O\left(\Upsilon M \log(M)\right)$.

3. If the problem is formulated in R^n, the complexity of the corresponding algorithm is $O(\Upsilon^{n-1} M \log(M))$, where M remains the total number of mesh points.

Remark 6.3 (A comment on the rate of convergence). Our proof of convergence in section 7 does not provide an estimate for the rate of convergence. We believe that this method is first-order; this belief is based on the first-order accuracy of the approximations behind the semi-Lagrangian discretization (used to calculate $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$) and is also confirmed by the numerical evidence (see section 9.4 and [38, 46]). Based on numerical experiments, we note that for sufficiently small h, $\|U-u\|_\infty$ is at worst $O(\Upsilon h)$. This is not surprising, since Υh is the largest distance over which the first-order accurate approximation might be performed when $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ is computed.

Remark 6.4 (A comment on mesh degeneracy). The fast Eikonal solvers described in section 4 rely on the *causality property*, which holds only for the acute simplexes. An additional "splitting section" construction is required to handle the nonacute case [21, 38]. Not surprisingly, the acuteness of simplexes in X is not required for the OUM introduced here. After all, the algorithm uses the mesh connectivity only to determine what becomes $Considered$, when a new mesh point is *Accepted*. All of the upwind-update-from-a-single-simplex values $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ are computed from the simplexes defined by the position of $AcceptedFront$ rather than from the simplexes present in X.

Nevertheless, in order to prove the convergence of $U(\boldsymbol{x})$ to the viscosity solution, we will have to assume that the mesh X cannot be arbitrarily degenerate. Namely, we will assume that if h is the diameter of X and h_{min} is the smallest triangle height in X, then the ratio $\eta = h/h_{min}$ is bounded for all sufficiently small h. See the proof of Lemma 7.5 for details.

Remark 6.5 (A comment on the order of *Acceptance*). Unlike in Sethian's Fast Marching Methods or in Tsitsiklis' algorithm, in the above method the mesh points *are not Accepted* in the order of increasing U. As was pointed out in section 5, for the anisotropic optimal trajectory problems the fact that the characteristic for $\boldsymbol{x}$ lies inside the simplex $\boldsymbol{x}\boldsymbol{x_j}\boldsymbol{x_k}$ does not mean that the gradient is pointing from that simplex. Thus, it is entirely possible that $U(\boldsymbol{x}) \leq V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}) < U(\boldsymbol{x_j})$. Nevertheless, we will show in Lemma 7.3 that the order of *Acceptance* is monotone, albeit in a much weaker sense than for the single-pass Eikonal solvers.

Remark 6.6 (Decoupling of the "extended semi-Lagrangian scheme"). Define the extended set of neighbors

$$N_K(\boldsymbol{x}) = \{\boldsymbol{x_1}\boldsymbol{x_2} \in X \mid \boldsymbol{x_1} \text{ and } \boldsymbol{x_2} \text{ are adjacent and } \exists \tilde{\boldsymbol{x}} \text{ on } \boldsymbol{x_1}\boldsymbol{x_2} \text{ s.t. } \|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq h\Upsilon\}.$$

Note that if we replace NF$(\boldsymbol{x})$ by $N_K(\boldsymbol{x})$, the formula (32) becomes

$$U(\boldsymbol{x}) = \min_{\boldsymbol{x_1}\boldsymbol{x_2} \in N_K(\boldsymbol{x})} V_{\boldsymbol{x_1}\boldsymbol{x_2}}(\boldsymbol{x}). \tag{34}$$

This is an "extended" version of the semi-Lagrangian scheme (25), and it is easy to show that its solution U converges to the viscosity solution u. Equation (34) can be solved by successive approximation techniques described in [18], for example. However, a single-pass algorithm cannot be used to find U since we need to consider all possible directions of motion for the vehicle starting at the point $\boldsymbol{x}$ (i.e., $U(\boldsymbol{x})$ might potentially depend upon $U(\boldsymbol{y})$ for all $\boldsymbol{y} \in N_K(\boldsymbol{x})$, including the values $U(\boldsymbol{y}) > U(\boldsymbol{x})$). Therefore, the formula (32) can be interpreted as an upwinding analogue of (34).

The above comparison is just an analogue—not an equivalence. The numerical values produced by executing the above OUM will be different from those obtained by solving the coupled system (34); thus, the convergence of the OUM has to be proven separately.

7. Proof of convergence.

In this section we prove the convergence of the above algorithm to the viscosity solution.[10]

We will assume that the numerical solution $U(\boldsymbol{x})$ is computed for each $x \in X$, using the OUM described in section 6. For the points $\boldsymbol{x} \in \Omega \backslash X$, $U(\boldsymbol{x})$ is defined by linear interpolation as follows.

If $\boldsymbol{x}$ is inside Ω but is not a mesh point, then it lies in some simplex $\boldsymbol{x_1 x_2 x_3}$. In that case, there exist $\zeta_1, \zeta_2, \zeta_3 \geq 0$ such that

$$\zeta_1 + \zeta_2 + \zeta_3 = 1, \qquad \zeta_1 \boldsymbol{x_1} + \zeta_2 \boldsymbol{x_2} + \zeta_3 \boldsymbol{x_3} = \boldsymbol{x}. \tag{35}$$

The value at $\boldsymbol{x}$ is defined to be $U(\boldsymbol{x}) = \zeta_1 U(\boldsymbol{x_1}) + \zeta_2 U(\boldsymbol{x_2}) + \zeta_3 U(\boldsymbol{x_3})$.

Suppose that h_{min} is the smallest triangle height in the mesh X. We will use the constant $\eta = \frac{h}{h_{min}}$ to characterize the degree of "degeneracy" of the mesh X.

7.1. Properties of the numerical solution.

The following lemmas demonstrate several properties of the numerical solution U, which are necessary to prove the convergence and also mirror the properties of the value function for the optimal trajectory problem (section 3.2).

7.1.1. Is NF(x) big enough?

Suppose that the mesh point $\bar{\boldsymbol{x}}$ is about to be *Accepted* (hence, $V(\bar{\boldsymbol{x}}) = \min_{\boldsymbol{x} \in Considered} V(\boldsymbol{x})$).

LEMMA 7.1. *For every Considered mesh point $\boldsymbol{x}$ define*

$$W(\boldsymbol{x}) = \min_{\boldsymbol{x_1 x_2} \in AF} \; \min_{\zeta \in [0,1]} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \boldsymbol{a})} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta) U(\boldsymbol{x_2})) \right\}, \tag{36}$$

where $\tau(\zeta) = \|(\zeta \boldsymbol{x_1} + (1-\zeta)\boldsymbol{x_2}) - \boldsymbol{x}\|$ and $\boldsymbol{a} = \frac{\zeta(\boldsymbol{x_1} - \boldsymbol{x}) + (1-\zeta)(\boldsymbol{x_2} - \boldsymbol{x})}{\tau(\zeta)}$. If $\bar{\boldsymbol{x}}$ is about to be Accepted, *then $U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}}) = W(\bar{\boldsymbol{x}})$.*

Proof. First, $U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}})$ simply because $\bar{\boldsymbol{x}}$ is about to be *Accepted.*

Recall that $V(\boldsymbol{x})$ for every *Considered* mesh point $\boldsymbol{x}$ is computed by formula (32) as follows:

$$V(\boldsymbol{x}) = \min_{\boldsymbol{x_1 x_2} \in \mathrm{NF}(\boldsymbol{x})} \; \min_{\zeta \in [0,1]} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \boldsymbol{a})} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta) U(\boldsymbol{x_2})) \right\},$$

[10] As of now, we do not know of any natural discretized version of the Hamilton–Jacobi–Bellman PDE that would be exactly satisfied by the numerical solution $U(\boldsymbol{x})$ produced by the OUM in section 6. Since $U(\boldsymbol{x})$ is defined constructively (i.e., by an algorithm to compute it), we cannot rely on properties of a discretized equation for the proof of convergence; thus, the proof in this section has to rely on the properties of the algorithm itself.

where $\mathrm{NF}(\boldsymbol{x})$ is the part of the *AcceptedFront* "relevant to $\boldsymbol{x}$": $\mathrm{NF}(\boldsymbol{x}) = \{\boldsymbol{x_1 x_2} \in AF \mid \exists \tilde{\boldsymbol{x}}$ on the line segment $\boldsymbol{x_1 x_2}$ s.t. $\|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq h\Upsilon\}$. Since $\mathrm{NF}(\boldsymbol{x}) \subset AF$, we immediately see that for any *Considered* mesh point $\boldsymbol{x}$

$$V(\boldsymbol{x}) \geq W(\boldsymbol{x}). \tag{37}$$

Let $\boldsymbol{x_1 x_2} \in AF$ and $\zeta \in [0,1]$ be such that the minimum in formula (36) is attained; i.e., if $\hat{\boldsymbol{x}} = (\zeta \boldsymbol{x_1} + (1-\zeta)\boldsymbol{x_2})$, then

$$W(\bar{\boldsymbol{x}}) = \frac{\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f(\bar{\boldsymbol{x}}, \frac{\hat{\boldsymbol{x}}-\bar{\boldsymbol{x}}}{\|\hat{\boldsymbol{x}}-\bar{\boldsymbol{x}}\|})} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2}))\,. \tag{38}$$

Let $\boldsymbol{x_3}$ be the *Considered* mesh point adjacent to both $\boldsymbol{x_1}$ and $\boldsymbol{x_2}$. Then $U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}}) \leq V(\boldsymbol{x_3})$ since $\bar{\boldsymbol{x}}$ is about to be accepted. $V(\boldsymbol{x_3})$ is also computed by formula (32); thus,

$$V(\boldsymbol{x_3}) \leq \frac{\|\hat{\boldsymbol{x}} - \boldsymbol{x_3}\|}{f(\boldsymbol{x_3}, \frac{\hat{\boldsymbol{x}}-\boldsymbol{x_3}}{\|\hat{\boldsymbol{x}}-\boldsymbol{x_3}\|})} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2})) \leq \frac{h}{f_1} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2}))\,.$$

Combining this with the inequalities (37) and(38), we obtain

$$\begin{aligned} \frac{\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f_2} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2})) \leq W(\bar{\boldsymbol{x}}) \leq V(\bar{\boldsymbol{x}}) &\leq V(\boldsymbol{x_3}) \\ &\leq \frac{h}{f_1} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2}))\,, \end{aligned}$$

which implies $\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| \leq h\Upsilon$. Therefore, $\boldsymbol{x_1 x_2} \in \mathrm{NF}(\bar{\boldsymbol{x}})$ and $W(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}})$. □

7.1.2. Uniform upper bound.

LEMMA 7.2. *If Ω is convex and $d(\boldsymbol{x})$ is the distance from $\boldsymbol{x} \in \Omega$ to the boundary $\partial\Omega$, then*

$$U(\boldsymbol{x}) \leq \frac{d(\boldsymbol{x})}{f_1} + q_2. \tag{39}$$

Proof. If $\boldsymbol{x} \in \partial\Omega$, then the inequality holds trivially since $0 \leq q(\boldsymbol{x}) \leq q_2$.

If $\boldsymbol{x}$ is a mesh point inside Ω, we prove the lemma by induction: assume that the inequality (39) holds for all the mesh points that are on the *AcceptedFront* just before $\boldsymbol{x} = \bar{\boldsymbol{x}}$ is *Accepted*. Consider a (possibly nonunique) shortest path from $\bar{\boldsymbol{x}}$ to the boundary. By the properties of the distance function $d(\cdot)$, that shortest path is a straight line. Moreover, suppose that line intersects the segment of *AcceptedFront* $\boldsymbol{x_1 x_2} \in AF$ at the point $\hat{\boldsymbol{x}} = (\zeta \boldsymbol{x_1} + (1-\zeta)\boldsymbol{x_2})$. It is trivial to show that $d(\bar{\boldsymbol{x}}) = d(\hat{\boldsymbol{x}}) + \|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|$. Using Lemma 7.1,

$$U(\bar{\boldsymbol{x}}) \;=\; W(\bar{\boldsymbol{x}}) \;\leq\; \frac{\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f(\bar{\boldsymbol{x}}, \frac{\hat{\boldsymbol{x}}-\bar{\boldsymbol{x}}}{\|\hat{\boldsymbol{x}}-\bar{\boldsymbol{x}}\|})} + (\zeta U(\boldsymbol{x_1}) + (1-\zeta)U(\boldsymbol{x_2}))\,.$$

Based on the assumption of induction,

$$U(\bar{\boldsymbol{x}}) \;\leq\; \frac{\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f_1} + \zeta\left(\frac{d(\boldsymbol{x_1})}{f_1} + q_2\right) + (1-\zeta)\left(\frac{d(\boldsymbol{x_2})}{f_1} + q_2\right).$$

By the convexity of Ω, the distance-to-boundary function $d(\boldsymbol{x})$ is concave and $d(\hat{\boldsymbol{x}}) \geq \zeta d(\boldsymbol{x_1}) + (1-\zeta) d(\boldsymbol{x_2})$. Therefore,

$$U(\bar{\boldsymbol{x}}) \;\leq\; \frac{1}{f_1}(\|\hat{\boldsymbol{x}} - \bar{\boldsymbol{x}}\| + d(\hat{\boldsymbol{x}})) + q_2 \;=\; \frac{d(\bar{\boldsymbol{x}})}{f_1} + q_2,$$

which completes the proof by induction. (The base of induction is obvious, since only the mesh points on the boundary $\partial\Omega$ are already *Accepted* when the algorithm starts.)

If $\boldsymbol{x}$ is inside Ω but is not a mesh point, then it lies in some simplex $\boldsymbol{x_1 x_2 x_3}$ and there exist $\zeta_1, \zeta_2, \zeta_3 \geq 0$ such that

(40)
$$\zeta_1 + \zeta_2 + \zeta_3 = 1, \quad \boldsymbol{x} = \zeta_1 \boldsymbol{x_1} + \zeta_2 \boldsymbol{x_2} + \zeta_3 \boldsymbol{x_3}, \quad U(\boldsymbol{x}) = \zeta_1 U(\boldsymbol{x_1}) + \zeta_2 U(\boldsymbol{x_2}) + \zeta_3 U(\boldsymbol{x_3}).$$

Once again, using the concavity of the distance function,

$$\begin{aligned} U(\boldsymbol{x}) &\leq \zeta_1 \left(\frac{d(\boldsymbol{x_1})}{f_1} + q_2 \right) + \zeta_2 \left(\frac{d(\boldsymbol{x_2})}{f_1} + q_2 \right) + \zeta_3 \left(\frac{d(\boldsymbol{x_3})}{f_1} + q_2 \right) \\ &\leq q_2 + \frac{1}{f_1} \left(\zeta_1 d(\boldsymbol{x_1}) + \zeta_2 d(\boldsymbol{x_2}) + \zeta_3 d(\boldsymbol{x_3}) \right) \;\leq\; \frac{d(\boldsymbol{x})}{f_1} + q_2. \qquad \square \end{aligned}$$

The obtained bound is "uniform" since it is independent of the diameter h of the mesh X. We also note that a uniform upper bound on U can be derived even for a nonconvex Ω, assuming that η remains bounded and the boundary $\partial\Omega$ is adequately represented by the mesh as h tends to zero.

7.1.3. Relaxed monotonicity of the *Accepted*. In contrast with Dijkstra-like Eikonal solvers, the OUM introduced in section 6 is not computing (and accepting) the values in a monotone fashion: "$\boldsymbol{x_i}$ is *Accepted* after $\boldsymbol{x_j}$" does not imply "$U(\boldsymbol{x_i}) \geq U(\boldsymbol{x_j})$" (see Remark 6.5). However, a weaker monotonicity property can still be formulated, based on the evolution of AF during the computation. Recall that AF is defined as the set of the line segments $\boldsymbol{x_j x_k}$, where $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ are adjacent mesh points on the $AcceptedFront$ such that there exists a $Considered$ mesh point $\boldsymbol{x_i}$ adjacent to both $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$. Define U_{min}^{AF} (and U_{max}^{AF}) as the min (max) value of U on the set AF. Note that, since U is defined by the linear interpolation, both U_{min}^{AF} and U_{max}^{AF} are attained at the mesh points.

The following definitions are useful for discussing the evolution of $AcceptedFront$:

— $AF_{\bar{\boldsymbol{x}}}$ is the state of AF *immediately before* $\bar{\boldsymbol{x}}$ *is Accepted.*

— $U_{min}^{AF_{\bar{\boldsymbol{x}}}}$ and $U_{max}^{AF_{\bar{\boldsymbol{x}}}}$ are the minimum and maximum values of U on $AF_{\bar{\boldsymbol{x}}}$.

— $AF^{\bar{\boldsymbol{x}}}$ is the state of AF *immediately after* $\bar{\boldsymbol{x}}$ *is Accepted.*

— $U_{min}^{AF^{\bar{\boldsymbol{x}}}}$ and $U_{max}^{AF^{\bar{\boldsymbol{x}}}}$ are the minimum and maximum values of U on $AF^{\bar{\boldsymbol{x}}}$.

LEMMA 7.3 (Monotonicity of AF's evolution). *Suppose that h_{min} is the smallest triangle height in the triangulated mesh X on Ω. Then the following weak monotonicity results hold for the numerical solution U:*

(i)

$$U_{min}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h_{min}}{f_2} \;\leq\; U(\bar{\boldsymbol{x}}) \;\leq\; U_{max}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h}{f_1}. \tag{41}$$

(ii)

$$U_{min}^{AF_{\bar{\boldsymbol{x}}}} \;\leq\; U_{min}^{AF^{\bar{\boldsymbol{x}}}}. \tag{42}$$

(iii) *If* $\boldsymbol{x_i}$ *is Accepted before* $\boldsymbol{x_j}$, *then* $U_{min}^{AF_{\boldsymbol{x_i}}} \le U_{min}^{AF_{\boldsymbol{x_j}}}$.

(iv) *If* $U_{max}^{AF_{\bar{\boldsymbol{x}}}} \le U_{min}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h}{f_1}$, *then* $U_{max}^{AF^{\bar{\boldsymbol{x}}}} \le U_{min}^{AF^{\bar{\boldsymbol{x}}}} + \frac{h}{f_1}$.

Proof. (i) Let $\boldsymbol{x_1}$ be a mesh point on $AF_{\bar{\boldsymbol{x}}}$ such that $U(\boldsymbol{x_1}) = U_{min}^{AF_{\bar{\boldsymbol{x}}}}$. Since it is on *AcceptedFront* immediately before $\bar{\boldsymbol{x}}$ is *Accepted*, there exists at that time a *Considered* mesh point $\boldsymbol{x_2}$ adjacent to $\boldsymbol{x_1}$. Thus,

$$V(\boldsymbol{x_2}) \le U(\boldsymbol{x_1}) + \frac{\|\boldsymbol{x_2} - \boldsymbol{x_1}\|}{f(\boldsymbol{x_2}, \frac{\boldsymbol{x_2}-\boldsymbol{x_1}}{\|\boldsymbol{x_2}-\boldsymbol{x_1}\|})}.$$

Since $\bar{\boldsymbol{x}}$ is about to be *Accepted*, $U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}}) \le V(\boldsymbol{x_2}) \le U_{min}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h}{f_1}$. On the other hand,

$$U(\bar{\boldsymbol{x}}) = V(\bar{\boldsymbol{x}}) = U(\tilde{\boldsymbol{x}}) + \frac{\|\tilde{\boldsymbol{x}} - \bar{\boldsymbol{x}}\|}{f(\bar{\boldsymbol{x}}, \frac{\tilde{\boldsymbol{x}}-\bar{\boldsymbol{x}}}{\|\tilde{\boldsymbol{x}}-\bar{\boldsymbol{x}}\|})}$$

for some $\tilde{\boldsymbol{x}} \in AF_{\bar{\boldsymbol{x}}}$. Thus, $U(\bar{\boldsymbol{x}}) \ge U_{min}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h_{min}}{f_2}$.

(ii) As $\bar{\boldsymbol{x}}$ is *Accepted*, several mesh points might be removed from the *AcceptedFront*, but the only point possibly added to the *AcceptedFront* is $\bar{\boldsymbol{x}}$ itself. ($\bar{\boldsymbol{x}}$ will be added if there still is a not-yet-*Accepted* mesh point adjacent to it.) Since $U_{min}^{AF_{\bar{\boldsymbol{x}}}} \le U(\bar{\boldsymbol{x}})$, it follows that $U_{min}^{AF_{\bar{\boldsymbol{x}}}} \le U_{min}^{AF^{\bar{\boldsymbol{x}}}}$.

(iii) This point follows trivially by induction from the inequality (42).

(iv) Since $\bar{\boldsymbol{x}}$ is the only point possibly added to the *AcceptedFront*,

$$U_{max}^{AF^{\bar{\boldsymbol{x}}}} \le \max\left(U_{max}^{AF_{\bar{\boldsymbol{x}}}}, U(\bar{\boldsymbol{x}})\right) \le U_{min}^{AF_{\bar{\boldsymbol{x}}}} + \frac{h}{f_1} \le U_{min}^{AF^{\bar{\boldsymbol{x}}}} + \frac{h}{f_1}. \qquad \square$$

Remark 7.4. It immediately follows from the above Lemma that if $q_2 \le q_1 + h/f_1$, then $U_{max}^{AF} \le U_{min}^{AF} + h/f_1$ at all times. Thus, if the exit time-penalty q is approximately constant on $\partial\Omega$, then the AF will be approximately a level set of U throughout the computation. Moreover, even if q is not approximately constant, the AF will still approximate a level set of U as soon as U_{min}^{AF} becomes bigger than $(q_2 - h/f_1)$.

7.1.4. Uniform Lipschitz-continuity.

LEMMA 7.5. (i) *Let* $L_1 = \eta/f_1$. *If* $\boldsymbol{x_1}$ *and* $\boldsymbol{x_2}$ *are two adjacent mesh points inside* Ω, *then*

$$|U(\boldsymbol{x_1}) - U(\boldsymbol{x_2})| \le L_1\|\boldsymbol{x_1} - \boldsymbol{x_2}\|. \tag{43}$$

(ii) *Let* $L_2 = \eta L_1$. *If* $\nabla U(\boldsymbol{x})$ *is defined for some* $\boldsymbol{x} \in \Omega\backslash\partial\Omega$ *such that* $d(\boldsymbol{x}) > h$ *(i.e.,* $\boldsymbol{x}$ *is not in a simplex immediately adjacent to* $\partial\Omega$*), then*

$$\|\nabla U(\boldsymbol{x})\| \le L_2. \tag{44}$$

(iii) *Finally, for arbitrary points* $\boldsymbol{x_1}, \boldsymbol{x_2} \in \Omega$,

$$|U(\boldsymbol{x_1}) - U(\boldsymbol{x_2})| \le L_2\|\boldsymbol{x_1} - \boldsymbol{x_2}\|. \tag{45}$$

Proof. (i) Suppose that $\boldsymbol{x_1}, \boldsymbol{x_2} \in \Omega\backslash\partial\Omega$ are two adjacent mesh points. Without loss of generality, assume that $\boldsymbol{x_1}$ was *Accepted* before $\boldsymbol{x_2}$. Thus, immediately before $\boldsymbol{x_2}$ is *Accepted*, $\boldsymbol{x_1}$ will still be on the *AcceptedFront* and

$$U(\boldsymbol{x_2}) \le \frac{\|\boldsymbol{x_1} - \boldsymbol{x_2}\|}{f(\boldsymbol{x_2}, \frac{\boldsymbol{x_1}-\boldsymbol{x_2}}{\|\boldsymbol{x_1}-\boldsymbol{x_2}\|})} + U(\boldsymbol{x_1}) \le \frac{\|\boldsymbol{x_1} - \boldsymbol{x_2}\|}{f_1} + U(\boldsymbol{x_1}) \le L_1\|\boldsymbol{x_1} - \boldsymbol{x_2}\| + U(\boldsymbol{x_1}).$$

Since U's are not necessarily *Accepted* in the ascending order, it is not generally true that $U(\boldsymbol{x_2}) \geq U(\boldsymbol{x_1})$, but from Lemma 7.3,

$$\begin{aligned} U(\boldsymbol{x_1}) &\leq U_{min}^{AF\boldsymbol{x_1}} + \frac{h}{f_1} \leq U_{min}^{AF\boldsymbol{x_2}} + \frac{h}{f_1} \leq U(\boldsymbol{x_2}) + \frac{h}{f_1} \\ &= U(\boldsymbol{x_2}) + \eta\frac{h_{min}}{f_1} \leq U(\boldsymbol{x_2}) + L_1\|\boldsymbol{x_1} - \boldsymbol{x_2}\|, \end{aligned}$$

which concludes the proof of inequality (43).

(ii) Let $\boldsymbol{x_1}, \boldsymbol{x_2}, \boldsymbol{x_3}$ be the vertices of the simplex in the mesh X which contains $\boldsymbol{x}$. Since $d(\boldsymbol{x}) > h$, we know that $\boldsymbol{x_1}$, $\boldsymbol{x_2}$, and $\boldsymbol{x_3}$ are also inside Ω, i.e., not on the boundary. Inside each simplex, U is defined by the linear interpolation, and ∇U is a constant. Whatever the direction of ∇U, a straight line parallel to it passes through one of the vertices and intersects the opposite side of the triangle. Without loss of generality, assume that that line passes through $\boldsymbol{x_1}$ and intersects the side $\boldsymbol{x_2 x_3}$ at the point $\boldsymbol{x_4}$. Since $\boldsymbol{x_4}$ lies on $\boldsymbol{x_2 x_3}$, either $(\boldsymbol{x_2} - \boldsymbol{x_1}) \cdot (\boldsymbol{x_4} - \boldsymbol{x_1}) \geq \|\boldsymbol{x_4} - \boldsymbol{x_1}\|^2$ or $(\boldsymbol{x_3} - \boldsymbol{x_1}) \cdot (\boldsymbol{x_4} - \boldsymbol{x_1}) \geq \|\boldsymbol{x_4} - \boldsymbol{x_1}\|^2$. Without loss of generality, assume the latter. Since $\|\boldsymbol{x_4} - \boldsymbol{x_1}\| \geq h_{min}$,

$$\|\nabla U\| h_{min} \leq \|\nabla U\| \|\boldsymbol{x_4} - \boldsymbol{x_1}\| = |U(\boldsymbol{x_4}) - U(\boldsymbol{x_1})| \leq |U(\boldsymbol{x_3}) - U(\boldsymbol{x_1})| \leq L_1 h.$$

Thus, $\|\nabla U\| \leq L_1 \frac{h}{h_{min}} = L_2$.

(iii) This point is obvious, since U is piecewise linear, with the slope bounded by L_2 in every simplex. □

Remark 7.6. Better estimates of L_1 and L_2 can be derived if f and q are smooth and h is sufficiently small. However, to prove the uniform convergence of U to the value function u, it is just necessary to show that some such L_2 independent of h does indeed exist. The dependence of L_2 upon η is not dangerous: if the triangulated mesh X_r does not become more and more "degenerate" as $h_r \to 0$, then η_r will be bounded.

7.2. Convergence to a viscosity solution.

THEOREM 7.7. *Consider a sequence of meshes* $\{X_r\}$ *such that* $h_r \to 0$ *but* $\eta^r = \frac{h_r}{h_{r_{min}}} < \eta$ *as* $r \to \infty$. *Let* U^r *be the approximate solution obtained on the mesh* X_r *by the algorithm described in section* 6. *As* $h_r \to 0$, U^r *uniformly converges to the viscosity solution of* (22) *(defined by the inequalities* (23) *and* (24) *in section* 3.3*).*

Proof. Since $\{U^r\}$ are bounded and uniformly Lipschitz-continuous, by the Arzela–Ascoli theorem, there exists a subsequence $\{X_p\}$ of the sequence $\{X_r\}$ such that $h_p \to 0$ as $p \to \infty$, and a function u such that $U^p \to u$ uniformly as $p \to \infty$. Boundedness and uniform continuity of u immediately follow from the properties of U^p.

(i) Consider any function $\phi \in C_c^\infty(\Omega)$, and suppose that $(u - \phi)$ has a *strict local minimum* at $\boldsymbol{x_0} \in \Omega$. Define B_δ to be the closed ball of radius δ around $\boldsymbol{x_0}$. Then there exists some $\delta > 0$ such that $B_\delta \subset \Omega$ and $\boldsymbol{x} \in B_\delta$ implies

$$(u - \phi)(\boldsymbol{x_0}) < (u - \phi)(\boldsymbol{x}). \tag{46}$$

If $D_2(\boldsymbol{x})$ is the matrix of second derivatives of $\phi(\boldsymbol{x})$, then there exists $\mu > 0$ such that $\|D_2(\boldsymbol{x})\|_2 \leq \mu$ for all $\boldsymbol{x} \in B_\delta$. Now let $\boldsymbol{x_0}^p$ be a minimum point for $(U^p - \phi)$ over B_δ; from (46) and from the uniform convergence of U^p's it follows that

$$\lim_{p \to \infty} \boldsymbol{x_0}^p = \boldsymbol{x_0}. \tag{47}$$

If $\boldsymbol{x_0}^p$ is not a mesh point of X_p and lies in the interior of some simplex s, we define $\boldsymbol{x_1}^p$ to be the vertex of s closest to it. If $\boldsymbol{x_0}^p$ lies on the edge of a simplex, we take $\boldsymbol{x_1}^p$ to be the closest endpoint of that edge; finally, we use $\boldsymbol{x_1}^p = \boldsymbol{x_0}^p$ if $\boldsymbol{x_0}^p$ is a mesh point. In any case, since ϕ is smooth and U^p is linear on every simplex, we know that $U^p(\boldsymbol{x_1}^p) - U^p(\boldsymbol{x_0}^p) = \nabla\phi(\boldsymbol{x_0}^p) \cdot (\boldsymbol{x_1}^p - \boldsymbol{x_0}^p)$ and

$$(U^p - \phi)(\boldsymbol{x_1}^p) \leq (U^p - \phi)(\boldsymbol{x_0}^p) + \frac{\mu {h_p}^2}{2}. \tag{48}$$

Moreover, using inequality (48), we obtain for every $\boldsymbol{x} \in B_\delta$

$$\begin{aligned} \phi(\boldsymbol{x}) - \phi(\boldsymbol{x_1}^p) &= (\phi(\boldsymbol{x}) - \phi(\boldsymbol{x_0}^p)) + (\phi(\boldsymbol{x_0}^p) - \phi(\boldsymbol{x_1}^p)) \\ &\leq (U^p(\boldsymbol{x}) - U^p(\boldsymbol{x_0}^p)) + \left(U^p(\boldsymbol{x_0}^p) - U^p(\boldsymbol{x_1}^p) + \frac{\mu {h_p}^2}{2} \right) = U^p(\boldsymbol{x}) - U^p(\boldsymbol{x_1}^p) + \frac{\mu {h_p}^2}{2}. \end{aligned} \tag{49}$$

Since $\|\boldsymbol{x_0}^p - \boldsymbol{x_1}^p\| \leq h_p$, it is also clear that $\lim_{p \to \infty} \boldsymbol{x_1}^p = \boldsymbol{x_0}$. So, for big enough p, $h_p \Upsilon \leq \delta$; thus, by the update formula (31), there exists $\tilde{\boldsymbol{x}}^{\boldsymbol{p}} \in AF_{\boldsymbol{x_1}^p} \bigcap B_\delta$ such that

$$U^p(\boldsymbol{x_1}^p) = \frac{\tau_p}{f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)} + U^p(\tilde{\boldsymbol{x}}^{\boldsymbol{p}}), \tag{50}$$

where $\tau_p = \|\tilde{\boldsymbol{x}}^p - \boldsymbol{x_1}^p\|$ and $\boldsymbol{a}^p = \frac{\tilde{\boldsymbol{x}}^p - \boldsymbol{x_1}^p}{\|\tilde{\boldsymbol{x}}^p - \boldsymbol{x_1}^p\|}$.

Using the smoothness of ϕ, the inequality (49), and the equality (50), we obtain

$$\begin{aligned} \nabla\phi(\boldsymbol{x_1}^p) \cdot \boldsymbol{a}^p + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)} &\leq \frac{\phi(\boldsymbol{x_1}^p + \tau_p \boldsymbol{a}^p) - \phi(\boldsymbol{x_1}^p)}{\tau_p} + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)} + \tau_p \mu \\ &\leq \frac{U^p(\boldsymbol{x_1}^p + \tau_p \boldsymbol{a}^p) - U^p(\boldsymbol{x_1}^p) + (\mu {h_p}^2/2)}{\tau_p} + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)} + \tau_p \mu \\ &= \frac{U^p(\tilde{\boldsymbol{x}}^{\boldsymbol{p}}) - U^p(\boldsymbol{x_1}^p) + \tau_p / f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)}{\tau_p} + \frac{\mu {h_p}^2}{2\tau_p} + \tau_p \mu = \frac{\mu {h_p}^2}{2\tau_p} + \tau_p \mu. \end{aligned} \tag{51}$$

Since $\tilde{\boldsymbol{x}}$ lies on the $AF_{\boldsymbol{x_1}^p}$ and $\tau_p = \|\tilde{\boldsymbol{x}}^p - \boldsymbol{x_1}^p\|$, it is at least as big as the minimal triangle height in the mesh X_p, i.e., $\tau_p \geq \frac{h_p}{\eta}$. On the other hand, $\tau_p \leq h_p \Upsilon$ because $\tilde{\boldsymbol{x}}^p \in \mathrm{NF}(\boldsymbol{x_1}^p)$. Combining these bounds with inequality (51), we see that

$$\nabla\phi(\boldsymbol{x_1}^p) \cdot \boldsymbol{a}^p + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a}^p)} \leq \mu \left(\frac{\eta}{2} + \Upsilon \right) h_p. \tag{52}$$

The sequence $\{\boldsymbol{a}^p\}$ has to have a subsequence converging to some vector $\boldsymbol{b} \in S_1$; we restrict our attention to that subsequence, but will still use the subscript p to avoid further cluttering of the notation. Now we can use the continuity of f, the smoothness of ϕ, and the uniformity of convergence of U^p to pass to a limit as $p \to \infty$ in the inequality (52):

$$\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{b} + \frac{1}{f(\boldsymbol{x_0}, \boldsymbol{b})} \leq 0 \implies (\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{b}) f(\boldsymbol{x_0}, \boldsymbol{b}) + 1 \leq 0,$$

which completes the first half of the proof, since

$$\min_{\boldsymbol{a} \in S_1} \{(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a}) f(\boldsymbol{x_0}, \boldsymbol{a})\} \leq (\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{b}) f(\boldsymbol{x_0}, \boldsymbol{b}).$$

(ii) Consider any function $\phi \in C_c^\infty(\Omega)$, and suppose that $(u-\phi)$ has a *strict local maximum* at $\boldsymbol{x_0} \in \Omega$. Define B_δ to be the closed ball of radius δ around $\boldsymbol{x_0}$. Then there exists some $\delta > 0$ such that $B_\delta \subset \Omega$ and $\boldsymbol{x} \in B_\delta$ implies

$$(u-\phi)(\boldsymbol{x_0}) > (u-\phi)(\boldsymbol{x}). \tag{53}$$

If $\nabla\phi(\boldsymbol{x_0}) = 0$, then the inequality (24) is trivially satisfied. Thus, we will further assume that $\|\nabla\phi(x)\| \geq \nu > 0$ for all $\boldsymbol{x} \in B_\delta$. If $D_2(\boldsymbol{x})$ is the matrix of second derivatives of $\phi(\boldsymbol{x})$, then there exists $\mu > 0$ such that $\|D_2(\boldsymbol{x})\|_2 \leq \mu$ for all $\boldsymbol{x} \in B_\delta$. Now let $\boldsymbol{x_0}^p$ be a maximum point for $(U^p - \phi)$ over B_δ; from (53) and from the uniform convergence of U^p's it follows that

$$\lim_{p\to\infty} \boldsymbol{x_0}^p = \boldsymbol{x_0}. \tag{54}$$

If $\boldsymbol{x_0}^p$ is not a mesh point of X_p and lies in the interior of some simplex s, we define $\boldsymbol{x_1}^p$ to be the vertex of s closest to it. If $\boldsymbol{x_0}^p$ lies on the edge of a simplex, we take $\boldsymbol{x_1}^p$ to be the closest endpoint of that edge; finally, we use $\boldsymbol{x_1}^p = \boldsymbol{x_0}^p$ if $\boldsymbol{x_0}^p$ is a mesh point. In any case, since ϕ is smooth and U^p is linear on every simplex, we know that $U^p(\boldsymbol{x_1}^p) - U^p(\boldsymbol{x_0}^p) = \nabla\phi(\boldsymbol{x_0}^p) \cdot (\boldsymbol{x_1}^p - \boldsymbol{x_0}^p)$ and

$$(U^p - \phi)(\boldsymbol{x_1}^p) \geq (U^p - \phi)(\boldsymbol{x_0}^p) - \frac{\mu {h_p}^2}{2}. \tag{55}$$

Moreover, using the inequality (55), we obtain for every $\boldsymbol{x} \in B_\delta$,

$$\begin{aligned}&\phi(\boldsymbol{x}) - \phi(\boldsymbol{x_1}^p) = (\phi(\boldsymbol{x}) - \phi(\boldsymbol{x_0}^p)) + (\phi(\boldsymbol{x_0}^p) - \phi(\boldsymbol{x_1}^p))\\ &\geq (U^p(\boldsymbol{x}) - U^p(\boldsymbol{x_0}^p)) + \left(U^p(\boldsymbol{x_0}^p) - U^p(\boldsymbol{x_1}^p) - \frac{\mu {h_p}^2}{2}\right) = U^p(\boldsymbol{x}) - U^p(\boldsymbol{x_1}^p) - \frac{\mu {h_p}^2}{2}.\end{aligned} \tag{56}$$

Since $\|\boldsymbol{x_0}^p - \boldsymbol{x_1}^p\| \leq h_p$, it is also clear that $\lim_{p\to\infty} \boldsymbol{x_1}^p = \boldsymbol{x_0}$. As proven in section 3.4,

$$\min_{\boldsymbol{a}\in S_1} \{(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a}) f(\boldsymbol{x_0}, \boldsymbol{a})\} = \min_{\boldsymbol{a}\in S_1^{\phi,\boldsymbol{x_0}}} \{(\nabla\phi(\boldsymbol{x_0}) \cdot \boldsymbol{a}) f(\boldsymbol{x_0}, \boldsymbol{a})\}. \tag{57}$$

Thus, to prove (24), we need to consider only $\boldsymbol{a} \in S_1^{\phi,\boldsymbol{x_0}}$, i.e., only $\boldsymbol{a}$ such that

$$\boldsymbol{a} \cdot \nabla\phi(\boldsymbol{x_0}) \leq -\Upsilon^{-1}\|\nabla\phi(\boldsymbol{x_0})\| \leq -\nu\Upsilon^{-1}. \tag{58}$$

Suppose that a particular $\boldsymbol{a} \in S_1^{\phi,\boldsymbol{x_0}}$ was chosen. We would like to show that, for sufficiently small h_p,

(*) *if we start at $\boldsymbol{x_1}^p$ and go some distance $\tau_p = O(h_p)$ in the direction $\boldsymbol{a}$, then we will have to intersect the $AF_{\boldsymbol{x_1}^p}$.*

If the local maximum were attained at the mesh point (i.e., the case $\boldsymbol{x_1}^p = \boldsymbol{x_0}^p$) and the test function ϕ were linear, then (*) would be almost obvious: ϕ would be linearly decreasing in the direction $\boldsymbol{a}$, and so would U^p, because of the local maximum condition, and, as we know from Lemma 7.3,

$$U^p(x) \geq U_{min}^{AF_{\boldsymbol{x_1}^p}} + \frac{h_p}{\eta f_2}$$

for every mesh point $x \in X_p$ *Accepted* after the point $\boldsymbol{x_1}^p$. Since ϕ is generally not linear and $\boldsymbol{x_1}^p \neq \boldsymbol{x_0}^p$, we will have to be more careful.

Suppose we start moving from $\boldsymbol{x_1}^p$ in the direction $\boldsymbol{a}$ for some time t_p. Using the inequality (56), the smoothness of ϕ, and the inequality (58), we obtain

$$\begin{aligned} U^p(\boldsymbol{x_1}^p + t_p\boldsymbol{a}) - U^p(\boldsymbol{x_1}^p) &\leq (\phi(\boldsymbol{x_1}^p + t_p\boldsymbol{a}) - \phi(\boldsymbol{x_1}^p)) + \frac{\mu {h_p}^2}{2} \\ &\leq \left(t_p(\nabla\phi(\boldsymbol{x_1}^p)\cdot\boldsymbol{a}) + \frac{\mu {t_p}^2}{2} \right) + \frac{\mu {h_p}^2}{2} \leq -\nu t_p \Upsilon^{-1} + \mu\frac{{h_p}^2 + {t_p}^2}{2}. \end{aligned} \tag{59}$$

In order to prove (*) we will need the following inequality to be satisfied:

$$-\nu t_p \frac{f_1}{f_2} + \mu\frac{{h_p}^2 + {t_p}^2}{2} \leq -\frac{h_p}{f_1}. \tag{60}$$

Let $t_p = Ah_p$. We will now show that the constant A can be chosen such that (60) holds for small enough h_p. Indeed, (60) can be rewritten as

$$h_p^2\left(\mu\frac{1+A^2}{2}\right) + h_p\left(\frac{1}{f_1} - \nu A\frac{f_1}{f_2}\right) \leq 0. \tag{61}$$

If A is such that $(\frac{1}{f_1} - \nu A\frac{f_1}{f_2}) > 0$, then we also have that (60) is satisfied for all $h_p \in [0, (\nu A\frac{f_1}{f_2} - f_2)\frac{2}{\mu(1+A^2)}]$. Thus, choosing any $A > (\frac{f_2^2}{\nu f_1})$, we ensure that (60) is satisfied for the sufficiently small h_p. Combining this with the inequality (59) and using the monotonicity result in Lemma 7.3, we see that

$$U^p(\boldsymbol{x_1}^p + t_p\boldsymbol{a}) \leq U^p(\boldsymbol{x_1}^p) - \frac{h_p}{f_1} \leq U_{min}^{AF_{\boldsymbol{x_1}^p}},$$

i.e., the point $(\boldsymbol{x_1}^p + t_p\boldsymbol{a})$ cannot be inside the $AF_{\boldsymbol{x_1}^p}$. Since $\boldsymbol{x_1}^p$ is inside $AF_{\boldsymbol{x_1}^p}$, that means that (*) holds: there exists some $\tau_p \in [0, t_p]$ such that

$$\tilde{\boldsymbol{x}}^{\boldsymbol{p}} = (\boldsymbol{x_1}^p + \tau_p\boldsymbol{a}) \in AF_{\boldsymbol{x_1}^p}.$$

By Lemma 7.1,

$$U^p(\boldsymbol{x_1}^p) = W^p(\boldsymbol{x_1}^p) \leq \frac{\tau_p}{f(\boldsymbol{x_1}^p, \boldsymbol{a})} + U^p(\tilde{\boldsymbol{x}}^{\boldsymbol{p}}). \tag{62}$$

The remainder of the proof is similar to what we have done to prove (i).

Using the smoothness of ϕ, the inequality (56), and the inequality (62), we obtain

$$\begin{aligned} \nabla\phi(\boldsymbol{x_1}^p)\cdot\boldsymbol{a} + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a})} &\geq \frac{\phi(\boldsymbol{x_1}^p + \tau_p\boldsymbol{a}) - \phi(\boldsymbol{x_1}^p)}{\tau_p} + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a})} - \tau_p\mu \\ &\geq \frac{U^p(\boldsymbol{x_1}^p + \tau_p\boldsymbol{a}) - U^p(\boldsymbol{x_1}^p) - (\mu {h_p}^2/2)}{\tau_p} + \frac{1}{f(\boldsymbol{x_1}^p, \boldsymbol{a})} - \tau_p\mu \\ &= \frac{U^p(\tilde{\boldsymbol{x}}^{\boldsymbol{p}}) - U^p(\boldsymbol{x_1}^p) + \tau_p/f(\boldsymbol{x_1}^p, \boldsymbol{a})}{\tau_p} - \frac{\mu {h_p}^2}{2\tau_p} - \tau_p\mu \geq -\frac{\mu {h_p}^2}{2\tau_p} - \tau_p\mu. \end{aligned} \tag{63}$$

Since $\tilde{\boldsymbol{x}}$ lies on the $AF_{\boldsymbol{x_1}^p}$ and $\tau_p = \|\tilde{\boldsymbol{x}}^p - \boldsymbol{x_1}^p\|$, it is at least as big as the minimal triangle height in the mesh X_p, i.e., $\tau_p \geq \frac{h_p}{\eta}$. On the other hand, $\tau_p \leq t_p = Ah_p$, where A is a constant chosen for this particular ϕ, but independent of h_p. Combining these bounds with inequality (63), we see that

$$\nabla\phi(\boldsymbol{x_1}^p)\cdot\boldsymbol{a}+\frac{1}{f(\boldsymbol{x_1}^p,\boldsymbol{a})}\geq-\mu\left(\frac{\eta}{2}+A\right)h_p. \tag{64}$$

We can now use the continuity of f, the smoothness of ϕ, and the uniformness of convergence of U^p to pass to a limit as $p\to\infty$ in the inequality (64):

$$\nabla\phi(\boldsymbol{x_0})\cdot\boldsymbol{a}+\frac{1}{f(\boldsymbol{x_0},\boldsymbol{a})}\geq 0 \implies (\nabla\phi(\boldsymbol{x_0})\cdot\boldsymbol{a})f(\boldsymbol{x_0},\boldsymbol{a})+1\geq 0,$$

which completes the proof of inequality (24), since $\boldsymbol{a}$ was chosen to be an arbitrary vector in $S_1^{\phi,\boldsymbol{x_0}}$.

In this proof we have several times passed to a subsequence. If some other subsequence of U^r converges to a different limit $\bar{u}$, the above argument could be repeated for that subsequence to prove that $\bar{u}$ also satisfies (23) and (24). The uniqueness of the viscosity solution (proven in [10, 9]) implies $u=\bar{u}$; thus, the entire sequence U^r converges to u uniformly as $r\to\infty$. □

7.3. Additional comments. First, the above proof of convergence, as well as the preceding lemmas, can be easily repeated for the corresponding method in higher dimensions. Moreover, if the update formula (31) in the description of the method is replaced by any other update-from-a-single-simplex formula such that

1. the update formula is consistent (converges to the PDE as $h\to 0$),
2. the update formula is upwinding (the update is computed/accepted only from the simplex, which contains the characteristic direction), and
3. the update formula is stable (there exists a uniform bound for U),

then the resulting numerical solutions should converge to the viscosity solution of the Hamilton–Jacobi–Bellman PDE. This conjecture is the basis for the methods based on finite-difference discretization discussed in section 8.2.

Second, the above proof uses the continuity of the speed function f, but not the Lipschitz-continuity. Thus, if the viscosity solution can be defined for $f\in C(\Omega)$, then the above proof will still be valid. The majority of the control-theoretic papers to which we are referring in this work require the speed of motion f (or, equivalently, the running cost K) to be Lipschitz-continuous. Nevertheless, the value function u can be defined for a much broader class of control problems, including those for which f is discontinuous. Some examples of our method applied to such problems can be found in section 9.4. Numerical evidence confirms that the method described above works correctly in that more general case. This is not surprising, since Bellman's optimality principle is valid even when the speed $f(\boldsymbol{x},\boldsymbol{a})$ is very ill-behaved, and our numerical methods merely mimic the logic of that principle.

8. Front propagation problems and OUMs. Anisotropic aspects of front propagation have been studied in several different contexts, including geometric optics, geophysics, tomography, and crystal growth; our primary emphasis is on an application-neutral analysis, concentrating on the properties of the particular class of static Hamilton–Jacobi PDEs. We begin with the correspondence between anisotropic optimal trajectory problems and a class of anisotropic front expansion (contraction) problems described in section 8.1. Our goal is to determine a set of the anisotropic front expansion (contraction) problems, which can be solved efficiently by our semi-Lagrangian OUM, and to construct a family of OUMs based on fully Eulerian discretizations.

8.1. Front propagation problems: Static Hamilton–Jacobi approach. Consider a simple curve Γ_t moving in R^2 in the direction normal to itself with some speed $F(\boldsymbol{x}, \boldsymbol{n})$, where $\boldsymbol{n}$ is an "outwards pointing" unit vector normal to the curve as it passes through the point $\boldsymbol{x}$. If the curve is not smooth, then $\boldsymbol{n}$ is not defined, but a geometric construction based on a variant of Huygens' principle can still be used to define the evolution of Γ_t. An important subclass of the front propagation problems consists of applications in which the speed function F never changes sign. If the function F is strictly positive (or negative), then the front always expands (or contracts). This implies that the front passes through each point only once. Thus, we can define $u(\boldsymbol{x})$ to be the arrival time: $u(\boldsymbol{x}) = t \iff \boldsymbol{x} \in \Gamma_t$. If F is always nonnegative, the outwards unit normal vector can be expressed as $\boldsymbol{n}(\boldsymbol{x}) = \frac{\nabla u(\boldsymbol{x})}{\|\nabla u(\boldsymbol{x})\|}$ and, assuming that $\boldsymbol{n}(\boldsymbol{x})$ is always defined, it is straightforward to show that the arrival time u satisfies the PDE

$$\|\nabla u(\boldsymbol{x})\| F\left(\boldsymbol{x}, \frac{\nabla u(\boldsymbol{x})}{\|\nabla u(\boldsymbol{x})\|}\right) = 1, \tag{65}$$

$$u = 0 \text{ on } \Gamma_0.$$

This is a static Hamilton–Jacobi PDE of the form $H(\nabla u, \boldsymbol{x}) = 1$, where the Hamiltonian H is homogeneous of degree one in the first argument. To interpret (65) where ∇u does not exist, one normally uses the unique viscosity solution, as defined in [9, 10]. As follows from the results in [14] and [41], the level sets of the viscosity solution u of (65) will correspond to the evolution of Γ_0 defined by Huygens' principle.

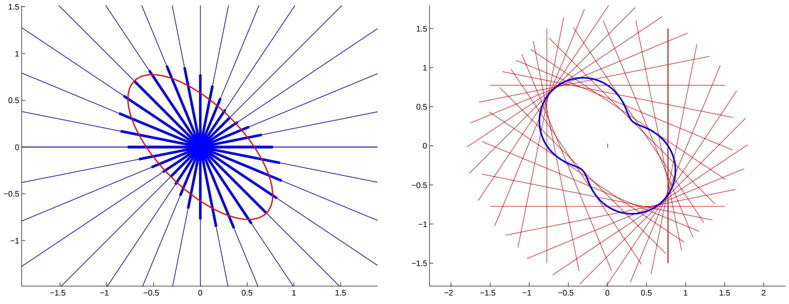
We note that, in general, the Hamiltonian $H(\nabla u, \boldsymbol{x}) = \|\nabla u\| F(\boldsymbol{x}, \frac{\nabla u}{\|\nabla u\|})$ is not convex. As shown in [14], such $H(\nabla u, \boldsymbol{x})$ can always be considered as a result of a differential game model. Several iterative numerical schemes are based on this approach (see [4] or [16], for example). However, if H is convex, it can be alternatively considered as a product of a dual min-time optimal control problem [41]. Using two interpretations of the Hamiltonian, we can show that the speeds F and f are related by a homogeneous Legendre transform:

$$F(\boldsymbol{x}, \boldsymbol{n}) = \max_{\boldsymbol{a} \in S_1} \{(\boldsymbol{n} \cdot (-\boldsymbol{a})) f(\boldsymbol{x}, \boldsymbol{a})\}, \tag{66}$$

$$f(\boldsymbol{x}, \boldsymbol{a}) = \min_{\boldsymbol{n} \in S_1,\, (\boldsymbol{n} \cdot \boldsymbol{a}) < 0} \left\{ \frac{F(\boldsymbol{x}, \boldsymbol{n})}{(-\boldsymbol{n} \cdot \boldsymbol{a})} \right\}. \tag{67}$$

Remark 8.1. We note that $F(\boldsymbol{x}, \boldsymbol{n})$ is the speed of the front's movement in the direction normal to itself (here, $\boldsymbol{n} = \frac{\nabla u(\boldsymbol{x})}{\|\nabla u(\boldsymbol{x})\|}$), whereas $f(\boldsymbol{x}, \boldsymbol{a})$ is the speed of the vehicle's motion in the direction $\boldsymbol{a}$. Correspondingly, the correct $\boldsymbol{n}$ is fully determined by the gradient direction of the function $u(\boldsymbol{x})$, while the optimal $\boldsymbol{a} \in S_1$ is determined by the direction of the characteristic passing through the point $\boldsymbol{x}$ and, therefore, is a function of the particular Hamilton–Jacobi–Bellman equation. In the isotropic case, however, there is no difference since (66) yields $f(\boldsymbol{x}) = F(\boldsymbol{x})$.

Define the vehicle's speed profile $S_f(\boldsymbol{x}) = \{\boldsymbol{a} f(\boldsymbol{x}, \boldsymbol{a}) \mid \boldsymbol{a} \in S_1\}$, its flipped (center symmetry applied) version $S_{-f}(\boldsymbol{x}) = \{-\boldsymbol{a} f(\boldsymbol{x}, \boldsymbol{a}) \mid \boldsymbol{a} \in S_1\}$, and the front propagation speed profile $S_F(\boldsymbol{x}) = \{\boldsymbol{n} F(\boldsymbol{x}, \boldsymbol{n}) \mid \boldsymbol{n} \in S_1\}$. The formulas (66) and (67) can now be



(a) (b)

FIG. 4. (a) *Using S_f to construct S_F;* (b) *using S_F to construct S_f.*

interpreted geometrically:[11]

— $F(\boldsymbol{x}, \boldsymbol{n})$ can be obtained by projecting $S_{-f}(\boldsymbol{x})$ onto a unit vector $\boldsymbol{n}$ and then by taking the maximum of this (signed) projection (see Figure 4(a));

— $S_{-f}(x)$ can be obtained as an envelope of lines perpendicular to $\boldsymbol{n}$ drawn at every point of $S_F(x)$ (see Figure 4(b)).

By the above construction, S_f is always convex. Thus, different optimal trajectory problems will yield the same Hamilton–Jacobi–Bellman equation, provided that the speed profiles have the same convex hull.[12] See [30] and the references therein for an additional discussion of Wulff shapes and mutual properties of functions related by the homogeneous Legendre transform.

Finally, we note that the correspondence between these two types of anisotropic problems can be used to build an alternative definition of Huygens' principle: using scaled speed profiles S_{-f} at each point of the wavefront instead of the circles of front-direction-dependent radius; see [14], [40], or [46].

8.2. OUMs for Eulerian discretizations. Given $0 < F_1 \leq F(\boldsymbol{x}, \boldsymbol{n}) < F_2$ for all $\boldsymbol{x}$ and $\boldsymbol{n}$, we can use the formula (67) to prove that $0 < F_1 = f_1 \leq f(\boldsymbol{x}, \boldsymbol{a}) < f_2 = F_2$ for all $\boldsymbol{x}$ and $\boldsymbol{a}$. Thus, the corresponding control problem can be treated by the OUMs with the semi-Lagrangian update formula described in section 6.

We now proceed to construct the OUMs for the fully Eulerian approximation of $\|\nabla u\| F(\boldsymbol{x}, \frac{\nabla u}{\|\nabla u\|}) = 1$. The key idea is that any consistent upwind finite difference discretization can be used to compute an update-from-a-single-simplex $V_{\boldsymbol{x_j}, \boldsymbol{x_k}}(\boldsymbol{x})$. Our derivation of such discretizations generalizes the approach used in defining the Fast Marching Method on unstructured meshes given in [38].

[11] In wave physics, $F(\boldsymbol{x}, \boldsymbol{n})$ corresponds to the *"phase velocity"* if $\boldsymbol{n}$ is the direction normal to the wavefront [11]. In crystalline variational problems, $F(\boldsymbol{x}, \boldsymbol{n})$ corresponds to the *"surface free energy"* if $\boldsymbol{n}$ is the direction normal to the surface [43]. Additionally, $f(\boldsymbol{x}, \boldsymbol{a})$ corresponds to the *"group velocity,"* i.e., the speed with which a blob of energy is moving in the direction $\boldsymbol{a}$ [11]. Finally, this speed profile is often referred to as a *"ray surface"* or *"impulse-response surface"* [11, 31]. The corresponding object in crystalline variational problems is the *"Wulff shape"*—the shape which minimizes the free surface energy for a fixed volume with no additional constraints [43].

[12] Similar geometric construction is common in tomography; the formulas (67) and (66) are related to the *inverse Radon transform* [20]. Analytic expressions for F in terms of f and for f in terms of F can be easily derived for R^2 (see [30, 46], for example). Similar formulas expressing the relationship between the *group speed* and the *phase speed* were known in wave physics [28] at least as early as 1837.

8.2.1. Upwind finite-difference discretization. Consider an unstructured triangulated mesh X of diameter h (i.e., if the mesh points $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ are adjacent, then $\|\boldsymbol{x_j} - \boldsymbol{x_k}\| \leq h$). Let $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$ be two adjacent mesh points and choose some other mesh point $\boldsymbol{x} \in \Omega\backslash\partial\Omega$. Define the unit vectors $\boldsymbol{P_1} = \frac{\boldsymbol{x}-\boldsymbol{x_j}}{\|\boldsymbol{x}-\boldsymbol{x_j}\|}$ and $\boldsymbol{P_2} = \frac{\boldsymbol{x}-\boldsymbol{x_k}}{\|\boldsymbol{x}-\boldsymbol{x_k}\|}$. Assume that $\boldsymbol{P_1}$ and $\boldsymbol{P_2}$ are linearly independent, and consider the 2×2 nonsingular matrix P having $\boldsymbol{P_1}$ and $\boldsymbol{P_2}$ as its rows. Let $v_r(\boldsymbol{x})$ be the value of the directional derivative for the direction $\boldsymbol{P_r}$ evaluated at the point $\boldsymbol{x}$. Assuming that the function u is differentiable at $\boldsymbol{x}$, we have $P\nabla u(\boldsymbol{x}) = \boldsymbol{v}(\boldsymbol{x})$, where $\boldsymbol{v}(\boldsymbol{x}) = \left[\begin{smallmatrix} v_1(\boldsymbol{x}) \\ v_2(\boldsymbol{x}) \end{smallmatrix}\right]$. Recall that the front propagation equation (65) can be written as $\|\nabla u(\boldsymbol{x})\|^2 F^2(\boldsymbol{x}, \frac{\nabla u(\boldsymbol{x})}{\|\nabla u(\boldsymbol{x})\|}) = 1$, which can be restated in terms of $\boldsymbol{v}(\boldsymbol{x})$:

$$\boldsymbol{v}(\boldsymbol{x})^T (PP^T)^{-1} \boldsymbol{v}(\boldsymbol{x}) F^2 \left(\boldsymbol{x}, \frac{P^{-1}\boldsymbol{v}(\boldsymbol{x})}{\|P^{-1}\boldsymbol{v}(\boldsymbol{x})\|}\right) = 1. \tag{68}$$

To obtain the discretized equation, we now replace each v_r with a difference approximation: $v_r(\boldsymbol{x}) \approx w_r \equiv a_r U + b_r$, where the b_r's linearly depend on the values of U (and possibly of ∇U for higher-order schemes) at the mesh points $\boldsymbol{x_j}$ and $\boldsymbol{x_k}$.

Remark 8.2. In general, the choice of the difference approximation will depend upon the structure of the mesh and will also affect the rate of convergence of the method. The simplest first-order finite-difference approximation is obtained by choosing

$$a_1 = \frac{1}{\|\boldsymbol{x} - \boldsymbol{x_j}\|}, \quad b_1 = \frac{-U(\boldsymbol{x_j})}{\|\boldsymbol{x} - \boldsymbol{x_j}\|}, \quad a_2 = \frac{1}{\|\boldsymbol{x} - \boldsymbol{x_k}\|}, \quad b_2 = \frac{-U(\boldsymbol{x_k})}{\|\boldsymbol{x} - \boldsymbol{x_k}\|}.$$

Higher-order accurate operators can be built using the computed value for ∇U at the mesh points (see [38, 46] for further details).

For convenience, let $Q = (PP^T)^{-1}$ and use $\boldsymbol{v}(\boldsymbol{x}) \approx \boldsymbol{w}(\boldsymbol{x}) = V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})\boldsymbol{a} + \boldsymbol{b}$. Then the discretized version of (68) can be used as an equation for the upwind-update-from-a-single-simplex $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$:

$$\left((\boldsymbol{a}^T Q \boldsymbol{a})(V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}))^2 + (2\boldsymbol{a}^T Q \boldsymbol{b}) V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}) + (\boldsymbol{b}^T Q \boldsymbol{b})\right) F^2 \left(\boldsymbol{x}, \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|}\right) = 1. \tag{69}$$

Remark 8.3. In the isotropic case, the analogous equation was just a quadratic (see the appendix and [38]). Equation (69) is a more complex nonlinear equation since $\boldsymbol{w}(\boldsymbol{x})$ also depends on $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$. In general, this equation will have to be solved approximately, and the overall efficiency of the method will also depend on the iterative numerical method used to solve (69). Since these iterations are generally unavoidable, we will consider solving this equation as a single operation in the further analysis of computational complexity. We note that the iterative zero-finding required to compute $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ is *local* (i.e., $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ can be computed independently from any other $V_{\boldsymbol{x_i},\boldsymbol{x_l}}(\boldsymbol{x_m})$) and thus should not be confused with the iterations necessary to solve a coupled system of nonlinear equations (such as (25)) simultaneously.

8.2.2. Upwinding criterion and combined update formula. We need to ensure that the value of $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ computed from (69) is truly upwind, i.e., that the characteristic for the mesh point $\boldsymbol{x}$ lies inside the simplex $\boldsymbol{x}\boldsymbol{x_j}\boldsymbol{x_k}$. The approximate gradient $P^{-1}(V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})\boldsymbol{a} + \boldsymbol{b})$ can be used to compute an approximation to the characteristic direction $\boldsymbol{a}(\boldsymbol{x})$. For R^n, the requirement that the characteristic direction should point into the simplex $\boldsymbol{x}\boldsymbol{x_1}\ldots\boldsymbol{x_n}$ is equivalent to the condition that all the elements of the vector $(P^T)^{-1}\boldsymbol{a}(\boldsymbol{x})$ should be positive.

The unfortunate feature of this upwinding criterion is that it is based on the approximate rather than the exact characteristic direction. Due to the approximation error, it is possible that an upwinding criterion will not be satisfied even though the true characteristic for the mesh point $\boldsymbol{x}$ lies inside the simplex $\boldsymbol{x}\boldsymbol{x_j}\boldsymbol{x_k}$. If that simplex is small enough, this can happen only when one of the elements of the vector $(P^T)^{-1}\boldsymbol{a}(\boldsymbol{x})$ is close to zero, i.e., only when the characteristic direction almost coincides with $(-\boldsymbol{P_1})$ or $(-\boldsymbol{P_2})$. That corresponds to the situation in which $U(\boldsymbol{x})$ can be computed based on either $U(\boldsymbol{x_j})$ or $U(\boldsymbol{x_k})$. Thus, we define the "one-sided-update" formula in a manner consistent with the control-theoretic perspective:

$$V_{\boldsymbol{x_i}}(\boldsymbol{x}) = \frac{\|\boldsymbol{x_i}-\boldsymbol{x}\|}{f(\boldsymbol{x}, \frac{\boldsymbol{x_i}-\boldsymbol{x}}{\|\boldsymbol{x_i}-\boldsymbol{x}\|})} + U(\boldsymbol{x_i}). \tag{70}$$

Therefore, the final formula for the upwind-update-from-a-single-simplex becomes

(71)

$$V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x}) = \begin{cases} \text{solution of (69)} & \text{if } \boldsymbol{P_1} \text{ and } \boldsymbol{P_2} \text{ are linearly independent} \\ & \text{and the upwinding criterion is satisfied,} \\ \min(V_{\boldsymbol{x_j}}(\boldsymbol{x}),\, V_{\boldsymbol{x_k}}(\boldsymbol{x})) & \text{otherwise.} \end{cases}$$

Using the finite-difference update formula (71) instead of the formula (31) in the algorithm described in section 6, we obtain a new OUM for solving the front expansion problem (Hamilton–Jacobi equation (65)). In fact, this defines a whole family of such methods, since different upwind finite-difference operators can be used to approximate $w_r(\boldsymbol{x})$ in (68).

We note that the resulting methods

- are single-pass and have the same computational complexity as the semi-Lagrangian OUM introduced in section 6,
- work equally well on acute and nonacute triangulated meshes,
- are applicable for a general anisotropic optimal trajectory problem described in section 3,
- can be easily extended to R^n and manifolds. (The generalizations of the mapping $\boldsymbol{n} \mapsto \boldsymbol{a}$, of (68), and of the upwinding criterion are obvious.)

Remark 8.4 (Convergence). In the appendix, we show the connection between a particular first-order Eulerian OUM (based on Remark 8.2) and the first-order semi-Lagrangian OUM (introduced in section 6); in this case, the convergence to the viscosity solution follows from section 7. However, as of right now, we do not have a proof of convergence for the general (higher-order) OUMs based on the Eulerian discretization. We rely on general convergence considerations (see the remarks following the proof of Theorem 7.7) and on the numerical evidence (section 9.4 and [39, 46]). In all of our numerical experiments the numerical solution U produced by these methods converges to the viscosity solution of the original PDE. The rate of convergence depends on the particular finite-difference operators used to approximate $w_r(\boldsymbol{x})$ in (68).

9. Implementation and numerical results.

9.1. Implementation notes. An efficient implementation of the described numerical methods for the anisotropic optimal-trajectory and front-propagation problems requires dealing with several algorithmic issues. Storing and sorting the current

AcceptedFront, for example, has to be implemented rather carefully to enable efficient search for the "*AcceptedFront* neighborhood" $\mathrm{NF}(\boldsymbol{x})$ for every *Considered* point $\boldsymbol{x}$. The inverse operation (searching for all *Considered* $\boldsymbol{x}$ such that $\bar{\boldsymbol{x}} \in \mathrm{NF}(\boldsymbol{x})$) is another major component of the implementation. Efficient use of data structures allows us to construct an algorithm with the computational complexity of $O(\Upsilon M \log M)$.

The connection between a particular class of anisotropic front-propagation and optimal-trajectory problems allows us to build both semi-Lagrangian and fully Eulerian single-pass methods. On a fixed mesh X, the computational complexity of these methods will be the same. However, the overall efficiency of each program will be affected by the chosen upwind-update-from-a-single-simplex formula. The optimal choice depends on the particular speed functions F and f and on the details of implementation: the semi-Lagrangian method requires performing a local minimization at each mesh point (using (31)), whereas the finite-differences upwind update formula requires finding the roots of the nonlinear equation (69). Generally, both the minimization and the root-finding have to be done approximately, and the overall efficiency depends on the particular numerical method used to compute the approximate update. Our implementations used the "golden section search" and the Newton–Raphson method to numerically resolve the control-theoretic and finite-difference update formulas, respectively; the implementation details of these and other numerical minimization and zero-finding techniques can be found in [42].

We note that the above complexity and efficiency discussion is limited to finding a numerical solution on a fixed grid. The speed of convergence (of the numerical approximation $U(\boldsymbol{x})$ to the viscosity solution $u(\boldsymbol{x})$ as the grid is refined) is a separate issue. Thus, the availability of the higher-order accurate upwind update formulas is a significant advantage of the Eulerian approach.

9.2. Using a local anisotropy coefficient. So far we have always used the global bounds on the speed function $0 < F_1 \leq F(\boldsymbol{x}, \boldsymbol{p}) \leq F_2$ for all $\boldsymbol{p}$ and $\boldsymbol{x}$. We now define the local bounds on F,

$$F_1(\boldsymbol{x}) = \min_{\boldsymbol{p} \in S_1} F(\boldsymbol{x}, \boldsymbol{p}), \qquad F_2(\boldsymbol{x}) = \max_{\boldsymbol{p} \in S_1} F(\boldsymbol{x}, \boldsymbol{p}),$$

and the local anisotropy coefficient $\Upsilon(\boldsymbol{x}) = \frac{F_2(\boldsymbol{x})}{F_1(\boldsymbol{x})}$.

We note that many of the lemmas stated in section 3 for $u(\boldsymbol{x})$ in terms of F_1 and F_2 can be restated in terms of $F_1(\boldsymbol{x})$ and $F_2(\boldsymbol{x})$. Most importantly, this is true for Remark 3.7, which establishes a bound on the angle between the characteristic and gradient directions. Thus, it is also possible to build the numerical method using $\Upsilon(\boldsymbol{x})$ instead of Υ in the definition of $\mathrm{NF}(\boldsymbol{x})$. Moreover, if F is smooth and the maximum/minimum in defining $F_1(\boldsymbol{x})$ and $F_2(\boldsymbol{x})$ are taken not just at the point but over some closed ball B centered at $\boldsymbol{x}$, then the resulting algorithm provably converges to the viscosity solution. (Indeed, for small enough h, $\mathrm{NF}(\boldsymbol{x}) \subset B$ even if $NF(\boldsymbol{x})$ were defined using the global anisotropy coefficient Υ.)

This observation leads to a substantially more efficient algorithm since the global anisotropy coefficient Υ can be much larger than $\sup_{\boldsymbol{x} \in \Omega} \Upsilon(\boldsymbol{x})$ for the front propagating in a strongly inhomogeneous medium.

9.3. Heuristic: Relaxing the update procedure. In the algorithm described in section 6, there are two different situations in which the tentative value $V(\boldsymbol{x})$ is recomputed for a *Considered* point $\boldsymbol{x}$:

- $V(\boldsymbol{x})$ is first computed using the entire $\mathrm{NF}(\boldsymbol{x})$ at the moment when $\boldsymbol{x}$ is added to *Considered*;

- $V(\boldsymbol{x})$ is then recalculated from at most two simplexes every time the newly *Accepted* mesh point $\bar{\boldsymbol{x}}$ belongs to $\mathrm{NF}(\boldsymbol{x})$.

If the boundary condition for the PDE is nearly constant (i.e., if $q_2 \leq q_1 + h/f_1$, where h is the diameter of the triangulated mesh), Lemma 7.3 shows that the AF will also approximate the level set throughout the execution of the algorithm. On the other hand, Lemma 3.4 shows that the optimal trajectory for $\boldsymbol{x}$ intersects a level set at some point $\tilde{\boldsymbol{x}}$ such that $\|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq d_1 \Upsilon$, where d_1 is the distance from $\boldsymbol{x}$ to that level set. This means that if AF were exactly the level set, the initial evaluation of $V(\boldsymbol{x})$ would capture all the necessary information about all the potential characteristic directions for $\boldsymbol{x}$; thus, the further reevaluations of $V(\boldsymbol{x})$ would not be necessary. Since AF is only approximating the level set, capturing all the necessary directions requires "widening" the set $\mathrm{NF}(\boldsymbol{x})$. Carefully combining Lemmas 7.3 and 3.4, and assuming $U \approx u$ on AF, we can show that all the characteristic directions are still covered if $\mathrm{NF}(\boldsymbol{x})$ is taken to be two times "wider":

$$\widehat{\mathrm{NF}}(\boldsymbol{x}) \;=\; \{\boldsymbol{x_j x_k} \in AF \;\mid \exists \tilde{\boldsymbol{x}} \text{ on } \boldsymbol{x_j x_k} \text{ s.t. } \|\tilde{\boldsymbol{x}} - \boldsymbol{x}\| \leq 2h\Upsilon(\boldsymbol{x})\}\,.$$

This still leads to the total of roughly 2Υ evaluations of V_s for each mesh point, but it is no longer necessary to search for all *Considered* $\boldsymbol{x}$ such that $\bar{\boldsymbol{x}} \in \mathrm{NF}(\boldsymbol{x})$ each time a new $\bar{\boldsymbol{x}}$ is *Accepted*.[13]

Furthermore, an additional update relaxation can be used with the Eulerian discretization-based methods if the boundary condition for the PDE is nearly constant. In the initial computation of $V(\boldsymbol{x})$ it is often not necessary to consider the entire $\mathrm{NF}(\boldsymbol{x})$: we can stop as soon as we find $\boldsymbol{x_j x_k} \in \mathrm{NF}(\boldsymbol{x})$ such that $V_{\boldsymbol{x_j},\boldsymbol{x_k}}(\boldsymbol{x})$ satisfies the upwinding conditions (see section 8.2.2). The viscosity solution u of the Hamilton–Jacobi PDE is Lipschitz-continuous, and therefore ∇u exists almost everywhere. As shown in [46], if u is differentiable at the point $\boldsymbol{x}$ and the vehicle's speed profile $S_f(\boldsymbol{x})$ is strictly convex, then there exists a unique optimizing control $\boldsymbol{a}(\boldsymbol{x})$. Thus, away from the shocks, there should not be multiple simplexes in $\mathrm{NF}(\boldsymbol{x})$ producing updates which satisfy the upwinding criteria.

For a fixed grid X, the numerical evidence suggests that the "relaxation" significantly improves efficiency of the program. As the grid is refined, the numerical solution obtained by the "relaxed" scheme converges to the viscosity solution—sometimes slower, but often (depending on the type of anisotropy) even faster than the solution computed by the "full-update" scheme. However, the *asymptotic order of accuracy* of the "relaxed" and "full-update" schemes seems to be the same in all of our numerical experiments (e.g., see section 9.4.1).

9.4. Numerical experiments.

In this section we consider several test problems, each of which can be described by a non-Eikonal (anisotropic) Hamilton–Jacobi PDE. In each case, the speed function is assumed to be known from the characterization of a particular application domain. For example, in the optimal-trajectory test problem, $f(\boldsymbol{x}, \boldsymbol{a})$ reflects the assumptions about the speed of the controlled vehicle, while in the seismic imaging test problem, the front-expansion speed F is derived using the assumptions about the elliptical nature of the "impulse-response surface" for the anisotropic medium.

9.4.1. Geodesic distances on manifolds.

The first test problem is to find the geodesic distance on a manifold $z = g(x, y)$. As described in [21] and [36], this can

[13] The numerical experiments indicate that a much smaller "widening" of *NF* is sufficient in practice.

be accomplished by approximating the manifold with a triangulated mesh and then solving the distance equation $\|\nabla u\| = 1$ on that mesh. Since the latter equation is Eikonal, the Fast Marching Method can be used to solve it efficiently. However, if one desires to formulate the problem in the $x-y$ plane instead of the intrinsic manifold coordinates, then the corresponding equation for u is not Eikonal. Indeed, in the $x-y$ plane, the manifold's geodesic distance function u has to satisfy (65) with the speed function F defined as

$$F(x, y, \omega) = \sqrt{\frac{1 + g_y^2 \cos^2(\omega) + g_x^2 \sin^2(\omega) - g_x g_y \sin(2\omega)}{1 + g_x^2 + g_y^2}}, \tag{72}$$

where ω is the angle between $\nabla u(x, y)$ and the positive direction of the x-axis. The degree of anisotropy in this equation is substantial, since the dependence of F upon ω can be pronounced when ∇g is relatively large.[14]

As shown in section 8.1, u can also be considered as a value function for the corresponding min-time optimal-trajectory problem and must, therefore, satisfy (22). The vehicle's speed function $f(x, y, \boldsymbol{a})$ can be defined by applying (67) to the speed of front propagation $F(x, y, \omega)$. However, it is even easier to obtain f from the control-theoretic considerations. If the vehicle moving with speed $f(x, y, \boldsymbol{a})$ in the x-y plane is just a shadow of another vehicle moving with a unit speed on the manifold, then this vehicle's speed profile is just an orthogonal projection of a unit circle from the manifold's tangent plane onto the x-y plane, i.e.,

$$f(x, y, \boldsymbol{a}) = (1 + (\nabla g(x, y) \cdot \boldsymbol{a})^2)^{-\frac{1}{2}}, \tag{73}$$

where $\boldsymbol{a}$ is a vector of unit length and f is the control-theoretic speed of motion in the direction $\boldsymbol{a}$ (see section 3.1 and section 8.1 for details).

As an example, we consider the manifold $g(x, y) = .9 \sin(2\pi x) \sin(2\pi y)$ and compute the geodesic distance on it from the origin. The *anisotropy coefficient* for this problem is $\Upsilon = \frac{F_2}{F_1} = \sqrt{100 + 324\pi^2}/10 \approx 5.7$. Since the analytical solution is not available, we use the results of the tested method on the mesh with 385×385 mesh points as an estimate of the "true" value function. This estimate is used to perform the convergence analysis on coarser regular meshes in the x-y plane for the following:

M1: iterative solution to the first-order semi-Lagrangian scheme (25),
M2: OUM based on the first-order semi-Lagrangian scheme (section 6),
M3: same as M2, but with the "relaxed update" (section 9.3),
M4: OUM based on the first-order finite-differences scheme (section 8).

See Figure 5 for the level sets of the value function and for the table of error estimates.

9.4.2. First arrivals in inhomogeneous anisotropic medium. Finally, we include an example of the first arrival travel times computation with applications to seismic imaging. We start with a computational domain which suggests material layering under a sinusoidal profile. The computational domain is the square $[-a, a] \times [-a, a]$, with layer shapes

$$C(x) = A \sin\left(\frac{m\pi x}{a} + \beta\right), \tag{74}$$

where A is the amplitude of the sinusoidal profile, m is the number of periods, and β is the phase offset. The domain is split into n layers by the curves $y_i(x) = C(x) + b_i$, where $i = 1, \ldots, (n - 1)$.

[14] The algorithm presented in [21] using the manifold-approximating mesh is certainly more efficient for this problem; here, it serves as a convenient test problem for the general anisotropic OUMs.

FIG. 5. *The geodesic distance from the origin on the surface* $z = .9\sin(2\pi x)\sin(2\pi y)$ *computed on the square* $[-.5, .5] \times [-.5, .5]$ *in the x-y plane. The error estimates were produced on refined meshes taking the corresponding method on a* 385^2 *mesh to be the true solution (hence the seemingly higher-than-first-order rate at the end).*

In each layer, the anisotropic speed profile S_f is given at every point (x, y) by an ellipse with the bigger axis (of length $2F_2$) tangential to the curve $C(x)$ and the smaller axis (of length $2F_1$) normal to the curve. F_1 and F_2 are constants in each layer. Thus, the ellipse's orientation and shape depend on (x, y).

This leads to an anisotropic Hamilton–Jacobi equation of the form

$$\|\nabla u(x, y)\|F = 1, \qquad u(0, 0) = 0, \tag{75}$$

where the front propagation speed at every point (x, y) is given by the formula

$$F(x, y, u_x, u_y) = F_2 \left(\frac{(1 + q^2)u_x^2 + (1 + p^2)u_y^2 - 2pqu_xu_y}{(1 + p^2 + q^2)(u_x^2 + u_y^2)} \right)^{1/2}, \tag{76}$$

with

$$\begin{bmatrix} p \\ q \end{bmatrix} = \frac{\sqrt{(\frac{F_2}{F_1})^2 - 1}}{\sqrt{1 + \left(\frac{dC}{dx}(x)\right)^2}} \begin{bmatrix} \frac{dC}{dx}(x) \\ -1 \end{bmatrix}.$$

Formula (76) is derived using the the elliptical shape of $S_f(x, y)$ and applying formula (66) of section 8.1.

These calculations are performed using the OUMs with the control-theoretic and finite-difference formulas for computing an update-from-a-single-simplex. Both methods produce numerical solutions converging to the value function of the corresponding min-time optimal trajectory problem.

The equi-arrival curves shown in Figure 6 are obtained on a 193 × 193 regular mesh using the following parameter values:

$$a = .5, \quad A = .1225, \quad m = 2, \quad \beta = 0, \quad \text{and layer offsets } b_i = (-.25, 0, 0.25).$$

The max/min speed pair (F_2, F_1) for each layer is given in the figures. We note that in one of these examples the global *anisotropy coefficient* $\Upsilon = \frac{3}{.2} = 15$.

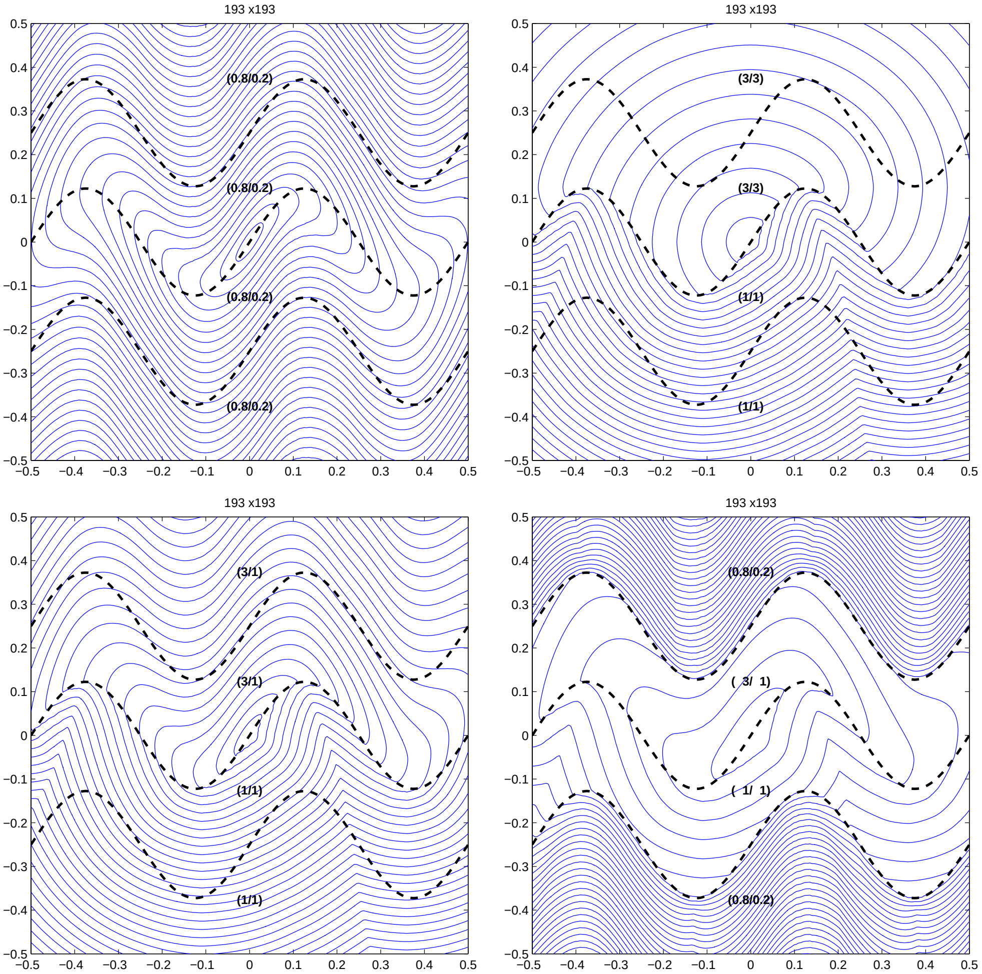

FIG. 6. *Seismic imaging test problem: equi-arrival curves in an inhomogeneous, multilayer medium.*

Remark 9.1. Since the speed function F is discontinuous across the layer boundaries, the standard viscosity solution results for the Hamilton–Jacobi–Bellman equation [10, 9] are not directly applicable. Thus, our proof of convergence in section 7 is not valid in this case either. Nevertheless, the produced numerical solutions seem to converge to the true value function of the corresponding control problem. This is not surprising since our methods are based on approximating Bellman's optimality principle, which is valid for a value function u under much more general assumptions about the speed (or the cost) of motion.

9.5. Conclusions. The methods presented in this paper are applicable for the static Hamilton–Jacobi–Bellman PDEs with convex Hamiltonian and finite speed function bounded away from zero (see [46] for additional background information and details of the proofs). We are currently working on extending these OUMs to a wider class of problems including treatment of nonconvex Hamiltonians, discontinuous speed functions, degenerate speed profiles (i.e., $f_1 = 0$), and stochastic control. We also note that parallelizable single-pass methods based on the same upwinding techniques may be built extending the ideas behind Dial's algorithm for the shortest path on the network.

We believe that similar decoupling techniques hold much promise for the nonlinear problems for which the notion of "information propagation" is well defined.

Appendix. We present a proof of the causality property for the semi-Lagrangian discretization of the Eikonal equation on an unstructured mesh with acute simplexes. We begin by restating the discretization formula (25) for the n-dimensional simplex s with the vertices at $\boldsymbol{x}, \boldsymbol{x_1}, \dots, \boldsymbol{x_n}$. If $\tilde{\boldsymbol{x}}$ is a point on the $\boldsymbol{x_1} \dots \boldsymbol{x_n}$ face of the simplex, we will use $\zeta = (\zeta_1, \dots, \zeta_n)$ for its barycentric coordinates:

$$\zeta_i \in [0,1] \text{ for all } i, \qquad \sum_{i=1}^{n} \zeta_i = 1, \qquad \sum_{i=1}^{n} \zeta_i \boldsymbol{x_i} = \tilde{\boldsymbol{x}}.$$

Using Ξ to denote the set of all possible barycentric coordinates, we can write the isotropic version of the upwinding update formula (25):

$$V_s(\boldsymbol{x}) = \min_{\zeta \in \Xi} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x})} + \sum_{i=1}^{n} \zeta_i U(\boldsymbol{x_i}) \right\}, \tag{77}$$

where $\tau(\zeta) = \|\tilde{\boldsymbol{x}} - \boldsymbol{x}\|$. Define the unit directional vectors $\boldsymbol{P_i} = \frac{\boldsymbol{x} - \boldsymbol{x_i}}{\|\boldsymbol{x} - \boldsymbol{x_i}\|}$. To justify using Dijkstra-like decoupling with this discretization, we prove the following version of Property (4.1).

PROPERTY A.1 (Causality). *If $(P_j \cdot P_k) \geq 0$ for all j and k, and if $\zeta = (\zeta_1, \dots, \zeta_n)$ is the minimizer in formula* (77)*, then "$\zeta_i > 0$" implies "$V_s > U(\boldsymbol{x_i})$."*

Proof. Suppose $\zeta_i > 0$ for all $i \in \{1, \dots, n\}$. (If that is not the case, the same argument can be repeated for the lower-dimensional simplex on which all barycentric coordinates are positive.)

Noting that $\frac{\partial \tau}{\partial \zeta_i}(\zeta) = \frac{(\boldsymbol{x} - \boldsymbol{x_i}) \cdot (\boldsymbol{x} - \tilde{\boldsymbol{x}})}{\tau(\zeta)}$, we can write the Kuhn–Tucker optimality conditions for ζ as follows:

$$\frac{(\boldsymbol{x} - \boldsymbol{x_i}) \cdot (\boldsymbol{x} - \tilde{\boldsymbol{x}})}{\tau(\zeta) f(\boldsymbol{x})} + U(\boldsymbol{x_i}) = \lambda \qquad \text{for all } i \in \{1, \dots, n\}, \tag{78}$$

where λ is the Lagrange multiplier. We note that

$$\lambda - U(\boldsymbol{x_i}) = \frac{\|\boldsymbol{x} - \boldsymbol{x_i}\| \sum_{j=1}^{n} \zeta_j \|\boldsymbol{x} - \boldsymbol{x_j}\| (\boldsymbol{P_i} \cdot \boldsymbol{P_j})}{\tau(\zeta) f(\boldsymbol{x})} > 0, \tag{79}$$

by the acuteness of simplex s and since $\zeta_i > 0$. Next, we note that, multiplying (78) by ζ_i and summing over all i's,

(80)
$$\lambda = \lambda \left(\sum_{i=1}^{n} \zeta_i \right) = \frac{\left(\sum_{i=1}^{n} \zeta_i (\boldsymbol{x} - \boldsymbol{x_i}) \right) \cdot (\boldsymbol{x} - \tilde{\boldsymbol{x}})}{\tau(\zeta) f(\boldsymbol{x})} + \sum_{i=1}^{n} \zeta_i U(\boldsymbol{x_i}) = \frac{\tau(\zeta)}{f(\boldsymbol{x})} + \sum_{i=1}^{n} \zeta_i U(\boldsymbol{x_i}) = V_s.$$

Thus, $V_s > U(\boldsymbol{x_i})$ follows from (79). $\square$

We note that the proof holds on an arbitrary "acute" unstructured mesh in R^n and on manifolds. The "splitting section" techniques developed for the Fast Marching Method can also be used to implement Dijkstra-like decoupling of the above discretization on meshes with obtuse simplexes; see [21, 38] for details.

Finally, to explore the connection between semi-Lagrangian and finite-difference schemes, we further consider a column vector $\boldsymbol{w}$, with the entries $w_i = (V_s - U(\boldsymbol{x_i}))/\|\boldsymbol{x} - \boldsymbol{x_i}\|$. Using formula (79) and a matrix P whose rows are $\boldsymbol{P_i}$'s, we see that

$$\boldsymbol{w} = \frac{1}{\tau(\zeta) f(x)} P(\boldsymbol{x} – \tilde{\boldsymbol{x}}) \ \Rightarrow\ P^{-1}\boldsymbol{w} = \frac{\boldsymbol{x} - \tilde{\boldsymbol{x}}}{\tau(\zeta) f(x)} \ \Rightarrow\ \boldsymbol{w}^T \left(PP^T\right)^{-1} \boldsymbol{w} = \frac{\|\boldsymbol{x} - \tilde{\boldsymbol{x}}\|^2}{\left(\tau(\zeta) f(x)\right)^2} = \frac{1}{f^2(x)}.$$

The latter is a quadratic equation in V_s and coincides with the particular first-order finite-difference upwind formula chosen in [38] for the isotropic front-propagation problems.

Furthermore, the analogous correspondence can be demonstrated for the first-order schemes in the anisotropic case. Starting from the general first-order semi-Lagrangian formula

$$V_s(\boldsymbol{x}) = \min_{\zeta \in \Xi} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)})} + \sum_{i=1}^{n} \zeta_i U(\boldsymbol{x_i}) \right\}, \tag{81}$$

where $\tau(\zeta)$, $\tilde{\boldsymbol{x}}$, $\boldsymbol{P_i}$, and w_i are defined as above, we note that

$$\begin{aligned} 0 &= \min_{\zeta \in \Xi} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)})} + \sum_{i=1}^{n} \zeta_i \left(U(\boldsymbol{x_i}) - V_s(\boldsymbol{x})\right) \right\} \\ &= \max_{\zeta \in \Xi} \left\{ \sum_{i=1}^{n} \zeta_i \left(V_s(\boldsymbol{x}) - U(\boldsymbol{x_i})\right) - \frac{\tau(\zeta)}{f(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)})} \right\}. \end{aligned}$$

Moreover, since

$$\begin{aligned} \sum_{i=1}^{n} \zeta_i \left(V_s(\boldsymbol{x}) - U(\boldsymbol{x_i})\right) &= \sum_{i=1}^{n} \left(\zeta_i \|\boldsymbol{x} - \boldsymbol{x_i}\|\right) w_i \\ &= \sum_{i=1}^{n} \left(\zeta_i (\boldsymbol{x} - \boldsymbol{x_i})^T P^{-1}\right) w_i = (\boldsymbol{x} - \tilde{\boldsymbol{x}})^T \left(P^{-1}\boldsymbol{w}\right), \end{aligned}$$

we have

$$\max_{\zeta \in \Xi} \left\{ \frac{\tau(\zeta)}{f(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)})} \left[\left(\left(-\frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)} \right) \cdot \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|} \right) \|P^{-1}\boldsymbol{w}\| f\left(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)}\right) - 1 \right] \right\} = 0.$$

Since both functions τ and f are strictly positive, the above is equivalent to

$$\max_{\zeta \in \Xi} \left\{ \left[\left(-\frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)} \right) \cdot \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|} \right] \|P^{-1}\boldsymbol{w}\| f\left(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)}\right) - 1 \right\} = 0$$

or, more conveniently,

$$\|P^{-1}\boldsymbol{w}\| \max_{\zeta \in \Xi} \left\{ \left[\left(-\frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)} \right) \cdot \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|} \right] f\left(\boldsymbol{x}, \frac{\tilde{\boldsymbol{x}} - \boldsymbol{x}}{\tau(\zeta)}\right) \right\} = 1. \tag{82}$$

Let $\boldsymbol{n} = \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|}$. We note that, as ζ varies, $\boldsymbol{a} = \frac{\tilde{\boldsymbol{x}}-\boldsymbol{x}}{\tau(\zeta)}$ covers all directions within this simplex; moreover, the ζ minimizing (81) will also be the maximizer for (82). If all the ζ_i's are positive, then the corresponding $\boldsymbol{a}$ yields a local maximum of the expression $(-\boldsymbol{a}\cdot\boldsymbol{n})f(\boldsymbol{x},\boldsymbol{a})$. As discussed in section 8.1, such a local maximum is unique if S_f is convex; thus, by the formula (66), equation (82) is equivalent to

$$\|P^{-1}\boldsymbol{w}\|F\left(\boldsymbol{x}, \frac{P^{-1}\boldsymbol{w}}{\|P^{-1}\boldsymbol{w}\|}\right) = 1.$$

Finally, the square of this expression is a variant of the finite-difference formula (69) obtained for the first-order Eulerian discretization in section 8.2.1. The upwinding criterion required for the latter scheme is equivalent to verifying that all ζ_i's are positive.

As of right now, we are unaware of any such connections between the higher-order semi-Lagrangian and Eulerian schemes for the Eikonal or general Hamilton–Jacobi–Bellman equations.

A HYBRID COLLOCATION METHOD FOR VOLTERRA INTEGRAL EQUATIONS WITH WEAKLY SINGULAR KERNELS[*]

YANZHAO CAO[†], TERRY HERDMAN[‡], AND YUESHENG XU[§]

Abstract. The commonly used graded piecewise polynomial collocation method for weakly singular Volterra integral equations may cause serious round-off error problems due to its use of extremely nonuniform partitions and the sensitivity of such time-dependent equations to round-off errors. The singularity preserving (nonpolynomial) collocation method is known to have only local convergence. To overcome the shortcoming of these well-known methods, we introduce a hybrid collocation method for solving Volterra integral equations of the second kind with weakly singular kernels. In this hybrid method we combine a singularity preserving (nonpolynomial) collocation method used near the singular point of the derivative of the solution and a graded piecewise polynomial collocation method used for the rest of the domain. We prove the optimal order of *global* convergence for this method. The convergence analysis of this method is based on a singularity expansion of the exact solution of the equations. We prove that the solutions of such equations can be decomposed into two parts, with one part being a linear combination of some known singular functions which reflect the singularity of the solutions and the other part being a smooth function. A numerical example is presented to demonstrate the effectiveness of the proposed method and to compare it to the graded collocation method.

Key words. Volterra integral equations, hybrid collocation methods, weakly singular kernels

1. Introduction.

We propose in this paper a hybrid collocation method for solving Volterra integral equations of the second kind with weakly singular kernels. By using the singularity expansion of the exact solution, we analyze this method and prove that it has an optimal order of global convergence. Specifically, for given kernels $K, M \in C(I \times I)$ with $I := [0,1]$ and a given parameter $\alpha \in (0,1)$, we define a Volterra integral operator $T_\alpha : C(I) \to C(I)$ by

$$(T_\alpha y)(t) = \int_0^t G_\alpha(t,s) y(s) ds, \quad t \in I,$$

where

$$G_\alpha(t,s) := (t-s)^{\alpha-1} K(t,s) + M(t,s) \quad \text{for} \quad 0 \le s \le t, \quad 0 \le t \le 1,$$

and consider the Volterra integral equation of the second kind

$$y(t) - (T_\alpha y)(t) = f(t), \quad t \in I, \tag{1.1}$$

where $f \in C(I)$ is a given function and $y \in C(I)$ is the unknown function to be determined. The kernel M is of practical importance because it occurs in the applications to aeroelastic modeling problems [7], where a class of neutral delay equations are converted to integral equations in the form of (1.1). Other related references include [4, 11].

Since $0 < \alpha < 1$, the kernel G_α has a singularity along the diagonal. When (1.1) is solved by a numerical method such as a collocation method or a product-integration method using the piecewise polynomial approximation, the accuracy of the approximate solution depends on the order of piecewise polynomials used in the approximation as well as the degree of smoothness of the exact solution. For instance, when $y \in C^r(I)$ and the approximate subspaces are chosen to be piecewise polynomials of order r, the optimal order r of convergence for the approximate solution y_h to y is achieved, that is,

$$\|y - y_h\|_\infty = O(N^{-r}), \tag{1.2}$$

where N is the number of subintervals in the uniform partition associated with the piecewise polynomial spaces. However, the solution of (1.1) exhibits, in general, singularities at the zero in its derivatives even if the forcing term f is a smooth function and the numerical methods mentioned above may not even yield first order accuracy (see, e.g., [2, 5]). In other words, the use of piecewise polynomials of high order does not produce high order convergence for the numerical method.

There have been many attempts to overcome the difficulties caused by the singularity of the solution of (1.1). One of the most commonly used methods [3, 5, 6, 9, 10, 14, 15, 16] is the graded collocation (GC) method using piecewise polynomials with a graded mesh on interval I according to the behavior of the exact solution near the singular point, which was first introduced by Rice in [13]. Specifically, the GC method partitions I by the following knots:

$$t_i = \left(\frac{i}{N}\right)^{\frac{r}{\alpha}}, \quad i = 0, 1, \ldots, N, \tag{1.3}$$

which ensures that the GC method retains the optimal error estimate (1.2). However, as pointed out in [2, 10], the main disadvantage of the GC method is that subintervals near the singular point in the graded mesh have very small length and thus may cause serious round-off error problems for small α and high order polynomials. Since Volterra equations are time-dependent equations, the numerical solutions of these equations are very sensitive to round-off errors.

Another approach for solving (1.1) is to include some nonpolynomial singular functions which reflect the singularity of the exact solution as part of the basis for the finite dimensional subspace in the collocation method (see [2]). We call it the nonpolynomial collocation (NPC) method. For this method, only a *local* convergence result (in [2]) has been seen so far. It does not seem that an optimal order of *global* convergence can be proved for this method. The idea of including some known singular functions in the usual finite element spaces or piecewise polynomial spaces has been explored in [8] to successfully construct Galerkin methods of high convergence order for Fredholm integral equations of the second kind with weakly singular kernels. This idea leads us to the consideration of the present method.

To treat the problems discussed above for the existing methods, we propose a hybrid collocation (HC) method for solving (1.1) which combines the strength of both the GC and NPC methods. In this method, we introduce a graded mesh different from

(1.3) that avoids using small subintervals near the zero and uses the nonpolynomial function approximation *only* in the first subinterval. Specifically, the length of the first subinterval in the HC method is the same as in a *quasi-uniform* partition, that is, there exist positive constants c_1, c_2 such that

$$\frac{c_1}{N} \leq t_1 \leq \frac{c_2}{N},$$

and a graded partition is used only on $[t_1, 1]$ so that the instability problem appearing in the GC method can be avoided. We compensate the use of a large subinterval for the first interval in the partition by employing nonpolynomial functions $t^{i+j\alpha}$, $i+j\alpha < r$, which characterize the singularity of the exact solution y of (1.1), as trial functions in the first subinterval $[t_0, t_1]$. The primary purpose of this paper is to prove that this method provides an optimal order of *global* convergence by taking the strength of both the GC method and the NPC method, while avoiding the problems from which both these methods have suffered.

To prepare for the analysis of this method, we derive a singularity expansion of the exact solution of (1.1). In other words, we decompose the exact solution into two parts, one being a linear combination of singular functions $t^{i+j\alpha}$ which reflect the singularity of the exact solution and the other being a smooth function. This subject has been well studied in [5]. We will make use of the results presented in [5] and construct further a form of expansion that is useful for the development of the HC method.

We organize this paper in five sections. In section 2, we derive the singularity expansion of the exact solution of (1.1). Section 3 is devoted to a study of hybrid interpolation operators which serve as a base for the development of the HC method. In section 4, we describe the HC method which combines the NPC method used near the singular point based on the singularity expansion obtained in section 2 and a GC method elsewhere. We prove the optimal order of global convergence of this method. Furthermore, we present a theoretical result which gives a comparison of the computational cost of the HC method and the GC method, and the length of the smallest subintervals used in both methods. Our theory shows that the HC method is better than the GC method. Finally in section 5, we provide a numerical example to demonstrate the effectiveness of the HC method. We compare the numerical performance of the HC method with that of the GC method. The numerical results confirm the theory presented in section 4.

2. Singularity expansions.

In this section we establish a preliminary result on the singularity decomposition for the solution of (1.1). Singularity of the solution of (1.1) when the kernel M is zero has been systematically studied in [5]. In the next theorem, we make use of the results in [5] and derive the singularity expansion crucial for the development of the HC method for the general case when $M \neq 0$.

THEOREM 2.1. *Let r be a nonnegative integer. Suppose that K, $M \in C^r(I \times I)$ and f has the form*

$$f(t) = \sum_{j+i\alpha<m} f_{ij} t^{j+i\alpha} + f_m(t), \qquad t \in I, \tag{2.1}$$

where f_{ij} are constants and $f_m \in C^m[0,1]$ for some fixed integer m with $0 \leq m \leq r$. Let y denote the solution of (1.1). *Then there exist constants c_{ij} such that*

$$y(t) = \sum_{j+i\alpha<m} c_{ij} t^{j+i\alpha} + v_m(t), \quad t \in I, \tag{2.2}$$

where $v_m \in C^m(I)$.

Proof. When $M \equiv 0$ formula (2.2) follows from Theorem 1.3.15 of [5] with some modification. The modification is necessary to treat the series in the expansion appearing in Theorem 1.3.15 of [5] so that we have form (2.2).

The general case where the kernel M is not zero will be proved by induction on m. The case when $m = 0$ is obvious. We assume that the theorem holds for $m = k$ and proceed to the case $m = k + 1$. By the induction hypothesis, the solution y of (1.1) has a representation

$$y(t) = \sum_{j+i\alpha<k} c_{ij} t^{j+i\alpha} + v_k(t), \quad t \in I, \tag{2.3}$$

where $v_k \in C^k(I)$. For $t \in I$, we let

$$x(t) := \int_0^t M(t,s) y(s) ds.$$

Substituting (2.3) into the expression of function x gives

$$x(t) = \int_0^t M(t,s) \left[\sum_{j+i\alpha<k} c_{ij} s^{j+i\alpha} + v_k(s) \right] ds, \quad t \in I.$$

To simplify the expression of x, we denote

$$w_{k+1}(t) = \int_0^t M(t,s) v_k(s) ds \quad \text{and} \quad m_{ij}(t) = \int_0^1 M(t,st) s^{j+i\alpha} ds.$$

A simplification with a change of variables leads to the following formula:

$$x(t) = \sum_{j+i\alpha<k+1} c_{i,j-1} m_{i,j-1}(t) t^{j+i\alpha} + w_{k+1}(t), \quad t \in I.$$

It is easily seen that w_{k+1}, $m_{ij} \in C^{k+1}(I)$. Applying the Taylor theorem to the functions m_{ij}, we obtain that

$$x(t) = \sum_{j+i\alpha<k+1} d_{ij} t^{j+i\alpha} + u_{k+1}(t), \quad t \in I,$$

where d_{ij} are constants and u_{k+1} is a function in $C^{k+1}(I)$. Let $\tilde{f} := f - x$ and rewrite (1.1) as

$$y(t) + \int_0^t (t-s)^{\alpha-1} K(t,s) y(s) ds = \tilde{f}(t), \quad t \in I.$$

Note that $\tilde{f}$ has the form (2.1) with $m = k + 1$. By the first part of this proof, we conclude the result of the theorem for the case $m = k + 1$, which advances the induction hypothesis and completes the proof. □

3. Nonpolynomial interpolation operators. Motivated by the singularity expansion of the solution of (1.1), in the next section we will develop the HC method for solving (1.1). To prepare for this development, we define a hybrid interpolation operator and study the bound of this operator.

We first define a nonpolynomial finite dimensional subspaces of $C(I)$. As usual, we denote by N_0 the set of nonnegative integers. For $0 < \alpha < 1$ and a positive integer r we introduce an index set by setting

$$W_{\alpha,r} := \{i + j\alpha : i, j \in N_0, i + j\alpha < r\}.$$

Let ℓ denote the cardinality of the set $W_{\alpha,r}$. Clearly, $W_{\alpha,r}$ contains the first r nonnegative integers $i = 0, 1, \ldots, r-1$. For notational convenience, we write

$$W_{\alpha,r} = \{\nu_j : j = 0, 1, \ldots, \ell - 1\}$$

with the convention that $\nu_j = j$ for $j = 0, 1, \ldots, r-1$. Associated with this index set, we define a finite dimensional space V_r of nonpolynomial functions by

$$V_r := \operatorname{span}\{t^{\nu_j} : j = 0, 1, \ldots, \ell - 1\}.$$

We remark that Theorem 2.1 ensures the solution y of (1.1) has the decomposition

$$y = u + v, \quad u \in C^r(I), \quad \text{and} \quad v \in V_r.$$

Also, we denote by P_r the space of polynomials of degree $\leq r-1$. Because the set $W_{\alpha,r}$ contains the integers $i = 0, 1, \ldots, r-1$, it is clear that $P_r \subset V_r$. In addition, space V_r contains nonpolynomial functions t^{ν_j}, $j = r, r+1, \ldots, \ell - 1$, that reflect the singularity of the derivative of the solution of (1.1).

We next describe a finite dimensional space whose elements are piecewise in V_r. For a given positive integer N, we divide the interval I into N subintervals, that is, $0 = t_0 < t_1 < \cdots < t_N = 1$. For a subinterval J of I and a function $f \in C(I)$, we use $f|_J$ for the restriction of f on J and, moreover, for $V \subseteq C(I)$ we let

$$V|_J := \{v|_J : v \in V\}.$$

Let $h_i = t_i - t_{i-1}$ and $h = \max_{1 \leq i \leq N} h_i$. We define a space of functions piecewise in V by

$$(V)_h := \{v : v|_{[t_{i-1}, t_i]} \in V|_{[t_{i-1}, t_i]},\ i = 1, 2, \ldots, N\},$$

and, in particular, we let $V_{r,h} := (V_r)_h$ and $S_{r,h} := (P_r)_h$. Clearly, we have that $V_r \subseteq V_{r,h}$ and $S_{r,h} \subseteq V_{r,h}$.

We now define interpolation operators $P_{h,1}$ from $C(I)$ to $S_{r,h}$ and $P_{h,2}$ from $C(I)$ to $V_{r,h}$, respectively. To this end, we choose ℓ points τ_j in I such that $0 < \tau_1 < \tau_2 < \cdots < \tau_\ell < 1$. The interpolation points on interval $[t_{k-1}, t_k]$ are obtained by setting $t_{kj} := t_{k-1} + \tau_j h_k$, $k = 1, 2, \ldots, N$, $j = 1, 2, \ldots, \ell$. The interpolation operators $P_{h,1} : C(I) \to S_{r,h}$ and $P_{h,2} : C(I) \to V_{r,h}$ are defined as follows. For $f \in C(I)$

$$(P_{h,1}f)(t_{ij}) = f(t_{ij}), \quad j = 1, 2, \ldots, r,\ i = 1, 2, \ldots, N,$$

and

$$(P_{h,2}f)(t_{ij}) = f(t_{ij}), \quad j = 1, 2, \ldots, \ell,\ i = 1, 2, \ldots, N.$$

Note that for the definition of $P_{h,1}$ we use only the first r points τ_j, $j = 1, 2, \dots, r$. It is known (see [2, 5]) that the operators $P_{h,i}$ for $i = 1, 2$ are uniquely defined.

For a function u that is continuous on $[t_{i-1}, t_i]$, $i = 1, 2, \dots, N$, with possible discontinuities at t_i, define its maximum norm on $[t_m, t_n]$ with $0 \le m < n \le N$ by

$$\|u\|_{[t_m,t_n]} = \max_{m \le i \le n} \max_{t_{i-1} \le t \le t_i} |u(t)|.$$

We will simply use $\|u\|$ when $[t_m, t_n] = I$.

Next we show that the norm of the restriction of $P_{h,2}f$ on $[t_0, t_1]$ is bounded by a constant independent of the choice of t_1. For this purpose, we define, for $i = 1, 2, \dots, \ell$, the Lagrange functions

$$L_{1i}|_{[t_0,t_1]} \in V_r|_{[t_0,t_1]}$$

and

$$L_{1i}(t) = 0, \quad t \in [t_1, 1]$$

such that

$$L_{1i}(t_{1j}) = \delta_{ij}, \quad j = 1, 2, \dots, \ell.$$

It is easily verified that

$$(P_{h,2}f)(t) = \sum_{j=1}^{\ell} f(t_{1j}) L_{1j}(t), \quad t \in [t_0, t_1]. \tag{3.1}$$

Lemma 3.1. *There exists a positive constant c such that for all $t_1 \in (0,1)$ and $i = 1, 2, \dots, \ell$*

$$\|L_{1i}\| = \|L_{1i}\|_{[t_0,t_1]} \le c.$$

Proof. For $i = 1, 2, \dots, \ell$, we write

$$L_{1i}(t) = \sum_{p=1}^{\ell} a_{ip} t^{\nu_p}, \quad t \in [t_0, t_1].$$

For $t \in [t_0, t_1]$, there exists a $\tau \in I$ such that $t = t_0 + h_1 \tau$. For $i = 1, 2, \dots, \ell$ and $p = 1, 2, \dots, \ell$ we set $b_{ip} := h_1^{\nu_p} a_{ip}$. Using these notations, we have that

$$L_{1i}(t) = \sum_{p=1}^{\ell} b_{ip} \tau^{\nu_p}, \quad t \in [t_0, t_1]. \tag{3.2}$$

By the definition of L_{1i} we observe that

$$\sum_{p=1}^{\ell} b_{ip} \tau_j^{\nu_p} = \delta_{ij}, \quad j = 1, 2, \dots, \ell. \tag{3.3}$$

We introduce an $\ell \times \ell$ matrix $\mathbf{D}$ by setting $\mathbf{D} := [d_{jp} : j, p = 1, 2, \dots, \ell]$, where $d_{jp} := \tau_j^{\nu_p}$ and a vector $\mathbf{b}_i$ by $\mathbf{b}_i = [b_{ip} : p = 1, 2, \dots, \ell]^T$. It is easy to verify that the matrix $\mathbf{D}$ is invertible and since all entries d_{jp} are independent of the choice of t_1

we conclude that $\|\mathbf{D}^{-1}\|_\infty$ is bounded by a constant independent of the choice of t_1 where the norm used here is the matrix norm induced from the vector norm $\|\cdot\|_\infty$. Thus, it follows from (3.3) that

$$\|\mathbf{b}_i\|_\infty \le \|\mathbf{D}^{-1}\|_\infty.$$

Hence from (3.2) we confirm the result of this lemma with the constant

$$c := \max_{0\le\tau\le 1}\left(\sum_{p=1}^{\ell}\tau^{\nu_p}\right)\|\mathbf{D}^{-1}\|_\infty. \qquad \square$$

The following lemma, which provides a bound of the norm of $P_{h,2}f$ on $[t_0, t_1]$, is a direct consequence of Lemma 3.1.

LEMMA 3.2. *There exists a positive constant c such that for all $t_1 \in (0,1)$ and for any $f \in C(I)$*

$$\|P_{h,2}f\|_{[t_0,t_1]} \le c\|f\|_{[t_0,t_1]}.$$

The next proposition presents order of convergence for the interpolation $P_{h,2}f$ to a function f having form (2.1).

PROPOSITION 3.3. *There exists a positive constant c such that for all $t_1 \in (0,1)$ and for $f = u + v$, where $u \in C^r(I)$ and $v \in V_r$,*

$$\|f - P_{h,2}f\|_{[t_0,t_1]} \le ch_1^r\|u^{(r)}\|_{[t_0,t_1]}.$$

Proof. For all functions f having the form $f = u+v$, where $u \in C^r(I)$ and $v \in V_r$, recalling that $P_{h,2}v = v$ for $v \in V_r$ we have that

$$f - P_{h,2}f = u + v - P_{h,2}(u+v) = u - P_{h,2}u.$$

Noting that

$$P_{h,2}P_{h,1} = P_{h,1}$$

we conclude that

$$f - P_{h,2}f = (I - P_{h,1})u + P_{h,2}P_{h,1}u - P_{h,2}u = (I - P_{h,2})(I - P_{h,1})u.$$

It follows from Lemma 3.2 that there exists a positive constant c such that for all $t_1 \in (0,1)$ and all such f

$$\|f - P_{h,2}f\|_{[t_0,t_1]} \le c\|(I - P_{h,1})u\|_{[t_0,t_1]} \le ch_1^r\|u^{(r)}\|_{[t_0,t_1]},$$

where the last inequality follows from a standard error estimate for polynomial interpolations. $\square$

We next define a *hybrid* interpolation which has a *global* convergence. To this end, we describe a graded partition of I in terms of parameters α and r. Specifically, for $q := \frac{r}{\alpha}$ we let i_0 be an integer such that

$$\left[\left(\frac{N}{i_0}\right)^q\right] = N,$$

where $[a]$ denotes the largest integer less than or equal to a, and set $N' := N - i_0 + 1$. The partition on I is given by

$$t_0 = 0,\ t_i = \left(\frac{i_0 + i - 1}{N}\right)^q, \quad i = 1, 2, \ldots, N'. \tag{3.4}$$

Note that $t_{N'} = 1$ and the integer i_0 satisfies the condition that

$$N^{1-1/q} \leq i_0 \leq N(N-1)^{-1/q}. \tag{3.5}$$

We remark that as far as stability is concerned this partition is better than the partition (1.3) used in a standard GC method. This point will be made clearer in the next section.

Associated with the graded partition (3.4), we define the *hybrid interpolation* operator Q_h by

$$(Q_h f)|_{[0,t_1]} = (P_{h,2} f)|_{[0,t_1]} \text{ and } (Q_h f)|_{[t_1,1]} = (P_{h,1} f)|_{[t_1,1]}. \tag{3.6}$$

That is, on the first subinterval we use singularity preserving (nonpolynomial) interpolation and on the rest of intervals we use the standard piecewise polynomial interpolation. The operator Q_h will be used in the next section for the development of a *hybrid collocation* method. To prepare for this development, we present an expression of projection Q_h in terms of the Lagrange basis functions. To this end, we define the Lagrange polynomial basis $L_i \in P_r$, $i = 1, 2, \ldots, r$, such that

$$L_i(\tau_j) = \delta_{ij}, \quad j = 1, 2, \ldots, r,$$

and for $k = 2, 3, \ldots, N'$ we define the Lagrange piecewise polynomial basis functions by setting

$$L_{ki}(t) = \begin{cases} L_i\left(\frac{t - t_{k-1}}{h_k}\right), & t \in [t_{k-1}, t_k], \\ 0, & \text{otherwise.} \end{cases}$$

Thus, for all $k = 2, 3 \ldots, N'$ there hold the relations that

$$\|L_{ki}\| = \|L_i\|, \quad i = 1, 2, \ldots, r, \tag{3.7}$$

and we have that

$$(P_{h,1} f)(t) = \sum_{k=2}^{N'} \sum_{j=1}^{r} f(t_{kj}) L_{kj}(t), \quad t \in [t_1, 1].$$

To present projection Q_h, we introduce a notation

$$r_k := \begin{cases} \ell, & k = 1, \\ r, & k = 2, 3, \ldots, N'. \end{cases} \tag{3.8}$$

Consequently, we have that

$$(Q_h f)(t) = \sum_{k=1}^{N'} \sum_{j=1}^{r_k} f(t_{kj}) L_{kj}(t), \quad t \in I. \tag{3.9}$$

In the next proposition, we establish a *global* convergence result for the interpolation projection Q_h.

PROPOSITION 3.4. *Let Q_h be the hybrid interpolation operator defined in* (3.6) *associated with the partition* (3.4). *Suppose that f has a decomposition $f = u + v$, where $u \in C^r(I)$ and $v \in V_r$. Then there exists a positive constant c independent of N such that for all such functions f*

$$\|f - Q_h f\| \leq cN^{-r}.$$

Proof. Note that

$$\|f - Q_h f\| = \max\left\{\|f - Q_h f\|_{[0,t_1]}, \|f - Q_h f\|_{[t_1,1]}\right\}.$$

Employing Proposition 3.3 we conclude that there exists a positive constant c such that

$$\|f - Q_h f\|_{[0,t_1]} = \|f - P_{h,2} f\|_{[0,t_1]} \leq ch_1^r \|u^{(r)}\|_{[0,t_1]}.$$

Noting that by the definition of partition (3.4),

$$h_1 = t_1 = \left(\frac{i_0}{N}\right)^q \leq \left(\frac{N(N-1)^{-1/q}}{N}\right)^q = \frac{1}{N-1} \leq \frac{2}{N},$$

we obtain that

$$\|f - Q_h f\|_{[0,t_1]} \leq c\frac{1}{N^r}.$$

We next estimate the error $\|f - Q_h f\|_{[t_1,1]}$ following a well-known argument by Rice [13]. Since $f = u + v$ with $u \in C^r(I)$ and $v \in V_r$, we have that

$$|f^{(r)}(t)| \leq ct^{\alpha - r} \quad \text{for} \quad t \in [t_1, 1],$$

and the function $t^{\alpha - r}$ is decreasing in t. For $i = 2, 3, \ldots, N'$, we find that

$$h_i = \left[(i + i_0 - 1)^q - (i + i_0 - 2)^q\right] N^{-q} = (i + i_0 - 2)^q \left\{\left[1 + (i + i_0 - 2)^{-1}\right]^q - 1\right\} N^{-q}.$$

By the mean value theorem, there exists θ with $0 < \theta < (i + i_0 - 2)^{-1}$ such that

$$h_i = q(i + i_0 - 2)^{q-1}(1 + \theta)^{q-1} N^{-q} \leq c(i + i_0 - 2)^{q-1} N^{-q}. \tag{3.10}$$

Thus, there exists a positive constant c such that for $i = 2, 3, \ldots, N'$

$$\begin{aligned}\|f - Q_h f\|_{[t_{i-1},t_i]} &= \|f - P_{h,2} f\|_{[t_{i-1},t_i]} \leq ch_i^r \|f^{(r)}\|_{[t_{i-1},t_i]} \\ &\leq c(i + i_0 - 2)^{(q-1)r} N^{-qr} \left(\frac{i + i_0 - 2}{N}\right)^{q(\alpha - r)} = c\frac{1}{N^r},\end{aligned}$$

which completes the proof of this proposition. □

4. A hybrid collocation method. In this section, we use the hybrid interpolation operator Q_h introduced in the last section to develop a hybrid collocation method for solving (1.1). We prove that this method has an optimal order of global convergence. Notice that the singularity in the derivative of the exact solution of (1.1) occurs only at the left end point of the interval I. This fact suggests that we use a singularity preserving collocation method near the left end point and use a standard piecewise polynomial collocation method with a graded partition elsewhere.

We now describe the hybrid collocation method for (1.1). We seek y_h such that

$$y_h|_{[0,t_1]} \in V_{r,h}|_{[0,t_1]}, \quad y_h|_{[t_1,1]} \in S_{r,h}|_{[t_1,1]},$$

and

$$y_h - Q_h T_\alpha y_h = Q_h f, \tag{4.1}$$

where Q_h is the hybrid interpolation operator defined by (3.6) associated with the graded partition (3.4).

To analyze the order of convergence for the hybrid collocation method (4.1), we define an integral operator $T_{\alpha,1}$ by

$$(T_{\alpha,1}y)(t) := (T_\alpha y)(t) \quad \text{for} \quad t \in [0, t_1] \tag{4.2}$$

and

$$(T_{\alpha,1}y)(t) := \int_{t_1}^{t} G_\alpha(t,s)y(s)ds \quad \text{for} \quad t \in [t_1, 1].$$

The study of the error $\|y - y_h\|$ demands a bound on the errors

$$e_{kj} := y(t_{kj}) - y_h(t_{kj}), \quad j = 1, 2, \ldots, r_k,$$

where r_k is defined by (3.8). To this end, we introduce vectors

$$\mathbf{e}_k := [e_{kj} : j = 1, 2, \ldots, r_k]^T \quad \text{for} \quad k = 1, 2, \ldots, N'.$$

We also need vectors

$$\epsilon_k := [\epsilon_{kj} : j = 1, 2, \ldots, r_k]^T \quad \text{for} \quad k = 1, 2, \ldots, N',$$

where

$$\epsilon_{kj} := (T_{\alpha,1}(y - Q_h y))(t_{kj}) + ((T_\alpha - T_{\alpha,1})(y - y_h))(t_{kj}). \tag{4.3}$$

Note that when $k = 1$, it becomes that

$$\epsilon_{1j} = (T_\alpha(y - Q_h y))(t_{1j}).$$

We will bound the vectors $\mathbf{e}_k$ by ϵ_k.

Next, we derive a linear system that gives a recursive formula for the vector $\mathbf{e}_k$. Toward this goal, for $k = 1, 2, \ldots, N'$ and $j = 1, 2, \ldots, r_k$ we evaluate (1.1) and (4.1) at t_{kj} to obtain that

$$y(t_{kj}) - (T_\alpha y)(t_{kj}) = f(t_{kj}) \tag{4.4}$$

and

$$y_h(t_{kj}) - (T_\alpha y_h)(t_{kj}) = f(t_{kj}), \tag{4.5}$$

respectively. Subtracting (4.5) from (4.4) yields

$$e_{kj} = (T_{\alpha,1}(y - y_h))(t_{kj}) + ((T_\alpha - T_{\alpha,1})(y - y_h))(t_{kj}). \tag{4.6}$$

Noticing that Q_h is a projection and $y_h = Q_h y_h$, we have that

$$y - y_h = y - Q_h y + Q_h(y - y_h). \tag{4.7}$$

Substituting (4.7) into the first term in the right-hand side of (4.6) and recalling the definition of ϵ_{kj}, we obtain that

$$e_{kj} = (T_{\alpha,1} Q_h(y - y_h))(t_{kj}) + \epsilon_{kj} \quad \text{for} \quad k = 1, 2, \dots, N', \ j = 1, 2, \dots, r_k. \tag{4.8}$$

We are required to study the first term in the right-hand side of (4.8). In (3.9), we replace f by $y - y_h$ and conclude that

$$(Q_h(y - y_h))(t) = \sum_{i=1}^{N'} \sum_{p=1}^{r_i} e_{ip} L_{ip}(t), \quad t \in I.$$

Applying the operator $T_{\alpha,1}$ to both sides of this equation with evaluating at $t = t_{kj}$ yields

$$(T_{\alpha,1} Q_h(y - y_h))(t_{kj}) = \sum_{i=1}^{N'} \sum_{p=1}^{r_i} e_{ip} (T_{\alpha,1} L_{ip})(t_{kj}).$$

We next make use of the property of the Lagrange basis functions L_{ip} to simplify the right-hand side of the equation above. For notational convenience, we define

$$a_{jp}^k := \int_{t_{k-1}}^{t_{kj}} G_\alpha(t_{kj}, s) L_{kp}(s) ds$$

and

$$d_{jp}^{ki} := \int_{t_{i-1}}^{t_i} G_\alpha(t_{kj}, s) L_{ip}(s) ds.$$

Noting that L_{ip} vanishes outside the interval $[t_{i-1}, t_i]$, an elementary computation leads to the formula that

$$(T_{\alpha,1} Q_h(y - y_h))(t_{kj}) = \sum_{p=1}^{r_k} a_{jp}^k e_{kp} + \sum_{i=2}^{k-1} \sum_{p=1}^{r} d_{jp}^{ki} e_{ip},$$

where we have used the relation that $r_i = r$ for $i = 2, 3, \dots, k-1$. Substituting this equation into the right-hand side of (4.8) yields

$$e_{kj} = \sum_{p=1}^{r_k} a_{jp}^k e_{kp} + \sum_{i=2}^{k-1} \sum_{p=1}^{r} d_{jp}^{ki} e_{ip} + \epsilon_{kj}, \quad j = 1, 2, \dots, r_k. \tag{4.9}$$

By introducing an $r_k \times r_k$ matrix

$$\mathbf{A}_k := [a_{jp}^k : j, p = 1, 2, \dots, r_k] \tag{4.10}$$

and $r \times r$ matrices

$$\mathbf{D}_{ki} := [d_{jp}^{ki} : j, p = 1, 2, \dots, r], \quad i = 2, 3, \dots, k-1, \tag{4.11}$$

we write (4.9) in matrix form as

$$\mathbf{e}_k = \mathbf{A}_k\mathbf{e}_k + \sum_{i=2}^{k-1}\mathbf{D}_{ki}\mathbf{e}_i + \epsilon_k, \quad k = 1, 2, \ldots, N'. \tag{4.12}$$

The matrices $\mathbf{A}_k$ and $\mathbf{D}_{ki}$ are all dependent on the mesh sizes h_i, and we next study such a dependence. Recalling the transformations $s = t_{k-1} + h_k\tau$ when $s \in [t_{k-1}, t_k]$ and $\tau \in [0, 1]$ and $t_{kj} = t_{k-1} + h_k\tau_j$ and using the notations

$$\tilde{K}(t,\tau) := K(t, t_{k-1}+h_k\tau), \;\; \tilde{M}(t,\tau) := M(t, t_{k-1}+h_k\tau), \;\; \tilde{L}_{kp}(\tau) := L_{kp}(t_{k-1}+h_k\tau),$$

$$\tilde{a}^k_{jp} := \int_0^{\tau_j}\left[(\tau_j-\tau)^{\alpha-1}\tilde{K}(t_{kj},\tau) + h_k^{1-\alpha}\tilde{M}(t_{kj},\tau)\right]\tilde{L}_{kp}(\tau)d\tau,$$

and

$$\tilde{d}^{ki}_{jp} := \int_0^1\left[\left(\frac{t_{k-1}-t_{i-1}+h_k\tau_j}{h_i} - \tau\right)^{\alpha-1}\tilde{K}(t_{kj},\tau) + h_i^{1-\alpha}\tilde{M}(t_{kj},\tau)\right]\tilde{L}_{ip}(\tau)d\tau,$$

by changes of variables we have that

$$a^k_{jp} = h_k^\alpha\tilde{a}^k_{jp} \;\text{ and }\; d^{ki}_{jp} = h_i^\alpha\tilde{d}^{ki}_{jp}.$$

By introducing new matrices

$$\tilde{\mathbf{A}}_k := [\tilde{a}^k_{jp} : j, p = 1, 2, \ldots, r_k] \;\text{ and }\; \tilde{\mathbf{D}}_{ki} := [\tilde{d}^{ki}_{jp} : j, p = 1, 2, \ldots, r], \;\; i = 2, 3, \ldots, k-1,$$

we observe that

$$\tilde{\mathbf{A}}_k = h_k^{-\alpha}\mathbf{A}_k \;\text{ and }\; \tilde{\mathbf{D}}_{ki} = h_k^{-\alpha}\mathbf{D}_{ki}.$$

Hence, (4.12) becomes

$$\mathbf{e}_k = h_k^\alpha\tilde{\mathbf{A}}_k\mathbf{e}_k + \sum_{i=2}^{k-1}h_i^\alpha\tilde{\mathbf{D}}_{ki}\mathbf{e}_i + \epsilon_k, \quad k = 1, 2, \ldots, N'. \tag{4.13}$$

Since both $\tilde{K}$ and $\tilde{M}$ are continuous functions on $I \times I$, by using Lemma 3.1 and (3.7) we observe that there exists a positive constant c_1 such that for $k = 1, 2, \ldots, N'$ and $j, p = 1, 2, \ldots, r_k$

$$|\tilde{a}^k_{jp}| \le c_1\int_0^{\tau_j}\left[(\tau_j-\tau)^{\alpha-1} + 1\right]d\tau \le c_1\left(1 + \frac{1}{\alpha}\right) \tag{4.14}$$

and

$$|\tilde{d}^{ki}_{jp}| \le c_1\int_0^1\left(\frac{t_{k-1}-t_{i-1}+h_k\tau_j}{h_i} - \tau\right)^{\alpha-1}d\tau, \quad i = 2, 3, \ldots, k-1. \tag{4.15}$$

Estimate (4.14) implies that there exists a positive constant $c_2 := c_1\ell\left(1 + \frac{1}{\alpha}\right)$ for all $k = 1, 2, \ldots, N'$,

$$\|\tilde{\mathbf{A}}_k\|_\infty \le c_2.$$

Let $h := \max\{h_i : 1 \le i \le N'\}$ and choose $h < c_2^{-1/\alpha}$. It follows that for such an h the matrix $I - h_k^\alpha \tilde{\mathbf{A}}_k$ is invertible and there exists a positive constant c such that

$$\|(I - h_k^\alpha \tilde{\mathbf{A}}_k)^{-1}\| \le c. \tag{4.16}$$

Thus, from (4.13) we conclude that

$$\mathbf{e}_k = (I - h_k^\alpha \tilde{\mathbf{A}}_k)^{-1} \left[\sum_{i=2}^{k-1} h_i^\alpha \tilde{\mathbf{D}}_{ki} \mathbf{e}_i + \epsilon_k \right]. \tag{4.17}$$

We next use estimate (4.15) to study the bound of the entries of matrices $\tilde{\mathbf{D}}_{ki}$. Noting that $h_i < h_{i+1} < \cdots < h_{k-1}$, we have that

$$\frac{t_{k-1} - t_{i-1}}{h_i} = \frac{h_i + \cdots + h_{k-1}}{h_i} \ge k - i$$

and conclude that

$$|\tilde{d}_{jp}^{ki}| \le c_1 \int_0^1 (k - i - \tau)^{\alpha - 1} d\tau. \tag{4.18}$$

It can be verified from a direct computation that there exists a positive constant c such that for all $i = 2, 3, \ldots, k-1$

$$\int_0^1 (k - i - \tau)^{\alpha-1} d\tau \le c(k-i)^{\alpha-1}.$$

Using this estimate in inequality (4.18) yields for $i = 2, 3, \ldots, k-1$ and $j, p = 1, 2, \ldots, r_k$ that

$$|\tilde{d}_{jp}^{ki}| \le c(k-i)^{\alpha-1}$$

and thus

$$\|\tilde{\mathbf{D}}_{ki}\|_\infty \le c(k-i)^{\alpha-1}. \tag{4.19}$$

Combining estimates (4.16) and (4.19) with (4.17) gives

$$\|\mathbf{e}_k\|_\infty \le c \sum_{i=2}^{k-1} h_i^\alpha (k-i)^{\alpha-1} \|\mathbf{e}_i\|_\infty + c\|\epsilon_k\|_\infty.$$

Recalling from (3.10) that there exists a positive constant c such that

$$h_i \le c(i + i_0 - 2)^{q-1} N^{-q},$$

since $i + i_0 - 2 \le 2N$ we conclude that there exists a positive constant c such that

$$h_i \le cN^{-1}.$$

Therefore, we have that

$$\|\mathbf{e}_k\|_\infty \le c \left(\frac{1}{N}\right)^\alpha \sum_{i=2}^{k-1} (k-i)^{\alpha-1} \|\mathbf{e}_i\|_\infty + c\|\epsilon_k\|_\infty. \tag{4.20}$$

We next use inequality (4.20) to obtain the error estimate of the hybrid collocation method (4.1). For this purpose, we recall a discrete Gronwall-type inequality (cf. [5]).

LEMMA 4.1. *Let $0 < \alpha < 1$ and $\{z_i : i = 1, 2, \ldots, n\}$ be a sequence of positive numbers and $n \leq N$. Let ρ and β be two positive numbers such that for all $k = 1, 2, \ldots, n$*

$$z_k \leq \left(\frac{1}{N}\right)^{\alpha} \beta \sum_{i=1}^{k-1} (k-i)^{\alpha-1} z_i + \rho.$$

Then there exists a positive constant c depending only on α and β such that $k = 1, 2, \ldots, n$,

$$z_k \leq c\rho.$$

We are now ready to prove the main result of this paper, which gives an optimal order of global convergence for the hybrid collocation method.

THEOREM 4.2. *Let y be the exact solution of* (1.1), *let N be a positive integer, and let Q_h be the hybrid interpolation operator defined by* (3.6) *associated with the graded partition* (3.4). *Suppose that the forcing function f in* (1.1) *has the form* (2.1). *Then, for sufficiently large N,* (4.1) *has a unique solution y_h and there exists a positive constant c independent of N such that*

$$\|y - y_h\| \leq cN^{-r}.$$

Proof. It follows from Theorem 2.1 that the solution of (1.1) has the form $y = u+v$, where $u \in C^r(I)$ and $v \in V_r$. This allows us to use Proposition 3.4 to prove the result. We first estimate the error on $[t_0, t_1]$. From (4.3) there exists a constant c such that

$$\|\epsilon_1\|_\infty \leq \|T_\alpha(y - Q_h y)\|_{[t_0,t_1]} \leq c\|y - Q_h y\|_{[t_0,t_1]}.$$

It follows from (4.20) and Proposition 3.4 that

$$\|\mathbf{e}_1\|_\infty \leq c\|y - Q_h y\|_{[t_0,t_1]} \leq cN^{-r}.$$

Using Lemma 3.1 and the above estimate we obtain that

$$\|Q_h(y - y_h)\|_{[t_0,t_1]} \leq c\|\mathbf{e}_1\|_\infty \leq cN^{-r},$$

which with Proposition 3.4 gives that

$$\|y - y_h\|_{[t_0,t_1]} \leq \|Q_h(y - y_h)\|_{[t_0,t_1]} + \|Q_h y - y\|_{[t_0,t_1]} \leq cN^{-r}. \tag{4.21}$$

Next we estimate the error on $[t_1, 1]$. Using (4.3) we have that for $k = 2, 3, \ldots, N'$

$$\|\epsilon_k\|_\infty \leq \|T_{\alpha,1}(y - Q_h y)\|_{[t_1,1]} + \|(T_\alpha - T_{\alpha,1})(y - y_h)\|_{[t_1,1]}.$$

Now, by using Proposition 3.4 and estimate (4.21) we conclude that there exists a positive constant c such that

$$\|\epsilon_k\|_\infty \leq c(\|y - Q_h y\|_{[t_1,1]} + \|y - y_h\|_{[t_0,t_1]}) \leq cN^{-r}.$$

Combining the above estimate with (4.20) we obtain that

$$\|\mathbf{e}_k\|_\infty \leq cN^{-\alpha} \sum_{i=2}^{k-1} (k-i)^{\alpha-1} \|\mathbf{e}_i\|_\infty + cN^{-r}.$$

Using Lemma 4.1 with $z_1 = 0$ and $z_i = \|\mathbf{e}_i\|_\infty$ for $i = 2, 3, \ldots N'$, we conclude that there exists a positive constant c such that for all $k = 2, 3, \ldots, N'$

$$\|\mathbf{e}_k\|_\infty \leq cN^{-r}.$$

Now, by the uniform boundedness (3.7) of $\|L_{ij}\|$ for $i = 2, 3, \ldots, N'$ there exists a positive constant c such that

$$\|Q_h(y - y_h)\|_{[t_1,1]} \leq c \max\{\|\mathbf{e}_k\|_\infty : k = 2, 3, \ldots, N'\} \leq cN^{-r}.$$

It follows that there exists a positive constant c such that

$$\|y - y_h\|_{[t_1,1]} \leq \|Q_h(y - y_h)\| + \|Q_h y - y\| \leq cN^{-r},$$

which concludes the proof of the theorem. □

We may also use the compactness of operator T_α and the uniform boundedness of Q_h to prove Theorem 4.2 (see, for example, [1]). In fact, such a proof is more concise. We choose the current proof, for it provides guidance for the construction of a numerical algorithm in our numerical experiments.

In the next proposition, we compare the graded collocation (GC) method with the hybrid collocation (HC) method. To this end, we let $\mathcal{N}_{GC}$ and $\mathcal{N}_{HC}$ denote the number of subintervals used in the GC method and the HC method, and we let $\mathcal{L}_{GC}$ and $\mathcal{L}_{HC}$ denote the length of the smallest subinterval used in the GC method and the HC method, respectively. We also consider the ratios of the largest subinterval over the smallest subinterval for the partitions that associate with the GC method and the HC method, which are denoted by $\mathcal{R}_{GC}$ and $\mathcal{R}_{HC}$. Such a ratio is a good measure for the stability of the corresponding collocation method.

PROPOSITION 4.3. *There hold the estimates that*

$$\mathcal{N}_{GC} - \mathcal{N}_{HC} \geq \frac{N}{\sqrt[q]{N}} - 1,$$

$$\mathcal{L}_{GC} = \frac{1}{N^q}, \qquad \mathcal{L}_{HC} \geq \frac{\sqrt[q]{N}}{N^2},$$

and

$$\mathcal{R}_{GC} \geq q(N-1)^{q-1}, \qquad \mathcal{R}_{HC} \leq \frac{qN}{\sqrt[q]{N}}.$$

Proof. Since $\mathcal{N}_{GC} = N$ and $\mathcal{N}_{HC} = N - i_0 + 1 \leq N - N^{1-1/q} + 1$, we have that

$$\mathcal{N}_{GC} - \mathcal{N}_{HC} \geq N - (N - N^{1-1/q} + 1) = \frac{N}{\sqrt[q]{N}} - 1.$$

The smallest interval used in the GC method is $[0, N^{-q}]$ and thus $\mathcal{L}_{GC} = \frac{1}{N^q}$. For the HC method, it is easily verified that $\mathcal{L}_{HC} = \min\{h_1, h_2\}$, where $h_1 = \left(\frac{i_0}{N}\right)^q$ and $h_2 = \left(\frac{i_0+1}{N}\right)^q - \left(\frac{i_0}{N}\right)^q$. Recalling that i_0 satisfies that condition $N^{1-\frac{1}{q}} \leq i_0 \leq N(N-1)^{-\frac{1}{q}}$, we derive that

$$h_1 \geq \left(\frac{N^{1-\frac{1}{q}}}{N}\right)^q = \frac{1}{N} \geq \frac{\sqrt[q]{N}}{N^2}.$$

On the other hand, there exists a constant θ with $0 < \theta < 1/i_0$ such that

$$h_2 = q i_0^{q-1}(1+\theta)^{q-1}N^{-q}.$$

Thus

$$h_2 \geq q i_0^{q-1}N^{-q} \geq qN^{\frac{1}{q}-2} \geq \frac{\sqrt[q]{N}}{N^2}.$$

This concludes the second estimate in this proposition. The third estimate can be similarly obtained. □

We remark that it follows from Proposition 4.3 that the HC method requires less computational cost than the GC method even though they have the same order of convergence. For example, when $\alpha = \frac{1}{2}$, $r = 3$, and $N = 100$, the HC method uses 54 subintervals while the GC method uses 100 subintervals.

Another important point made in the last proposition is that the HC method is more stable than the GC method since the length of the smallest subinterval used in the HC method is larger than the length of the smallest subinterval used in the GC method. Notice that the length of the smallest interval used in the HC method is not as sensitive to r and α as that in the GC method. For instance, when $N = 1000$, $\alpha = \frac{1}{2}$, and $r = 3$, the length of the smallest interval used in the GC method is $h_1 = 10^{-24}$ while the length of the smallest interval used the HC method is 4.217×10^{-5}. In addition, we see from the proposition that for the GC method $\mathcal{R}_{GC}$ grows in the order $\mathcal{O}(N^{q-1})$ while for the HC method $\mathcal{R}_{HC}$ grows slower than $\mathcal{O}(N)$. When p is large, which is the case when α is small or r is large, $\mathcal{R}_{GC}$ is extremely large. This may cause serious instability problems. The result in the proposition shows that the HC method is much more stable than the GC method.

5. Numerical experiments. In this section, we report results of numerical experiments which confirm the theoretical analysis for the HC method presented in the last section and demonstrate the effectiveness of the method.

In (1.1) we choose $K(s,t) = M(s,t) = 1$, $\alpha = 1/2$ and choose f such that the equation has the exact solution

$$y(t) = \sqrt{t^2+t}\cos t + \sin t, \quad t \in I.$$

Note that the first derivative of this solution has a singularity at $t = 0$.

The purpose of these numerical experiments is to compare the numerical performance of the HC method with the GC method. For both of the methods we use piecewise polynomials of degree 2, that is, $r = 3$, and, in addition, for the HC method we use

$$V_3 = \operatorname{span}\{1,\ t,\ t^2,\ t^{\frac{1}{2}},\ t^{\frac{3}{2}},\ t^{\frac{5}{2}}\}$$

on the first interval.

Tables 5.1 and 5.2 are given to compare the numerical performance of the two methods, where "order of conv." stands for the order of convergence. The weakly singular integrals that appear in these methods are computed by a numerical integration scheme presented in [12] specifically designed for weakly singular integrals of this type.

The HC method and the GC method have the same orders of convergence. The computed orders of convergence are consistent with the theoretical order, which is $r =$

Table 5.1
Numerical performance of the HC method.

N	$\|y - y_h\|$	Order of conv.	$\mathcal{N}_{HC}$	$\mathcal{L}_{HC}$
20	3.666e-4	-	8	7.5419e-02
40	4.680e-5	2.9698	19	2.7681e-02
60	1.408e-5	2.9616	30	1.9022e-02
80	5.983e-6	2.9759	42	1.3423e-02
100	3.069e-6	2.9916	54	1.0779e-02

Table 5.2
Numerical performance of the GC method.

N	$\|y - y_h\|$	Order of conv.	$\mathcal{N}_{GC}$	$\mathcal{L}_{GC}$
20	1.993e-4	-	20	1.5625e-08
40	3.446e-5	2.9720	40	2.4414e-10
60	1.240e-5	2.9576	60	2.1433e-11
80	6.011e-6	2.9776	80	3.8147e-12
100	3.430e-6	2.9896	100	1.0000e-12

3 for both methods. In terms of convergence both methods give satisfactory numerical performance. However, the HC method uses much fewer subintervals. Therefore, it requires less computational cost than the GC method. Also, the length of the smallest subinterval used in the HC method is significantly larger than that in the GC method. When N is large and α is small, for the GC method, the length of the first interval is extremely small, which may cause serious round-off errors. The HC method has a rather uniform partition, which avoids the problem of having small subintervals. In these two aspects, the HC method has performed better than the GC method.

Acknowledgment. The authors are grateful to two referees for their suggestions that improve the presentation of this paper.

ON THE TIME-CONTINUOUS MASS TRANSPORT PROBLEM AND ITS APPROXIMATION BY AUGMENTED LAGRANGIAN TECHNIQUES*

K. GUITTET[†]

Abstract. In [J. D. BENAMOU AND Y. BRENIER, *Numer. Math.*, 84 (2000), pp. 375–393], a computational fluid dynamic approach was introduced for computing the optimal map occurring in the Monge–Kantorovich problem. Though the described augmented Lagrangian method involves a Hilbertian framework, the discussion was purely formal. Taking advantage of the recent progress in optimal transport theory [L. A. CAFFARELLI, *Comm. Pure Appl. Math.*, 45 (1992), pp. 1141–1151], [L. A. CAFFARELLI, *Ann. of Math.* (2), 144 (1996), pp. 453–496], [D. CORDERO-ERAUSQUIN, *C. R. Acad. Sci. Paris Sér.* I *Math.*, 329 (1999), pp. 199–202], [R. J. MCCANN, *Geom. Funct. Anal.*, 11 (2001), pp. 589–608] and despite the lack of coercivity of the Hilbertian problem, we establish an existence result. Then, under a reasonable assumption of positivity for the density, we prove the existence of saddle-points for both Lagrangians defined in Benamou and Brenier, and finally prove the convergence of the numerical method.

Introduction. Given two nonnegative density functions ρ_0 and ρ_T on $\mathbb{R}^d$ satisfying the compatibility condition

$$\int_{\mathbb{R}^d} \rho_0(x)dx = \int_{\mathbb{R}^d} \rho_T(x)dx, \tag{0.1}$$

a map M is said to transport ρ_0 to ρ_T if, for any bounded subset A of $\mathbb{R}^d$,

$$\int_A \rho_T(x)dx = \int_{M(A)} \rho_0(x)dx. \tag{0.2}$$

Then the Monge–Kantorovich problem (MKP) consists of finding a map M transporting ρ_0 to ρ_T and minimizing the cost

$$\int_{\mathbb{R}^d} |M(x) - x|^2 \rho_0(x)dx. \tag{0.3}$$

The problem of the existence and the characterization of the optimal map has been solved in [2] by Brenier, who showed that the optimal map is the gradient of a convex potential. This result has then been extended to the cases of more general cost functions in [8] and more general geometries in [10]. From a numerical point of view, the computation of the optimal map seems to be a challenging problem (see [1] for a brief review of existing methods). In their work [1], Benamou and Brenier used an artificial (time) variable to linearize the constraints (0.2). Then an augmented numerical resolution of the resulting problem was presented. Although the optimal

[†]INRIA Rocquencourt, Action OTTO, Domaine de Voluceau, Rocquencourt-B.P. 105, 78153 Le Chesnay Cedex, France (kevin.guittet@inria.fr).

mass transport problem is naturally set up in the frame of probability measures and continuous test functions, the augmented method used in [1] is largely of Hilbertian nature. In order to prove the convergence of the method, it is therefore natural to study the optimal mass transport problem from a Hilbertian point of view. This article presents a step-by-step justification of the numerical method in the required Hilbertian framework and finally provides a convergence proof. As in [1], we will consider only the case of the torus, which considerably simplifies the analysis. Now we define the time-continuous MKP (TCMKP) as follows.

Let $\mathbb{T}^d$ be the d-dimensional unit cube with periodic boundary. Define $Q = [0;T] \times \mathbb{T}^d$. In this study, we note

$$H(Q;\mathrm{div}) = \{f \in L^2(Q)^{1+d} \text{ s.t. } \nabla_{t,x}.f \in L^2(Q)\}, \tag{0.4}$$

$$V(Q) = \{f \in L^2(Q)^{1+d} \text{ s.t. } \|\nabla_{t,x}.f\|_{L^2(Q)} = 0\}. \tag{0.5}$$

Given two densities (ρ_0, ρ_T) in $L^2(\mathbb{T}^d)$ satisfying the compatibility condition (0.1), the TCMKP is to minimize

$$K(\rho, m) = \int_0^T \int_{\mathbb{T}^d} \frac{|m|^2}{2\rho} dxdt, \tag{0.6}$$

over all pairs (ρ, m) in $V(Q)$ satisfying the boundary conditions

$$\begin{aligned} \rho(0,.) &= \rho_0 \qquad \text{in } L^2(\mathbb{T}^d), \\ \rho(T,.) &= \rho_T \qquad \text{in } L^2(\mathbb{T}^d). \end{aligned} \tag{0.7}$$

We denote by $E(\rho_0, \rho_T)$ this minimum.

Remark 0.1. The link between the MKP and the TCMKP may be unclear. This link is used as an important tool in the proof of the main theorem of section 1, to which we refer for more explanation.

In this paper, our aim is to derive a rigorous Hilbertian theory for the TCMKP, and to prove the convergence of the augmented Lagrangian method used in [1]. Thus section 1 deals with the well-posedness of the Hilbertian problem. The formal existence result proved in [1] is made rigorous in the Hilbertian framework, and the link between the optimal cost $E(\rho_0, \rho_T)$ and the Wasserstein distance between ρ_0 and ρ_T is recalled. In section 2, we look at the Lagrangian formulation of the TCMKP and prove an abstract existence result of a saddle-point. Since this Lagrangian L is the starting point of the numerical method, we expect this result to be an important step when looking for a convergence result. Next the purpose of section 3 is to get more information on the saddle-point. Specifically, we show that the Lagrange multiplier of the mass conservation constraint is linked to the optimal pair (ρ^*, m^*). Then we recall the second Lagrangian $\mathcal{L}$ introduced in [1] and use the saddle-points of L to characterize the saddle-points of $\mathcal{L}$. We therefore get an existence result for a saddle-point of $\mathcal{L}$. Finally, section 4 presents a convergence result for the numerical algorithm. This result may be unexpected since some of the classical assumptions required for convergence are not fulfilled.

1. Well-posedness of the Hilbertian problem. In this section, the main result is the existence of a minimizer of the TCMKP and the characterization of the optimal cost $E(\rho_0, \rho_T)$. Those results are summarized in the following theorem.

Theorem 1.1. *For any nonnegative* (ρ_0, ρ_T) *in* $(L^2(\mathbb{T}^d))^2$ *satisfying* (0.1), *we have*

$$E(\rho_0, \rho_1) = \frac{1}{2T} d^2_{Wass}(\rho_0, \rho_1). \tag{1.1}$$

Moreover, there exists a minimizer (ρ^*, m^*) *such that*

$$\|\rho^*\|_{L^\infty([0;T];L^p(\mathbb{T}^d))} \leq M_p, \tag{1.2}$$

$$\|m^*\|_{L^\infty([0;T];L^p(\mathbb{T}^d))} \leq M_p \frac{\sqrt{d}}{T}, \tag{1.3}$$

where $M_p = \max(\|\rho_0\|_{L^p(\mathbb{T}^d)}, \|\rho_T\|_{L^p(\mathbb{T}^d)})$ *for any* $p \in]1; \infty]$.

Sketch of the proof. First, we give a precise definition for the kinetic energy $K(\rho, m)$ defined in (0.6). A first inequality is then derived using the nonlinear interpolation between ρ_0 and ρ_1 introduced by McCann in [9]. The proof of the converse inequality is based on a formal argument of Benamou and Brenier. A minimizing sequence is carefully lifted and mollified, so that this argument actually holds.

The rigorous definition of the kinetic energy follows from the observation that for positive ρ

$$\frac{|m|^2}{2\rho} = \sup_{a + \frac{|b|^2}{2} \leq 0} [a\rho + b.m]. \tag{1.4}$$

Then $K(\rho, m)$ can be defined through the following equality:

$$K(\rho, m) = \sup \int_Q a\rho + b.m, \tag{1.5}$$

where $(a, b) \in L^2(Q) \times L^2(Q)^d$ are subject to the constraint that for all nonnegative $f \in L^\infty(Q)$

$$\int_0^T \int_{\mathbb{T}^d} f \left(a + \frac{|b|^2}{2} \right) dx \leq 0. \tag{1.6}$$

We denote by $\tilde{K}$ the set of all pairs $(a, b) \in L^2(Q)^{1+d}$ satisfying (1.6). It is easy to see that $\tilde{K}$ is a closed convex set in $L^2(Q)^{1+d}$. Moreover, for any fixed pair $(a, b) \in \tilde{K}$, the application $(\rho, m) \mapsto \int_Q a\rho + b.m$ is convex and continuous, and then lower semicontinuous. Then the upper envelope K of those functions is still convex and l.s.c. This property of K will prove to be useful in what follows.

Remark 1.2. Such a characterization of the kinetic energy has been used by Brenier in [3]. The test functions were taken in $\mathcal{C}^0(Q)$, so that the interior of $\tilde{K}$ was not empty. This property allowed Brenier to use a duality theorem of Rockafellar to get the existence of a minimizer. However, this minimizer was found in the set of Radon measures. Since we expect more regularity for our minimizer, our definition of $\tilde{K}$ is slightly different, and this set turns out to be of empty interior.

In order to get the first inequality, we use the interpolation defined by McCann in [9]. Specifically, we have the following lemma.

Lemma 1.3. *Let* (ρ_0, ρ_T) *be two nonnegative densities in* $L^2(\mathbb{T}^d)$. *Then there exists some* $(\rho^*, m^*) \in V(Q)$ *satisfying* (0.7), (1.2), *and* (1.3) *and such that*

$$K(\rho^*, m^*) \leq \frac{1}{2T} d^2_{Wass}(\rho_0, \rho_T). \tag{1.7}$$

Proof. Denote by $\nabla_x \phi$ the optimal transport (which is known to be the gradient of a convex potential) from ρ_0 to ρ_T. It means that $(\nabla_x\phi)_\sharp \rho_0 = \rho_T$. Then, following McCann, we can use this transport to define the nonlinear interpolation between ρ_0 and ρ_T:

$$\bar\rho_t = \frac{1}{T}((T-t)Id + t\nabla_x\phi)_\sharp \rho_0. \tag{1.8}$$

For any $p \in]1;\infty]$, the L^p-norm of $\bar\rho_t$ is displacement convex, which means in particular that

$$\|\bar\rho_t\|_{L^p(\mathbb{T}^d)} \leq \max\left(\|\rho_0\|_{L^p(\mathbb{T}^d)}, \|\rho_T\|_{L^p(\mathbb{T}^d)}\right). \tag{1.9}$$

Now define the characteristics associated with $\nabla_x\phi$,

$$X(t,x) = \frac{1}{T}((T-t)Id + t\nabla_x\phi)(x) = \nabla_x\phi_t(x), \tag{1.10}$$

and the velocity field

$$\begin{cases} v(t, X(t,x)) = \frac{1}{T}(\nabla_x\phi(x) - x) & \text{on } X(t, \{x \in \mathbb{T}^d | \rho_0(x) > 0\}), \\ v(t,y) = 0 & \text{elsewhere.} \end{cases} \tag{1.11}$$

Then define $\bar m(t,x) = \bar\rho(t,x)v(t,x)$. Assuming some regularity, this construction ensures that $(\bar\rho, \bar m) \in V(Q)$ and

$$K(\bar\rho, \bar m) = \frac{1}{2T} d^2_{Wass}(\rho_0, \rho_T). \tag{1.12}$$

Moreover, since $\nabla_x\phi$ is the optimal transport on the torus, we get that for any $x \in \mathbb{T}^d$, $\|\nabla_x\phi(x) - x\| \leq d$. As a consequence, we have the following estimate for any $p \in]1;\infty]$:

$$\|\bar m\|_{L^\infty([0;T];L^p(\mathbb{T}^d))} \leq \frac{\sqrt{d}}{T} \max\left(\|\rho_0\|_{L^p(\mathbb{T}^d)}, \|\rho_T\|_{L^p(\mathbb{T}^d)}\right). \tag{1.13}$$

Now, regularizing the boundary densities and using the regularity theory for the MKP, it is possible to build a weakly converging sequence in $H(Q, \mathrm{div})$. Denote the limit by (ρ^*, m^*). By construction, (ρ^*, m^*) is in $V(Q)$ and satisfies (0.7). Moreover, K is convex and l.s.c, and it follows that

$$E(\rho_0, \rho_1) \leq K(\rho^*, m^*) \leq \frac{1}{2T} d^2_{Wass}(\rho_0, \rho_T). \tag{1.14}$$

Finally, (1.2) and (1.3) follow simply from (1.9) and (1.13). This achieves the proof of Lemma 1.3. □

Now we have to get the converse inequality. Let $(\rho_n, m_n)_{n\in\mathbb{N}}$ be a minimizing sequence for the TCMKP. For any n in $\mathbb{N}^*$, we define

$$\begin{cases} \rho_n^{(1)} = \rho_n + \dfrac{1}{n}, \\ m_n^{(1)} = m_n. \end{cases} \tag{1.15}$$

By construction, we have $(\rho_n^{(1)}, m_n^{(1)}) \in V(Q)$ and

$$\forall (t,x) \in Q, \qquad \rho_n^{(1)}(t,x) \geq \frac{1}{n}. \tag{1.16}$$

Moreover, the definition of K leads to

$$K(\rho_n^{(1)}, m_n^{(1)}) \leq K(\rho_n, m_n). \tag{1.17}$$

Now we want to build a smooth "outer" (in the sense that the time-boundary data are not satisfied, but only carefully approximated) minimizing sequence. This regularization will be necessary in order to define a smooth velocity field and some characteristics, which will then allow us to apply Benamou and Brenier's argument. We therefore define f in $\mathcal{C}(\mathbb{R} \times \mathbb{T}^d)$ as follows:

$$\begin{cases} f(t,x) = (0,x) & \text{if} \quad t < 0, \\ f(t,x) = (t,x) & \text{if} \quad t \in [0;T], \\ f(t,x) = (T,x) & \text{if} \quad t > T. \end{cases} \tag{1.18}$$

Define $\rho_n^* = \rho_n^{(1)} \circ f$ and $m_n^* = \chi_{[0;T]}[m_n^{(1)} \circ f]$. We have $(\rho_n^*, m_n^*) \in V(Q)$. This extension of the functions allows a good convergence of the time-boundary values. Fix $n \in \mathbb{N}^*$. For any k in $\mathbb{N}^*$ we define

$$g_k(t,x) = \left(-\frac{T}{k} + \left(1 + \frac{2}{k}\right)t, x\right). \tag{1.19}$$

The sequence (ρ_n^k, m_n^k) is then defined as follows:

$$\begin{cases} \rho_n^k(t,x) = \xi_{\frac{T}{k}} * [\rho_n^* \circ g_k], \\ m_n^k(t,x) = \left(1 + \dfrac{2}{k}\right) \xi_{\frac{T}{k}} * [m_n^* \circ g_k], \end{cases} \tag{1.20}$$

where ξ is a positive mollifier with support contained in the unit ball of $\mathbb{R}^{d+1}$. It is easy to see that for any k in $\mathbb{N}^*$, (ρ_n^k, m_n^k) is in $V(Q)$. Moreover, the pair (ρ_n^k, m_n^k) satisfies the following properties,

$$\begin{cases} \rho_n^k \in \mathcal{C}^\infty(Q), \\ m_n^k \in \mathcal{C}^\infty(Q)^d \\ \forall (t,x) \in Q, \quad \dfrac{1}{n} \leq \rho_n^k(t,x), \end{cases} \tag{1.21}$$

and some subsequence (still labeled by k) satisfies

$$\begin{cases} \lim_{k\to\infty} \|(\rho_n^k, m_n^k) - (\rho_n^{(1)}, m_n^{(1)})\|_{H(Q;div)} = 0, \\ \lim_{k\to\infty} \|\rho_n^k(0,.) - \rho_0^n\|_{L^2(\mathbb{T}^d)} = 0, \\ \lim_{k\to\infty} \|\rho_n^k(T,.) - \rho_T^n\|_{L^2(\mathbb{T}^d)} = 0. \end{cases} \tag{1.22}$$

Moreover, the sequence $(1/\rho_n^k)_{k\in\mathbb{N}}$ converges weakly* in $L^\infty(\mathbb{T}^d)$ towards $1/\rho_n^{(1)}$. This, together with (1.22), ensures the convergence of $K(\rho_n^k, m_n^k)$ towards $K(\rho_n^{(1)}, m_n^{(1)})$. We then get that there exists a k_n in $\mathbb{N}$ such that

$$K(\rho_n^{k_n}, m_n^{k_n}) \leq K(\rho_n^{(1)}, m_n^{(1)}) + \frac{1}{n}, \tag{1.23}$$

$$\|\rho_n^{k_n}(0,.) - \rho_0^n\|_{L^2(\mathbb{T}^d)} \leq \frac{1}{n}, \tag{1.24}$$

$$\|\rho_n^{k_n}(T,.) - \rho_T^n\|_{L^2(\mathbb{T}^d)} \leq \frac{1}{n}. \tag{1.25}$$

Define $(\rho_n^{(2)}, m_n^{(2)}) = (\rho_n^{k_n}, m_n^{k_n})$. By construction, we have

$$\begin{cases} (\rho_n^{(2)}, m_n^{(2)}) \in \mathcal{C}^\infty(Q)^{d+1} \\ \forall (t,x) \in Q, \ \rho_n^{(2)} \geq \dfrac{1}{n}. \end{cases} \tag{1.26}$$

Moreover, (1.23) implies that

$$K(\rho_n^{(2)}, m_n^{(2)}) \leq K(\rho_n^{(1)}, m_n^{(1)}) + \frac{1}{n}. \tag{1.27}$$

Hence $(\rho_n^{(2)}, m_n^{(2)})$ is an "outer" minimizing sequence. It is now possible to use Benamou and Brenier's argument to get the required inequality. We therefore define the velocity field

$$v_n^{(2)} = \frac{m_n^{(2)}}{\rho_n^{(2)}}. \tag{1.28}$$

$v_n^{(2)}$ is in $\mathcal{C}^\infty(Q)^d$. We are now able to define the characteristics. We look at the differential system

$$\begin{cases} \partial_t X(t,x) = v_n^{(2)}(t, X(t,x)), \\ X(0,x) = x. \end{cases} \tag{1.29}$$

Since $v_n^{(2)}$ is a $\mathcal{C}^\infty$ function, this system is well defined, and the solution is uniquely defined on $[0;T]$. Now we recall the computations in [1] to show that the "optimal displacement" between $X(0,.)$ and $X(T,.)$ follows straight lines. Indeed, we have

$$\begin{aligned} T\int_{\mathbb{T}^d}\int_0^T \rho_n^{(2)}(t,x)|v_n^{(2)}(t,x)|^2 dxdt &= T\int_{\mathbb{T}^d}\int_0^T \rho_n^{(2)}(0,x)|v_n^{(2)}(t,X(t,x))|^2 dxdt \\ &= T\int_{\mathbb{T}^d}\int_0^T \rho_n^{(2)}(0,x)|\partial_t X(t,x)|^2 dxdt \\ &\geq \int_{\mathbb{T}^d} \rho_n^{(2)}(0,x)|X(T,x) - X(0,x)|^2 dx \\ &= \int_{\mathbb{T}^d} \rho_n^{(2)}(0,x)|X(T,x) - x|^2 dx. \end{aligned}$$

It is then sufficient to consider the MKP between the densities $\rho_n^{(2)}(0,.)$ and $\rho_n^{(2)}(T,.)$. From [6], we get the existence of a convex function ϕ_n such that $\nabla_x \phi_n$ minimizes

$$\int_{\mathbb{T}^d} \rho_n^{(2)}(0,x)|M(x)-x|^2 dx \tag{1.30}$$

in the set of application M pushing $\rho_n^{(2)}(0,.)$ forward to $\rho_n^{(2)}(T,.)$. This minimum is the definition of the Wasserstein distance between $\rho_n^{(2)}(0,.)$ and $\rho_n^{(2)}(T,.)$. We then get that

$$d_{Wass}^2(\rho_n^{(2)}(0,.),\rho_n^{(2)}(T,.)) \leq 2T\ K(\rho_n^{(2)}, m_n^{(2)}). \tag{1.31}$$

Summarizing (1.17), (1.27), (1.31), we get

$$\begin{aligned} \frac{1}{2T} d_{Wass}^2(\rho_n^{(2)}(0,.),\rho_n^{(2)}(T,.)) &\leq K(\rho_n^{(2)}, m_n^{(2)}) \\ &\leq K(\rho_n^{(1)}, m_n^{(1)}) + \frac{1}{n} \\ &\leq K(\rho_n, m_n) + \frac{1}{n}. \end{aligned}$$

The Wasserstein distance is continuous with respect to the L^2 distance on the torus (thanks to its finite diameter). Hence we get that $d_{Wass}^2(\rho_n^{(2)}(0,.),\rho_n^{(2)}(T,.))$ converges to $d_{Wass}^2(\rho_0,\rho_T)$ as n goes to infinity. Passing to the limit in the previous inequality, we get

$$\frac{1}{2T} d_{Wass}^2(\rho_0,\rho_T) \leq E(\rho_0,\rho_T). \tag{1.32}$$

This, together with (1.14), achieves the proof of Theorem 1.1.

2. Existence of a saddle-point for the Lagrangian. From now on, we will assume that the optimal density ρ^* satisfies the following assumption:

$$\exists \alpha_1 > 0 \text{ s.t. } \forall (t,x) \in Q,\ \rho^*(x,t) \geq \alpha_1. \tag{2.1}$$

Notice that this assumption is always satisfied for strictly positive smooth boundary data. Indeed, when ρ_0 and ρ_1 are of class $\mathcal{C}^{\alpha,l}(\mathbb{T}^d)$, the regularity theory developed for the optimal mass transport problem by Caffarelli in the case of convex bounded domains (see [4], [5]) and recently applied by Cordero-Erausquin [6] in the case of the flat torus $\mathbb{T}^d = \mathbb{R}^d/\mathbb{Z}^d$ ensures that ϕ is of class $\mathcal{C}^{\alpha,l+2}(\mathbb{T}^d)$. Then the Monge–Ampère equation

$$\rho^*(t, \nabla_x \phi_t(x)) \det(\nabla_x^2 \phi_t(x)) = \rho_0(x) \tag{2.2}$$

holds, and ρ^* is smooth. Moreover, we have $(1-t)^d \leq \det(\nabla_x^2 \phi_t(x)) \leq C$ for a constant C depending only on ρ_0 and ρ_1. This implies that the optimal density ρ^* is bounded from below away from zero, and (2.1) is proved. However, the existence of the first saddle-point defined in [1] may be obtained without the regularity assumption on the boundary densities.

Theorem 2.1. *Assume that the solution* (ρ^*, m^*) *of the TCMKP satisfies* (2.1). *Then there exists a* $\lambda^* \in L_0^2(Q)$ *such that* (ρ^*, m^*, λ^*) *is a saddle-point of the Lagrangian L, defined as follows:*

$$L(\rho, m, \lambda) = K(\rho, m) + \int_0^T \int_{\mathbb{T}^d} (\partial_t \rho + \nabla_x . m)\lambda \; dxdt. \tag{2.3}$$

The proof of this theorem relies mainly on an application of the Hahn–Banach theorem. The two convex sets we want to separate are defined as follows:

$$S = \left\{ (K(\rho, m) - K(\rho^*, m^*) + s, \partial_t \rho + \nabla_x . m) \;\middle|\; \begin{array}{l} (\rho, m) \in H(Q; \mathrm{div}), \\ (0.7) \text{ holds}, \\ s \geq 0, \end{array} \right\}$$

$$T = \left\{ (-t, 0) \in \mathbb{R} \times L_0^2(Q), t > 0 \right\}.$$

The next three lemmas show that S and T satisfy the required assumptions for the Hahn–Banach theorem.

Lemma 2.2. *S and T are convex.*

Proof. The convexity of T is obvious. Let (r_1, ψ_1) and (r_2, ψ_2) be in S. There exists (ρ_1, m_1, s_1) and (ρ_2, m_2, s_2) such that

$$(K(\rho_i, m_i) - K(\rho^*, m^*) + s_i, \partial_t \rho + \nabla_x . m) = (r_i, \psi_i). \tag{2.4}$$

From the convexity of K, we get

$$K\left(\frac{1}{2}(\rho_1 + \rho_2, m_1 + m_2)\right) \leq \frac{1}{2}(K(\rho_1, m_1) + K(\rho_2, m_2)). \tag{2.5}$$

Let $s_3 = \frac{1}{2}(s_1 + s_2) + \frac{1}{2}(K(\rho_1, m_1) + K(\rho_2, m_2)) - K(\frac{1}{2}(\rho_1 + \rho_2, m_1 + m_2))$. We have $s_3 \geq 0$. Define then

$$(\rho_3, m_3) = \frac{1}{2}(\rho_1 + \rho_2, m_1 + m_2),$$

$$\psi_3 = \frac{1}{2}(\psi_1 + \psi_2),$$

$$r_3 = \frac{1}{2}(r_1 + r_2).$$

From the linearity of the divergence operator, we get $\psi_3 = \nabla_{t,x}.(\rho_3, m_3)$. Then we have that $s_3 \geq 0$ and $\psi_3 \in H(Q; \mathrm{div})$ such that

$$(K(\rho_3, m_3) - K(\rho^*, m^*) + s_3, \partial_t \rho + \nabla_x . m) = (r_3, \psi_3).$$

Hence (r_3, ψ_3) is in S. This proves the convexity of S. □

Lemma 2.3. $S \cap T = \emptyset$.

Proof. Let (r, ψ) be in $S \cap T$. We have $\psi = 0$. Let (ρ, m, s) such that

$$(K(\rho, m) - K(\rho^*, m^*) + s, \partial_t \rho + \nabla_x . m) = (r, 0). \tag{2.6}$$

Using the definition of (ρ^*, m^*), we have $r \geq s$. Hence $r \geq 0$. But we should have $r < 0$ since (r, ψ) is in T. This is a contradiction. We conclude that $S \cap T = \emptyset$. □

Lemma 2.4. *The interior of S is not empty.*

Proof. Let $s_0 > 0$. As we will show, $(s_0, 0)$ is an interior point of S. Let $0 < \epsilon < 1/2$. Take (r, g) in a neighborhood of $(s_0, 0)$, that is, such that

$$|r - s_0| + \|g\|_{L^2} < \epsilon. \tag{2.7}$$

We want to prove that (r, g) is in S for ϵ small enough. We are therefore looking for a (ρ, m, s) such that

$$\begin{cases} K(\rho, m) - K(\rho^*, m^*) + s = r, \\ \\ \nabla_{t,x}.(\rho, m) = g. \end{cases}$$

One of the difficulties comes from the fact that ρ has to satisfy some positivity property. In order to control the L^∞-norm of the new density, we integrate the mass production induced by g. We then define $h(t) = \int_0^t \int_{\mathbb{T}^d} g(u, x)dxdu$. Since g is in $L^2_0(Q)$, we have $h(T) = 0$. This condition is necessary to allow the recovery of the boundary conditions for ρ. Our strategy is then to split ρ into two parts. The first part has to stay close to the optimal density, while the second has to track the mass production. We therefore define $\rho_2(t, x) = \theta\alpha_1 + h(t)$ for some θ. Then we must have the following equality:

$$\nabla_x.m(t, x) = g(t, x) - \int_{\mathbb{T}^d} g(t, y)dy. \tag{2.8}$$

For almost every t in $[0; T]$, we solve the system

$$\begin{cases} \Delta_x(\psi_t) = g(t, x) - \displaystyle\int_{\mathbb{T}^d} g(t, y)dy, \\ \\ \psi_t \in H^1(\mathbb{T}^d) \cap L^2_0(\mathbb{T}^d), \end{cases}$$

under periodic boundary conditions. We then take $\tilde{m}(t, x) = \nabla_x \psi_t(x)$. By construction, we have

$$\|\tilde{m}(t, .)\|_{L^2(\mathbb{T}^d)} \leq C\|g(t, .)\|_{L^2(\mathbb{T}^d)}. \tag{2.9}$$

Integrating in t, we get $\|\tilde{m}\|_{L^2(Q)} \leq C\|g\|_{L^2(Q)}$.

Remark 2.5. This construction does not take care of the measurability of the resulting function $\tilde{m}$, which could be easily stated. Anyway, the bound (2.9) allows some regularization process ...

Now we consider $K(\rho^* + h(t), m^* + \tilde{m})$. We want to prove that this action is close to the minimum. Therefore, we define

$$(\rho_1, m_1) = (\rho^* - \theta\alpha_1, m^*), \tag{2.10}$$

$$(\rho_2, m_2) = (h(t) + \theta\alpha_1, \tilde{m}). \tag{2.11}$$

The inequality $K((\rho_1, m_1) + (\rho_2, m_2)) \leq K(\rho_1, m_1) + K(\rho_2, m_2)$ follows from the convexity and the homogeneity property of K.

$$\begin{aligned} K(\rho_1, m_1) &= \int_{\mathbb{T}^d} \int_0^T \frac{|m^*|^2}{2(\rho^* - \theta\alpha_1)} dxdt \\ &= \int_{\mathbb{T}^d} \int_0^T \frac{|m^*|^2}{2\rho^*} \frac{\rho^*}{\rho^* - \theta\alpha_1} dxdt. \end{aligned}$$

But we have $\alpha_1 \leq \rho^*$, so that $\rho^* - \theta\alpha_1 \geq (1-\theta)\rho^*$. Hence we have

$$K(\rho_1, m_1) \leq \frac{1}{1-\theta} K(\rho^*, m^*).$$

Finally, we get

$$K(\rho_1, m_1) - K(\rho^*, m^*) \leq \frac{\theta}{1-\theta} K(\rho^*, m^*). \tag{2.12}$$

Now we have to estimate $K(\rho_2, m_2)$. We have

$$\begin{aligned} \rho_2(t,x) &= \int_0^t \int_{\mathbb{T}^d} g(u,x) dx du + \theta\alpha_1 \\ &= \int_0^T \int_{\mathbb{T}^d} g(u,x)\chi_{[0;t]} dx du + \theta\alpha_1. \end{aligned} \tag{2.13}$$

Then for all $(t,x) \in Q$

$$\theta\alpha_1 - \|g\|_{L^2(Q)}\sqrt{t} \leq \rho_2(t,x) \leq \theta\alpha_1 + \|g\|_{L^2(Q)}\sqrt{t}.$$

Hence for $\|g\|_{L^2(Q)} \leq \frac{1}{\sqrt{T}}\theta\alpha_1$ we have

$$\forall (t,x) \in Q, \qquad \rho_2(t,x) \geq 0.$$

Moreover, taking $2\epsilon\sqrt{T} \leq \alpha_1\theta$, we get

$$\begin{aligned} K(\rho_2, m_2) &\leq \int_0^T \int_{\mathbb{T}^d} \frac{1}{\theta\alpha_1} |m_2|^2 \\ &\leq \frac{1}{\theta\alpha_1} \|m_2\|^2_{L^2(Q)} \\ &\leq \frac{C}{\theta\alpha_1} \|g\|^2_{L^2(Q)}. \end{aligned}$$

Finally, we get

$$\begin{aligned} K(\rho, m) - K(\rho^*, m^*) &\leq \frac{\theta}{1-\theta} K(\rho^*, m^*) + \frac{C}{\theta\alpha_1} \|g\|^2_{L^2(Q)} \\ &\leq \frac{\theta}{1-\theta} K(\rho^*, m^*) + \frac{C}{\theta\alpha_1} \epsilon^2 \\ &\leq 4\epsilon \frac{\sqrt{T}}{\alpha_1} K(\rho^*, m^*) + \frac{C}{2\sqrt{T}} \epsilon \quad \text{when taking } \theta = 2\epsilon \frac{\sqrt{T}}{\alpha_1}. \end{aligned}$$

We want $K(\rho, m) - K(\rho^*, m^*) \leq r$. It is sufficient to take a small ϵ, since r is of the same order as s_0. It is then possible to take $s = r - (K(\rho, m) - K(\rho^*, m^*))$, and we finally get (ρ, m, s) such that

$$(K(\rho, m) - K(\rho^*, m^*) + s, \partial_t\rho + \nabla_x.m) = (r, g). \tag{2.14}$$

We deduce that the interior of S is not empty. $\square$

It is now possible to finish the proof of the theorem. From the Hahn–Banach theorem, there exists a nonzero linear form separating S and T. We then have $(\alpha_0, \phi_0) \in \mathbb{R} \times L^2_0$ such that

$$\forall(\rho, m, s, t),\ \alpha_0(K(\rho, m) - K(\rho^*, m^*) + s)\ + \langle \nabla_{t,x}.(\rho, m), \phi_0\rangle\ \geq\ -\alpha_0 t. \tag{2.15}$$

First we take $(\rho, m) = (\rho^*, m^*)$. We have

$$\forall(s, t), \qquad s \geq 0, t > 0, \alpha_0 s \geq \alpha_0 t.$$

We deduce that α_0 is nonnegative. Assume now that $\alpha_0 = 0$. Then (2.15) becomes

$$\forall(\rho, m, s), \qquad \langle \nabla_{t,x}.(\rho, m), \phi_0\rangle \geq 0. \tag{2.16}$$

Let ψ be the solution in L^2_0 of the following system:

$$\begin{cases} \Delta\psi = -\phi_0, \\ \partial_t\psi(0, .) = \rho_0, \\ \partial_t\psi(T, .) = \rho_T, \end{cases}$$

with periodic boundary conditions in space.

We define $(\rho, m) = \nabla_{t,x}\psi$. We then get $\|\phi_0\|^2_{L^2} \leq 0$, and therefore $\phi_0 = 0$, which is a contradiction. We deduce that $\alpha_0 > 0$. Finally, define $\lambda^* = \frac{\phi_0}{\alpha_0}$. We have to check that the triplet (ρ^*, m^*, λ^*) is indeed a saddle-point of L. Taking $s = 0$ and letting t go to 0, we get

$$\forall(\rho, m) \in H(Q; \text{div}), \qquad L(\rho^*, m^*, \lambda^*) \leq L(\rho, m, \lambda^*). \tag{2.17}$$

Moreover, we have $\nabla_{t,x}.(\rho^*, m^*) = 0$, and therefore

$$\forall\lambda \in L^2_0, \qquad L(\rho^*, m^*, \lambda) \leq L(\rho^*, m^*, \lambda^*). \tag{2.18}$$

Hence, the triplet (ρ^*, m^*, λ^*) is a saddle-point of L, and Theorem 2.1 is proved.

3. More on the saddle-point.

Now we prove some properties of the saddle-point. Indeed, we have

$$K(\rho^*, m^*) = \sup_{(a,b)\in\tilde{K}} \int_{[0;T]} \int_{\mathbb{T}^d} a\rho^* + b.m^* dxdt. \tag{3.1}$$

As a consequence of the uniform boundedness of the velocity fields in the proof of Lemma 1.3, we see that the optimal pair (a^*, b^*) is actually reached and bounded in $L^\infty(Q)$. Indeed, this pair is given by the following equalities:

$$\begin{cases} a^* = -\dfrac{|m^*|^2}{2{\rho^*}^2}, \\ b^* = \dfrac{m^*}{\rho^*}. \end{cases} \tag{3.2}$$

Let $(\tilde{\rho}, \tilde{m})$ in $\mathcal{C}^\infty(Q)^{1+d}$ and δ in $\mathbb{R}$. Assume furthermore that

$$\tilde{\rho}(0,.) = 0, \qquad \tilde{\rho}(T,.) = 0. \tag{3.3}$$

Then the pair $(\rho = \rho^* + \tilde{\rho}, m = m^* + \tilde{m})$ satisfies

$$0 \leq \delta \int_{[0;T]} \int_{\mathbb{T}^d} (a^* \tilde{\rho} + b^* . \tilde{m}) + \lambda^* \nabla_{t,x} . (\tilde{\rho}, \tilde{m}) dx dt + O(\delta^2). \tag{3.4}$$

Letting δ go to 0 and then using the density of $\mathcal{C}^\infty(Q)^{1+d}$ in $H(Q; \mathrm{div})$, we get that for any $(\tilde{\rho}, \tilde{m})$ in $H(Q; \mathrm{div})$ satisfying (3.3)

$$\int_{\mathbb{T}^d} (a^* \tilde{\rho} + b^* . \tilde{m}) + \lambda^* \nabla_{t,x} . (\tilde{\rho}, \tilde{m}) dx dt = 0. \tag{3.5}$$

We recall now that any function u in $L^2(Q)^{1+d}$ can be uniquely (and continuously) decomposed in $L^2(Q)^{1+d}$ as a sum $u = u_1 + u_2$ such that

$$\begin{gathered} u_1 = \nabla_{t,x} \phi \quad \text{for some } \phi \in H^1(Q), \\ u_2 \text{ satisfies } \left\{ \begin{array}{ll} \nabla_{t,x} . u_2 = 0 & \text{in } L^2(Q), \\ u_2 . n = 0 & \text{on } \partial Q. \end{array} \right. \end{gathered} \tag{3.6}$$

We then write $(a^*, b^*) = \nabla \phi^* + v^*$. Inserting into (3.5) and integrating by part, we get that for all $(\tilde{\rho}, \tilde{m})$ in $H(Q; \mathrm{div})$ satisfying (3.3)

$$\int_{[0;T]} \int_{\mathbb{T}^d} (\lambda^* - \phi^*) \nabla_{t,x} . (\tilde{\rho}, \tilde{m}) dx dt + \int_{[0;T]} \int_{\mathbb{T}^d} v^* . (\tilde{\rho}, \tilde{m}) dx dt = 0. \tag{3.7}$$

Hence we get that if $\nabla_{t,x} . (\tilde{\rho}, \tilde{m}) = 0$,

$$\int_{[0;T]} \int_{\mathbb{T}^d} v^* . (\tilde{\rho}, \tilde{m}) dx dt = 0. \tag{3.8}$$

Integrating by parts the product $\langle v^*, \nabla_{t,x} \phi \rangle$ for any ϕ in $H^1(Q)$ and using the definition of v^*, we get 0. Then using the decomposition property of $L^2(Q)^{1+d}$ for any v in $L^2(Q)^{1+d}$, we conclude that $v^* = 0$. Then inserting into (3.7) and using the definition of a saddle-point, we see that (ρ^*, m^*, ϕ^*) is a saddle-point of L.

As in [1], we are now ready to define a new Lagrangian $\mathcal{L}$. We also take the same notations

$$\left\{ \begin{array}{l} \mu = (\rho, m), \\ q = (a, b), \\ F(q) = \left\{ \begin{array}{l} 0 \text{ if } q \in \tilde{K}, \\ +\infty \text{ else}, \end{array} \right. \\ G(\phi) = \displaystyle\int_{\mathbb{T}^d} [\phi(0,.)\rho_0 - \phi(T,.)\rho_T], \\ \langle \mu, q \rangle = \displaystyle\int_{[0;T]} \int_{\mathbb{T}^d} \mu . q \; dx dt \end{array} \right.$$

to get that for all $(\mu, q, \phi) \in L^2(Q)^{d+1} \times L^2(Q)^{d+1} \times H^1(Q)$ (from now on, this space will be denoted by $E(Q)$)

$$\mathcal{L}(\mu, q, \phi) = -F(q) - G(\phi) + \langle \mu, q - \nabla_{t,x} \phi \rangle. \tag{3.9}$$

We now have the following theorem.

THEOREM 3.1. *(μ^*, q^*, ϕ^*) is a saddle-point of $\mathcal{L}$ in $E(Q)$. Moreover, any saddle-point of $\mathcal{L}$ in $E(Q)$ is of the form $(\tilde{\mu}, q^*, \phi^* + \tilde{C})$, where $\tilde{C}$ is a constant, and $\tilde{\mu}$ is a solution of the time-continuous mass transport problem.*

Proof. Let μ be in $L^2(Q)^{1+d}$. We have $\langle \mu, q^* - \nabla_{t,x}\phi^* \rangle = 0 = \langle \mu, q^* - \nabla_{t,x}\phi^* \rangle$. Hence we have

$$\mathcal{L}(\mu^*, q^*, \phi^*) \leq \mathcal{L}(\mu, q^*, \phi^*).$$

Let (q, ϕ) be in $\tilde{K} \times H^1(Q)$. First we observe that a simple integration by parts gives $\langle \mu^*, \nabla_{t,x}\phi \rangle = -G(\phi)$, since μ^* is in $V(Q)$ and satisfies (0.7). Then we have

$$\begin{aligned}
\mathcal{L}(\mu^*, q, \phi) &= \langle \mu^*, q - \nabla_{t,x}\phi \rangle - G(\phi) \\
&= \langle \mu^*, q \rangle \\
&\leq \langle \mu^*, q^* \rangle \\
&\leq \langle \mu^*, q^* - \nabla_{t,x}\phi^* \rangle - G(\phi^*) \\
&\leq \mathcal{L}(\mu^*, q^*, \phi^*).
\end{aligned}$$

Then, summarizing these inequalities, we get that for any (μ, q, ϕ) in $L^2(Q)^{1+d} \times L^2(Q)^{1+d} \times H^1(Q)$ we have

$$\mathcal{L}(\mu^*, q, \phi) \leq \mathcal{L}(\mu^*, q^*, \phi^*) \leq \mathcal{L}(\mu, q^*, \phi^*), \tag{3.10}$$

which means that (μ^*, q^*, ϕ^*) is a saddle-point of $\mathcal{L}$.

Let $(\tilde{\mu}, \tilde{q}, \tilde{\phi})$ in $L^2(Q)^{1+d} \times L^2(Q)^{1+d} \times H^1(Q)$ be another saddle-point of $\mathcal{L}$. We have $\tilde{q} \in \tilde{K}$. Assume next that $\tilde{q} \neq \nabla_{t,x}\tilde{\phi}$, and define $\mu_n = n(\nabla_{t,x}\tilde{\phi} - \tilde{q})$. From the definition of a saddle-point, we get that

$$\begin{aligned}
\mathcal{L}(\tilde{\mu}, \tilde{q}, \tilde{\phi}) &\leq \langle \mu_n, \tilde{q} - \nabla_{t,x}\tilde{\phi} \rangle - G(\tilde{\phi}) \\
&\leq -n\|\tilde{q} - \nabla_{t,x}\tilde{\phi}\|^2_{L^2(Q)} - G(\tilde{\phi}).
\end{aligned}$$

We obtain a contradiction by letting n go to infinity. Then $\tilde{q}$ is a gradient. Using the decomposition property if $L^2(Q)^{1+d}$, we write $\tilde{\mu} = \mu^* + \bar{\mu} + \nabla_{t,x}\bar{\phi}$. From the definition of a saddle-point, we know that for any (q, ϕ) in $L^2(Q)^{1+d} \times H^1(Q)$ we have

$$\mathcal{L}(\tilde{\mu}, q, \phi) \leq \mathcal{L}(\tilde{\mu}, \tilde{q}, \tilde{\phi}). \tag{3.11}$$

Assume that there exists some ϕ_1 such that $\langle \tilde{\mu}, \nabla_{t,x}\phi_1 \rangle + G(\phi_1) < 0$. Then taking $(q, \phi) = (0, n\phi_1)$ in (3.11), we get

$$-n\left(\langle \tilde{\mu}, \nabla_{t,x}\phi_1 \rangle + G(\phi_1)\right) \leq \mathcal{L}(\tilde{\mu}, \tilde{q}, \tilde{\phi}). \tag{3.12}$$

Letting n go to infinity, we obtain a contradiction. Hence we see that for all ϕ in $H^1(Q)$, $\langle \tilde{\mu}, \nabla_{t,x}\phi \rangle + G(\phi) = 0$. In particular, this has to be true with $\bar{\phi}$. Using our decomposition of $\tilde{\mu}$, we get

$$\begin{aligned}
0 &= \langle \mu^* + \bar{\mu} + \nabla_{t,x}\bar{\phi}, \bar{\phi} \rangle + G(\bar{\phi}) \\
&= \langle \mu^*, \nabla_{t,x}\bar{\phi} \rangle + G(\bar{\phi}) + \langle \bar{\mu}, \nabla_{t,x}\bar{\phi} \rangle + \|\nabla_{t,x}\bar{\phi}\|^2_{L^2(Q)}.
\end{aligned}$$

Integrating by parts and using the properties of μ^* and $\bar{\mu}$, we deduce that $\nabla_{t,x}\bar{\phi}$ is null. Hence we see that $\tilde{\mu}$ is in fact in $V(Q)$ and satisfies the boundary conditions (0.7).

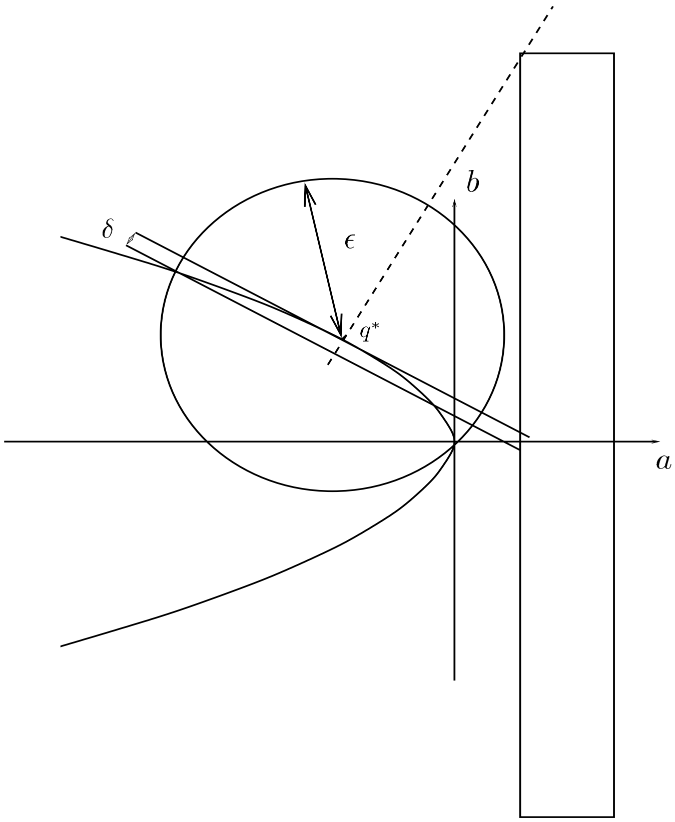

FIG. 3.1. *Geometrical intuition.*

We now have to prove that $\tilde{q} = q^*$. From the fact that both pairs have to define saddle-points, we get

$$\langle \tilde{\mu}, q^* - \tilde{q} \rangle = 0, \tag{3.13}$$

$$\langle \mu^*, q^* - \tilde{q} \rangle = 0, \tag{3.14}$$

$$\langle \mu^*, q^* \rangle = \langle \tilde{\mu}, \tilde{q} \rangle. \tag{3.15}$$

The identity $\tilde{q} = q^*$ follows quite obviously from (3.14). Indeed, the set $\tilde{K}$ is strictly convex, and the L^∞ bounds on q^* ensure that we have some kind of uniform strict convexity. Specifically, we have the following result.

LEMMA 3.2. *Let $\tilde{q}$ be in $L^2(Q)$ such that $\langle \mu^*, q^* - \tilde{q} \rangle = 0$. Then $\tilde{q} = q^*$ a.e. on Q.*

Proof. Since q^* is bounded in $L^\infty(Q)$, we can have uniform estimates on the strict convexity of $\tilde{K}$. The geometric intuition is easily understood when looking at Figure 3.1.

Let $\epsilon > 0$. There exists some $\delta > 0$ such that for any (t, x) in Q

$$\|q^* - \tilde{q}\| > \epsilon \Rightarrow \mu^*.(q^* - \tilde{q}) < -\delta \|\mu^*\|. \tag{3.16}$$

Let $A_\epsilon = \{(t, x) \in Q \text{ s.t. } \|q^* - \tilde{q}\| > \epsilon\}$. We have

$$\begin{aligned}0 &= \langle \mu^*, q^* - q\rangle \\ &\leq \int_{A_\epsilon} \mu^*.(q^* - q)dtdx \\ &\leq -\delta \int_{A_\epsilon} \|\mu^*\| \\ &\leq -\delta\alpha_1 |A_\epsilon|.\end{aligned}$$

Then we get that $|A_\epsilon| = 0$. This achieves the proof of the lemma. □

Finally, since $(\tilde{\mu}, \tilde{q}, \tilde{\phi})$ is a saddle-point of $\mathcal{L}$, we have

$$\langle \tilde{\mu}, \tilde{q}\rangle = K(\tilde{\rho}, \tilde{m}). \tag{3.17}$$

Then we get from (3.15) (and from the fact that $\tilde{\mu}$ is in $V(Q)$ and satisfies (0.7)) that $\tilde{\mu}$ is a solution of the time-continuous mass transport problem. This achieves the proof of Theorem 3.1. □

This theorem answers a question that was left open in [1] on the existence of the saddle-point for $\mathcal{L}$ in the infinite-dimensional case. Moreover, we give a precise functional background for searching this saddle-point.

Remark 3.3. In Theorem 3.1, the variable μ is taken in $L^2(Q)^{1+d}$ rather than in $H(Q; \mathrm{div})$. This will remove a constraint when the question turns to the effective search for the saddle-point.

4. On the algorithm of [1]. In [1], the authors defined an augmented Lagrangian as a preliminary for their numerical method. To get some more coercivity, they perturbed the functional F. Here, since we have already made an assumption of boundedness away from zero on the saddle-point, such a perturbation is not necessary. We then define on $E(Q)$ the augmented Lagrangian

$$\begin{aligned}L_r(\mu, q, \phi) = F(q) + G(\phi) &+ \langle \mu, \nabla_{t,x}\phi - q\rangle \\ &+ \frac{r}{2}\langle \nabla_{t,x}\phi - q, \nabla_{t,x}\phi - q\rangle,\end{aligned} \tag{4.1}$$

where r is a positive parameter.

Remark 4.1. We can change the signs since we proved the existence of a saddle-point of $\mathcal{L}$. In this formulation, the constraint is to get q as a gradient. This constraint has been augmented, instead of the old constraint that μ is in $V(Q)$ and satisfies (0.7).

It is a classical result (see [7]) that if (μ, q, ϕ) is a saddle-point of L_r, it is also a saddle-point of $\mathcal{L}$ (and conversely). Benamou and Brenier then used a numerical algorithm ALG2 to solve the problem. We recall here this algorithm and refer to [1] for more explanation on the steps and some numerical results. Here we are now concerned with the convergence of the method in the continuous case.

ALGORITHM ALG2.

- $(\phi^{n-1}, q^{n-1}, \mu^n)$ are given.
- Step A. Find ϕ^n in $H^1(Q) \cap L^2_0(Q)$ such that

$$L_r(\phi^n, q^{n-1}, \mu^n) \leq L_r(\phi, q^{n-1}, \mu^n) \ \ \forall \phi. \tag{4.2}$$

- Step B. Find q^n in $L^2(Q)^{1+d}$ such that

$$L_r(\phi^n, q^n, \mu^n) \leq L_r(\phi^n, q, \mu^n) \ \ \forall q. \tag{4.3}$$

- Step C. Do

$$\mu^{n+1} = \mu^n + \delta(\nabla_{t,x}\phi^n - q^n) \tag{4.4}$$

(where $r > 0$ is the parameter of the augmented Lagrangian).

- Go back to Step A.

Remark 4.2. In Step A, the minimization is performed over $H^1(Q) \cap L^2_0(Q)$ in order to have a unique solution. Moreover, it is a way to fix the additive constant from Theorem 3.1.

The convergence of the sequence constructed by ALG2 is proved in [7] under some quite general assumptions, which are unfortunately not fully satisfied here. However, their proof can be adapted in order to deal with the problem under consideration.

THEOREM 4.3. *Assume that*

$$0 < \delta < \delta_M = \frac{1+\sqrt{5}}{2} r. \tag{4.5}$$

*Then the sequence constructed by ALG*2 *satisfies the following convergence properties:*

$$\phi^n \to \phi^* \textit{ strongly in } H^1(Q), \tag{4.6}$$

$$q^n \to q^* \textit{ strongly in } L^2(Q)^{1+d}, \tag{4.7}$$

$$\mu^{n+1} - \mu^n \to 0 \textit{ strongly in } L^2(Q)^{1+d}, \tag{4.8}$$

$$\mu^n \textit{ is bounded in } L^2(Q)^{1+d}. \tag{4.9}$$

Moreover, if $\tilde{\mu}$ *is a (weak) cluster point of* (μ^n) *in* $L^2(Q)^{1+d}$, *then* $(\tilde{\mu}, q^*, \phi^*)$ *is a saddle-point of* L_r *on* $E(Q)$.

Proof. The proof of the convergence of ALG2 in [7] requires some uniform convexity properties for F, which are not satisfied here. However, due to the particular form of our function F, the first part of their proof simplifies (since any term containing F vanishes). Hence a simple rewriting of their (intricate) calculations leads to ($|f|$ denotes the L^2-norm of f)

$$\begin{cases} (|\bar{\mu}^n|^2 + \delta r|\bar{q}^{n-1}|^2) - (|\bar{\mu}^{n+1}|^2 + \delta r|\bar{q}^n|^2) \geq \delta(2r-\delta)|\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2 \\ \quad + \delta r|\bar{q}^n - \bar{q}^{n-1}|^2 - \delta|r-\delta| \left(\dfrac{1}{\alpha}|\nabla_{t,x}\bar{\phi}^{n-1} - \bar{q}^{n-1}|^2 + \alpha|\bar{q}^n - \bar{q}^{n-1}|^2\right), \end{cases} \tag{4.10}$$

where $\bar{\mu}^n = \mu^n - \mu^*$, $\bar{q}^n = q^n - q^*$, $\bar{\phi}^n = \phi^n - \phi^*$, and $\alpha > 0$ is a parameter.

If $0 < \delta \leq r$, taking $\alpha = 1$ and observing that $|r - \delta| = r - \delta$, we get

$$v_{n-1} - v_n \geq \delta r|\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2 + \delta^2|\bar{q}^n - \bar{q}^{n-1}|^2, \tag{4.11}$$

with $v_n = (|\bar{\mu}^{n+1}|^2 + \delta r|\bar{q}^n|^2 + \delta(r-\delta)|\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2)$. If $r < \delta < \delta_M$, taking $\alpha = \frac{1+\sqrt{5}}{2}$, we have

$$w_{n-1} - w_n \geq \frac{\delta_M \delta}{r}(\delta_M - \delta)|\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2 + \delta(\delta_M - \delta)|\bar{q}^n - \bar{q}^{n-1}|^2, \tag{4.12}$$

with $w_n = (|\bar{\mu}^{n+1}|^2 + \delta r|\bar{q}^n|^2 + \frac{\delta r}{\delta_M}(\delta - r)|\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2)$.

In (4.11) and (4.12), the right-hand sides are nonnegative. Then the sequences (v_n) and (w_n) are decreasing. Hence we have that (μ_n) and (q_n) are uniformly bounded in $L^2(Q)^{1+d}$. Moreover, we see from the right-hand sides that $\sum_{n=1}^{\infty} |\nabla_{t,x}\bar{\phi}^n - \bar{q}^n|^2$ and $\sum_{n=1}^{\infty} |\bar{q}^n - \bar{q}^{n-1}|^2$ are finite. It implies that

$$\begin{cases} \nabla_{t,x}\bar{\phi}^n - \bar{q}^n \to 0 \quad \text{strongly in } L^2(Q)^{1+d}, \\ \\ (\bar{q}^n) \quad \text{is a Cauchy sequence in } L^2(Q)^{1+d}. \end{cases} \tag{4.13}$$

We then have that (q_n) converges strongly in $L^2(Q)^{1+d}$ to some $\tilde{q}$. Hence we have that $(\nabla_{t,x}\phi_n)$ also converges strongly to $\tilde{q}$ in $L^2(Q)^{1+d}$. Since ϕ_n is in $L^2_0(Q)$, we see then that the sequence (ϕ_n) converges strongly in $H^1(Q) \cap L^2_0(Q)$ to some $\tilde{\phi}$. Moreover, the sequence (μ_n) is bounded in $L^2(Q)^{1+d}$. We can then extract a subsequence (still denoted by n) weakly converging in $L^2(Q)^{1+d}$ to some $\tilde{\mu}$. We now have to prove that $\tilde{q} = q^*$ and $\tilde{\phi} = \phi^*$.

Step A means that for any ϕ in $H^1(Q)$

$$\begin{aligned} 0 \le G(\phi) - G(\phi^n) &+ \langle \mu^n, \nabla_{t,x}\phi - \nabla_{t,x}\phi^n \rangle \\ &+ r\langle \nabla_{t,x}\phi^n - q^{n-1}, \nabla_{t,x}\phi - \nabla_{t,x}\phi^n \rangle. \end{aligned} \tag{4.14}$$

Step B means that for any q in $L^2(Q)^{1+d}$

$$0 \le F(q) - \langle \mu^n, q - q^n \rangle + r\langle q^n - \nabla_{t,x}\phi^n, q - q^n \rangle. \tag{4.15}$$

Taking $\phi = \phi^*$ in (4.14) and $q = q^*$ in (4.15), and letting n tend to infinity, we get

$$0 \le G(\phi^*) - G(\tilde{\phi}) + \langle \tilde{\mu}, \nabla_{t,x}\phi^* - \nabla_{t,x}\tilde{\phi} \rangle, \tag{4.16}$$

$$0 \le -\langle \tilde{\mu}, q^* - \tilde{q} \rangle. \tag{4.17}$$

Then, adding the two inequalities and using that $\nabla_{t,x}\tilde{\phi} = \tilde{q}$ and $\nabla_{t,x}\phi^* = q^*$, we get

$$G(\tilde{\phi}) \le G(\phi^*). \tag{4.18}$$

Moreover, since (μ^*, q^*, ϕ^*) is a saddle-point of L_r, we have

$$G(\phi^*) \le G(\tilde{\phi}). \tag{4.19}$$

We deduce that $G(\phi^*) = G(\tilde{\phi})$. We recall now that for any ϕ in $H^1(Q)$, we have $G(\phi) + \langle \mu^*, \nabla_{t,x}\phi \rangle = 0$. Using this equality with ϕ^* and $\tilde{\phi}$, we get

$$\langle \mu^*, q^* \rangle = \langle \mu^*, \tilde{q} \rangle. \tag{4.20}$$

We now recall Lemma 3.2 to get $\tilde{q} = q^*$. Hence $\tilde{\phi} = \phi^*$. To end the proof of Theorem 4.3, it remains to show that $(\tilde{\mu}, q^*, \phi^*)$ is a saddle-point of L_r. Letting n go to infinity in (4.14) and (4.15) and adding the resulting inequalities, we get that for any (q, ϕ) in $L^2(Q)^{1+d} \times H^1(Q)$,

$$G(\phi^*) \le F(q) + G(\phi) + \langle \tilde{\mu}, \nabla_{t,x}\phi - q \rangle. \tag{4.21}$$

We conclude that $(\tilde{\mu}, q^*, \phi^*)$ is a saddle-point of $\mathcal{L}$ and then also a saddle-point of L_r. This achieves the proof of Theorem 4.3. □

Acknowledgments. The author would like to thank J. D. Benamou and Y. Brenier, whose careful reading of the manuscript substantially improved the paper.

COMPUTATION OF PERIODIC SOLUTION BIFURCATIONS IN ODES USING BORDERED SYSTEMS*

E. J. DOEDEL†, W. GOVAERTS‡, AND YU. A. KUZNETSOV§

Abstract. We consider numerical methods for the computation and continuation of the three generic secondary periodic solution bifurcations in autonomous ODEs, namely the fold, the period-doubling (or flip) bifurcation, and the torus (or Neimark–Sacker) bifurcation. In the fold and flip cases we append one scalar equation to the standard periodic BVP that defines the periodic solution; in the torus case four scalar equations are appended. Evaluation of these scalar equations and their derivatives requires the solution of linear BVPs, whose sparsity structure (after discretization) is identical to that of the linearization of the periodic BVP. Therefore the calculations can be done using existing numerical linear algebra techniques, such as those implemented in the software AUTO and COLSYS.

Key words. bifurcations, periodic solutions, continuation, boundary value problems

1. Introduction.

We consider parameterized ODEs of the form

$$\frac{dx}{dt} \equiv x' = f(x, \alpha), \tag{1.1}$$

where $x \in \mathbf{R}^n$ is the *state variable*, where $\alpha \in \mathbf{R}^m$ represents *parameters*, and where $f(x, \alpha) \in \mathbf{R}^n$ is a (usually nonlinear) smooth function of x and α. Examples of systems of the form (1.1) are ubiquitous in mathematical models in physics, engineering, chemistry, economics, finance, etc.

The simplest solutions of (1.1) are the *equilibria*, that is, solutions of the equation

$$f(x, \alpha) = 0.$$

An equilibrium (x_0, α_0) is asymptotically stable if all eigenvalues of the Jacobian matrix $f_x(x_0, \alpha_0)$ have a strictly negative real part; it is unstable if there is at least one eigenvalue with a strictly positive real part. In generic one-parameter problems, i.e., when $m = 1$, eigenvalues on the imaginary axis appear in two ways: as a simple zero eigenvalue, or as a conjugate pair $\pm i\omega$, $\omega > 0$, of purely imaginary eigenvalues. The first singularity corresponds generically to a *limit point bifurcation*, where two solutions coalesce and annihilate each other under parameter variation. The second singularity corresponds generically to a *Hopf bifurcation*, from which a family of periodic solutions emerges. Early papers on the numerical computation of bifurcations of equilibria are [16], [22], and [20].

Periodic solutions are solutions for which $x(T) = x(0)$ for some number $T > 0$. The minimal such T is called the *period*. In generic one-parameter problems, periodic solutions can bifurcate in several ways that can be characterized by the properties of the *monodromy matrix*. The monodromy matrix is the linearized T-shift along orbits of (1.1), evaluated at the point $x(0)$ on the periodic solution. The eigenvalues of this matrix are called the *Floquet multipliers* of the periodic solution [14], [17].

A periodic solution always has a multiplier equal to 1. If this multiplier has geometric multiplicity 1, then we call the periodic solution *regular*. The corresponding eigenvector of the monodromy matrix is the tangent vector to the periodic solution at the point where the monodromy matrix is computed. If all other multipliers are strictly inside the unit circle in the complex plane, then the periodic solution is asymptotically stable. If at least one multiplier has modulus greater than 1, then the periodic solution is unstable. In all other cases, one should take into account higher-order derivatives of the T-shift to decide whether or not the periodic orbit is stable.

Three singularities, determined by the monodromy matrix, can occur along a one-parameter family ("curve" or "branch") of periodic solutions, namely (1) *a fold singularity*, when the multiplier 1 has algebraic multiplicity equal to or greater than 2; (2) *a flip singularity*, when there is a multiplier equal to -1; (3) *a Neimark–Sacker singularity*, when there is a conjugate pair of complex multipliers with modulus 1.

Under some genericity conditions, each of these singularities implies a certain bifurcation scenario. These conditions always include some *spectral conditions* on the critical multipliers, i.e., multiplicity restrictions and the absence of other critical multipliers. Furthermore, there are *nondegeneracy conditions* that can be formulated in terms of the system at the critical parameter values, and *transversality conditions* that are determined by the system's dependence on the parameter (see [17]). We shall list all relevant genericity conditions in the following sections.

Generically, the first critical case (fold) corresponds to a point on the periodic solution family where the curve turns quadratically with respect to the free parameter. This phenomenon is called a *limit point* (*fold*) *bifurcation*: Two periodic solutions collide and disappear when the parameter passes the critical value. The second case (flip) indicates generically a *period-doubling* of the periodic solution; i.e., there are nearby periodic solutions of approximately double period. It is also called the *flip bifurcation*. Finally, the third case (Neimark–Sacker) corresponds generically to a bifurcation of an *invariant torus*, on which the flow contains periodic or quasi-periodic motions. This phenomenon is often called the *Neimark–Sacker bifurcation*. There is some ambiguity in calling a bifurcation by the same name as the corresponding singularity. However, this is a common practice in the applied literature.

The aim of this paper is to formulate the computation and continuation of the three generic periodic solution bifurcation curves as *minimally extended BVPs* to which standard numerical approximation methods as well as convergence theory apply. *Fully extended BVPs* for continuing periodic solution bifurcations have been implemented in AUTO [6] (see also [7], [15]). The latter approach doubles the number of function components in the case of the period-doubling and fold bifurcations, and triples it in the case of the torus bifurcation. Fully extended BVPs also yield a more complicated Jacobian sparsity structure (after discretization) than that corresponding to the underlying periodic BVP. There are efficient solution techniques for such sparse linear systems; see, for example, [10]. However, these are not very easy to implement and they are specific for each bifurcation. By contrast, the minimal BVPs presented in this paper for the period-doubling and fold bifurcations have the same number of function components as the periodic solution problem. In the torus case the number of BVP function components is only doubled, but the resulting system is overdetermined. The most important numerical advantage is that only one type of sparse system needs to be solved, namely the one corresponding to the underlying periodic BVP. Conceptually, the approach used in this paper is similar to the *bordering technique* for equilibrium bifurcations [5], [12], [13], [17].

The paper is organized as follows. Section 2 is devoted to the computation of one-parameter families of periodic solutions to (1.1). Classical results on the regularity of BVPs defining families of periodic solutions are proved here for completeness. Sections 3 and 4 present the main results of the paper. Here we construct functionals that vanish at bifurcation points of periodic solutions and we prove that they are well-defined and regular. As is usual, only some of the nondegeneracy conditions that appear in bifurcation analysis are necessary for regularity. Section 5 deals with various computational issues, including efficient computation of the defining systems and their derivatives. A numerical example is given in section 6.

2. Computation and continuation of periodic solutions. Numerical continuation is a technique to compute solution curves to an underdetermined system of equations. Details can be found, for example, in [1], [3], [12], and [16]. It is a basic ingredient of the numerical bifurcation algorithms implemented in AUTO [6] and CONTENT [18]. In this case only one parameter is free, so for practical purposes the parameter vector reduces to a scalar. In this paper we restrict our discussion to issues that are specific to the case of periodic orbits.

To compute a periodic solution of period T of (1.1), one first fixes the period by rescaling time. Then (1.1) becomes

$$x'(t) = Tf(x(t), \alpha), \tag{2.1}$$

and we look for solutions of period 1, that is,

$$x(0) = x(1). \tag{2.2}$$

The period T is one of the unknowns of the problem. In a continuation context, we assume that a solution $(x_{k-1}(\cdot), T_{k-1}, \alpha_{k-1})$ is known, and we want to find $(x_k(\cdot), T_k, \alpha_k)$, which we denote by $(x(\cdot), T, \alpha)$. Equations (2.1) and (2.2) together do not fix the solution completely, since any solution can be translated freely in time; that is, if $x(t)$ is a solution, then so is $x(t+\sigma)$ for any σ. To fix the solution it is necessary to add a "phase condition." In AUTO [6] and CONTENT [18] the integral constraint

$$\int_0^1 x^*(\tau)x'_{k-1}(\tau)\; d\tau = 0 \tag{2.3}$$

is used to fix the phase. (We use "*" to denote transpose.)

The periodic solution is now determined by (2.1), (2.2), (2.3), which together form a BVP with an integral constraint.

In our continuation context, the periodic orbit $x(t)$ and the scalars T and α vary along the solution family. In the setting of Keller's pseudoarclength continuation method [16] the continuation equation is

$$\int_0^1 (x(\tau) - x_{k-1}(\tau))^* \dot{x}_{k-1}(\tau)\; d\tau \;\; + (T - T_{k-1})\dot{T}_{k-1} + (\alpha - \alpha_{k-1})\dot{\alpha}_{k-1} = \Delta s, \tag{2.4}$$

where the derivatives are taken with respect to arclength in the function space, and should not be confused with the time derivatives in, for example, (2.3).

A widely used method to discretize the above BVP is the method of orthogonal collocation with piecewise polynomials. It is used in COLSYS [2], as well as in AUTO and CONTENT. The method is known for its high accuracy [4], and it is particularly suitable for difficult problems, due to its known optimal mesh adaptation techniques [21]. The numerical continuation of the discretized equations leads to structured, sparse linear systems [9]. To describe these systems it is convenient to formulate the BVP in terms of operators on function spaces.

Denote by $\mathcal{C}^k([a,b],\mathbf{R}^n)$ the space of k times continuously differentiable functions defined on $[a,b]$ and with values in $\mathbf{R}^n$. Let D be the differentiation operator acting from $\mathcal{C}^1([a,b],\mathbf{R}^n)$ to $\mathcal{C}^0([a,b],\mathbf{R}^n)$. Any $n \times n$ matrix $M(t)$ smoothly depending on $t \in [a,b]$ defines an operator from $\mathcal{C}^1([a,b],\mathbf{R}^n)$ into itself by the matrix multiplication $(M\psi)(t) = M(t)\psi(t)$. The Dirac evaluation operator at the point t is denoted δ_t.

For a given $\phi \in \mathcal{C}^0([0,1],\mathbf{R}^n)$ we denote by Int_ϕ the linear functional from $\mathcal{C}^0([0,1],\mathbf{R}^n)$ into $\mathbf{R}$ defined by

$$\mathrm{Int}_\phi(v) = \langle \phi, v\rangle = \int_0^1 \phi^*(\tau)v(\tau)\, d\tau.$$

Suppose we want to compute a periodic solution of (1.1); i.e., we want to solve the system (2.1), (2.2), (2.3), and (2.4) for $(x(t), T, \alpha)$ by a Newton-like method. The Fréchet derivative operator corresponding to this problem has the form

$$\begin{pmatrix} D - Tf_x(x(t),\alpha) & -f(x(t),\alpha) & -Tf_\alpha(x(t),\alpha) \\ \delta_0 - \delta_1 & 0 & 0 \\ \mathrm{Int}_{x'_{k-1}}(\cdot) & 0 & 0 \\ \mathrm{Int}_{\dot{x}_{k-1}}(\cdot) & \dot{T}_{k-1} & \dot{\alpha}_{k-1} \end{pmatrix}. \tag{2.5}$$

The discrete version of these linear operators is a square matrix that has a large matrix corresponding to $D - Tf_x(x(t),\alpha)$ in the upper left corner, bordered on the right by two extra columns and at the bottom by $n+2$ extra rows. The big matrix in the upper left corner is a block band matrix. Systems of this form are solved in AUTO by a specially adapted elimination algorithm that computes the multipliers as a by-product [9].

Consider the fundamental variational equation

$$X' - Tf_x(x(t),\alpha)X = 0 \tag{2.6}$$

and the adjoint equation

$$X' + Tf_x^*(x(t),\alpha)X = 0. \tag{2.7}$$

Denote by $\Phi(t)$ the fundamental matrix solution of (2.6), for which $\Phi(0) = I$, where $I = I_{n\times n}$ is the n-dimensional identity matrix. Then $\Phi(1)$ is the monodromy matrix of the periodic solution. The eigenvalues of $\Phi(1)$ are the Floquet multipliers, and there is always at least one multiplier that is equal to 1. A corresponding eigenvector is $x'(0)$. For a *regular periodic solution* the multiplier 1 has geometric multiplicity 1. Similarly, denote by $\Psi(t)$ the fundamental matrix solution to (2.7) for which $\Psi(0) = I$. One has $\Psi(t) = [(\Phi(t))^{-1}]^*$.

If $v(t)$ is a vector solution to (2.6) with initial values $v(0) = v_0$ and $w(t)$ is a vector solution to (2.7) with initial values $w(0) = w_0$, then the inner product satisfies $w^*(t)v(t) = w_0^* v_0$; i.e., it is independent of time t.

The left and right eigenvectors of the monodromy matrix $\Phi(1)$ for a geometrically simple eigenvalue 1 will be denoted p_0, q_0, respectively. It is easily seen that p_0 (respectively, q_0) is also the right (respectively, left) eigenvector of $\Psi(1)$ for the eigenvalue 1. Furthermore, q_0 is a scalar multiple of $x'(0)$.

We now state some basic facts about the linear operator (2.5) when linearized about a regular periodic solution $(x(t), T, \alpha)$.

PROPOSITION 1. *If* $(x(t), T, \alpha)$ *is a regular periodic solution of* (2.1), *then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) \\ \delta_1 - \delta_0 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \to \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \tag{2.8}$$

has a one-dimensional kernel spanned by Φq_0. *Its range has codimension* 1; *if* $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, *then* $(\zeta, r)^*$ *is in the range if and only if* $\langle \Psi p_0, \zeta \rangle = p_0^* r$. *In particular, if* $r = 0$, *then* $(\zeta, 0)^*$ *is in the range if and only if* $\langle \Psi p_0, \zeta \rangle = 0$.

Proof. First, let $v(t)$ be in the kernel of (2.8). Then v must have the form $v(t) = \Phi(t)v_0$ for a vector v_0. Since $0 = (\delta_1 - \delta_0)v = v(1) - v(0) = (\Phi(1) - I)v_0$, we infer that v_0 must be a right eigenvector of $\Phi(1)$ for the eigenvalue 1.

Next, let $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, be given. If $(\zeta, r)^*$ is in the range of (2.8), then there must exist a $v \in \mathcal{C}^1([0,1], \mathbf{R}^n)$ for which

$$v'(t) - Tf_x(x(t), \alpha)v(t) = \zeta(t).$$

The general solution of this linear differential equation is

$$v(t) = \Phi(t) \left[v_0 + \int_0^t \Psi^*(\tau)\zeta(\tau)\, d\tau \right],$$

where $v_0 = v(0)$ is an initial vector. Also, we must have $v(1) - v(0) = r$, that is,

$$(\Phi(1) - I)v_0 + \Phi(1) \int_0^1 \Psi^*(\tau)\zeta(\tau)\, d\tau = r.$$

Such a vector v_0 can be found if and only if

$$p_0^* \left(\Phi(1) \int_0^1 \Psi^*(\tau)\zeta(\tau)\, d\tau \ - r \right) = 0,$$

that is, if

$$p_0^* \int_0^1 \Psi^*(\tau)\zeta(\tau)\, d\tau \ - p_0^* r = 0,$$

from which the second result follows. □

COROLLARY 1. *If* $(x(t), T, \alpha)$ *is a regular periodic solution of* (2.1), *then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) \\ \delta_1 - \delta_0 \\ \mathrm{Int}_\phi \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R} \tag{2.9}$$

is one-to-one if and only if $\langle \phi, \Phi q_0 \rangle \neq 0$.

PROPOSITION 2. *If* $(x(t), T, \alpha)$ *is a regular periodic solution of* (2.1), *then the operator*

$$\begin{bmatrix} D + T f_x^*(x(t), \alpha) \\ \delta_1 - \delta_0 \end{bmatrix} \; : \; \mathcal{C}^1([0,1], \mathbf{R}^n) \;\to\; \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n$$

has a one-dimensional kernel spanned by Ψp_0. *Its range has codimension* 1; *if* $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, *then* $(\zeta, r)^*$ *is in the range if and only if* $\langle \Phi q_0, \zeta \rangle = q_0^* r$. *In particular, if* $r = 0$, *then* $(\zeta, 0)^*$ *is in the range if and only if* $\langle \Phi q_0, \zeta \rangle = 0$.

Proof. The proof is similar to the proof of Proposition 1. □

COROLLARY 2. *If* $(x(t), T, \alpha)$ *is a regular periodic solution of* (2.1), *then the operator*

$$\begin{bmatrix} D + T f_x^*(x(t), \alpha) \\ \delta_1 - \delta_0 \\ \mathrm{Int}_\psi \end{bmatrix} \; : \; \mathcal{C}^1([0,1], \mathbf{R}^n) \;\to\; \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R} \tag{2.10}$$

is one-to-one if and only if $\langle \psi, \Psi p_0 \rangle \neq 0$.

PROPOSITION 3. *Let* $(x(t), T, \alpha)$ *be a regular periodic solution of* (2.1), *and let* $\phi_0, \psi_0 \in \mathcal{C}^0([0,1], \mathbf{R}^n)$ *be such that* $\langle \phi_0, \Phi q_0 \rangle \neq 0$, $\langle \psi_0, \Psi p_0 \rangle \neq 0$. *Then the operator*

$$\begin{bmatrix} D - T f_x(x(t), \alpha) & \psi_0 \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{\phi_0} & 0 \end{bmatrix} \; : \; \mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R} \;\to\; \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$$

is one-to-one and onto.

Proof. To prove that the operator is one-to-one, suppose that

$$\begin{bmatrix} D - T f_x(x(t), \alpha) & \psi_0 \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{\phi_0} & 0 \end{bmatrix} \begin{pmatrix} v \\ G \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

for $v \in \mathcal{C}^1([0,1], \mathbf{R}^n), G \in \mathbf{R}$. In particular, it follows that

$$\begin{bmatrix} D - T f_x(x(t), \alpha) \\ \delta_0 - \delta_1 \end{bmatrix} v = \begin{pmatrix} -G\psi_0 \\ 0 \end{pmatrix}.$$

Since $\langle \psi_0, \Psi p_0 \rangle \neq 0$, it follows from the last statement in Proposition 1 that $G = 0$. By Corollary 1 and the assumption that $\langle \phi_0, \Phi q_0 \rangle \neq 0$, it follows that $v = 0$ as well.

To prove that the operator is onto we consider the equation

$$\begin{bmatrix} D - T f_x(x(t), \alpha) & \psi_0 \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{\phi_0} & 0 \end{bmatrix} \begin{pmatrix} v \\ G \end{pmatrix} = \begin{pmatrix} \zeta \\ r \\ s \end{pmatrix}, \tag{2.11}$$

where $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n), r \in \mathbf{R}^n, s \in \mathbf{R}$. In particular, the first two equations can be written

$$\begin{bmatrix} D - T f_x(x(t), \alpha) \\ \delta_1 - \delta_0 \end{bmatrix} v = \begin{pmatrix} \zeta - G\psi_0 \\ r \end{pmatrix}. \tag{2.12}$$

By Proposition 1 this equation is solvable for v, say, $v = v_p$, if

$$\langle \Psi p_0, \zeta - G\psi_0 \rangle = p_0^* r,$$

that is, if we choose

$$G = G_p \equiv \frac{\langle \Psi p_0, \zeta \rangle - p_0^* r}{\langle \Psi p_0, \psi_0 \rangle},$$

where, by assumption, the denominator does not vanish. Now

$$v(t) = v_p(t) + c\Phi(t)q_0$$

is also a solution of (2.12) for any constant c. The third equation in (2.11) can now be written as

$$\int_0^1 \phi_0^*(\tau)[v_p(\tau) + c\Phi(\tau)q_0]d\tau = s.$$

By the assumption that $\langle \phi_0, \Phi q_0 \rangle \neq 0$ it follows that the third equation is satisfied if we take

$$c = \frac{s - \int_0^1 \phi_0^*(\tau)v_p(\tau)d\tau}{\int_0^1 \phi_0^*(\tau)\Phi(\tau)q_0 \ d\tau} . \qquad \square$$

PROPOSITION 4. *Let* $(x(t), T, \alpha)$ *be a regular periodic solution of* (2.1)*, and let* $\phi_0, \psi_0 \in \mathcal{C}^0([0,1], \mathbf{R}^n)$ *be such that* $\langle \phi_0, \Phi q_0 \rangle \neq 0$*,* $\langle \psi_0, \Psi p_0 \rangle \neq 0$*. Then the operator*

$$\begin{bmatrix} D + Tf_x^*(x(t), \alpha) & \phi_0 \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{\psi_0} & 0 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R} \ \rightarrow \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$$

is one-to-one and onto.

Proof. The proof is similar to the proof of Proposition 3. $\square$

3. Test functionals for bifurcations of periodic solutions.

For the fold and Hopf singularities of equilibria, several test functions, and corresponding minimally extended defining systems, are discussed in [12] and incorporated in CONTENT [11]. To obtain similar systems for the case of periodic orbits, we define *simple singularities* of periodic solutions, specifically the limit point, the period-doubling bifurcation, and the torus bifurcation, and we then construct functionals that vanish at these singularities.

3.1. A test functional for the fold bifurcation.

Let $(x(t), T, \alpha)$ define a periodic solution of (1.1); i.e., it satisfies (2.1), (2.2), and (2.3). We say that the solution has a *simple fold singularity* if the monodromy matrix $\Phi(1)$ has an eigenvalue $+1$ with algebraic multiplicity 2 and geometric multiplicity 1, while there are no other critical multipliers.[1]

Let p_0 and q_0 denote the corresponding left and right eigenvectors, which satisfy

$$(\Phi(1) - I)q_0 = 0, \qquad (\Psi(1) - I)p_0 = 0,$$

$$(\Phi(1) - I)^* p_0 = 0, \qquad (\Psi(1) - I)^* q_0 = 0,$$

with

$$p_0^* p_0 = q_0^* q_0 = 1.$$

[1] A geometrically double eigenvalue +1 corresponds to a higher degeneracy. Recall that by definition a *regular* periodic solution has a geometrically simple multiplier +1.

At a simple fold, where the multiplier 1 has algebraic multiplicity 2, we also have generalized eigenvectors p_1 and q_1 satisfying

$$(\Phi(1) - I)q_1 = q_0, \qquad (\Psi(1) - I)p_1 = p_0,$$

where q_1 and p_1 can be chosen so that

$$q_1^* q_0 \; = \; p_1^* p_0 \; = \; 0.$$

Note that in the multiplicity-2 case we also have $p_0^* q_0 = p_1^*(\Psi(1) - I)^* q_0 = 0$.

PROPOSITION 5. *If $(x(t), T, \alpha)$ is a regular periodic solution of* (2.1)*, then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) & -f(x(t), \alpha) \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot), \alpha)} & 0 \end{bmatrix} \tag{3.1}$$

from $\mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R}$ into $\mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$ is one-to-one if the multiplier 1 *has algebraic multiplicity* 1*. If the multiplier* 1 *has algebraic multiplicity* 2*, i.e., at a simple fold, then the operator has a one-dimensional kernel, spanned by the vector*

$$\begin{pmatrix} v \\ 1 \end{pmatrix} \in \mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R}, \tag{3.2}$$

where $v(t) = \frac{c_0}{T}\Phi(t)(c_2 q_0 - (q_1 - tq_0))$, where c_2 is determined by the condition that

$$q_0^* \int_0^1 \Phi^*(\tau)\Phi(\tau)[c_2 q_0 - (q_1 - \tau q_0)] \; d\tau = 0,$$

and where c_0 is determined by the condition that $x'(0) = c_0 q_0$.

Proof. Consider the homogeneous equations

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) & -f(x(t), \alpha) \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot), \alpha)} & 0 \end{bmatrix} \begin{pmatrix} v \\ S \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}. \tag{3.3}$$

From the first equation in (3.3) we have

$$\begin{aligned} v(t) \;&=\; \Phi(t)\left[v_0 + S\int_0^t \Psi^*(\tau)f(x(\tau), \alpha) \; d\tau\right] \;=\; \Phi(t)\left[v_0 + \tfrac{S}{T}\int_0^t \Psi^*(\tau)x'(\tau) \; d\tau\right] \\ &=\; \Phi(t)\left[v_0 + \tfrac{S}{T}\int_0^t \Psi^*(\tau)\Phi(\tau) \; d\tau \; x'(0)\right] \;=\; \Phi(t)\left[v_0 + \tfrac{St}{T}x'(0)\right], \end{aligned}$$

where we used the facts that $\Psi^*(\tau)\Phi(\tau) = I$ and $x'(t) = \Phi(t)x'(0)$. Above, $v_0 = v(0)$ is an initial vector. By the second equation in (3.3) we have

$$0 = v(1) - v(0) = (\Phi(1) - I)v_0 + \frac{S}{T}x'(0),$$

that is,

$$(\Phi(1) - I)v_0 = -\frac{S}{T}x'(0).$$

Now $(\Phi(1) - I)x'(0) = 0$, so that $x'(0) = c_0 q_0$, for some $c_0 \in \mathbf{R}$, $c_0 \neq 0$. Thus we must solve

$$(\Phi(1) - I)v_0 = -c_0 \frac{S}{T} q_0, \tag{3.4}$$

where q_0 spans the kernel of $\Phi(1) - I$.

If the multiplier 1 has algebraic multiplicity 1, then we must have $S = 0$, $v_0 = c_1 q_0$, and hence $v(t) = c_1 \Phi(t) q_0$. By the third equation in (3.3)

$$0 = \int_0^1 f^*(x(\tau), \alpha) v(\tau)\ d\tau = \frac{1}{T}\int_0^1 x'^*(\tau) v(\tau)\ d\tau = \frac{1}{T}\int_0^1 \left[\Phi(\tau)x'(0)\right]^* c_1 \Phi(\tau) q_0\ d\tau$$

or

$$c_0 c_1\ q_0^* \left(\int_0^1 \Phi^*(\tau)\Phi(\tau)\ d\tau\right)\ q_0 = 0,$$

from which it follows that $c_1 = 0$. Thus $v(t) \equiv 0$. It follows that the operator (3.1) is one-to-one.

At a simple fold the multiplier 1 has algebraic multiplicity 2. In this case (3.4) is also solvable if S is nonzero, namely

$$v_0 = -c_0 \frac{S}{T} q_1 + c_2 q_0,$$

where $c_2 \in \mathbf{R}$ is arbitrary. The third equation in (3.3) then implies

$$\begin{aligned} 0 &= \int_0^1 x'^*(\tau) v(\tau)\ d\tau \\ &= \int_0^1 x'^*(\tau)\Phi(\tau)[v_0 + \tfrac{S\tau}{T} x'(0)]\ d\tau \\ &= \int_0^1 x'^*(\tau)\Phi(\tau)[-c_0 \tfrac{S}{T} q_1 + c_2 q_0 + \tfrac{S\tau}{T} c_0 q_0]\ d\tau \\ &= \int_0^1 [\Phi(\tau)x'(0)]^* \Phi(\tau)[-c_0 \tfrac{S}{T} q_1 + c_2 q_0 + \tfrac{S\tau}{T} c_0 q_0]\ d\tau \\ &= c_0 q_0^* \int_0^1 \Phi^*(\tau)\Phi(\tau)[-c_0 \tfrac{S}{T} q_1 + c_2 q_0 + \tfrac{S\tau}{T} c_0 q_0]\ d\tau, \end{aligned}$$

from which it follows that

$$c_2 = \frac{c_0 S q_0^* \int_0^1 \Phi^*(\tau)\Phi(\tau)[q_1 - \tau q_0]\ d\tau}{T\ q_0^* \int_0^1 \Phi^*(\tau)\Phi(\tau)\ d\tau\ q_0}. \qquad \square$$

PROPOSITION 6. *Let* $(x(t), T, \alpha)$ *be a regular periodic solution of* (2.1) *and consider the operator*

$$M_1 = \begin{bmatrix} D - T f_x(x(t), \alpha) & -f(x(t), \alpha) \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot), \alpha)} & 0 \end{bmatrix} \tag{3.5}$$

from $\mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R}$ *into* $\mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$. *If the multiplier* 1 *has algebraic multiplicity* 1, *then* M_1 *is onto. If it has algebraic multiplicity* 2, *i.e., at a simple fold,* *then the range of M_1 has codimension* 1 *and the vector*

$$\left(\begin{array}{c} \Psi p_0 \\ -p_0 \\ 0 \end{array} \right) \in \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R} \tag{3.6}$$

is complementary to the range space.

Proof. Consider a vector $(\xi, \eta, \omega)^*$ in $\mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$. This vector is in the range of M_1 if and only if there exist $(v, S)^*$ in $\mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R}$ such that

$$M_1 \left(\begin{array}{c} v \\ S \end{array} \right) = \left(\begin{array}{c} \xi \\ \eta \\ \omega \end{array} \right). \tag{3.7}$$

The first equation in (3.7) implies that

$$v(t) = \Phi(t) \left[v(0) + \int_0^t \Psi^*(\tau)(\xi(\tau) + Sf(x(\tau), \alpha))\ d\tau \right].$$

The second equation in (3.7) then implies

$$\eta = v(1) - v(0) = (\Phi(1) - I)v(0) + \Phi(1) \int_0^1 \Psi^*(\tau)(\xi(\tau) + Sf(x(\tau), \alpha))\ d\tau.$$

Now

$$\int_0^1 \Psi^*(\tau) f(x(\tau), \alpha) d\tau = \frac{1}{T} \int_0^1 \Psi^*(\tau) x'(\tau)\ d\tau = \frac{1}{T} \int_0^1 \Psi^*(\tau) c_0 \Phi(\tau) q_0\ d\tau = \frac{c_0}{T} q_0.$$

So

$$\eta = (\Phi(1) - I)v(0) + \frac{Sc_0}{T} q_0 + \Phi(1) \int_0^1 \Psi^*(\tau)\xi(\tau)\ d\tau. \tag{3.8}$$

If 1 is an algebraically simple eigenvalue of $\Phi(1)$, then q_0 is not in the range of $(\Phi(1) - I)$. For given ξ and η, (3.8) can be solved for $v(0)$ and S. Moreover, the solution is unique up to the addition of a scalar multiple of q_0 to $v(0)$. Since

$$\int_0^1 (x'(\tau))^* \Phi(\tau) q_0\ d\tau = c_0 \int_0^1 (\Phi(\tau) q_0)^* \Phi(\tau) q_0\ d\tau \neq 0,$$

the scalar is determined uniquely by the third equation in (3.7).

If 1 is an algebraically double eigenvalue of $\Phi(1)$, i.e., at a fold point, then (3.8) is solvable if and only if

$$p_0^* \eta = p_0^* \int_0^1 \Psi^*(\tau) \xi(\tau)\ d\tau.$$

If so, the third equation in (3.7) again determines the solution uniquely. □

PROPOSITION 7. *If $(x(t), T, \alpha)$ is a regular periodic solution of* (2.1)*, then the operator*

$$\left[\begin{array}{cc} D + Tf_x^*(x(t), \alpha) & -f(x(t), \alpha) \\ \delta_1 - \delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot), \alpha)} & 0 \end{array} \right] \tag{3.9}$$

from $\mathcal{C}^1([0,1],\mathbf{R}^n)\times\mathbf{R}\to\mathcal{C}^0([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}$ *is one-to-one if the multiplier* 1 *has algebraic multiplicity* 1*. If the multiplier* 1 *has algebraic multiplicity* 2*, i.e., at a simple fold, then the operator has a one-dimensional kernel, spanned by* $(\Psi^* p_0, 0)^* \in \mathcal{C}^1([0,1],\mathbf{R}^n)\times\mathbf{R}$.

Proof. Consider the homogeneous equations

$$\begin{bmatrix} D+Tf_x^*(x(t),\alpha) & -f(x(t),\alpha) \\ \delta_1-\delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot),\alpha)} & 0 \end{bmatrix}\begin{pmatrix} w \\ R\end{pmatrix} = \begin{pmatrix} 0\\0\\0\end{pmatrix}. \tag{3.10}$$

From the first equation in (3.10) we have

$$w(t)=\Psi(t)\left[w_0+\frac{R}{T}\int_0^t \Phi^*(\tau)x'(\tau)\,d\tau\right],$$

where $w_0 = w(0)$ is an initial vector. The second equation in (3.10) implies

$$0 = w(1)-w(0) = (\Psi(1)-I)w_0 + \frac{R}{T}\Psi(1)\int_0^1 \Phi^*(\tau)x'(\tau)\,d\tau$$

or

$$(\Psi(1)-I)w_0 = -\frac{R}{T}\Psi(1)\int_0^1 \Phi^*(\tau)\Phi(\tau)\,d\tau\; x'(0).$$

Given R, this equation is solvable for w_0 if

$$-Rq_0^*\Psi(1)\int_0^1 \Phi^*(\tau)\Phi(\tau)\,d\tau\; x'(0)=0,$$

that is, recalling that $x'(0)=c_0q_0$, $c_0\neq 0$, and $q_0^*\Psi(1)=q_0^*$ if

$$c_0Rq_0^*\int_0^1 \Phi^*(\tau)\Phi(\tau)\,d\tau\; q_0 = 0.$$

It follows that $R=0$, independently of the algebraic multiplicity of the eigenvalue 1. Thus $w(t)=\Psi(t)w_0$, where $(\Psi(1)-I)w_0=0$, so that $w_0=c_3p_0$ for some $c_3\in\mathbf{R}$.

From the third equation in (3.10) it follows that

$$\begin{aligned} 0 = \int_0^1 w^*(\tau)x'(\tau)\,d\tau &= \int_0^1 [c_3\Psi(\tau)p_0]^*\Phi(\tau)x'(0)\,d\tau \\ &= c_0\;c_3\;p_0^*\int_0^1 \Psi^*(\tau)\Phi(\tau)\,d\tau\; q_0 = c_0\;c_3\;p_0^*q_0. \end{aligned}$$

If the multiplier 1 has algebraic multiplicity 1, then $p_0^*q_0\neq 0$. In this case $c_3=0$ and hence $w(t)\equiv 0$; that is, the operator (3.9) is one-to-one.

If the multiplier 1 has algebraic multiplicity 2, then $p_0^*q_0=0$, and we can choose $c_3\neq 0$. In this case $w_0\neq 0$; hence $w(t)\not\equiv 0$. It follows that the operator (3.9) has a one-dimensional kernel. □

PROPOSITION 8. *If* $(x(t),T,\alpha)$ *is a regular periodic solution of* (2.1)*, then the operator*

$$M_2 = \begin{bmatrix} D+Tf_x^*(x(t),\alpha) & -f(x(t),\alpha) \\ \delta_1-\delta_0 & 0 \\ \mathrm{Int}_{f(x(\cdot),\alpha)} & 0 \end{bmatrix} \tag{3.11}$$

from $\mathcal{C}^1([0,1],\mathbf{R}^n)\times\mathbf{R}\to\mathcal{C}^0([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}$ *is onto if the multiplier* 1 *has algebraic multiplicity* 1*. If the multiplier* 1 *has algebraic multiplicity* 2*, i.e., at a simple fold, then the range has codimension* 1*, and the vector* $(0,0,1)^*\in\mathcal{C}^0([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}$ *is complementary to the range space.*

Proof. Consider a vector $(\xi,\eta,\omega)^*$ in $\mathcal{C}^0([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}$. This vector is in the range of M_2 if and only if there exist $(w,R)^*$ in $\mathcal{C}^1([0,1],\mathbf{R}^n)\times\mathbf{R}$ such that

$$M_2\begin{pmatrix} w\\ R\end{pmatrix}=\begin{pmatrix}\xi\\ \eta\\ \omega\end{pmatrix}. \tag{3.12}$$

The first equation in (3.12) implies that

$$w(t)=\Psi(t)\left[w(0)+\int_0^t\Phi^*(\tau)(\xi(\tau)+Rc_0\Phi(\tau)q_0)\;d\tau\right].$$

The second equation in (3.12) then implies

$$\eta=w(1)-w(0)=(\Psi(1)-I)w(0)+\Psi(1)\int_0^1\Phi^*(\tau)(\xi(\tau)+Rc_0\Phi(\tau)q_0)d\tau.$$

We thus obtain the equation

$$(\Psi(1)-I)w(0)=\eta-Rc_0\Psi(1)\int_0^1\Phi^*(\tau)\Phi(\tau)q_0\;d\tau-\Psi(1)\int_0^1\Phi^*(\tau)\xi(\tau)\;d\tau.$$

This equation is solvable for $w(0)$ if and only if

$$q_0^*\eta=Rc_0q_0^*\int_0^1\Phi^*(\tau)\Phi(\tau)q_0\;d\tau+q_0^*\int_0^1\Phi^*(\tau)\xi(\tau)d\tau.$$

The latter equation is solvable uniquely for R, so the previous one is solvable for $w(0)$ and defines it up to the addition of a scalar multiple of p_0.

Now suppose that $(w,R)^*$ solve the first two equations in (3.12), where $w(0)=w_0+rp_0$ and r is arbitrary. The third equation in (3.12) then requires

$$c_0q_0^*(w_0+rp_0)=\omega+\text{two integral terms which are linear in }\xi(t)\text{ and }R.$$

If the eigenvalue 1 of $\Phi(1)$ has algebraic multiplicity 1, then this equation has a unique solution in r and thus M_2 is one-to-one and onto. If the eigenvalue has algebraic multiplicity 2, then the range of M_2 has codimension at most 1. If we set $\xi(t)\equiv0$, $\eta=0$, $\omega=1$, then necessarily $R=0$, $\omega=0$ as well, and thus the third equation in (3.12) cannot be solved. So the range of M_2 has codimension 1, and $(0,0,1)^*$ is a vector complementary to the range. □

PROPOSITION 9. *Let* $(x(t),T,\alpha)$ *be a regular periodic solution of* (2.1) *that has a simple fold singularity; i.e.,* $\Phi(1)$ *has eigenvalue* 1 *with algebraic multiplicity* 2*. Then there exist* $v_{01},w_{01},\ v_{11},w_{11}\in\mathcal{C}^0([0,1],\mathbf{R}^n)$*,* $w_{02},v_{12}\in\mathbf{R}^n$*,* $w_{03},v_{02},v_{13},w_{12}\in\mathbf{R}$ *such that*

$$N_1=\begin{bmatrix} D-Tf_x(x(t),\alpha) & -f(x(t),\alpha) & w_{01}\\ \delta_1-\delta_0 & 0 & w_{02}\\ \mathrm{Int}_{f(x(\cdot),\alpha)} & 0 & w_{03}\\ \mathrm{Int}_{v_{01}} & v_{02} & 0\end{bmatrix}$$

and

$$N_2 = \begin{bmatrix} D + Tf_x^*(x(t),\alpha) & -f(x(\cdot),\alpha) & v_{11} \\ \delta_1 - \delta_0 & 0 & v_{12} \\ \mathrm{Int}_{f(x(\cdot),\alpha)} & 0 & v_{13} \\ \mathrm{Int}_{w_{11}} & w_{12} & 0 \end{bmatrix}$$

from $\mathcal{C}^1([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}$ *to* $\mathcal{C}^0([0,1],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}\times\mathbf{R}$ *are one-to-one and onto.*

For any such choice of the bordering elements we define $v, w \in \mathcal{C}^1([0,1],\mathbf{R}^n)$ *and* $S, G, H, R \in \mathbf{R}$ *by the equations*

$$N_1 \begin{pmatrix} v \\ S \\ G \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix} \tag{3.13}$$

and

$$N_2 \begin{pmatrix} w \\ R \\ H \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 0 \\ -1 \end{pmatrix}. \tag{3.14}$$

Then in a neighborhood of $(x(t),T,\alpha)$, $G = 0$ *if and only if* $H = 0$. *Moreover, this happens if and only if the regular periodic solution has a simple fold singularity.*

Proof. We choose

$$\begin{pmatrix} v_{01}(t) \\ v_{02} \end{pmatrix} = \begin{pmatrix} v(t) \\ 1 \end{pmatrix},$$

where v is given in the statement of Proposition 5. Further we set

$$\begin{pmatrix} w_{01}(t) \\ w_{02} \\ w_{03} \end{pmatrix} = \begin{pmatrix} \Psi^*(t)p_0 \\ 0 \\ 0 \end{pmatrix}.$$

By Propositions 5 and 6, N_1 is one-to-one and onto. We further set

$$\begin{pmatrix} w_{11}(t) \\ w_{12} \end{pmatrix} = \begin{pmatrix} \Psi^*(t)p_0 \\ 0 \end{pmatrix},$$

$$\begin{pmatrix} v_{11}(t) \\ v_{12} \\ v_{13} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

By Propositions 7 and 8, N_2 is one-to-one and onto. The last statement in the proposition is proved by standard arguments. □

3.2. A test functional for the period-doubling bifurcation. By definition, at a *simple flip singularity* there is an algebraically simple Floquet multiplier equal to -1 and no other multipliers with unit modulus, except for an algebraically simple multiplier $+1$. The left and right eigenvectors of the monodromy matrix $\Phi(1)$ for the eigenvalue -1 will be denoted by p_2 and q_2, respectively. They are also the right and left eigenvector, respectively, of $\Psi(1)$ for the eigenvalue -1.

PROPOSITION 10. *If $(x(t), T, \alpha)$ corresponds to a simple flip singularity, then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) \\ \delta_0 + \delta_1 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \to \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n$$

has a one-dimensional kernel spanned by Φq_2. Its range has codimension 1; if $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, then $(\zeta, r)^*$ is in the range if and only if $\langle \Psi p_2, \zeta \rangle = -p_2^* r$. In particular, if $r = 0$, then $(\zeta, 0)^*$ is in the range if and only if $\langle \Psi p_2, \zeta \rangle = 0$.

Proof. The proof is similar to the proof of Proposition 1. □

COROLLARY 3. *If $(x(t), T, \alpha)$ corresponds to a simple flip singularity, then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) \\ \delta_0 + \delta_1 \\ \mathrm{Int}_\phi \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R} \tag{3.15}$$

is one-to-one if and only if $\langle \phi, \Phi q_2 \rangle \neq 0$.

PROPOSITION 11. *If $(x(t), T, \alpha)$ corresponds to a simple flip singularity, then the operator*

$$\begin{bmatrix} D + Tf_x^*(x(t), \alpha) \\ \delta_0 + \delta_1 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n$$

has a one-dimensional kernel spanned by Ψp_2. Its range has codimension 1; if $\zeta \in \mathcal{C}^0([0,1], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, then $(\zeta, r)^*$ is in the range if and only if $\langle \Phi q_2, \zeta \rangle = -q_2^* r$. In particular, if $r = 0$, then $(\zeta, 0)^*$ is in the range if and only if $\langle \Phi q_2, \zeta \rangle = 0$.

Proof. The proof is similar to the proof of Proposition 2. □

COROLLARY 4. *If $(x(t), T, \alpha)$ corresponds to a simple flip singularity, then the operator*

$$\begin{bmatrix} D + Tf_x^*(x(t), \alpha) \\ \delta_0 + \delta_1 \\ \mathrm{Int}_\psi \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R} \tag{3.16}$$

is one-to-one if and only if $\langle \psi, \Psi p_2 \rangle \neq 0$.

PROPOSITION 12. *Let $(x(t), T, \alpha)$ correspond to a simple flip singularity, and let $\phi_0, \psi_0 \in \mathcal{C}^0([0,1], \mathbf{R}^n)$ be such that $\langle \phi_0, \Phi q_2 \rangle \neq 0$, $\langle \psi_0, \Psi p_2 \rangle \neq 0$. Then the operator*

$$\begin{bmatrix} D - Tf_x(x(t), \alpha) & \psi_0 \\ \delta_0 + \delta_1 & 0 \\ \mathrm{Int}_{\phi_0} & 0 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R} \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$$

is one-to-one and onto.

Proof. The proof is similar to the proof of Proposition 3. □

PROPOSITION 13. *Let $(x(t), T, \alpha)$ correspond to a simple flip singularity, and let $\phi_0, \psi_0 \in \mathcal{C}^0([0,1], \mathbf{R}^n)$ be such that $\langle \phi_0, \Phi q_2 \rangle \neq 0$, $\langle \psi_0, \Psi p_2 \rangle \neq 0$. Then the operator*

$$\begin{bmatrix} D + Tf_x^*(x(t), \alpha) & \phi_0 \\ \delta_0 + \delta_1 & 0 \\ \mathrm{Int}_{\psi_0} & 0 \end{bmatrix} : \mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R} \ \to \ \mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$$

is one-to-one and onto.

Proof. The proof is similar to the proof of Proposition 4. □

PROPOSITION 14. *Let $(x(t), T, \alpha)$ be a periodic solution close to a simple flip singularity, and let $\phi_0, \psi_0 \in \mathcal{C}^0([0,1], \mathbf{R}^n)$ be such that $\langle \phi_0, \Phi q_2 \rangle \neq 0$, $\langle \psi_0, \Psi p_2 \rangle \neq 0$, so that the operators M_3 and M_4 (defined below) from $\mathcal{C}^1([0,1], \mathbf{R}^n) \times \mathbf{R}$ into $\mathcal{C}^0([0,1], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}$ are both one-to-one and onto. Let $v, w \in \mathcal{C}^1([0,1], \mathbf{R}^n), G$, $H \in \mathbf{R}$ be defined by the equations*

$$M_3 \begin{pmatrix} v \\ G \end{pmatrix} \equiv \begin{bmatrix} D - Tf_x(x(t), \alpha) & \psi_0 \\ \delta_0 + \delta_1 & 0 \\ \mathrm{Int}_{\phi_0} & 0 \end{bmatrix} \begin{pmatrix} v \\ G \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}, \tag{3.17}$$

$$M_4 \begin{pmatrix} w \\ H \end{pmatrix} \equiv \begin{bmatrix} D + Tf_x^*(x(t), \alpha) & \phi_0 \\ \delta_0 + \delta_1 & 0 \\ \mathrm{Int}_{\psi_0} & 0 \end{bmatrix} \begin{pmatrix} w \\ H \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ -1 \end{pmatrix}. \tag{3.18}$$

Then $G = H$. Furthermore, $G = 0$ if and only if the periodic solution corresponds to a simple flip singularity. If so, then $v(0)$ is the right eigenvector of the monodromy matrix for the eigenvalue -1.

Proof. Multiplying the first equation in (3.17) on the left with $w^*(t)$, integrating over the interval $[0,1]$, and using the last equation in (3.18) we obtain

$$\int_0^1 w^* v'(\tau)\, d\tau - T \int_0^1 w^*(\tau) f_x(x(\tau), \alpha) v(\tau)\, d\tau - G = 0.$$

Integrating the first term by parts, using the second equations in (3.17) and (3.18), we obtain

$$-\int_0^1 v^*(\tau) w'(\tau)\, d\tau - T \int_0^1 v^*(\tau) f_x^*(x(\tau), \alpha) w(\tau)\, d\tau - G = 0.$$

Using the first equation in (3.18) we get

$$-\langle v, (-H\phi_0) \rangle - G = 0.$$

Using the third equation in (3.17) we obtain $G = H$. The other statements in the proposition are now obvious. □

3.3. A test functional for the torus bifurcation. We say that a periodic solution has a *simple Neimark–Sacker singularity* if the monodromy matrix $\Phi(1)$ has a conjugate pair of simple complex multipliers with modulus 1 (i.e., $e^{\pm i\theta}$, $0 < \theta < \pi$) and no other multipliers with unit modulus, except an algebraically simple eigenvalue $+1$. Furthermore, let $p_1, p_2 \in \mathbf{R}^n$ (respectively, $q_1, q_2 \in \mathbf{R}^n$) be such that $p_1 + ip_2$ (respectively, $q_1 + iq_2$) is a left (respectively, right) complex eigenvector of the monodromy matrix $\Phi(1)$. Thus

$$\begin{gathered} (p_1 + ip_2)^H \Phi(1) = e^{i\theta}(p_1 + ip_2)^H, \\ \Phi(1)(q_1 + iq_2) = e^{i\theta}(q_1 + iq_2), \\ \Psi(1)(p_1 + ip_2) = e^{i\theta}(p_1 + ip_2), \\ (q_1 + iq_2)^H \Psi(1) = e^{i\theta}(q_1 + iq_2)^H, \end{gathered}$$

where $(p_1 + ip_2)^H = p_1^* - ip_2^*$, $(q_1 + iq_2)^H = q_1^* - iq_2^*$.

In this section it is convenient to extend the definition of $x(t), \Phi(t)$, and $\Psi(t)$ to the interval $[0,2]$ by periodicity with period 1 and to redefine

$$\mathrm{Int}_{\phi}(v) = \langle \phi, v \rangle = \int_0^2 \phi^*(\tau) v(\tau)\ d\tau.$$

We start with the following result.

PROPOSITION 15. *Let $(x(t), T, \alpha)$ define a periodic solution; i.e., it satisfies* (2.1), (2.2), *and* (2.3). *Let $(x(t), T, \alpha)$ correspond to a simple Neimark–Sacker singularity with multipliers $e^{\pm i\theta}$, $0 < \theta < \pi$. Let $\kappa = \cos\theta$ and consider the operator*

$$\left[\begin{array}{c} D - T f_x(x(t), \alpha) \\ \delta_0 - 2\kappa\delta_1 + \delta_2 \end{array} \right] \ :\ \mathcal{C}^1([0,2], \mathbf{R}^n) \ \rightarrow\ \mathcal{C}^0([0,2], \mathbf{R}^n) \times \mathbf{R}^n. \tag{3.19}$$

Then we have the following:

(i) *The operator* (3.19) *has a two-dimensional kernel spanned by $\Phi(t)q_1$ and $\Phi(t)q_2$.*

(ii) *The operator* (3.19) *has a range with* codim 2. *The vectors*

$$\left(\begin{array}{c} \Psi p_1 \\ 0 \end{array} \right), \left(\begin{array}{c} \Psi p_2 \\ 0 \end{array} \right) \in \mathcal{C}^0([0,2], \mathbf{R}^n) \times \mathbf{R}^n$$

span a two-dimensional subspace that is complementary to the range of (3.19).

Proof. Let v be in the kernel of (3.19). Then v must have the form $v(t) = \Phi(t)v_0$ with $v_0 \in \mathbf{R}^n$. We further have

$$0 = (\delta_0 - 2\kappa\delta_1 + \delta_2)v = v(0) - 2\kappa v(1) + v(2) = (\Phi(1) - e^{i\theta}I)(\Phi(1) - e^{-i\theta}I)v_0.$$

We infer that it is necessary and sufficient that v_0 is in the span of q_1, q_2.

As a first step in the proof of (ii) we consider $\zeta \in \mathcal{C}^0([0,2], \mathbf{R}^n)$, $r \in \mathbf{R}^n$, and we give a necessary and sufficient condition in order that $(\zeta, r)^*$ be in the range of (3.19). First, there must exist a $v \in \mathcal{C}^1([0,2], \mathbf{R}^n)$ for which

$$v'(t) - T f_x(x(t), \alpha) v(t) = \zeta(t).$$

The general solution of this linear differential equation is

$$v(t) = \Phi(t) \left[v_0 + \int_0^t \Psi^*(\tau)\zeta(\tau)\ d\tau \right],$$

where $v_0 = v(0)$ is an initial vector. Also, we must have $v(0) - 2\kappa v(1) + v(2) = r$, that is,

$$(\Phi(1) - e^{i\theta}I)(\Phi(1) - e^{-i\theta}I)v_0 - 2\kappa\Phi(1) \int_0^1 \Psi^*(\tau)\zeta(\tau)\ d\tau + \Phi(1)^2 \int_0^2 \Psi^*(\tau)\zeta(\tau) d\tau = r.$$

This is an equation for v_0 which is solvable if and only if

$$-2\kappa p^H \Phi(1) \int_0^1 \Psi^*(\tau)\zeta(\tau)\ d\tau + p^H \Phi(1)^2 \int_0^2 \Psi^*(\tau)\zeta(\tau)\ d\tau = p^H r$$

or, equivalently,

$$-2\kappa e^{i\theta} \int_0^1 p^H \Psi^*(\tau)\zeta(\tau)\ d\tau + e^{2i\theta} \int_0^2 p^H \Psi^*(\tau)\zeta(\tau)\ d\tau = p^H r.$$

If we define the linear functional L by setting

$$L(\zeta) = -2\kappa e^{i\theta} \int_0^1 p^H \Psi^*(\tau)\zeta(\tau)\, d\tau + e^{2i\theta} \int_0^2 p^H \Psi^*(\tau)\zeta(\tau)\, d\tau, \tag{3.20}$$

then we infer that $(\zeta, r)^*$ is in the range of (3.19) if and only if $L(\zeta) = p^H r$.

As a second step in the proof of (ii) we compute $L(\Psi p_1)$ and $L(\Psi p_2)$. We have

$$L(\Psi p_1) = -2\cos\theta e^{i\theta} \int_0^1 p^H \Psi^*(\tau)\Psi(\tau)p_1\, d\tau + e^{2i\theta} \int_0^2 p^H \Psi^*(\tau)\Psi(\tau)p_1\, d\tau$$

$$= e^{i\theta}(-2\cos\theta+\cos\theta+i\sin\theta) \int_0^1 p^H \Psi^*(\tau)\Psi(\tau)p_1\, d\tau + e^{2i\theta} \int_0^1 p^H \Psi^*(1+\tau)\Psi(1+\tau)p_1\, d\tau.$$

Now we note that

$$\Psi(1+\tau)p_1 = \Psi(\tau)\Psi(1)p_1 = \Psi(\tau)(\cos\theta p_1 - \sin\theta p_2)$$

and

$$p^H \Psi^*(1+\tau) = [\Psi(\tau)\Psi(1)p]^H = [e^{i\theta}\Psi(\tau)p]^H = e^{-i\theta} p^H \Psi^*(\tau).$$

Hence

$$L(\Psi p_1) = i\sin\theta e^{i\theta} \int_0^1 p^H \Psi^*(\tau)\Psi(\tau)p\, d\tau = (-\sin\theta + i\cos\theta)\sin\theta \int_0^1 \|\Psi(\tau)p\|^2\, d\tau.$$

By a similar argument we find that

$$L(\Psi p_2) = (\cos\theta + i\sin\theta)\sin\theta \int_0^1 \|\Psi(\tau)p\|^2 d\tau.$$

As a third step in the proof of (ii) we show that the range of (3.19) has codimension 2 by proving that every $(\xi, r)^*$ can be written in a unique way as

$$\begin{pmatrix} \xi \\ r \end{pmatrix} = \begin{pmatrix} \xi_0 \\ r_0 \end{pmatrix} + \alpha \begin{pmatrix} 0 \\ p_1 \end{pmatrix} + \beta \begin{pmatrix} 0 \\ p_2 \end{pmatrix}, \tag{3.21}$$

with $(\xi_0, r_0)^*$ in the range of (3.19) and $\alpha, \beta \in \mathbf{R}$.

Obviously $\xi_0 = \xi$, and r_0 has to satisfy the conditions

$$p^H r_0 = L(\xi), \quad r_0 = r - \alpha p_1 - \beta p_2.$$

These conditions imply

$$\begin{pmatrix} p_1^* p_1 & p_1^* p_2 \\ p_2^* p_1 & p_2^* p_2 \end{pmatrix} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \begin{pmatrix} p_1^* r - \text{Re}\,[L(\xi)] \\ p_2^* r + \text{Im}\,[L(\xi)] \end{pmatrix}.$$

This nonsingular linear system defines α, β in a unique way. Next, r_0 is defined by the requirement $r_0 = r - \alpha p_1 - \beta p_2$, and with this choice we have $p^H r_0 = L(\xi)$.

As the fourth and last step to prove (ii) we will show that

$$\begin{pmatrix} \Psi p_1 \\ 0 \end{pmatrix}, \begin{pmatrix} \Psi p_2 \\ 0 \end{pmatrix},$$

and we will also span a two-dimensional space complementary to the range of (3.19). To this end we decompose

$$\begin{pmatrix} \Psi p_1 \\ 0 \end{pmatrix} = \begin{pmatrix} \Psi p_1 \\ r_1 \end{pmatrix} + \alpha_1 \begin{pmatrix} 0 \\ p_1 \end{pmatrix} + \beta_1 \begin{pmatrix} 0 \\ p_2 \end{pmatrix},$$

$$\begin{pmatrix} \Psi p_2 \\ 0 \end{pmatrix} = \begin{pmatrix} \Psi p_2 \\ r_2 \end{pmatrix} + \alpha_2 \begin{pmatrix} 0 \\ p_1 \end{pmatrix} + \beta_2 \begin{pmatrix} 0 \\ p_2 \end{pmatrix}$$

in the decomposition of (3.21). Then $\alpha_1, \beta_1, \alpha_2, \beta_2$ are defined by the matrix equation

$$\begin{pmatrix} p_1^* p_1 & p_1^* p_2 \\ p_2^* p_1 & p_2^* p_2 \end{pmatrix} \begin{pmatrix} \alpha_1 & \alpha_2 \\ \beta_1 & \beta_2 \end{pmatrix} = \begin{pmatrix} -\mathrm{Re}\,[L(\Psi p_1)] & -\mathrm{Re}\,[L(\Psi p_2)] \\ \mathrm{Im}\,[L(\Psi p_1)] & \mathrm{Im}\,[L(\Psi p_2)] \end{pmatrix}.$$

The proof of (ii) is complete if we show that

$$\begin{pmatrix} \alpha_1 & \alpha_2 \\ \beta_1 & \beta_2 \end{pmatrix}$$

is a nonsingular matrix or, equivalently, that

$$\begin{pmatrix} -\mathrm{Re}\,[L(\Psi p_1)] & -\mathrm{Re}\,[L(\Psi p_2)] \\ \mathrm{Im}\,[L(\Psi p_1)] & \mathrm{Im}\,[L(\Psi p_2)] \end{pmatrix}$$

is nonsingular. By the second step this matrix is equal to

$$\begin{pmatrix} \sin\theta & -\cos\theta \\ \cos\theta & \sin\theta \end{pmatrix} \sin\theta \int_0^1 \|\Psi(\tau)p\|^2 d\tau. \tag{3.22}$$

Since $\sin\theta \neq 0$ in (3.22) the proof is complete. □

PROPOSITION 16. *Let $(x(t), T, \alpha)$ define a periodic solution; that is, it satisfies* (2.1), (2.2), *and* (2.3). *Let $(x(t), T, \alpha)$ correspond to a simple Neimark–Sacker singularity with multipliers $e^{\pm i\theta}$, $0 < \theta < \pi$. Set $\kappa = \cos\theta$ and consider the operator*

$$\begin{bmatrix} D + T f_x^*(x(t), \alpha) \\ \delta_0 - 2\kappa\delta_1 + \delta_2 \end{bmatrix} : \mathcal{C}^1([0,2], \mathbf{R}^n) \to \mathcal{C}^0([0,2], \mathbf{R}^n) \times \mathbf{R}^n. \tag{3.23}$$

Then we have the following:

(i) *The operator* (3.23) *has a two-dimensional kernel spanned by $\Psi(t)p_1$ and $\Psi(t)p_2$.*

(ii) *The operator* (3.23) *has a range of codimension* 2. *The vectors*

$$\begin{pmatrix} \Phi q_1 \\ 0 \end{pmatrix}, \begin{pmatrix} \Phi q_2 \\ 0 \end{pmatrix} \in \mathcal{C}^0([0,2], \mathbf{R}^n) \times \mathbf{R}^n$$

span a two-dimensional subspace that is complementary to the range of (3.23).

Proof. The proof is similar to the proof of the preceding proposition. □

COROLLARY 5. *Let $(x(t), T, \alpha)$ correspond to a simple Neimark–Sacker singularity of a periodic solution. If $\kappa = \cos\theta$, then the operators*

$$\begin{bmatrix} D - T f_x(x(t), \alpha) & \Psi p_1 & \Psi p_2 \\ \delta_0 - 2\kappa\delta_1 + \delta_2 & 0 & 0 \\ \mathrm{Int}_{\Phi(\cdot)q_1} & 0 & 0 \\ \mathrm{Int}_{\Phi(\cdot)q_2} & 0 & 0 \end{bmatrix} : \mathcal{C}^1([0,2], \mathbf{R}^n) \times \mathbf{R}^2 \to \mathcal{C}^0([0,2], \mathbf{R}^n) \times \mathbf{R}^n \times \mathbf{R}^2$$

and

$$\begin{bmatrix} D+Tf_x^*(x(t),\alpha) & \Phi q_1 & \Phi q_2 \\ \delta_0-2\kappa\delta_1+\delta_2 & 0 & 0 \\ \mathrm{Int}_{\Psi(\cdot)p_1} & 0 & 0 \\ \mathrm{Int}_{\Psi(\cdot)p_2} & 0 & 0 \end{bmatrix} : \mathcal{C}^1([0,2],\mathbf{R}^n)\times\mathbf{R}^2 \rightarrow \mathcal{C}^0([0,2],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}^2$$

are both one-to-one and onto.

Proof. The proof is standard. □

Proposition 17. *Let $(x(t),T,\alpha)$ be close to a simple Neimark–Sacker singularity of periodic solutions and κ close to the value $\cos\theta$ at the singular point. Furthermore, let (ψ_0,ψ_1) span a space sufficiently close to the span of $(\Psi p_1,\Psi p_2)$, and let (ϕ_0,ϕ_1) span a space sufficiently close to $(\Phi q_1,\Phi q_2)$, so that the operators*

$$M_5 = \begin{bmatrix} D-Tf_x(x(t),\alpha) & \psi_0 & \psi_1 \\ \delta_0-2\kappa\delta_1+\delta_2 & 0 & 0 \\ \mathrm{Int}_{\phi_0} & 0 & 0 \\ \mathrm{Int}_{\phi_1} & 0 & 0 \end{bmatrix} : \mathcal{C}^1([0,2],\mathbf{R}^n)\times\mathbf{R}^2 \rightarrow \mathcal{C}^0([0,2],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}^2$$

and

$$M_6 = \begin{bmatrix} D+Tf_x^*(x(t),\alpha) & \phi_0 & \phi_1 \\ \delta_0-2\kappa\delta_1+\delta_2 & 0 & 0 \\ \mathrm{Int}_{\psi_0} & 0 & 0 \\ \mathrm{Int}_{\psi_1} & 0 & 0 \end{bmatrix} : \mathcal{C}^1([0,2],\mathbf{R}^n)\times\mathbf{R}^2 \rightarrow \mathcal{C}^0([0,2],\mathbf{R}^n)\times\mathbf{R}^n\times\mathbf{R}^2$$

are both one-to-one and onto. Let $v_1,v_2,w_1,w_2 \in \mathcal{C}^1([0,2],\mathbf{R}^n), G,H \in \mathbf{R}^{2\times 2}$ be defined by the equations

$$M_5\begin{pmatrix} v_1 & v_2 \\ G_{11} & G_{12} \\ G_{21} & G_{22} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{3.24}$$

$$M_6\begin{pmatrix} w_1 & w_2 \\ H_{11} & H_{21} \\ H_{12} & H_{22} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 0 & 0 \\ -1 & 0 \\ 0 & -1 \end{pmatrix}. \tag{3.25}$$

If $(x(t),T,\alpha)$ is a periodic solution, then $G=0$ if and only if $H=0$. Moreover, this happens if and only if $(x(t),T,\alpha)$ corresponds to a simple Neimark–Sacker singularity of periodic solutions with the multipliers $e^{\pm i\theta}$, where $\kappa=\cos(\theta)$.

Proof. The proof is standard. □

4. Regularity of the defining systems. In this section we prove that, under natural nondegeneracy and transversality conditions, the test functionals constructed in the previous section are regular (with respect to the arclength parameter along the periodic solution family). This implies regularity of defining systems consisting of the periodic BVP (2.1), (2.2), (2.3), and the condition for the corresponding functional to vanish, for the two-parameter continuation of the bifurcation.

4.1. Regularity at a fold bifurcation. To prove the regularity of the test functional G for the simple fold singularity in Proposition 9, we proceed as in the case of the fold singularity of equilibria [12], [3].

The computation of periodic orbits is based on the equation

$$F(X,\alpha)=0, \tag{4.1}$$

where $X \equiv (x(\cdot),T) \in \mathcal{C}^1([0,1],\mathbf{R}) \times \mathbf{R}$, and $F(X) \in \mathcal{C}^0([0,1],\mathbf{R}) \times \mathbf{R}^n \times \mathbf{R}$ is given by

$$F(X) \equiv \begin{pmatrix} x'(t) - Tf(x(t),\alpha) \\ x(1)-x(0) \\ \displaystyle\int_0^1 x^*(\tau)x'_{k-1}(\tau)\, d\tau \end{pmatrix}$$

(see (2.1), (2.2), and (2.3)). The Fréchet derivative $F_X(X,\alpha)$ of this operator (with x_{k-1} substituted by x upon differentiation) is M_1 as defined in (3.1). By Propositions 5 and 6, if the periodic orbit has a simple fold singularity, then F_X is singular. Moreover, the left and right singular vectors are then

$$\begin{pmatrix} \Psi p_0 \\ -p_0 \\ 0 \end{pmatrix}$$

and

$$\begin{pmatrix} v \\ 1 \end{pmatrix},$$

given in (3.2) and (3.6), respectively. By definition, a simple fold point is *nondegenerate* if

$$\begin{pmatrix} \Psi p_0 \\ -p_0 \\ 0 \end{pmatrix}^* F_{XX} \begin{pmatrix} v \\ 1 \end{pmatrix} \begin{pmatrix} v \\ 1 \end{pmatrix} \neq 0. \tag{4.2}$$

Let α be a scalar parameter in (1.1). A nondegenerate fold point is called *regular* if $[F_X \;\; F_\alpha]$ is onto at the singularity. This is the usual *transversality condition* for the limit point bifurcation, which can be equivalently expressed as

$$\begin{pmatrix} \Psi p_0 \\ -p_0 \\ 0 \end{pmatrix}^* F_\alpha \neq 0. \tag{4.3}$$

Let s denote arclength along the family of periodic orbits. We think of X and α as functions of s so that (4.1) is an identity in s. By (3.13) this also defines G as a function of s. Suppose that a fold singularity occurs at $s = s_0$. We will prove that $G_s(s_0) \neq 0$ near a regular fold point, i.e., a simple fold singularity where both (4.2) and (4.3) hold.

Taking derivatives of (3.13) with respect to s we find

$$N_1 \begin{pmatrix} v_s \\ S_s \\ G_s \end{pmatrix} = \begin{pmatrix} (F_{XX}X_s + F_{X\alpha}\alpha_s)\begin{pmatrix} v \\ S \end{pmatrix} \\ 0 \end{pmatrix}. \tag{4.4}$$

In this expression

$$\begin{pmatrix} v \\ S \end{pmatrix}$$

is a right singular vector of F_X. Furthermore, at the fold singularity $\alpha_s = 0$. Since $F_X X_s + F_\alpha \alpha_s \equiv 0$ it follows that X_s is also a right singular vector of F_X. Now by (4.4) we have $G_s(s_0) \neq 0$ if and only if

$$F_{XX} \begin{pmatrix} v \\ 1 \end{pmatrix} \begin{pmatrix} v \\ 1 \end{pmatrix}$$

is not in the range of M_1; under our assumptions this is equivalent to (4.2).

4.2. Regularity at a period-doubling bifurcation. We have seen that locally, near a simple flip singularity, the system consisting of (2.1), (2.2), (2.3), and $G = 0$ (where G is given by (3.17)) defines the set of simple flips in $(x(\cdot), T, \alpha)$-space if the conditions $\langle \phi_0, \Phi q_2 \rangle \neq 0$, $\langle \psi_0, \Psi p_2 \rangle \neq 0$ hold. We will now prove that this is a regular system if an appropriate transversality condition for the period-doubling bifurcation holds.

Let s denote arclength along the family of periodic orbits so that $(x(s)(t), T(s), \alpha(s))$ is a solution of (2.1), (2.2), and (2.3) for all s near the bifurcation value s_0. The simplicity of the flip singularity implies that -1 is the algebraically simple eigenvalue of $\Phi(s_0)(1)$ so that it can be continued smoothly, together with its left and right eigenvectors, for nearby values of s. Specifically, we denote by $\lambda(s)$ an eigenvalue of $\Phi(s)(1)$, with left and right eigenvectors $p(s), q(s)$, that is,

$$\begin{array}{ll} \Phi(s)(1)q(s) = \lambda(s)q(s), & p^*(s)\Phi(s)(1) = \lambda(s)p^*(s), \\ \Psi(s)(1)p(s) = \lambda^{-1}(s)p(s), & q^*(s)\Psi(s)(1) = \lambda^{-1}(s)q^*(s), \\ p(s_0) = p_2, & q(s_0) = q_2, \\ \lambda(s_0) = -1. & \end{array} \tag{4.5}$$

The simplicity condition implies that

$$p^*(s)q(s) \neq 0$$

for all s sufficiently close to s_0. By standard arguments, (4.5) implies

$$p^*(s)q(s)\lambda_s(s) = p^*(s)\Phi_s(s)(1)q(s). \tag{4.6}$$

To get an explicit formula for $\Phi_s(s_0)(1)$ we start from the observation that

$$(D - T(s)f_x(x(s), \alpha(s)))\Phi = 0.$$

Taking derivatives, and using somewhat simplied notation, we obtain

$$(D - Tf_x)\Phi_s = (Tf_x)_s\Phi.$$

Multiplying on the right by an arbitrary vector $\xi \in \mathbf{R}^n$, we have

$$(D - Tf_x)\Phi_s\xi = (Tf_x)_s\Phi\xi.$$

This is a linear differential equation for $\Phi_s\xi$ with solution

$$\Phi_s(s)(t)\xi = \Phi(s)(t)\left[\zeta + \int_0^t \Psi^*(s)(\tau)(Tf_x)_s(s)(\tau)\Phi(s)(\tau)\xi \, d\tau\right]$$

for some $\zeta \in \mathbf{R}^n$. For $t = 0$ this reduces to

$$\Phi_s(s)(0)\xi = \Phi(s)(0)\zeta.$$

Since $\Phi(s)(0) = I$, $\Phi_s(s)(0) = 0$, this implies that $\zeta = 0$, so that

$$\Phi_s(s)(t)\xi = \Phi(s)(t) \int_0^t \Psi^*(s)(\tau)(Tf_x)_s(s)(\tau)\Phi(s)(\tau)\xi \, d\tau \tag{4.7}$$

for all $\xi \in \mathbf{R}^n$. From (4.6) we get

$$p^*(s)q(s)\lambda_s(s) = \lambda(s)p^*(s) \int_0^1 \Psi^*(\tau)(Tf_x)_s(s)(\tau)\Phi(s)(\tau)q(s) \, d\tau. \tag{4.8}$$

The natural transversality condition for the period-doubling bifurcation is $\lambda_s(s_0) \neq 0$. We now show that this is equivalent to $G_s(s_0) \neq 0$, thus establishing regularity.

Proposition 18. *The conditions $\lambda_s(s_0) \neq 0$ and $G_s(s_0) \neq 0$ are equivalent near a simple flip singularity.*

Proof. The equations (3.17) are to be considered as identities in s; by taking derivatives we obtain

$$(D - Tf_x)v_s = (Tf_x)_s v - \psi_0 G_s, \tag{4.9}$$

$$(\delta_0 + \delta_1)v_s = 0, \tag{4.10}$$

$$\mathrm{Int}_{\phi_0} v_s = 0.$$

The solution of (3.17) at $s = s_0$ is given by $G(s_0) = 0$, $v(s_0)(t) = \Phi(s_0)(t)q_2$. Now, at $s = s_0$ (4.9) is a linear differential equation for $v_s(s_0)(t)$ with solution

$$v_s(s_0)(t) = \Phi(s_0)(t) \left[\zeta + \int_0^t \Psi^*(s_0)(\tau)((Tf_x)_s(s_0)(\tau)v(s_0)(\tau) - \psi_0 G_s(s_0)) \, d\tau\right]$$

for some vector $\zeta \in \mathbf{R}^n$. Using (4.10) we find

$$0 = (I + \Phi(s_0)(1))\zeta + \Phi(s_0)(1) \int_0^1 \Psi^*(s_0)(\tau)((Tf_x)_s(s_0)(\tau)\Phi(s_0)(\tau)q_2 - \psi_0 G_s(s_0)) \, d\tau.$$

This equation in ζ has a solution if and only if

$$p^*(s_0)\Phi(s_0)(1) \int_0^1 \Psi^*(s_0)(\tau)((Tf_x)_s(s_0)(\tau)\Phi(s_0)(\tau)q_2 - \psi_0 G_s(s_0)) \, d\tau = 0,$$

that is,

$$p_2^* \int_0^1 \Psi^*(s_0)(\tau)(Tf_x)_s(s_0)(\tau)\Phi(s_0)(\tau)q_2 \, d\tau = \langle \psi_0, \Psi p_2 \rangle G_s(s_0).$$

By (4.8) this implies

$$-(p_2^* q_2)\lambda_s(s_0) = \langle \psi_0, \Psi p_2 \rangle G_s(s_0).$$

Since $p_2^* q_2$ and $\langle \psi_0, \Psi p_2 \rangle$ are nonzero, this completes the proof. □

4.3. Regularity at a torus bifurcation. Again, let s denote arclength along the family of periodic orbits so that $(x(s)(t), T(s), \alpha(s))$ is a solution of (2.1), (2.2), and (2.3) for all s near the critical value s_0 corresponding to a simple Neimark–Sacker singularity. Thus $\Phi(s_0)(1)$ has algebraically simple eigenvalues $e^{\pm i\theta}$. Let $\lambda(s) = \lambda_1(s) + i\lambda_2(s)$, $p(s) = p_1(s) + ip_2(s)$, $q(s) = q_1(s) + iq_2(s)$ be the smooth continuations of the critical multiplier $e^{i\theta}$ and the corresponding left and right eigenvectors. The natural transversality condition for the torus bifurcation is the requirement that $\lambda(s)$ crosses the unit circle in the complex plane at nonzero velocity, i.e.,

$$\lambda_1(s_0)\lambda_{1s}(s_0) + \lambda_2(s_0)\lambda_{2s}(s_0) \neq 0. \tag{4.11}$$

Proposition 19. *The system consisting of* (2.1), (2.2), (2.3), *and the conditions*

$$\begin{array}{rcl} G_{11} & = & 0, \\ G_{12} & = & 0, \\ G_{21} & = & 0, \\ G_{22} & = & 0, \end{array} \tag{4.12}$$

where the G_{ij} are defined in Proposition 17, *together form a regular defining system for periodic solutions having a simple Neimark–Sacker singularity if the natural transversality condition* (4.11) *is satisfied.*

Proof. To prove that the system (2.1), (2.2), (2.3), (4.12) is a regular defining system (i.e., has full linear rank), we consider the implicit solution $(x(s)(t), T(s), \alpha(s))$ of (2.1), (2.2), (2.3). So $G_{11}, G_{12}, G_{21}, G_{22}$ are functions of s, κ only, and we have to prove that

$$\begin{pmatrix} G_{11s} & G_{11\kappa} \\ G_{12s} & G_{12\kappa} \\ G_{21s} & G_{21\kappa} \\ G_{22s} & G_{22\kappa} \end{pmatrix}$$

has rank 2. Assume that $c_1, c_2 \in \mathbf{R}$ are such that

$$c_1 G_{ijs} + c_2 G_{ij\kappa} = 0, \quad (i, j = 1, 2). \tag{4.13}$$

We start by noting that $p^H(s)q(s) \neq 0$ in a neighborhood of $s = s_0$. By standard arguments

$$(p^H q)\lambda_s = p^H \Phi_s(1) q, \tag{4.14}$$

where for simplicity of notation we have suppressed the dependence on s. To get an expression for $\Phi_s(1)$ we start from the identity

$$(D - Tf_x)\Phi \equiv 0.$$

Taking derivatives with respect to s and multiplying with any vector $\zeta \in \mathbf{R}^n$ we find

$$(D - Tf_x)\Phi_s \zeta = (Tf_x)_s \Phi \zeta.$$

The solution of this linear differential equation in $\Phi_s \zeta$ is

$$\Phi_s \zeta(t) = \Phi(s)(t) \left[\xi + \int_0^t \Psi^*(s)(\tau)(Tf_x)_s(s)(\tau)\Phi(s)(\tau)\zeta \, d\tau \right],$$

where ξ is determined by the initial conditions. Since for $t = 0$ we have $\Phi(0) = I, \Phi_s(0) = 0$, it follows that $\xi = 0$. Choosing $\zeta = q$ we obtain from (4.14) that

$$(p^H q)\lambda_s = \lambda p^H \int_0^1 \Psi^*(s)(\tau)(Tf_x)_s(s)(\tau)\Phi(s)(\tau)q \; d\tau. \tag{4.15}$$

From (3.24) we infer that

$$M_5 \begin{bmatrix} v_{1s} & v_{2s} \\ G_{11s} & G_{12s} \\ G_{21s} & G_{22s} \end{bmatrix} = \begin{bmatrix} (Tf_x)_s v_1 & (Tf_x)_s v_2 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \tag{4.16}$$

$$M_5 \begin{bmatrix} v_{1\kappa} & v_{2\kappa} \\ G_{11\kappa} & G_{12\kappa} \\ G_{21\kappa} & G_{22\kappa} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 2v_1(1) & 2v_2(1) \\ 0 & 0 \\ 0 & 0 \end{bmatrix}. \tag{4.17}$$

Combining (4.13), (4.16), and (4.17) we obtain

$$M_5 \begin{bmatrix} c_1 v_{1s} + c_2 v_{1\kappa} & c_1 v_{2s} + c_2 v_{2\kappa} \\ 0 & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} c_1 (Tf_x)_s v_1 & c_1 (Tf_x)_s v_2 \\ 2c_2 v_1(1) & 2c_2 v_2(1) \\ 0 & 0 \\ 0 & 0 \end{bmatrix}.$$

Hence

$$\begin{pmatrix} c_1 (Tf_x)_s v_1 \\ 2c_2 v_1(1) \end{pmatrix}, \begin{pmatrix} c_1 (Tf_x)_s v_2 \\ 2c_2 v_2(1) \end{pmatrix}$$

are both in the range of (3.19). As an essential step in the proof of Proposition 15 it was shown that this implies

$$c_1 L((Tf_x)_s v_1) = 2c_2 p^H v_1(1),$$

$$c_1 L((Tf_x)_s v_2) = 2c_2 p^H v_2(1),$$

where the linear operator L is defined in (3.20). Since v_1, v_2 are in the kernel of (3.19) we have

$$v_1(\tau) = \Phi(\tau) v_1(0), \quad v_2(\tau) = \Phi(\tau) v_2(0).$$

Combining the last four formulae we find

$$c_1 L((Tf_x)_s \Phi q) = 2c_2 p^H \Phi(1) q = 2c_2 e^{i\theta}(p^H q). \tag{4.18}$$

Now,

$$\begin{aligned} L((Tf_x)_s \Phi q) &= -2\kappa e^{i\theta} \int_0^1 p^H \Psi^*(\tau)(Tf_x)_s \Phi(\tau) q \; d\tau + e^{2i\theta} \int_0^2 p^H \Psi^*(\tau)(Tf_x)_s \Phi(\tau) q \; d\tau \\ &= e^{i\theta}(\cos\theta + i\sin\theta - 2\cos\theta) \int_0^1 p^H \Psi^*(\tau)(Tf_x)_s \Phi(\tau) q \; d\tau \\ &\quad + e^{2i\theta} \int_0^1 p^H \Psi^*(1+\tau)(Tf_x)_s \Phi(1+\tau) q \; d\tau. \end{aligned}$$

Also,

$$p^H\Psi^*(1+\tau) = (\Psi(1+\tau)p)^H = (\Psi(\tau)\Psi(1)p)^H = p^H\Phi^{-1}(1)\Psi^*(\tau) = e^{-i\theta}p^H\Psi^*(\tau)$$

and

$$\Phi(1+\tau)q = \Phi(\tau)\Phi(1)q = e^{i\theta}\Phi(\tau)q.$$

Hence

$$L((Tf_x)_s\Phi q) = e^{i\theta}2i\sin\theta\int_0^1 p^H\Psi^*(\tau)(Tf_x)_s\Phi(\tau)q\ d\tau.$$

By (4.15) this implies

$$L((Tf_x)_s\Phi q) = 2i\sin\theta(p^Hq)\lambda_s.$$

Using (4.18) we further obtain

$$2ic_1\sin\theta(p^Hq)\lambda_s = 2c_2e^{i\theta}(p^Hq).$$

Dividing by $2(p^Hq)$ we obtain

$$(-\sin\theta\lambda_{2s} + i\sin\theta\lambda_{1s})c_1 = (\cos\theta + i\sin\theta)c_2.$$

Taking real and imaginary parts of this complex equality we find

$$\begin{pmatrix} -\sin\theta\lambda_{2s} & -\cos\theta \\ \sin\theta\lambda_{1s} & -\sin\theta \end{pmatrix}\begin{pmatrix} c_1 \\ c_2 \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}.$$

The determinant of the 2×2 matrix in this expression is equal to

$$\sin\theta(\cos\theta\lambda_{1s} + \sin\theta\lambda_{2s}) = \sin\theta(\lambda_1\lambda_{1s} + \lambda_2\lambda_{2s}).$$

By (4.11) and $\sin\theta \neq 0$ this implies that $c_1 = c_2 = 0$, which completes the proof. □

5. Computational issues. In this section we discuss computational issues related to the implementation of our defining systems, namely the computation of the derivatives of the test functionals with respect to the unknowns of the system, $x(t), \alpha, T$, as well as the problem of adapting the defining systems along the bifurcation branch. We also explicitly show the BVPs that must be solved.

5.1. Fold bifurcation. Proposition 9 implies that locally, near a simple fold singularity of periodic solutions, the system consisting of (2.1), (2.2), (2.3), and

$$G = 0$$

defines the set of simple folds in $(x(\cdot), T, \alpha)$-space; here G is defined by (3.13). Under natural nondegeneracy and transversality conditions, the regularity of this system was proved in section 4.1.

We need the derivatives of G with respect to the unknowns of the system, i.e., with respect to $x(\cdot), \alpha, T$.

Denoting by z any component of α or T we infer from (3.13) that

$$N_1 \begin{pmatrix} v_z \\ S_z \\ G_z \end{pmatrix} = \begin{pmatrix} [Tf_x(x(t),\alpha]_z v + [f(x(t),\alpha)]_z S \\ 0 \\ -\mathrm{Int}_{[f(x(\cdot),\alpha)]_z} v \\ 0 \end{pmatrix}.$$

Numerically we solve a discretized version of this equation, say

$$N_1^d \begin{pmatrix} v_z \\ S_z \\ G_z \end{pmatrix} = \begin{pmatrix} ([Tf_x(x(t),\alpha]_z v + [f(x(t),\alpha)]_z S)_d \\ 0 \\ -(\mathrm{Int}_{[f(x(\cdot),\alpha)]_z} v)_d \\ 0 \end{pmatrix}, \tag{5.1}$$

where N_1^d is the discretized version of N_1, i.e., a large square matrix with a structure that can be efficiently factorized, for example, as in AUTO [9].

Note that a large number of linear systems having the same structured matrix N_1^d must be solved. Moreover, all right-hand sides are known before the factorization. Thus the solution can be done in a single factorization process, without storing the factors.

$(N_1^d)^T$ has a block structure that is very similar to N_1^d. If an efficient solution strategy for $(N_1^d)^T$ is also developed, then it is possible to avoid solving (5.1) for all relevant z. Instead, a single system with $(N_1^d)^T$ is to be solved. In transposed form it is given by

$$(w_1^*, w_2^*, w_3, w_4) N_1^d = (0, 0, 1). \tag{5.2}$$

Combining (5.1) and (5.2) we find

$$G_z = w_1^*([Tf_x(x(t),\alpha]_z v + [f(x(t),\alpha)]_z S)_d - w_3(\mathrm{Int}_{[f(x(\cdot),\alpha)]_z} v)_d.$$

Notice that (3.13) is equivalent to the system

$$\left\{ \begin{array}{rcl} v'(t) - Tf_x(x(t),\alpha)v(t) - Sf(x(t),\alpha) + Gw_{01}(t) &=& 0, \\ v(1) - v(0) + Gw_{02} &=& 0, \\ \displaystyle\int_0^1 v^*(\tau) f(x(\tau),\alpha)\, d\tau + Gw_{03} &=& 0, \\ \displaystyle\int_0^1 v^*(\tau) v_{01}(\tau)\, d\tau + Sv_{02} &=& 1, \end{array} \right. \tag{5.3}$$

while (3.14) can be explicitly written as

$$\left\{ \begin{array}{rcr} w'(t) + Tf_x^*(x(t),\alpha)w(t) - Rf(x(t),\alpha) + Hv_{11}(t) &=& 0, \\ w(1) - w(0) + Hv_{12} &=& 0, \\ \displaystyle\int_0^1 w^*(\tau) f(x(\tau),\alpha)\, d\tau + Hv_{13} &=& 0, \\ \displaystyle\int_0^1 w^*(\tau) w_{11}(\tau)\, d\tau + Rw_{12} &=& -1. \end{array} \right. \tag{5.4}$$

Discretizations of these systems, for example by orthogonal collocation, result in linearized Newton systems having the same sparsity as the linear systems arising from

(2.5). They can therefore be solved using the same numerical linear algebra algorithms.

In practice we need to adapt the auxiliary variables (i.e., $w_{01}, w_{02}, w_{03}, v_{01}, v_{02}, v_{11}, v_{12}, v_{13}$, w_{11}, and w_{12}) along a computed branch of fold bifurcations of periodic orbits. For the bordering rows in N_1 and N_2, the natural choice is to take the kernel vectors of M_1 and M_2, respectively, at a previously computed solution point. These kernel vectors are obtained as a by-product of solving (5.3) and (5.4). For the column bordering of N_1 we need a vector that is not in the range of M_1. By Proposition 6, a possible choice is

$$\begin{pmatrix} w_{01} \\ w_{02} \\ w_{03} \end{pmatrix} = \begin{pmatrix} \Psi p_0 \\ 0 \\ 0 \end{pmatrix},$$

which by Proposition 7 can be derived from the solution of (5.4). Finally, a bordering column for N_2 is given in Proposition 8:

$$\begin{pmatrix} v_{11} \\ v_{12} \\ v_{13} \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

Therefore, problems (5.3) and (5.4) actually take the following simplified forms:

$$\begin{cases} v'(t) - Tf_x(x(t),\alpha)v(t) - Sf(x(t),\alpha) + Gw_{01}(t) &= 0, \\ v(1) - v(0) &= 0, \\ \displaystyle\int_0^1 v^*(\tau) f(x(\tau),\alpha)\, d\tau &= 0, \\ \displaystyle\int_0^1 v^*(\tau) v_{01}(\tau)\, d\tau + S &= 1 \end{cases}$$

and

$$\begin{cases} w'(t) + Tf_x^*(x(t),\alpha)w(t) - Rf(x(t),\alpha) &= 0, \\ w(1) - w(0) &= 0, \\ \displaystyle\int_0^1 w^*(\tau) f(x(\tau),\alpha)\, d\tau + H &= 0, \\ \displaystyle\int_0^1 w^*(\tau) w_{11}(\tau)\, d\tau &= -1. \end{cases}$$

5.2. Period-doubling. By Proposition 14, simple flips are determined by (2.1), (2.2), (2.3), and the condition $G = 0$, where G is given by (3.17), assuming the conditions $\langle \phi_0, \Phi q_2 \rangle \neq 0$, $\langle \psi_0, \Psi p_2 \rangle \neq 0$ hold. To solve such systems numerically, we need the derivatives of G with respect to the unknowns of the system, i.e., with respect to $x(t), \alpha, T$. These can be approximated by finite differences, using (3.17). As in the fold case, they can be obtained exactly by solving an "adjoint problem" to (3.17). In this case the adjoint problem is (3.18).

Proposition 20. *Let z denote a component of the problem parameter vector α, or let z denote the period T, on both of which the quantity G in* (3.17) *depends. Let v and w be obtained from* (3.17) *and* (3.18), *respectively. Then the derivative of G with respect to z can be written as*

$$G_z = -\int_0^1 w^*(\tau)[Tf_x(x(\tau),\alpha)]_z v(\tau)\, d\tau,$$

while the linear part of the variation of G *with respect to* $x \mapsto x + \delta x$ *is given by*

$$\delta G = -\int_0^1 w^*(\tau) T f_{xx}(x(\tau), \alpha)) v(\tau)(\delta x)(\tau)\ d\tau.$$

Proof. By differentiating (3.17) we obtain

$$M_1 \begin{pmatrix} v_z \\ G_z \end{pmatrix} = \begin{pmatrix} [Tf_x(x(t), \alpha)]_z v \\ 0 \\ 0 \end{pmatrix}. \tag{5.5}$$

Multiplying the first equation in (5.5) from the left with w^*, integrating over the interval $[0, 1]$, and using the third equation in (3.18) we get

$$\begin{aligned} &\int_0^1 w^*(\tau) v_z'(\tau)\ d\tau - \int_0^1 w^*(\tau) T f_x(x(\tau), \alpha) v_z(\tau)\ d\tau - G_z \\ &= \int_0^1 w^*(\tau)[Tf_x(x(\tau), \alpha)]_z v(\tau)\ d\tau. \end{aligned}$$

Integrating the first term in this expression by parts, and using the second equations in (3.18) and (5.5), we obtain

$$\begin{aligned} &-\int_0^1 v_z^*(\tau) w'(\tau)\ d\tau - \int_0^1 v_z^*(\tau) T f_x^*(x(\tau), \alpha) w(\tau)\ d\tau - G_z \\ &= \int_0^1 w^*(\tau)[Tf_x(x(\tau), \alpha)]_z v(\tau)\ d\tau. \end{aligned}$$

Using the first equation in (3.18) we get

$$-\int_0^1 v_z^*(\tau)(-\phi_0(\tau) H)\ d\tau - G_z = \int_0^1 w^*(\tau)[Tf_x(x(\tau), \alpha)]_z v(\tau)\ d\tau.$$

By the last equation in (5.5) the first part of the proposition follows.

The linear parts of the variations of G and v under variation of x satisfy

$$M_1 \begin{pmatrix} \delta v \\ \delta G \end{pmatrix} = \begin{pmatrix} T f_{xx}(x(t), \alpha) v\ \delta x \\ 0 \\ 0 \end{pmatrix}.$$

Similar to the derivation above, this implies the second part of the proposition. □

Notice that (3.17) is equivalent to the system

$$\left\{ \begin{array}{rcl} v'(t) - T f_x(x(t), \alpha) v(t) + G\psi_0(t) & = & 0, \\ v(0) + v(1) & = & 0, \\ \displaystyle\int_0^1 \phi_0^*(\tau) v(\tau)\ \ d\tau & = & 1, \end{array} \right. \tag{5.6}$$

while (3.18) can be explicitly written as

$$\left\{ \begin{array}{rcr} w'(t) + T f_x^*(x(t), \alpha) w(t) + H\phi_0(t) & = & 0, \\ w(0) + w(1) & = & 0, \\ \displaystyle\int_0^1 \psi_0^*(\tau) w(\tau)\ \ d\tau & = & -1. \end{array} \right. \tag{5.7}$$

Discretizations of these systems, for example by orthogonal collocation, result in linearized Newton systems having the same sparsity as the linear systems arising from (2.5). They can therefore be solved using the same numerical linear algebra algorithms.

The natural choice for starting values of ϕ_0, ψ_0 is

$$\phi_0(t) = \Phi(t)q_2, \quad \psi_0(t) = \Psi(t)p_2.$$

In a continuation context, it is necessary to regularly update ϕ_0 and ψ_0. Specifically, v obtained from (3.17) can be used to update ϕ_0, and w obtained from (3.18) can be used to update ψ_0. Indeed, after convergence to a period-doubling bifurcation, v spans the kernel of

$$\begin{pmatrix} D - Tf_x(x(t), \alpha) \\ \delta_0 + \delta_1 \end{pmatrix},$$

and, similarly, w spans the kernel of

$$\begin{pmatrix} D + Tf_x^*(x(t), \alpha) \\ \delta_0 + \delta_1 \end{pmatrix}.$$

5.3. Torus bifurcation. We have proved in Proposition 17 that the matrix equation $G = 0$ can be used to continue numerically curves of periodic solutions having Neimark–Sacker singularities, in particular, torus bifurcation points. Some issues require further attention.

First of all, we mention that the BVP for G is defined on the interval $[0, 2]$ and that 3-*point boundary conditions* are involved (at $t = 0, 1$, and 2).

To solve the system (2.1), (2.2), (2.3), (4.12) efficiently by a Newton-like method, one needs the derivatives G_{ijz}, where z is T or a component of α. From (3.24) we infer that

$$M_5 \begin{pmatrix} v_{1z} & v_{2z} \\ G_{11z} & G_{12z} \\ G_{21z} & G_{22z} \end{pmatrix} = \begin{pmatrix} [Tf_x(x(t), \alpha]_z v_1 & [Tf_x(x(t), \alpha)]_z v_2 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

One also needs the derivatives with respect to κ; for this we find

$$M_5 \begin{pmatrix} v_{1\kappa} & v_{2\kappa} \\ G_{11\kappa} & G_{12\kappa} \\ G_{21\kappa} & G_{22\kappa} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 2v_1(1) & 2v_2(1) \\ 0 & 0 \\ 0 & 0 \end{pmatrix}.$$

Numerically we solve the discretized versions of these equations, say

$$M_5^d \begin{pmatrix} v_{1z} & v_{2z} \\ G_{11z} & G_{12z} \\ G_{21z} & G_{22z} \end{pmatrix} = \begin{pmatrix} [Tf_x(x(t), \alpha]_z v_1 & [Tf_x(x(t), \alpha)]_z v_2 \\ 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{pmatrix}. \tag{5.8}$$

One also needs the derivatives with respect to κ; for this we find

$$M_5^d \begin{pmatrix} v_{1\kappa} & v_{2\kappa} \\ G_{11\kappa} & G_{12\kappa} \\ G_{21\kappa} & G_{22\kappa} \end{pmatrix} = \begin{pmatrix} 0 & 0 \\ 2v_1(1) & 2v_2(1) \\ 0 & 0 \\ 0 & 0 \end{pmatrix}, \tag{5.9}$$

where M_5^d is the discretized version of M_5, i.e., a large square matrix of the same structure as that factored efficiently in AUTO.

We again note that a large number of linear systems with the same structured matrix M_5^d has to be solved. All right-hand sides are known when the factorization is done. Thus the solution of all systems can be done during a single factorization process of M_5^d without storing the factors.

$(M_5^d)^*$ has a block structure that is very similar to that of M_5^d. If an efficient solution strategy for $(M_5^d)^*$ is also developed, then it is possible to avoid solving (5.8) for all relevant z and (5.9). Instead, a single system with $(M_5^d)^*$ is to be solved. In transposed form it is given by

$$\begin{pmatrix} w_1^{1*} & w_1^{2*} & G_{11} & G_{12} \\ w_2^{1*} & w_2^{2*} & G_{21} & G_{22} \end{pmatrix} M_5^d = \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.10}$$

Combining (5.8) and (5.10) we find

$$\begin{pmatrix} G_{11z} & G_{12z} \\ G_{21z} & G_{22z} \end{pmatrix} = \begin{pmatrix} w_1^{1*}[Tf_x(x(t),\alpha)]_z v_1 & w_1^{1*}[Tf_x(x(t),\alpha)]_z v_2 \\ w_2^{1*}[Tf_x(x(t),\alpha)]_z v_1 & w_2^{1*}[Tf_x(x(t),\alpha)]_z v_2 \end{pmatrix}$$

if z is T or one of the components of x, α. For κ we find

$$\begin{pmatrix} G_{11\kappa} & G_{12\kappa} \\ G_{21\kappa} & G_{22\kappa} \end{pmatrix} = \begin{pmatrix} 2w_1^{2*}v_1(1) & 2w_1^{2*}v_2(1) \\ 2w_2^{2*}v_1(1) & 2w_2^{2*}v_2(1) \end{pmatrix}.$$

Next notice that (3.24) is equivalent to the system

$$\left\{ \begin{array}{lcl} v_1' - Tf_x(x(t),\alpha)v_1 + G_{11}\psi_0 + G_{21}\psi_1 & = & 0, \\ v_2' - Tf_x(x(t),\alpha)v_2 + G_{12}\psi_0 + G_{22}\psi_1 & = & 0, \\ v_1(0) - 2\kappa v_1(1) + v_1(2) & = & 0, \\ v_2(0) - 2\kappa v_2(1) + v_2(2) & = & 0, \\ \displaystyle\int_0^2 \phi_0^*(\tau)v_1(\tau)\ d\tau & = & 1, \\ \displaystyle\int_0^2 \phi_1^*(\tau)v_2(\tau)\ d\tau & = & 0, \\ \displaystyle\int_0^2 \phi_0^*(\tau)v_1(\tau)\ d\tau & = & 0, \\ \displaystyle\int_0^2 \phi_1^*(\tau)v_2(\tau)\ d\tau & = & 1, \end{array} \right. \tag{5.11}$$

while (3.25) can be explicitly written as

$$(5.12)\qquad \begin{cases} w_1' + Tf_x^*(x(t),\alpha)w_1 + H_{11}\phi_0 + H_{21}\phi_1 & = \quad 0, \\ w_2' + Tf_x^*(x(t),\alpha)w_2 + H_{12}\phi_0 + H_{22}\phi_1 & = \quad 0, \\ w_1(0) - 2\kappa w_1(1) + w_1(2) & = \quad 0, \\ w_2(0) - 2\kappa w_2(1) + w_2(2) & = \quad 0, \\ \displaystyle\int_0^2 \psi_0^*(\tau)w_1(\tau) \quad d\tau & = \ -1, \\ \displaystyle\int_0^2 \psi_1^*(\tau)w_2(\tau) \quad d\tau & = \quad 0, \\ \displaystyle\int_0^2 \psi_0^*(\tau)w_1(\tau) \quad d\tau & = \quad 0, \\ \displaystyle\int_0^2 \psi_1^*(\tau)w_2(\tau) \quad d\tau & = \ -1. \end{cases}$$

Discretizations of these systems, for example by orthogonal collocation, result in linearized Newton systems having the same sparsity as the linear systems arising from (2.5). They can therefore be solved using the same numerical linear algebra algorithms.

In a continuation context, the vector-functions $\phi_0, \phi_1, \psi_0, \psi_1$ should be updated. This can be done by solving both (5.11) and (5.12). Indeed, v_1, v_2 span the two-dimensional space in which ϕ_0, ϕ_1 should be chosen and w_1, w_2 similarly span the space in which ψ_0, ψ_1 should be chosen (some orthogonalization and scaling may be appropriate).

Finally, recall that we compute the Neimark–Sacker points by using essentially an overdetermined system. This necessitates some changes in the elimination strategy when solving the linear systems.

6. Numerical example.

In this section we illustrate our new techniques on a test example, a simple feedback control system of Lur'e type:

$$(6.1)\qquad \begin{cases} \dot{x}_1 & = & x_2, \\ \dot{x}_2 & = & x_3, \\ \dot{x}_3 & = & -\alpha x_3 - \beta x_2 - x_1 + x_1^2, \end{cases}$$

where α and β are positive parameters. It is well known (see, for example [17, section 5.4]) that the equilibrium $x_1 = x_2 = x_3 = 0$ of (6.1) has a supercritical Hopf bifurcation at

$$\alpha_0 = \frac{1}{\beta},$$

generating a stable periodic solution that exists for $\alpha < \alpha_0$. This periodic solution has a supercritical period-doubling bifurcation at $\alpha_1 \approx 0.630302$.

The discretized continuation problem (2.1), (2.2), and (2.3) for the periodic solution has been programmed in the MATLAB Continuation Toolbox [19]. The method of orthogonal collocation with piecewise polynomials is used, similar to the one implemented in AUTO. It is characterized by the number `NTST` of mesh points and the number `NCOL` of collocation points. At each computed point on the solution curve, a discrete version of (5.6) is set up and solved. This gives a value of the test function G to detect a flip singularity. A constant bordering function ψ_0 is used, while the

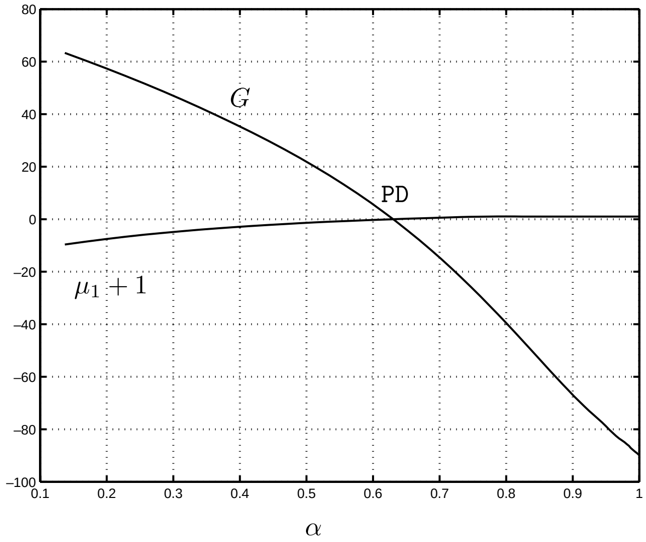

FIG. 1. *Test function $G(\alpha)$ and $\mu_1(\alpha) + 1$ for $\beta = 1$.*

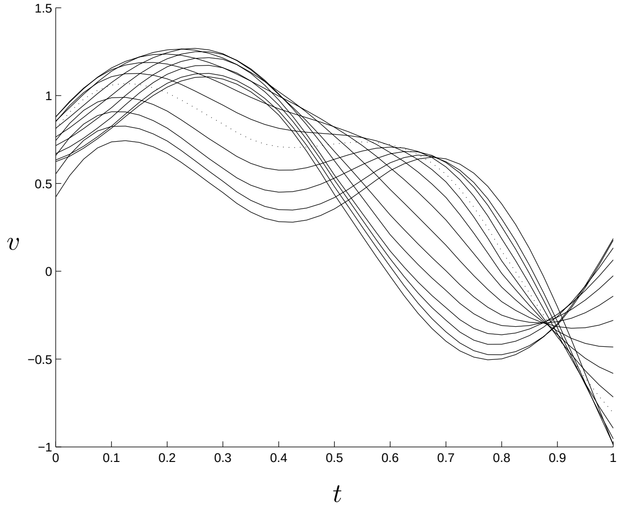

FIG. 2. *Solutions $v(t)$ at different α-values for $\beta = 1$.*

computed approximation to v is used to update the bordering function ϕ_0. Figures 1 and 2 are produced with `NTST=10` and `NCOL=4`.

Figure 1 shows the behavior of G as a function of α for $\beta = 1$. For this value of β, Hopf bifurcation occurs at $\alpha_0 = 1$. In the same figure, the function $\mu_1 + 1$ is plotted, where μ_1 is a nontrivial Floquet multiplier of the periodic solution for which $\mu_1(\alpha_1) = -1$. The multipliers are computed via a specially adapted elimination algorithm from AUTO. As can be seen, G vanishes together with $\mu_1 + 1$. Moreover, close examination of numerical data gives the above bifurcation value α_1 with seven correct decimal places.

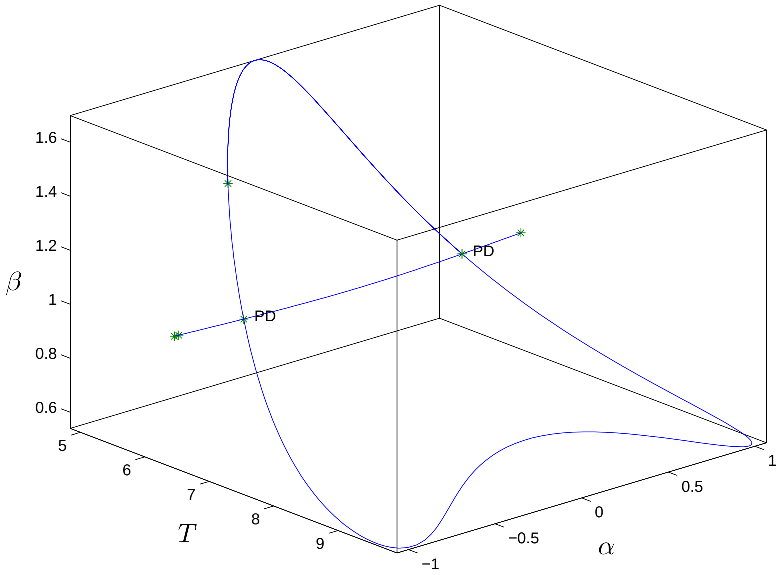

FIG. 3. *Cycle and period-doubling branches.*

Figure 2 shows a family of computed profiles $v(t)$ along the solution curve. The dashed solution corresponds to the bifurcation parameter value α_1. Finally, Figure 3 shows the two-parameter continuation of the period-doubling bifurcation curve, which corresponds to a close curve. The continuation is started at one of the PD points in the one-parameter path of periodic solutions discussed above.

We now briefly address the important issue of comparing our new method for continuing period-doubling bifurcations to the algorithm based on a fully extended system, i.e., (2.1), (2.2), and (2.3), augmented by

$$\left\{\begin{array}{rcl} v'(t) - Tf_x(x(t),\alpha)v(t) & = & 0, \\ v(0)+v(1) & = & 0, \\ \displaystyle\int_0^1 \phi_0^*(\tau)v(\tau) \;\; d\tau & = & 1, \end{array}\right.$$

as implemented in AUTO. The corresponding discretized system is nearly twice the size as the discretized minimally extended system composed of (2.1), (2.2), (2.3), and $G = 0$, where G is to be computed from (5.6). However, for the minimally extended system one has to solve the extra BVP (5.7) in order to calculate the Jacobian matrix of the discretized bordered system. For comparison, both methods were implemented in a similar fashion, using the standard sparse matrix solver in the Continuation Toolbox [19], and tested using different choices for the number of mesh points and the number of collocation points. Table 1 shows the execution times required by the two methods for computing the same number (300) of solution points along the period-doubling curve shown in Figure 3. Computations were done on a 350 Mhz PC.

Clearly the bordered system of this paper is faster, and its advantage widens as the number of mesh points and the number of collocation points increases. In the computations we used an adaptive step length, and the bordered system actually resulted in larger steps than the fully extended system. Details of the implementation and more extensive comparisons will be reported elsewhere.

Table 1

NTST	NCOL	Minimally extended system	Fully extended system
10	4	101,8 s	122,3 s

THE P_1^{mod} ELEMENT: A NEW NONCONFORMING FINITE ELEMENT FOR CONVECTION-DIFFUSION PROBLEMS*

PETR KNOBLOCH† AND LUTZ TOBISKA‡

Abstract. We consider a nonconforming streamline diffusion finite element method for solving convection-diffusion problems. The loss of the Galerkin orthogonality of the streamline diffusion method when applied to nonconforming finite element approximations results in an additional error term which cannot be estimated uniformly with respect to the perturbation parameter for the standard piecewise linear or rotated bilinear elements. Therefore, starting from the Crouzeix–Raviart element, we construct a modified nonconforming first order finite element space on shape regular triangular meshes satisfying a patch test of higher order. A rigorous error analysis of this P_1^{mod} element applied to a streamline diffusion discretization is given. The numerical tests show the robustness and the high accuracy of the new method.

Key words. convection-diffusion problems, streamline diffusion method, nonconforming finite elements, error estimates

1. Introduction.

We consider the convection-diffusion equation

$$-\varepsilon\,\Delta\,u+\boldsymbol{b}\cdot\nabla u+c\,u=f\quad\text{in }\Omega,\qquad\qquad u=u_b\quad\text{on }\partial\Omega, \tag{1.1}$$

where $\Omega\subset\mathbb{R}^2$ is a bounded domain with a polygonal boundary $\partial\Omega$, $\varepsilon\in(0,1)$ is constant, $\boldsymbol{b}\in W^{1,\infty}(\Omega)^2$, $c\in L^\infty(\Omega)$, $f\in L^2(\Omega)$, and $u_b\in H^{3/2}(\partial\Omega)$. We assume that

$$c-\frac{1}{2}\operatorname{div}\boldsymbol{b}\geq c_0\,, \tag{1.2}$$

where c_0 is a positive constant. This assumption guarantees that (1.1) admits a unique solution for all positive values of the parameter ε.

In the convection dominated case, in which $\varepsilon\ll 1$, the standard Galerkin finite element method produces unphysical oscillations if the local mesh size is not small enough. Among several possible remedies for this undesirable behavior, the streamline diffusion method [8], [15] attracted considerable attention over the last decade, in particular because of its structural simplicity, generality, and the quality of the numerical solution. Summarizing the existing literature we come to the conclusion that in the case of conforming finite element approximations the convergence properties of the streamline diffusion methods are well understood; see, e.g., [6], [10], [14], [15], [18]. Particularly, using piecewise polynomial approximations of degree k in the convection dominated regime ($\varepsilon\leq h$), one can prove the error estimate

$$|||u-u_h|||\leq C\,h^{k+1/2}\,\|u\|_{k+1,\Omega}\,, \tag{1.3}$$

where $|||\cdot|||$ denotes the streamline diffusion norm defined in section 3.

The situation changes dramatically if nonconforming finite element approximations are used. Finite element methods of nonconforming type are attractive in computational fluid dynamics since they easily fulfill the Babuška–Brezzi condition. Moreover, because of their edge-oriented degrees of freedom they result in cheap local communication when implementing the method on a MIMD-machine (cf. [5], [9], [16]). Unfortunately, compared to conforming approximations much less is known about the convergence properties of streamline diffusion-type methods for nonconforming finite element approximations.

It has been shown in [12] that special care is necessary to prove the error estimate (1.3) in the nonconforming case. Indeed, when considering nonconforming approximation spaces we lose the continuity property over inner element edges, and the coercivity of the corresponding bilinear form depends on the type of discretization for the convective term. Our assumptions guarantee that the bilinear form with the so-called skew-symmetric discretization of the convective term (cf. the bilinear form a_h^{skew} in section 3) is always coercive in contrast to the convective form (cf. the bilinear form a_h^{conv} in subsection 4.1). On the other hand, the skew-symmetric form leads to an additional term in the consistency error which is difficult to estimate uniformly in ε. In [11], [12] these difficulties have been overcome by adding some special jump terms and thus modifying the standard streamline diffusion finite element method. However, a drawback of these jump terms is that they decrease the sparsity of the stiffness matrix and that they are difficult to implement. So we would like to avoid the jump terms, but then the coercivity of the convective bilinear form is open in general. Recently, it has been discovered in [17] that this coercivity can be guaranteed for the nonconforming rotated bilinear element on rectangular meshes if $|\boldsymbol{b}|_{1,\infty,\Omega}$ is small compared to c_0. Unfortunately, a similar result is not true for the nonconforming linear triangular Crouzeix–Raviart element [4], not even on three-directional meshes. However, also in cases when the convective bilinear form is coercive, the optimal order $O(h^{k+1/2})$ cannot be shown in general. For example, in [17] a superconvergence property on uniform meshes was necessary to prove an ε-uniform convergence result of optimal order $O(h^{3/2})$. Thus, summarizing the known results we see that in general, without using jump terms and on general meshes, we cannot guarantee the same optimal convergence results as in the conforming case.

Particularly, our numerical experiences show that, in the convection dominated regime, it is often not possible to obtain an acceptable accuracy using the mentioned Crouzeix–Raviart element combined with the standard streamline diffusion discretization. In fact, this method is—even for smooth functions—not ε-uniformly convergent. Therefore, the aim of this paper is to develop a first order nonconforming method on general triangular meshes which guarantees the same optimal convergence properties as in the conforming case but does not employ any modifications (such as the above jump terms) of the standard streamline diffusion method. Let us mention that our ideas are not restricted to the first order of accuracy and that an extension to higher order methods is straightforward.

Our method is based on using the standard streamline diffusion discretization with the skew-symmetric form of the convective term and on introducing a new nonconforming finite element space. The theoretical analysis presented in this paper shows that the optimal convergence order known from the conforming finite element method can be recovered if the nonconforming space satisfies a patch test of order 3 since then a better estimate of the consistency error can be obtained. We shall construct such a space by enriching the Crouzeix–Raviart space by suitable nonconforming bubble functions and by restricting the enlarged space to its subspace of functions satisfying the patch test of order 3. The finite element space obtained in such a way contains *modified* Crouzeix–Raviart functions and therefore we call this new element the P_1^{mod} element. This new element not only guarantees the optimal convergence order but also leads to very robust discretizations and much more accurate results than the Crouzeix–Raviart element. In addition, the iterative solver used to compute the discrete solution converges much faster than for the Crouzeix–Raviart element. Let us also mention that the P_1^{mod} element satisfies a discrete Korn inequality (cf. [13]), which is not true for most first order nonconforming finite elements, including the Crouzeix–Raviart element.

The enrichment of the Crouzeix–Raviart space by bubble functions may resemble the techniques where the bubble functions are used to recover various stabilized methods and to find a reasonable rule for the choice of the stabilizing parameters (cf., e.g., [1], [2]). However, our approach is completely different since we start from a stabilized method and the bubble functions are added not to replace the stabilization but to provide an additional stability. In addition, the bubble functions are coupled with the Crouzeix–Raviart functions so that they cannot be eliminated from the discrete problem.

The paper is organized in the following way. Section 2 introduces various notation which will be used in the subsequent sections. In section 3, we recall the weak formulation of (1.1) and describe a nonconforming streamline diffusion finite element discretization. Then the error analysis is presented in section 4. Section 5 is devoted to the construction of the P_1^{mod} element. Section 6 shows that the piecewise linear part of a P_1^{mod} discrete solution asymptotically behaves in the same way as the discrete solution itself, which is useful for postprocessing. Finally, in section 7, we present numerical results which demonstrate the good behavior of discretizations employing the P_1^{mod} element.

2. Notation. We assume that we are given a family $\{\mathcal{T}_h\}$ of triangulations of the domain Ω parametrized by a positive parameter $h \to 0$. Each triangulation $\mathcal{T}_h$ consists of a finite number of closed triangular elements K such that $h_K \equiv \operatorname{diam}(K) \leq h$, $\overline{\Omega} = \bigcup_{K\in\mathcal{T}_h} K$, and any two different elements K, $\widetilde{K} \in \mathcal{T}_h$ are either disjoint or possess either a common vertex or a common edge. In order to prevent the elements from degenerating when h tends to zero, we assume that the family of triangulations is regular; i.e., there exists a constant C independent of h such that

$$\frac{h_K}{\varrho_K} \leq C \qquad \forall\ K \in \mathcal{T}_h,\ h > 0\,,$$

where ϱ_K is the maximum diameter of circles inscribed into K.

We denote by $\mathcal{E}_h$ the set of edges E of $\mathcal{T}_h$. The set of inner edges will be denoted by $\mathcal{E}_h^i$ and the set of boundary edges by $\mathcal{E}_h^b$. Further, we denote by h_E the length of the edge E and by S_E the union of the elements adjacent to E (i.e., S_E consists of one or two elements). For any edge E, we choose a fixed unit normal vector $\boldsymbol{n}_E$ to E. If $E \in \mathcal{E}_h^b$, then $\boldsymbol{n}_E$ coincides with the outer normal vector to $\partial\Omega$. Consider any $E \in \mathcal{E}_h^i$, and let K, $\widetilde{K}$ be the two elements possessing the edge E denoted in such a way that $\boldsymbol{n}_E$ points into $\widetilde{K}$. If v is a function belonging to the space

$$H^{1,h}(\Omega) = \{v \in L^2(\Omega)\,;\ v|_K \in H^1(K)\ \ \forall\ K \in \mathcal{T}_h\}\,,$$

then we define the jump of v across E by

$$[|v|]_E = (v|_K)|_E - (v|_{\widetilde{K}})|_E\,. \tag{2.1}$$

If $E \in \mathcal{E}_h^b$, then we set $[|v|]_E = v|_E$, which is the jump defined by (2.1) with v extended by zero outside Ω.

To formulate a streamline diffusion method for (1.1), we need finite element functions which are piecewise H^2. We assume this regularity with respect to subdivisions of the elements of the triangulation only, which allows more flexibility in the construction of finite element spaces approximating $H_0^1(\Omega)$ (cf. Remark 5.1). The subdivisions can be defined using a triangulation $\widehat{\mathcal{G}}$ of the standard reference element $\widehat{K}$, and we assume that the set $\widehat{\mathcal{G}}$ is invariant under affine regular mappings of $\widehat{K}$ onto $\widehat{K}$. Then, for any element $K \in \mathcal{T}_h$, we can introduce a subdivision

$$\mathcal{G}_K = \{F_K(\widehat{G})\,;\ \widehat{G} \in \widehat{\mathcal{G}}\}\,,$$

where $F_K : \widehat{K} \to K$ is any affine regular mapping which maps $\widehat{K}$ onto K. In view of the invariance of the triangulation $\widehat{\mathcal{G}}$, the set $\mathcal{G}_K$ is independent of the choice of F_K. The space of piecewise H^2 functions with respect to the above subdivision of $\mathcal{T}_h$ will be denoted by

$$H^{2,h}_{\widehat{\mathcal{G}}}(\Omega) = \left\{v \in L^2(\Omega)\,;\ v|_G \in H^2(G)\ \ \forall\, G \in \mathcal{G}_K,\, K \in \mathcal{T}_h\right\}.$$

In the following sections, we shall also need the spaces

$$\widetilde{\mathrm{V}}_h^{conf} = \{v_h \in C(\overline{\Omega})\,;\ v_h|_K \in P_1(K)\ \ \forall\, K \in \mathcal{T}_h\}\,, \qquad \mathrm{V}_h^{conf} = \widetilde{\mathrm{V}}_h^{conf} \cap H_0^1(\Omega)\,,$$
$$\mathrm{V}_h^{nc} = \left\{v_h \in L^2(\Omega)\,;\ v_h|_K \in P_1(K)\ \ \forall\, K \in \mathcal{T}_h\,,\ \ \int_E [|v_h|]_E\,\mathrm{d}\sigma = 0\ \ \forall\, E \in \mathcal{E}_h\right\},$$

and we shall denote by $i_h : H^2(\Omega) \to \widetilde{\mathrm{V}}_h^{conf}$ the Lagrange interpolation operator.

Throughout the paper we use standard notation $L^p(\Omega)$, $W^{k,p}(\Omega)$, $H^k(\Omega) = W^{k,2}(\Omega)$, $C(\overline{\Omega})$, etc. for the usual function spaces; see, e.g., [3]. The norm and seminorm in the Sobolev space $W^{k,p}(\Omega)$ will be denoted by $\|\cdot\|_{k,p,\Omega}$ and $|\cdot|_{k,p,\Omega}$, respectively, and we set $\|\cdot\|_{k,\Omega} = \|\cdot\|_{k,2,\Omega}$ and $|\cdot|_{k,\Omega} = |\cdot|_{k,2,\Omega}$. For the space $H^{1,h}(\Omega)$, we define an analogue of $|\cdot|_{1,\Omega}$ by

$$|v|_{1,h} = \left(\sum_{K\in\mathcal{T}_h} |v|^2_{1,K}\right)^{1/2}, \qquad v \in H^{1,h}(\Omega)\,.$$

The inner product in the space $L^2(G)$ will be denoted by $(\cdot,\cdot)_G$, and we set $(\cdot,\cdot) = (\cdot,\cdot)_\Omega$. Finally, we denote by C a generic constant independent of h and ε.

3. Weak formulation and discrete problem. Denoting by $\widetilde{u}_b \in H^2(\Omega)$ an extension of u_b, a natural weak formulation of the convection-diffusion equation (1.1) reads as follows:

Find $u \in H^1(\Omega)$ such that $u - \widetilde{u}_b \in H_0^1(\Omega)$ and

$$a(u,v) = (f,v) \qquad \forall\, v \in H_0^1(\Omega)\,,$$

where

$$a(u,v) = \varepsilon\,(\nabla u, \nabla v) + (\boldsymbol{b}\cdot\nabla u, v) + (c\,u, v)\,.$$

This weak formulation has a unique solution.

We intend to approximate the space $H_0^1(\Omega)$ by a nonconforming finite element space V_h and at this stage we assume only that

$$\mathrm{V}_h^{conf} \subset \mathrm{V}_h \subset H^{1,h}(\Omega) \cap H^{2,h}_{\widehat{\mathcal{G}}}(\Omega)\,. \tag{3.1}$$

The inclusion $\mathrm{V}_h^{conf} \subset \mathrm{V}_h$ ensures first order approximation properties of V_h with respect to $|\cdot|_{1,h}$ when $h \to 0$.

A finite element discretization of (1.1) could be simply obtained by using the bilinear forms

$$a_h^d(u,v) = \varepsilon \sum_{K\in\mathcal{T}_h} (\nabla u, \nabla v)_K\,, \quad a_h^c(u,v) = \sum_{K\in\mathcal{T}_h} (\boldsymbol{b}\cdot\nabla u, v)_K\,, \qquad u,v \in H^{1,h}(\Omega)\,,$$

instead of the first two terms in $a(u,v)$ and by replacing the space $H_0^1(\Omega)$ in the weak formulation by the finite element space V_h. However, the bilinear form corresponding to the discrete problem generally would not be coercive and therefore, before passing from the weak formulation to the discrete problem, we first apply integration by parts to the convective term $(\boldsymbol{b}\cdot\nabla u, v)$ to obtain

$$(\boldsymbol{b}\cdot\nabla u, v) = \frac{1}{2}\left[(\boldsymbol{b}\cdot\nabla u, v) - (\boldsymbol{b}\cdot\nabla v, u) - (\operatorname{div}\boldsymbol{b}, u\,v)\right], \qquad u \in H^1(\Omega),\ v \in H_0^1(\Omega)\,.$$

Thus, a discrete analogue of the second term in the bilinear form a also is

$$a_h^s(u,v) = \frac{1}{2}\sum_{K\in\mathcal{T}_h}\left[(\boldsymbol{b}\cdot\nabla u, v)_K - (\boldsymbol{b}\cdot\nabla v, u)_K - (\operatorname{div}\boldsymbol{b}, u\,v)_K\right], \qquad u,v \in H^{1,h}(\Omega)\,.$$

This bilinear form is skew-symmetric if $\operatorname{div}\boldsymbol{b} = 0$. That gives rise to the notation a_h^{skew} below. For $u \in H^{2,h}_{\widehat{\mathcal{G}}}(\Omega)$ and $v \in H^{1,h}(\Omega)$, we define a streamline diffusion term by

$$a_h^{sd}(u,v) = \sum_{K\in\mathcal{T}_h}\sum_{G\in\mathcal{G}_K} (-\varepsilon\,\Delta\,u + \boldsymbol{b}\cdot\nabla u + c\,u,\ \delta_K\,\boldsymbol{b}\cdot\nabla v)_G\,,$$

where $\delta_K \geq 0$ is a control parameter. Now, denoting

$$\begin{aligned} a_h^{skew}(u,v) &= a_h^d(u,v) + a_h^s(u,v) + (c\,u, v) + a_h^{sd}(u,v)\,,\\ l_h(v) &= (f,v) + \sum_{K\in\mathcal{T}_h} (f,\ \delta_K\,\boldsymbol{b}\cdot\nabla v)_K\,, \end{aligned}$$

the streamline diffusion finite element method investigated in this paper reads as follows:

Find $u_h \in H^{1,h}(\Omega)$ such that $u_h - i_h\widetilde{u}_b \in \mathrm{V}_h$ and

$$a_h^{skew}(u_h, v_h) = l_h(v_h) \qquad \forall\ v_h \in \mathrm{V}_h\,. \tag{3.2}$$

A natural norm for investigating the properties of the problem (3.2) is the streamline diffusion norm

$$|||v||| = \left(\sum_{K\in\mathcal{T}_h}\{\varepsilon\,|v|_{1,K}^2 + c_0\,\|v\|_{0,K}^2 + \delta_K\,\|\boldsymbol{b}\cdot\nabla v\|_{0,K}^2\}\right)^{1/2}.$$

Using standard arguments (cf. [3, Chapter III]), we deduce that there exist constants μ_1, μ_2 independent of h such that

$$\|\Delta\, v_h\|_{0,G} \le \mu_1\, h_K^{-1}\, |v_h|_{1,G} \qquad \forall\; v_h \in \mathrm{V}_h,\, G \in \mathcal{G}_K,\, K \in \mathcal{T}_h\,, \tag{3.3}$$

$$|v_h|_{1,K} \le \mu_2\, h_K^{-1}\, \|v_h\|_{0,K} \qquad \forall\; v_h \in \mathrm{V}_h,\, K \in \mathcal{T}_h\,. \tag{3.4}$$

Assuming that the control parameter δ_K satisfies

$$0 \le \delta_K \le \min\left\{\frac{c_0}{2\,\|c\|^2_{0,\infty,K}}, \frac{h_K^2}{2\,\varepsilon\,\mu_1^2}\right\}\,, \tag{3.5}$$

one can prove (cf. [12]) that the bilinear form a_h^{skew} is coercive, i.e.,

$$a_h^{skew}(v_h, v_h) \ge \frac{1}{2}\,|||v_h|||^2 \qquad \forall\; v_h \in \mathrm{V}_h\,. \tag{3.6}$$

This implies that the discrete problem (3.2) has a unique solution and that this solution does not depend on the choice of the extension $\widetilde{u}_b$ of u_b (cf. also Remark 5.2).

REMARK 3.1. *We admit $\delta_K = 0$ in (3.5) since the streamline diffusion stabilization is important in convection dominated regions only.*

4. Error analysis. If the weak solution of (1.1) satisfies $u \in H^2(\Omega)$, then it fulfills (1.1) almost everywhere in Ω. Multiplying (1.1) by $v_h \in \mathrm{V}_h$ and integrating by parts, we infer that

$$a_h^{skew}(u, v_h) = l_h(v_h) + r_h^d(u, v_h) + r_h^s(u, v_h) \qquad \forall\; v_h \in \mathrm{V}_h\,, \tag{4.1}$$

where the consistency errors r_h^d and r_h^s are given by

$$r_h^d(u, v_h) = \varepsilon \sum_{K \in \mathcal{T}_h} \int_{\partial K} \frac{\partial u}{\partial \boldsymbol{n}_{\partial K}}\, v_h \,\mathrm{d}\sigma = \varepsilon \sum_{E \in \mathcal{E}_h} \int_E \frac{\partial u}{\partial \boldsymbol{n}_E}\, [|v_h|]_E \,\mathrm{d}\sigma\,,$$

$$r_h^s(u, v_h) = -\frac{1}{2} \sum_{K \in \mathcal{T}_h} \int_{\partial K} (\boldsymbol{b} \cdot \boldsymbol{n}_{\partial K})\, u\, v_h \,\mathrm{d}\sigma = -\frac{1}{2} \sum_{E \in \mathcal{E}_h} \int_E (\boldsymbol{b} \cdot \boldsymbol{n}_E)\, u\, [|v_h|]_E \,\mathrm{d}\sigma$$

with $\boldsymbol{n}_{\partial K}$ denoting the unit outer normal vector to the boundary of K. For estimating the consistency errors, we shall use the following lemma.

LEMMA 4.1. *For any edge $E \in \mathcal{E}_h$ and any integer $k \ge 0$, let $\mathcal{M}_E^k$ be the projection operator from $L^2(E)$ onto $P_k(E)$ defined by*

$$\int_E q\, \mathcal{M}_E^k\, v \,\mathrm{d}\sigma = \int_E q\, v \,\mathrm{d}\sigma \qquad \forall\; q \in P_k(E),\, v \in L^2(E)\,.$$

Then there exists a constant C independent of E and h such that

$$\left|\int_E \varphi\, (v - \mathcal{M}_E^k\, v) \,\mathrm{d}\sigma\right| \le C\, h_E^{k+1}\, |\varphi|_{1,K}\, |v|_{k+1,K} \tag{4.2}$$

for all $K \in \mathcal{T}_h$, $E \subset \partial K$, $\varphi \in H^1(K)$, and $v \in H^{k+1}(K)$.

Proof. See [4, Lemma 3]. □

Now we are in a position to prove a convergence result for the discrete problem (3.2).

Theorem 4.2. *Let the assumptions* (3.1) *and* (3.5) *be fulfilled, and let the space* V_h *satisfy the patch test of order* $k+1$*, i.e.,*

$$\int_E [|v_h|]_E\, q\, \mathrm{d}\sigma = 0 \qquad \forall\ v_h \in \mathrm{V}_h,\ q \in P_k(E),\ E \in \mathcal{E}_h\,, \tag{4.3}$$

where $k \geq 0$ *is a given integer. Let the weak solution of* (1.1) *belong to* $H^m(\Omega)$*, let* $m = \max\{2, k+1\}$*, and let* $\boldsymbol{b} \in W^{k+1,\infty}(\Omega)^2$*. Then the discrete solution* u_h *satisfies*

$$|||u-u_h||| \leq C\,h \left(\sum_{K\in\mathcal{T}_h} \gamma_K\, |u|^2_{2,K}\right)^{1/2} + C\,h^k \left(\sum_{E\in\mathcal{E}_h} \gamma_E\, \|u\|^2_{m,S_E}\right)^{1/2}, \tag{4.4}$$

where

$$\gamma_K = \varepsilon + h_K^2 + \delta_K + (\max\{\varepsilon,\delta_K\})^{-1}\, h_K^2\,, \qquad \gamma_E = \min\left\{\frac{h_E^2}{\varepsilon}, 1\right\}.$$

Proof. Denoting $w = i_h u - u$ and $w_h = i_h u - u_h$, we have $w_h \in \mathrm{V}_h$ and it follows from (3.2) and (4.1) that

$$a_h^{skew}(w_h, v_h) = a_h^{skew}(w, v_h) + r_h^d(u, v_h) + r_h^s(u, v_h) \qquad \forall\ v_h \in \mathrm{V}_h\,. \tag{4.5}$$

Integrating by parts, we obtain for any $v_h \in \mathrm{V}_h$

$$a_h^s(w, v_h) = -a_h^c(v_h, w) - (\operatorname{div}\boldsymbol{b}, w\,v_h) + n_h^s(w, v_h)\,,$$

where

$$n_h^s(w, v_h) = \frac{1}{2} \sum_{E\in\mathcal{E}_h} \int_E (\boldsymbol{b}\cdot\boldsymbol{n}_E)\, w\, [|v_h|]_E\, \mathrm{d}\sigma\,.$$

Hence denoting

$$a_h(w, v_h) = a_h^d(w, v_h) - a_h^c(v_h, w) + (c - \operatorname{div}\boldsymbol{b}, w\,v_h) + a_h^{sd}(w, v_h)\,,$$

we have

$$a_h^{skew}(w, v_h) = a_h(w, v_h) + n_h^s(w, v_h)\,. \tag{4.6}$$

Combining (4.5), (4.6), (3.6), and the triangular inequality, we infer that

$$\begin{aligned}\frac{1}{2}\,|||u-u_h||| \leq \frac{1}{2}\,|||w||| &+ \sup_{v_h\in\mathrm{V}_h} \frac{a_h(w, v_h)}{|||v_h|||} \\ &+ \sup_{v_h\in\mathrm{V}_h} \frac{n_h^s(w, v_h)}{|||v_h|||} + \sup_{v_h\in\mathrm{V}_h} \frac{r_h^d(u, v_h)}{|||v_h|||} + \sup_{v_h\in\mathrm{V}_h} \frac{r_h^s(u, v_h)}{|||v_h|||}\,.\end{aligned}$$

The first two terms on the right-hand side are well known from the conforming analysis of the problem (3.2) (cf., e.g., [15]) and can be estimated by

$$\frac{1}{2}\,|||w||| + \sup_{v_h\in\mathrm{V}_h} \frac{a_h(w, v_h)}{|||v_h|||} \leq C\,h \left(\sum_{K\in\mathcal{T}_h} \gamma_K\, |u|^2_{2,K}\right)^{1/2}. \tag{4.7}$$

The remaining three terms are purely nonconforming terms. The estimation of $r_h^d(u,v_h)$ is the easiest one: In view of (4.3), we have for any $E \in \mathcal{E}_h$

$$\int_E \frac{\partial u}{\partial \boldsymbol{n}_E}\,[|v_h|]_E\,\mathrm{d}\sigma = \int_E \left(\frac{\partial u}{\partial \boldsymbol{n}_E} - \mathcal{M}_E^0\,\frac{\partial u}{\partial \boldsymbol{n}_E}\right)[|v_h|]_E\,\mathrm{d}\sigma,$$

and hence, applying (4.2), we deduce that

$$r_h^d(u,v_h) \le C\,h\,\varepsilon^{1/2}\,|u|_{2,\Omega}\,|||v_h|||\,.$$

To estimate $r_h^s(u,v_h)$, we apply (4.3) and Lemma 4.1, and we obtain

$$\begin{aligned}\int_E (\boldsymbol{b}\cdot\boldsymbol{n}_E)\,u\,[|v_h|]_E\,\mathrm{d}\sigma &= \int_E [(\boldsymbol{b}\cdot\boldsymbol{n}_E)\,u - \mathcal{M}_E^k((\boldsymbol{b}\cdot\boldsymbol{n}_E)\,u)]\,[|v_h|]_E\,\mathrm{d}\sigma\\ &\le C\,h_E^{k+1}\,\|u\|_{k+1,S_E}\,|v_h|_{1,S_E}\,,\end{aligned}$$

where the norms over S_E are considered to be defined elementwise. Using (3.4), we derive

$$\int_E (\boldsymbol{b}\cdot\boldsymbol{n}_E)\,u\,[|v_h|]_E\,\mathrm{d}\sigma \le C\,h_E^k\,\|u\|_{k+1,S_E}\,\gamma_E^{1/2}\,(\varepsilon\,|v_h|_{1,S_E}^2 + c_0\,\|v_h\|_{0,S_E}^2)^{1/2}\,,$$

which implies that

$$r_h^s(u,v_h) \le C\,h^k\left(\sum_{E\in\mathcal{E}_h}\gamma_E\,\|u\|_{k+1,S_E}^2\right)^{1/2}|||v_h|||\,.$$

The term $n_h^s(w,v_h)$ can be estimated analogously. The only difference is that we also use the estimate $\|w\|_{k+1,S_E} \le C\,h_E\,|u|_{2,S_E} + \min\{1,k\}\,\|u\|_{k+1,S_E}$. So, we get

$$n_h^s(w,v_h) \le C\,h^{\max\{1,k\}}\left(\sum_{E\in\mathcal{E}_h}\gamma_E\,\|u\|_{m,S_E}^2\right)^{1/2}|||v_h|||\,. \tag{4.8}$$

As we see, for $k=0$, the consistency error $r_h^s(u,v_h)$ behaves worse than the term $n_h^s(w,v_h)$ and does not allow any ε-uniform convergence. Summing up all the estimates, we obtain the theorem. □

REMARK 4.1. *The above estimate together with the condition* (3.5) *suggests setting*

$$\delta_K = \begin{cases}\kappa_K\,h_K & \textit{if } h_K > \varepsilon,\\ 0 & \textit{if } h_K \le \varepsilon,\end{cases}$$

where κ_K is bounded independently of h and satisfies

$$0 < \kappa_0 \le \kappa_K \le \min\left\{\frac{c_0}{2\,\|c\|_{0,\infty,K}^2\,h_K},\frac{h_K}{2\,\varepsilon\,\mu_1^2}\right\}\,.$$

Then $(\max\{\varepsilon,\delta_K\})^{-1}\,h_K^2 \le (\min\{1,\kappa_0\})^{-1}\,h_K$*, and hence* $\gamma_K \le C\,(\varepsilon + h_K)$*.*

Let us consider the convection dominated case $\varepsilon \leq h$, and let δ_K be defined as in Remark 4.1, which implies that $\gamma_K \leq C\,h$. Since the sum over edges in (4.4) stems from the nonconformity only, we obtain for $\mathrm{V}_h = \mathrm{V}_h^{conf}$ the well-known estimate

$$|||u - u_h||| \leq C\,h^{3/2}\,|u|_{2,\Omega}\,,$$

where the constant C is independent of u, h, and ε. Therefore, the estimate is called ε-uniform. It is known that this estimate is optimal on general meshes.

For a general nonconforming space V_h satisfying the assumptions of Theorem 4.2, the estimate (4.4) leads to the ε-uniform estimate

$$|||u - u_h||| \leq C\,h^{3/2}\,|u|_{2,\Omega} + C\,h^k\|u\|_{\max\{2,k+1\},\Omega}\,. \tag{4.9}$$

Thus, if we use the space $\mathrm{V}_h = \mathrm{V}_h^{nc}$, which satisfies (4.3) for $k = 0$ only, the ε-uniform convergence order is 0. Numerical experiments really confirm this pessimistic prediction (see section 7), which suggests that it is generally a property of the method and not a consequence of an inaccurate estimation. On the other hand, the estimate (4.9) shows that the optimal ε-uniform convergence order 3/2 can be recovered if the space V_h satisfies the patch test of order 3, i.e., $k = 2$. This is an unusual requirement for a nonconforming first order finite element space, but we shall show in section 5 that such spaces can easily be constructed.

4.1. Remarks on the convective discretization. In numerical computations, one also often considers the discrete problem (3.2) with a_h^{skew} replaced by the convective bilinear form a_h^{conv} defined by

$$a_h^{conv}(u,v) = a_h^d(u,v) + a_h^c(u,v) + (c\,u,v) + a_h^{sd}(u,v)\,. \tag{4.10}$$

Note that a result similar to (3.6) does not hold for this bilinear form. Indeed,

$$a_h^{conv}(v_h,v_h) \geq \frac{1}{2}\,|||v_h|||^2 + \frac{1}{2}\sum_{E\in\mathcal{E}_h}\int_E (\boldsymbol{b}\cdot\boldsymbol{n}_E)\,[|v_h^2|]_E\,\mathrm{d}\sigma \qquad \forall\ v_h \in \mathrm{V}_h\,,$$

where the additional term is of order $O(\|v_h\|_{0,\Omega}^2/h)$ in general (cf. [17]). Of course, the coercivity is not necessary to prove the unique solvability and to establish error estimates. It would be sufficient if an inf-sup condition were satisfied, precisely, if the constants

$$\alpha_h = \inf_{w_h\in V_h^{nc}}\ \sup_{v_h\in V_h^{nc}} \frac{a_h^{conv}(w_h,v_h)}{|||v_h|||\ |||w_h|||} \tag{4.11}$$

could be bounded from below by some positive constant independent of h or at least with a known dependence on h. Unfortunately, this is an open problem.

Let us consider the discrete problem (3.2) with a_h^{skew} replaced by a_h^{conv}. We again set $w = i_h u - u$ and $w_h = i_h u - u_h$. To estimate the error $u - u_h = w_h - w$ it suffices to investigate w_h since w can be estimated by (4.7). Since there is no consistency error induced by the convective term, we obtain

$$\alpha_h\,|||w_h||| \leq \sup_{v_h\in\mathrm{V}_h}\frac{a_h(w,v_h)}{|||v_h|||} + 2\sup_{v_h\in\mathrm{V}_h}\frac{n_h^s(w,v_h)}{|||v_h|||} + \sup_{v_h\in\mathrm{V}_h}\frac{r_h^d(u,v_h)}{|||v_h|||}\,.$$

Hence $\alpha_h\,|||w_h|||$ can be estimated by the right-hand side of (4.4). However, for $k = 0$, we can apply (4.8) and hence, for δ_K defined as in Remark 4.1, we always get at least

$$|||u - i_h u||| + \alpha_h\,|||i_h u - u_h||| \leq C\,h\,|u|_{2,\Omega}\,.$$

Moreover, for $\mathrm{V}_h = \mathrm{V}_h^{nc}$ and $u \in H^3(\Omega)$, we have the estimate

$$\int_E (\boldsymbol{b} \cdot \boldsymbol{n}_E)\, w\, [|v_h|]_E \,\mathrm{d}\sigma \le C\, h_E^3\, \|u\|_{3,S_E}\, |v_h|_{1,S_E} \tag{4.12}$$

so that in the convection dominated case $\varepsilon \le h$ we even obtain

$$|||u - i_h u||| + \alpha_h\, |||i_h u - u_h||| \le C\, h^{3/2}\, \|u\|_{3,\Omega}\,.$$

Let us mention how to prove (4.12). We denote by j_h the piecewise quadratic Lagrange interpolation operator and, for any edge $E \in \mathcal{E}_h$, we set $\boldsymbol{b}_E = \mathcal{M}_E^0\, \boldsymbol{b}$. Then we have for any $E \in \mathcal{E}_h$

$$\begin{aligned}\int_E (\boldsymbol{b} \cdot \boldsymbol{n}_E)\, w\, [|v_h|]_E \,\mathrm{d}\sigma &= \int_E ((\boldsymbol{b} - \boldsymbol{b}_E) \cdot \boldsymbol{n}_E)\, w\, [|v_h|]_E \,\mathrm{d}\sigma \\ &+ \int_E (\boldsymbol{b}_E \cdot \boldsymbol{n}_E)\, (j_h u - u)\, [|v_h|]_E \,\mathrm{d}\sigma + \int_E (\boldsymbol{b}_E \cdot \boldsymbol{n}_E)\, (i_h u - j_h u)\, [|v_h|]_E \,\mathrm{d}\sigma\,.\end{aligned} \tag{4.13}$$

The last term on the right-hand side vanishes since $i_h u - j_h u$ is even on E and $[|v_h|]_E$ is odd on E. Using Lemma 4.1, we derive for any $z \in H^1(\Omega)$

$$\int_E z\, [|v_h|]_E \,\mathrm{d}\sigma = \int_E (z - \mathcal{M}_E^0\, z)\, [|v_h|]_E \,\mathrm{d}\sigma \le C\, h_E\, |z|_{1,S_E}\, |v_h|_{1,S_E}\,.$$

This implies that the first two terms on the right-hand side of (4.13) can be estimated by $C\, h_E^3\, (|u|_{2,S_E} + |u|_{3,S_E})\, |v_h|_{1,S_E}$, which proves (4.12).

The above considerations suggest that, in some cases, the bilinear form a_h^{conv} may lead to better results than a_h^{skew}, particularly in the case that $\alpha_h \ge \alpha_0 > 0$ could be verified.

5. Definition of the P_1^{mod} element.

We have seen above that it is desirable to construct nonconforming first order finite element spaces satisfying the patch test of a higher order than usual. In this section, we present a possible way of constructing such spaces. The idea is to enrich the space V_h^{nc} by suitable supplementary functions and then to restrict the enlarged space to its subspace of functions satisfying the patch test of a given order. Our basic requirement is that this procedure must not destroy the edge-oriented structure of the space V_h^{nc}. This construction will lead to a new finite element space containing as a subspace modified functions from V_h^{nc}. Therefore, we denote the new space V_h^{mod}, and we call the corresponding finite element the P_1^{mod} element.

We introduce the P_1^{mod} element by describing the respective shape functions on the standard reference triangle $\widehat{K}$. It turns out that independently of the required order of the patch test it suffices to enrich the space $P_1(\widehat{K})$ corresponding to V_h^{nc} by three functions $\widehat{b}_1$, $\widehat{b}_2$, and $\widehat{b}_3$ associated, respectively, with the edges $\widehat{E}_1$, $\widehat{E}_2$, and $\widehat{E}_3$ of the element $\widehat{K}$. This gives the space

$$P_1^{mod}(\widehat{K}) = P_1(\widehat{K}) \oplus \mathrm{span}\{\widehat{b}_1, \widehat{b}_2, \widehat{b}_3\}\,.$$

We assume for $i \in \{1, 2, 3\}$ that

$$\widehat{b}_i \in H^1(\widehat{K})\,, \qquad \widehat{b}_i|_{\partial\widehat{K}\setminus\widehat{E}_i} = 0\,, \tag{5.1}$$

$$\widehat{b}_i|_{\widehat{E}_i} \text{ is odd with respect to the midpoint of } \widehat{E}_i, \tag{5.2}$$

$$\int_{\widehat{E}_i} [(1 - 2\,\widehat{\lambda}_{i+1}) + \widehat{b}_i]\, \widehat{q} \,\mathrm{d}\widehat{\sigma} = 0 \qquad \forall\, \widehat{q} \in P_1(\widehat{E}_i)\,, \tag{5.3}$$

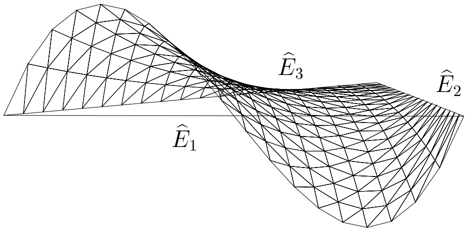

FIG. 5.1. *Function* $\widehat{\lambda}_2^2\,\widehat{\lambda}_3 - \widehat{\lambda}_2\,\widehat{\lambda}_3^2$.

where $\widehat{\lambda}_i$ is the barycentric coordinate on $\widehat{K}$ with respect to the vertex of $\widehat{K}$ opposite the edge $\widehat{E}_i$. (We set $\widehat{\lambda}_4 \equiv \widehat{\lambda}_1$.) In addition, because of the streamline diffusion method, we suppose that on the triangulation $\widehat{\mathcal{G}}$ of $\widehat{K}$

$$\widehat{b}_i|_{\widehat{G}} \in H^2(\widehat{G}) \qquad \forall\, \widehat{G} \in \widehat{\mathcal{G}}\,. \tag{5.4}$$

Note that to verify (5.3), it suffices to prove its validity for $\widehat{q} = \widehat{\lambda}_{i+1}|_{\widehat{E}_i}$. A simple example of $\widehat{b}_i$ satisfying the assumptions (5.1)–(5.4) is the function (cf. Figure 5.1)

$$\widehat{b}_i = 10\,(\widehat{\lambda}_{i+1}^2\,\widehat{\lambda}_{i+2} - \widehat{\lambda}_{i+1}\,\widehat{\lambda}_{i+2}^2)\,, \tag{5.5}$$

where the indices are to be considered modulo 3.

For any element $K \in \mathcal{T}_h$, we introduce a regular affine mapping $F_K : \widehat{K} \to K$ such that $F_K(\widehat{K}) = K$ and, using this mapping, we transform the shape functions from $\widehat{K}$ onto K. In this way, we obtain the spaces

$$P_1^{mod}(K) = P_1(K) \oplus \operatorname{span}\{b_{K,E}|_K\}_{E\in\mathcal{E}_h,\, E\subset\partial K}\,,$$

where

$$b_{K,E} = \begin{cases} \widehat{b}_i \circ F_K^{-1} & \text{in } K, \\ 0 & \text{in } \Omega \setminus K \end{cases}$$

for $E = F_K(\widehat{E}_i)$, $i = 1, 2, 3$. For each element K, we introduce six local nodal functionals

$$I_{K,E}(v) = \frac{1}{h_E}\int_E v\,\mathrm{d}\sigma\,, \quad J_{K,E}(v) = \frac{3}{h_E}\int_E v\,(2\,\lambda_E - 1)\,\mathrm{d}\sigma\,, \quad E \in \mathcal{E}_h,\, E \subset \partial K\,,$$

where $\lambda_E \in P_1(E)$ equals 1 at one endpoint of E and 0 at the other endpoint of E. It is easy to verify that these functionals are unisolvent with the space $P_1^{mod}(K)$. Of course, we could also use other local nodal functionals. However, we prefer the above functionals since they lead to dual basis functions having nice properties.

Now, the finite element space V_h^{mod} approximating the space $H_0^1(\Omega)$ is defined in a standard way: It consists of all functions which belong to the space $P_1^{mod}(K)$ on any element $K \in \mathcal{T}_h$, which are continuous on all inner edges in the sense of the equality of nodal functionals and for which all nodal functionals associated with boundary edges vanish. This means that

$$\mathrm{V}_h^{mod} = \Bigg\{ v_h \in L^2(\Omega)\,;\; v_h|_K \in P_1^{mod}(K) \;\; \forall\, K \in \mathcal{T}_h\,, \qquad \int_E [|v_h|]_E\, q\,\mathrm{d}\sigma = 0 \;\; \forall\, q \in P_1(E),\, E \in \mathcal{E}_h \Bigg\}\,.$$

For any inner edge $E \in \mathcal{E}_h^i$, we define global nodal functionals

$$I_E(v) = I_{K,E}(v)\,, \qquad\qquad J_E(v) = J_{K,E}(v)\,,$$

where K is any element adjacent to E. (Note that, for $v \in \mathrm{V}_h^{mod}$, the choice of K has no influence on the values of $I_{K,E}(v)$ and $J_{K,E}(v)$.) We denote by $\{\psi_E, \chi_E\}_{E\in\mathcal{E}_h^i}$ a basis of V_h^{mod} which is dual to the functionals I_E, J_E; i.e., for any $E, E' \in \mathcal{E}_h^i$, we have

$$I_E(\psi_{E'}) = \delta_{E,E'}\,, \qquad J_E(\psi_{E'}) = 0\,, \qquad I_E(\chi_{E'}) = 0\,, \qquad J_E(\chi_{E'}) = \delta_{E,E'}\,,$$

where $\delta_{E,E'} = 1$ for $E = E'$ and $\delta_{E,E'} = 0$ for $E \neq E'$. To establish formulas for ψ_E and χ_E, we denote by K, $\widetilde{K}$ the two elements adjacent to E; by E, E_1, E_2 the edges of K; by E, E_3, E_4 the edges of $\widetilde{K}$; and by ζ_E the standard basis function of V_h^{nc} associated with the edge E (i.e., ζ_E is piecewise linear, equals 1 on E, and vanishes at the midpoints of all edges different from E). Then

$$\psi_E = \zeta_E + \beta_{E,1}\, b_{K,E_1} + \beta_{E,2}\, b_{K,E_2} + \beta_{E,3}\, b_{\widetilde{K},E_3} + \beta_{E,4}\, b_{\widetilde{K},E_4}\,, \tag{5.6}$$

$$\chi_E = \beta_{E,5}\, b_{K,E} + \beta_{E,6}\, b_{\widetilde{K},E}\,, \tag{5.7}$$

where the coefficients $\beta_{E,1}, \dots, \beta_{E,6}$ are uniquely determined and equal 1 or -1. If the functions $\widehat{b}_1, \widehat{b}_2, \widehat{b}_3$ are chosen in a suitable way (e.g., $\widehat{b}_i = \widehat{b}_1 \circ \widehat{F}_i$, where $\widehat{F}_i$ is an affine transformation of $\widehat{K}$ onto $\widehat{K}$), then $\chi_E \in H_0^1(\Omega)$, and hence the functions χ_E generate a conforming subspace of V_h^{mod}. (This is also the case for the functions χ_E presented in subsection 5.2 below.) The functions ψ_E are always purely nonconforming functions since they have jumps across the edges $E_1, \dots, E_4$, and they can be viewed as modified basis functions of V_h^{nc}. In addition, from (5.6) and (5.7), it follows that, for any $v_h \in \mathrm{V}_h^{mod}$ and any $E \in \mathcal{E}_h$, the jump $[|v_h|]_E$ is odd with respect to the midpoint of E. Therefore,

$$\int_E [|v_h|]_E\, q\, \mathrm{d}\sigma = 0 \tag{5.8}$$

for any even function $q \in L^1(E)$. Particularly, (5.8) holds for any $q \in P_2(E)$ vanishing at the endpoints of E. This together with the definition of V_h^{mod} implies that (5.8) holds for any $q \in P_2(E)$; i.e., the space V_h^{mod} satisfies the patch test of order 3. Moreover, if (5.3) holds for any $\widehat{q} \in P_k(\widehat{E}_i)$ with some $k > 1$, then it is easy to show that the basis functions ψ_E and χ_E satisfy the patch test of order $k+1$. Consequently, the whole space V_h^{mod} then satisfies the patch test of order at least $k+1$.

Let us mention that, denoting

$$\mathrm{B}_h = \operatorname{span}\{b_{K,E}\}_{K\in\mathcal{T}_h,\, E\in\mathcal{E}_h,\, E\subset\partial K}\,, \tag{5.9}$$

the space V_h^{mod} can also be written as

$$\mathrm{V}_h^{mod} = \left\{ v_h \in \mathrm{V}_h^{nc} \oplus \mathrm{B}_h\,;\; \int_E [|v_h|]_E\, q\, \mathrm{d}\sigma = 0 \;\; \forall\, q \in P_2(E),\, E \in \mathcal{E}_h \right\}.$$

Therefore, the space V_h^{mod} can be regarded as the space V_h^{nc} enriched by the nonconforming bubble functions $b_{K,E}$ and then restricted to the subspace of functions satisfying the patch test of order 3.

5.1. Properties of the modified method. As we required at the beginning, the space V_h^{mod} is an edge-oriented nonconforming finite element space possessing first order approximation properties with respect to $|\cdot|_{1,h}$. The supports of the basis functions ψ_E, χ_E are contained in the supports of the basis functions ζ_E of V_h^{nc}, and hence the space V_h^{mod} can be implemented using the same data structures as the space V_h^{nc}. In addition, owing to (5.4), the space V_h^{mod} consists of piecewise continuous functions which are continuous in the midpoints of inner edges and vanish in the midpoints of boundary edges. This is a further feature common with the space V_h^{nc}.

However, as we have shown above, there is an immense difference in the behavior of the solutions to the discrete problem (3.2) for these two spaces: Whereas no ε-uniform convergence can be shown for the space V_h^{nc}, the space V_h^{mod} guarantees the ε-uniform estimate (cf. (4.9))

$$|||u - u_h||| \le C\, h^{\min\{l,3/2\}}\, \|u\|_{l+1,\Omega}\,, \qquad l = 1, 2\,. \tag{5.10}$$

Thus, for $u \in H^3(\Omega)$, we get the optimal ε-uniform convergence order 3/2. Moreover, numerical tests indicate that discretizations using the space V_h^{mod} are much more accurate than those ones using the space V_h^{nc} (cf. section 7).

The price we pay for the ε-uniform estimate (5.10) is that $\dim \mathrm{V}_h^{mod} = 2 \dim \mathrm{V}_h^{nc}$ and that, consequently, the stiffness matrix corresponding to V_h^{mod} is generally four times larger than the one corresponding to V_h^{nc}. However, this does not mean that using the space V_h^{mod} is more expensive than using the space V_h^{nc} since typically a prescribed accuracy can be attained with the space V_h^{mod} on much coarser meshes than with the space V_h^{nc}.

The number of nonzero entries of the stiffness matrix corresponding to the space V_h^{mod} can be reduced to about 80 % by using functions $\widehat{b}_1, \widehat{b}_2, \widehat{b}_3$ with disjoint interiors of their supports (cf. Remark 5.1 below). In this case, the functions χ_E can be easily eliminated from the discrete problem by static condensation. That halves the number of unknowns and reduces the number of nonzero entries to about 65 %.

The dimension of the space V_h^{mod} is asymptotically the same as for the nonconforming piecewise quadratic element [7]. Since this element has second order approximation properties with respect to $|\cdot|_{1,h}$ one would expect a faster convergence than for the P_1^{mod} element. However, the element of [7] satisfies the patch test of order 2 only, and hence the corresponding consistency error tends to zero with the ε-uniform convergence order 1 (cf. the second term in (4.4)). Consequently, the ε-uniform convergence order of the discrete solution is at most 1 in the convection dominated case, whereas we have 3/2 for the P_1^{mod} element. Note also that the P_1^{mod} element is more suitable for a parallel implementation than the element of [7].

Remark 5.1. *Functions $\widehat{b}_1, \widehat{b}_2, \widehat{b}_3$ with disjoint interiors of their supports mentioned above can be obtained in the following way. We divide the reference triangle $\widehat{K}$ into three subtriangles by connecting the barycenter of $\widehat{K}$ with the vertices of $\widehat{K}$ and denote by $\widehat{K}_i$ the subtriangle adjacent to the edge $\widehat{E}_i$, $i = 1, 2, 3$. Then we require that $\widehat{b}_i$ vanishes outside the subtriangle $\widehat{K}_i$. On $\widehat{K}_i$, the function $\widehat{b}_i$ can be defined, e.g., by* (5.5)*, where $\widehat{\lambda}_{i+1}$ and $\widehat{\lambda}_{i+2}$ are now considered as barycentric coordinates on $\widehat{K}_i$ with respect to the endpoints of $\widehat{E}_i$. If we set $\widehat{\mathcal{G}} = \{\widehat{K}_1, \widehat{K}_2, \widehat{K}_3\}$, then all the assumptions on $\widehat{b}_i$ made above are satisfied. Note that generally $\widehat{b}_i \notin H^2(\widehat{K})$ so that the assumption that finite element functions are piecewise H^2 only with respect to a subdivision of $\mathcal{T}_h$ really has a practical importance.*

Remark 5.2. *In the discrete problem* (3.2)*, inhomogenous Dirichlet boundary conditions are represented by the condition $u_h - i_h\widetilde{u}_b \in \mathrm{V}_h$. This is equivalent to*

$u_h - \widetilde{u}_{bh} \in \mathrm{V}_h$, where $\widetilde{u}_{bh} \in H^{1,h}(\Omega)$ is any function satisfying $\widetilde{u}_{bh} - i_h\widetilde{u}_b \in \mathrm{V}_h$. Now let us consider the P_1^{mod} element. If we extend the definitions of the global nodal functionals I_E, J_E and the basis functions ψ_E, χ_E to boundary edges, then

$$i_h\widetilde{u}_b = \sum_{E\in\mathcal{E}_h} I_E(i_h\widetilde{u}_b)\,\psi_E + J_E(i_h\widetilde{u}_b)\,\chi_E\,.$$

Thus, the inhomogenous Dirichlet boundary conditions can be implemented by setting

$$\widetilde{u}_{bh} = \sum_{E\in\mathcal{E}_h^b} I_E(i_h\widetilde{u}_b)\,\psi_E + J_E(i_h\widetilde{u}_b)\,\chi_E\,.$$

It is easy to see that then $\widetilde{u}_{bh}$ does not depend on the choice of the extension $\widetilde{u}_b$ of u_b.

5.2. Simple representation of the basis functions $\boldsymbol{\psi_E}$ and $\boldsymbol{\chi_E}$. Let us close this section by returning to the example of $\widehat{b}_i$ given in (5.5) and rewriting the formulas (5.6), (5.7) for this particular case. We denote by K and $\widetilde{K}$ the two elements adjacent to an edge $E \in \mathcal{E}_h^i$ and by λ_1, λ_2 and $\widetilde{\lambda}_1$, $\widetilde{\lambda}_2$ the barycentric coordinates on K and $\widetilde{K}$ with respect to the endpoints of E. Further, we respectively denote by λ_3 and $\widetilde{\lambda}_3$ the remaining barycentric coordinates on K and $\widetilde{K}$. Then

$$\psi_E = \begin{cases} 1 - 2\,\lambda_3 - 10\,(\lambda_1^2\,\lambda_3 - \lambda_1\,\lambda_3^2) - 10\,(\lambda_2^2\,\lambda_3 - \lambda_2\,\lambda_3^2) & \text{in } K,\\ 1 - 2\,\widetilde{\lambda}_3 - 10\,(\widetilde{\lambda}_1^2\,\widetilde{\lambda}_3 - \widetilde{\lambda}_1\,\widetilde{\lambda}_3^2) - 10\,(\widetilde{\lambda}_2^2\,\widetilde{\lambda}_3 - \widetilde{\lambda}_2\,\widetilde{\lambda}_3^2) & \text{in } \widetilde{K}\setminus E,\\ 0 & \text{in } \Omega\setminus\{K\cup\widetilde{K}\}, \end{cases}$$

and, after dividing by 10,

$$\chi_E = \begin{cases} \lambda_1^2\,\lambda_2 - \lambda_1\,\lambda_2^2 & \text{in } K,\\ \widetilde{\lambda}_1^2\,\widetilde{\lambda}_2 - \widetilde{\lambda}_1\,\widetilde{\lambda}_2^2 & \text{in } \widetilde{K}\setminus E,\\ 0 & \text{in } \Omega\setminus\{K\cup\widetilde{K}\}. \end{cases}$$

These basis functions were used in the numerical calculations presented in section 7.

6. Convergence of the piecewise linear part $\boldsymbol{u_h^{lin}}$ of $\boldsymbol{u_h}$. Let us consider the discrete problem (3.2) with $\mathrm{V}_h = \mathrm{V}_h^{mod}$. Then the discrete solution u_h belongs to $\widetilde{\mathrm{V}}_h^{nc} \oplus \mathrm{B}_h$, where

$$\widetilde{\mathrm{V}}_h^{nc} = \left\{ v_h \in L^2(\Omega)\,;\; v_h|_K \in P_1(K) \;\;\forall\, K \in \mathcal{T}_h\,,\;\; \int_E [|v_h|]_E\,\mathrm{d}\sigma = 0 \;\;\forall\, E \in \mathcal{E}_h^i \right\}$$

and B_h was defined in (5.9). Thus, u_h can be uniquely decomposed into its piecewise linear part $u_h^{lin} \in \widetilde{\mathrm{V}}_h^{nc}$ and its bubble part $u_h^{bub} \in \mathrm{B}_h$, i.e.,

$$u_h = u_h^{lin} + u_h^{bub}\,.$$

We shall show that u_h^{lin} converges to the weak solution with the same convergence order as u_h. First, let us prove the following orthogonality result.

LEMMA 6.1. *The spaces $\widetilde{\mathrm{V}}_h^{nc}$ and B_h are orthogonal with respect to the $H_0^1(\Omega)$ inner product, i.e.,*

$$\sum_{K\in\mathcal{T}_h} (\nabla v_h, \nabla b_h)_K = 0 \qquad \forall\, v_h \in \widetilde{\mathrm{V}}_h^{nc},\, b_h \in \mathrm{B}_h\,. \tag{6.1}$$

Consequently,

$$|v_h|_{1,h}^2 + |b_h|_{1,h}^2 = |v_h + b_h|_{1,h}^2 \qquad \forall\, v_h \in \widetilde{\mathrm{V}}_h^{nc},\ b_h \in \mathrm{B}_h\,. \tag{6.2}$$

Moreover, for any element $K \in \mathcal{T}_h$ and any $\boldsymbol{a} \in \mathbb{R}^2$, we have

$$\|\boldsymbol{a}\cdot\nabla v_h\|_{0,K}^2 + \|\boldsymbol{a}\cdot\nabla b_h\|_{0,K}^2 = \|\boldsymbol{a}\cdot\nabla(v_h + b_h)\|_{0,K}^2 \qquad \forall\, v_h \in \widetilde{\mathrm{V}}_h^{nc},\ b_h \in \mathrm{B}_h\,. \tag{6.3}$$

Proof. For any $v_h \in \widetilde{\mathrm{V}}_h^{nc}$, $b_h \in \mathrm{B}_h$, $i, j \in \{1, 2\}$, and $K \in \mathcal{T}_h$, we derive

$$\int_K \frac{\partial v_h}{\partial x_i}\,\frac{\partial b_h}{\partial x_j}\,\mathrm{d}x = -\int_K \frac{\partial^2 v_h}{\partial x_i\,\partial x_j}\,b_h\,\mathrm{d}x + \int_{\partial K} \frac{\partial (v_h|_K)}{\partial x_i}\,(\boldsymbol{n}_{\partial K})_j\,b_h|_K\,\mathrm{d}\sigma = 0\,.$$

Hence we obtain (6.1) and also

$$(\boldsymbol{a}\cdot\nabla v_h, \boldsymbol{a}\cdot\nabla b_h)_K = 0 \qquad \forall\, v_h \in \widetilde{\mathrm{V}}_h^{nc},\ b_h \in \mathrm{B}_h,\ K \in \mathcal{T}_h,\ \boldsymbol{a} \in \mathbb{R}^2\,.$$

The validity of (6.2) and (6.3) is then obvious. □

With respect to the $L^2(\Omega)$ norm, an analogous orthogonality result is generally not available. Nevertheless, transforming the functions v_h, b_h onto the reference element and using the equivalence of norms on finite-dimensional spaces, we can prove that

$$\|v_h\|_{0,\Omega} + \|b_h\|_{0,\Omega} \le C\,\|v_h + b_h\|_{0,\Omega} \qquad \forall\, v_h \in \widetilde{\mathrm{V}}_h^{nc},\ b_h \in \mathrm{B}_h\,. \tag{6.4}$$

Let the weak solution of (1.1) belong to $H^2(\Omega)$. Then it follows from (6.2) that

$$|u_h^{lin} - i_h u|_{1,h} \le |u_h - i_h u|_{1,h}, \tag{6.5}$$

and hence, with respect to $|\cdot|_{1,h}$, the function u_h^{lin} approximates the piecewise linear interpolate of u at least as well as u_h. Moreover, we obtain the following result.

Theorem 6.2. *Let $u \in H^2(\Omega)$. Then*

$$|u - u_h^{lin}|_{1,h} \le |u - u_h|_{1,h} + 2\,|u - i_h u|_{1,\Omega}\,, \tag{6.6}$$

$$\|u - u_h^{lin}\|_{0,\Omega} \le C\,\|u - u_h\|_{0,\Omega} + C\,\|u - i_h u\|_{0,\Omega}\,, \tag{6.7}$$

$$|||u - u_h^{lin}||| \le C\left(1 + \max_{K\in\mathcal{T}_h} \delta_K^{1/2}\right)(|||u - u_h||| + |||u - i_h u|||)\,. \tag{6.8}$$

Proof. Inequality (6.6) is a direct consequence of (6.5). Analogously, using (6.4), we get (6.7). To prove (6.8), let us consider any $K \in \mathcal{T}_h$ and any $\boldsymbol{a} \in \mathbb{R}^2$. Applying (6.3), we deduce that

$$\begin{aligned}\|\boldsymbol{b}\cdot\nabla(i_h u - u_h^{lin})\|_{0,K} &\le \|(\boldsymbol{b} - \boldsymbol{a})\cdot\nabla(i_h u - u_h^{lin})\|_{0,K} + \|\boldsymbol{a}\cdot\nabla(i_h u - u_h)\|_{0,\Omega}\\ &\le \|\boldsymbol{b} - \boldsymbol{a}\|_{0,\infty,K}\,(|i_h u - u_h^{lin}|_{1,K} + |i_h u - u_h|_{1,K}) + \|\boldsymbol{b}\cdot\nabla(i_h u - u_h)\|_{0,K}\,.\end{aligned}$$

Since $\inf_{\boldsymbol{a}\in\mathbb{R}^2} \|\boldsymbol{b} - \boldsymbol{a}\|_{0,\infty,K} \le C\,h_K\,|\boldsymbol{b}|_{1,\infty,K}$, it follows from (3.4) that

$$\|\boldsymbol{b}\cdot\nabla(i_h u - u_h^{lin})\|_{0,K} \le C\,(\|i_h u - u_h^{lin}\|_{0,K} + \|i_h u - u_h\|_{0,K}) + \|\boldsymbol{b}\cdot\nabla(i_h u - u_h)\|_{0,K}\,.$$

Now, using (6.6), (6.7), and the triangular inequality, we obtain (6.8). □

The above estimates show that u_h^{lin} converges to the weak solution with the same convergence orders as u_h and that the estimate of Theorem 4.2 remains valid for u_h^{lin}. Therefore, it is possible and for practical reasons sensible to consider the piecewise linear part of u_h as a discrete solution of (1.1).

7. Numerical results. In this section, we present numerical results computed using either the discretization (3.2) or a discretization obtained from (3.2) by replacing a_h^{skew} by a_h^{conv} defined in (4.10). We used the P_1^{nc} element ($\mathrm{V}_h = \mathrm{V}_h^{nc}$) and the P_1^{mod} element ($\mathrm{V}_h = \mathrm{V}_h^{mod}$) defined using $\widehat{b}_i$ given in (5.5). (We considered the basis functions presented in subsection 5.2.) For the P_1^{mod} element, we obtained almost identical results for a_h^{conv} and a_h^{skew}, and therefore we show only results obtained for the following three discretizations: a_h^{conv}/P_1^{nc}, a_h^{skew}/P_1^{nc}, and a_h^{skew}/P_1^{mod}.

The bilinear forms a_h^{skew} and a_h^{conv} were computed exactly, whereas the right-hand side l_h was evaluated using a quadrature formula which is exact for piecewise cubic f. The arising linear systems were solved applying the GMRES method with ILU preconditioning. The computations were terminated if the ratio of the norms of the residuum and the right-hand side was smaller than 10^{-8}.

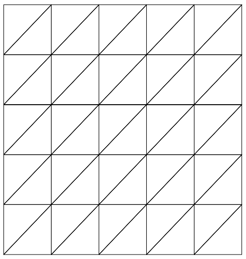

FIG. 7.1. *Type of triangulations used in numerical computations.*

All presented computational results were obtained for $\Omega = (0,1)^2$ discretized using Friedrichs–Keller triangulations of the type depicted in Figure 7.1. We present results obtained for $h \doteq 7.07 \cdot 10^{-2}$, $h \doteq 3.54 \cdot 10^{-2}$, $h \doteq 1.77 \cdot 10^{-2}$, and $h \doteq 8.84 \cdot 10^{-3}$, which corresponds to 800, 3200, 12800, and 51200 elements, respectively. The errors of the discrete solutions were measured in the norms $\|\cdot\|_{0,\Omega}$, $|\cdot|_{1,h}$, $|||\cdot|||$ and in the discrete L^∞ norm $\|\cdot\|_{0,\infty,h}$ which is defined as the maximum of the errors in the midpoints of edges. The evaluation of $\|\cdot\|_{0,\Omega}$ (resp., $|\cdot|_{1,h}$) was exact for piecewise quadratic (resp., cubic) functions. For the P_1^{mod} element, we give the errors of the piecewise linear part u_h^{lin} of u_h. (See section 6.) The convergence orders were always computed using values from triangulations with $h \doteq 1.77 \cdot 10^{-2}$ and $h \doteq 8.84 \cdot 10^{-3}$.

The three discretizations were used to solve the convection-diffusion equation (1.1) for three types of solutions specified in Examples 7.1–7.3 below. The parameter δ_K was defined as in Remark 4.1 with $\kappa_K = 1$, $\kappa_K = 0.25$, and $\kappa_K = 0.2$, respectively. Examples 7.1 and 7.2 are the same as in [11] and [12].

EXAMPLE 7.1 (smooth polynomial solution). *Let* $\boldsymbol{b} = (3,2)$, $c = 2$, *and* $u_b = 0$. *For a given* $\varepsilon > 0$, *the right-hand side* f *is chosen such that*

$$u(x,y) = 100\,x^2\,(1-x)^2\,y\,(1-y)\,(1-2\,y)$$

is the exact solution of (1.1); *see Figure* 7.2.

For $\varepsilon = 1$, we observed optimal convergence orders for all three discretizations, and the errors of the discrete solutions were very similar. To investigate whether the methods are ε-uniform, i.e., whether an estimate of the type

$$|||u - u_h||| \le C\,h^\nu\,\|u\|$$

holds with C and ν independent of ε, we considered $\varepsilon = h^\alpha$ for various values of α. Tables 7.1–7.3 show results obtained for $\alpha = 4$. We remark that the values of h

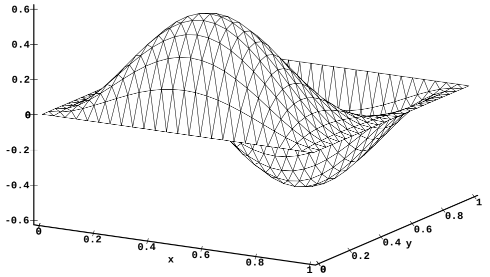

FIG. 7.2. *Exact solution of Example* 7.1.

and ε are rounded in all the tables. The solutions of the discretization a_h^{conv}/P_1^{nc} converge with the optimal order 3/2 in the streamline diffusion norm $|||\cdot|||$, which is in correspondence with subsection 4.1. Note, however, that on unstructured meshes this optimal convergence order was not observed, which indicates that the constants α_h in (4.11) generally cannot be bounded from below by some $\alpha_0 > 0$ independent of h. The influence of the consistency error r_h^s with respect to ε can clearly be seen from Table 7.2: the solution of (3.2) with the P_1^{nc} element does not converge in $|||\cdot|||$, which is in agreement with Theorem 4.2. Table 7.3 shows that the P_1^{mod} element leads to best possible convergence orders which can be expected from a first order finite element space. Particularly, we observe the convergence order 3/2 in the streamline

diffusion norm, which is again in agreement with our theory in section 4. The convergence orders are better than for a_h^{conv}/P_1^{nc} and a_h^{skew}/P_1^{nc}, and the discrete solutions obtained using the P_1^{mod} element are in all cases more accurate than P_1^{nc} solutions. Table 7.4 shows results obtained for various values of ε on a fixed triangulation. The errors for a_h^{skew}/P_1^{mod} are almost independent of ε in all norms, whereas the errors for a_h^{conv}/P_1^{nc} increase when ε decreases.

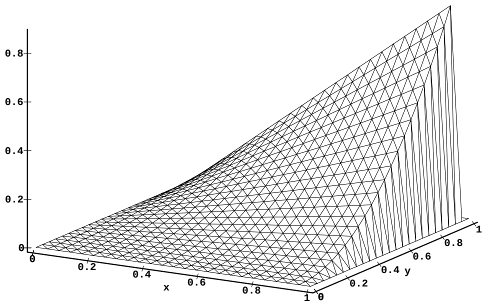

FIG. 7.3. *Exact solution of Example* 7.2.

EXAMPLE 7.2 (layers at the outflow part of the boundary). *Let* $\boldsymbol{b} = (2,3)$ *and* $c = 1$. *For a given* $\varepsilon > 0$, *the right-hand side* f *and the boundary condition* u_b *are chosen such that*

$$u(x,y) = x\,y^2 - y^2 \exp\left(\frac{2\,(x-1)}{\varepsilon}\right) - x \exp\left(\frac{3\,(y-1)}{\varepsilon}\right) + \exp\left(\frac{2\,(x-1)+3\,(y-1)}{\varepsilon}\right)$$

is the exact solution of (1.1). *This function has boundary layers at* $x = 1$ *and* $y = 1$; *see Figure* 7.3.

All three discretizations gave identical errors in $\vert\vert\vert \cdot \vert\vert\vert$ with convergence order 1.00 and in $\vert \cdot \vert_{1,h}$ with convergence order 0.50. The reduction of the convergence order

is caused by the interpolation error in the boundary layer region since the thickness of the layers is smaller than h for all triangulations used. The errors in $\|\cdot\|_{0,\Omega}$ and $\|\cdot\|_{0,\infty,h}$ are shown in Table 7.5. The errors for a_h^{conv}/P_1^{nc} increase for decreasing h and the errors for a_h^{skew}/P_1^{nc} do not change significantly. For a_h^{skew}/P_1^{mod}, the discrete solution converges in $\|\cdot\|_{0,\Omega}$ with order 0.50. Since the boundary layer is not resolved by the mesh, no convergence is observed in the maximum norm.

The streamline diffusion method with conforming finite element approximations is known to approximate solutions with layers on nonlayer-adapted meshes at least outside the layers very precisely. Tables 7.6–7.8 show the behavior of the discrete solutions outside the boundary layers in the domain $\Omega^* = (0, 0.8)^2$. The discretizations a_h^{conv}/P_1^{nc} and a_h^{skew}/P_1^{mod} give optimal convergence orders, but a_h^{skew}/P_1^{mod} is about 10 times more accurate than a_h^{conv}/P_1^{nc} in all norms except for $|||\cdot|||$. Table 7.7 shows that the discretization a_h^{skew}/P_1^{nc} is completely useless.

Example 7.3 (inner and boundary layers). *We set* $\boldsymbol{b} = (1/2, \sqrt{3}/2)$, $c = 0$, $f = 0$, *and*

$$u_b(x,y) = \begin{cases} 0 & \textit{for } x \geq 1/2 \textit{ or } y = 1, \\ 1 & \textit{else.} \end{cases}$$

For $\varepsilon \to 0$, *the solution* u *of* (1.1) *tends to the function*

$$u^0(x,y) = \begin{cases} 0 & \textit{for } y \leq \sqrt{3}\,(x - 1/2), \\ 1 & \textit{else,} \end{cases}$$

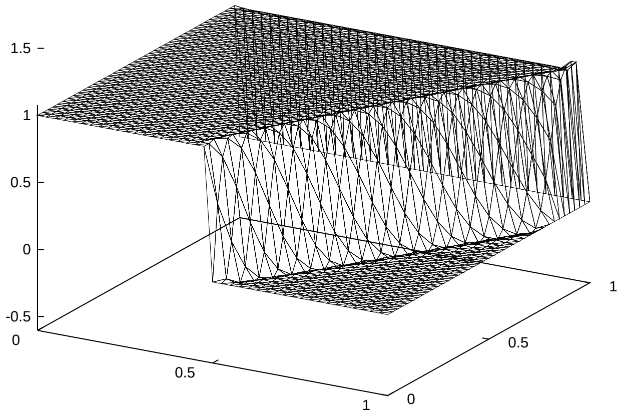

FIG. 7.4. *Solution of Example* 7.3 *for* $h \doteq 3.54 \cdot 10^{-2}$.

which is the solution of the hyperbolic limit of (1.1). *Thus, for small* ε, *the solution* u *has an inner layer along the line* $y = \sqrt{3}\,(x - 1/2)$ *and boundary layers along* $y = 1$ *and* $x = 1$, $y > \sqrt{3}/2$. *We consider* $\varepsilon = 10^{-6}$ *below.*

This example does not fit into the theory presented in this paper, particularly since $u_b \notin H^{3/2}(\partial\Omega)$. However, it is a challenging test case which can indicate the quality of numerical methods for solving (1.1).

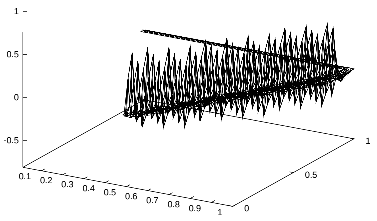

FIG. 7.5. *Example* 7.3; *errors larger than* 0.01 *for* $h \doteq 1.77 \cdot 10^{-2}$.

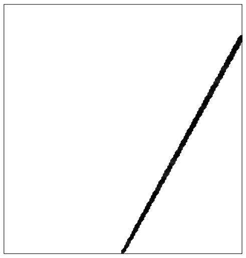

FIG. 7.6. *Example* 7.3; *region of errors larger than* 0.1 *for* $h \doteq 8.84 \cdot 10^{-3}$.

Figures 7.4–7.6 show results computed using the discrete problem (3.2) with the P_1^{mod} element. Instead of showing the discontinuous solution u_h directly, we present a corresponding conforming function $\widetilde{u}_h \in \widetilde{\mathrm{V}}_h^{conf}$ such that the value of $\widetilde{u}_h$ at any inner vertex is equal to the arithmetic mean value of the values of u_h at the midpoints of edges connected with this vertex. The errors of $\widetilde{u}_h$ in Figures 7.5 and 7.6 were computed using the limit solution u^0. We see that inner and boundary layers are detected very well and that the method behaves in a robust way, although the assumptions made in section 1 are not satisfied.

We can conclude that in all numerical tests we have performed, the P_1^{mod} element always led to optimal convergence orders and behaved very robustly with respect to ε. The accuracy of solutions obtained using the P_1^{mod} element was always better than for the P_1^{nc} element and, moreover, the iterative solver used to compute the discrete solutions converged much faster for the P_1^{mod} element than for discretizations using the P_1^{nc} element. Thus, the P_1^{mod} element not only improves the stability of the discrete solution but also the convergence properties of the solver.

APPROXIMATION OF TIME-DEPENDENT VISCOELASTIC FLUID FLOW: SUPG APPROXIMATION*

VINCENT J. ERVIN† AND WILLIAM W. MILES†

Abstract. In this article we consider the numerical approximation to the time-dependent viscoelasticity equations with an Oldroyd B constitutive equation. The approximation is stabilized by using a streamline upwind Petrov–Galerkin (SUPG) approximation for the constitutive equation. We analyze both the semidiscrete and fully discrete numerical approximations. For both discretizations we prove the existence of, and derive a priori error estimates for, the numerical approximations.

Key words. viscoelasticity, finite element method, fully discrete, SUPG

1. Introduction.

Accurate numerical simulations of time-dependent viscoelastic flows are important to the understanding of many phenomena in non-Newtonian fluid mechanics, particularly those associated with flow instabilities. Aside from [3], previous numerical analysis in this area has been for steady-state flows.

In the case of Newtonian fluid flow, the assumption that the extra stress tensor is proportional to the deformation tensor allows the stress to be eliminated from the modeling equations, giving the Navier–Stokes equations. In viscoelasticity, assuming an Oldroyd B-type fluid, the stress is defined by a (hyperbolic) differential constitutive equation. Very different from computational fluid dynamics simulations, in viscoelasticity, because of a "slow flow" assumption, the nonlinearity in the momentum equation is often neglected. The difficulty in performing accurate numerical computations arises from the hyperbolic character of the constitutive equation, which does not contain a dissipative (stabilizing) term for the stress. Care must be used in discretizing the constitutive equation to avoid the introduction of spurious oscillations into the approximation.

The first error analysis for the steady-state finite element (FE) approximation of viscoelastic fluid was presented by Baranger and Sandri [2]. In [2] a discontinuous FE formulation was used for the discretization of the constitutive equation, with the approximation for the stress being discontinuous. Motivated by implementation considerations, Najib and Sandri in [12] modified the discretization in [2] to obtain a decoupled system of two equations, showed the algorithm was convergent, and derived a priori error estimates. In [14], Sandri presented an analysis of an FE approximation to this problem, wherein the constitutive equation was discretized using a streamline upwind Petrov–Galerkin (SUPG) method. For the constitutive equation discretized using the method of characteristics, Baranger and Machmoum in [1] analyzed this approach and gave error estimates for the approximations.

For the analysis of the time-dependent problem, Baranger and Wardi [3] studied a discontinuous Galerkin (DG) approximation to inertialess flow in $\mathbb{R}^2$, using techniques similar to those used for the steady-state problem. With the Hood–Taylor

FE pair used to approximate the velocity and pressure and a discontinuous linear approximation for the stress, they showed, under the assumption $\Delta t \leq C_1 h^{3/2}$, that the discrete H^1 and L^2 errors for the velocity and stress, respectively, were bounded by $C(\Delta t + h^{3/2})$.

In this paper we analyze the SUPG approximation to the time-dependent equations in $\mathbb{R}^{\acute{d}}$, $\acute{d} = 2, 3$. For the fully discrete analysis we extend the approach used in [11] for compressible Navier–Stokes equations to non-Newtonian flow. For ν denoting the SUPG coefficient, and assuming Hood–Taylor FE pair approximation for the velocity and pressure, and a continuous FE approximation for the viscoelastic stress, under the assumption $\Delta t,\ \nu \leq C_1 h^{\acute{d}/2}$, we obtain that the discrete H^1 and L^2 errors for the velocity and stress, respectively, are bounded by $C(\Delta t + \nu + h^2)$.

This paper is organized as follows. A description of the modeling equations is presented in section 2. Section 3 contains a description of the mathematical notation and several lemmas used in the analysis. The semidiscrete and fully discrete approximations are then presented and analyzed in sections 4 and 5, respectively.

2. The Oldroyd B model and the approximating system.

In this section we describe the modeling equations for viscoelastic fluid flow (see also [2]).

2.1. The problem.

Consider a fluid flowing in a bounded, connected domain $\Omega \in \mathcal{R}^{\acute{d}}$. The boundary of Ω, $\partial\Omega$ is assumed to be Lipschitzian. The vector $\mathbf{n}$ represents the outward unit normal to $\partial\Omega$. The velocity vector is denoted by $\mathbf{u}$, pressure by p, total stress by $\mathbf{T}$, and extra stress by τ. For ease of notation, we use the convention of summation on repeated indices and denote differentiation with a comma. For example, $\frac{\partial \mathbf{u}}{\partial x_i}$ is written $u_{,i}$. Then for a tensor τ and a vector $\mathbf{w}$, $\nabla \cdot \tau$ denotes $\tau_{ij,j}$, and $\mathbf{w} \cdot \nabla$ denotes the operator $w_i \frac{\partial}{\partial x_i}$. The deformation tensor, $D(\mathbf{u})$, and the vorticity tensor, $W(\mathbf{u})$, are given by

$$D(\mathbf{u}) \ = \ \frac{1}{2}\left(\nabla\mathbf{u} + (\nabla\mathbf{u})^T\right), \qquad W(\mathbf{u}) \ = \ \frac{1}{2}\left(\nabla\mathbf{u} - (\nabla\mathbf{u})^T\right).$$

The Oldroyd model can be described using an *objective derivative* [2], denoted by $\hat{\partial}\sigma/\partial t$, where

$$\frac{\hat{\partial}\sigma}{\partial t} := \frac{\partial \sigma}{\partial t} + \mathbf{u}\cdot\nabla\sigma + g_a(\sigma, \nabla\mathbf{u}), \qquad\qquad a \in [-1, 1],$$

and

$$\begin{aligned} g_a(\sigma, \nabla\mathbf{u}) &:= \sigma W(\mathbf{u}) - W(\mathbf{u})\sigma - a(D(\mathbf{u})\sigma + \sigma D(\mathbf{u})) \\ &= \frac{1-a}{2}\left(\sigma\nabla\mathbf{u} + (\nabla\mathbf{u})^T\sigma\right) - \frac{1+a}{2}\left((\nabla\mathbf{u})\sigma + \sigma(\nabla\mathbf{u})^T\right). \end{aligned}$$

Oldroyd's model for stress employs a decomposition of the extra stress into two parts: a Newtonian part and a viscoelastic part. Thus $\tau = \tau_N + \tau_V$. The Newtonian part is given by $\tau_N = 2(1-\alpha)D(\mathbf{u})$. The $(1-\alpha)$ represents that part of the total viscosity which is considered Newtonian. Hence $\alpha \in (0, 1)$ represents the proportion of the total viscosity that is considered to be viscoelastic in nature. For example, if a polymer is immersed within a Newtonian carrier fluid, α is related to the percentage of polymer in the mix. The constitutive law is (see [2])

$$\tau_V + \lambda\frac{\hat{\partial}\tau_V}{\partial t} - 2\alpha D(\mathbf{u}) = 0, \tag{2.1}$$

where λ is the Weissenberg number, which is a dimensionless constant defined as the product of the relaxation time and a characteristic strain rate [4]. For notational simplicity, the subscript V is dropped, and τ will be used below to denote the viscoelastic component of the extra stress.

The momentum balance for the fluid is given by

$$Re\left(\frac{d\mathbf{u}}{dt}\right) = -\nabla p + \nabla\cdot(2(1-\alpha)D(\mathbf{u}) + \tau) + \mathbf{f}, \tag{2.2}$$

where Re is the Reynolds number, $\mathbf{f}$ the body forces acting on the fluid, and $d\mathbf{u}/dt$ is the material derivative. Recall that

$$Re = \frac{LV\rho}{\mu}, \qquad \begin{aligned} L &= \text{characteristic length scale,}\\ V &= \text{characteristic velocity scale,}\\ \rho &= \text{fluid density,}\\ \mu &= \text{fluid viscosity.}\end{aligned}$$

In addition to (2.1) and (2.2) we also have the incompressibility condition

$$\nabla\cdot\mathbf{u} = 0 \qquad \text{in } \Omega.$$

To fully specify the problem, appropriate boundary conditions must also be given. The simplest such condition is the homogeneous Dirichlet condition for velocity. In this case, there is no inflow boundary, and, thus, no boundary condition is required for stress. Summarizing, the modeling equations are

$$Re\left(\frac{\partial\mathbf{u}}{\partial t} + \mathbf{u}\cdot\nabla\mathbf{u}\right) + \nabla p - 2(1-\alpha)\nabla\cdot D(\mathbf{u}) - \nabla\cdot\tau = \mathbf{f} \qquad \text{in } \Omega, \tag{2.3}$$

$$\tau + \lambda\left(\frac{\partial\tau}{\partial t} + \mathbf{u}\cdot\nabla\tau + g_a(\tau,\nabla\mathbf{u})\right) - 2\alpha D(\mathbf{u}) = 0 \qquad \text{in } \Omega, \tag{2.4}$$

$$\nabla\cdot\mathbf{u} = 0 \qquad \text{in } \Omega, \tag{2.5}$$

$$\mathbf{u} = 0 \qquad \text{on } \partial\Omega, \tag{2.6}$$

$$\mathbf{u}(0,\mathbf{x}) = \mathbf{u}_0(\mathbf{x}) \qquad \text{in } \Omega, \tag{2.7}$$

$$\tau(0,\mathbf{x}) = \tau_0(\mathbf{x}) \qquad \text{in } \Omega. \tag{2.8}$$

In [8], Guillope and Saut proved the following for the “slow-flow” model of (2.3)–(2.8) (i.e., the $\mathbf{u}\cdot\nabla\mathbf{u}$ term in (2.3) is ignored):

1. local existence, in time, of a unique, regular solution, and
2. under a small data assumption on $\mathbf{f}, \mathbf{f}', \mathbf{u}_0, \tau_0$, the global existence (in time) of a unique solution for $\mathbf{u}$ and τ.

In contrast to the Navier–Stokes equations, well-posedness for general models in viscoelasticity is still not well understood. Results which are known fall into one of three types [13]:

1. for initial value problems, solutions have been shown to exist locally in time,
2. global existence (in time) of solutions if the initial conditions are small perturbations of the rest state, and
3. for steady-state problems, existence of solutions which are small perturbations of the analogous Newtonian case.

2.2. The variational formulation. In this section, we develop the variational formulation of (2.3)–(2.6). The following notation will be used. The $L^2(\Omega)$ norm and inner product will be denoted by $\|\cdot\|$ and $(\cdot,\cdot)$. Likewise, the $L^p(\Omega)$ norms and the Sobolev $W^k_p(\Omega)$ norms are denoted by $\|\cdot\|_{L^p}$ and $\|\cdot\|_{W^k_p}$, respectively. For the semi-norm in $W^k_p(\Omega)$ we use $|\cdot|_{W^k_p}$. H^k is used to represent the Sobelev space W^k_2, and $\|\cdot\|_k$ denotes the norm in H^k. The following function spaces are used in the analysis:

$$\begin{aligned}
\text{Velocity space} : X &:= H^1_0(\Omega) := \left\{\mathbf{u} \in H^1(\Omega) : \mathbf{u} = 0 \ \text{ on } \ \partial\Omega\right\},\\
\text{Stress space} : S &:= \left\{\tau = (\tau_{ij}) : \tau_{ij} = \tau_{ji}; \tau_{ij} \in L^2(\Omega); 1 \le i,j \le 3\right\}\\
&\quad \cap \left\{\tau = (\tau_{ij}) : \mathbf{u}\cdot\nabla\tau \ \in L^2(\Omega), \forall \mathbf{u} \in X\right\},\\
\text{Pressure space} : Q &:= L^2_0(\Omega) = \left\{q \in L^2(\Omega) : \int_\Omega q \, dx = 0\right\},\\
\text{Divergence-free space} : Z &:= \left\{v \in X : \int_\Omega q(\nabla\cdot v)\, dx = 0, \ \forall\, q \in Q\right\}.
\end{aligned}$$

The variational formulation of (2.3)–(2.6) proceeds in the usual manner. Taking the inner product of (2.3), (2.4), and (2.5) with a velocity test function, a stress test function, and a pressure test function, respectively, we obtain

(2.9)
$$Re\left(\frac{\partial\mathbf{u}}{\partial t} + \mathbf{u}\cdot\nabla\mathbf{u}, \mathbf{v}\right) - (p, \nabla\cdot\mathbf{v}) + (2(1-\alpha)D(\mathbf{u}) + \tau, D(\mathbf{v})) = (\mathbf{f}, \mathbf{v}) \qquad \forall\, \mathbf{v} \in X,$$

$$\left(\tau + \lambda\left(\frac{\partial\tau}{\partial t} + \mathbf{u}\cdot\nabla\tau + g_a(\tau, \nabla\mathbf{u})\right) - 2\alpha D(\mathbf{u}), \psi\right) = 0 \qquad \forall\, \psi \in S, \tag{2.10}$$

$$(\nabla\cdot\mathbf{u}, q) = 0 \qquad \forall\, q \in Q. \tag{2.11}$$

The space Z is the space of weakly divergence-free functions. Note that the condition

$$(\nabla\cdot\mathbf{u}, q) = 0 \qquad \forall\, q \in Q, \ \mathbf{u} \in X,$$

is equivalent in a “distributional” sense to

$$(\mathbf{u}, \nabla q) = 0 \qquad \forall\, q \in Q, \ \mathbf{u} \in X, \tag{2.12}$$

where in (2.12), $(\cdot,\cdot)$ denotes the duality pairing between H^{-1} and H^1_0 functions. In addition, note that the velocity and pressure spaces X and Q satisfy the *inf-sup* condition

$$\inf_{q\in Q} \sup_{\mathbf{v}\in X} \frac{(q, \nabla\cdot\mathbf{v})}{\|q\|\,\|\mathbf{v}\|_1} \ge \beta > 0. \tag{2.13}$$

Since the inf-sup condition (2.13) holds, an equivalent variational formulation to (2.9)–(2.11) is the following: *Find* $(\mathbf{u}, \tau) : [0, T] \to X \times S$ *such that*

$$Re\left(\frac{\partial\mathbf{u}}{\partial t} + \mathbf{u}\cdot\nabla\mathbf{u}, \mathbf{v}\right) + (2(1-\alpha)D(\mathbf{u}) + \tau, D(\mathbf{v})) = (\mathbf{f}, \mathbf{v}) \ \ \forall\, \mathbf{v} \in Z, \tag{2.14}$$

$$\left(\tau + \lambda\left(\frac{\partial\tau}{\partial t} + \mathbf{u}\cdot\nabla\tau + g_a(\tau, \nabla\mathbf{u})\right) - 2\alpha D(\mathbf{u}), \psi\right) = 0 \qquad \forall\, \psi \in S. \tag{2.15}$$

Before discussion of the numerical approximation of (2.14), (2.15), we summarize the mathematical notation and interpolation properties used in the analysis.

3. Mathematical notation. In this section the mathematical framework and approximation properties are summarized.

Let $\Omega \subset \mathbb{R}^{\acute{d}} (\acute{d} = 2, 3)$ be a polygonal domain, and let T_h be a triangulation of Ω made of triangles (in $\mathbb{R}^2$) or tetrahedrals (in $\mathbb{R}^3$). Thus, the computational domain is defined by

$$\Omega = \bigcup K, \qquad K \in T_h.$$

We assume that there exist constants c_1, c_2 such that

$$c_1 h \le h_K \le c_2 \rho_K,$$

where h_K is the diameter of triangle (tetrahedral) K, ρ_K is the diameter of the greatest ball (sphere) included in K, and $h = \max_{K \in T_h} h_K$. Let $P_k(A)$ denote the space of polynomials on A of degree no greater than k. Then we define the FE spaces as follows:

$$\begin{aligned} X_h &:= \left\{ \mathbf{v} \in X \cap C(\bar{\Omega})^{\acute{d}} : \mathbf{v}|_K \in P_k(K)\ \forall K \in T_h \right\}, \\ S_h &:= \left\{ \sigma \in S \cap C(\bar{\Omega})^{\acute{d} \times \acute{d}} : \sigma|_K \in P_m(K)\ \forall K \in T_h \right\}, \\ Q_h &:= \left\{ q \in Q \cap C(\bar{\Omega}) : q|_K \in P_q(K)\ \forall K \in T_h \right\}, \\ Z_h &:= \left\{ \mathbf{v} \in X_h : (q, \nabla \cdot \mathbf{v}) = 0\ \forall q \in Q_h \right\}, \end{aligned}$$

where $C(\bar{\Omega})^{\acute{d}}$ denotes a vector valued function with $\acute{d}$ components continuous on $\bar{\Omega}$. Analogous to the continuous spaces, we assume that X_h and Q_h satisfy the discrete *inf-sup* condition

$$\inf_{q \in Q_h} \sup_{\mathbf{v} \in X_h} \frac{(q, \nabla \cdot \mathbf{v})}{\|q\| \, \|\mathbf{v}\|_1} \ge \beta > 0. \tag{3.1}$$

We summarize several properties of FE spaces and Sobolev's spaces which we will use in our subsequent analysis. For $(\mathbf{u}, p) \in H^{k+1}(\Omega)^{\acute{d}} \times H^{q+1}(\Omega)$ we have (see [7]) that there exists $(\mathcal{U}, \mathcal{P}) \in Z_h \times Q_h$ such that

$$\|\mathbf{u} - \mathcal{U}\| \le C_I h^{k+1} |\mathbf{u}|_{W_2^{k+1}}, \tag{3.2}$$

$$\|\mathbf{u} - \mathcal{U}\|_{W_2^1} \le C_I h^{k} |\mathbf{u}|_{W_2^{k+1}}, \tag{3.3}$$

$$\|p - \mathcal{P}\| \le C_I h^{q+1} |p|_{W_2^{q+1}}. \tag{3.4}$$

Let $\mathcal{T} \in S_h$ be a P_1 continuous interpolant of τ. For $\tau \in H^{m+1}(\Omega)^{\acute{d} \times \acute{d}}$ we have that

$$\|\tau - \mathcal{T}\| \ + \ h|\tau - \mathcal{T}|_{W_2^1} \le C_I h^{m+1} \|\tau\|_{W_2^{m+1}}, \tag{3.5}$$

$$\|\tau - \mathcal{T}\|_{L^4} \ + \ h|\tau - \mathcal{T}|_{W_4^1} \le C_I h^{m+1-\acute{d}/4} \|\tau\|_{W_2^{m+1}}. \tag{3.6}$$

From [5], we have the following results.

LEMMA 3.1. *Let $\{T_h\}$, $0 < h \le 1$, denote a quasi-uniform family of subdivisions of a polyhedral domain $\Omega \subset \mathbb{R}^{\acute{d}}$. Let $(\hat{K}, P, N)$ be a reference finite element such that $P \subset W_p^l(\hat{K}) \cap W_q^m(\hat{K})$, where $1 \le p \le \infty$, $1 \le q \le \infty$, and*

$0 \leq m \leq l$. For $K \in T_h$, let (K, P_K, N_K) be the affine equivalent element, and $V_h = \{v : v$ is measurable and $v|_K \in P_K \forall K \in T_h\}$. Then there exists $C = C(l, p, q)$ such that

$$\left[\sum_{K \in T_h} \|v\|^p_{W^l_p(K)}\right]^{1/p} \leq C\, h^{m-l+\min(0,\, \frac{\acute{d}}{p} - \frac{\acute{d}}{q})} \left[\sum_{K \in T_h} \|v\|^q_{W^m_q(K)}\right]^{1/q} \tag{3.7}$$

for all $v \in V_h$. □

LEMMA 3.2. *Let I_h denote the interpolant of v. Then for all $v \in W^m_p(\Omega) \cap C^r(\Omega)$ and $0 \leq s \leq \min\{m, r+1\}$,*

$$\|v - I_h\|_{s,\infty} \leq C\, h^{m-s-\acute{d}/p}\, |v|_{W^m_p}. \quad □ \tag{3.8}$$

When $v(\mathbf{x}, t)$ is defined on the entire time interval $(0, T)$, we define

$$\|v\|_{\infty,k} := \sup_{0<t<T} \|v(\cdot, t)\|_k,$$

$$\|v\|_{0,k} := \left(\int_0^T \|v(\cdot, t)\|^2_k \, dt\right)^{1/2}.$$

For the analysis of the fully discrete approximation, we use Δt to denote the step size for t so that $t_n = n\Delta t$, $n = 0, 1, 2, \ldots, N$, and define

$$f^n := f(n\Delta t) \quad \text{and} \quad d_t f := \frac{f(t_n) - f(t_{n-1})}{\Delta t}. \tag{3.9}$$

We also use the following additional norms:

$$|||v|||_{\infty,k} := \max_{1 \leq n \leq N} \|v^n\|_k,$$

$$|||v|||_{0,k} := \left[\sum_{n=1}^N \Delta t\, \|v^n\|^2_k\right]^{1/2}.$$

4. Semidiscrete approximation. In this section we present the analysis of a semidiscrete approximation to (2.14), (2.15). We begin by introducing some notation specific to the semidiscrete approximation and cite some lemmas used in the analysis.

For $\sigma_u := \sigma + \nu h\, \mathbf{u} \cdot \nabla\sigma$ we define

$$A(\mathbf{w}, (\mathbf{u}, \tau), (\mathbf{v}, \psi)) := (\tau, \psi_w) - 2\alpha(D(\mathbf{u}), \psi_w) + 2\alpha(\tau, D(\mathbf{v})) + \alpha(1-\alpha)(\nabla\mathbf{u}, \nabla\mathbf{v}), \tag{4.1}$$

$$B(\mathbf{u}, \mathbf{v}, \tau, \sigma) := (\mathbf{u} \cdot \nabla\tau, \sigma_v) + \frac{1}{2}(\nabla \cdot \mathbf{u}\, \tau, \sigma), \tag{4.2}$$

$$c(\mathbf{w}, \mathbf{u}, \mathbf{v}) := (\mathbf{w} \cdot \nabla\mathbf{u}, \mathbf{v}), \tag{4.3}$$

$$\tilde{c}(\mathbf{w}, \mathbf{u}, \mathbf{v}) := \frac{1}{2}\left(c(\mathbf{w}, \mathbf{u}, \mathbf{v}) - c(\mathbf{w}, \mathbf{v}, \mathbf{u})\right). \tag{4.4}$$

LEMMA 4.1 (see [10]). *For $\mathbf{u}, \mathbf{v}, \mathbf{w} \in X$, there exists a constant C_1 such that*

$$|\tilde{c}(\mathbf{u}, \mathbf{v}, \mathbf{w})| \leq C_1 \|\mathbf{u}\|^{1/2} \|\nabla\mathbf{u}\|^{1/2} \|\nabla\mathbf{v}\|^{1/2} \|\nabla\mathbf{w}\|^{1/2}. \quad □ \tag{4.5}$$

Note the following:

(i) $\tilde{c}(\mathbf{u},\mathbf{v},\mathbf{w}) = c(\mathbf{u},\mathbf{v},\mathbf{w})$ when $\nabla\cdot\mathbf{u} = 0$ in Ω, and $\mathbf{u} = 0$ on $\partial\Omega$.

(ii) $\tilde{c}(\mathbf{u},\mathbf{v},\mathbf{v}) = 0$, even when $\nabla\cdot\mathbf{u} \neq 0$.

(iii) For $\mathbf{u} \in X$, from the Poincaré–Friedrichs inequality we have that there exists a constant $C_{PF} = C(\Omega)$ such that $\|\mathbf{u}\|^2 \leq C_{PF}^2 \|\nabla\mathbf{u}\|^2$.

The operators $A(\cdot,(\cdot,\cdot),(\cdot,\cdot)) : X \times (X \times H^1(\Omega)^{n\times n}) \times (X \times H^1(\Omega)^{n\times n}) \to \mathbb{R}$ and $B(\cdot,\cdot,\cdot,\cdot) : X \times X \times H^1(\Omega)^{n\times n} \times H^1(\Omega)^{n\times n} \to \mathbb{R}$ are the same as those used in [2], [14]. When $\mathbf{u} = \mathbf{v}$, we omit the second variable in $B(\cdot,\cdot,\cdot,\cdot)$.

Lemma 4.2. *We have that*

$$B(\mathbf{u},\tau,\tau) \;=\; \nu h(\mathbf{u}\cdot\nabla\tau, \mathbf{u}\cdot\nabla\tau). \tag{4.6}$$

Proof. On integrating $(\mathbf{u}\cdot\nabla\tau,\sigma)$ by parts we have

$$B(\mathbf{u},\mathbf{v},\tau,\sigma) \;:=\; -(\mathbf{u}\cdot\nabla\sigma,\tau) \;+\; \nu\, h\,(\mathbf{u}\cdot\nabla\tau, \mathbf{v}\cdot\nabla\sigma) \;-\; \frac{1}{2}(\nabla\cdot\mathbf{u}\,\sigma,\tau). \tag{4.7}$$

Setting $\mathbf{v} = \mathbf{u}$, $\sigma = \tau$, and combining (4.2) and (4.7), the stated result follows. □

Lemma 4.3. *For $\mathbf{w} \in X$, $(\mathbf{u},\tau) \in X \times S$ and h sufficiently small, we have*

$$A(\mathbf{w},(\mathbf{u},\tau),(\mathbf{u},\tau)) \;+\; \lambda B(\mathbf{w},\tau,\tau) \geq C_A(\|\tau\|^2 + \|\mathbf{u}\|_1^2).$$

Proof. Using the definitions of A and B, we obtain

$$\begin{aligned}
A(\mathbf{w},(\mathbf{u},\tau),(\mathbf{u},\tau)) + \lambda B(\mathbf{w},\tau,\tau) \;&=\; \|\tau\|^2 \;+\; (\tau, \nu h\,\mathbf{w}\cdot\nabla\tau) \;-\; 2\alpha(D(\mathbf{u}),\tau) \\
&\quad - 2\alpha(D(\mathbf{u}), \nu h\,\mathbf{w}\cdot\nabla\tau) + 2\alpha(\tau, D(\mathbf{u})) + \alpha(1-\alpha)\|\nabla\mathbf{u}\|^2 \\
&\quad + \lambda\nu h\|\mathbf{w}\cdot\nabla\tau\|^2 \\
&\geq \|\tau\|^2 + \alpha(1-\alpha)\|\nabla\mathbf{u}\|^2 + \lambda\nu h\,\|\mathbf{w}\cdot\nabla\tau\|^2 - \frac{1}{2}\|\tau\|^2 \\
&\quad - \frac{1}{2}\nu^2 h^2\,\|\mathbf{w}\cdot\nabla\tau\|^2 \;-\; \frac{1}{2}\alpha(1-\alpha)\|\nabla\mathbf{u}\|^2 - \frac{\alpha\nu^2 h^2}{2(1-\alpha)}\|\mathbf{w}\cdot\nabla\tau\|^2 \\
&\geq \frac{1}{2}\|\tau\|^2 + \frac{\alpha(1-\alpha)}{2}\|\nabla\mathbf{u}\|^2 + \left(\lambda\nu h \;-\; \frac{\nu^2 h^2}{2} \;-\; \frac{\alpha\nu^2 h^2}{2(1-\alpha)}\right)\|\mathbf{w}\cdot\nabla\tau\|^2 \qquad (4.8) \\
&\geq C_A\left(\|\tau\|^2 + \|\mathbf{u}\|_1^2\right)
\end{aligned}$$

for h sufficiently small, using (iii). □

Now we define the semidiscrete approximation of (2.14), (2.15) as

Find $(\mathbf{u}_h,\tau_h) : [0,T] \;\to\; X_h \times S_h$ such that

(4.9)

$$Re\,(\mathbf{u}_{h\,t},\mathbf{v}) + Re\,\tilde{c}(\mathbf{u}_h,\mathbf{u}_h,\mathbf{v}) \;+\; (1-\alpha)(\nabla\mathbf{u}_h,\nabla\mathbf{v}) \;+\; (\tau_h, D(\mathbf{v})) \;=\; (\mathbf{f},\mathbf{v}) \;\;\forall\,\mathbf{v}\in Z_h,$$

(4.10)

$$\lambda\,(\tau_{h\,t},\sigma) + \lambda\,B(\mathbf{u}_h,\tau_h,\sigma) + \lambda(g_a(\tau_h,\nabla\mathbf{u}_h),\sigma_{u_h}) + (\tau_h,\sigma_{u_h}) - 2\alpha(D(\mathbf{u}_h),\sigma_{u_h}) = 0 \quad \forall\,\sigma\in S_h.$$

4.1. Analysis of the semidiscrete approximation. In this section, we show that, under suitable conditions, a unique solution to the discretized system exists. Fixed point theory is used to establish the desired result. The proof is established using the following four steps:

1. Define an iterative map in such a way that a fixed point of the map is a solution to (4.9), (4.10).
2. Show that the map is well defined and bounded on bounded sets.
3. Show that there exists an invariant ball on which the map is a contraction.
4. Apply Schauder's fixed point theorem to establish the existence and uniqueness of the discrete approximation.

THEOREM 4.4. *Assume that the system* (2.3)–(2.8) *(and thus* (2.14)–(2.15)*) has a solution* $(\mathbf{u}, \tau, \mathbf{p}) \in L^2(0, T; H^{k+1}) \times L^\infty(0, T; H^{m+1}) \times L^2(0, T; H^{q+1})$*. In addition assume that* $k, m \geq \acute{d}/2$*, and*

$$\|\nabla \mathbf{u}\|_\infty, \|\tau\|_\infty, \|\nabla \tau\|_\infty, \|\mathbf{u}\|_{k+1}, \|\tau\|_{m+1}, \|p\|_{q+1} \leq D_0 \quad \forall t \in [0, T]. \tag{4.11}$$

Then for D_0 *and* h *sufficiently small, there exists a unique solution to* (4.9)–(4.10) *satisfying*

$$\int_0^T \left(\|\mathbf{u} - \mathbf{u}_h\|^2 \, + \, \|\nabla(\mathbf{u} - \mathbf{u}_h)\|^2 \right) \, dt \leq C h^{\min\{k, m, q+1\}}, \tag{4.12}$$

$$\sup_{0 \leq t \leq T} \|\tau - \tau_h\| \leq C h^{\min\{k, m, q+1\}}. \tag{4.13}$$

Proof. Step 1. *The iterative map.* A mapping $\xi : L^2(0, T; Z_h) \times L^\infty(0, T; S_h) \rightarrow L^2(0, T; Z_h) \times L^\infty(0, T; S_h)$ is defined via $(\mathbf{u}_2, \tau_2) = \xi(\mathbf{u}_1, \tau_1)$, where $(\mathbf{u}_2, \tau_2)$ satisfies

(4.14)
$$Re\,(\mathbf{u}_{2\,t}, \mathbf{v}) + \; Re\, \tilde{c}(\mathbf{u}_1, \mathbf{u}_2, \mathbf{v}) + (1 - \alpha)(\nabla \mathbf{u}_2, \nabla \mathbf{v}) + (\tau_2, D(\mathbf{v})) = (\mathbf{f}, \mathbf{v}) \;\; \forall \, \mathbf{v} \in Z_h,$$

(4.15)
$$\lambda(\tau_{2\,t}, \sigma) + \lambda B(\mathbf{u}_1, \tau_2, \sigma) + (\tau_2, \sigma_{u_1}) - 2\alpha(D(\mathbf{u}_h), \sigma_{u_1}) = -\lambda(g_a(\tau_1, \nabla \mathbf{u}_1), \sigma_{u_1}) \qquad \forall \, \sigma \in S_h.$$

Thus, given an initial guess $(\mathbf{u}_h, \tau_h) \approx (\mathbf{u}_1, \tau_1)$, solving (4.14), (4.15) for $(\mathbf{u}_2, \tau_2)$ gives a new approximation to the solution. Also, it is clear that a fixed point of (4.14), (4.15) is a solution to the approximating system (4.9), (4.10) (i.e., $\xi(\mathbf{u}_1, \tau_1) = (\mathbf{u}_1, \tau_1)$ implies that $(\mathbf{u}_1, \tau_1)$ is a solution to (4.9), (4.10)).

Step 2. *Show that* ξ *is well defined and bounded on bounded sets.* Note that (4.14), (4.15) corresponds to a first order system of ODEs for the FEM (finite element method) coefficients $\mathbf{c}_{\mathbf{u}_2}$ and $\mathbf{c}_{\tau_2}$ of $\mathbf{u}_2$ and τ_2, respectively. That is, (4.14), (4.15) is equivalent to

$$\begin{bmatrix} A_{11} & 0 \\ 0 & A_{22} \end{bmatrix} \begin{bmatrix} \mathbf{c}_{\mathbf{u}_2} \\ \mathbf{c}_{\tau_2} \end{bmatrix}' \; = \; \mathbf{F}(t, \mathbf{c}_{\mathbf{u}_2}, \mathbf{c}_{\tau_2}),$$

where

$$\mathbf{F}(t, \mathbf{c}_{\mathbf{u}_2}, \mathbf{c}_{\tau_2}) = \begin{bmatrix} (\mathbf{f}, \mathbf{v}) \, - \, Re\, \tilde{c}(\mathbf{u}_1, \mathbf{u}_2, \mathbf{v}) \, - \, (1 - \alpha)(\nabla \mathbf{u}_2, \nabla \mathbf{v}) \, - \, (\tau_2, D(\mathbf{v})) \\ -\lambda(g_a(\tau_h, \nabla \mathbf{u}_h), \sigma_{u_1}) \, - \, \lambda\, B(\mathbf{u}_1, \tau_2, \sigma) \, - \, (\tau_2, \sigma_{u_1}) \, + \, 2\alpha(D(\mathbf{u}_h), \sigma_{u_1}) \end{bmatrix},$$

and A_{11} and A_{22} are "mass" (invertible) matrices.

Note that $\mathbf{F} : [0, T] \times \mathbb{R}^{dim(\mathbf{c}_{\mathbf{u}_2})} \times \mathbb{R}^{dim(\mathbf{c}_{\tau_2})} \rightarrow \mathbb{R}^{dim(\mathbf{c}_{\mathbf{u}_2})} \times \mathbb{R}^{dim(\mathbf{c}_{\tau_2})}$ is a linear function with respect to the FEM coefficients $\mathbf{c}_{\mathbf{u}_2}, \mathbf{c}_{\tau_2}$. Thus, for $f(t)$ a continuous function of t, we have that $\mathbf{F}$ is Lipschitz continuous. Then, from ODE theory (see

[6]), we are guaranteed that there exists a unique local solution for $(\mathbf{c}_{\mathbf{u}_2}, \mathbf{c}_{\tau_2})$, and hence for $(\mathbf{u}_2, \tau_2)$.

Next, to establish the existence of $(\mathbf{u}_2, \tau_2)$ on $[0, T]$, we show that it remains bounded in the appropriate norms on that interval.

Multiplying (4.14) through by 2α and adding the result to (4.15), $(\mathbf{u}_2, \tau_2)$ is equivalently determined via

$$\begin{aligned} &2\alpha Re(\mathbf{u}_{2\,t}, \mathbf{v}) + 2\alpha Re\tilde{c}(\mathbf{u}_1, \mathbf{u}_2, \mathbf{v}) + A(\mathbf{u}_1, (\mathbf{u}_2, \tau_2), (\mathbf{v}, \sigma)) + \lambda(\tau_{2\,t}, \sigma) + \lambda B(\mathbf{u}_1, \tau_2, \sigma) \\ &\qquad = 2\alpha(\mathbf{f}, \mathbf{v}) - \lambda(g_a(\tau_1, \nabla \mathbf{u}_1), \sigma_{u_1}) \ \ \forall\ (\mathbf{v}, \sigma) \in Z_h \times S_h. \end{aligned} \tag{4.16}$$

Choosing $\mathbf{v} = \mathbf{u}_2$, $\sigma = \tau_2$ in (4.16) and using (ii) and (4.8) implies

$$\begin{aligned} \alpha Re\, \|\mathbf{u}_2\|_t^2 \,+\, &\frac{\lambda}{2}\, \|\tau_2\|_t^2 \,+\, \frac{1}{2}\|\tau_2\|^2 + \frac{\alpha(1-\alpha)}{2}\|\nabla \mathbf{u}_2\|^2 \\ &+ \left(\lambda \nu h \,-\, \nu^2 h^2 \left(\frac{1}{2} \,+\, \frac{\alpha}{2(1-\alpha)}\right)\right) \|\mathbf{u}_1 \cdot \nabla \tau_2\|^2 \\ &\le 2\alpha \|\mathbf{f}\|_{-1} \|\mathbf{u}_2\|_1 \,+\, \lambda \|g_a(\tau_1, \nabla \mathbf{u}_1)\| \left(\|\tau_2\| \,+\, \nu h \, \|\mathbf{u}_1 \cdot \nabla \tau_2\|\right) \\ &\le \frac{2(1 + C_{PF}^2)}{(1-\alpha)} \|\mathbf{f}\|_{-1}^2 \,+\, \frac{\alpha^2(1-\alpha)}{2}\|\nabla \mathbf{u}_2\|^2 \,+\, \lambda^2 \|g_a(\tau_1, \nabla \mathbf{u}_1)\|^2 \\ &\quad + \frac{1}{2}\|\tau_2\|^2 \,+\, \frac{\nu^2 h^2}{2}\, \|\mathbf{u}_1 \cdot \nabla \tau_2\|^2. \end{aligned} \tag{4.17}$$

Thus for $c_1 = \min\{\alpha Re,\ \lambda/2\}$ and the restriction $\nu h \le 2\lambda(1-\alpha)/(2-\alpha)$,

$$\frac{d}{dt}\left(\|\mathbf{u}_2\|^2 \,+\, \|\tau_2\|^2\right) \le \frac{2(1 + C_{PF}^2)}{c_1(1-\alpha)}\|\mathbf{f}\|_{-1}^2 \,+\, \frac{\lambda^2}{c_1}\|g_a(\tau_1, \nabla \mathbf{u}_1)\|^2.$$

Hence for $0 \le t \le T$,

$$\begin{aligned} \|\mathbf{u}_2\|^2(t) \,+\, \|\tau_2\|^2(t) \le \|\mathbf{u}_2\|^2(0) \,+\, \|\tau_2\|^2(0) \,+\, &\frac{2(1 + C_{PF}^2)}{c_1(1-\alpha)}\|\mathbf{f}\|_{0,-1}^2 \\ + &\frac{\lambda^2\, \acute{d}^2}{c_1}\|\tau_1\|_{\infty,\infty}^2\, \|\nabla \mathbf{u}_1\|_{0,0}^2. \end{aligned} \tag{4.18}$$

By the equivalence of norm in finite dimensional spaces (and $\mathbf{u}_2(0) = \mathbf{u}_1(0)$, $\tau_2(0) = \tau_1(0)$), we therefore have that $(\mathbf{u}_2,\ \tau_2) \in L^2(0, T; Z_h) \times L^\infty(0, T; S_h)$.

Note that (4.18) also establishes that the mapping ξ is bounded on bounded sets.

Step 3. *Existence of an invariant ball for ξ.* We begin by defining an invariant ball. Let $R = c^* h^{\min\{k,m,q+1\}}$ for $0 < c^* < 1$, and define the ball B_h as

$$\begin{aligned} B_h := \Bigg\{ &(\mathbf{v}, \sigma) \in L^2(0, T; Z_h) \times L^\infty(0, T; S_h) \ : \\ &\int_0^T \|\mathbf{u} - \mathbf{v}\|^2 + \|\nabla(\mathbf{u} - \mathbf{v})\|^2 \, dt \le R^2, \sup_{0 \le t \le T} \|\tau - \sigma\| \le R \Bigg\}. \end{aligned} \tag{4.19}$$

The exact solution $(\mathbf{u}, p, \tau)$ of (2.9)–(2.11) satisfies

$$\begin{aligned} &2\alpha Re\,(\mathbf{u}_t, \mathbf{v}) + 2\alpha Re\, \tilde{c}(\mathbf{u}, \mathbf{u}, \mathbf{v}) \,+\, A(\mathbf{u}_1, (\mathbf{u}, \tau), (\mathbf{v}, \sigma)) \,+\, \lambda\, (\tau_t, \sigma) \,+\, \lambda\, B(\mathbf{u}, \mathbf{u}_1, \tau, \sigma) \\ &\qquad = 2\alpha(p, \nabla \cdot \mathbf{v}) \,+\, 2\alpha(\mathbf{f}, \mathbf{v}) - \lambda(g_a(\tau, \nabla \mathbf{u}), \sigma_{u_1}) \ \ \forall\ (\mathbf{v}, \sigma) \in Z \times S. \end{aligned} \tag{4.20}$$

Subtracting (4.16) from (4.20) implies that

$$\begin{aligned}
2\alpha Re\,((\mathbf{u}-\mathbf{u}_2)_t,\mathbf{v}) + 2\alpha Re\,\tilde{c}(\mathbf{u},\mathbf{u},\mathbf{v}) \,-\, 2\alpha Re\,\tilde{c}(\mathbf{u}_1,\mathbf{u}_2,\mathbf{v})& \\
+ A(\mathbf{u}_1,(\mathbf{u}-\mathbf{u}_2,\tau-\tau_2),(\mathbf{v},\sigma))& \\
+\lambda\,((\tau-\tau_2)_t,\sigma) \,+\, \lambda\,B(\mathbf{u}_1,(\tau-\tau_2),\sigma)& \\
= 2\alpha(p,\nabla\cdot\mathbf{v}) \,-\, \lambda\,((g_a(\tau,\nabla\mathbf{u}),\sigma_{u_1}) - (g_a(\tau_1,\nabla\mathbf{u}_1),\sigma_{u_1}))& \\
-\lambda B(\mathbf{u},\mathbf{u}_1,\tau,\sigma) \,+\, \lambda B(\mathbf{u}_1,\tau,\sigma) \;\; \forall\;(\mathbf{v},\sigma)\in Z_h\times S_h.&
\end{aligned}\tag{4.21}$$

Let

$$\Lambda := \mathbf{u}-\mathcal{U}, \qquad E := \mathcal{U}-\mathbf{u}_2, \tag{4.22}$$

$$\Gamma := \tau-\mathcal{T}, \qquad F := \mathcal{T}-\tau_2, \tag{4.23}$$

$$\text{and}\quad \epsilon_{\mathbf{u}} := \Lambda + E \,=\, \mathbf{u}-\mathbf{u}_2, \qquad \epsilon_\tau := \Gamma + F \,=\, \tau-\tau_2. \tag{4.24}$$

Rewriting (4.21) using these definitions, along with the choice $\sigma = F$, $\mathbf{v} = E$, we obtain

$$\begin{aligned}
2\alpha Re\,(E_t,E) + 2\alpha Re\,\tilde{c}(\mathbf{u},\mathbf{u},E) \,-\, 2\alpha Re\,\tilde{c}(\mathbf{u}_1,\mathbf{u}_2,E) \,+\, A(\mathbf{u}_1,(E,F),(E,F))& \\
+\,\lambda\,(F_t,F) \,+\, \lambda\,B(\mathbf{u}_1,F,F)& \\
= -2\alpha Re\,(\Lambda_t,E) \,-\, A(\mathbf{u}_1,(\Lambda,\Gamma),(E,F)) \,-\, \lambda\,(\Gamma_t,F) \,-\, \lambda\,B(\mathbf{u}_1,\Gamma,F)& \\
+\,2\alpha(p,\nabla\cdot E) \,-\, \lambda\,((g_a(\tau,\nabla\mathbf{u}),F_{u_1}) - (g_a(\tau_1,\nabla\mathbf{u}_1),F_{u_1}))& \\
-\lambda B(\mathbf{u},\mathbf{u}_1,\tau,F) \,+\, \lambda B(\mathbf{u}_1,\tau,F).&
\end{aligned}\tag{4.25}$$

We now proceed to bound E in terms of F, $\mathbf{u}$, and $\mathbf{u}_1$. For the $\tilde{c}$ terms we have

$$\begin{aligned}
\tilde{c}(\mathbf{u},\mathbf{u},E) \,-\, \tilde{c}(\mathbf{u}_1,\mathbf{u}_2,E) &= \tilde{c}(\mathbf{u}-\mathbf{u}_1,\mathbf{u},E) \,+\, \tilde{c}(\mathbf{u}_1,\mathbf{u}-\mathbf{u}_2,E) \\
&= \tilde{c}(\mathbf{u}-\mathbf{u}_1,\mathbf{u},E) \,+\, \tilde{c}(\mathbf{u}_1,E+\Lambda,E) \\
&= \tilde{c}(\mathbf{u}-\mathbf{u}_1,\mathbf{u},E) \,+\, \tilde{c}(\mathbf{u}_1,\Lambda,E) \quad \text{(using (4))}.
\end{aligned}\tag{4.26}$$

We estimate the first term on the right-hand side (rhs) of (4.26) by

$$\begin{aligned}
|\tilde{c}(\mathbf{u}-\mathbf{u}_1,\mathbf{u},E)| &\le C_1\,\|\mathbf{u}-\mathbf{u}_1\|^{1/2}\|\nabla(\mathbf{u}-\mathbf{u}_1)\|^{1/2}\|\nabla\mathbf{u}\|\|\nabla E\| \;\; \text{(using (4.5))} \\
&\le \epsilon_1\|\nabla E\|^2 \,+\, \frac{C_1^2}{4\epsilon_1}\|\mathbf{u}-\mathbf{u}_1\|\|\nabla(\mathbf{u}-\mathbf{u}_1)\|\|\nabla\mathbf{u}\|^2.
\end{aligned}\tag{4.27}$$

For the second term on the rhs of (4.26),

$$\begin{aligned}
|\tilde{c}(\mathbf{u}_1,\Lambda,E)| &\le |-\tilde{c}((\mathbf{u}-\mathbf{u}_1),\Lambda,E)| \,+\, |\tilde{c}(\mathbf{u},\Lambda,E)| \\
&\le C_1\,\|\mathbf{u}-\mathbf{u}_1\|^{1/2}\|\nabla(\mathbf{u}-\mathbf{u}_1)\|^{1/2}\|\nabla\Lambda\|\|\nabla E\| \,+\, C_2\|\mathbf{u}\|_\infty\|\nabla\Lambda\|\|\nabla E\| \\
&\le \epsilon_3\|\nabla E\|^2 \,+\, \frac{C_1^2}{4\epsilon_3}\|\mathbf{u}-\mathbf{u}_1\|_1^2\|\nabla\Lambda\|^2 \,+\, \epsilon_4\|\nabla E\|^2 \,+\, \frac{C_2^2}{4\epsilon_4}\|\mathbf{u}\|_\infty^2\|\nabla\Lambda\|^2.
\end{aligned}\tag{4.28}$$

In view of the estimates (4.8) and (4.6), we proceed next to consider the terms on the rhs of (4.25):

$$(\Lambda_t,E) \le \|\Lambda_t\|\|E\| \;\le\; \epsilon_5\|\nabla E\|^2 \,+\, \frac{C_{PF}^2}{4\epsilon_5}\|\Lambda_t\|^2, \tag{4.29}$$

$$(\Gamma_t,F) \le \|\Gamma_t\|\|F\| \;\le\; \epsilon_6\|F\|^2 \,+\, \frac{1}{4\epsilon_6}\|\Gamma_t\|^2. \tag{4.30}$$

For the pressure term we have

$$\begin{aligned}2\alpha\,|(p,\nabla\cdot E)| \;=\; 2\alpha\,|((p-\mathcal{P}),\nabla\cdot E)| &\leq 2\alpha\,\|p-\mathcal{P}\|\|\nabla\cdot E\| \\ &\leq 2\alpha\acute{d}^{1/2}\,\|p-\mathcal{P}\|\|\nabla E\| \\ &\leq \frac{\alpha^2\acute{d}}{\epsilon_7}\,\|p-\mathcal{P}\|^2 \,+\, \epsilon_7\|\nabla E\|^2.\end{aligned}\tag{4.31}$$

Writing out the A term on the rhs of (4.25), we have the terms

$$A(\mathbf{u}_1,(\Lambda,\Gamma),(E,F)) \;=\; (\Gamma,F_{u_1})-2\alpha(D(\Lambda),F_{u_1})+2\alpha(\Gamma,D(E))+\alpha(1-\alpha)(\nabla\Lambda,\nabla E).\tag{4.32}$$

For the first term in A we obtain

$$\begin{aligned}(\Gamma,F_{u_1}) &= (\Gamma,F) \,+\, (\Gamma,\nu h\,\mathbf{u}_1\cdot\nabla F) \\ &= \|\Gamma\|\,\|F\| \,+\, \|\Gamma\|\,\nu h\,\|\mathbf{u}_1\cdot\nabla F\| \\ &= \epsilon_8\|F\|^2 \,+\, \frac{1}{4\epsilon_8}\|\Gamma\|^2 \,+\, \nu^2h^2\,\|\mathbf{u}_1\cdot\nabla F\|^2 \,+\, \frac{1}{4}\|\Gamma\|^2.\end{aligned}\tag{4.33}$$

Similarly,

$$2\alpha\,(D(\Lambda),F_{u_1}) \leq \epsilon_9\|F\|^2 \,+\, \frac{\alpha^2}{\epsilon_9}\|D(\Lambda)\|^2 \,+\, \nu^2h^2\,\|\mathbf{u}_1\cdot\nabla F\|^2 \,+\, \alpha^2\|D(\Lambda)\|^2,\tag{4.34}$$

$$2\alpha\,(\Gamma,D(E)) \leq \epsilon_{10}\|\nabla E\|^2 \,+\, \frac{\alpha^2}{4\epsilon_{10}}\|\Gamma\|^2,\tag{4.35}$$

$$\alpha(1-\alpha)\,(\nabla\Gamma,\nabla E) \leq \epsilon_{11}\|\nabla E\|^2 \,+\, \frac{\alpha^2(1-\alpha)^2}{4\epsilon_{11}}\|\nabla\Gamma\|^2.\tag{4.36}$$

Bounding the $g_a(\cdot,\cdot)$ terms on the rhs of (4.25) is more involved. We rewrite the difference as the sum of three terms and then bound each of the terms individually.

We have that

$$\begin{aligned}(g_a(\tau,\nabla\mathbf{u})-g_a(\tau_1,\nabla\mathbf{u}_1),F_{u_1}) &= (g_a(\tau-\tau_1,\nabla\mathbf{u}),\,F_{u_1})+(g_a(\tau_1,\nabla(\mathbf{u}-\mathbf{u}_1)),F_{u_1}) \\ &= (g_a(\tau-\tau_1,\nabla\mathbf{u}),F_{u_1})+(g_a(\tau_1-\tau,\nabla(\mathbf{u}-\mathbf{u}_1)),F_{u_1}) \\ &\quad+\,(g_a(\tau,\nabla(\mathbf{u}-\mathbf{u}_1)),F_{u_1})\,.\end{aligned}\tag{4.37}$$

For the first term on the rhs of (4.37) we have

$$\begin{aligned}(g_a(\tau-\tau_1,\nabla\mathbf{u}),F_{u_1}) &\leq 4\|(\tau-\tau_1)\nabla\mathbf{u}\|\|F\|+4\|(\tau-\tau_1)\nabla\mathbf{u}\|\|\nu h\mathbf{u}_1\cdot\nabla F\| \\ &\leq 4\acute{d}\|\nabla\mathbf{u}\|_\infty\|(\tau-\tau_1)\|\|F\|+4\acute{d}\|\nabla\mathbf{u}\|_\infty\|(\tau-\tau_1)\|\|\nu h\mathbf{u}_1\cdot\nabla F\| \\ &\leq \epsilon_{12}\|F\|^2+\frac{4\acute{d}^2}{\epsilon_{12}}\|\nabla\mathbf{u}\|_\infty^2\|(\tau-\tau_1)\|^2+\nu^2h^2\|\nu h\mathbf{u}_1\cdot\nabla F\|^2 \\ &\quad+4\acute{d}^2\|\nabla\mathbf{u}\|_\infty^2\|(\tau-\tau_1)\|^2.\end{aligned}\tag{4.38}$$

For the second term we have

$$\begin{aligned}(g_a(\tau-\tau_1,\nabla(\mathbf{u}\,-\,\mathbf{u}_1)),F_{u_1}) &\leq 4\|(\tau-\tau_1)\nabla(\mathbf{u}-\mathbf{u}_1)\|\|F\| \\ &\quad+4\|(\tau-\tau_1)\nabla(\mathbf{u}-\mathbf{u}_1)\|\|\nu h\mathbf{u}_1\cdot\nabla F\| \\ &\leq \epsilon_{13}\|F\|^2+\frac{4}{\epsilon_{13}}\|(\tau-\tau_1)\nabla(\mathbf{u}-\mathbf{u}_1)\|^2+\nu^2h^2\|\nu h\mathbf{u}_1\cdot\nabla F\|^2 \\ &\quad+4\|(\tau-\tau_1)\nabla(\mathbf{u}-\mathbf{u}_1)\|^2.\end{aligned}\tag{4.39}$$

Note that

$$\|(\tau - \tau_1)\,\nabla(\mathbf{u} - \mathbf{u}_1)\| \le \|(\tau - \tau_1)\|_{L^4}\,\|\nabla(\mathbf{u} - \mathbf{u}_1)\|_{L^4},$$

and, using (3.7),

$$\begin{aligned}\|\tau_1 - \mathcal{T}\|_{L^4} &\le C_I h^{-\acute{d}/4}\|\tau_1 - \mathcal{T}\|\\ &\le C_I h^{-\acute{d}/4}\|\tau_1 - \tau\| \,+\, C_I h^{-\acute{d}/4}\|\tau - \mathcal{T}\|.\end{aligned}$$

Thus,

$$\begin{aligned}\|\tau - \tau_1\|_{L^4} &\le \|\tau - \mathcal{T}\|_{L^4} \,+\, \|\mathcal{T} - \tau_1\|_{L^4}\\ &\le \|\tau - \mathcal{T}\|_{L^4} \,+\, Ch^{-\acute{d}/4}\|\tau_1 - \tau\| \,+\, Ch^{-\acute{d}/4}\|\tau - \mathcal{T}\|\\ &\le 2C_I h^{m+1-\acute{d}/4}\|\tau\|_{m+1} \,+\, C_I h^{-\acute{d}/4}\|\tau_1 - \tau\|. \end{aligned}\tag{4.40}$$

Similarly,

$$\begin{aligned}\|\nabla(\mathbf{u} - \mathbf{u}_1)\|_{L^4} &\le \|\nabla(\mathbf{u} - \mathcal{U})\|_{L^4} \,+\, Ch^{-\acute{d}/4}\|\mathbf{u} - \mathbf{u}_1\|_1 \,+\, Ch^{-\acute{d}/4}\|\mathbf{u} - \mathcal{U}\|_1\\ &\le 2C_I h^{k-\acute{d}/4}\|\mathbf{u}\|_{k+1} \,+\, C_I h^{-\acute{d}/4}\|\mathbf{u} - \mathbf{u}_1\|_1. \end{aligned}\tag{4.41}$$

Combining (4.40), (4.41) with (4.39) yields

$$\begin{aligned}|(g_a(\tau - \tau_1, \nabla(\mathbf{u} - \mathbf{u}_1)), F_{u_1})| &\le \epsilon_{13}\|F\|^2 + \nu^2 h^2\|\mathbf{u}_1 \cdot \nabla F\|^2\\ &\quad + \left(\frac{4}{\epsilon_{13}} + 4\right)\left(2C_I h^{m+1-\acute{d}/4}\|\tau\|_{m+1} + C_I h^{-\acute{d}/4}\|\tau_1 - \tau\|\right)^2\\ &\quad \times \left(2C_I h^{k-\acute{d}/4}\|\mathbf{u}\|_{k+1} + C_I h^{-\acute{d}/4}\|\mathbf{u} - \mathbf{u}_1\|_1\right)^2. \end{aligned}\tag{4.42}$$

For the third $g_a(\cdot,\cdot)$ terms on the rhs of (4.37) we have

$$\begin{aligned}|(g_a(\tau, \nabla(\mathbf{u} - \mathbf{u}_1)),\, F_{u_1})| &\le 4\|\tau\,\nabla(\mathbf{u} - \mathbf{u}_1)\|\,\|F\| \;+\; 4\|\tau\,\nabla(\mathbf{u} - \mathbf{u}_1)\|\;\|\nu h\,\mathbf{u}_1 \cdot \nabla F\|\\ &\le 4\acute{d}\,\|\tau\|_\infty\|\nabla(\mathbf{u} - \mathbf{u}_1)\|\,\|F\| \,+\, 4\acute{d}\,\|\tau\|_\infty\|\nabla(\mathbf{u} - \mathbf{u}_1)\|\,\|\nu h\,\mathbf{u}_1 \cdot \nabla F\|\\ &\le \epsilon_{14}\|F\| \,+\, \frac{4\acute{d}^2}{\epsilon_{14}}\|\tau\|_\infty^2\|\nabla(\mathbf{u} - \mathbf{u}_1)\|^2 \,+\, \nu^2 h^2\,\|\mathbf{u}_1 \cdot \nabla F\|^2\\ &\qquad + 4\acute{d}^2\|\tau\|_\infty^2\|\nabla(\mathbf{u} - \mathbf{u}_1)\|^2. \end{aligned}\tag{4.43}$$

What remains is to estimate the three B terms on the rhs of (4.25). We begin by rewriting the terms in a more convenient form:

$$\begin{aligned}-B(\mathbf{u}_1, \Gamma, F\,) \,-\, B(\mathbf{u}, \mathbf{u}_1, \tau, F) \,+\, B(\mathbf{u}_1, \tau, F) &= B(\mathbf{u}_1, \mathcal{T}, F) \,-\, B(\mathbf{u}, \mathbf{u}_1, \tau, F)\\ &= -B(\mathbf{u} - \mathbf{u}_1, \mathbf{u}_1, \mathcal{T}, F) \,-\, B(\mathbf{u}, \mathbf{u}_1, \Gamma, F)\\ &= B(\mathbf{u} - \mathbf{u}_1, \mathbf{u}_1, \Gamma, F) \,-\, B(\mathbf{u} - \mathbf{u}_1, \mathbf{u}_1, \tau, F)\\ &\qquad - B(\mathbf{u}, \mathbf{u}_1, \Gamma, F). \end{aligned}\tag{4.44}$$

For the first B term in (4.44) we have

$$\begin{aligned}B(\mathbf{u} - \mathbf{u}_1, \mathbf{u}_1, \Gamma, F) &= ((\mathbf{u} - \mathbf{u}_1) \cdot \nabla\Gamma, F) \,+\, ((\mathbf{u} - \mathbf{u}_1) \cdot \nabla\Gamma, \nu h\,\mathbf{u}_1 \cdot \nabla F)\\ &\quad + \frac{1}{2}\,(\nabla \cdot (\mathbf{u} - \mathbf{u}_1)\,\Gamma, F)\end{aligned}$$

$$\begin{aligned}
&\le \|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\Gamma\|\|F\| + \|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\Gamma\|\|\nu h\,\mathbf{u}_1\cdot\nabla F\| \\
&\quad + \frac{1}{2}\|\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\,\Gamma\|\|F\| \\
&\le \epsilon_{15}\|F\|^2 + \left(\frac{1}{4\epsilon_{15}} + \frac{1}{4}\right)\|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\Gamma\|^2 + \nu^2h^2\|\mathbf{u}_1\cdot\nabla F\|^2 \\
&\quad + \epsilon_{16}\|F\|^2 + \frac{1}{16\epsilon_{16}}\|\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\Gamma\|^2.
\end{aligned}\tag{4.45}$$

For I_u the interpolant of $\mathbf{u}$ we have, using (3.7), (3.8),

$$\begin{aligned}
\|\mathbf{u}-\mathbf{u}_1\|_\infty &\le \|\mathbf{u}-I_u\|_\infty + \|I_u-\mathbf{u}_1\|_\infty \\
&\le C_n h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} + C_v h^{-\acute{d}/2}\|I_u-\mathbf{u}_1\| \\
&\le C_n h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} + C_v h^{-\acute{d}/2}\|I_u-\mathbf{u}\| + C_v h^{-\acute{d}/2}\|\mathbf{u}-\mathbf{u}_1\| \\
&\le C_{nv} h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} + C_v h^{-\acute{d}/2}\|\mathbf{u}-\mathbf{u}_1\|.
\end{aligned}\tag{4.46}$$

Using this estimate, we obtain that

$$\begin{aligned}
\|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\Gamma\| &\le \acute{d}\|\mathbf{u}-\mathbf{u}_1\|_\infty\|\nabla\Gamma\| \\
&\le \acute{d}\,(C_{nv}h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} + C_v h^{-\acute{d}/2}\|\mathbf{u}-\mathbf{u}_1\|)\|\nabla\Gamma\|.
\end{aligned}\tag{4.47}$$

Also,

$$\begin{aligned}
\|\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\,\Gamma\| &\le \acute{d}^{3/2}\|\nabla(\mathbf{u}-\mathbf{u}_1)\|\|\Gamma\|_\infty \\
&\le C_{vi}\acute{d}^{3/2}h^{m+1-\acute{d}/2}\,\|\mathbf{u}-\mathbf{u}_1\|_1\|\tau\|_{m+1}.
\end{aligned}\tag{4.48}$$

Combining (4.45), (4.47), and (4.48), we have

$$\begin{aligned}
B(\mathbf{u}-\mathbf{u}_1,\mathbf{u}_1,\Gamma,F) &\le (\epsilon_{15}+\epsilon_{16})\|F\|^2 + \nu^2h^2\|\mathbf{u}_1\cdot\nabla F\|^2 \\
&\quad + \left(\frac{1}{4\epsilon_{15}}+\frac{1}{4}\right)\acute{d}^2\,(C_{nv}h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} + C_v h^{-\acute{d}/2}\|\mathbf{u}-\mathbf{u}_1\|)^2\|\nabla\Gamma\|^2 \\
&\quad + \frac{1}{16\epsilon_{16}}(C_{vi}\acute{d}^{3/2}h^{m+1-\acute{d}/2}\,\|\mathbf{u}-\mathbf{u}_1\|_1\|\tau\|_{m+1})^2.
\end{aligned}\tag{4.49}$$

For the second B term on the rhs of (4.44) we have

$$\begin{aligned}
B(\mathbf{u}-\mathbf{u}_1,\mathbf{u}_1,\tau,F) &= ((\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau,F) + ((\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau,\nu h\,\mathbf{u}_1\cdot\nabla F) \\
&\quad + \frac{1}{2}\,(\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\,\tau,F) \\
&\le \|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau\|\,\|F\| + \|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau\|\,\|\nu h\,\mathbf{u}_1\cdot\nabla F\| \\
&\quad + \frac{1}{2}\|\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\,\tau\|\,\|F\| \\
&\le \epsilon_{17}\|F\|^2 + \frac{1}{4\epsilon_{17}}\|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau\|^2 + \nu^2h^2\,\|\mathbf{u}_1\cdot\nabla F\|^2 \\
&\quad + \frac{1}{4}\|(\mathbf{u}-\mathbf{u}_1)\cdot\nabla\tau\|^2 \\
&\quad + \epsilon_{18}\|F\|^2 + \frac{1}{16\epsilon_{18}}\|\nabla\cdot(\mathbf{u}-\mathbf{u}_1)\,\tau\|^2 \\
&\le (\epsilon_{17}+\epsilon_{18})\|F\|^2 + \nu^2h^2\,\|\mathbf{u}_1\cdot\nabla F\|^2 \\
&\quad + \acute{d}^3\left(\frac{1}{4\epsilon_{17}}+\frac{1}{4}\right)\|\nabla\tau\|_\infty^2\|\mathbf{u}-\mathbf{u}_1\|^2 + \frac{\acute{d}^3}{16\epsilon_{18}}\|\tau\|_\infty^2\|\nabla(\mathbf{u}-\mathbf{u}_1)\|^2.
\end{aligned}\tag{4.50}$$

For the third B term on the rhs of (4.44) we have

$$\begin{aligned}
B(\mathbf{u}, \mathbf{u}_1, \Gamma, F) &= (\mathbf{u} \cdot \nabla\Gamma, F) \,+\, (\mathbf{u} \cdot \nabla\Gamma, \nu h\, \mathbf{u}_1 \cdot \nabla F) \,+\, \frac{1}{2}\,(\nabla \cdot \mathbf{u}\,\Gamma, F) \\
&\le \|\mathbf{u} \cdot \nabla\Gamma\|\,\|F\| \,+\, \|\mathbf{u} \cdot \nabla\Gamma\|\,\nu h\,\|\mathbf{u}_1 \cdot \nabla F\| \,+\, \frac{1}{2}\|\nabla \cdot \mathbf{u}\,\Gamma\|\,\|F\| \\
&\le (\epsilon_{19} \,+\, \epsilon_{20})\|F\|^2 \,+\, \nu^2 h^2\,\|\mathbf{u}_1 \cdot \nabla F\|^2 \\
&\quad + \acute{d}\left(\frac{1}{4\epsilon_{19}} + \frac{1}{4}\right)\|\mathbf{u}\|_\infty^2\|\nabla\Gamma\|^2 \,+\, \frac{\acute{d}^2}{16\epsilon_{20}}\|\nabla\mathbf{u}\|_\infty^2\|\Gamma\|^2. \qquad (4.51)
\end{aligned}$$

Returning to (4.25) and putting everything back together, we obtain

$$\begin{aligned}
&\alpha Re\frac{d}{dt}\|E\|^2 + \frac{\lambda}{2}\frac{d}{dt}\|F\|^2 + \frac{1}{2}\|F\|^2 + \frac{\alpha(1-\alpha)}{2}\|\nabla E\|^2 \\
&+ \left(\lambda\nu h - \frac{1}{2}\nu^2h^2 - \frac{\alpha\nu^2h^2}{2(1-\alpha)}\right)\|\mathbf{u}_1 \cdot \nabla F\|^2 - 2\alpha(\epsilon_1 + \epsilon_3 + \epsilon_4)\|\nabla E\|^2 \\
&- 2\alpha\frac{C_1^2}{4\epsilon_1}\|\nabla\mathbf{u}\|^2\|\mathbf{u} - \mathbf{u}_1\|_1^2 - 2\alpha\frac{C_1^2}{4\epsilon_3}\|\mathbf{u} - \mathbf{u}_1\|_1^2\|\nabla\Lambda\|^2 - 2\alpha\frac{C_2^2}{4\epsilon_4}\|\mathbf{u}\|_\infty^2\|\nabla\Lambda\|^2 \\
&\le 2\alpha Re\,\frac{C_{PF}^2}{4\epsilon_5}\|\Lambda_t\|^2 + 2\alpha\epsilon_5\|\nabla E\|^2 + \frac{1}{4\epsilon_6}\|\Gamma\|^2 + \epsilon_6\|F\|^2 \\
&+ \epsilon_8\|F\|^2 \,+\, \frac{1}{4\epsilon_8}\|\Gamma\|^2 \,+\, \frac{1}{4}\|\Gamma\|^2 \,+\, \nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \\
&+ \frac{1}{4}\|\Gamma\|^2 \,+\, \nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \,+\, \frac{\alpha^2}{2\epsilon_9}\|\nabla\Lambda\|^2 \,+\, \epsilon_9\|F\|^2 \,+\, \frac{\alpha^2}{2}\|\nabla\Lambda\|^2 \\
&+ \nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \,+\, \frac{\alpha^2}{4\epsilon_{10}}\|\Gamma\|^2 \,+\, \epsilon_{10}\|\nabla E\|^2 \,+\, \frac{\alpha^2(1-\alpha)^2}{4\epsilon_{11}}\|\nabla\Gamma\|^2 \\
&+ \epsilon_{11}\|\nabla E\|^2 + \frac{\lambda}{4\epsilon_6}\|\Gamma_t\|^2 \,+\, \lambda\epsilon_6\|F\|^2 \,+ +\, \frac{\alpha^2}{\epsilon_7}\acute{d}\|p - \mathcal{P}\|^2 \,+\, \epsilon_7\|\nabla E\|^2 \\
&+ \lambda\frac{4\acute{d}^2}{\epsilon_{12}}\|\nabla\mathbf{u}\|_\infty^2\|\tau - \tau_1\|^2 \,+\, \lambda 4\acute{d}^2\,\|\nabla\mathbf{u}\|_\infty^2\|\tau - \tau_1\|^2 \,+\, \lambda\epsilon_{12}\|F\|^2 \\
&+ \lambda\nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \\
&+ \lambda\left(\frac{4}{\epsilon_{13}} + 4\right)\left(2C_I h^{m+1-\acute{d}/4}\|\tau\|_{m+1} \,+\, C_I h^{-\acute{d}/4}\|\tau_1 - \tau\|\right)^2 \\
&\quad \times\left(2C_I h^{k-\acute{d}/4}\|\mathbf{u}\|_{k+1} \,+\, C_I h^{-\acute{d}/4}\|\mathbf{u} - \mathbf{u}_1\|_1\right)^2 \\
&+ \lambda\epsilon_{13}\|F\|^2 \,+\, \lambda\nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \,+\, \lambda 4\acute{d}^2\left(\frac{1}{\epsilon_{14}} + 1\right)\|\tau\|_\infty^2\|\mathbf{u} - \mathbf{u}_1\|^2 \\
&+ \lambda\epsilon_{14}\|F\|^2 + \lambda\nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 \\
&+ \lambda\left(\frac{1}{4\epsilon_{15}} + \frac{1}{4}\right)\acute{d}^2\,\left(C_{nv}h^{k+1-\acute{d}/2}\|\mathbf{u}\|_{k+1} \,+\, C_v h^{-\acute{d}/2}\|\mathbf{u} - \mathbf{u}_1\|\right)^2\|\nabla\Gamma\|^2 \\
&+ \lambda\frac{1}{16\,\epsilon_{16}}\left(C_{vi}\acute{d}^{3/2}h^{m+1-\acute{d}/2}\,\|\mathbf{u} - \mathbf{u}_1\|_1\|\tau\|_{m+1}\right)^2 + \lambda\,(\epsilon_{15} \,+\, \epsilon_{16})\|F\|^2 \\
&+ \lambda\,\nu^2h^2\|\mathbf{u}_1 \cdot \nabla F\|^2 + \lambda\,(\epsilon_{17} \,+\, \epsilon_{18})\|F\|^2 \,+\, \lambda\,\nu^2h^2\,\|\mathbf{u}_1 \cdot \nabla F\|^2 \\
&+ \lambda\,\acute{d}^3\left(\frac{1}{4\epsilon_{17}} + \frac{1}{4}\right)\|\nabla\tau\|_\infty\,\|\mathbf{u} - \mathbf{u}_1\| \,+\, \lambda\,\frac{\acute{d}^3}{16\epsilon_{18}}\|\tau\|_\infty\|\nabla(\mathbf{u} - \mathbf{u}_1)\|^2 \\
&+ \lambda\,(\epsilon_{19} \,+\, \epsilon_{20})\|F\|^2 \,+\, \lambda\,\nu^2h^2\,\|\mathbf{u}_1 \cdot \nabla F\|^2
\end{aligned}$$

$$+\ \lambda\,\acute{d}\left(\frac{1}{4\epsilon_{19}}+\frac{1}{4}\right)\|\mathbf{u}\|_\infty^2\|\nabla\Gamma\|^2\ +\ \lambda\,\frac{\acute{d}^2}{16\epsilon_{20}}\|\nabla\mathbf{u}\|_\infty^2\|\Gamma\|^2. \tag{4.52}$$

We rewrite (4.52), collecting the terms involving E, ∇E, F, and ∇F on the lhs. The remaining terms are collected on the rhs and grouped as terms "controlled" by the *ball*, terms controlled by *interpolation approximation*, and terms controlled by both the ball and interpolation approximation. The resulting inequality is

$$\begin{aligned}
\alpha Re\,\frac{d}{dt}\|E\|^2 + \frac{\lambda}{2}\frac{d}{dt}\|F\|^2 + \left(\frac{\alpha(1-\alpha)}{2} - 2\alpha(\epsilon_1+\epsilon_3+\epsilon_4+\epsilon_5) - (\epsilon_7+\epsilon_{10}+\epsilon_{11})\right)\|\nabla E\|^2 \\
+ \left(\frac{1}{2} - (\epsilon_6+\epsilon_8+\epsilon_9) - \lambda(\epsilon_6+\epsilon_{12}+\epsilon_{13}+\epsilon_{14}+\epsilon_{15}+\epsilon_{16}+\epsilon_{17}\right. \\
\left. + \epsilon_{18}+\epsilon_{19}+\epsilon_{20})\right)\|F\|^2 \\
+ \left(\lambda\nu h - \nu^2h^2\left(\frac{7}{2} - \frac{\alpha}{2(1-\alpha)} + 6\lambda\right)\right)\|\mathbf{u}_1\cdot\nabla F\|^2 \\
\le \|\mathbf{u}-\mathbf{u}_1\|^2\left\{\lambda 4\acute{d}^2\left(\frac{1}{\epsilon_{14}}+1\right)\|\tau\|_\infty^2 + \lambda\acute{d}^3\left(\frac{1}{4\epsilon_{17}}+\frac{1}{4}\right)\|\nabla\tau\|_\infty^2\right\} \\
+ \|\tau-\tau_1\|^2\left\{\lambda\frac{4\acute{d}^2}{\epsilon_{12}}\|\nabla\mathbf{u}\|_\infty^2\ +\ 4\lambda\acute{d}^2\|\nabla\mathbf{u}\|_\infty^2\right\} \\
+ \|\mathbf{u}-\mathbf{u}_1\|_1^2\left\{2\alpha\frac{C_1^2}{4\epsilon_1}\|\nabla\mathbf{u}\|^2 + \lambda\frac{\acute{d}^3}{16\epsilon_{18}}\|\tau\|_\infty^2\right\} \\
+ \|\mathbf{u}-\mathbf{u}_1\|_1^2\|\tau-\tau_1\|^2\left\{\lambda\left(\frac{4}{\epsilon_{13}}+4\right)C_I^2 4h^{-\acute{d}}\right\} \\
+ \|\Gamma\|^2\left\{\frac{1}{4}+\frac{1}{4\epsilon_6}+\frac{\alpha^2}{4\epsilon_{10}}+\lambda\frac{\acute{d}^2}{16\epsilon_{20}}\|\nabla\mathbf{u}\|_\infty^2\right\}\ +\ \|\Gamma_t\|^2\left\{\frac{\lambda}{4\epsilon_6}\right\} \\
+ \|\nabla\Gamma\|^2\left\{\frac{\alpha^2(1-\alpha)^2}{4\epsilon_{11}}\ +\ 2C_{nv}^2h^{2k+2-\acute{d}}\|\mathbf{u}\|_{k+1}^2\ +\ \lambda\acute{d}\left(\frac{1}{4\epsilon_{19}}+\frac{1}{4}\right)\|\mathbf{u}\|_\infty^2\ \right\} \\
+ \|\Lambda_t\|^2\left\{2\alpha Re\frac{C_{PF}^2}{4\epsilon_5}\right\}\ +\ \|\nabla\Lambda\|^2\left\{2\alpha\frac{C_2^2}{4\epsilon_4}\|\mathbf{u}\|_\infty^2\ +\ \frac{\alpha^2}{2\epsilon_9}\ +\ \frac{\alpha^2}{2}\right\} \\
+ \|p-\mathcal{P}\|^2\left\{\acute{d}\frac{\alpha^2}{\epsilon_7}\right\}\ +\ \lambda\left(\frac{4}{\epsilon_{13}}+4\right)C_I^2 64h^{2m+2k+2-\acute{d}}\|\tau\|_{m+1}^2\|\mathbf{u}\|_{k+1}^2 \\
+ \|\mathbf{u}-\mathbf{u}_1\|^2\left\{2\lambda\left(\frac{1}{4\epsilon_{15}}+\frac{1}{4}\right)\acute{d}^2C_v^2h^{-\acute{d}}\|\nabla\Gamma\|^2\right\} \\
+ \|\mathbf{u}-\mathbf{u}_1\|_1^2\left\{2\alpha\frac{C_1^2}{4\epsilon_3}\|\nabla\Lambda\|^2\right\} \\
+ \|\tau-\tau_1\|^2\left\{\lambda\left(\frac{4}{\epsilon_{13}}+4\right)C_I^2 16h^{2k-\acute{d}}\|\mathbf{u}\|_{k+1}^2\right\} \\
+ \|\mathbf{u}-\mathbf{u}_1\|_1^2\left\{\lambda\left(\frac{4}{\epsilon_{13}}+4\right)C_I^2 16h^{2m+2-\acute{d}}\|\tau\|_{m+1}^2\right. \\
\left. + \frac{1}{16\epsilon_{16}}C_{vi}^2\acute{d}^3h^{2m+2-\acute{d}}\|\tau\|_{m+1}^2\right\}.
\end{aligned} \tag{4.53}$$

With our assumptions that $0 < \alpha < 1$ and $\lambda > 0$, we can choose values for the ϵ_i's, and νh sufficiently small, such that the lhs of (4.53) is bounded below by

$$\alpha Re \frac{d}{dt}\|E\|^2 + \frac{\lambda}{2}\frac{d}{dt}\|F\|^2 + \frac{1}{4}\|F\|^2 + \frac{\alpha(1-\alpha)}{4}\|\nabla E\|^2 + \frac{\lambda \nu h}{2}\|\mathbf{u}_1 \cdot \nabla F\|^2. \tag{4.54}$$

Let D_i, $i = 1, \dots, 6$, denote constants dependent upon $\mathbf{u}$, p, τ, their derivatives, and T. (Recall the definition of c^*, R in (4.19), and D_0 in Theorem 4.4.) As usual, C_j, $j = 4, \dots, 10$, denote constants independent of the solution $\mathbf{u}$, p, τ and the mesh parameter h.

Using (4.54) and integrating (4.53), we obtain

$$\begin{aligned} \|E\|^2(t) \ + \ \|F\|^2(t) \ + \ \int_0^t \|\nabla E\|^2(s)\, ds \le {} & R^2 C_4 D_0 \\ & + R^4 C_5 h^{-\acute{d}} \\ & + D_1 h^{2m+2} \ + \ D_2 h^{2m+2} \\ & + C_6 D_0 h^{2m} \ + \ D_3 h^{2k+2m+2-\acute{d}} \\ & + D_4 h^{2k+2} \ + \ C_7 D_0 h^{2k} \\ & + C_8 D_0 h^{2q+2} \ + \ D_5 h^{2k+2m+2-\acute{d}} \\ & + R^2 C_9 D_0 h^{2m-\acute{d}} \\ & + R^2 D_6 h^{2k} \\ & + R^2 C_6 D_0 h^{2k-\acute{d}} \\ & + R^2 C_7 D_0 h^{2m+2-\acute{d}}. \end{aligned} \tag{4.55}$$

Now, in view of (4.24), we have that for h, D_0, and c^* sufficiently small

$$\begin{aligned} \|\tau - \tau_2\|^2(t) &\le 2\|F\|^2(t) \ + \ 2\|\Gamma\|^2(t) \\ &\le cR^2 + C_{10} D_0 \left(h^{2m} + h^{2k}\right) + 2D_0 h^{2m+2} \\ &\le \tilde{c} R^2, \end{aligned} \tag{4.56}$$

where $0 < \tilde{c} < 1$. Similarly, for h sufficiently small

$$\begin{aligned} \|\mathbf{u} - \mathbf{u}_2\|^2(t) &\le 2\|E\|^2(t) \ + \ 2\|\Lambda\|^2(t) \\ &\le cR^2 + C_{10} D_0 \left(h^{2m} + h^{2k}\right) + 2D_0 h^{2k+2}; \end{aligned} \tag{4.57}$$

hence

$$\int_0^T \|\mathbf{u} - \mathbf{u}_2\|^2(t)\, dt \le \frac{\tilde{c}}{2} R^2. \tag{4.58}$$

Also, for h sufficiently small

$$\begin{aligned} \int_0^T \|\nabla(\mathbf{u} - \mathbf{u}_2)\|^2(t)\, dt &\le 2\int_0^T \|\nabla E\|^2(t)\, dt \ + \ 2\int_0^T \|\nabla \Lambda\|^2(t)\, dt \\ &\le c1 R^2 \ + \ 2D_0 T h^{2k} \\ &\le \frac{\tilde{c}}{2} R^2. \end{aligned} \tag{4.59}$$

Combining (4.56)–(4.59), we have for h sufficiently small that ξ is a strict contraction on the *ball* defined in (4.19).

Step 4. A direct application of Schauder's fixed point theorem now establishes the uniqueness of the approximation and the stated error estimates. □

5. Fully discrete approximation. In this section we analyze a fully discrete approximation to (2.14), (2.15).

We assume that the fluid flow satisfies the following properties:

$$\|\mathbf{u}\|_\infty,\ \|\tau\|_\infty,\ \|\nabla\mathbf{u}\|_\infty,\ \|\nabla\tau\|_\infty\ \le M \tag{5.1}$$

for all $t \in [0, T]$.

Note that it follows from (5.1) and inverse estimates that

$$\|\mathcal{U}^n\|_\infty, \|\nabla\mathcal{U}^n\|_\infty \le \tilde{M} \approx M. \tag{5.2}$$

Below, for simplicity, we take $\tilde{M} = M$.

To simplify the notation, the following definition is used in the analysis.

Definition 5.1.

$$b(\mathbf{u}, \tau, \psi)\ :=\ (\mathbf{u}\cdot\nabla\tau, \psi). \tag{5.3}$$

To obtain the fully discretized approximation, the time derivatives are replaced by backward differences, and the nonlinear terms are lagged. As we are assuming "slow flow," i.e., $Re \equiv O(1)$, we use a conforming FE method to discretize the momentum equation. For the constitutive equation for stress, we use a SUPG discretization to control the production of spurious oscillations in the approximation. The discrete approximating system of equations is then the following.

Approximating system. For $n = 1, 2, \ldots, N$, find $\mathbf{u}_h^n \in Z_h, \tau_\mathbf{h}^\mathbf{n} \in S_h$ such that

$$Re\,(d_t\mathbf{u}_h^n, \mathbf{v}) + Re\ c\left(\mathbf{u}_h^{n-1}, \mathbf{u}_h^n, \mathbf{v}\right) + (1-\alpha)\,(\nabla\mathbf{u}_h^n, \nabla\mathbf{v}) + (\tau_h^n, D(\mathbf{v})) = (\mathbf{f}^n, \mathbf{v})\,, \qquad \mathbf{v} \in Z_h, \tag{5.4}$$

$$\frac{1}{\lambda}\,(\tau_h^n, \tilde{\sigma}) + (d_t\tau_h^n, \sigma) + b\left(\mathbf{u}_h^{n-1}, \tau_h^n, \tilde{\sigma}\right) - \overline{\lambda}\,(D(\mathbf{u}_h^n), \tilde{\sigma}) = -\left(g_a(\tau_h^{n-1}, \nabla\mathbf{u}_h^{n-1}), \tilde{\sigma}\right), \qquad \sigma \in S_h, \tag{5.5}$$

where $\tilde{\sigma} := \sigma + \nu\sigma_u^n$, $\sigma_u^n := \mathbf{u}_h^{n-1}\cdot\nabla\sigma$, ν is a small positive constant, and $\overline{\lambda} := (2\alpha)/\lambda$.

The parameter $\nu > 0$ is used to suppress the production of spurious oscillations in the approximation. Note that for $\nu = 0$ the discretization of the constitutive equation is a conforming Galerkin method. The goal in choosing ν is to keep it as small as possible, but large enough to control the generation of catastrophic spurious oscillations in the approximate stress.

To ensure computability of the algorithm, we begin by showing that (5.4)–(5.5) is uniquely solvable for $\mathbf{u}_h$ and τ_h at each time step n. We use the following induction hypothesis:

$$\left\|\mathbf{u}_h^{n-1}\right\|_\infty, \left\|\tau_h^{n-1}\right\|_\infty \le K. \tag{IH1}$$

Lemma 5.2. *Assume* (IH1) *is true. For sufficiently small step size Δt, there exists a unique solution $(\mathbf{u}_h^n, \tau_h^n) \in Z_h \times S_h$ satisfying* (5.4)–(5.5).

Proof. For notational simplicity, in this proof we drop the subscript h from the variables. Choosing $\mathbf{v} = \mathbf{u}_h^n,\ \sigma = \tau_h^n$, multiplying (5.4) by $\overline{\lambda}$, and adding to (5.5), we obtain

$$\begin{aligned} &a(\mathbf{u}^n, \tau^n; \mathbf{u}^n, \tau^n) \\ &\quad = \overline{\lambda}\,(\mathbf{f}^n, \mathbf{u}^n) + \overline{\lambda}\frac{Re}{\Delta t}\left(\mathbf{u}^{n-1}, \mathbf{u}^n\right) - \left(g_a\left(\tau^{n-1}, \nabla\mathbf{u}^{n-1}\right), \tilde{\tau}^n\right) + \frac{1}{\Delta t}\left(\tau^{n-1}, \tau^n\right), \end{aligned} \tag{5.6}$$

where the bilinear form $a(\mathbf{u},\tau;\mathbf{v},\sigma)$ is defined as

$$\begin{aligned}
&a(\mathbf{u},\tau;\mathbf{v},\sigma)\\
&\quad := \overline{\lambda}\frac{Re}{\Delta t}\,(\mathbf{u},\mathbf{v}) + \overline{\lambda}\;Re\;c(\mathbf{u}^{n-1},\mathbf{u},\mathbf{v}) + \overline{\lambda}(1-\alpha)\,(\nabla\mathbf{u},\nabla\mathbf{v}) + \frac{1}{\lambda}\,(\tau,\tilde{\sigma}) + \frac{1}{\Delta t}\,(\tau,\sigma)\\
&\qquad + b\left(\mathbf{u}^{n-1},\tau,\sigma\right) + b\left(\mathbf{u}^{n-1},\tau,\nu\mathbf{u}^{n-1}\cdot\nabla\sigma\right) - \overline{\lambda}\left(D(\mathbf{u}),\nu\mathbf{u}^{n-1}\cdot\nabla\sigma\right).
\end{aligned}$$

We now estimate the terms in $a(\mathbf{u}^n,\tau^n;\mathbf{u}^n,\tau^n)$. We have

$$\begin{aligned}
\left|c(\mathbf{u}^{n-1},\mathbf{u},\mathbf{u})\right| = \left|\left(\mathbf{u}^{n-1}\cdot\nabla\mathbf{u},\mathbf{u}\right)\right| &\le \acute{d}^{\frac{1}{2}}\left\|\mathbf{u}^{n-1}\right\|_\infty\|\nabla\mathbf{u}\|\,\|\mathbf{u}\|\\
&\le \epsilon_1\|\nabla\mathbf{u}\|^2 + \frac{\acute{d}K^2}{4\epsilon_1}\|\mathbf{u}\|^2,\\
\left|b(\mathbf{u}^{n-1},\tau,\tau)\right| = \left|\left(\mathbf{u}^{n-1}\cdot\nabla\tau,\tau\right)\right| &\le \left\|\mathbf{u}^{n-1}\cdot\nabla\tau\right\|\|\tau\|\\
&\le \epsilon_2\left\|\mathbf{u}^{n-1}\cdot\nabla\tau\right\|^2 + \frac{1}{4\epsilon_2}\|\tau\|^2,\\
b(\mathbf{u}^{n-1},\tau,\nu\mathbf{u}^{n-1}\cdot\nabla\tau) &= \nu\left\|\mathbf{u}^{n-1}\cdot\nabla\tau\right\|^2,\\
\left|\left(D(\mathbf{u}),\nu\mathbf{u}^{n-1}\cdot\nabla\tau\right)\right| &\le \|D(\mathbf{u})\|\left\|\nu\mathbf{u}^{n-1}\cdot\nabla\tau\right\|\\
&\le \epsilon_3\|D(\mathbf{u})\|^2 + \frac{\nu^2}{4\epsilon_3}\left\|\mathbf{u}^{n-1}\cdot\nabla\tau\right\|^2\\
&\le \epsilon_3\|\nabla\mathbf{u}\|^2 + \frac{\nu^2}{4\epsilon_3}\left\|\mathbf{u}^{n-1}\cdot\nabla\tau\right\|^2.
\end{aligned}$$

Applying these inequalities to the bilinear form $a(\cdot,\cdot;\cdot,\cdot)$ yields

$$\begin{aligned}
a(\mathbf{u}^n,\tau^n;\mathbf{u}^n,\tau^n) \ge{}& \overline{\lambda}\;Re\left(\frac{1}{\Delta t} - \frac{\acute{d}K^2}{4\epsilon_1}\right)\|\mathbf{u}^n\|^2 + \overline{\lambda}\left((1-\alpha) - Re\;\epsilon_1 - \epsilon_3\right)\|\nabla\mathbf{u}\|^2\\
&+\left(\frac{1}{\lambda} + \frac{1}{\Delta t} - \frac{1}{4\epsilon_2}\right)\|\tau^n\|^2 + \left(\nu - \epsilon_2 - \frac{\nu^2}{4\epsilon_3}\right)\left\|\mathbf{u}^{n-1}\cdot\nabla\tau^n\right\|^2.
\end{aligned}$$

Choosing $\epsilon_1 = \frac{(1-\alpha)}{4\,Re}, \epsilon_2 = \frac{\nu}{3}, \epsilon_3 = \frac{(1-\alpha)}{4}, \nu \le \frac{2(1-\alpha)}{3}$, and $\Delta t \le \min\{\frac{1-\alpha}{Re\;\acute{d}K^2},\nu\}$, it follows that the bilinear form $a(\cdot,\cdot;\cdot,\cdot)$ is positive. Hence, (5.6) has at most one solution. Since (5.6) is a finite dimensional linear system, the uniqueness of the solution implies the existence of the solution. □

The discrete Gronwall's lemma plays an important role in the following analysis.

LEMMA 5.3 (discrete Gronwall's lemma; see [9]). *Let Δt, H, and a_n, b_n, c_n, γ_n (for integers $n \ge 0$) be nonnegative numbers such that*

$$a_l \;+\; \Delta t\sum_{n=0}^{l} b_n \;\le\; \Delta t\sum_{n=0}^{l}\gamma_n\,a_n \;+\; \Delta t\sum_{n=0}^{l} c_n \;+\; H \quad \textit{for } l \ge 0.$$

Suppose that $\Delta t\,\gamma_n < 1\,\forall\,n$, and set $\sigma_n = (1-\Delta t\,\gamma_n)^{-1}$. Then

$$a_l \;+\; \Delta t\sum_{n=0}^{l} b_n \;\le\; \exp\left(\Delta t\sum_{n=0}^{l}\sigma_n\,\gamma_n\right)\left\{\Delta t\sum_{n=0}^{l} c_n \;+\; H\right\} \quad \textit{for } l \ge 0. \tag{5.7}$$

□

5.1. Analysis of the fully discrete approximation. In this section we analyze the error between the finite element approximation given by (5.4), (5.5) and the true solution. A priori error estimates for the approximation are given in Theorem 5.4.

THEOREM 5.4. *Assume that the system* (2.3)–(2.8) *(and thus,* (2.14)–(2.15)*) has a solution* $(\mathbf{u}, \tau, \mathbf{p}) \in C^2(0,T;H^{k+1}) \times C^2(0,T;H^{m+1}) \times C(0,T;H^{q+1})$*. In addition, assume that* $\Delta t,\ \nu \leq c\,h^{d/2}$*, and*

$$\|\mathbf{u}\|_\infty, \|\nabla \mathbf{u}\|_\infty, \|\tau\|_\infty, \|\nabla\tau\|_\infty \leq M \ \forall t \in [0,T]. \tag{5.8}$$

Then, the finite element approximation (5.4)–(5.5) *is convergent to the solution of* (2.14)–(2.15) *on the interval* $(0,T)$ *as* $\Delta t,\ h \to 0$*. In addition, the approximation* $(\mathbf{u}_h, \tau_h)$ *satisfies the following error estimates:*

$$\left\|\left|\mathbf{u}_h - \mathbf{u}\right|\right\|_{\infty,0} + \left\|\left|\tau_h - \tau\right|\right\|_{\infty,0} \leq \mathbf{F}(\Delta t, \nu, h), \tag{5.9}$$

$$\left\|\left|\mathbf{u}_h - \mathbf{u}\right|\right\|_{0,1} + \left\|\left|\tau_h - \tau\right|\right\|_{0,0} \leq \mathbf{F}(\Delta t, \nu, h), \tag{5.10}$$

where

$$\begin{aligned}
\mathbf{F}(\Delta t, \nu, h) = C\ &\left(h^k \left\|\left|\mathbf{u}\right|\right\|_{0,k+1} + h^{k+1} \left\|\left|\mathbf{u}_t\right|\right\|_{0,k+1}\right) \\
&+ C\ \left(h^m \left\|\left|\tau\right|\right\|_{0,m+1} + h^{m+1} \left\|\left|\tau_t\right|\right\|_{0,m+1}\right) \\
&+ C\ h^{q+1} \left\|\left|p\right|\right\|_{0,q+1} + C\left(h^{k+1} \left\|\left|\mathbf{u}\right|\right\|_{\infty,k+1} + h^{m+1} \left\|\left|\tau\right|\right\|_{\infty,m+1}\right) \\
&+ C\,|\Delta t| \left(\|\mathbf{u}_t\|_{0,1} + \|\mathbf{u}_{tt}\|_{0,0} + \|\tau_t\|_{0,1} + \|\tau_{tt}\|_{0,0}\right) \\
&+ C\ \nu \left(\left\|\left|\tau_t\right|\right\|_{0,1} + \left\|\left|\tau_t\right|\right\|_{\infty,0}\right).
\end{aligned}$$

In order to establish the estimates (5.9)–(5.10), we begin by introducing the following notation. Let $\mathbf{u}^n = \mathbf{u}(t_n), \tau^n = \tau(t_n)$ represent the solution of (2.14)–(2.15), and $\mathbf{u}^n_h, \tau^n_h$ denote the solution of (5.4)–(5.5).

Define $\mathbf{\Lambda}^n, \mathbf{E}^n, \mathbf{\Gamma}^n, \mathbf{F}^n, \epsilon_u, \epsilon_\tau$ as

$$\begin{aligned}
\mathbf{\Lambda}^n &= \mathbf{u}^n - \mathcal{U}^n, & \mathbf{E}^n &= \mathcal{U}^n - \mathbf{u}^n_h, \\
\mathbf{\Gamma}^n &= \tau^n - \mathcal{T}^n, & \mathbf{F}^n &= \mathcal{T}^n - \tau^n_h, \\
\epsilon_u &= \mathbf{u} - \mathbf{u}^n_h, & \epsilon_\tau &= \tau - \tau^n_h.
\end{aligned}$$

The proof of Theorem 5.4 is established in three steps:

1. Prove a lemma, assuming two induction hypotheses.
2. Show that the induction hypotheses are true.
3. Prove the error estimates given in (5.9), (5.10).

Step 1. We prove the following lemma.

LEMMA 5.5. *Under the induction hypothesis* (IH1) *and the additional assumption*

$$\sum_{n=1}^{l-1} \Delta t \left\|\nabla E^n\right\|_\infty \leq 1, \tag{IH2}$$

we have that

$$\left\|\mathbf{E}^l\right\|^2 + \left\|\mathbf{F}^l\right\|^2 \leq G(\Delta t, h, \nu), \tag{5.11}$$

where

$$\begin{aligned}
G(\Delta t, h, \nu) = C\ & \left(h^{2k}\, |||\mathbf{u}|||^2_{0,k+1} + h^{2k+2}\, |||\mathbf{u}_t|||^2_{0,k+1}\right) \\
& + C\ \left(h^{2m}\, |||\tau|||^2_{0,m+1} + h^{2m+2}\, |||\tau_t|||^2_{0,m+1}\right) \\
& + C\ h^{2q+2}\, |||p|||^2_{0,q+1} + C\, |\Delta t|^2 \left(|||\mathbf{u}_t|||^2_{0,1} + |||\mathbf{u}_{tt}|||^2_{0,0} + |||\tau_t|||^2_{0,1} + |||\tau_{tt}|||^2_{0,0}\right) \\
& + C\ \nu^2 \left(|||\tau_t|||^2_{0,1} + |||\tau_t|||^2_{\infty,0}\right).
\end{aligned}$$

Proof of Lemma 5.5. From (2.14)–(2.15), it is clear that the true solution $(\mathbf{u}, \tau)$ satisfies

$$\begin{aligned}
& Re\ \left(d_t\mathbf{u}^n, \mathbf{v}\right) + Re\ c\left(\mathbf{u}_h^{n-1}, \mathbf{u}^n, \mathbf{v}\right) + (1-\alpha)\left(\nabla\mathbf{u}^n, \nabla\mathbf{v}\right) + \left(\tau^n, D(\mathbf{v})\right) \\
& \qquad = \left(\mathbf{f}^n, \mathbf{v}\right) + \left(p^n, \nabla\cdot\mathbf{v}\right) + R_1(\mathbf{v}) \qquad \forall\ \mathbf{v} \in Z_h, \qquad (5.12)
\end{aligned}$$

$$\begin{aligned}
& \left(d_t\tau^n, \sigma\right) + b\left(\mathbf{u}_h^{n-1}, \tau^n, \tilde{\sigma}\right) - \hat{\lambda}\left(D(\mathbf{u}^n), \tilde{\sigma}\right) + \frac{1}{\lambda}\left(\tau^n, \tilde{\sigma}\right) \\
& \qquad = -\left(g_a\left(\tau_h^{n-1}, \nabla\mathbf{u}_h^{n-1}\right), \tilde{\sigma}\right) + R_2(\sigma) \qquad \forall \sigma \in S_h, \qquad (5.13)
\end{aligned}$$

where $\hat{\lambda} := (2\alpha)/\lambda$,

$$R_1(\mathbf{v}) := Re\ \left(d_t\mathbf{u}^n, \mathbf{v}\right) - Re\ \left(\mathbf{u}_t^n, \mathbf{v}\right) + Re\ c(\mathbf{u}_h^{n-1}, \mathbf{u}^n, \mathbf{v}) - Re\ c(\mathbf{u}^n, \mathbf{u}^n, \mathbf{v}),$$

and

$$\begin{aligned}
R_2(\sigma) := {} & \left(d_t\tau^n, \sigma\right) - \left(\tau_t^n, \sigma\right) - \nu\left(\tau_t^n, \mathbf{u}_h^{n-1}\cdot\nabla\sigma\right) + b(\mathbf{u}_h^{n-1}, \tau^n, \tilde{\sigma}) \\
& - b(\mathbf{u}^n, \tau^n, \tilde{\sigma}) + \left(g_a\left(\tau_h^{n-1}, \nabla\mathbf{u}_h^{n-1}\right), \tilde{\sigma}\right) - \left(g_a\left(\tau^n, \nabla\mathbf{u}^n\right), \tilde{\sigma}\right).
\end{aligned}$$

Subtracting (5.4)–(5.5) from (5.12)–(5.13), we obtain the following equations for ϵ_u and ϵ_τ:

$$\begin{aligned}
& Re\ \left(d_t\epsilon_u, \mathbf{v}\right) + Re\ c(\mathbf{u}_h^{n-1}, \epsilon_u, \mathbf{v}) + (1-\alpha)\left(\nabla\epsilon_u, \nabla\mathbf{v}\right) + \left(\epsilon_\tau, D(\mathbf{v})\right) \\
& \qquad = \left(p^n, \nabla\cdot\mathbf{v}\right) + R_1(\mathbf{v})\ \ \forall\ \mathbf{v}\ \in\ Z_h, \qquad (5.14)
\end{aligned}$$

$$(5.15) \quad \left(d_t\epsilon_\tau, \sigma\right) + b(\mathbf{u}_h^{n-1}, \epsilon_\tau, \tilde{\sigma}) - \hat{\lambda}\left(D(\epsilon_u), \tilde{\sigma}\right) + \frac{1}{\lambda}\left(\epsilon_\tau, \tilde{\sigma}\right) = R_2(\sigma)\quad \forall\ \sigma\ \in\ S_h.$$

Substituting $\epsilon_u = \mathbf{E}^n + \mathbf{\Lambda}^n,\ \epsilon_\tau = \mathbf{F}^n + \mathbf{\Gamma}^n,\ \mathbf{v} = \mathbf{E}^n,\ \sigma = \mathbf{F}^n$ into (5.14)–(5.15), we obtain

(5.16)

$$Re\left(d_t\mathbf{E}^n, \mathbf{E}^n\right) + Re\, c(\mathbf{u}_h^{n-1}, \mathbf{E}^n, \mathbf{E}^n) + (1-\alpha)\left(\nabla\mathbf{E}^n, \nabla\mathbf{E}^n\right) + \left(\mathbf{F}^n, D(\mathbf{E}^n)\right) = \mathcal{F}_1(\mathbf{E}^n),$$

$$(5.17) \qquad \left(d_t\mathbf{F}^n, \mathbf{F}^n\right) + b(\mathbf{u}_h^{n-1}, \mathbf{F}^n, \tilde{\mathbf{F}}^n) - \hat{\lambda}(D(\mathbf{E}^n), \tilde{\mathbf{F}}^n) + \frac{1}{\lambda}(\mathbf{F}^n, \tilde{\mathbf{F}}^n) = \mathcal{F}_2(\mathbf{F}^n),$$

where

$$\begin{aligned}
\mathcal{F}_1(\mathbf{E}^n) = {} & \left(p^n, \nabla\cdot\mathbf{E}^n\right) + R_1(\mathbf{E}^n) - Re\ \left(d_t\mathbf{\Lambda}^n, \mathbf{E}^n\right) - Re\ c(\mathbf{u}_h^{n-1}, \mathbf{\Lambda}^n, \mathbf{E}^n) \\
& - (1-\alpha)\left(\nabla\mathbf{\Lambda}^n, \nabla\mathbf{E}^n\right) - \left(\mathbf{\Gamma}^n, D(\mathbf{E}^n)\right), \\
\mathcal{F}_2(\mathbf{F}^n) = {} & R_2(\mathbf{F}^n) - \left(d_t\mathbf{\Gamma}^n, \mathbf{F}^n\right) - b(\mathbf{u}_h^{n-1}, \mathbf{\Gamma}^n, \tilde{\mathbf{F}}^n) + \hat{\lambda}(D(\mathbf{\Lambda}^n), \tilde{\mathbf{F}}^n) - \frac{1}{\lambda}(\mathbf{\Gamma}^n, \tilde{\mathbf{F}}^n).
\end{aligned}$$

Multiplying (5.16) by $\hat{\lambda}$ and adding to (5.17), we obtain the single equation

$$\begin{aligned} &\mathit{Re}\,\hat{\lambda}\,(d_t\mathbf{E}^n,\mathbf{E}^n) + \mathit{Re}\,\hat{\lambda}\,c(\mathbf{u}_h^{n-1},\mathbf{E}^n,\mathbf{E}^n) + (1-\alpha)\hat{\lambda}\,(\nabla\mathbf{E}^n,\nabla\mathbf{E}^n) + (d_t\mathbf{F}^n,\mathbf{F}^n) \\ &\qquad + b(\mathbf{u}_h^{n-1},\mathbf{F}^n,\tilde{\mathbf{F}}^n) - \hat{\lambda}\left(D(\mathbf{E}^n),\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right) + \frac{1}{\lambda}(\mathbf{F}^n,\tilde{\mathbf{F}}^n) \\ &\qquad = \hat{\lambda}\mathcal{F}_1(\mathbf{E}^n) + \mathcal{F}_2(\mathbf{F}^n). \end{aligned} \tag{5.18}$$

Note that

$$\begin{aligned} (d_t\mathbf{E}^n,\mathbf{E}^n) &= \frac{1}{\Delta t}\left[(\mathbf{E}^n,\mathbf{E}^n) - \left(\mathbf{E}^{n-1},\mathbf{E}^n\right)\right] \\ &\geq \frac{1}{\Delta t}\left[\|\mathbf{E}^n\|^2 - \|\mathbf{E}^n\|\,\left\|\mathbf{E}^{n-1}\right\|\right] \\ &\geq \frac{1}{2\Delta t}\left[\|\mathbf{E}^n\|^2 - \left\|\mathbf{E}^{n-1}\right\|^2\right], \end{aligned}$$

and similarly, $(d_t\mathbf{F}^n,\mathbf{F}^n) \geq \frac{1}{2\Delta t}[\|\mathbf{F}^n\|^2 - \|\mathbf{F}^{n-1}\|^2]$. Thus, we have

$$\begin{aligned} &\frac{\mathit{Re}\,\hat{\lambda}}{2\Delta t}\left[\|\mathbf{E}^n\|^2 - \left\|\mathbf{E}^{n-1}\right\|^2\right] + \frac{1}{2\Delta t}\left[\|\mathbf{F}^n\|^2 - \left\|\mathbf{F}^{n-1}\right\|^2\right] + (1-\alpha)\hat{\lambda}\,\|\nabla\mathbf{E}^n\|^2 \\ &\qquad + \nu\left\|\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right\|^2 + \frac{1}{\lambda}\,\|\mathbf{F}^n\|^2 \\ &\leq -\mathit{Re}\,\hat{\lambda}\,c(\mathbf{u}_h^{n-1},\mathbf{E}^n,\mathbf{E}^n) - b(\mathbf{u}_h^{n-1},\mathbf{F}^n,\mathbf{F}^n) + \hat{\lambda}\left(D(\mathbf{E}^n),\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right) \\ &\quad - \frac{1}{\lambda}\left(\mathbf{F}^n,\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right) + \hat{\lambda}\mathcal{F}_1(\mathbf{E}^n) + \mathcal{F}_2(\mathbf{F}^n). \end{aligned} \tag{5.19}$$

Multiplying (5.19) by Δt and summing from $n = 1$ to l yields

$$\begin{aligned} &\frac{\mathit{Re}\,\hat{\lambda}}{2}\left[\left\|\mathbf{E}^l\right\|^2 - \left\|\mathbf{E}^0\right\|^2\right] + \frac{1}{2}\left[\left\|\mathbf{F}^l\right\|^2 - \left\|\mathbf{F}^0\right\|^2\right] + (1-\alpha)\hat{\lambda}\sum_{n=1}^{l}\Delta t\,\|\nabla\mathbf{E}^n\|^2 \\ &\qquad + \nu\sum_{n=1}^{l}\Delta t\left\|\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right\|^2 + \frac{1}{\lambda}\sum_{n=1}^{l}\Delta t\,\|\mathbf{F}^n\|^2 \\ &\quad \leq \Delta t\sum_{n=1}^{l}\Bigg[-\mathit{Re}\,\hat{\lambda}\,c(\mathbf{u}_h^{n-1},\mathbf{E}^n,\mathbf{E}^n) - b(\mathbf{u}_h^{n-1},\mathbf{F}^n,\mathbf{F}^n) \\ &\qquad\qquad + \hat{\lambda}\left(D(\mathbf{E}^n),\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right) - \frac{1}{\lambda}\left(\mathbf{F}^n,\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right)\Bigg] \\ &\qquad + \hat{\lambda}\Delta t\sum_{n=1}^{l}\mathcal{F}_1(\mathbf{E}^n) + \Delta t\sum_{n=1}^{l}\mathcal{F}_2(\mathbf{F}^n). \end{aligned} \tag{5.20}$$

We now estimate each term on the rhs of (5.20). For $c(\mathbf{u}_h^{n-1},\mathbf{E}^n,\mathbf{E}^n)$ we have that

$$\begin{aligned} \left|c(\mathbf{u}_h^{n-1},\mathbf{E}^n,\mathbf{E}^n)\right| &\leq \left|\left(\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{E}^n,\mathbf{E}^n\right)\right| \\ &\leq \left\|\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{E}^n\right\|\,\|\mathbf{E}^n\| \\ &\leq \left\|\mathbf{u}_h^{n-1}\right\|_\infty \acute{d}^{\frac{1}{2}}\,\|\nabla\mathbf{E}^n\|\,\|\mathbf{E}^n\| \\ &\leq \epsilon_1\,\|\nabla\mathbf{E}^n\|^2 + \frac{\acute{d}K^2}{4\epsilon_1}\,\|\mathbf{E}^n\|^2, \qquad \text{using (IH1).} \end{aligned} \tag{5.21}$$

Note that for $\mathbf{v} = 0$ on $\partial\Omega$, applying Green's theorem, we have

$$b(\mathbf{v}, \tau, \sigma) = -b(\mathbf{v}, \sigma, \tau) - (\nabla \cdot \mathbf{v}\, \tau, \sigma)\,, \tag{5.22}$$

which implies

$$b(\mathbf{v}, \tau, \tau) = -\frac{1}{2}\,(\nabla \cdot \mathbf{v}\, \tau, \tau)\,. \tag{5.23}$$

Using (5.23),

$$\begin{aligned}
\left|b(\mathbf{u}_h^{n-1}, \mathbf{F}^n, \mathbf{F}^n)\right| &= \frac{1}{2}\left|\left(\nabla \cdot \mathbf{u}_h^{n-1}\, \mathbf{F}^n, \mathbf{F}^n\right)\right| \\
&= \frac{1}{2}\left|\left(\nabla \cdot (\mathbf{u}_h^{n-1} - \mathcal{U}^{n-1})\, \mathbf{F}^n, \mathbf{F}^n\right) + \left(\nabla \cdot \mathcal{U}^{n-1}\, \mathbf{F}^n, \mathbf{F}^n\right)\right| \\
&\le \frac{1}{2}\left\|\nabla \cdot \mathbf{E}^{n-1}\right\|_\infty \|\mathbf{F}^n\|^2 + \frac{1}{2}\left\|\nabla \cdot \mathcal{U}^{n-1}\right\|_\infty \|\mathbf{F}^n\|^2 \\
&\le \frac{1}{2}\left\|\nabla \cdot \mathbf{E}^{n-1}\right\|_\infty \|\mathbf{F}^n\|^2 + \frac{1}{2}M\,\|\mathbf{F}^n\|^2\,, \qquad \text{using (5.2).}
\end{aligned}$$

Next,

$$\begin{aligned}
\left|\left(D(\mathbf{E}^n), \nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right)\right| &\le \|D(\mathbf{E}^n)\|\,\left\|\nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\| \\
&\le \|\nabla\mathbf{E}^n\|\,\left\|\nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\| \\
&\le \epsilon_2\,\|\nabla\mathbf{E}^n\|^2 + \frac{\nu^2}{4\epsilon_2}\left\|\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\|^2.
\end{aligned}$$

Also,

$$\begin{aligned}
\left|\left(\mathbf{F}^n, \nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right)\right| &= \nu\left|\left(\mathbf{F}^n, \mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right)\right| \\
&\le \nu\,\|\mathbf{F}^n\|\,\left\|\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\| \\
&\le \|\mathbf{F}^n\|^2 + \frac{\nu^2}{4}\left\|\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\|^2.
\end{aligned}$$

Thus, for the first summation on the rhs of (5.20), we have

$$\begin{aligned}
\Delta t \sum_{n=1}^{l} \Bigg[&- Re\;\hat{\lambda}\, c(\mathbf{u}_h^{n-1}, \mathbf{E}^n, \mathbf{E}^n) - b(\mathbf{u}_h^{n-1}, \mathbf{F}^n, \mathbf{F}^n) + \hat{\lambda}\left(D(\mathbf{E}^n), \nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right) \\
&\qquad - \frac{1}{\lambda}\left(\mathbf{F}^n, \nu\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right)\Bigg] \\
&\le \Delta t \sum_{n=1}^{l}(Re\;\hat{\lambda}\epsilon_1 + \hat{\lambda}\epsilon_2)\,\|\nabla\mathbf{E}^n\|^2 + \Delta t \sum_{n=1}^{l} \frac{Re\;\hat{\lambda}\acute{d}K^2}{4\epsilon_1}\,\|\mathbf{E}^n\|^2 \\
&\qquad + \Delta t \sum_{n=1}^{l}\left(\frac{\hat{\lambda}\nu^2}{4\epsilon_2} + \frac{\nu^2}{\lambda 4\epsilon_3}\right)\left\|\mathbf{u}_h^{n-1} \cdot \nabla\mathbf{F}^n\right\|^2 \\
&\qquad + \Delta t \sum_{n=1}^{l}\left(\frac{1}{2}M + \ \frac{1}{2}\left\|\nabla \cdot \mathbf{E}^{n-1}\right\|_\infty + \frac{\epsilon_3}{\lambda}\right)\|\mathbf{F}^n\|^2\,.
\end{aligned} \tag{5.24}$$

Next we consider $\mathcal{F}_1(\mathbf{E}^n)$:

$$
\begin{aligned}
|(p^n, \nabla \cdot \mathbf{E}^n)| &= |(p^n - \mathcal{P}^n, \nabla \cdot \mathbf{E}^n)| \\
&\le \|p^n - \mathcal{P}^n\| \, \acute{d}^{\frac{1}{2}} \, \|\nabla \mathbf{E}^n\| \\
&\le \epsilon_4 \, \|\nabla \mathbf{E}^n\|^2 + \frac{\acute{d}}{4\epsilon_4} \, \|p^n - \mathcal{P}^n\|^2 \, , \qquad (5.25) \\
|(d_t \mathbf{\Lambda}^n, \mathbf{E}^n)| &\le \|\mathbf{E}^n\| \, \|d_t \mathbf{\Lambda}^n\| \\
&\le \|\mathbf{E}^n\|^2 + \frac{1}{4} \, \|d_t \mathbf{\Lambda}^n\|^2 \, , \\
\left| c(\mathbf{u}_h^{n-1}, \mathbf{\Lambda}^n, \mathbf{E}^n) \right| &\le \|\mathbf{E}^n\| \, \left\| \mathbf{u}_h^{n-1} \cdot \nabla \mathbf{\Lambda}^n \right\| \\
&\le \|\mathbf{E}^n\| \, \left\| \mathbf{u}_h^{n-1} \right\|_\infty \acute{d}^{\frac{1}{2}} \, \|\nabla \mathbf{\Lambda}^n\| \\
&\le \|\mathbf{E}^n\|^2 + \frac{K^2 \acute{d}}{4} \, \|\nabla \mathbf{\Lambda}^n\|^2 \, , \qquad \text{using (IH1)}, \qquad (5.26) \\
|(\nabla \mathbf{\Lambda}^n, \nabla \mathbf{E}^n)| &\le \|\nabla \mathbf{E}^n\| \, \|\nabla \mathbf{\Lambda}^n\| \\
&\le \epsilon_5 \, \|\nabla \mathbf{E}^n\|^2 + \frac{1}{4\epsilon_5} \, \|\nabla \mathbf{\Lambda}^n\|^2 \, , \qquad (5.27) \\
|(\mathbf{\Gamma}^n, D(\mathbf{E}^n))| &\le \|D(\mathbf{E}^n)\| \, \|\mathbf{\Gamma}^n\| \\
&\le \|\nabla \mathbf{E}^n\| \, \|\mathbf{\Gamma}^n\| \\
&\le \epsilon_6 \, \|\nabla \mathbf{E}^n\|^2 + \frac{1}{4\epsilon_6} \, \|\mathbf{\Gamma}^n\|^2 \, . \qquad (5.28)
\end{aligned}
$$

For the $R_1(\mathbf{E}^n)$ terms we have

$$
|(d_t \mathbf{u}^n, \mathbf{E}^n) - (\mathbf{u}_t^n, \mathbf{E}^n)| \le \|\mathbf{E}^n\|^2 + \frac{1}{4} \, \|d_t \mathbf{u}^n - \mathbf{u}_t^n\|^2 \, , \qquad (5.29)
$$

$$
\begin{aligned}
&\left| c(\mathbf{u}_h^{n-1}, \mathbf{u}^n, \mathbf{E}^n) - c(\mathbf{u}^n, \mathbf{u}^n, \mathbf{E}^n) \right| \\
&\quad = |c(\mathbf{u}_h^{n-1} - \mathcal{U}^{n-1}, \mathbf{u}^n, \mathbf{E}^n) + c(\mathcal{U}^{n-1} - \mathbf{u}^{n-1}, \mathbf{u}^n, \mathbf{E}^n) \\
&\qquad + c(\mathbf{u}^{n-1} - \mathbf{u}^n, \mathbf{u}^n, \mathbf{E}^n)| \\
&\quad \le \|\mathbf{E}^{n-1} \cdot \nabla \mathbf{u}^n\| \, \|\mathbf{E}^n\| \\
&\qquad + \|\mathbf{\Lambda}^{n-1} \cdot \nabla \mathbf{u}^n\| \, \|\mathbf{E}^n\| + \|(\mathbf{u}^n - \mathbf{u}^{n-1}) \cdot \nabla \mathbf{u}^n\| \, \|\mathbf{E}^n\| \\
&\quad \le \acute{d} M \|\mathbf{E}^{n-1}\| \, \|\mathbf{E}^n\| + \acute{d} M \|\mathbf{\Lambda}^{n-1}\| \, \|\mathbf{E}^n\| + \acute{d} M \|(\mathbf{u}^n - \mathbf{u}^{n-1})\| \, \|\mathbf{E}^n\| \\
&\quad \le \frac{\acute{d} M}{2} \left\| \mathbf{E}^{n-1} \right\|^2 + \left(\frac{\acute{d} M}{2} + 2 \right) \|\mathbf{E}^n\|^2 + \frac{\acute{d}^2 M^2}{4} \left\| \mathbf{\Lambda}^{n-1} \right\|^2 \\
&\qquad + \frac{\acute{d}^2 M^2}{4} \Delta t \int_{t_{n-1}}^{t_n} \|\mathbf{u}_t\|^2 \, dt. \qquad (5.30)
\end{aligned}
$$

Combining (5.25)–(5.30), we have the following estimate for $\mathcal{F}_1(\mathbf{E}^n)$:

$$
\begin{aligned}
|\hat{\lambda} \mathcal{F}_1(\mathbf{E}^n)| &\le \hat{\lambda} (\epsilon_4 + \epsilon_5 + \epsilon_6) \, \|\nabla \mathbf{E}^n\|^2 + \hat{\lambda} \; Re \left(\frac{\acute{d} M}{2} + 5 \right) \|\mathbf{E}^n\|^2 \\
&\quad + \hat{\lambda} \; Re \frac{\acute{d} M}{2} \left\| \mathbf{E}^{n-1} \right\|^2 + \hat{\lambda} \frac{\acute{d}}{4\epsilon_4} \, \|(p^n - \mathcal{P}^n)\|^2 + \hat{\lambda} \; Re \frac{\acute{d}^2 M^2}{4} \left\| \mathbf{\Lambda}^{n-1} \right\|^2 \\
&\quad + \hat{\lambda} \left(\frac{Re \; K^2 \acute{d}}{4} + \frac{(1-\alpha)}{4\epsilon_5} \right) \|\nabla \mathbf{\Lambda}^n\|^2 + Re \frac{1}{4} \, \|d_t \mathbf{\Lambda}^n\|^2 + \hat{\lambda} \frac{1}{4\epsilon_6} \, \|\mathbf{\Gamma}^n\|^2 \\
&\quad + \hat{\lambda} \; Re \frac{1}{4} \, \|d_t \mathbf{u}^n - \mathbf{u}_t^n\|^2 + \hat{\lambda} \; Re \frac{\acute{d}^2 M^2}{4} \Delta t \int_{t_{n-1}}^{t_n} \|\mathbf{u}_t\|^2 \, dt. \qquad (5.31)
\end{aligned}
$$

Next we consider the terms in $\mathcal{F}_2(\mathbf{F}^n)$:

$$|(d_t\mathbf{\Gamma}^n,\mathbf{F}^n)| \le \|\mathbf{F}^n\|^2 + \frac{1}{4}\|d_t\mathbf{\Gamma}^n\|^2 , \tag{5.32}$$

$$\begin{aligned}
|b(\mathbf{u}_h^{n-1},\mathbf{\Gamma}^n,\tilde{\mathbf{F}}^n)| &= \left|b(\mathbf{u}_h^{n-1},\mathbf{\Gamma}^n,\mathbf{F}^n) + b(\mathbf{u}_h^{n-1},\mathbf{\Gamma}^n,\nu\mathbf{F}_u^n)\right| \\
&\le \left\|\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{\Gamma}^n\right\|\|\mathbf{F}^n\| + \left\|\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{\Gamma}^n\right\|\|\nu\mathbf{F}_u^n\| \\
&\le \acute{d}^{\frac{1}{2}}\left\|\mathbf{u}_h^{n-1}\right\|_\infty\|\nabla\mathbf{\Gamma}^n\|\|\mathbf{F}^n\| + \acute{d}^{\frac{1}{2}}\left\|\mathbf{u}_h^{n-1}\right\|_\infty\|\nabla\mathbf{\Gamma}^n\|\|\nu\mathbf{F}_u^n\| \\
&\le \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2 + \frac{\acute{d}K^2}{2}\|\nabla\mathbf{\Gamma}^n\|^2 , \qquad (5.33)
\end{aligned}$$

$$\begin{aligned}
|(D(\mathbf{\Lambda}^n)\tilde{\mathbf{F}}^n)| &= |(D(\mathbf{\Lambda}^n),\mathbf{F}^n) + (D(\mathbf{\Lambda}^n),\nu\mathbf{F}_u^n)| \\
&\le \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2 + \frac{1}{2}\|\nabla\mathbf{\Lambda}^n\|^2 , \qquad (5.34)
\end{aligned}$$

$$\begin{aligned}
|(\mathbf{\Gamma}^n\tilde{\mathbf{F}}^n)| &= |(\mathbf{\Gamma}^n,\mathbf{F}^n) + \nu\,(\mathbf{\Gamma}^n,\nu\mathbf{F}_u^n)| \\
&\le \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2 + \frac{1}{2}\|\mathbf{\Gamma}^n\|^2 . \qquad (5.35)
\end{aligned}$$

For the terms making up $R_2(\mathbf{F}^n)$ we have

$$|(d_t\tau^n,\mathbf{F}^n) - (\tau_t^n,\mathbf{F}^n)| \le \|\mathbf{F}^n\|^2 + \frac{1}{4}\|d_t\tau^n - \tau_t^n\|^2 , \tag{5.36}$$

$$\begin{aligned}
|(\tau_t^n,\nu\mathbf{F}_u^n)| &= \left|\left(\tau_t^n,\nu\mathbf{u}_h^{n-1}\cdot\nabla\mathbf{F}^n\right)\right| \\
&= \left|b(\nu\mathbf{u}_h^{n-1},\mathbf{F}^n,\tau_t^n)\right| \\
&\le \left|b(\nu\mathbf{u}_h^{n-1},\tau_t^n,\mathbf{F}^n)\right| + \left|\left(\nabla\cdot\mathbf{u}_h^{n-1}\,\nu\mathbf{F}^n,\tau_t^n\right)\right| \quad \text{(using (5.22))} \\
&\le \nu\left\|\mathbf{u}_h^{n-1}\cdot\nabla\tau_t^n\right\|\|\mathbf{F}^n\| + \left|\left(\nabla\cdot(\mathbf{u}_h^{n-1} - \mathcal{U}^{n-1})\,\nu\mathbf{F}^n,\tau_t^n\right)\right| \\
&\quad + \left|\left(\nabla\cdot\mathcal{U}^{n-1}\,\nu\mathbf{F}^n,\tau_t^n\right)\right| \\
&\le \nu\left\|\mathbf{u}_h^{n-1}\right\|_\infty\acute{d}^{\frac{1}{2}}\|\nabla\tau_t^n\|\|\mathbf{F}^n\| + \nu\left\|\nabla\cdot(\mathbf{u}_h^{n-1} - \mathcal{U}^{n-1})\right\|_\infty\|\mathbf{F}^n\|\|\tau_t^n\| \\
&\quad + \left\|\nabla\cdot\mathcal{U}^{n-1}\right\|_\infty\nu\|\mathbf{F}^n\|\|\tau_t^n\| \\
&\le \left(2 + \left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\right)\|\mathbf{F}^n\|^2 + \frac{\nu^2}{4}\acute{d}^2\left(M^2 + \left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\right)\|\tau_t^n\|^2 \\
&\quad + \frac{\nu^2}{4}K^2\acute{d}\,\|\nabla\tau_t^n\|^2 \quad \text{(using (5.2) and (IH1))}, \qquad (5.37)
\end{aligned}$$

$$\begin{aligned}
|b(\mathbf{u}_h^{n-1},\tau^n,\tilde{\mathbf{F}}^n) - b(\mathbf{u}^n,\tau^n,\tilde{\mathbf{F}}^n)| &= |((\mathbf{u}_h^{n-1} - \mathbf{u}^n)\cdot\nabla\tau^n\tilde{\mathbf{F}}^n)| \\
&\le \left\|(\mathbf{u}_h^{n-1} - \mathbf{u}^n)\cdot\nabla\tau^n\right\|\|\tilde{\mathbf{F}}^n\| \\
&\le \frac{1}{2}\|\tilde{\mathbf{F}}^n\|^2 + \frac{1}{2}\acute{d}^3\|\nabla\tau^n\|_\infty^2\left\|\mathbf{u}_h^{n-1} - \mathbf{u}^n\right\|^2 \\
&\le \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2 + \frac{1}{2}\acute{d}^3M^2\left\|-\mathbf{E}^{n-1} - \mathbf{\Lambda}^{n-1} + \mathbf{u}^{n-1} - \mathbf{u}^n\right\|^2 \\
&\le \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2 + \frac{3}{2}\acute{d}^3M^2\left\|\mathbf{E}^{n-1}\right\|^2 + \frac{3}{2}\acute{d}^3M^2\left\|\mathbf{\Lambda}^{n-1}\right\|^2 \\
&\quad + \frac{3}{2}\acute{d}^3M^2\Delta t\int_{t_{n-1}}^{t_n}\|\mathbf{u}_t\|^2\,dt. \qquad (5.38)
\end{aligned}$$

In order to estimate the g_a terms in $\mathcal{F}_2(\cdot)$, note that

$$\begin{aligned} g_a\left(\tau_h^{n-1}, \nabla \mathbf{u}_h^{n-1}\right) - g_a\left(\tau^n, \nabla \mathbf{u}^n\right) \\ &= g_a\left(\tau_h^{n-1}, \nabla(\mathbf{u}_h^{n-1} - \mathcal{U}^{n-1})\right) + g_a\left(\tau_h^{n-1}, \nabla(\mathcal{U}^{n-1} - \mathbf{u}^{n-1})\right) \\ &\quad + g_a\left(\tau_h^{n-1}, \nabla(\mathbf{u}^{n-1} - \mathbf{u}^n)\right) + g_a\left(\tau_h^{n-1} - \mathcal{T}^{n-1}, \nabla \mathbf{u}^n\right) \\ &\quad + g_a\left(\mathcal{T}^{n-1} - \tau^{n-1}, \nabla \mathbf{u}^n\right) + g_a\left(\tau^{n-1} - \tau^n, \nabla \mathbf{u}^n\right) \\ &= -g_a\left(\tau_h^{n-1}, \nabla \mathbf{E}^{n-1}\right) - g_a\left(\tau_h^{n-1}, \nabla \mathbf{\Lambda}^{n-1}\right) - g_a\left(\tau_h^{n-1}, \nabla(\mathbf{u}^n - \mathbf{u}^{n-1})\right) \\ &\quad - g_a\left(\mathbf{F}^{n-1}, \nabla \mathbf{u}^n\right) - g_a\left(\mathbf{\Gamma}^{n-1}, \nabla \mathbf{u}^n\right) - g_a\left(\tau^n - \tau^{n-1}, \nabla \mathbf{u}^n\right). \end{aligned} \tag{5.39}$$

Bounding each of the terms on the rhs of (5.39), we obtain

$$\begin{aligned} |(g_a\left(\tau_h^{n-1}, \nabla \mathbf{E}^{n-1}\right)\tilde{\mathbf{F}}^n)| &\le \left\|g_a\left(\tau_h^{n-1}, \nabla \mathbf{E}^{n-1}\right)\right\| \|\tilde{\mathbf{F}}^n\| \\ &\le 4\acute{d}\left\|\tau_h^{n-1}\right\|_\infty \left\|\nabla \mathbf{E}^{n-1}\right\| \|\tilde{\mathbf{F}}^n\| \\ &\le \epsilon_7 \left\|\nabla \mathbf{E}^{n-1}\right\|^2 + \frac{8\acute{d}^2K^2}{\epsilon_7}\|\mathbf{F}^n\|^2 + \frac{8\acute{d}^2K^2}{\epsilon_7}\nu^2\|\mathbf{F}_u^n\|^2, \end{aligned} \tag{5.40}$$

$$|(g_a\left(\tau_h^{n-1}, \nabla \mathbf{\Lambda}^{n-1}\right)\tilde{\mathbf{F}}^n)| \le 8\acute{d}^2K^2\left\|\nabla \mathbf{\Lambda}^{n-1}\right\|^2 + \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2, \tag{5.41}$$

$$|(g_a\left(\tau_h^{n-1}, \nabla(\mathbf{u}^n - \mathbf{u}^{n-1})\right)\tilde{\mathbf{F}}^n)| \le 8\acute{d}^2K^2\Delta t\int_{t_{n-1}}^{t_n}\|\nabla \mathbf{u}_t\|^2\, dt + \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2, \tag{5.42}$$

$$|(g_a\left(\mathbf{F}^{n-1}, \nabla \mathbf{u}^n\right)\tilde{\mathbf{F}}^n)| \le 8\acute{d}^2M^2\left\|\mathbf{F}^{n-1}\right\|^2 + \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2, \tag{5.43}$$

$$|(g_a\left(\mathbf{\Gamma}^{n-1}, \nabla \mathbf{u}^n\right)\tilde{\mathbf{F}}^n)| \le 8\acute{d}^2M^2\left\|\mathbf{\Gamma}^{n-1}\right\|^2 + \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2, \tag{5.44}$$

$$|(g_a\left(\tau^n - \tau^{n-1}, \nabla \mathbf{u}^n\right)\tilde{\mathbf{F}}^n)| \le 8\acute{d}^2M^2\Delta t\int_{t_{n-1}}^{t_n}\|\tau_t\|^2\, dt + \|\mathbf{F}^n\|^2 + \nu^2\|\mathbf{F}_u^n\|^2. \tag{5.45}$$

Combining the estimates in (5.32)–(5.38), (5.40)–(5.45), we obtain the following estimate for $\mathcal{F}_2(\mathbf{F}^n)$:

$$\begin{aligned} |\mathcal{F}_2(\mathbf{F}^n)| \le \epsilon_7\left\|\nabla \mathbf{E}^{n-1}\right\|^2 + \nu^2\|\mathbf{F}_u^n\|^2\left(7 + \frac{8\acute{d}^2K^2}{\epsilon_7} + \hat{\lambda} + \frac{1}{\lambda}\right) \\ + \|\mathbf{F}^n\|^2\left(11 + \frac{8\acute{d}^2K^2}{\epsilon_7} + \left\|\nabla \mathbf{E}^{n-1}\right\|_\infty + \hat{\lambda} + \frac{1}{\lambda}\right) \\ + \left\|\mathbf{E}^{n-1}\right\|^2\left(\frac{3}{2}\acute{d}^3M^2\right) + \left\|\mathbf{F}^{n-1}\right\|^2\left(8\acute{d}^2M^2\right) \\ + \|\nabla \mathbf{\Lambda}^n\|^2\left(\frac{\hat{\lambda}}{2}\right) + \|\nabla \mathbf{\Gamma}^n\|^2\left(\frac{\acute{d}K^2}{2}\right) + \|\mathbf{\Gamma}^n\|^2\left(\frac{1}{2\lambda}\right) + \|d_t\mathbf{\Gamma}^n\|^2\left(\frac{1}{4}\right) \\ + \left\|\nabla \mathbf{\Lambda}^{n-1}\right\|^2(8\acute{d}^2K^2) + \left\|\mathbf{\Lambda}^{n-1}\right\|^2\left(\frac{3}{2}\acute{d}^3M^2\right) + \left\|\mathbf{\Gamma}^{n-1}\right\|^2(8\acute{d}^2M^2) \end{aligned}$$

$$
\begin{aligned}
&+\ \frac{1}{4}\left\|d_t\tau^n-\tau_t^n\right\|^2+\frac{\nu^2}{4}\acute{d}^2\left(M^2+\left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\right)\left\|\tau_t^n\right\|^2\\
&+\ \frac{\nu^2}{4}K^2\acute{d}\left\|\nabla\tau_t^n\right\|^2\\
&+\ \frac{3}{2}\acute{d}^3M^2\Delta t\int_{t_{n-1}}^{t_n}\left\|\mathbf{u}_t\right\|^2\,dt+8\acute{d}^2M^2\Delta t\int_{t_{n-1}}^{t_n}\left\|\tau_t\right\|^2\,dt\\
&+\ 8\acute{d}^2K^2\Delta t\int_{t_{n-1}}^{t_n}\left\|\nabla\mathbf{u}_t\right\|^2\,dt. \qquad (5.46)
\end{aligned}
$$

With the choices $\epsilon_1=\frac{(1-\alpha)}{12\ Re\ \hat{\lambda}}, \epsilon_2=\epsilon_4=\epsilon_5=\epsilon_6=\epsilon_7=\frac{(1-\alpha)}{12\hat{\lambda}}, \mathbf{u}_h^0=\mathcal{U}^0(\Rightarrow\mathbf{E}^0=0), \tau_h^0=\mathcal{T}^0(\Rightarrow\mathbf{F}^0=0)$, substituting (5.24), (5.31), (5.46) into (5.20) yields

$$
\begin{aligned}
&\frac{Re\ \hat{\lambda}}{2}\left\|\mathbf{E}^l\right\|^2+\frac{1}{2}\left\|\mathbf{F}^l\right\|^2+\frac{(1-\alpha)}{2}\hat{\lambda}\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{E}^n\right\|^2\\
&\qquad+\ \left[\nu-\nu^2\left(\frac{3\hat{\lambda}^2+96\acute{d}^2K^2\hat{\lambda}}{(1-\alpha)}+7+\hat{\lambda}+\frac{5}{4\lambda}\right)\right]\sum_{n=1}^{l}\Delta t\left\|\mathbf{F}_u^n\right\|^2\\
&\quad\le C_1\sum_{n=1}^{l}\Delta t\left\|\mathbf{E}^n\right\|^2+C_2\sum_{n=1}^{l}\Delta t\left\|\mathbf{F}^n\right\|^2+C_3\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\left\|\mathbf{F}^n\right\|^2\\
&\qquad+\ C_4\sum_{n=1}^{l}\Delta t\left\|\mathbf{\Lambda}^n\right\|^2+C_5\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{\Lambda}^n\right\|^2\\
&\qquad+\ \frac{1}{4}\sum_{n=1}^{l}\Delta t\left\|d_t\mathbf{\Lambda}^n\right\|^2+C_6\sum_{n=1}^{l}\Delta t\left\|\mathbf{\Gamma}^n\right\|^2+Re\frac{\hat{\lambda}}{4}\sum_{n=1}^{l}\Delta t\left\|d_t\mathbf{u}^n-\mathbf{u}_t^n\right\|^2\\
&\qquad+\ \left(\frac{\acute{d}K^2}{2}\right)\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{\Gamma}^n\right\|^2+\frac{1}{4}\sum_{n=1}^{l}\Delta t\left\|d_t\mathbf{\Gamma}^n\right\|^2+\frac{1}{4}\sum_{n=1}^{l}\Delta t\left\|d_t\tau^n-\tau_t^n\right\|^2\\
&\qquad+\ \frac{\nu^2}{4}\sum_{n=1}^{l}\Delta t\acute{d}^2\left(M^2+\left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\right)\left\|\tau_t^n\right\|^2+\sum_{n=1}^{l}\Delta t\left\|p^n-\mathcal{P}^n\right\|^2\\
&\qquad+\ |\Delta t|^2\,\acute{d}\left(Re\ \acute{d}M^2\frac{\hat{\lambda}}{4}\left\|\mathbf{u}_t\right\|_{0,0}^2+\frac{3}{2}\acute{d}^2M^2\left\|\mathbf{u}_t\right\|_{0,0}^2\right.\\
&\qquad\qquad\left.+\ 8\acute{d}M^2\left\|\tau_t\right\|_{0,0}^2+8\acute{d}K^2\left\|\mathbf{u}_t\right\|_{0,1}^2\right)+\ \frac{\nu^2}{4}K^2\acute{d}\ \vert\vert\vert\nabla\tau_t\vert\vert\vert_{0,0}^2\,. \qquad (5.47)
\end{aligned}
$$

We now apply the interpolation properties of the approximating spaces to estimate the terms on the rhs of (5.47). Using elements of order k for velocity, elements of order m for stress, and elements of order q for pressure, we have

$$
\begin{aligned}
&\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{\Lambda}^n\right\|^2+\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{\Gamma}^n\right\|^2\\
&\qquad\le C\left(h^{2k}\sum_{n=1}^{l}\Delta t\left\|\mathbf{u}^n\right\|_{k+1}^2+h^{2m}\sum_{n=1}^{l}\Delta t\left\|\tau^n\right\|_{m+1}^2\right)\\
&\qquad\le C\left(h^{2k}\,\vert\vert\vert\mathbf{u}\vert\vert\vert_{0,k+1}^2+h^{2m}\,\vert\vert\vert\tau\vert\vert\vert_{0,m+1}^2\right), \qquad (5.48)
\end{aligned}
$$

$$
\begin{aligned}
\sum_{n=1}^{l} \Delta t \left\| \mathbf{\Lambda}^n \right\|^2 &+ \sum_{n=1}^{l} \Delta t \left\| \mathbf{\Gamma}^n \right\|^2 + \sum_{n=1}^{l} \Delta t \left\| p - \mathcal{P}^n \right\|^2 \\
&\leq C \left(h^{2k+2} \sum_{n=1}^{l} \Delta t \left\| \mathbf{u}^n \right\|_{k+1}^2 + h^{2m+2} \sum_{n=1}^{l} \Delta t \left\| \tau^n \right\|_{m+1}^2 + h^{2q+2} \sum_{n=1}^{l} \Delta t \left\| p^n \right\|_{q+1}^2 \right) \\
&\leq C \left(h^{2k+2} \left\| \mathbf{u} \right\|_{0,k+1}^2 + h^{2m+2} \left\| \tau \right\|_{0,m+1}^2 + h^{2q+2} \left\| p \right\|_{0,q+1}^2 \right),
\end{aligned}
$$

(5.49)

$$
\begin{aligned}
\sum_{n=1}^{l} \Delta t \left\| d_t \mathbf{\Lambda}^n \right\|^2 &= \sum_{n=1}^{l} \Delta t \left\| \frac{1}{\Delta t} \int_{t_{n-1}}^{t_n} 1 \frac{\partial \Lambda}{\partial t} dt \right\|^2 \\
&\leq \sum_{n=1}^{l} \Delta t \left(\frac{1}{\Delta t} \right)^2 \int_{\Omega} \left(\int_{t_{n-1}}^{t_n} 1 \, dt \right) \left(\int_{t_{n-1}}^{t_n} \left(\frac{\partial \Lambda}{\partial t} \right)^2 \, dt \right) d\mathbf{x} \\
&\leq C h^{2k+2} \left\| \mathbf{u}_t \right\|_{0,k+1}^2, \qquad (5.50)
\end{aligned}
$$

and similarly,

$$
\sum_{n=1}^{l} \Delta t \left\| d_t \mathbf{\Gamma}^n \right\|^2 \leq C h^{2m+2} \left\| \tau_t \right\|_{0,m+1}^2. \qquad (5.51)
$$

Note that $d_t \mathbf{u}^n - \mathbf{u}_t^n$ may be expressed as

$$
d_t \mathbf{u}^n - \mathbf{u}_t^n = \frac{1}{2\Delta t} \int_{t_{n-1}}^{t_n} \mathbf{u}_{tt}(\cdot, t)(t_{n-1} - t) \, dt.
$$

Also,

$$
\begin{aligned}
\left(\frac{1}{2\Delta t} \int_{t_{n-1}}^{t_n} \mathbf{u}_{tt}(\cdot, t)(t_{n-1} - t) \, dt \right)^2 &\leq \frac{1}{4 \left| \Delta t \right|^2} \int_{t_{n-1}}^{t_n} \mathbf{u}_{tt}^2(\cdot, t) \, dt \int_{t_{n-1}}^{t_n} (t_{n-1} - t)^2 \, dt \\
&= \frac{1}{12} \Delta t \int_{t_{n-1}}^{t_n} \mathbf{u}_{tt}^2(\cdot, t) \, dt.
\end{aligned}
$$

Therefore it follows that

$$
\begin{aligned}
\sum_{n=1}^{l} \Delta t \left\| d_t \mathbf{u}^n - \mathbf{u}_t^n \right\|^2 &\leq \sum_{n=1}^{l} \Delta t \int_{\Omega} \frac{1}{12} \Delta t \int_{t_{n-1}}^{t_n} \mathbf{u}_{tt}^2(\cdot, t) \, dt \, d\mathbf{x} \\
&= \frac{1}{12} \left| \Delta t \right|^2 \left\| \mathbf{u}_{tt} \right\|_{0,0}^2. \qquad (5.52)
\end{aligned}
$$

Similarly, for $d_t \tau^n - \tau_t^n$ we have

$$
\sum_{n=1}^{l} \Delta t \left\| d_t \tau^n - \tau_t^n \right\|^2 \leq \frac{1}{12} \left| \Delta t \right|^2 \left\| \tau_{tt} \right\|_{0,0}^2. \qquad (5.53)
$$

In view of (5.48)–(5.53), our induction hypotheses (IH1), (IH2), and with ν chosen such that

$$
\nu \leq \frac{1}{2} \left(\frac{3\hat{\lambda}^2 + 96 d'^2 K^2 \hat{\lambda}}{(1 - \alpha)} + 7 + \hat{\lambda} + \frac{5}{4\lambda} \right)^{-1}, \qquad (5.54)
$$

from (5.47) we obtain

$$
\begin{aligned}
&\frac{Re\ \hat{\lambda}}{2}\left\|\mathbf{E}^l\right\|^2+\frac{1}{2}\left\|\mathbf{F}^l\right\|^2+\frac{(1-\alpha)}{2}\hat{\lambda}\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{E}^n\right\|^2+\frac{\nu}{2}\sum_{n=1}^{l}\Delta t\left\|\mathbf{F}_u^n\right\|^2\\
&\qquad\le C\sum_{n=1}^{l}\Delta t\left(\left\|\mathbf{E}^n\right\|^2+\left\|\mathbf{F}^n\right\|^2\right)+C\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{E}^{n-1}\right\|_\infty\left\|\mathbf{F}^n\right\|^2\\
&\qquad\quad+C\nu^2\left(|||\tau_t|||_{0,1}^2+|||\tau_t|||_{\infty,0}^2\right)\\
&\qquad\quad+C\left|\Delta t\right|^2\left(\left\|\mathbf{u}_t\right\|_{0,1}^2+\left\|\mathbf{u}_{tt}\right\|_{0,0}^2+\left\|\tau_t\right\|_{0,0}^2+\left\|\tau_{tt}\right\|_{0,0}^2\right)+Ch^{2k+2}|||\mathbf{u}|||_{0,k+1}^2\\
&\qquad\quad+Ch^{2m+2}|||\tau|||_{0,m+1}^2+Ch^{2q+2}|||p|||_{0,q+1}^2+Ch^{2k}\ |||\mathbf{u}|||_{0,k+1}^2\\
&\qquad\quad+Ch^{2k+2}\left\|\mathbf{u}_t\right\|_{0,k+1}^2+Ch^{2m}|||\tau|||_{0,m+1}^2+Ch^{2m+2}\left\|\tau_t\right\|_{0,m+1}^2\,,
\end{aligned}
\tag{5.55}
$$

where the C's denote constants independent of $l, \Delta t, h, \nu$. Applying Gronwall's lemma and (IH2) to (5.55), the estimate given in (5.11) follows. □

Step 2. We show that the induction hypotheses (IH1) and (IH2) are true.

Verification of (IH1). Assume that (IH1) holds true for $n = 1, 2, \ldots, l-1$. By interpolation properties, inverse estimates, and (5.11), we have that

$$
\begin{aligned}
\left\|\mathbf{u}_h^l\right\|_\infty &\le \left\|\mathbf{u}_h^l-\mathbf{u}^l\right\|_\infty+\left\|\mathbf{u}^l\right\|_\infty\\
&\le \left\|\mathbf{E}^l\right\|_\infty+\left\|\Lambda^l\right\|_\infty+M\\
&\le Ch^{-\frac{\acute{d}}{2}}\left\|\mathbf{E}^l\right\|_0+Ch^{-\frac{\acute{d}}{2}}\left\|\Lambda^l\right\|_0+M\\
&\le C\left(\left|\Delta t\right|h^{-\frac{\acute{d}}{2}}+\nu h^{-\frac{\acute{d}}{2}}+h^{k-\frac{\acute{d}}{2}}+h^{m-\frac{\acute{d}}{2}}+h^{q+1-\frac{\acute{d}}{2}}+h^{k+1-\frac{\acute{d}}{2}}\right)+M.
\end{aligned}
\tag{5.56}
$$

Note that the expression $C(\left|\Delta t\right|h^{-\frac{\acute{d}}{2}}+\nu h^{-\frac{\acute{d}}{2}}+h^{k-\frac{\acute{d}}{2}}+h^{m-\frac{\acute{d}}{2}}+h^{q+1-\frac{\acute{d}}{2}}+h^{k+1-\frac{\acute{d}}{2}})$ is independent of l. Hence, if we set $k, m \ge \frac{\acute{d}}{2}, q \ge \frac{\acute{d}}{2}-1$, and choose $h, \Delta t, \nu$ such that

$$
h^{k-\frac{\acute{d}}{2}}, h^{m-\frac{\acute{d}}{2}}, h^{q+1-\frac{\acute{d}}{2}} \le \frac{1}{C}, \qquad \Delta t, \nu \le \frac{h^{\frac{\acute{d}}{2}}}{C},
\tag{5.57}
$$

then from (5.56)

$$
\left\|\mathbf{u}_h^l\right\|_\infty \le M+6.
$$

Similarly it follows that $\left\|\tau_h^l\right\|_\infty \le M+6$. □

Verification of (IH2). Assume that (IH2) is true for $n = 1, 2, \ldots, l-1$. Equations (5.11) and (5.55) imply

$$
\sum_{n=1}^{l}\Delta t\left\|\nabla\mathbf{E}^n\right\|_0^2 \le C\left(h^{2k}+h^{2m}+h^{2q+2}+\left|\Delta t\right|^2+\nu^2\right).
\tag{5.58}
$$

Applying the inverse estimate and using the inequality

$$
\sum_{n=1}^{l}a_n \le \sqrt{l}\left(\sum_{n=1}^{l}a_n^2\right)^{\frac{1}{2}},
$$

from (5.58) we obtain

$$\begin{aligned}\sum_{n=1}^{l} \Delta t \, \|\nabla \mathbf{E}^n\|_\infty &\le C h^{-\frac{d}{2}} \sum_{n=1}^{l} \Delta t \, \|\nabla \mathbf{E}^n\| \\ &\le C h^{-\frac{d}{2}} \sqrt{\Delta t} \, \sqrt{l} \left(\sum_{n=1}^{l} \Delta t \, \|\nabla \mathbf{E}^n\|^2 \right)^{\frac{1}{2}} \\ &\le \tilde{C} \left(\Delta t \, h^{-\frac{d}{2}} + \nu h^{-\frac{d}{2}} + h^{k-\frac{d}{2}} + h^{m-\frac{d}{2}} + h^{q+1-\frac{d}{2}} \right),\end{aligned}$$

where $\tilde{C} = C\sqrt{T}$ is a constant independent of $l, h, \Delta t$, and ν. Hence when

$$\nu, \Delta t \le \frac{h^{\frac{d}{2}}}{5\tilde{C}} \tag{5.59}$$

and

$$h^{k-\frac{d}{2}}, h^{m-\frac{d}{2}}, h^{q+1-\frac{d}{2}} \le \frac{1}{5\tilde{C}},$$

(IH2) holds. □

Step 3. We derive the error estimates in (5.9) and (5.10).

Proof of Theorem 5.4. Using estimates (5.11) and (approximation properties), we have

$$\begin{aligned}|||\mathbf{u} - \mathbf{u}_h|||_{\infty,0}^2 + |||\tau - \tau_h|||_{\infty,0}^2 &\le |||\mathbf{E}|||_{\infty,0}^2 + |||\Lambda|||_{\infty,0}^2 + |||\mathbf{F}|||_{\infty,0}^2 + |||\Gamma|||_{\infty,0}^2 \\ &\le G(\Delta t, h, \nu) + C \left(h^{2k+2} \, |||\mathbf{u}|||_{\infty,k+1}^2 + h^{2m+2} \, |||\tau|||_{\infty,m+1}^2 \right).\end{aligned}$$

Note the restrictions on ν from (5.54), (5.57), (5.59), and on Δt from (3.1), (5.57), (5.59). Hence, we obtain the stated estimate (5.9).

To establish (5.10), from (5.11), (5.55) we have

$$|||\nabla \mathbf{E}|||_{0,0}^2 + \Delta t \, |||\mathbf{F}_u|||_{0,0}^2 \le C(T+1) G(\Delta t, h, \nu) \tag{5.60}$$

and

$$|||\mathbf{E}|||_{0,0}^2 + |||\mathbf{F}|||_{0,0}^2 \le T \, G(\Delta t, h, \nu). \tag{5.61}$$

Hence

$$|||\mathbf{E}|||_{1,0}^2 + |||\mathbf{F}|||_{0,0}^2 \le \tilde{C} G(\Delta t, h, \nu). \qquad \square \tag{5.62}$$

We conclude this analysis with some comments on the sensitivity of the error bounds to the physical parameters in the modeling equations. From (5.47) we note that the constants C_1, C_2, C_3 involve the terms $K^2, M^2, Re, \bar{\lambda}(= \lambda/2\alpha), \lambda^{-1}$. Thus, in view of the exponential multiplicative factor in the discrete Gronwall's lemma, we have that the generic constants C in (5.9), (5.10), (5.11) depend exponentially on these terms.

ADAPTIVE MESH METHODS FOR ONE- AND TWO-DIMENSIONAL HYPERBOLIC CONSERVATION LAWS*

HUAZHONG TANG† AND TAO TANG‡

Abstract. We develop efficient moving mesh algorithms for one- and two-dimensional hyperbolic systems of conservation laws. The algorithms are formed by two independent parts: PDE evolution and mesh-redistribution. The first part can be any appropriate high-resolution scheme, and the second part is based on an iterative procedure. In each iteration, meshes are first redistributed by an equidistribution principle, and then on the resulting new grids the underlying numerical solutions are updated by a *conservative-interpolation* formula proposed in this work. The iteration for the mesh-redistribution at a given time step is complete when the meshes governed by a nonlinear equation reach the equilibrium state. The main idea of the proposed method is to keep the mass-conservation of the underlying numerical solution at each redistribution step. In one dimension, we can show that the underlying numerical approximation obtained in the mesh-redistribution part satisfies the desired TVD property, which guarantees that the numerical solution at any time level is TVD, provided that the PDE solver in the first part satisfies such a property. Several test problems in one and two dimensions are computed using the proposed moving mesh algorithm. The computations demonstrate that our methods are efficient for solving problems with shock discontinuities, obtaining the same resolution with a much smaller number of grid points than the uniform mesh approach.

Key words. adaptive mesh method, hyperbolic conservation laws, finite volume method

1. Introduction.

Adaptive mesh methods have important applications for a variety of physical and engineering areas such as solid and fluid dynamics, combustion, heat transfer, material science, etc. The physical phenomena in these areas develop dynamically singular or nearly singular solutions in fairly localized regions, such as shock waves, boundary layers, detonation waves, etc. The numerical investigation of these physical problems may require extremely fine meshes over a small portion of the physical domain to resolve the large solution variations. In multidimensions, developing effective and robust adaptive grid methods for these problems becomes necessary. Successful implementation of the adaptive strategy can increase the accuracy of the numerical approximations and also decrease the computational cost. In the past two decades, there has been important progress in developing mesh methods for PDEs, including the variational approach of Winslow [36], Brackbill [5], and Brackbill and Saltzman [6]; finite element methods by Miller and Miller [25] and Davis and Flaherty [11]; the moving mesh PDEs of Cao, Huang, and Russell [7], Stockie, Mackenzie, and Russell [33], Li and Petzold [23], and Ceniceros and Hou [8]; and moving mesh methods based on harmonic mapping of Dvinsky [12] and Li, Tang, and Zhang [21, 22].

Harten and Hyman [14] began the earliest study in this direction, by moving the grid at an adaptive speed in each time step to improve the resolution of shocks and contact discontinuities. After their work, many other moving mesh methods for hyperbolic problems have been proposed in the literature, including those of Azarenok and collaborators [1, 2, 3], Fazio and LeVeque [13], Liu, Ji, and Liao [24], Saleri and Steinberg [29], and Stockie, Mackenzie, and Russell [33]. However, many existing moving mesh methods for hyperbolic problems are designed for one space dimension. In one dimension, it is generally possible to compute on a very fine grid, and so the need for moving mesh methods may not be clear. Multidimensional moving mesh methods are often difficult to use in fluid dynamics problems, since the grid will typically suffer large distortions and possible tangling. It is therefore useful to design a simple and robust moving mesh algorithm for hyperbolic problems in multidimensions.

The main objective of this paper is to develop one- and two-dimensional (1D and 2D) moving mesh methods for hyperbolic systems of conservation laws. Following Li, Tang, and Zhang [21] we propose a moving mesh method containing two separate parts: PDE time-evolution and mesh-redistribution. The first part can be any suitable high-resolution method such as the wave-propagation algorithm, central schemes, and ENO methods. Once numerical solutions are obtained at the given time level, the mesh will be redistributed using an iteration procedure. At each iteration, the grid is moved according to a variational principle, and the underlying numerical solution on the new grid will be updated using some simple methods (such as conventional interpolation). It is noted that the direct use of conventional interpolation is unsatisfactory for hyperbolic problems, since many physical properties such as mass-conservation and TVD (in one dimension) may be destroyed. In order to preserve these physical properties, we propose to use conservative-interpolation in the solution-updating step. The idea of using conservative-interpolation is new and is shown to work successfully for hyperbolic problems. This approach also preserves the total mass of the numerical solutions, and by the well-known Lax–Wendroff theory the numerical solutions converge to the weak solution of the underlying hyperbolic system.

The paper is organized as follows. In section 2, we briefly review some theory of the variational approach for moving mesh methods, which is relevant to the mesh-redistribution part of our algorithm. In section 3, we propose a 1D moving mesh algorithm for solving hyperbolic systems of conservation laws, which will be extended to a 2D algorithm in section 4. Numerical experiments are carried out in sections 5 and 6, where several 1D and 2D examples are considered.

2. Mesh generation based on the variational approach. Let $\vec{x} = (x_1, x_2, \dots, x_d)$ and $\vec{\xi} = (\xi_1, \xi_2, \dots, \xi_d)$ denote the physical and computational coordinates, respectively. Here $d \geq 1$ denotes the number of spatial dimensions. A one-to-one coordinate transformation from the computational (or logical) domain Ω_c to the physical domain Ω_p is denoted by

$$\vec{x} = \vec{x}(\vec{\xi}), \qquad \vec{\xi} \in \Omega_c. \tag{2.1}$$

Its inversion is denoted by

$$\vec{\xi} = \vec{\xi}(\vec{x}), \qquad \vec{x} \in \Omega_p. \tag{2.2}$$

In the variational approach, the mesh map is provided by the minimizer of a functional of the following form:

$$E(\vec{\xi}) = \frac{1}{2}\sum_k \int_{\Omega_p} \nabla\xi_k^T G_k^{-1} \nabla\xi_k d\vec{x}, \tag{2.3}$$

where $\nabla := (\partial_{x_1}, \partial_{x_2}, \ldots, \partial_{x_d})^T$ and G_k are given symmetric positive definite matrices called *monitor functions*. In general, monitor functions depend on the underlying solution to be adapted. More terms can be added to the functional (2.3) to control other aspects of the mesh such as orthogonality and mesh alignment with a given vector field [5, 6].

The variational mesh is determined by the Euler–Lagrange equation of the above functional:

$$\nabla \cdot \left(G_k^{-1}\nabla\xi_k\right) = 0, \qquad 1 \le k \le d. \tag{2.4}$$

One of the simplest choices of monitor functions is $G_k = \omega I$, $1 \le k \le d$, where I is the identity matrix and ω is a positive weight function, e.g., $\omega = \sqrt{1 + |\nabla u|^2}$. Here u is the solution of the underlying PDE. In this case, we obtain Winslow's variable diffusion method [36]:

$$\nabla \cdot \left(\frac{1}{\omega}\nabla\xi_k\right) = 0, \qquad 1 \le k \le d. \tag{2.5}$$

By using the above equations, a map between the physical domain Ω_p and the logical domain Ω_c can be computed. Typically, the map transforms a uniform mesh in the logical domain, clustering grid points in those regions of the physical domain where the solution has the largest gradients.

2.1. 1D case. Although the main objective of this work is to provide an effective moving mesh algorithm for 2D conservation laws, it is easier to illustrate the basic moving mesh ideas by starting with some 1D discussions. Let x and ξ denote the physical and computational coordinates, respectively, which are (without loss of generality) assumed to be in $[a, b]$ and $[0, 1]$, respectively. A one-to-one coordinate transformation between these domains is denoted by

$$\begin{aligned} &x = x(\xi), \qquad && \xi \in [0, 1], \\ &x(0) = a, && x(1) = b. \end{aligned} \tag{2.6}$$

The 1D Euler–Lagrange equation has the form

$$(\omega^{-1}\xi_x)_x = 0. \tag{2.7}$$

Using the above equation, we can obtain the conventional 1D *equidistribution principle*: $\omega x_\xi =$ constant, or equivalently,

$$(\omega x_\xi)_\xi = 0. \tag{2.8}$$

Both (2.7) and (2.8) have the same form, and therefore solving either of them will yield the desired mesh map $x = x(\xi)$. However, the situation is different in the 2D case, where we will choose to solve equations of the form (2.8), as will be described in the next subsection.

2.2. 2D case. We will consider the Winslow's variable diffusion method (2.5). The extension to the general Euler–Lagrange equation (2.4) is straightforward. Let $(x, y) = (x(\xi, \eta), y(\xi, \eta))$ be the mesh map in two dimensions. Then (2.5) becomes

$$\begin{aligned} &(\omega^{-1}\xi_x)_x + (\omega^{-1}\xi_y)_y = 0, \\ &(\omega^{-1}\eta_x)_x + (\omega^{-1}\eta_y)_y = 0. \end{aligned} \tag{2.9}$$

In practice, the physical domain Ω_p may have a very complex geometry, and as a result, solving the elliptic system (2.9) directly on structured grids is unrealistic. Therefore we usually solve the corresponding mesh generation equations on the computational domain Ω_c by interchanging the dependent and independent variables in (2.9):

$$\begin{aligned} &\frac{x_\xi}{J}\left[\left(x_\eta \frac{1}{J\omega} x_\eta + y_\eta \frac{1}{J\omega} y_\eta\right)_\xi - \left(x_\xi \frac{1}{J\omega} x_\eta + y_\xi \frac{1}{J\omega} y_\eta\right)_\eta\right] \\ &\qquad + \frac{x_\eta}{J}\left[-\left(x_\eta \frac{1}{J\omega} x_\xi + y_\eta \frac{1}{J\omega} y_\xi\right)_\xi + \left(x_\xi \frac{1}{J\omega} x_\xi + y_\xi \frac{1}{J\omega} y_\xi\right)_\eta\right] = 0, \\ &\frac{y_\xi}{J}\left[\left(x_\eta \frac{1}{J\omega} x_\eta + y_\eta \frac{1}{J\omega} y_\eta\right)_\xi - \left(x_\xi \frac{1}{J\omega} x_\eta + y_\xi \frac{1}{J\omega} y_\eta\right)_\eta\right] \\ &\qquad + \frac{y_\eta}{J}\left[-\left(x_\eta \frac{1}{J\omega} x_\xi + y_\eta \frac{1}{J\omega} y_\xi\right)_\xi + \left(x_\xi \frac{1}{J\omega} x_\xi + y_\xi \frac{1}{J\omega} y_\xi\right)_\eta\right] = 0. \end{aligned} \tag{2.10}$$

Note that system (2.10) is more complicated than the Euler–Lagrange equation (2.9), which requires more computational effort in obtaining numerical approximations. An alternative approach, as observed by Ceniceros and Hou [8], is to consider a functional defined in the computational domain,

$$\tilde{E}[x, y] = \frac{1}{2}\int_{\Omega_c} \left(\widetilde{\nabla}^T x G_1 \widetilde{\nabla} x + \widetilde{\nabla}^T y G_2 \widetilde{\nabla} y\right)\, d\xi d\eta, \tag{2.11}$$

to replace the conventional functional (2.3), where G_k are monitor functions, and $\widetilde{\nabla} = (\partial_\xi, \partial_\eta)^T$. The corresponding Euler–Lagrange equation is

$$\begin{aligned} &\partial_\xi(G_1\partial_\xi x) + \partial_\eta(G_1\partial_\eta x) = 0, \\ &\partial_\xi(G_2\partial_\xi y) + \partial_\eta(G_2\partial_\eta y) = 0. \end{aligned} \tag{2.12}$$

In particular, with the choice $G = \omega I$ we have

$$\widetilde{\nabla} \cdot (\omega\widetilde{\nabla} x) = 0, \qquad \widetilde{\nabla} \cdot (\omega\widetilde{\nabla} y) = 0. \tag{2.13}$$

The monitor functions will be chosen based on the properties of the physical solutions. A typical choice used in [8] is $\omega = \sqrt{1 + \alpha_1|u|^2 + \alpha_2|\widetilde{\nabla} u|^2}$ or $\omega = \sqrt{1 + \alpha_1|u|^2 + \alpha_2|\nabla u|^2}$, where α_1, α_2 are some nonnegative constants.

3. 1D algorithm. For convenience, we assume that a fixed uniform mesh on the computational domain is given by $\xi_j = j/(J+1), 0 \le j \le J+1$. We denote the cell average of the solution $u(x)$ over the interval $[x_j, x_{j+1}]$ as

$$u_{j+\frac{1}{2}} = \frac{1}{\Delta x_{j+\frac{1}{2}}}\int_{x_j}^{x_{j+1}} u(x)\, dx,$$

where $\Delta x_{j+\frac{1}{2}} = x_{j+1} - x_j$. In practice, the monitor function ω is always associated with the underlying solution u or/and its derivatives, but without loss of generality we assume that $\omega = \omega(u)$. For monitor functions involving first or second derivatives, central differencing will be used to approximate these derivatives.

3.1. Mesh-redistribution. In order to solve the mesh-redistribution equation (2.8), we introduce an artificial time τ and solve

$$x_\tau = (\omega x_\xi)_\xi, \qquad 0 < \xi < 1, \tag{3.1}$$

subject to boundary conditions $x(0,\tau) = a$ and $x(1,\tau) = b$. We discretize (3.1) on the uniform mesh in Ω_c:

$$\tilde{x}_j = x_j + \frac{\Delta\tau}{\Delta\xi^2}\left[\omega(u_{j+\frac{1}{2}})(x_{j+1} - x_j) - \omega(u_{j-\frac{1}{2}})(x_j - x_{j-1})\right], \quad 1 \le j \le J, \tag{3.2}$$

where $\Delta\xi = 1/(J+1)$ is the step size in Ω_c. Solving (3.2) with boundary conditions $x_0 = a$ and $x_{J+1} = b$ leads to a new grid in the physical domain Ω_p. Some advantages of using the approach (3.1) and (3.2) to solve the mesh redistribution equation (2.8) will be seen from Lemma 3.1 and Theorem 3.1.

3.2. Solution-updating on new grids. After obtaining the new grid $\{\widetilde{x}_j\}$, we need to update u at the grid point $\widetilde{x}_{j+\frac{1}{2}} = (\widetilde{x}_j + \widetilde{x}_{j+1})/2$ based on the knowledge of $\{x_{j+\frac{1}{2}}, \widetilde{x}_{j+\frac{1}{2}}, u_{j+\frac{1}{2}}\}$. The traditional way to do this is using the conventional interpolation

$$\widetilde{u}_{j+\frac{1}{2}} = u_{k+\frac{1}{2}} + \frac{u_{k+\frac{1}{2}} - u_{k-\frac{1}{2}}}{x_{k+\frac{1}{2}} - x_{k-\frac{1}{2}}}(\widetilde{x}_{j+\frac{1}{2}} - x_{k+\frac{1}{2}}) \qquad \text{if } \widetilde{x}_{j+\frac{1}{2}} \in [x_{k-\frac{1}{2}}, x_{k+\frac{1}{2}}]. \tag{3.3}$$

Since the monitor function ω is dependent on the underlying solution u, the grid redistribution equations (3.2)–(3.3) form a nonlinear system. It is therefore natural to make several iterations to solve (3.2)–(3.3) in order to gain better control of the grid distribution near those regions where the solution u has a large gradient. In solving hyperbolic conservation laws with strong discontinuities (e.g., shocks), iteration techniques based on (3.2)–(3.3) have been employed, and it is found that the results for the solution and the mesh are not satisfactory. The main problem is that the linear interpolation (3.3) cannot preserve conservation of mass, which, by the Lax–Wendroff theory, is an essential requirement for a good numerical scheme for hyperbolic conservation laws.

In the following we will introduce a new method to update u, noting that mass-conservation is an essential requirement for hyperbolic conservation laws. To begin with, assume that the difference between $\tilde{x}_{j+\frac{1}{2}}$ and $x_{j+\frac{1}{2}}$ is small. Let $\widetilde{u}_{j+\frac{1}{2}}$ and $u_{j+\frac{1}{2}}$ be cell averages of the solution $u(x)$ over the intervals $[\widetilde{x}_j, \widetilde{x}_{j+1}]$ and $[x_j, x_{j+1}]$, respectively. We will derive a formula for $\widetilde{u}_{j+\frac{1}{2}}$ using the perturbation method. If

$\widetilde{x} = x - c(x)$ with a small displacement $c(x)$, i.e., $|c(x)| \ll 1$, then we have

$$\begin{aligned}\int_{\widetilde{x}_j}^{\widetilde{x}_{j+1}} \tilde{u}(\widetilde{x})\, d\widetilde{x} &= \int_{x_j}^{x_{j+1}} u(x - c(x))(1 - c'(x))\, dx \\ &\approx \int_{x_j}^{x_{j+1}} (u(x) - c(x)u_x(x))(1 - c'(x))\, dx \\ &\approx \int_{x_j}^{x_{j+1}} (u(x) - (cu)_x)\, dx \\ &= \int_{x_j}^{x_{j+1}} u(x)\, dx - ((cu)_{j+1} - (cu)_j), \end{aligned} \tag{3.4}$$

where we have neglected higher-order terms, and $(cu)_j$ denotes the value of cu at the jth cell interface. The following almost conservative-interpolation formula follows from (3.4):

$$\Delta\widetilde{x}_{j+\frac{1}{2}}\widetilde{u}_{j+\frac{1}{2}} = \Delta x_{j+\frac{1}{2}} u_{j+\frac{1}{2}} - \big((cu)_{j+1} - (cu)_j\big), \tag{3.5}$$

where $\Delta\widetilde{x}_{j+\frac{1}{2}} = \widetilde{x}_{j+1} - \widetilde{x}_j$ and $c_j = x_j - \widetilde{x}_j$. Note that the above solution-updating method guarantees the conservation of mass in the following sense:

$$\sum_j \Delta\widetilde{x}_{j+\frac{1}{2}}\widetilde{u}_{j+\frac{1}{2}} = \sum_j \Delta x_{j+\frac{1}{2}} u_{j+\frac{1}{2}}. \tag{3.6}$$

The linear flux cu in (3.5) will be approximated by some upwinding numerical flux; see (3.11) below.

If the function u is suitably smooth, then it can be shown that the size of the moving speed $c(x)$ is small. It is known that the first and second derivatives of the parabolic-type equation (3.1) are bounded, provided that the initial data and the monitor function satisfy some regularity requirements. By the definition of $c(x)$, we have

$$\begin{aligned} c(x) &= x - \widetilde{x} = -(x_\tau)\Delta\tau = \mathcal{O}(\Delta\tau), \\ c'(x) &= 1 - \tilde{x}_x = 1 - \frac{\widetilde{x}_\xi}{x_\xi} = -\frac{x_{\xi\tau}}{x_\xi}\Delta\tau = \mathcal{O}(\Delta\tau), \end{aligned}$$

which indicate that the moving speed in each cell is indeed very small.

3.3. Solution procedure. Our solution procedure is based on two independent parts: a mesh-redistribution algorithm and a solution algorithm. The first part will be based on an iteration procedure using (3.2) and (3.5). The second part will be independent of the first, and it can be any of the standard codes for solving the given PDEs, such as ENO schemes [31, 39], central schemes [17, 27], relaxation schemes [16, 26, 34], BGK schemes [38, 35], and several other types of high-resolution methods (see, e.g., [20, 15, 18]). The solution procedure can be illustrated by the following flowchart.

ALGORITHM 0.

Step 1. Given a uniform (fixed) partition of the logical domain Ω_c, use the equidistribution principle (2.8) to generate an initial partition $x_j^{[0]} := x_j$ of the physical domain Ω_p. Then compute the grid values $u_{j+\frac{1}{2}}^{[0]}$ based on the cell average for the initial data $u(x, 0)$.

Step 2. Move grid $\{x_j^{[\nu]}\}$ to $\{x_j^{[\nu+1]}\}$ based on scheme (3.2), and compute $\{u_{j+\frac{1}{2}}^{[\nu+1]}\}$ on the new grid based on scheme (3.5) for $\nu \geq 0$. Repeat the updating procedure for a fixed number of iterations or until $\|x^{[\nu+1]} - x^{[\nu]}\| \leq \epsilon$. The mesh-redistribution scheme (3.2) can be also replaced by the Gauss–Seidel iteration procedure (3.32), as discussed at the end of this section.

Step 3. Evolve the underlying PDEs using a high-resolution finite volume method on the mesh $\{x_j^{[\nu+1]}\}$ to obtain the numerical approximations $u_{j+\frac{1}{2}}^{n+1}$ at the time level t_{n+1}.

Step 4. If $t_{n+1} \leq T$, then let $u_{j+\frac{1}{2}}^{[0]} := u_{j+\frac{1}{2}}^{n+1}$ and $x_j^{[0]} := x_j^{[\nu+1]}$ and go to **Step 2**.

3.3.1. Some discussions on Step 2. A new mesh $x_j^{[\nu+1]}$ is obtained using (3.2):

$$x_j^{[\nu+1]} = \alpha_{j+\frac{1}{2}} x_{j+1}^{[\nu]} + (1 - \alpha_{j+\frac{1}{2}} - \alpha_{j-\frac{1}{2}}) x_j^{[\nu]} + \alpha_{j-\frac{1}{2}} x_{j-1}^{[\nu]} \tag{3.7}$$

where

$$\alpha_{j+\frac{1}{2}} = \frac{\Delta\tau}{\Delta\xi^2} \omega(u_{j+\frac{1}{2}}^{[\nu]}).$$

The above equation is solved subject to the following stability condition:

$$\max_j \alpha_{j+\frac{1}{2}} \leq \frac{1}{2}. \tag{3.8}$$

Next, numerical solutions are updated on the new grids $\{x_j^{[\nu+1]}\}$ (at the same time level) using (3.5),

$$u_{j+\frac{1}{2}}^{[\nu+1]} = \beta_j^{[\nu]} u_{j+\frac{1}{2}}^{[\nu]} - \gamma_j^{[\nu]} ((\widehat{cu})_{j+1}^{[\nu]} - (\widehat{cu})_j^{[\nu]}), \tag{3.9}$$

where

$$\gamma_j^{[\nu]} = (x_{j+1}^{[\nu+1]} - x_j^{[\nu+1]})^{-1}, \qquad \beta_j^{[\nu]} = \gamma_j^{[\nu]} \cdot (x_{j+1}^{[\nu]} - x_j^{[\nu]}), \tag{3.10}$$

and the numerical flux $\widehat{cu}_j$ is defined by

$$(\widehat{cu})_j = \frac{c_j}{2}(u_{j+\frac{1}{2}} + u_{j-\frac{1}{2}}) - \frac{|c_j|}{2}(u_{j+\frac{1}{2}} - u_{j-\frac{1}{2}}). \tag{3.11}$$

The wave speed c_j above is defined by $c_j^{[\nu]} = x_j^{[\nu]} - x_j^{[\nu+1]}$.

Remark 3.1. In our numerical computation, the first-order numerical flux $(\widehat{cu})_j$ defined by (3.11) will be replaced by a second-order one as the following:

$$(\widehat{cu})_j = \frac{c_j}{2}(u_j^+ + u_j^-) - \frac{|c_j|}{2}(u_j^+ - u_j^-), \tag{3.12}$$

where u_j^+ and u_j^- will be defined by (3.19) below.

Remark 3.2. In practice, it is common to use some temporal or spatial *smoothing* on the monitor function to obtain smoother meshes. One of the reasons for using smoothing is to avoid very singular mesh and/or large approximation errors near those regions where the solution has a large gradient. In this work, we apply the following low pass filter to smooth the monitor:

$$\omega_{j+\frac{1}{2}} \leftarrow \frac{1}{4}(\omega_{j+\frac{3}{2}} + 2\omega_{j+\frac{1}{2}} + \omega_{j-\frac{1}{2}}), \tag{3.13}$$

where $\omega_{j+\frac{1}{2}} = \omega(u_{j+\frac{1}{2}})$.

3.3.2. Some discussions on Step 3. This step is independent of Step 2, and, as a result, it can be done using any efficient modern numerical technique for hyperbolic conservation laws. As an example, we consider a second-order finite volume approach to solving the 1D scalar hyperbolic conservation laws

$$u_t + f(u)_x = 0, \qquad t > 0, \tag{3.14}$$

with compactly supported initial condition

$$u(x,0) = u_0(x), \qquad u_0 \in L^\infty \cap BV. \tag{3.15}$$

Integrating (3.14) over the control volume $[t_n, t_{n+1}) \times [x_j, x_{j+1}]$ leads to the following (explicit) finite volume method:

$$u^{n+1}_{j+\frac{1}{2}} = u^n_{j+\frac{1}{2}} - \frac{t_{n+1} - t_n}{x_{j+1} - x_j}\left(\widehat{f}^n_{j+1} - \widehat{f}^n_j\right), \tag{3.16}$$

where $\widehat{f}^n_j$ is some appropriate numerical flux satisfying

$$\widehat{f}^n_j = \widehat{f}(u^{n,-}_j, u^{n,+}_j), \qquad \widehat{f}(u,u) = f(u). \tag{3.17}$$

An example of such a numerical flux is the Lax–Friedrichs flux:

$$\widehat{f}(a,b) = \frac{1}{2}\left[f(a) + f(b) - \max_u \{|f_u|\}\,(b-a)\right]. \tag{3.18}$$

In (3.17), $u^{n,\pm}_j$ are defined by

$$u^{n,\pm}_j = u^n_{j\pm\frac{1}{2}} + \frac{1}{2}(x_j - x_{j\pm1})\tilde{S}_{j\pm\frac{1}{2}}, \tag{3.19}$$

where $\tilde{S}_{j+\frac{1}{2}}$ is an approximation of the slope u_x at $x_{j+\frac{1}{2}}$, defined by

$$\tilde{S}_{j+\frac{1}{2}} = \left(\operatorname{sign}(\tilde{S}^+_{j+\frac{1}{2}}) + \operatorname{sign}(\tilde{S}^-_{j+\frac{1}{2}})\right)\frac{|\tilde{S}^+_{j+\frac{1}{2}}\tilde{S}^-_{j+\frac{1}{2}}|}{|\tilde{S}^+_{j+\frac{1}{2}}| + |\tilde{S}^-_{j+\frac{1}{2}}|}, \tag{3.20}$$

with

$$\tilde{S}^+_{j+\frac{1}{2}} = \frac{u^n_{j+\frac{3}{2}} - u^n_{j+\frac{1}{2}}}{x_{j+\frac{3}{2}} - x_{j+\frac{1}{2}}}, \qquad \tilde{S}^-_{j+\frac{1}{2}} = \frac{u^n_{j+\frac{1}{2}} - u^n_{j-\frac{1}{2}}}{x_{j+\frac{1}{2}} - x_{j-\frac{1}{2}}}.$$

The MUSCL (monotone upstream-centered scheme for conservation laws)-type finite volume method (3.16)–(3.18), which is of second-order accuracy in smooth regions, will be applied in the 1D numerical experiments.

3.4. Some theoretical results on the adaptive mesh solutions. In one dimension, some good theoretical guarantees for the numerical grids can be obtained. In the following, we prove some theoretical results for the mesh-redistribution equation (3.7) and the solution-updating equation (3.9). We first demonstrate that the new mesh $x^{[\nu+1]}$ generated by (3.7) keeps the monotonic order of $x^{[\nu]}$.

Lemma 3.1. *Assume $x^{[\nu]}_{j+1} > x^{[\nu]}_j$ for $0 \le j \le J$. If the new mesh $x^{[\nu+1]}$ is obtained using* (3.7)*, with $\alpha_{j+\frac{1}{2}}$ satisfying the stability condition* (3.8)*, then $x^{[\nu+1]}_{j-1} < x^{[\nu]}_j < x^{[\nu+1]}_{j+1}$ for $1 \le j \le J$, and $x^{[\nu+1]}_{j+1} > x^{[\nu+1]}_j$ for $0 \le j \le J$.*

Proof. Using the stability condition (3.8) gives $1-\alpha_{j+\frac{1}{2}}-\alpha_{j-\frac{1}{2}}\geq 0$. Moreover, $\alpha_{j\pm\frac{1}{2}}$ are all positive. Therefore, it follows from (3.7) and the assumption $x_{j+1}^{[\nu]}>x_j^{[\nu]}$ that $x_{j-1}^{[\nu+1]}<x_j^{[\nu]}<x_{j+1}^{[\nu+1]}$. We now rewrite (3.7) into the following form:

$$x_j^{[\nu+1]}=\alpha_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}}^{[\nu]}+x_j^{[\nu]}-\alpha_{j-\frac{1}{2}}\Delta x_{j-\frac{1}{2}}^{[\nu]}, \tag{3.21}$$

where $\Delta x_{j+\frac{1}{2}}=x_{j+1}-x_j$. It follows from the above equation that

$$\Delta x_{j-\frac{1}{2}}^{[\nu+1]}=\alpha_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}}^{[\nu]}+(1-2\alpha_{j-\frac{1}{2}})\Delta x_{j-\frac{1}{2}}^{[\nu]}+\alpha_{j-\frac{3}{2}}\Delta x_{j-\frac{3}{2}}^{[\nu]}.$$

Since the first and last coefficients of the right-hand side are positive and the second one is nonnegative (due to the stability condition (3.8)), the assumption $x_{j+1}^{[\nu]}>x_j^{[\nu]}$ yields $\Delta x_{j-\frac{1}{2}}^{[\nu+1]}>0$. This shows that $x_{j+1}^{[\nu+1]}>x_j^{[\nu+1]}$ for $0\leq j\leq J$. □

Remark 3.3. A consequence of Lemma 3.1 is that $x_j^{[\nu+1]}\in(x_{j-1}^{[\nu]},x_{j+1}^{[\nu]})$, which implies that the speed of mesh moving is finite. This is important in better controlling grid distribution near the regions of large gradients in the solution.

Next, we provide a necessary condition under which the updated solution $u_{j+\frac{1}{2}}^{[\nu+1]}$ satisfies the TVD property.

LEMMA 3.2. *Assume that the initial data* $u^{[0]}$ *is compactly supported and that the stability condition* (3.8) *is satisfied. If* $x_{j-1}^{[\nu+1]}\leq x_j^{[\nu]}\leq x_{j+1}^{[\nu+1]}$ *and* $x_{j+1}^{[\nu+1]}>x_j^{[\nu+1]}$, *then the solution-updating scheme* (3.9)–(3.11) *satisfies*

$$\mathsf{TV}(u^{[\nu+1]})\leq\mathsf{TV}(u^{[\nu]}),$$

where the total variation is defined by

$$\mathsf{TV}(u):=\sum_j\left|u_{j+\frac{1}{2}}-u_{j-\frac{1}{2}}\right|.$$

Proof. For ease of notation we denote $\tilde{x}=x^{[\nu+1]},x=x^{[\nu]},\tilde{u}=u^{[\nu+1]},u=u^{[\nu]}$. Note that $c_{j+1}-c_j=\Delta x_{j+\frac{1}{2}}-\Delta\tilde{x}_{j+\frac{1}{2}}$. This fact, together with the scheme (3.9) and the numerical flux (3.11), gives

$$\begin{aligned}\Delta\tilde{x}_{j+\frac{1}{2}}\tilde{u}_{j+\frac{1}{2}}&=\left(c_{j+1}-c_j+\Delta\tilde{x}_{j+\frac{1}{2}}\right)u_{j+\frac{1}{2}}+\frac{1}{2}\left(|c_{j+1}|-c_{j+1}\right)u_{j+\frac{3}{2}}\\&\quad+\frac{1}{2}\left(c_j-|c_j|-c_{j+1}-|c_{j+1}|\right)u_{j+\frac{1}{2}}+\frac{1}{2}\left(|c_j|+c_j\right)u_{j-\frac{1}{2}}\\&=\Delta\tilde{x}_{j+\frac{1}{2}}u_{j+\frac{1}{2}}+m_{j+1}u_{j+\frac{3}{2}}-m_{j+1}u_{j+\frac{1}{2}}-M_ju_{j+\frac{1}{2}}+M_ju_{j-\frac{1}{2}},\end{aligned}$$

where $M_j=\max(0,c_j)$ and $m_j=-\min(0,c_j)$. Note that both M_j and m_j are nonnegative. It follows from the above result that

$$\tilde{u}_{j+\frac{1}{2}}=u_{j+\frac{1}{2}}+\frac{m_{j+1}}{\Delta\tilde{x}_{j+\frac{1}{2}}}\Delta u_{j+1}-\frac{M_j}{\Delta\tilde{x}_{j+\frac{1}{2}}}\Delta u_j, \tag{3.22}$$

where $\Delta u_j=u_{j+\frac{1}{2}}-u_{j-\frac{1}{2}}$. It follows from (3.22) that

$$\Delta\tilde{u}_j=\Delta u_j+\frac{m_{j+1}}{\Delta\tilde{x}_{j+\frac{1}{2}}}\Delta u_{j+1}-\left(\frac{M_j}{\Delta\tilde{x}_{j+\frac{1}{2}}}+\frac{m_j}{\Delta\tilde{x}_{j-\frac{1}{2}}}\right)\Delta u_j+\frac{M_{j-1}}{\Delta\tilde{x}_{j-\frac{1}{2}}}\Delta u_{j-1},$$

which gives

(3.23)

$$\sum_j |\Delta \tilde{u}_j| \le \sum_j \frac{m_j}{\Delta \tilde{x}_{j-\frac{1}{2}}} |\Delta u_j| + \sum_j \left| 1 - \frac{M_j}{\Delta \tilde{x}_{j+\frac{1}{2}}} - \frac{m_j}{\Delta \tilde{x}_{j-\frac{1}{2}}} \right| |\Delta u_j| \sum_j \frac{M_j}{\Delta \tilde{x}_{j+\frac{1}{2}}} |\Delta u_j|.$$

It can be verified using the definition of c_j that the condition $\tilde{x}_{j-1} \le x_j \le \tilde{x}_{j+1}$ is equivalent to $-\Delta \tilde{x}_{j-\frac{1}{2}} \le c_j \le \Delta \tilde{x}_{j+\frac{1}{2}}$. This fact, together with the observation that $M_j = 0$ when $c_j \le 0$ and $m_j = 0$ when $c_j \ge 0$, yields

$$1 - \frac{M_j}{\Delta \tilde{x}_{j+\frac{1}{2}}} - \frac{m_j}{\Delta \tilde{x}_{j-\frac{1}{2}}} \ge 0. \tag{3.24}$$

It follows from (3.23) and (3.24) that $\mathsf{TV}(\tilde{u}) \le \mathsf{TV}(u)$. □

With the two ingredients above, the following TVD property for Step 2 of Algorithm 0 is established.

THEOREM 3.1. *Assume that the initial data* $u^{[0]}$ *is compactly supported and that the stability condition* (3.8) *is satisfied. Then the iterated mesh and solution* $\{x^{[\nu+1]}, u^{[\nu+1]}\}$ *generated by* (3.7)–(3.11) *satisfies* $\mathsf{TV}(u^{[\nu+1]}) \le \mathsf{TV}(u^{[\nu]})$.

Remark 3.4. If the PDE solver in Step 3 of Algorithm 0 is TVB (i.e., TV-bounded) (or TVD), then the above theorem guarantees the TVB (or TVD) property of the moving mesh solution at any time level. It can be also proved similarly that the l^∞- and the l^1-stabilities are also preserved.

THEOREM 3.2. *Assume that the initial function* u_0 *in* (3.15) *is compactly supported and that the stability condition* (3.8) *is satisfied. Then the moving mesh solution generated by Algorithm* 0, *with* (3.7)–(3.11) *for Step* 2 *and* (3.16) *for Step* 3, *is a weak solution of the conservation law* (3.14).

Proof. Without loss of generality we assume that only one iteration is used in Step 2 of Algorithm 0. Then, given $\{x_j^n, u_{j+\frac{1}{2}}^n\}$, the solution $\{x_j^{n+1}, u_{j+\frac{1}{2}}^{n+1}\}$ is computed by the following operator-splitting-type algorithm:

$$U_{j+\frac{1}{2}}^n = u_{j+\frac{1}{2}}^n - \frac{\Delta t_n}{\Delta x_{j+\frac{1}{2}}^n} \left(f_{j+1}^n - f_j^n \right), \tag{3.25}$$

$$x_j^{n+1} = x_j^n + \frac{\Delta \tau}{\Delta \xi^2} \left[\omega(U_{j+\frac{1}{2}}^n)(x_{j+1}^n - x_j^n) - \omega(U_{j-\frac{1}{2}}^n)(x_j^n - x_{j-1}^n) \right], \tag{3.26}$$

$$\Delta x_{j+\frac{1}{2}}^{n+1} u_{j+\frac{1}{2}}^{n+1} = \Delta x_{j+\frac{1}{2}}^n U_{j+\frac{1}{2}}^n - ((cU^n)_{j+1} - (cU^n)_j), \tag{3.27}$$

where $c_j = x_j^n - x_j^{n+1}$ and the numerical flux f_j^n satisfies the consistency requirement. Multiplying the first equation above by a test function $\phi \in C_0^\infty(\mathbf{R} \times (0, T])$ gives

$$\Delta x_{j+\frac{1}{2}}^n U_{j+\frac{1}{2}}^n \phi(x_j^n, t_n) = \Delta x_{j+\frac{1}{2}}^n u_{j+\frac{1}{2}}^n \phi(x_j^n, t_n) - \Delta t_n \left(f_{j+1}^n - f_j^n \right) \phi(x_j^n, t_n),$$

which, together with the interpolation step (3.27), gives

$$\begin{aligned} &\Delta x_{j+\frac{1}{2}}^{n+1} u_{j+\frac{1}{2}}^{n+1} \phi(x_j^n, t_n) + ((cU^n)_{j+1} - (cU^n)_j) \phi(x_j^n, t_n) \\ &\quad = \Delta x_{j+\frac{1}{2}}^n u_{j+\frac{1}{2}}^n \phi(x_j^n, t_n) - \Delta t_n \left(f_{j+1}^n - f_j^n \right) \phi(x_j^n, t_n). \end{aligned} \tag{3.28}$$

Standard summation by parts yields

$$\sum_j \sum_{n=0}^{N} \left[\Delta x_{j+\frac{1}{2}}^{n+1} u_{j+\frac{1}{2}}^{n+1} - \Delta x_{j+\frac{1}{2}}^{n} u_{j+\frac{1}{2}}^{n}\right] \phi(x_j^n, t_n)$$

$$= -\sum_j \sum_{n=0}^{N} ((cU^n)_{j+1} - (cU^n)_j)\phi(x_j^n, t_n) - \sum_{n=0}^{N} \sum_j \Delta t_n \left(f_{j+1}^n - f_j^n\right) \phi(x_j^n, t_n)$$

and then

$$\begin{aligned} -\sum_j \Delta x_{j+\frac{1}{2}}^0 u_{j+\frac{1}{2}}^0 \phi(x_j^0, 0) &- \sum_j \sum_{n=1}^{N} [\phi(x_j^n, t_n) - \phi(x_j^{n-1}, t_{n-1})] \Delta x_{j+\frac{1}{2}}^n u_{j+\frac{1}{2}}^n \\ &= \sum_j \sum_{n=0}^{N} [\phi(x_j^n, t_n) - \phi(x_{j-1}^n, t_n)](x_j^n - x_j^{n+1}) U_j^n \\ &\quad + \sum_{n=0}^{N} \sum_j \Delta t_n \left[\phi(x_j^n, t_n) - \phi(x_{j-1}^n, t_n)\right] f_j^n, \end{aligned} \tag{3.29}$$

where we have used the fact $\phi(x, t_N) = 0$ with $t_N = T$. We can show that $\Delta x_{j+\frac{1}{2}}^0 \to 0$ as $J \to \infty$. Without loss of generality, assume that the monitor function is the one associated with the equidistribution principle, i.e., $\omega(u) = \sqrt{1 + u_x^2}$. Then

$$L = \sqrt{1 + u_x^2(x_j^0, 0)}\Delta x_{j+\frac{1}{2}}^0, \qquad 0 \le j \le J - 1, \tag{3.30}$$

is a constant independent of j. It follows from the definition of L that

$$L \le \left(1 + |u_x(x_j^0, 0)|\right) \Delta x_{j+\frac{1}{2}}^0, \qquad 0 \le j \le J - 1,$$

which gives

$$JL \le \text{the size of } u_0\text{'s support} + \mathsf{TV}(u^0).$$

This, together with the definition (3.30), leads to

$$\Delta x_{j+\frac{1}{2}}^0 \le \text{const. } J^{-1} \to 0 \qquad \text{as} \quad J \to \infty. \tag{3.31}$$

Moreover, since $\{x_j^n\}$, with $n \ge 1$, are obtained by solving a parabolic equation, we have $\Delta x_{j+\frac{1}{2}}^n \sim \mathcal{O}(\Delta\xi) \to 0$ for $n \ge 1$. Taking limits on both sides of (3.29) leads to

$$-\int u(x, 0)\phi(x, 0)dx - \int\int (\phi_x x_t + \phi_t) u dx dt = -\int\int \phi_x x_t u dx dt + \int\int \phi_x f(u) dx dt,$$

provided that the numerical solution is convergent to u almost everywhere, where for the second term on the LHS (left-hand side) of (3.29) we have used the fact $\phi(x, t)_t = \phi_t x_t + \phi_t$, and for the first term on the RHS (right-hand side) we have used the fact that $c_j = x_j^n - x_j^n \sim x_t dt$. The above result leads to

$$\int\int (\phi_t u + \phi_x f(u)) dx dt + \int u(x, 0)\phi(x, 0) dx = 0,$$

which indicates that the moving mesh solution is indeed a weak solution of the underlying conservation law. □

3.5. Grid-motion with Gauss–Seidel iteration. In practice, we also use the following Gauss–Seidel-type iteration to solve the mesh moving equation (2.8):

$$\omega(u^{[\nu]}_{j+\frac{1}{2}})(x^{[\nu]}_{j+1} - x^{[\nu+1]}_j) - \omega(u^{[\nu]}_{j-\frac{1}{2}})(x^{[\nu+1]}_j - x^{[\nu+1]}_{j-1}) = 0. \tag{3.32}$$

It can also be demonstrated that the new mesh $x^{[\nu+1]}$ generated by (3.32) keeps the monotonic order of $x^{[\nu]}$.

LEMMA 3.3. *Assume $x^{[\nu]}_{j+1} > x^{[\nu]}_j$ for $0 \leq j \leq J$. If the new mesh $x^{[\nu+1]}$ is obtained by using the Gauss–Seidel iterative scheme* (3.32)*, with positive monitor function ω, then $x^{[\nu+1]}_j > x^{[\nu+1]}_{j-1}$ for $1 \leq j \leq J+1$. Moreover, $x^{[\nu]}_j > x^{[\nu+1]}_{j-1}$ for $1 \leq j \leq J+1$.*

Proof. We again denote $\tilde{x} = x^{[\nu+1]}, x = x^{[\nu]}$. It follows from (3.32) that

$$-\alpha_j x_{j+1} + \tilde{x}_j - \beta_j \tilde{x}_{j-1} = 0, \tag{3.33}$$

where $\alpha_j > 0, \beta_j > 0$ (due to the positivity assumption of the monitor function), and $\alpha_j + \beta_j = 1$. It follows from the above equation that

$$\tilde{x}_j - x_{j+1} - \beta_j(\tilde{x}_{j-1} - x_j) = \beta_j(x_j - x_{j+1}) \leq 0,$$

which gives that

$$\tilde{x}_j - x_{j+1} \leq \left(\prod_{k=1}^{j} \beta_k\right)(\tilde{x}_0 - x_1) = \left(\prod_{k=1}^{j} \beta_k\right)(x_0 - x_1) < 0.$$

The above result yields $\tilde{x}_j < x_{j+1}$, which, together with (3.32), also leads to $\tilde{x}_j > \tilde{x}_{j-1}$. □

If we can further show that $x^{[\nu]}_j \leq x^{[\nu+1]}_{j+1}$ for the Gauss–Seidel iteration (3.32), then based on Lemma 3.2 the solution-updating scheme (3.9) together with the mesh-redistribution scheme (3.32) will also satisfy the TVD property, i.e., $\mathsf{TV}(u^{[\nu+1]}) \leq \mathsf{TV}(u^{[\nu]})$. However, it seems unlikely that $x^{[\nu]}_j \leq x^{[\nu+1]}_{j+1}$ holds for (3.32) in general situations. On the other hand, the combination of (3.9) and (3.32) has been employed in our numerical experiments, and the numerical results are quite satisfactory. Therefore, both (3.7) and (3.32) can be used in Step 2 of Algorithm 0 to redistribute grid points. In most test problems considered in this work, the grid updating procedure at each time step takes five full Gauss–Seidel iterations, although the difference between solutions with three and five iterations is very small.

4. 2D algorithm.

One of the advantages of the adaptive mesh methods described in the last section is that they can be naturally extended to two dimensions. In the following, we briefly discuss this extension, together with the boundary point redistribution technique which is necessary for 2D mesh redistribution.

4.1. A conservative solution-updating method. In two dimensions, the logical domain $\bar{\Omega}_c = \{(\xi, \eta) | 0 \leq \xi \leq 1, 0 \leq \eta \leq 1\}$ is covered by the square mesh:

$$\left\{(\xi_j, \eta_k) \,\middle|\, \xi_j = \frac{j}{(J_x+1)}, \eta_k = \frac{k}{(J_y+1)};\ 0 \leq j \leq J_x+1, 0 \leq k \leq J_y+1\right\}.$$

Correspondingly, the numerical approximations to $x = x(\xi, \eta)$ and $y = y(\xi, \eta)$ are denoted by $x_{j,k} = x(\xi_j, \eta_k)$ and $y_{j,k} = y(\xi_j, \eta_k)$. As in the 1D case, we will derive a

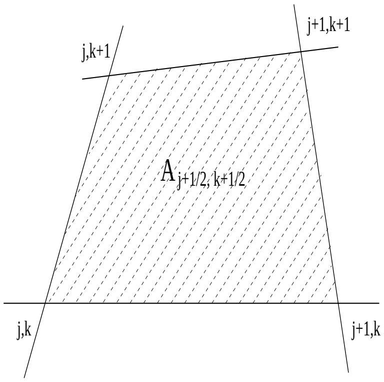

FIG. 4.1. *A control volume.*

conservative scheme to evaluate approximate values at new grid points. Let $A_{j+\frac{1}{2},k+\frac{1}{2}}$ be a control volume as shown in Figure 4.1. Let $\widetilde{A}_{j+\frac{1}{2},k+\frac{1}{2}}$ denote the quadrangle of the finite control volume with four vertices $(\widetilde{x}_{j+p,k+q}, \widetilde{y}_{j+p,k+q})$, $0 \leq p, q \leq 1$, which is of setup similar to Figure 4.1.

Assume that $\widetilde{u}_{j+\frac{1}{2},k+\frac{1}{2}}$ and $u_{j+\frac{1}{2},k+\frac{1}{2}}$ are cell averages of $u(x,,y)$ over $\widetilde{A}_{j+\frac{1}{2},k+\frac{1}{2}}$ and $A_{j+\frac{1}{2},k+\frac{1}{2}}$, respectively. As in the 1D case, we use the perturbation method to evaluate the numerical approximation on the resulting new grids $(\widetilde{x}_{j,k}, \widetilde{y}_{j,k})$. If $(\widetilde{x}, \widetilde{y}) = (x - c^x(x,y),\, y - c^y(x,y))$, where we assume that the speeds (c^x, c^y) have small amplitude, then we have

$$\begin{aligned}
&\int_{\widetilde{A}_{j+\frac{1}{2},k+\frac{1}{2}}} \widetilde{u}(\widetilde{x},\widetilde{y})\ d\widetilde{x}d\widetilde{y} \\
&= \int_{A_{j+\frac{1}{2},k+\frac{1}{2}}} u(x-c^x,\, y-c^y) \det\left(\frac{\partial(\tilde{x},\tilde{y})}{\partial(x,y)}\right) dxdy \\
&\approx \int_{A_{j+\frac{1}{2},k+\frac{1}{2}}} (u(x,y) - c^x u_x - c^y u_y)(1 - c^x_x - c^y_y)\ dxdy \\
&\approx \int_{A_{j+\frac{1}{2},k+\frac{1}{2}}} [u(x,y) - c^x u_x - c^y u_y - c^x_x u - c^y_y u] dxdy \\
&= \int_{A_{j+\frac{1}{2},k+\frac{1}{2}}} [u(x,y) - (c^x u)_x - (c^y u)_y] dxdy \\
&= \int_{A_{j+\frac{1}{2},k+\frac{1}{2}}} u(x,y)\ dxdy - \left[(c_n u)_{j+1,k+\frac{1}{2}} + (c_n u)_{j,k+\frac{1}{2}}\right] \\
&\qquad - \left[(c_n u)_{j+\frac{1}{2},k+1} + (c_n u)_{j+\frac{1}{2},k}\right],
\end{aligned} \tag{4.1}$$

where we have neglected higher-order terms, $c_n := c^x n_x + c^y n_y$ with (n_x, n_y) the unit normal, and $(c_n u)_{j,k+\frac{1}{2}}$ and $(c_n u)_{j+\frac{1}{2},k}$ denote the values of $c_n u$ at the corresponding surfaces of the control volume $A_{j+\frac{1}{2},k+\frac{1}{2}}$. From (4.1), we obtain a conservative-interpolation:

$$\begin{aligned}
&|\widetilde{A}_{j+\frac{1}{2},k+\frac{1}{2}}| \widetilde{u}_{j+\frac{1}{2},k+\frac{1}{2}} = |A_{j+\frac{1}{2},k+\frac{1}{2}}| u_{j+\frac{1}{2},k+\frac{1}{2}} \\
&\quad - \left[(c_n u)_{j+1,k+\frac{1}{2}} + (c_n u)_{j,k+\frac{1}{2}}\right] - \left[(c_n u)_{j+\frac{1}{2},k+1} + (c_n u)_{j+\frac{1}{2},k}\right],
\end{aligned} \tag{4.2}$$

where $|\widetilde{A}|$ and $|A|$ denote the areas of the control volumes $\widetilde{A}$ and A, respectively. It can be verified that the above solution-updating scheme satisfies mass-conservation:

$$\sum_{j,k} |\widetilde{A}_{j+\frac{1}{2},k+\frac{1}{2}}|\widetilde{u}_{j+\frac{1}{2},k+\frac{1}{2}} = \sum_{j,k} |A_{j+\frac{1}{2},k+\frac{1}{2}}|u_{j+\frac{1}{2},k+\frac{1}{2}}. \tag{4.3}$$

4.2. Solution procedure. The solution procedure of our adaptive mesh strategy for two-dimensional hyperbolic problems is almost the same as that of Algorithm 0 provided in section 3.3. Some details of the steps used for our 2D algorithm are given below.

Step i. Give an initial partition $\vec{z}^{[0]}_{j,k} = \big(x^{[0]}_{j,k}, y^{[0]}_{j,k}\big) := (x_{j,k}, y_{j,k})$ of the physical domain Ω_p and a uniform (fixed) partition of the logical domain Ω_c, and compute grid values $u^{[0]}_{j+\frac{1}{2},k+\frac{1}{2}}$ by cell averaging the initial data $u(x,y,0)$ over the control volume $A_{j+\frac{1}{2},k+\frac{1}{2}}$.

Step ii. For $\nu = 0, 1, 2, \ldots,$ do the following:

(a) Move grid $\vec{z}^{[\nu]}_{j,k} = \{(x^{[\nu]}_{j,k}, y^{[\nu]}_{j,k})\}$ to $\vec{z}^{[\nu+1]}_{j,k} = \{(x^{[\nu+1]}_{j,k}, y^{[\nu+1]}_{j,k})\}$ by solving $\vec{z}_\tau = (\omega \vec{z}_\xi)_\xi + (\omega \vec{z}_\eta)_\eta$ with the conventional explicit scheme. This step can be also done by solving $(\omega \vec{z}_\xi)_\xi + (\omega \vec{z}_\eta)_\eta = 0$ with the following Gauss–Seidel iteration:

$$\begin{aligned} &\alpha_{j+\frac{1}{2},k}\big(\vec{z}^{[\nu]}_{j+1,k} - \vec{z}^{[\nu+1]}_{j,k}\big) - \alpha_{j-\frac{1}{2},k}\big(\vec{z}^{[\nu+1]}_{j,k} - \vec{z}^{[\nu+1]}_{j-1,k}\big) \\ &\quad + \beta_{j,k+\frac{1}{2}}\big(\vec{z}^{[\nu]}_{j,k+1} - \vec{z}^{[\nu+1]}_{j,k}\big) - \beta_{j,k-\frac{1}{2}}\big(\vec{z}^{[\nu+1]}_{j,k} - \vec{z}^{[\nu+1]}_{j,k-1}\big) = 0 \end{aligned} \tag{4.4}$$

for $1 \le j \le J_x$ and $1 \le k \le J_y$, where

$$\begin{aligned} \alpha_{j\pm\frac{1}{2},k} &= \omega\big(u^{[\nu]}_{j\pm\frac{1}{2},k}\big) = \omega\big(\tfrac{1}{2}(u^{[\nu]}_{j\pm\frac{1}{2},k+\frac{1}{2}} + u^{[\nu]}_{j\pm\frac{1}{2},k-\frac{1}{2}})\big), \\ \beta_{j,k\pm\frac{1}{2}} &= \omega\big(u^{[\nu]}_{j,k\pm\frac{1}{2}}\big) = \omega\big(\tfrac{1}{2}(u^{[\nu]}_{j+\frac{1}{2},k\pm\frac{1}{2}} + u^{[\nu]}_{j-\frac{1}{2},k\pm\frac{1}{2}})\big). \end{aligned}$$

(b) Compute $\{u^{[\nu+1]}_{j+\frac{1}{2},k+\frac{1}{2}}\}$ on the new grid using the conservative-interpolation (4.2). The approximations for c^x, c^y, etc. are direct extensions of those defined for the 1D case.

(c) Repeat the updating procedure (a) and (b) for a fixed number of iterations (say, three or five) or until $\|\vec{z}^{[\nu+1]} - \vec{z}^{[\nu]}\| \le \epsilon$.

Step iii. Evolve the underlying PDEs using 2D high-resolution finite volume methods on the mesh $\{(x^{[\nu+1]}_{j,k}, y^{[\nu+1]}_{j,k})\}$ to obtain the numerical approximations $u^{n+1}_{j+\frac{1}{2},k+\frac{1}{2}}$ at the time level t_{n+1}.

Step iv. If $t_{n+1} \le T$, then let $u^{[0]}_{j+\frac{1}{2},k+\frac{1}{2}} := u^{n+1}_{j+\frac{1}{2},k+\frac{1}{2}}$ and $(x^{[0]}_{j,k}, y^{[0]}_{j,k}) := (x^{[\nu+1]}_{j,k}, y^{[\nu+1]}_{j,k})$, and go to Step ii.

4.3. Boundary redistribution. In many flow situations, discontinuities may initially exist in boundaries or move to boundaries at a later time. As a consequence, boundary point redistribution should be made in order to improve the quality of the solution near boundaries. A simple redistribution strategy is proposed as follows. (For convenience, our attention is restricted to the case in which the physical domain Ω_p is rectangular.) Assume that a new set of grid points $\{\tilde{x}_{j,k}, \tilde{y}_{j,k}\}$ is obtained in Ω_p by solving the moving mesh equation (4.4). Then the speeds of the internal grid point $(x_{j,k}, y_{j,k})$ are given by

$$(c^1, c^2)_{j,k} := (\widetilde{x} - x, \widetilde{y} - y)_{j,k} \qquad \text{for} \quad 1 \le j \le J_x,\ 1 \le j \le J_y.$$

We assume that the points of the left and bottom boundaries are moving with the same speed as the tangential component of the speed for the internal points adjacent to those boundary points, namely,

$$\begin{aligned}(c^1, c^2)_{0,k} &= (0, c^2_{1,k}), \qquad 1 \le j \le J_y,\\ (c^1, c^2)_{j,0} &= (c^1_{j,1}, 0), \qquad 1 \le j \le J_x.\end{aligned}$$

Thus new boundary points $(\widetilde{x}_{0,k}, \widetilde{y}_{0,k})$ and $(\widetilde{x}_{j,0}, \widetilde{y}_{j,0})$ are defined by

$$\begin{aligned}(\widetilde{x}, \widetilde{y})_{0,k} &= (x, y)_{0,k} + (c^1, c^2)_{0,k}, \qquad 1 \le k \le J_y,\\ (\widetilde{x}, \widetilde{y})_{j,0} &= (x, y)_{j,0} + (c^1, c^2)_{j,0}, \qquad 1 \le j \le J_x.\end{aligned}$$

The redistribution for other boundaries can be carried out in a similar way. Numerical experiments show that the above procedure for moving the boundary points is useful in improving the solution resolution.

5. Numerical experiments for 1D problems. In this section, we first implement our adaptive mesh methods presented in the last section for several 1D model problems. One of the main advantages of Algorithm 0 is that the solution algorithm (i.e., PDE solver) and the mesh redistribution algorithm are independent of each other. Several solution schemes, such as the MUSCL-type finite volume method (3.16)–(3.18), the second-order MUSCL-type gas-kinetic approach [38], and the second-order central scheme [27], have been employed to evolve the underlying PDEs in Step 3 of Algorithm 0. The results obtained by the three methods are in good agreement.

5.1. 1D example. Three examples will be considered in this subsection. All of them have been used by several authors to test various numerical schemes.

Example 5.1. *Burgers' equation.* This example is the inviscid Burgers' equation

$$u_t + \left(\frac{u^2}{2}\right)_x = 0, \qquad 0 \le x \le 2\pi, \tag{5.1}$$

subject to the 2π-periodic initial data

$$u(x, 0) = 0.5 + \sin(x), \quad x \in [0, 2\pi).$$

The solution propagates to the right, steepening until the critical time $t_c = 1$, at which a shock forms. Figure 5.1 shows the solutions at $t = 2$, when the shock is well developed. Also shown in Figure 5.1 is the trajectory of the grid points up to $t = 2$, obtained with $J = 30$ and $J = 50$. The ability of the adaptive mesh method to capture and follow the moving shock is clearly demonstrated in this figure. Some details in this example are the following: the monitor function used in the computation is $\omega = \sqrt{1 + 0.2|u_\xi|^2}$; the number of Gauss–Seidel iterations used is 5; the scheme for evolving Burgers' equation is a (formally) second-order MUSCL finite volume scheme (with the Lax–Friedrichs flux) together with a second-order Runge–Kutta discretization; the CFL number used is 0.3.

In Table 5.1, L^1-error and convergence rate are listed for $t = 0.9$ and $t = 0.999$. It is observed that a second-order rate of convergence can be obtained for the adaptive mesh method.

Example 5.2. *Nonconvex conservation laws.* Here we apply the adaptive mesh algorithm to the Riemann problem of a scalar hyperbolic conservation law with a nonlinear nonconvex flux:

$$u_t + f(u)_x = 0, \qquad f(u) = \frac{1}{4}(u^2 - 1)(u^2 - 4). \tag{5.2}$$

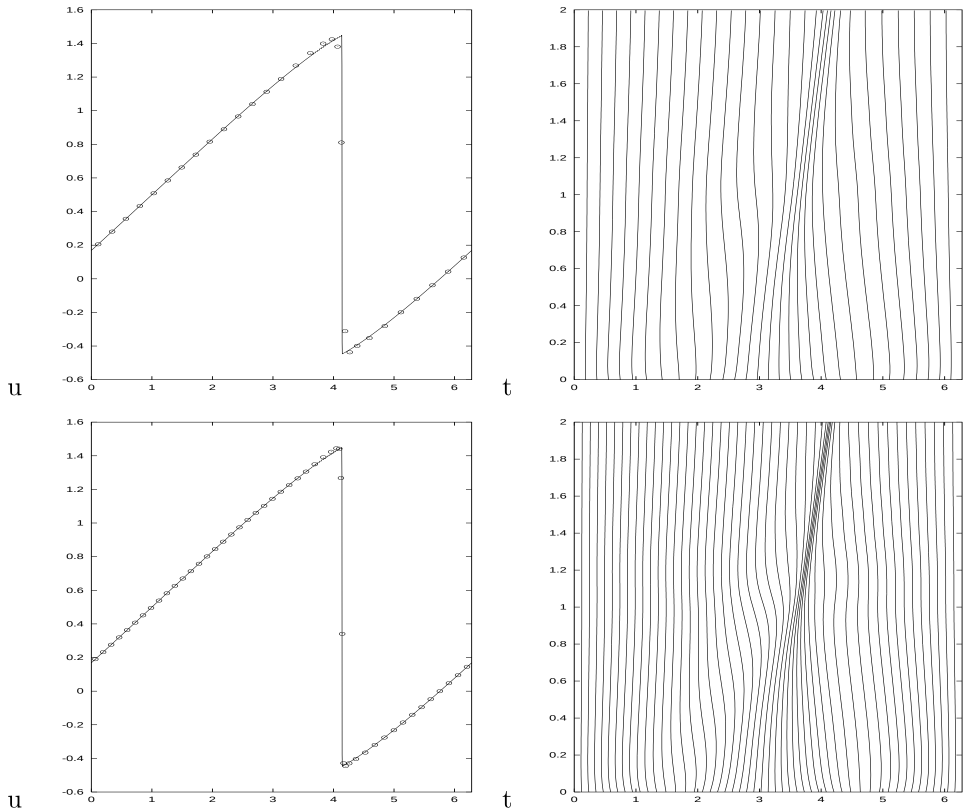

FIG. 5.1. *Example* 5.1. *Left: numerical ("o") and exact solutions (solid line) at* $t = 2$. *Right: trajectory of the mesh for* $0 \leq t \leq 2$. *Top:* $J = 30$; *and bottom:* $J = 50$.

TABLE 5.1
Example 5.1: L^1*-error and convergence order at* $t = 0.9$ *and* $t = 0.999$.

J	40	80	160	320
$t = 0.9$	4.73e-2 (–)	1.48e-2 (1.68)	3.76e-3 (1.98)	7.90e-4 (2.25)
$t = 0.999$	5.84e-2 (–)	1.85e-2 (1.67)	5.23e-3 (1.82)	1.33e-3 (1.98)

The initial data are $u(x, 0) = -2\text{sign}(x)$.

The problem was also considered in [17]. In contrast with Burgers' equation, the flux function for this problem is nonconvex, which leads to difficulties with some numerical schemes and so serves as a good test problem. The numerical solution at $t = 1.2$ is shown for an adaptive mesh in Figure 5.2, with $J = 30$ and 50. Some details in this example are the following: the monitor function used in the computation is $\omega = \sqrt{1 + |u_\xi|^2}$; the number of Gauss–Seidel iterations is 5; the scheme for evolving (5.2) is a (formally) second-order MUSCL finite volume scheme (with the Lax–Friedrichs flux) together with a second-order Runge–Kutta discretization. It is seen that the numerical solution gives sharp shock profiles.

Example 5.3. *Euler equations of gas dynamics.* In this example, we test our

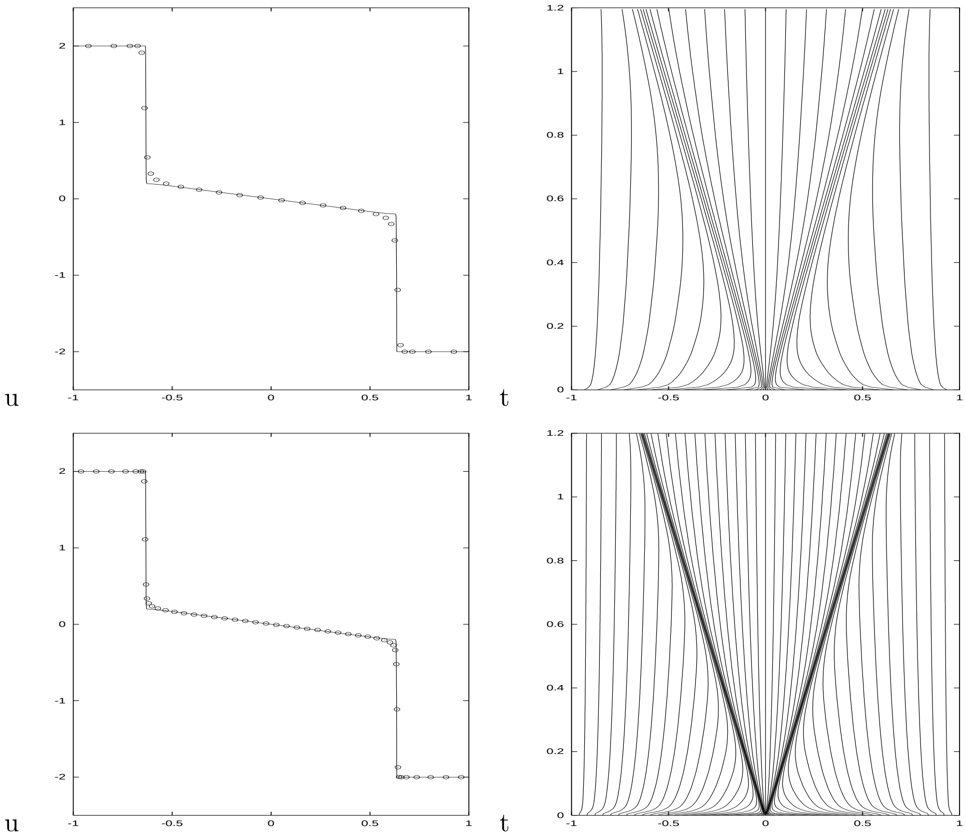

FIG. 5.2. *Example* 5.2. *Left: numerical ("o") and exact solutions (solid line) at* $t = 1.2$*. Right: trajectory of the mesh for* $0 \le t \le 1.2$*. Top:* $J = 30$*; and bottom:* $J = 50$*.*

adaptive mesh algorithm with the one-dimensional Euler equations of gas dynamics,

$$\begin{bmatrix} \rho \\ \rho u \\ E \end{bmatrix}_t + \begin{bmatrix} \rho u \\ \rho u^2 + p \\ u(E+p) \end{bmatrix}_x = 0, \tag{5.3}$$

where ρ, u, p, and E are density, velocity, pressure, and total energy, respectively. The above system is closed by the equation of state, $p = (\gamma - 1)(E - \rho u^2/2)$. The initial data are chosen as

$$(\rho, \rho u, E) = \begin{cases} (1,\ 0,\ 2.5) & \text{if } x < 0.5, \\ (0.125,\ 0,\ 0.25) & \text{if } x > 0.5. \end{cases}$$

This is a well known test problem proposed by Sod [32]. The monitor function employed for this computation is $G = \omega I$ with

$$\omega = \sqrt{1 + \alpha_1 \left(\frac{u_\xi}{\max_\xi |u_\xi|} \right)^2 + \alpha_2 \left(\frac{s_\xi}{\max_\xi |s_\xi|} \right)^2}, \tag{5.4}$$

where $s = p/\rho^\gamma$, and the parameters α_i $(i = 1, 2)$ are some nonnegative constants. The above monitor function was suggested by Stockie, Mackenzie, and Russell [33], who also discussed several other choices for the monitor function. The numerical results are obtained with $J = 100$, $\alpha_1 = 20, \alpha_2 = 100$ and are presented in Figure 5.3.

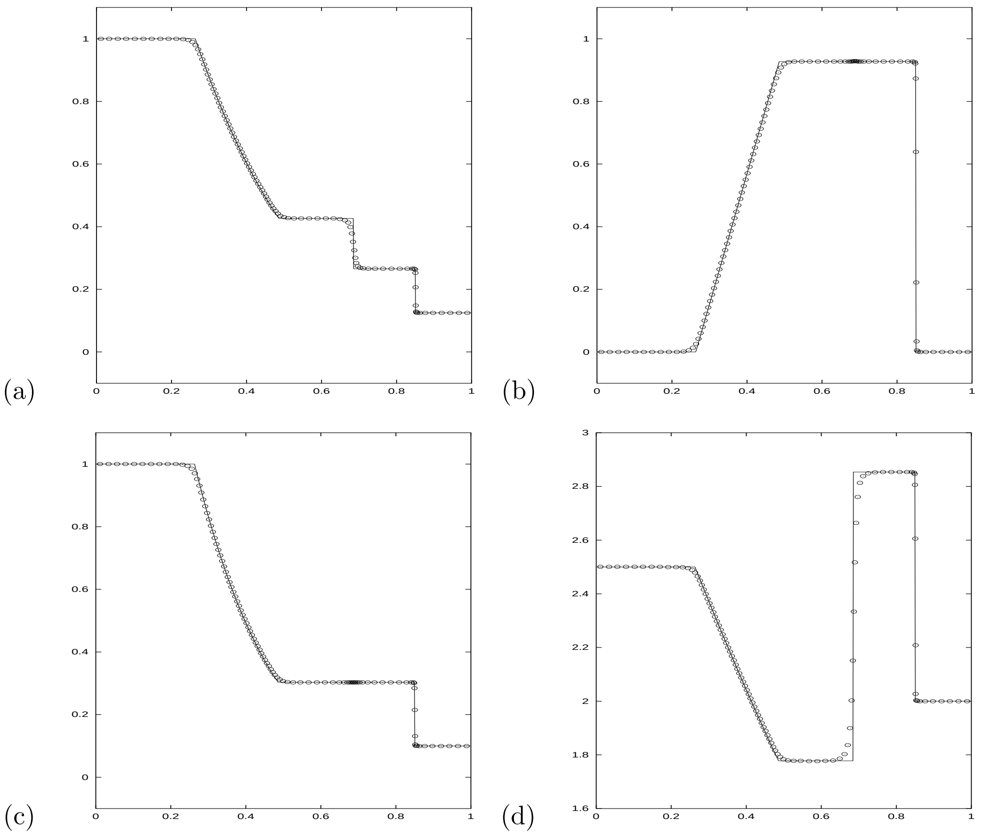

FIG. 5.3. *Example* 5.3: *adaptive mesh solution at* $t = 0.2$. (a) *density,* (b) *velocity,* (c) *pressure, and* (d) *internal energy. "o" and solid lines denote numerical and exact solutions, respectively.*

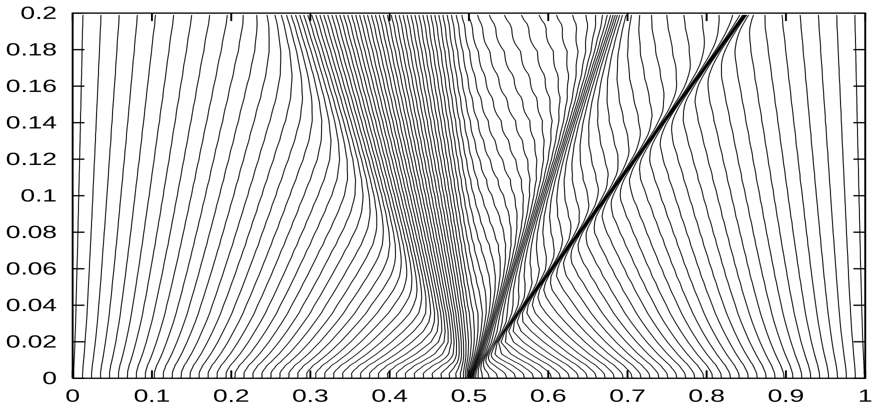

FIG. 5.4. *Example* 5.3: *trajectory of the grid points.*

It is found that the contact and shock discontinuities are well resolved, although quite a number of grid points are also moved to the rarefaction wave region. This can also be observed from the mesh contour plotted in Figure 5.4.

6. Numerical experiment for 2D problems. In this section, we will test our adaptive mesh algorithm presented in section 3.3 for some 2D problems, including 2D Riemann problems, a double-Mach reflection problem, and flow past a circular cylinder.

6.1. 2D grid generation. We begin by testing Step 2 of Algorithm 0, i.e., testing the mesh distribution part with given functions.

Example 6.1. *2D grid generation.* We consider grid generation in the physical domain $[-1,1] \times [-1,1]$ for the following functions:

$$u(x,y) = \exp(-8(4x^2 + 9y^2 - 1)^2), \tag{6.1}$$

$$u(x,y) = \exp(-100(y - x^2 + 0.5)^2), \tag{6.2}$$

$$u(x,y) = 50\exp(-2500(x^2 + y^2)), \tag{6.3}$$

$$u(x,y) = \begin{cases} 1 & \text{if } |x| \leq |y|, \\ 0 & \text{otherwise.} \end{cases} \tag{6.4}$$

The monitor function is taken as $G = \omega I$ with $\omega = \sqrt{1 + \alpha u^2}$, with $\alpha = 100$. Grid generations based on the above functions have been investigated by many authors; see e.g., [7, 21, 28]. Our results plotted in Figure 6.1 can be favorably compared with published results. Our results indicate that Step 2 of Algorithm 0 for two dimensions performs well for functions with large gradients or singularities.

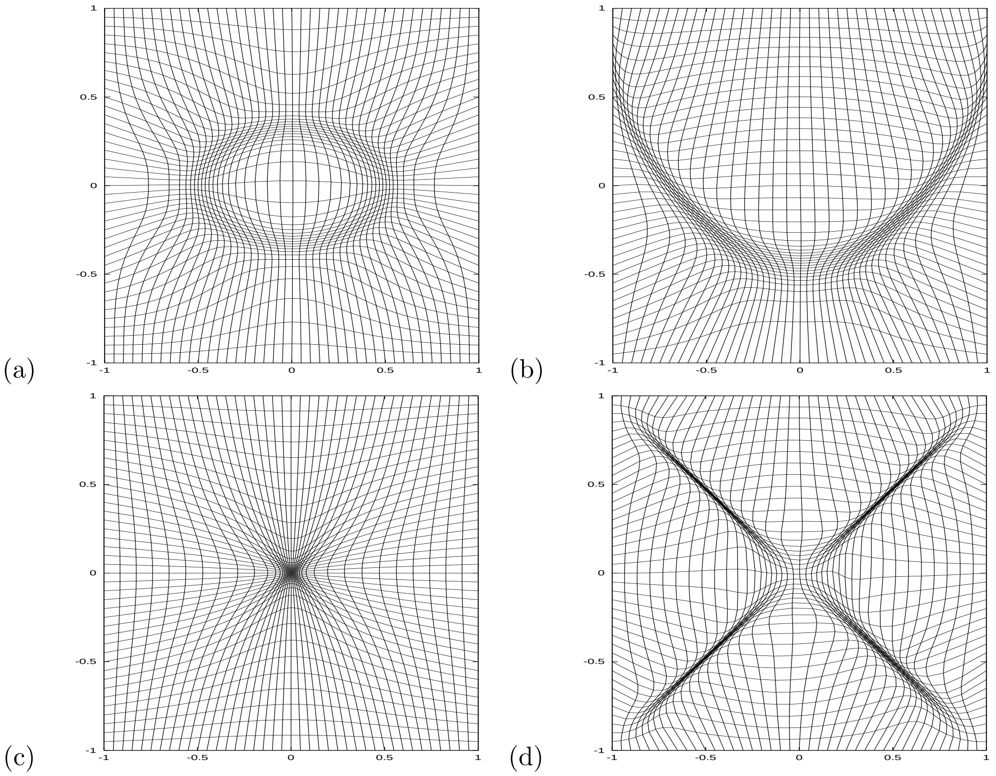

Fig. 6.1. *Example* 6.1: *the adaptive meshes for* (a) *function* (6.1), (b) *function* (6.2), (c) *function* (6.3), *and* (d) *function* (6.4).

6.2. 2D examples for Euler equations of gas dynamics. In this subsection we consider some well known test examples in two dimensions, including three Riemann problems and a double-Mach reflection problem.

Example 6.2. 2*D Riemann problem* I: *Shock waves.* Two-dimensional Euler equations of gas dynamics can be written as

$$\begin{bmatrix} \rho \\ \rho u \\ \rho v \\ E \end{bmatrix}_t + \begin{bmatrix} \rho u \\ \rho u^2 + p \\ \rho uv \\ u(E+p) \end{bmatrix}_x + \begin{bmatrix} \rho v \\ \rho uv \\ \rho v^2 + p \\ v(E+p) \end{bmatrix}_y = 0, \tag{6.5}$$

where ρ, (u, v), p, and E are the density, velocity, pressure, and total energy, respectively. For an ideal gas, the equation of state, $p = (\gamma - 1)(E - \rho(u^2 + v^2)/2)$, is provided. The initial data are chosen as

$$(\rho, u, v, p) = \begin{cases} (1.1,\ 0.0,\ 0.0,\ 1.1) & \text{if } x > 0.5, \quad y > 0.5, \\ (0.5065,\ 0.8939,\ 0.0,\ 0.35) & \text{if } x < 0.5, \quad y > 0.5, \\ (1.1,\ 0.8939,\ 0.8939,\ 1.1) & \text{if } x < 0.5, \quad y < 0.5, \\ (0.5065,\ 0.0,\ 0.8939,\ 0.35) & \text{if } x > 0.5, \quad y < 0.5, \end{cases}$$

which corresponds to the case of left forward shock, right backward shock, upper backward shock, and lower forward shock. We refer the readers to [19, 30] for details.

In [19], Lax and Liu computed 2D Riemann problems with various initial data using positive schemes. The problem considered here corresponds to Configuration 4 discussed in their paper. We use our adaptive mesh algorithm with $(J_x, J_y) = (50, 50)$ and $(J_x, J_y) = (100, 100)$ to compute this Riemann problem and display the mesh and density at $t = 0.25$ in Figure 6.2. It is found that our results with $J_x = J_y = 100$ give sharper shock resolution than that of the positive schemes with $(J_x, J_y) = (400, 400)$ (see [19, p. 333]). The monitor function used in this computation is $G = \omega I$, with $\omega = \sqrt{1 + 2(\rho_\xi^2 + \rho_\eta^2)x}$.

Example 6.3. 2*D Riemann problem* II: *Contact discontinuities.* We reconsider Configurations 6 and 7 in Lax and Liu's paper [19], whose solutions contain contact discontinuities. The first configuration has initial data

$$(\rho, u, v, p) = \begin{cases} (1,\ 0.75,\ -0.5,\ 1) & \text{if } x > 0.5, \quad y > 0.5, \\ (2,\ 0.75,\ 0.5,\ 1) & \text{if } x < 0.5, \quad y > 0.5, \\ (1,\ -0.75,\ 0.5,\ 1) & \text{if } x < 0.5, \quad y < 0.5, \\ (3,\ -0.75,\ -0.5,\ 1) & \text{if } x > 0.5, \quad y < 0.5, \end{cases}$$

and the second configuration has initial data

$$(\rho, u, v, p) = \begin{cases} (1,\ 0.1,\ 0.1,\ 1) & \text{if } x > 0.5, \quad y > 0.5, \\ (0.5197,\ -0.6259,\ 0.1,\ 0.4) & \text{if } x < 0.5, \quad y > 0.5, \\ (0.8,\ 0.1,\ 0.1,\ 0.4) & \text{if } x < 0.5, \quad y < 0.5, \\ (0.5197,\ 0.1,\ -0.6259,\ 0.4) & \text{if } x > 0.5, \quad y < 0.5. \end{cases}$$

The adaptive mesh results for Configuration 6 at $t = 0.3$ and for Configuration 7 at $t = 0.25$ are displayed in Figure 6.3. The number of grid points are $(J_x, J_y) = (100, 100)$. It can be observed that the adaptive mesh results with $J_x = J_y = 100$ for Configuration 7 are comparable with those obtained by using the positive schemes with $J_x = J_y = 400$ (see [19, p. 334]). However, this seems not to be the case for the results for Configuration 6. Although the resolution can be improved by using more

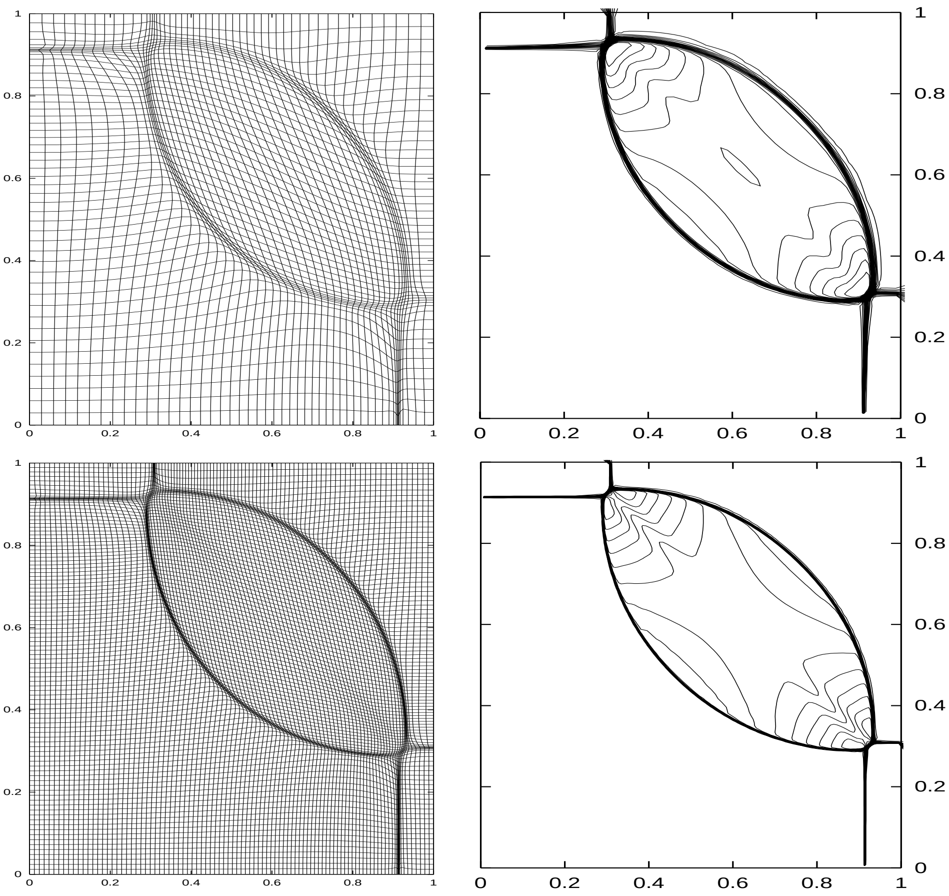

FIG. 6.2. *Example* 6.2. *The contours of the mesh (left) and the density (right). Top:* $J_x = J_y = 50$*; and bottom:* $J_x = J_y = 100$*.* 30 *equally spaced contour lines are used for the density.*

grid points, it is quite clear from this computation and Example 6.2 that the treatment of contact discontinuities is less effective than the treatment of shocks. It is expected that the monitor functions used in this paper are suitable for shock discontinuities but may be less appropriate for contact discontinuities. Therefore, it requires further investigation to obtain more effective monitor functions for contact discontinuities.

For this computation, the monitor function can be chosen as $G = \omega I$, with $\omega = \sqrt{1 + \alpha(\rho_\xi^2 + \rho_\eta^2)}$. It is found that in both cases if the parameter α is chosen in the range $[0.1, 1]$, then the efficiency and effectiveness of the adaptive mesh approach seem satisfactory. The results in Figure 6.3 are obtained using $\alpha = 0.1$ (for Configuration 6) and $\alpha = 0.9$ (for Configuration 7).

Example 6.4. *The double-Mach reflection problem.* This problem was studied extensively in Woodward and Colella [37] and later by many others. We use exactly the same setup as in [37], i.e., the same initial and boundary conditions and same solution domain $\Omega_p = [0, 4] \times [0, 1]$. Initially a right-moving Mach 10 shock is positioned at $x = \frac{1}{6}$, $y = 0$ and makes a 60° angle with the x-axis. More precisely, the initial data are

$$U = \begin{cases} U_L & \text{for} \quad y \geq h(x, 0), \\ U_R & \text{otherwise}, \end{cases}$$

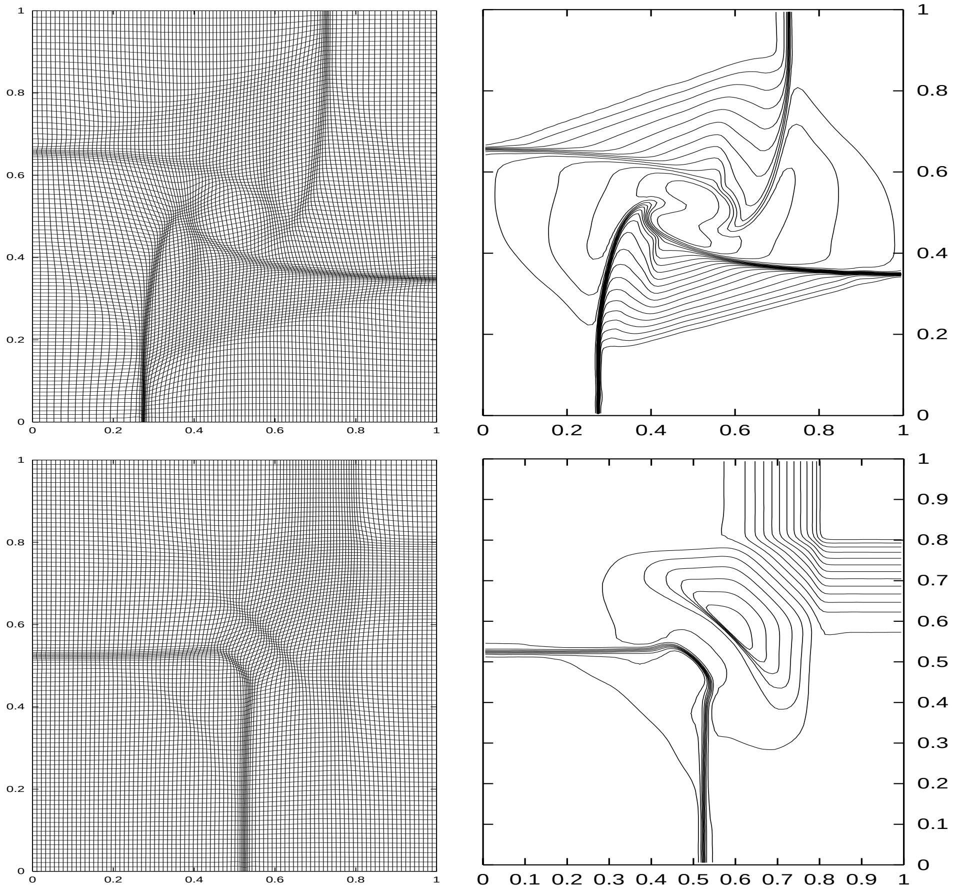

FIG. 6.3. *Adaptive mesh results for Example* 6.3 *with* 100×100 *grid points. Top: Configuration* 6; *bottom: Configuration* 7. *Left: the adaptive mesh; Right: density.* 19 *equally spaced contour lines are used for the density.*

where the state on the left, the state on the right, and the shock strength are, respectively,

$$U_L = (8,\ 57.1597,\ -33.0012,\ 563.544)^T,$$
$$U_R = (1.4,\ 0.0\ 0.0,\ 2.5)^T, \qquad h(x,t) = \sqrt{3}(x - 1/6) - 20t.$$

As in [37], only the results in $[0,3] \times [0,1]$ are displayed. In Figure 6.4, the adaptive meshes with $(J_x, J_y) = (80, 20)$, $(160, 40)$, and $(320, 80)$ are displayed, while the corresponding contours of density are displayed in Figure 6.5. By comparing the density plots, it is found that the adaptive computation results with $(J_x, J_y) = (320, 80)$ have similar resolution to the results obtained by the second-order discontinuous Galerkin method with $(J_x, J_y) = (960, 240)$ (see [10, p. 214]) and by the second-order central scheme with $(J_x, J_y) = (960, 240)$ (see [10, p. 67]). Moreover, the adaptive results with $(J_x, J_y) = (160, 40)$ have slightly better resolution than the results of fifth-order weighted ENO and the fourth-order ENO with 480×119 grids [10, p. 406]. Of course, this is not too surprising, since these published results are computed using uniform meshes.

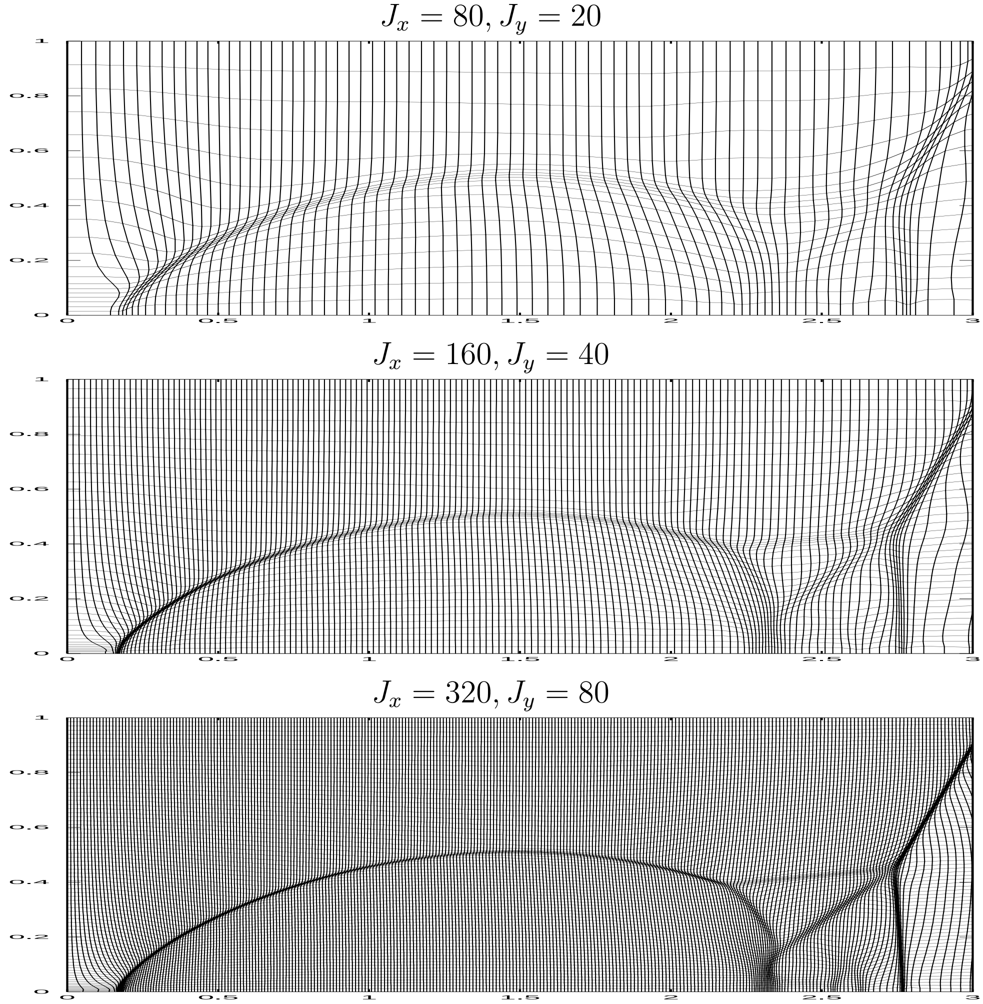

FIG. 6.4. *2D double-Mach reflection at* $t = 0.2$*: the contours of meshes. From top to bottom:* $(J_x, J_y) = (80, 20)$, $(160, 40)$, *and* $(320, 80)$.

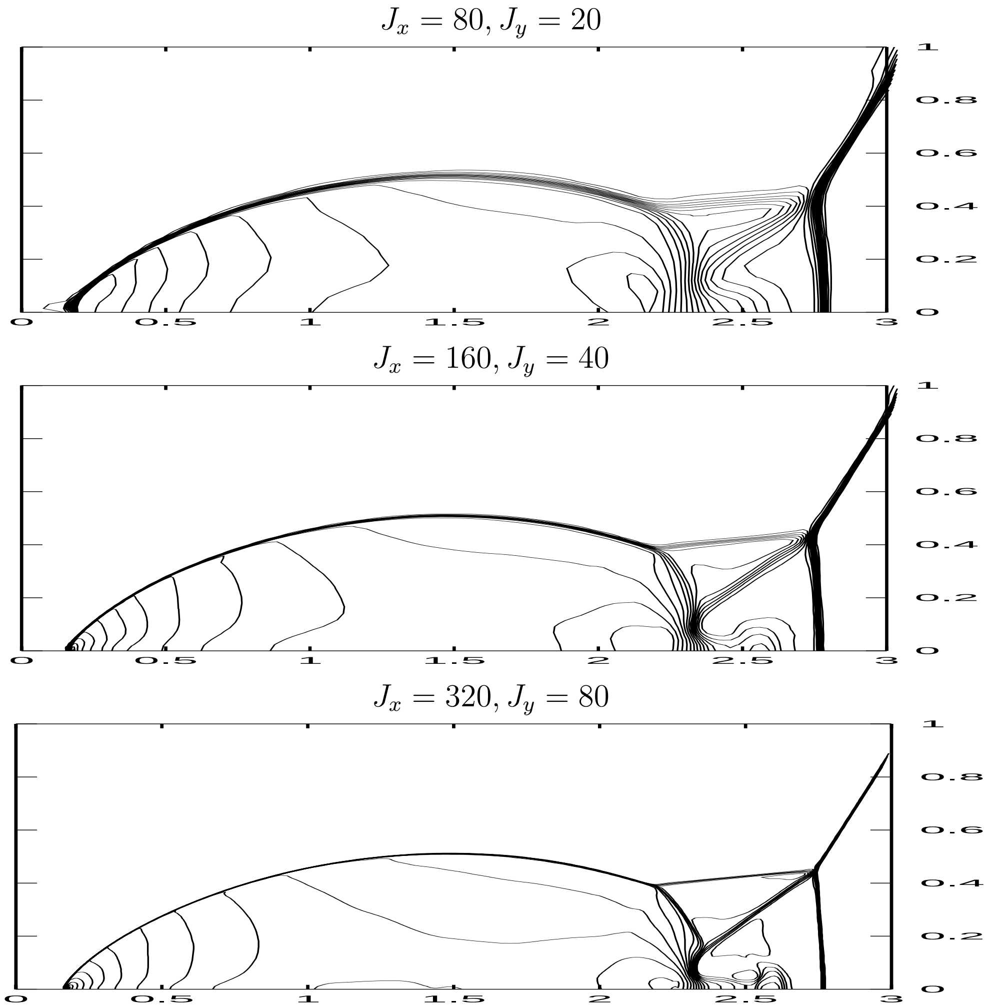
We also show a *blow up* portion around the double-Mach region in Figure 6.6. In our computations, we used 640×160 and 960×240 grid points. The corresponding mesh contours in the blow up region are shown in Figure 6.7. The smallest Δx and Δy in these runs are listed in Tables 6.1 and 6.2. It is seen that ratios between the largest and smallest mesh sizes in the adaptive grids are quite large (≥ 20), which is a desired feature of the adaptive grid methods. The fine details of the complicated structure in this region were previously obtained by Cockburn and Shu [9], who used high-order discontinuous Galerkin (RKDG) methods with 960×240 and 1920×480 grid points. Although the moving mesh algorithm gives a good resolution in this blow up portion, it is observed that, even with approximately the same number of grid points (960×240), the third-order RKDG results [10, p. 216] have a slightly better resolution of the complex structure. The monitor function used for this example is taken as $G = \omega I$, with $\omega = \sqrt{1 + 0.125(\rho_\xi^2 + \rho_\eta^2)}$.



$J_x = 80, J_y = 20$

$J_x = 160, J_y = 40$

$J_x = 320, J_y = 80$

FIG. 6.5. $2D$ *double-Mach reflection at* $t = 0.2$: *the contours of density. From top to bottom:* $(J_x, J_y) = (80, 20)$, $(160, 40)$, *and* $(320, 80)$. 30 *equally spaced contour lines are used.*

6.3. Example of a nonconvex physical domain. So far, the numerical examples in two dimensions have been restricted to rectangular domains. In the final example, we consider a test problem whose domain is not even convex. In this case, as long as the domain can be smoothly transformed to a rectangle, the adaptive mesh algorithm can be handily applied.

Example 6.5. *Flow past a cylinder.* This example is concerned with the supersonic flow past a cylinder with unit radius, which is positioned at the origin on an x-y plane. The problem is initialized by a Mach 3 *free-stream* moving toward the cylinder from the left. Since the physical domain Ω_p is nonconvex, we first transform Ω_p to a square domain $\widehat{\Omega}_c = [0, 1] \times [0, 1]$ by using the following mapping:

$$\begin{aligned} x &= -(R_x - (R_x - 1)\widehat{x}) \cos(\theta(2\widehat{y} - 1)), \\ y &= (R_y - (R_y - 1)\widehat{x}) \sin(\theta(2\widehat{y} - 1)), \end{aligned} \tag{6.6}$$

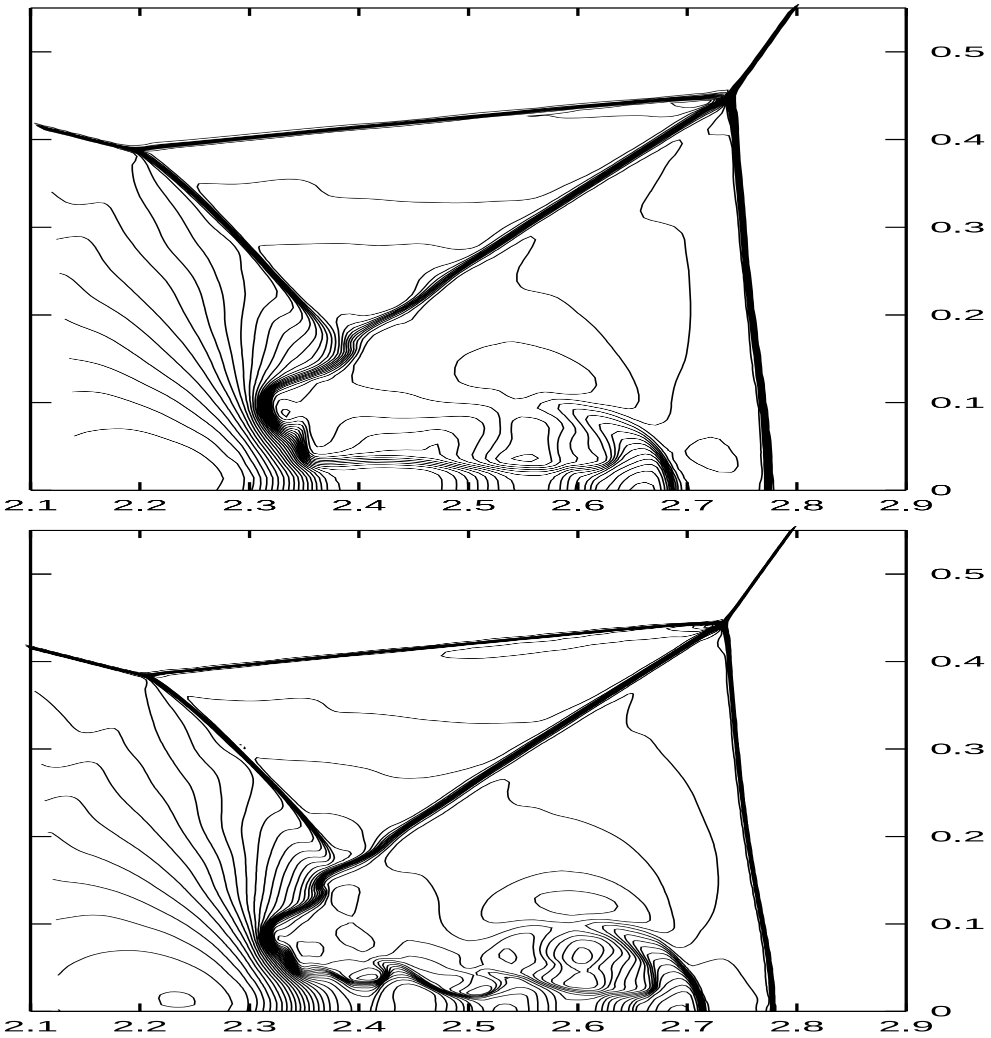


FIG. 6.6. *Double-Mach reflection problem: density ρ in blowup region around the double-Mach stems. Top: $(J_x, J_y) = (640, 160)$; bottom: $(J_x, J_y) = (960, 240)$. 45 equally spaced contour lines are used.*

with $R_x = 3$, $R_y = 5$, and $\theta = 5\pi/12$. A reflective boundary condition is imposed at the surface of the cylinder, i.e., $\hat{x} = 1$; inflow boundary condition is applied at $\hat{x} = 0$; and outflow boundary conditions are applied at $\hat{y} = 0$ and 1. We then solve the problem in $\widehat{\Omega}_c$ using the adaptive mesh algorithm, with a logical domain Ω_c as before. This procedure will lead to numerical solution in $\widehat{\Omega}_c$, and the mapping (6.6) finally gives the numerical approximation in the physical domain Ω_p.

We present an illustration of the mesh in the physical space and the pressure contour in Figure 6.8, by using 30×40, 60×80, and 120×160 grid points. The monitor function used for this example is taken as $G = \omega I$ with $\omega = \sqrt{1 + 0.125(\rho_\xi^2 + \rho_\eta^2)}$. As can be seen from these figures, the advantages of the adaptive mesh methods are quite obvious. The shock location computed by our adaptive mesh algorithm is approximately 0.703 (the distance between the shock curve and the surface of the cylinder), which is in good agreement with the experimental results reported in [4].

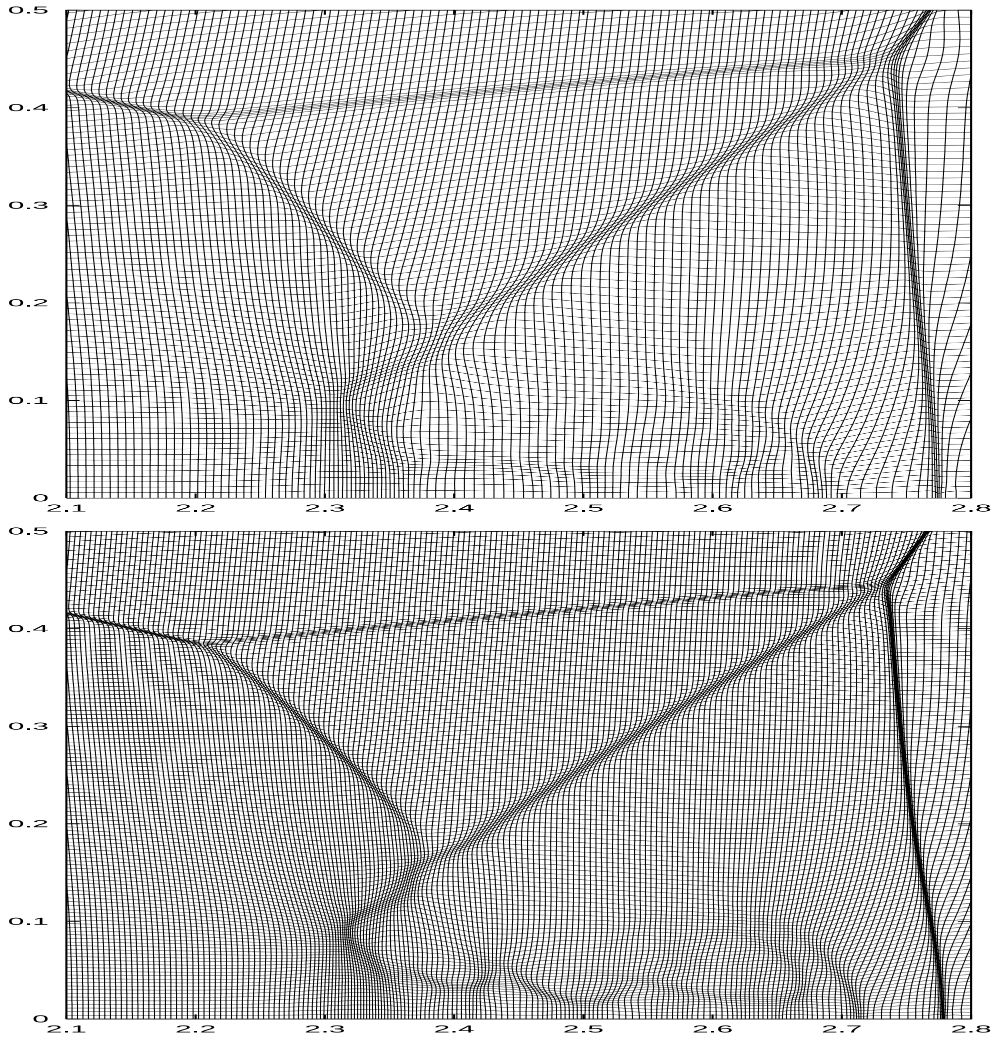

FIG. 6.7. *Double-Mach reflection problem: the adaptive mesh in blowup region around the double-Mach stems. Top:* $(J_x, J_y) = (640, 160)$*; bottom:* $(J_x, J_y) = (960, 240)$.

ON THE CONVERGENCE OF DIFFERENCE SCHEMES FOR HYPERBOLIC PROBLEMS WITH CONCENTRATED DATA*

BOSKO S. JOVANOVIĆ[†] AND LUBIN G. VULKOV[‡]

Abstract. Hyperbolic equations with unbounded coefficients and even generalized functions (in particular, Dirac-delta functions) occur both naturally and artificially and must be treated in numerical schemes. An abstract operator method is proposed for studying these equations. For finite difference schemes approximating several one-dimensional initial-boundary value problems convergence rate estimates in special discrete energetic Sobolev's norms, compatible with the smoothness of the solutions, are obtained.

Key words. concentrated mass, difference scheme, Sobolev spaces, generalized solution, rate of convergence

AMS subject classification. 65M15

1. Introduction.

The study of properties of numerical schemes for discretizing of hyperbolic equations is of great interest in applied mathematics. Numerous works have been concerned with classical schemes for these equations in homogeneous whole space (especially studies of stability and dispersion relations). Other works have studied the approximations of waves at plane boundaries or interfaces. Here we analyze the convergence of difference schemes for hyperbolic equations in the case when the coefficients are discontinuous or change sharply; an important application is in the situation where these are unbounded functions and even generalized functions (in particular, Dirac-delta functions).

The solutions of hyperbolic problems with nonsmooth or discontinuous data (coefficients, initial and boundary functions) are weak solutions, i.e., functions from Sobolev space [20, 21]. Since such solutions do not possess continuous partial derivatives, one cannot use the classical Taylor technique to establish the convergence of discrete approximations. The role of Taylor's formula is often taken by the Bramble–Hilbert lemma and its generalizations [4, 12, 17].

The theory of convergence rate estimates *compatible* with the smoothness of the differential problem solutions was formulated in the 80s by Samarskii, Lazarov, and Makarov (see, e.g., [12]). This concept has been systematically developed in the monographs [4] and [17], where a key role in the analysis is played by the Bramble–Hilbert lemma. Further, results for hyperbolic problems have been obtained in [4, 5, 6]. In all these works, problems with variable coefficients including discontinuous coefficients have been considered.

The basic mechanical system corresponding to the hyperbolic problem considered in the present paper is that of forced oscillations of a string with concentrated mass at the ends or in interior points of the string. Our aim is to treat these problems as a second order abstract evolution equation (2.1) with self-adjoint positive linear operators A, B defined in a Hilbert space H, and then to use energy methods from the theory of operators on a Hilbert space. Discrete analysis of appropriate subspaces of the Sobolev spaces are used with alternative inner products that are equivalent to the Sobolev inner product and yet that allow the discrete operators to be self-adjoint on the space involved. The second important idea of our method consists of constructing special integral representations of the truncation error of the difference schemes. The use of the Bramble–Hilbert lemma for truncation error estimates involves all partial derivatives of the solution up to the corresponding order, although only some of them could have discontinuity on the interface. Therefore, the present approach gives more precise results than does the Bramble–Hilbert lemma.

The remainder of this paper is organized as follows. Energy estimates for the solutions of an abstract Cauchy problem for a second order evolution equation and for an operator-difference scheme can be found in the next section. Section 3 is devoted to the derivation of convergence rate estimates in special discrete Sobolev norms of difference scheme approximations to wave equations with discontinuous coefficients and dynamical conditions of conjugation, i.e., in which the time derivative of the solution is involved. In sections 4 and 5 we treat hyperbolic second order equations with dynamical boundary conditions and elliptic equations with dynamical conditions of conjugation. Analogous results for parabolic equations are obtained in [9, 10]. Results concerning finite difference schemes on uniform meshes for the equation of a vibrating string with concentrated mass are reported in [11].

In this article we consider one-dimensional problems. The approach presented in this paper will be applied to similar two-dimensional problems in a forthcoming paper. The method proposed here can be developed for evolution problems modeling vibrations of beam-mass systems, i.e., problems of the type (2.1) in which A is a fourth order elliptic operator. Also, the method works for interface problems in which the Dirac-delta functions appear in the lowest coefficients [7], or on the right-hand side of the equation.

Convergence to classical solutions for parabolic and hyperbolic equations with dynamical boundary conditions or dynamical conditions of conjugations are studied in [1, 2, 3, 21].

2. Preliminary results.

Let H be a real separable Hilbert space with scalar product $(\cdot,\cdot)$ and norm $\|\cdot\|$, and let S be an unbounded self-adjoint positively defined linear operator on a domain $D(S)$ which is dense in H. The bilinear form $(u,v)_S = (Su,v)$, $u,v \in D(S)$, satisfies the axioms of the scalar product. Let the Hilbert space $H_S \subset H$ be the completion of $D(S)$ in the norm $\|u\|_S = (u,u)_S^{1/2}$. Then the scalar product (u,v) is continuously extended on $H_S^* \times H_S$, where H_S^* is a space which is dual to H_S, and the operator S is extended to the map $S : H_S \to H_S^*$. There exists the unbounded self-adjoint positive linear operator $S^{1/2}$ (see [13, 15]) and $D(S^{1/2}) = H_S$, $(u,v)_S = (Su,v) = (S^{1/2}u, S^{1/2}v)$. We also introduce the space $L_2(a,b;H)$ and the function $u = u(t)$ mapping the segment $(a,b) \subset R$ in H with the scalar product $(u,v)_{L_2(a,b;H)} = \int_a^b (u(t),v(t))dt$ (see [13]).

Let A and B be unbounded self-adjoint positive linear operators that do not depend on t and are defined in the Hilbert space H. We suppose that $D(A)$ is dense in H and $H_A \subset H_B$. In the general case, A and B are noncommutative. Let us consider the abstract Cauchy problem (see [22])

$$Bu'' + Au = f(t), \quad 0 < t < T, \qquad u(0) = u_0, \quad u'(0) = u_1, \tag{2.1}$$

where $u_0 \in H_0$, $u_1 \in H_B$, $f(t) \in L_2(0,T;H_{B^{-1}})$ are given and $u(t) \in H_A$ is the unknown function. Letting $f(t) = g'(t)$ in (2.1), we get the Cauchy problem

$$Bu'' + Au = g'(t), \quad 0 < t < T, \qquad u(0) = u_0, \quad u'(0) = u_1. \tag{2.2}$$

The following lemma holds.

LEMMA 2.1. *The a priori estimate for the solution of the problem* (2.1) *is valid*

$$\max_{t\in[0,T]} \left[\|u(t)\|_A^2 + \|u'(t)\|_B^2\right] \le C\left[\|u_0\|_A^2 + \|u_1\|_B^2 + \int_0^T \|f(t)\|_{B^{-1}}^2 dt\right].$$

At the less strong assumptions, $u_0 \in H_B$, $Bu_1 \in H_{A^{-1}}$, and $f \in L_2(0,T;H_{A^{-1}})$, the estimate

$$\max_{t\in[0,T]} \|u(t)\|_B^2 \le C\left[\|u_0\|_B^2 + \|Bu_1\|_{A^{-1}}^2 + \int_0^T \|f(t)\|_{A^{-1}}^2 dt\right]$$

holds true. For the solution of the problem (2.2), *if $u_0 \in H_B$, $Bu_1 \in H_{A^{-1}}$, and $g \in L_2(0,T;H_{B^{-1}})$, the estimate*

$$\max_{t\in[0,T]} \|u(t)\|_B^2 \le C\left[\|u_0\|_B^2 + \|Bu_1 - g(0)\|_{A^{-1}}^2 + \int_0^T \|g(t)\|_{B^{-1}}^2 dt\right]$$

holds true.

Proof. The proof can be found by using the energy method and Grönwall's lemma.

Similar results are true for operator-difference schemes. Let H_h be a finite-dimensional real Hilbert space with scalar product $(\cdot,\cdot)_h$ and norm $\|\cdot\|_h$. Also, let A_h and B_h be constant self-adjoint positively defined in H_h linear operators, i.e.,

$$A_h \ne A_h(t), \quad A_h = A_h^* \ge d_1 E_h, \qquad B_h \ne B_h(t), \quad B_h = B_h^* \ge d_2 E_h,$$

where $d_1, d_2 = \text{const} > 0$ and E_h is the identity operator in H_h. As in the previous case, we assume that the operators A_h and B_h in the general case are noncommutative. By H_{S_h}, where $S_h = S_h^* > 0$, we denote the space $H_{S_h} = H_h$ with scalar product and norm

$$(v,w)_{S_h} = (S_h v, w)_h, \qquad \|v\|_{S_h} = (S_h v, v)_h^{1/2}.$$

Let ω_τ be a uniform mesh on $(0,T)$ with step $\tau = T/m$, $\omega_\tau^- = \omega_\tau \cup \{0\}$, and $\bar\omega_\tau = \omega_\tau \cup \{0,T\}$. Further we shall make use of standard notations of the difference schemes [17]: $v = v(t)$, $\hat v = v(t+\tau)$, $\check v = v(t-\tau)$, $v_t = (\hat v - v)/\tau$, $v_{\bar t} = (v - \check v)/\tau$.

Let us consider the simplest three-layer operator-difference scheme with weights

$$B_h v_{t\bar t} + A_h v^{(\sigma)} = \phi(t), \quad t \in \omega_\tau, \qquad v(0) = v_0, \quad v_t(0) = v_1, \tag{2.3}$$

where $\sigma \ge 1/4$ is the weight parameter; $v^{(\sigma)} = \sigma\hat v + (1-2\sigma)v + \sigma\check v$; v_0, v_1 are given elements of H_h; and $\phi(t)$ and $v(t)$ are given unknown mesh functions with values in H_h. We also study the scheme

$$B_h v_{t\bar t} + A_h v^{(\sigma)} = \psi_{\bar t}, \quad t \in \omega_\tau, \qquad v(0) = v_0, \quad v_t(0) = v_1, \tag{2.4}$$

where $\psi(t)$ is a given mesh function with values in H_h. The following analogue of Lemma 2.1 holds.

LEMMA 2.2. *For the solution of the problem* (2.3) *the a priori estimates are valid:*

$$\max_{t\in\omega_\tau^-}\left[\left\|\frac{(\hat{v}+v)}{2}\right\|^2_{A_h}+\|v_t\|^2_{B_h}\right]\le C\left[\|v_0\|^2_{A_h}+\|v_1\|^2_{B_h}+\tau^2\|v_1\|^2_{A_h}+\tau\sum_{t\in\omega_\tau}\|\phi\|^2_{B_h^{-1}}\right],$$

$$\max_{t\in\omega_\tau^-}\left\|\frac{(\hat{v}+v)}{2}\right\|^2_{B_h}\le C\left[\|v_0\|^2_{B_h}+\|B_hv_1\|^2_{A_h^{-1}}+\tau^2\|v_1\|^2_{B_h}+\tau\sum_{t\in\omega_\tau}\|\phi\|^2_{A_h^{-1}}\right].$$

For the solution of problem (4) *the a priori estimate holds:*

$$\max_{t\in\omega_\tau^-}\left\|\frac{(\hat{v}+v)}{2}\right\|^2_{B_h}\le C\left[\|v_0\|^2_{B_h}+\|B_hv_1-\psi(0)\|^2_{A_h^{-1}}+\tau^2\|v_1\|^2_{B_h}+\tau\sum_{t\in\omega_\tau^-}\|\psi\|^2_{B_h^{-1}}\right].$$

Proof. The proof is analogous to the proof of Lemma 2.1.

3. Equation of string vibrations with concentrated mass. Let us consider the first initial-boundary value problem (IBVP) for the equation of vibrating string with concentrated mass at the interior point $x=\xi$ (see [19]):

(3.1)
$$\big[c(x)+K\delta(x-\xi)\big]\frac{\partial^2u}{\partial t^2}-\frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big)=f(x,t),\quad (x,t)\in Q=(0,1)\times(0,T),$$

$$u(0,t)=0,\quad u(1,t)=0,\quad 0<t<T, \tag{3.2}$$

$$u(x,0)=u_0(x),\quad \frac{\partial u(x,0)}{\partial t}=u_1(x),\quad x\in(0,1), \tag{3.3}$$

where $K>0$, $0<c_1\le a(x)\le c_2$, $0<c_3\le c(x)\le c_4$, and $\delta(x)$ is the Dirac distribution [22]. It follows from (3.1) that the solution for this problem satisfies for $(x,t)\in Q_1=(0,\xi)\times(0,T)$ and $(x,t)\in Q_2=(\xi,1)\times(0,T)$ the differential equation

$$c(x)\frac{\partial^2u}{\partial t^2}-\frac{\partial}{\partial x}\left(a(x)\frac{\partial u}{\partial x}\right)=f(x,t),$$

and for $x=\xi$ the conditions of conjugation

$$[u]_{x=\xi}\equiv u(\xi+0,t)-u(\xi-0,t)=0,\qquad \left[a\frac{\partial u}{\partial x}\right]_{x=\xi}=K\frac{\partial^2u(\xi,t)}{\partial t^2}.$$

It is easy to see that the IBVP (3.1)–(3.3) can be reduced to the form (2.1), letting $H=L_2(0,1)$, $Au=-\frac{\partial}{\partial x}(a(x)\frac{\partial u}{\partial x})$, and $Bu=\big[c(x)+K\delta(x-\xi)\big]u(x,t)$. Then

$$\|w\|^2_A=\int_0^1a(x)[w'(x)]^2dx\asymp\|w\|^2_{W_2^1(0,1)},\qquad w\in\overset{\circ}{W}{}_2^1(0,1),$$

$$\|w\|_B^2 = \int_0^1 c(x)w^2(x)dx + Kw^2(\xi) \asymp \|w\|_{L_2(0,1)}^2 + w^2(\xi).$$

In such a way $H_A = \overset{\circ}{W}{}_2^1(0,1)$, $H_{A^{-1}} = W_2^{-1}(0,1)$, H_B is the space of all $w \in L_2(0,1)$ with finite norm $\|w\|_B$, and $H_{B^{-1}}$ is the space of all Schwarz distributions on $(0,1)$ with finite norm

$$\|w\|_{B^{-1}} = \sup_{u \in H_B} \frac{|(u,w)|}{\|u\|_B}.$$

Further, we assume that the function $c(x)$ is continuous on $[0,1]$ and $a(x)$ has finite jump in the point $x = \xi$.

3.1. The functional spaces $\boldsymbol{\widetilde{W}_2^k(0,1)}$ and $\boldsymbol{\widetilde{W}_2^k(Q)}$. By $\widetilde{L}_2(0,1) = \widetilde{W}_2^0(0,1)$ we denote the subspace of functions $w(x) \in L_2(0,1)$ with scalar product and norm

$$(u,w)_{\widetilde{L}_2(0,1)} = \int_0^1 u(x)w(x)dx + u(\xi)w(\xi), \qquad \|w\|_{\widetilde{L}_2(0,1)} = (u,w)_{\widetilde{L}_2(0,1)}^{1/2}.$$

Further, we let $\widetilde{W}_2^1(0,1) = \overset{\circ}{W}{}_2^1(0,1)$ and $\widetilde{W}_2^k(0,1) = \overset{\circ}{W}{}_2^1(0,1) \cap W_2^k(0,\xi) \cap W_2^k(\xi,1)$, $k = 2,3,\dots$.

We define also the spaces $\widetilde{W}_2^k(Q)$ $(k = 0,1,2,\dots)$ as subsets of functions $w \in L_2(Q)$ for which

$$\begin{aligned}
&w(0,t) = w(1,t) = 0,\\
&\frac{\partial^i w}{\partial t^i} \in L_2(0,T;\widetilde{L}_2(0,1)), \quad i = 0,1,\dots,k,\\
&\frac{\partial^i w}{\partial x \partial t^{i-1}} \in L_2(Q), \quad i = 1,2,\dots,k,\\
&\frac{\partial^i w}{\partial x^j \partial t^{i-j}} \in L_2(Q_1) \cap L_2(Q_2), \quad 2 \le j \le k,\ i = j,\dots,k,
\end{aligned}$$

and norms defined as usual

$$\|w\|_{\widetilde{W}_2^k(Q)}^2 = \sum_{i=0}^k \left(\left\| \frac{\partial^i w(\xi,\cdot)}{\partial t^i} \right\|_{L_2(0,T)}^2 + \left\| \frac{\partial^i w}{\partial t^i} \right\|_{L_2(Q)}^2 \right)$$

$$+ \sum_{i=1}^k \left\| \frac{\partial^i w}{\partial x \partial t^{i-1}} \right\|_{L_2(Q)}^2 + \sum_{j=2}^k \sum_{i=j}^k \left(\left\| \frac{\partial^i w}{\partial x^j \partial t^{i-j}} \right\|_{L_2(Q_1)}^2 + \left\| \frac{\partial^i w}{\partial x^j \partial t^{i-j}} \right\|_{L_2(Q_2)}^2 \right).$$

Differentiating (3.1) with respect to x and t and applying Lemma 2.1, we easily obtain the following assertion.

LEMMA 3.1. (i) *Let* $a \in W_2^2(0,\xi) \cap W_2^2(\xi,1)$, $c \in W_2^2(0,1)$, $f \in W_2^2(Q_1) \cap W_2^2(Q_2)$, $f(0,t) = f(1,t) = 0$, $[f]_{x=\xi} = 0$, $u_0 \in \widetilde{W}_2^3(0,1)$, $u_1 \in \widetilde{W}_2^2(0,1)$, *and the compatibility conditions hold*

$$U_{tt}(0) = U_{tt}(1) = 0, \quad [U_{tt}]_{x=\xi} = 0, \quad [au_0']_{x=\xi} = K \lim_{x \to \xi} U_{tt}(x),$$

where

$$U_{tt}(x) = \frac{a(x)u_0''(x) + a'(x)u_0'(x) + f(x,0)}{c(x)}, \qquad ' \equiv \frac{d}{dx}.$$

Then the problem (3.1)–(3.3) *has unique solution* $u \in \widetilde{W}_2^3(Q)$.

(ii) *Let* $a \in W_2^3(0,\xi) \cap W_2^3(\xi,1)$, $c \in W_2^3(0,1)$, $f \in W_2^3(Q_1) \cap W_2^3(Q_2)$, $f(0,t) = f(1,t) = 0$, $[f]_{x=\xi} = 0$, $u_0 \in \widetilde{W}_2^4(0,1)$, $u_1 \in \widetilde{W}_2^3(0,1)$, *and in addition to the last compatibility conditions, the following hold:*

$$U_{ttt}(0) = U_{ttt}(1) = 0, \quad [U_{ttt}]_{x=\xi} = 0, \quad [au_1']_{x=\xi} = K \lim_{x\to\xi} U_{ttt}(x),$$

where

$$U_{ttt}(x) = \left(a(x)u_1''(x) + a'(x)u_1'(x) + \frac{\partial f(x,0)}{\partial t} \right) / c(x).$$

Then problem (3.1)–(3.3) *has unique solution* $u \in \widetilde{W}_2^4(Q)$.

3.2. The difference scheme. Let $\omega_h = \{x_1, x_2, \ldots, x_{n-1}\}$ be a nonuniform mesh in $(0,1)$, chosen so that ξ is a grid point. Define $\omega_h^- = \omega_h \cup \{x_0\}$, $\omega_h^+ = \omega_h \cup \{x_n\}$, $\bar\omega_h = \omega_h \cup \{x_0, x_n\}$, $x_0 = 0$, $x_n = 1$, and $h_i = x_i - x_{i-1}$. Also, let

$$v_x = \frac{(v_+ - v)}{h_+}, \quad v_{\bar x} = \frac{(v - v_-)}{h}, \quad v_{\hat x} = \frac{(v_+ - v)}{\hbar},$$

$$v = v(x), \quad v_\pm = v(x_\pm), \quad x = x_i, \quad x_\pm = x_{i\pm1}, \quad \hbar = \frac{(h + h_+)}{2}.$$

We assume that the following condition is fulfilled:

$$\frac{1}{c_0} \le \frac{h_+}{h} \le c_0, \quad c_0 = \text{const} \ge 1.$$

We approximate the problem (3.1)–(3.3) on the mesh $\bar\omega_h \times \bar\omega_\tau$ by the weighted difference scheme with averaged right-hand side

$$(c + K\delta_h)v_{t\bar t} - (\tilde a v_{\bar x}^{(\sigma)})_{\hat x} = T_x^2 T_t^2 f, \quad (x,t) \in \omega_h \times \omega_\tau, \tag{3.4}$$

$$v(0,t) = 0, \quad v(1,t) = 0, \quad t \in \bar\omega_\tau, \quad v(x,0) = u_0(x), \quad x \in \omega_h, \tag{3.5}$$

(3.6)
$$(c + K\delta_h)v_t(x,0) = T_x^2(cu_1) + K\delta_h u_1 + 0.5\tau T_x^2 \left[\widetilde{T}_t^2 f(x,0) + (au_0'(x))' \right], \quad x \in \omega_h,$$

where $\sigma \ge 1/4$, $\tilde a(x) = \big[a(x) + a(x-h)\big]/2$ if $x \ne \xi, \xi_+$, $\tilde a(\xi) = \big[a(\xi - 0) + a(\xi_-)\big]/2$, $\tilde a(\xi_+) = \big[a(\xi_+) + a(\xi + 0)\big]/2$,

$$\delta_h = \delta_h(x - \xi) = \begin{cases} 0, & x \in \omega_h \setminus \{\xi\}, \\ 1/\hbar, & x = \xi, \end{cases}$$

is the discrete Dirac-function, and

$$T_t f(x,t) = T_t^- f\left(x, t+\frac{\tau}{2}\right) = T_t^+ f\left(x, t-\frac{\tau}{2}\right) = \frac{1}{\tau}\int_{t-\tau/2}^{t+\tau/2} f(x,t')dt',$$

$$\widetilde{T}_t^2 f(x,0) = \frac{2}{\tau}\int_0^\tau \left(1-\frac{t'}{\tau}\right) f(x,t')dt',$$

$$T_x^- f(x,t) = \frac{1}{h}\int_{x_-}^{x} f(x',t)dx', \qquad T_x^+ f(x,t) = \frac{1}{h_+}\int_{x}^{x_+} f(x',t)dx',$$

$$T_x^2 f(x,t) = \frac{1}{\hbar}\int_{x_-}^{x_+} \kappa(x,x')f(x',t)dx', \quad \kappa(x,x') = \begin{cases} 1+(x'-x)/h, & x_- < x' < x, \\ 1-(x'-x)/h_+, & x < x' < x_+, \end{cases}$$

are Steklov averaged operators [4, 10, 12, 17]. Note that these operators are commutative and map derivatives into finite differences, for example,

$$T_x^2 \frac{\partial^2 u}{\partial x^2} = u_{\bar{x}\hat{x}}, \qquad T_t^- \frac{\partial u}{\partial t} = u_{\bar{t}}.$$

Let H_h be the set of mesh functions defined on the mesh $\bar{\omega}_h$ and zero at $x=0$ and $x=1$. We define the scalar products

$$(v,w)_h = \sum_{x\in\omega_h} v(x)w(x)\hbar, \qquad (v,w]_{h\star} = \sum_{x\in\omega_h^+} v(x)w(x)h,$$

and the corresponding norms

$$\|w\|_h = \|w\|_{L_{2,h}} = (w,w)_h^{1/2}, \qquad \|w]|_{h\star} = (w,w]_{h\star}^{1/2}.$$

The difference scheme (3.4)–(3.6) can be written in the form (2.3), setting $A_h v = -(\tilde{a}v_{\bar{x}})_{\hat{x}}$ and $B_h v = (c + K\delta_h)v$. For $w \in H_h$ we have

$$\|w\|_{A_h}^2 = (A_h w, w)_h = \sum_{x\in\omega_h^+} \tilde{a}(x)w_{\bar{x}}^2(x)h = \|w_{\bar{x}}]|_{h\star}^2,$$

$$\|w\|_{B_h}^2 = (B_h w, w)_h = \sum_{x\in\omega_h} c(x)w^2(x)\hbar + Kw^2(\xi) \asymp \|w\|_{B_{0h}}^2,$$

and

$$\|w\|_{B_h^{-1}}^2 = (B_h^{-1}w, w)_h = \sum_{x\in\omega_h\setminus\{\xi\}} \frac{w^2(x)}{c(x)}\hbar + \frac{\hbar^2(\xi)}{K+\hbar c(\xi)}w^2(\xi) = \|w\|_{B_{0h}^{-1}}^2,$$

where $B_{0h}w = (1+\delta_h)w$.

We define the following norms of Sobolev type:

$$\|w\|_{\widetilde{L}_{2,h}}^2 = \|w\|_{B_{0h}}^2 = \|w\|_{L_{2,h}}^2 + w^2(\xi), \qquad \|w\|_{\widetilde{W}_{2,h}^1}^2 = \|w_{\bar{x}}]|_{h\star}^2 + \|w\|_h^2,$$

$$\|v\|_{h\tau}^{(0)} = \max_{t\in\omega_\tau^-} \left\| \frac{(v(\cdot,t+\tau)+v(\cdot,t))}{2} \right\|_{\widetilde{L}_{2,h}},$$

$$\|v\|_{h\tau}^{(1)} = \max_{t\in\omega_\tau^-} \left[\left\| \frac{(v(\cdot,t+\tau)+v(\cdot,t))}{2} \right\|_{\widetilde{W}_{2,h}^1}^2 + \|v_t(\cdot,t)\|_{\widetilde{L}_{2,h}}^2 \right]^{1/2}.$$

3.3. Convergence of the difference scheme in the norm $\|\cdot\|^{(0)}_{h\tau}$. Let u be the solution of the problem (3.1)–(3.3) and v the solution of (3.4)–(3.6). The error $z = u - v$ satisfies the problem

$$(c + K\delta_h)z_{t\bar t} - (\tilde a z^{(\sigma)}_{\bar x})_{\hat x} = \varphi_{\hat x} + \eta_{t\bar t}, \quad (x,t) \in \omega_h \times \omega_\tau, \tag{3.7}$$

$$z(0,t) = 0, \quad z(1,t) = 0, \quad t \in \bar\omega_\tau, \quad z(x,0) = 0, \quad x \in \omega_h, \tag{3.8}$$

$$(c + K\delta_h)z_t(x,0) = \eta_t(x,0) + \chi_{\hat x}(x), \quad x \in \omega_h, \tag{3.9}$$

where it is denoted

$$\varphi = T_x^- T_t^2\Big(a\frac{\partial u}{\partial x}\Big) - \tilde a u^{(\sigma)}_{\bar x} - \frac{h^2}{6}(cu)_{\bar x t\bar t}, \qquad \eta = cu - T_x^2(cu) + \Big(\frac{h^2}{6}(cu)_{\bar x}\Big)_{\hat x},$$

$$\chi = \Big\{\frac{\tau}{2}T_x^-\Big[a\Big(\widetilde{T}_t^2\frac{\partial u}{\partial x} - \frac{du_0}{dx}\Big)\Big] - \frac{h^2}{6}(cu)_{\bar x t}\Big\}\Big|_{t=0}.$$

From Lemma 2.2, using the inequality

$$\|\varphi_{\hat x}\|_{A_h^{-1}} = \max_{w\in H_h}\frac{|(\varphi_{\hat x}, w)_h|}{\|w\|_{A_h}} = \max_{w\in H_h}\frac{|-(\varphi, w_{\bar x}]_{h\star}|}{\|w\|_{A_h}} \le \max_{w\in H_h}\frac{\|\varphi]|_{h\star}\|w_{\bar x}]|_{h\star}}{\|w\|_{A_h}} \le \frac{1}{c_1}\|\varphi]|_{h\star}, \tag{3.10}$$

we immediately get the following a priori estimate for the solution of problem (3.7)–(3.9):

$$\|z\|^{(0)}_{h\tau} \le C\left[\|\chi]|^2_{h\star} + \tau^2\|\chi_{\hat x}\|^2_{B_{0h}^{-1}} + \tau\sum_{t\in\omega_\tau}\|\varphi(\cdot,t)]|^2_{h\star} + \tau\sum_{t\in\bar\omega_\tau^-}\|\eta_t(\cdot,t)\|^2_{B_{0h}^{-1}}\right]^{1/2}. \tag{3.11}$$

Therefore, in order to estimate the rate of convergence of the difference scheme (3.4)–(3.6) in the norm $\|\cdot\|^{(0)}_{h\tau}$, it is sufficient to estimate the right-hand side of (3.11).

We let

$$\varphi = \varphi_1 + \varphi_2 + \varphi_3 + \varphi_4 + \varphi_5, \quad \text{where} \quad \varphi_1 = T_x^- T_t^2\Big(a\frac{\partial u}{\partial x}\Big) - (T_x^- a)\Big(T_x^- T_t^2\frac{\partial u}{\partial x}\Big),$$

$$\varphi_2 = [(T_x^- a) - \tilde a]\Big(T_x^- T_t^2\frac{\partial u}{\partial x}\Big), \quad \varphi_3 = \tilde a\Big[\Big(T_x^- T_t^2\frac{\partial u}{\partial x}\Big) - \Big(T_x^-\frac{\partial u}{\partial x}\Big)\Big],$$

$$\varphi_4 = -\sigma\tau^2\tilde a\Big(T_x^- T_t^2\frac{\partial^3 u}{\partial x\partial t^2}\Big), \quad \varphi_5 = -\frac{h^2}{6}\Big(T_x^- T_t^2\frac{\partial^3(cu)}{\partial x\partial t^2}\Big).$$

Using the integral representation

$$\varphi_1(x,t) = \frac{1}{2h^2\tau}\int_{t-\tau}^{t+\tau}\int_{x_-}^{x}\int_{x_-}^{x}\int_{x''}^{x'}\int_{x'}^{x''}\Big(1-\frac{|t'-t|}{\tau}\Big)a'(y')\frac{\partial^2 u(y'',t')}{\partial x^2}dy''dy'dx''dx'dt',$$

$$\varphi_2(x,t) = \left(\frac{-1}{2h}\int_{x_-}^{x}\int_{x'}^{x}\int_{x'}^{x''} a''(x''')dx'''dx''dx'\right) \cdot \left[\frac{1}{h\tau}\int_{x_-}^{x}\int_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial u(x',t')}{\partial x}dx'dt'\right],$$

$$\varphi_3(x,t) = \frac{a(x)+a(x_-)}{2h\tau}\int_{x_-}^{x}\int_{t-\tau}^{t+\tau}\int_{t}^{t'}\int_{t}^{t''}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial^3 u(x',t''')}{\partial x\partial t^2}dt'''dt''dt'dx',$$

$$\varphi_4(x,t) = -\sigma\tau^2\frac{a(x)+a(x_-)}{2h\tau}\int_{x_-}^{x}\int_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial^3 u(x',t')}{\partial x\partial t^2}dt'dx',$$

$$\varphi_5(x,t) = -\frac{h^2}{6h\tau}\int_{x_-}^{x}\int_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial^3 (cu)(x',t')}{\partial x\partial t^2}dt'dx',$$

we immediately get by summing over the grid,

$$\Big\{\tau\sum_{t\in\omega_\tau}\|\varphi(\cdot,t)]|_{h\star}^2\Big\}^{1/2} \le C(h_{max}^2+\tau^2)\Big(\|a\|_{W_2^2(0,\xi)}+\|a\|_{W_2^2(\xi,1)}+\|c\|_{W_2^2(0,1)}\Big)$$

$$\times\Big(\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)}+\Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial u}{\partial x}\Big\|_{L_2(Q)}\Big). \tag{3.12}$$

The integral formula

$$\begin{aligned}\eta_t(x,t) = {} & \frac{1}{\hbar\tau}\int_{t-\tau}^{t}\int_{x_-}^{x}\int_{x'}^{x}\int_{x}^{x''}\Big(1+\frac{x'-x}{h}\Big)\frac{\partial^3 (cu)(x''',t')}{\partial x^2\partial t}dx'''dx''dx'dt' \\ & + \frac{1}{\hbar\tau}\int_{t-\tau}^{t}\int_{x}^{x_+}\int_{x'}^{x}\int_{x}^{x''}\Big(1-\frac{x'-x}{h_+}\Big)\frac{\partial^3 (cu)(x''',t')}{\partial x^2\partial t}dx'''dx''dx'dt' \\ & + \frac{h}{6\hbar\tau}\int_{t-\tau}^{t}\int_{x_-}^{x}\int_{x'}^{x}\frac{\partial^3 (cu)(x'',t')}{\partial x^2\partial t}dx''dx'dt' \\ & + \frac{h_+}{6\hbar\tau}\int_{t-\tau}^{t}\int_{x}^{x_+}\int_{x}^{x'}\frac{\partial^3 (cu)(x'',t')}{\partial x^2\partial t}dx''dx'dt'\end{aligned} \tag{3.13}$$

implies

$$\left\{\tau\sum_{t\in\omega_\tau^-}\|\eta_t(\cdot,t)\|_{B_{0h}^{-1}}^2\right\}^{1/2} \le Ch_{max}^2\|c\|_{W_2^2(0,1)}$$

$$\times\Big(\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q)}\Big), \tag{3.14}$$

and the representation

$$\chi(x) = \frac{1}{h}\int_{x_-}^{x}\int_{0}^{\tau}\int_{0}^{t'}\Big(1-\frac{t'}{\tau}\Big)a(x')\frac{\partial^2 u(x',t'')}{\partial x\partial t}dt''dt'dx' \tag{3.15}$$

$$- \frac{h}{6\tau}\int_{x_-}^{x}\int_{0}^{\tau}\frac{\partial^2 (cu)(x',t')}{\partial x\partial t}dt'dx'$$

implies

$$\|\chi]|_{h\star} \le C\tau^{3/2}\Big(\|a\|_{W_2^1(0,\xi)} + \|a\|_{W_2^1(\xi,1)}\Big)\Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q_\tau)}$$

$$+ Ch_{max}^2\tau^{-1/2}\|c\|_{W_2^1(0,1)}\Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q_\tau)},$$

where $Q_\tau = (0,1)\times(0,\tau)$. Hence, using the inequality (see [14])

$$\|g\|_{L_2(0,\varepsilon)} \le C\sqrt{\varepsilon}\|g\|_{W_2^1(0,1)}, \qquad 0<\varepsilon<1, \tag{3.16}$$

we get

$$\|\chi]|_{h\star} \le C(h_{max}^2+\tau^2)(\|a\|_{W_2^1(0,\xi)} + \|a\|_{W_2^1(\xi,1)} + \|c\|_{W_2^1(0,1)})$$

$$\times\Big(\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q)}\Big). \tag{3.17}$$

Exploiting (3.15) again, we obtain

$$\tau\|\chi\|_{B_{0h}^{-1}} \le C(h_{max}^2+\tau^2)(\|a\|_{W_2^2(0,\xi)} + \|a\|_{W_2^2(\xi,1)} + \|c\|_{W_2^2(0,1)})$$

$$\times\Big(\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_1)} + \Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_2)} + \Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q)}\Big). \tag{3.18}$$

Now from (3.11), (3.12), (3.14), (3.17), and (3.18) we get the desired convergence rate estimate of the difference scheme (3.4)–(3.6) as follows.

THEOREM 3.2. *Let the assumptions of part* (i) *of Lemma* 3.1 *hold. Then*

$$\|z\|_{h\tau}^{(0)} \le C(h_{max}^2+\tau^2)(\|a\|_{W_2^2(0,\xi)} + \|a\|_{W_2^2(\xi,1)} + \|c\|_{W_2^2(0,1)})\|u\|_{\widetilde{W}_2^3(Q)}. \tag{3.19}$$

Therefore, although the difference scheme on the nonuniform mesh has first order of approximation in the space, the rate of convergence in the "weak" norm $\|\cdot\|_{h\tau}^{(0)}$ is second order with respect to h_{max}.

3.4. Approximation and convergence in the norm $\|\cdot\|_{h\tau}^{(1)}$. Following [18], we approximate (3.1) as follows:

$$(c+K\delta_h)v_{t\bar t} + \Big(\frac{h^2}{6}(cv)_{\bar x t\bar t}\Big)_{\hat x} - (\tilde a v_{\bar x}^{(\sigma)})_{\hat x} - \frac{h_+ - h}{6}\big(a_x v_{\bar x\hat x}^{(\sigma)} - a_{\bar x\hat x}v_{\bar x}^{(\sigma)}\big) = T_x^2T_t^- f, \tag{3.20}$$

$$(x,t) \in \omega_h \times \omega_\tau .$$

In the expressions $a_x(\xi_-)$ and $a_{\bar x\hat x}(\xi_-)$, the value $a(\xi)$ must be changed by $a(\xi-0)$, and in the expressions $a_x(\xi)$ and $a_{\bar x\hat x}(\xi_+)$, the value $a(\xi)$ must be replaced by $a(\xi+0)$. We approximate the boundary and the first initial condition as above, by (3.5). The second initial conditions we approximate letting

(3.21)
$$(c+K\delta_h)v_t(x,0) = T_x^2(cu_1) - \Big(\frac{h^2}{6}(cu_1)_{\bar x}\Big)_{\hat x} + K\delta_h u_1 + 0.5\tau T_x^2\big[f(x,0) + (au_0')'\big],$$

$$x \in \omega_h .$$

As compared with (3.4)–(3.6), the scheme (3.20), (3.5), (3.21) has second order local approximation in the space variable. It can be written in the form

$$(B_h + B_{h1})v_{t\bar t} + (A_h + A_{h1})v^{(\sigma)} = \tilde f(t),$$

where $B_{h1}v = (\frac{h^2}{6}(cv)_{\bar x})_{\hat x}$ and $A_{h1}v = -\frac{h_+-h}{6}\big(a_x v_{\bar x\hat x} - a_{\bar x\hat x}v_{\bar x}\big)$ are "small" nonselfadjoint operators in H_h.

For the grid $\bar\omega_h$ we additionally suppose $h_+ = h$ at $x = \xi$.

The error $z = u - v$, where u is the solution of the problem (3.1)–(3.3) and v is the solution of the difference problem (3.20), (3.5), (3.21), satisfies the difference scheme

$$(3.22)\qquad (c+K\delta_h)z_{t\bar t} + \Big(\frac{h^2}{6}(cz)_{\bar x t\bar t}\Big)_{\hat x} - (\tilde a z_{\bar x}^{(\sigma)})_{\hat x} - \frac{h_+-h}{6}\big(a_x z_{\bar x\hat x}^{(\sigma)} - a_{\bar x\hat x} z_{\bar x}^{(\sigma)}\big) = \phi,$$

$$(x,t) \in \omega_h \times \omega_\tau ,$$

with homogeneous boundary and first initial condition (3.8). The second initial condition takes the form

$$(3.23)\qquad (c+K\delta_h)z_t(x,0) = \zeta, \qquad x \in \omega_h .$$

In (3.22) and (3.23)

$$\phi = \phi_1 + \phi_2 = T_t^2\bigg[c\frac{\partial^2 u}{\partial t^2} - T_x^2\Big(c\frac{\partial^2 u}{\partial t^2}\Big) + \Big(\frac{h^2}{6}\Big(c\frac{\partial^2 u}{\partial t^2}\Big)_{\bar x}\Big)_{\hat x}\bigg]$$

$$- \bigg[(\tilde a u_{\bar x}^{(\sigma)})_{\hat x} + \frac{h_+-h}{6}\big(a_x u_{\bar x\hat x}^{(\sigma)} - a_{\bar x\hat x}u_{\bar x}^{(\sigma)}\big) - T_x^2 T_t^2\frac{\partial}{\partial x}\Big(a\frac{\partial u}{\partial x}\Big)\bigg],$$

$$\zeta = \zeta_1 + \zeta_2 + \zeta_3 = \bigg[cu_1 - T_x^2(cu_1) + \Big(\frac{h^2}{6}(cu_1)_{\bar x}\Big)_{\hat x}\bigg]$$

$$+ \frac{\tau}{2}(c+K\delta_h)\Big(\widetilde{T}_t^2\frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial t^2}\Big)\bigg|_{t=0} + \frac{\tau}{2}\bigg[c\frac{\partial^2 u}{\partial t^2} - T_x^2\Big(c\frac{\partial^2 u}{\partial t^2}\Big)\bigg]\bigg|_{t=0}.$$

Using the energy method and Grönwall's lemma, one easily obtains the following result.

LEMMA 3.3. *If* $c \in C^1[0,1]$ *and* $a \in C^1[0,\xi] \cap C^1[\xi,1]$, *then the difference scheme* (3.22), (3.8), (3.23) *is stable in the norm* $\|\cdot\|_{h\tau}^{(1)}$ *and the following a priori estimate holds:*

$$\|z\|_{h\tau}^{(1)} \le C\Big\{\|\zeta\|^2_{B_{0h}^{-1}} + \tau^2\|(B_{0h}^{-1}\zeta)_{\bar{x}}]|^2_{h\star} + \sum_{t\in\omega_\tau}\|\phi(\cdot,t)\|^2_{B_{0h}^{-1}}\Big\}^{1/2}. \tag{3.24}$$

Therefore, in order to estimate the rate of convergence of the difference scheme (3.20), (3.5), (3.21) in the norm $\|\cdot\|_{h\tau}^{(1)}$, it is sufficient to estimate the right-hand side of (3.24).

Using the identity

$$\phi_1 = \eta_{t\bar{t}}$$

and the integral representation (3.13), we get the estimate

$$\Big\{\tau\sum_{t\in\omega_\tau}\|\phi_1(\cdot,t)\|^2_{B_{0h}^{-1}}\Big\}^{1/2} \le Ch^2_{max}\|c\|_{W_2^2(0,1)}\bigg(\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)}$$

$$+\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_2)} + \Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)}\bigg). \tag{3.25}$$

For $x \ne \xi$ the addendum ϕ_2 can be expanded as follows:

$$\phi_2 = \phi_{20} + \phi_{21} + \phi_{22} + \phi_{23} + \phi_{24} + \phi_{25} + \phi_{26} + \phi_{27} + \phi_{28} + \phi_{29}$$

$$= -\frac{1}{2}\Big(T_x^2\frac{\partial^2(au)}{\partial x^2} - T_x^2T_t^2\frac{\partial^2(au)}{\partial x^2}\Big) - \frac{1}{2}\Big(a + \frac{h_+ - h}{3}a_x\Big)\Big(T_x^2\frac{\partial^2 u}{\partial x^2} - T_x^2T_t^2\frac{\partial^2 u}{\partial x^2}\Big)$$

$$-\frac{1}{2}\Big(a - T_x^2 a + \frac{h_+ - h}{3}a_x\Big)T_x^2T_t^2\frac{\partial^2 u}{\partial x^2} - \frac{1}{2}\Big[\big(T_x^2 a\big)\Big(T_x^2T_t^2\frac{\partial^2 u}{\partial x^2}\Big) - T_x^2T_t^2\Big(a\frac{\partial^2 u}{\partial x^2}\Big)\Big]$$

$$+\frac{1}{2}\big(T_x^2 a''\big)\Big(u + \frac{h_+ - h}{3}u_{\bar{x}} - T_t^2 u - \frac{h_+ - h}{3}T_t^2 u_{\bar{x}}\Big) + \frac{1}{2}\big(T_x^2 a''\big)T_t^2\Big(u - T_x^2 u + \frac{h_+ - h}{3}u_{\bar{x}}\Big)$$

$$+\frac{1}{2}\Big[\big(T_x^2 a''\big)\big(T_x^2T_t^2 u\big) - T_x^2T_t^2\big(a''u\big)\Big] - \frac{\sigma\tau^2}{2}T_x^2T_t^2\frac{\partial^4(au)}{\partial x^2\partial t^2}$$

$$-\frac{\sigma\tau^2}{2}\Big(a + \frac{h_+ - h}{3}a_x\Big)T_x^2T_t^2\frac{\partial^4 u}{\partial x^2\partial t^2} + \frac{\sigma\tau^2}{2}\Big(T_x^2 a\Big)\Big[\Big(T_t^2\frac{\partial^2 u}{\partial t^2}\Big) + \frac{h_+ - h}{3}\Big(T_t^2\frac{\partial^2 u}{\partial t^2}\Big)_{\bar{x}}\Big].$$

The integral representation

$$\phi_{20}(x,t) = -\frac{1}{2\hbar\tau}\int_{x_-}^{x_+}\int_{t-\tau}^{t}\int_{t'}^{t}\int_{t}^{t''}\kappa(x,x')\Big(1 - \frac{|t'-t|}{\tau}\Big)\frac{\partial^4(au)(x',t''')}{\partial x^2\partial t^2}dt'''dt''dt'dx',$$

$$x \neq \xi,$$

implies the estimate

(3.26)
$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{20}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^2(0,\xi)} \Big(\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)} + \Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q_1)}\Big).$$

In a similar way, we obtain

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{21}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^1(0,\xi)} \Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)}. \tag{3.27}$$

Using a known estimate for an expression of the form $a - T_x^2 a + \frac{h_+ - h}{3} a_x$ (see [8]), we find

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{22}^2(x,t)\hbar\Big\}^{1/2} \le Ch_{max}^2 \|a\|_{W_2^3(0,\xi)} \Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)}. \tag{3.28}$$

The addendum ϕ_{25} can be estimated in a similar way:

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{25}^2(x,t)\hbar\Big\}^{1/2} \le Ch_{max}^2 \|a\|_{W_2^3(0,\xi)} \Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)}. \tag{3.29}$$

Using the integral representation

$$\phi_{23}(x,t) = -\frac{1}{4\hbar^2\tau} \int_{x_-}^{x_+} \int_{x_-}^{x_+} \int_{t-\tau}^{t+\tau} \kappa(x,x')\kappa(x,x'')\Big(1 - \frac{|t'-t|}{\tau}\Big)$$

$$\times \Big(\int_{x''}^{x'} a'(x''')dx'''\Big)\Big(\int_{x'}^{x''} \frac{\partial^3 u(x''',t')}{\partial x^3} dx'''\Big) dt' dx'' dx', \quad x \neq \xi,$$

and the embedding $W_2^2(0,\xi) \subset C^1[0,\xi]$, we get

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{23}^2(x,t)\hbar\Big\}^{1/2} \le Ch_{max}^2 \|a\|_{W_2^2(0,\xi)} \Big\|\frac{\partial^3 u}{\partial x^3}\Big\|_{L_2(Q_1)}. \tag{3.30}$$

In a similar way we obtain

(3.31)
$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\, x<\xi} \phi_{26}^2(x,t)\hbar\Big\}^{1/2} \le Ch_{max}^2 \|a\|_{W_2^3(0,\xi)} \Big(\Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)} + \Big\|\frac{\partial u}{\partial x}\Big\|_{L_2(Q_1)}\Big).$$

The obvious inequality

$$|\phi_{24}| \le C\|a''\|_{C[0,\xi]} \max_{x\in[0,\xi]} |u - T_t^2 u|$$

and the embedding $W_2^3(0,\xi) \subset C^2[0,\xi]$ imply

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\ x<\xi} \phi_{24}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^3(0,\xi)} \Big\|\frac{\partial^3 u}{\partial x \partial t^2}\Big\|_{L_2(Q_1)}. \tag{3.32}$$

In a similar way we get

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\ x<\xi} \phi_{29}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^2(0,\xi)} \bigg(\Big\|\frac{\partial^3 u}{\partial x \partial t^2}\Big\|_{L_2(Q_1)} + \Big\|\frac{\partial^2 u}{\partial t^2}\Big\|_{L_2(Q_1)}\bigg). \tag{3.33}$$

From the integral representation

$$\phi_{27}(x,t) = -\frac{\sigma\tau}{2\hbar} \int_{x_-}^{x_+} \int_{t-\tau}^{t+\tau} \kappa(x,x')\Big(1 - \frac{|t'-t|}{\tau}\Big) \frac{\partial^4 (au)(x',t')}{\partial x^2 \partial t^2} dt' dx'$$

follows the estimate

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\ x<\xi} \phi_{27}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^2(0,\xi)} \bigg(\Big\|\frac{\partial^4 u}{\partial x^2 \partial t^2}\Big\|_{L_2(Q_1)} + \Big\|\frac{\partial^3 u}{\partial x \partial t^2}\Big\|_{L_2(Q_1)}\bigg). \tag{3.34}$$

In a similar way we estimate ϕ_{28}:

$$\Big\{\tau \sum_{t\in\omega_\tau} \sum_{x\in\omega_h,\ x<\xi} \phi_{28}^2(x,t)\hbar\Big\}^{1/2} \le C\tau^2 \|a\|_{W_2^1(0,\xi)} \Big\|\frac{\partial^4 u}{\partial x^2 \partial t^2}\Big\|_{L_2(Q_1)}. \tag{3.35}$$

For $x = \xi$ we set

$$\phi_2 = \phi_{2,10} + \phi_{2,11} + \phi_{2,12} = -[(\tilde a u_{\bar x})_{\hat x} - T_t^2(\tilde a u_{\bar x})_{\hat x}]$$

$$- \bigg[T_t^2(\tilde a u_{\bar x})_{\hat x} - T_x^2 T_t 2 - \frac{\partial}{\partial x}\Big(a\frac{\partial u}{\partial x}\Big)\bigg] - \sigma\tau^2(\tilde a u_{\bar x})_{\hat x t\bar t}.$$

The integral representations

$$\hbar\phi_{2,10}(\xi,t) = \frac{a(\xi-0)+a(\xi-h)}{2h\tau} \int_{\xi_-}^{\xi} \int_{t-\tau}^{t+\tau} \int_{t'}^{t} \int_{t}^{t''} \Big(1 - \frac{|t'-t|}{\tau}\Big) \frac{\partial^3 u(x',t''')}{\partial x \partial t^2} dt''' dt'' dt' dx'$$

$$-\frac{a(\xi+0)+a(\xi+h)}{2h\tau} \int_{\xi}^{\xi_+} \int_{t-\tau}^{t+\tau} \int_{t'}^{t} \int_{t}^{t''} \Big(1 - \frac{|t'-t|}{\tau}\Big) \frac{\partial^3 u(x',t''')}{\partial x \partial t^2} dt''' dt'' dt' dx',$$

$$\hbar\phi_{2,11}(\xi,t) = \frac{1}{2h\tau} \int_{\xi_-}^{\xi} \int_{x'}^{\xi} \int_{x'}^{x''} \int_{t-\tau}^{t+\tau} \Big(1 - \frac{|t'-t|}{\tau}\Big) \bigg(a''(x''') \frac{\partial u(x'',t')}{\partial x} - a'(x'') \frac{\partial^2 u(x''',t')}{\partial x^2}\bigg) dx''' dx'' dx' dt'$$

$$-\frac{1}{2h\tau}\int\limits_{\xi}^{\xi_+}\int\limits_{x'}^{\xi_+}\int\limits_{x'}^{x''}\int\limits_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\Big(a''(x''')\frac{\partial u(x'',t')}{\partial x}-a'(x'')\frac{\partial^2 u(x''',t')}{\partial x^2}\Big)dx'''dx''dx'dt',$$

and

$$\hbar\phi_{2,12}(\xi,t)=\sigma\tau\frac{a(\xi-0)+a(\xi-h)}{2h}\int_{\xi_-}^{\xi}\int_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial^3 u(x',t')}{\partial x\partial t^2}dt'dx'$$

$$-\sigma\tau\frac{a(\xi+0)+a(\xi+h)}{2h}\int_{\xi}^{\xi_+}\int_{t-\tau}^{t+\tau}\Big(1-\frac{|t'-t|}{\tau}\Big)\frac{\partial^3 u(x',t')}{\partial x\partial t^2}dt'dx'$$

imply

$$\Big\{\tau\sum_{t\in\omega_\tau}\phi_2^2(\xi,t)\hbar^2\Big\}^{1/2}\le C(h_{max}^2+\tau^2)\Big[\|a\|_{W_2^3(0,\xi)}\Big(\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q_1)}$$

$$+\Big\|\frac{\partial^3 u}{\partial x^3}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial u}{\partial x}\Big\|_{L_2(Q_1)}\Big)+\|a\|_{W_2^1(\xi,1)}\Big(\Big\|\frac{\partial^4 u}{\partial^2 x\partial t^2}\Big\|_{L_2(Q_2)}$$

$$+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^3 u}{\partial x^3}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^2 u}{\partial x^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial u}{\partial x}\Big\|_{L_2(Q_1)}\Big)\Big]. \tag{3.36}$$

From (3.26)–(3.35), similar estimates for $x>\xi$, and (3.36), we finally obtain an estimate for ϕ_2:

$$\Big\{\tau\sum_{t\in\omega_\tau}\|\phi_2(\cdot,t)\|_{B_{0h}^{-1}}^2\Big\}^{1/2}\le C(h_{max}^2+\tau)\big(\|a\|_{W_2^3(0,\xi)}+\|a\|_{W_2^3(\xi,1)}\big)\|u\|_{\widetilde{W}_2^4(Q)}. \tag{3.37}$$

It remains to estimate the expression ζ. The addendum ζ_1 has a form similar to η, η_t, and $\eta_{t\bar t}=\phi_1$. Therefore,

$$\|\zeta_1\|_{B_{0h}^{-1}}\le Ch_{max}^2\|c\|_{W_2^2(0,1)}(\|u_1''\|_{L_2(0,\xi)}+\|u_1''\|_{L_2(\xi,1)}+\|u_1'\|_{L_2(0,1)}),$$

from which, applying the trace theorem, we get

$$\|\zeta_1\|_{B_{0h}^{-1}}\le Ch_{max}^2\|c\|_{W_2^2(0,1)}\Big(\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_1)}$$

$$+\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)}+\Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q)}\Big). \tag{3.38}$$

Also, we have

$$\tau\|(B_{0h}^{-1}\zeta_1)_{\bar x}]|\le Ch_{max}\tau\|c\|_{W_2^2(0,1)}\Big(\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_1)}+\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_1)}$$

$$+\Big\|\frac{\partial^4 u}{\partial x^2\partial t^2}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^3 u}{\partial x^2\partial t}\Big\|_{L_2(Q_2)}+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)}+\Big\|\frac{\partial^2 u}{\partial x\partial t}\Big\|_{L_2(Q)}\Big). \tag{3.39}$$

From the integral representation

$$B_h^{-1}\zeta_2(x) = \frac{1}{\hbar}\int_{x_-}^{x_+}\int_0^{\tau}\int_0^{t'} \kappa(x,x')\Big(1-\frac{t'}{\tau}\Big)\frac{\partial^3 u(x',t'')}{\partial t^3}dt''dt'dx'$$

$$+\frac{1}{\hbar}\int_{x_-}^{x_+}\int_{x'}^{x}\int_0^{\tau}\int_0^{t'} \kappa(x,x')\Big(1-\frac{t'}{\tau}\Big)\frac{\partial^4 u(x'',t'')}{\partial x\partial t^3}dt''dt'dx''dx', \quad x \neq \xi,$$

$$B_h^{-1}\zeta_2(\xi) = \int_0^{\tau}\int_0^{t'} \Big(1-\frac{t'}{\tau}\Big)\frac{\partial^3 u(\xi,t'')}{\partial t^3}dt''dt',$$

and

$$(B_h^{-1}\zeta_2)_x = \frac{1}{h}\int_{x_-}^{x}\int_0^{\tau}\int_0^{t'} \Big(1-\frac{t'}{\tau}\Big)\frac{\partial^4 u(x',t'')}{\partial x\partial t^3}dt''dt'dx',$$

applying (3.16), we find

$$\|\zeta_2\|_{B_{0h}^{-1}} \leq C(h_{max}^2+\tau^2)\Big(\Big\|\frac{\partial^4 u}{\partial t^4}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^3 u}{\partial t^3}\Big\|_{L_2(Q)}$$

$$+\Big\|\frac{\partial^4 u}{\partial x\partial t^3}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^4 u(\xi,\cdot)}{\partial t^4}\Big\|_{L_2(0,T)} + \Big\|\frac{\partial^3 u(\xi,\cdot)}{\partial t^3}\Big\|_{L_2(0,T)}\Big) \tag{3.40}$$

and

$$\tau\|(B_{0h}^{-1}\zeta_2)_{\bar{x}}]| \leq C\tau^{5/2}\Big\|\frac{\partial^4 u}{\partial x\partial t^3}\Big\|_{L_2(Q)}. \tag{3.41}$$

Next, using the integral formula

$$\zeta_3(x) = \frac{\tau}{2\hbar}\int_{x_-}^{x_+}\int_{x'}^{x}\kappa(x,x')\frac{\partial}{\partial x}\Big(c\frac{\partial^2 u}{\partial t^2}\Big)\Big|_{(x'',0)}dx''dx'$$

and the trace theorem, we obtain the estimate

$$\|\zeta_3\|_{B_{0h}^{-1}} \leq C(h_{max}^2+\tau^2)\|c\|_{W_2^2(0,1)}\Big(\Big\|\frac{\partial^4 u}{\partial x\partial t^3}\Big\|_{L_2(Q)}$$

$$+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^3 u}{\partial t^3}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^2 u}{\partial t^2}\Big\|_{L_2(Q)}\Big) \tag{3.42}$$

and

$$\tau\|(B_{0h}^{-1}\zeta_3)_{\bar{x}}]| \leq C\tau^2\|c\|_{W_2^2(0,1)}\Big(\Big\|\frac{\partial^4 u}{\partial x\partial t^3}\Big\|_{L_2(Q)}$$

$$+\Big\|\frac{\partial^3 u}{\partial x\partial t^2}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^3 u}{\partial t^3}\Big\|_{L_2(Q)} + \Big\|\frac{\partial^2 u}{\partial t^2}\Big\|_{L_2(Q)}\Big). \tag{3.43}$$

Finally, from (3.25), (3.37), and (3.38)–(3.43) we get the required convergence rate estimate of the scheme (3.20), (3.5), (3.21).

THEOREM 3.4. *Let the assumptions of part* (ii) *of Lemma* 3.1 *hold. Then*

$$\|z\|_{h\tau}^{(1)} \le C(h_{max}^2 + \tau)(\|a\|_{W_2^3(0,\xi)} + \|a\|_{W_2^3(\xi,1)} + \|c\|_{W_2^2(0,1)} + 1)\|u\|_{\widetilde{W}_2^4(Q)}. \tag{3.44}$$

Remark. Analogous results hold for the IBVP where the mass is concentrated at several points $\xi_i \in (0,1)$, $i = 1, 2, \ldots, L$. In such cases $Bu = [c(x) + \sum_{i=1}^{L} K_i \delta(x - \xi_i)]u(x,t)$ and $\|w\|_B^2 \asymp \|w\|_{L_2(0,1)}^2 + \sum_{i=1}^{L} w^2(\xi_i)$.

4. Problem with dynamical boundary condition. Let us consider the initial-boundary value problem of string vibrations with dynamical boundary condition at $x = 0$ (see [19]):

$$c(x)\frac{\partial^2 u}{\partial t^2} - \frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big) = f(x,t), \quad x \in (0,1), \quad 0 < t < T, \tag{4.1}$$

$$K\frac{\partial^2 u(0,t)}{\partial t^2} = a(0)\frac{\partial u(0,t)}{\partial x}, \quad u(1,t) = 0, \quad 0 < t < T, \tag{4.2}$$

$$u(x,0) = u_0(x), \quad \frac{\partial u(x,0)}{\partial t} = u_1(x), \quad x \in (0,1), \tag{4.3}$$

where, as in section 3, $K > 0$, $0 < c_1 \le a(x) \le c_2$, and $0 < c_3 \le c(x) \le c_4$.

The problem (4.1)–(4.3) can be reduced to a problem of the form (3.1)–(3.3) using even extension of the input data: $c(x) = c(-x)$, $a(x) = a(-x)$, $u_0(x) = u_0(-x)$, $u_1(x) = u_1(-x)$, and $f(x,t) = f(-x,t)$ for $x \in (-1,0)$. It easily follows that the solution $u(x,t)$ can also be extended by even fashion on $(-1,0) \times (0,T)$ and satisfies the problem

$$\big[c(x) + 2K\delta(x)\big]\frac{\partial^2 u}{\partial t^2} - \frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big) = f(x,t), \quad x \in (-1,1), \quad 0 < t < T, \tag{4.4}$$

$$u(-1,t) = 0, \quad u(1,t) = 0, \quad 0 < t < T, \tag{4.5}$$

$$u(x,0) = u_0(x), \quad \frac{\partial u(x,0)}{\partial t} = u_1(x), \quad x \in (-1,1). \tag{4.6}$$

The problem (4.4)–(4.6) can be written in the form (2.1) if one lets $H = L_2(-1,1)$,

$$Au = -\frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big), \qquad \text{and} \qquad Bu = \big[c(x) + 2K\delta(x)\big]u(x,t).$$

If $w(x)$ is an even function on the segment $(-1,1)$, then

$$\|w\|_A^2 = \int_{-1}^{1} a(x)[w'(x)]^2 dx = 2\int_0^1 a(x)[w'(x)]^2 dx,$$

$$\|w\|_B^2 = \int_{-1}^{1} c(x)w^2(x)dx + 2Kw^2(0) = 2\int_0^1 c(x)w^2(x)dx + 2Kw^2(0).$$

Further, we assume that the functions $c(x)$ and $a(x)$ are continuous on $[0,1]$.

By $\widehat{L}_2(0,1) = \widehat{W}_2^0(0,1)$ we denote the subspace of functions $w(x) \in L_2(0,1)$ equipped with scalar product and norm

$$(u,w)_{\widehat{L}_2(0,1)} = \int_0^1 u(x)w(x)dx + u(0)w(0), \qquad \|w\|_{\widehat{L}_2(0,1)} = (u,w)^{1/2}_{\widehat{L}_2(0,1)}.$$

We let $\widehat{W}_2^1(0,1) = \{w \in W_2^1(0,1) : w(1) = 0\}$ and $\widehat{W}_2^k(0,1) = \widehat{W}_2^1(0,1) \cap W_2^k(0,1)$, $k = 2,3,\dots$.

We also define the space $\widehat{W}_2^k(Q)$ $(k = 0,1,2,\dots)$ as the space of functions $w \in W_2^k(Q)$ for which

$$\frac{\partial^i w}{\partial t^i} \in L_2(0,T;\widehat{L}_2(0,1)), \quad i = 0,1,\dots,k,$$

and the norm is defined as follows:

$$\|w\|^2_{\widehat{W}_2^k(Q)} = \|w\|^2_{W_2^k(Q)} + \sum_{i=0}^k \left\| \frac{\partial^i w(\xi,\cdot)}{\partial t^i} \right\|^2_{L_2(0,T)}.$$

The following analogue of Lemma 3.1 holds true.

Lemma 4.1. (i) *Let $a,c \in W_2^2(0,1)$, $f \in W_2^2(Q)$, $f(1,t) = 0$, $u_0 \in \widehat{W}_2^3(0,1)$, $u_1 \in \widehat{W}_2^2(0,1)$, and the compatibility conditions*

$$U_{tt}(1) = 0, \quad a(0)u_0'(0) = KU_{tt}(0)$$

hold, where $U_{tt}(x)$ is defined as in Lemma 3.1. *Then the problem* (4.1)–(4.3) *has a unique solution $u \in \widehat{W}_2^3(Q)$.*

(ii) *Let $a,c \in W_2^3(0,1)$, $f \in W_2^3(Q)$, $f(1,t) = 0$, $u_0 \in \widehat{W}_2^4(0,1)$, $u_1 \in \widehat{W}_2^3(0,1)$, and the compatibility conditions*

$$U_{ttt}(1) = 0, \quad a(0)u_0'(0) = KU_{ttt}(0)$$

hold, where $U_{ttt}(x)$ is defined as in Lemma 3.1. *Then the problem* (4.1)–(4.3) *has a unique solution $u \in \widehat{W}_2^4(Q)$.*

On the segment $[0,1]$ we introduce the nonuniform mesh $\bar{\omega}_h$. Let $\widehat{H}_h$ be the space of mesh functions, equal to zero at $x = 1$. We will use the following scalar product

$$[v,w)_h = \frac{h_1}{2}v(0)w(0) + \sum_{x\in\omega_h} v(x)w(x)\hbar,$$

and the corresponding norm $|[w\|_h = |[w\|_{L_{2,h}} = [w,w)_h^{1/2}$. We also define the mesh norms

$$|[w\|^2_{\widehat{L}_{2,h}} = |[w\|^2_{L_{2,h}} + w^2(0), \qquad |[w\|^2_{\widehat{W}^1_{2,h}} = \|w_{\bar{x}}]|^2_{h\star} + |[w\|^2_h,$$

$$|[v\|^{(0)}_{h\tau} = \max_{t\in\omega_\tau^-} \left| \left[\frac{(v(\cdot,t+\tau) + v(\cdot,t))}{2} \right\|_{\widehat{L}_{2,h}} \right.,$$

$$|[v\|_{h\tau}^{(1)} = \max_{t\in\omega_\tau^-}\left[\left|\left[\frac{(v(\cdot,t+\tau)+v(\cdot,t))}{2}\right\|^2_{\widehat{W}^1_{2,h}} + |[v_t(\cdot,t)\|^2_{\widehat{L}_{2,h}}\right]^{1/2}.$$

We approximate the problem (4.1)–(4.3) by the difference scheme

$$(c+2K\delta_h)v_{t\bar t} - (\tilde a v_{\bar x}^{(\sigma)})_{\hat x} = T_x^2T_t^2 f, \quad (x,t)\in\omega_h^-\times\omega_\tau, \tag{4.7}$$

$$v(1,t)=0, \quad t\in\bar\omega_\tau, \quad v(x,0)=u_0(x), \quad x\in\omega_h^-, \tag{4.8}$$

(4.9)
$$(c+2K\delta_h)v_t(x,0) = T_x^2(cu_1) + \delta_h\big(2Ku_1+\tau a u_0'\big) + \frac{\tau}{2}T_x^2\left[\widetilde{T}_t^2 f(x,0) + (au_0')'\right],$$

$$x\in\omega_h^-,$$

where $\sigma\ge 1/4$, $\delta_h(0)=1/h_1$,

$$(\tilde a v_{\bar x})_{\hat x}|_{x=0} = \frac{2}{h_1}(\tilde a v_{\bar x})\Big|_{x=x_1} \quad \text{and} \quad T_x^2 f(0,t) = \frac{2}{h_1}\int_0^{x_1}\Big(1-\frac{x'}{h_1}\Big)f(x',t)dx'.$$

We also consider the higher order difference scheme

(4.10)
$$(c+2K\delta_h)v_{t\bar t} + \Big(\frac{h^2}{6}(cv)_{\bar x t\bar t}\Big)_{\hat x} - (\tilde a v_{\bar x}^{(\sigma)})_{\hat x} - \theta\frac{h_+-h}{6}\big(a_x v_{\bar x\hat x}^{(\sigma)} - a_{\bar x\hat x}v_{\bar x}^{(\sigma)}\big) = T_x^2T_t^2 f,$$

$$(x,t)\in\omega_h^-\times\omega_\tau, \quad \theta(0)=0, \quad \theta(x)=1 \text{ for } x\in\omega_h,$$

(4.11)
$$(c+2K\delta_h)v_t(x,0) = T_x^2(cu_1) - \Big(\frac{h^2}{6}(cu_1)_{\bar x}\Big)_{\hat x} + \delta_h\big(2Ku_1+\tau a u_0'\big) + \frac{\tau}{2}T_x^2\big[f(x,0)+(au_0')'\big],$$

$$x\in\omega_h^-,$$

where the boundary condition at $x=1$ and the first initial condition are approximated by (4.8).

Using results obtained in section 3, we immediately obtain the following result.

THEOREM 4.2. *If the assumptions of part* (i) *of Lemma* 4.1 *hold, then the difference scheme* (4.7)–(4.9) *converges and the following error bound holds:*

$$|[u-v\|_{h\tau}^{(0)} \le C(h_{max}^2+\tau^2)(\|a\|_{W_2^2(0,1)} + \|c\|_{W_2^2(0,1)})\|u\|_{\widehat{W}_2^3(Q)}.$$

If the assumptions of part (ii) *of Lemma* 4.1 *hold, then the difference scheme* (4.10), (4.8), (4.11) *converges and the following error bound holds:*

$$|[u-v\|_{h\tau}^{(1)} \le C(h_{max}^2+\tau^2)\big(\|a\|_{W_2^3(0,1)} + \|c\|_{W_2^2(0,1)} + 1\big)\|u\|_{\widehat{W}_2^4(Q)}.$$

5. Weakly hyperbolic equation. We consider the initial-boundary value problem

$$\delta(x-\xi)\frac{\partial^2 u}{\partial t^2} - \frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big) = f(x,t), \quad x \in (0,1), \quad 0 < t < T, \tag{5.1}$$

$$u(0,t) = 0, \quad u(1,t) = 0, \quad 0 < t < T, \tag{5.2}$$

$$u(\xi,0) = u_0 = \text{const}, \quad \frac{\partial u(\xi,0)}{\partial t} = u_1 = \text{const}, \tag{5.3}$$

where $0 < c_1 \le a(x) \le c_2$ and $\delta(x)$ is the Dirac-distribution. From (5.1) it follows that the solution at $(x,t) \in Q_1$ and $(x,t) \in Q_2$ satisfies the equation

$$-\frac{\partial}{\partial x}\Big(a(x)\frac{\partial u}{\partial x}\Big) = f(x,t),$$

and at $x = \xi$ the conjugation conditions

$$[u]_{x=\xi} \equiv u(\xi+0,t) - u(\xi-0,t) = 0, \qquad \Big[a\frac{\partial u}{\partial x}\Big]_{x=\xi} = \frac{\partial^2 u(\xi,t)}{\partial t^2}.$$

Therefore, at fixed t, the equation is elliptic on $(0,\xi)$ and $(\xi,1)$, and its hyperbolic character is exhibited only in the point $x = \xi$.

The problem (5.1)–(5.3) also has the form (2.1), where $Au = -\frac{\partial}{\partial x}(a(x)\frac{\partial u}{\partial x})$ and $Bu = \delta(x-\xi)u(x,t)$. The operator A is positively definite in the space $H_A = \overset{\circ}{W}{}_2^1(0,1)$. The operator B is nonnegative in H_A, and

$$\|w\|_B = |w(\xi)|.$$

It is easy to see that in this case the second estimate of Lemma 2.1 in which the operator B^{-1} doesn't participate is valid.

Retaining the notations from section 3, we approximate the problem (5.1)–(5.3) by the weighted difference scheme with averaged right-hand side

$$\delta_h v_{t\bar{t}} - (\tilde{a} v_{\bar{x}}^{(\sigma)})_{\hat{x}} = T_x^2 T_t^2 f, \quad (x,t) \in \omega_h \times \omega_\tau, \tag{5.4}$$

$$v(0,t) = 0, \quad v(1,t) = 0, \quad t \in \bar{\omega}_\tau, \tag{5.5}$$

$$v(\xi,0) = u_0, \quad v_t(\xi,0) = u_1 + \frac{\tau}{2}\Big[a\frac{\partial u}{\partial x}\Big]_{(\xi,0)}. \tag{5.6}$$

At $t = 0$ the problem (5.1)–(5.3) disintegrates in two second order ordinary differential equations

$$-(aU')' = f(x,0), \quad 0 < x < \xi, \qquad U(0) = 0, \quad U(\xi) = u_0$$

and

$$-(aU')' = f(x,0), \quad \xi < x < 1, \qquad U(\xi) = u_0, \quad U(1) = 0,$$

where $U(x) = u(x, 0)$, the solution of which can be derived explicitly. Therefore, we have an effective way to calculate the approximation of the initial boundary condition (5.6):

$$\Big[a\frac{\partial u}{\partial x}\Big]_{(\xi,0)} = [aU']|_{x=\xi} = \int_0^1 f(x,0)dx - \Big(\int_0^\xi \frac{dx}{a(x)}\Big)^{-1}\Big(u_0 + \int_0^\xi \int_0^x \frac{f(x',0)}{a(x)}dx'dx\Big)$$

$$- \Big(\int_\xi^1 \frac{dx}{a(x)}\Big)^{-1}\Big(u_0 + \int_\xi^1 \int_x^1 \frac{f(x',0)}{a(x)}dx'dx\Big).$$

The error $z = u - v$ satisfies the condition

$$\delta_h z_{t\bar{t}} - (\tilde{a} z_{\bar{x}}^{(\sigma)})_{\hat{x}} = \overline{\varphi}_{\hat{x}}, \quad (x,t) \in \omega_h \times \omega_\tau, \tag{5.7}$$

$$z(0,t) = 0, \quad z(1,t) = 0, \quad t \in \bar{\omega}_\tau, \tag{5.8}$$

$$z(\xi, 0) = 0, \quad z_t(\xi, 0) = \mu, \tag{5.9}$$

where (see section 3.3)

$$\overline{\varphi} = \varphi_1 + \varphi_2 + \varphi_3 + \varphi_4 = \tilde{a}u_{\bar{x}} - T_x^- T_t^2\Big(a\frac{\partial u}{\partial x}\Big) \quad \text{and} \quad \mu = \frac{\tau}{2}\Big(\widetilde{T}_t^2 \frac{\partial^2 u}{\partial t^2} - \frac{\partial^2 u}{\partial t^2}\Big)\Big|_{(\xi,0)}.$$

The difference scheme (5.7)–(5.9) takes the form (2.3), where $A_h v = -(\tilde{a}v_{\bar{x}})_{\hat{x}}$ is a positive linear operator in H_h and $B_h v = \delta_h v$ is a nonnegative linear operator in H_h. Also

$$\|w\|_{A_h} = \Big\{\sum_{x\in\omega_h^+} \tilde{a} w_{\bar{x}}^2 \hbar\Big\}^{1/2} \asymp \|w_{\bar{x}}]|_{h\star}, \qquad \|w\|_{B_h} = |w(\xi)|.$$

We also need the norm

$$|v|_{h\tau}^{(0)} = \max_{t\in\omega_\tau^-}\Big|\frac{v(\xi,t) + v(\xi,t+\tau)}{2}\Big|.$$

From Lemma 2.2, using (3.10), we get the a priori estimate

$$|z|_{h\tau}^{(0)} \le C\Big[\|\mu\|_{B_h}^2 + \tau \sum_{t\in\omega_\tau} \|\overline{\varphi}(\cdot,t)]|_{h\star}^2\Big]^{1/2}. \tag{5.10}$$

Since $\varphi = \overline{\varphi}$ at $c(x,t) = 0$, we obtain the estimate of $\overline{\varphi}$ immediately from (3.12). Using the integral representation

$$\mu = \int_0^\tau \int_0^{t'} \Big(1 - \frac{t'}{\tau}\Big)\frac{\partial^3 u(\xi, t'')}{\partial t^3} dt'' dt'$$

and (3.16), we get

$$\|\mu\|_{B_h} = |\mu| \le C\tau^2\Big(\Big\|\frac{\partial^4 u(\xi,\cdot)}{\partial t^4}\Big\|_{L_2(0,T)} + \Big\|\frac{\partial^3 u(\xi,\cdot)}{\partial t^3}\Big\|_{L_2(0,T)}\Big). \tag{5.11}$$

Thus from (5.10), (3.12), and (5.11) we get the following convergence rate estimate for the difference scheme (5.4)–(5.6):

$$|z|_{h\tau}^{(0)} \leq C(h_{max}^2 + \tau^2)(\|a\|_{W_2^2(0,\xi)} + \|a\|_{W_2^2(\xi,1)} + 1)\left(\left\|\frac{\partial^4 u(\xi,\cdot)}{\partial t^4}\right\|_{L_2(0,T)}\right.$$

(5.12)

$$\left. + \left\|\frac{\partial^3 u(\xi,\cdot)}{\partial t^3}\right\|_{L_2(0,T)} + \left\|\frac{\partial^3 u}{\partial x \partial t^2}\right\|_{L_2(Q)} + \left\|\frac{\partial^2 u}{\partial x^2}\right\|_{L_2(Q_1)} + \left\|\frac{\partial^2 u}{\partial x^2}\right\|_{L_2(Q_2)} + \left\|\frac{\partial u}{\partial x}\right\|_{L_2(Q)}\right).$$

The estimate (5.12) guarantees the convergence only at $x = \xi$. However, with its help the error can be estimated in all nodes of the mesh $\omega_h \times \omega_\tau$. In fact, $z^{(\sigma)}$ at $0 \leq x \leq \xi$ satisfies the conditions

$$-(z_{\bar{x}}^{(\sigma)})_{\hat{x}} = \overline{\varphi}_{\hat{x}}, \quad z^{(\sigma)}(0,t) = 0, \quad z^{(\sigma)}(\xi,t) \neq 0.$$

Applying the maximum principle [16], we get

$$\max_{x \in \omega_h \cap [0,\xi]} |z^{(\sigma)}(x,t)| \leq C\Big(\|\overline{\varphi}(\cdot,t)]|_{h\star} + |z^{(\sigma)}(\xi,t)|\Big). \tag{5.13}$$

A similar a priori estimate also holds for $\xi \leq x \leq 1$. At $\sigma = 1/4$ from (3.12), (3.16), (5.12), and (5.13) follows the convergence rate estimate

$$\max_{(x,t) \in \omega_h \times \omega_\tau} |z^{(1/4)}(x,t)| \leq C(h_{max}^2 + \tau^2)(\|a\|_{W_2^2(0,\xi)} + \|a\|_{W_2^2(\xi,1)} + 1)\|u\|_{\widetilde{W}_2^4(Q)}.$$

H-CONVERGENCE AND NUMERICAL SCHEMES FOR ELLIPTIC PROBLEMS*

ROBERT EYMARD[†] AND THIERRY GALLOUËT[‡]

Abstract. We study the convergence of two coupled numerical schemes, which are a discretization of a so-called elliptic-hyperbolic system. Only weak convergence properties are proved on the discrete diffusion of the elliptic problem, and an adaptation of the H-convergence method gives a convergence property of the elliptic part of the scheme. The limit of the approximate solution is then the solution of an elliptic problem, the diffusion of which is not in the general case the H-limit of the discrete diffusion. In a particular case, a kind of weak limit is then obtained for the hyperbolic equation.

Key words. H-convergence, finite volume schemes, two-phase flow, porous media

1. Introduction.

Numerical simulation takes an important place in oil recovery engineering. In many cases, the engineer should represent at the same time the thermodynamical evolution of the hydrocarbon components during the pressure drop due to the extraction of oil and the mass transfers in the oil reservoir. In this paper, we focus on the consequences of a mobility contrast between an injected fluid (generally water) and the oil in place, in a very simple case: oil and water are assumed to be incompressible immiscible fluid phases with a common pressure, and the reservoir is supposed to be a horizontal homogeneous isotropic domain. Following [3], the conservation equations for such a two-phase flow in this particular case, using Darcy's law, can be written as

$$\left.\begin{aligned} &\frac{\partial s}{\partial t} - \operatorname{div}(\gamma(s)\lambda(s)\nabla u) \\ &\quad = (\bar f)^+\gamma(\bar s) - (\bar f)^-\gamma(s), \\ &\frac{\partial(1-s)}{\partial t} - \operatorname{div}((1-\gamma(s))\lambda(s)\nabla u) \\ &\quad = (\bar f)^+(1-\gamma(\bar s)) - (\bar f)^-(1-\gamma(s)) \end{aligned}\right\} \text{ in } \Omega, \tag{1}$$

with the boundary conditions

$$\begin{aligned} &u = 0 \text{ on } \partial\Omega \times \mathbb{R}_+, \\ &s = \hat s \text{ on } \{(x,t) \in \partial\Omega \times \mathbb{R}_+, \nabla u(x,t)\cdot \mathbf{n}_{\partial\Omega}(x) \ge 0\}. \end{aligned} \tag{2}$$

In (1) and (2), the domain Ω represents the porous medium, u represents the common pressure of the two phases, s represents the saturation of the water phase, $\gamma(s)$ is a nondecreasing function which is called the "fractional flow," with $\gamma(0) = 0$ and $\gamma(1) = 1$, the positive function $\lambda(s)$ is the "total mobility" of the two phases (the sum of the mobility of water and the mobility of oil), the function $\bar f(x,t)$ represents the rates at

the wells, $\bar{s}(x,t)$ is the saturation of the injected fluids (the injected rate corresponds to the positive part of the function $\bar{f}$, the produced rate corresponds to the negative part, and the repartition of the production between water and oil is determined by the saturation in the reservoir), and the function $\hat{s}(x,t)$ is the saturation of incoming fluids at the boundary. We denote, for all real value z, $z^+ = \max(z,0)$ and $z^- = \max(-z,0)$.

The existence of a solution to (1) is an open problem if the function λ is not reduced to a constant. A number of numerical schemes for this problem have already been discussed in the literature. Nevertheless, their convergence has only recently been studied in the only case of a constant function λ: the convergence of a numerical scheme involving a finite volume method for the computation of the saturation s and a standard finite element for the computation of the pressure u is proved in [7], whereas a convergence proof for a finite volume method for the discretization of both equations is presented in [21] and a convergence proof for a mixed finite element/finite volume scheme is given in [15].

The objective of this paper is the study of the convergence properties of finite volume methods in the case where the function λ is not a constant function. This problem appears to be very close to the study of the convergence, when $\varepsilon \longrightarrow 0$ of the solution of the problem

$$\left.\begin{aligned} &\frac{\partial s_\varepsilon}{\partial t} - \operatorname{div}(\gamma(s_\varepsilon)\lambda(s_\varepsilon)\nabla u_\varepsilon) - \varepsilon\Delta s_\varepsilon \\ &\qquad = (\bar{f})^+\gamma(\bar{s}) - (\bar{f})^-\gamma(s_\varepsilon), \\ &\frac{\partial(1-s_\varepsilon)}{\partial t} - \operatorname{div}((1-\gamma(s_\varepsilon))\lambda(s_\varepsilon)\nabla u_\varepsilon) + \varepsilon\Delta s_\varepsilon \\ &\qquad = (\bar{f})^+(1-\gamma(\bar{s})) - (\bar{f})^-(1-\gamma(s_\varepsilon)) \end{aligned}\right\} \text{ in } \Omega, \tag{3}$$

where the additional term $\varepsilon\Delta s_\varepsilon$ stands for a diffusive term, which is similar to the diffusion added by the upstream weighted numerical schemes. Such a diffusive term is slightly different from that which comes from the introduction of a capillary pressure term, yielding some degeneration similar to that of the porous media equation (see [1], [2], [4], [11], and [5] for the existence of a solution of the continuous problem and see [10] for the proof of the convergence of a finite volume scheme).

In order to make clear the tools that appear, we shall consider a steady-state version of (1) (see (50) below). The main result of this paper is the proof that, using a coupled finite volume scheme for the approximation of this system of equations, the approximate pressure converges in $L^2(\Omega)$ to the solution of an elliptic problem whose coefficients are obtained by the same method as the classical H-convergence proof (following [17], [14], or [19]), whereas the approximate saturation converges only in a weak sense (namely, in $L^\infty(\Omega)$ for the weak $\star$ topology [13]). The use, in the discrete setting, of a notion similar to H-convergence is natural: indeed, the existence of a limit as $\varepsilon \longrightarrow 0$ to the family of pressures $(u_\varepsilon)_{\varepsilon>0}$, the solution to the sum of a steady version of the equations (3), immediately results from H-convergence (see section 2). Note that an extension of the H-convergence background to a discrete setting has been performed; see [16] and mainly [12] for the proof of the existence of an "H-limit" to a subsequence of a sequence of discrete elliptic operators, using regular structured grids and finite differences. The objective here is to study the limit of a sequence of finite volume approximations on general meshes, whereas the discrete diffusion results from the coupling of the two discrete conservation equations. The fact that the two unknowns are computed in the same grids makes different, in the general case, the notion of continuous and discrete H-limits, which suggests to distinguish the vocabulary devoted to both notions.

It is also interesting to notice that the question of the independence of these limit coefficients on the way that some diffusion is added in (1) is not known. It is, however, clear that the limit (u, s) of the numerical scheme or of the parabolic regularization (namely (3)) is a solution of (1) if a strong convergence result can be proved for the saturation. This sufficient condition seems to be necessary for a large class of data: for example, it is already necessary in the case of a constant function λ when the function γ is genuinely nonlinear.

This paper is organized as follows:

- In section 2, a short review of the concept of H-convergence is made, and some examples of application of this notion are given.
- In section 3, results are recalled on finite volume methods for elliptic problems.
- In section 4, an adaptation of H-convergence to the study of the convergence of numerical schemes for elliptic problems is made.
- The convergence study of the coupled scheme for the two-phase flow problem is done in section 5.
- Some concluding remarks give guidelines for further works.

2. Some results of H-convergence.

The notion of H-convergence is used for the physical description of effective properties, at the macroscopic level, of heterogeneous materials in which some diffusive phenomena occur. The assumption which is then made is that the scale of the heterogeneities is small compared to the macroscopic scale. Let us take the example of the Dirichlet problem, which models, for example, the steady flow of a monophasic incompressible fluid in a heterogeneous porous medium, using Darcy's law. We assume that the pressure of the fluid is constant at the boundary of the domain and that some volumic source terms represent the injection and the production of fluid throughout some wells. The question of the existence of an "effective" permeability field, which could allow the computation of an accurate approximate solution using only a coarse discretization (which means a discretization at the macroscopic scale), is of major interest for the industrial applications; this question can, in some cases, be handled using the notion of H-convergence.

2.1. Notations for the Dirichlet problem.

Let Ω be an open bounded subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$, and let α and β be two real numbers, with $0 < \alpha \leq \beta$. We denote by $\mathcal{M}(\alpha, \beta, \Omega)$ the set of measurable functions $M \ : \Omega \longrightarrow \mathcal{L}(\mathbb{R}^N, \mathbb{R}^N)$ such that, for a.e. $x \in \Omega$ and for all $(\xi, \chi) \in (\mathbb{R}^N)^2$, $\alpha|\xi|^2 \leq M(x)\xi \cdot \xi \leq \beta|\xi|^2$, and $M(x)\xi \cdot \chi = \xi \cdot M(x)\chi$. In the particular case where there exists a function $\mu \in L^\infty(\Omega)$ such that, for a.e. $x \in \Omega$, $M(x) = \mu(x)I_N$, where I_N denotes the identity application from $\mathbb{R}^N$ to $\mathbb{R}^N$, we then denote $M = \mu$. In this case, we say that M represents an isotropic field; otherwise, we say that the field M is anisotropic.

For a given source term $b \in H^{-1}(\Omega)$ and a given $M \in \mathcal{M}(\alpha, \beta, \Omega)$, we denote by $\mathcal{F}(b, M)$ the unique solution $\overline{u}$ of

$$\overline{u} \in H_0^1(\Omega) \text{ and } \int_\Omega M(x)\nabla\overline{u}(x) \ \cdot \nabla\bar{v}(x)dx = b(\bar{v}) \ \forall \bar{v} \in H_0^1(\Omega).$$

2.2. The H-convergence theorem.

The following result, given in [17] (in which it was called G-convergence, in reference to some works of de Giorgi), has been extended in [19] to some more general configurations.

Theorem 1 (H-convergence). *Let Ω be an open bounded subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let two real numbers α and β be such that $0 < \alpha \leq \beta$. Let $(M_n)_{n\in\mathbb{N}}$ be a sequence of elements of $M_n \in \mathcal{M}(\alpha, \beta, \Omega)$.*

Then there exists a subsequence of $(M_n)_{n\in\mathbb{N}}$, again denoted $(M_n)_{n\in\mathbb{N}}$, and a function $M \in \mathcal{M}(\alpha,\beta,\Omega)$ such that

- *for all $b \in H^{-1}(\Omega)$, $\mathcal{F}(b, M_n)$ weakly converges to $\mathcal{F}(b, M)$ in $H^1_0(\Omega)$ as $n \longrightarrow \infty$;*
- *for all $b \in H^{-1}(\Omega)$, $M_n\nabla\mathcal{F}(b, M_n)$ weakly converges to $M\nabla\mathcal{F}(b, M)$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$.*

We then say that the sequence $(M_n)_{n\in\mathbb{N}}$ H-converges to M, called the H-limit of the sequence.

We now give some examples of H-convergence results.

2.3. The one-dimensional case. In the case $N = 1$, let us suppose that $\Omega = (0, 1)$. The sequence $(M_n)_{n\in\mathbb{N}}$ such that for all $n \in \mathbb{N}$, $M_n \in \mathcal{M}(\alpha,\beta,\Omega)$ is then a sequence of functions belonging to $L^\infty(\Omega)$ and $1/M_n(x) \in [1/\beta, 1/\alpha]$ for a.e. $x \in \Omega$. For a given $f \in L^2(\Omega)$, we denote by $\hat{f}$ the continuous function defined, for all $x \in (0, 1)$, by $\hat{f}(x) = \int_{(0,x)} f(s)ds$. We then have, for all $x \in \Omega$,

$$\mathcal{F}(f, M_n)(x) = \frac{\int_{(0,x)}(1/M_n(t))dt}{\int_{(0,1)}(1/M_n(t))dt}\int_{(0,1)}\frac{\hat{f}(t)}{M_n(t)}dt - \int_{(0,x)}\frac{\hat{f}(t)}{M_n(t)}dt.$$

Up to a subsequence, we can suppose that the sequence $(1/M_n)_{n\in\mathbb{N}}$ converges to a function $1/M$ for the weak $\star$ topology of $L^\infty(\Omega)$. We then get that, for all $x \in \Omega$,

$$\lim_{n\longrightarrow\infty}\mathcal{F}(f, M_n)(x) = \frac{\int_{(0,x)}(1/M(t))dt}{\int_{(0,1)}(1/M(t))dt}\int_{(0,1)}\frac{\hat{f}(t)}{M(t)}dt - \int_{(0,x)}\frac{\hat{f}(t)}{M(t)}dt,$$

which proves that M is the H-limit of this subsequence. Unfortunately, such a relation between the limit for the weak $\star$ topology of $L^\infty(\Omega)$ and the H-limit cannot be obtained in the general case $N > 1$.

2.4. Two-dimensional examples. Let $\mu_r > 0$ and $\mu_b > 0$ be two real values, respectively, defining the permeability of two materials, respectively called "red" and "black." We first define the so-called checkerboard problem, setting $M_1 : \mathbb{R}^2 \longrightarrow \mathbb{R}$ by $(x_1, x_2) \rightarrow \mu_r$ if $\text{Int}(x_1)+\text{Int}(x_2) \in 2\mathbb{Z}$ (denoting for all $z \in \mathbb{R}$ by $\text{Int}(z)$ the largest relative integer value lower than z), else $(x_1, x_2) \rightarrow \mu_b$ (for example, $\text{Int}(0.5)+\text{Int}(0.5) = 0$ and $M_1(0.5, 0.5) = \mu_r$, $\text{Int}(1.5)+\text{Int}(-1.5) = 1 - 2 = -1$ and $M_1(1.5, -1.5) = \mu_b$; see Figure 1). Then we define, for all $n \in \mathbb{N}_*$, $M_n : \mathbb{R}^2 \longrightarrow \mathbb{R}$ by $M_n(x_1, x_2) = M_1(nx_1, nx_2)$. It can then be shown that, in all open domain Ω of $\mathbb{R}^2$, the sequence $(M_n)_{n\in\mathbb{N}}$ H-converges to the constant function $(x_1, x_2) \rightarrow \sqrt{\mu_r\mu_b}$. In this case, the H-limit of a sequence of isotropic heterogeneous fields is an isotropic homogeneous field. Another example involving two materials is the multilayer case, obtained with defining $M_1 : \mathbb{R}^2 \longrightarrow \mathbb{R}$ by $(x_1, x_2) \rightarrow \mu_r$ if $\text{Int}(x_1) \in 2\mathbb{Z}$, else $(x_1, x_2) \rightarrow \mu_b$ (for example, $\text{Int}(0.5) = 0$ and $M_1(0.5, 10) = \mu_r$, $\text{Int}(1.5) = 1$ and $M_1(1.5, -4) = \mu_b$; see Figure 2). We again define the sequence $(M_n)_{n\in\mathbb{N}}$, by $M_n : \mathbb{R}^2 \longrightarrow \mathbb{R}$, $(x_1, x_2) \mapsto M_1(nx_1, nx_2)$, for all $n \in \mathbb{N}_*$. Then it can be proved that the sequence $(M_n)_{n\in\mathbb{N}}$ H-converges, in all open domain Ω of $\mathbb{R}^2$, to the constant field, the value of which is the linear function defined by $(1, 0) \rightarrow (\frac{2\mu_r\mu_b}{\mu_r+\mu_b}, 0)$ and $(0, 1) \rightarrow (0, \frac{\mu_r+\mu_b}{2})$. We can remark that $\frac{2\mu_r\mu_b}{\mu_r+\mu_b}$ is the harmonic average of μ_r and μ_b, that is, the invert of the average value of the inverts of μ_r and μ_b (this is exactly the value obtained by H-convergence in the one-dimensional case), whereas $\frac{\mu_r+\mu_b}{2}$ is the arithmetic average of μ_r and μ_b. In this two-dimensional case, the H-limit of a sequence of isotropic heterogeneous fields is an anisotropic homogeneous field.

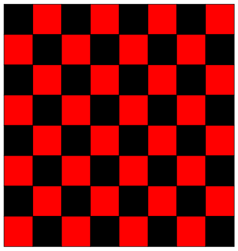

FIG. 1. *The checkerboard case.*

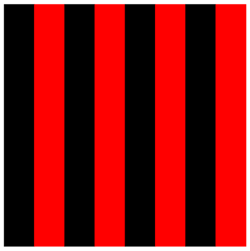

FIG. 2. *The multilayer case.*

Note that in the two above examples the limit of $(M_n)_{n\in\mathbb{N}}$ for the weak $\star$ topology of $L^\infty(\Omega)$ is the constant function $(x_1, x_2) \to \frac{\mu_r+\mu_b}{2}$. Using the notion of nonlinear weak $\star$ convergence (see [9]), the limit of $(M_n)_{n\in\mathbb{N}}$ in terms of Young's measure is the constant field of probability measure $\frac{1}{2}\delta_{\mu_r} + \frac{1}{2}\delta_{\mu_b}$, equivalently given by the function $\mu \in L^\infty(\Omega \times (0,1))$ such that, for a.e. $x \in \Omega$ and $s \in (0, \frac{1}{2})$, $\mu(x,s) = \mu_r$, and for a.e. $x \in \Omega$ and $s \in (\frac{1}{2}, 1)$, $\mu(x,s) = \mu_b$. Thus we see that the notion of nonlinear weak $\star$ convergence does not account for the spatial structure of the heterogeneity and justifies the attempts of finding some more suitable generalized limit (see, for example, [20]).

3. Finite volume meshes and schemes.

3.1. Admissible meshes. We first introduce the notion of admissible discretization [9] which is useful to define a finite volume scheme.

DEFINITION 1 (admissible discretization). *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$ (in general, we have $N = 2$ or $N = 3$). We denote $\partial\Omega = \overline{\Omega} \setminus \Omega$. An admissible finite volume discretization of Ω, denoted by $\mathcal{D}$, is given by $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$, where we have the following:*

- *$\mathcal{T}$ is a finite family of nonempty open polygonal convex disjoint subsets of Ω (the "control volumes") such that $\overline{\Omega} = \cup_{K\in\mathcal{T}}\overline{K}$. We then denote, for all $K \in \mathcal{T}$, by $\partial K = \overline{K} \setminus K$ the boundary of K and $m_K > 0$ the N-dimensional Lebesgue measure of K (it is the area of K in the two-dimensional case and the volume in the three-dimensional case).*
- *$\mathcal{E}$ is a finite family of disjoint subsets of $\overline{\Omega}$ (the "edges" of the mesh) such that, for all $\sigma \in \mathcal{E}$, there exists a hyperplane E of $\mathbb{R}^N$ and $K \in \mathcal{T}$ with $\overline{\sigma} = \partial K \cap E$ and σ is a nonempty open subset of E. We then denote $m_\sigma > 0$ the $(N-1)$-dimensional measure of σ. We assume that, for all $K \in \mathcal{T}$, there exists a subset $\mathcal{E}_K$ of $\mathcal{E}$ such that $\partial K = \cup_{\sigma\in\mathcal{E}_K}\overline{\sigma}$. It then results from the previous*

hypotheses that, for all $\sigma \in \mathcal{E}$, either $\sigma \subset \partial\Omega$ or there exists $(K, L) \in \mathcal{T}^2$ with $K \neq L$ such that $\overline{K} \cap \overline{L} = \overline{\sigma}$; we denote in the latter case $\sigma = K|L$.

- *$\mathcal{P}$ is a family of points of Ω indexed by $\mathcal{T}$, denoted by $\mathcal{P} = (x_K)_{K\in\mathcal{T}}$. This family is such that, for all $K \in \mathcal{T}$, $x_K \in K$. For all $\sigma \in \mathcal{E}$ such that there exists $(K, L) \in \mathcal{T}^2$ with $\sigma = K|L$, it is assumed that the straight line (x_K, x_L) going through x_K and x_L is orthogonal to $K|L$. For all $K \in \mathcal{T}$ and all $\sigma \in \mathcal{E}_K$, let y_σ be the orthogonal projection of x_K on σ. We suppose that $y_\sigma \in \sigma$.*

The following notations are used. The size of the discretization is defined by

$$\mathrm{size}(\mathcal{D}) = \sup\{\mathrm{diam}(K), K \in \mathcal{T}\}.$$

For all $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$, we denote by $\mathbf{n}_{K,\sigma}$ the unit vector normal to σ outward to K. We define a subset of K associated with the edge σ by

$$D_{K,\sigma} = \{tx_K + (1-t)y,\ t \in (0,1),\ y \in \sigma\}$$

(the letter "D" stands for "diamond") and denote by $d_{K,\sigma}$ the euclidean distance between x_K and σ. We then define

$$\tau_{K,\sigma} = \frac{m_\sigma}{d_{K,\sigma}}.$$

The set of interior (resp., boundary) edges is denoted by $\mathcal{E}_{\text{int}}$ (resp., $\mathcal{E}_{\text{ext}}$), that is, $\mathcal{E}_{\text{int}} = \{\sigma \in \mathcal{E};\ \sigma \not\subset \partial\Omega\}$ (resp., $\mathcal{E}_{\text{ext}} = \{\sigma \in \mathcal{E};\ \sigma \subset \partial\Omega\}$).

3.2. Discrete functional properties.

Definition 2. *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$ be an admissible finite volume discretization of Ω in the sense of Definition 1. We denote by $H_{\mathcal{D}}(\Omega) \subset L^2(\Omega)$ the space of functions which admit a constant value in each $K \in \mathcal{T}$. For all $u \in H_{\mathcal{D}}(\Omega)$ and for all $K \in \mathcal{T}$, we denote by u_K the constant value of u in K and we define $(u_\sigma)_{\sigma\in\mathcal{E}}$ by*

$$u_\sigma = 0\ \forall \sigma \in \mathcal{E}_{\text{ext}} \tag{4}$$

and

$$\tau_{K,\sigma}(u_\sigma - u_K) + \tau_{L,\sigma}(u_\sigma - u_L) = 0\ \forall \sigma \in \mathcal{E}_{\text{int}}, \sigma = K|L. \tag{5}$$

We now give a definition of an approximate gradient of the functions of $H_{\mathcal{D}}(\Omega)$. We define a function, denoted $\mathbf{G}_{\mathcal{D}} : H_{\mathcal{D}}(\Omega) \longrightarrow (L^2(\Omega))^N$, $u \longrightarrow \mathbf{G}_{\mathcal{D}}u$ with

$$\mathbf{G}_{\mathcal{D}}u(x) = \frac{N}{d_{K,\sigma}}(u_\sigma - u_K)\mathbf{n}_{K,\sigma}, \quad \textit{for a.e. } x \in D_{K,\sigma}\ \forall K \in \mathcal{T},\ \forall \sigma \in \mathcal{E}_K. \tag{6}$$

Let two real numbers α and β be such that $0 < \alpha \leq \beta$. We denote by $\mathcal{M}_{\mathcal{D}}(\alpha, \beta) \subset L^\infty(\Omega)$ the set of functions μ such that for all $\sigma \in \mathcal{E}$ there exists a constant value, denoted $\mu_\sigma \in [\alpha, \beta]$, such that

$$\mu(x) = \mu_\sigma\ \forall x \in D_{K,\sigma},\ \textit{where } K \textit{ is such that } \sigma \in \mathcal{E}_K.$$

The function which takes the constant value 1 on Ω is denoted by 1. For $(u, v) \in (H_{\mathcal{D}}(\Omega))^2$ and $\varphi \in C^0(\overline{\Omega})$, we denote by

$$[u, v]_{\mathcal{D},\mu,\varphi} = \sum_{K\in\mathcal{T}} \varphi(x_K) \sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(v_\sigma - v_K). \tag{7}$$

We define the following norm in $H_{\mathcal{D}}(\Omega)$ *(see Lemma* 1*) by*

$$|u|_{\mathcal{D}} = \left([u,u]_{\mathcal{D},1,1}\right)^{1/2}.$$

Remark 1. *For all edges* σ *such that* $\sigma = K|L$*, the function* $\mathbf{G}_{\mathcal{D}}u$ *is constant on* $D_{K,\sigma} \cup D_{L,\sigma}$.

We have the following properties.

Lemma 1 (discrete Poincaré inequality). *Let* Ω *be an open bounded polygonal subset of* $\mathbb{R}^N$*, with* $N \in \mathbb{N}_*$*. Let* $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$ *be an admissible finite volume discretization of* Ω *in the sense of Definition* 1*. Then for all* $u \in H_{\mathcal{D}}(\Omega)$ *(cf. Definition* 2*) one has*

$$\|u\|_{L^2(\Omega)} \le \operatorname{diam}(\Omega)\ |u|_{\mathcal{D}}. \tag{8}$$

The proof of Lemma 1 is given in [9].

Lemma 2 (relative compactness in $L^2(\Omega)$). *Let* Ω *be an open bounded polygonal subset of* $\mathbb{R}^N$*, with* $N \in \mathbb{N}_*$*. We consider a sequence* $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$ *such that, for all* $n \in \mathbb{N}$*,* $\mathcal{D}_n$ *is an admissible finite volume discretization of* Ω *in the sense of Definition* 1 *and* $u_n \in H_{\mathcal{D}_n}(\Omega)$ *(cf. Definition* 2*). Let us assume that*

$$\lim_{n\longrightarrow\infty} \operatorname{size}(\mathcal{D}_n) = 0$$

and that there exists $C > 0$ *such that, for all* $n \in \mathbb{N}$*,* $|u_n|_{\mathcal{D}_n} \le C$.

Then there exists a subsequence of $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$*, again denoted* $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$*, and* $\overline{u} \in H_0^1(\Omega)$ *such that* u_n *tends to* $\overline{u}$ *in* $L^2(\Omega)$ *as* $n \longrightarrow \infty$*,* $\mathbf{G}_{\mathcal{D}_n}u_n$ *weakly tends to* $\nabla\overline{u}$ *in* $(L^2(\Omega))^N$ *as* $n \longrightarrow \infty$*, and*

$$\int_\Omega \varphi(x)(\nabla\overline{u}(x))^2 dx \le \liminf_{n\longrightarrow\infty} [u_n, u_n]_{\mathcal{D}_n,1,\varphi} \quad \forall\varphi \in C^0(\overline{\Omega}, \mathbb{R}_+). \tag{9}$$

Proof. The proof of the existence of a subsequence of $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$, and $\overline{u} \in H_0^1(\Omega)$ such that u_n tends to $\overline{u}$ in $L^2(\Omega)$ as $n \longrightarrow \infty$ is given in [9]. The proof of (9) is given in [10]. Therefore, we have only to prove that, up to a subsequence, $\mathbf{G}_{\mathcal{D}_n}u_n$ weakly tends to $\nabla\overline{u}$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$. Since for all $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$ the measure of $D_{K,\sigma}$ is equal to $m_\sigma d_{K,\sigma}/N$, we have

$$\left(\|\mathbf{G}_{\mathcal{D}_n}u_n\|_{(L^2(\Omega))^N}\right)^2 = N\left(|u_n|_{\mathcal{D}_n}\right)^2 \le NC^2. \tag{10}$$

Thus there exists a subsequence of $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$, and $\bar{\mathbf{g}} \in (L^2(\Omega))^N$ such that $\mathbf{G}_{\mathcal{D}_n}u_n$ converges weakly to $\bar{\mathbf{g}}$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$. It now remains to prove that $\bar{\mathbf{g}} = \nabla\overline{u}$. Let $\varphi \in (C_c^\infty(\Omega))^N$. Let G_0 be defined by

$$G_0 = \int_\Omega \nabla\overline{u}(x)\cdot\varphi(x)dx = -\int_\Omega \overline{u}(x)\operatorname{div}\varphi(x)dx.$$

For a given $n \in \mathbb{N}$, we consider the expression

$$G_{0,n} = -\int_\Omega u_n \operatorname{div}\varphi(x)dx.$$

We then have $\lim_{n\longrightarrow\infty} G_{0,n} = G_0$. Since we have (omitting indexes n in discrete terms)

$$G_{0,n} = -\sum_{K\in\mathcal{T}} u_K \int_K \operatorname{div}\varphi(x)dx = \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} (u_\sigma - u_K)\int_\sigma \varphi(x)\cdot\mathbf{n}_{K,\sigma}d\gamma(x)$$

(in which $d\gamma(x)$ is the $N-1$-dimensional measure), we get

$$G_{0,n} = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \frac{N}{d_{K,\sigma}}(u_\sigma - u_K) \int_{D_{K,\sigma}} \varphi_\sigma \cdot \mathbf{n}_{K,\sigma} dx,$$

in which we denote

$$\varphi_\sigma = \frac{1}{m_\sigma} \int_\sigma \varphi(x) d\gamma(x) \ \forall \sigma \in \mathcal{E}.$$

If we now set

$$G_{1,n} = \int_\Omega \mathbf{G}_{\mathcal{D}_n} u_n(x) \cdot \varphi(x) dx,$$

we have, on the one hand, $\lim_{n\longrightarrow\infty} G_{1,n} = \int_\Omega \bar{\mathbf{g}}(x) \cdot \varphi(x) dx$ and, on the other hand,

$$G_{1,n} = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \frac{N}{d_{K,\sigma}}(u_\sigma - u_K) \int_{D_{K,\sigma}} \varphi(x) \cdot \mathbf{n}_{K,\sigma} dx.$$

Therefore, denoting $C_{0,\varphi} > 0$ a value such that $|\varphi(x) - \varphi(y)| \le C_{0,\varphi}|x-y|$, we have

$$|G_{1,n} - G_{0,n}| \le C_{0,\varphi} \text{size}(\mathcal{D}_n) \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} m_\sigma |u_\sigma - u_K|,$$

and thanks to the Cauchy–Schwarz inequality,

$$\begin{aligned} (G_{1,n} - G_{0,n})^2 &\le C_{0,\varphi}^2 \text{size}(\mathcal{D}_n)^2 N m_\Omega \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \tau_{K,\sigma}(u_\sigma - u_K)^2 \\ &\le C_{0,\varphi}^2 \text{size}(\mathcal{D}_n)^2 N m_\Omega C, \end{aligned}$$

where m_Ω denotes the measure of Ω which verifies $N m_\Omega = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} m_\sigma d_{K,\sigma}$. This proves that $\lim_{n\longrightarrow\infty} G_{0,n} = \lim_{n\longrightarrow\infty} G_{1,n}$, and therefore

$$\int_\Omega \bar{\mathbf{g}}(x) \cdot \varphi(x) dx = \int_\Omega \nabla \overline{u}(x) \cdot \varphi(x) dx.$$

Since the above equation is true for all $\varphi \in (C_c^\infty(\Omega))^N$, we then deduce that $\bar{\mathbf{g}}(x) = \nabla\overline{u}(x)$, for a.e. $x \in \Omega$. Thanks to the uniqueness of this limit, this proves that all of the sequence $(\mathcal{D}_n, u_n)_{n\in\mathbb{N}}$ such that u_n tends to $\overline{u}$ in $L^2(\Omega)$ as $n \longrightarrow \infty$ verifies that $\mathbf{G}_{\mathcal{D}_n} u_n$ weakly tends to $\nabla\overline{u}$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$.

Remark 2. *In the preceding proof, the convergence of* $\mathbf{G}_{\mathcal{D}_n} u_n$*, as* $n \longrightarrow \infty$*, cannot be in* $(L^2(\Omega))^N$*, except if it converges to* 0*, since we get* $\liminf_n \|\mathbf{G}_{\mathcal{D}_n} u_n\|_{(L^2(\Omega))^N} \ge \sqrt{N}\|\nabla\overline{u}\|_{(L^2(\Omega))^N}$ *from* (10) *and* (9) *with* $\varphi = 1$ *(see also Remark* 7 *for a more general case).*

3.3. Finite volume scheme. We now give a finite volume scheme for a Dirichlet problem on Ω. Let $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$ be an admissible discretization of Ω in the sense of Definition 1. Let two real numbers α and β be such that $0 < \alpha \le \beta$ and let $\mu \in \mathcal{M}_\mathcal{D}(\alpha, \beta)$. For a given $f \in L^2(\Omega)$, let $u \in H_\mathcal{D}(\Omega)$ (cf. Definition 2) be such that

$$-\sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K) = \int_K f(x) dx \ \forall K \in \mathcal{T} \tag{11}$$

(the existence and uniqueness of a $u \in H_{\mathcal{D}}(\Omega)$ solution of (11) results from the inequality $\mu_\sigma \geq \alpha$ for all $\sigma \in \mathcal{E}$ and from (8); see [9]). Since, for all $v \in H_{\mathcal{D}}(\Omega)$, $\sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)v_\sigma = 0$ thanks to (4)–(5), (11) is equivalent to

$$u \in H_{\mathcal{D}}(\Omega) \text{ and } [u,v]_{\mathcal{D},\mu,1} = \int_\Omega f(x)v(x)dx \ \forall v \in H_{\mathcal{D}}(\Omega). \tag{12}$$

Using the results of Lemma 2 for the points concerning the approximate gradient, we then have the following results, given in [9].

LEMMA 3 (finite volume method). *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$ be an admissible finite volume discretization of Ω in the sense of Definition* 1. *Let two real numbers α and β be such that $0 < \alpha \leq \beta$ and let $\mu \in \mathcal{M}_{\mathcal{D}}(\alpha, \beta)$. Let $f \in L^2(\Omega)$.*

Then there exists one and only one $u \in H_{\mathcal{D}}(\Omega)$ (cf. Definition 2*) given by* (11). *We then denote $u = F_{\mathcal{D}}(f, \mu)$. Moreover,*

$$\alpha|u|_{\mathcal{D}} \leq \operatorname{diam}(\Omega)\ \|f\|_{L^2(\Omega)}. \tag{13}$$

In the case $\mu = 1$, we have the following convergence results: $F_{\mathcal{D}}(f,1)$ converges to $\mathcal{F}(f,1)$ in $L^2(\Omega)$ as $\text{size}(\mathcal{D}) \longrightarrow 0$, *$\mathbf{G}_{\mathcal{D}}F_{\mathcal{D}}(f,1)$ weakly converges to $\nabla\mathcal{F}(f,1)$ as* $\text{size}(\mathcal{D}) \longrightarrow 0$ *in $(L^2(\Omega))^N$, and*

$$\begin{aligned}&\int_\Omega \varphi(x)(\nabla\mathcal{F}(f,1)(x))^2dx = \lim_{\text{size}(\mathcal{D})\longrightarrow 0} [F_{\mathcal{D}}(f,1), F_{\mathcal{D}}(f,1)]_{\mathcal{D},1,\varphi}\\ &\forall \varphi \in C^0(\overline{\Omega}).\end{aligned} \tag{14}$$

4. Adaptation of H-convergence to numerical schemes.

4.1. The Hd-convergence theorem and relations with H-convergence.

The following theorem (proved in sections 4.2 and 4.3 below) expresses a discrete version of Theorem 1.

THEOREM 2 (Hd-convergence). *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let two real numbers α and β be such that $0 < \alpha \leq \beta$. Let $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ be a sequence such that, for all $n \in \mathbb{N}$, $\mathcal{D}_n$ is an admissible discretization of Ω in the sense of Definition* 1, *and $\mu_n \in \mathcal{M}_{\mathcal{D}_n}(\alpha, \beta)$. We assume that* $\lim_{n\longrightarrow\infty} \text{size}(\mathcal{D}_n) = 0$.

Then there exist a subsequence of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, and a unique measurable function $M \in \mathcal{M}(\alpha, \beta, \Omega)$ (this set is defined in section 2*) such that*

- *for all $f \in L^2(\Omega)$, $F_{\mathcal{D}_n}(f, \mu_n)$ converges to $\mathcal{F}(f, M)$ in $L^2(\Omega)$ as $n \longrightarrow \infty$ and $\mathbf{G}_{\mathcal{D}_n}F_{\mathcal{D}_n}(f, \mu_n)$ weakly converges to $\nabla\mathcal{F}(f, M)$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$ (the functions $F_{\mathcal{D}}(f, \mu)$, denoting the discrete solution of a finite volume scheme for an elliptic problem with the homogeneous Dirichlet boundary condition, the right-hand side f, and a discrete diffusion field μ, and $\mathbf{G}_{\mathcal{D}}F_{\mathcal{D}}(f, \mu)$, denoting a discrete gradient of this numerical solution, are defined in section* 3 *and the function $\mathcal{F}(f, M)$, denoting the solution of an elliptic problem with the homogeneous Dirichlet boundary condition, the right-hand side f, and a diffusion matrix field M, is defined in section* 2*);*
- *for all $f \in L^2(\Omega)$, $\mu_n\mathbf{G}_{\mathcal{D}_n}F_{\mathcal{D}_n}(f, \mu_n)$ weakly converges to $M\nabla\mathcal{F}(f, M)$ in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$.*

We then say that the sequence $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ Hd-converges to M, called the Hd-limit of the sequence.

Some comments can be made on the relation between Hd-convergence and H-convergence. Let us first study the one-dimensional case. We take again the case and the notations of section 2.3. Let $\Omega = (0,1)$, α, and β be such that $0 < \alpha \leq \beta$. In order to define an admissible discretization of Ω, let $p \in \mathbb{N}_*$ and let $(y_k)_{k=0,\ldots,p}$ and $(x_k)_{k=1,\ldots,p}$ be real values such that

$$y_0 = 0 < x_1 < y_1 < x_2 \ldots < y_{k-1} < x_k < y_k \ldots < y_{p-1} < x_p < y_p = 1.$$

Then the discretization $\mathcal{D} = (\mathcal{T}, \mathcal{E}, \mathcal{P})$ defined by $\mathcal{T} = \{(y_{k-1}, y_k),\ k = 1,\ldots,p\}$, $\mathcal{E} = \{\{y_k\},\ k = 0,\ldots,p\}$, and $\mathcal{P} = \{x_k,\ k = 1,\ldots,p\}$ is an admissible discretization of Ω in the sense of Definition 1. Let $f \in L^2(\Omega)$ and $\mu \in \mathcal{M}_{\mathcal{D}}(\alpha,\beta)$ be given (recall that the function μ takes constant values in $(0,x_1)$, $\ldots$, (x_k, x_{k+1}),$\ldots$, $(x_p, 1)$). We again define the function $\hat{f}$ by $\hat{f}(x) = \int_{(0,x)} f(t)dt$ for all $x \in \Omega$, and we introduce the function $\hat{f}_{\mathcal{D}}$ defined by $\hat{f}_{\mathcal{D}}(x) = 0 = \hat{f}(y_0)$ for all $x \in (0,x_1)$, by $\hat{f}_{\mathcal{D}}(x) = \hat{f}(y_k)$ for all $x \in (x_k, x_{k+1})$, and by $\hat{f}_{\mathcal{D}}(x) = \hat{f}(1)$ for all $x \in (x_p, 1)$. Some calculations show that the solution of the finite volume scheme (11) is defined by

$$\begin{aligned}(15) \qquad & F_{\mathcal{D}}(f,\mu)(x) = \frac{\int_{(0,x_k)}(1/\mu(t))dt}{\int_{(0,1)}(1/\mu(t))dt}\int_{(0,1)}\frac{\hat{f}_{\mathcal{D}}(t)}{\mu(t)}dt - \int_{(0,x_k)}\frac{\hat{f}_{\mathcal{D}}(t)}{\mu(t)}dt \\ & \forall x \in (y_{k-1}, y_k), \quad \forall k = 1,\ldots,p.\end{aligned}$$

Let $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ be a sequence such that, for all $n \in \mathbb{N}$, $\mathcal{D}_n$ is an admissible discretization of Ω in the sense of Definition 1, and $\mu_n \in \mathcal{M}_{\mathcal{D}_n}(\alpha,\beta)$. We assume that $\lim_{n\longrightarrow\infty} \text{size}(\mathcal{D}_n) = 0$. Up to a subsequence, we can suppose that the sequence $(1/\mu_n)_{n\in\mathbb{N}}$ converges to a function $1/M$ for the weak $\star$ topology of $L^\infty(\Omega)$. Since the sequence $(\hat{f}_{\mathcal{D}_n})_{n\in\mathbb{N}}$ strongly converges to the continuous function $\hat{f}$ as $n \longrightarrow \infty$, we get, using (15) in which we let $\mathcal{D} = \mathcal{D}_n$ and $\mu = \mu_n$, that the limit of the sequence $(F_{\mathcal{D}_n}(f,\mu_n))_{n\in\mathbb{N}}$ is exactly the function $\mathcal{F}(f,M)$ defined, for all $x \in \Omega$, by

$$\mathcal{F}(f,M)(x) = \frac{\int_{(0,x)}(1/M(t))dt}{\int_{(0,1)}(1/M(t))dt}\int_{(0,1)}\frac{\hat{f}(t)}{M(t)}dt - \int_{(0,x)}\frac{\hat{f}(t)}{M(t)}dt.$$

This proves that the Hd-limit of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ is the function M, and therefore coincides, when using the finite volume scheme (11), with the H-limit of $(\mu_n)_{n\in\mathbb{N}}$; the use of some convergence for the weak $\star$ topology of $L^\infty(\Omega)$ is again sufficient to pass to the limit.

REMARK 3. *Note that the coincidence of the discrete and the continuous H-limits is not true for all the one-dimensional numerical schemes which can be associated with the same function μ. Indeed, assume, in order to simplify, that $y_k - y_{k-1} = h$, for $k = 1,\ldots,p$ (with $h = 1/p$), $x_k = (y_k + y_{k-1})/2$, for $k = 1,\ldots,p$, and that the function μ takes constant values in $(0,x_1)$, $\ldots$, (x_k,x_{k+1}), $\ldots$, $(x_p,1)$ which are μ_r and μ_b in alternance. If we discretize the Dirichlet problem with this function μ as the diffusion coefficient and the piecewise linear finite element scheme with nodes located at the points $(y_k)_{k=0,\ldots,p}$, we obtain an approximate solution which is exactly the same as the one which is obtained by the same method (piecewise linear finite element) and a constant value of μ as the diffusion coefficient, namely the arithmetic average of μ_r and μ_b. Then, this approximate solution converges, as $h \longrightarrow 0$, towards*

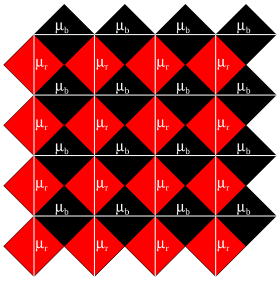

FIG. 3. *Case of the discrepancy between the H- and Hd-limits.*

the solution of the Dirichlet problem whose diffusion is this arithmetic average of μ_r and μ_b. However, the H-limit as $h \longrightarrow 0$ of the continuous operators is given by the harmonic average of μ_r and μ_b.

However, in the case $N > 1$ and even in the isotropic case, the obtention of the Hd-limit by passing to the limit for the weak $\star$ topology of $L^\infty(\Omega)$ is no longer possible. Indeed, let us consider the sequence of admissible discretizations $\mathcal{D}_n$ of $\Omega = (0,1)\times(0,1)$, where the control volumes are some $(k/n,(k{+}1)/n)\times(l/n,(l{+}1)/n)$, for integer values k and l between 0 and $n-1$ (see Figure 3). Assume that the function μ_n is defined by the value $\mu_r > 0$ on the vertical edges $\{k/n\}\times(l/n,(l+1)/n)$ and by the value $\mu_b > 0$ on the horizontal edges $(k/n,(k+1)/n)\times\{l/n\}$. Then the function $\mu_n \in \mathcal{M}_{\mathcal{D}_n}(\alpha,\beta)$ (with $\alpha = \min(\mu_r,\mu_b)$ and $\beta = \max(\mu_r,\mu_b)$) corresponds to the first two-dimensional example of section 2.4 (recall that the function μ_n is constant on subsets which, in this case, are the squares of lengthside equal to $1/(n\sqrt{2})$, tilted with an angle of measure $\pi/4$ with respect to the grid. As seen in section 2, the H-limit of $(\mu_n)_{n\in\mathbb{N}}$ is the field with constant value $\sqrt{\mu_r\mu_b}$. We then remark that for a given $f \in L^2(\Omega)$ the discrete values solutions of the finite volume scheme (11) are identical to those obtained from (11), written in the case where $\tilde{\Omega} = (0,1/\sqrt{\mu_r})\times(0,1/\sqrt{\mu_b})$, the grid is given by the subsets $(k/(n\sqrt{\mu_r}),(k+1)/(n\sqrt{\mu_r}))\times(l/(n\sqrt{\mu_b}),(l+1)/(n\sqrt{\mu_b}))$, $\mu = 1$, and the right-hand side $\tilde{f} = f(\cdot\sqrt{\mu_r},\cdot\sqrt{\mu_b})$. Thanks to Lemma 3 which states the convergence of the finite volume scheme for $\mu = 1$ we then get that $u_{\mathcal{D}_n}$ converges to $\overline{u} = \tilde{u}(\cdot/\sqrt{\mu_r},\cdot/\sqrt{\mu_b})$ with $\tilde{u} = \mathcal{F}_{\tilde{\Omega}}(\tilde{f},1)$, denoting here by $\mathcal{F}_{\tilde{\Omega}}$ the function $\mathcal{F}$ obtained when the Dirichlet problem is solved in the domain $\tilde{\Omega}$. An easy change of variable proves that $\overline{u} = \mathcal{F}(f,M)$, where M is the constant field, the value of which is the linear application defined by $(1,0)\to(\mu_r,0)$ and $(0,1)\to(0,\mu_b)$. This field M, which is homogeneous anisotropic and differs from the H-limit of $(\mu_n)_{n\in\mathbb{N}}$, is therefore the Hd-limit of $(\mathcal{D}_n,\mu_n)_{n\in\mathbb{N}}$.

The physical reason for this discrepancy is the fact that in this example the heterogeneous behavior and the grid are at the same scale: note that this occurs when solving the coupled two-phase flow in porous media problem using a coupled scheme on the same grid (see section 5). On the contrary, in the cases where it is possible to let the size of the mesh tend to zero faster than the size of the heterogeneities, the obtained H- and Hd-limits are equal.

REMARK 4. *Similar results to Theorem* 2 *can be obtained within the finite element framework, leading to the same distinction between the resulting Hd-limit and the H-limit (see Remark* 3 *for an example in the one-dimensional case).*

REMARK 5. *Exactly in the same manner as for the continuous case, it is possible to show the local character of Hd-convergence in the sense of Theorem* 2 *and the* *independence of the Hd-limit on the boundary conditions (see* [16] *for such results within the finite difference setting).*

4.2. Existence of limit operators. The first step leading to the proof of Theorem 2 is given by the results of the following lemma, which are similar to the continuous ones (see [14], [19]).

LEMMA 4. *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let two real numbers α and β be such that $0 < \alpha \leq \beta$. Let $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ be a sequence such that, for all $n \in \mathbb{N}$, $\mathcal{D}_n$ is an admissible discretization of Ω in the sense of Definition* 1*, and $\mu_n \in \mathcal{M}_{\mathcal{D}_n}(\alpha,\beta)$. We assume that $\lim_{n\longrightarrow\infty} \operatorname{size}(\mathcal{D}_n) = 0$.*

Then there exists a subsequence of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, that verifies that there exists an invertible continuous linear application $\overline{F} : H^{-1}(\Omega) \longrightarrow H_0^1(\Omega)$ and a continuous linear application $\overline{\mathbf{G}} : H^{-1}(\Omega) \longrightarrow (L^2(\Omega))^N$ such that

- *for all $f \in L^2(\Omega)$, the sequence $(F_{\mathcal{D}_n}(f,\mu_n))_{n\in\mathbb{N}}$ converges to $\overline{F}(f)$ in $L^2(\Omega)$ and the sequence $(\mathbf{G}_{\mathcal{D}_n} F_{\mathcal{D}_n}(f,\mu_n))_{n\in\mathbb{N}}$ weakly converges to $\nabla\overline{F}(f)$ in $(L^2(\Omega))^N$;*
- *for all $f \in L^2(\Omega)$, the sequence $(\mu_n \mathbf{G}_{\mathcal{D}_n} F_{\mathcal{D}_n}(f,\mu_n))_{n\in\mathbb{N}}$ weakly converges to $\overline{\mathbf{G}}(f)$ in $(L^2(\Omega))^N$;*
- *the following relation holds:*

$$(16) \qquad \int_\Omega \overline{\mathbf{G}}(b)(x) \cdot \nabla\bar{v}(x)dx = b(\bar{v}) \ \forall \bar{v} \in H_0^1(\Omega), \ \forall b \in H^{-1}(\Omega).$$

Proof. Let us assume the hypotheses of the lemma. Let $f \in L^2(\Omega)$. Thanks to (13), for all $n \in \mathbb{N}$, denoting $u_n = F_{\mathcal{D}_n}(f,\mu_n)$, we have

$$(17) \qquad \alpha|u_n|_{\mathcal{D}_n} \leq \operatorname{diam}(\Omega)\ \|f\|_{L^2(\Omega)}.$$

This shows that the hypotheses of Lemma 2 are satisfied. Therefore, there exists a subsequence of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, and $\overline{u} \in H_0^1(\Omega)$ such that the sequence $(F_{\mathcal{D}_n}(f,\mu_n))_{n\in\mathbb{N}}$ converges to $\overline{u}$ in $L^2(\Omega)$. We again denote $u_n = F_{\mathcal{D}_n}(f,\mu_n)$.

Let us introduce the functions $\bar{w} \in H_0^1(\Omega)$ defined by $\bar{w} = \mathcal{F}(f,1)$ and, for all $n \in \mathbb{N}$, $w_n = F_{\mathcal{D}_n}(f,1)$. For $n \in \mathbb{N}$, we deduce from (12) that

$$(18) \qquad \int_\Omega f(x)u_n(x)dx = [u_n,u_n]_{\mathcal{D}_n,\mu_n,1} \geq \alpha\left(|u_n|_{\mathcal{D}_n}\right)^2$$

and, thanks to the Cauchy–Schwarz inequality,

$$(19) \qquad \int_\Omega f(x)u_n(x)dx = [w_n,u_n]_{\mathcal{D}_n,1,1} \leq |w_n|_{\mathcal{D}_n}\ |u_n|_{\mathcal{D}_n}.$$

Therefore (18) and (19) yield

$$\alpha|u_n|_{\mathcal{D}_n} \leq |w_n|_{\mathcal{D}_n}.$$

Passing to the limit on $n \longrightarrow \infty$ in the above equation gives, using (14),

$$\alpha \limsup_{n\longrightarrow\infty} |u_n|_{\mathcal{D}_n} \leq \|\nabla\bar{w}\|_{(L^2(\Omega))^N},$$

which gives, since $\|f\|_{H^{-1}(\Omega)} = \|\nabla\bar{w}\|_{(L^2(\Omega))^N}$,

$$(20) \qquad \alpha \limsup_{n\longrightarrow\infty} |u_n|_{\mathcal{D}_n} \leq \|f\|_{H^{-1}(\Omega)}.$$

Thanks to (9), we get

$$\alpha\|\overline{u}\|_{H_0^1(\Omega)} \le \|f\|_{H^{-1}(\Omega)}. \tag{21}$$

Turning to the study of the sequence $\mathbf{g}_n = \mu_n \mathbf{G}_{\mathcal{D}_n} F_{\mathcal{D}_n}(f,\mu_n)$ for $n \in \mathbb{N}$, we have (in a similar way as the case $\mu_n = 1$ handled in Lemma 2),

$$\left(\|\mathbf{g}_n\|_{(L^2(\Omega))^N}\right)^2 \le N\beta^2 \left(|u_n|_{\mathcal{D}_n}\right)^2,$$

which yields, using (20),

$$\limsup_{n\longrightarrow\infty} \|\mathbf{g}_n\|_{(L^2(\Omega))^N} \le \frac{\sqrt{N}\beta}{\alpha}\|f\|_{H^{-1}(\Omega)}. \tag{22}$$

Thus there exists a subsequence of $(\mathcal{D}_n,\mu_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n,\mu_n)_{n\in\mathbb{N}}$ and $\bar{\mathbf{g}} \in (L^2(\Omega))^N$, such that $\mathbf{g}_n = \mu_n \mathbf{G}_{\mathcal{D}_n} F_{\mathcal{D}_n}(f,\mu_n)$ converges weakly to $\bar{\mathbf{g}}$ as $n \longrightarrow \infty$ in $(L^2(\Omega))^N$. Passing to the limit in (22), we then get

$$\|\bar{\mathbf{g}}\|_{(L^2(\Omega))^N} \le \frac{\sqrt{N}\beta}{\alpha}\|f\|_{H^{-1}(\Omega)}. \tag{23}$$

We then consider a sequence $(f_m)_{m\in\mathbb{N}}$ of functions of $L^2(\Omega)$ which is dense in $H^{-1}(\Omega)$. We can then extract a subsequence (using the classical diagonal process), again denoted $(\mathcal{D}_n,\mu_n)_{n\in\mathbb{N}}$, such that for all $m \in \mathbb{N}$ the sequence $(F(f_m,\mathcal{D}_n,\mu_n))_{n\in\mathbb{N}}$ converges to some function denoted $\overline{F}(f_m) \in H_0^1(\Omega)$ in $L^2(\Omega)$ and the sequence $(\mu_n \mathbf{G}_{\mathcal{D}_n} F(f_m,\mathcal{D}_n,\mu_n))_{n\in\mathbb{N}}$ converges to some function denoted $\overline{\mathbf{G}}(f_m) \in (L^2(\Omega)^N)$ weakly in $(L^2(\Omega)^N)$. The linear functions $\overline{F}$ (resp., $\overline{\mathbf{G}}$) can then be prolonged by continuity, thanks to (21) (resp., (23)) to a continuous linear function, again denoted $\overline{F}\ : H^{-1}(\Omega) \longrightarrow H_0^1(\Omega)$ (resp., $\overline{\mathbf{G}}\ : H^{-1}(\Omega) \longrightarrow (L^2(\Omega))^N$).

Let us now prove (16). Let $f \in L^2(\Omega)$. We set $\overline{u} = \overline{F}(f)$ and $\bar{\mathbf{g}} = \overline{\mathbf{G}}(f)$. Let $\varphi \in C_c^\infty(\Omega)$. For a given $n \in \mathbb{N}$, we denote $\mathcal{D}_n = (\mathcal{T}_n, \mathcal{E}_n, \mathcal{P}_n)$, $u_n = F_{\mathcal{D}_n}(f,\mu_n)$. Omitting the indexes n in the discrete expressions, we set, for all $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$,

$$R_{K,\sigma} = \frac{1}{d_{K,\sigma}}(\varphi(y_\sigma) - \varphi(x_K)) - \frac{N}{m_\sigma d_{K,\sigma}} \int_{D_{K,\sigma}} \nabla\varphi(x)\cdot \mathbf{n}_{K,\sigma} dx.$$

Then there exists $C_\varphi > 0$ which depends only on φ such that $|R_{K,\sigma}| \le \text{size}(\mathcal{D}_n) C_\varphi$. Setting

$$T_n = \sum_{K\in\mathcal{T}_n} \sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma) - \varphi(x_K)),$$

we then get $\lim_{n\longrightarrow\infty} \left|T_n - \int_\Omega \mathbf{g}_n(x)\cdot\nabla\varphi(x)dx\right| = 0$ which yields

$$\lim_{n\longrightarrow\infty} T_n = \int_\Omega \bar{\mathbf{g}}(x)\cdot\nabla\varphi(x)dx. \tag{24}$$

Since, using (11), we have

$$T_n = \sum_{K\in\mathcal{T}_n} \int_K f(x)dx\ \varphi(x_K), \tag{25}$$

we also get $\lim_{n\longrightarrow\infty} T_n = \int_\Omega f(x)\varphi(x)dx$. We thus get

$$\int_\Omega \bar{\mathbf{g}}(x)\cdot\nabla\varphi(x)dx = \int_\Omega f(x)\varphi(x)dx \;\forall\varphi\in C_c^\infty(\Omega). \tag{26}$$

Using (26) and the density of $C_c^\infty(\Omega)$ in $H_0^1(\Omega)$, we conclude (16).

Let us show that $\overline{F}$ is invertible. We consider the bilinear form $a\ :\ \left(H^{-1}(\Omega)\right)^2 \longrightarrow \mathbb{R}$ defined by

$$\forall (b,b')\in \left(H^{-1}(\Omega)\right)^2,\ a(b,b') = b(\overline{F}(b')).$$

Let again $f\in L^2(\Omega)$. We introduce the functions $\overline{u},\bar{w}\in H_0^1(\Omega)$ defined by $\overline{u}=\overline{F}(f)$, $\bar{w}=\mathcal{F}(f,1)$, and, for all $n\in\mathbb{N}$, $u_n = F_{\mathcal{D}_n}(f,\mu_n)$ and $w_n = F_{\mathcal{D}_n}(f,1)$. We have

$$a(f,f) = \int_\Omega f(x)\overline{F}(f)(x)dx = \lim_{n\longrightarrow\infty}\int_\Omega f(x)u_n(x)dx.$$

We can write, on the one hand,

$$\int_\Omega f(x)u_n(x)dx = [u_n,u_n]_{\mathcal{D}_n,\mu_n,1},$$

which yields

$$\int_\Omega f(x)u_n(x)dx \geq \alpha\left(|u_n|_{\mathcal{D}_n}\right)^2. \tag{27}$$

We have, on the other hand,

$$\int_\Omega f(x)w_n(x)dx = [u_n,w_n]_{\mathcal{D}_n,\mu_n,1}$$

and

$$\int_\Omega f(x)w_n(x)dx = \left(|w_n|_{\mathcal{D}_n}\right)^2.$$

This yields

$$\left(|w_n|_{\mathcal{D}_n}\right)^2 = [u_n,w_n]_{\mathcal{D}_n,\mu_n,1}.$$

Since

$$\begin{array}{rcl}([u_n,w_n]_{\mathcal{D}_n,\mu_n,1})^2 & \leq & [u_n,u_n]_{\mathcal{D}_n,\mu_n,1}\ [w_n,w_n]_{\mathcal{D}_n,\mu_n,1}\\ & \leq & \beta^2[u_n,u_n]_{\mathcal{D}_n,1,1}\ [w_n,w_n]_{\mathcal{D}_n,1,1},\end{array}$$

we therefore get

$$\left(|w_n|_{\mathcal{D}_n}\right)^2 \leq \beta|u_n|_{\mathcal{D}_n}|w_n|_{\mathcal{D}_n}. \tag{28}$$

From (27) and (28) we deduce

$$\int_\Omega f(x)u_n(x)dx \geq \frac{\alpha}{\beta^2}\left(|w_n|_{\mathcal{D}_n}\right)^2. \tag{29}$$

Letting $n \longrightarrow \infty$ in (29) gives

$$a(f,f) \geq \frac{\alpha}{\beta^2} \int_\Omega (\nabla \bar{w}(x))^2 dx, \tag{30}$$

which shows that

$$a(f,f) \geq \frac{\alpha}{\beta^2} \left(\|f\|_{H^{-1}(\Omega)} \right)^2. \tag{31}$$

By continuity of a, this property is available on $H^{-1}(\Omega)$, which shows the coercivity of a. Let $\bar{v} \in H_0^1(\Omega)$. The problem, find $b \in H^{-1}(\Omega)$ such that for all $b' \in H^{-1}(\Omega)$, $a(b', b) = b'(\bar{v})$, has a unique solution b, thanks to Lax–Milgram's theorem. It then satisfies $\overline{F}(b) = \bar{v}$.

REMARK 6. *The previous lemma could be stated using sequences $(F_{\mathcal{D}_n}(f, \mu_n))_{n\in\mathbb{N}}$ and $(\mathbf{G}_{\mathcal{D}_n} F_{\mathcal{D}_n}(f, \mu_n))_{n\in\mathbb{N}}$ with $f \in H^{-1}(\Omega)$ (see* [6] *for the definition of the finite volume scheme in this case).*

4.3. Proof of Theorem 2. We assume the hypotheses of Theorem 2, which are the same as those of Lemma 4. Therefore, let $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ denote a subsequence of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$, and let $\overline{F} : H^{-1}(\Omega) \longrightarrow H_0^1(\Omega)$ and $\overline{\mathbf{G}} : H^{-1}(\Omega) \longrightarrow (L^2(\Omega)^N)$ denote the linear continuous functions verifying the conclusions of Lemma 4. It suffices now to prove that there exists a function $M : \Omega \longrightarrow \mathcal{L}(\mathbb{R}^N, \mathbb{R}^N)$ such that for a.e. $x \in \Omega$, $\overline{\mathbf{G}}(b)(x) = M(x)\nabla \overline{F}(b)(x)$, for all $b \in H^{-1}(\Omega)$, and for all $(\xi, \chi) \in (\mathbb{R}^N)^2$, $\alpha|\xi|^2 \leq M(x)\xi \cdot \xi \leq \beta|\xi|^2$, and $M(x)\xi \cdot \chi = \xi \cdot M(x)\chi$. Let $f, g \in L^2(\Omega)$. We set $\overline{u} = \overline{F}(f)$ and $\bar{v} = \overline{F}(g)$. Let $\varphi \in C_c^\infty(\Omega)$. For a given $n \in \mathbb{N}$, we denote $\mathcal{D}_n = (\mathcal{T}_n, \mathcal{E}_n, \mathcal{P}_n)$, $u_n = F_{\mathcal{D}_n}(f, \mu_n)$, $v_n = F_{\mathcal{D}_n}(g, \mu_n)$, and we consider the expression

$$A_n = [u_n, v_n]_{\mathcal{D}_n, \mu_n, \varphi}. \tag{32}$$

We get $A_n = B_n - C_n$, where B_n and C_n are defined by (omitting indexes n in the right-hand sides)

$$B_n = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma)v_\sigma - \varphi(x_K)v_K)$$

and

$$C_n = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} v_\sigma \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma) - \varphi(x_K)).$$

Since $B_n = \sum_{K\in\mathcal{T}} \int_K f(x)dx\ \varphi(x_K)v_K$, we then get

$$\lim_{n\longrightarrow\infty} B_n = \int_\Omega f(x)\varphi(x)\bar{v}(x)dx.$$

Let $\tilde{v} \in C_c^\infty(\Omega)$ be a function which is meant to tend to $\bar{v}$ in $H_0^1(\Omega)$. We set

$$\tilde{B}_n = \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma)\tilde{v}(y_\sigma) - \varphi(x_K)\tilde{v}(x_K))$$

and we again have $\tilde{B}_n = \sum_{K\in\mathcal{T}} \int_K f(x)dx\ \varphi(x_K)\tilde{v}(x_K)$, which yields

$$\lim_{n\longrightarrow\infty} \tilde{B}_n = \int_\Omega f(x)\varphi(x)\tilde{v}(x)dx.$$

Using (24), we have

$$\lim_{n\longrightarrow\infty} \tilde{B}_n = \int_\Omega \overline{\mathbf{G}}(f)(x)\cdot\nabla(\varphi(x)\tilde{v}(x))dx.$$

We thus get

$$\int_\Omega f(x)\varphi(x)\tilde{v}(x)dx = \int_\Omega \overline{\mathbf{G}}(f)(x)\cdot\nabla(\varphi(x)\tilde{v}(x))dx. \tag{33}$$

In (33), we let $\tilde{v}\longrightarrow\bar{v}$ in $H^1_0(\Omega)$. It gives

$$\int_\Omega f(x)\varphi(x)\bar{v}(x)dx = \int_\Omega \overline{\mathbf{G}}(f)(x)\cdot\nabla(\varphi(x)\bar{v}(x))dx, \tag{34}$$

and therefore

$$\lim_{n\longrightarrow\infty} B_n = \int_\Omega \overline{\mathbf{G}}(f)(x)\cdot\nabla(\varphi(x)\bar{v}(x))dx. \tag{35}$$

We now study C_n. Let $\hat{v}_n$ be the function defined by

$$\hat{v}_n(x) = v_\sigma\ \forall x\in D_{K,\sigma},\ \forall K\in\mathcal{T},\ \forall\sigma\in\mathcal{E}_K. \tag{36}$$

Since $|v_n|_{\mathcal{D}_n}$ remains bounded, it is easy to see that $\hat{v}_n - v_n$ converges to 0 in $L^2(\Omega)$. We set

$$\hat{C}_n = \int_\Omega \hat{v}_n(x)\ \mu_n\mathbf{G}_{\mathcal{D}_n}F_{\mathcal{D}_n}(f,\mu_n)(x)\cdot\nabla\varphi(x)dx.$$

We easily get, thanks to the Cauchy–Schwarz inequality,

$$|C_n - \hat{C}_n| \le C(\varphi,\beta)\text{size}(\mathcal{D}_n)\ |u_n|_{\mathcal{D}_n}\ \|\hat{v}_n\|_{L^2(\Omega)},$$

which shows that

$$\lim_{n\longrightarrow\infty} C_n = \lim_{n\longrightarrow\infty}\hat{C}_n = \int_\Omega \bar{v}(x)\ \overline{\mathbf{G}}(f)(x)\cdot\nabla\varphi(x)dx. \tag{37}$$

We thus get, gathering (35) and (37), recalling that $\bar{v} = \overline{F}(g)$,

$$\lim_{n\longrightarrow\infty} A_n = \int_\Omega \varphi(x)\ \overline{\mathbf{G}}(f)(x)\cdot\nabla\overline{F}(g)(x)dx. \tag{38}$$

Note that the preceding proof ((32)–(38)) also gives a discrete version of a compensated compactness lemma; see Remark 7 below. We can now exchange the roles of f and g in (38). We thus get

$$\lim_{n\longrightarrow\infty} A_n = \int_\Omega \varphi(x)\ \overline{\mathbf{G}}(g)(x)\cdot\nabla\overline{F}(f)(x)dx. \tag{39}$$

This yields

$$\int_\Omega \varphi(x)\overline{\mathbf{G}}(f)(x)\cdot\nabla\overline{F}(g)(x)dx = \int_\Omega \varphi(x)\overline{\mathbf{G}}(g)(x)\cdot\nabla\overline{F}(f)(x)dx. \tag{40}$$

In order to prove the existence of M as it is given in Theorem 2, we now proceed exactly as in the continuous setting. Since (40) is true for all $\varphi \in C_c^\infty(\Omega)$, we get

$$\overline{\mathbf{G}}(f)(x) \cdot \nabla \overline{F}(g)(x) = \overline{\mathbf{G}}(g)(x) \cdot \nabla \overline{F}(f)(x), \text{ for a.e. } x \in \Omega. \tag{41}$$

Since (41) is true for all f and g in $L^2(\Omega)$, by continuity of $\overline{F}$ and $\overline{\mathbf{G}}$, we get

$$\begin{aligned}&\overline{\mathbf{G}}(b)(x) \cdot \nabla \overline{F}(b')(x) = \overline{\mathbf{G}}(b')(x) \cdot \nabla \overline{F}(b)(x)\\ &\forall b,\ b' \in H^{-1}(\Omega), \quad \text{for a.e. } x \in \Omega.\end{aligned} \tag{42}$$

Since $\overline{F}$ is invertible, we can choose some $b_i \in H^{-1}(\Omega)$ such that, in an open set ω such that $\overline{\omega} \subset \Omega$, $\overline{F}(b_i)(x) = x \cdot \mathbf{e}_i$ and then $\nabla \overline{F}(b_i)(x) = \mathbf{e}_i$ (where $\mathbf{e}_i$ is the ith unit vector of $\mathbb{R}^N$), for $i = 1, \ldots, N$. Thus, for a.e. $x \in \omega$, we can define $M(x) \in \mathcal{L}(\mathbb{R}^N, \mathbb{R}^N)$ by $M^\star(x)\mathbf{e}_i = \overline{\mathbf{G}}(b_i)(x)$, for $i = 1, \ldots, N$, where $M^\star$ is the adjoint operator of M. We thus get

$$\overline{\mathbf{G}}(b)(x) = M(x)\nabla \overline{F}(b)(x) \ \forall b \in H^{-1}(\Omega) \text{ for a.e. } x \in \omega.$$

Taking $b = b_i$ and $b' = b_j$ in (42) proves that $M(x)$ is symmetric in ω. Since ω is arbitrary, we then obtain M a.e. in Ω such that

$$\overline{\mathbf{G}}(b)(x) = M(x)\nabla \overline{F}(b)(x) \ \forall b \in H^{-1}(\Omega) \text{ for a.e. } x \in \Omega. \tag{43}$$

The uniqueness of M is a direct consequence of the invertibility of $\overline{F}$. We now prove that $M \in \mathcal{M}(\alpha, \beta, \Omega)$. Letting $f = g$ in (32), and taking $\varphi \geq 0$, we get, using (38), that

$$\lim_{n \longrightarrow \infty} [u_n, u_n]_{\mathcal{D}_n, \mu_n, \varphi} = \int_\Omega \varphi(x) M(x) \nabla \overline{u}(x) \cdot \nabla \overline{u}(x) dx.$$

Since

$$\begin{aligned}\lim_{n \longrightarrow \infty} [u_n, u_n]_{\mathcal{D}_n, \mu_n, \varphi} &\geq \alpha \liminf_{n \longrightarrow \infty} [u_n, u_n]_{\mathcal{D}_n, 1, \varphi}\\ &\geq \alpha \int_\Omega \varphi(x) (\nabla \overline{u}(x))^2 dx,\end{aligned} \tag{44}$$

we get, for a.e. $x \in \Omega$, $M(x)\nabla \overline{F}(f)(x) \cdot \nabla \overline{F}(f)(x) \geq \alpha(\nabla \overline{F}(f)(x))^2$. By density and invertibility of $\overline{F}$, since f can be arbitrarily chosen, this proves that, for a.e. $x \in \Omega$ and for all $\xi \in \mathbb{R}^N$, $M(x)\xi \cdot \xi \geq \alpha(\xi)^2$. Let $\varphi \in C_c^\infty(\Omega, \mathbb{R}_+)$, and let $(f, g) \in (L^2(\Omega))^N$, $\overline{u} = \overline{F}(f)$, and $\bar{w} = \mathcal{F}(f, 1)$. For $n \in \mathbb{N}$, we define $u_n = F_{\mathcal{D}_n}(f, \mu_n)$ and $w_n = F_{\mathcal{D}_n}(g, 1)$. We define D_n by

$$D_n = [u_n, w_n]_{\mathcal{D}_n, \mu_n, \varphi}. \tag{45}$$

We study D_n in the same manner as A_n. Since w_n converges to $\bar{w}$ in $L^2(\Omega)$, we get

$$\lim_{n \longrightarrow \infty} D_n = \int_\Omega \varphi(x) M(x) \nabla \overline{u}(x) . \nabla \bar{w}(x) dx.$$

On the other hand, we have

$$(D_n)^2 \leq \quad [u_n, u_n]_{\mathcal{D}_n, \mu_n, \varphi} \quad [w_n, w_n]_{\mathcal{D}_n, \mu_n, \varphi}, \tag{46}$$

and therefore

$$(D_n)^2 \leq \beta \ [u_n, u_n]_{\mathcal{D}_n, \mu_n, \varphi} \quad [w_n, w_n]_{\mathcal{D}_n, 1, \varphi}. \tag{47}$$

We thus get

$$\lim_{n\longrightarrow\infty}(D_n)^2 \le \beta \int_\Omega \varphi(x)M(x)\nabla\overline{u}(x).\nabla\overline{u}(x)dx \quad \int_\Omega \varphi(x)(\nabla\bar{w}(x))^2dx,$$

which gives

$$\begin{aligned}(48)\qquad &\left(\int_\Omega \varphi(x)M(x)\nabla\overline{u}(x).\nabla\bar{w}(x)dx\right)^2\\ &\le \beta \quad \int_\Omega \varphi(x)M(x)\nabla\overline{u}(x).\nabla\overline{u}(x)dx \quad \int_\Omega \varphi(x)(\nabla\bar{w}(x))^2dx.\end{aligned}$$

Since g can be arbitrarily chosen, it is therefore possible to let $\bar{w} \longrightarrow \overline{u}$ (in $H_0^1(\Omega)$) in (48). We thus get

$$(49)\qquad \int_\Omega \varphi(x)M(x)\nabla\overline{u}(x).\nabla\overline{u}(x)dx \le \beta \quad \int_\Omega \varphi(x)(\nabla\overline{u}(x))^2dx,$$

which yields, for a.e. $x \in \Omega$, $M(x)\nabla\overline{u}(x)\cdot\nabla\overline{u}(x) \le \beta(\nabla\overline{u}(x))^2$. By density and invertibility of $\overline{F}$, since f can be arbitrarily chosen, we get that, for a.e. $x \in \Omega$ and for all $\xi \in \mathbb{R}^N$, $M(x)\xi\cdot\xi \le \beta\xi^2$.

This concludes the proof of Theorem 2.

REMARK 7. *Note that, as in the continuous setting (see* [14] *and* [19]*) and as in the finite difference framework (see* [12] *and* [16]*), an important step of the above proof (from* (32) *to* (38)*) consists of passing to the limit in some nonlinear terms. Indeed, the same proof as above also yields the following discrete version of a compensated compactness lemma (namely a discrete simplified "div-curl" lemma).*

LEMMA 5 (discrete compensated compactness lemma). *Let Ω be an open bounded polygonal subset of $\mathbb{R}^N$, with $N \in \mathbb{N}_*$. Let $(\mathcal{D}_n)_{n\in\mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition* 1 *such that $\lim_{n\longrightarrow\infty}\text{size}(\mathcal{D}_n) = 0$. Let us suppose that for all $n \in \mathbb{N}$ there exists $W_n, X_n \in V_{\mathcal{D}_n} \subset (L^2(\Omega))^N$ such that*

- *$W_n \longrightarrow W$ weakly in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$;*
- *$X_n \longrightarrow X$ weakly in $(L^2(\Omega))^N$ as $n \longrightarrow \infty$;*
- *$\text{div}_{\mathcal{D}_n}W_n$ weakly converges in $L^2(\Omega)$ as $n \longrightarrow \infty$;*
- *there exists $u_n \in H_{\mathcal{D}_n}(\Omega)$ such that $X_n = \mathbf{G}_{\mathcal{D}_n}u_n$.*

Then $\lim_{n\longrightarrow\infty}\langle W_n, G_n\rangle_{\mathcal{D}_n} = \int_\Omega W(x)\cdot X(x)dx$.

In the preceding lemma, we denote, for any admissible discretization $\mathcal{D}$ of Ω in the sense of Definition 1*, by $V_\mathcal{D}$ the subset of $(L^2(\Omega))^N$ of functions W verifying that there exists a family of real values $(w_{K,\sigma})_{K\in\mathcal{T},\sigma\in\mathcal{E}_K}$ such that*

$$W(x) = Nw_{K,\sigma}\mathbf{n}_{K,\sigma}, \quad \textit{for a.e. } x \in D_{K,\sigma}\ \forall K \in \mathcal{T},\ \forall\sigma \in \mathcal{E}_K,$$

and $w_{K,\sigma} + w_{L,\sigma} = 0$ for all $\sigma = K|L$.

For all $W \in V_\mathcal{D}$, we denote by $\text{div}_\mathcal{D}W$ the piecewise constant function, whose value in $K \in \mathcal{T}$ is $\sum_{\sigma\in\mathcal{E}_K} m_\sigma w_{K,\sigma}$. We then get $\mathbf{G}_\mathcal{D}u \in V_\mathcal{D}$ for all $u \in H_\mathcal{D}(\Omega)$. For $(W,X) \in (V_\mathcal{D})^2$, we then define $\langle W,X\rangle_\mathcal{D} = \frac{1}{N}\int_\Omega W(x)\cdot X(x)dx$. It is interesting to notice that, under the hypotheses of the lemma, neither the sequence $(W_n)_{n\in\mathbb{N}}$ nor $(X_n)_{n\in\mathbb{N}}$ converges in $(L^2(\Omega))^N$, except if the limit is 0*. Note also that, contrary to the classical compensated compactness lemma, the sequence which converges in the distribution sense to $W\cdot X$ is not $(W_n\cdot X_n)_{n\in\mathbb{N}}$, but it is $\frac{1}{N}(W_n\cdot X_n)_{n\in\mathbb{N}}$.*

5. Application to a coupled problem.

5.1. A continuous system of equations. We now study the steady-state version of the evolution problem (1). We thus get the following system:

$$\left.\begin{aligned} -\mathrm{div}(\lambda(s)\nabla u) &= \bar{f} \\ -\mathrm{div}(\gamma(s)\lambda(s)\nabla u) &= (\bar{f})^{+}\gamma(\bar{s}) - (\bar{f})^{-}\gamma(s) \end{aligned}\right\} \text{ in } \Omega, \tag{50}$$

with the boundary conditions

$$\begin{aligned} &u = 0 \text{ on } \partial\Omega, \\ &s = \hat{s} \text{ on } \{x \in \partial\Omega, \nabla u(x)\cdot \mathbf{n}_{\partial\Omega}(x) \geq 0\}. \end{aligned} \tag{51}$$

We refer to the introduction for the physical meaning of the quantities appearing in (50) and (51). The following assumptions (denoted in the following Hypotheses (H)) are made on the data:

- the domain Ω is an open polygonal connected subset of $\mathbb{R}^N$, with $N = 2$ or $N = 3$;
- $\gamma \in C^0([0,1],[0,1])$ is a nondecreasing Lipschitz continuous function with $\gamma(0) = 0$ and $\gamma(1) = 1$, and Lipschitz constant $L_\gamma > 0$;
- there exists two real numbers α and β, with $0 < \alpha \leq \beta$, such that $\lambda \in C^0([0,1],[\alpha,\beta])$ (recall that λ is the "total mobility") verifies that $\gamma\lambda$ (the mobility of the phase 1, also denoted below k_1) is nondecreasing and $(1-\gamma)\lambda$ (the mobility of the phase 2) is nonincreasing;
- $\bar{f} \in L^2(\Omega)$ represents the rates at the wells;
- $\bar{s} \in L^\infty(\Omega)$ is such that $0 \leq \bar{s} \leq 1$ a.e. in Ω;
- $\hat{s} \in L^\infty(\partial\Omega)$ is such that $0 \leq \hat{s} \leq 1$ a.e. in $\partial\Omega$ (for the $N-1$-dimensional Lebesgue measure).

5.2. Finite volume coupled scheme. Let us assume Hypotheses (H). Let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition 1. We set

$$\left.\begin{aligned} &\bar{f}_K = \int_K \bar{f}(x)dx,\ \bar{s}_K = \frac{1}{m_K}\int_K \bar{s}(x)dx \quad \forall K \in \mathcal{T}, \\ &\hat{s}_\sigma = \frac{1}{m_\sigma}\int_\sigma \hat{s}(x)dx \qquad\qquad\qquad\quad \forall \sigma \in \mathcal{E}_{\mathrm{ext}}. \end{aligned}\right\} \tag{52}$$

We introduce the set $L_{\mathcal{D}}(\Omega,[0,1])$ of the functions of $L^\infty(\Omega)$ whose value on each $K \in \mathcal{T}$ is a constant value belonging to $[0,1]$. For all $s \in L_{\mathcal{D}}(\Omega,[0,1])$ and $K \in \mathcal{T}$, we denote $s_K \in [0,1]$ the constant value of s in K. For all $u \in H_{\mathcal{D}}(\Omega)$ and $s \in L_{\mathcal{D}}(\Omega,[0,1])$, the upstream evaluation of the saturation at the edges $\sigma \in \mathcal{E}$ is defined by the functions $s_\sigma(u,s,\hat{s})$ such that

$$\begin{aligned} &\left.\begin{aligned} s_\sigma(u,s,\hat{s}) &= s_K && \text{if } u_K \geq u_L \\ s_\sigma(u,s,\hat{s}) &= s_L && \text{if } u_K < u_L \end{aligned}\right\} \quad \forall \sigma \in \mathcal{E}_{\mathrm{int}},\ \sigma = K|L, \\ &\left.\begin{aligned} s_\sigma(u,s,\hat{s}) &= s_K && \text{if } u_K \geq 0 \\ s_\sigma(u,s,\hat{s}) &= \hat{s}_\sigma && \text{if } u_K < 0 \end{aligned}\right\} \quad \forall \sigma \in \mathcal{E}_{\mathrm{ext}},\ \sigma \in \mathcal{E}_K, \end{aligned} \tag{53}$$

and the functions $\mu(u,s,\hat{s}) \in \mathcal{M}_{\mathcal{D}}(\alpha,\beta)$ by

$$\mu_\sigma(u,s,\hat{s}) = \lambda(s_\sigma(u,s,\hat{s}))\ \forall \sigma \in \mathcal{E}. \tag{54}$$

We consider the following scheme (classical in petroleum engineering), a solution of which is some $(u,s) \in H_{\mathcal{D}}(\Omega) \times L_{\mathcal{D}}(\Omega,[0,1])$:

$$u = F(\bar{f},\mathcal{D},\mu(u,s,\hat{s})), \tag{55}$$

$$-\sum_{\sigma\in\mathcal{E}_K}\gamma(s_\sigma(u,s,\hat{s}))\,\mu_\sigma(u,s,\hat{s})\,\tau_{K,\sigma}\,(u_\sigma-u_K)=\gamma(\bar{s}_K)(\bar{f}_K)^+-\gamma(s_K)(\bar{f}_K)^-\ \ \forall K\in\mathcal{T}.$$
(56)

Remark 8. *Note that the function λ is also evaluated in* (54) *using an upstream weighted scheme. This corresponds to the industrial scheme classically used in reservoir simulation, in which the mobility of each phase is upstream weighted. However, it would be natural to use a centered approximation in* (54) *and use an upstream weighted scheme for γ in the left-hand side of* (56)*, but in such a case the convergence results given in Theorem* 4 *should be weakened.*

5.2.1. Existence of a solution to the coupled scheme.

Lemma 6. *Let us assume Hypotheses (H). Let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition* 1*. Then there exists at least one solution $(u,s)\in H_{\mathcal{D}}(\Omega)\times L_{\mathcal{D}}(\Omega,[0,1])$ to scheme* (52)*–*(56)*.*

Proof. We prove the existence of a solution of (52)–(56) using Brouwer's fixed point theorem. For all $K\in\mathcal{T}$, let us define $\bar{f}_K$, $\bar{s}_K$, $\hat{s}_K$ by (52). We denote by

$$E=\{u\in H_{\mathcal{D}}(\Omega),\alpha|u|_{\mathcal{D}}\le\operatorname{diam}(\Omega)\ \|\bar{f}\|_{L^2(\Omega)}\}.$$

We define the application $\mathcal{A}\ :E\times L_{\mathcal{D}}(\Omega,[0,1])\longrightarrow E\times L_{\mathcal{D}}(\Omega,[0,1])$ by $\mathcal{A}(u,s)=(u',s')$, with $u'=F(\bar{f},\mathcal{D},\mu(u,s,\hat{s}))$, and for a real value $k>0$ which will be chosen later we define $(s'_K)_{K\in\mathcal{T}}$ by

$$s'_K=s_K+\frac{k}{m_K}\left(\begin{array}{l}\displaystyle\sum_{\sigma\in\mathcal{E}_K}\gamma(s_\sigma(u',s,\hat{s}))\,\mu_\sigma(u,s,\hat{s})\,\tau_{K,\sigma}\,(u'_\sigma-u'_K)\\ +\ \gamma(\bar{s}_K)(\bar{f}_K)^+-\gamma(s_K)(\bar{f}_K)^-\end{array}\right)\tag{57}$$
$$\forall K\in\mathcal{T}.$$

Since $\lambda\ge\alpha$, one has, using (13), that $u'\in E$. Then, in order to prove that $\mathcal{A}(u,s)\in E\times L_{\mathcal{D}}(\Omega,[0,1])$, we have only to prove that we can choose $k>0$ such that, for all $K\in\mathcal{T}$, $0\le s'_K\le 1$ (the operator $\mathcal{A}$ is then defined with this value of k). Using (13), we get

$$|u'_\sigma-u'_K|\le\left(\frac{\operatorname{diam}(\Omega)\ \|f\|_{L^2(\Omega)}}{\alpha\displaystyle\inf_{K\in\mathcal{T},\sigma\in\mathcal{E}_K}\tau_{K,\sigma}}\right)^{1/2}\quad\forall K\in\mathcal{T},\forall\sigma\in\mathcal{E}_K.\tag{58}$$

Denoting by M_{du} the right-hand side of inequality (58), we then take $k>0$ such that

$$k\le\inf_{K\in\mathcal{T}}\frac{m_K}{L_\gamma\left(\beta M_{du}\displaystyle\sum_{\sigma\in\mathcal{E}_K}\tau_{K,\sigma}+|\bar{f}_K|\right)}\tag{59}$$

(recall that L_γ is a Lipschitz constant for γ). With such a choice for k, we can now prove that for all $K\in\mathcal{T}$, $s'_K\in[0,1]$. Indeed, for $K\in\mathcal{T}$, let us multiply (11) (in which we set $\mu=\mu(u,s,\hat{s})$ and $f=\bar{f}$) by $\gamma(s_K)$ and substract the result from (57). We then get

$$s'_K=s_K+\frac{k}{m_K}\left(\sum_{\sigma\in\mathcal{E}_K}T_{K,\sigma}(s_\sigma(u',s,\hat{s})-s_K)+T_K(\bar{s}_K-s_K)\right),$$

where we define the nonnegative values $T_{K,\sigma}$ and T_K by

$$\begin{cases} T_{K,\sigma} = \dfrac{\gamma(s_\sigma(u',s,\hat{s})) - \gamma(s_K)}{s_\sigma(u',s,\hat{s}) - s_K}\mu_\sigma(u,s,\hat{s})\tau_{K,\sigma}(u'_\sigma - u'_K)^+ & \text{if } s_\sigma(u',s,\hat{s}) \neq s_K, \\ T_{K,\sigma} = L_\gamma \mu_\sigma(u,s,\hat{s})\tau_{K,\sigma}(u'_\sigma - u'_K)^+ & \text{if } s_\sigma(u',s,\hat{s}) = s_K \end{cases}$$

and

$$\begin{cases} T_K = \dfrac{\gamma(\bar{s}_K) - \gamma(s_K)}{\bar{s}_K - s_K}(\bar{f}_K)^- & \text{if } \bar{s}_K \neq s_K, \\ T_K = L_\gamma \ (\bar{f}_K)^- & \text{if } \bar{s}_K = s_K. \end{cases}$$

Then, for $k > 0$ verifying (59), we have

$$0 \leq 1 - \frac{k}{m_K}\left(\sum_{\sigma\in\mathcal{E}_K} T_{K,\sigma} + T_K\right),$$

which ensures that s'_K is a convex combination of $(s_K)_{K\in\mathcal{T}}$, $(\hat{s}_\sigma)_{\sigma\in\mathcal{E}_{\text{ext}}}$, and $(\bar{s}_K)_{K\in\mathcal{T}}$. This proves that $0 \leq s'_K \leq 1$.

Since $\mathcal{A}$ is continuous, we can apply Brouwer's fixed point theorem. This gives the existence of $(u,s) \in E \times L_{\mathcal{D}}(\Omega,[0,1])$ such that $\mathcal{A}(u,s) = (u,s)$, which proves the existence of a solution to (52)–(56).

5.2.2. Convergence of the scheme. We have the following result, which appears to be very weak compared to the initial ambition of approximating problem (50).

Theorem 3. *Let us assume Hypotheses (H). Let $(\mathcal{D}_n)_{n\in\mathbb{N}}$ be a sequence such that, for all $n \in \mathbb{N}$, $\mathcal{D}_n$ is an admissible discretization of Ω in the sense of Definition* 1, *and* $\lim_{n\longrightarrow\infty} \text{size}(\mathcal{D}_n) = 0$.

Then there exists a subsequence of $(\mathcal{D}_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n)_{n\in\mathbb{N}}$, such that, denoting for all $n \in \mathbb{N}$, $(u_n, s_n, \mu_n) \in H_{\mathcal{D}_n}(\Omega)\times L_{\mathcal{D}_n}(\Omega,[0,1])\times\mathcal{M}_{\mathcal{D}_n}(\alpha,\beta)$ the solution given by the scheme (52)*–*(56) *with $\mathcal{D} = \mathcal{D}_n$, we have that*

- *the sequence $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$ Hd-converges in the sense of Theorem 2 to a measurable function $M \in \mathcal{M}(\alpha,\beta,\Omega)$, which implies that u_n converges to $\bar{u} = \mathcal{F}(\bar{f}, M)$ in $L^2(\Omega)$ as $n \longrightarrow \infty$;*
- *there exists a function $s \in L^\infty(\Omega)$, with $0 \leq s \leq 1$ a.e. such that the sequence $(s_n)_{n\in\mathbb{N}}$ converges to s for the weak $\star$ topology of $L^\infty(\Omega)$ and there exists a function $\bar{\gamma} \in L^\infty(\Omega)$, with $0 \leq \bar{\gamma} \leq 1$ a.e. such that the sequence $(\gamma(s_n))_{n\in\mathbb{N}}$ converges to $\bar{\gamma}$ for the weak $\star$ topology of $L^\infty(\Omega)$;*

The first item of the conclusion of Theorem 3 is a direct consequence of Theorem 2. The second item is a consequence of the sequential weak $\star$ compactness of the closed balls of L^∞. Note that, since the way to handle the convergence of (56) does not seem to be clear, no relation is given in the previous theorem between the limit of $(\gamma(s_n)\lambda(s_n))_{n\in\mathbb{N}}$, which is a possibly degenerate diffusion if we consider the second equation of (50) as an elliptic equation on u, and the Hd-limit of $(\mathcal{D}_n, \mu_n)_{n\in\mathbb{N}}$. Such a relation can be found in the following particular case, where there exists a nondecreasing Lipschitz continuous function $k_1 \ : [0,1] \longrightarrow \mathbb{R}$, with $k_1(0) = 0$ and $k_1(1) > 0$, and a real $\Lambda \in (0,1)$ such that

$$\gamma(s) = \frac{k_1(s)}{k_1(s) + \Lambda(k_1(1) - k_1(s))}, \tag{60}$$
$$\lambda(s) = k_1(s) + \Lambda(k_1(1) - k_1(s)) \qquad \forall s \in [0,1].$$

Note that we can take in this case $\beta = k_1(1)$ and $\alpha = \Lambda k_1(1)$. This particular case corresponds to a mobility of the second phase defined by the function $\Lambda\ (k_1(1) - k_1(.))$ (this can be acceptable in some physical situations; recall that k_1 is the mobility of the first phase). We can then give the following result, which is more complete than Theorem 3 (as previously mentioned, the following theorem does not give the limit of the scheme as a solution of (50) since we could obtain such a result only within a strong convergence property for $(s_n)_{n\in\mathbb{N}}$).

THEOREM 4. *Let us assume Hypotheses (H) in the particular case* (60)*. Let $(\mathcal{D}_n)_{n\in\mathbb{N}}$ be a sequence such that, for all $n \in \mathbb{N}$, $\mathcal{D}_n$ is an admissible discretization of Ω in the sense of Definition* 1*, and* $\lim_{n\longrightarrow\infty} \mathrm{size}(\mathcal{D}_n) = 0$.

Then there exists a subsequence of $(\mathcal{D}_n)_{n\in\mathbb{N}}$, again denoted $(\mathcal{D}_n)_{n\in\mathbb{N}}$, such that, denoting for all $n \in \mathbb{N}$, $(u_n, s_n, \mu_n) \in H_{\mathcal{D}_n}(\Omega) \times L_{\mathcal{D}_n}(\Omega, [0,1]) \times \mathcal{M}_{\mathcal{D}_n}(\Lambda k_1(1), k_1(1))$ the solution given by the scheme (52)–(56) *with $\mathcal{D} = \mathcal{D}_n$, we have, in addition to the conclusions of Theorem* 3*, the existence of a function $\bar{\gamma} \in L^\infty(\Omega)$, with $0 \le \bar{\gamma} \le 1$ a.e. such that the sequence $(\gamma(s_n))_{n\in\mathbb{N}}$ converges to $\bar{\gamma}$ for the weak $\star$ topology of $L^\infty(\Omega)$ and*

$$\begin{aligned}&\int_\Omega \frac{1}{1-\Lambda}(M(x) - \Lambda k_1(1) I_N)\nabla\overline{u}(x)\cdot\nabla\bar{v}(x)dx \\ &= \int_\Omega (\gamma(\bar{s}(x))(\bar{f}(x))^+ - \bar{\gamma}(x)(\bar{f}(x))^-)\ \bar{v}(x)dx \qquad \forall \bar{v} \in H_0^1(\Omega).\end{aligned} \tag{61}$$

Note that $k_1(\cdot) = \lambda(\cdot)\gamma(\cdot) = \frac{1}{1-\Lambda}(\lambda(\cdot) - \Lambda k_1(1))$.

Proof. We have only to prove (61). Let us assume the hypotheses of Theorem 4. Let $\varphi \in C_c^\infty(\Omega)$. We define, for $n \in \mathbb{N}$ and omitting indexes n in the right-hand sides,

$$D_n = \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} \mu_\sigma \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma) - \varphi(x_K))$$

and

$$E_n = \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma) - \varphi(x_K)).$$

We have, using the results of Theorem 2,

$$\lim_{n\longrightarrow\infty} D_n = \int_\Omega M(x)\nabla\overline{u}(x)\cdot\nabla\varphi(x)dx.$$

On the other hand, we have

$$\lim_{n\longrightarrow\infty} E_n = \int_\Omega \nabla\overline{u}(x)\cdot\nabla\varphi(x)dx.$$

Since we assume the particular case (60), we get that

$$\begin{aligned}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} \gamma(s_\sigma(u,s,\hat{s}))\ \mu_\sigma(u,s,\hat{s})\ \tau_{K,\sigma}(u_\sigma - u_K)(\varphi(y_\sigma) - \varphi(x_K))& \\ = \frac{1}{1-\Lambda}(D_n - \Lambda k_1(1)E_n).&\end{aligned}$$

Using the fact that $\sum_{K\in\mathcal{T}}\gamma(s_K)(\bar{f}_K)^-\varphi(x_K) \longrightarrow \int_\Omega \bar{\gamma}(x)(\bar{f}(x))^-\varphi(x)dx$ as $n \longrightarrow \infty$ (thanks to the L^∞ weak $\star$ convergence of $\gamma(s_n)$ to $\bar{\gamma}$), we thus get (61) with $\varphi \in C_c^\infty(\Omega)$. Then we obtain (61) using a classical result of density.

6. Concluding remarks. The notion of Hd-convergence, developed in this paper, gives a useful tool for studying the convergence of a discrete finite volume scheme, used for the approximation of a two-phase flow in a porous medium. The proof of the Hd-convergence theorem mimics that of the H-convergence theorem; however, although the methods are similar, the limits can be different. This discrete tool is therefore adapted to the case of a coupled discretization: the discrete pressure field is the solution of a discrete scheme for an elliptic equation, the coefficients of which result from another discrete scheme in the same grid.

This tool thus helps to get the limit problem of which the limit of the approximate pressure is the solution. A weak limit also exists for the saturation since the discrete values are bounded, as well as the continuous ones. Unfortunately, we are not able to link the Hd-limit of the sequence of discrete total mobilities and a convenient limit of the sequence of saturations.

Finally, the time-dependent problem must now be studied. Following [18] in which the G-convergence notion is adapted to general parabolic time-dependent operators, it is then possible to develop a discrete H-convergence in the case of a two-phase flow in compressible porous media (see [8]).

NUMERICAL APPROXIMATION OF THE LIFSHITZ–SLYOZOV–WAGNER EQUATION*

FRANCIS FILBET[†] AND PHILIPPE LAURENÇOT[‡]

Abstract. The Lifshitz–Slyozov–Wagner theory of coarsening (Ostwald ripening) describes the late stages of the growth by diffusional mass transfer of the grains of a new phase from a supersaturated solution. It results in a nonlinear transport equation with a nonlocal nonlinearity for the volume distribution function of the grains. A time explicit finite volume numerical scheme is proposed to solve this equation in self-similar variables and is shown to converge under a CFL condition. Numerical simulations are also presented.

Key words. Lifshitz–Slyozov–Wagner model, Ostwald ripening, finite volume method, convergence

1. Introduction.

The theory of coarsening (Ostwald ripening) in alloys describes the late stages of the formation and growth of grains of a new phase from a supersaturated solution. During these stages, no new grains can form, and the determining process is the growth of the grains by diffusional mass exchange [13, 25]. More precisely, the grains of the new phase that are larger than some critical size grow at the expense of smaller ones, the critical size varying in time as a function of the degree of supersaturation. A mean-field approach for this process has been formulated by Lifshitz and Slyozov [13] and Wagner [25]. For very dilute solutions at large times, the variation in the degree of supersaturation may be neglected, and the time evolution of the volume distribution function f of the grains is given by

$$\partial_t f + \partial_x (\mathcal{V}\ f) = 0, \quad (t,x) \in \mathbb{R}_+^2, \tag{1.1}$$

with the constraint (total volume conservation)

$$\int_0^\infty x\ f(t,x)\ dx = \text{ const.}, \quad t \in \mathbb{R}_+. \tag{1.2}$$

Here $x \in \mathbb{R}_+ := (0, +\infty)$ is the volume of the grains, $t \in \mathbb{R}_+$ is the time variable, and $\mathcal{V} = \mathcal{V}(t,x)$ denotes the rate of growth of the grains, which is determined by the mechanism of mass transfer between the grains, e.g., volume diffusion [13, 25] or grain-boundary diffusion [22]. In general, one has $\mathcal{V}(t,x) = k(x)u(t) - q(x)$, where k and q are computed from the modeling of the mechanism of mass transfer between the grains [13, 22, 25]. For instance, in the model considered in [13], where the mass transfer is driven by diffusion, $\mathcal{V}$ is explicitly computable and $k(x) = 3\ x^{1/3}$, $q(x) = 3$,

$x \in \mathbb{R}_+$. The function u is then determined by requiring that the solution f to (1.1) comply with (1.2), that is,

$$u(t) \int_0^\infty k(x)\ f(t,x)\ dx = \int_0^\infty q(x)\ f(t,x)\ dx, \quad t \in \mathbb{R}_+. \tag{1.3}$$

The main purpose of this work is to present a numerical scheme for solving (1.1)–(1.2) and to study the properties and the convergence of this scheme when the functions k and q determining the rate of growth of the grains $\mathcal{V}$ are given by

$$k(x) = x^\alpha \quad \text{and} \quad q(x) = 1, \quad x \in \mathbb{R}_+, \tag{1.4}$$

for some $\alpha \in (0,1)$. (Recall that $\alpha = 1/3$ is the case considered in [13].) We will not, however, study (1.1)–(1.2) directly but will first perform a couple of transformations to obtain an equivalent formulation more suitable for our purposes. As in [17], we first introduce the number $F(t,x)$ of grains of size larger than x at time t, that is,

$$F(t,x) = \int_x^\infty f(t,x')\ dx', \quad (t,x) \in \mathbb{R}_+^2. \tag{1.5}$$

The constraint (1.2) then straightforwardly translates to the conservation of the L^1-norm of $F(t)$ throughout time evolution, and F solves

$$\partial_t F + \mathcal{V}\ \partial_x F = 0, \qquad \int_0^\infty F(t,x)\ dx = \text{ const.}, \quad (t,x) \in \mathbb{R}_+^2. \tag{1.6}$$

The second transformation we shall perform is related to the large time behavior of solutions to (1.1)–(1.2) and is motivated by the following fact: formal asymptotic expansions performed in [13] for $\alpha = 1/3$ indicate that the pair (f,u) approaches a self-similar form as time increases to infinity with the following scaling:

$$f(t,x) \sim t^{-2}\ f_\infty\left(\frac{x}{t}\right) \quad \text{and} \quad u(t) \sim u_\infty\ t^{-\alpha}.$$

Observing that convergence to a self-similar profile translates to convergence to a steady state in self-similar variables, we introduce

$$\left\{ \begin{aligned} F(t,x) &= (1+t)^{-1}\ G\left(\ln(1+t), x/(1+t)\right), \\ u(t) &= (1+t)^{-\alpha}\ v\left(\ln(1+t)\right), \end{aligned} \right. \qquad (t,x) \in \mathbb{R}_+^2. \tag{1.7}$$

It then follows from (1.6) that (G,v) satisfies

$$\partial_t G + \mathcal{W}\ \partial_x G = G, \qquad \int_0^\infty G(t,x) = \text{ const.}, \tag{1.8}$$

where $\mathcal{W}(t,x) = x^\alpha\ v(t) - 1 - x$, $(t,x) \in \mathbb{R}_+^2$. In this paper, we will focus on this alternative formulation of the Lifshitz–Slyozov–Wagner (LSW) equation (1.1)–(1.2). We investigate the properties and the convergence of a numerical scheme for (1.8) built upon an explicit Euler discretization with respect to the time variable t and a finite volume discretization with respect to the volume variable x. Finally, numerical simulations will be presented, allowing us to check the numerical convergence of the scheme and to compare the large time behavior of our approximation with that expected for the solution to (1.8).

Let us provide some comments about the behavior of our numerical scheme, referring to section 5 for a more complete discussion. Unlike what was conjectured by Lifshitz and Slyozov [13], the large time behavior of solutions to (1.8) is complex and very sensitive to perturbations. In particular, according to the analysis in [14, 20], the behavior for large times of solutions to (1.8) with compactly supported initial data changes drastically in the presence of a small diffusion (say, an additional term $\eta\, \partial_x^2 G$ on the right-hand side of (1.8) with $\eta > 0$). Since our numerical scheme is a classical upwind method, a small numerical diffusion comes into play during the simulations. It is then unlikely that our scheme reproduces the correct large time behavior for compactly supported initial data, and this is exactly what we observe in the numerical simulations. On the other hand, our scheme gives the correct limit for noncompactly supported initial data. In order to capture the expected behavior for large times for arbitrary initial data, it seems that a less diffusive numerical scheme is needed. One possibility is to use a higher-order scheme, and this is the approach developed by Carrillo and Goudon in [2], where a WENO (weight essentially nonoscillatory)-type scheme is used to numerically compute the solutions to (1.8). (The main focus of [2] is actually the variant of (1.8) described in Remark 1.1 below.) The numerical simulations reported in [2] show that such a scheme gives the expected behavior for intermediate times, providing better results than our scheme. Still, for larger times, some numerical diffusion effects also come into play and drive the numerical solution away from the theoretical predictions. Another approach relies on a nonlinear and antidissipative scheme [5]. It has been recently considered by Lagoutière and seems to successfully compute the correct behavior, even for large times [8]. Let us point out, however, that no convergence proof seems to be available for these schemes.

Before describing our results more precisely, let us recall that the LSW equation (1.1)–(1.2) has been the object of several studies recently; existence and uniqueness of weak solutions have been proved in [10, 17, 19] for the initial value problem (1.1)–(1.2) under various assumptions on the functions k and q determining the growth rate of the grains $\mathcal{V}$ and the initial data. Also, the large time asymptotics have been investigated in [1, 16] by analytical means and in [2, 6] by numerical simulations.

Remark 1.1. A different version of the LSW equation (originally introduced in [13]), in which the constraint (1.2) is replaced by

$$u(t) + A \int_0^\infty x\, f(t,x)\, dx = Q, \quad t \in \mathbb{R}_+, \tag{1.9}$$

is actually the main concern of [2, 18]. In (1.9), Q is the total initial supersaturation and A is a physical constant [13]. Still, the large time behavior of solutions to (1.1), (1.9) is expected to be the same as that of (1.1), (1.2), provided that $u(t)$ defined by (1.9) converges to zero, which is true for initial data with a sufficiently wide support [2, 18]. Let us also mention that the well-posedness of the initial value problem (1.1), (1.9) has been studied in [3, 9, 17].

We now briefly outline the contents of the paper. In the next section, we introduce the numerical approximation of (1.8) and state the convergence result, which we prove in sections 3 and 4. Two points are worth mentioning here. First, it readily follows from (1.5) and the nonnegativity of f that $x \mapsto F(t,x)$ is nonincreasing and so is $x \mapsto G(t,x)$ by (1.8). At the discrete level, our approximation of G also enjoys this property. Secondly, since the definition of v involves the inverse of a moment of G (recall the definition (1.3) of u), an important step of the convergence proof is the derivation of a uniform L^∞-estimate on the approximations of v. For compactly supported initial data, such a bound has been obtained by estimating the time evolution of the support of the solution [10, 17], but this method does not seem to work here because of the (small) viscosity induced by the numerical approximation. We therefore use a different approach and obtain a new L^∞-bound in terms of the first moment of G. Since the proof of this estimate is quite technical at the discrete level, we also provide a (formal) proof for (1.1)–(1.2) in the appendix, hoping to clarify the underlying idea. The final section (section 5) is devoted to some numerical simulations performed with the numerical scheme presented in section 2.

2. Main results. Before describing our numerical scheme and stating a convergence result, we first introduce some notation and assumptions and recall previous results on (1.8). As already mentioned, we focus on the approximation of the initial value problem

$$\partial_t G + \partial_x (\mathcal{W}\ G) = S, \quad (t,x) \in \mathbb{R}_+^2, \tag{2.1}$$

$$\alpha\ v(t) \int_0^\infty x^{\alpha-1}\ G(t,x)\ dx = G(t,0), \quad t \in \mathbb{R}_+, \tag{2.2}$$

$$G(0,x) = G_0(x), \quad x \in \mathbb{R}_+, \tag{2.3}$$

where $\alpha \in (0,1)$ is fixed,

$$\begin{aligned} \mathcal{W}(t,x) &= x^\alpha\ v(t) - 1 - x, \quad (t,x) \in \mathbb{R}_+^2, \\ S(t,x) &= \alpha\ x^{\alpha-1}\ v(t)\ G(t,x), \quad (t,x) \in \mathbb{R}_+^2, \end{aligned} \tag{2.4}$$

and we assume that the initial datum G_0 satisfies

(2.5) $G_0 \in W^{1,1}(\mathbb{R}_+) \cap L^1(\mathbb{R}_+, xdx)$ is a nonnegative and nonincreasing function and $G_0 \not\equiv 0$.

Here and below, the notation $L^1(\mathbb{R}_+, xdx)$ stands for the space of the Lebesgue measurable real-valued functions on $\mathbb{R}_+$ which are integrable with respect to the measure xdx.

Observe that (2.1) is nothing but $\partial_t G + \mathcal{W}\ \partial_x G = G$ written in conservative form. Next, as a consequence of [10, Theorem 2] and Proposition A.1, there are at least a pair of nonnegative functions (G, v) satisfying

$$G \in \mathcal{C}([0,T]; L^1(\mathbb{R}_+)) \cap \mathcal{C}^1(0,T; L^1(\mathbb{R}_+, \min\{x,1\}dx)), \qquad v \in L^\infty(0,T)$$

for each $T \in \mathbb{R}_+$ and (2.1), (2.2), (2.3) with $\mathcal{W}$ given by (2.4). In addition, $x \mapsto G(t,x)$ is a nonincreasing function for each $t \geq 0$ and

$$\int_0^\infty G(t,x)\ dx = \int_0^\infty G_0(x)\ dx, \quad t \geq 0, \tag{2.6}$$

the identity (2.6) being actually equivalent to (2.2). Furthermore, the uniqueness of the pair (G, v) follows from [18] if G_0 is compactly supported, and from [19] in the general case. (Only the case $\alpha = 1/3$ is actually considered in [18, 19], but their proofs extend to $\alpha \in (0,1)$.) Let us finally point out that the integrability assumption $G_0 \in L^1(\mathbb{R}_+; xdx)$ is not needed for the existence of a solution to (2.1), (2.2), (2.3). It can probably be dispensed with herein also but allows us to avoid many technicalities in the proof of the L^∞-bound for v and its approximations.

Next, let $h \in (0,1)$ denote the mesh size and set

$$x_{-1/2} = 0, \quad x_i = x_{i-1/2} + \frac{h}{2}, \quad x_{i+1/2} = x_{i-1/2} + h, \tag{2.7}$$

and $\Lambda_i^h = [x_{i-1/2}, x_{i+1/2})$ for $i \geq 0$. Since x ranges in the unbounded domain $\mathbb{R}_+$, the numerical solution will actually be computed on the bounded domain $[0, x_{I^h+1/2})$, where I^h is a large integer depending on h. We shall of course require that $h\ I^h \to +\infty$ as $h \to 0$. We then define the approximation $G^{0,h}$ of the initial datum G_0 as usual by

$$G^{0,h} = \sum_{i=0}^{I^h} G_i^{0,h}\ \mathbf{1}_{\Lambda_i^h} \quad \text{with} \quad G_i^{0,h} = \frac{1}{h} \int_{\Lambda_i^h} G_0(x)\ dx, \tag{2.8}$$

and recall that

$$\|G^{0,h}\|_{L^1} \leq \|G_0\|_{L^1} \quad \text{and} \quad \lim_{h \to 0} \|G^{0,h} - G_0\|_{L^1} = 0. \tag{2.9}$$

Here and below, $\mathbf{1}_E$ denotes the characteristic function of the subset E of $\mathbb{R}_+$.

Finally, let $T \in \mathbb{R}_+$ be some final time and N the number of time iterations, and set

$$\Delta t = \frac{T}{N}, \qquad t^n = n\ \Delta t, \quad 0 \leq n \leq N.$$

The data h, Δt, and I^h have to fulfill the following conditions: we first require that the domain of computation approach $[0, +\infty)$ and the discrete initial data be close enough to G_0, that is,

$$\lim_{h \to 0} h\ I^h = +\infty, \qquad \|G^{0,h}\|_{L^1} \geq \frac{1}{2}\ \|G_0\|_{L^1}. \tag{2.10}$$

We also impose the following CFL condition:

$$10\ \frac{\Delta t}{h}\ \left(h\ I^h\right) \leq 1. \tag{2.11}$$

Observe that the above constraints are satisfied when $I^h \sim h^{-1-\vartheta}$ for some $\vartheta > 0$ and when $\Delta t\ h^{-1-\vartheta}$ is sufficiently small.

Denoting by $G_i^{n,h}$ an approximation of the mean value of $G(t^n)$ on Λ_i^h for $i \in \{0, \ldots, I^h\}$, and by v^n an approximation of $v(t^n)$, the numerical scheme to be studied in this paper reads

$$G_i^{n+1,h} = G_i^{n,h} - \frac{\Delta t}{h}\ \left(F_{i+1/2}^{n,h} - F_{i-1/2}^{n,h}\right) + \Delta t\ S_i^{n,h}, \quad 0 \leq i \leq I^h, \tag{2.12}$$

$$G_{-1}^{n,h} = G_{I^h+1}^{n,h} = 0, \tag{2.13}$$

$$h\ v^{n+1}\ \left(\sum_{i=0}^{I^h} a_i^h\ G_i^{n+1,h}\right) = G_0^{n+1,h}, \tag{2.14}$$

for $n \in \{0, \ldots, N-1\}$, with initial data $(G_i^{0,h})_{0 \leq i \leq I^h}$ defined in (2.8) and v^0 given by (2.14) with $n = -1$. In (2.12) the approximate flux $F_{i+1/2}^{n,h}$ is given by

$$F_{i+1/2}^{n,h} = \nu_+^n(x_{i+1/2})\ G_i^{n,h} - \nu_-^n(x_{i+1/2})\ G_{i+1}^{n,h}, \quad -1 \leq i \leq I^h, \tag{2.15}$$

with

$$\nu^n(x) = x^\alpha\ v^n - 1 - x, \quad x \in \mathbb{R}_+, \tag{2.16}$$

$\nu_+^n(x) = \max\{0, \nu^n(x)\}$, $\nu_-^n(x) = \max\{0, -\nu^n(x)\}$, and the source term $S_i^{n,h}$ is given by

$$S_i^{n,h} = a_i^h \; v^n \; G_i^{n,h}, \quad \text{with} \quad a_i^h = \frac{\alpha}{h} \int_{\Lambda_i^h} x^{\alpha-1} \, dx, \quad 0 \le i \le I^h. \tag{2.17}$$

Remark 2.1. Note that the boundary condition $G_{I^h+1}^{n,h} = 0$ in (2.13) is needed only when $\nu^n(x_{I^h+1/2}) < 0$.

Before stating some properties on the scheme (2.12)–(2.17), let us briefly comment on its derivation, which relies obviously on an explicit Euler scheme for the time variable and on a finite volume approach for the volume variable (see, e.g., [7, 12]). Concerning the latter, the formula (2.15) comes from the approximation by a classical upwind scheme of the fluxes $\mathcal{W}(t^n, x_{i+1/2})$ and $\mathcal{W}(t^n, x_{i-1/2})$ arising from the integration of (2.1) over the cell Λ_i^h. As for (2.14), it is a discrete version of (2.2), which guarantees the conservation of the L^1-norm of G^h; see (2.20) below.

Under the conditions (2.10), (2.11) and if hI^h is large enough, the solution $(G_i^{n,h})$ to the scheme (2.12)–(2.17) enjoys properties similar to those of G, which we gather in Proposition 2.2 below.

PROPOSITION 2.2. *There is a positive constant $x_\star$ depending only on α, G_0, and T such that, if*

$$h \; I^h \ge x_\star \tag{2.18}$$

and the conditions (2.10), (2.11) *are fulfilled, the solution* $(G_i^{n,h})$ *to the scheme* (2.12)–(2.17) *satisfies the following:*

- *nonnegativity and monotonicity:*

$$0 \le G_{i+1}^{n,h} \le G_i^{n,h} \le G_0^{n,h}, \quad 0 \le i \le I^h - 1, \tag{2.19}$$

- *conservation of the total volume:*

$$\sum_{i=0}^{I^h} h \; G_i^{n,h} = \sum_{i=0}^{I^h} h \; G_i^{0,h} \tag{2.20}$$

for $n \in \{0, \ldots, N\}$.

We next define the numerical approximation (G^h, v^h) of (G, v) by

$$G^h(t,x) = \sum_{i=0}^{I^h} G_i^{n,h} \; \mathbf{1}_{\Lambda_i^h}(x), \quad v^h(t) = v^n, \quad x \in \mathbb{R}_+, \tag{2.21}$$

for $t \in [t^n, t^{n+1})$ and $n \in \{0, \ldots, N-1\}$, and

$$G^h(T,x) = \sum_{i=0}^{I^h} G_i^{N,h} \; \mathbf{1}_{\Lambda_i^h}(x), \quad v^h(T) = v^N, \quad x \in \mathbb{R}_+. \tag{2.22}$$

We may now state our main result.

THEOREM 2.3. *Assume that the conditions* (2.10), (2.11), *and* (2.18) *are fulfilled and that G_0 satisfies* (2.5). *Then*

$$G^h \longrightarrow G \quad in \quad L^\infty(0,T; L^1(\mathbb{R}_+)), \tag{2.23}$$

$$v^h \overset{*}{\rightharpoonup} v \quad in \quad L^\infty(0,T), \tag{2.24}$$

where (G,v) is the weak solution to (2.1), (2.2), (2.3) *on* $[0,T]$ *with initial datum* G_0. *More precisely,* (G,v) *is a pair of nonnegative functions satisfying*

$$(2.25)\qquad \begin{cases} G \in \mathcal{C}([0,T];L^1(\mathbb{R}_+)) \cap L^\infty\big(0,T;W^{1,1}(\mathbb{R}_+;(1+x)dx)\big), \\ v \in L^\infty(0,T) \end{cases}$$

and

$$(2.26)\qquad \int_0^\infty (G(t)-G_0)\ \varphi\ dx = \int_0^t \int_0^\infty (G(s) - \mathcal{W}(s)\ \partial_x G(s))\ \varphi\ dxds$$

for each $t \in [0,T]$ *and* $\varphi \in L^\infty(\mathbb{R}_+)$, *where* v *and* $\mathcal{W}$ *are given by* (2.2) *and* (2.4), *respectively. Equivalently,* G *satisfies* (2.6). *In addition,* $x \mapsto G(t,x)$ *is nonincreasing for each* $t \in [0,T]$.

Observe that each term in (2.26) makes sense since, by (2.25), $\mathcal{W}$ and $\partial_x G$ belong to $L^\infty((0,T)\times\mathbb{R}_+,(1+x)^{-1}dtdx)$ and $L^\infty(0,T;L^1(\mathbb{R}_+,(1+x)dx))$, respectively.

Let us finally explain the main steps of the proof of Theorem 2.3. Similarly to the existence proof in [10], the proof of Theorem 2.3 relies on estimates of G^h and its discrete gradient in $L^\infty(0,T;L^1(\mathbb{R}_+,(1+x)dx))$ and on an $L^\infty(0,T)$-estimate on v^h. On the continuous equation (2.1), (2.2), (2.3), these bounds are obtained as follows: uniform estimates for G in $L^1(\mathbb{R}_+)$ and $L^\infty(\mathbb{R}_+)$ are straightforward consequences of (2.6) and (2.1), respectively. The main new observation then is that an upper bound on v can be obtained from (2.2) and the previous estimates in terms of the $L^1(\mathbb{R}_+;xdx)$-norm of G (Lemma 3.1). Inserting this estimate into (2.1) yields a uniform estimate for G in $L^1(\mathbb{R}_+;xdx)$, and thus an upper bound for v in $L^\infty(0,T)$ (Lemma 3.2). The equation satisfied by $\partial_x G$ then reveals an $L^1(\mathbb{R}_+)$-weak compactness estimate on $\partial_x G$, which, in turn, implies some time equicontinuity on G (see Lemmas 3.5 and 3.7 and (4.12) below). From these estimates, one deduces that G lies in compact subsets of $\mathcal{C}([0,T];L^1(\mathbb{R}_+))$ and $L^1(0,T;W^{1,1}(\mathbb{R}_+))$. At the discrete level, we perform the same steps for (G^h,v^h), which is possible thanks to the conditions (2.10), (2.11), and (2.18).

3. Properties of $(G_i^{n,h})$.

This section is devoted to the proof of Proposition 2.2 and the uniform bounds satisfied by $(G_i^{n,h})$. The parameters h, Δt, and I^h being fixed such that (2.10), (2.11), and (2.18) are fulfilled, we omit the superscript h throughout this section. Also, owing to (2.10), we may assume without loss of generality that $h \in (0,1)$ and $x_{I+1/2} \geq 2$.

Lemma 3.1. *Let* $n \in \{0,\dots,N\}$ *be such that*

$$(3.1)\qquad \sum_{i=0}^{I} h\ G_i^n = \sum_{i=0}^{I} h\ G_i^0 \quad \text{and} \quad G_i^n \geq 0 \quad \text{for} \quad i \in \{0,\dots,I\}.$$

Then there is a positive constant C_1 *depending only on* α *and* $\|G_0\|_{L^1}$ *such that*

$$(3.2)\qquad 0 \leq v^n \leq C_1\ G_0^n\ \left(1 + \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{1-\alpha}\right),$$

where $\ell \in \{0,\dots,I/2\}$ *denotes the integer such that* $1 \in \Lambda_\ell$.

Proof. We infer from (2.10), (3.1), and the Hölder inequality that

$$\begin{aligned}\frac{\|G_0\|_{L^1}}{2} &\le \sum_{i=0}^{I} h\ G_i^0 = \sum_{i=0}^{I} h\ G_i^n \\ &\le \left(\sum_{i=0}^{I} h\ x_{i+1/2}^{\alpha-1}\ G_i^n\right)^{1/(2-\alpha)} \left(\sum_{i=0}^{I} h\ x_{i+1/2}\ G_i^n\right)^{(1-\alpha)/(2-\alpha)}, \\ \left(\frac{\|G_0\|_{L^1}}{2}\right)^{2-\alpha} &\le \left(\frac{1}{\alpha}\ \sum_{i=0}^{I} h\ a_i\ G_i^n\right) \left(\sum_{i=0}^{I} h\ x_{i+1/2}\ G_i^n\right)^{1-\alpha}.\end{aligned}$$

Multiplying both sides of the above inequality by v^n and using (2.14) yields

$$\left(\frac{\|G_0\|_{L^1}}{2}\right)^{2-\alpha}\ v^n \le \frac{G_0^n}{\alpha}\ \left(\sum_{i=0}^{I} h\ x_{i+1/2}\ G_i^n\right)^{1-\alpha}.$$

Since $x_{i+1/2} \le x_{\ell+1/2} \le 2$ for $0 \le i \le \ell$, and $x_{i+1/2} \le 2\ x_{i-1/2}$ for $i \ge \ell+1$, we deduce from (2.9) and (3.1) that

$$\begin{aligned}\sum_{i=0}^{I} h\ x_{i+1/2}\ G_i^n &\le 2\ \sum_{i=0}^{\ell} h\ G_i^n + 2\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n \\ &\le 2\ \|G_0\|_{L^1} + 2\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n.\end{aligned}$$

Combining the previous two inequalities, we end up with

$$\begin{aligned}v^n &\le \left(\frac{2}{\|G_0\|_{L^1}}\right)^{2-\alpha}\ \frac{2^{1-\alpha}\ G_0^n}{\alpha}\ \left(\|G_0\|_{L^1}^{1-\alpha} + \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{1-\alpha}\right) \\ &\le C_1\ G_0^n\ \left(1 + \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{1-\alpha}\right),\end{aligned}$$

whence (3.2). □

LEMMA 3.2. *Let $n \in \{0,\dots,N-1\}$ be such that* (3.1) *holds true and*

$$\nu_+^n(x_{I+1/2}) = 0. \tag{3.3}$$

Then

$$\sum_{i=0}^{I} h\ G_i^{n+1} = \sum_{i=0}^{I} h\ G_i^0, \tag{3.4}$$

$$0 \le G_i^{n+1} \le (1+\Delta t)\ \sup_j \{G_j^n\}, \quad 0 \le i \le I, \tag{3.5}$$

$$\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1} \le \left(1 + C_2\ \left(1 + \sup_i \{G_i^n\}\right)\ \Delta t\right)\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n$$
$$+ C_2\ \left(1 + \left(\sup_i \{G_i^n\}\right)^{(1+\alpha)/\alpha}\right)\ \Delta t, \tag{3.6}$$

where C_2 is a positive constant depending only on α and $\|G_0\|_{L^1}$.

Proof. We first check (3.4). For $n \in \{0, \dots, N-1\}$, it follows from (2.12), (2.13), (2.14), and (2.15) that

$$\begin{aligned}\sum_{i=0}^{I} h\, G_i^{n+1} &= \sum_{i=0}^{I} h\, G_i^n - \Delta t \sum_{i=1}^{I+1} F_{i-1/2}^n + \Delta t \sum_{i=0}^{I} F_{i-1/2}^n + h\, \Delta t\, v^n \sum_{i=0}^{I} a_i\ G_i^n \\ &= \sum_{i=0}^{I} h\, G_i^n - \Delta t\, G_0^n - \Delta t\, \nu_+^n(x_{I+1/2})\ G_I^n + h\, \Delta t\, v^n \sum_{i=0}^{I} a_i\ G_i^n \\ &= \sum_{i=0}^{I} h\, G_i^n - \Delta t\, \nu_+^n(x_{I+1/2})\ G_I^n,\end{aligned}$$

whence (3.4) by (3.3). Before completing the proof of Lemma 3.2, we provide an alternative formulation of (2.12). By (2.15) we have

$$\begin{aligned}F_{i+1/2}^n - F_{i-1/2}^n &= \nu_+^n(x_{i+1/2})\ G_i^n - \nu_-^n(x_{i+1/2})\ G_{i+1}^n \\ &\quad - \nu_+^n(x_{i-1/2})\ G_{i-1}^n + \nu_-^n(x_{i-1/2})\ G_i^n \\ &= (\nu^n(x_{i+1/2}) - \nu^n(x_{i-1/2}))\ G_i^n \\ &\quad + \nu_-^n(x_{i+1/2})\ (G_i^n - G_{i+1}^n) + \nu_+^n(x_{i-1/2})\ (G_i^n - G_{i-1}^n).\end{aligned}$$

Since

$$\nu^n(x_{i-1/2}) - \nu^n(x_{i+1/2}) + h\ a_i\ v^n = h, \tag{3.7}$$

we insert the above formula for $F_{i+1/2}^n - F_{i-1/2}^n$ into (2.12) and obtain

$$G_i^{n+1} = (1 + \Delta t)\ G_i^n + \frac{\Delta t}{h}\ \nu_-^n(x_{i+1/2})\ (G_{i+1}^n - G_i^n)$$
$$+ \frac{\Delta t}{h}\ \nu_+^n(x_{i-1/2})(G_{i-1}^n - G_i^n). \tag{3.8}$$

Now, since $\nu_+^n(x_{I+1/2}) = 0$ by (3.3) and $x_{I+1/2} \ge 1$, we have $v^n \le 2\ x_{I+1/2}^{1-\alpha}$, and (2.11) ensures that

$$\left|\nu^n(x_{i+1/2})\right| \le x_{i+1/2}^\alpha\ v^n + 1 + x_{i+1/2} \le 2\ x_{I+1/2} + 2\ x_{I+1/2} \le \frac{h}{2\ \Delta t} \tag{3.9}$$

for $0 \le i \le I$. Owing to (3.9) and the nonnegativity (3.1) of $(\Delta t\ G_i^n)$, it follows from (3.8) that G_i^{n+1} lies above a convex combination of G_{i-1}^n, G_i^n, and G_{i+1}^n, which are nonnegative by (3.1), whence the nonnegativity of G_i^{n+1} for $0 \le i \le I$. Similarly, we infer from (3.8) and (3.9) that $G_i^{n+1}/(1 + \Delta t)$ is a convex combination of G_{i-1}^n, G_i^n, and G_{i+1}^n, from which we deduce (3.5).

We next turn to (3.6). We infer from (2.13), (3.1), and (3.8) that

$$\begin{aligned}
&\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ \left(G_i^{n+1} - (1+\Delta t)\ G_i^n\right) \\
&= \Delta t \sum_{i=\ell+2}^{I+1} x_{i-3/2}\ \nu_-^n(x_{i-1/2})\ G_i^n + \Delta t \sum_{i=\ell}^{I-1} x_{i+1/2}\ \nu_+^n(x_{i+1/2})\ G_i^n \\
&\quad - \Delta t \sum_{i=\ell+1}^{I} x_{i-1/2}\ \left(\nu_-^n(x_{i+1/2}) + \nu_+^n(x_{i-1/2})\right)\ G_i^n \\
&\le \Delta t \sum_{i=\ell+1}^{I} (x_{i-3/2} - x_{i-1/2})\ \nu_-^n(x_{i-1/2})\ G_i^n \\
&\quad + \Delta t \sum_{i=\ell+1}^{I} x_{i-1/2}\ \left(\nu_-^n(x_{i-1/2}) - \nu_-^n(x_{i+1/2})\right)\ G_i^n \\
&\quad + \Delta t \sum_{i=\ell+1}^{I} (x_{i+1/2} - x_{i-1/2})\ \nu_+^n(x_{i-1/2})\ G_i^n \\
&\quad + \Delta t \sum_{i=\ell+1}^{I} x_{i+1/2}\ \left(\nu_+^n(x_{i+1/2}) - \nu_+^n(x_{i-1/2})\right)\ G_i^n \\
&\quad + \Delta t\ x_{\ell+1/2}\ \nu_+^n(x_{\ell+1/2})\ G_\ell^n \\
&\le \Delta t \sum_{i=\ell+1}^{I} h\ \nu^n(x_{i-1/2})\ G_i^n \\
&\quad + \Delta t \sum_{i=\ell+1}^{I} x_{i-1/2}\ \left(\nu^n(x_{i-1/2}) - \nu^n(x_{i+1/2})\right)_-\ G_i^n \\
&\quad + \Delta t \sum_{i=\ell+1}^{I} x_{i+1/2}\ \left(\nu^n(x_{i+1/2}) - \nu^n(x_{i-1/2})\right)_+\ G_i^n \\
&\quad + \Delta t\ x_{\ell+1/2}\ \nu_+^n(x_{\ell+1/2})\ G_\ell^n,
\end{aligned}$$

the last inequality being a consequence of the subadditivity of $r \mapsto r_+$ and $r \mapsto r_-$. Since $h \in (0,1)$, the choice of ℓ guarantees that $x_{\ell+1/2} \le 2$ and $x_{i+1/2} \le 2\ x_{i-1/2}$ for $i \ge \ell+1$. Consequently, for $i \ge \ell+1$,

$$\begin{aligned}
x_{i-1/2}\ \left(\nu^n(x_{i-1/2}) - \nu^n(x_{i+1/2})\right)_- &\le v^n\ x_{i-1/2}\ \left(x_{i-1/2}^\alpha - x_{i+1/2}^\alpha\right)_- \\
&\le v^n\ x_{i-1/2}\ \alpha\ h\ x_{i-1/2}^{\alpha-1} \\
&\le h\ v^n\ x_{i-1/2}^\alpha,
\end{aligned}$$

$$x_{i+1/2}\ \left(\nu^n(x_{i+1/2}) - \nu^n(x_{i-1/2})\right)_+ \le 2\ h\ v^n\ x_{i-1/2}^\alpha,$$

and $\nu^n(x_{i-1/2}) \le v^n\ x_{i-1/2}^\alpha$, while

$$x_{\ell+1/2}\ \nu_+^n(x_{\ell+1/2})\ \le v^n\ x_{\ell+1/2}^{1+\alpha} \le 4\ v^n.$$

Therefore, since $G_i^n \geq 0$ by (3.1),

$$\begin{aligned} &\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ \left(G_i^{n+1} - (1+\Delta t)\ G_i^n\right) \\ &\leq \Delta t\ v^n\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}^{\alpha}\ G_i^n + 3\ \Delta t\ v^n\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}^{\alpha}\ G_i^n + 4\ \Delta t\ v^n\ G_\ell^n \\ &\leq 4\ \Delta t\ v^n\ \left(\sum_{i=\ell+1}^{I} h\ G_i^n\right)^{1-\alpha}\ \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{\alpha} + 4\ \Delta t\ v^n\, G_\ell^n \end{aligned}$$

by the Hölder inequality. Using (3.1) once more yields

$$\begin{aligned} &\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ \left(G_i^{n+1} - (1+\Delta t)\ G_i^n\right) \\ &\leq 4\ \Delta t\ \|G_0\|_{L^1}^{1-\alpha}\ v^n\ \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{\alpha} + 4\ \Delta t\ v^n\ G_\ell^n. \end{aligned} \tag{3.10}$$

Owing to (3.1), we may use Lemma 3.1 and insert (3.2) into (3.10) to obtain, with the help of the Young inequality,

$$\begin{aligned} &\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ \left(G_i^{n+1} - (1+\Delta t)\ G_i^n\right) \\ &\leq C_1'\ \Delta t\ G_0^n\ \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{\alpha} + C_1'\ \Delta t\ G_0^n\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n \\ &\quad + C_1'\ \Delta t\ G_0^n\ \sup_i\ \{G_i^n\} + C_1'\ \Delta t\ G_0^n\ \sup_i\ \{G_i^n\}\ \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right)^{1-\alpha} \\ &\leq 2\ C_1'\ \Delta t\ \sup_i\ \{G_i^n\}\ \left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n + 1 + \sup_i\ \{G_i^n\}^{1/\alpha}\right), \end{aligned}$$

with $C_1' = 4C_1 \max\{1, \|G_0\|_{L^1}^{1-\alpha}\}$, whence (3.6), and the proof of Lemma 3.2 is complete. □

We now introduce

$$\begin{aligned} &K_1 := 2\ C_1\ \|G_0\|_{L^\infty}\ e^T, \qquad K_2 := C_2\ \left(1 + \|G_0\|_{L^\infty}\ e^T\right), \\ &K_3 := C_2\ \left(1 + \|G_0\|_{L^\infty}^{(1+\alpha)/\alpha}\ e^{(1+\alpha)T/\alpha}\right), \\ &x_\star := \left\{K_1\ e^{K_2 T}\ \left(1 + \int_0^\infty x\ G_0(x)\ dx + K_3\ T\right)\right\}^{1/(1-\alpha)}. \end{aligned}$$

Proposition 3.3. *Assume that* (2.18) *holds true. For* $n \in \{0, \ldots, N\}$, *we have*

$$\sum_{i=0}^{I} h\ G_i^n = \sum_{i=0}^{I} h\ G_i^0, \tag{3.11}$$

$$0 \le G_i^n \le (1+\Delta t)^n \ \|G_0\|_{L^\infty}, \quad 0 \le i \le I, \tag{3.12}$$

$$\begin{aligned}\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n \le (1+K_2\ \Delta t)^n \ \int_0^\infty x\ G_0(x)\ dx \\ + K_3\ \Delta t\ \sum_{j=0}^{n-1} (1+K_2\ \Delta t)^j\ ,\end{aligned} \tag{3.13}$$

$$0 \le v^n \le K_1\ \left(1+\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n\right) \le x_\star^{1-\alpha}. \tag{3.14}$$

Proof. We proceed by induction on $n \in \{0,\dots,N\}$ and first consider the case $n=0$. The assertion (3.11) is obvious in that case, while (3.12) and (3.13) readily follow from (2.5) and (2.8). We then infer from Lemma 3.1, (3.12), (3.13), and the Young inequality that

$$\begin{aligned} v^0 &\le 2\ C_1\ G_0^0\ \left(1+\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^0\right) \\ &\le K_1\ \left(1+\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^0\right) \\ &\le K_1\ e^{K_2 T}\ \left(1+\int_0^\infty x\ G_0(x)\ dx + K_3\ T\right) = x_\star^{1-\alpha}, \end{aligned}$$

and we have checked that Proposition 3.3 is valid for $n=0$. Consider now $n \in \{0,\dots,N-1\}$ such that the assertions (3.11)–(3.14) hold true. By (2.18) and (3.14), we have

$$\nu^n(x_{I+1/2}) \le (h\ I)^\alpha\ v^n - (h\ I) \le (h\ I)^\alpha\ \left(x_\star^{1-\alpha} - (h\ I)^{1-\alpha}\right) \le 0,$$

and thus $\nu_+^n(x_{I+1/2}) = 0$. This fact, together with (3.11) and (3.12), allows us to use Lemma 3.2 to conclude that (3.4)–(3.6) hold true. Then, (3.11) for $n+1$ follows at once from (3.4), while (3.12) for $n+1$ is a consequence of (3.5) and (3.12) for n. In addition, inserting (3.12) into (3.6) yields

$$\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1} \le (1+K_2\ \Delta t)\ \sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^n + K_3\ \Delta t.$$

Taking into account (3.13) for n, we deduce (3.13) for $n+1$. A straightforward consequence of (3.13) for $n+1$ is that

$$\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1} \le e^{K_2\ T}\ \left(\int_0^\infty x\ G_0(x)\ dx + K_3\ T\right). \tag{3.15}$$

Since (3.11) and (3.12) hold true for $n+1$ by the previous analysis, we are in a position to apply Lemma 3.1 and conclude that

$$v^{n+1} \le C_1\ G_0^{n+1}\ \left(1+\left(\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1}\right)^{1-\alpha}\right).$$

Using the Young inequality and (3.12) for $n+1$, we are led to

$$\begin{aligned} v^{n+1} &\le C_1\ \|G_0\|_{L^\infty}\ e^T\ \left(2+\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1}\right) \\ &\le K_1\ \left(1+\sum_{i=\ell+1}^{I} h\ x_{i-1/2}\ G_i^{n+1}\right), \end{aligned}$$

whence the first inequality in (3.14) for $n+1$. Combining this last inequality with (3.15) finally entails that $v^{n+1} \le x_\star^{1-\alpha}$, and the proof of Proposition 3.3 is complete. □

Summarizing the outcome of Proposition 3.3, we have proved that (G_i^n) satisfies the following estimate.

Corollary 3.4. *There is a positive constant C_3 depending only on α, G_0, and T such that*

$$\sup_i\ \{G_i^n\} + v^n + \sum_{i=0}^{I} h\ (1+x_{i-1/2})\ G_i^n \le C_3$$

for $n \in \{0,\dots,N\}$.

Recalling that the solution $G(t)$ to (2.1), (2.2), (2.3) is nonincreasing with respect to the variable x for each $t \ge 0$, we now show that this property is also enjoyed by (G_i^n).

Lemma 3.5. *For $n \in \{0,\dots,N\}$,*

$$G_{i+1}^n \le G_i^n, \quad 0 \le i \le I, \tag{3.16}$$

$$\sum_{i=0}^{I} \left|G_{i+1}^n - G_i^n\right| \le \|\partial_x G_0\|_{L^1}\ e^T. \tag{3.17}$$

Proof. For $n \in \{0,\dots,N\}$ and $i \in \{0,\dots,I\}$, we set $g_{i+1/2}^n = (G_{i+1}^n - G_i^n)/h$ and use (3.8) to compute $g_{i+1/2}^n$:

$$\begin{aligned} h\ g_{i+1/2}^{n+1} &= (1+\Delta t)\ G_{i+1}^n + \Delta t\ \nu_-^n(x_{i+3/2})\ g_{i+3/2}^n - \Delta t\ \nu_+^n(x_{i+1/2})\ g_{i+1/2}^n \\ &\quad - (1+\Delta t)\ G_i^n - \Delta t\ \nu_-^n(x_{i+1/2})\ g_{i+1/2}^n + \Delta t\ \nu_+^n(x_{i-1/2})\ g_{i-1/2}^n, \end{aligned}$$

$$\begin{aligned} g_{i+1/2}^{n+1} &= \left(1+\Delta t - \frac{\Delta t}{h}\ \left|\nu^n(x_{i+1/2})\right|\right)\ g_{i+1/2}^n \\ &\quad + \frac{\Delta t}{h}\ \nu_-^n(x_{i+3/2})\ g_{i+3/2}^n + \frac{\Delta t}{h}\ \nu_+^n(x_{i-1/2})\ g_{i-1/2}^n. \end{aligned} \tag{3.18}$$

Since $r \mapsto r_+$ and $r \mapsto r_-$ are subadditive, we realize that

$$\begin{aligned} &\nu_-^n(x_{i+3/2}) + \nu_+^n(x_{i-1/2}) - |\nu^n(x_i+1/2)| \\ &\quad = \nu_-^n(x_{i+3/2}) - \nu_-^n(x_{i+1/2}) + \nu_+^n(x_{i-1/2}) - \nu_+^n(x_{i+1/2}) \\ &\quad \le \big(\nu^n(x_{i+3/2}) - \nu^n(x_{i+1/2})\big)_- + \big(\nu^n(x_{i-1/2}) - \nu^n(x_{i+1/2})\big)_+ \\ &\quad \le \big((x_{i+3/2}^\alpha - x_{i+1/2}^\alpha)\ v^n - h\big)_- + \big((x_{i-1/2}^\alpha - x_{i+1/2}^\alpha)\ v^n + h\big)_+. \end{aligned}$$

Then,

$$\nu_-^n(x_{i+3/2}) + \nu_+^n(x_{i-1/2}) - |\nu^n(x_{i+1/2})| \le 2h. \tag{3.19}$$

Introducing

$$\lambda_{2,i}^n = \frac{\Delta t}{(1+3\ \Delta t)h}\ \nu_-^n(x_{i+3/2}), \qquad \lambda_{3,i}^n = \frac{\Delta t}{(1+3\ \Delta t)h}\ \nu_+^n(x_{i-1/2}),$$
$$\lambda_{1,i}^n = \frac{1}{(1+3\ \Delta t)}\ \left(1+\Delta t - \frac{\Delta t}{h}\ |\nu^n(x_{i+1/2})|\right), \qquad \lambda_{4,i}^n = 1-\sum_{j=1}^{3}\lambda_{j,i}^n,$$

we clearly have $\lambda_{2,i}^n \geq 0$, $\lambda_{3,i}^n \geq 0$, while (3.9) ensures that $\lambda_{1,i}^n \geq 0$. In addition, it follows from (3.19) that

$$1-\lambda_{4,i}^n \leq \frac{1}{(1+3\ \Delta t)}\ \left(1+\Delta t+\frac{\Delta t}{h}\ 2\ h\right) \leq 1,$$

whence $\lambda_{4,i}^n \geq 0$. Consequently, $\lambda_{j,i}^n \in [0,1]$ for $1 \leq j \leq 4$, and $g_{i+1/2}^{n+1}/(1+3\Delta t)$ is a convex combination of $g_{i+1/2}^n$, $g_{i+3/2}^n$, $g_{i-1/2}^n$, and 0.

Now, let $\Psi : \mathbb{R} \to [0,+\infty)$ be a nonnegative and convex function with $\Psi(0)=0$ and such that

$$\Psi(\lambda\ r) \leq \lambda^\gamma\ \Psi(r), \quad (r,\lambda) \in [0,+\infty) \times [1,+\infty), \tag{3.20}$$

for some $\gamma \geq 1$. The convexity of Ψ then entails that

$$\sum_{i=0}^{I} \Psi\left(\frac{g_{i+1/2}^{n+1}}{(1+3\ \Delta t)}\right) \leq \sum_{i=0}^{I}\left(\lambda_{1,i}^n\ \Psi(g_{i+1/2}^n) + \lambda_{2,i}^n\ \Psi(g_{i+3/2}^n) + \lambda_{3,i}^n\ \Psi(g_{i-1/2}^n)\right).$$

Since $\nu_+^n(x_{-1/2}) = 0$, we have $\lambda_{3,0}^n = 0$ and

$$\begin{aligned}(1+3\ \Delta t)\ \sum_{i=0}^{I}\Psi\left(\frac{g_{i+1/2}^{n+1}}{(1+3\ \Delta t)}\right) &\leq \sum_{i=0}^{I}\left(1+\Delta t-\frac{\Delta t}{h}\ |\nu^n(x_{i+1/2})|\right)\ \Psi(g_{i+1/2}^n)\\ &\quad + \sum_{i=1}^{I}\frac{\Delta t}{h}\ \nu_-^n(x_{i+1/2})\ \Psi(g_{i+1/2}^n)\\ &\quad + \sum_{i=0}^{I-1}\frac{\Delta t}{h}\ \nu_+^n(x_{i+1/2})\ \Psi(g_{i+1/2}^n)\\ &\leq (1+\Delta t)\ \sum_{i=0}^{I}\Psi(g_{i+1/2}^n).\end{aligned}$$

Owing to (3.20), we end up with

$$\begin{aligned}\sum_{i=0}^{I}\Psi(g_{i+1/2}^{n+1}) &= \sum_{i=0}^{I}\Psi\left(\frac{(1+3\ \Delta t)\ g_{i+1/2}^{n+1}}{(1+3\ \Delta t)}\right)\\ &\leq (1+3\ \Delta t)^{\gamma-1}\ (1+\Delta t)\ \sum_{i=0}^{I}\Psi(g_{i+1/2}^n).\end{aligned}$$

The discrete Gronwall lemma yields

$$\sum_{i=0}^{I}\Psi(g_{i+1/2}^n) \leq e^{(3(\gamma-1)+1)T}\ \sum_{i=0}^{I}\Psi(g_{i+1/2}^0). \tag{3.21}$$

We first take $\Psi(r) = r_+$, which obviously satisfies (3.20) with $\gamma = 1$. The assertion (3.16) then readily follows from (3.21) since $g^0_{i+1/2} \le 0$ for $i \in \{0, \dots, I\}$ by (2.5) and (2.8). Similarly, $\Psi(r) = |r|$ satisfies (3.20) with $\gamma = 1$, and (3.17) is a straightforward consequence of (3.21), taking into account that

$$\sum_{i=0}^{I} h \, \left| g^0_{i+1/2} \right| \le \|\partial_x G_0\|_{L^1},$$

and the proof of Lemma 3.5 is complete. □

Remark 3.6. Note that $\Psi(r) = r^p$ satisfies (3.20) for $p \in [1, \infty)$ with $\gamma = p$. In that case, (3.21) simply means that the discrete L^p-norm of $(g^n_{i+1/2})$ remains finite if it is initially finite.

At this point, note that Proposition 2.2 is a consequence of Proposition 3.3 and Lemma 3.5.

We end this section with the time equicontinuity of (G^n_i).

LEMMA 3.7. *For each $R \ge 1$ there is a constant $C_4(R)$ depending only on α, G_0, T, and R such that, for $n \in \{0, \dots, N-1\}$,*

$$\sum_{i=0}^{\ell_R} h \, \left| G^{n+1}_i - G^n_i \right| \le C_4(R) \, \Delta t, \tag{3.22}$$

where ℓ_R denotes the integer such that $R \in \Lambda_{\ell_R}$.

Proof. By Corollary 3.4, Lemma 3.5, and (3.8), we have for $n \in \{0, \dots, N-1\}$ and $i \in \{0, \dots, \ell_R\}$

$$\begin{aligned} \left| G^{n+1}_i - G^n_i \right| &\le \Delta t \, \left\{ C_3 + x^\alpha_{i+1/2} \, v^n \, \frac{G^n_i - G^n_{i+1}}{h} + x^\alpha_{i-1/2} \, v^n \, \frac{G^n_{i-1} - G^n_i}{h} \right\} \\ &\le \Delta t \, \left\{ C_3 + (1+R)^\alpha \, C_1 \, \left(\frac{G^n_i - G^n_{i+1}}{h} + \frac{G^n_{i-1} - G^n_i}{h} \right) \right\}. \end{aligned}$$

We sum up the above inequalities for $i \in \{0, \dots, \ell_R\}$ and use (3.17) to conclude that (3.22) holds true. □

4. Convergence. As a consequence of the analysis of the previous section, the sets $\{G^h\}_h$ and $\{v^h\}_h$ enjoy the following compactness properties.

LEMMA 4.1. *There are a subsequence of (G^h, v^h) (not relabeled) and a pair of nonnegative functions $G \in \mathcal{C}([0,T]; L^1(\mathbb{R}_+))$ and $v \in L^\infty(0,T)$ such that*

$$G^h \longrightarrow G \quad in \quad L^\infty(0,T; L^1(\mathbb{R}_+)), \tag{4.1}$$

$$v^h \overset{*}{\rightharpoonup} v \quad in \quad L^\infty(0,T), \tag{4.2}$$

and $G \in L^\infty(0,T; L^1(\mathbb{R}_+, xdx))$ satisfies (2.6).

Proof. We introduce the auxiliary function

$$\mathcal{G}^h(t,x) = \sum_{i=0}^{I^h} \left\{ G^{n,h}_i + \frac{(t-t^n)}{\Delta t} \, \left(G^{n+1,h}_i - G^{n,h}_i \right) \right\} \mathbf{1}_{\Lambda^h_i}(x), \quad (t,x) \in [t^n, t^{n+1}] \times \mathbb{R}_+,$$

for $n \in \{0, \dots, N-1\}$. Clearly, $\mathcal{G}^h \in \mathcal{C}([0,T]; L^1(\mathbb{R}_+))$, and it readily follows from Lemma 3.7 that

$$\sup_{[0,T]} \left\| G^h(t) - \mathcal{G}^h(t) \right\|_{L^1(0,R)} \le C_4(R) \, \Delta t \tag{4.3}$$

for any $R \ge 1$.

We next fix $R \geq 1$. On the one hand, it follows from Corollary 3.4 and (3.17) that $(\mathcal{G}^h)$ is bounded in $L^\infty(0,T;BV(0,R))$. On the other hand, an easy computation shows that (3.22) implies

$$\left\| \mathcal{G}^h(t) - \mathcal{G}^h(s) \right\|_{L^1(0,R)} \leq C_4(R)\ |t-s|$$

for $(s,t) \in [0,T] \times [0,T]$. Since $BV(0,R)$ is compactly embedded in $L^1(0,R)$, a classical compactness result [21, Theorem 5] entails that

$$(\mathcal{G}^h) \quad \text{is relatively compact in} \quad \mathcal{C}([0,T];L^1(0,R)), \tag{4.4}$$

and (4.4) is valid for every $R \geq 1$. Also, by Corollary 3.4, there is a constant C depending only on α, G_0, and T such that

$$\int_0^\infty \left(G^h(t,x) + \mathcal{G}^h(t,x) \right)\ x\ dx \leq C, \quad t \in [0,T]. \tag{4.5}$$

Thanks to (4.5), we may improve the compactness (4.4) of $(\mathcal{G}^h)$ and conclude that $(\mathcal{G}^h)$ is relatively compact in $\mathcal{C}([0,T];L^1(\mathbb{R}_+))$. Consequently, there are a subsequence of $(\mathcal{G}^h)$ (not relabeled) and a function G in $\mathcal{C}([0,T];L^1(\mathbb{R}_+))$ such that

$$\mathcal{G}^h \longrightarrow G \quad \text{in} \quad \mathcal{C}([0,T];L^1(\mathbb{R}_+)).$$

Recalling (4.3) and (4.5), we readily conclude that (4.1) holds true and that G is a nonnegative function in $L^\infty(0,T;L^1(\mathbb{R}_+,xdx))$. Moreover, the convergence (4.1) of (G^h), (2.9), and (3.11) imply that G satisfies (2.6). The convergence (4.2) and the nonnegativity of v are then straightforward consequences of Corollary 3.4 and the nonnegativity of v^h. □

We next show that (3.11), (3.21), and the integrability of $\partial_x G_0$ guarantee that G enjoys the regularity properties claimed in Theorem 2.3.

LEMMA 4.2. *We have* $\partial_x G \in L^\infty(0,T;L^1(\mathbb{R}_+,(1+x)dx))$*, and* $t \mapsto G(t,x)$ *is nonincreasing for each* $t \geq 0$*.*

Proof. For $\varphi \in L^\infty(\mathbb{R}_+)$, we define the discrete gradient $D_h\varphi$ by

$$D_h\varphi(x) := \frac{\varphi(x+h)-\varphi(x)}{h}, \quad x \in \mathbb{R}_+.$$

We first observe that

$$D_h G^h(t,x) = \sum_{i=0}^{I^h} \left(\frac{G_{i+1}^{n,h} - G_i^{n,h}}{h} \right) \mathbf{1}_{\Lambda_i^h}(x), \quad x \in \mathbb{R}_+, \tag{4.6}$$

for $t \in [t^n, t^{n+1})$ and $n \in \{1,\ldots,N\}$ and recall that Lemma 3.5 and in particular (3.21) provide some information on $((G_{i+1}^{n,h} - G_i^{n,h})/h)$. It turns out that the available information allows us to show the weak compactness of $(D_h G^h)$ in $L^1((0,T)\times\mathbb{R}_+)$. Indeed, we first notice that

$$\sup_{t\in[0,T]} \int_0^\infty (1+x)\ \left| D_h G^h(t,x) \right|\ dx \leq C \tag{4.7}$$

for some constant C depending only on α, G_0, and T. Indeed, (4.7) readily follows from (3.11), (3.16), and (3.17), thanks to the identity

$$\sum_{i=0}^{I^h} x_{i+1/2}\ \left| G_{i+1}^{n,h} - G_i^{n,h} \right| = \sum_{i=0}^{I^h} h\ G_i^{n,h}.$$

We next recall that, since $\partial_x G_0 \in L^1(\mathbb{R}_+)$, a refined version of the de la Vallée–Poussin theorem [11, Proposition I.1.1] ensures that there is a nonnegative and convex function $\Psi_0 \in \mathcal{C}^1([0,+\infty)) \cap W^{2,\infty}_{\text{loc}}(\mathbb{R}_+)$ satisfying

$$\lim_{r\to+\infty} \frac{\Psi_0(r)}{r} = +\infty, \tag{4.8}$$

with $\Psi_0(0) = 0$, $\Psi_0'(0) \geq 0$, Ψ_0' a concave function on $[0,+\infty)$, and such that $\Psi_0(|\partial_x G_0|) \in L^1(\mathbb{R}_+)$. (See also, e.g., [4, p. 38] for the construction of such a function Ψ_0 without the requirement that Ψ_0' be concave.) Thanks to the concavity of Ψ_0' and the nonnegativity of $\Psi_0'(0)$, we have $\Psi_0'(\lambda r) \leq \lambda\ \Psi_0'(r)$ for $r \geq 0$ and $\lambda \geq 1$. Integrating this inequality yields

$$\Psi_0(\lambda r) \leq \lambda^2\ \Psi_0(r), \quad (r,\lambda) \in [0,+\infty) \times [1,+\infty). \tag{4.9}$$

Since Ψ_0 is nondecreasing, the function Ψ defined by $\Psi(r) = \Psi_0(|r|)$ is a nonnegative and convex function with $\Psi(0) = 0$, which satisfies (3.20) with $\gamma = 2$ by (4.9). Consequently, we infer from (3.21) and (4.6) that

$$\sup_{t\in[0,T]} \int_0^\infty \Psi_0\left(\left|D_h G^h(t,x)\right|\right)\ dx \leq e^{4T} \int_0^\infty \Psi_0\left(\left|D_h G^h(0,x)\right|\right)\ dx. \tag{4.10}$$

However,

$$\int_0^\infty \Psi_0\left(\left|D_h G^h(0,x)\right|\right)\ dx = h\ \sum_{i=0}^{I^h} \Psi_0\left(\left|\frac{G^{0,h}_{i+1} - G^{0,h}_i}{h}\right|\right), \tag{4.11}$$

and it follows from (2.5), (2.8), (4.9), the convexity of Ψ_0, and the Jensen inequality that

$$\begin{aligned}
&\Psi_0\left(\left|\frac{G^{0,h}_{i+1} - G^{0,h}_i}{h}\right|\right) \\
&\quad \leq \Psi_0\left(\frac{1}{h}\ \int_{\Lambda_i^h} |\partial_x G_0|\ dx + \frac{1}{h}\ \int_{\Lambda_{i+1}^h} |\partial_x G_0|\ dx\right) \\
&\quad \leq 2\ \left\{\Psi_0\left(\frac{1}{h}\ \int_{\Lambda_i^h} |\partial_x G_0|\ dx\right) + \Psi_0\left(\frac{1}{h}\ \int_{\Lambda_{i+1}^h} |\partial_x G_0|\ dx\right)\right\} \\
&\quad \leq \frac{2}{h}\ \left\{\int_{\Lambda_i^h} \Psi_0\left(|\partial_x G_0|\right)\ dx + \int_{\Lambda_{i+1}^h} \Psi_0\left(|\partial_x G_0|\right)\ dx\right\},
\end{aligned}$$

whence

$$h\ \sum_{i=0}^{I^h} \Psi_0\left(\left|\frac{G^{0,h}_{i+1} - G^{0,h}_i}{h}\right|\right) \leq 4\ \|\partial_x G_0\|_{L^1}.$$

Inserting this estimate into (4.11), we deduce from (4.10) that

$$\sup_{t\in[0,T]} \int_0^\infty \Psi_0\left(\left|D_h G^h(t,x)\right|\right)\ dx \leq C \tag{4.12}$$

for some constant C depending on α, G_0, and T. Owing to (4.7), (4.8), and (4.12), we are in a position to apply the Dunford–Pettis theorem and conclude that (D_hG^h) is relatively weakly sequentially compact in $L^1((0,T)\times\mathbb{R}_+)$. We may thus extract a subsequence of (D_hG^h) (not relabeled) such that

$$D_hG_h \rightharpoonup g \quad \text{in} \quad L^1((0,T)\times\mathbb{R}_+) \tag{4.13}$$

for some function $g \in L^1((0,T)\times\mathbb{R}_+)$. Now, it follows from (4.7) and (4.13) that g belongs to $L^\infty(0,T;L^1(\mathbb{R}_+,(1+x)dx))$, while a classical computation entails that $g = \partial_x G$ in the sense of distributions. In addition, $D_hG^h \le 0$ by (3.16), whence $\partial_x G \le 0$, and the proof of Lemma 4.2 is complete. □

We are now in a position to complete the proof of Theorem 2.3.

Proof of Theorem 2.3. We first observe that Lemmas 4.1 and 4.2 ensure that (G,v) enjoy the regularity properties (2.25).

We next consider $\varphi \in \mathcal{C}_0^\infty([0,T)\times[0,+\infty))$ with supp $\varphi \subset [0,\tau)\times[0,R)$ for some $\tau \in [0,T)$ and $R \in \mathbb{R}_+$ and set

$$\varphi_i^{n,h} = \frac{1}{h\ \Delta t}\int_{t^n}^{t^{n+1}}\int_{\Lambda_i^h}\varphi(t,x)\ dxdt$$

for $i \ge 0$ and $n \in \{0,\dots,N-1\}$. We also assume that h and Δt are sufficiently small so that $\tau \le t^{N-2}$ and $R \le x_{I^h-1/2}$, and we denote by ℓ_R^h the integer such that $R \in \Lambda^h_{\ell_R^h}$. In the following we denote by C_φ any nonnegative constant depending only on α, G_0, T, and φ.

We multiply (3.8) by $\varphi_i^{n,h}$ and sum up the resulting identities to obtain

$$Y_1^h = Y_2^h,$$

where

$$Y_1^h := \sum_{n=0}^{N-1}\sum_{i=0}^{I^h} h\ (G_i^{n+1,h} - G_i^{n,h})\ \varphi_i^{n,h}$$

and

$$\begin{aligned}Y_2^h := h\ \Delta t\ &\sum_{n=0}^{N-1}\sum_{i=0}^{I^h} G_i^{n,h}\ \varphi_i^{n,h} + \Delta t\ \sum_{n=0}^{N-1}\sum_{i=0}^{I^h}\nu_-^n(x_{i+1/2})\ \left(G_{i+1}^{n,h} - G_i^{n,h}\right)\ \varphi_i^{n,h}\\ &+ \Delta t\ \sum_{n=0}^{N-1}\sum_{i=0}^{I^h}\nu_+^n(x_{i-1/2})\ \left(G_{i-1}^{n,h} - G_i^{n,h}\right)\ \varphi_i^{n,h}.\end{aligned}$$

We next introduce

$$Z_1^h := -\int_0^T\int_0^\infty G^h(t,x)\ \partial_t\varphi(t,x)\ dtdx - \int_0^\infty G_0(x)\ \varphi(0,x)\ dx,$$

$$\begin{aligned}Z_2^h := &\int_0^T\int_0^\infty G^h(t,x)\ \varphi(t,x)\ dtdx - \int_0^T G^h(t,0)\ \varphi(t,0)\ dt\\ &+ \int_0^T\int_0^\infty G^h(t,x)\ \partial_x\left(\mathcal{W}^h\ \varphi\right)(t,x)\ dxdt,\end{aligned}$$

where

$$\mathcal{W}^h(t,x) = x^\alpha \ v^h(t) - 1 - x, \quad (t,x) \in [0,T] \times \mathbb{R}_+.$$

On the one hand, since φ is compactly supported, it follows at once from (4.1) and (4.2) that

$$\lim_{h,\Delta t \to 0} Z_1^h = -\int_0^T \int_0^\infty G(t,x) \ \partial_t \varphi(t,x) \ dtdx - \int_0^\infty G_0(x) \ \varphi(0,x) \ dx, \tag{4.14}$$

and

$$\begin{aligned} &\lim_{h,\Delta t \to 0} \left(Z_2^h + \int_0^T G^h(t,0) \ \varphi(t,0) \ dt \right) \\ &\qquad = \int_0^T \int_0^\infty G(t,x) \ \left(\varphi + \partial_x \left(\mathcal{W} \ \varphi\right)\right)(t,x) \ dxdt. \end{aligned} \tag{4.15}$$

On the other hand, we have

$$\begin{aligned} &\int_0^T \left(G^h(t,0) - G(t,0)\right) \ \varphi(t,0) \ dt \\ &\quad = \int_0^T \sum_{i=0}^{I^h} \left(G^h(t,x_{i-1/2}) - G^h(t,x_{i+1/2})\right) \ \varphi(t,0) \ dt + \int_0^\infty \partial_x G(t,x) \ \varphi(t,0) \ dxdt \\ &\quad = \int_0^T \int_0^\infty \left(\partial_x G(t,x) - D_h G^h(t,x)\right) \ \varphi(t,0) \ dxdt. \end{aligned}$$

We then infer from (4.13) that the right-hand side of the above identity converges to zero as $h \to 0$. Inserting this result into (4.15), we end up with

$$\begin{aligned} \lim_{h,\Delta t \to 0} Z_2^h = &-\int_0^T G(t,0) \ \varphi(t,0) \ dt \\ &+ \int_0^T \int_0^\infty G(t,x) \ \left(\varphi + \partial_x \left(\mathcal{W} \ \varphi\right)\right)(t,x) \ dxdt. \end{aligned} \tag{4.16}$$

Having identified the limits of (Z_1^h) and (Z_2^h) as $h \to 0$, we next aim at comparing the terms Y_k^h and Z_k^h, $k = 1, 2$, in order to show that $Z_1^h - Z_2^h$ converges to zero as $(h, \Delta t) \to 0$.

We first compute $(Z_1^h - Y_1^h)$. Since G^h is constant on $[t^n, t^{n+1}) \times \Lambda_i^h$ for $i \geq 0$ and $n \in \{0, \ldots, N-1\}$, we have

$$\begin{aligned} Z_1^h &= -\sum_{n=0}^{N-1} \int_0^\infty G^h(t^n, x) \ \left(\varphi(t^{n+1}, x) - \varphi(t^n, x)\right) \ dx - \int_0^\infty G_0(x) \ \varphi(0,x) \ dx \\ &= \sum_{n=0}^{N-1} \int_0^\infty \left(G^h(t^{n+1}, x) - G^h(t^n, x)\right) \ \varphi(t^{n+1}, x) \ dx \\ &\quad + \int_0^\infty \left(G^h(0,x) - G_0(x)\right) \ \varphi(0,x) \ dx, \end{aligned}$$

from which we deduce that

$$\begin{aligned}\left|Z_1^h - Y_1^h\right| &\le \sum_{n=0}^{N-1} \sum_{i=0}^{\ell_R^h} \left|G_i^{n+1,h} - G_i^{n,h}\right| \int_{t^n}^{t^{n+1}} \int_{\Lambda_i^h} |\partial_t \varphi| \ dxdt \\ &\quad + \|G^h(0,.) - G_0(.)\|_{L^1} \ \|\varphi\|_{L^\infty} \\ &\le T \ \|\partial_t\varphi\|_{L^\infty} \ \sup_{0\le n\le N-1} \sum_{i=0}^{\ell_R^h} h \ \left|G_i^{n+1,h} - G_i^{n,h}\right| \\ &\quad + \|G^h(0,.) - G_0(.)\|_{L^1} \ \|\varphi\|_{L^\infty}.\end{aligned}$$

We now use (2.9) and Lemma 3.7 to conclude that

$$\left|Z_1^h - Y_1^h\right| \le C_\varphi \ \Delta t. \tag{4.17}$$

We next turn to $(Z_2^h - Y_2^h)$. Since $\mathcal{W}^h(t^n, x_{i+1/2}) = \nu^n(x_{i+1/2})$, G^h is constant on $[t^n, t^{n+1}) \times \Lambda_i^h$ for $i \ge 0$, and $n \in \{0, \ldots, N-1\}$, we have

$$\begin{aligned}Z_2^h = &\sum_{n=0}^{N-1} \sum_{i=0}^{I^h} G_i^{n,h} \int_{t^n}^{t^{n+1}} \int_{\Lambda_i^h} \varphi(t,x) \ dxdt - \sum_{n=0}^{N-1} G_0^n \int_{t^n}^{t^{n+1}} \varphi(t,0) \ dt \\ &+ \sum_{n=0}^{N-1} \sum_{i=0}^{I^h} G_i^{n,h} \int_{t^n}^{t^{n+1}} \left(\nu^n(x_{i+1/2}) \ \varphi(t, x_{i+1/2}) - \nu^n(x_{i-1/2}) \ \varphi(t, x_{i-1/2})\right) \ dt.\end{aligned}$$

Since $\nu^n(x) = \nu_+^n(x) - \nu_-^n(x)$ and $\nu^n(x_{-1/2}) = -1$, a discrete integration by parts yields

$$\begin{aligned}Z_2^h = &\sum_{n=0}^{N-1} \sum_{i=0}^{I^h} G_i^{n,h} \int_{t^n}^{t^{n+1}} \int_{\Lambda_i^h} \varphi(t,x) \ dxdt \\ &+ \sum_{n=0}^{N-1} \sum_{i=0}^{I^h} \nu_+^n(x_{i-1/2}) \ \left(G_{i-1}^{n,h} - G_i^{n,h}\right) \int_{t^n}^{t^{n+1}} \varphi(t, x_{i-1/2}) \ dt \\ &+ \sum_{n=0}^{N-1} \sum_{i=0}^{I^h} \nu_-^n(x_{i+1/2}) \ \left(G_{i+1}^{n,h} - G_i^{n,h}\right) \int_{t^n}^{t^{n+1}} \varphi(t, x_{i+1/2}) \ dt.\end{aligned}$$

It is then easy to compute $(Z_2^h - Y_2^h)$ and deduce from Corollary 3.4 that

$$\begin{aligned}\left|Z_2^h - Y_2^h\right| &\le h \ \Delta t \ \sum_{n=0}^{N-1} \sum_{i=0}^{\ell_R^h} \nu_+^n(x_{i-1/2}) \ \left|G_{i-1}^{n,h} - G_i^{n,h}\right| \ \|\partial_x\varphi\|_{L^\infty} \\ &\quad + h \ \Delta t \ \sum_{n=0}^{N-1} \sum_{i=0}^{\ell_R^h} \nu_-^n(x_{i+1/2}) \ \left|G_{i+1}^{n,h} - G_i^{n,h}\right| \ \|\partial_x\varphi\|_{L^\infty} \\ &\le C_\varphi \ h \ \sup_{0\le n\le N-1} \sum_{i=0}^{I^h} \left|G_{i+1}^{n,h} - G_i^{n,h}\right|,\end{aligned}$$

whence

$$\left|Z_2^h - Y_2^h\right| \le C_\varphi \ h \tag{4.18}$$

by (3.17). Since $Y_1^h = Y_2^h$, we infer from (4.17) and (4.18) that $(Z_1^h - Z_2^h)$ converges to zero as $(h, \Delta t) \to 0$. This fact, together with (4.14) and (4.16), immediately ensures that G satisfies

$$\int_0^T \int_0^\infty G(t,x)\ \partial_t\varphi(t,x)\ dtdx + \int_0^\infty G_0(x)\ \varphi(0,x)\ dx$$
$$= -\int_0^T G(t,0)\ \varphi(t,0)\ dt + \int_0^T \int_0^\infty G(t,x)\ \left(\varphi + \partial_x\left(\mathcal{W}\ \varphi\right)\right)(t,x)\ dxdt.$$

Owing to the regularity of G, standard approximation arguments allow us to conclude from the previous identity that G actually satisfies (2.26).

To conclude the proof, it remains to show that v is given by (2.2). The easiest way to see it is to take $\varphi \equiv 1$ in (2.26), from which (2.2) readily follows, since we already know that G satisfies (2.6). We may, however, prove it directly by passing to the limit in (2.14). Indeed, consider $\varphi \in \mathcal{C}(0,T)$. Arguing as in the proof of (4.16), we realize that

$$\lim_{(h,\Delta t)\to 0} \int_0^T \left(G^h(t,0) - G(t,0)\right)\ \varphi(t)\ dt = 0. \tag{4.19}$$

We next claim that

$$\lim_{(h,\Delta t)\to 0} \sup_{t\in[0,T]} \int_0^\infty x^{\alpha-1}\ \left|G^h(t,x) - G(t,x)\right|\ dx = 0. \tag{4.20}$$

Indeed, it follows from Corollary 3.4 and (2.25) that, for $\delta \in (0,1)$ and $t \in [0,T]$,

$$\begin{aligned}\int_0^\infty x^{\alpha-1}\ \left|G^h(t,x) - G(t,x)\right|\ dx &\le \frac{\delta^\alpha}{\alpha}\ \left(\|G^h(t)\|_{L^\infty} + \|G(t)\|_{L^\infty}\right)\\ &\quad + \delta^{\alpha-1}\ \int_\delta^\infty \left|G^h(t,x) - G(t,x)\right|\ dx\\ &\le C\ \delta^\alpha + \delta^{\alpha-1}\ \sup_{s\in[0,T]} \left\|G^h(s) - G(s)\right\|_{L^1}\end{aligned}$$

for some constant C depending only on α, G_0, T, and G. Thanks to (4.1), we may pass to the limit as $(h,\Delta t) \to 0$ and obtain

$$\limsup_{(h,\Delta t)\to 0} \sup_{t\in[0,T]} \int_0^\infty x^{\alpha-1}\ \left|G^h(t,x) - G(t,x)\right|\ dx \le C\ \delta^\alpha.$$

As $\delta \in (0,1)$ is arbitrary, we let $\delta \to 0$ to obtain the claim (4.20).

Now, owing to (4.2) and (4.20), it is straightforward to check that

$$\lim_{(h,\Delta t)\to 0} \int_0^T \int_0^\infty x^{\alpha-1}\ \left(v^h(t)\ G^h(t,x) - v(t)\ G(t,x)\right)\ \varphi(t)\ dxdt = 0. \tag{4.21}$$

Thanks to (4.19) and (4.21), we may pass to the limit in (2.14) and conclude that v is given by (2.2). □

5. Numerical simulations. In this section, we perform numerical experiments with $\alpha = 1/3$, which corresponds to the original model of Lifshitz and Slyozov [13]. Our aim is twofold: first, to study the numerical accuracy of the scheme analyzed in the previous sections and second, to see its behavior for large times.

We first check the order of the scheme with the following explicit stationary solution to (2.1)–(2.2):

$$G_{LS}(x) := \frac{6}{\left(1-(2x)^{1/3}\right)^{5/3}\ \left(1+(x/4)^{1/3}\right)^{4/3}}\ \exp\left(-\frac{(2x)^{1/3}}{1-(2x)^{1/3}}\right) \tag{5.1}$$

Table 1
Relative errors in the L^1- and L^∞-norms with respect to the number of grid points I^h.

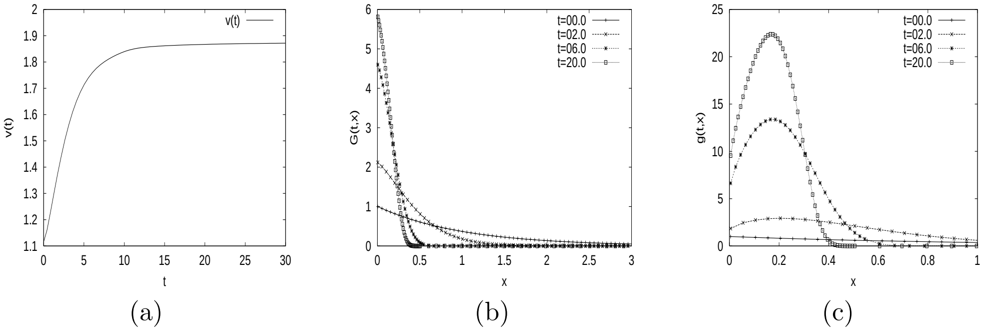
Number of points	Number of iterations	L^1 Error	L^∞ Error
200	221	$1.4\ 10^{-3}$	$1.5\ 10^{-3}$
400	443	$7.5\ 10^{-4}$	$7.5\ 10^{-4}$
800	887	$4.0\ 10^{-4}$	$3.8\ 10^{-4}$
1600	1776	$2.0\ 10^{-4}$	$2.0\ 10^{-4}$

for $x \in [0,1/2]$ and $G_{LS}(x) = 0$ if $x \geq 1/2$. Since G_{LS} is compactly supported in $[0,1/2]$, we take $hI^h = 1$ and $T = 1$. We compute the relative errors at $T = 1$ in the L^1- and L^∞-norms for different values of I^h, which are reported in Table 1. As expected, the scheme is first-order; that is, the error is proportional to h.

We next turn to the large time behavior and first recall that, for (2.1)–(2.3), it is much more complex that originally conjectured by Lifshitz and Slyozov in [13]. As already mentioned, formal asymptotic expansions performed in [13] indicate that the pair (G,v) converges towards a stationary solution (G_∞, v_∞) to (2.1)–(2.3), and it was further conjectured in [13] (and also in [25], but for a different choice of functions k and q) that the asymptotic profile (G_∞, v_∞) does not depend on the shape of the initial data G_0 but only on $\|G_0\|_{L^1}$. More precisely, the conjecture in [13] states that $G_\infty = a\, G_{LS}$ (defined by (5.1) above), with $a = \|G_0\|_{L^1}\ \|G_{LS}\|_{L^1}^{-1}$, while $v_\infty = V_{LS} := 3/2^{2/3}$. It was, however, noticed in [13] that (2.1)–(2.2) actually has a continuum $(G_V)_{V\geq V_{LS}}$ of stationary solutions (with $G_{V_{LS}} = G_{LS}$) satisfying $\|G_V\|_{L^1} = \|G_{LS}\|_{L^1}$, but it was argued that G_V is "unstable" for $V > V_{LS}$. This conjecture turns out to be false, as noticed on the ground of physical arguments in [6, 15] and confirmed by numerical simulations performed in [6]. More precisely, if the initial datum is compactly supported, the asymptotic profile (G_∞, v_∞) is determined by the way in which the initial datum vanishes at the edge of its support. Mathematical proofs of these facts have subsequently been supplied in [1] for $\alpha = 1$ by means of the Laplace transform. Though a convergence proof is still lacking in the general case $\alpha \in (0,1)$, necessary conditions for convergence are provided in [16] when $\alpha = 1/3$. In addition, it is established in [16] that, if one can prove that $v(t)$ converges to some $V > V_{LS}$ as $t \to +\infty$, then $G(t)$ converges towards G_V as $t \to +\infty$. Analogous results for the variant (1.1), (1.9) have subsequently been obtained in [18], still in the case $\alpha = 1/3$. It is also shown in [1, 16, 18] that there are initial data for which convergence towards a stationary solution does not hold at all. In addition, several numerical simulations have been performed in [2] with an accurate numerical method. The results in [2] provide further numerical evidence that the solutions to (2.1)–(2.3) with compactly supported initial data do not converge to the asymptotic profile (G_{LS}, V_{LS}) conjectured in [13] but to the one determined by the way the initial datum vanishes at the edge of its support; that is, (G_V, V) for some $V > V_{LS}$. Still, it is expected that the Lifshitz–Slyozov conjecture is valid for noncompactly supported initial data (with a "smooth" behavior for large x), and the aim of our first computations is to provide some numerical evidence of this fact. We thus choose

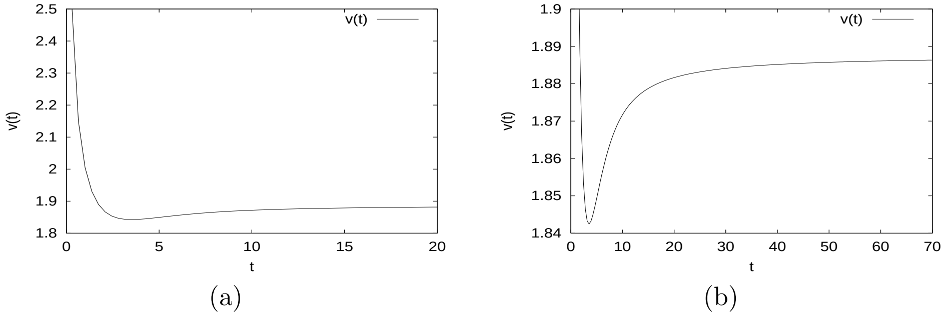
$$G_0(x) = \|G_{LS}\|_{L^1}\ \exp(-x), \quad x \in \mathbb{R}_+, \tag{5.2}$$

and report in Figure 1 the time evolution of v, G, and $g = -\partial_x G$ obtained by the scheme (2.12)–(2.17). For this simulation, we take the number of grid points $I^h = 1000$ with $h\, I^h = 10$, and the final time is $T = 30$. Noticing that $v(0) < V_{LS}$, we see that the function v first increases rapidly towards V_{LS} and then stabilizes to this value



(a) (b) (c)

FIG. 1. *Evolution of* (a) $v(t)$, (b) $G(t,x)$, *and* (c) $g(t,x)$ *corresponding to the initial datum* (5.2).



(a) (b)

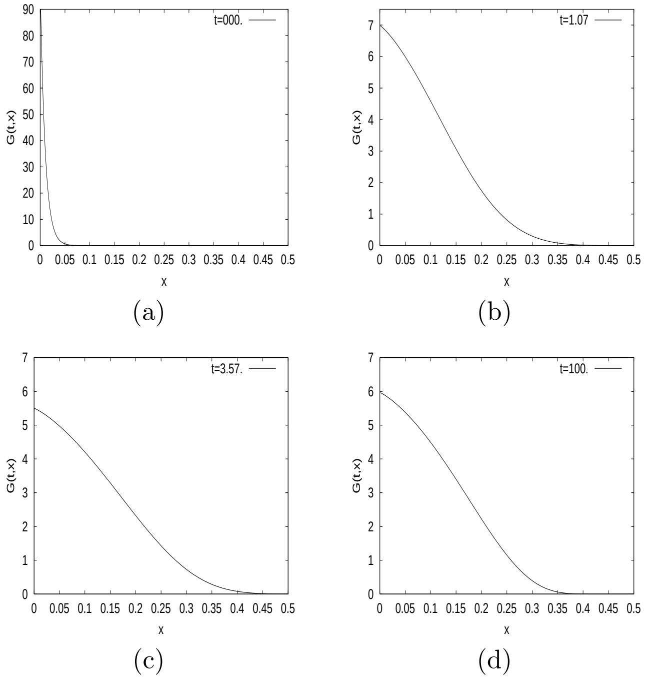
as conjectured. As for G, its support decreases with time towards $[0,1/2]$, and $G(t)$ converges to the stationary solution G_{LS} with a good accuracy.

We next investigate what happens to a similar initial datum but with $v(0) > V_{LS}$. More precisely, we take

$$G_0(x) = 100\,\|G_{LS}\|_{L^1}\,\exp(-100\,x), \quad x \in \mathbb{R}_+, \tag{5.3}$$

and observe that G_0 has the same L^1-norm as (5.2) but decreases faster for large x. In this case, we take $I^h = 1000$ with $h\,I^h = 1$, and the final time is $T = 100$. We observe that the behavior of v differs from that in the previous simulation. Indeed, $v(0)$ being greater than V_{LS}, v first decreases with time but to a smaller value than V_{LS}, as shown in Figure 2. It then increases again towards V_{LS} and finally stabilizes to V_{LS}. The evolution of G in that case is presented in Figure 3, which shows the convergence of G to G_{LS}.

Finally, following the previous discussion on the large time behavior for compactly supported initial data, one may wonder what the behavior of our scheme in that case might be. We have performed numerical simulations with $G_0(x) = (1-x)_+$ and observe that, in this case also, the numerical solution converges to (G_{LS}, V_{LS}), which is definitely not the behavior predicted by the theory [16]. It is, however, not surprising, as the numerical scheme induces some small diffusive effects, and diffusion is known to significantly modify large time behavior. More precisely, it is conjectured that solutions to a diffusive perturbation of (2.1)–(2.3) with a time-dependent diffusion coefficient vanishing for large times should converge to (G_{LS}, V_{LS}) (see [14, 20, 23]



(a) (b) (c) (d)

Fig. 3. *Evolution of $G(t,x)$ at time $t = 0, 1.07, 3.57, 100$ corresponding to the initial datum* (5.3).

and the references therein). The initial datum $G_0(x) = (1-x)_+$ being quite far from its expected limit, the diffusive effects of the scheme become not negligible after some time and thus induce a difference between the behavior of the numerical and the exact solutions. In an attempt to quantify the time of appearance of diffusive effects, it is interesting to look at the behavior of the scheme if the initial datum is one of the stationary solutions (G_V, V) for some $V > V_{LS}$. Given $V > V_{LS}$, this solution G_V is given by

$$G_V(x) := \frac{6\,\left(1-(x/x_0)^{1/3}\right)^{-\lambda_0}}{\left(1-(x/x_-)^{1/3}\right)^{\lambda_-}\,\left(1-(x/x_+)^{1/3}\right)^{\lambda_+}}, \tag{5.4}$$

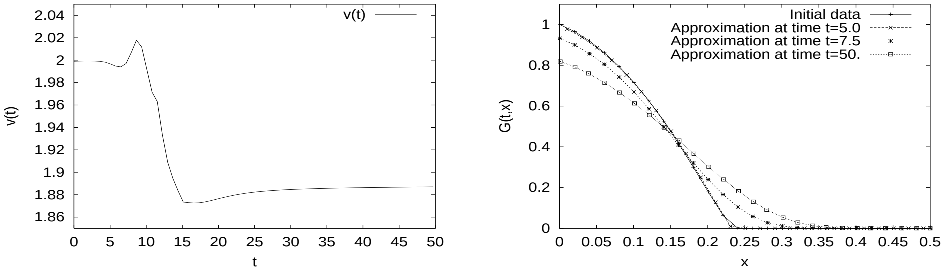
where λ_-, λ_0, λ_+ satisfy

$$\lambda_* = \frac{3\,x_*^{2/3}}{3\,x_*^{2/3} - V} \qquad \text{for} \qquad * \in \{-, 0, +\}$$

and $x_-^{1/3}$, $x_0^{1/3}$, $x_+^{1/3}$ are solutions of the following equation:

$$X^3 - V\,X + 1 = 0 \quad \text{with} \quad x_- \leq 0 \leq x_0 \leq x_+.$$

We choose $V = 2$ and $G_0 = G_2$ with $I^h = 1000$, $h\,I^h = 1$, and $T = 50$. The numerical simulations are reported in Figure 4, and we observe that, for $t \in [0,5]$, the computed solution remains close to G_2. After that time, diffusive effects come into play and the numerical solution evolves towards (G_{LS}, V_{LS}). In order to capture the expected behavior for compactly supported initial data for larger times, one thus needs a less



(a) (b)

FIG. 4. *Evolution of* (a) $v(t)$ *and* (b) $G(t,x)$ *corresponding to the initial datum* G_2*.*

diffusive numerical scheme such as the one used in [2], to which we refer for a more complete discussion on that issue.

Appendix. An L^∞-estimate for u. We consider a nonnegative function $f_0 \in L^1(\mathbb{R}_+, (1+x^2)dx)$, $f_0 \not\equiv 0$, and denote by f a weak solution to (1.1)–(1.2) (in the sense of [10, Theorem 2]) with initial datum f_0, the functions k and q being still given by (1.4) with $\alpha \in (0,1)$, so that $\mathcal{V}(t,x) = x^\alpha\ u(t) - 1$. We have the following result.

PROPOSITION A.1. *There is a constant C depending only on α and f_0 such that, for each $t \geq 0$,*

$$u(t) + \int_0^\infty x^2\ f(t,x)\ dx \leq C\ \exp(Ct). \tag{A.1}$$

Proof. For $\lambda \in [0,2]$ and $t \geq 0$, we set

$$M_\lambda(t) := \int_0^\infty x^\lambda\ f(t,x)\ dx.$$

Consider $t \in \mathbb{R}_+$. Since $\mathcal{V}(t,0) = -1$, we infer from (1.1) that $M_0(t) \leq M_0(0)$ and

$$\frac{dM_2}{dt}(t) \leq 2\ \int_0^\infty x\ \mathcal{V}(t,x)\ f(t,x)\ dx \leq 2\ u(t)\ M_{1+\alpha}(t). \tag{A.2}$$

We next infer from the Hölder inequality and (1.2) that

$$M_{1+\alpha}(t) \leq M_1(t)^{1-\alpha}\ M_2(t)^\alpha \leq C\ M_2(t)^\alpha,$$

$$0 < M_1(0) = M_1(t) \leq M_\alpha(t)^{1/(2-\alpha)}\ M_2(t)^{(1-\alpha)/(2-\alpha)}.$$

As a consequence of the first inequality and (A.2), we deduce that

$$\frac{dM_2}{dt}(t) \leq C\ u(t)\ M_2(t)^\alpha, \tag{A.3}$$

while the second inequality and (1.3) yield

$$u(t) = \frac{M_0(t)}{M_\alpha(t)} \leq \frac{M_0(0)}{M_1(0)^{2-\alpha}}\ M_2(t)^{1-\alpha}. \tag{A.4}$$

Combining (A.3) and (A.4), we end up with

$$\frac{dM_2}{dt}(t) \leq C\ M_2(t)$$

and use the Gronwall lemma to conclude that $M_2(t) \leq C \exp{(Ct)}$ for $t \geq 0$. A similar bound for u then follows by (A.4). □

Remark A.2. Observe that (A.3) and (A.4) are the continuous analogues of (3.10) and (3.2), respectively.

Acknowledgments. We thank Professor J. A. Carrillo for enlightening discussions on the computational issues of the LSW model. We are also grateful to the referees for their careful reading of the manuscript and their helpful suggestions.

A PRECONDITIONED CONJUGATE GRADIENT METHOD FOR NONSELFADJOINT OR INDEFINITE ORTHOGONAL SPLINE COLLOCATION PROBLEMS[*]

RAKHIM AITBAYEV[†] AND BERNARD BIALECKI[‡]

Abstract. We study the computation of the orthogonal spline collocation solution of a linear Dirichlet boundary value problem with a nonselfadjoint or an indefinite operator of the form $Lu = \sum a_{ij}(x)u_{x_ix_j} + \sum b_i(x)u_{x_i} + c(x)u$. We apply a preconditioned conjugate gradient method to the normal system of collocation equations with a preconditioner associated with a separable operator, and prove that the resulting algorithm has a convergence rate independent of the partition step size. We solve a problem with the preconditioner using an efficient direct matrix decomposition algorithm. On a uniform $N \times N$ partition, the cost of the algorithm for computing the collocation solution within a tolerance ϵ is $\mathrm{O}(N^2 \ln N |\ln \epsilon|)$.

Key words. nonselfadjoint or indefinite elliptic boundary value problem, orthogonal spline collocation, conjugate gradient method, preconditioner, matrix decomposition algorithm

1. Introduction.

On $\Omega = (0,1) \times (0,1)$ with boundary $\partial\Omega$, we consider the Dirichlet boundary value problem (BVP)

$$Lu = f(x),\ x \in \Omega, \quad u(x) = 0,\ x \in \partial\Omega, \tag{1.1}$$

where $x = (x_1, x_2)$ and

$$Lu \ = \ \sum_{i,j=1}^{2} a_{ij}(x)\, u_{x_ix_j} + \sum_{i=1}^{2} b_i(x)\, u_{x_i} + c(x)\, u. \tag{1.2}$$

We assume that a_{ij}, c_i, b, and f are sufficiently smooth, $a_{12}(x) = a_{21}(x)$, $x \in \Omega$, and the a_{ij} satisfy the uniform ellipticity condition

$$\nu \sum_{i=1}^{2} \eta_i^2 \ \leq \ \sum_{i,j=1}^{2} a_{ij}(x)\, \eta_i\, \eta_j, \qquad x \in \Omega, \qquad \eta_1,\ \eta_2 \in R, \qquad \nu > 0. \tag{1.3}$$

In general, the operator L of (1.2) is nonselfadjoint and could be indefinite with respect to the L^2 inner product. The principal part of L is given in nondivergence form rather than the divergence form $\sum_{i,j=1}^{2} \left(a_{ij}(x)\, u_{x_i}\right)_{x_j}$. While the divergence form is natural for the standard finite element Galerkin method, the nondivergence form is more appropriate for the orthogonal spline collocation (OSC) method since, in this case, the implementation of the OSC method requires neither partial derivatives

of the equation coefficients nor their approximations. Also, in comparison with finite element methods, the OSC method requires no integrals or their approximations to set up the corresponding linear system.

An analysis of OSC for the BVP (1.1)–(1.3) was given in [7], where optimal order L^2 and H^1 error estimates and an optimal H^2 error estimate were obtained. The solution of the resulting linear system by banded Gaussian elimination requires $\mathrm{O}(N^4)$ operations on $N \times N$ partition [24, 25, 34]. The application of iterative methods reduces this cost. Classical iterative methods, such as Jacobi, Gauss–Seidel, or SOR, for the OSC solution of Poisson's equation on a uniform partition were studied in [23, 29, 37]. ADI methods for solving OSC problems with separable operators were investigated in [5, 13, 19].

Since the operator in the BVP is nonseparable, nonselfadjoint, or indefinite, one can attempt to solve the corresponding linear system by preconditioned BICGSTAB, QMR, CGS, and GMRES methods described in [35]. On the other hand, the preconditioned conjugate gradient (PCG) method is an effective method for solving a linear system with a symmetric and positive-definite matrix. We solve the OSC problem by a PCG method applied to a linear system of normal equations. This method is called PCGNR (see section 5.2 in [4] and section 9.5 in [35]).

Preconditioning of a selfadjoint positive-definite operator by a spectrally equivalent operator was suggested by Kantorovich [26]. This idea, used first by D'yakonov [17, 18] for the finite difference solution of a BVP by Richardson's method, was later extended to the PCG method for the finite element and finite difference solutions of nonselfadjoint or indefinite BVPs [10, 11, 20, 31]. Preconditioning for some nonseparable OSC problems was studied in [6, 27, 28, 38].

Before describing our approach to solving the OSC problem, let us discuss some common techniques used in other discretization methods. Let L_h be a finite difference or a finite element operator associated with a nonselfadjoint or indefinite BVP, and let L_h^* be the adjoint of L_h with respect to an appropriate inner product $(\cdot,\cdot)_h$. Two well-known approaches for solving the equation $L_h u_h = f_h$ are based on preconditioned normal equations:

$$L_h^* M_h^{-2} L_h u_h = L_h^* M_h^{-2} f_h, \tag{1.4}$$

$$M_h^{-1} L_h^* M_h^{-1} L_h u_h = M_h^{-1} L_h^* M_h^{-1} f_h, \tag{1.5}$$

where a selfadjoint and positive-definite operator M_h is a preconditioner for L_h [10, 11, 20, 30, 31]. The operators $L_h^* M_h^{-2} L_h$ and $M_h^{-1} L_h^* M_h^{-1} L_h$ are selfadjoint with respect to $(\cdot,\cdot)_h$-inner product and M_h-inner product, respectively. Therefore, the equations (1.4) and (1.5) can be solved by the CG method with the corresponding inner products. Analyses of the CG solution of (1.4) and (1.5) are, respectively, related to L^2-norm and H^1-norm analyses of a finite difference or a finite element discretization. The finite element equation $L_h u_h = f_h$ can also be solved by modern preconditioned domain decomposition and multilevel methods (see, for example, [33, 36]). However, since these methods are not well developed for OSC, in this article we consider the solution of the OSC problem $L_h u_h = f_h$ approximating BVP (1.1)–(1.2) based on the normal equation

$$(M_h^* M_h)^{-1} L_h^* L_h u_h \;=\; (M_h^* M_h)^{-1} L_h^* f_h, \tag{1.6}$$

where a nonselfadjoint or indefinite OSC operator M_h is associated with a separable operator $\tilde{L}$ which is "close" to L. Following an H^2-norm analysis of [7], we show that $M_h^* M_h$ and $L_h^* L_h$ are spectrally equivalent with respect to $(\cdot,\cdot)_h$-inner product. Since the operator $(M_h^* M_h)^{-1} L_h^* L_h$ is selfadjoint and positive-definite with respect to $M_h^* M_h$-inner product, we solve (1.6) by the corresponding CG method. This method is equivalent to solving the equation $L_h^* L_h u_h = L_h^* f_h$ by PCG with $M_h^* M_h$ as a preconditioner. At each iteration of PCG, a new matrix decomposition algorithm allows us to solve the equation $M_h^* M_h w = r$ in one step rather than in two separate steps $M_h^* z = r$ and $M_h w = z$. On a uniform $N \times N$ partition, the total cost of our PCG algorithm with a tolerance ϵ is $\mathrm{O}(N^2 \ln N |\ln \epsilon|)$. The approach presented in this paper was used in [1] for the solution of a nonlinear OSC Dirichlet BVP by Newton's method.

An outline of this paper is as follows. Notation and auxiliary results are introduced in section 2. We prove spectral equivalence of the OSC operators in section 3 and discuss the matrix-vector form of the OSC problem in section 4. In section 5, we prove convergence of the PCG algorithm, and in section 6, we formulate matrix decomposition algorithms for the solution of an equation with the preconditioner. The implementation and the cost are discussed in section 7. In section 8, we present results of our numerical tests, and finally, section 9 is devoted to our conclusions.

2. Preliminaries. For $k = 1, 2$, let $\pi_k = \{x_{k,i}\}_{i=0}^{N_k}$ be a partition of the interval $[0, 1]$ such that

$$0 = x_{k,0} < x_{k,1} < \cdots < x_{k,N_k} = 1,$$

and let $h_{k,i} = x_{k,i} - x_{k,i-1}$ for $i = 1, \ldots, N_k$. Let

$$\underline{h}_k = \min_i h_{k,i}, \quad \overline{h}_k = \max_i h_{k,i}, \quad h = \max(\overline{h}_1, \overline{h}_2).$$

Throughout we assume that the partitions $\pi_h = \pi_1 \times \pi_2$ are regular; that is, there exist positive constants σ_1, σ_2, and σ_3, all independent of h, such that $\sigma_1 \overline{h}_1 \le \underline{h}_1$, $\sigma_1 \overline{h}_2 \le \underline{h}_2$, and $\sigma_2 \le \overline{h}_1/\overline{h}_2 \le \sigma_3$.

For an integer $r \ge 3$, let P_r be the set of all polynomials of degree $\le r$. For $k = 1, 2$, let

$$V_k = \{v \in C^1[0,1] : \, v|_{[x_{k,i-1},x_{k,i}]} \in P_r, \; i = 1, \ldots, N_k\}$$

be the space of Hermite splines of degree r associated with the partition π_k, and let $V_k^0 = \{v \in V_k : \, v(0) = v(1) = 0\}$. It is easy to verify that the dimension of V_k^0 is $K_k = (r-1)N_k$. Let $V^0 = V_1^0 \otimes V_2^0$, where $\otimes$ denotes the tensor product of vector spaces. Note that V^0 is the set of all functions that are finite linear combinations of products $v_1(x_1)\, v_2(x_2)$, where $v_1 \in V_1^0$ and $v_2 \in V_2^0$. The dimension of V^0 is $K = K_1 K_2$.

Let $\{\eta_l\}_{l=1}^{r-1}$ and $\{\omega_l\}_{l=1}^{r-1}$ be, respectively, the nodes and the weights of the $(r-1)$-point Gauss quadrature rule on $(0, 1)$. For $k = 1, 2$, let $\mathcal{G}_k$ consist of the points

$$\xi_{k,i,l} \; = \; x_{k,i-1} + h_{k,i}\eta_l, \quad i = 1, \ldots, N_k, \quad l = 1, \ldots, r-1. \tag{2.1}$$

Then $\mathcal{G} = \mathcal{G}_1 \times \mathcal{G}_2$ is the set of Gauss points in Ω associated with the partition π_h. Corollary 5.3 of [32] implies that any $v \in V^0$ is uniquely defined by its values on $\mathcal{G}$.

For v and z defined on $\mathcal{G}$, let

$$(v, z)_h = \sum_{i=1}^{N_1} h_{1,i} \sum_{k=1}^{r-1} \omega_k \sum_{j=1}^{N_2} h_{2,j} \sum_{l=1}^{r-1} \omega_l \, (vz)(\xi_{1,i,k}, \xi_{2,j,l}) \tag{2.2}$$

and let $\|v\|_h = \sqrt{(v,v)_h}$. Let $\rho(x)$ be a continuous positive function on $\overline{\Omega}$, and let $\rho_{\min} = \min_{x\in\overline{\Omega}} \rho(x)$ and $\rho_{\max} = \max_{x\in\overline{\Omega}} \rho(x)$. We shall also use

$$(v,z)_{h,\rho} \;=\; (\rho v, z)_h \tag{2.3}$$

and $\|v\|_{h,\rho} = \sqrt{(v,v)_{h,\rho}}$. We note that $(\cdot,\cdot)_{h,\rho}$ and $\|\cdot\|_{h,\rho}$ are, respectively, an inner product and a norm in V^0. It is easy to see that

$$\rho_{\min}\|v\|_h \;\le\; \|v\|_{h,\rho} \;\le\; \rho_{\max}\|v\|_h \tag{2.4}$$

for any v defined on $\mathcal{G}$.

Throughout, $H^l(\Omega)$ denotes the Sobolev space with the standard norm $\|\cdot\|_{H^l(\Omega)}$ [12]. We write $\partial_k^l = \partial^l/\partial x_k^l$ and $\partial^{(i,j)} = \partial^{i+j}/(\partial x_1^i \partial x_2^j)$. In the following, C denotes a generic positive constant independent of h.

The OSC problem for (1.1)–(1.2) consists of finding $u_h \in V^0$ such that

$$Lu_h(\xi) \;=\; f(\xi), \qquad \xi \in \mathcal{G}. \tag{2.5}$$

The following result was proved in [7, Theorem 3.3].

Theorem 2.1. *Let operator L of* (1.2) *be one-to-one from $\{v \in H^2(\Omega) : v = 0$ on $\partial\Omega\}$ to $L^2(\Omega)$, and let h be sufficiently small. Then the OSC problem* (2.5) *has a unique solution $u_h \in V^0$. Moreover, if $u \in H^{r+1}(\Omega)$ is the solution of* (1.1), *then*

$$\|u-u_h\|_{H^2(\Omega)} \;\le\; C\, h^{r-1}\, \|u\|_{H^{r+1}(\Omega)}.$$

3. Spectral equivalence of the OSC operators.

The following is the key result of this paper.

Theorem 3.1. *Let the assumptions of Theorem* 2.1 *be satisfied. Then there are positive constants γ_1 and γ_2 independent of h such that*

$$\gamma_1\|v\|_{H^2(\Omega)} \;\le\; \|Lv\|_{h,\rho} \;\le\; \gamma_2\|v\|_{H^2(\Omega)}, \qquad v\in V^0. \tag{3.1}$$

Proof. We note that the inequality

$$C\,\|v\|_{H^2(\Omega)} \;\le\; \|Lv\|_h + \|v\|_{L^2(\Omega)}, \quad v \in V^0,$$

was proved in [7, (3.20)]. Also, it follows from Lemma 3.2 and (3.21) of [7] that

$$C\,\|v\|_{L^2(\Omega)} \;\le\; h\,\|v\|_{H^2(\Omega)} + \|Lv\|_h, \quad v\in V^0.$$

Thus, for h sufficiently small, we have $C\|v\|_{H^2(\Omega)} \le \|Lv\|_h$, $v \in V^0$, which, along with the first inequality in (2.4), gives the first inequality in (3.1).

Using (1.2) and the boundedness of the coefficients of L, we obtain

$$\|Lv\|_h \;\le\; C \sum_{0\le i+j\le 2} \left\|\partial^{(i,j)}v\right\|_h, \quad v\in V^0. \tag{3.2}$$

Applying the inverse inequality of Theorem 3.2.6 in [12], we have

$$\left\|\partial^{(i,j)}v\right\|_h \;\le\; C\,\left\|\partial^{(i,j)}v\right\|_{L^2(\Omega)}, \quad v\in V^0, \quad 0\le i+j\le 2. \tag{3.3}$$

Using the second inequality in (2.4), (3.2), (3.3), and the Cauchy–Schwarz inequality, we obtain the second inequality in (3.1). ∎

We also consider the separable differential operator

$$\tilde{L} \;=\; \tilde{L}_1 + \tilde{L}_2, \tag{3.4}$$

where, for $k = 1, 2$,

$$\tilde{L}_k v \;=\; \tilde{a}_k(x_k)\, v_{x_k x_k} + \tilde{b}_k(x_k)\, v_{x_k} + \tilde{c}_k(x_k)\, v, \tag{3.5}$$

$\tilde{a}_k$, $\tilde{b}_k$, and $\tilde{c}_k$ are sufficiently smooth, and

$$\tilde{a}_k(x) \geq \nu > 0, \quad x \in \Omega, \quad k = 1, 2.$$

LEMMA 3.1. *Let the assumptions of Theorem* 2.1 *be satisfied and let the operator* $\tilde{L}$ *be one-to-one from* $\{v \in H^2(\Omega) : v = 0$ *on* $\partial\Omega\}$ *to* $L^2(\Omega)$. *Then there are positive constants* α *and* β, *independent of* h, *such that*

$$\sqrt{\alpha}\, \|\tilde{L}v\|_{h,\rho} \;\leq\; \|Lv\|_{h,\rho} \;\leq\; \sqrt{\beta}\, \|\tilde{L}v\|_{h,\rho}, \quad v \in V^0. \tag{3.6}$$

Proof. Since $\tilde{L}$ is a special case of L, Theorem 3.1 implies that

$$\tilde{\gamma}_1\, \|v\|_{H^2(\Omega)} \;\leq\; \|\tilde{L}v\|_{h,\rho} \;\leq\; \tilde{\gamma}_2\, \|v\|_{H^2(\Omega)}, \qquad v \in V^0, \tag{3.7}$$

where the positive constants $\tilde{\gamma}_1$ and $\tilde{\gamma}_2$ are independent of h. Using (3.1) and (3.7), we obtain (3.6) with $\sqrt{\alpha} = \gamma_1/\tilde{\gamma}_2$ and $\sqrt{\beta} = \gamma_2/\tilde{\gamma}_1$. □

If L_h and M_h are OSC operators from V^0 to V^0 associated with L of (1.2) and $\tilde{L}$ of (3.4)–(3.5), respectively, then (3.6) shows that $L_h^* L_h$ and $M_h^* M_h$ are spectrally equivalent with respect to the inner product $(\cdot,\cdot)_{h,\rho}$. This is equivalent to L_h and M_h being uniformly L^2-norm equivalent (see (1.15) in [30]). Consequently, our Lemma 3.1 is the OSC counterpart of Lemma 3.1 in [30] for continuous operators.

4. Matrix-vector form of the OSC problem. For $k = 1, 2$, let $\{\phi_{k,j}\}_{j=1}^{K_k}$ be a basis for V_k^0. Then $\{\phi_j(x)\}_{j=1}^{K}$, where

$$\phi_{K_2(j_1-1)+j_2}(x) \;=\; \phi_{1,j_1}(x_1)\phi_{2,j_2}(x_2), \quad j_k = 1, \ldots, K_k, \quad k = 1, 2, \tag{4.1}$$

is a basis for V^0. Thus, for any $v \in V^0$, there exists a unique vector $[v]_{\mathcal{H}} = [v_1, \ldots, v_K]^T \in R^K$ such that

$$v(x) \;=\; \sum_{j=1}^{K} v_j\, \phi_j(x), \quad x \in \overline{\Omega}. \tag{4.2}$$

Let $\mathcal{G} = \{\xi_i\}_{i=1}^{K}$, where

$$\xi_{(i_1-1)K_2+i_2} = (\xi_{1,i_1}, \xi_{2,i_2}), \quad i_k = 1, \ldots, K_k, \quad k = 1, 2, \tag{4.3}$$

$$\xi_{k,(i-1)(r-1)+l} = \xi_{k,i,l}, \qquad i = 1, \ldots, N_k, \qquad l = 1, \ldots, r-1, \tag{4.4}$$

and $\xi_{k,i,l}$ are given by (2.1). For any v defined on $\mathcal{G}$, we introduce the vector $[v]_{\mathcal{G}} = [v(\xi_1), \ldots, v(\xi_K)]^T \in R^K$.

For a matrix A, its (i,j) entry is denoted by $(A)_{ij}$. Let M_L be the matrix defined by

$$(M_L)_{ij} \;=\; (L\phi_j)(\xi_i), \quad i, j = 1, \ldots, K. \tag{4.5}$$

Then using (4.2) and (4.5), we have

$$[Lv]_{\mathcal{G}} \;=\; M_L[v]_{\mathcal{H}}, \qquad v \in V^0. \tag{4.6}$$

Let $\rho(x)$ be a continuous positive function on $\overline{\Omega}$. We introduce

$$D \;=\; \operatorname{diag}(\rho(\xi_1), \ldots, \rho(\xi_K)), \tag{4.7}$$

$$W \;=\; W_1 \otimes W_2, \tag{4.8}$$

where $\otimes$ denotes the matrix tensor product and, for $k = 1, 2$,

$$W_k \;=\; \operatorname{diag}\,(h_{k,1}, \ldots, h_{k,N_k}) \otimes \operatorname{diag}\,(\omega_1, \ldots, \omega_{r-1}). \tag{4.9}$$

From (2.3), (2.2), (4.3), (4.4), and (4.7)–(4.9), we have

$$(v, z)_{h,\rho} \;=\; [v]_{\mathcal{G}}^T W D [z]_{\mathcal{G}}. \tag{4.10}$$

Using (4.6), the OSC problem (2.5) can be rewritten in the matrix-vector form

$$M_L[u_h]_{\mathcal{H}} \;=\; [f]_{\mathcal{G}}. \tag{4.11}$$

Multiplying this equation by $M_L^T W D$ on the left, we obtain

$$A\,\vec{u} \;=\; \vec{f}, \tag{4.12}$$

where

$$A = M_L^T W D M_L, \quad \vec{u} = [u_h]_{\mathcal{H}}, \quad \text{and} \quad \vec{f} = M_L^T W D [f]_{\mathcal{G}}. \tag{4.13}$$

5. PCG algorithm. Let the operator $\tilde{L}$ be as in (3.4)–(3.5), and let

$$\tilde{A} \;=\; M_{\tilde{L}}^T\, W\, D\, M_{\tilde{L}}, \tag{5.1}$$

where $M_{\tilde{L}}$ is defined by

$$(M_{\tilde{L}})_{ij} \;=\; (\tilde{L}\phi_j)(\xi_i), \quad i, j = 1, \ldots, K. \tag{5.2}$$

It follows easily from (4.13) and (5.1) that A and $\tilde{A}$ are symmetric.

LEMMA 5.1. *Let the assumptions of Lemma* 3.1 *be satisfied. Then the matrices* A *of* (4.13) *and* $\tilde{A}$ *of* (5.1) *are positive-definite. Moreover,*

$$\alpha\, \vec{v}^T \tilde{A} \vec{v} \;\le\; \vec{v}^T A \vec{v} \;\le\; \beta\, \vec{v}^T \tilde{A} \vec{v}, \qquad \vec{v} \in R^K, \tag{5.3}$$

where the positive constants α *and* β *are the same as in* (3.6).

Proof. Using (4.10), (4.6), and (4.13), we obtain, for $v \in V^0$,

$$\|Lv\|_{h,\rho}^2 = (Lv, Lv)_{h,\rho} = [Lv]_{\mathcal{G}}^T W D [Lv]_{\mathcal{G}} = [v]_{\mathcal{H}}^T M_L^T W D M_L [v]_{\mathcal{H}} = [v]_{\mathcal{H}}^T A [v]_{\mathcal{H}}. \tag{5.4}$$

Hence the first inequality in (3.1) and $\gamma_1 > 0$ imply that A is positive-definite. Similarly, we have $\|\tilde{L}v\|_{h,\rho}^2 = [v]_{\mathcal{H}}^T \tilde{A}\,[v]_{\mathcal{H}}$. Therefore, (5.3) follows from (3.6) and (5.4). The second inequality in (5.3) and $\beta > 0$ imply that $\tilde{A}$ is also positive-definite. □

We solve (4.12) by the PCG method (see Algorithm 9.4.14 in [22]) with $\tilde{A}$ as a preconditioner.

THEOREM 5.1. *Let the assumptions of Lemma* 3.1 *be satisfied. For an iterate $\vec{u}_k$ generated by the PCG method, let $u_{h,k} \in V^0$ be such that $[u_{h,k}]_{\mathcal{H}} = \vec{u}_k$. Then*

$$\|f - Lu_{h,k}\|_{h,\rho} \;\le\; 2\delta^k \|f - Lu_{h,0}\|_{h,\rho}, \quad k = 0, 1, 2, \ldots, \tag{5.5}$$

where $\delta = (\sqrt{\beta/\alpha} - 1)/(\sqrt{\beta/\alpha} + 1)$ and α and β are the same as in (3.6).

Proof. Since A and $\tilde{A}$ are symmetric positive-definite, (5.5) follows from (5.3), Theorem 9.4.14 in [22], (5.4), and (2.5). □

COROLLARY 5.1. *With δ of Theorem* 5.1*, we have*

$$\|u_h - u_{h,k}\|_{H^2(\Omega)} \;\le\; C\delta^k \|u_h - u_{h,0}\|_{H^2(\Omega)}, \quad k = 0, 1, 2, \ldots . \tag{5.6}$$

Proof. Inequality (5.6) follows from (5.5), (2.5), and (3.1). □

Let $\tilde{r}_k = [f]_{\mathcal{G}} - M_L \vec{u}_k$, $k = 0, 1, \ldots$. Then (2.5), (5.4), and (4.11) give $\|\tilde{r}_k\|_{WD} = \|f - Lu_{h,k}\|_{h,\rho}$. Hence, if $\tilde{r}_k$ is required at each iteration and the iterations are terminated when

$$\|f - Lu_{h,k}\|_{h,\rho} \;\le\; \epsilon \|f - Lu_{h,0}\|_{h,\rho}, \tag{5.7}$$

then the PCG method can be rewritten in the following form (cf. Algorithm 9.7 in [35]).

ALGORITHM 5.1.

```
select $\vec{u}_0$, $\tilde{r}_0 = [f]_{\mathcal{G}} - M_L\vec{u}_0$, $\vec{r}_0 = M_L^T WD\tilde{r}_0$, solve $\tilde{A}\vec{p}_0 = \vec{r}_0$, $\rho_0 = \vec{r}_0^T\vec{p}_0$,
for $k = 0, 1, 2, \ldots$ (as long as $\|\tilde{r}_k\|_{WD} > \epsilon\|\tilde{r}_0\|_{WD}$):
    $\vec{w}_k = M_L\vec{p}_k$, $\alpha_k = \rho_k/(\vec{w}_k^T WD\vec{w}_k)$, $\vec{u}_{k+1} = \vec{u}_k + \alpha_k\vec{p}_k$,
    $\tilde{r}_{k+1} = \tilde{r}_k - \alpha_k\vec{w}_k$, $\vec{r}_{k+1} = M_L^T WD\tilde{r}_k$,
    solve $\tilde{A}\vec{z}_{k+1} = \vec{r}_{k+1}$, $\rho_{k+1} = \vec{r}_{k+1}^T\vec{z}_{k+1}$, $\vec{p}_{k+1} = \vec{z}_{k+1} + (\rho_{k+1}/\rho_k)\vec{p}_k$.
```

6. Preconditioning.

At each iteration of Algorithm 5.1, a linear system

$$\tilde{A}\vec{w} \;=\; \vec{r} \tag{6.1}$$

must be solved, where $\tilde{A}$ is defined by (5.1)–(5.2). If $\tilde{b}_1 = 0$ or $\tilde{b}_2 = 0$, then (6.1) can be solved by matrix decomposition algorithms which we describe assuming $\tilde{b}_1 = 0$.

For $k = 1, 2$, let I_k be the identity matrix of order K_k, and let the matrices A_k and B_k be defined by

$$(A_k)_{ij} \;=\; (\tilde{L}_k\phi_{k,j})\,(\xi_{k,i}), \qquad (B_k)_{ij} \;=\; \phi_{k,j}\,(\xi_{k,i}), \qquad i, j = 1, 2, \ldots, K_k, \tag{6.2}$$

where $\tilde{L}_k$ is given by (3.5). It follows from (5.2), (3.4), (4.1), (4.3), and (6.2) that

$$M_{\tilde{L}} \;=\; A_1 \otimes B_2 + B_1 \otimes A_2. \tag{6.3}$$

With $\tilde{a}_1$ of (3.5) for $k = 1$, let

$$D_1 = \operatorname{diag}(1/\tilde{a}_1(\xi_{1,1}), \ldots, 1/\tilde{a}_1(\xi_{1,K_1})). \tag{6.4}$$

We introduce the $K_1 \times K_1$ matrices

$$G = B_1^T W_1 D_1 A_1, \quad F = B_1^T W_1 D_1 B_1, \tag{6.5}$$

where W_1 is given by (4.9). It was proved in [8, Lemma 3.1] that F is symmetric positive-definite and G is symmetric. Therefore, it follows from [21, Corollary 8.7.2] that there exists a real diagonal matrix

$$\Lambda = \operatorname{diag}(\lambda_1, \ldots, \lambda_{K_1}) \tag{6.6}$$

and a real nonsingular matrix Z such that

$$Z^T G Z = \Lambda, \quad Z^T F Z = I_1. \tag{6.7}$$

Now we discuss two approaches to solving (6.1). In the first, we take $\rho = 1$ in $(\cdot,\cdot)_{h,\rho}$ of (2.3) and obtain $D = I$ by (4.7). Hence, by (5.1), the linear system (6.1) becomes

$$M_{\tilde{L}}^T W M_{\tilde{L}} \vec{w} \;=\; \vec{r},$$

where the diagonal matrix W is defined by (4.8)–(4.9). Thus, the system in (6.1) can be solved as follows.

Algorithm 6.1.

Step 1. Determine Λ and Z satisfying (6.7).

Step 2. Solve $M_{\tilde{L}}^T \vec{z} = \vec{r}$ by a modification of Algorithm I in [8] (see below).

Step 3. Solve the diagonal system $W\vec{v} = \vec{z}$.

Step 4. Solve $M_{\tilde{L}} \vec{w} = \vec{v}$ by Algorithm I in [8].

We note that the matrix decomposition Algorithm I of [8] is based on the decomposition

$$(Z^T B_1^T W_1 D_1 \otimes I_2) M_{\tilde{L}} (Z \otimes I_2) = \Lambda \otimes B_2 + I_1 \otimes A_2,$$

which follows easily from (6.3), (6.5), and (6.7). By taking the transpose of both sides, we also have

$$(Z^T \otimes I_2) M_{\tilde{L}}^T (W_1 D_1 B_1 Z \otimes I_2) = \Lambda \otimes B_2^T + I_1 \otimes A_2^T.$$

Therefore, Step 2 is implemented in a way similar to Step 4 (see [8] for details).

In the second approach to solving (6.1), we take $\rho(x_1, x_2) = 1/\tilde{a}_1(x_1)$, $(x_1, x_2) \in \overline{\Omega}$, which, by (4.7), gives

$$D \;=\; D_1 \otimes I_2, \tag{6.8}$$

where D_1 is given by (6.4). Then the system in (6.1) can be solved in one step by a matrix decomposition algorithm which we describe in the following. Since $Z \otimes I_2$ is nonsingular, the system in (6.1) is equivalent to

$$S\vec{y} = \vec{d}, \tag{6.9}$$

where $\vec{y} = (Z \otimes I_2)^{-1}\vec{w}$, $\vec{d} = (Z^T \otimes I_2)\vec{r}$, and

$$S \;=\; (Z^T \otimes I_2)\tilde{A}(Z \otimes I_2). \tag{6.10}$$

Lemma 6.1. *Assume that $\tilde{L}$ satisfies the assumptions in Lemma* 3.1 *and that h is sufficiently small. Then S of* (6.10) *is a real block diagonal matrix with $K_2 \times K_2$ symmetric positive-definite diagonal blocks*

$$S_i \;=\; (A_2 + \lambda_i B_2)^T\, W_2\, (A_2 + \lambda_i B_2), \quad i = 1, \dots, K_1. \tag{6.11}$$

Proof. Using (5.1), (6.3), (4.8), (6.8), (6.5), and $G = G^T$, we obtain

$$\begin{aligned} \tilde{A} &= (A_1^T \otimes B_2^T + B_1^T \otimes A_2^T)(W_1 D_1 \otimes W_2)(A_1 \otimes B_2 + B_1 \otimes A_2) \\ &= A_1^T W_1 D_1 A_1 \otimes B_2^T W_2 B_2 + G \otimes B_2^T W_2 A_2 \\ &\quad + G \otimes A_2^T W_2 B_2 + F \otimes A_2^T W_2 A_2. \end{aligned} \tag{6.12}$$

The second equations in (6.5) and (6.7) give

$$B_1 Z Z^T B_1^T W_1 D_1 \;=\; I_1. \tag{6.13}$$

Using (6.13), the first equations in (6.7) and (6.5), and $G^T = G$, we obtain

$$Z^T A_1^T W_1 D_1 A_1 Z = Z^T A_1^T W_1 D_1 B_1 Z Z^T B_1^T W_1 D_1 A_1 Z = \Lambda^2. \tag{6.14}$$

Thus, (6.10), (6.12), (6.14), and (6.7) give

$$S \;=\; \Lambda^2 \otimes B_2^T W_2 B_2 + \Lambda \otimes B_2^T W_2 A_2 + \Lambda \otimes A_2^T W_2 B_2 + I_1 \otimes A_2^T W_2 A_2. \tag{6.15}$$

It follows from (6.15) and (6.6) that S is real block diagonal with the diagonal blocks given by (6.11).

We see from (6.11) that each matrix S_i is symmetric and $\vec{v}^T S_i \vec{v} \geq 0$ for any $\vec{v} \in R^{K_2}$. Since Z is nonsingular and $\tilde{A}$ is positive-definite (see Lemma 5.1), it follows from (6.10) that S is nonsingular. This implies that S_i is nonsingular and hence positive-definite. □

For $\vec{v} \in R^K$, let $[\vec{v}]_i = [v_{(i-1)K_2+1}, \ldots, v_{iK_2}]^T \in R^{K_2}$, $i = 1, \ldots, K_1$. Based on (6.9) and Lemma 6.1, we can formulate the following matrix decomposition algorithm for the solution of (6.1).

Algorithm 6.2.

```
Step 1. Determine $\Lambda$ and $Z$ satisfying (6.7).
Step 2. Compute $\vec{d} = (Z^T \otimes I_2)\vec{r}$.
Step 3. Solve $S_i[\vec{y}]_i = [\vec{d}]_i$ for $i = 1, \ldots, K_1$.
Step 4. Compute $\vec{w} = (Z \otimes I_2)\vec{y}$.
```

7. Implementation and cost. To discuss the implementation and cost, we assume that the basis functions $\{\phi_{k,j}\}_{j=1}^{K_k}$ for V_k^0, $k = 1, 2$, are B-splines or Hermite-type functions ordered in the standard way. Then matrices A_k and B_k, $k = 1, 2$, in (6.2) are almost block diagonal and have the structure described in [3], depending on the type of basis functions.

Step 1 of Algorithms 6.1 and 6.2 involves solving the symmetric generalized eigenproblem (6.7). This can be done by one of the following three algorithms.

Algorithm 7.1.

```
Step 1. Compute $G$ and $F$ of (6.5).
Step 2. Compute band Cholesky factorization $F = LL^T$.
Step 3. Compute full symmetric $C = L^{-1} G L^{-T}$.
Step 4. Use QR algorithm to compute the diagonal $\Lambda$ and an orthogonal $Q$
            such that $Q^T C Q = \Lambda$.
Step 5. Compute $Z = L^{-T} Q$.
```

Algorithm 7.2.

```
Step 1. Compute $G$ and $F$ of (6.5).
Step 2. Compute band Cholesky factorization $F = LL^T$.
Step 3. Use Crawford's algorithm to compute $C$ and $X$.
Step 4. Use band QR algorithm to compute the diagonal $\Lambda$ and
            an orthogonal $Q$ such that $Q^T C Q = \Lambda$.
Step 4. Compute $Z = XQ$.
```

Algorithm 7.3.

```
Step 1. Compute full symmetric $C = (W_1 D_1)^{1/2} A_1 B_1^{-1} (W_1 D_1)^{-1/2}$.
Step 2. Use QR algorithm to compute the diagonal $\Lambda$ and an orthogonal $Q$
            such that $Q^T C Q = \Lambda$.
Step 3. Compute $Z = B_1^{-1} (W_1 D_1)^{-1/2} Q$.
```

TABLE 7.1
Costs of Algorithms 7.1–7.3.

Compute	Algorithm 7.1	Algorithm 7.2	Algorithm 7.3
F, G	$\mathrm{O}(K_1)$	$\mathrm{O}(K_1)$	–
L	$\mathrm{O}(K_1)$	$\mathrm{O}(K_1)$	–
C (X for Alg. 7.2)	$\mathrm{O}(K_1^2)$	$\mathrm{O}(K_1^2)$	$\mathrm{O}(K_1)$
Λ, Q	$9K_1^3$	$6K_1^3$	$9K_1^3$
Z	$\mathrm{O}(K_1^2)$	$2K_1^3$	$\mathrm{O}(K_1^2)$
total cost	$9K_1^3+\mathrm{O}(K_1^2)$	$8K_1^3+\mathrm{O}(K_1^2)$	$9K_1^3+\mathrm{O}(K_1^2)$

Algorithm 7.1 is the standard Wilkinson's algorithm (see Algorithm 8.7.1 in [21]). Algorithm 7.2 is based on Crawford's algorithm (see [2] and [14] for details). If $F = LL^T$ is the band Cholesky factorization of F, Crawford's algorithm computes band symmetric C and $X = L^{-T}P$, with P orthogonal, such that $C = X^TGX$ and C is orthogonally similar to Λ. Algorithm 7.3 is based on Step 1 of Algorithm II of [8]. The algorithm uses the factorization $F = LL^T$ with $L = B_1^T(W_1D_1)^{1/2}$. The costs of Algorithms 7.1–7.3 are given in Table 7.1.

The implementation of Step 4 of Algorithm 6.1 and its cost of $4K_1^2K_2$ are discussed in [8]. The implementation of Step 2 of Algorithm 6.1 is similar and its cost is also $4K_1^2K_2$.

Step 2 and Step 4 of Algorithm 6.2 involve K_2 multiplications by $K_1\times K_1$ matrices Z^T and Z, respectively, and hence each step requires $2K_1^2K_2$ operations. Each $K_2\times K_2$ matrix S_i in (6.11) is symmetric, positive-definite, and block tridiagonal with $r-1$ by $r-1$ blocks. A linear system with S_i can be solved by a direct block tridiagonal solver (for example, by the routine BLKTRI from the package FISHPACK described in [39]) at the cost $\mathrm{O}(K_2)$. Therefore, the cost of Step 3 of Algorithm 6.2 is $\mathrm{O}(K_1K_2)$. Since A_2 and B_2 are almost block diagonal, so is S_i. Hence a linear system with S_i can also be solved by two calls to the routine COLROW [15, 16].

Of course, when Algorithms 6.1 and 6.2 are used in Algorithm 5.1 to solve a linear system with the coefficient matrix $\tilde{A}$, the matrices Λ and Z are precomputed first. For Algorithm 6.1, the remaining cost is $8K_1^2K_2$ since this is the cost of all multiplications by Z^T and Z. For Algorithm 6.2, the remaining cost is half of that of Algorithm 6.1.

In a special case of $r = 3$, a uniform partition π_1, constant coefficients $\tilde{a}_1$, $\tilde{c}_1$ of $\tilde{L}$ in (3.5), and $\tilde{b}_1 = 0$, the matrices Λ and Z in (6.7) are known in a closed form. Moreover, it follows from Theorem 2.3 in [9] that matrix Z is given in terms of sines and cosines. Therefore, all multiplications by Z^T and Z in Algorithm 6.1 can be performed using FFTs with the cost $\mathrm{O}(K_1K_2\log K_1)$. Thus, the total cost of Algorithm 6.1 is $\mathrm{O}(K_1K_2\log K_1)$. In this case, it follows from (5.6) that the cost of our PCG Algorithm 5.1 with a tolerance ϵ on an $N\times N$ partition is $\mathrm{O}(N^2\ln N|\ln\epsilon|)$.

8. Numerical tests.

Before considering our numerical tests, we present an additional result which was used in the tests. Let $\hat{a}_1(x)$, $\hat{a}_2(x)$, and $\hat{c}(x)$ be sufficiently smooth functions on Ω, and for $i = 1, 2$, let $\hat{a}_i(x) \geq \nu > 0$, $x \in \Omega$. Let

$$\hat{L}v \;=\; (\hat{a}_1(x)v_{x_1})_{x_1} + (\hat{a}_2(x)v_{x_2})_{x_2} + \hat{c}(x)v. \tag{8.1}$$

The operator $\hat{L}$ is selfadjoint with respect to the standard L^2-inner product, and it is negative-definite if $\hat{c}(x) \leq 0$, $x \in \Omega$. We prove that $\hat{L}$ is indefinite if

$$\min_{x\in\Omega}\{\hat{c}(x)\} > 2\pi^2 \max_{x\in\Omega}\{\hat{a}_1(x),\, \hat{a}_2(x)\}. \tag{8.2}$$

Using Green's formula and (8.2), we have, for $v \neq 0$,

$$\begin{aligned}\int_\Omega \hat{L}v(x)\,v(x)\,dx &= -\int_\Omega (\hat{a}_1 v_{x_1}^2 + \hat{a}_2 v_{x_2}^2)\,dx + \int_\Omega \hat{c}v^2\,dx \\ &\geq -\max_{x\in\Omega}\{\hat{a}_1(x),\, \hat{a}_2(x)\}\|\nabla v\|^2_{L^2(\Omega)} + \min_{x\in\Omega}\{\hat{c}(x)\}\|v\|^2_{L^2(\Omega)} \\ &> \max_{x\in\Omega}\{\hat{a}_1(x),\, \hat{a}_2(x)\}\left(2\pi^2\|v\|^2_{L^2(\Omega)} - \|\nabla v\|^2_{L^2(\Omega)}\right), \end{aligned} \tag{8.3}$$

where $\|\nabla v\|^2_{L^2(\Omega)} = \int_\Omega (v_{x_1}^2 + v_{x_2}^2)dx$. It is easy to see that, for

$$v_{k,l}(x) \;=\; 2\sin(k\pi x_1)\sin(l\pi x_2), \quad x \in \Omega,$$

with integers k and l, we have

$$\|\nabla v_{k,l}\|^2_{L^2(\Omega)} \;=\; \pi^2(k^2 + l^2)\|v_{k,l}\|^2_{L^2(\Omega)}. \tag{8.4}$$

Thus, from (8.3) and (8.4), we obtain $\int_\Omega \hat{L}v_{1,1}(x)\,v_{1,1}(x)\,dx > 0$.

On the other hand, by (8.4), we have

$$\begin{aligned}\int_\Omega \hat{L}v_{k,l}(x)\,v_{k,l}(x)\,dx &\leq -\nu\|\nabla v_{k,l}\|^2_{L^2(\Omega)} + \max_{x\in\Omega}\{\hat{c}(x)\}\|v_{k,l}\|^2_{L^2(\Omega)} \\ &= \left(\max_{x\in\Omega}\{\hat{c}(x)\} - \nu\pi^2(k^2+l^2)\right)\|v_{k,l}\|^2_{L^2(\Omega)}.\end{aligned}$$

Hence, $\int_\Omega \hat{L}v_{k,l}(x)\,v_{k,l}(x)\,dx < 0$ for sufficiently large k^2 or l^2. Thus, under the condition (8.2), $\hat{L}$ is indefinite.

Now we describe our numerical tests. The operator L in (1.2) was taken with the coefficients

$$\begin{aligned}&a_{11}(x) = e^{x_1x_2}, \quad a_{12}(x) = \alpha/(1+x_1+x_2), \quad a_{22}(x) = e^{-x_1x_2}, \\ &b_1(x) = x_2e^{x_1x_2} + \beta_1\cos[\pi(x_1+x_2)], \quad b_2(x) = -x_1e^{-x_1x_2} + \beta_2\sin(2\pi x_1x_2), \\ &c(x) = \gamma[1 + 1/(1+x_1+x_2)],\end{aligned} \tag{8.5}$$

where α, β_1, β_2, and γ are parameters. In BVP (1.1), we set $f(x) = Lu(x)$ for $u(x) = e^{x_1+x_2}x_1x_2(1-x_1)(1-x_2)$.

We note that, for the coefficients given by (8.5) with $\alpha = \beta_1 = \beta_2 = 0$, we have $b_1 = (a_{11})_{x_1}$ and $b_2 = (a_{22})_{x_2}$. Therefore, in this case, the operator L in (1.2) can be written in the form of (8.1) with $\hat{a}_i(x) = a_{ii}(x)$, $i = 1, 2$, and $\hat{c}(x) = c(x)$. It follows from (8.5) with $\gamma \geq 0$ that

$$\min_{x\in\Omega}\{c(x)\} = (4/3)\gamma, \quad \max_{x\in\Omega}\{a_{11}(x),\, a_{22}(x)\} = e.$$

Hence, if $\gamma > (3/2)\pi^2 e \approx 40.243$, then the operator L is indefinite by (8.2).

In our numerical tests, we considered the case of $r = 3$, that is, V^0 is the space of Hermite bicubic splines on a uniform $N \times N$ partition of $\overline{\Omega}$ with the step size $h = 1/N$ (hence, $K_1 = K_2 = 2N$ and $K = 4N^2$). In this case, the standard basis for V^0 is defined as follows. For $k = 1, 2$, let $v_{k,j}, s_{k,j} \in V_k$, $j = 0, \dots, N$, be the "value function" and the "scaled slope function" associated with the node $x_{k,j}$ and defined respectively by

$$v_{k,j}(x_{k,i}) \;=\; \delta_{ij}, \quad [v_{k,j}]'(x_{k,i}) \;=\; 0, \quad i = 0, \dots, N,$$

and

$$s_{k,j}(x_{k,i}) \;=\; 0, \qquad [s_{k,j}]'(x_{k,i}) \;=\; \delta_{ij}/h, \qquad i = 0, \ldots, N,$$

where δ_{ij} is the Kronecker delta. Then

$$\{\phi_{k,1}, \ldots, \phi_{k,K_k}\} \;=\; \{s_{k,0}, v_{k,1}, s_{k,1}, \ldots, v_{k,N_k-1}, s_{k,N_k-1}, s_{k,N_k}\}$$

is a basis for V_k^0, $k = 1, 2$, and basis functions for V^0 are given by (4.1).

The OSC problem (2.5) was solved by Algorithm 5.1 with the initial approximation $\vec{u}_0 = \vec{0}$ and the stopping condition (5.7) with $\epsilon = 10^{-10}$. A linear system with a preconditioner was solved by Algorithm 6.2. Since the partition is uniform, Step 1 of Algorithm 6.2 need not be performed, and we used FFTs to implement Steps 2 and 4.

We tested convergence properties of Algorithm 5.1 with two choices of the preconditioner $\tilde{A}$ of (5.1)–(5.2), the first corresponding to $\tilde{L} = \partial^2/\partial x_1^2 + \partial^2/\partial x_2^2$ and the second to the variable coefficient operator $\tilde{L}$ of (3.4)–(3.5) with

$$\begin{array}{llll} (8.6) & \tilde{a}_1(x_1) = a_{11}(0.5, 0.5), & \tilde{b}_1(x_1) = 0, & \tilde{c}_1(x_1) = 0, \\ & \tilde{a}_2(x_2) = a_{22}(0.5, x_2), & \tilde{b}_2(x_2) = b_2(0.5, x_2), & \tilde{c}_2(x_2) = c(0.5, x_2). \end{array}$$

We refer to these two preconditioners as the Laplacian preconditioner and the variable coefficient preconditioner, respectively. The following cases were tested:

1. selfadjoint negative-definite L ($\alpha = \beta_1 = \beta_2 = \gamma = 0$);
2. selfadjoint indefinite L ($\alpha = \beta_1 = \beta_2 = 0$ and $\gamma = 100$);
3. nonselfadjoint L ($\beta_2 = 100$ and $\alpha = \beta_1 = \gamma = 0$);
4. general L ($\alpha = 0.5$, $\beta_1 = 10$, $\beta_2 = \gamma = 50$).

The numerical results are shown in Table 8.1. We see that PCG with the variable coefficient preconditioner requires fewer iterations than PCG with the Laplacian preconditioner. Moreover, as N increases, the number of PCG iterations grows much slower with the variable coefficient preconditioner than with the Laplacian preconditioner.

In Figure 8.1, we present logarithmic plots of the relative residual curves. The vertical axis represents the values of

$$\log_{10}\left(\|f - Lu_{h,k}\|_{h,\rho}/\|f\|_{h,\rho}\right).$$

For both the Laplacian and the variable coefficient preconditioners, we observe monotone convergence. Curve LP1 shows that the Laplacian preconditioner works quite well for the selfadjoint negative-definite problem, but the Laplacian preconditioner

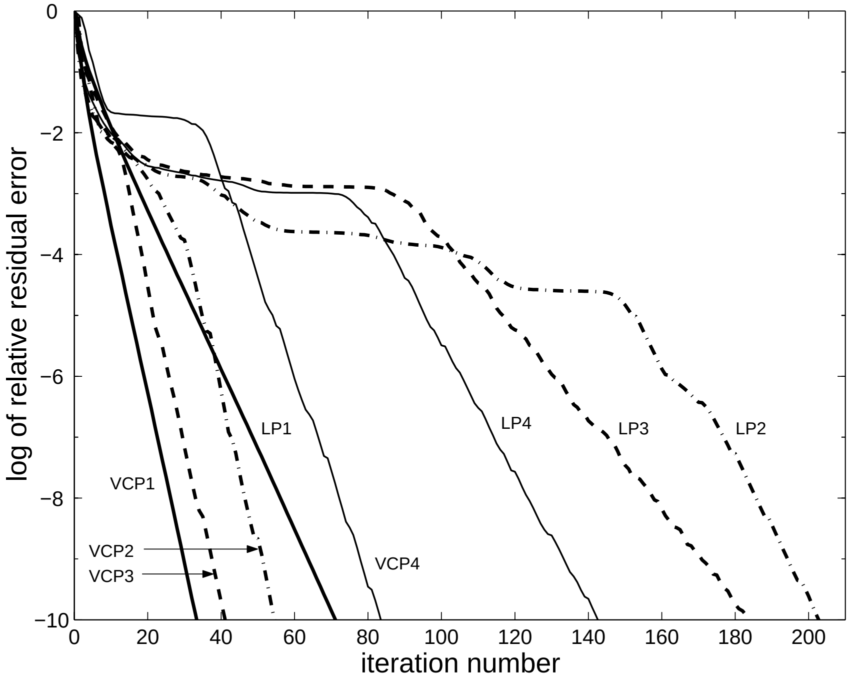

Fig. 8.1. *Logarithmic plots of relative residual curves for Algorithm* 5.1 ($N = 128$)*.* LP# = *Laplacian preconditioner,* VCP# = *variable coefficient preconditioner.* LP1, VCP1 = *selfadjoint negative-definite L;* LP2, VCP2 = *selfadjoint indefinite L;* LP3, VCP3 = *nonselfadjoint L;* LP4, VCP4 = *general L.*

is not so good for the indefinite, the nonselfadjoint, and the general problems (see the plateaus of curves LP2–LP4). The variable coefficient preconditioner does well in all cases (see curves VCP1–VCP4), although, for the general operator L, the curve VCP4 has a plateau as well. We see that curves VCP1–VCP3 are nearly parallel for large iteration numbers, which indicates that the convergence rates of the PCG with the variable coefficient preconditioner are about the same for different types of L. We observe the same behavior for the Laplacian preconditioner for the selfadjoint and the general problems (see curves LP1, LP2, and LP4). We see from curves LP1 and VCP1 that the convergence of PCG for the selfadjoint negative-definite problem is almost linear. We note that, for the first few iterations, the Laplacian preconditioner works well in all cases; for the general problem, even better than the variable coefficient preconditioner. However, for the larger iteration numbers, curve LP4 has a longer plateau and a smaller slope than curve VCP4.

Next we tested convergence properties of OSC for the general L. Let u_h be the computed OSC solution, and let $e_h = u - u_h$. For any v defined on the partition π_h, let $\|v\|_{\pi_h} = \max_{x\in\pi_h} |v(x)|$. We computed the maximal nodal errors $\|\partial^{(i,j)}e_h\|_{\pi_h}$ for $i, j = 0, 1$ and the Sobolev norms $\|e_h\|_{H^i(\Omega)}$ for $i = 0, 1, 2$, and determined approximate convergence orders using

$$\log_2\left(\|\partial^{(i,j)}e_h\|/\|\partial^{(i,j)}e_{h/2}\|\right),$$

Table 8.2

64	1.13E–09	4.02	2.31E–07	3.03	9.60E–05	2.04
128	7.01E–11	4.01	2.87E–08	3.01	2.38E–05	2.01

where $\|\cdot\|$ is $\|\cdot\|_{\pi_h}$ or $\|\cdot\|_{H^i(\Omega)}$. From the results presented in Table 8.2, we observe the expected order 4 for $\|e_h\|_{\pi_h}$ and the orders 4, 4, and 3 for $\|(e_h)_{x_1}\|_{\pi_h}$, $\|(e_h)_{x_2}\|_{\pi_h}$, and $\|(e_h)_{x_1x_2}\|_{\pi_h}$, respectively. The last three orders indicate a superconvergence property of OSC. The results in Table 8.3 demonstrate the expected optimal convergence orders for the Sobolev norms.

9. Conclusions. We have shown that PCG is an efficient algorithm for solving the OSC problem (2.5). The convergence analysis of this algorithm is carried out using an H^2 norm analysis of OSC. The convergence rate of PCG is independent of the partition step size h. The approach allows us to use a preconditioner associated with a nonselfadjoint or an indefinite separable operator $\tilde{L}$. A linear system with the preconditioner can be solved very efficiently using a matrix decomposition algorithm. On a uniform $N \times N$ partition, PCG with a tolerance ϵ requires $\mathrm{O}(N^2 \ln N |\ln \epsilon|)$ operations to obtain the Hermite bicubic spline solution of the OSC problem.

Our future work will involve the construction of nonselfadjoint or indefinite OSC domain decomposition and multilevel preconditioners for the OSC problem (2.5).

Acknowledgment. The authors wish to thank Graeme Fairweather for his assistance during the preparation of this paper.

MONOTONICITY-PRESERVING LINEAR MULTISTEP METHODS*

WILLEM HUNDSDORFER†, STEVEN J. RUUTH‡, AND RAYMOND J. SPITERI§

Abstract. In this paper we provide an analysis of monotonicity properties for linear multistep methods. These monotonicity properties include positivity and the diminishing of total variation. We also pay particular attention to related boundedness properties such as the total variation bounded (TVB) property. In the analysis the multistep methods are considered in combination with suitable starting procedures. This allows for monotonicity statements for classes of methods which are important and often used in practice but which were thus far not covered by theoretical results.

Key words. multistep schemes, monotonicity, positivity, TVD, TVB, strong stability

1. Introduction.

In this paper we shall be concerned with preservation of certain monotonicity properties for systems of ordinary differential equations (ODEs) in $\mathbb{R}^m$, $m \geq 1$,

$$w'(t) = F(w(t)), \quad w(0) = w_0. \tag{1.1}$$

Specifically we are interested in the discrete preservation of these properties by numerical approximations $w_n \approx w(t_n)$, $t_n = n\Delta t$, generated by linear multistep methods. The multistep methods will be considered in combination with suitable starting procedures. Hence for a given problem (1.1) and step size Δt, we can regard the sequence $\{w_n\}_{n\geq 1}$ as being determined by the initial value w_0 only, just as for the true solution of (1.1).

There are a number of closely related monotonicity concepts. In this paper we shall mainly consider the property

$$\|w_n\| \ \leq \ \|w_0\| \qquad \text{for all } n \geq 1,\ w_0 \in \mathbb{R}^m, \tag{1.2}$$

where $\|\cdot\|$ is a given seminorm, such as the total variation over the components; see, for instance, (2.1). Related concepts, such as positivity and contractivity, are considered in the next section. Note that for one-step methods, such as Runge–Kutta methods, property (1.2) is equivalent to

$$\|w_n\| \ \leq \ \|w_{n-1}\| \qquad \text{for all } n \geq 1 \text{ with arbitrary } w_0 \in \mathbb{R}^m. \tag{1.3}$$

The relevant monotonicity property should hold for the ODE system (1.1) itself, of course. In the following we assume that there is a maximal step size $\Delta t_{FE} > 0$, under which (1.3) holds for the forward Euler method,

$$\|v + \Delta t F(v)\| \ \leq \ \|v\| \qquad \text{for all } 0 < \Delta t \leq \Delta t_{FE},\ v \in \mathbb{R}^m, \tag{1.4}$$

and we shall determine constants C_{LM} such that the property is valid for a multistep method with suitable starting procedure under the step size restriction

$$\Delta t \;\le\; C_{LM}\,\Delta t_{FE}. \tag{1.5}$$

In our analysis it is crucial to consider the linear multistep method in combination with suitable starting procedures. If a linear k-step method is considered with *arbitrary* starting vectors $w_1, \ldots, w_{k-1}$, in addition to w_0, then a natural generalization of (1.3) is

$$\|w_n\| \;\le\; \max_{0\le j\le k-1} \|w_j\| \qquad \text{for all } n \ge k,\;\; w_0, w_1, \ldots, w_{k-1} \in \mathbb{R}^m. \tag{1.6}$$

This is a common generalization for the purpose of analyzing multistep methods. However, there is no direct analogy with the analysis of (1.1), where the solution is determined by w_0 only. More importantly, it turns out that the insistence on arbitrary starting vectors severely limits the class of methods for which monotonicity can be demonstrated; for example, the familiar backward differentiation formulae (BDF) and Adams methods are then excluded. Consequently, relevant properties of many popular methods used in practice have not been covered yet by theoretical results.

In section 2 some related monotonicity properties are briefly discussed, together with existing results on multistep methods of the type (1.6) that were obtained in [2, 4, 12, 13, 15, 17]. Then in section 3 we analyze the time-step restrictions for (1.2) of both explicit and implicit two-step methods with various starting procedures. Apart from the monotonicity property (1.2), we also consider related boundedness properties $\|w_n\| \le M\|w_0\|$ with constant $M \ge 1$. In section 4 we extend our analysis to linear multistep methods of higher order. Finally, in section 5 we provide some numerical examples to illustrate our results.

2. Background.

2.1. Related monotonicity concepts. If the ODE system (1.1) is derived from a spatial discretization of a one-dimensional partial differential equation (PDE), then the components $w_j(t)$ of $w(t)$ will approximate the PDE solution $u(x,t)$ at grid points $x = x_j$ or surrounding cells. In that case $w_n = (w_j^n)$ contains the fully discrete method-of-lines approximation to $u(x_j, t_n)$. Consider for vectors $v = (v_j)$ the seminorm $\|v\| = \mathrm{TV}(v)$ given by

$$\mathrm{TV}(v) = \sum_j |v_j - v_{j-1}|. \tag{2.1}$$

We note that this is a seminorm, and not a norm, because $\mathrm{TV}(v)$ may vanish for $v \ne 0$; viz. v_j constant. For a pure initial-value PDE on an unbounded domain, the index j will run over all integers; but in general, boundary or periodicity conditions will result in a finite-dimensional ODE system. If (1.3) is valid, that is, $\mathrm{TV}(w_n) \le \mathrm{TV}(w_{n-1})$, $n \ge 1$, the scheme is called *total variation diminishing* (TVD). With property (1.2) we have

$$\mathrm{TV}(w_n) \;\le\; M\,\mathrm{TV}(w_0), \quad n \ge 1, \tag{2.2}$$

with constant $M = 1$. A scheme satisfying (2.2) with some $M \ge 1$ is called *total variation bounded* (TVB). Although this is formally weaker than TVD, conservative schemes with this boundedness property are known to converge to the correct entropy solutions for hyperbolic conservation laws; see, for instance, [5] for details. If (2.2) holds with $M = 1$, no spatial oscillations can be introduced during the time stepping; such spatial oscillations can be regarded as local overshoots and undershoots. Moreover, the scheme will then also be *monotonicity-preserving* in the sense that if the initial data w_j^0 is monotonically increasing or decreasing in j, then this will be preserved over time [14].

Another property related to avoiding undershoots is *positivity* [2], where it is required that

$$w_n \;\geq\; 0 \quad \text{whenever } w_0 \;\geq\; 0. \tag{2.3}$$

Here inequalities for vectors are to be interpreted componentwise. The corresponding requirement on the forward Euler method then reads

$$v + \Delta t F(v) \;\geq\; 0 \qquad \text{for all } 0 < \Delta t \leq \Delta t_{FE},\;\; v \geq 0. \tag{2.4}$$

Although we shall mainly focus on the relations (1.2), (1.4), results for positivity with (2.3), (2.4) can be derived in the same way. Positivity is often a natural requirement for general ODE systems, not necessarily semidiscrete PDEs, especially if the components $w_j(t)$ represent physical quantities such as mass or chemical concentrations that must be nonnegative by definition.

Further, related to (1.3) one can consider the *contractivity* property where the difference $\|\tilde{w}_n - w_n\|$ between any two sequences is required to be nonincreasing with increasing n [10, 17]. If we are dealing with a genuine norm, this is a strong stability requirement. Recently [4], methods satisfying (1.3) have also been called *strong stability-preserving*, and there is a tradition in the computational gas dynamics literature of referring to TVB, TVD, monotonicity preservation, and other nonlinear conditions as *nonlinear stability* [11]. However, properties like TVD or positivity are not directly related to the classical numerical concept of stability, which deals with growth between two sequences, one of which is viewed as a perturbation of the other. For linear problems we could well associate (1.3) with numerical stability, whereas for general nonlinear problems it may be viewed as a (strong) boundedness property.

Finally, we note that the term *monotonicity* appears in the numerical analysis literature for a variety of related concepts. For example, it is sometimes also used for properties like maximum principles ($\min_j w_j^0 \leq w_j^n \leq \max_j w_j^0$) or comparison principles ($\tilde{w}_0 \leq w_0$ implies $\tilde{w}_n \leq w_n$). In this paper we restrict ourselves to (1.2) and (2.3), but related properties could be studied in a similar way.

2.2. Monotonicity with arbitrary starting values. In this paper we mainly consider explicit linear multistep methods

$$w_n \;=\; \sum_{j=1}^{k} \big(a_j w_{n-j} + b_j \Delta t F(w_{n-j})\big), \quad n \geq k, \tag{2.5}$$

where starting vectors $w_0, w_1, \ldots, w_{k-1}$ are either given or computed by an appropriate starting procedure. Consistency of the method implies that

$$\sum_{j=1}^{k} a_j \;=\; 1. \tag{2.6}$$

Assume for the moment that all $a_j, b_j \geq 0$. By regarding the step (2.5) as a linear combination of scaled forward Euler steps,

$$w_n \;=\; \sum_{j=1}^{k} a_j \,\big(w_{n-j} + c_j \Delta t F(w_{n-j})\big), \qquad c_j = \frac{b_j}{a_j}, \tag{2.7}$$

it easily follows that

$$\|w_n\| \;\leq\; \max_{1\leq j\leq k} \|w_{n-j}\| \tag{2.8}$$

will hold under (1.4) with the step size restriction

$$\Delta t \;\leq\; K_{\scriptscriptstyle LM}\,\Delta t_{\scriptscriptstyle FE}, \qquad K_{\scriptscriptstyle LM} = \min_{1\leq j\leq k}\left(\frac{a_j}{b_j}\right) \quad \text{if } a_j, b_j \geq 0 \text{ for all } j. \tag{2.9}$$

By convention, terms of the form 0/0 should be omitted in the minimization, and if some coefficient a_j, b_j is negative, we leave $K_{\scriptscriptstyle LM}$ undefined. Note that (2.8) can also be formulated equivalently as (1.6).

This result, obtained with scaled forward Euler steps, is due to Shu [15], where it was formulated with total variations. Related results for multistep methods were derived by Bolley and Crouzeix [2] in terms of positivity for linear systems. Contractivity for linear systems was studied by Spijker [17] and Lenferink [12, 13]. The results in [2, 4, 13, 17] also cover implicit methods; we discuss implicit methods in some detail in section 3.

However, these results exclude many schemes that are useful in practice, and also may give unnecessary step size restrictions. This is due to the fact that (2.8) should hold with *arbitrary* initial vectors $w_0, w_1, \ldots, w_{k-1}$. As a simple example, consider the familiar BDF2 method applied to the trivial problem $w'(t) = 0$. Then

$$w_2 = \frac{4}{3}w_1 - \frac{1}{3}w_0.$$

It is obvious that one cannot have $w_2 \geq 0$ for arbitrary $w_0, w_1 \geq 0$. Likewise, it is not always possible to have $\|w_2\| \leq \|w_0\|$ whenever $\|w_1\| \leq \|w_0\|$. On the other hand, it is also clear that only the choice $w_1 = w_0$ makes sense for this trivial problem, in which case the inequality $\|w_2\| \leq \|w_0\|$ trivially holds. For this reason we shall analyze the monotonicity properties of multistep schemes with suitable starting procedures. As a result, schemes like BDF2 can be included in the theory.

Remark 2.1. To arrive at (2.9), the assumption $a_j \geq 0$ is necessary to have a convex combination of scaled forward Euler steps. The assumption $b_j \geq 0$ is then needed to ensure that the scaled step sizes $c_j\Delta t$ are nonnegative. As noted in [15, 16], the latter assumption can be avoided for discretizations of the conservation law

$$u_t + f(u)_x = 0,$$

by first applying the discretization in time followed by the spatial discretization (i.e., a transverse method-of-lines discretization), instead of starting with the semidiscrete system $w' = F(w)$. The only modification to our previous treatment is that if some $b_j < 0$, then $F(w_{n-j})$ in (2.5) should be replaced by $\tilde{F}(w_{n-j})$, where $w' = -\tilde{F}(w)$ is the semidiscretization of

$$u_t - f(u)_x = 0,$$

that is, of the equation with reversed time. Its realization in practice is simply a reversal of the upwind direction in the spatial discretization. Along with (1.4), we then also assume

$$\|v - \Delta t\tilde{F}(v)\| \;\le\; \|v\| \qquad \text{for all } 0 < \Delta t \le \Delta t_{\scriptscriptstyle FE},\;\; v \in \mathbb{R}^m, \tag{2.10}$$

and this counteracts the negativity of a_j/b_j in (2.7). Instead of (2.9), this modification will give the step size restriction

$$\Delta t \;\le\; \tilde{K}_{\scriptscriptstyle LM}\,\Delta t_{\scriptscriptstyle FE}, \qquad \tilde{K}_{\scriptscriptstyle LM} = \min_{1\le j\le k}\left(\frac{a_j}{|b_j|}\right) \quad \text{if } a_j \ge 0 \text{ for all } j \tag{2.11}$$

to achieve (2.8). □

3. Two-step methods.

3.1. Reformulations. In this section we derive monotonicity results for two-step methods, including some familiar implicit methods [1, 7]. The standard form is written as

$$w_n - b_0\Delta tF_n \;=\; a_1w_{n-1} + a_2w_{n-2} + b_1\Delta tF_{n-1} + b_2\Delta tF_{n-2}, \qquad n \ge 2, \tag{3.1}$$

where $F_{n-j} = F(w_{n-j})$. To obtain precise results, this recursion will be fully written out to include the starting values. Let $\theta \ge 0$ be a parameter to be specified later. Then the two-step recursion can be written in three-step form as

$$\begin{aligned} w_n - b_0\Delta tF_n \;=\; &(a_1-\theta)w_{n-1} + (b_1+\theta b_0)\Delta tF_{n-1} + (a_2+\theta a_1)w_{n-2} \\ &+ (b_2+\theta b_1)\Delta tF_{n-2} + \theta a_2w_{n-3} + \theta b_2\Delta tF_{n-3}, \qquad n \ge 3. \end{aligned}$$

Continuing this way, by subtracting and adding $\theta^j w_{n-j}$ and using (3.1), we arrive at

$$\begin{aligned} w_n - b_0\Delta tF_n \;=\; &(a_1-\theta)w_{n-1} + (b_1+\theta b_0)\Delta tF_{n-1} \\ &+ \sum_{j=2}^{n-2}\theta^{j-2}\big((a_2+\theta a_1-\theta^2)w_{n-j} + (b_2+\theta b_1+\theta^2 b_0)\Delta tF_{n-j}\big) \\ &+ \;\theta^{n-3}\big((a_2+\theta a_1)w_1 + (b_2+\theta b_1)\Delta tF_1 + \theta a_2w_0 + \theta b_2\Delta tF_0\big). \end{aligned} \tag{3.2}$$

This formula is valid for all $n \ge 3$, with empty sums naturally defined as zero. The reformulation (3.2) will be the basis for our derivations. To bound the last term in (3.2), together with w_1, w_2, appropriate starting procedures will be considered. Further, we shall determine θ so as to obtain nonnegative coefficients

$$a_1-\theta \ge 0, \quad a_2+\theta(a_1-\theta) \ge 0, \quad b_1+\theta b_0 \ge 0, \quad b_2+\theta(b_1+\theta b_0) \ge 0, \tag{3.3}$$

with optimal ratio $r(\theta)$ given by

$$r_1(\theta) = \frac{a_1-\theta}{b_1+\theta b_0}, \quad r_2(\theta) = \frac{a_2+\theta(a_1-\theta)}{b_2+\theta(b_1+\theta b_0)}, \quad r(\theta) = \min(r_1(\theta), r_2(\theta)). \tag{3.4}$$

As before, values 0/0 are ignored when taking the minimum.

3.2. Explicit second-order two-step methods. The maximal size of the threshold factor K_{LM} in (2.9) for explicit k-step methods of order p has been analyzed by Lenferink [12]. For explicit methods of order $p = 1$, we have $K_{LM} \leq 1$, a bound which is already attained by Euler's method. For explicit methods with $k \geq 2$, Lenferink showed that

$$K_{LM} \leq \frac{k-p}{k-1}. \tag{3.5}$$

Hence $K_{LM} > 0$ is not possible for second-order explicit two-step methods. By allowing $b_2 < 0$, Shu [15] obtained an explicit two-step method with $p = 2$, $\tilde{K}_{LM} = \frac{1}{2}$. However, this result is applicable only to semidiscretizations of conservation laws. Moreover, with $b_1 > 0$, $b_2 < 0$, both F_j and $\tilde{F}_j$ have to be calculated in the process, making the scheme twice as expensive computationally as the standard form (3.1).

Here we consider the monotonicity property (1.2) for schemes (3.1), and optimal threshold factors C_{LM} will be derived for second-order explicit two-step methods combined with suitable starting procedures. The main assumptions on the starting procedures will be

$$\begin{aligned} &\|w_1\| \leq M\|w_0\|, \qquad \|w_2\| = \|a_1 w_1 + b_1 \Delta t F_1 + a_2 w_0 + b_2 \Delta t F_0\| \leq M\|w_0\|, \\ &\|(a_2 + \theta a_1) w_1 + (b_2 + \theta b_1)\Delta t F_1 + \theta a_2 w_0 + \theta b_2 \Delta t F_0\| \leq (a_2 + \theta) M \|w_0\| \end{aligned} \tag{3.6}$$

for a given step size $\Delta t > 0$ and with $M = 1$. To derive weaker properties, such as (2.2), constants $M > 1$ will also be allowed.

Lemma 3.1. *Assume that* (1.4) *holds. Let $\theta \geq 0$ satisfy* (3.3), *and let $r(\theta)$ be given by* (3.4) *with $b_0 = 0$. Suppose that $\Delta t \leq r(\theta)\Delta t_{FE}$ and* (3.6) *holds with $M \geq 1$. Then*

$$\|w_n\| \leq M\|w_0\| \quad \textit{for all } n \geq 1. \tag{3.7}$$

Proof. From (3.2) and (3.3) we obtain

$$\|w_n\| \leq (a_1 - \theta)\|w_{n-1}\| + \sum_{j=2}^{n-2} \theta^{j-2}\big(a_2 + \theta a_1 - \theta^2\big)\|w_{n-j}\| + \theta^{n-3}(a_2 + \theta) M \|w_0\|.$$

By assumption, the lemma is valid for $n = 1, 2$. Since we have, in view of (2.6), the relation

$$(a_1 - \theta) + \sum_{j=2}^{n-2} \theta^{j-2}\big(a_2 + \theta a_1 - \theta^2\big) + \theta^{n-3}(a_2 + \theta) = 1, \quad n \geq 3,$$

the proof now follows easily by induction. □

To apply this lemma to specific methods, we shall determine θ to obtain an optimal constant

$$C^*_{LM} = \max\{\, r(\theta) : \theta \text{ satisfies } (3.3)\,\}. \tag{3.8}$$

This will give a step size restriction $\Delta t \leq C^*_{LM}\Delta t_{FE}$, which is intrinsic for the specific two-step method. The requirement (3.6) with $M = 1$ may give an additional restriction, say $\Delta t \leq C^0_{LM}\Delta t_{FE}$, depending on the starting procedure and the coefficients of the multistep method. For the combined scheme we then obtain the monotonicity property (1.2) under the step size restriction (1.5) with

$$C_{LM} \;=\; \min\{C^0_{LM}, C^*_{LM}\}. \tag{3.9}$$

The above derivation will be applied to explicit second-order two-step methods, which constitute a one-parameter family given by (3.1) with $b_0 = 0$ and

$$a_1 = 2-\xi, \quad a_2 = \xi - 1, \quad b_1 = 1 + \frac{1}{2}\xi, \quad b_2 = \frac{1}{2}\xi - 1. \tag{3.10}$$

The methods in this class are zero-stable if and only if $0 < \xi \le 2$, and we shall restrict ourselves to these parameter values. Examples of practical interest are the two-step Adams–Bashforth method ($\xi = 1$) and the extrapolated BDF2 method ($\xi = \frac{2}{3}$). With this class of second-order methods it follows, by a straightforward but somewhat tedious calculation, that optimality in (3.8) is attained by setting $b_2 + \theta b_1 = 0$, which gives

$$\theta \;=\; \frac{2-\xi}{2+\xi}, \qquad C^*_{LM} \;=\; \frac{2(1+\xi)(2-\xi)}{(2+\xi)^2}. \tag{3.11}$$

To obtain a complete bound (3.9), various starting procedures will be considered next.

Remark 3.2. In the remainder of this section we shall focus primarily on condition (3.6) with $M = 1$. For these results all coefficients in the occurring expressions will be required to be nonnegative. Consequently, results on positivity (2.3) with (2.4) can be derived under the same assumptions.

We shall also derive results with $M > 1$. These will only be qualitative. Precise bounds for M can be obtained by using

$$\max_{\Delta t \le C \Delta t_{FE}} \|v + \gamma \Delta t F(v)\| \;\le\; \max\{1, |2\gamma C - 1|\}\, \|v\| \tag{3.12}$$

for arbitrary $C > 0$, $\gamma \in \mathbb{R}$, and $v \in \mathbb{R}^m$. This relation is an obvious consequence of (1.4) if $0 \le \gamma C \le 1$. For values γC outside the interval $[0, 1]$, it follows by using in addition the implication $\Delta t_{FE}\, \|F(v)\| \le 2\, \|v\|$ from (1.4). □

3.2.1. Starting with the forward Euler method. The natural candidate to compute the starting vector w_1 for an explicit two-step method of order $p = 2$ is the forward Euler method

$$w_1 = w_0 + \Delta t F_0.$$

Of course, the forward Euler method itself is only first-order accurate; but because it is applied only once, the accuracy of the combined scheme will still be of order two.

With this starting procedure the first condition in (3.6) holds with $M = 1$ for $\Delta t \le \Delta t_{FE}$, of course. The second condition, $\|w_2\| \le M\|w_0\|$, can be written as

$$\|(a_1 - \tilde\theta) w_1 + b_1 \Delta t F_1 + (a_2 + \tilde\theta) w_0 + (b_2 + \tilde\theta)\Delta t F_0\| \le M \|w_0\|,$$

where an optimal $\tilde\theta$ should be selected. With $M = 1$ it is easily seen that the optimal value is $\tilde\theta = \frac{1}{2}(2-\xi)$, under which the inequality holds for all step sizes

$$\Delta t \;\le\; \frac{2-\xi}{2+\xi}\, \Delta t_{FE}. \tag{3.13}$$

With larger step sizes we will have a bound with $M > 1$. We note that this step size restriction for $M = 1$ is more stringent than $\Delta t \le C^*_{LM} \Delta t_{FE}$ for any $\xi \in (0, 2)$. Finally, with θ given by (3.11), the third condition in (3.6) reads

$$\|(a_2 + \theta)w_0 + (a_2 + \theta a_1 + \theta b_2)\Delta t F_0\| \;\le\; (a_2 + \theta)M\,\|w_0\|,$$

which can be written here as

$$\left\| w_0 + \frac{1}{2\xi}(3\xi - 2)\Delta t F_0 \right\| \;\le\; M\,\|w_0\|.$$

Hence $M = 1$ now requires

$$\Delta t \;\le\; \frac{2\xi}{3\xi - 2}\,\Delta t_{FE}, \qquad \xi \ge \frac{2}{3}. \tag{3.14}$$

If either the step size is allowed to be larger or $0 < \xi < \frac{2}{3}$, then we obtain a bound with $M > 1$ (see Remark 3.2), where it should be mentioned that we will have $M \sim \xi^{-1}$ for $\xi \downarrow 0$. We note that for $\xi \ge \frac{2}{3}$ the restriction (3.14) is less stringent than (3.13). The above results can be summarized as follows.

THEOREM 3.3. *Consider the explicit second-order two-step method* (3.1), (3.10), *and let w_1 be computed by the forward Euler method. Then the monotonicity property* (1.2) *will hold under* (1.4) *with the restriction*

$$\Delta t \;\le\; \frac{2 - \xi}{2 + \xi}\,\Delta t_{FE}\,, \qquad \frac{2}{3} \le \xi \le 2\,.$$

Under (1.4) *with the weaker restriction*

$$\Delta t \;\le\; \frac{2(1 + \xi)(2 - \xi)}{(2 + \xi)^2}\,\Delta t_{FE}, \qquad 0 < \xi \le 2,$$

the boundedness property (3.7) *will hold with $M \ge 1$.*

3.2.2. A modified two-step starting procedure. The use of the forward Euler method as starting procedure for the second-order two-step methods (3.1), (3.10) leads to a step size restriction for monotonicity that is more stringent than $\Delta t \le C^*_{LM} \Delta t_{FE}$. Similar restrictions were obtained with standard two-stage Runge–Kutta methods.

As an alternative starting procedure that can be used for semidiscrete conservation laws following Remark 2.1, we compute w_1 with the forward Euler method but use for the second step a modified scheme,

$$w_1 = w_0 + \Delta t F_0\,, \;\; w_2 = a_1 w_1 + a_2 w_0 + b_1 \Delta t F_1 + \alpha b_2 \Delta t F_0 + (1 - \alpha) b_2 \Delta t \tilde{F}_0, \tag{3.15}$$

where $\tilde{F}_0 = \tilde{F}(w_0)$ and $\alpha \in [0, 1]$ is to be determined later. We assume $\tilde{F}$ satisfies (2.10). We note that because $\tilde{F}$ is evaluated only once (for w_0), the computational costs will not increase significantly.

Consider the optimal θ value (3.11), for which $b_2 + \theta b_1 = 0$. With the modified second step, it follows that (3.2) with $b_0 = 0$ will change accordingly to

$$\begin{aligned} w_n = (a_1 - \theta)w_{n-1} + b_1 \Delta t F_{n-1} + \sum_{j=2}^{n-1} \theta^{j-2}(a_2 + \theta a_1 - \theta^2) w_{n-j} \\ + \theta^{n-2}\Big(\theta w_1 + a_2 w_0 + \alpha b_2 \Delta t F_0 + (1 - \alpha) b_2 \Delta t \tilde{F}_0\Big). \end{aligned}$$

If the last term can be bounded by $\theta^{n-2}(a_2+\theta)\|w_0\|$ and if $\|w_1\| \le \|w_0\|$, the result of Lemma 3.1 will remain valid with $M=1$. With the forward Euler approximation w_1, we thus get the requirement

$$\|(a_2+\theta)w_0 + (\alpha b_2+\theta)\Delta t F_0 + (1-\alpha)b_2 \Delta t \tilde{F}_0\| \;\le\; (a_2+\theta)\|w_0\| \tag{3.16}$$

for $\Delta t \le C^0_{\scriptscriptstyle LM}\Delta t_{\scriptscriptstyle FE}$, where an optimal $C^0_{\scriptscriptstyle LM} \in (0,1]$ will be selected by a favorable choice of the parameter α.

The contribution of F_0 in this inequality is minimized by taking $\alpha = -\theta/b_2 = 1/b_1$. By using (2.10), it then follows that $\|w_1\| \le \|w_0\|$ and (3.16) will be satisfied for $\Delta t \le C^0_{\scriptscriptstyle LM}\Delta t_{\scriptscriptstyle FE}$ with

$$C^0_{\scriptscriptstyle LM} = \min\left\{1, \frac{2\xi}{2-\xi}\right\}.$$

Taking $C_{\scriptscriptstyle LM} = \min\{C^0_{\scriptscriptstyle LM}, C^*_{\scriptscriptstyle LM}\}$, we can summarize this result as follows.

THEOREM 3.4. *Consider the explicit second-order two-step method* (3.1), (3.10) *for* $n \ge 3$*, and let* w_1, w_2 *be computed by* (3.15) *with* $\alpha = 1/b_1$*. Then the monotonicity property* (1.2) *will hold under* (1.4) *and* (2.10) *with the step size restriction*

$$\Delta t \;\le\; C_{\scriptscriptstyle LM}\,\Delta t_{\scriptscriptstyle FE}, \qquad C_{\scriptscriptstyle LM} \;=\; \begin{cases} \dfrac{2\xi}{2-\xi} & \text{if} \quad 0<\xi<\dfrac{1}{\frac12+\sqrt{2}}, \\[2ex] \dfrac{2(1+\xi)(2-\xi)}{(2+\xi)^2} & \text{if} \quad \dfrac{1}{\frac12+\sqrt{2}} \le \xi \le 2. \end{cases}$$

If the step size restriction in this theorem for $\xi < 1/(\frac12+\sqrt{2})$ is not satisfied, but still $\Delta t \le C^*_{\scriptscriptstyle LM}\Delta t_{\scriptscriptstyle FE}$, then we will have, as with other starting procedures, the boundedness property (3.7) with $M>1$.

A somewhat related result was obtained in [9] for the extrapolated BDF2 method ($\xi = \frac23$) in the so-called one-leg form. For that particular method it was demonstrated that (1.2) holds for all $\Delta t \le C^*_{\scriptscriptstyle LM}\Delta t_{\scriptscriptstyle FE}$, provided that an appropriate two-stage Runge–Kutta starting method is used. Also it was observed in [9] that this implies boundedness of $\|w_n\|$ for the standard multistep form (3.1) of the extrapolated BDF2 method if a special starting procedure is used. From the above we see that the boundedness property holds for any starting procedure and all $0<\xi\le 2$.

3.3. Implicit second-order two-step methods. In this section we consider the implicit two-step methods of order 2. These methods form a two-parameter family with coefficients

$$a_1 = 2-\xi, \;\; a_2 = \xi-1, \;\; b_0=\eta, \;\; b_1 = 1+\frac12\xi-2\eta, \;\; b_2 = \eta+\frac12\xi-1. \tag{3.17}$$

As for the explicit methods (3.10), we need $0<\xi\le 2$ for zero-stability. The methods are A-stable if and only if in addition $\eta \ge \frac12$. If $\eta=\frac12$, these methods are reducible to the trapezoidal rule, in the sense that if w_1 is calculated by the trapezoidal rule, then the whole sequence $\{w_n\}$ will satisfy the trapezoidal rule recurrence; see [3, 7]. Two interesting subclasses in (3.17) are $\xi=\frac23$, giving BDF2-type methods, and $\xi=1$, giving implicit two-step Adams methods.

In order to deal with implicit terms in (3.1), we shall use, in addition to (1.4),

$$\|v\| \;\le\; \|v-\Delta t F(v)\| \qquad \text{for all } \Delta t>0,\;\; v\in\mathbb{R}^m. \tag{3.18}$$

This can be interpreted as a condition on the implicit Euler method: $\|v_1\| \le \|v_0\|$ if $v_1 = v_0 + \Delta t F(v_1)$. It might appear that (3.18) should be imposed as an additional assumption to (1.4), but it is in fact a simple consequence. From $v_1 = v_0 + \Delta t F(v_1)$ it follows that

$$\left(1 + \frac{\Delta t}{\Delta t_{FE}}\right) v_1 \;=\; v_0 + \frac{\Delta t}{\Delta t_{FE}} \left(v_1 + \Delta t_{FE} F(v_1)\right) \,,$$

$$\left(1 + \frac{\Delta t}{\Delta t_{FE}}\right) \|v_1\| \;\le\; \|v_0\| + \frac{\Delta t}{\Delta t_{FE}} \|v_1\| \,,$$

and hence $\|v_1\| \le \|v_0\|$ for any $\Delta t > 0$. Thus under (1.4), the implicit Euler method gives the monotonicity property (1.2) without any step size restriction. However, this is only a first-order method, and for practical applications higher accuracy is often required. In the following we therefore concentrate on the class of second-order methods (3.17).

It was shown by Lenferink [13], in terms of contractivity for linear systems, that the threshold value K_{LM} in (2.9) is bounded by 2 for all two-step methods of order $p > 1$. The optimal $K_{LM} = 2$ is attained by the trapezoidal rule. In view of the results for explicit methods, one might hope that such severe restrictions could be circumvented in our formulation (1.2) with suitable starting procedures. Using (3.18), we can follow the derivation of Lemma 3.1, just as for explicit methods. Depending on the starting procedure, according to (3.6), this will give monotonicity (1.2) or boundedness (3.7) for $\Delta t \le r(\theta)\Delta t_{FE}$. We now consider the factors C^*_{LM} that are obtained by optimal values for θ in (3.8).

Determination of the optimal factors C^*_{LM} in analytical form is cumbersome, even if we restrict ourselves to subclasses such as $\xi = \frac{2}{3}$ and $\xi = 1$. On the other hand, numerically it is easy to compute the optimal θ values in (3.8). The corresponding threshold values C^*_{LM} are given in Figure 3.1 for $\xi = \frac{2}{3}, 1$ as function of η. We note that $C^*_{LM} = \frac{1}{2}$ for the familiar implicit BDF2 method ($\xi = \eta = \frac{2}{3}$).

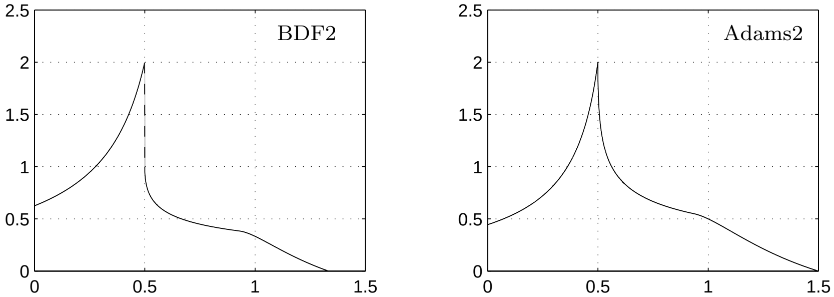

FIG. 3.1. *Threshold values C^*_{LM} versus $\eta \in [0, 1.5]$, with $\xi = \frac{2}{3}$ (left) and $\xi = 1$ (right).*

The results are rather disappointing. The largest numbers $C^*_{LM} = 2$ are found for the values $\eta = \frac{1}{2}$, and numerical verification shows that the same also holds with other choices of $\xi \in (0, 2]$. With $\eta = \frac{1}{2}$ the function r_2 in (3.4) has a removable singularity, which is related to the reducibility of the method, and this is the reason why the curves for $\eta < \frac{1}{2}$ and $\eta > \frac{1}{2}$ are very different, even having a discontinuity for the case $\xi = \frac{2}{3}$.

Of course, for a complete bound, suitable starting procedures such as the implicit Euler method should also be taken into account. However, the main result is that we obtain restrictions that are hardly better than those for explicit methods, and such restrictions have been confirmed in numerical experiments [8]. For practical purposes this means that the implicit schemes are not competitive with the explicit ones if monotonicity properties like (1.2) or (2.3) are crucial in an application. For this reason we shall restrict ourselves in the following section to explicit methods.

Remark 3.5. For the class of BDF2-type methods, threshold values for monotonicity were calculated analytically in [8] for linear, constant-coefficient problems $w'(t) = Aw(t)$. The curve in Figure 3.1 with $\xi = \frac{2}{3}$ almost coincides with the linear result for $\eta \lesssim 0.9$, but for larger η an extra condition sets in due to nonlinearity. For linear systems the restrictions in (3.3) can be relaxed by allowing negative values for $b_0 + \theta b_1$ and $b_2 + \theta(b_0 + \theta b_1)$.

The essential difference between linear and nonlinear results is most easily illustrated by the simple one-step method

$$w_n - \eta \Delta t F_n = w_{n-1} + (1-\eta)\Delta t F_{n-1}, \tag{3.19}$$

with parameter $\eta \geq 0$, whose stability function is given by

$$R(z) = (1-\eta z)^{-1}(1 + (1-\eta)z).$$

Let γ be the largest number such that R and all its derivatives are nonnegative on $[-\gamma, 0]$. It has been shown in [2, 17] (in terms of positivity and contractivity) that the monotonicity property (1.2) will hold under (1.4) for linear systems $w'(t) = Aw(t)$, provided that $\Delta t \leq \gamma \Delta t_{FE}$. Thus for linear problems we get the restriction

$$\Delta t \ \leq \ \gamma \, \Delta t_{FE}, \qquad \gamma = \begin{cases} (1-\eta)^{-1} & \text{if } \eta < 1, \\ \infty & \text{if } \eta \geq 1. \end{cases}$$

On the other hand, for nonlinear problems the optimal condition is seen to be

$$\Delta t \ \leq \ C \, \Delta t_{FE}, \qquad C = \begin{cases} (1-\eta)^{-1} & \text{if } \eta < 1, \\ \infty & \text{if } \eta = 1, \\ 0 & \text{if } \eta > 1. \end{cases}$$

Note that for $\eta > 1$ the coefficient in front of F_{n-1} becomes negative. For linear problems this can be counteracted by the implicit term, but for general nonlinear problems we need this coefficient to be nonnegative. □

4. Higher-order methods. This section contains derivations of boundedness results for various important higher-order explicit linear multistep methods: the extrapolated BDF and explicit Adams methods of order three or greater. To study the boundedness property (3.7), with $M \geq 1$, it is not necessary to specify the starting schemes: although the value of M may vary according to the choice of starting procedure, the boundedness property itself is independent of this choice.

4.1. Reformulations. We begin with a reformulation for the explicit multistep schemes. This is similar to formula (3.2) for two-step schemes, but to obtain proper step size restrictions different θ_j will be used in the various stages. To keep the presentation concise we give the reformulation here in detail only for three-step schemes. Consider (2.5) with $k = 3$. Then by subtracting and adding $\theta_1 \ldots \theta_j w_{n-j}$,

$j = 1, 2, \ldots, n-3$, substituting w_{n-j} in terms of $w_{n-j-1}, \ldots, w_{n-j-3}$, and collecting terms, it follows that w_n can be expressed as

$$w_n = \sum_{j=1}^{n-3} \big(\alpha_j w_{n-j} + \beta_j \Delta t F_{n-j}\big) + \sum_{i=0}^{2} \big(\rho_{i,n} w_i + \sigma_{i,n} \Delta t F_i\big), \tag{4.1}$$

where the coefficients α_j, β_j are given by

$$\alpha_1 = a_1 - \theta_1, \quad \alpha_2 = a_2 + a_1\theta_1 - \theta_1\theta_2, \quad \alpha_3 = a_3 + a_2\theta_1 + a_1\theta_1\theta_2 - \theta_1\theta_2\theta_3,$$

$$\alpha_j = \left(\prod_{k=1}^{j-3} \theta_k\right) (a_3 + a_2\theta_{j-2} + a_1\theta_{j-2}\theta_{j-1} - \theta_{j-2}\theta_{j-1}\theta_j), \quad j \geq 4,$$

$$\beta_1 = b_1, \quad \beta_2 = b_2 + b_1\theta_1, \quad \beta_3 = b_3 + b_2\theta_1 + b_1\theta_1\theta_2,$$

$$\beta_j = \left(\prod_{k=1}^{j-3} \theta_k\right) (b_3 + b_2\theta_{j-2} + b_1\theta_{j-2}\theta_{j-1}), \quad j \geq 4.$$

We shall take $\theta_i \geq 0$ such that

$$\alpha_j \geq 0, \quad \beta_j \geq 0 \qquad \text{for all } j \geq 1, \tag{4.2}$$

and we define

$$C^*_{LM} = \max_{\{\theta_i\}_{i\geq 1}} \min_{j\geq 1} \frac{\alpha_j}{\beta_j}. \tag{4.3}$$

Then it follows, similar to Lemma 3.1, that the boundedness property (3.7) will hold with $M \geq 1$ under the step size restriction $\Delta t \leq C^*_{LM} \Delta t_{FE}$. To obtain results on monotonicity (1.2), that is, $M = 1$, it is also necessary to study the coefficients $\rho_{i,n}$, $\sigma_{i,n}$ of the remainder term in (4.1) and to include specific starting procedures.

For k-step methods with $k \geq 4$ we can proceed similarly. In the above reformulation (4.1) we get the same expressions for α_1, α_2, α_3 and β_1, β_2, β_3; the other α_j, β_j will then involve more terms.

4.2. Boundedness and TVB. First we give the step size restrictions for boundedness and the related TVB property for the third-order extrapolated BDF3 scheme

$$w_n = \frac{18}{11} w_{n-1} - \frac{9}{11} w_{n-2} + \frac{2}{11} w_{n-3} + \frac{18}{11} \Delta t F_{n-1} - \frac{18}{11} \Delta t F_{n-2} + \frac{6}{11} \Delta t F_{n-3} \tag{4.4}$$

and the fourth-order extrapolated BDF4 scheme

$$\begin{aligned} w_n \ = \ & \frac{48}{25} w_{n-1} - \frac{36}{25} w_{n-2} + \frac{16}{25} w_{n-3} - \frac{3}{25} w_{n-4} \\ & + \frac{48}{25} \Delta t F_{n-1} - \frac{72}{25} \Delta t F_{n-2} + \frac{48}{25} \Delta t F_{n-3} - \frac{12}{25} \Delta t F_{n-4}. \end{aligned} \tag{4.5}$$

THEOREM 4.1. *Assume that* (1.4) *holds. The extrapolated BDF*3 (4.4) *scheme satisfies the boundedness property* (3.7) *with* $M \geq 1$, *provided* $\Delta t \leq \frac{7}{18} \Delta t_{FE}$. *For the extrapolated BDF*4 (4.5) *scheme the boundedness property will hold if* $\Delta t \leq \frac{7}{32} \Delta t_{FE}$. *These values* $\frac{7}{18}, \frac{7}{32}$ *are optimal within* (4.2), (4.3).

Proof. Consider (4.4). We first maximize α_1/β_1 over the constraint $\beta_2 \geq 0$ to get $\theta_1 = 1$. This also maximizes α_2/β_2; so next we maximize α_3/β_3 over the constraints

$\alpha_2 \geq 0, \beta_3 \geq 0$ to get $\theta_2 = \frac{2}{3}$. Maximizing α_4/β_4 over the constraints $\alpha_3 \geq 0, \beta_4 \geq 0$ gives $\theta_3 = \frac{1}{2}$. We can now set the remaining $\theta_j = \frac{1}{2}$, $j \geq 4$, because this choice is admissible in the sense of (4.2) and does not contribute to the step size restriction; indeed, $\frac{1}{2}$ is the value that minimizes the factor $(b_3 + b_2\theta_{j-2} + b_1\theta_{j-2}\theta_{j-1})$ in β_j, $j \geq 4$. Since

$$\min_{j\geq 1} \frac{\alpha_j}{\beta_j} \;=\; \min\left\{\frac{\alpha_1}{\beta_1}, \frac{\alpha_2}{\beta_2}, \frac{\alpha_3}{\beta_3}, \frac{\alpha_4}{\beta_4}, \frac{\alpha_5}{\beta_5}\right\} \;=\; \frac{\alpha_1}{\beta_1} \;=\; \frac{7}{18},$$

and we first optimized over α_1/β_1, we see that $C^*_{LM} = \frac{7}{18}$.

The result for the extrapolated BDF4 scheme follows in a similar manner, except that an admissible value for θ_3 is more difficult to find; for this we used a numerical search. We remark that in both cases the constant M will depend on the choice of starting procedure used. □

Another popular class of methods is formed by the explicit k-step Adams methods with order $p = k$. The third-order method is

$$w_n = w_{n-1} + \frac{23}{12}\Delta t F(w_{n-1}) - \frac{16}{12}\Delta t F(w_{n-2}) + \frac{5}{12}\Delta t F(w_{n-3}), \tag{4.6}$$

and the coefficients a_j, b_j for the higher-order methods can be found in [6], for example. For these methods the results are less favorable than for the extrapolated BDF schemes.

Theorem 4.2. *Assume that* (1.4) *holds. The explicit three-step Adams method* (4.6) *satisfies the boundedness property* (3.7) *with* $M \geq 1$*, provided* $\Delta t \leq \frac{84}{529}\Delta t_{FE}$. *For the explicit Adams methods with* $k \geq 4$*, no positive* C^*_{LM} *value in* (4.3) *exists.*

Proof. To have $\beta_2 \geq 0$ we need $\theta_1 \geq -b_2/b_1$, and consequently

$$\frac{\alpha_1}{\beta_1} \;\leq\; \frac{1 + b_2/b_1}{b_1} \;=\; \frac{1}{b_1^2}\big(b_1 + b_2\big).$$

If $k = 3$ we have $b_1 = \frac{23}{12}$ and $b_2 = -\frac{16}{12}$, leading to $C^*_{LM} \leq \frac{84}{529}$. Moreover, it follows by some simple calculations that this upper bound is attained by taking all $\theta_i = \frac{16}{23}$.

To show that we cannot have $C^*_{LM} > 0$ if $k \geq 4$, note that the k-step explicit Adams method may be written as

$$w_n \;=\; w_{n-1} + \Delta t \sum_{j=0}^{k-1} \gamma_j \nabla^j F_{n-1},$$

where ∇^j represent the usual backward differences and the γ_j are positive constants given in [6, section III.1]. A straightforward calculation for $k \geq 4$ shows that

$$b_1 \;=\; \sum_{j=0}^{k-1} \gamma_j \;=\; \frac{55}{24} + \sum_{j=4}^{k-1} \gamma_j, \qquad b_2 \;=\; -\sum_{j=0}^{k-1} j\gamma_j \;=\; -\frac{59}{24} - \sum_{j=4}^{k-1} j\gamma_j.$$

Therefore $b_1 + b_2 \leq \frac{-4}{24} < 0$, implying that $\alpha_1/\beta_1 < 0$. Hence the scheme does not possess a positive threshold value C^*_{LM}. □

Remark 4.3. Following the same lines, it is also straightforward to show that none of the explicit Nyström methods [6] has a positive threshold value C^*_{LM}. □

The generation of monotonicity results for high-order multistep schemes such as extrapolated BDF3 by means of optimized strong-stability-preserving Runge–Kutta starting procedures [4, 18] is part of our current research.

5. Numerical illustrations.

5.1. Linear positivity test. As a first numerical test we consider the positivity property (2.3) for the linear advection problem $u_t + u_x = 0$, $0 \le x \le 1$, with inflow boundary condition $u(0,t) = 0$ and initial mass $u(x,0)$ concentrated at the inflow boundary. The semidiscrete system is obtained with first-order upwind discretization in space and constant mesh width $\Delta x = 1/m$. The resulting linear ODE system in $\mathbb{R}^m$ is

$$w'(t) = Aw(t)\,, \qquad A = \frac{1}{\Delta x}\begin{pmatrix} -1 & & & \\ 1 & -1 & & \\ & \ddots & \ddots & \\ & & 1 & -1 \end{pmatrix}, \qquad w_0 = \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}. \tag{5.1}$$

The dimension of the system is taken to be $m = 100$. For this system we determined experimentally the largest Courant number $\nu = \Delta t/\Delta x$ for which $w_n \ge 0$ is maintained up to $n = 1000$. We note that with the forward Euler method this will hold up to $\nu = 1$. Further we note that, by changing $w_j(t)$ in (5.1) into $1-w_j(t)$, identical results can be obtained with the condition $\|w_n\|_\infty \le \|w_0\|_\infty$.

First we consider the class of explicit two-step methods (3.10) with parameter values $\xi = j/20$, $j = 0, 1, \ldots, 40$. Along with the forward Euler method and the modified two-step procedure (3.15), we also consider the exact starting value $w_1 = \exp(\Delta t A)w_0$. The results are plotted in Figure 5.1, in combination with the theoretical values C^*_{LM} from (3.11).

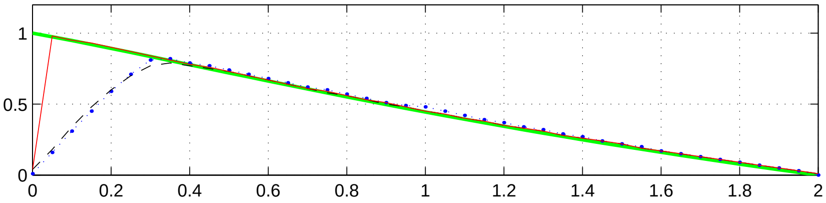

FIG. 5.1. *Positivity test for the explicit two-step methods* (3.10). *Courant numbers versus* $\xi \in [0,2]$*, starting with exact solution values [dots], forward Euler [solid line], and the modified two-step procedure* (3.15) *[dashed line]. The thick gray line is the* C^*_{LM}*-curve from* (3.11).

The influence of the starting values as given in the Theorems 3.3, 3.4 does not show up accurately in Figure 5.1. We note, however, that the test problem here is linear, whereas the theoretical results were obtained for nonlinear problems.

In a similar manner the behavior of the implicit two-step Adams and BDF-type methods has been tested. The results are shown in Figure 5.2. The starting value w_1 was computed with the implicit Euler method and with method (3.19), where the parameter η is the same as in (3.17); taking an exact starting value for w_1 did give results close to the latter starting procedure. For $\xi > \frac{1}{2}$ the results with implicit Euler and (3.19) also almost coincide.

The Courant numbers in Figure 5.2 are close to the theoretical bound C^*_{LM} in Figure 3.1 for $\eta \lesssim 0.9$. In particular, the different behavior for $\eta < \frac{1}{2}$ and $\eta > \frac{1}{2}$ shows up very clearly. Quantitatively, only the results with the BDF-type methods with $\eta \le \frac{1}{2}$ and the implicit Euler method as starting procedure are somewhat more favorable than the bound C^*_{LM}. The difference between the curves in Figure 3.1 for the larger η

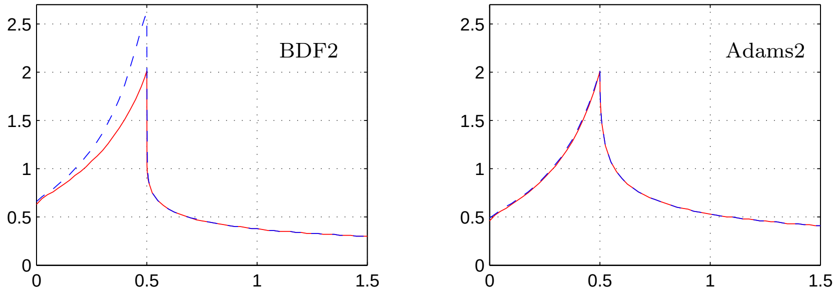

FIG. 5.2. *Positivity test for the implicit two-step methods* (3.17) *with* $\xi = \frac{2}{3}$ *[left] and* $\xi = 1$ *[right]. Courant numbers versus* $\eta \in [0, \frac{3}{2}]$*, starting with implicit Euler [dashed lines] and method* (3.19) *[solid lines].*

values is due to the fact that the values C^*_{LM} were obtained for nonlinear problems; see Remark 3.5. As noted previously, the rather small Courant numbers allowed with the implicit methods in practice mean that these implicit second-order two-step methods are not competitive with the explicit ones for problems where monotonicity is crucial.

In Table 5.1 the experimental positivity results are presented for the k-step extrapolated BDF schemes (eBDFk) and the k-step explicit Adams methods, which are also known as the Adams–Bashforth methods (ABk), $k = 3, 4$. Here we also list the theoretical bounds on the Courant numbers for these methods that were obtained in section 4. The experimental bounds were found with exact starting values and with high-order Runge–Kutta starting procedures, giving approximately the same values.

TABLE 5.1

5.2. Nonlinear accuracy test. To compare the explicit linear multistep methods for a nonlinear example, we consider the Burgers equation

$$u_t + (u^2)_x = 0, \quad 0 \le x \le 1,\ 0 \le t \le \frac{1}{4},$$

with periodic boundary conditions and initial profile $u(x, 0)$ given by the block function which equals 0 for $x \in (0, \frac{1}{2}]$ and 1 for $x \in (\frac{1}{2}, 1]$. For increasing time the solution $u(x, t)$ consists of a shock at $x = t$ and a rarefaction wave between $\frac{1}{2} \le x \le \frac{1}{2} + 2t$; see Figure 5.3.

Spatial discretization is performed with the flux-limited scheme of van Leer [19], which combines a second-order upwind-biased discretization (in smooth solution regions) with first-order upwind fluxes; see also [14, p. 180] and [8]. For this test, with $u \in [0, 1]$, it can be shown that the forward Euler method is TVD and positive for Courant numbers $\nu = 2\Delta t/\Delta x \le \frac{1}{2}$. However, to achieve a reasonable accuracy the Courant number should be taken significantly smaller than $\frac{1}{2}$, because otherwise the

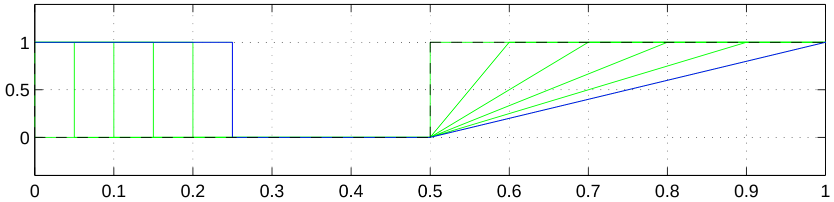

FIG. 5.3. *Solution of Burgers equation for $0 \leq x \leq 1$ at $t = 0$ [dashed] and $t = \frac{1}{4}$ [solid line]. The light gray lines indicate the time evolution.*

rarefaction wave suffers from compression due to linear instability of the forward Euler method with the second-order discretization. For Courant numbers in the range $[\frac{1}{2}, 1]$ the forward Euler method is no longer strictly TVD, but the oscillations are quite small. This can be understood heuristically by the observation that with the first-order upwind discretization the forward Euler method is TVD up to $\nu = 1$, and in nonsmooth regions, where monotonicity matters most, the flux-limited scheme becomes close to first-order upwinding.

The same observations apply to the multistep methods used in this test; the theoretical limits for monotonicity can be nearly doubled without introducing large temporal errors. Still, the theoretical predictions based on the threshold values C^*_{LM} show up when compared with forward Euler. The choice of starting procedures did have only minor significance; for the results presented here the first step was taken with the forward Euler method. In this test the discrete L_1-errors

$$\Delta x \sum_{j=1}^{m} |u(x_j, t_n) - w_j^n|, \qquad m\,\Delta x = 1,$$

were measured for different Courant numbers in the range $[0, 1]$ at time $t_n = \frac{1}{4}$. The test was performed on a fixed grid with mesh width $\Delta x = 10^{-2}$. The results for various second-order two-step methods (3.10) are shown in Figure 5.4.

The methods in Figure 5.4(a) are the extrapolated BDF2 scheme (eBDF2, $\xi = \frac{2}{3}$), the two-step Adams–Bashforth method (AB2, $\xi = 1$), and the second-order modified two-step method (Sh2) of Shu [15],

$$w_n = \frac{4}{5}w_{n-1} + \frac{1}{5}w_{n-2} + \frac{8}{5}\Delta t F(w_{n-1}) - \frac{2}{5}\Delta t \tilde{F}(w_{n-2}), \tag{5.2}$$

which is the modified form of (3.10), $\xi = \frac{6}{5}$, with threshold factor $\tilde{K}_{LM} = \frac{1}{2}$; see Remark 2.1. This scheme is more expensive in CPU time, and in this test it does not perform as well as the other two, of which the extrapolated BDF2 scheme has a slight advantage over the explicit two-step Adams method.

In Figure 5.4(b) the results are given for the methods (3.10) with $\xi = \frac{1}{5}, \frac{6}{5}, \frac{9}{5}$. For comparison, results for the forward Euler method are also included. As predicted by the bound C^*_{LM} of (3.11), the method with $\xi = \frac{9}{5}$ can only be used with small Courant numbers. The method with $\xi = \frac{1}{5}$ does provide results for larger Courant numbers, but its accuracy deteriorates for large ν. The results with $\xi = \frac{6}{5}$ are intermediate, where it should be noted that this method is competitive with the more expensive modified method (5.2), which is based on the same parameter choice.

In Figure 5.4 we have also indicated the spatial errors of the flux-limited van Leer discretization with $\Delta x = 10^{-2}$; that is, the L_1 difference between a semidiscrete

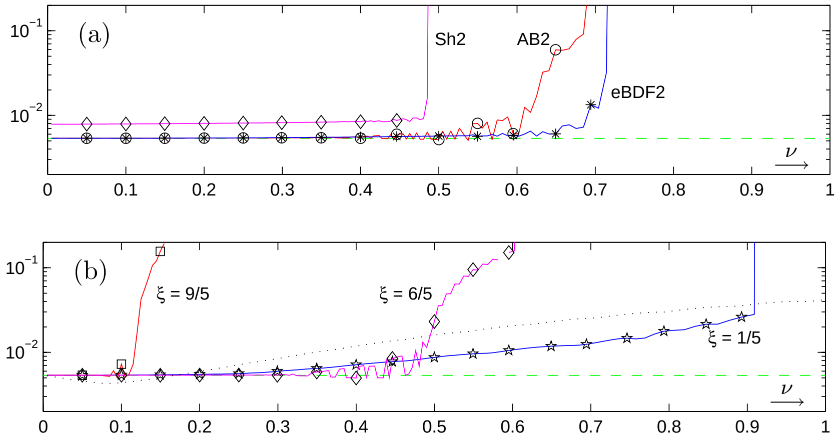

FIG. 5.4. *Burgers equation, L_1-errors versus Courant numbers ν for explicit two-step methods* (3.10). (a) *eBDF*2$[\xi = \frac{2}{3}]$, *AB*2$[\xi = 1]$, *and Sh*2$[\tilde{\xi} = \frac{6}{5}]$; (b) $\xi = \frac{1}{5}$, $\xi = \frac{6}{5}$, *and* $\xi = \frac{9}{5}$, *together with forward Euler results [dotted line]. The light dashed horizontal line indicates the spatial error.*

solution and PDE solution at $t = \frac{1}{4}$ on this spatial grid. The modified scheme (5.2) gives larger errors for $\nu \to 0$. This is due to the use of $\tilde{F}$, which introduces some extra numerical dissipation, in particular at the bottom and top of the rarefaction wave. With most of the methods the L_1-errors show oscillations as a function of ν before becoming unbounded. This is an onset of instability, due to spatial oscillations at the top of the shock or rarefaction wave.

Method (3.10) with $\xi = \frac{1}{5}$ could be used with relatively large Courant numbers ν without becoming unstable, but for the larger values ν the results are no longer accurate, due to compression of the rarefaction wave. With the forward Euler method this compression is much more pronounced. Time-stepping methods with high order will mostly be beneficial for smooth solutions. The present test is primarily intended to show the relevance of monotonicity. This should also be kept in mind with the results for the third-order methods below.

The fact that the starting procedures did not matter significantly in this test is somewhat more surprising than with the previous linear example. In the derivation of our theoretical results for nonlinear problems no relation at all was assumed between terms like $F(w_n)$ and $F(w_{n-1})$. For grid points x_j adjacent to the shock the spatial discretization becomes close to the first-order upwind scheme and elsewhere we will have $F_j(w_n) = F_j(w_{n-1}) + \mathcal{O}(\Delta t)$. It is not clear, however, how such arguments could be used in a rigorous mathematical fashion.

In the same way some three-step methods were tested. The results are shown in Figure 5.5. Here we selected the extrapolated BDF3 scheme (eBDF3) and the three-step Adams–Bashforth method (AB3). Also included are the results for the second-order three-step method

$$w_n = \frac{3}{4} w_{n-1} + \frac{1}{4} w_{n-3} + \frac{3}{2} \Delta t F(w_{n-1}) \tag{5.3}$$

of Shu [15] with threshold value $K_{LM} = \frac{1}{2}$, which is optimal among the three-step methods of order 2; see also Lenferink [12]. In the figure this method is indicated as Sh2,3. Since this is a second-order method, comparison with AB2 or eBDF2 is actually more appropriate. As expected from the theoretical bounds, the eBDF3 scheme does

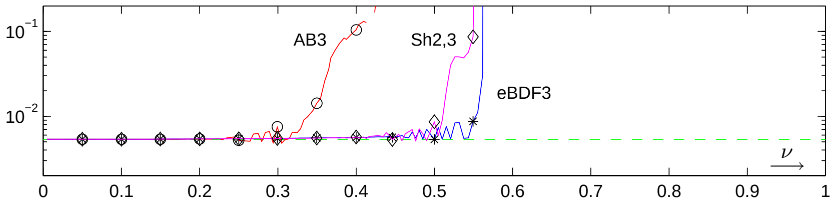

FIG. 5.5. *Burgers equation, L_1-errors versus Courant numbers ν for the explicit three-step methods eBDF*3*, AB*3*, and Sh*2, 3*. The light dashed horizontal line indicates the spatial error.*

perform better than the AB3 method. Also with these three-step methods, starting procedures turned out not to be very influential. Here a standard two-stage second-order Runge–Kutta method was used.

In summary we can say that the theoretical step-size restrictions of section 3 for the monotonicity property (1.2) are probably somewhat pessimistic, but the step-size restrictions under which the more general boundedness property (3.7) could be proved give a good indication of the applicability of the various methods.

6. Summary and conclusions.

We have shown that inclusion of starting procedures in multistep schemes allows for statements on monotonicity (1.2) and boundedness (3.7) with classes of methods that are important in practice (such as the Adams and BDF-type methods). We find that the standard second-order two-step methods AB2 (second-order Adams–Bashforth),

$$w_n = w_{n-1} + \frac{3}{2}\Delta t F(w_{n-1}) - \frac{1}{2}\Delta t F(w_{n-2}),$$

and eBDF2 (second-order extrapolated BDF),

$$w_n = \frac{4}{3}w_{n-1} - \frac{1}{3}w_{n-2} + \frac{4}{3}\Delta t F(w_{n-1}) - \frac{2}{3}\Delta t F(w_{n-2}),$$

have more relaxed time-stepping restrictions than schemes with positive coefficients when monotonicity-preservation is required. Similarly, the well-known higher-order schemes AB3 (4.6), eBDF3 (4.4), and eBDF4 (4.5) have more relaxed time-stepping restrictions than schemes with positive coefficients when related boundedness properties are required. Numerical tests confirm the results of these theoretical studies: these standard methods performed better than specially constructed methods with positive coefficients. We particularly recommend the well-known extrapolated BDF schemes.

Finally we have found that implicit second-order two-step schemes are not competitive with the explicit ones when monotonicity properties are crucial, generalizing one of the results in [8] for the two-step BDF-type schemes. The restrictions on the step sizes for monotonicity and boundedness with the implicit schemes were shown to be only marginally better than for the explicit schemes, and in practical computations this will not be enough to justify the increase in computational work with the implicit schemes.

P_1-NONCONFORMING QUADRILATERAL FINITE ELEMENT METHODS FOR SECOND-ORDER ELLIPTIC PROBLEMS*

CHUNJAE PARK† AND DONGWOO SHEEN‡

Abstract. A P_1-nonconforming quadrilateral finite element is introduced for second-order elliptic problems in two dimensions. Unlike the usual quadrilateral nonconforming finite elements, which contain quadratic polynomials or polynomials of degree greater than 2, our element consists of only piecewise linear polynomials that are continuous at the midpoints of edges. One of the benefits of using our element is convenience in using rectangular or quadrilateral meshes with the least degrees of freedom among the nonconforming quadrilateral elements. An optimal rate of convergence is obtained. Also a nonparametric reference scheme is introduced in order to systematically compute stiffness and mass matrices on each quadrilateral. An extension of the P_1-nonconforming element to three dimensions is also given. Finally, several numerical results are reported to confirm the effective nature of the proposed new element.

1. Introduction.

We are concerned with nonconforming finite element methods for second-order elliptic problems. Nonconforming elements have been used effectively especially in fluid and solid mechanics due to their stability. Recently, these elements have attracted increasing attention from scientists and engineers in more wide areas, as this type of element is potentially useful in parallel computing.

The use of finite elements for Stokes problems, which is fundamental in fluid mechanics, usually requires the discrete Babuška–Brezzi condition (inf-sup condition) to be satisfied by the velocity and pressure variables, generally set in the mixed finite element formulation; for instance, the standard P_1-P_0 pair for triangular decompositions or the Q_1-P_0 pair for quadrilateral decompositions of the computational domain lead to checkerboard solutions for pressure. However, if the nonconforming elements introduced in [3, 8, 15, 5] are used to approximate the velocity part instead of the usual P_1 or Q_1 elements, the Babuška–Brezzi condition is easily satisfied, and thus stable solutions are obtained. Nonconforming finite element methods have been proved to be effective for several parameter dependent elasticity problems in a stable fashion such that the methods converge independently of the Lamé parameters, while standard conforming methods fail to converge as the parameters tend to a locking limit; see [2, 12, 13].

Moreover, in view of domain decomposition methods, the use of nonconforming elements facilitates the exchange of information across each subdomain and provides spectral radius estimates for the iterative domain decomposition operator [9].

The nonconforming simplicial finite element space of lowest degree introduced by Crouzeix and Raviart [8] is identical to the corresponding conforming one (that

is, P_1 in both cases), and thus it is rather simple to understand. Although the triangular meshes are popular to use, in many cases one wishes to use quadrilateral meshes with appropriate elements instead, when the problem geometry is of quadrilateral nature, especially in three dimensions. Concerning rectangular nonconforming elements, Han [11] introduced a rectangular element with local degrees of freedom being five, and Rannacher and Turek [15] introduced the rotated Q_1 nonconforming elements of two types: the first set of local degrees of freedom consists of the four values at the midpoints of the edges, while the second one is composed of the four average values over the edges. Recently, new nonconforming elements, which use only the four values at the midpoints of the edges as degrees of freedom, have been announced by Douglas et al. [9], who in a sense combined and improved the two types of local degrees of freedom for rotated Q_1 elements, using high-order polynomials with the degrees of freedom still being four. These elements were successfully applied to solve Navier–Stokes problems by Cai, Douglas, and Ye [5]. A recent observation by Arnold, Boffi, and Falk [1] implies that where the rectangular elements are applied to truly quadrilateral meshes, the optimality in convergence will be lost. Thus for the truly quadrilateral case, an extra element should be added [4], with the local degrees of freedom being five; the extra degrees of freedom can be eliminated easily at an element level since they are essentially bubble functions.

The purpose of this paper is to introduce P_1-nonconforming finite element spaces on quadrilateral meshes which have the lowest degrees of freedom. The motivation for our new element comes from the observation that any P_1 function on a quadrilateral can be uniquely determined at any three of the four midpoints of edges.

The degrees of freedom for our P_1-nonconforming quadrilateral element are about half of those for the other rectangular nonconforming elements, and about a third of those for the P_1 triangular nonconforming space on the mesh with each quadrilateral being divided into two triangles. Indeed, our P_1-nonconforming quadrilateral element space turns out to be a subspace of P_1-nonconforming triangular element spaces by dividing each quadrilateral into two triangles.

In the Q_1-conforming quadrilateral element case, it is convenient to use a fixed reference rectangle and basis from which, corresponding to each quadrilateral, a bilinear transformation can be used to calculate stiffness and mass matrices by pulling back to the reference rectangle without losing the order of convergence. However, as mentioned above, such a reference system does not guarantee optimal convergence any more with existing nonconforming quadrilateral elements with only four degrees of freedom [1]. We present a nonparametric reference scheme in section 4, which provides an efficient way of calculating the stiffness and mass matrices from a reference rectangle without losing the order of convergence.

As discussed earlier, one of the motivations for seeking the P_1-nonconforming quadrilateral element space is to try to use it for the approximation of the velocities and the P_0 space for the pressure as in [8, 11, 15, 4]. However, we remark that with this combination the discrete inf-sup condition is not fulfilled, as there are only three degrees of freedom for the normal components at the midpoints of a quadrilateral. But the current element works well as a locking-free element for elasticity problems [14].

The organization of the paper is as follows. In the next section we present two P_1-nonconforming element spaces on quadrilateral meshes. Then section 3 describes an interpolation operator and also deals with a brief analysis of convergence in the cases of Dirichlet and Robin problems. Then a nonparametric reference scheme is introduced in section 4. The analysis carried out in the current paper has a counterpart in three dimensions: P_1-nonconforming hexahedral finite elements will be briefly discussed in section 5, detailed analyses being treated in a forthcoming paper. Finally, numerical examples are illustrated in section 6.

2. The P_1-nonconforming element on quadrilateral meshes.

2.1. The P_1-nonconforming quadrilateral element.

Let Ω be a simply connected polygonal domain in $\mathbb{R}^2$ with boundary Γ. Let $(\mathcal{T}_h)_{h>0}$ be a *regular* family of decompositions (or triangulations) of Ω into convex quadrilaterals, where $h = \max_{Q\in\mathcal{T}_h} h_Q$ with $h_Q = \operatorname{diam}(Q)$. For the standard definition of regular decomposition, we refer to [10]. Henceforth, in this paper, a quadrilateral will be implicitly assumed to be convex.

For a general quadrilateral Q, denote by $v_j, 1 \le j \le 4$, its four vertices and by $m_j, 1 \le j \le 4$, the midpoints of edges of Q such that $m_j = \frac{v_{j-1}+v_j}{2}, 1 \le j \le 4$, with the identification $v_0 = v_4$. Let $P_1(Q) = \operatorname{Span}\{1, x, y\}$. The following lemmas are trivial but useful in what follows.

Lemma 2.1. *If $u \in P_1(Q)$, then $u(m_1) + u(m_3) = u(m_2) + u(m_4)$. Conversely, if u_j is a given value at m_j, for $1 \le j \le 4$, satisfying $u_1 + u_3 = u_2 + u_4$, then there is a unique $u \in P_1(Q)$ such that $u(m_j) = u_j, 1 \le j \le 4$.*

Proof. The first half is trivial:

$$\begin{aligned} u(m_1) + u(m_3) &= \frac{u(v_4) + u(v_1)}{2} + \frac{u(v_2) + u(v_3)}{2} \\ &= \frac{u(v_1) + u(v_2)}{2} + \frac{u(v_3) + u(v_4)}{2} = u(m_2) + u(m_4). \end{aligned}$$

For the latter half, suppose that $u_1 + u_3 = u_2 + u_4$ and then choose a $u \in P_1(Q)$ such that $u(m_j) = u_j, j = 1, 2, 3$. Then by the first half of the lemma, $u_1 + u_3 = u_2 + u(m_4)$, which implies that $u(m_4) = u_4$, so that $u(m_j) = u_j, 1 \le j \le 4$. Uniqueness is obvious. □

Lemma 2.2. *For $1 \le j \le 4$, let $\widehat{\varphi}_j \in P_1(Q)$ be defined such that*

$$\widehat{\varphi}_j(m_k) = \begin{cases} 1, & k = j, j+1 \mod 4, \\ 0, & \textit{otherwise}. \end{cases}$$

Then $\operatorname{Span}\{\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3, \widehat{\varphi}_4\} = P_1(Q)$. Indeed, any three of $\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3, \widehat{\varphi}_4$ span $P_1(Q)$.

Proof. Clearly $\operatorname{Span}\{\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3, \widehat{\varphi}_4\} \subset P_1(Q)$. To show the other direction of inclusion, it suffices to show that $P_1(Q) \subset \operatorname{Span}\{\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3\}$; then rotational symmetry would imply that any three of $\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3, \widehat{\varphi}_4$ span $P_1(Q)$. Let $u \in P_1(Q)$ be arbitrary. Set

$$\psi = u(m_1)\widehat{\varphi}_1 + [u(m_2) - u(m_1)]\widehat{\varphi}_2 + [u(m_3) - u(m_2) + u(m_1)]\widehat{\varphi}_3.$$

Then it is immediate to see that $\psi(m_j) = u(m_j), j = 1, 2, 3$. Lemma 2.1 implies that $\psi(m_4) = u(m_4)$ and therefore ψ is identical to u. This proves that $P_1(Q) \subset \operatorname{Span}\{\widehat{\varphi}_1, \widehat{\varphi}_2, \widehat{\varphi}_3\}$. □

Given a decomposition $\mathcal{T}_h$ of Ω into quadrilaterals, let N_Q, N_V, and N_E denote

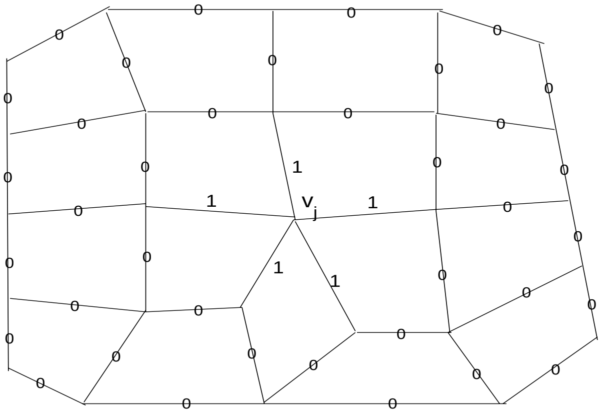

FIG. 1. *Values at the midpoints of the basis function φ_j associated with the vertex v_j.*

the numbers of quadrilaterals, vertices, and edges, respectively. Then set

$$\begin{aligned}
\mathcal{T}_h &= \{Q_1, Q_2, \ldots, Q_{N_Q}\}; \quad \bigcup_{j=1}^{N_Q} Q_j = \overline{\Omega},\\
\mathcal{V} &= \{v_1, v_2, \ldots, v_{N_V}\}: \text{ the set of all vertices of } Q \in \mathcal{T}_h,\\
\mathcal{E} &= \{e_1, e_2, \ldots, e_{N_E}\}: \text{ the set of all edges of } Q \in \mathcal{T}_h,\\
\mathcal{M} &= \{m_1, m_2, \ldots, m_{N_E}\}: \text{ the set of all midpoints of } e \in \mathcal{E}.
\end{aligned}$$

In particular, let N_V^i, N_E^i, and N_M^i denote the numbers of interior vertices, edges, and midpoints of $Q \in \mathcal{T}_h$, respectively. Our objective is to introduce a P_1-nonconforming finite element space associated with the quadrilateral decomposition $\mathcal{T}_h$.

Set

$$\begin{aligned}
\mathcal{NC}^h &= \{v_h : \Omega \to \mathbb{R} |\ v_h|_Q \in P_1(Q) \text{ for all } Q \in \mathcal{T}_h,\\
&\qquad v_h \text{ is continuous at every } m \in \mathcal{M} \setminus \Gamma\},\\
\mathcal{NC}_0^h &= \{v_h \in \mathcal{NC}^h |\ v_h(m) = 0 \text{ for all } m \in \Gamma \cap \mathcal{M}\}.
\end{aligned}$$

For each vertex $v_j \in \mathcal{V}$, denote by $\mathcal{E}(j)$ the set of all edges $e \in \mathcal{E}$ such that one of the endpoints is v_j, and by $\mathcal{M}(j)$ the set of all midpoints m of edges in $\mathcal{E}(j)$. Let $\varphi_j \in \mathcal{NC}^h$ be such that

$$\varphi_j(m) = \begin{cases} 1 & \text{if } m \in \mathcal{M}(j), \\ 0 & \text{if } m \in \mathcal{M} \setminus \mathcal{M}(j). \end{cases} \tag{2.1}$$

An example of such a function φ_j is shown in Figure 1. Notice that $\widehat{\varphi}_k, 1 \le k \le 4$, given in Lemma 2.2 belong to the restriction of $\varphi_j, j = 1, \ldots, N_V$, to Q.

Remark 2.3. Obviously $\varphi_j|_Q(v_j) < 2$ for all $Q \in \mathcal{T}_h$, with v_j being one of its vertices; moreover, $\varphi_j|_Q(v_j) = 3/2$ if Q is a parallelogram. Therefore, if $\mathcal{T}_h$ is decomposed into parallelograms, φ_j is continuous at v_j for all j. However, φ_j may not be continuous in general. Examples of basis functions in conforming and nonconforming cases are depicted in Figure 3(b),(c) for a simple mesh given in Figure 3(a).

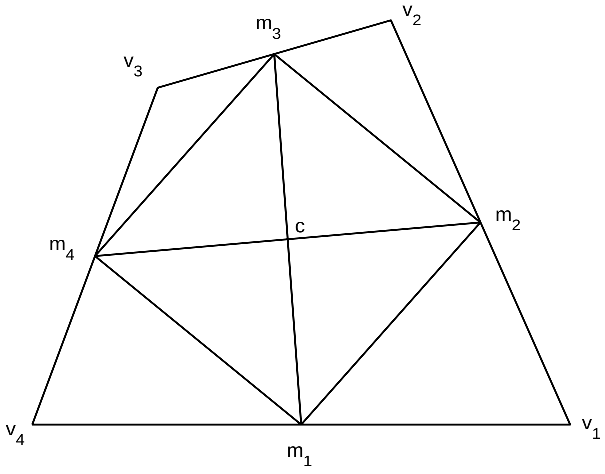

FIG. 2. *The midpoints $m_j, 1 \leq j \leq 4$, form a parallelogram in the quadrilateral with vertices $v_j, 1 \leq j \leq 4$.*

2.2. The dimension and basis for $\mathcal{NC}_0^h$. We proceed to investigate in the dimension of $\mathcal{NC}_0^h$; that of $\mathcal{NC}^h$ will be discussed in the next subsection. Implicitly the following assumption will be imposed on the decomposition in the rest of this article, especially for Dirichlet problems, in order to exclude pathological cases.

ASSUMPTION I. *Each interior edge has at least one interior vertex as its endpoint.*

There are cases in which Assumption I is violated. For instance, some decompositions $\mathcal{T}_h$ of Ω may contain elements whose four vertices lie on the boundary of Ω; in these cases, the reduced decomposition $\mathcal{T}_h'$, obtained by eliminating such elements from $\mathcal{T}_h$, fulfills Assumption I.

An upper bound of $\dim(\mathcal{NC}_0^h)$ is given in the following lemma.

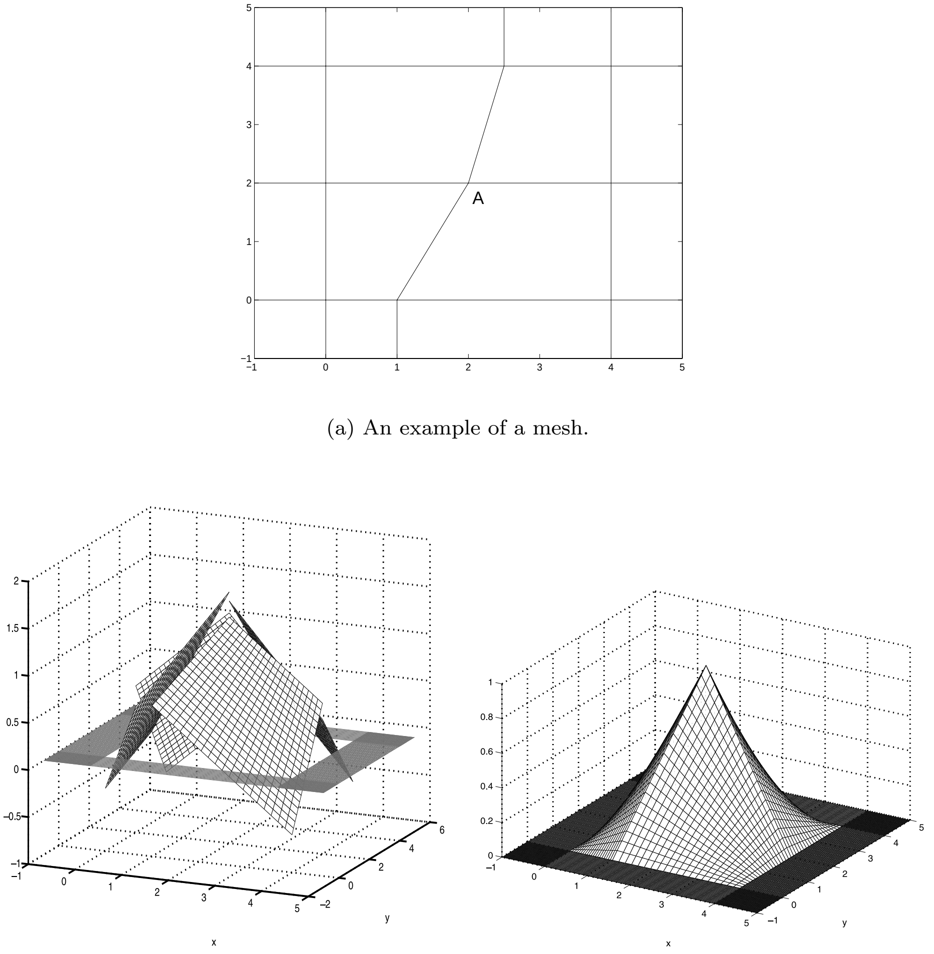
LEMMA 2.4. $\dim(\mathcal{NC}_0^h) \leq N_V^i$.

Proof. For the degrees of freedom for $\mathcal{NC}_0^h$ define $\mathbf{d} : \mathcal{NC}_0^h \to \mathbb{R}^{N_E^i}$ by

$$\mathbf{d}(\varphi) := (d_1(\varphi), \ldots, d_{N_E^i}(\varphi))^t, \quad \varphi \in \mathcal{NC}_0^h,$$

with $d_j(\varphi) = \varphi(m_j)$ for each interior midpoint $m_j, j = 1, \ldots, N_E^i$. If $\varphi \in \mathcal{NC}_0^h$ satisfies $d_j(\varphi) = 0$ for all $j = 1, \ldots, N_E^i$, clearly $\varphi = 0$. This implies that $\{d_j\}_{j=1}^{N_E^i}$ spans $(\mathcal{NC}_0^h)'$, the dual of $\mathcal{NC}_0^h$. Note that, for any $j = 1, \ldots, N_E^i$, the component d_j of $\mathbf{d}$ is nontrivial, since for each $m_j \in \mathcal{M} \setminus \Gamma$ there exists a function φ such that $\varphi(m_j) \neq 0$, as defined in (2.1) by Assumption I.

Due to Lemma 2.1, for each $Q_j \in \mathcal{T}_h$ having $m_{j_1}, m_{j_2}, m_{j_3}$, and m_{j_4} as its midpoints of edges as in Figure 2, one of the following linear restrictions should be



(a) An example of a mesh.

(b) The P_1-nonconforming basis whose values are equal to 1 at the midpoints of edges which meet with the vertex A, and 0 at all the other midpoints.

(c) The Q_1-conforming basis whose values are 1 at the vertex A, and 0 at all the other vertices.

FIG. 3. *Shapes of* P_1*-nonconforming* (b) *and* Q_1*-conforming* (c) *basis functions in the quadrilateral mesh shown in* (a).

imposed:

$$\begin{aligned} d_{j_1} + d_{j_3} - d_{j_2} - d_{j_4} &= 0 \qquad \text{if } m_{j_k} \notin \Gamma, 1 \le k \le 4, \\ d_{j_1} + d_{j_3} - d_{j_2} &= 0 \qquad \text{if } m_{j_1}, m_{j_2}, m_{j_3} \notin \Gamma \text{ and } m_{j_4} \in \Gamma, \\ d_{j_1} - d_{j_2} &= 0 \qquad \text{if } m_{j_1}, m_{j_2} \notin \Gamma \text{ and } m_{j_3}, m_{j_4} \in \Gamma, \end{aligned}$$

which can be written formally as

$$A_j \mathbf{d} = 0. \tag{2.2}$$

Here, $A_j = (A_{j,1}, \dots, A_{j,N_E^i})$ is a row vector in $\mathbb{R}^{N_E^i}$ with at most four nontrivial entries such that

$$\begin{aligned} A_{j,j_1} = A_{j,j_3} = -A_{j,j_2} = -A_{j,j_4} = 1 \qquad & \text{if } m_{j_k} \notin \Gamma, 1 \le k \le 4,\\ A_{j,j_1} = A_{j,j_3} = -A_{j,j_2} = 1 \qquad & \text{if } m_{j_1}, m_{j_2}, m_{j_3} \notin \Gamma \text{ and } m_{j_4} \in \Gamma,\\ A_{j,j_1} = -A_{j,j_2} = 1 \qquad & \text{if } m_{j_1}, m_{j_2} \notin \Gamma \text{ and } m_{j_3}, m_{j_4} \in \Gamma. \end{aligned}$$

We therefore see that

$$\begin{aligned} \dim(\mathcal{N}C_0^h) &= \dim((\mathcal{N}C_0^h)') \\ &\le \dim\{\mathbf{d} = (d_1, \dots, d_{N_E^i})^t;\ A_j\mathbf{d} = 0, j = 1, \dots, N_Q\}. \end{aligned} \tag{2.3}$$

We proceed to see whether $A_j, j = 1, \dots, N_Q$, are linearly independent vectors or not. For this, assume that for some proper subset $J \subsetneqq \{1, 2, \dots, N_Q\}$,

$$\sum_{j\in J} c_j A_j = 0, \tag{2.4}$$

with $c_j \neq 0$ for all $j \in J$. Set $\overline{\Omega}_J = \bigcup_{j\in J} \overline{Q}_j$. Then there exist an interior midpoint $m_l \in \partial\Omega_J \cap \mathcal{M} \setminus \Gamma$ and $Q_k \subset \Omega_J$ for which m_l is a midpoint of an edge of Q_k, since $\Omega_J \subsetneqq \Omega$. From the linear restriction concerning Q_k, $A_k\mathbf{d} = 0$, we see that A_k has a nonzero entry in the lth column; moreover, A_k is the unique vector that has a nonzero value in the lth entry among all $A_j, j \in J$, since m_l is at the boundary of Ω_J. Thus (2.4) implies that $c_k = 0$, which is a contradiction. Therefore, we have

$$\text{any } N_Q - 1 \text{ elements from } \{A_1, A_2, \dots, A_{N_Q}\} \text{ are linearly independent in } \mathbb{R}^{N_E^i}.$$

Let $A = (A_1^t, \dots, A_{N_Q-1}^t)^t$ be the $(N_Q - 1) \times N_E^i$ matrix whose jth row is A_j. Then the collection of (2.2) for $j = 1, \dots, N_Q - 1$ can be written formally in the matrix form

$$A\mathbf{d} = 0,$$

with the rank of A being $N_Q - 1$. Notice from (2.3) that

$$\dim(\mathcal{N}C_0^h) \le \dim\{\mathbf{d} = (d_1, \dots, d_{N_E^i})^t;\ A\mathbf{d} = 0\}. \tag{2.5}$$

Let B be an $(N_E^i - (N_Q - 1)) \times N_E^i$ matrix such that $\bar{A} = \left(\begin{smallmatrix} A \\ B \end{smallmatrix}\right)$ is invertible: such a matrix exists as $\operatorname{rank}(A) = N_Q - 1$. Setting $(\psi_1, \dots, \psi_{N_E^i-(N_Q-1)})^t = B\mathbf{d}$, we have

$$\bar{A}\mathbf{d} = (0, \dots, 0, \psi_1, \dots, \psi_{N_E^i-(N_Q-1)})^t \in \mathbb{R}^{N_E^i}.$$

This implies that $\{\psi_j\}_{j=1}^{N_E^i-(N_Q-1)}$ spans $\{\mathbf{d} = (d_1, \dots, d_{N_E^i})^t;\ A\mathbf{d} = 0\}$, since $\bar{A}$ is invertible. Therefore, from (2.5), we see that

$$\dim(\mathcal{N}C_0^h) \le N_E^i - (N_Q - 1).$$

Recall Euler's formula for a simply connected domain, $N_V - N_E + N_Q = 1$, which is equivalent to $N_V^i - N_E^i + N_Q = 1$. The following lemma is thus obtained: $\dim(\mathcal{N}C_0^h) \le N_E^i - (N_Q - 1) = N_V^i$. ◻

The dimension and basis functions for $\mathcal{N}C_0^h$ are given in the following theorem.

THEOREM 2.5. *Let φ_j be the function defined in* (2.1) *with interior vertex $v_j \in \mathcal{V} \setminus \Gamma$, $j = 1, \dots, N_V^i$. Then $\{\varphi_1, \varphi_2, \dots, \varphi_{N_V^i}\}$ forms a basis for $\mathcal{N}C_0^h$. Therefore,*

$\dim(\mathcal{N}C_0^h) = N_V^i$. *That is, the degrees of freedom for* $\mathcal{N}C_0^h$ *is equal to the number of interior vertices in* $\mathcal{T}_h$.

Proof. Suppose $\sum_{j=1}^{N_V^i} c_j\varphi_j = 0$. Choose a vertex v_l located at the boundary Γ. Since Ω is connected, there exists an interior vertex v_k adjacent to $v_l \in \Gamma$. Let m be the midpoint of $\overline{v_l v_k}$. Then we have

$$0 = \sum_{j=1}^{N_V^i} c_j\varphi_j(m) = c_k.$$

The coefficients c_j of the φ_j's corresponding to all the vertices adjacent to Γ will vanish in this manner. Then, stripping out all the boundary elements, we continue the above argument to the next layer to show again that all the coefficients c_j of the φ_j's corresponding to all the vertices adjacent to that boundary layer vanish. We can continue the argument to show that all the coefficients vanish until the domain is exhausted. Thus $\{\varphi_1, \varphi_2, \dots, \varphi_{N_V^i}\}$ is linearly independent. Moreover, $\{\varphi_1, \varphi_2, \dots, \varphi_{N_V^i}\}$ forms a basis for $\mathcal{N}C_0^h$ since $\dim(\mathcal{N}C_0^h) \le N_V^i$ by Lemma 2.4, and therefore $\dim(\mathcal{N}C_0^h) = N_V^i$. This completes the proof. □

Remark 2.6. Let $\widetilde{\mathcal{T}_h}$ be the triangulation of Ω into triangles by dividing each quadrilateral into two triangles. Consider the P_1-nonconforming simplicial element space $\widetilde{\mathcal{N}C_0^h}$ on $\widetilde{\mathcal{T}_h}$. We then observe that $\mathcal{N}C_0^h \subset \widetilde{\mathcal{N}C_0^h}$. Moreover,

$$\dim(\widetilde{\mathcal{N}C_0^h}) = N_E^i + N_Q = N_V^i + 2N_Q - 1 = \dim(\mathcal{N}C_0^h) + 2N_Q - 1.$$

2.3. The dimension and basis for $\mathcal{N}C^h$. The dimension and basis for $\mathcal{N}C^h$ is then obtained by the arguments in the previous subsection with slight modifications. Indeed, we have the following result.

LEMMA 2.7. $\dim(\mathcal{N}C^h) \le N_E - N_Q = N_V - 1$.

Proof. The arguments of the proof are essentially identical to those for Lemma 2.4 with minor modifications, but for the sake of the reader's convenience we repeat most of the arguments with proper modifications.

First, define $\mathbf{d} : \mathcal{N}C^h \to \mathbb{R}^{N_E}$ by

$$\mathbf{d}(\varphi) := (d_1(\varphi), \dots, d_{N_E}(\varphi))^t, \quad \varphi \in \mathcal{N}C^h,$$

with $d_j(\varphi) = \varphi(m_j)$ for each midpoint m_j, $j = 1, \dots, N_E$. Then one sees that $\{d_j\}_{j=1}^{N_E}$ spans $(\mathcal{N}C^h)'$, the dual of $\mathcal{N}C^h$.

For each $Q_j \in \mathcal{T}_h$ having $m_{j_1}, m_{j_2}, m_{j_3}$, and m_{j_4} as its midpoints of edges, the following linear restriction should be imposed:

$$d_{j_1} + d_{j_3} - d_{j_2} - d_{j_4} = 0,$$

which can be written formally as

$$A_j\mathbf{d} = 0,$$

where $A_j = (A_{j,1}, \dots, A_{j,N_E})$ is a row vector in $\mathbb{R}^{N_E}$ with at most four nontrivial entries such that

$$A_{j,j_1} = A_{j,j_3} = -A_{j,j_2} = -A_{j,j_4} = 1.$$

Consequently,

$$\dim(\mathcal{N}C^h) = \dim((\mathcal{N}C^h)') \leq \dim\{\mathbf{d} = (d_1, \ldots, d_{N_E})^t;\ A_j\mathbf{d} = 0, j = 1, \ldots, N_Q\}.$$

Next, assume that for a subset $J \subsetneqq \{1, 2, \ldots, N_Q\}$,

$$\sum_{j\in J} c_j A_j = 0, \tag{2.6}$$

with $c_j \neq 0$ for all $j \in J$. Set $\overline{\Omega}_J = \bigcup_{j\in J} \overline{Q}_j$. Then there exist a midpoint $m_l \in \partial\Omega_J \cap \mathcal{M}$ and $Q_k \subset \Omega_J$ for which m_l is a midpoint of an edge of Q_k. From the linear restriction concerning Q_k, $A_k\mathbf{d} = 0$, we see that A_k has a nonzero entry in the lth column; moreover, A_k is the unique vector that has a nonzero value in the lth entry among all $A_j, j \in J$, since m_l is at the boundary of Ω_J. Thus (2.6) implies that $c_k = 0$, which is a contradiction. Therefore, we have

$$\{A_1, A_2, \ldots, A_{N_Q}\} \text{ are linearly independent in } \mathbb{R}^{N_E}.$$

Then by an argument quite identical to the proof of Lemma 2.4, we see that

$$\dim(\mathcal{N}C^h) \leq N_E - N_Q.$$

Recall Euler's formula for a simply connected domain, $N_V - N_E + N_Q = 1$. The lemma thus is obtained: $\dim(\mathcal{N}C^h) \leq N_E - N_Q = N_V - 1$. □

The dimension and a basis functions for $\mathcal{N}C^h$ are given in the following theorem.

THEOREM 2.8. *Let φ_j be the function defined in* (2.1) *with each vertex $v_j \in \mathcal{V}$, $j = 1, \ldots, N_V$. Choose any vertex $v_{j_0} \in \mathcal{V}$. Then $\{\varphi_1, \varphi_2, \ldots, \varphi_{N_V}\} \setminus \{\varphi_{j_0}\}$ forms a basis for $\mathcal{N}C^h$. Moreover,* $\dim(\mathcal{N}C^h) = N_V - 1$. *That is, the degrees of freedom for $\mathcal{N}C^h$ is equal to the number of vertices in $\mathcal{T}_h$ minus* 1.

Proof. Without loss of generality, assume $v_{j_0} = v_{N_V}$. Suppose $\sum_{j=1}^{N_V-1} c_j\varphi_j = 0$. Let v_k be any vertex adjacent to v_{N_V}, and let m be the midpoint of $\overline{v_k v_{N_V}}$. Then

$$0 = \sum_{j=1}^{N_V-1} c_j\varphi_j(m) = c_k,$$

since $m \in \mathcal{E}(j)$ only if $j = N_V$ or k. Therefore we see that $c_{k_1} = 0$ for all k_1 such that v_{k_1} is a vertex of an edge $e \in \mathcal{E}(N_V)$. From all such v_{k_1}'s, we then proceed to show that that $c_{k_2} = 0$ for all k_2 such that v_{k_2} is a vertex of an edge $e \in \mathcal{E}(k_1)$. Since Ω is connected, by a finite repetition of the argument, we can conclude that all $c_j, j = 1, \ldots, N_V - 1$, are zeroes. Thus $\{\varphi_1, \varphi_2, \ldots, \varphi_{N_V-1}\}$ is linear independent and forms a basis for $\mathcal{N}C^h$ since $\dim(\mathcal{N}C^h) \leq N_V - 1$ by Lemma 2.7. □

3. The interpolation operator and convergence analysis. In this section we define an interpolation operator and analyze convergence. The case of Dirichlet problems is considered and convergence results are obtained by using standard arguments. The case of Neumann problems, which is analogous to that of Dirichlet problems, is then discussed in brief.

We first consider the following Dirichlet problem:

$$-\nabla \cdot \alpha\nabla u + \beta u = f, \quad \Omega, \tag{3.1a}$$

$$u = 0, \quad \Gamma, \tag{3.1b}$$

with $\alpha = (\alpha_{jk}), \alpha_{jk}, \beta \in L^\infty(\Omega), j,k = 1,2,\ 0 < \alpha_*|\xi|^2 \leq \xi^t\alpha(x)\xi \leq \alpha^*|\xi|^2 < \infty$, $\xi \in \mathbb{R}^2, \beta(x) \geq 0, x \in \Omega$, and $f \in H^{-1}(\Omega)$. The weak problem is given as usual: find $u \in H_0^1(\Omega)$ such that

$$a(u,v) = \langle f, v\rangle\,, \quad v \in H_0^1(\Omega), \tag{3.2}$$

where $a(u,v) = (\alpha\nabla u, \nabla v) + (\beta u, v)$, with $(\cdot,\cdot)$ being the $L^2(\Omega)$ inner product and $\langle\cdot,\cdot\rangle$ the duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$.

Our P_1-nonconforming method for problem (3.1a) is stated as follows: find $u_h \in \mathcal{NC}_0^h$ such that

$$a_h(u_h, v_h) = \langle f, v_h\rangle\,, \quad v_h \in \mathcal{NC}_0^h, \tag{3.3}$$

where

$$a_h(u,v) = \sum_{Q\in\mathcal{T}_h} a_Q(u,v),$$

with $a_Q : H^1(Q) \times H^1(Q) \to \mathbb{R}$ being the restriction of a to Q.

For our convergence analysis, define the projection $\Pi_h : H^2(\Omega) \cap H_0^1(\Omega) \to \mathcal{NC}_0^h$ such that, for $\varphi \in H^2(\Omega) \cap H_0^1(\Omega)$,

$$\Pi_h\varphi(m) = \frac{1}{2}(\varphi(v_1) + \varphi(v_2)) \qquad \text{for all } m \in \mathcal{M},$$

where v_1 and v_2 are the two vertices of the edge in $\mathcal{T}_h$ whose midpoint is m. Notice that Π_h is well defined. Indeed, with $Q \in \mathcal{T}_h$, $v_j, m_j, 1 \leq j \leq 4$, given as in Figure 2, one has

$$\Pi_h\varphi(m_1) + \Pi_h\varphi(m_3) = \frac{1}{2}(\varphi(v_1) + \varphi(v_2) + \varphi(v_3) + \varphi(v_4)) = \Pi_h\varphi(m_2) + \Pi_h\varphi(m_4).$$

Thus by Lemma 2.1, $\Pi_h\varphi \in P_1(Q)$. Clearly $\Pi_h\varphi$ is continuous at all midpoints of edges of $\mathcal{T}_h$. Therefore $\Pi_h\varphi \in \mathcal{NC}_0^h$.

Since Π_h preserves $P_1(Q)$ for all $Q \in \mathcal{T}_h$, standard interpolation approximation results, not by using a reference element but by applying the Bramble–Hilbert lemma to each actual element, lead to the finding that

$$\sum_{Q\in\mathcal{T}_h} ||\varphi - \Pi_h\varphi||_{L^2(Q)} + h\sum_{Q\in\mathcal{T}_h} ||\varphi - \Pi_h\varphi||_{H^1(Q)} \leq Ch^2||\varphi||_{H^2(\Omega)}, \quad \varphi \in H^2(\Omega) \cap H_0^1(\Omega). \tag{3.4}$$

(For instance, a slight modification to Exercise 3.1.2 in [6] using the result of [7] would give the estimate.)

Also, letting $\gamma_j = \partial\Omega \cap \partial Q_j, \gamma_{jk} = \partial Q_j \cap \partial Q_k$, and denoting the midpoint of γ_j and γ_{jk} by m_j and m_{jk}, respectively, define

$$\Lambda^h = \{\lambda \in \Pi_{j,k}\mathcal{P}_0(\gamma_{jk}) \times \Pi_j\mathcal{P}_0(\gamma_j) \mid \lambda_{jk} + \lambda_{kj} = 0, \text{ where } \lambda_{jk} = \lambda|_{\gamma_{jk}},\, \lambda_j = \lambda|_{\gamma_j}\},$$

where $\mathcal{P}_0(S)$ denotes the set of constant functions on a set S. Then define the projection $P_0 : H^2(\Omega) \to \Lambda^h$ so that if $v \in H^2(\Omega)$,

$$\left\langle \alpha\frac{\partial v_j}{\partial \nu_j} - P_0 v_j, z\right\rangle_\gamma = 0 \quad \text{for all } z \in \mathcal{P}_0(\gamma),\ \gamma = \gamma_{jk} \text{ or } \gamma_j, \tag{3.5}$$

where $v_j = v|_{Q_j}$ and ν_j is the unit outward normal to Q_j. One then has

$$\left\{ \sum_j \left\| \alpha \frac{\partial v_j}{\partial \nu_j} - P_0 v \right\|_{L^2(\partial Q_j)} \right\}^2 \leq C h^{\frac{1}{2}} ||v||_2. \tag{3.6}$$

With the broken energy norm

$$||\varphi||_h = a_h(\varphi, \varphi)^{\frac{1}{2}},$$

we are now in a position to state the usual second Strang lemma [16, 17, 6].

LEMMA 3.1. *Let $u \in H^1(\Omega)$ and $u_h \in \mathcal{N}C_0^h$ be the solutions of* (3.2) *and* (3.3), *respectively. Then,*

$$\|u - u_h\|_h \leq C \left\{ \inf_{v \in \mathcal{N}C_0^h} \|u - v\|_h + \sup_{w \in \mathcal{N}C_0^h} \frac{|a_h(u, w) - \langle f, w \rangle \,|}{\|w\|_h} \right\}.$$

Notice that (3.4) implies that

$$\inf_{v \in \mathcal{N}C_0^h} \|u - v\|_h \leq C \|u\|_2 h. \tag{3.7}$$

Next, for the consistency error term, by a simple calculation one has

$$a_h(u, w) - \langle f, w \rangle = \sum_j \left\langle \alpha \frac{\partial u_j}{\partial \nu_j}, w \right\rangle_{\partial Q_j \setminus \gamma_j}.$$

Since a function w in $\mathcal{N}C_0^h$ is linear on each γ_{jk} and continuous at the midpoints, the following useful orthogonality holds:

$$\langle P_0 u_j, w_j \rangle_{\gamma_{jk}} + \langle P_0 u_k, w_k \rangle_{\gamma_{kj}} = \langle P_0 u_j, w_j - w_k \rangle_{\gamma_{jk}} = 0 \qquad \text{for all } w \in \mathcal{N}C_0^h. \tag{3.8}$$

From the two orthogonalities (3.5) and (3.8),

$$a_h(u, w) - \langle f, w \rangle = \sum_j \left\langle \alpha \frac{\partial u_j}{\partial \nu_j} - P_0 u_j, w - m_j \right\rangle_{\partial Q_j \setminus \gamma_j}, \tag{3.9}$$

where m_j is chosen to be the average of w on Q_j. Due to (3.4), (3.6), and a trace theorem,

$$\begin{aligned} &\left| \sum_j \left\langle \alpha \frac{\partial u_j}{\partial \nu_j} - P_0 u_j, w - m_j \right\rangle_{\partial Q_j} \right| \\ &\qquad \leq C ||u||_2 h^{\frac{1}{2}} \left(\sum_j ||w - m_j||_{L^2(Q_j)} ||\nabla (w - m_j)||_{L^2(Q_j)} \right)^{\frac{1}{2}} \\ &\qquad \leq C ||u||_2 h \left(\sum_j ||\nabla w||^2_{L^2(Q_j)} \right)^{\frac{1}{2}} \leq C ||u||_2 ||w||_h h. \end{aligned} \tag{3.10}$$

Consequently, applying the estimates (3.7) and (3.10), combined with (3.9), in Lemma 3.1 gives the usual energy-norm error estimate. The use of a duality argument is

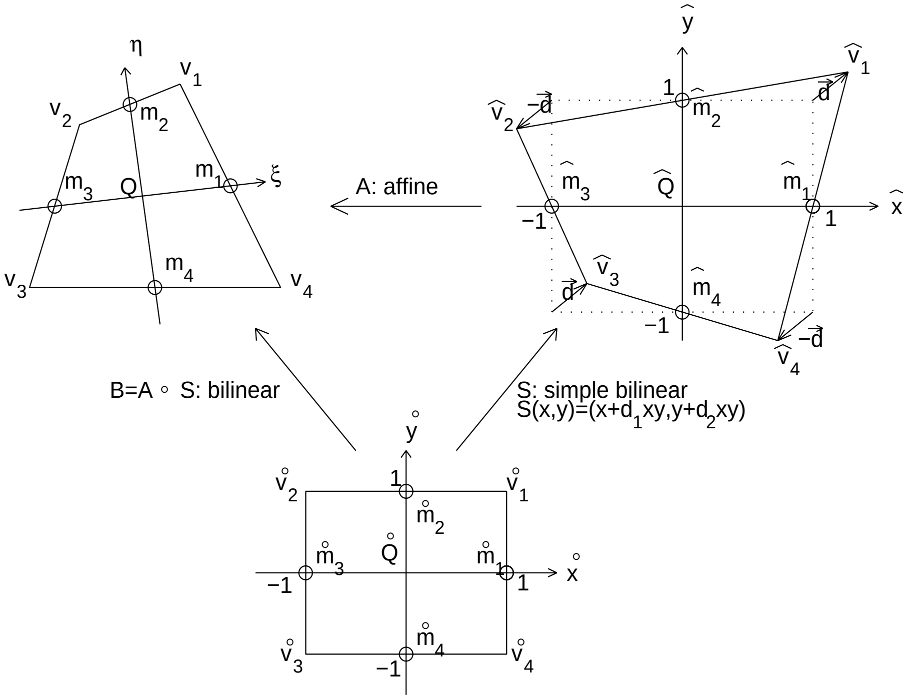


FIG. 4. *The nonparametric reference scheme: a general bilinear mapping B can be regarded as the composition of a simple bilinear map S and an affine map A.*

analogous to that in [9], and therefore we omit the details. To sum up, we have the following theorem.

THEOREM 3.2. *Let $u \in H^1(\Omega)$ and $u_h \in \mathcal{NC}_0^h$ be the solutions of* (3.2) *and* (3.3)*, respectively. Then we have*

$$||u - u_h||_h \leq Ch||u||_{H^2(\Omega)}.$$

Moreover, if Ω is convex and $f \in L^2(\Omega)$, then we have

$$||u - u_h||_{L^2(\Omega)} \leq Ch^2||u||_{H^2(\Omega)}.$$

Remark 3.3. The case of Robin problems is similar to that of Dirichlet problems, replacing the space $H_0^1(\Omega)$ and $\mathcal{NC}_0^h$ $H^1(\Omega)$ and $\mathcal{NC}^h$, as usual.

Remark 3.4. For the case of mixed boundary value problems, the dimension and basis functions can be computed and constructed analogously. Indeed, the dimension and basis functions are between those for the Dirichlet and Robin boundary problems.

4. A nonparametric reference scheme. In this section we introduce a nonparametric reference scheme with which finite elements in general quadrilaterals can be easily built from a fixed reference basis function space defined on a reference domain.

For given $Q \in \mathcal{T}_h$ with vertices $v_j, 1 \leq j \leq 4$, and midpoints of edges $m_j, 1 \leq j \leq 4$, as in Figure 4, there is a unique affine transformation $A : \mathbb{R}^2 \rightarrow Q$ such that

$$A(1,0) = m_1,\ A(0,1) = m_2,\ A(-1,0) = m_3,\ A(0,-1) = m_4,$$

since the four midpoints of any quadrilateral form a parallelogram. In fact, A is given by

$$A(\hat{x},\hat{y}) = \frac{v_1+v_2+v_3+v_4}{4} + \frac{v_1-v_2-v_3+v_4}{4}\hat{x} + \frac{v_1+v_2-v_3-v_4}{4}\hat{y}.$$

Denote $\widehat{Q} = A^{-1}(Q)$ and let $\widehat{m}_j, 1 \le j \le 4$, indicate the points $(1,0)$, $(0,1)$, $(-1,0)$, $(0,-1)$, respectively. Define $\widehat{\varphi}_j \in \mathrm{Span}\{1,\hat{x},\hat{y}\}, 1 \le j \le 4$, such that

$$\widehat{\varphi}_j(\widehat{m}_k) = \begin{cases} 1, & k = j, j+1 \mod 4, \\ 0, & \text{otherwise.} \end{cases}$$

Then, by Lemma 2.2, $P_1(Q) = \mathrm{Span}\{\widehat{\varphi}_j \circ A^{-1}; 1 \le j \le 4,\}$. This enables us to construct a basis function space by using this fixed reference basis function space $\{\widehat{\varphi_j}\}_{j=1}^4$, although $\widehat{Q}$ may vary.

A possible drawback due to the variance of $\widehat{Q}$ may come from difficulty in calculating the integrals of products of basis functions and their gradients on $\widehat{Q}$. However, this will be overcome easily as follows. Let $\mathring{Q}= [-1,1]^2$ and denote its vertices by $\mathring{v}_j, 1 \le j \le 4$, as in Figure 4. Then there is a unique bilinear transformation $B : \mathring{Q} \rightarrow Q$,

$$B(\mathring{x},\mathring{y}) = v_1 + (v_2 - v_1)\frac{1-\mathring{x}}{2} + (v_4 - v_1)\frac{1-\mathring{y}}{2} + (v_3 + v_1 - v_2 - v_4)\frac{1-\mathring{x}}{2}\frac{1-\mathring{y}}{2},$$

so that $B(\mathring{v}_j) = v_j, 1 \le j \le 4$. Indeed, $S = A^{-1} \circ B$ is given by

$$S(\mathring{x},\mathring{y}) = (\mathring{x} + d_1 \mathring{x}\mathring{y}, \mathring{y} + d_2 \mathring{x}\mathring{y}),$$

where

$$(d_1,d_2) = (v_1 + v_3 - v_2 - v_4)\begin{pmatrix} v_1 - v_3 - v_2 + v_4 \\ v_1 - v_3 + v_2 - v_4 \end{pmatrix}^{-1}.$$

Now, we can pull back the integrals on $\widehat{Q}$ to those on $\mathring{Q}$ by a change of variables, using the transformation S. For example, suppose $\varphi_j = \widehat{\varphi}_j \circ A^{-1}, j = 1,2$, to be two basis functions on Q. Then the integral on Q can be calculated as follows:

$$\int_Q \beta(x,y)\varphi_1(x,y)\varphi_2(x,y)\; dxdy$$
$$= \int_{\mathring{Q}} \beta(B(\mathring{x},\mathring{y}))\widehat{\varphi}_1(S(\mathring{x},\mathring{y}))\widehat{\varphi}_2(S(\mathring{x},\mathring{y}))\; |\det DB|\; d\,\mathring{x}\; d\,\mathring{y}.$$

5. The extension to three dimensions.

We give only a brief remark to extend the results in sections 2, 3, and 4, to three dimensions. For the sake of simplicity, let R be a three-dimensional hexahedron, with $m_j, j = 1,\dots,6$, being the barycenters of the six faces such that m_j and m_k are barycenters of opposite faces if $j+k=7$. Analogously to Lemma 2.1, if $u \in P_1(R)$, then

$$u(m_1) + u(m_6) = u(m_2) + u(m_5) = u(m_3) + u(m_4).$$

Conversely, if u_j is a given value at m_j, for $1 \le j \le 6$, satisfying $u_1 + u_6 = u_2 + u_5 = u_3 + u_4$, then there is a unique $u \in P_1(R)$ such that $u(m_j) = u_j, 1 \le j \le$

TABLE 1
Degrees of freedom for Q_1-conforming, P_1-nonconforming, and other nonconforming elements.

Elements	4^2	8^2	16^2	32^2	64^2	128^2	256^2
Q_1-conforming element	9	49	225	961	3969	16129	65025
P_1-NC element	9	49	225	961	3969	16129	65025
Other NC elements	24	112	480	1984	8064	32512	130560

6. This fact therefore leads to the conclusion that the local degrees of freedom for the three-dimensional nonconforming hexahedral element is four. Indeed, the space Span$\{1, x, y, z\}$ serves as the basis for the local nonconforming hexahedral element space for each hexahedron.

Concerning the global basis, consider a standard decomposition $\mathcal{T}_h$ of a three-dimensional domain Ω into the union of hexahedrons R_j with vertices p_k and barycenters m_l. At each vertex p_k, the global basis function φ_k is then defined analogously to the two-dimensional case: $\varphi_k|_{R_j} \in P_1(R_j)$, $\varphi_k(m_l) = 1$ if m_l is the barycenter of a face whose vertex contains p_k; $\varphi_k(m_l) = 0$ otherwise.

Then extensions of the rest of sections 2, 3, and 4 to three dimensions will be valid with suitable modifications.

6. Numerical results. In this section we present several numerical results to compare lowest-order quadrilateral elements which are either conforming or nonconforming. More precisely, six different elements are examined here including the P_1-nonconforming quadrilateral element and the standard Q_1-conforming element. We also test the two rotated Q_1-nonconforming elements introduced by Rannacher and Turek [15] with the degrees of freedom being the four midpoint values at the midpoints of edges and the four average values over edges. In addition, comparisons are made with the elements given by Douglas et al. [9], the local basis of which is of the form Span$\{1, x, y, \theta_l(x) - \theta_l(y)\}$, $l = 1, 2$, where the θ_l is given by

$$\theta_l(t) = \begin{cases} t^2 - \frac{5}{3}t^4, & l = 1, \\ t^2 - \frac{25}{6}t^4 + \frac{7}{2}t^6, & l = 2. \end{cases}$$

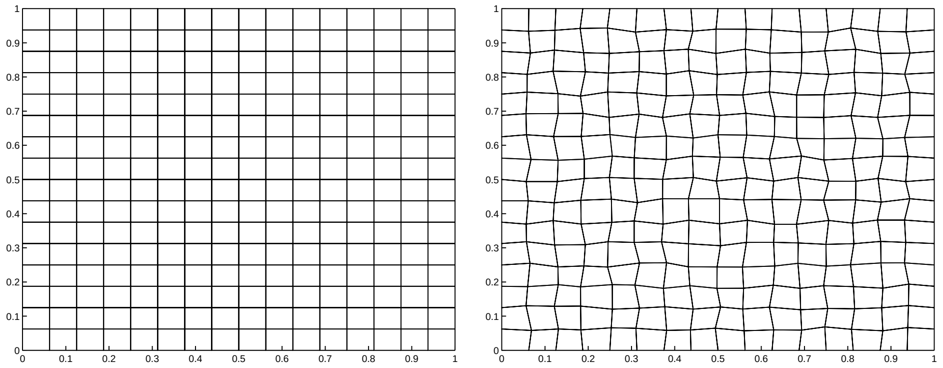
The following Dirichlet boundary problem is employed:

$$\begin{cases} -\triangle u = f, & \Omega, \\ u = 0, & \partial\Omega, \end{cases}$$

with the domain $\Omega = [0, 1]^2$ and the exact solution $u(x, y) = \sin(2\pi x)\sin(2\pi y)(x^3 - y^4 + x^2y^3)$, the function f being generated.

In every figure the logarithmic errors with base 2 are plotted against the logarithmic values of degrees of freedom again with base 2. With the uniform mesh as in Figure 5(a), the numerical errors are given in Figure 6. Convergence behaves more or less in optimal fashion for every element. Notice that the degrees of freedom for P_1-nonconforming and Q_1-conforming are nearly half of those of other nonconforming elements, as shown in Table 1.

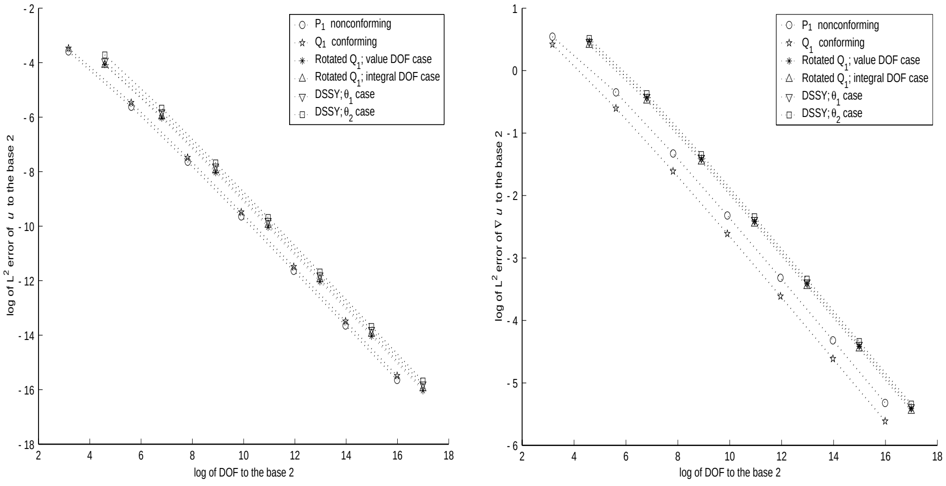
We observed that the optimal convergence patterns break for nonconforming elements if the nonuniform mesh depicted in Figure 5(b) is used with the standard bilinear reference scheme, since the nonconforming spaces do not contain the linear space as explained in [1]. In Figure 7 we show the error behaviors for the P_1-nonconforming element method, using the nonparametric reference scheme introduced in section 4,



(a) Uniform mesh.

(b) Nonuniform mesh.

FIG. 5. *The uniform and nonuniform meshes on* Ω*.*



(a) $||u - u_h||_{L^2(\Omega)}$.

FIG. 6. $L^2(\Omega)$ *errors of* u_h *and* ∇u_h *(in logarithmic scale) on the uniform mesh.*

and compare them with those for the Q_1-conforming element method with the standard bilinear reference scheme applied. These two cases perform as well as we can expect, and the convergence rates are drawn in Figure 7. Our nonparametric reference scheme, which seems to be specific to the P_1-nonconforming quadrilateral element, does not work for the other known nonconforming quadrilateral elements mentioned in the paper; hence it does not seem fair to report such results here, some of which can be found in [14].

Several experiments were performed with the Robin problem. The errors, omitted here, behave quite similarly to those for the case of Dirichlet problems, as discussed above. Some reports can be found in [14].

SPACE LOCALIZATION AND WELL-BALANCED SCHEMES FOR DISCRETE KINETIC MODELS IN DIFFUSIVE REGIMES[*]

LAURENT GOSSE[†] AND GIUSEPPE TOSCANI[‡]

Abstract. We derive and study well-balanced schemes for quasi-monotone discrete kinetic models. By means of a rigorous localization procedure, we reformulate the collision terms as nonconservative products and solve the resulting Riemann problem, whose solution is self-similar. The construction of an asymptotic preserving (AP) Godunov scheme is straightforward, and various compactness properties are established within different scalings. Finally, some computational results are supplied to show that this approach is realizable and efficient on concrete 2×2 models.

Key words. kinetic equations, diffusive relaxation schemes, nonconservative products

1. Introduction.

In this paper, we are interested in the numerical analysis of the forthcoming one-dimensional system of semilinear equations,

$$\partial_t f^\pm \pm \partial_x f^\pm = \mp G(f^+, f^-), \qquad x \in \mathbb{R}, \qquad t > 0, \tag{1.1}$$

in both rarefied and diffusive regimes, the latter being obtained through the transformation $t \to t/\varepsilon^2$, $x \to x/\varepsilon$; see (3.4). The unknowns $0 \leq f^\pm$ are supposed to be at least *bounded variation (BV) functions* [39] in the space variable.

One motivation comes from the study of classical Boltzmann models,

$$\partial_t f + \vec{\xi} \cdot \nabla f = Q(f, f), \tag{1.2}$$

where $0 \leq f(t, x, \xi)$ stands for a density of particles moving with velocity $\vec{\xi}$ in the ambient space and $Q(f, f)$ is a collision operator satisfying some structural assumptions; see, e.g., [7, 38]. Such a model relaxes under certain variables scale

$$\varepsilon \partial_t f + \vec{\xi} \cdot \nabla f = \frac{Q(f, f)}{\varepsilon}, \qquad \varepsilon \to 0+,$$

towards the incompressible Navier–Stokes system [28], whereas for $\varepsilon \simeq 1$, it describes the flow of some cloudy bulk of rarefied molecules.

Coming back to our simplified model (3.4), we consider only particles moving with velocity ±1. Therefore, the density f in (1.2) boils down to a two-component vector satisfying the system (1.1), and the collision term takes a simple form [36]. In order to ensure some stability properties, namely $L^1(\mathbb{R})$-contraction [24, 33, 38], we ask for the so-called *quasimonotonicity* of the right-hand side, which reads

$$G \in C^1(\mathbb{R}^2),\ G(0, 0) = 0, \qquad \partial_+ G \overset{def}{=} \frac{\partial G}{\partial f^+} \geq 0, \qquad \partial_- G \overset{def}{=} \frac{\partial G}{\partial f^-} < 0. \tag{1.3}$$

This matches essentially the standard hypotheses encountered in [8, 29, 30], with the notable exception of [31], in which compactness results are established by means of a different methodology. Our present objective is then to develop and study robust numerical processes for (1.1), (3.4), stable and reliable on the whole range $0 \leq \varepsilon \leq 1$. We aim also at establishing rigorous compactness properties for these schemes in the spirit of the former articles [8, 29].

Part of this program has already been reached by the authors of [17, 21, 22], who introduced the notion of *asymptotic preserving (AP)* schemes relying on former works devoted to semilinear hyperbolic relaxation; in the present context, we refer to [30] and the quotations therein. Although the aforementioned schemes are computationally competitive, they still lack rigorous stability results as the stiffness strengthens in the diffusive limit; see, however, [19, 23]. On the other hand, the discretizations proposed in [2, section 3.1] do not fully address the issue of stability as $\varepsilon \to 0$.

Thus we propose to work out this twofold objective making use of the so-called *well-balanced (WB)* schemes [12, 15] (see also [4, 18, 26, 34]), built on a localization procedure already used in [1, 10, 11]. It relies on a rather simple idea: to reformulate the collision terms as a *nonconservative (NC) product* [25], in order to be able to solve *exactly* self-similar Riemann problems inside a classical Godunov procedure [9].

The concentration process for the right-hand side is carried out within section 2 by means of uniform BV estimates and representation of weak-$\star$ limits of measures. Then in section 3, we deduce in a rather straightforward way a Godunov scheme whose building blocks are nonconservative Riemann problems. Such a scheme turns out to be WB in the rarefied regime (see section 3.1) and AP in the diffusive limit $\varepsilon \to 0$ (see sections 3.2, 3.3). We give several compactness results under very reasonable CFL conditions of the type $\Delta t \simeq \max(\varepsilon h, h^2)$ (where $h, \Delta t$ stand for the space/time steps) by means of uniform BV bounds. Finally, we display some numerical results to illustrate various estimates in section 4 on widely used discrete kinetic models such as Carleman's [6] or Ruijgrok and Wu's [37].

2. A nonconservative reformulation for the kinetic model.

In the present section, we are about to follow the canvas of [10] in order to reformulate (1.1) as a *homogeneous* but *nonconservative* weakly coupled 2×2 system.

2.1. Uniform BV estimates.

We consider the Cauchy problem for $1 \geq \epsilon > 0$:

$$(2.1) \quad \partial_t f^{\pm} \pm \partial_x f^{\pm} = \mp G(f^+, f^-)\partial_x a^{\epsilon}, \qquad 0 \leq f^{\pm}(0,x) = f_0^{\pm}(x) \in L^1 \cap BV(\mathbb{R}).$$

We assume that a^ϵ is Lipschitz continuous for $\epsilon > 0$; more precisely,

$$a^\epsilon(x) = \begin{cases} jh & \text{for} \quad x \in \left] jh, \left(j + \frac{1}{2} - \frac{\epsilon}{2}\right) h \right], \\ \frac{x}{\epsilon} + \left(j + \frac{1}{2}\right) h \left(1 - \frac{1}{\epsilon}\right) & \text{for} \quad x \in \left] \left(j + \frac{1}{2} - \frac{\epsilon}{2}\right) h, \left(j + \frac{1}{2} + \frac{\epsilon}{2}\right) h \right], \\ (j+1)h & \text{for} \quad x \in \left] \left(j + \frac{1}{2} + \frac{\epsilon}{2}\right) h, (j+1)h \right]. \end{cases}$$

(2.2)

This means that $a^{\epsilon=1}(x) = x$, $a^\epsilon \in BV_{loc}(\mathbb{R})$ uniformly in ϵ, $\partial_x a^\epsilon \geq 0$, and moreover, ($\mathbf{1}_A$ stands for the characteristic function of a set A)

$$a^\epsilon \overset{\epsilon \to 0}{\longrightarrow} \sum_{j \in \mathbb{Z}} jh \mathbf{1}_{](j-\frac{1}{2})h, (j+\frac{1}{2})h]}, \qquad h > 0.$$

From [24, 33], one deduces that the Cauchy problem for (2.1) is well posed for any $\epsilon > 0$ but becomes ambiguous in the limit $\epsilon \to 0$ because a so-called *nonconservative product* [25] appears on the right-hand side as $\partial_x a^\epsilon$ concentrates into a Dirac comb.

LEMMA 1. *Let $f_0^\pm \in L^1 \cap BV(\mathbb{R})$ have compact support; then the weak solutions to* (2.1) *$f^\pm$ belong to $BV_{loc}(\mathbb{R}_*^+ \times \mathbb{R})$ uniformly in ϵ.*

Proof. We split the proof into several steps for the sake of clarity.

(i) From [33] and the fact that G is quasi-monotone and $\partial_x a^\epsilon \geq 0$, one deduces a $L^1(\mathbb{R})$ contraction principle for any value $\epsilon > 0$: if $\tilde{f}_0^\pm \in L^1 \cap BV(\mathbb{R})$,

$$(2.3) \qquad \forall t > 0, \qquad \partial_t \int_{\mathbb{R}} (|f^+(t,x) - \tilde{f}^+(t,x)| + |f^-(t,x) - \tilde{f}^-(t,x)|)dx \leq 0.$$

As $G(0,0) = 0$, the null solution trivially satisfies (2.1), and this ensures the L^1 stability and the positivity-preserving property. As we assumed that either $-\partial_- G$ (or $\partial_+ G$) is strictly positive, we can use the implicit function theorem to deduce that the equation $G(u,v) = 0$ admits as a unique solution a smooth curve $v = M(u)$, $M' \geq 0$, called the *Maxwellian distribution*. Therefore, using these curves as comparison functions inside (2.3) gives a maximum principle. More precisely, as in [38], the following domain,

$$[0, \|f_0^+\|_{L^\infty(\mathbb{R})}] \times [0, M(\|f_0^+\|_{L^\infty(\mathbb{R})})],$$

is positively invariant for (2.1). But since (2.1) isn't translation invariant, (2.3) doesn't guarantee the uniform $BV(\mathbb{R})$ stability.

(ii) Differentiating each equation in (2.1) with respect to time, multiplying by $(\mathrm{sgn}(\partial_t f^+), \mathrm{sgn}(\partial_t f^-))^T$, and integrating on $x \in \mathbb{R}$, the same way one reaches

$$(2.4) \qquad \forall t > 0, \qquad \partial_t \int_{\mathbb{R}} (|\partial_t f^+(t,x)| + |\partial_t f^-(t,x)|)dx \leq 0.$$

This implies that $\partial_t f^\pm(t,.)$ are bounded measures on $\mathbb{R}$, and the same holds true for $G(f^+, f^-)\partial_x a^\epsilon$ by the L^∞ stability and (2.2); but by their very definition, one has also

$$(2.5) \qquad |\partial_x f^\pm| - |G(f^+, f^-)\partial_x a^\epsilon| \leq |\partial_t f^\pm| \leq |\partial_x f^\pm| + |G(f^+, f^-)\partial_x a^\epsilon|.$$

So inside any interval $a < 0 < b$ large enough, one gets out of (2.4), (2.5) for any $t > 0$,

$$\int_a^b |\partial_x f^+(t,x)| + |\partial_x f^-(t,x)| dx \leq \int_{\mathbb{R}} |\partial_x f_0^+| + |\partial_x f_0^-| + 4\|G(f^+, f^-)\|_{L^\infty} \int_a^b |\partial_x a^\epsilon|,$$

and this ensures the $BV_{loc}(\mathbb{R})$ stability for $t > 0$.

(iii) It remains to check the L^1 modulus of continuity in the time variable. Thanks to the BV_{loc} bound, we deduce from (2.1) that on the same interval there holds for $t > s \geq 0$ (TV stands for the total variation in space):

$$\int_a^b |f^\pm(t,x) - f^\pm(s,x)| dx \leq |t-s| \left[TV(f_0^+) + TV(f_0^-) + 6\|G(f^+, f^-)\|_{L^\infty} \int_a^b |\partial_x a^\epsilon| \right].$$

And this is enough to conclude the proof. □

Of course, by the classical Helly's compactness principle, we deduce that the sequence of weak solutions to (2.1) is relatively compact in the strong topology of $L^1_{loc}(\mathbb{R}_*^+ \times \mathbb{R})$ as $\epsilon \to 0$.

2.2. Limiting values of the right-hand side. In order to shed complete light on the limit system emanating from (2.1) as $\epsilon \to 0$, we must give a precise meaning to the ambiguous product appearing on its right-hand side. This can be done within the recent theory of *nonconservative products* [25], which can be applied thanks to the uniform BV-bound established in the preceding section.

In order to reveal the nature of the limit for $G(f^+, f^-)\partial_x a^\epsilon$ in the weak-$\star$ topology of measures, we pick up a test function $\psi \in C^0_c(\mathbb{R}^+_* \times \mathbb{R})$ that is continuous and compactly supported and look at the behavior of the sequence

$$\mathcal{I}^\epsilon = \int_{\mathbb{R}^+_* \times \mathbb{R}} G(f^+, f^-)\partial_x a^\epsilon \psi(t,x)dtdx, \qquad \epsilon \to 0.$$

PROPOSITION 1. *Under the assumptions of Lemma* 1, *there holds as* $\epsilon \to 0$,

$$G(f^+, f^-)\partial_x a^\epsilon \overset{weak-\star}{\rightharpoonup} \mathcal{M}$$
$$\sum_{j\in\mathbb{Z}} h \left(\int_0^1 G(\bar{f}^+_{j+\frac{1}{2}}, \bar{f}^-_{j+\frac{1}{2}})(t,\xi)d\xi \right) \delta\left(x - \left(j + \frac{1}{2}\right)h\right),$$

where δ stands for the Dirac mass in $x = 0$ and the "microscopic profiles" $\bar{f}^\pm_{j+\frac{1}{2}}$ satisfy the ordinary differential system

$$\partial_\xi \bar{f}^\pm_{j+\frac{1}{2}} = -hG(\bar{f}^+_{j+\frac{1}{2}}, \bar{f}^-_{j+\frac{1}{2}}), \qquad \xi \in [0,1], \tag{2.6}$$

with the initial data for $t \in \mathbb{R}^+$ and $x = \left(j + \frac{1}{2}\right)h$, $j \in \mathbb{Z}$:

$$\bar{f}^+_{j+\frac{1}{2}}(t, \xi = 0) = f^+(t, x-0), \qquad \bar{f}^-_{j+\frac{1}{2}}(t, \xi = 1) = f^+(t, x+0). \tag{2.7}$$

We stress that the left/right values of $f^\pm(t,.)$ in (2.7) make sense, thanks to the uniform BV-regularity.

Proof. We notice at once that, thanks to the definition (2.2) of a^ϵ, we have

$$\mathcal{I}^\epsilon = \int_{\mathbb{R}^+_*} \sum_{j\in\mathbb{Z}} \int_{(j+\frac{1}{2}-\frac{\epsilon}{2})h}^{(j+\frac{1}{2}+\frac{\epsilon}{2})h} \frac{G(f^+, f^-)}{\epsilon} \psi(t,x)dxdt.$$

Thus it is convenient to perform a rescaling of the space variable:

$$[0,1] \ni \xi = \frac{1}{h\epsilon}\left(x - \left(j + \frac{1}{2} - \frac{\epsilon}{2}\right)h\right), \quad x = \left(j + \frac{1}{2} - \frac{\epsilon}{2}\right)h + \xi h\epsilon \overset{\epsilon\to 0}{\to} \left(j + \frac{1}{2}\right)h.$$

Inside any stripe $\left]\left(j + \frac{1}{2} - \frac{\epsilon}{2}\right)h, \left(j + \frac{1}{2} + \frac{\epsilon}{2}\right)h\right]$, the unknowns $f^\pm$ satisfy the following semilinear boundary value problem for $\xi \in [0,1]$:

$$\begin{cases} \epsilon h \partial_t f^\pm \pm \partial_\xi f^\pm = \mp h.G(f^+, f^-), \qquad t > 0, \\ f^+(t, \xi = 0) = f^+\left(t, \left(j + \frac{1}{2} - \frac{\epsilon}{2}\right)h\right), \\ f^-(t, \xi = 1) = f^-\left(t, \left(j + \frac{1}{2} + \frac{\epsilon}{2}\right)h\right), \\ f^\pm(t = 0, \xi) = f^\pm_0(\xi). \end{cases}$$

Its solution can be computed by the method of characteristics for $t \in [\tau_0, \tau_0 + \epsilon h]$,

$$\dot{\xi}^\pm_{\tau_0} = \tfrac{\pm 1}{\epsilon h}, \qquad \xi^+_{\tau_0}(\tau_0) = 0,\ \xi^-_{\tau_0}(\tau_0) = 1;$$
$$\dot{f}^\pm = \tfrac{\mp 1}{\epsilon} G(f^+, f^-), \qquad f^\pm(t) = f^\pm(t, \xi^\pm_{\tau_0}(t)).$$

One sees, therefore, that along $\xi^{\pm}_{\tau_0}$, there holds

$$\partial_\xi f^{\pm} = \dot{f}^{\pm}\left(\dot{\xi}^{\pm}_{\tau_0}\right)^{-1} = -h.G(f^+, f^-).$$

Since the system is semilinear, $\xi^{\pm}_{\tau_0}$ realizes a diffeomophism from $[\tau_0, \tau_0 + \epsilon h]$ onto $[0,1]$ and has an inverse we note $\tau^{\pm}$; it satisfies

$$\forall \xi \in [0,1], \qquad \tau^+(0) = \tau^-(1) = \tau_0, \qquad \frac{d\tau^{\pm}}{d\xi} = \epsilon h \overset{\epsilon \to 0}{\to} 0.$$

This means in particular that for $\xi \in [0,1]$,

$$f^{\pm}(t) = f^{\pm}(t, \xi^{\pm}_{\tau_0}(t)) = f^{\pm}(\tau^{\pm}(\xi), \xi) \overset{\epsilon \to 0}{\to} f^{\pm}(\tau_0, \xi)$$

and keeps on satisfying the differential equation. It remains to rewrite

$$\mathcal{I}^{\epsilon} = \int_{\mathbb{R}^+_*} \sum_{j \in \mathbb{Z}} \int_0^1 h.G(f^+, f^-)(t, \xi)\psi\left(\left(j + \frac{1}{2} - \frac{\epsilon}{2}\right) h + \xi h \epsilon\right) d\xi dt.$$

We can invoke Lebesgue's dominated convergence theorem in order to pass to the limit $\epsilon \to 0$ in $\mathcal{I}^{\epsilon}$, and we are done. □

From now on, the meaning of the "distributions product" in

$$\partial_t f^{\pm} \pm \partial_x f^{\pm} = \mp \sum_{j \in \mathbb{Z}} h.G(f^+, f^-)\delta\left(x - \left(j - \frac{1}{2}\right) h\right) \tag{2.8}$$

is to be *always* understood as following from Proposition 1. In particular, this last result provides a unique way to solve the Riemann problem for (2.8) with three simple waves, two of them moving with velocity ±1 associated with the convection process, and the static one rendering the action of the localized collision term. More precisely, if we supply four constant states at time $t = 0$ separated by a discontinuity in $x = \left(j - \frac{1}{2}\right) h$ $f^{\pm}_{L/R}$, the self-similar solution to (2.8) is given by

$$\begin{cases} (f^+_L, f^-_L) & \text{for} \quad x - \left(j - \frac{1}{2}\right) h < -t, \\ (f^+_L, \tilde{f}^-) & \text{for} \quad -t < x - \left(j - \frac{1}{2}\right) h < 0, \\ (\tilde{f}^+, f^-_R) & \text{for} \quad 0 < x - \left(j - \frac{1}{2}\right) h < t, \\ (f^+_R, f^-_R) & \text{for} \quad x - \left(j - \frac{1}{2}\right) h > t, \end{cases} \tag{2.9}$$

where, according to the notation of Proposition 1,

$$\tilde{f}^+ = \bar{f}^+_{j-\frac{1}{2}}(t, \xi = 1) \quad \text{and} \quad \tilde{f}^- = \bar{f}^-_{j-\frac{1}{2}}(t, \xi = 0).$$

Such a construction has already been successfully used inside a numerical processing of the so-called *hyperbolic heat equations* in [13]. We also stress that it is but a particular case of the "*h*-Riemann solvers" introduced in [1] within a different context.

2.3. Uniqueness via $L^1(\mathbb{R})$ contraction. Thanks to the dissipative structure of (2.1), it is straightforward to establish uniqueness for the singular problem (2.8) as soon as it has been given a rigorous sense within the theory of distributions.

Proposition 2. *Under the assumptions of Lemma* 1*, let $f_0^\pm, \tilde{f}_0^\pm$ be two sets of initial data for* (2.8)*. The following holds for all $t > 0$:*

$$\|f^+(t,.)-\tilde{f}^+(t,.)\|_{L^1(\mathbb{R})}+\|f^-(t,.)-\tilde{f}^-(t,.)\|_{L^1(\mathbb{R})} \leq \|f_0^+-\tilde{f}_0^+\|_{L^1(\mathbb{R})}+\|f_0^--\tilde{f}_0^-\|_{L^1(\mathbb{R})}.$$

In particular, the weak solution in the sense of Proposition 1 *to* (2.8)*, $f_0^\pm \in L^1 \cap BV(\mathbb{R})$ with compact support, is unique and belongs to $L^\infty(\mathbb{R}^+; BV(\mathbb{R})) \cap Lip(\mathbb{R}^+; L^1(\mathbb{R}))$.*

Proof. We proceed by approximation and come back to (2.1), for which the contraction property (2.3) holds uniformly in ϵ. It remains to integrate it in time and make use of the compactness results to conclude. □

Remark 1. *We would like to mention at this level that the present construction provides an alternative route to the compactness results of* [10] *concerning the convex scalar balance law whose right-hand side concentrates like* (2.1), (2.2):

$$\partial_t u + \partial_x f(u) = k(x) g(u) \partial_x a^\epsilon, \qquad 0 \leq u(t=0,x) = u_0(x) \in L^1 \cap BV(\mathbb{R}).$$

Indeed, if it is assumed that $0 \leq k \in C_c^0(\mathbb{R})$, $g' \leq 0$, and $g(\bar{u}) = 0$ for a $\bar{u} > 0$, then the $L^1(\mathbb{R})$ contraction principle [24] *holds uniformly in ϵ, and the interval*

$$[0, \max(\bar{u}, \|u_0\|_{L^\infty(\mathbb{R})})]$$

is positively invariant since its endpoints give rise as initial data to sub-/supersolutions of the associated homogeneous conservation law. Therefore, it is easy to follow the lines of Lemma 1 *to derive*

$$\partial_t \left(\int_{\mathbb{R}} |\partial_t u|(t,x) dx \right) \leq 0,$$

which gives in turn, as long as k has compact support,

$$\int_{\mathbb{R}} |\partial_x f(u)|(t,x) dx \leq \int_{\mathbb{R}} |\partial_x f(u_0)| + 2\|k(x)g(u)\|_{L^\infty} \int_{Supp(k)} |\partial_x a^\epsilon|,$$

together with a time Lipschitz-modulus of continuity. If, moreover, a nonresonance assumption $f' \geq c > 0$ holds, it turns out that this is enough to establish a uniform $BV_{loc}(\mathbb{R}_*^+ \times \mathbb{R})$ bound for u as $\epsilon \to 0$. Therefore we recover (part of) the conclusion of Lemma 7 *in* [10].

We close this section by introducing $\mathbf{S}$, the *solution operator* for (2.8) as follows.

Proposition 3. *There exists a unique "nonconservative contraction semigroup" $\mathbf{S}$, whose domain is $L^1 \cap BV(\mathbb{R})$ and such that any trajectory $0 < t \mapsto \mathbf{S}(t) f_0^\pm$ coincides with the unique weak solution to* (2.8)*, $f^\pm(t=0,.) = f_0^\pm$, in the sense of distributions.*

3. Derivation and convergence of well-balanced schemes.

Roughly speaking, we are about to develop and study Godunov schemes [9] for (1.1), relying on solving elementary Riemann problems for (2.8) whose self-similar solution is given by (2.9). More precisely, given a time-step $\Delta t > 0$ and a mesh-size $h > 0$, we can define a computational Cartesian grid. The cells read for all $j, n \in \mathbb{Z} \times \mathbb{N}$,

$$C_j = \left] \left(j - \frac{1}{2}\right) h, \left(j + \frac{1}{2}\right) h \right], \qquad I^n = [n\Delta t, (n+1)\Delta t[.$$

Let $\mathcal{P}^h$ be the standard L^2 projector on piecewise-constant functions:

$$\begin{array}{rccc} \mathcal{P}^h: & L^1 \cap BV(\mathbb{R}) & \to & L^1 \cap BV(\mathbb{R}), \\ & \varphi & \mapsto & \left(\int_{C_j} \frac{\varphi(x)}{h} dx \right)_{j \in \mathbb{Z}}. \end{array}$$

It remains to discretize the initial data as follows: we define a piecewise constant approximation $f_h^{\pm}(t=0,.)$ by taking the pointwise values

$$\forall j \in \mathbb{Z}, \qquad f_{j,0}^{\pm} = f_0^{\pm}(jh),$$

and this makes sense thanks to the BV regularity of the considered functions. Our well-balanced Godunov scheme therefore reads as

$$f_h^{\pm}(t,.) = \mathbf{S}(t - n\Delta t) \circ (\mathcal{P}^h \circ \mathbf{S}(\Delta t))^n f_h^{\pm}(t=0,.), \tag{3.1}$$

where n stands for the integer part of $t/\Delta t$. Therefore Riemann problems for (2.8) are to be solved at the endpoints of each C_j, $j \in \mathbb{Z}$.

3.1. The rarefied regime. We focus first on (1.1) in its hyperbolic scaling. Using the divergence theorem, one sees that the Godunov scheme (3.1) generates the following values as $n \in \mathbb{N}$, $j \in \mathbb{Z}$:

$$f_{j,n+1}^{+} = f_{j,n}^{+} - \frac{\Delta t}{h}(f_{j,n}^{+} - f_{j-\frac{1}{2},n}^{+}), \qquad f_{j,n+1}^{-} = f_{j,n}^{-} + \frac{\Delta t}{h}(f_{j+\frac{1}{2},n}^{-} - f_{j,n}^{-}). \tag{3.2}$$

The values at the borders of each cell C_j are given by the generalized jump relations (2.6), (2.7). Thus the upwind scheme (3.2) can be rewritten as

$$\begin{aligned} f_{j,n+1}^{+} &= f_{j,n}^{+} - \frac{\Delta t}{h}(f_{j,n}^{+} - f_{j-1,n}^{+}) - \Delta t \int_0^1 G(\bar{f}_{j-\frac{1}{2}}^{+}, \bar{f}_{j-\frac{1}{2}}^{-})(n\Delta t, \xi) d\xi, \\ f_{j,n+1}^{-} &= f_{j,n}^{-} + \frac{\Delta t}{h}(f_{j+1,n}^{-} - f_{j,n}^{-}) + \Delta t \int_0^1 G(\bar{f}_{j+\frac{1}{2}}^{+}, \bar{f}_{j+\frac{1}{2}}^{-})(n\Delta t, \xi) d\xi. \end{aligned} \tag{3.3}$$

This highlights the ability of this scheme to preserve *exactly* the steady-state curves of (1.1) since, by their very definition, they satisfy the following (cf. (2.6), (2.7)) for all $j \in \mathbb{Z}$:

$$\begin{aligned} f_{j,0}^{+} - f_{j-1,0}^{+} &= -h \int_0^1 G(\bar{f}_{j-\frac{1}{2}}^{+}, \bar{f}_{j-\frac{1}{2}}^{-})(0, \xi) d\xi, \\ f_{j+1,0}^{-} - f_{j,0}^{-} &= -h \int_0^1 G(\bar{f}_{j+\frac{1}{2}}^{+}, \bar{f}_{j+\frac{1}{2}}^{-})(0, \xi) d\xi. \end{aligned}$$

The following stability result is easily established.

LEMMA 2. *Let $f_0^{\pm} \in L^1 \cap BV(\mathbb{R})$; under the hyperbolic CFL condition $\Delta t \leq h$, the approximate solutions $f_h^{\pm}$ obtained from* (3.1), (3.2) *satisfy*

$$TV(f_h^{+}(t,.)) + TV(f_h^{-}(t,.)) \leq \exp\left(2\frac{t}{h}(\exp(Lip(G)h) - 1)\right)[TV(f_0^{+}) + TV(f_0^{-})],$$

where $Lip(G)$ stands for the Lipschitz constant of G.

Proof. We start from (3.3) and follow the proof of Lemma 10 in [10]: by the classical theory of differential equations and a linearization of G, one gets the following inequalities:

$$\begin{aligned}
|f^+_{j,n+1} - f^+_{j-1,n+1}| \leq {} & |f^+_{j,n} - f^+_{j-1,n}| \left(1 - \frac{\Delta t}{h}\right) \\
& + \frac{\Delta t}{h}(1 + (\exp(Lip(G)h) - 1))|f^+_{j-1,n} - f^+_{j-2,n}| \\
& + \frac{\Delta t}{h}(\exp(Lip(G)h) - 1)|f^-_{j+1,n} - f^-_{j,n}|, \\
|f^-_{j+1,n+1} - f^-_{j,n+1}| \leq {} & |f^-_{j+1,n} - f^-_{j,n}| \left(1 - \frac{\Delta t}{h}\right) \\
& + \frac{\Delta t}{h}(1 + (\exp(Lip(G)h) - 1))|f^-_{j+2,n} - f^-_{j+1,n}| \\
& + \frac{\Delta t}{h}(\exp(Lip(G)h) - 1)|f^+_{j,n} - f^+_{j-1,n}|.
\end{aligned}$$

It remains to add these two inequalities, to sum on $j \in \mathbb{Z}$ to derive

$$\begin{aligned}
& \sum_{j\in\mathbb{Z}}(|f^+_{j,n+1} - f^+_{j-1,n+1}| + |f^-_{j+1,n+1} - f^-_{j,n+1}|) \\
\leq {} & \left(1 + \frac{2\Delta t}{h}(\exp(Lip(G)h) - 1)\right) \sum_{j\in\mathbb{Z}}(|f^+_{j,n} - f^+_{j-1,n}| + |f^-_{j+1,n} - f^-_{j,n}|).
\end{aligned}$$

And this is enough to conclude, since $BV(\mathbb{R}) \subset L^\infty(\mathbb{R})$. □

REMARK 2. *This proof is a direct adaptation to* (1.1) *of the one given for Lemma* 10 *in* [10]*. We mention here that there exists, however, a much quicker way to establish this former compactness result, relying on* [27]*. Indeed, one can consider any nonhomogeneous scalar balance law endowed with a localized right-hand side,*

$$\partial_t u + \partial_x f(u) - g(u)\partial_x a = 0, \qquad \partial_t a = 0,$$

as an elementary but nonconservative 2×2 *Temple system whose wave curves are the level sets of the strong Riemann invariants (in the notation of* [10]*):*

$$a \text{ and } w(u, a) = \phi^{-1} \circ (\phi(u) - a), \qquad \phi'(u) = \frac{f'(u)}{g(u)}.$$

Therefore Lemmas 3.1 *and* 3.2 *in* [27] *imply that the Godunov scheme decreases the total variation of* $w(t, .)$*. This entails control on the* $u(t, .)$ *variable in the case in which*

$$0 < c \leq \partial_u w(u, a) \leq C < +\infty,$$

and this is a consequence of the nonresonance assumption $f'(u) \neq 0$*. Thus strong* L^1_{loc} *compactness for the scalar "well-balanced" scheme follows. It does not seem that the same shortcut applies here in order to shrink the proof of Lemma* 2*.*

By standard arguments, we can establish strong L^1_{loc} compactness for $f^\pm_h$ as $h \to 0$, relying on the bound stated in Lemma 2.

3.2. The diffusive regime: BV stability. We move now to the study of numerical approximations to (1.1) in its *diffusive scaling*, that is to say,

$$\partial_t f^{\pm} \pm \frac{1}{\varepsilon}\partial_x f^{\pm} = \mp\frac{1}{\varepsilon^2}G(f^+,f^-), \qquad 0<\varepsilon<1, \qquad x\in\mathbb{R}, \qquad t>0. \tag{3.4}$$

In this perspective, the so-called *hyperbolic heat equations* treated in [13] correspond to the special case $G(f^+,f^-)=f^+-f^-$. We assume also that the Maxwellian distribution is given by $M(f)=f$, that is to say,

$$f^+=f^- \qquad \Rightarrow \qquad G(f^+,f^-)=0.$$

In this setting and for any $\varepsilon>0$, the previous technique relying on a localization of the source term onto a Dirac comb still applies, but the differential system (2.6), (2.7) in Proposition 1 has to be rescaled,

$$\forall j\in\mathbb{Z}, \qquad \partial_\xi \bar f^{\pm}_{j+\frac12} = \frac{-h}{\varepsilon}G(\bar f^+_{j+\frac12}, \bar f^-_{j+\frac12}), \tag{3.5}$$

and the stability result given in Lemma 2 becomes obsolete because of both the unrealistic restriction $\Delta t\le\varepsilon h$ and the fact that $Lip(G)/\varepsilon$ can be made arbitrarily big. It is therefore of interest to consider the *macroscopic variables*, which read

$$\rho=f^++f^-, \qquad J=\frac{f^+-f^-}{\varepsilon}, \tag{3.6}$$

and within which the system (3.5) can be rewritten as

$$\partial_\xi J=0, \qquad \partial_\xi\rho=-\frac{2h}{\varepsilon}G\left(\frac12(\rho+\varepsilon J),\frac12(\rho-\varepsilon J)\right)\overset{def}{=}-2hA(\rho,J,\varepsilon J). \tag{3.7}$$

Indeed, the precise form of A can be revealed, relying on the mean-value theorem:

$$A(\rho,J,\varepsilon J)=\frac1\varepsilon\underbrace{G\left(\frac\rho2,\frac\rho2\right)}_{=0}+\frac J2(\partial_+G-\partial_-G)\left(\frac{\rho+\theta\varepsilon J}{2},\frac{\rho-\theta\varepsilon J}{2}\right)$$

for some $\theta\in[0,1]$. As ρ and J also realize the first two moments of the discrete kinetic model (1.1), it can be expected that they satisfy the semilinear hyperbolic system

$$\partial_t\rho+\partial_xJ=0, \qquad \varepsilon^2\partial_tJ+\partial_x\rho=-2A(\rho,J,\varepsilon J), \tag{3.8}$$

which has been shown recently to exhibit diffusive asymptotics as $\varepsilon\to0$. More precisely, by the implicit function theorem, one goes formally from (3.8) to

$$J=-B(\rho,\partial_x\rho), \qquad \partial_t\rho=\partial_x(B(\rho,\partial_x\rho)),$$

and this limiting behavior holds rigorously, for instance, if

- $A(\rho,J,\varepsilon J)=A(\rho,J)=\rho^\alpha J$ and $B(\rho,\partial_x\rho)=\frac12\rho^{-\alpha}\partial_x\rho$, $\alpha<-1$ (see [29]),
- $A(\rho,J,\varepsilon J)=J-\frac12(\rho^2+(\varepsilon J)^2)$ and $B(\rho,\partial_x\rho)=-\frac12(\rho^2-\partial_x\rho)$ (see [8]).

Some other results are available in different contexts; see, for instance, [5, 31].

The main point of the AP schemes [17, 21] is to capture these features numerically as $\varepsilon\to0$ with a fixed (and reasonable!) $h>0$.

Following Proposition 1, we integrate (3.7) on $\xi \in [0,1]$ and, inverting (3.6), we find within the notation of (2.9) and with $\bar\rho = \bar f^+ + \bar f^-$

$$\Phi(J; f_L^+, f_R^-) \overset{def}{=} (2f_R^- + \varepsilon J) - (2f_L^+ - \varepsilon J) + 2h \int_0^1 A(\bar\rho, J, \varepsilon J) d\xi = 0. \tag{3.9}$$

We plan to apply the implicit function theorem to Φ since

$$\partial_J \Phi = 2\varepsilon + 2h \int_0^1 \partial_J A(\bar\rho, J, \varepsilon J) d\xi, \qquad \partial_J A = \frac{1}{2}(\partial_+ G - \partial_- G) > 0.$$

Therefore, the solution of (3.9) in J is given by a smooth *flux function*:

$$\begin{array}{rccc} F: & (\mathbb{R}_*^+)^2 & \to & \mathbb{R}, \\ & (f_L^+, f_R^-) & \mapsto & J = F(f_L^+, f_R^-). \end{array} \tag{3.10}$$

Moreover, we know that

$$\nabla F = \left(\frac{-1}{\partial_J \Phi} \right) \nabla \Phi.$$

Therefore we propose the following definition.

DEFINITION 1. *We say that the flux function F* (3.10) *is monotone if $F(0,0) = 0$, and it is increasing (resp., decreasing) with respect to its first (resp., second) variable:*

$$\partial_+ F \geq 0, \qquad \partial_- F \leq 0.$$

We also aim at treating (3.4) by means of the modified (partly implicit) numerical scheme one gets out of (3.1), (3.2), (3.3):

$$\begin{aligned} f_{j,n+1}^+ &= f_{j,n}^+ - \frac{\Delta t}{\varepsilon h}(f_{j,n+1}^+ - f_{j,n+1}^-) + \frac{\Delta t}{h} F(f_{j-1,n}^+, f_{j,n}^-), \\ f_{j,n+1}^- &= f_{j,n}^- + \frac{\Delta t}{\varepsilon h}(f_{j,n+1}^+ - f_{j,n+1}^-) - \frac{\Delta t}{h} F(f_{j,n}^+, f_{j+1,n}^-). \end{aligned} \tag{3.11}$$

In sharp contrast with (3.3), this emphasizes the consistency of such a discretization with a diffusive asymptotic behavior for $\rho_{j,n} = f_{j,n}^+ + f_{j,n}^-$. Of course, we keep on using the notation $f_h^\pm$ for the piecewise constant numerical approximations to (3.4) generated by (3.11).

LEMMA 3. *Let $0 \leq f_0^\pm \in L^1 \cap BV(\mathbb{R})$; if the flux function F is monotone and under the parabolic CFL condition $(\Delta t + \varepsilon h) Lip(F) \leq h$, one has for all $t > 0$, $\varepsilon > 0$*

- $\|f_h^+(.,t)\|_{L^1(\mathbb{R})} + \|f_h^-(.,t)\|_{L^1(\mathbb{R})} \leq \|f_0^+\|_{L^1(\mathbb{R})} + \|f_0^-\|_{L^1(\mathbb{R})}$,
- $TV(f_h^+(.,t)) + TV(f_h^-(.,t)) \leq TV(f_0^+) + TV(f_0^-)$,

and the scheme (3.11) *is positivity preserving.*

The aforementioned CFL condition is said to be *parabolic* because $Lip(F)$ is $O(h^{-1})$ and doesn't blow up as $\varepsilon \to 0$. It means also in most cases that $\varepsilon \leq O(h)$; in this sense, it completes the picture with (3.2), which is stable in the complementary range of parameters.

REMARK 3. *We stress that there exist many cases of interest for which the monotonicity of F can be established rigorously. For instance if $A(\rho, J) = k(\rho)J$, $k > 0$ (see* [29]*), one may use a different functional:*

$$\tilde\Phi(J; f_L^+, f_R^-) \overset{def}{=} \phi(2f_R^- + \varepsilon J) - \phi(2f_L^+ - \varepsilon J) + 2hJ = 0, \qquad \phi'(\rho) = \frac{1}{k(\rho)}. \tag{3.12}$$

Proof. For ease of writing, we denote $a = 1 + \frac{\Delta t}{\varepsilon h}$, $b = \frac{\Delta t}{\varepsilon h}$. The system (3.11) can be explicitly solved, and this is a desirable feature according to [17]:

$$\begin{aligned} f^+_{j,n+1} &= \frac{a}{a+b}\left(f^+_{j,n} + \frac{\Delta t}{h}F(f^+_{j-1,n}, f^-_{j,n})\right) + \frac{b}{a+b}\left(f^-_{j,n} - \frac{\Delta t}{h}F(f^+_{j,n}, f^-_{j+1,n})\right), \\ f^-_{j,n+1} &= \frac{b}{a+b}\left(f^+_{j,n} + \frac{\Delta t}{h}F(f^+_{j-1,n}, f^-_{j,n})\right) + \frac{a}{a+b}\left(f^-_{j,n} - \frac{\Delta t}{h}F(f^+_{j,n}, f^-_{j+1,n})\right). \end{aligned}$$

In order to control the L^1 norm, we linearize F around $(0,0)$:

$$F(f^+_{j-1,n}, f^-_{j,n}) = \partial_+F(\xi_{j-\frac{1}{2},n})f^+_{j-1,n} + \partial_-F(\xi_{j-\frac{1}{2},n})f^-_{j,n}.$$

The monotonicity property of the flux function together with the CFL restriction give

$$\begin{aligned} |f^+_{j,n+1}| \le \frac{1}{a+b}\Bigg[&|f^+_{j,n}|\left(a - \frac{b\Delta t}{h}\partial_+F(\xi_{j+\frac{1}{2},n})\right) + |f^+_{j-1,n}|\frac{a\Delta t}{h}\partial_+F(\xi_{j-\frac{1}{2},n}) \\ &+ |f^-_{j,n}|\left(b + \frac{a\Delta t}{h}\partial_-F(\xi_{j-\frac{1}{2},n})\right) - |f^-_{j+1,n}|\frac{b\Delta t}{h}\partial_-F(\xi_{j+\frac{1}{2},n})\Bigg], \\ |f^-_{j,n+1}| \le \frac{1}{a+b}\Bigg[&|f^+_{j,n}|\left(b - \frac{a\Delta t}{h}\partial_+F(\xi_{j+\frac{1}{2},n})\right) + |f^+_{j-1,n}|\frac{b\Delta t}{h}\partial_+F(\xi_{j-\frac{1}{2},n}) \\ &+ |f^-_{j,n}|\left(a + \frac{b\Delta t}{h}\partial_-F(\xi_{j-\frac{1}{2},n})\right) - |f^-_{j+1,n}|\frac{a\Delta t}{h}\partial_-F(\xi_{j+\frac{1}{2},n})\Bigg]. \end{aligned}$$

Such a convex combination ensures the positivity-preserving property for (3.11). Adding the two inequalities leads to

$$\sum_{j\in\mathbb{Z}} h(|f^+_{j,n+1}| + |f^-_{j,n+1}|) \le \sum_{j\in\mathbb{Z}} h(|f^+_{j,n}| + |f^-_{j,n}|).$$

The decay in time of the total variation in space is shown by similar arguments. □

This stability result is already enough to ensure strong compactness for the numerical approximations $f^\pm_h$ generated by (3.11) as $h \to 0$, as long as the relaxation parameter ε remains strictly positive.

3.3. The diffusive regime: Limiting behavior. We are now interested in the behavior of (3.11) as $\varepsilon \to 0$. The forthcoming result completes Lemma 3.

LEMMA 4. *Under the hypotheses of Lemma* 3, *we suppose* $\varepsilon\|\tilde{F}\|_{L^\infty} < 1$ *in the following decomposition, which holds for* F, *uniformly in* $h \ge 0$:

$$\begin{gathered} F(f^+_h, f^-_h) = (f^+_h - f^-_h)\tilde{F}(f^+_h, f^-_h) + g(f^+_h, f^-_h), \\ \tilde{F} \in C^1(\mathbb{R}^2), \quad \tilde{F}(f^+_h, f^-_h) \in L^\infty(\mathbb{R}), \quad g(f^+_h, f^-_h) \in L^1(\mathbb{R}). \end{gathered} \tag{3.13}$$

Then one has the estimates uniformly in $\varepsilon \ge 0$ *(where* C *is an absolute constant):*

- $\|f^+(t,.) - f^-(t,.)\|_{L^1(\mathbb{R})} \le \|f^+_0 - f^-_0\|_{L^1(\mathbb{R})}$
  $+ C\varepsilon(\|g\|_{L^1(\mathbb{R})} + hLip(F)(TV(f^+_0) + TV(f^-_0))),$
- $\|f^+(t,.) - f^+(s,.)\|_{L^1(\mathbb{R})} + \|f^-(t,.) - f^-(s,.)\|_{L^1(\mathbb{R})} \le \sqrt{|t-s|}$
  $\times \left[\frac{2}{\varepsilon}\|f^+_0 - f^-_0\|_{L^1(\mathbb{R})} + hLip(F)(1+C)(TV(f^+_0) + TV(f^-_0)) + C\|g\|_{L^1(\mathbb{R})}\right].$

The condition $\varepsilon\|\tilde{F}\|_{L^\infty} < 1$ roughly means that $\varepsilon < O(h)$; this kind of restriction has already been encountered in [14] in order to show compactness in the context of another relaxation problem. The technical assumption (3.13) will be checked in the numerical examples later on: it expresses the fact that the Maxwellian distribution for (3.4), (1.1) should be given by $f^+ = f^-$. (In the case of the Goldstein–Taylor model, the decomposition is trivial, $\tilde{F} \equiv \frac{1}{h+\varepsilon}$, $g \equiv 0$; see [13].)

Proof. We keep on using the same notations; from (3.11), we get

$$(1+2b)(f^+_{j,n+1} - f^-_{j,n+1}) = (f^+_{j,n} - f^-_{j,n}) + \frac{2\Delta t}{h} F(f^+_{j,n}, f^-_{j,n})$$
$$+ \frac{\Delta t}{h}[F(f^+_{j-1,n}, f^-_{j,n}) + F(f^+_{j,n}, f^-_{j+1,n}) - 2F(f^+_{j,n}, f^-_{j,n})].$$

We now use the decomposition (3.13) in order to get

$$(1+2b)|f^+_{j,n+1} - f^-_{j,n+1}| \leq |f^+_{j,n} - f^-_{j,n}| \left(1 + \frac{2\Delta t}{h}\|\tilde{F}\|_{L^\infty}\right)$$
$$+ \frac{2\Delta t}{h}|g(f^+_{j,n}, f^-_{j,n})| + \frac{\Delta t}{h} Lip(F)[|f^+_{j-1,n} - f^+_{j,n}| + |f^-_{j+1,n} - f^-_{j,n}|].$$

Thus an elementary computation shows that

$$\alpha \overset{def}{=} \frac{1 + \frac{2\Delta t}{h}\|\tilde{F}\|_{L^\infty}}{1 + \frac{2\Delta t}{\varepsilon h}} < 1 \qquad \Leftrightarrow \qquad \varepsilon\|\tilde{F}\|_{L^\infty} < 1.$$

This implies that

$$\|f^+(t,.) - f^-(t,.)\|_{L^1(\mathbb{R})} \leq \|f^+_0 - f^-_0\|_{L^1(\mathbb{R})}$$
$$+ \frac{\varepsilon}{1-\alpha}(\|g\|_{L^1(\mathbb{R})} + h.Lip(F)[TV(f^+_0) + TV(f^-_0)]),$$

and the control on the Maxwellian distribution follows.

Concerning the L^1-modulus of continuity in time, following [13], we rewrite the first equation in (3.11) as

$$f^+_{j,n+1} - f^+_{j,n} + \frac{\Delta t}{\varepsilon h}(f^+_{j,n+1} - f^+_{j,n}) = \frac{\Delta t}{\varepsilon h}(f^-_{j,n+1} - f^-_{j,n}) - \frac{\Delta t}{\varepsilon h}(f^+_{j,n} - f^-_{j,n}) + \frac{\Delta t}{h}F(f^+_{j-1,n}, f^-_{j,n}),$$

in order to derive for all $j \in \mathbb{Z}$, $n \in \mathbb{N}$,

$$|f^+_{j,n+1} - f^+_{j,n}|\left(1 + \frac{\Delta t}{\varepsilon h}\right) - \frac{\Delta t}{\varepsilon h}|f^-_{j,n+1} - f^-_{j,n}| \leq \frac{\Delta t}{\varepsilon h}|f^+_{j,n} - f^-_{j,n}| + \frac{\Delta t}{h}|F(f^+_{j-1,n}, f^-_{j,n})|,$$

together with a similar expression for the f^- variable. Therefore, we arrive at

$$|f^+_{j,n+1} - f^+_{j,n}| + |f^-_{j,n+1} - f^-_{j,n}| \leq \frac{2\Delta t}{\varepsilon h}|f^+_{j,n} - f^-_{j,n}|$$
$$+ \frac{\Delta t}{h} Lip(F)[|f^+_{j-1,n} - f^+_{j,n}| + |f^-_{j+1,n} - f^-_{j,n}|],$$

and we are done with the second inequality of Lemma 4, just summing on $j \in \mathbb{Z}$ and noticing that under a parabolic CFL condition, $\frac{\Delta t}{h} = O(h) = O(\sqrt{\Delta t})$. □

As a consequence of Lemma 4, strong compactness as $\varepsilon \to 0$, $h > 0$ fixed follows as soon as one provides a so-called well-prepared initial datum, that is to say,

$$\|f_0^+ - f_0^-\|_{L^1(\mathbb{R})} = O(\varepsilon). \tag{3.14}$$

Such an initialization for (3.4) cancels any kind of *initial layer*, which would destroy the Hölder time regularity of the process (see also [35] for a similar remark) in $t = 0+$.

With obvious notation, we can easily deduce the asymptotic behavior of the scheme (3.11) as $\varepsilon \to 0$; adding the two equations, we derive

$$\rho_{j,n+1} = \rho_{j,n} + \frac{\Delta t}{h}\left(F\left(\frac{\rho_{j-1,n}}{2}, \frac{\rho_{j,n}}{2}\right) - F\left(\frac{\rho_{j,n}}{2}, \frac{\rho_{j+1,n}}{2}\right)\right) + \mathcal{R}_{j,n}, \tag{3.15}$$

and the estimates from Lemma 4 ensure that the remaining term is of the order of ε in L^1 as a consequence of the smoothness of F. This has already been evidenced by explicit computations with the Goldstein–Taylor model in [13].

Remark 4. *At this point, we underline that, relying on the monotonicity of F,* (3.13) *can be easily fulfilled using the mean-value theorem:*

$$F(f^+, f^-) = (f^+ - f^-)\partial_+ F(\xi) + \operatorname{div}(F)(\xi) f^-, \qquad \xi \in (\mathbb{R}^+)^2. \tag{3.16}$$

Since $f^\pm(t,.) \in L^1(\mathbb{R})$, what we need is just $\operatorname{div}(F) = O(1)$ *uniformly in $h \geq 0$. It turns out that this corresponds to a splitting of the flux function F between a diffusive and a convective part when looking at the scheme* (3.15) *since it can be rewritten as*

$$\rho_{j,n+1} = \rho_{j,n} + \frac{\Delta t}{2h}\partial_+ F(\xi_{j,n})(\rho_{j+1,n} - 2\rho_{j,n} + \rho_{j-1,n}) - \frac{\Delta t}{2h}\operatorname{div}(F)(\xi_{j,n})(\rho_{j+1,n} - \rho_{j,n}).$$

One readily checks that this scheme is L^∞-stable; its L^1 and BV stability are just particular cases of Lemma 3.

As a byproduct of Lemmas 3 and 4, we can state the following theorem, which deals with the cases investigated by Lions and Toscani in [29].

Theorem 1. *Assume that $0 \leq f_0^\pm \in L^1 \cap BV(\mathbb{R})$ are initial data for* (3.4) *with $G(f^+, f^-) = (f^+ + f^-)^\alpha (f^+ - f^-)$, $\alpha \leq 0$, and satisfy* (3.14). *Then as $h, \varepsilon \to 0$ under the prescribed CFL conditions, the sequence $f_h^\pm$ generated by the scheme* (3.11) *is relatively compact in the strong topology of $L^1_{loc}(\mathbb{R}^+_* \times \mathbb{R})$. In particular, $\rho_h = f_h^+ + f_h^-$ converges towards the unique solution in the sense of distributions to*

$$\partial_t \rho = \frac{1}{2}\partial_x(\rho^{-\alpha}\partial_x \rho), \qquad \rho(t=0,.) = 2f_0^+ = 2f_0^-.$$

Proof. We are precisely in position to use the modified functional $\tilde{\Phi}$ in (3.12) since in the notation of Remark 3, $k(\rho) = \rho^\alpha \geq 0$. Thus the flux function F exists and is monotone in the sense of Definition 1. Moreover, the Maxwellian distribution is $f^+ = f^-$, and we can take $g \equiv 0$ in (3.13) since by the mean-value theorem we get some expression for the flux function from (3.12):

$$F(f_L^+, f_R^-) = \frac{f_L^+ - f_R^-}{h.k(\zeta) + \varepsilon}, \qquad \zeta \in \mathbb{R}^+. \tag{3.17}$$

The conclusion thus follows from Lemma 4 and (3.15). □

We left behind the cases $0 < \alpha \leq 1$ (fast diffusion equations) as $\tilde{\Phi}$ can become singular if $\rho = 0$; this isn't an issue in practical computations (see section 4.3).

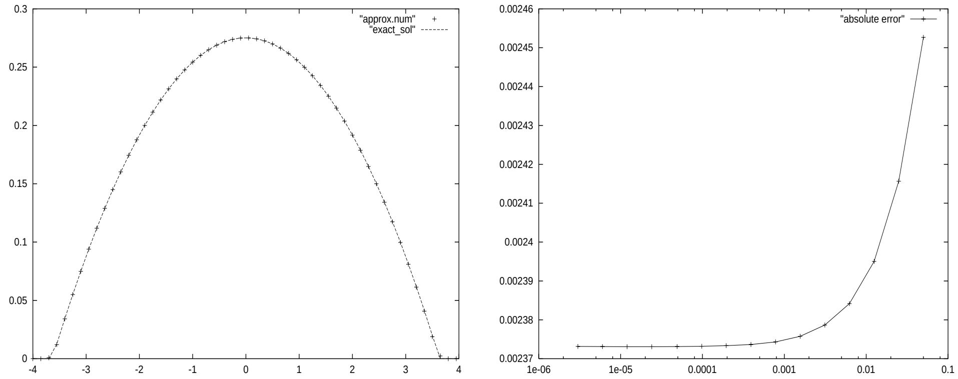

FIG. 4.1. *Numerical results for* (3.11) *on Barenblatt's problem in* $T = 3$*:* $3.10^{-6} \leq \varepsilon \leq 5.10^{-2}$.

4. Numerical experiments.

We illustrate in this section the results previously stated by means of some numerical runs of increasing difficulty inspired by those in [13, 19].

4.1. The porous media equation.

We simulate here the so-called Barenblatt's problem [3], which consists of finding a particular solution to the porous media equation whose analytical expression is known. More precisely, we select $A(\rho, J) = \frac{J}{4\rho}$ in (3.8), which gives $\alpha = -1$ in Theorem 1, and we look for

$$\rho(t,x) = \frac{1}{r(t)} \left(1 - \left(\frac{x}{r(t)} \right)^2 \right) \mathbf{1}_{|x| \leq r(t)}, \qquad r(t) = \big(12(1+t)\big)^{\frac{1}{3}}.$$

In this case, (3.12) is solved explicitly, and the flux function is given by

$$F(f_L^+, f_R^-) = \frac{(f_L^+)^2 - (f_R^-)^2}{(h/4) + \varepsilon(f_L^+ + f_R^-)}.$$

The partial derivatives do not change signs, whatever values ε, h take, since the scheme (3.11) preserves positivity and

$$\partial_+ F(f_L^+, f_R^-) = \frac{2hf_L^+ + 4\varepsilon(f_L^+ + f_R^-)^2}{\big(h + 4\varepsilon(f_L^+ + f_R^-)\big)^2}, \qquad \partial_- F(f_L^+, f_R^-) = -\frac{2hf_R^- + 4\varepsilon(f_L^+ + f_R^-)^2}{\big(h + 4\varepsilon(f_L^+ + f_R^-)\big)^2}.$$

Notice that, since we deal with a quadratic nonlinearity, the value of ζ in (3.17) is simply given by an arithmetic average. Numerical results are shown in Figure 4.1 in time $T = 3$, with the parameters $h = 0.15$ and $\Delta t = 0.01$. On the right, the absolute error between (3.11) and the exact solution is displayed as a function of ε; it stalls below a certain value as the value of h becomes a limiting factor.

4.2. The advection-diffusion equation.

We move on now to another equation which has been investigated from the relaxation point of view in [20, 5, 2]:

$$(4.1) \qquad \partial_t \rho + \partial_x \rho = \frac{1}{2} \partial_{xx} \rho, \qquad x \in \mathbb{R}, \qquad t > 0.$$

Here, we apply the same program, relying on (3.8) together with the right-hand side $A(\rho, J) = J - \rho$. Once again, we are able to solve (3.7), and the flux function F is

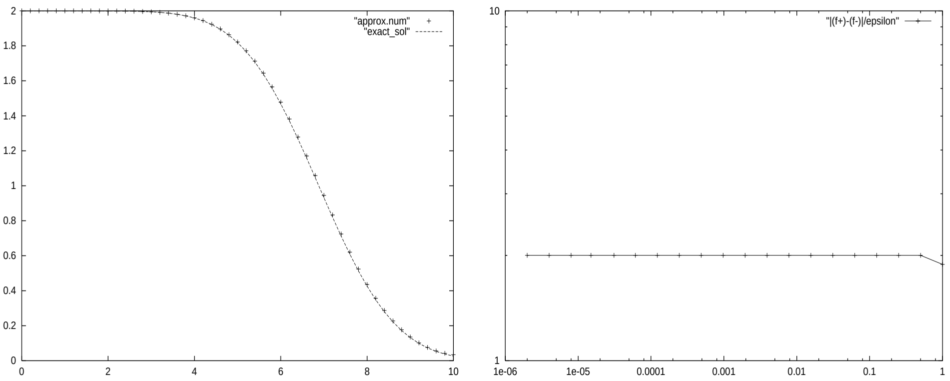

FIG. 4.2. *Numerical results for* (3.11), (4.1) *on a Riemann problem:* $2.10^{-6} \leq \varepsilon \leq 1$.

monotone since it comes out to be

$$F(f_L^+, f_R^-) = 2\frac{\exp(2h)f_L^+ - f_R^-}{\exp(2h) - 1 + \varepsilon(1 + \exp(2h))}.$$

By means of Lemma 3, compactness holds in $h \geq 0$ under the CFL condition

$$\frac{2(\Delta t + \varepsilon h)}{1 - \exp(-2h)} \leq h \qquad \Rightarrow \qquad 0 \leq \Delta t = O(h^2),\ \varepsilon < h,$$

and one can check therefore that for (3.16),

$$\operatorname{div}(F) = \frac{2}{1 + \varepsilon\left(\frac{\exp(2h)+1}{\exp(2h)-1}\right)} = O(1), \qquad 0 \leq h \leq 1.$$

Moreover, concerning (3.13) and Lemma 4, we can choose $\tilde{F} = \partial_+ F$ and we get

$$\varepsilon\|\tilde{F}\|_{L^\infty} < 1 \quad \Leftrightarrow \quad \varepsilon < h < 1.$$

Therefore, gathering inside Lemmas 3, 4 and Remark 4, we obtain an analogue of Theorem 1 for (4.1).

THEOREM 2. *Assume that* $0 \leq f_0^\pm \in L^1 \cap BV(\mathbb{R})$ *are initial data for* (3.6), (3.8) *with* $A(\rho, J) = J - \rho$ *and satisfy* (3.14). *Then as* $h, \varepsilon \to 0$ *under the prescribed conditions, the sequence* $f_h^\pm$ *generated by the scheme* (3.11) *is relatively compact in the strong topology of* $L^1_{loc}(\mathbb{R}_*^+ \times \mathbb{R})$. *In particular,* $\rho_h = f_h^+ + f_h^-$ *converges towards the unique solution to* (4.1), $\rho(t = 0, .) = 2f_0^+ = 2f_0^-$.

We close this paragraph by presenting some numerical results which illustrate our statements. We choose some Maxwellian initial data $f_0^\pm(x) = \mathbf{1}_{x<5}$ to compute the solution of (3.8) in $x \in [0, 10]$ for $T = 2$. Of course, the exact solution of (4.1) is given by $\rho(t, x) = 1 - \operatorname{erf}((x - t - 5)/\sqrt{2t})$. We took $h = 0.2$ and $\Delta t = 0.02$; see Figure 4.2.

4.3. The Carleman model. We consider the so-called Carleman's model [6], which corresponds to the choice $A(\rho, J) = \rho J$, that is to say, $\alpha = 1$ in Theorem 1. This presents a difficulty as the asymptotic behavior is singular if $\rho = 0$; anyway, we succeeded in simulating the following *initial-boundary value problem* by means of the

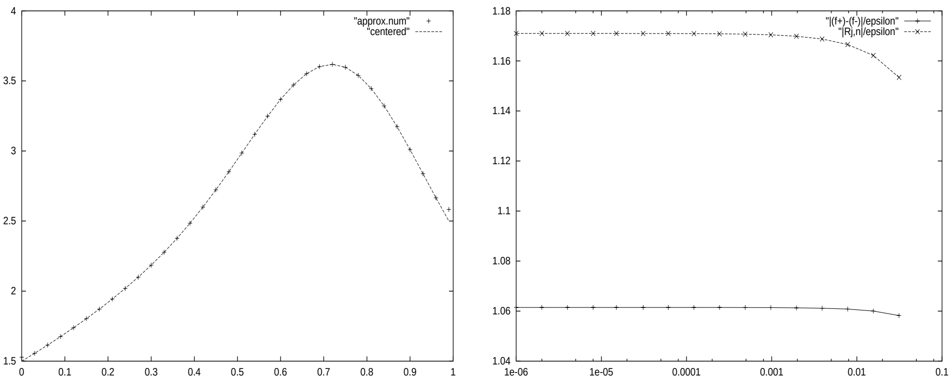

FIG. 4.3. *Transient regime (*$T = 0.01$*) for Carleman's model on the IBVP (initial boundary value problem)* (4.2): $10^{-6} \leq \varepsilon \leq 3.10^{-2}$.

scheme (3.11):

$$\begin{aligned} &\partial_t \rho = \frac{1}{2}\partial_{xx}(\ln(\rho)), \qquad \rho(0,.) = 1 + \mathbf{1}_{x>0.5}; \\ &\rho(.,x=0) = 1.5, \qquad \rho(.,x=1) = 2.5. \end{aligned} \tag{4.2}$$

The computational domain is $x \in [0,1]$, and we took $h = 0.03$, $\Delta t = 0.001$ in order to produce the results displayed in Figure 4.3. In this case, the flux function cannot be known analytically, but it turns out from (3.12) that the equation

$$F(f_L^+, f_R^-) = J = \frac{1}{2h}\ln\left(\frac{2f_L^+ - \varepsilon J}{2f_R^- + \varepsilon J}\right)$$

can be easily solved by means of a fixed point algorithm if ε is small enough. We compared our results with those generated by a standard second order centered scheme for (4.2): the absolute error between them is of the order of ε, as announced in (3.15).

4.4. The Ruijgrok–Wu model. We close this section devoted to numerical tests with the Ruijgrok and Wu model of the Boltzmann equation [8, 29, 30], which relaxes under a diffusive scaling of variables towards the viscous Burgers equation [16]. More precisely, we aim at reproducing with (3.11) the smooth solution of the initial-boundary value problem

$$\begin{aligned} &\partial_t \rho + \rho\partial_x \rho = \frac{1}{2}\partial_{xx}\rho, \qquad \rho(0,.) = 2\big(2 - \mathbf{1}_{x>0}\big); \\ &\rho(.,x=-1) = 4, \qquad \rho(.,x=1) = 2, \end{aligned} \tag{4.3}$$

by means of (3.8) with the right-hand side $A(\rho, J, \varepsilon J) = J - \frac{\varepsilon^2}{2}J^2 - \frac{1}{2}\rho^2$.

Several features make this difficult: first is that, according to [8, 30], this 2×2 system is not unconditionally quasi-monotone. Indeed, this property holds only in case the initial data satisfy $f_0^- \leq 1/2\varepsilon$; this has to be taken into account when starting the simulation. Moreover, the differential equation (3.7) cannot always be solved analytically, and we integrated it approximately through the midpoint rule. Thus the flux function we used comes out of a fixed point algorithm on the following equation, which is deduced from (3.9):

$$J = \frac{1}{2h}\left[(2f_L^+ - \varepsilon J)\left(1 + \frac{h}{2}(2f_L^+ - \varepsilon J)\right) - (2f_R^- + \varepsilon J)\left(1 - \frac{h}{2}(2f_R^- + \varepsilon J)\right) + \varepsilon h J^2\right].$$

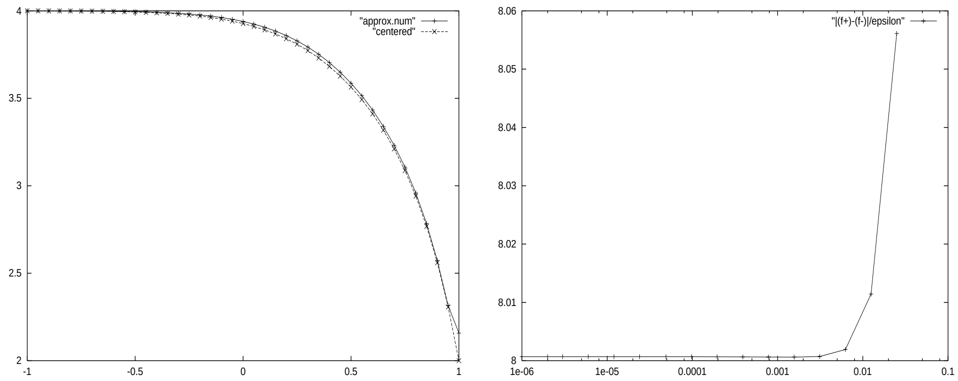

FIG. 4.4. *Transient regime ($T = 0.3$) for Ruijgrok and Wu's model on* (4.3): $10^{-6} \le \varepsilon \le 3.10^{-2}$.

This choice led to the results displayed in Figure 4.4 with the parameters $h = 0.05$, $\Delta t = 0.001$. This demonstrates the fact that an approximate treatment of the jump relation (3.7) still gives a good outcome on a nonlinear problem, and the Maxwellian estimate of Lemma 4 is kept.

5. Conclusion. We presented in this paper a study of a well-balanced scheme for discrete 2×2 kinetic models. This scheme is endowed with several interesting properties as it preserves steady-state curves in the rarefied regime (1.1) and is asymptotic preserving in the sense of [17] as $\varepsilon \to 0$ in (3.4). Moreover, these statements can be rigorously established in many significant situations like, for instance, the cases investigated in [29]. From this point of view, this work can be seen as an extension of [10, 11] to relaxation problems with a diffusive behavior. The present approach may be further developed in several directions; first, multidimensional problems could be considered, then more complex asymptotics could also be tackled in the spirit of [31]. In any case, intermediate scalings considered in [8, 32] (the so-called *incompressible Euler limits*) relaxing to conservation laws can be handled by a suitable modification of (3.5) inside the scheme (3.11).

OPTIMAL ERROR ESTIMATES OF THE CHEBYSHEV–LEGENDRE SPECTRAL METHOD FOR SOLVING THE GENERALIZED BURGERS EQUATION*

HUA WU†, HEPING MA†, AND HUIYUAN LI†‡

Abstract. In this paper the Chebyshev–Legendre collocation method is applied to the generalized Burgers equation. Optimal error estimate of the method is proved for the problem with the Dirichlet boundary conditions. Also, a Legendre–Galerkin–Chebyshev collocation method is given for the generalized Burgers equation. The scheme is basically formulated in the Legendre spectral form but with the nonlinear term being treated by the Chebyshev collocation method so that the scheme can be implemented at Chebyshev–Gauss–Lobatto points efficiently. Optimal order convergence is also obtained through coupling estimates in the L^2-norm and the H^1-norm.

Key words. optimal error estimate, Chebyshev–Legendre method, generalized Burgers equation

1. Introduction.

The spectral method is used widely in seeking numerical solutions of partial differential equations because of its "infinite order" of convergence [4, 2, 9]. It is well known that the Chebyshev method is easier to implement than the Legendre method, but it is more difficult to justify in numerical analysis than the latter. In 1994, Don and Gottlieb first introduced the Chebyshev–Legendre (CL) method [6], where the Legendre method was implemented on Chebyshev points. The boundary conditions were imposed via a penalty technique, and the scheme was in a collocation form. It was shown that the method was stable in the unweighted L^2-norm, and error estimates were given for linear problems [6, 9]. In 1989, Reyna [21] analyzed an L^2-estimate of a modified Chebyshev collocation method for a linear system of equations. Shen [24, 25] recommended the CL method for elliptic problems with simple schemes and efficient implementation. Ma [15, 16] applied CL viscosity methods to the nonlinear conservation laws. Error analysis of a similar CL method but using the Chebyshev–Gauss (CG) points, which are not as common as the Chebyshev–Gauss–Lobatto (CGL) points, can be found in [13].

In this paper, we consider CL methods for the following generalized Burgers equation:

$$
(1.1)\qquad \begin{cases} \partial_t U(x,t) + \partial_x F(U(x,t)) - \nu \partial_x^2 U(x,t) = 0, & (x,\,t) \in (-1,\,1) \times (0,\,T), \\ \alpha U(1,\,t) + \beta \partial_x U(1,\,t) = g^+(t), & t \in (0,\,T), \\ \gamma U(-1,\,t) + \delta \partial_x U(-1,\,t) = g^-(t), & t \in (0,\,T), \\ U(x,0) = U_0(x), & x \in (-1,\,1), \end{cases}
$$

where $F(z)$ is a smooth function of z, the parameters α, γ, β are nonnegative, and δ is nonpositive. Much work has been done on numerical analysis of spectral methods

for Burgers' equation [18, 19, 3, 17, 7], where error estimates of the Legendre spectral/pseudospectral method and the Chebyshev spectral/pseudospectral method for Burgers' equation have been established. The key to the numerical analysis of the Chebyshev method is the coercive property of the nonsymmetric bilinear form, which is true if the function vanishes on the boundaries. This becomes unavailable at the interface points when the method is used with domain decompositions. In order to overcome this difficulty, a modified Chebyshev pseudospectral method is given in [8] which introduced linear polynomials so that the new unknown vanishes at interface points. The CL methods enjoy both advantages of easy implementation of the Chebyshev method and good stability of the Legendre method for the nonlinear problems and can be applied to multidomain cases without such a difficulty. The aim of this paper is to give optimal error estimates of CL methods for solving the generalized Burgers equation. Besides the Chebyshev–Legendre collocation (CLC) method in [6], a Legendre–Galerkin–Chebyshev collocation (LGCC) scheme is presented. The scheme is basically formulated in the Legendre–Galerkin form but with the nonlinear term being treated with the Chebyshev collocation method. Here the CGL points are adopted. By combining Galerkin and collocation methods, the scheme seems more flexible and easier to be generalized to multidomain approaches. In numerical analysis of such methods, we need to consider the stability and approximation properties of the Chebyshev interpolation operator in the L^2-norm rather than in the Chebyshev weighted norm. Also, due to the property of the Chebyshev interpolation operator, we find that it is difficult to get the desired L^2-estimate directly for our fully discrete scheme. This is why an H^1-estimate is involved in analysis. Optimal convergence rate of the methods is obtained through combining L^2- and H^1-estimates.

Given the history of success with the preconditioning methods discussed in [20, 5, 10, 11, 12], such methods will probably be successful in the CLC case, which may be more preferable for high dimensional problems. The LGCC scheme can be solved by efficient direct solvers developed in [22, 23].

2. Schemes. Let $I = (-1, 1)$. Denote by $(\cdot,\cdot)$ and $\|\cdot\|$ the inner product and norm of the space $L^2(I)$, respectively. For $\sigma > 0$, let $H^\sigma(I)$ be the classical Sobolev space equipped with the norm $\|\cdot\|_\sigma$ and the seminorm $|\cdot|_\sigma$. Let $\mathbb{P}_N$ be the set of all algebraic polynomials of degree at most N.

We first apply the CLC method in [6] to the following problem (1.1) [9]: Find $u \in \mathbb{P}_N$ such that for $0 \le j \le N$,

$$\begin{cases} \partial_t u(x_j, t) + (\partial_x I_N^C F(u))(x_j, t) - \nu\partial_x^2 u(x_j, t) = -R(x_j, t), \\ u(x_j, 0) = U_0(x_j), \end{cases} \tag{2.1}$$

where $x_j = \cos(\frac{\pi j}{N})$ $(0 \le j \le N)$ are the CGL points, I_N^C is the Chebyshev interpolation operator at the CGL points, and [6]

$$R(x, t) = \tau_0 Q^+(x)[B^+(t) - g^+(t)] + \tau_N Q^-(x)[B^-(t) - g^-(t)]$$

with

$$Q^+(x) = \frac{(1+x)L_N'(x)}{2L_N'(1)}, \qquad B^+(t) = \alpha u(1, t) + \beta\partial_x u(1, t),$$

$$Q^-(x) = \frac{(1-x)L_N'(x)}{2L_N'(-1)}, \qquad B^-(t) = \gamma u(-1, t) + \delta\partial_x u(-1, t),$$

where $L_N(x)$ is the Legendre polynomial of degree N. For the time advance, we adopt the second order Crank–Nicolson/leapfrog (CNLF) scheme. Let τ be the mesh size in time, and let $S_t = \{k\tau \ : \ k = 1, 2, \ldots, n_t, \ t = n_t\tau\}$. The notations $v_{\hat{t}}(t)$ and $\hat{v}(t)$ are used as

$$v_{\hat{t}}(t) = \frac{v(t+\tau) - v(t-\tau)}{2\tau}, \qquad \hat{v}(t) = \frac{1}{2}[v(t+\tau) + v(t-\tau)].$$

The fully discrete CL scheme for (1.1) is to find $u \in \mathbb{P}_N$ such that for $0 \le j \le N$,

$$\text{(2.2)} \qquad \begin{cases} u_{\hat{t}}(x_j, t) + (\partial_x I_N^C F(u))(x_j, t) - \nu\partial_x^2 \hat{u}(x_j, t) = -\hat{R}(x_j, t), \quad t \in S_{T-\tau}, \\ u(x_j, \tau) = U_0(x_j) + \tau\partial_t U(x_j, 0), \\ u(x_j, 0) = U_0(x_j), \end{cases}$$

where $\partial_t U(x, 0) = \nu\partial_x^2 U_0(x) - \partial_x F(U_0(x))$ is computed via (1.1).

We next give an LGCC scheme. For simplicity, we consider only the homogenous Dirichlet boundary condition. Other kinds of cases can be treated as in [22]. Define the approximation space

$$V_N^0 = \mathbb{P}_N \cap H_0^1(I), \qquad H_0^1(I) = \left\{v \in H^1(I) \ : \ v(-1) = v(1) = 0\right\}.$$

The fully discrete LGCC scheme for (1.1) is to find $u(t) \in V_N^0$ such that

$$\text{(2.3)} \qquad \begin{cases} (u_{\hat{t}},\, v) + (\partial_x I_N^C F(u),\, v) + \nu(\partial_x \hat{u},\, \partial_x v) = 0 \quad \forall v \in V_N^0, \quad t \in S_{T-\tau}, \\ u(\tau) = I_N^C(U_0 + \tau\partial_t U(0)), \\ u(0) = I_N^C U_0, \end{cases}$$

where $\partial_t U(0) = \nu\partial_x^2 U_0 - \partial_x F(U_0)$. We choose appropriate base functions of V_N^0 as in [22] to set up the corresponding system of equations. For $0 \le n \le N-2$, let $c_n = 1/(2n+1)$ and $\phi_n(x) = c_{n+1}[L_n(x) - L_{n+2}(x)]$, where $\{L_n(x)\}$ are the Legendre polynomials, so that $\partial_x\phi_n(x) = -L_{n+1}(x)$. Expanding $u(x,t) = \sum_{n=0}^{N-2} a_n(t)\phi_n(x)$ and taking $v = \phi_m$ in (2.3) lead to

$$\text{(2.4)} \quad \begin{aligned} \sum_{n=0}^{N-2} [(\phi_n, \phi_m) + 2c_{n+1}\nu\tau\delta_{mn}]a_n(t+\tau) &= -2\tau(I_N^C F(u(t)), L_{m+1}) \\ &\quad + \sum_{n=0}^{N-2} [(\phi_n, \phi_m) - 2c_{n+1}\nu\tau\delta_{mn}]a_n(t-\tau), \quad 0 \le m \le N-2, \ t \in S_{T-\tau}. \end{aligned}$$

The matrix of above system is pentadiagonal [22]. We note that the nonlinear term in (2.4) can be computed by the fast Legendre transform (FLT) [1] between the coefficients of the Legendre series and its values at the CGL points, such as

$$\{a_n\} \xrightarrow{FLT} \{u(x_j)\} \to \{F(u(x_j)\} \xrightarrow{FLT} \{(\widehat{I_N^C F(u)})_n^L\},$$

where $(\widehat{I_N^C F(u)})_n^L$ are the Legendre expansion coefficients of $I_N^C F(u)$.

3. Preliminary. In this section, we introduce a suitable comparison function and give some lemmas needed in error analysis. We shall denote by C a generic positive constant independent of N or any function. Define $P_{1,N} : H^1(I) \to \mathbb{P}_N$ such that

$$P_{1,N}u(x) = u(-1) + \int_{-1}^{x} P_{N-1}^{L} \partial_y u \, dy,$$

where $P_N^L : L^2(I) \to \mathbb{P}_N$ denotes the Legendre orthogonal projection operator. We have from the definition of $P_{1,N}$ immediately that

$$(\partial_x P_{1,N}u, \partial_x v) = (\partial_x u, \partial_x v) \qquad \forall\, v \in \mathbb{P}_N. \tag{3.1}$$

Also, it is easy to see that $P_{1,N}u - u \in H_0^1(I)$ and

$$\begin{aligned}(P_{1,N}u - u, v) &= (P_{1,N}u - u, \partial_x \partial_x^{-1} v) \\ &= (P_{N-1}^{L}\partial_x u - \partial_x u, \partial_x^{-1} v) = 0 \qquad \forall\, v \in \mathbb{P}_{N-2},\end{aligned} \tag{3.2}$$

where $\partial_x^{-1} v := \int_{-1}^{x} v(y)\, dy \in \mathbb{P}_{N-1}$. We will need an estimate in the following negative norm:

$$\|u\|_{-1} := \sup_{v \in H_0^1(I), v \neq 0} \frac{|(u,v)|}{\|v\|_1}.$$

Lemma 3.1 (see [4, 15]). *If $u \in H^\sigma(I)\,(\sigma \geq 1)$, then*

$$\|P_{1,N}u - u\|_l \leq CN^{l-\sigma}\, \|u\|_\sigma, \qquad -1 \leq l \leq 1. \tag{3.3}$$

Proof. We prove only (3.3) with $l = -1$. The other cases can be found in [4, 15]. For any $v \in H_0^1(I)$, on the use of (3.2) and the result (3.3) with $l = 0$, we get

$$(P_{1,N}u - u, v) = (P_{1,N}u - u, v - P_{1,N-2}v) \leq CN^{-\sigma-1}\|u\|_\sigma \|v\|_1,$$

which gives the desired result. □

In general, the discrete inner product and norm are defined as follows:

$$(u,v)_N = \sum_{j=0}^{N} u(y_j)v(y_j)\omega_j, \qquad \|u\|_N = \sqrt{(u,u)_N},$$

where y_j and ω_j $(j = 0, \dots, N)$ are the Legendre–Gauss–Lobatto points and the corresponding quadrature weights. Associating with this quadrature rule, we denote by I_N^L the Legendre interpolation operator.

Lemma 3.2 (see [4, 9]). *If $u \in H^\sigma(I)\,(\sigma \geq 1)$, then*

$$\|I_N^L u - u\|_l \leq CN^{l-\sigma}\|u\|_\sigma, \qquad 0 \leq l \leq 1, \tag{3.4}$$

$$|(u,v) - (u,v)_N| \leq CN^{-\sigma}\|u\|_\sigma\, \|v\| \qquad \forall v \in \mathbb{P}_N. \tag{3.5}$$

Further, if $u \in \mathbb{P}_N$, then

$$\|u\| \leq \|u\|_N \leq \sqrt{2 + \frac{1}{N}}\, \|u\|, \tag{3.6}$$

$$\|u\|_{L^\infty(I)} \leq \frac{N+1}{\sqrt{2}}\|u\|. \tag{3.7}$$

Lemma 3.3 (see [15]). *If $u \in H^1(I)$, then*

$$N\|I_N^C u - u\| + |I_N^C u|_1 \le C\|u\|_1. \tag{3.8}$$

Moreover, if $u \in H^\sigma(I)\,(\sigma \ge 1)$, then

$$\|I_N^C u - u\|_l \le CN^{l-\sigma}\|u\|_\sigma, \qquad 0 \le l \le 1. \tag{3.9}$$

We note that although I_N^C is the Chebyshev interpolation operator, the norms in (3.8) and (3.9) are in the Legendre form rather than in the weighted Chebyshev form. These results are useful for numerical analysis of CL spectral methods.

4. The stability and convergence of the CLC method. In this section, we first consider the stability of the semidiscrete scheme (2.1) with the Dirichlet boundary conditions ($\alpha = \gamma = 1, \beta = \delta = 0$) and then give the proof of its convergence. Suppose that u and the term on the right-hand side in (2.1) have the errors $\tilde{u}$ and $\tilde{f}$, respectively. Then by (2.1) we have

$$(\partial_t \tilde{u}, v)_N + (\partial_x I_N^C \tilde{F}, v) - \nu(\partial_x^2 \tilde{u}, v) + (\tilde{R}, v)_N = (\tilde{f}, v)_N \quad \forall v \in \mathbb{P}_N, t \in (0,T), \tag{4.1}$$

where $\tilde{F} := F(u+\tilde{u}) - F(u)$ and

$$\tilde{R}(x,t) := \tau_0 Q^+(x)\tilde{u}(1,t) + \tau_N Q^-(x)\tilde{u}(-1,t).$$

Taking $v = \tilde{u}$ in (4.1), we get

$$\begin{aligned} &\frac{d}{dt}\|\tilde{u}\|_N^2 + \nu|\tilde{u}|_1^2 + \tau_0\omega_0\tilde{u}^2(1) + \tau_N\omega_N\tilde{u}^2(-1) \\ &\qquad = (\tilde{f}, \tilde{u})_N - (\partial_x I_N^C \tilde{F}, \tilde{u}) + \nu\tilde{u}(1)\partial_x\tilde{u}(1) - \nu\tilde{u}(-1)\partial_x\tilde{u}(-1). \end{aligned} \tag{4.2}$$

We bound the terms on the right-hand side of the above equation. First,

$$|(\tilde{f}, \tilde{u})_N| \le \|\tilde{f}\|_N^2 + \|\tilde{u}\|_N^2.$$

Next, let

$$\tau_0, \tau_N \ge \frac{1}{4}\max\{4\nu, 1\}\, N^2(N+1)^2. \tag{4.3}$$

Then it can be seen that

$$\begin{aligned} &|\nu\tilde{u}(1)\partial_x\tilde{u}(1) - \nu\tilde{u}(-1)\partial_x\tilde{u}(-1)| \\ &\qquad \le \frac{\nu}{4}(\omega_0|\partial_x\tilde{u}(1)|^2 + \omega_N|\partial_x\tilde{u}(-1)|^2) + \frac{\nu}{\omega_0}|\tilde{u}(1)|^2 + \frac{\nu}{\omega_N}|\tilde{u}(-1)|^2 \\ &\qquad \le \frac{\nu}{4}|\tilde{u}|_1^2 + \frac{1}{4}\tau_0\omega_0|\tilde{u}(1)|^2 + \frac{1}{4}\tau_N\omega_N|\tilde{u}(-1)|^2. \end{aligned}$$

As for the nonlinear term, by integrating by parts and noting that $\omega_0 = \omega_N = \frac{2}{N(N+1)}$, we get from (3.7) and (3.8) that

$$\begin{aligned} &\left|(\partial_x I_N^C \tilde{F}, \tilde{u})\right| \\ &\le \left|(I_N^C\tilde{F} - \tilde{F}, \partial_x\tilde{u}) + (\tilde{F}, \partial_x\tilde{u})\right| + \left|I_N^C\tilde{F}(1)\tilde{u}(1) - I_N^C\tilde{F}(-1)\tilde{u}(-1)\right| \\ &\le \frac{\nu}{4}|\tilde{u}|_1^2 + 2\|I_N^C\tilde{F} - \tilde{F}\|^2 + 2\|\tilde{F}\|^2 + \omega_0|\tilde{F}(1)|^2 + \omega_N|\tilde{F}(-1)|^2 + \frac{\tilde{u}^2(1)}{4\omega_0} + \frac{\tilde{u}^2(-1)}{4\omega_N} \\ &\le \frac{\nu}{4}|\tilde{u}|_1^2 + 2\|I_N^C\tilde{F} - \tilde{F}\|^2 + 5\|\tilde{F}\|^2 + 3\|I_N^L\tilde{F} - \tilde{F}\|^2 + \frac{1}{4}\tau_0\omega_0\tilde{u}^2(1) + \frac{1}{4}\tau_N\omega_N\tilde{u}^2(-1) \\ &\le \frac{\nu}{4}|\tilde{u}|_1^2 + CN^{-2}|\tilde{F}|_1^2 + C\|\tilde{F}\|^2 + \frac{1}{4}\tau_0\omega_0\tilde{u}^2(1) + \frac{1}{4}\tau_N\omega_N\tilde{u}^2(-1). \end{aligned}$$

Let C_0 be a positive constant and

$$\begin{aligned} u_M &= \max_{0\le s\le T}\left\{\|u(s)\|_{L^\infty(I)} + N^{-1}\|\partial_x u(s)\|_{L^\infty(I)}\right\}, \\ C_F(z_1,z_2) &= \max_{|z|\le|z_1|+|z_2|}|F'(z)| + (|z_1|+|z_2|)\max_{|z|\le|z_1|+|z_2|}|F''(z)|. \end{aligned} \tag{4.4}$$

For any given $t\in(0,T)$, if

$$\|\tilde{u}(s)\|_{L^\infty(I)} \le C_0 \qquad \forall\, s\in(0,t), \tag{4.5}$$

then

$$\begin{aligned} &\|\tilde{F}\| + N^{-1}|\tilde{F}|_1 \\ &= \left\|\int_0^1 F'(u+\theta\tilde{u})\tilde{u}d\theta\right\| + N^{-1}\left\|\int_0^1 (F''(u+\theta\tilde{u})(\partial_x u + \theta\partial_x\tilde{u})\tilde{u} + F'(u+\theta\tilde{u})\partial_x\tilde{u})d\theta\right\| \\ &\le C_F(u_M,C_0)\|\tilde{u}\| + \frac{1}{4}\nu|\tilde{u}|_1 \qquad \forall\, s\in(0,t). \end{aligned}$$

Therefore, integrating (4.2) in time leads to

$$E(\tilde{u},t) \le \rho(\tilde{u},\tilde{f},t) + C^*\int_0^t E(\tilde{u},s)ds, \tag{4.6}$$

where C^* is a positive constant depending on $C_F(u_M,C_0)$ and

$$\begin{aligned} E(\tilde{u},t) &= \|\tilde{u}(t)\|_N^2 + \int_0^t \{\nu|\tilde{u}(s)|_1^2 + \tau_0\omega_0\tilde{u}^2(1,s) + \tau_N\omega_N\tilde{u}^2(-1,s)\}ds, \\ \rho(\tilde{u},\tilde{f},t) &= \|\tilde{u}(0)\|_N^2 + \int_0^t \|\tilde{f}(s)\|_N^2 ds. \end{aligned}$$

We have the following stability result.

Theorem 4.1. *If $\rho(\tilde{u},\tilde{f},T)\le 2C_0^2e^{-C^*T}(N+1)^{-2}$, then*

$$E(\tilde{u},t) \le \rho(\tilde{u},\tilde{f},t)e^{C^*t}. \tag{4.7}$$

Proof. Following the line in [14], we first prove that

$$\max_{0\le s\le T}\|\tilde{u}(s)\|_{L^\infty(I)} \le C_0. \tag{4.8}$$

Otherwise, there must exist $t_1 < T$ such that

$$\max_{0\le s\le t_1}\|\tilde{u}(s)\|_{L^\infty(I)} \le C_0, \quad \|\tilde{u}(t_1)\|_{L^\infty(I)} = C_0, \tag{4.9}$$

while by (4.6) and the Gronwall inequality we have

$$E(\tilde{u},t_1) \le \rho(\tilde{u},\tilde{f},t_1)e^{C^*t_1} < \rho(\tilde{u},\tilde{f},T)e^{C^*T} \le 2C_0^2(N+1)^{-2}.$$

Thus, from Lemma 3.2,

$$\begin{aligned} \|\tilde{u}(t_1)\|_{L^\infty(I)} &\le \frac{N+1}{\sqrt{2}}\|\tilde{u}(t_1)\| \le \frac{N+1}{\sqrt{2}}\|\tilde{u}(t_1)\|_N \\ &\le (N+1)\sqrt{\frac{E(\tilde{u},t_1)}{2}} < C_0, \end{aligned}$$

which is contradictory with (4.9). Thus (4.8) holds, and we derive (4.7) from the Gronwall inequality. □

Next we consider the convergence of the scheme (2.1) with the Dirichlet boundary conditions $\alpha = \gamma = 1$, $\beta = \delta = 0$. Setting $w = P_{1,N}U$ and $\eta = u - w$, we get from (1.1) and (2.1) that

$$(4.10) \qquad (\partial_t \eta, v)_N + (\partial_x I_N^C \tilde{G}, v) - \nu(\partial_x^2 \eta, v) + (R(\eta, t), v)_N = g(v) \qquad \forall\, v \in \mathbb{P}_N,$$

where $\tilde{G} = F(w + \eta) - F(w)$ and

$$(4.11) \quad \begin{aligned} g(v) &:= [(\partial_t U, v) - (\partial_t w, v)_N] + (\partial_x (F(U) - I_N^C F(w)), v) - \nu(\partial_x^2 (U - w), v), \\ R(\eta, t) &= \tau_0 Q^+(x)\eta(1, t) + \tau_N Q^-(x)\eta(-1, t). \end{aligned}$$

Similar to (4.4), we let

$$U_M = \max_{0 \le s \le T} \{\|w(s)\|_{L^\infty(I)} + N^{-1}\|\partial_x w(s)\|_{L^\infty(I)}\}.$$

Then, as in the analysis of stability, we need to estimate $g(\eta)$ in (4.11). We separate it into

$$\begin{aligned} g(\eta) &= [(\partial_t U, \eta) - (\partial_t w, \eta)_N] + (\partial_x (F(U) - I_N^C F(w)), \eta) - \nu(\partial_x^2 (U - w), \eta) \\ &:= \sum_{i=1}^{3} J_i. \end{aligned}$$

First, by (3.5), (3.6), (3.4), and (3.3),

$$(4.12) \qquad \begin{aligned} |J_1| &\le |(\partial_t U, \eta) - (\partial_t U, \eta)_N| + |(\partial_t I_N^L U, \eta)_N - (\partial_t w, \eta)_N| \\ &\le C N^{-\sigma} \|\partial_t U\|_\sigma \|\eta\|_N + 2\|\partial_t I_N^L U - \partial_t w\| \, \|\eta\|_N \\ &\le C N^{-\sigma} \|\partial_t U\|_\sigma \|\eta\|_N. \end{aligned}$$

Next, by (3.9) we have

$$\begin{aligned} |J_2| &= |(F(U) - I_N^C F(w), \partial_x \eta)| \le C\|F(U) - I_N^C F(w)\|^2 + \frac{\nu}{8}|\eta|_1^2 \\ &\le C(\|(I - I_N^C)(F(w) - F(U))\|^2 + \|(I - I_N^C)F(U)\|^2 + \|F(U) - F(w)\|^2) + \frac{\nu}{8}\nu|\eta|_1^2 \\ &\le C(N^{-2}|F(w) - F(U)|_1^2 + \|F(U) - F(w)\|^2) + C N^{-2\sigma}\|F(U)\|_\sigma^2 + \frac{\nu}{8}|\eta|_1^2 \\ &\le C C_F'\Big(\|U\|_{L^\infty(I)}, \|w\|_{L^\infty(I)}\Big)\Big(1 + N^{-1}(\|\partial_x U\|_{L^\infty(I)} + \|\partial_x w\|_{L^\infty(I)})\Big) N^{-2\sigma}\|U\|_\sigma^2 \\ &\quad + \frac{\nu}{8}|\eta|_1^2 + C N^{-2\sigma}\|F(U)\|_\sigma^2, \end{aligned}$$

where

$$C_F'(z_1, z_2) = \max_{|z| \le \max\{z_1, z_2\}} \{|F'(z)|, |F''(z)|\}.$$

Finally, let $\tau_0, \tau_N \ge C N^6$. Then, from integrating by parts, (3.1), (3.3), and (3.4), we also have

$$\begin{aligned}|J_3| &= |\nu\{\partial_x(U-w)\eta\}|_{-1}^{1}|\\ &\le \frac{1}{8}\tau_0\omega_0\eta^2(1)+\frac{1}{8}\tau_N\omega_N\eta^2(-1)+\frac{2\nu^2}{\tau_0\omega_0}|\partial_x(U-w)(1)|^2+\frac{2\nu^2}{\tau_N\omega_N}|\partial_x(U-w)(-1)|^2\\ &\le \frac{1}{8}\tau_0\omega_0\eta^2(1)+\frac{1}{8}\tau_N\omega_N\eta^2(-1)+CN^{-2}\|\partial_x(U-w)\|_N^2\\ &\le \frac{1}{8}\tau_0\omega_0\eta^2(1)+\frac{1}{8}\tau_N\omega_N\eta^2(1)+CN^{-2\sigma}\|U\|_\sigma^2.\end{aligned}$$

For the initial error, we have from (3.3) and (3.9) that

$$\begin{aligned}\|\eta(0)\|_N &\le C\|\eta(0)\| \le C\|(I_N^C-P_{1,N})U_0\|^2\\ &\le C\|(I_N^C-I)U_0\|^2+C\|(I-P_{1,N})U_0\|^2\le CN^{-2\sigma}\|U_0\|_\sigma^2.\end{aligned} \tag{4.13}$$

We end this section with the following convergence theorem.

THEOREM 4.2. *Let U and u be the solutions of* (1.1) *and* (2.1)*, respectively. Assume that $\sigma \ge 2$, $U \in H^1(0,T;H^\sigma(I))$, $F(z)\in C^\sigma(\mathbb{R})$, and $\tau_0,\tau_N \ge CN^6$. Then there exists a positive constant C depending on ν^{-1} and the regularities of U and F such that*

$$\|u(t)-U(t)\| \le CN^{-\sigma} \qquad \forall\, t\in(0,T).$$

5. The stability and convergence of LGCC method. In this section, we consider the stability and convergence of the fully discrete scheme (2.3). We assume that all functions below are valued at time s unless otherwise specified. Suppose u and the term on the right-hand side in (2.3) have the error $\tilde{u}$ and $\tilde{f}$, respectively. Then by (2.3) we have

$$(\tilde{u}_{\hat{t}},v)+(\partial_x I_N^C\tilde{F},v)+\nu(\partial_x\hat{\tilde{u}},\partial_x v)=(\tilde{f},v) \qquad \forall\, v\in V_N^0,\quad t\in S_{t-\tau}. \tag{5.1}$$

Taking $v=\hat{\tilde{u}}$ in (5.1), we get

$$\frac{1}{2}\|\tilde{u}\|_{\hat{t}}^2+\nu|\hat{\tilde{u}}|_1^2=(\tilde{f},\hat{\tilde{u}})+(I_N^C\tilde{F},\partial_x\hat{\tilde{u}}). \tag{5.2}$$

We need to bound the term $\|I_N^C\tilde{F}\|$, which would be easy to do, provided that I_N^C is replaced by the Legendre–Galerkin/collocation operator or the norm is in the weighted Chebyshev one. But here we cannot deal with this directly. So we turn to the stability property of I_N^C given in (3.8). Taking $v=\tilde{u}_{\hat{t}}$ in (5.1), we have

$$\|\tilde{u}_{\hat{t}}\|^2+\frac{1}{2}\nu(|\tilde{u}|_1^2)_{\hat{t}}=(\tilde{f},\tilde{u}_{\hat{t}})-(\partial_x I_N^C\tilde{F},\tilde{u}_{\hat{t}}). \tag{5.3}$$

Combining (5.2) and (5.3) through the factor N^{-2}, we arrive at

$$\begin{aligned}&(\|\tilde{u}\|^2+N^{-2}\nu|\tilde{u}|_1^2)_{\hat{t}}+2(\nu|\hat{\tilde{u}}|_1^2+N^{-2}\|\tilde{u}_{\hat{t}}\|^2)\\ &\quad=2(\tilde{f},\hat{\tilde{u}})+2(I_N^C\tilde{F},\partial_x\hat{\tilde{u}})+2N^{-2}((\tilde{f},\tilde{u}_{\hat{t}})-(\partial_x I_N^C\tilde{F},\tilde{u}_{\hat{t}}))\\ &\quad\le C(\|\tilde{f}\|_{-1}^2+\|I_N^C\tilde{F}\|^2+N^{-2}\|\tilde{f}\|^2+N^{-2}|I_N^C\tilde{F}|_1^2)+\nu|\hat{\tilde{u}}|_1^2+N^{-2}\|\tilde{u}_{\hat{t}}\|^2,\end{aligned} \tag{5.4}$$

where C is a positive constant dependent on ν^{-1}. Summing (5.4) for $s\in S_{t-\tau}$ gives

$$E(\tilde{u},t)\le\rho(\tilde{u},\tilde{f},t)+C\tau\sum_{s\in S_{t-\tau}}(\|I_N^C\tilde{F}(s)\|^2+N^{-2}|I_N^C\tilde{F}(s)|_1^2), \tag{5.5}$$

where

$$\begin{aligned} E(\tilde u, t) &= \|\tilde u(t)\|^2 + N^{-2}\nu|\tilde u(t)|_1^2 + 2\tau \sum_{s\in S_{t-\tau}} (\nu|\hat{\tilde u}(s)|_1^2 + N^{-2}\|\tilde u_{\hat t}(s)\|^2),\\ \rho(\tilde u, \tilde f, t) &= \|\tilde u(0)\|^2 + N^{-2}\nu|\tilde u(0)|_1^2 + \|\tilde u(\tau)\|^2 + N^{-2}\nu|\tilde u(\tau)|_1^2\\ &\quad + C\tau \sum_{s\in S_{t-\tau}} (\|\tilde f(s)\|_{-1}^2 + N^{-2}\|\tilde f(s)\|^2). \end{aligned}$$

For any given $t \in S_T$, if

$$\|\tilde u(s)\|_{L^\infty(I)} \le C_0 \qquad \forall\, s \in S_{t-\tau}, \tag{5.6}$$

then by (3.8) and (3.9)

$$\begin{aligned} &\|I_N^C\tilde F\| + N^{-1}|I_N^C\tilde F|_1 \le \|\tilde F\| + \|I_N^C\tilde F - \tilde F\| + N^{-1}|I_N^C\tilde F|_1 \le \|\tilde F\| + CN^{-1}|\tilde F|_1\\ &= \left\|\int_0^1 F'(u+\theta\tilde u)\tilde u d\theta\right\| + CN^{-1}\left\|\int_0^1 (F''(u+\theta\tilde u)(\partial_x u + \theta\partial_x\tilde u)\tilde u + F'(u+\theta\tilde u)\partial_x\tilde u)d\theta\right\|\\ &\le C_F(u_M, C_0)(\|\tilde u\| + N^{-1}|\tilde u|_1) \qquad \forall\, s \in S_{t-\tau}. \end{aligned}$$

Thus, we have shown that for any $t \in S_T$, if (5.6) holds, then

$$E(\tilde u, t) \le \rho(\tilde u, \tilde f, t) + C^*\tau \sum_{s\in S_{t-\tau}} E(\tilde u, s), \tag{5.7}$$

where C^* is a positive constant dependent on $C_F(u_M, C_0)$ and ν^{-1}.

THEOREM 5.1. *Let τ be suitably small. If $\rho(\tilde u, \tilde f, T) \le 2C_0^2 e^{-C^*T}/(N+1)^2$, then*

$$E(\tilde u, t) \le \rho(\tilde u, \tilde f, t)e^{C^*t} \qquad \forall\, t \in S_T. \tag{5.8}$$

Proof. We prove the result by induction over $t \in S_T$. It is easy to see that the result (5.8) is true for $t = \tau$. Assume that it is true for all $s \in S_{t-\tau}$:

$$E(\tilde u, s) \le \rho(\tilde u, \tilde f, s)e^{C^*s}. \tag{5.9}$$

Then, from the inverse inequality (3.7), we have

$$\|\tilde u(s)\|_{L^\infty(I)}^2 \le \frac{(N+1)^2}{2}\|\tilde u(s)\|^2 \le \frac{(N+1)^2}{2}\rho(\tilde u, \tilde f, s)e^{C^*s} \le C_0^2,$$

which means (5.6) holds. Therefore, we have from (4.6) and (5.9) that

$$\begin{aligned} E(\tilde u, t) &\le \rho(\tilde u, \tilde f, t) + C^*\tau \sum_{s\in S_{t-\tau}} E(\tilde u, s) \le \rho(\tilde u, \tilde f, t) + C^*\tau \sum_{s\in S_{t-\tau}} \rho(\tilde u, \tilde f, s)e^{C^*s}\\ &\le \rho(\tilde u, \tilde f, t)\left(1 + C^*\tau \sum_{s\in S_{t-\tau}} e^{C^*s}\right) \le \rho(\tilde u, \tilde f, t)e^{C^*t}. \end{aligned}$$

Thus the proof is completed. □

Next we consider the convergence of the scheme (2.3). Setting $w = P_{1,N}U$ and $\eta = u - w$, we get from (1.1) and (2.3) that

$$(\eta_{\hat t}, v) + (\partial_x I_N^C\tilde G, v) + \nu(\partial_x\hat\eta, \partial_x v) = (\tilde g, v) \qquad \forall\, v \in V_N^0, \tag{5.10}$$

where

$$\tilde{g} = \partial_t \hat{U} - U_{\hat{t}} + U_{\hat{t}} - w_{\hat{t}} + \partial_x(F(U) - I_N^C F(w) + \frac{\tau^2}{2} F(U)_{t\bar{t}}), \tag{5.11}$$

$$v_{t\bar{t}}(t) := \frac{1}{\tau^2}(v(t+\tau) - 2v(t) + v(t-\tau)). \tag{5.12}$$

Let C_* be a positive constant dependent on $C_F(U_M, C_0)$ and ν^{-1}. Then, as in Theorem 5.1, if $\rho(\eta, \tilde{g}, T) \leq 2C_0 e^{-C_* T}/(N+1)^2$, we have

$$E(\eta, t) \leq \rho(\eta, \tilde{g}, t) e^{C_* t} \qquad \forall\, t \in S_T. \tag{5.13}$$

We arrive at the following convergence result.

Theorem 5.2. *Let U and u be the solution of* (1.1) *and* (2.3), *respectively. Assume that $\sigma \geq 2$ and $U \in C(0,T; H_0^1(I) \cap H^\sigma(I)) \cap H^1(0,T; H_0^1(I) \cap H^{\sigma-1}(I)) \cap H^3(0,T; L^2(I)) \cap H^2(0,T; H^1(I))$, $\partial_t U(0) \in H^{\sigma/2}(I)$, and $F(z) \in C^{\max\{3,\sigma\}}(\mathbb{R})$. Then there exists a positive constant C depending on ν^{-1} and the regularities of U and F such that if $\tau\sqrt{N} \leq c_0$ being suitably small,*

$$\|u(t) - U(t)\| \leq C(\tau^2 + N^{-\sigma}) \qquad \forall\, t \in S_T.$$

Proof. We need only to estimate $\rho(\eta, \tilde{g}, t)$ in (5.13). We separate $\tilde{g}$ in (5.11) into

$$\begin{aligned}\tilde{g} &= (\partial_t \hat{U} - U_{\hat{t}}) + (U_{\hat{t}} - w_{\hat{t}}) + \partial_x(F(U) - I_N^C F(U)) \\ &\quad + \partial_x I_N^C(F(U) - F(w)) + \frac{\tau^2}{2}\partial_x F(U)_{t\bar{t}} := \sum_{j=1}^{5} \tilde{g}_j.\end{aligned}$$

A simple calculation and (3.3) give

$$\begin{aligned}&\tau \sum_{s \in S_{t-\tau}} (\|\tilde{g}_1\|_{-1}^2 + N^{-2}\|\tilde{g}_1\|^2) \leq C\tau^4(\|\partial_t^3 U\|_{L^2(0,T;H^{-1}(I))}^2 + N^{-2}\|\partial_t^3 U\|_{L^2(0,T;L^2(I))}^2), \\ &\tau \sum_{s \in S_{t-\tau}} (\|\tilde{g}_2\|_{-1}^2 + N^{-2}\|\tilde{g}_2\|^2) \leq CN^{-2\sigma}\tau \sum_{s \in S_{t-\tau}} \|U_{\hat{t}}\|_{\sigma-1}^2 \\ &\qquad \leq CN^{-2\sigma}\|\partial_t U\|_{L^2(0,T;H^{\sigma-1}(I))}^2.\end{aligned}$$

From (3.9) and (3.3),

$$\begin{aligned}&\|\tilde{g}_3\|_{-1} + N^{-1}\|\tilde{g}_3\| \\ &\quad \leq \|F(U) - I_N^C F(U)\| + N^{-1}|F(U) - I_N^C F(U)|_1 \leq CN^{-\sigma}\|F(U)\|_\sigma, \\ &\|\tilde{g}_4\|_{-1} + N^{-1}\|\tilde{g}_4\| \\ &\quad \leq \|F(U) - F(w)\| + \|(I_N^C - I)(F(U) - F(w))\| + N^{-1}|I_N^C(F(U) - F(w))|_1 \\ &\quad \leq \|F(U) - F(w)\| + CN^{-1}|F(U) - F(w)|_1 \\ &\quad \leq CC_F'(\|U\|_{L^\infty(I)}, \|w\|_{L^\infty(I)})(1 + N^{-1}(\|\partial_x U\|_{L^\infty(I)} + \|\partial_x w\|_{L^\infty(I)}))N^{-\sigma}\|U\|_\sigma.\end{aligned}$$

Also,

$$\begin{aligned}\tau \sum_{s \in S_{t-\tau}} (\|\tilde{g}_5\|_{-1}^2 + N^{-2}\|\tilde{g}_5\|^2) &\leq \tau^5 \sum_{s \in S_{t-\tau}} (\|F(U)_{t\bar{t}}\|^2 + N^{-2}|F(U)_{t\bar{t}}|_1^2) \\ &\leq C\tau^4(\|\partial_t^2 F(U)\|_{L^2(0,T;L^2(I))}^2 + N^{-2}\|\partial_t^2 F(U)\|_{L^2(0,T;H^1(I))}^2) \\ &\leq CC_F''\tau^4(\|U\|_{H^2(0,T;L^2(I))}^2 + \|\partial_t U\|_{L^4(I\times(0,T))}^4 + N^{-2}\|U\|_{H^2(0,T;H^1(I))}^2) \\ &\leq CC_F''\tau^4\|U\|_{H^2(0,T;H^1(I))}^2,\end{aligned}$$

where

$$C_F'' = \max_{|z| \le \|U\|_{C(\bar{I}\times[0,T])}} \left\{ |\partial_z^l F(z)|^2 \ : \ l = 1,2,3 \right\}.$$

For the initial errors we have

$$\|\eta(0)\| + N^{-1}|\eta(0)|_1 = \|(I_N^C - P_{1,N})U_0\| + N^{-1}|(I_N^C - P_{1,N})U_0|_1 \le CN^{-\sigma}\|U_0\|_\sigma,$$

and from Taylor's formula

$$\begin{aligned}
&\|\eta(\tau)\| + N^{-1}|\eta(\tau)|_1\\
&\le \|(I_N^C - I)U_0\| + N^{-1}|(I_N^C - I)U_0|_1 + \tau(\|(I_N^C - I)U(\tau)\| + N^{-1}|(I_N^C - I)U(\tau)|_1)\\
&\quad + \tau^2(\|\partial_t^2 U\|_{C(0,\tau;L^2(I))} + N^{-1}\|\partial_t^2 U\|_{C(0,\tau;H^1(I))})\\
&\quad + \|(I - P_{1,N})U(\tau)\| + N^{-1}|(I - P_{1,N})U(\tau)|_1\\
&\le CN^{-\sigma}(\|U_0\|_\sigma + \|U(\tau)\|_\sigma) + C\tau N^{-\sigma/2}\|\partial_t U(0)\|_{\sigma/2} + C\tau^2\|\partial_t^2 U\|_{C(0,\tau;H^1(I))}.
\end{aligned}$$

Thus the proof is completed by (5.13) and (3.3) with the triangle inequality. □

Remark 5.1. If we consider only the semidiscrete scheme, the stability and optimal error estimate similar to Theorems 4.1–4.2 can be established for (2.1) with all three kinds of boundary conditions by combining the arguments given in [6, 13], provided that

$$\tau_0 = \begin{cases} \nu\beta^{-1}\omega_0^{-1}, & \beta \ne 0, \\ CN^6, & \beta = 0, \end{cases} \qquad \tau_N = \begin{cases} -\nu\delta^{-1}\omega_N^{-1}, & \delta \ne 0, \\ CN^6, & \delta = 0. \end{cases} \tag{5.14}$$

For the fully discrete CNLF scheme, it seems difficult to get desired results in that way. The difference is that in the semidiscrete case one has the term $|\tilde{u}(t)|_1$ which can be used to control the nonlinear term, while in the fully discrete case one has only the term $|\tilde{u}(t+\tau) + \tilde{u}(t-\tau)|_1$ (but the nonlinear term is set at t for ease of computation). However, an H^1-estimate can be obtained for the fully discrete scheme of the problem with the Neumann or Robin boundary condition. Under the condition (5.14) with $\beta \ne 0$ and $\delta \ne 0$, which is also applied in [6] to the problem with the Neumann boundary condition, the scheme (2.1) reads as follows: For any $v \in \mathbb{P}_N$,

(5.15)
$$\begin{cases} (\partial_t u(t), v)_N + (\partial_x I_N^C F(u(t)), v) + \nu(\partial_x u(t), \partial_x v) \\ \qquad + \nu\beta^{-1}(\alpha u(1,t) - g^+(t))v(1) + \nu|\delta|^{-1}(\gamma u(-1,t) - g^-(t))v(-1) = 0, \\ (u(0), v)_N = (I_N^C U_0, v)_N. \end{cases}$$

This is just a pseudospectral scheme with the boundary condition being treated in a natural way. Then the fully discrete CNLF scheme is the following: For any $v \in \mathbb{P}_N$,

(5.16)
$$\begin{cases} (u_{\hat{t}}(t),\, v)_N + (\partial_x I_N^C F(u(t)),\, v) + \nu(\partial_x \hat{u}(t),\, \partial_x v) \\ \qquad + \nu\beta^{-1}(\alpha\hat{u}(1,t) - \hat{g}^+(t))v(1) + \nu|\delta|^{-1}(\gamma\hat{u}(-1,t) - \hat{g}^-(t))v(-1) = 0, \end{cases}$$

with the initial values as in (2.2). The LGCC scheme can be set by simply replacing $(\cdot,\cdot)_N$ with $(\cdot,\cdot)$ in (5.15) and (5.16), respectively. In both cases, the stability and

optimal error estimates in the H^1-norm can be derived for the fully CNLF scheme by an argument similar to the one given in the proofs of Theorems 5.1–5.2. When an H^1-estimate is considered, the nonlinear term can be estimated directly by using the stability property (3.8) of the Chebyshev interpolation operator.

6. Numerical results. In this section, we will give some numerical results of the LGCC method and the Legendre collocation (LC) method to make a comparison.

Example 6.1. *Consider the generalized Burgers equation*

$$\partial_t U + U^m \partial_x U - \nu \partial_x^2 U = 0, \tag{6.1}$$

with the following analytical solution:

$$U(x,t) = \left\{ \frac{(m+1)\omega}{2} \left[1 - \tanh\left(\frac{m\omega}{2\nu}(x - \omega t - x_0) \right) \right] \right\}^{1/m}, \qquad \omega > 0.$$

It is computed by the LGCC method and the LC method with $m = 1$, $\nu = 0.1$, $\omega = 0.5$, $I = [-5, 5]$, $x_0 = -3$, $t \in [0, 12]$, and $m = 2$, $\nu = 7$, $\omega = 10$, $I = [-10, 10]$, $x_0 = -6$, $t \in [0, 1]$. The maximum errors are reported in Table 1 at $t = 12$ and Table 2 at $t = 1$, respectively.

Example 6.2. *Consider the Burgers equation*

$$\partial_t U + U^2 \partial_x U - \nu \partial_x^2 U = g, \tag{6.2}$$

with a soliton-like solution

$$U(x,t) = \operatorname{sech}^2(ax - bt - c).$$

Numerical results of the LGCC method and the LC method with $a = b = 1$, $c = -4$, $\nu = 1$, and $I = [-10, 10]$ are reported in Table 3 at $t = 8$. From Tables 1–3, we can

Table 3
Maximum error at $t = 8$ *for Example* 6.2 *with* $a = b = 1$, $c = -4$, $\nu = 1$, $I = [-10, 10]$.

		LGCC		LC	
τ	N	L^∞ error	Time	L^∞ error	Time
1.e-1	16	1.5660e-01	0.79	2.3770e-01	0.16
1.e-2	32	2.9800e-02	0.89	3.2700e-02	0.81
1.e-3	64	3.1580e-04	9.79	3.0556e-04	11.00
1.e-4	128	1.7111e-08	149.21	1.5117e-08	279.72
1.e-5	256	8.2430e-12	3629.76	8.3099e-12	9937.84

see that the LGCC method obtained nearly the same precision as the LC method. But the LGCC method spends less time than the LC method, especially when the number of collocation points increases.

Acknowledgment. The authors thank the referees for their valuable suggestions and comments.

FAST SWEEPING ALGORITHMS FOR A CLASS OF HAMILTON–JACOBI EQUATIONS[*]

YEN-HSI RICHARD TSAI[†], LI-TIEN CHENG[‡], STANLEY OSHER[§], AND HONG-KAI ZHAO[¶]

Abstract. We derive a Godunov-type numerical flux for the class of strictly convex, homogeneous Hamiltonians that includes $H(p,q)=\sqrt{ap^2+bq^2-2cpq}$, $c^2<ab$. We combine our Godunov numerical fluxes with simple Gauss–Seidel-type iterations for solving the corresponding Hamilton–Jacobi (HJ) equations. The resulting algorithm is fast since it does not require a sorting strategy as found, e.g., in the fast marching method. In addition, it provides a way to compute solutions to a class of HJ equations for which the conventional fast marching method is not applicable. Our experiments indicate convergence after a few iterations, even in rather difficult cases.

Key words. Hamilton–Jacobi equations, fast marching, fast sweeping, upwind finite differencing, eikonal equations

1. Introduction.

Hamilton–Jacobi (HJ) equations have a rich pool of applications, ranging from those of optimal control theory and geometrical optics, to essentially any problem that needs the (weighted) distance function [14]. Examples include crystal growth, ray tracing, etching, robotic motion planning, and computer vision. Solutions of these types of equations usually develop singularities in their derivatives, and thus the unique viscosity solution [6] is sought.

In this article, we focus on the class of time independent HJ equations with Dirichlet boundary condition

$$H(\mathbf{x},\nabla u)=r(\mathbf{x}),\qquad u|_\Gamma=0;$$

$H(\mathbf{x},\mathbf{p})$ are strictly convex nonnegative, and $\lim_{\lambda\to 0}H(\mathbf{x},\lambda\mathbf{p})=0$. We explain our method using the following important model equation:

$$H(\phi_x,\phi_y)=\sqrt{a\phi_x^2+b\phi_y^2-2c\phi_x\phi_y}=r, \tag{1.1}$$

where $\phi:\mathbb{R}^2\mapsto\mathbb{R}$ is continuous and a, b, c, and r can be either constants or scalar functions; in the latter case, H depends also on x, defined on $\mathbb{R}^2$, satisfying $ab>c^2$, $a,b,r>0$. With $a=b=1$ and $c=0$, we have the standard eikonal equation for

which many numerical methods have been developed. This equation has the essential features of HJ equations with convex Hamiltonians, so that we can easily explain our algorithm, and is general enough that fast marching is not applicable.

In the following subsections, we will review some of the solution methods for the eikonal equation since it forms the motivation of our work. We then present a fast Gauss–Seidel-type iteration method for (1.1) which utilizes a monotone upwind Godunov flux for the Hamiltonian. We show numerically that this algorithm can be applied directly to equations of the above type with variable coefficients.

1.1. Solving eikonal equations. In geometrical optics [10], the eikonal equation

$$\sqrt{\phi_x^2 + \phi_y^2} = r(x, y) \tag{1.2}$$

is derived from the leading term in an asymptotic expansion

$$e^{i\omega(\phi(x,y)-t)} \sum_{j=0}^{\infty} A_j(x, y, t)(i\omega)^{-j}$$

of the wave equation

$$w_{tt} - c^2(x, y)(w_{xx} + w_{yy}) = 0,$$

where $r(x, y) = 1/|c(x, y)|$ is the function of slowness. The level sets of the solution ϕ can thus be interpreted as the first arrival time of the wave front that is initially Γ. It can also be interpreted as the "distance" function to Γ.

We first restrict our attention for now to the case in which $r = 1$. Let Γ be a closed subset of $\mathbb{R}^2$. It can be shown easily that the distance function defined by

$$d(\mathbf{x}) = \text{dist }(\mathbf{x}, \Gamma) := \min_{p\in\Gamma} ||\mathbf{x} - p||, \qquad \mathbf{x} = (x, y) \in \mathbb{R}^2,$$

is the viscosity solution to (1.2) with the boundary condition

$$\phi(x, y) = 0 \qquad \text{for } (x, y) \in \Gamma.$$

Rouy and Tourin [20] proved the convergence to the viscosity solution of an iterative method solving (1.2) with the Godunov Hamiltonian approximating $||\nabla\phi||$. The Godunov Hamiltonian function can be written in the following form:

$$H_G(p_-, p_+, q_-, q_+) = \sqrt{\max\{p_-^+, p_+^-\}^2 + \max\{q_-^+, q_+^-\}^2}, \tag{1.3}$$

where $p_\pm = D_\pm^x\phi_{i,j}$, $q_\pm = D_\pm^y\phi_{i,j}$, $D_\pm^x\phi_{i,j} = \pm(\phi_{i\pm1,j} - \phi_{i,j})/h$ and accordingly for $D_\pm^y\phi_{i,j}$, and $x^+ = \max(x, 0)$, $x^- = -\min(x, 0)$.

Osher [13] provided a link to time dependent eikonal equations by proving that the t-level set of $\phi(x, y)$ is the zero level set of the viscosity solution of the evolution equation at time t,

$$\psi_t = ||\nabla\psi|| = 0,$$

with appropriate initial conditions. In fact, the same is true for a very general class of HJ equations (see [13]). As a consequence, one can try to solve the time dependent equation by the level set formulation [17] with high order approximations on the partial derivatives [9, 18]. Crandall and Lions proved that the discrete solution obtained with a consistent, monotone numerical Hamiltonian converges to the desired viscosity solution [5].

Tsitsiklis [25] combined heap sort with a variant of the classical Dijkstra algorithm to solve the steady state equation of the more general problem

$$||\nabla\phi|| = r(\mathbf{x}).$$

This was later rederived in [23] and also reported in [8]. It has become known as the fast marching method, whose complexity is $\mathcal{O}(N\log(N))$, where N is the number of grid points. Osher and Helmsen [15] have extended the fast marching-type method to somewhat more general HJ equations. We will comment on this in a following section.

1.2. Anisotropic eikonal equation. We return to the Hamiltonian in question: $H(p,q) = \sqrt{ap^2+bq^2-2cpq}$. Writing the quadratic form as

$$ap^2+bq^2-2cpq = \begin{pmatrix} p & q \end{pmatrix}\begin{pmatrix} a & -c \\ -c & b \end{pmatrix}\begin{pmatrix} p \\ q \end{pmatrix},$$

it is easy to see that we can diagonalize the symmetric matrix in the middle of the equation for our previously noted choices of a, b, c and find a coordinate system ξ-η such that, after rescaling, the Hamiltonian becomes

$$H(\tilde{p},\tilde{q}) = \sqrt{\tilde{p}^2+\tilde{q}^2}.$$

The eigensystem of the above matrix defines the anisotropy. Indeed, the authors in [15] proposed to solve the constant coefficient equation (1.1) by first transforming it to (1.2) in the ξ-η coordinate system.

This anisotropy occurs in fields such as ray tracing in special media, e.g., crystals, in which there are "preferred" directions. Furthermore, we will see that it can be a result of considering the geodesic distance function on a manifold M that is defined as the graph of a smooth function f.

Let ϕ be the distance function such that

$$\phi(x,y) = \min_{\gamma\subset M}\int_\gamma ds$$

and γ connects the point (x,y) with the set $\Gamma\subset M$. The minimizing curve is called the geodesic, and ϕ the distance function to Γ on M. Moreover, ϕ solves

$$||P_{\nabla\psi}\nabla\phi||^2 = 1, \qquad \phi|_\Gamma = 0, \tag{1.4}$$

where $\psi(x,y,z) = f(x,y) - z$, and the projection operator [4]

$$P_{\nabla\psi} = I - \frac{\nabla\psi\bigotimes\nabla\psi}{||\nabla\psi||^2},$$

which projects a vector onto a plane whose normal is parallel to $\nabla\psi$. Using the fact that $P_{\nabla\psi}$ is a projection operator, a simple calculation shows that

(1.5)

$$||P_{\nabla\psi}\nabla\phi||^2 = \left(1-\frac{f_x^2}{f_x^2+f_y^2+1}\right)\phi_x^2 + \left(1-\frac{f_y^2}{f_x^2+f_y^2+1}\right)\phi_y^2 - 2\frac{f_xf_y}{f_x^2+f_y^2+1}\phi_x\phi_y.$$

This is clearly of the form of Hamiltonians that we are interested in. We will apply our algorithm to compute the geodesic distance later in this paper.

There are other approaches that are designed to compute distances on manifolds. For example, [11] provided an algorithm to compute the geodesic distance on triangulated manifolds. Barth [2] uses the discontinuous Galerkin method to find distance on graphs of functions that are represented by spline functions. In [4], the authors embed the manifold as the zero level set of a Lipschitz continuous function and solve the corresponding time dependent eikonal equation (1.4) in the embedding space. As we have mentioned in the previous subsection, the zero level set of the time dependent eikonal equation at time t_1 is the t_1-level set of the solution to the stationary eikonal equations (see [13]). In [12], the authors adopted the standard fast marching method to solve the isotropic eikonal equation in a thin band of thickness ϵ, which encloses the manifold M, and proved that the restriction of the solution to M converges to the geodesic distance as ϵ goes to 0. In [21, 22], the authors provide an ordered upwind method to solve a general class of static HJ equations. We will comment on their method in a later subsection.

1.3. Osher's fast marching criteria. Since the fast marching method is by now well known, we will not give much detail on its implementation in this paper. In general, this involves a sorting procedure and the solution of

$$H_G(D_-^x\phi_{i,j}, D_+^x\phi_{i,j}, D_-^y\phi_{i,j}, D_+^y\phi_{i,j}) = 1 \tag{1.6}$$

for ϕ_{ij} in terms of its four neighboring values. More precisely, the heap sort strategy of the fast marching method requires a monotone update sequence. The updated value of a grid node has to be greater than or equal to those of the grid nodes used to form the finite difference stencil. This amounts to the condition

$$pH_p + qH_q \geq 0,$$

which dictates that the solution be nondecreasing along the characteristics. However, if we use one-sided upwind finite difference approximations for partial derivatives of ϕ on a Cartesian grid, it is equivalent to demanding that the partial derivatives of ϕ (i.e., p and q) and their corresponding components of the characteristics directions (i.e., dx/dt and dy/dt) have the same sign. Since $dx/dt = H_p$ and $dy/dt = H_q$, we have the stricter Osher's fast marching criterion

$$pH_p \geq 0, \quad qH_q \geq 0. \tag{1.7}$$

It does not matter whether the Hamiltonian is convex or not; as long as criterion (1.7) is satisfied, a simple fast marching algorithm can be applied. But if the criterion is not satisfied, fast marching cannot be applied to the problem on a Cartesian grid. Of course there are Hamiltonians that do not satisfy (1.7). In the class of Hamiltonians that we consider, as long as $c \neq 0$, it is likely that the values of p and q differ to the extent that the above criterion is no longer satisfied. In light of criterion (1.7), we have also tried to find directions $\xi(x, y)$ and $\eta(x, y)$ locally in which $\tilde{p}H_{\tilde{p}} \geq 0, \tilde{q}H_{\tilde{q}} \geq 0$. However, if one insists on using Cartesian grids, the implementation of this approach might be a bit hairy. We are interested especially in tackling, over a Cartesian grid, problems where the solution is nondecreasing along characteristics but where Osher's fast marching criterion is not satisfied.

1.4. The sweeping idea. Danielsson [7] proposed an algorithm to compute Euclidean distance to a subset of grid points on a two dimensional grid by visiting each grid node in some predefined order. In [3], Boué and Dupuis suggest a similar "sweeping" approach to solve the steady state equation which, by experience, results in an $\mathcal{O}(N)$ algorithm for the problem at hand. This "sweeping" approach has recently been used in [24] and [27] to compute the distance function to an arbitrary data set in computer vision. In [26], the author provides some theoretical evidence indicating that sweeping converges to an approximate Euclidean distance function, i.e., to an approximate viscosity solution of $|\nabla\phi| = 1$ in $2d$ predetermined iterations. We will talk about these iterations in a later section. Using this "sweeping" approach, the complexity of the algorithms drops from $\mathcal{O}(N \log N)$ in fast marching to $\mathcal{O}(N)$, and the implementation of the algorithms becomes a bit easier than the fast marching method that requires heap sort.

This sweeping idea is best illustrated by solving the eikonal equation in $[0, 1]$:

$$|u_x| = 1, \qquad u(0) = u(1) = 0.$$

Let $u_i = u(x_i)$ denote the grid values associated with the uniform grid composed of the gridpoints $0 = x_0 < x_1 < \cdots < x_n = 1$. We then solve the discretized nonlinear system

$$\sqrt{\max(\max(D_- u_i, 0)^2, \min(D_+ u_i, 0)^2)} = 1, \qquad u_0 = u_n = 0, \tag{1.8}$$

by our sweeping approach. We initially set $u_i^{(0)} = \infty$, $i = 1, \ldots, n-1$. In practice, ∞ can be replaced by some number K, which is larger than $\max_{x\in[0,1]} u$. Let us begin by sweeping from 0 to 1; i.e., we update u_i from $i = 1$ increasing to $i = n-1$. This is "equivalent" to following the characteristics emanating from x_0. Let $u_i^{(1)}$ denote the grid values after this sweep. We then have

$$u_i^{(1)} = \begin{cases} \frac{i}{n} \text{ if } i = 1, \ldots, n-2, \\ \frac{1}{n} \text{ if } i = n-1. \end{cases}$$

Notice that at $i = n-1$, we actually use the upwind information from the neighboring right boundary point. Furthermore, notice that $u_i^{(1)}$ already has the correct desired values for $i \le n/2$ since the sweep goes from left to right, the desired upwind direction for these i. In the second sweep, we update u_i from $i = n-1$ decreasing to 1, starting with $u_i^{(1)}$. During this sweep, we follow the characteristics emanating from x_n. The use of (1.8) is essential, since it determines what happens when two characteristics cross each other. It is then not hard to see that, after the second sweep,

$$u_i = \begin{cases} \frac{i}{n} \text{ if } i \le \frac{n}{2}, \\ \frac{(n-i)}{n} \text{ otherwise.} \end{cases}$$

Notice that the correct values at $i \le n/2$ derived after the first sweep are unchanged, and new and correct values for $i > n/2$ are created. In summary, this simple iterative algorithm can be described as follows: at the kth iteration, solve

$$\max\left(\max\left(\frac{u_i^{(k)} - u_{i-1}^{(k-1)}}{\Delta x}, 0\right), \min\left(\frac{u_{i+1}^{(k-1)} - u_i^{(k)}}{\Delta x}, 0\right)\right) = 1$$

for $u_i^{(k)}$ for each i going from 1 to $n-1$ in the first iteration ($k = 1$), and from $n-1$ to 1 for the second iteration ($k = 2$). However, for more complicated equations and boundary conditions, it is not so easy to write down the equivalent explicit solution.

In this paper, we will extend this sweeping approach to a class of HJ equations that cannot be solved by the fast marching algorithm, by first deriving a Godunov Hamiltonian.

In [21, 22], the authors proposed a one-pass method that is based on a control-theoretic viewpoint. In principle, they solve the HJB equation

$$\max_{\mathbf{a}} \nabla u \cdot \mathbf{a} f(\mathbf{a}, \mathbf{x}) = 1, \tag{1.9}$$

where $\mathbf{p} = (p, q)$ and the function $f(\mathbf{a}, \mathbf{x})$ is the speed of motion. This formula is the second Legendre transform taken on the sphere; see, e.g., [16, 19].

The idea is still to follow the characteristics and update the grid value in a monotone sequence. In a notation similar to the two dimensional setting of [21, 22], we let u_o be the grid value we are updating. To update u_o, we have to look for two other grid values u_r and u_s, which are not necessarily the immediate grid neighbors of u_o. For example, if u_o is the grid value $u_{i,j}$, the immediate neighbors of u_o are then $u_{i+1,j}$,$u_{i,j+1}$,$u_{i-1,j}$, and $u_{i,j-1}$. As we indicated in the previous subsection, it is possible that u_o is less than all its immediate neighboring values. We then need to find two other grid values, here denoted as u_s and u_r, to form an upwinding stencil. Then u_o is found by minimizing a nonlinear expression derived from (1.9), using the values of u_r, u_s, and f. The heap sort data structures are used in order to find u_r and u_s; therefore, the complexity is $N \log N$, where N is the total number of grid points. Also, since u_r and u_s may not lie on the immediate neighbors, this algorithm may need a larger region around the initial wave front to get started.

As one will see in the following section, our proposed method is also based on following the characteristics. To update u_o, our method uses only the immediate neighboring grid values and does not need the heap sort data structure. More importantly, our algorithm follows the characteristics with certain directions simultaneously, in a parallel way, instead of a sequential way as in the fast marching method. The Godunov flux is essential in our algorithm, since it determines what neighboring grid values should be used to update u on a given grid node o. At least in the examples presented, we need only to solve a simple quadratic equation and run some simple tests to determine the value to be updated. This simple procedure is performed in each sweep, and the solution is obtained after a few sweeps. Our code is not much more than what is presented in section 3.2. We also point out the ease of implementing our proposed algorithm and its extension to more dimensions; this will be described in a sequel paper.

2. A Godunov flux for strictly convex Hamiltonians.

By solving the Riemann problem for HJ equations (Godunov's procedure), Bardi and Osher [1] proved rigorously that

$$H_G(p_-, p_+; q_-, q_+) = \underset{p \in I[p_-, p_+]}{\text{ext}} \; \underset{q \in I[q_-, q_+]}{\text{ext}} H(p, q), \tag{2.1}$$

where

$$\underset{p \in I[a,b]}{\text{ext}} = \min_{p \in [a,b]} \quad \text{if } a \le b,$$

$$\underset{p \in I[a,b]}{\text{ext}} = \max_{p \in [b,a]} \quad \text{if } a > b,$$

$$H_G(D_-^x \phi_{ij}, D_+^x \phi_{ij}, D_-^y \phi_{ij}, D_+^y \phi_{ij}) = H_G(p_-, p_+; q_-, q_+),$$

and $I[a,b]$ denotes the closed interval bounded by a and b. This is a monotone upwind flux function, which implies convergence. Godunov's scheme (1.3) for the eikonal equation $\sqrt{\phi_x^2+\phi_y^2}=1$ can be derived from the above formula. It is one of the central topics of this paper to derive an explicit formula for the class of strictly convex Hamiltonians in question. Especially, we will demonstrate our numerical methods on $H=\sqrt{a\phi_x^2+b\phi_y^2-2c\phi_x\phi_y}$, $c^2<ab$.

Note that, in general, if we reverse the order on p and q in our ext-ext decision, the result might be different, although they both give convergent monotone methods. However, in the convex Hamiltonian at hand, the results are order independent.

For convenience, we will also use $H_G(\phi_{i,j},\phi_{i\pm1,j},\phi_{i,j\pm1})$ to denote the evaluation of our Godunov Hamiltonian $H_G(D_-^x\phi_{ij},D_+^x\phi_{ij},D_-^y\phi_{ij},D_+^y\phi_{ij})$.

2.1. Derivation of the flux. In order to derive a compact expression that satisfies (2.1), we need to study the extremum of the Hamiltonian on $I_p\times I_q\subset\mathbb{R}^2$, where I_p is a shorthand for $I[p_-,p_+]$.

The extremum may occur on either the critical points of H or the boundary of $I_p\times I_q$. Let us first look at the partial derivatives of H, i.e., H_p and H_q, and their zeros. Fix a q_0; the extremum of $H(p,q_0)$ occurs at either the critical point of $H(p,q_0)$ (i.e., where $H_p=0$) or the boundary of $I[p_-,p_+]$. We denote the critical point by $p_\sigma(q_0)$. Similarly, given p_0, we obtain the critical point $q_\sigma(p_0)$. For convenience, we shall denote $p_\sigma(q_0)$ by p_σ when q_0 can be determined from the context, and (p_σ,q_σ) is the critical point of H such that $H_p(p_\sigma,q_\sigma)=H_q(p_\sigma,q_\sigma)=0$. *Therefore, we consider separately* $H(p_\sigma,q_\sigma)$, $H(p_-,q_\sigma(p_-))$, $H(p_+,q_\sigma(p_+))$, $H(p_\sigma(q_-),q_-)$, $H(p_\sigma(q_+),q_+)$, *and* $H(p_\pm,q_\pm)$ *as possible evaluations of* (2.1).

For fixed p, we have

$$H_G(p,q_-,q_+)=H(p,\operatorname{sgn}\max\{(q_--q_\sigma)^+,(q_+-q_\sigma)^-\}+q_\sigma\,), \tag{2.2}$$

where

$$\begin{aligned}\operatorname{sgn}\max(x,y)&=x^+\quad\text{if}\quad\max\{x^+,y^-\}=x^+,\\ \operatorname{sgn}\max(x,y)&=-y^-\quad\text{if}\quad\max\{x^+,y^-\}=y^-.\end{aligned}$$

The expression for fixed q is a direct analogy to (2.2). It is easy to see that $H_G(\cdot,\cdot;q_-,q_+)$ is increasing in q_- and decreasing in q_+. By symmetry, $H_G(p_-,p_+;\cdot,\cdot)$ is increasing in p_- and decreasing in p_+.

Details of the derivation of the above expression are provided in the appendix.

The following proposition will be of use in analyzing this introduced Godunov flux.

PROPOSITION 1. *If* $H_{pp}>0,H_{qq}>0$, $pH_p\geq0,qH_q\geq0$, *and* $p_\sigma(0)=q_\sigma(0)=0$, *then* $p_\sigma(q)\equiv0\ \forall q$, *and* $q_\sigma(p)\equiv0\ \forall p$.

Proof. $p_\sigma(q)$, by definition, is the zero of $H_p(p_\sigma(q),q)=0$. We will write p_σ in place of $p_\sigma(q)$ for brevity. This proposition is then proved by simple manipulation of the definitions:

$$\begin{aligned}\frac{d}{dq}p_\sigma H(p_\sigma,q)&=p_\sigma'H_p(p_\sigma,q)+p_\sigma(H_{pp}(p_\sigma,q)p_\sigma'+H_{pq}(p_\sigma,q))\\ &=p_\sigma p_\sigma'H_{pp}(p_\sigma,q)+\frac{\partial}{\partial q}H_p(p_\sigma,q)\\ &=p_\sigma p_\sigma'H_{pp}(p_\sigma,q)\\ &=0.\end{aligned}$$

The hypothesis $H_{pp} > 0$ implies that

$$p_\sigma(q) = 0 \ \forall q \quad \text{or} \quad p'_\sigma(q) = 0 \ \forall q.$$

Again, by the hypothesis that $p_\sigma(0) = q_\sigma(0) = 0$, we can conclude that $p_\sigma(q) \equiv 0 \ \forall q$.

Similarly, $q_\sigma(p) \equiv 0 \ \forall p$. □

Notice that if the Hamiltonian is $\sqrt{p^2+q^2}$, our upwinding expression in (2.2) is identical to the conventional expression $\max(p_-^+, p_+^-)$. (In this case, the sign of the second argument does not matter since we are really evaluating its square product in the eikonal equation.) In fact, we have the following corollary, which is a direct consequence of Proposition 1.

Corollary 1. *If $H_{pp} > 0, H_{qq} > 0$, $pH_p \geq 0, qH_q \geq 0$, $p_\sigma(0) = q_\sigma(0) = 0$, and $H(p,q) = H(|p|,|q|)$, then the Godunov flux can be simplified to*

$$H_G(p_-, p_+; q_-, q_+) = H(\max\{p_-^+, p_+^-\}, \max\{q_-^+, q_+^-\}).$$

3. The sweeping algorithms.

We will use the model equation (1.1) as a concrete example for the exposition of our algorithm. We stress here again that the scheme described below is valid for a general class of convex, homogeneous HJ equations.

From the assumption that the solution is nondecreasing along the characteristics, i.e.,

$$pH_p + qH_q \geq 0,$$

we can easily deduce that the solution is nondecreasing at least in either the x- or y- direction; i.e., either $pH_p \geq 0$ or $qH_q \geq 0$. Since we approximate the derivatives $\phi_x(x_{i,j})$ by finite differencing using the neighbors of $\phi_{i,j}$, the above monotonicity property translates to the following requirement in the solution $\phi_{i,j}$.

Definition 1. *Let $\phi_{i,j}$ be the solution of $H_G(\phi, \phi_{i\pm1,j}, \phi_{i,j\pm j}) = r_{i,j}$. We say that ϕ satisfies the monotonicity requirement if*

$$\phi_{i,j} \geq \min\{\phi_{i\pm1,j}, \phi_{i,j\pm1}\}.$$

3.1. Derivation of the scheme.

Without loss of generality, we assume that $r(x,y) = 1$. Let us reexamine the equation to be solved:

$$H(p,q) = 1, \tag{3.1}$$

where

$$H : \mathbb{R} \times \mathbb{R} \to \mathbb{R}.$$

Equation (3.1) dictates a level set relation; namely, the solution is the 1-level set of H in the p-q plane (denoted here as Λ). Correspondingly, the solutions of the HJ equation with the Godunov Hamiltonian

$$H_G(p_+, p_-; q_+, q_-) = \underset{p \in I[p_-,p_+]}{\text{ext}} \ \underset{q \in I[q_-,q_+]}{\text{ext}} H(p,q) = r \tag{3.2}$$

satisfy the following two properties:

- they are the intersections of Λ and the set $I[p_-,p_+] \times I[q_-,q_+]$;
- they are either the critical points of H or the boundary points of the set $I[p_-,p_+] \times I[q_-,q_+]$.

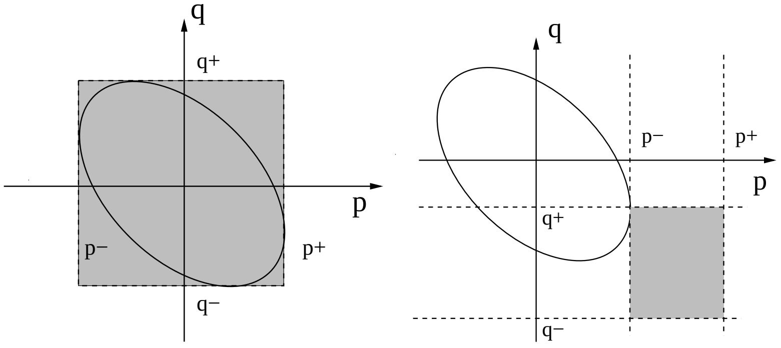

FIG. 1. *The* 1*-level set of* H *and the box* $I[p-,p+]xI[q-,q+]$.

Figure 1 demonstrates two possible configurations of the intervals. So what our algorithm should do is find a suitable value of ϕ on each grid node so that the divided forward and backward differences of ϕ at that grid node satisfy (3.2).

Suppose we are on the grid node (i,j), and it is determined that

$$H_G(p_+,p_-;q_+,q_-) = H(p_-,q_+) = 1.$$

Correspondingly, for our model equation (1.1) we have to solve the following quadratic equation:

$$a\left(\frac{\phi_{i,j}-\phi_{i-1,j}}{\Delta x}\right)^2 + b\left(\frac{\phi_{i,j+1}-\phi_{i,j}}{\Delta y}\right)^2 - 2c\left(\frac{\phi_{i,j}-\phi_{i-1,j}}{\Delta x}\right)\left(\frac{\phi_{i,j+1}-\phi_{i,j}}{\Delta y}\right) = 1. \tag{3.3}$$

The solution $\phi_{i,j}$ not only has to satisfy the above equation, but ultimately has to be a solution to (3.2), given its four neighbors $\phi_{i-1,j}$, $\phi_{i+1,j}$, $\phi_{i,j-1}$, and $\phi_{i,j+1}$. The subfigure on the right in Figure 1 shows one such possible configuration; i.e.,

$$\frac{\phi_{i,j}-\phi_{i-1,j}}{\Delta x} < \frac{\phi_{i+1,j}-\phi_{i,j}}{\Delta x} \quad \text{and} \quad \frac{\phi_{i,j}-\phi_{i,j-1}}{\Delta y} < \frac{\phi_{i,j+1}-\phi_{i,j}}{\Delta y}$$

such that

$$\operatorname*{ext}_{p\in I[p_-,p_+]}\ \operatorname*{ext}_{q\in I[q_-,q_+]} H(p,q) = \min_{p\in I[p_-,p_+]}\ \min_{q\in I[q_-,q_+]} H(p,q) = 1.$$

One can, of course, implement a tree of all the probable cases from the complete listing of that of the Godunov Hamiltonian (2.1). However, we have a more straightforward approach that utilizes the compact expressions for the Godunov Hamiltonian (2.2) that we obtained from the previous section.

Instead, we solve the equation with the following reduced formulas for the original Godunov Hamiltonian:

$$H_G(p_+,p_-;q_+,q_-) = \operatorname*{ext}_{q\in I[q_-,q_+]} H(p_-,q), \tag{3.4}$$

$$H_G(p_+,p_-;q_+,q_-) = \operatorname*{ext}_{q\in I[q_-,q_+]} H(p_+,q), \tag{3.5}$$

$$H_G(p_+, p_-; q_+, q_-) = \underset{p \in I[p_-, p_+]}{\text{ext}} H(p, q_-), \tag{3.6}$$

$$H_G(p_+, p_-; q_+, q_-) = \underset{p \in I[p_-, p_+]}{\text{ext}} H(p, q_+), \tag{3.7}$$

$$H_G(p_+, p_-; q_+, q_-) = H(p_\sigma, q_\sigma). \tag{3.8}$$

For example, in the first case, the flux is equivalent to

$$H(p_-, \operatorname{sgn}\max\{(q_- - q_\sigma)^+, (q_+ - q_\sigma)^-\} + q_\sigma) = 1.$$

The possible evaluations of $\operatorname{sgn}\max\{(q_- - q_\sigma)^+, (q_+ - q_\sigma)^-\} + q_\sigma$ are q_-, q_+, $q_\sigma(p_-)$, and 0. We thus end up solving the HJ equation with all possible arguments for the Hamiltonian.

Suppose we algebraically solve $H(p_-, q_+) = 1$ for $\phi_{i,j}$ and call the solution ϕ^{can}. We then compute the divided differences $p_\pm$ and $q_\pm$ using this ϕ^{can} in place of $\phi_{i,j}$. We call ϕ^{can} valid if both

$$H(p_-, \operatorname{sgn}\max\{(q_- - q_\sigma)^+, (q_+ - q_\sigma)^-\} + q_\sigma) = 1,$$

$$H(\operatorname{sgn}\max\{(p_- - p_\sigma)^+, (p_+ - p_\sigma)^-\} + p_\sigma\, , q_+) = 1,$$

and ϕ^{can} satisfies the monotonicity requirement (Definition 1).

Finally, we set $\phi_{i,j}$ to be the minimum of those in the set of all valid candidate solutions ϕ^{can} obtained from using all the possible combinations of the arguments of H. This is motivated by the first arrival time interpretation of the function ϕ.

In essence, we are solving for the central value in the Godunov Hamiltonian in terms of its four neighbors. It is well known and easy to show that any monotone Hamiltonian, let alone Godunov's, is a monotone function of this value. For these Hamiltonians, this value goes from $-\infty$ to $+\infty$. Thus there is always a unique solution.

Definition 2 (sweeping iteration). *A compact way of writing this sweeping iterations in C/C++ is the following:*

```
for(s1=-1;s1<=1;s1+=2)
for(s2=-1;s2<=1;s2+=2)
for(i=(s1<0?nx:0);(s1<0?i>=0:i<=nx);i+=s1)
for(j=(s2<0?ny:0);(s2<0?j>=0:j<=ny);j+=s2)
  update $\phi_{i,j}$.
```

3.2. The algorithm. For the brevity of the algorithm, we define respectively

$$h_{G1}(p, q_-, q_+) := \operatorname{sgn}\max\{(q_- - q_\sigma(p))^+, (q_+ - q_\sigma(p))^-\} + q_\sigma(p),$$

$$h_{G2}(p_-, p_+, q) := \operatorname{sgn}\max\{(p_- - p_\sigma(q))^+, (p_+ - p_\sigma(q))^-\} + p_\sigma(q),$$

where $q_\sigma(p) = pc/b$ and $p_\sigma(q) = qc/a$.

Algorithm. We assume that $\phi(i,j)$ is given the exact values in a small neighborhood of Γ. We denote this neighborhood $\text{Nbd}(\Gamma)$. We initialize ϕ by setting $\phi(i,j) = \phi^{(0)}_{i,j}$ to ∞.[1] We begin by computing $\phi^{(n)}_{i,j}$ for $n = 1$.

Do the following steps while $||\phi^{(n)} - \phi^{(n-1)}|| > \delta$ ($\delta > 0$ is the given tolerance):

[1] Notice that we only need to use a large value in actual implementation.

1. For each grid point (i, j) visited in the sweeping iteration, if $x_{i,j} \neq \mathrm{Nbd}(\Gamma)$, do the following:
   - (a) For $(s_x, s_y) = (-1, 1)$, $(-1, -1)$, $(1, -1)$, and $(1, 1)$
     - i. Solve

       $$H\left(\tfrac{s_x \cdot (\phi_{tmp}(s_x,s_y) - \phi^{(n)}(i-s_x,j))}{dx}, \tfrac{s_y \cdot (\phi_{tmp}(s_x,s_y) - \phi^{(n)}(i,j-s_y))}{dy}\right) = r(i, j)$$

       for $\phi_{tmp}(s_x, s_y)$.
     - ii. Let

       $$p(s_x, s_y) = \frac{s_x \cdot (\phi_{tmp}(s_x, s_y) - \phi^{(n)}(i - s_x, j))}{dx}$$

       and

       $$q(s_x, s_y) = \frac{s_y \cdot (\phi_{tmp}(s_x, s_y) - \phi^{(n)}(i, j - s_y))}{dy}.$$
     - iii. Let $T_{G1}(s_x, s_y)$ be the logical evaluation of the equality

       $$H(p(s_x, s_y), h_{G1}(p(s_x, s_y), q(s_x, 1), q(s_x, -1))) = r(i, j),$$

       and $T_{G2}(s_x, s_y)$ be that of

       $$H(h_{G2}(p(1, s_y), p(-1, s_y), q(s_x, s_y)), q(s_x, s_y)) = r(i, j).$$
     - iv. Let $M(s_x, s_y) = \phi_{tmp}(s_x, s_y) - \min(\phi^{(n)}(i - s_x, j), \phi^{(n)}(i, j - s_y))$.
     - v. If $T_{G1}(s_x, s_y)$, $T_{G2}(s_x, s_y)$ are true and $M(s_x, s_y) \geq 0$, add $\phi_{tmp}(s_x, s_y)$ to the list `phi_candidate.`
   - (b) For $(s_x, s_y) = (1, 0)$, $(-1, 0)$
     - i. Solve

       $$H\left(\tfrac{s_x \cdot (\phi_{tmp}(s_x,0) - \phi^{(n)}(i-s_x,j))}{dx}, \tfrac{s_x \cdot (\phi_{tmp}(s_x,0) - \phi^{(n)}(i-s_x,j))}{dx} \tfrac{c}{b}\right) = r(i, j)$$

       for $\phi_{tmp}(s_x, s_y)$.
     - ii. Compute $p(s_x, s_y)$ and $q(s_x, s_y)$, following the definition.
     - iii. Evaluate $T_{G1}(s_x, s_y)$.
     - iv. If $T_{G1}(s_x, s_y)$ is true and $M(s_x, s_y) \geq 0$, add $\phi_{tmp}(s_x, s_y)$ to the list `phi_candidate.`
   - (c) For $(s_x, s_y) = (0, 1)$ and $(0, -1)$
     - i. Solve

       $$H\left(\tfrac{s_y \cdot (\phi_{tmp}(0,s_y) - \phi^{(n)}(i,j-s_y))}{dy} \tfrac{c}{a}, \tfrac{s_y \cdot (\phi_{tmp}(0,s_y) - \phi^{(n)}(i,j-s_y))}{dy}\right) = r(i, j)$$

       for $\phi_{tmp}(s_x, s_y)$.
     - ii. Compute $p(s_x, s_y)$ and $q(s_x, s_y)$, following the definition.
     - iii. Evaluate $T_{G2}(s_x, s_y)$.
     - iv. If $T_{G2}(s_x, s_y)$ is true and $M(s_x, s_y) \geq 0$, add $\phi_{tmp}(s_x, s_y)$ to the list `phi_candidate.`
   - (d) Let ϕ_{min} be the minimum element of `phi_candidate`.

     $$\phi^{(n)}(i, j) = \min(\phi^{(n)}(i, j), \phi_{min}).$$

(e) Clear `phi_candidate`.

2. Set $n = n + 1$; go back to step 1.

As described in the previous section, we have to solve the HJ equation with all possible arguments for the Hamiltonian and take the minimum of those in the set of all valid candidate solutions. The possible arguments of the Hamiltonian consist of the forward/backward differences of ϕ and the critical points centered at each grid node. In the above algorithm, this set of all possible arguments is indexed by $\{-1, 0, 1\}^2$. Therefore, by $X(-1, 1)$ we denote the quantity X that is computed using $H(p_-, q_+)$. The number 0 encodes the cases of critical points. For example, $\phi_{tmp}(-1, 1)$ denotes the roots of the quadratic equation formed by $H(p_-, q_+) = r$; $\phi_{tmp}(1, 0)$ denotes that of $H(p_+, q_\sigma(p_+))$.

We remark that in the case of $c = 0$, our algorithm is equivalent to what is used in the fast marching method under the Rouy–Tourin formula (1.3). Secondly, in our numerical implementation, we put a threshold value in the evaluations T_{G1} and T_{G2} for numerical accuracy reasons.

4. Examples.

Proposition 1 and Corollary 1 show the equivalence of the Godunov flux derived in this paper to the one commonly used in the fast marching applications. The use of this sweeping approach with the Godunov flux (1.3) has been reported in [24, 26] for eikonal equations; we will not repeat those examples in this paper. Instead, we present results of our algorithm applied to our model equation.

4.1. Quadratic Hamiltonians $\sqrt{ap^2 + bq^2 - 2cpq}$, $ab > c^2$, $a, b > 0$.

In each of the following examples, we compute the difference in the approximations in each successive iteration, i.e., $||\phi^{n+1} - \phi^n||_{L_1}$, and say that the iterations have converged if this distance is less than $\varepsilon\Delta x$, where $\varepsilon > 0$ and Δx is the grid size. In the examples presented in this paper, we simply set the threshold to be 10^{-10}. Notice also that the set Γ, on which $\phi = 0$, is either a rectangle, an L-shaped piecewise linear object, or a set of isolated points. The reader can identify their location easily from the figures.

We started out by testing our algorithm on constant coefficient cases. In the case

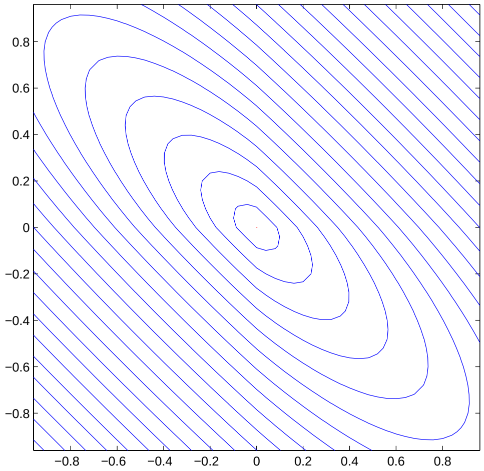

FIG. 2. *A sweeping result after* 2 *sweeping iterations on a* 50×50 *grid. The initial boundary is a single point in the center.* $a = 1.0$, $b = 1.0$, $c = 0.9$.

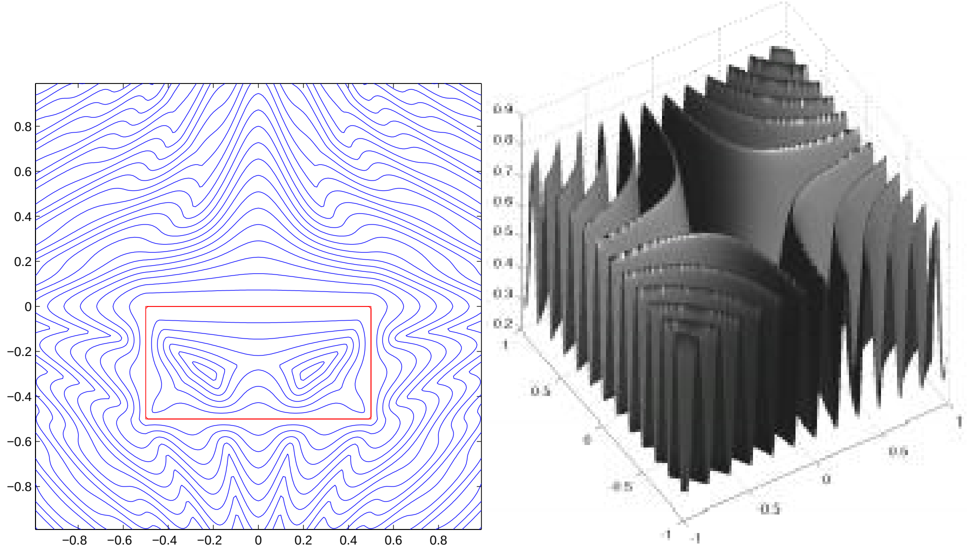

Fig. 3. *$a = 1$, $b = 1$, $c = 0$, with a more oscillatory $r(x) = 2.1 - \cos(4\pi^2 xy)$, on a 200×200 grid; convergence is reached in 7 sweeping iterations. The subplot on the left is the contour of the solution started with the square in the center. On the right is the graph of $r(x)$. Level curves with step 0.02 are plotted.*

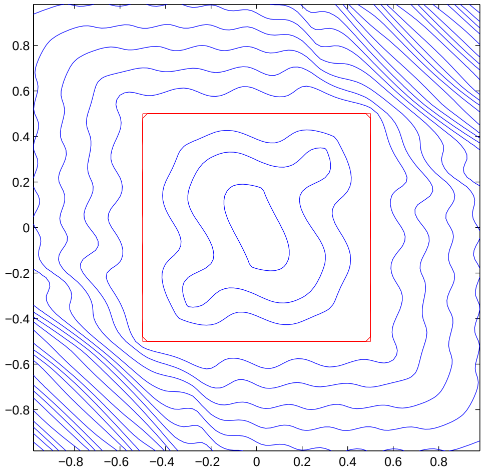

Fig. 4. *(A very degenerate case) $a = 0.375$, $b = 0.25$, $c = 0.29$, with a more oscillatory $r(x) = (2.1 - \cos(4\pi^2 xy))/4.0$, on a 100×100 grid. Notice that, in this case, $ab = 0.0938$ is barely greater than $c^2 = 0.0841$. The contour of the solution is plotted. Convergence is reached at 43 sweeping iterations.*

of $a = b$, $c = 0$, we have solutions that match the fast marching solutions. Figure 2 shows a result of a computation of the anisotropic case in which $a = b = 1$, $c = 0.9$. This is our first example in which the fast marching method is not applicable.

Next we apply the sweeping algorithm directly to cases in which the coefficients of the quadratic Hamiltonian or the right-hand sides are not constant. Figure 3 shows a computational result on a constant coefficient isotropic Hamiltonian and rather oscillatory forcing function. The rectangle in the middle is the set Γ. Figure 4

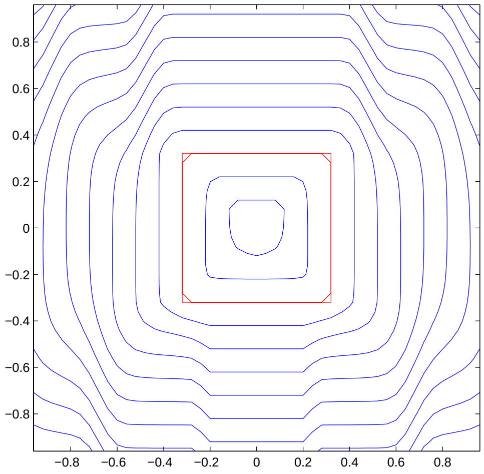

Fig. 5. *$a = 1$, $b = 1$, $c(x, y) = 0.9 \sin(5\pi x)$, and $r(x, y) = 1$, on a 50×50 grid. Convergence occurs after 10 iterations.*

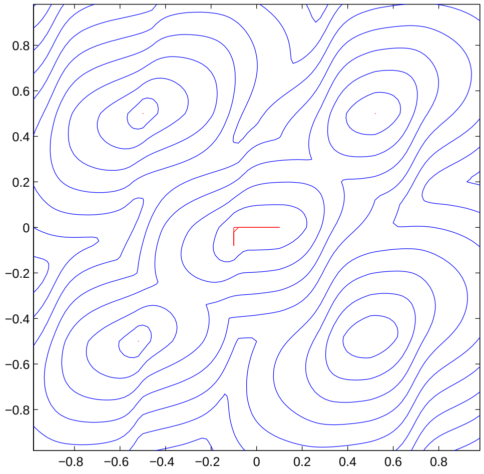

Fig. 6. *$a = 1.5 + \sin(5\pi x)$, $b = 1$, $c = -0.6$, on a 50×50 grid. Convergence occurs after 10 iterations.*

shows a computational result for a very anisotropic case. We notice that the number of iterations needed for convergence seems to depend on the anisotropy of the Hamiltonian and also on how oscillatory the forcing term is. Figures 5, 6, and 7 show results obtained from variable coefficient Hamiltonians with constant and variable forcing function $r(x, y)$.

4.2. Examples of distance on manifolds. We now apply our sweeping algorithm to compute the geodesic distance on manifolds that are the graphs of certain functions. Given a function $f(x, y)$, with graph $z = f(x, y)$, we compute the coefficients $a(x, y)$, $b(x, y)$, and $c(x, y)$ according to (1.5) and apply our algorithm directly to the corresponding HJ equation. We first test the algorithm on a half-sphere with radius one. Figures 8 and 9 show the equidistance lines to one and two seed points,

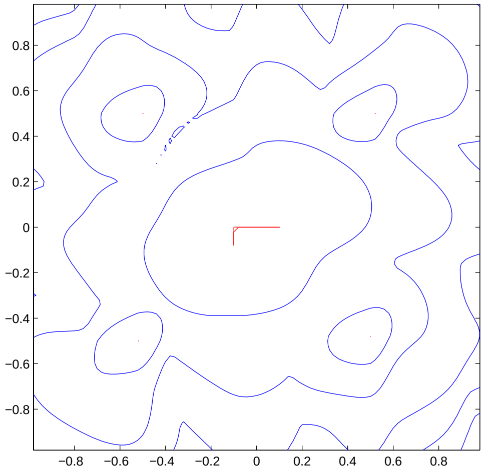

FIG. 7. *$a = 1.5 + \sin(5\pi x)$, $b = 1$, $c = -0.6$, and $r(x, y) = 2.1 + \cos(4\pi xy)$, on a 100×100 grid. Convergence occurs after 10 iterations.*
