$$\begin{aligned}&-\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L))) \\ &\qquad = \sum_{\sigma\in\mathcal{E}} v_\sigma u_{\sigma,+}(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))).\end{aligned}$$

However, as in the proof of Proposition 3.1 (because $\varphi_m \circ S_k$ is nondecreasing), we have $u_{\sigma,+}(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))) \le 0$ if $\sigma \notin \mathcal{A}$, where $\mathcal{A} = \{\sigma \in \mathcal{E} \mid u_{\sigma,+} \ge u_{\sigma,-}, u_{\sigma,+} < 0\} \cup \{\sigma \in \mathcal{E} \mid u_{\sigma,+} < u_{\sigma,-}, u_{\sigma,+} \ge 0\}$. Thus,

$$\begin{aligned}&-\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L))) \\ &\le \sum_{\sigma\in\mathcal{A}} v_\sigma u_{\sigma,+}(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))) \\ &\le ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \sum_{\sigma\in\mathcal{A}} \text{meas}(\sigma)|u_{\sigma,+}|\,|\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))|.\end{aligned} \tag{35}$$

Let $a_{k,\sigma} = \int_0^1 \varphi_m'(S_k(u_{\sigma,+}) + t(S_k(u_{\sigma,-}) - S_k(u_{\sigma,+})))\,dt \geq 0$, so that

$$\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+})) = a_{k,\sigma}(S_k(u_{\sigma,-}) - S_k(u_{\sigma,+})). \tag{36}$$

We can write

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)|u_{\sigma,+}|\,|\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))|\\
&= \sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)a_{k,\sigma}^{\frac12}|u_{\sigma,+}|a_{k,\sigma}^{\frac12}|S_k(u_{\sigma,-}) - S_k(u_{\sigma,+})|\\
&\leq \left(\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)d_\sigma a_{k,\sigma}u_{\sigma,+}^2\right)^{\frac12}\left(\sum_{\sigma\in\mathcal{A}} \tau_\sigma a_{k,\sigma}(S_k(u_{\sigma,-}) - S_k(u_{\sigma,+}))^2\right)^{\frac12}.
\end{aligned}$$

But, by (36), $a_{k,\sigma}(S_k(u_{\sigma,-}) - S_k(u_{\sigma,+}))^2 = (S_k(u_{\sigma,-}) - S_k(u_{\sigma,+}))(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+})))$, so that

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)|u_{\sigma,+}|\,|\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))|\\
&\leq \left(\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)d_\sigma a_{k,\sigma}u_{\sigma,+}^2\right)^{\frac12}\\
&\times \left(\sum_{\sigma\in\mathcal{A}} \tau_\sigma (S_k(u_{\sigma,-}) - S_k(u_{\sigma,+}))(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+})))\right)^{\frac12}.
\end{aligned}\tag{37}$$

Moreover, for all $\sigma \in \mathcal{A}$, $u_{\sigma,+}$ and $u_{\sigma,-}$ have the same sign and $|u_{\sigma,+}| \leq |u_{\sigma,-}|$. Thus, for such σ, $(S_k(u_{\sigma,+}), S_k(u_{\sigma,-}))$ have the same sign and $|S_k(u_{\sigma,+})| \leq |S_k(u_{\sigma,-})|$ and, by Lemma 3.2 stated after this proof, we deduce that

$$a_{k,\sigma} \leq \frac{1}{(1+|S_k(u_{\sigma,+})|)^m} \leq 1.$$

Since $|u_{\sigma,+}| \leq k + |S_k(u_{\sigma,+})|$, we deduce that

$$a_{k,\sigma}u_{\sigma,+}^2 \leq 2k^2 + 2\frac{|S_k(u_{\sigma,+})|^2}{(1+|S_k(u_{\sigma,+})|)^m},$$

which gives, in (37), using $\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)d_\sigma \leq \sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma)d_\sigma = d\mathrm{meas}(\Omega)$ and $(\alpha+\beta)^{1/2} \leq \alpha^{1/2} + \beta^{1/2}$ for all nonnegative (α, β),

$$\begin{aligned}
&\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)|u_{\sigma,+}|\,|\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))|\\
&\leq \sqrt{2d\mathrm{meas}(\Omega)}kA_k + \sqrt{2}A_k\left(\sum_{\sigma\in\mathcal{A}} \mathrm{meas}(\sigma)d_\sigma\psi(S_k(u_{\sigma,+}))^2\right)^{\frac12},
\end{aligned}\tag{38}$$

where $\psi(s) = \frac{|s|}{(1+|s|)^{\frac{m}{2}}}$ and

$$\begin{aligned}
A_k &= \left(\sum_{\sigma\in\mathcal{E}} \tau_\sigma (S_k(u_{\sigma,-}) - S_k(u_{\sigma,+}))(\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+})))\right)^{\frac12}\\
&= \left(\sum_{\sigma\in\mathcal{E}} \tau_\sigma (S_k(u_K) - S_k(u_L))(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L)))\right)^{\frac12}.
\end{aligned}$$

(Recall that $\sigma = K|L$ if $\sigma \in \mathcal{E}_{\rm int}$, that $u_L = 0$ if $\sigma \in \mathcal{E}_{\rm ext} \cap \mathcal{E}_K$, and that $\{u_{\sigma,+}, u_{\sigma,-}\} = \{u_K, u_L\}$ for all $\sigma \in \mathcal{E}$.)

We have, since $d_{K,\sigma} \geq \zeta d_\sigma$ for all $K \in \mathcal{T}$ and all $\sigma \in \mathcal{E}_K$,

$$\begin{aligned}\sum_{\sigma\in\mathcal{A}} {\rm meas}(\sigma) d_\sigma \psi(S_k(u_{\sigma,+}))^2 &\leq \sum_{K\in\mathcal{T}} \psi(S_k(u_K))^2 \left(\sum_{\sigma\in\mathcal{A}\cap\mathcal{E}_K \ | \ v_{K,\sigma}\geq 0} {\rm meas}(\sigma) d_\sigma\right)\\ &\leq \frac{1}{\zeta}\sum_{K\in\mathcal{T}} \psi(S_k(u_K))^2 \left(\sum_{\sigma\in\mathcal{E}_K} {\rm meas}(\sigma) d_{K,\sigma}\right)\\ &= \frac{1}{\zeta}\sum_{K\in\mathcal{T}} \psi(S_k(u_K))^2 \times d{\rm meas}(K) = \frac{d}{\zeta}||\psi(S_k(u_\mathcal{T}))||^2_{L^2(\Omega)}.\end{aligned}$$

By Proposition 2.2, and since $\psi(S_k(u_\mathcal{T})) = 0$ outside $E_k = \{|u_\mathcal{T}| > k\}$, we can thus find $r > 2$ and $C_1 > 0$ depending only on (Ω, ζ) such that

$$\left(\sum_{\sigma\in\mathcal{A}} {\rm meas}(\sigma) d_\sigma \psi(S_k(u_{\sigma,+}))^2\right)^{\frac{1}{2}} \leq C_1 {\rm meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} ||\psi(S_k(u_\mathcal{T}))||_{1,2,\mathcal{M}}.$$

But, by Lemma 3.3 below and the definition of A_k,

$$||\psi(S_k(u_\mathcal{T}))||^2_{1,2,\mathcal{M}} = \sum_{\sigma\in\mathcal{E}} \tau_\sigma \psi(S_k(u_K)) - \psi(S_k(u_L))^2 \leq 4A_k^2,$$

so that

$$\left(\sum_{\sigma\in\mathcal{A}} {\rm meas}(\sigma) d_\sigma \psi(S_k(u_{\sigma,+}))^2\right)^{\frac{1}{2}} \leq 2C_1 A_k {\rm meas}(E_k)^{\frac{1}{2}-\frac{1}{r}}.$$

Returning to (38), we thus find

$$\begin{aligned}&\sum_{\sigma\in\mathcal{A}} {\rm meas}(\sigma)|u_{\sigma,+}|\,|\varphi_m(S_k(u_{\sigma,-})) - \varphi_m(S_k(u_{\sigma,+}))|\\ &\qquad \leq \sqrt{2d{\rm meas}(\Omega)}kA_k + 2\sqrt{2}C_1 {\rm meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} A_k^2.\end{aligned}\tag{39}$$

Then (33), (34), (35), (39), and the fact that $b_K u_K \varphi_m(S_k(u_K)) \geq 0$ give

$$\begin{aligned}&\sum_{\sigma\in\mathcal{E}} \tau_\sigma (u_K - u_L)(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L)))\\ &\leq \frac{1}{m-1} + ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}\sqrt{2d{\rm meas}(\Omega)}kA_k + 2\sqrt{2}||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} C_1 {\rm meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} A_k^2\\ &\leq \frac{1}{m-1} + C_2k^2 + \frac{1}{2}A_k^2 + C_2{\rm meas}(E_k)^{\frac{1}{2}-\frac{1}{r}} A_k^2, \qquad (40)\end{aligned}$$

where C_2 depends only on $(\Omega, \mathbf{v}, \zeta)$. However, φ_m and S_k are nondecreasing and S_k is Lipschitz-continuous with Lipschitz constant 1, and thus

$$\begin{aligned}&(S_k(u_K) - S_k(u_L))(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L)))\\ &\qquad \leq (u_K - u_L)(\varphi_m(S_k(u_K)) - \varphi_m(S_k(u_L))),\end{aligned}$$

and (40) gives

$$\sum_{\sigma\in\mathcal{E}}\tau_\sigma(S_k(u_K)-S_k(u_L))(\varphi_m(S_k(u_K))-\varphi_m(S_k(u_L)))\le\frac{2}{m-1}+2C_2k^2$$
$$+\,2C_2\mathrm{meas}(E_k)^{\frac12-\frac1r}\sum_{\sigma\in\mathcal{E}}\tau_\sigma(S_k(u_K)-S_k(u_L))(\varphi_m(S_k(u_K))-\varphi_m(S_k(u_L))).\tag{41}$$

By Corollary 3.1, there exists $k_0>0$ depending only on $(\Omega,\mathbf{v},C_2,r)$ (i.e., depending only on $(\Omega,\mathbf{v},\zeta)$) such that $2C_2\mathrm{meas}(E_k)^{\frac12-\frac1r}\le\frac12$. We deduce from (41) that

$$\sum_{\sigma\in\mathcal{E}}\tau_\sigma(S_{k_0}(u_K)-S_{k_0}(u_L))(\varphi_m(S_{k_0}(u_K))-\varphi_m(S_{k_0}(u_L)))\le\frac{4}{m-1}+4C_2k_0^2,$$

which gives (27).

Step 2: Estimate on $T_{k_0}(u_\mathcal{T})$. Multiplying each equation of (8) by $\varphi_m(T_{k_0}(u_K))$, summing on $K\in\mathcal{T}$, and reordering the sums on the edges, we find

$$\sum_{\sigma\in\mathcal{E}}\tau_\sigma(u_K-u_L)(\varphi_m(T_{k_0}(u_K))-\varphi_m(T_{k_0}(u_L)))+\sum_{K\in\mathcal{T}}\mathrm{meas}(K)b_Ku_K\varphi_m(T_{k_0}(u_K))$$
$$=\sum_{K\in\mathcal{T}}\mu(K)\varphi_m(T_{k_0}(u_K))-\sum_{\sigma\in\mathcal{E}}v_{K,\sigma}u_{\sigma,+}(\varphi_m(T_{k_0}(u_K))-\varphi_m(T_{k_0}(u_L))).\tag{42}$$

As before, we have

$$\left|\sum_{K\in\mathcal{T}}\mu(K)\varphi_m(T_{k_0}(u_K))\right|\le\frac{1}{m-1},\tag{43}$$

and, with the previous notations,

$$\begin{aligned}-\sum_{\sigma\in\mathcal{E}}&v_{K,\sigma}u_{\sigma,+}(\varphi_m(T_{k_0}(u_K))-\varphi_m(T_{k_0}(u_L)))\\&=\sum_{\sigma\in\mathcal{E}}v_\sigma u_{\sigma,+}(\varphi_m(T_{k_0}(u_{\sigma,-}))-\varphi_m(T_{k_0}(u_{\sigma,+})))\\&\le\sum_{\sigma\in\mathcal{A}}v_\sigma u_{\sigma,+}(\varphi_m(T_{k_0}(u_{\sigma,-}))-\varphi_m(T_{k_0}(u_{\sigma,+}))).\end{aligned}$$

If $\sigma\in\mathcal{A}$, then $0\le u_{\sigma,+}\le u_{\sigma,-}$ or $u_{\sigma,-}\le u_{\sigma,+}\le 0$. In either case, if $|u_{\sigma,+}|\ge k_0$, then $T_{k_0}(u_{\sigma,+})=T_{k_0}(u_{\sigma,-})$, so that $\varphi_m(T_{k_0}(u_{\sigma,-}))-\varphi_m(T_{k_0}(u_{\sigma,+}))=0$. Thus, in the previous sum, we can suppress the terms $\sigma\in\mathcal{A}$ such that $|u_{\sigma,+}|\ge k_0$ and we have

$$\begin{aligned}&-\sum_{\sigma\in\mathcal{E}}v_{K,\sigma}u_{\sigma,+}(\varphi_m(T_{k_0}(u_K))-\varphi_m(T_{k_0}(u_L)))\\&\le k_0\sum_{\sigma\in\mathcal{A}}v_\sigma|\varphi_m(T_{k_0}(u_{\sigma,-}))-\varphi_m(T_{k_0}(u_{\sigma,+}))|\\&\le k_0||\,|\mathbf{v}|\,||_{L^\infty(\Omega)}\left(\sum_{\sigma\in\mathcal{E}}\mathrm{meas}(\sigma)d_\sigma\right)^{\frac12}\left(\sum_{\sigma\in\mathcal{E}}\tau_\sigma(\varphi_m(T_{k_0}(u_{\sigma,-}))-\varphi_m(T_{k_0}(u_{\sigma,+})))^2\right)^{\frac12}.\end{aligned}$$

Here φ_m and T_{k_0} are nondecreasing and φ_m is Lipschitz-continuous with Lipschitz constant 1; thus, for all $\sigma \in \mathcal{E}$,

$$\begin{aligned}(\varphi_m(T_{k_0}(u_{\sigma,-})) &- \varphi_m(T_{k_0}(u_{\sigma,+})))^2\\ &\le (T_{k_0}(u_{\sigma,-}) - T_{k_0}(u_{\sigma,+}))(\varphi_m(T_{k_0}(u_{\sigma,-})) - \varphi_m(T_{k_0}(u_{\sigma,+})))\\ &= (T_{k_0}(u_K) - T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L))).\end{aligned}$$

Using this inequality and the fact that $\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma = d\mathrm{meas}(\Omega)$, we find

$$\begin{aligned}&-\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L)))\\ &\le k_0 ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \sqrt{d\mathrm{meas}(\Omega)}\\ &\quad\times \left(\sum_{\sigma\in\mathcal{E}} \tau_\sigma (T_{k_0}(u_K) - T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L)))\right)^{\frac{1}{2}}.\end{aligned} \tag{44}$$

Since φ_m and T_{k_0} are nondecreasing and T_{k_0} is Lipschitz-continuous with Lipschitz constant 1, we have

$$\begin{aligned}(T_{k_0}(u_K) &- T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L)))\\ &\le (u_K - u_L)(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L))).\end{aligned}$$

Combined with (42), (43), (44), and the fact that $b_K u_K \varphi_m(T_{k_0}(u_K)) \ge 0$, this inequality gives

$$\begin{aligned}&\sum_{\sigma\in\mathcal{E}} \tau_\sigma (T_{k_0}(u_K) - T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L)))\\ &\le \frac{1}{m-1} + k_0 ||\,|\mathbf{v}|\,||_{L^\infty(\Omega)} \sqrt{d\mathrm{meas}(\Omega)}\\ &\quad\times \left(\sum_{\sigma\in\mathcal{E}} \tau_\sigma (T_{k_0}(u_K) - T_{k_0}(u_L))(\varphi_m(T_{k_0}(u_K)) - \varphi_m(T_{k_0}(u_L)))\right)^{\frac{1}{2}},\end{aligned}$$

from which we deduce (28). □

What remains is to state and prove the two technical lemmas which were used in Step 1 of the above proof.

LEMMA 3.2. *Let $m \in (1,2)$ and $\varphi_m(s) = \int_0^s \frac{dt}{(1+|t|)^m}$. If (x,y) have the same sign and $|x| \le |y|$, then*

$$\int_0^1 \varphi_m'(x + t(y-x))\,dt \le \frac{1}{(1+|x|)^m}.$$

Proof of Lemma 3.2. Suppose that $0 \le x \le y$. Then, for all $t \in [0,1]$, $0 \le x \le x + t(y-x)$, so that $\varphi_m'(x+t(y-x)) = \frac{1}{(1+(x+t(y-x)))^m} \le \frac{1}{(1+|x|)^m}$. Integrating this relation on $[0,1]$ gives the desired inequality. If $y \le x \le 0$, we use the fact that φ_m' is even and apply the previous result to $(-x,-y)$. □

LEMMA 3.3. *Let $m \in (1,2)$, $\varphi_m(s) = \int_0^s \frac{dt}{(1+|t|)^m}$, and $\psi(s) = \frac{|s|}{(1+|s|)^{\frac{m}{2}}}$. Then for all $(x,y) \in \mathbb{R}^2$, one has*

$$(\psi(x) - \psi(y))^2 \le 4(x-y)(\varphi_m(x) - \varphi_m(y)).$$

Proof of Lemma 3.3. The function ψ is Lipschitz-continuous and, for all $s \in \mathbb{R}$,

$$|\psi'(s)| = \left| \frac{\mathrm{sgn}(s)}{(1+|s|)^{\frac{m}{2}}} - \frac{\frac{m}{2}\mathrm{sgn}(s)|s|}{(1+|s|)^{1+\frac{m}{2}}} \right| \leq \frac{1+\frac{m}{2}}{(1+|s|)^{\frac{m}{2}}} \leq \frac{2}{(1+|s|)^{\frac{m}{2}}},$$

so that, for all $(x,y) \in \mathbb{R}^2$, by the Cauchy–Schwarz inequality,

$$\begin{aligned}|\psi(x)-\psi(y)| = \left| \int_y^x \psi'(s)\,ds \right| &\leq \left| \int_y^x \frac{4\,ds}{(1+|s|)^m} \right|^{\frac{1}{2}} |x-y|^{\frac{1}{2}} \\ &\leq 2|\varphi_m(x)-\varphi_m(y)|^{\frac{1}{2}}|x-y|^{\frac{1}{2}}.\end{aligned}$$

Taking the power 2 of this inequality and using the fact that φ_m is nondecreasing, we deduce the desired inequality. ◻

We shall now deduce the key estimate on $u_{\mathcal{T}}$ (Theorem 2.2) from Proposition 3.2 and the following lemma.

LEMMA 3.4. *Let $\mathcal{M}$ be an admissible mesh and let $\zeta > 0$ be defined by* (15)*. Let $F : (1,2) \to \mathbb{R}^+$ be a function. For $m \in (1,2)$, we define $\varphi_m(s) = \int_0^s \frac{dt}{(1+|t|)^m}$. If $v_{\mathcal{T}} = (v_K)_{K\in\mathcal{T}} \in X(\mathcal{T})$ satisfies, for all $m \in (1,2)$,*

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma (v_K - v_L)(\varphi_m(v_K) - \varphi_m(v_L)) \leq F(m)$$

(where we have denoted, as usual, $\sigma = K|L$ if $\sigma \in \mathcal{E}_{\mathrm{int}}$ and $u_L = 0$ if $\sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}_K$), then, for all $q \in [1, \frac{d}{d-1})$, there exists $C > 0$ depending only on (Ω, ζ, F, q) such that $||v_{\mathcal{T}}||_{1,q,\mathcal{M}} \leq C$.

Proof of Lemma 3.4. Let $q \in [1, \frac{d}{d-1})$.

Take $m \in (1,2)$ (fixed later as a function of d and q) and define $a_{m,\sigma} = \int_0^1 \varphi_m'(v_K + t(v_L - v_K))\,dt$. We have $\varphi_m(v_K) - \varphi_m(v_L) = (v_K - v_L)a_{m,\sigma}$, so that

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma a_{m,\sigma} (D_\sigma v_{\mathcal{T}})^2 \leq F(m).$$

By Hölder's inequality, we have, since $1 \leq q < 2$,

$$\begin{aligned}&\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma \left(\frac{D_\sigma v_{\mathcal{T}}}{d_\sigma}\right)^q \\ &\qquad\leq \left(\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma a_{m,\sigma} \left(\frac{D_\sigma v_{\mathcal{T}}}{d_\sigma}\right)^2\right)^{\frac{q}{2}} \left(\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma a_{m,\sigma}^{-\frac{q}{2-q}}\right)^{\frac{2-q}{2}} \\ &\qquad\leq F(m)^{\frac{q}{2}} \left(\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma a_{m,\sigma}^{-\frac{q}{2-q}}\right)^{\frac{2-q}{2}}. \qquad (45)\end{aligned}$$

For all $(x,y) \in \mathbb{R}^2$ and all $t \in [0,1]$, one has $|x + t(y-x)| \leq \sup(|x|,|y|)$, so that

$$\begin{aligned}\varphi_m'(x + t(y-x)) = \frac{1}{(1+|x+t(y-x)|)^m} &\geq \frac{1}{(1+\sup(|x|,|y|))^m} \\ &\geq \inf\left(\frac{1}{(1+|x|)^m}, \frac{1}{(1+|y|)^m}\right).\end{aligned}$$

Taking $x = v_K$, $y = v_L$ and integrating the previous inequality on $t \in [0,1]$, we find

$$a_{m,\sigma} \geq \inf\left(\frac{1}{(1+|v_K|)^m}, \frac{1}{(1+|v_L|)^m}\right),$$

which implies

$$a_{m,\sigma}^{-\frac{q}{2-q}} \leq \sup\left((1+|v_K|)^{\frac{mq}{2-q}}, (1+|v_L|)^{\frac{mq}{2-q}}\right) \leq 2^{\frac{mq}{2-q}}\left(1+|v_K|^{\frac{mq}{2-q}} + |v_L|^{\frac{mq}{2-q}}\right).$$

We deduce from (45), using the fact that $\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma)d_\sigma = d\mathrm{meas}(\Omega)$ and reordering the sum on the control volumes,

$$||v_{\mathcal{T}}||_{1,q,\mathcal{M}}^q \leq C_1\left(1 + \sum_{K\in\mathcal{T}} |v_K|^{\frac{mq}{2-q}}\left(\sum_{\sigma\in\mathcal{E}_K} \mathrm{meas}(\sigma)d_\sigma\right)\right)^{\frac{2-q}{2}},$$

where C_1 depends only on (F, m, q, Ω). But since $d_{K,\sigma} \geq \zeta d_\sigma$ for all $K \in \mathcal{T}$ and all $\sigma \in \mathcal{E}_K$, we have $\sum_{\sigma\in\mathcal{E}_K} \mathrm{meas}(\sigma)d_\sigma \leq \frac{1}{\zeta}\sum_{\sigma\in\mathcal{E}_K} \mathrm{meas}(\sigma)d_{K,\sigma} = \frac{d}{\zeta}\mathrm{meas}(K)$, and we thus obtain

$$||v_{\mathcal{T}}||_{1,q,\mathcal{M}}^q \leq C_2\left(1 + ||v_{\mathcal{T}}||_{L^{\frac{mq}{2-q}}(\Omega)}^{\frac{mq}{2}}\right), \tag{46}$$

where C_2 depends only on (F, m, q, Ω). (Notice that, since $m > 1$, we always have $\frac{mq}{2-q} \geq 1$.)

By Proposition 2.2, there exists C_3 depending only on (Ω, q, ζ) such that, if $q^* = \frac{dq}{d-q}$ (note that $q < \frac{d}{d-1} \leq d$),

$$||v_{\mathcal{T}}||_{L^{q^*}(\Omega)} \leq C_3||v_{\mathcal{T}}||_{1,q,\mathcal{M}}.$$

Using this in (46), we obtain

$$||v_{\mathcal{T}}||_{L^{q^*}(\Omega)}^q \leq C_3^q C_2\left(1 + ||v_{\mathcal{T}}||_{L^{\frac{mq}{2-q}}(\Omega)}^{\frac{mq}{2}}\right).$$

If $q < \frac{d}{d-1}$, one has $\frac{q}{2-q} < q^*$, so that we can choose $m \in (1,2)$ (depending only on (q,d)) such that $\frac{mq}{2-q} \leq q^*$. We thus obtain, with such a choice of m and Hölder's inequality,

$$||v_{\mathcal{T}}||_{L^{q^*}(\Omega)}^q \leq C_4\left(1 + ||v_{\mathcal{T}}||_{L^{q^*}(\Omega)}^{\frac{mq}{2}}\right),$$

where C_4 depends only on (Ω, ζ, q, F). Since $\frac{mq}{2} < q$ (recall that $m < 2$), this inequality gives us C_5 depending only on (Ω, ζ, q, F) such that $||v_{\mathcal{T}}||_{L^{q^*}(\Omega)} \leq C_5$, and, returning to (46), we deduce the desired estimate on $||v_{\mathcal{T}}||_{1,q,\mathcal{M}}$. ∎

3.3. Proof of Theorem 2.2. Here we give the proof of the key estimate on $||u_{\mathcal{T}}||_{1,q,\mathcal{M}}$, which was stated in Theorem 2.2 and which is crucial to showing the existence and convergence of the solution to the finite volume scheme.

Proof of Theorem 2.2. Let $\Lambda > ||\mu||_{M(\overline{\Omega})}$ (to avoid dividing by 0). Since (8)–(10) make up a linear problem, we see that $u_{\mathcal{T}}/\Lambda$ is a solution to (8)–(10) with μ/Λ instead of μ.

Since $||\mu/\Lambda||_{M(\overline{\Omega})} \le 1$, we can apply Proposition 3.2 to $u_{\mathcal{T}}/\Lambda$; let $k_0 > 0$ depending only on $(\Omega, \mathbf{v}, \zeta)$ given by this proposition. $S_{k_0}(u_{\mathcal{T}}/\Lambda)$ and $T_{k_0}(u_{\mathcal{T}}/\Lambda)$ then satisfy the hypotheses of Lemma 3.4 with a function F depending only on $(\Omega, \mathbf{v}, \zeta)$. We deduce from this lemma that, for all $q \in [1, \frac{d}{d-1})$, there exists $C > 0$ depending only on $(\Omega, \mathbf{v}, \zeta, q)$ such that

$$||S_{k_0}(u_{\mathcal{T}}/\Lambda)||_{1,q,\mathcal{M}} \le C \quad \text{and} \quad ||T_{k_0}(u_{\mathcal{T}}/\Lambda)||_{1,q,\mathcal{M}} \le C.$$

Since $u_{\mathcal{T}}/\Lambda = S_{k_0}(u_{\mathcal{T}}/\Lambda) + T_{k_0}(u_{\mathcal{T}}/\Lambda)$ and $||\cdot||_{1,q,\mathcal{M}}$ is a norm, this gives $||u_{\mathcal{T}}/\Lambda||_{1,q,\mathcal{M}} \le C$, that is to say, $||u_{\mathcal{T}}||_{1,q,\mathcal{M}} \le C\Lambda$. Letting Λ tend to $||\mu||_{M(\overline{\Omega})}$, we obtain the desired estimate on $u_{\mathcal{T}}$. □

4. Proof of Theorem 2.1. We first prove the uniqueness of the solution to (14), which does not involve numerical analysis methods, and then the existence and convergence of the approximate solutions (which yields the existence of a solution to (14)).

Proof of the uniqueness of the solution to (14). This proof uses the regularity results of [22] on the variational solution to $-\Delta v = f \in L^2(\Omega)$, $v_{|\partial\Omega} = 0$, for Ω polygonal (or polyhedral) open set in $\mathbb{R}^d$, $d = 2$ or 3.

Problem (14) being linear, it is sufficient to prove that, if u is a solution to (14) with $\mu = 0$, then $u = 0$.

Let $\theta \in L^\infty(\Omega)$, and take $\varphi \in H_0^1(\Omega) \cap L^\infty(\Omega)$ as the solution to

$$(47) \quad \int_\Omega \nabla\varphi \cdot \nabla\psi \, d\lambda - \int_\Omega \psi \mathbf{v} \cdot \nabla\varphi \, d\lambda + \int_\Omega b\varphi\psi \, d\lambda = \int_\Omega \theta\psi \, d\lambda \quad \text{for all } \psi \in H_0^1(\Omega).$$

The existence of such a φ is ensured by the results of [9]. Letting $\Theta = \theta + \mathbf{v}\cdot\nabla\varphi - b\varphi \in L^2(\Omega)$, we see that $\varphi \in H_0^1(\Omega)$ satisfies $-\Delta\varphi = \Theta$ on Ω.

Since Ω is a polygonal (or polyhedral) open set in $\mathbb{R}^2$ or $\mathbb{R}^3$, the results of [22] give us $\eta > 0$ such that $\varphi \in H^{\frac{3}{2}+\eta}(\Omega)$. Thus, by the Sobolev injections (see [1]), there exists $s > d$ such that $\varphi \in W_0^{1,s}(\Omega)$. (In the case $d = 2$, to obtain such an $s > 2$ we could also have used the result of [28], which is stated for regular open sets but is also true for open sets with Lipschitz-continuous boundary; see [21].)

Thanks to this additional regularity, a density argument allows us to see that (47) is also true for $\psi \in W_0^{1,s'}(\Omega)$, where s' is the conjugate exponent to s, that is, such that $\frac{1}{s} + \frac{1}{s'} = 1$.

We can thus use φ in the equation satisfied by u and u in the equation satisfied by φ to obtain

$$0 = \int_\Omega \nabla u \cdot \nabla\varphi \, d\lambda - \int_\Omega u\mathbf{v} \cdot \nabla\varphi \, d\lambda + \int_\Omega bu\varphi \, d\lambda = \int_\Omega \theta u \, d\lambda.$$

We deduce from this equality, satisfied for all $\theta \in L^\infty(\Omega)$, that $u = 0$, i.e., the uniqueness of the solution to (14). □

Proof of the existence and convergence results. The existence of a unique solution to (8)–(10) is an immediate consequence of the estimate of Theorem 2.2: Indeed, if $\mu = 0$, then this theorem shows that any solution to (8)–(10) is null, that is to say, the square matrix defining this linear system is invertible.

Let us now prove the convergence result. The techniques used here are easy adaptations of the convergence proof of [14].

Let $(u_n)_{n\in\mathbb{N}}$ be a sequence of functions of $L^2(\Omega)$ such that u_n is a solution to (8)–(10) for $\mathcal{M} = \mathcal{M}_n$, where $(\mathcal{M}_n)_{n\in\mathbb{N}}$ is a family of admissible meshes $\mathcal{M}$ satisfying (15) (for some fixed $\zeta > 0$), and such that size$(\mathcal{M}_n)$ tends to 0 as n tends to $+\infty$.

We first prove (Steps 0 to 5) that if $(u_n)_{n\in\mathbb{N}}$ tends to u in $L^p(\Omega)$ for all $p<\frac{d}{d-2}$ as n tends to $+\infty$ (and $\mathrm{size}(\mathcal{M}_n)\to 0$), with $u\in\cap_{q<\frac{d}{d-1}}W_0^{1,q}(\Omega)$, then u is a solution to (14).

We then prove (Step 6), thanks to the a priori estimates of section 3, the compactness of the sequence $(u_n)_{n\in\mathbb{N}}$ and conclude, thanks to the uniqueness result which was proved above, the convergence of $(u_n)_{n\in\mathbb{N}}$ to the solution u to (14).

Step 0: Density argument. By the density of $C_c^\infty(\Omega)$ in $W_0^{1,s}(\Omega)$ for all $s\in(d,\infty)$ and by the regularity results on u, it is clearly sufficient to prove that u satisfies the equations of (14) for all $\varphi\in C_c^\infty(\Omega)$. Take such a φ. Multiplying (8) by $\varphi(x_K)$ and summing over $K\in\mathcal{T}$, we have, by the conservativity of the fluxes and by dropping the index n,

$$\sum_{\sigma\in\mathcal{E}}\tau_\sigma(u_K-u_L)(\varphi(x_K)-\varphi(x_L))+\sum_{\sigma\in\mathcal{E}}v_{K,\sigma}u_{\sigma,+}(\varphi(x_K)-\varphi(x_L)) \\ +\sum_{K\in\mathcal{T}}\mathrm{meas}(K)b_Ku_K\varphi(x_K)=\sum_{K\in\mathcal{T}}\varphi(x_K)\mu(K). \tag{48}$$

We shall now pass to the limit as $\mathrm{size}(\mathcal{M})$ tends to 0 in (48) and prove the convergence of each of the terms to the corresponding term in (14). In fact, the proof of convergence of the first and third terms of the left-hand side can be found in [14] or [15], as can the proof of the second term under a stronger regularity condition. The proof of convergence of the right-hand side may be found in [19], so that the only new part in this proof is Step 4, which shows the convergence of the convective term with a continuous convection velocity (rather than C^1 in previous works). However, we give a quick proof for all terms for the sake of completeness.

Step 1: Convergence of the lower order terms. Denote by $\varphi_\mathcal{T}\in X(\mathcal{T})$ the function defined by $\varphi_K=\varphi(x_K)$ for all $K\in\mathcal{T}$. By the regularity of φ, we have $\varphi_\mathcal{T}\to\varphi$ uniformly on Ω as $\mathrm{size}(\mathcal{M})\to 0$, and thus

$$\sum_{K\in\mathcal{T}}\varphi(x_K)\mu(K)=\int_\Omega\varphi_\mathcal{T}\,d\mu\to\int_\Omega\varphi\,d\mu \tag{49}$$

as $\mathrm{size}(\mathcal{M})\to 0$. (Notice that $\varphi_\mathcal{T}=0$ near $\partial\Omega$ for $\mathrm{size}(\mathcal{M})$ small enough.)

By regularity of b, $b_\mathcal{T}=(b_K)_{K\in\mathcal{T}}$ tends to b in $L^2(\Omega)$ as $\mathrm{size}(\mathcal{M})\to 0$; thus, since $\varphi_\mathcal{T}\to\varphi$ in $L^\infty(\Omega)$ and $u_\mathcal{T}\to u$ in $L^2(\Omega)$ (because $2<d/(d-2)$) as $\mathrm{size}(\mathcal{M})\to 0$, we have

$$\sum_{K\in\mathcal{T}}\mathrm{meas}(K)b_Ku_K\varphi(x_K)=\int_\Omega b_\mathcal{T}u_\mathcal{T}\varphi_\mathcal{T}\,d\lambda\to\int_\Omega bu\varphi\,d\lambda \tag{50}$$

as $\mathrm{size}(\mathcal{M})\to 0$.

Step 2: Convergence of the diffusion term. Gathering by control volumes, we have

$$\sum_{\sigma\in\mathcal{E}}\tau_\sigma(u_K-u_L)(\varphi(x_K)-\varphi(x_L))=\sum_{K\in\mathcal{T}}u_K\sum_{\sigma\in\mathcal{E}_K}\tau_\sigma(\varphi(x_K)-\varphi(x_L)).$$

But, by regularity of φ,

$$\tau_\sigma(\varphi(x_K)-\varphi(x_L))=-\int_\sigma\nabla\varphi\cdot\mathbf{n}_{K,\sigma}\,d\gamma+\mathrm{meas}(\sigma)R_{K,\sigma},$$

where $|R_{K,\sigma}| \le C_1 \mathrm{size}(\mathcal{M})$ (C_1 does not depend on the mesh) and $R_{K,\sigma} = -R_{L,\sigma}$ whenever $\sigma = K|L \in \mathcal{E}_{\mathrm{int}}$. Thus, gathering by edges,

$$\begin{aligned}\sum_{\sigma\in\mathcal{E}} \tau_\sigma(u_K - u_L)(\varphi(x_K) - \varphi(x_L)) + \sum_{K\in\mathcal{T}} u_K \int_{\partial K} \nabla\varphi\cdot\mathbf{n}_K\,d\gamma \\ = \sum_{K\in\mathcal{T}} u_K \sum_{\sigma\in\mathcal{E}_K} \mathrm{meas}(\sigma) R_{K,\sigma} = \sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) R_{K,\sigma}(u_K - u_L).\end{aligned}$$

However,

$$\begin{aligned}\left|\sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) R_{K,\sigma}(u_K - u_L)\right| &\le C_1 \mathrm{size}(\mathcal{M}) \sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma \frac{D_\sigma u_{\mathcal{T}}}{d_\sigma} \\ &= C_1 \mathrm{size}(\mathcal{M}) ||u_{\mathcal{T}}||_{1,1,\mathcal{M}},\end{aligned}$$

and this last quantity tends to 0 as $\mathrm{size}(\mathcal{M}) \to 0$ (because, by Theorem 2.2, $||u_{\mathcal{T}}||_{1,1,\mathcal{M}}$ stays bounded). By noticing that

$$\sum_{K\in\mathcal{T}} u_K \int_{\partial K} \nabla\varphi\cdot\mathbf{n}_K\,d\gamma = \sum_{K\in\mathcal{T}} u_K \int_K \Delta\varphi\,d\lambda = \int_\Omega u_{\mathcal{T}} \Delta\varphi\,d\lambda,$$

and since $u_{\mathcal{T}} \to u$ in $L^1(\Omega)$ as $\mathrm{size}(\mathcal{M}) \to 0$, we deduce that

$$\sum_{\sigma\in\mathcal{E}} \tau_\sigma(u_K - u_L)(\varphi(x_K) - \varphi(x_L)) \to -\int_\Omega u\Delta\varphi\,d\lambda = \int_\Omega \nabla u\cdot\nabla\varphi\,d\lambda \tag{51}$$

as $\mathrm{size}(\mathcal{M}) \to 0$.

Step 3: Preliminary to the convergence of the convection term. (In fact, we prove here the convergence of the convection term if $\mathbf{v}$ is regular.)

Let $\mathbf{w} \in (C^1(\overline{\Omega}))^d$, and define, for $K \in \mathcal{T}$ and $\sigma \in \mathcal{E}_K$, $w_{K,\sigma} = \int_\sigma \mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma$. (Notice that, if $\sigma = K|L \in \mathcal{E}_{\mathrm{int}}$, then $w_{K,\sigma} = -w_{L,\sigma}$.) We want to study the limit, as $\mathrm{size}(\mathcal{M}) \to 0$, of $\sum_{\sigma\in\mathcal{E}} w_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L))$ (that is to say, the convection term of (48) with $\mathbf{w}$ instead of $\mathbf{v}$).

We have

$$\begin{aligned}&\sum_{\sigma\in\mathcal{E}} w_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) \\ &= \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma} u_{\sigma,+}\varphi(x_K) \\ &= \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma}(u_{\sigma,+} - u_K)\varphi(x_K) + \sum_{K\in\mathcal{T}} \varphi(x_K) u_K \sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma}. \qquad (52)\end{aligned}$$

Since $\sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma} = \int_{\partial K} \mathbf{w}\cdot\mathbf{n}_K\,d\gamma = \int_K \mathrm{div}(\mathbf{w})\,d\lambda$, we have

$$\sum_{K\in\mathcal{T}} \varphi(x_K) u_K \sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma} = \int_\Omega u_{\mathcal{T}} \varphi_{\mathcal{T}} \mathrm{div}(\mathbf{w})\,d\lambda \to \int_\Omega u\varphi \mathrm{div}(\mathbf{w})\,d\lambda \tag{53}$$

as $\mathrm{size}(\mathcal{M}) \to 0$.

Moreover,

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma}(u_{\sigma,+}-u_K)\varphi(x_K) = \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K}(u_{\sigma,+}-u_K)\int_\sigma \varphi\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma \\ + \sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K}(u_{\sigma,+}-u_K)\int_\sigma (\varphi(x_K)-\varphi)\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma.$$

Since, for size($\mathcal{M}$) small enough, the support of φ does not intersect the cells K such that $\partial K\cap\partial\Omega\neq\emptyset$, we have

$$\sum_{K\in\mathcal{T}}\sum_{\sigma=K|L\in\mathcal{E}_K} u_{\sigma,+}\int_\sigma \varphi\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma \\ = \sum_{\sigma\in\mathcal{E}_{\rm int}} u_{\sigma,+}\left(\int_\sigma \varphi\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma + \int_\sigma \varphi\mathbf{w}\cdot\mathbf{n}_{L,\sigma}\,d\gamma\right) = 0,$$

because $\mathbf{n}_{K,\sigma}=-\mathbf{n}_{L,\sigma}$ if $\sigma=K|L\in\mathcal{E}_{\rm int}$. On the other hand,

$$-\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} u_K\int_\sigma \varphi\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma = -\sum_{K\in\mathcal{T}} u_K\int_K {\rm div}(\varphi\mathbf{w})\,d\lambda \\ = -\int_\Omega u_{\mathcal{T}}{\rm div}(\varphi\mathbf{w})\,d\lambda \to -\int_\Omega u{\rm div}(\varphi\mathbf{w})\,d\lambda$$

as size($\mathcal{M}$) → 0. By regularity of φ, we have C_5 depending only on φ such that

$$\left|\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K}(u_{\sigma,+}-u_K)\int_\sigma(\varphi(x_K)-\varphi)\mathbf{w}\cdot\mathbf{n}_{K,\sigma}\,d\gamma\right| \\ \le C_5||\,|\mathbf{w}|\,||_{C(\overline{\Omega})}{\rm size}(\mathcal{M})\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K}{\rm meas}(\sigma)|u_{\sigma,+}-u_K| \\ \le C_5||\,|\mathbf{w}|\,||_{C(\overline{\Omega})}{\rm size}(\mathcal{M})\sum_{\sigma\in\mathcal{E}}{\rm meas}(\sigma)D_\sigma u_{\mathcal{T}} \\ = C_5||\,|\mathbf{w}|\,||_{C(\overline{\Omega})}{\rm size}(\mathcal{M})||u_{\mathcal{T}}||_{1,1,\mathcal{M}}.$$

The last quantity tending to 0 as size($\mathcal{M}$) → 0, we deduce from the preceding that

$$\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma}(u_{\sigma,+}-u_K)\varphi(x_K)\to -\int_\Omega u{\rm div}(\varphi\mathbf{w})\,d\lambda \tag{54}$$

as size($\mathcal{M}$) → 0.

Using (53) and (54) in (52), we obtain

$$\sum_{\sigma\in\mathcal{E}} w_{K,\sigma}u_{\sigma,+}(\varphi(x_K)-\varphi(x_L)) \to \int_\Omega u\varphi{\rm div}(\mathbf{w})\,d\lambda - \int_\Omega u{\rm div}(\varphi\mathbf{w})\,d\lambda \\ = -\int_\Omega u\mathbf{w}\cdot\nabla\varphi\,d\lambda \tag{55}$$

as size($\mathcal{M}$) → 0.

Step 4. Convergence of the convection term. Let $\varepsilon > 0$ and take $\mathbf{w} \in (C^1(\overline{\Omega}))^d$ such that $|| \, |\mathbf{v} - \mathbf{w}| \, ||_{C(\overline{\Omega})} \leq \varepsilon$. By the regularity of φ,

$$\left|\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) - \sum_{\sigma\in\mathcal{E}} w_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L))\right| \\ \leq C_2\varepsilon \sum_{\sigma\in\mathcal{E}} \mathrm{meas}(\sigma) d_\sigma |u_{\sigma,+}|,$$

where C_2 depends only on φ. Gathering by control volumes, we deduce that

$$\left|\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) - \sum_{\sigma\in\mathcal{E}} w_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L))\right| \\ \leq C_2\varepsilon \sum_{K\in\mathcal{T}} |u_K| \sum_{\sigma\in\mathcal{E}_K \,|\, v_{K,\sigma}\geq 0} \mathrm{meas}(\sigma) d_\sigma.$$

However, by our hypothesis on the mesh, $\sum_{\sigma\in\mathcal{E}_K \,|\, v_{K,\sigma}\geq 0} \mathrm{meas}(\sigma) d_\sigma \leq \zeta^{-1} \sum_{\sigma\in\mathcal{E}_K} \mathrm{meas}(\sigma) d_{K,\sigma} = \zeta^{-1} d\mathrm{meas}(K)$, so that

$$\left|\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) - \sum_{\sigma\in\mathcal{E}} w_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L))\right| \\ \leq C_3\varepsilon \sum_{K\in\mathcal{T}} \mathrm{meas}(K)|u_K| \leq C_4\varepsilon, \tag{56}$$

where C_3 and C_4 depend neither on the mesh $\mathcal{M}$ nor on ε. ($\sum_{K\in\mathcal{T}} \mathrm{meas}(K)|u_K| = ||u_\mathcal{T}||_{L^1(\Omega)}$ is bounded.)

We also notice that

$$\left|\int_\Omega u\mathbf{v} \cdot \nabla\varphi \, d\lambda - \int_\Omega u\mathbf{w} \cdot \nabla\varphi \, d\lambda\right| \leq C_6\varepsilon, \tag{57}$$

where C_6 does not depend on ε.

Next using (55) and (57) in (57), we obtain

$$\limsup_{\mathrm{size}(\mathcal{M})\to 0} \left|\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) + \int_\Omega u\mathbf{v} \cdot \nabla\varphi \, d\lambda\right| \leq C_7\varepsilon,$$

where C_7 does not depend on ε. This being true for any $\varepsilon > 0$, we deduce that

$$\sum_{\sigma\in\mathcal{E}} v_{K,\sigma} u_{\sigma,+}(\varphi(x_K) - \varphi(x_L)) \to -\int_\Omega u\mathbf{v} \cdot \nabla\varphi \, d\lambda \tag{58}$$

as size($\mathcal{M}$) → 0.

Step 5: Passage to the limit in the scheme. Using (49), (50), (51), and (58), we may pass to the limit in (48) to obtain

$$\int_\Omega \nabla u \cdot \nabla\varphi \, d\lambda - \int_\Omega u\mathbf{v} \cdot \nabla\varphi \, d\lambda + \int_\Omega bu\varphi \, d\lambda = \int_\Omega \varphi \, d\mu,$$

which proves that u is a solution to (14).

Step 6: Proof of the convergence of $(u_n)_{n\in\mathbb{N}}$. Thanks to Theorem 2.2 and to Propositions 2.3 and 2.4, we see that $(u_n)_{n\geq 1}$ is relatively compact in $L^q(\Omega)$ for all $q \in [1, \frac{d}{d-1})$ and that the adherence values (in $L^q(\Omega)$) of this sequence are in $W_0^{1,q}(\Omega)$ (for $q \in (1, \frac{d}{d-1})$). Up to a subsequence, we can thus suppose that $u_n \to u$ in $L^q(\Omega)$ for all $q \in [1, \frac{d}{d-1})$, with $u \in \cap_{q<\frac{d}{d-1}} W_0^{1,q}(\Omega)$; by Proposition 2.2 and Theorem 2.2, $(u_n)_{n\geq 1}$ is also bounded in $L^p(\Omega)$ for all $p < \frac{d}{d-2}$, so that, by an easy consequence of the Vitali convergence theorem, $u_n \to u$ in $L^p(\Omega)$ for all $p < \frac{d}{d-2}$.

By what we have just proved, we see that u is then a solution to (14); since this solution is unique, this proves that the whole sequence $(u_n)_{n\geq 1}$ converges to u.

As a by-product, this convergence entails the existence of a solution to (14) (which can be deduced from previous works, for instance, [2] and [9]). □

5. A scheme with jump of the fluxes.

Until now, we have considered, in the definition of "admissible mesh," a partition of Ω into convex polygonal (or polyhedral) sets. We then defined a finite volume scheme where the conservativity of the numerical fluxes can be written as $F_{K,\sigma} = -F_{L,\sigma}$ for all $\sigma = K|L \in \mathcal{E}_{\rm int}$.

There is, however, another manner of dealing with the discretization of a right-hand-side measure, which was implemented, for instance, in [17] for the numerical simulation of fuel cells. In this formulation, we write that if the support of the measure intersects a given edge, then there is a jump of the flux on this edge. This leads to the following scheme.

The mesh $\mathcal{M}$ that we consider now is defined by a finite family $\mathcal{T}$ of polygonal (or polyhedral) open disjoint subsets of Ω, by a finite family $\mathcal{E}$ of subsets of $\overline{\Omega}$ contained in affine hyperplanes, and by a finite family $\mathcal{P} = (x_K)_{K\in\mathcal{T}}$ of points of Ω such that

(a) $\mathcal{T} \cup \mathcal{E}$ is a partition of $\overline{\Omega}$;

(b) for each $\sigma \in \mathcal{E}$, there exists $K \in \mathcal{T}$ and a nonempty open subset O of ∂K such that $O \subset \sigma \subset \overline{O}$;

(c) items (iii)–(vi) of Definition 2.1 hold.

The notation concerning the mesh is the same as before, and the reader can easily verify that Propositions 2.1–2.4 are still true for such meshes.

Still defining $(b_K)_{K\in\mathcal{T}}$ and $(v_{K,\sigma})_{K\in\mathcal{T}\,,\,\sigma\in\mathcal{E}_K}$ by (7), the new scheme is

$$\text{for all } K \in \mathcal{T},\ \sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma} + \sum_{\sigma\in\mathcal{E}_K} v_{K,\sigma} u_{\sigma,+} + \text{meas}(K) b_K u_K = \mu(K), \tag{59}$$

$$\begin{aligned} &\text{for all } \sigma = K|L \in \mathcal{E}_{\rm int}\,, \quad F_{K,\sigma} = -\tfrac{\text{meas}(\sigma)}{d_{K,\sigma}}(u_\sigma - u_K),\\ &\text{for all } \sigma \in \mathcal{E}_{\rm ext} \cap \mathcal{E}_K, \quad\ \ F_{K,\sigma} = \tau_\sigma u_K, \end{aligned} \tag{60}$$

$$\text{for all } \sigma = K|L \in \mathcal{E}_{\rm int}, \quad F_{K,\sigma} + F_{L,\sigma} = -\mu(\sigma), \tag{61}$$

$$\begin{aligned} &\text{for all } \sigma = K|L \in \mathcal{E}_{\rm int}, \quad u_{\sigma,+} = u_K \text{ if } v_{K,\sigma} \geq 0\,, \quad u_{\sigma,+} = u_L \text{ otherwise},\\ &\text{for all } \sigma \in \mathcal{E}_{\rm ext} \cap \mathcal{E}_K\,, \quad u_{\sigma,+} = u_K \text{ if } v_{K,\sigma} \geq 0\,, \quad u_{\sigma,+} = 0 \text{ otherwise}. \end{aligned} \tag{62}$$

Notice that the unknowns of this scheme are $(u_K)_{K\in\mathcal{T}}$ and $(u_\sigma)_{\sigma\in\mathcal{E}}$ (which represent approximate values on the edges), but that relation (61) allows us to eliminate the $(u_\sigma)_{\sigma\in\mathcal{E}}$; this scheme can thus be considered as a linear system on $(u_K)_{K\in\mathcal{T}}$.

In fact, the elimination of u_σ thanks to (61) gives, for $\sigma = K|L \in \mathcal{E}_{\rm int}$,

$$F_{K,\sigma} = \frac{\text{meas}(\sigma)}{d_\sigma}(u_K - u_L) - \frac{d_{L,\sigma}}{d_\sigma}\mu(\sigma).$$

Thus, this new scheme is in fact the scheme (8)–(10), where we have changed, for all $K \in \mathcal{T}$, $\mu(K)$ by $\widetilde{\mu}_K = \mu(K) + \sum_{\sigma\in\mathcal{E}_K} \frac{d_{L,\sigma}}{d_\sigma}\mu(\sigma)$ (with $\sigma = K|L$ if $\sigma \in \mathcal{E}_{\text{int}}$, and $d_{L,\sigma} = 0$ if $\sigma \in \mathcal{E}_{\text{ext}} \cap \mathcal{E}_K$), which is just another way to discretize the measure μ (forgetting the values of μ on the boundary of the domain, which does not modify the problem since we consider Dirichlet boundary conditions).

The matrix of (59)–(62) is thus the same as the matrix of (8)–(10), and, since $(\widetilde{\mu}_K)_{K\in\mathcal{T}}$ satisfies

$$\begin{aligned}\sum_{K\in\mathcal{T}} |\widetilde{\mu}_K| &\leq \sum_{K\in\mathcal{T}} |\mu(K)| + \sum_{\sigma\in\mathcal{E}} \left(\frac{d_{K,\sigma}}{d_\sigma} + \frac{d_{L,\sigma}}{d_\sigma}\right) |\mu(\sigma)| \\ &= \sum_{K\in\mathcal{T}} |\mu(K)| + \sum_{\sigma\in\mathcal{E}} |\mu(\sigma)| \leq ||\mu||_{M(\overline{\Omega})}\end{aligned}$$

(because $\mathcal{T} \cup \mathcal{E}$ is a partition of $\overline{\Omega}$), the a priori estimates on the solutions to (59)–(62) are obtained in exactly the same way as the estimates of the solutions to (8)–(10).

We also have, for $\varphi \in C_c(\Omega)$, for $\sigma = K|L \in \mathcal{E}_{\text{int}}$,

$$\left|\frac{d_{L,\sigma}}{d_\sigma}\varphi(x_K)\mu(\sigma) + \frac{d_{K,\sigma}}{d_\sigma}\varphi(x_L)\mu(\sigma) - \int_\sigma \varphi\, d\mu\right| \leq \omega(\varphi, \text{size}(\mathcal{M}))|\mu(\sigma)|,$$

where $\omega(\varphi, h)$ is the modulus of continuity of φ; thus,

$$\sum_{K\in\mathcal{T}} \varphi(x_K)\widetilde{\mu}_K \to \int_\Omega \varphi\, d\mu$$

as $\text{size}(\mathcal{M}) \to 0$, and the convergence of the solution of (59)–(62) as $\text{size}(\mathcal{M}) \to 0$ is obtained by the same technique as in the proof of Theorem 2.1.

6. Numerical results.

We performed a few simple numerical experiments on problems to which the exact solution is known, in order to try and obtain some rates of convergence of the finite volume scheme in the presence of a nonregular right-hand side. Numerical results were also shown in [11] in the noncoercive case with right-hand side in H^{-1}, so we shall concentrate here on tests in the irregular data case.

6.1. Comparison of the two finite volume schemes.

The first numerical experiment is concerned with the comparison of the treatment of the singularity in the one-dimensional case. In this case, the Dirac is not a very "mean" measure, in the sense that the solution of the problem is continuous; the jump is only on the derivative. In the first version of the finite volume scheme (scheme (8)–(10), which we shall call Scheme 1 in what follows), the Dirac measure is taken in its integral form in the right-hand side, while in the second version (scheme (59)–(62), which we shall call Scheme 2), the mesh is adapted so as to be able to write the numerical jump of the flux on a cell interface. We solve $-u'' = \delta_{1/2}$, $u(0) = 0$, $u(1) = 0$, on the interval $(0, 1)$; the exact solution is $u(x) = \frac{x}{2}$ for $x < .5$, $u(x) = \frac{(1-x)}{2}$ for $x \geq .5$. We use a uniform mesh and ensure that the number of cells is even, so that in the second scheme, the flux jump is located on a cell interface. The error function e is defined by $e(x) = u(x_K) - u_K$ for any $x \in K$, where $u(x_K)$ denotes the value of the exact solution of the continuous problem at point x_K, and $(u_K)_{K\in\mathcal{T}}$ denotes the solution to the finite volume scheme.

We analyze the rate of convergence by showing the L^1, L^2, and L^∞ norms of the error e versus the number of cells with a log-log scale in Figure 3.

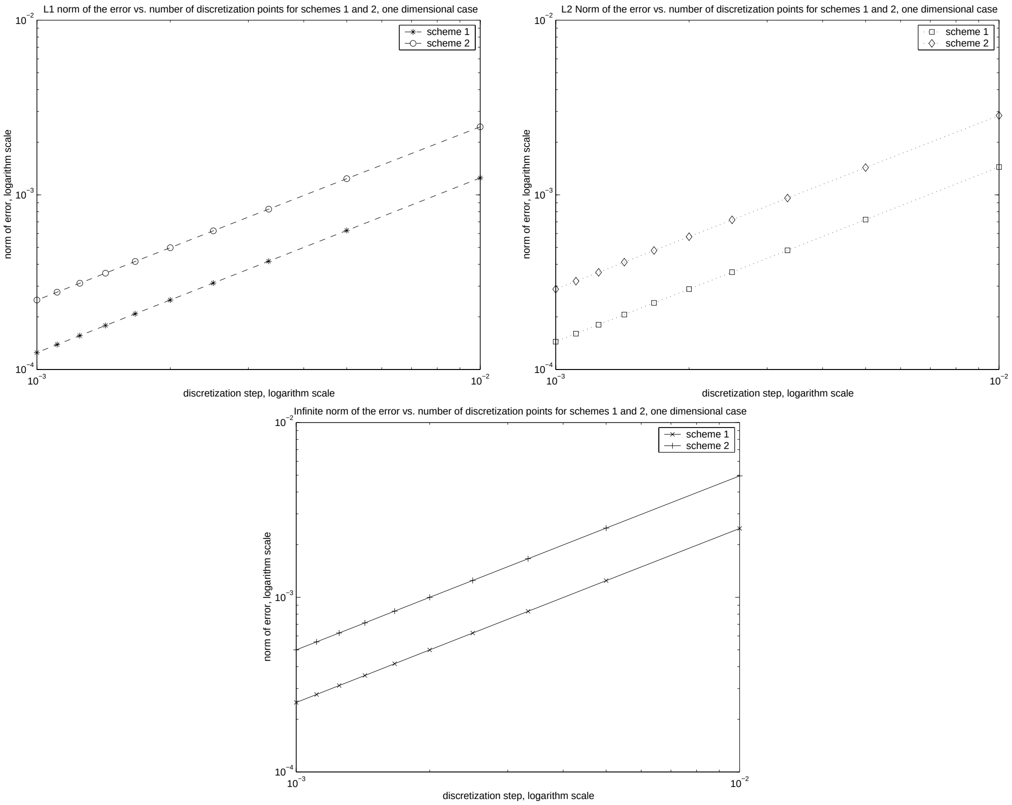

FIG. 3. *Convergence rates in the one-dimensional case.*

TABLE 1
Values of (C, α) *for Schemes* 1 *and* 2*, in the one-dimensional case.*

α	L^1 norm	L^2 norm	L^∞ norm
Scheme 1	1.0000	1.0000	0.9961
Scheme 2	0.9923	0.9941	0.9961

C	L^1 norm	L^2 norm	L^∞ norm
Scheme 1	0.1250	0.1443	0.2431
Scheme 2	0.2365	0.2768	0.4861

The results show straight lines for all three norms, so that it is natural to try and evaluate the norms of the error as $||e|| \equiv Ch^\alpha$. The computation of the coefficients C and α from the numerical results are given in Table 1. These coefficients are computed using the two finest meshes.

These results show that the two schemes have a rate of convergence which is roughly the same (close to one) and that the constant C is about twice as large for Scheme 2 (jump of flux) than for Scheme 1 (Dirac in one cell). This is quite in accordance with what can be seen from the implementation of the schemes, because Scheme 2 amounts to spreading the Dirac measure over two cells, instead of the one in Scheme 1.

6.2. Two- and three-dimensional tests on a Cartesian mesh. We also implemented the finite volume scheme on the square (resp., cubic) domain $\Omega = (-1, 1)^2$ (resp., $\Omega = (-1, 1)^3$). The domain is discretized with a uniform mesh, and the L^p norm of the error is computed for an increasing number of cells, so as to evaluate the

FIG. 5. *Convergence rate, two-dimensional case, right-hand side Dirac at zero, nonsymmetric discrete problem.*

rate of convergence.

We first tested the two-dimensional code for regular data, obtaining the exact solution $u(x, y) = \sin x \sin y$; results are shown in Figure 4. In this case, since the mesh is rectangular and the exact solution regular, the consistency error on the flux is of order 2, and the rate of convergence in the L^2 norm can theoretically be shown to be of order 2 ([14], [20]; see also [5] for a related covolume scheme). The rate of convergence was computed for the piecewise constant error function defined by $e_K = u(x_K) - u_K$ for $K \in \mathcal{T}$, where u is the exact solution and $(u_K)_{K\in\mathcal{T}}$ is the solution to the finite volume scheme.

We then performed some tests with a right-hand side given by a Dirac measure at 0. The boundary conditions were taken such that the exact solution would be the restriction of the solution of $-\Delta u = \delta_0$ in the whole set $\mathbb{R}^2$ (resp., $\mathbb{R}^3$). It is well known that this function lies in $L^p(\mathbb{R}^2)$ for $p \in [1, +\infty)$ (resp., $L^p(\mathbb{R}^3)$ for $p \in [1, 3)$).

We obtain the results (in log-log scale) given in Figure 5. The coefficients C and α such that $||e|| = Ch^\alpha$ are again evaluated for the norms $L^1(\Omega)$ and $L^2(\Omega)$, and are also given in Figure 5.

In these tests, the mesh is such that the point $(0, 0)$ is located at the corner of the cell $[0, h] \times [0, h]$, where h is the discretization step of the mesh. Hence the radial

FIG. 7. *Convergence rate, two-dimensional case, right-hand side Dirac at zero, nonsymmetric discrete problem, norm computed on a "regular zone."*

symmetry of the solution is broken by the mesh. If we restore it by allocating one fourth of the Dirac measure to each of the four cells $[0,h]\times[0,h]$, $[0,h]\times[0,-h]$, $[-h,0]\times[0,h]$, and $[-h,0]\times[-h,0]$, we gain in the order of convergence, as can be seen in Figure 6. Hence the order of convergence depends on the singularity of the data, but also on the preservation of the symmetry of the solution.

A question of interest is whether the singular data influences the rate of convergence outside of the region of singularity. In order to check this point, we compute the norm of the error between the exact and approximate solutions on the region $\{x \le -.5\} \times \{y \le -.5\}$. We find that, in this case, we recover an order of convergence close to 1 in all norms if the Dirac measure is located at the corner of a cell, in which case the symmetry of the solution is not preserved by the discretization (see Figure 7). In this case, the rate of convergence in the regular zone is perturbed by the singularity outside this zone. (Recall that the theoretical rate of convergence for regular solutions on rectangular meshes is 2; see [20], [14].) However, if we restore the symmetry of the problem as described above, then the rate of convergence is close to 2 (see Figure 8).

We then implemented a three-dimensional Cartesian mesh and found, for the nonsymmetric discrete problem (Dirac located at a corner of the cell $[0,h]^3$), a rate

L^2 norm	0.4809	.2062

FIG. 9. *Convergence rate, three-dimensional case, right-hand side Dirac at zero, nonsymmetric discrete problem.*

of convergence close to 1 in norm L^1 and .5 in norm L^2, as shown in Figure 9. Recall that in this case the exact solution is in L^p for $1 \leq p < 3$.

If the Dirac measure is distributed on the eight cells neighboring the origin, in order to symmetrize the discrete problem, as was done in the two-dimensional case, then one obtains a rate of convergence of 1.631 in the L^1 norm and .504 in the L^2 norm. This seems to indicate a superconvergence in the L^1 norm, although not to the second order (see also Remark 6.1).

6.3. Two-dimensional tests on an unstructured mesh. We also tested our algorithm on an unstructured triangular mesh. Numerical experiments for the cell-centered scheme on triangular meshes were performed in [4] and in [7] in the case of coercive convection-diffusion equations and regular data. These experiments show a convergence rate of order 2, as in the finite element case, although this superconvergence is still, to our knowledge, an open problem in the finite volume case. We show in Figure 10 the rate of convergence which we obtain for the Poisson equation where the right-hand side is a Dirac measure at 0 and the boundary conditions are such that the exact solution is $u(x_1, x_2) = \ln(x_1^2 + x_2^2)$. The refined meshes are not imbedded,

so that the convergence lines are not straight, but one can figure out that the L^1 and L^2 norms of the error between the exact and approximate solutions are bounded by $0.1\text{size}(\mathcal{M})^{0.7}$.

6.4. Spherical domain and mesh. We also made some experiments for a three-dimensional spherical problem: We searched for the solution of $-\Delta u = \delta_0$ on the Euclidean unit ball $B(0,1)$ of $\mathbb{R}^3$, with boundary conditions such that the exact solution is the restriction of the solution of $-\Delta u = \delta_0$ in the whole set $\mathbb{R}^3$. The control volumes are defined by $K_i = \{x \in B(0,1);\, ih \le |x| \le (i{+}1)h\}$, for $i = 0, \dots, N$, where $h = \frac{1}{N+1/2}$. As we noted in Remark 2.1, such domains and meshes are not strictly contained in Definition 2.1 of an admissible mesh, since a sphere is hardly a polyhedral domain, but in fact, the discretization of the normal flux on the boundaries of such a spherical mesh is clearly consistent when looking at spherical solutions of (1). Indeed, the numerical flux at interface $i + 1/2$ is taken as $F_{i+1/2} = \frac{4\pi i^2 h^2}{h}(u_{i+1} - u_i)$, where the $(u_i)_{i=0,\dots,N}$ denote the discrete unknowns. In this case, the rate of convergence of the method was found to be 2 in norm L^1 and .5 in norm L^2: see Figure 11.

Hence the symmetry of the problem seems to improve the performance of the method, at least on the L^1 norm.

Remark 6.1. We recall that, in the three-dimensional case, the exact solution

Table 2

Convergence rate, three-dimensional case. Left: the right-hand side is a Dirac measure at zero, spherical case, norm computed on a "regular zone"; right: the right-hand side is a two-dimensional Lebesgue measure supported on the sphere of radius $1/2$*. The norm is computed on the whole set* Ω*.*

	α	C

L^2 norm	0.9993	.1787
L^∞ norm	0.9983	.2006

$-\Delta u = \delta_0$ is in $L^{3-\varepsilon}$ for any $\varepsilon > 0$; hence we can expect a convergence in L^p for $1 \le p < 3$. From a convergence in $L^{3-\varepsilon}$ for any $\varepsilon > 0$, and a convergence with a rate h^α in L^1, one may deduce (from Hölder's inequality) a convergence in the L^2 norm with a rate of at least $h^{\frac{\alpha}{4}-\varepsilon}$ for any $\varepsilon > 0$. The above numerical results are in accordance with this estimate, both in the spherical case and in the Cartesian case of section 6.2.

We also give in Table 2 the rate of convergence obtained when computing the norm of the error on a zone where the solution is regular, i.e., on the set $\{x \in \mathbb{R}^3, |x| > 1/2\}$. Again, we find in this case a rate of convergence of 2 (even a little more than 2) for all norms.

If we now search for the solution of $-\Delta u = \mu$ on the three-dimensional unit ball, with μ the two-dimensional Lebesgue measure supported on the sphere of radius .5, then the obtained convergence rate is again 1, even though the exact solution is more regular than the solution to the Dirac problem; see Figure 8. Note that, in this case, the exact solution is in L^∞ (and even in H^1).

7. Appendix.

Throughout this section, for any $q \in (1, +\infty)$ we denote by q' its conjugate exponent, that is, $q' \in (1, +\infty)$ such that $\frac{1}{q} + \frac{1}{q'} = 1$.

Proof of Proposition 2.1. The case $q = 2$ is addressed in [14]. We use the same method for $q \in [1, 2)$.

Define, for $\sigma \in \mathcal{E}$ and $(x, y) \in \mathbb{R}^d$, $\chi_\sigma(x, y) = 1$ if $\sigma \cap [x, y] \neq \emptyset$ and $\chi_\sigma(x, y) = 0$ otherwise. Let $\mathbf{d}$ be a unit vector and define, for $x \in \Omega$, $y(x)$ as the point on the semi-line, with origin x and direction $\mathbf{d}$, such that $y(x) \in \partial\Omega$ and $[x, y(x)] \subset \overline{\Omega}$. If $\sigma \in \mathcal{E}$, we let $c_\sigma = |\mathbf{n}_\sigma \cdot \mathbf{d}|$, where $\mathbf{n}_\sigma$ is a unit normal to σ.

For all $x \in \Omega$ such that x does not belong to an affine hyperplane generated by some $\sigma \in \mathcal{E}$, i.e., for almost every $x \in \Omega$, we have

$$|v_\mathcal{T}(x)| \le \sum_{\sigma \in \mathcal{E}} \chi_\sigma(x, y(x)) D_\sigma v_\mathcal{T}.$$

(Recall that $v_\mathcal{T}(x) = v_K$ for the $K \in \mathcal{T}$ such that $x \in K$.) Take such an x and suppose that, for some $\sigma \in \mathcal{E}$, $c_\sigma = 0$; we then have $\chi_\sigma(x, y(x)) = 0$ (indeed, otherwise x would belong to the affine hyperplane generated by σ). Thus, the preceding sum can be reduced to the $\sigma \in \mathcal{E}$ such that $c_\sigma \neq 0$, and we can write, thanks to Hölder's inequality, for almost every $x \in \Omega$,

(63)

$$|v_\mathcal{T}(x)|^q \le \left(\sum_{\sigma \in \mathcal{E} \,|\, c_\sigma \neq 0} \chi_\sigma(x, y(x)) d_\sigma c_\sigma^{-\frac{q}{q'}} \left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma} \right)^q \right) \left(\sum_{\sigma \in \mathcal{E} \,|\, c_\sigma \neq 0} \chi_\sigma(x, y(x)) d_\sigma c_\sigma \right)^{\frac{q}{q'}}.$$

Since we have $\sum_{\sigma\in\mathcal{E}} \chi_\sigma(x,y(x))d_\sigma c_\sigma \le \operatorname{diam}(\Omega)$ for all $x\in\Omega$ (see [14]) and $\int_\Omega \chi_\sigma(x,y(x))\,d\lambda(x) \le \operatorname{diam}(\Omega)\operatorname{meas}(\sigma)c_\sigma$, we obtain, integrating (63) on Ω,

$$\int_\Omega |v_\mathcal{T}|^q\,d\lambda \le \operatorname{diam}(\Omega)^{\frac{q}{q'}} \sum_{\sigma\in\mathcal{E}\,|\,c_\sigma\neq 0} \operatorname{diam}(\Omega)\operatorname{meas}(\sigma)d_\sigma {c_\sigma}^{1-\frac{q}{q'}} \left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma}\right)^q.$$

However, $q\le 2$, so that $1-\frac{q}{q'} = 2-q \ge 0$ and $c_\sigma^{2-q}\le 1$, which concludes this proof. □

Proof of Proposition 2.2. The case $d=2$ has already been covered in the course of the proof of the discrete Sobolev inequalities in [14, inequality (9.73), p. 791].

For $d=3$, the case $q=2$ may be found in [8]. The case of a general q is similar; we use the following inequality [14, inequality (9.75), p. 793]: for any $w_\mathcal{T}\in X(\mathcal{T})$,

$$\int_\Omega |w_\mathcal{T}|^{\frac{3}{2}}\,d\lambda \le \left(\sum_{\sigma\in\mathcal{E}} \operatorname{meas}(\sigma)D_\sigma w_\mathcal{T}\right)^{\frac{3}{2}}.$$

Applying this to $w_K = |v_K|^{\frac{2q}{3-q}}\operatorname{sgn}(v_K)$, and since $D_\sigma w_\mathcal{T} \le \frac{2q}{3-q}(|v_K|^{\frac{3(q-1)}{3-q}} + |v_L|^{\frac{3(q-1)}{3-q}})$ $\cdot\, D_\sigma v_\mathcal{T}$ (with $\sigma = K|L\in\mathcal{E}_{\rm int}$ or $v_L=0$ if $\sigma\in\mathcal{E}_{\rm ext}\cap\mathcal{E}_K$), we deduce, by the Hölder inequality,

$$\begin{aligned}\left(\int_\Omega |v_\mathcal{T}|^{\frac{3q}{3-q}}\,d\lambda\right)^{\frac{2}{3}} &\le \frac{2q}{3-q}\sum_{\sigma\in\mathcal{E}} \operatorname{meas}(\sigma)d_\sigma \left(|v_K|^{\frac{3(q-1)}{3-q}} + |v_L|^{\frac{3(q-1)}{3-q}}\right)\frac{D_\sigma v_\mathcal{T}}{d_\sigma}\\ &\le \frac{2q}{3-q}\left(\sum_{\sigma\in\mathcal{E}} \operatorname{meas}(\sigma)d_\sigma\left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma}\right)^q\right)^{\frac{1}{q}}\\ &\quad\times\left(\sum_{\sigma\in\mathcal{E}} \operatorname{meas}(\sigma)d_\sigma\left(2^{q'-1}|v_K|^{\frac{3q}{3-q}} + 2^{q'-1}|v_L|^{\frac{3q}{3-q}}\right)\right)^{\frac{1}{q'}}.\end{aligned}$$

However, by the hypothesis on ζ,

$$\begin{aligned}\sum_{\sigma\in\mathcal{E}} \operatorname{meas}(\sigma)d_\sigma|v_K|^{\frac{3q}{3-q}} &= \sum_{K\in\mathcal{T}} |v_K|^{\frac{3q}{3-q}} \sum_{\sigma\in\mathcal{E}_K} \operatorname{meas}(\sigma)d_\sigma\\ &\le \frac{1}{\zeta}\sum_{K\in\mathcal{T}} |v_K|^{\frac{3q}{3-q}} \sum_{\sigma\in\mathcal{E}_K} \operatorname{meas}(\sigma)d_{K,\sigma}\\ &= \frac{3}{\zeta}\sum_{K\in\mathcal{T}} \operatorname{meas}(K)|v_K|^{\frac{3q}{3-q}}\\ &= \frac{3}{\zeta}||v_\mathcal{T}||^{\frac{3q}{3-q}}_{L^{\frac{3q}{3-q}}(\Omega)}.\end{aligned}$$

Thus, we finally have

$$\left(\int_\Omega |v_\mathcal{T}|^{\frac{3q}{3-q}}\,d\lambda\right)^{\frac{2}{3}} \le C||v_\mathcal{T}||_{1,q,\mathcal{M}}||v_\mathcal{T}||^{\frac{3(q-1)}{3-q}}_{L^{\frac{3q}{3-q}}(\Omega)},$$

where C depends only on (q,ζ), and this gives the desired estimate. □

Proof of Proposition 2.3. Define $\chi_\sigma(x,y)$ as at the beginning of the proof of Proposition 2.1.

Suppose first that $q > 1$, and take $h \in \mathbb{R}^d \backslash \{0\}$. Define, for $\sigma \in \mathcal{E}$, $c_\sigma = |\mathbf{n}_\sigma \cdot \frac{h}{|h|}|$ (where $\mathbf{n}_\sigma$ is a unit normal to σ).

We have, for almost every $x \in \Omega$ (in fact, for all x which do not belong to an affine hyperplane generated by some $\sigma \in \mathcal{E}$),

$$|w_\mathcal{T}(x+h) - w_\mathcal{T}(x)| \le \sum_{\sigma \in \mathcal{E}} \chi_\sigma(x+h,x) D_\sigma v_\mathcal{T}. \tag{64}$$

As in the proof of Proposition 2.1, this sum can be limited to those $\sigma \in \mathcal{E}$ such that $c_\sigma \neq 0$, and we have then, by Hölder, for almost every $x \in \Omega$,

$$|w_\mathcal{T}(x+h) - w_\mathcal{T}(x)| \le \left(\sum_{\sigma \in \mathcal{E} \,|\, c_\sigma \neq 0} \frac{\chi_\sigma(x+h,x) d_\sigma}{c_\sigma} \left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma} \right)^q \right)^{\frac{1}{q}} \times \left(\sum_{\sigma \in \mathcal{E}} \chi_\sigma(x+h,x) d_\sigma c_\sigma^{\frac{q'}{q}} \right)^{\frac{1}{q'}}.$$

Since $q \le 2$ (and hence $q'/q \ge 1$) and $c_\sigma \in [0,1]$, we have $c_\sigma^{q'/q} \le c_\sigma$; however (see [14]), $\sum_{\sigma \in \mathcal{E}} \chi_\sigma(x+h,x) d_\sigma c_\sigma \le |h| + C\text{size}(\mathcal{M})$, where C depends only on Ω. Thus,

$$|w_\mathcal{T}(x+h) - w_\mathcal{T}(x)|^q \le (|h| + C\text{size}(\mathcal{M}))^{q-1} \sum_{\sigma \in \mathcal{E} \,|\, c_\sigma \neq 0} \frac{\chi_\sigma(x+h,x) d_\sigma}{c_\sigma} \left(\frac{D_\sigma v_\mathcal{T}}{d_\sigma} \right)^q.$$

Since $\int_{\mathbb{R}^d} \chi_\sigma(x+h,x)\, d\lambda(x) \le \text{meas}(\sigma) c_\sigma |h|$, we deduce, after integrating, the desired estimate (17).

If $q = 1$, we simply integrate (64), and this directly gives (bounding $\int_{\mathbb{R}^d} \chi_\sigma(x+h, x)\, d\lambda(x)$ by $\text{meas}(\sigma)|h|$) the estimate.

The compactness result is then an immediate application of Kolmogorov's theorem, with the use of Proposition 2.1 to obtain a bound in $L^q(\Omega)$. □

Proof of Proposition 2.4. Applying (17) to v_n and passing to the limit $n \to \infty$, we get, for $h \in \mathbb{R}^d \backslash \{0\}$,

$$\int_{\mathbb{R}^d} \frac{|w(x+h) - w(x)|^q}{h^q}\, d\lambda(x) \le C,$$

where C does not depend on h and w is the extension of v to $\mathbb{R}^d$ by 0 outside Ω.

Since $q > 1$, this estimate classically gives $w \in W^{1,q}(\mathbb{R}^d)$, and, by the regularity of Ω, since w is the extension of v by 0 outside Ω, $v \in W_0^{1,q}(\Omega)$. □

A POSTERIORI ERROR ESTIMATORS FOR REGULARIZED TOTAL VARIATION OF CHARACTERISTIC FUNCTIONS[*]

FRANCESCA FIERRO[†] and ANDREAS VEESER[†]

Abstract. We consider a nonuniformly elliptic double obstacle problem arising from "convexifying" and regularizing a minimization of a functional with total variation in the set of characteristic functions. We derive a posteriori estimators for the discretization error with linear finite elements, which are uniform in the regularization, incorporate computable and local information on the conditioning, vanish in the intersection of discrete and exact contact sets, and are not affected by possible nonuniqueness. Moreover, we integrate these estimators in an adaptive algorithm and illustrate their properties by various numerical experiments.

Key words. a posteriori error estimates, adaptive finite element methods, total variation, mean curvature, obstacle problems

1. Motivation and introduction.

The minimization of the functional

$$\mathcal{I}(v) := \int_\Omega |Dv| - \int_\Omega \kappa v \quad \text{in} \quad \mathrm{BV}\big(\Omega; \{\pm 1\}\big) \tag{1.1}$$

constitutes a weak formulation of the prescribed mean curvature problem: the hyper surface $\partial\{\chi = 1\}$ of any minimum point χ has mean curvature $\kappa/(2d)$ and normal contact with $\partial\Omega$ in a weak sense; cf. Finn [12], and see section 2 for the notation. Such minimization has applications in capillary surfaces, time discretizations of mean curvature flow, and phase transition models; see, e.g., [2, 12, 13, 20].

To approximate minimum points of (1.1) numerically, Bellettini, Paolini, and Verdi [5, 6] observed that $\mathcal{I}$ can be "equivalently" minimized in the convex set $\mathrm{BV}\big(\Omega, [-1, 1]\big)$ and considered the additionally regularized minimization of

$$\mathcal{I}(v; \epsilon) := \int_\Omega \sqrt{\epsilon^2 + |Dv|^2} - \int_\Omega \kappa v \quad \text{in} \quad \mathrm{BV}\big(\Omega; [-1, 1]\big) \tag{1.2}$$

with parameter $\epsilon > 0$. Discretizing (1.2) with continuous linear finite elements offers the minimization of "semistrictly" convex functionals which Γ-converge in $L_1(\Omega)$ to $\mathcal{I}$ as ϵ and the mesh size decrease to 0 independently. Notice that the case $\epsilon = 1$ of (1.2) is also interesting in itself.

The *nonuniform* convexity of $\mathcal{I}(\cdot, \epsilon)$ and the presence of obstacles in (1.2) strongly suggest the use of *adaptive* methods; see also [10]. In this connection, it also seems worthwhile to consider a space-dependent regularization parameter ϵ. This paper concerns the adaptive computation of approximations to regular minimum points of (1.2), where ϵ is a strictly positive and piecewise constant function. In its theoretical

part we derive a posteriori error estimators for the discretization of (1.2), which are used to guide adaptive algorithms in its computational part.

We outline the results and organization of this paper in more detail. In section 2 we introduce the notation used as well as regular and discrete minimum points of (1.2) together with their variational inequalities. We observe that both types of minimum points are not unique in general and recall a characterization of their uniqueness. Furthermore, similar to [15, 17, 18], we associate with the minimum points auxiliary functionals, which recover information lost by the variational inequalities. The "discrete auxiliary functional," i.e., the one associated with discrete minimum points, may however differ from those in [15, 17, 18]. This difference allows for a complete and thus better localization; see Remark 4.4.

In section 3 we introduce an error notion. It measures a "distance" between the classes of discrete and regular minimum points including an error in the auxiliary functional. In addition, it bounds the error in the approximation of the minimum value in (1.2) from above; see (3.10). The latter means that the error notion is useful when (1.2) is interpreted as an approximation of (1.1). Moreover, we relate the introduced error to an adaptation of the Galerkin functional in [17]; this relationship will guide us in deriving upper and lower a posteriori bounds.

In section 4 we derive a conditional a posteriori upper bound for the aforementioned error. Here "conditional" means that the upper bound holds under the assumption of an a posteriori condition, i.e., a condition involving only the computed minimum point and (discretization) data. The upper bound enjoys the following properties:

- Its indicators do not depend on the particular choice of the discrete minimum point if the latter is not unique.
- It is uniform in the regularization "parameter" ϵ.
- Its local indicators inside the discrete contact set are 0 whenever the discrete minimum point is unique and κ satisfies a local sign condition; the latter holds particularly in the exact contact set.
- Only weighted jump residuals, weighted data oscillation (which is of higher order), and indicators controlling a consistency error of the discrete auxiliary functional are involved; interior residuals do not appear.

Apart from the aforementioned ingredients, the upper bound's proof utilizes (and generalizes) ideas of [11, section 5] in regard to the handling of the underlying operator.

In section 5 we derive a posteriori local lower bounds complementing the upper bound. The lower bound involving the jump residual exhibits a gap with respect to the upper bound; see Remark 5.1. This gap is related to the quotient of the extreme eigenvalues of the underlying operator. Its avoidance probably requires information on the direction of the error. Important ingredients for the proofs of the lower bounds are section 3, Verfürth's constructive argument, and, for the lower bound related to the consistency error of the discrete auxiliary functional, an adaptation of [15, Lemma 6.4] whose proof is inspired by Lemma 3.3 of Chen and Nochetto [8].

In section 6 we formulate an adaptive algorithm guided by the derived estimators and present several numerical experiments. Studying situations with singular or nonunique solutions as well as "dynamic" regularization, we illustrate the properties of the derived estimators.

2. Regular and discrete minimum points.

After fixing some notation and the setting, we introduce regular and discrete minimum points of (1.2) as well as associated functionals. Furthermore, we discuss some of their properties.

The following notation is used throughout this article (and, partially, was already used in section 1). For $q \in [1, \infty]$ and an open set $U \subset \mathbb{R}^d$, the space of Lebesgue-measurable and q-integrable functions is denoted by $L_q(U)$. We shall write $\|\cdot\|_{0,q;U}$ for its norm. For any set $A \subset \mathbb{R}$, we define $L_q(U; A) := \{v \in L_q(U) \mid v(x) \in A$ for a.e. $x \in U\}$; this notation is used also for analogous subsets of other Banach spaces. $W^1_q(U)$ is the Sobolev space of $L_q(U)$-functions that have first weak derivatives in $L_q(U)$. For $\epsilon \in L_1(U; \mathbb{R}^+)$ and $v \in L_1(U)$, we set

$$\int_U \sqrt{\epsilon^2 + |Dv|^2} := \sup \left\{ \int_U \left(\epsilon g_{d+1} + v \sum_{i=1}^{d} \partial_i g_i \right) \;\middle|\; \begin{array}{l} g = (g_1, \dots, g_{d+1}) \text{ in} \\ C^1_0(U; \mathbb{R}^{d+1}) \text{ and } |g| \le 1 \end{array} \right\}. \tag{2.1}$$

Note that (2.1) is the total variation $\int_\Omega |Dv|$ of v if $\epsilon = 0$ in U. The subset of $L_1(U)$ of the functions with bounded total variation is denoted by $\mathrm{BV}(U)$.

Let $\mathcal{T}_h$ be a (conforming) triangulation of a bounded, connected, open set Ω in $\mathbb{R}^d$, $d \ge 2$, with Lipschitz boundary $\partial\Omega$. Moreover, let $\kappa \in L_\infty(\Omega)$ and $\epsilon \in L_\infty(\Omega; \mathbb{R}^+)$ be constant on each $T \in \mathcal{T}_h$. Finally, let u be a *regular minimum point*; i.e., u is a minimum point of (1.2) and $u \in W^1_1(\Omega)$. Denoting the gradient of $v \in W^1_1(\Omega)$ by ∇v, we have $\int_\Omega \sqrt{\epsilon^2 + |Dv|^2} = \int_\Omega \sqrt{\epsilon^2 + |\nabla v|^2}$ and u satisfies the variational inequality

$$\forall\, v \in W^1_1\big(\Omega; [-1, 1]\big), \quad \int_\Omega a(\nabla u; \epsilon) \cdot \nabla(u - v) \le \int_\Omega \kappa(u - v), \tag{2.2}$$

where $a(p; r) := p/\sqrt{r^2 + |p|^2}$ for all $p \in \mathbb{R}^d$ and $r > 0$. Note that u is not necessarily the only regular minimum point. However, if $\tilde{u}$ is also a regular minimum point, then

$$\exists\, c \in \mathbb{R}, \quad \tilde{u} = u + c \text{ in } \Omega, \tag{2.3a}$$

$$\left[\int_\Omega \kappa \ne 0 \text{ or } \left(\sup_\Omega u = 1 \text{ and } \inf_\Omega u = -1 \right) \right] \implies c = 0. \tag{2.3b}$$

If u is the only regular minimum point, then the condition in (2.3b) is implied.

We associate the functional $\sigma_\epsilon \in W^1_1(\Omega)^*$ defined by

$$\forall\, \varphi \in W^1_1(\Omega), \quad \langle \sigma_\epsilon, \varphi \rangle := \int_\Omega \kappa\varphi - \int_\Omega a(\nabla u; \epsilon) \cdot \nabla\varphi \tag{2.4}$$

with the class of regular minimum points. In fact, σ_ϵ does not depend on the particular choice of u thanks to (2.3a). Important properties of σ_ϵ are (they express that σ_ϵ is a subgradient in u of the convex potential associated with the constraint $|u| \le 1$)

$$\begin{gathered} \sigma_\epsilon = \kappa \le 0 \text{ in } \operatorname{int}\{u = -1\}, \qquad \sigma_\epsilon = \kappa \ge 0 \text{ in } \operatorname{int}\{u = 1\}, \\ \sigma_\epsilon = 0 \text{ in } \{-1 < u < 1\}. \end{gathered} \tag{2.5}$$

Here $\operatorname{int}\{u = -1\}$ $\big($or $\operatorname{int}\{u = 1\}\big)$ stands for the biggest open subset of Ω on which u is equal to -1 (or 1) in a distributional sense, while $\{-1 < u < 1\} := \bigcup_{\delta > 0} \operatorname{int}\{-1 + \delta \le u \le 1 - \delta\}$, where $\operatorname{int}\{-1 + \delta \le u \le 1 - \delta\}$ is the biggest open subset of Ω on which the given inequalities hold in a distributional sense.

In what follows, we shall use the letter h as lower index to indicate a "discrete object" or, often together with ϵ, to indicate the dependence on the triangulation $\mathcal{T}_h$. Let W_h be the space of continuous affine finite elements over $\mathcal{T}_h$, i.e.,

$$W_h := \big\{ w_h \in C^0(\overline{\Omega}) \mid \forall\, T \in \mathcal{T}_h \; w_h|_T \in P_1(T) \big\}.$$

Hereafter, $P_m(T)$ denotes the space of polynomials on T with degree smaller than or equal to $m \in \mathbb{N}_0$. Moreover, we set $\mathcal{K}_h := \{w_h \in W_h \mid |w_h| \le 1\}$, which is a subset of $W^1_1\big(\Omega, [-1,1]\big)$. An algorithm for the minimization of the functional $\mathcal{I}(\cdot,\epsilon)$ in $\mathcal{K}_h$ is described in [6]. Let u_h be a minimum point of $\mathcal{I}(\cdot,\epsilon)$ in $\mathcal{K}_h$, i.e., a *discrete minimum point.* Similarly to a regular minimum point, the discrete minimum point u_h satisfies the discrete variational inequality

$$\forall\, v_h \in \mathcal{K}_h, \quad \int_\Omega a(\nabla u_h;\epsilon)\cdot\nabla(u_h - v_h) \le \int_\Omega \kappa(u_h - v_h) \tag{2.6}$$

and may not be the only discrete minimum point; there holds

$$\exists\, c \in \mathbb{R}, \quad \tilde{u}_h = u_h + c \text{ in } \Omega, \tag{2.7a}$$

$$\left[\int_\Omega \kappa \ne 0 \text{ or } \left(\sup_\Omega u_h = 1 \text{ and } \inf_\Omega u_h = -1\right)\right] \implies c = 0 \tag{2.7b}$$

if $\tilde{u}_h$ is also a discrete minimum point.

Next, we define a counterpart $\sigma_{\epsilon h}$ of the functional σ_ϵ in (2.4). To this end, we denote the set of nodes of W_h (or vertices of simplices in $\mathcal{T}_h$) by $\mathcal{N}_h$ and recall that the hat functions $(\phi_z)_{z\in\mathcal{N}_h}$ defined by $\phi_z \in W_h$, $\phi_z(y) = 0$ for $y \in \mathcal{N}_h \setminus \{z\}$, and $\phi_z(z) = 1$ constitute a basis of W_h. The properties of σ_ϵ in (2.5) are imitated on the discrete level by

$$\begin{gathered} \Sigma_z \le 0 \text{ if } u_h(z) = -1, \quad \Sigma_z \ge 0 \text{ if } u_h(z) = 1, \\ \Sigma_z = 0 \text{ if } -1 < u_h(z) < 1, \end{gathered} \tag{2.8}$$

where

$$\Sigma_z := \left[\int_\Omega \phi_z\right]^{-1}\left[\int_\Omega \kappa\phi_z - \int_\Omega a(\nabla u_h;\epsilon)\cdot\nabla\phi_z\right]. \tag{2.9}$$

Note that we suppress the dependence of Σ_z on $\mathcal{T}_h$ and ϵ in the notation; this convention will be used also for other computable quantities in the following.

In [15, 17, 18] mass lumping was used to extend (2.8) in the spirit of (2.5). Here, we shall use another approach which exploits that the hat functions $(\phi_z)_{z\in\mathcal{N}_h}$ constitute a partition of unity on Ω. More precisely, let $\omega_z := \operatorname{supp}\phi_z$ be the support of ϕ_z for any $z \in \mathcal{N}_h$ and define a function $\sigma_{\epsilon h} \in L_\infty(\Omega)$ by

$$\sigma_{\epsilon h} = \sum_{z\in\mathcal{N}_h} \sigma_{\epsilon h,z}\phi_z \quad \text{with} \quad \sigma_{\epsilon h,z}(x) := \begin{cases} \kappa(x) & \text{if } z \in \mathcal{C}_{\epsilon h}, \\ \Sigma_z & \text{if } z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}, \end{cases} \quad x \in \omega_z, \tag{2.10a}$$

where the set $\mathcal{C}_{\epsilon h}$ of "full-contact nodes" is defined as follows:

$$\begin{aligned} &\text{if the condition in (2.7b) holds, then} \\ &\quad \mathcal{C}_{\epsilon h} := \big\{z \in \mathcal{N}_h \mid (u_h = -1,\ \kappa \le 0 \text{ on } \omega_z) \text{ or } (u_h = 1,\ \kappa \ge 0 \text{ on } \omega_z)\big\}; \\ &\text{else } \mathcal{C}_{\epsilon h} := \emptyset. \end{aligned} \tag{2.10b}$$

Note that $\sigma_{\epsilon h}$ depends only on the class of discrete minimum points and not on the particular choice u_h. In general, $\sigma_{\epsilon h}$ is not a subgradient in u_h of the convex potential associated with the constraint $|u_h| \le 1$. However (we use the convention that simplices are closed),

$$\sigma_{\epsilon h} = 0 \text{ in } \bigcup\big\{T \in \mathcal{T}_h \,:\, u_h(T) \subset\,]{-1}, 1[\big\} \tag{2.11a}$$

and, provided that the condition in (2.7b) holds,

$$\sigma_{\epsilon h} = \kappa \leq 0 \text{ in } \bigcup \big\{ T \in \mathcal{T}_h \,:\, u_h = -1,\, \kappa \leq 0 \text{ in } \omega_T \big\}, \tag{2.11b}$$

$$\sigma_{\epsilon h} = \kappa \geq 0 \text{ in } \bigcup \big\{ T \in \mathcal{T}_h \,:\, u_h = 1,\, \kappa \geq 0 \text{ in } \omega_T \big\}, \tag{2.11c}$$

where ω_T denotes the union of all simplices touching $T \in \mathcal{T}_h$.

The sign conditions on κ in (2.10b) might appear artificial at first glance. They are crucial, however, because (2.8) provides less information than (2.5). In fact, $u_h = -1$ (or $u_h = 1$) in ω_z determines only the sign of $\int_\Omega \kappa \phi_z$ but not the sign of κ in ω_z. See also Remark 4.5 below.

3. Error and the Galerkin functional.

We introduce a functional $\mathcal{G}_{\epsilon h}$ that, for our purposes, plays the same role in the context of the variational inequality (2.2) as the residual in the context of unconstrained problems. Motivated by properties of $\mathcal{G}_{\epsilon h}$, we introduce an error notion for couples $(u_h, \sigma_{\epsilon h})$ of discrete minimum points u_h and associated functionals $\sigma_{\epsilon h}$. This error notion does not depend on the particular choice of the discrete minimum point u_h and bounds the error in the approximate minimum value $\mathcal{I}(u_h)$.

Let the functional $\mathcal{G}_{\epsilon h} \in W^1_1(\Omega)^*$ be defined by

$$\langle \mathcal{G}_{\epsilon h}, \varphi \rangle := \int_\Omega a(\nabla u_h; \epsilon) \cdot \nabla \varphi + \int_\Omega \sigma_{\epsilon h} \varphi - \int_\Omega \kappa \varphi, \tag{3.1}$$

where u_h is a discrete minimum point and $\sigma_{\epsilon h}$ is defined as in (2.10). Note that $\mathcal{G}_{\epsilon h}$ does not depend on the particular choice of u_h. Definition (3.1) adapts the Galerkin functional of [17] to the variational inequality (2.2) and the definition (2.10). In particular, it generalizes the residual $\mathcal{R}_{\epsilon h} := -\operatorname{div} a(\nabla u_h; \epsilon) - \kappa \in W^1_1(\Omega)^*$: if u_h touches neither the lower nor the upper obstacle, then $\mathcal{G}_{\epsilon h} = \mathcal{R}_{\epsilon h}$. The residual $\mathcal{R}_{\epsilon h}$ is a key quantity for the derivation of a posteriori estimators; see the books [1, 19] and, in particular, [11], where the unconstrained case with $\epsilon \equiv 1$ and Dirichlet boundary values is analyzed.

We observe that, for any regular minimum point u, definition (2.4) yields

$$\langle \mathcal{G}_{\epsilon h}, \varphi \rangle = \int_\Omega \big[a(\nabla u_h; \epsilon) - a(\nabla u; \epsilon) \big] \cdot \nabla \varphi + \langle \sigma_{\epsilon h} - \sigma_\epsilon, \varphi \rangle \tag{3.2}$$

for all $\varphi \in W^1_1(\Omega)$. The discretization error introduced below will consist of two parts. The first part is associated with the first term in the right-hand side of (3.2) and can be considered also in the unconstrained case, while the second part is associated with the second term and is only relevant if u or u_h touches at least one obstacle.

The following immediate generalization of Lemma 3.1 in [11] concerns the first term in the right-hand side of (3.2).

LEMMA 3.1 (monotonicity of a). *Let $p_1, p_2 \in \mathbb{R}^d$ and $r > 0$. We have*

$$\big[a(p_1; r) - a(p_2; r) \big] \cdot (p_1 - p_2) \;=\; \left| \frac{P_1}{|P_1|} - \frac{P_2}{|P_2|} \right|^2 \frac{|P_1| + |P_2|}{2} \tag{3.3}$$

with $P_i := (p_i, -r) \in \mathbb{R}^{d+1}$ for $i = 1, 2$.

Proof. We calculate (note that all dots after the first equal sign denote the scalar product in $\mathbb{R}^{d+1}$)

$$\begin{aligned}\big[a(p_1;r)-a(p_2;r)\big]\cdot(p_1-p_2) &= \left(\frac{P_1}{|P_1|}-\frac{P_2}{|P_2|}\right)\cdot(P_1-P_2)\\ &= \left(\frac{P_1}{|P_1|}-\frac{P_2}{|P_2|}\right)\cdot\frac{P_1}{|P_1|}\,|P_1| + \left(\frac{P_2}{|P_2|}-\frac{P_1}{|P_1|}\right)\cdot\frac{P_2}{|P_2|}\,|P_2|.\end{aligned}$$

Combining this with the identity $(N_1-N_2)\cdot N_1 = \frac{1}{2}|N_1-N_2|^2$ for $|N_1|=|N_2|=1$, we arrive at (3.3). □

Lemma 3.1 and the geometrical interpretation for $r=1$ of the right-hand side in (3.3) motivate the following definitions (see also [11, section 3]):

$$A(p;r) := \sqrt{|p|^2+|r|^2}, \quad N(p;r) := \frac{(p,-r)}{A(p;r)}$$

for all $p\in\mathbb{R}^d$ and $r>0$ and

$$e_{\epsilon h} := \left(\int_\Omega |N(\nabla u_h;\epsilon)-N(\nabla u;\epsilon)|^2\,\frac{A(\nabla u_h;\epsilon)+A(\nabla u;\epsilon)}{2}\right)^{1/2}. \tag{3.4}$$

Note that $e_{\epsilon h}$ does not depend on the particular choices of u_h and u and so measures an error between the classes of discrete and regular minimum points.

Testing (3.2) with $\varphi = u_h - u$ yields

$$e_{\epsilon h}^2 = \langle \mathcal{G}_{\epsilon h}, u_h-u\rangle - \langle \sigma_{\epsilon h}-\sigma_\epsilon, u_h-u\rangle. \tag{3.5}$$

This identity suggests estimating $e_{\epsilon h}$ by bounding appropriately $\langle \mathcal{G}_{\epsilon h}, u_h-u\rangle$ from above and $\langle \sigma_{\epsilon h}-\sigma_\epsilon, u_h-u\rangle$ from below. Both bounds are established in section 4 with the help of local computable quantities. The upper bound for $\langle \mathcal{G}_{\epsilon h}, u_h-u\rangle$ is established similarly to the one for $\langle \mathcal{R}_{\epsilon h}, u_h-u\rangle$ in the unconstrained case. The lower bound for $\langle \sigma_{\epsilon h}-\sigma_\epsilon, u_h-u\rangle = \langle \sigma_{\epsilon h}, u_h-u\rangle + \langle \sigma_\epsilon, u-u_h\rangle$ exploits that $\sigma_{\epsilon h}$ is an "approximate subgradient" in u_h; cf. (2.11).

We next discuss the error part associated with the second term in the right-hand side of (3.2). To this end, we observe $|a(\nabla u_h;\epsilon)-a(\nabla u;\epsilon)| \le |N(\nabla u_h;\epsilon)-N(\nabla u;\epsilon)|$ and introduce the seminorm

$$|\varphi|_{\epsilon h} := \left(\int_\Omega |\nabla\varphi|^2 A(\nabla u_h;\epsilon)^{-1}\right)^{1/2}$$

with the computable weight $A(\nabla u_h;\epsilon)^{-1}$. We thus obtain

$$\left|\int_\Omega \big[a(\nabla u_h;\epsilon)-a(\nabla u;\epsilon)\big]\cdot\nabla\varphi\right| \le \sqrt{2}e_{\epsilon h}|\varphi|_{\epsilon h}. \tag{3.6}$$

This suggests measuring the error of $\sigma_{\epsilon h}$ in the dual seminorm of $|\cdot|_{\epsilon h}$, that is,

$$|\Psi|_{\epsilon h;*} := \sup\big\{\langle\Psi,\varphi\rangle \mid \varphi\in W_2^1(\Omega),\ |\varphi|_{\epsilon h}\le 1\big\}. \tag{3.7}$$

In fact, (3.2) then implies

$$|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h;*} \le |\mathcal{G}_{\epsilon h}|_{\epsilon h;*} + \sqrt{2}e_{\epsilon h}. \tag{3.8}$$

As $e_{\epsilon h}$ before, $|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h;*}$ does not depend on the particular choices of u_h and u. The upper bound for $|\mathcal{G}_{\epsilon h}|_{\epsilon h;*}$ is established in section 4. It does not lead to additional computable quantities; see (4.19) in the proof of Theorem 4.6. Thus the upper bound of $e_{\epsilon h}$ essentially implies the one of $|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h;*}$ and the computable quantities bounding $e_{\epsilon h}$ even estimate the combined error $e_{\epsilon h}+|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h;*}$ from above.

Local estimates in the inverse direction will rely on

$$|\mathcal{G}_{\epsilon h}|_{\epsilon h,\omega;*}\le\sqrt{2}e_{\epsilon h}(\omega)+|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h,\omega;*} \tag{3.9}$$

for any open set ω in Ω, which is again a consequence of (3.2) and (3.6). Here, $|\cdot|_{\epsilon h,\omega;*}$ and $e_{\epsilon h}(\omega)$ are the local counterparts of $|\cdot|_{\epsilon h;*}$ and $e_{\epsilon h}$; that is,

$$\begin{aligned}|\Psi|_{\epsilon h,\omega;*}&:=\sup\bigl\{\langle\Psi,\varphi\rangle\mid\varphi\in W_2^1(\Omega),\ \operatorname{supp}\varphi\subset\overline{\omega},\ |\varphi|_{\epsilon h}\le 1\bigr\},\\ e_{\epsilon h}(\omega)&:=\left(\int_\omega|N(\nabla u_h;\epsilon)-N(\nabla u;\epsilon)|^2\,\frac{A(\nabla u_h;\epsilon)+A(\nabla u;\epsilon)}{2}\right)^{1/2}.\end{aligned}$$

We conclude this section by showing that $e_{\epsilon h}$ is closely related to the error in the minimum value, i.e., to the difference $\mathcal{I}(u_h;\epsilon)-\mathcal{I}(u;\epsilon)$. On the one hand, we have $\mathcal{I}(u_h;\epsilon)-\mathcal{I}(u;\epsilon)\ge 0$, and on the other hand,

$$\begin{aligned}\mathcal{I}(u;\epsilon)-\mathcal{I}(u_h;\epsilon)&\ge\int_\Omega a(\nabla u_h;\epsilon)\cdot\nabla(u-u_h)-\kappa(u-u_h)\\&\ge\int_\Omega\bigl[a(\nabla u_h;\epsilon)-a(\nabla u;\epsilon)\bigr]\cdot\nabla(u-u_h)=-e_{\epsilon h}^2\end{aligned}$$

by the convexity of $A(\cdot;r)$, $\nabla A(\cdot;r)=a(\cdot;r)$, the variational inequality (2.2), and Lemma 3.1. Combining the two inequalities yields

$$0\le\mathcal{I}(u_h;\epsilon)-\mathcal{I}(u;\epsilon)\le e_{\epsilon h}^2. \tag{3.10}$$

4. Upper bound. We derive an a posteriori upper bound for the error $e_{\epsilon h}+|\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h;*}$ introduced in section 3. To this end, we follow the discussion therein: we first establish appropriate bounds involving computable quantities for

$$|\mathcal{G}_{\epsilon h}|_{\epsilon h;*},\ \langle\mathcal{G}_{\epsilon h},u_h-u\rangle,\quad\text{and }\langle\sigma_{\epsilon h}-\sigma_\epsilon,u_h-u\rangle \tag{4.1}$$

and then combine these bounds with (3.5) and (3.8).

The first two terms in (4.1) are estimated with the help of the following lemma, which involves the computable quantities $(\eta_z)_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}}$ defined by

$$\eta_z^2=h_z\|J_{\epsilon h}\|_{0,2;\gamma_z}^2+h_z^d\|\kappa-\kappa_z\|_{0,d;\omega_z}^2. \tag{4.2}$$

Here, u_h satisfies (2.6), the index set $\mathcal{C}_{\epsilon h}$ is defined as in (2.10b), ω_z denotes the support of the hat function ϕ_z, h_z is the diameter of ω_z, $\kappa_z:=\int_\Omega\kappa\phi_z/\int_\Omega\phi_z$ is the mean value of κ with respect to the weight ϕ_z, γ_z is the union of all sides in ω_z, $\|\cdot\|_{0,2;\gamma_z}$ denotes the L_2-norm with respect to the $(d-1)$-dimensional Hausdorff measure restricted to γ_z, and $J_{\epsilon h}:=J(u_h;\epsilon)$ is defined as follows: for any side S between simplices T_1 and T_2,

$$J(u_h;\epsilon)|_S:=\bigl[a(\nabla u_h|_{T_1};\epsilon)-a(\nabla u_h|_{T_2};\epsilon)\bigr]\cdot n, \tag{4.3a}$$

where n is the normal of S pointing from T_2 to T_1 (note that this definition does not depend on the choice of T_1 and T_2); for any boundary side $S \subset \partial\Omega$,

$$J(u_h;\epsilon)|_S := -a(\nabla u_h|_T;\epsilon)\cdot n, \tag{4.3b}$$

where T is the simplex containing S, and n is the normal of S pointing outward of T. Note that $h_z^d\|\kappa-\kappa_z\|^2_{0,d;\omega_z}$ "scales" in h_z like $h_z^2\|\kappa-\kappa_z\|^2_{0,2;\omega_z}$; cf. [11, Remark 5.1].

In what follows, we shall use "$\preccurlyeq$" instead of "$\leq C$," where C may depend on d and the *shape-regularity* γ_h of $\mathcal{T}_h$ defined by

$$\gamma_h := \max_{T\in\mathcal{T}_h} h_T/\rho_T \in \,]1,\infty[,$$

where h_T denotes the diameter of the smallest ball containing T and ρ_T the diameter of the biggest ball contained in T.

LEMMA 4.1. *Let $\mathcal{G}_{\epsilon h}$ be defined as in* (3.1) *and $\varphi \in W_1^1(\Omega)$. Then*

$$\langle \mathcal{G}_{\epsilon h},\varphi\rangle \preccurlyeq \sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} h_z^{-d/2}\,\eta_z\,\|\nabla\varphi\|_{0,1;\omega_z}.$$

Proof. Simplexwise integration by parts, $\sum_{z\in\mathcal{N}_h}\phi_z = 1$ in Ω, and (2.10a) yield

$$\langle \mathcal{G}_{\epsilon h},\varphi\rangle = -\sum_{z\in\mathcal{N}_h}\left[\int_{\gamma_z} J_{\epsilon h}\varphi\phi_z + \int_{\omega_z}\kappa\varphi\phi_z - \int_{\omega_z}\sigma_{\epsilon h,z}\varphi\phi_z\right]. \tag{4.4}$$

Suppose that $z\in\mathcal{C}_{\epsilon h}$. Then $J_{\epsilon h}=0$ on γ_z and $\sigma_{\epsilon h,z}=\kappa$, and we obtain

$$\int_{\gamma_z} J_{\epsilon h}\varphi\phi_z + \int_{\omega_z}\kappa\varphi\phi_z - \int_{\omega_z}\sigma_{\epsilon h,z}\varphi\phi_z = 0.$$

Consequently, only nodes in $\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}$ contribute to the sum on the right-hand side in (4.4). Let $z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}$ be such a node. Then $\sigma_{\epsilon h,z}=\Sigma_z$ is a constant, and the definition (2.9) of Σ_z implies $\int_{\omega_z}\sigma_{\epsilon h,z}\varphi\phi_z = \left(\int_{\gamma_z}J_{\epsilon h}\phi_z + \int_{\omega_z}\kappa\phi_z\right)\varphi_z$, with the mean value $\varphi_z := \int_\Omega\varphi\phi_z/\int_\Omega\phi_z$. Using in addition $\int_{\omega_z}(\varphi-\varphi_z)\phi_z = 0$, we arrive at

$$\int_{\gamma_z} J_{\epsilon h}\varphi\phi_z + \int_{\omega_z}\kappa\varphi\phi_z - \int_{\omega_z}\sigma_{\epsilon h,z}\varphi\phi_z = \int_{\gamma_z}J_{\epsilon h}(\varphi-\varphi_z)\phi_z + \int_{\omega_z}(\kappa-\kappa_z)(\varphi-\varphi_z)\phi_z.$$

The right-hand side can be estimated along standard lines. We apply the "scaled" trace theorem $\|\psi\|_{0,1;\gamma_z} \preccurlyeq h_z^{-1}\|\psi\|_{0,1;\omega_z} + \|\nabla\psi\|_{0,1;\omega_z}$ and the scaled Sobolev inequality $\|\psi\|_{0,d;\omega_z} \preccurlyeq h_z^{-1}\|\psi\|_{0,1;\omega_z} + \|\nabla\psi\|_{0,1;\omega_z}$ with $\psi=\varphi-\varphi_z$. We then exploit the invariance $\varphi-\varphi_z = (\varphi-c)-(\varphi-c)_z$ and the stability property $\|\psi_z\|_{0,1;\omega_z}\preccurlyeq\|\psi\|_{0,1;\omega_z}$, where $\psi=\varphi-c$ with some $c\in\mathbb{R}$. The variant $\inf_{c\in\mathbb{R}}\|\varphi-c\|_{0,1;\omega_z}\preccurlyeq h_z\|\nabla\varphi\|_{0,1;\omega_z}$ (cf. [16, (4.2)]) of the Bramble–Hilbert lemma finally implies

$$\left|\int_{\gamma_z}J_{\epsilon h}(\varphi-\varphi_z)\phi_z + \int_{\omega_z}(\kappa-\kappa_z)(\varphi-\varphi_z)\phi_z\right| \preccurlyeq h_z^{-d/2}\eta_z\|\nabla\varphi\|_{0,1;\omega_z}. \qquad \square$$

Remark 4.1 (no interior residuals). If $\sigma_{\epsilon h}=0$ on Ω, then $\mathcal{G}_{\epsilon h}=\mathcal{R}_{\epsilon h}$ and Lemma 4.1 improves upon inequality (5.7) in [11], since, as h_z decreases, the data oscillation indicator $h_z^{d/2}\,\|\kappa-\kappa_z\|_{0,d,\omega_z}$ vanishes asymptotically faster than the local interior residual $h_z^{d/2}\,\|\kappa\|_{0,d,\omega_z}$. Estimates, where the interior residual is replaced by data oscillation, seem to appear first in section 2 of Babuška and Miller [3]; if $\sigma_{\epsilon h} = 0$ in Ω, the proof of Lemma 4.1 exploits $\sum_{z\in\mathcal{N}_h} \phi_z = 1$ and the definition of the discrete solution in a similar way as Carstensen and Verfürth [7, Theorem 7.1] and Morin, Nochetto, and Siebert [14].

A straightforward consequence of Lemma 4.1 is the following upper bound for $|\mathcal{G}_{\epsilon h}|_{\epsilon h;*}$, which additionally involves the computable quantities

$$\underline{\Lambda}_z := \inf_{\omega_z}\big[A(\nabla u_h;\epsilon)^{-1}\big], \quad z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}. \tag{4.5}$$

These quantities are related to the maximum eigenvalue

$$\Lambda(p;r) = \big(r^2 + |p|^2\big)^{-1/2} \tag{4.6}$$

of the matrix $Da(p;r)$, $p \in \mathbb{R}^d$, $r > 0$: if $\nabla u_h = p$ and $\epsilon = r$ on ω_z, then $\underline{\Lambda}_z = \Lambda(p;r)$.

Corollary 4.2. *The Galerkin functional $\mathcal{G}_{\epsilon h}$ defined in* (3.1) *satisfies*

$$|\mathcal{G}_{\epsilon h}|_{\epsilon h;*} \preccurlyeq \left(\sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} \underline{\Lambda}_z^{-1}\eta_z^2\right)^{1/2}.$$

Proof. We use $\|\nabla\varphi\|_{0,1;\omega_z} \preccurlyeq h_z^{d/2}\underline{\Lambda}_z^{-1/2}\big(\int_{\omega_z}|\nabla\varphi|^2 A(\nabla u_h;\epsilon)^{-1}\big)^{1/2}$ in Lemma 4.1 and then Cauchy–Schwarz as well as

$$\#\{z \in \mathcal{N}_h \mid \omega_z \supset T\} = d+1 \tag{4.7}$$

for any $T \in \mathcal{T}_h$. □

Next, we derive an upper bound of $\langle \mathcal{G}_{\epsilon h}, u_h - u\rangle$. To this end, the following inequality, which generalizes [11, Lemma 5.1], will be useful.

Lemma 4.3. *Let $p_1, p_2 \in \mathbb{R}^d$, $r > 0$, and set $P_i := (p_i, -r)$ for $i = 1, 2$. We have*

$$|p_1 - p_2|\,\frac{r^2}{|P_1|^2} \;\le\; 2\left|\frac{P_1}{|P_1|} - \frac{P_2}{|P_2|}\right|\sqrt{|P_1|}\,\frac{r}{\sqrt{|P_1|}} + \left|\frac{P_1}{|P_1|} - \frac{P_2}{|P_2|}\right|^2 |P_2|.$$

Proof. We first observe

$$|p_1 - p_2| \;=\; |P_1 - P_2| \;\le\; \left|\frac{P_1}{|P_1|} - \frac{P_2}{|P_2|}\right| |P_1| + \big||P_1| - |P_2|\big|.$$

Moreover, we estimate

$$\begin{aligned}\big||P_1| - |P_2|\big|\,\frac{r^2}{|P_1|^2} \;&\le\; r^2\left|\frac{|P_1| - |P_2|}{|P_1|\,|P_2|}\right| + r\left|\frac{|P_1| - |P_2|}{|P_1|}\left(\frac{r}{|P_1|} - \frac{r}{|P_2|}\right)\right| \\ &\le\; r\left|\frac{r}{|P_1|} - \frac{r}{|P_2|}\right| + \left|\frac{r}{|P_1|} - \frac{r}{|P_2|}\right|^2 |P_2|.\end{aligned}$$

We insert the last inequality in the first one multiplied with $r^2/|P_1|^2$ and establish the claim by observing $|P_1| \ge r$ and $\big|r/|P_1| - r/|P_2|\big| \le \big|P_1/|P_1| - P_2/|P_2|\big|$. □

To give an interpretation of the new quantities in the estimate of Lemma 4.3, we recall (4.6) and observe that, for $p \in \mathbb{R}^d$ and $r > 0$,

$$\lambda(p;r) = r^2\big(r^2 + |p|^2\big)^{-3/2} \quad\text{and}\quad Q(p;r) = \big(r^2 + |p|^2\big)r^{-2},$$

where $\lambda(p;r)$ is the minimum eigenvalue and $Q(p;r) = \Lambda(p;r)/\lambda(p;r)$ is the quotient of the extreme eigenvalues of the matrix $Da(p;r)$. The weight $r^2/|P_1|^2$ of the estimated term $|p_1 - p_2|$ is the inverse of the quotient $Q(p_1;r) = \Lambda(p_1;r)/\lambda(p_1;r)$. Moreover, the weight of the leading order term $\big|P_1/|P_1| - P_2/|P_2|\big|\sqrt{|P_1|}$ on the right-hand side is $r/|P_1|^{1/2}$. Thus the squared quotient of the two weights satisfies

$$\left(\frac{r^2/|P_1|^2}{r/|P_1|^{1/2}}\right)^2 = \lambda(p_1;r).$$

The following upper bound for $\langle \mathcal{G}_{\epsilon h}, u_h - u\rangle$, derived with the help of Lemmas 4.1 and 4.3, involves the computable quantities

$$Q_z := \sup_{\omega_z} \frac{\epsilon^2 + |\nabla u_h|^2}{\epsilon^2} \quad \text{and} \quad \lambda_z := Q_z^{-2} \inf_{\omega_z} \frac{\sqrt{\epsilon^2 + |\nabla u_h|^2}}{\epsilon^2}. \tag{4.8}$$

PROPOSITION 4.4. *If u_h is a discrete minimum point, u a regular one, $\mathcal{G}_{\epsilon h}$ the functional defined in* (3.1), *and $M_h := \max_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} Q_z h_z^{-d/2}\eta_z$, then*

$$\begin{aligned}\langle \mathcal{G}_{\epsilon h}, u_h - u\rangle \;-\; &\frac{1}{2}\int_\Omega |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2 \,\frac{A(\nabla u_h;\epsilon)}{2}\\ &\preccurlyeq \sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} \lambda_z^{-1}\eta_z^2 \;+\; M_h \int_\Omega |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2\,\frac{A(\nabla u;\epsilon)}{2}.\end{aligned}$$

Proof. Given Lemmas 4.1 and 4.3, the proof essentially follows from arguments presented in step 4 of [11]. For the convenience of the reader, we adapt those arguments. Thanks to Lemma 4.3, we have

$$\frac{|\nabla(u_h - u)|}{Q(\nabla u_h;\epsilon)} \le 2\epsilon|N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)| + |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2 A(\nabla u;\epsilon)$$

on ω_z for any $z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}$, whence

$$\begin{aligned}\langle \mathcal{G}_{\epsilon h}, u_h - u\rangle \;\le\; &C \sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} Q_z\, h_z^{-d/2}\,\eta_z \int_{\omega_z} |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|\,\epsilon\\ &+ C \sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} Q_z\, h_z^{-d/2}\,\eta_z \int_{\omega_z} |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2\, A(\nabla u;\epsilon)\\ &=: \mathrm{I} + \mathrm{II}\end{aligned} \tag{4.9}$$

by means of Lemma 4.1. We first consider sum I. The inequality

$$\begin{aligned}&\int_{\omega_z} |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|\,\epsilon\\ &\preccurlyeq\; h_z^{d/2}\left[\sup_{\omega_z} \frac{\epsilon^2}{\sqrt{|\epsilon|^2 + |\nabla u_h|^2}}\right]^{1/2} \left[\int_{\omega_z} |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2\, A(\nabla u_h;\epsilon)\right]^{1/2},\end{aligned}$$

the identity $Q_z^2 \sup_{\omega_z} \epsilon^2/\sqrt{\epsilon^2 + |\nabla u_h|^2} \;=\; \lambda_z^{-1}$, and

$$\forall\, s,t \ge 0,\ \delta > 0, \qquad st \le \frac{\delta}{2}s^2 + \frac{1}{2\delta}t^2 \tag{4.10}$$

as well as (4.7) yield

$$\mathrm{I} - \frac{1}{2}\int_\Omega |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2\,\frac{A(\nabla u_h;\epsilon)}{2} \preccurlyeq \sum_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} \lambda_z^{-1}\,\eta_z^2. \tag{4.11}$$

It remains to consider sum II. Using again (4.7), we obtain

$$\mathrm{II} \preccurlyeq \left(\max_{z\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} Q_z\, h_z^{-d/2}\,\eta_z\right)\int_\Omega |N(\nabla u_h;\epsilon) - N(\nabla u;\epsilon)|^2\,\frac{A(\nabla u;\epsilon)}{2} \tag{4.12}$$

and conclude by inserting (4.11) and (4.12) into (4.9). □

We still have to estimate the last term $\langle\sigma_{\epsilon h} - \sigma_\epsilon, u_h - u\rangle$ of (4.1). To this end, we have to encounter the fact that $\sigma_{\epsilon h}$ is not quite a subgradient in u_h of the convex potential associated with the constraint $|u_h| \le 1$. This consistency error will be controlled by means of the computable quantities $\Sigma_z d_z$, $z \in \mathcal{F}_{\epsilon h}$, where

$$\mathcal{F}_{\epsilon h} := \big\{z \in \mathcal{N}_h \mid z \notin \mathcal{C}_{\epsilon h} \text{ and } \Sigma_z \neq 0\big\} \tag{4.13}$$

are the "free boundary nodes," Σ_z is defined as in (2.9), and

$$d_z := \begin{cases} \int_{\omega_z}(1-u_h)\phi_z & \text{if } \Sigma_z > 0,\\ -\int_{\omega_z}(u_h+1)\phi_z & \text{if } \Sigma_z < 0. \end{cases} \tag{4.14}$$

Since Σ_z, $z \in \mathcal{N}_h$, and $\mathcal{C}_{\epsilon h}$ do not depend on the particular choice of u_h, the same holds for $\mathcal{F}_{\epsilon h}$ and d_z, $z \in \mathcal{F}_{\epsilon h}$. In view of (2.8), $\Sigma_z > 0$ implies $u_h(z) = 1$ and $\Sigma_z < 0$ implies $u_h(z) = -1$. The quantity $|d_z|$ therefore measures the detachment of u_h from a free boundary node $z \in \mathcal{F}_{\epsilon h}$. Furthermore, there holds $\Sigma_z d_z \ge 0$ for all $z \in \mathcal{F}_{\epsilon h}$.

Proposition 4.5 (quasi-monotonicity of auxiliary functionals). *If the pairs* $(u_h, \sigma_{\epsilon h})$ *and* (u, σ_ϵ) *satisfy* (2.6), (2.10), (2.2), *and* (2.4), *respectively, then*

$$\langle\sigma_{\epsilon h} - \sigma_\epsilon, u_h - u\rangle \ge -\sum_{z\in\mathcal{F}_{\epsilon h}} \Sigma_z d_z.$$

Proof. We may write $\langle\sigma_{\epsilon h} - \sigma_\epsilon, u_h - u\rangle = \langle\sigma_{\epsilon h}, u_h - u\rangle + \langle\sigma_\epsilon, u - u_h\rangle$. Since $u_h \in W_1^1\big(\Omega;[-1,1]\big)$, (2.4) and (2.2) imply $\langle\sigma_\epsilon, u - u_h\rangle \ge 0$, and it remains to consider

$$\int_\Omega \sigma_{\epsilon h}(u_h - u) = \sum_{z\in\mathcal{N}_h}\int_\Omega \sigma_{\epsilon h,z}(u_h - u)\phi_z.$$

Some terms of the right-hand side are nonnegative. In fact, if $z \in \mathcal{C}_{\epsilon h}$, then $|u| \le 1$ in Ω and (2.10a) yield $\sigma_{\epsilon h,z}(u_h - u) \ge 0$. Moreover, if $z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}$ and $\Sigma_z = 0$, then (2.10a) implies $\sigma_{\epsilon h,z} = 0$. We can therefore estimate

$$\int_\Omega \sigma_{\epsilon h}(u_h - u) \ge \sum_{z\in\mathcal{F}_{\epsilon h}}\int_\Omega \sigma_{\epsilon h,z}(u_h - u)\phi_z. \tag{4.15}$$

The remaining terms are treated by considering two cases. Let $z \in \mathcal{F}_{\epsilon h}$ with $\Sigma_z < 0$. Then (2.10a) and $u \ge -1$ give

$$\int_\Omega \sigma_{\epsilon h,z}(u_h - u)\phi_z = \int_{\omega_z}\Sigma_z(u_h+1)\phi_z + \int_{\omega_z}\Sigma_z(-1-u)\phi_z \ge -\Sigma_z d_z.$$

Since also $u \leq 1$, the same inequality holds if we replace $\Sigma_z < 0$ by $\Sigma_z > 0$. Thus we finish the proof by inserting these inequalities into (4.15). $\square$

Finally, we combine the derived estimates to obtain an a posteriori upper bound for the combined error $e_{\epsilon h} + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*}$ under an a posteriori condition. The involved computable quantities are defined in (2.9), (2.10b), (4.2), (4.8), (4.14), and (4.13).

Theorem 4.6 (conditional upper bound). *Let u_h and u be a discrete and regular minimum point, and let $\sigma_{\epsilon h}$ and σ_ϵ be defined as in* (2.4) *and* (2.10). *There exists a constant C depending only on the shape-regularity γ_h of the triangulation $\mathcal{T}_h$ such that the following holds: if*

$$\max_{z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}} Q_z h_z^{-d/2} \eta_z \leq C, \tag{4.16}$$

then the error $e_{\epsilon h} + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*}$ defined by (3.4) *and* (3.7) *is bounded from above in terms of computable quantities and a multiplicative constant depending on γ_h:*

$$e_{\epsilon h} + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*} \preccurlyeq \left(\sum_{z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}} \lambda_z^{-1} \eta_z^2 + \sum_{z \in \mathcal{F}_{\epsilon h}} \Sigma_z d_z \right)^{1/2}. \tag{4.17}$$

Proof. Let $1/(2C)$ be the constant hidden in "$\preccurlyeq$" of (4.12), and suppose that (4.16) holds with this choice of C. We then obtain

$$e_{\epsilon h} \preccurlyeq \left(\sum_{z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}} \lambda_z^{-1} \eta_z^2 + \sum_{z \in \mathcal{F}_{\epsilon h}} \Sigma_z d_z \right)^{1/2} \tag{4.18}$$

by using Propositions 4.4 and 4.5 in (3.5). In view of (3.8), Corollary 4.2, and

$$\underline{\Lambda}_z^{-1} \leq \lambda_z^{-1}, \tag{4.19}$$

adding $|\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*}$ to the left-hand side of (4.18) changes only the constant hidden in "$\preccurlyeq$." $\square$

Remark 4.2 (a posteriori condition). The upper bound in Theorem 4.6 cannot be expected to be valid in general, i.e., without any condition as, e.g., (4.16); see [11, (5.1) and Example 5.1], which shows that (the size of) the discrete gradient defining λ_z may be quite different from the exact one.

Moreover, we point out that (4.16) is of "a posteriori" nature: if we knew C explicitly, then (4.16) could be verified since its left-hand side is computable. In any case, the latter quantity can be monitored during computations as in [11, section 7.1], where numerical experiments show that it decreases for exact solutions with moderate gradients within a reasonable number of unknowns.

Remark 4.3 (uniform in regularization). We stress that the relationship between error and computable quantities in the upper bound of Theorem 4.6 is independent of the regularization "parameter" ϵ.

Remark 4.4 (complete localization). It is worthwhile to mention that the upper bound in Theorem 4.6 involves only indicators related to the typically proper subset $\bigcup\{\omega_z : z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}\}$ of Ω. We refer to this property as "complete localization" to the discrete non-full-contact set. Remarkably, the complement of the latter subset contains at least $\bigcup\{T : u_h = u = 1 \text{ or } u_h = u = -1 \text{ in } \omega_T\}$, that is, approximately the intersection of the discrete and exact contact sets. In fact, for the involved nodes, the sign conditions on κ in (2.10b) are satisfied due to (2.5).

The upper bounds in [17, 18] exhibit a "partial localization" in that there are indicators in the discrete contact set with higher order than the ones in the discrete noncontact set. This improvement in the upper bound for the first error part $e_{\epsilon h}$ is due to the new definition (2.10) of the auxiliary functional.

Remark 4.5 (importance of sign conditions). Suppose that (4.16) and the condition in (2.7b) hold. Then the upper bound in Theorem 4.6 does not hold in general if one replaces $\mathcal{C}_{\epsilon h}$ by $\tilde{\mathcal{C}}_{\epsilon h} := \{z \in \mathcal{N}_h \mid u_h = -1 \text{ on } \omega_z \text{ or } u_h = 1 \text{ on } \omega_z\}$. This reveals the example of Chen and Nochetto [8, Remark 4.2], where, in the case of the obstacle problem for the Laplacian, the discrete solution is different from the exact one and the only nonzero indicator corresponds to a node in $\tilde{\mathcal{C}}_{\epsilon h} \setminus \mathcal{C}_{\epsilon h}$.

5. Lower bounds.

We derive a posteriori local lower bounds for the error introduced in section 3. More precisely, we estimate the sum of the error $e_{\epsilon h}(\omega_z) + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h,\omega_z;*}$ in a star ω_z and associated data oscillation $h_y^{d/2} \|\kappa - \kappa_y\|_{0,d;\omega_y}$ from below in terms of

$$h_z^{1/2} \|J_{\epsilon h}\|_{0,2;\gamma_z} \quad \text{and} \quad \sqrt{\Sigma_z d_z}. \tag{5.1}$$

To this end, we shall use (3.9). The computable quantities (5.1) appear in the upper bound of section 4. Consequently, the following bounds concern their efficiency up to data oscillation, which is formally of higher order.

We begin with a lower bound involving the jump residual, i.e., the first term in (5.1). Apart from (3.9), the main step is an adaptation of Verfürth's constructive argument (see, e.g., [19, section 1.2]) to the representation formula of $\mathcal{G}_{\epsilon h}$ in Lemma 4.1. The use of (3.9) entails the computable weight

$$\Lambda_z := \sup_{\omega_z} \big[A(\nabla u_h; \epsilon)^{-1}\big], \tag{5.2}$$

differing from $\underline{\Lambda}_z$ defined in (4.5). In addition, the following index set is useful:

$$\mathcal{N}_h(z) := \big(\mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}\big) \cap \omega_z. \tag{5.3}$$

THEOREM 5.1 (lower bound I). *Let $z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}$ be a node, and let $\|J_{\epsilon h}\|_{0,2;\gamma_z}$ be defined as in* (4.2). *There holds*

$$\frac{h_z^{1/2}}{\Lambda_z^{1/2}} \|J_{\epsilon h}\|_{0,2;\gamma_z} \preccurlyeq e_{\epsilon h}(\omega_z) + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h,\omega_z;*} + \sum_{y \in \mathcal{N}_h(z)} \frac{h_y^{d/2}}{\Lambda_z^{1/2}} \|\kappa - \kappa_y\|_{0,d;\omega_y}.$$

Proof. We first prove a more local estimate for the jump residual $\|J_{\epsilon h}\|_{0,2;S}$ of a side S with $S \subset \gamma_z$. To this end, we recall the representation formula

$$\langle \mathcal{G}_{\epsilon h}, \varphi \rangle = -\sum_{y \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}} \left[\int_{\gamma_y} J_{\epsilon h}(\varphi - \varphi_y)\phi_y + \int_{\omega_y} (\kappa - \kappa_y)(\varphi - \varphi_y)\phi_y \right] \tag{5.4}$$

established in the proof of Lemma 4.1 and construct an appropriate test function φ. Let $\psi_S := \prod_{x \in \mathcal{N}_h \cap S} \phi_x$ and $\omega_S := \operatorname{supp} \psi_S$. Moreover, for any $T \in \mathcal{T}_h$ with $T \subset \omega_S$, let $\psi_T := \prod_{x \in \mathcal{N}_h \cap T} \phi_x$, and choose $\alpha_{T,x} \in \mathbb{R}$, $x \in \mathcal{N}_h \cap T$, such that

$$\sum_{x \in \mathcal{N}_h \cap T} \alpha_{T,x} \int_T \psi_T \phi_x \phi_y = \int_T \psi_S \phi_y \tag{5.5}$$

for any $y \in \mathcal{N}_h \cap T$. Finally, note that $J_{\epsilon h}|_S$ is a constant, and set

$$\varphi := J_{\epsilon h}|_S \left(\psi_S - \sum_{T\subset\omega_S, x\in\mathcal{N}_h\cap T} \alpha_{T,x}\psi_T\phi_x \right).$$

The support of φ is ω_S. Let $\mathcal{N}_h(S) := (\mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}) \cap \omega_S$ and $\Lambda_S := \sup_{\omega_S} A(\nabla u_h;\epsilon)^{-1}$. We obtain

$$\begin{aligned}\|J_{\epsilon h}\|^2_{0,2;S} &\preccurlyeq \sum_{y\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} \int_S J_{\epsilon h}\varphi\phi_y = -\langle \mathcal{G}_{\epsilon h}, \varphi\rangle - \sum_{y\in\mathcal{N}_h\setminus\mathcal{C}_{\epsilon h}} \int_{\omega_y} (\kappa-\kappa_y)\varphi\phi_y \\ &\preccurlyeq \Lambda_S^{1/2} |\mathcal{G}_{\epsilon h}|_{\epsilon h,\omega_S;*} \|\nabla\varphi\|_{0,2;\omega_S} + \sum_{y\in\mathcal{N}_h(S)} \|\kappa-\kappa_y\|_{0,2;\omega_S} \|\varphi\|_{0,2;\omega_S}\end{aligned}$$

by $\varphi|_S = \big(J_{\epsilon h}\psi_S\big)|_S$ and $\int_S 1 \preccurlyeq \int_S \psi_S\phi_y$ for $y \in \mathcal{N}_h \cap S$, by $\int_{\omega_y} \varphi\phi_y = 0$ for any $y \in \mathcal{N}_h$ and (5.4), and by (3.7). Hence, if h_S is the diameter of the side S,

$$\|J_{\epsilon h}\|_{0,2;S} \preccurlyeq \Lambda_S^{1/2} h_S^{-1/2} |\mathcal{G}_{\epsilon h}|_{\epsilon h,\omega_S;*} + h_S^{1/2} \sum_{y\in\mathcal{N}_h(S)} \|\kappa-\kappa_y\|_{0,2;\omega_S}$$

with the help of $\|\nabla\varphi\|_{0,2;\omega_S} + h_S\|\varphi\|_{0,2;\omega_S} \preccurlyeq h_S^{-1/2}\|\varphi\|_{0,2;S} \le h_S^{-1/2}\|J_{\epsilon h}\|_{0,2;S}$, which in turn follows from the fact that $\alpha_{T,x}$ in (5.5) does not depend on h_S. Employing (3.9), we finally arrive at

$$h_S^{1/2}\|J_{\epsilon h}\|_{0,2;S} \;\preccurlyeq\; \Lambda_S^{1/2}\big[e_{\epsilon h}(\omega_s) + |\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h,\omega_S;*}\big] + h_S \sum_{y\in\mathcal{N}_h(S)} \|\kappa-\kappa_y\|_{0,2;\omega_S}.$$

In view of (4.7), $\Lambda_S \le \Lambda_z$ for any $z \in \mathcal{N}_h \cap S$, and $h_S \approx h_y$ for all $y \in \mathcal{N}_h \cap \omega_S$, and the claimed estimate follows. □

Remark 5.1 (gap for jump residual). The jump residual $h_z^{1/2}\|J_{\epsilon h}\|_{0,2;\gamma_z}$ and the data oscillation are accompanied by different weights in the bounds of Theorems 4.6 and 5.1—by $\lambda_z^{-1/2}$ in the upper bound and by $\Lambda_z^{-1/2}$ in the lower bound. This gap between the two bounds seems to be unavoidable as long as the a posteriori error analysis does not take the unknown direction of the error into account; see also section 5.2 of [11], where different numerical experiments indicate that both bounds constitute possible worst cases.

We next bound the computable quantities $\sqrt{\Sigma_z d_z}$, $z \in \mathcal{F}_{\epsilon h}$, controlling the consistency error of $\sigma_{\epsilon h}$. To this end, we derive separate estimates for the two factors in the square root. For the estimate of Σ_z, $z \in \mathcal{F}_{\epsilon h}$, Verfürth's constructive argument and (3.9) are again important ingredients.

LEMMA 5.2. *Let $z \in \mathcal{F}_{\epsilon h}$ and Σ_z be defined as in* (2.9). *If $d_z \neq 0$, then*

$$\Lambda_z^{-1/2} h_z^{(d+2)/2} |\Sigma_z| \;\preccurlyeq\; e_{\epsilon h}(\omega_z) + |\sigma_{\epsilon h}-\sigma_\epsilon|_{\epsilon h,\omega_z;*} + \Lambda_z^{-1/2} h_z^{d/2} \|\kappa-\kappa_z\|_{0,d;\omega_z}.$$

Proof. Suppose that $d_z < 0$ for $z \in \mathcal{F}_{\epsilon h}$. Then $\Sigma_z < 0$ thanks to (4.14), and there are a simplex $T \in \mathcal{T}_h$ containing z and another node $y \in \mathcal{N}_h \cap T$ such that $u_h(y) > -1$. The latter implies $\Sigma_y \ge 0$ thanks to (2.8). Moreover, since all nodes $x \in \mathcal{N}_h \cap T$ are in $\mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}$, the definition (2.10) of $\sigma_{\epsilon h}$ yields $\sigma_{\epsilon h} \in P_1(T)$. Denoting the diameter of T by h_T and using an inverse estimate, we thus obtain

$$\begin{aligned}|\Sigma_z| &\le \sigma_{\epsilon h}(y) - \sigma_{\epsilon h}(z) = \nabla\sigma_{\epsilon h|T}\cdot(y-z) \le h_T\|\nabla\sigma_{\epsilon h}\|_{0,\infty;T} \\ &= h_T\|\nabla(\sigma_{\epsilon h}-\kappa_z)\|_{0,\infty;T} \preccurlyeq h_T^{-d/2}\|\sigma_{\epsilon h}-\kappa_z\|_{0,2;T}.\end{aligned} \tag{5.6}$$

The same inequality can be derived for $d_z > 0$ in a similar manner.

Consequently, it remains to estimate $\|\sigma_{\epsilon h} - \kappa_z\|_{0,2;T}$ for $T \in \mathcal{T}_h$ with $T \subset \omega_z$ appropriately. We proceed similarly to the estimation of the jump residual in the proof of Theorem 5.1. The function $\psi_T = \prod_{x \in \mathcal{N}_h \cap T} \phi_x$ satisfies

$$\int_T |w_h|^2 \preccurlyeq \int_T |w_h|^2 \psi_T \quad \text{and} \quad \|\nabla(w_h \psi_T)\|_{0,2;T} \preccurlyeq h_T^{-1} \|w_h \psi_T\|_{0,2;T} \tag{5.7}$$

for all $w_h \in P_1(T)$; see [19, Lemma 3.3]. Setting $\varphi := (\sigma_{\epsilon h} - \kappa_z)\psi_T$, we derive

$$\begin{aligned}\|\sigma_{\epsilon h} - \kappa_z\|_{0,2;T}^2 &\preccurlyeq \int_T (\sigma_{\epsilon h} - \kappa_z)\varphi = \langle \mathcal{G}_{\epsilon h}, \varphi\rangle + \int_T (\kappa - \kappa_z)\varphi \\ &\preccurlyeq \Lambda_z^{1/2} |\mathcal{G}_{\epsilon h}|_{\epsilon h, T; *} \|\nabla \varphi\|_{0,2;T} + \|\kappa - \kappa_z\|_{0,2;T} \|\varphi\|_{0,2;T}\end{aligned}$$

with the help of (5.7), (3.1), and $\int_T a(\nabla u_h) \cdot \nabla \varphi = 0$ (integrate by parts). Therefore,

$$\Lambda_z^{-1/2} h_T \|\sigma_{\epsilon h} - \kappa_z\|_{0,2;T} \preccurlyeq e_{\epsilon h}(T) + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h, T; *} + \Lambda_z^{-1/2} h_T \|\kappa - \kappa_z\|_{0,2;T} .$$

Using this inequality in (5.6), $h_T \approx h_z$, and a Hölder inequality finishes the proof. □

For the estimation of d_z, $z \in \mathcal{F}_{\epsilon h}$, we adapt [15, Lemma 6.4] to the operator and boundary conditions of (2.2). The adaptation's proof is different from [15], and its second part resembles the one of Lemma 3.3 in Chen and Nochetto [8], which measures the deviation of positivity preserving interpolation from a projection.

LEMMA 5.3 (discrete growth around critical point). *Let $w_h \in W_h$ and $z \in \mathcal{N}_h$. If $w_h \geq 0$ in the star ω_z and $w_h(z) = 0$, then*

$$\int_{\omega_z} w_h \ \preccurlyeq \ \underline{\Lambda}_z(\nabla w_h; \epsilon)^{-1}\, h_z^2\, \|J(w_h; \epsilon)\|_{0,1;\gamma_z} ,$$

where $\underline{\Lambda}_z(\nabla w_h; \epsilon) := \inf_{\omega_z} \left[A(\nabla w_h; \epsilon)^{-1}\right]$, $J(\cdot; \epsilon)$ is defined as in (4.3), and γ_z is the union of all sides in ω_z.

Proof. We first replace the domain ω_z of integration by a part of a ball; this will be useful in what follows. Let B be the biggest ball with center z and $B \cap \Omega \subset \omega_z$. The equivalence of norms in $P_1(\hat{T})$, where $\hat{T}$ is the reference simplex, implies $\|w_h\|_{0,1;T} \preccurlyeq \|w_h\|_{0,1;T \cap B}$ for any $T \in \mathcal{T}_h$ with $T \subset \omega_z$. Combining this with $w_h \geq 0$ in ω_z yields

$$\int_{\omega_z} w_h \preccurlyeq \int_{B \cap \Omega} w_h \leq \underline{\Lambda}_z(\nabla w_h; \epsilon)^{-1} \int_{B \cap \Omega} \frac{w_h}{A(\nabla w_h; \epsilon)}. \tag{5.8}$$

The function w_h can be represented with the help of its gradient ∇w_h. In fact, since $w_h(z) = 0$ and ∇w_h is piecewise constant, we have $w_h(x) = \nabla w_h|_T \cdot (x - z)$ for all $x \in T$ and any $T \in \mathcal{T}_h$ with $T \subset \omega_z$. Therefore,

$$\int_{B \cap \Omega} \frac{w_h}{A(\nabla w_h; \epsilon)} = \int_{B \cap \Omega} a(\nabla w_h; \epsilon) \cdot (\mathrm{id} - z), \tag{5.9}$$

where id stands for the identity of Ω. To relate the integral on the right-hand side to the jumps $J(w_h; \epsilon)$, we observe that $\mathrm{id} - z = \frac{1}{2} \nabla |\mathrm{id} - z|^2$ and integrate by parts:

$$2 \int_{B \cap \Omega} a(\nabla w_h; \epsilon) \cdot (\mathrm{id} - z) = - \int_{\gamma_z \cap B} J(w_h; \epsilon) |\mathrm{id} - z|^2 + \int_{\partial B \cap \Omega} a(\nabla w_h; \epsilon) \cdot n |\mathrm{id} - z|^2,$$

where n denotes the outer normal of $B \cap \Omega$. Since B is a ball, the function $|\operatorname{id} - z|^2$ is constant on $\partial B \cap \Omega$, and it equals the radius r of B. The second integral of the right-hand side can thus be rewritten by means of the divergence theorem as

$$\int_{\partial B \cap \Omega} a(\nabla w_h; \epsilon) \cdot n |\operatorname{id} - z|^2 = r^2 \int_{\partial B \cap \Omega} a(\nabla w_h; \epsilon) \cdot n = r^2 \int_{\gamma_z \cap B} J(w_h; \epsilon).$$

Consequently, we obtain

$$2 \int_{B \cap \Omega} a(\nabla w_h; \epsilon) \cdot (\operatorname{id} - z) = \int_{\gamma_z \cap B} J(w_h; \epsilon) \big(r^2 - |\operatorname{id} - z|^2 \big) \leq h_z^2 \left\| J(w_h; \epsilon) \right\|_{0,1;\gamma_z}$$

by using $r \leq h_z$ and conclude by recalling (5.8) and (5.9). □

An immediate consequence of Lemma 5.3 is an estimate for d_z, $z \in \mathcal{F}_{\epsilon h}$.

COROLLARY 5.4. *Let $z \in \mathcal{F}_{\epsilon h}$. For d_z as in* (4.14)*, there holds*

$$\underline{\Lambda}_z h_z^{-(d+2)/2} |d_z| \preccurlyeq h_z^{1/2} \left\| J_{\epsilon h} \right\|_{0,2;\gamma_z}$$

with $\underline{\Lambda}_z$ and $J_{\epsilon h}$ as in (4.5) *and* (4.2)*, respectively.*

Proof. Let $z \in \mathcal{F}_{\epsilon h}$. It holds that $\Sigma_z \neq 0$, which, due to (2.8), implies $u_h(z) \in \{\pm 1\}$. Since $-1 \leq u_h \leq 1$ in Ω, we can apply Lemma 5.3 with $w_h = 1 - u_h$ or $w_h = u_h + 1$. The estimate $\left\| J_{\epsilon h} \right\|_{0,1;\gamma_z} \preccurlyeq h_z^{(d-1)/2} \left\| J_{\epsilon h} \right\|_{0,2;\gamma_z}$ completes the proof. □

The combination of Theorem 5.1, Lemma 5.2, and Corollary 5.4 finally yields the desired estimate for $\sqrt{\Sigma_z d_z}$, $z \in \mathcal{F}_{\epsilon h}$.

THEOREM 5.5 (lower bound II). *Let $z \in \mathcal{F}_{\epsilon h}$. For $\sqrt{\Sigma_z d_z}$ with Σ_z as in* (2.9) *and d_z as in* (4.14)*, there holds*

$$\frac{\underline{\Lambda}_z^{1/2}}{\Lambda_z^{1/2}} \sqrt{\Sigma_z d_z} \preccurlyeq e_{\epsilon h}(\omega_z) + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h, \omega_z; *} + \Lambda_z^{-1/2} \sum_{y \in \mathcal{N}_h(z)} h_y^{d/2} \left\| \kappa - \kappa_y \right\|_{0,d;\omega_y},$$

where $\underline{\Lambda}_z$, Λ_z, and $\mathcal{N}_h(z)$ are defined as in (4.5), (5.2), *and* (5.3).

Proof. We can assume $d_z \neq 0$ without loss of generality. Then,

$$\begin{aligned} 2 \frac{\underline{\Lambda}_z^{1/2}}{\Lambda_z^{1/2}} \sqrt{\Sigma_z d_z} &\leq \Lambda_z^{-1/2} h_z^{(d+2)/2} |\Sigma_z| + \underline{\Lambda}_z \Lambda_z^{-1/2} h_z^{-(d+2)/2} |d_z| \\ &\preccurlyeq e_{\epsilon h}(\omega_z) + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h, \omega_z; *} + \Lambda_z^{-1/2} h_z^{d/2} \left\| \kappa - \kappa_z \right\|_{0,d;\omega_z} \\ &\quad + \Lambda_z^{-1/2} h_z^{1/2} \left\| J_{\epsilon h} \right\|_{0,2;\gamma_z} \end{aligned} \tag{5.10}$$

with the help of (4.10) with $\delta = 1$, Lemma 5.2, and Corollary 5.4. Applying Theorem 5.1 to the last term on the right-hand side concludes the proof. □

Remark 5.2 (moderate gap for $\Sigma_z d_z$). The gap concerning $\sqrt{\Sigma_z d_z}$ between the upper and lower bounds is moderate with respect to the one for the jump residual $h_z^{1/2} \left\| J_{\epsilon h} \right\|_{0,2;\omega_z}$. In particular, if $\nabla u_h \approx p$ and $\epsilon \approx r$, then $\underline{\Lambda}_z^{1/2} / \Lambda_z^{1/2} \approx 1$.

6. Adaptive algorithm and numerical experiments. We derive a simplified upper bound, and, relying on this simplification, we formulate an adaptive algorithm for fixed regularization parameter ϵ. After some remarks on our implementation, we present our numerical results illustrating the various properties of the indicators derived in sections 4 and 5.

6.1. Simplified upper bound. A refined version of (5.10) allows us to eliminate the indicators $\Sigma_z d_z$ from the upper bound in Theorem 4.6 at the expense of some sharpness and a slightly modified weight λ_z^{-1}. The new version of λ_z, defined in (4.8), is given by

$$\tilde{\lambda}_z = \begin{cases} \min\{\lambda_z, \underline{\Lambda}_z^2/\Lambda_z\} & \text{if } z \in \mathcal{F}_{\epsilon h}, \\ \lambda_z & \text{otherwise}, \end{cases} \qquad z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}. \tag{6.1}$$

Note that if the regularization ϵ is constant in Ω, then $\tilde{\lambda}_z = \lambda_z$ for all $z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}$.

THEOREM 6.1 (simple upper bound). *Suppose that the assumptions including* (4.16) *of Theorem* 4.6 *are fulfilled. Then there holds*

$$e_{\epsilon h} + |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*} \preccurlyeq \left(\sum_{z \in \mathcal{N}_h \setminus \mathcal{C}_{\epsilon h}} \tilde{\lambda}_z^{-1} \eta_z^2 \right)^{1/2}.$$

Proof. Proceeding similarly as in the proof of (5.10) but also using the full flexibility of (4.10), we get

$$\begin{aligned} \Sigma_z d_z &\preccurlyeq \delta \Big[e_{\epsilon h}(\omega_z)^2 + |\sigma_{\epsilon h} - \sigma_\epsilon|^2_{\epsilon h, \omega_z;*} + \Lambda_z^{-1} h_z^d \, \|\kappa - \kappa_z\|^2_{0,d;\omega_z} \Big] \\ &\quad + \delta^{-1} \Lambda_z \underline{\Lambda}_z^{-2} h_z \, \|J_{\epsilon h}\|^2_{0,2;\gamma_z} \end{aligned} \tag{6.2}$$

for any $\delta > 0$ and all $z \in \mathcal{F}_{\epsilon h}$. In order to sum over $z \in \mathcal{F}_{\epsilon h}$, we first show that

$$\sum_{z \in \mathcal{F}_{\epsilon h}} |\sigma_{\epsilon h} - \sigma_\epsilon|^2_{\epsilon h, \omega_z;*} \preccurlyeq |\sigma_{\epsilon h} - \sigma_\epsilon|^2_{\epsilon h;*}. \tag{6.3}$$

To establish this, let $w \in \mathring{H}^1(\Omega) := \{v \in W_2^1(\Omega) \mid v = 0 \text{ on } \partial\Omega\}$ be defined by the Riesz representation theorem through

$$\forall\, \varphi \in \mathring{H}^1(\Omega), \qquad \int_\Omega \frac{\nabla w \cdot \nabla \varphi}{A(\nabla u_h; \epsilon)} = \langle \sigma_{\epsilon h} - \sigma_\epsilon, \varphi \rangle.$$

We then have

$$|\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h, \omega_z;*} \leq \left(\int_{\omega_z} \frac{|\nabla w|^2}{A(\nabla u_h; \epsilon)} \right)^{1/2}, \qquad |\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*} = |w|_{\epsilon h},$$

and therefore (6.3) follows from the following consequence of (4.7):

$$\sum_{z \in \mathcal{F}_{\epsilon h}} \int_{\omega_z} \frac{|\nabla w|^2}{A(\nabla u_h; \epsilon)} \preccurlyeq \int_\Omega \frac{|\nabla w|^2}{A(\nabla u_h; \epsilon)}.$$

Summing (6.2) over $z \in \mathcal{F}_{\epsilon h}$ and using (6.3), (4.7), and $\Lambda_z \underline{\Lambda}_z^{-2} \leq \tilde{\lambda}_z^{-1}$ yield

$$\begin{aligned} \sum_{z \in \mathcal{F}_{\epsilon h}} \Sigma_z d_z &\preccurlyeq \delta \Bigg(e_{\epsilon h}^2 + |\sigma_{\epsilon h} - \sigma_\epsilon|^2_{\epsilon h;*} + \sum_{z \in \mathcal{F}_{\epsilon h}} \lambda_z^{-1} h_z^d \, \|\kappa - \kappa_z\|^2_{0,d;\omega_z} \Bigg) \\ &\quad + \delta^{-1} \sum_{z \in \mathcal{F}_{\epsilon h}} \tilde{\lambda}_z^{-1} h_z \, \|J_{\epsilon h}\|^2_{0,2;\gamma_z} \end{aligned} \tag{6.4}$$

for the second sum in the right-hand side of the upper bound (4.17). If (4.16) holds, the claimed upper bound follows from (4.17), $\sqrt{s^2 + t^2} \leq s + t$ for $s, t \geq 0$, (6.4), $\lambda_z^{-1} \leq \tilde{\lambda}_z^{-1}$, and choosing $\delta = \delta(\gamma_h) > 0$ sufficiently small. □

The local lower bound that complements the simplified upper bound in Theorem 6.1 is already given in Theorem 5.1.

6.2. Adaptive algorithm and implementation. We describe the main steps of an adaptive algorithm for the convexified and regularized minimization (1.2). To this end, we rely on the a posteriori bounds in Theorems 5.1 and 6.1 by using the computable quantities η_z, Λ_z, and $\tilde{\lambda}_z$ defined in (4.2), (5.2), and (6.1), respectively. Moreover, we replace the subscript "h" by an iteration counter "l."

ALGORITHM 6.1. *Let a tolerance* tol > 0*, a marking parameter* $\theta \in \,]0, 1]$*, and an initial triangulation* $\mathcal{T}_0$ *be given. Set* $l := 0$*, and iterate the following steps:*

1. *Compute a minimum point of* $\mathcal{I}(\cdot; \epsilon)$ *in* $\mathcal{K}_l$ *over* $\mathcal{T}_l$*.*
2. *Compute* η_z*,* $\tilde{\lambda}_z$*, and* Λ_z *for* $z \in \mathcal{N}_l \setminus \mathcal{C}_{\epsilon l}$*.*
3. *If* $\sum_{z\in\mathcal{N}_l\setminus\mathcal{C}_{\epsilon l}} \tilde{\lambda}_z^{-1}\eta_z^2 \leq \mathrm{tol}^2$*, then STOP.*
4. *Choose the smallest* $\hat{\mathcal{N}}_l \subset \mathcal{N}_l \setminus \mathcal{C}_{\epsilon l}$ *such that*

$$\sum_{z\in\hat{\mathcal{N}}_l} \Lambda_z^{-1}\eta_z^2 \geq \theta^2 \sum_{z\in\mathcal{N}_l\setminus\mathcal{C}_{\epsilon l}} \Lambda_z^{-1}\eta_z^2.$$

5. *Refine all triangles in* $\mathcal{T}_l$ *with a node in* $\hat{\mathcal{N}}_l$ *to obtain a new triangulation* $\mathcal{T}_{l+1}$ *in such a way that the shape-regularities are bounded uniformly in* l*.*
6. *Increment* l *and go to step* 1*.*

The marking parameter $\theta \in \,]0, 1[$ leads to adaptive refinement, while $\theta = 1$ entails nonadaptive uniform refinement. The stopping test in step 3 is motivated by Theorem 6.1 and may be extended as indicated in Remark 4.2. The aim of the iteration in Algorithm 6.1 is to satisfy the stopping test "as soon as possible," that is, to reduce $\sum_{z\in\mathcal{N}_l\setminus\mathcal{C}_{\epsilon l}} \lambda_z^{-1}\eta_z^2$ efficiently. To this end, one might use $\tilde{\lambda}_z^{-1}\eta_z^2$ also as marking indicators in Dörfler's fixed fraction strategy [9] in step 4. However, this can produce overrefinement in regions where the gradient of the discrete solution is big and, consequently, a slowdown of the convergence speed; see [11, section 7.2]. We therefore replace $\tilde{\lambda}_z^{-2}\eta_z^2$ by $\Lambda_z^{-1}\eta_z^2 = \Lambda_z^{-1}h_z \,\|J_{\epsilon h}\|_{0,2;\gamma_z}^2 + \Lambda_z^{-1}h_z^d \,\|\kappa - \kappa_z\|_{0,d;\omega_z}^2$. The higher order of the second part and Theorem 5.1 guarantee that this indicator does not lead to the aforementioned overrefinement. For the convergence properties of this strategy or a very similar one, we refer to section 6.3 and [11, sections 7.2–7.3].

We conclude this section with some comments on our two-dimensional implementation of Algorithm 6.1. Step 1 is performed with the help of the constrained quasi-Newton method introduced in [6]. In all experiments the tolerance tol > 0 was so small that the stopping test in step 3 was not satisfied if the number of unknowns $N_l = \#\mathcal{N}_l$ was below $50,000$. Following [9] and thus slightly reducing complexity, we construct an approximation of $\hat{\mathcal{N}}_l$ in step 4. In all adaptive experiments we used the marking parameter $\theta = 0.5$. The triangles to be refined in step 5 are bisected by means of the algorithm of Bänsch [4].

6.3. Uniformity in regularization and singular solutions. We present numerical experiments corroborating that the hidden constants in Theorems 4.6, 5.1, and 6.1 do not depend on the regularization ϵ. Moreover, we illustrate that the performance of adaptive refinement is superior to the one of nonadaptive uniform refinement in the presence of singularities. We start by introducing the following example.

Example 6.1 (transition layer). Given $\epsilon_0 > 0$, we consider minimization (1.2) with constant regularization $\epsilon \equiv \epsilon_0$ in $\Omega := \,]-2, 2[\, \times \,]-1, 1[$ and $\kappa(x_1, x_2) = \operatorname{sgn} x_1$ for $(x_1, x_2) \in \Omega$. The unique exact solution does not depend on x_2 and is odd in x_1;

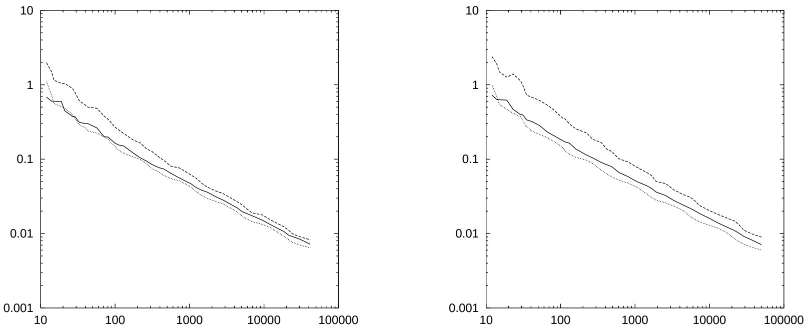

FIG. 6.1. *Example* 6.1 *with* $\epsilon_0 = 2$ *(left) and* $\epsilon_0 = 1.5$ *(right):* $e_{\epsilon l}$ *(solid),* $0.175\,\overline{\xi}_l$ *(dotted), and* $0.175\,\underline{\xi}_l$ *(dashed) as functions of* N_l *in* log-log *scale.*

setting

$$B(\epsilon_0) := \begin{cases} \sqrt{2\epsilon_0 - 1}/\epsilon_0 & \text{if } \epsilon_0 \geq 1, \\ 1 & \text{if } 0 < \epsilon_0 \leq 1, \end{cases}$$

it is given on $]0, 2[\, \times \,]{-1}, 1[$ by

$$u(x_1, x_2; \epsilon) = \begin{cases} 1 & \text{if } x_1 \geq B(\epsilon_0), \\ 1 + \epsilon_0 \Big[\sqrt{1 - \big(B(\epsilon_0) - x\big)^2} - 1 \Big] & \text{if } 0 < x_1 \leq B(\epsilon_0). \end{cases}$$

All experiments concerning Example 6.1 start from the same triangulation $\mathcal{T}_0$. The triangles of $\mathcal{T}_0$ and all its refinements do not cross the line $\{0\} \times \,]{-1}, 1[$, where κ and possibly $u(\cdot;\epsilon)$ have a jump; this facilitates the precise computation of indicators and error. Moreover, $\mathcal{T}_0$ and all its refinements do not exhibit symmetries in x_1 and x_2 corresponding to those of the exact solution $u(\cdot;\epsilon)$.

Providing numerical support that the hidden constants in Theorems 4.6, 5.1, and 6.1 do not depend on the regularization ϵ is complicated by the fact that the error part $|\sigma_{\epsilon h} - \sigma_\epsilon|_{\epsilon h;*}$ is not computable. We propose proceeding as follows. We apply Algorithm 6.1 to Example 6.1 with given ϵ_0, determine *one* constant $C_0 > 0$ such that the computable part $e_{\epsilon l}$ of the error satisfies

$$C_0 \underline{\xi}_l \leq e_{\epsilon l} \ \leq \ C_0 \overline{\xi}_l \tag{6.5}$$

with $\underline{\xi}_l^2 := \sum_{z \in \mathcal{N}_l \setminus \mathcal{C}_{\epsilon l}} \Lambda_z^{-1} \eta_z^2$ and $\overline{\xi}_l^2 := \sum_{z \in \mathcal{N}_l \setminus \mathcal{C}_{\epsilon l}} \tilde{\lambda}_z^{-1} \eta_z^2$ for all l with $N_l \geq 5\,000$, and then investigate whether (6.5) with the determined value of C_0 still holds for other choices of ϵ_0. The requirement of one common constant for both inequalities in (6.5) constrains the possible choices significantly and should enforce a sharp choice in each single inequality. Figure 6.1 (left) shows that $C_0 = 0.175$ is a possible choice for $\epsilon_0 = 2$. Figure 6.1 (right) depicts the case $\epsilon_0 = 1.5$ and reveals the validity of (6.5) with the chosen C_0. We affirmatively tested also other choices of ϵ_0. Since the oscillation of κ is of higher order (in particular, it is only nonzero for nodes in the line $\{0\} \times \,]{-1}, 1[$), the observed validity of the first inequality in (6.5) corroborates that the hidden constant in Theorem 5.1 does not depend on ϵ. Moreover, the observed validity of the second inequality corroborates that also the hidden constant in (4.18) does not depend on ϵ. This in turn supports the same statement for the hidden constants in Theorems 4.6 and 6.1.

Next, we illustrate the superior performance of adaptive refinement for singular solutions. If $\epsilon_0 = 1$ in Example 6.1, then $u(\cdot;\epsilon)$ is singular in the sense that $|\nabla u(x_1, x_2; \epsilon)| \to \infty$ as $x_1 \to 0$ in such a way that $u(\cdot;\epsilon) \notin W_2^1(\Omega)$. If $0 < \epsilon_0 < 1$, then $u(\cdot;\epsilon)$ has even a jump of size $2(1-\epsilon_0)$ across the line $\{0\} \times]-1,1[$, and thus it barely holds that $u(\cdot;\epsilon) \in \mathrm{BV}(\Omega)$. We measure the performance by investigating the relationship of the computable part $e_{\epsilon l}$ and the number of unknowns N_l as l increases. More precisely, we suppose the relationship $e_{\epsilon l} = DN_l^{-p}$ or, equivalently, $\log e_{\epsilon l} = \log D - p \log N_l$, with unknown constants $D, p > 0$, and determine p as slope of the corresponding regression line. The following table displays the (rounded) values of the experimental convergence order p obtained for adaptive ($\theta = 0.5$) and uniform ($\theta = 1$) refinement and regularization parameter $\epsilon_0 \in \{0.5, 1, 1.5\}$; the regression line was determined by using the data corresponding to l with $5000 \leq N_l \lesssim 50,000$ if $\theta = 0.5$ or $4000 \leq N_l \lesssim 50,000$ if $\theta = 1$.

	$\epsilon_0 = 0.5$	$\epsilon_0 = 1$	$\epsilon_0 = 1.5$
$\theta = 0.5$	0.43	0.45	0.51
$\theta = 1$	0.26	0.36	0.50

These values suggest the following. Adaptive refinement offers a significantly higher asymptotic convergence speed in the presence of singularities. In the case of regular solutions, the asymptotic convergence speed is not improved by adaptivity. However, it typically leads to a smaller constant D; see also [11, section 7.3].

6.4. Nonuniqueness.

We study effects of nonuniqueness in the original minimization (1.1) on the convexified and regularized minimization (1.2). In the course of the discussion, we also observe robustness of Algorithm 6.1 with respect to instabilities in the computational minimization of step 1.

The following example was proposed to us by Stefan Luckhaus.

Example 6.2 (a time step of mean curvature flow). Let $\epsilon_0 \geq 0$ and $\tau > 0$, and consider minimization (1.2) with constant regularization $\epsilon \equiv \epsilon_0$ in $\Omega :=]-1,1[^2$ and $\kappa(x_1, x_2) := \frac{1}{\tau}\,\mathrm{sgn}(x_1 x_2) \min\{|x_1|, |x_2|\}$ for $(x_1, x_2) \in \Omega$.

Example 6.2 corresponds to a convexified (and regularized if $\epsilon_0 > 0$) time step with length τ of the mean curvature flow evolving the region $]-1,0[^2 \cup]0,1[^2$; see [2, 10, 13]. The undiscretized flow, which shortens the boundary $\{(x_1,x_2) \in \Omega \mid x_1 x_2 = 0\}$, is not unique; in fact, the evolved region may become connected or not connected. The same holds for the first time step using (1.1), and thus Example 6.2 with $\epsilon_0 = 0$ has several solutions.

We apply Algorithm 6.1 to Example 6.2 with $\epsilon_0 = 0.175$ and $\tau = 0.2$ starting from a symmetric or an “asymmetric” initial triangulation. We shall use the letters “S” and “A” to distinguish the two initial triangulations and their corresponding runs. Triangulations S and A are depicted in the first row of Figure 6.2 on the left- and right-hand sides, respectively.

Note that $\int_\Omega \kappa = 0$ and, consequently, the exact and discrete solutions are unique iff they touch both obstacles. However, numerical integration of κ may not yield 0, and the computed solution is therefore pushed toward one of the obstacles. This is illustrated in Figure 6.3 for run A: on the left-hand side the computed solution touches the upper obstacle, while on the right-hand side it touches the opposite one. In spite of this unstable behavior of the computed solution, the indicators of Algorithm 6.1 yield

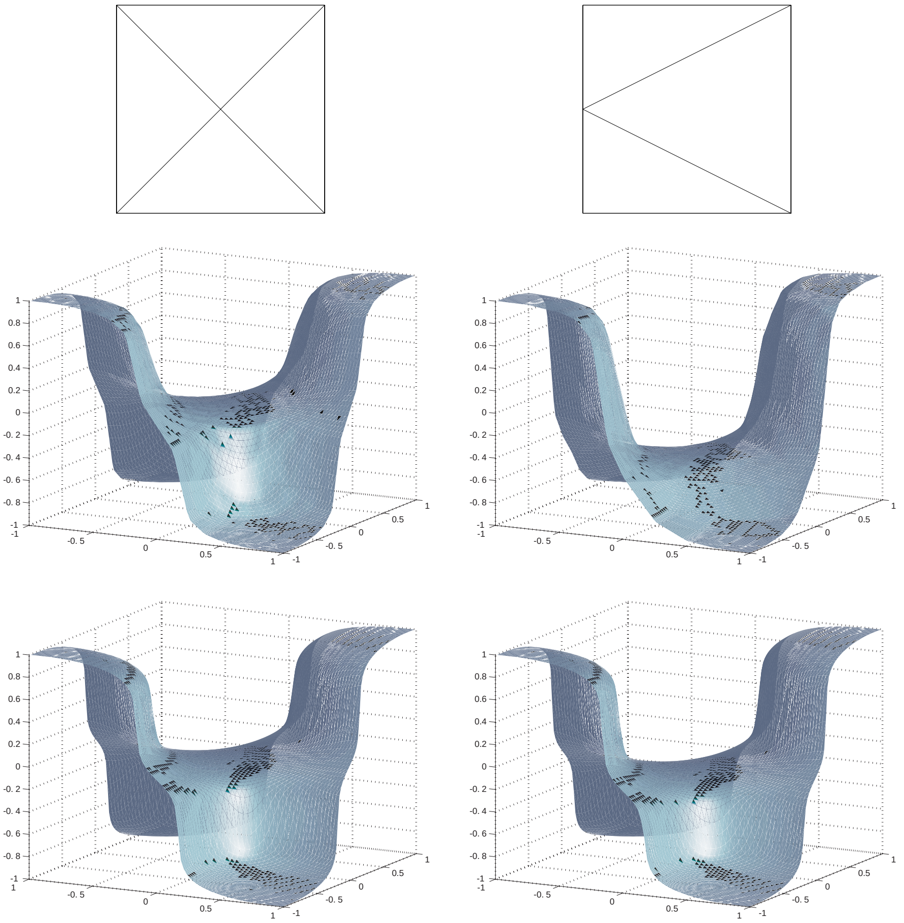

FIG. 6.2. *Example* 6.2 *with* $\epsilon_0 = 0.175$ *and* $\tau = 0.2$*: Initial triangulations (first row), solutions corresponding to* $N_l \approx 560$ *(second row), and* $N_l \approx 50\,000$ *(third row) of run S (left column) and run A (right column).*

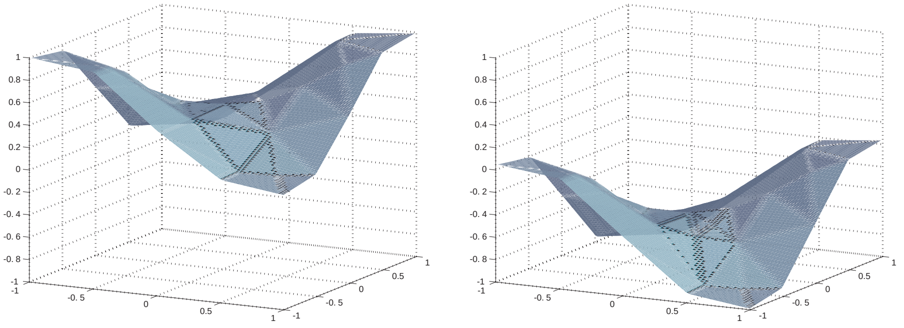

FIG. 6.3. *Example* 6.2 *with* $\epsilon_0 = 0.175$ *and* $\tau = 0.2$*: Unstable computational minimization illustrated by two successive (*$N_l = 33$ *(left) and* $N_l = 37$ *(right)) solutions of run A.*

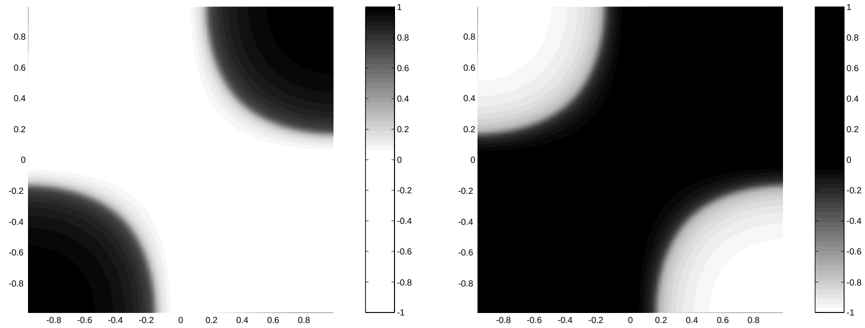

FIG. 6.4. *Example* 6.2 *with* $\epsilon_0 = 0.175$ *and* $\tau = 0.2$*: Contour plot of positive (left) and negative (right) levels of the last solution in run S.*

a reasonable refinement, and, for about 100 nodes, the computed solution touches both obstacles, thus being unique and stable.

For about 560 nodes, the computed solution of run S has a saddle point close to the origin, while the saddle point of the corresponding solution of run A is clearly below the origin; see the second row of Figure 6.2. (The opposite, a saddle point above the origin, can be produced by starting from another "asymmetric" initial triangulation.) However, the last row of Figure 6.2 suggests that this sensibility with respect to the initial triangulation disappears with further adaptive refinement according to Algorithm 6.1.

Let us conclude this subsection with an interpretation of the obtained approximate solutions. To this end, we recall the following statement from [5, section 1.1]: *if* u *is a minimum point of the convexified minimization* (1.2) *with* $\epsilon \equiv 0$*, then, for almost all* $t \in [0, 1]$*, the characteristic function of* $\{x \in \Omega \mid u(x) \geq t\}$ *is a minimum point of the non-convex minimization* (1.1)*.* This fact suggests the following interpretations: the approximate solutions in the last row of Figure 6.2 indicate the two minimum points of the limiting nonconvex minimization (1.1); see Figure 6.4, where positive and negative level lines of the last solution of run S are depicted. The temporary "asymmetry" in run A is a dominance of one minimum point depending on the underlying triangulation.

6.5. Nonconstant regularization. We study an example with nonconstant regularization. Here the meaning of "nonconstant" is twofold: the regularization will depend on space and on the iteration counter "l" in Algorithm 6.1. We choose the following example.

Example 6.3 (quarter of the 2-circle). Consider minimization (1.2) with $\epsilon \equiv 0$ and $\kappa(x) := -|x| + 5/2$ for $x \in \Omega :=]0, 4[^2$. The unique solution is the characteristic function of the sector $\{x \in \Omega \mid |x| \leq 2\}$. In order to approximate $\epsilon \equiv 0$ "dynamically," we use the piecewise constant regularization ϵ_l defined by

$$\forall T \in \mathcal{T}_l, \quad \epsilon_l|_T = \frac{1 + \big||x_T| - 2\big|}{2^{2+l/20}}, \quad \text{where } x_T \text{ is the barycenter of } T,$$

in iteration l of Algorithm 6.1.

We apply Algorithm 6.1 to Example 6.3 starting from an initial triangulation with 41 nodes. In order to measure the quality of the solution u_l computed in iteration l,

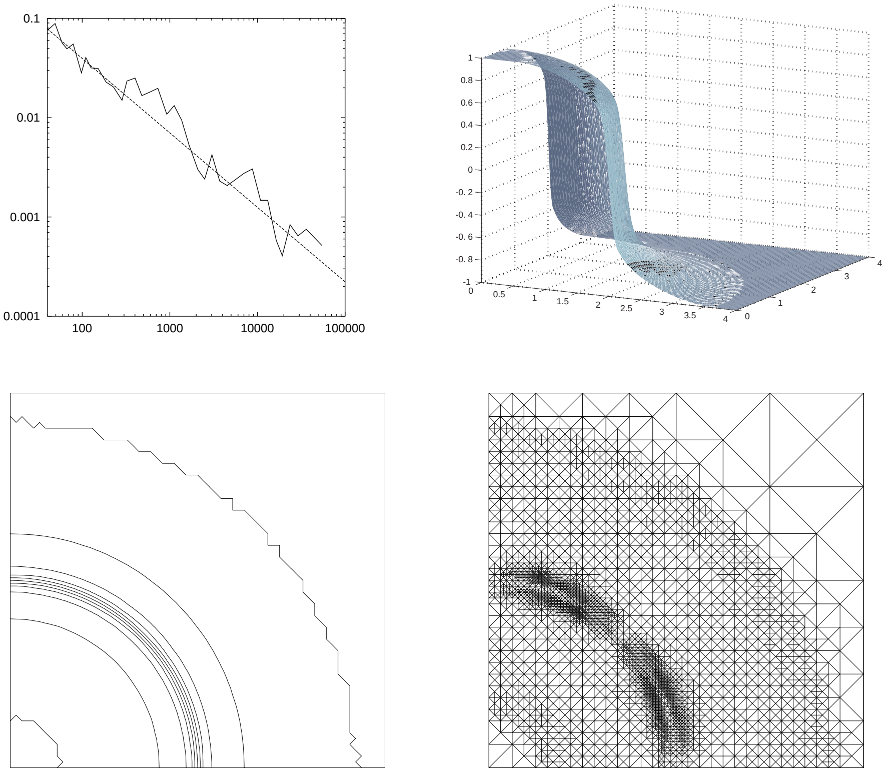

FIG. 6.5. *Example* 6.3: *δ_l as a function of N_l in* log-log *scale accompanied by a line with slope* 0.75 *(top left), solution (top right), its level lines $-1 + 0.2k$, $k = 0, \dots, 10$ (lower left), and the triangulation (lower right) for $N_l = 3042$.*

we introduce

$$\delta_l := \max\Big\{ \big| |x| - 2 \big| \mid x \in \Omega \text{ and } u_l(x) = 0 \Big\},$$

which measures the distance between the "interface" $\Gamma := \{x \in \Omega \mid |x| = 2\}$ of the sector $\{x \in \Omega \mid |x| \leq 2\}$ and its approximation $\Gamma_l := \{x \in \Omega \mid u_l(x) = 0\}$. Figure 6.5 (top left) shows δ_l as a function of $N_l = \#\mathcal{N}_l$ as l increases; the slope of the dashed line in the same picture is 0.75 and represents an approximation of the experimental convergence order. For $N_l = 3024$, the graph and level lines of u_l as well as the triangulation $\mathcal{T}_l$ are also depicted in Figure 6.5. In accordance with Remark 4.4, we observe a very coarse triangulation close to the corner points $(0, 0)$ and $(4, 4)$ due to the complete localization to the discrete non-full-contact set. Inside the discrete noncontact set, the triangulation is still graded. It is relatively coarse off the interface Γ and, with an exceptional thin stripe, relatively fine close to the interface Γ. In light of the rigidity of the used linear finite elements, this may be interpreted as follows: relatively big second derivatives of the exact solution, which are indicated by big jump residuals, require a relatively high density of the degrees of freedom. However, this relationship is affected by the size of the gradient of the exact solution through the weight Λ_z^{-1}, which provides local information on the conditioning. Note that, in the considered situation, incorporating the weight Λ_z^{-1} into the marking indicator intensifies the grading within the discrete noncontact set. This is correct because, as discussed in section 6.2, the marking indicator $\Lambda_z^{-1}\eta_z^2$ does not lead to an overrefinement where the gradient of the solution is big. Finally, note that, in the discrete noncontact set, the mesh is slightly finer close to the free boundaries than away from the interface Γ. This is a consequence of the spatial dependence of the regularization ϵ_l; with constant regularization $\tilde{\epsilon}_l \equiv 2^{-(2+l/20)}$, the triangulation is not finer there.

GENERALIZATIONS AND ACCELERATIONS OF LIONS' NONOVERLAPPING DOMAIN DECOMPOSITION METHOD FOR LINEAR ELLIPTIC PDE[*]

W. GUO[†] AND L. S. HOU[‡]

Abstract. In this paper, a one-parameter generalization of Lions' nonoverlapping domain decomposition method for linear elliptic PDEs is proposed and studied. The generalized methods are shown to be descent-direction methods for minimizing an interface bias functional. Iteration convergence of both the continuous and finite element versions of the proposed methods is established. It is theoretically and numerically demonstrated that for generic choices of the parameter the generalized methods converge faster than Lions' original method. Algorithms are given and numerical results are presented.

Key words. domain decomposition, Lions' nonoverlapping method, optimization-based domain decomposition, convergence acceleration, descent-direction method, finite element, parallel computation

1. Introduction.

Domain decompositon methods (DDMs) have been a flourishing area of research in scientific computing in the last two decades; see, e.g., the proceedings or monographs [11, 12, 13, 14, 24, 26, 27, 33, 50] and the web site http://www.ddm.org. The interests and research efforts in this subject have continued to expand in recent years; see, e.g., [8, 9, 15, 17, 20, 21, 28, 30, 32, 34, 42, 44, 47, 48, 49]. The various DDMs can be loosely classified into two categories based on the decomposition of subdomains: overlapping and nonoverlapping. The classic Schwarz alternating method [43, 25, 35], which is based on successive exchanges of Dirichlet data, is a century-old example of overlapping DDMs and is still an active topic of research [37, 38, 39]. The history of nonoverlapping DDMs is much shorter than that of overlapping ones. Early works on nonoverlapping DDMs include [2, 3, 4, 5, 6, 7, 10, 18]. One of the most popular nonoverlapping DDMs is the well-known Lions' method [36], which is based on successive exchanges of interface Robin data. The objective of this paper is to design and analyze a one-parameter generalization of Lions' nonoverlapping method for solutions of linear elliptic partial differential equations (PDEs) and establish the acceleration properties of the generalized methods.

Though our generalized method at each iteration step appears to simply involve a weighted average of Lions' interface updates and the Robin data of the previous iteration step, the analysis of those methods will be based on viewing Lions' method as a descent-direction method with a fixed step length for minimizing an interface bias functional. The accelerations are achieved by choosing suitable variable step lengths in the descent-direction method. In the sense of minimizing an interface bias functional our methods are akin to the optimization-based DDMs studied in [20, 21, 28, 30] (see also the earlier works [18, 25] and a relevant reference [45]). However, our methods

make use of a descent direction which in general is not the gradient direction; this is different from the work of [20, 21, 28, 30], which used gradient methods or optimality systems to find the minima of interface bias functionals.

Noteworthy features of the generalized methods include (i) true parallelism in the sense that each new iterate makes use of all subdomain solutions obtained in the previous step and thus calls for multiple processors (whereas Lions' method is an alternating domain method); (ii) $L^2(\Gamma)$ norm convergence for the interface bias of the Robin data (this is an improvement over the well-known $H^{-1/2}(\Gamma)$ norm convergence result for Lions' method—see [17, 20]); (iii) an explicit range of acceptable step lengths that is independent of the underlying elliptic operator (in contrast, the range of step lengths for the gradient methods typically depends on the spectrum of the elliptic operator—see [21]).

This paper is organized as follows. In section 2 we describe Lions' nonoverlapping method and define its generalizations for a linear elliptic problem. In section 3 we study the properties of certain operators associated with Robin boundary value problems, prove that Lions' method and the generalized methods are descent-direction algorithms for minimizing an interface bias functional, and demontstrate the convergence of the generalized methods. In section 4 we establish the convergence and acceleration properties of the finite element versions of the generalized methods. Finally, in section 5 we propose two algorithms (one with locally optimal step lengths and the other with a fixed step length) and present the results of numerical experiments.

2. Lions' DDM and its generalizations. In this section we review Lions' nonoverlapping DDM and define our generalizations of that method.

We consider the following linear elliptic PDE with a homogeneous boundary condition:

$$-\operatorname{div}[A(\mathbf{x})\nabla u] = f \quad \text{in } \Omega, \qquad u = 0 \quad \text{on } \partial\Omega, \tag{2.1}$$

where Ω is a two- or three-dimensional Lipschitz domain, f is a given function in $L^2(\Omega)$, and A is a symmetric-matrix-valued $C^1(\overline{\Omega})$ function that is uniformly positive definite. For simplicity and clarity of exposition we will describe Lions' method and our generalized methods on a partition of Ω into two disjoint subdomains Ω_1 and Ω_2. The extensions of these methods to partitions of Ω into multiple subdomains are straightforward [17].

We denote $\Gamma = \overline{\Omega_1} \cap \overline{\Omega_2}$ and $\Gamma_i = \partial\Omega_i \setminus \Gamma$, $i = 1, 2$. Let $\mathbf{n}_i$ be the unit outward normal to $\partial\Omega_i$ along the interface Γ (see Figure 2.1).

In a nonoverlapping DDM for (2.1) one solves

$$-\operatorname{div}[A(\mathbf{x})\nabla u] = f \quad \text{in } \Omega_i, \qquad u|_{\Gamma_i} = 0 \tag{2.2}$$

for $i = 1, 2$ separately with certain boundary conditions on the interface Γ. The boundary conditions on Γ are updated iteratively and (2.2) is solved repeatedly until convergence. Iterative boundary conditions on Γ are often designed based on an equivalent form of the transmission conditions:

$$u_1 - u_2 = 0 \quad \text{on } \Gamma \qquad \text{and} \qquad [A(\mathbf{x})\nabla u_1]\cdot\mathbf{n}_1 + [A(\mathbf{x})\nabla u_2]\cdot\mathbf{n}_2 = 0 \quad \text{on } \Gamma. \tag{2.3}$$

The well-known alternating domain methods [14, 19, 22, 40, 41] can be viewed as examples of iterations that arise from (2.3).

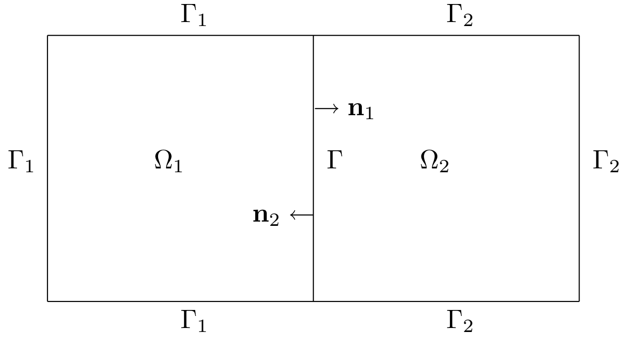

FIG. 2.1.

It can be easily checked that (2.3) is equivalent to the following Robin-type transmission conditions:

$$\begin{aligned} &u_1 + \lambda[A(\mathbf{x})\nabla u_1]\cdot\mathbf{n}_1 = u_2 - \lambda[A(\mathbf{x})\nabla u_2]\cdot\mathbf{n}_2 \quad \text{on } \Gamma,\\ &u_2 + \lambda[A(\mathbf{x})\nabla u_2]\cdot\mathbf{n}_2 = u_1 - \lambda[A(\mathbf{x})\nabla u_1]\cdot\mathbf{n}_1 \quad \text{on } \Gamma, \end{aligned} \tag{2.4}$$

where $\lambda > 0$ is a constant. An iterative implementation of (2.4) yields the following Lions' method: choose initial guesses $u_1^{(1)}$ in Ω_1 and $u_2^{(1)}$ in Ω_2; for $k = 1, 2, 3, \dots,$ solve

$$\left\{ \begin{aligned} &-\operatorname{div}[A(\mathbf{x})\nabla u_1^{(k+1)}] = f \quad \text{in } \Omega_1\,, \qquad u_1^{(k+1)} = 0 \quad \text{on } \Gamma_1,\\ &u_1^{(k+1)} + \lambda[A(\mathbf{x})\nabla u_1^{(k+1)}]\cdot\mathbf{n}_1 = u_2^{(k)} - \lambda[A(\mathbf{x})\nabla u_2^{(k)}]\cdot\mathbf{n}_2 \quad \text{on } \Gamma \end{aligned} \right. \tag{2.5}$$

and

$$\left\{ \begin{aligned} &-\operatorname{div}[A(\mathbf{x})\nabla u_2^{(k+1)}] = f \quad \text{in } \Omega_2\,, \qquad u_2^{(k+1)} = 0 \quad \text{on } \Gamma_2\,,\\ &u_2^{(k+1)} + \lambda[A(\mathbf{x})\nabla u_2^{(k+1)}]\cdot\mathbf{n}_2 = u_1^{(k)} - \lambda[A(\mathbf{x})\nabla u_1^{(k)}]\cdot\mathbf{n}_1 \quad \text{on } \Gamma\,. \end{aligned} \right. \tag{2.6}$$

By setting

$$g_i^{(k)} = u_i^{(k)} + \lambda[A(\mathbf{x})\nabla u_i^{(k)}]\cdot\mathbf{n}_i\,, \qquad i = 1, 2\,, \tag{2.7}$$

Lions' iterations (2.5)–(2.6) were recast into the following form that is more amenable to implementations due to the avoidance of normal derivative calculations (see [17]): choose initial guesses $g_1^{(1)}$ on Γ and $g_2^{(1)}$ on Γ; for $k = 1, 2, 3, \dots,$ solve

$$\left\{ \begin{aligned} &-\operatorname{div}[A(\mathbf{x})\nabla u_i^{(k)}] = f \quad \text{in } \Omega_i\,,\\ &u_i^{(k)} = 0 \quad \text{on } \Gamma_i\,, \qquad u_i^{(k)} + \lambda[A(\mathbf{x})\nabla u_i^{(k)}]\cdot\mathbf{n}_i = g_i^{(k)} \quad \text{on } \Gamma, \quad i = 1, 2, \end{aligned} \right. \tag{2.8}$$

and update

$$g_1^{(k+1)} = 2u_2^{(k)} - g_2^{(k)}\,, \qquad g_2^{(k+1)} = 2u_1^{(k)} - g_1^{(k)}\,. \tag{2.9}$$

Lions' method (2.5)–(2.6) was proposed in [36] with a proof for its convergence. The equivalent variant (2.8)–(2.9) along with finite element approximations was studied in [17]. Lions' method (2.5)–(2.6) and its variant (2.8)–(2.9) were also derived in

[20] through an optimization approach. An overlapping version of Lions' method was studied in [46].

We define a one-parameter generalization of Lions' method as follows: choose initial guesses $u_1^{(1)}$ in Ω_1 and $u_2^{(1)}$ in Ω_2; for $k = 1, 2, 3, \dots$, solve

$$\left\{\begin{aligned} &-\mathrm{div}\,[A(\mathbf{x})\nabla u_1^{(k+1)}] = f \quad \text{in } \Omega_1\,, \qquad u_1^{(k+1)} = 0 \quad \text{on } \Gamma_1\,,\\ &u_1^{(k+1)} + \lambda[A(\mathbf{x})\nabla u_1^{(k+1)}]\cdot \mathbf{n}_1\\ &= (1-\delta_k)\big(u_1^{(k)} + \lambda[A(\mathbf{x})\nabla u_1^{(k)}]\cdot \mathbf{n}_1\big) + \delta_k\big(u_2^{(k)} - \lambda[A(\mathbf{x})\nabla u_2^{(k)}]\cdot \mathbf{n}_2\big) \text{ on } \Gamma \end{aligned}\right. \tag{2.10}$$

and

$$\left\{\begin{aligned} &-\mathrm{div}\,[A(\mathbf{x})\nabla u_2^{(k+1)}] = f \quad \text{in } \Omega_2\,, \qquad u_2^{(k+1)} = 0 \quad \text{on } \Gamma_2\,,\\ &u_2^{(k+1)} + \lambda[A(\mathbf{x})\nabla u_2^{(k+1)}]\cdot \mathbf{n}_2\\ &= (1-\delta_k)\big(u_2^{(k)} + \lambda[A(\mathbf{x})\nabla u_2^{(k)}]\cdot \mathbf{n}_2\big) + \delta_k\big(u_1^{(k)} - \lambda[A(\mathbf{x})\nabla u_1^{(k)}]\cdot \mathbf{n}_1\big) \text{ on } \Gamma, \end{aligned}\right. \tag{2.11}$$

where $\{\delta_k\} \subset [\delta_{\min}, \delta_{\max}] \subset (0,1]$. If $\delta_k = 1$ for all k, then (2.10)–(2.11) reduce to Lions' method (2.5)–(2.6). Also, by introducing $g_i^{(k)}$ as defined by (2.7), we may recast (2.10)–(2.11) into the following form that avoids the calculations of normal derivatives: choose initial guesses $g_1^{(1)}$ on Γ and $g_2^{(1)}$ on Γ; for $k = 1, 2, 3, \dots$, solve

$$\left\{\begin{aligned} &-\mathrm{div}\,[A(\mathbf{x})\nabla u_i^{(k)}] = f \quad \text{in } \Omega_i\,,\\ &u_i^{(k)} = 0 \quad \text{on } \Gamma_i\,, \quad u_i^{(k)} + \lambda[A(\mathbf{x})\nabla u_i^{(k)}]\cdot \mathbf{n}_i = g_i^{(k)} \quad \text{on } \Gamma, \quad i = 1, 2, \end{aligned}\right. \tag{2.12}$$

and update

$$\left\{\begin{aligned} g_1^{(k+1)} &= (1-\delta_k) g_1^{(k)} + \delta_k (2u_2^{(k)} - g_2^{(k)})\,,\\ g_2^{(k+1)} &= (1-\delta_k) g_2^{(k)} + \delta_k (2u_1^{(k)} - g_1^{(k)})\,. \end{aligned}\right. \tag{2.13}$$

Remark 2.1. An observation of Lions' method is that it is not a truly parallel method. In fact, the sequence of iterative solutions

$$\{(u_1^{(1)}, u_2^{(1)}), (u_1^{(2)}, u_2^{(2)}), (u_1^{(3)}, u_2^{(3)}), \dots\}$$

on the two subdomains can be separated into two independent sequences:

$$\{u_1^{(1)}, u_2^{(2)}, u_1^{(3)}, u_2^{(4)}, \dots\}\,, \qquad \{u_2^{(1)}, u_1^{(2)}, u_2^{(3)}, u_1^{(4)}, \dots\},$$

each consisting of iterates of solutions alternating on the two subdomains. One needs only to compute one of the two separate sequences of solutions; thus at each iteration, only one processor is needed. In contrast, the generalized method when $\delta_k \in (0,1)$ naturally calls for two processors at each iteration with the single iteration sequence $\{(u_1^{(1)}, u_2^{(1)}), (u_1^{(2)}, u_2^{(2)}), (u_1^{(3)}, u_2^{(3)}), (u_1^{(4)}, u_2^{(4)}), \dots\}$.

To analyze the generalized method (2.12)–(2.13) in a proper mathematical framework, we introduce some notation and recast Lions' method and the generalized methods into weak formulations.

Let $H^s(\mathcal{D})$ denote the standard Sobolev space of order s on a set $\mathcal{D}$ with the norm $\|\cdot\|_{s,\mathcal{D}}$. Vector-valued Sobolev spaces are denoted by $\mathbf{H}^s(\mathcal{D})$ with the norm still denoted by $\|\cdot\|_{s,\mathcal{D}}$. Of course, $H^0(\mathcal{D}) = L^2(\mathcal{D})$ and $\mathbf{H}^0(\mathcal{D}) = \mathbf{L}^2(\mathcal{D})$. We denote the $L^2(\mathcal{D})$- and $\mathbf{L}^2(\mathcal{D})$-inner products by $[\cdot,\cdot]_{\mathcal{D}}$, i.e.,

$$[u, v]_{\mathcal{D}} = \int_{\mathcal{D}} u\, v \, d\mathcal{D} \quad \forall\, u, v \in L^2(\mathcal{D}) \quad \text{and} \quad [\mathbf{u}, \mathbf{v}]_{\mathcal{D}} = \int_{\mathcal{D}} \mathbf{u}\cdot\mathbf{v}\, d\mathcal{D} \quad \forall\, \mathbf{u}, \mathbf{v} \in \mathbf{L}^2(\mathcal{D}).$$

Also, we use the standard notation for the space $H^1_0(\Omega) = \{v \in H^1(\Omega) \mid v = 0 \text{ on } \partial\Omega\}$.

The weak formulation for the elliptic boundary value problem (2.1) is given by

$$a[u, v] = [f, v]_\Omega \qquad \forall\, v \in H^1_0(\Omega), \tag{2.14}$$

where the bilinear form $a[\cdot,\cdot]$ is defined by

$$a[u, v] = \int_\Omega A(\mathbf{x})\nabla u \cdot \nabla v \, d\mathbf{x} \qquad \forall\, u, v \in H^1(\Omega).$$

For $i = 1, 2$ we define the space $X_i = \{v \in H^1(\Omega_i) \mid v = 0 \text{ on } \Gamma_i\}$ equipped with the norm $\|\cdot\|_{X_i} = \|\cdot\|_{1,\Omega_i}$. We also introduce the subdomain bilinear forms

$$a_i[u, v] = \int_{\Omega_i} A(\mathbf{x})\nabla u \cdot \nabla v \, d\mathbf{x} \qquad \forall\, u, v \in X_i,\ i = 1, 2.$$

In terms of weak formulations Lions' method (2.8)–(2.9) can be stated as follows: choose initial guesses $g_1^{(k)} \in L^2(\Gamma)$ and $g_2^{(k)} \in L^2(\Gamma)$; for $k = 1, 2, 3, \dots$, solve for $u_i^{(k)} \in X_i$ $(i = 1, 2)$ from

$$a_i[u_i^{(k)}, v_i] + \lambda^{-1}[u_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i^{(k)}, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,,\ i = 1, 2, \tag{2.15}$$

and update

$$g_1^{(k+1)} = 2u_2^{(k)} - g_2^{(k)} \qquad \text{and} \qquad g_2^{(k+1)} = 2u_1^{(k)} - g_1^{(k)}\,. \tag{2.16}$$

The weak formulation of the generalized method (2.12)–(2.13) is as follows: choose initial guesses $g_1^{(1)} \in L^2(\Gamma)$ and $g_2^{(1)} \in L^2(\Gamma)$; for $k = 1, 2, 3, \dots$, solve for $u_i^{(k)} \in X_i$ $(i = 1, 2)$ from

$$a_i[u_i^{(k)}, v_i] + \lambda^{-1}[u_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i^{(k)}, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,,\ i = 1, 2, \tag{2.17}$$

and update

$$\begin{cases} g_1^{(k+1)} = (1-\delta_k)g_1^{(k)} + \delta_k(2u_2^{(k)} - g_2^{(k)})\,, \\ g_2^{(k+1)} = (1-\delta_k)g_2^{(k)} + \delta_k(2u_1^{(k)} - g_1^{(k)})\,. \end{cases} \tag{2.18}$$

We will reveal that Lions' method and the generalized methods are descent-direction algorithms for minimizing the interface bias functional

$$\frac{1}{2}\int_\Gamma \Big(|u_1 - u_2|^2 + \lambda^2 \Big| [A(\mathbf{x})\nabla u_1]\cdot\mathbf{n}_1 + [A(\mathbf{x})\nabla u_2]\cdot\mathbf{n}_2 \Big|^2 \Big), \tag{2.19}$$

where $u_i \in X_i$ $(i = 1, 2)$ are solutions of the subdomain Robin boundary value problem

$$a_i[u_i, v_i] + \lambda^{-1}[u_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,,\ i = 1, 2. \tag{2.20}$$

Obviously, (2.19) attains the minimum value 0 when $u_1 = \widehat{u}|_{\Omega_1}$ and $u_2 = \widehat{u}|_{\Omega_2}$, where $\widehat{u} \in H_0^1(\Omega)$ is the solution of the problem (2.1) or (2.14) on the entire domain Ω. We will show that the generalized method (2.17)–(2.18) converges to the minimum of the functional (2.19); i.e., the subdomain solutions defined by (2.17)–(2.18) converges to the global solution $\widehat{u}$. In the course of the convergence proofs, the acceleration properties of the generalized methods will become clear.

3. Convergence of the generalized method. In this section we will first study some properties of a Robin–Robin map (which maps a Robin-type boundary value on Γ into another Robin-type boundary value) and then prove the convergence of iterations (2.17)–(2.18).

3.1. Solution operators for the Robin boundary value problems. It is well known that Robin-type boundary value problems on subdomains (for a fixed $\lambda > 0$)

$$\begin{cases} -\mathrm{div}\,[A(\mathbf{x})\nabla u_i] = f \quad \text{in } \Omega_i, \\ u_i = 0 \quad \text{on } \Gamma_i\,, \qquad u_i + \lambda[A(\mathbf{x})\nabla u_i]\cdot \mathbf{n}_i = g_i \quad \text{on } \Gamma, \end{cases} \tag{3.1}$$

$i = 1, 2$, admit a unique solution in the sense of the following weak formulation: seek a $u_i \in X_i$, $i = 1, 2$, such that

$$a_i[u_i, v_i] + \lambda^{-1}[u_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,. \tag{3.2}$$

For $i = 1, 2$ we denote by $S_i^f : L^2(\Gamma) \to X_i$ the solution operator for the Robin boundary value problem (3.2); i.e., $u_i = S_i^f g_i$ for $g_i \in L^2(\Gamma)$ if and only if u_i and g_i satisfy (3.2). We define the operator $S^f : \mathbf{L}^2(\Gamma) \to X_1 \times X_2$ by $S^f\mathbf{g} = (S_1^f g_1, S_2^f g_2)$ for all $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$. If $f = 0$, we write S_i^0 and S^0 in place of S_i^f and S^f, respectively.

We also denote by $T : L^2(\Omega) \to X_1 \times X_2$ the solution operator for (3.2) with homogeneous Robin boundary condition; i.e., for every $f \in L^2(\Omega)$, $(u_1, u_2) = Tf = (T_1 f, T_2 f)$ if and only if $(u_1, u_2) \in X_1 \times X_2$ is the solution of

$$a_i[u_i, v_i] + \lambda^{-1}[u_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} \qquad \forall\, v_i \in X_i\,,\ i = 1, 2. \tag{3.3}$$

The operator T is obviously linear.

LEMMA 3.1. *If* $\mathbf{g}, \widetilde{\mathbf{g}} \in \mathbf{L}^2(\Gamma)$ *and* c_1, c_2 *are constants, then*

(a) $S^0(c_1\mathbf{g} + c_2\widetilde{\mathbf{g}}) = c_1 S^0\mathbf{g} + c_2 S^0\widetilde{\mathbf{g}}$;

(b) $S^f = S^0 + Tf$;

(c) $S^0(\mathbf{g} - \widetilde{\mathbf{g}}) = S^f\mathbf{g} - S^f\widetilde{\mathbf{g}}$.

Proof. By definition, the operator S^0 is defined as follows: for every $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$, $(u_1, u_2) = (S_1^0 g_1, S_2^0 g_2)$ if and only if

$$a_i[u_i, v_i] + \lambda^{-1}[u_i, v_i]_\Gamma = \lambda^{-1}[g_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i. \tag{3.4}$$

Thus it is obvious that S_i^0 and S^0 are linear operators and (a) holds.

The solution of (3.2) evidently can be split into the sum of the solution for (3.3) and the solution for (3.4). In other words, $S^f\mathbf{g} = Tf + S^0\mathbf{g}$ for every $\mathbf{g} \in \mathbf{L}^2(\Gamma)$. This proves (b).

As an easy consequence of (b) and (a), we obtain (c):

$$S^f\mathbf{g} - S^f\widetilde{\mathbf{g}} = S^0\mathbf{g} + Tf - S^0\widetilde{\mathbf{g}} - Tf = S^0(\mathbf{g} - \widetilde{\mathbf{g}}). \qquad \square$$

3.2. The Robin–Robin map and its basic properties. We define the Robin–Robin map $R^f : \mathbf{L}^2(\Gamma) \to \mathbf{L}^2(\Gamma)$ as follows. For any $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$,

$$R^f \mathbf{g} = (R_1^f \mathbf{g}, R_2^f \mathbf{g}) \equiv \Big(2(S_2^f g_2)|_\Gamma - g_2 \, , 2(S_1^f g_1)|_\Gamma - g_1 \Big). \tag{3.5}$$

If $f = 0$, we write R^0 in place of R^f.

We denote by $\widehat{u}$ the unique exact solution of (2.14) in $H_0^1(\Omega)$. Following the proofs of [23, Theorem I.2.5 and Corollary I.2.6] we may justify that $[A(\mathbf{x})\nabla \widehat{u}] \cdot \mathbf{n}_i|_\Gamma \in H^{-1/2}(\Gamma)$. We make the regularity assumption

$$[A(\mathbf{x})\nabla \widehat{u}_i] \cdot \mathbf{n}_i|_\Gamma \in L^2(\Gamma), \qquad i = 1, 2, \tag{3.6}$$

so that

$$a_i[\widehat{u}_i, v_i] = [f, v_i]_{\Omega_i} + [(A(\mathbf{x})\nabla \widehat{u}_i) \cdot \mathbf{n}_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,. \tag{3.7}$$

We define $\widehat{u}_i$ and $\widehat{g}_i$ by

$$\widehat{u}_i = \widehat{u}|_{\Omega_i}, \qquad \widehat{g}_i = \widehat{u}_i + \lambda [A(\mathbf{x})\nabla \widehat{u}_i] \cdot \mathbf{n}_i\,, \qquad i = 1, 2. \tag{3.8}$$

Of course, $\widehat{u}_1$ and $\widehat{u}_2$ satisfy the transmission conditions

$$\widehat{u}_1|_\Gamma = \widehat{u}_2|_\Gamma \qquad \text{and} \qquad [A(\mathbf{x})\nabla \widehat{u}_1] \cdot \mathbf{n}_1 = -[A(\mathbf{x})\nabla \widehat{u}_2] \cdot \mathbf{n}_2 \quad \text{on } \Gamma. \tag{3.9}$$

Also, (3.7) implies

$$a_i[\widehat{u}_i, v_i] + \lambda^{-1}[\widehat{u}_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[\widehat{g}_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,. \tag{3.10}$$

It is easily verified that Lions' iterations (2.15)–(2.16) can be simply written as fixed point iterations

$$\begin{cases} \mathbf{g}^{(1)} \text{ given,} \\ \mathbf{g}^{(k+1)} = R^f \mathbf{g}^{(k)}, \qquad k = 1, 2, 3, \dots. \end{cases}$$

It is well known that Lions' iterations converge to the exact solution $\widehat{u}$ (see [17, 36]). Thus we expect $\widehat{\mathbf{g}} = (\widehat{g}_1, \widehat{g}_2)$ defined by (3.8) to be a fixed point of R^f, as will be proved in the following lemma.

LEMMA 3.2. $\mathbf{g} \in \mathbf{L}^2(\Gamma)$ *satisfies* $R^f \mathbf{g} = \mathbf{g}$ *if and only if* $\mathbf{g} = \widehat{\mathbf{g}}$.

Proof. If $\mathbf{g} = \widehat{\mathbf{g}}$, using definition (3.8) and the transmission conditions (3.9), we have

$$\begin{aligned} R^f \widehat{\mathbf{g}} &= (2\widehat{u}_2 - \widehat{g}_2 \, , 2\widehat{u}_1 - \widehat{g}_1) = \Big(\widehat{u}_2 - \lambda[A(\mathbf{x})\nabla \widehat{u}_2] \cdot \mathbf{n}_2 \, , \widehat{u}_1 - \lambda[A(\mathbf{x})\nabla \widehat{u}_1] \cdot \mathbf{n}_1 \Big) \\ &= \Big(\widehat{u}_1 + \lambda[A(\mathbf{x})\nabla \widehat{u}_1] \cdot \mathbf{n}_1 \, , \widehat{u}_2 + \lambda[A(\mathbf{x})\nabla \widehat{u}_2] \cdot \mathbf{n}_2 \Big) = \widehat{\mathbf{g}}\,. \end{aligned}$$

To prove the converse, we assume that $\mathbf{g} \in \mathbf{L}^2(\Gamma)$ satisfies $R^f \mathbf{g} = \mathbf{g}$, i.e.,

$$2u_2 - g_2 = g_1 \quad \text{and} \quad 2u_1 - g_1 = g_2 \quad \text{on } \Gamma, \tag{3.11}$$

where $u_i = S_i^f g_i$, $i = 1, 2$. Subtracting the two equations of (3.11), we immediately obtain

$$u_1 = u_2 \quad \text{on } \Gamma. \tag{3.12}$$

Thus the function $u \in L^2(\Omega)$ defined by

$$u = \begin{cases} u_1 & \text{in } \Omega_1, \\ \\ u_2 & \text{in } \Omega_2 \end{cases}$$

satisfies $u \in H_0^1(\Omega)$. By definition $u_i = S_i^f g_i$ is determined by (3.2). Let an arbitrary $v \in H_0^1(\Omega)$ be given. Setting $v_i = v|_{\Omega_i}$ in (3.2) for $i = 1, 2$ and adding the two equations, we obtain

$$a[u, v] = [f, v]_\Omega + \lambda^{-1}[g_1 + g_2 - u_1 - u_2, v]_\Gamma \,.$$

Substituting (3.11) into the last equation, we are led to

$$a[u, v] = [f, v]_\Omega \qquad \forall\, v \in H_0^1(\Omega)\,.$$

Thus $u = \widehat{u}$. Then a comparison of (3.2) (now $u = \widehat{u}$) and (3.10) yields $(g_1, g_2) = (\widehat{g}_1, \widehat{g}_2)$. □

We next derive some basic properties of R^f. We easily see that R^f and R^0 satisfy the following relations in terms of the operators S^f and T:

$$R^0\mathbf{g} = \Big(2(S^0\mathbf{g})|_\Gamma - \mathbf{g}\Big)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \tag{3.13}$$

and

$$\begin{aligned} R^f\mathbf{g} &= \Big(2(S^f\mathbf{g})|_\Gamma - \mathbf{g}\Big)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \Big(2(S^0\mathbf{g})|_\Gamma - \mathbf{g} + 2(Tf)|_\Gamma\Big)\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \\ &= R^0\mathbf{g} + 2(Tf)|_\Gamma \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \end{aligned} \tag{3.14}$$

Relations (3.13)–(3.14) and Lemma 3.1 trivially yield the following lemma.

LEMMA 3.3. *If* $\mathbf{g}, \widetilde{\mathbf{g}} \in \mathbf{L}^2(\Gamma)$ *and* c_1, c_2 *are constants, then*

(a) $R^0(\mathbf{g} - \widetilde{\mathbf{g}}) = R^f\mathbf{g} - R^f\widetilde{\mathbf{g}}$*;*

(b) $R^0(\mathbf{g} - \widehat{\mathbf{g}}) = R^f\mathbf{g} - \widehat{\mathbf{g}}$*, where* $\widehat{g}$ *is defined in* (3.8)*;*

(c) $R^0(c_1\mathbf{g} + c_2\widetilde{\mathbf{g}}) = c_1R^0\mathbf{g} + c_2R^0\widetilde{\mathbf{g}}$*.*

PROPOSITION 3.4. *Let* $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$ *and* $u_i = S_i^f g_i$*. Then*

$$\|R^f\mathbf{g}\|_{0,\Gamma}^2 = \|\mathbf{g}\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^{2} \Big(a_i[u_i, u_i] - [f, u_i]_{\Omega_i}\Big).$$

In particular, if $f = 0$*, then*

$$\|R^0\mathbf{g}\|_{0,\Gamma}^2 = \|\mathbf{g}\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^{2} a_i[S_i^0 g_i, S_i^0 g_i]\,.$$

Proof. The proof is adapted from that of [17]. We recall that $u_i = S_i^f\mathbf{g}$ is defined by (3.2). Setting $v_i = u_i$ in (3.2), we obtain

$$\int_\Gamma (u_iu_i - g_iu_i) = -\lambda\Big(a_i[u_i, u_i] - [f, u_i]_{\Omega_i}\Big), \quad i = 1, 2.$$

Thus

$$\begin{aligned}\|R^f\mathbf{g}\|_{0,\Gamma}^2 &= \int_\Gamma |2u_1 - g_1|^2 + \int_\Gamma |2u_2 - g_2|^2 \\ &= \int_\Gamma (g_1^2 + g_2^2) + 4\int_\Gamma (u_1^2 - u_1 g_1) + 4\int_\Gamma (u_2^2 - u_2 g_2) \\ &= \|\mathbf{g}\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^2 \Big(a_i[u_i, u_i] - [f, u_i]_{\Omega_i} \Big). \qquad \square\end{aligned}$$

3.3. An interface bias functional and a descent direction.

We define the interface bias functional $E^f(\mathbf{g})$ associated with subdomain Robin-type boundary value problem (3.2) by

$$E^f(\mathbf{g}) = \frac{1}{2}\int_\Gamma \Big(|u_1 - u_2|^2 + |u_1 + u_2 - g_1 - g_2|^2 \Big), \tag{3.15}$$

where $(u_1, u_2) = S^f\mathbf{g}$ is defined through (3.2). If $[A(\mathbf{x})\nabla u_i] \cdot \mathbf{n}_i|_\Gamma \in L^2(\Gamma)$, $i = 1, 2$, then E^f can be rewritten as

$$E^f(\mathbf{g}) = \frac{1}{2}\int_\Gamma \Big(|u_1 - u_2|^2 + \lambda^2 \Big| [A(\mathbf{x})\nabla u_1] \cdot \mathbf{n}_1 + [A(\mathbf{x})\nabla u_2] \cdot \mathbf{n}_2 \Big|^2 \Big);$$

i.e., E^f indeed measures the interface bias.

The minimum value 0 of E^f is uniquely attained at $\widehat{\mathbf{g}}$ which is defined in (3.8). It is easily verified that the generalized method (2.17)–(2.18) can be simply expressed by

$$\begin{cases} \mathbf{g}^{(1)} \text{ given}, \\ \mathbf{g}^{(k+1)} = \mathbf{g}^{(k)} + \delta_k (R^f \mathbf{g}^{(k)} - \mathbf{g}^{(k)}), \qquad k = 1, 2, \ldots. \end{cases} \tag{3.16}$$

We will show that $R^f\mathbf{g} - \mathbf{g}$ provides a descent direction for E^f at any $\mathbf{g}$ so that the generalized method (3.16) is a descent-direction method for solving the following minimization problem:

$$\min_{\mathbf{g} \in \mathbf{L}^2(\Gamma)} E^f(\mathbf{g}) \text{ subject to (3.2)}, \ i = 1, 2. \tag{3.17}$$

We first establish the following identities.

PROPOSITION 3.5. *Let* $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$. *Then*

$$E^f(\mathbf{g}) = \frac{1}{4}\int_\Gamma |\mathbf{g} - R^f\mathbf{g}|^2 = \frac{1}{4}\int_\Gamma \Big(|g_1 - R_1^f\mathbf{g}|^2 + |g_2 - R_2^f\mathbf{g}|^2 \Big) \tag{a}$$

and

$$E^f(R^f\mathbf{g}) = E^f(\mathbf{g}) - 4\lambda \sum_{i=1}^2 a_i[S_i^f(g_i) - S_i^f(R_i^f\mathbf{g}), S_i^f(g_i) - S_i^f(R_i^f\mathbf{g})]\,. \tag{b}$$

Proof. We set $u_i = S_i^f g_i$ and $\widetilde{u}_i = S_i^f(R_i^f\mathbf{g})$, $i = 1, 2$. From the definition of R^f, i.e., (3.5), we have

$$(R_1^f\mathbf{g} - g_1) - (R_2^f\mathbf{g} - g_2) = 2(u_2 - u_1) \quad \text{on } \Gamma$$

and

$$(R_1^f\mathbf{g} - g_1) + (R_2^f\mathbf{g} - g_2) = 2(u_1 + u_2) - 2(g_1 + g_2) \quad \text{on } \Gamma.$$

Squaring both sides of the last two equations and adding them together, we deduce

$$(R_1^f\mathbf{g} - g_1)^2 + (R_2^f\mathbf{g} - g_2)^2 = 2(u_1 - u_2)^2 + 2|u_1 + u_2 - g_1 - g_2|^2 \quad \text{on } \Gamma,$$

which readily yields (a).

To prove (b) we note that identity (a), Lemma 3.3 (a), Proposition 3.4, and Lemma 3.1 (c) lead us to

$$\begin{aligned} E^f(R^f\mathbf{g}) &= \|R^f\mathbf{g} - R^f(R^f\mathbf{g})\|_{0,\Gamma}^2 = \|R^0(\mathbf{g} - R^f\mathbf{g})\|_{0,\Gamma}^2 \\ &= \|\mathbf{g} - R^f\mathbf{g}\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^2 \int_{\Omega_i} \left|\nabla\Big(S_i^0(g_i - R_i^f\mathbf{g})\Big)\right|^2 \\ &= \|\mathbf{g} - R^f\mathbf{g}\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^2 a_i[S_i^f(g_i) - S_i^f(R_i^f\mathbf{g}), S_i^f(g_i) - S_i^f(R_i^f\mathbf{g})]\,. \qquad \square \end{aligned}$$

PROPOSITION 3.6. *Let* $\mathbf{g} \in \mathbf{L}^2(\Gamma)$. *Then* $\Lambda(\mathbf{g}) \equiv \|\mathbf{g} - 2R^f\mathbf{g} + R^fR^f\mathbf{g})\|_{0,\Gamma}^2 = 0$ *if and only if* $\mathbf{g} = \widehat{\mathbf{g}}$.

Proof. If $\mathbf{g} = \widehat{\mathbf{g}}$, then Lemma 3.2 implies $R^f\widehat{\mathbf{g}} = \widehat{\mathbf{g}}$ so that

$$\Lambda(\widehat{\mathbf{g}}) = \|\widehat{\mathbf{g}} - 2R^f\widehat{\mathbf{g}} + R^fR^f\widehat{\mathbf{g}}\|_{0,\Gamma}^2 = 0\,.$$

Conversely, we assume that $\Lambda(\mathbf{g}) = 0$ and proceed to show that $R^f\mathbf{g} = \mathbf{g}$. Obviously $\Lambda(\mathbf{g}) = 0$ implies $\mathbf{g} - R^f\mathbf{g} = R^f\mathbf{g} - R^f(R^f\mathbf{g})$. Using this relation and employing Proposition 3.5 (a) repeatedly, we have

$$E^f(\mathbf{g}) = \frac{1}{4}\|\mathbf{g} - R^f\mathbf{g}\|_{0,\Gamma}^2 = \frac{1}{4}\|R^f\mathbf{g} - R^fR^f\mathbf{g})\|_{0,\Gamma}^2 = E^f(R^f\mathbf{g})$$

so that by Proposition 3.5 (b) we deduce

$$a_1[u_1 - \widetilde{u}_1, u_1 - \widetilde{u}_1] + a_2[u_2 - \widetilde{u}_2, u_2 - \widetilde{u}_2] = 0,$$

where $u_i = S_i^f g_i$ and $\widetilde{u}_i = S_i^f(R_i^f\mathbf{g})$, $i = 1, 2$. Thus, by virtue of the Poincaré inequality, we obtain

$$u_i - \widetilde{u}_i = 0 \quad \text{in } \Omega_i \qquad \text{and} \qquad u_i - \widetilde{u}_i = 0 \quad \text{on } \Gamma \tag{3.18}$$

for $i = 1, 2$. By the definition of S_i^f we have, for $i = 1, 2$,

$$a_i[u_i, v_i] + \lambda^{-1}[u_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i, v_i]_\Gamma \qquad \forall\, v_i \in X_i$$

and

$$a_i[\widetilde{u}_i, v_i] + \lambda^{-1}[\widetilde{u}_i, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[R_i^f\mathbf{g}, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,.$$

Subtracting the last two equations and applying (3.18), we obtain $g_i = R_i^f\mathbf{g}$, $i = 1, 2$, i.e., $\mathbf{g} = R^f\mathbf{g}$. Thus by Lemma 3.2 we conclude $\mathbf{g} = \widehat{\mathbf{g}}$. $\square$

A review of the proof of Proposition 3.6 reveals the following.

COROLLARY 3.7. *Let* $\mathbf{g} \in \mathbf{L}^2(\Gamma)$. *The following statements are equivalent:*

(i) $\Lambda(\mathbf{g}) = 0$*;*

(ii) $\mathbf{g} = \widehat{\mathbf{g}}$*;*

(iii) $\mathbf{g} = R^f\mathbf{g}$*;*

(iv) $E^f(\mathbf{g}) = 0$*;*

(v) $E^f(\mathbf{g}) = E^f(R^f\mathbf{g})$.

As a consequence of Proposition 3.5 and Corollary 3.7, we have the following.

COROLLARY 3.8. $E^f(R^f\mathbf{g}) < E^f(\mathbf{g})$ *whenever* $\mathbf{g} \in \mathbf{L}^2(\Gamma)$ *and* $\mathbf{g} \neq \widehat{\mathbf{g}}$.

The main result of this section is the following.

THEOREM 3.9. *Assume that* $\mathbf{g} \in \mathbf{L}^2(\Gamma)$ *and* $\Lambda(\mathbf{g}) \equiv \|\mathbf{g}-2R^f\mathbf{g}+R^fR^f\mathbf{g})\|^2_{0,\Gamma} \neq 0$. *Then there is a* $\delta_0 = \delta_0(\mathbf{g}) \geq 1/2$ *such that*

$$E^f(\mathbf{g}) > E^f(\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g})) \qquad \forall\, \delta \in (0, 2\delta_0)\,.$$

Moreover, $E^f(\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g}))$ *as a function of* δ *is strictly decreasing on* $[0, \delta_0]$ *and strictly increasing on* $[\delta_0, 2\delta_0]$.

Proof. Assume that $\mathbf{g} \in \mathbf{L}^2(\Gamma)$ and $\Lambda(\mathbf{g}) \equiv \|\mathbf{g} - 2R^f\mathbf{g} + R^fR^f\mathbf{g})\|^2_{0,\Gamma} \neq 0$. Using Lemma 3.3 (a) repeatedly, we have

$$\begin{aligned} R^f(\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g})) &= R^f(\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g})) - R^f\mathbf{g} + R^f\mathbf{g} \\ &= R^0(\delta(R^f\mathbf{g} - \mathbf{g})) + R^f\mathbf{g} = \delta(R^f(R^f\mathbf{g}) - R^f\mathbf{g}) + R^f\mathbf{g}. \end{aligned}$$

The last equation and Proposition 3.5 imply

$$\begin{aligned} \phi(\delta) \equiv 4E^f(\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g})) &= \|\mathbf{g} + \delta(R^f\mathbf{g} - \mathbf{g}) - (\delta(R^f(R^f\mathbf{g}) - R^f\mathbf{g}) + R^f\mathbf{g})\|^2_{0,\Gamma} \\ &= \|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} + \delta^2\|\mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})\|^2_{0,\Gamma} \\ &\qquad - 2\delta[\mathbf{g} - R^f\mathbf{g}, \mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})]_\Gamma\,. \end{aligned}$$

Thus $\phi(\delta)$ attains its minimum at

$$\delta_0 = \delta_0(\mathbf{g}) = \frac{[\mathbf{g} - R^f\mathbf{g}, \mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})]_\Gamma}{\|\mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})\|^2_{0,\Gamma}} \tag{3.19}$$

with the minimum value

$$\phi(\delta_0) = 4E^f(\mathbf{g} + \delta_0(R^f\mathbf{g} - \mathbf{g})) = \|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} - \frac{[\mathbf{g} - R^f\mathbf{g}, \mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})]^2_\Gamma}{\|\mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})\|^2_{0,\Gamma}}.$$

We verify $\delta_0 > 0$ as follows:

$$\begin{aligned} &[\mathbf{g} - R^f\mathbf{g}, \mathbf{g} - 2R^f\mathbf{g} + R^f(R^f\mathbf{g})]_\Gamma \\ &\qquad = \|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} - [\mathbf{g} - R^f\mathbf{g}, R^f\mathbf{g} - R^f(R^f\mathbf{g})]_\Gamma \\ &\qquad \geq \|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} - \frac{1}{2}\|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} - \frac{1}{2}\|R^f\mathbf{g} - R^f(R^f\mathbf{g})\|^2_{0,\Gamma} \\ &\qquad = \frac{1}{2}\|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} - \frac{1}{2}\|R^f\mathbf{g} - R^f(R^f\mathbf{g})\|^2_{0,\Gamma} = 2[E^f(\mathbf{g}) - E^f(R^f\mathbf{g})] > 0, \end{aligned}$$

where in the last step we used Proposition 3.5 (a) and Corollary 3.8.

The function $\phi(\delta) \equiv E^f(\mathbf{g}+\delta(R^f\mathbf{g}-\mathbf{g}))$, a quadratic function of δ, is strictly decreasing on $(-\infty,\delta_0]$ and strictly increasing on $\in [\delta_0,\infty)$. Straightforward calculations reveal

$$\phi(2\delta_0) = \|\mathbf{g} - R^f\mathbf{g}\|^2_{0,\Gamma} = 4E^f(\mathbf{g}) \qquad \text{and} \qquad \phi(1) = 4E^f(R^f\mathbf{g}).$$

Thus an application of Corollary 3.8 yields $\phi(2\delta_0) > \phi(1)$ so that $2\delta_0 \geq 1$. □

3.4. Convergence of the generalized method. By virtue of Theorem 3.9 the generalized method (3.16), which is equivalent to iterations (2.17)–(2.18), is a descent-direction method for solving the minimization problem (3.17). We have the following convergence result for iterations (3.16).

THEOREM 3.10. *Assume that* $\mathbf{g}^{(1)} \in \mathbf{L}^2(\Gamma)$ *and* $\{\delta_k\}_{k=1}^\infty \subset [\delta_{\min},1] \subset (0,1]$. *Let* $\{\mathbf{g}^{(k)}\}_{k=2}^\infty$ *be defined by* (3.16) *and* $(u_1^{(k)},u_2^{(k)}) = S^f\mathbf{g}^{(k)}$, $k=1,2,3,\ldots.$ *Then*

$$\|u_i^{(k)} - \widehat{u}_i\|_{1,\Omega_i} \to 0 \quad \text{as } k\to\infty,\ i=1,2.$$

Proof. Recall that $\widehat{\mathbf{g}} = R^f\widehat{\mathbf{g}}$ and $R^f\mathbf{g}^{(k)} - R^f\widehat{\mathbf{g}} = R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})$. Thus

$$\mathbf{g}^{(k+1)} - \widehat{\mathbf{g}} = (1-\delta_k)(\mathbf{g}^{(k)}-\widehat{\mathbf{g}}) + \delta_k R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\,.$$

It follows that

$$\begin{aligned}\|\mathbf{g}^{(k+1)} - \widehat{\mathbf{g}}\|^2_{0,\Gamma} &= (1-\delta_k)^2\|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} + \delta_k^2\|R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\|^2_{0,\Gamma}\\ &\qquad + 2\delta_k(1-\delta_k)[\mathbf{g}^{(k)}-\widehat{\mathbf{g}}, R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})]_{0,\Gamma}\\ &\leq (1-\delta_k)^2\|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} + \delta_k^2\|R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\|^2_{0,\Gamma}\\ &\qquad + \delta_k(1-\delta_k)\{\|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} + \|R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\|^2_{0,\Gamma}\}\\ &= (1-\delta_k)\|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} + \delta_k\|R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\|^2_{0,\Gamma}\,.\end{aligned}$$

On the other hand, using Proposition 3.4 and Lemma 3.1 (c) and noting that $(\widehat{u}_1,\widehat{u}_2) = S^f\widehat{\mathbf{g}}$, we have

$$\|R^0(\mathbf{g}^{(k)}-\widehat{\mathbf{g}})\|^2_{0,\Gamma} = \|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} - 4\lambda\sum_{i=1}^2 a_i[u_i^{(k)}-\widehat{u}_i, u_i^{(k)}-\widehat{u}_i],$$

where $(u_1^{(k)},u_2^{(k)}) = S^f\mathbf{g}^{(k)}$. Combining the last two relations, we obtain

$$\begin{aligned}\|\mathbf{g}^{(k+1)} - \widehat{\mathbf{g}}\|^2_{0,\Gamma} &\leq \|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} - 4\lambda\delta_k\sum_{i=1}^2\int_{\Omega_i}|\nabla(u_i^{(k)}-\widehat{u}_i)|^2\\ &\leq \|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} - 4\lambda\delta_{\min}\sum_{i=1}^2\int_{\Omega_i}|\nabla(u_i^{(k)}-\widehat{u}_i)|^2\end{aligned}$$

or, equivalently,

$$4\lambda\delta_{\min}\sum_{i=1}^2 a_i[u_i^{(k)}-\widehat{u}_i, u_i^{(k)}-\widehat{u}_i] \leq \|\mathbf{g}^{(k)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} - \|\mathbf{g}^{(k+1)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma}.$$

Summing in k from 1 to an arbitrary $N \geq 1$, we have

$$4\lambda\delta_{\min}\sum_{k=1}^N\sum_{i=1}^2 a_i[u_i^{(k)}-\widehat{u}_i, u_i^{(k)}-\widehat{u}_i] \leq \|\mathbf{g}^{(1)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} - \|\mathbf{g}^{(N+1)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma} \leq \|\mathbf{g}^{(1)}-\widehat{\mathbf{g}}\|^2_{0,\Gamma}\,.$$

This implies that

$$\sum_{i=1}^{2} a_i[u_i^{(k)} - \widehat{u}_i, u_i^{(k)} - \widehat{u}_i] \to 0 \quad \text{as } k \to \infty.$$

From the Poincaré inequality, we conclude that

$$\|u_i^{(k)} - \widehat{u}_i\|_{1,\Omega_i} \to 0 \quad \text{as } k \to \infty. \qquad \square$$

Next, we will demonstrate that $E^f(\mathbf{g}^{(k)}) \to 0$ as $k \to \infty$. We will need the following lemma.

LEMMA 3.11. *Assume that* $\{r_k\}_{k=1}^\infty$, $\{b_k\}_{k=1}^\infty$, *and* $\{a_k\}_{k=1}^\infty$ *satisfy* $\lim_{k\to\infty} b_k = 0$,

$$0 \le r_k \le r_{\max} < 1\,, \quad |a_{k+1}| \le r_k |a_k| + |b_k|\,, \quad |a_k| \le M \qquad \forall\, k,$$

where $r_{\max}$ *and* M *are constants independent of* k. *Then* $\lim_{k\to\infty} a_k = 0$.

Proof. Let an $\epsilon > 0$ be given. As $\lim_{k\to\infty} b_k = 0$, we may choose an integer $K_1 > 0$ such that $|b_k| < (1 - r_{\max})\epsilon/2$ for all $k \ge K_1$. Since $r_{\max} \in [0, 1)$, we may choose an integer $K_2 > 0$ such that $|r_{\max}|^k < \epsilon/(2M)$ for all $k \ge K_2$. Hence, for $k > K_1 + K_2$, using the relation

$$|a_{m+1}| \le r_{\max}\, |a_m| + |b_m|$$

recursively, we obtain

$$\begin{aligned} |a_k| &\le |r_{\max}|^{K_2} |a_{k-K_2}| + |r_{\max}|^{K_2-1} |b_{k-K_2}| + \cdots + |r_{\max}|\, |b_{k-2}| + |b_{k-1}| \\ &\le |r_{\max}|^{K_2} M + (|r_{\max}|^{K_2-1} + \cdots + |r_{\max}| + 1) \frac{1 - r_{\max}}{2}\, \epsilon \\ &< \frac{\epsilon}{2M} \cdot M + \frac{1}{1 - r_{\max}} \frac{1 - r_{\max}}{2}\, \epsilon = \epsilon. \qquad \square \end{aligned}$$

THEOREM 3.12. *Assume that* $\mathbf{g}^{(1)} \in \mathbf{L}^2(\Gamma)$ *and* $\{\delta_k\}_{k=1}^\infty \subset [\delta_{\min}, \delta_{\max}] \subset (0, 1)$. *Let* $\{\mathbf{g}^{(k)}\}_{k=2}^\infty$ *be defined by* (3.16) *and* $(u_1^{(k)}, u_2^{(k)}) = S^f \mathbf{g}^{(k)}$, $k = 1, 2, 3, \ldots$. *Then* $E^f(\mathbf{g}^{(k)}) \to 0$ *as* $k \to \infty$.

Proof. Theorem 3.10 and the trace theorem imply

$$\|u_i^{(k)} - \widehat{u}_i\|_{0,\Gamma}^2 \to 0 \quad \text{as } k \to \infty$$

so that using a triangle inequality and the fact that $\widehat{u}_1|_\Gamma = \widehat{u}_2|_\Gamma$, we have

$$\|u_1^{(k)} - u_2^{(k)}\|_{0,\Gamma}^2 \to 0 \quad \text{as } k \to \infty. \tag{3.20}$$

We also have, for every $k \ge 1$,

$$\begin{aligned} &u_1^{(k+1)} + u_2^{(k+1)} - g_1^{(k+1)} - g_2^{(k+1)} \\ &\quad = u_1^{(k+1)} + u_2^{(k+1)} - (1 - \delta_k)(g_1^{(k)} + g_2^{(k)}) - \delta_k (2u_1^{(k)} + 2u_2^{(k)} - g_1^{(k)} - g_2^{(k)}) \\ &\quad = u_1^{(k+1)} - u_1^{(k)} + u_2^{(k+1)} - u_2^{(k)} + (1 - 2\delta_k)(u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}) \end{aligned}$$

so that

$$\begin{aligned}&\|u_1^{(k+1)} + u_2^{(k+1)} - g_1^{(k+1)} - g_2^{(k+1)}\|_{0,\Gamma}^2\\ &\le \|u_1^{(k+1)} - u_1^{(k)}\|_{0,\Gamma}^2 + \|u_2^{(k+1)} - u_2^{(k)}\|_{0,\Gamma}^2 + |1-2\delta_k|\,\|u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}\|_{0,\Gamma}^2 .\end{aligned}$$

Thus, by setting

$$\begin{aligned}&r_k = |1-2\delta_k|, \quad a_k = \|u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}\|_{0,\Gamma}^2,\\ &\text{and} \quad b_k = \|u_1^{(k+1)} - u_1^{(k)}\|_{0,\Gamma}^2 + \|u_2^{(k+1)} - u_2^{(k)}\|_{0,\Gamma}^2 ,\end{aligned}$$

we have $\lim_{k\to\infty} b_k = 0$,

$$a_{k+1} \le |1-2\delta_k|\, a_k + b_k\,, \quad 0 \le r_k \le r_{\max} \qquad \forall\, k,$$

where $r_{\max} \equiv \max\{|1-2\delta_{\min}|, |1-2\delta_{\max}|\}$. The fact that $(1-2\delta)^2 < 1$ for all $\delta \in (0,1)$ implies $r_{\max} < 1$. Also, by virtue of Theorem 3.9, $E^f(\mathbf{g}^{(k)})$ is a nonincreasing nonnegative sequence and is thus bounded. This in turn yields the boundedness of $\{a_k\}$. Hence an application of Lemma 3.11 yields

$$a_k = \|u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}\|_{0,\Gamma}^2 \to 0 \quad \text{as } k \to \infty. \tag{3.21}$$

Combining (3.20) and (3.21), we conclude $E^f(\mathbf{g}^{(k)}) \to 0$. □

Remark 3.13. If $\delta_k = 1$ for all k, it is well known [17] that $\|g_i^{(k)} - \widehat{g}_i\|_{H^{-\frac{1}{2}}(\Gamma)} \to 0$. Triangle inequalities and the fact that $\|\widehat{u}_1 + \widehat{u}_2 - \widehat{g}_1 - \widehat{g}_2\|_{-1/2,\Gamma}^2 = 0$ yield

$$\begin{aligned}&\|u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}\|_{-1/2,\Gamma}^2\\ &\quad\le \|u_1^{(k)} - \widehat{u}_1\|_{-1/2,\Gamma}^2 + \|u_2^{(k)} - \widehat{u}_2\|_{-1/2,\Gamma}^2 + \|\widehat{g}_1 - g_1^{(k)}\|_{-1/2,\Gamma}^2 + \|\widehat{g}_1 - g_1^{(k)}\|_{-1/2,\Gamma}^2\end{aligned}$$

so that $\|u_1^{(k)} + u_2^{(k)} - g_1^{(k)} - g_2^{(k)}\|_{-1/2,\Gamma}^2 \to 0$ as $k \to \infty$. However, this does not imply $E^f(\mathbf{g}^{(k)}) \to 0$ (the assumptions of Theorem 3.12 exclude the case $\delta_k = 1$).

Remark 3.14. The acceleration properties of the generalized methods can now be explained. First, if δ_k is chosen between 1 and the optimal $\delta_0(\mathbf{g}^{(k)})$, then Theorem 3.9 implies that at this step, the interface bias functional E^f descends faster with the generalized methods than with Lions' method. Second, the interface bias in Theorem 3.12 is measured by $\|u_1 - u_2\|_{0,\Gamma}^2 + \|u_1 + u_2 - g_1 - g_2\|_{0,\Gamma}^2$, whereas the interface bias for Lions' method can only be measured by $\|u_1 - u_2\|_{0,\Gamma}^2 + \|u_1 + u_2 - g_1 - g_2\|_{-1/2,\Gamma}^2$ (see Remark 3.13); hence when the interface bias is measured in the same norms (i.e., measured in terms of $\|u_1 - u_2\|_{0,\Gamma}^2 + \|u_1 + u_2 - g_1 - g_2\|_{-1/2,\Gamma}^2$), we expect the convergence for the generalized methods to be faster than that for Lions' method.

4. The finite element version of the generalized methods. The finite element version of the generalized methods can be analyzed in essentially the same way as the continuous version. We will state without proofs all results parallel to those of the continuous case. We will also establish mesh-dependent geometric convergence for the finite element version of the generalized methods.

We assume that Ω is a two-dimensional polygon or a three-dimensional polyhedron partitioned into two subdomains Ω_1 and Ω_2 as shown in Figure 2.1. Let $\mathcal{T}^h(\Omega)$ be a family of regular triangulations of Ω such that no element of the triangulations crosses the interface Γ. Let $X^h \subset H_0^1(\Omega)$ be a family of finite element spaces, and we set $X_i^h \subset X^h|_{\Omega_i}$ $(i = 1, 2)$ and

$$G^h = G_1^h \times G_2^h \equiv X_1^h|_\Gamma \times X_2^h|_\Gamma \,.$$

We assume X^h and X_i^h satisfy standard approximation properties [16].

The finite element version of the generalized method (2.17)–(2.18) is described as follows: choose initial guesses $g_1^{h,1} \in G_1^h$ and $g_2^{h,1} \in G_2^h$; for $k = 1, 2, 3, \ldots$, solve for $u_i^{h,k} \in X_i^h$ $(i = 1, 2)$ from

$$(4.1)\quad a_i[u_i^{h,k}, v_i^h] + \lambda^{-1}[u_i^{h,k}, v_i^h]_\Gamma = [f, v_i^h]_{\Omega_i} + \lambda^{-1}[g_i^{h,k}, v_i^h]_\Gamma \quad \forall\, v_i^h \in X_i^h,\ i = 1, 2,$$

and update

$$(4.2)\qquad \begin{aligned} g_1^{h,k+1} &= (1 - \delta_k) g_1^{h,k} + \delta_k (2u_2^{h,k} - g_2^{h,k}) \,, \\ g_2^{h,k+1} &= (1 - \delta_k) g_2^{h,k} + \delta_k (2u_1^{h,k} - g_1^{h,k}) \,. \end{aligned}$$

4.1. Solution operators for the discrete Robin boundary value problems. For given $f \in L^2(\Omega)$ and $\mathbf{g} = (g_1, g_2) \in \mathbf{L}^2(\Gamma)$, the discrete Robin-type boundary value problems on subdomains are defined as follows: seek a $u_i^h \in X_i^h$, $i = 1, 2$, such that

$$(4.3)\qquad a_i[u_i^h, v_i^h] + \lambda^{-1}[u_i^h, v_i^h]_\Gamma = [f, v_i^h]_{\Omega_i} + \lambda^{-1}[g_i, v_i^h]_\Gamma \qquad \forall\, v_i^h \in X_i^h.$$

For $i = 1, 2$ we denote by $S_{i,h}^f : L^2(\Gamma) \to X_i^h$ the solution operator for the discrete Robin boundary value problem (4.3); i.e., $u_i^h = S_{i,h}^f\, g_i$ for all $g_i \in L^2(\Gamma)$ if and only if u_i^h and g_i satisfy (4.3). We define the operator $S_h^f : \mathbf{L}^2(\Gamma) \to X_1^h \times X_2^h$ by $S_h^f \mathbf{g} = (S_{1,h}^f\, g_1, S_{2,h}^f\, g_2)$ for all $\mathbf{g} \in \mathbf{L}^2(\Gamma)$. If $f = 0$, we write S_h^0 in place of S_h^f.

We also denote by $T_h : L^2(\Omega) \to X_1^h \times X_2^h$ the solution operator for (4.3) with homogeneous Robin boundary condition; i.e., for every $f \in L^2(\Omega)$, $(u_1^h, u_2^h) = T_h f = (T_{1,h}\, f, T_{2,h}\, f)$ if and only if $(u_1^h, u_2^h) \in X_1^h \times X_2^h$ is the solution of

$$(4.4)\qquad a_i[u_i^h, v_i^h] + \lambda^{-1}[u_i^h, v_i^h]_\Gamma = [f, v_i^h]_{\Omega_i} \qquad \forall\, v_i^h \in X_i^h,\ i = 1, 2.$$

The operator T_h is obviously linear.

Lemma 4.1. *If* $\mathbf{g}, \widetilde{\mathbf{g}} \in \mathbf{L}^2(\Gamma)$ *and* c_1, c_2 *are constants, then*

(a) $S_h^0(c_1\mathbf{g} + c_2\widetilde{\mathbf{g}}) = c_1 S_h^0\mathbf{g} + c_2 S_h^0\widetilde{\mathbf{g}}$*;*

(b) $S_h^f = S_h^0 + T_h f$*;*

(c) $S_h^0(\mathbf{g} - \widetilde{\mathbf{g}}) = S_h^f\mathbf{g} - S_h^f\widetilde{\mathbf{g}}$.

4.2. The discrete Robin–Robin map and its basic properties. We define the finite element Robin–Robin map $R_h^f : G^h \to G^h$ as follows. For any $\mathbf{g}^h = (g_1^h, g_2^h) \in G^h$,

$$(4.5)\qquad R_h^f\mathbf{g}^h = (R_{1,h}^f\mathbf{g}^h, R_{2,h}^f\mathbf{g}^h) \equiv (2u_2^h|_\Gamma - g_2^h, 2u_1^h|_\Gamma - g_1^h),$$

where $u_i^h = S_{i,h}^f g_i^h$, $i = 1, 2$. If $f = 0$, we write R_h^0 in place of R_h^f.

We denote by $\widehat{u}^h \in X^h$ the unique finite element solution of the discrete elliptic problem, i.e.,

$$(4.6)\qquad a[\widehat{u}^h, v^h] = [f, v^h]_\Omega \qquad \forall\, v^h \in X^h\,.$$

Then we have

$$a_i[\widehat{u}^h, v_i^h] = [f, v_i^h]_{\Omega_i} \qquad \forall\, v_i^h \in X_i^h \cap H_0^1(\Omega_i)\,.$$

The results of [29] allow us to find a $\widehat{t}_i^h \in G_i^h = X_i^h|_\Gamma$ such that

$$a_i[\widehat{u}^h, v_i^h] = [f, v_i^h]_\Omega + [\widehat{t}_i^h, v_i^h]_\Gamma \qquad \forall\, v_i^h \in X_i^h\,. \tag{4.7}$$

We define

$$\widehat{u}_i^h = \widehat{u}^h|_{\Omega_i}, \qquad \widehat{g}_i^h = \widehat{u}_i^h + \lambda \widehat{t}_i^h, \qquad i = 1, 2. \tag{4.8}$$

For an arbitrary $v^h \in X^h$, setting $v_i^h = v^h|_{\Omega_i}$ $(i = 1, 2)$ in (4.7) and adding the two equations, we obtain

$$a[\widehat{u}^h, v^h] = [f, v^h]_\Omega + [\widehat{t}_1^h + \widehat{t}_2^h, v^h]_\Gamma \qquad \forall\, v^h \in X^h\,.$$

A comparison of the last equation with (4.6) yields

$$[\widehat{t}_1^h + \widehat{t}_2^h, v^h]_\Gamma = 0 \qquad \forall\, v^h \in X^h$$

so that

$$\widehat{t}_1^h + \widehat{t}_2^h = 0\,. \tag{4.9}$$

Of course, we have

$$\widehat{u}_1^h|_\Gamma = \widehat{u}_2^h|_\Gamma\,. \tag{4.10}$$

Also, (4.7) and (4.8) imply

$$a_i[\widehat{u}_i^h, v_i^h] + \lambda^{-1}[\widehat{u}_i^h, v_i^h]_\Gamma = [f, v_i^h]_{\Omega_i} + \lambda^{-1}[\widehat{g}_i^h, v_i^h]_\Gamma \qquad \forall\, v_i^h \in X_i^h\,,\ i = 1, 2\,. \tag{4.11}$$

Lemma 4.2. *$\mathbf{g}^h \in G^h$ satisfies $R_h^f \mathbf{g}^h = \mathbf{g}^h$ if and only if $\mathbf{g}^h = \widehat{\mathbf{g}}^h$.*

We easily see that R_h^f and R_h^0 satisfy the following relations:

$$R_h^0 \mathbf{g}^h = \Big(2(S_h^0 \mathbf{g}^h)|_\Gamma - \mathbf{g}^h\Big) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \tag{4.12}$$

and

$$\begin{aligned} R_h^f \mathbf{g}^h &= \Big(2(S_h^f \mathbf{g}^h)|_\Gamma - \mathbf{g}^h\Big) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \\ &= \Big(2(S_h^0 \mathbf{g}^h)|_\Gamma - \mathbf{g}^h + 2(T_h f)|_\Gamma\Big) \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = R_h^0 \mathbf{g}^h + 2(T_h f)|_\Gamma \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \end{aligned} \tag{4.13}$$

Relations (4.12)–(4.13) and Lemma 4.1 trivially yield the following.

Lemma 4.3. *If $\mathbf{g}^h, \widetilde{\mathbf{g}}^h \in G^h$ and c_1, c_2 are constants, then*

(a) $R_h^0(\mathbf{g}^h - \widetilde{\mathbf{g}}^h) = R_h^f \mathbf{g}^h - R_h^f \widetilde{\mathbf{g}}^h$;

(b) $R_h^0(\mathbf{g}^h - \widehat{\mathbf{g}}^h) = R_h^f \mathbf{g}^h - \widehat{\mathbf{g}}^h$;

(c) $R_h^0(c_1 \mathbf{g}^h + c_2 \widetilde{\mathbf{g}}^h) = c_1 R_h^0 \mathbf{g}^h + c_2 R_h^0 \widetilde{\mathbf{g}}^h$.

Proposition 4.4. *Let $\mathbf{g}^h = (g_1^h, g_2^h) \in G^h$ and $u_i^h = S_{i,h}^f\, g_i^h$. Then*

$$\|R_h^f \mathbf{g}^h\|_{0,\Gamma}^2 = \|\mathbf{g}^h\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^{2} \Big(a_i[u_i^h, u_i^h] - [f, u_i^h]_{\Omega_i}\Big).$$

In particular, if $f = 0$, then

$$\|R^0 \mathbf{g}^h\|_{0,\Gamma}^2 = \|\mathbf{g}^h\|_{0,\Gamma}^2 - 4\lambda \sum_{i=1}^{2} a_i[S_{i,h}^0\, g_i^h, S_{i,h}^0\, g_i^h]\,.$$

4.3. A discrete interface bias functional and a descent direction. We define the interface bias functional $E_h^f(\mathbf{g}^h)$ associated with discrete subdomain Robin-type boundary value problem (4.3) by

$$E_h^f(\mathbf{g}^h) = \frac{1}{2}\int_\Gamma \Big(|u_1^h - u_2^h|^2 + |u_1^h + u_2^h - g_1^h - g_2^h|^2\Big), \tag{4.14}$$

where $(u_1^h, u_2^h) = S_h^f \mathbf{g}^h$.

The minimum value 0 of E_h^f is uniquely attained at $\widehat{\mathbf{g}}^h$ which is defined in (4.8). It is easily verified that the generalized method (4.1)–(4.2) can be simply expressed by

$$\begin{cases} \mathbf{g}^{h,1} \text{ given,} \\ \mathbf{g}^{h,k+1} = \mathbf{g}^{h,k} + \delta_k(R_h^f \mathbf{g}^{h,k} - \mathbf{g}^{h,k}), \quad k = 1,2,3,\dots. \end{cases} \tag{4.15}$$

We may show that $R_h^f \mathbf{g}^h - \mathbf{g}^h$ provides a descent direction for E_h^f at any $\mathbf{g}^h$ so that the generalized method (4.15) is a descent-direction method for solving the following minimization problem:

$$\min_{\mathbf{g}^h \in G^h} E_h^f(\mathbf{g}^h) \text{ subject to (4.3)}, \ i = 1, 2. \tag{4.16}$$

The following identities hold.

Proposition 4.5. *Let* $\mathbf{g}^h = (g_1^h, g_2^h) \in G^h$. *Then*

$$\text{(a)} \quad E_h^f(\mathbf{g}^h) = \frac{1}{4}\|\mathbf{g}^h - R_h^f \mathbf{g}^h\|_{0,\Gamma}^2 \equiv \frac{1}{4}\int_\Gamma \Big(|g_1^h - R_{1,h}^f\, \mathbf{g}^h|^2 + |g_2^h - R_{2,h}^f\, \mathbf{g}^h|^2\Big)$$

and

$$\text{(b)} \ E_h^f(R_h^f \mathbf{g}^h) = E_h^f(\mathbf{g}^h) - 4\lambda \sum_{i=1}^2 a_i[S_{i,h}^f(g_i^h) - S_{i,h}^f(R_{i,h}^f\, \mathbf{g}^h), S_{i,h}^f(g_i^h) - S_{i,h}^f(R_{i,h}^f\, \mathbf{g}^h)]\,.$$

Proposition 4.6. *Let* $\mathbf{g}^h \in G^h$. *Then* $\Lambda_h(\mathbf{g}^h) \equiv \|\mathbf{g}^h - 2R_h^f \mathbf{g}^h + R_h^f R_h^f \mathbf{g}^h)\|_{0,\Gamma}^2 = 0$ *if and only if* $\mathbf{g}^h = \widehat{\mathbf{g}}^h$.

Corollary 4.7. *Let* $\mathbf{g}^h \in G^h$. *The following statements are equivalent:*

(i) $\Lambda_h(\mathbf{g})^h = 0$;

(ii) $\mathbf{g}^h = \widehat{\mathbf{g}}$;

(iii) $\mathbf{g}^h = R_h^f \mathbf{g}$;

(iv) $E_h^f \mathbf{g}^h = 0$;

(v) $E_h^f(\mathbf{g}^h) = E_h^f(R_h^f \mathbf{g}^h)$.

As a consequence of Proposition 4.5 and Corollary 4.7, we have the following.

Corollary 4.8. $E_h^f(R_h^f \mathbf{g}^h) < E_h^f(\mathbf{g}^h)$ *whenever* $\mathbf{g}^h \in G^h$ *and* $\mathbf{g}^h \neq \widehat{\mathbf{g}}^h$.

The main result of this subsection is the following theorem concerning the optimal step length in the descent direction.

Theorem 4.9. *Assume* $\mathbf{g}^h \in G^h$ *and* $\Lambda_h(\mathbf{g}^h) \equiv \|\mathbf{g}^h - 2R_h^f \mathbf{g}^h + R_h^f R_h^f \mathbf{g}^h)\|_{0,\Gamma}^2 \neq 0$. *Then there is a* $\delta_0^h = \delta_0^h(\mathbf{g}^h) \geq 1/2$ *such that*

$$E_h^f(\mathbf{g}^h) > E_h^f(\mathbf{g}^h + \delta(R_h^f \mathbf{g}^h - \mathbf{g}^h)) \qquad \forall\, \delta \in (0, 2\delta_0^h).$$

Moreover, $E_h^f(\mathbf{g}^h + \delta(R_h^f \mathbf{g}^h - \mathbf{g}^h))$ *as a function of* δ *is strictly decreasing on* $[0, \delta_0^h]$ *and strictly increasing on* $[\delta_0^h, 2\delta_0^h]$.

4.4. Convergence of the discrete version of the generalized method. Recall that the discrete version of the generalized method (4.1)–(4.2) can be expressed by (4.15). By virtue of Theorem 4.9 the generalized method (4.15) is a descent-direction method for solving the discrete minimization problem (4.16).

We have the following convergence result for iterations (4.15).

THEOREM 4.10. *Assume that* $\mathbf{g}^{h,1} \in G^h$ *and* $\{\delta_k\} \subset [\delta_{\min}, 1] \subset (0,1]$. *Let* $\{\mathbf{g}^{h,k}\}_{k=2}^{\infty}$ *be defined by* (4.15) *and* $(u_1^{h,k}, u_2^{h,k}) = S_h^f \mathbf{g}^{h,k}$, $k = 1,2,3,\ldots$. *Then*

$$\|u_i^{h,k} - \widehat{u}_i^h\|_{1,\Omega_i} \to 0 \quad \textit{as } k \to \infty,\ i = 1,2.$$

THEOREM 4.11. *Assume that* $\{\delta_k\} \subset [\delta_{\min}, \delta_{\max}] \subset (0,1)$ *and* $\mathbf{g}^{h,1} \in G^h$. *Let* $\{\mathbf{g}^{h,k}\}_{k=2}^{\infty}$ *be defined by* (4.15) *and* $(u_1^{h,k}, u_2^{h,k}) = S_h^f \mathbf{g}^{h,k}$, $k = 1,2,3,\ldots$. *Then* $E_h^f(\mathbf{g}^{h,k}) \to 0$ *as* $k \to \infty$.

To conclude this finite element section, we prove the geometric convergence for algorithm (4.15).

THEOREM 4.12. *Assume that* $\{\delta_k\} \subset [\delta_{\min}, \delta_{\max}] \subset (0,1]$ *and* $\mathbf{g}^{h,1} \in G^h$. *Let* $\{\mathbf{g}^{h,k}\}_{k=2}^{\infty}$ *be defined by* (4.15), $k = 1,2,3,\ldots$. *Then* $\|\mathbf{g}^{h,k} - \widehat{\mathbf{g}}^h\|_{0,\Gamma} \to 0$ *geometrically as* $k \to \infty$.

Proof. Mimicking the proof of Theorem 3.10 in the finite element context, we have

$$(4.17)\qquad \|\mathbf{g}^{h,k+1} - \widehat{\mathbf{g}}^h\|_{0,\Gamma}^2 = \|\mathbf{g}^{h,k} - \widehat{\mathbf{g}}^h\|_{0,\Gamma}^2 - 4\lambda\delta_{\min} \sum_{i=1}^{2} a_i[u_i^{h,k} - \widehat{u}_i^h, u_i^{h,k} - \widehat{u}_i^h]\,.$$

Invoking [29, Lemma 11] (see also [1]), we may find a $\widetilde{v}_i^h \in X_i^h$ such that

$$\widetilde{v}_i^h|_\Gamma = g_i^{h,k} - \widehat{g}_i^h \quad \text{and} \quad \|\widetilde{v}_i^h\|_{1,\Omega_i} \le C\|g_i^{h,k} - \widehat{g}_i^h\|_{1/2,\Gamma}\,.$$

Subtracting (4.3) from (4.11), setting $v_i^h = \widetilde{v}_i^h$, and then using the Poincaré inequality, trace theorems, and inverse inequalities, we deduce that

$$\begin{aligned}\|g_i^{h,k} - \widehat{g}_i^h\|_{0,\Gamma}^2 &= a_i[u_i^h - \widehat{u}_i^h, \widetilde{v}_i^h] + \lambda^{-1}[u_i^h - \widehat{u}_i^h, \widetilde{v}_i^h]_\Gamma \\ &\le C\|u_i^h - \widehat{u}_i^h\|_{1,\Omega_i}\|\widetilde{v}_i^h\|_{1,\Omega_i} \le C\Big(a_i[u_i^h - \widehat{u}_i^h, u_i^h - \widehat{u}_i^h]\Big)^{1/2}\|g_i^{h,k} - \widehat{g}_i^h\|_{1/2,\Gamma} \\ &\le Ch^{-1/2}\Big(a_i[u_i^h - \widehat{u}_i^h, u_i^h - \widehat{u}_i^h]\Big)^{1/2}\|g_i^{h,k} - \widehat{g}_i^h\|_{0,\Gamma}, \qquad i = 1,2\,.\end{aligned}$$

This leads to

$$(4.18)\qquad a_i[u_i^h - \widehat{u}_i^h, u_i^h - \widehat{u}_i^h] \ge Ch\|g_i^{h,k} - \widehat{g}_i^h\|_{0,\Gamma}^2, \qquad i = 1,2\,.$$

We choose a $\widetilde{\delta} \in (0, \delta_{\min}]$ such that $0 < 1 - 8\lambda C\widetilde{\delta}h < 1$, where C is the constant in (4.18). Combining (4.18) with (4.17), we obtain

$$\|\mathbf{g}^{h,k+1} - \widehat{\mathbf{g}}^h\|_{0,\Gamma}^2 \le (1 - 8\lambda C\delta_{\min}h)\|\mathbf{g}^{h,k} - \widehat{\mathbf{g}}^h\|_{0,\Gamma}^2 \le (1 - 8\lambda C\widetilde{\delta}h)\|\mathbf{g}^{h,k} - \widehat{\mathbf{g}}^h\|_{0,\Gamma}^2\,.$$

Hence $\|\mathbf{g}^{h,k} - \widehat{\mathbf{g}}^h\|_{0,\Gamma} \to 0$ geometrically as $k \to \infty$. □

5. Algorithms and numerical experiments. The generalized method was put into the concise form (3.16), which can be rewritten as

$$(5.1)\qquad \begin{cases} \mathbf{g}^{(1)} \text{ given,} \\ \mathbf{g}^{(k+1)} = (1 - \delta_k)\mathbf{g}^{(k)} + \delta_k R^f \mathbf{g}^{(k)}, \qquad k = 1,2,3,\ldots. \end{cases}$$

According to Theorem 3.9, at the kth iteration step with a known $\mathbf{g}^{(k)}$, the choice of step length $\delta_k = \delta_0(\mathbf{g}^{(k)})$ defined by (3.19) will lead to maximum descent in the descent direction $(R^f\mathbf{g}^{(k)} - \mathbf{g}^{(k)})$. Algorithm I given below will be based on such choices of locally optimal step lengths. Here we give only the continuous version of the algorithm. The corresponding discrete version is obvious.

ALGORITHM I (locally optimal step lengths).

```
specify $(g_1^{(1)}, g_2^{(1)}) \in \mathbf{L}^2(\Gamma)$;
for $k = 1, 2, \dots,$
        – solve for $(u_1^{(k)}, u_2^{(k)}) \in X_1 \times X_2$ from
            $a_i[u_i^{(k)}, v_i] + \lambda^{-1}[u_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + [g_i^{(k)}, v_i]_\Gamma \quad \forall\, v_i \in X_i\,,\ i = 1, 2;$
        – set $(\widetilde{g}_1^{(k)}, \widetilde{g}_2^{(k)}) = (2u_2^{(k)} - g_2^{(k)}, 2u_1^{(k)} - g_1^{(k)})$ on $\Gamma$;
        – solve for $(\widetilde{u}_1^{(k)}, \widetilde{u}_2^{(k)}) \in X_1 \times X_2$ from
            $a_i[\widetilde{u}_i^{(k)}, v_i] + \lambda^{-1}[\widetilde{u}_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + [\widetilde{g}_i^{(k)}, v_i]_\Gamma \quad \forall\, v_i \in X_i\,,\ i = 1, 2;$
        – set $(\widetilde{\widetilde{g}}_1^{(k)}, \widetilde{\widetilde{g}}_2^{(k)}) = (2\widetilde{u}_2^{(k)} - \widetilde{g}_2^{(k)}, 2\widetilde{u}_1^{(k)} - \widetilde{g}_1^{(k)})$ on $\Gamma$;
        – calculate
            $\delta_k = \dfrac{[\mathbf{g}^{(k)} - \widetilde{\mathbf{g}}^{(k)}, \mathbf{g}^{(k)} - 2\widetilde{\mathbf{g}}^{(k)} + \widetilde{\widetilde{\mathbf{g}}}^{(k)}]_\Gamma}{\|\mathbf{g}^{(k)} - 2\widetilde{\mathbf{g}}^{(k)} + \widetilde{\widetilde{\mathbf{g}}}^{(k)}\|_{0,\Gamma}^2}\,;$
        – set $(g_1^{(k+1)}, g_2^{(k+1)}) = \delta_k(\widetilde{g}_1^{(k)}, \widetilde{g}_2^{(k)}) + (1 - \delta_k)(g_1^{(k)}, g_2^{(k)})$ on $\Gamma$;
end for
```

Remark 5.1. In Algorithm I the $\widetilde{\widetilde{\mathbf{g}}}^{(k)}$ step is an additional Lions' step, and it is performed purely for the purpose of calculating the optimal step length δ_k.

In Algorithm II below a fixed step length δ is used. In general, one should choose a $\delta \in [1/2, 1)$ since the optimal step lengths are always greater than or equal to 1/2. In the absence of any further guidance as to a good choice of a constant δ, we suggest using the golden ratio constant $(\sqrt{5} - 1)/2 \approx 0.618$. Again, we describe only the continuous version of the algorithm.

ALGORITHM II (fixed step length δ).

```
specify $(g_1^{(1)}, g_2^{(1)}) \in \mathbf{L}^2(\Gamma)$;
for $k = 1, 2, \dots,$
        – solve for $(u_1^{(k)}, u_2^{(k)}) \in X_1 \times X_2$ from
            $a_i[u_i^{(k)}, v_i] + \lambda^{-1}[u_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + [g_i^{(k)}, v_i]_\Gamma \quad \forall\, v_i \in X_i\,,\ i = 1, 2;$
        – set $(g_1^{(k+1)}, g_2^{(k+1)}) = \delta(2u_2^{(k)} - g_2^{(k)}, 2u_1^{(k)} - g_1^{(k)}) + (1 - \delta)(g_1^{(k)}, g_2^{(k)})$ on
          $\Gamma$;
end for
```

Stopping criteria. Based on Corollary 3.7, we may use one or more of the following as stopping criteria for Algorithms I and II:

$$\|\mathbf{g}^{(k+1)} - \mathbf{g}^{(k)}\|_{0,\Gamma}^2 < \text{tol}; \qquad E^f(\mathbf{g}^{(k)}) - E^f(R^f\mathbf{g}^{(k)}) < \text{tol};$$

$$E^f(\mathbf{g}^{(k)}) < \text{tol}; \qquad \|R^f\mathbf{g}^{(k)} - \mathbf{g}^{(k)}\|_{0,\Gamma}^2 < \text{tol}.$$

Computational results. In Remark 3.14 we explained that we expect the generalized methods with suitable choices of step lengths $\{\delta_k\}$ to converge faster than

Lions' method. We will demonstrate numerically that this is indeed the case. We implemented both Algorithms I and II for the boundary value problem

$$-\Delta u = f \quad \text{in } \Omega\,, \qquad u|_{\partial\Omega} = 0\,.$$

The following three examples were used in our numerical testing.

Example 1. An example with a known exact solution (from [30]):

$$\begin{aligned}&\Omega = (0,2)\times(0,1), \quad \Omega_1 = (0,1)\times(0,1), \quad \Omega_2 = (1,2)\times(0,1),\\ &f = \Delta[(x-2)y(\sin x)\cos(\pi y/2)], \quad \mathbf{g}^{(1)} = (1,1),\\ &16\times 16 \text{ grids for each } \Omega_i,\ i=1,2.\end{aligned}$$

Example 2. An example with a known exact solution having multiple humps:

$$\begin{aligned}&\Omega = (0,2)\times(0,1), \quad \Omega_1 = (0,1)\times(0,1), \quad \Omega_2 = (1,2)\times(0,1),\\ &f = -\Delta[(x-2)y(\sin 2\pi x)\cos(3\pi y/2)], \quad \mathbf{g}^{(1)} = (1,1),\\ &32\times 32 \text{ grids for each } \Omega_i,\ i=1,2.\end{aligned}$$

Example 3. An example with generic choices of f and initial guesses:

$$\begin{aligned}&\Omega = (0,2)\times(0,1), \quad \Omega_1 = (0,1)\times(0,1), \quad \Omega_2 = (1,2)\times(0,1),\\ &f = x^2+y^2+\sin(\pi xy), \quad \mathbf{g}^{(1)} = (2,3),\\ &16\times 16 \text{ grids for each } \Omega_i,\ i=1,2.\end{aligned}$$

For each example we implemented Algorithms I and II with a number of choices of fixed step lengths δ. We used $E_h^f(\mathbf{g}^{h,k}) <$ tol as the stopping criterion. The calculation of $E_h^f(\mathbf{g}^{(k)})$ involved integrals on Γ which were approximated by composite Simpson rules. Also, we choose $\lambda = 1$ in all examples. For each example and for each algorithm (Algorithms I and II with different choices of δ), the computed values of the interface bias $E_h(k) \equiv E_h^f(\mathbf{g}^{h,k})$ for iterations 1 through 5 are given in Tables 5.1–5.3. The optimal step lengths for Examples 1–3, which were calculated in the implementations of Algorithm I, are given in Table 5.4. To illustrate graphically the convergence acceleration of the generalized methods compared to Lions' method, we plot in Figure 5.1 the curves $E_h(k)$ for Algorithm II with $\delta = 1$ (the Lions' method) and Algorithm I (optimal δ_k).

Dependence on mesh sizes and initial guesses. Our computation results suggest that the iterative reduction in $E^f(\mathbf{g}^{(k)})$ for Algorithm I (optimal step lengths) is essentially unaffected by mesh refinements, whereas the reduction in $E^f(\mathbf{g}^{(k)})$ for Lions' original method (i.e., $\delta_k = 1$) markedly slowed down as the mesh was refined; computational results with different mesh sizes for Examples 1 and 2 are plotted in Figure 5.2. See [31] for more computational examples. Also, the performance of Algorithm I is less sensitive to choices of initial guesses than that of Lions' original algorithm. See [31] for further illustrations.

Comparison with gradient methods. For comparison we derive below the gradient method for minimizing the particular interface functional (3.15) subject to the subdomain Robin boundary value problems (3.2). We introduce Lagrange multipliers ξ_i $(i = 1,2)$ and form the Lagrangian functional

$$\begin{aligned}\mathcal{L}(g_1,g_2,u_1,u_2,\xi_1,\xi_2) &= \frac{1}{2}\int_\Gamma |u_1-u_2|^2 + \frac{1}{2}\int_\Gamma |u_1+u_2-g_1-g_2|^2\\ &\quad - \sum_{i=1}^{2}\Big(a_i[u_i,\xi_i] + \lambda^{-1}[u_i,\xi_i]_\Gamma - [f,\xi_i]_{\Omega_i} - \lambda^{-1}[g_i,\xi_i]_\Gamma\Big)\,.\end{aligned}$$

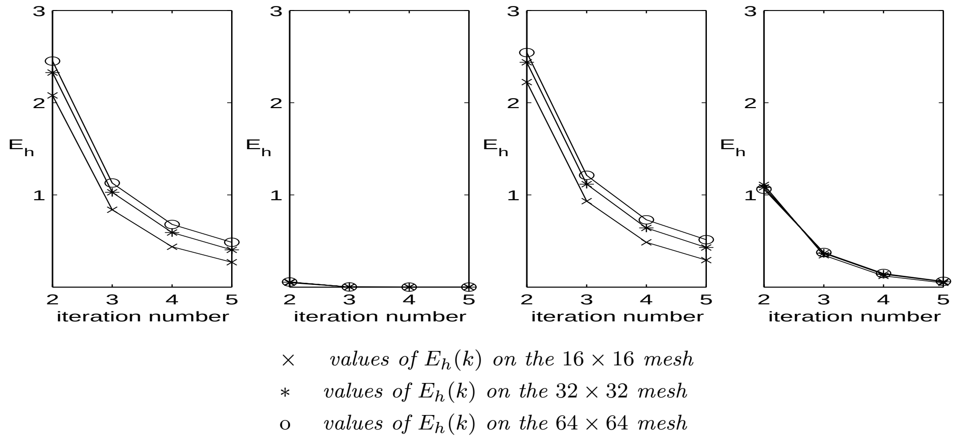

FIG. 5.2. *$E_h(k)$ curves for Examples* 1–2 *by Lions' method and Algorithm* I *on three different meshes. First plot from left: Example* 1*, Lions' method; second from left: Example* 1*, Algorithm* I; *third plot from left: Example* 2*, Lions' method; fourth from left: Example* 2*, Algorithm* I.

Taking variations of the Lagrangian $\mathcal{L}$ with respect to u_1 and u_2, respectively, we obtain

$$a_1[\xi_1, w_1] + \lambda^{-1}[\xi_1, w_1]_\Gamma = [2u_1 - g_1 - g_2, w_1]_\Gamma \qquad \forall\, w_1 \in X_1 \tag{5.2}$$

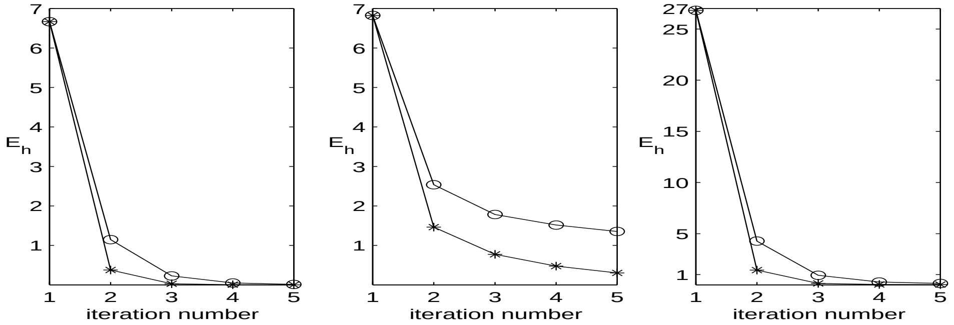
and

$$a_2[\xi_2, w_2] + \lambda^{-1}[\xi_2, w_2]_\Gamma = [2u_2 - g_1 - g_2, w_2]_\Gamma \qquad \forall\, w_2 \in X_2\,. \tag{5.3}$$

By taking variations of the Lagrangian $\mathcal{L}$ with respect to g_1 and g_2, respectively, we obtain the Frechét derivative of $E^f(g_1, g_2)$:

$$\begin{aligned}\langle (E^f)'(g_1, g_2), (z_1, z_2)\rangle = &- [u_1 + u_2 - g_1 - g_2, z_1]_\Gamma - [u_1 + u_2 - g_1 - g_2, z_2]_\Gamma \\ &+ \lambda^{-1}[z_1, \xi_1]_\Gamma + \lambda^{-1}[z_2, \xi_2]_\Gamma \qquad \forall\,(z_1, z_2) \in \mathbf{L}^2(\Gamma)\,,\end{aligned}$$

i.e., $(E^f)'(g_1, g_2) = (\lambda^{-1}\xi_1 - u_1 - u_2 + g_1 + g_2, \lambda^{-1}\xi_2 - u_1 - u_2 + g_1 + g_2)$, where ξ_1 and ξ_2 are defined by (5.2) and (5.3), respectively. Hence the kth step iteration formulae



o *values of* $E_h(k)$ *obtained by gradient method* ($\delta_k \equiv \delta = 0.5$)

$*$ *values of* $E_h(k)$ *obtained by Algorithm* II ($\delta = 0.5$)

FIG. 5.3. $E_h(k)$ *curves for Example* 1 *(left), Example* 2 *(center), and Example* 3 *(right).*

for the variable step length gradient method is given by

$$\begin{aligned}(g_1^{(k+1)}, g_2^{(k+1)}) &= (g_1^{(k)}, g_2^{(k)})\\ &\quad - \delta_k(\lambda^{-1}\xi_1^{(k)} - u_1^{(k)} - u_2^{(k)} + g_1^{(k)} + g_2^{(k)}, \lambda^{-1}\xi_2^{(k)} - u_1^{(k)} - u_2^{(k)} + g_1^{(k)} + g_2^{(k)}),\end{aligned}$$

where $u_i^{(k)}$, $i = 1, 2$, are defined by

$$a_i[u_i^{(k)}, v_i] + \lambda^{-1}[u_i^{(k)}, v_i]_\Gamma = [f, v_i]_{\Omega_i} + \lambda^{-1}[g_i^{(k)}, v_i]_\Gamma \qquad \forall\, v_i \in X_i\,,\ i = 1, 2\,,$$

and $\xi_i^{(k)}$, $i = 1, 2$, are defined by

$$a_i[\xi_i^{(k)}, w_i] + \lambda^{-1}[\xi_i^{(k)}, w_i]_\Gamma = [2u_i^{(k)} - g_1^{(k)} - g_2^{(k)}, w_i]_\Gamma \qquad \forall\, w_i \in X_i\,.$$

We implemented the gradient method with a fixed step length $\delta = 0.5$ for Examples 1–3. The results are plotted in Figure 5.3. For comparison, computational results for Algorithm II with a fixed step length $\delta = 0.5$ are also plotted in Figure 5.3.

Neumann boundary value problems. Algorithms I and II can be easily adapted to treat the case of a Neumann boundary value problem

$$-\text{div}\,[A(\mathbf{x})\nabla u] = f \quad \text{in } \Omega, \qquad [A(\mathbf{x})\nabla u]\cdot\mathbf{n} = d \quad \text{on } \partial\Omega\,,$$

where $f \in L^2(\Omega)$ and $d \in L^2(\partial\Omega)$. The results of sections 3 and 4 also can be carried over to this case with straightforward modifications, e.g., replacing $[f, v]$ by $[f, v] + [d, v]_{\partial\Omega}$ and $[f, v_i]_{\Omega_i}$ by $[f, v_i]_{\Omega_i} + [d, v_i]_{\Gamma_i}$.

Acknowledgment. The authors thank anonymous referees for various useful suggestions.

A FAST NUMERICAL METHOD FOR THE BLACK–SCHOLES EQUATION OF AMERICAN OPTIONS*

HOUDE HAN† AND XIAONAN WU‡

Abstract. This paper introduces a fast numerical method for computing American option pricing problems governed by the Black–Scholes equation. The treatment of the free boundary is based on some properties of the solution of the Black–Scholes equation. An artificial boundary condition is also used at the other end of the domain. The finite difference method is used to solve the resulting problem. Computational results are given for some American call option problems. The results show that the new treatment is very efficient and gives better accuracy than the normal finite difference method.

Key words. American option, free boundary, artificial boundary condition, finite difference method

DOI. 10.1137/S0036142901390238

1. Introduction.

In option pricing theory, the Black–Scholes equation is one of the effective models for option pricing [2]. For European options, the Black–Scholes equation results in a boundary value problem of a diffusion equation. For American options, the Black–Scholes equation results in a free boundary value problem. There are usually two ways to solve the option pricing problem—the analytic and numerical approaches. For European options, the analytic solution is relatively easier to obtain. For the analytic approach, efforts have been mainly on the American options. Johnson [16] and MacMillan [18] use analytical approximation for American puts on a nondividend paying stock. For American options on dividend paying stock, Geske and Johnson [10] give an analytic solution in a series form. When closed form solutions cannot be obtained, or when the formulas for the exact solutions are too difficult to be practically usable, numerical solution is a natural way to solve the problem. The binomial method is a simple and very effective method for solving American options; this is introduced by Cox, Ross, and Rubinstein [7], and the convergence of the binomial method for American options is proved by Amin and Khanna [1]. Brennan and Schwartz [3], [4] and Schwartz [19] introduced finite difference methods for solving American options. Jaillet, Lamberton, and Lapeyre [15] show the convergence of the finite difference method. A comparison of different numerical methods for option pricing can be found in [5], [11].

In solving the Black–Scholes equation for American options, a natural approach is to transform the original equation to a standard forward diffusion equation over an infinite domain. The finite difference method is applied to the equation over a truncated finite domain, and the original asymptotic infinite boundary conditions are shifted to the ends of the truncated finite domain. To avoid generating large errors

in the solution due to this approximation of the boundary conditions, the truncated domain must be large enough, which results in a large cost. Obviously, a large part of the finite difference solution is actually useless, and the reason to compute these is only to guarantee the accuracy of the rest of the solutions. Kangro and Nicolaides [17] give error estimates of the numerical solutions with far field boundary conditions. Artificial boundary conditions have been applied to different problems on infinite domains; see, for examples, [8], [12], [13], [14]. In this paper, we find the accurate boundary conditions on the far boundary for the American option problem, which is actually a relation between the function and its partial derivatives. Then this boundary condition is discretized and combined with the finite difference discretization for the partial differential equation. With these boundary conditions, we can make the computational domain small and obtain accurate solutions. For the free boundary, we give some properties of the solution of the Black–Scholes equations. Using these properties, we design a simple numerical method to determine the location of the free boundary. Some computational results are given for the American options with dividend paying, and the results are compared with approximations using standard finite difference methods.

The computational results show that these algorithms give more accurate numerical results than the standard finite difference approximation. With a relatively small truncated domain, the standard finite difference method usually cannot give satisfactory results. Our algorithms give more accurate numerical results, and the option price can be obtained for all the asset prices.

2. Some properties of the solution of the Black–Scholes equation. Assume that S is the asset price, t is the time, and C is the call option value. Let r denote the risk-free interest rate, let σ denote the volatility of the asset price, and let D_0 denote the continuous dividend yield. Then the call value of the American option is given by the free boundary value problem of the Black–Scholes equation [20],

$$\begin{aligned} &\frac{\partial C}{\partial t} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2 C}{\partial S^2} + (r - D_0)S\frac{\partial C}{\partial S} - rC = 0, \\ &0 < S < S_f(t), \qquad 0 \le t < T, \end{aligned} \tag{1}$$

where $S_f(t)$ is the free boundary of early exercise. The final and boundary conditions are given by

$$C(S,T) = h(S), \qquad 0 \le S \le S_f(T) = S_0, \tag{2}$$

$$C(S_f(t),t) = h(S_f(t)), \quad \frac{\partial C}{\partial S}(S_f(t),t) = 1, \qquad 0 \le t \le T, \tag{3}$$

$$C(S,t) \to 0 \quad \text{as} \quad S \to 0, \qquad 0 \le t \le T, \tag{4}$$

where $h(S) = \max(S - E, 0)$, with $E > 0$ and $S_0 = \max(E, rE/D_0)$.

We introduce the change of variable for t:

$$t = T - \frac{2\tau}{\sigma^2}.$$

Denote

$$\begin{aligned}&C^*(S,\tau)=C(S,t)=C(S,T-2\tau/\sigma^2),\\&S_f^*(\tau)=S_f(T-2\tau/\sigma^2),\\&r^*=\frac{2r}{\sigma^2},\\&D^*=\frac{2D_0}{\sigma^2},\\&\tau^*=\frac{\sigma^2T}{2}.\end{aligned}$$

Then the free boundary value problem (1)–(4) is equivalent to the following problem:

$$LC^*\equiv-\frac{\partial C^*}{\partial\tau}+S^2\frac{\partial^2C^*}{\partial S^2}+(r^*-D^*)S\frac{\partial C^*}{\partial S}-r^*C^*=0,\tag{5}$$
$$0<S<S_f^*(\tau),\qquad 0<\tau<\tau^*,$$
$$C^*(S,0)=h(S),\qquad 0\le S\le S_f^*(0),\tag{6}$$
$$C^*(S_f^*(\tau),\tau)=h(S_f^*(\tau)),\qquad\frac{\partial C^*}{\partial S}(S_f^*(\tau),\tau)=1,\qquad 0\le\tau\le\tau^*,\tag{7}$$
$$C^*(S,\tau)\to0\quad\text{as}\quad S\to0.\tag{8}$$

Let

$$\begin{aligned}&k'=r^*-D^*,\\&\alpha=\frac{-(k'-1)}{2},\qquad\beta=\frac{-(k'-1)^2}{4}-r^*.\end{aligned}$$

Furthermore, we introduce the change of variables

$$\begin{aligned}&S=Ee^x,\\&C^*(S,\tau)=Ee^{\alpha x+\beta\tau}u(x,\tau).\end{aligned}$$

Then the free boundary value problem (5)–(8) is equivalent to the following problem:

$$\frac{\partial u}{\partial\tau}=\frac{\partial^2u}{\partial x^2},\qquad-\infty<x<x_f(\tau),\tag{9}$$
$$u(x,0)=g(x,0),\qquad-\infty<x\le x_f(0),\tag{10}$$
$$u(x_f(\tau),\tau)=g(x_f(\tau),\tau),\ \alpha u(x_f(\tau),\tau)+\frac{\partial u(x_f(\tau),\tau)}{\partial x}\tag{11}$$
$$=e^{(1-\alpha)x_f(\tau)-\beta\tau},\ 0\le\tau\le\tau^*,$$
$$u(x,\tau)\to0\text{ as }x\to-\infty,\tag{12}$$

where

$$g(x,\tau)=e^{-\alpha x-\beta\tau}\max(e^x-1,0).$$

The free boundary $x_f(\tau)=\ln(S_f^*(\tau)/E)$. It is known that $x_f(\tau)>0$ for $\tau>0$.

We now consider the problem (5)–(8). Let

$$W=\frac{\partial C^*(S,\tau)}{\partial S};$$

then W satisfies

$$\begin{gathered}-\frac{\partial W}{\partial \tau}+S^2\frac{\partial^2 W}{\partial S^2}+(2+r^*-D^*)S\frac{\partial W}{\partial S}-D^*W=0,\\ 0<S<S_f^*(\tau),\qquad 0<\tau\le\tau^*,\end{gathered}\tag{13}$$

$$W(S,0)=0,\qquad 0<S<E,\qquad \text{and } W(S,0)=1,\qquad E<S<S_f^*(0),\tag{14}$$

$$W(S_f^*(\tau),\tau)=1,\qquad 0<\tau\le\tau^*.\tag{15}$$

For $W(S,\tau)$, we have the following lemma.

Lemma 1.

$$W(S,\tau)=\frac{\partial C^*(S,\tau)}{\partial S}\to 0 \textit{ when } S\to 0^+.$$

Proof. Since

$$\begin{aligned}W(S,\tau)&=\frac{\partial C^*(S,\tau)}{\partial S}\\ &=\frac{\partial}{\partial S}\left(Ee^{\alpha x+\beta\tau}u(x,\tau)\right)\\ &=\frac{\partial}{\partial x}\left(Ee^{\alpha x+\beta\tau}u(x,\tau)\right)\frac{dx}{dS}\\ &=e^{(\alpha-1)x+\beta\tau}\left(\frac{\partial u(x,\tau)}{\partial x}+\alpha u(x,\tau)\right),\end{aligned}\tag{16}$$

where $u(x,\tau)$ satisfies (9)–(12), let $\phi(\tau)=u(0,\tau)$, $\phi(0)=0$, and then [6]

$$\begin{aligned}u(x,\tau)&=\frac{-x}{2\sqrt{\pi}}\int_0^\tau e^{-\frac{x^2}{4(\tau-\lambda)}}\frac{\phi(\lambda)d\lambda}{(\tau-\lambda)^{3/2}},\qquad x<0,\\ |u(x,\tau)|&\le\frac{|x|}{2\sqrt{\pi}}\Phi\int_0^\tau e^{-\frac{x^2}{4(\tau-\lambda)}}\frac{d\lambda}{(\tau-\lambda)^{3/2}}\\ &\le\frac{4\Phi}{\sqrt{\pi}}\int_0^\tau e^{-\frac{x^2}{8(\tau-\lambda)}}\frac{d\lambda}{\sqrt{\tau-\lambda}}\\ &=\frac{4\Phi}{\sqrt{\pi}}e^{-\frac{x^2}{8\tau}}\int_0^\tau e^{-\frac{x^2}{8}\left(\frac{1}{\tau-\lambda}-\frac{1}{\tau}\right)}\frac{d\lambda}{\sqrt{\tau-\lambda}}\\ &\le\frac{8\Phi}{\sqrt{\pi}}\sqrt{\tau}e^{-\frac{x^2}{8\tau}},\qquad x\le-1,\quad 0\le\tau\le\tau^*,\end{aligned}\tag{17}$$

where

$$\Phi=\max_{0\le\lambda\le\tau^*}|\phi(\lambda)|.$$

Similarly,

$$\left|\frac{\partial u(x,\tau)}{\partial x}\right|\le C_0\Phi\sqrt{\tau}e^{-\frac{x^2}{8\tau}},\qquad x\le-1,\quad 0\le\tau\le\tau^*,\tag{18}$$

where C_0 is a constant. Combining (16)–(18), we obtain

$$\lim_{S\to 0^+}W(S,\tau)=\lim_{S\to 0^+}\frac{\partial C^*(S,\tau)}{\partial S}=0.\qquad\square\tag{19}$$

Finally, we know that $W(S,\tau)$ is the solution of problem (13)–(15) and (19). By the strong maximum principle of the parabolic equation [9] we have the following theorem.

THEOREM 1. *$W(S,\tau)$ satisfies the following inequality:*

$$0 < W(S,\tau) < 1, \quad 0 < S < S_f^*(\tau), \quad 0 < \tau \le \tau^*.$$

Namely,

$$0 < \frac{\partial C^*(S,\tau)}{\partial S} < 1, \quad 0 < S < S_f^*(\tau), \quad 0 < \tau \le \tau^*,$$

and

$$0 < e^{(\alpha-1)x+\beta\tau}\left(\frac{\partial u(x,\tau)}{\partial x} + \alpha u(x,\tau)\right) < 1, \quad 0 < x < x_f(\tau), \quad 0 < \tau \le \tau^*. \tag{20}$$

For the solution $\{C^*(S,\tau), S_f^*(\tau)\}$ of the problem (5)–(8), we extend $C^*(S,\tau)$ to the domain

$$S_f^*(\tau) < S < +\infty, \quad 0 \le \tau \le \tau^*,$$

by

$$C^*(S,\tau) = h(S), \quad S_f^*(\tau) < S < +\infty, \quad 0 \le \tau \le \tau^*.$$

For a given smooth boundary $S = \hat{S}(\tau)$ and a given τ_j, $0 < \tau_j < \tau^*$, satisfying

$$S_f^*(\tau) < \hat{S}(\tau), \quad \tau_j < \tau \le \tau^*,$$

consider the following auxiliary problem:

$$L\hat{C}(S,\tau) = 0, \quad 0 < S < \hat{S}(\tau), \quad \tau_j < \tau \le \tau^*, \tag{21}$$

$$\hat{C}(S,\tau) \to 0, \quad S \to 0, \tag{22}$$

$$\hat{C}(\hat{S}(\tau),\tau) = h(\hat{S}(\tau)), \quad \tau_j < \tau \le \tau^*, \tag{23}$$

$$\hat{C}(S,\tau_j) = C^*(S,\tau_j), \quad 0 \le S \le \hat{S}(\tau_j). \tag{24}$$

Problem (21)–(24) has a solution $\hat{C}(S,\tau)$ on

$$\Omega = \{(S,\tau) \mid 0 < S < \hat{S}(\tau),\ \tau_j \le \tau \le \tau^*\}.$$

Let

$$\varepsilon(S,\tau) = C^*(S,\tau) - \hat{C}(S,\tau).$$

A computation shows that

$$L\varepsilon(S,\tau) = \begin{cases} 0, & 0 < S < S_f^*(\tau),\ \tau_j < \tau \le \tau^*, \\ -D^*S + r^*E \le 0, & S_f^*(\tau) \le S \le \hat{S}(\tau),\ \tau_j < \tau \le \tau^*, \end{cases}$$

and

$$\frac{\partial \varepsilon(S,\tau)}{\partial S} \text{ is continuous on } S = S_f^*(\tau), \quad \tau_j < \tau \le \tau^*.$$

From the strong maximum principle we get

$$\varepsilon(S,\tau) > 0, \qquad 0 < S < \hat{S}(\tau), \quad \tau_j < \tau \le \tau^*.$$

When $S_f^*(\tau) < S < \hat{S}(\tau)$, we have

$$\varepsilon(S,\tau) = C^*(S,\tau) - \hat{C}(S,\tau) = h(S) - \hat{C}(S,\tau) > 0,$$

namely,

$$\hat{C}(S,\tau) < h(S), \qquad S_f^*(\tau) < S < \hat{S}(\tau), \quad \tau_j < \tau \le \tau^*. \tag{25}$$

Let

$$\hat{C}(S,\tau) = Ee^{\alpha x+\beta\tau}\hat{u}(x,\tau)$$

with $S = Ee^x$. Then the auxiliary problem (21)–(24) is equivalent to the problem

$$\frac{\partial \hat{u}}{\partial \tau} = \frac{\partial^2 \hat{u}}{\partial x^2}, \qquad -\infty < x < \hat{x}_f(\tau), \tag{26}$$

$$\hat{u}(x,0) = u(x,0), \qquad -\infty < x \le \hat{x}_f(\tau), \tag{27}$$

$$\hat{u}(\hat{x}_f(\tau),\tau) = g(\hat{x}_f(\tau),\tau), \tag{28}$$

$$\hat{u}(x,\tau) \to 0 \text{ as } x \to -\infty, \tag{29}$$

where $\hat{x}_f(\tau) = \ln(\hat{S}(\tau)/E) \ge x_f(\tau)$, $\tau_j < \tau \le \tau^*$.

From inequality (25) we obtain the following theorem.

THEOREM 2. *For the solution $\hat{u}(x,\tau)$ of the auxiliary problem* (26)–(29) *the following inequality holds:*

$$\hat{u}(x,\tau) < g(x,\tau), \qquad x_f(\tau) < x < \hat{x}_f(\tau), \quad \tau_j < \tau \le \tau^*. \tag{30}$$

The inequality (30) is very useful for determining the location of the free boundary in the numerical schemes.

3. An exact boundary condition on the artificial boundary. We now return to the problem (9)–(12), which is defined on an unknown unbounded domain $\bar{\Omega}$:

$$\bar{\Omega} = \{(x,\tau) \mid -\infty < x < x_f(\tau),\ 0 < \tau \le \tau^*\}.$$

It is known that the free boundary $x_f(\tau) > 0$, $0 < \tau \le \tau^*$. Let $a < 0$ be a real number. We introduce an artificial boundary Γ_a:

$$\Gamma_a = \{(x,\tau) \mid x = a,\ 0 < \tau \le \tau^*\}.$$

The artificial boundary Γ_a divides the domain Ω into two parts, the bounded part Ω_i and the unbounded part Ω_e:

$$\Omega_i = \{(x,\tau) \mid a < x < x_f(\tau),\ 0 < \tau \le \tau^*\},$$
$$\Omega_e = \{(x,\tau) \mid -\infty < x < a,\ 0 < \tau \le \tau^*\}.$$

If we can find a suitable boundary condition on the artificial boundary Γ_a, then the problem (9)–(12) can be reduced on the bounded domain Ω_i. On Ω_e, the solution of (9)–(12), $u(x,\tau)$, satisfies

$$\frac{\partial u}{\partial \tau} = \frac{\partial^2 u}{\partial x^2}, \qquad -\infty < x < a, \quad 0 < \tau \le \tau^*, \tag{31}$$

$$u(x,0) = 0, \qquad -\infty < x < a. \tag{32}$$

The problem (31)–(32) is an incompletely posed problem. If we know the value of $u(x,\tau)$ on the boundary Γ_a,

$$u(a,\tau) = \phi(\tau) \tag{33}$$

with $\phi(0)=0$, then the solution of (31)–(33) is given by [6]

$$u(x,\tau) = \frac{-(x-a)}{2\sqrt{\pi}} \int_0^\tau e^{\frac{-(x-a)^2}{4(\tau-\lambda)}} \frac{\phi(\lambda)d\lambda}{(\tau-\lambda)^{3/2}}. \tag{34}$$

Introducing the new variable

$$\mu = \frac{x-a}{2\sqrt{\tau-\lambda}},$$

we get

$$u(x,\tau) = \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\frac{x-a}{2\sqrt{\tau}}} \phi\left(\tau - \frac{(x-a)^2}{4\mu^2}\right) e^{-\mu^2} d\mu. \tag{35}$$

Then we have

$$\begin{aligned}
\frac{\partial u(x,\tau)}{\partial x} &= \frac{2}{\sqrt{\pi}}\phi(0)e^{-\frac{(x-a)^2}{4\tau}} \cdot \frac{1}{2\sqrt{\tau}} \\
&\quad + \frac{2}{\sqrt{\pi}} \int_{-\infty}^{\frac{x-a}{2\sqrt{\tau}}} \phi'\left(\tau - \frac{(x-a)^2}{4\mu^2}\right)\left(-\frac{x-a}{2\mu^2}\right) e^{-\mu^2} d\mu \\
&= -\frac{2}{\sqrt{\pi}} \int_{-\infty}^{\frac{x-a}{2\sqrt{\tau}}} \phi'\left(\tau - \frac{(x-a)^2}{4\mu^2}\right)\left(\frac{x-a}{2\mu^2}\right) e^{-\mu^2} d\mu \\
&= \frac{1}{\sqrt{\pi}} \int_0^\tau e^{-\frac{(x-a)^2}{4(\tau-\lambda)}} \frac{\phi'(\lambda)d\lambda}{\sqrt{\tau-\lambda}}, \quad x < a.
\end{aligned}$$

Thus we have

$$\left.\frac{\partial u}{\partial x}\right|_{x=a} = \frac{1}{\sqrt{\pi}} \int_0^\tau \frac{\partial u(a,\lambda)}{\partial \lambda} \frac{d\lambda}{\sqrt{t-\lambda}}. \tag{36}$$

The relationship in (36) is an exact boundary condition satisfied by $u(x,\tau)$, the solution of problem (9)–(12), on the artificial boundary Γ_a. By the exact boundary condition (36), the free boundary value problem for an American call option with dividend paying in an unbounded domain Ω is reduced to a problem in a bounded domain Ω_i:

$$\frac{\partial u}{\partial \tau} = \frac{\partial^2 u}{\partial x^2}, \qquad a < x < x_f(\tau), \quad 0 < \tau \le \tau^*, \tag{37}$$

$$u(x,0) = g(x,0), \qquad a < x < x_f(0), \tag{38}$$

$$u(x_f(\tau),\tau) = g(x_f(\tau),\tau), \qquad 0 < \tau \le \tau^*, \tag{39}$$

$$e^{(\alpha-1)x_f(\tau)+\beta\tau}\left[\frac{\partial u(x_f(\tau),\tau)}{\partial x} + \alpha u(x_f(\tau),\tau)\right] = 1, \qquad 0 \le \tau \le \tau^*, \tag{40}$$

$$\left.\frac{\partial u}{\partial x}\right|_{x=a} = \frac{1}{\sqrt{\pi}} \int_0^\tau \frac{\partial u(a,\lambda)}{\partial \lambda} \frac{d\lambda}{\sqrt{t-\lambda}}. \tag{41}$$

It is straightforward to check that the problem (9)–(12) is equivalent to the problem (37)–(41) in the following sense: If $\{u(x,\tau), x_f(\tau)\}$ is the solution of problem (9)–(12), then $\{u(x,\tau), x_f(\tau)\}$ is the solution of problem (37)–(41). If $\{u^*(x,\tau), x_f^*(\tau)\}$ is the solution of problem (37)–(41), let

$$\begin{aligned}
&x_f(\tau) = x_f^*(\tau),\\
&u(x,\tau) = \left\{ \begin{array}{cc} u^*(x,\tau), & a \le x \le x_f(\tau), \quad 0 \le \tau \le \tau^*,\\ -\frac{(x-a)}{2\sqrt{\pi}} \int_0^\tau \frac{u^*(a,\lambda)e^{-(x-a)^2/4(\tau-\lambda)}}{(\tau-\lambda)^{3/2}} d\lambda, & x < a, \quad 0 \le \tau \le \tau^*, \end{array} \right.
\end{aligned}$$

and then $\{u(x,\tau), x_f(\tau)\}$ is the solution of problem (9)–(12).

4. Finite difference approximation. In this section, we consider the numerical approximation of the problem (37)–(41). Let $\delta\tau$ and δx denote the step sizes of the finite difference approximation. Let $x_n = a + n\delta x$ and $\tau_m = m\delta\tau$, and denote the approximate solution of $u(x_n, \tau_m)$ by u_n^m. Using the Crank–Nicolson finite difference for (37), we get

$$\begin{aligned}
&\frac{u_n^m - u_n^{m-1}}{\delta\tau} = \frac{1}{2}\left(\frac{u_{n+1}^{m-1} - 2u_n^{m-1} + u_{n-1}^{m-1}}{(\delta x)^2} + \frac{u_{n+1}^m - 2u_n^m + u_{n-1}^m}{(\delta x)^2} \right),\\
&n = 1, 2, \ldots, \qquad m = 0, 1, \ldots.
\end{aligned}$$

Letting $\rho = \delta t/(\delta x)^2$, we have

$$(1+\rho)u_1^m - \frac{\rho}{2}u_2^m = b_1, \tag{42}$$

$$-\frac{\rho}{2}u_{n-1}^m + (1+\rho)u_n^m - \frac{\rho}{2}u_{n+1}^m = b_n, \qquad n = 2, 3, \ldots, \tag{43}$$

where

$$\begin{aligned}
b_1 &= \frac{\rho}{2}(u_0^{m-1} + u_2^{m-1}) + (1-\rho)u_1^{m-1} + \frac{\rho}{2}u_0^m,\\
b_n &= \frac{\rho}{2}(u_{n-1}^{m-1} + u_{n+1}^{m-1}) + (1-\rho)u_n^{m-1}, \qquad n = 2, 3, \ldots.
\end{aligned}$$

The solution u_n^m can be obtained as follows. Let $s_1 = 1 + \rho$ and $y_1 = b_1$; then we have

$$s_1 u_1^m - \frac{\rho}{2}u_2^m = y_1.$$

Solving for u_1^m and substituting into (43), we get

$$s_2 u_2^m - \frac{\rho}{2}u_2^m = y_2,$$

where

$$s_2 = 1 + \rho - \frac{\rho^2}{4s_1}, \qquad y_2 = b_2 + \frac{\rho y_1}{2s_1}.$$

In general, we have

$$s_n u_n^m - \frac{\rho}{3}u_{n+1}^m = y_n,$$

where

$$s_n = 1 + \rho - \frac{\rho^2}{4s_{n-1}}, \qquad y_n = b_n + \frac{\rho y_{n-1}}{2s_{n-1}}.$$

If the boundary condition

$$u^m_{N_e+1} = g_{N_e+1}$$

is given at certain point, then u^m_n, $n \leq N_e$, can be obtained by back substitution. From Theorems 1 and 2 we know that for a given τ the free boundary is the only point satisfying the partial differential equation and the condition

$$e^{(\alpha-1)x+\beta\tau}\left(\frac{\partial u(x,\tau)}{\partial x} + \alpha u(x,\tau)\right) = 1$$

or, equivalently,

$$\frac{\partial C(S,t)}{\partial S} = 1,$$

and if the boundary condition $u(x,\tau) = g(x,\tau)$ is given at $x > x_f(\tau)$, then $u(x,\tau) < g(x,\tau)$ will occur on the left of the boundary. Let N_e be the largest number such that

$$u^m_{N_e} \geq g_{N_e};$$

then we have

$$\begin{aligned} u^m_{N_e} &= \frac{1}{s_{N_e}}\left(b_{N_e} + \frac{\rho}{2}g_{N_e+1} + \frac{\rho y_{N_e-1}}{2s_{N_e-1}}\right), \\ u^m_n &= \frac{1}{s_n}\left(y_n + \frac{\rho}{2}u^m_{n+1}\right) \qquad \text{for } n = N_e-1, N_e-2, \ldots, 1. \end{aligned}$$

For the artificial boundary condition, since

$$\begin{aligned} \int_0^{\tau_m} \frac{\partial u(a,\lambda)}{\partial \lambda}\frac{d\lambda}{\sqrt{\tau_m-\lambda}} &= \sum_{j=1}^m \int_{\tau_{j-1}}^{\tau_j} \frac{\partial u(a,\lambda)}{\partial \lambda}\frac{d\lambda}{\sqrt{\tau_m-\lambda}} \\ &= \sum_{j=1}^m \frac{\partial u(a,\xi_j)}{\partial \tau}\int_{\tau_{j-1}}^{\tau_j} \frac{d\lambda}{\sqrt{\tau_m-\lambda}} \\ &= \sum_{j=1}^m \frac{2(\tau_j-\tau_{j-1})u_\tau(a,\xi_j)}{\sqrt{\tau_m-\tau_j}+\sqrt{\tau_m-\tau_{j-1}}}, \end{aligned}$$

equation (41) is approximated by

$$\frac{u^m_1 - u^m_{-1}}{2\delta x} = \frac{1}{\sqrt{\pi}}\sum_{j=1}^m \frac{2(u^j_0 - u^{j-1}_0)}{\sqrt{\tau_m-\tau_j}+\sqrt{\tau_m-\tau_{j-1}}}. \tag{44}$$

Approximating (37) at $x = a$, we get

$$\frac{u^m_0 - u^{m-1}_0}{\delta\tau} = \frac{u^m_1 - 2u^m_0 + u^m_{-1}}{(\delta x)^2}. \tag{45}$$

From (44) and (45) we obtain the boundary condition

$$u_0^m = \frac{\theta H_1 + \sqrt{\pi} H_2/4}{\theta + \sqrt{\pi}(1+2\theta^2)/4}, \tag{46}$$

where $\theta = \sqrt{\delta\tau}/\delta x$, $H_2 = u_0^{m-1} + \theta^2 u_1^m$, and

$$H_1 = u_0^{m-1} + \sqrt{\pi}\theta u_1^m/4 - \sum_{j=1}^{m-1} \frac{u_0^j - u_0^{j-1}}{\sqrt{m-j} + \sqrt{m-j+1}}.$$

Thus we have the following algorithm.

Algorithm.

At each time step, do the following:

1. Set up the linear system using the Crank–Nicolson finite difference method for $x \geq a$.
2. Combine the artificial boundary condition (46) and (42) to eliminate u_0^m.
3. Use the elimination for the linear system in the interval $[a, b]$. Move the right boundary b until the free boundary is found.
4. Use back substitution to find all solutions in $[a, b]$.

At the end τ^*, use (34) to find all solutions to the left of a.

5. Computational results.

To compare the above algorithm with the standard finite difference approximations, we computed two examples of call options. The second example was also computed by Broadie and Detemple [5]. The comparisons are based on the accuracy of the approximate option values and the total computation cost, i.e., the CPU time. Since the exact option values are unknown, we use the binomial method with large steps (15000) to find the option values. The results of the binomial method with large steps are considered very accurate. Thus we take these values as the exact option values for the purpose of comparison. All the algorithms are implemented using MATLAB for testing purposes, and the computations are carried out on an IBM RS/6000 43P Model 260 workstation.

In both examples, ABF stands for the numerical method given in the previous section, artificial boundary condition with free boundary treatment. FDP stands for the Crank–Nicolson finite difference approximation with projected SOR iteration to impose the free boundary condition. FDE stands for the Crank–Nicolson finite difference approximation with elimination-backsubstitution. In both FDP and FDE methods, the systems are set up in the interval $[x_m, x_p]$, where $x_m = a < 0$ and $x_p > x_f(\tau) > 0$ for all $\tau > 0$. The asymptotic boundary conditions are applied at both ends $x = x_m$ and $x = x_p$.

Example 1. Consider a six-month American call option with a dividend rate $D_0 = 0.03$. The exercise price is \$100, the risk-free interest rate is $r = 0.03$, and the volatility is 40% per annum. The right boundary is set to $x_p = 0.8$. (The largest value of $x_f(\tau)$ is about 0.62.) A step size $m = 400$ with ratio $\rho = 1$ is taken for all methods. Table 1 shows the results. When $a = -0.2$, the corresponding asset price is about 81.87. Thus the option values corresponding to $S \leq 80$ are not shown for FDP and FDE methods. Similarly, when $a = -0.6$, the corresponding asset price is about 54.88, and the option values corresponding to $S \leq 50$ are not shown. However, the ABF method can give the option values corresponding to any asset prices.

From the computational results shown in Table 1, it is clear that the accuracy of the option values are largely affected by the choice of the left boundary $x = a$. To obtain an accurate option value for the asset price $S = 80$, a must be smaller than

Table 1
American call option value (maturity T= 0.5, M= 400).

-0.4, and for $S = 70$, a must be smaller than -0.5. The ABF method gives much more accurate solutions. Compared with the FDP and FDE methods, to obtain an accurate option value for $S = 80$, $a = -0.2$ is enough, and for $S = 70$, $a = -0.4$ is enough.

Figure 1 shows the comparison of error and CPU for the FDE and ABF methods. The error e is measured by

$$e = \left[\frac{1}{K} \sum_{i=1}^{K} (C_i - \bar{C}_i)^2 \right]^{1/2},$$

where C_i is the binomial value, $\bar{C}_i$ is the value of the FDE method, or of the value of the ABF method, and K is the total number of option values taken. The figure shows clearly that the ABF method is much more efficient than the FDE method.

When the maturity time is longer, the error generated due to the rough approximation at the left boundary can be more serious. In example 2, we compare the different algorithms for option value with longer maturity time.

Example 2. Consider a three-year American call option with a dividend rate $D_0 = 0.07$. The exercise price is \$100, the risk-free interest rate is $r = 0.03$, and the volatility is 40% per annum. The right boundary is set to $x_p = 0.8$. (The largest value of $x_f(\tau)$ is about 0.7.) A step size $m = 400$ with ratio $\rho = 1$ is taken for all methods. Table 2 shows the results. The corresponding asset price for $a = -0.4$ is

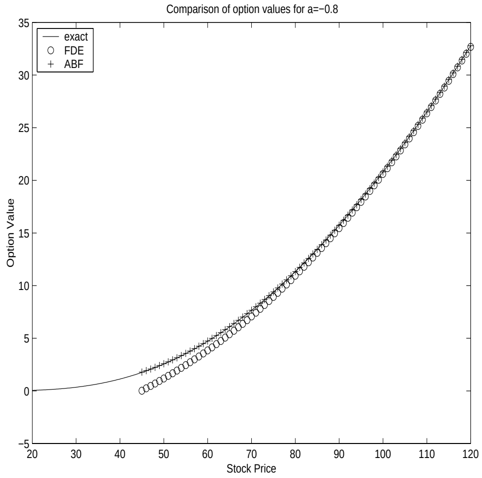

Fig. 3.

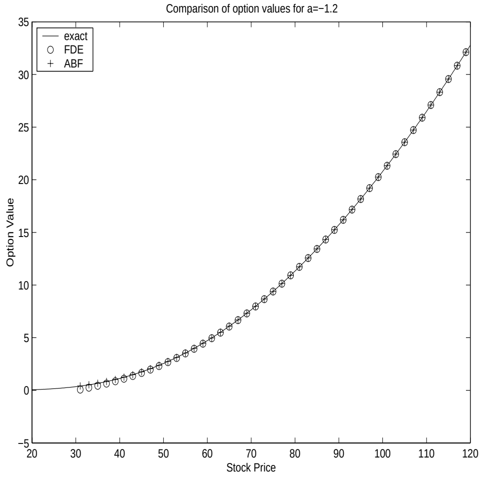

Fig. 4.

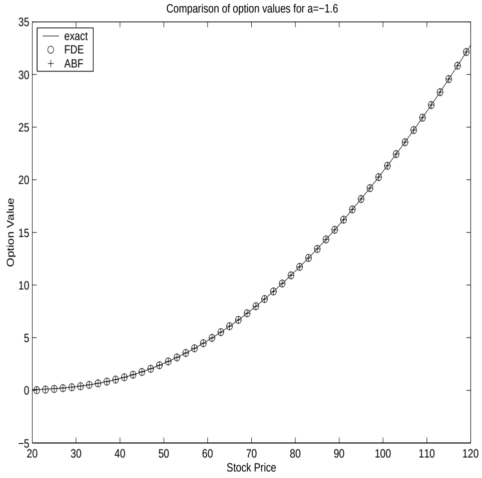

Fig. 5.

about 67.03, that for $a = -0.8$ is about 44.93, that for $a = -1.2$ is about 30.12, and that for $a = -1.6$ is about 20.19. Option values corresponding to asset prices smaller than these values for the FDP and FDE methods are not shown.

For the FDP and FDE methods, the option values are totally wrong for $a = -0.4$. When $a = -0.8$, the option values are still not accurate for asset prices up to $S = 90$, although the left boundary is about $S = 44.93$. To obtain accurate option values, the left boundary needs to be $a = -2.0$. The ABF method improved the results greatly. Even for $a = -0.4$, the option values are close to the true values.

In comparison of the efficiency of all algorithms, we can see from the table that if more option values are needed, then a large saving can be resulted by using artificial boundary conditions. For example, if the option values for $S = 20$ to $S = 120$ are needed, then for the FDP and FDE methods, a must be at least -2.0, and the corresponding CPU time is about 31.21 seconds for the FDP method and 10.7

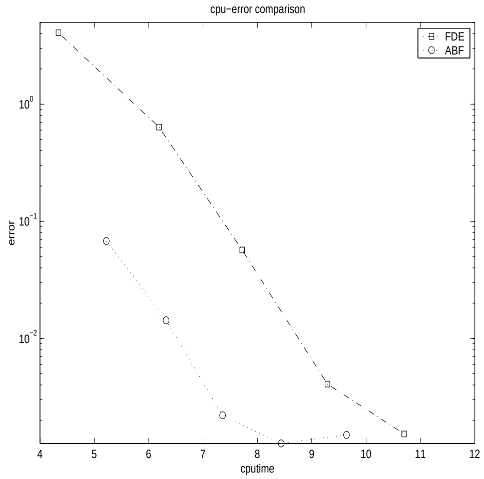

Fig. 6.

seconds for the FDE method. However, the ABF method with $a = -0.4$ can give more accurate option values, while the CPU time is only 5.22 seconds. For this example, the savings in CPU time is nearly 50%. The savings in CPU time will be different for different cases, but it is clear that the savings are significant.

Figures 2–5 show close comparisons of the option values for the FDE method and the ABF method, where the exact option values are obtained by the ABF method with $m = 2000$ on a large interval, $x \geq -2$; the results are very accurate. The four figures show the comparison results for $a = -0.4$, $a = -0.8$, $a = -1.2$, and $a = -1.6$. It is clear from the figures that the results of the FDE method are not acceptable for $a = -0.4$ and $a = -0.8$. When $a = -1.2$, the error can still be seen for the FDE method, while the ABF method gives accurate values for all the cases.

Figure 6 shows the comparison of error and CPU for the FDE and ABF methods. Again, we can see that the ABF method is much more efficient than the FDE method.

6. Conclusion. The artificial boundary conditions give accurate relations of the solutions at the boundary. By using the artificial boundary conditions in the finite difference approximation, we obtained the solution in a small truncated domain. Numerical results show that the solution is very accurate. The treatment for the free boundary is also very efficient. The computational cost is greatly reduced.

Acknowledgment. The authors wish to thank the referees for many valuable suggestions.

ATTRACTION RATES, ROBUSTNESS, AND DISCRETIZATION OF ATTRACTORS*

LARS GRÜNE†

Abstract. We investigate necessary and sufficient conditions for the convergence of attractors of discrete time dynamical systems induced by numerical one-step approximations of ODEs to an attractor for the approximated ODE. We show that both the existence of uniform attraction rates (i.e., uniform speed of convergence toward the attractors) and uniform robustness with respect to perturbations of the numerical attractors are necessary and sufficient for this convergence property. In addition, we can conclude estimates for the rate of convergence in the Hausdorff metric.

Key words. ODE, numerical one-step approximation, attractor, attraction rate, robustness

1. Introduction.

The long time behavior of dissipative dynamical systems is essentially determined by the attractors of these systems, since for large times its trajectories will typically stay on or near an attractor. Even for moderately complex finite dimensional systems, however, it is rarely possible to determine attractors by analytic methods. Hence numerical approximations form a natural part of a systematic analysis. It is therefore important to know about the effects of discretization errors on attractors in order to give a reasonable interpretation to numerical experiments and to justify numerical findings.

For dynamical systems induced by ODEs, numerical one-step approximations like Runge–Kutta or Taylor schemes form an important class of schemes. It follows from a result of Kloeden and Lorenz in 1986 [18] for attracting sets that if the ODE possesses an attractor A, then the discrete time dynamical system induced by such a numerical scheme also has an attractor contained in a neighborhood N of A, where the size of N shrinks down to A as the time-step of the discretization approaches 0.

A number of examples (see, e.g., [7, Example (2.12)], [9, Example 1.1.1], or [11] for the case of finite dimensional approximations of infinite dimensional systems) shows that the limit set for a convergent sequence of numerical attractors for vanishing time-steps may be strictly smaller than A. This fact, however, imposes a major problem for the interpretation of numerical results, since it implies that in general one cannot conclude the existence of a real attractor close to a numerical attractor. Hence it is important to derive techniques or conditions which allow us to conclude convergence of numerical attractors to a real attractor.

There are three main approaches for tackling this problem: The first is to impose suitable conditions on the approximated system which ensure a faithful numerical approximation and exclude the appearance of numerical artifacts. Typical examples of this approach are, for instance, results on the numerical approximation of Morse–Smale systems by Garay [5, 6], on the discretization of gradient systems by Hale and Raugel [12] or Stuart and Humphries [22, section 7.7], and a result on hyperbolic attractors by the author [8, Remark 2.10(ii)].

The second approach is to design algorithms which can be shown to converge to the right objects under no or very mild conditions on the approximated system. An example for this approach is the subdivision algorithm for the computation of attractors originally developed by Dellnitz and Hohmann [3] using a rigorous discretization as proposed by Junge [14, 15]; see also [9, section 6.3] for a description and a quantitative convergence analysis of this method based on robust Lyapunov functions.

The idea of the third approach is the formulation of conditions on the behavior of the numerical systems under which we can ensure convergence of the respective sets or the existence of respective nearby sets for the approximated system. A typical example are the sufficient conditions for the convergence of numerical attracting sets in the Galerkin approximation to Navier–Stokes equations by Kloeden [16]. For finite dimensional systems, in [8] a necessary and sufficient condition of this type was developed based on uniform attraction properties of the numerical attractors, which were characterized using (uniformly) shrinking families of neighborhoods which are mapped onto each other by suitable perturbations of the numerical flows.

The present paper follows this third approach. As in [8] we are going to formulate necessary and sufficient conditions for the convergence of numerical attractors to a real attractor in terms of uniform attraction properties. The difference from [8] lies in the type of uniformity properties used for this purpose, because (i) here we formulate the properties directly in terms of the numerical attractors instead of using auxiliary attracting sets, (ii) we use comparison functions for characterizing attraction properties instead of using geometrical characterizations by means of shrinking neighborhoods which are difficult to identify in a numerical simulation, and (iii) most importantly, instead of using a condition on the rate of attraction (i.e., the speed of convergence toward the attractor) for perturbed numerical systems, here we "decouple" the rate and the perturbation and give two different conditions—one based on the attraction rate for the unperturbed numerical systems and the other based on the robustness against perturbations.

More precisely, we prove that a sequence of numerical attractors converges to a real attractor

- if and only if the numerical attractors are attracting with uniformly bounded attraction rates (cf. Theorem 6.2(iii));
- if and only if the numerical attractors are robust against perturbation with uniformly bounded robustness gains (cf. Theorem 6.2(ii) and Theorem 6.4).

In addition, in Theorem 6.5 we give estimates for the discretization error based on the local error of the numerical scheme and the robustness gains of the respective attractors.

The tools we need in order to obtain these results are developed step by step in this paper, which is organized as follows. After defining the setup and stating some preliminary results in section 2, in section 3 we define a suitable robustness concept for attracting sets with respect to perturbations, describe the concept of embedding systems into each other, and show how this applies to numerical one-step approximations. In section 4 we study the relation between the robustness of attracting sets and their rate of attraction. In section 5 we prove some useful results on the relation between a continuous time system and its time-h map, and finally, in section 6 we state the main results on attractors under one-step discretization.

2. Setup and preliminaries.

We consider ODEs given by

$$\dot{x} = f(x) \tag{2.1}$$

and, for some time-step $h > 0$, discrete time systems of the form

$$x(t+h) = \Phi_h(x(t)), \tag{2.2}$$

where f and Φ_h are maps from $\mathbb{R}^d$ to $\mathbb{R}^d$, $d \in \mathbb{N}$.

For simplicity of exposition (cf. Remark 2.1, below) we assume global Lipschitz properties of the respective systems; i.e., we assume that there exists a constant $L > 0$ such that the inequalities

$$\|f(x) - f(y)\| \leq L\|x - y\| \text{ for all } x,\, y \in \mathbb{R}^d \tag{2.3}$$

and

$$\|F_h(x) - F_h(y)\| \leq L\|x - y\| \text{ for all } x,\, y \in \mathbb{R}^d \tag{2.4}$$

hold, where $F_h(x) = (\Phi_h(x) - x)/h$.

The trajectories of system (2.1) with initial value $x_0 \in \mathbb{R}^d$ for initial time $t = 0$ are denoted by $\varphi(t, x_0)$ for $t \in \mathbb{R}_0^+$, and the respective trajectories for (2.2) are denoted by $\Phi_h(t, x)$ for $t \in h\mathbb{N}_0 := \{hk \,|\, k \in \mathbb{N}_0\}$.

It will often be convenient to combine continuous and discrete time trajectories in one notation. For this we use the notation $\Phi(t, x)$, which either denotes $\varphi(t, x)$ or $\Phi_h(t, x)$, where the precise meaning will be clear from the context. Whenever we consider a discrete time system with time-step $h > 0$, the time t is implicitly assumed to be in the respective discrete time-scale $h\mathbb{N}_0$.

For sets $C \subset \mathbb{R}^d$ we use the notation

$$\Phi(t, C) = \bigcup_{x \in C} \{\Phi(t, x)\}.$$

A special type of a discrete time system is the time-h map of (2.1) which is defined by the discrete time system

$$x(t+h) = \varphi(h, x(t)). \tag{2.5}$$

The trajectories of (2.5) are denoted by $\varphi_h(t, x)$. Note that if (2.1) satisfies (2.3) for some $L > 0$, then Gronwall's lemma implies that the time-h map (2.5) satisfies (2.4) for the Lipschitz constant $\widetilde{L} = Le^{hL} > L$.

Another special type of a discrete time system (2.2) is a numerical one-step approximation $\widetilde{\Phi}_h$ of (2.1) which is supposed to satisfy (2.4) and is such that there exist constants c, $q > 0$ with

$$\|\widetilde{\Phi}_h(x) - \varphi(h, x)\| \leq ch^{q+1} \text{ for all } x \in \mathbb{R}^d. \tag{2.6}$$

Here q is called the order of the scheme. Examples for such approximations are Taylor and Runge–Kutta schemes; for details we refer, e.g., to the textbooks [4, 13, 21].

Remark 2.1. The global estimates in the inequalities (2.3), (2.4), and (2.6) are in general quite restrictive. However, since we are interested in the behavior on bounded subsets of the state space, one can always assume these properties without loss of generality by applying standard cutoff techniques.

Since we are going to measure distances between different sets, we need the following definitions.

DEFINITION 2.2. *Let C, $D \subset \mathbb{R}^d$ be nonempty compact sets, $x \in \mathbb{R}^d$, and let $\|\cdot\|$ be the Euclidean norm on $\mathbb{R}^d$. We define the distance from a point to a set by*

$$\|x\|_D := \min_{y\in D} \|x - y\|,$$

the nonsymmetric Hausdorff distance between two compact sets by

$$\operatorname{dist}(C, D) := \max_{x\in C} \min_{y\in D} \|x - y\|,$$

and the Hausdorff metric for compact sets by

$$d_H(C, D) := \max\{\operatorname{dist}(C, D), \operatorname{dist}(D, C)\}.$$

We use these distances for arbitrary bounded sets C, $D \subset \mathbb{R}^d$ by defining

$$\|x\|_D := \|x\|_{\operatorname{cl} D},\ \ \operatorname{dist}(C, D) := \operatorname{dist}(\operatorname{cl} C, \operatorname{cl} D) \text{ and } d_H(C, D) := d_H(\operatorname{cl} C, \operatorname{cl} D).$$

For $\varepsilon > 0$ we denote the (open) ε-ball around C by $\mathcal{B}(\varepsilon, C) := \{y \in \mathbb{R}^d \mid \|y\|_C < \varepsilon\}$. If $C = \{x\}$, we also write $\mathcal{B}(\varepsilon, x)$.

Note that for all bounded sets $C, D, E \subset \mathbb{R}^d$, the equivalences $\operatorname{dist}(C, D) = 0 \Leftrightarrow C \subseteq \operatorname{cl} D$ and $d_H(C, D) = 0 \Leftrightarrow \operatorname{cl} C = \operatorname{cl} D$ and the implication $C \subseteq E \Rightarrow \operatorname{dist}(C, D) \leq \operatorname{dist}(E, D)$ hold.

Our main objects of interest are attracting sets and attractors as given by the following definition.

DEFINITION 2.3. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2). *Consider a compact set $A \subset \mathbb{R}^d$ and an open and bounded set $B \subset \mathbb{R}^d$ with $A \subset B$. Then A is called an* attracting set *with* attracted neighborhood B *if it is forward invariant, i.e.,*

$$\Phi(t, A) \subseteq A \text{ for all } t \geq 0,$$

and satisfies

$$\lim_{t\to\infty} \operatorname{dist}(\Phi(t, B), A) \to 0.$$

An attracting set is called an attractor *if it is invariant, i.e.,*

$$\Phi(t, A) = A \text{ for all } t \geq 0.$$

In order to characterize quantitative properties of attracting sets and attractors, we make use of comparison functions as introduced by Hahn [10].

DEFINITION 2.4. *We define the following classes of* comparison functions.

$$\begin{aligned}
\mathcal{K} \quad &:= \quad \{\gamma : \mathbb{R}_0^+ \to \mathbb{R}_0^+ \mid \gamma \text{ is continuous, strictly increasing and } \gamma(0) = 0\},\\
\mathcal{L} \quad &:= \quad \{\sigma : \mathbb{R}_0^+ \to \mathbb{R}_0^+ \mid \sigma \text{ is continuous, strictly decreasing and } \lim_{r\to\infty} \sigma(r) = 0\},\\
\mathcal{KL} \quad &:= \quad \{\beta : \mathbb{R}_0^+ \times \mathbb{R}_0^+ \to \mathbb{R}_0^+ \mid \beta(\cdot, r) \in \mathcal{K} \text{ and } \beta(r, \cdot) \in \mathcal{L} \text{ for each } r \geq 0\}.
\end{aligned}$$

Remark 2.5. The functions $\beta \in \mathcal{KL}$ are closely related to the usual ε-δ definition of asymptotic stability. More precisely, for any function $a : \mathbb{R}_0^+ \times \mathbb{R}_0^+ \to \mathbb{R}_0^+$ satisfying the two properties

(i) for all $\varepsilon > 0$ there exists $\delta > 0$ such that if $r \leq \delta$, then $a(r, t) < \varepsilon$ for all $t \geq 0$,

(ii) for all $\varepsilon > 0$ and for all $R > 0$ there exists $T > 0$ such that $a(r,t) < \varepsilon$ for all $0 \le r \le R$ and for all $t \ge T$,

there exists a function $\beta \in \mathcal{KL}$ with $a(r,t) \le \beta(r,t)$ for all r, $t \ge 0$.

This fact was already implicitly used in Hahn's book [10]; in this form it is stated (but not proved) in Albertini and Sontag [1, Lemma 4.1] and proved (but not explicitly stated) by Lin, Sontag, and Wang [19, section 3].

Using class $\mathcal{KL}$ functions we can define rates of attraction for attracting sets.

DEFINITION 2.6. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2), *and let A be an attracting set with attracted neighborhood B. Then $\beta \in \mathcal{KL}$ is called* rate of attraction *of A if the inequality*

$$\|\Phi(t,x)\|_A \le \beta(\|x\|_A, t)$$

holds for each $x \in B$ and each $t \ge 0$.

The following lemma shows that each attracting set possesses a rate of attraction.

LEMMA 2.7. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2), *and let A be an attracting set with attracted neighborhood B. Then there exists a rate of attraction $\beta \in \mathcal{KL}$ for A.*

Proof. Using the forward invariance and attractivity properties of A and the (uniform) continuous dependence of a trajectory on the initial value (as induced by Gronwall's lemma for (2.1) or by induction for (2.2)), one easily verifies that the function $a : \mathbb{R}_0^+ \times \mathbb{R}_0^+ \to \mathbb{R}_0^+$ defined by $a(0,t) = 0$ for $t \in \mathbb{R}_0^+$ and

$$a(r,t) := \sup_{\tau \ge t} \operatorname{dist}\left(\Phi\left(\tau, \mathcal{B}(r,A) \cap B\right),\, A\right)$$

satisfies the properties (i) and (ii) of Remark 2.5. Hence there exists $\beta \in \mathcal{KL}$ with $a \le \beta$ and consequently

$$\|\Phi(x,t)\|_A \le \sup_{\tau \ge t} \operatorname{dist}\left(\Phi\left(\tau, \mathcal{B}(\|x\|_A, A) \cap B\right),\, A\right) = a(\|x\|_A, t) \le \beta(\|x\|_A, t)$$

for all $x \in B$ and all $t \ge 0$. This shows the claim. □

We end this section by stating some useful properties of attractors which we will need in what follows.

LEMMA 2.8. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2), *and let A be an attracting set with attracted neighborhood B. Then A contains an attractor with attracted neighborhood B.*

Proof. Verification of the desired properties shows that

$$\widetilde{A} := \bigcap_{T \ge 0} \operatorname{cl} \bigcup_{t \ge T} \Phi(t,B)$$

is the desired attractor; see [22, Theorem 2.7.4] for details. □

LEMMA 2.9. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2). *Then a compact forward invariant attracting set A for Φ with attracted neighborhood B is an attractor with attracted neighborhood B if and only if it is the minimal compact forward invariant attracting set (with respect to set inclusion) with attracted neighborhood B. In particular, for each open and bounded set $B \subset \mathbb{R}^d$, there exists at most one attractor with attracted neighborhood B.*

Proof. Let A be an attractor with attracted neighborhood B. Then, in particular, A is invariant. Now assume that $\tilde{A} \subset A$, $\tilde{A} \ne A$ is a forward invariant attracting set.

Then there exists a neighborhood $\mathcal{N} \supset \tilde{A}$ with $A \not\subseteq \mathcal{N}$ such that $\Phi(t, B) \subset \mathcal{N}$ for some $t \geq 0$, i.e., in particular, $\Phi(t, A) \neq A$, which contradicts the invariance of A.

Let conversely A be a minimal forward invariant attracting set. Then, by Lemma 2.8, A contains an attractor which again is a forward invariant attracting set. Hence by minimality it coincides with A. □

The next lemma shows that the attractor is also the maximal compact invariant set contained in int$B$.

LEMMA 2.10. *Let Φ denote the trajectories of a system of type* (2.1) *or* (2.2), *and let A be an attractor with attracted neighborhood B for Φ. Then each compact invariant set $D \subset B$ for Φ is contained in A.*

Proof. Let $D \subset B$ be an invariant set for Φ. Then $D = \Phi(t, D) \subset \Phi(t, B)$ for all $t \geq 0$. On the other hand, for each neighborhood $\mathcal{N} \supset A$ we know that $\Phi(t, B) \subset \mathcal{N}$ for all $t \geq 0$ sufficiently large. Hence $D \subset \mathcal{N}$, which implies the assertion. □

3. Inflation, robustness, and embedding.

The main technique that we will use in this paper in order to obtain results on convergence of numerical attractors is the embedding of the numerical approximation into a perturbed continuous time system, and vice versa. In this section we define suitable perturbed systems, the corresponding attracting sets, and a useful robustness concept for attracting sets. In addition, we give a mathematically precise meaning for the embedding property.

The following definition gives the appropriate perturbed systems (see also [17] for an equivalent definition using differential inclusions).

DEFINITION 3.1. *For $\alpha \in \mathbb{R}$, $\alpha \geq 0$, we define the set of perturbation values*

$$W_\alpha := \{w \in \mathbb{R}^d \,|\, \|w\| \leq \alpha\}$$

and the space of measurable functions with values in W_α by

$$\mathcal{W}_\alpha := \{w : \mathbb{R} \to \mathbb{R}^d \,|\, w \textit{ measurable with } w(t) \in W_\alpha \textit{ for almost all } t \in \mathbb{R}\}.$$

For functions $w \in \mathcal{W}_\alpha$ and real values $a < b$, we define $\|w\|_{[a,b]} := \operatorname{ess\,sup}_{t\in[a,b]}\|w(t)\|$.

For a continuous time system (2.1) *we define the α-*inflated system *by*

$$\dot{x} = f(x) + w, \quad w \in W_\alpha, \tag{3.1}$$

and for a discrete time system we define it by

$$x(t+h) = \Phi_h(x(t)) + \int_t^{t+h} w(t)dt, \quad w \in \mathcal{W}_\alpha. \tag{3.2}$$

For each initial value $x \in \mathbb{R}^d$ and each $w \in \mathcal{W}_\alpha$ we denote the corresponding trajectory by $\varphi(t, x, w)$ or $\Phi_h(t, x, w)$, respectively. It should be noted that the discrete time inflation (3.2) *of the time-h map* (2.5) *of a continuous time system* (2.1) *differs from the time-h map of the continuous time inflation* (3.1) *of system* (2.1) *defined by*

$$x(t+h) = \varphi(h, x(t), w(t + \cdot)), \tag{3.3}$$

where $\varphi(h, x(t), w(t+\cdot))$ denotes the solution of $\dot{y}(s) = f(y(s)) + w(t+s)$ with $y(0) = x(t)$.

Throughout this paper, the term inflated time-h map *refers to system* (3.3), *whose trajectories will be denoted by $\varphi_h(t, x, w)$.*

As for the unperturbed systems, we use $\Phi(t, x, w)$ to denote both discrete and continuous time trajectories, depending on the context. Furthermore, for $\alpha > 0$, $x \in \mathbb{R}^d$, and a subset $C \subseteq \mathbb{R}^d$, we use the notation

$$\Phi^\alpha(t, x) := \bigcup_{w \in \mathcal{W}_\alpha} \{\Phi(t, x, w)\} \quad \textit{and} \quad \Phi^\alpha(t, C) := \bigcup_{x \in C} \Phi^\alpha(t, x).$$

Next we define suitable attracting sets for inflated systems and a robustness property of attracting sets.

Definition 3.2. *Consider an inflated continuous time system* (3.1)*, an inflated discrete time system* (3.2)*, or an inflated time-h map* (3.3) *with trajectories denoted by $\Phi(t, x, w)$. Then a compact set A_α with open neighborhood B is called an* α-attracting set *with* attracted neighborhood B *if it is α-forward invariant, i.e.,*

$$\Phi^\alpha(t, A) \subseteq A \textit{ for all } t \geq 0,$$

and satisfies

$$\lim_{t \to \infty} \operatorname{dist}(\Phi^\alpha(t, B), A) \to 0.$$

Let $\alpha_0 > 0$ and $\gamma \in \mathcal{K}$. Then an attracting set (or attractor) A with attracted neighborhood B for an unperturbed system (2.1) *or* (2.2) *is called* γ-robust *for γ and α_0 if for each $\alpha \in (0, \alpha_0]$ there exists an α-attracting set A_α with attracted neighborhood B for the corresponding inflated system with $A \subseteq A_\alpha$ and*

$$d_H(A, A_\alpha) \leq \gamma(\alpha).$$

Here $\gamma \in \mathcal{K}$ is called robustness gain.

Remark 3.3. Analogous to Lemma 2.7, one sees that for each α-attracting set A_α with attracted neighborhood B there exists $\beta \in \mathcal{KL}$ such that

$$\|\Phi(t, x, w)\|_{A_\alpha} \leq \beta(\|x\|_{A_\alpha}, t)$$

for all $x \in B$, $t \geq 0$, and $w \in \mathcal{W}_\alpha$.

We now define what we mean by an embedded system. For our purpose it is sufficient to define this concept for discrete time systems.

Definition 3.4. *Consider two inflated discrete time systems of type* (3.2) *with perturbations from $\mathcal{W}_{\tilde{\alpha}_0}$ and $\mathcal{W}_{\alpha_0}$, respectively. Denote the trajectories of the systems by Φ_h and Ψ_h, respectively, and let $\alpha \geq 0$ and $C \geq 1$. Then we say that the second system Ψ_h is* (α, C)-embedded *in the first Φ_h if for each $x \in \mathbb{R}^d$ and each $w \in \mathcal{W}_{\alpha_0}$ there exist $\tilde{w} \in \mathcal{W}_{\tilde{\alpha}_0}$ with $\|\tilde{w}\|_{[t,t+h]} \leq \alpha + C\|w\|_{[t,t+h]}$ and*

$$\Phi_h(t, x, \tilde{w}) = \Psi_h(t, x, w)$$

for all $t \in h\mathbb{N}_0$.

Here we call Φ_h the embedding system *and Ψ_h the* embedded system.

Lemma 3.5. *Consider three discrete time inflated systems Φ_h, Ψ_h, and Θ_h of type* (2.2)*, and assume that Ψ_h is $(\alpha_1,\ C_1)$-embedded in Θ_h and Θ_h is $(\alpha_2,\ C_2)$-embedded in Φ_h. Then Ψ_h is $(\alpha_1 + C_1\alpha_2,\ C_1C_2)$-embedded in Φ_h.*

Proof. The proof is straightforward using Definition 3.4. □

The following proposition shows how the inflated numerical system

$$x(t + h) = \widetilde{\Phi}_h(t, x(t)) + \int_t^{t+h} w(s)ds, \tag{3.4}$$

with trajectories denoted by $\widetilde{\Phi}_h(t,x,w)$, can be embedded into the inflated time-h map (3.3), and vice versa.

PROPOSITION 3.6. *Consider the numerical approximation $\widetilde{\Phi}_h$ of system* (2.1) *for some $h > 0$. Let $\alpha_0 > 0$, and consider the constants L and c from* (2.3) *and* (2.6).

Then the α_0-inflated numerical system $\widetilde{\Phi}_h(t,x,w)$ from (3.4) *is $(ch^q,\ 1+hL)$-embedded in the $ch^q + (1+hL)\alpha_0$-inflated time-h map φ_h from* (3.3).

Conversely, the α_0-inflated time-h map φ_h from (3.3) *is $(e^{hL}ch^q,\ e^{hL})$-embedded in the $e^{hL}ch^q + e^{hL}\alpha_0$-inflated numerical system $\widetilde{\Phi}_h(t,x,w)$ from* (3.4).

Proof. Consider the auxiliary system defined by

$$x(t+h) := \varphi(h,x(t)) + \int_t^{t+h} w(s)ds$$

for $t \in h\mathbb{N}_0$, and denote the trajectories with initial value $x \in \mathbb{R}^d$ at initial time $t = 0$ by $\tilde{\varphi}_h(t,x,w)$. It is immediate from Definition 3.4 and inequality (2.6) that $\tilde{\varphi}_h$ is $(ch^q, 1)$-embedded in $\widetilde{\Phi}_h$ and that $\widetilde{\Phi}_h$ is $(ch^q, 1)$-embedded in $\tilde{\varphi}_h$.

We claim that the system $\tilde{\varphi}_h$ is $(0,\ 1+Lh)$-embedded in φ_h and that φ_h is $(0,\ e^{Lh})$-embedded in $\tilde{\varphi}_h$. Then the assertion follows from Lemma 3.5.

In order to prove the embedding relation between φ_h and $\tilde{\varphi}_h$, fix some $w \in \mathcal{W}_{\alpha_0}$. It is sufficient to show the embedding for $t = h$ since then we can continue by induction. We first construct $\tilde{w}$ such that $\varphi_h(h,x,\tilde{w}) = \tilde{\varphi}_h(h,x,w)$.

Consider the perturbation

$$\tilde{w}(t) = f(\varphi(t,x)) + w(t) - f\left(\varphi(t,x) + \int_0^t w(\tau)d\tau\right)$$

for $t \in [0,h]$. Then we obtain

$$\begin{aligned}\frac{d}{dt}\left(\varphi(t,x) + \int_0^t w(\tau)d\tau\right) &= f(\varphi(t,x)) + w(t)\\ &= f\left(\varphi(t,x) + \int_0^t w(\tau)d\tau\right) + \tilde{w}(t)\end{aligned}$$

and

$$\frac{d}{dt}\varphi(t,x,\tilde{w}) = f(\varphi(t,x,\tilde{w})) + \tilde{w}(t),$$

which by the uniqueness of the solution to this differential equation implies

$$\varphi_h(h,x,\tilde{w}) = \varphi(h,x,\tilde{w}) = \varphi(h,x) + \int_0^h w(\tau)d\tau = \tilde{\varphi}_h(h,x,w).$$

From the Lipschitz estimate (2.3) we obtain for almost all $\tau \in [0,h]$ the inequality

$$\|\tilde{w}(\tau)\| \le \|w(\tau)\| + L\left\|\int_0^\tau w(s)ds\right\|,$$

which implies

$$\|\tilde{w}\|_{[0,h]} \le \|w\|_{[0,h]} + Lh\|w\|_{[0,h]}$$

and thus shows the claim.

Conversely, given again $w \in \mathcal{W}_{\alpha_0}$, we now construct $\tilde{w}$ such that $\tilde{\varphi}_h(h, x, \tilde{w}) = \varphi_h(h, x, w)$.

For this purpose, consider $\tilde{w}$ given by

$$\tilde{w}(t) = f(\varphi(t, x, w)) + w(t) - f(\varphi(t, x))$$

for $t \in [0, h]$. Then arguments similar to those above yield the equality $\tilde{\varphi}_h(h, x, \tilde{w}) = \varphi_h(h, x, w)$. By Gronwall's lemma one easily obtains $\|\varphi(\tau, x, w) - \varphi(\tau, x)\| \le \|w\|_{[0,\tau]}(e^{L\tau} - 1)/L$, which shows that $\|f(\varphi(\tau, x, w)) - f(\varphi(\tau, x))\| \le \|w\|_{[0,\tau]}(e^{L\tau} - 1)$ and thus

$$\|\tilde{w}(\tau)\| \le \|w(\tau)\| + \|w\|_{[0,\tau]}(e^{L\tau} - 1)$$

for almost all $\tau \in [0, h]$, implying

$$\|\tilde{w}\|_{[0,h]} \le \|w\|_{[0,h]} + \|w\|_{[0,h]}(e^{Lh} - 1) = e^{Lh}\|w\|_{[0,h]},$$

i.e., the desired estimate. □

In the following two propositions we show the relations between attracting sets of embedding and embedded systems.

PROPOSITION 3.7. *Consider a discrete time system with trajectories Ψ_h which is (α, C)-embedded in some other discrete time system with trajectories denoted by Φ_h for some $\alpha \ge 0$, $C \ge 1$. Assume that the embedding system Φ_h has an attracting set A which is γ-robust for some $\gamma \in \mathcal{K}$ and some $\alpha_0 \ge \alpha$. Then the embedded system Ψ_h has an attracting set $\widetilde{A}$ with attracted neighborhood B which satisfies*

$$d_H(\widetilde{A}, A) \le \gamma(\alpha).$$

Proof. By the embedding property we obtain $\Psi_h(t, B) \subseteq \Phi_h^\alpha(t, B)$. Hence the α-attracting set A_α for the inflated embedding system Φ_h^α is an attracting set for the embedded system Ψ_h. Hence $\widetilde{A} = A_\alpha$ is the desired set. □

The next proposition shows that we can even conclude the existence of robust attracting sets for the embedded system if we are willing to allow a larger distance between $\widetilde{A}$ and A.

PROPOSITION 3.8. *Consider a discrete time system with trajectories Ψ_h which is (α, C)-embedded in some other discrete time system with trajectories denoted by Φ_h for some $\alpha \ge 0$, $C \ge 1$. Assume that the embedding system Φ_h has an attracting set A which is γ-robust for some $\gamma \in \mathcal{K}$ and some $\alpha_0 > \alpha$. Then for each $D > 1$ with $D\alpha \le \alpha_0$ the embedded system Ψ_h has an attracting set $\widetilde{A}$, which is $\gamma(CD \cdot /(D-1))$-robust for $\alpha_1 = \alpha_0(D-1)/(CD)$ and satisfies $d_H(\widetilde{A}, A) \le \gamma(D\alpha)$.*

Proof. We set $\widetilde{A} = A_{D\alpha}$. The assumption on the (α, C)-embedding implies the inclusions

$$\Psi^{\alpha'}(t, x) \subseteq \Phi^{D\alpha}(t, x) \text{ for all } \alpha' \in [0, (D-1)\alpha/C]$$

and

$$\Psi^{\alpha'}(t, x) \subseteq \Phi^{CD\alpha'/(D-1)}(t, x) \text{ for all } \alpha' \ge (D-1)\alpha/C.$$

Hence setting $\widetilde{A}_{\alpha'} = A_{D\alpha}$ for $\alpha' \in [0, (D-1)\alpha/C]$ and $\widetilde{A}_{\alpha'} = A_{CD\alpha'/(D-1)}$ for $\alpha' \ge (D-1)\alpha/C$ gives attracting sets $\widetilde{A}_{\alpha'}$ for $\Psi^{\alpha'}$ satisfying

$$d_H(\widetilde{A}_{\alpha'}, \widetilde{A}) \le d_H(\widetilde{A}_{\alpha'}, A) \le CD\alpha'/(D-1) \text{ for all } \alpha' \ge 0.$$

This shows the claim. □

4. Robustness and attraction rates. In this section we investigate the relation between the robustness gain γ and the attraction rate β. We start by showing that we can find an upper bound for the robustness gain of an attracting set A which is essentially determined by its rate of attraction.

THEOREM 4.1. *There exist maps*

$$\mu : \mathcal{KL} \times \mathbb{R}^+ \times \mathbb{R}^+ \to \mathcal{K} \quad \textit{and} \quad \sigma : \mathcal{KL} \times \mathbb{R}^+ \times \mathbb{R}^+ \to \mathbb{R}^+$$

such that each compact attracting set $A \subset \mathbb{R}^d$ with attraction rate $\beta \in \mathcal{KL}$ and attracted neighborhood B for a system of type (2.1) *or* (2.2) *is γ-robust for $\gamma = \mu(\beta, d_H(B,A), L)$ and all $\alpha_0 > 0$ satisfying $\alpha_0 \le \sigma(\beta, d_H(B,A), L)$ and $\mathcal{B}(\gamma(\alpha_0), A) \subset B$, where L is the Lipschitz constant from* (2.3) *or* (2.4), *respectively.*

Proof. Set $r_0 = d_H(A,B)$. For all $r \in (0, r_0]$ we can define

$$T_\beta(r) = \min\left\{ t \ge 0 \;\middle|\; \beta(s,t) \le \frac{s}{4} \text{ for all } s \in [r, r_0] \right\}.$$

Note that T_β is finite for all $r > 0$ (because $\beta(s,t) \le \beta(r_0,t) \to 0$ as $t \to \infty$), monotone decreasing, and continuous from above; i.e., for $r_n \searrow r$ it follows that $T_\beta(r_n) \to T_\beta(r)$ as a consequence of the continuity of β. This definition implies $\beta(s, T_\beta(r) + t) \le r/4$ for all $t \ge 0$ and all $s \in [0, r]$. We set

$$\alpha_0 = \sigma(\beta, r_0, L) := e^{-LT_\beta(r_0)} \min\{r_0, \beta(r_0, 0)\}/4.$$

Now for all $\alpha \in (0, \alpha_0]$ consider the sets

$$D_\alpha := \operatorname{cl} \mathcal{B}(r(\alpha), A),$$

where $r(\alpha)$ is chosen minimal such that $e^{LT_\beta(r(\alpha))}\alpha \le r(\alpha)/4$. The function $r(\alpha)$ is well defined because of the continuity from above of T_β. Observe that r depends only on β, r_0, and L and that it is monotone increasing with $r(\alpha) \to 0$ as $\alpha \to 0$. By Gronwall's lemma for continuous time systems or by induction for discrete time systems we obtain for $t \le T_\beta(\|x\|_A)$

$$\|\Phi(t,x,w)\|_A \le \beta(\|x\|_A, t) + e^{Lt}\alpha \tag{4.1}$$

for all $w \in \mathcal{W}_\alpha$, which implies that for each point $x \in D_\alpha$ we obtain

$$\Phi(T_\beta(r(\alpha)), x, w) \in D_\alpha \tag{4.2}$$

and

$$\|\Phi(t,x,w)\|_A \le \beta(r(\alpha), 0) + r(\alpha)/4 \text{ for all } t \in [0, T_\beta(r(\alpha))]. \tag{4.3}$$

Furthermore, for any $w \in \mathcal{W}_\alpha$ and any $x \in B$ inequality (4.1) implies that the trajectory satisfies

$$\|\Phi(i\,T_\beta(r(\alpha)), x, w)\|_A \le \max\{r_0/2^i, r(\alpha)\} \text{ for all } i \in \mathbb{N} \tag{4.4}$$

and hence hits D_α in some uniformly bounded finite time. Now we set

$$A_\alpha := \bigcup_{t \in [0, T_\beta(r(\alpha))]} \operatorname{cl} \Phi^\alpha(t, D_\alpha).$$

These sets are α-forward invariant by construction and by (4.2) and α-attracting by (4.4). Furthermore, they satisfy $A \subseteq A_\alpha$ for $\alpha \in (0, \alpha_0]$, $\mathcal{B}(r(\alpha), A) \subseteq A_\alpha$, and because of (4.3) one obtains $d_H(A_\alpha, A) \leq \gamma(\alpha)$ with

$$\gamma(\alpha) = \mu(\beta, r_0, L)(\alpha) := \beta(r(\alpha), 0) + r(\alpha)/4.$$

This shows the desired robustness property. □

In general, this construction of γ might not yield the best possible robustness gain for a given system and attracting set. However, the importance of this theorem is the uniformity that can be deduced from it: knowing the attraction rate, the distance between B and A, and the Lipschitz constant of the system allows us to give an upper bound for the robustness gain, no matter what the geometric structure of A or the behavior of Φ around or on A look like. In particular, when uniform attraction holds for a family of systems with uniform Lipschitz properties and uniform distance between the attracting sets and their attracted neighborhoods, then uniform robustness can also be deduced.

Let us illustrate one special case in which the proof of Theorem 4.1 yields an explicit expression for μ.

Example 4.2. Assume that A attracts exponentially; i.e., there exist constants $\rho > 0$ and $\lambda > 0$ such that $\beta(r, t) = \rho e^{-\lambda t} r$. In this case we obtain $T_\beta(r) = \ln(4\rho)/\lambda$, and thus $r(\alpha) = c_1\alpha$ for $c_1 = 4(4\rho)^{L/\lambda}$, and consequently $\mu(\beta, d_H(B, A), L)(\alpha) = c_2\alpha$ for $c_2 = c_1(\rho + 1/4)$. Hence exponential attraction yields γ-robustness with linear robustness gain.

Another interesting consequence of Theorem 4.1 is the following corollary.

COROLLARY 4.3. *Consider an attracting set A for a system of type* (2.1) *or* (2.2)*. Then there exist $\alpha_0 > 0$ and $\gamma \in \mathcal{K}$ such that A is γ-robust for γ and α_0.*

Proof. By Lemma 2.7 there exists an attraction rate $\beta \in \mathcal{KL}$ for A. Hence Theorem 4.1 immediately gives the assertion. □

Knowing that any attracting set admits a robustness gain, we can easily find an upper bound for a robustness gain for nested attracting sets.

LEMMA 4.4. *Let A be an attracting set with attracted neighborhood B for a system of type* (2.1) *or* (2.2)*, and let $\widehat{A} \supset A$ be an attracting set which is contained in B and is $\hat{\gamma}$-robust for the α_0-inflated system for some $\hat{\gamma} \in \mathcal{K}$ and some $\alpha_0 > 0$. Let $\rho :=$ dist$(\widehat{A}, A)$. Then A is γ-robust for this α_0 and some $\gamma \in \mathcal{K}$ satisfying $\gamma(r) \leq \hat{\gamma}(r) + \rho$.*

Proof. By Corollary 4.3 there exist $\tilde{\alpha}_0 > 0$ and $\tilde{\gamma} \in \mathcal{K}$ such that A is $\tilde{\gamma}$-robust for the $\tilde{\alpha}_0$-inflated system. Without loss of generality, we may assume $\tilde{\alpha_0} \leq \alpha_0$ and $\tilde{\gamma}(\tilde{\alpha}_0) \geq \hat{\gamma}(\tilde{\alpha}_0) + \rho$. Now for each $\alpha \in (0, \alpha_0]$ there exists an α-attracting set $\widehat{A}_\alpha \supseteq \widehat{A}$ with dist$(\widehat{A}_\alpha, \widehat{A}) \leq \hat{\gamma}(\alpha)$. Since this implies

$$\operatorname{dist}(\widehat{A}_\alpha, A) \leq \operatorname{dist}(\widehat{A}_\alpha, \widehat{A}) + \operatorname{dist}(\widehat{A}, A) \leq \hat{\gamma}(\alpha) + \rho,$$

we can conclude that A is γ-robust with γ defined by

$$\gamma(\alpha) := \begin{cases} \min\{\tilde{\gamma}(\alpha), \hat{\gamma}(\alpha) + \rho\}, & \alpha \in [0, \tilde{\alpha}_0], \\ \hat{\gamma}(\alpha) + \rho, & \alpha \in [\tilde{\alpha}_0, \alpha_0]. \end{cases}$$

This γ is easily verified to be of class $\mathcal{K}$; thus the assertion follows. □

We end this section by proving a "uniform attraction" property of the α-attracting sets appearing in the definition of the γ-robustness property.

PROPOSITION 4.5. *Consider an attracting set A with attracted neighborhood B for a system of type* (2.1) *or* (2.2) *which is γ-robust for some $\gamma \in \mathcal{K}$ and some $\alpha_0 > 0$. Then for each $\varepsilon > 0$ there exists a function $\beta \in \mathcal{KL}$ such that the inequality*

$$\|\Phi(t,x,w)\|_A \le \beta(\|x\|_A, t) + (1+\varepsilon)\gamma(\alpha) \tag{4.5}$$

holds for all $t \ge 0$, all $x \in B$, all $\alpha \in [0,\alpha_0]$, all $w \in \mathcal{W}_\alpha$, and the trajectories of the corresponding inflated system.

Proof. It is easily seen that there exists a monotone decreasing sequence $\alpha_n \to 0$ such that α_0 is the inflation parameter from the assumption and $\gamma(\alpha) < (1+\varepsilon)\gamma(\alpha_{n+1})$ for all $\alpha \in [\alpha_{n+1}, \alpha_n]$. We set $d_n = (1+\varepsilon)\gamma(\alpha_{n+1})$ and $r_0 = d_H(B,A)$. Now for each $r \in (0, r_0]$ we define the functions

$$\sigma_n(r,t) := \sup_{\tau \ge t} \operatorname{dist}(\Phi^{\alpha_n}(\tau, \mathcal{B}(r,A) \cap B), A)$$

and

$$\mu_n(r,t) := \max\{\sigma_n(r,t) - d_n, 0\}.$$

It is immediate that for all $r,t > 0$ the sequences $\sigma_n(r,t)$ and $\mu_n(r,t) + d_n$ are monotone decreasing in n and monotone increasing in r. From Remark 3.3 we obtain the existence of functions $\beta_n \in \mathcal{KL}$ such that

$$\operatorname{dist}(\Phi^{\alpha_n}(t,x), A_{\alpha_n}) \le \beta_n(\|x\|_{A_{\alpha_n}}, t). \tag{4.6}$$

This implies

$$\limsup_{t\to\infty} \operatorname{dist}(\Phi^{\alpha_n}(\tau, \mathcal{B}(r_0,A) \cap B), A) \le \gamma(\alpha_n) < d_n,$$

and thus for each $n \in \mathbb{N}$ there exists $T > 0$ such that

$$\mu_k(r,t) = 0 \text{ for all } k = 1,\dots,n, \text{ all } r \in (0,r_0], \text{ and all } t \ge T. \tag{4.7}$$

Furthermore, since $A \subseteq A_\alpha$ for all $\alpha \in (0,\alpha_0]$, from (4.6) for each $n \in \mathbb{N}$ and all $r > 0$ sufficiently small (depending on n) we obtain

$$\sigma_n(r,0) \le \beta_n(r,0) + \gamma(\alpha_n) \le d_n.$$

Hence for each $n \in \mathbb{N}$ there exists $R > 0$ such that

$$\mu_k(r,t) = 0 \text{ for all } k = 1,\dots,n, \text{ all } r \in [0,R], \text{ and all } t \ge 0. \tag{4.8}$$

Now consider the function $a(r,t) := \sup_{n\in\mathbb{N}_0} \mu_n(r,t)$. From the definition of the μ_n we obtain

$$\|\Phi(t,x,w)\|_A \le \mu_n(\|x\|_A, t) + d_n \le a(\|x\|_A, t) + d_n \le a(\|x\|_A, t) + (1+\varepsilon)\gamma(\alpha)$$

for all $t \ge 0$, all $\alpha \in [\alpha_{n+1}, \alpha_n]$, and all $w \in \mathcal{W}_\alpha$. Furthermore, $a(r,t)$ is monotone increasing in r and monotone decreasing in t. If we fix $n \in \mathbb{N}$ and choose $T > 0$ such that (4.7) holds, then (4.7) and the monotonicity of $\mu_n(r,t) + d_n$ in n imply

$$a(r,t) \le \sup_{k\in\mathbb{N}_0} \mu_k(r,t) \le \sup_{k\ge n} \mu_k(r,t) \le \sup_{k\ge n} \mu_k(r,t) + d_k \le \mu_n(r,t) + d_n \le d_n$$

for all $t \geq T$. Similarly, from (4.8) one sees that for each $n \in \mathbb{N}$ and each $t \geq 0$ there exists $R \geq 0$ such that $a(r,t) \leq d_n$ for all $r \leq R$. Thus, since $d_n \to 0$ as $n \to \infty$, we obtain $a(r,t) \to 0$ if either $r \to 0$ or $t \to \infty$. Hence by Remark 2.5 a can be bounded from above by some function $\beta \in \mathcal{KL}$, which shows the claim. □

Remark 4.6. Inequality (4.5) describes a property which in nonlinear control theory is known as *input-to-state stability (ISS);* see, e.g., the survey [20]. For a detailed comparative study of various robustness concepts for attracting sets including their characterization via Lyapunov functions, we refer to [9].

5. Discrete and continuous time systems. By its very nature, a numerical one-step approximation with time-step $h > 0$ gives only an approximation to the time-h map φ_h (2.5) of the continuous time system φ (2.1). It is therefore necessary to obtain information on the dynamical behavior of φ from its time-h map φ_h. In this section we give two results for this purpose.

PROPOSITION 5.1. *Consider a sequence of time-steps $h_n \to 0$ and a sequence of γ_n-robust attracting sets A_n for $\gamma_n \in \mathcal{K}$ and $\alpha_n > 0$, each with the same attracted neighborhood B for the inflated time-h_n maps* (3.3)*, where $\alpha_n \to \alpha_0 > 0$ as $n \to \infty$. Assume there exist $\gamma \in \mathcal{K}$ such that* $\limsup_{n\to\infty} \gamma_n(\alpha) \leq \gamma(\alpha)$ *and a compact set $A \subset B$ such that* $\lim_{n\to\infty} d_H(A_n, A) = 0$.

Then A is a γ-robust attracting set for the continuous time system (2.1) *for γ and each $\tilde{\alpha}_0 \in (0, \alpha_0)$.*

Proof. We first show that A is an attracting set for φ. For this, fix $\varepsilon > 0$ and consider $n \in \mathbb{N}$ such that $d_H(A_n, A) < \varepsilon/3$ and $h_n M < \varepsilon/3$, where M is a bound on $\|f(x)\|$ for x in a sufficiently large neighborhood of B. Then it is easily seen that there exists $T > 0$ such that $\varphi(ih_n, B) \subset \mathcal{B}(\varepsilon/3, A_n)$ for all $i \in \mathbb{N}$ with $ih_n \geq T$. Consequently, we obtain $\varphi(t, B) \subset \mathcal{B}(\varepsilon, A)$ for all $t \geq T$, and since $\varepsilon > 0$ was arbitrary, this shows the desired convergence $\operatorname{dist}(\varphi(t,B), A) \to 0$ as $t \to \infty$.

It remains to show the γ-robustness. To this end, fix some $\alpha \in (0, \alpha_0)$ and consider the set

$$A^\alpha = \bigcap_{n\geq 0} \operatorname{cl} \bigcup_{k\geq n} A_n^\alpha,$$

where the A_n^α denote the α-attracting sets for the inflated time-h_n maps (3.3). Using the fact that

$$d_H\left(\operatorname{cl} \bigcup_{k\geq n} A_n^\alpha,\, A^\alpha\right) \to 0 \text{ as } k \to \infty$$

(cf. [2, Proposition 1.1.5]), with the same argument as above one sees that this set is α-attracting for the inflated system. Since for each $\varepsilon > 0$ we find $N \in \mathbb{N}$ such that for all $n \geq N$ the inequalities

$$d_H(A_n, A) < \varepsilon/2 \quad \text{and} \quad d_H(A_n^\alpha, A_n) \leq \gamma_n(\alpha) \leq \gamma(\alpha) + \varepsilon/2$$

hold, we can conclude that $d_H(A_n^\alpha, A) \leq \gamma(\alpha) + \varepsilon$ for all $n \geq N$ and thus

$$d_H(A_n^\alpha, A) \leq \gamma(\alpha) + \varepsilon,$$

which shows the desired distance since $\varepsilon > 0$ was arbitrary. □

While in general an attracting set for the time-h map is not an attracting set for the continuous time system, this property is always true for attractors, as the following lemma shows.

LEMMA 5.2. *Let $h > 0$ and A_h be an attractor with attracted neighborhood B for the time-h map φ_h* (2.5) *of the continuous time system* (2.1). *Then A_h is also an attractor with attracted neighborhood B for the continuous time system* (2.1).

Proof. We first show forward invariance of A_h for φ, i.e., $\varphi(t, A_h) \subseteq A_h$ for each $t \geq 0$. By invariance of A_h for φ_h, for each $t \geq 0$ we know that $\varphi_h(h, \varphi(t, A_h)) = \varphi(t, \varphi_h(h, A_h)) = \varphi(t, A_h)$; hence $\varphi(t, A_h)$ is a compact invariant set for φ_h, and by Lemma 2.10 it is contained in A_h.

Now we show that A_h is an attracting set for the continuous time system φ. Forward invariance of A_h and continuous dependence on the initial value imply that for each $\delta > 0$ there exists $\varepsilon > 0$ such that

$$d_H(D, A_h) < \varepsilon \quad \Rightarrow \quad d_H(\varphi(t, D), A_h) < \delta$$

for all $t \in [0, h]$ and arbitrary bounded sets $D \subset \mathbb{R}^d$. Since attractivity of A_h for φ_h implies $\lim_{i \to \infty, i \in \mathbb{N}} \operatorname{dist}(\varphi(ih, B), A) = 0$, we can conclude $\lim_{t \to \infty} \operatorname{dist}(\varphi(t, B), A_h) = 0$; i.e., A_h is also an attracting set for φ with attracted neighborhood B.

It remains to show that A_h is an attractor for φ. By Lemma 2.8 there exists an attractor $A \subseteq A_h$ for φ. This, in turn, is also an attractor set for φ_h; hence by Lemma 2.9 it must coincide with A_h. Thus A_h is an attractor for φ. □

6. Numerical discretization. In this section we combine the results from the previous sections in order to derive criteria under which one can conclude the existence of attracting sets and attractors from numerical approximations. We start with sufficient conditions for the existence of attracting sets.

PROPOSITION 6.1. *Consider the continuous time system* (2.1) *and a numerical one-step approximation $\widetilde{\Phi}_h$ for $h > 0$ satisfying* (2.6) *for $c\,q > 0$. Let L denote a Lipschitz constant for both systems from* (2.3) *and* (2.4), *respectively.*

(a) *Let A be a γ-robust attracting set for* (2.1) *for $\gamma \in \mathcal{K}$ and $\alpha_0 \geq e^{hL}ch^q$. Then there exists an attracting set A_h for the discrete time system induced by the numerical approximation $\widetilde{\Phi}_h$ satisfying*

$$d_H(A_h, A) \leq \gamma(e^{hL}ch^q).$$

(b) *Let A_h be a γ-robust attracting set for $\widetilde{\Phi}_h$, for $\gamma \in \mathcal{K}$, and $\alpha_0 \geq ch^q$. Then there exists an attracting set $\widetilde{A}_h$ for the time-h map* (2.5) *of the continuous time system satisfying*

$$d_H(\widetilde{A}_h, A_h) \leq \gamma(ch^q).$$

Proof. This follows directly from Propositions 3.6 and 3.7. □

THEOREM 6.2. *Consider the continuous time system* (2.1) *and a family of numerical one-step approximations $\widetilde{\Phi}_{h_n}$ satisfying* (2.6) *for a sequence of time-steps $h_n \to 0$ as $n \to \infty$. Let A_n be attractors for the discrete time systems induced by these numerical approximations, each with the same attracted neighborhood B, and assume that there exists a compact set $A \subset B$ with $d_H(A_n, A) \to$ as $n \to \infty$.*

Then the following properties are equivalent:

(i) *A is an attractor for* (2.1) *with attracted neighborhood B.*

(ii) *There exist $N \in \mathbb{N}$, $\gamma \in \mathcal{K}$, $\alpha_0 > 0$, and sequences $C_n \to 1$ and $\rho_n \to 0$ such that for each $n \geq N$ the attractor A_n is γ_n-robust for the numerical system $\widetilde{\Phi}_{h_n}$ for α_0 and $\gamma_n(r) \leq \gamma(C_n r) + \rho_n$.*

(iii) *There exist $N \in \mathbb{N}$, $\beta \in \mathcal{KL}$, and a sequence $\varepsilon_n \to 0$ such that for each $n \geq N$ the attractor A_n for the numerical system $\widetilde{\Phi}_{h_n}$ has attraction rate $\beta_n \in \mathcal{KL}$ satisfying $\beta_n(r,t) \leq \beta(r+\varepsilon_n, t) + \varepsilon_n$.*

In addition, if (ii) *holds for $\gamma \in \mathcal{K}$ and $\alpha_0 > 0$, then A is γ-robust for this γ and each $\tilde{\alpha}_0 \in (0, \alpha_0)$, and if* (iii) *holds for $\beta \in \mathcal{KL}$, then A is attracting with this rate β for this continuous time system* (2.1).

Proof. (i)⇒(ii): Since A is an attracting set by Corollary 4.3, it is also γ-robust for some suitable $\gamma \in \mathcal{K}$ and $\tilde{\alpha}_0 > 0$. Since by Proposition 3.6 the α_0-inflated numerical system (3.4) for $\alpha_0 = \tilde{\alpha}_0/2$ and n sufficiently large is embedded in the $\tilde{\alpha}_0$-inflated time-h_n map (3.3), Proposition 3.8 applied with $\alpha = ch_n^q$, $C = 1 + h_n L$, and $D = 1/\sqrt{ch_n^q}$ implies the existence of $\tilde{\gamma}_n$-robust attracting sets $\widetilde{A}_n$ with $d_H(A, \widetilde{A}_n) \leq \gamma(\sqrt{ch_n^q})$ and

$$\tilde{\gamma}_n(r) \leq \gamma\left(\frac{1 + h_n L}{1 - \sqrt{ch_n^q}} r\right).$$

Since the attractors A_n converge to A and—by minimality—are contained in the attracting sets $\widetilde{A}_n$, we can conclude that $\rho_n = \operatorname{dist}(A_n, \widetilde{A}_n) \to 0$ as $n \to \infty$; hence by Lemma 4.4 the A_n are γ_n-robust with $\gamma_n(r) \leq \tilde{\gamma}_n(r) + \rho_n$ and α_0, which shows the claim.

(i) ⇒ (iii): Since A is an attracting set, by Corollary 4.3 and Proposition 4.5, it satisfies inequality (4.5) for suitable β, γ, and ε. Thus by Proposition 3.6 for all sufficiently large $n \in \mathbb{N}$, all $x \in B$, and all $i \in \mathbb{N}$, we find some $w \in \mathcal{W}_{e^{h_n L} ch_n^q}$ such that

$$\varphi(ih_n, x, w) = \widetilde{\Phi}_{h_n}(ih_n, x).$$

This yields

$$\begin{aligned}
\|\widetilde{\Phi}_{h_n}(ih_n, x)\|_{A_n} &\leq \|\widetilde{\Phi}_{h_n}(ih_n, x)\|_A + d_H(A_n, A) \\
&= \|\varphi(ih_n, x, w)\|_A + d_H(A_n, A) \\
&\leq \beta(\|x\|_A, ih_n) + d_H(A_n, A) + (1+\varepsilon)\gamma(e^{h_n L} ch_n^q) \\
&\leq \beta(\|x\|_{A_n} + d_H(A_n, A), ih_n) + d_H(A_n, A) + (1+\varepsilon)\gamma(e^{h_n L} ch_n^q),
\end{aligned}$$

which shows the assertion for $\varepsilon_n = d_H(A_n, A) + (1+\varepsilon)\gamma(e^{h_n L} ch_n^q)$.

(ii) ⇒ (i): Similar to the arguments in case "(i) ⇒ (ii)," we obtain that for sufficiently large $n \in \mathbb{N}$ there exist $\gamma_n(D_n \cdot)$-robust attracting sets $\widetilde{A}_n$ for the inflated time-h_n map (3.3) of the α_n-inflated system for suitable constants $C_n \to 1$ and $\alpha_n \to \alpha_0$, such that $d_H(\widetilde{A}_n, A) \to 0$. Hence by Proposition 5.1 we obtain that A is a γ-robust attracting set for each $\tilde{\alpha}_0 \in (0, \alpha_0)$ for (2.1). It remains to show that A is an attractor. If this is not the case, then by Lemmas 2.8 and 2.9 there exists an attractor $\widetilde{A}$ for φ with $\widetilde{A} \subset A$, $\widetilde{A} \neq A$, and attracted neighborhood B. Denote $\eta := d_H(\widetilde{A}, A) > 0$. Again following the arguments from the case "(i) ⇒ (ii)," this implies that for all sufficiently large $n \in \mathbb{N}$ the attractors A_n for the numerical systems $\widetilde{\Phi}_{h_n}$ must satisfy $\operatorname{dist}(A_n, \widetilde{A}) < \eta/2$. This implies $d_H(A_n, A) \geq \eta/2$ and hence contradicts the convergence $d_H(A_n, A) \to 0$ for $n \to \infty$.

(iii) ⇒ (i): Fixing some $T > 0$ and some $\varepsilon > 0$, by Gronwall's lemma for all $n > 0$ sufficiently large and all $x \in B$ we obtain the inequality

$$\|\widetilde{\Phi}_h(i_n h_n, x) - \varphi(T, x)\| \leq \varepsilon,$$

where $i_n \in \mathbb{N}$ can be chosen such that $|T - i_n h_n| < \varepsilon$. Hence from the convergence of A_n to A and from the properties of β_n and β we obtain

$$\|\varphi(T,x)\|_A \leq \beta(\|x\|_A + \varepsilon, T + \varepsilon) + \varepsilon,$$

and since $\varepsilon > 0$ was arbitrary by continuity of β, this implies

$$\|\varphi(T,x)\|_A \leq \beta(\|x\|_A, T),$$

which implies that A is an attracting set since $T > 0$ was arbitrary. The fact that A is an attractor follows similarly to the case "(ii) ⇒ (i)," above. □

In other words, Theorem 6.2 states that a sequence of "numerical" attractors converges to a "real" attractor if and only if the elements of this sequence are either uniform robust or attracting with a uniform rate.

Remark 6.3. Note that we have used the minimality of attractors only in the proof of the implication "(i) ⇒ (ii)." Hence the equivalence "(i) ⇔ (iii)" and the implication "(ii) ⇒ (i)" remain true for general attracting sets.

In the next theorem we shift our attention to a sequence of uniformly robust numerical attractors (in the sense of Theorem 6.2 (ii)) without the a priori assumption about convergence of these sets. It turns out that this sequence of numerical attractors converges to a set if and only if this set is an attractor.

THEOREM 6.4. *Consider the continuous time system* (2.1) *and a family of numerical one-step approximation* $\widetilde{\Phi}_{h_n}$ *satisfying* (2.6) *for a sequence of time-steps* $h_n \to 0$ *as* $n \to \infty$*. Let* A_n *be attractors for the discrete time systems induced by these numerical approximations, each with the same attracted neighborhood* B*, assume that they are* γ_n*-robust for the numerical system* $\widetilde{\Phi}_{h_n}$*, for some* $\alpha_0 > 0$ *and* $\gamma_n(r) \leq \gamma(C_n r) + \rho_n$ *for some suitable* $\gamma \in \mathcal{K}$ *and sequences* $C_n \to 1$ *and* $\rho_n \to 0$*, and let* $A \subset B$ *be a compact set.*

Then the following statements are equivalent.

(i) *A is an attractor for* (2.1) *with attracted neighborhood* B*.*

(ii) $d_H(A_n, A) \to 0$ *as* $n \to \infty$*.*

In this case, A is γ-robust for (2.1) *for* γ *and each* $\tilde{\alpha}_0 \in (0, \alpha_0)$*.*

Proof. (i) ⇒ (ii): Since by Lemma 2.7 and Theorem 4.1 the attractor A is γ-robust for some suitable $\gamma \in \mathcal{K}$, by Proposition 6.1(a) and Lemma 2.8 we can conclude $\operatorname{dist}(A_n, A) \to 0$ as $n \to \infty$. For the converse "dist" estimate, by the assumption on the γ_n-robustness of the A_n, for each $\varepsilon > 0$ and all $n \in \mathbb{N}$ sufficiently large there exist attracting sets $\widetilde{A}_n$ for the time-h_n map of the continuous time system with $\operatorname{dist}(\widetilde{A}_n, A_n) \leq \varepsilon$. By Lemma 2.8 each of these sets contains an attractor for the time-h_n map (2.5) and attracted neighborhood B, which by Lemma 5.2 coincides with A. This implies $\operatorname{dist}(A, A_n) \leq \varepsilon$, and since $\varepsilon > 0$ was arbitrary we obtain $\operatorname{dist}(A, A_n) \to 0$ as $n \to \infty$. This shows the desired convergence.

(ii) ⇒ (i): This follows from the implication "(ii) ⇒ (i)" in Theorem 6.2. □

In other words, Theorem 6.4 states that a sequence of uniformly robust "numerical" attractors converges to some set A if and only if it is a "real" attractor.

Finally, we are going to investigate the rates of convergence of A_n to A under the assumptions of Theorem 6.4.

THEOREM 6.5. *Consider the continuous time system* (2.1) *and a family of numerical one-step approximation* $\widetilde{\Phi}_{h_n}$ *satisfying* (2.6) *for a sequence of time-steps* $h_n \to 0$ *as* $n \to \infty$ *and constants* c*,* $q > 0$*. Let* A_n *be attractors for the discrete time systems* *induced by these numerical approximations, each with the same attracted neighborhood B, and assume that they are γ_n-robust for the numerical system $\widetilde{\Phi}_{h_n}$ for some $\alpha_0 > 0$ and $\gamma_n(r) \le \gamma(C_n r) + \rho_n$ for some suitable $\gamma \in \mathcal{K}$ and sequences $C_n \to 1$ and $\rho_n \to 0$. Let $A \subset B$ be a compact set, and assume that one of the following two conditions is satisfied:*

(i) *A is an attractor for (2.1) with attracted neighborhood B.*

(ii) *$d_H(A_n, A) \to 0$ as $n \to \infty$.*

Then for all sufficiently large $n \in \mathbb{N}$ we obtain the estimates

$$\operatorname{dist}(A, A_n) \le \gamma(C_n e^{Lh_n} c h_n^q) + \rho_n \quad \textit{and} \quad \operatorname{dist}(A_n, A) \le \gamma(c h_n^q)$$

for the rate of convergence of A_n to A.

Proof. Under the assumptions, Theorem 6.4 implies that A is γ-robust for (2.1). Hence by Proposition 6.1 we obtain the existence of attracting sets for the numerical systems and the time-h_n maps, respectively, with the desired distances. By Lemmas 2.8, 2.9, and 5.2, the attractors A_n and A are contained in these attracting sets, and hence the "dist" estimates remain valid. □

ON THE VELOCITY-PRESSURE-VORTICITY LEAST-SQUARES MIXED FINITE ELEMENT METHOD FOR THE 3D STOKES EQUATIONS[*]

HUO-YUAN DUAN[†] AND GUO-PING LIANG[†]

Abstract. This paper provides a new strict mathematical analysis for the velocity-pressure-vorticity least-squares methods (i.e., the standard linear element method and the Bochev–Gunzburger method) for the 3D Stokes problem with homogeneous velocity boundary condition. The analysis shows that, in general, the divergence of the vorticity does not affect the coerciveness and the accuracy. This admits the use of the edge element for the vorticity to reduce the number of whole unknowns. Moreover, the analysis also shows that, in the standard linear element method, the L^2 error bound for the velocity is $\mathcal{O}(h^{3/2})$ generally. Numerical examples are presented.

Key words. Stokes equation, velocity-pressure-vorticity least-squares mixed finite element method, Aubin–Nitsche duality argument

AMS subject classification. 65N30

DOI. 10.1137/S0036142901399604

1. Introduction. As far as the Stokes problem is concerned, it is well known that the primal form in terms of velocity-pressure requires the approximating spaces to satisfy the Babuška–Brezzi condition in order to obtain stability and convergence. Generally, this condition excludes the use of simple equal low-order elements (e.g., the continuous linear elements). Besides, an indefinite system is often a source of trouble in practical implementation; see [13], [14] for more details.

In addition, when some important variable (e.g., the vorticity) in the Stokes problem is needed, it seems impossible to obtain accurate approximate solutions in the mixed method in terms of vector potential-vorticity, with the use of the continuous linear elements; see, e.g., [13].

During the past decade, the least-squares mixed finite element method has been demonstrated to be very effective as an alternative approach to numerically solve the Stokes problem (see [1], [2], [3], [4], [5], [6], [7], [8], [9], [10], [11], [12]), which offers many advantages such as that any combination of simple low-order approximating spaces (e.g., the linear elements) can be employed for all variables and that the weak problem is generally coercive; cf. [2].

Undoubtedly, the least-squares scheme in terms of velocity-pressure-vorticity for the Stokes problem is such a method (cf. [1], [3], [6], [9], [10]). Due to solving only seven unknowns (the three dimensional (3D) case), this scheme is the simplest and the most widely used one in all schemes of least-squares type for the Stokes problem. To our best knowledge, however, a strict mathematical analysis for this scheme has been missing for many years. (In the earlier works [9], [35], the mathematical analysis and conclusions are not correct due to the fact that the H^1 coerciveness does not hold for all variables.)

On the other hand, as is pointed out by several authors (see [1], [2], [3], [4], [5]), in three dimensions the divergence of the vorticity is indispensable to both coerciveness

[†] Institute of Mathematics, Chinese Academy of Sciences, Beijing 100080, People's Republic of China (dhymath@yahoo.com.cn, guoping@math03.math.ac.cn).

and accuracy, although it is not so in two dimensions. This viewpoint is drawn from the Agmon–Doulis–Nirenberg (ADN) theory (cf. [4], [5]). However, up until now, it in fact has not been very clear whether both coerciveness and accuracy are affected if the divergence of the vorticity is not introduced. Clearly, if the divergence of the vorticity can be dropped, then the tangential continuous element (i.e., the edge element or the Nédélec element [23], [24]) can be used for this variable, and as a consequence, the number of unknowns will be greatly reduced, without loss of accuracy.

Therefore, it is of interest and importance to investigate the coerciveness and the accuracy for the velocity-pressure-vorticity least-squares method when employing the continuous elements and not including the divergence of the vorticity.

In this paper, we show that the weak problem of this scheme is indeed coercive for both pressure and vorticity over the L^2 space and for velocity over the H^1 space and that the accuracy is not affected generally, even if the divergence of the vorticity is not introduced into the weak problem.

In particular, without including the divergence of the vorticity in the Bochev–Gunzburger method (cf. [4], [2], [3]), we show that the error bounds for all variables are still optimal. This corrects the traditional viewpoint.

Moreover, for the least-squares scheme (without the divergence of the vorticity) with the use of the continuous linear elements for all variables, in general, we show that the L^2 error bound for the velocity is $\mathcal{O}(h^{3/2})$. The numerical results given in the last section support these theoretical results on error bounds.

We remark that all these L^2 error estimates are derived from the classical Aubin–Nitsche duality argument (cf. [15], [16], [18]), which usually prerequisitely requires that the domain occupied by the flow be suitably smooth to ensure the existence of the solution and some regularities.

In addition, owing to that the auxiliary variational problem, introduced in the duality argument, cannot be coercive over the whole space for both pressure and vorticity and that it is no longer a least-squares first-order system, the existence of the solution cannot be directly deduced from either the Lax–Milgram lemma (cf. [15], [18]) or the ADN theory (cf. [4], [5]). In fact, it turns out that the existence of the solution and the corresponding regularities, which are derived from a constructive approach in this paper, are not trivial.

Let us mention the recent work [34]. A completely different approach is taken in [34] to obtain the same error bounds in the energy norm, but no error estimates are given for the velocity in the L^2 norm.

This paper is outlined as follows: In section 2, we recall some Hilbert spaces and inequalities and the regularities to classical problems. In section 3, for the velocity-pressure-vorticity least-squares method, dropping the divergence of the vorticity, we obtain both coerciveness and basic error bounds. In section 4, using the Aubin–Nitsche duality argument, we derive an improved error bound $\mathcal{O}(h^{3/2})$ for the velocity in the standard linear element method. In section 5, we show that the error bounds in the Bochev–Gunzburger method are still optimal, even without introducing the divergence of vorticity. In section 6, numerical examples are given to verify the theoretical results in sections 3 and 4.

2. Inequalities and regularities.

Let $\Omega \subset \Re^3$ be an open bounded domain, with boundary $\Gamma = \partial\Omega$ and $\boldsymbol{n}$ the unit normal vector to Γ. Elementary differential operators are recalled as follows:

$$\partial^r v = \frac{\partial^{|r|} v}{\partial x_1^{r_1} \partial x_2^{r_2} \partial x_3^{r_3}}, \quad |r| = r_1 + r_2 + r_3,$$

$$\bigtriangledown v = (\partial v/\partial x_1, \partial v/\partial x_2, \partial v/\partial x_3), \quad \mathbf{curl}\, \boldsymbol{v} = \bigtriangledown \times \boldsymbol{v}, \quad \mathrm{div}\, \boldsymbol{v} = \bigtriangledown \cdot \boldsymbol{v}.$$

We introduce the Hilbert spaces

$$\begin{aligned}
L^2(\Omega) &= \{v; \textstyle\int_\Omega v^2 < \infty\},\\
L^2_0(\Omega) &= \{q \in L^2(\Omega); \textstyle\int_\Omega q = 0\},\\
H^m(\Omega) &= \{\partial^r v \in L^2(\Omega), 0 \le |r| \le m\} \quad (m \ge 1),\\
H^1_0(\Omega) &= \{v \in L^2(\Omega); \bigtriangledown v \in (L^2(\Omega))^3, v_{|\Gamma} = 0\},\\
H(\mathbf{curl}; \Omega) &= \{\boldsymbol{v} \in (L^2(\Omega))^3; \mathbf{curl}\, \boldsymbol{v} \in (L^2(\Omega))^3\},\\
H_0(\mathbf{curl}; \Omega) &= \{\boldsymbol{v} \in H(\mathbf{curl}; \Omega); \boldsymbol{v} \times \boldsymbol{n}_{|\Gamma} = \mathbf{0}\},\\
H(\mathrm{div}; \Omega) &= \{\boldsymbol{v} \in (L^2(\Omega))^3; \mathrm{div}\, \boldsymbol{v} \in L^2(\Omega)\},\\
H_0(\mathrm{div}; \Omega) &= \{\boldsymbol{v} \in H(\mathrm{div}; \Omega); \boldsymbol{v} \cdot \boldsymbol{n}_{|\Gamma} = 0\},
\end{aligned}$$

where all the above spaces are equipped with natural norms (cf. [16], [13], [27], [26]). The following norms will be encountered in this paper:

$$||\boldsymbol{v}||^2_{0,\mathrm{div}} = ||\boldsymbol{v}||^2_0 + ||\mathrm{div}\, \boldsymbol{v}||^2_0, \qquad ||\boldsymbol{v}||^2_{0,\mathbf{curl}} = ||\boldsymbol{v}||^2_0 + ||\mathbf{curl}\, \boldsymbol{v}||^2_0.$$

In addition, H^{-1} is the dual space of $H^1_0(\Omega)$.

Two of Green's formulae of integration by parts are as follows (cf. [13]):

$$\begin{aligned}
(\boldsymbol{v}, \bigtriangledown \phi) + (\mathrm{div}\, \boldsymbol{v}, \phi) &= \int_\Gamma \boldsymbol{v} \cdot \boldsymbol{n}\, \phi \quad \forall \boldsymbol{v} \in H(\mathrm{div}; \Omega), \forall \phi \in H^1(\Omega),\\
(\mathbf{curl}\, \boldsymbol{v}, \boldsymbol{\phi}) - (\boldsymbol{v}, \mathbf{curl}\, \boldsymbol{\phi}) &= \int_\Gamma \boldsymbol{v} \times \boldsymbol{n}\, \boldsymbol{\phi} \quad \forall \boldsymbol{v} \in H(\mathbf{curl}; \Omega), \forall \boldsymbol{\phi} \in (H^1(\Omega))^3.
\end{aligned}$$

PROPOSITION 2.1 (see [13, 20, 21, 30]). *Assume that $\Omega \subset \Re^3$ is a simply connected and bounded domain with a Lipschitz continuous boundary Γ. Then*

$$||\boldsymbol{v}||_0 \le C\, \{||\mathbf{curl}\, \boldsymbol{v}||_0 + ||\mathrm{div}\, \boldsymbol{v}||_0\} \quad \forall \boldsymbol{v} \in H_0(\mathrm{div}; \Omega) \cap H(\mathbf{curl}; \Omega). \tag{2.1}$$

PROPOSITION 2.2 (see [13, 31]). *Assume that $\Omega \subset \Re^3$ is a simply connected bounded domain with $C^{1,1}$ boundary Γ or is a bounded and convex polyhedron. Then*

$$|\boldsymbol{v}|_1 \le C\, \{||\mathbf{curl}\, \boldsymbol{v}||_0 + ||\mathrm{div}\, \boldsymbol{v}||_0\} \quad \forall \boldsymbol{v} \in H_0(\mathrm{div}; \Omega) \cap (H^1(\Omega))^3. \tag{2.2}$$

PROPOSITION 2.3 (see [13, 17, 22]). *Assume that $\Omega \subset \Re^3$ is a simply connected and bounded domain with a Lipschitz continuous boundary Γ. Given $\boldsymbol{\chi} \in (H^{-1}(\Omega))^3$ and $g \in L^2_0(\Omega)$, there exists a unique solution $(\boldsymbol{u}, p) \in (H^1_0(\Omega))^3 \times (H^1(\Omega) \cap L^2_0(\Omega))$ to the Stokes problem*

$$-\Delta\, \boldsymbol{u} + \bigtriangledown p = \boldsymbol{\chi}, \quad \mathrm{div}\, \boldsymbol{u} = g, \quad \boldsymbol{u}_{|\Gamma} = \mathbf{0}, \tag{2.3}$$

the solution of which satisfies

$$||\boldsymbol{u}||_1 + ||p||_0 \le C\, (||\boldsymbol{\chi}||_{-1} + ||g||_0). \tag{2.4}$$

Moreover, if $g \equiv 0$, then $p \in L^2_0(\Omega)$ satisfies

$$(p, \mathrm{div}\, \boldsymbol{v}) = (\mathbf{curl}\, \boldsymbol{u}, \mathbf{curl}\, \boldsymbol{v}) - (\boldsymbol{\chi}, \boldsymbol{v}) \quad \forall \boldsymbol{v} \in (H^1_0(\Omega))^3. \tag{2.5}$$

If additionally $\Gamma \in C^{r+2}$, $\boldsymbol{\chi} \in (H^r(\Omega))^3$, and $g \in H^{r+1}(\Omega)$ with $r = 0, 1$, we have

$$||\boldsymbol{u}||_{r+2} + ||p||_{r+1} \le C\, (||\boldsymbol{\chi}||_r + ||g||_{r+1}). \tag{2.6}$$

3. Coerciveness without the divergence of the vorticity. We consider the Stokes problem in 3D space,

$$-\Delta\, \boldsymbol{u} + \bigtriangledown p = \boldsymbol{f}, \quad \operatorname{div} \boldsymbol{u} = 0, \quad \text{in } \Omega, \quad \boldsymbol{u} = \boldsymbol{0}, \quad \text{on } \Gamma, \tag{3.1}$$

where $\boldsymbol{u} \in (H_0^1(\Omega))^3$ and $p \in L_0^2(\Omega)$ are velocity and pressure, respectively, $\boldsymbol{f} \in (L^2(\Omega))^3$ is the given function, and $\Omega \subset \Re^3$ is the domain occupied by the flow, with boundary $\Gamma = \partial\Omega$ and the unit normal vector $\boldsymbol{n}$ to Γ.

Let the vorticity

$$\boldsymbol{\omega} = \mathbf{curl}\, \boldsymbol{u} \tag{3.2}$$

be a new unknown; in the light of $\mathbf{curl}\,\mathbf{curl}\, \boldsymbol{u} = -\Delta\, \boldsymbol{u} + \bigtriangledown \operatorname{div} \boldsymbol{u}$ and $\operatorname{div} \boldsymbol{u} = 0$, we can write (3.1) in the first-order system as follows:

$$\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p = \boldsymbol{f}, \quad \boldsymbol{\omega} = \mathbf{curl}\, \boldsymbol{u}, \quad \operatorname{div} \boldsymbol{u} = 0, \quad \text{in } \Omega, \tag{3.3}$$

where

$$\boldsymbol{u}_{|\Gamma} = \boldsymbol{0}, \qquad \int_\Omega p = 0. \tag{3.4}$$

Remark 3.1. Clearly, there naturally hold (cf. [11], [33])

$$\boldsymbol{\omega} \cdot \boldsymbol{n}_{|\Gamma} = 0, \quad \operatorname{div} \boldsymbol{\omega} = 0, \tag{3.5}$$

which are redundant equations for the first-order system (3.3) and (3.4). This can be seen from Theorem 3.1.

Let

$$\mathcal{J}(\boldsymbol{u}, p, \boldsymbol{\omega}) = ||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p||_0^2 + ||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\operatorname{div} \boldsymbol{u}||_0^2, \tag{3.6}$$

$$\mathcal{J}^+(\boldsymbol{u}, p, \boldsymbol{\omega}) = \mathcal{J}(\boldsymbol{u}, p, \boldsymbol{\omega}) + ||\operatorname{div} \boldsymbol{\omega}||_0^2. \tag{3.7}$$

THEOREM 3.1. *Under the same conditions as in Proposition* 2.2*, there holds*

$$\mathcal{J}(\boldsymbol{u}, p, \boldsymbol{\omega}) \geq C\, \{||\boldsymbol{u}||_1^2 + ||p||_0^2 + ||\boldsymbol{\omega}||_0^2\} \tag{3.8}$$

for all $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$.

Proof. Let $\alpha > 0$ be a constant to be determined; in the light of $(\boldsymbol{\omega}, \mathbf{curl}\, \boldsymbol{u}) = (\mathbf{curl}\, \boldsymbol{\omega}, \boldsymbol{u})$, we have

$$\begin{aligned} ||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 = &\frac{1}{2}\, \{||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u} + \alpha\, \mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u} - \alpha\, \boldsymbol{\omega}||_0^2\} \\ &+ \alpha \left(1 - \frac{\alpha}{2}\right) \{||\mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\boldsymbol{\omega}||_0^2\} - 2\, \alpha\, (\mathbf{curl}\, \boldsymbol{\omega}, \boldsymbol{u}). \end{aligned} \tag{3.9}$$

In the light of $(\bigtriangledown p, \boldsymbol{u}) = -(\operatorname{div} \boldsymbol{u}, p)$, we have

$$\begin{aligned} ||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p||_0^2 = &||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p - \alpha\, \boldsymbol{u}||_0^2 \\ &+ 2\, \alpha\, (\mathbf{curl}\, \boldsymbol{\omega}, \boldsymbol{u}) - 2\, \alpha\, (\operatorname{div} \boldsymbol{u}, p) - \alpha^2\, ||\boldsymbol{u}||_0^2, \end{aligned} \tag{3.10}$$

where for some constant $\varepsilon_1 > 0$ we have

$$-2\, \alpha\, (\operatorname{div} \boldsymbol{u}, p) \geq -\varepsilon_1\, ||p||_0^2 - \frac{C_1\, \alpha^2}{\varepsilon_1}\, ||\operatorname{div} \boldsymbol{u}||_0^2. \tag{3.11}$$

Owing to the inf-sup condition [13]

$$\sup_{\boldsymbol{v}\in(H_0^1(\Omega))^3}\frac{(\operatorname{div}\boldsymbol{v},q)}{||\boldsymbol{v}||_1}\geq C\,||q||_0\quad\forall q\in L_0^2(\Omega),\tag{3.12}$$

we can find $\boldsymbol{v}^*\in(H_0^1(\Omega))^3$ such that

$$(\operatorname{div}\boldsymbol{v}^*,p)=||p||_0^2,\quad ||\boldsymbol{v}^*||_1\leq C\,||p||_0.\tag{3.13}$$

Let $\gamma>0$ be a constant to be determined; in the light of $(\mathbf{curl}\,\boldsymbol{\omega},\boldsymbol{v}^*)=(\boldsymbol{\omega},\mathbf{curl}\,\boldsymbol{v}^*)$ and $(\operatorname{div}\boldsymbol{v}^*,p)=||p||_0^2$, we have

$$\begin{aligned}||\mathbf{curl}\,\boldsymbol{\omega}+\bigtriangledown p||_0^2=&||\mathbf{curl}\,\boldsymbol{\omega}+\bigtriangledown p+\gamma\,\boldsymbol{v}^*||_0^2\\&-2\,\gamma\,(\boldsymbol{\omega},\mathbf{curl}\,\boldsymbol{v}^*)+2\,\gamma\,||p||_0^2-\gamma^2\,||\boldsymbol{v}^*||_0^2,\end{aligned}\tag{3.14}$$

where for some constant $\varepsilon_2>0$, in the light of $||\boldsymbol{v}^*||_1\leq C\,||p||_0$, we have

$$-2\,\gamma\,(\boldsymbol{\omega},\mathbf{curl}\,\boldsymbol{v}^*)\geq-\varepsilon_2\,||\boldsymbol{\omega}||_0^2-\frac{C_2\,\gamma^2}{\varepsilon_2}\,||p||_0^2.\tag{3.15}$$

In the light of $||\boldsymbol{v}^*||_0^2\leq C\,||\boldsymbol{v}^*||_1^2\leq C_3\,||p||_0^3$, we then get

$$||\mathbf{curl}\,\boldsymbol{\omega}+\bigtriangledown p||_0^2\geq\gamma\,\left[2-\gamma\,\left(C_3+\frac{C_2}{\varepsilon_2}\right)\right]\,||p||_0^2-\varepsilon_2\,||\boldsymbol{\omega}||_0^2.\tag{3.16}$$

From (3.10), (3.11), and (3.16), we have

$$\begin{aligned}2\,||\mathbf{curl}\,\boldsymbol{\omega}+\bigtriangledown p||_0^2\geq&\left\{\gamma\,\left[2-\gamma\,\left(C_3+\frac{C_2}{\varepsilon_2}\right)\right]-\varepsilon_1\right\}\,||p||_0^2\\&-\varepsilon_2\,||\boldsymbol{\omega}||_0^2-\alpha^2\,||\boldsymbol{u}||_0^2\\&+2\,\alpha\,(\mathbf{curl}\,\boldsymbol{\omega},\boldsymbol{u})-\frac{C_1\,\alpha^2}{\varepsilon_1}\,||\operatorname{div}\boldsymbol{u}||_0^2,\end{aligned}\tag{3.17}$$

where, in the light of $||\boldsymbol{u}||_0\leq C\,\{||\mathbf{curl}\,\boldsymbol{u}||_0+||\operatorname{div}\boldsymbol{u}||_0\}$, we have

$$-\alpha^2\,||\boldsymbol{u}||_0^2\geq-C_4\,\alpha^2\,||\mathbf{curl}\,\boldsymbol{u}||_0^2-C_4\,\alpha^2\,||\operatorname{div}\boldsymbol{u}||_0^2.\tag{3.18}$$

Summing (3.9) and (3.17) and in the light of (3.18), we have

$$\begin{aligned}&||\boldsymbol{\omega}-\mathbf{curl}\,\boldsymbol{u}||_0^2+2\,||\mathbf{curl}\,\boldsymbol{\omega}+\bigtriangledown p||_0^2\\&\geq\alpha\,\left[1-\alpha\,\left(\frac{1}{2}+C_4\right)\right]\,||\mathbf{curl}\,\boldsymbol{u}||_0^2+\left[\alpha\,\left(1-\frac{\alpha}{2}\right)-\varepsilon_2\right]\,||\boldsymbol{\omega}||_0^2\\&\quad+\left\{\gamma\,\left[2-\gamma\,\left(C_3+\frac{C_2}{\varepsilon_2}\right)\right]-\varepsilon_1\right\}\,||p||_0^2\\&\quad-\alpha^2\,\left(\frac{C_1}{\varepsilon_1}+C_4\right)\,||\operatorname{div}\boldsymbol{u}||_0^2.\end{aligned}\tag{3.19}$$

Therefore, let $\beta > 0$ be a constant to be determined, and we have

$$\begin{aligned} &||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + 2\, ||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p||_0^2 + \beta\, ||\mathrm{div}\, \boldsymbol{u}||_0^2 \\ &\quad \geq \alpha \left[1 - \alpha \left(\frac{1}{2} + C_4\right)\right] ||\mathbf{curl}\, \boldsymbol{u}||_0^2 + \left[\alpha \left(1 - \frac{\alpha}{2}\right) - \varepsilon_2\right] ||\boldsymbol{\omega}||_0^2 \\ &\qquad + \left\{\gamma \left[2 - \gamma \left(C_3 + \frac{C_2}{\varepsilon_2}\right)\right] - \varepsilon_1\right\} ||p||_0^2 \\ &\qquad + \left[\beta - \alpha^2 \left(\frac{C_1}{\varepsilon_1} + C_4\right)\right] ||\mathrm{div}\, \boldsymbol{u}||_0^2. \end{aligned} \tag{3.20}$$

Taking

$$0 < \alpha < \frac{2}{1 + 2\, C_4}, \quad 0 < \varepsilon_2 < \alpha \left(1 - \frac{\alpha}{2}\right), \tag{3.21}$$

$$0 < \gamma < \frac{2\, \varepsilon_2}{\varepsilon_2\, C_3 + C_2}, \quad 0 < \varepsilon_1 < \gamma \left[2 - \gamma \left(C_3 + \frac{C_2}{\varepsilon_2}\right)\right], \tag{3.22}$$

$$\beta > \alpha^2 \left(\frac{C_1}{\varepsilon_1} + C_4\right), \tag{3.23}$$

we have

$$\begin{aligned} &||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + 2\, ||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p||_0^2 + \beta\, ||\mathrm{div}\, \boldsymbol{u}||_0^2 \\ &\geq C\, \{||\mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\mathrm{div}\, \boldsymbol{u}||_0^2 + ||p||_0^2 + ||\boldsymbol{\omega}||_0^2\}. \end{aligned} \tag{3.24}$$

Finally, we have

$$\begin{aligned} \mathcal{J}(\boldsymbol{u}, p, \boldsymbol{\omega}) &\geq \frac{1}{\max(2, \beta)} \{||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + 2\, ||\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p||_0^2 + \beta\, ||\mathrm{div}\, \boldsymbol{u}||_0^2\} \\ &\geq C\, \{||\mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\mathrm{div}\, \boldsymbol{u}||_0^2 + ||p||_0^2 + ||\boldsymbol{\omega}||_0^2\}. \end{aligned} \tag{3.25}$$

We further have

$$\mathcal{J}(\boldsymbol{u}, p, \boldsymbol{\omega}) \geq C\, \{||\boldsymbol{u}||_1^2 + ||p||_0^2 + ||\boldsymbol{\omega}||_0^2\} \tag{3.26}$$

because of $||\boldsymbol{u}||_1 \leq C\, \{||\mathbf{curl}\, \boldsymbol{u}||_0 + ||\mathrm{div}\, \boldsymbol{u}||_0\}$. □

COROLLARY 3.1. *Under the same hypotheses as in Theorem* 3.1*, we have*

$$\mathcal{J}^+(\boldsymbol{u}, p, \boldsymbol{\omega}) \geq C\, \{||\boldsymbol{u}||_1^2 + ||p||_0^2 + ||\boldsymbol{\omega}||_{\mathrm{div}}^2\} \tag{3.27}$$

for all $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times (H(\mathbf{curl}; \Omega) \cap H(\mathrm{div}; \Omega))$.

Now, we describe the finite element method.

Let $\mathcal{C}_h$ be the regular triangulation of Ω into tetrahedra (cf. [15]). Define

$$V_h = \{v \in H^1(\Omega); v_{|_K} \in \mathcal{P}_1(K)\ \forall K \in \mathcal{C}_h\}, \tag{3.28}$$

where $\mathcal{P}_1(K)$ is the space of linear polynomials. Let $\tilde{v} \in V_h$ be the standard interpolant to $v \in H^2(\Omega)$, and from the standard interpolation theory in [15], we have

$$||v - \tilde{v}||_0 + h\, ||v - \tilde{v}||_1 \leq C\, h^2\, ||v||_2. \tag{3.29}$$

Define

$$U_h = (V_h \cap H_0^1(\Omega))^3, \quad Q_h = V_h \cap L_0^2(\Omega), \quad W_h = (V_h)^3. \tag{3.30}$$

The finite element method is to find $(\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h) \in U_h \times Q_h \times W_h$ such that

$$\begin{aligned} &(\mathbf{curl}\,\boldsymbol{\omega}_h + \bigtriangledown p_h, \mathbf{curl}\,\boldsymbol{z} + \bigtriangledown q) \\ &\quad + (\boldsymbol{\omega}_h - \mathbf{curl}\,\boldsymbol{u}_h, \boldsymbol{z} - \mathbf{curl}\,\boldsymbol{v}) + (\operatorname{div}\boldsymbol{u}_h, \operatorname{div}\boldsymbol{v}) \\ &\quad = (\boldsymbol{f}, \mathbf{curl}\,\boldsymbol{z} + \bigtriangledown q) \quad \forall(\boldsymbol{v}, q, \boldsymbol{z}) \in U_h \times Q_h \times W_h. \end{aligned} \tag{3.31}$$

THEOREM 3.2. *Under the same conditions as in Theorem* 3.1*, let* $(\boldsymbol{u}, p, \boldsymbol{\omega})$ *and* $(\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h)$ *be the solutions of* (3.3) *and* (3.31)*, respectively. If* $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H^2(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$*, then*

$$||\boldsymbol{u} - \boldsymbol{u}_h||_1 + ||p - p_h||_0 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 \le C\,h\,\{||\boldsymbol{u}||_2 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{3.32}$$

Proof. Let $\mathcal{A}((\boldsymbol{u}, p, \boldsymbol{\omega}); (\boldsymbol{v}, q, \boldsymbol{z}))$ be the bilinear form on $(H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$, defined by

$$\begin{aligned} \mathcal{A}((\boldsymbol{u}, p, \boldsymbol{\omega}); (\boldsymbol{v}, q, \boldsymbol{z})) &= (\mathbf{curl}\,\boldsymbol{\omega} + \bigtriangledown p, \mathbf{curl}\,\boldsymbol{z} + \bigtriangledown q) \\ &\quad + (\boldsymbol{\omega} - \mathbf{curl}\,\boldsymbol{u}, \boldsymbol{z} - \mathbf{curl}\,\boldsymbol{v}) + (\operatorname{div}\boldsymbol{u}, \operatorname{div}\boldsymbol{v}). \end{aligned} \tag{3.33}$$

We have the error orthogonality

$$\mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{v}, q, \boldsymbol{z})) = 0 \quad \forall(\boldsymbol{v}, q, \boldsymbol{z}) \in U_h \times Q_h \times W_h, \tag{3.34}$$

where $(\boldsymbol{u}, p, \boldsymbol{\omega})$ and $(\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h)$ are the solutions of (3.3) and (3.31), respectively.

Moreover, let $(\tilde{\boldsymbol{u}}, \tilde{p}, \tilde{\boldsymbol{\omega}}) \in U_h \times Q_h \times W_h$ be the standard interpolants to $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H_0^1(\Omega) \cap H^2(\Omega))^3 \times (H^2(\Omega) \cap L_0^2(\Omega)) \times (H^2(\Omega))^3$, respectively, and the interpolation error estimations similar to (3.29) hold.

In the light of (3.34) and the Schwarz inequality, we have

$$\begin{aligned} &\mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h)) \\ &\quad = \mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}})) \\ &\quad \le \mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h))^{1/2} \\ &\qquad \times \mathcal{A}((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2}. \end{aligned}$$

We then have

$$\begin{aligned} &\mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h))^{1/2} \\ &\quad \le \mathcal{A}((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2}. \end{aligned} \tag{3.35}$$

Therefore, we get

$$\begin{aligned} &||\boldsymbol{u} - \boldsymbol{u}_h||_1 + ||p - p_h||_0 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 \\ &\quad \le C\,\mathcal{A}((\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h); (\boldsymbol{u} - \boldsymbol{u}_h, p - p_h, \boldsymbol{\omega} - \boldsymbol{\omega}_h))^{1/2} \\ &\quad \le C\,\mathcal{A}((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2} \\ &\quad \le C\,\{||\boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}||_{0,\mathbf{curl}} + ||p - \tilde{p}||_1 + ||\boldsymbol{u} - \tilde{\boldsymbol{u}}||_1\} \\ &\quad \le C\,h\,\{||\boldsymbol{u}||_2 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \qquad \square \end{aligned} \tag{3.36}$$

Remark 3.2. It is obvious that one can use tangential continuous elements such as Nédélec edge elements (see [23], [24]) to approximate the vorticity, and the error bound becomes

$$||\boldsymbol{u} - \boldsymbol{u}_h||_1 + ||p - p_h||_0 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 \le C\,h\,\{||\boldsymbol{u}||_2 + ||p||_2 + ||\boldsymbol{f}||_1\} \tag{3.37}$$

since, in this case, from [19], [25] we have $||\tilde{\boldsymbol{\omega}} - \boldsymbol{\omega}||_{0,\mathbf{curl}} \leq C\, h\, \{||\boldsymbol{\omega}||_1 + ||\mathbf{curl}\, \boldsymbol{\omega}||_1\}$; here $\tilde{\boldsymbol{\omega}}$ is the interpolant in the Nédélec space.

Remark 3.3. Theorem 3.1 holds for the Navier–Stokes equations as follows:

$$-\nu\, \Delta\, \boldsymbol{u} + \boldsymbol{a} \cdot \bigtriangledown \boldsymbol{u} + \sigma\, \boldsymbol{u} + \bigtriangledown p = \boldsymbol{f}, \quad \operatorname{div} \boldsymbol{u} = 0, \quad \text{in } \Omega, \quad \boldsymbol{u}_{|\Gamma} = \mathbf{0}, \tag{3.38}$$

where $\boldsymbol{a}$ is the convection term satisfying $\operatorname{div} \boldsymbol{a} = 0$, and $\nu > 0$ is the viscosity and $\sigma \geq 0$ is a constant. Specifically, applying the same argument as in Theorem 3.1, we have

$$\begin{aligned} &||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\nu\, \mathbf{curl}\, \boldsymbol{\omega} + \boldsymbol{a} \cdot \bigtriangledown \boldsymbol{u} + \sigma\, \boldsymbol{u} + \bigtriangledown p||_0^2 + ||\operatorname{div} \boldsymbol{u}||_0^2 \\ &\quad \geq C\, \Bigg\{ \nu^2\, ||\mathbf{curl}\, \boldsymbol{u}||_0^2 + \nu^2\, ||\boldsymbol{\omega}||_0^2 \\ &\qquad + \frac{\nu^2}{\nu^2 + \sigma^2 + ||\boldsymbol{a}||_\infty^2}\, ||p||_0^2 + \frac{\nu^2 + \sigma^2 + ||\boldsymbol{a}||_\infty^2}{\nu^2}\, ||\operatorname{div} \boldsymbol{u}||_0^2 + \nu\, \sigma\, ||\boldsymbol{u}||_0^2 \Bigg\}, \end{aligned} \tag{3.39}$$

where $C > 0$ is independent of $\boldsymbol{a}, \sigma, \nu$.

Remark 3.4. The linear elasticity problem is as follows:

$$-\mu\, \Delta\, \boldsymbol{u} - (\lambda + \mu) \bigtriangledown \operatorname{div} \boldsymbol{u} = \boldsymbol{f}, \quad \text{in } \Omega, \quad \boldsymbol{u} = \mathbf{0}, \quad \text{on } \Gamma, \tag{3.40}$$

where λ and μ are Lamé coefficients. Introducing

$$\boldsymbol{\omega} = \mathbf{curl}\, \boldsymbol{u}, \quad p = (\lambda + 2\, \mu) \operatorname{div} \boldsymbol{u}, \tag{3.41}$$

we can rewrite (3.40) in the form

$$\mu\, \mathbf{curl}\, \boldsymbol{\omega} - \bigtriangledown p = \boldsymbol{f}, \quad \operatorname{div} \boldsymbol{u} - \frac{1}{\lambda + 2\, \mu} p = 0, \quad \boldsymbol{\omega} = \mathbf{curl}\, \boldsymbol{u}. \tag{3.42}$$

Then, we can obtain

$$\begin{aligned} &||\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}||_0^2 + ||\mu\, \mathbf{curl}\, \boldsymbol{\omega} - \bigtriangledown p||_0^2 + \left|\left| \operatorname{div} \boldsymbol{u} - \frac{1}{\lambda + 2\, \mu}\, p \right|\right|_0^2 \\ &\quad \geq C\, \{\mu^2\, ||\mathbf{curl}\, \boldsymbol{u}||_0^2 + \mu^2\, ||\boldsymbol{\omega}||_0^2 + ||p||_0^2 + ||\operatorname{div} \boldsymbol{u}||_0^2\}, \end{aligned} \tag{3.43}$$

where $C > 0$ is independent of λ and μ.

Remark 3.5. So far, we have shown that the divergence of the vorticity is not essential and does not affect the coerciveness. This corrects the traditional viewpoint (cf. [1], [2], [3], [4], [5]).

4. On the L^2 error bound for velocity. In this section, with the classical Aubin–Nitsche duality argument, we show that the L^2 error bound for the velocity is in fact $\mathcal{O}(h^{3/2})$.

Let us consider the auxiliary variational problem: to find $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$ such that

$$\mathcal{A}((\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*); (\boldsymbol{v}, q, \boldsymbol{z})) = (\boldsymbol{\chi}, \boldsymbol{v}) \tag{4.1}$$

for all $(\boldsymbol{v}, q, \boldsymbol{z}) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$, where $\boldsymbol{\chi} \in (H^1(\Omega))^3$.

THEOREM 4.1. *Under the same conditions as in Proposition* 2.3, *problem* (4.1) *has a unique solution* $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*)$, *which satisfies*

$$||\boldsymbol{u}^*||_2 \leq C\, ||\boldsymbol{\chi}||_0, \quad ||p^*||_2 + ||\boldsymbol{\omega}^*||_2 \leq C\, ||\boldsymbol{\chi}||_1. \tag{4.2}$$

Proof. The proof is divided into four steps, where the last step is used for verification.

Step 1. We consider the following problem: to find $\boldsymbol{v}_0 \in (H_0^1(\Omega))^3$ and $q_0 \in H^1(\Omega) \cap L_0^2(\Omega)$ such that

$$-\Delta\,\boldsymbol{v}_0 + \bigtriangledown q_0 = \boldsymbol{\chi}, \quad \mathrm{div}\boldsymbol{v}_0 = 0, \quad \boldsymbol{v}_{0|_\Gamma} = \mathbf{0}, \tag{4.3}$$

the solution of which satisfies

$$||\boldsymbol{v}_0||_2 + ||q_0||_1 \le C\,||\boldsymbol{\chi}||_0, \quad ||\boldsymbol{v}_0||_3 + ||q_0||_2 \le C\,||\boldsymbol{\chi}||_1. \tag{4.4}$$

Moreover, $q_0 \in L_0^2(\Omega)$ satisfies

$$(q_0, \mathrm{div}\,\boldsymbol{v}) = (\mathbf{curl}\,\mathbf{curl}\,\boldsymbol{v}_0 - \boldsymbol{\chi}, \boldsymbol{v}) \quad \forall \boldsymbol{v} \in (H_0^1(\Omega))^3. \tag{4.5}$$

Step 2. We consider the following problem: to find $\boldsymbol{u}_0 \in (H_0^1(\Omega))^3$ and $p_0 \in H^1(\Omega) \cap L_0^2(\Omega)$ such that

$$-\Delta\,\boldsymbol{u}_0 + \bigtriangledown p_0 = \boldsymbol{v}_0, \quad \mathrm{div}\,\boldsymbol{u}_0 = -q_0, \quad \boldsymbol{u}_{0|_\Gamma} = \mathbf{0}, \tag{4.6}$$

the solution of which satisfies

$$||\boldsymbol{u}_0||_2 + ||p_0||_1 \le C\,||\boldsymbol{\chi}||_0, \quad ||\boldsymbol{u}_0||_3 + ||p_0||_2 \le C\,||\boldsymbol{\chi}||_1. \tag{4.7}$$

Step 3. Define

$$\boldsymbol{u}^* = \boldsymbol{u}_0 + \boldsymbol{v}_0, \quad p^* = p_0 + q_0, \quad \boldsymbol{\omega}^* = \mathbf{curl}\,\boldsymbol{u}_0. \tag{4.8}$$

We have

$$||\boldsymbol{u}^*||_2 + ||p^*||_1 + ||\boldsymbol{\omega}^*||_1 \le C\,||\boldsymbol{\chi}||_0, \tag{4.9}$$
$$||\boldsymbol{u}^*||_3 + ||p^*||_2 + ||\boldsymbol{\omega}^*||_2 \le C\,||\boldsymbol{\chi}||_1. \tag{4.10}$$

Step 4. Note that

$$\mathbf{curl}\,\boldsymbol{\omega}^* + \bigtriangledown p^* = \boldsymbol{v}_0, \tag{4.11}$$
$$\boldsymbol{\omega}^* - \mathbf{curl}\,\boldsymbol{u}^* = -\mathbf{curl}\,\boldsymbol{v}_0, \quad \mathrm{div}\,\boldsymbol{u}^* = -q_0. \tag{4.12}$$

We can easily verify that $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*)$ satisfies (4.1). □

COROLLARY 4.1. *Let* $\boldsymbol{u}$ *and* $\boldsymbol{u}_h$ *be the exact and the approximate solutions. Under the same hypotheses as in Theorem* 4.1, *if* $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H^2(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$, *we have*

$$||\boldsymbol{u} - \boldsymbol{u}_h||_0 \le C\,h^{3/2}\,\{||\boldsymbol{u}||_2 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{4.13}$$

Proof. In (4.1), take $\boldsymbol{\chi} = \boldsymbol{u} - \boldsymbol{u}_h$.

Let $(\boldsymbol{u}, p, \boldsymbol{\omega}), (\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*)$ be the solutions to (3.3) and (4.1), respectively, and $(\tilde{\boldsymbol{u}}, \tilde{p}, \tilde{\boldsymbol{\omega}}), (\widetilde{\boldsymbol{u}^*}, \widetilde{p^*}, \widetilde{\boldsymbol{\omega}^*})$ are their corresponding interpolants in $U_h \times Q_h \times W_h$.

From the standard Aubin–Nitsche duality argument, we have

$$\begin{aligned} ||\boldsymbol{u} - \boldsymbol{u}_h||_0^2 \le\, & \mathcal{A}((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2} \\ & \times \mathcal{A}((\boldsymbol{u}^* - \widetilde{\boldsymbol{u}^*}, p^* - \widetilde{p^*}, \boldsymbol{\omega}^* - \widetilde{\boldsymbol{\omega}^*}); (\boldsymbol{u}^* - \widetilde{\boldsymbol{u}^*}, p^* - \widetilde{p^*}, \boldsymbol{\omega}^* - \widetilde{\boldsymbol{\omega}^*}))^{1/2}. \end{aligned} \tag{4.14}$$

In the light of the standard interpolation properties and (4.2) and (3.32), we conclude that (4.13) holds. □

Remark 4.1. Similarly, we can obtain

$$||\boldsymbol{u} - \boldsymbol{u}_h||_{-1} \leq C\, h^2 \,\{||\boldsymbol{u}||_2 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{4.15}$$

Remark 4.2. In addition, we may investigate the L^2 error bounds for both pressure and vorticity, but, in general, there do not yield improved error estimates, even if the divergence and the homogeneous normal boundary condition of the vorticity are added. Nonetheless, for a pathological domain (cf. [28]) for which there holds $H_0(\mathbf{curl};\Omega) \cap (H^1(\Omega))^3 \equiv (H_0^1(\Omega))^3$ (this does not hold generally; cf. [29]), we can show that the L^2 error bounds for both velocity and pressure are $\mathcal{O}(h^2)$ in the standard linear element method without the divergence of the vorticity. If introducing both the divergence and the homogeneous normal boundary condition of the vorticity, we can further show that the L^2 error bound for this variable is also $\mathcal{O}(h^2)$; see [32] for details.

5. On the Bochev–Gunzburger method. In this section, following an argument similar to that of the previous section, we show that the error bounds for all variables are still optimal in the Bochev–Gunzburger method, even without including the divergence of the vorticity in the weak problem.

Let us first recall the Bochev–Gunzburger method: to find $(\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h) \in V_h \times Q_h \times W_h$ such that

$$\mathcal{A}_h((\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h); (\boldsymbol{v}, q, \boldsymbol{z})) = (\boldsymbol{f}, \mathbf{curl}\, \boldsymbol{z} + \bigtriangledown q) \quad \forall (\boldsymbol{v}, q, \boldsymbol{z}) \in V_h \times Q_h \times W_h, \tag{5.1}$$

where Q_h, W_h are still defined as in (3.30), but

$$V_h = \{\boldsymbol{v} \in (H_0^1(\Omega))^3; \boldsymbol{v}_{|_K} \in (\mathcal{P}_2(K))^3, K \in \mathcal{C}_h\} \tag{5.2}$$

with $\mathcal{P}_2(K)$ the space of quadratic polynomials, and

$$\begin{aligned}\mathcal{A}_h((\boldsymbol{u}, p, \boldsymbol{\omega}); (\boldsymbol{v}, q, \boldsymbol{z})) &= (\mathbf{curl}\, \boldsymbol{\omega} + \bigtriangledown p, \mathbf{curl}\, \boldsymbol{z} + \bigtriangledown q)\\ &\quad + h^{-2}\,(\boldsymbol{\omega} - \mathbf{curl}\, \boldsymbol{u}, \boldsymbol{z} - \mathbf{curl}\, \boldsymbol{v}) + h^{-2}\,(\mathrm{div}\, \boldsymbol{u}, \mathrm{div}\, \boldsymbol{v}).\end{aligned} \tag{5.3}$$

Remark 5.1. The original Bochev–Gunzburger method includes the divergence of the vorticity. As is proved in section 3, the introduction of the divergence of the vorticity is unnecessary for the coerciveness. In what follows, we will show that it does not affect the accuracy, either.

THEOREM 5.1. *Let $(\boldsymbol{u}, p, \boldsymbol{\omega})$ and $(\boldsymbol{u}_h, p_h, \boldsymbol{\omega}_h)$ be the exact solution to* (3.3) *and the finite element solution to* (5.1)*, respectively. Under the same conditions as in Theorem* 3.1*, if $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H^3(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$, then*

$$||\boldsymbol{u} - \boldsymbol{u}_h||_1 + ||p - p_h||_0 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 \leq C\, h\, \{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}, \tag{5.4}$$

$$||\boldsymbol{\omega} - \boldsymbol{\omega}_h - \mathbf{curl}\,(\boldsymbol{u} - \boldsymbol{u}_h)||_0 + ||\mathrm{div}\,(\boldsymbol{u} - \boldsymbol{u}_h)||_0 \leq C\, h^2\, \{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{5.5}$$

Proof. It is obvious that

$$\begin{aligned}&\mathcal{A}_h((\boldsymbol{v}, q, \boldsymbol{z}); (\boldsymbol{v}, q, \boldsymbol{z}))\\ &\quad \geq C\, \{\mathcal{J}(\boldsymbol{v}, q, \boldsymbol{z}) + h^{-2}\,(||\boldsymbol{z} - \mathbf{curl}\, \boldsymbol{v}||_0^2 + ||\mathrm{div}\, \boldsymbol{v}||_0^2)\}\\ &\quad \geq C\, \{||\boldsymbol{v}||_1^2 + ||\boldsymbol{z}||_0^2 + ||q||_0^2 + h^{-2}\,(||\boldsymbol{z} - \mathbf{curl}\, \boldsymbol{v}||_0^2 + ||\mathrm{div}\, \boldsymbol{v}||_0^2)\},\end{aligned} \tag{5.6}$$

where we have used Theorem 3.1. Applying the standard interpolation estimation, from (5.6) we can easily obtain (5.4) and (5.5). □

Now we turn to the L^2 error bound for the vorticity.

Let us consider the auxiliary variational problem: to find $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$ such that

$$\mathcal{A}_h((\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*); (\boldsymbol{v}, q, \boldsymbol{z})) = (\boldsymbol{\chi}, \boldsymbol{z}) \tag{5.7}$$

holds for all $(\boldsymbol{v}, q, \boldsymbol{z}) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$, with $\boldsymbol{\chi} \in H(\mathbf{curl}; \Omega)$.

THEOREM 5.2. *Under the same conditions as in Proposition* 2.3*, problem* (5.7) *has a unique solution* $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*)$*, which satisfies*

$$||\boldsymbol{u}^*||_1 + ||\boldsymbol{\omega}^*||_0 + ||p^*||_0 \leq C\, ||\boldsymbol{\chi}||_0. \tag{5.8}$$

Moreover, there exists $(\boldsymbol{u}_0, p_0, \boldsymbol{\omega}_0) \in (H_0^1(\Omega))^3 \times (H^1(\Omega) \cap L_0^2(\Omega)) \times H(\mathbf{curl}; \Omega)$ *such that*

$$||\boldsymbol{u}_0||_3 + ||\boldsymbol{\omega}_0||_2 + ||p_0||_2 \leq C\, ||\boldsymbol{\chi}||_0, \tag{5.9}$$

$$\mathbf{curl}\,(\boldsymbol{\omega}^* - \boldsymbol{\omega}_0) + \bigtriangledown (p^* - p_0) = \mathbf{0}, \tag{5.10}$$

$$||\boldsymbol{\omega}^* - \boldsymbol{\omega}_0 - \mathbf{curl}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0 \leq C\, h^2\, ||\boldsymbol{\chi}||_0, \tag{5.11}$$

$$||\mathrm{div}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0 \leq C\, h^2\, ||\boldsymbol{\chi}||_0. \tag{5.12}$$

Proof. The proof is divided into five steps, where the last step is used for verification.

Step 1. We consider the following problem: to find $\boldsymbol{v}_0 \in (H_0^1(\Omega))^3$ and $q_0 \in H^1(\Omega) \cap L_0^2(\Omega)$ such that

$$-\Delta\, \boldsymbol{v}_0 + \bigtriangledown q_0 = \mathbf{curl}\, \boldsymbol{\chi}, \quad \mathrm{div}\, \boldsymbol{v}_0 = 0, \quad \boldsymbol{v}_{0|_\Gamma} = \mathbf{0}, \tag{5.13}$$

the solution of which satisfies

$$||\boldsymbol{v}_0||_1 + ||q_0||_0 \leq C\, ||\boldsymbol{\chi}||_0, \quad ||\boldsymbol{v}_0||_2 + ||q_0||_1 \leq C\, ||\mathbf{curl}\, \boldsymbol{\chi}||_0. \tag{5.14}$$

Moreover, $q_0 \in L_0^2(\Omega)$ satisfies

$$(q_0, \mathrm{div}\, \boldsymbol{v}) = (\mathbf{curl}\, \boldsymbol{v}_0 - \boldsymbol{\chi}, \mathbf{curl}\, \boldsymbol{v}) \quad \forall \boldsymbol{v} \in (H_0^1(\Omega))^3. \tag{5.15}$$

Step 2. We consider the following problem: to find $\boldsymbol{u}_0 \in (H_0^1(\Omega))^3$ and $p_0 \in H^1(\Omega) \cap L_0^2(\Omega)$ such that

$$-\Delta\, \boldsymbol{u}_0 + \bigtriangledown p_0 = \boldsymbol{v}_0, \quad \mathrm{div}\, \boldsymbol{u}_0 = 0, \quad \boldsymbol{u}_{0|_\gamma} = \mathbf{0}, \tag{5.16}$$

the solution of which satisfies

$$||\boldsymbol{u}_0||_3 + ||p_0||_2 \leq C\, ||\boldsymbol{\chi}||_0. \tag{5.17}$$

Step 3. We consider the following problem: to find $\boldsymbol{u}^+ \in (H_0^1(\Omega))^3$ and $p^+ \in H^1(\Omega) \cap L_0^2(\Omega)$ such that

$$-\Delta\, \boldsymbol{u}^+ + \bigtriangledown p^+ = -h^2\, \mathbf{curl}\, \boldsymbol{\chi} + h^2\, \mathbf{curl}\, \mathbf{curl}\, \boldsymbol{v}_0, \quad \mathrm{div}\, \boldsymbol{u}^+ = h^2\, q_0, \quad {\boldsymbol{u}^+}_{|_\Gamma} = \mathbf{0}, \tag{5.18}$$

the solution of which satisfies

$$||\boldsymbol{u}^+||_1 + ||p^+||_0 \leq C\, h^2\, ||\boldsymbol{\chi}||_0, \quad ||\boldsymbol{u}^+||_2 + ||p^+||_1 \leq C\, h^2\, ||\mathbf{curl}\, \boldsymbol{\chi}||_0. \tag{5.19}$$

Step 4. Define

$$\boldsymbol{u}^* = \boldsymbol{u}_0 + \boldsymbol{u}^+, \quad p^* = p_0 + p^+ - h^2\, q_0, \quad \boldsymbol{\omega}^* = \mathbf{curl}\,\boldsymbol{u}^* + h^2\,(\boldsymbol{\chi} - \mathbf{curl}\,\boldsymbol{v}_0), \tag{5.20}$$

$$\boldsymbol{\omega}_0 = \mathbf{curl}\,\boldsymbol{u}_0. \tag{5.21}$$

We have

$$\mathbf{curl}\,(\boldsymbol{\omega}^* - \boldsymbol{\omega}_0) + \bigtriangledown(p^* - p_0) = \mathbf{0}, \tag{5.22}$$

$$||\boldsymbol{\omega}^* - \boldsymbol{\omega}_0 - \mathbf{curl}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0 \le C\,h^2\,||\boldsymbol{\chi}||_0, \tag{5.23}$$

$$||\mathrm{div}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0 \le C\,h^2\,||\boldsymbol{\chi}||_0. \tag{5.24}$$

Step 5. Note that

$$\mathbf{curl}\,\boldsymbol{\omega}^* + \bigtriangledown p^* = \boldsymbol{v}_0, \tag{5.25}$$

$$\boldsymbol{\omega}^* - \mathbf{curl}\,\boldsymbol{u}^* = h^2\,(\boldsymbol{\chi} - \mathbf{curl}\,\boldsymbol{v}_0), \quad \mathrm{div}\,\boldsymbol{u}^* = h^2\,q_0. \tag{5.26}$$

We can easily verify that $(\boldsymbol{u}^*, p^*, \boldsymbol{\omega}^*)$ satisfies (5.7). □

THEOREM 5.3. *Let $\boldsymbol{\omega}$ and $\boldsymbol{\omega}_h$ be the exact and the approximate solutions. Under the same hypotheses as in Theorem* 5.2 *and if $(\boldsymbol{u}, p, \boldsymbol{\omega}) \in (H^3(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$, then there holds*

$$||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 + ||\boldsymbol{u} - \boldsymbol{u}_h||_1 \le C\,h^2\,\{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{5.27}$$

Proof. In (5.7), take $\boldsymbol{\chi} = \boldsymbol{\omega} - \boldsymbol{\omega}_h$.

Let $(\tilde{\boldsymbol{u}}, \tilde{p}, \tilde{\boldsymbol{\omega}})$ and $(\tilde{\boldsymbol{u}_0}, \tilde{p_0}, \tilde{\boldsymbol{\omega}_0})$ be the interpolants in $V_h \times Q_h \times W_h$ to $(\boldsymbol{u}, p, \boldsymbol{\omega})$ and $(\boldsymbol{u}_0, p_0, \boldsymbol{\omega}_0)$, respectively.

By the duality argument, we have

$$\begin{aligned} &||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0^2 \\ &\quad \le \mathcal{A}_h((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2} \\ &\qquad \times \mathcal{A}_h((\boldsymbol{u}^* - \tilde{\boldsymbol{u}_0}, p^* - \tilde{p_0}, \boldsymbol{\omega}^* - \tilde{\boldsymbol{\omega}_0}); (\boldsymbol{u}^* - \tilde{\boldsymbol{u}_0}, p^* - \tilde{p_0}, \boldsymbol{\omega}^* - \tilde{\boldsymbol{\omega}_0}))^{1/2}, \end{aligned} \tag{5.28}$$

where

$$\begin{aligned} &\mathcal{A}_h((\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}); (\boldsymbol{u} - \tilde{\boldsymbol{u}}, p - \tilde{p}, \boldsymbol{\omega} - \tilde{\boldsymbol{\omega}}))^{1/2} \\ &\qquad \le C\,h\,\{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}, \end{aligned} \tag{5.29}$$

$$\begin{aligned} &\mathcal{A}_h((\boldsymbol{u}^* - \tilde{\boldsymbol{u}_0}, p^* - \tilde{p_0}, \boldsymbol{\omega}^* - \tilde{\boldsymbol{\omega}_0}); (\boldsymbol{u}^* - \tilde{\boldsymbol{u}_0}, p^* - \tilde{p_0}, \boldsymbol{\omega}^* - \tilde{\boldsymbol{\omega}_0}))^{1/2} \\ &\quad \le C\,\mathcal{A}_h((\boldsymbol{u}_0 - \tilde{\boldsymbol{u}_0}, p_0 - \tilde{p_0}, \boldsymbol{\omega}_0 - \tilde{\boldsymbol{\omega}_0}); (\boldsymbol{u}_0 - \tilde{\boldsymbol{u}_0}, p_0 - \tilde{p_0}, \boldsymbol{\omega}_0 - \tilde{\boldsymbol{\omega}_0}))^{1/2} \\ &\qquad + C\,h^{-1}\,(||\boldsymbol{\omega}^* - \boldsymbol{\omega}_0 - \mathbf{curl}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0 + ||\mathrm{div}\,(\boldsymbol{u}^* - \boldsymbol{u}_0)||_0) \\ &\quad \le C\,h\,\{||\boldsymbol{u}_0||_3 + ||p_0||_2 + ||\boldsymbol{\omega}_0||_2 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0\} \\ &\quad \le C\,h\,||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0. \end{aligned} \tag{5.30}$$

Hence we get

$$||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0 \le C\,h^2\,\{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}. \tag{5.31}$$

From (5.5) and (5.27), we then immediately know that

$$\begin{aligned} ||\boldsymbol{u} - \boldsymbol{u}_h||_1 &\le C\,\{||\boldsymbol{\omega} - \boldsymbol{\omega}_h - \mathbf{curl}\,(\boldsymbol{u} - \boldsymbol{u}_h)||_0 + ||\mathrm{div}\,(\boldsymbol{u} - \boldsymbol{u}_h)||_0 + ||\boldsymbol{\omega} - \boldsymbol{\omega}_h||_0\} \\ &\le C\,h^2\,\{||\boldsymbol{u}||_3 + ||p||_2 + ||\boldsymbol{\omega}||_2\}, \end{aligned} \tag{5.32}$$

where we have used the inequality $||\boldsymbol{v}||_1 \leq C\{||\mathbf{curl}\,\boldsymbol{v}||_0 + ||\mathrm{div}\,\boldsymbol{v}||_0\}$ on $(H_0^1(\Omega))^3$. □

Remark 5.2. Regarding the pressure, following a similar argument, we can establish the L^2 error bound $\mathcal{O}(h^2)$ for this variable.

Remark 5.3. When Ω is convex polyhedron, both methods (3.31) and (5.1) are coercive. When additionally the exact solution $(\boldsymbol{u}, p, \boldsymbol{\omega})$ is in $(H^3(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$, we obtain basic error bounds (3.32), (5.4), and (5.5).

If the solution of the Stokes problem (2.3) is in the same spaces as above (the right-hand side functions $\boldsymbol{\chi}$ and g may be required to be in $(H^1(\Omega))^3$ and $H^2(\Omega)$, respectively), then with the help of the Aubin–Nitsche duality argument we obtain the L^2 error bound (4.13) for the linear element method (3.31) and recover the optimal error bounds for the Bochev–Gunzburger method (5.1).

To our best knowledge, from [13, p. 88] we know that if the boundary Γ is in C^3 (the right-hand side functions need corresponding regularities), then it holds that $(\boldsymbol{u}, p, \boldsymbol{\omega})$ is in $(H^3(\Omega))^3 \times H^2(\Omega) \times (H^2(\Omega))^3$.

6. Numerical examples.

In this section we report the results of numerical examples to illustrate the theoretical error bounds for the least-squares linear element method (3.31).

We take the domain as $\Omega = [0,1]^3$ and consider a 3D Stokes problem

$$-\Delta\,\boldsymbol{u} + \bigtriangledown p = \boldsymbol{f}, \quad \mathrm{div}\,\boldsymbol{u} = 0, \quad \boldsymbol{u}_{|\Gamma} = \mathbf{0}, \tag{6.1}$$

the exact solution of which is known: let

$$\boldsymbol{\Phi} = \begin{pmatrix} x(1-x)y^2(1-y)^2z^2(1-z)^2 \\ x^2(1-x)^2y(1-y)z^2(1-z)^2 \\ x^2(1-x)^2y^2(1-y)^2z(1-z) \end{pmatrix}$$

and

$$p = -2xyz + x^2 + y^2 + z^2 + xy + xz + yz - x - y - z.$$

We take

$$\boldsymbol{u} = \mathbf{curl}\,\boldsymbol{\Phi}, \quad \boldsymbol{\omega} = \mathbf{curl}\,\boldsymbol{u}, \quad \boldsymbol{f} = \mathbf{curl}\,\boldsymbol{\omega} + \bigtriangledown p,$$

and we can easily verify that such a $(\boldsymbol{u}, p, \boldsymbol{\omega}, \boldsymbol{f})$ satisfies (6.1).

We partition Ω into a set of h^{-3} cubic subdomains with side-length h and use piecewise trilinear elements $(\mathcal{P}_1(K))^3$ to approximate all variables. We also set $p_h(0,0,0) = 0$, instead of $\int_\Omega p_h = 0$, to ensure the uniqueness.

In our computer codes, we use the double precision conjugate gradient method (CGM) to solve the associated linear system with an initial guess $(0,0,0,0,0,0,0)$, and the stopping criterion is the l^2 norm of the residual vector less than 10^{-11}. Computational results are collected in Tables 1– 7. The rates of convergence in Tables 5, 6, and 7 are computed the following intuitive way: for any two consecutive sets of data with respect to the mesh sizes $h1$ and $h2$, the rate of conv:=$\ln(\|e1\|/\|e2\|)/\ln(h1/h2)$.

We find that the numerical results in Tables 5– 7 support the conclusions obtained in this paper.

ELIMINATION OF FIRST ORDER ERRORS IN TIME DEPENDENT SHOCK CALCULATIONS*

MALIN SIKLOSI[†] AND GUNILLA KREISS[†]

Abstract. First order errors downstream of shocks have been detected in computations with higher order shock-capturing schemes in one and two dimensions. We use matched asymptotic expansions to analyze the phenomenon for one dimensional time dependent hyperbolic systems and show how to design the artificial viscosity term in order to avoid the first order error. Numerical computations verify that second order accurate solutions are obtained.

Key words. hyperbolic conservation laws, shock wave, artificial viscosity, asymptotic analysis

1. Introduction.

In many cases, solutions of conservation laws obtained by formally higher order methods are only first order accurate downstream of shocks; see, e.g., [2], [5], and [4]. Basically, errors from the shock region follow outgoing characteristics and pollute the solution downstream. Examples in one space dimension in which this effect can be seen are steady-state calculations for systems with a source term and time dependent calculations for systems with nonconstant solution. The effect cannot be seen in one dimensional Riemann problems, because the exact global conservation determines the postshock states.

This degeneration in accuracy is troublesome, even though the first order term for reasonable mesh-sizes seems to be small in many cases. In some applications, e.g., aeroacoustics, where waves with small amplitude need to be computed accurately, it is particularly important to achieve very high accuracy. It is also important to understand the phenomenon more deeply in order to be able to design new methods which do not suffer from this deficiency.

The aim of this paper is to show that the first order error can be understood by matched asymptotic analysis of the modified equation and that the analysis can be used to construct methods that yield second order accurate solutions.

We consider the case of systems with time dependent solutions. We assume that the numerical solution can be modeled by a slightly viscous equation, a so-called modified equation. In the shock layer, the coefficient of the viscous term is $\mathcal{O}(h)$, where h is the grid size. We analyze the solution of the modified equation using matched asymptotic expansions. It is assumed that an inner solution is valid in the shock region, and an outer solution is valid elsewhere. The two solutions are matched in a so-called matching zone. From the analysis, we see that generally the outer solution contains a term of $\mathcal{O}(h)$ downstream of the shock. We also see that if the inner solution satisfied a certain condition, the $\mathcal{O}(h)$ term would be eliminated. Based on this observation, we design a matrix valued viscosity coefficient, which gives the inner solution the right shape to eliminate the $\mathcal{O}(h)$ downstream term. We construct a numerical scheme, using this matrix valued viscosity coefficient, and show in numerical

[†]Department of Numerical Analysis and Computer Science, Royal Institute of Technology, SE-100 44 Stockholm, Sweden (malins@nada.kth.se, gunillak@nada.kth.se).

experiments that the first order downstream error really is eliminated. However, we do not claim to have constructed an efficient and robust numerical method which can be used in realistic computations.

Similar analysis and construction of a matrix valued viscosity coefficient is done in [8] for the case of a steady-state solution of a system with a source term. In [3], matched asymptotic expansions for a problem that is very similar to the problem studied in this paper are analyzed for other purposes. The phenomenon has also been studied by other methods in [5] and [2]. In [5], analytic examples are constructed where the numerical solution is only first order accurate downstream of a shock, although the numerical scheme is formally second order. It is also shown that a converging numerical method will yield solutions having the formal order of accuracy in domains where no characteristics have passed through a shock. In [2], the first order downstream error is numerically detected in solutions of a shock-sound interaction problem solved by a fourth order ENO method. A scalar, linear equation is used to model the problem. It can be seen that the solution of the model problem computed with the fourth order ENO method behaves qualitatively differently depending on whether the discontinuity is located on a cell interface or in the interior of a cell. In the first case, the solution is fourth order in all of the domain, but in the second case the solution is only first order downstream of the discontinuity. Based on this observation, the numerical method is modified such that the shock position will always be on a cell interface, and fourth order accuracy of the solution of the shock-sound interaction problem is obtained both upstream and downstream. Also in [1], shock wave solutions are analyzed, and it is concluded that the structure in the shock region is of crucial importance for the solution outside the shock region. However, the analysis in [1] concerns another numerical phenomenon and considers methods where the shock is so narrow that it is not well modeled by the solution of a slightly viscous equation.

This paper is organized as follows. In section 2, we use asymptotic analysis to explain the first order downstream error and derive a matrix valued viscosity coefficient that eliminates it. In section 3, we implement a numerical method using the matrix valued viscosity coefficient and show in computations that the first order downstream error is eliminated.

2. Analysis.

2.1. The inviscid problem.

Consider the inviscid problem

$$\mathbf{u}_t + \mathbf{f}(\mathbf{u})_x = 0, \quad 0 \le x \le x_{\text{end}}, \tag{1}$$

$$\mathbf{u}(x,0) = \mathbf{g}(x), \tag{2}$$

where $\mathbf{u}(x,t), \mathbf{g}(x) \in \mathbf{R}^n$, $\mathbf{f} : \mathbf{R}^n \to \mathbf{R}^n$, and $\mathbf{g}$ is a piecewise smooth function. We denote the Jacobian of the flux function $\mathbf{f}'(\mathbf{u})$ by $J(\mathbf{u})$. We assume that the eigenvalues of $J(\mathbf{u})$, denoted $\lambda_i(\mathbf{u}), i = 1, 2, \dots, n$, are real and ordered in increasing order and that the eigenvectors span $\mathbf{R}^n$.

The initial and boundary conditions are chosen such that a shock forms at some inner point $s(t)$. At the shock, the solution satisfies the Rankine–Hugoniot condition

$$\dot{s}[\mathbf{u}] = [\mathbf{f}(\mathbf{u})].$$

Here $[\mathbf{u}] = \mathbf{u}^+ - \mathbf{u}^-$, where $\mathbf{u}^\pm = \lim_{\delta \to 0^+} \mathbf{u}(s(t) \pm \delta, t)$. Corresponding notation for other quantities will be used frequently.

We assume that the shock is a classical Lax 1-shock, i.e.,

$$\begin{aligned} \dot{s} &< \lambda_1^-, \\ \lambda_1^+ < \dot{s} &< \lambda_2^+, \end{aligned}$$

and that the matrix

$$D = \begin{pmatrix} S_{II}^+ & [\mathbf{u}] \end{pmatrix} \tag{3}$$

is nonsingular. Here the columns of S_{II}^+ are the eigenvectors of J^+ corresponding to the eigenvalues $\lambda_2^+, \lambda_3^+, \dots, \lambda_n^+$.

To complete the problem we also need boundary conditions. At each boundary we need as many boundary conditions as there are ingoing characteristics. We consider pointwise boundary conditions, i.e., boundary conditions where the quantities involved are prescribed pointwise at the boundary to some function of time. One example of such boundary conditions is when the ingoing characteristic variables are prescribed as a function of time. We call these boundary conditions mathematical boundary conditions to distinguish them from numerical boundary conditions. For more details concerning mathematical boundary conditions for hyperbolic equations, we refer to [9].

Remark. For 1-shocks and n-shocks there is just one downstream side. Hence, the first order error appears on only one side of the shock. For other Lax shocks, both sides of the shock are downstream sides, and first order errors appear on both sides. The phenomenon can be analyzed by the same method in both cases, but the analysis becomes less involved when only one side must be considered. Hence, here we analyze a 1-shock.

2.2. The slightly viscous model. We intend to study the behavior of numerical solutions of (1); i.e., we want to study the behavior of discrete functions that are the solutions of difference equations. A useful technique for studying the behavior of solutions to difference equations is to model the difference equation by a differential equation. Such a differential equation is often called a modified equation; see, e.g., [11], [6]. Many numerical solutions of (1) can be viewed as higher order accurate solutions of the modified equation

$$\mathbf{u}_t^\varepsilon + \mathbf{f}(\mathbf{u}^\varepsilon)_x = (\Gamma \mathbf{u}_x^\varepsilon)_x, \quad 0 \le x \le x_{\text{end}}.$$

In the shock region, the modified equation can be shown to be valid only for weak shocks; see, e.g., [7]. However, our computations indicate that it applies also for strong shocks. In the neighborhood of a shock layer we must have $\Gamma = \mathcal{O}(h)$, where h is the grid size, in order to avoid oscillations in the solution. Outside the shock region, Γ can be smaller. In this paper we consider methods which can be modeled by

$$\mathbf{u}_t^\varepsilon + \mathbf{f}(\mathbf{u}^\varepsilon)_x = \varepsilon(\phi \mathbf{u}_x^\varepsilon)_x + c_2 \varepsilon^2 \mathbf{u}_{xx}^\varepsilon, \tag{4}$$

where $\varepsilon = c_1 h$ and c_1 and c_2 a scalar constants. Here ϕ is a smooth function of $(x - s(t))/\varepsilon$ satisfying

$$\phi\left(\frac{x - s(t)}{\varepsilon}\right) = \begin{cases} 1 & \text{for } |\frac{x-s(t)}{\varepsilon}| \le K_0, \\ 0 & \text{for } |\frac{x-s(t)}{\varepsilon}| \ge K_1, \end{cases}$$

where $K_0 < K_1$ are constants with K_0 sufficiently large.

We must also model the initial data. In computations, the shape of the shock profile will depend on the method. If the initial data does not have exactly the right shape, the profile will after a short time adjust and obtain the right shape. In this process, small diffusion waves appear and flow out of the shock region, following the outgoing characteristics; see [12] and the references therein. We are not interested in studying this initial effect, and consequently we assume that the initial profile is exactly the right profile for the method that is modeled. We specify the initial profile in (12) and (13).

We consider the same mathematical boundary conditions for $\mathbf{u}^\varepsilon$ as for $\mathbf{u}$. When (1) is solved numerically, the mathematical boundary conditions must be augmented by numerical boundary conditions. Correspondingly, additional boundary conditions that model the numerical boundary conditions are needed for $\mathbf{u}^\varepsilon$. Numerical boundary conditions can introduce boundary layers in the solution. We consider numerical boundary conditions where such effects are $\mathcal{O}(h^2)$ or smaller, e.g., extrapolation of outgoing characteristic variables.

We define the position of the viscous shock layer as the smallest x-value such that $\mathbf{u}^{\varepsilon(1)}(x,t) = (\mathbf{u}^{-(1)} + \mathbf{u}^{+(1)})/2$, and denote this point by x_ε; i.e., the viscous shock position is defined as the point where the first component of the viscous solution $\mathbf{u}^\varepsilon$ is halfway between the right and left states in the corresponding inviscid shock.

2.3. Asymptotic expansions. We assume the following: The solution of (4) can be described by an inner solution, valid in the shock layer, and an outer solution, valid elsewhere. These solutions can be expanded in powers of ε and matched in a region of overlap. Also, the position of the shock layer can be expanded in ε. To leading order, the outer solution is equal to the solution of the corresponding inviscid problem.

We will now show that the outer solution downstream of the shock contains an $\mathcal{O}(h)$ term; i.e., downstream, the solution of (4) is just a first order approximation of the solution of the corresponding inviscid problem (1). There is no $\mathcal{O}(h)$ term upstream.

The inner solution is expressed using the variables $(\tilde{x}, \tilde{t})$, where

$$\tilde{x} = \frac{x - s(t)}{\varepsilon},$$
$$\tilde{t} = t.$$

Thus we have expansions of the form

$$\text{(5)} \qquad \text{Outer:} \quad \mathbf{u}^\varepsilon \sim \mathbf{u}(x,t) + \varepsilon \mathbf{u}_1(x,t) + \varepsilon^2 \mathbf{u}_2(x,t) + \cdots,$$
$$\text{Inner:} \quad \mathbf{u}^\varepsilon \sim \mathbf{U}_0(\tilde{x},\tilde{t}) + \varepsilon \mathbf{U}_1(\tilde{x},\tilde{t}) + \varepsilon^2 \mathbf{U}_2(\tilde{x},\tilde{t}) + \cdots,$$
$$\text{(6)} \qquad \text{Position:} \; x_\varepsilon \sim s(t) + \varepsilon x_1(t) + \varepsilon^2 x_2(t) + \cdots.$$

In [3], analysis of the asymptotic expansions for a very similar problem is presented, and also the existence of an asymptotic expansion is treated. For a detailed presentation of matched asymptotic expansions, we refer to [10].

We will match the inner and the outer solutions at an upstream and a downstream matching point, $x_m^-(t)$ and $x_m^+(t)$. The matching points must satisfy $\lim_{\varepsilon \to 0} |x_m^\pm - s| = 0$. We will also need $e^{\mp \tilde{x}_m^\pm} = \mathbf{o}(1)$. Choosing $x_m^\pm = s \mp \varepsilon \log(\varepsilon)$, we have $e^{\mp \tilde{x}_m^\pm} = \mathcal{O}(\varepsilon)$, and both requirements are satisfied.

The viscous problem (4) models a method which is a second order accurate approximation of (1) away from the shock region. We claim that the solution will be second order accurate upstream of the shock, but in general only first order downstream. Hence we must show that $\mathbf{u}_1 = 0$ upstream and $\mathbf{u}_1 \neq 0$ downstream. To do this we need equations, initial data, and boundary conditions for $\mathbf{u}_1$. Via the boundary conditions in the shock region, the outer solution will be coupled to the inner solution. Specifically, to derive boundary conditions for $\mathbf{u}_1$ we need information about $\mathbf{U}_0$. Hence, we derive equations and boundary conditions also for $\mathbf{U}_0$.

To obtain equations for the terms in the outer and inner expansions we substitute the expansions into (4), Taylor expand, and collect terms multiplying the same power of ε. The equation for $\mathbf{U}_0$ is

$$(\phi \mathbf{U}_{0\tilde{x}})_{\tilde{x}} + \dot{s}\mathbf{U}_{0\tilde{x}} - \mathbf{f}(\mathbf{U}_0)_{\tilde{x}} = 0, \quad -\infty < \tilde{x} < \infty, \tag{7}$$

where we have used that the relations between derivatives in x and t and derivatives in $\tilde{x}$ and $\tilde{t}$ are

$$\begin{aligned} \frac{\partial}{\partial x} &= \frac{1}{\varepsilon}\frac{\partial}{\partial \tilde{x}}, \\ \frac{\partial}{\partial t} &= -\frac{\dot{s}}{\varepsilon}\frac{\partial}{\partial \tilde{x}} + \frac{\partial}{\partial \tilde{t}}. \end{aligned}$$

The inner and outer expansions of $\mathbf{u}^\varepsilon$ are assumed to be valid in a region of overlap containing the matching points $x_m^\pm$. Hence, in the matching points, we must have $\lim_{\varepsilon \to 0} |\mathbf{U}_0 - \mathbf{u}| = 0$, i.e.,

$$\lim_{\varepsilon \to 0} |\mathbf{U}_0(\mp \log(\varepsilon), \tilde{t}) - \mathbf{u}(s \mp \varepsilon \log(\varepsilon), t)| = 0,$$

where we have used that $x_m^\pm = s \mp \varepsilon \log(\varepsilon)$. Evaluating the limit, we arrive at the matching conditions

$$\mathbf{U}_0(\pm\infty, \tilde{t}) = \mathbf{u}^\pm(t), \tag{8}$$

where $\mathbf{U}_0(\pm\infty, \tilde{t}) = \lim_{\tilde{x} \to \pm\infty} \mathbf{U}_0(\tilde{x}, \tilde{t})$. Note that (7) and (8) determine the shape of $\mathbf{U}_0$ but not the exact position of the shock layer.

We define $\hat{\mathbf{U}}(\tilde{x}, \tilde{t})$ by

$$\hat{\mathbf{U}}_{\tilde{x}\tilde{x}} + \dot{s}\hat{\mathbf{U}}_{\tilde{x}} - \mathbf{f}(\hat{\mathbf{U}})_{\tilde{x}} = 0, \quad -\infty < \tilde{x} < \infty, \tag{9}$$

$$\hat{\mathbf{U}}(\tilde{x}, \tilde{t}) = \mathbf{u}(s \pm 0, \tilde{t}) \quad \text{as } \tilde{x} \to \pm\infty, \tag{10}$$

$$\hat{\mathbf{U}}^{(1)}(0, \tilde{t}) = (\mathbf{u}^{-(1)} + \mathbf{u}^{+(1)})/2. \tag{11}$$

We see that $\hat{\mathbf{U}}$ differs from $\mathbf{U}_0$ in two ways. First, $\hat{\mathbf{U}}$ is independent of ϕ, which makes the equation for $\hat{\mathbf{U}}$ much easier to analyze. Second, the position of $\hat{\mathbf{U}}$ is fixed at $\tilde{x} = 0$. We note that both problems are independent of ε.

Let us first compare the shape of solutions of (7) and (8) with the shape of solutions of (9) and (10), disregarding the difference in shock position. It is easy to show that $\hat{\mathbf{U}}$ approaches its limit values exponentially fast as $\tilde{x} \to \pm\infty$. If one constructs the equations for the difference $\hat{\mathbf{U}} - \mathbf{U}_0$ and uses the exponential behavior of $\hat{\mathbf{U}}$, one can conclude that $\mathbf{U}_0$ also approaches its limit values exponentially fast and that $|\hat{\mathbf{U}} - \mathbf{U}_0|_\infty < e^{-K}$, where K is a large constant.

Since the position of the shock layer has the expansion (6), we have, except for exponentially small terms, to leading order

$$\mathbf{U}_0(\tilde{x}, \tilde{t}) = \hat{\mathbf{U}}(\tilde{x} - x_1(\tilde{t}), \tilde{t}).$$

Below we will derive an ordinary differential equation for $x_1(\tilde{t})$. The initial value of $x_1(\tilde{t})$ is determined by the initial condition $\mathbf{g}^\varepsilon$, which we now specify:

$$\text{Outer region: } \mathbf{g}^\varepsilon(x) = \mathbf{g}(x), \tag{12}$$

$$\text{Inner region: } \mathbf{g}^\varepsilon(\tilde{x}) = \hat{\mathbf{U}}(\tilde{x}, 0). \tag{13}$$

This is sufficient for our purposes. However, if one considers more terms in the inner expansion, one would have to add the corresponding terms to (13). Note that (13) means that $x_1(0) = 0$.

The equation for $\mathbf{u}_1$ is

$$\mathbf{u}_{1t} + (\mathbf{f}'(\mathbf{u})\mathbf{u}_1)_x = 0, \quad x \in \text{outer region}, \tag{14}$$

where we have used that $\phi = 0$ in the outer region. We also need initial data and boundary conditions for $\mathbf{u}_1$. The initial conditions for $\mathbf{u}^\varepsilon$, (12), gives $\mathbf{u}_1(x, 0) = 0$. Since $\mathbf{u}^\varepsilon$ and $\mathbf{u}$ satisfy the same mathematical boundary conditions and since boundary layer effects, due to numerical boundary conditions, are assumed to be $\mathcal{O}(h^2)$ or smaller, we conclude that all boundary conditions for $\mathbf{u}_1$ at $x = 0$ and $x = x_{\text{end}}$ are homogeneous. At the upstream side of the shock, no further boundary conditions are needed since all characteristics of (14) are going into the shock. Since $\mathbf{u}_1$ in the upstream region is the solution of a homogeneous equation with homogeneous initial data and homogeneous boundary conditions, we have $\mathbf{u}_1 \equiv 0$ in the upstream region. To determine $\mathbf{u}_1$ in the downstream region, we also need boundary conditions at $x = s^+$. We derive such boundary conditions in the next section.

2.4. Downstream boundary condition for the first order outer term.

Integration of the viscous equation (4) over the shock layer, from matching point x_m^- to matching point x_m^+, gives

$$\int_{x_m^-}^{x_m^+} \mathbf{u}_t^\varepsilon \, dx + [\mathbf{f}(\mathbf{u}^\varepsilon)]_{x_m^-}^{x_m^+} = \mathcal{O}(\varepsilon^2), \tag{15}$$

where we have used that ϕ vanishes in the matching regions. Using the outer expansion of $\mathbf{u}^\varepsilon$, we obtain

$$[\mathbf{f}(\mathbf{u}^\varepsilon)]_{x_m^-}^{x_m^+} = [\mathbf{f}(\mathbf{u})]_{x_m^-}^{x_m^+} + \varepsilon[J(\mathbf{u})\mathbf{u}_1]_{x_m^-}^{x_m^+} + \mathcal{O}(\varepsilon^2). \tag{16}$$

By integrating the inviscid (1) over the same interval, we obtain

$$[\mathbf{f}(\mathbf{u})]_{x_m^-}^{x_m^+} = \dot{s}[\mathbf{u}] - \int_{x_m^-}^{s^-} \mathbf{u}_t \, dx - \int_{s^+}^{x_m^+} \mathbf{u}_t \, dx. \tag{17}$$

Note that $\mathbf{u}$ is discontinuous at $x = s(t)$ and the Rankine–Hugoniot condition applies across the discontinuity. After taking into account that $\mathbf{u}_1 \equiv 0$ to the left of the shock layer and introducing (16) and (17) into (15), we arrive at

$$\dot{s}[\mathbf{u}] + \varepsilon J(\mathbf{u}(x_m^+, t))\mathbf{u}_1(x_m^+, t) + I_1 = \mathcal{O}(\varepsilon^2), \tag{18}$$

where we have introduced the notation

$$I_1 = \int_{x_m^-}^{s^-} (\mathbf{u}_t^\varepsilon - \mathbf{u}_t) \, dx + \int_{s^+}^{x_m^+} (\mathbf{u}_t^\varepsilon - \mathbf{u}_t) \, dx.$$

After Taylor expansion of $\mathbf{u}$ and $\mathbf{u}_1$ around $x = s^+$, (18) can be rewritten as

$$\dot{s}[\mathbf{u}] + \varepsilon J(\mathbf{u}(s^+, t))\mathbf{u}_1(s^+, t) + I_1 = \mathbf{o}(\varepsilon). \tag{19}$$

In the coordinate system $(\tilde{x}, \tilde{t})$ we have

$$I_1 = -\dot{s}A + \varepsilon I_2,$$

where

$$A = \int_{\tilde{x}_m^-}^{0^-} (\mathbf{u}^\varepsilon - \mathbf{u})_{\tilde{x}}\, d\tilde{x} + \int_{0^+}^{\tilde{x}_m^+} (\mathbf{u}^\varepsilon - \mathbf{u})_{\tilde{x}}\, d\tilde{x},$$
$$I_2 = \int_{\tilde{x}_m^-}^{0^-} (\mathbf{u}^\varepsilon - \mathbf{u})_{\tilde{t}}\, d\tilde{x} + \int_{0^+}^{\tilde{x}_m^+} (\mathbf{u}^\varepsilon - \mathbf{u})_{\tilde{t}}\, d\tilde{x}.$$

Evaluating the integral yields

$$A = [\mathbf{u}] + [\mathbf{u}^\varepsilon - \mathbf{u}]_{\tilde{x}_m^-}^{\tilde{x}_m^+}.$$

By using the outer expansion of $\mathbf{u}^\varepsilon$, taking into account that $\mathbf{u}_1$ is zero upstream and Taylor expanding $\mathbf{u}_1$ around $x = s^+$, we obtain

$$A = [\mathbf{u}] + \varepsilon \mathbf{u}_1^+ + \mathbf{o}(\varepsilon).$$

Next, consider I_2. Using the inner expansion of $\mathbf{u}^\varepsilon$, the Taylor expansion of $\mathbf{u}$ around $x = s \pm 0$, and $\mathbf{U}_0(\tilde{x}, \tilde{t}) = \hat{\mathbf{U}}(\tilde{x} - x_1, \tilde{t})$, we obtain

$$I_2 = \int_{\tilde{x}_m^-}^{0} (\hat{\mathbf{U}}(\tilde{x} - x_1, \tilde{t}) - \mathbf{u}^-)_{\tilde{t}}\, d\tilde{x} + \int_{0}^{\tilde{x}_m^+} (\hat{\mathbf{U}}(\tilde{x} - x_1, \tilde{t}) - \mathbf{u}^+)_{\tilde{t}}\, d\tilde{x} + \mathbf{o}(1).$$

We rewrite I_2 in two steps. First we make the substitution $\hat{x} = \tilde{x} - x_1$. Next, we use the fact that $\hat{\mathbf{U}}$ approaches the limit values exponentially fast, and the matching points are chosen such that $e^{\mp\tilde{x}_m^\pm} = \mathcal{O}(\varepsilon)$. Hence we can extend the integration interval to infinity, still keeping the remainder term $\mathbf{o}(1)$. We obtain

$$I_2 = I_{3\tilde{t}} - (x_1[\mathbf{u}])_{\tilde{t}} + \mathbf{o}(1),$$

where

$$I_3(\tilde{t}) = \int_{-\infty}^{0} (\hat{\mathbf{U}}(\tilde{x}, \tilde{t}) - \mathbf{u}^-)\, d\tilde{x} + \int_{0}^{\infty} (\hat{\mathbf{U}}(\tilde{x}, \tilde{t}) - \mathbf{u}^+)\, d\tilde{x}.$$

Since I_2, I_3, x_1, and $[\mathbf{u}]$ are functions of $\tilde{t}$ only, and since $\tilde{t} = t$, this can be written as

$$I_2(t) = \frac{\partial}{\partial t}\left(I_3(t) - x_1(t)[\mathbf{u}](t)\right) + \mathbf{o}(1).$$

Hence we have

$$I_1 = -\dot{s}[\mathbf{u}] + \varepsilon(-\dot{s}\mathbf{u}_1^+ + I_{3t} - (x_1[\mathbf{u}])_t) + \mathbf{o}(\varepsilon).$$

Substituting this into (19) and rearranging, we obtain

$$(J^+ - \dot{s}I)\mathbf{u}_1^+ - (x_1[\mathbf{u}])_t + I_{3t} = \mathbf{o}(1).$$

Hence the equations for $\mathbf{u}_1^+$ and $x_1(t)$ are

$$(J^+ - \dot{s}I)\mathbf{u}_1^+(t) - (x_1(t)[\mathbf{u}])_t = -I_{3t}, \tag{20}$$

$$x_1(0) = 0. \tag{21}$$

The two equations (20) and (21) constitute the boundary conditions for $\mathbf{u}_1$ at $x = s^+$. To make (20) and (21) easier to understand, we rewrite them using the characteristic variables of $\mathbf{u}_1$. Let w_I be the characteristic variable of $\mathbf{u}_1$ going into the shock, and $\mathbf{w}_{II}$ be the characteristic variables going out of the shock. We then have

$$\mathbf{u}_1^+ = (S_I^+ S_{II}^+) \begin{pmatrix} \mathrm{w}_I^+ \\ \mathbf{w}_{II}^+ \end{pmatrix},$$

where S_I^+ is the eigenvector of J^+ corresponding to the eigenvalue λ_1^+ and the columns of S_{II}^+ are the eigenvectors of J^+ corresponding to the eigenvalues $\lambda_2^+, \lambda_3^+, \ldots, \lambda_n^+$. Expressed in the characteristic variables, the boundary condition is

$$\begin{pmatrix} \mathbf{w}_{II}^+ \\ \dot{x}_1 \end{pmatrix} = \begin{pmatrix} \Lambda_{II}^+ - \dot{s}I & 0 \\ 0 & -1 \end{pmatrix}^{-1} D^{-1} \left(-I_{3t} + x_1[\mathbf{u}]_t - S_I^+(\lambda_1^+ - \dot{s})\mathrm{w}_I^+\right), \tag{22}$$

$$x_1(0) = 0, \tag{23}$$

where $\Lambda_{II}^+ = \mathrm{diag}(\lambda_2^+, \lambda_3^+, \ldots, \lambda_n^+)$ and D is defined by (3).

By solving (22) and (23) for $x_1(t)$ and then substituting the solution into (22) again, we can express $\mathbf{w}_{II}^+$ in w_I^+ and known functions of time. The energy method (see [9]) shows that the equation, boundary conditions, and initial data for $\mathbf{w}$ constitute a well-posed problem. Well-posedness implies that for any I_{3t} there exists a unique solution. The boundary condition for $\mathbf{w}$ at $x = s^+$ is homogeneous if $I_{3t} \equiv 0$, and nonhomogeneous otherwise. Since $\mathbf{w}$ is a transformation of $\mathbf{u}_1$, the same applies for $\mathbf{u}_1$.

It is now clear that I_{3t} is crucial for the order of accuracy of $\mathbf{u}^\varepsilon$. In the special case $I_{3t} \equiv 0$ we have $\mathbf{u}_1 \equiv 0$ in the downstream region, since $\mathbf{u}_1$ is the solution of a homogeneous equation with homogeneous initial data and boundary conditions. From (5) it then follows that $\mathbf{u}^\varepsilon$ is a second order accurate approximation of $\mathbf{u}$. However, in the general case, we have $\mathbf{u}_1(x,t) \neq 0$ for $x > s$, and $\mathbf{u}^\varepsilon$ will be a first order accurate approximation of $\mathbf{u}$.

2.5. A matrix valued viscosity coefficient eliminating the $\mathcal{O}(h)$ error.

We will now investigate whether it is possible to design the viscosity term such that the first order downstream error is eliminated and second order accurate solutions are obtained. We consider a method which has the modified equation

$$\mathbf{u}_t^\varepsilon + \mathbf{f}(\mathbf{u}^\varepsilon)_x = \varepsilon(\phi(x)E(\mathbf{u}^\varepsilon)\mathbf{u}_x^\varepsilon)_x + c_2\varepsilon^2\mathbf{u}_{xx}^\varepsilon, \tag{24}$$

where $E(\mathbf{u}^\varepsilon)$ is a matrix valued function. The solutions given by such a method can be analyzed in the same way as in the previous sections. The only point which will change in the analysis is the equation for $\hat{\mathbf{U}}$. The new equation for $\hat{\mathbf{U}}$ is

$$(E(\hat{\mathbf{U}})\hat{\mathbf{U}}_{\tilde{x}})_{\tilde{x}} + \dot{s}\hat{\mathbf{U}}_{\tilde{x}} - \mathbf{f}(\hat{\mathbf{U}})_{\tilde{x}} = 0, \tag{25}$$

together with the conditions (10) and (11). The boundary condition for $\mathbf{u}_1$ at $x = s^+$ is still given by (22) and (23). If $E(\hat{\mathbf{U}})$ can be chosen such that $I_{3t} \equiv 0$, we will have $\mathbf{u}_1(x,t) \equiv 0$ also in the downstream region.

We note that if $\hat{\mathbf{U}} = \hat{\mathbf{U}}^*$ with

$$\hat{\mathbf{U}}^* = \mathbf{u}^- + \gamma(\tilde{x})[\mathbf{u}], \tag{26}$$

where γ is a scalar smooth function, we obtain

$$I_3 = c_\gamma[\mathbf{u}],$$

where

$$c_\gamma = \int_{-\infty}^{0} \gamma(\tilde{x})\, d\tilde{x} + \int_{0}^{\infty} (\gamma(\tilde{x}) - 1)\, d\tilde{x}.$$

If γ is antisymmetric around $(0, 0.5)$ with

$$\gamma(-\infty) = 0, \quad \gamma'(-\infty) = 0, \quad \gamma(\infty) = 1, \quad \gamma'(\infty) = 0,$$

then $c_\gamma = 0$ and the boundary conditions (10) and (11) are satisfied.

It now remains to investigate whether it is possible to choose the matrix valued function $E(\hat{\mathbf{U}})$ such that $\hat{\mathbf{U}}^*$ satisfies (25). Integrating (25) from $-\infty$ to $\tilde{x}$ and substituting $\hat{\mathbf{U}}^*$ gives

$$\gamma'(\tilde{x})E(\hat{\mathbf{U}}^*)[\mathbf{u}] = \mathbf{q}(\hat{\mathbf{U}}^*), \tag{27}$$

where

$$\mathbf{q}(\mathbf{U}) = \mathbf{f}(\mathbf{U}) - \mathbf{f}(\mathbf{u}^-) - \dot{s}(\mathbf{U} - \mathbf{u}^-).$$

Note that $E(\hat{\mathbf{U}})$ is a function of $\hat{\mathbf{U}}$ only, with no explicit $\tilde{x}$ dependence. Hence, in order to solve (27) for $E(\hat{\mathbf{U}})$, we must be able to express γ' as a function of $\hat{\mathbf{U}}$. This is the case if we can express γ' in terms of γ, and if γ is monotone. Now solving (27) for $E(\hat{\mathbf{U}}^*)$ gives

$$E(\hat{\mathbf{U}}^*) = \frac{1}{\gamma'} \frac{\mathbf{q}(\hat{\mathbf{U}}^*)\mathbf{q}^T(\hat{\mathbf{U}}^*)}{\mathbf{q}^T(\hat{\mathbf{U}}^*)[\mathbf{u}]}. \tag{28}$$

To ensure that $E(\mathbf{u}^\varepsilon)$ is bounded as $\tilde{x} \to \pm\infty$ we must also require

$$\lim_{\tilde{x}\to-\infty} \frac{\gamma}{\gamma'} = M^-, \quad \lim_{\tilde{x}\to\infty} \frac{\gamma - 1}{\gamma'} = M^+,$$

where $|M^\pm| < \infty$.

Note that in order to evaluate $E(\hat{\mathbf{U}})$ the quantities $\dot{s}$, $\mathbf{u}^-$, and $\mathbf{u}^+$ must be known or estimated.

Remark. Prescribing the viscous profile as above means that the solution follows a straight line in phase space between the upstream and the downstream states. Many other shapes of the solution, and hence, paths in phase space, would also be possible. The properties of $E(\mathbf{u}^\varepsilon)$ will depend on which path is chosen. In order to obtain a stable method, it is necessary that the total viscosity coefficient of the method be positive definite. Since the term $c_2\varepsilon^2\mathbf{u}^\varepsilon_{xx}$ is also present, it is sufficient that $E(\mathbf{u}^\varepsilon)$ be positive semidefinite. We have found that the choice (28) is not positive semidefinite for all problems. In order to design a robust numerical method, we must further investigate what paths in phase space to use. Probably, this will differ depending on the equation that is to be solved. However, we are interested only in showing that it is possible to obtain second order accuracy also downstream, and for this purpose it is good enough to use $E(\mathbf{u}^\varepsilon)$ defined by (28).

3. Numerical experiments. In this section we test how the matrix valued viscosity coefficient derived in the previous section behaves in computations, and compare the results to corresponding computations with a scalar viscosity coefficient.

3.1. The test problems. We consider two test problems. In both problems, the equations, domain, initial data, and boundary condition at $x = x_{\text{end}}$ are the same, while the boundary condition at $x = 0$ differs.

We consider the Euler equations with Riemann initial data connected by a 1-shock. That is, we consider (1) and (2) with

$$\mathbf{u} = \begin{pmatrix} \rho \\ \rho u \\ E \end{pmatrix}, \quad \mathbf{f}(\mathbf{u}) = \begin{pmatrix} \rho u \\ \rho u^2 + p \\ u(E+p) \end{pmatrix}, \quad x_{\text{end}} = 6,$$

$$\mathbf{u}(x,0) = \begin{cases} \mathbf{u}_L & \text{for } x \le s_0, \\ \mathbf{u}_R & \text{for } x > s_0, \end{cases} \tag{29}$$

where E and p are connected by the equation of state for a polytropic gas

$$E = \frac{p}{\gamma - 1} + \frac{1}{2}\rho u^2, \quad \gamma = 1.4.$$

Since $\mathbf{u}_L$ and $\mathbf{u}_R$ are connected by a 1-shock, they are fully determined if ρ_L, u_L, and p_L—the initial density, velocity, and pressure at $x \le s_0$—and p_R, the initial pressure at $x > s_0$, are specified. We have used $\rho_L = 3$, $u_L = 1.2$, $p_L = 2$, and $p_R = 5$. This gives a 1-shock with speed ≈ -0.26. We have not specified the initial shock position s_0 explicitly. In the computations, which will be further described below, we started the computation at $t = -1$, with the profile (31) and the shock located at $x = 1.75$. We computed for one time unit using $\mathbf{u}(0,t) = \mathbf{u}_L$. In this way we obtained a good initial profile. We do this to avoid pollution of the numerical solution by disturbances due to nonperfect initial data. We have also used a rather large x_{end} in order to avoid reflection of such disturbances at the boundary $x = x_{\text{end}}$.

At $x = x_{\text{end}}$ we have the boundary condition

$$R_1(x_{\text{end}}, t) = R_1(x_{\text{end}}, 0),$$

where $R_1 = u - 2c/(\gamma - 1)$ is the Riemann invariant connected to λ_1, and $c = \sqrt{\gamma p/\rho}$ is the local speed of sound.

At $x = 0$ the boundary condition is specified by

$$p(0,t) = p_L(1 + \alpha d(t)),$$
$$\rho(0,t) = \rho_L \left(\frac{p(0,t)}{p_L}\right)^{1/\gamma},$$
$$u(0,t) = u_L + \frac{2}{\gamma - 1}(c(0,t) - c_L)$$

(see [2]); i.e., a disturbance with amplitude α is introduced into the Riemann invariant R_1, while the two other Riemann invariants are held constant. If α is small, this models an acoustic disturbance. We have considered the following two test problems:

Test problem 1: $\alpha = -0.2, \quad d(t) = (1 - \mathrm{e}^{-5t}) \sin 2t;$

Test problem 2: $\alpha = -0.1, \quad d(t) = \mathrm{e}^{-10(t-0.7)^2}.$

In the test problems, α is rather large, in order to make the first order effect more visible.

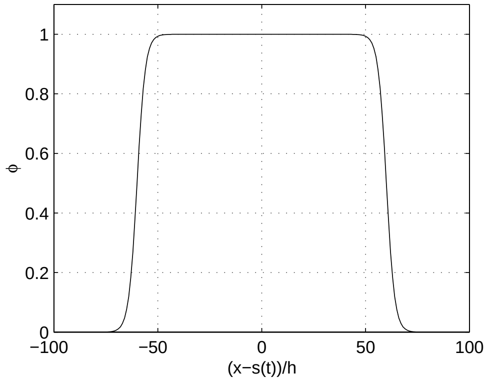

FIG. 1. *The function ϕ, with $s_1 = 60$ and $s_2 = 4$.*

3.2. The standard method. A common way to solve (1) is to discretize in space using central differences and add artificial viscosity. To avoid oscillations in the solution, the viscosity must be $\mathcal{O}(h)$ in the shock layer. Outside the shock region, the viscosity can be smaller. We obtain a formally second order method, whose solutions can be modeled by (4), using the semidiscrete scheme

$$(\mathbf{u}_j)_t + D_0\mathbf{f}(\mathbf{u}_j) = \kappa_1 h D_+ \phi_j D_- \mathbf{u}_j + \zeta h^2 D_+ D_- \mathbf{u}_j. \tag{30}$$

For test problem 1, we used $\kappa_2 = 1$ and $\zeta = 20$, and for test problem 2, we used $\kappa_1 = 0.5$ and $\zeta = 40$. We discretized in space by introducing $x_j = jh$, $h = 1/N$, $j = 0, 1, \ldots, N$, where $\mathbf{u}_j(t)$ is a grid function with $\mathbf{u}_j(t) \approx \mathbf{u}^\varepsilon(x_j, t)$. The system of ODEs (30) was solved with the classical fourth order Runge–Kutta method. The time step was chosen as $k = 0.5h$, i.e., CFL-number 0.5.

The switch ϕ was

$$\phi(x) = \begin{cases} 0.5\tanh((x - s(t) + s_1 h)/s_2 h) + 0.5, & x \le s(t), \\ 0.5\tanh((x - s(t) - s_1 h)/s_2 h) + 0.5, & x > s(t), \end{cases}$$

with $s_1 = 60$ and $s_2 = 4$; see Figure 1. Generally, there will be approximately $2s_1$ points where $\phi > 0.5$, and hence we have used a very wide switch. The parameter s_2 determines how steep the gradient of ϕ is in the transition area. The shock position $s(t)$ was numerically determined.

At $x = 6$ we used the mathematical boundary condition

$$R_1(6, t) = R_1(6, 0)$$

and the numerical boundary conditions

$$R_i(6, t) = 2R_i(6 - h, t) - R_i(6 - 2h, t), \quad i = 2, 3,$$

where the Riemann invariants R_2 and R_3 are

$$R_2 = \frac{p}{\rho^\gamma}, \quad R_3 = u + \frac{2c}{\gamma - 1}.$$

The initial data was obtained in the following way. We started the computations at $t = -1$ with the profile (31) and the shock located at $x = 1.75$. We computed for one time unit using $\mathbf{u}(0, t) = \mathbf{u}_L$.

We will refer to this method as the standard method.

3.3. The matrix viscosity method. We will now introduce a method which can be modeled by (24), and we will refer to it as the matrix viscosity method. The matrix viscosity method is the same as the standard method, except that (30) is replaced by

$$(\mathbf{u}_j)_t + D_0\mathbf{f}(\mathbf{u}_j) = \kappa_2 h D_+ \phi_j E_j D_- \mathbf{u}_j + \zeta h^2 D_+ D_- \mathbf{u}_j.$$

Here $E_j \approx E(\mathbf{u}^\varepsilon(x_j, t))$. Our implementation is described below. When solving test problem 1, we used $\kappa_2 = 15$, $\zeta = 20$, and CFL-number 0.05. For test problem 2, we used $\kappa_2 = 7$, $\zeta = 40$, and CFL-number 0.1.

To implement E_j in a robust and accurate way is difficult. The expression (28) is not suited for computations. The solution changes rapidly in the shock layer from being close to $\mathbf{u}^-$ to being close to $\mathbf{u}^+$. The quantities $\dot{s}$, $\mathbf{u}^-$, and $\mathbf{u}^+$ must be numerically determined; hence it is difficult to compute $\mathbf{q}$ with high accuracy. Also, both $\mathbf{q}$ and γ' tend rapidly to zero as $\tilde{x} \to \pm\infty$. However, for large $\tilde{x}$ we can linearize the expression for $\mathbf{q}$ and find

$$\mathbf{q} = \begin{cases} \gamma(J^- - \dot{s}I)[\mathbf{u}] & \text{as } \tilde{x} \to -\infty, \\ (\gamma - 1)(J^+ - \dot{s}I)[\mathbf{u}] & \text{as } \tilde{x} \to \infty. \end{cases}$$

By the assumptions on γ we find

$$E = \begin{cases} E^- & \text{as } \tilde{x} \to -\infty, \\ E^+ & \text{as } \tilde{x} \to \infty, \end{cases}$$

where

$$E^\pm = M^\pm \frac{(J^\pm - \dot{s}I)[\mathbf{u}][\mathbf{u}]^T (J^\pm - \dot{s}I)^T}{[\mathbf{u}]^T (J^\pm - \dot{s}I)^T [\mathbf{u}]}.$$

We have used

$$\gamma(\tilde{x}) = \frac{1}{2}(\tanh(\tilde{x}) + 1),$$

and hence we have $M^- = 1/2$ and $M^+ = -1/2$.

In the computations we have used

$$E_j = (1 - \gamma(\tilde{x}_j))E^- + \gamma(\tilde{x}_j)E^+.$$

The quantities $\dot{s}$, $\mathbf{u}^-$, and $\mathbf{u}^+$ were numerically determined. First, we approximated $\mathbf{u}^\pm$ by simply taking the value of the numerical solution 20 points upstream and downstream, respectively, of the approximated shock position. The shock speed $\dot{s}$ was approximated by

$$\dot{s}_{\text{approx}} = \sum_{k=1}^{3} [\mathbf{f}^{(k)}(\mathbf{u})] \Big/ \sum_{k=1}^{3} [\mathbf{u}^{(k)}].$$

By adding the jumps in the different components of $\mathbf{f}(\mathbf{u})$ and dividing by the sum of the jumps in the different components of $\mathbf{u}$, we avoid introducing large errors in $\dot{s}_{\text{approx}}$ due to rounding effects. This method for approximating $\mathbf{u}^\pm$ and $\dot{s}$ was used when test problem 1 was solved, and we obtain second order accuracy both upstream and downstream. The results are further presented in section 3.4.

The approximation of $\mathbf{u}^{\pm}$ mentioned above has an error which is small, but independent of h. Hence, there will be a small $\mathcal{O}(1)$ error in our approximation of $E(\mathbf{u}^{\varepsilon})$, which will cause a small $\mathcal{O}(h)$ error in the solution. This first order effect became evident as we tried to solve test problem 2. In order to eliminate it, we needed to use an estimate of $\mathbf{u}^{\pm}$ with an error which is $\mathcal{O}(h)$. We obtain this if we make use of the fact that the solution in the shock region follows a straight line in phase space between $\mathbf{u}^{-}$ and $\mathbf{u}^{+}$, and that the function γ determines how fast the solution is approaching the limit values. We pick the value of the solution $2\kappa_2$ points upstream and downstream of the approximate shock position. Since γ is known, we know how far from the end states these values are and correct for this. The shock speed $\dot{s}$ is still computed as above. Test problem 2 was solved using this improved approximation of $\mathbf{u}^{\pm}$, and we obtained second order accuracy both upstream and downstream.

The implementation of $E(\mathbf{u}^{\varepsilon})$ described above requires a fixed number of computations, independent of h.

As initial profile at $t = -1$, we used

$$\mathbf{u}_j = \mathbf{u}_L + \gamma(\tilde{x}_j)(\mathbf{u}_R - \mathbf{u}_L); \tag{31}$$

i.e., in the shock region the profile satisfies (26). The initial profile (31) is used to avoid diffusion waves in the solution (see section 2.2). Ideally, using this initial profile, no such waves should appear. However, in our numerical computations we see diffusion waves, but they are very small.

In computations not reported here, we have also tried to use

$$\mathbf{u}(x,-1) = \begin{cases} \mathbf{u}_L & \text{for } x \leq 1.75, \\ \mathbf{u}_R & \text{for } x > 1.75. \end{cases} \tag{32}$$

As expected, the profile rapidly adjusts, and diffusion waves appear and move out of the shock region following outgoing characteristics. Also as expected, for the matrix method, the diffusion waves are much larger with (32) as initial data than if (31) is used. However, the order of accuracy of the solution behind the diffusion waves is the same.

3.4. Results. We have numerically investigated the rate of convergence of the standard method and of the matrix viscosity method by solving the two test problems described in section 3.1 with successively refined space step.

First, consider test problem 1. In Figure 2 we see the solution at $t = 1.25$. We have solved test problem 1 with successively halved space step h with both methods. We started with $h = 0.02$. In all, we computed six solutions with the matrix viscosity method and eight solutions with the standard method.

The computational order of accuracy, r_h, was estimated in the standard way,

$$r_h = \log\left(\frac{||\rho u_{4h} - \rho u_{2h}||}{||\rho u_{2h} - \rho u_h||}\right) \Big/ \log 2,$$

where ρu_h denotes the discrete approximation of ρu with space step h, and the norm used was the discrete L_2-norm on the interval $(0, 0.7)$ in the upstream region and $(1.4, 2.2)$ in the downstream region. In Table 1 we see that the standard method is second order accurate upstream, but only first order accurate downstream of the

shock. The matrix viscosity method is second order accurate, both upstream and downstream of the shock; see Table 2.

In Figure 3 we see an overview of how the ρ-component of the solution converges, and in Figure 4 we see a close-up. Note that the aim when designing the matrix viscosity method was to avoid the first order error outside the shock region. Hence, the matrix viscosity method performs better than the standard method for fine grids, where the first order downstream error destroys the convergence rate of the standard method. For coarse grids, however, the matrix viscosity method is not better.

If the order of accuracy is r, then the error in the ρu-component of the solution

can be estimated:

$$||e_h|| = \frac{1}{2^r - 1}||u_{2h} - u_h||.$$

Hence, $||e_h||$ is computed with $r = 2$ in the upstream region for the standard method, and both upstream and downstream for the matrix method. For the standard method downstream of the shock, we have used $r = 1$. Again we use the discrete L_2-norm, on the same interval as above.

Corresponding computations for the ρ- and E-components of the solution give qualitatively the same result.

By plotting the shock profile in phase space (see Figure 5), we see that the shock

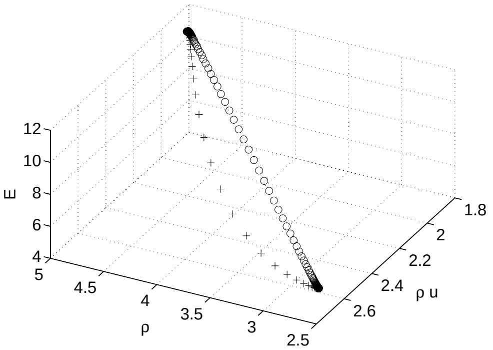

FIG. 5. *Numerical phase diagram of the shock profile computed by the matrix viscosity method* (o) *and the standard method* (+). *Both solutions are computed using* $h = 6.25 \cdot 10^{-4}$. *The shock profile computed by the matrix viscosity method follows a straight line in phase space quite closely.*

profile obtained by the matrix viscosity method approximately follows a straight line between the shock states. The shock profile of the standard method clearly has another shape.

Next, consider test problem 2. In Figure 6, we see the solution of test problem 2 at $t = 1.9$. Test problem 2 was also solved with successively halved space step h with both methods, starting with $h = 0.02$. Again, in all we computed eight solutions with the standard method and six solutions with the matrix viscosity method. In Table 3, we see the estimated order of accuracy for the standard method. Again, we have used the interval $(0, 0.7)$ in the upstream region. In the downstream region the discrete L_2-norm was computed on the interval $(1.1, 3)$. Upstream, the solution is second order. Downstream the convergence is slower, and the order of accuracy is slowly approaching one. In Table 4 we see that the matrix viscosity method is second order accurate both upstream and downstream. In Figure 7 we see an overview of how the ρ-component converges, and in Figure 8 we see a close-up. In phase space, the shock profiles of the solutions of test problem 2 are qualitatively the same as in Figure 5.

POINTWISE ERROR ESTIMATES FOR DIFFERENCES IN PIECEWISE LINEAR FINITE ELEMENT APPROXIMATIONS*

ALFRED H. SCHATZ[†] AND LARS B. WAHLBIN[†]

Abstract. We consider piecewise linear finite element approximations u_h to u the solution of an elliptic boundary value problem. New estimates for the differences $|e(x_1) - e(x_2)|$ (where $e(x) = u(x) - u_h(x)$ is the error and x_1 and x_2 are any two points in the domain) are obtained in terms of weighted L_∞ norms. As a consequence, so-called asymptotic expansion inequalities are derived that have been applied to obtain asymptotically exact a posteriori estimators for the gradient on each element.

Key words. finite element methods, pointwise estimates, boundary value problems

1. Introduction and statement of results.

The aim of this paper is to provide both local and global estimates for differences in the error at any two points in a domain when the finite element method is used with continuous piecewise linear functions to approximate solutions of second order elliptic boundary value problems. The results of this paper rely on, and can be viewed as extensions of, the results given in Schatz [6] and [7], which play an essential role in their derivation. An important feature of all of these pointwise estimates for the error is that they are bounded in terms of weighted L_∞ norms that sharply localize the dependence of the error on the solution. Using this feature, the results of [6] were applied in Hoffmann et al. [4] to obtain local asymptotically exact a posteriori estimators for quadratic or higher order finite elements. The results of this paper have been applied in [9] to obtain local asymptotically exact a posteriori estimators in the case of linear finite elements.

An outline of this paper is as follows: In section 1.1 we consider a global Neumann problem. The main result for this case is stated in Theorem 1. An important corollary is then given, namely, Corollary 1, which contains a so-called asymptotic error expansion inequality. It is this result that is used in [9]. Section 1.2 is concerned with local estimates. The main result is given in Theorem 2, and the corresponding local asymptotic error expansion inequality is given in Corollary 2. Section 2 contains some preliminaries needed for the proofs of Theorems 1 and 2. Section 3 contains a proof of Theorem 1 and section 4 a proof of Theorem 2.

1.1. A global Neumann problem.

Let Ω be a bounded domain in $\mathbb{R}^N$, $N \geq 2$, with smooth boundary $\partial\Omega$, and consider the Neumann problem with a homogeneous conormal boundary condition,

$$\mathcal{L}u = -\sum_{i,j=1}^{N} \frac{\partial}{\partial x_i}\Big(a_{ij}(x)\frac{\partial u}{\partial x_j}\Big) + \sum_{i=1}^{N} b_i(x)\frac{\partial u}{\partial x_i} + c(x)u = f(x) \quad \text{in } \Omega, \tag{1.1}$$

[†] Department of Mathematics, Cornell University, Ithaca, NY 14853 (schatz@math.cornell.edu, wahlbin@math.cornell.edu).

$$\frac{\partial u}{\partial n_{\mathcal{L}}} = \sum_{i,j=1}^{N} \Big(a_{ij} \frac{\partial u}{\partial x_j} \Big) n_i = 0 \quad \text{on } \partial\Omega. \tag{1.2}$$

We shall assume that the coefficients are smooth and that $\mathcal{L}$ is uniformly elliptic in Ω; i.e., there exists a constant $c_{\text{ell}} > 0$ such that

$$c_{\text{ell}} |\zeta|^2 \le \sum_{i,j=1}^{N} a_{ij} \zeta_i \zeta_j \quad \text{for all } \zeta \in \mathbb{R}^N. \tag{1.3}$$

Let $u \in W_2^1(\Omega)$ be a weak solution of (1.1), (1.2) satisfying

$$\begin{aligned} A(v,v) &= \int_\Omega \left(\sum_{i,j=1}^{N} a_{ij}(x) \frac{\partial u}{\partial x_i} \, \frac{\partial v}{\partial x_j} + \sum_{i=1}^{N} b_i(x) \frac{\partial u}{\partial x_i} v + c(x) uv dx \right) \\ &= \int_\Omega fv dx = (f,v) \quad \text{for all } v \in W_2^1(\Omega). \end{aligned} \tag{1.4}$$

Here for simplicity it will be assumed that $A(\cdot,\cdot)$ is coercive; i.e., for some $c_{co} > 0$

$$c_{co} \|u\|^2_{W_2^1(\Omega)} \le A(u,u). \tag{1.5}$$

Now consider the approximation of u using the finite element method. For $0 < h < 1$, let S_h be a family of subspaces of $W_\infty^1(\Omega)$, each S_h consisting of continuous piecewise linear functions defined on a quasi-uniform triangulation by simplexes of roughly size h that fit $\partial\Omega$ exactly. Thus curved faces are allowed at the boundary. By a quasi-uniform triangulation of roughly size h we mean that there exist constants $0 < c_* < c^*$ such that each simplex τ contains a ball of radius $c_* h$ and is contained in a ball of radius $c^* h$, where c_* and c^* are independent of τ and h. Now let $u_h \in S_h$ be the finite element approximation of u defined by

$$A(u_h, \varphi) = (f, \varphi) \quad \text{for all } \varphi \in S_h \tag{1.6}$$

so that

$$A(u - u_h, \varphi) = 0 \quad \text{for all } \varphi \in S_h. \tag{1.7}$$

We are interested in estimating the differences $e(x_2) - e(x_1)$, where x_1 and x_2 are arbitrary points in $\overline{\Omega}$, and $e(x) = u(x) - u_h(x)$. Our estimates will be given in terms of weighted L_∞ norms that we will now describe. Set $\rho = |x_2 - x_1|$, $\overline{x} = \frac{x_1 + x_2}{2}$, and for any real s

$$\sigma_{\overline{x}}^s(y) = \left(\frac{\max(h,\rho)}{|\overline{x} - y| + \max(h,\rho)} \right)^s. \tag{1.8}$$

For $p = 1$ or ∞, define the weighted norms

$$\|u\|_{W_p^1(\Omega),\overline{x},s} = \|\sigma_{\overline{x}}^s(y) u(y)\|_{L_p(\Omega)} + \|\sigma_{\overline{x}}^s(y) \nabla u(y)\|_{L_p(\Omega)}. \tag{1.9}$$

Our first result is as follows.

Theorem 1. *Let u and u_h satisfy* (1.7). *There exist positive constants C and k such that if x_1 and x_2 are any two points in $\overline{\Omega}$, then the following hold:*

(i) *If* $\rho \leq kh$ *and* $0 \leq s \leq 1$,

$$|e(x_2) - e(x_1)| \leq C\rho\Big(\ln\frac{1}{h}\Big)^{\overline{s}}\Big(\min_{\chi \in S^h}\|u-\chi\|_{W^1_\infty(\Omega),\overline{x},s}\Big). \tag{1.10}$$

Here, $\overline{s} = 1$ *if* $s = 1$, *and* $\overline{s} = 0$ *otherwise.*

(ii) *If* $\rho \geq kh$ *and* $0 \leq s < 1$,

$$|e(x_2) - e(x_1)| \leq Ch\Big(\ln\frac{\rho}{h}\Big)\Big(\inf_{\chi \in S^h}\|u-\chi\|_{W^1_\infty(\Omega),\overline{x},s}\Big). \tag{1.11}$$

In (1.10) and (1.11), C depends on c_{ell}, c_{c_0}, s, Ω, and the maximum norm of the coefficients of $\mathcal{L}$ and sufficiently many of their derivatives. It is independent of u, u_h, h, x_1, and x_2 (and hence also of ρ).

Remark 1.1. The case $s = 1$ has been excluded from the estimate (1.11). An estimate for this case easily follows from the proof given in section 3 but involves an additional logarithmic factor. We have not included this estimate since it is not the sharpest possible. However, the proof of a sharper result would require a much longer paper: essentially, we would not *use* the results of [6] but *redo* them with appropriate modifications.

An immediate consequence of Theorem 1 are so-called asymptotic error expansion inequalities.

Corollary 1. *Suppose that Theorem* 1 *holds, and in addition, let* $\varepsilon > 0$ *be arbitrary but fixed. Then the following hold:*

(i) *If* $\rho \leq kh$,

$$|e(x_2) - e(x_1)| \leq C_\varepsilon \rho h\left(\sum_{|\alpha|=2}|D^\alpha u(\overline{x})| + h^{1-\varepsilon}\|u\|_{W^3_\infty(\Omega)}\right). \tag{1.12}$$

(ii) *If* $\rho \geq kh$,

$$|e(x_2) - e(x_1)| \leq C_\varepsilon h^2\Big(\ln\frac{\rho}{h}\Big)\left(\sum_{|\alpha|=2}|D^\alpha u(\overline{x})| + \rho^{1-\varepsilon}\|u\|_{W^3_\infty(\Omega)}\right). \tag{1.13}$$

Corollary 1 has been applied to the problem of a posteriori estimates in [9]. The inequalities (1.12) and (1.13) follow from (1.10) and (1.11), respectively, by using standard approximation properties of piecewise linear functions and Taylor's theorem.

Remark 1.2. In the case of quadratic or higher elements, $r = 3, 4, \dots$, we have from [6] that

$$|e(x)| \leq C_\varepsilon h^r\left(\sum_{|\alpha|=r}|D^\alpha u(x)| + h^{1-\varepsilon}\|u\|_{W^{r+1}_\infty(\Omega)}\right).$$

However, Demlow [2] has shown that such an estimate is impossible in the piecewise linear case, $r = 2$ (even allowing for logarithmic factors). In [9], Corollary 1 above is a substitute estimate, strong enough to give the desired result.

1.2. Local estimates. We shall next describe some results that are local analogues of the estimates (1.12) and (1.13). Toward this end, for $d > 0$, let $B_{2d}(x_0)$ denote the ball of radius $2d$ centered at x_0. Furthermore, let $S^h(B_{2d}(x_0))$, $0 < h < 1$, be a family of continuous piecewise linear elements defined on quasi-uniform triangulations of roughly size h that cover $B_{2d}(x_0)$. It will be assumed that $kh < d$ for some fixed k sufficiently large. We wish to estimate the error $|e(x_2) - e(x_1)|$ for any two points $x_1, x_2 \in B_d(x_0)$. Here $u_h \in S^h(B_{2d}(x_0))$, and $e(x) = u(x) - u_h(x)$ satisfies the local equations

$$\begin{aligned} A(e,\varphi) = \int_{B_{2d}(x_0)} \Bigg(\sum_{i,j=1}^{N} a_{ij}(x) \frac{\partial e}{\partial x_i}\, \frac{\partial \varphi}{\partial x_j} \\ + \sum_{i=1}^{N} b_i(x) \frac{\partial e}{\partial x_i} \varphi + c(x) e \varphi \Bigg) dx = 0 \\ \text{for all } \varphi \in \overset{\circ}{S}{}^h(B_{2d}(x_0)), \end{aligned} \tag{1.14}$$

where $\overset{\circ}{S}{}^h(B_{2d}(x_0))$ denotes the subspace of $S^h(B_{2d}(x_0))$ of functions whose support is contained in $B_{2d}(x_0)$. Our main local result is as follows.

THEOREM 2. *Let u and u_h satisfy* (1.14), *let $1 \le p \le \infty$, and let t be a nonnegative integer. There exist positive constants C and k such that if x_1 and x_2 are any two points in $\overline{B}_d(x_0)$, $\rho = |x_2 - x_1|$, $\overline{x} = \frac{x_1+x_2}{2}$, $d \ge \max(\rho, kh)$, then the following hold:*

(i) *If $\rho \le kh$ and $0 \le s \le 1$,*

$$\begin{aligned} |e(x_2) - e(x_1)| \le C\rho \Bigg(\Big(\ln \frac{1}{h} \Big)^{\overline{s}} \min_{\chi \in S^h} \|u - \chi\|_{W^1_\infty(B_{2d}(x_0)), \overline{x}, s} \\ + d^{-t-1-N/\rho} \|e\|_{W_p^{-t}(B_{2d}(x_0))} \Bigg), \end{aligned} \tag{1.15}$$

where $\overline{s} = 1$ if $s = 1$, and $\overline{s} = 0$ otherwise.

(ii) *If $\rho \ge kh$ and $0 \le s < 1$,*

$$\begin{aligned} |e(x_2) - e(x_1)| \le & Ch \ln \Big(\frac{\rho}{h} \Big) \Big(\min_{\chi \in S^h} \|u - \chi\|_{W^1_\infty(B_{2d}(x_0)), \overline{x}, s} \Big) \\ & + C\rho d^{-t-1-N/p} \|e\|_{W_p^{-t}(B_{2d}(x_0))}. \end{aligned} \tag{1.16}$$

In (1.15) and (1.16), C depends on c_{ell}, c_{co}, s, t, p, and the maximum norms of the coefficients and sufficiently many derivatives. It is independent of u, u_h, h, x_1, x_2 (hence also of ρ), and d. Furthermore, for any open set G and $\frac{1}{p} + \frac{1}{q} = 1$,

$$\|u\|_{W_p^{-t}(G)} = \sup \int_G u \eta dx. \tag{1.17}$$

As a consequence of Theorem 2 we have the following local "asymptotic expansion inequalities."

COROLLARY 2. *Suppose that Theorem 2 holds, and in addition, let $\varepsilon > 0$ be arbitrary but fixed. Then, for all x_1 and x_2 in $B_d(x_0)$, the following hold:*

(i) *If $\rho \le kh$,*

$$\begin{aligned} |e(x_2) - e(x_1)| \le C_\varepsilon \rho h \Bigg(\sum_{|\alpha|=2} |D^\alpha u(\overline{x})| + h^{1-\varepsilon} \|u\|_{W^3_\infty(B_{2d}(x_0))} \Bigg) \\ + C d^{-t-1N/p} \|e\|_{W_p^{-t}(B_{2d}(x_0))}. \end{aligned} \tag{1.18}$$

(ii) *If $\rho \geq kh$,*

$$|e(x_2) - e(x_1)| \leq C_\varepsilon h^2 \ln\left(\frac{\rho}{h}\right)\left[\left(\sum_{|\alpha|=2} |D^\alpha u(\overline{x})| + \rho^{1-\varepsilon}\|u\|_{W^3_\infty(B_{2d}(x_0))}\right)\right] + C\rho d^{-t-1-N/p}\|e\|_{W_p^{-t}(B_{2d}(x_0))}. \tag{1.19}$$

2. Preliminaries. Here we shall collect some known results that will be essential in our proofs of Theorems 1 and 2. Lemma 2.1 is concerned with a special case of estimates derived in [6] for the gradient at a point for the global Neumann problem. Lemma 2.2 deals with analogous local estimates given in [7]. Lemma 2.3 is concerned with some pointwise estimates given in Krasovskii [5] for the Green's function for the problem (1.1), (1.2).

LEMMA 2.1. *Let Ω be a bounded domain in $\mathbb{R}^N$ with a smooth boundary $\partial\Omega$, and let $S^h(\Omega)$ be the continuous piecewise linear functions defined on a globally quasi-uniform mesh of roughly size h, $0 < h < 1$, that fits the boundary exactly. Let $u \in W^1_\infty(\Omega)$ and $u_h \in S^h(\Omega)$ satisfy* (1.7), *and suppose* $0 \leq s \leq 1$. *Then there exists a constant C such that if $x \in \overline{\Omega}$ is arbitrary,*

$$|e(x)| + |\nabla e(x)| \leq C\Big(\ln\frac{1}{h}\Big)^{\overline{s}}\Big(\min_{\chi\in S^h}\|u-\chi\|_{W^1_\infty(\Omega),x,s}\Big). \tag{2.1}$$

Here $\overline{s} = 1$ if $s = 1$, and $\overline{s} = 0$ otherwise. C depends on c_{ell}, c_{co}, s, Ω, and the maximum norm of the coefficients of $\mathcal{L}$ and sufficiently many of their derivatives. It is independent of u, u_h, h, and x.

Remark 2.1. At its points of discontinuity, $\nabla u_h(x)$ is to be interpreted as the limit from inside any simplex for which x is a boundary point.

We shall need a local analogue of Lemma 2.1. In Lemma 2.2 we shall use the notation of section 1.2.

LEMMA 2.2. *Let $u \in W^1_\infty(B_{2d}(x_0))$ and $u_h \in S^h(B_{2d}(x_0))$ satisfy* (1.14). *There exists a constant c such that if $x \in \overline{B_d(x_0)}$ is arbitrary, then if* $0 \leq s \leq 1$,

$$|e(x)| + |\nabla e(x)| \leq C\Big(\Big(\ln\frac{1}{h}\Big)^{\overline{s}}\min_{\chi\in S^h(B_{2d}(x_0))}\|u-\chi\|_{W^1_\infty(B_{2d}(x_0)),x,s} + d^{-t-1-N/p}\|e\|_{W_p^{-t}(B_{2d}(x_0))}\Big). \tag{2.2}$$

Here $\overline{s} = 1$ if $s = 1$, and $\overline{s} = 0$ otherwise. C depends on c_{ell}, c_{co}, s, and the maximum norm of the coefficients of $\mathcal{L}$ and sufficiently many of their derivatives. It is independent of u, u_h, h, d, and x.

Let $G^x(y)$ denote the Green's function for the problem (1.1), (1.2) with singularity at x.

LEMMA 2.3. *There exists a constant C such that if $x, y \in \overline{\Omega}$,*

$$|D_x^\alpha D_y^\beta G^x(y)| \leq C|x-y|^{2-N-|\alpha+\beta|} \text{ for } |\alpha+\beta| > 0. \tag{2.3}$$

Here C depends on c_{co}, c_{ell}, and various norms of the coefficients of $\mathcal{L}$.

3. A proof of Theorem 1, global estimates. For simplicity of proof, we will assume that Ω is convex. We start by proving (1.10).

In this case $\rho \le kh$, and by the fundamental theorem of calculus, there exists a point $\widehat{x}$ on the line joining x_1 and x_2 such that, in view of (2.1),

$$|e(x_2) - e(x_1)| \le \rho |\nabla e(\widehat{x})| \le c\rho \Big(\ln \frac{1}{h} \Big)^{\overline{s}} \min_{\chi \in S^h} \|u - \chi\|_{W^1_\infty(\Omega), \widehat{x}, s}. \tag{3.1}$$

We next note that since the function $\lambda \to \frac{\lambda}{A+\lambda}$, $A > 0$, is an increasing function for $\lambda > 0$, we have the following string of elementary inequalities:

$$\begin{aligned} \sigma_{\widehat{x}}(y) = \frac{\max(\rho, h)}{|\widehat{x} - y| + \max(\rho, h)} &\le \frac{2\max(\rho, h)}{|\overline{x} - y| - |\widehat{x} - \overline{x}| + 2\max(\rho, h)} \\ &\le \frac{2\max(\rho, h)}{|\overline{x} - y| + \max(\rho, h)} = 2\sigma_{\overline{x}}(y). \end{aligned} \tag{3.2}$$

In the next to last step we have used that $|\widehat{x} - \overline{x}| \le \rho$. It follows from (3.2) and the definition (1.9) that

$$\|v\|_{W^1_\infty(\Omega), \widehat{x}, s} \le 2\|v\|_{W^1_\infty(\Omega), \overline{x}, s} \text{ for all } v \in W^1_\infty.$$

Using this in (3.1), the inequality (1.10) follows (the case $\rho \le kh$).

We now turn to a proof of (1.11) (the case $\rho \ge kh$). We can then write

$$e(x_2) - e(x_1) = A(e(y), G^{x_2} - G^{x_1}), \tag{3.3}$$

where $G^x(y)$ is the Green's function for the adjoint problem with singularity at x,

$$\mathcal{L}^* G^x(y) = \delta^x(y) \text{ in } \Omega, \ \frac{\partial G^x}{\partial n_{\mathcal{L}^*}} = 0 \text{ on } \partial\Omega. \tag{3.4}$$

Hence for any $\psi \in S^h(\Omega)$

$$\begin{aligned} |e(x_2) - e(x_1)| &\le |A(e, G^{x_2} - G^{x_1} - \psi)| \\ &\le C\Big(\|e\|_{W^1_\infty(\Omega), \overline{x}, s} \|G^{x_2} - G^{x_1} - \psi\|_{W^1_1(\Omega), \overline{x}, -s} \Big). \end{aligned} \tag{3.5}$$

The remainder of this section will be devoted to showing that, for $0 \le s < 1$ and $\rho \ge kh$,

$$\|e\|_{W^1_\infty(\Omega), \overline{x}, s} \le C \inf_{\chi \in S^h} \|u - \chi\|_{W^1_\infty(\Omega), \overline{x}, s} \tag{3.6}$$

and that there exists a $\psi \in S^h$ so that

$$\|G^{x_2} - G^{x_1} - \psi\|_{W^1_1(\Omega), \overline{x}, -s} \le Ch \Big(\ln \frac{\rho}{h} \Big), \tag{3.7}$$

where C is as in Theorem 1. Granting the last two inequalities for a moment, the proof of (1.11) follows from (3.5), (3.6), and (3.7), which would complete the proof of Theorem 1.

We now turn to the proof of (3.6). In view of (2.1), we have for any $z \in \overline{\Omega}$

$$|e(z)| + |\nabla e(z)| \le C \inf_{\chi \in S^h} \Big(\|\sigma^s_z(y)(u - \chi)(y)\|_{L_\infty(\Omega)} + \|\sigma^s_z(y)(\nabla(u - \chi))(y)\|_{L_\infty(\Omega)} \Big).$$

Now multiplying both sides by $\sigma^s_{\overline{x}}(z)$, we obtain

$$\begin{aligned}\sigma^s_{\overline{x}}(z)|e(z)| &+ \sigma^s_{\overline{x}}(z)|\nabla e(z)| \\ &\le C \inf_{\chi\in S^h}\Big(\|\sigma^s_{\overline{x}}(z)\sigma^s_z(y)(u-\chi)(y)\|_{L_\infty(\Omega)} \\ &\qquad + \|\sigma^s_{\overline{x}}(z)\sigma^s_z(y)(\nabla(u-\chi))(y)\|_{L_\infty(\Omega)}\Big).\end{aligned} \tag{3.8}$$

For the product of weights in the right-hand side, we have

$$\begin{aligned}\sigma_{\overline{x}}(z)\sigma_z(y) &\equiv \Big(\frac{\rho}{|\overline{x}-z|+\rho}\Big)\Big(\frac{\rho}{|z-y|+\rho}\Big) \le \Big(\frac{\rho}{|\overline{x}-z|+\rho}\Big)\Big(\frac{|\overline{x}-z|+\rho}{|z-y|+|\overline{x}-z|+\rho}\Big) \\ &= \frac{\rho}{|\overline{x}-z|+|z-y|+\rho} \le \frac{\rho}{|\overline{x}-y|+\rho} \equiv \sigma_{\overline{x}}(y).\end{aligned}$$

Using this in the right-hand side of (3.8), which then becomes independent of z, and taking the maximum norm of the left-hand side in z, we arrive at (3.6).

It remains to prove (3.7). For $d > 0$ and $x \in \Omega$, let

$$M_d(x) = B_d(x) \cap \Omega = \{y \in \Omega : |y-x| < d\}.$$

Next, for $i = 1, 2$, define $\psi_i \in S^h$ by

$$\psi_i(y) = (G^{x_i}(y))_{\mathrm{Int}}, \tag{3.9}$$

where the interpolation operator is of any standard type involving local averaging; see, e.g., Clément [1], Hilbert [3], or Scott and Zhang [10]. Set

$$\psi = \psi_1 - \psi_2.$$

Using the triangle inequality (recall that $\rho = |x_1 - x_2|$ and $\overline{x} = (x_1 + x_2)/2$), we have

$$\begin{aligned}&\|G^{x_2} - G^{x_1} - \psi\|_{W^1_1(\Omega),\overline{x},-s} \\ &\quad\le 4^s \sum_{i=1}^{2} \|G^{x_i} - \psi_i\|_{W^1_1(M_{4\rho}(x_i))} + \|G^{x_2} - G^{x_1} - \psi\|_{W^1_1(\Omega/M_{3\rho}(\overline{x})),\overline{x},-s} \\ &\quad= I_1 + I_2.\end{aligned} \tag{3.10}$$

We begin by estimating each term in I_1. Now

$$\begin{aligned}&\|G^{x_i} - \psi_i\|_{W^1_1(M_{4\rho}(x_i))} \\ &\quad\le \|G^{x_i} - \psi_i\|_{W^1_1(M_{2kh}(x_i))} + \|G^{x_i} - \psi_i\|_{W^1_1(M_{4\rho}(x_i)/M_{2kh}(x_i))}.\end{aligned} \tag{3.11}$$

Using stability properties of the ψ_i for the first term on the right, we have

$$\begin{aligned}\|G^{x_i} - \psi_i\|_{W^1_1(M_{2kh}(x_i))} &\le C\|G^{x_i}\|_{W^1_1(M_{3kh}(x_i))} \\ &\le C\int_{0\le r\le 3kh} \frac{r^{N-1}}{r^{N-1}}dr \le Ch.\end{aligned} \tag{3.12}$$

Here we have set $r = |x - x_i|$ and used the bounds (2.3) for the Green's function. Now using approximation properties of the ψ_i, and (3.12) in (3.11),

$$\begin{aligned}&\|G^{x_i} - \psi_i\|_{W^1_1(M_{4\rho}(x_i)/M_{2kh}(x_i))} \\ &\quad\le Ch\|G^{x_i}\|_{W^2_1(M_{5\rho}(x_i)/M_{kh}(x_i))} \\ &\quad\le Ch\int_{kh\le r\le 5\rho} \frac{r^{N-1}}{r^N}dr \le Ch\ln\Big(\frac{\rho}{h}\Big).\end{aligned} \tag{3.13}$$

Combining (3.13), (3.12), and (3.11), we arrive at

$$I_1 \leq Ch\Big(\ln\frac{\rho}{h}\Big). \tag{3.14}$$

It remains to estimate I_2. For this purpose, let

$$d_j = 2^{-j},\ j = 0, 1, 2, \ldots,$$

and introduce the "annuli"

$$\begin{aligned}
&\Omega_j = \{y \in \Omega : d_{j+1} < |y - \overline{x}| < d_j\} \text{ for } j = 0, 1, 2, \ldots,\\
&\Omega_j' = \Omega_{j-1} \cup \overline{\Omega}_j \cup \Omega_{j+1} \text{ for } j = 1, 2, \ldots,\\
&\Omega_0' = \overline{\Omega}_0 \cup \Omega_1.
\end{aligned}$$

Also set

$$J = \left[\ln_2\left(\frac{1}{3\rho}\right)\right] + 1.$$

Using the triangle inequality and assuming for convenience that $\Omega \subset M_1(\overline{x})$,

$$\begin{aligned}
I_2 &\leq \sum_{j=0}^{J}\Big(\frac{d_j}{\rho}\Big)^s \|G^{x_2} - G^{x_1} - \psi\|_{W_1^1(\Omega_j)}\\
&\leq C\sum_{j=0}^{J}\frac{d_j^{N+s}}{\rho^s}\|G^{x_2} - G^{x_1} - \psi\|_{W_\infty^1(\Omega_j)}\\
&\leq Ch\sum_{j=0}^{J}\frac{d_j^{N+s}}{\rho^s}|G^{x_2} - G^{x_1}|_{W_\infty^2(\Omega_j')},
\end{aligned} \tag{3.15}$$

where we have used the standard approximation properties of ψ. Next, by the fundamental theorem of calculus and (2.3), we have for any multi-index β with $|\beta| = 2$

$$|D_y^\beta(G^{x_2}(y) - G^{x_1}(y))| \leq \sum_{|\alpha|=1}\int_\Gamma |D_x^\alpha D_y^\beta G^x|dx \leq C\rho d_j^{-N-1}, \tag{3.16}$$

where Γ is the line joining x_1 and x_2. Using (3.16) in (3.15), we arrive at

$$I_2 \leq Ch\sum_{j=0}^{J}\frac{d_j^{N+s}\rho d_j^{-N-1}}{\rho^s} = Ch\sum_{j=0}^{J}\Big(\frac{\rho}{d_j}\Big)^{1-s},$$

or

$$I_2 \leq C(s)h \quad \text{for } 0 \leq s < 1. \tag{3.17}$$

Combining (3.16) and (3.14) into (3.10) leads to (1.11), which completes the proof of Theorem 1.

Remark 3.1. If $s = 1$, then $I_2 \leq Ch\ln\frac{1}{\rho}$. Hence the estimate (1.11) may be extended to the case $s = 1$ but with an additional $\ln\frac{1}{\rho}$ factor; cf. Remark 1.1.

4. A proof of Theorem 2, interior estimates. The proof of interior estimates involves some additional technical difficulties when compared with the proof of Theorem 1. These difficulties can be overcome by well-established techniques developed in [8]. There are some parts where the proof relies on techniques used in the proof of Theorem 1. In order to avoid tedious and repetitive details, we shall restrict ourselves to giving an outline of the proof, except at essentially new points.

Proof. We begin with a proof of (1.15). Proceeding as in the proof of (1.10), we have

$$|e(x_2) - e(x_1)| \leq \rho |\nabla e(\widehat{x})|,$$

where $\widehat{x}$ is a point on the line joining x_1 and x_2. Applying (2.2), we obtain for $0 \leq s \leq 1$

$$\begin{aligned} |e(x_2) - e(x_1)| &\leq C\rho\Big[\Big(\ln\frac{1}{h}\Big)^{\overline{s}}\Big(\min_{\chi\in S^h}\|u-\chi\|_{W^1_\infty(B_d(\widehat{x})),\widehat{x},s}\Big) + d^{-1-t-N/p}\|e\|_{W_p^{-t}(B_d(\widehat{x}))}\Big] \\ &\leq C\rho\Big[\Big(\ln\frac{1}{h}\Big)^{\overline{s}}\Big(\min_{\chi\in S^h}\|u-\chi\|_{W^1_\infty(B_{2d}(x_0)),\overline{x},s}\Big) + d^{-1-t-N/p}\|e\|_{W_p^{-t}(B_{2d}(x_0))}\Big]. \end{aligned}$$

In the last step we used that $|\widehat{x} - \overline{x}| \leq p/2$. This is (1.15).

The proof of (1.16) will be separated into two steps, following the general procedure established in [8], with a slight modification given in [7]. In the first step the case $d = 1$ will be treated, and, in the second step, the result for any $d < 1$ will be reduced to the first case via a standard scaling argument.

Step 1. Let $\widehat{d} > 0$ be any number independent of u and h. Assume we could show, for $x_1, x_2 \in B_{\widehat{d}}(\widehat{x}_0)$, any $\widehat{x}_0 \in B_1(x_0)$, that

$$|e(x_2) - e(x_1)| \leq Ch\ln(\rho/h)\min_{\chi\in S^h}\|u-\chi\|_{W^1_\infty(B_1(\widehat{x}_0)),\overline{x},s} + C\rho\|e\|_{W_p^{-t}(B_1(\widehat{x}_0))}. \tag{4.1}$$

Then clearly (1.16) for $d = 1$ would follow by a covering argument (and inserting points between x_1 and x_2 if $p = |x_2 - x_1| > \widehat{d}$, i.e., when the weight is of no consequence).

For notational simplicity, we shall now let $\widehat{x}_0 = 0$ and write B_d for $B_d(0)$.

It would be convenient if $A(\cdot,\cdot)$ were coercive on B_1, i.e., if

$$c_{\mathrm{co}}\|u\|^2_{W^1_2(B_1)} \leq A(u,u) \qquad \text{for all} \quad u \in W^1_2(B_1).$$

This is not assumed. However, this difficulty may be overcome by modifying the form in the following manner. For $\mu > 0$ and $\widehat{d} > 0$, set

$$A_\mu(u,v) = A(u,v) + \mu\int_{B_1}\widehat{w}(x)u(x)v(x)dx,$$

where $\widehat{w} \in C^\infty$, $\widehat{w} \geq 0$, $\widehat{w} = 0$ for $|x| < 2\widehat{d}$, $\widehat{w} = 1$ for $|x| \geq 3\widehat{d}$. Let $Q = \sum_{i=1}^N \|b_i\|_{L_\infty(B_1)}| + \|c\|_{L_\infty(B_1)}$. From Lemma 2.1 of [7] we know that there do exist $\widehat{d}$ and μ depending only on Q and c_{ell}, such that

$$\frac{c_{\mathrm{ell}}}{4}\|u\|^2_{W^1_2(B_1)} \leq A_\mu(u,u) \text{ for } \quad u \in W^1_2(B_1). \tag{4.2}$$

Note that, by construction,

$$A_\mu(u,v) = A(u,v) \text{ for all } \quad v \in \overset{\circ}{W}{}^1_2(B_{2\widehat{d}}). \tag{4.3}$$

We now begin the proof of (1.16) by slightly modifying the proof of Theorem 1. Let $G^x(y)$ be the Green's function for the Neumann problem

$$\mathcal{L}^* G^x(y) = \delta^x(y) \text{ in } B_1, \ \frac{\partial G^x(y)}{\partial n_{\mathcal{L}^*}} = 0 \text{ on } \partial B_1,$$

where $\mathcal{L}^*$ is the adjoint of $\mathcal{L}_\lambda = \mathcal{L} + \mu \widehat{w} I$. Let $w(y) \in C_0^\infty$ be a cut-off function,

$$w(y) = \begin{cases} 1 & \text{for } |y| \leq \widehat{d}, \\ 0 & \text{for } |y| \geq 3\widehat{d}/2. \end{cases}$$

Then, for $x_1, x_2 \in B_{\widehat{d}}$,

$$e(x_2) - e(x_1) = A_\mu(we, G^{x_2} - G^{x_1}). \tag{4.4}$$

A straightforward but tedious calculation yields

$$A_\mu(we, G^{x_2} - G^{x_1}) = A_\mu(e, w(G^{x_2} - G^{x_1})) + R, \tag{4.5}$$

where, for any $1 \leq p \leq \infty$ and integer $t \geq 0$,

$$|R| \leq C\|e\|_{W_p^{-t}(B_1)} \left(\sum_{|\alpha|=1}^{2} \sum_{|\beta|=0}^{1} \|(D^\alpha w) D^\beta (G^{x_1} - G^{x_2})\|_{W_q^t(B_1 \setminus B_{\widehat{d}})} \right). \tag{4.6}$$

Here we have used the fact that $D^\alpha w$ vanishes on $B_{\widehat{d}}$ for $|\alpha| \geq 1$. Estimating $D_y^\beta(G^{x_2} - G^{x_1})$ as in (3.16), we arrive at

$$|R| \leq C\rho \|e\|_{W_p^{-t}(B_1)}. \tag{4.7}$$

According to (4.5), it remains to estimate $I = A_\mu(e, w(G^{x_2} - G^{x_1})) = A(e, w(G^{x_2} - G^{x_1}))$, by (4.3). Hence, for any $\psi \in \overset{\circ}{S}{}^h(B_{2\widehat{d}})$,

$$I = A(e, w(G^{x_2} - G^{x_1}) - \psi).$$

Analogously to (3.9), let $\psi_i = (wG^{x_i})_{\mathrm{Int}}$, $i = 1, 2$, be a suitable (locally averaged) interpolant of wG^{x_i}, and set $\psi = \psi_2 - \psi_1$. For h small enough, $\psi \in \overset{\circ}{S}{}^h(B_{2\widehat{d}})$ since w is supported in $B_{3\widehat{d}/2}$. Thus

$$|I| \leq C\|e\|_{W_\infty^1(B_{2\widehat{d}}), \overline{x}, s} \|w(G^{x_2} - G^{x_1}) - \psi\|_{W_1^1(B_{2\widehat{d}}), \overline{x}, -s}. \tag{4.8}$$

The last term on the right of (4.8) can be estimated by following the same procedure used in estimating the terms in (3.10) to obtain

$$\|w(G^{x_2} - G^{x_1}) - \psi\|_{W_1^1(B_{2\widehat{d}}), \overline{x}, -s} \leq Ch \ln\left(\frac{\rho}{h}\right) \quad \text{for } 0 \leq s < 1. \tag{4.9}$$

Combining (4.9) with (4.8) and using Lemma 2.2 with $d = 2\widehat{d}$,

$$|I| \leq Ch \ln(\rho/h) \Big(\min_{\chi \in S^h} \|u - \chi\|_{W_1^1(B_1), \overline{x}, s} + \|e\|_{W_p^{-1}(B_1)} \Big).$$

In view of (4.4), (4.5), and (4.7), this gives

$$|e(x_2) - e(x_1)| \le Ch \ln\left(\frac{\rho}{h}\right) \min_{\chi \in S^h} \|u - \chi\|_{W^1_\infty(B_1),\bar{x},s} \\ + C\rho\Big(\frac{h}{\rho}\ln\left(\frac{\rho}{h}\right) + 1\Big)\|e\|_{W_p^{-t}(B_1)}.$$

Since $\rho \ge kh$, where we may assume without loss of generality that $k \ge 2$, we have $|h/\rho \ln(\rho/h)| \le 1/e$. Hence this gives (4.1) and, as already noted, proves (1.16) for $d = 1$.

Step 2. We now turn to a proof of (1.16) in the case $d < 1$. As remarked before, this will be reduced to the case $d = 1$ by a standard scaling argument (see [7], [8]).

For simplicity we shall take x_0 to be the origin. Then the transformation $z = \frac{x}{d}$ maps $B_{2d}(x_0)$ to $B_2(x_0)$. Set $\widehat{u}(z) = u(dz)$, $\widehat{u}_h(z) = u_h(dz)$, and $\widehat{e}(z) = \widehat{u}(z) - \widehat{u}_h(z)$. By a change in variables we have

$$A(e, \chi) \equiv d^{N-2}\widehat{A}(\widehat{e}, \widehat{\chi}) = 0 \text{ for all } \chi \in \overset{\circ}{S}{}^h(B_{2d})$$

or

$$\widehat{A}(\widehat{e}, \widehat{\chi}) = 0 \text{ for all } \widehat{\chi} \in \overset{\circ}{S}{}^{h/d}(B_2), \tag{4.10}$$

where

$$\widehat{A}(\widehat{e}, \widehat{\chi}) = \int_{B_2} \left(\sum_{i,j=1}^N a_{ij}(dz) \frac{\partial \widehat{e}}{\partial z_i} \frac{\partial \widehat{\chi}}{\partial z_j} + \sum_{i=1}^N d b_i(dz) \frac{\partial \widehat{e}}{\partial z_i} \widehat{\chi} + d^2 c(dz) \widehat{e}\widehat{\chi} \right) dz.$$

Thus the mesh size for (4.10) for $\widehat{e}$ is h/d. Notice that the size of c_{ell} and the coefficients and derivatives of $\widehat{A}$ are no larger than those for A. Hence Theorem 2 in the case that $\rho \ge kh$ and $d = 1$ may be applied with appropriate bounds for c_{ell}, $\sum_{i=1}^N d\|b_i(dz)\|_{L_\infty(B_2)}$, and $d^2\|c(dz)\|_{L_\infty(B_2)}$ (and sufficiently many of their derivatives) that can be chosen independent of $d \le 1$. We obtain

$$|e(z_2) - e(z_1)| \le C\Big(\frac{h}{d} \ln \frac{\rho/d}{h/d}\Big)\Big[\min_{\chi \in S^{h/d}} \|\sigma^s_{\bar{x}}(\nabla_z(u - \chi))\|_{L_\infty(B_2)} \\ + \|\sigma^s_{\bar{x}}(u - \chi)\|_{L_\infty(B_2)})\Big] \\ + C\Big(\frac{\rho}{d}\Big)\|e\|_{W_p^{-t}(B_2)}, \tag{4.11}$$

where in (4.11)

$$\sigma^s_{\bar{x}} = \Big(\frac{\rho/d}{|z| + \rho/d}\Big).$$

The inequality (1.16) now follows from (4.11) by scaling B_2 back to the ball B_{2d}, via $z = \frac{x}{d}$, and taking into account how each norm transforms. This completes the outline of the proof.

Acknowledgment. The authors thank a referee for detailed comments which helped improve the presentation.

ERROR ANALYSIS OF A SEMIDISCRETE NUMERICAL SCHEME FOR DIFFUSION IN AXIALLY SYMMETRIC SURFACES[*]

KLAUS DECKELNICK[†], GERHARD DZIUK[‡], AND CHARLES M. ELLIOTT[§]

Abstract. We analyze a semidiscrete numerical scheme for approximating the evolution of axially symmetric surfaces by surface diffusion. The fourth order equation is split into two coupled second order problems, which are approximated by linear finite elements. We prove error bounds for the resulting scheme and present numerical test calculations that confirm our analysis.

Key words. surface diffusion, finite elements, error estimates, fourth order parabolic equation

1. Introduction.

In recent years motion by mean curvature has been extensively studied from the computational point of view. However, the related curvature flow of motion by the surface Laplacian has received far less attention in the numerical analysis literature. The geometrical problem is to find a time-dependent surface $\Gamma(t)$ evolving according to the law of motion

$$V = \Delta_{\Gamma(t)}\kappa \qquad \text{on } \Gamma(t), \tag{1.1}$$

where V and κ denote, respectively, the normal velocity and the mean curvature of the surface. Our sign convention is that κ with respect to the outer normal is positive for spheres. The Laplace–Beltrami or surface Laplacian operator for Γ is denoted by Δ_Γ. This evolution has interesting geometrical properties: if $\Gamma(t)$ is a closed surface bounding a domain $\Omega(t)$, then the volume of $\Omega(t)$ is preserved and the surface area of $\Gamma(t)$ decreases. It is known that for closed curves in the plane or closed surfaces in $\mathbb{R}^3$ balls are asymptotically stable subject to small perturbations; see [9], [10]. However, it is also known that topological changes such as pinch-off are possible [11], [13].

Equation (1.1) is referred to as a surface diffusion equation because it models the diffusion of mass within the bounding surface of a solid body. At the atomistic level atoms on the surface move along the surface due to a driving force consisting of a chemical potential difference. For a surface with constant surface energy density the appropriate chemical potential in this setting is the mean curvature κ. This leads to the flux law

$$\rho V = -\mathrm{div}_\Gamma \mathbf{j},$$

where ρ is the mass density and $\mathbf{j}$ is the mass flux in the surface, with the constitutive flux law [12], [14]

$$\mathbf{j} = -D\nabla_\Gamma \kappa.$$

Here, D is the diffusion constant. From these equations we obtain the law (1.1) after an appropriate nondimensionalization. The notion of surface diffusion is due to Mullins [14] and for a review we refer to [2].

In applications one is interested in the stability of so-called whiskers, which are axially symmetric cylindrical bodies of small diameter with respect to their length; see [15], [3], [1], and [16]. We shall be concerned with an axially symmetric cylindrical body, whose boundary

$$\Gamma(t) = \{\mathbf{x} \in \mathbb{R}^3 \,|\, \mathbf{x} = (x, r(x,t)\cos\phi, r(x,t)\sin\phi), x \in [0,L], \phi \in [0,2\pi]\}$$

evolves by surface diffusion. We assume that the radius r is a smooth positive function, which is periodic in x, so that $r(0,t) = r(L,t)$. In these coordinates the mean curvature of $\Gamma(t)$ is

$$\kappa = \frac{1}{r\sqrt{1+r_x^2}} - \frac{r_{xx}}{\sqrt{1+r_x^2}^3} = \frac{1}{r\sqrt{1+r_x^2}} - \left(\frac{r_x}{\sqrt{1+r_x^2}}\right)_x, \tag{1.2}$$

while the normal velocity and surface Laplacian of the mean curvature of the surface, respectively, are given by

$$V = \frac{r_t}{\sqrt{1+r_x^2}}, \qquad \Delta_\Gamma \kappa = \frac{1}{r\sqrt{1+r_x^2}}\left(\frac{r\kappa_x}{\sqrt{1+r_x^2}}\right)_x.$$

It follows from these two equations that r satisfies the quasi-linear fourth order parabolic problem

$$r_t = \frac{1}{r}\left(\frac{r\kappa_x}{\sqrt{1+r_x^2}}\right)_x \quad \text{in } I \times (0,T], \tag{1.3}$$

$$r(0,t) = r(L,t) \quad \text{in } (0,T], \tag{1.4}$$

$$\kappa(0,t) = \kappa(L,t) \quad \text{in } (0,T], \tag{1.5}$$

$$r(\cdot,0) = r_0 \quad \text{in } I, \tag{1.6}$$

where $I = (0,L)$ and κ is given by (1.2). The initial function r_0 is assumed to be periodic and positive.

Our concern in this paper is the analysis of a finite element discretization based on the above natural splitting of the fourth order problem into two coupled second order equations for the radial variable r and the mean curvature κ. We note that [4] proposed a similar second order splitting scheme and used $R = r^2$ and κ as the variables. Our principal result is an error estimate for the spatial discretization, which is actually attained in numerical experiments.

The paper is organized as follows: in section 2 we introduce the numerical scheme, prove the local existence and uniqueness of the discrete solution, and formulate our main error estimate. This result is proved in section 3, while section 4 contains numerical tests.

2. The discrete problem.

As already mentioned in the introduction, our discretization of (1.3) is based on the idea of splitting the elliptic part, which is of fourth order, into two second order operators. This is similar in spirit to the second order splitting techniques proposed for the numerical approximation of the Cahn–Hilliard equation in [8]. To begin, we deduce from (1.2)

$$r\kappa = \frac{1}{\sqrt{1+r_x^2}} - r\left(\frac{r_x}{\sqrt{1+r_x^2}}\right)_x = \sqrt{1+r_x^2} - \left(\frac{rr_x}{\sqrt{1+r_x^2}}\right)_x . \tag{2.1}$$

Thus (1.3) and (2.1) allow the variational formulation

$$\int_I rr_t\eta dx = -\int_I \frac{r\kappa_x\eta_x}{\sqrt{1+r_x^2}}dx \qquad \forall\eta \in H^1_{per}(I), \tag{2.2}$$

$$\int_I r\kappa\zeta dx = \int_I \sqrt{1+r_x^2}\,\zeta dx + \int_I \frac{rr_x\zeta_x}{\sqrt{1+r_x^2}}dx \qquad \forall\zeta \in H^1_{per}(I), \tag{2.3}$$

where $H^1_{per}(I) = \{\eta \in H^1(I)\,|\,\eta(0) = \eta(L)\}$. We employ (2.2), (2.3) in order to define a semidiscrete scheme using linear finite elements to approximate r and κ. Let $0 = x_0 < x_1 < \cdots < x_N = L$, $h_j := x_j - x_{j-1}$, and $h := \max_{1\le j\le N} h_j$. We shall make an inverse assumption of the form

$$h \le \rho h_j \qquad \forall j = 1, \dots, N, \tag{2.4}$$

where $\rho > 0$ is independent of h. The space of linear finite elements is defined by

$$X_h := \{\phi_h \in C^0(\bar{I})\,|\,\phi_{h|[x_{j-1},x_j]} \in P^1, 1 \le j \le N, \phi_h(0) = \phi_h(L)\}.$$

Our discrete problem now reads as follows: find $r_h, \kappa_h : [0, T] \to X_h$ such that

$$\int_I r_h r_{h,t}\eta_h dx = -\int_I \frac{r_h\kappa_{h,x}\eta_{h,x}}{\sqrt{1+r_{h,x}^2}}dx \qquad \forall\eta_h \in X_h, t \in (0, T], \tag{2.5}$$

$$\int_I r_h\kappa_h\zeta_h dx = \int_I \sqrt{1+r_{h,x}^2}\,\zeta_h dx + \int_I \frac{r_h r_{h,x}\zeta_{h,x}}{\sqrt{1+r_{h,x}^2}}dx \qquad \forall\zeta_h \in X_h, t \in [0, T], \tag{2.6}$$

$$r_h(0) = I_h r_0, \tag{2.7}$$

where I_h denotes the Lagrange interpolation operator.

LEMMA 2.1. *There exists $T_h > 0$ such that* (2.5)–(2.7) *has a unique solution $(r_h, \kappa_h) \in C^1([0, T_h]; X_h \times X_h)$ satisfying $\frac{1}{2}\min_{[0,L]} r_0 \le r_h \le 2\max_{[0,L]} r_0$ in $[0, L] \times [0, T_h]$.*

Proof. Choose a smooth globally Lipschitz-continuous function $\beta : \mathbb{R} \to \mathbb{R}$ with the properties $\beta(s) = s$ for $\frac{1}{2}\min_{[0,L]} r_0 \le s \le 2\max_{[0,L]} r_0$, $\frac{1}{4}\min_{[0,L]} r_0 \le \beta(s) \le 4\max_{[0,L]} r_0$ for all $s \in \mathbb{R}$. We first consider the following modified problem: find $r_h, \kappa_h : [0, T] \to X_h$ such that

$$\int_I \beta(r_h) r_{h,t}\eta_h dx = -\int_I \frac{r_h\kappa_{h,x}\eta_{h,x}}{\sqrt{1+r_{h,x}^2}}dx \qquad \forall\eta_h \in X_h, t \in [0, T], \tag{2.8}$$

$$\int_I \beta(r_h)\kappa_h\zeta_h dx = \int_I \sqrt{1+r_{h,x}^2}\,\zeta_h dx + \int_I \frac{r_h r_{h,x}\zeta_{h,x}}{\sqrt{1+r_{h,x}^2}}dx \qquad \forall\zeta_h \in X_h, t \in [0, T], \tag{2.9}$$

$$r_h(0) = I_h r_0. \tag{2.10}$$

Denoting by $\psi_1, \dots, \psi_N$ the usual nodal basis of X_h, we can represent (r_h, κ_h) as

$$r_h(\cdot, t) = \sum_{j=1}^N r_j(t)\psi_j, \qquad \kappa_h(\cdot, t) = \sum_{j=1}^N \kappa_j(t)\psi_j \tag{2.11}$$

and write $\underline{r}(t) = (r_1(t), \ldots, r_N(t))^T$, $\underline{\kappa}(t) = (\kappa_1(t), \ldots, \kappa_N(t))^T$. In view of the properties of β we may rewrite (2.9) in the form $\underline{\kappa}(t) = G(\underline{r}(t))$ with a Lipschitz-continuous mapping $G : \mathbb{R}^N \to \mathbb{R}^N$. Inserting this into (2.8) and using again the properties of β, we may write this relation as

$$\underline{r}'(t) = F(\underline{r}(t)), \quad \underline{r}(0) = (r_0(x_1), \ldots, r_0(x_N))^T,$$

with a Lipschitz-continuous $F : \mathbb{R}^N \to \mathbb{R}^N$. The existence and uniqueness of $\underline{r}$ on some interval $[0, T_h]$ follows directly from the theory of ODEs. The corresponding functions r_h and κ_h given by (2.11) will then solve (2.8)–(2.10). Since $r_h(0) = I_h r_0$ and by making T_h smaller if necessary, we may assume that $\frac{1}{2}\min_{[0,L]} r_0 \leq r_h \leq 2\max_{[0,L]} r_0$ in $[0, L] \times [0, T_h]$ so that, in view of the properties of β, (r_h, κ_h) also solves (2.5)–(2.7). □

Using $\eta_h = \kappa_h$ in (2.5) and $\zeta_h = r_{h,t}$ in (2.6) and taking the difference of the resulting equations, we obtain

$$\begin{aligned} 0 &= \int_I \sqrt{1 + r_{h,x}^2}\, r_{h,t} dx + \int_I \frac{r_h r_{h,x} r_{h,tx}}{\sqrt{1 + r_{h,x}^2}} dx + \int_I \frac{r_h \kappa_{h,x}^2}{\sqrt{1 + r_{h,x}^2}} dx \\ &= \frac{d}{dt} \int_I r_h \sqrt{1 + r_{h,x}^2} dx + \int_I \frac{r_h \kappa_{h,x}^2}{\sqrt{1 + r_{h,x}^2}} dx. \end{aligned}$$

Thus

$$\sup_{0 \leq t \leq T_h} \int_I r_h \sqrt{1 + r_{h,x}^2} dx + \int_0^{T_h} \int_I \frac{r_h \kappa_{h,x}^2}{\sqrt{1 + r_{h,x}^2}} dx dt \leq C(r_0). \tag{2.12}$$

Before we formulate an error estimate for the scheme (2.5)–(2.7), we state a local existence and uniqueness result for the continuous problem.

THEOREM 2.2. *Suppose that $r_0 \in H^4_{per}(I)$ is strictly positive. Then there exists $T_0 > 0$ such that (1.3)–(1.6) has a unique solution (r, κ), which satisfies $r \in L^\infty\big(0, T_0; H^4_{per}(I)\big)$, $r_t \in L^2\big(0, T_0; H^2_{per}(I)\big)$, and $r(x, t) > 0$ for all $(x, t) \in I \times [0, T_0]$.*

Proof. A similar result was proved in [11] for a formulation of (1.1) in terms of the distance function to a fixed reference curve. Since the resulting equation has the same structure as (1.3)–(1.6), the methods employed in [11] can be applied to our situation. □

We denote by $[0, T_{\max})$, $T_{\max} \in (0, \infty]$ the maximal time interval on which the solution from Theorem 2.2 exists and fix $T < T_{\max}$. Then there exist constants $0 < c_0 \leq C_0$ and $M \geq 0$ (depending on T) such that

$$c_0 \leq r \leq C_0, \quad |r_x| \leq C_0 \quad \text{on } [0, L] \times [0, T], \tag{2.13}$$

$$\sup_{t \in (0,T)} \|r(., t)\|^2_{H^4(I)} + \int_0^T \|r_t\|^2_{H^2(I)} dt \leq M^2. \tag{2.14}$$

Combining these bounds with (1.2), (1.3), and the inequality $\|f\|_{L^\infty(I)} \leq C\|f\|_{H^1(I)}$, we note for later use

$$\|\kappa(.,t)\|_{H^{1,\infty}(I)}+\|\kappa(.,t)\|_{H^2(I)}+\|r_t(.,t)\|_{L^2(I)} \le C \qquad \text{uniformly in } t \in [0,T], \tag{2.15}$$

where C depends on L, c_0, C_0, and M.

Our main result is the following error estimate, the proof of which will be given in the next section.

THEOREM 2.3. *There exists an $h_0 > 0$ such that for all $0 < h \le h_0$ the discrete solution (r_h, κ_h) exists on $[0,T]$ and*

$$\sup_{0\le t\le T} \|(r-r_h)(t)\|^2_{H^1(I)} + \int_0^T \|\kappa-\kappa_h\|^2_{H^1(I)} dt \le Ch^2. \tag{2.16}$$

The constant C depends on L, T, c_0, C_0, M, and ρ.

3. Proof of Theorem 2.3.

Let us define

$$\hat{T}_h := \sup\Big\{ t \in [0,T] \,|\, (r_h,\kappa_h) \text{ solves (2.5)–(2.7) on } [0,t] \text{ and } \frac{1}{2}c_0 \le r_h \le 2C_0,\ |r_{h,x}| \le 2C_0 \text{ on } [0,t]\Big\}.$$

By choosing T_h smaller if necessary (in order to satisfy the bound on $r_{h,x}$), we may deduce from Lemma 2.1 that $\hat{T}_h > 0$. Our aim is to show that $\hat{T}_h = T$ for small h. This will be achieved by proving the bounds (2.16) on $[0,\hat{T}_h]$, which will enable us to continue the discrete solution. By the definition of $\hat{T}_h$ we have

$$\frac{1}{2}c_0 \le r_h \le 2C_0, \quad |r_{h,x}| \le 2C_0 \text{ on } [0,L]\times[0,\hat{T}_h). \tag{3.1}$$

In what follows, we shall denote by C a constant which may depend on L, T, c_0, C_0, M, and ρ. Additional dependencies of C will be stated explicitly. We start with a useful auxiliary lemma.

LEMMA 3.1. *Let $v \in H^1_{per}(I), t \in [0,\hat{T}_h)$. Then we have for $\epsilon > 0$*

$$\Big|\int_I \frac{r_h}{r} v\, r\, r_t dx - \int_I v\, r_h r_{h,t} dx\Big| \le \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon\|v\|^2_{H^1(I)} + Ch^2 + C\|r-r_h\|^2_{H^1(I)}.$$

Proof. Fix $t \in [0,\hat{T}_h)$ and denote by $Q_h : L^2(I) \to X_h$ the following weighted projection: for a given $u \in L^2(I)$ let $Q_h u \in X_h$ be defined by

$$\int_I r_h u\, \zeta_h dx = \int_I r_h Q_h u\, \zeta_h dx \qquad \forall \zeta_h \in X_h. \tag{3.2}$$

We claim that

$$\|u - Q_h u\|_{L^2(I)} + h\|u_x - (Q_h u)_x\|_{L^2(I)} \le Ch\|u_x\|_{L^2(I)} \qquad \forall u \in H^1_{per}(I). \tag{3.3}$$

To see this, we first note that (3.1), (3.2), and an interpolation inequality imply

$$\frac{c_0}{2}\int_I |u-Q_h u|^2 \le \int_I r_h(u-Q_h u)(u-Q_h u) = \int_I r_h(u-Q_h u)(u-I_h u) \le 2C_0\|u-Q_h u\|_{L^2(I)}\, h\|u_x\|_{L^2(I)},$$

which yields the first part of (3.3). In view of (2.4) we have that $\|v_{h,x}\|_{L^2(I)} \leq Ch^{-1}\|v_h\|_{L^2(I)}$ for $v_h \in X_h$, and therefore

$$\begin{aligned}\|u_x - (Q_h u)_x\|_{L^2(I)} &\leq \|u_x - (I_h u)_x\|_{L^2(I)} + \|(I_h u)_x - (Q_h u)_x\|_{L^2(I)} \\ &\leq 2\|u_x\|_{L^2(I)} + Ch^{-1}\|I_h u - Q_h u\|_{L^2(I)} \\ &\leq 2\|u_x\|_{L^2(I)} + Ch^{-1}\big(\|u - I_h u\|_{L^2(I)} + \|u - Q_h u\|_{L^2(I)}\big) \\ &\leq C\|u_x\|_{L^2(I)},\end{aligned}$$

where we used the bound on $\|u - Q_u\|_{L^2(I)}$. This proves (3.3).

Next we infer from (3.2) and (2.5) that

$$\int_I v\, r_h r_{h,t} dx = \int_I Q_h v\, r_h r_{h,t} dx = -\int_I \frac{r_h \kappa_{h,x} (Q_h v)_x}{\sqrt{1 + r_{h,x}^2}} dx \qquad \forall v \in H^1_{per}(I).$$

If we combine this relation with (2.2), we may continue with

$$\begin{aligned}&\int_I \frac{r_h}{r} v\, r\, r_t dx - \int_I v\, r_h r_{h,t} dx \\ &= -\int_I \frac{r\kappa_x (\frac{r_h}{r} v)_x}{\sqrt{1 + r_x^2}} dx + \int_I \frac{r_h \kappa_{h,x} (Q_h v)_x}{\sqrt{1 + r_{h,x}^2}} dx \\ &= -\int_I \frac{r\kappa_x v}{\sqrt{1 + r_x^2}} \frac{r_{h,x} r - r_x r_h}{r^2} dx + \int_I \frac{r - r_h}{\sqrt{1 + r_x^2}} \kappa_x v_x \, dx \\ &\quad + \int_I \left(\frac{r_h}{\sqrt{1 + r_{h,x}^2}} - \frac{r}{\sqrt{1 + r_x^2}} \right) \kappa_{h,x} (Q_h v)_x dx \\ &\quad + \int_I \frac{r}{\sqrt{1 + r_x^2}} (\kappa_{h,x} - \kappa_x)(Q_h v)_x dx + \int_I \frac{r\, \kappa_x}{\sqrt{1 + r_x^2}} (Q_h v - v)_x \, dx \\ &\equiv \sum_{i=1}^5 S_i.\end{aligned}$$

In view of (2.13), (2.15), and (3.1), we then have

$$\begin{aligned}|S_1| &\leq C \int_I |v| \big(|r - r_h| + |r_x - r_{h,x}| \big) dx \leq \|v\|^2_{L^2(I)} + C\|r - r_h\|^2_{H^1(I)}, \\ |S_2| &\leq \|v_x\|^2_{L^2(I)} + C\|r - r_h\|^2_{L^2(I)}.\end{aligned}$$

Next, (2.15) and (3.3) imply

$$\begin{aligned}|S_3| &\leq \int_I \left| \frac{r_h}{\sqrt{1 + r_{h,x}^2}} - \frac{r}{\sqrt{1 + r_x^2}} \right| \big(|\kappa_x| + |\kappa_{h,x} - \kappa_x| \big) |(Q_h v)_x| \, dx \\ &\leq C \int_I \big(|r - r_h| + |r_x - r_{h,x}| \big) |(Q_h v)_x| \, dx + C \int_I |\kappa_x - \kappa_{h,x}| \, |(Q_h v)_x| \, dx \\ &\leq \epsilon \|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon \|v_x\|^2_{L^2(I)} + C\|r - r_h\|^2_{H^1(I)},\end{aligned}$$

and similarly,

$$|S_4| \leq \epsilon \|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon \|v_x\|^2_{L^2(I)}.$$

Finally, integration by parts, (1.3), (2.15), and (3.3) yield

$$\begin{aligned}|S_5| &= \left| -\int_I \left(\frac{r\,\kappa_x}{\sqrt{1+r_x^2}} \right)_x (Q_h v - v)\,dx \right| \\ &\leq Ch\|v_x\|_{L^2(I)}\|r_t\|_{L^2(I)} \leq Ch^2 + C\|v_x\|^2_{L^2(I)}.\end{aligned}$$

Collecting the above estimates concludes the proof of the lemma. □

As a first application of the above result we derive a differential inequality for the L^2-error.

LEMMA 3.2.

$$\frac{1}{2}\frac{d}{dt}\|r - r_h\|^2_{L^2(I)} \leq \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon\|r - r_h\|^2_{H^1(I)} + Ch^2.$$

Proof. Clearly,

$$\begin{aligned}\frac{1}{2}\frac{d}{dt}\|r - r_h\|^2_{L^2(I)} &= \int_I (r - r_h)(r_t - r_{h,t})dx \\ &= \int_I \frac{1}{r}(r - r_h) r r_t dx - \int_I \frac{1}{r_h}(r - r_h) r_h r_{h,t} dx.\end{aligned} \tag{3.4}$$

If we apply Lemma 3.1 to the function

$$v := \frac{1}{r_h}(r - r_h)(\cdot, t) \qquad \text{for } t \in (0, \hat{T}_h),$$

the result follows. □

The main part of the proof of Theorem 2.3 consists in controlling the H^1-seminorms of $r - r_h$ and $\kappa - \kappa_h$. The idea is to mimic the argument which led to the a priori estimate (2.12) in such a way that it can be applied to the difference between exact and discrete solution. This suggests using $\eta_h = I_h\kappa - \kappa_h$, $\zeta_h = I_h r_t - r_{h,t}$ in the error relations satisfied by $r - r_h$, $\kappa - \kappa_h$. In order to derive these relations we use $\eta = \eta_h \in X_h$ in (2.2) and $\zeta = \zeta_h \in X_h$ in (2.3) and take the difference with (2.5), (2.6), respectively. This leads to

$$\int_I \big(r\,r_t - r_h r_{h,t}\big)\eta_h dx = -\int_I \left(\frac{r\kappa_x}{\sqrt{1+r_x^2}} - \frac{r_h\kappa_{h,x}}{\sqrt{1+r_{h,x}^2}} \right)\eta_{h,x} dx \quad \forall \eta_h \in X_h, \tag{3.5}$$

$$\begin{aligned}\int_I (r\,\kappa - r_h\kappa_h)\zeta_h dx &= \int_I \big(\sqrt{1+r_x^2} - \sqrt{1+r_{h,x}^2}\big)\zeta_h dx \\ &\quad + \int_I \left(\frac{r r_x}{\sqrt{1+r_x^2}} - \frac{r_h r_{h,x}}{\sqrt{1+r_{h,x}^2}} \right)\zeta_{h,x} dx \quad \forall \zeta_h \in X_h.\end{aligned} \tag{3.6}$$

LEMMA 3.3. *We have for all $\epsilon > 0$*

$$\begin{aligned}&\frac{d}{dt}\int_I r_h \left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x} r_x + 1}{\sqrt{1+r_x^2}} \right) dx + \int_I \frac{r_h}{\sqrt{1+r_{h,x}^2}}(\kappa_x - \kappa_{h,x})^2 dx \\ &\leq C\epsilon\|\kappa - \kappa_h\|^2_{H^1(I)} + C_\epsilon(1 + \|r_t\|_{H^2(I)})\|r - r_h\|^2_{H^1(I)} + C_\epsilon h^2(1 + \|r_t\|^2_{H^2(I)}).\end{aligned} \tag{3.7}$$

Proof. Using $\zeta_h = I_h r_t - r_{h,t}$ in (3.6), we obtain

$$\begin{aligned}\int_I (r\kappa - r_h\kappa_h)(I_h r_t - r_{h,t})dx &= \int_I \big(\sqrt{1+r_x^2} - \sqrt{1+r_{h,x}^2}\big)(I_h r_t - r_{h,t})dx \\ &\quad + \int_I r_h \left(\frac{r_x}{\sqrt{1+r_x^2}} - \frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)(r_{tx} - r_{h,tx})dx \\ &\quad + \int_I (r - r_h)\frac{r_x}{\sqrt{1+r_x^2}}(r_{tx} - r_{h,tx})dx \\ &\quad + \int_I \left(\frac{r r_x}{\sqrt{1+r_x^2}} - \frac{r_h r_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)\big((I_h r_t)_x - r_{tx}\big)dx.\end{aligned}\tag{3.8}$$

Note first that the second integral can be written as

$$\begin{aligned}&\int_I r_h \left(\frac{r_x}{\sqrt{1+r_x^2}} - \frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)(r_{tx} - r_{h,tx})dx \\ &= \int_I r_h \frac{\partial}{\partial t}\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}\right)dx \\ &\quad + \int_I r_h r_{t,x}\left(\frac{r_{h,x}}{\sqrt{1+r_x^2}} - \frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}} + \frac{r_x}{\sqrt{1+r_x^2}} - \frac{1 + r_x r_{h,x}}{1+r_x^2}\frac{r_x}{\sqrt{1+r_x^2}}\right)dx \\ &= \frac{d}{dt}\int_I r_h\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}\right)dx - \int_I r_{h,t}\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}\right)dx \\ &\quad + \int_I r_h r_{t,x}\left(\frac{r_{h,x}}{\sqrt{1+r_x^2}} - \frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}} + \frac{r_x}{\sqrt{1+r_x^2}} - \frac{1 + r_x r_{h,x}}{1+r_x^2}\frac{r_x}{\sqrt{1+r_x^2}}\right)dx.\end{aligned}$$

Integration by parts together with (1.2) implies for the third term in (3.8)

$$\begin{aligned}&\int_I (r - r_h)\frac{r_x}{\sqrt{1+r_x^2}}(r_{tx} - r_{h,tx})dx \\ &= -\int_I (r_x - r_{h,x})\frac{r_x}{\sqrt{1+r_x^2}}(r_t - r_{h,t})dx - \int_I (r - r_h)\left(\frac{r_x}{\sqrt{1+r_x^2}}\right)_x (r_t - r_{h,t})dx \\ &= -\int_I r_t(r_x - r_{h,x})\frac{r_x}{\sqrt{1+r_x^2}}dx + \int_I r_{h,t}\sqrt{1+r_x^2}\,dx - \int_I r_{h,t}\frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}dx \\ &\quad - \int_I (r - r_h)\frac{1}{r\sqrt{1+r_x^2}}(r_t - r_{h,t})dx + \int_I (r - r_h)\kappa(r_t - r_{h,t})dx.\end{aligned}$$

Inserting the above equations into (3.8), we derive

$$\begin{aligned}\int_I (r\kappa - r_h\kappa_h)(I_h r_t - r_{h,t})dx &= \frac{d}{dt}\int_I r_h\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}\right)dx \\ &\quad + \int_I \big(\sqrt{1+r_x^2} - \sqrt{1+r_{h,x}^2}\big)I_h r_t dx - \int_I r_t(r_x - r_{h,x})\frac{r_x}{\sqrt{1+r_x^2}}\,dx\end{aligned}\tag{3.9}$$

$$+\int_I r_h r_{tx}\left(\frac{r_{h,x}}{\sqrt{1+r_x^2}}-\frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}}+\frac{r_x}{\sqrt{1+r_x^2}}-\frac{1+r_x r_{h,x}}{1+r_x^2}\frac{r_x}{\sqrt{1+r_x^2}}\right)dx$$
$$-\int_I (r-r_h)\frac{1}{r\sqrt{1+r_x^2}}(r_t-r_{h,t})dx+\int_I (r-r_h)\kappa(r_t-r_{h,t})dx$$
$$+\int_I\left(\frac{rr_x}{\sqrt{1+r_x^2}}-\frac{r_h r_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)\big((I_h r_t)_x-r_{tx}\big)dx.$$

Let us next insert $\eta_h = I_h\kappa - \kappa_h$ into (3.5):

$$\begin{aligned}(3.10)\qquad &\int_I (rr_t - r_h r_{h,t})(I_h\kappa-\kappa_h)dx\\ &=-\int_I\left(\frac{r\kappa_x}{\sqrt{1+r_x^2}}-\frac{r_h\kappa_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)\big((I_h\kappa)_x-\kappa_{h,x}\big)dx\\ &=\int_I\left(\frac{r\kappa_x}{\sqrt{1+r_x^2}}-\frac{r_h\kappa_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)\big(\kappa_x-(I_h\kappa)_x\big)dx\\ &\quad-\int_I\frac{r_h}{\sqrt{1+r_{h,x}^2}}(\kappa_x-\kappa_{h,x})^2dx\\ &\quad-\int_I\left(\frac{r}{\sqrt{1+r_x^2}}-\frac{r_h}{\sqrt{1+r_{h,x}^2}}\right)\kappa_x(\kappa_x-\kappa_{h,x})dx.\end{aligned}$$

Combining (3.9) and (3.10), we obtain

$$(3.11)\quad \frac{d}{dt}\int_I r_h\left(\sqrt{1+r_{h,x}^2}-\frac{r_{h,x}r_x+1}{\sqrt{1+r_x^2}}\right)dx+\int_I\frac{r_h}{\sqrt{1+r_{h,x}^2}}(\kappa_x-\kappa_{h,x})^2dx=\sum_{i=1}^{8}\tilde{S}_i,$$

where

$$\tilde{S}_1=\int_I(r\kappa-r_h\kappa_h)(I_h r_t-r_{h,t})dx-\int_I(rr_t-r_h r_{h,t})(I_h\kappa-\kappa_h)dx$$
$$-\int_I(r-r_h)\kappa(r_t-r_{h,t})dx,$$
$$\tilde{S}_2=-\int_I r_t\left(\sqrt{1+r_x^2}-\sqrt{1+r_{h,x}^2}-(r_x-r_{h,x})\frac{r_x}{\sqrt{1+r_x^2}}\right)dx,$$
$$\tilde{S}_3=-\int_I r_h r_{tx}\left(\frac{r_{h,x}}{\sqrt{1+r_x^2}}-\frac{r_{h,x}}{\sqrt{1+r_{h,x}^2}}+\frac{r_x}{\sqrt{1+r_x^2}}-\frac{1+r_x r_{h,x}}{1+r_x^2}\frac{r_x}{\sqrt{1+r_x^2}}\right)dx,$$
$$\tilde{S}_4=\int_I(r-r_h)\frac{1}{r\sqrt{1+r_x^2}}(r_t-r_{h,t})dx,$$
$$\tilde{S}_5=\int_I\big(\sqrt{1+r_x^2}-\sqrt{1+r_{h,x}^2}\big)(r_t-I_h r_t)dx,$$

$$\tilde{S}_6 = -\int_I \left(\frac{r r_x}{\sqrt{1+r_x^2}} - \frac{r_h r_{h,x}}{\sqrt{1+r_{h,x}^2}} \right) \big((I_h r_t)_x - r_{tx} \big) dx,$$

$$\tilde{S}_7 = \int_I \left(\frac{r \kappa_x}{\sqrt{1+r_x^2}} - \frac{r_h \kappa_{h,x}}{\sqrt{1+r_{h,x}^2}} \right) \big(\kappa_x - (I_h \kappa)_x \big) dx,$$

$$\tilde{S}_8 = -\int_I \left(\frac{r}{\sqrt{1+r_x^2}} - \frac{r_h}{\sqrt{1+r_{h,x}^2}} \right) \kappa_x (\kappa_x - \kappa_{h,x}) dx.$$

The terms $\tilde{S}_1, \ldots, \tilde{S}_8$ have been organized in such a way that each of them is quadratic in an appropriate difference. To see this, let us examine them in more detail. First,

$$\begin{aligned}\tilde{S}_1 =& \int_I (r\kappa - r_h \kappa_h)(r_t - r_{h,t}) dx - \int_I (r r_t - r_h r_{h,t})(\kappa - \kappa_h) dx - \int_I (r - r_h) \kappa (r_t - r_{h,t}) dx \\ &+ \int_I (r\kappa - r_h\kappa_h)(I_h r_t - r_t) dx - \int_I (r r_t - r_h r_{h,t})(I_h \kappa - \kappa) dx \\ =& -\int_I r_t (\kappa - \kappa_h)(r - r_h) dx + \int_I (r\kappa - r_h \kappa_h)(I_h r_t - r_t) dx - \int_I (r r_t - r_h r_{h,t})(I_h\kappa - \kappa) dx \\ \equiv& A_1 + A_2 + A_3.\end{aligned}$$

Using an interpolation estimate, (2.15), and the continuous embedding $H^1(I) \hookrightarrow L^\infty(I)$, we obtain

$$\begin{aligned}|A_1 + A_2| &\le C\|r_t\|_{L^2(I)} \|\kappa - \kappa_h\|_{L^2(I)} \|r - r_h\|_{L^\infty(I)} + Ch\|r_{tx}\|_{L^2(I)} \|r\kappa - r_h\kappa_h\|_{L^2(I)} \\ &\le \epsilon \|\kappa - \kappa_h\|^2_{L^2(I)} + C_\epsilon \|r - r_h\|^2_{H^1(I)} + C_\epsilon h^2 \|r_{tx}\|^2_{L^2(I)},\end{aligned}$$

while

$$A_3 = \int_I (I_h\kappa - \kappa) r_h r_{h,t} dx - \int_I \frac{r_h}{r} (I_h \kappa - \kappa) r r_t dx + \int_I (I_h \kappa - \kappa) \Big(\frac{r_h}{r} - 1 \Big) r r_t dx.$$

We infer from Lemma 3.1 with $v = \kappa - I_h\kappa$ and well-known interpolation estimates that

$$\begin{aligned}|A_3| \le& \epsilon \|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon \|\kappa - I_h \kappa\|^2_{H^1(I)} + Ch^2 + C\|r - r_h\|^2_{H^1(I)} \\ &+ C\|r_t\|_{L^2(I)} \|r - r_h\|_{L^\infty(I)} \|\kappa - I_h \kappa\|_{L^2(I)} \\ \le& \epsilon \|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon h^2 \|\kappa\|^2_{H^2(I)} + C\|r - r_h\|^2_{H^1(I)}.\end{aligned}$$

Recalling (2.15), we conclude

$$|\tilde{S}_1| \le \epsilon \|\kappa - \kappa_h\|^2_{H^1(I)} + C_\epsilon \|r - r_h\|^2_{H^1(I)} + C_\epsilon (1 + \|r_{tx}\|^2_{L^2(I)}) h^2.$$

Next, observing that

$$\left| \sqrt{1+q^2} - \sqrt{1+p^2} - (q-p) \frac{q}{\sqrt{1+q^2}} \right| \le C(q-p)^2 \qquad \forall q, p \in \mathbb{R}, \tag{3.12}$$

we obtain

$$|\tilde{S}_2| \le C\|r_t\|_{L^\infty(I)} \|r_x - r_{h,x}\|^2_{L^2(I)} \le C\|r_t\|_{H^1(I)} \|r_x - r_{h,x}\|^2_{L^2(I)}.$$

Let us now examine $\tilde{S}_3$. A short calculation shows

$$\begin{aligned}
&\frac{p}{\sqrt{1+q^2}} - \frac{p}{\sqrt{1+p^2}} + \frac{q}{\sqrt{1+q^2}} - \frac{1+pq}{1+q^2}\frac{q}{\sqrt{1+q^2}} \\
&= \frac{p(1+q^2)\big(\sqrt{1+p^2}-\sqrt{1+q^2}\big) - q^2\sqrt{1+p^2}(p-q)}{\sqrt{1+q^2}^3\sqrt{1+p^2}} \\
&= \frac{p}{\sqrt{1+q^2}\sqrt{1+p^2}}\left(\sqrt{1+p^2}-\sqrt{1+q^2}-(p-q)\frac{p}{\sqrt{1+p^2}}\right) \\
&\qquad + \frac{p-q}{\sqrt{1+q^2}^3(1+p^2)}\big(p^2(1+q^2)-q^2(1+p^2)\big),
\end{aligned}$$

which implies in view of (3.12)

$$\left|\frac{p}{\sqrt{1+q^2}} - \frac{p}{\sqrt{1+p^2}} + \frac{q}{\sqrt{1+q^2}} - \frac{1+pq}{1+q^2}\frac{q}{\sqrt{1+q^2}}\right| \quad \leq \quad C(p-q)^2$$

for all $p, q \in \mathbb{R}$. Therefore,

$$|\tilde{S}_3| \leq C\|r_{tx}\|_{L^\infty(I)}\|r_x - r_{h,x}\|^2_{L^2(I)} \leq C\|r_{tx}\|_{H^1(I)}\|r_x - r_{h,x}\|^2_{L^2(I)}.$$

If we write

$$\tilde{S}_4 = \int_I (r-r_h)\frac{1}{r\sqrt{1+r_x^2}}(r_t - r_{h,t})dx = \int_I \frac{r_h}{r} v r r_t dx - \int_I v r_h r_{h,t} dx$$

with $v = \frac{r-r_h}{r_h r\sqrt{1+r_x^2}}$ and apply Lemma 3.1, we deduce

$$\begin{aligned}
|\tilde{S}_4| &\leq \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon\left\|\frac{r-r_h}{r_h r\sqrt{1+r_x^2}}\right\|^2_{H^1(I)} + Ch^2 + C\|r-r_h\|^2_{H^1(I)} \\
&\leq \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon\|r-r_h\|^2_{H^1(I)} + Ch^2.
\end{aligned}$$

In view of interpolation estimates, Young's inequality, and (2.15),

$$\begin{aligned}
|\tilde{S}_5| &\leq Ch\|r_{tx}\|_{L^2(I)}\|r_x - r_{h,x}\|_{L^2(I)} \leq Ch^2\|r_{tx}\|^2_{L^2(I)} + C\|r_x - r_{h,x}\|^2_{L^2(I)}, \\
|\tilde{S}_6| &\leq Ch\|r_{txx}\|_{L^2(I)}\|r - r_h\|_{H^1(I)} \leq Ch^2\|r_{txx}\|^2_{L^2(I)} + C\|r - r_h\|^2_{H^1(I)}, \\
|\tilde{S}_7| &\leq Ch\|\kappa_{xx}\|_{L^2(I)}\big(\|\kappa_x - \kappa_{h,x}\|_{L^2(I)} + \|r - r_h\|_{H^1(I)}\big) \\
&\leq \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon h^2 + C\|r - r_h\|^2_{H^1(I)}.
\end{aligned}$$

Finally,

$$|\tilde{S}_8| \leq \epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon\|r - r_h\|^2_{H^1(I)}.$$

If we insert the above estimates for $\tilde{S}_1, \ldots, \tilde{S}_8$ into (3.11), the result is

$$\begin{aligned}
&\frac{d}{dt}\int_I r_h\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x + 1}{\sqrt{1+r_x^2}}\right)dx + \int_I \frac{r_h}{\sqrt{1+r_{h,x}^2}}(\kappa_x - \kappa_{h,x})^2 dx \\
&\qquad \leq C\epsilon\|\kappa - \kappa_h\|^2_{H^1(I)} + C_\epsilon(1 + \|r_t\|_{H^2(I)})\|r - r_h\|^2_{H^1(I)} + C_\epsilon(1 + \|r_t\|^2_{H^2(I)})h^2,
\end{aligned}$$

which completes the proof of the lemma. □

Remark 3.4. (a) In order to interpret the integral

$$\int_I r_h \left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x} r_x + 1}{\sqrt{1+r_x^2}} \right) dx \tag{3.13}$$

occurring in (3.7), we note that

$$\nu = \frac{1}{\sqrt{1+r_x^2}} \big(-r_x, \cos\phi, \sin\phi \big), \quad \nu_h = \frac{1}{\sqrt{1+r_{h,x}^2}} \big(-r_{h,x}, \cos\phi, \sin\phi \big)$$

are the unit outward normals to

$$\Gamma(t) = \{ \mathbf{x} \in \mathbb{R}^3 \,|\, \mathbf{x} = (x, r(x,t)\cos\phi, r(x,t)\sin\phi), x \in [0,L], \phi \in [0, 2\pi] \},$$
$$\Gamma_h(t) = \{ \mathbf{x} \in \mathbb{R}^3 \,|\, \mathbf{x} = (x, r_h(x,t)\cos\phi, r_h(x,t)\sin\phi), x \in [0,L], \phi \in [0, 2\pi] \},$$

respectively. Observing that $dS = r_h \sqrt{1+r_{h,x}^2}\, dx d\phi$ is the surface element on Γ_h, a short calculation shows that

$$\int_I r_h \left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x} r_x + 1}{\sqrt{1+r_x^2}} \right) dx = \frac{1}{2\pi} \int_{\Gamma_h} |\nu - \nu_h|^2 dS.$$

A similar relation was used in [5], [6] in an error analysis for the mean curvature flow of graphs.

(b) Under the conditions (2.13) and (3.1), the expression (3.13) is equivalent to $\|r_x - r_{h,x}\|^2_{H^1(I)}$. To see this, note that

$$\begin{aligned}
&\sqrt{1+r_{h,x}^2} - \frac{r_{h,x} r_x + 1}{\sqrt{1+r_x^2}} \\
&= \frac{\big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} - (r_{h,x} r_x + 1) \big) \big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} + (r_{h,x} r_x + 1) \big)}{\sqrt{1+r_x^2} \big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} + (r_{h,x} r_x + 1) \big)} \\
&= \frac{(r_x - r_{h,x})^2}{\sqrt{1+r_x^2} \big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} + (r_{h,x} r_x + 1) \big)},
\end{aligned}$$

which implies

$$\begin{aligned}
\frac{c_0}{4(1+C_0^2)\sqrt{1+4C_0^2}} \|r_x - r_{h,x}\|^2_{H^1(I)} &\le \int_I r_h \left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x} r_x + 1}{\sqrt{1+r_x^2}} \right) dx \\
&\le C_0 \|r_x - r_{h,x}\|^2_{H^1(I)},
\end{aligned} \tag{3.14}$$

since

$$\begin{aligned}
1 &\le \sqrt{1+r_x^2} \big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} + (r_{h,x} r_x + 1) \big) \\
&\le \sqrt{1+r_x^2} \big(\sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} + \sqrt{1+r_{h,x}^2}\sqrt{1+r_x^2} \big) \;\le\; 2(1+C_0^2)\sqrt{1+4C_0^2}.
\end{aligned}$$

It remains to derive an estimate for $\|\kappa - \kappa_h\|_{L^2(I)}$.

Lemma 3.5.

$$\|\kappa - \kappa_h\|_{L^2(I)} \le C\big(\|r - r_h\|_{H^1(I)} + \|\kappa_x - \kappa_{h,x}\|_{L^2(I)} + h\big).$$

Proof. Clearly,

$$\begin{aligned}&\int_I r_h(\kappa-\kappa_h)^2 dx\\ &= -\int_I (r-r_h)\kappa(\kappa-\kappa_h)dx + \int_I (r\kappa - r_h\kappa_h)(\kappa - I_h\kappa)dx + \int_I (r\kappa - r_h\kappa_h)(I_h\kappa-\kappa_h)dx.\end{aligned}$$

Using (3.6) in order to rewrite the third integral, we deduce

$$\begin{aligned}\int_I r_h(\kappa-\kappa_h)^2 dx &= -\int_I (r-r_h)\kappa(\kappa-\kappa_h)dx + \int_I (r\kappa - r_h\kappa_h)(\kappa - I_h\kappa)dx\\ &\quad + \int_I (I_h\kappa - \kappa_h)\big(\sqrt{1+r_x^2} - \sqrt{1+r_{h,x}^2}\big)dx + \int_I \left(\frac{r r_x}{\sqrt{1+r_x^2}} - \frac{r_h r_{h,x}}{\sqrt{1+r_{h,x}^2}}\right)\big(I_h\kappa - \kappa_h\big)_x dx\\ &\le C\|r-r_h\|_{L^2(I)}\|\kappa-\kappa_h\|_{L^2(I)} + C\big(\|r-r_h\|_{L^2(I)} + \|\kappa-\kappa_h\|_{L^2(I)}\big)\|\kappa - I_h\kappa\|_{L^2(I)}\\ &\quad + C\|I_h\kappa-\kappa_h\|_{L^2(I)}\|r_x - r_{h,x}\|_{L^2(I)} + C\|(I_h\kappa)_x - \kappa_{h,x}\|_{L^2(I)}\|r-r_h\|_{H^1(I)}\\ &\le \epsilon\|\kappa-\kappa_h\|^2_{L^2(I)} + C_\epsilon\|r-r_h\|^2_{H^1(I)} + C_\epsilon h^2 + C\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)}.\end{aligned}$$

Here we have again used (2.15). Choosing $\epsilon = \frac{c_0}{4}$ and recalling (3.1), we complete the proof of the lemma. □

We are now in position to complete the proof of Theorem 2.3. Combining Lemmas 3.2, 3.3, and 3.5 and (3.1), we obtain with $\lambda = \frac{c_0}{2\sqrt{1+4C_0^2}}$

$$\begin{aligned}&\frac{1}{2}\frac{d}{dt}\|r-r_h\|^2_{L^2(I)} + \frac{d}{dt}\int_I r_h\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x+1}{\sqrt{1+r_x^2}}\right)dx + \lambda\|\kappa_x-\kappa_{h,x}\|^2_{L^2(I)}\\ &\le C\epsilon\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} + C_\epsilon(1+\|r_t\|_{H^2(I)})\|r-r_h\|^2_{H^1(I)} + C_\epsilon(1+\|r_t\|^2_{H^2(I)})h^2.\end{aligned}$$

Choosing ϵ sufficiently small and recalling (3.14), the function

$$\phi(t) := \frac{1}{2}\|(r-r_h)(t)\|^2_{L^2(I)} + \int_I r_h\left(\sqrt{1+r_{h,x}^2} - \frac{r_{h,x}r_x+1}{\sqrt{1+r_x^2}}\right)(t)dx$$

satisfies

$$\phi'(t) + \frac{\lambda}{2}\|\kappa_x - \kappa_{h,x}\|^2_{L^2(I)} \le C(1+\|r_t\|^2_{H^2(I)})h^2 + C(1+\|r_t\|_{H^2(I)})\phi(t), \qquad 0 \le t \le \hat{T}_h. \tag{3.15}$$

Now, (2.7) and (3.14) yield $\phi(0) \le Ch^2$, so that Gronwall's lemma implies

$$\phi(t) \le C\,h^2\left(1 + \int_0^T \|r_t\|^2_{H^2(I)}dt\right)\exp\left(\int_0^T C(1+\|r_t\|_{H^2(I)})dt\right), \qquad 0 \le t \le \hat{T}_h.$$

Therefore,

$$\sup_{0<t<\hat{T}_h} \|(r-r_h)(t)\|_{H^1(I)} \le Ch, \tag{3.16}$$

and, using (3.15) together with Lemma 3.5,

$$\int_0^{\hat{T}_h} \|\kappa - \kappa_h\|^2_{H^1(I)} dt \le Ch^2. \tag{3.17}$$

We can now prove that $\hat{T}_h = T$. If not, we would have $\hat{T}_h < T$; the smoothness of r, (3.16), and an inverse estimate then would imply that

$$\|(r - r_h)(t)\|_{H^{1,\infty}(I)} \le C\sqrt{h}, \qquad 0 \le t \le \hat{T}_h,$$

which combined with (2.13) would give

$$\frac{3}{4}c_0 \le r_h \le \frac{3}{2}C_0,\ |r_{h,x}| \le \frac{3}{2}C_0 \quad \text{in } I \times [0, \hat{T}_h]$$

provided that $h \le h_0$ and h_0 is sufficiently small. However, then we could extend the discrete solution to an interval $[0, \hat{T}_h + \delta]$ for some $\delta > 0$ with

$$\frac{1}{2}c_0 \le r_h \le 2C_0,\ |r_{h,x}| \le 2C_0 \quad \text{in } I \times [0, \hat{T}_h + \delta],$$

which contradicts the definition of $\hat{T}_h$. Thus $\hat{T}_h = T$ for $h \le h_0$ and (3.16), (3.17) imply our result.

4. Numerical results.

We use the notation

$$r_j(t) = r_h(x_j, t),\ \ \kappa_j(t) = \kappa_h(x_j, t),\ \ j = 0, \ldots, N,$$
$$q_j(t) = \sqrt{h_j^2 + \big(r_j(t) - r_{j-1}(t)\big)^2},\ \ j = 1, \ldots, N.$$

The spatially discrete problem (2.5), (2.6) then is translated into the following system of ODEs. By a dot we denote the time derivative. For numerical tests we shall use an additional right-hand side f which we include in the equations here.

$$\begin{aligned}
&\frac{h_j}{6}(r_{j-1} + r_j)\dot{r}_{j-1} + \left(\frac{h_j}{6}r_{j-1} + \frac{1}{2}(h_j + h_{j+1})r_j + \frac{h_{j+1}}{6}r_{j+1}\right)\dot{r}_j \\
&\qquad + \frac{h_{j+1}}{6}(r_j + r_{j+1})\dot{r}_{j+1} - \frac{r_{j-1} + r_j}{q_j}\kappa_{j-1} + \left(\frac{r_{j-1} + r_j}{q_j} + \frac{r_j + r_{j+1}}{q_{j+1}}\right)\kappa_j \\
&\qquad - \frac{r_j + r_{j+1}}{q_{j+1}}\kappa_{j+1} = \frac{1}{2}\big(q_j(r_{j-1} + r_j)f_{j-\frac{1}{2}} + q_{j+1}(r_j + r_{j+1})f_{j+\frac{1}{2}}\big), \\
&\frac{h_j}{6}(r_{j-1} + r_j)\kappa_{j-1} + \left(\frac{h_j}{6}r_{j-1} + \frac{1}{2}(h_j + h_{j+1})r_j + \frac{h_{j+1}}{6}r_{j+1}\right)\kappa_j \\
&\qquad + \frac{h_{j+1}}{6}(r_j + r_{j+1})\kappa_{j+1} + \frac{r_{j-1} + r_j}{q_j}r_{j-1} - \left(\frac{r_{j-1} + r_j}{q_j} + \frac{r_j + r_{j+1}}{q_{j+1}}\right)r_j \\
&\qquad + \frac{r_j + r_{j+1}}{q_{j+1}}r_{j+1} = q_j + q_{j+1}
\end{aligned} \tag{4.1}$$

for $j = 1, \ldots, N$, $t \in (0, T]$, with periodic boundary conditions and initial condition $r_j(0) = r_0(x_j)$, $j = 0, \ldots, N$. For the right-hand side term involving f we have used a simple integration formula and the notation $f_{j\pm\frac{1}{2}} = f((x_j + x_{j\pm 1})/2)$.

The time discretization is done via a semi-implicit scheme which also linearizes the problem. Furthermore we use mass lumping at suitable positions. Let $\tau > 0$ be the time step size and $M = [T/\tau]$. For a generic function w we denote by w^m ($0 \leq m \leq M$) the evaluation on the mth time level: $w^m = w(\cdot, m\tau)$. The fully discrete scheme then reads as follows.

Algorithm 4.1. Let $r_j^0 = r_0(x_j)$, $j = 0, \dots, N$. For $m = 1, \dots, M$ solve

$$\begin{aligned}
&\frac{1}{\tau}(h_j + h_{j+1}) r_j^{m-1}(r_j^m - r_j^{m-1}) \\
&\quad - \frac{r_{j-1}^{m-1} + r_j^{m-1}}{q_j^{m-1}} \kappa_{j-1}^m + \left(\frac{r_{j-1}^{m-1} + r_j^{m-1}}{q_j^{m-1}} + \frac{r_j^{m-1} + r_{j+1}^{m-1}}{q_{j+1}^{m-1}} \right) \kappa_j^m - \frac{r_j^{m-1} + r_{j+1}^{m-1}}{q_{j+1}^{m-1}} \kappa_{j+1}^m \\
&\qquad = \frac{1}{2}\big(q_j^{m-1}(r_{j-1}^{m-1} + r_j^{m-1}) f_{j-\frac{1}{2}}^m + q_{j+1}^{m-1}(r_j^{m-1} + r_{j+1}^{m-1}) f_{j+\frac{1}{2}}^m \big), \\
&(h_j + h_{j+1}) r_j^{m-1} \kappa_j^m \\
&\quad + \frac{r_{j-1}^{m-1} + r_j^{m-1}}{q_j^{m-1}} r_{j-1}^m - \left(\frac{r_{j-1}^{m-1} + r_j^{m-1}}{q_j^{m-1}} + \frac{r_j^{m-1} + r_{j+1}^{m-1}}{q_{j+1}^{m-1}} \right) r_j^m + \frac{r_j^{m-1} + r_{j+1}^{m-1}}{q_{j+1}^{m-1}} r_{j+1}^m \\
&\qquad = q_j^{m-1} + q_{j+1}^{m-1}
\end{aligned}$$

for $j = 1, \dots, N$, $m = 1, \dots, M$.

In every time step a linear system for $\underline{r}^m = (r_1^m, \dots, r_N^m)$ and $\underline{\kappa}^m = (\kappa_1^m, \dots, \kappa_N^m)$ of the form

$$\frac{1}{\tau} M^{m-1} \underline{r}^m + S^{m-1} \underline{\kappa}^m = \underline{c}^{m-1}, \tag{4.2}$$

$$M^{m-1} \underline{\kappa}^m - S^{m-1} \underline{r}^m = \underline{d}^{m-1} \tag{4.3}$$

has to be solved. Here M^{m-1} is a suitable mass matrix, S^{m-1} is a stiffness matrix, and $\underline{c}^{m-1}$, $\underline{d}^{m-1}$ are right-hand sides depending on the quantities of the $(m-1)$st time step with built-in periodic boundary conditions. Note that the time discretization is semi-implicit with respect to the position r but is fully implicit with respect to curvature κ. The linear system (4.2), (4.3) was solved by inserting the second equation into the first one, which leads to the following linear system for $\underline{r}^m$:

$$\left(\frac{1}{\tau} M^{m-1} + S^{m-1}(M^{m-1})^{-1} S^{m-1} \right) \underline{r}^m = \underline{c}^{m-1} - S^{m-1}(M^{m-1})^{-1} \underline{d}^{m-1}. \tag{4.4}$$

Note that the matrix M^{m-1} is a diagonal matrix. The system (4.4) was solved by a conjugate gradient method.

For all computations we have used uniform spatial grids $h_j = h$ with h as indicated.

We test the scheme with a known continuous solution. We choose

$$r(x,t) = (1 + 0.25 \sin \pi(x-1))(1 + 0.125 \cos t)$$

on the interval $I = [0, 2]$ for $T = 1$ and calculate the corresponding right-hand side f from (1.3) and (1.2). Now we are able to compute the error between continuous solution r, κ and discrete solution r_h^m, κ_h^m and calculate the experimental order of convergence from the errors for two grids. As time step size we have chosen $\tau = 0.1h^2$.

Table 4.1

Absolute errors in various norms and experimental orders of convergence (in brackets) for the test problem for the choice $\tau = 0.1h^2$.

N	h	$\|r - r_h\|_{L^\infty(H^1)}$	$\|\kappa - \kappa_h\|_{L^2(H^1)}$
20	0.1	0.3010	2.2669
40	0.05	0.1544 (0.96)	1.1693 (0.96)
80	0.025	0.07784 (0.99)	0.5892 (0.99)
160	0.0125	0.03903 (1.00)	0.2952 (1.00)
320	0.00625	0.01953 (1.00)	0.1477 (1.00)

Table 4.2

Absolute errors in various norms and experimental orders of convergence (in brackets) for the test problem for the choice $\tau = 0.1h$.

N	h	$\|r - r_h\|_{L^\infty(H^1)}$	$\|\kappa - \kappa_h\|_{L^2(H^1)}$
20	0.1	0.2575	2.2597
40	0.05	0.1399 (0.88)	1.1672 (0.95)
80	0.025	0.07363 (0.93)	0.5886 (0.99)
160	0.0125	0.03790 (0.96)	0.2950 (1.00)
320	0.00625	0.01922 (0.98)	0.1476 (1.00)

The results are shown in Table 4.1. We measured the errors

$$\|r - r_h\|_{L^\infty((0,T),H^1(I))} \quad \text{and} \quad \|\kappa - \kappa_h\|_{L^2((0,T),H^1(I))}.$$

The results confirm the error estimates in Theorem 2.3 precisely. A quite astonishing result is that these convergence results experimentally also hold in the case of linear coupling of time step size and spatial grid size (see Table 4.2), in particular, that no stability problems arise even though the scheme is only semi-implicit. This is in some sense similar to the case of mean curvature flow, for which in [7] stability of a semi-implicit scheme was proved without any time step restriction.

In [3] it was shown that solutions of axially symmetric surface diffusion may exhibit the following dynamical behavior: After an initial rapid decay, some perturbations slowly grow in amplitude and finally lead to pinch-off. We recomputed an example from [3], for which the initial surface is given by

$$r_0(x) = 1 + 0.05\left(\sin\left(\frac{m+1}{2}x\right) + \sin\left(\frac{m}{2}x\right)\right), \; x \in (0, n\pi). \tag{4.5}$$

Figure 4.1 shows the rapid decay of perturbations for $m = 10$. For better visibility we scaled the graphics vertically by 100.

For $m = 14$ we show the long time behavior of the solution $r = r(x,t)$. In order to make the dynamical behavior more transparent we plot the solution in Figure 4.2 for $t \in [0, 10]$ and in Figure 4.3 for $t \in [20, 27.861]$. We have used 400 nodes and a time step size $\tau = 0.1\, h^2$. Note that our error analysis is only valid as long as r is bounded away from zero. For calculations near the pinch-off singularity we adapted the time step according to $\tau = 0.1\, h^2 \min_{[0,4\pi]} r_h^3$, a criterion which was found experimentally. Finally, we computed the solution of axisymmetric surface diffusion for the initial surface given by

$$r_0(x) = 1 - 0.95\, |x| \sin\frac{\pi}{x}, \; x \in (-1, 1). \tag{4.6}$$

Here we have used 500 spatial nodes and a time discretization as in the previous example. The results are shown in Figure 4.4.

PERFORMING INTERPOLATION AND ANTERPOLATION ENTIRELY BY FAST FOURIER TRANSFORM IN THE 3-D MULTILEVEL FAST MULTIPOLE ALGORITHM[*]

JUKKA SARVAS[†]

Abstract. The fast multipole methods are used for solving a scalar acoustic or vector electromagnetic wave equation by integral equation methods with a large number of unknowns. In this paper a new method is presented for performing interpolation and anterpolation in both spherical coordinates θ and ϕ by FFT in the three-dimensional (3-D) multilevel fast multipole algorithm (MLFMA). The key idea is to approximate functions on the unit sphere by truncated Fourier series in two variables rather than by the usual spherical harmonics.

The proposed method is exact in interpolating and anterpolating and has the high numerical efficiency of FFT. The method is numerically compared to the method of performing interpolation and anterpolation using Lagrangian interpolation, which presently is probably the fastest method for those operations, and the results suggest that the proposed new method is equally or more efficient, depending on the desired accuracy.

Key words. fast multipole method, 3-D multilevel fast multipole algorithm, interpolation, anterpolation, fast Fourier transform

1. Introduction.

The fast multipole methods, with two levels [1] or multiple levels [2], [3], are usually applied to solving a scalar acoustic or vector electromagnetic wave equation as an integral equation with a large number of unknowns. They are designed to speed up the matrix-vector multiply in a numerical solution using an iterative method. The multilevel fast multipole algorithm (MLFMA) leads to a computational cost of order $N \log N$, with N being the number of unknowns [4], [3], compared with the usual cost of order N^2 for the direct matrix-vector multiply. In this paper, we consider MLFMA for the scalar wave equation. Our results can easily be extended to the vector case in the usual way; see, e.g., [5], [3].

The key issue in MLFMA is to control the computational accuracy and cost of the scattered fields, both globally and locally, by a tree-like data structure. The global field representations are iteratively constructed by shifts and interpolations, and the local ones iteratively by translations, shifts, and anterpolations. We assume that the reader is familiar with the data structure of the MLFMA; see, e.g., [2], [5], [6], [7], [3]. Here we only outline the procedure for the needs of the present paper.

We consider a scatterer in 3-space; either its surface is triangulated for the surface integral method, or its volume is subdivided into a three-dimensional (3-D) grid for a volume integral method. In both cases, the unknown scalar source density is presented in terms of appropriate local basis functions. The scatterer is enclosed in a large cube, which is partitioned into eight subcubes. Every subcube is then, successively, subdivided until the finest level is reached, with the side length of a cube equal to about half of the wave length. The levels are indexed $M = 0, 1, \ldots, M_{\max}$. On the

finest level $M = M_{\max}$, those cubes containing basis functions are indexed, and subsequently, on each level the nonempty parental cubes are indexed. The data structure is constructed in uptree, or *aggregation*, steps and in downtree, or *disaggregation*, steps.

In the aggregation steps, for every level $M = 1, 2, \ldots, M_{\max} - 1$ and for each nonempty cube Q on that level, the far field, due to sources in Q, is formed from the far fields of the subcubes of Q on the level $M + 1$.

The far fields, which are smooth functions on the unit sphere, are in this paper presented by truncated Fourier series, i.e., by *trigonometric polynomials*, in the spherical coordinates θ and ϕ, rather than in terms of the spherical harmonics. For the trigonometric polynomial presentation, we extend the functions on the unit sphere in the θ coordinate from $0 \le \theta \le \pi$ to $-\pi \le \theta \le \pi$. This extension makes them smooth 2π-periodic functions in both θ and ϕ, and consequently, a numerically very efficient approximation of these functions by trigonometric polynomials can be performed using the fast Fourier transform (FFT). The redundancy due to the extension into $-\pi \le \theta \le 0$ can be completely removed in the data storage and in the computations with FFT.

In forming the level M far fields from the level $M + 1$ fields, shifting and interpolation are used. The interpolation can be carried out for trigonometric polynomials accurately with FFT without any approximation error, which makes this operation numerically very efficient and straightforward for trigonometric polynomials.

In the disaggregation steps local presentations for the scattered fields F are formed in terms of plane waves by the integral

$$F(x) = \int_{|z|=1} v(z) e^{ikx\cdot z} dz, \quad x \in \mathbb{R}^3, \tag{1.1}$$

where the integral is a surface integral over the unit sphere $\{z \in \mathbb{R}^3 : |z| = 1\}$, $\mathbb{R}^3$ is the 3-space, and the function v in (1.1) is called the *amplitude field* of F. In a disaggregation step from the level $M - 1$ to M, the local field for each level M cube Q, due to sources outside of Q and its immediate neighbor cubes on level M, is formed in terms of plane waves. This is done by translating the far fields of cubes on the level M to a local field in Q and shifting and anterpolating the level $M + 1$ local field, corresponding to the parental cube of Q, into Q.

In this paper, we also present the amplitude fields in (1.1) in terms of trigonometric polynomials. Our choice makes it possible to carry out the anterpolation accurately and effectively by FFT.

In the disaggregation step from the level $M_{\max} - 1$ to the level $M_{\max}$, we eventually need to compute the scattered fields from the local amplitude fields v as in (1.1). After having estimated the amplitude field v and the function $e^{ikx\cdot z}$ in (1.1) by trigonometric polynomials, the resulting field integral can be computed efficiently in a closed form without any extra integration error.

In the last section of this paper, our method using trigonometric polynomials and FFT in the interpolation and anterpolation in three dimensions is compared to the Lagrangian interpolation method of performing those operations [2], [6], [3], which presently is probably the fastest method in this area. The comparison shows that, for a lower accuracy demand, both methods numerically are about equally efficient, but for a higher accuracy, the method of this paper is more efficient.

Furthermore, with no approximation errors in interpolation and anterpolation, the present method also makes accuracy control in MLFMA easier than in using other methods. Though the method of this paper was intended to be used primarily with the time-harmonic MLFMA, it is also well suited for the time-dependent MLFMA [8].

To finish the introduction, we fix some notation. We denote by $\mathbb{R}$ and $\mathbb{C}$ the real and complex numbers, respectively. The imaginary unit is $i = \sqrt{-1}$. The complex conjugate of $z \in \mathbb{C}$ is denoted by $\overline{z}$. For a real number t, $\mathit{floor}(t)$ is the largest integer $\leq t$, and $\mathit{ceil}(t)$ is the smallest integer $\geq t$. For a sequence $a = (a_1, \dots, a_n)$ of numbers, we denote by $\mathit{length}(a)$ the length n of the sequence. The element-by-element product $c = \{c_n\} = \{a_n b_n\}$ of two sequences $a = \{a_n\}$ and $b = \{b_n\}$, of the same length, is denoted by $c = ab$. For a number a_n in a sequence $a = \{a_n\}$ we also use the notation $a_n = a(n)$.

2. Discrete Fourier transform. We use a centralized discrete Fourier transform (DFT). For a sequence $u = \{u_n\}$ of length N, we define the centralized DFT $v = \mathcal{F}_N u$ of u, with the period N, by the formula

$$v_n = v(n) = (\mathcal{F}_N u)(n) = \sum_{m=-N_1}^{N_2} u(m) e^{-i \frac{2\pi}{N} nm}, \tag{2.1}$$

$-N_1 \leq n \leq N_2$, where $N_1 = \mathit{floor}(N/2)$ and $N_2 = N - N_1 - 1$. We also write $\mathcal{F}$ for $\mathcal{F}_N$.

In the context of DFT, we always consider the sequences u and v in (2.1) to be extended to be N-periodic for all n, i.e., $u(n + N) = u(n)$ for all integers n.

The inverse transform (IDFT) $\mathcal{F}_N^{-1}$ is defined by

$$u(m) = (\mathcal{F}_N^{-1} v)(m) = \frac{1}{N} \sum_{n=-N_1}^{N_2} v(n) e^{i \frac{2\pi}{N} mn} \quad \text{for all } m. \tag{2.2}$$

For a (P, Q)-matrix $u = \{u_{mn};\, -P_1 \leq m \leq P_2,\, -Q_1 \leq n \leq Q_2\}$, with $P_1 = \mathit{floor}(P/2), P_2 = P - P_1 - 1$, and $Q_1 = \mathit{floor}(Q/2)$, $Q_2 = Q - Q_1 - 1$, we denote the nth column by $u(:, n)$, and the mth row by $u(m, :)$, respectively. We also write $u(m, n)$ for u_{mn}. Again, we tacitly assume that each column $u(:, n)$ is extended to be a P-periodic sequence, and likewise, each row is extended to be a Q-periodic sequence.

We define our two-dimensional (2-D) discrete centralized Fourier transform $\mathcal{F}_{P,Q}$, with the periods P and Q, for a (P, Q)-matrix u by

$$(\mathcal{F}_{P,Q} u)(m, n) = \sum_{p=-P_1}^{P_2} \sum_{q=-Q_1}^{Q_2} u(p, q) e^{-i(\frac{2\pi}{P} mp + \frac{2\pi}{Q} nq)} \tag{2.3}$$

for all m, n. We also denote $\mathcal{F}_{P,Q}$ by $\mathcal{F}$. The inverse transform $\mathcal{F}_{P,Q}^{-1}$ is defined by

$$(\mathcal{F}_{P,Q}^{-1} v)(p, q) = \frac{1}{PQ} \sum_{m=-P_1}^{P_2} \sum_{n=-Q_1}^{Q_2} v(m, n) e^{i(\frac{2\pi}{P} pm + \frac{2\pi}{Q} qn)} \tag{2.4}$$

for all p, q. The 2-D DFT and its inverse transform can also be given, and usually are computed, in the terms of one-dimensional (1-D) DFT's as follows:

$$(\mathcal{F}_{P,Q} u)(m, n) = (\mathcal{F}_Q v(m, :))(n), \quad \text{where} \quad v(p, q) = (\mathcal{F}_P u(:, q))(p), \tag{2.5}$$

for all m, n, p, and q, or the order is reversed: first take $\mathcal{F}_Q$ rowwise and then $\mathcal{F}_P$ columnwise. A similar equation holds for $\mathcal{F}_{P,Q}^{-1}$ in terms of $\mathcal{F}_P^{-1}$ and $\mathcal{F}_Q^{-1}$.

The DFT is closely related to truncated Fourier series, i.e., *trigonometric polynomials.* Consider a trigonometric polynomial

$$U(t) = \sum_{n=-N}^{N'} a_n e^{int}, \quad t \in \mathbb{R}, \tag{2.6}$$

with $N' = N - 1$ or N, depending on whether the length of the coefficient sequence $\{a_n\}$ is, respectively, even or odd, and we say that the *kind* of U, denoted by $Kind(U)$, is then even or odd, respectively. The integer N is the *degree* of U, denoted by *Degree*(U), and it also is the half bandwidth of U.

As is well known, the coefficient sequence $a = \{a_n\}$ is related to U by equations

$$a = \frac{1}{M}\mathcal{F}_M(u) \quad \text{and} \quad u = M\mathcal{F}_M^{-1}(a), \tag{2.7}$$

where $u(n) = U(n\frac{2\pi}{M})$, $-N \le n \le N'$, $M = N + N' + 1$ is the period of $\mathcal{F}_M$, and u is the sample sequence of U, denoted by $u = \mathit{Sample}(U)$. The equations (2.7) show that we can identify a trigonometric polynomial U either with the sample sequence u or with its coefficient sequence a, which we denote by $a = \mathit{Coef}(U)$.

It is also well known that a smooth 2π-periodic function $V(t) = V(t + 2\pi)$, $t\epsilon\mathbb{R}$, can be approximated by an interpolating trigonometric polynomial (2.6) so that

$$u(n) = U(t_n) = V(t_n), \quad t_n = n\frac{2\pi}{M}, \quad -N \le n \le N',$$

and the approximation $U \simeq V$ improves as the *sampling rate* $N = \mathit{Degree}(U)$ increases.

We also consider trigonometric polynomials, i.e., truncated Fourier series, in two variables, but only of the following form:

$$U(\theta, \phi) = \sum_{m=-M}^{M} \sum_{n=-N}^{N-1} a(m,n) e^{i(m\theta + n\phi)}, \tag{2.8}$$

where $M, N > 0$ are integers. The coefficient matrix a is a $(2M+1, 2N)$-matrix, and

$$a = \frac{1}{(2M+1)2N}\mathcal{F}_{2M+1,2N}(u) \quad \text{with} \tag{2.9}$$

$$u(m,n) = U\left(m\frac{2\pi}{2M+1}, n\frac{\pi}{N}\right) \tag{2.10}$$

for $-M \le m \le M$, $-N \le n \le N-1$. We denote that $u = \mathit{Sample}(U)$ and $(M,N) = \mathit{Degree}(U)$, and also call (M,N) the *sampling rate* for U. As in the case of one variable, we can approximate a smooth function $V(\theta, \phi)$, 2π-periodic both in θ and ϕ, by the trigonometric polynomial $U(\theta, \phi)$ in (2.8), by choosing

$$a = \frac{1}{(2M+1)2N}\mathcal{F}v \quad \text{with} \quad v(m,n) = V\left(m\frac{2\pi}{2M+1}, n\frac{\pi}{N}\right)$$

for all $-M \le m \le M$ and $-N \le n \le N-1$.

3. Smooth functions on a sphere. We want to approximate far fields and amplitude fields on a unit sphere by trigonometric polynomials using DFT. For that purpose we must extend them to be 2π-periodic in both the spherical coordinates θ and ϕ.

Let $S = \{x\epsilon\mathbb{R}^3 : |x| = 1\}$ be the unit sphere in $\mathbb{R}^3$, and let $W : S \longrightarrow \mathbb{C}$ be a complex valued function on S, i.e., $W(x) \in \mathbb{C}$ for $x = (x_1, x_2, x_3) \in S$. If we write $x = (x_1, x_2, x_3)$ in the spherical coordinates (θ, ϕ), we can identify W with the function $V(\theta, \phi)$, for $0 \leq \theta \leq \pi$, $-\pi \leq \phi \leq \pi$, given by

$$V(\theta, \phi) = W(\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta) \tag{3.1}$$

for $0 \leq \theta \leq \pi$, $-\pi \leq \phi \leq \pi$. By (3.1) we now can extend $V(\theta, \phi)$ for all $\theta, \phi \in \mathbb{R}$. This makes the extension $V(\theta, \phi)$ be 2π-periodic both in θ and ϕ and satisfy the equation

$$V(-\theta, \phi) = V(\theta, \phi + \pi) \quad \text{for all } \theta, \phi \in \mathbb{R}. \tag{3.2}$$

In general, we here call a function $V(\theta, \phi)$, $\theta, \phi \in \mathbb{R}$, *spherical* if it is 2π-periodic in θ and ϕ and satisfies (3.2).

We approximate a smooth spherical function V with a trigonometric polynomial of the form

$$U(\theta, \phi) = \sum_{m=-M}^{M} \sum_{n=-N}^{N-1} a(m, n) e^{i(m\theta + n\phi)}, \tag{3.3}$$

where

$$a = \frac{1}{(2M+1)2N} \mathcal{F}_{2M+1,2N}(v), \tag{3.4}$$

$$v(m, n) = V\left(m\frac{2\pi}{2M+1}, n\frac{\pi}{N}\right) \tag{3.5}$$

for $-M \leq m \leq M$, $-N \leq n \leq N - 1$. Because in (3.4) the first period $2M + 1$ is odd and the second period $2N$ is even, it is easily seen that (3.5) and the sphericality of V imply that

$$a(-m, n) = (-1)^n a(m, n) \quad \text{for all } m, n, \tag{3.6}$$

a condition which also makes $U(\theta, \phi)$ a spherical function. This implies that $u = \mathit{Sample}(U) = v$ satisfies the condition

$$u(-m, n) = u(m, n + N) \quad \text{for all } m, n. \tag{3.7}$$

We here call a $(2M + 1, 2N)$-matrix u *spherical* if it satisfies (3.7), and *transspherical* if it satisfies (3.6).

In the later interpolation and anterpolation operations we will frequently apply DFT on spherical matrices and IDFT on transspherical ones. The conditions (3.6) and (3.7) can be effectively utilized and the resulting computation reduced by half by using the following lemma, which is easily proved.

Lemma 3.1. *Consider a $(2M + 1, 2N)$-matrix u. If u is spherical and v_1 and v_2 are obtained from u by taking DFT columnwise and rowwise, i.e.,*

$$v_1(m, n) = (\mathcal{F}_{2M+1} u(:, n))(m) \quad \textit{and} \tag{3.8}$$

$$v_2(m, n) = (\mathcal{F}_{2N} u(m, :))(n) \tag{3.9}$$

for all m, n, then v_1 is spherical and v_2 is transspherical. Conversely, if u is transspherical and v_1 and v_2 are as in (3.8) *and* (3.9)*, then v_1 is transspherical and v_2 is spherical. Furthermore, the lemma also holds if $\mathcal{F}$ is replaced by $\mathcal{F}^{-1}$.*

The above lemma with the (2.5) yields the following corollary.

Corollary 3.2. *If u is a spherical $(2M+1, 2N)$-matrix, then $v = \mathcal{F}_{2M+1,2N}(u)$ is transspherical. If v is a transspherical $(2M+1, 2N)$-matrix, then $u = \mathcal{F}^{-1}_{2M+1,2N}(v)$ is spherical.*

We usually use FFT when computing the DFT and IDFT. The above lemma and its corollary can be used to reduce this computing of spherical and transspherical matrices, as follows. For a given spherical $(2M+1, 2N)$-matrix u, compute $w = \mathcal{F}_{2M+1,2N}u$ as follows. Let

$$\begin{aligned} v(m,n) &= (\mathcal{F}u(:,n))(m) \text{ for } -M \le m \le M, -N \le n \le -1, \\ v(m,n) &= v(-m, n-N) \text{ for } -M \le m \le M, 0 \le n \le N-1, \\ w(m,n) &= (\mathcal{F}v(m,:))(n) \text{ for } -M \le m \le 0, -N \le n \le N-1, \\ w(m,n) &= (-1)^n w(-m,n) \text{ for } 1 \le m \le M, -N \le n \le N-1. \end{aligned}$$

Similarly, we can, with a reduced workload, compute $\mathcal{F}^{-1}_{(2M+1,2N)}v$ for a transspherical matrix v.

Note also that only one half of a spherical, or a transspherical, matrix must be stored, and also that the DFT and IDFT can be performed using that half storage space. These reductions in computing the DFT and IDFT can be used in the interpolation and anterpolation operations, because transsphericality is preserved in zero-padding and truncation of coefficient sequences in DFT.

In addition to the possibility of performing interpolation and anterpolation by FFT, the use of trigonometric polynomials in MLFMA has the advantage that, after estimating functions by trigonometric polynomials, the field integrals can be computed efficiently in a closed form without any further integration error. The needed integral formula is given in the following lemma.

Lemma 3.3. *Let U and V be trigonometric polynomials in two variables and of degree (M, N). If U and V also are spherical functions, then*

$$\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} U(\theta,\phi)\overline{V(\theta,\phi)}d\theta d\phi$$

$$= \frac{4\pi^2}{(2M+1)N}\left[\sum_{n=0}^{N-1} u(0,n)\overline{v(0,n)} + \sum_{m=1}^{M}\sum_{n=-N}^{N-1} u(m,n)\overline{v(m,n)}\right],$$

where $u = Sample(U)$ and $v = Sample(V)$.

Proof. Let $a = Coef(U)$ and $b = Coef(V)$. Start by using the orthogonality of terms $e^{i(m\theta+n\phi)}$ in integrating over $-\pi \le \theta, \phi \le \pi$, and then use (2.9), the Parseval's identity for 2-D DFT, and the sphericality property of u and v to get

$$\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} U(\theta,\phi)\overline{V(\theta,\phi)}d\theta d\phi$$

$$= \int_{-\pi}^{\pi}\int_{-\pi}^{\pi}\left[\sum_{m=-M}^{M}\sum_{n=-N}^{N-1} a(m,n)e^{i(m\phi+n\phi)}\right]\left[\sum_{m=-M}^{M}\sum_{n=-N}^{N-1} \overline{b(m,n)}e^{-i(m\phi+n\phi)}\right]d\theta d\phi$$

$$= 4\pi^2 \sum_{m=-M}^{M} \sum_{n=-N}^{N-1} a(m,n)\overline{b(m,n)} = \frac{4\pi^2}{(2M+1)2N} \sum_{m=-M}^{M} \sum_{n=-N}^{N-1} u(m,n)\overline{v(m,n)}$$

$$= \frac{4\pi^2}{(2M+1)N} \left[\sum_{n=0}^{N-1} u(0,n)\overline{v(0,n)} + \sum_{m=1}^{M} \sum_{n=-N}^{N-1} u(m,n)\overline{v(m,n)} \right],$$

where in the last step we have used the equation $u(-m,n)\overline{v(-m,n)} = u(m,n+N)\overline{v(m,n+N)} = u(m,n-N)\overline{v(m,n-N)}$ for all m,n, due to the sphericality of u and v and the periodicity in n with the period $2N$. This completes the proof. □

4. Interpolation and anterpolation. Interpolation and anterpolation are here applied to trigonometric polynomials of one and two variables. These operations are essentially zero-padding and truncation, applied to coefficient sequences or matrices.

We say that a sequence c is obtained from a sequence b by *zero-padding* by M, and denote $c = \mathit{Pad}(b, M)$, if c is obtained from b by adding M zeros at both ends of b.

If U and V are trigonometric polynomials of one variable and

$$\mathit{Coef}(V) = \mathit{Pad}(\mathit{Coef}(U), M),$$

we say that $v = \mathit{Sample}(V)$ is obtained from $u = \mathit{Sample}(U)$ by *interpolating* u from the sampling rate $N = \mathit{Degree}(U)$ to the sampling rate $N + M$, and we denote that by

$$v = \mathit{Interp}(u, N+M). \tag{4.1}$$

Due to (2.7), the interpolation can be computed by FFT using the equation

$$\mathit{Interp}(u, N+M) = (L+2M)\mathcal{F}^{-1}_{L+2M}(\mathit{Pad}(a, M)), \tag{4.2}$$

where $a = L^{-1}\mathcal{F}_L(u)$, $L = \mathit{Length}(u)$, and $N = \mathit{floor}(L/2)$.

For a trigonometric polynomial U of two variables the interpolation of $u = \mathit{Sample}(U)$ from the sampling rate $(N_1, N_2) = \mathit{Degree}(U)$ to the sampling rate $(N_1 + M_1, N_2 + M_2)$ is defined in an analogous way, and the resulting matrix is denoted by $\mathit{Interp}(u, N_1 + M_1, N_2 + M_2)$. It is computed by FFT by applying (4.2) to the coefficient matrix

$$a = (2N_1 + 1)^{-1}(2N_2 + 1)^{-1}\mathcal{F}_{2N_1+1,2N_2}(u)$$

column- and rowwise. If u is spherical, the computational cost is lowered in the way discussed at the end of the last section.

We say that a sequence c is obtained from a sequence $b = (b_{-N}, \dots, b_{N'})$ by *truncating* b by M elements from each end if $c = (b_{-N+M}, \dots, b_{N'-M})$, and we denote $c = \mathit{Trunc}(b, M)$.

If U and V are trigonometric polynomials of one variable and

$$\mathit{Coef}(V) = \mathit{Trunc}(\mathit{Coef}(U), M),$$

we say that V and $v = \mathit{Sample}(V)$ are obtained from U and $u = \mathit{Sample}(U)$, respectively, by *anterpolating* U and u from the degree $N = \mathit{Degree}(U)$ to the degree $N - M$, and we denote

$$V = \mathit{Anterp}(U, N-M) \quad \text{and} \quad v = \mathit{Anterp}(u, N-M).$$

The sample sequence $v = \mathit{Anterp}(u, N - M)$ can be computed by FFT using the equation

$$\mathit{Anterp}(u, N - M) = (L - 2M)\mathcal{F}_{L-2M}^{-1}(\mathit{Trunc}(a, M)), \tag{4.3}$$

where $a = L^{-1}\mathcal{F}_L(u)$, $L = \mathit{Length}(u)$, and $N = \mathit{floor}(L/2)$.

The anterpolation can be, in an obvious way, extended to functions U given by a Fourier series, i.e., $\mathit{Degree}(U) = \infty$.

The anterpolation of a trigonometric polynomial of two variables is defined in an analogous way and is computed by (4.3) column- and rowwise. For a spherical u, the resulting reductions of computational cost can be utilized.

In MLFMA the following theorem is fundamental for implementing the anterpolation in an optimal manner. The theorem is essentially due to the fact that if in DFT we undersample a trigonometric polynomial appropriately, the resulting aliasing corrupts only coefficients of higher order, leaving the lower ones unchanged.

Theorem 4.1 (anterpolation of a product). *Let U and V be trigonometric polynomials of one variable and of the odd kind. Let*

$$\mathit{Degree}(U) = N \quad \text{and} \quad \mathit{Degree}(V) \geq N + M$$

for an integer $M \geq 0$. Then

$$\mathit{Anterp}(UV, M) = \mathit{Anterp}(W, M), \tag{4.4}$$

where W is a trigonometric polynomial of degree $N + M$, of the odd kind, and given by its sample sequence $\mathit{Sample}(W) = w$ so that

$$w(n) = u_1(n)v_1(n) \quad \text{for} \quad -N - M \leq n \leq N + M, \quad \text{where}$$
$$u_1 = \mathit{Interp}(\mathit{Sample}(U), N + M), \quad v_1 = \mathit{Sample}(\mathit{Anterp}(V, N + M)).$$

The theorem also holds for V with $\mathit{Degree}(V) = \infty$; i.e., V is a function given by a Fourier series.

Proof. Let $a = \mathit{Coef}(U)$, $b = \mathit{Coef}(V)$, and $c = \mathit{Coef}(UV)$. If $-M \leq m \leq M$, then

$$c(m) = \sum_{n=-N}^{N} a(n)b(m - n) = \sum_{n=-N-M}^{N+M} \tilde{a}(n)\tilde{b}(m - n) = (\tilde{a} * \tilde{b})(m), \tag{4.5}$$

where the sequences $\tilde{a}$ and $\tilde{b}$ are the P-periodic extensions of the sequences $\mathit{Pad}(a, M)$ and $\{b(n);\ -N-M \leq n \leq N+M\}$, and the sequence $\tilde{a}*\tilde{b}$ is the P-periodic convolution of $\tilde{a}$ and $\tilde{b}$ with $P = 2(N + M) + 1$. By the convolution theorem for the inverse DFT and by the coefficient rule (2.7), we get

$$\begin{aligned}\tilde{a} * \tilde{b} &= \mathcal{F}_P\big(\mathcal{F}_P^{-1}(\tilde{a} * \tilde{b})\big) = \mathcal{F}_P\big(P(\mathcal{F}_P^{-1}\tilde{a})(\mathcal{F}_P^{-1}\tilde{b})\big)\\ &= \frac{1}{P}\mathcal{F}_P(u_1v_1) = \frac{1}{P}\mathcal{F}_P(w) = \mathit{Coef}(W).\end{aligned}$$

This with (4.5) implies (4.4) and proves the theorem. □

For anterpolation with respect to the ϕ variable, we also need the following lemma.

LEMMA 4.2. *Let U_1, U_2, and U_3 be trigonometric polynomials of one variable with*

$$Degree(U_1) = N \geq Degree(U_3) = M.$$

Assume that $\overline{U_2}U_3$ can be approximated with sufficient accuracy by a trigonometric polynomial V, i.e., $\overline{U_2}U_3 \simeq V$, with $Degree(V) = N$, and U_1, V, and U_3 are all of the even kind. Then

$$\int_{-\pi}^{\pi} U_1(t)U_2(t)\overline{U_3(t)}dt \simeq \int_{-\pi}^{\pi} W(t)\overline{U_3(t)}dt,$$

where $W = Anterp(S, M)$ and S is the trigonometric polynomial with $Sample(S)(n) = U_1(t_n)U_2(t_n), t_n = n\pi/N$ for $-N \leq n \leq N-1$.

Proof. Let $a = Coef(U_3)$, $b = Coef(S)$, and $t_n = n\pi/N$ for $-N \leq n \leq N-1$. Reasoning as in Lemma 3.3 with the trigonometric polynomials U and V of one variable, we get

$$\begin{aligned}
&\int_{-\pi}^{\pi} U_1(t)U_2(t)\overline{U_3(t)}dt \simeq \int_{-\pi}^{\pi} U_1(t)\overline{V(t)}dt \\
&= \frac{2\pi}{2N}\sum_{n=-N}^{N-1} U_1(t_n)\overline{V(t_n)} \simeq \frac{\pi}{N}\sum_{n=-N}^{N-1} S(t_n)\overline{U_3(t_n)} = 2\pi\sum_{n=-N}^{N-1} b(n)\overline{a(n)} \\
&= 2\pi\sum_{m=-M}^{M-1} b(n)\overline{a(n)} = \int_{-\pi}^{\pi} W(t)\overline{U_3(t)}dt,
\end{aligned}$$

which completes the proof of the lemma. □

5. Translation from a far field to a local field.

We begin with a short review of the derivation of the fundamental translation formula from a far field to a local field; see, e.g., [1], [3]. This formula is the key step in the two-level and multilevel (nonstatic) fast multipole methods.

We start with the well-known expansion for the 3-D Helmholtz kernel $e^{ik|x|}/(4\pi|x|)$ in terms of incoming multipoles (e.g., see [3, p. 80]),

$$\frac{e^{ik|p+x|}}{4\pi|p+x|} = \sum_{n=0}^{\infty} a_n j_n(k|x|)P_n\left(\frac{p}{|p|}\cdot\frac{x}{|x|}\right), \tag{5.1}$$

where

$$a_n = \frac{ik}{4\pi}(-1)^n(2n+1)h_n^{(1)}(k|p|),$$

$h_n^{(1)}$ is a spherical Hankel function of the first kind, j_n is a spherical Bessel function, and P_n is the Legendre polynomial of order n. The series converges absolutely and uniformly for $|x| \leq r$ with any fixed $r < |p|$. If we truncate the series at $n = L$ and use the identity (e.g., see [9, p. 31])

$$\int_{|z|=1} e^{ikz\cdot x}P_n\left(\frac{p}{|p|}\cdot z\right)dz = 4\pi i^n j_n(k|x|)P_n\left(\frac{p}{|p|}\cdot\frac{x}{|x|}\right),$$

we get

$$\sum_{n=0}^{L} a_n j_n(k|x|) P_n\left(\frac{p}{|p|}\cdot\frac{x}{|x|}\right) = \int_{|z|=1} \frac{1}{4\pi} T_L\left(k|p|, \frac{p}{|p|}\cdot z\right) e^{ikx\cdot z} dz, \tag{5.2}$$

where the surface integral is over the unit sphere and

$$T_L\left(k|p|, \frac{p}{|p|}\cdot z\right) = \frac{k}{4\pi}\sum_{n=0}^{L}(2n+1) i^{n+1} h_n^{(1)}(k|p|) P_n\left(\frac{p}{|p|}\cdot z\right), \tag{5.3}$$

where and T_L is the Rokhlin translation function (see [1]).

Now, consider a source distribution $\rho(y)$, $y \in \mathbb{R}^3$, with $\rho(y) = 0$ outside of a bounded domain $D \subset \mathbb{R}^3$. Let

$$F(x) = \frac{1}{4\pi}\int_D \frac{e^{ik|x-y|}}{|x-y|}\rho(y)dy, \quad x \in \mathbb{R}^3, \tag{5.4}$$

be the scalar field due to this source, where k is the wave number. Suppose $D \subset \{z \in \mathbb{R}^3;\ |z| < R\}$ and $p \in \mathbb{R}^3$ with $R < |p|$.

The expansion (5.1), when applied to $x - y$ instead of x, allows us to expand $F(p + x)$ locally at the point p for all $x, |x| < r$, with any $r < |p| - R$:

$$F(p+x) = \int_D \left[\sum_{n=0}^{\infty} a_n j_n(k|x-y|) P_n\left(\frac{p}{|p|}\cdot\frac{(x-y)}{|x-y|}\right)\right]\rho(y)dy. \tag{5.5}$$

If we truncate the series in (5.5) at $n = L$, $F(p + x)$ will be approximated, the more accurately the larger L is, by the integral

$$\begin{aligned} F(p+x) &\simeq \int_D \left[\sum_{n=0}^{L} a_n j_n(k|x-y|) P_n\left(\frac{p}{|p|}\cdot\frac{(x-y)}{|x-y|}\right)\right]\rho(y)dy \\ &= \int_{|z|=1}\left[\frac{1}{4\pi}\int_D e^{-iky\cdot z}\rho(y)dy\right] T_L\left(k|p|, \frac{p}{|p|}\cdot z\right) e^{ikx\cdot z}dz, \end{aligned} \tag{5.6}$$

where we have applied (5.2) to $x-y$ instead of x and changed the order of integration. The obtained result is the wanted translation formula,

$$F(p+x) \simeq \int_{|z|=1} U_\infty(z) T_L\left(k|p|, \frac{p}{|p|}\cdot z\right) e^{ikx\cdot z}dz, \tag{5.7}$$

where

$$U_\infty(z) = \frac{1}{4\pi}\int_D e^{-iky\cdot z}\rho(y)dy, \quad |z| = 1, \tag{5.8}$$

is the far field due to the source distribution ρ.

Usually for the interpolation and anterpolation in MLFMA, the integral in (5.7) is thought to be evaluated by expanding $U_\infty(z)e^{ikx\cdot z}$ in spherical harmonics. It can be shown that an L, the degree of T_L, which makes (5.7) accurate is also a sufficient number of terms needed in the truncated series expansion of $U_\infty(z)e^{ikx\cdot z}$ to make it accurately estimate $U_\infty(z)e^{ikx\cdot z}$ for all x with $|x| \le r$. In practice, this estimation is done by simply representing $U_\infty(z)$ and $e^{ikx\cdot z}$ by their sample matrices. Because the spherical harmonics are orthogonal with respect to the scalar product induced by the integral over the unit sphere, the usual strategy for interpolation and anterpolation follows.

Because we have expanded U_∞ and $e^{ikx\cdot z}$ in trigonometric polynomials, we need to change the integration in (5.7) over the parameter square $-\pi \le \theta \le \pi, -\pi \le \phi \le \pi$ for the spherical coordinates θ and ϕ, because the terms $e^{i(m\theta+n\phi)}$ are orthogonal functions only with respect to scalar product induced by the integral over that square.

For making the needed change in the integral in (5.7), note that all functions involved are smooth on the unit sphere, and in the spherical coordinates they can be extended to be 2π-periodic in both θ and ϕ for all $\theta, \phi \in \mathbb{R}$. We obtain

$$(5.9) \quad \int_{|z|=1} U_\infty(z)T_L(z)e^{ikx\cdot z}dz = \int_{-\pi}^{\pi}\left[\int_0^{\pi} U_\infty(\theta,\phi)T_L(\theta,\phi)e^{ikx\cdot z(\theta,\phi)}\sin\theta\,d\theta\right]d\phi$$
$$= \frac{1}{2}\int_{-\pi}^{\pi}\int_{-\pi}^{\pi} U_\infty(\theta,\phi)T_L(\theta,\phi)e^{ikx\cdot z(\theta,\phi)}|\sin\theta|d\theta d\phi,$$

where $z(\theta,\phi) = (\sin\theta\cos\phi, \sin\theta\sin\phi, \cos\theta)$, $U_\infty(\theta,\phi) = U_\infty(z(\theta,\phi))$, and $T_L(\theta,\phi) = T_L(z(\theta,\phi))$. Above, we have also used the fact that for a spherical function $v(\theta,\phi)$ we get

$$\int_{-\pi}^{\pi}\left[\int_{-\pi}^{0} v(\theta,\phi)|\sin\theta|d\theta\right]d\phi = \int_{-\pi}^{\pi}\left[\int_0^{\pi} v(\theta,\phi+\pi)|\sin\theta|d\theta\right]d\phi$$
$$= \int_{-\pi}^{\pi}\left[\int_0^{\pi} v(\theta,\phi)|\sin\theta|d\theta\right]d\phi,$$

because $v(-\theta,\phi) = v(\theta,\phi+\pi)$ and $v(\theta,\phi)$ is 2π-periodic in ϕ.

Note that in the right-hand side of (5.9) in the integral there is $|\sin\theta|$, which is not a smooth function at $\theta = 0$. This prevents us from approximating it in a numerically efficient way by sampling and using a trigonometric polynomial. In fact, this problem arises only in the variable θ and in the anterpolation in the disaggregation steps. However, the Fourier series of $|\sin\theta|$ is well known, and it can be directly used with the anterpolation Theorem 4.1 for implementing an efficient anterpolation strategy in the variable θ.

6. Aggregation and disaggregation steps in MLFMA. In this section, we consider the tree-like data structure of MLFMA in three dimensions by using FFT in the interpolation and anterpolation operations. The data structure is constructed in aggregation and disaggregation iteration steps.

In the aggregation iteration steps we construct the far field representations for each level. At every level M we choose an appropriate sampling rate (N, N') so that the far field is represented by a $(2N+1, 2N')$-sample matrix with a desired accuracy. Because the matrix is spherical, only a $(2N+1, N'+1)$-matrix must be stored.

Also we choose the order L for the translation function T_L for the level M. The order L can be chosen, for instance, as suggested in [3]. The sampling rate (N, N') could be taken so that $N = N' = L+1$, as is the usual choice with the spherical harmonics, or N and N' could, possibly, be chosen more economically. The optimal, accuracy-dependent values for N and N' can be numerically searched and pretabulated; see the numerical example in the next section.

After these choices, the aggregation step from level $M+1$ to level M will be performed. Let Q be a cube on level M, and let (N_1, N_1') and (N_2, N_2') be the sampling rates for levels $M+1$ and M, respectively. Let $Q_1, \ldots, Q_r$ be the level $M+1$ nonempty subcubes of Q, q_j the vector from the center of Q to that of Q_j, and U_j the trigonometric polynomial approximating the far field due to sources in Q_j and represented by the $(2N_1+1, 2N_1')$-matrix $u_j = \mathit{Sample}(U_j)$. The far field corresponding to Q is approximated by

$$U(z) = \sum_{j=1}^{r} e^{-ikq_j \cdot z} U_j(z), \quad |z| = 1,$$

and that is approximated by a trigonometric polynomial U_∞ with a sample matrix $u_\infty = \mathit{Sample}(U_\infty)$. The matrix u_∞ is formed by interpolating and shifting as follows,

$$u_\infty(m,n) = \sum_{j=1}^{r} v_j(m,n) w_j(m,n), \tag{6.1}$$

where $w_j = \mathit{Interp}(\mathit{Sample}(U_j), N_2, N_2')$, and v_j is the sample matrix

$$v_j(m,n) = e^{-ikq_j \cdot z(\theta_m, \phi_n)},$$

where $\theta_m = m\frac{2\pi}{(2N_2+1)}$, $-N_2 \le m \le N_2$, and $\phi_n = n\frac{\pi}{N_2'}$, $-N_2' \le n \le N_2' - 1$. The matrix u_∞ is saved, and the aggregation iteration step is completed.

For the disaggregation step from level $M-1$ to M, we consider a cube Q on level M. Let $M < M_{\max}$. Our aim is to form the amplitude field V of the incoming field due to sources outside both Q and its immediate level M neighbor cubes.

The field V is divided into two parts: $V = V_1 + V_2$.

The *interaction list* of Q is defined to be the list of those level M subcubes that are neither Q itself nor its immediate neighbors but are contained in the immediate level $M-1$ neighbor cubes of the parental cube P of Q. The field V_1 is due to the sources in the subcubes of the interaction list of Q. The field V_2 is due to sources outside P and its immediate $M-1$ level neighbor cubes.

First consider V_1. Let Q_j be a cube in the interaction list of Q. The field F due to sources in Q_j is represented as a far field U_∞, with origin at the center c_j of Q_j. Let U_∞ have been stored as a sample matrix u_∞ sampled with the level M sampling rate (N_1, N_1'). We need to translate F to be an incoming field in Q and to form its amplitude field. Let $T_L(z) = T_L(k|p|, \frac{p}{|p|} \cdot z)$ be the translation function from Q_j to Q with p being the vector from the center c_j of Q_j to that of Q. For convenience, we may assume that $c_j = 0$. Due to (5.7) and (5.9),

$$F(p+x) \simeq \frac{1}{2} \int_{-\pi}^{\pi} \left(\int_{-\pi}^{\pi} U_\infty(\theta,\phi) T_L(\theta,\phi) e^{ikx\cdot z(\theta,\phi)} d\phi \right) |\sin\theta| d\theta. \tag{6.2}$$

We first treat the integration with respect to ϕ. Due to the proper choice of L, the function $U_\infty(\theta,\phi)e^{ikx\cdot z(\theta,\phi)}$, with $p+x$ in Q, can be approximated by a spherical harmonics expansion of degree L which is also a trigonometric polynomial of degree $(L, L+1)$, and the function $e^{-ikx\cdot z(\theta,\phi)}$ can be approximated by a trigonometric polynomial of degree (N_1, N_1'). By applying Lemma 4.2 to the ϕ-integration with $T_L = U_1$, $U_\infty = U_2$, and $e^{-ikx\cdot z} \simeq U_3$, we get, after changing the order of integration,

$$F(p+x) \simeq \frac{1}{2} \int_{-\pi}^{\pi} \left(\int_{-\pi}^{\pi} W(\theta,\phi) |\sin\theta| e^{ikx\cdot z(\theta,\phi)} d\theta \right) d\phi, \tag{6.3}$$

where $W(\theta,\phi)$ is the trigonometric polynomial formed from the sample matrix $s(n) = U_\infty(\theta,\phi_n)T_L(\theta,\phi_n)$, $\phi_n = n\pi/(L+1)$, $-L-1 \leq n \leq L$, by anterpolating s in the ϕ-variable from degree $L+1$ to N_1', as Lemma 4.2 states. Accordingly, $\mathit{Degree}(W) = (N_1+L, N_1')$, because $\mathit{Degree}(U_\infty T_L) = (N_1+L, N_1'+L+1)$.

In practice, we form $w = \mathit{Sample}(W)$ as follows. Start with sample matrices u_∞ and $\mathit{Sample}(T_L)$ and interpolate both of them to sampling rate $(N_1+L, L+1)$. Thereafter, multiply them with each other, element by element, to get a matrix s, and anterpolate that in the ϕ-variable, i.e., rowwise, to degree (N_1+L, N_1'), to get w.

Next we treat the integration with respect to θ in (6.3). Because $e^{ikx\cdot z(\theta,\phi_n)}$ can be approximated in θ by a trigonometric polynomial of degree N_1, we can anterpolate $\frac{1}{2}W(\theta,\phi_n)|\sin\theta|$ down to degree N_1 without changing the value of the integral within the desired accuracy. This anterpolation in θ is carried out in four steps as Theorem 4.1 describes. First, interpolate $\frac{1}{2}\mathit{Sample}(W) = \frac{1}{2}w$ in θ, i.e., columnwise, from sampling rate (N_1+L, N_1) to $(2N_1+L, N_1)$ and get the sample matrix u_1. Then anterpolate $|\sin\theta|$ down to degree $2N_1+L$ as follows: truncate the series expansion

$$(6.4) \qquad |\sin\theta| = \sum_{m=-\infty}^{\infty} a_m e^{im\theta}, \qquad a_m = \begin{cases} \frac{2}{\pi}\frac{1}{1-m^2} & \text{if } m \text{ is even,} \\ 0 & \text{if } m \text{ is odd,} \end{cases}$$

by summing m only from $-2N_1-L$ to $2N_1+L$; get a trigonometric polynomial S of order $2N_1+L$; and let $u_2 = \mathit{Sample}(S)$. Next multiply the columns of u_1 by u_2, element by element, and get u_3, i.e., $u_3(m,n) = u_1(m,n)u_2(m)$, for $-2N_1-L \leq m \leq 2N_1+L$ and $-N_1' \leq n \leq N_1'-1$. Thereafter, anterpolate u_3 in θ, i.e., columnwise, from degree $(2N_1+L, N_1')$ to (N_1, N_1'), and get the sample matrix v_{Q_j}. The trigonometric polynomial V_{Q_j}, with $\mathit{Sample}(V_{Q_j}) = v_{Q_j}$, is the wanted amplitude field, i.e.,

$$(6.5) \qquad F(p+x) \simeq \int_{-\pi}^{\pi}\int_{-\pi}^{\pi} V_{Q_j}(\theta,\phi)e^{ikx\cdot z(\theta,\phi)}d\theta d\phi$$

for $p+x$ in Q. Finally, sum up v_{Q_j} over the subcubes Q_j in the interaction list of Q, and get v_1 so that the trigonometric polynomial V_1, with $\mathit{Sample}(V_1) = v_1$, is the wanted joint amplitude field.

Note that, in practice, there is a more economical order of operations for forming the needed v_1. Namely, form the above sample matrices s of the products $U_\infty T_L$ for each Q_j and sum them up; anterpolate the sum matrix u_1 rowwise and, thereafter, columnwise interpolate it to get u_3; and multiply it by u_2 and anterpolate the product as explained above. Also in practice, we can take the θ-direction sizes of the matrices s, u_3 and the length of vector u_2 to be smaller than the above theoretical upper bounds are, as the example in the next section shows. This seems to be due to the fact that, in practice, the anterpolated $|\sin\theta|$ increases the degree of $U_\infty T_L|\sin\theta|$ less than Theorem 4.1 suggests.

Next we treat the amplitude field V_2 due to sources outside P and its immediate level $M-1$ neighbor cubes. In the previous iteration step this amplitude field is already formed with origin at the center c' of P and stored as a sample matrix, say w, sampled with the level $M-1$ sampling rate (N_2, N_2'). We shift the origin from c' to the center c of Q, and obtain an incoming field in Q of the form

$$(6.6) \qquad \begin{aligned} F(x) &= \int_{-\pi}^{\pi}\int_{-\pi}^{\pi} W(\theta,\phi)e^{ik(p+x)\cdot z(\theta,\phi)}d\theta\, d\phi \\ &= \int_{-\pi}^{\pi}\int_{-\pi}^{\pi} W(\theta,\phi)e^{ikp\cdot z(\theta,\phi)}e^{ikx\cdot z(\theta,\phi)}d\theta\, d\phi \end{aligned}$$

for $c + x$ in Q with $p = c - c'$ and W being the trigonometric polynomial with $\mathit{Sample}(W) = w$. Next apply an obvious two variable version of Lemma 4.2. Because $e^{-ik(p+x)\cdot z}$ and $e^{-ikx\cdot z}$, with $c+x$ in Q, can be approximated with trigonometric polynomials of degrees (N_2, N_2') and (N_1, N_1'), respectively, we can reason that, without changing the value of the integral (6.6) within the desired accuracy, $We^{ikp\cdot z}$ in the right-hand side of (6.6) can be replaced by a trigonometric polynomial V_2, which is obtained by anterpolating S from degree (N_2, N_2') to (N_1, N_1') with

$$\mathit{Sample}(S)(m,n) = s(m,n) = w(m,n)e^{ikp\cdot z(\theta_m,\phi_n)}, \tag{6.7}$$

$\theta_m = m2\pi/(2N_2+1)$, $-N_2 \le m \le N_2$, $\phi_n = n\pi/N_2'$, $-N_2' \le n \le N_2' - 1$. This V_2 is the wanted amplitude field. Thus, in practice, we only form the sample matrix s in (6.7), anterpolate that from degree (N_2, N_2') to (N_1, N_1'), and get the wanted $v_2 = \mathit{Sample}(V_2)$.

Finally, let $V = V_1 + V_2$, and store $v = v_1 + v_2 = \mathit{Sample}(V)$. The disaggregation iteration step from level $M - 1$ to level M is completed.

After having completed the last disaggregation step from level $M_{\max} - 1$ to $M_{\max}$, we want to compute the final incoming field F for any level $M_{\max}$ cube Q due to sources outside Q and its immediate level $M_{\max}$ neighbors. This field we get from the amplitude field V, corresponding to Q, by Lemma 3.3,

$$\begin{aligned} F(c+x) &\simeq \int_{-\pi}^{\pi}\int_{-\pi}^{\pi} V(\theta,\phi)e^{ikx\cdot z(\theta,\phi)}d\theta d\phi \\ &\simeq \frac{4\pi^2}{(2N+1)N'}\left[\sum_{n=0}^{N'-1} v(0,n)e^{ikx\cdot z(0,\phi_n)} + \sum_{m=1}^{N}\sum_{n=-N'}^{N'-1} v(m,n)e^{ikx\cdot z(\theta_m,\phi_n)}\right], \end{aligned} \tag{6.8}$$

where c is the center of Q, $v = \mathit{Sample}(V)$, and $\theta_m = m2\pi/(2N+1)$, $-N \le m \le N$, $\phi_n = n\pi/N'$, $-N' \le n \le N' - 1$, because $e^{-ikx\cdot z(\theta,\phi)}$ can be approximated by a trigonometric polynomial of degree (N, N'), which is the level $M_{\max}$ sampling rate.

7. A numerical example and comparisons. We present a numerical example where the method of this paper for interpolation, anterpolation, and integrating the fields, here called the *DFT method*, is tested and compared with the usual method of using polynomial interpolation, spherical harmonics, and Gaussian integration for the same operations, here called the *filter method*; see [6], [3].

In the example we simulate the main operations of the aggregation and disaggregation steps by setting a distributed source into a cube Q corresponding to a division cube on the level $M = M_{\max} - m$ for $m = 1, 2, \ldots, 5$. We interpolate and shift the associated far fields from the level $M+1$ subcubes of Q into Q, translate the resulting field into a local field in a nonimmediate neighbor P of Q, anterpolate that local field into a level $M+1$ subcube of P, and compare the obtained field to its exact value. This procedure is carried out with both the DFT and filter methods, using in the latter case both 4 × 4 and 6 × 6 Lagrangian interpolation stencils. Finally, we compare the computational costs of the three simulations at given accuracy levels. Our numerical example illustrates the numerical efficiencies of the compared methods in MLFMA with six or fewer levels.

We normalize the wave number $k = 1$. We consider a cube Q on the level $M = M_{\max} - m, m = 1, 2, \ldots, 5$, with the center at the origin, with vertices

$$R_{r_1,r_2,r_3} = 2^m\pi(r_1,r_2,r_3), \quad r_j = \pm\frac{1}{2}, j = 1,2,3, \tag{7.1}$$

and with the side length $s_m = 2^m\pi$, and its nonimmediate neighbor cube P on the same level M with vertices $2s_m(1,0,0) + R_{r_1,r_2,r_3}$, $r_j = \pm\frac{1}{2}, j = 1,2,3$. Accordingly, $s_m = 2^m\lambda/2$ with the wave length $\lambda = 2\pi$ for $k = 1$.

The source is chosen to be the constant planar source density $\rho = 4\pi$ on the diagonal square A,

$$A = \left\{(x_1, x_2, x_3)\epsilon\mathbb{R}^3;\ -\frac{s_m}{2} \le x_1, x_2 \le \frac{s_m}{2},\ x_3 = x_1\right\}. \tag{7.2}$$

The cube Q is divided into eight level $M+1$ subcubes, and those four subcubes containing the source are enumerated $Q_1, \dots, Q_4$. The far field U_j due to the source distribution in Q_j is computed by (5.8) using a 5×5 Gaussian integration grid over the subsquares of A. In fact, this numerical integral is the actual far field U_j in our example. It is accurately sampled with $N_1 + 1$ points in the θ-direction and $2N_1$ points in the ϕ-direction, both uniformly spaced, for the DFT method, and with $L+1$ Gaussian points in the θ-direction and $2(L+1)$ uniformly spaced points in the ϕ-direction for the filter method. The far field U_∞ due to the source ρ in Q is computed by the formula

$$U_\infty = \sum_{j=1}^{4} e^{-ikq_j\cdot z} U_j, \tag{7.3}$$

where q_j is the vector from the center of Q to that of Q_j. The far fields U_j, by using the sample matrices u_j, are approximated by trigonometric polynomials in the DFT method, and by spherical harmonics in the filter method. The far field U_∞ is approximated by a sample matrix u_∞, by sampling U_∞ in a denser level M grid so that the shift function $e^{-ikq_j\cdot z}$ is directly sampled in that denser grid and each u_j is interpolated into that grid.

For the DFT method our example proceeds as follows. On each level M, we choose the degree $L \ge N_1$ for the translation function T_L and take the denser grid to be an $(N_2+1) \times 2(L+1)$ grid with $N_2 \ge L$. Thereafter, T_L is sampled in that grid. Additionally, u_∞ is formed in that grid by DFT interpolation and shifting. The element-by-element product of the two sample matrices is formed, and its columns are multiplied by the sample vector of $\frac{1}{2}Anterp(|\sin\theta|, N_2)$. The obtained local field in the cube P is shifted and DFT anterpolated down to degree (N_1, N_1) into a level $M+1$ subcube P_1 of P with center $c+q$, where $c = 2s_m(1,0,0)$ is the center of P and $q = s_m/4(-1,1,1)$. Finally, the local field in P_1 is integrated using (6.8), the obtained field is compared to the exact field, and an average relative error E_{DFT} in P_1 is computed.

For illustrating the efficiency of the DFT method, for each accuracy level $10^{-p}, p = 1,2,3$, we choose the smallest L, N_1, and N_2 so that $E_{DFT} \le 10^{-p}$. We also estimate the computational cost of the entire procedure in the example with the DFT method for each MLFMA level M and accuracy level p. The cost is estimated by counting the number of scalar multiplications and using the cost $n\log_2 n$ for the FFT of a vector with length n. The results are presented in Table 7.1.

The filter method is treated in our example as follows. For each level $M = M_{\max} - m$, $m = 1, 2, \dots, 5$, an optimal degree L_M for the translation function T_L is chosen in a way explained later. On the level M the sample matrix u_∞ is formed in the grid $(L_M + 1) \times 2L_M$ from the level $M+1$ sample matrices u_j by the polynomial interpolation and shifting using both the 4-points and 6-points Lagrangian interpolation in the ϕ- and θ-directions. The function T_L with $L = L_M$ is sampled in the same grid and multiplied,

Table 7.1

Comparison of the computational costs of the DFT method and the filter method with stencil sizes 4×4 and 6×6; here $p = 1, 2, 3$ refers to accuracy level 10^{-p}.

		DFT				4×4 stencil		6×6 stencil	
M	p	L	N_1	N_2	cost/10^3	L	cost/10^3	L	cost/10^3
$M_{\max} - 1$	1	8	5	8	7.1	11	12.1	8	10.0
	2	9	5	11	9.8			14	28.6
	3	13	7	19	24.6				
$M_{\max} - 2$	1	15	7	14	22.1	23	44.9	16	33.5
	2	18	9	21	40.5			27	92.6
	3	20	10	28	58.7				
$M_{\max} - 3$	1	27	12	27	82.1	31	89.2	28	96.3
	2	34	15	35	138			42	215
	3	37	17	49	206				
$M_{\max} - 4$	1	46	20	46	261	61	288	60	386
	2	60	24	60	444			79	684
	3	65	27	76	607				
$M_{\max} - 5$	1	105	37	104	1394	110	932	120	1522
	2	121	44	119	1917			137	2063
	3	130	48	135	2351				

element by element, by u_∞. The local field in P is shifted and anterpolated into the subcube P_1 of P; the anterpolation is carried out as an adjoint operation of the polynomial interpolation from the $(L_{M+1} + 1) \times 2L_{M+1}$ grid to the $(L_M + 1) \times 2L_M$ grid. Finally, the resulting local field in P_1 is computed, and the relative errors $E_{4\times4}$ and $E_{6\times6}$ in P_1 are computed for both stencil sizes.

For illustrating the efficiency of the filter method, for each accuracy level 10^{-p}, $p = 1, 2, 3$, and for each $n \times n$ stencil, $n = 4, 6$, we choose the smallest degrees L_M for $M = M_{\max} - m, m = 1, 2, \ldots, 5$, so that the relative error $E_{n\times n} \leq 10^{-p}$ on each level M. It turns out that this is possible for the 4×4 stencil only for $p = 1$, and for the 6×6 stencil only for $p = 1, 2$; higher accuracy levels for these stencil sizes cannot be reached. Finally, the computational cost for the entire procedure with the filter method is estimated. The cost on the level M for the interpolation, as well as for anterpolation, is about $2n(L_{M+1} + L_M)(L_M + 1)$ for an $n \times n$ stencil when the interpolation is performed first columnwise and then rowwise. The results for both stencil sizes are presented in Table 7.1.

Table 7.1 shows that the computational cost is lowest for the DFT method but roughly of the same order for all three methods. Higher accuracy is reached in the DFT method by only increasing the sample rate, while in the filter method increasing the stencil size is also needed.

The lower cost with the DFT method is due to the fact that the same accuracy level is reached in the DFT method with smaller sampling rates than in the filter method. This mainly follows from the fact that in the filter method for interpolation and anterpolation an oversampling by a factor of 2 is needed [10]; also the filter method, because of the Lagrangian interpolation, is more sensitive to sampling noise than the DFT method.

There is also another point of view on smaller sampling rates. Usually in MLFMA more than half of the computational cost arises from translating outgoing fields into local fields in the disaggregation steps. The cost of this operation for a cube Q depends on the size of the sample matrices for $u_\infty T_L$ and on the length of the interaction list of Q, which may vary from about 20 to 189. In Table 7.1 these matrix sizes are $(N_2+1)\times 2(L+1)$ for the DFT method, and $(L+1)\times 2(L+1)$, with a different L, for the filter method. We see that those sizes are about 2 times larger for the filter methods, and accordingly our example suggests that the DFT method is, altogether, about 1.5 to 2 times more efficient than the filter method, at least for MLFMA with six or fewer levels.

8. Conclusions. A new method is presented for using FFT in interpolation and anterpolation in a 3-D MLFMA. The associated far fields and the amplitude fields of the plane wave expansions of the local fields on the 3-D unit sphere are extended to be 2π-periodic in both the spherical coordinates θ and ϕ. This enables as effective a field presentation in terms of trigonometric polynomials as the usual presentation in the terms of spherical harmonics. Furthermore, with the trigonometric polynomials and DFT, an effective and exact procedure for interpolation and anterpolation, together with field computing, can be facilitated, whereas these operations can be performed only approximately when using spherical harmonics and polynomial interpolation. In a numerical example, the proposed new method is compared to the usual method employing spherical harmonics and polynomial interpolation in 3-D MLFMA. The comparison shows that the proposed new method is about from 1.5 to 2 times more efficient, at least for MLFMA with six or fewer levels.

Acknowledgments. The main part of this paper was written during the author's sabbatical visit in 1999–2000 to the Center for Computational Electromagnetics at the University of Illinois at Urbana-Champaign. The author greatly thanks Prof. Weng Chew and Dr. Jiming Song for valuable discussions and comments. Warm thanks are also due to Prof. Eric Michielssen and Dr. Sanjay Velamparambil for helpful discussions.

MULTILEVEL FIRST-ORDER SYSTEM LEAST SQUARES FOR NONLINEAR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS[*]

A. L. CODD[†], T. A. MANTEUFFEL[‡], AND S. F. MCCORMICK[‡]

Abstract. A fully variational approach is developed for solving nonlinear elliptic equations that enables accurate discretization and fast solution methods. The equations are converted to a first-order system that is then linearized via Newton's method. First-order system least squares (FOSLS) is used to formulate and discretize the Newton step, and the resulting matrix equation is solved using algebraic multigrid (AMG). The approach is coupled with nested iteration to provide an accurate initial guess for finer levels using coarse-level computation. A general theory is developed that confirms the usual full multigrid efficiency: accuracy comparable to the finest-level discretization is achieved at a cost proportional to the number of finest-level degrees of freedom. In a companion paper, the theory is applied to elliptic grid generation (EGG) and supported by numerical results.

Key words. least-squares discretization, multigrid, nonlinear elliptic boundary value problems

1. Introduction.

We develop a theoretical foundation for a method for solving nonlinear elliptic equations that combines first-order system least squares (FOSLS) with Newton's method, algebraic multigrid (AMG), and nested iteration (NI). The algorithm achieves accuracy comparable to the finest-level discretization at a cost proportional to the number of finest-level degrees of freedom. In a companion paper [17], we apply this theory to the elliptic grid generation (EGG) equations and numerically validate the theory established below.

Our development assumes that the target problem is a first-order system whose associated least-squares functional applied to functions in $H^{1+\delta}$, $\delta \in (0,1)$, has quadratic part that is equivalent to the product H^1 norm. Higher-order differential systems can be recast in the standard way as a first-order system, but care must be taken to ensure such product ellipticity when it is feasible (cf. [15, 14]). Our particular interest is in quasilinear first-order systems where the nonlinearity is a product of variables, of which at most one is a derivative term. For example, if u and v are the variables in a two-dimensional problem, then we admit terms like u, v, u^2u_x, and uvv_y, but not uu_x^2. (Admitting product derivative terms while retaining $H^{1+\delta}$ spaces for the variables would prevent the use of L^2 norms for the equations and inhibit analysis of the linearized equations.)

Our algorithm applies to the first-order system in three separate stages. The outermost stage is NI, which starts on the coarsest level where the discrete nonlinear problem is solved by any appropriate method. The result is then interpolated to the

next finer level, where it is used as an initial guess for *one* Newton linearization (the middle stage) of the nonlinear problem. A functional is created on that level using a least-squares principle, and the resulting matrix equation is solved using *one, two, or three* V-cycles of AMG (the innermost stage). The result is then interpolated up to the next finer level, with the steps repeated until the finest level is processed. Our theoretical results confirm that this *direct* NI-Newton-FOSLS-AMG scheme converges in *one* overall step to an approximation on the finest level that is accurate to *the level of discretization error*. Numerical experiments for the EGG equations, described in a companion paper [17], confirm this result.

One advantage that the FOSLS system has over standard minimization techniques is that the minimum value of the functional is zero at the exact solution of the differential equation. This property has implications for adaptive refinement that are to be explored in future work. Another advantage is that FOSLS used with finite element discretization and Newton linearization of the elliptic equations results in self-adjoint positive-definite matrix problems that themselves correspond to a well-posed elliptic system, so the discrete problems can be efficiently solved by multigrid. We demonstrate this attribute qualitatively in the theory here and numerically in the companion paper.

The idea of using Newton iterations coupled with a multilevel scheme is not new. In [20], for example, a multilevel nested iteration Newton scheme was applied to differential eigenproblems. An abstract theory and numerical results confirmed the need for only one Newton step on the finest level. In [5], optimal parameters were calculated for the damped approximate Newton's method to ensure quadratic convergence of a particular finite element approximation of nonlinear elliptic partial differential equations. This was later combined with multilevel techniques [6] to obtain a convergence result that asymptotically required just one Newton linearization per level. This last result is similar to ours but does not include the derivative terms in the nonlinearity that are present in our target application, EGG. The NI approach is also used in recent work on cascadic multigrid [22], although again their form of the nonlinearity does not include the more complicated case needed here.

The "mesh-independence" theory developed for Newton's method in [21, 4, 3, 2] addresses the same property of NI that we exploit here. Unfortunately, this theory cannot easily be applied to our setting because it requires more smoothness of the infinite-dimensional iterates than ours appear to possess. We are also unable to apply the mesh-independence-based theory developed in [18, 19] because the nonlinearity for the Navier–Stokes equations treated there appears only in the lower-order terms.

This paper is organized as follows. Section 2 introduces the equations and function spaces. In section 3, we describe the NI-Newton-FOSLS method for solving the nonlinear equations. Section 4 contains theory on convergence of the Newton iterates in H^1 and on accuracy estimates for the NI-Newton-FOSLS-AMG scheme. We conclude with some remarks in the final section.

2. Setup. We use standard notation for the associated spaces. Restricting ourselves to two dimensions, consider a generic open domain, $\Omega \in R^2$, with Lipschitz boundary Γ. Suppose $m \geq 0$ and $n \geq 1$ are given integers. Let $(\cdot,\cdot)_{0,\Omega}$ denote the inner product on $L^2(\Omega)^n$, $\|\cdot\|_{0,\Omega}$ its induced norm, and $H^m(\Omega)^n$ the standard Sobolev space with norm $\|\cdot\|_{m,\Omega}$ and seminorms $|\cdot|_{i,\Omega}$ $(0 \leq i \leq m)$. (We suppress superscript n, because dependence of the vector norms on dimension is clear by context.) For $\delta \in (0,1)$, let $H^{m+\delta}(\Omega)$ (cf. [11]) denote the Sobolev space associated with the norm defined by

$$\|u\|^2_{m+\delta,\Omega} \equiv \|u\|^2_{m,\Omega} + \sum_{|\alpha|=m} \int_\Omega \int_\Omega \frac{|\partial_\alpha u(x) - \partial_\alpha u(y)|^2}{|x-y|^{2(1+\delta)}} dxdy.$$

(This definition allows the use of the "real interpolation" method [1, 11].) Also, let $H^{\frac{1}{2}}(\Gamma)$ denote the trace Sobolev space associated with the norm

$$\|u\|_{\frac{1}{2},\Gamma} \equiv \inf\{\|v\|_{1,\Omega} : v \in H^1(\Omega), \text{ trace } v = u \text{ on } \Gamma\}.$$

Finally, let $C^m(\Omega)$ denote the space of functions with continuous derivatives in Ω of up to order $m \geq 0$, and define the $C^0(\Omega)$ norm of $f \in C^0(\Omega)$ by

$$\|f\|_{\infty,\Omega} \equiv \sup_{x \in \Omega} |f(x)|.$$

From Sobolev's lemma [1], there exists a constant C, depending only on Ω and δ, such that

$$\|f\|_{\infty,\Omega} \leq C\|f\|_{1+\delta,\Omega} \qquad \forall\ f \in H^{1+\delta}(\Omega).$$

The method we develop applies to elliptic quasi-linear partial differential equations, where the highest-order derivative terms appear linearly, with the exception that their coefficients may include lower-order terms. In fact, we assume that the equations have been formulated as a $p \times q$ first-order system with appropriate boundary conditions. It is straightforward to rewrite higher-order equations in first-order form, although care must be taken to ensure that the resulting system is elliptic in the H^1 product norm (assuming that this is even feasible; cf. [15, 14]). This process is exemplified by the reformulation of the EGG equations in the companion paper [17].

Let the first-order system be represented abstractly by the p-vector equation

$$\mathbf{p}(\mathbf{J}) = \mathbf{0} \qquad \text{in} \quad \Omega, \tag{2.1}$$

with boundary conditions

$$\mathbf{BJ} = \mathbf{g} \qquad \text{on} \quad \Gamma, \tag{2.2}$$

where $\mathbf{J}$ is the q-vector of unknowns. (Here p and q are positive integers, generally with $p \geq q$.) To ensure that we can apply least squares to this system, we must have $\mathbf{p}(\mathbf{J}) \in L^2(\Omega)^p$. We want to allow product terms involving a combination of elements of $\mathbf{J}$, one of which may involve a partial derivative. Therefore, we cannot allow $\mathbf{J}$ to roam freely in $H^1(\Omega)^q$, because such products would not necessarily be in $L^2(\Omega)$ and we would thus be prevented from using $L^2(\Omega)$ norms for the functional. However, from Sobolev's lemma, the $C^0(\Omega)$ norm is bounded by the $H^{1+\delta}(\Omega)$ norm in R^2 when $\delta \in (0,1)$. Thus, everything in $H^{1+\delta}(\Omega)$ is continuous, and our product terms are in $L^2(\Omega)$. We therefore choose the space for $\mathbf{J}$ to be $H^{1+\delta}(\Omega)^q$, ensuring $\mathbf{p}(\mathbf{J}) \in L^2(\Omega)^p$. This obviously places restrictions on the allowable boundary functions $\mathbf{g}$. In fact, we assume that the solution $\mathbf{J}^*$ of (2.1)–(2.2) is in $H^{2+\delta}(\Omega)^q$, which places even further restrictions on $\mathbf{g}$. In addition, the coercivity requirement on the first Fréchet derivative of our system influences the allowable spaces for both the boundary and boundary conditions, which in turn influences the solution space for $\mathbf{J}^*$. This issue is addressed implicitly in the abstract theory of section 4 and in detail for the EGG application in the companion paper [17].

In other FOSLS applications [13, 15, 7, 8, 14], both H^{-1} and L^2 norms are used for the domain, and $H^{\frac{1}{2}}$ norms for the boundary. With appropriate smoothness [15], FOSLS functionals for general second-order elliptic partial differential equations exhibit H^1 equivalence for the functionals based on L^2 norms for the domain and $H^{\frac{1}{2}}$ norms for the boundary. In practice, while L^2 norms are used for the domain, it is common either to use L^2 norms scaled by $\frac{1}{h}$ for the boundary norms or to impose the boundary conditions. We focus here for simplicity on imposing boundary conditions, although some of our numerical results in [17] take the scaled L^2 norm approach for illustration.

It is more convenient in the analysis to consider homogeneous boundary conditions. To this end, we extend $\mathbf{g}$ smoothly into Ω: assume that we are given a q-vector function $\mathbf{E}$, defined on Ω, that satisfies

$$\mathbf{BE} = \mathbf{g} \qquad \text{on } \Gamma.$$

Now, writing $\mathbf{J} = \mathbf{D} + \mathbf{E}$ and $\mathbf{P}(\mathbf{D}) = \mathbf{p}(\mathbf{D} + \mathbf{E})$, our target problem becomes

$$\mathbf{P}(\mathbf{D}) = \mathbf{0} \qquad \text{in } \Omega, \tag{2.3}$$

with homogeneous boundary conditions

$$\mathbf{BD} = \mathbf{0} \qquad \text{on } \Gamma. \tag{2.4}$$

Generally, $\mathbf{E}$ needs to be as smooth as we require $\mathbf{J}^* = \mathbf{D}^* + \mathbf{E}$ to be, but this requirement is implicit in the following assumptions that we make on (2.3)–(2.4).

We start by defining the space on which this system is posed. For any $\nu > 0$, define

$$\mathcal{H}_\nu = \{\mathbf{D} \in H^\nu(\Omega)^q : \mathbf{BD} = \mathbf{0} \text{ on } \Gamma\}. \tag{2.5}$$

We assume that our solution $\mathbf{D}^*$ resides in $\mathcal{H}_{2+\delta}$, and we look for it in $\mathcal{H}_{1+\delta}$. Note that $\mathbf{D} \in \mathcal{H}_{1+\delta}$ implies $\mathbf{P}(\mathbf{D}) \in L^2(\Omega)^p$.

3. Method. There are several decisions to be made about how (2.3) is solved. Our basic choice is to use Newton's method and FOSLS to obtain a quadratic minimization problem, finite elements for the discretization, and then AMG with NI to solve the resulting matrix equations. Within this basic framework, we need to choose how Newton's method and FOSLS are related. A FOSLS-Newton method would involve forming the least-squares functional, setting its gradient to zero, and then solving this nonlinear problem with Newton's method. A Newton-FOSLS method would involve linearizing the equations first, and then forming the least-squares functional and setting its gradient to zero. The gradient equations that result from these two approaches differ only by a term coming from the second Fréchet derivative of the system operator that, near the solution, is dominated by the other operator terms. Because nested iteration guarantees proximity to the solution on each level, the performance of these two approaches tends to be much the same. We therefore focus on the Newton-FOSLS approach because of its theoretical and numerical simplicity.

Our method involves first applying Newton's method to nonlinear system (2.3) on the coarsest finite element level. We then form an L^2 functional from the linearized equations and minimize a coarsest-level discretization of it by AMG (or perhaps a direct matrix solver). The resulting approximate Newton iterate computed at the

$$\mathbf{D}_0 \overset{N}{\to} \mathbf{D}_1 \overset{N}{\to} \mathbf{D}_2 \overset{N}{\to} \mathbf{D}_3 \overset{N}{\to} \mathbf{D}_4 \;\cdots\; \mathbf{D}_n \overset{N}{\to} \mathbf{D}_{n+1} \overset{N}{\to} \;\cdots\; \mathbf{D}^*$$

FIG. 3.1. *The Newton-FOSLS infinite-dimensional algorithm.*

coarsest-level scale is then used on the next finer level as an initial guess for an analogous discrete Newton step there: system (2.3) is linearized about this initial guess, an L^2 minimization principle is applied, and then AMG is used to approximate the minimizer on this finer scale. This process continues, with the iterates approximated on successively finer levels, until a desired accuracy is reached.

Applying Newton's method to system (2.3) gives us the following linearized problem: given $\mathbf{D}_n \in \mathcal{H}_{1+\delta}$, find $\mathbf{D}_{n+1} \in \mathcal{H}_{1+\delta}$ such that

$$\mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n] = -\mathbf{P}(\mathbf{D}_n), \tag{3.1}$$

where $\mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n]$ denotes the first Fréchet derivative of $\mathbf{P}(\mathbf{D}_n)$ with respect to $\mathbf{D}_n$ in direction $\mathbf{D}_{n+1} - \mathbf{D}_n$.

To solve (3.1) for $\mathbf{D}_{n+1}$, consider the least-squares functional

$$\begin{aligned}\mathbf{G}_0(\mathbf{D}_{n+1}) &\equiv \|\mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n] + \mathbf{P}(\mathbf{D}_n)\|^2_{0,\Omega} \\ &= \left(\mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n] + \mathbf{P}(\mathbf{D}_n),\;\; \mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n] + \mathbf{P}(\mathbf{D}_n)\right).\end{aligned}$$

Note that $\mathbf{G}_0$ depends on $\mathbf{D}_n$ and $\mathbf{E}$. To minimize $\mathbf{G}_0$, we set to zero its first Fréchet derivative, taken with respect to $\mathbf{D}_{n+1}$ (cancelling the factor 2 for convenience): given $\mathbf{D}_n \in \mathcal{H}_{1+\delta}$, find $\mathbf{D}_{n+1} \in \mathcal{H}_{1+\delta}$ such that

$$(\mathbf{P}'(\mathbf{D}_n)[\mathbf{K}],\;\; \mathbf{P}'(\mathbf{D}_n)[\mathbf{D}_{n+1} - \mathbf{D}_n] + \mathbf{P}(\mathbf{D}_n)) = \mathbf{0} \quad \forall\, \mathbf{K} \in \mathcal{H}_{1+\delta}. \tag{3.2}$$

We illustrate this infinite-dimensional Newton process in Figure 3.1, where $\overset{N}{\to}$ indicates one Newton step.

In practice, we need to discretize (3.2) on some given finite element space H^h. However, we then need an approximation for $\mathbf{D}_n$. The main point to keep in mind in this approximation is that early iterates are relatively crude approximations to $\mathbf{D}^*$, and thus they can be approximated on relatively coarse grids. In general, if final iterate $\mathbf{D}_{n+1}$ is approximated by a best approximation $\mathbf{U}_{n+1}$ in H^{h_n}, then $\mathbf{D}_n$ need only be approximated on a grid with mesh size $\mathcal{O}(h_n^{\frac{1}{2}})$. This is a natural consequence of quadratic convergence, and this premise is served well by a coarse grid of mesh size $2h$. This view gives rise to our nested iteration approach that supplies the initial guess for one Newton iterate on grid h by first iterating on grid $2h$. In particular, consider a nested sequence of $m+1$ finite-dimensional subspaces of $\mathcal{H}_{1+\delta}$ denoted by $H^{h_0} \subset H^{h_1} \subset \cdots \subset H^{h_m} \subset \mathcal{H}_{1+\delta}$, where $h_n = 2^{-n}h_0$, $0 \le n \le m$. Note that piecewise bilinears on rectangles are in $H^{1+\delta}(\Omega)$ for $\delta \in [0, \frac{1}{2})$ (see [16]). Let $\mathbf{U}_0$ denote the initial guess in H^{h_0}. For $n = 0, 1, \ldots, m$ in turn, define the grid H^{h_n} problem as follows: given $\mathbf{U}_n \in H^{h_n}$, find $\mathbf{U}_{n+1} \in H^{h_n} \subset H^{h_{n+1}}$ such that

$$\big(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}^{h_n}],\;\; \mathbf{P}'(\mathbf{U}_n)[\mathbf{U}_{n+1} - \mathbf{U}_n] + \mathbf{P}(\mathbf{U}_n)\big) = \mathbf{0} \quad \forall\, \mathbf{K}^{h_n} \in H^{h_n}. \tag{3.3}$$

3.1. NI-Newton-FOSLS. The discretization in (3.3) amounts to approximating the finest-level solution $\mathbf{U}^*_m$ by a nested iteration on subspaces H^{h_n}, $n = 0, 1, \ldots, m$. This NI approach involves first solving problem (3.3) on the coarsest subspace, H^{h_0}.

$$\begin{tikzcd}
\mathbf{U}_0 \arrow[r, "Nh_0"] \arrow[dr, "N"] & \mathbf{U}_1 \arrow[r, "Nh_1"] \arrow[dr, "N"] & \mathbf{U}_2 \arrow[r, "Nh_2"] \arrow[dr, "N"] & \mathbf{U}_3 \arrow[r, "Nh_3"] \arrow[dr, "N"] & \mathbf{U}_4 \cdots \arrow[dr, phantom, "\ddots"] & \\
& \widetilde{\mathbf{D}}_1 & \widetilde{\mathbf{D}}_2 & \widetilde{\mathbf{D}}_3 & \widetilde{\mathbf{D}}_4 & \cdots
\end{tikzcd}$$

FIG. 3.2. *The NI-Newton-FOSLS algorithm.*

In practice, we can use any sensible solution process here because this space is presumably of very low dimension. We can simply iterate with a (possibly damped) discrete Newton iteration until the error in the approximation is below discretization error. However, because our theory assumes that we are sufficiently close to $\mathbf{D}^*$, we have assumed, for convenience, that this coarsest approximation is computed by only one discrete Newton iteration applied to a sufficiently close approximation $\mathbf{U}_0 \in H^{h_0}$. Now, the resulting iterate $\mathbf{U}_1$ is interpolated to the next finer level, where it is used as an initial guess for one discrete Newton step. The resulting approximation $\mathbf{U}_2$ on subspace H^{h_1} is then used as an initial guess for the next finer level. In general, the initial guess for Newton on level h_n comes from the final Newton step on level h_{n-1}: $\mathbf{U}_n$. The process is repeated until the finest subspace is reached, where one final Newton step is then applied. Note that $\mathbf{U}_{n+1}$ can be interpreted as a discrete approximation to the result $\widetilde{\mathbf{D}}_{n+1}$ of one infinite-dimensional Newton step applied to $\mathbf{U}_n$. This NI procedure is illustrated in Figure 3.2, where $\overset{Nh_n}{\to}$ indicates one Newton step on H^{h_n} and $\overset{N}{\searrow}$ indicates one infinite-dimensional Newton step applied to discrete initial guess $\mathbf{U}_n$.

One of our main objectives in this paper is to prove that this nested iteration process, involving only one discrete Newton step on each level, produces a result on the finest level that is within discretization error of the infinite-dimensional solution.

3.2. AMG. Our theory assumes a standard V-cycle multigrid algorithm because of its superior theoretical basis. However, because of its enhanced robustness, we use AMG in practice as the matrix solver for approximating $\mathbf{U}_{n+1}$. See [12] for basic descriptions of multigrid and AMG.

AMG starts on the coarsest level with initial guess $\mathbf{V}_0 = \mathbf{U}_0$. We apply ν_0 cycles of AMG to the matrix problem arising from (3.3) with $n = 0$. The result, $\mathbf{V}_1$, becomes the initial guess for level h_1, where the process continues. In general, the initial guess for AMG on level h_n comes from the final AMG approximation on level h_{n-1}: $\mathbf{V}_n$. In Figure 3.3, we illustrate the NI-Newton-FOSLS-AMG algorithm, with $\overset{\mathcal{M}h_n}{\to}$ denoting one approximate multigrid-Newton step on H^{h_n}, and $\overset{Nh_n}{\searrow}$ denoting the exact discrete Newton step with initial guess $\mathbf{V}_n$ (with result $\widetilde{\mathbf{U}}_{n+1}$).

$$\begin{tikzcd}
\mathbf{V}_0 \arrow[r, "\mathcal{M}h_0"] \arrow[dr, "Nh_0"] & \mathbf{V}_1 \arrow[r, "\mathcal{M}h_1"] \arrow[dr, "Nh_1"] & \mathbf{V}_2 \arrow[r, "\mathcal{M}h_2"] \arrow[dr, "Nh_2"] & \mathbf{V}_3 \arrow[r, "\mathcal{M}h_3"] \arrow[dr, "Nh_3"] & \mathbf{V}_4 \cdots \arrow[dr, phantom, "\ddots"] & \\
& \widetilde{\mathbf{U}}_1 & \widetilde{\mathbf{U}}_2 & \widetilde{\mathbf{U}}_3 & \widetilde{\mathbf{U}}_4 & \cdots
\end{tikzcd}$$

FIG. 3.3. *The NI-Newton-FOSLS-AMG algorithm.*

4. Abstract theory.

Bounds on various quantities used in the theory developed here involve many different constants. To avoid proliferation, we use uppercase C to denote a generic constant that, unless otherwise specified, can change meaning with each occurrence. When it is important to track the origin of these constants, we instead use lowercase c with unique subscripts. In every occurrence, these constants are independent of h and n, but they may depend on the value of the $H^{1+\delta}(\Omega)^q$ norm of the approximation. (Here and in what follows, $\delta \in (0,1)$ is a fixed constant.) To make sure that these values are properly bounded, we start with an initial guess in a small $H^{1+\delta}(\Omega)^q$ ball about $\mathbf{D}^*$. We show that the approximations remain in this ball and, in fact, attain order h accuracy in the $H^1(\Omega)^q$ norm. This also controls the values of the $H^{1+\delta}(\Omega)^q$ norm (see Lemma 4.5 below).

Assume that there exists a solution $\mathbf{D}^*$ of (2.3) in $\mathcal{H}_{2+\delta}$. (Recall that $\mathcal{H}_\nu$ is defined in (2.5) for any $\nu > 0$.) Denote the open $H^{1+\delta}(\Omega)^q$ ball centered at $\mathbf{D}^*$ of radius $r > 0$ by $B_r \equiv \{\mathbf{D} \in \mathcal{H}_{1+\delta} : \|\mathbf{D}^* - \mathbf{D}\|_{1+\delta,\Omega} < r\}$. Several of our norm assumptions and estimates involve both integer and fractional norms. So that our statements apply to both cases, we let $\epsilon = 0$ or δ. Assume now that $\mathbf{P}[\mathbf{D}] \in H^\epsilon(\Omega)^p$ for every $\mathbf{D} \in B_r$: there exists a constant C, depending only on $\mathbf{D}^*$, $\mathbf{E}$, r, Ω, and δ, such that

$$\|\mathbf{P}(\mathbf{D})\|_{\epsilon,\Omega} \le C \quad \forall\ \mathbf{D} \in B_r.$$

Further assume uniform coercivity and continuity of $\mathbf{P}'(\mathbf{D})[\,\cdot\,]$ as a mapping from $\mathcal{H}_{1+\epsilon}(\Omega)$ to $H^\epsilon(\Omega)^p$: for every $\mathbf{D} \in B_r$, there exist constants c_c and c_b, depending only on $\mathbf{D}^*, \mathbf{E}, r, \Omega$, and δ, such that

$$\frac{1}{c_c}\|\mathbf{K}\|_{1+\epsilon,\Omega} \le \|\mathbf{P}'(\mathbf{D})[\mathbf{K}]\|_{\epsilon,\Omega} \le c_b\|\mathbf{K}\|_{1+\epsilon,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_{1+\epsilon}(\Omega). \tag{4.1}$$

Note that coercivity implies that $\mathbf{P}'(\mathbf{D})[\,\cdot\,]$ is one-to-one on $\mathcal{H}_{1+\epsilon}(\Omega)$ for every $\mathbf{D} \in B_r$, including, of course, $\mathbf{D} = \mathbf{D}^*$. We also assume boundedness of the second Fréchet derivative of $\mathbf{P}(\mathbf{D})$ for all $\mathbf{D} \in B_r$: for every $\mathbf{D} \in B_r$ there exists a constant c_2, depending only on $\mathbf{D}^*$, $\mathbf{E}$, r, Ω, and δ, such that

$$\|\mathbf{P}''(\mathbf{D})[\mathbf{K},\mathbf{K}]\|_{\epsilon,\Omega} \le c_2\|\mathbf{K}\|_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\epsilon,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_{1+\epsilon}(\Omega). \tag{4.2}$$

Here, $\mathbf{P}''(\mathbf{D})[\mathbf{K},\mathbf{K}]$ denotes the second Fréchet derivative of $\mathbf{P}(\mathbf{D}_n)$ with respect to $\mathbf{D}_n$ in directions $\mathbf{K}$ and $\mathbf{K}$.

Let $\mathcal{P}^h$ and $\mathcal{Q}^h$ denote the respective $H^{1+\delta}$ and H^1 projections of $\mathcal{H}_{1+\delta}$ onto H^h. Note that

$$\|\mathcal{P}^h\mathbf{D}\|_{1+\delta,\Omega} \le \|\mathbf{D}\|_{1+\delta,\Omega} \quad \forall\ \mathbf{D} \in \mathcal{H}_{1+\delta}$$

and

$$\|\mathcal{Q}^h\mathbf{D}\|_{1,\Omega} \le \|\mathbf{D}\|_{1,\Omega} \quad \forall\ \mathbf{D} \in \mathcal{H}_{1+\delta}. \tag{4.3}$$

Assume that our finite element spaces satisfy the usual *approximation properties* (cf. [9]):

$$\|\mathbf{D}^* - \mathcal{P}^h\mathbf{D}^*\|_{\gamma,\Omega} \le c_d h^{2+\delta-\gamma}\|\mathbf{D}^*\|_{2+\delta,\Omega} \quad \forall\ \gamma \in [0, 1+\delta] \tag{4.4}$$

and

$$\|\mathbf{D}^* - \mathcal{Q}^h\mathbf{D}^*\|_{1,\Omega} \le c_d h^{1+\delta}\|\mathbf{D}^*\|_{2+\delta,\Omega}. \tag{4.5}$$

Assume that they also satisfy the *inverse estimate* (cf. [9, 11]):

$$\|\mathbf{U}\|_{\beta,\Omega} \le \frac{c_i}{h^{\beta-\gamma}}\|\mathbf{U}\|_{\gamma,\Omega} \quad \forall\ \mathbf{U} \in H^h,\ \beta \in [0, 1+\delta],\ \gamma \in [0, \beta]. \tag{4.6}$$

Assume finally that h_0 is so small that $B_r \cap H^{h_0} \neq \phi$ and that initial guess $\mathbf{U}_0$ is in $B_r \cap H^{h_0}$.

The following theory shows that $\mathbf{U}_n$ is in an $H^1(\Omega)$ ball about $\mathbf{D}^*$ of radius $(1+\eta)c_d h_n$, where η is any predetermined positive constant and c_d is the constant in (4.4) and (4.5). For simplicity, we choose $\eta = 1$ and thus define

$$\mathcal{S}_n = \{\mathbf{U} \in H^{h_n} : \|\mathbf{D}^* - \mathbf{U}\|_{1,\Omega} \le 2c_d h_n\} \tag{4.7}$$

and

$$\mathcal{S} = \cup_{n=0}^{m} \mathcal{S}_n.$$

Lemma 4.5 shows that $\mathcal{S}$ is bounded in $H^{1+\delta}(\Omega)^q$ and, hence, compact in $H^1(\Omega)^q$.

We first state our three central theorems. Their proofs follow from a series of results developed in the next subsection.

For all three theorems, we assume that $r > 0$ is sufficiently small. For Theorem 4.2, with r fixed, we assume further that $h_0 > 0$ is sufficiently small, especially so that $\mathcal{S}_0 \subset B_r$. For Theorem 4.1, with r fixed, we assume that $h_0 > 0$ is possibly smaller still. We do this so that, in addition to $\mathcal{S}_0 \subset B_r$, we are sure that the exact discrete iterate $\mathbf{U}_{n+1}$ is even closer to $\mathbf{D}^*$ than to $2c_d h_n$, which in turn allows us to deduce that the multigrid approximation $\mathbf{V}_{n+1}$ is within $2c_d h_n$ of $\mathbf{D}^*$. Finally, Theorem 4.3 also assumes that, on each level, the discrete Newton problem is approximately solved with a sufficient but fixed number ν_0 of multigrid V-cycles.

THEOREM 4.1 (Newton). *With $\mathbf{D}_n \in B_r$ given, let $\mathbf{D}_{n+1}$ be the exact infinite-dimensional Newton step defined by* (3.2). *Then $\mathbf{D}_{n+1} \in B_r$ and there exists a constant c_q, depending only on $\mathbf{D}^*$, $\mathbf{E}$, Ω, and δ, such that*

$$\|\mathbf{D}^* - \mathbf{D}_{n+1}\|_{1+\epsilon,\Omega} \le c_q\|\mathbf{D}^* - \mathbf{D}_n\|_{1+\epsilon,\Omega}\|\mathbf{D}^* - \mathbf{D}_n\|_{1+\delta,\Omega}, \quad \epsilon = 0, \delta. \tag{4.8}$$

THEOREM 4.2 (discrete Newton). *Assume that $\mathbf{U}_0 \in S_0$. Then $\mathbf{U}_{n+1} \in \mathcal{S}_{n+1}$: the Newton approximation on level h_n based on initial guess $\mathbf{U}_n$ satisfies the error bound*

$$\|\mathbf{D}^* - \mathbf{U}_{n+1}\|_{1,\Omega} \le 2c_d h_{n+1} = c_d h_n. \tag{4.9}$$

THEOREM 4.3 (inexact discrete Newton). *Assume that $\mathbf{V}_0 \in S_0$. Then $\mathbf{V}_{n+1} \in \mathcal{S}_{n+1}$: the multigrid approximation on level h_n based on initial guess $\mathbf{V}_n$ satisfies the error bound*

$$\|\mathbf{D}^* - \mathbf{V}_{n+1}\|_{1,\Omega} \le 2c_d h_n. \tag{4.10}$$

4.1. Preliminaries.

Although we pose problem (2.3) on $\mathcal{H}_{1+\delta} \subset H^{1+\delta}(\Omega)^q$, we prove convergence in the weaker $H^1(\Omega)^q$ norm. Since $\mathcal{H}_{1+\delta}$ is not complete in the $H^1(\Omega)^q$ norm, we cannot appeal to standard Newton convergence theory. Fortunately, the result we need (Theorem 4.1) is weaker.

LEMMA 4.4. *Let $\mathbf{D} \in B_r$ and $\widetilde{\mathbf{D}} = \theta\mathbf{D} + (1-\theta)\mathbf{D}^*$, with $\theta \in [0, 1]$. Then*

$$\|\widetilde{\mathbf{D}}\|_{1+\delta,\Omega} \le r + \|\mathbf{D}^*\|_{1+\delta,\Omega}.$$

Proof. The result follows directly from the triangle inequality and is thus omitted. □

LEMMA 4.5. *Suppose that* $\mathbf{U}_n \in \mathcal{S}_n$. *Then*

$$\|\mathbf{D}^* - \mathbf{U}_n\|_{1+\delta,\Omega} \le c_\delta h_n^{1-\delta}, \tag{4.11}$$

where $c_\delta = 2c_ic_d + (1+c_i)c_dh_0^\delta\|\mathbf{D}^*\|_{2+\delta,\Omega}$. *Thus,* $\mathcal{S} = \cup_{n=0}^m \mathcal{S}_n \subset B_r$, *provided that* h_0 *is so small that* $c_\delta h_0^{1-\delta} \le r$.

Proof. The bound follows the triangle inequality, (4.6), the triangle inequality again, (4.4), the definition of $\mathcal{S}_n$ in (4.7), and (4.4) again:

$$\begin{aligned}
\|\mathbf{D}^* - \mathbf{U}_n\|_{1+\delta,\Omega} &\le \|\mathbf{D}^* - \mathcal{P}^{h_n}\mathbf{D}^*\|_{1+\delta,\Omega} + \|\mathcal{P}^{h_n}\mathbf{D}^* - \mathbf{U}_n\|_{1+\delta,\Omega} \\
&\le c_dh_n\|\mathbf{D}^*\|_{2+\delta,\Omega} + \frac{c_i}{{h_n}^\delta}\|\mathcal{P}^{h_n}\mathbf{D}^* - \mathbf{U}_n\|_{1,\Omega} \\
&\le c_dh_n\|\mathbf{D}^*\|_{2+\delta,\Omega} + \frac{c_i}{{h_n}^\delta}\left[\|\mathbf{D}^* - \mathcal{P}^{h_n}\mathbf{D}^*\|_{1,\Omega} + \|\mathbf{D}^* - \mathbf{U}_n\|_{1,\Omega}\right] \\
&\le c_dh_n\|\mathbf{D}^*\|_{2+\delta,\Omega} + \frac{c_i}{{h_n}^\delta}\left[c_d{h_n}^{1+\delta}\|\mathbf{D}^*\|_{2+\delta,\Omega} + 2c_dh_n\right] \\
&\le c_\delta {h_n}^{1-\delta}.
\end{aligned}$$

This lemma confirms max norm $O(h^{1-\delta})$ convergence. □

LEMMA 4.6. *Suppose that* $\mathbf{V}_n \in \mathcal{S}_n$ *for sufficiently small* r. *Let* $\widetilde{\mathbf{U}}_{n+1}$ *denote one exact discrete Newton step with initial guess* $\mathbf{V}_n$, *and let* $\mathbf{V}_{n+1}$ *denote its multigrid approximation. Then*

$$\|\widetilde{\mathbf{U}}_{n+1} - \mathbf{V}_{n+1}\|_{1,\Omega} \le \rho^{\nu_0}\|\widetilde{\mathbf{U}}_{n+1} - \mathbf{V}_n\|_{1,\Omega}. \tag{4.12}$$

Here, $\rho \in [0,1)$ *is a bound on the multigrid convergence factor for any level* n *and any initial guess* $\mathbf{V} \in \mathcal{S}_n$; *it depends only on* $\mathbf{D}^*, \mathbf{E}, r, \Omega, \delta, c_d$, *and* c_i.

Proof. Convergence estimate (4.12) follows from standard multigrid theory (cf. [10]) using the $H^1(\Omega)^q$ equivalence result in (4.1) with $\mathbf{D} = \mathbf{V}_n$. □

We have now established the tools that allow us to prove our central theorems.

4.2. Proofs of Theorems 4.1, 4.2, and 4.3.

Proof of Theorem 4.1. Consider a Taylor expansion for $\mathbf{P}(\mathbf{D}^*)$ about $\mathbf{D}_n$:

$$\mathbf{0} = \mathbf{P}(\mathbf{D}^*) = \mathbf{P}(\mathbf{D}_n) + \mathbf{P}'(\mathbf{D}_n)[\mathbf{D}^* - \mathbf{D}_n] + \frac{1}{2}\mathbf{P}''(\widetilde{\mathbf{D}})[\mathbf{D}^* - \mathbf{D}_n, \mathbf{D}^* - \mathbf{D}_n],$$

where $\widetilde{\mathbf{D}} = \theta\mathbf{D}_n + (1-\theta)\mathbf{D}^*$ for some $\theta \in [0,1]$ is bounded in the $H^{1+\delta}(\Omega)^q$ norm (Lemma 4.4). Then the lower bound in (4.1), combining the above expansion with (3.1), and using (4.2) proves (4.8):

$$\begin{aligned}
\|\mathbf{D}^* - \mathbf{D}_{n+1}\|_{1+\epsilon,\Omega} &\le c_c\|\mathbf{P}'(\mathbf{D}_n)[\mathbf{D}^* - \mathbf{D}_{n+1}]\|_{\epsilon,\Omega} \\
&= \frac{c_c}{2}\|\mathbf{P}''(\widetilde{\mathbf{D}})[\mathbf{D}^* - \mathbf{D}_n, \mathbf{D}^* - \mathbf{D}_n]\|_{\epsilon,\Omega} \\
&\le \frac{c_cc_2}{2}\|\mathbf{D}^* - \mathbf{D}_n\|_{1+\delta,\Omega}\|\mathbf{D}^* - \mathbf{D}_n\|_{1+\epsilon,\Omega}. \qquad (4.13)
\end{aligned}$$

To show that $\mathbf{D}_{n+1} \in B_r$, consider (4.13) with $\epsilon = \delta$. For $\mathbf{D}_n \in B_r$, this reduces to

$$\|\mathbf{D}^* - \mathbf{D}_{n+1}\|_{1+\delta,\Omega} \le \frac{c_cc_2}{2}r^2,$$

and we just require

$$r \le \frac{2}{c_c c_2}. \qquad \square \tag{4.14}$$

Proof of Theorem 4.2. First assume that r is so small that (4.14) is satisfied. Assume also that h_0 is so small that

$$c_\delta h_0^{1-\delta} = 2c_i c_d h_0^{1-\delta} + (1+c_i)c_d\|\mathbf{D}^*\|_{2+\delta,\Omega} h_0 \le r.$$

Hence, by Lemma 4.5 and because we assume that $\mathbf{U}_0 \in \mathcal{S}_0$, we must have $\mathbf{U}_0 \in B_r$. Suppose now that we could show that $\mathbf{U}_n \in \mathcal{S}_n$ implies that $\mathbf{U}_{n+1} \in \mathcal{S}_{n+1}$ for all $n \ge 0$. Then, since $\mathbf{U}_0 \in \mathcal{S}_0$, we would know that $\mathbf{U}_1 \in \mathcal{S}_1$, which in turn would imply that $\mathbf{U}_2 \in \mathcal{S}_2$. Continuing in this way would show that (4.9) holds for all $n \ge 0$.

To this end, assume that (4.9) holds for n replaced by $n-1$, with $\mathbf{U}_n \in \mathcal{S}_n$:

$$\|\mathbf{D}^* - \mathbf{U}_n\|_{1,\Omega} \le 2c_d h_n. \tag{4.15}$$

From Lemma 4.5, we see that

$$\|\mathbf{D}^* - \mathbf{U}_n\|_{1+\delta,\Omega} \le c_\delta h_n^{1-\delta}. \tag{4.16}$$

We bound the left-hand side of (4.9) by first using the triangle inequality:

$$\|\mathbf{D}^* - \mathbf{U}_{n+1}\|_{1,\Omega} \le \|\mathbf{D}^* - \widetilde{\mathbf{D}}_{n+1}\|_{1,\Omega} + \|\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}\|_{1,\Omega}, \tag{4.17}$$

where $\widetilde{\mathbf{D}}_{n+1}$ is the result of infinite-dimensional Newton step (3.2) based on initial guess $\mathbf{U}_n$.

Consider the first term on the right-hand side of (4.17). By Theorem 4.1 with $\epsilon = 0$, (4.11), and (4.15), we have that

$$\begin{aligned}\|\mathbf{D}^* - \widetilde{\mathbf{D}}_{n+1}\|_{1,\Omega} &\le c_q\|\mathbf{D}^* - \mathbf{U}_n\|_{1,\Omega}\|\mathbf{D}^* - \mathbf{U}_n\|_{1+\delta,\Omega}\\ &\le 2c_d c_q c_\delta h_n^{2-\delta}.\end{aligned} \tag{4.18}$$

For the second term on the right-hand side of (4.17), we now show that

$$\|\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}\|_{1,\Omega} \le c_b c_c(4c_d c_q c_\delta h_0^{1-\delta} + c_d h_0^{\delta}\|\mathbf{D}^*\|_{2+\delta,\Omega})h_n. \tag{4.19}$$

To this end, let $\mathbf{f} \equiv \mathbf{P}'(\mathbf{U}_n)[\mathbf{U}_n] - \mathbf{P}(\mathbf{U}_n)$. Then discrete Newton step (3.3) becomes the following: given $\mathbf{U}_n \in H^{h_n}$, find $\mathbf{U}_{n+1} \in H^{h_n}$ such that

$$\big(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}^{h_n}],\ \mathbf{P}'(\mathbf{U}_n)[\mathbf{U}_{n+1}]\big) = \big(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}^{h_n}],\ \mathbf{f}\big) \quad \forall\ \mathbf{K}^{h_n} \in H^{h_n}. \tag{4.20}$$

Note that $\widetilde{\mathbf{D}}_{n+1} \in \mathcal{H}_{1+\delta}$, which is generally not in H^{h_n}, is defined by

$$(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}],\ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1}]) = (\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}]\ ,\ \mathbf{f}) \quad \forall\ \mathbf{K} \in \mathcal{H}_{1+\delta}. \tag{4.21}$$

Combining (4.20) and (4.21) for $\mathbf{K} = \mathbf{K}^{h_n} \in H^{h_n}$, we have that

$$(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}^{h_n}],\ \ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]) = 0,$$

from which it follows that

$$\begin{aligned}&(\mathbf{P}'(\mathbf{U}_n)[\mathbf{K}],\ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}])\\ &\quad = (\mathbf{P}'(\mathbf{U}_n)[\mathbf{K} - \mathbf{K}^{h_n}],\ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]).\end{aligned}$$

Letting $\mathbf{K} = \widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}$ and $\mathbf{K}^{h_n} = \mathcal{Q}^{h_n}(\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}) = \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}$, so that $\mathbf{K} - \mathbf{K}^{h_n} = \widetilde{\mathbf{D}}_{n+1} - \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1}$, then yields

$$\begin{aligned} &(\mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}],\ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]) \\ &\quad = (\mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1}],\ \mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]). \end{aligned} \tag{4.22}$$

Applying the Cauchy–Schwarz inequality to the right-hand side of (4.22), then cancelling the term $\|\mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]\|_{0,\Omega}$ that results on both sides, yields

$$\|\mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}]\|_{0,\Omega} \le \|\mathbf{P}'(\mathbf{U}_n)[\widetilde{\mathbf{D}}_{n+1} - \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1}]\|_{0,\Omega}.$$

However, (4.1) confirms that $\mathbf{P}'(\mathbf{U}_n)[\mathbf{M}]$ is coercive and bounded in the $H^1(\Omega)^q$ norm for $\mathbf{M} \in \mathcal{H}_{1+\delta}$, and so the above bound becomes

$$\|\widetilde{\mathbf{D}}_{n+1} - \mathbf{U}_{n+1}\|_{1,\Omega} \le c_b c_c \|\widetilde{\mathbf{D}}_{n+1} - \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1}\|_{1,\Omega}. \tag{4.23}$$

We now bound the right-hand side of (4.23) using the triangle inequality, (4.3), (4.5), (4.18), and relation $h_n \le h_0$:

$$\begin{aligned} \|\widetilde{\mathbf{D}}_{n+1} - \mathcal{Q}^{h_n}\widetilde{\mathbf{D}}_{n+1}\|_{1,\Omega} &\le \|\widetilde{\mathbf{D}}_{n+1} - \mathbf{D}^*\|_{1,\Omega} + \|\mathbf{D}^* - \mathcal{Q}^{h_n}\mathbf{D}^*\|_{1,\Omega} \\ &\qquad + \|\mathcal{Q}^{h_n}(\mathbf{D}^* - \widetilde{\mathbf{D}}_{n+1})\|_{1,\Omega} \\ &\le 2\|\widetilde{\mathbf{D}}_{n+1} - \mathbf{D}^*\|_{1,\Omega} + c_d h_n^{1+\delta}\|\mathbf{D}^*\|_{2+\delta,\Omega} \\ &\le (4c_d c_q c_\delta h_0^{1-\delta} + c_d h_0^\delta \|\mathbf{D}^*\|_{2+\delta,\Omega}) h_n. \end{aligned} \tag{4.24}$$

Bound (4.19) now follows from bounds (4.23) and (4.24).

Combining (4.17), (4.18), (4.19), and relation $h_n \le h_0$ yields

$$\|\mathbf{D}^* - \mathbf{U}_{n+1}\|_{1,\Omega} \le (2(1 + 2c_b c_c)c_q c_\delta h_0^{1-\delta} + c_b c_c \|\mathbf{D}^*\|_{2+\delta,\Omega} h_0^\delta)(c_d h_n).$$

Theorem 4.2 now follows by choosing h_0 perhaps smaller still so that

$$2(1 + 2c_b c_c)c_q c_\delta h_0^{1-\delta} + c_b c_c \|\mathbf{D}^*\|_{2+\delta,\Omega} h_0^\delta \le 1. \qquad \square$$

Proof of Theorem 4.3. As in Theorem 4.2, we need h_0 sufficiently small, but even smaller yet to account for the fact that we do not solve the Newton steps exactly: we need h_0 so small that the error in approximating $\widetilde{\mathbf{U}}_{n+1}$ (the exact discrete Newton step) by $\mathbf{V}_{n+1}$ keeps these iterates in S_{n+1}.

From Theorem 4.2, we have that if $\mathbf{U}_n \in \mathcal{S}_n$, then $\mathbf{U}_{n+1} \in \mathcal{S}_{n+1}$. This result can be tightened by choosing a smaller value for h_0: choosing h_0 such that, say,

$$2(1 + 2c_b c_c)c_q c_\delta h_0^{1-\delta} + c_b c_c \|\mathbf{D}^*\|_{2+\delta,\Omega} h_0^\delta \le \frac{2}{3},$$

means that $\mathbf{U}_n \in \mathcal{S}_n$ implies that

$$\|\mathbf{D}^* - \mathbf{U}_{n+1}\|_{1,\Omega} \le \frac{4}{3}c_d h_{n+1} = \frac{2}{3}c_d h_n. \tag{4.25}$$

As for Theorem 4.2, to prove that (4.10) holds for n, we may assume that it holds for n replaced by $n-1$:

$$\|\mathbf{D}^* - \mathbf{V}_n\|_{1,\Omega} \le 2c_d h_n. \tag{4.26}$$

Letting $\widetilde{\mathbf{U}}_{n+1}$ as before denote one exact discrete Newton step with initial guess $\mathbf{V}_n$, then

$$\|\mathbf{D}^* - \mathbf{V}_{n+1}\|_{1,\Omega} \le \|\mathbf{D}^* - \widetilde{\mathbf{U}}_{n+1}\|_{1,\Omega} + \|\widetilde{\mathbf{U}}_{n+1} - \mathbf{V}_{n+1}\|_{1,\Omega}. \tag{4.27}$$

For sufficiently small h_0, we know that $\mathbf{V}_n$ is in $\mathcal{S}_n \subset B_r$, and, with the reduced value of h_0, the first term on the right-hand side is bounded according to (4.25):

$$\|\mathbf{D}^* - \widetilde{\mathbf{U}}_{n+1}\|_{1,\Omega} \le \frac{2}{3} c_d h_n. \tag{4.28}$$

For the second term, we use (4.12), the triangle inequality, (4.28), and (4.26):

$$\begin{aligned}
\|\mathbf{U}_{n+1} - \mathbf{V}_{n+1}\|_{1,\Omega} &\le \rho^{\nu_0} \|\widetilde{\mathbf{U}}_{n+1} - \mathbf{V}_n\|_{1,\Omega} \\
&\le \rho^{\nu_0} \left[\|\widetilde{\mathbf{U}}_{n+1} - \mathbf{D}^*\|_{1,\Omega} + \|\mathbf{D}^* - \mathbf{V}_n\|_{1,\Omega} \right] \\
&\le \rho^{\nu_0} \left[\frac{2}{3} c_d h_n + 2 c_d h_n \right] \\
&= \frac{8}{3} c_d \rho^{\nu_0} h_n \\
&\le \frac{1}{3} c_d h_n, \qquad (4.29)
\end{aligned}$$

where ν_0 is chosen so large that $\rho^{\nu_0} \le \frac{1}{8}$. Combining bounds (4.27), (4.28), and (4.29) then yields

$$\|\mathbf{D}^* - \mathbf{V}_{n+1}\|_{1,\Omega} \le c_d h_n,$$

which proves Theorem 4.3. □

5. Conclusion.

The general theory developed here applies to virtually any set of quasi-linear partial differential equations that can be reformulated as a first-order system, provided it is amenable to an H^1-elliptic least-squares principle. The approach uses nested iteration based on one Newton step per level, implemented using a fixed number of multigrid V-cycles. The theory shows that, for a sufficiently fine coarsest grid, the method produces a final approximation to the solution of the first-order system that is H^1 accurate to the level of discretization error. Use of this general theory is illustrated in the companion paper [17] by applying it to a first-order system for the elliptic grid generation equations. The companion paper also reports on numerical experiments that support the theory.

MULTILEVEL FIRST-ORDER SYSTEM LEAST SQUARES FOR ELLIPTIC GRID GENERATION*

A. L. CODD[†], T. A. MANTEUFFEL[‡], S. F. MCCORMICK[‡], and J. W. RUGE[‡]

Abstract. A new fully variational approach is studied for elliptic grid generation (EGG). It is based on a general algorithm developed in a companion paper [A. L. Codd, T. A. Manteuffel, and S. F. McCormick, *SIAM J. Numer. Anal.*, 41 (2003), pp. 2197–2209] that involves using Newton's method to linearize an appropriate equivalent first-order system, first-order system least squares (FOSLS) to formulate and discretize the Newton step, and algebraic multigrid (AMG) to solve the resulting matrix equation. The approach is coupled with nested iteration to provide an accurate initial guess for finer levels using coarse-level computation. The present paper verifies the assumptions of the companion work and confirms the overall efficiency of the scheme with numerical experiments.

Key words. least-squares discretization, multigrid, nonlinear elliptic boundary value problems

1. Introduction.

A companion paper [10] develops an algorithm using Newton's method, first-order system least squares (FOSLS), and algebraic multigrid (AMG) for efficient solution of general nonlinear elliptic equations. The equations are first converted to an appropriate first-order system, and an approximate solution to the coarsest-grid problem is then computed (by any suitable method such as Newton iteration coupled perhaps with direct solvers, damping, or continuation). The approximation is then interpolated to the next finer level, where it is used as an initial guess for one Newton linearization of the nonlinear problem, with a few AMG cycles applied to the resulting matrix equation. This algorithm repeats itself until the finest grid is processed, again by *one* Newton/AMG step. At each Newton step, FOSLS is applied to the linearized system, and the resulting matrix equation is solved using just a few V-cycles of AMG.

In the present paper, we apply this algorithm to elliptic grid generation (EGG) equations. Grid generation is usually based on a map between a relatively simple *computational* region and a possibly complicated *physical* region. It can be used numerically to create a mesh for a discretization method to solve a given system of equations posed on the physical domain. Alternatively, it can be used to transform equations posed on the physical region into ones posed on the computational region, where the transformed equations are then solved. If the Jacobian of the transformation is positive throughout the computational region, the equation type is unchanged [12]. Actually, the relative minimum value of the Jacobian is important in practice because relatively small values signal small angles between the grid lines and large errors in approximating the equations [20].

Our interest is in EGG using the Winslow generator [12], which allows us to specify the boundary maps completely. Moreover, by choosing the two-dimensional computational region to be convex, we can ensure that the Jacobian of the map is positive, which in turn ensures that the map is one-to-one and onto and therefore does not fold [8]. The Winslow generator tends to create smooth grids, with good aspect ratios. The map also tends to control variations in gridline spacing and nonorthogonality of the gridline intersections in the physical space. See Thompson, Warsi, and Mastin [20] and Knupp and Steinberg [12] for background on grid generation in general and EGG in particular. Several discretization methods for the EGG equations together with their associated errors are discussed in [20]. In [12], the EGG equations are derived, and several existing methods are described for solving them.

A brief description of the first-order EGG system is given in section 2. The assumptions needed to apply the theory in [10] are verified in section 3. Section 4 discusses scaling of the functional terms used for the computations as well as numerical results for two representative problems. The last section includes some final remarks.

2. Equations. We use standard notation for the associated spaces. Restricting ourselves to two dimensions, we consider a generic open domain $\Omega \in R^2$, with Lipschitz boundary $\Gamma \in C^{3,1}$. (The superscript 1 indicates Lipschitz continuity of the functions and their derivatives.) Suppose that $m \geq 0$ and $n \geq 1$ are given integers. Let $(\cdot,\cdot)_{0,\Omega}$ denote the inner product on $L^2(\Omega)^n$, $\|\cdot\|_{0,\Omega}$ its induced norm, and $H^m(\Omega)^n$ the standard Sobolev space with norm $\|\cdot\|_{m,\Omega}$ and seminorms $|\cdot|_{i,\Omega}$ $(0 \leq i \leq m)$. (The superscript n is omitted when dependence is clear by context.) For $\delta \in (0,1)$, let $H^{m+\delta}(\Omega)$ (cf. [6]) denote the Sobolev space associated with the norm defined by

$$\|u\|^2_{m+\delta,\Omega} \equiv \|u\|^2_{m,\Omega} + \sum_{|\alpha|=m} \int_\Omega \int_\Omega \frac{|\partial_\alpha u(x) - \partial_\alpha u(y)|^2}{|x-y|^{2(1+\delta)}} dxdy.$$

(This definition allows the use of the "real interpolation" method [1, 6].) Also, let $H^{\frac{1}{2}}(\Gamma)$ denote the trace Sobolev space associated with the norm

$$\|u\|_{\frac{1}{2},\Gamma} \equiv \inf\{\|v\|_{1,\Omega} : v \in H^1(\Omega),\ \text{trace } v = u \text{ on } \Gamma\}.$$

We start by mapping a known convex computational region, $\Omega \in R^2$ with boundary $\Gamma \in C^{3,1}$, to a given physical region, $\Omega_{\mathbf{x}} \in R^2$ with boundary $\Gamma_{\mathbf{x}} \in C^{3,1}$. We define map $\boldsymbol{\xi} : \bar{\Omega}_{\mathbf{x}} \to \bar{\Omega}$ and its inverse $\mathbf{x} : \bar{\Omega} \to \bar{\Omega}_{\mathbf{x}}$. The coordinates in $\Omega_{\mathbf{x}}$ are denoted by the vector of unknowns $\mathbf{x} = (x \quad y)^t$, and those in Ω by $\boldsymbol{\xi} = (\xi \quad \eta)^t$.

For the EGG smoothness or Winslow generator, we choose $\boldsymbol{\xi}$ to be harmonic:

$$\begin{aligned} \Delta\boldsymbol{\xi} &= \mathbf{0} && \text{in} \quad \Omega_{\mathbf{x}}, \\ \boldsymbol{\xi} &= \mathbf{v}(\mathbf{x}) && \text{on} \quad \Gamma_{\mathbf{x}}, \end{aligned} \tag{2.1}$$

where $\mathbf{v} \in H^{\frac{7}{2}}(\Gamma_{\mathbf{x}})$ is a given homeomorphism (continuous and one-to-one) from the boundary of the physical region onto the boundary of the computational region. ($H^{\frac{7}{2}}(\Gamma_{\mathbf{x}})$ is consistent with our boundary smoothness assumption, $\Gamma \in C^{3,1}$.) With $\Omega_{\mathbf{x}}$ bounded, the weak form of Laplace system (2.1) has one and only one solution $\boldsymbol{\xi}^*$ in $H^4(\Omega_{\mathbf{x}})^2$ (see [11]) and, by Weyl's lemma [22], $\boldsymbol{\xi}^* \in C^\infty_{loc}(\Omega_{\mathbf{x}}) \equiv \{\boldsymbol{\xi} \in C^\infty(K)\ \forall\, K \subset \Omega_{\mathbf{x}}\}$.

Map $\boldsymbol{\xi}^*$ is posed on $\Omega_{\mathbf{x}}$, and thus computing an approximation to it would nominally involve specifying a grid on the physical region. But specifying such a grid is the aim of EGG in the first place, and so this formulation is not useful. We therefore choose instead to solve the inverse of problem (2.1), which takes a regular grid in Ω and maps it onto a grid in $\Omega_{\mathbf{x}}$, thus achieving our objective. To this end, we assume $\Omega_{\mathbf{x}}$ and Ω to be simply connected and bounded, and $\bar{\Omega}$ to be convex, so that Γ and $\Gamma_{\mathbf{x}}$ are simple closed curves. Map $\boldsymbol{\xi}^*$ is continuous and harmonic, and $\mathbf{v}$ is a homeomorphism of $\Gamma_{\mathbf{x}}$ onto Γ, so Rado's theorem (cf. [16]) implies the existence of a unique inverse map $\mathbf{x}^*$ from Ω onto $\Omega_{\mathbf{x}}$. An outline of the proof is provided in [14]. It then follows that domain map $\boldsymbol{\xi}^*$ is a diffeomorphism [8, 12], and the associated Jacobian $J^*_{\mathbf{x}} \equiv \xi^*_x \nu^*_y - \xi^*_y \nu^*_x$ is continuous and uniformly positive and bounded on $\Omega_{\mathbf{x}}$. ($J_0 \leq |J^*_{\mathbf{x}}(x,y)| \leq J_1$ for some constants $J_0, J_1 \in R^+$ and all $(x,y) \in \Omega_{\mathbf{x}}$.) The choice of the space for $\mathbf{x}^*$ follows from the assumptions for $\boldsymbol{\xi}^*$, $\Gamma_{\mathbf{x}}$, and $\mathbf{v}$ and is discussed further in section 3.

The inverse map satisfies the following equations (positive Jacobian throughout $\Omega_{\mathbf{x}}$ ensures that the solution of (2.1) is an invertible map):

$$\begin{aligned}
(x_\eta^2 + y_\eta^2)x_{\xi\xi} - (x_\xi x_\eta + y_\xi y_\eta)(x_{\xi\eta} + x_{\eta\xi}) + (x_\xi^2 + y_\xi^2)x_{\eta\eta} &= 0 \quad \text{in} \quad \Omega,\\
(x_\eta^2 + y_\eta^2)y_{\xi\xi} - (x_\xi x_\eta + y_\xi y_\eta)(y_{\xi\eta} + y_{\eta\xi}) + (x_\xi^2 + y_\xi^2)y_{\eta\eta} &= 0 \quad \text{in} \quad \Omega,\\
x &= w_1(\xi,\eta) \quad \text{on} \quad \Gamma,\\
y &= w_2(\xi,\eta) \quad \text{on} \quad \Gamma,
\end{aligned} \tag{2.2}$$

where function $\mathbf{w} = \binom{w_1(\xi,\eta)}{w_2(\xi,\eta)}$ is the inverse of function $\mathbf{v} = \binom{v_1(x,y)}{v_2(x,y)}$ (i.e., $\mathbf{x} = \mathbf{w}(\mathbf{v}(\mathbf{x}))$). See [12] for more detail. The inverse map $\mathbf{x}^*$ exists and solves (2.2). We assume that the Fréchet derivative of the operator in (2.2) at $\mathbf{x}^*$ is one-to-one on $H_0^{2+\delta}(\Omega)^2$ (subscript 0 denoting homogeneous Dirichlet conditions on Γ). This is easily verified when $\mathbf{x}^*$ deviates from a constant map by a sufficiently small amount.

To apply our method, we begin by converting (2.2) to a first-order system. We could write these equations in a simple way using the standard notation of a 2×2 matrix for the Jacobian matrix, but this is not convenient for the linearized equations treated in section 3. Our notation is therefore based primarily on writing the Jacobian matrix as a 4×1 vector:

$$\mathbf{J} = \begin{pmatrix} x_\xi \\ x_\eta \\ y_\xi \\ y_\eta \end{pmatrix} = \begin{pmatrix} J_{11} \\ J_{21} \\ J_{12} \\ J_{22} \end{pmatrix}.$$

On the other hand, at times it is useful to refer to the matrix form of the unknowns. We therefore define the block-structured matrix $\underline{\mathbf{J}}$ and its classical adjoint $\hat{\underline{\mathbf{J}}}$ as follows:

$$\underline{\mathbf{J}} = \begin{pmatrix} J_{11} & J_{21} & 0 & 0 \\ J_{12} & J_{22} & 0 & 0 \\ 0 & 0 & J_{11} & J_{21} \\ 0 & 0 & J_{12} & J_{22} \end{pmatrix} \quad \text{and} \quad \hat{\underline{\mathbf{J}}} = \begin{pmatrix} J_{22} & -J_{21} & 0 & 0 \\ -J_{12} & J_{11} & 0 & 0 \\ 0 & 0 & J_{22} & -J_{21} \\ 0 & 0 & -J_{12} & J_{11} \end{pmatrix}.$$

Note that the Jacobian of the inverse transformation is given by

$$J \equiv x_\xi y_\eta - x_\eta y_\xi = J_{11}J_{22} - J_{21}J_{12} = \sqrt{\det \underline{\mathbf{J}}}.$$

Also, $J = \frac{1}{J_{\mathbf{x}}}$ and $\|J\|_{\infty,\Omega} = \|\frac{1}{J_{\mathbf{x}}}\|_{\infty,\Omega_{\mathbf{x}}} = \frac{1}{\|J_{\mathbf{x}}\|_{\infty,\Omega_{\mathbf{x}}}} > 0$.

In keeping with the vector notation, denote grad, div, and curl, respectively, by

$$\nabla = \begin{pmatrix} \partial_\xi & 0 \\ \partial_\eta & 0 \\ 0 & \partial_\xi \\ 0 & \partial_\eta \end{pmatrix}, \quad \nabla\cdot = \begin{pmatrix} \partial_\xi & \partial_\eta & 0 & 0 \\ 0 & 0 & \partial_\xi & \partial_\eta \end{pmatrix}, \quad \nabla\times = \begin{pmatrix} -\partial_\eta & \partial_\xi & 0 & 0 \\ 0 & 0 & -\partial_\eta & \partial_\xi \end{pmatrix}.$$

The same calculus notation is used in both $\Omega_{\mathbf{x}}$ and Ω (e.g., ∇, $\nabla\cdot$, and $\nabla\times$). Differentiation in $\Omega_{\mathbf{x}}$ is with respect to x and y, and differentiation in Ω is with respect to ξ and η. Let the boundary unit normal vector be denoted by

$$\mathbf{n} = \begin{pmatrix} n_1 & 0 \\ n_2 & 0 \\ 0 & n_1 \\ 0 & n_2 \end{pmatrix}. \tag{2.3}$$

As in previous applications of the FOSLS methodology (cf. [7]), the natural first-order system is often augmented with a curl equation to ensure that the system is elliptic in the H^1 product norm. The augmented system also allows for the possibility of solving for the unknowns in two separate stages: we can solve for $\mathbf{J}$ alone in the first stage, then fix $\mathbf{J}$ and solve for $\mathbf{x}$ alone in the second stage, as the following development shows. The curl-augmented system we consider here is

$$\begin{aligned} \mathbf{J} - \nabla\mathbf{x} &= \mathbf{0} && \text{in} \quad \Omega, \\ (\underline{\hat{\mathbf{J}}}\underline{\hat{\mathbf{J}}}^t\nabla)\cdot\mathbf{J} &= \mathbf{0} && \text{in} \quad \Omega, \\ \nabla\times\mathbf{J} &= \mathbf{0} && \text{in} \quad \Omega, \\ \mathbf{x} &= \mathbf{w} && \text{on} \quad \Gamma, \\ \mathbf{n}\times\mathbf{J} &= \mathbf{n}\times\nabla\mathbf{w} && \text{on} \quad \Gamma. \end{aligned} \tag{2.4}$$

To be very clear about our notation, note that derivatives apply only to terms on their right. Thus, for $(\underline{\hat{\mathbf{J}}}\underline{\hat{\mathbf{J}}}^t\nabla)\cdot$ in the second equation of (2.4), the matrix multiplication is applied first, keeping the order of each entry in the resulting matrix consistent with the multiplication. To perform the dot product, the matrix is transposed without altering the order of the terms in each component. For example, if we write

$$\underline{\hat{\mathbf{J}}}\underline{\hat{\mathbf{J}}}^t = \begin{pmatrix} \alpha & -\beta & 0 & 0 \\ -\beta & \gamma & 0 & 0 \\ 0 & 0 & \alpha & -\beta \\ 0 & 0 & -\beta & \gamma \end{pmatrix},$$

then

$$(\underline{\hat{\mathbf{J}}}\underline{\hat{\mathbf{J}}}^t\nabla)\cdot\mathbf{J} = \begin{pmatrix} \alpha\frac{\partial J_{11}}{\partial\xi} - \beta\frac{\partial J_{11}}{\partial\eta} - \beta\frac{\partial J_{21}}{\partial\xi} + \gamma\frac{\partial J_{21}}{\partial\eta} \\ \alpha\frac{\partial J_{12}}{\partial\xi} - \beta\frac{\partial J_{12}}{\partial\eta} - \beta\frac{\partial J_{22}}{\partial\xi} + \gamma\frac{\partial J_{22}}{\partial\eta} \end{pmatrix}.$$

We consider a two-stage algorithm, but focus only on the following first stage:

$$\begin{aligned} (\underline{\hat{\mathbf{J}}}\underline{\hat{\mathbf{J}}}^t\nabla)\cdot\mathbf{J} &= \mathbf{0} && \text{in} \quad \Omega, \\ \nabla\times\mathbf{J} &= \mathbf{0} && \text{in} \quad \Omega, \\ \mathbf{n}\times\mathbf{J} &= \mathbf{n}\times\nabla\mathbf{w} && \text{on} \quad \Gamma. \end{aligned} \tag{2.5}$$

Note that $\mathbf{x}$ can be recovered from the solution of (2.5) by a second stage that minimizes $\|\nabla\mathbf{x}-\mathbf{J}\|^2_{0,\Omega}+\|\mathbf{x}-\mathbf{w}\|^2_{\frac{1}{2},\Gamma}$ over $\mathbf{x}$ with the computed $\mathbf{J}$ held fixed. The homogeneous part of the first term in this functional is precisely the $H^1(\Omega)^4$ seminorm of $\mathbf{x}$, so minimizing this functional leads to a simple system of decoupled Poisson equations. The remainder of our analysis therefore focuses on (2.5).

To obtain homogeneous boundary conditions, we rewrite the equations in terms of the perturbation $\mathbf{D}$ of a smooth extension of $\mathbf{w}$ into Ω. To this end, suppose that some function $\mathbf{w} \in H^4(\Omega)^2$ is given so that its trace agrees with $\mathbf{w}$ on Γ. Defining $\mathbf{E} \equiv \nabla\mathbf{w} \in H^3(\Omega)^4$, we thus have

$$\mathbf{n}\times\mathbf{E} = \mathbf{n}\times\nabla\mathbf{w} \qquad \text{on } \Gamma. \tag{2.6}$$

(In practice, we do not really need an extension of $\mathbf{w}$, but rather just an extension of its gradient: any $\mathbf{E} \in H^3(\Omega)^4$ that satisfies (2.6) will do. However, if this extension is not necessarily a gradient, then $\mathbf{E}$ must be included in the curl term in (2.7) below.)

In the notation of the companion paper [10], we have

$$\mathbf{P}(\mathbf{D}) \equiv \begin{pmatrix} ((\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}})(\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}})^t\nabla)\cdot(\mathbf{E}+\mathbf{D}) \\ \nabla\times\mathbf{D} \end{pmatrix} = \mathbf{0}, \tag{2.7}$$

with boundary conditions

$$\mathbf{n}\times\mathbf{D} = \mathbf{0}. \tag{2.8}$$

System (2.7)–(2.8) corresponds to the inverse Laplace problem with Dirichlet boundary conditions. Existence of a solution $\mathbf{D}^*$ that yields a positive Jacobian is guaranteed by Rado's theorem. We show in section 3 that $\mathbf{D}^* \in H^3(\Omega)^4$. One implication of this smoothness property is that $(\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}}^*)(\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}}^*)^t$ is a uniformly positive definite and bounded matrix on Ω.

From the companion paper [10], we define

$$\mathcal{H}_{1+\delta} \equiv \{\mathbf{D} \in H^{1+\delta}(\Omega)^4 : \mathbf{n}\times\mathbf{D} = \mathbf{0} \text{ on } \Gamma\}.$$

Restricting $\mathbf{D}$ to $H^{1+\delta}(\Omega)^4$ ensures that $((\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}})(\underline{\hat{\mathbf{E}}}+\underline{\hat{\mathbf{D}}})^t\nabla)\cdot(\mathbf{E}+\mathbf{D}) \in L^2(\Omega)^2$, as the results of the next section show.

The first Fréchet derivative of (2.7) in direction $\mathbf{K}$ is

$$\mathbf{P}'(\mathbf{D})[\mathbf{K}] = \begin{pmatrix} ((\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})(\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})^t\nabla)\cdot\mathbf{K}+\mathbf{B}\cdot\mathbf{K} \\ \nabla\times\mathbf{K} \end{pmatrix}, \tag{2.9}$$

where

$$\mathbf{B}\cdot\mathbf{K} \equiv (\underline{\hat{\mathbf{K}}}(\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})^t\nabla)\cdot(\mathbf{D}+\mathbf{E}) + ((\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})\underline{\hat{\mathbf{K}}}^t\nabla)\cdot(\mathbf{D}+\mathbf{E}),$$

and the second Fréchet derivative in directions $\mathbf{K}$ and $\mathbf{M}$ is

$$\begin{aligned} \mathbf{P}''(\mathbf{D})[\mathbf{K},\mathbf{M}] = & \begin{pmatrix} (\underline{\hat{\mathbf{M}}}(\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})^t\nabla)\cdot\mathbf{K} + ((\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})\underline{\hat{\mathbf{M}}}^t\nabla)\cdot\mathbf{K} \\ \mathbf{0} \end{pmatrix} \\ & + \begin{pmatrix} (\underline{\hat{\mathbf{K}}}(\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})^t\nabla)\cdot\mathbf{M} + ((\underline{\hat{\mathbf{D}}}+\underline{\hat{\mathbf{E}}})\underline{\hat{\mathbf{K}}}^t\nabla)\cdot\mathbf{M} \\ \mathbf{0} \end{pmatrix} \\ & + \begin{pmatrix} (\underline{\hat{\mathbf{K}}}\underline{\hat{\mathbf{M}}}^t\nabla)\cdot(\mathbf{D}+\mathbf{E}) + (\underline{\hat{\mathbf{M}}}\underline{\hat{\mathbf{K}}}^t\nabla)\cdot(\mathbf{D}+\mathbf{E}) \\ \mathbf{0} \end{pmatrix}. \end{aligned} \tag{2.10}$$

3. The assumptions and their verification. Consider the assumptions made in our companion paper [10]. The first is existence of a solution in $\mathcal{H}_{2+\delta}$. From [16], we know that a unique inverse map exists and that it provides a solution $\mathbf{D}^*$ to (2.7). Recall that $\boldsymbol{\xi}^* \in H^4(\Omega_{\mathbf{x}})^2$. In Lemma 3.4 below, we show that $\mathbf{D}^* \in \mathcal{H}_3$. This establishes our first assumption for the EGG equations for any $\delta \in (0,1)$.

The remaining assumptions we need to establish are, for $\epsilon = 0$ or δ, that $\mathbf{P}[\mathbf{D}] \in H^\epsilon(\Omega)^4$ for every $\mathbf{D} \in B_r$ (Lemma 3.5), that $\|\mathbf{P}'(\mathbf{D})[\,\cdot\,]\|_{\epsilon,\Omega}$ is $H^{1+\epsilon}(\Omega)^4$ equivalent (Lemma 3.6), and that the second Fréchet derivative of $\mathbf{P}(\mathbf{D})$ is bounded for all $\mathbf{D} \in B_r$ (Lemma 3.7). (The discretization assumptions are standard.) But first we need three results that follow directly from a corollary to the Sobolev imbedding theorem [11], which (tailored to our needs) states that the product of a function in $H^{m_1}(\Omega)$ and a function in $H^{m_2}(\Omega)$ is in $H^m(\Omega)$, provided that either $m_1+m_2-m \geq 1$, $m_1 > m$, and $m_2 > m$ or $m_1+m_2-m > 1$, $m_1 \geq m$, and $m_2 \geq m$.

Assume that $r > 0$ is so small that matrix $(\hat{\underline{\mathbf{E}}} + \hat{\underline{\mathbf{D}}})(\hat{\underline{\mathbf{E}}} + \hat{\underline{\mathbf{D}}})^t$ is positive definite and bounded uniformly on Ω and over $\mathbf{D} \in B_r \equiv \{\mathbf{D} \in \mathcal{H}_{1+\delta} : \|\mathbf{D}^* - \mathbf{D}\|_{1+\delta,\Omega} < r\}$. This assumption is possible because it is true at $\mathbf{D} = \mathbf{D}^*$ and because the matrix is continuous as a function defined on B_r. Assume that $a, b, c \in H^{1+\delta}(\Omega)$. For convenience, we let ∂ denote either ∂_x or ∂_y. In the proof of Lemma 3.4, we also use ∂^2 to denote any of the four second partial derivatives, and ∂^3 for any combination of third partial derivatives. Note that $(\partial a)^2$ could mean $a_x a_y$, for example.

Lemma 3.1. *There exists a constant C, depending only on Ω and δ, such that*

$$\|ab\partial c\|_{\epsilon,\Omega} \leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\delta,\Omega}\|c\|_{1+\epsilon,\Omega}.$$

Proof. Using the corollary to the Sobolev imbedding theorem [11] with $m_1 = 1+\delta,\ m_2 = \epsilon$, and $m = \epsilon$ twice yields

$$\begin{aligned}\|ab\partial c\|_{\epsilon,\Omega} &\leq C\|a\|_{1+\delta,\Omega}\|b\partial c\|_{\epsilon,\Omega} \\ &\leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\delta,\Omega}\|\partial c\|_{\epsilon,\Omega} \\ &\leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\delta,\Omega}\|c\|_{1+\epsilon,\Omega}. \qquad \square\end{aligned}$$

Lemma 3.2. *There exists a constant C, depending only on Ω and δ, such that*

$$\|ab\partial c\|_{\epsilon,\Omega} \leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\epsilon,\Omega}\|c\|_{1+\delta,\Omega}.$$

Proof. Using the corollary to the Sobolev imbedding theorem [11] first with $m_1 = 1+\delta,\ m_2 = \epsilon$, and $m = \epsilon$, then with $m_1 = 1+\epsilon,\ m_2 = \delta$, and $m = \epsilon$ yields

$$\begin{aligned}\|ab\partial c\|_{\epsilon,\Omega} &\leq C\|a\|_{1+\delta,\Omega}\|b\partial c\|_{\epsilon,\Omega} \\ &\leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\epsilon,\Omega}\|\partial c\|_{\delta,\Omega} \\ &\leq C\|a\|_{1+\delta,\Omega}\|b\|_{1+\epsilon,\Omega}\|c\|_{1+\delta,\Omega}. \qquad \square\end{aligned}$$

Lemma 3.3. *Assume that $a, b \in H^{2+\delta}(\Omega)$ and $k \in H^{1+\delta}(\Omega)$. Then there exists a constant C, depending only on Ω and δ, such that*

$$\|ak\partial b\|_{1,\Omega} \leq C\|a\|_{1+\delta,\Omega}\|b\|_{2+\delta,\Omega}\|k\|_{1,\Omega}.$$

Proof.

$$\begin{aligned}\|ak\partial b\|_{1,\Omega} &\le C\|a\|_{1+\delta,\Omega}\|k\partial b\|_{1,\Omega}\\ &\le C\|a\|_{1+\delta,\Omega}\|\partial b\|_{1+\delta,\Omega}\|k\|_{1,\Omega}\\ &\le C\|a\|_{1+\delta,\Omega}\|b\|_{2+\delta,\Omega}\|k\|_{1,\Omega},\end{aligned}$$

where we have used the corollary to the Sobolev imbedding theorem from [11] with $m_1 = 1+\delta,\ m_2 = 1$, and $m = 1$ twice. □

LEMMA 3.4. *The solution* $\mathbf{D}^*$ *of* (2.7) *is in* $H^3(\Omega)^4$.

Proof. We have

$$\mathbf{J}^* \equiv \mathbf{E} + \mathbf{D}^* = \begin{pmatrix} J^*_{11}\\ J^*_{21}\\ J^*_{12}\\ J^*_{22}\end{pmatrix} = \begin{pmatrix} x^*_\xi\\ x^*_\eta\\ y^*_\xi\\ y^*_\eta\end{pmatrix} = \frac{1}{J^*_{\mathbf{x}}}\begin{pmatrix} \eta^*_y\\ -\xi^*_y\\ -\eta^*_x\\ \xi^*_x\end{pmatrix},$$

where $\mathbf{E} \in H^3(\Omega_{\mathbf{x}})^4$ and $\boldsymbol{\xi}^* \in H^4(\Omega_{\mathbf{x}})^2$. We now show that $\mathbf{J}^* \in H^3(\Omega)^4$, from which follows the result that $\mathbf{D}^* \in H^3(\Omega)^4$.

Since $\boldsymbol{\xi}^* \in H^4(\Omega_{\mathbf{x}})^2$, then $\xi^*_x, \xi^*_y, \eta^*_x, \eta^*_y \in H^3(\Omega_{\mathbf{x}})$. From the corollary to the Sobolev imbedding theorem (with $m_1 = 3,\ m_2 = 3$, and $m = 3$), we must have $J^*_{\mathbf{x}} = \xi^*_x\eta^*_y - \xi^*_y\eta^*_x \in H^3(\Omega_{\mathbf{x}})$. Recall from section 2 that $\mathbf{J}^*$ is continuous and uniformly positive and bounded: $J_0 \le |J^*_{\mathbf{x}}(x,y)| \le J_1$ for some constants $J_0, J_1 \in R^+$ and all $(x,y) \in \Omega_{\mathbf{x}}$.

Dropping the superscript * for convenience, consider J_{11}. (The other entries are treated similarly.) Using the corollary to the Sobolev imbedding theorem [11] with $m_1 = 3,\ m_2 = 3$, and $m = 3$, we get

$$\|J_{11}\|_{3,\Omega} = \left\|\frac{1}{J_{\mathbf{x}}}\eta_y\right\|_{3,\Omega_{\mathbf{x}}} \le C\left\|\frac{1}{J_{\mathbf{x}}}\right\|_{3,\Omega_{\mathbf{x}}}\|\eta_y\|_{3,\Omega_{\mathbf{x}}}.$$

Therefore, we need only show that $\frac{1}{J_{\mathbf{x}}} \in H^3$. But

$$\left\|\frac{1}{J_{\mathbf{x}}}\right\|^2_{3,\Omega_{\mathbf{x}}} = \sum_{i\le 3}\left\|\partial^i\frac{1}{J_{\mathbf{x}}}\right\|^2_{0,\Omega_{\mathbf{x}}}.$$

We consider each order separately. By Theorem 3.2 in [21], for any $a \in C^0(\Omega_{\mathbf{x}})$ and $b \in L^2(\Omega_{\mathbf{x}})$, we have

$$\|ab\|_{0,\Omega_{\mathbf{x}}} \le \|a\|_{\infty,\Omega_{\mathbf{x}}}\|b\|_{0,\Omega_{\mathbf{x}}}. \tag{3.1}$$

For the zeroth-order term, using (3.1) yields

$$\left\|\frac{1}{J_{\mathbf{x}}}\right\|_{0,\Omega_{\mathbf{x}}} \le \left\|\frac{1}{J_{\mathbf{x}}}\right\|_{\infty,\Omega_{\mathbf{x}}}\|1\|_{0,\Omega_{\mathbf{x}}} \le \frac{1}{J_0}\|1\|_{0,\Omega_{\mathbf{x}}}.$$

For the first-order term, we use (3.1) to get

$$\left\|\partial\frac{1}{J_{\mathbf{x}}}\right\|_{0,\Omega_{\mathbf{x}}} = \left\|\frac{-1}{J^2_{\mathbf{x}}}\partial J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \le \frac{1}{J_0^2}\|\partial J_{\mathbf{x}}\|_{0,\Omega_{\mathbf{x}}} \le \frac{1}{J_0^2}\|J_{\mathbf{x}}\|_{1,\Omega_{\mathbf{x}}}.$$

For the second-order term, we use the triangle inequality, (3.1), and the corollary to the Sobolev imbedding theorem with $m_1 = m_2 = 1$ and $m = 0$ to get

$$\begin{aligned}
\left\|\partial^2 \frac{1}{J_{\mathbf{x}}}\right\|_{0,\Omega_{\mathbf{x}}} &= \left\|\frac{2}{J_{\mathbf{x}}^3}(\partial J_{\mathbf{x}})^2 + \frac{-1}{J_{\mathbf{x}}^2}\partial^2 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le \left\|\frac{2}{J_{\mathbf{x}}^3}(\partial J_{\mathbf{x}})^2\right\|_{0,\Omega_{\mathbf{x}}} + \left\|\frac{1}{J_{\mathbf{x}}^2}\partial^2 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le \frac{2}{J_0^3}\left\|(\partial J_{\mathbf{x}})^2\right\|_{0,\Omega_{\mathbf{x}}} + \frac{1}{J_0^2}\left\|\partial^2 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le C\left(\frac{2}{J_0^3}\left\|\partial J_{\mathbf{x}}\right\|_{1,\Omega_{\mathbf{x}}}^2 + \frac{1}{J_0^2}\left\|J_{\mathbf{x}}\right\|_{2,\Omega_{\mathbf{x}}}\right) \\
&\le C\left(\frac{2}{J_0^3}\left\|J_{\mathbf{x}}\right\|_{2,\Omega_{\mathbf{x}}}^2 + \frac{1}{J_0^2}\left\|J_{\mathbf{x}}\right\|_{2,\Omega_{\mathbf{x}}}\right).
\end{aligned}$$

For the third-order term, we use the triangle inequality, (3.1), and the Corollary to the Sobolev imbedding theorem once with $m_1 = 1$, $m_2 = \frac{3}{4}$, and $m = 0$, once with $m_1 = m_2 = 1$ and $m = 0$, and once with $m_1 = m_2 = 1$ and $m = \frac{3}{4}$ to get

$$\begin{aligned}
\left\|\partial^3 \frac{1}{J_{\mathbf{x}}}\right\|_{0,\Omega_{\mathbf{x}}} &= \left\|\frac{-6}{J_{\mathbf{x}}^4}(\partial J_{\mathbf{x}})^3 + \frac{6}{J_{\mathbf{x}}^3}\partial J_{\mathbf{x}}\partial^2 J_{\mathbf{x}} + \frac{-1}{J_{\mathbf{x}}^2}\partial^3 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le \left\|\frac{6}{J_{\mathbf{x}}^4}(\partial J_{\mathbf{x}})^3\right\|_{0,\Omega_{\mathbf{x}}} + \left\|\frac{6}{J_{\mathbf{x}}^3}\partial J_{\mathbf{x}}\partial^2 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} + \left\|\frac{1}{J_{\mathbf{x}}^2}\partial^3 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le \frac{6}{J_0^4}\left\|(\partial J_{\mathbf{x}})^3\right\|_{0,\Omega_{\mathbf{x}}} + \frac{6}{J_0^3}\left\|\partial J_{\mathbf{x}}\partial^2 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} + \frac{1}{J_0^2}\left\|\partial^3 J_{\mathbf{x}}\right\|_{0,\Omega_{\mathbf{x}}} \\
&\le C\left(\frac{6}{J_0^4}\left\|\partial J_{\mathbf{x}}\right\|_{1,\Omega_{\mathbf{x}}}^3 + \frac{6}{J_0^3}\left\|\partial J_{\mathbf{x}}\right\|_{1,\Omega_{\mathbf{x}}}\left\|\partial^2 J_{\mathbf{x}}\right\|_{1,\Omega_{\mathbf{x}}} + \frac{1}{J_0^2}\left\|J_{\mathbf{x}}\right\|_{3,\Omega_{\mathbf{x}}}\right) \\
&\le C\left(\frac{6}{J_0^4}\left\|J_{\mathbf{x}}\right\|_{2,\Omega_{\mathbf{x}}}^3 + \frac{6}{J_0^3}\left\|J_{\mathbf{x}}\right\|_{2,\Omega_{\mathbf{x}}}\left\|J_{\mathbf{x}}\right\|_{3,\Omega_{\mathbf{x}}} + \frac{1}{J_0^2}\left\|J_{\mathbf{x}}\right\|_{3,\Omega_{\mathbf{x}}}\right).
\end{aligned}$$

The result follows from these bounds. □

LEMMA 3.5. $\mathbf{P}[\mathbf{D}] \in H^{\epsilon}(\Omega)^p$ *for every* $\mathbf{D} \in B_r$*: there exists a constant* C*, depending only on* $\mathbf{D}^*$*,* $\mathbf{E}$*,* r*,* Ω*, and* δ*, such that*

$$\|\mathbf{P}(\mathbf{D})\|_{\epsilon,\Omega} \le C \quad \forall\ \mathbf{D} \in B_r. \tag{3.2}$$

Proof. The products in (2.7) are of the form treated in Lemma 3.1. In fact, there exists a constant C, depending only on Ω and δ, such that

$$\|\mathbf{P}(\mathbf{D})\|_{\epsilon,\Omega} \le C(\|\mathbf{D}+\mathbf{E}\|_{1+\delta,\Omega}^2\|\mathbf{D}+\mathbf{E}\|_{1+\epsilon,\Omega} + \|\mathbf{D}\|_{1+\epsilon,\Omega}), \tag{3.3}$$

and so (3.2) follows because $\mathbf{D} \in B_r$. □

Next we establish uniform coercivity and continuity of $\mathbf{P}'$ in a neighborhood of $\mathbf{D}^*$. This result needs the assumption that $\mathbf{P}'(\mathbf{D}^*)[\,\cdot\,]$ is one-to-one on $\mathcal{H}_{1+\delta}$, which is a consequence of an analogous assumption on the original EGG equations.

LEMMA 3.6 (ellipticity property). $\|\mathbf{P}'(\mathbf{D})[\,\cdot\,]\|_{\epsilon,\Omega}$ *is* $H^{1+\epsilon}(\Omega)^4$ *equivalent: there exist constants* c_c *and* c_b*, depending only on* $\mathbf{D}^*, \mathbf{E}, r, \Omega$*, and* δ*, such that*

$$\frac{1}{c_c}\|\mathbf{K}\|_{1+\epsilon,\Omega} \le \|\mathbf{P}'(\mathbf{D})[\mathbf{K}]\|_{\epsilon,\Omega} \le c_b\|\mathbf{K}\|_{1+\epsilon,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_{1+\epsilon}. \tag{3.4}$$

Proof. The products in (2.9) are of the form treated in Lemmas 3.1 and 3.2. In fact, there exists a constant C, depending only on Ω and δ, such that

$$\|\mathbf{P}'(\mathbf{D})[\mathbf{K}]\|_{\epsilon,\Omega} \leq C(\|\mathbf{D}+\mathbf{E}\|^2_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\epsilon,\Omega} + \|\mathbf{K}\|_{1+\epsilon,\Omega}). \tag{3.5}$$

Proof of the lower bound follows from Theorem 10.5 of [2], as we now show. We first need to prove H^{m+1} boundedness and coercivity for $\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}]$: there exist constants c_1 and c_3, depending only on $\mathbf{D}^*, \mathbf{E}, m$, and Ω, such that

$$\frac{1}{c_1}\|\mathbf{K}\|_{m+1,\Omega} \leq \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}]\|_{m,\Omega} \leq c_3\|\mathbf{K}\|_{m+1,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_{m+1}, \tag{3.6}$$

for any $m \in [0,1]$. The upper bound is simply an application of the corollary to the Sobolev imbedding theorem similar to Lemmas 3.1 and 3.2. Consider the lower bound. It would be a simple matter to just assume $\mathbf{D}^* \in \mathcal{H}_{3+\delta}$ and then, because the coefficients would be sufficiently smooth, apply the theory of [2] (herafter referred to as ADN2 theory) for both $m = 0$ and $m = 1$. Instead, we just have $\mathbf{D}^* \in \mathcal{H}_{2+\delta}$, so while the higher-order coefficients are in C^1, the lower-order coefficients are only in C^0. This means that we need more care.

First consider $m = 0$. What follows for this case is a straightforward application of ADN2 theory to the entire system because all of the coefficients are sufficiently smooth. Recall that Ω is a bounded open subset of R^2 with $C^{3,1}$ boundary Γ. We write the system as

$$\begin{array}{rcl} \mathcal{L}\mathbf{K} = \mathbf{f} & \text{in} & \Omega, \\ \mathcal{B}\mathbf{K} = \mathbf{g} & \text{on} & \Gamma, \end{array} \tag{3.7}$$

where $\mathcal{L} \equiv \mathbf{P}'(\mathbf{D}^*)$ and $\mathcal{B} = \mathbf{n}\times$. (Recall that $\mathbf{n}$ is the outward unit normal on Γ (2.3).) For convenience, we write the coefficients using $\mathbf{J}^* = \mathbf{D}^* + \mathbf{E}$ and drop the * from the components. Note that $\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2$ and $l_{ij} = l'_{ij} + l''_{ij}$, where

$$\mathcal{L}_1 = (l'_{ij}(\boldsymbol{\xi}, \partial)) = \begin{pmatrix} \alpha\partial_\xi - \beta\partial_\eta & -\beta\partial_\xi + \gamma\partial_\eta & 0 & 0 \\ 0 & 0 & \alpha\partial_\xi - \beta\partial_\eta & -\beta\partial_\xi + \gamma\partial_\eta \\ -\partial_\eta & \partial_\xi & 0 & 0 \\ 0 & 0 & -\partial_\eta & \partial_\xi \end{pmatrix},$$

$$\begin{aligned} \mathcal{L}_2 &= (l''_{ij}(\boldsymbol{\xi}, \partial)) \\ &= \begin{pmatrix} 2J_{11}J_{21,\eta} - J_{21}(J_{11,\eta} + J_{21,\xi}) & 2J_{11}J_{22,\eta} - J_{21}(J_{12,\eta} + J_{22,\xi}) & 0 & 0 \\ 2J_{21}J_{11,\xi} - J_{11}(J_{11,\eta} + J_{21,\xi}) & 2J_{21}J_{12,\xi} - J_{11}(J_{12,\eta} + J_{22,\xi}) & 0 & 0 \\ 2J_{12}J_{21,\eta} - J_{22}(J_{11,\eta} + J_{21,\xi}) & 2J_{12}J_{22,\eta} - J_{22}(J_{12,\eta} + J_{22,\xi}) & 0 & 0 \\ 2J_{22}J_{11,\xi} - J_{12}(J_{11,\eta} + J_{21,\xi}) & 2J_{22}J_{12,\xi} - J_{12}(J_{12,\eta} + J_{22,\xi}) & 0 & 0 \end{pmatrix}^t, \end{aligned}$$

$$\alpha = J_{21}^2 + J_{22}^2, \qquad \beta = J_{11}J_{21} + J_{12}J_{22}, \qquad \gamma = J_{11}^2 + J_{12}^2.$$

Note that

$$\mathcal{B} = (b_{ij}(\boldsymbol{\xi}, \partial)) = \begin{pmatrix} -n_2 & n_1 & 0 & 0 \\ 0 & 0 & -n_2 & n_1 \end{pmatrix}. \tag{3.8}$$

In ADN2 theory, three types of integer weights are used to determine the leading order terms for boundary value problem (3.7). Weight $s_i \leq 0$ refers to the ith equation, weight $t_j \geq 0$ to the jth dependent variable, and weight r_k to the kth boundary condition. These weights are chosen as small as possible but so that

$$\deg l_{ij}(\boldsymbol{\xi}, \partial) \leq s_i + t_j, \quad \deg b_{kj}(\boldsymbol{\xi}, \partial) \leq r_k + t_j, \quad i, j = 1, 2, 3, 4, \quad k = 1, 2,$$

where deg refers to the order of the derivatives. Our weights are

$$s_i = 0, \qquad t_j = 1, \qquad r_k = -1, \qquad i, j = 1, 2, 3, 4, \quad k = 1, 2.$$

The leading order part of $\mathcal{L}$ consists of the elements l_{ij} for which $\deg l_{ij}(\boldsymbol{\xi}, \partial) = s_i + t_j = 1$. Therefore, $\mathcal{L}_1$ is the leading order (in this case, first-order) part. The leading order part of $\mathcal{B}$ consists of elements b_{kj} for which $\deg b_{kj}(\boldsymbol{\xi}, \partial) = r_k + t_j = 0$. Therefore, the leading order (in this case, zeroth-order) part of $\mathcal{B}$ is $\mathcal{B}$ itself.

We must show that $\mathcal{L}_1$ satisfies two ADN2 conditions: the *supplementary condition on its determinant* and *uniform ellipticity*. ($\mathcal{L}_1$ will then automatically be elliptic.) ADN2 also requires that the system of equations and boundary conditions be well posed. This means that $\mathcal{L}_1$ and $\mathcal{B}$, when combined, must satisfy the *complementing boundary condition*. Let L denote the determinant of $\mathcal{L}_1$:

$$L(\boldsymbol{\xi}, \partial) = \det(l'_{ij}) = -(\alpha\partial_\xi^2 - 2\beta\partial_\xi\partial_\eta + \gamma\partial_\eta^2)^2.$$

Since $J > 0$ (see section 2), then

$$\begin{aligned} \beta^2 - \alpha\gamma &= (x_\xi x_\eta + y_\xi y_\eta)^2 - (x_\eta^2 + y_\eta^2)(x_\xi^2 + y_\xi^2) \\ &= -(x_\xi y_\eta - y_\xi x_\eta)^2 = -J^2 < 0. \end{aligned} \tag{3.9}$$

Let $\mathbf{d} = (d \quad e)^t$ and $\mathbf{p} = (p \quad q)^t$ be any two linearly independent vectors. To aid clarity of the following discussion, we first define some quantities:

$$\begin{aligned} \mathcal{A} &= \alpha dp - \beta(pe + dq) + \gamma eq, \\ \mathcal{B} &= \sqrt{\mathcal{DC} - \mathcal{A}^2} = J|pe - dq|, \\ \mathcal{C} &= \alpha d^2 - 2\beta de + \gamma e^2, \\ \mathcal{D} &= \alpha p^2 - 2\beta pq + \gamma q^2. \end{aligned}$$

Note that $\mathcal{B} > 0$ since $J > 0$ and linear independence of $\mathbf{p}$ and $\mathbf{d}$ implies $|pe - dq| > 0$.

The *supplementary condition on L* requires the equation

$$L(\boldsymbol{\xi}, \mathbf{d} + \tau\mathbf{p}) = -\{\mathcal{C} + 2\tau\mathcal{A} + \tau^2\mathcal{D}\}^2 = 0 \tag{3.10}$$

to have exactly two roots in τ with positive imaginary part. Polynomial (3.10) has two double roots ($\iota = \sqrt{-1}$),

$$\tau = \frac{-\mathcal{A} \pm \iota\mathcal{B}}{\mathcal{D}},$$

which form two complex conjugate pairs. Thus, (3.10) does indeed have exactly two roots with positive imaginary part (one such double root).

To satisfy *uniform ellipticity*, we need to show that

$$\frac{1}{C}\|\mathbf{d}\|^4 \leq |L(\boldsymbol{\xi}, \mathbf{d})| \leq C\|\mathbf{d}\|^4, \tag{3.11}$$

with $\|\mathbf{d}\| = \sqrt{d^2 + e^2}$, for all vectors $\mathbf{d} \neq \mathbf{0}$ and points $\boldsymbol{\xi}$ in Ω.

To prove the left bound in (3.11), let $\rho = \frac{|\beta|}{\sqrt{\alpha\gamma}} < 1$ (see (3.9)). Then

$$\begin{aligned}
|L\,(\boldsymbol{\xi}, \mathbf{d})| &= (\alpha d^2 - 2\beta de + \gamma e^2)^2 \\
&\geq (\alpha d^2 - 2|\beta||d||e| + \gamma e^2)^2 \\
&= (\alpha d^2 - 2\rho\sqrt{\alpha\gamma}|d||e| + \gamma e^2)^2 \\
&= ((1-\rho)(\alpha d^2 + \gamma e^2) + \rho(\sqrt{\alpha} d - \sqrt{\gamma} e)^2)^2 \\
&\geq ((1-\rho)(\alpha d^2 + \gamma e^2))^2 \\
&\geq \min((1-\rho)^2\alpha^2, (1-\rho)^2\gamma^2)(d^2 + e^2)^2 \\
&= \min((1-\rho)^2\alpha^2, (1-\rho)^2\gamma^2)\|\mathbf{d}\|^4.
\end{aligned}$$

To prove the right bound in (3.11), note that Hölder's inequality implies that

$$\begin{aligned}
|L\,(\boldsymbol{\xi}, \mathbf{d})| &\leq (\alpha d^2 + 2|\beta||d||e| + \gamma e^2)^2 \\
&\leq (\alpha d^2 + |\beta|(d^2 + e^2) + \gamma e^2)^2 \\
&\leq \max((\alpha + |\beta|)^2, (\gamma + |\beta|)^2)(d^2 + e^2)^2 \\
&= \max((\alpha + |\beta|)^2, (\gamma + |\beta|)^2)\|\mathbf{d}\|^4.
\end{aligned}$$

We then establish (3.11) by choosing

$$C = \max\left\{\frac{1}{(1-\rho)^2\alpha^2}, \frac{1}{(1-\rho)^2\gamma^2}, (\alpha + |\beta|)^2, (\gamma + |\beta|)^2\right\}.$$

This shows that operator L satisfies the two conditions of ADN2. We now prove that the problem is well posed by showing that $\mathcal{L}_1$ and $\mathcal{B}$ satisfy the *complementing boundary condition*. This condition involves comparing two polynomials. We consider a point on the boundary with normal $\mathbf{d} = (d \ \ e)^t$ and tangent $\mathbf{p} = (p \ \ q)^t$ vectors. The first polynomial is formed from the roots of (3.10) with positive imaginary parts:

$$M^+(\boldsymbol{\xi}, \mathbf{d}, \tau) = \left[\tau + \frac{\mathcal{A} - \iota\mathcal{B}}{\mathcal{D}}\right]^2. \tag{3.12}$$

The second polynomial is formed from the leading order elements of $\mathcal{L}$ and $\mathcal{B}$:

$$\sum_{k=1}^{2} a_k (BL)_{km}, \tag{3.13}$$

where

$$(BL)_{km} = \sum_{j=1}^{4} b_{kj}(\boldsymbol{\xi}, \mathbf{d} + \tau\mathbf{p}) l^{jm}(\boldsymbol{\xi}, \mathbf{d} + \tau\mathbf{p}),$$

and $l^{jm}(\boldsymbol{\xi}, \mathbf{d} + \tau\mathbf{p})$ are the elements of the (classical) adjoint $(l'_{ij} l^{jm} = \delta_i^m L,\ i, j, m = 1, 2, 3, 4)$ of $l'_{ij}(\boldsymbol{\xi}, \mathbf{d} + \tau\mathbf{p})$ and b_{kj} is defined in (3.8).

The polynomials for (3.13) are

$$\left(\sum_{k=1}^{2} a_k (BL)_{km}\right) = \mathcal{D}\left[\tau + \frac{\mathcal{A} + \iota\mathcal{B}}{\mathcal{D}}\right]\left[\tau + \frac{\mathcal{A} - \iota\mathcal{B}}{\mathcal{D}}\right]\begin{pmatrix} a_1(pe - qd) \\ a_2(pe - qd) \\ a_1(\mathcal{A} + \tau\mathcal{D}) \\ a_2(\mathcal{A} + \tau\mathcal{D}) \end{pmatrix}^t. \tag{3.14}$$

Comparing polynomials (3.12) and (3.14) and noting that $\mathcal{B} > 0$, we have that (3.12) is not a factor of (3.14). Thus, the *complementing boundary condition* is satisfied.

Theorem 10.5 from [2] implies that, for $l_{ij} \in C^m(\overline{\Omega}), b_{kj} \in C^{m+1}(\Gamma)$, there exists a constant c_1 that depends only on $\mathbf{D}^*, \mathbf{E}, r, \Omega$, and δ such that, if $K_j \in H^1(\Omega)$, $1 \leq j \leq 4$, solves (3.7) and is unique, then $K_j \in H^{m+1}(\Omega)$ and

$$\|K_j\|_{m+1,\Omega} \leq \frac{c_1}{4} \left[\sum_{i=1}^{4} \|f_i\|_{m,\Omega} + \sum_{i=1}^{2} \|g_i\|_{m+\frac{1}{2},\Gamma} \right],$$

where f_i and g_i are the components of $\mathbf{f}$ and $\mathbf{g}$, respectively, in (3.7). The coefficients of $\mathcal{L}$ are at least in $H^{1+\delta}(\Omega)$ and $C^0(\Omega)$. For the boundary conditions, we have $\mathcal{B} = \mathbf{n}\times$ and $\Gamma \in C^{3,1}$, and thus we get $b_{kj} \in C^2(\Gamma)$. The boundary conditions are homogeneous, and so we can drop the boundary term in the inequality. We therefore have

$$\|\mathbf{K}\|_{1,\Omega} \leq c_1 \|\mathcal{L}(\mathbf{D}^*)[\mathbf{K}]\|_{0,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_1(\Omega)^4. \tag{3.15}$$

Now consider $m = 1$. We cannot simply apply ADN2 to the whole system because the coefficients are not sufficiently smooth. Instead, we split the operator according to $\mathcal{L} = \mathcal{L}_1 + \mathcal{L}_2$ and restrict our ADN2 result to reduced system

$$\begin{aligned} \mathcal{L}_1\mathbf{K} = \mathbf{f} \quad &\text{in} \quad \Omega, \\ \mathcal{B}\mathbf{K} = \mathbf{g} \quad &\text{on} \quad \Gamma. \end{aligned}$$

Operator $\mathcal{L}_1$ satisfies the ADN2 conditions (as illustrated for case $m = 0$), and thus

$$\|\mathbf{K}\|_{2,\Omega} \leq c_1 \|\mathcal{L}_1(\mathbf{D}^*)[\mathbf{K}]\|_{1,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_2. \tag{3.16}$$

The coefficients of $\mathcal{L}_1$ are in $H^{2+\delta}(\Omega)$ and $C^1(\Omega)$. For the boundary conditions, we have $\mathcal{B} = \mathbf{n}\times$ and $\Gamma \in C^{3,1}$, and thus we get $b_{kj} \in C^2(\Gamma)$. The boundary conditions are homogeneous, and so we can drop the boundary term in the inequality.

We use Lemma 3.3 to obtain

$$\|\mathcal{L}_2(\mathbf{D}^*)[\mathbf{K}]\|_{1,\Omega} \leq c_2 \|\mathbf{K}\|_{1,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_2. \tag{3.17}$$

Note that c_2 depends continuously on $\sup_{\mathbf{D} \in B_r} \|\mathbf{D}^* + \mathbf{E}\|_{2+\delta,\Omega}$, and thus it depends on $\mathbf{D}^*, \mathbf{E}, r$, Ω, and δ.

Combining (3.16) and (3.17) yields

$$\|\mathbf{K}\|_{2,\Omega} \leq C(\|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}]\|_{1,\Omega} + \|\mathbf{K}\|_{1,\Omega}) \quad \forall\ \mathbf{K} \in \mathcal{H}_2. \tag{3.18}$$

This is a Gårdings inequality (cf. [13, 19]), which allows us now to prove that

$$\frac{1}{c_c} \|\mathbf{K}\|_{2,\Omega} \leq \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}]\|_{1,\Omega} \quad \forall\ \mathbf{K} \in \mathcal{H}_2. \tag{3.19}$$

To this end, assume that (3.19) is not true. Then there exists a sequence $\mathbf{K}_j \in \mathcal{H}_2$ such that

$$\|\mathbf{K}_j\|_{2,\Omega} = 1 \tag{3.20}$$

and

$$\|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}_j]\|_{1,\Omega} = \frac{1}{j}, \quad j = 1, 2 \ldots. \tag{3.21}$$

Now, because $H^2(\Omega)$ is compactly imbedded in $H^1(\Omega)$ (cf. the Rellich selection theorem [5]), then (3.20) implies that there exists a limit $\hat{\mathbf{K}} \in \mathcal{H}_2$ of a subsequence $\mathbf{K}_{j_k} \to \hat{\mathbf{K}}$ in the $H^1(\Omega)$ norm. Combining this with (3.18) and (3.21), we know that $\mathbf{K}_{j_k}$ must also be a Cauchy sequence in the $H^2(\Omega)$ norm with some limit $\bar{\mathbf{K}}$. However, from the upper bound in (3.4), we have

$$\begin{aligned}\lim_{j_k\to\infty} \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}_{j_k}] - \mathbf{P}'(\mathbf{D}^*)[\bar{\mathbf{K}}]\|_{1,\Omega} &= \lim_{j_k\to\infty} \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}_{j_k} - \bar{\mathbf{K}}]\|_{1,\Omega} \\ &\le \lim_{j_k\to\infty} \|\mathbf{K}_{j_k} - \bar{\mathbf{K}}\|_{2,\Omega} = 0.\end{aligned}$$

From (3.21), we thus obtain

$$\|\mathbf{P}'(\mathbf{D}^*)[\bar{\mathbf{K}}]\|_{1,\Omega} \le \lim_{j_k\to\infty} \{\|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}_{j_k}] - \mathbf{P}'(\mathbf{D}^*)[\bar{\mathbf{K}}]\|_{1,\Omega} + \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}_{j_k}]\|_{1,\Omega}\} = 0.$$

However, $\mathbf{P}'(\mathbf{D}^*)[\,\cdot\,]$ is one-to-one. Hence, $\mathbf{P}'(\mathbf{D}^*)[\bar{\mathbf{K}}] = \mathbf{0}$ implies that $\bar{\mathbf{K}} = \mathbf{0}$, which in turn implies that $\|\bar{\mathbf{K}}\|_{1,\Omega} = 0$, contradicting (3.20). Thus, (3.4) and the lemma are established for $m = 1$. We have thus established (3.6) for both $m = 0$ and $m = 1$.

For the general case of $m \in [0, 1]$, bound (3.6) follows from the results in [17, 3, 18] and the following proof of elliptic regularity of the formal adjoint problem.

Consider boundary value problem (3.7), for $\mathbf{K} \in \mathcal{H}_{m+1}$ and $\mathcal{L}\mathbf{K} \in \mathcal{V}_m = \{\mathbf{D} \in H^m(\Omega)^4\}$. From [2], we know that $\mathcal{L}\mathbf{K} = \mathbf{f}$ is onto. This system has normal boundary conditions, and hence, the formal adjoint problem has normal boundary conditions of the same type [17]. We thus consider

$$\begin{aligned}\mathcal{L}^*\mathbf{M} = \mathbf{f}_1 \quad &\text{in} \quad \Omega,\\ \mathcal{B}^*\mathbf{M} = \mathbf{0} \quad &\text{on} \quad \Gamma,\end{aligned}$$

for $\mathbf{M} \in (\mathcal{V}_m)^* = \{\mathbf{M} \in H^{-m}(\Omega)^4 : \mathcal{B}^*\mathbf{M} = \mathbf{0} \text{ on } \Gamma\}$ and $\mathcal{L}^*\mathbf{M} \in (\mathcal{H}_{m+1})^*$. The system is both Petrovskii elliptic, because $s_1 = s_2 = s_3 = s_4 = 0$, and homogeneous elliptic, because $t_1 = t_2 = t_3 = t_4$; cf. [17]. Thus, the adjoint system is elliptic [17] and has a similar ellipticity result in the dual space: for all $\mathbf{M} \in (\mathcal{V}_m)^*$ we have

$$\begin{aligned}\|\mathbf{M}\|_{-m,\Omega} &= \sup_{\mathbf{V}\neq 0\in\mathcal{V}_m} \frac{(\mathbf{M},\mathbf{V})}{\|\mathbf{V}\|_{m,\Omega}}\\ &= \sup_{\mathbf{K}\neq 0\in\mathcal{H}_{m+1}} \frac{(\mathbf{M},\mathcal{L}\mathbf{K})}{\|\mathcal{L}\mathbf{K}\|_{m,\Omega}}\\ &\le c_1 \sup_{\mathbf{K}\neq 0\in\mathcal{H}_{m+1}} \frac{(\mathcal{L}^*\mathbf{M},\mathbf{K})}{\|\mathbf{K}\|_{m+1,\Omega}}\\ &= c_1\|\mathcal{L}^*\mathbf{M}\|_{-(m+1),\Omega}\end{aligned}$$

and

$$\begin{aligned}\|\mathbf{M}\|_{-m,\Omega} &= \sup_{\mathbf{V}\neq 0\in\mathcal{V}_m} \frac{(\mathbf{M},\mathbf{V})}{\|\mathbf{V}\|_{m,\Omega}}\\ &= \sup_{\mathbf{K}\neq 0\in\mathcal{H}_{m+1}} \frac{(\mathbf{M},\mathcal{L}\mathbf{K})}{\|\mathcal{L}\mathbf{K}\|_{m,\Omega}}\\ &\ge \frac{1}{c_3} \sup_{\mathbf{K}\neq 0\in\mathcal{H}_{m+1}} \frac{(\mathcal{L}^*\mathbf{M},\mathbf{K})}{\|\mathbf{K}\|_{m+1,\Omega}}\\ &= \frac{1}{c_3}\|\mathcal{L}^*\mathbf{M}\|_{-(m+1),\Omega}.\end{aligned}$$

The result for all $m \in [0,1]$ now follows from interpolation [15], use of local maps, and a partition of unity. (If we had assumed $\mathbf{D}^* \in C^\infty(\Omega)^4$ and $\Gamma \in C^\infty$, then the ellipticity result would hold for all real m; we only need this result for $m \in [0,1]$, and so we are able to reduce the continuity requirements of [15], as we have.)

We now generalize the result for $\mathbf{D} \in B_r$. Using a Taylor expansion, the triangle inequality, Lemmas 3.5 and 3.7, and (3.6), we have (for $\epsilon = 0$ or δ)

$$\begin{aligned}
\|\mathbf{P}'(\mathbf{D})[\mathbf{K}]\|_{\epsilon,\Omega} &= \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}] + \mathbf{P}''(\widetilde{\mathbf{D}})[\mathbf{K}, \mathbf{D}^* - \mathbf{D}]\|_{\epsilon,\Omega} \\
&\geq \|\mathbf{P}'(\mathbf{D}^*)[\mathbf{K}]\|_{\epsilon,\Omega} - \|\mathbf{P}''(\widetilde{\mathbf{D}})[\mathbf{K}, \mathbf{D}^* - \mathbf{D}]\|_{\epsilon,\Omega} \\
&\geq c_1\|\mathbf{K}\|_{1+\epsilon,\Omega} - c_4\|\widetilde{\mathbf{D}} + \mathbf{E}\|_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\epsilon,\Omega}\|\mathbf{D}^* - \mathbf{D}\|_{1+\delta,\Omega} \\
&\geq \|\mathbf{K}\|_{1+\epsilon,\Omega}(c_1 - c_4 r(\|\mathbf{D}^*\|_{1+\delta,\Omega} + \|\mathbf{E}\|_{1+\delta,\Omega} + r)) \\
&\geq \tfrac{1}{c_c}\|\mathbf{K}\|_{1+\epsilon,\Omega}
\end{aligned} \tag{3.22}$$

for sufficiently small r. The lemma now follows. □

LEMMA 3.7. *The second Fréchet derivative of* $\mathbf{P}(\mathbf{D})$ *is bounded for all* $\mathbf{D} \in B_r$*: for every* $\mathbf{D} \in B_r$ *there exists a constant* c_2*, depending only on* $\mathbf{D}^*$, $\mathbf{E}$, r, Ω, *and* δ, *such that*

$$\|\mathbf{P}''(\mathbf{D})[\mathbf{K}, \mathbf{K}]\|_{\epsilon,\Omega} \leq c_2\|\mathbf{K}\|_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\epsilon,\Omega} \quad \forall\, \mathbf{K} \in \mathcal{H}_{1+\epsilon}(\Omega). \tag{3.23}$$

Here, $\mathbf{P}''(\mathbf{D})[\mathbf{K}, \mathbf{K}]$ *denotes the second Fréchet derivative of* $\mathbf{P}(\mathbf{D}_n)$ *with respect to* $\mathbf{D}_n$ *in directions* $\mathbf{K}$ *and* $\mathbf{K}$.

Proof. The products in (2.10) are of the form treated in Lemmas 3.1 and 3.2. In fact, there exists a constant C, depending only on Ω and δ, such that

$$\|\mathbf{P}''(\mathbf{D})[\mathbf{K}, \mathbf{K}]\|_{\epsilon,\Omega} \leq C\|\mathbf{D} + \mathbf{E}\|_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\delta,\Omega}\|\mathbf{K}\|_{1+\epsilon,\Omega} \qquad \forall\, \mathbf{K} \in H^{1+\delta}(\Omega).$$

The lemma now follows. □

4. Numerical results. Here we validate our algorithm with numerical tests. Define H^h as the space of continuous piecewise bilinear functions corresponding to a uniform grid. Note that $H^h \subset H^{1+\delta}(\Omega)$ for any $\delta < \frac{1}{2}$. The functional to be minimized is

$$\begin{aligned}
&\mathbf{G}(\mathbf{x}_{n+1}, \mathbf{J}_{n+1}; \mathbf{x}_n, \mathbf{J}_n, \mathbf{w}) \\
&\quad = \varepsilon\|\mathbf{J}_{n+1} - \nabla\mathbf{x}_{n+1}\|^2_{0,\Omega} \\
&\quad + (1-\varepsilon)\left\|\tfrac{1}{J_n}\left[(\underline{\hat{\mathbf{J}}_n\hat{\mathbf{J}}^t_n}\nabla)\cdot\mathbf{J}_{n+1} + (\underline{\hat{\mathbf{J}}_{n+1}\hat{\mathbf{J}}^t_n}\nabla)\cdot\mathbf{J}_n + (\underline{\hat{\mathbf{J}}_n\hat{\mathbf{J}}^t_{n+1}}\nabla)\cdot\mathbf{J}_n - 2(\underline{\hat{\mathbf{J}}_n\hat{\mathbf{J}}^t_n}\nabla)\cdot\mathbf{J}_n\right]\right\|^2_{0,\Omega} \\
&\quad + (1-\varepsilon)\|\nabla \times \mathbf{J}_{n+1}\|^2_{0,\Omega} + \varepsilon\|\mathbf{x}_{n+1} - \mathbf{w}\|^2_{\frac{1}{2},\Gamma} + (1-\varepsilon)\|\mathbf{n} \times \mathbf{J}_{n+1} - \mathbf{n} \times \nabla\mathbf{w}\|^2_{\frac{1}{2},\Gamma}.
\end{aligned} \tag{4.1}$$

There are three aspects of (4.1) worth noting. The first is that we are solving for $\mathbf{x}_{n+1}, \mathbf{J}_{n+1}$ and not $\mathbf{D}_{n+1}$ as we did for the theory. While it was more convenient in the theory to incorporate the boundary conditions into the equations, here we enforce them, so that the last two terms in (4.1) vanish. A second aspect is the interstage scale factor ε. In [10], we discussed the two-stage algorithm, where, in the first stage, we set $\varepsilon = 0$ and solve for $\mathbf{J}_{n+1}$ and, in the second, we set $\varepsilon = 1$ and solve for $\mathbf{x}_{n+1}$. The second stage amounts to a simple system of decoupled Poisson equations. For $\varepsilon \in (0,1)$, minimizing (4.1) amounts to a single-stage algorithm. In section 4.1, we compare performance of the first stage of the two-stage algorithm with the single-stage algorithm for the pinched square (Figure 4.1, below). For the single stage, we set $\varepsilon = \frac{1}{2}$ and multiply the entire functional by 2 for fair comparison. Results for both algorithms are similar, and thus the remaining tests are for the single-stage algorithm.

The third aspect of (4.1) to notice is the presence of the equation scale factor $\frac{1}{J_n}$ in the second functional term. The EGG equations are derived from the well-understood Laplace equations, so we exploit this correspondence now to guide the choice of scales. First note that the augmented first stage of the first-order system [7] associated with the Laplace equations (2.1) that define $\boldsymbol{\xi}$ is (ignoring boundary conditions and with $\boldsymbol{\Psi} = \nabla\boldsymbol{\xi}$)

$$\begin{pmatrix} \nabla \cdot \boldsymbol{\Psi} \\ \nabla \times \boldsymbol{\Psi} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{0} \end{pmatrix}.$$

Transforming this system to that for the gradient $\mathbf{J}$ of the inverse map (without cancelling terms) yields

$$\text{(4.2)} \qquad \frac{1}{J^2}\underline{\hat{\mathbf{J}}} \begin{pmatrix} \frac{1}{J}[(\underline{\hat{\mathbf{J}}\hat{\mathbf{J}}}^t \nabla) \cdot \mathbf{J}] \\ \nabla \times \mathbf{J} \end{pmatrix} = \begin{pmatrix} \mathbf{0} \\ \mathbf{0} \end{pmatrix}.$$

The key in scaling this new system is to understand the relative balance between its two equations. Thus, $\frac{1}{J^2}\underline{\hat{\mathbf{J}}}$ can be dropped in deference to the relative scale reflected in the $\frac{1}{J}$ term in the first equation of (4.2). To mimic the Laplace scaling for the EGG system, we thus choose to scale the second term in (4.1) by $\frac{1}{J}$. This expresses the scaling we use in the numerical experiments. To improve performance in practice, we use $\frac{1}{J}$ just to scale the norm; it is *not* involved in the linearization process. (Presence of the scale factor $\frac{1}{J}$ in this way does not affect the theoretical results, so it was omitted in the analysis to simplify the calculations.) The scaling effect is demonstrated in section 4.3, where we study the convergence factors for increasingly distorted maps for the pinched square using both unscaled and scaled functionals. In both sections 4.1 and 4.2, we measure actual errors as well as functional values and validate the equivalence of the square root of the functional and the H^1 errors as proved theoretically in section 3.

In section 4.2, we first test the performance of AMG on the one-sided pinched square with grid size $h = \frac{1}{64}$. We compare the performance of V(q,s)-cycles with $q + s \leq 3$, where q is the number of relaxation steps before coarse grid correction and s is the number after. We use V(1,1)-cycles for the rest of our tests because these initial results suggest that it is one of the most efficient of these choices. We then test dependence of the linear solver on grid size. We study how the convergence factor for linear solves suffers with increasingly large perturbations from the identity map for several different grid sizes.

The method we use to obtain an approximation to $\mathbf{D}^*$ (or $\mathbf{J}^*$) is discussed in some detail in [10]. Here we give a brief overview. We use a nested sequence of $m+1$ rectangular grids with continuous piecewise bilinear function subspaces of $\mathcal{H}_{1+\delta}$ denoted by $H^{h_0} \subset H^{h_1} \subset \cdots \subset H^{h_m} \subset \mathcal{H}_{1+\delta}$, where $h_n = 2^{-n}h_0$, $0 \leq n \leq m$. Let $\mathbf{V}_0$ denote the initial guess in H^{h_0} obtained by solving the problem on the coarsest subspace, H^{h_0}. In practice, we simply iterate with a discrete Newton iteration until the error in the approximation is below discretization error. The result, $\mathbf{V}_1$, becomes the initial guess for level h_1, where the process continues. In general, the initial guess for AMG on level h_n comes from the final AMG approximation on level h_{n-1}: $\mathbf{V}_n$.

In sections 4.2 and 4.4, we study performance of the NI algorithm. Here we use transfinite interpolation (TFI), which is analogous to linear interpolation, to form the initial guess. The basic principle is to add the linear interpolant between the north and south boundary maps to the linear interpolant between the east and west boundary

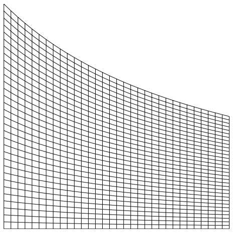

FIG. 4.1. *Pinched square with $a = 1$.*

maps, then subtract the interpolant between the four corners. The computational domain is the unit square. For boundary conditions $\mathbf{x} = \mathbf{w}(\boldsymbol{\xi})$, we get

$$\begin{aligned}\mathbf{x} = \eta\mathbf{w}_n(\xi) &+ (1-\eta)\mathbf{w}_s(\xi) + \xi\mathbf{w}_e(\eta) + (1-\xi)\mathbf{w}_w(\eta)\\ &- \left[\xi\eta\mathbf{w}_a + \xi(1-\eta)\mathbf{w}_b + (1-\xi)(1-\eta)\mathbf{w}_c + (1-\xi)\eta\mathbf{w}_d\right],\end{aligned}$$

where we define $\mathbf{w}_n$, $\mathbf{w}_s$, $\mathbf{w}_e$, and $\mathbf{w}_w$ as the boundary maps on the north, south, east, and west boundaries, respectively, and $\mathbf{w}_a$, $\mathbf{w}_b$, $\mathbf{w}_c$, and $\mathbf{w}_d$ as the values on the northeast, southeast, southwest, and northwest corners, respectively. The initial condition we use for $\mathbf{J}$ is the Jacobian of this map.

On the north and south boundaries, boundary conditions are needed for x, y, J_{11}, and J_{12}. On the east and west boundaries, boundary conditions are needed for x, y, J_{21}, and J_{22}. Boundary conditions are imposed on the finite element space.

We first establish the similarity between the first stage of the two-stage algorithm ($\varepsilon = 0$) and the single-stage algorithm ($\varepsilon = \frac{1}{2}$ and the functional in (4.1) multiplied by 2). Second, we test the effect of different numbers of relaxation sweeps for multigrid V-cycles to suggest a good choice for the remainder of the tests. Third, we study performance of the AMG solver for increasingly distorted grids for the pinched square. Finally, we study the algorithm on the arch. Further results can be found in [9].

4.1. First-stage and single-stage algorithms. The one-sided pinched square map has the following exact solution:

$$\begin{aligned}&x = \xi, && y = \frac{\eta}{a\xi+1},\\ &J_{11} = 1, && J_{21} = 0,\\ &J_{12} = \frac{a\eta}{(a\xi+1)^2}, && J_{22} = \frac{1}{a\xi+1},\end{aligned} \tag{4.3}$$

where $a \in [0, 1]$. The physical domain is a square for $a = 0$, with the pinch increasing as a increases. See Figure 4.1.

To test performance of the first-stage and single-stage algorithms for standard Newton iterations and NI on the pinched square with $a = 1.0$, we add a varying amount of small error at each grid point (except for those on the boundary) to TFI (the exact solution in this case) to form the initial guess:

$$\begin{aligned}&x = \xi + \mathbf{g}\sin(b\xi + c\eta), && y = \frac{\eta}{\xi+1} + \mathbf{g}\sin(d\xi + e\eta),\\ &J_{11} = 1 + \mathbf{g}\sin(b\xi + c\eta), && J_{21} = \mathbf{g}\sin(b\xi + c\eta),\\ &J_{12} = \frac{\eta}{(\xi+1)^2} + \mathbf{g}\sin(d\xi + e\eta), && J_{22} = \frac{1}{\xi+1} + \mathbf{g}\sin(d\xi + e\eta),\end{aligned}$$

TABLE 4.1
Asymptotic convergence factors for $V(1,1)$-cycles, with varying grid size and Newton iterations.

5	0.25	0.32	0.40	0.41
6	0.25	0.33	0.40	0.44

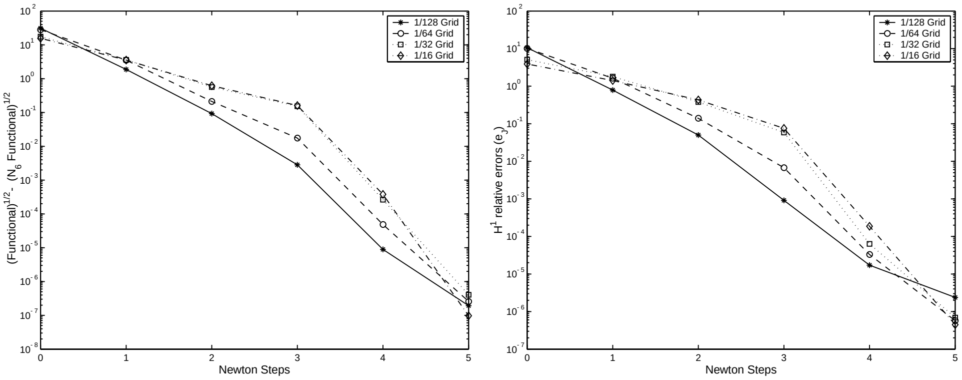

FIG. 4.2. *First-stage functional. Newton convergence, using standard Newton iterations with imposed boundary conditions, in both functional (left) and H^1 error (right) measures. Differences between the values at the current and sixth Newton steps are plotted.*

where

$$\begin{aligned}&\mathbf{g} = f\xi\eta(1-\xi)(1-\eta),\\ &b = 12967493.946193764, \quad c = 491843027.481264509,\\ &d = 184625498.4710938, \quad e = 174365204.5761938,\end{aligned}$$

with $f = 2$ for grid $h = \frac{1}{128}$, $f = 4$ for grids $h = \frac{1}{64}$ and $h = \frac{1}{32}$, $f = 7$ for grid $h = \frac{1}{16}$, and $f = 24$ for NI (with coarsest grid $h = \frac{1}{4}$). Note that the exact solutions for x, J_{11}, and J_{21} are in the finite-dimensional subspaces.

Consider the first-stage one-sided pinched square. (Recall that there are no x or y terms.) Table 4.1 depicts asymptotic convergence factors for the AMG solver. Note the poor performance shown in the early Newton steps. This degradation probably occurs because the functional is suffering from loss of elliptic character due to the crude initial guess inheriting poor values for the Jacobian map. Nested iteration tends to ameliorate this potential difficulty, so we may focus on later Newton iterations, where these results suggest that two $V(1,1)$-cycles yield overall convergence factors of about 0.2. We use two $V(1,1)$-cycles in the tests that follow.

Figure 4.2 depicts Newton convergence results for grids $h = \{\frac{1}{16}, \frac{1}{32}, \frac{1}{64}, \frac{1}{128}\}$. We study performance in terms of both the functional error measure (i.e., square root of the functional) and the relative H^1 errors in $\mathbf{J}$,

$$e_{\mathbf{J}} \equiv \frac{\|\mathbf{J}^* - \mathbf{J}_n\|_{1,\Omega}}{\sqrt{\|\mathbf{J}^*\|_{1,\Omega}\|\mathbf{J}_n\|_{1,\Omega}}}.$$

The graphs show the differences between the values at the current and sixth Newton steps. We are interested in the functional measure because it is equivalent to the H^1

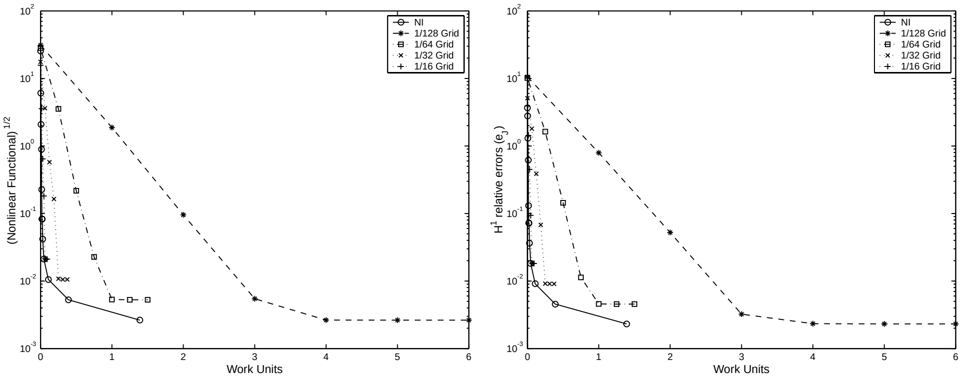

FIG. 4.3. *First-stage functional. Functional and H^1 error measures for standard Newton iterations and NI with imposed boundary conditions. One work unit is the equivalent of one step on the $h = \frac{1}{128}$ grid using two $V(1,1)$-cycles.*

norm of the errors, as we established theoretically in [10] and as these graphs suggest. The left-hand graph contains the functional values, and the right-hand graph contains the errors. Convergence appears to be approximately linear, which is consistent with the theoretical result. The factors also appear to be bounded independent of grid size.

Figure 4.3 compares standard Newton and NI results. We again report on the functional and relative H^1 error measures in $\mathbf{J}$. For proper comparison of cost, we now base the data on a *work unit*, defined to be the equivalent of one Newton step on the $h = \frac{1}{128}$ grid. (One Newton step has two V(1,1)-cycles.) We thus count one Newton step on the $h = \frac{1}{64}$ grid as $\frac{1}{4}$ of a work unit, $\frac{1}{16}$ on the next coarser grid, and so on. After about the sixth standard Newton step for each of the grid sizes, the change in the functional value (and the H^1 error) at each iteration is very small relative to the functional value itself. The exact solution is only approximated by the finite-dimensional subspace. Thus, while the functional value for the exact solution is zero, the minimum on the finite-dimensional subspace is not. With more Newton steps, we can thus get as close as we choose to the finite-dimensional approximation of the exact solution, but the decrease in the functional and, hence, in the error, stalls because discretization error is reached. The ratios of the functional and the relative H^1 error measures in $\mathbf{J}$ are about 1.16 near the solution for grids $h = \{\frac{1}{16}, \frac{1}{32}, \frac{1}{64}\}$ and 1.14 for grid $h = \frac{1}{128}$. After the third Newton step, this ratio is a constant for all grid sizes, which affirms H^1 equivalence.

Next we study performance of the single-stage algorithm, with the same map and initial guess. Again, we report on functional and relative H^1 error measures in $\mathbf{J}$. Figure 4.4 contains graphs of differences between these values at the current and sixth Newton steps. Consistent with the theory, convergence using this measure appears to be approximately linear, with factors bounded independent of grid size.

Figure 4.5 compares standard Newton iterations with NI based on work units as defined above. Behavior of the errors for the single stage is essentially the same as for the first stage. The ratios of functional measures of the single stage to the first stage varies between 0.87 and 1.12, fixing at 1.09 after Newton step 4 for each grid. For NI, the ratio is 1.09 for all the finer grids.

The relative error in the computed solution does not appear to vary with grid size because the variation is small compared to the error. Again, on any finite-dimensional subspace, we cannot expect to reduce the error to zero because of discretization error.

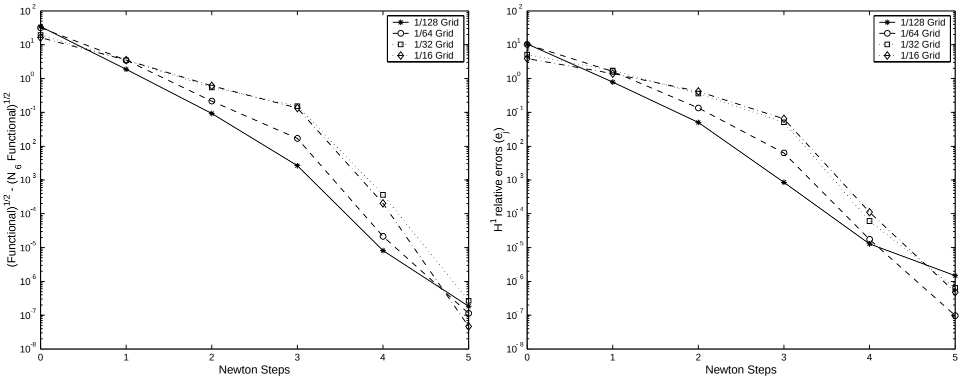

FIG. 4.4. *Newton convergence, using standard Newton iterations with imposed boundary conditions, in both functional (left) and H^1 error (right) measures. Differences between the value at the current and sixth Newton steps are plotted.*

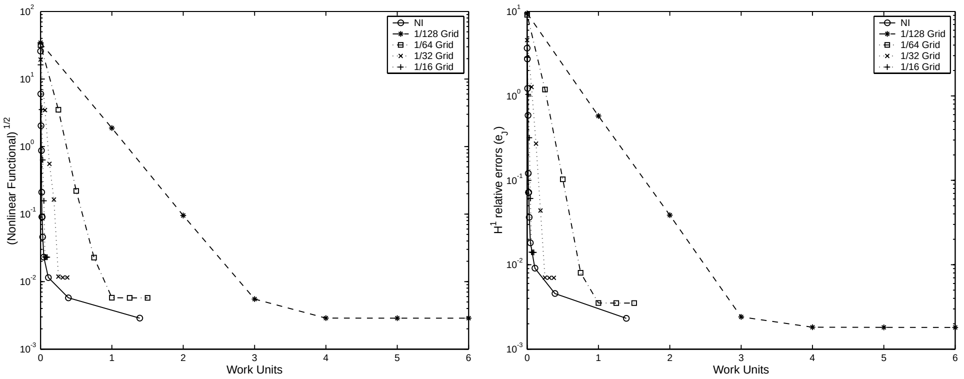

FIG. 4.5. *Newton versus NI results, with imposed boundary conditions, in both functional (left) and H^1 error (right) measures.*

The ratios of the functional and H^1 error measures in $\mathbf{J}$ are about 1.3 near the solution for grids $h = \{\frac{1}{16}, \frac{1}{32}, \frac{1}{64}\}$ and 1.2 for grid $h = \frac{1}{128}$. After the third Newton step, this ratio is a constant for all grid sizes, which affirms H^1 equivalence. We need at least 4 standard Newton steps to reduce the functional to about the same level for which NI needed an equivalent of only about 1.5 steps. We expect this difference to widen for larger problems, where the required steps for standard Newton would tend to grow, while NI would probably remain below an equivalent of two.

4.2. V-cycle tests. To determine which V(q,s)-cycle is most efficient, we study asymptotic convergence factors with $q + s \leq 3$ and $h = \frac{1}{64}$. Here we linearize the equations about the exact solution, set the right-hand side to zero, start with a random initial guess, and then observe residual reduction factors after many V-cycles. Table 4.2 shows the observed V-cycle convergence factors for different values of a. The cycles with more relaxation sweeps naturally have better convergence factors but involve more computation. We thus consider a measure of the time required to reduce the initial residual by a factor of 10. Since we are interested only in comparisons, we choose the *relative* measure $t \equiv (q+s+c)\ln(0.1)/\ln(r)$, where r is the observed asymptotic convergence factor for the V(q,s)-cycle and c estimates the fixed cost of a cycle. We choose $c = 2$ because of residual calculations and intergrid transfers. Observed

Table 4.2

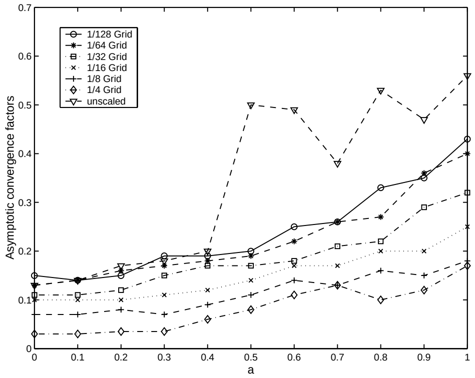

Fig. 4.6. *Asymptotic convergence factors for various grid sizes and values of a. The scaled functional was used in all but the test for $h = \frac{1}{64}$.*

values for t for the $h = \frac{1}{64}$ grid and different values of a are given in Table 4.3. While performance of the V(1,1)- or V(2,0)-cycles were similar, we chose the V(1,1)-cycle for the remainder of our tests.

4.3. AMG tests. We next test the performance of the linear solver with varying h. Again, the equations are linearized about the solution and the right-hand side is set to zero. We study the deterioration in asymptotic convergence factors as a increases from zero to one; the results are plotted in Figure 4.6. In all but one test, we used the scaled functional in (4.1) with the boundary conditions enforced so that the boundary terms vanish. For the test marked “unscaled” and for which $h = \frac{1}{64}$, factor $\frac{1}{J_n}$ in the second term of the functional in (4.1) was omitted. For the scaled functional, asymptotic convergence factors increase as a increases, as expected. At $a = 0$, which corresponds to the identity map, convergence factors are similar to those for the Laplace problem. There is some variation with respect to the grid size, although for smaller h $\left(\frac{1}{64}\text{ and }\frac{1}{128}\right)$ the factors are similar. The results for the unscaled and scaled convergence factors for the $h = \frac{1}{64}$ grid confirm that scaling the second term of the functional in (4.1) by $\frac{1}{J_n}$ significantly improves convergence factors: the unscaled factors are significantly larger than the scaled factors for $a \geq 0.5$.

TABLE 4.4
Asymptotic convergence factors for the $V(1,1)$-cycle, with varying grid size and Newton iterations, for the arch.

Newton	$\frac{1}{16}$	$\frac{1}{32}$	$\frac{1}{64}$	$\frac{1}{128}$
1	0.59	0.50	0.43	0.59
2	0.63	0.65	0.67	0.61
3	0.66	0.67	0.68	0.67
4	0.63	0.67	0.66	0.67
5	0.66	0.68	0.66	0.68

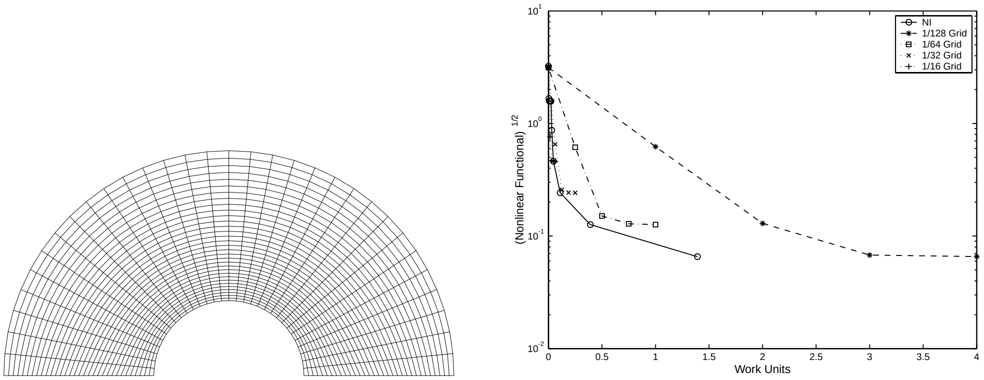

FIG. 4.7. *NI and standard Newton methods for the arch.*

4.4. Nested iteration for the arch. We compare standard Newton iterations for $h = \frac{1}{128}, \frac{1}{64}, \frac{1}{32}$, and $\frac{1}{16}$ to NI with $h = \frac{1}{4}$ for the coarsest grid and $h = \frac{1}{128}$ for the finest grid. The initial guess for the arch is

$$\begin{aligned} x &= 1.5 + (1.5 - \xi)\cos(\pi(1-\eta)), & y &= (1.5 - \xi)\sin(\pi(1-\eta)), \\ J_{11} &= -\cos(\pi(1-\eta)), & J_{21} &= \pi(1.5 - \xi)\sin(\pi(1-\eta)), \\ J_{12} &= -\sin(\pi(1-\eta)), & J_{22} &= -\pi(1.5 - \xi)\cos(\pi(1-\eta)). \end{aligned}$$

Choices of the numbers of V(1,1)-cycles per iteration and Newton steps on each grid are currently made by observation. In the theoretical section of [10], we suggested $\rho^{\nu_0} \leq \frac{1}{8}$ as a criterion, where ρ is the convergence factor and ν_0 is the number of V-cycles. A significantly larger value would allow the iterates to wander too far from the true solution as the grid was refined. We could choose a smaller value for ρ^{ν_0} so that the multigrid solutions would shadow the exact finite-dimensional solutions more closely. But too small a value would likely be less efficient than simply proceeding to finer meshes. NI required significantly less work to obtain the same discretization error than did the standard Newton method. Standard Newton needed just a few steps to reach discretization error for our tests anyway, but the savings afforded by NI for smaller h should be much larger still. More results can be found in [9].

Table 4.4 depicts asymptotic convergence factors for standard Newton iterations. These factors are not small enough to allow just one V-cycle per Newton step. We thus used three V(1,1)-cycles to solve each Newton step. Thus one work unit is three V(1,1)-cycles on the $\frac{1}{128}$ grid. Here we performed two coarsest-grid Newton iterations, with only one on all finer grids.

Three standard Newton steps were required to reach discretization error, while NI required less than one-and-a-half equivalents (see Figure 4.7). The final functional value decreases by about a factor of four as the grid size is halved, which confirms the $\mathcal{O}(h)$ approximation in the $H^1(\Omega)$ norm.

5. Conclusion. We showed theoretically that the nested iteration process involving only one discrete Newton step on each level produces a result on the finest level that is within discretization error of the exact solution. We also showed this result numerically using an $H^{1+\delta}(\Omega)$ discrete space for each of the unknowns. Future directions involve automating the numerical tests to include the following choices: number of relaxations before and after coarsening, number of V-cycles, number of Newton steps on each grid, size and choice of solvers for the coarsest grid, parameterization of the boundary maps, and adaptive mesh refinement.

The first three choices dictate the overall efficiency of the algorithm and should be considered carefully for maximum effectiveness. Automation would require heuristics to sense performance of smoothing and coarse-grid correction, as well as linearization trade-offs. We used one Newton step on all but the coarsest grid in our examples and theory, but severely distorted regions may dictate more such steps to improve effectiveness, and possibly other continuation methods to address the Newton method's local convergence characteristics. In any case, the special ability of the FOSLS functional to signal errors could be exploited to make these choices in an effective and automatic way. The fourth coarsest-grid choice rests heavily on the geometry of the particular map. Complex regions may require a fairly small coarsest grid and a significant amount of effort to solve the nonlinear problem there. Damped Newton methods and various forms of continuation techniques may come into play. Of course, complicated regions generally require very fine meshes to supply meaningful simulations, so the relative cost of such coarsest-grid effort may again be fairly minimal. Moreover, the special properties of the FOSLS functional may also be exploited for these choices. The fifth choice would be to use a parameterization of the boundary in the associated terms of the functional that would allow concentration of grid points near special boundary features. The final choice of adaptive mesh refinement can be served by noting that the functional value on each element is a sharp measure of the error on that element, which makes it suitable as a measure for determining which elements need to be further subdivided (cf. [4]).

NUMERICAL DISCRETIZATION OF BOUNDARY CONDITIONS FOR FIRST ORDER HAMILTON–JACOBI EQUATIONS[*]

RÉMI ABGRALL[†]

Abstract. We provide two simple ways of discretizing a large class of boundary conditions for first order Hamilton–Jacobi equations. We show the convergence of the numerical scheme under mild assumptions. However, many types of such boundary conditions can be written in this way. Some provide "good" numerical results (i.e., without boundary layers), whereas others do not. To select a good one, we first give some general results for monotone schemes which mimic the maximum principle of the continuous case, and then we show in particular cases that no boundary layer can exist. Some numerical applications illustrate the method. An extension to a geophysical problem is also considered.

Key words. Hamilton–Jacobi equations, approximation of boundary conditions

DOI. 10.1137/S0036142998345980

1. Introduction.

The problem of discretizing first order Hamilton–Jacobi equations in $\mathbb{R}^N$ has been considered by several authors (see, e.g., [8, 9, 3]) on various types of meshes (see the previous references and [1]). However, in our knowledge, the discretization of boundary conditions has not yet been considered in a systematic way. The aim of this paper is to provide a simple and systematic way of discretizing a wide variety of boundary conditions. This is done in the framework of discontinuous viscosity solutions [4]. More precisely, we consider the following problem:

$$\begin{cases} H(x,u,Du)=0, & x\in\Omega,\\ F(x,u,Du)=0, & x\in\partial\Omega, \end{cases} \tag{1.1}$$

where the Hamiltonian is continuous on $\overline{\Omega}\times\mathbb{R}\times\mathbb{R}^N$ and the boundary condition F is continuous on $\partial\Omega\times\mathbb{R}\times\mathbb{R}^N$.

For any function z, we consider the upper semicontinuous (u.s.c) and lower semicontinuous (l.s.c) envelopes of z with respect to all variables. These are defined by

$$z^*(x)=\limsup_{x\to y} z(y) \quad\text{and}\quad z_*(x)=\liminf_{x\to y} z(y).$$

Following [4], we introduce the function G:

$$G(x,u,p)=\begin{cases} H(x,u,p), & x\in\Omega,\\ F(x,u,p), & x\in\partial\Omega. \end{cases}$$

A locally bounded u.s.c function u defined on $\overline{\Omega}$ is a viscosity subsolution of (1.1) if and only if, for any $\phi\in C^1(\overline{\Omega})$, if $x_0\in\overline{\Omega}$ is a local maximum of $u-\phi$, then

$$G_*(x_0,u(x_0),D\phi(x_0))\le 0. \tag{1.2}$$

[†] Mathématiques Appliquées de Bordeaux, Université Bordeaux I, 351 Cours de la Libération, 33 405 Talence cedex, France, and Institut Universitaire de France (abgrall@math.u-bordeaux.fr).

Similarly, u, a locally bounded l.s.c. function defined on $\overline{\Omega}$, is a viscosity supersolution of (1.1) if and only if, for any $\phi \in C^1(\overline{\Omega})$, if $x_0 \in \overline{\Omega}$ is a local minimum of $u - \phi$, then

$$G^*(x_0, u(x_0), D\phi(x_0)) \geq 0. \tag{1.3}$$

The computation of G_* and G^* is easy, and we have

$$\begin{cases} G_*(x,u,p) = G^*(x,u,p) = H(x,u,p) & \text{if } x \in \Omega, \\ G_*(x,u,p) = \min(H(x,u,p), F(x,u,p)) & \text{if } x \in \partial\Omega, \\ G^*(x,u,p) = \max(H(x,u,p), F(x,u,p)) & \text{if } x \in \partial\Omega. \end{cases} \tag{1.4}$$

More specifically, we consider the cases of the Dirichlet and Neumann boundary conditions, but the results of this paper may extend to more general boundary conditions, provided they are of the form (1.1) and if some regularity on F is assumed. In the case of Dirichlet boundary conditions, namely $u = \varphi$, we have

$$F(x,u,p) = u(x) - \varphi(x), \tag{1.5}$$

and for Neumann boundary conditions we have

$$F(x,u,p) = \frac{\partial u}{\partial n} - g(x), \tag{1.6}$$

where g is defined on $\partial\Omega$ and continuous.

This paper is organized as follows. We first recall a convergence result by Barles and Souganidis [5]. Then, starting from the dynamical programming principle, we indicate a way of discretizing general boundary conditions, and show the convergence of this scheme. In a second part, we describe several particular cases for convex and nonconvex Hamiltonians. A particular emphasis is set on the Dirichlet boundary conditions because it is more difficult to provide effective boundary conditions in that case, at least more difficult than for Neumann conditions. This problem is explained and has many similarities with the technical difficulties encountered in the study of these conditions in the continuous case. We provide numerical illustrations that show the effectiveness of the schemes. It is known that first order Hamilton–Jacobi equations have many similarities with a particular class of hyperbolic systems. Because of that, one might think that boundary conditions built on the structure of inflow and outflow characteristics would be efficient enough. This is true if the structure of the solution is known a priori. This is rarely the case in practice, and we provide an example where the structure of the solution at the boundary is not known a priori, so more sophisticated approximations are required. Another example has its origin in seismology problems.

Throughout the paper, we consider an open and bounded domain Ω. To simplify the presentation, we assume $\Omega \subset \mathbb{R}^2$, but our results are also valid for $\mathbb{R}^N$, $N \geq 2$. The open set Ω is discretized by a triangulation $\mathcal{T}_\rho$. The nodes of the mesh are denoted by $x_i, i = 1, \dots, n_s$; the triangles are denoted by $T_k, k = 1, \dots, n_T$. The vertices of T are denoted by $x_{i_k}, k = 1, \dots, 3$. The parameter ρ above is, for example, the largest radius of the circumscribed circles of T_k, $k = 1, \dots, n_T$.

2. A convergence result.

2.1. Preliminaries. All our results rely on the following one by Barles and Souganidis [5]. The symbol $B(\overline{\Omega})$ denotes the set of bounded functions over $\overline{\Omega}$.

They consider approximations schemes of the form

$$S(\rho, x, u^\rho(x), u^\rho) = 0 \qquad \text{in } \overline{\Omega}, \tag{2.1}$$

where S maps $\mathbb{R}^+ \times \overline{\Omega} \times \mathbb{R} \times B(\overline{\Omega})$ onto $\mathbb{R}$, is locally bounded, and has the following properties:

1. monotonicity: if $u \geq v$, for all $\rho \geq 0$, $x \in \overline{\Omega}$, $t \in \mathbb{R}$, and $u, v \in L^\infty(\overline{\Omega})$ we have

$$S(\rho, x, t, u) \leq S(\rho, x, t, v); \tag{2.2}$$

2. stability: for all $\rho > 0$ there exists a solution $u^\rho \in L^\infty(\overline{\Omega})$ to (2.1) with a bound independent of ρ;
3. consistency: for all $x \in \overline{\Omega}$ and $\phi \in C_b^\infty(\overline{\Omega})$ (the set of C^∞ bounded functions),

$$\limsup_{\rho \to 0, y \to x, \xi \to 0} S(\rho, y, \phi(y) + \xi, \phi + \xi) \leq G^*(x, \phi(x), D\phi(x)) \tag{2.3}$$

and

$$\liminf_{\rho \to 0, y \to x, \xi \to 0} S(\rho, y, \phi(y) + \xi, \phi + \xi) \geq G_*(x, \phi(x), D\phi(x)); \tag{2.4}$$

4. strong uniqueness principle: if $u \in L^\infty(\overline{\Omega})$ is an u.s.c subsolution of (1.1) and $v \in L^\infty(\overline{\Omega})$ is an l.s.c supersolution of (1.1), then $u \leq v$ on $\overline{\Omega}$.

THEOREM 2.1 (from Barles and Souganidis). *Assuming the monotonicity, consistency, and stability of the scheme* (2.1) *and the strong uniqueness property of the problem* (1.1), *then the solution* u^ρ *of* (2.1) *converges locally uniformly to the unique continuous viscosity solution of* (1.1).

The stability, (2.2), (2.3), and (2.4) imply that the functions

$$\bar{u} = \limsup_{\rho \to 0, y \to x} u^\rho(y) \qquad \text{and} \qquad \underline{u} = \liminf_{\rho \to 0, y \to x} u^\rho(y)$$

are defined on $\overline{\Omega}$; they are, respectively, u.s.c. subsolutions and l.s.c. supersolutions of (1.1). By definition, we have $\underline{u} \leq \overline{u}$. The opposite inequality follows from the uniqueness property. Note that if we have only this uniqueness property on Ω, as is the case for Dirichlet boundary conditions, the same argument shows that $\underline{u} = \overline{u}$ on Ω.

2.2. Two numerical schemes. We consider a bounded open domain Ω that is discretized by means of a triangulation $\mathcal{T}_\rho$. The parameter ρ is the maximum, on the elements T of $\mathcal{T}_\rho$, of the radius of the smallest disk containing T.

We consider a scheme for $H(x, u, Du) = 0$ that is defined for any point of the mesh except perhaps for the boundary nodes. It is written as

$$S_H(\rho, x, u^\rho(x), u^\rho) = 0. \tag{2.5}$$

We also consider an approximation of the boundary conditions that is defined for any node of the triangulation on the boundary of Ω,

$$S_F(\rho, x, u^\rho(x), u^\rho) = 0. \tag{2.6}$$

Let $(x, t, p) \mapsto H_b(x, t, p)$ be a Hamiltonian defined at least in a neighborhood of $\partial\Omega \times \mathbb{R} \times \mathbb{R}^N$. It fulfills the same assumptions as H. We also have a numerical scheme S_{H_b} for the Hamiltonian H_b. We define the following scheme for (1.1):

$$0 = S(\rho, x, u^\rho(x), u^\rho) = \begin{cases} S_H(\rho, x, u^\rho(x), u^\rho) & \text{if } x \in \Omega, \\ \max(S_{H_b}(\rho, x, u^\rho(x), u^\rho), S_F(\rho, x, u^\rho(x), u^\rho)) & \text{if } x \in \partial\Omega. \end{cases} \tag{2.7}$$

Another a priori reasonable scheme could also be

$$0 = S(\rho, x, u^\rho(x), u^\rho) = \begin{cases} S_H(\rho, x, u^\rho(x), u^\rho) & \text{if } x \in \Omega, \\ \min(S_{H_b}(\rho, x, u^\rho(x), u^\rho), S_F(\rho, x, u^\rho(x), u^\rho)) & \text{if } x \in \partial\Omega. \end{cases} \tag{2.8}$$

The questions are the following: On which conditions can the scheme (2.7) or (2.8) be considered as a good numerical approximation of (1.1)? Can we identify criteria for preferring scheme (2.7) to (2.8)?

Before giving conditions that ensure the convergence of the schemes (2.7) and (2.8), we motivate the "max" condition of (2.7) in the case of a convex Hamiltonian. The justification comes from the dynamical programming principle and is therefore valid for convex Hamiltonians. We could make the same type of justification for the "min" condition of (2.8) for concave Hamiltonians.

Dynamical programming principle. We assume that the Hamiltonian is given by

$$H(x, u, p) = \sup_{v \in V} \left\{ -b(x, v) \,.\, p + \lambda u - f(x, v) \right\},$$

where the space of controls V is compact, and we have standard assumptions on b and f. We also assume $\lambda > 0$. For the Dirichlet condition (1.5), the solution of (1.1) is given by, for any $T > 0$,

$$0 = u(x) - \inf_{v(.)} \left[\int_0^{\min(T,\tau)} f(y_x(t), v(t)) e^{-\lambda t} dt + 1_{\{T<\tau\}} u(y_x(T)) e^{-\lambda T} + 1_{\{T \geq \tau\}} \varphi(y_x(\tau)) e^{-\lambda \tau} \right]. \tag{2.9}$$

As usual, the trajectory $y_x(.)$ satisfies $y_x(0) = x \in \Omega$ and

$$\frac{d}{dt} y_x(t) = b(y_x(t), v(t)) \quad \text{for } t > 0.$$

The exit time τ is

$$\tau = \inf\{t \geq 0, y_x(t) \notin \Omega\}.$$

Now, the set of controls can be split into two parts: the set V_1 for which $T < \tau$, and V_2 for which $T \geq \tau$. Hence,

$$u(x) = \min \left(\inf_{v \in V_1} [\cdots], \inf_{v \in V_2} [\cdots] \right).$$

Let $\vec{n}$ be the interior normal to Ω at $x \in \overline{\Omega}$. Since T is arbitrary, it can be chosen as small as possible. In the limit $T \to 0$, the set V_1 would be the set of controls for which

$b(x,v)\,.\,\vec{n} > 0$, i.e., the control for which the trajectory goes into Ω. The dynamical programming principle $\inf_{v\in V_1}[\cdots] - u(x) = 0$ corresponds to the Hamiltonian

$$H_b(x,t,p) = \sup_{v\in V_1}\{b(x,v)\,.\,p + \lambda t - f(x,v)\}.$$

We also have the relation $H_b \leq H$.

The "inf" on V_2 can be approximated, if T is small, by $\varphi(y_x(\tau))$. Since $T \leq \tau$ and if we can choose controls for which $T \simeq \tau$, we get

$$\varphi(y_x(\tau)) \simeq \varphi(x)$$

because φ is continuous. Thus, by setting $S_F = u(x) - \varphi(x)$, we see that (2.9) can be approximated by

$$0 = \max(S_{H_b}, S_F),$$

which is want we wanted. We have the following result.

THEOREM 2.2. *Assume that*

1. $H_b \leq H$*;*
2. S_H*,* S_{H_b}*, and* S_F *are monotone and stable;*
3. *for all* $\phi \in C_b^\infty(\overline{\Omega})$*, we have*

$$\begin{aligned}
&\textit{for any } x \in \overline{\Omega},\\
&\lim_{\rho\to 0, y\to x, \xi\to 0} S_H(\rho, y, \varphi(y)+\xi, \varphi+\xi) = H(x, \varphi(x), D\varphi(x)),\\
&\textit{for any } x \textit{ in a neighborhood of } \partial\Omega,\\
&\lim_{\rho\to 0, y\to x, \xi\to 0} S_{H_b}(\rho, y, \varphi(y)+\xi, \varphi+\xi) = H_b(x, \varphi(x), D\varphi(x)),\\
&\textit{for any } x \in \partial\Omega,\\
&\lim_{\rho\to 0, y\to x, \xi\to 0} S_F(\rho, y, \varphi(y)+\xi, \varphi+\xi) = F(x, \varphi(x), D\varphi(x));
\end{aligned}$$

4. *the equation* (1.1) *has a uniqueness principle.*

Then the family u^ρ *defined by* (2.7) *converges locally uniformly to the solution of* (1.1) *in* Ω*. We have the same result for* (2.8)*, provided that the condition* 1 *is replaced by* $H \leq H_b$*.*

Proof. We make the proof for the scheme (2.7). The proof for (2.8) is similar.

We first note that, on the boundary,

$$\begin{aligned}
&\limsup_{\rho\to 0, y\to x, \xi\to 0} S(\rho, y, \varphi(y)+\xi, \varphi+\xi)\\
&\qquad = \max\big(H(x,\varphi(x),D\varphi(x)), \max(H_b(x,\varphi(x),D\varphi(x)), F(x,\varphi(x),D\varphi(x)))\big),
\end{aligned}$$

$$\begin{aligned}
&\liminf_{\rho\to 0, y\to x, \xi\to 0} S(\rho, y, \varphi(y)+\xi, \varphi+\xi)\\
&\qquad = \min\big(H(x,\varphi(x),D\varphi(x)), \max(H_b(x,\varphi(x),D\varphi(x)), F(x,\varphi(x),D\varphi(x)))\big),
\end{aligned}$$

while in the interior points,

$$\lim_{\rho\to 0, y\to x\xi\to 0} S(\rho, y, \varphi(y)+\xi, \varphi+\xi) = H(x,\varphi(x),D\varphi(x)). \tag{2.10}$$

Then we proceed as in [4]. We define

$$\overline{u}(x) = \limsup_{y\to x, \rho\to 0} u^\rho(y) \quad \text{and} \quad \underline{u}(x) = \liminf_{y\to x, \rho\to 0} u^\rho(y).$$

They are defined on $\overline{\Omega}$ because u^ρ has bounds independent of ρ. We will show now that the functions $\overline{u}$ and $\underline{u}$ are, respectively, sub- and supersolutions of (1.1). In fact, we show first that if $x_0 \in \partial\Omega$ is a local minimum of $\underline{u} - \phi$, then

$$\max\big(H(x_0, \underline{u}(x_0), D\varphi(x_0)), \max(H_b(x_0, \underline{u}(x_0), D\varphi(x_0)), F(x_0, \underline{u}(x_0), D\varphi(x_0)))\big) \geq 0, \tag{2.11}$$

while if $x_0 \in \partial\Omega$ is a local maximum of $\overline{u} - \phi$ for some $\phi \in C^b_\infty(\overline{\Omega})$, then

$$\min\big(H(x_0, \overline{u}(x_0), D\varphi(x_0)), \max(H_b(x_0, \underline{u}(x_0), D\varphi(x_0)), F(x_0, \overline{u}(x_0), D\varphi(x_0)))\big) \leq 0. \tag{2.12}$$

To show (2.11), we repeat Barles and Souganidis's arguments. Equation (2.12) is obtained in the same way. We may assume that x_0 is a strict minimum, $\underline{u}(x_0) = \phi(x_0)$, and $\phi \leq 2\inf_\rho ||u^\rho||_\infty$ outside of $B(x_0, r)$, where r is such that

$$\underline{u}(x) - \phi(x) \geq \underline{u}(x_0) - \phi(x_0) = 0 \quad \text{in } B(x_0, r).$$

There exist sequences ρ_n and $y_n \in \overline{\Omega}$ such that $n \to +\infty$, $\rho_n \to 0$, $y_n \to x_0$, $u^{\rho_n}(y_n) \to \underline{u}(x_0)$, and y_n is a global minimum of $u^{\rho_n} - \phi$. We denote by ξ_n the quantity $u^{\rho_n}(y_n) - \phi(y_n)$. We have $\xi_n \to 0$ and $u^{\rho_n}(y) \geq \phi(y) + \xi_n$ in $B(x_0, r)$. Since S is monotone, we get

$$0 \leq \limsup_n S(\rho_n, y_n, \phi(y_n) + \xi_n, \phi + \xi_n) \leq \limsup_{\rho\to 0, y\to x_0, \xi\to 0} S(\rho, y, \varphi(y) + \xi, \varphi + \xi)$$

$$= \max(H(x_0, \varphi(x_0), D\varphi(x_0)), \max(H_b(x_0, \varphi(x_0), D\varphi(x_0)), F(x, \varphi(x_0), D\varphi(x_0)))).$$

If $x_0 \in \Omega$ is a local maximum (resp., minimum) of $\overline{u} - \phi$ (resp., $\underline{u} - \phi$), we use (2.10) and the same arguments as above to get

$$H(x_0, \overline{u}(x_0), D\phi(x_0)) \leq 0 \qquad (\text{resp., } H(x_0, \underline{u}(x_0), D\phi(x_0)) \geq 0). \tag{2.13}$$

Now we have to check that the condition (2.12) (resp., (2.11)) implies the supersolution (resp., subsolution) condition.

- *Inequality* (2.12). If $F(x_0, \underline{u}(x_0), D\phi(x_0)) \leq 0$, there is nothing to prove. We assume $F(x_0, \underline{u}(x_0), D\phi(x_0)) > 0$. We have either

  $$H(x_0, \underline{u}(x_0), D\varphi(x_0)) \leq 0 \tag{2.14}$$

  or

  $$\max(H_b(x_0, \underline{u}(x_0), D\phi(x_0)), F(x_0, \underline{u}(x_0), D\phi(x_0))) \leq 0.$$

  In the second case, we necessarily have (2.14), and in both cases the inequality holds.

- *Inequality* (2.11). If $F(x_0, \overline{u}(x_0), D\phi(x_0)) \geq 0$, there is nothing to prove. If we assume $F(x_0, \overline{u}(x_0), D\phi(x_0)) < 0$, then we must have either $H(x_0, \overline{u}(x_0), D\phi(x_0)) \geq 0$ or

$$\max(H_b(x_0, \overline{u}(x_0), D\phi(x_0)), F(x_0, \overline{u}(x_0), D\phi(x_0))) \geq 0.$$

Since $F < 0$, this inequality implies $H_b \geq 0$, so that

$$H(x_0, \overline{u}(x_0), D\phi(x_0)) \geq H_b(x_0, \overline{u}(x_0), D\phi(x_0)) \geq 0.$$

Thus, in both cases, we get $H(x_0, \overline{u}(x_0), D\phi(x_0)) \geq 0$, which is what we wanted.

This shows that $\underline{u}$ is a supersolution and $\overline{u}$ is a subsolution of (1.1). The strong uniqueness principle enables us to conclude. □

In the following section, we explain the role of H_b and give some examples for (2.7). These examples can easily be extended to (2.8). In section 4.1, we provide some simple criteria on H for choosing between (2.7) and (2.8).

3. Some examples. In [9, 1], two classes of numerical Hamiltonian were considered, Godunov and Lax–Friedrichs Hamiltonians. Here, we recall the main results of [1] because they can be applied to a more general setting than those of [9] from which they are inspired. In both cases, only the case of the domain $\mathbb{R}^N$ has been studied, i.e., in the present setting, the case of *interior* nodes.

In order to discretize the problem

$$\begin{cases} u_t + H(Du) = 0, \\ u(x,0) = u_0(x) \end{cases}$$

for $x \in \mathbb{R}^N$ and $t > 0$, where u_0 is Lipschitz continuous, we have considered the scheme

$$\begin{aligned} &u_i^0 = u_0(x_i), \\ &u_i^{n+1} = u_i^n - \Delta t \mathcal{H}_\rho(D_{T_1}u^n, \dots, D_{T_{k_i}}u^n). \end{aligned} \tag{3.1}$$

In (3.1), u^n represents the piecewise linear interpolant of (u_j^n), the set $\{T_1, \dots, T_{k_i}\}$ is the set of triangles that contain x_i, and $D_T u^n$ represents the (constant) gradient of u^n in the triangle T. The parameter ρ describes the local geometry of the mesh. In the examples to come, we specify this parameter; see Remark 1. For any $R > 0$, let us introduce the set $\mathcal{C}_R$ of continuous piecewise linear functions defined by

$$\mathcal{C}_R = \{u \text{ continuous piecewise linear s.t. } ||D_T u|| \leq R \text{ for any triangle } T\}. \tag{3.2}$$

We have to define the numerical Hamiltonians $(p_1, \dots, p_k) \mapsto \mathcal{H}_\rho(p_1, \dots, p_{k_i})$. They have been designed to have the following properties:

1. consistency: $\mathcal{H}_\rho(p, \dots, p) = H(p)$,
2. monotonicity: there exists Δt_R such that for all $\Delta t \leq \Delta t_R$, if $u^n, v^n \in \mathcal{C}_R$ and if $u_i^n \leq v_i^n$ for all i, then $u_i^{n+1} \leq v_i^{n+1}$,
3. intrinsicness: the definition of $\mathcal{H}_\rho$ does not depend on the geometrical description of u^n. For any vertex x_i, for any triangle T such that x_i is a vertex of T, if T is split into two triangles T_1 and T_2 for which x_i is still a vertex, then the value of the numerical Hamiltonian is not modified; see Figure 1.

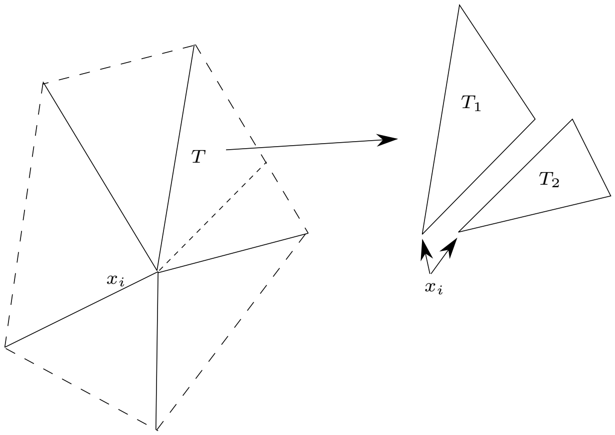

Fig. 1. *Geometrical elements for the intrinsic property: the numerical Hamiltonian is not modified if the triangle T is split into T_1 and T_2 and the value of u at the new vertex is evaluated by linear interpolation.*

We also assume that $\mathcal{H}_\rho$ is *uniformly* continuous in the p and ρ variables. Of course, the number of arguments changes from one mesh point to the other, but if the mesh is regular, the number of neighbors is bounded above, and, thanks to the "intrinsicness" property, we can think of $\mathcal{H}_\rho$ as the same function everywhere. Assuming these properties, it is possible to show the convergence of the scheme (3.1) and to give an error estimate [8, 1].

Notation. In what follows, when we consider numerical schemes that can be put in the form (3.1), sometimes the $D_{T_l}u^n$'s are rewritten in terms of u_i^n and the values of u^n for the neighboring nodes of x_i. For the sake of convenience, we denote the set of the neighbors of x_i (excluding x_i) by $\mathcal{N}_i$, and we rewrite the scheme as

$$u_i^{n+1} = G_\rho(u_i^n, \{u_j^n, j \in \mathcal{N}_i\}; \Delta t). \tag{3.3}$$

More generally, when the Hamiltonian is of the form $H(x, u(x), Du(x))$, the scheme is sometimes rewritten as

$$u_i^{n+1} = G_\rho(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}; \Delta t) = u_i^n - \Delta t \mathcal{H}_\rho \left(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}\right). \tag{3.4}$$

In the G-function, $G_\rho(x, t, \{t_l, l \in \mathcal{N}\}; \Delta t)$, t is similar to $u^\rho(x)$, and the variables t, $\{t_l, l \in \mathcal{N}\}$, provide a description of u^ρ in a neighborhood of x_i.

When we are interested in steady problems, the scheme, in the most general case considered in the paper, is

$$\mathcal{H}_\rho(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}) = 0. \tag{3.5}$$

Similar definitions are also considered for implicit schemes.

In the case of schemes (3.3) and (3.4), the monotonicity condition is equivalent to the following property of G_ρ: $(x, t, \{t_l, l \in \mathcal{N}_i\}) \mapsto G_\rho(x, t, \{t_l, l \in \mathcal{N}_i\}; \Delta t)$. For any fixed grid point $x = x_i$, G should be increasing in t and $\{t_l, l \in \mathcal{N}_i\}$. In practice, the numerical Hamiltonian $\mathcal{H}_\rho$ is an increasing function of $\{t_l, l \in \mathcal{N}_i\}$ and decreasing in t, so that the monotonicity condition for the explicit scheme is true, provided that a CFL-type condition on the time step holds. In the case of schemes (3.5), the monotonicity condition stated in Theorem 2.1 is less restrictive than for unsteady problems: $\mathcal{H}_\rho$ is decreasing with respect to t and increasing with respect to t_l.

Two types of Hamiltonians have been constructed so far, and for the sake of simplicity we describe them in the simplest case. The general case can be treated by "freezing" the x and $u(x)$ variables. They all satisfy the following "translation invariance" property, which mimics the facts that the t-arguments are used to approximate a gradient:

$$\forall x, t, t_l, C \in \mathbb{R}, \ \ G_\rho(x, t+C, \{t_l + C, l \in \mathcal{N}_i\}; \Delta t) = G_\rho(x, t, \{t_l, l \in \mathcal{N}_i\}; \Delta t). \tag{3.6}$$

Godunov Hamiltonians. If $H = H_1 + H_2$, where H_1 (resp., H_2) is convex (resp., concave),[1] then we set

$$\mathcal{H}^G_\rho(p_1, \dots, p_{k_i}) = \inf_{q \in \mathbb{R}^2} \max_{0 \le l \le k_i} \sup_{y \in -\Omega_l + q} \left[(p_i \mid y - q) - H_1^*(y) - H_2^*(q)\right], \tag{3.7}$$

where Ω_l, $l = 1, \dots, k_1$, are the angular sectors defined by the triangles $T_1, \dots, T_{k_i}$ at node x_i; H_1^*, for any l, $-\Omega_l$ is the symmetric of Ω_l with respect to x_i; and H_2^* are the Legendre transforms of H_1 and H_2. We have denoted by $(x \mid y)$ the dot product of x and y.

If h is the smallest radius of the circles of center x_i contained in $\cup_{i=1}^{k_i} T_i$, and if L_1 and L_2 are Lipschitz constants for H_1 and H_2, then the scheme is monotone, provided that the time step satisfies

$$\frac{\Delta t}{h}(L_1 + L_2) \le \frac{1}{2}.$$

The numerical Hamiltonian (3.7) is obtained by saying that $H_1 + H_2$ is bounded below by the convex functions $H_q(p) = H_1(p) - (p \mid q) + H_2^*(q)$. Another monotone Hamiltonian can also be obtained, as in [1], by saying that $H_1 + H_2$ is bounded above by the concave functions $H_q(p) = H_2(q) + (p \mid q) - H_1^*(p)$.

Lax–Friedrichs Hamiltonians. Here we set

$$\mathcal{H}^{LF}_\rho(p_1, \dots, p_{k_i}) = H(\bar{U}) - \frac{\epsilon}{h} \oint_{C_h} [u(x) - u(x_i)] dl,$$

where C_h (resp., D_h) is a circle (resp., disk) of center x_i and radius h,

$$\widehat{U} = \frac{\int_{D_h} Du \, dxdy}{\pi h^2},$$

and ϵ is larger than any Lipschitz constant of H divided by 2π.

Remark 1. For the Godunov and Lax–Friedrichs Hamiltonians, and at a mesh node x, the ρ parameter is the set of unit vectors defining the edges of the triangles at this node and the angles (at node x) of the triangles; see Figure 2.

3.1. Godunov boundary Hamiltonians for convex Hamiltonians. We look for a Hamiltonian $\mathcal{H}^b_\rho$ of the form

$$\mathcal{H}^b_\rho(p_1, \dots, p_k) = \max_{0 \le l \le k_i} \sup_{z \in -\Omega_l} \{(p_l \mid z) - H_b^*(z)\},$$

where the p_i's are the local gradients of a piecewise linear continuous function defined on $\overline{\Omega}$ and the Ω_l's are the angular sectors as before. We need that

$$\mathcal{H}^b_\rho(p, \dots, p) = H_b(p) \le H(p).$$

[1] In the case of a Cartesian mesh, this assumption can be relaxed as shown in [9].

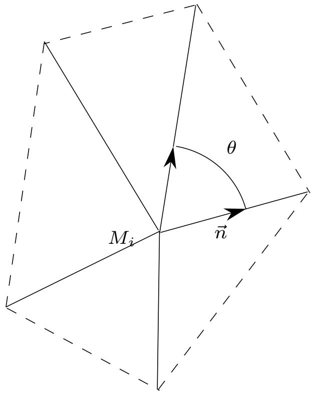

FIG. 2. *A description of ρ.*

If we assume that H_b is convex, this inequality implies $H_b^* \geq H^*$; the most natural choice is to take

$$\begin{cases} H_b^*(q) = H^*(q) & \text{if } q \in \cup_{j=1}^{k_i} \Omega_j, \\ H_b^*(q) = +\infty & \text{otherwise,} \end{cases} \tag{3.8}$$

but any convex Hamiltonian K such that $K^* \geq H_b^*$, which domain is included in $\cup_{j=1}^{k_i}\Omega_j$, would also be a solution. The monotonicity condition is automatically satisfied, thanks to the Hopf formula. In the case of an unsteady problem, the same CFL condition is valid; i.e., if L is a Lipschitz constant of H, the time step satisfies

$$\frac{\Delta t}{h} L \leq \frac{1}{2},$$

because the Lipschitz constant of H_b is at most that of H. If L is a Lipschitz constant of H, $H^*(p)$ may be finite only if p belongs to the ball $B(0, L)$ of center 0 and radius L. Since H_b^* is finite when H is finite, a Lipschitz constant of H is a Lipschitz constant for H_b.

Note that the Hamiltonian (3.8) is the largest possible choice and is the one suggested by the analysis from the dynamical programming principle. It can be interpreted by saying that we take into account all the outgoing rays.

3.2. Godunov boundary Hamiltonians for concave Hamiltonians. The analysis via the dynamical programming principle suggests choosing the boundary condition (2.8). We define H_b by (3.8), where the $+\infty$ condition is replaced by $-\infty$.

3.3. Lax–Friedrichs boundary Hamiltonians for convex Hamiltonians. Here, we are looking for Hamiltonians of the type

$$\mathcal{H}_\rho^b(p_1, \dots, p_k) = K(\bar{U}) - \frac{\epsilon_b}{h} \oint_{C_h} [u(x) - u(x_i)] dl,$$

where K is unknown, as well as the numerical dissipation ϵ_b. The average state is once more defined by

$$\bar{U} = \frac{\int_{D_h \cap \Omega} Du \, dxdy}{|D_h \cap \Omega|}.$$

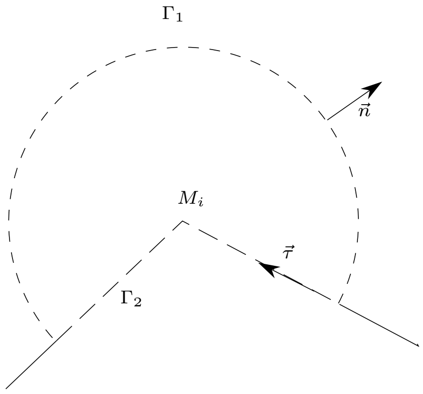

FIG. 3. *Definition of* Γ_1 *and* Γ_2.

The monotonicity condition is satisfied, provided that, L_b being a Lipschitz constant of K,

$$\epsilon_b \geq \frac{L_b\, h}{|D_h \cap \Omega)|}.$$

The area $\partial(D_h \cap \Omega)$ is $\theta\, h$, where θ is the angle of $D_h \cap \Omega$ at x_i. This can be seen by using the same arguments as in [1].

We denote by Γ_1 the part of $\partial(D_h \cap \Omega)$ which is inside Ω, and by Γ_2 the boundary part; see Figure 3. To determine K, we consider the consistency condition. It is easy to see that

$$H_b(p) \equiv \mathcal{H}^b_\rho(p, \dots, p) = K(p) - \frac{\epsilon_b}{h}\left(p\Big|\left\{\int_{\Gamma_1} \vec{n} dl - \int_{\Gamma_2} \vec{\tau} dl\right\}\right),$$

where $\vec{n}$ is the outward unit normal to Γ_1 and $\vec{\tau}$ is the unit tangent vector to Γ_2. The vector

$$\vec{N} = -\frac{1}{h}\left(\int_{\Gamma_1} \vec{n} dl - \int_{\Gamma_2} \vec{\tau} dl\right)$$

enters into Ω if $\partial\Omega$ is regular enough.

The convergence property of Theorem 2.2 is satisfied if $H_b \leq H$. When H_b is assumed to be convex, this condition is equivalent to asking for K to be convex and

$$\left(K + \epsilon_b \left(\vec{N}\mid\ .\ \right)\right)^*(q) \geq H^*(q) \quad \forall q \in \mathbb{R}^2.$$

The Legendre transform of $x \mapsto K(x) + \epsilon_b(\vec{N}|x)$ is

$$q \mapsto K^*(q + \epsilon_b \vec{N}),$$

and consequently K^* is defined by the relation

$$K^*(q) \geq H^*(q - \epsilon_b \vec{N}). \tag{3.9}$$

Let us call $\mathrm{Dom}(H^*)$ (resp., $\mathrm{Dom}(H_b)$) the subset of $\mathbb{R}^2$ for which $H^*(q)$ (resp., $(H^b)^*$) is finite. If L is a Lipschitz constant of H, $\mathrm{Dom}(H^*) \subset B(L)$. A similar result holds

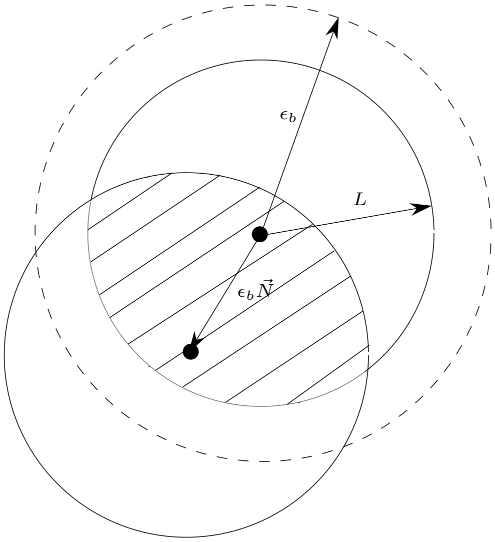

FIG. 4. *Geometrical representation of the conditions.*

for K. These sets are convex. There is a solution to the problem (different from $K = -\infty$) if and only if we can find ϵ_B such that

$$(\text{Dom}(H) - \epsilon_b\vec{N}) \cap \text{Dom}(H) \neq \emptyset, \qquad (3.10)$$
$$(\text{Dom}(H) - \epsilon_b\vec{N}) \cap B(\epsilon_b) \neq \emptyset.$$

See Figure 4 for a representation of these conditions.

In some cases, there is *no* solution at all. The simplest counterexample is given by

$$H(x) = (\vec{a} \mid x)$$

with $\vec{a} \neq 0$. In this case, $\text{Dom}(H) = \{\vec{a}\}$. The first condition implies $\epsilon_b = 0$ (thus $||\vec{a}|| = 0$); the second one gives $\vec{a} = 0$.

In some cases, there are solutions. An example is given by any Hamiltonian for which $\min H > -\infty$: since $0 \in \text{Dom}(H)$, we can set $\epsilon_b = 0$ and $K \equiv \min H$. Another example is provided by $H(x) = ||x||$. Here, we can choose any $\epsilon_b \in [0, \frac{1}{2||\vec{N}||}]$.

3.4. Other choices. In sections 3.1 and 3.3, a very obvious choice would be $H_b \equiv -\infty$. This choice enables us to satisfy our convergence conditions. In fact we have

$$\min(H, \max(-\infty, F)) = \min(H, F),$$
$$\max(H, \max(-\infty, F)) = \max(H, F),$$

so that the viscosity inequalities are obviously satisfied. This reduces to strongly imposing the boundary conditions. However, this is not be the best choice, since a numerical boundary layer may be generated, especially in the case of Dirichlet boundary conditions. The scheme converges, but very slowly, as can be seen by numerical experiments; see section 5. Moreover, the results of this paper have been formally extended to more general cases, particularly the case of discontinuous Dirichlet conditions. In this particular case, the choice $H_b = -\infty$ may prevent convergence, whereas the Godunov or Lax Friedrichs boundary Hamiltonian seems to ensure convergence.

It now becomes clear that some selection procedures must be established. We will provide some, in special cases.

4. Some selection criteria. In this section, we discuss the problem of finding suitable boundary Hamiltonians and the question of selecting between the min and max conditions. These two questions are related, but the most difficult one is to find a "good" boundary Hamiltonian. If no care is taken, the numerical solution may develop a boundary layer structure, especially in the case of Dirichlet conditions; i.e., the gradient of the numerical solution may become unbounded when the mesh size tends to zero. If Theorem 2.2 provides some necessary conditions for convergence, this is not acceptable in general because practical calculations are done with finite but nonvanishing mesh sizes.

This situation is very similar to the technical difficulties encountered in the analysis of the boundary problem in the continuous case; see [4]. To explain this point, let us consider a simple one dimensional example.

If, for example, we think of a numerical scheme for

$$\begin{cases} |u'(x)| = 1, & x \in]0,1[, \\ u(0) = 0, & u(1) = 2, \end{cases}$$

where the boundary conditions are strongly imposed as being modeled by

$$\begin{cases} |u'(x)| - \epsilon u_{xx} = 1, & x \in]0,1[, \\ u(0) = 0, & u(1) = 2, \end{cases} \tag{4.1}$$

the solution should look like

$$u_\epsilon(x) = x + \frac{\exp\left(\frac{x-1}{\epsilon}\right) - \exp\left(-\frac{1}{\epsilon}\right)}{1 - \exp\left(-\frac{1}{\epsilon}\right)},$$

and hence a boundary layer exists: the derivative of u is not bounded at $x = 1$ when $\epsilon \to 0$. Its thickness tends to 0 as $\epsilon \to 0$.

This simple example is quite generic from the numerical point of view. Assume that the numerical solution u^ρ converges in the neighborhood of the boundary to a regular solution u. Then, up to second order truncation errors, the numerical Hamiltonian behaves like

$$H(p_1, \dots, p_{k_i}) \simeq H(Du) - \epsilon(\rho) D^2 u,$$

where D^2u represents some elliptic operator and $\epsilon(\rho) \to 0$ as the mesh size tends to zero. In [8], some numerical schemes are constructed by directly using this idea. Because of that, if one sets the boundary condition strongly on $\partial\Omega$, as in the example (4.1), a boundary layer must exist in the vicinity of $\partial\Omega$. Its thickness tends to 0 as $\epsilon \to 0$. Its thickness also tends to 0 as $\epsilon(\rho) \to 0$.

4.1. Choosing between the "min" and "max" conditions for Dirichlet boundary conditions. In some situations, the choice can be motivated by some a priori knowledge of the behavior of the exact solution. For example, if one makes the following assumption—there exists $R \in]0, +\infty[$ such that

$$\lim_{\lambda \to +\infty} H(x, u, p - \lambda \vec{n}) = +\infty$$

uniformly on x in a neighborhood of $\partial\Omega$, $-R \le u \le R$ and p bounded[2]—then one can prove that if φ is continuous and u is the solution of

$$\begin{aligned} &H(x,u(x),Du(x)) = 0, && x \in \Omega, \\ &u(x) = \varphi(x), && x \in \partial\Omega, \end{aligned}$$

then $u(x) \le \varphi(x)$ on $\partial\Omega$ (see [4]). The boundary condition (2.7) implies that $u \le \phi$ at the discrete level, while (2.8) implies the opposite inequality. Hence, when the above assumption is true, the boundary condition (2.7) is the natural one to consider. This situation is encountered for nonbounded convex Hamiltonians.

When we have

$$\lim_{\lambda\to+\infty} H(x,u,p-\lambda\vec{n}) = -\infty,$$

the boundary condition (2.8) is the natural one to consider. This situation is encountered for nonbounded concave Hamiltonians.

4.2. The case of coercive Hamiltonians and boundary conditions (2.7). We are not able to provide an error bound between the numerical and the exact solutions. However, when the Hamiltonians H and H_b are coercive, we can show that no numerical boundary layer can appear; i.e., the gradient of the numerical solution is bounded when the mesh size tends to zero.

We say that H is coercive if

$$H(x,u,p) \to +\infty \quad \text{when } ||p|| \to +\infty$$

uniformly for $x \in \Omega$, $u \in [-R,R]$, $R \in]0,+\infty[$. We say that the boundary Hamiltonian is coercive if

$$H_b(x,u,p) \to +\infty \quad \text{when } ||p|| \to +\infty \text{ and } (p \mid \vec{n}) \ge 0$$

uniformly for $x \in \partial\Omega$, $u \in [-R,R]$ for all $R \in [0,+\infty[$. Here $\vec{n}$ is the inward unit vector at point $x \in \partial\Omega$. We have implicitly assumed that $\partial\Omega$ is C^1. In what follows, we consider the Dirichlet problem

$$\text{(4.2)} \quad \begin{cases} \mathcal{H}_\rho(x_i,u_i,D_{T_1}u,\dots,D_{T_{i_k}}u) = 0, & x_i \text{ interior node and } i_l \in \mathcal{N}_i, \\ \max(\mathcal{H}_\rho(x_i,u_i,D_{T_1}u,\dots,D_{T_{i_k}}u), u_i - \varphi(x_i)) = 0, & x_i \text{ boundary node and } i_l \in \mathcal{N}_i \end{cases}$$

but our results clearly extend to the more general case considered in this paper.

PROPOSITION 4.1. *Let $\mathcal{H}_\rho$ and $\mathcal{H}_\rho^b$ be monotone Hamiltonians consistent with H and H_b. Assume that $\mathcal{H}_\rho$ and $\mathcal{H}_\rho^b$ also satisfy* (3.6), *and that H and H_b are continuous, convex, and coercive. Assume also that the mesh is regular. Then the scheme* (2.7) *is convergent and the maximum over the triangles T of the norm of the numerical solution, when $h \to 0$ remains bounded.*

The boundary of $\Omega_h = \cup_{T\in\mathcal{T}_h} T$ is denoted by Γ_h.

Proof. The convergence is a consequence of Theorem 2.2. The uniform boundedness of the gradients is a consequence of the following lemma. □

LEMMA 4.2. *If H, $\mathcal{H}_\rho$, $\mathcal{H}_\rho^b$, and the mesh satisfy the assumptions of Proposition* 4.1, *and if u is a subsolution of* (4.2), *then there exists C independent of h such that for any two mesh points M_i, M_j we have*

$$|u_i - u_j| \le CM_iM_j.$$

[2] $\vec{n}$ is the inward unit normal to $\partial\Omega$.

Proof. For the sake of simplicity, we assume that H and H_b depend only on the p variable.

Let $K > 0$ and x_i be a mesh point. For now we let K be free. Since Ω_h has a finite number of points, there exists M', a mesh point such that $u_l - KM_lM_i$ is maximum at M':

$$u_l - KM_lM_i \leq u_{M'} - KM'M_i.$$

This indicates that $v_l = (u(x') - K\, ||x' - x_i||) + K\, ||x_l - x_i||$ is greater that u, with an equality at node x'. Hence, using the same techniques as in Appendix A, if x' is an interior node,

$$0 \geq \mathcal{H}_\rho(u) \geq \mathcal{H}_\rho(K\, ||x - x_i||), \tag{4.3}$$

where we have written $\mathcal{H}_\rho(u)$ instead of $\mathcal{H}_\rho(D_{T_{i_1}}u, \dots, D_{T_{i_k}}u)$, for short. Similarly, since $\max(\mathcal{H}^b_\rho(u), u - \varphi) \leq 0$, we have $\mathcal{H}^b_\rho(u)$, and by the monotonicity of $\mathcal{H}^b_\rho$, we get

$$0 \geq \mathcal{H}_\rho(K\, ||x - x_i||) \tag{4.4}$$

at x' if it is on the boundary. Assume that $x' \neq x_i$. We show that if K is large enough, we have a contradiction. We can assume that $x_i = 0$ so that we have to deal with the piecewise interpolant $\pi_h||x||$ of the convex function $x \mapsto ||x||$. Note that $0 = x_i$ does not lie in the interior of any triangle. A simple consequence of the Taylor formula [7] shows that there exists $C' > 0$ such that if the mesh is regular,

$$\left|\left| D_T\pi_h|x| - \frac{x_G}{||x_G||} \right|\right| \leq C_1 h,$$

where x_G is the gravity center of T.

Since H is regular, there exist $C_2 > 0$ such that

$$\left| \mathcal{H}_\rho(\pi_h||x||) - \mathcal{H}_\rho\left(K\frac{x_{G_1}}{||x_{G_1}||}, \dots, K\frac{x_{G_k}}{||x_{G_k}||} \right) \right| \leq C_2 h.$$

The same inequality is also true for $\mathcal{H}^b_\rho$. Since the scheme is consistent with uniformly continuous numerical Hamiltonians, and because $O = x_i$ does not belong to the interior of the molecule associated with x', we can replace $\mathcal{H}_\rho(K\frac{x_{G_1}}{||x_{G_1}||}, \dots, K\frac{x_{G_k}}{||x_{G_k}||})$ by $H(K\, \frac{x'}{||x'||})$ up to an $O(h)$ term. The same is true for $\mathcal{H}^b_\rho$. Hence we get that $H(K\, \frac{x'}{||x'||}) \leq O(h)$, which is impossible if K is large enough. This shows that if $K = C + 1$, where C is chosen so that

$$H(C\, p) < 0 \text{ with } ||p|| = 1 \quad \text{and} \quad H_b(C\, p) < 0 \text{ with } ||p|| = 1 \text{ and } (p \mid \vec{n}) < 0,$$

we have that $x' = x_i$, and then

$$u_l - u_i \leq K||x_l - x_i||$$

when h is small enough. The conclusion holds by symmetry. □

An example. We consider the example of a convex Hamiltonian. The boundary Hamiltonian consistent with the Godunov boundary Hamiltonian is

$$H_b(p) = \max_{(y \mid \vec{n}) \leq 0} \left((y \mid p) - H^*(y) \right),$$

where $\vec{n}$ is the inward unit vector. If we assume that H is smooth enough, the optimal ray is $p^* = DH(p)$. A sufficient (and crude) condition to ensure that H_b is coercive if H is coercive is to state that $(p^* \mid \vec{n}) \leq 0$, because in this case $H_b(p) = H(p)$. To obtain this sufficient condition, it is enough to say that

$$\lambda \in \mathbb{R}^+ \mapsto H(p + \lambda \vec{n})$$

is monotone increasing. This has to be connected to the conditions of section 4.1. An example where $(p^* \mid \vec{n}) \leq 0$ is given by the eikonal Hamiltonian because $p^* = \frac{p}{||p||}$.

4.3. Extension to nonconvex Hamiltonians. Let us consider a problem where $H = H_1 + H_2$, with H_1 convex and H_2 concave. Following (3.7), a natural boundary Hamiltonian is also

$$\mathcal{H}^b_\rho(p_1, \dots, p_{k_i}) = \inf_{q \in \mathbb{R}^2} \max_{0 \leq l \leq k_i} \sup_{y \in -\Omega_l + q} \left[(p_i \mid y - q) - H_1^*(y) - H_2^*(q) \right].$$

Since $\cup_l \Omega_l$ is a strict subset of $\mathbb{R}^2$, we have

$$H^b(p) \equiv \inf_{q \in \mathbb{R}^2} \sup_{(y \mid \vec{n}) \geq 0} \left[(p \mid y - q) - H_1^*(y) - H_2^*(q) \right] \leq H(p),$$

and the conditions of Theorem 2.2 are satisfied.

If the family $\{H_1(p) - (p \mid q)\}_{q \in \mathbb{R}^2}$ is uniformly coercive, then the numerical solution develops no numerical layer; this is a simple consequence of Proposition 4.1.

5. Applications.

5.1. Some numerical tests. We have not been able to get error estimates for the schemes presented above. Even in the case of the crudest approximations of the boundary condition, i.e., by taking $H_b = -\infty$, we can show the convergence of the numerical solution. However, we have shown in a special case that no numerical boundary layer exists even for Dirichlet conditions when the Hamiltonians are coercive.

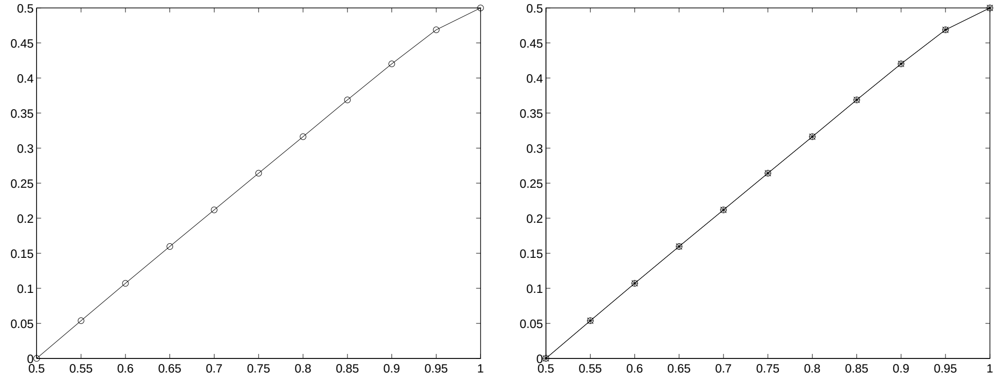
The purpose of this paragraph is to illustrate the various phenomena that we have encountered, for Dirichlet and Neuman conditions. In each case, the strong boundary conditions are obtained with $H_b = -\infty$, and the weak ones with H_b being the Godunov Hamiltonian. In sections 5.1.1 and 5.1.2, the interior Hamiltonian is the Lax–Friedrichs one. In section 5.2, it is the Godunov Hamiltonian. Other experiments with the Lax–Friedrichs condition have been done, but they are not reported here. They provide the same results. We also show the behavior of the schemes on a problem with nonconvex Hamiltonians and Dirichlet conditions; this is the subject of section 5.1.3.

5.1.1. Dirichlet conditions. The domain Ω is limited by two "concentric" circles of radius 0.5 and 1. It is discretized by a finite element–type mesh, but this is not essential. The problems are

$$\begin{cases} ||Du|| = 1 & \text{in } \Omega, \\ u = 0 & \text{for } ||x|| = 0.5, \\ u = C & \text{for } ||x|| = 1. \end{cases} \tag{5.1}$$

Table 5.1
Boundary condition for the Dirichlet boundary conditions.

Case	1	2	3	4
C	0.5	10	0.25	-11



(a) (b)

Fig. 5. *Comparison of different implementations of Dirichlet conditions for problem* (5.1) *and Case* 1: (a) *weak conditions,* (b) *comparison of weak* ($\circ$) *and strong* ($*$).

The constant C takes the values displayed in Table 5.1.

The viscosity solution is given as follows:

- Case 1 and 2: $u(x) = ||x|| - 0.5$;
- Case 3: $u(x) = ||x|| - \frac{1}{2}$ if $||x|| \in [\frac{1}{2}, \frac{7}{8}]$ and $u(x) = -||x|| + \frac{5}{4}$ if $||x|| \in [\frac{7}{8}, 1]$;
- Case 4: $u(x) = -||x|| + \frac{1}{2}$.

The difference between these test cases is that for Cases 1 and 3, the boundary conditions on $||x|| = 1$ are enforced strongly, whereas for 2 and 4, they are enforced in the viscosity sense only.

We plot the cross section only in the y-direction and positive abscissa. Two kinds of tests have been done. In the first, we have strongly imposed the boundary conditions; i.e., we have taken $H_b = -\infty$. In the second test, the conditions have been imposed weakly, with the Godunov boundary Hamiltonian.

Comparison of Figures 5, 6, 7, 8 clearly shows that when the boundary condition is *strongly* enforced by the viscosity solution, no special treatment is needed. On the contrary, when it is only weakly enforced, then a special treatment is mandatory, otherwise a boundary layer–type phenomenon is observed.

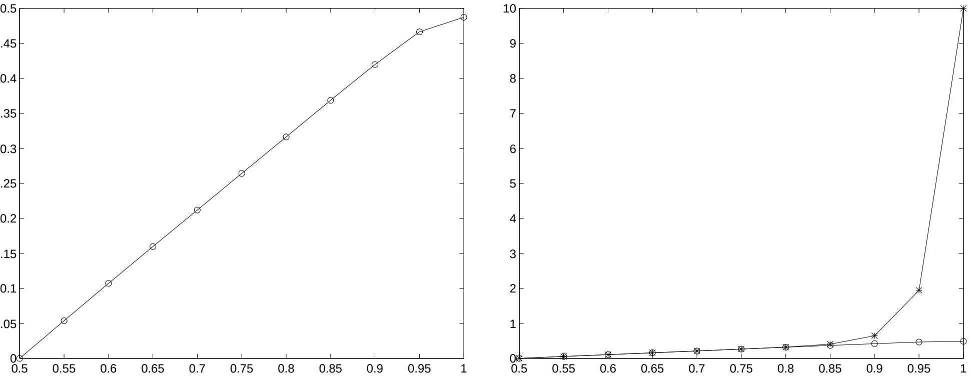
5.1.2. Neumann conditions. Here, we test the problem

$$\left\{ \begin{array}{ll} ||Du|| = 1 & \text{in } \Omega, \\ u = 0 & \text{for } ||x|| = 1, \\ \frac{\partial u}{\partial n} = 0 & \text{for } ||x|| = 0.5. \end{array} \right. \tag{5.2}$$

Its solution is $u(x) = -||x|| + \frac{1}{2}$.

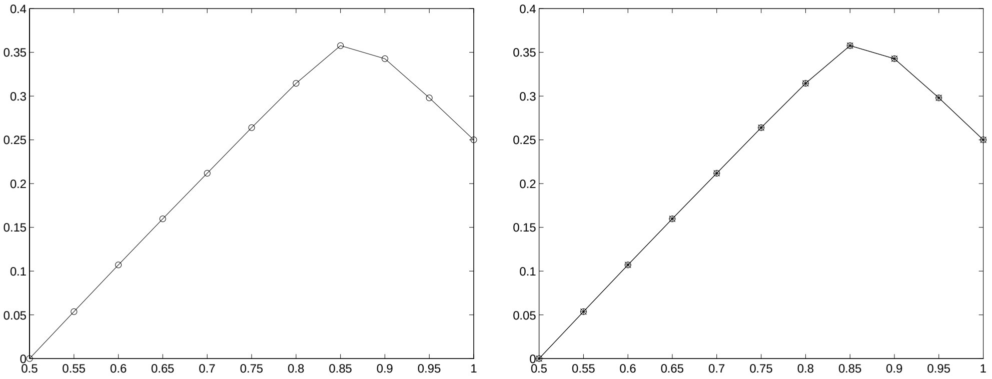
The viscosity solution is given by the solution for Case 1. Once more, the numerical solution is obtained by imposing the boundary conditions either strongly or weakly.

The problem $\frac{\partial u}{\partial n} = g$ is approximated at node A in the following way (see Figure 9). The outward unit normal is approximated as $\vec{n}_A = \overrightarrow{AB}^{\perp} + \overrightarrow{AC}^{\perp}$, which is



(a) (b)

Fig. 6. *Comparison of different implementations of Dirichlet conditions for problem* (5.1) *and Case* 2: (a) *weak conditions,* (b) *comparison of weak* ($\circ$) *and strong* ($*$).



(a) (b)

Fig. 7. *Comparison of different implementation of Dirichlet conditions for problem* (5.1) *and Case* 3: (a) *weak conditions,* (b) *comparison of weak* ($\circ$) *and strong* ($*$).

normalized. Here, $\vec{x}^{\perp}$ is the orthogonal vector to $\vec{x}$ such that $(\vec{x}, \vec{x}^{\perp})$ is positive. Then we consider a node D which is on the side of the triangle opposite to D, which is cut by $-\vec{n}_A$. We then set

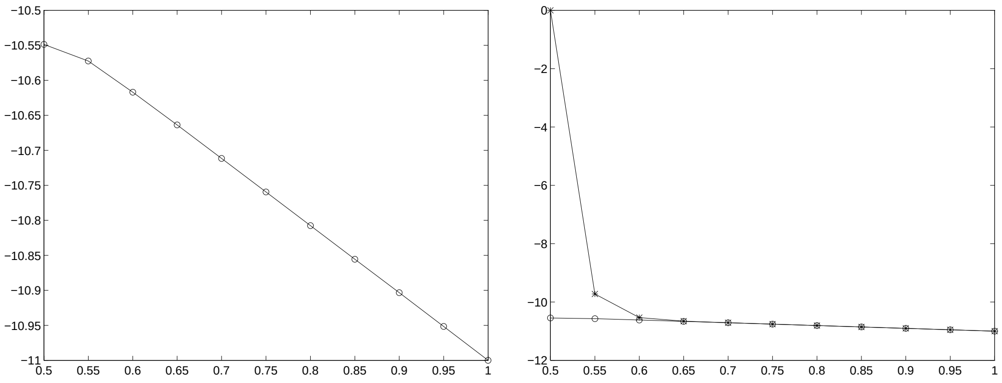
$$u(A) = ||\overrightarrow{AD}||g(A) + u(C). \tag{5.3}$$

Here, u is the piecewise linear interpolation of the data.

In the strong formulation, we use (5.3) directly. In the weak formulation, we set

$$\max\left(\frac{u_A^{n+1} - u_A^n}{\Delta t} - \mathcal{H}_\rho^b(u^n), \frac{u_A^{n+1} - u_C^{n+1}}{AC} - g(u_A^n)\right) = 0.$$

From Figure 10, it is clear that the weak formulation gives much better results. However, the difference between the two formulations is not as important as for the Dirichlet problem, as expected.



(a) (b)

FIG. 8. *Comparison of different implementation of Dirichlet conditions for problem* (5.1) *and Case* 4: (a) *weak conditions,* (b) *comparison of weak* (○) *and strong* (∗).

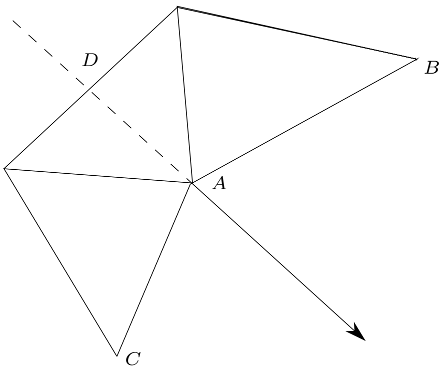


FIG. 9. *Schema for the approximation of the Neuman boundary conditions.*

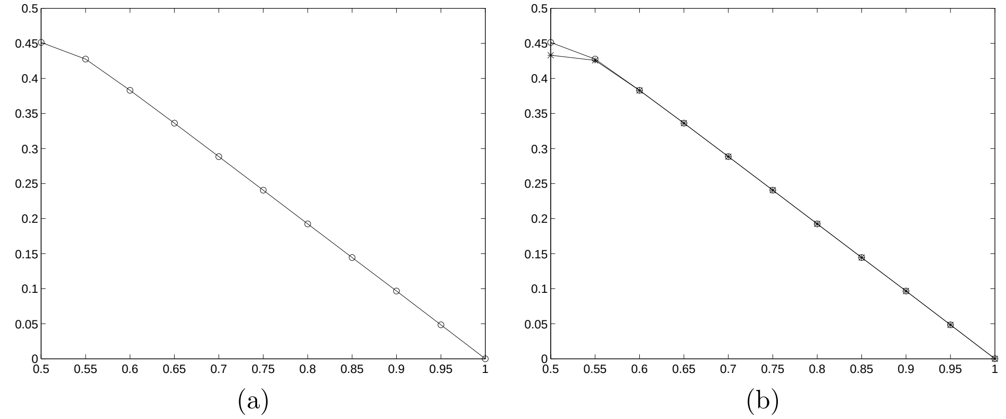
5.1.3. The case of a nonconvex Hamiltonian and Dirichlet conditions. In general, it is difficult to compute analytically the solution of a first order Hamilton–Jacobi equation, and the situation is even worse when the Hamiltonian is not convex (nor concave), because the analogy with hyperbolic systems becomes looser in general. Hence, it becomes more difficult to judge the quality of numerical results. To overcome this difficulty in a special case, we consider $H(p) = (||p|| - 1)^3$ and the problem

$$\begin{array}{ll} H(Du) = 0 & \text{on } \Omega, \\ u = 0 & \text{on } \Gamma_1, \\ u = 10 & \text{on } \Gamma_2, \end{array} \tag{5.4}$$

where Ω is depicted in Figure 11. Since $t \mapsto t^3$ is monotone increasing, u is a solution of (5.4) if and only if it is a solution of

$$\begin{array}{ll} ||Dv|| - 1 = 0 & \text{on } \Omega, \\ v = 0 & \text{on } \Gamma_1, \\ v = 10 & \text{on } \Gamma_2. \end{array} \tag{5.5}$$

The solution of (5.4) and (5.5) is the distance to Γ_1.



(a)

(b)

FIG. 10. *Comparison of different implementations of homogeneous Neumann conditions for problem* (5.2): (a) *weak conditions,* (b) *comparison of weak* (○) *and strong* (∗).

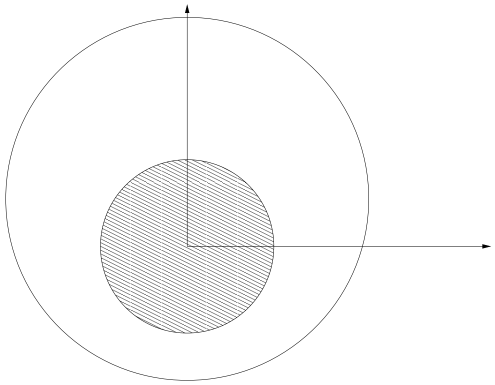


FIG. 11. *Computational domain for problem* (5.4). Γ_1 *is the inner circle of center* $(0,0)$ *and radius* $r = 1$, Γ_2 *is the outer circle of center* $(0,0.5)$ *and radius* $r = 3$.

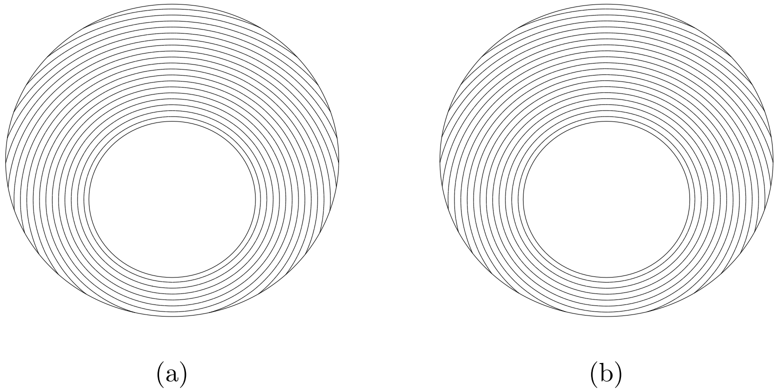
In order to discretize (5.4), we write $H = H_1 + H_2$, with $H_1(p) = \max(|p|| - 1, 0)^3$ and $H_2(p) = \min(||p|| - 1, 0)^3$. These functions are respectively convex and concave. The numerical Hamiltonian and the boundary Hamiltonian are the same as in sections 3 and 4.3. The numerical solution is displayed in Figure 12(a). The solution of (5.5) with the Godunov Hamiltonian is provided in Figure 12(b). A close comparison shows that they are (almost) identical.

Another application of the boundary conditions developed in this paper is given by the approximation of the following problem, on the same geometry:

$$\begin{aligned} &H(Du) = 0 && \text{on } \Omega,\\ &u(x,y) = 0, && (x,y) \in \Gamma_1,\\ &u(x,y) = 3\cos(2\pi x), && (x,y) \in \Gamma_2. \end{aligned} \tag{5.6}$$

Since H is nonconvex, it is difficult to know a priori what the value of the solution on the boundary would be. The computed solution is given in Figure 13(a). It can be seen that the solution satisfies the boundary condition strongly on Γ_2 and only weakly on Γ_1 (in contrast to the previous example). Note, however, that the boundary conditions have been numericaly *weakly* imposed on Γ_1 and Γ_2. The solution is also



(a) (b)

FIG. 12. (a) *Solution of problem* (5.4)*,* min = 0*,* max = 1.48*.* (b) *Solution of problem* (5.10)*,* min = 0*,* max = 1.504*.*

FIG. 13. (a) *Solution of problem* (5.6)*,* min = −3*,* max = −1.53*.* (b) *Solution of problem* (5.7)*,* min = −3*,* max = −1*,* 47*.*

in very good agreement with the one obtained from the discretization of

$$\begin{array}{ll} ||Dv|| - 1 = 0 & \text{on } \Omega, \\ v(x,y) = 0, & (x,y) \in \Gamma_1, \\ v(x,y) = 3\cos(2\pi x), & (x,y) \in \Gamma_2, \end{array} \tag{5.7}$$

which is displayed in Figure 13(b).

5.2. Application to a problem in geophysics. In [6] is developed a technique to compute the multivalued solutions τ of the Eikonal equation with an initial condition

$$\tau(x_S) = 0$$

at the source term x_S. This corresponds to the problem of computing the very high frequency approximation of the wave equation in a possibly inhomogeneous media, when the source term is located at a single point with a Dirac source term. In this case, the solution consists of a wave front that might have a very complex structure.

The solution of this problem is important in geophysics applications; it is the core of an inverse method for reconstructing the index of the media knowing only the arrival times of the wave fronts at the ground.

In Benamou's method [6], we need to be able to solve, in several arbitrary domains Ω containing x_S, the following problem:

$$\left\{ \begin{array}{ll} ||D\tau|| - n(x) = 0 & \text{in } \Omega, \\ \tau(x_S) = 0, & \\ \tau(x) = +\infty & \text{if } x \in \partial\Omega - \{x_S\}. \end{array} \right. \tag{5.8}$$

The boundary conditions have to be understood in the viscosity sense. In particular, the second boundary solution corresponds to the Soner boundary condition. The solution to this problem is known,

$$\tau(x) = \inf_{y_x} \left[\int_0^{\min(T,\zeta)} n(y_x(s)) \left| \frac{dy_x}{ds} \right| ds \right], \tag{5.9}$$

where the trajectory y_x starts at x_S for $s = 0$, and ζ is its first exit time, i.e.,

$$\zeta = \inf\{s \geq 0; y_x(s) \notin \overline{\Omega}\}.$$

In other words, we do not take into account the rays that start at x_S and come into Ω.

The idea is to characterize the solution of (5.8) as the steady solution of

$$\left\{ \begin{array}{ll} u_t + ||Du|| - n(x), & t > 0 \text{ and } x \in \Omega, \\ u(x, t = 0) = 0, & x \in \Omega, \\ u(x_S, t) = 0 & \text{at } x_S \\ u(x, t) = +\infty, & x \in \partial\Omega - \{x_S\}. \end{array} \right. \tag{5.10}$$

It is clear that neither (5.9) nor (5.10) falls into the framework that we have considered here. The idea is to introduce an approximation of τ_ρ^e, the solution of

$$\left\{ \begin{array}{ll} ||D\tau|| - 1 = 0 & \text{in } \Omega, \\ \tau(x_S) = 0, & \\ \tau(x) = 0, & x \in \partial\Omega - \{x_S\}, \end{array} \right. \tag{5.11}$$

given by (5.9) for $n \equiv 1$. We then show that the scheme (5.12) can be rewritten as

$$\left\{ \begin{array}{ll} \frac{u_i^{n+1} - u_i^n}{\Delta t} + \mathcal{H}_\rho(D_{T_1}u^n, \dots, D_{T_1}u^n) - n(x_i), & n > 0 \text{ and } x_i \text{ interior point}, \\ u_i^0 = 0 & \text{for all } i, \\ u_{x_S}^n = 0 & \text{for } n \geq 1, \\ u_i^n = \min(u_i^n - \Delta t \mathcal{H}_\rho^b(D_{T_1}u^n, \dots, D_{T_1}u^n) - n(x_i), K\tau_\rho^e), & n > 0 \text{ and } x_i \neq x_S, \end{array} \right. \tag{5.12}$$

for K large enough, uniformly in ρ. Once this is shown, we can apply the arguments of (2.2) to conclude. In what follows, we restrict ourselves to the case of the Godunov Hamiltonian.

5.2.1. Finding an elementary supersolution of (5.11) when $n \equiv 1$.

Our aim is to find an elementary supersolution of

$$\left\{ \begin{array}{ll} \mathcal{H}_\rho(u, x_i) = 1 & \text{for any node different from } x_S, \\ & \\ u(x_S) = 0. & \end{array} \right. \tag{5.13}$$

Here, the numerical Hamiltonian is the Godunov Hamiltonian for $H(x,p) = ||p|| - 1$.

For any mesh points x_i and x_j, we consider a path $P(x_i \to x_j) = x_i \dots P_k \dots x_j$ connecting x_i and x_j. The points P_k of $P(x_i \to x_j)$ are nodes of the mesh. We define $\#(P(x_i \to x_j))$ as the number of nodes that define the path $P(x_i \to x_j)$. We consider u defined by

$$u^e(x_i) = \min_{P(x_i \to x_S))} \left(\sum_{l=1}^{\#(P(x_i \to x_S))} P_l P_{l+1} \right), \tag{5.14}$$

with the convention $P_1 = x_i$ and $P_{\#(P(x_i \to x_S))} = x_S$.

LEMMA 5.1. *Let $k \geq 0$. We have, for any mesh point x_ℓ,*

$$\tau_\rho^e(x_i) = \min_{P(x_i \to x_S)} \left(\sum_{l=0}^{\#(P(x_i \to x_S))} P_j P_{j+1} + \tau_\rho^e(x_\ell) \right).$$

Proof. Let P be an optimal path that connects x_ℓ to x_S, and P' be a path that connects x_i to x_ℓ. The path $P \cup P'$ connects x_i to x_S, and we have

$$\tau_\rho^e(x_i) \leq \sum_{j=1}^{\#(P(x_i \to x_S))} P_j P_{j+1} + \tau_\rho^e(x_\ell).$$

By taking the infinum, we have the first inequality. Let P now be an optimal path for

$$v(x_i) = \min_{P(x_i \to x_\ell)} \left(\sum_{l=0}^{\#(P(x_i \to x_S))} P_j P_{j+1} + \tau_\rho^e(x_\ell) \right).$$

If P' is an optimal path for $u(x_\ell)$, by connecting the two paths, we get the opposite inequality. □

We show that τ_ρ^e defined in (5.14) is a supersolution of the problem. First it is clear that $u(x_S) = 0$. For any node x_i, we denote by $\mathcal{N}(x_i)$ the neighboring nodes of x_i in the mesh. We show now that

$$\max_{x \in \mathcal{N}(x_i)} \left(\frac{\tau_\rho^e(x_i) - \tau_\rho^e(x)}{||x_i - x||} \right) \geq 1. \tag{5.15}$$

This is a direct consequence of Lemma 5.1. Since $\mathcal{H}_\rho \geq \max_{x \in \mathcal{N}(x_i)} \left(\frac{\tau_\rho^e(x_i) - \tau_\rho^e(x)}{||x_i - x||} \right)$,[3] the function τ_ρ^e is a supersolution of (5.12) when $n \equiv 1$.

5.2.2. Study of the scheme (5.12).

For any $K > \max_\Omega n(x)$, we consider the scheme (5.12). By using the maximum principle, it is easy to get the next result.

PROPOSITION 5.2. *Under the CFL restriction $\frac{\Delta t}{h} \leq 1/2$, the numerical values $(u_i^n)_{x_i, n \geq 0}$ satisfy the following:*

- *at the source point x_S, $u_{x_S}^n = 0$ for any $n \geq 0$.*

[3] This is true because on each angular sector the maximum is reached by one of the terms $\frac{\tau_\rho^e(x_i) - \tau_\rho^e(x)}{||x_i - x||}$ for $x \in \mathcal{N}_i$ or by the gradient of τ_ρ^e in this angular sector. If we take $\vec{e} = \frac{x - x_i}{||x - x_i||}$, we have $\frac{\tau_\rho^e(x_i) - \tau_\rho^e(x)}{||x_i - x||} \leq |\,(Du \mid \vec{e})\,| \leq ||D\tau_\rho^e||$, and the inequality follows.

- $0 \leq u_i^n \leq K\tau_\rho^e(x_i)$ *for any* x_i, $t_n = n\Delta t$.
- *For any* i, *the sequence* (u_i^n) *has a limit when* $n \to +\infty$, *which is the solution of*

$$\begin{cases} \mathcal{H}_\rho(D_{T_1}u, \dots, D_{T_1}u) - n(x_i) = 0 & \textit{for any } x_i, \\ u_{x_S} = 0 & \textit{at } x_S, \\ \max\left(\mathcal{H}_\rho^b(D_{T_1}u, \dots, D_{T_1}u) - n(x_i), K\tau_\rho^e(x_i)\right) & \textit{on the boundary.} \end{cases}$$

In particular, u_i^n is *independent* of K and ρ when $K \geq \max_\Omega n(x)$.

Proof.

- $0 \leq u_i^n$. This is obvious since the scheme is monotone and $u_i^0 = 0$.
- $u_i^n \leq K\tau_\rho^e(x_i)$. The previous results show that $K\tau_\rho^e$ is a supersolution of (5.12) when $K \geq \max_\Omega n(x)$. The uniqueness principle shows that $u_i^n \leq K\tau_\rho^e(x_i)$.
- At the source point, $u_{x_S}^n = 0$. This is true for $n = 0$. Assume that $u_{x_S}^n = 0$. Since $0 \leq u_i^n$, and thanks to the monotonicity property of $\mathcal{H}_\rho$, we have $\mathcal{H}_\rho \leq 0$ at x_S. Since $\tau_\rho^e(x_S) = 0$, we have

$$u_{x_S}^{n+1} = \min(-\Delta t \mathcal{H}_\rho + \Delta t n(x_S), 0) = 0.$$

The last statement is obvious by continuity. □

By applying the result of Theorem 2.2, we conclude the following.

PROPOSITION 5.3. *The solution of the scheme*

$$\begin{cases} \mathcal{H}_\rho(D_{T_1}u, \dots, D_{T_1}u) - n(x_i) = 0 & \textit{for any } x_i, \\ u_{x_S} = 0 & \textit{at } x_S, \\ \max\left(\mathcal{H}_\rho^b(D_{T_1}u, \dots, D_{T_1}u) - n(x_i), K\tau_\rho^e(x_i)\right) & \textit{on the boundary} \end{cases}$$

converges, as $\rho \to 0$, *to the function* (5.9) *when* Ω *is smooth enough.*

5.2.3. Numerical application. We have considered in numerical applications [2] the index n given by a realistic model of the underground of the Gabon gulf, the Marmousi model developed by the French Petroleum Institute (IFP). Since there is no exact solution in closed form for this problem, it is probably more enlightening to consider a more academical problem where an exact solution is known. The computational domain is represented in Figure 14, and the solution at any point M is the distance between the point S and M. A mesh is displayed in Figure 15. The numerical solution is shown in Figure 16. The boundary conditions are very well taken into account: there is no boundary layer, and the isolines of the solution are orthogonal to the circle, as they should be. In Figure 17, we display the isolines of the logarithm of the error between the exact and the computed solutions.

6. Conclusion and summary.

In this paper, we have described two ways of discretizing boundary conditions for first order Hamilton–Jacobi equations for which convergence can be proved. This is done through a boundary numerical Hamiltonian. In the case of convex or concave Hamiltonians, we have given explicit formulas. In the case of a coercive Hamiltonian, we have shown that the natural boundary conditions prevent the appearance of numerical boundary layers. Then we have illustrated the schemes by simple numerical examples. An extension to geophysics is also provided.

Appendix A. Some properties of monotone numerical schemes.

The aim of this section is to provide some properties of the maximum principle type for monotone numerical schemes:

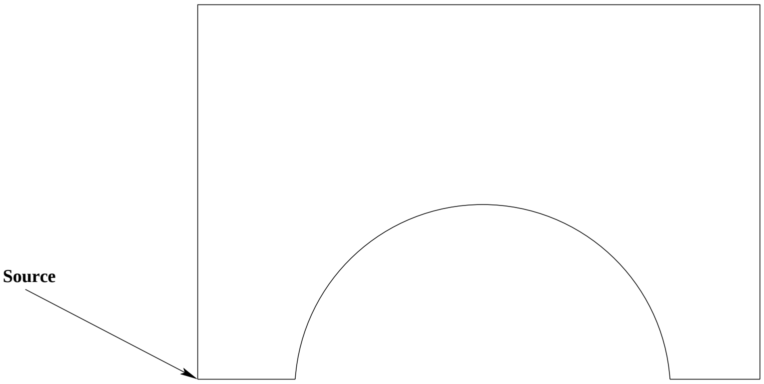

FIG. 14. *Test case for the Soner/source boundary conditions. The Soner condition is imposed everywhere except at the source.*

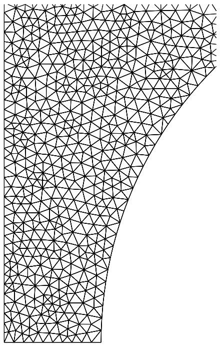

FIG. 15. *Zoom of the mesh around the source. Number of vertices:* 5906; *number of triangles:* 11430.

- For steady problems,

$$\mathcal{H}_\rho(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}) = 0. \tag{A.1}$$

- For unsteady problems,

$$u_i^{n+1} = G_\rho(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}; \Delta t) = u_i^n - \Delta t \mathcal{H}_\rho\left(x_i, u_i^n, \{u_j^n, j \in \mathcal{N}_i\}\right). \tag{A.2}$$

These results are useful in section 4. The notation is the same as in section 3.

As in the continuous case, we say that a piecewise linear function u is a discrete subsolution of (A.1) if we have

$$\text{for any } x_i, \quad \mathcal{H}_\rho(x_i, u(x_i), D_{T_1}u, \dots, D_{T_k}u) \le 0.$$

It is a supersolution of (A.1) if

$$\text{for any } x_i, \quad \mathcal{H}_\rho(x_i, u(x_i), D_{T_1}u, \dots, D_{T_k}u) \ge 0.$$

Similarly, let $R > 0$ and $\Delta t \le \Delta t_R$ to ensure the monotonicity of the operator G in (A.2). We say that $u \in \mathcal{C}_R$ is a subsolution of the explicit scheme (A.2) if for all

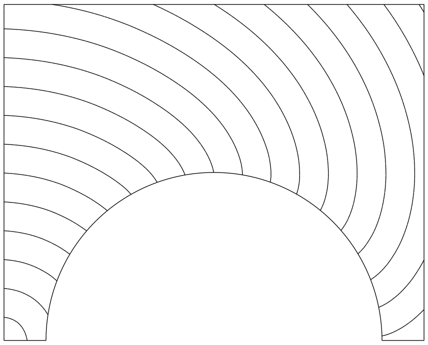

FIG. 16. *Numerical solution.*

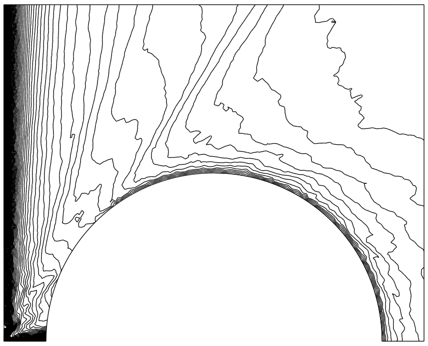

FIG. 17. *Isolines of* $\log_{10}(\tau^{exact} - \tau^{num})$, *max* $= -1.82$.

$n \geq 0$,

$$\text{for any } x_i, \quad \frac{u_i^{n+1} - u_i^n}{\Delta t} + \mathcal{H}_\rho(x_i, u^n(x_i), D_{T_1} u^n, \dots, D_{T_k} u^n) \leq 0.$$

$v \in \mathcal{C}_R$ is a supersolution when the opposite inequality holds. The case of implicit schemes is dealt with the same way.

A solution is obviously a sub- and supersolution, and by maximum principle we understand the following: if u (resp., v) is a sub- (resp., super-)solution of (A.1) such that for any x_i on the boundary of Ω_h we have

$$u(x_i) \leq v(x_i),$$

then the same inequality is true for any node of Ω_h. We say that there is a maximum principle on (A.2) and (A.1) if when u and v are sub- and supersolutions of (A.2) and (A.1) with $u_i^n \leq v_i^n$ on the boundary nodes of Ω_h and for any node of Ω_h at $t = 0$ or t_N, then $u_i^n \leq v_i^n$ everywhere.

We want to show that under the assumptions (H0)–(H1) or (H0)–(H2) below, we have a maximum principle for some classes of schemes of the type

$$G_\rho(x_i, \xi; \{\zeta_l\}_{l \in \mathcal{N}_i}) = 0. \tag{A.3}$$

(H0) The numerical Hamiltonian $\mathcal{H}_\rho$ is monotone increasing in ζ_i and monotone decreasing in $\zeta_l, l \neq i$, for any i. It also satisfies the following: for any i, $\xi \in \mathbb{R}$, and any $(\zeta_1, \dots, \zeta_k)$, $\mathcal{H}_\rho$ is invariant by translation on the ζ_ks.

(H1) For any $R > 0$, for any u, v such that $-R \leq v \leq u \leq R$, for any $p_1, \dots, p_k$ vectors, and for any mesh point x_i, we have

$$\gamma_R(u - v) \leq \mathcal{H}_\rho(x_i, u, p_1, \dots, p_k) - \mathcal{H}_\rho(x_i, v, p_1, \dots, p_k).$$

Here, k is the number of triangles having x_i as vertex.

(H2) The Hamiltonian $\mathcal{H}_\rho$ is convex in the variables $p_1, \dots, p_k$, and there exists a subsolution $\Phi_i, i = 1, \dots, n_s$, and $\alpha < 0$ such that $\mathcal{H}_\rho(x_i, D_{T_1}\Phi, \dots, D_{T_k}\Phi) \leq \alpha$ for any i.

The assumptions (H1) and (H2) are only the discrete analogue of classical assumptions on the Hamiltonian H.

Here, we provide a maximum principle for a monotone Hamiltonian and a *fixed* mesh only. The arguments are too crude to pass to the limit.

A.1. Maximum principle in the steady case.

THEOREM A.1. *We assume that the scheme satisfies* (H0) *and* (H1). *If* $(u_i)_{x_i}$ *and* $(v_i)_{x_i}$ *are sub- (super-)solutions of* (A.3) *in the interior nodes of* Ω_h *and satisfy* $u_i \leq v_i$ *on its boundary nodes, then* $u_i \leq v_i$ *everywhere.*

Proof. Let $R = \max_{x_i, i=1,\dots,n_s}(|u_i|, |v_i|)$ and x_{i_0} be the mesh point where $\{u_i - v_i\}_i$ reaches its maximum. Let us call this maximum M. If x_{i_0} belongs to the boundary, then $M \leq 0$ and we are done. If x_{i_0} is an interior point, then we have

$$\phi = v_{i_0} - u_{i_0} + u = -M + u \leq v$$

on Ω_h, by assumption. Moreover, $\phi(x_{i_0}) = v_{i_0}$.

Since $\mathcal{H}_\rho$ is monotone, we have

$$\begin{aligned} 0 &\leq G_\rho(x_{i_0}, v_{i_0}, v_{i_1}, \dots, vi_k) \\ &\leq G_\rho(x_{i_0}, v_{i_0}, \phi(x_{i_1}), \dots, \phi(x_{i_k})) \\ &= G_\rho(x_{i_0}, \phi(x_{i_0}), \phi(x_{i_1}), \dots, \phi(x_{i_k})) \\ &= \mathcal{H}_\rho(x_{i_0}, D_{T_1}u, \dots, D_{T_k}u). \end{aligned}$$

Then, since u is a subsolution, assuming $M > 0$, we have

$$\gamma_R(u_{i_0} - v_{i_0}) \leq \mathcal{H}_\rho(x_{i_0}, u_{i_0}; D_{T_1}u, \dots, D_{T_k}u) - \mathcal{H}_\rho(x_{i_0}, v_{i_0}; D_{T_1}u, \dots, D_{T_k}u) \leq 0,$$

which is absurd. □

THEOREM A.2. *Under* (H0)–(H2), *there is a maximum principle.*

Proof. We consider u and v a sub- and supersolution of $\mathcal{H}_\rho = 0$ with $u \leq v$ on the boundary of Ω_h. We can assume that $\phi \leq v$ on the boundary of Ω_h, thanks to (H0).

Let $\lambda \in [0, 1]$ and $u_i^\lambda = \lambda u_i + (1 - \lambda)\phi_i$. It is clear that u^λ is a subsolution of $\mathcal{H}_\rho = (1 - \lambda)\alpha$ and $u^\lambda \leq v$ on the boundary of Ω_h. Let us assume that $u^\lambda - v$ reaches its maximum C_λ at an interior point x_{i_0}.

By assumption, we have $\mathcal{H}_\rho(x_{i_0}, v_{i_0}, v_{i_1}, \dots, v_k) \geq 0$ and $\mathcal{H}_\rho(x_{i_0}, u_{i_0}^\lambda, u_{i_1}^\lambda, \dots, u_k^\lambda) \leq (1 - \lambda)\alpha < 0$. The same arguments as in the proof of Theorem A.1 show that

$$(1 - \lambda)\alpha \geq \mathcal{H}_\rho(x_{i_0}, u_{i_0}^\lambda, u_{i_1}^\lambda, \dots) \geq \mathcal{H}_\rho(x_{i_0}, u_{i_0}^\lambda, v_{i_1} + C_\lambda, \dots) = \mathcal{H}_\rho(x_{i_0}, v_{i_0}, v_{i_1}, \dots),$$

and we have a contradiction. Thus, $u^\lambda - v$ is maximum on the boundary, and then

$$u^\lambda \leq v$$

in Ω. By taking the limit when $\lambda \to 1$, we conclude that $u \leq v$ in Ω. □

A.2. Maximum principle in the unsteady case.

Theorem A.3. *If the scheme* (A.2) *is monotone under $\Delta t \leq \Delta t_R$, then we have a maximum principle. If $u^n \in \mathcal{C}_R$ (resp., $v^n \in \mathcal{C}_R$) is a subsolution (resp., supersolution) of* (A.2) *such that $u_i^0 \leq v_i^0$ for all i and $u_i^n \leq v_i^n$ for each $n \geq 0$ and boundary node, then $u_i^n \leq v_i^n$ for all $n \geq 0$ and i.*

The same result holds for an implicit scheme.

Proof. We give the proof for the scheme (A.2). The proof for an implicit scheme is the same. We proceed by induction on n. For $n = 0$, the result is true by assumption. Since $u_i^0 \leq v_i^0$ for the interior points and the boundary points, we have $u_i^1 \leq v_i^1$ for the *interior* nodes. By assumption, $u_i^1 \leq v_i^1$ for the boundary points, and the result follows by induction. □

A.3. A uniqueness principle. We consider the scheme

$$\text{(A.4)} \qquad \begin{cases} \mathcal{H}_\rho^b(x_i, u_i; u_i, \{u_l, l \in \mathcal{N}_i\}) = 0 & \text{if } x_i \text{ interior node} \\ \\ \max(\mathcal{H}_\rho(x_i, u_i; u_i, \{u_l, l \in \mathcal{N}_i\}), u_i - \varphi(x_i)) = 0 & \text{otherwise,} \end{cases}$$

which discretizes the Dirichlet problem

$$\begin{array}{ll} H(x, u(x), Du(x)) = 0 & \text{if } x \in \Omega, \\ u = \phi & \text{otherwise.} \end{array}$$

We have the following result.

Theorem A.4. *Under the assumptions* (H0)–(H1) *or* (H0)–(H2) *for $\mathcal{H}_\rho$ and $\mathcal{H}_\rho^b$, if u (resp., v) is a subsolution (resp., supersolution) of* (A.4), *then $u_i \leq v_i$ for any mesh point x_i.*

A direct consequence of this result is that if (A.4) has a solution, it is unique.

Proof. We consider $M = \max_{x_i}(u_i - v_i)$, and we assume $M > 0$. Since the set x_i is finite, the maximum is reached at x_{i_0}. If x_{i_0} is not on the boundary, then we can repeat the arguments for the discrete maximum principle. Thus we can assume that x_{i_0} is on the boundary, and we have

$$\begin{array}{l} \max(\mathcal{H}_\rho^b(x_{i_0}, u_{i_0}; u_{i_0}, \{u_l, l \in \mathcal{N}_{i_0}\}), u_{i_0} - \varphi(x_{i_0})) \leq 0, \\ \max(\mathcal{H}_\rho^b(x_{i_0}, v_{i_0}; v_{i_0}, \{v_l, l \in \mathcal{N}_{i_0}\}), u_{i_0} - \varphi(x_{i_0})) \geq 0. \end{array}$$

The conditions on u give

$$\mathcal{H}_\rho^b(x_{i_0}, u_{i_0}; u_{i_0}, \{u_l, l \in \mathcal{N}_{i_0}\}) \leq 0 \quad \text{and} \quad u_{i_0} \leq \varphi(x_{i_0}).$$

Those on v give

$$\mathcal{H}_\rho^b(x_{i_0}, u_{i_0}; u_{i_0}, \{u_l, l \in \mathcal{N}_{i_0}\}) \geq 0 \quad \text{or} \quad v_{i_0} \geq \varphi(x_{i_0}).$$

First case. $u_{i_0} \leq \varphi(x_{i_0})$ and $v_{i_0} \geq \varphi(x_{i_0})$. There is nothing to prove; $M \leq 0$.

Second case. $\mathcal{H}_\rho^b(x_{i_0}, u_{i_0}; u_{i_0}, \{u_l, l \in \mathcal{N}_{i_0}\}) \leq 0$ and $\mathcal{H}_\rho^b(x_{i_0}, u_{i_0}; u_{i_0}, \{u_l, l \in \mathcal{N}_{i_0}\}) \geq 0$. By using the same arguments as in the maximum principle, we get an absurdity when $M > 0$.

Thus we have proved that $M \leq 0$, i.e., $u_i \leq v_i$ for any x_i. □

ENTROPY FORMULATION FOR PARABOLIC DEGENERATE EQUATIONS WITH GENERAL DIRICHLET BOUNDARY CONDITIONS AND APPLICATION TO THE CONVERGENCE OF FV METHODS*

ANTHONY MICHEL† AND JULIEN VOVELLE‡

Abstract. This paper is devoted to the analysis and the approximation of parabolic hyperbolic degenerate problems defined on bounded domains with *nonhomogeneous* boundary conditions. It consists of two parts. The first part is devoted to the definition of an original notion of entropy solutions to the continuous problem, which can be adapted to define a notion of measure-valued solutions, or entropy process solutions. The uniqueness of such solutions is established. In the second part, the convergence of the finite volume method is proved. This result relies on (weak) estimates and on the theorem of uniqueness of the first part. It also entails the existence of a solution to the continuous problem.

Key words. parabolic degenerate equations, boundary conditions, finite volume methods

1. Introduction.

Let Ω be an open bounded polyhedral subset of $\mathbb{R}^d$ and $T \in \mathbb{R}_+^*$. Let us denote by Q the set $(0,T)\times\Omega$, and by Σ the set $(0,T)\times\partial\Omega$.

We consider the following parabolic-hyperbolic problem:

$$(1) \qquad \begin{cases} u_t + \operatorname{div}(F(t,x,u)) - \Delta\varphi(u) = 0, & (t,x)\in Q,\\ u(0,x) = u_0(x), & x\in\Omega,\\ u(t,x) = \bar{u}(t,x), & (t,x)\in\Sigma\,. \end{cases}$$

Such an equation of quasilinear advection with degenerate diffusion governs the evolution of the saturation of the wetting fluid in the study of diphasic flow in porous media [GMT96], [Mic01], [EHM01]. In that case, the function φ can be expressed using the capillary pressure and the relative mobilities. The function φ is only supposed to be a nondecreasing Lipschitz continuous function. In particular, the study of problem (1) includes the study of nonlinear hyperbolic problems (cases where $\varphi' = 0$).

The analysis of the approximation of nonlinear hyperbolic problems via the finite volume (FV) method began in the mid 1980s, involving several authors including, for example, Cockburn, Coquel, and LeFloch [CCL95], Szepessy [Sze91], Vila [Vil94], Kröner, Rokyta, and Wierse [KRW96], and Eymard, Gallouët, and Herbin [EGH00]. Results on the convergence of FV schemes for degenerate problems in general came to light in more recent years [EGHM02], [Ohl01]. See also [BGN00], [EK00] for other methods of approximation.

When the function φ is strictly increasing, problem (1) is of parabolic type. In that case, the existence of a unique weak solution is well known. In the case where $\varphi' = 0$, problem (1) is a nonlinear hyperbolic problem, the uniqueness of a weak

solution is not ensured, and one has to define a notion of entropy solutions to recover uniqueness [Kru70]. Therefore, it is quite difficult to define a notion of solution in the case where φ is merely a nonincreasing function. In fact, as far as the Cauchy problem in the whole space is concerned, such a definition has been done for a long time, since Volpert and Hudjaev [VH69], but uniqueness with nonlinear parabolic terms has only been proved recently by Carrillo [Car99] (see also [KO01], [KR00]).

Another difficulty in the study of degenerate parabolic problems is analysis of the boundary conditions (see [LBS93], [RG99]). It is not always easy to give a correct formulation of the boundary conditions, or of the way they have to be taken into account. In the case where the function φ is strictly increasing, the classical framework of variational solutions of parabolic equations is enough to satisfy this wish. In the case where $\varphi' = 0$, things are completely different. Even if the (entropy) solution u of problem (1) admits a trace (say, γu) on Σ, the equality $\gamma u = \overline{u}$ on Σ does not necessarily hold. Actually, a condition on Σ can be given, which is known as the BLN condition [BLN79]: this is the right way to formulate boundary conditions in the study of scalar hyperbolic problems. However, the notion of entropy solution to nonlinear Cauchy–Dirichlet hyperbolic problems given by Bardos, LeRoux, and Nédélec is not really suitable to the study of FV schemes since it requires that the solution u be in a space BV (because the trace of u is involved in the formulation of the BLN condition), and it is known that it is difficult to get BV estimates on the numerical approximations given by the FV method on non-Cartesian grids. Actually, Otto gave an integral formulation of entropy solutions to scalar hyperbolic problems with boundary conditions [Ott96], and this indeed allows us to prove the convergence of the FV method [Vov02].

To our knowledge, the problem that we deal with (convergence of the FV method for degenerate parabolic equations with nonhomogeneous boundary conditions) has never been considered before. Nevertheless, in [MPT02], the authors give a definition of entropy solution for which uniqueness and consistency with the parabolic approximation are proved. This definition is not completely in integral form and therefore not suitable for proving the convergence of the FV method, since only poor compactness results are available on the numerical approximation. That is why we give an original definition of the problem (see Definition 3.1). This complete integral formulation includes the definition of Otto but not exactly the one of Carrillo (see the comments that follow Definition 3.1). It is well suited to the study of the convergence of several approximations of problem (1) and is used, for example, in [GMT02] to prove the convergence of a discrete Bhatnagar–Gross–Krook (BGK) model (see also [MPT02] for the parabolic approximation).

Notice that some particular cases have been fully treated: in [EGHM02], the authors prove the convergence of the FV method in the case where $F(x,t,s) = \mathbf{q}(x,t)f(s)$, $\operatorname{div}(\mathbf{q}) = 0$, with $\mathbf{q} \cdot \mathbf{n} = 0$ on Σ. In that case, the boundary condition does not act on the hyperbolic part of the equation. From a technical point of view, this means that the influence of the boundary condition appears in the terms related to the parabolic degenerate part of the equation. These parabolic degenerate terms are estimated by following the methods of Carrillo in [Car99], who deals with homogeneous boundary conditions. On the other hand, in [Vov02], the author proves the convergence of an FV method in the case where $\varphi' = 0$, adapting the ideas of Otto [Ott96]. In that case, the effects of the boundary condition in the hyperbolic equation are the center of the work. In this paper we mix these two precedent approaches to deal with the parabolic degenerate problem with general boundary conditions.

We will make the following assumptions on the data:

(H1) $F : (t, x, s) \mapsto F(t, x, s) \in C^1(\mathbb{R}^+ \times \mathbb{R}^d \times \mathbb{R})\,, \quad \text{div}_x F = 0,$
$\dfrac{\partial F}{\partial s}$ is locally Lipschitz continuous uniformly with respect to (t, x);

(H2) $\varphi : s \mapsto \varphi(s)$ is a nondecreasing Lipschitz continuous function;

(H3) $u_0 : x \mapsto u_0(x) \in L^\infty(\Omega)$; and

(H4) the function $\bar{u} : (x, t) \mapsto \bar{u}(x, t) \in L^\infty(\Sigma)$ and is the trace of a function $\bar{u} \in L^\infty(Q)$with $\varphi(\bar{u}) \in L^2(0, T; H^1(\Omega))\,.$

To prove the convergence of the FV method, we will also assume that the boundary datum satisfies

(H5) the function $\bar{u} : (x, t) \mapsto \bar{u}(x, t) \in L^\infty(\Sigma)$ and is the trace of a function $\bar{u} \in L^\infty(Q)$ with $\varphi(\bar{u}) \in L^2(0, T; H^1(\Omega))\,,\ \nabla\bar{u} \in L^2(Q)\,,\ \bar{u}_t \in L^1(Q)\,.$

In the course of the proof of uniqueness of the entropy process solution (Theorem 4.1), additional hypotheses on the boundary datum are required. Using the notation defined in subsection 4.1, they read

$$\text{(H6)}\ \overline{u}_\Sigma \in W^{1,1}((0, T) \times B \cap Q) \quad \text{and} \quad \Delta\varphi(\overline{u}_\Sigma) \in L^1((0, T) \times B \cap Q)\,.$$

Remark 1.1. As suggested by Porretta [MPT02], hypothesis (H6) may be relaxed as

$$\text{(H6Bis)}\ \overline{u}_\Sigma \in W^{1,1}((0, T) \times B \cap Q) \quad \text{and}$$
$$\Delta\varphi(\overline{u}_\Sigma) \text{ is a bounded Radon measure on } (0, T) \times \Pi\,.$$

We do not give a justification of this assertion now. Indeed, hypothesis (H6) is involved in the proof of Lemma 4.2, and we have waited until Remark 4.1, just after this proof, to specify to what extent hypothesis (H6Bis) is admissible.

Under assumptions (H3)–(H4), there exists $(A, B) \in \mathbb{R}^2$ such that

$$A \le \min\left(\operatorname*{ess\,inf}_\Omega(u_0), \operatorname*{ess\,inf}_Q(\bar{u})\right) \le \max\left(\operatorname*{ess\,sup}_\Omega(u_0), \operatorname*{ess\,sup}_Q(\bar{u})\right) \le B, \tag{2}$$

and we set

$$M = \max\left\{\left|\frac{\partial F}{\partial s}(t, x, s)\right|\,,\ (t, x, s) \in Q \times [A, B]\right\}\,.$$

We introduce the function ζ defined by $\zeta' = \sqrt{\varphi'}$. (This makes sense in view of (H2).) We will derive $L^2(0, T; H^1)$ estimates on nonlinear quantities such as $\zeta(u)$. A simple explanation for this fact is the following. Consider the equation $u_t - \Delta\varphi(u) = 0$ on $(0, T) \times \Omega$. Multiply it by u, and sum the result with respect to $x \in \Omega$. The formal identity $\int_\Omega \nabla\varphi(u) \cdot \nabla u = \int_\Omega |\nabla\zeta(u)|^2$ then leads to $\frac{1}{2}\frac{d}{dt}\int_\Omega u^2 dx + \int_\Omega |\nabla\zeta(u)|^2 \le 0$, from which can be derived an energy estimate.

Notice that the hypothesis $\text{div}_x F = 0$ can be relaxed, and source terms can be considered in the right-hand side of (1).

The assumption that $\bar{u}$ is the trace of an L^∞ function $\bar{u}$ such that $\varphi(\bar{u}) \in L^2(0, T; H^1(\Omega))$ is a necessary condition for the existence of solutions to problem (1);

the additional hypotheses introduced in (H5) are involved in the proofs of different estimates on the approximate solution, defined thanks to the FV method.

As implied at the beginning of this introduction, one of the main points in the study of problem (1) is the definition of a notion of solution suitable for the classical techniques of convergence of FV schemes. This point is specified in section 2. In section 3, we introduce and define a notion of entropy process solutions (a concept similar to the concept of measure-valued solutions), and in section 4 we prove the uniqueness of such solutions (see Theorem 4.1). Section 5 is devoted to the FV scheme used to approximate problem (1); a priori estimates are derived and the convergence is proved.

2. Entropy weak solution. Here, as in the study of purely hyperbolic problems, the concept of weak solutions is not sufficient since the uniqueness of such solutions may fail. Thus, we turn to the notion of weak entropy solutions. The entropy-flux pairs considered in the definition of this solution are the so-called Kruzhkov semi entropy-flux pairs $(\eta_\kappa^\pm, \Phi_\kappa^\pm)$ (see [Car99], [Ser96], [Vov02]). They are defined by the formula

$$\begin{cases}\eta_\kappa^+(s) = (s-\kappa)^+ = s\top\kappa - \kappa,\\ \eta_\kappa^-(s) = (s-\kappa)^- = \kappa - s\bot\kappa,\end{cases} \qquad \begin{cases}\Phi_\kappa^+(t,x,s) = (s-\kappa)^+ = F(t,x,s\top\kappa) - F(t,x,\kappa),\\ \Phi_\kappa^-(t,x,s) = (s-\kappa)^- = F(t,x,\kappa) - F(t,x,s\bot\kappa),\end{cases}$$

with $a\top b = \max(a,b)$ and $a\bot b = \min(a,b)$. Notice that, in the case where κ is considered as a variable, for example when the doubling variable technique of Kruzhkov is used, the entropy-fluxes will be written

$$\Phi^+(x,t,s,\kappa) = \Phi_\kappa^+(t,x,s) \quad \text{and} \quad \Phi^-(x,t,s,\kappa) = \Phi_\kappa^-(t,x,s).$$

Definition 2.1 (entropy weak solution). *A function u of $L^\infty(Q)$ is said to be an entropy weak solution to problem* (1) *if it is a weak solution of problem* (1)*, that is, if $\varphi(u) - \varphi(\overline{u}) \in L^2(0,T;H_0^1(\Omega))$ and*

$$\forall\theta \in \mathcal{C}_c^\infty([\,0,T)\times\Omega)\,, \quad \int_Q u\,\theta_t + (F(t,x,u) - \nabla\varphi(u))\cdot\nabla\theta \;\,dx\,dt \,+ \int_\Omega u_0\,\theta(0,x)\,dx \,= 0, \tag{3}$$

and if it satisfies the following entropy inequalities for all $\kappa \in [A,B]$, for all $\psi \in \mathcal{C}_c^\infty([\,0,T)\times\mathbb{R}^d)$ such that $\psi \geq 0$ and $\operatorname{sgn}^\pm(\varphi(\overline{u}) - \varphi(\kappa))\psi = 0$ a.e. on Σ:

$$\int_Q \eta_\kappa^\pm(u)\,\psi_t + (\,\Phi_\kappa^\pm(t,x,u) - \nabla\,(\varphi(u)-\varphi(\kappa))^\pm\,)\cdot\nabla\psi\;dx\,dt \,+ \int_\Omega \eta_\kappa^\pm(u_0)\,\varphi(0,x)\,dx \\ + M\int_\Sigma \eta_\kappa^\pm(\bar{u})\psi\,d\gamma(x)\,dt \geq 0. \tag{4}$$

Notice that the weak equation (3) is superfluous, for it is a consequence of (4). However, if the function φ were (strictly) increasing, (3) would be enough to define a notion of the solution of problem (1) for which existence and uniqueness hold: in that case, problem (1) would merely be a nonlinear parabolic problem. For general φ, the uniqueness of the solution will be a consequence of the entropy inequalities (4); indeed, the class of Kruzhkov semi entropy-flux pairs is wide enough to ensure the uniqueness of the weak entropy solution, while—and we stress this fact—the class of classical Kruzhkov entropy-flux pairs $s \mapsto |s-\kappa|$ is not.

Also notice that, first, in the homogeneous case $\bar{u} = 0$, the previous definition is slightly different from the original definition given by Carrillo [Car99] and that, second, if $\varphi' = 0$ (problem (1) becomes hyperbolic), then the previous definition of the entropy solution coincides with the definition of a solution suitable for hyperbolic problems; see Otto [Ott96] and [Vov02]. A notion of an entropy solution for degenerate parabolic problems with nonhomogeneous boundary conditions has also been defined by Mascia, Porretta, and Terracina in [MPT02]. It is interesting to notice that, in their definition, they directly require that the entropy condition satisfy the entropy condition on the boundary (14) as stated in Proposition 4.1. We prove that this property (14) is, in fact, a consequence of the entropy inequalities (4) and then follow the main lines of the uniqueness theorem proved in [MPT02].

3. Entropy process solution. The proof of the existence of a weak entropy solution to problem (1) lies in the study of the numerical solution u_D defined by an FV method for problem (1) (see section 5.2). Theorem 5.1 states that the numerical solution satisfies approximate entropy inequalities (see (50)), but the bounds on u_D (a bound in $L^\infty(Q)$ and a bound on the discrete H^1-norm of $\varphi(u_D)$) do not give strong compactness, only weak compactness. Therefore, in order to be able to take the limit of the nonlinear terms of u_D (as $\Phi_\kappa^\pm(u_D)$, in particular), we have to turn to the notion of measure-valued solutions (see DiPerna [DiP85], Szepessy [Sze91]) or, equivalently, to the notion of entropy process solution defined by Eymard, Gallouët, and Herbin [EGH00]. In light of the following theorem, it appears that the notion of entropy process solution is indeed well suited to compensate for the weakness of the compactness estimates on the approximate solution u_D and to deal with nonlinear expressions of u_D.

Theorem 3.1 (nonlinear convergence for the weak-$\star$ topology). *Let $\mathcal{O}$ be a Borel subset of $\mathbb{R}^m$, R be positive, and (u^n) be a sequence of $L^\infty(\mathcal{O})$ such that, for all $n \in \mathbb{N}$, $||u^n||_{L^\infty} \le R$. Then there exists a subsequence, still denoted by (u^n) and $\mu \in L^\infty(\mathcal{O} \times (0,1))$, such that*

$$\forall g \in \mathcal{C}(\mathbb{R}), \quad g(u^n) \longrightarrow \int_0^1 g(\mu(.,\alpha))\, d\alpha \quad \text{in } L^\infty(\mathcal{O}) \text{ weak-}\star\,.$$

Now the notion of an entropy process solution can be defined.

Definition 3.1 (weak entropy process solution). *Let u be in $L^\infty(Q \times (0,1))$. The function u is said to be an entropy process solution to problem* (1) *if*

$$\varphi(u) - \varphi(\overline{u}) \in L^2(0,T; H_0^1(\Omega)) \tag{5}$$

and if u satisfies the following entropy inequalities for all $\kappa \in [A,B]$, for all $\psi \in \mathcal{C}_c^\infty([\,0,T) \times \mathbb{R}^d)$ such that $\psi \ge 0$ and $\operatorname{sgn}^\pm(\varphi(\overline{u}) - \varphi(\kappa))\psi = 0$ a.e. on Σ:

$$\begin{aligned}\int_Q \int_0^1 & \eta_\kappa^\pm(u(t,x,\alpha))\, \psi_t(t,x) \\ & + \left(\Phi_\kappa^\pm(t,x,u(t,x,\alpha)) - \nabla\left(\varphi(u)(t,x) - \varphi(\kappa)\right)^\pm\right) \cdot \nabla\psi(t,x) d\alpha dx dt \\ & + \int_\Omega \eta_\kappa^\pm(u_0)\, \psi(0,x)\, dx + M \int_\Sigma \eta_\kappa^\pm(\bar{u})\psi\, d\gamma(x) dt \ge 0\,.\end{aligned} \tag{6}$$

Notice that if the function u is an entropy process solution of problem (1), then it satisfies condition (5), which means in particular that $\varphi(u)$ does not depend on the last variable α and is denoted by $\varphi(u)(t,x)$.

Notation. We set $\mathcal{Q} = Q \times (0,1)$.

We will now show that any entropy *process* solution actually reduces to an entropy *weak* solution.

4. Uniqueness of the entropy process solution.

THEOREM 4.1 (uniqueness of the entropy process solution). *Let u, $v \in L^\infty(Q \times (0,1))$ be two entropy process solutions of problem* (1) *in accordance with Definition* 3.1. *Suppose that Ω is either a polyhedral open subset of $\mathbb{R}^d$ or a strong $\mathcal{C}^{1,1}$ open subset of $\mathbb{R}^d$, and assume hypotheses* (H1), (H2), (H3), (H4), *and* (H6) *(or* (H6Bis)*). Then there exists a function $w \in L^\infty(Q)$ such that*

$$u(t,x,\alpha) = w(t,x) = v(t,x,\beta) \text{ for almost every } (t,x,\alpha,\beta) \in Q \times (0,1)^2 .$$

COROLLARY 4.1 (uniqueness of the weak entropy solution). *If Ω is either a polyhedral open subset of $\mathbb{R}^d$ or a strong $\mathcal{C}^{1,1}$ open subset of $\mathbb{R}^d$, and under hypotheses* (H1), (H2), (H3), (H4), *and* (H6) *(or* (H6Bis)*), problem* (1) *admits at most one weak entropy solution.*

In the case where Ω is a polyhedral open subset of $\mathbb{R}^d$, the proof of Theorem 4.1 is slightly more complicated than the proof in the case where Ω is a strong $\mathcal{C}^{1,1}$ open subset of $\mathbb{R}^d$. Besides, although the study of the FV method applied to (1) relies on Theorem 4.1 only in the case of Ω polyhedral, we wish to specify the validity of Theorem 4.1 when Ω is $\mathcal{C}^{1,1}$. Indeed, problem (1) may of course be posed on such an open set, and, in that case, Theorem 4.1 would be one of the major steps in the proof of the convergence of such an approximation, as for the vanishing viscosity approximation, for example.

We therefore explain the proof of Theorem 4.1 in the case where Ω is $\mathcal{C}^{1,1}$ and then indicate how to adapt it to the case where Ω is a polyhedral open subset of $\mathbb{R}^d$ (see subsection 4.6).

4.1. Proof of Theorem 4.1: Definitions and notation.

4.1.1. Localization near the boundary. We suppose that Ω is a strong $\mathcal{C}^{1,1}$ open subset of $\mathbb{R}^d$. In that case, there exists a finite open cover $(B_\nu)_{0,\dots,N}$ of $\overline{\Omega}$ and a partition of unity $(\lambda_\nu)_{0,\dots,N}$ on $\overline{\Omega}$ subordinate to $(B_\nu)_{0,\dots,N}$ such that, for $\nu \geq 1$, up to a change of coordinates represented by an orthogonal matrix A_ν, the set $\Omega \cap B_\nu$ is the epigraph of a $\mathcal{C}^{1,1}$-function $f_\nu : \mathbb{R}^{d-1} \to \mathbb{R}$; that is,

$$\begin{aligned} \Omega \cap B_\nu &= \{x \in B_\nu \ ; \ (A_\nu x)_d > f_\nu(\overline{A_\nu x})\} \quad \text{and} \\ \partial\Omega \cap B_\nu &= \{x \in B_\nu \ ; \ (A_\nu x)_d = f_\nu(\overline{A_\nu x})\} , \end{aligned}$$

where $\overline{y}$ stands for $(y_i)_{1,d-1}$ if $y \in \mathbb{R}^d$.

Until the end of the proof of Theorem 4.1, the problem will be localized with the help of a function λ_ν. We drop the index ν and, for the sake of clarity, suppose that the change of coordinates is trivial: $A = I_d$. We denote by $\Pi = \{\bar{x}, x \in \Omega \cap B\} \subset \mathbb{R}^{d-1}$ the projection of $B \cap \Omega$ onto the $(d-1)$ first components, and $\Pi_\lambda = \{\bar{x}, x \in \text{supp}\,(\lambda) \cap \Omega\}$ (see Figure 1). If a function ψ is defined on Σ, we denote by ψ_Σ the function defined on $[0,T) \times B \cap Q$ by $\psi_\Sigma(t,x) = \psi(t,\bar{x},f(\overline{x}))$. Notice that the function ψ_Σ does not depend on x_d and that, by abusing the notation, we shall also denote by ψ_Σ the restriction of ψ_Σ to $[0,T) \times \Pi$. In the same way, if L_i is defined on $[0,T] \times \Pi$, we also denote by L_i the function defined on $[0,T) \times B \cap Q$ by $L_i(t,x) = L_i(t,\overline{x})$.

4.1.2. Weak notion of trace. An important step in the proof of the uniqueness of entropy process solutions is the derivation of the condition satisfied by any entropy

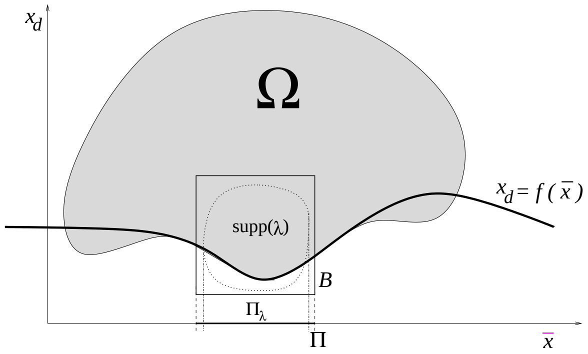

FIG. 1. *Localization by λ in the ball B.*

process solution on the boundary of the domain. This condition is the matter of Proposition 4.1. (It can be viewed as a kind of BLN condition [BLN79], balanced by second order terms issued from the degenerate parabolic part of the equation of (1).) In the course of the proof of Proposition 4.1, we need to define the normal trace of certain fluxes $(\Phi_\kappa^+(t,x,u) - \nabla(\varphi(u) - \varphi(\kappa))^+$, among others, for example) and, more precisely, to ensure the consistency of this definition of the normal trace with different approximations. For that purpose, we turn to the work of Chen and Frid [CF02]. Adapted to our context, the main theorem of [CF02] is the following.

THEOREM 4.2 (see Chen and Frid [CF02]). *Recall that $Q = (0,T)\times\Omega$, and denote by ν the outward unit normal to Q. Let $\mathcal{F} \in (L^2(Q))^{d+1}$ be such that* div$\mathcal{F}$ *is a bounded Radon measure on Q. Then there exists a linear functional $\mathcal{T}_\nu$ on $W^{1/2,2}(\partial Q)\cap\mathcal{C}(\partial Q)$ which represents the normal traces $\mathcal{F}\cdot\nu$ on ∂Q in the sense that, first, the following Gauss–Green formula holds: for all $\psi \in \mathcal{C}_c^\infty(\overline{Q})$,*

$$\langle \mathcal{T}_\nu, \psi\rangle = \int_Q \psi \,\mathrm{div}\mathcal{F} + \int_Q \nabla\psi\cdot\mathcal{F}. \tag{7}$$

Second, $\langle \mathcal{T}_\nu, \psi\rangle$ depends only on $\psi_{|\partial Q}$, while, third, if (B,λ,f) is as above (subsection localization near the boundary), then for all $\psi \in \mathcal{C}_c^\infty([0,T)\times\overline{\Omega})$,

$$\begin{aligned}\langle \mathcal{T}_\nu, \psi\lambda\rangle = -\lim_{s\to 0}\frac{1}{s}\Bigg(&\int_s^T\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}\mathcal{F}\cdot\begin{pmatrix}-\nabla f(\overline{x})\\ 1\\ 0\end{pmatrix}\psi\lambda\,dx_d\,d\overline{x}\,dt\\ &+\int_0^s\int_\Omega\mathcal{F}\cdot\begin{pmatrix}0\\0\\1\end{pmatrix}\psi\lambda\,dx\,dt\Bigg).\end{aligned} \tag{8}$$

Let u be an entropy weak solution of problem (1). The entropy inequality (4) shows that the divergence of the field

$$\mathcal{F}_\kappa^+(t,x) = \begin{pmatrix}(u-\kappa)^+\\ \Phi_\kappa^+(t,x,u) - \nabla(\varphi(u)-\varphi(\kappa))^+\end{pmatrix}$$

is a bounded Radon measure on Q. This field belongs to $(L^2(Q))^{d+1}$, and according to the previous theorem, there exists a linear functional $\mathcal{T}_{\nu,\kappa}^+$ on $W^{1/2,2}(\partial Q)\cap\mathcal{C}(\partial Q)$ which represents $\mathcal{F}_\kappa^+(t,x)\cdot\nu$. Then, to define a notion of the normal trace of the flux

$\Phi^+_\kappa(t,x,u) - \nabla(\varphi(u)-\varphi(\kappa))^+$, we set

$$\langle \mathcal{T}^+_{n,\kappa}, \psi\rangle = \langle \mathcal{T}^+_{\nu,\kappa}, \psi\rangle + \int_\Omega (u_0-\kappa)^+\psi(0,x)\,dx \qquad \forall \psi \in \mathcal{C}^\infty_c([0,T)\times\overline{\Omega})\,. \tag{9}$$

This definition makes sense because the entropy weak solution assumes the values of the initial data u_0:

$$\lim_{s\to 0}\frac{1}{s}\int_0^s\int_\Omega (u-\kappa)^+\psi\,dx\,dt = \int_\Omega (u_0-\kappa)^+\psi(0,x)\,dx\,,$$

as can be seen by choosing $\frac{s-t}{s}\chi_{(0,s)}(t)\psi$ as a test-function in (4). In particular, $\langle \mathcal{T}^+_{n,\kappa}, \psi\lambda\rangle$ depends only on $\psi_{|\Sigma}$, and from (8) we can derive the formula

$$\begin{aligned}&\langle \mathcal{T}^+_{n,\kappa}, \psi\lambda\rangle\\ &= -\lim_{s\to 0}\frac{1}{s}\int_s^T\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}(\Phi^+_\kappa(t,x,u)-\nabla(\varphi(u)-\varphi(\kappa))^+)\cdot\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix}\psi\lambda\,dx_d\,d\overline{x}\,dt\end{aligned}$$

for all $\psi\in\mathcal{C}^\infty_c([0,T)\times\overline{\Omega})$.

4.1.3. Mollifiers ρ_n and the cut-off function ω_ε. Technically, the heart of the proof of uniqueness is the doubling of variables. This technique involves mollifiers, which are defined as $\rho_n(t) = n\rho(nt)$, where ρ is a nonnegative function of $\mathcal{C}^\infty_c(-1,0)$ such that $\int_{-1}^0 \rho(t)\,dt = 1$. (Notice that the the support of the function ρ is located to the left of zero.) For ε a positive number, ρ_ε naturally denotes the map $t\mapsto \frac{1}{\varepsilon}\rho(\frac{t}{\varepsilon})$, and we define $R_n(t) = \int_{-\infty}^{-t}\rho_n(s)\,ds$. Since the technique of doubling of variables interferes with a certain evaluation of the boundary behavior of the entropy process solution (described by (14)), we need to define a cut-off function ω_ε built upon the sequence of mollifiers. We set

$$\omega_\varepsilon(x) = \int_{f(\overline{x})-x_d}^0 \rho_\varepsilon(z)\,dz = \int_{\frac{f(\overline{x})-x_d}{\varepsilon}}^0 \rho(z)\,dz. \tag{10}$$

On $\Omega\cap B$, the function ω_ε vanishes in a neighborhood of $\partial\Omega$ and equals 1 if $\mathrm{dist}(x,\partial\Omega) > \varepsilon$; in particular, $\omega_\varepsilon\to 1$ in $L^1(\Omega\cap B)$ and, if $\psi\in H^1(\Omega)$, then

$$\int_\Omega \lambda\,\psi\cdot\nabla\omega_\varepsilon = -\int_\Omega \mathrm{div}(\lambda\,\psi)\,\omega_\varepsilon \overset{\varepsilon\to 0}{\to} -\int_\Omega \mathrm{div}(\lambda\,\psi) = -\int_{\partial\Omega}\lambda\,\psi\cdot\mathbf{n}\,.$$

Roughly speaking, if $F:\Omega\to\mathbb{R}^d$, then $-F\cdot\nabla\omega_\varepsilon$ approaches the normal trace $F\cdot\mathbf{n}$. To make this idea more precise, for the field $F = \Phi^+_\kappa(t,x,u) - \nabla(\varphi(u)-\varphi(\kappa))^+$ we call upon the notion of normal trace defined above (subsection 4.1.2). Let $\psi\in\mathcal{C}^\infty_c([0,T)\times\overline{\Omega})$. Since $\psi = \psi(1-\omega_\varepsilon)$ on Σ, $\langle \mathcal{T}^+_{n,\kappa}, \psi\lambda\rangle = \langle \mathcal{T}^+_{n,\kappa}, \psi\lambda(1-\omega_\varepsilon)\rangle$. The definition of $\mathcal{T}^+_{n,\kappa}$ (see (9)) and the Gauss–Green formula (7) yield

$$\langle \mathcal{T}^+_{n,\kappa}, \psi\lambda\rangle = \int_Q \psi(1-\omega_\varepsilon)\lambda\,\mathrm{div}\mathcal{F}^+_\kappa + \int_Q \nabla(\psi(1-\omega_\varepsilon)\lambda)\cdot\mathcal{F}^+_\kappa + \int_\Omega (u_0-\kappa)^+\psi(1-\omega_\varepsilon)\lambda\,dx.$$

Since $0\le 1-\omega_\varepsilon\le 1$ and $\omega_\varepsilon(x)\to 1$ for all $x\in\Omega\cap B$, the dominated convergence theorem ensures that $\lim_{\varepsilon\to 0}\int_Q \psi(1-\omega_\varepsilon)\lambda\,\mathrm{div}\mathcal{F}^+_\kappa = 0$ and

$$\langle \mathcal{T}^+_{n,\kappa}, \psi\lambda\rangle = -\lim_{\varepsilon\to 0}\int_Q [\Phi^+_\kappa(t,x,u) - \nabla(\varphi(u)-\varphi(\kappa))^+]\cdot\nabla\omega_\varepsilon\,\psi\lambda\,dx\,dt\,.$$

4.1.4. Otto entropy-fluxes. Let $u \in L^\infty(Q \times (0,1))$ be an entropy process solution of problem (1) and $\kappa \in [A,B]$. Set $\Phi = \Phi^+ + \Phi^-$. We denote by $\mathcal{G}_x(t,x,u,\kappa)$ the quantity

$$\mathcal{G}_x(t,x,u,\kappa) = \Phi(t,x,u(t,x,\alpha),\kappa) - \nabla_x|\varphi(u)(t,x) - \varphi(\kappa)|\,. \tag{11}$$

For $w \in \mathbb{R}$, the function $\mathcal{F}_\varphi$ is defined by the formula

$$\mathcal{F}_\varphi(t,x,u,\kappa,w) = \mathcal{G}_x(t,x,u,\kappa) + \mathcal{G}_x(t,x,u,w) - \mathcal{G}_x(t,x,\kappa,w)\,. \tag{12}$$

4.2. A result of approximation.

LEMMA 4.1. *Let U be a bounded open subset of $\mathbb{R}^q$, $q \geq 1$. If $f \in L^\infty \cap BV(U)$, then, given $\varepsilon > 0$, there exists $g \in \mathcal{C}(\overline{U})$ such that*

$$g \geq f \quad \text{a.e. on } U \qquad \text{and} \qquad \int_U (g(x) - f(x))\,dx < \varepsilon\,.$$

This result may be false if $f \notin BV(U)$ (consider $f = \mathbb{1}_{\mathbb{Q}\cap(0,1)}$ on $U = (0,1)$), but this is not a necessary condition, because, on $U = (0,1)$, the function $f = \mathbb{1}_K$, where K is the triadic Cantor, can be approximated in $L^1(0,1)$ by continuous functions g such that $g \geq f$ a.e. Indeed, we claim that, if E is a measurable subset of U, then $f = \mathbb{1}_E$ satisfies the conclusion of Lemma 4.1 if and only if

$$m(E) = \inf\{m(K)\,;\ E \subset K\,,\ K \text{ compact}\}\,. \tag{13}$$

(Here, m denotes the Lebesgue measure on $\mathbb{R}^q$.)

Before proving Lemma 4.1, let us justify this assertion. If (13) holds, then, given $\varepsilon > 0$, there exists a compact K of U such that $E \subset K$ and $m(K \setminus E) < \varepsilon$. Since the Lebesgue measure is regular, there exists an open subset V of U such that $K \subset V \subset \overline{V} \subset U$ and $m(V \setminus K) < \varepsilon$. Then the function $g : x \mapsto d(x, \mathbb{R}^q \setminus V)/(d(x,K) + d(x, \mathbb{R}^q \setminus V))$ is continuous on $\mathbb{R}^q$, $g \geq \mathbb{1}_E$, and $\int_U (g - \mathbb{1}_E) < 2\varepsilon$.

Conversely, suppose that, given $\varepsilon > 0$, there exists $g \in \mathcal{C}(\overline{U})$ such that $g \geq \mathbb{1}_E$ and $\int_U (g - \mathbb{1}_E) < \varepsilon$. Then $K = \{x \in \overline{U}\,;\ g(x) \geq 1\}$ is compact, $E \subset K$, and $m(K \setminus E) < \varepsilon$.

Proof of Lemma 4.1. Notice that, if E is a measurable subset of U such that $m(\partial E) = 0$, then (13) holds (consider the compact $\overline{E}$). If E is a level set of a BV function, then E has almost surely a finite perimeter and, consequently, $m(\partial E) = 0$, which ensures that $\mathbb{1}_E$ satisfies the conclusion of Lemma 4.1. This result may be seen as the heart of the proof. Indeed, first suppose that $0 \leq f(x) \leq 1$ for every $x \in U$. For $t \in [0,1]$, set $E_t = \{x \in U\,;\ f(x) < t\}$. Then, for almost every t, E_t is a set with finite perimeter since $f \in BV(U)$. Let (t_n) be a sequence of reals dense in $[0,1]$ and such that $t_1 = 1$; E_{t_n} is a set with finite perimeter for every n. We will define a sequence of simple functions $\theta_n = \sum_{i=1}^n \alpha_i^n \mathbb{1}_{A_i^n}$ which approximate f from above and such that each set A_i^n is built upon the level sets E_{t_i}. To that purpose, first define $\theta_1(x) = 1$ for all $x \in U$. If $n > 1$, let $\{k_1, \dots, k_n\}$ be an enumeration of $\{1, \dots, n\}$ such that $t_{k_1} > \cdots > t_{k_n}$. Set

$$\begin{aligned} &A_i^n = E_{t_{k_i}} \setminus E_{t_{k_{i+1}}} \quad \text{if} \quad 1 \leq i < n\,,\\ &A_n^n = E_{t_{k_n}} \end{aligned}$$

and $\theta_n = \sum_{i=1}^n t_{k_i} \mathbb{1}_{A_i^n}$. Notice that $(A_i^n)_{1\leq i\leq n}$ is a partition of U and that $A_i^n \subset E_{t_{k_i}}$; therefore, if $x \in U$, say $x \in A_i^n$, then $\theta_n(x) = t_{k_i} > f(x)$ and $\theta_n \geq f$. Besides, the sequence $(E_{t_{k_i}})_{1\leq i\leq n}$ is decreasing, and this, together with the definition of A_i^n, ensures that $\theta_n(x) \leq t_i$ if $x \in E_{t_i}$ for $1 \leq i \leq n$. Now, given $x \in U$ and $\varepsilon > 0$, there exists n_0 such that $f(x) + \varepsilon > t_{n_0} > f(x)$. Then, for every $n \geq n_0$, $x \in E_{t_{n_0}}$ and, consequently, $\theta_n(x) \leq t_{n_0} < f(x) + \varepsilon$. Thus, (θ_n) converges to f everywhere on U (in fact, the convergence is monotone, but we do not prove this fact), and, since $0 \leq \theta_n \leq 1$, the dominated convergence theorem shows that

$$\lim_{n\to+\infty} \int_U \theta_n - f = 0\,.$$

However, for each fixed n, the function θ_n satisfies the conclusion of the lemma. Indeed, let $\varepsilon > 0$ be fixed. Since $E_{t_{k_{i+1}}} \subset E_{t_{k_i}}$, we have $\mathbb{1}_{A_i^n} = \mathbb{1}_{E_{t_{k_i}}} - \mathbb{1}_{E_{t_{k_{i+1}}}}$. The functions $\mathbb{1}_{E_{t_{k_i}}}$ and $\mathbb{1}_{E_{t_{k_{i+1}}}}$ are in $BV(U)$, by the definition of a set with finite perimeter. Thus $\mathbb{1}_{A_i^n}$ is BV too, and A_i^n is a set with finite perimeter. As noticed in the beginning of the proof, A_i^n satisfies (13), and there exists $g_i \in \mathcal{C}(\overline{U})$ such that $g_i \geq t_{k_i}\,\mathbb{1}_{A_i^n}$ and $\int_U (g_i - t_{k_i}\,\mathbb{1}_{A_i^n}) < \varepsilon/n$. Moreover, we can suppose that $g_i \leq t_{k_i}$ for every i. Set $g = \max_{1\leq i\leq n} g_i$. The function g is continuous on $\overline{U}$, and $g \geq \theta_n$ on U by construction. It remains to compute $||g - \theta_n||_{L^1(U)}$. If $x \in A_i^n$, then $g_i(x) = t_{k_i}$, and the condition $g_j \leq t_{k_j}$ enforces the maximum of the $g_j(x)$ to be reached for $j \in \{i, \dots, n\}$. We then have

$$(g - \theta_n)(x) = g_j(x) - t_{k_i} \leq g_j(x) - t_{k_j}\,\mathbb{1}_{A_j^n}(x).$$

Indeed, if $j = i$, this is obvious, and if $j > i$, we have $\mathbb{1}_{A_j^n}(x) = 0$, while $t_{k_i} \geq 0$. Consequently, $(g - \theta_n)(x) \leq \sum_{i=1}^n (g_j - t_{k_j}\,\mathbb{1}_{A_j^n})(x)$ and $\int_U (g - \theta_n) < n \times \varepsilon/n = \varepsilon$. If n has been chosen such that $\int_U (\theta_n - f) < \varepsilon$, then g is relevant to the conclusion of the lemma.

We suppose that $0 \leq f(x) \leq 1$ for every $x \in U$. For a general function $f \in L^\infty \cap BV(U)$, we can suppose, after an adequate modification of the function on a set of negligible measure, that $-M \leq f(x) \leq M$ for every $x \in U$, where $M = ||f||_{L^\infty(U)}$. Then we consider the function $f_1 = (f + M)/(2M)$. Given $\varepsilon > 0$, there exists $g_1 \in \mathcal{C}(\overline{U})$ such that $g_1(x) \geq f_1(x)$ and $||g_1 - f_1||_{L^1(U)} < \varepsilon/(2M)$ and $g = 2Mg_1 - M$ is convenient. $\square$

4.3. Proof of Theorem 4.1 (preliminary): Boundary condition.

PROPOSITION 4.1 (boundary condition). *Let $u \in L^\infty(Q \times (0,1))$ be an entropy process solution of problem* (1)*, and let $\mathcal{F}_\varphi$ be defined by* (12)*. Assume hypotheses* (H1)*,* (H2)*,* (H3)*,* (H4)*, and* (H6) *(or* (H6Bis)*). Then, for all $\kappa \in [A, B]$, for all nonnegative $\psi \in \mathcal{C}_c^\infty([0,T) \times \mathbb{R}^d)$,*

$$\lim_{\varepsilon\to 0} \int_Q \mathcal{F}_\varphi(t, x, u(t, x, \alpha), \kappa, \overline{u}_\Sigma(t, x)) \cdot \nabla\omega_\varepsilon(x)\,\psi(t, x)\,\lambda(x)\,d\alpha\,dx\,dt \;\leq 0\,. \tag{14}$$

In the case of a purely hyperbolic problem ($\varphi' = 0$), inequality (14) is the boundary condition written by Otto [Ott96], equivalent to the BLN condition [BLN79] for BV solutions. If the problem is strictly parabolic (that is, $\varphi'(u) \geq \Phi_{min} > 0$), then inequality (14) is trivially satisfied by any weak solution of the problem (1). In [MPT02], the condition (14) is listed among the conditions that an entropy solution should satisfy *by definition.* We refer to [MPT02] for a complete discussion of (14).

Proof of Proposition 4.1. We first aim to prove the following result: for every $\tilde\kappa \in [A,B]$, for every nonnegative $\psi \in \mathcal{C}_c^\infty([0,T)\times\mathbb{R}^d)$,

(15)

$$\lim_{\varepsilon\to 0}\int_Q [\Phi^+(t,x,u,\tilde\kappa\top\overline{u}_\Sigma) - \nabla(\varphi(u)-\varphi(\tilde\kappa\top\overline{u}_\Sigma))^+]\cdot\nabla\omega_\varepsilon(x)\,\psi(t,x)\,\lambda(x)\,d\alpha\,dx\,dt \ \le 0.$$

Fix $\tilde\kappa\in[A,B]$. In subsections 4.1.2 and 4.1.3, we defined a notion of normal trace for the flux $\Phi^+_\kappa(t,x,u)-\nabla(\varphi(u)-\varphi(\kappa))^+$ when u is an entropy weak solution of problem (1). Of course, the same can be done when u is an entropy process solution of problem (1); this time just consider the field $\mathcal{F}^+_\kappa$ defined by

$$\mathcal{F}^+_\kappa = \begin{pmatrix} \int_0^1 (u-\kappa)^+\,d\alpha \\ \int_0^1(\Phi^+_\kappa(t,x,u)-\nabla(\varphi(u)-\varphi(\kappa))^+)d\alpha \end{pmatrix}.$$

Moreover, if $\mathcal{T}^+_{n,\kappa}$ still denotes the normal trace of the spatial part of $\mathcal{F}^+_\kappa$, for all $\psi\in\mathcal{C}_c^\infty([\,0,T)\times\mathbb{R}^d)$,

(16)

$$\langle\mathcal{T}^+_{n,\kappa},\psi\lambda\rangle$$
$$=-\lim_{s\to 0}\frac{1}{s}\int_s^T\int_0^1\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}(\Phi^+_\kappa(t,x,u)-\nabla(\varphi(u)-\varphi(\kappa))^+)\cdot\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix}\psi\lambda\,dx_d\,d\overline{x}\,dt\,d\alpha$$

and

$$\text{(17)}\quad \langle\mathcal{T}^+_{n,\kappa},\psi\lambda\rangle = -\lim_{\varepsilon\to 0}\int_Q[\Phi^+_\kappa(t,x,u)-\nabla(\varphi(u)-\varphi(\kappa))^+]\cdot\nabla\omega_\varepsilon\,\psi\lambda\,dx\,dt\,d\alpha\,.$$

Therefore, if ψ is a nonnegative function of $\mathcal{C}_c^\infty([\,0,T)\times\mathbb{R}^d)$ such that $\mathrm{sgn}^+(\varphi(\overline{u})-\varphi(\kappa))\overline{\psi}=0$ a.e. on $(0,T)\times\partial\Omega$, then, choosing $\psi(1-\omega_\varepsilon)$ as a test-function in (6), we get

$$\text{(18)}\qquad -\langle\mathcal{T}^+_{n,\kappa},\psi\lambda\rangle \le M\int_\Sigma(\overline{u}-\kappa)^+\,\psi\,\lambda\,d\gamma(x)\,dt\,.$$

Now, we intend to define a notion of normal trace for the flux $\Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde\kappa)-\nabla(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde\kappa))^+$. To that purpose, we set

$$\text{(19)}\qquad \overline{\mathcal{F}}^+ = \begin{pmatrix}\int_0^1(u-\overline{u}_\Sigma\top\tilde\kappa)^+\,d\alpha \\ \int_0^1(\Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde\kappa)-\nabla(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde\kappa))^+)d\alpha\end{pmatrix},$$

and we prove the following lemma.

Lemma 4.2. *Let $u\in L^\infty(Q\times(\,0,1))$ be an entropy process solution of problem* (1)*, and let the field $\overline{\mathcal{F}}^+\in(L^2((0,T)\times B\cap Q))^{d+1}$ be defined by* (19)*. Assume hypotheses* (H1)*,* (H2)*,* (H3)*,* (H4)*, and* (H6) *(or* (H6Bis)*). Then, for every open subset D of B such that $\overline{D}\subset B$, the divergence of $\overline{\mathcal{F}}^+$ is a bounded Radon measure on $(0,T)\times D\cap Q$.*

Proof of Lemma 4.2. Set $g=\partial_t\,\overline{u}_\Sigma+\mathrm{div}_x\,F(t,x,\overline{u}_\Sigma)-\Delta\,\varphi(\overline{u}_\Sigma)$. From hypothesis (H6) we have $g\in L^1((0,T)\times B\cap Q)$, and the function $\overline{u}_\Sigma$ (which, we recall, belongs to $W^{1,1}((0,T)\times B\cap Q)))$ can be seen as an entropy solution of the equation $\partial_t\,w+$

$\operatorname{div}_x F(t,x,w) - \Delta\,\varphi(w) = g$ with unknown w. The identity $(\overline{u}_\Sigma \top \tilde{\kappa} - \kappa)^- = (\overline{u}_\Sigma - \kappa)^- - (\overline{u}_\Sigma - \tilde{\kappa} \bot \kappa)^-$ ensures that the function $\overline{u}_\Sigma \top \tilde{\kappa}$ satisfies the entropy inequality

$$\int_Q \left[(\overline{u}_\Sigma \top \tilde{\kappa} - \kappa)^-\, \theta_t + [\Phi^-(t,x,\overline{u}_\Sigma \top \tilde{\kappa}, \kappa) - \nabla(\varphi(\overline{u}_\Sigma \top \tilde{\kappa}) - \varphi(\kappa))^-] \cdot \nabla\theta \right] d\alpha\, dx\, dt$$
$$+ \int_\Omega (\overline{u}_\Sigma \top \tilde{\kappa}(0,x) - \kappa)^-\, \theta(0)\, dx + \int_Q \operatorname{sgn}^-(\overline{u}_\Sigma \top \tilde{\kappa} - \kappa)\, g\, \theta\, dx\, dt\, d\alpha \ \geq 0$$

for every $\kappa \in [A,B]$ and nonnegative function $\theta \in \mathcal{C}_c^\infty([0,T) \times B \cap Q)$. Now we use a result of comparison and assert that, for any nonnegative function $\theta \in \mathcal{C}_c^\infty([0,T) \times B \cap Q)$, we have

$$\int_Q \left[(u - \overline{u}_\Sigma \top \tilde{\kappa})^+\, \theta_t + [\Phi^+(t,x,u,\overline{u}_\Sigma \top \tilde{\kappa}) - \nabla(\varphi(u) - \varphi(\overline{u}_\Sigma \top \tilde{\kappa}))^+] \cdot \nabla\theta \right] d\alpha\, dx\, dt$$
$$+ \int_\Omega (u_0 - \overline{u}_\Sigma \top \tilde{\kappa}(0,x))^+\, \theta(0)\, dx + \int_Q \operatorname{sgn}^+(u - \overline{u}_\Sigma \top \tilde{\kappa})\, g\, \theta\, dx\, dt\, d\alpha \ \geq 0. \tag{20}$$

This result of comparison, proved in [Car99] for entropy weak solution, remains true when applied to entropy process solutions. Notice that we state a result of comparison *inside* $[0,T) \times \Omega$ (the previous function θ vanishes on $[0,T) \times \partial\Omega$); this point is crucial. A result of comparison on the whole domain Q is the object of Theorem 4.1, which we are actually proving. As a matter of fact, we would like to rule out the hypothesis that θ vanishes on $[0,T) \times \partial\Omega$. Toward that end, first notice that (20) is still true if $\theta \in \mathcal{C}_c^1([0,T) \times (B \cap \overline{\Omega}))$ and $\theta = 0$ on $[0,T) \times (B \cap \partial\Omega)$. Let $\tilde{\theta} \in \mathcal{C}_c^\infty([0,T) \times (B \cap \overline{\Omega}))$, define, for $s > 0$, $h_s(x) = \min([x_d - f(\overline{x})]/s, 1)$, and choose $\theta = \tilde{\theta}\, h_s$ in (20) to get

$$\int_Q \left[(u - \overline{u}_\Sigma \top \tilde{\kappa})^+\, \tilde{\theta}_t + [\Phi^+(t,x,u,\overline{u}_\Sigma \top \tilde{\kappa}) - \nabla(\varphi(u) - \varphi(\overline{u}_\Sigma \top \tilde{\kappa}))^+] \cdot \nabla\tilde{\theta} \right] h_s\, d\alpha\, dx\, dt$$
$$+ \int_\Omega (u_0 - \overline{u}_\Sigma \top \tilde{\kappa}(0,x))^+\, \tilde{\theta}(0)\, h_s\, dx + \int_Q \operatorname{sgn}^+(u - \overline{u}_\Sigma \top \tilde{\kappa})\, g\, \tilde{\theta}\, h_s\, dx\, dt\, d\alpha \ \geq A_s + B_s, \tag{21}$$

where

$$A_s = -\frac{1}{s} \int_0^T \int_0^1 \int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} \Phi^+(t,x,u,\overline{u}_\Sigma \top \tilde{\kappa}) \cdot \nabla_x(x_d - f(\overline{x}))\, \tilde{\theta}\, dx_d\, d\overline{x}\, dt\, d\alpha,$$
$$B_s = \frac{1}{s} \int_0^T \int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} \nabla(\varphi(u) - \varphi(\overline{u}_\Sigma \top \tilde{\kappa}))^+ \cdot \nabla_x(x_d - f(\overline{x}))\, \tilde{\theta}\, dx_d\, d\overline{x}\, dt.$$

Let C be a bound of $\Phi^+(t,x,z,w) \cdot \nabla_x(x_d - f(\overline{x}))$ in $L^\infty(Q \times [A,B]^2)$. Such a bound exists and, for every s,

$$A_s \geq -C\, T\, |\Pi|\, ||\tilde{\theta}||_{L^\infty([0,T) \times (B \cap \overline{\Omega}))}\,. \tag{22}$$

On the other hand, the term B_s can be decomposed as $B_s = \overline{B_s} + B_s^d$, where

$$\overline{B_s} = -\frac{1}{s} \int_0^T \int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} \nabla_{\overline{x}}(\varphi(u) - \varphi(\overline{u}_\Sigma \top \tilde{\kappa}))^+ \cdot \nabla_{\overline{x}} f(\overline{x})\, \tilde{\theta}\, dx_d\, d\overline{x}\, dt,$$
$$B_s^d = \frac{1}{s} \int_0^T \int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} \partial_{x_d}(\varphi(u) - \varphi(\overline{u}_\Sigma \top \tilde{\kappa}))^+\, \tilde{\theta}\, dx_d\, d\overline{x}\, dt.$$

Integration by parts with respect to $\overline{x}$ in $\overline{B_s}$ and integration by parts with respect to x_d in B_s^d (we use the fact that $\varphi(u)(t,\overline{x},f(\overline{x}))=\varphi(\overline{u}_\Sigma)(t,\overline{x})$) yields the following: for almost every positive s (small enough),

$$\begin{aligned}\overline{B_s} &= \frac{1}{s}\int_0^T\!\!\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+\mathrm{div}_{\overline{x}}\nabla_{\overline{x}}f(\overline{x})\,\tilde{\theta}\,dx_d\,d\overline{x}\,dt,\\ B_s^d &= -\frac{1}{s}\int_0^T\!\!\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+\,\partial_{x_d}\tilde{\theta}\,dx_d\,d\overline{x}\,dt\\ &\quad+\frac{1}{s}\int_0^T\!\!\int_\Pi(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+(t,\overline{x},f(\overline{x})+s)\,\tilde{\theta}(\overline{x},f(\overline{x})+s)d\overline{x}\,dt.\end{aligned}$$

Notice that, first, the second term on the right-hand side of the previous equality in nonnegative; that, second, $\lim_{s\to0}\overline{B_s}=0$ and $\lim_{s\to0}\frac{1}{s}\int_0^T\int_\Pi\int_{f(\overline{x})}^{f(\overline{x})+s}(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+\,\partial_{x_d}\tilde{\theta}\,dx_d\,d\overline{x}\,dt\;=0$ (because the trace of $\varphi(u)$ is $\varphi(\bar{u})$); and that, third, h_s converge to 1 in $L^1(B\cap\Omega)$. Consequently, letting s go to zero on both sides of inequality (21) yields

$$\begin{aligned}&\int_Q\Big[(u-\overline{u}_\Sigma\top\tilde{\kappa})^+\,\tilde{\theta}_t+[\Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde{\kappa})-\nabla(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+]\cdot\nabla\tilde{\theta}\Big]\,d\alpha\,dx\,dt\\ &+\int_\Omega(u_0-\overline{u}_\Sigma\top\tilde{\kappa}(0,x))^+\,\tilde{\theta}(0)\,dx+\int_Q\mathrm{sgn}^+(u-\overline{u}_\Sigma\top\tilde{\kappa})\,g\,\tilde{\theta}\,dx\,dt\,d\alpha\geq\liminf_{s\to0}A_s.\end{aligned}$$

Let D be an open subset of B whose closure is a subset of B too. From (22), it appears that $\liminf_{s\to0}A_s$ can be viewed as the action of a certain distribution A_∞ on $\tilde{\theta}$ and that A_∞ is a bounded Radon measure on $[0,T)\times D\cap Q$. Since $\int_0^1\mathrm{sgn}^+(u-\overline{u}_\Sigma)\,g\,d\alpha$ and $(u_0-\overline{u}_\Sigma\top\tilde{\kappa}(0,x))^+\delta_{t=0}$ are bounded Radon measures on $[0,T)\times D\cap Q$, the previous inequality shows that the divergence of the field $\overline{\mathcal{F}}^+$ is a bounded Radon measure on $[0,T)\times D\cap Q$. This ends the proof of Lemma 4.2. □

Remark 4.1. If $\overline{u}_\Sigma$ satisfies (H6Bis) instead of (H6), then $\overline{u}_\Sigma$ can be seen as the entropy solution of the equation $\partial_t\,w+\mathrm{div}_x\,F(t,x,w)-\Delta\,\varphi(w)=g$, with a source term g which is a bounded Radon measure on $(0,T)\times B\cap Q$. In the proof of the previous lemma we used a theorem of comparison of Carrillo (Theorem 8 in [Car99]) between two entropy solutions u_i ($i\in\{1,2\}$) of the equation

$$\partial_tu_i+\mathrm{div}F(t,x,u_i)-\Delta\varphi(u_i)=f_i$$

(where $f_i\in L^1$) to derive the inequality (20). A careful study of the proof of the result of comparison given by Carrillo shows that it still holds if $f_1=0$ and f_2 is a bounded Radon measure. Consequently, inequality (20) remains true under hypothesis (H6Bis) and Lemma 4.2 also.

As a consequence of this lemma, we can define a functional $\overline{\mathcal{T}}^+_{n,\tilde{\kappa}}$, which represents the normal trace of the flux $\Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde{\kappa})-\nabla(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+$ on $(0,T)\times(\partial\Omega\cap D)$ and satisfies the analogue of the relations (16) and (17), where κ has been replaced by $\overline{u}_\Sigma\top\tilde{\kappa}$ in these latter. (We use the fact that there exists an open set D such that $\mathrm{supp}(\lambda)\subset D\subset\overline{D}\subset B$ to ensure that these limits make sense.)

Now, denote by $\overline{\mathcal{S}}$ the set of all the functions $v:(0,T)\times\Pi\to\mathbb{R}$ satisfying

$$v(t,x)=\sum_{i=1}^{N_v}w_i\,L_i(t,x), \tag{23}$$

where

$$\forall i, \quad w_i \in \mathbb{R},\, L_i \in \mathcal{C}^\infty([0,T]\times\Pi),\; L_i \geq 0, \text{ and } \sum_{i=1}^{N_v} L_i = 1 \quad \text{on } [0,T]\times\Pi_\lambda. \tag{24}$$

We say that $v \in \overline{\mathcal{S}}^+$ if $v \in \overline{\mathcal{S}}$ and admits a decomposition as (23) such that $w_i \geq \overline{u}_\Sigma$ a.e. on $\operatorname{supp}(L_i)$ for all i. If $v \in \overline{\mathcal{S}}$ and satisfies (23), we set

$$\langle \mathcal{T}^+_{n,v\top\tilde\kappa}, \psi\lambda\rangle \;=\; \sum_{i=1}^{N_v} \langle \mathcal{T}^+_{n,w_i\top\tilde\kappa}, L_i\psi\lambda\rangle.$$

Notice that this is a *notation* and not a *definition*, because the decomposition (23) with w_i, L_i satisfying (24) is not unique. An immediate consequence of (18) is the following: if $v \in \overline{\mathcal{S}}^+$, then

$$-\langle \mathcal{T}^+_{n,v\top\tilde\kappa}, \psi\lambda\rangle \leq 0 \quad \forall\psi \in \mathcal{C}^\infty_c([0,T)\times\mathbb{R}^d),\; \psi \geq 0. \tag{25}$$

Furthermore, we claim that, if $v \in \overline{\mathcal{S}}^+$, then

$$\langle \mathcal{T}^+_{n,v\top\tilde\kappa} - \overline{\mathcal{T}}^+_{n,\tilde\kappa}, \psi\lambda\rangle \leq M\sqrt{1+||\nabla_{\overline{x}} f||^2_\infty}\; \sum_{i=1}^{N_v} \int_0^T\!\!\int_\Pi |w_i - \overline{u}_\Sigma|\, \psi\lambda\, L_i\, d\overline{x}\, dt. \tag{26}$$

Let us prove this result: from (16) we have $\langle \mathcal{T}^+_{n,v\top\tilde\kappa} - \overline{\mathcal{T}}^+_{n,\tilde\kappa}, \psi\lambda\rangle = -\lim\limits_{s\to 0} \sum_{i=1}^{N_v} (H_i(s) + P_i(s))$, where

$$\begin{aligned} H_i(s) = \frac{1}{s}\int_s^T\!\!\int_0^1\!\!\int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} &(\, \Phi\,^+(t,x,u,w_i\top\tilde\kappa) \\ &- \Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde\kappa)) \cdot \begin{pmatrix} -\nabla f(\overline{x}) \\ 1 \end{pmatrix} L_i\psi\lambda\, dx_d\, d\overline{x}\, dt\, d\alpha, \end{aligned}$$

$$\begin{aligned} P_i(s) = \frac{1}{s}\int_s^T\!\!\int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} &\nabla((\, \varphi\,(u) - \varphi(\overline{u}_\Sigma\top\tilde\kappa))^+ \\ &- (\varphi(u) - \varphi(w_i\top\tilde\kappa))^+) \cdot \begin{pmatrix} -\nabla f(\overline{x}) \\ 1 \end{pmatrix} L_i\psi\lambda\, dx_d\, d\overline{x}\, dt. \end{aligned}$$

Since the function $\Phi^+(t,x,u,v)$ is M-Lipschitz continuous with respect to v, uniformly with respect to $(t,x,u) \in Q\times[A,B]$, we have

$$\begin{aligned} H_i(s) &\geq -\frac{1}{s} M\sqrt{1+||\nabla_{\overline{x}} f||^2_\infty} \int_0^T\!\!\int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} |w_i\top\tilde\kappa - \overline{u}_\Sigma\top\tilde\kappa|\, L_i\psi\lambda\, dx_d\, d\overline{x}\, dt \\ &\geq -\frac{1}{s} M\sqrt{1+||\nabla_{\overline{x}} f||^2_\infty} \int_0^T\!\!\int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} |w_i - \overline{u}_\Sigma|\, L_i\psi\lambda\, dx_d\, d\overline{x}\, dt\,. \end{aligned}$$

Consequently,

$$\sum_{i=1}^{N_v} H_i(s) \geq -\frac{1}{s} M\sqrt{1+||\nabla_{\overline{x}} f||^2_\infty} \sum_{i=1}^{N_v} \int_0^T\!\!\int_\Pi \int_{f(\overline{x})}^{f(\overline{x})+s} |w_i - \overline{u}_\Sigma|\, \psi\lambda\, L_i\, dx_d\, d\overline{x} dt,$$

and the limit of the right-hand side of this latter inequality can be explicitly computed since the function $\psi\lambda\, L_i$ is smooth:

$$\lim_{s\to 0}\sum_{i=1}^{N_v} H_i(s) \geq -M\sqrt{1+||\nabla_{\overline{x}} f||_\infty^2}\sum_{i=1}^{N_v}\int_0^T\!\!\int_\Pi |w_i-\overline{u}_\Sigma|\,\psi\lambda\, L_i\, d\overline{x}\, dt\,. \tag{27}$$

On the other hand, we have $\limsup_{s\to 0} P_i(s) \geq 0$. We will not detail the proof of this result, for it is identical to the justification of the fact that $\limsup_{s\to 0} B_s \geq 0$ in the proof of Lemma 4.2. Together with (27), the result $\limsup_{s\to 0} P_i(s) \geq 0$ yields (26). Furthermore, (26) combined with (25) shows that, if $v \in \overline{\mathcal{S}}^+$($v$ satisfies (23), with $w_i \geq \overline{u}_\Sigma$ a.e. on $\mathrm{supp}(L_i)$), then

$$-\langle \overline{\mathcal{T}}^+_{n,\tilde{\kappa}}, \psi\lambda\rangle \leq M\sqrt{1+||\nabla_{\overline{x}} f||_\infty^2}\sum_{i=1}^{N_v}\int_0^T\!\!\int_\Pi (w_i-\overline{u}_\Sigma)\,\psi\lambda\, L_i\, d\overline{x}\, dt. \tag{28}$$

Since

$$\langle \overline{\mathcal{T}}^+_{n,\tilde{\kappa}}, \psi\lambda\rangle = -\lim_{\varepsilon\to 0}\int_Q [\Phi^+(t,x,u,\overline{u}_\Sigma\top\tilde{\kappa}) - \nabla(\varphi(u)-\varphi(\overline{u}_\Sigma\top\tilde{\kappa}))^+]\cdot\nabla\omega_\varepsilon\,\psi\lambda\, dx\, dt\, d\alpha\,,$$

our first aim, which is the proof of (15), will be reached if the right-hand side of (28) can be made as small as desired. Let us prove this fact: $\varepsilon > 0$. Since $\overline{u}_\Sigma \in L^\infty\cap W^{1,1}((0,T)\times\Pi)$ (hypothesis (H6)), we have $\overline{u}_\Sigma \in L^\infty \cap BV((0,T)\times\Pi)$, and Lemma 4.1 shows that there exists $g\in\mathcal{C}([0,T]\times\overline{\Pi})$ such that $g\geq\overline{u}_\Sigma$ a.e. on $(0,T)\times\Pi$ and $\int_{(0,T)\times\Pi} g-\overline{u}_\Sigma < \varepsilon$. Let η be a modulus of uniform continuity of g on $[0,T]\times\overline{\Pi}$. The set $(0,T)\times\Pi$ (with compact closure) can be covered by a finite number of balls with radius η centered in $(0,T)\times\Pi$, say $V_1,\dots,V_Q$. Let $(L_i)_{1,Q}$ be a regular partition of unity subordinate to the open coverage (V_i) of $[0,T]\times\overline{\Pi}$. For a certain $(t_i,\overline{x}_i)\in V_i$, set $w_i = g(t_i,\overline{x}_i)+\varepsilon$ and define $v=\sum_{i=1}^Q w_i\, L_i$. Then $v\in\overline{\mathcal{S}}^+$ and

$$\begin{aligned}\sum_{i=1}^{Q}\int_0^T\!\!\int_\Pi (w_i-\overline{u}_\Sigma)\,\psi\lambda\, L_i\, d\overline{x}\, dt &= \int_0^T\!\!\int_\Pi (v-\overline{u}_\Sigma)\,\psi\lambda\, d\overline{x}\, dt\\ &= \int_0^T\!\!\int_\Pi (v-g)\,\psi\,\lambda\, d\overline{x}\, dt + \int_0^T\!\!\int_\Pi (g-\overline{u}_\sigma)\,\psi\,\lambda\, d\overline{x}\, dt\\ &\leq 2||\psi\,\lambda||_\infty\, T\,|\Pi|\,\varepsilon.\end{aligned}$$

This completes the proof of (15). Similarly, we can prove

$$\lim_{\varepsilon\to 0}\int_Q [\Phi^-(t,x,u,\tilde{\kappa}\bot\overline{u}_\Sigma) - \nabla(\varphi(u)-\varphi(\tilde{\kappa}\bot\overline{u}_\Sigma))^-]\cdot\nabla\omega_\varepsilon(x)\,\psi(t,x)\,\lambda(x)\, d\alpha\, dx\, dt \leq 0 \tag{29}$$

for every $\tilde{\kappa}\in[A,B]$ and for every nonnegative $\psi\in\mathcal{C}_c^\infty([0,T)\times\mathbb{R}^d)$. Then Proposition 4.1 follows from the formula

$$\begin{aligned}\mathcal{F}_\varphi(t,x,u,\kappa,w) = &\left[\,\Phi^{\,+}(t,x,u,\kappa\top w) - \nabla(\varphi(u)-\varphi(\kappa\top w))^+\right]\\ &+\left[\Phi^-(t,x,u,\kappa\bot w) - \nabla(\varphi(u)-\varphi(\kappa\bot w))^-\right].\qquad\square\end{aligned}$$

4.4. Proof of Theorem 4.1 (step 1): Inner comparison. Let u and $v \in L^\infty(Q\times(0,1))$ be two entropy process solutions of problem (1). The following result of comparison between u and v involving test-functions which *vanish* on the boundary of Ω can be proved (see [Car99] or [EGHM02]).

PROPOSITION 4.2 (inner comparison). *Let u and $v \in L^\infty(Q\times(0,1))$ be two entropy process solutions of problem* (1). *Assume hypotheses* (H1), (H2), (H3), *and* (H4). *Let ζ be a nonnegative function of $\mathcal{C}^\infty([0,T)\times\mathbb{R}^d\times[0,T)\times\mathbb{R}^d)$ such that*

$$\begin{cases} \forall (s,y)\in Q\,,\ (t,x)\longmapsto \zeta(t,x,s,y)\in\mathcal{C}_c^\infty([0,T)\times\Omega), \\ \forall (t,x)\in Q\,,\ (s,y)\longmapsto \zeta(t,x,s,y)\in\mathcal{C}_c^\infty([0,T)\times\Omega). \end{cases}$$

Then we have

$$\begin{aligned} &\int_Q\!\!\int_Q \left[\begin{array}{c} |u(t,x,\alpha)-v(s,y,\beta)|(\zeta_t+\zeta_s) \\ +\,\mathcal{G}_x(t,x,u(t,x,\alpha),v(s,y,\beta))\cdot\nabla_x\zeta \\ +\,\mathcal{G}_y(s,y,v(s,y,\beta),u(t,x,\alpha))\cdot\nabla_y\zeta \\ -\,\nabla_x|\varphi(u)(t,x)-\varphi(v)(s,y)|\cdot\nabla_y\zeta \\ -\,\nabla_y|\varphi(u)(t,x)-\varphi(v)(s,y)|\cdot\nabla_x\zeta \end{array}\right] d\alpha dx dt d\beta dy ds \\ &+\int_Q\int_\Omega |u_0(x)-v(s,y,\beta)|\,\zeta(0,x,s,y)\,dx\,d\beta\,dy\,ds \\ &+\int_Q\int_\Omega |u_0(y)-u(t,x,\alpha)|\,\zeta(t,x,0,y)\,dy\,d\alpha\,dx\,dt\ \geq 0. \end{aligned} \tag{30}$$

4.5. Proof of Theorem 4.1 (step 2): General test-function. We now follow the lines of the proof of uniqueness given by Mascia, Porretta, and Terracina in [MPT02].

First, we would like to consider test-functions which do not necessarily vanish on $\partial\Omega$ and are localized into the ball B. For $\overline{x}\in\mathbb{R}^{d-1}$, set $\rho_m(\overline{x})=\rho_m(x_1)\cdots\rho_m(x_{d-1})$ and define the function ξ by

$$\xi(t,s,x,y)=\psi(t,x)\,\rho_l(t-s)\,\rho_m(\overline{x}-\overline{y})\,\rho_n(x_d-y_d)\,. \tag{31}$$

We took care to choose ρ satisfying $\operatorname{supp}(\rho)\subset[-1,0)$ to ensure

$$\begin{aligned} &\forall (t,x)\in Q\,,\ (s,y)\longmapsto \xi(t,s,x,y)\in\mathcal{C}_c^\infty(Q)\,, \\ &\forall (t,s,x)\in[0,T)\times[0,T)\times\operatorname{supp}(\lambda),\ \operatorname{supp}_y\xi(t,s,x,\cdot)\subset B. \end{aligned} \tag{32}$$

For $\varepsilon>0$ define ζ to be the function

$$\zeta\,:\,(t,s,x,y)\longmapsto \omega_\varepsilon(x)\,\xi(t,s,x,y)\,\lambda(x).$$

Then, for m large enough compared with n, the assumptions of Proposition 4.2 are satisfied, and, with this particular choice of function ζ, inequality (30) turns into the inequality

$$\int_{\mathcal{Q}}\int_{\mathcal{Q}}\left[\begin{array}{l} \qquad\qquad |u-\widehat{v}|\,\omega_\varepsilon(x)\,((\xi\lambda)_t+(\xi\lambda)_s) \\ +\Big(\mathcal{G}_x(t,x,u,\widehat{v})\cdot\nabla_x(\xi\,\lambda) \\ \qquad\qquad +\mathcal{G}_y(t,y,\widehat{v},u)\cdot\nabla_y(\xi\,\lambda)\Big)\,\omega_\varepsilon(x) \\ -\Big(\nabla_x|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_y(\xi\,\lambda) \\ \qquad\qquad +\nabla_y|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_x(\xi\,\lambda)\Big)\,\omega_\varepsilon(x) \end{array}\right] dxdtd\alpha dydsd\beta$$
$$+\int_{\mathcal{Q}}\int_{\mathcal{Q}} \mathcal{G}_x(t,x,u,\widehat{v})\cdot\nabla\omega_\varepsilon(x)\;\xi\,\lambda\,d\alpha\,dx\,dt\;\,d\beta\,dy\,ds$$
$$-\int_{\mathcal{Q}}\int_{\mathcal{Q}} \nabla_y|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,dx\,dt\,d\alpha\,dy\,ds\,d\beta$$
$$+\int_{\Omega}\int_{\mathcal{Q}} |u_0(x)-\widehat{v}|\,(\xi\,\lambda)(0,x,y)\,\omega_\varepsilon(x)\,dx\delta\beta\,dy\,ds\geq 0,$$

where

$$u=u(t,x,\alpha)\quad\text{and}\quad \widehat{v}=v(s,y,\beta).$$

Using formula (12), this inequality can be rewritten as

$$\int_{\mathcal{Q}}\int_{\mathcal{Q}}\left[\begin{array}{l} \qquad\qquad |u-\widehat{v}|\,\omega_\varepsilon(x)\,((\xi\,\lambda)_t+(\xi\lambda)_s) \\ +(\mathcal{G}_x(t,x,u,\widehat{v})\cdot\nabla_x(\xi\,\lambda)+\mathcal{G}_y(t,y,\widehat{v},u)\cdot\nabla_y(\xi\,\lambda))\,\omega_\varepsilon(x) \\ -(\nabla_x|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_y(\xi\,\lambda) \\ \quad +\nabla_y|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_x(\xi\,\lambda))\,\omega_\varepsilon(x) \end{array}\right] d\alpha dxdtd\beta dyds$$

(33)

$$+\int_{\mathcal{Q}}\int_{\mathcal{Q}} \mathcal{F}_\varphi(t,x,u,\widehat{v},\overline{u}_\Sigma)\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,d\alpha\,dx\,dt\,d\beta\,dy\,ds$$
$$+\int_{\Omega}\int_{\mathcal{Q}} |u_0(x)-\widehat{v}|\,(\xi\,\lambda)(0,x,y)\,\omega_\varepsilon(x)\,dx\,dy\,ds\,d\beta\;\geq\;A+B+C,$$

where

$$A=\int_Q\int_Q \nabla_y|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,dx\,dt\,dy\,ds,$$
$$B=-\int_{\mathcal{Q}}\int_{\mathcal{Q}} \mathcal{G}_x(t,x,\widehat{v},\overline{u}_\Sigma)\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,d\alpha\,dx\,dt\,d\beta\,dy\,ds,$$
$$C=\int_{\mathcal{Q}}\int_{\mathcal{Q}} \mathcal{G}_x(t,x,u,\overline{u}_\Sigma)\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,d\alpha\,dx\,dt\,d\beta\,dy\,ds.$$

Using Proposition 4.1 and taking the limit of both sides of the previous inequality with respect to ε then yields

$$\int_{\mathcal{Q}}\int_{\mathcal{Q}}\left[\begin{array}{c} |u-\widehat{v}|\,((\xi\,\lambda)_t+(\xi\,\lambda)_s) \\ +\mathcal{G}_x(t,x,u,\widehat{v})\cdot\nabla_x(\xi\,\lambda)+\mathcal{G}_y(t,y,\widehat{v},u)\cdot\nabla_y(\xi\,\lambda) \\ -\nabla_x|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_y(\xi\,\lambda)+\nabla_y|\varphi(u)-\varphi(\widehat{v})|\cdot\nabla_x(\xi\,\lambda) \end{array}\right] d\alpha\,dx\,dt\,d\beta\,dy\,ds$$
$$+\int_{\Omega}\int_{\mathcal{Q}} |u_0(x)-\widehat{v}|\,(\xi\,\lambda)(0,x,y)\,d\beta\,dy\,ds\,dx\geq\lim_{\varepsilon\to 0}\,(A+B+C\,),$$

or (using formula (11))

$$\begin{aligned}&\int_{\mathcal{Q}}\int_{\mathcal{Q}}\left[\begin{array}{c}|u-\widehat{v}|\,((\xi\,\lambda)_t+(\xi\,\lambda)_s)\\ +\,\Phi(t,x,u,\widehat{v})\cdot\nabla_x(\xi\,\lambda)+\Phi(t,y,\widehat{v},u)\cdot\nabla_y(\xi\,\lambda)\\ -\,(\nabla_x|\varphi(u)-\varphi(\widehat{v})|+\nabla_y|\varphi(u)-\varphi(\widehat{v})|)\cdot(\nabla_y+\nabla_x)(\xi\,\lambda)\end{array}\right]d\alpha\,dx\,dt\,d\beta\,dy\,ds\\ &+\int_\Omega\int_{\mathcal{Q}}|u_0(x)-\widehat{v}|\,(\xi\,\lambda)(0,x,y)\,d\beta\,dy\,ds\,dx\geq\lim_{\varepsilon\to0}\,(A+B+C\,).\end{aligned}\tag{34}$$

Now, we intend to pass to the limit on l, m, and n in the previous inequality. We will do so (on l and m and, eventually, on n), but notice that the study of the behavior of A, B, and C as $[\varepsilon\to0]$ and the doubling variable technique itself interfere with each other.

Using the definition of ξ from (31), it appears that C does not depend on l, m, and n:

$$C=\int_{\mathcal{Q}}\mathcal{G}_x(t,x,u,\overline{u}_\Sigma)\cdot\nabla\omega_\varepsilon(x)\,\psi\,\lambda\,d\alpha\,dx\,dt.$$

Moreover, inequality (34) can be rewritten as

$$\begin{aligned}&\int_{\mathcal{Q}}\int_{\mathcal{Q}}\left[\begin{array}{c}|u-\widehat{v}|\,\rho_l\,\rho_m\,\rho_n(\psi\,\lambda)_t\\ +\,\Phi(t,x,u,\widehat{v})\cdot\nabla_x(\psi\,\lambda)\rho_l\,\rho_m\,\rho_n\\ -\,(\nabla_x|\varphi(u)-\varphi(\widehat{v})|+\nabla_y|\varphi(u)-\varphi(\widehat{v})|)\cdot\nabla_x(\psi\,\lambda)\,\rho_l\,\rho_m\,\rho_n\end{array}\right]d\alpha\,dx\,dt\,d\beta\,dy\,ds\\ &\quad+\int_\Omega\int_\Omega|u_0(x)-u_0(y)|\,(\psi\,\lambda)(0,x)\,\rho_m\,\rho_n\,dx\,dy\;\geq\;\lim_{\varepsilon\to0}\,(A+B+C\,)+D+E,\end{aligned}\tag{35}$$

where

$$D=-\int_{\mathcal{Q}}\int_{\mathcal{Q}}[\Phi(t,x,u,\widehat{v})-\Phi(t,y,u,\widehat{v})]\cdot\nabla_x(\rho_l\,\rho_m\,\rho_n)\,\psi\,\lambda\,d\alpha\,dx\,dt\,d\beta\,dy\,ds,$$

$$E=\int_\Omega\int_{\mathcal{Q}}|u_0(y)-\widehat{v}|\,(\psi\,\lambda)(0,x)\,\rho_l(-s)\,\rho_m\,\rho_n\;d\beta\,dy\,ds\,dx.$$

The term E can be estimated by using the fact that the solution v completely satisfies the initial condition, which means, for example, that $\operatorname{ess\,lim}_{s\to0^+}\int_\Omega\int_0^1|v(s,y,\alpha)-u_0(y)|\,d\beta\,dy=0$. On the other hand, if the flux function F does not depend on the (t,x)-variables, then $D=0$, and more generally, one can prove (see [CH99]) $D+E\geq H$, where

$$\begin{aligned}H=-C(F,\psi)\sup\Bigg\{&\int_{\mathcal{Q}}|v(s,\overline{y},y_d,\beta)-v(s+\sigma,\overline{y}+\overline{h},y_d+k,\beta)|ds\,d\overline{y}\,dy_d\,d\beta\,;\\ &|\sigma|\leq\frac{1}{l},|\overline{h}|\leq\frac{1}{m},|k|\leq\frac{1}{n}\Bigg\}.\end{aligned}\tag{36}$$

Notice that, by continuity of the translations in L^1, we have $\lim_{l,m,n\to+\infty}H=0$.

4.5.1. Study of $A+B$. Going back to the study of A, B, we write $A+B = I + J^y + J^x$, where

$$\begin{aligned}
I &= -\int_{\mathcal{Q}}\int_{\mathcal{Q}} (\Phi(t,x,\widehat{v},\overline{u}_\Sigma(t,\overline{x}))\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,d\alpha\,dx\,dt\,d\beta\,dy\,ds,\\
J^y &= \int_Q\int_Q \nabla_y|\varphi(u)(t,x)-\varphi(v)(s,y)|\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,dx\,dt\,dy\,ds,\\
J^x &= \int_Q\int_Q \nabla_x|\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma(t,\overline{x}))|\cdot\nabla\omega_\varepsilon(x)\,\xi\,\lambda\,dx\,dt\,dy\,ds.
\end{aligned}$$

Recall that

$$\nabla\omega_\varepsilon(x) = \rho_\varepsilon(f(\overline{x})-x_d)\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix},$$

so that

$$\begin{aligned}
\widetilde{I} &= \lim_{\varepsilon\to 0} I\\
&= -\int_{\mathcal{Q}}\int_{[0,T)\times\Pi\times(0,1)} (\Phi(t,\overline{x},f(\overline{x}),\widehat{v},\overline{u}_\Sigma(t,\overline{x}))\cdot\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix}(\xi\,\lambda)_{\Sigma_x}d\alpha d\overline{x}dtd\beta dyds,
\end{aligned}$$

where the index Σ_x indicates that the transformation concerns only the x variable. Here, for example, $(\xi\,\lambda)_{\Sigma_x}(t,x,y) = \xi(t,\overline{x},f(\overline{x}),y)\lambda(\overline{x},f(\overline{x}))$. To study the term J^x, we notice that the function $\overline{u}_\Sigma$ does not depend on x_d, and thus

$$\widetilde{J^x} = \lim_{\varepsilon\to 0} J^x = -\int_{[0,T)\times\Pi}\int_Q \nabla_{\overline{x}}\,|\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma(t,\overline{x}))|\cdot\nabla f(\overline{x})\,(\xi\,\lambda)_{\Sigma_x}\,d\overline{x}\,dt\,dy\,ds.$$

Integration by parts with respect to $\overline{x}$ in $\widetilde{J^x}$ yields $\widetilde{J^x} = \widetilde{J^x_f} + \widetilde{J^x_\psi} + \widetilde{J^x_{\rho_m}} + \widetilde{J^x_{\rho_n}}$, where

$$\begin{aligned}
\widetilde{J^x_f} &= \int_{[0,T)\times\Pi}\int_Q |\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma)|\Delta f(\overline{x})\,(\psi\,\lambda)_{\Sigma_x}\,\rho_l(t-s)\\
&\qquad\times\rho_m(\overline{x}-\overline{y})\,\rho_n(f(\overline{x})-y_d)\,d\overline{x}\,dt\,dy\,ds,\\
\widetilde{J^x_\psi} &= \int_{[0,T)\times\Pi}\int_Q |\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma)|\nabla f(\overline{x})\\
&\qquad\cdot\nabla_{\overline{x}}\,((\psi\,\lambda)_{\Sigma_x})\rho_l(t-s)\,\rho_m(\overline{x}-\overline{y})\rho_n(f(\overline{x})-y_d)d\overline{x}dtdyds,\\
\widetilde{J^x_{\rho_m}} &= \int_{[0,T)\times\Pi}\int_Q |\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma)|\nabla f(\overline{x})\\
&\qquad\cdot\nabla_{\overline{x}}\,\rho_m(\overline{x}-\overline{y})\,\rho_n(f(\overline{x})-y_d)\,\rho_l(t-s)\,\psi\,\lambda\,d\overline{x}\,dt\,dy\,ds,\\
\widetilde{J^x_{\rho_n}} &= \int_{[0,T)\times\Pi}\int_Q |\varphi(\widehat{v})-\varphi(\overline{u}_\Sigma)||\nabla f(\overline{x})|^2\rho_l(t-s)\\
&\qquad\times\rho_m(\overline{x}-\overline{y})\,\rho'_n(f(\overline{x})-y_d)\,(\psi\,\lambda)_{\Sigma_x}d\overline{x}dtdyds.
\end{aligned}$$

On the other hand, via integration by parts in J^y with respect to y, and recalling that the boundary condition $\varphi(u)=\varphi(\overline{u})$ on Σ is strongly satisfied according to Definition 3.1, we get

$$\begin{aligned}
\widetilde{J^y} &= \lim_{\varepsilon\to 0} J^y\\
&= -\int_{[0,T)\times\Pi}\int_Q |\varphi(\overline{u}_\Sigma(t,\overline{x}))-\varphi(\widehat{v})|\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix}\cdot\nabla_y(\xi\,\lambda)(t,s,\overline{x},f(\overline{x}),y)\,d\overline{x}\,dt\,dy\,ds,
\end{aligned}$$

and, developing the scalar product,

$$\begin{aligned}\widetilde{J^y} = &\int_{[0,T)\times\Pi}\int_Q |\varphi(\overline{u}_\Sigma(t,\overline{x})) - \varphi(\widehat{v})|\nabla f(\overline{x})\cdot\nabla_{\overline{y}}(\xi\,\lambda)(t,s,\overline{x},f(\overline{x}),y)dy\,d\overline{x}\,dt\,ds\\ &-\int_{[0,T)\times\Pi}\int_Q |\varphi(\overline{u}_\Sigma(t,\overline{x})) - \varphi(\widehat{v})|\partial_{y_d}(\xi\,\lambda)(t,s,\overline{x},f(\overline{x}),y)\,dy\,d\overline{x}\,dt\,ds\\ = &-\widetilde{J^x_{\rho_m}} + \int_{[0,T)\times\Pi}\int_Q |\varphi(\overline{u}_\Sigma) - \varphi(\widehat{v})|\rho_l(t-s)\\ &\qquad\times\ \rho_m(\overline{x}-\overline{y})\,\rho_n'(f(\overline{x})-y_d)\,(\psi\,\lambda)_{\Sigma_x}dy\,d\overline{x}\,dt\,ds,\end{aligned}$$

so that

$$\begin{aligned}\widetilde{J^x}+\widetilde{J^y} = \widetilde{J^x_f}+\widetilde{J^x_\psi} + &\int_{[0,T)\times\Pi}\int_\Omega |\varphi(\overline{u}_\Sigma) - \varphi(\widehat{v})|\,(1+|\nabla f(\overline{x})|^2)\\ &\times\rho_l(t-s)\,\rho_m(\overline{x}-\overline{y})\rho_n'(f(\overline{x})-y_d)\,(\psi\,\lambda)_{\Sigma_x}\,d\overline{x}\,dt\,dy\,ds.\end{aligned}$$

In particular, no derivatives of the functions ρ_m or ρ_l appear in J^x+J^y. Hence, summing up by $\widetilde{v}$ the quantity $v(t,\overline{x},y_d,\beta)$ and passing to the limit $[l,m\to+\infty]$ in $\lim_{\varepsilon\to 0}(A+B) = \widetilde{I}+\widetilde{J^x}+\widetilde{J^y}$, we get

$$\lim_{l,m\to+\infty}\lim_{\varepsilon\to 0}(A+B) = \overline{I}+\overline{J_f}+\overline{J_\psi}+\overline{J_{\rho_n}}\,,$$

with

$$\begin{aligned}\overline{I} = -\int_{[0,T)\times\Pi\times(0,1)}&\int_0^\infty\int_0^1 \Phi(t,\overline{x},f(\overline{x}),\widetilde{v},\overline{u}_\Sigma)\\ &\cdot\begin{pmatrix}-\nabla f(\overline{x})\\ 1\end{pmatrix}\rho_n(f(\overline{x})-y_d)(\psi\,\lambda)_{\Sigma_x}d\overline{x}dtd\alpha dy_d d\beta,\end{aligned}$$

$$\overline{J_f} = \int_{[0,T)\times\Pi}\int_0^\infty |\varphi(\widetilde{v})-\varphi(\overline{u}_\Sigma)|\Delta f(\overline{x})\,(\psi\,\lambda)_{\Sigma_x}\,\rho_n(f(\overline{x})-y_d)\,d\overline{x}\,dt\,dy_d,$$

$$\overline{J_\psi} = \int_{[0,T)\times\Pi}\int_0^\infty |\varphi(\widetilde{v})-\varphi(\overline{u}_\Sigma)|\nabla f(\overline{x})\cdot\nabla_{\overline{x}}\,((\psi\,\lambda)_{\Sigma_x})\,\rho_n(f(\overline{x})-y_d)\,d\overline{x}\,dt\,dy_d,$$

$$\overline{J_{\rho_n}} = \int_{[0,T)\times\Pi}\int_0^\infty |\varphi(\widetilde{v})-\varphi(\overline{u}_\Sigma)|\,(1+|\nabla f(\overline{x})|^2)\,\rho_n'(f(\overline{x})-y_d)\,(\psi\,\lambda)_{\Sigma_x}\,d\overline{x}\,dt\,dy_d.$$

To compute the limit as n tends to $+\infty$ of the four preceding terms, first recall that $\text{trace}((\varphi(v))-\varphi(\overline{u}_\Sigma)) = 0$, and that, consequently,

$$\lim_{n\to+\infty}\overline{J_f} = 0 \quad\text{and}\quad \lim_{n\to+\infty}\overline{J_\psi} = 0.$$

Besides, we note that

$$\Delta\,\omega_{1/n}(x) = -\rho_n'(f(\overline{x})-x_d)\,(1+|\nabla f(\overline{x})|^2) + \rho_n(f(\overline{x})-x_d)\,\Delta f(\overline{x}),$$

so that, replacing y_d by x_d in $\overline{J_{\rho_n}}$, we have

$$\begin{aligned}\overline{J_{\rho_n}} &= -\int_Q |\varphi(v)-\varphi(\overline{u}_\Sigma(t,\overline{x}))|\,\Delta\,\omega_{1/n}(x)\,(\psi\,\lambda)(t,\overline{x},f(\overline{x}))\,dx\,dt+\overline{J_f}\\ &= \int_Q \nabla|\varphi(v)-\varphi(\overline{u}_\Sigma(t,\overline{x}))|\,\nabla\,\omega_{1/n}(x)\,(\psi\,\lambda)(t,\overline{x},f(\overline{x}))\,dx\,dt+\overline{\varepsilon^1_n}\,.\end{aligned}$$

Here, the quantity $\overline{\varepsilon_n^1} = \overline{J_f} + \int_Q |\varphi(v) - \varphi(\overline{u}_\Sigma(t,\overline{x}))|\, \nabla\omega_{1/n}(x)\cdot\nabla(\psi\,\lambda)_{\Sigma_x}\,dx\,dt$ tends to zero when $n\to+\infty$. Moreover,

$$\overline{I} = -\int_{\mathcal{Q}} \Phi(t,x,v,\overline{u}_\Sigma)\cdot\nabla\omega_{1/n}(x)\,(\psi\,\lambda)_{\Sigma_x}\,d\beta\,dx\,dt\ +\overline{\varepsilon_n^2}\,,$$

where $\overline{\varepsilon_n^2} = \int_{\mathcal{Q}} (\Phi(t,x,v,\overline{u}_\Sigma) - \Phi(t,\overline{x},f(\overline{x}),v,\overline{u}_\Sigma))\cdot\nabla\omega_{1/n}(x)\,(\psi\,\lambda)_{\Sigma_x} d\beta\,dx\,dt$ tends to zero when $n\to+\infty$.

Using formula (11), we get

$$\begin{aligned}&\liminf_{n\to+\infty}\ \lim_{l,m\to+\infty}\ \lim_{\varepsilon\to 0}(A+B)\\ &\qquad= -\limsup_{n\to+\infty}\int_{\mathcal{Q}} \mathcal{G}_x(t,x,v(t,x,\beta),\overline{u}_\Sigma)\cdot\nabla\omega_{1/n}(x)\,(\psi\,\lambda)_\Sigma\,dx\,dt\,d\beta\,.\end{aligned}$$

Starting from inequality (35) and taking the limit with respect to l, m, then the limit with respect to n of both sides yields

$$\int_Q\int_0^1\int_0^1 \left[|u-v|\,(\psi\lambda)_t + \mathcal{G}_x(t,x,u,v)\cdot\nabla(\psi\lambda)\right]\,d\beta\,d\alpha\,dx\,dt \tag{37}$$

$$\geq \left[\begin{array}{l} -\displaystyle\lim_{n\to+\infty}\int_Q\int_0^1 \mathcal{G}_x(t,x,v(t,x,\beta),\overline{u}_\Sigma(t,\overline{x}))\cdot\nabla\omega_{1/n}\,(\psi\,\lambda)(t,\overline{x},f(\overline{x}))\,d\beta\,dx\,dt\\ +\displaystyle\lim_{\varepsilon\to 0}\int_Q\int_0^1 \mathcal{G}_x(t,x,u,\overline{u}_\Sigma(t,\overline{x}))\cdot\nabla\omega_\varepsilon(x)\,(\psi\,\lambda)(t,\overline{x},f(\overline{x}))\,d\alpha\,dx\,dt\\ +\displaystyle\lim_{n\to+\infty}\ \lim_{l,m\to+\infty} H\end{array}\right].$$

Since $\lim_{n\to+\infty}\lim_{l,m\to+\infty} H = 0$ (see (36)), the right-hand side of (37) is an antisymmetric function in (u,v), while the left-hand side of (37) is a symmetric function of (u,v). We therefore have

$$\int_{\mathcal{Q}}\int_0^1 \left[|u-v|\,(\psi\lambda)_t + \mathcal{G}_x(t,x,u,v)\cdot\nabla(\psi\lambda)\right]\,d\beta\,d\alpha\,dx\,dt \geq 0. \tag{38}$$

Now, recall that $\lambda=\lambda_\alpha$ is an element of the partition of unity $(\lambda_\alpha)_{0\leq\alpha\leq N}$; summing the previous inequality over $\alpha\in 0,\dots,N$ yields

$$\int_{\mathcal{Q}}\int_0^1 \left[|u-v|\,\psi_t + \mathcal{G}_x(t,x,u,v)\cdot\nabla\psi\right]\,d\beta\,d\alpha\,dx\,dt \geq 0. \tag{39}$$

We define the nonnegative function ψ_0 by $\psi_0(t,x) = \psi_0(t) = (T-t)\chi_{(0,T)}(t)$, and apply (39) with ψ_0 as a test-function to get

$$\int_0^T\int_\Omega\int_0^1\int_0^1 |u(t,x,\alpha)-v(t,x,\beta)|\,d\beta\,d\alpha\ dx\,dt \leq 0.$$

Consequently, we have $u(t,x,\alpha) = v(t,x,\beta)$ for a.e. $(t,x,\alpha,\beta)\in Q\times(\,0,1)\times(\,0,1)$. Defining the function w by the formula

$$w(t,x) = \int_0^1 u(t,x,\alpha)\,d\alpha$$

and accounting for the product structure of the measurable space $Q\times(\,0,1)\times(\,0,1)$, we conclude

$$u(t,x,\alpha)\ =\ w(t,x)\ =\ v(t,x,\beta)\ \text{for a.e.}\ \ (t,x,\alpha,\beta)\in Q\times(\,0,1)^2. \qquad\square$$

4.6. Proof of Theorem 4.1 for Ω a bounded polyhedral subset. Let d be the Euclidean distance on $\mathbb{R}^d$. Denote by $(\partial\Omega_i)_{i=1,\dots,N}$ the faces of Ω, and by $\mathbf{n}_i$ the outward unit normal to Ω along $\partial\Omega_i$. For $\varepsilon > 0$ small, let B_i^ε be the subset of all $x \in \Omega$ such that $d(x, \partial\Omega_i) < \varepsilon$ and $d(x, \partial\Omega_i) < d(x, \partial\Omega_j)$ if $i \neq j$; define G_i^ε to be the largest cylinder generated by $\mathbf{n}_i$ included in B_i^ε, and set $\Delta_i^\varepsilon = B_i^\varepsilon \setminus G_i^\varepsilon$, $\Omega_\varepsilon = \Omega \setminus (\cup_{1,N} \Delta_i^\varepsilon)$, and $b^\varepsilon = \mathbb{1}_{\Omega_{\varepsilon/2}} \star \rho_{\varepsilon/4}$. We have $\text{meas}(\Omega \setminus \Omega_\varepsilon) \leq C\varepsilon^2$. If $\lambda_i \in \mathcal{C}_c^\infty(\mathbb{R}^d)$ is such that $\text{supp}(\lambda_i) \cap \partial\Omega \subset \partial\Omega_i$ and such that the orthogonal projection of $\text{supp}(\lambda_i)$ on the affine hyperplane determined by $\partial\Omega_i$ is included in $\partial\Omega_i$, then of course the whole previous proof explained in the case where Ω is $\mathcal{C}^{1,1}$ applies here (we look at a half-space), to give a result of comparison on $\text{supp}(\lambda)$. Otherwise, for such a choice of function λ_i, (38) is true. Equation (38) is also still true if $\lambda = \lambda_0$, where $\lambda_0 \in \mathcal{C}_c^\infty(\mathbb{R}^d)$ and $\text{supp}(\lambda_0) \subset \Omega$ (use Proposition 4.2). Since the function b^ε can be written as $b^\varepsilon = \sum_{i=0,N} \lambda_i$ for functions λ_i as above, we have

$$\int_{\mathcal{Q}} \int_0^1 \left[|u - v| \, (\psi b^\varepsilon)_t + \mathcal{G}_x(t, x, u, v) \cdot \nabla(\psi b^\varepsilon) \right] d\beta \, d\alpha \, dx \, dt \geq 0. \tag{40}$$

Equation (40) can be rewritten as

$$\int_{\mathcal{Q}} \int_0^1 \left[|u - v| \, \psi_t + \mathcal{G}_x(t, x, u, v) \cdot \nabla\psi \right] d\beta \, d\alpha \, dx \, dt \geq \alpha_\varepsilon,$$

where $\alpha_\varepsilon = \int_{\mathcal{Q}} \int_0^1 \mathcal{G}_x(t, x, u, v) \cdot \nabla b^\varepsilon \psi \, d\beta \, d\alpha \, dx \, dt$ tends to zero when $\varepsilon \to 0$. Indeed, we have $\nabla b^\varepsilon = 0$ on Ω_ε, so that, setting $\mathcal{R}_\varepsilon = (0, T) \times (\Omega \setminus \Omega_\varepsilon) \times (0, 1)^2$, we have

$$\begin{aligned} \alpha_\varepsilon &\leq ||\psi||_{L^\infty} ||\mathcal{G}_x(t, x, u, v)||_{L^1(\mathcal{R}_\varepsilon)} ||\nabla b^\varepsilon||_{L^\infty(\mathcal{R}_\varepsilon)} \\ &\leq ||\psi||_{L^\infty} \text{meas}(\mathcal{R}_\varepsilon)^{1/2} ||\mathcal{G}_x(t, x, u, v)||_{L^2(\mathcal{R}_\varepsilon)} || \mathbb{1}_{\Omega_{\varepsilon/2}} ||_{L^\infty(\mathcal{R}_\varepsilon)} ||\nabla \rho_{\varepsilon/4}||_{L^1(\mathcal{R}_\varepsilon)} \\ &\leq C(T, \psi) \;\; \varepsilon \cdot ||\mathcal{G}_x(t, x, u, v)||_{L^2(\mathcal{R}_\varepsilon)} \cdot \tfrac{1}{\varepsilon}, \end{aligned}$$

and we conclude by using $||\mathcal{G}_x(t, x, u, v)||_{L^2(\mathcal{R}_\varepsilon)} \to 0$ when $\varepsilon \to 0$. We thus obtain (39), from which Theorem 4.1 follows. □

5. The FV scheme.

The mesh used to discretize problem (1) has to be regular enough to ensure the consistency of the numerical fluxes, mainly because a second order problem is considered (at least when the function φ is not constant). This is specified in the following section.

5.1. Assumptions and notation.

We set d to be the Euclidean distance on $\mathbb{R}^d$ and denote by γ the $(d-1)$-Hausdorff measure on $\partial\Omega$.

Definition 5.1 (admissible mesh of Ω). *An admissible mesh of Ω consists of a set $\mathcal{T}$ of open bounded polyhedral convex subsets of Ω called control volumes, a family $\mathcal{E}$ of subsets of $\bar{\Omega}$ contained in hyperplanes of $\mathbb{R}^d$ with positive measure, and a family of points (the "centers" of control volumes) satisfying the following properties:*

(i) *The closure of the union of all control volumes is $\bar{\Omega}$.*

(ii) *For any $K \in \mathcal{T}$, there exists a subset $\mathcal{E}_K$ of $\mathcal{E}$ such that $\partial K = \bar{K} \backslash K = \cup_{\sigma \in \mathcal{E}_K} \bar{\sigma}$. Furthermore, $\mathcal{E} = \cup_{K \in \mathcal{T}} \mathcal{E}_K$.*

(iii) *For any $(K, L) \in \mathcal{T}^2$ with $K \neq L$, either the "length" (i.e., the $(d-1)$-dimensional Lebesgue measure) of $\bar{K} \cap \bar{L}$ is 0 or $\bar{K} \cap \bar{L} = \bar{\sigma}$ for some $\sigma \in \mathcal{E}$. In the latter case, we shall write $\sigma = K|L$ and $\mathcal{E}_{int} = \{\sigma \in \mathcal{E}, \exists (K, L) \in \mathcal{T}^2, \sigma = K|L\}$. For any $K \in \mathcal{T}$, we shall denote by $\mathcal{N}_K$ the set of neighbor control volumes of K, i.e., $\mathcal{N}_K = \{L \in \mathcal{T}, K|L \in \mathcal{E}_K\}$.*

(iv) *The family of points $(x_K)_{K\in\mathcal{T}}$ is such that $x_K \in K$ (for all $K \in \mathcal{T}$), and, if $\sigma = K|L$, it is assumed that the straight line (x_K, x_L) is orthogonal to σ.*

Given a control volume $K \in \mathcal{T}$, we will denote by $m(K)$ its measure and by $\mathcal{E}_{ext,K}$ the subset of the edges of K included in the boundary $\partial\Omega$. If $L \in \mathcal{N}_K$, $m(K|L)$ will denote the measure of the edge between K and L, and $T_{K|L}$ the "transmissibility" through $K|L$, defined by $T_{K|L} = \frac{m(K|L)}{d(x_K,x_L)}$. Similarly, if $\sigma \in \mathcal{E}_{ext,K}$, we will denote by $m(\sigma)$ its measure and by τ_σ the "transmissibility" through σ, defined by $\tau_\sigma = \frac{m(\sigma)}{d(x_K,\sigma)}$. One also denotes by $\mathcal{E}_{ext}$ the union of the edges included in the boundary of Ω: $\cup_{K\in\mathcal{T}}\mathcal{E}_{ext,K}$. The size of the mesh $\mathcal{T}$ is defined by

$$\text{size}(\mathcal{T}) = \max_{K\in\mathcal{T}} \text{diam}(K),$$

and we introduce the following geometrical factor, linked with the regularity of the mesh, defined by

$$\text{reg}(\mathcal{T}) = \min_{K\in\mathcal{T},\sigma\in\mathcal{E}_K} \frac{d(x_K,\sigma)}{\text{diam}(K)}.$$

Remark 5.1. Some examples of meshes satisfying these assumptions are the triangular meshes, which verify the acute angle condition (in fact this condition may be weakened to the Delaunay condition), the rectangular meshes, or the Voronoï meshes; see [EGH99] or [EGH00] for more details.

Definition 5.2 (time discretization of $(0,T)$). *A time discretization of $(0,T)$ is given by an integer value N and by an increasing sequence of real values $(t^n)_{n\in[\![0,N+1]\!]}$ with $t^0 = 0$ and $t^{N+1} = T$. The time steps are then defined by $\delta t^n = t^{n+1} - t^n$, for $n \in [\![0,N]\!]$.*

Definition 5.3 (space-time discretization of Q). *A finite volume discretization D of Q is a family $D = (\mathcal{T}, \mathcal{E}, (x_K)_{K\in\mathcal{T}}, N, (t^n)_{n\in[\![0,N]\!]})$, where $\mathcal{T}$, $\mathcal{E}$, $(x_K)_{K\in\mathcal{T}}$ is an admissible mesh of Ω according to Definition 5.1 and N, $(t^n)_{n\in[\![0,N+1]\!]}$ is a time discretization of $(0,T)$ according to Definition 5.2. For a given FV discretization D, one defines*

$$\text{size}(D) = \max(\text{size}(\mathcal{T}), (\delta t^n)_{n\in[\![0,N]\!]}) \quad \textit{and} \quad \text{reg}(D) = \text{reg}(\mathcal{T}).$$

5.2. The FV scheme. We may now define the FV discretization of (1). Let D be a FV discretization of Q according to Definition 5.3. First, the initial and boundary data are discretized by setting

$$U_K^0 = \frac{1}{m(K)} \int_K u_0(x)dx \quad \forall K \in \mathcal{T} \tag{41}$$

and

$$\bar{U}_\sigma^{n+1} = \frac{1}{\delta t^n\ m(\sigma)} \int_{t^n}^{t^{n+1}} \int_\sigma \bar{u}(t,x)d\gamma(x)dt \quad \forall\sigma \in \mathcal{E}_{ext}, \forall n \in [\![0,N]\!]. \tag{42}$$

An *implicit FV scheme* for the discretization of problem (1) is given by the following set of nonlinear equations with unknowns $U_D = (U_K^{n+1})_{K\in\mathcal{T},n\in[\![0,N]\!]}$: $\forall K \in \mathcal{T}, \forall n \in [\![0,N]\!]$,

(43)
$$\frac{U_K^{n+1} - U_K^n}{\delta t^n}\ m(K) + \sum_{\sigma\in\mathcal{E}_K} m(\sigma) F_{K,\sigma}^{n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) - \sum_{\sigma\in\mathcal{E}_K} \tau_\sigma(\varphi(U_{K_\sigma}^{n+1}) - \varphi(U_K^{n+1})) = 0,$$

where

$$U_{K_\sigma}^{n+1} = \begin{cases} U_L^{n+1} \ \textit{if } \sigma = K|L, \\ \bar{U}_\sigma^{n+1} \ \textit{if } \sigma \in \mathcal{E}_{ext}, \end{cases} \tag{44}$$

and where the function $F_{K,\sigma}^{n+1}$ is a monotonous flux consistent with the function F, which means that

- for all $v \in \mathbb{R}$, $u \mapsto F_{K,\sigma}^{n+1}(u,v)$ is a nondecreasing function and for all $u \in \mathbb{R}$, $v \to F_{K,\sigma}^{n+1}(u,v)$ is a nonincreasing function,
- $F_{K,\sigma}^{n+1}(u,v) = -F_{K,\sigma}^{n+1}(v,u)$ for all $(u,v) \in \mathbb{R}^2$,
- $F_{K,\sigma}^{n+1}$ is M-Lipschitz continuous with respect to each variable,
- $F_{K,\sigma}^{n+1}(s,s) = \frac{1}{\delta t_n}\frac{1}{m(\sigma)}\int_{t^n}^{t^{n+1}}\int_\sigma F(x,t,s)\cdot \mathbf{n}_{K,\sigma} d\gamma(x)\,dt$.

The Godunov scheme and the splitting flux scheme of Osher may be the most common examples of schemes with monotone fluxes.

We call an *approximate solution* the piecewise constant function u_D defined a.e. on Q by

$$u_D(t,x) = U_K^{n+1}\,, \quad t \in (t_n, t_{n+1}),\ x \in K. \tag{45}$$

5.3. Monotony of the scheme and direct consequences. As already said in the introduction, it is a necessity to select a physically admissible solution by means of the entropy inequalities. The schemes with monotonous fluxes are well known to add numerical viscosity to the equations. They are L^∞ stable, and they are monotonous so that they respect discrete entropy inequalities. In other words, continuous entropy inequalities have their discrete analogue, and they are respected by any solution of (41)–(44). This is summarized in the following proposition.

PROPOSITION 5.1 (monotony). *Assume hypotheses* (H1), (H2)*,* (H3)*, and* (H4)*. Then there exists a unique solution to the scheme. Moreover, this solution satisfies the following maximum principle and discrete entropy inequalities:* $\forall K \in \mathcal{T}, \forall n \in [\![0,N]\!]$*,*

$$A \le U_K^{n+1} \le B, \tag{46}$$

$$\begin{aligned} \frac{\eta_\kappa^\pm(U_K^{n+1}) - \eta_\kappa^\pm(U_K^n)}{\delta t^n} m(K) + \sum_{\sigma\in\mathcal{E}_K} m(\sigma)\Phi_{K,\sigma,\kappa}^{\pm,n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) \\ - \sum_{\sigma\in\mathcal{E}_K} \tau_\sigma\big(\eta_\kappa^\pm(\varphi(U_{K_\sigma}^{n+1})) - \eta_\kappa^\pm(\varphi(U_K^{n+1}))\big) \le 0, \end{aligned} \tag{47}$$

where $\Phi_{K,\sigma,\kappa}^{+,n+1}$ *and* $\Phi_{K,\sigma,\kappa}^{-,n+1}$ *are the numerical entropy-fluxes defined by*

$$\begin{aligned} \Phi_{K,\sigma,\kappa}^{+,n+1}(u,v) &= F_{K,\sigma}^{n+1}(u\top\kappa, v\top\kappa) - F_{K,\sigma}^{n+1}(\kappa,\kappa) \quad \textit{and} \\ \Phi_{K,\sigma,\kappa}^{-,n+1}(u,v) &= F_{K,\sigma}^{n+1}(\kappa,\kappa) - F_{K,\sigma}^{n+1}(u\bot\kappa, v\bot\kappa). \end{aligned} \tag{48}$$

Proof. We give only some elements of the proof of this proposition because it consists of rewriting the proofs of three lemmas that can be found in [EGHM02] (Lemmas 3.1, 3.3, and 3.4 there) in the case where the convective flux $\mathbf{q}(x,t)f(u)$ is replaced by a more general flux $F(x,t,u)$ and the Kruzhkov entropies are replaced by the semi-Kruzhkov entropies as in the work of Vovelle [Vov02].

We follow the classical framework of implicit FV schemes for conservation laws (see [EGH00]). The function U_D is defined in an implicit way, so we first show, using the monotony of the scheme, that if a function U_D is a solution to the scheme, then it satisfies the discrete inequalities (47). Then we derive the maximum principle (46) that provides a result of existence by use of the Leray–Schauder theorem. Uniqueness of U_D is proved by using a method analogous to the one used to prove the discrete entropy inequalities. □

5.4. A priori estimates. The inequalities derived from the properties of monotony and local conservation are L^∞ and L^1 estimates. We will prove now L^2 estimates. We introduce a discretization $\bar{U}_D = (\bar{U}_K^{n+1})_{\{K\in\mathcal{T}, n\in[\![0,N]\!]\}}$ of $\bar{u}$ defined by

$$\bar{U}_K^{n+1} = \frac{1}{\delta t_n}\frac{1}{m(K)}\int_{t^n}^{t^{n+1}}\int_K \bar{u}\,dx\,dt \quad \forall K\in\mathcal{T},\ \forall n\in[\![0,N]\!].$$

Proposition 5.2 ($L^2(0,T,H^1(\Omega))$ and weak BV estimate). *Assume hypotheses* (H1), (H2), (H3), (H4), *and* (H5). *Let u_D be the approximate solution defined by* (41)–(44), *and assume that $reg(D)\geq\xi$, where $\xi>0$. Then there exists a constant C depending only on ξ, T, Ω, $Lip(\varphi)$, M, $\bar{u}$, A, B such that*

$$\big(\mathcal{N}_D(\zeta(u_D))\big)^2 = \sum_{n=0}^{N}\delta t_n\sum_{K\in\mathcal{T}}\left(\frac{1}{2}\sum_{\sigma\in\mathcal{E}_{int,K}}\tau_\sigma(\zeta(U_K^{n+1})-\zeta(U_{K_\sigma}^{n+1}))^2 + \sum_{\sigma\in\mathcal{E}_{ext,K}}\tau_\sigma(\zeta(U_K^{n+1})-\zeta(U_{K_\sigma}^{n+1}))^2\right)\leq C$$

and

$$\sum_{n=0}^{N}\delta t_n\sum_{K\in\mathcal{T}}\frac{1}{2}\sum_{\sigma\in\mathcal{E}_{int,K}}m(\sigma)\max_{U_K^{n+1}\leq c\leq d\leq U_{K_\sigma}^{n+1}}\big((F_{K,\sigma}^{n+1}(d,c)-F_{K,\sigma}^{n+1}(d,d))^2 + (F_{K,\sigma}^{n+1}(d,c)-F_{K,\sigma}^{n+1}(c,c))^2\big)\leq C. \tag{49}$$

Remark 5.2. The inequality (49) is called the "weak BV inequality." See [EGH00], [CGH93], or [CH99].

Proof. As for Proposition 5.1, the proof has already been done in a simpler case in [EGHM02] (Proposition 3.1). The details of the proof differ only by some arguments that can be found in [Vov02].

These estimates are discrete energy estimates. They are obtained by multiplying (41)–(44) by $\delta t_n(U_K^{n+1}-\bar{U}_K^{n+1})$ and summing over $K\in\mathcal{T}$ and $n\in[\![0,N]\!]$. In the proof, we separate terms that contain only U_D from terms containing U_D and $\bar{U}_D$. Then we use the Cauchy–Schwarz inequality and regularity hypotheses (H5) on $\bar{u}$ to control the second type of terms. To get a bound on $\mathcal{N}_D(\bar{U}_D)$, which is a discrete $L^2(0,T,H^1)$-norm for $\bar{U}_D$, we use the following inequality proved in [EGH99]:

$$\mathcal{N}_D(\bar{u})\leq C(reg(D))\|\nabla\bar{u}\|_{L^2(Q)}.$$

This is a consequence of the local conservativity of the scheme combined with the consistency of the numerical fluxes.

The last ingredient is the assumption $\mathrm{div}_x(F(x,t,u))=0$, which ensures that the boundary terms in the discrete integrations-by-parts concerning the hyperbolic terms can be controlled. The constant C depends on ξ, $m(\Omega)$, T, B, A, $Lip(F_{K,\sigma}^{n+1})$, $\|\bar{u}_t\|_{L^1(Q)}$, and on $\|\nabla\bar{u}\|_{L^2(Q)}$. □

5.5. Continuous entropy inequalities. From the discrete entropy inequalities we deduce continuous approximate entropy inequalities. The following theorem is central in the proof of the convergence of the scheme.

THEOREM 5.1 (continuous approximate entropy inequalities). *Assume hypotheses* (H1), (H2), (H3), (H4), *and* (H5). *Let D be an admissible discretization of Q, and let u_D be the corresponding approximate solution defined above. Then u_D satisfies the following approximate entropy inequalities: for all $\kappa \in \mathbb{R}$, for all $\psi \in \mathcal{C}^\infty(\mathbb{R}_+ \times \mathbb{R}^d)$ such that $\psi \geq 0$ and $(\varphi(\bar{u}) - \varphi(\kappa))^{\pm}\,\psi = 0$ a.e. on Σ,*

$$\int_Q \eta_\kappa^\pm(u_D)\psi_t + \Phi_\kappa^\pm(t,x,u_D)\cdot\nabla\psi + \eta_{\varphi(\kappa)}^\pm(\varphi(u_D))\Delta\psi\, dxdt - \int_\Sigma \eta_{\varphi(\kappa)}^\pm(\varphi(\bar{u}))\nabla\psi\cdot\mathbf{n}d\gamma(x)dt$$

$$+\int_\Omega \eta_\kappa^\pm(u_0)\psi(0)dx + M\int_\Sigma \eta_\kappa^\pm(\bar{u})\psi\, d\gamma(x)dt \geq -\mathcal{E}_D^\pm(\psi). \tag{50}$$

Also assume that a uniform CFL condition $\delta t_n \leq C\mathrm{size}(\mathcal{T})$ for all n holds true (with a CFL number C that can be as large as desired). Then, for a given ψ, $\mathcal{E}_D^\pm(\psi)$ tends to zero when the size of the discretization tends to zero.

Proof. The proof of Theorem 5.1 is quite similar to the proof of Theorem 5.1 in [EGHM02], except for the boundary terms, which require extra care. We will therefore stress the analysis of these terms and make reference to [EGHM02] when needed. Of course, we can also limit ourselves to giving the proof of (50) when the nonnegative Kruzhkov entropy pairs are under consideration.

Let $\kappa \in \mathbb{R}$, and let $\psi \in \mathcal{C}^\infty(\mathbb{R}_+ \times \mathbb{R}^d)$ be a nonnegative function satisfying $(\varphi(\bar{u}) - \varphi(\kappa))^+\psi = 0$ a.e. on Σ. We define discrete values of ψ with respect to the mesh as

$$\Psi_K^0 = \psi(0,x_K) \quad \forall K \in \mathcal{T},$$
$$\Psi_K^{n+1} = \frac{1}{\delta t_n}\int_{t^n}^{t^{n+1}} \psi(t,x_K)dt \quad \forall K \in \mathcal{T}, \forall n \in [\![0,N]\!],$$
$$\psi_\sigma^{n+1} = \frac{1}{\delta t_n}\int_{t^n}^{t^{n+1}} \psi(t,x_\sigma)dt \quad \forall \sigma \in \mathcal{E}_{ext}, \forall n \in [\![0,N]\!]$$

and set $\Psi_{K,\sigma}^{n+1} = \Psi_L^{n+1}$ if $\sigma = K|L$ and $\Psi_{K,\sigma}^{n+1} = \psi_\sigma^{n+1}$ if $\sigma \in \mathcal{E}_{ext,K}$.

The definition of the numerical flux $\Phi_{K,\sigma,\kappa}^{+,n+1}$ (see (48)) ensures that it is a conservative flux, consistent with the function Φ_κ^+. Therefore, we have

$$\sum_{\sigma\in\mathcal{E}_K} m(\sigma)\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_K^{n+1}) = 0 \quad \forall K \in \mathcal{T}, n \in [\![0,N]\!],$$

and the discrete entropy inequality (47) can then be rewritten as

$$\frac{\eta_\kappa^+(U_K^{n+1}) - \eta_\kappa^+(U_K^n)}{\delta t^n}m(K) + \sum_{\sigma\in\mathcal{E}_K} m(\sigma)(\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) - \Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_K^{n+1}))$$
$$- \sum_{\sigma\in\mathcal{E}_K} \tau_\sigma\big(\eta_{\varphi(\kappa)}^+(\varphi(U_{K_\sigma}^{n+1})) - \eta_{\varphi(\kappa)}^+(\varphi(U_K^{n+1}))\big) \leq 0. \tag{51}$$

Multiplying (51) by $\delta t_n \Psi_K^{n+1}$ and summing over $K \in \mathcal{T}$ and $n \in [\![0,N]\!]$ yields

$$A1 + A2 + A3 \leq 0,$$

where

$$A1 = \sum_{n=0}^{N} \sum_{K\in\mathcal{T}} m(K)(\eta_\kappa^+(U_K^{n+1}) - \eta_\kappa^+(U_K^n))\Psi_K^{n+1}\,,$$

and, summing over the edges, $A2 = A2\text{int} + A2\text{ext}$, with

$$A2\text{int} = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \frac{1}{2} \sum_{\sigma\in\mathcal{E}_{int,K}} m(\sigma)\big(\Psi_K^{n+1}(\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) - \Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_K^{n+1})) \\ - \Psi_{K,\sigma}^{n+1}(\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) - \Phi_{K,\sigma,\kappa}^{+,n+1}(U_{K_\sigma}^{n+1}, U_{K_\sigma}^{n+1}))\big)$$

and

$$A2\text{ext} = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_{ext,K}} m(\sigma)\Psi_K^{n+1}\big(\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_{K_\sigma}^{n+1}) - \Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1}, U_K^{n+1})\big).$$

Similarly, $A3$ admits the decomposition $A3 = A3\text{int} + A3\text{ext}$, with

$$A3\text{int} = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \frac{1}{2} \sum_{\sigma\in\mathcal{E}_{int,K}} \tau_\sigma\big(\eta_{\varphi(\kappa)}^+(\varphi(U_K^{n+1})) - \eta_{\varphi(\kappa)}^+(\varphi(U_{K_\sigma}^{n+1}))\big)(\Psi_K^{n+1} - \Psi_{K,\sigma}^{n+1})$$

and

$$A3\text{ext} = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}_{ext,K}} \tau_\sigma\big(\eta_{\varphi(\kappa)}^+(\varphi(U_K^{n+1})) - \eta_{\varphi(\kappa)}^+(\varphi(U_{K_\sigma}^{n+1}))\big)\Psi_K^{n+1}\,.$$

Now, set

$$\begin{aligned} I1 &= -\int_Q \eta_\kappa^+(u_D)\psi_t\,dx\,dt - \int_\Omega \eta_\kappa^+(u_0)\psi(0,x)\,dx, \\ I2 &= -\int_Q \Phi_\kappa^+(t,x,u_D)\cdot\nabla\psi\,dx\,dt - M\int_\Sigma \eta_\kappa^+(\bar{u})\psi\,d\gamma(x)dt, \\ I3 &= -\int_Q \eta_{\varphi(\kappa)}^+(\varphi(u_D))\Delta\psi\,dx\,dt + \int_\Sigma \eta_{\varphi(\kappa)}^+(\varphi(\bar{u}))\nabla\psi\cdot\mathbf{n}\,d\gamma(x)\,dt\,. \end{aligned}$$

We aim at proving the estimate $I1 + I2 + I3 \leq \mathcal{E}_D^+(\psi)$ and, to that purpose, compare $I1$ to $A1$, $I2$ to $A2$, and $I3$ to $A3$, respectively.

A discrete integration by parts leads to $|I1 - A1| \leq \mathcal{E}_{1,D}(\psi)$, with $\mathcal{E}_{1,D}(\psi) \to 0$ as $\text{size}(D) \to 0$ (see [EGHM02]).

Using integration by parts in $I2$ and the fact that u_D is piecewise constant, we obtain

$$I2 = I2\text{int} + I2\text{ext},$$

where $I2$ext is the boundary term and $I2$int gathers the sums on the internal edges. Precisely, we have

$$I2\text{int} = -\sum_{n=0}^{N} \sum_{K\in\mathcal{T}} \frac{1}{2} \sum_{\sigma\in\mathcal{E}_{int,K}} \left(\int_{t^n}^{t^{n+1}}\int_\sigma \Phi_\kappa^+(t,x,U_K^{n+1})\cdot\mathbf{n}_{K,\sigma}\psi\,d\gamma(x)\,dt \right. \\ \left. -\int_{t^n}^{t^{n+1}}\int_\sigma \Phi_\kappa^+(t,x,U_{K_\sigma}^{n+1})\cdot\mathbf{n}_{K,\sigma}\psi\,d\gamma(x)\,dt\right)$$

and

$$I2\text{ext} = -\sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}_{ext,K}}\int_{t^n}^{t^{n+1}}\int_{\sigma}\Phi_{\kappa}^{+}(t,x,U_K^{n+1})\cdot\mathbf{n}_{K,\sigma}\psi d\gamma(x)dt - M\int_{\Sigma}\eta_{\kappa}^{+}(\bar{u})\psi d\gamma(x)dt.$$

As in [EGHM02], we prove $|I2\text{int} - A2\text{int}| \le \mathcal{E}_{2,D}^{\text{int}}(\psi)$, with $\mathcal{E}_{2,D}^{\text{int}}(\psi) \to 0$ as $\text{size}(D) \to 0$.

The comparison of $I2$ext with $A2$ext involves a term corresponding to the consistency error, and three terms related to the approximation of the boundary data:

$$I2\text{ext} - A2\text{ext} \le \mathcal{E}_{2,D}^{c1,\text{ext}}(\psi) + \mathcal{E}_{2,D}^{b1,\text{ext}}(\psi) + \mathcal{E}_{2,D}^{b2,\text{ext}}(\psi) - T_{2,D}^{b2,\text{ext}}(\psi),$$

where

$$\mathcal{E}_{2,D}^{c1,\text{ext}}(\psi) = \sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}\text{ext}\kappa}\left|\int_{t^n}^{t^{n+1}}\int_{\sigma}(\Psi_K^{n+1}-\psi)\Phi_{\kappa}^{+}(\cdot,\cdot,U_K^{n+1})\cdot\mathbf{n}_{K,\sigma}\,d\gamma(x)\,dt\right|,$$

$$\mathcal{E}_{2,D}^{b1,\text{ext}}(\psi) = \sum_{n=0}^{N}\delta t_n\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}\text{ext}\kappa} m(\sigma)|(\Psi_K^{n+1}-\psi_{\sigma}^{n+1})\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1},U_{K_\sigma}^{n+1})|,$$

and

$$\mathcal{E}_{2,D}^{b2,\text{ext}}(\psi) = M\sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}\text{ext}\kappa}\Bigg|\int_{t^n}^{t^{n+1}}\int_{\sigma}(\bar{u}-\kappa)^{+}\psi\,d\gamma(x)\,dt$$
$$-\,\delta t_n\,m(\sigma)(U_{K_\sigma}^{n+1}-\kappa)^{+}\psi_{\sigma}^{n+1}\Bigg|$$

are three terms converging to zero when size$(D) \to 0$ and

$$T_{2,D}^{b2,\text{ext}}(\psi) = \sum_{n=0}^{N}\delta t_n\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}\text{ext}\kappa} m(\sigma)\psi_{\sigma}^{n+1}\left(\Phi_{K,\sigma,\kappa}^{+,n+1}(U_K^{n+1},U_{K_\sigma}^{n+1}) + M(U_{K_\sigma}^{n+1}-\kappa)^{+}\right).$$

From the definition of $\Phi_{K,\sigma,\kappa}^{+,n+1}$ (see (48)) and from the monotony of the scheme,

$$\Phi_{K,\sigma,\kappa}^{+,n+1}(a,b) = F_{K,\sigma}^{n+1}(a\top\kappa, b\top\kappa) - F_{K,\sigma}^{n+1}(\kappa,\kappa) \ge -Lip(F_{K,\sigma}^{n+1})(b-\kappa)^{+}$$

follows, and this entails $T_{2,D}^{b2,\text{ext}}(\psi) \ge 0$.

Now, to compare $I3$ to $A3$ we make the distinction between the different contributions of the terms (inside and on the boundary of Ω). Indeed, since the approximate solution u_D is piecewise constant, the term $I3$ reads as $I3 = I3\text{int} + I3\text{ext}$, where

$$I3\text{int} = \sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\frac{1}{2}\sum_{\sigma\in\mathcal{E}\text{int}\kappa}(\eta_{\varphi(\kappa)}^{+}(\varphi(U_{K_\sigma}^{n+1})) - \eta_{\varphi(\kappa)}^{+}(\varphi(U_K^{n+1})))\int_{t^n}^{t^{n+1}}\int_{\sigma}\nabla\psi\cdot\mathbf{n}_{K,\sigma}\,d\gamma(x)\,dt$$

and

$$I3\text{ext} = \sum_{n=0}^{N}\sum_{K\in\mathcal{T}}\sum_{\sigma\in\mathcal{E}\text{ext}\kappa}\int_{t^n}^{t^{n+1}}\int_{\sigma}(\eta_{\varphi(\kappa)}^{+}(\varphi(\bar{u})) - \eta_{\varphi(\kappa)}^{+}(\varphi(U_K^{n+1})))\nabla\psi\cdot\mathbf{n}_{K,\sigma}\,d\gamma(x)\,dt.$$

A consistency error term controls the proximity of $A3\text{int}$ to $I3\text{int}$:

$$|I3\text{int} - A3\text{int}| \leq \mathcal{E}_{3,D}^{c,\text{int}}(\psi),$$

with $\mathcal{E}_{3,D}^{c,\text{int}}(\psi) \to 0$ when size$(D) \to 0$ [EGHM02].

In order to compare $I3\text{ext}$ and $A3\text{ext}$, rearrange the term $I3\text{ext}$, up to consistency or approximation errors, to get

$$I3\text{ext} \leq \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}\text{ext}\kappa} \tau_\sigma \left(\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) - \eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_K))\right)(\Psi^{n+1}_{K,\sigma} - \Psi^{n+1}_K) \\ + \mathcal{E}_{3,D}^{c,\text{ext}}(\psi) + \mathcal{E}_{3,D}^{b1,\text{ext}}(\psi),$$

where

$$\mathcal{E}_{3,D}^{c,\text{ext}}(\psi) \\ = \sum_{n=0}^{N} \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}\text{ext}\kappa} 2 \max_{u\in[A,B]} \eta^+_{\varphi(\kappa)}(\varphi(u)) \left| \int_{t^n}^{t^{n+1}} \int_\sigma \left(\nabla\psi\cdot\mathbf{n} - \frac{\psi^{n+1}_\sigma - \Psi^{n+1}_K}{d_K,\sigma}\right) d\gamma(x)\, dt \right|,$$

$$\mathcal{E}_{3,D}^{b1,\text{ext}}(\psi) = \sum_{n=0}^{N} \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}\text{ext}\kappa} \int_{t^n}^{t^{n+1}} \int_\sigma \left|\varphi(\bar{u}) - \varphi(\bar{U}^{n+1}_\sigma)\right| \left|\nabla\psi\cdot\mathbf{n}\right| d\gamma(x)\, dt.$$

Then we have

$$I3\text{ext} - A3\text{ext} = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}\text{ext}\kappa} \tau_\sigma(\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) - \eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_K)))\Psi^{n+1}_{K,\sigma} \\ + \mathcal{E}_{3,D}^{c,\text{ext}}(\psi) + \mathcal{E}_{3,D}^{b1,\text{ext}}(\psi)\,.$$

Now, either $\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) = 0$, and in that case

$$(\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) - \eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_K))\Psi^{n+1}_{K,\sigma}) \leq 0,$$

or $\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) > 0$. In the latter case, the condition $(\varphi(\bar{u}) - \varphi(\kappa))^+\,\psi = 0$ a.e. on Σ ensures that there exists $(t,x) \in [t^n, t^{n+1}] \times \sigma$ such that $\psi(t,x) = 0$. Consequently, we have

$$\Psi^{n+1}_{K,\sigma} \leq Lip(\psi)(\delta t_n + diam(\sigma))\,.$$

This estimate, combined with the inequality

$$\eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_{K_\sigma})) - \eta^+_{\varphi(\kappa)}(\varphi(U^{n+1}_K)) \leq (\eta^+_{\varphi(\kappa)})'(\varphi(\bar{U}^{n+1}_\sigma))(\varphi(\bar{U}^{n+1}_\sigma) - \varphi(U^{n+1}_K)),$$

which is consequence of the convexity of the function $\eta^+_{\varphi(\kappa)}$, leads to

$$I3\text{ext} - A3\text{ext} \leq \mathcal{E}_{3,D}^{b2,\text{ext}}(\psi) + \mathcal{E}_{3,D}^{c,\text{ext}}(\psi) + \mathcal{E}_{3,D}^{b1,\text{ext}}(\psi),$$

where

$$\mathcal{E}_{3,D}^{b2,\text{ext}}(\psi) = \sum_{n=0}^{N} \delta t_n \sum_{K\in\mathcal{T}} \sum_{\sigma\in\mathcal{E}\text{ext}\kappa} \tau_\sigma Lip(\psi)(\delta t_n + diam(\sigma))|\varphi(\bar{U}^{n+1}_\sigma) - \varphi(U^{n+1}_K)|\,.$$

Using the Cauchy–Schwarz inequality, together with the $L^2(0,T;H_0^1(\Omega))$ estimate of Proposition 5.2 and the inequality $\varphi(a)-\varphi(b) \le \sqrt{Lip(\varphi)}(\zeta(a)-\zeta(b))$, yields

$$\mathcal{E}_{3,D}^{b2,\mathrm{ext}}(\psi) \le C\sum_{n=0}^{N}\delta t_n \sum_{K\in\mathcal{T}}\ \sum_{\sigma\in\mathcal{E}\mathrm{ext}\kappa} \tau_\sigma(\delta t_n + diam(\sigma))^2 \,.$$

Therefore, a simple way to ascertain that $\mathcal{E}_{3,D}^{b2,\mathrm{ext}}(\psi)$ converges to zero is to suppose a uniform CFL condition such as $\delta t_n \le C\mathrm{size}(\mathcal{T})$ for all n (where the CFL number C can be as large as desired). Then we conclude the proof of Theorem 5.1 by defining $\mathcal{E}_D^+(\psi)$ as the sum of the errors $\mathcal{E}_{1,D}(\psi)$, $\mathcal{E}_{2,D}^{\mathrm{int}}(\psi)$, $\mathcal{E}_{2,D}^{c1,\mathrm{ext}}(\psi)$, $\mathcal{E}_{2,D}^{b1,\mathrm{ext}}(\psi)$, $\mathcal{E}_{2,D}^{b2,\mathrm{ext}}(\psi)$, $\mathcal{E}_{3,D}^{c,\mathrm{int}}(\psi)$, $\mathcal{E}_{3,D}^{c,\mathrm{ext}}(\psi)$, $\mathcal{E}_{3,D}^{b1,\mathrm{ext}}(\psi)$, and $\mathcal{E}_{3,D}^{b2,\mathrm{ext}}(\psi)$. □

5.6. Convergence of the scheme. Let D_n be a sequence of discretizations, such that size(D_n) tends to zero. We wish to prove the convergence of u_{D_n} to an entropy solution of problem (1). For that purpose, in view of the uniqueness Theorem 4.1, it suffices to show that, up to a subsequence, u_{D_n} tends in the nonlinear weak-$\star$ sense to an entropy process solution of (1). We obtain compactness properties using estimates on u_{D_n} derived from discrete estimates on U_{D_n}, then pass to the limit in inequality (50).

5.6.1. Nonlinear weak-$\star$ compactness. The maximum principle ensures that (u_{D_n}) is bounded in $L^\infty(Q)$. Consequently, there exist $u \in L^\infty(Q\times(0,1))$ such that, up to a subsequence, u_{D_n} tends to u in the nonlinear weak-$\star$ sense.

5.6.2. Compactness in $L^2(Q)$. From discrete estimates obtained in Proposition 5.2 we easily deduce (see, e.g., [EGH00]) the following inequalities on $z_D = \zeta(u_D)-\zeta(\bar u_D)$.

PROPOSITION 5.3 (space translation estimates). *Assume hypotheses* (H1), (H2), (H3), (H4), *and* (H5). *There exists a constant C_1 such that*

$$\forall y \in \mathbb{R}^d, \quad \int_0^T\!\!\int_{\Omega_y} (z_D(t,x+y)-z_D(t,x))^2 dxdt \le C_1|y|(|y|+\mathrm{size}(\mathcal{T})),$$

where $\Omega_y = \{x\in\Omega, [x,x+y]\subset\Omega\}$.

The hypothesis (H5) includes the assumption $\bar u_t \in L^1(Q)$, while the discrete evolution equation (43) relates the discrete time derivative of u_D to its discrete space derivative. Therefore the following time translation estimate on z_D is available.

PROPOSITION 5.4 (time translation estimates). *Assume hypotheses* (H1), (H2), (H3), (H4), *and* (H5). *There exists a constant C_2 such that*

$$\forall s>0, \quad \int_0^{T-s}\int_\Omega (z_D(t+s,x)-z_D(t,x))^2 dxdt \le C_2\, s.$$

Since the function z_D vanishes on Σ, it can be extended by zero out of Q. Then using the Fréchet–Kolmogorov theorem (see, e.g., [Bre83]), we get the existence of a function $z \in L^2(0,T,H^1(\Omega))$ such that, up to a subsequence, $z_{D_n} \to z$ in $L^2(Q)$. Besides, since $z_D = \zeta(u_D)-\zeta(\bar u_D)$ and $\zeta(\bar u_D)$ converges to $\zeta(\bar u)$ in $L^2(Q)$, we get the convergence of $\zeta(u_{D_n})$ in $L^2(Q)$ (to $\zeta(\bar u)+z$). On the other hand, the nonlinear weak-$\star$ convergence of (u_{D_n}) shows that $\zeta(u_{D_n})$ converges also to $\zeta(u)$ weakly in $L^\infty(Q)$, so that $\zeta(\bar u)+z=\zeta(u)$. In particular, $\zeta(u)$ does not depend on the last argument α, and the trace of $\zeta(u)$ on Σ is $\zeta(\bar u)$. See [EGHM02] for more details on this step of the proof.

5.6.3. Conclusion. It remains to pass to the limit in the continuous entropy inequalities to prove that u is an entropy process solution. The uniqueness Theorem 4.1 proves that u does not depend on α and is the unique entropy weak solution of problem (1). Besides, the whole sequence u_{D_n} is convergent (u is the unique possible limit), and by definition of the nonlinear weak-$\star$ convergence, $(u_{D_n})^2$ also converges weakly to $(u)^2$ so that u_{D_n} converges to u in $L^2(Q)$ (strong), and in all $L^p(Q)$, for $1 \leq p < +\infty$. Therefore, we have proved the following theorem.

THEOREM 5.2. *Let D_n be a sequence of discretizations, such that size(D_n) tends to zero. Assume hypotheses* (H1)*,* (H2)*,* (H3)*,* (H4)*,* (H5)*, and* (H6) *(or* (H6bis)*). Then, for every $1 \leq p < +\infty$, (u_{D_n}) converges to the unique entropy solution of problem* (1) *in $L^p(Q)$.*

Acknowledgments. We warmly thank R. Eymard, M. Ohlberger, A. Porretta, and T. Gallouët for wise advice and fruitful discussions.

ASYMPTOTICALLY EXACT A POSTERIORI ERROR ESTIMATORS, PART I: GRIDS WITH SUPERCONVERGENCE*

RANDOLPH E. BANK† AND JINCHAO XU‡

Abstract. In Part I of this work, we develop superconvergence estimates for piecewise linear finite element approximations on quasi-uniform triangular meshes where most pairs of triangles sharing a common edge form approximate parallelograms. In particular, we first show a superconvergence of the gradient of the finite element solution u_h and to the gradient of the interpolant u_I. We then analyze a postprocessing gradient recovery scheme, showing that $Q_h \nabla u_h$ is a superconvergent approximation to ∇u. Here Q_h is the global L^2 projection. In Part II, we analyze a superconvergent gradient recovery scheme for general unstructured, shape regular triangulations. This is the foundation for an a posteriori error estimate and local error indicators.

Key words. superconvergence, gradient recovery

1. Introduction.

The study of superconvergence and a posteriori error estimates has been an area of active research; see the monographs by Verfürth [17], Chen and Huang [8], Wahlbin [18], Lin and Yan [16], and Babuška and Strouboulis [3] and a recent article by Lakhany, Marek, and Whiteman [13] for overviews of the field. In this two-part work we study some new superconvergence results. In Part I, we develop some superconvergence results for finite element approximations of a general class of elliptic partial differential equations (PDEs), based mainly on the geometry of the underlying triangular mesh. In Part II, we develop a gradient recovery technique that can force superconvergence on general shape regular meshes. Patch recovery techniques have been studied by Zienkiewicz and Zhu and this subject has itself evolved into an active subfield of research [25, 14, 23, 24, 9, 22]. Although our algorithm in some respects resembles this and other similar schemes [12, 19, 4, 6, 2, 10], it draws much of its motivation from multilevel iterative methods.

Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with Lipschitz boundary $\partial\Omega$. For simplicity of exposition, we assume that Ω is a polygon. We assume that Ω is partitioned by a shape regular triangulation $\mathcal{T}_h$ of mesh size $h \in (0,1)$. Let $\mathcal{V}_h \subset H^1(\Omega)$ be the corresponding continuous piecewise linear finite element space associated with this triangulation $\mathcal{T}_h$, and $u_h \in \mathcal{V}_h$ be a finite element approximation to a second order elliptic boundary value problem.

Our development has three main steps. In the first step, we prove a superconvergence result for $|u_h - u_I|_{1,\Omega}$, where u_I is the piecewise linear interpolant for u. In

particular, we show in Theorem 3.1 that

$$|u_h - u_I|_{1,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{1.1}$$

Estimate (1.1) holds on quasi-uniform meshes, where an $O(h^2)$ approximate parallelogram property is satisfied for pairs of adjacent triangles in most parts of Ω except for a region of size $O(h^{2\sigma})$; see section 2 for details.

The estimate (1.1) is well known in the literature for the special case $\sigma = \infty$; namely, the $O(h^2)$ approximate parallelogram property is satisfied for all pairs of adjacent triangles, and it is also known for cases when the $O(h^2)$ approximate parallelogram property is satisfied except for triangles along a few lines (see Xu [20] and Lin and Xu [15]) or triangles along the domain boundary (see Lin and Yan [16], Hlaváček and Křížek [11]). Lakhany, Marek, and Whiteman [13] consider a less restrictive $O(h^{1+\alpha})$ approximate parallelogram property. Our new estimate (1.1) is a significant generalization of these known results. First, our analysis is based on local identities for each element that simplify existing techniques. For example, our result can be extended in a straightforward fashion to the mesh in which an $O(h^{1+\alpha})$ (instead of $O(h^2)$) approximate parallelogram property holds for most pairs of triangles (see [13]). Second, the assumptions that we make are weaker than existing ones and should hold for many practical grids for some $\sigma > 0$, although in some cases σ could be very small.

One important case that our theory does not cover in this paper is locally refined grids. Lakhany, Marek, and Whiteman [13] have some results on this topic for piecewise uniform grids (see also Lin and Xu [15]). Because of the local nature of our analysis, our technique can be extended to this type of grid. We will report this type of extension in future work.

Superconvergence results typically depend on delicate estimates involving cancellation of the lowest order terms in some asymptotic expansion of the local error. When one derives elementwise expressions using continuous finite element spaces, often one encounters boundary integrals involving the normal component of the gradient of the test function. Thus, although one can determine that some cancellation takes place between certain error local components, it is difficult to combine elementwise statements because the normal components of the gradient of $v_h \in \mathcal{V}_h$ are discontinuous. On the other hand, *tangential* components of ∇v_h along element edges are continuous. Thus our approach is to derive some expressions for the element error that involve only the tangential derivative of the test function on the element boundary. The key identity of this type is Lemma 2.3.

We also note that Lemma 2.3 is an identity rather than an estimate. Thus global versions of this identity give exact characterizations of the error for arbitrary triangulations. In effect, one can see exactly the cancellations that might occur even on completely unstructured meshes. The $O(h^2)$ approximate parallelogram property can be viewed in this context as one set of sufficient conditions for obtaining superconvergent bounds for those terms.

The techniques used in our analysis are related to but much more refined than many existing superconvergence techniques in the literature such as those summarized in [8, 16]. For example, the identity in Lemma 2.3 may be compared with the integral identities for rectangular elements [16]. In fact it was not known how the integral identities for rectangular elements in [16] could be generalized to triangular elements. Lemma 2.3 offers clues for such generalizations, and more work can obviously be done in this direction.

The second major component of our analysis is a superconvergent approximation to ∇u. This approximation is generated by a gradient recovery procedure. In particular, in Theorem 4.2 we show

$$\|\nabla u - Q_h \nabla u_h\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}, \tag{1.2}$$

where Q_h is the L^2 projection. When the mesh does not satisfy the $O(h^2)$ parallelogram property or σ becomes very close to zero, then the superconvergence demonstrated in (1.2) will be diminished. Intuitively, it appears that this is due mainly to high frequency errors introduced by the small nonuniformities of the mesh. Preferentially attenuating high frequency errors in mesh functions is of course a widely studied problem in multilevel iterative methods. Our proposal here is to apply these ideas in the present context. Thus, to enhance the superconvergence effect on general shape regular meshes, we compute $S^m Q_h \nabla u_h$, where S is an appropriate multigrid-like smoothing operator. In Part II of this manuscript [7], we analyze this procedure and prove superconvergence estimates somewhat like (1.2) for $\|u - S^m Q_h \nabla u_h\|_{0,\Omega}$.

In the third major component of our analysis, we use the recovered gradient to develop an a posteriori error estimate. An obvious choice is to use $(I - S^m Q_h)\nabla u_h$ to approximate the true error $\nabla(u - u_h)$. In [7], we show that this is a good choice and that in many circumstances we can expect the error estimate to be *asymptotically exact;* that is,

$$\lim \frac{\|(I - S^m Q_h)\nabla u_h\|_{0,\Omega}}{\|\nabla(u - u_h)\|_{0,\Omega}} = 1$$

as $h \to 0$ and $m \to \infty$ in an appropriate fashion.

We also use the recovered gradient to construct local approximations of interpolation errors to be used as local error indicators for adaptive meshing algorithms; see [7] for details.

We remark that both our gradient recovery scheme and our a posteriori error estimate are largely independent of the details of the PDE. Indeed, all of the preliminary lemmas in section 2 are also independent of the PDE. The PDE directly enters only in the proof of Theorem 3.1, and there the properties that we assume are standard. This suggests that superconvergence can be expected for a wide variety of problems, as long as the adaptive meshing yields smoothly varying, shape regular meshes.

The rest of this paper is organized as follows: section 2 contains technical identities and estimates that form the basis for the estimate (1.1). In section 3, we prove (1.1) for general linear elliptic boundary value problems under standard assumptions. We also explore an application to nonlinear elliptic problems. In section 4 we develop and analyze the superconvergent gradient recover scheme in the case of $O(h^2)$ parallelogram meshes. In section 5 we present a few numerical examples illustrating the effectiveness of our procedures.

2. Preliminary lemmas. We begin with some geometric identities for a canonical element τ. Let τ have vertices $\boldsymbol{p}_k^t = (x_k, y_k)$, $1 \le k \le 3$, oriented counterclockwise, and corresponding nodal basis functions (barycentric coordinates) $\{\phi_k\}_{k=1}^3$. Let $\{e_k\}_{k=1}^3$ denote the edges of element τ, $\{\theta_k\}_{k=1}^3$ the angles, $\{\boldsymbol{n}_k\}_{k=1}^3$ the unit outward normal vectors, $\{\boldsymbol{t}_k\}_{k=1}^3$ the unit tangent vectors with counterclockwise orientation, $\{\ell_k\}_{k=1}^3$ the edge lengths, and $\{d_k\}_{k=1}^3$ the perpendicular heights (see Figure 2.1). Let $\tilde{\boldsymbol{p}}$ be the point of intersection for the perpendicular bisectors of the three sides of τ. Let $|s_k|$ denote the distance between $\tilde{\boldsymbol{p}}$ and side k. If τ has no obtuse angles, then the

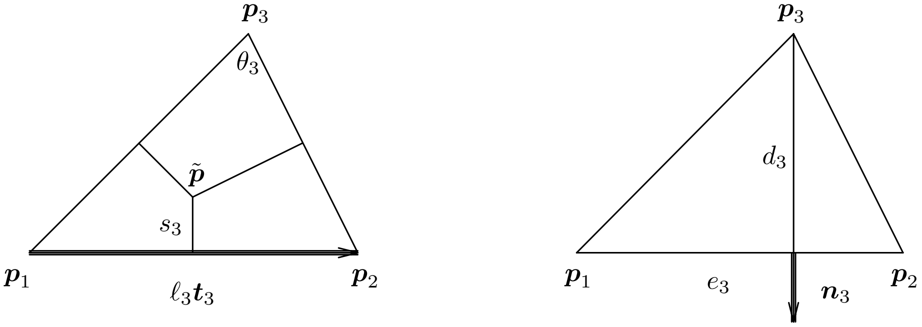

Fig. 2.1. *Parameters associated with the triangle τ.*

s_k will be nonnegative; otherwise, the distance to the side opposite the obtuse angle will be negative.

There are many relationships among these quantities; in particular, we note the following, which hold for $1 \leq k \leq 3$ and $k \pm 1$ permuted cyclically:

$$\begin{gathered} \ell_k d_k = \ell_{k+1}\ell_{k-1}\sin\theta_k = 2|\tau|, \\ 2\ell_{k+1}\ell_{k-1}\cos\theta_k = \ell_{k+1}^2 + \ell_{k-1}^2 - \ell_k^2, \\ \sin\theta_k = \boldsymbol{n}_{k-1}\cdot\boldsymbol{t}_{k+1} = -\boldsymbol{n}_{k+1}\cdot\boldsymbol{t}_{k-1}, \\ \cos\theta_k = -\boldsymbol{t}_{k-1}\cdot\boldsymbol{t}_{k+1} = -\boldsymbol{n}_{k-1}\cdot\boldsymbol{n}_{k+1}, \\ \nabla\phi_k = -\frac{\boldsymbol{n}_k}{d_k}, \\ s_k = -|\tau|\;\ell_k\nabla\phi_{k-1}\cdot\nabla\phi_{k+1} = \frac{\ell_k\cos\theta_k}{2\sin\theta_k}. \end{gathered}$$

Let $\mathcal{D}_\tau$ be a symmetric 2×2 matrix with constant matrix entries. We define

$$\xi_k = -\boldsymbol{n}_{k+1}\cdot\mathcal{D}_\tau\boldsymbol{n}_{k-1}.$$

The important special case $\mathcal{D}_\tau = I$ corresponds to $-\Delta$, and in this case $\xi_k = \cos\theta_k$. Let $q_k = \phi_{k+1}\phi_{k-1}$ denote the quadratic bump function associated with edge e_k, and let $\psi_k = \phi_k(1-\phi_k)$. In Lemma 2.1 we collect several simple identities that are used in the proof of Lemma 2.3.

Lemma 2.1.

$$\sin\theta_k\nabla u\cdot\mathcal{D}_\tau\boldsymbol{n}_k = \xi_{k-1}\frac{\partial u}{\partial\boldsymbol{t}_{k-1}} - \xi_{k+1}\frac{\partial u}{\partial\boldsymbol{t}_{k+1}}, \tag{2.1}$$

$$\frac{\partial u}{\partial\boldsymbol{t}_{k+1}} = -\cos\theta_{k-1}\frac{\partial u}{\partial\boldsymbol{t}_k} - \sin\theta_{k-1}\frac{\partial u}{\partial\boldsymbol{n}_k}, \tag{2.2}$$

$$\frac{\partial u}{\partial\boldsymbol{t}_{k-1}} = -\cos\theta_{k+1}\frac{\partial u}{\partial\boldsymbol{t}_k} + \sin\theta_{k+1}\frac{\partial u}{\partial\boldsymbol{n}_k}, \tag{2.3}$$

$$\int_\tau\frac{\partial u}{\partial\boldsymbol{t}_k} = -\sin\theta_{k+1}\int_{e_{k-1}} u + \sin\theta_{k-1}\int_{e_{k+1}} u, \tag{2.4}$$

$$\sin\theta_k\int_{e_{k-1}} q_{k-1}u = \int_\tau\psi_{k+1}\frac{\partial u}{\partial\boldsymbol{t}_{k+1}} + \sin\theta_{k-1}\int_{e_k} q_k u, \tag{2.5}$$

$$\sin\theta_k \int_{e_{k+1}} q_{k+1} u = -\int_\tau \psi_{k-1} \frac{\partial u}{\partial \boldsymbol{t}_{k-1}} + \sin\theta_{k+1} \int_{e_k} q_k u. \tag{2.6}$$

Proof. We note that (2.1) is an immediate consequence of

$$\mathcal{D}_\tau \boldsymbol{n}_k = \frac{\boldsymbol{n}_{k+1}\cdot \mathcal{D}_\tau \boldsymbol{n}_k}{\boldsymbol{n}_{k+1}\cdot \boldsymbol{t}_{k-1}} \boldsymbol{t}_{k-1} + \frac{\boldsymbol{n}_{k-1}\cdot \mathcal{D}_\tau \boldsymbol{n}_k}{\boldsymbol{n}_{k-1}\cdot \boldsymbol{t}_{k+1}} \boldsymbol{t}_{k+1} = \frac{\xi_{k-1}}{\sin\theta_k}\boldsymbol{t}_{k-1} - \frac{\xi_{k+1}}{\sin\theta_k}\boldsymbol{t}_{k+1}.$$

Proofs for (2.2)–(2.3) follow the same pattern. For (2.4), we note that from Green's identity

$$\int_\tau \nabla u \cdot \boldsymbol{t}_k = \sum_{j=1}^{3} \boldsymbol{n}_j \cdot \boldsymbol{t}_k \cdot \int_{e_k} u.$$

For (2.5)–(2.6), we note that ψ_k is constant along lines parallel to e_k, and $\partial\psi_k/\partial\boldsymbol{t}_k \equiv 0$. Thus

$$\frac{\partial(\psi_k u)}{\partial \boldsymbol{t}_k} = \psi_k \frac{\partial u}{\partial \boldsymbol{t}_k}.$$

Also, on edge e_k we have $q_k = \psi_{k+1} = \psi_{k-1}$. Equations (2.5)–(2.6) follow from these observations and (2.4). □

LEMMA 2.2. *Let $u \in W^{3,\infty}(\Omega)$. Let u_I and u_q be the continuous piecewise linear and piecewise quadratic interpolants, respectively, for u. Then*

$$\int_{e_k} (u - u_I) = \frac{\ell_k^2}{2} \int_{e_k} q_k \frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}, \tag{2.7}$$

$$\int_\tau (u - u_I) = -\frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u_q}{\partial \boldsymbol{t}_k^2} + \int_\tau (u - u_q). \tag{2.8}$$

Proof. Identity (2.7) is equivalent to the following:

$$\int_a^b u(s)ds - \frac{(b-a)}{2}(u(a) + u(b)) = \frac{1}{2}\int_a^b (s-a)(s-b)u''(s)ds,$$

which follows by an integration by parts. To show (2.8), we note that $u_q - u_I$ is a piecewise quadratic polynomial that is zero at all of the vertices in the mesh and that therefore can be expressed in terms of the quadratic bump functions. A simple calculation shows in a given element τ

$$u_q - u_I = \sum_{k=1}^{3} \ell_k^2 \boldsymbol{t}_k^t M_\tau \boldsymbol{t}_k \, q_k(x,y), \tag{2.9}$$

where

$$M_\tau = -\frac{1}{2}\begin{pmatrix} \partial_{11} u_q & \partial_{12} u_q \\ \partial_{21} u_q & \partial_{22} u_q \end{pmatrix}. \tag{2.10}$$

The matrix M_τ is constant since u_q is quadratic. Let $m_k = (p_{k+1} + p_{k-1})/2$ denote the midpoint of the kth edge. Then

$$\frac{\boldsymbol{t}_k^t M_\tau \boldsymbol{t}_k}{2} = \frac{2u(m_k) - u(p_{k+1}) - u(p_{k-1})}{\ell_k^2}.$$

Identity (2.8) follows from

$$\begin{aligned}\int_\tau (u-u_I) &= \int_\tau (u_q-u_I) + \int_\tau (u-u_q)\\ &= -\frac{1}{2}\sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u_q}{\partial \boldsymbol{t}_k^2}\int_\tau q_k + \int_\tau (u-u_q)\\ &= -\frac{|\tau|}{24}\sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u_q}{\partial \boldsymbol{t}_k^2} + \int_\tau (u-u_q)\\ &= -\frac{1}{24}\int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u_q}{\partial \boldsymbol{t}_k^2} + \int_\tau (u-u_q). \qquad \square\end{aligned}$$

The following is a fundamental identity in our analysis.

Lemma 2.3. *Let $\mathcal{D}_\tau$ be a 2×2 symmetric matrix with constant entries. Then*

$$\begin{aligned}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h &= \sum_{k=1}^{3}\int_{e_k}\frac{\xi_k q_k}{2\sin\theta_k}\left\{(\ell_{k+1}^2-\ell_{k-1}^2)\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} + 4|\tau|\frac{\partial^2 u}{\partial \boldsymbol{t}_k\partial \boldsymbol{n}_k}\right\}\frac{\partial v_h}{\partial \boldsymbol{t}_k}\\ &- \int_\tau \sum_{k=1}^{3}\frac{\ell_k\xi_k}{2\sin^2\theta_k}\left\{\ell_{k+1}\psi_{k-1}\frac{\partial^3 u}{\partial^2 \boldsymbol{t}_{k+1}\partial \boldsymbol{t}_{k-1}} + \ell_{k-1}\psi_{k+1}\frac{\partial^3 u}{\partial^2 \boldsymbol{t}_{k-1}\partial \boldsymbol{t}_{k+1}}\right\}\frac{\partial v_h}{\partial \boldsymbol{t}_k}.\end{aligned}$$

Proof. Using Lemmas 2.1–2.2, we have

$$\begin{aligned}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h &= \sum_{k=1}^{3}\int_{e_k}(u-u_I)\nabla v_h v_h\cdot\mathcal{D}_\tau \boldsymbol{n}_k\\ &= \sum_{k=1}^{3}\int_{e_k}(u-u_I)\left\{\frac{\xi_{k-1}}{\sin\theta_k}\frac{\partial v_h}{\partial \boldsymbol{t}_{k-1}} - \frac{\xi_{k+1}}{\sin\theta_k}\frac{\partial v_h}{\partial \boldsymbol{t}_{k+1}}\right\}\\ &= \sum_{k=1}^{3}\left\{\frac{\xi_k}{\sin\theta_{k+1}}\int_{e_{k+1}}(u-u_I)\frac{\partial v_h}{\partial \boldsymbol{t}_k}\right\} - \left\{\frac{\xi_k}{\sin\theta_{k-1}}\int_{e_{k-1}}(u-u_I)\frac{\partial v_h}{\partial \boldsymbol{t}_k}\right\}\\ &= \sum_{k=1}^{3}\left\{\frac{\ell_{k+1}^2\xi_k}{2\sin\theta_{k+1}}\int_{e_{k+1}}q_{k+1}\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2}\frac{\partial v_h}{\partial \boldsymbol{t}_k}\right\} - \left\{\frac{\ell_{k-1}^2\xi_k}{2\sin\theta_{k-1}}\int_{e_{k-1}}q_{k-1}\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2}\frac{\partial v_h}{\partial \boldsymbol{t}_k}\right\}\\ &= \sum_{k=1}^{3}\frac{\ell_k\xi_k}{2\sin\theta_k}\left\{\ell_{k+1}\int_{e_{k+1}}q_{k+1}\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2}\frac{\partial v_h}{\partial \boldsymbol{t}_k} - \ell_{k-1}\int_{e_{k-1}}q_{k-1}\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2}\frac{\partial v_h}{\partial \boldsymbol{t}_k}\right\}\\ &= \sum_{k=1}^{3}\frac{\xi_k}{2\sin\theta_k}\int_{e_k}q_k\left\{\ell_{k+1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2} - \ell_{k-1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2}\right\}\frac{\partial v_h}{\partial \boldsymbol{t}_k}\\ &\quad - \int_\tau \sum_{k=1}^{3}\frac{\ell_k\xi_k}{2\sin^2\theta_k}\left\{\ell_{k+1}\psi_{k-1}\frac{\partial^3 u}{\partial \boldsymbol{t}_{k-1}\partial \boldsymbol{t}_{k+1}^2} + \ell_{k-1}\psi_{k+1}\frac{\partial^3 u}{\partial \boldsymbol{t}_{k+1}\partial \boldsymbol{t}_{k-1}^2}+\right\}\frac{\partial v_h}{\partial \boldsymbol{t}_k}.\end{aligned}$$

To complete the proof, we focus attention on the term

$$\ell_{k+1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2} - \ell_{k-1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2}.$$

Using Lemma 2.1 once again, we have

$$\begin{aligned}\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2} &= \cos^2\theta_{k-1}\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} + 2\cos\theta_{k-1}\sin\theta_{k-1}\frac{\partial^2 u}{\partial \boldsymbol{t}_k \partial \boldsymbol{n}_k} + \sin^2\theta_{k-1}\frac{\partial^2 u}{\partial \boldsymbol{n}_k^2},\\ \frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2} &= \cos^2\theta_{k+1}\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} - 2\cos\theta_{k+1}\sin\theta_{k+1}\frac{\partial^2 u}{\partial \boldsymbol{t}_k \partial \boldsymbol{n}_k} + \sin^2\theta_{k+1}\frac{\partial^2 u}{\partial \boldsymbol{n}_k^2}.\end{aligned}$$

We also need the following identities:

$$\begin{gathered}\ell_{k+1}^2\sin^2\theta_{k-1} - \ell_{k-1}^2\sin^2\theta_{k+1} = 0,\\ \ell_{k+1}^2\cos^2\theta_{k-1} - \ell_{k-1}^2\cos^2\theta_{k+1} = \ell_{k+1}^2 - \ell_{k-1}^2,\\ \ell_{k+1}^2 2\cos\theta_{k-1}\sin\theta_{k-1} + \ell_{k-1}^2 2\cos\theta_{k+1}\sin\theta_{k+1} = 4|\tau|.\end{gathered}$$

Combining these equations leads to

$$\ell_{k+1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2} - \ell_{k-1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2} = (\ell_{k+1}^2 - \ell_{k-1}^2)\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} + 4|\tau|\frac{\partial^2 u}{\partial \boldsymbol{t}_k \partial \boldsymbol{n}_k},$$

completing the proof. □

Let e be an interior edge in the triangulation $\mathcal{T}_h$. Let τ and τ' be the two elements sharing e. We say that τ and τ' form an $O(h^2)$ approximate parallelogram if the lengths of any two opposite edges differ only by $O(h^2)$. Let x be a vertex lying on $\partial\Omega$, and let e and e' be the two boundary edges sharing x as an endpoint. Let τ and τ' be the two elements having e and e', respectively, as edges, and let $\boldsymbol{t}$ and and $\boldsymbol{t}'$ be the unit tangents. Take e and e' as one pair of corresponding edges, and make a clockwise traversal of $\partial\tau$ and $\partial\tau'$ to define two additional corresponding edge pairs. In this case, we say that τ and τ' form an $O(h^2)$ approximate parallelogram if $|\boldsymbol{t} - \boldsymbol{t}'| = O(h)$, and the lengths of any two corresponding edges differ only by $O(h^2)$.

Definition 2.4. *The triangulation $\mathcal{T}_h$ is $O(h^{2\sigma})$ irregular if the following hold:*

1. *Let $\mathcal{E} = \mathcal{E}_1 \oplus \mathcal{E}_2$ denote the set of interior edges in $\mathcal{T}_h$. For each $e \in \mathcal{E}_1$, τ and τ' form an $O(h^2)$ approximate parallelogram, while $\sum_{e\in\mathcal{E}_2}|\tau| + |\tau'| = O(h^{2\sigma})$.*
2. *Let $\mathcal{P} = \mathcal{P}_1 \oplus \mathcal{P}_2$ denote the set of boundary vertices. The elements associated with each $x \in \mathcal{P}_1$ form an $O(h^2)$ approximate parallelogram, and $|\mathcal{P}_2| = \kappa$, where κ is fixed independent of h.*

The boundary points $\mathcal{P}$ and the decomposition $\mathcal{P} = \mathcal{P}_1 \oplus \mathcal{P}_2$ are used only in the case of Neumann boundary conditions. Generally speaking, we expect $\mathcal{P}_2$ to consist of the geometric corners of Ω and perhaps a few other isolated points.

We can now state our main lemma.

Lemma 2.5. *Let the triangulation $\mathcal{T}_h$ be $O(h^{2\sigma})$ irregular. Let $\mathcal{D}_\tau$ be a piecewise constant matrix function defined on $\mathcal{T}_h$, whose elements $\mathcal{D}_{\tau ij}$ satisfy*

$$\begin{gathered}|\mathcal{D}_{\tau ij}| \lesssim 1,\\ |\mathcal{D}_{\tau ij} - \mathcal{D}_{\tau' ij}| \lesssim h,\end{gathered}$$

for $i = 1, 2$, $j = 1, 2$. Here τ and τ' are a pair of triangles sharing a common edge. Then

$$\left|\sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u - u_I)\cdot\mathcal{D}_\tau\nabla v_h\right| \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}|v_h|_{1,\Omega}. \tag{2.11}$$

Proof. Applying Lemma 2.3,

$$\sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h = I_1+I_2, \tag{2.12}$$

where

$$I_1=\sum_{\tau\in\mathcal{T}_h}\sum_{k=1}^{3}\int_{e_k}\frac{\xi_k q_k}{2\sin\theta_k}\left\{(\ell_{k+1}^2-\ell_{k-1}^2)\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}+4|\tau|\frac{\partial^2 u}{\partial\boldsymbol{t}_k\partial\boldsymbol{n}_k}\right\}\frac{\partial v_h}{\partial\boldsymbol{t}_k},$$

$$I_2=-\sum_{\tau\in\mathcal{T}_h}\int_\tau\sum_{k=1}^{3}\frac{\ell_k\xi_k}{2\sin^2\theta_k}\left\{\ell_{k+1}\psi_{k-1}\frac{\partial^3 u}{\partial^2\boldsymbol{t}_{k+1}\partial\boldsymbol{t}_{k-1}}+\ell_{k-1}\psi_{k+1}\frac{\partial^3 u}{\partial^2\boldsymbol{t}_{k-1}\partial\boldsymbol{t}_{k+1}}\right\}\frac{\partial v_h}{\partial\boldsymbol{t}_k},$$

I_2 is easily estimated by

$$|I_2|\lesssim h^2\|u\|_{3,\Omega}|v_h|_{1,\Omega}. \tag{2.13}$$

To estimate I_1, let $\mathcal{E}=\mathcal{E}_1\oplus\mathcal{E}_2$ denote the set of interior edges. For each $e\in\mathcal{E}$, let τ and τ' share e as a common edge. Denote, with respect to τ,

$$\alpha_e=\frac{\xi_k}{2\sin\theta_k}(\ell_{k+1}^2-\ell_{k-1}^2),\qquad \beta_e=\frac{\xi_k}{2\sin\theta_k}4|\tau|,$$

and with respect to τ',

$$\alpha_e'=\frac{\xi_{k'}}{2\sin\theta_{k'}}(\ell_{k'+1}^2-\ell_{k'-1}^2),\qquad \beta_e'=\frac{\xi_{k'}}{2\sin\theta_{k'}}4|\tau'|.$$

Take $\boldsymbol{n}$ and $\boldsymbol{t}$ to correspond to τ. Then we can write

$$I_1=I_{11}+I_{12}+I_{13},$$

where

$$I_{1j}=\sum_{e\in\mathcal{E}_j}\int_e q_e\left\{(\alpha_e-\alpha_e')\frac{\partial^2 u}{\partial\boldsymbol{t}^2}+(\beta_e-\beta_e')\frac{\partial^2 u}{\partial\boldsymbol{t}\partial\boldsymbol{n}}\right\}\frac{\partial v_h}{\partial\boldsymbol{t}}$$

for $j=1,2$, and

$$I_{13}=\sum_{e\subset\partial\Omega}\int_e q_e\left\{\alpha_e\frac{\partial^2 u}{\partial\boldsymbol{t}^2}+\beta_e\frac{\partial^2 u}{\partial\boldsymbol{t}\partial\boldsymbol{n}}\right\}\frac{\partial v_h}{\partial\boldsymbol{t}}.$$

Using the elementary identity

$$\left|\int_e f\right|\lesssim h^{-1}\int_\tau|f|+\int_\tau|\nabla f|,$$

we obtain (for $\boldsymbol{z}=\boldsymbol{t}$ and $\boldsymbol{z}=\boldsymbol{n}$)

$$\left|\int_e q_e\frac{\partial^2 u}{\partial\boldsymbol{t}\partial\boldsymbol{z}}\frac{\partial v_h}{\partial\boldsymbol{t}}\right|\lesssim h^{-1}\int_\tau|\nabla^2 u||\nabla v_h|+\int_\tau|\nabla^3 u||\nabla v_h|. \tag{2.14}$$

We can estimate this term in a slightly different way:

$$\left|\int_e q_e \frac{\partial^2 u}{\partial \boldsymbol{t} \partial \boldsymbol{z}} \frac{\partial v_h}{\partial \boldsymbol{t}}\right| \lesssim h^{-1}|u|_{2,\infty,\Omega} \int_\tau |\nabla v_h|. \tag{2.15}$$

For $e \in \mathcal{E}_1$,

$$|\alpha_e - \alpha'_e| \lesssim h^3,$$
$$|\beta_e - \beta'_e| \lesssim h^3.$$

Combining this with (2.14), we have

$$|I_{11}| \lesssim h^2 \int_\Omega (|\nabla^2 u| + h\nabla^3 u|)|\nabla v_h| \lesssim h^2 \|u\|_{3,\Omega} |v_h|_{1,\Omega}, \tag{2.16}$$

or, by (2.15), we have

$$|I_{11}| \lesssim h^2 |u|_{2,\infty,\Omega} |v_h|_{1,\Omega}.$$

Now we turn to the estimate for I_{12}. For $e \in \mathcal{E}_2$, we simply estimate

$$|\alpha_e - \alpha'_e| \le |\alpha_e| + |\alpha'_e| \lesssim h^2,$$
$$|\beta_e - \beta'_e| \le |\beta_e| + |\beta'_e| \lesssim h^2.$$

Using (2.15), this leads to

$$|I_{12}| \lesssim h^{1+\sigma} |u|_{2,\infty,\Omega} |v_h|_{1,\Omega}.$$

We now consider I_{13}. It is easy to see that, if $v_h = 0$ on $\partial\Omega$, then $I_{13} = 0$. In the general case, we set

$$B_e(u) = \alpha_e \frac{\partial^2 u}{\partial \boldsymbol{t}^2} + \beta_e \frac{\partial^2 u}{\partial \boldsymbol{t} \partial \boldsymbol{n}}$$

and

$$\overline{B}_e(u) = |e|^{-1} \int_e B_e(u).$$

Then

$$\begin{aligned} I_{13} &= \sum_{e \subset \partial\Omega} \int_e q_e B_e(u) \frac{\partial v_h}{\partial \boldsymbol{t}} \\ &= \sum_{e \subset \partial\Omega} \int_e q_e \overline{B}_e(u) \frac{\partial v_h}{\partial \boldsymbol{t}} + \sum_{e \subset \partial\Omega} \int_e q_e (B_e(u) - \overline{B}_e(u)) \frac{\partial v_h}{\partial \boldsymbol{t}}. \end{aligned}$$

For the second term, we have

$$\begin{aligned} \left| \sum_{e \subset \partial\Omega} \int_e q_e (B_e(u) - \overline{B}_e(u)) \frac{\partial v_h}{\partial \boldsymbol{t}} \right| &\lesssim h^3 |u|_{3,\infty,\Omega} \sum_{e \subset \partial\Omega} \int_e \left| \frac{\partial v_h}{\partial \boldsymbol{t}} \right| \\ &\lesssim h^{5/2} |u|_{3,\infty,\Omega} |v_h|_{1,\Omega}. \end{aligned}$$

We now estimate the first term. Let $\mathcal{P} = \mathcal{P}_1 \oplus \mathcal{P}_2$ denote the set of vertices on $\partial\Omega$. Then we have

$$\begin{aligned}\sum_{e\subset\partial\Omega}\int_e q_e\overline{B}_e(u)\frac{\partial v_h}{\partial \boldsymbol{t}} &= \sum_{e\subset\partial\Omega}\overline{B}_e(u)\frac{\partial v_h}{\partial \boldsymbol{t}}\int_e q_e\\ &= \sum_{e\subset\partial\Omega}\overline{B}_e(u)\frac{\partial v_h}{\partial \boldsymbol{t}}\frac{|e|}{6}\\ &= \frac{1}{6}\sum_{x\in\mathcal{P}}\left(\overline{B}_e(u)-\overline{B}_{e'}(u)\right)v_h(x).\end{aligned}$$

For $x \in \mathcal{P}_1$, we have

$$\begin{aligned}|\alpha_e - \alpha_{e'}| &\lesssim h^3,\\ |\beta_e - \beta_{e'}| &\lesssim h^3.\end{aligned}$$

Thus

$$\left|\overline{B}_e(u)-\overline{B}_{e'}(u)\right| \lesssim h^3|u|_{3,\infty,\Omega}.$$

For $x \in \mathcal{P}_2$, we have

$$\left|\overline{B}_e(u)-\overline{B}_{e'}(u)\right| \le \left|\overline{B}_e(u)\right| + \left|\overline{B}_{e'}(u)\right| \lesssim h^2|u|_{2,\infty,\Omega}.$$

Combining these estimates, we have

$$\begin{aligned}\left|\sum_{x\in\mathcal{P}}\left(\overline{B}_e(u)-\overline{B}_{e'}(u)\right)v_h(x)\right| &\lesssim h^2\left(|u|_{3,\infty,\Omega}+\kappa|u|_{2,\infty,\Omega}\right)\|v_h\|_{\infty,\partial\Omega}\\ &\lesssim h^2|\log h|^{1/2}\|u\|_{3,\infty,\Omega}\|v_h\|_{1,\Omega}.\end{aligned}$$

In the last step, we used the well-known Sobolev inequality

$$\|v_h\|_{\infty,\Omega} \lesssim |\log h|^{1/2}\|v_h\|_{1,\Omega}.$$

Here $\|v_h\|_{1,\Omega}$ can be replaced by $|v_h|_{1,\Omega}$ by a standard argument. Thus our final estimate is

$$|I_{13}| \lesssim h^2|\log h|^{1/2}\|u\|_{3,\infty,\Omega}|v_h|_{1,\Omega}.$$

Consequently

$$|I_1| \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}|v_h|_{1,\Omega}. \tag{2.17}$$

Combining (2.12) with (2.13) and (2.17), we obtain (2.11). □

For pure Dirichlet boundary conditions, we have the following better estimate.

COROLLARY 2.6. *Assume the conditions of Lemma* 2.5, *except for the second part of Definition* 2.4 *concerning regularity on the elements near the boundary. Then*

$$\begin{aligned}&\left|\sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h\right|\\ &\qquad\lesssim h^{1+\min(1,\sigma)}(\|u\|_{3,\Omega}+\|u\|_{2,\infty,\Omega})|v_h|_{1,\Omega}, \qquad v_h\in\mathcal{V}_h\cap H_0^1(\Omega).\end{aligned}$$

Proof. Use $I_{13} = 0$ in Lemma 2.5. □

In the general case, without the second part of Definition 2.4, we have this slightly weaker result.

COROLLARY 2.7. *Assume the conditions of Lemma* 2.5*, except for the second part of Definition* 2.4 *concerning regularity on the elements near the boundary. Then*

$$\left|\sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h\right| \lesssim h^{1+\min(1/2,\sigma)}(\|u\|_{3,\Omega}+\|u\|_{2,\infty,\Omega})|v_h|_{1,\Omega}, \qquad v_h\in\mathcal{V}_h.$$

Proof. We always have the following estimate for I_{13}:

$$|I_{13}| \lesssim h^{3/2}|u|_{2,\infty,\partial\Omega}|v_h|_{1,\Omega}. \qquad \square$$

We conclude with a final technical result needed in section 4.

LEMMA 2.8. *Let the triangulation $\mathcal{T}_h$ be $O(h^{2\sigma})$ irregular. Then*

$$\left|\sum_\tau\int_{\partial\tau}\sum_{k=1}^{3}\ell_k^2\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}\boldsymbol{v}_h\cdot\boldsymbol{n}\right| \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}\|\boldsymbol{v}_h\|_{0,\Omega}. \tag{2.18}$$

Proof. Let $e\equiv e_k$ be an arbitrary edge of element τ. We begin with the identity

$$\ell_k^2\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}+\ell_{k+1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k+1}^2}+\ell_{k-1}^2\frac{\partial^2 u}{\partial \boldsymbol{t}_{k-1}^2} = (\alpha_e-\delta_e)\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}+\beta_e\frac{\partial^2 u}{\partial \boldsymbol{t}_k\partial \boldsymbol{n}_k}+\delta_e\frac{\partial^2 u}{\partial \boldsymbol{n}_k^2},$$

where

$$\begin{aligned}\alpha_e &= \ell_k^2+\ell_{k+1}^2+\ell_{k-1}^2,\\ \beta_e &= (\ell_{k+1}^2-\ell_{k-1}^2)4|\tau|/\ell_k^2,\\ \delta_e &= 8|\tau|^2/\ell_k^2.\end{aligned}$$

For $e\in\mathcal{E}$, let τ and τ' share e as a common edge. Take $\boldsymbol{n}$ and $\boldsymbol{t}$ to correspond to τ. Then we can write

$$\sum_\tau\int_{\partial\tau}\sum_{k=1}^{3}\ell_k^2\frac{\partial^2 u}{\partial \boldsymbol{t}_k^2}\boldsymbol{v}_h\cdot\boldsymbol{n} = I_1+I_2+I_3,$$

where

$$I_j = \sum_{e\in\mathcal{E}_j}\int_e\left\{(\alpha_e-\alpha_e')\frac{\partial^2 u}{\partial \boldsymbol{t}^2}+(\beta_e-\beta_e')\frac{\partial^2 u}{\partial \boldsymbol{t}\partial \boldsymbol{n}}\right\}\boldsymbol{v}_h\cdot\boldsymbol{n}$$

for $j=1,2$ and

$$I_3 = \sum_{e\in\partial\Omega}\int_e\left\{(\alpha_e-\delta_e)\frac{\partial^2 u}{\partial \boldsymbol{t}^2}+\beta_e\frac{\partial^2 u}{\partial \boldsymbol{t}\partial \boldsymbol{n}}+\delta_e\frac{\partial^2 u}{\partial \boldsymbol{n}^2}\right\}\boldsymbol{v}_h\cdot\boldsymbol{n}.$$

Following the pattern of proof in Lemma 2.5, we estimate

$$\begin{aligned}|I_1| &\lesssim h^2\|u\|_{3,\Omega}\|\boldsymbol{v}_h\|_{0,\Omega},\\ |I_2| &\lesssim h^{1+\sigma}|u|_{2,\infty,\Omega}\|\boldsymbol{v}_h\|_{0,\Omega},\\ |I_3| &\lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}\|\boldsymbol{v}_h\|_{0,\Omega}.\end{aligned}$$

Equation (2.18) now follows directly from these estimates. □

3. Elliptic boundary value problems. We consider the non–self-adjoint and possibly indefinite problem: find $u \in H^1(\Omega)$ such that

$$B(u,v) = \int_\Omega (\mathcal{D}\nabla u + \boldsymbol{b}u)\cdot\nabla v + cuv\,dx = f(v) \tag{3.1}$$

for all $v \in H^1(\Omega)$. Here $\mathcal{D}$ is a 2×2 symmetric positive definite matrix, $\boldsymbol{b}$ a vector, and c a scalar, and $f(\cdot)$ is a linear functional. We assume that all the coefficient functions are smooth.

In order to insure that (3.1) has a unique solution, we assume that the bilinear form $B(\cdot,\cdot)$ satisfies the continuity condition

$$|B(\phi,\eta)| \le \nu\, \|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega} \tag{3.2}$$

for all $\phi, \eta \in H^1(\Omega)$. We also assume the inf-sup conditions

$$\inf_{\phi\in H^1}\sup_{\eta\in H^1}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} = \sup_{\phi\in H^1}\inf_{\eta\in H^1}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} \ge \mu > 0. \tag{3.3}$$

Let $\mathcal{V}_h \subset H^1(\Omega)$ be the space of continuous piecewise linear polynomials associated with the triangulation $\mathcal{T}_h$, and consider the approximate problem: find $u_h \in \mathcal{V}_h$ such that

$$B(u_h, v_h) = f(v_h) \tag{3.4}$$

for all $v_h \in \mathcal{V}_h$. To insure a unique solution for (3.4) we assume the inf-sup conditions

$$\inf_{\phi\in \mathcal{V}_h}\sup_{\eta\in \mathcal{V}_h}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} = \sup_{\phi\in \mathcal{V}_h}\inf_{\eta\in \mathcal{V}_h}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} \ge \mu > 0. \tag{3.5}$$

Xu and Zikatanov [21] have shown that, under these assumptions,

$$\|u-u_h\|_{1,\Omega} \le \frac{\nu}{\mu}\inf_{v_h\in\mathcal{V}_h}\|u-v_h\|_{1,\Omega}.$$

See also Aziz and Babuška [1].

We define the piecewise constant matrix function $\mathcal{D}_\tau$ in terms of the diffusion matrix $\mathcal{D}$ as follows:

$$\mathcal{D}_{\tau ij} = \frac{1}{|\tau|}\int_\tau \mathcal{D}_{ij}\,dx.$$

Note that $\mathcal{D}_\tau$ is symmetric and positive definite.

Theorem 3.1. *Assume that the solution of* (3.1) *satisfies* $u \in W^{3,\infty}(\Omega)$. *Further, assume the hypotheses of Lemma* 2.5, *with* $\mathcal{D}_\tau$ *defined as above. Then*

$$\|u_h - u_I\|_{1,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}.$$

Proof. We begin with the identity

$$B(u-u_I, v_h) = \sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u-u_I)\cdot\mathcal{D}_\tau\nabla v_h\,dx + \sum_{\tau\in\mathcal{T}_h}\int_\tau \nabla(u-u_I)\cdot(\mathcal{D}-\mathcal{D}_\tau)\nabla v_h\,dx$$
$$+\int_\Omega (u-u_I)(\boldsymbol{b}\cdot\nabla v_h + cv_h)\,dx = I_1 + I_2 + I_3.$$

The first term I_1 is estimated using Lemma 2.5. I_2 and I_3 can be easily estimated by

$$|I_2| + |I_3| \lesssim h^2 \|u\|_{2,\Omega} \|v_h\|_{1,\Omega}.$$

Thus

$$|B(u - u_I, v_h)| \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega} \|v_h\|_{1,\Omega}.$$

We complete the proof using the inf-sup condition in

$$\begin{aligned} \mu \|u_h - u_I\|_{1,\Omega} &\le \sup_{v_h \in \mathcal{V}_h} \frac{B(u_h - u_I, v_h)}{\|v_h\|_{1,\Omega}} \\ &= \sup_{v_h \in \mathcal{V}_h} \frac{B(u - u_I, v_h)}{\|v_h\|_{1,\Omega}} \\ &\lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}. \qquad \square \end{aligned}$$

We now consider a more general nonlinear problem: find $u \in H^1(\Omega)$ such that

$$\mathcal{B}(u, v) = f(v) \tag{3.6}$$

for all $v \in H^1(\Omega)$. Here the form $\mathcal{B}(\cdot,\cdot)$ is assumed to be linear in its second argument, but nonlinear in its first. Once again, $f(v)$ is a linear functional. Let u_h be the finite element approximation: find $u_h \in \mathcal{V}_h$ such that

$$\mathcal{B}(u_h, v_h) = f(v_h) \tag{3.7}$$

for all $v_h \in \mathcal{V}_h$. We assume that $\mathcal{B}(\cdot,\cdot)$ is such that its linearization about u is a bilinear form $B(\cdot,\cdot)$ as in (3.1), although the coefficient functions will now generally depend on u. We assume that $B(\cdot,\cdot)$ satisfies the continuity and inf-sup conditions (3.2), (3.3), and (3.5), so that both (3.6) and (3.7) have unique solutions. The linearization process also satisfies

$$\mathcal{B}(u, v_h) - \mathcal{B}(u_h, v_h) = B(u - u_h, v_h) + \mathcal{Q}(u - u_h, v_h) = 0$$

for all $v_h \in \mathcal{V}_h$. The form $\mathcal{Q}(\cdot,\cdot)$ contains higher order truncation terms in the linearization process; as with $\mathcal{B}(\cdot,\cdot)$, it is linear in its second argument. We assume

$$|\mathcal{Q}(u - u_h, v_h)| \lesssim \|u - u_h\|_{1,\Omega}^2 \|v_h\|_{1,\Omega}. \tag{3.8}$$

THEOREM 3.2. *Assume the hypotheses of Theorem* 3.1 *and* (3.8). *Then*

$$\|u_h - u_I\|_{1,\Omega} \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega} + \|u - u_h\|_{1,\Omega}^2.$$

Proof. As in the proof of Theorem 3.1,

$$\begin{aligned} \mu \|u_h - u_I\|_{1,\Omega} &\le \sup_{v_h \in \mathcal{V}_h} \frac{B(u_h - u_I, v_h)}{\|v_h\|_{1,\Omega}} \\ &\le \sup_{v_h \in \mathcal{V}_h} \frac{B(u - u_I, v_h)}{\|v_h\|_{1,\Omega}} + \frac{\mathcal{Q}(u - u_h, v_h)}{\|v_h\|_{1,\Omega}} \\ &\lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega} + \|u - u_h\|_{1,\Omega}^2. \qquad \square \end{aligned}$$

If $\|u - u_h\|_{1,\Omega}$ is sufficiently small (e.g., $\|u - u_h\|_{1,\Omega} \le C(u)h$), then we will observe superconvergence.

4. A gradient recovery algorithm for $O(h^2)$ approximate parallelogram meshes. In this section, we show that $Q_h \nabla u_I$ can superconverge to ∇u for meshes that are $O(h^{2\sigma})$ irregular.

THEOREM 4.1. *Let $u \in W^{3,\infty}(\Omega)$, and assume the hypotheses of Lemma 2.8. Then*

$$\|\nabla u - Q_h \nabla u_I\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}.$$

Proof. Given $\boldsymbol{v}_h \in \mathcal{V}_h \times \mathcal{V}_h$, we have

$$(Q_h \nabla(u-u_I), \boldsymbol{v}_h) = (\nabla(u-u_I), \boldsymbol{v}_h) = -((u-u_I), \nabla \cdot \boldsymbol{v}_h) + \int_{\partial\Omega} (u-u_I)\boldsymbol{v}_h \cdot \boldsymbol{n}. \tag{4.1}$$

We estimate the two terms on the right-hand side of (4.1). First,

$$\left| \int_{\partial\Omega} (u-u_I)\boldsymbol{v}_h \cdot \boldsymbol{n} \right| \lesssim h^{3/2} |u|_{2,\infty,\Omega} \|\boldsymbol{v}_h\|_{0,\Omega}.$$

For the other, we use Lemma 2.2 to get

$$\begin{aligned}
\int_\tau (u-u_I)\nabla \cdot \boldsymbol{v}_h &= -\frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u_q}{\partial \boldsymbol{t}_k^2} \nabla \cdot \boldsymbol{v}_h + \int_\tau (u-u_q)\nabla \cdot \boldsymbol{v}_h \\
&= -\frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} \nabla \cdot \boldsymbol{v}_h \\
&\qquad - \frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 (u_q - u)}{\partial \boldsymbol{t}_k^2} \nabla \cdot \boldsymbol{v}_h + \int_\tau (u-u_q)\nabla \cdot \boldsymbol{v}_h \\
&= -\frac{1}{24} \int_{\partial\tau} \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} \boldsymbol{v}_h \cdot \boldsymbol{n} + \frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \nabla \frac{\partial^2 u}{\partial \boldsymbol{t}_k^2} \boldsymbol{v}_h \\
&\qquad - \frac{1}{24} \int_\tau \sum_{k=1}^{3} \ell_k^2 \frac{\partial^2 (u_q - u)}{\partial \boldsymbol{t}_k^2} \nabla \cdot \boldsymbol{v}_h + \int_\tau (u-u_q)\nabla \cdot \boldsymbol{v}_h \\
&= I_1 + I_2 + I_3 + I_4.
\end{aligned}$$

Easy estimates show

$$\begin{aligned}
|I_3| + |I_4| &\lesssim h^3 \|u\|_{3,\tau} |\boldsymbol{v}_h|_{1,\tau} \lesssim h^2 \|u\|_{3,\tau} \|\boldsymbol{v}_h\|_{0,\tau}, \\
|I_2| &\lesssim h^2 \|u\|_{3,\tau} \|\boldsymbol{v}_h\|_{0,\tau}.
\end{aligned}$$

$|I_1|$ is estimated using Lemma 2.8. Consequently,

$$|(Q_h \nabla(u-u_I), \boldsymbol{v}_h)| \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega} \|\boldsymbol{v}_h\|_{0,\Omega}.$$

Taking $\boldsymbol{v}_h = Q_h \nabla(u-u_I)$, it follows that

$$\|Q_h \nabla(u-u_I)\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}.$$

Theorem 4.1 now follows from the triangle inequality

$$\|\nabla u - Q_h \nabla u_I\|_{0,\Omega} \le \|\nabla u - Q_h \nabla u\|_{0,\Omega} + \|Q_h \nabla(u-u_I)\|_{0,\Omega}. \qquad \square$$

The next result is an immediate consequence of Theorems 3.1 and 4.1.

Theorem 4.2. *Let $u \in W^{3,\infty}(\Omega)$, and assume the hypotheses of Theorems* 3.1 *and* 4.1. *Then*

$$\|\nabla u - Q_h \nabla u_h\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}.$$

Proof. Using the triangle inequality,

$$\begin{aligned} \|\nabla u - Q_h \nabla u_h\|_{0,\Omega} &\le \|\nabla u - Q_h \nabla u_I\|_{0,\Omega} + \|Q_h \nabla (u_I - u_h)\|_{0,\Omega} \\ &\le \|\nabla u - Q_h \nabla u_I\|_{0,\Omega} + \|\nabla (u_I - u_h)\|_{0,\Omega}. \end{aligned} \tag{4.2}$$

We estimate the two terms on the right-hand side of (4.2) using Theorems 4.1 and 3.1. □

Finally, we would like to point out that many results presented above (such as Theorems 3.1, 3.2, 4.1, and 4.2) can be refined in many ways. Before the end of this section, let us give one such refinement for a piecewise $O(h^{2\sigma})$ irregular grid.

Definition 4.3. *The triangulation $\mathcal{T}_h$ is piecewise $O(h^{2\sigma})$ irregular if Ω can be written as the union of a bounded number of polygonal subdomains and $\mathcal{T}_h$ is $O(h^{2\sigma})$ irregular on each of these subdomains.*

By applying Lemma 2.5 on each subdomain, we can easily get the following result.

Theorem 4.4. *Lemma* 2.5, *Lemma* 2.8, *Theorem* 3.1, *Theorem* 3.2, *Theorem* 4.1, *and Theorem* 4.2 *are all valid for piecewise $O(h^{2\sigma})$ grids.*

The above theorem is related to superconvergence results on piecewise regular (or strongly regular) grids that were discussed in earlier literature (cf. Xu [20] and Lin and Xu [15]). The significance of such an extension will be discussed in the following section.

5. Applications and numerical experiments.

In this section, we develop a few simple applications of our results and present some numerical examples. The numerical experiments were performed using the PLTMG software package [5]. The experiments were done on an Linux PC using double precision arithmetic and the g77 compiler.

We begin our discussion with a very simple example of piecewise uniform grids. As shown in Figure 5.1, we began with a uniform 3×3 mesh with $nt = 8$ elements, and computed a sequence of uniformly refined meshes through regular refinement of each element of a given mesh into four similar triangles in the refined mesh by connecting the midpoints pairwise.

This grid is $O(h)$ irregular ($\sigma = 1/2$) by Definition 2.4, but piecewise $O(h^{2\sigma})$ irregular with $\sigma = \infty$ (namely, piecewise regular) by Definition 4.3. Consequently, for this example, the result claimed by Theorem 4.4 is $O(h^{1/2})$ better than the corresponding result from previous sections. In our first experiment, we consider the problem

$$-\Delta u + u = f, \tag{5.1}$$

$\Omega = (0,1) \times (0,1)$ with either Dirichlet or Neumann boundary conditions. The right-hand side f and the boundary conditions were chosen such that $u = e^{x+y}$ was the exact solution. In this experiment, we begin with the uniform 3×3 mesh with eight triangles described above, and make seven levels of uniform regiment. The results are

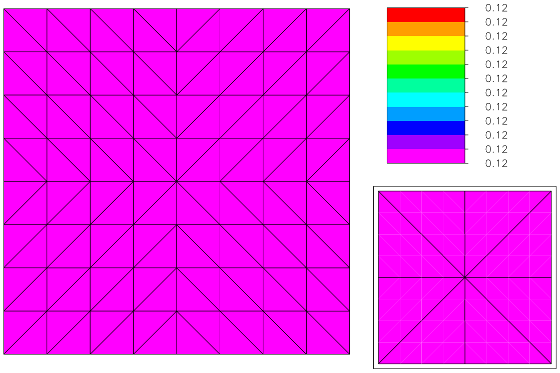

FIG. 5.1. *A (globally) $O(h^{2\sigma})$ irregular grid with $\sigma = 1/2$, but piecewise $O(h^{2\sigma})$ irregular grid with $\sigma = \infty$.*

TABLE 5.1
Results for a square domain, uniform refinement.

reported in Table 5.1. In Table 5.1 and subsequent tables,

$$H_1 = \|\nabla(u - u_h)\|_{0,\Omega},$$
$$\widetilde{H}_1 = \|\nabla(u_I - u_h)\|_{0,\Omega},$$
$$\overline{H}_1 = \|\nabla u - Q_h \nabla u_h)\|_{0,\Omega},$$

where u_I is the linear interpolant of u. In the last line, the order of convergence was estimated from the reported data using a least squares technique.

In Table 5.1, we see quite clearly the first order convergence of $\|\nabla(u - u_h)\|_{0,\Omega}$ and the superconvergence of $\|\nabla(u_I - u_h)\|_{0,\Omega}$. In the latter case, the rate is nearly second order, which is consistent with Theorem 4.4. We also note superconvergence of $\|\nabla u - Q_h \nabla u_h)\|_{0,\Omega}$, with order close to 3/2. This is perhaps the result of most practical significance.

We then repeated the experiment, replacing uniform refinement with the adaptive refinement procedure in PLTMG. This adaptive refinement procedure is based on longest-edge bisection and also includes a mesh smoothing phase that allows the vertices in the mesh to move. The result was a sequence of unstructured, nonuniform, nonnested, shape regular meshes. The target values for the adaptive procedure were selected to produce a sequence of meshes with approximately the same number of elements as for the uniform refinement case. The results are shown in Table 5.2.

For the adaptive meshes, the story is a quite different; $\|\nabla(u_I - u_h)\|_{0,\Omega}$ and $\|\nabla u -$

$Q_h\nabla u_h)\|_{0,\Omega}$ show less superconvergence. In this case $\sigma > 0$, but it is clearly much smaller than in the uniform refinement case. In Part II of this work [7], we show how to obtain strong superconvergence for such meshes using $S^m Q_h \nabla u_h$ as the recovered gradient. Here S is a multigrid-like smoothing operator, and m is a small integer ($m = 1$ or $m = 2$ is usually satisfactory). Analysis and a complete description are deferred to Part II of this work.

In our second experiment, we solved (5.1) on a domain Ω in the shape of Lake Superior. The true solution u in this case was chosen to be $u = \sin x \sin y$. In this case, the initial mesh with $nt = 2765$ elements was unstructured and nonuniform, but shape regular. This mesh is shown in Figure 5.2. As in the first example, we first computed a sequence of uniformly refined meshes through regular refinement of each element of a given mesh into four similar triangles. The results are shown in Table 5.3.

In Table 5.3, we see quite clearly the first order convergence of $\|\nabla(u-u_h)\|_{0,\Omega}$ and the superconvergence of $\|\nabla(u_I - u_h)\|_{0,\Omega}$. In the latter case, the rate is nearly second order, which is again consistent with Theorem 4.4. Evidently, the many small uniform

patches were sufficient to produce a very strong superconvergence effect. We also see superconvergence of $Q_h \nabla u_h$ to ∇u, in a way similar to that of the first example.

We then repeated the experiment, replacing uniform with adaptive refinement. The target values for the adaptive procedure once again were selected to produce a sequence of meshes with approximately the same numbers of elements as in the uniform refinement case. The results are shown in Table 5.4.

The results here are qualitatively similar to those for the first example. In Table 5.4 we note slightly elevated estimates for the estimated order of convergence of $\|\nabla(u - u_h)\|_{0,\Omega}$. This is an artifact of the least squares procedure. Notice that in the first adaptive step there was an unusually large decrease in $\|\nabla(u - u_h)\|_{0,\Omega}$. This was because the initial nonuniform mesh was adapted mainly to the complex geometry of Ω and not to the character of the solution. In subsequent adaptive refinement steps, the error is rapidly approaching first order behavior. The orders for H_1 and $\overline{H}_1$ are also slightly elevated by unusually large decreases in the first adaptive step.

Acknowledgment. The ideas for this manuscript germinated while the authors were attending the workshop on *A Posteriori Error Estimation and Adaptive Approaches in the Finite Element Method,* held at the Mathematical Sciences Research Institute, University of California, Berkeley, April 3–14, 2000. We are grateful for the opportunity to attend this workshop and for the stimulating scientific environment at MSRI. We also thank the reviewers for their careful reviews and their suggestions for improvements.

ASYMPTOTICALLY EXACT A POSTERIORI ERROR ESTIMATORS, PART II: GENERAL UNSTRUCTURED GRIDS*

RANDOLPH E. BANK† AND JINCHAO XU‡

Abstract. In Part I of this work [*SIAM J. Numer. Anal.*, 41 (2003), pp. 2294–2312], we analyzed superconvergence for piecewise linear finite element approximations on triangular meshes where most pairs of triangles sharing a common edge form approximate parallelograms. In this work, we consider superconvergence for general unstructured but shape regular meshes. We develop a postprocessing gradient recovery scheme for the finite element solution u_h, inspired in part by the smoothing iteration of the multigrid method. This recovered gradient superconverges to the gradient of the true solution and becomes the basis of a global a posteriori error estimate that is often asymptotically exact. Next, we use the superconvergent gradient to approximate the Hessian matrix of the true solution and form local error indicators for adaptive meshing algorithms. We provide several numerical examples illustrating the effectiveness of our procedures.

Key words. superconvergence, gradient recovery, a posteriori error estimates

DOI. 10.1137/S0036142901398751

1. Introduction.

In Part I of this work [10], we developed some superconvergence estimates and a gradient recovery algorithm appropriate for piecewise linear finite element approximations of elliptic boundary problems. In that work, we restricted attention to triangular meshes that are $O(h^{2\sigma})$ irregular [10]. In this work, we extend the gradient recovery scheme to more general meshes and develop an a posteriori error estimate and local error indicator for use in adaptive meshing algorithms. See [15, 23, 24, 25, 14, 22, 12, 16, 20, 5, 13, 1] for related work, and in particular the monographs by Verfürth [18], Babuška and Strouboulis [4], Chen and Huang [11], Lin and Yan [17], and Wahlbin [19] for recent surveys of the field as a whole.

Our overall development has three major steps. Let $\mathcal{V}_h \subset H^1(\Omega)$ be the finite element subspace consisting of continuous piecewise linear polynomials associated with a shape regular triangulation $\mathcal{T}_h$. Let $u_h \in \mathcal{V}_h$ be the finite element solution of an appropriate linear or nonlinear elliptic boundary value problem. In the first component of our development, we prove a superconvergence result for $|u_h - u_I|_{1,\Omega}$, where u_I is the piecewise linear interpolant for u. In particular, in Part I of this manuscript [10], we prove that

$$|u_h - u_I|_{1,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{1.1}$$

Estimate (1.1) holds on nonuniform meshes, where most pairs of adjacent triangles satisfy an $O(h^2)$ approximate parallelogram property. $\sigma > 0$ in some sense measures the extent to which this condition is violated; see [10] for details.

The second major component is a superconvergent approximation to ∇u. This approximation is generated by a gradient recovery procedure. In particular, in section 2 of this manuscript we compute $S^m Q_h \nabla u_h$, where S is an appropriate smoothing operator and Q_h is the L^2 projection operator. In words, the discontinuous, piecewise constant gradient ∇u_h is projected into the space of continuous piecewise linear polynomials, and then smoothed, using a multigrid-like smoothing operator. Although the L^2 projection operator is global, the overall work estimate is still $O(N)$ for a mesh with N vertices. In the case of a small number of smoothing steps (the most interesting case), Theorem 2.7 shows that

$$\|\nabla u - S^m Q_h \nabla u_h\|_{0,\Omega} \lesssim h \left\{ \min\left(h^{\min(1,\sigma)} |\log h|, \left[\frac{\kappa - 1}{\kappa}\right]^m \right) + m\, h^{1/2} \right\} \|u\|_{3,\infty,\Omega}. \tag{1.2}$$

Here $\kappa > 1$ is a constant independent of h and u. The term $(1 - \kappa^{-1})^m$ illustrates the well-known effectiveness of a few smoothing steps and is reminiscent of terms arising in connection with multigrid convergence analysis [7]. If σ is sufficiently large, then the L^2 projection itself ($m = 0$) is sufficient to produce superconvergence. The purpose of smoothing is to improve the performance when $\sigma \approx 0$ and the mesh is shape regular.

In the third major component of our analysis, presented in section 3 of this manuscript, we use the recovered gradient to develop an a posteriori error estimate. An obvious choice is to use $(I - S^m Q_h)\nabla u_h$ to approximate the true error $\nabla(u - u_h)$. In Theorem 3.1 we show this is a good choice, and that in many circumstances we can expect the error estimate to be *asymptotically exact*; that is,

$$\lim \frac{\|(I - S^m Q_h)\nabla u_h\|_{0,\Omega}}{\|\nabla(u - u_h)\|_{0,\Omega}} = 1$$

as $h \to 0$ and $m \to \infty$ in an appropriate fashion.

We also use the recovered gradient to construct local approximations of interpolation errors to be used as local error indicators for adaptive meshing algorithms. This is motivated by noting that, under certain circumstances, $|u_q - u_I|_{1,\Omega}$ is an asymptotically exact estimate of $|u - u_h|_{1,\Omega}$. Here u_q is the piecewise quadratic interpolant for u. Thus $u_q - u_I$ is a locally defined quadratic polynomial with value zero at all vertices of the mesh. On a given element τ, $u_q - u_I$ can be expressed as a linear combination of quadratic "bump functions" q_k associated with the edge midpoints of τ,

$$u_q - u_I = \sum_{k=1}^{3} \ell_k^2 \boldsymbol{t}_k^t M_\tau \boldsymbol{t}_k \, q_k(x, y), \tag{1.3}$$

where ℓ_k is the length of edge k, $\boldsymbol{t}_k$ is the unit tangent, and

$$M_\tau = -\frac{1}{2} \begin{pmatrix} \partial_{11} u_q & \partial_{12} u_q \\ \partial_{21} u_q & \partial_{22} u_q \end{pmatrix} \tag{1.4}$$

is the Hessian matrix (for details, see section 3). For convenience in notation, we let $\partial_i u$ denote the partial derivative $\partial u / \partial x_i$. All terms on the right-hand side of (1.3) are known except for the second derivatives appearing in the Hessian matrix M_τ. In our local error indicator, we simply replace $\partial_{ij} u_q$ by $\partial_i S^m Q_h \partial_j u_h$. Let ϵ_τ

denote this locally defined a posteriori error estimate. In Theorem 3.2, we prove the superconvergence estimate

$$\|\partial_i(\partial_k u - S^m Q_h \partial_k u_h)\|_{0,\Omega} \lesssim \left\{ \min\left(h^{\min(1,\sigma)} |\log h|, \left[\frac{\kappa - 1}{\kappa}\right]^m \right) + m\, h^{1/2} \right\} \|u\|_{3,\infty,\Omega}. \tag{1.5}$$

We remark that both our gradient recovery scheme and our a posteriori error estimate are largely independent of the details of the PDE. This suggests that superconvergence can be expected for a wide variety of problems, as long as the adaptive meshing yields smoothly varying, shape regular meshes.

It also is interesting to note that the superconvergent global approximation to ∇u emphasizes once again a classic dilemma in error estimation. On the one hand, generally it seems quite advantageous to take the superconvergent approximation $S^m Q_h \nabla u_h$ as the "accepted" approximation to ∇u. Not only is it of higher order than ∇u_h, but also it is globally continuous and differentiable, often desirable properties. On the other hand, the a posteriori error estimates and resulting adaptive meshing algorithms use $S^m Q_h \nabla u_h$ to estimate the error in ∇u_h. In some respects, the situation is analogous to adaptive time step selection schemes for initial value problems where order p and $p+1$ approximations are computed to estimate the local error in the order p approximation, which is then used to control the time step.

Finally, as a point of practical interest, since the gradient recovery and a posteriori error estimates are independent of the PDE, a single implementation can be used across a broad spectrum of problems. There is no need to have special implementations for each problem class, as is typical of schemes that involve the solution of local problems in each element or patch of elements [3, 9].

The rest of this paper is organized as follows: In section 2, we first provide some notation, describe our gradient recovery scheme, and summarize the main superconvergence estimates of [10] for the case of $O(h^{2\sigma})$ irregular meshes. We then extend the gradient recovery scheme to more general meshes through the use of a multigrid smoother. In section 3, we develop and analyze our a posteriori error estimate and prove (1.5). Finally, in section 4, we present several numerical examples, involving both uniform and nonuniform (adaptive) meshes, with some solutions that satisfy our smoothness assumptions and some that do not. In the latter cases, we observe superconvergence away from singularities for adaptive meshes, although this effect is not covered by our current analysis.

2. A gradient recovery algorithm for shape regular triangulations. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with Lipschitz boundary $\partial\Omega$. For simplicity of exposition, we assume that Ω is a polyhedron. We assume that Ω is partitioned by a shape regular triangulation $\mathcal{T}_h$ of mesh size h. Let $\mathcal{V}_h \subset H^1(\Omega)$ be the corresponding continuous piecewise linear finite element space associated with this triangulation $\mathcal{T}_h$.

We consider the non–self-adjoint and possibly indefinite problem: Find $u \in H^1(\Omega)$ such that

$$B(u,v) = \int_\Omega (\mathcal{D}\nabla u + \boldsymbol{b}u)\cdot\nabla v + cuv\,dx = f(v) \tag{2.1}$$

for all $v \in H^1(\Omega)$. Here $\mathcal{D}$ is a 2×2 symmetric positive definite matrix, $\boldsymbol{b}$ a vector, and c a scalar, and $f(\cdot)$ is a linear functional. We assume that all the coefficient functions are smooth. Choosing $H^1(\Omega)$ as trial space implies Neumann boundary conditions, a choice made for convenience. In [10], we also analyzed more general nonlinear PDEs and boundary conditions. However, since the details of the PDE do not strongly influence our gradient recovery scheme, here we consider only the most simple case.

In order to insure that (2.1) has a unique solution, we assume that the bilinear form $B(\cdot,\cdot)$ satisfies the continuity condition

$$|B(\phi,\eta)| \le \nu \, \|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega} \tag{2.2}$$

for all $\phi,\eta \in H^1(\Omega)$. We also assume the inf-sup conditions

$$\inf_{\phi\in H^1}\sup_{\eta\in H^1}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} = \sup_{\phi\in H^1}\inf_{\eta\in H^1}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} \ge \mu > 0. \tag{2.3}$$

For simplicity, we assume that μ and ν are such that the standard Galerkin finite element approximation is an appropriate discretization. Let $\mathcal{V}_h \subset H^1(\Omega)$ be the space of continuous piecewise linear polynomials associated with the triangulation $\mathcal{T}_h$, and consider the approximate problem: Find $u_h \in \mathcal{V}_h$ such that

$$B(u_h, v_h) = f(v_h) \tag{2.4}$$

for all $v_h \in \mathcal{V}_h$. To insure a unique solution for (2.4), we assume the inf-sup conditions

$$\inf_{\phi\in \mathcal{V}_h}\sup_{\eta\in \mathcal{V}_h}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} = \sup_{\phi\in \mathcal{V}_h}\inf_{\eta\in \mathcal{V}_h}\frac{B(\phi,\eta)}{\|\phi\|_{1,\Omega}\|\eta\|_{1,\Omega}} \ge \mu > 0. \tag{2.5}$$

Xu and Zikatanov [21] have shown that, under these assumptions,

$$\|u-u_h\|_{1,\Omega} \le \frac{\nu}{\mu}\inf_{v_h\in\mathcal{V}_h}\|u-v_h\|_{1,\Omega}.$$

See also Babuška and Aziz [2]. In this situation, we have standard a priori estimates of the form

$$\|u-u_h\|_{\alpha,\Omega} \lesssim h^{2-\alpha}\|u\|_{2,\Omega}$$

for $0 \le \alpha \le 1$.

We define the piecewise constant matrix function $\mathcal{D}_\tau$ in terms of the diffusion matrix $\mathcal{D}$ as follows:

$$\mathcal{D}_{\tau ij} = \frac{1}{|\tau|}\int_\tau \mathcal{D}_{ij}\,dx.$$

Note that $\mathcal{D}_\tau$ is symmetric and positive definite. The following results are proved in [10].

THEOREM 2.1. *Let the triangulation $\mathcal{T}_h$ be $O(h^{2\sigma})$ irregular* [10]. *Assume that $\mathcal{D}_\tau$ defined above satisfies*

$$|\mathcal{D}_{\tau ij}| \lesssim 1,$$
$$|\mathcal{D}_{\tau ij} - \mathcal{D}_{\tau' ij}| \lesssim h$$

for $i=1,2$, $j=1,2$. Here τ and τ' are a pair of triangles sharing a common edge. Assume that the solution of (2.1) *satisfies $u \in W^{3,\infty}(\Omega)$ and that $u_h \in \mathcal{V}_h$ is the solution of* (2.4). *Then*

$$\|\nabla u_h - \nabla u_I\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega},$$
$$\|\nabla u - Q_h\nabla u_I\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega},$$
$$\|\nabla u - Q_h\nabla u_h\|_{0,\Omega} \lesssim h^{1+\min(1,\sigma)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}.$$

When the mesh is not $O(h^{2\sigma})$ irregular or when σ becomes very close to zero, the superconvergence demonstrated in Theorem 2.1 will be diminished. Intuitively, it appears that superconvergence of $Q_h \nabla u_h$ is diminished mainly because of high frequency errors introduced by the small nonuniformities of the mesh. Preferentially attenuating high frequency errors in mesh functions is of course a widely studied problem in multilevel iterative methods. Our proposal here is to apply these ideas in the present context. In particular, we construct a multigrid smoother S and take $S^m Q_h \nabla u_h$ as our recovered gradient. As with multigrid methods, we expect that a very small number of smoothing steps will suffice; in our code, we take $m = 2$ as default.

Our postprocessing gradient recovery scheme is based on the following bilinear form:

$$a(u, v) = (\nabla u, \nabla v) + (u, v). \tag{2.6}$$

We introduce the discrete operator $A : v_h \mapsto \mathcal{V}_h$ defined by

$$(Au_h, v_h) = a(u_h, v_h) \quad \forall u_h, v_h \in \mathcal{V}_h.$$

We note that A is symmetric positive definite on $\mathcal{V}_h$ and

$$\lambda \equiv \rho(A) \eqsim h^{-2}. \tag{2.7}$$

Using A, we introduce the smoothing operator S defined by

$$S = I - \lambda^{-1} A.$$

The usual multigrid convergence function

$$f(\alpha, \beta) = \frac{\alpha^\alpha \beta^\beta}{(\alpha + \beta)^{(\alpha+\beta)}},$$

$\alpha, \beta > 0$, plays an important role. Here we summarize some standard properties of $f(\alpha, \beta)$. Let $p, \alpha, \beta > 0$. Then

$$\begin{aligned} \sup_{x \in [0,1]} x^\alpha (1 - x)^\beta &= f(\alpha, \beta), \\ f(\alpha, \beta)^p &= f(p\alpha, p\beta), \\ f(\alpha, \beta) &= f(\beta, \alpha). \end{aligned}$$

For convenience in notation, we let $\partial_i u$ denote the partial derivative $\partial u / \partial x_i$. We now state and prove some preliminary lemmas leading up to the main Theorem 2.7 in this section.

LEMMA 2.2. *For any $z \in \mathcal{V}_h$,*

$$\|(I - S^m) z\|_{0,\Omega} \lesssim mh \big(\|z - \partial_i u\|_{1,\Omega} + h \|u\|_{3,\Omega} + h^{1/2} |u|_{2,\infty,\partial\Omega} \big).$$

Proof. We note, from the definition of S,

$$\begin{aligned} \|(I - S^m) z\| &= \lambda^{-1} \|(I - S^m)(I - S)^{-1} A z\| \\ &\le \lambda^{-1} \max_{s \in [0,1]} [(1 - s^m)(1 - s)^{-1}] \|Az\| \\ &\le \lambda^{-1} m \|Az\| \\ &\lesssim mh^2 \|Az\|. \end{aligned}$$

Let $w = Az$. By definition,

$$(w, \phi) = (\nabla z, \nabla \phi) + (z, \phi) \tag{2.8}$$

for all $\phi \in \mathcal{V}_h$. We take $\phi = w$ in (2.8) and estimate the terms on the right-hand side. The critical term is $(\nabla z, \nabla w)$, where we have

$$\begin{aligned}(\nabla z, \nabla w) &= (\nabla(z - \partial_i u), \nabla w) + (\nabla \partial_i u, \nabla w)\\ &\lesssim \|\nabla(z - \partial_i u)\| \|\nabla w\| - (\Delta \partial_i u, w) + \int_{\partial\Omega} \nabla \partial_i u \cdot \boldsymbol{n}\, w\, ds\\ &\lesssim (h^{-1}\|z - \partial_i u\|_{1,\Omega} + \|u\|_{3,\Omega})\|w\|_{0,\Omega} + |u|_{2,\infty,\partial\Omega} \int_{\partial\Omega} |w|\, ds\\ &\lesssim \left(h^{-1}\|z - \partial_i u\|_{1,\Omega} + \|u\|_{3,\Omega} + h^{-1/2}|u|_{2,\infty,\partial\Omega}\right)\|w\|_{0,\Omega}.\end{aligned}$$

Also

$$(z, w) = (z - \partial_i u, w) + (\partial_i u, w) \lesssim (h^{-1}\|z - \partial_i u\|_{1,\Omega} + \|u\|_{3,\Omega})\|w\|_{0,\Omega}.$$

Thus for $z \in \mathcal{V}_h$,

$$\|Az\| \lesssim h^{-1}\|z - \partial_i u\|_{1,\Omega} + \|u\|_{3,\Omega} + h^{-1/2}|u|_{2,\infty,\partial\Omega},$$

completing the proof. □

LEMMA 2.3. *Suppose that for $v \in \mathcal{V}_h$ and some $0 < \alpha \le 1$ we have*

$$\begin{aligned}\|v\| &\le \omega(h, v),\\ \|v\|_{-\alpha} \equiv \|A^{-\alpha/2}v\| &\le (\mathcal{C}h)^{\alpha}\omega(h, v).\end{aligned}$$

Then

$$\|S^m v\| \le \varepsilon_m\, \omega(h, v),$$

where

$$\varepsilon_m = \begin{cases} \kappa^{\alpha/2} f(m, \alpha/2) \lesssim m^{-\alpha/2} & \text{for } m > (\kappa - 1)\alpha/2,\\ [(\kappa - 1)/\kappa]^m & \text{for } m \le (\kappa - 1)\alpha/2,\end{cases}$$

and $\kappa = (\mathcal{C}h)^2\lambda$.

Proof. Let $0 \le \beta \le \alpha$. Then from the Hölder inequality

$$\|v\|_{-\beta} \le \|v\|_{-\alpha}^{\beta/\alpha}\|v\|^{1-\beta/\alpha}$$

and the hypotheses of the lemma, it follows that

$$\|v\|_{-\beta} \le (\mathcal{C}h)^{\beta}\omega(h, v)$$

for $0 \le \beta \le \alpha$.

Now,

$$\begin{aligned}\|S^m v\| &= \lambda^{\beta/2}\|S^m(I - S)^{\beta/2}A^{-\beta/2}v\|\\ &\le \lambda^{\beta/2} \max_{s\in[0,1]}[s^m(1 - s)^{\beta/2}]\|A^{-\beta/2}v\|\\ &\le \lambda^{\beta/2} f(m, \beta/2)(\mathcal{C}h)^{\beta}\omega(h, v)\\ &\le \kappa^{\beta/2} f(m, \beta/2)\omega(h, v),\end{aligned}$$

where $\kappa = (\mathcal{C}h)^2\lambda$. We now minimize this bound with respect to β on the interval $0 \le \beta \le \alpha$.

$$\begin{aligned}\frac{\partial \kappa^{\beta/2} f(m,\beta/2)}{\partial\beta} &= \frac{1}{2}\log\left\{\frac{(\kappa\beta)}{(2m+\beta)}\right\}\cdot\kappa^{\beta/2} f\left(m,\frac{\beta}{2}\right) = 0\\ &\Leftrightarrow \frac{\kappa\beta}{(2m+\beta)} = 1\\ &\Rightarrow \beta = \frac{2m}{(\kappa-1)}.\end{aligned}$$

There are two cases: The first is when $2m/(\kappa-1) > \alpha$. Here the minimum occurs at $\beta = \alpha$. Hence, for $m > (\kappa-1)\alpha/2$,

$$\varepsilon_m = \kappa^{\alpha/2} f(m,\alpha/2).$$

The second case is when $2m/(\kappa-1) \le \alpha$. Here $\beta = 2m/(\kappa-1)$ and

$$\varepsilon_m = \left(\frac{\kappa-1}{\kappa}\right)^m. \qquad \square$$

LEMMA 2.4. *Let $w \in H^1(\Omega)$. Then, for $1/2 < \alpha \le 1$,*

$$\|S^m Q_h \partial_i w\|_{0,\Omega} \lesssim \varepsilon_m\left(h^{-1}\|w\|_{0,\Omega} + \|w\|_{1,\Omega} + h^{-\alpha}\|w\|_{0,\infty,\partial\Omega}\right),$$

with ε_m defined as in Lemma 2.3.

Proof. Our plan is to apply Lemma 2.3 to $v = Q_h\partial_i w$. Note that

$$\|v\|_{-\alpha} = \|Q_h\partial_i w\|_{-\alpha} = \sup_{\phi\in\mathcal{V}_h}\frac{(Q_h\partial_i w,\phi)}{\|\phi\|_\alpha} = \sup_{\phi\in\mathcal{V}_h}\frac{(\partial_i w,\phi)}{\|\phi\|_\alpha}.$$

Using integration by parts,

$$\begin{aligned}(\partial_i w,\phi) &= -(w,\partial_i\phi) + \int_{\partial\Omega} w\phi n_i\, ds\\ &\lesssim \|w\|_{0,\Omega}\|\phi\|_{1,\Omega} + \|w\|_{0,\infty,\partial\Omega}\int_{\partial\Omega}|\phi|\, ds\\ &\lesssim h^{\alpha-1}\|w\|_{0,\Omega}\|\phi\|_{\alpha,\Omega} + \|w\|_{0,\infty,\partial\Omega}\|\phi\|_{\alpha,\Omega}\\ &\lesssim (h^{\alpha-1}\|w\|_{0,\Omega} + \|w\|_{0,\infty,\partial\Omega})\|\phi\|_{\alpha,\Omega}.\end{aligned}$$

Thus

$$\|v\|_{-\alpha,\Omega} \lesssim h^\alpha\omega(h,v)$$

with

$$\omega(h,v) = h^{-1}\|w\|_{0,\Omega} + \|w\|_{1,\Omega} + h^{-\alpha}\|w\|_{0,\infty,\partial\Omega}.$$

Since

$$\|v\|_{0,\Omega} = \|Q_h\partial_i w\|_{0,\Omega} \le \omega(h,v),$$

the desired estimate now follows from Lemma 2.3. $\square$

Lemma 2.5. *Let $u \in H^3(\Omega) \cap W^{2,\infty}(\Omega)$. Then for any $v_h \in \mathcal{V}_h$ and $1/2 < \alpha \leq 1$ we have*

$$\|\nabla u - S^m Q_h \nabla v_h\|_{0,\Omega} \lesssim m h^{3/2}\big(h^{1/2}\|u\|_{3,\Omega} + |u|_{2,\infty,\partial\Omega}\big) + \varepsilon_m \left(h^{-1}\|u - v_h\|_{0,\Omega} + \|u - v_h\|_{1,\Omega} + h^{-\alpha}\|u - v_h\|_{0,\infty,\partial\Omega}\right),$$

with ε_m defined as in Lemma 2.3.

Proof. By the triangle inequality,

$$\|\partial_i u - S^m Q_h \partial_i v_h\|_{0,\Omega} \leq \|(I - Q_h)\partial_i u\|_{0,\Omega} + \|(I - S^m)Q_h \partial_i u\|_{0,\Omega} + \|S^m Q_h \partial_i (u - v_h)\|_{0,\Omega}.$$

We now estimate these three terms. The first term is easy; by standard arguments,

$$\|(I - Q_h)\partial_i u\|_{0,\Omega} \lesssim h^2 \|u\|_{3,\Omega}.$$

The second term is estimated by Lemma 2.2 with $z = Q_h \partial_i u$. For the third, we apply Lemma 2.4 with $w = u - v_h$. □

In the case in which $v_h = u_h \in \mathcal{V}_h \cap H_0^1(\Omega)$ is the finite element approximation to $u \in H_0^1(\Omega)$, the boundary terms vanish and

$$\|\nabla u - S^m Q_h \nabla v_h\|_{0,\Omega} \lesssim h(mh + \varepsilon_m)\|u\|_{3,\Omega}.$$

In the more general case, if $v_h = u_h \in \mathcal{V}_h$ and $1/2 < \alpha < 1$, we use the well-known L^∞ norm estimate for the linear finite element approximation to obtain

$$h^{-\alpha}\|u - u_h\|_{0,\infty,\partial\Omega} \lesssim h^{1-\alpha}|\log h| h |u|_{2,\infty,\Omega} \lesssim h|u|_{2,\infty,\Omega}$$

and, hence,

$$\|\nabla u - S^m Q_h \nabla v_h\|_{0,\Omega} \lesssim h(mh^{1/2} + \varepsilon_m)(\|u\|_{3,\Omega} + |u|_{2,\infty,\Omega}).$$

Similar estimates hold for the case $v = u_I$. We now turn to the main theorems in this section. The next theorem is based only on the results developed in this section and summarizes the above discussion.

Theorem 2.6. *Let $u \in H^3(\Omega) \cap W^{2,\infty}(\Omega)$ and $u_h \in \mathcal{V}_h$ be an approximation of u satisfying*

$$\|u - u_h\|_{k,\Omega} \lesssim h^{2-k}|u|_{2,\Omega}, \quad k = 0, 1,$$
$$\|u - u_h\|_{0,\infty\Omega} \lesssim h^2 |\log h||u|_{2,\infty\Omega}.$$

Then

$$\|\nabla u - S^m Q_h \nabla u_h\|_{0,\Omega} \lesssim h(mh^{1/2} + \varepsilon_m)\left(\|u\|_{3,\Omega} + |u|_{2,\infty,\Omega}\right),$$

where ε_m is defined as in Lemma 2.3 *and $1/2 < \alpha < 1$.*

The following theorem combines results from this section with our earlier superconvergence results.

Theorem 2.7. *Let $u \in W^{3,\infty}(\Omega)$, and assume the hypotheses of Theorem* 2.1. *Then*

$$\|\nabla u - S^m Q_h \nabla u_I\|_{0,\Omega} \lesssim h\big(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\, h^{1/2}\big)\|u\|_{3,\infty,\Omega}, \tag{2.9}$$

$$\|\nabla u - S^m Q_h \nabla u_h\|_{0,\Omega} \lesssim h\big(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\, h^{1/2}\big)\|u\|_{3,\infty,\Omega}, \tag{2.10}$$

where ε_m is defined as in Lemma 2.3 *and $1/2 < \alpha < 1$.*

Proof. Our proof combines Lemma 2.5 and Theorem 2.1. We first use the triangle inequality

$$\|\partial_i u - S^m Q_h \partial_i u_I\|_{0,\Omega} \le \|(I - Q_h)\partial_i u\|_{0,\Omega} + \|(I - S^m)Q_h \partial_i u\|_{0,\Omega} + \|S^m Q_h \partial_i (u - u_I)\|_{0,\Omega}.$$

The first two terms are estimated as in Lemma 2.5. For the third term, we can first use Theorem 2.1 as

$$\begin{aligned}\|S^m Q_h \partial_i (u - u_I)\|_{0,\Omega} &\lesssim \|Q_h \partial_i (u - u_I)\|_{0,\Omega} \\ &\lesssim \|\partial_i u - Q_h \partial_i u_I\|_{0,\Omega} + \|(I - Q_h)\partial_i u\|_{0,\Omega} \\ &\lesssim h^{1+\min(1,\sigma)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega} + h^2 \|u\|_{3,\Omega}.\end{aligned}$$

The third term can also be estimated as in Lemma 2.5. Taken together, these estimates establish (2.9). The proof of (2.10) is identical. □

We conclude with a few implementation details. First, with respect to the selection of the critical parameter m: Balancing the terms

$$\left(\frac{\kappa - 1}{\kappa}\right)^m \approx m h^{-1/2}$$

suggests that m should grow in a logarithmic-like fashion as the mesh is refined. On the other hand, in our empirical investigations, we have found that taking $m \le 2$ has been adequate for scalar PDE equations involving $O(10^5)$ unknowns, which suggests that a simple fixed strategy is good enough for most purposes.

Second, with respect to the L^2 projection: This linear system is solved approximately by an iterative method, in our case, a symmetric Gauss–Seidel method with conjugate gradient acceleration (SGSCG). The mass matrix is assembled in the standard nodal basis and is sparse and diagonally dominant, so convergence is very rapid; typically 4–6 iterations are sufficient. In the context of an adaptive refinement feedback loop, the initial guess is taken as zero for the first (coarsest) mesh and interpolated from the previous mesh at all subsequent refinement steps. The overall complexity of this step is thus $O(N)$ for a mesh with N vertices. If necessary, this step could be made more efficient (in terms of the size of the constant, not the order of complexity) by using some standard mass lumping scheme to construct a diagonal approximation to the mass matrix. This would also make the calculation *local* rather than global.

Third, with respect to the smoothing steps: We do not compute the constant λ exactly. In fact, we use a Jacobi conjugate gradient (JCG) iteration. The stiffness matrix A corresponding to the operator $-\Delta$ is assembled in the nodal basis; this matrix is symmetric positive semidefinite with a one dimensional kernel corresponding the constant function. (We used the complete H^1 inner product in our analysis to avoid the technical complications introduced by a nontrivial kernel.) Then m JCG steps are applied to the linear system $Ax = 0$, with initial guess corresponding to the finite element function $Q_h \partial_i u_h$. Our default choice is $m = 2$ iterations; thus this step also has complexity $O(N)$.

3. An a posteriori error estimator. In this section we use the recovered gradient to develop an a posteriori error estimator. The obvious choice for a global a posteriori error estimator is to approximate $\|\nabla(u - u_h)\|_{0,\Omega}$ by $\|(I - S^m Q_h)\nabla u_h\|_{0,\Omega}$. In Theorem 3.1, we show that this is indeed a good approximation.

THEOREM 3.1. *Assume the hypotheses of Theorem* 2.7. *Then*

$$\|\nabla(u-u_h)\|_{0,\Omega} \le \|(I-S^mQ_h)\nabla u_h\|_{0,\Omega} + Ch\big(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\,h^{1/2}\big)\|u\|_{3,\infty,\Omega}, \tag{3.1}$$

$$\|(I-S^mQ_h)\nabla u_h\|_{0,\Omega} \le \|\nabla(u-u_h)\|_{0,\Omega} + Ch\big(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\,h^{1/2}\big)\|u\|_{3,\infty,\Omega}, \tag{3.2}$$

where ε_m *is defined as in Lemma* 2.3 *for* $1/2<\alpha<1$. *Furthermore, if there exists a positive constant* $c_0(u)$ *independent of* h *such that*

$$\|\nabla(u-u_h)\|_{0,\Omega} \ge c_0(u)h, \tag{3.3}$$

then

$$\left|\frac{\|(I-S^mQ_h)\nabla u_h\|_{0,\Omega}}{\|\nabla(u-u_h)\|_{0,\Omega}} - 1\right| \lesssim \min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\,h^{1/2}. \tag{3.4}$$

Proof. The proof of (3.1)–(3.2) is just a simple application of the triangle inequalities

$$\|\nabla(u-u_h)\|_{0,\Omega} \le \|(I-S^mQ_h)\nabla u_h\|_{0,\Omega} + \|\nabla u - S^mQ_h\nabla u_h\|_{0,\Omega},$$
$$\|(I-S^mQ_h)\nabla u_h\|_{0,\Omega} \le \|\nabla(u-u_h)\|_{0,\Omega} + \|\nabla u - S^mQ_h\nabla u_h\|_{0,\Omega}$$

and Theorem 2.7. Estimate (3.4) follows from (3.1)–(3.2) and from the assumption (3.3). □

Taken together, (3.1)–(3.2) show that if the true error is first order, $\|\nabla(u-u_h)\|_{0,\Omega} = O(h)$, then the a posteriori error estimate $\|(I-S^mQ_h)\nabla u_h\|_{0,\Omega}$ will also be $O(h)$. In particular, given a superconvergent approximation to ∇u, we can expect the effectivity ratio $\|(I-S^mQ_h)\nabla u_h\|_{0,\Omega}/\|\nabla(u-u_h)\|_{0,\Omega}$ to be close to unity. Furthermore, in this case Theorem 3.1 shows that the a posteriori error estimate will be asymptotically exact.

In terms of local error indicators, an obvious choice would be to estimate the local error in a given element τ by $\|(I-S^mQ_h)\nabla u_h\|_{0,\tau}$. For practical reasons discussed below, we prefer an alternative approach where the recovered gradient is used to approximate the Hessian matrix of second derivatives of u. By way of motivation, we note that for an $O(h^{2\sigma})$ irregular mesh

$$\begin{aligned}\|\nabla(u-u_h)\|_{0,\Omega} &\le \|\nabla(u-u_q)\|_{0,\Omega} + \|\nabla(u_q-u_I)\|_{0,\Omega} + \|\nabla(u_I-u_h)\|_{0,\Omega}\\ &\le C(u)h^{1+\min(1,\sigma)}|\log h| + \|\nabla(u_q-u_I)\|_{0,\Omega},\\ \|\nabla(u_q-u_I)\|_{0,\Omega} &\le \|\nabla(u_q-u)\|_{0,\Omega} + \|\nabla(u-u_h)\|_{0,\Omega} + \|\nabla(u_h-u_I)\|_{0,\Omega}\\ &\le C(u)h^{1+\min(1,\sigma)}|\log h| + \|\nabla(u-u_h)\|_{0,\Omega}.\end{aligned}$$

From this pair of estimates, it follows that $\|\nabla(u_q-u_I)\|_{0,\Omega} = O(h)$ if and only if $\|\nabla(u-u_h)\|_{0,\Omega} = O(h)$, and that in this case $\|\nabla(u_q-u_I)\|_{0,\Omega}$ is asymptotically exact.

The function u_q-u_I is a locally defined, piecewise quadratic polynomial with value zero at all vertices of the mesh. Let a canonical element $\tau\in\mathcal{T}_h$ have vertices $\boldsymbol{p}_k^t=(x_k,y_k)$, $1\le k\le 3$, oriented counterclockwise, and corresponding nodal basis functions (barycentric coordinates) $\{\psi_k\}_{k=1}^3$. Let $\{e_k\}_{k=1}^3$ denote the edges of element

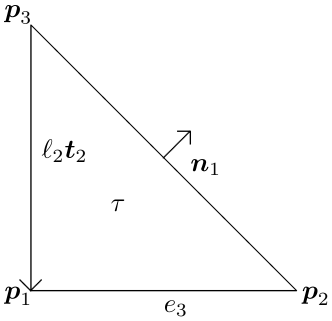

FIG. 3.1. *Parameters associated with the triangle τ.*

τ, $\{\boldsymbol{n}_k\}_{k=1}^3$ the unit outward normal vectors, $\{\boldsymbol{t}_k\}_{k=1}^3$ the unit tangent vectors with counterclockwise orientation, and $\{\ell_k\}_{k=1}^3$ the edge lengths (see Figure 3.1). Let $q_k = \psi_{k+1}\psi_{k-1}$ denote the quadratic bump function associated with edge k of τ, where $(k-1,k,k+1)$ is a cyclic permutation of $(1,2,3)$. Thus in element τ, $u_q - u_I$ is a linear combination of the quadratic bump functions associated with the edge midpoints of the element,

$$u_q - u_I = \sum_{k=1}^{3} \ell_k^2 \boldsymbol{t}_k^t M_\tau \boldsymbol{t}_k \, q_k(x,y),$$

where

$$M_\tau = -\frac{1}{2}\begin{pmatrix} \partial_{11}u_q & \partial_{12}u_q \\ \partial_{21}u_q & \partial_{22}u_q \end{pmatrix}.$$

In our local error indicator, we simply approximate the second derivatives in the Hessian matrix M_τ using gradients of $S^m Q_h \partial_i u_h$. In particular, let

$$\tilde{M}_\tau = -\frac{1}{2}\begin{pmatrix} \partial_1 S^m Q_h \partial_1 u_h & \partial_1 S^m Q_h \partial_2 u_h \\ \partial_2 S^m Q_h \partial_1 u_h & \partial_2 S^m Q_h \partial_2 u_h \end{pmatrix},$$
$$\bar{M}_\tau = \frac{\alpha_\tau}{2}(\tilde{M}_\tau + \tilde{M}_\tau^t),$$

where $\alpha_\tau > 0$ is a constant described below. For the case of meshes that are $O(h^{2\sigma})$ irregular, we can have $m = 0$, but for general shape regular meshes, we have $m > 0$. In either case, the local error estimate ϵ_τ is given by

$$\epsilon_\tau = \sum_{k=1}^{3} \ell_k^2 \boldsymbol{t}_k^t \bar{M}_\tau \boldsymbol{t}_k \, q_k(x,y). \tag{3.5}$$

The normalization constant α_τ is chosen such that the local error indicator η_τ satisfies

$$\eta_\tau \equiv \|\nabla \epsilon_\tau\|_{0,\tau} = \|(I - S^m Q_h)\nabla u_h\|_{0,\tau}.$$

Normally we expect that $\alpha_\tau \approx 1$, which is likely to be the case in regions where the Hessian matrix for the true solution is well defined. Near singularities, u is not smooth, and we anticipate difficulties in estimating the Hessian. For elements near such singularities, α_τ provides a heuristic for partly compensating for poor approximation.

The form of our a posteriori error estimate (3.5) is quite useful in practice. It explicitly shows the dependence on the shape, size, and orientation of the elements, as well as the dependence on the second derivatives of u. This leads to many interesting algorithms for adaptive mesh smoothing and topology modification (e.g., "edge flipping") [8]. For example, if $\bar{M}_\tau$ is assumed to be constant, then ϵ_τ and η_τ^2 are rational functions of vertex locations, and derivatives with respect to the vertex locations are easily computed.

Using ϵ_τ also provides a simple, robust, and elegant solution to an important practical problem for adaptive mesh refinement schemes: how to provide error estimates for the refined elements without immediately resolving the global problem. In the past, most schemes were based on crude (or not-so-crude) extrapolation ideas, using the error indicator of the parent element as a basis. In most such schemes it is difficult to take into account the details of the geometry, and they tend to become very inaccurate after only a few levels of refinement. On the other hand, with our error estimator, the children elements inherit only the Hessian matrix from the parent, and all the geometrical information is derived from the refined elements themselves. Thus it is possible to have many levels of refinement before the approximation breaks down and a new global solution is required. This has proved to be very effective in the PLTMG 8.0 package [6], which employs this scheme, but uses a different a posteriori error estimate to compute the approximate Hessian matrix [8]. In Theorem 3.2, we show that our recovered gradients can provide reasonable approximation to the Hessian.

THEOREM 3.2. *Assume the hypotheses of Theorem* 2.7. *Then*

$$\|\partial_i(\partial_k u - S^m Q_h \partial_k u_h)\|_{0,\Omega} \lesssim \left(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\, h^{1/2}\right)\|u\|_{3,\infty,\Omega}, \tag{3.6}$$

where ε_m *is defined as in Lemma* 2.3 *for* $1/2 \leq \alpha < 1$.

Proof. Let $z = I_h \partial_k u \in \mathcal{V}_h$. Then

$$\begin{aligned}
\|\partial_i(\partial_k u - S^m Q_h \partial_k u_h)\|_{0,\Omega} &\leq \|\partial_i(\partial_k u - z)\|_{0,\Omega} + \|\partial_i(z - S^m Q_h \partial_k u_h)\|_{0,\Omega} \\
&\lesssim h\|u\|_{3,\Omega} + h^{-1}\|z - S^m Q_h \partial_k u_h\|_{0,\Omega} \\
&\lesssim h\|u\|_{3,\Omega} + h^{-1}\left(\|z - \partial_k u\|_{0,\Omega} + \|\partial_k u - S^m Q_h \partial_k u_h\|_{0,\Omega}\right) \\
&\lesssim \left(\min(h^{\min(1,\sigma)}|\log h|, \varepsilon_m) + m\, h^{1/2}\right)\|u\|_{3,\infty,\Omega}. \qquad \square
\end{aligned}$$

4. Numerical experiments.

In this section, we present some numerical illustrations of our recovery scheme in the cases of uniform and adaptively refined (nonuniform) meshes. Our gradient recovery scheme and a posteriori error estimate were implemented in the PLTMG package [6], which was then used for our numerical experiments. The experiments were done on an SGI Octane using double precision arithmetic.

In our first example, we consider the solution of the problem

$$\begin{aligned}
-\Delta u &= f \qquad \text{in } \Omega = (0,1) \times (0,1), \\
u &= g \qquad \text{on } \partial\Omega,
\end{aligned}$$

where f and g are chosen such that $u = e^{x+y}$ is the exact solution. This is a very smooth solution that satisfies all the assumptions of our theory. Here we will compare the recovery scheme with $m = 2$ smoothing steps, for the case of uniform and adaptive meshes. We begin with a uniform 3×3 mesh consisting of eight right triangles, as shown in Figure 4.1. Elements in Figure 4.1 are shaded according to size; this allows

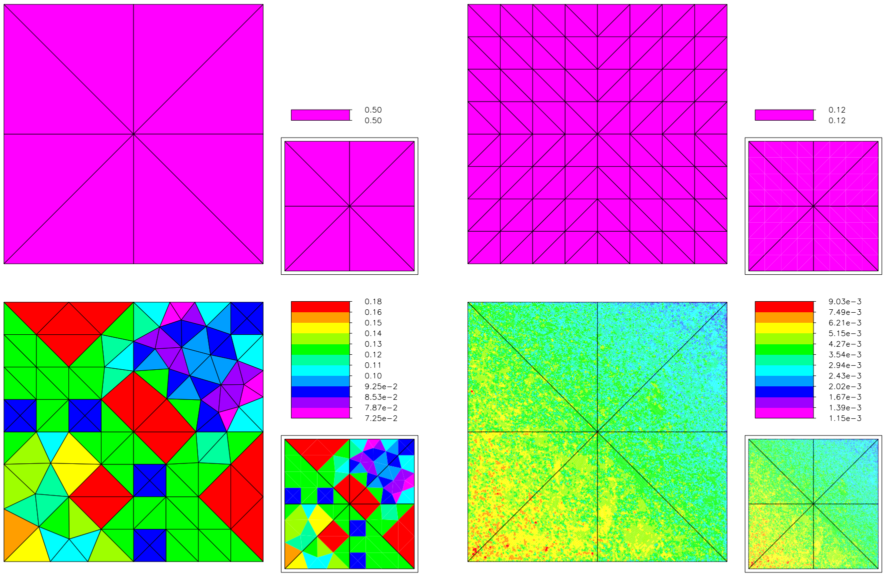

FIG. 4.1. *Top left:* 3×3 *initial mesh. Top right: uniform refinement with* $nt = 128$*. Bottom left: adaptive refinement with* $nt = 134$*. Bottom right: adaptive refinement with* $nt = 130961$*. Elements are shaded according to size.*

one to obtain some impression of the structure of highly refined meshes with many elements, even if individual elements can no longer be resolved.

In Table 4.1, we record the results of the computation. We give the error as a function of the number of elements, choosing targets for the adaptive refinement procedure to produce adaptive meshes with numbers of elements similar to those for the uniform refinement case. The values are defined as follows:

$$\begin{aligned} L2 &= \|u - u_h\|_{0,\Omega}, \\ H1 &= \|\nabla u - S^m Q_h \nabla u_h\|_{0,\Omega}, \\ \widetilde{H1} &= \|\nabla(u - u_h)\|_{0,\Omega}, \\ Ef &= \frac{\|(I - S^m Q_h)\nabla u_h\|_{0,\Omega}}{\|\nabla(u - u_h)\|_{0,\Omega}}. \end{aligned}$$

For the cases of $L2$, $H1$, and $\widetilde{H1}$, we made a least squares fit of the data to a function of the form $F(N) = CN^{-p/2}$ to estimate the order of convergence p. All integrals were approximated using a 12-point order 7 quadrature formula applied to each triangle.

What is most striking is the similarity in the data. $L2$ is approximately the same for both uniform and adaptive refinement, while $H1$ is slightly better in the adaptive case. This is consistent with our strategy, which adaptively refines with respect to $\|\nabla\epsilon_\tau\|_{0,\tau}$. Nonetheless, both cases exhibit some superconvergence for the recovered gradients. This is further supported by noting that the effectivity ratios Ef suggest asymptotic exactness of the a posteriori error estimates.

In Table 4.2, we show the effect of varying the number of smoothing steps. To reduce the amount of data, we report only the case of adaptive meshes. Since the a posteriori error estimates are used to create the meshes, the meshes differ for each value of m but at level K have $nt \approx 2^{2K+1}$ elements. For $m = 0$, we note only slight superconvergence; thus although the meshes are shape regular and quasi-uniform, apparently $\sigma \approx 0$. In contrast, uniform meshes for $m = 0$ have a computed order of convergence for $H1$ of 1.52, essentially that predicted by our theory. However, the data show that the situation for adaptive meshes improves dramatically for $m = 1, 2$. For $m = 10$, one can see the effects of "too many" smoothings; Ef becomes more erratic, and $H1$ *increases* for some of the coarser refinement steps. But even in this case, for more refined meshes (e.g., $K = 8$), Ef again appears to be converging towards 1. This is likely due to the well-known (and in this case extremely useful) effect of the smoothing iteration "slowing down" quickly as h becomes smaller.

In Table 4.3, we explore the effect of "lumping" the mass matrix in the L^2 projection step. In particular, the mass matrix was replaced by a diagonal matrix, with diagonal entries given by the sum of all nonzero entries of the corresponding row of the mass matrix. In Table 4.3, we see results that are quite comparable to those of Table 4.1, although the gradient errors are generally slightly larger. Nonetheless, these results suggest that our gradient recovery algorithm could be modified to use only local calculations without much loss in effectiveness.

In our second example, we consider the nonlinear problem

$$\begin{aligned} -\nabla\cdot(a\nabla u) + e^u = f \qquad & \text{in } \Omega = (0,1)\times(0,1), \\ u = 0 \qquad & \text{on } \partial\Omega, \end{aligned}$$

Table 4.3
The effect of a lumped *mass matrix.*

where a is the 2×2 diagonal matrix

$$a = \begin{pmatrix} .01 & \\ & 1 \end{pmatrix}.$$

The function f is chosen such that $u = x(1-x)^3 y^5 (1-y)$ is the exact solution. We repeat the same computations as in the first example, with uniform and adaptive meshes. The uniform meshes are identical to those of the first example. Some of the adaptive meshes are shown in Figure 4.2. The numerical results are summarized in Table 4.4.

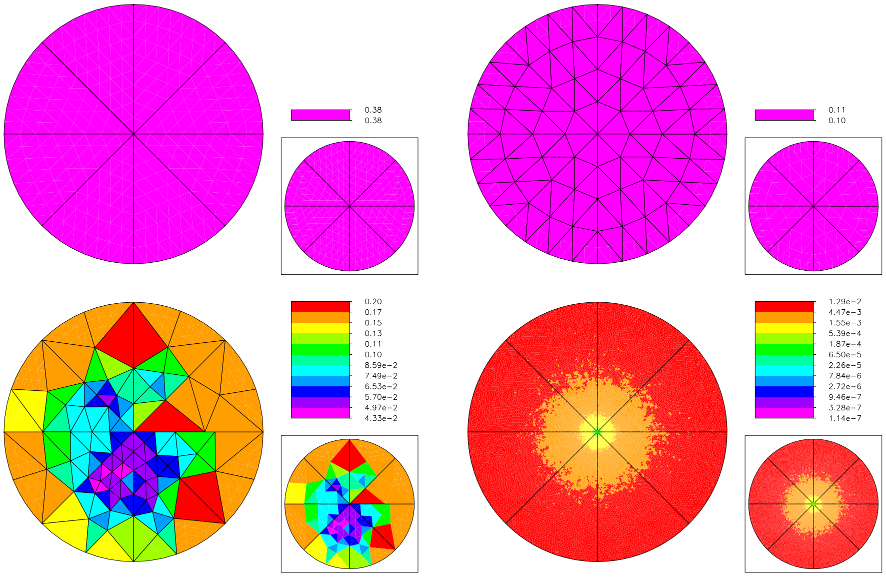

FIG. 4.3. *Top left: the initial mesh. Top right: uniform refinement with* $nt = 128$. *Bottom left: adaptive refinement with* $nt = 138$. *Bottom right: adaptive refinement with* $nt = 131105$. *Elements are shaded according to size.*

This problem is more difficult than the first in several respects. The diffusion is anisotropic, and the operator is nonlinear. The solution is smooth but generally has larger derivatives than the first example. Nonetheless, we see a similar behavior of the gradient recovery scheme and a posteriori error estimate. In this example, the adaptive meshes are more strongly graded than in the first example, suggesting that localization and equilibration of the error are more important effects for superconvergence of our gradient recovery procedure than geometric uniformity in the mesh.

In our third example, we consider the problem

$$\begin{aligned} -\Delta u &= 0 && \text{in } \Omega, \\ u &= g && \text{on } \partial\Omega_1, \\ u_n &= 0 && \text{on } \partial\Omega_2, \end{aligned}$$

where Ω is a circle of radius one centered at the origin, and with a crack along the positive x-axis, $0 \le x \le 1$. $\partial\Omega_2$ is the bottom edge of the crack, and $\partial\Omega_1 = \partial\Omega - \partial\Omega_2$. The function g is chosen such that the exact solution is $u = r^{1/4}\sin(\theta/4)$, the leading term of the singularity associated with the interior angle of 2π and change in boundary conditions at the origin. In Figure 4.3 we illustrate the initial mesh and several of the uniformly and adaptively refined meshes.

Convergence results for uniform and adaptive refinement are reported in Table 4.5. The solution u is not smooth in this case ($u \in H^{5/4-\epsilon}(\Omega)$), and this is reflected in the results. For the case of uniform refinement, the 0.25 order of convergence of the gradient coincides with the smoothness of the solution. For the adaptive meshes, the order of convergence improves and seems to be approaching order one for the gradient. This sort of behavior is typical of a reasonable adaptive refinement procedure. However, even in this case, there is no apparent superconvergence.

Let Ω' now denote the union of all triangles in Ω with a least one vertex outside a circle of $r = 0.1$; note that this definition of Ω' is mesh dependent, but eventually Ω' excludes small triangles close to the singularity. In Table 4.6, we report results for the same computations but with the error calculation restricted to Ω'. For $L2'$, the results do not change much. However, for the gradients ($H1'$), the results are quite striking. For the case of adaptive refinement, the improvement is quite dramatic, in that, away from the singularity, the gradient recovery scheme exhibits the same sort of behavior as for a smooth problem. For the case of uniform refinement, there is also some improvement in order of convergence, but the recovered gradient does not appear significantly more accurate than ∇u_h. We also note the quite different behavior of Ef' compared with Ef for the case of uniform refinement. Taken as a whole, it seems likely that the error in the uniform refinement case is not localized, and pollution effects are still dominant even on the most refined meshes.

In our fourth example, we consider a problem with discontinuous coefficients:

$$\begin{aligned} -\nabla \cdot (a \nabla u) &= f \qquad \text{in } \Omega, \\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned}$$

where Ω is once again the unit square $(0,1) \times (0,1)$. The scalar coefficient function $a(p) = 1$ for $p \in \Omega_1 \equiv (0,1/2) \times (0,1/2) \cup (1/2,1) \times (1/2,1)$, and $a(p) = 10^{-2}$ for $p = \Omega - \Omega_1$. The function f is given by $f = 8\pi^2 \sin(2\pi x) \sin(2\pi y)$, and the exact solution u is given by $u = a^{-1} \sin(2\pi x) \sin(2\pi y)$. The initial mesh is the same as that in the first two examples. In Table 4.7, we give the results for both uniform and

adaptive meshes. Here we note no superconvergence for $H1$ in either case; indeed, in the uniform mesh case, $S^m Q_h \nabla u_h$ is much less accurate than ∇u_h in terms of order of convergence. The gradient of the exact solution is discontinuous along the lines $x = 1/2$ and $y = 1/2$. Since the mesh is aligned with the discontinuity, ∇u_h is able to capture this discontinuity with no problem. Since $Q_h \nabla u_h$ is continuous, the lack of superconvergence is due to the global L^2 projection; making local L^2 projections in each of the four subregions where $a(p)$ is constant would allow the projected gradient to remain discontinuous along the interfaces. In Table 4.8, we show the results for such a calculation. We computed $S^m \hat{Q}_h \nabla u_u$, where $\hat{Q}_h$ corresponds to the four local L^2 projections. Since we used a different projection, the adaptive meshes changed slightly. Nonetheless, we see quite clearly that allowing for the discontinuity in ∇u corrects the problems. We observe superconvergence in $H1'$ for both the uniform and adaptive meshes, as well as significant improvement in the effectivity ratios Ef'. We note in passing that, away from the discontinuities, the approximation $S^m Q_h \nabla u_h$ is superconvergent. In this respect, the behavior here is similar to that in the third example.

These numerical examples show that the effectiveness of our adaptive scheme does not necessarily depend critically on either the quasi-uniformity of the mesh or on the global regularity of the solution. However, theoretically there is still much work to do to fill in the gaps. We believe that our quasi-uniformity assumption on the triangular meshes can be removed with some extra effort. Our results are very local in the sense that the domain Ω in our theorems could be any subdomain of the actual physical domain. It will be much more challenging to obtain theoretical results with more realistic assumptions on a continuous solution's regularity. However, heuristically speaking, at places where the solution is singular, the solution will have large (or infinite) W^3_∞ norm, and as a result, our error indicator will be large in those regions and hence the grid will be refined there.

Acknowledgments. The ideas for this manuscript germinated while the authors were attending the workshop on *A Posteriori Error Estimation and Adaptive Approaches in the Finite Element Method,* held at the Mathematical Sciences Research Institute, University of California, Berkeley, April 3–14, 2000. We are grateful for the opportunity to attend this workshop and for the stimulating scientific environment at MSRI. We also thank Lars B. Wahlbin for helpful discussions during the aforementioned workshop, and the reviewers for their careful reviews and suggestions for improvements.

CONVERGENCE ANALYSIS OF SPECTRAL COLLOCATION METHODS FOR A SINGULAR DIFFERENTIAL EQUATION[*]

WEIZHANG HUANG[†], HEPING MA[‡], AND WEIWEI SUN[§]

Abstract. Solutions of partial differential equations with coordinate singularities often have special behavior near the singularities, which forces them to be smooth. Special treatment for these coordinate singularities is necessary in spectral approximations in order to avoid degradation of accuracy and efficiency. It has been observed numerically in the past that, for a scheme to attain high accuracy, it is unnecessary to impose all the pole conditions, the constraints representing the special solution behavior near singularities. In this paper we provide a theoretical justification for this observation. Specifically, we consider an existing approach, which uses a pole condition as the boundary condition at a singularity and solves the reformulated boundary value problem with a commonly used Gauss–Lobatto collocation scheme. Spectral convergence of the Legendre and Chebyshev collocation methods is obtained for a singular differential equation arising from polar and cylindrical geometries.

Key words. coordinate singularity, convergence, spectral collocation method

1. Introduction.

Physical problems in polar, cylindrical, or spherical geometries often give rise to mathematical models involving singular partial differential equations (PDEs) with smooth solutions. A common feature of these PDEs is that their solutions have special behavior near coordinate singularities, which forces the solutions to be smooth. For the spectral solution of this type of equation, special treatment for the coordinate singularities is needed, since a traditional spectral scheme either does not fully capture the special solution behavior or is ill-suited to fast transform techniques; e.g., see [6, 7, 11].

A number of spectral approaches have been developed in the past in attempts to capture the solution behavior near coordinate singularities. They include those expanding the solution in specially designed basis functions, such as spherical harmonics, parity-modified Fourier series, modified Robert functions, and eigenfunctions of singular Sturm–Liouville problems [6, 9, 11, 20, 21, 22, 27]; approaches using inherent symmetries of the solution [9, 10]; and methods using pole conditions (i.e., compatibility conditions at the center of polar coordinates) as boundary conditions in the collocation context [12] and the Galerkin context [24, 25]. Many of these approaches have been successfully applied to steady state and time dependent problems including the Navier–Stokes equations; e.g., see [13, 14, 20, 23, 26, 28].

The solution behavior of PDEs near coordinate singularities can be described by an infinite number of pole conditions derived either from the underlying differential equation, by assuming some kind of smoothness of the solution, or more generally from the analyticity of the solution at singularities. Most of the existing methods are developed more or less to accommodate this behavior. However, it is observed numerically first by Orszag [21] and then by many other researchers (e.g., [6]) that it is unnecessary to impose all of the pole conditions in order for a numerical scheme to attain high accuracy. In fact, Huang and Sloan [12], using some of these pole conditions as the boundary conditions at the coordinate singularities, show numerically that the spectral collocation approximation of the Helmholtz equation on the unit disk has a spectral convergence rate.

Three Legendre-type pseudospectral schemes and their convergence analysis have been developed for axisymmetric domains by Bernardi, Dauge, and Maday in their recent book [1]. The basic idea behind these schemes is to incorporate the natural measure rdr of the coordinate singularity into the quadrature formula defining the spectral approximation. In the radial direction the formula reads as

$$\int_0^1 v(r)rdr = \sum_{j=0}^{N} v(r_j)\omega_j \qquad \forall v \in \mathbf{P}, \tag{1.1}$$

where $\mathbf{P}$ is a polynomial space, $r_j = (1+\rho_j)/2$, and the ω_j's are the corresponding weights. Three sets of ρ_j's and $\mathbf{P}$ are chosen, one for each scheme:

Method A (Gauss–Radau): $\mathbf{P} = \mathbf{P}_{2N}$, $\rho_N = 1$,
ρ_j $(0 \le j \le N-1)$ are the roots of $L'_{N+1}(\rho)$;
Method B (Gauss–Lobatto): $\mathbf{P} = \mathbf{P}_{2N-1}$, $\rho_0 = -1$, $\rho_N = 1$,
ρ_j $(1 \le j \le N-1)$ are the roots of $\left(\frac{L_N(\rho)+L_{N+1}(\rho)}{1+\rho}\right)'$;
Method C (Gauss–Radau): $\mathbf{P} = \mathbf{P}_{2N-1}$, $\rho_N = 1$,
ρ_j $(0 \le j \le N-1)$ are the roots of $L_{N+1}(\rho) - L_N(\rho)$,

where L_N is the Legendre polynomial of degree N. The pseudospectral approximations are then defined through the boundary condition(s) and the Galerkin formulation of the underlying problem in the discrete inner product $((u,v))_N \equiv \sum_{j=0}^{N} u(r_j)v(r_j)\omega_j$ induced from the quadrature formula (1.1). It is noted that the nodes used in these schemes are different from those in a traditional (unweighted) spectral collocation method. Moreover, among these three schemes, only Method C is equivalent to a collocation system. Furthermore, the authors of the book suggest that two boundary conditions $u(0) = 0$ (which is a pole condition, cf. (2.6)) and $u(1) = g$ be used for a reduced equation (see (2.1)–(2.2)) with $n \neq 0$. Thus, only Method B, which uses the Gauss–Lobatto nodes but cannot be interpreted as a collocation scheme, can be applied to the case $n \neq 0$.

The objective of this paper is to provide a theoretical justification for the method developed in [12], which uses a pole condition as the boundary condition at the coordinate singularity and solves the reformulated boundary value problem with a Gauss–Lobatto collocation scheme. The method corresponds to the standard quadrature formula

$$\int_0^1 v(r)\omega(r)dr = \sum_{j=0}^{N} w_j v(r_j) \qquad \text{for } v \in \mathbf{P}_{2N-1}, \tag{1.2}$$

where $\omega(r)$ is the weight function and $r_j = (1+\rho_j)/2$. For example, $\omega(r) = 1$ and ρ_j $(0 \le j \le N)$ are the roots of $(1-\rho^2)L_N^{'}(\rho)$ for the Legendre collocation method, and $\omega(r) = (r-r^2)^{-1/2}$ and $\rho_j = \cos\frac{\pi(N-j)}{N}$ $(0 \le j \le N)$ for the Chebyshev collocation method. We emphasize that the method of [12], which is no more than a traditional collocation method, is different from those considered by Bernardi, Dauge, and Maday [1]. The method shares with many existing methods the common feature of explicitly using pole conditions, and has been successfully applied to practical problems including the Navier–Stokes equations; e.g., see [13, 14]. Our analysis is given for both the Legendre and Chebyshev schemes. A Chebyshev collocation scheme is often desirable in practical computation because the fast Fourier transformation (FFT) can be utilized. We find that for the current situation with coordinate singularities the corresponding bilinear form lacks the coercive property which is often crucial to the convergence analysis of a Chebyshev scheme. Because of this, the error estimate of the Chebyshev scheme is obtained in the weighted energy norm $\|\cdot\|_{E_n,\omega}$ with $\omega(r)$ being the Chebyshev weight function for the reduced equation with $n > 0$, but in the unweighted norm $\|\cdot\|_{E_n}$ for the case $n = 0$.

An outline of this paper is as follows. The method of [12] is briefly described in section 2. The convergence analysis of the Legendre and Chebyshev methods is given in section 3. In section 4 we present numerical results to verify the theoretical findings. Finally, section 5 contains conclusions and further comments.

2. Pole conditions and spectral collocation approximation.

In this section we briefly describe the spectral collocation method of [12] for a model problem

$$-\frac{d^2u}{dr^2} - \frac{1}{r}\frac{du}{dr} + \frac{n^2}{r^2}u = f, \quad 0 < r < 1, \tag{2.1}$$

$$u(1) = g, \tag{2.2}$$

where $n \ge 0$ is a given integer. This problem is obtained using separation of variables for the Poisson equation on the unit disk.

2.1. Pole conditions.

Equation (2.1) has a coordinate singularity at $r = 0$. Assume that both f and u are sufficiently smooth. A Taylor series expansion of u about $r = 0$ yields the pole conditions

$$O\left(\frac{1}{r^2}\right) : n^2 u(0) = 0, \tag{2.3}$$

$$O\left(\frac{1}{r}\right) : (n^2-1)\frac{du}{dr}(0) = 0, \tag{2.4}$$

$$O(1) : \left(\frac{n^2}{2} - 2\right)\frac{d^2u}{dr^2}(0) = f(0), \tag{2.5}$$

$$\cdots\cdots$$

These conditions contain full information about the solution behavior near $r = 0$. It was observed first by Orszag [21] and later by many other researchers (see [6]) that it is unnecessary to impose all of these pole conditions in order for a numerical scheme to obtain high accuracy. In fact, using one constraint

$$\begin{cases} u(0) = 0 & \text{for } n \ne 0, \\ \frac{du}{dr}(0) = 0 & \text{for } n = 0 \end{cases} \tag{2.6}$$

as the boundary condition at $r = 0$, Huang and Sloan [12] obtain spectrally accurate solutions; also see [24, 25] for the spectral Galerkin approximation. Once a boundary condition has been defined at $r = 0$, it is straightforward to apply a traditional spectral collocation scheme to the singular problem (2.1) and (2.2).

2.2. Legendre and Chebyshev collocation approximations. Hereafter, the weight functions $\omega(r) = 1$ and $\omega(r) = (r-r^2)^{-1/2}$ will be associated with the Legendre and Chebyshev methods, respectively. For simplicity, we use subscript ω in common notation for both methods and for those which apply only to the Chebyshev method, and suppress the subscript for the Legendre method.

For a given integer $N > 0$, let $\{\rho_{j,\omega}\}_{j=0}^{N}$ be a set of Gauss–Lobatto points associated with the weight function $\omega(r)$. Define

$$r_{j,\omega} = \frac{1+\rho_{j,\omega}}{2}, \qquad j = 0, 1, \dots, N. \tag{2.7}$$

The solution $u(r)$ is approximated by

$$u^N(r) = \sum_{j=0}^{N} u_{j,\omega} l_{j,\omega}(r), \tag{2.8}$$

where $u_{j,\omega}$ denotes the approximation of $u(r_{j,\omega})$ and $l_{j,\omega}(r)$ is the Lagrangian interpolation polynomial

$$l_{j,\omega}(r) = \prod_{\substack{i=0\\ i\neq j}}^{N} \frac{r - r_{i,\omega}}{r_{j,\omega} - r_{i,\omega}}. \tag{2.9}$$

A collocation approximation to (2.1), (2.2), and (2.6) is then defined by the collocation equations

$$-\frac{d^2u^N}{dr^2}(r_{j,\omega}) - \frac{1}{r_{j,\omega}}\frac{du^N}{dr}(r_{j,\omega}) + \frac{n^2}{r_{j,\omega}^2}u^N(r_{j,\omega}) = f(r_{j,\omega}), \qquad j = 1, \dots, N-1, \tag{2.10}$$

$$u^N(1) = g, \tag{2.11}$$

$$\begin{cases} u^N(0) = 0 & \text{for } n \neq 0, \\ \frac{du^N}{dr}(0) = 0 & \text{for } n = 0. \end{cases} \tag{2.12}$$

Recall that the transformed Gauss–Lobatto quadrature rule satisfies

$$\int_0^1 v(r)\omega(r)dr = \sum_{j=0}^{N} w_{j,\omega} v(r_{j,\omega}) \qquad \text{for } v \in \mathbf{P}_{2N-1}, \tag{2.13}$$

where the $w_{j,\omega}$'s are the corresponding weights and $\mathbf{P}_{2N-1}$ is the space of real polynomials (in r) of degree no more than $2N-1$. The associated interpolation operator $I^N : C[0,1] \to \mathbf{P}_N$ is defined as

$$I^N v \in \mathbf{P}_N : \quad (I^N v)(r_{j,\omega}) = v(r_{j,\omega}), \qquad j = 0, 1, \dots, N. \tag{2.14}$$

We use the notation

$$\langle u, v\rangle_\omega = \int_0^1 uv\omega dr, \quad \|u\|_\omega = \langle u, u\rangle_\omega^{1/2}, \tag{2.15}$$

$$\|u\|_{m,\omega} = \left(\sum_{k=0}^{m} \left\|\frac{d^k u}{dr^k}\right\|_\omega^2\right)^{1/2} \qquad \text{for } u \in H_\omega^m, \tag{2.16}$$

$$\langle u, v\rangle_{\omega,N} = \sum_{j=0}^{N} w_{j,\omega} u(r_{j,\omega}) v(r_{j,\omega}), \quad \|u\|_{\omega,N} = \langle u, u\rangle_{\omega,N}^{1/2}, \tag{2.17}$$

where H_ω^m $(m \geq 0)$ is a (weighted) Sobolev space on [0, 1].

For the Legendre collocation scheme, the set of Legendre–Gauss–Lobatto points is defined by $\rho_0 = -1$, $\rho_N = 1$, and ρ_j $(j = 1, 2, \ldots, N-1)$ being the roots of $L_N^{'}$, the first derivative of the Legendre polynomial L_N of degree N. We have

$$l_j(r) = \frac{2}{N(N+1)} \frac{r(1-r)\bar{L}_N^{'}(r)}{(r-r_j)\bar{L}_N(r_j)}, \qquad w_j = \frac{1}{N(N+1)} \frac{1}{\bar{L}_N^2(r_j)},$$

with $\bar{L}_N(r)$ being the transformed Legendre polynomial $L_N(2r-1)$.

For the Chebyshev approximation, the set of Gauss–Lobatto points is defined by $\rho_{0,\omega} = -1$, $\rho_{N,\omega} = 1$, and $\rho_{j,\omega}$ $(j = 1, 2, \ldots, N-1)$ being the roots of $T_N^{'}$, the derivative of the Chebyshev polynomial T_N of degree N. We have

$$l_{j,\omega}(r) = (-1)^{j+1} \frac{2}{c_j N^2} \frac{r(1-r)\bar{T}_N^{'}(r)}{(r - r_{j,\omega})}, \qquad w_{j,\omega} = \frac{\pi}{c_j N},$$

where $\bar{T}_k(r)$ is the transformed Chebyshev polynomial $T_k(2r-1)$ and

$$c_j = \begin{cases} 2, & j = 0, N, \\ 1, & j = 1, \ldots, N-1. \end{cases}$$

3. Convergence analysis.

3.1. Preliminary approximation results. To start with, we introduce some preliminary results. Hereafter, C is used to denote the generic constant. We shall assume that $N \gg m$ (the smoothness order of functions); otherwise, the estimates given below, especially those involving seminorms, will not be true.

LEMMA 3.1. *Let P^N denote the Legendre (or Chebyshev) truncated operator; i.e., $P^N v$ is the truncated Legendre (or Chebyshev) series of v. Then, for $m \geq 0$ and for $\omega(r) = 1$ (the Legendre case) or $\omega(r) = (r - r^2)^{-1/2}$ (the Chebyshev case),*

$$\|v - P^N v\|_\omega \leq CN^{-m} \left\|(r - r^2)^{m/2} \frac{d^m v}{dr^m}\right\|_\omega \qquad \forall v \in H_\omega^m. \tag{3.1}$$

LEMMA 3.2. *For $\omega(r) = 1$ (the Legendre case) or $\omega(r) = (r - r^2)^{-1/2}$ (the Chebyshev case) and for $m \geq 1$,*

$$\begin{aligned} &\left\|(r - r^2)^{-1/2}(v - I^N v)\right\|_\omega + N^{-1}\|v - I^N v\|_{1,\omega} \\ &\qquad \leq CN^{-m} \left\|(r - r^2)^{\frac{m-1}{2}} \frac{d^m v}{dr^m}\right\|_\omega \qquad \forall v \in H_\omega^m. \end{aligned} \tag{3.2}$$

Lemma 3.3. *Let $\omega(r) = 1$ (for the Legendre case) or $\omega(r) = (r - r^2)^{-1/2}$ (for the Chebyshev case). There exists a positive constant C, independent of N and M, such that for all $\phi \in \mathbf{P}_M$ with M being any nonnegative integer,*

$$\|\phi\|_{\omega,N} \le C\left(1 + \frac{M}{N}\right)\|\phi\|_{\omega}, \tag{3.3}$$

$$\|\phi\|_{\omega} \le \ \|\phi\|_{\omega,N} \ \le C\|\phi\|_{\omega}. \tag{3.4}$$

The interested reader is referred to [2, 3, 4, 7, 16, 18, 19] for the proofs of these Lemmas. Lemmas 3.1 and 3.2 are the improvements of existing results in terms of the weight and can be obtained by the method in the aforementioned references.

3.2. Convergence analysis of the Legendre method. We now proceed to the convergence analysis for the Legendre approximation (2.10)–(2.12). Let ϕ be an arbitrary polynomial in $\mathbf{P}_N$ satisfying

$$\begin{cases} \phi(1) = \phi(0) = 0 & \text{if } n \neq 0, \\ \phi(1) = 0 & \text{if } n = 0. \end{cases} \tag{3.5}$$

Multiplying (2.10) by $r_j w_j \phi(r_j)$ and summing over the range of j from 1 to $N-1$, we have

$$\sum_{j=1}^{N-1} w_j\phi(r_j)\left[-r_j\frac{d^2u^N}{dr^2}(r_j) - \frac{du^N}{dr}(r_j) + \frac{n^2}{r_j}u^N(r_j)\right] = \sum_{j=1}^{N-1} r_j w_j \phi(r_j) f(r_j). \tag{3.6}$$

It is not difficult to see from (3.5) that

$$\begin{aligned} & w_N\phi(r_N)\left[-r_N\frac{d^2u^N}{dr^2}(r_N) - \frac{du^N}{dr}(r_N) + \frac{n^2}{r_N}u^N(r_N)\right] \\ & = r_N w_N \phi(r_N) f(r_N) \\ & = 0. \end{aligned} \tag{3.7}$$

Noticing that $u^N(r)/r$ is a polynomial of degree not greater than $N-1$, that $\phi(r_0) = 0$ (see (3.5)) when $n \neq 0$, and that $(du^N/dr)(r_0) = 0$ when $n = 0$, we have

$$\begin{aligned} & w_0\phi(r_0)\left[-r_0\frac{d^2u^N}{dr^2}(r_0) - \frac{du^N}{dr}(r_0) + \frac{n^2}{r_0}u^N(r_0)\right] \\ & = r_0 w_0 \phi(r_0) f(r_0) \\ & = 0. \end{aligned} \tag{3.8}$$

Thus, (3.6)–(3.8) imply that

$$\left\langle -r\frac{d^2u^N}{dr^2} - \frac{du^N}{dr} + \frac{n^2}{r}u^N, \phi\right\rangle_N = \langle rf, \phi\rangle_N. \tag{3.9}$$

Since $r\phi(d^2u^N/dr^2)$, $\phi(du^N/dr)$, and $n^2u^N\phi/r$ are in $\mathbf{P}_{2N-1}$, (2.13) and (3.9) lead to

$$\left\langle -r\frac{d^2u^N}{dr^2} - \frac{du^N}{dr} + \frac{n^2}{r}u^N, \phi\right\rangle = \langle rf, \phi\rangle_N \tag{3.10}$$

or, taking integration by parts,

$$\left\langle \frac{du^N}{dr}, r\frac{d\phi}{dr}\right\rangle + n^2\left\langle \frac{u^N}{r}, \phi\right\rangle \;=\; \langle rf, \phi\rangle_N. \tag{3.11}$$

Multiplying the continuous equation (2.1) by $r\phi$ and integrating from $r = 0$ to 1, we obtain

$$\left\langle \frac{du}{dr}, r\frac{d\phi}{dr}\right\rangle + n^2\left\langle \frac{u}{r}, \phi\right\rangle \;=\; \langle rf, \phi\rangle. \tag{3.12}$$

Then, subtracting (3.11) from (3.12) gives the error equation

$$\left\langle \frac{d(u-u^N)}{dr}, r\frac{d\phi}{dr}\right\rangle + n^2\left\langle \frac{u-u^N}{r}, \phi\right\rangle \;=\; \langle rf, \phi\rangle - \langle rf, \phi\rangle_N, \tag{3.13}$$

which can be written in a simpler form as

$$a_{r,n}(u-u^N, \phi) = F_r(\phi) \quad \forall \phi \in \mathbf{P}_N, \tag{3.14}$$

where

$$\begin{aligned} a_{r,n}(u,v) \;&=\; \left\langle \frac{du}{dr}, r\frac{dv}{dr}\right\rangle + n^2\left\langle u, \frac{v}{r}\right\rangle, \\ \|v\|_{E_n} \;&=\; a_{r,n}(v,v)^{1/2}, \\ F_r(\phi) \;&=\; \langle rf, \phi\rangle - \langle rf, \phi\rangle_N. \end{aligned} \tag{3.15}$$

We first consider the case $n \neq 0$. Recall that we have $u^N(0) = u(0) = 0$ (cf. (2.6)). Let

$$V_{0g} = \{v \in H^1(I) : v(0) = 0, v(1) = g\}, \quad V_{0g}^N = V_{0g} \cap \mathbf{P}_N.$$

Lemma 3.4. *Let u and u^N be the solutions of the problem* (2.1)–(2.2) ($n \neq 0, u(0) = 0$) *and the approximation* (2.10)–(2.11) ($u^N(0) = 0$), *respectively. We have*

$$\|u - u^N\|_{E_n} \leq \sup_{\varphi \in V_{00}^N} \frac{F_r(\varphi)}{\|\varphi\|_{E_n}} + 2 \inf_{v \in V_{0g}^N} \|v - u\|_{E_n}. \tag{3.16}$$

Proof. Equation (3.14) can be rewritten as

$$a_{r,n}(v-u^N, \phi) = F_r(\phi) + a_{r,n}(v-u, \phi) \qquad \forall \phi \in V_{00}^N \text{ and } v \in V_{0g}^N.$$

Taking $\phi = v - u^N \in V_{00}^N$ results in

$$\|v-u^N\|_{E_n}^2 = a_{r,n}(v-u^N, \phi) \leq \sup_{\varphi \in V_{00}^N} \frac{F_r(\varphi)}{\|\varphi\|_{E_n}} \|\phi\|_{E_n} + a_{r,n}(v-u, \phi)\,.$$

Since

$$\begin{aligned} &a_{r,n}(v-u, \phi) \\ &\quad \leq \|r^{1/2}(v-u)_r\| \cdot \|r^{1/2}\phi_r\| + n^2\|r^{-1/2}(v-u)\| \cdot \|r^{-1/2}\phi\| \\ &\quad \leq \left(\|r^{1/2}(v-u)_r\|^2 + n^2\|r^{-1/2}(v-u)\|^2\right)^{1/2} \left(\|r^{1/2}\phi_r\|^2 + n^2\|r^{-1/2}\phi\|^2\right)^{1/2} \\ &\quad \leq C a_{r,n}(v-u, v-u)^{1/2} a_{r,n}(\phi, \phi)^{1/2} \\ &\quad = C\|v-u\|_{E_n} \cdot \|v-u^N\|_{E_n}, \end{aligned}$$

we have

$$\|v-u^N\|_{E_n}^2 \le C\left(\sup_{\varphi\in V_{00}^N}\frac{F_r(\varphi)}{\|\varphi\|_{E_n}}+\|v-u\|_{E_n}\right)\|v-u^N\|_{E_n}.$$

Then the desired result follows from

$$\|u-u^N\|_{E_n}\le\|u-v\|_{E_n}+\|v-u^N\|_{E_n}. \qquad \square$$

We now use Lemma 3.4 to obtain the estimate of $\|u-u^N\|_{E_n}$. For the first term on the right-hand side of (3.16), we have from the Cauchy–Schwarz inequality and Lemmas 3.1–3.3 that, for any $\phi\in\mathbf{P}_N$,

$$\begin{aligned}|F_r(\phi)| &= |\langle rf,\phi\rangle-\langle rf,\phi\rangle_N|\\ &= |\langle rf,\phi\rangle-\langle P^{N-1}(rf),\phi\rangle\\ &\quad+\langle P^{N-1}(rf),\phi\rangle-\langle I^N(rf),\phi\rangle_N|\\ &\le|\langle rf-P^{N-1}(rf),\phi\rangle|+|\langle P^{N-1}(rf)-I^N(rf),\phi\rangle_N|\\ &\le\|rf-P^{N-1}(rf)\|\,\|\phi\|+C\|P^{N-1}(rf)-I^N(rf)\|\,\|\phi\|_N\\ &\le\|rf-P^{N-1}(rf)\|\,\|\phi\|+C\left(\|rf-P^{N-1}(rf)\|+\|rf-I^N(rf)\|\right)\|\phi\|\\ &= C\left(\|rf-P^{N-1}(rf)\|+\|rf-I^N(rf)\|\right)\|\phi\|.\end{aligned} \tag{3.17}$$

By Lemmas 3.1 and 3.2 (and taking $v=rf\in H^{\bar m}$, $\bar m:=\max\{m-1,1\}$), we obtain

$$\begin{aligned}|F_r(\phi)| &\le CN^{1-m}\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|\|\phi\|\\ &\le CN^{1-m}\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|\|\phi\|_{E_n}.\end{aligned} \tag{3.18}$$

For the second term on the right-hand side of (3.16), taking $v=I^Nu$ and using the definition of the energy norm leads to

$$\begin{aligned}\|v-u\|_{E_n} &\le |v-u|_1+\|[r(1-r)]^{-1/2}(v-u)\|\\ &\le CN^{1-m}\left\|(r-r^2)^{\frac{m-1}{2}}\frac{d^m u}{dr^m}\right\|.\end{aligned} \tag{3.19}$$

Substituting (3.18) and (3.19) into (3.16), we obtain the estimate

$$\|u-u^N\|_{E_n}\le CN^{1-m}\left(\left\|(r-r^2)^{\frac{m-1}{2}}\frac{d^m u}{dr^m}\right\|+\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|\right). \tag{3.20}$$

We now consider the case $n=0$. Recall again that we have $\frac{du^N}{dr}(0)=\frac{du}{dr}(0)=0$. Define

$$W_g=\{v\in H^1(I):v(1)=g\},\qquad W_g^N=W_g\cap\mathbf{P}_N.$$

LEMMA 3.5. *Let u and u^N be the solutions of the problem* (2.1)–(2.2) ($n=0$, $\frac{du}{dr}(0)=0$) *and the approximation* (2.10)–(2.11) ($\frac{du^N}{dr}(0)=0$), *respectively. We have*

$$\|u-u^N\|_{E_0}\le 2\sup_{\varphi\in W_0^N}\frac{F_r(\varphi)}{\|\varphi\|_{E_0}}+2\inf_{v\in W_g^N}\|v-u\|_{E_0}.$$

Proof. Equation (3.14) can be written as

$$a_{r,0}(v-u^N,\phi)=F_r(\phi)+a_{r,0}(v-u,\phi) \qquad \forall\phi\in W_0^N \text{ and } v\in W_g^N.$$

Taking $\phi=v-u^N\in W_0^N$, we have

$$\begin{aligned}\|v-u^N\|_{E_0}^2&=a_{r,0}(v-u^N,\phi)\\&\le\left(\sup_{\varphi\in W_0^N}\frac{F_r(\varphi)}{\|\varphi\|_{E_0}}+\|v-u\|_{E_0}\right)\|v-u^N\|_{E_0}.\end{aligned}$$

Then the conclusion follows. □

From the Hardy-type inequality

$$\|v\|\le\left\|\sqrt{r}\frac{dv}{dr}\right\|=\|v\|_{E_0} \qquad \forall v\in W_0,$$

Lemma 3.5 leads to the same result as in (3.20). Hence, we have proved the following theorem.

THEOREM 3.1. *For any integer $m\ge1$, the Legendre-collocation approximation u^N defined by the scheme* (2.10)–(2.12) *for the problem* (2.1) *and* (2.2) *satisfies*

$$\|u-u^N\|_{E_n}\le CN^{1-m}\left(\left\|(r-r^2)^{\frac{m-1}{2}}\frac{d^mu}{dr^m}\right\|+\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|\right), \tag{3.21}$$

where u is the exact solution of (2.1) *and* (2.2) *and* $\bar m=\max\{m-1,1\}$.

This theorem shows that the Legendre collocation approximation is convergent and the error decays faster than algebraically, provided that the right-hand-side term f and the solution u are infinitely differentiable. As shown in [1], the correct regularity requirement for u and f should be considered in a weighted Sobolev space

$$H_r^s=\left\{v\;\middle|\;\sum_{l=0}^{s}\left\|\sqrt{r}\frac{d^lv}{dr^l}\right\|^2<\infty\right\} \tag{3.22}$$

for some integer s. It is not difficult to see that the terms in the bracket on the right-hand side of (3.21) are bounded for $u\in H_r^m$ and $f\in H_r^{\bar m}$ with $m\ge2$. In this sense, the result of Theorem 3.1 is optimal.

3.3. Convergence analysis of the Chebyshev method. We now consider the convergence of the Chebyshev method (2.10)–(2.12). Let ϕ be the same as in (3.5). As for (3.10), we have

$$\left\langle -r\frac{d^2u^N}{dr^2}-\frac{du^N}{dr}+\frac{n^2}{r}u^N,\phi\right\rangle_\omega = \langle rf,\phi\rangle_{\omega,N} \tag{3.23}$$

or, taking integration by parts,

$$\left\langle\frac{du^N}{dr},r\frac{d(\phi\omega)}{dr}\right\rangle+n^2\left\langle\frac{u^N}{r},\phi\right\rangle_\omega = \langle rf,\phi\rangle_{\omega,N}. \tag{3.24}$$

The error equation reads as

$$\begin{aligned}&\left\langle\frac{d(u-u^N)}{dr},r\frac{d(\phi\omega)}{dr}\right\rangle+n^2\left\langle\frac{u-u^N}{r},\phi\right\rangle_\omega\\&=\langle rf,\phi\rangle_\omega-\langle rf,\phi\rangle_{\omega,N}.\end{aligned} \tag{3.25}$$

We also write it in a simpler form

$$a_{r,n,\omega}(u-u^N,\phi)=F_{r,\omega}(\phi)\qquad \forall\phi\in\mathbf{P}_N, \tag{3.26}$$

where

$$\begin{aligned} a_{r,n,\omega}(u,v) &= b_{r,\omega}(u,v)+n^2\left\langle u,\frac{v}{r}\right\rangle_\omega,\\ b_{r,\omega}(u,v) &= \left\langle \frac{du}{dr}, r\frac{d(v\omega)}{dr}\right\rangle,\\ F_{r,\omega}(\phi) &= \langle rf,\phi\rangle_\omega-\langle rf,\phi\rangle_{\omega,N}. \end{aligned} \tag{3.27}$$

It is known that the nonsymmetric bilinear form $b_{r,\omega}(\cdot,\cdot)$, without the factor r, is coercive (see [3, 7, 8, 17, 15]). On the other hand, in the current situation, $b_{r,\omega}(v,v)$ can become negative for some polynomials subject to the boundary conditions $v(-1)=v(1)=0$ or $\frac{dv}{dr}(-1)=v(1)=0$. We have the following Gårding-type inequality.

Lemma 3.6. *For all $u,v\in H^1_{\omega,0}$ we have*

$$\frac{1}{4}\left\|\sqrt{r}\frac{dv}{dr}\right\|_\omega^2+\frac{3}{8}\left\|\frac{v}{\sqrt{1-r}}\right\|_\omega^2-\frac{1}{8}\left\|\frac{v}{\sqrt{r}}\right\|_\omega^2\le b_{r,\omega}(v,v)\le\left\|\sqrt{r}\frac{dv}{dr}\right\|_\omega^2, \tag{3.28}$$

$$|b_{r,\omega}(u,v)|\le 3\left\|\sqrt{r}\frac{du}{dr}\right\|_\omega\left\|\sqrt{r}\frac{dv}{dr}\right\|_\omega. \tag{3.29}$$

Proof. For notational simplicity, define

$$I_1(v)=\int_0^1\left(\frac{dv}{dr}\right)^2 r\omega\,dr. \tag{3.30}$$

We have from integrating by parts

$$\begin{aligned} b_{r,\omega}(v,v) &= I_1(v)-\int_0^1\frac{dv}{dr}v\frac{1-2r}{2(r-r^2)}r\omega\,dr\\ &= I_1(v)-\frac{1}{8}\int_0^1 v^2r(1-2r+4r^2)\omega^5\,dr\\ &= I_1(v)-\frac{3}{8}\int_0^1 v^2r^3\omega^5\,dr-\frac{1}{8}\int_0^1 v^2r(1-r)^2\omega^5\,dr. \end{aligned} \tag{3.31}$$

Thus $b_{r,\omega}(v,v)\le I_1(v)$. On the other hand,

$$\begin{aligned} 0 &\le \int_0^1\left(\frac{dv}{dr}+vr\omega^2\right)^2 r\omega\,dr\\ &= I_1(v)+\int_0^1 v^2r^3\omega^5\,dr+\int_0^1\frac{d(v^2)}{dr}r^2\omega^3\,dr\\ &= I_1(v)-\frac{1}{2}\int_0^1 v^2r^2\omega^5\,dr, \end{aligned} \tag{3.32}$$

which gives

$$b_{r,\omega}(v,v)\ge\frac{1}{4}I_1(v)+\frac{3}{8}\int_0^1 v^2r^2(1-r)\omega^5\,dr-\frac{1}{8}\int_0^1\frac{v^2}{r}\omega\,dr. \tag{3.33}$$

The result (3.28) follows. To prove (3.29), we estimate $b_{r,\omega}(u,v)$ by

$$\begin{aligned} |b_{r,\omega}(u,v)| &\le \left|\int_0^1 \frac{du}{dr}\frac{dv}{dr} r\omega\, dr\right| + \left|\int_0^1 \frac{du}{dr} v \frac{1-2r}{2(r-r^2)} r\omega\, dr\right| \\ &\le [I_1(u)]^{1/2}[I_1(v)]^{1/2} + I_2(u,v), \end{aligned} \tag{3.34}$$

where

$$I_2(u,v) = \left|\int_0^1 \frac{du}{dr} v \frac{1-2r}{2(r-r^2)} r\omega\, dr\right| \le [I_1(u)]^{1/2}[I_3(v)]^{1/2} \tag{3.35}$$

with

$$I_3(v) = \int_0^1 v^2 \frac{(1-2r)^2}{4(r-r^2)^2} r\omega\, dr = \frac{1}{4}\int_0^1 v^2 r(1-2r)^2\omega^5\, dr. \tag{3.36}$$

On the other hand, from integrating by parts,

$$I_2(v,v) = \frac{1}{8}\int_0^1 v^2(2r^2 + r(1-2r)^2)\omega^5\, dr \ge \frac{1}{2} I_3(v). \tag{3.37}$$

Thus we get from (3.37) and (3.35)

$$I_3(v) \le 2I_2(v,v) \le 2[I_1(v)]^{1/2}[I_3(v)]^{1/2}, \tag{3.38}$$

which gives $I_3(v) \le 4I_1(v)$ and

$$\begin{aligned} |b_{r,\omega}(u,v)| &\le [I_1(u)]^{1/2}([I_1(v)]^{1/2} + [I_3(v)]^{1/2}) \\ &\le 3[I_1(u)]^{1/2}[I_1(v)]^{1/2}. \qquad \square \end{aligned} \tag{3.39}$$

We first consider the case $n \neq 0$. Let V_{0g} and V_{0g}^N be the same as before and

$$\|v\|_{E_n,\omega} = \left(\left\| \sqrt{r}\frac{dv}{dr} \right\|_\omega^2 + n^2 \left\| \frac{v}{\sqrt{r}} \right\|_\omega^2 \right)^{1/2}.$$

LEMMA 3.7. *Let u and u^N be the solutions of the problem* (2.1)–(2.2) ($n \neq 0, u(0) = 0$) *and the Chebyshev approximation* ($u^N(0) = 0$)*, respectively. We have*

$$\|u - u^N\|_{E_n,\omega} \le C \sup_{\varphi \in V_{00}^N} \frac{F_{r,\omega}(\varphi)}{\|\varphi\|_{E_n,\omega}} + C \inf_{v \in V_{0g}^N} \|v - u\|_{E_n,\omega}. \tag{3.40}$$

Proof. Equation (3.26) can be rewritten as

$$a_{r,n,\omega}(v - u^N, \phi) = F_{r,\omega}(\phi) + a_{r,n,\omega}(v - u, \phi) \qquad \forall \phi \in V_{00}^N \text{ and } v \in V_{0g}^N.$$

Taking $\phi = v - u^N \in V_{00}^N$ and using the inequality (3.28) of Lemma 3.6 yields

$$\|v - u^N\|_{E_n,\omega}^2 \le Ca_{r,n,\omega}(v - u^N, \phi) \le C \sup_{\varphi \in V_{00}^N} \frac{F_{r,\omega}(\varphi)}{\|\varphi\|_{E_n,\omega}} \|\phi\|_{E_n,\omega} + Ca_{r,n,\omega}(v - u, \phi)\,.$$

From (3.29) of Lemma 3.6 we have

$$\begin{aligned}
&a_{r,n,\omega}(v-u,\phi)\\
&\quad\le C\left\|\sqrt{r}\frac{d(v-u)}{dr}\right\|_\omega\left\|\sqrt{r}\frac{d\phi}{dr}\right\|_\omega+n^2\left\|\frac{v-u}{\sqrt{r}}\right\|_\omega\left\|\frac{\phi}{\sqrt{r}}\right\|_\omega\\
&\quad\le C\left(\left\|\sqrt{r}\frac{d(v-u)}{dr}\right\|_\omega^2+n^2\left\|\frac{v-u}{\sqrt{r}}\right\|_\omega^2\right)^{1/2}\left(\left\|\sqrt{r}\frac{d(\phi)}{dr}\right\|_\omega^2+n^2\left\|\frac{\phi}{\sqrt{r}}\right\|_\omega^2\right)^{1/2}\\
&\quad= C\|v-u\|_{E_n,\omega}\cdot\|v-u^N\|_{E_n,\omega},
\end{aligned}$$

and therefore

$$\|v-u^N\|_{E_n,\omega}^2\le C\left(\sup_{w\in V_{00}^N}\frac{F_{r,\omega}(w)}{\|w\|_{E_n,\omega}}+\|v-u\|_{E_n,\omega}\right)\|v-u^N\|_{E_n,\omega}.$$

Then, the desired result follows from the triangular inequality:

$$\|u-u^N\|_{E_n,\omega}\le\|u-v\|_{E_n,\omega}+\|v-u^N\|_{E_n,\omega}. \qquad \square$$

We now use Lemma 3.7 to obtain the estimate of $\|u-u^N\|_{E_n,\omega}$. For the first term on the right-hand side of (3.40), we have from the Cauchy–Schwarz inequality and Lemmas 3.1–3.3 that, for any $\phi\in\mathbf{P}_N$,

$$\begin{aligned}
|F_{r,\omega}(\phi)|&=|\langle rf,\phi\rangle_\omega-\langle rf,\phi\rangle_{\omega,N}|\\
&=|\langle rf,\phi\rangle_\omega-\langle P^{N-1}(rf),\phi\rangle_\omega+\langle P^{N-1}(rf),\phi\rangle_\omega-\langle I^N(rf),\phi\rangle_{\omega,N}|\\
&=C\left(\|rf-P^{N-1}(rf)\|_\omega+\|rf-I^N(rf)\|_\omega\right)\|\phi\|_\omega.
\end{aligned}$$

Then, by Lemmas 3.1 and 3.2,

$$\begin{aligned}
|F_{r,\omega}(\phi)|&\le CN^{1-m}\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|_\omega\|\phi\|_\omega\\
&\le CN^{1-m}\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|_\omega\|\phi\|_{E_n,\omega}. \qquad (3.41)
\end{aligned}$$

For the second term on the right-hand side of (3.16), taking $v=I^Nu$ leads to

$$\begin{aligned}
\|v-u\|_{E_n,\omega}&\le\left\|\sqrt{r}\frac{d(v-u)}{dr}\right\|_\omega+\left\|\frac{v-u}{\sqrt{r(1-r)}}\right\|_\omega\\
&\le CN^{1-m}\left\|(r-r^2)^{\frac{m-1}{2}}\frac{d^mu}{dr^m}\right\|_\omega. \qquad (3.42)
\end{aligned}$$

Substituting (3.41) and (3.42) into (3.16), we obtain the estimate

$$\begin{aligned}
&\|u-u^N\|_{E_n,\omega}\\
&\quad\le CN^{1-m}\left(\left\|(r-r^2)^{\frac{m-1}{2}}\frac{d^mu}{dr^m}\right\|_\omega+\left\|(r-r^2)^{\frac{\bar m-1}{2}}\frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\|_\omega\right). \qquad (3.43)
\end{aligned}$$

We now consider the case $n=0$. In this case, $a_{r,0,\omega}(\cdot,\cdot)=b_{r,\omega}(\cdot,\cdot)$ is not coercive. Thus it does not seem likely to us that an error bound can be obtained in the weighted energy norm $\|\cdot\|_{E_0,\omega}$. For this reason, we conduct the estimation in the energy norm $\|\cdot\|_{E_0}$ without the Chebyshev weight. We first note that the polar condition $\frac{du^N}{dr}(0)=0$ allows us to extend the collocation equations

$$-r_{j,\omega}\frac{d^2u^N}{dr^2}(r_{j,\omega})-\frac{du^N}{dr}(r_{j,\omega})=r_{j,\omega}f(r_{j,\omega}),\qquad 1\le j\le N-1, \tag{3.44}$$

to the point $r=r_{j,\omega}=0$. Since the left-hand side of (3.44) is a polynomial of degree $N-1$, (3.44) holds for all $r\in[0,1]$, provided that $f\in\mathbf{P}_{N-2}$. We introduce an auxiliary interpolation operator $\tilde{I}^{N-2}$: $C([0,1])\to\mathbf{P}_{N-2}$ defined by

$$\tilde{I}^{N-2}v(r_j)=v(r_j),\qquad 1\le j\le N-1. \tag{3.45}$$

Thus we are able to rewrite (3.44) as

$$-r\frac{d^2u^N}{dr^2}(r)-\frac{du^N}{dr}(r)=r\tilde{I}^{N-2}f(r),\qquad 0\le r\le 1. \tag{3.46}$$

Let W_g and W_g^N be the same as before.

Lemma 3.8. *Let u and u^N be the solutions of the problem* (2.1)–(2.2) ($n=0$, $\frac{du}{dr}(0)=0$) *and the Chebyshev collocation approximation* ($\frac{du^N}{dr}(0)=0$), *respectively. We have*

$$\|u-u^N\|_{E_0}\le\sup_{\varphi\in W_0^N}\frac{\tilde{F}_r(\varphi)}{\|\varphi\|_{E_0}}+2\inf_{v\in W_g^N}\|v-u\|_{E_0},$$

where $\tilde{F}_r(\varphi)=\langle rf-r\tilde{I}^{N-2}f,\varphi\rangle$.

Proof. We have from (2.1) and (3.46)

$$a_{r,0}(v-u^N,\phi)=\tilde{F}_r(\phi)+a_{r,0}(v-u,\phi)\qquad\forall\phi\in W_0^N\text{ and }v\in W_g^N.$$

Taking $\phi=v-u^N\in W_0^N$, we have

$$\begin{aligned}\|v-u^N\|_{E_0}^2&=a_{r,0}(v-u^N,\phi)\\&\le\left(\sup_{\varphi\in W_0^N}\frac{\tilde{F}_r(\varphi)}{\|\varphi\|_{E_0}}+\|v-u\|_{E_0}\right)\|v-u^N\|_{E_0},\end{aligned}$$

which gives the desired result. □

We need further to estimate the term $\tilde{F}_r(\varphi)$. According to the definition, it is easy to see that $(r-r^2)\tilde{I}^{N-2}f=I^N((r-r^2)f)$. Therefore, we have from the Cauchy–Schwarz inequality and Lemma 3.2 that, for any $\varphi\in W_0^N$,

$$\begin{aligned}|\tilde{F}_r(\varphi)|&=|\langle(r-r^2)f-I^N((r-r^2)f),(1-r)^{-1}\varphi\rangle|\\&\le\|(r-r^2)f-I^N((r-r^2)f)\|\,\|(1-r)^{-1}\varphi\|\\&\le CN^{1-m}\left\|(r-r^2)^{\frac{\bar{m}-1}{2}}\frac{d^{\bar{m}}((r-r^2)f)}{dr^{\bar{m}}}\right\|_{\omega}\|\varphi\|_{E_0},\end{aligned} \tag{3.47}$$

where we have used

$$\|(1-r)^{-1}\varphi\|\le 2\left\|\sqrt{r}\frac{d\varphi}{dr}\right\|\qquad\forall\varphi\in W_0^N, \tag{3.48}$$

which can be derived from

$$\begin{aligned}0 &\le \int_0^1 \left(\sqrt{r}\frac{d\varphi}{dr} - \frac{1}{2}(1-r)^{-1}\varphi\right)^2 dr \\ &= \left\|\sqrt{r}\frac{d\varphi}{dr}\right\|^2 + \frac{1}{4}\|(1-r)^{-1}\varphi\|^2 - \frac{1}{2}\int_0^1 \frac{d(\varphi)^2}{dr} r^{1/2}(1-r)^{-1}\, dr \\ &\le \left\|\sqrt{r}\frac{d\varphi}{dr}\right\|^2 - \frac{1}{4}\|(1-r)^{-1}\varphi\|^2. \qquad (3.49)\end{aligned}$$

Hence, we have proved the following theorem.

THEOREM 3.2. *For any integer $m \ge 1$, the Chebyshev-collocation approximation u^N defined by the scheme* (2.10)–(2.12) *for the problem* (2.1) *and* (2.2) *satisfies*

$$\begin{aligned}\|u - u^N\|_{E_n} \le CN^{1-m} &\left(\left\|(r-r^2)^{\frac{m}{2}-\frac{3}{4}} \frac{d^m u}{dr^m}\right\| + \left\|(r-r^2)^{\frac{\bar m}{2}-\frac{3}{4}} \frac{d^{\bar m}(rf)}{dr^{\bar m}}\right\| \right. \\ &\left. + \left\|(r-r^2)^{\frac{\bar m}{2}-\frac{3}{4}} \frac{d^{\bar m}((r-r^2)f)}{dr^{\bar m}}\right\| \right), \qquad (3.50)\end{aligned}$$

where u is the exact solution of (2.1) *and* (2.2) *and* $\bar m = \max\{m-1, 1\}$. *For the case $n \ne 0$,* (3.50) *also holds in the stronger norm* $\|\cdot\|_{E_n,\omega}$.

Thus, we obtain a convergence result similar to that of the Legendre collocation method. As in Theorem 3.1, when $u \in H_r^m$ and $f \in H_r^{\bar m}$ with $m \ge 5/2$, the terms in the bracket on the right-hand side of (3.50) are bounded.

4. Numerical experiments. In this section we present some numerical results to demonstrate the accuracy of the Legendre and Chebyshev collocation methods (2.10)–(2.12) for the model problem (2.1)–(2.2).

Example 1. The function $f(r)$ and the Dirichlet boundary condition at $r = 1$ are chosen such that the exact solution of (2.1) and (2.2) is

$$u(r) = r^2 \cos(10\pi r), \qquad 0 < r < 1. \qquad (4.1)$$

We note that the energy norm $\|\cdot\|_{E_n}$ is stronger than the L^∞ norm for $n > 0$. (This is not true for $n = 0$.) For this reason, we use the maximum norm to measure the error for the case $n > 0$, but use the energy norm for the case $n = 0$. These norms are numerically approximated in the computations, viz.,

$$E_{0,N} = \left\{ \sum_{j=0}^N r_j \left| \frac{du}{dr}(r_j) - \frac{du^N}{dr}(r_j)\right|^2 w_j \right\}^{1/2} \qquad \text{for } n = 0, \qquad (4.2)$$

$$E_{1,N} = \max_{0 \le j \le N} |u(r_{j,\omega}) - u^N(r_{j,\omega})| \qquad \text{for } n = 1, \qquad (4.3)$$

where the Legendre points $\{r_j\}$ are used in (4.2) and both the Legendre and Chebyshev points $\{r_{j,\omega}\}$ are used in (4.3). The numerical results for the cases $n = 0$ and $n = 1$ are listed in Table 1. The spectral convergence of the methods is clearly shown in the table. One may also notice that the Legendre and Chebyshev collocation methods produce very comparable results.

Example 2. The function $f(r)$ and the boundary condition at $r = 1$ are chosen such that the problem has a less regular solution

$$u(r) = r^{5/2}, \qquad 0 < r < 1. \qquad (4.4)$$

Table 1

Numerical results obtained with the Legendre (LC) and Chebyshev (CC) collocation methods for Example 1*. The convergence order is* N^{-Order}.

	$n = 0$				$n = 1$			
	LC-method		CC-method		LC-method		CC-method	
N	$E_{0,N}$	Order	$E_{0,N}$	Order	$E_{1,N}$	Order	$E_{1,N}$	Order

Table 2

Numerical results obtained with the Legendre collocation method for Example 2*. The convergence order is* N^{-Order}.

	$n = 0$		$n = 1$	
N	$E_{0,N}$	Order	$E_{1,N}$	Order
40	3.2e−07		1.7e−08	
80	1.2e−08	4.75	5.6e−10	4.96
120	1.7e−09	4.79	7.4e−11	4.97
160	4.2e−10	4.81	1.8e−11	4.98
200	1.4e−10	4.82	5.8e−12	4.96
240	5.9e−11	4.83	2.4e−12	4.91

The computation is done with the Legendre collocation method for $n = 0$ and $n = 1$. The solution error and the convergence order are listed in Table 2. One can easily see that $E_{0,N} \approx \mathrm{O}\left(N^{-5}\right)$ and $E_{1,N} \approx \mathrm{O}\left(N^{-5}\right)$. That is, the rate of convergence is nearly twice the exponent of r in (4.4), 5/2. On the other hand, it is not difficult to show that the first term on the right-hand side of (3.21) is bounded for $m < 5$, while the second term is bounded for $\bar{m} < 3$ or $m < 4$ for the current example. Thus, the right-hand-side terms are bounded for $m < 4$. From Theorem 3.1, we have $\|u - u^N\|_{E_n} \approx \mathrm{O}(N^{-3})$. This indicates that the convergence rate predicted by (3.21) is not sharp, although the estimate is optimal according to the regularity requirement ([1]; also cf. (3.22)). Such an order loss seems typical in the convergence analysis of collocation schemes, especially for problems involving force terms; e.g., see [4] for comparison of typical estimates for the Legendre Galerkin method ((8.7) on p. 274) and the Legendre collocation method ((15.15) on p. 310). It is interesting to note that sharp estimates have been obtained for the p-version finite element method (which is of Galerkin type); e.g., see Babuska and Suri [5]. Finally, we mention that the Chebyshev collocation method leads to very comparable results.

5. Conclusions and comments.

In the previous sections we have proved that the Legendre and Chebyshev collocation approximations presented in [12] are convergent and that the error decays faster than algebraically when f and u are infinitely differentiable for the singular problem (2.1) and (2.2). Our main results are given in Theorems 3.1 and 3.2.

The key feature of the spectral collocation approximation is that it uses a pole condition as the boundary condition at the singularity and employs a commonly used collocation scheme. Thus, the convergence result provides a theoretical justification for the well-known fact that it is unnecessary to impose all the pole conditions in order for numerical schemes to obtain high accuracy. Because most of the existing spectral approaches for singular problems use more or less the pole conditions, we expect that our result can also be regarded as a theoretical justification for these methods.

Finally we make a few comments on the method we analyzed. The method has been successfully applied to solving steady-state Navier–Stokes equations in [13, 14]. However, since it uses the Chebyshev or Legendre type of collocation methods in the r interval (0,1), one may suspect that the clustering of grid points near $r = 0$ leads to a very severe restriction on time steps for time dependent problems. To see this, let us consider the time dependent problem on the unit disk

$$u_t = \Delta u + au_x + bu_y. \tag{5.1}$$

In polar coordinates the equation becomes

$$\begin{aligned} u_t = {} & \frac{\partial^2 u}{\partial r^2} + \frac{1}{r}\frac{\partial u}{\partial r} + \frac{1}{r^2}\frac{\partial^2 u}{\partial \theta^2} \\ & + (a\cos\theta + b\sin\theta)\frac{\partial u}{\partial r} + (-a\sin\theta + b\cos\theta)\frac{1}{r}\frac{\partial u}{\partial \theta}. \end{aligned} \tag{5.2}$$

Assume that (5.2) is approximated in r using the Legendre or Chebyshev collocation, and in θ using Fourier collocation. Then it is not difficult to see that for the diffusion term the time step restriction for an explicit integration scheme is

$$\Delta t_{\max} \approx \min\{(\Delta r_0)^2, r_1 \Delta r_0\} \approx (r_1)^2 = O\left(\frac{1}{N^4}\right) \tag{5.3}$$

at $r \approx 0$ and

$$\Delta t_{\max} \approx \min\{(\Delta r_{N-1})^2, r_N \Delta r_{N-1}\} \approx \left(\frac{1}{N^4}\right) \tag{5.4}$$

at $r \approx 1$. Obviously these two time scales are the same. For the convection term we have at $r \approx 0$

$$\Delta t_{\max} \approx \min\{\Delta r_0, r_1\} \approx O\left(\frac{1}{N^2}\right) \tag{5.5}$$

and at $r \approx 1$

$$\Delta t_{\max} \approx \min\{\Delta r_{N-1}, r_N\} \approx O\left(\frac{1}{N^2}\right). \tag{5.6}$$

Once again they are the same. Thus, the above simple analysis tells us that the clustering of grid points near the singularity does not result in a time restriction worse than that near the outer boundary. Of course, just like spectral methods applied to nonsingular problems, a restriction $O(1/N^4)$ on time steps is too severe. Implicit or semi-implicit time integrators should be used. The resultant algebraic systems can be solved using either iterative methods with effective preconditioners [7, 12] or fast direct solvers [24].

For problems in spheric geometries the method can be applied straightforwardly. However, the severe restriction on time steps at the north and south poles could be a potential problem for the method (see discussion in [6, pp. 480–482]). This issue deserves further investigation.

Acknowledgment. The authors would like to thank the anonymous referees for their valuable comments.

EXISTENCE VERIFICATION FOR HIGHER DEGREE SINGULAR ZEROS OF NONLINEAR SYSTEMS*

R. BAKER KEARFOTT[†] AND JIANWEI DIAN[‡]

Abstract. Finding approximate solutions to systems of n nonlinear equations in n real variables is a much studied problem in numerical analysis. Somewhat more recently, researchers have developed numerical methods to provide mathematically rigorous error bounds on such solutions. (We say that we "verify" existence of the solution within those bounds on the variables.) However, when the Jacobi matrix is singular at the solution, no computational techniques to verify existence can handle the general case. Nonetheless, computational verification that one or more solutions exists within a region in complex space containing the real bounds is possible by computing the topological degree. In a previous paper, we presented theory and algorithms for the simplest case, when the rank-defect of the Jacobian matrix at the solution is 1 and the topological index is 2. Here, we generalize that result to arbitrary topological index $d \geq 2$: We present theory, algorithms, and experimental results. We also present a heuristic for determining the degree, obtaining a value that we can subsequently verify with our algorithms. Although execution times are slow compared to corresponding bound verification processes for nonsingular systems, the order with respect to system size is still cubic.

Key words. complex nonlinear systems, interval computations, verified computations, singularities, topological degree

1. Introduction.

Solution of linear and nonlinear systems of equations is a fundamental problem in numerical analysis, underlying much, if not most, of modern scientific computation. A system of n equations in n unknowns, where the expressions defining the system are defined in some closed, bounded subset $\mathbf{D}$ of n-dimensional space, may be expressed mathematically by

$$F(x) = 0, \quad F : \mathbf{D} \subset \mathbb{R}^n \to \mathbb{R}^n. \tag{1.1}$$

Throughout scientific computing, floating point arithmetic is used to solve equations (1.1) approximately. If F is linear, for example, then various direct (Gaussian elimination–based) methods, or iterative methods such as the preconditioned conjugate gradient method, are used. If F is nonlinear, then numerical solution of (1.1) involves various iterative methods, and the corresponding computer code can be sophisticated or involve numerous heuristics. In both the linear and nonlinear cases, the result of the computation is an approximate solution vector $\check{x} \in \mathbb{R}^n$, $F(\check{x}) \approx 0$. Hopefully, $\check{x}$ is near an exact or "true" solution x^*, $F(x^*) = 0$, such that $\|\check{x} - x^*\|$ is small.[1] However, with a few exceptions, the computation that produces the approximate solution $\check{x}$ does not give a bound on $\|\check{x} - x^*\|$. Indeed, it is not hard to find

[1] Except when explicitly noted, we assume only that the norm is some fixed norm (independent of x), since the norm is discussed in terms of the order $\mathcal{O}(\|\cdot\|)$ and since we are working in finite-dimensional spaces.

instances of practical problems for which the output vector $\check{x}$ of an algorithm to solve a nonlinear system of the form (1.1) is not near a true solution at all, and for which the modeler does not recognize this fact; see, for example, [5].

On the other hand, efficient methods have been available for some time to construct bounds about such approximate solutions $\check{x}$ at which a true solution is known to exist. Specifically, an interval vector

$$\boldsymbol{x} = ([\underline{x}_1, \overline{x}_1], [\underline{x}_2, \overline{x}_2], \ldots, [\underline{x}_n, \overline{x}_n])^T \tag{1.2}$$

is found such that each width $\mathrm{w}([\underline{x}_i, \overline{x}_i]) = \overline{x}_i - \underline{x}_i$ is small (a small multiple of the machine precision, depending on the problem), and such that the computational process has proven mathematically (with no uncertainty due to roundoff error) that there is an exact solution $x^* \in \boldsymbol{x}$. Although it is not universally recognized within the general numerical analysis community, such methods can be developed to be practical more often than not and can give rigorous bounds that both are tighter than heuristic error estimates and are obtained with less effort; see, for example, [15]. An explanation of these methods appears in [6, 11, 17] and in numerous other works. The mathematical assumptions under which such verification methods can be expected to be successful are basically that the Jacobi matrix for the system is continuous and nonsingular at the solution; see the aforementioned references for a precise statement of the assumptions. For a practical implementation of such methods (with interval arithmetic), the function residuals and Jacobi matrix need to be representable as a computer program.

Although these verification methods involve interval arithmetic, notorious for impracticality due to overestimation when naively used, the intervals (the coordinates of $\boldsymbol{x}$) in a posteriori verification computations are small. It is known, from both theory and practice, that the overestimation in such small intervals is asymptotically insignificant, making such methods more generally applicable.

In this work, we consider not finding an approximate solution $\check{x}$ but constructing and verifying bounds $\boldsymbol{x}$ about such a point $\check{x}$ (however found) such that an exact solution x^* lies within $\boldsymbol{x}$. Specifically, we address the following problem.

(1.3)

> Given $F : \mathbf{D} \to \mathbb{R}^n$, where $\mathbf{D}$ is some closed, bounded subset of $\mathbb{R}^n$ with nonempty interior, and given an approximate solution $\check{x} \in \mathbf{D}$, construct bounds $\boldsymbol{x} \in \mathbb{IR}^n$, $\check{x} \in \boldsymbol{x}$, with $\boldsymbol{x}$ as in (1.2), for which we *rigorously* verify
>
> - there exists an $x^* \in \boldsymbol{x}$ such that $F(x^*) = 0$.

Throughout this paper, by "rigorous" we mean "with the same standard as for a traditional mathematical proof." Our algorithms for such verification will employ techniques derived from traditional floating point computations but will use directed roundings to take the finite nature of floating point arithmetic into account.

As is seen in [6, 11, 17] and elsewhere, when the Jacobian matrix $F'(x^*)$ is well-conditioned and not too quickly varying, interval computations have no trouble proving that there is a *unique* solution within small boxes with x^* reasonably near the center. (Various techniques, such as those in [16], can be used to initially construct the bounds over which the verification algorithm proceeds.) However, when $F'(x^*)$ is ill-conditioned or singular, in general, no computational techniques can verify the existence of a solution within a given region $\boldsymbol{x}$ of $\mathbb{R}^n$. Indeed, common thinking among researchers in such verification methods has been that verification is not possible in the singular case. Nonetheless, in [14] we introduced an algorithm for computational but rigorous verification, in the singular case, that a given number of true solutions exists within a region in complex space containing $\boldsymbol{x}$. There we studied the simplest case, when the rank-defect of the Jacobian matrix at the solution is one, and we developed and experimentally validated algorithms for the case when the topological index is 2. There, we also proved the special case of Theorem 3.1 (see section 3 below) when $d = 2$. Under the same assumptions as those in section 2 below, we developed specialized versions of the algorithms in section 4 below, and we presented varying-dimensional experimental results in [14].

We were surprised and pleased that the results in [14] could be generalized so easily. In particular, we developed an alternate simple, general proof for Theorem 3.1 below. Furthermore, the algorithms in section 4 below, although not taking advantage of special efficiencies in the degree-2 case as in [14], are similar in structure and have the same computational complexity as the algorithms in [14].

The developments below proceed by thinking of the function F in terms of a model of the form

$$F(x) = M(x) + R(x), \tag{1.4}$$

where $M(x)$ is a Taylor approximation to F about x^* and $R(x)$ is the error term. The number of solutions to $F(x) = 0$ is determined according to the topological degree (reviewed in section 1.2 below) of F. In Theorem 3.1 (see section 3 below) we show that, if $F(x) = M(x)$, where $M(x)$ has some verifiable properties, then the topological degree of F must equal d. (This proves existence, since the topological degree over a region in complex space is equal to the number of solutions in the region, counting multiplicities.) Basing the computations on the structure of M, we use a heuristic test to guess the integer d. Speaking roughly, we then take account of both roundoff error and the error term $R(x)$ with interval computations. In particular, we use the structure of M to efficiently arrange an exhaustive search that rigorously verifies that the topological degree actually is d. Even though the search is exhaustive, completion of the search requires only the same order of magnitude of computational work as a step of Newton's method on the system; this is due to the postulated structure of M and the way we have arranged the search.

As explained in [14, section 1.4], if d is even, it is meaningless to discuss the existence of a solution in $\mathbb{R}^n$ within the framework of errors in the data, model, and floating point system, since the topological degree in real space in such cases may be equal to 0. The even d case is a generalization of the situation with $f(x) = x^2$ at $x = 0$: The function f itself has a unique solution at $x = 0$, yet perturbations of f result in either no solutions or two solutions near $x = 0$. In contrast, $f(z) = (1+\epsilon_1)z^2+\epsilon_2 z+\epsilon_3$, $|\epsilon_i|$ small for $i = 1, 2, 3$, has two solutions, counting multiplicities, in all sufficiently large (but with diameters that can be chosen to be $\mathcal{O}(\epsilon)$ as $\epsilon \to 0$) open sets in $\mathbb{C}$ containing $z = 0$. This illustrates a general phenomenon: Whereas small perturbations of the data change the existence of (one or more) solutions near a particular point in $\mathbb{R}^n$, the solutions vary continuously with perturbations of complex extensions. We have presented one precise statement of this in Theorem 3.1 of [4]: Under the assumptions in that theorem (essentially, that the Jacobi matrix have rank defect 1 at the solution, and that certain derivative tensors up to order d vanish), $\mathrm{d}(F, \boldsymbol{x}, 0) = 0$ for a box $\boldsymbol{x} \in \mathbb{R}^n$ whenever d is even (and $\mathrm{d}(F, \boldsymbol{x}, 0) = \pm 1$ over such a box when d is odd). Thus, in that case when d is even (and, we believe, in many fairly general cases) verifying the value of the topological degree within the real context cannot verify existence of the solution. In contrast, $\mathrm{d}(F, \boldsymbol{z}, 0)$ must always be nonzero if there is a $z \in \boldsymbol{z}$ with $F(\boldsymbol{z}) = 0$ and $0 \notin \boldsymbol{\partial z}$, for $\boldsymbol{z} \subset \mathbb{C}^n$. Also, the *number* of solutions counting multiplicities can change under perturbations in $\mathbb{R}^n$, even for odd-order functions such as x^3, for which we can use techniques such as those in [4] to prove existence; in contrast, $\mathrm{d}(F, \boldsymbol{z}, 0)$ gives the exact number of solutions within $\boldsymbol{z}$, counting multiplicities, for complex-valued functions F of complex variables $\boldsymbol{z}$.

In this paper, we consider the case of general d, to verify the existence of solutions in small neighborhoods of $\mathbb{C}^n$, as illustrated in problem (1.5) below. Our hope is that such verification will be useful in analysis of systems having even-order roots, even though the validation is in a different space; in any case, rigorous validation of such systems in the original space may not be possible and may not be meaningful if the system was derived from measurements with errors. (We present special theory, analysis, and algorithms for the real case and odd-order roots in [4].)

(1.5) Given F, $\mathbf{D}$, and $\check{x}$ as in problem (1.3), consider an analytic extension $\tilde{F}$ of F to a domain $\tilde{\mathbf{D}} \subseteq \mathbb{C}^n$, $\mathbf{D} \subset \tilde{\mathbf{D}}$. Construct bounds $\boldsymbol{x}$ as in problem (1.3) and $\boldsymbol{y} = ([\underline{y}_1, \overline{y}_1], \ldots, [\underline{y}_n, \overline{y}_n])$, $0 \in \boldsymbol{y}$, for which we *rigorously* verify the following:

- there exists a $z^* \in \boldsymbol{z}$ such that $\tilde{F}(z^*) = 0$, where
- $\boldsymbol{z} = \big\{(x_1 + iy_1, x_2 + iy_2, \ldots, x_n + iy_n)^T \in \mathbb{C}^n \;\big|\; x_j \in \boldsymbol{x}_j,\, y_j \in \boldsymbol{y}_j,\, 1 \le j \le n\big\}$.

Hiding detail and revealing overall ideas, we have simplified the notation in this work, compared to that in [14].

After introducing our notation in section 1.1, we briefly review the relevant portions of topological degree theory in sections 1.2 and 1.3. We introduce our use of the structure of the model $M(x)$ in section 2. We present our scheme for setting the coordinate bounds $\boldsymbol{x}$ within which we prove the existence of solutions in section 2.2; though related, this scheme is improved and works more generally than that in [14]. In section 3, we show that the degree must be equal to d if $F(x) = M(x)$ (i.e., $R(x) = 0$), within the context introduced in section 2. In section 4, we present the algorithm that verifies that the degree is d for nonzero $R(x)$, within the framework introduced in section 2. In section 5, we present an easily implemented heuristic computation for guessing the value of d, necessary for the verification algorithm in section 4. Finally, in section 6.3 we present results of trying the computations on several examples; these results illustrate that the algorithm can be practical for a variety of problems, and that the computation does not necessarily increase rapidly with the dimension of the problem.

1.1. Notation.

We assume familiarity with the fundamentals of interval arithmetic; see [1, 6, 11, 17, 19] for introductory material.

Throughout, scalars and vectors will be denoted by lower case, while matrices will be denoted by upper case. Intervals, interval vectors (also called "boxes"), and interval matrices will be denoted by boldface. For instance, $\boldsymbol{x} = (\boldsymbol{x}_1, \ldots, \boldsymbol{x}_n)$ denotes an interval vector, $A = (a_{i,j})$ denotes a point matrix, and $\boldsymbol{A} = (\boldsymbol{a}_{i,j})$ denotes an interval matrix. The midpoint of an interval or interval vector $\boldsymbol{x}$ will be denoted by $\mathrm{m}(\boldsymbol{x})$. As in section 1, $\mathrm{w}(\boldsymbol{x})$ denotes the width of an interval $\boldsymbol{x} = [\underline{x}, \overline{x}]$, that is, $\mathrm{w}(\boldsymbol{x}) = \overline{x} - \underline{x}$; if $\boldsymbol{x}$ represents an interval vector, then the midpoint $\mathrm{m}(\boldsymbol{x})$ and width $\mathrm{w}(\boldsymbol{x})$ will be real vectors, understood componentwise. Real n-space will be denoted by $\mathbb{R}^n$, while complex n-space will be denoted by $\mathbb{C}^n$. The set of real interval vectors will be denoted by $\mathbb{IR}^n$, while the set of complex interval vectors will be denoted by $\mathbb{IC}^n$.

Suppose $\boldsymbol{x} = (\boldsymbol{x}_1, \dots, \boldsymbol{x}_n)$ is an n-dimensional real box, where $\boldsymbol{x}_k = [\underline{x}_k, \overline{x}_k]$. The nonoriented boundary of $\boldsymbol{x}$, denoted by $\boldsymbol{\partial x}$, consists of $2n$ $(n-1)$-dimensional real boxes

$$\boldsymbol{x}_{\underline{k}} \equiv (\boldsymbol{x}_1, \dots, \boldsymbol{x}_{k-1}, \underline{x}_k, \boldsymbol{x}_{k+1}, \dots, \boldsymbol{x}_n) \quad \text{and} \quad \boldsymbol{x}_{\overline{k}} \equiv (\boldsymbol{x}_1, \dots, \boldsymbol{x}_{k-1}, \overline{x}_k, \boldsymbol{x}_{k+1}, \dots, \boldsymbol{x}_n),$$

where $k = 1, \dots, n$.

The *orientation* of a region $\mathbf{D} \subset \mathbb{R}^n$ and of its boundary $\boldsymbol{\partial}\mathbf{D}$ is a generalization of the concept of orientation of a region and its boundary (counterclockwise being positive orientation) in complex analysis, or of the concepts of orientation of a region and its boundary when applying Green's theorem or Stokes' theorem; see [3, pp. 4–10] or [2], for example, for a detailed formal definition. In particular, a simplex $\langle a^{(0)}, a^{(1)}, \dots, a^{(n)} \rangle$, $a^{(k)} \in \mathbb{R}^n$, $0 \le k \le n$, is positively oriented, provided that a certain determinant formed from the coordinates of the points $a^{(k)}$ is positive, and is negatively oriented if that determinant is negative; polygonal regions formed by juxtaposing such oriented simplexes have a positive orientation, provided that each component simplex is positively oriented.

To explain the algorithms in this paper, we need concern ourselves only with the derived orientation of the boundary of an interval vector (i.e., of a box) $\boldsymbol{x}$. The following "definition" can be derived as a theorem from the general definition of a positively oriented polygonal region. (For a more detailed presentation, see our technical report [13, pp. 7–8].)

Definition 1.1. *Suppose that a box $\boldsymbol{x}$ as in* (1.2) *is positively oriented. Then the positively oriented boundary $b(\boldsymbol{x})$ is given by the formal sum*

$$\sum_{k=1}^{n} \left\{ (-1)^k \boldsymbol{x}_{\underline{k}} + (-1)^{k+1} \boldsymbol{x}_{\overline{k}} \right\}$$

of the $2n$ $(n-1)$-dimensional boxes $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$.

Our model $M(x)$ of $F(x)$ as in (1.4) is a multivariate Taylor polynomial. In particular we will write a component f_i of F as

$$f_i(x) = f_i(\check{x}) + \sum_{j=1}^{d} \frac{1}{j!} D^j f_i(\check{x})[x-\check{x}, \dots, x-\check{x}] + \mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}, \tag{1.6}$$

where

$$D^j f_i(\check{x})[x-\check{x}, \dots, x-\check{x}] = \sum_{k_1=1}^{n} \cdots \sum_{k_j=1}^{n} \frac{\partial^j f_i}{\partial x_{k_1} \cdots \partial x_{k_j}}(\check{x})(x_{k_1} - \check{x}_{k_1}) \cdots (x_{k_j} - \check{x}_{k_j}) \tag{1.7}$$

is the jth derivative tensor.

In our verification algorithms, the domains will be interval vectors, i.e., rectangular boxes $\boldsymbol{x}$. However, we state some of the known topological degree theory results more generally, in terms of the closed, bounded set $\mathbf{D}$ with nonempty interior that we introduced above.

1.2. Formulas from degree theory. In [14], we reviewed the topological degree in the context of this paper. Also see [2, 3, 8, 9, 18, 20]. Here, we repeat several properties used in the proofs in subsequent sections.

Although a formal definition of the topological degree is somewhat cumbersome, one obtains an intuitive understanding of the topological degree from its properties. In particular, for $n = 1$, the topological degree of F at 0 over an interval $\boldsymbol{x}$, denoted $\mathrm{d}(F, \boldsymbol{x}, 0)$, is the number of times the graph of F crosses the x-axis in the positive direction, minus the number of times the graph of F crosses the x-axis in the negative direction. If $F : \mathbb{C} \to \mathbb{C}$ and $\mathbf{D}$ is a simply connected region (a region without holes, such as a disk) containing the origin in $\mathbb{C}$, then the topological degree $\mathrm{d}(F, \mathbf{D}, 0)$ is equal to the winding number of F with respect to the curve bounding $\mathbf{D}$. Because of this fact, $\mathrm{d}(p_d, \mathbf{D}, 0) = d$, where p_d is any polynomial of degree d and $\mathbf{D}$ is any sufficiently large simply connected domain in $\mathbb{C}$ with $0 \in \mathbf{D}$ (where the size depends on the particular p_d). Thus, in $\mathbb{C}$, the topological degree roughly corresponds to the notion of algebraic degree, which is the same as the number of solutions, counting multiplicity. If we think of $\mathbf{D}$ as being the closure of a very small region containing a solution z^*, $F(z^*) = 0$, then $\mathrm{d}(F, \mathbf{D}, 0)$ is termed the *topological index* of z^*; the topological index corresponds to the multiplicity of z^*. For example, the topological index of z^d at $z^* = 0$ is equal to d. In this paper, we prove the existence of solutions within small domains $\mathbf{D}$ by verifying, essentially, that the topological index is nonzero.

Formal definitions of the topological degree can be given analytically (in terms of an integral) as in [18, Chapter 6], or in terms of fundamental concepts of algebraic topology, as in [2]. In either case, either definition can be obtained as a theorem, starting with the other one as the definition. We can actually think of the degree in terms of the following.

THEOREM 1.2 (see [18, p. 150]). *Suppose that F is continuous, and suppose that the Jacobian matrix $F'(x)$ is defined and nonsingular at each zero of F within a domain $\mathbf{D}$, which is the closure of an open region in $\mathbb{R}^n$, and suppose that $F(x) \neq 0$ when $x \in \boldsymbol{\partial}\mathbf{D}$. Then, the degree* $\mathrm{d}(F, \mathbf{D}, 0)$ *is equal to the number of zeros of F at which the determinant of the Jacobian matrix $F'(x)$ is positive, minus the number of zeros of F at which the determinant of the Jacobian matrix $F'(x)$ is negative.*

Basically, Theorem 1.2 states that the degree is an algebraic number of zeros of F in $\mathbf{D}$ when the Jacobian matrix is nonsingular at each zero. However, the degree does not change as F is perturbed, and we can imagine the degree remaining defined as two or more zeros of F coalesce into a single zero at which the Jacobian matrix is singular (important in our context here). Similarly, F need only be continuous (not necessarily differentiable) for $\mathrm{d}(F, \mathbf{D}, 0)$ to be defined. To define the degree for arbitrary continuous functions that do not vanish on the boundary $\boldsymbol{\partial}\mathbf{D}$, the analytic definition as in [18, Chapter 6] uses an integral and mollifying functions, whereas the topological definition approximates the image of the boundary $\boldsymbol{\partial}\mathbf{D}$ with a piecewise-linear simplicial complex (similar to how engineers approximate an object with triangles for the finite element method, except that the topologist's simplicial complex is oriented).

Starting either from the analytical definition of [18] or from the algebraic-topological definition of [2], we obtain the following properties of the degree. These properties are what will concern us in our verification procedures.

THEOREM 1.3 (see [18, p. 150]). *Let F, $G : \mathbf{D} \subset \mathbb{R}^n \to \mathbb{R}^n$ be two continuous functions that do not vanish on $\boldsymbol{\partial}D$. If $F(x) = G(x)$ for $x \in \boldsymbol{\partial}\mathbf{D}$, then* $\mathrm{d}(F, \mathbf{D}, 0) = \mathrm{d}(G, \mathbf{D}, 0)$.

Theorem 1.3 states one of the most important properties of degree: The degree depends only on the function values on the boundary.

THEOREM 1.4 (see [18, p. 157]). *Let F, $G : \mathbf{D} \subset \mathbb{R}^n \to \mathbb{R}^n$ be two continuous functions. If*

$$0 \notin \{tF(x) + (1-t)G(x) | x \in \boldsymbol{\partial}\mathbf{D} \text{ and } t \in [0, 1]\},$$

then

$$\mathrm{d}(F, \mathbf{D}, 0) = \mathrm{d}(G, \mathbf{D}, 0).$$

Theorem 1.4 is the famous Poincaré–Bohl theorem. It is a particular case of the homotopy invariant property of the topological degree. Since $\mathbf{D}$ is compact, this homotopy invariance implies, without too much argument, that the degree is a continuous function of F.

COROLLARY 1.5. *Suppose $F : \mathbf{D} \subset \mathbb{R}^n \to \mathbb{R}^n$ is continuous and $\mathrm{d}(F, \mathbf{D}, 0) = d$. Then there is an $\epsilon > 0$ such that, for all continuous $G : \mathbf{D} \to \mathbb{R}^n$ with $|F(x) - G(x)| < \epsilon$ for $x \in \mathbf{D}$, $\mathrm{d}(F, \mathbf{D}, 0) = \mathrm{d}(G, \mathbf{D}, 0)$.*

Suppose $F : \mathbf{D} \subset \mathbb{C}^n \to \mathbb{C}^n$ is analytic, and view the real and imaginary components of F and its argument $z \in \mathbb{C}^n$ as real components in $\mathbb{R}^{2n}$. Let $z = x + iy$ and $F(z) = u(x, y) + iv(x, y)$, where $x = (x_1, \ldots, x_n)$, $y = (y_1, \ldots, y_n)$, $u(x, y) = (u_1(x, y), \ldots, u_n(x, y))$, and $v(x, y) = (v_1(x, y), \ldots, v_n(x, y))$. We define $\tilde{\mathbf{D}}$ by

$$\tilde{\mathbf{D}} \equiv \{(x_1, y_1, \ldots, x_n, y_n) | (x_1 + iy_1, \ldots, x_n + iy_n) \in \mathbf{D}\}$$

and $\tilde{F} : \tilde{\mathbf{D}} \subset \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ by $\tilde{F} = (u_1, v_1, \ldots, u_n, v_n)$. We then have the following properties.

THEOREM 1.6 (see [14]). *Suppose that $F : \mathbf{D} \subset \mathbb{C}^n \to \mathbb{C}^n$ is analytic, with $F(z) \neq 0$ for any $z \in \boldsymbol{\partial}\mathbf{D}$, and suppose that $\tilde{\mathbf{D}}$ and $\tilde{F} : \tilde{\mathbf{D}} \to \mathbb{R}^{2n}$ are defined as above. Then $\mathrm{d}(\tilde{F}, \tilde{\mathbf{D}}, 0)$ is nonnegative and is equal to the number of solutions $z^* \in \mathbf{D}$, $F(z^*) = 0$, counting multiplicities.*

1.3. A basic degree computation formula. Theorem 1.7 below relates the basic theory of the topological degree to the computational verification procedures in section 4 below. Theorem 1.7 is similar to Theorem 2.5 of [14]. We can obtain Theorem 1.7 from formulas (4.12) and (4.14) in [20], by taking into account the orientations of the faces of $\boldsymbol{x}$.

Theorem 1.7 characterizes $\mathrm{d}(F, \boldsymbol{x}, 0)$ in terms of certain components of F on $\boldsymbol{\partial x}$. In particular, set

$$F_{\neg k}(\boldsymbol{x}) \equiv \big(f_1(\boldsymbol{x}), \ldots, f_{k-1}(\boldsymbol{x}), f_{k+1}(\boldsymbol{x}), \ldots, f_n(\boldsymbol{x})\big).$$

Then we have the following result.

THEOREM 1.7. *Let $s \in \{-1, 1\}$ be fixed arbitrarily, suppose $F \neq 0$ on $\boldsymbol{\partial x}$, and suppose that there is a p, $1 \leq p \leq n$, such that*

1. *$F_{\neg p} \equiv (f_1, \ldots, f_{p-1}, f_{p+1}, \ldots, f_n) \neq 0$ on $\boldsymbol{\partial x}_{\underline{k}}$ or $\boldsymbol{\partial x}_{\overline{k}}$, $k = 1, \ldots, n$; and*
2. *the Jacobi matrices of $F_{\neg p}$ are nonsingular at all solutions of $F_{\neg p} = 0$ on $\boldsymbol{\partial x}$ and are continuous in a neighborhood of such solutions.*

Then

$$\begin{aligned}\mathrm{d}(F, \boldsymbol{x}, 0) \ &= (-1)^{p-1} s \left\{ \sum_{k=1}^{n} (-1)^k \sum_{\substack{x \in \boldsymbol{x}_{\underline{k}} \\ F_{\neg p}(x) = 0 \\ \mathrm{sgn}(f_p(x)) = s}} \mathrm{sgn} \left| \frac{\partial F_{\neg p}}{\partial x_1 x_2 \cdots x_{k-1} x_{k+1} \cdots x_n}(x) \right| \right. \\ &\qquad \left. + \sum_{k=1}^{n} (-1)^{k+1} \sum_{\substack{x \in \boldsymbol{x}_{\overline{k}} \\ F_{\neg p}(x) = 0 \\ \mathrm{sgn}(f_p(x)) = s}} \mathrm{sgn} \left| \frac{\partial F_{\neg p}}{\partial x_1 x_2 \cdots x_{k-1} x_{k+1} \cdots x_n}(x) \right| \right\}.\end{aligned}$$

2. Assumptions and choice of box. In this section, we present the basic assumptions. We also introduce how we choose the coordinate bounds $\boldsymbol{x}_i = [\underline{x}_i, \overline{x}_i]$ to satisfy the assumptions and enable more efficient algorithms. When the rank of $F'(x^*)$ is $n-p$ for some $p>0$, an appropriate preconditioner can be used to reduce $\boldsymbol{F'}(\boldsymbol{x})$ to approximately the pattern shown in Figure 2.1. (See [11] and [14] for details on preconditioning.)

$$Y\boldsymbol{F'}(\boldsymbol{x}) \approx \begin{pmatrix} 1 & 0 & \cdots & 0 & \overbrace{*\cdots*}^{p} \\ 0 & 1 & 0\cdots & 0 & *\cdots* \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & \cdots & 0 & 1 & *\cdots* \\ 0 & \cdots & 0 & 0 & 0\cdots 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0\cdots 0 \end{pmatrix}.$$

FIG. 2.1. *An approximate form for a preconditioned singular interval system of approximate rank $n-p$, where "$*$" represents a nonzero element.*

In the analysis to follow, we assume that the system has already been preconditioned, so that it is, to within second-order terms with respect to $\mathrm{w}(\boldsymbol{x})$, of the form in Figure 2.1. That is, we assume that the preconditioned system is of the form seen in Figure 2.1 if we interpret "$*$" to represent any interval, "1" to represent intervals of the form $[1-\mathcal{O}(\|x-x^*\|), 1+\mathcal{O}(\|x-x^*\|)]$, and "0" to represent intervals of the form $[-\mathcal{O}(\|x-x^*\|), \mathcal{O}(\|x-x^*\|)]$. Here as in [14], we concentrate on the case $p=1$.

2.1. The basic assumptions. As in the special case $d=2$ of [14], we assume

1. $F : \mathbf{D} \subset \mathbb{R}^n \to \mathbb{R}^n$ can be extended to an analytic function in $\mathbb{C}^n$.
2. $\boldsymbol{x} = (\boldsymbol{x}_1, \ldots, \boldsymbol{x}_n) = ([\underline{x}_1, \overline{x}_1], \ldots, [\underline{x}_n, \overline{x}_n])$ is a small box constructed to be centered at an approximate solution $\check{x}$, i.e., $\mathrm{m}(\boldsymbol{x}) = (\check{x}_1, \ldots, \check{x}_n)$.
3. $\check{x}$ is near a point x^* with $F(x^*)=0$ such that $\|\check{x}-x^*\|$ is much smaller than the norm of the width of the box $\boldsymbol{x}$, and the width of the box $\boldsymbol{x}$ is small enough that mean value interval extensions lead, after preconditioning, to a system like Figure 2.1, with small intervals replacing the zeros.
4. F has been preconditioned as in Figure 2.1, and $F'(x^*)$ has null space of dimension 1.

Define

$$\begin{aligned} \alpha_k &\equiv \frac{\partial f_k}{\partial x_n}(\check{x}), \qquad 1 \le k \le n-1, \\ \alpha_n &\equiv -1, \\ \Delta_1 &\equiv \left| \frac{\partial F}{\partial x_1 \cdots \partial x_n}(\check{x}) \right| \\ \Delta_l &\equiv \sum_{k_1=1}^{n} \cdots \sum_{k_l=1}^{n} \frac{\partial^l f_n}{\partial x_{k_1} \cdots \partial x_{k_l}}(\check{x}) \alpha_{k_1} \cdots \alpha_{k_l}, \qquad 2 \le l. \end{aligned}$$

The following representation of $F(x)$ near $\check{x}$ is appropriate under these assumptions:

$$\begin{aligned}
&(2.1) \qquad f_k(x) = (x_k - \check{x}_k) + \alpha_k(x_n - \check{x}_n) + \mathcal{O}\left(\|x - \check{x}\|\right)^2 \\
&\qquad\qquad \text{for } 1 \le k \le n-1, \\
&(2.2) \qquad f_n(x) = \sum_{\ell=2}^{d} \frac{1}{\ell!} D^\ell f_n(\check{x})[x-\check{x}, \ldots, x-\check{x}] + \mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}.
\end{aligned}$$

Here and below, "d" is a fixed constant that represents the postulated topological index (obtained, say, with the heuristic in section 5 below); the index d will be verified with our proposed algorithms (in section 4 below).

We now introduce additional notation to describe the complex extensions. For $F : \mathbb{R}^n \to \mathbb{R}^n$, extend F to complex space: $x+iy$, with y in a small box $\boldsymbol{y} = (\boldsymbol{y}_1, \ldots, \boldsymbol{y}_n) = ([\underline{y}_1, \overline{y}_1], \ldots, [\underline{y}_n, \overline{y}_n])$, where $\boldsymbol{y}$ is centered at $(0, \ldots, 0)$. As in Theorem 1.6 above, define $\tilde{\boldsymbol{x}} \equiv (\boldsymbol{x}, \boldsymbol{y}) \equiv (\boldsymbol{x}_1, \boldsymbol{y}_1, \ldots, \boldsymbol{x}_n, \boldsymbol{y}_n) = ([\underline{x}_1, \overline{x}_1], [\underline{y}_1, \overline{y}_1], \ldots, [\underline{x}_n, \overline{x}_n], [\underline{y}_n, \overline{y}_n])$, $u_k(x,y) \equiv \Re(f_k(x+iy))$ and $v_k(x,y) \equiv \Im(f_k(x+iy))$. With this, define

$$\tilde{F}(x,y) \equiv (u_1(x,y), v_1(x,y), \ldots, u_n(x,y), v_n(x,y)) : \mathbb{R}^{2n} \to \mathbb{R}^{2n}.$$

Also define

$$\tilde{F}_{\neg u_n}(x,y) \equiv \big(u_1(x,y), v_1(x,y), \ldots, u_{n-1}(x,y), v_{n-1}(x,y), v_n(x,y)\big).$$

Then, based on (2.1) and (2.2), for $1 \le k \le (n-1)$,

$$(2.3) \qquad \left.\begin{array}{rcl} u_k(x,y) & = & (x_k - \check{x}_k) + \alpha_k(x_n - \check{x}_n) \\ & & + \, \mathcal{O}\left(\|(x-\check{x}, y)\|\right)^2, \\ v_k(x,y) & = & y_k + \alpha_k y_n + \mathcal{O}\left(\|(x-\check{x}, y)\|\right)^2, \end{array}\right\}$$

or

$$(2.4) \qquad \left.\begin{array}{rcl} u_k(x,y) & \approx & (x_k - \check{x}_k) + \alpha_k(x_n - \check{x}_n), \\ v_k(x,y) & \approx & y_k + \alpha_k y_n. \end{array}\right\}$$

2.2. Choosing the coordinate bounds. In our verification algorithms below, we drastically reduce the amount of computation required by astutely choosing the ratios of coordinate widths of the boxes $\boldsymbol{x}$ and $\boldsymbol{y}$. We will use a scheme similar to that of section 5 of [14]. In particular, having defined $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$ in section 1.1, we define $\boldsymbol{y}_{\underline{k}}$ and $\boldsymbol{y}_{\overline{k}}$ similarly:

$$\begin{aligned}
&\boldsymbol{y}_{\underline{k}} \equiv (\boldsymbol{x}_1, \boldsymbol{y}_1, \ldots, \boldsymbol{x}_{k-1}, \boldsymbol{y}_{k-1}, \boldsymbol{x}_k, \underline{y}_k, \boldsymbol{x}_{k+1}, \boldsymbol{y}_{k+1}, \ldots, \boldsymbol{x}_n, \boldsymbol{y}_n) \quad \text{and} \\
&\boldsymbol{y}_{\overline{k}} \equiv (\boldsymbol{x}_1, \boldsymbol{y}_1, \ldots, \boldsymbol{x}_{k-1}, \boldsymbol{y}_{k-1}, \boldsymbol{x}_k, \overline{y}_k, \boldsymbol{x}_{k+1}, \boldsymbol{y}_{k+1}, \ldots, \boldsymbol{x}_n, \boldsymbol{y}_n).
\end{aligned}$$

To compute the degree $\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0)$, we will consider $\tilde{F}_{\neg u_n}$ on the boundary of $\tilde{\boldsymbol{x}}$. This boundary consists of the $4n$ faces $\boldsymbol{x}_{\underline{1}}$, $\boldsymbol{x}_{\overline{1}}$, $\boldsymbol{y}_{\underline{1}}$, $\boldsymbol{y}_{\overline{1}}$, …, $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, $\boldsymbol{y}_{\overline{n}}$. We will set $\boldsymbol{x}_n$ and $\boldsymbol{y}_n$ so that the coordinate widths $\mathrm{w}(\boldsymbol{x}_k)$ obey

$$(2.5) \qquad \mathrm{w}(\boldsymbol{x}_n) \le \frac{1}{2} \min_{1 \le k \le n-1} \left\{ \frac{\mathrm{w}(\boldsymbol{x}_k)}{|\alpha_k|} \right\} \quad \text{and} \quad \mathrm{w}(\boldsymbol{y}_n) \le \frac{1}{2} \min_{1 \le k \le n-1} \left\{ \frac{\mathrm{w}(\boldsymbol{y}_k)}{|\alpha_k|} \right\}.$$

In the above two relationships, when $\alpha_k = 0$ for some k, that particular k can be ignored in obtaining the minima, and $\mathrm{w}(\boldsymbol{x}_k)$ and $\mathrm{w}(\boldsymbol{y}_k)$ can be set to any small positive values as long as the assumptions in section 2.1 are met. If $\alpha_k = 0$ for $k = 1, \ldots, n-1$, then $\mathrm{w}(\boldsymbol{x}_k)$ and $\mathrm{w}(\boldsymbol{y}_k)$, $k = 1, \ldots, n$, can independently be set to any small positive values, as long as the assumptions in section 2.1 are met.

Constructing the box widths this way will make it unlikely that $u_k(x,y) = 0$ on either $\boldsymbol{x}_{\underline{k}}$ or $\boldsymbol{x}_{\overline{k}}$ and unlikely that $v_k(x,y) = 0$ on either $\boldsymbol{y}_{\underline{k}}$ or $\boldsymbol{y}_{\overline{k}}$, for $k = 1, \ldots, n-1$. This, in turn, will allow us to replace searches on $4n-4$ of the $4n$ faces of $\boldsymbol{\partial\tilde{x}}$ by simple interval evaluations, reducing the total computational cost dramatically. See [14] for details.

A difference between the scheme used here and that of [14] is the way the ratio $\mathrm{w}(\boldsymbol{y}_n)/\mathrm{w}(\boldsymbol{x}_n)$ is chosen. In [14], $\mathrm{w}(\boldsymbol{y}_n)$ was chosen large relative to $\boldsymbol{x}_n$, to arrange no solutions of $u_n = 0$ on $\boldsymbol{y}_{\underline{n}}$ and $\boldsymbol{y}_{\overline{n}}$. When the degree is odd, that is not possible, and we have found the strategy represented by formula (4.1) below, implying $\mathrm{w}(\boldsymbol{y}_n)$ small relative to $\mathrm{w}(\boldsymbol{x}_n)$, as in Figure 4.1 below, to be more convenient.

3. When the polynomial model is exact.

In [14] we proved that, under the assumptions in section 2, if the $\mathcal{O}\left(\|x-\check{x}\|\right)^2$ term is absent in (2.1) and the $\mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}$ term is absent in (2.2) with $d = 2$, and if $\Delta_1 = 0$ but $\Delta_2 \neq 0$, then $\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = 2$. Here, we generalize that result to $\Delta_1 = \cdots = \Delta_{d-1} = 0$, $\Delta_d \neq 0$. Since the degree doesn't change under small perturbations of the function $\tilde{F}$ (see Theorem 1.5 above), the conclusion in Theorem 3.1 below also holds for more general continuous functions for which the $\mathcal{O}\left(\|x-\check{x}\|\right)^2$ and $\mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}$ terms are not absent but are sufficiently small. In our computational existence verification algorithm in the next section, we use interval arithmetic to rigorously encompass the $\mathcal{O}\left(\|x-\check{x}\|\right)^2$ and $\mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}$ terms. In this way, Theorem 3.1 below provides guidance for construction of our general algorithm.

THEOREM 3.1. *Suppose that*

1. $\tilde{\boldsymbol{x}}$ *is a nondegenerate box in* $\mathbb{R}^{2n}$ *as defined in section* 2;
2. $(\check{x}, \check{y}) = (\check{x}_1, \check{y}_1, \ldots, \check{x}_n, \check{y}_n)$ *is the midpoint of* $\tilde{\boldsymbol{x}}$*;*
3. F *and* $\tilde{F}$ *are as in section* 2;
4. F *is such that the* $\mathcal{O}\left(\|x-\check{x}\|\right)^2$ *and* $\mathcal{O}\left(\|x-\check{x}\|\right)^{d+1}$ *terms in* (2.1) *and* (2.2) *are absent; and*
5. $\Delta_1 = \cdots = \Delta_{d-1} = 0$, $\Delta_d \neq 0$, *where* $2 \leq d$.

Then $\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = d$.

In contrast to the proof in [14], we use a homotopy argument to prove Theorem 3.1.

Proof. Let $z = (z_1, \ldots, z_n) = (x_1 + iy_1, \ldots, x_n + iy_n)$. Then

$$F(z) = (f_1(z), \ldots, f_{n-1}(z), f_n(z)),$$

where

$$\begin{aligned} f_k(z) &= (z_k - \check{z}_k) + \frac{\partial f_k}{\partial x_n}(\check{x})(z_n - \check{z}_n) \\ &= (z_k - \check{z}_k) + \alpha_k(z_n - \check{z}_n) \\ &\qquad \text{for } 1 \leq k \leq n-1, \end{aligned}$$

$$f_n(z) = \sum_{\ell=2}^{d} \frac{1}{\ell!} D^\ell f_n(\check{x})[z - \check{z}, \ldots, z - \check{z}]. \tag{3.1}$$

We construct $A : \mathbb{C}^n \to \mathbb{C}^n$ by

$$A(z) = (a_1(z), \ldots, a_{n-1}(z), a_n(z)),$$

where

$$\begin{aligned} a_k(z) &= (z_k - \check{z}_k) + \alpha_k(z_n - \check{z}_n) \quad \text{for } 1 \le k \le n-1, \\ a_n(z) &= \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d. \end{aligned} \tag{3.2}$$

Let $r_k(x, y) \equiv \Re(a_k(x + iy))$ and $s_k(x, y) \equiv \Im(a_k(x + iy))$. With this, define $\tilde{A} : \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ by

$$\tilde{A}(x, y) \equiv (r_1(x, y), s_1(x, y), \ldots, r_n(x, y), s_n(x, y)).$$

We construct $G : \mathbb{C}^n \to \mathbb{C}^n$ by

$$G(z) = (g_1(z), \ldots, g_{n-1}(z), g_n(z)),$$

where

$$\begin{aligned} g_k(z) &= (z_k - \check{z}_k) \quad \text{for } 1 \le k \le n-1, \\ g_n(z) &= \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d. \end{aligned} \tag{3.3}$$

Let $p_k(x, y) \equiv \Re(g_k(x + iy))$ and $q_k(x, y) \equiv \Im(g_k(x + iy))$. With this, define $\tilde{G} : \mathbb{R}^{2n} \to \mathbb{R}^{2n}$ by

$$\tilde{G}(x, y) \equiv (p_1(x, y), q_1(x, y), \ldots, p_n(x, y), q_n(x, y)).$$

We will prove $\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{A}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0)$. First, we prove $\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{A}, \tilde{\boldsymbol{x}}, 0)$.

Define

$$\begin{aligned} \tilde{H}_1((x, y), t) &\equiv t\tilde{F}(x, y) + (1 - t)\tilde{A}(x, y) \\ \text{and} \qquad H_1(z, t) &\equiv tF(z) + (1 - t)A(z). \end{aligned}$$

We will prove that $\tilde{H}_1((x, y), t) \ne 0$ when $(x, y) \in \partial\tilde{\boldsymbol{x}}$ and $t \in [0, 1]$. It is clear that $\tilde{H}_1((x, y), t) = 0$ is equivalent to $H_1(z, t) = 0$, so we consider $H_1(z, t)$. The definition of H_1 and some rearrangement of terms give

$$\begin{aligned} H_1(z, t) = \Big(&(z_1 - \check{z}_1) + \alpha_1(z_n - \check{z}_n), \ldots, (z_{n-1} - \check{z}_{n-1}) + \alpha_{n-1}(z_n - \check{z}_n), \\ &tf_n(z) + (1 - t)\frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d\Big). \end{aligned}$$

Thus, $H_1(z, t) = 0$ implies $z_k = \check{z}_k - \alpha_k(z_n - \check{z}_n)$ for $k = 1, \ldots, n - 1$. By definition, $\alpha_n = -1$, and thus $z_n = \check{z}_n - \alpha_n(z_n - \check{z}_n)$. Substituting $z_k - \check{z}_k = -\alpha_k(z_n - \check{z}_n)$ for each such k ($k = 1, 2, \ldots, n$) in the derivative tensor evaluation $D^\ell f_n(\check{x})[z - \check{z}, \ldots, z - \check{z}]$ in (3.1), we obtain

$$D^\ell f_n(\check{x})[z - \check{z}, \ldots, z - \check{z}] = (-1)^\ell \Delta_\ell (z_n - \check{z}_n)^\ell, \quad 2 \le \ell \le d. \tag{3.4}$$

Since we are assuming that Δ_ℓ, $\ell < d$, vanish, (3.4) and (3.1) give

$$f_n(z) = \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d. \tag{3.5}$$

Thus, the last component of $H_1(z,t)$ is

$$\begin{aligned} t f_n(z) &+ (1-t)\frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d \\ &= t\frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d + (1-t)\frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d \\ &= \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d. \end{aligned}$$

Then, $H_1(z,t) = 0$ implies $(z_n - \check{z}_n)^d = 0$, and consequently, $z_n - \check{z}_n = 0$ or $z_n = \check{z}_n$. This implies $z_k = \check{z}_k - \alpha_k(z_n - \check{z}_n) = \check{z}_k$ for $k = 1, \dots, n-1$.

Now we know that $H_1(z,t)$ has a unique zero at $(\check{z}_1, \dots, \check{z}_{n-1}, \check{z}_n)$. This is saying that $\tilde{H}_1((x,y),t)$ has a unique zero at $(\check{x}, \check{y})$, which is the midpoint of nondegenerate box $\tilde{\boldsymbol{x}}$. Thus, $\tilde{H}_1((x,y),t) \neq 0$ for $(x,y) \in \boldsymbol{\partial}\tilde{\boldsymbol{x}}$ and $t \in [0,1]$. Then, by Theorem 1.4,

$$\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{A}, \tilde{\boldsymbol{x}}, 0).$$

Next, we prove $\mathrm{d}(\tilde{A}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0)$. Define

$$\begin{aligned} \tilde{H}_2((x,y),t) &\equiv t\tilde{A}(x,y) + (1-t)\tilde{G}(x,y) \\ \text{and} \qquad H_2(z,t) &\equiv tA(z) + (1-t)G(z). \end{aligned}$$

We will prove that $\tilde{H}_2((x,y),t) \neq 0$ when $(x,y) \in \partial\tilde{\boldsymbol{x}}$ and $t \in [0,1]$. It is clear that $\tilde{H}_2((x,y),t) = 0$ is equivalent to $H_2(z,t) = 0$, so we consider $H_2(z,t)$. The definition of H_2 and some rearrangement of terms give

$$\begin{aligned} H_2(z,t) = \Big((z_1 - \check{z}_1) &+ t\alpha_1(z_n - \check{z}_n), \dots, (z_{n-1} - \check{z}_{n-1}) + t\alpha_{n-1}(z_n - \check{z}_n), \\ &\frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d\Big). \end{aligned}$$

Because of the last component of $H_2(z,t)$, $H_2(z,t) = 0$ implies $z_n = \check{z}_n$. Then, from the first $n-1$ components of $H_2(z,t)$, $H_2(z,t) = 0$ implies $z_k = \check{z}_k - t\alpha_k(z_n - \check{z}_n) = \check{z}_k$ for $k = 1, \dots, n-1$. Thus, $H_2(z,t)$ has a unique zero at $(\check{z}_1, \dots, \check{z}_{n-1}, \check{z}_n)$. This is saying that $\tilde{H}_2((x,y),t)$ has a unique zero at $(\check{x}, \check{y})$, which is the midpoint of the nondegenerate box $\tilde{\boldsymbol{x}}$. Thus, $\tilde{H}_2((x,y),t) \neq 0$ for $(x,y) \in \boldsymbol{\partial}\tilde{\boldsymbol{x}}$ and $t \in [0,1]$. Then, by Theorem 1.4,

$$\mathrm{d}(\tilde{A}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0).$$

Next, we prove $\mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0) = d$. Perturb $G(z)$ by an arbitrary small ϵ to define

$$G_\epsilon(z) = (g_{1\epsilon}(z), \dots, g_{(n-1)\epsilon}(z), g_{n\epsilon}(z)),$$

where

$$\begin{aligned} g_{k\epsilon}(z) &= g_k(z) = (z_k - \check{z}_k) \quad \text{for } 1 \le k \le n-1, \\ g_{n\epsilon}(z) &= g_n(z) + \epsilon = \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d + \epsilon. \end{aligned} \tag{3.6}$$

Let $p_{k\epsilon}(x,y) \equiv \Re(g_{k\epsilon}(x+iy))$ and $q_{k\epsilon}(x,y) \equiv \Im(g_{k\epsilon}(x+iy))$. With this, define

$$\tilde{G}_\epsilon(x,y) \equiv (p_{1\epsilon}(x,y), q_{1\epsilon}(x,y), \ldots, p_{n\epsilon}(x,y), q_{n\epsilon}(x,y)).$$

It is obvious that $p_{k\epsilon}(x,y) = x_k - \check{x}_k$ and $q_{k\epsilon}(x,y) = y_k - \check{y}_k$ for $k = 1, \ldots, n-1$. Assume that ϵ is small enough. Then $G_\epsilon(z)$, and thus $\tilde{G}_\epsilon(x,y)$, have d zeros $\tilde{z} = (\tilde{z}_1, \ldots, \tilde{z}_{n-1}, \tilde{z}_n)$, or $\tilde{x} = (\tilde{x}_1, \tilde{y}_1, \ldots, \tilde{x}_{n-1}, \tilde{y}_{n-1}, \tilde{x}_n, \tilde{x}_n)$ in $\tilde{\boldsymbol{x}}$, with $\tilde{z}_k - \check{z}_k = 0$, or $\tilde{x}_k - \check{x}_k = 0$ and $\tilde{y}_k - \check{y}_k = 0$ for $k = 1, \ldots, n-1$, and $(\tilde{z}_n - \check{z}_n)^d = \frac{d!\epsilon}{(-1)^{d+1}\Delta_d} \neq 0$. $\frac{\partial g_{n\epsilon}}{\partial z_n}(\tilde{z}) = \frac{(-1)^d \Delta_d}{(d-1)!}(\tilde{z}_n - \check{z}_n)^{d-1} \neq 0$.

$$\begin{aligned}
\left|\frac{\partial \tilde{G}_\epsilon}{\partial x_1 \partial y_1 \ldots \partial x_n \partial y_n}(\tilde{x})\right| &= \begin{vmatrix} 1 & 0 & \cdots & 0 & 0 & 0 \\ 0 & 1 & \cdots & 0 & 0 & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \\ 0 & 0 & \cdots & 1 & 0 & 0 \\ 0 & 0 & \cdots & 0 & \frac{\partial p_{n\epsilon}}{\partial x_n} & \frac{\partial p_{n\epsilon}}{\partial y_n} \\ 0 & 0 & \cdots & 0 & \frac{\partial q_{n\epsilon}}{\partial x_n} & \frac{\partial q_{n\epsilon}}{\partial y_n} \end{vmatrix} \\
&= \begin{vmatrix} \frac{\partial p_{n\epsilon}}{\partial x_n} & \frac{\partial p_{n\epsilon}}{\partial y_n} \\ \frac{\partial q_{n\epsilon}}{\partial x_n} & \frac{\partial q_{n\epsilon}}{\partial y_n} \end{vmatrix} = \begin{vmatrix} \frac{\partial p_{n\epsilon}}{\partial x_n} & \frac{\partial p_{n\epsilon}}{\partial y_n} \\ -\frac{\partial p_{n\epsilon}}{\partial y_n} & \frac{\partial p_{n\epsilon}}{\partial x_n} \end{vmatrix} \qquad (3.7) \\
&= \left(\frac{\partial p_{n\epsilon}}{\partial x_n}\right)^2 + \left(\frac{\partial p_{n\epsilon}}{\partial y_n}\right)^2 = \left|\frac{\partial g_{n\epsilon}}{\partial z_n}(\tilde{z})\right|^2 > 0.
\end{aligned}$$

Thus, by Theorem 1.2, $\mathrm{d}(\tilde{G}_\epsilon, \tilde{\boldsymbol{x}}, 0) = d$, and then $\mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0) = d$ by Theorem 1.5. Finally,

$$\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = \mathrm{d}(\tilde{G}, \tilde{\boldsymbol{x}}, 0) = d. \qquad \square$$

Unless the components of F are exactly linear and degree-d polynomials, the $\mathcal{O}(\|x - \check{x}\|)^2$ and $\mathcal{O}(\|x - \check{x}\|)^{d+1}$ terms in (2.1) and (2.2) are not absent. However, since $\mathrm{d}(F, \boldsymbol{z}, 0)$ is a continuous function of F, $\mathrm{d}(F, \boldsymbol{z}, 0)$ will still be equal to d if the widths $\mathrm{w}(\boldsymbol{x}_k - \check{x}_k)$ (and hence $\|x_k - \check{x}_k\|$) are small, for $1 \leq k \leq n$. Nonetheless, the proof of Theorem 3.1 does not lead to a practical computational verification technique that the degree is d for such more general F: If we try to verify $H(z,t) \neq 0$ or $\tilde{H}((x,y),t) \neq 0$ when $(x,y) \in \partial\tilde{\boldsymbol{x}}$ and $t \in [0,1]$, then it would require an inordinate amount of work for a verification process that would normally require only a single step of an interval Newton method in the nonsingular case. First, we would need to compute Δ_d, which involves all partial derivatives of order 1 and order d. This is expensive when both n and d are large. Second, we would need to know where the solutions of $u_n(x) = 0$ and $v_n(x) = 0$ are on $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ when $z_k = \check{z}_k - t\alpha_k(z_n - \check{z}_n)$, and the search process for such solutions is expensive.

We could try to verify $H(z,t) \neq 0$ when $(x,y) \in \partial\tilde{\boldsymbol{x}}$ and $t \in [0,1]$ in another way: verify that $H(z,t) = 0$ has a unique solution in the interior of $\tilde{\boldsymbol{x}}$ when $t \in [0,1]$. However, we will run into the singular situation again if we do that.

In fact, there is an alternative algorithm to verify that the degree is d. That will be the subject of the next section.

4. Algorithm to verify a nonzero topological degree.

The algorithm we present here is similar to the algorithm in [14]. Based on Theorem 1.7 in section 1.2, the following theorem underlies our algorithm.

THEOREM 4.1. *Suppose that*

1. $u_k \neq 0$ *on* $\boldsymbol{x}_{\underline{k}}$ *and* $\boldsymbol{x}_{\overline{k}}$, *and* $v_k \neq 0$ *on* $\boldsymbol{y}_{\underline{k}}$ *and* $\boldsymbol{y}_{\overline{k}}$, $k = 1, \dots, n-1$;
2. $\tilde{F}_{\neg u_n} = 0$ *has solutions, if there are any, on* $\boldsymbol{x}_{\underline{n}}$ *and* $\boldsymbol{x}_{\overline{n}}$ *with* y_n *in the interior of* $\boldsymbol{y}_n$, *and* $\tilde{F}_{\neg u_n} = 0$ *has solutions, if there are any, on* $\boldsymbol{y}_{\underline{n}}$ *and* $\boldsymbol{y}_{\overline{n}}$ *with* x_n *in the interior of* $\boldsymbol{x}_n$;
3. $u_n \neq 0$ *at the solutions of* $\tilde{F}_{\neg u_n} = 0$ *in condition* 2; *and*
4. *the Jacobi matrices of* $\tilde{F}_{\neg u_n}$ *are nonsingular at the solutions of* $\tilde{F}_{\neg u_n} = 0$ *in condition* 2.

Then, for a fixed $s \in \{-1, 1\}$,

$$\begin{aligned}
\mathrm{d}(\tilde{F}, \tilde{\boldsymbol{x}}, 0) = -s & \sum_{\substack{x_n = \underline{x}_n \\ \tilde{F}_{\neg u_n}(x,y)=0 \\ \mathrm{sgn}(u_n(x,y))=s}} \mathrm{sgn} \left| \frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \cdots x_{n-1} y_{n-1} y_n}(x,y) \right| \\
+ s & \sum_{\substack{x_n = \overline{x}_n \\ \tilde{F}_{\neg u_n}(x,y)=0 \\ \mathrm{sgn}(u_n(x,y))=s}} \mathrm{sgn} \left| \frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \cdots x_{n-1} y_{n-1} y_n}(x,y) \right| \\
+ s & \sum_{\substack{y_n = \underline{y}_n \\ \tilde{F}_{\neg u_n}(x,y)=0 \\ \mathrm{sgn}(u_n(x,y))=s}} \mathrm{sgn} \left| \frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \cdots x_{n-1} y_{n-1} x_n}(x,y) \right| \\
- s & \sum_{\substack{y_n = \overline{y}_n \\ \tilde{F}_{\neg u_n}(x,y)=0 \\ \mathrm{sgn}(u_n(x,y))=s}} \mathrm{sgn} \left| \frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \cdots x_{n-1} y_{n-1} x_n}(x,y) \right| .
\end{aligned}$$

Proof. Condition 1 implies $\tilde{F} \neq 0$ on $\boldsymbol{x}_{\underline{k}}$, $\boldsymbol{x}_{\overline{k}}$, $\boldsymbol{y}_{\underline{k}}$, and $\boldsymbol{y}_{\overline{k}}$, $k = 1, \dots, n-1$, and conditions 2 and 3 imply $\tilde{F} \neq 0$ on $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$. Thus, $\tilde{F} \neq 0$ on $\boldsymbol{\partial} \tilde{\boldsymbol{x}}$. Now, condition 1 implies $\tilde{F}_{\neg u_n} \neq 0$ on $\boldsymbol{\partial x}_{\underline{k}}$, $\boldsymbol{\partial x}_{\overline{k}}$, $\boldsymbol{\partial y}_{\underline{k}}$, and $\boldsymbol{\partial y}_{\overline{k}}$, $k = 1, \dots, n-1$. $\boldsymbol{\partial x}_{\underline{n}}$ consists of $2(n-1)$ $(2n-2)$-dimensional boxes, each of which is either embedded in some $\boldsymbol{x}_{\underline{k}}$, $\boldsymbol{x}_{\overline{k}}$, $\boldsymbol{y}_{\underline{k}}$, or $\boldsymbol{y}_{\overline{k}}$, $1 \leq k \leq n-1$, or is embedded in $\boldsymbol{\partial y}_{\underline{n}}$ or $\boldsymbol{\partial y}_{\overline{n}}$. Thus, by 1 and 2, $\tilde{F}_{\neg u_n} \neq 0$ on $\boldsymbol{\partial x}_{\underline{n}}$. Similarly, $\tilde{F}_{\neg u_n} \neq 0$ on $\boldsymbol{\partial x}_{\overline{n}}$, $\boldsymbol{\partial y}_{\underline{n}}$, and $\boldsymbol{\partial y}_{\overline{n}}$. Thus, condition 1 in Theorem 1.7 is satisfied. Finally, with condition 4, all the conditions of Theorem 1.7 are satisfied. The formula is thus obtained. □

By constructing the box $\tilde{\boldsymbol{x}}$ according to (2.5), we can verify $u_k \neq 0$ on $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$, and $v_k \neq 0$ on $\boldsymbol{y}_{\underline{k}}$ and $\boldsymbol{y}_{\overline{k}}$, $k = 1, \dots, n-1$, since $u_k(x,y) \approx (x_k - \check{x}_k) + \alpha_k(x_n - \check{x}_n) \neq 0$ on $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$, and $v_k(x,y) \approx y_k + \alpha_k y_n \neq 0$ on $\boldsymbol{y}_{\underline{k}}$ and $\boldsymbol{y}_{\overline{k}}$. This needs only $4n-4$ interval evaluations. Then, we need to search only the four faces $\boldsymbol{x}_{\underline{n}}, \boldsymbol{x}_{\overline{n}}, \boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ for solutions of $\tilde{F}_{\neg u_n}(x,y) = 0$, regardless of how large n is. The four faces $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ remaining to be searched are $(2n-1)$-dimensional boxes. However, exploitation of (2.3) will reduce the search for solutions of $\tilde{F}_{\neg u_n}(x,y) = 0$ on the $(2n-1)$-dimensional boxes to a one-dimensional search. We use $\boldsymbol{x}_{\underline{n}}$ as an example to explain this.

On $\boldsymbol{x}_{\underline{n}}$, $x_n = \underline{x}_n$. We know from (2.3) that if x_n is known precisely, formally solving $\boldsymbol{u}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ for x_k gives sharper bounds $\tilde{\boldsymbol{x}}_k$ with $\mathrm{w}(\tilde{\boldsymbol{x}}_k) = \mathcal{O}\left(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|\right)^2$,

$1 \le k \le n-1$. Then, we can divide $\boldsymbol{y}_n$ into smaller subintervals. For a small subinterval $\boldsymbol{y}_n^0$ of $\boldsymbol{y}_n$, we can formally solve $\boldsymbol{v}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ for y_k to get sharper bounds $\tilde{\boldsymbol{y}}_k$ with $\mathrm{w}(\tilde{\boldsymbol{y}}_k) = \mathcal{O}(\max(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|^2, \|\boldsymbol{y}_n^0\|))$, $1 \le k \le n-1$. Thus, we have reduced the search to searching the one-dimensional interval $\boldsymbol{y}_n$, much less costly than searching a $(2n-1)$-dimensional box when n is large. Furthermore, if we know approximately where the solutions of $\tilde{F}_{\neg u_n}(x,y) = 0$ are, we can reduce even the cost of the one-dimensional search. To this end, we will next analyze the solutions of $\tilde{F}_{\neg u_n}(x,y) = 0$ on the four faces $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$.

To expedite the search, we obtain approximate locations of the places on $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ where $\tilde{F}_{\neg u_n}(x,y) = 0$. To obtain these locations, we assume that the $\mathcal{O}\left(\|x - \check{x}\|\right)^2$ terms in (2.1) and the $\mathcal{O}\left(\|x - \check{x}\|\right)^{d+1}$ terms in (2.2) are absent. Proceeding as in the proof of Theorem 3.1, we plug $z_k - \check{z}_k = -\alpha_k(z_n - \check{z}_n)$, $k = 1, \ldots, n-1$, into $f_n(z)$ to obtain

$$f_n(z) = \frac{(-1)^d \Delta_d}{d!}(z_n - \check{z}_n)^d$$

as before. Thus, $u_n(x,y) = \Re(f_n(z)) = \left\{(-1)^d \Delta_d / d!\right\} \Re((z_n - \check{z}_n)^d)$ and $v_n(x,y) = \Im(f_n(z)) = \left\{(-1)^d \Delta_d / d!\right\} \Im((z_n - \check{z}_n)^d)$. Setting $z_n - \check{z}_n = r(\cos(\theta) + i\sin(\theta))$, we obtain $u_n(x,y) = \left\{(-1)^d \Delta_d / d!\right\} r\cos(d\theta)$ and $v_n(x,y) = \left\{(-1)^d \Delta_d / d!\right\} r \sin(d\theta)$, so $u_n(x,y) = 0$ is equivalent to $\cos(d\theta) = 0$ and $v_n(x,y) = 0$ is equivalent to $\sin(d\theta) = 0$. If we choose $\boldsymbol{x}_n$ and $\boldsymbol{y}_n$ such that

$$\frac{\mathrm{w}(\boldsymbol{y}_n)}{\mathrm{w}(\boldsymbol{x}_n)} = \tan\left(\frac{\pi}{4d}\right), \qquad \text{that is,} \qquad \mathrm{w}(\boldsymbol{y}_n) = \tan\left(\frac{\pi}{4d}\right)\mathrm{w}(\boldsymbol{x}_n), \tag{4.1}$$

then all solutions of $v_n(x,y) = 0$, and consequently all solutions of $\tilde{F}_{\neg u_n}(x,y) = 0$, are arranged in a known pattern on $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$. In particular, on $\boldsymbol{x}_{\underline{n}}$, $\tilde{x}_n = \underline{x}_n$. $v_n(x,y) = 0$ has a unique solution $\tilde{y}_n = 0$. Substituting these into the conditions

$$\left.\begin{array}{rcl} x_k &=& \check{x}_k - \alpha_k(x_n - \check{x}_n), \\ y_k &=& -\alpha_k y_n, \end{array}\right\} \qquad 1 \le k \le n-1, \tag{4.2}$$

we get the unique solution of $\tilde{F}_{\neg u_n}(x,y) = 0$ with

$$(\tilde{x}, \tilde{y}) = (\check{x}_1 - \alpha_1(\underline{x}_n - \check{x}_n), 0, \ldots, \check{x}_{n-1} - \alpha_{n-1}(\underline{x}_n - \check{x}_n), 0, \underline{x}_n, 0)\,.$$

Similarly, $\tilde{F}_{\neg u_n}(x,y) = 0$ has a unique solution on $\boldsymbol{x}_{\overline{n}}$ with

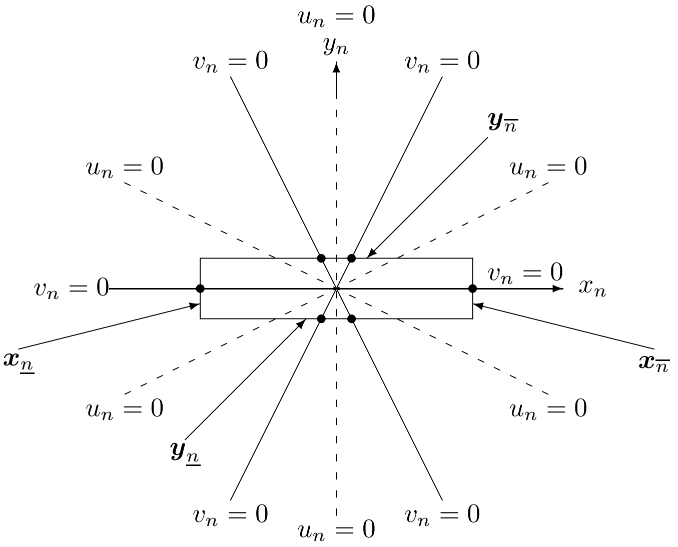
$$(\tilde{x}, \tilde{y}) = (\check{x}_1 - \alpha_1(\overline{x}_n - \check{x}_n), 0, \ldots, \check{x}_{n-1} - \alpha_{n-1}(\overline{x}_n - \check{x}_n), 0, \overline{x}_n, 0).$$

On $\boldsymbol{y}_{\underline{n}}$, $\tilde{y}_n = \underline{y}_n$. $v_n(x,y) = 0$ has $d-1$ solutions with

$$\tilde{x}_n = \check{x}_n + \frac{\mathrm{w}(\boldsymbol{y}_n)}{2\tan\left(\frac{m\pi}{d}\right)}, \quad m = d-1, d-2, \ldots, 1. \tag{4.3}$$

Substituting these into (4.2) gives the $d-1$ solutions $(\tilde{x}, \tilde{y})$ of $\tilde{F}_{\neg u_n}(x,y) = 0$ with

$$\begin{aligned} (\tilde{x}, \tilde{y}) = \big(&\check{x}_1 - \alpha_1\left(\tilde{x}_n - \check{x}_n\right), \alpha_1 \underline{y}_n, \ldots, \check{x}_{n-1} - \alpha_{n-1}\left(\tilde{x}_n - \check{x}_n\right), \\ &- \alpha_{n-1}\underline{y}_n, \tilde{x}_n, \underline{y}_n\big). \end{aligned}$$



$u_n = 0$
y_n
$v_n = 0$
$v_n = 0$
$\boldsymbol{y}_{\overline{n}}$
$u_n = 0$
$u_n = 0$
$v_n = 0$
$v_n = 0$
x_n
$\boldsymbol{x}_{\underline{n}}$
$\boldsymbol{x}_{\overline{n}}$
$u_n = 0$
$u_n = 0$
$\boldsymbol{y}_{\underline{n}}$
$v_n = 0$
$v_n = 0$
$u_n = 0$

FIG. 4.1. *The zero structure when d is odd. Here,* $d = 3$. $v_n = 0$ *on solid lines, and* $u_n = 0$ *on dashed lines. The thick dots are the solutions of* $\tilde{F}_{\neg u_n}(x, y) = 0$ *on* $\boldsymbol{\partial\tilde{x}}$.

Similarly, $\tilde{F}_{\neg u_n}(x, y) = 0$ has $d - 1$ solutions on $\boldsymbol{y}_{\overline{n}}$ with

$$\begin{aligned}(\tilde{x}, \tilde{y}) = (&\check{x}_1 - \alpha_1 (\tilde{x}_n - \check{x}_n), \dots, \check{x}_{n-1} - \alpha_{n-1} (\tilde{x}_n - \check{x}_n), \\ &- \alpha_{n-1}\overline{y}_n, \tilde{x}_n, \overline{y}_n).\end{aligned}$$

For example, Figure 4.1 gives the solutions of $v_n(x, y) = 0$ on the four faces $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ when $d = 3$.

To use the above analysis to find approximations to the solutions of $\tilde{F}_{\neg u_n} = 0$ on the faces we search, we need to know d; we present a heuristic for d in section 5 below.

Now, we present our algorithm. The algorithm consists of three phases:

1. the box-construction phase, where we set $\tilde{\boldsymbol{x}}$,
2. the elimination phase, where we use interval evaluations to verify that $u_k \neq 0$ on $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$, and $v_k \neq 0$ on $\boldsymbol{y}_{\underline{k}}$ and $\boldsymbol{y}_{\overline{k}}$, where $1 \leq k \leq n - 1$, and thus eliminate those $4n - 4$ faces, and
3. the search phase, where we
   (a) search $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ to locate the solutions of $\tilde{F}_{\neg u_n}(x, y) = 0$,
   (b) compute the signs of u_n and determinants of the Jacobi matrices of $\tilde{F}_{\neg u_n}$ at those solutions,
   (c) compute the degree contributions of each of the four faces $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ according to Theorem 4.1, and
   (d) finally sum up to get the degree.

ALGORITHM 1.
INPUT: An approximate solution $\check{x} \in \mathbf{D} \subseteq \mathbb{R}^n$ and a heuristically derived guess d for the topological index of the solution to $\tilde{F}(z) = 0$ near $\check{x}$. (See section 5 below.)
OUTPUT: Either "`A solution is verified`" or "`Verification failed`." If a solution is verified, then also output real bounds $\boldsymbol{x} \subset \mathbb{R}^n$, $\check{x} \in \boldsymbol{x}$, and imaginary bounds $\boldsymbol{y} \in \mathbb{R}^n$, $0 \in \boldsymbol{y}$, such that a solution of $\tilde{F}(z) = 0$ must lie in $(\boldsymbol{x}_1 + i\boldsymbol{y}_1, \dots, \boldsymbol{x}_n + i\boldsymbol{y}_n) \in \mathbb{IC}^n$.

```
Box-setting phase.
  1. Compute the preconditioner of the original system, using Gaussian elimination with full pivoting.
  2. Set the widths of $\boldsymbol{x}_k$ and $\boldsymbol{y}_k$ (see explanation below), for $1 \le k \le n-1$.
  3. Set the width of $\boldsymbol{x}_n$ as in (2.5).
  4. Set the width of $\boldsymbol{y}_n$ to be the minimum of that obtained from conditions (2.5) and (4.1).
Elimination phase.
Do for $1 \le k \le n-1$
  1. DO for $\boldsymbol{x}_{\underline{k}}$ and $\boldsymbol{x}_{\overline{k}}$
       (a) Compute the mean-value extension of $\boldsymbol{u}_k$ over that face.
       (b) IF $0 \in \boldsymbol{u}_k$, THEN STOP and signal failure.
     END DO
  2. DO for $\boldsymbol{y}_{\underline{k}}$ and $\boldsymbol{y}_{\overline{k}}$
       (a) Compute the mean-value extension of $\boldsymbol{v}_k$ over that face.
       (b) IF $0 \in \boldsymbol{v}_k$, THEN STOP and signal failure.
     END DO
Search phase.
  1. Set the value of $s \in \{+1, -1\}$.
       (a) Initialize $s$ to be $+1$. Initialize search_lower and search_upper to be false.
           (See the second note below.)
       (b) DO for $\boldsymbol{x}_{\underline{n}}$ and $\boldsymbol{x}_{\overline{n}}$
             i. Use mean-value extensions for $\boldsymbol{u}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $x_k$ to get
                sharper bounds $\tilde{\boldsymbol{x}}_k$ with width $\mathcal{O}\left(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|\right)^2$, $1 \le k \le n-1$,
                and thus to get a subface $\boldsymbol{x}_{\underline{n}}^0$ (or $\boldsymbol{x}_{\overline{n}}^0$) of $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$.).
             ii. IF $\tilde{\boldsymbol{x}}_k \cap \boldsymbol{x}_k = \emptyset$, THEN CYCLE.
             iii. Compute the mean-value extension $\boldsymbol{u}_n$ over $\boldsymbol{x}_{\underline{n}}^0$ (or $\boldsymbol{x}_{\overline{n}}^0$).
             iv. IF $\boldsymbol{u}_n$ contains 0, THEN
                   A. set search_lower (or search_upper) to be true
                   B. CYCLE.
                 END IF
             v. IF $\boldsymbol{u}_n$ does not contain 0, THEN set $s = -\mathrm{sgn}(\boldsymbol{u}_n)$.
           END DO
       (c) IF $\boldsymbol{u}_n$ does not contain 0 on both $\boldsymbol{x}_{\underline{n}}$ and $\boldsymbol{x}_{\overline{n}}$,
           THEN set $s$ to be the opposite sign to the sign of $\boldsymbol{u}_n$ on $\boldsymbol{x}_{\overline{n}}$, and
           IF $\boldsymbol{u}_n$ has different signs on $\boldsymbol{x}_{\underline{n}}$ and $\boldsymbol{x}_{\overline{n}}$,
           THEN set search_lower to be true.
  2. For $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$), IF search_lower (or search_upper) is true,
     THEN apply Algorithm 2 with $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$) and 0 as input, to compute the
     degree contribution of $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$).
  3. For $\boldsymbol{y}_{\underline{n}}$ (or $\boldsymbol{y}_{\overline{n}}$)
       (a) Use (4.3) to compute the $\tilde{x}_n^m$, $m = d-1, d-2, \ldots, 1$, $\tilde{x}_n^{d-1} < \tilde{x}_n^{d-2} <$
           $\cdots < \tilde{x}_n^1$, corresponding to the $d-1$ approximate solutions of $\tilde{F}_{\neg u_n} = 0$
           on $\boldsymbol{y}_{\underline{n}}$.
       (b) Divide $\boldsymbol{x}_n$ into $d-1$ parts $\boldsymbol{x}_n^m$, $m = 1, \ldots, d-1$, as follows:
           $\boldsymbol{x}_n^1 = [\underline{x}_n, (\tilde{x}_n^{d-1} + \tilde{x}_n^{d-2})/2]$,
           $\boldsymbol{x}_n^m = [(\tilde{x}_n^{d-(m-1)} + \tilde{x}_n^{d-m})/2, (\tilde{x}_n^{d-m} + \tilde{x}_n^{d-(m+1)})/2]$
           for $m = 2, \ldots, d-2$, and $\boldsymbol{x}_n^{d-1} = [(\tilde{x}_n^2 + \tilde{x}_n^1)/2, \overline{x}_n]$.
       (c) DO for $m = 1, \ldots, d-1$
             i. Set a subface $\boldsymbol{y}_{\underline{n}}^m$ of $\boldsymbol{y}_{\underline{n}}$ (or $\boldsymbol{y}_{\overline{n}}^m$ of $\boldsymbol{y}_{\overline{n}}$) by replacing $\boldsymbol{x}_n$ by $\boldsymbol{x}_n^m$.
```

```
            ii. Apply Algorithm 3 with $\boldsymbol{y}^m_{\underline{n}}$ and $\tilde{x}^m_n$ as inputs, to compute the degree
                contribution of $\boldsymbol{y}^m_{\underline{n}}$ (or $\boldsymbol{y}^m_{\overline{n}}$).
            END DO
        (d) Add the degree contributions in the last step to get the degree contribution of $\boldsymbol{y}_{\underline{n}}$ (or $\boldsymbol{y}_{\overline{n}}$).
    4. Add the degree contributions of $\boldsymbol{x}_{\underline{n}}$, $\boldsymbol{x}_{\overline{n}}$, $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{y}_{\overline{n}}$ to get the overall degree.
```

Notes for Algorithm 1.

1. In step 3 of the box-setting phase, the width $\mathrm{w}(\boldsymbol{x}_n)$ of $\boldsymbol{x}_n$ depends on the accuracy of the approximate solution $\check{x}$ of the system $F(x) = 0$: $\mathrm{w}(\boldsymbol{x}_n)$ should be much larger than $|\check{x}_k - x^*{}_k|$, but also should be small enough to make a quadratic model accurate over the box.
2. We may set s to minimize the amount of work required to evaluate the sum in Theorem 4.1. In particular, if we know $\mathrm{sgn}(u_n) = \sigma$ on a large number of faces, then setting $s = -\sigma$ will eliminate the need to search those faces.

Algorithm 2.

```
INPUT: $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$) and $\boldsymbol{y}$ from Algorithm 1.
OUTPUT: The contribution of $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$) to the degree in Algorithm 1.
    1. (a) Use mean-value extensions for $\boldsymbol{u}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $x_k$ to get sharper
           bounds $\tilde{\boldsymbol{x}}_k$ with width $\mathcal{O}\left(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|\right)^2$, $1 \le k \le n - 1$.
       (b) IF $\tilde{\boldsymbol{x}}_k \cap \boldsymbol{x}_k = \emptyset$,
           THEN RETURN the degree contribution of that face as 0.
       (c) Update $\boldsymbol{x}_k$.
    2. (a) Compute the mean-value extension $\boldsymbol{u}_n$ over that face.
       (b) IF $s \times \mathrm{sgn}(\boldsymbol{u}_n) < 0$,
           THEN RETURN the degree contribution of that face as 0.
    3. Construct a small subinterval $\boldsymbol{y}^0_n$ of $\boldsymbol{y}_n$ centered at $\check{y}_n$.
    4. (Steps 4 to 9 are identical to steps 1(d) to 1(i), respectively, of the search phase
       in the algorithm in [14]. These steps are repeated here for completeness.)
       (a) Use mean-value extensions for $\boldsymbol{v}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $y_k$ to get sharper
           bounds $\tilde{\boldsymbol{y}}_k$ with width $\mathcal{O}(\max(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|^2, \|\boldsymbol{y}^0_n\|))$, $1 \le k \le n-1$, thus
           getting a subface $\boldsymbol{x}^0_{\underline{n}}$ (or $\boldsymbol{x}^0_{\overline{n}}$) of $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$.)
       (b) IF $\tilde{\boldsymbol{y}}_k \cap \boldsymbol{y}_k = \emptyset$,
           THEN STOP and signal failure.
    5. (a) Set up an interval Newton method for $\tilde{F}_{\neg u_n}$ to verify existence and
           uniqueness of a zero in the subface $\boldsymbol{x}^0_{\underline{n}}$ (or $\boldsymbol{x}^0_{\overline{n}}$).
       (b) IF the zero cannot be verified,
           THEN STOP and signal failure.
    6. Inflate $\boldsymbol{y}^0_n$ as much as possible subject to verification of existence and uniqueness
       of the zero of $\tilde{F}_{\neg u_n}$ over the corresponding subface, and thus get a subinterval
       $\boldsymbol{y}^1_n$ of $\boldsymbol{y}_n$.
    7. In this step, we verify that $\tilde{F}_{\neg u_n} = 0$ has no solutions when $y_n \in \boldsymbol{y}_n \setminus \boldsymbol{y}^1_n$.
       $\boldsymbol{y}_n \setminus \boldsymbol{y}^1_n$ has two separate parts; we denote the lower part by $\boldsymbol{y}^l_n$ and the upper
       part by $\boldsymbol{y}^u_n$. We present the processing of only the lower part. The upper
       part can be processed similarly.
       (a) DO
           i. Use mean-value extensions for $\boldsymbol{v}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $y_k$ to get
              sharper bounds for $y_k$, $1 \le k \le n - 1$, and thus to get a subface of
              $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$).
           ii. Compute the mean-value extensions $\tilde{\boldsymbol{F}}_{\neg u_n}$ over the subface obtained
               in the last step.
```

```
            iii. IF $0 \in \tilde{\boldsymbol{F}}_{\neg u_n}$, THEN
                 A. bisect $\boldsymbol{y}_n^l$, update the lower part as a new $\boldsymbol{y}_n^l$;
                 B. CYCLE.
                 END IF
                 IF $0 \notin \tilde{\boldsymbol{F}}_{\neg u_n}$, THEN EXIT the loop.
            END DO
        (b) DO
            i. IF $\underline{y}_n^1 \le \overline{y}_n^l$, THEN EXIT the loop.
            ii. $\boldsymbol{y}_n^l \longleftarrow [\overline{y}_n^l, \overline{y}_n^l + \mathrm{w}(\boldsymbol{y}_n^l)]$.
            iii. Use mean-value extensions for $\boldsymbol{v}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $y_k$ to get
                 sharper bounds for $y_k$, $1 \le k \le n-1$, and thus to get a subface of
                 $\boldsymbol{x}_{\underline{n}}$ (or $\boldsymbol{x}_{\overline{n}}$).
            iv. Compute the mean-value extensions $\tilde{\boldsymbol{F}}_{\neg u_n}$ over the subface obtained
                in the last step.
            v. IF $0 \notin \tilde{\boldsymbol{F}}_{\neg u_n}$, THEN CYCLE.
               IF $0 \in \tilde{\boldsymbol{F}}_{\neg u_n}$, THEN
                 A. $\boldsymbol{y}_n^l \longleftarrow [\underline{y}_n^l, \mathrm{mid}(\boldsymbol{y}_n^l)]$;
                 B. CYCLE.
               END IF
            END DO
    8.  (a) Compute the mean-value extension of $\boldsymbol{u}_n$ over $\boldsymbol{x}_{\underline{n}}^0$ (or $\boldsymbol{x}_{\overline{n}}^0$).
        (b) IF $\boldsymbol{u}_n < 0$,
            THEN RETURN the degree contribution of that face as 0.
    9.  (a) Compute $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}_{\underline{n}}^0)|$ (or $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}_{\overline{n}}^0)|$).
        (b) IF $0 \in |\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}_{\underline{n}}^0)|$ (or $0 \in |\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}_{\overline{n}}^0)|$),
            THEN STOP and signal failure.
    10. Apply Theorem 4.1 to compute the degree contribution of $\boldsymbol{x}_{\underline{n}}$ or $\boldsymbol{x}_{\overline{n}}$.
```

ALGORITHM 3.

```
INPUT: $\boldsymbol{y}_{\underline{n}}$ (or $\boldsymbol{y}_{\overline{n}}$) and $\boldsymbol{x}$.
OUTPUT: The contribution of $\boldsymbol{y}_{\underline{n}}$ (or $\boldsymbol{y}_{\overline{n}}$) to the degree in Algorithm 1.
    1. (a) Use mean-value extensions for $\boldsymbol{v}_k(\boldsymbol{x}, \boldsymbol{y}) = 0$ to solve for $y_k$ to get sharper
           bounds $\tilde{\boldsymbol{y}}_k$ with width $\mathcal{O}\left(\|(\boldsymbol{x} - \check{x}, \boldsymbol{y})\|\right)^2$, $1 \le k \le n-1$.
       (b) IF $\tilde{\boldsymbol{y}}_k \cap \boldsymbol{y}_k = \emptyset$,
           THEN RETURN the degree contribution of that face as 0.
       (c) Update $\boldsymbol{y}_k$.
    2. (a) Compute the mean-value extension $\boldsymbol{u}_n$ over that face.
       (b) IF $s \times \mathrm{sgn}(\boldsymbol{u}_n) < 0$,
           THEN RETURN the degree contribution of that face as 0.
    3. Construct a small subinterval $\boldsymbol{x}_n^0$ of $\boldsymbol{x}_n$ which is centered at $\check{x}_n$.
    4. (Steps 4 to 9 are identical to steps 2(d) to 2(i), respectively, of the search
       phase in the algorithm in [14], but are included here for completeness.) Same
       as step 4 of Algorithm 2, except change $y_k$ to $x_k$, $\tilde{\boldsymbol{y}}_k$ to $\tilde{\boldsymbol{x}}_k$, $\boldsymbol{y}_k$ to $\boldsymbol{x}_k$, $\boldsymbol{x}_{\underline{n}}^0$ to
       $\boldsymbol{y}_{\underline{n}}^0$, $\boldsymbol{x}_{\overline{n}}^0$ to $\boldsymbol{y}_{\overline{n}}^0$, $\boldsymbol{x}_{\underline{n}}$ to $\boldsymbol{y}_{\underline{n}}$, and $\boldsymbol{x}_{\overline{n}}$ to $\boldsymbol{y}_{\overline{n}}$.
    5. Same as step 5 of Algorithm 2, except change $\boldsymbol{x}_{\underline{n}}^0$ to $\boldsymbol{y}_{\underline{n}}^0$ and $\boldsymbol{x}_{\overline{n}}^0$ to $\boldsymbol{y}_{\overline{n}}^0$.
    6. Same as step 6 of Algorithm 2, except change $\boldsymbol{y}_n^0$ to $\boldsymbol{x}_n^0$, $\boldsymbol{y}_n^1$ to $\boldsymbol{x}_n^1$, and $\boldsymbol{y}_n$
       to $\boldsymbol{x}_n$.
    7. Same as step 7 of Algorithm 2, except change $\boldsymbol{y}_n \setminus \boldsymbol{y}_n^1$ to $\boldsymbol{x}_n \setminus \boldsymbol{x}_n^1$.
```

8. Same as step 8 of Algorithm 2, except change $\boldsymbol{x}^0_{\underline{n}}$ to $\boldsymbol{y}^0_{\underline{n}}$ and $\boldsymbol{x}^0_{\overline{n}}$ to $\boldsymbol{y}^0_{\overline{n}}$.
9. Same as step 9 of Algorithm 2, except change $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}^0_{\underline{n}})|$ to $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} x_n}(\boldsymbol{y}^0_{\underline{n}})|$ and $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} y_n}(\boldsymbol{x}^0_{\overline{n}})|$ to $|\frac{\partial \tilde{F}_{\neg u_n}}{\partial x_1 y_1 \ldots x_{n-1} y_{n-1} x_n}(\boldsymbol{y}^0_{\overline{n}})|$.
10. Same as step 10 of Algorithm 2.

Notes for Algorithms 2 *and* 3.

1. Algorithms 2 and 3 are identical to steps 1 and 2 of the search phase of the algorithm in [14], except, in Algorithm 2, $\check{y}_n$ can be any interior point of $\boldsymbol{y}_n$, while $\check{y}_n$ is assumed to equal zero in step 1 of the search phase in the algorithm in [14]. Similarly, in Algorithm 3, $\check{x}_n$ can be any interior point of $\boldsymbol{x}_n$, whereas $\check{x}_n$ is assumed to equal the center of $\boldsymbol{x}_n$ in step 2 of the search phase in the algorithm in [14].
2. In the overall algorithm, Algorithm 1, the actual inputs are $\boldsymbol{y}^m_{\underline{n}}$ and $\tilde{x}^m_n$ when Algorithm 3 is applied. However, for notational simplicity, we use $\boldsymbol{y}_{\underline{n}}$ and $\check{x}_n$ as inputs in the presentation of Algorithm 3.

In a certain sense, the computational complexity of Algorithms 1, 2, and 3 is $\mathcal{O}(n^3)$. (See [14] for detailed analysis.) Thus, the computational complexity of the overall algorithm, Algorithm 1, is $\mathcal{O}(n^3)$. This is the best possible order, since computing preconditioners of the original system and the system $\tilde{F}_{\neg u_n}$ is necessary and computing each preconditioner is of order $\mathcal{O}(n^3)$.

5. A heuristic for the degree.

The algorithms in section 4 require a value for d to locate the approximate positions of solutions of $\tilde{F}_{\neg u_n} = 0$ on the faces we search. Here, we present a practical heuristic for the value of d.

Proceeding as in the proof of Theorem 3.1, we assume that the $\mathcal{O}\left(\|x - \check{x}\|\right)^2$ terms in (2.1) and the $\mathcal{O}\left(\|x - \check{x}\|\right)^{d+1}$ terms in (2.2) are absent, and we substitute $x_k - \check{x}_k = -\alpha_k(x_n - \check{x}_n)$, $k = 1, \ldots, n-1$, into f_n to enable us to define the univariate function

$$g(x_n - \check{x}_n) = \frac{(-1)^d \Delta_d}{d!}(x_n - \check{x}_n)^d = \frac{\Delta_d}{d!}(\check{x}_n - x_n)^d. \tag{5.1}$$

Setting

$$K(r, x_n - \check{x}_n) \equiv \frac{g(x_n - \check{x}_n)}{(x_n - \check{x}_n)^r} = \frac{\Delta_d}{d!}(\check{x}_n - x_n)^{d-r},$$

it is clear that $K(d, x_n - \check{x}_n) = \Delta_d/d!$ is independent of x_n, while $K(r, x_n - \check{x}_n)$ depends on x_n for any other r value. Letting δ be a heuristically chosen constant, we have the following ratios:

$$\frac{K(d, \delta(x_n - \check{x}_n))}{K(d, x_n - \check{x}_n)} = \frac{\frac{\Delta_d}{d!}}{\frac{\Delta_d}{d!}} = 1, \quad \text{while}$$

$$R(r) = \frac{K(r, \delta(x_n - \check{x}_n))}{K(r, x_n - \check{x}_n)} = \frac{\frac{\Delta_d}{d!}(\delta(\check{x}_n - x_n))^{d-r}}{\frac{\Delta_d}{d!}(\check{x}_n - x_n)^{d-r}} = \delta^{d-r}$$

for any other r value. The first ratio $R(d)$ always equals 1, but $R(r)$, $r \neq d$, depends on the δ value. We can choose δ to distinguish d from other r values. For example, if we choose $\delta = 100$, then $R(r)$ is not smaller than 100 when r is smaller than d, and is not larger than 0.01 when r is larger than d. Both values are sufficiently different from 1. We can also vary the δ value to check our detection of d. Thus, $R(r)$ is a good heuristic to determine the value of d.

The above discussion is based on the assumptions in section 2. However, unless the first $n-1$ components of F are exactly linear and the last component is a homogeneous degree-d polynomial of n variables, those assumptions are only approximately true. In practice, if $g(x_n - \check{x}_n) \approx \frac{\Delta_d}{d!}(\check{x}_n - x_n)^d$ is an accurate approximation, then $(\check{x}_n - x_n)^d$ should dominate the value of $g(x_n - \check{x}_n)$. Actually,

$$g(x_n - \check{x}_n) = \sum_{k=1}^{d-1} c_k \Delta_k (x_n - \check{x}_n)^k + c_d \Delta_d (x_n - \check{x}_n)^d + \sum_{k=d+1}^{\infty} c_k \Delta_k (x_n - \check{x}_n)^k,$$

where, approximately, $\Delta_1 = \cdots = \Delta_{d-1} = 0$, $\Delta_d \neq 0$. Thus, $x_n - \check{x}_n$ and $\delta(x_n - \check{x}_n)$ should not be too small, since $\sum_{k=1}^{d-1} c_k \Delta_k (x_n - \check{x}_n)^k$ could dominate otherwise. They should not be too big either, since $\sum_{k=d+1}^{\infty} c_k \Delta_k (x_n - \check{x}_n)^k$ could dominate otherwise. If $\Delta_k \approx 0, k = 1, \ldots, d-1$, are quite accurate, then we can choose $x_n - \check{x}_n$ very small, so both $\sum_{k=1}^{d-1} c_k \Delta_k (x_n - \check{x}_n)^k$ and $\sum_{k=d+1}^{\infty} c_k \Delta_k (x_n - \check{x}_n)^k$ can be ignored in the detection of d.

The choice of $x_n - \check{x}_n$ is independent of the settings of $\boldsymbol{x}_k$, $k = 1, \ldots, n$, since we only want to know what d is at that stage.

An alternative choice for detecting d is to compute the values of Δ_k, $k = 1, 2, \ldots$, by interval evaluations until we get some Δ_{k_0} that is sufficiently different from 0. Then, we can decide $d = k_0$. The obvious disadvantage of this method is that it is too expensive for just detecting the value of d, since computation of Δ_k involves computations of all kth-order derivatives. Furthermore, even if we actually evaluate Δ_k, $k = 1, 2, \ldots$, spending much time in the process, we still can not detect the value of d if the magnitudes of Δ_k, $k = 1, \ldots, d-1, d$, are not sufficiently different either due to the problem itself or due to the range overestimation in interval computations.

6. Numerical results.

In this section, we present numerical results for the algorithm in section 4.

The testing described in this section is not meant to be exhaustive, but is meant to illustrate that the algorithms are programmable and do succeed for a variety of problems, as well as to illustrate that the technique can be practical for higher-dimensional problems. We emphasize that, unless there are programming blunders, the implementation can never give an incorrect result. (That is, the degree can never be incorrectly verified to be d.) The only ways that the algorithms can fail are by either asserting that they cannot verify that the degree is d or by running out of computer resources (typically, CPU time limits).

6.1. Test problems.

Our test problems are represented in Examples 1 through 5 below. This set includes both simple problems, such as Example 1, and slightly more realistic problems, such as Example 4. There are both lower degree problems, like Example 2, and slightly higher degree problems, like Example 5.

Consistent with the analysis and algorithms in this paper, the null-space of the Jacobi matrix at the solution has dimension 1 in all of these examples. (We discuss the higher-order rank defect case in [12].)

Examples 2, 3, and 4 are variable-dimension examples coming from finite difference discretization of a bifurcation problem. In choosing these three problems, we looked for a simple way to vary both the actual topological index at the solution and the dimension of the problem. Actual verification procedures for differential equation models should differ somewhat from what is seen here, since the discretization error should also be taken into account, to be able to assert properties about the solutions to the differential equation itself, rather than just properties about solutions of the discretization.

Although Examples 2, 3, and 4 have a special structure (tridiagonal systems), this actual structure was not used in the present algorithms; that is, dense linear algebra was used throughout. In this sense, the observed dependence of computational time on dimension is representative, although the precise form of the nonlinearity conceivably could make a difference.

Example 1.

$$\begin{aligned} f_1(x_1, x_2) &= x_1^2 - x_2, \\ f_2(x_1, x_2) &= x_1^2 + x_2. \end{aligned}$$

Example 2 (the same as Example 3 from [14], motivated from considerations in [7]). *Set $F(x) = H(x,t) = (1-t)(Ax - x^2) - tx$, where $A \in \mathbb{R}^{n\times n}$ is the matrix corresponding to central difference discretization of the boundary value problem $-u'' = 0$, $u(0) = u(1) = 0$, and $x^2 = (x_1^2, \ldots, x_n^2)^T$. t was chosen to be equal to $t_1 = \lambda_1/(1+\lambda_1)$, where λ_1 is the largest eigenvalue of A.*

In Example 2, if we change the exponent of x from 2 to 3 and 4, then we get Examples 3 and 4.

Example 3. This example is identical to Example 2, except that we set $F(x) = H(x,t) = (1-t)(Ax - x^3) - tx$.

Example 4. This example is identical to Example 2, except that we set $F(x) = H(x,t) = (1-t)(Ax - x^4) - tx$.

We tested with $n = 5$, 10, 20, 40, 80, and 160 for Examples 2, 3, and 4.

Example 5.

$$\begin{aligned} f_1(x_1, x_2, x_3) &= x_1^5 + x_2 + x_2^6 + 3x_3, \\ f_2(x_1, x_2, x_3) &= 4x_1^5 + 5x_2 - 4x_2^6 + 5x_3 - x_3^6, \\ f_3(x_1, x_2, x_3) &= 7x_1^5 + 8x_2 - 100x_2^7 + 10x_3 + 50x_3^6. \end{aligned}$$

For each test problem, we used $(0, 0, \ldots, 0)$, the exact solution to $F(x) = 0$, as the approximate solution to the problem $F(x) = 0$. For each problem except Example 4, we set the widths $\mathrm{w}(\boldsymbol{x}_k)$ and $\mathrm{w}(\boldsymbol{y}_k)$ to 10^{-2} for $1 \le k \le n-1$; then the algorithm automatically computed $\mathrm{w}(\boldsymbol{x}_n)$ and $\mathrm{w}(\boldsymbol{y}_n)$. For Example 4, we set the widths $\mathrm{w}(\boldsymbol{x}_k)$ and $\mathrm{w}(\boldsymbol{y}_k)$ to 10^{-1}, instead of 10^{-2}, for $1 \le k \le n-1$. The reason for this setting for Example 4 is that the system $F(x)$ is flatter near the singular solution, since the degree is higher. Because of the flatness, the condition number of the Jacobian matrix of the system $\tilde{F}_{\neg u_n}$ is larger. Then, because of this ill-conditioning, the interval Newton method to verify the unique solutions of $\tilde{F}_{\neg u_n}$ in step 5 of Algorithm 2 and step 5 of Algorithm 3 is less efficient: More iterations can be expected. We tried 10^{-2} first, but the interval Newton method was not able to verify the solutions when the maximum allowed number of iterations was set to be the same as for Examples 2 and 3.

6.2. Test environment. We programmed the algorithms in section 4 in the Fortran 90 environment developed and described in [10, 11]. Similarly, the test functions were programmed using the same Fortran 90 system, which generated internal symbolic representations of the functions. In the actual tests, generic routines then interpreted the internal representations to obtain both floating point and interval values.

The Sun Fortran 95 compiler, version 6.0, was used on a Sparc Ultra-1 model 140 (with a 140 megaHertz clock) with optimization level 0 (that is, with no optimization).

Table 6.1
Numerical results.

		Heuristic		Verified		
Problem	n	degree	Success	degree	CPU time	Time ratio
Example 1	2	2	Yes	2	0.13	-
Example 2	5	2	Yes	2	1.13	-
Example 2	10	2	Yes	2	5.99	5.30
Example 2	20	2	Yes	2	38.40	6.41
Example 2	40	2	Yes	2	273.61	7.13
Example 2	80	2	Yes	2	2198.14	8.03
Example 2	160	2	Yes	2	13033.22	5.93
Example 3	5	3	Yes	3	39.27	-
Example 3	10	3	Yes	3	10.31	0.26
Example 3	20	3	Yes	3	74.32	7.21
Example 3	40	3	Yes	3	481.23	6.48
Example 3	80	3	Yes	3	3805.06	7.91
Example 3	160	3	Yes	3	33944.20	8.92
Example 4	5	4	Yes	4	23.02	-
Example 4	10	4	Yes	4	154.00	6.69
Example 4	20	4	Yes	4	115.55	0.75
Example 4	40	4	Yes	4	3867.51	33.47
Example 4	80	4	Yes	4	6671.20	1.72
Example 4	160	4	-	-	-	-
Example 5	3	5	Yes	5	16.43	-

Execution times were measured with the Port library routine `ETIME`. All times are given in CPU seconds.

6.3. Test results. We present the numerical results in Table 6.1. The column labels of the table are as follows:

Problem: names of the problems identified in section 6.1,
n: number of independent variables,
Heuristic degree: the heuristic value of the degree computed by the heuristic described in section 5,
Success: whether the algorithm was successful,
Verified degree: topological degree verified by the algorithm,
CPU time: CPU time in seconds of the algorithm,
Time ratio: the ratio of two successive CPU times. This column is only meaningful for Examples 2, 3, and 4.

The algorithm, that is, existence verification, succeeded for all problems except Example 4 when $n = 160$. For that problem, we aborted the program after it ran for 36 hours.

We can see from the CPU time ratios that the algorithm is approximately of order $\mathcal{O}(n^3)$ for Examples 2 and 3. However, as we pointed out at the end of section 6.1, when the degree is higher, the system $F(x)$ is flatter near the singular solution. Because of this ill-conditioning, the interval Newton method to verify the unique solutions of $\tilde{F}_{\neg u_n}$ in step 5 of Algorithm 2 and step 5 of Algorithm 3 will be less efficient: More iterations should be expected, and more irregularity in timing could occur. We can see this from the timing results of Example 4. The experimental results are consistent with our expectations.

In certain preliminary experiments, the heuristic failed to compute the correct value of d. The subsequent verification then returned fairly rapidly with "failure to verify" (generally due to failure to verify that there were no solutions to $u_k = 0$ on $\boldsymbol{x}_{\underline{k}}$ or $\boldsymbol{x}_{\overline{k}}$ or to $v_k = 0$ on $\boldsymbol{y}_{\underline{k}}$ or $\boldsymbol{y}_{\overline{k}}$). The heuristic is the weakest part of the verification process.

Although we arranged $\check{x}$ to be exactly the solution x^*, this should not be crucial to the functioning of the algorithm, as long as the box center $\check{x}$ is a sufficiently accurate approximation to an actual root x^* to allow us to choose a box that is large in relationship to this accuracy but small enough to satisfy our other criteria.

Finally, we expect that additional tuning (selection of initial box size, maximum number of inner iterations in the interval Gauss–Seidel method, etc.) could significantly change timing and success for particular problems. The actual times could improve significantly with a more efficient interval arithmetic environment than that of [10, 11], such as direct use of Sun's interval data type in Fortran.

Acknowledgments. We wish to thank both referees for their careful reading and their valuable suggestions to make the exposition more lucid.

A POSTERIORI ERROR ESTIMATES FOR A DISCONTINUOUS GALERKIN APPROXIMATION OF SECOND-ORDER ELLIPTIC PROBLEMS*

OHANNES A. KARAKASHIAN† AND FREDERIC PASCAL‡

Abstract. Several a posteriori error estimators are introduced and analyzed for a discontinuous Galerkin formulation of a model second-order elliptic problem. In addition to residual-type estimators, we introduce some estimators that are couched in the ideas and techniques of domain decomposition. Results of numerical experiments are presented.

Key words. discontinuous Galerkin methods, a posteriori estimates

AMS subject classifications. 65N55, 65F10

DOI. 10.1137/S0036142902405217

1. Introduction.

One of the important objectives of the numerical approximation of differential equations has been to obtain approximations whose error, as measured in some norm, falls in a given range, preferably as narrow as possible. In the finite element method, and specifically for elliptic boundary value problems, such a goal became possible with the advent of a posteriori estimates pioneered by Babuška and Rheinboldt [4, 5]. Acting on an approximation u_h calculated on a given mesh, such a posteriori estimates give lower and upper bounds on the error expressed in terms of contributions from individual triangles and interfaces. This makes it possible to calculate a new mesh by means of refinement and coarsening. For a survey of the vast amount of work spurred by the above two references, we refer the reader to the book by Verfürth [18]. More recently, attention has increasingly focused on the important issue of convergence, whereby a given tolerance is achieved after a finite number of refinement steps; cf., e.g., [10, 17, 15].

Our aim is to present a posteriori error estimates in the energy norm for a discontinuous Galerkin formulation of a simple second-order elliptic problem. In contrast to standard Galerkin methods, such work is still very rare. Indeed, we are aware only of [8] as taking the a posteriori approach; also, only the estimator (3.1) is treated, and with a different proof which relies on a Helmholtz-type decomposition of the gradient of the error, thus following a technique first used in the context of a posteriori estimates for nonconforming methods. See also [16] for a posteriori estimates in the L^2 norm. Recall that in discontinuous Galerkin methods the trial and test spaces consist of piecewise totally discontinuous polynomials. That is, no continuity constraints are explicitly imposed on the trial and test functions across the element interfaces. As a consequence, weak formulations must include jump terms across interfaces, and typically penalty terms are (artificially) added to control the jump terms. Several variants of this approach exist; cf., e.g., [2, 9, 19]. For a nice survey of various discontinuous Galerkin methods, see [3].

Discontinuous Galerkin methods have several advantages over other types of finite element methods. For example, the trial and test spaces are very easy to construct; they can naturally handle inhomogeneous boundary conditions and curved boundaries; and they allow the use of highly nonuniform and unstructured meshes. In addition, the fact that the mass matrices are block diagonal is an attractive feature in the context of time-dependent problems, especially if explicit time discretizations are used.

In this paper, we will concentrate on the construction and analysis of error estimators, postponing to a subsequent work the study of other important issues such as convergence of the adaptive scheme. In section 3 we present residual-type estimators whose form and analysis follow traditional lines, with the exception of some technical issues caused by the discontinuous nature of the finite element spaces.

In section 4 we present estimators requiring the solution of local problems. In a departure from more traditional techniques, ours flow from the ideas and techniques of domain decomposition, and specifically those expounded in [11]. In a nutshell, we view the computed solution u_h corresponding to a mesh $\mathcal{T}_h$ as a "coarse-mesh" approximation to a more accurate approximation u_h' to u, with an eye towards using $u_h' - u_h$ to estimate $u - u_h$. Obviously computing u_h' would prove too costly; instead, a good approximation thereof is obtained by adding to u_h the solutions of local problems, the supports of these local contributions playing the role of the subdomains. Indeed, our technique offers the tightest coupling yet known between a posteriori error estimation and domain decomposition, to the extent that the matrices involved in the solution of the local problems consist of the diagonal blocks of the global stiffness matrix that correspond to the individual triangles. A somewhat similar idea is found in [20] in the context of mortar finite elements. There are, however, substantial differences between the two approaches.

In section 5, we present results of numerical experiments focusing on the behavior of the effectivity indices as well as other characteristics of the various estimators.

2. Preliminaries. Let $\Omega \subset \mathbf{R}^d,\ d = 1, 2, 3$, be a bounded domain. We consider the following model problem:

$$-\Delta u = f \quad \text{in } \Omega, \tag{2.1}$$

$$u = 0 \quad \text{on } \partial\Omega. \tag{2.2}$$

The treatment of second-order elliptic problems with more general coefficients and boundary conditions will be contained in a parallel work [13].

Throughout this paper, the standard space, norm, and inner product notation are adopted. Their definitions can be found in [1]. Also, c is used to denote a generic positive mesh-independent constant.

The discontinuous Galerkin method considered in this paper for discretizing problem (2.1)–(2.2) is the one proposed in [6] and [7, 12], where the biharmonic and Stokes problems, respectively, were considered.

Let $\mathcal{T}_h = \{K_i : \ i = 1, 2, \dots, m_h\}$ be a family of star-like partitions (triangulations) of the domain Ω parametrized by $0 < h \le 1$. We assume the following:

(i) The elements of $\mathcal{T}_h$ satisfy the minimal angle condition. Specifically, there is a constant $\theta_0 > 0$ such that $h_K/\rho_K \ge \theta_0\ \forall K \in \mathcal{T}_h$, where h_K and ρ_K denote, respectively, the diameters of the circumscribed and inscribed balls to K.

(ii) $\mathcal{T}_h$ is locally quasi-uniform; that is, if two elements K_j and K_ℓ are adjacent in the sense that $\mu_{d-1}(\partial K_j \cap \partial K_\ell) > 0$, then $\mathrm{diam(K_j)} \approx \mathrm{diam(K_\ell)}$.

Here μ_{d-1} denotes the $(d-1)$-dimensional Lebesgue measure. On $\mathcal{T}_h$ we define the "energy space" $E_h = \Pi_{K\in\mathcal{T}_h} H^2(K) \subset L^2(\Omega)$. For $r \geq 2$, we define the finite element space $V_h^r \subset E_h$ by $V_h^r = \Pi_{K\in\mathcal{T}_h} P_{r-1}(K)$, where $P_{r-1}(K)$ denotes the space of polynomials of total degree $r-1$.

Given the discontinuous nature of the piecewise polynomial functions, we define $\mathcal{E}^I$ and $\mathcal{E}^B$ to be the set of all interior and boundary edges (faces in the case $d=3$), respectively:

$$\begin{aligned}\mathcal{E}^I &= \{e = \partial K_j \cap \partial K_\ell, \quad \mu_{d-1}(\partial K_j \cap \partial K_\ell) > 0\},\\ \mathcal{E}^B &= \{e = \partial K \cap \partial\Omega, \quad \mu_{d-1}(\partial K \cap \partial\Omega) > 0\}.\end{aligned}$$

We also set $\mathcal{E} = \mathcal{E}^I \cup \mathcal{E}^B$. We note that elements of $\mathcal{E}^B$ may be curved. Also, if $e \in \mathcal{E}^I$, then $e = \partial K^+ \cap \partial K^-$ for $K^+, K^- \in \mathcal{T}_h$. We may designate as K^+ the triangle with the higher of the two indices.

Note that elements of the energy space E_h are not functions in the proper sense, and care must be applied in defining their values on $\mathcal{E}$. This is done in the sense of trace.

In order to construct a weak formulation for the problem (2.1)–(2.2), we introduce the bilinear form $a_h^\gamma : E_h \times E_h \to \mathbf{R}$:

$$\begin{aligned} a_h^\gamma(u,v) = \sum_{K\in\mathcal{T}_h} (\nabla u, \nabla v)_K - \sum_{e\in\mathcal{E}^I} \Big[\langle\{\partial_n u\}, [v]\rangle_e + \langle\{\partial_n v\}, [u]\rangle_e - \gamma h_e^{-1} \langle [u], [v]\rangle_e \Big] \\ - \sum_{e\in\mathcal{E}^B} \Big[\langle \partial_n u, v\rangle_e + \langle \partial_n v, u\rangle_e - \gamma h_e^{-1} \langle u, v\rangle_e \Big], \end{aligned} \tag{2.3}$$

where $h_e =$ diam(e) and

$$\begin{aligned} (u,v)_D &= \int_D u\cdot v\, dx,\\ \langle u,v\rangle_\Gamma &= \int_\Gamma uv\, ds, \qquad \text{edge/surface integrals}, \qquad |v|_\Gamma = \langle v,v\rangle_\Gamma^{1/2},\\ [v]\,|_e &= v^+|_e - v^-|_e, \quad v^+ = v|_{K^+}, \quad v^- = v|_{K^-}, \quad e\in\mathcal{E}^I,\\ \{\partial_n v\}\big|_e &= \frac{\partial v^+}{\partial n^+}\bigg|_e, \quad \big[\partial_n v\big]\big|_e = \frac{\partial v^+}{\partial n^+}\bigg|_e - \frac{\partial v^-}{\partial n^+}\bigg|_e, \quad e\in\mathcal{E}^I,\\ \partial_n v\big|_e &= \frac{\partial v^+}{\partial n^+}\bigg|_e, \quad e\in\mathcal{E}^B. \end{aligned}$$

Some further comments on the nature of the form a_h^γ are in order:

(a) The third and sixth terms have been added to symmetrize a_h^γ. Note that the former is zero for smooth u, while the latter is a known quantity since $u\,\big|_{\partial\Omega}$ is given. The a priori estimates remain valid if these terms are removed.

(b) γ is a positive (penalty) parameter that must be chosen appropriately in order for a_h^γ to be coercive.

Remark 2.1. There is an alternative formulation due to Arnold [2], which is obtained by setting $\{\partial_n v\}\big|_e = \frac{1}{2}(\frac{\partial v^+}{\partial n^+} + \frac{\partial v^-}{\partial n^+})|_e$. The results presented in this paper should be valid for Arnold's formulation as well.

The form $a_h^\gamma(\cdot,\cdot)$ is consistent with the Laplacian in the sense that if $u\in H^2(\Omega)$, then

$$a_h^\gamma(u,v) = -(\Delta u, v) - \sum_{e\in\mathcal{E}^B} \big\langle u, \partial_n v - \gamma h_e^{-1} v\big\rangle_e \quad \forall v\in E_h. \tag{2.4}$$

Thus, we define the discontinuous Galerkin approximation of u to be the element u_h^γ in V_h^r that satisfies

$$a_h^\gamma(u_h^\gamma, v) = F(v) := (f, v) \quad \forall v \in V_h^r. \tag{2.5}$$

The existence of a unique u_h^γ follows from Lemma 2.1.

We define the "energy" norm on E_h by

$$\|v\|_{1,h} = \left(\sum_{K\in\mathcal{T}_h} ||\nabla v||_K^2 + \sum_{e\in\mathcal{E}^I} \left[h_e \left|\{\partial_n v\}\right|_e^2 + h_e^{-1}|[v]|_e^2 \right] \right.$$
$$\left. + \sum_{e\in\mathcal{E}^B} \left[h_e \left|\partial_n v\right|_e^2 + h_e^{-1}|v|_e^2 \right] \right)^{1/2}.$$

Concerning the continuity and coercivity of the form a_h^γ, we have the following result (cf. [7]).

Lemma 2.1. (i)

$$|a_h^\gamma(u, v)| \le (1+\gamma)\|u\|_{1,h}\|v\|_{1,h} \qquad \forall u, v \in E_h. \tag{2.6}$$

(ii) *There exist positive constants γ_0 and c_a such that for $\gamma \ge \gamma_0$*

$$a_h^\gamma(v, v) \ge c_a \|v\|_{1,h}^2 \qquad \forall v \in V_h^r. \tag{2.7}$$

Here γ_0 depends only on r and the (aspect) ratios h_K/ρ_K of the elements. In view of condition (i) on the mesh, γ_0 can grow only as a function of r. Numerical experiments reveal that $\gamma_0 \approx 5$ for $r = 2$ and $\gamma_0 \approx 15$ for $r = 3$.

The proofs of the above rely on the following *trace* and *inverse* inequalities. Let D be a regular and starlike domain, and let $\mu =$ diam (D). Then

$$|v|_{\partial D}^2 \le c_{tr}(\mu^{-1}\|v\|_D^2 + \mu\|\nabla v\|_D^2) \quad \forall v \in H^1(D). \tag{2.8}$$

Let $|\cdot|_{j,D}$ denote the seminorm of $H^j(D)$. Then

$$|v|_{j,D} \le c_{inv}\mu^{i-j}|v|_{i,D} \quad \forall v \in P_r,\ 0 \le i \le j \le 2, \tag{2.9}$$

the constant c_{inv} in (2.9) depending only on r.

We shall assume that the following approximation property holds: Let $0 \le m \le r$. Then there exists a constant $c > 0$, independent of $\mathcal{T}_h$, such that for any $u \in H^m(\Omega)$ and $K \in \mathcal{T}_h$ there exists $\chi \in P_{r-1}(K)$ satisfying

$$|u - \chi|_{j,K} \le c h_K^{m-j}|u|_{m,K}, \quad 0 \le j \le m. \tag{2.10}$$

It can be shown that the following error estimates hold (cf. [7]).

Theorem 2.1. *Let u and u_h^γ be the solutions of* (2.1)–(2.2) *and* (2.5), *respectively, and suppose that $u \in H^r(\Omega) \cap H_0^1(\Omega)$ with $r \ge 2$. Then there exists a positive constant c, which is independent of h and u, such that*

$$\|u - u_h^\gamma\|_{1,h} \le c \left(\sum_{K\in\mathcal{T}_h} h_K^{2(r-1)}|u|_{r,K}^2 \right)^{1/2}, \tag{2.11}$$

$$\|u - u_h^\gamma\| \le c h^r |u|_{r,\Omega}. \tag{2.12}$$

2.1. An approximation result. For our first residual-type a posteriori estimate we will need to see how well an element of V_h^r can be approximated by elements of $\overset{0}{V}{}_h^r = V_h^r \cap H_0^1(\Omega)$. The result, Theorem 2.2 below, can also be found in [14]. The proof we give here is constructive and differs entirely from the one given in [14]. We also consider separately in Theorem 2.3 the case when the mesh is nonconforming, i.e., is characterized by the presence of *hanging nodes*.

LEMMA 2.2. *Given N real numbers $\{\alpha_1, \ldots, \alpha_N\}$ let $\beta = \frac{1}{N}\sum_{j=1}^N \alpha_j$. Then,*

$$\sum_{j=1}^N |\alpha_j - \beta|^2 \le C \sum_{j=1}^{N-1} |\alpha_{j+1} - \alpha_j|^2, \tag{2.13}$$

where C depends only on N.

Proof. For any j, the Cauchy–Schwarz inequality gives

$$|\alpha_j - \beta|^2 = \frac{1}{N^2}\left|\sum_{i=1}^N (\alpha_j - \alpha_i)\right|^2 \le \frac{N-1}{N^2}\sum_{i=1}^N |\alpha_j - \alpha_i|^2.$$

Summing over j, we obtain $\sum_{j=1}^N |\alpha_j - \beta|^2 \le \frac{2(N-1)}{N}\sum_{j>i} |\alpha_j - \alpha_i|^2$. The required result now follows, upon writing $\alpha_j - \alpha_i = \sum_{k=i}^{j-1}(\alpha_{k+1} - \alpha_k)$ and using the arithmetic-geometric mean inequality. □

THEOREM 2.2. *Let $\mathcal{T}_h$ be a conforming mesh consisting of triangles when $d = 2$, and tetrahedra when $d = 3$. Then for any $v_h \in V_h^r$ there exists $\chi \in \overset{0}{V}{}_h^r$ satisfying*

$$\sum_{K \in \mathcal{T}_h} \|\nabla(v_h - \chi)\|_K^2 \le C \left(\sum_{e \in \mathcal{E}^I} h_e^{-1} |[v_h]|_e^2 + \sum_{e \in \mathcal{E}^B} h_e^{-1} |v_h|_e^2 \right) \tag{2.14}$$

for some constant C independent of h and v_h but which may depend on the constant θ_0 in assumption (i) *on the mesh.*

Proof. The main argument is quite natural. Given $v_h \in V_h^r$, we construct a function $\chi \in \overset{0}{V}{}_h^r$ as follows: At every node of the mesh $\mathcal{T}_h$ corresponding to a Lagrangian-type degree of freedom for $\overset{0}{V}{}_h^r$, the value of χ is set to the average of the values of v_h at that node.

For each $K \in \mathcal{T}_h$ let $\mathcal{N}_K = \{x_K^{(j)},\ j = 1, \ldots, m\}$ be the Lagrange nodes (points) of K and $\{\phi_K^{(j)},\ j = 1, \ldots, m\}$ the corresponding (local) basis functions satisfying $\phi_K^{(j)}(x_K^{(i)}) = \delta_{ij}$. Set $\mathcal{N} = \cup_{K \in \mathcal{T}_h} \mathcal{N}_K$. We view $\mathcal{N}$ as the union of three disjoint classes:

$$\begin{aligned}
\mathcal{N}_i &= \{\nu \in \mathcal{N} : \nu \text{ is interior to some element}\},\\
\mathcal{N}_b &= \{\nu \in \mathcal{N} : \nu \in e \in \mathcal{E}^B\},\\
\mathcal{N}_v &= \mathcal{N} \setminus (\mathcal{N}_i \cup \mathcal{N}_b).
\end{aligned}$$

For each $\nu \in \mathcal{N}$, let $\omega_\nu = \{K \in \mathcal{T}_h |\ \nu \in K\}$ and denote its cardinality by $|\omega_\nu|$. If $\nu \in \mathcal{N}_i$, then $|\omega_\nu| = 1$. On the other hand if $\nu \in \mathcal{N}_b \cup \mathcal{N}_v$, then $|\omega_\nu|$ is bounded by a constant depending only on the constant θ_0.

Now let $\overset{0}{\mathcal{N}}$ be the collection of distinct Lagrange nodes ν needed to construct a function $\chi \in \overset{0}{V}{}_h^r$. To each node $\nu \in \overset{0}{\mathcal{N}}$ we associate the basis function $\phi^{(\nu)}$ given by

$$\operatorname{supp} \phi^{(\nu)} = \bigcup_{K \in \omega_\nu} K, \quad \phi^{(\nu)}\big|_K = \phi_K^{(j)}, \quad x_K^{(j)} = \nu.$$

We make it a point to include the boundary nodes $\mathcal{N}_b$ in $\overset{0}{\mathcal{N}}$ even though this is not necessary in view of the vanishing on $\partial\Omega$ of the functions in $\overset{0}{V}{}_h^r$. We then can state the following characterization: $\overset{0}{\mathcal{N}} \subseteq \mathcal{N}$ and the mesh $\mathcal{T}_h$ is conforming if and only if $\overset{0}{\mathcal{N}} = \mathcal{N}$.

Now, given $v_h \in V_h^r$, written $v_h = \sum_{K \in \mathcal{T}_h} \sum_{j=1}^m \alpha_K^{(j)} \phi_K^{(j)}$, we define the function $\chi \in \overset{0}{V}{}_h^r$ by (note that $\overset{0}{\mathcal{N}} = \mathcal{N}$ since the mesh is conforming)

$$\chi = \sum_{\nu \in \overset{0}{\mathcal{N}}} \beta^{(\nu)} \phi^{(\nu)}, \text{ where } \beta^{(\nu)} = \begin{cases} 0 & \text{if } \nu \in \mathcal{N}_b, \\ \frac{1}{|\omega_\nu|} \sum_{x_K^{(j)} = \nu} \alpha_K^{(j)}, & \text{if } \nu \in \overset{0}{\mathcal{N}} \setminus \mathcal{N}_b. \end{cases} \tag{2.15}$$

Now set $\beta_K^{(j)} = \beta^{(\nu)}$ whenever $x_K^{(j)} = \nu$.

A simple scaling argument shows that $\|\nabla \phi_K^{(j)}\|_K^2 \le c h_K^{d-2}$. Hence

$$\begin{aligned} \sum_{K \in \mathcal{T}_h} \|\nabla(v_h - \chi)\|_K^2 &\le c\, m \sum_{K \in \mathcal{T}_h} h_K^{d-2} \sum_{j=1}^m \left|\alpha_K^{(j)} - \beta_K^{(j)}\right|^2 \\ &\le c \sum_{\nu \in \mathcal{N}} h_\nu^{d-2} \sum_{x_K^{(j)} = \nu} \left|\alpha_K^{(j)} - \beta^{(\nu)}\right|^2 \qquad \left(h_\nu = \max_{K \in \omega_\nu} h_K\right) \\ &= c \sum_{\nu \in \mathcal{N}_v} h_\nu^{d-2} \sum_{x_K^{(j)} = \nu} \left|\alpha_K^{(j)} - \beta^{(\nu)}\right|^2 + c \sum_{\nu \in \mathcal{N}_b} h_\nu^{d-2} \sum_{x_K^{(j)} = \nu} |\alpha_K^{(j)}|^2. \end{aligned} \tag{2.16}$$

Note that there are no contributions from $\mathcal{N}_i$. We now temporarily focus on the case $d = 2$. For $\nu \in \mathcal{N}_v$, we enumerate the elements of ω_ν as $\{K_1, \ldots, K_{|\omega_\nu|}\}$ so that any consecutive pair K_i, K_{i+1} in that list share an edge. Then from Lemma 2.2, with some constant c depending only on $|\omega_\nu|$ and thus on θ_0, we have

$$\sum_{x_K^{(j)} = \nu} \left|\alpha_K^{(j)} - \beta^{(\nu)}\right|^2 \le c \sum_{i=1}^{|\omega_\nu|-1} \left|\alpha_{K_i}^{(j_i)} - \alpha_{K_{i+1}}^{(j_{i+1})}\right|^2. \tag{2.17}$$

For $d = 3$, it may not be possible to enumerate ω_ν in such a way. However, by allowing some repetitions of its elements, we can write $\omega_\nu = \{K_{\ell_1}, \ldots, K_{\ell_{n(\nu)}}\}$ for some $n(\nu)$, so that in this case also K_{ℓ_i} and $K_{\ell_{i+1}}$ share a face or an edge. Having done so, by applying Lemma 2.2 to the list obtained by removing all repetitions of elements of ω_ν and then using the arithmetic-geometric mean inequality, we obtain

$$\sum_{x_K^{(j)} = \nu} \left|\alpha_K^{(j)} - \beta^{(\nu)}\right|^2 \le c \sum_{i=1}^{n(\nu)-1} \left|\alpha_{K_{\ell_i}}^{(j_{\ell_i})} - \alpha_{K_{\ell_{i+1}}}^{(j_{\ell_{i+1}})}\right|^2. \tag{2.18}$$

Using (2.17) if $d = 2$, or (2.18) if $d = 3$, from (2.16) we have

$$\begin{aligned}\sum_{K \in \mathcal{T}_h} \|\nabla(v_h - \chi)\|_K^2 \leq c \sum_{e \in \mathcal{E}^I} \sum_{\nu \in e} h_\nu^{d-2} \left| \alpha_{K^+}^{(j_\nu^+)} - \alpha_{K^-}^{(j_\nu^-)} \right|^2 \\ + c \sum_{\nu \in \mathcal{N}_b} \sum_{x_K^{(j)} = \nu} h_\nu^{d-2} \left| \alpha_K^{(j)} \right|^2,\end{aligned} \tag{2.19}$$

with $x_{K^+}^{(j_\nu^+)} = x_{K^-}^{(j_\nu^-)} = \nu$. Note that $\alpha_{K^+}^{(j_\nu^+)} - \alpha_{K^-}^{(j_\nu^-)}$ is the jump in the values of v_h at ν across e. Also, since the mesh $\mathcal{T}_h$ is locally quasi-uniform, it follows that

$$\begin{aligned}\sum_{\nu \in e} h_\nu^{d-2} \left| \alpha_{K^+}^{(j_\nu^+)} - \alpha_{K^-}^{(j_\nu^-)} \right|^2 &\leq c h_e^{d-2} |[v_h]|_{L^\infty(e)}^2 \\ &\leq c h_e^{-1} |[v_h]|_e^2,\end{aligned} \tag{2.20}$$

where the constant c depends on the number of nodes in e.

Similarly, it can be shown that for $\nu \in e \in \mathcal{E}^B$,

$$\sum_{x_K^{(j)} = \nu} h_\nu^{d-2} \left| \alpha_K^{(j)} \right|^2 \leq c h_e^{-1} |v_h|_e^2. \tag{2.21}$$

The required result now follows from (2.19)–(2.21). □

We now consider the case when the mesh is nonconforming. We make the following observations, using the notation established in Theorem 2.2:

(i) The hanging nodes are precisely the members of $\mathcal{N} \setminus \overset{0}{\mathcal{N}}$.

(ii) A hanging node cannot be a member of $\mathcal{N}_b$ or $\mathcal{N}_i$.

(iii) For every hanging node ν there is a nonempty proper subset $\tilde{\omega}_\nu$ of ω_ν such that if $\tilde{K} \in \tilde{\omega}_\nu$, then ν is not a local node of $\tilde{K}$. For $d = 2$, $|\tilde{\omega}_\nu| = 1$.

We shall also require that $\mathcal{T}_h$ be obtained from a conforming mesh $\mathcal{T}_h^0$ via a finite number of refinement/coarsening steps. In particular, we assume that there is a mapping $Level : \mathcal{T}_h \to N$, the set of nonnegative integers, such that

(iv) $Level(K) = 0 \ \forall K \in \mathcal{T}_h^0$ ($\mathcal{T}_h^0 \subseteq \mathcal{T}_h$).

(v) If $K \in \omega_\nu \setminus \tilde{\omega}_\nu$ and $\tilde{K} \in \tilde{\omega}_\nu$ are as in (iii) above, then $Level(K) > Level(\tilde{K})$.

An example of the mapping *Level* can be constructed for $d = 2$ as follows. Suppose that we *refine* a given triangle (the *father*) by cutting it in the usual way (see, e.g., Figure 3.2) into four triangles of equal area (the *sons*). On the other hand, we *coarsen* the mesh by merging four sons of the same father. Then we define $Level(K)$, $K \in \mathcal{T}_h$, by $|K| = |K^0|(\frac{1}{4})^{Level(K)}$, where K^0 is the triangle in $\mathcal{T}_h^0$ that contains K and where $|\cdot|$ denotes area.

We have the following result.

Theorem 2.3. *Let $\mathcal{T}_h$ be a nonconforming mesh consisting of triangles when $d = 2$ and tetrahedra when $d = 3$. We shall also assume that $\mathcal{T}_h$ can be described in terms of the mapping Level as discussed above. Then* (2.14) *holds, but the constant C may also depend on $L_{max} = \max\{Level(K), K \in \mathcal{T}_h\}$.*

Proof. Noting that an element of $\overset{0}{V_h^r}$ is still defined by its values at the nodes in $\overset{0}{\mathcal{N}}$, we define the approximant $\chi \in \overset{0}{V_h^r}$ of v_h via (2.15). This uniquely determines the values of χ at the hanging nodes, so we let $\beta^{(\nu)} = \chi(\nu)$ for $\nu \in \mathcal{N} \setminus \overset{0}{\mathcal{N}}$. In a similar fashion, we introduce the quantities $\tilde{\alpha}_{\tilde{K}}^{(\nu)} = (v_h\big|_{\tilde{K}})(\nu)$, $\tilde{K} \in \tilde{\omega}_\nu$, $\nu \in \mathcal{N} \setminus \overset{0}{\mathcal{N}}$.

Proceeding as in (2.16), we obtain

$$\begin{aligned}\sum_{K\in\mathcal{T}_h}\|\nabla(v_h-\chi)\|_K^2 &\le c\sum_{\ell=0}^{L_{max}}\sum_{K\in\mathcal{T}_h^\ell} h_K^{d-2}\sum_{j=1}^{m}\big|\alpha_K^{(j)}-\beta_K^{(j)}\big|^2\\ &\le c\sum_{\nu\in\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{x_K^{(j)}=\nu}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2 + c\sum_{\nu\in\mathcal{N}\setminus\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{\substack{x_K^{(j)}=\nu\\ K\in\omega_\nu\setminus\tilde{\omega}_\nu}}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2,\end{aligned}\tag{2.22}$$

where $\mathcal{T}_h^\ell=\{K\in\mathcal{T}_h \mid Level(K)=\ell\}$. The first sum on the right-hand side of (2.22) can be handled as in the conforming case using steps (2.17)–(2.21). As for the second sum, for a given $x_K^{(j)}=\nu,\ K\in\omega_\nu\setminus\tilde{\omega}_\nu$, we choose $\tilde{K}\in\tilde{\omega}_\nu$ such that K and $\tilde{K}$ share an edge or a face. A crucial observation is that $Level(\tilde{K})<Level(K)$. Then

$$\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2\le 2\big|\alpha_K^{(j)}-\tilde{\alpha}_{\tilde{K}}^{(\nu)}\big|^2+2\big|\tilde{\alpha}_{\tilde{K}}^{(\nu)}-\beta^{(\nu)}\big|^2.$$

Now $|\alpha_K^{(j)}-\tilde{\alpha}_{\tilde{K}}^{(\nu)}|$ is the jump in the values of v_h at the node ν which belongs to the interface e between K and $\tilde{K}$, and thus $h_\nu^{d-2}|\alpha_K^{(j)}-\tilde{\alpha}_{\tilde{K}}^{(\nu)}|^2$ can be bounded by $ch_e^{-1}|[v_h]|_e^2$ as was done in (2.20). On the other hand,

$$\tilde{\alpha}_{\tilde{K}}^{(\nu)}-\beta^{(\nu)}=\big(v_h\big|_{\tilde{K}}\big)(\nu)-\big(\chi\big|_{\tilde{K}}\big)(\nu)=\sum_{j=1}^{m}(\alpha_{\tilde{K}}^{(j)}-\beta_{\tilde{K}}^{(j)})\phi_{\tilde{K}}^{(j)}.$$

Thus,

$$\big|\tilde{\alpha}_{\tilde{K}}^{(\nu)}-\beta^{(\nu)}\big|^2\le\sum_{j=1}^{m}\big|\alpha_{\tilde{K}}^{(j)}-\beta_{\tilde{K}}^{(j)}\big|^2\cdot\sum_{j=1}^{m}\big|\phi_{\tilde{K}}^{(j)}(\nu)\big|^2\le c\sum_{j=1}^{m}\big|\alpha_{\tilde{K}}^{(j)}-\beta_{\tilde{K}}^{(j)}\big|^2$$

for some constant c independent of h. Gathering these results, we have

$$\begin{aligned}\sum_{\nu\in\mathcal{N}\setminus\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{\substack{x_K^{(j)}=\nu\\ K\in\omega_\nu\setminus\tilde{\omega}_\nu}}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2 &= \sum_{\nu\in\mathcal{N}\setminus\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{\ell=0}^{L_{max}}\sum_{K\in\mathcal{T}_h^\ell}\sum_{\substack{x_K^{(j)}=\nu\\ K\in\omega_\nu\setminus\tilde{\omega}_\nu}}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2\\ &\le c\sum_{e\in\mathcal{E}^I} h_e^{-1}|[v_h]|_e^2+c\sum_{\ell=0}^{L}\sum_{K\in\mathcal{T}_h^\ell} h_K^{d-2}\sum_{j=1}^{m}\big|\alpha_K^{(j)}-\beta_K^{(j)}\big|^2\\ &\le c\sum_{e\in\mathcal{E}^I} h_e^{-1}|[v_h]|_e^2+c\sum_{\nu\in\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{x_K^{(j)}=\nu}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2\\ &\quad+c\sum_{\nu\in\mathcal{N}\setminus\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{\ell=0}^{L}\sum_{K\in\mathcal{T}_h^\ell}\sum_{\substack{x_K^{(j)}=\nu\\ K\in\omega_\nu\setminus\tilde{\omega}_\nu}}\big|\alpha_K^{(j)}-\beta^{(\nu)}\big|^2\end{aligned}\tag{2.23}$$

for some L that satisfies $0\le L<L_{max}$. Repeating this argument a finite number of times, the last sum in (2.23) (over the hanging nodes) will be eventually replaced by $c\sum_{e\in\mathcal{E}^I} h_e^{-1}|[v_h]|_e^2+c\sum_{\nu\in\overset{0}{\mathcal{N}}} h_\nu^{d-2}\sum_{x_K^{(j)}=\nu}|\alpha_K^{(j)}-\beta^{(\nu)}|^2$. As we mentioned earlier, the latter term can be bounded by $c\left(\sum_{e\in\mathcal{E}^I} h_e^{-1}|[v_h]|_e^2+\sum_{e\in\mathcal{E}^B} h_e^{-1}|v_h|_e^2\right)$ just as in the conforming case. This concludes the proof. □

3. A posteriori estimates. This section is devoted to residual-type a posteriori estimates. The estimators as well as the exposition follow the lines found in Verfürth [18], with the exception of the technical details stemming from the discontinuous nature of V_h^r. We also note that our estimators (3.11) and (3.12) are entirely local.

Again for the sake of simplifying the exposition, and in this section only, we shall assume that f is a piecewise polynomial function on the mesh $\mathcal{T}_h$. Given that we have decided not to worry about quadrature errors, this is not an unreasonable assumption, since any given quadrature rule used to evaluate $(f|_K, v)$ cannot distinguish between $f|_K$ and the Lagrange interpolant of f at the quadrature points in K.

THEOREM 3.1. *Let $e = u - u_h^\gamma$. Then*

$$\sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 \le c\Big\{ \sum_{K\in\mathcal{T}_h} h_K^2 \|f + \Delta u_h^\gamma\|_K^2 + \sum_{e\in\mathcal{E}^I} h_e \big|\big[\partial_n u_h^\gamma\big]\big|_e^2 + \gamma^2 \sum_{e\in\mathcal{E}^I} h_e^{-1} |[u_h^\gamma]|_e^2 + \gamma^2 \sum_{e\in\mathcal{E}^B} h_e^{-1} |u_h^\gamma|_e^2 \Big\}. \tag{3.1}$$

Proof. From (2.4) and (2.5) there follows the orthogonality relation $a_h^\gamma(e, v_h) = 0 \; \forall v_h \in V_h^r$. Now for $v \in E_h$ and $v_h \in V_h^r$, let $\eta = v - v_h$. We have

$$\begin{aligned} a_h^\gamma(e,v) &= a_h^\gamma(e,\eta) = (f,\eta) - a_h^\gamma(u_h^\gamma,\eta) \\ &= (f,\eta) - \Bigg\{ \sum_{K\in\mathcal{T}_h} (\nabla u_h^\gamma, \nabla\eta)_K \\ &\qquad - \sum_{e\in\mathcal{E}^I} \Big[\langle \{\partial_n u_h^\gamma\}, [\eta] \rangle_e + \langle \{\partial_n \eta\}, [u_h^\gamma] \rangle_e - \gamma h_e^{-1} \langle [u_h^\gamma], [\eta] \rangle_e \Big] \\ &\qquad - \sum_{e\in\mathcal{E}^B} \Big[\langle \partial_n u_h^\gamma, \eta \rangle_e + \langle \partial_n \eta, u_h^\gamma \rangle_e - \gamma h_e^{-1} \langle u_h^\gamma, \eta \rangle_e \Big] \Bigg\}. \end{aligned} \tag{3.2}$$

Now, integrating by parts, we see that

$$\begin{aligned} \sum_{K\in\mathcal{T}_h} (\nabla u_h^\gamma, \nabla\eta)_K &= \sum_{K\in\mathcal{T}_h} (-\Delta u_h^\gamma, \eta)_K + \sum_{K\in\mathcal{T}_h} \langle \partial_n u_h^\gamma, \eta \rangle_{\partial K} \\ &= \sum_{K\in\mathcal{T}_h} (-\Delta u_h^\gamma, \eta)_K + \sum_{e\in\mathcal{E}^I} \Big[\langle \{\partial_n u_h^\gamma\}, [\eta] \rangle_e + \langle [\partial_n u_h^\gamma], \eta^* \rangle_e \Big] \\ &\qquad + \sum_{e\in\mathcal{E}^B} \langle \partial_n u_h^\gamma, \eta \rangle_e, \end{aligned} \tag{3.3}$$

where $\eta^* = \eta^-$ for Baker's method and $\eta^* = \frac{1}{2}(\eta^+ + \eta^-)$ for Arnold's method. Now, using (3.3) in (3.2), we obtain

$$\begin{aligned} a_h^\gamma(e,v) = &\sum_{K\in\mathcal{T}_h} (f + \Delta u_h^\gamma, \eta)_K \\ &+ \sum_{e\in\mathcal{E}^I} \Big[\langle \{\partial_n \eta\}, [u_h^\gamma] \rangle_e - \big\langle \big[\partial_n u_h^\gamma\big], \eta^* \big\rangle_e - \gamma h_e^{-1} \langle [u_h^\gamma], [\eta] \rangle_e \Big] \\ &+ \sum_{e\in\mathcal{E}^B} \Big[\langle \partial_n \eta, u_h^\gamma \rangle_e - \gamma h_e^{-1} \langle u_h^\gamma, \eta \rangle_e \Big]. \end{aligned} \tag{3.4}$$

From the definition of $a_h^\gamma(e,v)$ and using (3.4), we get

$$\begin{aligned}
\sum_{K\in\mathcal{T}_h}(\nabla e,\nabla v)_K+\gamma\sum_{e\in\mathcal{E}^I}h_e^{-1}\langle[e],[v]\rangle_e+\gamma\sum_{e\in\mathcal{E}^B}h_e^{-1}\langle e,v\rangle_e &= a_h^\gamma(e,v)\\
&\quad+\sum_{e\in\mathcal{E}^I}\Big[\langle\{\partial_n e\},[v]\rangle_e+\langle\{\partial_n v\},[e]\rangle_e\Big]\\
&\quad+\sum_{e\in\mathcal{E}^B}\Big[\langle\partial_n e,v\rangle_e+\langle\partial_n v,e\rangle_e\Big]\\
&= \sum_{K\in\mathcal{T}_h}(f+\Delta u_h^\gamma,\eta)_K+\sum_{e\in\mathcal{E}^I}\Big[\langle\{\partial_n\eta\},[u_h^\gamma]\rangle_e-\big\langle[\partial_n u_h^\gamma],\eta^*\big\rangle_e\\
&\quad+\langle\{\partial_n e\},[v]\rangle_e+\langle\{\partial_n v\},[e]\rangle_e-\gamma h_e^{-1}\langle[u_h^\gamma],[\eta]\rangle_e\Big]\\
&\quad+\sum_{e\in\mathcal{E}^B}\Big[\langle\partial_n\eta,u_h^\gamma\rangle_e+\langle\partial_n e,v\rangle_e+\langle\partial_n v,e\rangle_e-\gamma h_e^{-1}\langle u_h^\gamma,\eta\rangle_e\Big].
\end{aligned}\tag{3.5}$$

First note that

$$\langle\{\partial_n\eta\},[u_h^\gamma]\rangle_e+\langle\{\partial_n v\},[e]\rangle_e=-\langle\{\partial_n v_h\},[u_h^\gamma]\rangle_e,\quad e\in\mathcal{E}^I,$$

and

$$\langle\partial_n\eta,u_h^\gamma\rangle_e+\langle\partial_n v,e\rangle_e=-\langle\partial_n v_h,u_h^\gamma\rangle_e,\quad e\in\mathcal{E}^B.$$

We will choose v_h to be piecewise constant on $\mathcal{T}_h$. Thus these four terms are zero. Hence (3.5) reduces to

$$\begin{aligned}
\sum_{K\in\mathcal{T}_h}(\nabla e,\nabla v)_K+\gamma\sum_{e\in\mathcal{E}^I}h_e^{-1}\langle[e],[v]\rangle_e+\gamma\sum_{e\in\mathcal{E}^B}h_e^{-1}\langle e,v\rangle_e &= \sum_{K\in\mathcal{T}_h}(f+\Delta u_h^\gamma,\eta)_K\\
&\quad+\sum_{e\in\mathcal{E}^I}\Big[-\big\langle[\partial_n u_h^\gamma],\eta^*\big\rangle_e+\langle\{\partial_n e\},[v]\rangle_e-\gamma h_e^{-1}\langle[u_h^\gamma],[\eta]\rangle_e\Big]\\
&\quad+\sum_{e\in\mathcal{E}^B}\Big[\langle\partial_n e,v\rangle_e-\gamma h_e^{-1}\langle u_h^\gamma,\eta\rangle_e\Big].
\end{aligned}\tag{3.6}$$

At this point, we set $v=e$ and observe that

$$\begin{aligned}
\sum_{e\in\mathcal{E}^I}\langle\{\partial_n e\},[e]\rangle_e+\sum_{e\in\mathcal{E}^B}\langle\partial_n e,e\rangle_e &= -\sum_{e\in\mathcal{E}^I}\langle\{\partial_n e\},[u_h^\gamma]\rangle_e-\sum_{e\in\mathcal{E}^B}\langle\partial_n e,u_h^\gamma\rangle_e\\
&= -\sum_{e\in\mathcal{E}^I}\langle\{\partial_n e\},[u_h^\gamma-\chi]\rangle_e-\sum_{e\in\mathcal{E}^B}\langle\partial_n e,u_h^\gamma-\chi\rangle_e
\end{aligned}\tag{3.7}$$

for any $\chi\in\overset{0}{V}{}_h^r$. Since $a_h^\gamma(e,u_h^\gamma-\chi)=0$, we replace the terms $\sum_{e\in\mathcal{E}^I}\langle\{\partial_n e\},[e]\rangle_e+\sum_{e\in\mathcal{E}^B}\langle\partial_n e,e\rangle_e$ on the right-hand side of (3.6) with

$$\begin{aligned}
-\sum_{K\in\mathcal{T}_h}(\nabla e,\nabla(u_h^\gamma-\chi))_K-\sum_{e\in\mathcal{E}^I}\Big[\langle\{\partial_n(u_h^\gamma-\chi)\},[u_h^\gamma]\rangle_e-\gamma h_e^{-1}|[u_h^\gamma]|_e^2\Big]\\
-\sum_{e\in\mathcal{E}^B}\Big[\langle\partial_n(u_h^\gamma-\chi),u_h^\gamma\rangle_e-\gamma h_e^{-1}|u_h^\gamma|_e^2\Big]
\end{aligned}$$

to obtain

$$\begin{aligned}\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2 = {}& \sum_{K\in\mathcal{T}_h}(f+\Delta u_h^\gamma,\eta)_K - \sum_{e\in\mathcal{E}^I}\Big[\left\langle[\partial_n u_h^\gamma],\eta^*\right\rangle_e + \gamma h_e^{-1}\left\langle[u_h^\gamma],[\eta]\right\rangle_e\Big]\\ &- \gamma\sum_{e\in\mathcal{E}^B} h_e^{-1}\left\langle u_h^\gamma,\eta\right\rangle_e - \sum_{K\in\mathcal{T}_h}(\nabla e,\nabla(u_h^\gamma-\chi))_K\\ &- \sum_{e\in\mathcal{E}^I}\left\langle\{\partial_n(u_h^\gamma-\chi)\},[u_h^\gamma]\right\rangle_e - \sum_{e\in\mathcal{E}^B}\left\langle\partial_n(u_h^\gamma-\chi),u_h^\gamma\right\rangle_e. \qquad (3.8)\end{aligned}$$

Here we have used the facts that $\eta = e - v_h$, $[e]|_e = -[u_h]|_e\ \forall e\in\mathcal{E}^I$, and $e|_e = -u_h|_e\,\forall e\in\mathcal{E}^B$.

We now obtain bounds for the terms on the right-hand side of (3.8). Those that contain η are bounded by $\frac{1}{2}$ times

$$\begin{aligned}&\frac{1}{\epsilon_1}\sum_{K\in\mathcal{T}_h}h_K^2\|f+\Delta u_h^\gamma\|_K^2 + \frac{1}{\epsilon_2}\sum_{e\in\mathcal{E}^I}h_e\big|[\partial_n u_h^\gamma]\big|_e^2 + \frac{1}{\epsilon_3}\gamma\sum_{e\in\mathcal{E}^I}h_e^{-1}|[u_h^\gamma]|_e^2\\ &+\frac{1}{\epsilon_4}\gamma\sum_{e\in\mathcal{E}^B}h_e^{-1}|u_h^\gamma|_e^2 + \epsilon_1\sum_{K\in\mathcal{T}_h}h_K^{-2}\|\eta\|_K^2 + \epsilon_2\sum_{e\in\mathcal{E}^I}h_e^{-1}|\eta^*|_e^2\\ &+\epsilon_3\gamma\sum_{e\in\mathcal{E}^I}h_e^{-1}|[\eta]|_e^2 + \epsilon_4\gamma\sum_{e\in\mathcal{E}^B}h_e^{-1}|\eta|_e^2 \qquad (3.9)\end{aligned}$$

for any $\epsilon_i > 0,\ i = 1,\ldots,4$. To estimate the "$\eta$" terms in (3.9) we choose as v_h the best piecewise constant approximation of e. From (2.10) this gives

$$h_K^{-2}\|\eta\|_K^2 = h_K^{-2}\|e-v_h\|_K^2 \le c\|\nabla e\|_K^2.$$

Also, using the trace inequality (2.8) and (2.10), we obtain

$$\begin{aligned}h_e^{-1}\left(|\eta^*|_e^2+|[\eta]|_e^2\right) &\le c\sum_{K=K^+,K^-}h_e^{-1}(h_K^{-1}\|\eta\|_K^2 + h_K\|\nabla\eta\|_K^2)\\ &\le c\sum_{K=K^+,K^-}h_e^{-1}h_K\|\nabla e\|_K^2.\end{aligned}$$

The local quasiuniformity of the mesh implies that $h_e \approx h_{K^+}\approx h_{K^-}$. Thus $h_e^{-1}h_K \le c$. A similar bound holding for $\sum_{e\in\mathcal{E}^B}h_e^{-1}|\eta|_e^2$, we can now hide the "$\eta$" terms in the left-hand side of (3.8) by taking the ϵ's sufficiently small. In particular, we must take $\epsilon_3 \approx 1/\gamma$ and $\epsilon_4\approx 1/\gamma$.

To obtain (3.1), we need to estimate the terms containing $u_h^\gamma-\chi$. Indeed these are bounded by

$$\begin{aligned}&\epsilon\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2 + \frac{1}{\epsilon}\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-\chi)\|_K^2 + \sum_{e\in\mathcal{E}^I}h_e\big|\{\partial_n(u_h^\gamma-\chi)\}\big|_e^2\\ &+\sum_{e\in\mathcal{E}^I}h_e^{-1}|[u_h^\gamma]|_e^2 + \sum_{e\in\mathcal{E}^B}h_e\big|\partial_n(u_h^\gamma-\chi)\big|_e^2 + \sum_{e\in\mathcal{E}^B}h_e^{-1}|u_h^\gamma|_e^2. \qquad (3.10)\end{aligned}$$

Using the estimates (2.8) and (2.9), we see that the two terms in (3.10) that contain $\partial_n(u_h^\gamma-\chi)$ are bounded by $\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-\chi)\|_K^2$. In view of Theorem 2.2, the latter is bounded by $\sum_{e\in\mathcal{E}^I}h_e^{-1}\ |[u_h^\gamma]|_e^2 + \sum_{e\in\mathcal{E}^B}h_e^{-1}|u_h^\gamma|_e^2$. Using this fact completes the proof. □

THEOREM 3.2. *Suppose that f is a piecewise polynomial on $\mathcal{T}_h$. Then*
(i) *for each $K \in \mathcal{T}_h$,*

$$h_K^2 \|f + \Delta u_h^\gamma\|_K^2 \leq c\, \|\nabla e\|_K^2; \tag{3.11}$$

(ii) *for $e = K^+ \cap K^- \in \mathcal{E}^I$,*

$$h_e \big| \big[\partial_n u_h^\gamma \big] \big|_e^2 \leq c(\|\nabla e\|_{K^+}^2 + \|\nabla e\|_{K^-}^2). \tag{3.12}$$

Proof. To estimate $\|f + \Delta u_h^\gamma\|_K$, we set $v_h = 0$ and $v\big|_K = (f + \Delta u_h^\gamma)\, b_K$, where b_K is the "bubble" function $27\lambda_1\lambda_2\lambda_3$ expressed in terms of the barycentric coordinates of K; we extend v to the outside of K by zero. Using this v in (3.6), we obtain

$$\int_K (f + \Delta u_h^\gamma)^2\, b_K\, dx = (\nabla e, \nabla((f + \Delta u_h^\gamma)\, b_K))_K.$$

Now since $b_K > 0$ on $\mathrm{int}(K)$, $(\int_K (\cdot)^2\, b_K\, dx)^{1/2}$ defines a norm on $L^2(K)$, equivalent to the L^2 norm on $P_m(K)$ for any fixed m. Thus, there exists a constant $c > 0$ such that

$$\int_K (f + \Delta u_h^\gamma)^2\, b_K\, dx \geq c\, \|f + \Delta u_h^\gamma\|_K^2. \tag{3.13}$$

Since $\|b_K\|_{L^\infty(K)} = 1$, a scaling argument can be used to show that, while the constant c may depend on r and the degree of f, it is independent of h_K. On the other hand, using the inverse inequality (2.9), we have

$$\begin{aligned}(\nabla e, \nabla((f + \Delta u_h^\gamma)\, b_K))_K &\leq \|\nabla e\|_K \|\nabla((f + \Delta u_h^\gamma)\, b_K)\|_K \\ &\leq c\epsilon \|f + \Delta u_h^\gamma\|_K^2 + \frac{1}{\epsilon} h_K^{-2} \|\nabla e\|_K^2.\end{aligned}$$

This gives (i). We next estimate $h_e|[\partial_n u_h^\gamma]|_e^2$. Let $e = \partial K^+ \cap \partial K^-$ and suppose that e is a full edge of both K^+ and K^-. (See Remark 3.1 below.) Extend $\big[\partial_n u_h^\gamma\big]$ to a function ϕ defined over $\tilde{K} = K^+ \cup K^-$ by extending by constants along lines normal to e; see Figure 3.1. Also, let b denote the bubble function on $\tilde{K}$ given by

$$b\big|_{K^+} = 4\lambda_1^+\lambda_2^+, \quad b\big|_{K^-} = 4\lambda_1^-\lambda_2^-.$$

Let $v = \phi\, b$ and set $v_h = 0$. Using this v in (3.6), we get

$$\begin{aligned} h_e \int_e \big[\partial_n u_h^\gamma\big]^2 b\, ds &= h_e \sum_{K = K^+, K^-} \Big[(f + \Delta u_h^\gamma, \phi\, b)_K - (\nabla e, \nabla(\phi\, b))_K \Big] \\ &\leq h_e \sum_{K = K^+, K^-} \Big[\|f + \Delta u_h^\gamma\|_K \|\phi\, b\|_K + \|\nabla e\|_K \|\nabla(\phi\, b)\|_K \Big] \\ &\leq \frac{1}{2\epsilon} \sum_{K = K^+, K^-} \Big\{ h_K^2 \|f + \Delta u_h^\gamma\|_K^2 + \|\nabla e\|_K^2 \Big\} \qquad (3.14) \\ &\quad + \frac{\epsilon}{2} \sum_{K = K^+, K^-} \Big\{ \|\phi\, b\|_K^2 + h_K^2 \|\nabla(\phi\, b)\|_K^2 \Big\}. \end{aligned}$$

Using arguments similar to those leading to (3.13), we obtain

$$\int_e \big[\partial_n u_h^\gamma\big]^2 b\, ds \geq c \big| \big[\partial_n u_h^\gamma\big] \big|_e^2 \tag{3.15}$$

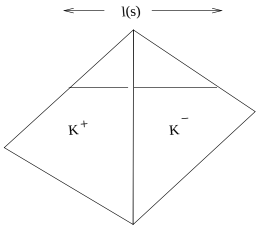

FIG. 3.1.

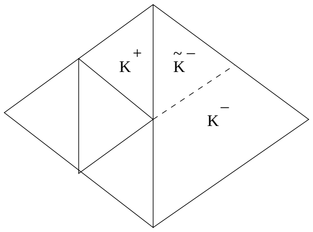

FIG. 3.2.

for some positive constant c depending only on r. Moreover,

$$\|\phi\, b\|^2_{\tilde{K}} \le \|\phi\|^2_{\tilde{K}} = \int_e \left[\partial_n u_h^\gamma\right]^2 l(s) ds \le h_e \big| \left[\partial_n u_h^\gamma\right] \big|^2_e, \tag{3.16}$$

where $l(s)$ is as in Figure 3.1. Using the inverse inequality (2.9), we see that

$$\sum_{K=K^+,K^-} h_K^2 \|\nabla(\phi\, b)\|^2_K \le c\|\phi\, b\|^2_{\tilde{K}} \le ch_e \big| \left[\partial_n u_h^\gamma\right] \big|^2_e. \tag{3.17}$$

The required estimate now follows from (3.14)–(3.17). □

Remark 3.1. If e is not a full edge of one of the triangles, say K^-, then we can work with $\tilde{K}^-$ instead; see Figure 3.2.

4. Estimates based on the solution of local problems. In this section, we shall introduce and analyze a posteriori estimates that are based on domain decomposition techniques proposed in [11]. The approach consists of viewing the computed solution u_h^γ as the coarse-mesh approximation to some function which is arguably a more accurate approximation to u. Before suggesting some choices for this quantity, let us say that there will be no attempt to compute it directly, but rather to approximate it by adding to u_h^γ a function obtained through the solution of "local" problems. For simplicity, we restrict the exposition to $d = 2$ and assume that $\mathcal{T}_h$ is a conforming mesh of triangles. Also, we should note that the results of [11] concern Baker's formulation only; however, we believe that similar results can be obtained for Arnold's formulation.

4.1. A nonoverlapping approach. To begin, let $\mathcal{T}_{h/2}$ be the mesh obtained by cutting every $K \in \mathcal{T}_h$ into four equal triangles. In a similar way, we may define $\mathcal{T}_{h'} := \mathcal{T}_{h/2^p}$, $h' := h/2^p$ by repeating this process p times. On the latter, we define a finite element space $V' := V_{h'}^{r'}$ of discontinuous piecewise polynomial functions of degree less than or equal to $r' - 1$, where $r' \ge r$. This way, V_h^r is a subspace of V'. On $V' \times V'$ we define the bilinear form $a' := a_{h'}^{\gamma'}$ just as in the definition of a_h^γ in (2.3). It is crucial for the analysis that a_h^γ be the restriction of a' to V_h^r in the sense that

$$a_h^\gamma(v, w) = a'(v, w) \quad \forall v, w \in V_h^r. \tag{4.1}$$

Remark 4.1. By comparing the penalty terms in a_h^γ and a', we see that (4.1) requires the condition $\gamma'(h')^{-1} = \gamma h^{-1}$, which, in view of the fact that $h' = h/2^p$, is equivalent to $\gamma' = \gamma 2^{-p}$. Now since the coercivity of the forms a' and a_h^γ can be guaranteed only if $\gamma' \ge \gamma_0'(r')$ and $\gamma \ge \gamma_0(r)$, respectively (see Lemma 2.1(i)), we see that γ must be chosen sufficiently large in order to have $\gamma 2^{-p} \ge \gamma_0'$. This does not present any theoretical difficulties, since γ can take on arbitrarily large values without having any result discussed in this work break down. On the other hand, the quality of the a priori and a posteriori estimates may suffer, as is the case with (3.1). (In this respect, see the discussion at the beginning of section 5 and Figures 5.5 and 5.6.) In practice, however, we anticipate that $r' = r + 1$ and/or $h' = h/2$ should be sufficient. This was indeed the case in all our numerical experiments.

For each $K \in \mathcal{T}_h$, we consider the "local" space $V'(K)$ obtained by restricting V' to K. By extending the elements of $V'(K)$ by zero to the rest of Ω, $V'(K)$ becomes a subspace of V'. Indeed, the latter is the direct sum of these local subspaces. On $V'(K) \times V'(K)$ we introduce the bilinear form $a'_K(\cdot,\cdot)$ as the restriction of $a'(\cdot,\cdot)$ to $V'(K) \times V'(K)$ (see (4.4) in [11]). As such, a'_K inherits the symmetry and coercivity of a' on $V'(K)$. In particular, for any $\gamma' \geq \gamma'_0$ there holds

$$a'_K(v,v) \geq c\|v\|^2_{1,K} \quad \forall v \in V'(K), \tag{4.2}$$

where $\|\cdot\|_{1,K}$ denotes the restriction of the $\|\cdot\|_{1,h'}$ norm to $V'(K)$. Adopting the terminology of [11], we consider $\mathcal{T}_h$ as the coarse mesh of $\mathcal{T}_{h'}$. Also, each $K \in \mathcal{T}_h$ is considered as a subdomain in $\mathcal{T}_{h'}$. In other words, $\mathcal{T}_h$ is both the coarse mesh and the subdomain partition of $\mathcal{T}_{h'}$.

Now let $u' := u^{\gamma'}_{h'} \in V'$ be the discontinuous Galerkin approximation of u in the space V'; i.e.,

$$a'(u',v) = (f,v) \quad \forall v \in V'. \tag{4.3}$$

At this point, we observe that, by virtue of (4.1), (2.5) and (4.3) imply the following orthogonality relation:

$$a'(u' - u^\gamma_h, v) = 0 \quad \forall v \in V^r_h. \tag{4.4}$$

Next, let the functions $\{\eta_K \in V'(K) \,|\, K \in \mathcal{T}_h\}$ be given as the solutions of the local problems

$$a'_K(\eta_K, v) = (f,v) - a'(u^\gamma_h, v) \quad \forall v \in V'(K). \tag{4.5}$$

The functions $\{\eta_K\}$ can be computed independently of each other and in parallel. Moreover, the function $\eta := \sum_{K\in\mathcal{T}_h} \eta_K$ approximates $\zeta := u' - u^\gamma_h$ in the following sense.

THEOREM 4.1. *There exist positive constants C_1 and C_2 such that*

$$C_1\,\|\eta\|_{1,h'} \leq \|\zeta\|_{1,h'} \leq C_2 \frac{h}{h'}\|\eta\|_{1,h'}. \tag{4.6}$$

Proof. Since $(f,v) = a'(u',v)$, $v \in V'$, from (4.5) we have

$$a'_K(\eta_K, v) = a'(\zeta, v) \quad \forall v \in V'(K). \tag{4.7}$$

Thus,

$$\sum_{K\in\mathcal{T}_h} a'_K(\eta_K,\eta_K) = a'(\zeta,\eta) \leq c\|\zeta\|_{1,h'}\|\eta\|_{1,h'}. \tag{4.8}$$

From (4.2) it follows that $\sum_{K\in\mathcal{T}_h} a'_K(\eta_K,\eta_K) \geq c\sum_{K\in\mathcal{T}_h} \|\eta_K\|^2_{1,K}$. On the other hand, it is easy to see that $\sum_{K\in\mathcal{T}_h} \|\eta_K\|^2_{1,K} \geq \|\eta\|^2_{1,h'}$. Thus, the first half of (4.6) follows.

To prove the second inequality, let $\zeta = \sum_{K\in\mathcal{T}_h} \zeta_K, \zeta_K \in V'(K)$. Let ζ_0 be the piecewise constant function on $\mathcal{T}_h$ defined by

$$\zeta_0\big|_K := \zeta_{K,0} = \frac{1}{|K|}\int_K \zeta_K\, dx.$$

Now since $\zeta_0 \in V_h^r$, it follows from (4.7) and (4.4) that

$$a'_K(\eta_K, \zeta_K - \zeta_{K,0}) = a'(\zeta, \zeta_K - \zeta_{K,0}) = a'(\zeta, \zeta_K).$$

Summing over $K \in \mathcal{T}_h$, we obtain

$$\sum_{K\in\mathcal{T}_h} a'_K(\eta_K, \zeta_K - \zeta_{K,0}) = a'(\zeta,\zeta) \geq c\|\zeta\|^2_{1,h'}. \tag{4.9}$$

Now, it follows from the Cauchy–Schwarz inequality that

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} a'_K(\eta_K, \zeta_K - \zeta_{K,0}) &\leq \left(\sum_{K\in\mathcal{T}_h} a'_K(\eta_K,\eta_K)\right)^{1/2} \\ &\quad \times \left(\sum_{K\in\mathcal{T}_h} a'_K(\zeta_K - \zeta_{K,0}, \zeta_K - \zeta_{K,0})\right)^{1/2}.\end{aligned} \tag{4.10}$$

Also from (4.8) it follows that

$$\left(\sum_{K\in\mathcal{T}_h} a'_K(\eta_K,\eta_K)\right)^{1/2} \leq c\|\zeta\|^{1/2}_{1,h'}\|\eta\|^{1/2}_{1,h'}. \tag{4.11}$$

On the other hand, with the interface bilinear form $I'(\cdot,\cdot)$ defined in (4.5) of [11],

$$\begin{aligned}I'(u,v) = \sum_{e'\in\mathcal{E}^I} \Big\{ &\left\langle \{\partial_n u\}, v^-\right\rangle_{e'} + \left\langle \{\partial_n v\}, u^-\right\rangle_{e'} \\ &- \gamma'(h')^{-1}\left[\left\langle u^+, v^-\right\rangle_{e'} + \left\langle v^+, u^-\right\rangle_{e'}\right]\Big\} \qquad \forall u, v \in V',\end{aligned}$$

we have

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} a'_K(\zeta_K - \zeta_{K,0}, \zeta_K - \zeta_{K,0}) &= a'(\zeta - \zeta_0, \zeta - \zeta_0) - I'(\zeta - \zeta_0, \zeta - \zeta_0) \\ &\leq 2a'(\zeta,\zeta) + 2a'(\zeta_0,\zeta_0) + \left|I'(\zeta - \zeta_0, \zeta - \zeta_0)\right|.\end{aligned} \tag{4.12}$$

In [11] it is proved that $a'(\zeta_0,\zeta_0)$ and $|I'(\zeta - \zeta_0, \zeta - \zeta_0)|$ are bounded by $c\frac{h}{h'}a'(\zeta,\zeta)$. Thus from (4.9)–(4.12) it follows that

$$\|\zeta\|^2_{1,h'} \leq c\left(\frac{h}{h'}\right)^{1/2}\|\zeta\|^{3/2}_{1,h'}\|\eta\|^{1/2}_{1,h'},$$

from which the second inequality of (4.6) follows. □

We shall use the equivalence just proved to obtain estimates for $e = u - u_h^\gamma$. Letting $e' = u - u'$, we have $e = e' + \zeta$. We now argue as follows: It is reasonable to expect that e' is much smaller than e, say in the energy norm; therefore e and ζ

are nearly equal. Since ζ is not computed, we shall approximate it, and hence e, by η, where the latter is obtained by solving local problems. To quantify matters, since $a'(e', v) = 0\ \forall v \in V'$ and $\zeta \in V'$, we obtain

$$a'(e, e) = a'(e', e') + a'(\zeta, \zeta). \tag{4.13}$$

It follows from this and (2.7) that $a'(e', e') = \epsilon\, a'(e, e)$ for some $0 < \epsilon < 1$. Based on a priori estimates, it is reasonable to expect that $\epsilon = O(\frac{(h')^{r'-1}}{h^{r-1}}) \ll 1$. Thus,

$$a'(e, e) = \frac{1}{1-\epsilon}\, a'(\zeta, \zeta).$$

In view of the equivalence between η and ζ provided by Theorem 4.1, we can use $a'(\eta, \eta)$ to obtain lower and upper bounds for $a'(e, e)$.

4.2. An overlapping approach. Let $\Omega = \cup_{e\in\mathcal{E}}\Omega_e$ be an overlapping decomposition of Ω, where each Ω_e is the following union of the triangles in $\mathcal{T}_h$: If $e \in \mathcal{E}^I$, then $e = \partial K^+ \cap \partial K^-$ and $\Omega_e = K^+ \cup K^-$; else if $e \in \mathcal{E}^B$, then $e = \partial K \cap \partial\Omega$ and $\Omega_e = K$.

On $\mathcal{T}_h$, we define a finite element space $V' := V_h^{r'}$ of discontinuous piecewise polynomial functions of degree less than or equal to $r' - 1$, where $r' \geq r + 1$; let us recall that $r \geq 2$ is fixed. We construct a subspace decomposition of this latter finite element space by defining the subspaces $\{V'_e\}_{e\in\mathcal{E}}$ associated with the subdomains $\{\Omega_e\}_{e\in\mathcal{E}}$ by

$$V'_e = \{v_h \in V', v_h = 0 \text{ in } \Omega \setminus \bar{\Omega}_e\}.$$

Thus the following decomposition, which is not direct, holds:

$$V' = V_h^r + \sum_{e\in\mathcal{E}} V'_e. \tag{4.14}$$

On $V' \times V'$, we define the bilinear form $a' := a_h^{\gamma'}$ as in the definition of a_h^γ in (2.3), and again it is crucial for the analysis that a_h^γ be the restriction of a' to V_h^r in the sense that

$$a_h^\gamma(v, w) = a'(v, w) \quad \forall v, w \in V_h^r. \tag{4.15}$$

For each edge $e \in \mathcal{E}$, we consider on $V'_e \times V'_e$ the symmetric and coercive bilinear form $a'_e(\cdot,\cdot)$ as the restriction of $a'(\cdot,\cdot)$ to $V'_e \times V'_e$ (see (4.4) in [11]),

$$a'_e(v, w) = a'(v, w) \quad \forall v, w \in V'_e. \tag{4.16}$$

Following [11], we are able to define the additive operator $T = T_0 + \sum_{e\in\mathcal{E}} T_e$, where T_0 is a projection operator from V' to V_h^r defined by

$$a_h^\gamma(T_0 u, v) = a'(T_0 u, v) = a'(u, v) \quad \forall v \in V_h^r \tag{4.17}$$

and T_e is a projection operator from V' to V'_e defined by

$$a'_e(T_e u, v) = a'(T_e u, v) = a'(u, v) \quad \forall v \in V'_e. \tag{4.18}$$

Lemmas 5.1–5.5 in [11] can easily be adapted to the present case with $H = h$, and $\delta \sim h$, and Theorem 5.7 in [11] then reads as follows.

THEOREM 4.2. *There exist positive constants c_1, c_2, which are independent of h and of the number of edges, such that there holds the estimate*

$$c_1 a'(v,v) \leq a'(Tv,Tv) \leq c_2 a'(v,v) \quad \forall v \in V'. \tag{4.19}$$

Now let $u' := u_h^{\gamma'} \in V'$ be the discontinuous Galerkin approximation of u in the space V'; i.e.,

$$a'(u',v) = (f,v) \quad \forall v \in V'. \tag{4.20}$$

Next, let the functions $\eta_e \in V'_e$ be given as the solutions of the local problems

$$a'_e(\eta_e, v) = (f,v) - a'(u_h^\gamma, v) \quad \forall v \in V'_e. \tag{4.21}$$

The functions $\{\eta_e\}_{e\in\mathcal{E}}$ can be computed independently of each other and in parallel, and the function $\eta := \sum_{e\in\mathcal{E}} \eta_e$ approximates $\zeta := u' - u_h^\gamma$ in the following sense.

THEOREM 4.3. *There exist positive constants C_1 and C_2 such that*

$$C_1 \|\zeta\|_{1,h} \leq \|\eta\|_{1,h} \leq C_2 \|\zeta\|_{1,h}. \tag{4.22}$$

Proof. Let us prove that $\eta = T\zeta$. Indeed, from (4.20) and (4.21) we get

$$a'_e(\eta_e, v) = a'(u' - u_h^\gamma, v) \quad \forall v \in V'_e, \tag{4.23}$$

which means from the definition (4.18) of T_e that $\eta_e = T_e\zeta$ $\forall e \in \mathcal{E}$.

Now, by virtue of (4.15), (2.5) and (4.20) imply the orthogonality relation

$$a'(u' - u_h^\gamma, v) = 0 \quad \forall v \in V_h^r, \tag{4.24}$$

which means from the definition of T_0 that $T_0\zeta = 0$.

Thus (4.22) follows from Theorem 4.2. □

We conclude, in a similar way as in section 4.1, that we can use $a'(\eta,\eta)$ to obtain lower and upper bounds for $a'(e,e)$.

Remark 4.2. As for the nonoverlapping approach, we could define the finite element space $V' := V_{h'}^{r'}$ with $h' = h/2^p$, where the mesh is obtained in dimension 2 by cutting p times every triangle into four equal triangles.

5. Numerical results in one dimension.

In this section, we present numerical results obtained from the one-dimensional (1-d) model problem

$$-\frac{d^2u}{dx^2} = f, \qquad 0 < x < 1, \quad u(0) = u(1) = 0, \tag{5.1}$$

with the exact solution $u(x) = e^{-\alpha(x-\frac{1}{2})^2}, \alpha = 100$.

For the sake of brevity, we shall consider in these numerical experiments only the weak formulation (2.3) due to Baker; for some comparisons with the Arnold formulation, we refer to the technical report [13].

5.1. Convergence with respect to γ and h.

For a number of years we have been interested in the behavior of the discontinuous Galerkin approximations as a function of the penalty parameter γ, and indeed we had a proof (unpublished) that

$$\lim_{\gamma\to\infty} u_h^\gamma = u_h^G, \tag{5.2}$$

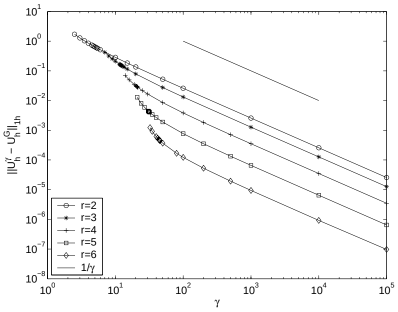

FIG. 5.1. $\|u_h^\gamma - u_h^G\|_{1,h}$ *versus* γ.

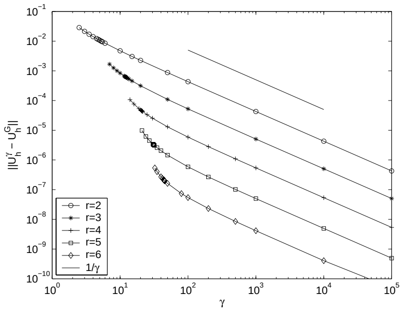

FIG. 5.2. $\|u_h^\gamma - u_h^G\|$ *versus* γ.

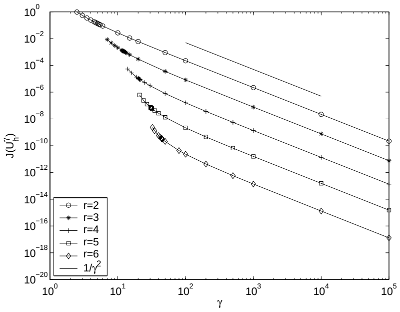

FIG. 5.3. $J(u_h^\gamma)$ *versus* γ.

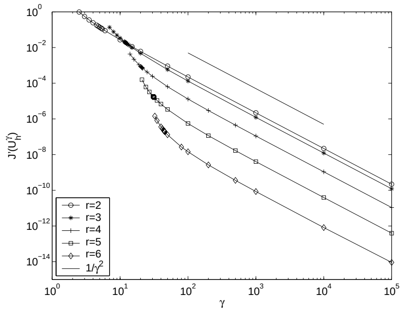

FIG. 5.4. $J'(u_h^\gamma)$ *versus* γ.

where u_h^G is the standard Galerkin approximation of u defined by

$$(\nabla u_h^G, \nabla \chi) = (f, \chi) \quad \forall \chi \in \overset{0}{V}{}_h^r. \tag{5.3}$$

A more recent proof can be found in [14]. Besides its intrinsic value, this result can be used to show that the discontinuous Galerkin method can yield more accurate results than the standard Galerkin version for a range of values of γ, as shown later in Figure 5.5.

In the first experiments, the domain $[0,1]$ is divided into a uniform mesh of 20 subintervals. The approximations u_h^γ, solution of (2.5), and u_h^G, solution of (5.3), are computed using piecewise polynomials of degree up to 5. Figures 5.1 and 5.2 show the difference between u_h^γ and u_h^G in the energy norm $\|\cdot\|_{1,h}$ and the L^2 norm, respectively, as a function of γ. These plots highlight the convergence (5.2) according to the rate $O(\frac{1}{\gamma})$. Similarly, Figure 5.3 shows the behavior of the jump in u_h^γ,

$$J(u_h^\gamma) \equiv \sum_{e\in\mathcal{E}^I} h_e^{-1} |[u_h^\gamma]|_e^2 + \sum_{e\in\mathcal{E}^B} h_e^{-1} |u_h^\gamma|_e^2, \tag{5.4}$$

as a function of γ. Note that $J(u_h^\gamma) = J(u_h^\gamma - u_h^G)$. We see that $J(u_h^\gamma)$ behaves as $\frac{1}{\gamma^2}$ when γ tends to infinity. In the same way, one can observe in Figure 5.4 that the jump of the derivative

$$J'(u_h^\gamma) \equiv \sum_{e\in\mathcal{E}^I} h_e \left|\{\partial_n (u_h^\gamma - u_h^G)\}\right|_e^2 + \sum_{e\in\mathcal{E}^B} h_e \left|\partial_n (u_h^\gamma - u_h^G)\right|_e^2 \tag{5.5}$$

behaves also as $\frac{1}{\gamma^2}$.

We now study the difference between the discontinuous Galerkin and exact solutions of the problem. For $h = \frac{1}{20}$ and $r = 2$, $\|u_h^\gamma - u\|$ and $|u_h^\gamma - u|_{1,h} \equiv (\sum_{K\in\mathcal{T}_h} ||\nabla(u_h^\gamma - u)||_K^2)^{1/2}$ are plotted in Figures 5.5 and 5.6, respectively. We see that these converge to values (represented by the dashed lines) which, in view of (5.2), must be $\|u_h^G - u\|$ and $\|\nabla(u_h^G - u)\|$, respectively. We also observe that there exists an optimal value γ_{opt} of the penalty parameter γ, for which $\|u_h^\gamma - u\|$ is minimized. From these and other numerical experiments not reported here (see the report [13] for other values of r), we claim that, in the case of the Baker formulation, this optimal value does not depend either on the mesh size or on u (or, from an equivalent point of view, on the function f), but depends on the degree of the polynomial approximations: It follows approximately the rule

$$\gamma_{opt} = (r-1)(r+3), \tag{5.6}$$

as can be seen in Figure 5.7, where the circles represent the numerical value of γ_{opt} for different values of $r-1$ and the continuous line represents the $(r-1)(r+3)$ function.

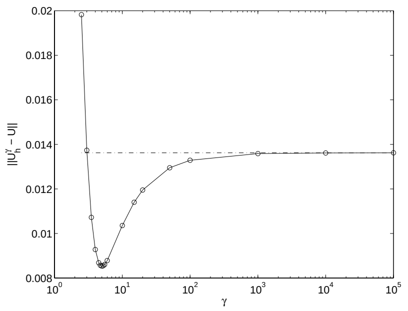

FIG. 5.5. $\|u_h^\gamma - u\|$ *versus* γ.

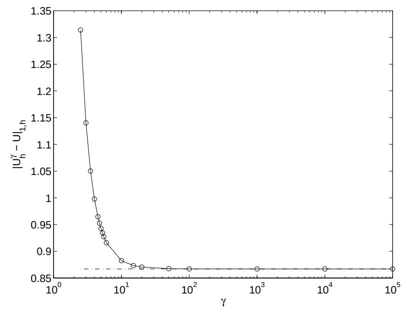

FIG. 5.6. $|u_h^\gamma - u|_{1,h}$ *versus* γ.

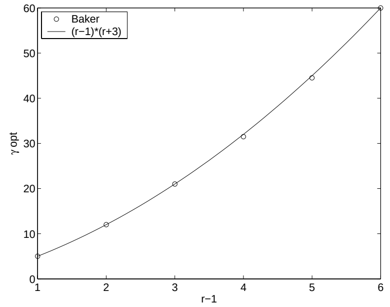

FIG. 5.7. γ_{opt} *versus* $r-1$.

For the parameter γ chosen approximately equal to γ_{opt}, we now investigate the convergence of u_h^γ to u on a sequence of uniformly refined meshes. The differences $\|u_h^\gamma - u\|$ and $\|u_h^\gamma - u\|_{1,h}$ are plotted in Figures 5.8 and 5.9, respectively, for piecewise polynomials of degree $r-1 = 1,2,3,4$. The observed rates of convergence of $O(h^r)$ and $O(h^{r-1})$, respectively, conform to the a priori estimates expressed in (2.12) and

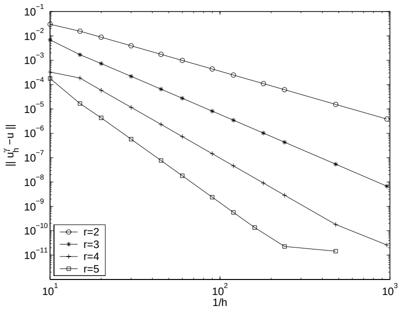

FIG. 5.8. $\|u_h^\gamma - u\|$ *versus* $1/h$.

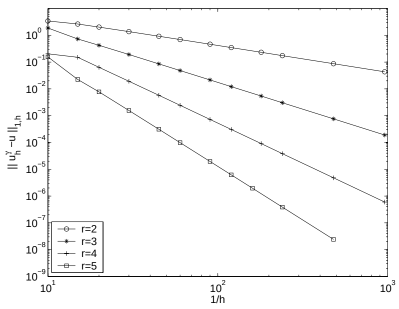

FIG. 5.9. $\|u_h^\gamma - u\|_{1,h}$ *versus* $1/h$.

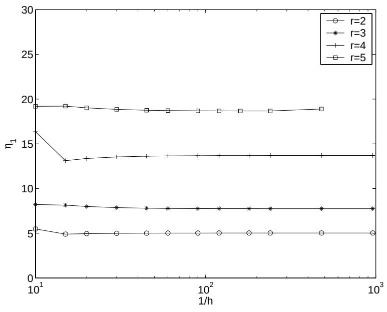

FIG. 5.10. η_1 *versus* $1/h$.

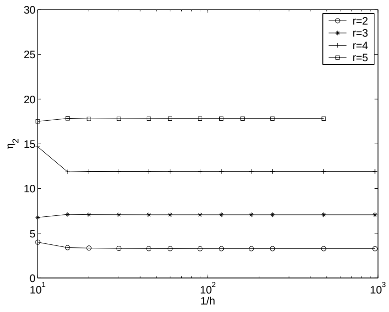

FIG. 5.11. η_2 *versus* $1/h$.

in (2.11): The distorted line for $r = 5$ is due to the limitations of computations in double precision.

5.2. Effectivity indices. In order to judge the quality of the various error estimators presented above, we compute for each an effectivity index, defined as the ratio of the estimator to the exact error. First, we study three estimators featured in Theorems 3.1 and 3.2. Specifically, in Figure 5.10, the effectivity index η_1 of the first estimator corresponding to Theorem 3.1 and formula (3.1) is plotted as a function of $1/h$ and for values of $r-1$ between 1 and 4:

$$\eta_1^2 = \frac{\displaystyle\sum_{K\in\mathcal{T}_h} h_K^2\|f+\Delta u_h^\gamma\|_K^2 + \sum_{e\in\mathcal{E}^I} h_e\big|\big[\partial_n u_h^\gamma\big]\big|_e^2 + \gamma^2\sum_{e\in\mathcal{E}^I} h_e^{-1}|[u_h^\gamma]|_e^2 + \gamma^2\sum_{e\in\mathcal{E}^B} h_e^{-1}|u_h^\gamma|_e^2}{\displaystyle\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2}. \tag{5.7}$$

In Figure 5.11, we plot the effectivity index η_2 of the second estimator, which corresponds to Theorem 3.2(i) and to (3.11):

$$\eta_2^2 = \frac{\displaystyle\sum_{K\in\mathcal{T}_h} h_K^2\|f+\Delta u_h^\gamma\|_K^2}{\displaystyle\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2}. \tag{5.8}$$

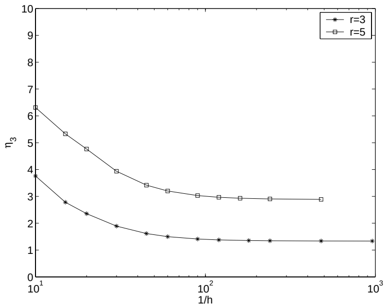

FIG. 5.12. *η_3 versus $1/h$ for even $r-1$.*

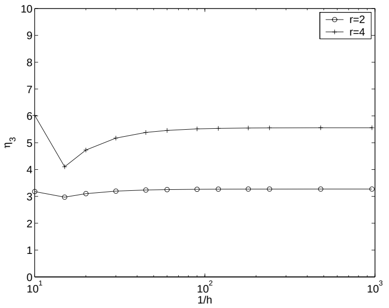

FIG. 5.13. *η_3 versus $1/h$ for odd $r-1$.*

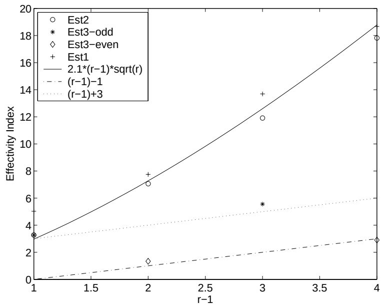

FIG. 5.14. *Effectivity indices versus $r-1$.*

Finally, Figures 5.12 and 5.13 represent for odd and even degrees of polynomials, respectively, the effectivity index η_3 of the estimator associated with Theorem 3.2(ii) and (3.12):

$$\eta_3^2 = \frac{\displaystyle\sum_{e\in\mathcal{E}^I} h_e \big|\big[\partial_n u_h^\gamma\big]\big|_e^2}{\displaystyle\sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2}. \tag{5.9}$$

It is seen that, as h decreases, these indices converge to values larger than 1. We also observe that η_1 and η_2 attain their respective asymptotic values rather quickly. On the other hand, while η_3 is somewhat slower in that respect, it is still nearly constant over a wide range of values of h.

Additionally, the asymptotic values depend strongly on r. Since it is desirable to have effectivity indices close to 1, we tried to find simple laws describing this dependence. As evidenced by Figure 5.14, the following functions seem to “fit” the asymptotic values reasonably well:

$$\eta_1 \sim \eta_2 \sim 2.1(r-1)\sqrt{r}, \tag{5.10}$$

$$\eta_3 \sim r-2 \quad \text{if } r-1 \text{ is even}, \tag{5.11}$$

$$\eta_3 \sim r+2 \quad \text{if } r-1 \text{ is odd}. \tag{5.12}$$

Indeed, dividing the above estimators by the corresponding asymptotic values should result in effectivity indices that are very close to 1.

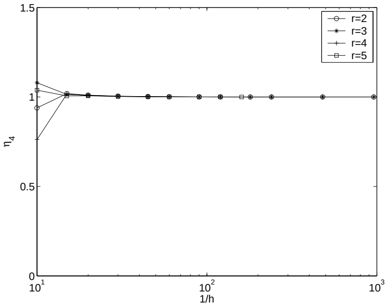

FIG. 5.15. *Effectivity index of the nonoverlapping approach–based estimator with $h' = h$ and $r' = r + 1$ versus h.*

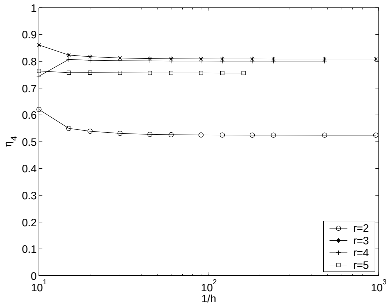

FIG. 5.16. *Effectivity index of the nonoverlapping approach–based estimator with $h' = h/2$ and $r' = r + 1$ versus h.*

The previous experiments are repeated with the two error estimators based on the nonoverlapping and overlapping domain decomposition approaches. More precisely, we define η_4 by

$$\eta_4 = \frac{\|\eta\|_{1,h'}}{\|e\|_{1,h'}}, \tag{5.13}$$

where $\eta = \sum_{K \in \mathcal{T}_h} \eta_K$ and η_K is the solution of the local problem (4.5). Among the various values of parameters that are possible, we chose the two combinations $h' = h$, $r' = r + 1$ and $h' = h/2$, $r' = r + 1$, the results being reported in Figures 5.15 and 5.16, respectively. In the former case, we observe that the index is exactly equal to 1 even for relatively large values of h and does not depend on r or on $r' > r$. In the latter case, the index is slightly less than 1 and depends on r and not on $r' \geq r + 1$.

In the same way,

$$\eta_5 = \frac{\|\eta\|_{1,h'}}{\|e\|_{1,h'}}, \tag{5.14}$$

where $\eta = \sum_{K \in \mathcal{T}_h} \eta_K$ and η_K is the solution of the local problem (4.21). The results for the case $h' = h$ and $r' = r + 1$ are reported in Figure 5.17. We observe that the effectivity index in this case is equal to 2, which is also the number of triangles in a subdomain Ω_e. In the case of $h' = h/2$ and $r' = r + 1$, this index is slightly higher than 1, as can be seen in Figure 5.18.

If any conclusions can be drawn after such a limited number of experiments, they would be that, while the estimators η_4 and η_5 based on the ideas of domain decomposition seem to be very robust, the estimators η_2 and η_3 are, in contrast, less expensive to implement, and offer the added advantage of being entirely local.

5.3. Adaptive mesh strategy. In order to gauge the efficiency of the a posteriori error estimates that we have derived, we present here two h-adaptive methods for approximating the solution of problem (5.1). We based our numerical experiments on the second estimate, which corresponds to Theorem 3.2(i) and to the effectivity index η_2 plotted in Figure 5.11.

Both strategies modify the mesh by refinement of some marked elements while keeping the degree of the polynomials constant. The goal is to generate a mesh in a finite number of steps such that a given tolerance is met by the approximate solution

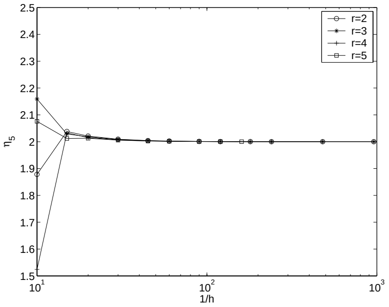

FIG. 5.17. *Effectivity index of the overlapping approach–based estimator with $h' = h$ and $r' = r + 1$ versus h.*

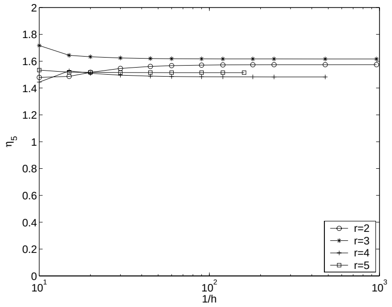

FIG. 5.18. *Effectivity index of the overlapping approach–based estimator with $h' = h/2$ and $r' = r + 1$ versus h.*

on this mesh. To do this, some optimality criteria have to be imposed. The first technique is based on the convergent adaptive algorithm proposed in [10] for solving Poisson's equation and used, for instance, in [17]. In order to minimize the total number of degrees of freedom, this strategy equidistributes the given tolerance (tol) on each element. Consequently, the local error of the optimal mesh $\mathcal{T}_h$ satisfies $\eta_K(u_h^\gamma)^2 \sim \frac{tol^2}{m_h}$, where m_h is the number of elements and u_h^γ the discontinuous Galerkin solution on $\mathcal{T}_h$. Since the number of iterations required to get this optimal mesh is quite large, we derived a second strategy, which turned out to require less cpu-time. We shall next describe these two strategies and apply them to problem (5.1), with the following exact solution:

$$u(x) = (1-x)\left(\tan^{-1}\left(\alpha\left(x-\frac{1}{2}\right)\right) + \tan^{-1}\left(\frac{\alpha}{2}\right)\right), \quad \alpha = 100.$$

Given an error tolerance tol and a coarse mesh $\mathcal{T}_0$, let u_0^γ denote the discontinuous Galerkin solution on $\mathcal{T}_0$. In this study, for simplicity reasons, we are not considering the effect of data oscillations as in [15]. Let $k = 0$. The first strategy involves the following steps:

(i) compute the local indicator $\eta_K^k(u_k^\gamma)$ such that

$$\eta_K^k(u_k^\gamma)^2 = \frac{{h_K^k}^2\|f + \Delta u_k^\gamma\|_K^2}{r(r-1)^2}\,; \tag{5.15}$$

(ii) compute the total error estimate

$$\eta^k(u_k^\gamma) = \left(\sum_{K\in\mathcal{T}_k} \eta_K^k(u_k^\gamma)^2\right)^{1/2}; \tag{5.16}$$

(iii) select a set $\hat{\mathcal{T}}_k$ of "marked" elements to be refined such that, for a given parameter θ (fixed in our experiments to 0.5),

$$\left(\sum_{K\in\hat{\mathcal{T}}_k} \eta_K^k(u_k^\gamma)^2\right)^{1/2} \geq \theta\eta^k(u_k^\gamma)\,; \tag{5.17}$$

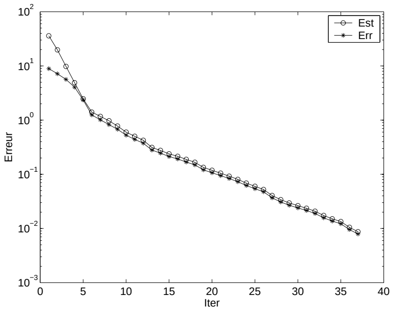

FIG. 5.19. *Strategy* 1: *estimate and exact error versus h-adaptive iterations (r* = 2*).*

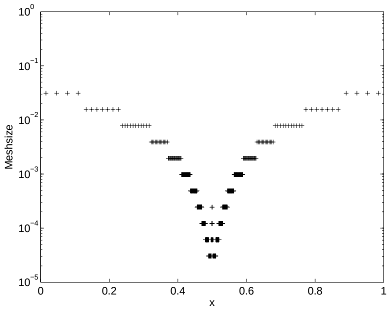

FIG. 5.20. *Strategy* 1: *mesh size versus x (r* = 2*).*

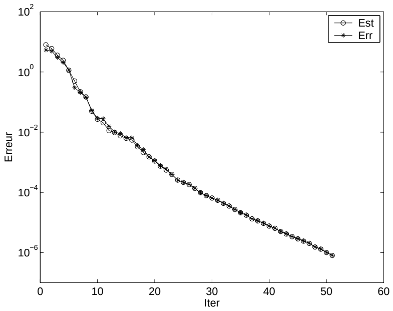

FIG. 5.21. *Strategy* 1: *estimate and exact error versus h-adaptive iterations (r* = 4*).*

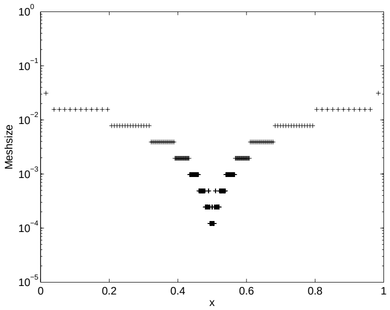

FIG. 5.22. *Strategy* 1: *mesh size versus x (r* = 4*).*

(iv) obtain a refined mesh $\mathcal{T}_{k+1}$ by dividing each element $K \in \hat{\mathcal{T}}_k$ (in two parts for a 1-d problem);

(v) compute the discontinuous Galerkin solution on $\mathcal{T}_{k+1}$;

(vi) $k \leftarrow k+1$ and go to step (i).

The algorithm is stopped when $\eta^k(u_k^\gamma) \leq tol$ in step (ii). In practice, for computing marked elements in step (iii), we follow the procedure proposed in [10]. Let us remark that, for changing to the other estimates, formula (5.15) just has to be adapted in step (i).

For $r = 2$ and $tol = 0.01$, this strategy required 37 iterations to reach the optimal mesh, which has 1411 elements and whose distribution of mesh size is plotted in Figure 5.20. For $r = 4$ and $tol = 10^{-6}$, 50 iterations were necessary, the final mesh has 471 elements, and the mesh size distribution is plotted in Figure 5.22. In both cases, the error estimate is an accurate approximation of the exact error (in energy norm), as can be seen in Figures 5.19 and 5.21.

Now let us observe that, to get $\sum_K \|\nabla e\|_K^2 \leq tol^2$, it is sufficient to distribute (not to equidistribute) the errors as follows:

$$\|\nabla e\|_K \leq \sqrt{\frac{|K|}{|\Omega|}}\, tol\,. \tag{5.18}$$

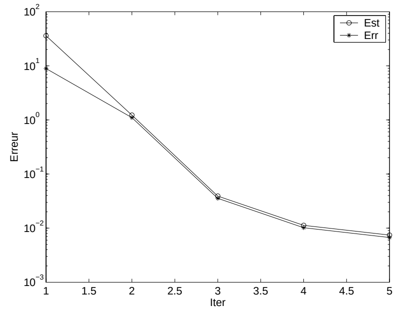

FIG. 5.23. *Strategy* 2: *estimate and exact error versus h-adaptive iterations (r* = 2*).*

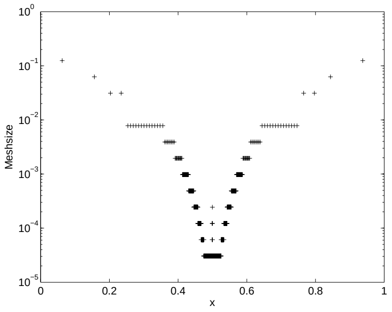

FIG. 5.24. *Strategy* 2: *mesh size versus x (r* = 2*).*

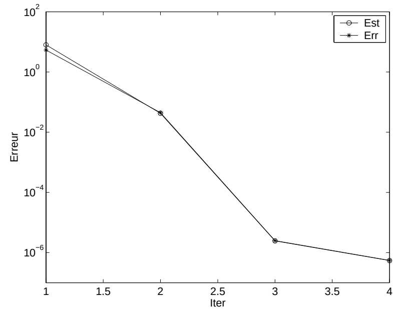

FIG. 5.25. *Strategy* 2: *estimate and exact error versus h-adaptive iterations (r* = 4*).*

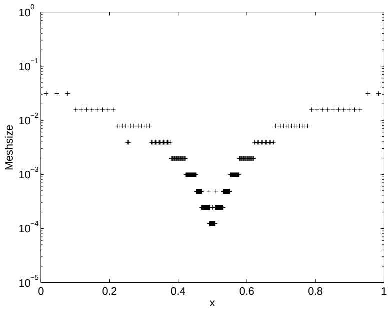

FIG. 5.26. *Strategy* 2: *mesh size versus x (r* = 4*).*

Therefore, we developed a strategy in which an element K, whose local error estimate η_K is larger than $\sqrt{|K|/|\Omega|}\,tol$, has to be refined as many times as necessary to reduce the local error by the amount $\sqrt{|K|}\,tol/\sqrt{|\Omega|}\,\eta_K$. Let us recall that from the a priori estimation (2.11) the rate of convergence in the energy norm is $O(h^{r-1})$. Thereafter, the number of times the element has to be divided can be estimated to be

$$nbr = \frac{\log\left(\dfrac{\sqrt{|\Omega|}\,\eta_K}{\sqrt{|K|}\,tol}\right)}{\log 2^{r-1}}. \tag{5.19}$$

In one dimension, this is equivalent to determining into how many segments, nbs, the element K has to be divided:

$$nbs = \left(\frac{\sqrt{|\Omega|}\,\eta_K}{\sqrt{|K|}\,tol}\right)^{\frac{1}{r-1}}. \tag{5.20}$$

The second strategy consists in the following steps:

(i) compute the local indicator $\eta_K^k(u_k^\gamma)$ given by (5.15),
(ii) compute the total error estimate $\eta^k(u_k^\gamma)$ according to (5.16),
(iii) compute for each element the nearest power of 2 of *nbs* defined in (5.20),
(iv) obtain a refined mesh $\mathcal{T}_{k+1}$ by dividing each element by this power of 2 for a 1-d problem,

(v) compute the discontinuous Galerkin solution on $\mathcal{T}_{k+1}$,

(vi) $k \leftarrow k+1$ and go to step (i).

The algorithm is stopped when $\eta^k(u_k^\gamma) \leq tol$ in step (ii).

For $r = 2$ and $tol = 0.01$, in only 5 steps this strategy reaches the mesh such that $\eta^k \leq tol$. The cpu-time is then significantly reduced. However, this time the number of elements is not optimal anymore and is equal to 2316 elements. For $r = 4$ and $tol = 10^{-6}$, we get the given tolerance in 4 iterations, and the final mesh has 573 elements. The distribution of mesh size plotted in Figures 5.24 and 5.26 is almost the same as in the first strategy, and, except for the first iteration, the a posteriori estimate gives a good approximation of the exact error, as shown in Figures 5.23 and 5.25.
